T_p is the operator used by an observer in the rest frame of a particle with momentum p. The reason for extracting this operator is that the collision geometry becomes less complicated when one of the particles is at rest. The geometry of the interaction process is crucial for the main part of the proof, which relies on the theory of Fourier integral operators and the method of stationary phase. With no reductions of the geometry, the explicit computations for justifying the hypotheses needed in order to realize the proof become quite involved. However, the explicit form of the kernel has become more complicated due to the change of frames. But the vital features of the kernel are maintained, so this will not affect the proof. The mapping $\omega \to \tilde{\omega}$ is, of course, a diffeomorphism since it is just a result of deforming one ellipsoid into another. The Jacobian J of this map only expresses the change of the eccentricity of the collision ellipsoids under changes of coordinate frames. Again, since b has compact support in p and q, there is uniform control of the eccentricity. Thus the Jacobian is bounded in the support of b, and we may still just denote the kernel bJ by b. Hence the operator T_p takes the form (recall that $\omega = \Gamma \circ A(p, q_{-p}, \tilde{\omega})$)

$$(2.14) \qquad T_p\varphi(q) = \int_{\mathbb{S}^{N-1}} b(p, q_{-p}, \omega)\varphi(a_0(q, \tilde{\omega})\tilde{\omega})d\tilde{\omega},$$

where b satisfies the conditions of Theorem 1.

If we can show that T_p is bounded from $H^{-(N-1)/2}(\mathbb{R}^N)$ into $L^2(\mathbb{R}^N)$ (the bound can certainly be taken independently of p since we are working in a compact domain), then we may conclude the proof of Theorem 1. To see this, first apply Hölder's inequality to equation (2.9) and then Jensen's inequality (recall that $g \geq 0$) to equation (2.10). From here, Theorem 1 follows if we observe that the Jacobian of the mapping $q \to \Lambda(p)q$ is harmless because b vanishes for p or q large. Hence we only have to prove the following.

THEOREM 2. *The operator T_p is bounded from $H^{-(N-1)/2}(\mathbb{R}^N)$ into $L^2(\mathbb{R}^N)$ and, more generally, from $H^s(\mathbb{R}^N)$ into $H^{s+(N-1)/2}(\mathbb{R}^N)$, $s \in \mathbb{R}$.*

We fix p in the support of b. An inverse Fourier transform yields, for all $\varphi \in \mathcal{S}(\mathbb{R}^N)$,

$$T_p\varphi(q) = \int_{\mathbb{R}^N}\int_{\mathbb{S}^{N-1}} (2\pi)^{-N} b(p, q_{-p}, \omega) e^{ia_0(q,\tilde{\omega})(\xi\cdot\tilde{\omega})}\hat{\varphi}(\xi)d\tilde{\omega}d\xi. \tag{2.15}$$

Let

$$s(p,q,\xi) = \int_{\mathbb{S}^{N-1}} b(p, q_{-p}, \omega)e^{i[a_0(q,\tilde{\omega})(\xi\cdot\tilde{\omega})-(q\cdot\xi)]}d\tilde{\omega}. \tag{2.16}$$

Clearly, $s(p,\cdot,\cdot) \in C^\infty(\mathbb{R}^{2N})$, and

$$T_p\varphi(q) = \int_{\mathbb{R}^N} (2\pi)^{-N} e^{i(q\cdot\xi)} s(p,q,\xi)\hat{\varphi}(\xi)d\xi. \tag{2.17}$$

We claim that s satisfies, for some $0 < \delta < 1/4$ depending on p,

$$s(p,q,\xi) = 0 \quad \text{if } |q| < \delta \text{ or if } |q_{-p}| > \delta^{-1}, \tag{2.18}$$

$$s(p,q,\xi) = c(p,q,\xi) \quad \text{if } |q\cdot\xi| \geq (1-2\delta)|q||\xi| \text{ and } |\xi| > 1/2, \tag{2.19}$$

and

$$\begin{aligned} s(p,q,\xi) &= e^{i[\phi_+(p,q,\xi)-(q\cdot\xi)]}a_+(p,q,\xi) + e^{i[\phi_-(p,q,\xi)-(q\cdot\xi)]}a_-(p,q,\xi) \\ &\qquad \text{if } |q\cdot\xi| \leq (1-\delta)|q||\xi| \text{ and } |\xi| > 1/2, \end{aligned} \tag{2.20}$$

where

$$\phi_\pm = \frac{(q\cdot\xi)}{2} \pm \frac{|q|\sqrt{\xi^2(e^2-q^2)+(q\cdot\xi)^2}}{e^2-q^2}. \tag{2.21}$$

Here and below, $e = 1 + q_0$ and

$$c(p,\cdot,\cdot) \in S^{-\infty}(\mathbb{R}^{2N}), \tag{2.22}$$

$$a_+(p,\cdot,\cdot), a_-(p,\cdot,\cdot) \in S^{-\frac{N-1}{2}}(\{|q| > \delta\} \times \{|\xi| > 1/2\}), \tag{2.23}$$

where $S^{-\infty} = \cap_{m\in\mathbb{R}} S^m$ and S^m is the usual class of symbols; see, for instance, [H3]. These claims will follow from the stationary-phase method, as will be clear below. First, we show that they are enough to prove Theorem 2. Therefore, assume that (2.18)–(2.20) are valid. Then we can write

$$\begin{aligned} s(p,q,\xi) &= (1-\zeta)(\xi)s(p,q,\xi) \\ &\quad + (1-\theta)\left(\frac{|q\cdot\xi|}{|q||\xi|}\right)\psi(q)\zeta(\xi)s(p,q,\xi) \\ &\quad + \theta\left(\frac{|q\cdot\xi|}{|q||\xi|}\right)\psi(q)\zeta(\xi)\left[e^{i[\phi_+-(q\cdot\xi)]}a_+ + e^{i[\phi_--(q\cdot\xi)]}a_-\right], \end{aligned} \tag{2.24}$$

where $\psi \in C_0^\infty(\mathbb{R}^N)$ with $\psi \equiv 0$ if $|q| \leq \delta/2$, $\psi \equiv 0$ if $|q_{-p}| \geq (\delta/2)^{-1}$, $\psi \equiv 1$ if $|q| \geq \delta$, and $\psi \equiv 1$ if $|q_{-p}| \leq (\delta)^{-1}$. We have also taken $\theta \in C_0^\infty(\mathbb{R})$ with $\theta(t) \equiv 0$ if $|t| \geq 1-\delta$, $\theta(t) \equiv 1$ if $|t| \leq 1-2\delta$, and $\zeta \in C^\infty(\mathbb{R}^N)$ with $\zeta(\xi) \equiv 0$ if $|\xi| \leq 1/2$, $\zeta(\xi) \equiv 1$ if $|\xi| \geq 1$.

The first term obviously belongs to $S^{-\infty}$, and this is also true for the second term because of (2.19) and (2.22). Thus, in view of (2.17), these two terms define bounded operators from $H^s(\mathbb{R}^N)$ into $H^{s+m}(\mathbb{R}^N)$ for all $m \in \mathbb{R}$ (see, for instance, S. Alinhac and P. Gérard [AG]). For the last term, we note that $\theta\psi\zeta a_\pm \in S^{-(N-1)/2}(\mathbb{R}^{2N})$ due to (2.23) and that the phase functions $\phi_\pm$ are positively homogeneous of degree one in ξ. If $\phi_\pm$ satisfy the crucial nondegeneracy condition on the support of $\theta\psi\zeta$, i.e.,

$$\det\left(\frac{\partial^2\phi_\pm}{\partial q_j \partial\xi_k}\right) \neq 0 \quad \text{on supp } \theta\psi\zeta, \tag{2.25}$$

then we could apply the theory of Fourier integral operators (see, e.g., L. Hörmander [H1], [H4] or A. Cordoba and C. Fefferman [CF]) to conclude that the symbols $\theta\psi\zeta e^{i[\phi_\pm-(q-\xi)]}a_\pm$ define bounded operators from H^s into $H^{s+(N-1)/2}$. Obviously, the claims in (2.18)–(2.20) and Lemma 1 below are enough to ascertain Theorem 2. Let us finish this argument by proving the following.

LEMMA 1. *$\phi_\pm$ are nondegenerate on the support of $\theta\psi\zeta$.*

Proof. The proof for ϕ_+ and ϕ_- are analogous, so we present it only for ϕ_+. We want to prove that (2.25) holds on the support of $\theta\psi\zeta$. The calculations become less tedious with a change of coordinates. Introduce the map $q \to t$,

$$t = \frac{q}{\sqrt{e^2 - q^2}}, \quad q \in \mathbb{R}^N, \tag{2.26}$$

which is invertible:

$$q = 2t\sqrt{1+t^2} =: 2tt_0. \tag{2.27}$$

For ϕ_+, we then obtain

$$\phi_+ = (t\cdot\xi)t_0 + |t|\sqrt{\xi^2 + (t\cdot\xi)^2}. \tag{2.28}$$

The Jacobian of the map $q \to t$ is certainly nonzero, so condition (2.25) is equivalent to

$$\det\left(\frac{\partial^2\phi_+}{\partial t_j \partial\xi_k}\right) \neq 0. \tag{2.29}$$

An explicit calculation yields (recall $|t|, |\xi| > 0$ on the support of $\theta\psi\zeta$)

$$\begin{aligned} \frac{\partial^2\phi_+}{\partial t_j\partial\xi_k} &= \delta_{jk}t_0 + \delta_{jk}|t|\frac{(t\cdot\xi)}{E} + t_jt_k\left(\frac{1}{t_0} + \frac{(t\cdot\xi)}{|t|E}\right) \\ &\quad + t_j\xi_k\frac{1}{|t|E} + \xi_jt_k\left(\frac{|t|}{E} - |t|\frac{(t\cdot\xi)^2}{E^3}\right) - \xi_j\xi_k|t|\frac{(t\cdot\xi)}{E^3}, \end{aligned} \tag{2.30}$$

where $E = \sqrt{\xi^2 + (t\cdot\xi)^2}$. With no loss of generality (the determinant is invariant under a change of basis), we may assume that $t_j = \xi_j = 0$ for $j > 2$. We find

$$\det\left(\frac{\partial^2\phi_+}{\partial t_j\partial\xi_k}\right) = \left(t_0 + |t|\frac{(t\cdot\xi)}{E}\right)^{N-2}\cdot Y, \tag{2.31}$$

where

$$\begin{aligned} Y &= t_0^2 + \left(3t_0|t| + \frac{t_0}{|t|}\right)\frac{(t\cdot\xi)}{E} \\ &\quad + (2t_0^2 + t^2)\frac{(t\cdot\xi)^2}{E^2} + t_0|t|\frac{(t\cdot\xi)^3}{E^3}. \end{aligned} \tag{2.32}$$

The first factor in (2.31) is obviously strictly positive, so it is enough to prove that Y is nonzero on the support of $\theta\psi\zeta$. To see this, we observe that Y factorizes

$$Y = t_0|t|\left(\frac{(t\cdot\xi)}{E}+\frac{|t|}{t_0}\right)\left(\frac{(t\cdot\xi)}{E}+\frac{t_0}{|t|}\right)^2. \tag{2.33}$$

A simple calculation now shows that $((t\cdot\xi)/E+|t|/t_0)=0$ if and only if $(t\cdot\xi)=-|t||\xi|$, which means that $(q\cdot\xi)=-|q||\xi|$. Accordingly, $((t\cdot\xi)/E+|t|/t_0)$ is strictly positive on the support of $\theta\psi\zeta$. This holds trivially for the last factor in (2.33), and we are done. □

Remark. If we had extracted the appropriate operator in the center-of-mass system, where the collision geometry is spherical, then the associated phase function would be degenerate. It is obvious that the operator in the center-of-mass system cannot be regularizing due to the fact that the hypersurfaces we integrate over do not move with q. In Lions [L], there is a discussion of the geometrical condition of the hypersurfaces for obtaining regularizing operators.

Let us now complete the proof of Theorem 2 by proving assertions (2.18)–(2.20). Statement (2.18) follows immediately from the nature of the kernel b. The two others will follow from the stationary-phase method. In order to apply this method, we keep the direction $\xi/|\xi|$ fixed and let the modulus $|\xi|$ go to infinity. We want to find the critical points over $\mathbb{S}^{N-1}$ of the C^∞ function

$$\phi = a_0(q,\tilde\omega)(\xi\cdot\tilde\omega). \tag{2.34}$$

Recall that we only have to consider $(q,\xi)\in\mathbb{R}^{2N}$ such that $|q|\geq\delta$, $|q_{-p}|\leq\delta^{-1}$, and $|\xi|>1/2$. If $\tilde\omega_c$ (here and below, $\tilde\omega_c$ denotes an arbitrary critical point) is a critical point of ϕ over $\mathbb{S}^{N-1}$, then the gradient of ϕ at $\tilde\omega_c$ will point in the direction of $\tilde\omega_c$. Hence the critical points are solutions of

$$\frac{\partial\phi}{\partial\tilde\omega}=\left(\frac{\partial\phi}{\partial\tilde\omega}\cdot\tilde\omega\right)\tilde\omega \tag{2.35}$$

or, explicitly,

$$(\xi\cdot\tilde\omega)(e^2+(q\cdot\tilde\omega)^2)q+(q\cdot\tilde\omega)(e^2-(q\cdot\tilde\omega)^2)\xi=2e^2(q\cdot\tilde\omega)(\xi\cdot\tilde\omega)\tilde\omega. \tag{2.36}$$

Next, observe that if $(q\cdot\tilde\omega)/|q|$ is sufficiently small (depending on p), then $((\hat q_{-p}-\hat p)\cdot\omega)/|\hat q_{-p}-\hat p|$ is also small (a collision sufficiently grazing in the rest frame of p is also grazing in the laboratory frame), so $b(p,q_{-p},\omega)$ vanishes. Therefore, we only have to look for critical points such that $(q\cdot\tilde\omega)\neq 0$. Assume first that q and ξ are not collinear. Then the ansatz

$$\tilde\omega_c=\frac{Aq+B\xi}{|Aq+B\xi|} \tag{2.37}$$

gives exactly four critical points $\pm\tilde\omega_+$ and $\pm\tilde\omega_-$. Here

$$\tilde\omega_\pm=\Gamma\left(\left(|q|(q\cdot\xi)\pm e\sqrt{\xi^2(e^2-q^2)+(q\cdot\xi)^2}\right)q\ +\ |q|(e^2-q^2)\xi\right) \tag{2.38}$$

and Γ is the same as above. As the directions of q and ξ become increasingly coincident (we have the parallel case in mind, the antiparallel case being similar), then $\tilde\omega_+$ approaches $q/|q|$, whereas $\tilde\omega_-$ approaches $\tilde\omega^\perp$, which is a unit vector in the plane generated by q and ξ orthogonal to q. Therefore, as $|q\cdot\xi|/|q||\xi|$ gets close to 1, then $|q\cdot\tilde{\omega}_+|/|q|$ and $|q\cdot\tilde{\omega}_-|/|q|$ approach 1 and 0, respectively. As we saw above, b vanishes if $|q\cdot\tilde{\omega}|/|q|$ is sufficiently small. In fact, this also happens if $|q\cdot\tilde{\omega}|$ is sufficiently close to 1 since then $|(q_{-p}-p)\cdot\omega|/|q_{-p}-p|$ is close to 1 and b vanishes according to the hypotheses made on b. Thus, if $|q\cdot\xi|/|q||\xi|$ is close to 1 no critical points are contained in the support of b, and an application of the stationary-phase lemma without critical points (see, for instance, [H2] and [GuS]) yields (2.19). Finally, we prove that our last claim (2.20) holds. Certainly, we only have to work in the domain

$$D=\left\{(q,\xi):|q|\geq\delta,\ |q_{-p}|\leq\delta^{-1},\ |\xi|>1/2,\ |q\cdot\xi|<(1-\delta)|q||\xi|\right\}. \tag{2.39}$$

We will consider only the two critical points $\tilde{\omega}_+$ and $\tilde{\omega}_-$ since the contributions from $-\tilde{\omega}_\pm$ are similar. (If we also assume that b is even in ω which is physically natural, then, since ϕ is also even in ω, the contributions are, in fact, identical.) We begin by computing the functions $\phi_\pm(q,\xi)$ defined by

$$\phi_\pm(q,\xi)=\phi(q,\xi,\tilde{\omega}_\pm). \tag{2.40}$$

For this, we make use of equation (2.36). With $\tilde{\omega}_c=(Aq+B\xi)/|Aq+B\xi|$, where A and B are defined in (2.38), we obtain (recall that q and ξ are not collinear in D)

$$\phi(q,\xi,\tilde{\omega}_c):=\frac{2e(q\cdot\tilde{\omega}_c)(\xi\cdot\tilde{\omega}_c)}{e^2-(q\cdot\tilde{\omega}_c)^2}=\frac{q\cdot(Aq+B\xi)}{eB}. \tag{2.41}$$

Inserting the expressions for A and B, we obtain

$$\phi_\pm(q,\xi)=\frac{e(q\cdot\xi)\pm|q|\sqrt{\xi^2(e^2-q^2)+(q\cdot\xi)^2}}{e^2-q^2}, \tag{2.42}$$

and (2.21) follows if we observe that $e^2-q^2=2(1+q_0)=2e$. Now, in order to apply the stationary-phase method (the case admitting critical points; see, e.g., [H2] or [GuS]), we have to compute the Hessian of ϕ over $\mathbb{S}^{N-1}$ at the critical points. We remark that, in general, the Hessian of a function f at a point p is well defined (independent of the particular local coordinate system chosen) if p is a critical point. Now let q and ξ be fixed. We introduce the functions $\psi_\pm: M_\epsilon\to\mathbb{R}$ defined by

$$\psi_\pm(\omega)=\phi(q,\xi,\omega)-\frac{e^2}{e^2-(q\cdot\tilde{\omega}_\pm)^2}\phi_\pm(q,\xi)|\omega|^2,\qquad\omega\in M_\epsilon, \tag{2.43}$$

where $M_\epsilon=\{\omega\in\mathbb{R}^N:|\omega|<1+\epsilon\}$ and ϵ is taken so small that ϕ is C^∞ on M_ϵ. (Of course, an ϵ that works for all q is possible to choose since $q\in D$.) The Hessians of $\psi_\pm$ and ϕ over $\mathbb{S}^{N-1}$ coincide, of course, since $|\omega|$ is constant on $\mathbb{S}^{N-1}$. Moreover, the factor in front of $|\omega|^2$ is taken in such a way that the gradient of $\psi_\pm$ with respect to $\mathbb{R}^N$ at the points $\tilde{\omega}_\pm$ vanishes. Thus, in view of the remark made above, we can compute the Hessian of $\psi_\pm$ over $\mathbb{S}^{N-1}$ at the critical points by restricting the Hessian of $\psi_\pm$ over $\mathbb{R}^N$ to the tangent plane at the critical points. To do this, choose coordinates (x,x'), where x is a coordinate in the direction of $\tilde{\omega}_+$ (respectively, $\tilde{\omega}_-$) and x' are coordinates in the tangent plane at $\tilde{\omega}_+$ (respectively, $\tilde{\omega}_-$). The derivatives are then taken with respect to x'. To simplify the computations, set

$$\eta=\frac{\sqrt{2e}\,\omega}{\sqrt{e^2-(q\cdot\omega)^2}},\qquad\omega\in M_\epsilon, \tag{2.44}$$

with inverse

$$\omega = \frac{e\eta}{\sqrt{2e + (q\cdot\eta)^2}}. \tag{2.45}$$

Expressed in these coordinates, $\psi_\pm$ take the form

$$\psi_\pm(\eta) = (q\cdot\eta)(\xi\cdot\eta) - H_\pm \frac{|\eta|^2}{2e + (q\cdot\eta)^2}, \qquad \eta \in \mathrm{Im}(M_\epsilon), \tag{2.46}$$

where

$$\eta_\pm = \frac{\sqrt{2e}\,\tilde{\omega}_\pm}{\sqrt{e^2 - (q\cdot\tilde{\omega}_\pm)^2}} \tag{2.47}$$

and

$$H_\pm = \frac{e^3|\eta_\pm|^2\phi_\pm(q,\xi)}{2} = \frac{e^3|\eta_\pm|^2(q\cdot\eta_\pm)(\xi\cdot\eta_\pm)}{2}. \tag{2.48}$$

As usual, to facilitate the reading, we present only the computations for the "+" case since the "−" case is analogous. Let us write $\eta = \eta_+ + \lambda\eta_+^\perp + \nu^\perp$, where $\eta_+^\perp$ is orthogonal to η_+ in the plane generated by q and ξ with $|\eta_+^\perp| = |\eta_+|$ and $\nu^\perp$ is orthogonal to the plane generated by q and ξ. Also, we introduce the notations $a = (q\cdot\eta_+)$, $\tilde{a} = (\xi\cdot\eta_+)$, $b = (q\cdot\eta_+^\perp)$, and $\tilde{b} = (\xi\cdot\eta_+^\perp)$. We then obtain

$$\psi_+ = a\tilde{a} + \lambda(a\tilde{b} + \tilde{a}b) + \lambda^2 b\tilde{b} - H_+\left(\frac{|\eta_+|^2(1+\lambda^2) + |\nu^\perp|^2}{2e + (a+\lambda b)^2}\right). \tag{2.49}$$

Accordingly, we wish to compute

$$\frac{\partial^2\psi_+}{\partial x_i\partial x_j}|_{(0,\ldots,0)} \quad \text{with } x = (\lambda, \nu_1^\perp, \ldots, \nu_{N-2}^\perp). \tag{2.50}$$

We readily obtain

$$\frac{\partial^2\psi_+}{\partial x_i\partial x_j}|_{(0,\ldots,0)} = 0 \quad \text{if } i \neq j. \tag{2.51}$$

Carrying out the calculations, we obtain

$$\psi_{\lambda\lambda} := \frac{\partial^2\psi_+}{\partial\lambda^2}|_{(0,\ldots,0)} = 2b\tilde{b} - \frac{2H_+|\eta_+|^2}{2e + a^2}\left[1 - \frac{b^2}{2e+a^2} + \frac{4a^2b^2}{(2e+a^2)^2}\right], \tag{2.52}$$

$$\frac{\partial^2\psi_+}{\partial\nu_j^{\perp 2}}|_{(0,\ldots,0)} = \frac{-2H_+}{2e + a^2}. \tag{2.53}$$

In order to apply the stationary-phase method, we have to compute the determinant of the Hessian. Certainly, the determinant depends on the local coordinate system chosen. However, we are only interested in the analytical behaviour of the determinant, so we will not be concerned about the square of the Jacobian which appears. This is necessarily positive and uniformly bounded from below and above since q belongs to a compact set. However, it is null homogeneous in ξ because $\tilde{\omega}_+ = \tilde{\omega}_+(q,\xi)$

is null homogeneous in ξ. Furthermore, observing that $\psi_{\lambda\lambda}$ is positively homogeneous of degree 1, we can write

$$\det\left(\frac{\partial^2\psi_+}{\partial x_i \partial x_j}|_{(0,\dots,0)}\right) = h_N\left(q, \frac{\xi}{|\xi|}\right)|\xi|\left(\phi_+(q,\xi)\right)^{N-2}. \tag{2.54}$$

Here we have inserted the expression for H_+—(2.48)—and $h_N \in C^\infty(\mathbb{R}^N \times \mathbb{S}^{N-1})$. Next, we will show that h_N and ϕ_+ are nonzero for all $q \in D$. Recall that

$$\phi_+(q,\xi) = \frac{e(q\cdot\xi) + |q|\sqrt{\xi^2(e^2-q^2)+(q\cdot\xi)^2}}{e^2-q^2}. \tag{2.55}$$

Since $q^2(\xi^2(e^2-q^2)+(q\cdot\xi)^2) - e^2(q\cdot\xi)^2 = (e^2-q^2)(q^2\xi^2-(q\cdot\xi)^2)$, we immediately conclude that $\phi_+ > \epsilon$ for some $\epsilon > 0$ on the domain D. To see that h_N is nonzero, we now only have to show that $\psi_{\lambda\lambda}$ is nonzero or, in fact, that $\psi_{\lambda\lambda} < 0$. A simple observation gives $a \geq 0$, $\tilde{a} \geq 0$, and $b\tilde{b} \leq 0$ for all q and ξ. Indeed, $a = (q\cdot\eta_+) \geq 0$ if and only if $(q\cdot\tilde{\omega}_+) \geq 0$ if and only if

$$q^2\left(|q|(q\cdot\xi) + e\sqrt{\xi^2(e^2-q^2)+(q\cdot\xi)^2}\right) + |q|(e^2-q^2)(q\cdot\xi) \geq 0. \tag{2.56}$$

But the second term is greater than the sum of the other two terms since

$$\begin{aligned} &e^2q^4(\xi^2(e^2-q^2)+(q\cdot\xi)^2) - q^2e^4(q\cdot\xi)^2 \\ &\quad = e^2q^2(e^2-q^2)(q^2\xi^2-(q\cdot\xi)^2). \end{aligned} \tag{2.57}$$

Similarly, $\tilde{a} = (\xi\cdot\eta_+) \geq 0$ if and only if

$$(q\cdot\xi)\left(|q|(q\cdot\xi) + e\sqrt{\xi^2(e^2-q^2)+(q\cdot\xi)^2}\right) + |q|(e^2-q^2)\xi^2 \geq 0. \tag{2.58}$$

However,

$$\begin{aligned} &\left(|q|(\xi^2(e^2-q^2)+(q\cdot\xi)^2)\right)^2 - e^2(q\cdot\xi)^2\left(\xi^2(e^2-q^2)+(q\cdot\xi)^2\right) \\ &\quad = (e^2-q^2)\left(\xi^2(e^2-q^2)+(q\cdot\xi)^2\right)\left(q^2\xi^2-(q\cdot\xi)^2\right), \end{aligned} \tag{2.59}$$

so a and $\tilde{a}$ are both positive and uniformly bounded a way from zero on D. Next, since $\eta_+ = Aq + B\xi$ with A and B both positive, the fact that $b\tilde{b} < 0$ on D is a purely geometrical consequence of the positivity of a and $\tilde{a}$. In view of (2.48), (2.52), and the discussion above, it is enough to show that

$$\frac{1}{(2e+a^2)^2}[(2e+a^2)^2 - b^2(2e+a^2) + 4a^2b^2] > 0 \tag{2.60}$$

in order to prove $\psi_{\lambda\lambda} < 0$. Evidently, the relation $a^2 + b^2 = q^2\eta_+^2$ holds. Using this relation and the expression for η_+ (2.47), we obtain for the numerator in (2.60)

$$\frac{4e^2}{(e^2-q^2s^2)^2}\left(e^4 - e^2q^2 + s^2e^2q^2 + s^2(4q^2-4s^2q^2)\right), \tag{2.61}$$

where $s = ((q/|q|)\cdot\tilde{\omega}_+)$. Clearly, $0 \leq s \leq 1$ so the positivity of (2.60) holds.

The analogous computations for the "$-$" case give

$$|\det|_\pm = \left|h_N\left(q, \frac{\xi}{|\xi|}\right)\right| |\phi_\pm|^{N-2}|\xi|. \tag{2.62}$$

In view of equation (2.52) and (2.53), we easily conclude that the signature of the Hessian is $-(N-1)$ for the "+" case, and we have, in addition (the "$-$"case),

$$\operatorname{sign}_{\pm} = \mp(N-1). \tag{2.63}$$

We may now apply the stationary-phase lemma to conclude that $a_+ \in S^{-(N-1)/2}$. We could immediately refer to [L] for this task but prefer to give the arguments below. In order to see that $a_+ \in S^{-(N-1)/2}$, we introduce a partition of unity on $\mathbb{S}^{N-1}$; $\chi_1, \dots, \chi_5$ with $\chi_i \in C^\infty(\mathbb{S}^{N-1})$, $0 \le \chi_i \le 1$, $\sum_{i=1}^{5} \chi_i = 1$ on $\mathbb{S}^{N-1}$. Here $\chi_i \equiv 1$, $i = 1, \dots, 4$, in a neighbourhood of the four critical points $\tilde{\omega}_+, \tilde{\omega}_-, -\tilde{\omega}_+$, and $-\tilde{\omega}_-$, respectively. Apparently, no critical points are contained in the support of χ_5, so we readily see that the symbol $\theta\psi\zeta \int_{\mathbb{S}^{N-1}} e^{i[\phi-(q\cdot\xi)]} b\chi_5 d\tilde{\omega} \in S^{-\infty}$. Hence we only have to show that

$$\begin{gathered} s_1 := \theta\left(\frac{|q\cdot\xi|}{|q||\xi|}\right)\psi(q)\zeta(\xi)\int_{\mathbb{S}^{N-1}}(2\pi)^{-N}e^{i[\phi-(q-\xi)]}b\chi_1 d\tilde{\omega} = e^{i[\phi_+-(q\cdot\xi)]}\,a_1, \\ \text{where } a_1 \in S^{-\frac{N-1}{2}}. \end{gathered} \tag{2.64}$$

A consequence of the stationary-phase lemma (see Hörmander [H2, p. 222] or Guillemin and Sternberg [GuS, p. 6]) is that there is an asymptotic expansion of s_1 such that (recall that $|\det|_+ = |\xi|^{N-1}|h_N(q,\xi/|\xi|)||\phi_+(q,\xi/|\xi|)|^{N-2}$)

$$\begin{aligned} &\Bigg| s_1 - e^{i[\phi_+-(q\cdot\xi)]}\left\{\theta\left(\frac{|q\cdot\xi|}{|q||\xi|}\right)\zeta(\xi)|\xi|^{-\frac{N-1}{2}}\right\} \\ &\quad\times\left[a^0\left(q,\frac{\xi}{|\xi|}\right)+|\xi|^{-1}a^1\left(q,\frac{\xi}{|\xi|}\right)+\dots+|\xi|^{-N}a^N\left(q,\frac{\xi}{|\xi|}\right)\right]\Bigg| \\ &\quad\le \frac{C}{(1+|\xi|)^{N+1}} \quad \text{on } \mathbb{R}^{2N}. \end{aligned} \tag{2.65}$$

Here

$$\theta\left(\frac{|q\cdot\xi|}{|q||\xi|}\right)\zeta(\xi)|\xi|^{-(\frac{N-1}{2}+j)}\,a^j\left(q,\frac{\xi}{|\xi|}\right) \in S^{-(\frac{N-1}{2}+j)} \quad \text{for all } j \ge 0. \tag{2.66}$$

It is also clear from (2.64) that for each pair of multiindices α and β, the estimate

$$|\partial_q^\beta\partial_\xi^\alpha a_1(q,\xi)| \le C(1+|\xi|)^{|\beta|}, \qquad (q,\xi) \in (\{|q| > \delta\} \times \{|\xi| > 1/2\}), \tag{2.67}$$

holds for some constant C depending on α and β. The estimates (2.65) and (2.67) are, in fact, enough (see Hörmander [H3, p. 67]) to conclude that $a_1 \in S^{-(N-1)/2}(\{|q| > \delta\} \times \{|\xi| > 1/2\})$, and the proof is complete. □

3. Applications of the regularizing theorem. The trend to a global equilibrium solution for the relativistic Boltzmann equation was recently studied by Glassey and Strauss in [GlS2] and [GlS3]. The second of their papers deals with the question of convergence to equilibrium in full physical space for small perturbations of the Jüttner equilibrium solution. We will not treat the full-space situation but concentrate on the periodic case, which was studied in [GlS2]. There the authors prove convergence in a variety of function spaces for initial data periodic in the space variables and *near* equilibrium. Theorem 3 below extends this result by proving strong L^1 convergence to a global Jüttner equilibrium solution for *arbitrary* initial data, periodic in the space variables, and satisfying the natural bounds of finite energy and entropy.

For the classical Boltzmann equation, the analogous result was first shown by Arkeryd [Ar5]. The essential technique in Arkeryd's work is a nonstandard measure-theoretical analysis of the entropy dissipation term. A standard proof of this result was then obtained by Lions [L] using a method based on the regularizing theorem and on approximations. In the relativistic situation, one may apply Arkeryd's or Lions' approach to obtain strong L^1 convergence to a local Jüttner equilibrium solution. Below we will see that the periodicity in the space variables implies that every local Jüttner solution is, in fact, a global one. This will require some different arguments in comparison to those given by Arkeryd [Ar4] in the nonrelativistic case.

We now specify the assumptions and the asymptotic result in detail. Consider the relativistic Boltzmann equation in a periodic box Λ, which after rescaling can be taken to be $\mathbb{R}^3/\mathbb{Z}^3$. The kernel satisfies the conditions given in §1. Further, we assume that the initial density distribution $f_0 = f(0)$ has finite energy and entropy

$$\int_\Lambda \int_{\mathbb{R}^3} f_0(p_0 + |\log f_0|) dp dx < \infty. \tag{3.1}$$

Solutions to (1.1) will be in the sense of renormalized solutions or any equivalent form (iterated-integral, exponential-multiplier, or mild-solution form). For a discussion of these matters, see [DPL1], [Ar2], and [Ar5].

We assume that the solutions of the initial value problem (1.1) together with (3.1) satisfy

$$\int_\Lambda \int_{\mathbb{R}^3} f(t)(p_0 + |\log f(t)|) dp dx \leq C, \quad t \geq 0, \tag{3.2}$$

and

$$0 \leq \int_0^\infty ds \int_E (f'f'_* - ff_*) \log \frac{f'f'_*}{ff_*} B d\mu \leq C. \tag{3.3}$$

Here $E = \Lambda \times \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{S}^2$ and

$$d\mu = \frac{dp}{p_0}\frac{dq}{q_0} dx d\Omega,$$

and we write $f = f(t,x,p)$, $f' = f(t,x,p')$, $f_* = f(t,x,q)$, and $f'_* = f(t,x,q')$. The solutions in [DEJ], adapted to the periodic case, satisfy (3.2). Condition (3.3) is a conseqence of the relativistic form of the entropy inequality

$$\begin{aligned} &\int_\Lambda \int_{\mathbb{R}^3} f \log f dp dx - \int_\Lambda \int_{\mathbb{R}^3} f_0 \log f_0 dp dx \\ &\qquad + \frac{1}{4} \int_0^t ds \int_E (f'f'_* - ff_*) \log \frac{f'f'_*}{ff_*} B d\mu \leq 0, \quad t \geq 0. \end{aligned} \tag{3.4}$$

This inequality is easily derived by reworking the proof of the corresponding inequality in the nonrelativistic case [DPL2] using the results in [DEJ]. To see that (3.3) can be derived from (3.4), we only have to show that the first term in (3.4) is a bounded function of t. In fact, since the integrand of the third term is positive, only boundedness from below remains to be shown. For this, we note that for all nonnegative functions g on $\Lambda \times \mathbb{R}^3$ and all $R < \infty$

$$\begin{aligned} \int_\Lambda \int_{B_R} g|\log g| dp dx &= \int_\Lambda \int_{B_R} g \log g dp dx - 2 \iint_{g \leq 1} g \log g dp dx \\ &\leq \int_\Lambda \int_{B_R} (g \log g + 2 g p_0) dp dx + 2 \int_\Lambda \int_{B_R} g \left(\log \frac{1}{g}\right) 1_{(g \leq \exp(-p_0))} dp dx. \end{aligned}$$

Applying the elementary inequality $t\log(1/t) \leq C\sqrt{t}$ for $0 < t < 1$ and some $C \geq 0$ and letting $R \to \infty$, we get

$$\int_\Lambda \int_{\mathbb{R}^3} g|\log g| dpdx \leq \int_\Lambda \int_{\mathbb{R}^3} (g\log g + 2gp_0)dpdx + C' \tag{3.5}$$

for some positive constant C' independent of g. Our claim follows from this general inequality and the fact that the energy and entropy of the solutions are bounded (see (3.2)). The driving force to equilibrium is, of course, the entropy inequality (3.3).

Let us now state the theorem concerning the asymptotic behaviour of solutions to the relativistic Boltzmann equation.

THEOREM 3. *Given a sequence $(t_k)_{k\in N}$, $t_k \nearrow \infty$, there is a subsequence $(t_{k'})$ and a global Jüttner equilibrium solution*

$$J(p) = \exp(\alpha - \beta_\mu p^\mu), \qquad \alpha \in \mathbb{R}, \quad \beta_\mu = (\beta_0, \beta) \in \mathbb{R}^4 \quad \textit{with } \beta_0 > |\beta|,$$

such that for $T > 0$, $f(\cdot + t_{k'}) \to J$ strongly in $L^1(\Lambda \times \mathbb{R}^3 \times [0,T])$, and for $t > 0$, $f(\cdot, t + t_{k'}) \to J$ strongly in $L^1(\Lambda \times \mathbb{R}^3)$.

Remarks. (1) The condition $\beta_0 > |\beta|$ (i.e., β_μ timelike) is necessary and sufficient for $J \in L^1(\mathbb{R}^3)$. (2) As in the classical case, we can not exclude that there are different limits J for different sequences $(t_k)_{k\in N}$. If the open question of energy conservation would find an affirmative resolution, then the uniqueness would follow.

Sketch of proof. Lions' method to prove the nonrelativistic version of Theorem 3 is based on the regularizing theorem and on approximations. The regularization, which crucially depends on the collision geometry, is in our case taken care of by Theorem 1. The approximations are easily adapted to the relativistic setting since they do not explicitly depend on the collision geometry. We remark that the minor difference in the hypothesis of the kernel b in the regularizing theorem, between the classical [L] and relativistic settings (Theorem 1), is irrelevant for the reworking of Lions' proof. Indeed, Lions only has to consider functions with compact support, so the fact that b has compact support according to the hypotheses of Theorem 1 does not affect the proof.

The author has applied Arkeryd's method to the relativistic case in [An]. In order to realize that proof, some specific results concerning the relativistic Boltzmann equation are needed. References of these results and details of the nonstandard approach are found in [An].

In conclusion, whether we rework Arkeryd's nonstandard proof or Lions' standard proof, we will obtain convergence to a local Jüttner solution J in the two senses given in Theorem 3. The local Jüttner solution, periodic in the space variables, satisfies the equation

$$\left(\partial_t + \frac{p}{p_0} \cdot \nabla_x\right) J = 0 \tag{3.6}$$

in the distribution sense and has the form

$$J(x,t,p) = \exp(\alpha(x,t) - \beta_\mu(x,t)p^\mu). \tag{3.7}$$

Here α and β are Lebesgue measurable functions with $\alpha(x,t)$, $\beta(x,t) \in \mathbb{R}$ for a.e. $(x,t) \in \Lambda \times \mathbb{R}_+$, and β_μ is timelike. Next, we show that the periodicity in the space variables implies that α and β are independent of x and t, i.e., J is a global Jüttner solution.

Now, not only J but also $\log J$ satisfies (3.6) in the distribution sense. This follows from a simple generalization of the arguments given by L. Desvillettes [De] in the analogous nonrelativistic situation. Thus

$$\left(\partial_t + \frac{p}{p_0} \cdot \nabla_x\right) [\alpha(x,t) - \beta_\mu(x,t)p^\mu] = 0 \tag{3.8}$$

holds in the distribution sense. Evaluating the derivatives and identifying the coefficients in front of the different functions of p by zero, we obtain

$$\partial_\mu \alpha = 0, \tag{3.9}$$

$$\partial_\mu \beta_\nu + \partial_\nu \beta_\mu = 0, \tag{3.10}$$

where $\partial_\mu f = \frac{\partial f}{\partial x_\mu}$ and $x_\mu = g_{\mu\nu} x^\nu = (t, -x)$, $g_{\mu\nu} = (+ - --)$.

Obviously, the function α is space–time independent, i.e., constant. The system (3.10) consists of ten equations in four unknowns, β_μ, and is called Killing's equation. Now, it is well known that the general solution of (3.10) is

$$\beta_\rho = \gamma_\rho + \omega_{\rho\nu} x^\nu, \tag{3.11}$$

where γ_ρ and $\omega_{\rho\nu}$ are constants and $\omega_{\rho\nu} = -\omega_{\nu\rho}$. Since $\omega_{\rho\nu}$ is antisymmetric, we have $\omega_{00} = 0$, so there is no time dependence in β_0 and the condition $\beta_0 > |\beta|$ implies $\omega_{\rho 0} = 0 = -\omega_{\rho 0}$. The periodicity condition forces the remaining coefficients of $\omega_{\rho\nu}$ to vanish, so $\omega_{\rho\nu} \equiv 0$. Hence J is a global Jüttner solution. □

The next application of Theorem 1 concerns the functional equation

$$f(p)f(q) = f(p')f(q') \quad \text{a.e. on } \mathbb{R}^{2N}_{p,q} \times \mathbb{S}^{N-1}, \tag{3.12}$$

where, as usual, $p + q = p' + q'$ and $p_0 + q_0 = p'_0 + q'_0$. This equation has been extensively studied under different assumptions on the regularity of f. Irrespective of the assumptions, the solutions turn out to be the Jüttner equilibrium solutions. This fact has been shown, for instance, by Chernikov [C], Bichteler [B], Marle [M], and Dijkstra [Di] under the assumption that solutions are differentiable of order 1 [B], continuous [C], [M] or measurable [Di]. However, a beautiful trick of Lions based on the regularizing theorem shows that solutions to the nonrelativistic analogue of (3.12) are necessarily smooth. In view of Theorem 1, the result is also available in the relativistic case. The generalization is straightforward, but we will present the proof and not only refer to Lions. The structure of the proof is essential for the discussion in the appendix, indicating a point of connection between Arkeryd's and Lions' approaches to the asymptotic problem (Theorem 3). Hence let us prove the following lemma.

LEMMA 2. *Solutions* $0 \leq f \in L^1_{\text{loc}}(\mathbb{R}^N)$ *of the functional equation* (3.12) *are smooth.*

Proof. If $0 \leq f \in L^1_{\text{loc}}(\mathbb{R}^N)$ is a solution of (3.12), then $g := \sqrt{f} \in L^2_{\text{loc}}(\mathbb{R}^N)$ also satisfies (3.12). If $g \equiv 0$, we are done. Otherwise, we introduce

$$b_\epsilon(p,q,\omega) = \zeta_R(|q|)\, \varphi^{(1)}_\epsilon(|p|)\, \varphi^{(2)}_\epsilon(|p-q|) \\ \times \varphi^{(3)}_\epsilon\left(\frac{|(\hat{p}-\hat{q})\cdot\omega|}{|\hat{p}-\hat{q}|}\right) \varphi^{(4)}_\epsilon\left(\frac{|(p-q)\cdot\omega|}{|p-q|}\right),$$

where $0 \leq \zeta_R, \varphi^{(j)}_\epsilon \leq 1$, $\zeta_R, \varphi^{(1)}_\epsilon \in C^\infty_0(\mathbb{R})$, $\zeta_R \equiv 1$ for $|q| \leq R$, and $\varphi^{(1)}_\epsilon \equiv 1$ for $|p| \leq \epsilon^{-1}$. Further, $\varphi^{(2,3)}_\epsilon \in C^\infty(\mathbb{R})$, supp $\varphi^{(2,3)}_\epsilon \subset (\epsilon/2, \infty)$, and $\varphi^{(2,3)}_\epsilon(t) = 1$ for

$t \geq \epsilon$. Finally, $\varphi_\epsilon^{(4)} \in C^\infty([0,1))$, supp $\varphi_\epsilon^{(4)} \subset [0, 1-\epsilon/2)$, and $\varphi_\epsilon^{(4)}(t) = 1$ for $t \leq 1 - \epsilon$.

Hence, for each $R > 0$, we have

$$l_\epsilon(q) := \int_{\mathbb{R}^N} \int_{\mathbb{S}^{N-1}} b_\epsilon(p,q,\omega) g(p) d\omega\, dp > 0 \tag{3.13}$$

on $\{|q| \leq R\}$ for ϵ small enough, and $l_\epsilon \in C_0^\infty(\mathbb{R}^N)$. In view of (3.12), we find that $g = Q^+(g,g)/l_\epsilon$ on $\{|q| \leq R\}$, and by Theorem 1, we obtain $g \in H_{\text{loc}}^{(N-1)/2}(\mathbb{R}^N)$. Next, we observe from the proof of this theorem that if $g \in L^1(\mathbb{R}^N)$ and $f \in H^s(\mathbb{R}^N)$, $s \in \mathbb{R}$, we have

$$\|Q^+(f,g)\|_{H^{s+\frac{N-1}{2}}} \leq C\|f\|_{H^s}\|g\|_{L^1}.$$

Therefore, by iterating the argument above, we deduce that $g \in H_{\text{loc}}^{k(N-1)/2}(\mathbb{R}^N)$ for all $k \geq 1$. Accordingly, $g \in C^\infty(\mathbb{R}^N)$. □

Appendix. A connection between the standard and the nonstandard approach. We will present a different and simpler proof of a lemma by Arkeryd [Ar1], [Ar3]. The lemma is crucial in his nonstandard (ns) approach to the asymptotic problem (i.e., the nonrelativistic analogue of Theorem 3). Our proof is based on the proof of Lemma 2 and hence on the regularizing theorem, which is the crucial part in Lions' approach to the asymptotic problem. A link between their methods of proofs is therefore indicated. In what follows, some nonstandard techniques and notations are used, and the reader not familiar with this matter may consult [HL] or [AFHL].

LEMMA 3 (see [Ar1], [Ar3]). *Let $f \in {}^\star L_+^1(\mathbb{R}^N)$ ($N \geq 2$ and finite) be given with*

$$\int_{{}^\star\mathbb{R}^N} p_0 f(p)\, {}^\star dp \tag{A.1}$$

finite and with

$$f(p)f(q) \approx f(p')f(q') \tag{A.2}$$

for Loeb a.e. $(p,q,\omega) \in \text{ns}\, {}^\star(\mathbb{R}^N \times \mathbb{R}^N \times \mathbb{S}^{N-1})$. Then either $f(p) \approx 0$ for Loeb a.e. $p \in \text{ns}\, {}^\star\mathbb{R}^N$ or ${}^\circ f(p) > 0$ for Loeb a.e. $p \in \text{ns}\, {}^\star\mathbb{R}^N$.

Remarks. (1) Condition (A.1) is a slight modification of the relativistic analogue of Arkeryd's original formulation. (2) Condition (A.1) together with $\int f(p) \log f(p)\, {}^\star dp$ finite implies that f is S-integrable, which is essential for the nonstandard approach to the asymptotic problem. For details we refer to [An].

Proof. For simplicity, we will consider only the two-dimensional case. It will be clear from the proof that the result in higher dimensions follows by a simple iteration of our arguments. Now, we rework the proof of Lemma 2 in the nonstandard context. Assume that ${}^\circ \int f\, {}^\star dp > 0$; if that is not the case, we have $f \approx 0$ Loeb a.e. in ${}^\star\mathbb{R}^2$. Observe that condition (A.1) implies that f is essentially concentrated in ns ${}^\star\mathbb{R}^2$; hence for some noninfinitesimal ϵ, we obtain $l_\epsilon > 0$. Accordingly, relation (A.2) implies that $f \approx h$ Loeb a.e., in ns ${}^\star\mathbb{R}^2$, where $\|\varphi h\|_{{}^\star H^1}$ is finite and φ is a localized standard function in $C_0^\infty(\mathbb{R}^2)$. Actually, $\|\varphi h\|_{{}^\star H^m}$ is finite for m finite (so, in addition, $h \in {}^\star C^k$ for k finite). Now, there is a $\star$-measurable set A of finite diameter and positive Loeb measure in ns ${}^\star\mathbb{R}^2$, where $h > \epsilon$ for some $\epsilon > 0$, $\epsilon \in \mathbb{R}$. Otherwise, $h \approx 0$ Loeb a.e. in ns ${}^\star\mathbb{R}^2$, implying $f \approx 0$ Loeb a.e. in ns ${}^\star\mathbb{R}^2$. We will show that $h > \epsilon/2$ on a ball with positive Loeb measure in ${}^\star\mathbb{R}^2$, and this will, in fact, be enough, in view of well-known arguments [Ar1], to conclude that ${}^\circ h > 0$ Loeb a.e. in ns ${}^\star\mathbb{R}^2$. Let $p \in A$, $\hat{d}$ be a unit vector in ${}^\star\mathbb{R}^2$, and $L(p, \delta, \hat{d})$ be the line segment between p and $p + \delta\hat{d}$. We then have the relation $|h(p+\delta\hat{d}) - h(p)| = |\int_{L(p,\delta,\hat{d})}(\nabla h\cdot\hat{d})\,{}^\star dp|$. If we could find a point $p_0 \in A$ and a positive number $\delta_0 \in \mathbb{R}$ such that

$$\left|\int_{L(p_0,\delta,\hat{d})} (\nabla h\cdot\hat{d})\,{}^\star dp\right| < \frac{\epsilon}{2} \quad \forall\hat{d} \in {}^\star\mathbb{S}^1 \text{ and } \forall\delta,\ 0 \le \delta \le \delta_0, \tag{A.3}$$

then ${}^\circ h > \epsilon/2$ on the ball $B(p_0, \delta_0)$. The proof is by contradiction. Assume that there is no point $p_0 \in A$ with such a property. We will show that this assumption implies that φh can not be in ${}^\star H^2$, where $\varphi \in C_0^\infty$ with $\varphi \equiv 1$ on a ball containing A (in N dimensions, we need ${}^\star H^N$). Let each point $p \in A$ be a center of a γ^{-1}-cube $C(p, \gamma^{-1})$, where $\gamma \in \mathbb{R}$ is large. From Wiener's covering lemma, there are at least $\eta := [\gamma^2 a]$ disjoint cubes (in three dimensions, $\eta \sim \gamma^3$), where a is a constant depending only on the dimension and the Loeb measure of A, and $[x]$ denotes the integer part of x. Let us denote the centers of the corresponding cubes by p_j, $j = 1, \ldots, \eta$. The assumption above implies that for each p_j, there is a unit vector $\hat{d}_j$ in ${}^\star\mathbb{R}^2$, such that

$$\int_{L(p_j,\hat{d}_j,\gamma^{-1}/2)} |(\nabla h\cdot\hat{d}_j)|\,{}^\star dp \ge \frac{\epsilon}{2}. \tag{A.4}$$

Without loss of generality, we assume that all of the unit vectors $\hat{d}_j$ are directed along p_1. Indeed, if this is not the case, it is easy to see that the estimates below will be changed by a factor depending only on the dimension. Let us fix j and denote by $L(\alpha)$ the line segment

$$L(\alpha) := \{p : p = p_j + \alpha n_2 + s n_1,\ s \in (0, \gamma^{-1}/2)\}, \tag{A.5}$$

where $n_{1,2}$ are unit vectors directed along the $p_{1,2}$-axes, respectively. Set $I_\alpha := \int_{L(\alpha)} |\frac{\partial h}{\partial p_1}|\,{}^\star dp_1$ and note that $I_0 \ge \epsilon/2$. Now, either $I_\alpha \ge \epsilon/4$ for $\alpha \in [0, \gamma^{-1}/2]$ or there exist some $\alpha_0 \in (0, \gamma^{-1}/2)$ with $I_{\alpha_0} < \epsilon/4$. In the first case,

$$\int_0^{\gamma^{-1}/2}\int_{L(\alpha)} |\partial_1 h|\,{}^\star dp_1 dp_2 \ge \gamma^{-1}\frac{\epsilon}{8}, \tag{A.6}$$

and in the second case, we obtain from Stoke's theorem (recall $|\nabla|f|| = |\nabla f|$ a.e. when $f \in H^1$; see, e.g., [Au, p. 82])

$$\int_0^{\alpha_0}\int_{L(\alpha)} |\partial_2\partial_1 h|\,{}^\star dp_1 dp_2 \ge \left|\int_0^{\alpha_0}\int_{L(\alpha)} \partial_2|\partial_1 h|\,{}^\star dp_1 dp_2\right| \tag{A.7}$$

$$= \left|\int_{L(0)} n_2|\partial_1 h|\,{}^\star dp_1 + \int_{L(\alpha_0)} n_2|\partial_1 h|\,{}^\star dp_1\right| \ge \frac{\epsilon}{2} - \frac{\epsilon}{4} = \frac{\epsilon}{4}. \tag{A.8}$$

There are η cubes, and one of the cases above occurs at least $\eta/2$ times. If the first case occurs $\eta/2$ times, then

$$\sum_{j=1}^{\eta}\int_{C(p_j,\gamma^{-1})} |\partial_1 h|^\star dp_1 dp_2 \ge \eta\epsilon\gamma^{-1}/16 \sim \gamma\epsilon \to \infty \quad \text{as } \gamma \to \infty. \tag{A.9}$$

In the second case,

$$\text{(A.10)} \qquad \sum_{j=1}^{\eta} \int_{C(p_j,\gamma^{-1})} |\partial_1 \partial_2 h|^\star dp_1 dp_2 \geq \eta\epsilon/8 \sim \gamma^2 \epsilon \to \infty \quad \text{as } \gamma \to \infty.$$

Thus φh cannot be in $^\star H^2$, and this completes the proof. □

Acknowledgments. I would like to thank Leif Arkeryd for suggesting the fascinating topic of relativistic kinetics and for the constant interest he has shown regarding my work.

I would also like to thank Bo Berndtsson for instructive and stimulating discussions concerning Fourier integral operators and Bernt Wennberg for valuable discussions and comments on the manuscript.

A TRANSMISSION PROBLEM IN THE SCATTERING OF ELECTROMAGNETIC WAVES BY A PENETRABLE OBJECT*

RODOLFO H. TORRES†

Abstract. Layer-potential techniques are used to study a transmission problem arising in the scattering of electromagnetic waves by a penetrable object. The method proposed does not involve the use of the calculus of pseudodifferential operators and hence it can be applied in domains with very little regularity. The solutions are represented as a combination of a curl and a double curl of a single layer-potential operator. The work relies on the important harmonic-analysis tools developed in recent years to study boundary-value problems in domains with minimal regularity assumptions.

Key words. Maxwell equations, reduced wave equation, layer-potential methods, transmission problems, scattering theory, nonsmooth domains

1. Introduction.

A classical problem arising in electromagnetism is that of determining the field scattered by a penetrable object from the knowledge of the tangential component on the surface of the object of an incoming field. See, e.g., [12] and [15]. The mathematical formulation of this problem leads to a transmission problem for the Maxwell equations on a bounded domain (see §2 below for the precise statement). The problem has been studied using several approaches based on layer-potentials techniques. In particular, we want to mention works by Wilde [20] and Costabel and Stephan [5]. Reference to related works can be found therein.

For time-harmonic electromagnetic waves, the solution of Maxwell equations are divergence-free solutions of the vector Helmholtz equation. In [20], very general transmission problems for the vector Helmholtz equation are considered. The solutions of the problems are obtained as a combination of several single- and double-layer potentials after solving, in appropriate Hölder spaces, a 4×4 system of of integral equations of the second kind on the boundary of the domain. This classical method requires the domain to be at least of class C^2 and, as a consequence, the solutions have continuous partial derivatives up to the boundary of the domain. On the other hand, in [5], the so-called direct method is used. This is a general method applicable to strongly elliptic boundary-value problems and relies on the coercivity on certain Sobolev spaces (the energy spaces) of a bilinear form related to the boundary data. In [5], the electromagnetic problem is transformed into a particular transmission problem for the vector Helmholtz equation which is solved, again, by inverting a matrix of operators on the boundary of the domain. In this work, the calculus of pseudodifferential operators is used and hence the domain is assumed to be C^∞. In addition, the boundary values of the solutions are prescribed in the distributional sense and not pointwise. The purpose of this paper is to develop an alternative approach to study the electromagnetic transmission problem in domains which are less regular than the one considered in the works just mentioned, allowing less regular boundary data, but still obtaining solutions whose boundary values are prescribed pointwise (nontangentially).

As is well known, the study of boundary-value problems using layer-potential techniques in domains which are C^1 or Lipschitz is very delicate. One of the main reasons for this is that some of the resulting integral operators on the boundary of the

† Department of Mathematics, University of Michigan, Ann Arbor, MI 48109. Current address: Department of Mathematics, University of Kansas, Lawrence, KS 66045-2142.

domain have to be interpreted as principal-value singular integrals. In particular, to consider L^p data and solutions with boundary values obtained pointwise, deep results from harmonic analysis are necessary. Dirichlet and conormal derivative problems for several equations and system of equations in nonsmooth domains have already been studied using harmonic-analysis techniques. A few examples are [9], [11], [17], [18], [7]. Using similar techniques, transmission problems have been considered in [8] and [16]. This last paper deals with the case of the scalar Helmholtz equation in Lipschitz domains. See also [19] and [6], where an approach to transmission problems related to [5] is used.

The study of the potential operators associated with Maxwell equations in C^1 and Lipschitz domains has been recently carried out in [13] and [14]. In particular, the so-called Maxwell, electric, and magnetic boundary-value problems for a perfect conducting object were solved with optimal estimates in the case of C^1 domains. This work depends heavily on the results in [2] and [3] about the Cauchy integral operator on Lipschitz curves as well as the developments in [9]. For the previously known results about these problems in the case of smoother domains, we refer to [4].

In this paper, we will combine the results of [13] with some of the ideas in [16] to study the electromagnetic transmission problem in domains which are only C^1 or Lipschitz. Unlike the approaches in [20] and [5], we propose as a solution for the electromagnetic transmission problem a combination of the curl and the curlcurl of the single-layer potential. After taking traces, this ansatz leads to a 2×2 system of integral operators on the boundary of the domain. The trace operator associated with the double curl of the single-layer potential is hypersingular (even on smooth domains). Nevertheless, in the case of the electromagnetic transmission problem, this operator appears in a regularized way. This allows us to consider it on an appropriate space of functions: the space $L_T^{2,\mathrm{Div}}$ consisting of tangential vector fields with surface divergence in L^2. It was shown in [14] that $L_T^{2,\mathrm{Div}}$ is the right space of boundary data to work with in domains with little regularity. As in [16], the solution of the system of integrals operators on the boundary relies on the knowledge of the spectrum of a singular integral operator. In our present situation, the singular-integral operator is the one obtained as the tangential component of the trace of the curl of the single-layer potential.

The paper is organized as follows. In §2, we recall some basic facts about nonsmooth domains and state the transmission problem with boundary data in $L_T^{2,\mathrm{Div}}$. In §3, we show for appropriate values of the electromagnetic characteristics of the object and surrounding media the uniqueness of solution to the problem in the case of Lipschitz domains. In §4, we collect several results from [13] about the layer-potential operators associated with Maxwell equations and include some new results regarding the double curl of the single-layer potential. In §5, we show some existence results.

2. The electromagnetic transmission problem.

The notation that we use is standard for the subject. In particular, we will follow very closely that of [13] which is our main reference. For the purposes of this paper, a Lipschitz, respectively, C^1, domain will always be an open, simply connected domain D of R^3, whose boundary, ∂D, is given locally by the graph of a Lipschitz, respectively, C^1, function. Let N be the exterior unit normal to ∂D and let $d\sigma$ denote surface measure on the boundary. The spaces $L^2(\partial D)$ of functions or vector fields and the space $L_T^2(\partial D)$ of tangential vector fields are defined with respect to $d\sigma$. The space $L^{2,1}(\partial D)$ is, as usual, the space of L^2 functions with tangential derivatives also in L^2. A vector field $A \in L_T^2(\partial D)$ is said to have a surface divergence if there exists a function $b \in L^2(\partial D)$ such that

$$\int_{\partial D} \langle \nabla_T \psi, A \rangle \, d\sigma = - \int_{\partial D} \psi \, b \, d\sigma$$

for all functions ψ which are Lipschitz in a neighborhood of ∂D. Here ∇_T denotes the tangential gradient and $\langle \cdot, \cdot \rangle$ denotes the inner product in R^3. The function b is denoted by $\operatorname{Div} A$ and the space of all such vector fields (see, e.g., [14]) is denoted by $L_T^{2,\mathrm{Div}}(\partial D)$. The space is equipped with the norm

$$\|A\|_{L_T^{2,\mathrm{Div}}(\partial D)} = \|A\|_{L^2(\partial D)} + \|\operatorname{Div} A\|_{L^2(\partial D)}.$$

At every point Q in the boundary of the domain, we consider an open, right-circular, doubly truncated cone $\Gamma(Q)$, with vertex at Q and two convex components, $\Gamma_i(Q)$ in D and $\Gamma_e(Q)$ in $\mathrm{R}^3 \backslash \overline{D}$, so that the resulting family of cones is a regular family in the sense of [17]. For a function u defined in D, the nontangential maximal function of u is defined by

$$u^*(P) = \sup_{X \in \Gamma_i(P)} |u(X)|.$$

The boundary values of functions defined inside D are assumed to be taken in nontangential fashion and almost everywhere with respect to $d\sigma$. That is, $u|_{\partial D}$ is to be interpreted as

$$u(P) = \lim_{\substack{X \longrightarrow P \\ X \in \Gamma_i(P)}} u(X),$$

whenever such a limit exists for almost every point in ∂D. Similar definitions apply for derivatives of a function and for each component of a vector-valued function. For example, if × denotes the exterior product in R^3 and A is a vector field defined inside D, then $N \times \operatorname{curl} A|_{\partial D}$ is given by

$$N \times \operatorname{curl} A(P) = \lim_{\substack{X \longrightarrow P \\ X \in \Gamma_i(P)}} N(P) \times \operatorname{curl} A(X).$$

For functions defined in the exterior of D, the nontangential maximal function and the boundary values are defined in the same way but using $\Gamma_e(P)$.

We can now state the electromagnetic transmission problem that we want to study. We follow the classical description in [15]. Let D represent an object made of an homogeneous material, and assume that the object is immersed in an homogeneous medium represented by the exterior of D. In all space, we consider a time-harmonic electromagnetic wave with frequency ω, described by the electric and magnetic vector fields E and H. These fields satisfy the Maxwell equations

$$\operatorname{curl} E = i\omega\mu_i H$$

$$\operatorname{curl} H = -i\omega\epsilon_i E \quad \text{in } D,$$

and

$$\operatorname{curl} E = i\omega\mu_e H,$$

$$\operatorname{curl} H = -i\omega\epsilon_e E \quad \text{in } \mathrm{R}^3\backslash\overline{D}.$$

The electromagnetic parameters of the object and the surrounding medium in the above equations are, respectively,

$$\epsilon_i = \epsilon_{0i} + \frac{i\sigma_i}{\omega}, \qquad \mu_i = \mu_{0i} + \frac{i\hat{\sigma}_i}{\omega},$$

$$\epsilon_e = \epsilon_{0e} + \frac{i\sigma_e}{\omega}, \qquad \mu_e = \mu_{0e} + \frac{i\hat{\sigma}_e}{\omega},$$

where ϵ_{0i} and ϵ_{0e} are the dielectric constants, μ_{0i} and μ_{0e} are the permeability, σ_i and σ_e are the electric conductivity, and $\hat{\sigma}_i$ and $\hat{\sigma}_e$ are the magnetic conductivity of each medium. The usual restrictions on the values of these parameters are

$$(1) \qquad 0 \leq \arg\omega < \pi,$$

$$(2) \qquad \epsilon_{0i},\, \epsilon_{0e} > 0 \quad \text{and} \quad \mu_{0i},\, \mu_{0e} > 0,$$

$$(3) \qquad \sigma_i,\, \sigma_e \geq 0 \quad \text{and} \quad \hat{\sigma}_i,\, \hat{\sigma}_e \geq 0$$

(see [15]). We will assume $\epsilon_i \neq \epsilon_e$ and $\mu_i \neq \mu_e$. The wave numbers in the interior and exterior of the obstacle are defined by

$$k_i^2 = \omega^2\epsilon_i\mu_i \quad \text{and} \quad k_e^2 = \omega^2\epsilon_e\mu_e,$$

where we assume

$$(4) \qquad 0 \leq \arg k_i, \qquad \arg k_e < \pi.$$

In the exterior of D, the vector fields are decomposed as the sum of a known incoming field and an unknown scattered field,

$$E = E_{\text{in}} + E_{\text{sc}},$$

$$H = H_{\text{in}} + H_{\text{sc}}.$$

Both the incoming and scattered fields satisfy Maxwell's equations in the exterior of D. We also assume that the scattered fields satisfy the radiation conditions

$$(5) \qquad \omega\mu_e\frac{X}{|X|} \times H_{\text{sc}} + k_e E_{\text{sc}} = o(|X|^{-1}) \quad \text{and} \quad E_{\text{sc}} = O(|X|^{-1})$$

as $|X| \to \infty$. The tangential components of the total vector fields must extend continuously across the boundary, so on ∂D we must have

$$N \times E - N \times E_{\text{sc}} = N \times E_{\text{in}},$$

$$N \times H - N \times H_{\text{sc}} = N \times H_{\text{in}},$$

where the values of $N \times E$ and $N \times H$ are taken from inside D. It follows that, in order to obtain the total electric and magnetic fields from the knowledge of the incoming fields, we can consider a transmission boundary-value problem with the tangential components of the incoming fields as datum. Because of the results in [13] and [14], we will assume that these tangential components are in $L_T^{2,\mathrm{Div}}(\partial D)$, and we will require the solutions to have nontangential maximal functions bounded on $L^2(\partial D)$. In fact, it was shown in [14] that if E and H solve Maxwell equations in a C^1 or Lipschitz domain and E has pointwise (nontangentially) boundary values in $L^2(\partial D)$ with bounded nontangential maximal function, then the companion field H also have pointwise boundary values if and only if the tangential component of E is in $L_T^{2,\mathrm{Div}}(\partial D)$. Since the roles of E and H can be interchanged, we have to require the same kind of boundary data for the tangential component of H. Thus we are lead to consider the following problem. Given two tangential vector fields A and B in $L_T^{2,\mathrm{Div}}(\partial D)$, find two vector fields in D, E_i and H_i, and two vector fields in $\mathrm{R}^3\backslash\overline{D}$, E_e and H_e, satisfying the radiation condition (5) and such that

$$(T)\begin{cases} \operatorname{curl} E_i = i\omega\mu_i H_i & \text{in } D,\\ \operatorname{curl} H_i = -i\omega\epsilon_i E_i & \text{in } D,\\ \|E_i^*\|_{L^2(\partial D)} + \|H_i^*\|_{L^2(\partial D)} < \infty, & \\ & \\ \operatorname{curl} E_e = i\omega\mu_e H_e & \text{in } \mathrm{R}^3\backslash\overline{D},\\ \operatorname{curl} H_e = -i\omega\epsilon_e E_e & \text{in } \mathrm{R}^3\backslash\overline{D},\\ \|E_e^*\|_{L^2(\partial D)} + \|H_e^*\|_{L^2(\partial D)} < \infty, & \\ & \\ N\times E_e - N\times E_i = A & \text{on } \partial D,\\ N\times H_e - N\times H_i = B & \text{on } \partial D. \end{cases}$$

3. Uniqueness of solution. The uniqueness of solution of problem (T) is given in [12] and [15] for smooth domains and functions continuous up to the boundary. We will consider here the case of Lipschitz domains, boundary data in $L_T^{2,\mathrm{Div}}(\partial D)$, and boundary values obtained nontangentially. We will always assume that the electromagnetic parameters satisfy the constrains in (1)–(4). Additional limitations in their values will be imposed, if necessary, in the statments of the results to be proved.

Usually, the proof of uniqueness results for boundary-value problems involves integral-representation formulas and some application of the divergence theorem. The standard technique to adapt these formulas to the case of nonsmooth domains is an approximation procedure. The main tool is the following lemma from [17].

LEMMA 3.1. *Let D be a bounded Lipschitz domain. Then it is possible to construct a sequence of C^∞ domains $\Omega_j \subset D$ (or $\Omega_j \supset D$) satisfying the following properties:*

(i) *There is a sequence of Lipschitz diffeomorphisms $\Lambda_j : \partial D \to \partial\Omega_j$ such that the Lipschitz constants of Λ_j and its inverse are uniformly bounded in j. Furthermore, $\Lambda_j(Q) \in \Gamma_i(Q)$ (or $\Gamma_e(Q)$) for all j and all $Q \in \partial D$ and $\sup_{Q\in\partial D} |Q - \Lambda_j(Q)| \le C/j$;*

(ii) *There are positive functions $\rho_j : \partial D \to R_+$ bounded away from zero and infinity uniformly in j such that for any measurable set $F \subset \partial D$, $\int_F \rho_j d\sigma = \int_{\Lambda_j(F)} d\sigma_j$ and such that $\rho_j \to 1$ a.e. and in every $L^p(\partial D)$, $1 \le p < \infty$;*

(iii) *The sequence of normal vectors to Ω_j, $N_j(\Lambda_j(\cdot))$ converges a.e. and in every $L^p(\partial D)$, $1 \le p < \infty$, to N.* □

Let k be a complex number with $\operatorname{Im} k \ge 0$ and consider the fundamental solution of the Helmholtz operator $\triangle + k^2$ in R^3,

$$\Phi(X) = -\frac{e^{ik|X|}}{4\pi|X|}.$$

We will need to use the following formulae regarding solutions of the vector Helmholtz equation.

LEMMA 3.2. *Let D be a Lipschitz domain and let E be a smooth vector field in D or $R^3\backslash\overline{D}$. Assume that E,* $\operatorname{curl} E$, *and* $\operatorname{div} E$ *have nontangentially boundary values on ∂D from the inside or the outside accordingly to where E is defined. Assume also that*

$$\|E^*\|_{L^2(\partial D)} + \|(\operatorname{div} E)^*\|_{L^2(\partial D)} + \|(\operatorname{curl} E)^*\|_{L^2(\partial D)} < \infty. \tag{6}$$

The following formulas hold:

(i) *The tangential vector field $N \times E$ has a surface divergence in $L^2(\partial D)$ and*

$$\operatorname{Div}(N \times E) = -\langle N, \operatorname{curl} E\rangle . \tag{7}$$

(ii) *If E is a solution of the vector Helmholtz equation $\triangle E + k^2 E = 0$ in D, then for all $X \in D$,*

$$\begin{aligned} E(X) = &-\int_{\partial D} \operatorname{curl}_X(\Phi(X-Q)N(Q) \times E(Q))d\sigma \\ &+\int_{\partial D} \nabla_X\Phi(X-Q)\,\langle N(Q), E(Q)\rangle\, d\sigma \\ &-\int_{\partial D} \Phi(X-Q)(N(Q) \times \operatorname{curl} E(Q) - \operatorname{div} E(Q)N(Q))d\sigma \end{aligned}$$

and

$$\begin{aligned} &\int_{\partial D} \langle N(Q) \times \overline{E}(Q), \operatorname{curl} E(Q)\rangle + \operatorname{div} E(Q)\,\langle N(Q), \overline{E}(Q)\rangle\, d\sigma \\ &= \int_D |\operatorname{curl} E(X)|^2 + |\operatorname{div} E(X)|^2 - k^2|E(X)|^2\, dX. \end{aligned}$$

(iii) *If E is a solution of the vector Helmholtz equation $\triangle E + k^2 E = 0$ in $R^3\backslash\overline{D}$ that satisfies at infinity the radiation condition*

$$\operatorname{curl} E \times \frac{X}{|X|} + \operatorname{div} E\frac{X}{|X|} - ikE = o(|X|^{-1}), \qquad E = O(|X|^{-1}), \tag{8}$$

then for all $X \in R^3\backslash\overline{D}$,

$$\begin{aligned} E(X) = &\int_{\partial D} \operatorname{curl}_X\{\Phi(X-Q)N(Q) \times E(Q)\}d\sigma \\ &-\int_{\partial D} \nabla_X\Phi(X-Q)\,\langle N(Q), E(Q)\rangle\, d\sigma \\ &+\int_{\partial D} \Phi(X-Q)(N(Q) \times \operatorname{curl} E(Q) - \operatorname{div} E(Q)N(Q))d\sigma \end{aligned}$$

and

$$\lim_{r\to\infty} \left(-\int_{|X|=r} |k|^2|E(X)|^2 + |\operatorname{curl} E(X) \times N(X) + \operatorname{div} E(X)N(X)|^2\, ds_r \right.$$

$$- 2\mathrm{Im}(k) \int_{D_r} |\mathrm{curl}\, E(X)|^2 + |\mathrm{div}\, E(X)|^2 + |k|^2 |E(X)|^2 \, dX \Big)$$

$$= 2\mathrm{Im} \left(k \int_{\partial D} \left(\langle N(Q), E(Q) \times \mathrm{curl}\, \overline{E}(Q) \rangle + \mathrm{div}\, \overline{E}(Q) \, \langle N(Q), E(Q) \rangle \right) d\sigma \right),$$

where ds_r is the surface measure on the ball of radius r, $B_r(0)$, and where $D_r = R^3 \setminus \overline{D} \cap B_r(0)$.

Proof. The above formulas are well known for smooth domains. The validity of them in the case of Lipschitz domains was justified in [14] using Lemma 3.1 and a limiting argument. We shall not repeat the details here (cf. the proof of Theorem 3.4 below). □

A simple consequence of the above lemma is the following result.

LEMMA 3.3. *Let D be a Lipschitz domain. Let E be a solution of the vector Helmholtz equation in $R^3 \setminus \overline{D}$ satisfying (6), the radiation condition (8), and the inequality*

$$\mathrm{Im} \left(k \int_{\partial D} \left(\langle N(Q), E(Q) \times \mathrm{curl}\, \overline{E}(Q) \rangle + \mathrm{div}\, \overline{E}(Q) \, \langle N(Q), E(Q) \rangle \right) d\sigma \right) \geq 0.$$

If $\mathrm{Im}\, k > 0$, *then $E = 0$ in $R^3 \setminus \overline{D}$.*

Proof. If $\mathrm{Im}\, k > 0$, then from the last part of Lemma 3.2,

$$\int_{D_r} |E(X)|^2 \, dX \to 0,$$

which implies that $E = 0$. □

We can now prove a uniqueness results for solutions of the transmission problem (T). Recall that solutions of the Maxwell equations

$$\mathrm{curl}\, E = i\omega\mu H,$$

$$\mathrm{curl}\, H = -i\omega\epsilon E$$

are divergence-free solutions of the vector Helmholtz equation with wave number $k^2 = \omega^2 \epsilon\mu$. Notice also the equivalence between the radiation conditions (5) and (8).

THEOREM 3.4. *Let D be a Lipschitz domain. Assume that* $\mathrm{Im}\, k_i > 0$ *and* $\mathrm{Im}\, k_e > 0$, *and let E_i, H_i, E_e,* and H_e *be solutions of (T) with boundary data $A = B = 0$. Then $E_i = H_i = 0$ in D and $E_e = H_e = 0$ in $R^3 \setminus \overline{D}$.*

Proof. We will use a limiting argument to adapt the proof in [15, p. 282], for the case of smooth domains to the present situation. Let Ω_j be a family of domains approximating D from inside as in Lemma 3.1. Since solutions of Maxwell equations are analytic inside D we can apply the divergence theorem on each domain Ω_j. We obtain

$$\int_{\Omega_j} (i\omega\epsilon_i |E_i|^2 - i\overline{\omega\mu_i} |H_i|^2) dX = \int_{\Omega_j} \mathrm{div}\, (\overline{E}_i \times H_i) dX$$

$$= \int_{\partial\Omega_j} \langle N_j, \overline{E}_i \times H_i \rangle \, d\sigma_j,$$

and using the change of coordinates Λ_j,

$$\int_{\Omega_j} (i\omega\epsilon_i|E_i|^2 - i\overline{\omega\mu_i}|H_i|^2)dX$$

$$= \int_{\partial D} \langle N_j(\Lambda_j(Q)), \overline{E}_i(\Lambda_j(Q)) \times H_i(\Lambda_j(Q))\rangle \, \rho_j d\sigma.$$

The integrals on the left of the above equality are uniformly bounded by

$$C \int_{\partial D} |E_i^*(Q)||H_i^*(Q)|d\sigma.$$

Since we are assuming that $\|E_i^*\|_{L^2(\partial D)} + \|H_i^*\|_{L^2(\partial D)} < \infty$, we can use the properties of the approximating domains together with the dominated-convergence theorem to get

$$\int_D (i\omega\epsilon_i|E_i|^2 - i\overline{\omega\mu_i}|H_i|^2)dX = \int_{\partial D} \langle N, \overline{E}_i \times H_i\rangle \, d\sigma.$$

A similar argument in the exterior of D shows that

$$\int_{D_r} (i\omega\epsilon_i|E_e|^2 - i\overline{\omega\mu_i}|H_e|^2)dX$$

$$= \int_{X=r} \left\langle \frac{X}{r}, \overline{E}_e \times H_e \right\rangle ds - \int_{\partial D} \langle N, \overline{E}_e \times H_e\rangle \, d\sigma.$$

Adding the formulas for the interior and exterior, using the transmission conditions with $A = B = 0$ and the radiation condition at infinity, we get

$$\int_D (i\omega\epsilon_i|E_i|^2 - i\overline{\omega\mu_i}|H_i|^2)dX + \int_{D_r} (i\omega\epsilon_i|E_e|^2 - i\overline{\omega\mu_i}|H_e|^2)dX$$

$$= \int_{X=r} \left\langle \frac{X}{r}, \overline{E}_e \times H_e \right\rangle ds$$

$$= \frac{\overline{k}_e}{\overline{\omega\mu_e}} \int_{X=r} |E_e|^2 ds + o(1).$$

Now, by the constraints on the electromagnetic parameters,

$$\mathrm{Re}\,(i\omega\epsilon) \leq 0 \;\text{ and }\; \mathrm{Re}\,(\overline{i\omega\mu)} \geq 0,$$

where ϵ denotes either ϵ_i or ϵ_e and μ denotes either μ_i or μ_e. In addition,

$$\mathrm{Re}\left(\frac{k_e}{\omega\mu_e}\right) \geq 0.$$

It follows that we must have

$$\mathrm{Re}\left(\int_D (i\omega\epsilon_i|E_i|^2 - i\overline{\omega\mu_i}|H_i|^2)dX\right) = 0, \tag{9}$$

$$\lim_{r\to\infty} \operatorname{Re}\left(\int_{D_r} (i\omega\epsilon_i|E_e|^2 - i\overline{\omega\mu_i}|H_e|^2)dX\right) = 0, \tag{10}$$

and

$$\lim_{r\to\infty} \operatorname{Re}\left(\frac{k_e}{\omega\mu_e}\right)\int_{X=r} |E_e|^2 ds = 0. \tag{11}$$

Moreover, since we are assuming $\operatorname{Im} k_i > 0$, one of the parameters ω, ϵ_i, and μ_i is not a real number. Then either $\operatorname{Re}(i\omega\epsilon_i) < 0$ or $\operatorname{Re}(-i\overline{\omega\mu_i}) < 0$. From (9), one of the fields vanishes in D and so both E_i and H_i must be identically zero in D. Finally, from the transmission conditions, the tangential components of E_e and H_e on the boundary have to be zero and, since $\operatorname{Im} k_e > 0$, Lemma 3.3 implies that E_e and H_e must be identically zero in the exterior of D. □

Remark. The conditions $\operatorname{Im} k_i > 0$ and $\operatorname{Im} k_e > 0$ in the above theorem are removed in [15] for the case of smooth domains by a more elaborated argument. Nevertheless, we will still need those conditions to prove existence of solutions.

We conclude this section with another uniqueness result. As we will see in the proof of existence of solutions, the transmission problem in the next theorem can be used, in a general sense, as adjoint problem for problem (T) (cf. [6]).

THEOREM 3.5. *Let D be a Lipschitz domain in R^3. Assume that* $\operatorname{Im} k_i > 0$ *and* $\operatorname{Im} k_e > 0$. *Assume also that either*

$$\operatorname{Im}\left(k_i\overline{k}_e^{-2}\frac{\mu_e}{\mu_i}\right) \leq 0, \tag{12}$$

$$\operatorname{Im}\left(k_i\frac{\mu_e}{\mu_i}\right) \geq 0 \tag{13}$$

or

$$\frac{\epsilon_e\mu_i}{\mu_e} = \epsilon'_{0e} + \frac{i\sigma'_e}{\omega} \quad \text{with } \epsilon'_{0e} > 0 \text{ and } \sigma'_e \geq 0, \tag{14}$$

$$\frac{\mu_e\epsilon_i}{\epsilon_e} = \mu'_{0e} + \frac{i\hat{\sigma}'_e}{\omega} \quad \text{with } \mu'_{0e} > 0 \text{ and } \hat{\sigma}'_e \geq 0. \tag{15}$$

Then the homogeneous transmission problem for the vector Helmholtz equation,

$$(T')\begin{cases} \triangle E_i + k_e^2 E_i = 0 & \text{in } D,\\ \operatorname{div} E_i = 0 & \text{in } D,\\ \|E_i^*\|_{L^2(\partial D)} + \|(\operatorname{curl} E_i)^*\|_{L^2(\partial D)} < \infty, & \\ \\ \triangle E_e + k_i^2 E_e = 0 & \text{in } R^3\backslash\overline{D},\\ \operatorname{div} E_e = 0 & \text{in } R^3\backslash\overline{D},\\ \|E_e^*\|_{L^2(\partial D)} + \|(\operatorname{curl} E_e)^*\|_{L^2(\partial D)} < \infty, & \\ \\ N\times E_e - N\times E_i = 0 & \text{on } \partial D,\\ \frac{\mu_i}{k_i^2}N\times \operatorname{curl}E_e - \frac{\mu_e}{k_e^2}N\times\operatorname{curl}E_i = 0 & \text{on } \partial D, \end{cases}$$

where E_e satisfies the radiation condition (8) with $k = k_i$, has the unique solution $E_i = 0$ in D and $E_e = 0$ in $R^3\backslash\overline{D}$.

Proof. Assume that conditions (12) and (13) are satisfied. Let E_i and E_e be solutions of problem (T'). Using the transmission conditions and the divergence theorem (whose used can be justified again via Lemma 3.1 and the boundedness of nontangential maximal functions), we get

$$\begin{aligned}\int_{\partial D} \langle N, E_e \times \operatorname{curl} \overline{E}_e \rangle \, d\sigma &= \int_{\partial D} \left\langle N, E_i \times \overline{\left(\frac{k_i^2 \mu_e}{k_e^2 \mu_i}\right)} \operatorname{curl} \overline{E}_i \right\rangle d\sigma \\ &= \int_D \left(\overline{\left(\frac{k_i^2 \mu_e}{k_e^2 \mu_i}\right)} |\operatorname{curl} E_i|^2 - \overline{\left(\frac{k_i^2 \mu_e}{\mu_i}\right)} |E_i|^2 \right) dX.\end{aligned}$$

Now using the constraints on the electromagnetic parameters, we see that

$$\operatorname{Im} \left(k_i \int_{\partial D} \langle N, E_e \times \operatorname{curl} \overline{E}_e \rangle \, d\sigma \right) \geq 0.$$

Since $\operatorname{div} E_e = 0$, Lemma 3.3 implies that $E_e = 0$. Again using the transmission conditions and the representation formula in Lemma 3.2 for the interior of D, we also obtain that $E_i = 0$.

Assume now that conditions (14) and (15) are satisfied. Let E_i and E_e again be solutions of the problem (T'). Then it follows that E_i, $H_i = 1/i\omega\mu_i' \operatorname{curl} E_i$ and E_e, $H_e = 1/i\omega\mu_e' \operatorname{curl} E_e$ are solutions of the homogeneous version of problem (T) with electromagnetic parameters $\epsilon_i' = \epsilon_e$ and $\mu_i' = \mu_e$ in the interior and $\epsilon_e' = \epsilon_e \mu_i / \mu_e$ and $\mu_e' = \mu_e \epsilon_i / \epsilon_e$ in the exterior. By Theorem 3.4, E_i and E_e must be zero. □

Remark. The conditions on the electromagnetic parameters in the above theorem look very technical because we have stated the result in great generality. If some of the parameters are real valued, these conditions become much simpler. See Theorem 5.2 below.

4. Boundary integral operators. We recall some properties about the layer-potential operators associated with the Helmholtz and Maxwell equations. The results are well known for smooth domains; see, e.g., [4]. For nonsmooth domains, we refer for proofs and details to [1] and [16] for the case of the scalar Helmholtz equation and to [14] for the vector-valued case.

Let D be a Lipschitz domain and let f be a function in $L^2(\partial D)$. The single and double acoustic layer potentials are given by

$$\mathcal{S}f(X) = \int_{\partial D} \Phi(X - Q) f(Q) d\sigma(Q), \qquad X \in \mathrm{R}^3,$$

and

$$\mathcal{D}f(X) = \int_{\partial D} \partial_{N_Q} \Phi(X - Q) f(Q) d\sigma(Q), \qquad X \in \mathrm{R}^3 \setminus \partial D.$$

Both $\mathcal{S}f$ and $\mathcal{D}f$ solve the Helmholtz equation in $\mathrm{R}^3 \setminus \partial D$ and, as a consequence of the results in [3], they satisfy

$$\|(\mathcal{S}f)^*\|_{L^2(\partial D)} + \|(\nabla \mathcal{S}f)^*\|_{L^2(\partial D)} + \|(\mathcal{D}f)^*\|_{L^p(\partial D)} \leq C \|f\|_{L^2(\partial D)}.$$

The trace values of $\mathcal{S}f$ are given by

$$\lim_{\substack{X \longrightarrow P \\ X \in \Gamma_i(P)}} \mathcal{S}f(X) = \lim_{\substack{X \longrightarrow P \\ X \in \Gamma_e(P)}} \mathcal{S}f(X) = \mathcal{S}f(P), \qquad P \in \partial D,$$

where

$$\mathcal{S}f(P) = -\frac{1}{4\pi}\int_{\partial D}\frac{e^{ik|Q-P|}}{|Q-P|}f(Q)\,d\sigma(Q), \qquad P \in \partial D.$$

The function $\mathcal{D}f$ has a jump discontinuity given by

$$\lim_{\substack{X\longrightarrow P\\ X\in\Gamma_i(P)}} \mathcal{D}f(X) = \left(\frac{1}{2}I + K\right)f(P), \qquad P \in \partial D,$$

$$\lim_{\substack{X\longrightarrow P\\ X\in\Gamma_e(P)}} \mathcal{D}f(X) = \left(-\frac{1}{2}I + K\right)f(P), \qquad P \in \partial D.$$

where

$$Kf(P) = \frac{1}{4\pi}\text{p.v.}\int_{\partial D}\frac{\langle N(Q), Q-P\rangle}{|Q-P|^3}e^{ik|Q-P|}(1-ik|Q-P|)f(Q)\,d\sigma(Q).$$

The normal derivative of the single-layer potential satisfies

$$\lim_{\substack{X\longrightarrow P\\ X\in\Gamma_i(P)}} \langle N(P), \nabla\mathcal{S}f(X)\rangle = \left(-\frac{1}{2}I + K^*\right)f(P)$$

and

$$\lim_{\substack{X\longrightarrow P\\ X\in\Gamma_e(P)}} \langle N(P), \nabla\mathcal{S}f(X)\rangle = \left(\frac{1}{2}I + K^*\right)f(P),$$

where K^* is the transpose operator of K. On the other hand, the tangential component of $\nabla\mathcal{S}f$ does not jump.

For the rest of the section, we will assume that the imaginary part of the wave number k is positive. This condition guarantees the invertibility results in the next lemma (see [1], [16]).

LEMMA 4.1. *Let D be a Lipschitz domain in R^3. Then the following hold:*

(i) *$S : L^2(\partial D) \longrightarrow L^2(\partial D)$ is compact.*

(ii) *$S : L^2(\partial D) \longrightarrow L^{2,1}(\partial D)$ is invertible.*

(iii) *$\pm\frac{1}{2}I + K : L^2(\partial D) \longrightarrow L^2(\partial D)$ are invertible.*

(iv) *$\pm\frac{1}{2}I + K : L^{2,1}(\partial D) \longrightarrow L^{2,1}(\partial D)$ are invertible.*

(v) *If ∂D is actually of class C^1, then the operator K is compact in $L^2(\partial D)$.* □

The action of the single and double layer-potential operators on vector fields is defined componentwise. In addition, the traces of the divergence and curl of the single-layer potential of a vector field A define bounded operators in $L^2(\partial D)$, and their values are given by

$$\lim_{\substack{X\to P\\ X\in\Gamma_i(P)}} \operatorname{div}\mathcal{S}A(X) = -\frac{1}{2}\langle N, A\rangle(P) + \text{p.v.}\int_{\partial D}\operatorname{div}_P(\Phi(P-Q)A(Q))d\sigma(Q),$$

$$\lim_{\substack{X\to P\\ X\in\Gamma_e(P)}} \operatorname{div}\mathcal{S}A(X) = \frac{1}{2}\langle N, A\rangle(P) + \text{p.v.}\int_{\partial D}\operatorname{div}_P(\Phi(P-Q)A(Q))d\sigma(Q),$$

and

$$\lim_{\substack{X\to P\\ X\in\Gamma_i(P)}} \operatorname{curl}\mathcal{S}A(X) = -\frac{1}{2}(N\times A)(P) + \text{p.v.}\int_{\partial D} \operatorname{curl}_P\left(\Phi(P-Q)A(Q)\right)d\sigma(Q),$$

$$\lim_{\substack{X\to P\\ X\in\Gamma_e(P)}} \operatorname{curl}\mathcal{S}A(X) = \frac{1}{2}(N\times A)(P) + \text{p.v.}\int_{\partial D} \operatorname{curl}_P\left(\Phi(P-Q)A(Q)\right)d\sigma(Q).$$

We also have

$$\|(\operatorname{div}\mathcal{S}A)^*\|_{L^2(\partial D)} + \|(\operatorname{curl}\mathcal{S}A)^*\|_{L^2(\partial D)} \le C\|A\|_{L^2(\partial D)}.$$

The function $\operatorname{curl}\mathcal{S}A$ satisfies the vector Helmholtz equation outside ∂D as well as the radiation condition (8) at infinity. In addition, the tangential component of the trace of the curl of the single-layer potential is given almost everywhere in ∂D by

$$\lim_{\substack{X\longrightarrow P\\ X\in\Gamma_i(P)}} N(P)\times\operatorname{curl}\mathcal{S}A(X) = \left(\frac{1}{2}I + M\right)A(P)$$

and

$$\lim_{\substack{X\longrightarrow P\\ X\in\Gamma_e(P)}} N(P)\times\operatorname{curl}\mathcal{S}A(X) = \left(-\frac{1}{2}I + M\right)A(P),$$

where MA is the tangential vector field defined by

$$MA(P) = \text{p.v.}\int_{\partial D} N(P)\times\operatorname{curl}_P\left(\Phi(P-Q)A(Q)\right)d\sigma(Q).$$

We recall from [13] the following result.

LEMMA 4.2. *Let D be a Lipschitz domain in R^3. Then the operator M maps $L^2_T(\partial D)$ into itself and $L^{2,\mathrm{Div}}_T(\partial D)$ into itself. Moreover, if D is actually C^1, then M is compact on both spaces.* □

In order to study the double curl of the single-layer potential, we need another important result obtained in [14].

LEMMA 4.3. *Let D be Lipschitz domain. A vector field A in $L^2_T(\partial D)$ has a surface divergence in $L^2(\partial D)$ if and only if $\|(\nabla(\operatorname{div}\mathcal{S}A))^*\|_{L^2(\partial D)} < +\infty$. In such a case, $\operatorname{div}\mathcal{S}A = \mathcal{S}(\operatorname{Div}A)$.* □

As a consequence of this last result, we can now prove the following.

LEMMA 4.4. *Let D be a Lipschitz domain. Let A be a vector field in $L^{2,\mathrm{Div}}_T(\partial D)$. Then $\|(\operatorname{curl}\operatorname{curl}\mathcal{S}A)^*\|_{L^2(\partial D)} < +\infty$ and*

$$\lim_{X\to P} N(P)\times\operatorname{curl}\operatorname{curl}\mathcal{S}A(X) = \left(N\times(k^2\mathcal{S}A + \nabla\mathcal{S}(\operatorname{Div}A))\right)(P)$$

nontangentially, both from the inside and outside of D. Moreover, if we define on ∂D the operator

$$LA(P) = \left(N\times(k^2\mathcal{S}A + \nabla\mathcal{S}(\operatorname{Div}A))\right)(P),$$

then L maps $L^{2,\mathrm{Div}}_T(\partial D)$ into itself.

Proof. Let A be a vector field in $L_T^{2,\mathrm{Div}}(\partial D)$. Using the identity

$$\mathrm{curl}\,\mathrm{curl} = -\triangle + \nabla\mathrm{div}$$

and Lemma 4.3, we see that

$$\mathrm{curl}\,\mathrm{curl}\,\mathcal{S}A = k^2\mathcal{S}A + \nabla\mathcal{S}(\mathrm{Div}\,A),$$

which implies the boundedness of the nontangential maximal function and the claimed boundary values (notice that $\mathcal{S}$ and the tangential component of $\nabla\mathcal{S}$ do not have jumps). Clearly, the resulting boundary operator L maps $L_T^{2,\mathrm{Div}}(\partial D)$ into $L_T^2(\partial D)$. If we now apply (7) to the vector field

$$E(X) = \mathrm{curl}\,\mathrm{curl}\,\mathcal{S}A(X),$$

we obtain that

$$\mathrm{Div}\,(LA) = \mathrm{Div}\,(N\times E) = -\langle N, \mathrm{curl}\,\mathrm{curl}\,\mathrm{curl}\,\mathcal{S}A\rangle = -\left\langle N, k^2\mathrm{curl}\,\mathcal{S}A\right\rangle,$$

and, therefore,

$$\begin{aligned}\|LA\|_{L_T^{2,\mathrm{Div}}(\partial D)} &= \|LA\|_{L_T^2(\partial D)} + \|\mathrm{Div}\,(LA)\|_{L^2(\partial D)}\\ &\le \|N\times(k^2\mathcal{S}A+\nabla\mathcal{S}(\mathrm{Div}\,A))\|_{L_T^2(\partial D)} + \|\langle N, k^2\mathrm{curl}\,\mathcal{S}A\rangle\|_{L^2(\partial D)}\\ &\le C(\|\mathcal{S}A\|_{L^2(\partial D)} + \|\nabla\mathcal{S}(\mathrm{Div}\,A)\|_{L^2(\partial D)} + \|\mathrm{curl}\,\mathcal{S}A\|_{L^2(\partial D)})\\ &\le C(\|A\|_{L_T^2(\partial D)} + \|\mathrm{Div}\,A)\|_{L^2(\partial D)}),\end{aligned}$$

which concludes the proof. □

We need to consider the potential-theoretic versions of some of the layer-potential operators already described. Let S_0, M_0, and L_0 be defined using the fundamental solution of the Laplace operator $\triangle$ in R^3,

$$\Phi_0(X) = -\frac{1}{4\pi|X|}.$$

The boundedness properties of the operators S_0, M_0, and L_0 are the same as those of S, M, and L. Moreover, we have the following.

LEMMA 4.5. *Let D be a Lipschitz domain in R^3. Then,*

(i) $M - M_0 : L_T^2(\partial D) \longrightarrow L_T^2(\partial D)$ *is compact.*

(ii) $M - M_0 : L_T^2(\partial D) \longrightarrow L_T^{2,\mathrm{Div}}(\partial D)$ *is bounded.*

(iii) $L - L_0 : L_T^2(\partial D) \longrightarrow L_T^2(\partial D)$ *is compact.*

(iv) $L - L_0 : L_T^2(\partial D) \longrightarrow L_T^{2,\mathrm{Div}}(\partial D)$ *is bounded.*

Proof. A straightforward computation shows that the differences of partial derivatives

$$\partial_i\Phi(P-Q) - \partial_i\Phi_0(P-Q)$$

and

$$\partial_i\partial_j\Phi(P-Q) - \partial_i\partial_j\Phi_0(P-Q)$$

have locally integrable singularities on ∂D. From this easily follows that $M - M_0$ and $L - L_0$ are compact operators in $L_T^2(\partial D)$ (cf. [16]). To show that these operators map $L_T^2(\partial D)$ into $L_T^{2,\mathrm{Div}}(\partial D)$, we notice that

$$\begin{aligned}\mathrm{Div}\,(M-M_0)A &= \mathrm{Div}\,(N\times\mathrm{curl}\,(\mathcal{S}-\mathcal{S}_0)A)\\ &= -\langle N, \mathrm{curl}\,\mathrm{curl}\,(\mathcal{S}-\mathcal{S}_0)A\rangle\\ &= -\left\langle N, k^2\mathrm{curl}\,\mathcal{S}A + \nabla\,\mathrm{div}((\mathcal{S}-\mathcal{S}_0)A)\right\rangle,\end{aligned}$$

which defines an operator with a kernel with a locally integrable singularity and bounded in $L^2(\partial D)$. Similarly,

$$\begin{aligned}\operatorname{Div}(L-L_0)A &= \operatorname{Div}(N\times \operatorname{curl}\operatorname{curl}(\mathcal{S}-\mathcal{S}_0)A)\\ &= -\langle N, \operatorname{curl}\operatorname{curl}\operatorname{curl}(\mathcal{S}-\mathcal{S}_0)A\rangle\\ &= -\left\langle N, k^2 \operatorname{curl}\mathcal{S}A\right\rangle,\end{aligned}$$

again producing a bounded operator in $L^2(\partial D)$. □

We conclude this section with a simple result about the spectrum of M_0 in C^1 domains.

LEMMA 4.6. *Let D be a C^1 domain in R^3. Then, for any complex number λ outside the interval $[-\frac{1}{2},\frac{1}{2}]$, the operator $\lambda I + M_0$ is invertible in $L^2_T(\partial D)$ and in $L_T^{2,\mathrm{Div}}(\partial D)$.*

Proof. Since by the results in [14] the operator M_0 still is L^2-compact in C^1 domains, it is enough to prove that $\lambda I + M_0$ is injective. This is done in [4, pp. 155–157] in the case of C^2 domains. Given the boundedness and invertibility properties of the layer-potential operators discussed in this section, the same proof extends without modification to the case of C^1 domains. Finally, observe that since M_0 is also compact in $L_T^{2,\mathrm{Div}}(\partial D)$, its spectrum in $L^2_T(\partial D)$ and in $L_T^{2,\mathrm{Div}}(\partial D)$ is the same. □

Remark. In the case of Lipschitz domains, the operators M and M_0 may not be compact in $L^2_T(\partial D)$. The invertibility of $\lambda I + M$ or $\lambda I + M_0$ can no longer be handled via Fredholm theory. The usual substitute technique to prove invertibility results in this kind of situation involves the use of Rellich-type identities (see, e.g., [17] and [7]). Such techniques were used in [8] and [10] to study the spectrum in $L^2(\partial D)$ of the double-layer potential for the Laplacian $\lambda I + K_0$. The spectral properties of K_0 in $L^{2,1}(\partial D)$ were studied in [16]. The spectral properties of M_0 in $L^2_T(\partial D)$ in the case of Lipschitz domains remain unknown, but from the results in [13], it follows that if $\lambda I + M_0$ is in vertible in $L^2_T(\partial D)$ for some λ, then it is also invertible in $L_T^{2,\mathrm{Div}}(\partial D)$. This missing information about the spectrum of M_0 in $L^2_T(\partial D)$ is the only additional result that would be necessary to extend Theorem 5.1 in the next section to the case of Lipschitz domains.

5. Existence of solutions.

We now present the existence of solutions to problem (T) using a particular boundary integral representation.

THEOREM 5.1. *Let D be a C^1 domain in R^3. Assume that the electromagnetic parameters satisfy the conditions in Theorem 3.5. Assume also that $\frac{\mu_e+\mu_i}{\mu_e-\mu_i}$ and $\frac{\epsilon_e+\epsilon_i}{\epsilon_e-\epsilon_i}$ are not real numbers in the interval $[-1,1]$. Then the transmission problem (T) has a unique solution for any A and B in $L_T^{2,\mathrm{Div}}(\partial D)$.*

Proof. In view of Theorem 3.4, we only need to show existence of solution. Let U and V be vector fields in $L_T^{2,\mathrm{Div}}(\partial D)$ and consider the ansatz

$$E_e(X) = \mu_e \operatorname{curl}\mathcal{S}_e U(X) + \operatorname{curl}\operatorname{curl}\mathcal{S}_e V(X) \quad \text{in } \mathrm{R}^3\backslash\overline{D},$$

$$E_i(X) = \mu_i \operatorname{curl}\mathcal{S}_i U(X) + \operatorname{curl}\operatorname{curl}\mathcal{S}_i V(X) \quad \text{in } D,$$

and

$$H_e(X) = \frac{1}{i\mu_e\omega}\operatorname{curl} E_e(X),$$

$$H_i(X) = \frac{1}{i\mu_e\omega}\operatorname{curl} E_i(X),$$

where $\mathcal{S}_e$ and $\mathcal{S}_i$ denote the single layer-potential operators defined using the wave numbers k_e and k_i. By the results of the previous section, for any U and V in $L_T^{2,\mathrm{Div}}(\partial D)$, these vector fields solve the Maxwell equations and satisfy the radiation condition at infinity. Then, to solve problem (T), it is enough to show that given A and B in $L_T^{2,\mathrm{Div}}(\partial D)$, we can find U and V such that the above electric fields satisfy on ∂D

$$N \times E_e - N \times E_i = A,$$

$$\frac{1}{\mu_e} N \times \operatorname{curl} E_e - \frac{1}{\mu_i} N \times \operatorname{curl} E_i = B.$$

That is, we need to solve the system

$$\mu_e \left(-\frac{1}{2} I + M_e \right) U + L_e V - \mu_i \left(\frac{1}{2} I + M_i \right) U - L_i V = A,$$

$$L_e U + \frac{k_e^2}{\mu_e} \left(-\frac{1}{2} I + M_e \right) V - L_i U - \frac{k_i^2}{\mu_i} \left(\frac{1}{2} I + M_i \right) V = B.$$

We rewrite this as

$$\begin{pmatrix} -\frac{\mu_e+\mu_i}{2} I + \mu_e M_e - \mu_i M_i & L_e - L_i \\ L_e - L_i & -\left(\frac{k_e^2}{2\mu_e} + \frac{k_i^2}{2\mu_i} \right) I + \frac{k_e^2}{\mu_e} M_e - \frac{k_i^2}{\mu_i} M_i \end{pmatrix} \cdot \begin{pmatrix} U \\ V \end{pmatrix}$$

$$= \begin{pmatrix} A \\ B \end{pmatrix}.$$

Notice that the above system, originally defined in the the product space $L_T^{2,\mathrm{Div}}(\partial D) \times L_T^{2,\mathrm{Div}}(\partial D)$, makes sense in the space $L_T^2(\partial D) \times L_T^2(\partial D)$. Now, we observe that if M_0 is the potential-theoretic version of M, the above matrix of operators can be decompose as the sum of two matrices, $\mathrm{W}_1 + \mathrm{W}_2$, where

$$\mathrm{W}_1 = \begin{pmatrix} -\frac{\mu_e+\mu_i}{2} I + (\mu_e - \mu_i) M_0 & 0 \\ 0 & -\left(\frac{k_e^2}{2\mu_e} + \frac{k_i^2}{2\mu_i} \right) I + \left(\frac{k_e^2}{\mu_e} - \frac{k_i^2}{\mu_i} \right) M_0 \end{pmatrix}$$

and

$$\mathrm{W}_2 = \begin{pmatrix} \frac{\mu_e}{2}(M_e - M_0) + \frac{\mu_i}{2}(M_0 - M_i) & L_e - L_i \\ L_e - L_i & \frac{k_i^2}{\mu_e}(M_e - M_0) + \frac{k_i^2}{\mu_i}(M_0 - M_i) \end{pmatrix}.$$

Since we are assuming that

$$\frac{\mu_e + \mu_i}{\mu_e - \mu_i} \quad \text{and} \quad \frac{\frac{k_e^2}{\mu_e} + \frac{k_i^2}{\mu_i}}{\frac{k_e^2}{\mu_e} - \frac{k_i^2}{\mu_i}} = \frac{\epsilon_e + \epsilon_i}{\epsilon_e - \epsilon_i}$$

are not in the interval $[-1, 1]$, Lemma 4.6 implies that the matrix W_1 is an invertible operator in both $L_T^2(\partial D) \times L_T^2(\partial D)$ and $L_T^{2,\mathrm{Div}}(\partial D) \times L_T^{2,\mathrm{Div}}(\partial D)$. On the other hand, by Lemma 4.5, the matrix W_2 is compact in $L_T^2(\partial D) \times L_T^2(\partial D)$ and maps this space into $L_T^{2,\mathrm{Div}}(\partial D) \times L_T^{2,\mathrm{Div}}(\partial D)$. From this follows that the matrix $\mathrm{W}_1 + \mathrm{W}_2$ has index zero in $L_T^2(\partial D) \times L_T^2(\partial D)$. It also follows that if U and V are solutions of the system of boundary integral equations in $L_T^2(\partial D) \times L_T^2(\partial D)$, then U and V are in $L_T^{2,\mathrm{Div}}(\partial D)$ if and only if A and B are in $L_T^{2,\mathrm{Div}}(\partial D)$. In particular, the null space of the matrix $\mathrm{W}_1 + \mathrm{W}_2$ is the same in both spaces. If we can show that this matrix of operators is one-to-one in $L_T^2(\partial D) \times L_T^2(\partial D)$, we will have by the previous observation that it is invertible in $L_T^2(\partial D) \times L_T^2(\partial D)$ and also in $L_T^{2,\mathrm{Div}}(\partial D) \times L_T^{2,\mathrm{Div}}(\partial D)$. This will conclude the proof of the theorem.

Assume that U and V are solutions of the system with $A = B = 0$. Since U and V must be in $L_T^{2,\mathrm{Div}}(\partial D)$, E_i, H_i and E_e, H_e are solutions of the homogeneous version of problem (T), and by Theorem 3.4, they must be identically zero. In particular, on the boundary of the domain,

$$N \times E_i = N \times E_e = N \times \operatorname{curl} E_i = N \times \operatorname{curl} E_e = 0.$$

Now consider the new vector fields

$$E_e'(X) = -\operatorname{curl} \mathcal{S}_i U(X) - \frac{1}{\mu_i} \operatorname{curl}\, \operatorname{curl} \mathcal{S}_i V(X) \quad \text{in } \mathrm{R}^3 \backslash \overline{D},$$

$$E_i'(X) = \operatorname{curl} \mathcal{S}_e U(X) + \frac{1}{\mu_e} \operatorname{curl}\, \operatorname{curl} \mathcal{S}_e V(X) \quad \text{in } D.$$

Going to the boundary, we obtain the trace values,

$$N \times E_e' = \left(\frac{1}{2} I - M_i\right) U - \frac{1}{\mu_i} L_i V,$$

$$N \times E_i' = \left(\frac{1}{2} I + M_e\right) U + \frac{1}{\mu_e} L_e V,$$

and

$$N \times \operatorname{curl} E_e' = -L_i U - \frac{k_i^2}{\mu_i} \left(-\frac{1}{2} I + M_i\right) V,$$

$$N \times \operatorname{curl} E_i' = L_e U + \frac{k_e^2}{\mu_e} \left(\frac{1}{2} I + M_e\right) V.$$

It follows that on ∂D,

$$N \times E_e' - N \times E_i' = -\frac{1}{\mu_i} N \times E_i - \frac{1}{\mu_e} N \times E_e = 0,$$

and also

$$\frac{\mu_i}{k_i^2} N \times \operatorname{curl} E_e' - \frac{\mu_e}{k_e^2} N \times \operatorname{curl} E_i' = -\frac{1}{k_i^2} N \times \operatorname{curl} E_i - \frac{1}{k_e^2} N \times \operatorname{curl} E_e = 0.$$

Therefore, E_i' and E_e' are solutions of problem (T') and, by Theorem 3.5, they must be identically zero too. In particular,

$$N \times E_i' = N \times E_e' = N \times \operatorname{curl} E_i' = N \times \operatorname{curl} E_e' = 0$$

using the trace results of the previous section. Finally,

$$U = N \times E_i + \mu_i N \times E_e' = 0,$$

and

$$-V = N \times E_e - \mu_e N \times E_i' = 0. \qquad \square$$

In physical applications, the parameters μ_i and μ_e are usually assumed to be real numbers. In such a case, the conditions on the electromagnetic parameters take the following simpler form.

THEOREM 5.2. *Let D be a C^1 domain in R^3. Let* $\operatorname{Im} k_i > 0$ *and* $\operatorname{Im} k_e > 0$*, and assume that μ_i, μ_e, and ω are positive numbers. Then the transmission problem (T) has a unique solution for any A and B in $L_T^{2,\mathrm{Div}}(\partial D)$.*

Proof. First, observe that if μ_i and μ_e are positive numbers, then

$$\left|\frac{\mu_e + \mu_i}{\mu_e - \mu_i}\right| > 1,$$

and if ω is a positive number, then the conditions $\operatorname{Im} k_i > 0$ and $\operatorname{Im} k_e > 0$ imply that

$$\left|\frac{\epsilon_e + \epsilon_i}{\epsilon_e - \epsilon_i}\right| > 1.$$

Also, conditions (13) and (14) are trivially satisfied. It follows that to use Theorem 3.5, we need only to check that either

$$\operatorname{Im}(k_i \overline{k}_e^{2}) \leq 0 \tag{16}$$

or

$$\operatorname{Im}\left(\frac{\epsilon_i}{\epsilon_e}\right) > 0 \text{ and } \operatorname{Re}\left(\frac{\epsilon_i}{\epsilon_e}\right) > 0. \tag{17}$$

By writing

$$\epsilon_i = |\epsilon_i| \exp\left(i \arctan \frac{\sigma_i}{\omega \epsilon_{0i}}\right),$$

$$\epsilon_e = |\epsilon_e| \exp\left(i \arctan \frac{\sigma_e}{\omega \epsilon_{0e}}\right),$$

we see that (16) is equivalent to

$$\frac{\sigma_i}{2\epsilon_{0i}} \leq \frac{\sigma_e}{\epsilon_{0e}}. \tag{18}$$

On the other hand, for positive ω, the real part of ϵ_i/ϵ_e is always positive, and a computation shows that (17) becomes equivalent to

$$\frac{\sigma_i}{\epsilon_{0i}} > \frac{\sigma_e}{\epsilon_{0e}}. \tag{19}$$

Obviously, either (18) or (19) is satisfied, which concludes the proof. $\square$

Finally, the proof of Theorem 5.1 shows that for a Lipschitz domain D the following result holds.

THEOREM 5.3. *Let D be a Lipschitz domain in R^3. Assume that the electromagnetic parameters satisfy the conditions in Theorem 3.5. Assume also that $\frac{\mu_e+\mu_i}{\mu_e-\mu_i}$ and $\frac{\epsilon_e+\epsilon_i}{\epsilon_e-\epsilon_i}$ are not in the spectrum of $2M_0$ as an operator in $L_T^2(\partial D)$. Then the transmission problem (T) has a unique solution for any A and B in $L_T^{2,\mathrm{Div}}(\partial D)$.* $\square$

DISSIPATION IN HAMILTONIAN SYSTEMS: DECAYING CNOIDAL WAVES*

G. DERKS† AND E. VAN GROESEN‡

Abstract. The uniformly damped Korteweg–de Vries (KdV) equation with periodic boundary conditions can be viewed as a Hamiltonian system with dissipation added. The KdV equation is the Hamiltonian part and it has a two-dimensional family of relative equilibria. These relative equilibria are space-periodic soliton-like waves, known as cnoidal waves.

Solutions of the dissipative system, starting near a cnoidal wave, are approximated with a long curve on the family of cnoidal waves. This approximation curve consists of a quasi-static succession of cnoidal waves. The approximation process is sharp in the sense that as a solution tends to zero as $t \to \infty$, the difference between the solution and the approximation tends to zero in a norm that sharply picks out their difference in shape. More explicitly, the difference in shape between a solution and a quasi-static cnoidal-wave approximation is of the order of the damping rate times the norm of the cnoidal-wave at each instant.

Key words. perturbed KdV equation, cnoidal waves, asymptotic behavior

AMS subject classifications. 35B20, 35Q53, 76B25

1. Introduction.

Consider the uniformly damped one-dimensional Korteweg–de Vries (KdV) equation with periodic boundary conditions

$$\begin{aligned} &u_t = -\partial_x \left[u_{xx} + u^2 \right] - \varepsilon\, u, && t > 0,\ \ x \in (0, 2\pi), \\ &u(0,t) = u(2\,\pi,t), \quad u_x(0,t) = u_x(2\,\pi,t), && t \geq 0. \end{aligned} \tag{1}$$

In this equation ε is a small parameter that gives the strength of the damping and the subscripts denote differentiation with respect to the given variable. Furthermore, we assume that the function $u(x,t)$ has mean value zero for all time:

$$\int_0^{2\pi} u(x,t)\, dx = 0, \qquad t \geq 0.$$

In [5] and [7], it is shown that the initial value problem of (1) with $\varepsilon = 0$ is well posed in H^s, $s \geq 1$. It is easy to see that if $\varepsilon \neq 0$, this property remains; see, e.g., [14].

If $\varepsilon = 0$, there is no damping present and the resulting equation is the KdV equation, which can be regarded as a Hamiltonian system with the Hamiltonian

$$H(u) = \int_0^{2\pi} \left[\frac{1}{2} u_x^2 - \frac{1}{3} u^3 \right] dx$$

and with the operator ∂_x as the structure map. The KdV equation was originally derived in 1895 as a model for planar, unidirectional waves propagating in shallow wa-

ter [21]. Over the last thirty years, the KdV equation has appeared as a model equation for many other physical situations that feature wave motion wherein nonlinearity and dispersion are comparable. For a review on the KdV equation, see [25] and [27].

The KdV equation is translation invariant. This invariance gives another first integral in the system besides the Hamiltonian, namely the L^2-norm of the solutions

$$I(u) = \frac{1}{2}\int_0^{2\pi} u^2\,dx.$$

(Moreover, the KdV equation is completely integrable, but here we use only the translation invariance.) The Hamiltonian I-flow is the translation operator (see [26])

$$(\Phi^I_\varphi(u))(x) = u(x+\varphi), \qquad x \in [0, 2\pi],\ \varphi \in [0, 2\pi].$$

The tangent vector to this flow is the Hamiltonian I-vector field, denoted by

$$X_I(u) = \partial_x I'(u) = \partial_x u.$$

Profiles of traveling-wave solutions of a translation-invariant Hamiltonian system can be found as critical points of the Hamiltonian for fixed values of I. In other words, they are relative equilibria (see [1]), and the family of all traveling-wave profiles is called the manifold of relative equilibria (MRE). In case of the periodic KdV equation, the relative equilibria are solitary-wave solutions, the so-called cnoidal waves. The cnoidal waves with minimal period 2π form a two-dimensional family which can be parameterized with the value of the integral I (a quantity related to the amplitude of the cnoidal wave) and the "position" of the cnoidal wave. The MRE consists of traveling-wave profiles, but for simplicity, the two-dimensional manifold consisting of the relative equilibrium solutions—hence the traveling-wave solutions—is also called the MRE. (Only when this can cause ambiguity, we will distinguish between these two manifolds by calling the second one the traveling-wave MRE.)

The cnoidal waves are orbitally stable solutions. In [4], this orbital stability is proved by using that in fact the cnoidal waves are constrained minima of the Hamiltonian for fixed values of the integral I. Here orbital stability means stability modulo translations. In other words, the profile of the cnoidal waves is dynamically stable; its "position" is ignored. This is the strongest kind of stability possible for this system because a small change in the speed or amplitude can cause a translational drift. For this reason, in this article, we consider only the profile of the waves and do not bother much about the "position" of the waves.

For the cnoidal waves, this implies that we are only interested in the one-dimensional family of wave profiles. For every fixed value of $I = \gamma$, we choose the cnoidal-wave profile that has its maximum at $x = 0$ (this profile is symmetric around $x = 0$) and denote it by $\bar{u}(\gamma)$. Then the set

$$\{\bar{u}(\gamma) \mid \gamma \geq 0\}$$

is a one-dimensional submanifold of the MRE from which the translations are divided out. The wave speed of the cnoidal wave with $I = \gamma$ is denoted by $\lambda(\gamma)$; it is also the Lagrange multiplier in the Euler–Lagrange equation of the constrained critical-point problem

$$(2) \qquad \partial_x(\bar{u}_{xx} + \bar{u}^2 + \lambda(\gamma)\,\bar{u}) = 0 \quad \text{or} \quad \bar{u}_{xx} + \bar{u}^2 + \lambda(\gamma)\,\bar{u} = \alpha(\gamma)$$

with $\alpha(\gamma)=\frac{\gamma}{2\pi}$, which follows by integrating the equation from 0 to 2π. The cnoidal waves can also be found as unconstrained critical points. To see this, for $\gamma \geq 0$, we define the modified KdV Hamiltonian

$$H_\gamma(u) = H(u) - \lambda(\gamma) I(u).$$

Then for every $\gamma \geq 0$, the cnoidal wave $\bar{u}(\gamma)$ is a critical point of H_γ.

The first general method for using the variational characterization of relative equilibria to draw conclusions about the stability was given in 1985 in [17]. Later, this method was extended to the energy-momentum method in [28] and [29]. In [15] and [23], the sufficient conditions for the stability of the relative equilibria were weakened. In this article, we will extend the use of the variational characterization of the relative equilibria to draw conclusions about the approximation with the cnoidal waves in the damped KdV equation.

For $\varepsilon \neq 0$, the cnoidal waves are no longer solutions of equation (1) and every solution decays to the zero state. This follows from the time behavior of the L^2-norm of u (which equals $I(u)$):

$$\frac{\mathrm{d}}{\mathrm{d}t} I(u) = (I'(u), \partial_x H'(u) - \varepsilon P(u)) = -\varepsilon \int_0^{2\pi} u^2\, dx = -2\varepsilon I(u). \tag{3}$$

(We use the notation $F'(u)$ to denote the variational derivative of a differentiable functional $F(u)$.) In other words, (3) states that $I(u(t)) = I(u(0))\, e^{-2\varepsilon t}$ and that $\lim_{t\to\infty} I(u(t)) = 0$, which implies that $\lim_{t\to\infty} u(t) = 0$.

Although a solution never stays in the neighborhood of one specific cnoidal-wave profile, the full MRE can be useful to approximate the behavior of a solution that starts near a cnoidal wave. This behavior is indicated by numerical experiments and analytical approximations; see [16]. A similar behavior can be found (numerically and experimentally) for the KdV equation with dissipation on an infinite interval. However, in this case, some problems arise in the derivation of an analytical approximation since the decay of the mass functional $M(u) = \int u$ then has to be taken into account; see [18]–[20].

In this article, we approximate a solution of the damped KdV equation on a periodic interval by a projection of the solution on the MRE. An important issue in this article is the justification of the approximation of a solution with this projection. We will use a norm in the Sobolev space H^1_{per} to derive this justification. The usual H^1_{per}-norm is given by

$$\|u\|^2_{H^1_{\mathrm{per}}} = \int_0^{2\pi} [\, u(x)^2 + u_x(x)^2\,]\, dx = \|u\|_0^2 + \|u_x\|_0^2, \qquad u \in H^1_{\mathrm{per}},$$

where $\|\,.\,\|_0$ denotes the L^2_{per}-norm. Because we consider only functions with mean value zero, by the Poincaré inequality, the following norm is equivalent to the H^1_{per}-norm:

$$\|u\|_1^2 = \int_0^{2\pi} u_x(x)^2\, dx = \|u_x\|_0^2, \qquad u \in H^1_{\mathrm{per},0},$$

where $H^1_{\mathrm{per},0}$ is the subspace of H^1_{per} consisting of 2π-periodic functions with mean value 0. Furthermore, we will often use the following Poincaré inequalities comparing the L^2_{per}-norm (respectively, the L^∞_{per}-norm) and the $H^1_{\text{per},0}$-norm:

$$\|u\|_0^2 = \int_0^{2\pi} \left| \int_{x_0}^{x} u_x(\xi)d\xi \right|^2 dx \leq \int_0^{2\pi} \left[\int_0^{2\pi} |u_x(\xi)|d\xi \right]^2 dx \leq (2\pi)^2 \|u\|_1^2, \tag{4}$$

$$\|u\|_\infty = \max_{x\in[0,2\pi]} |u(x)| = \max_{x\in[0,2\pi]} \left| \int_{x_0}^{x} u_x(\xi)d\xi \right| \leq \sqrt{2\pi}\, \|u\|_1. \tag{5}$$

Here x_0 denotes any zero of $u(t)$. (This zero exists because $u(t)$ has mean value zero.)

As we stated before, we are not interested in differences caused by translations. Therefore, we define (analogously to [3, 4]) translation-invariant distances related to the L^2_{per}- and $H^1_{\text{per},0}$-norm, denoted by ρ_0 and ρ_1, respectively, as

$$\rho_i(u_1, u_2) = \min_{\varphi\in[0,2\pi]} \|\Phi^I_\varphi(u_2) - u_1\|_i = \min_{\varphi\in[0,2\pi]} \|\Phi^I_\varphi(u_1) - u_2\|_i, \qquad i = 0, 1.$$

See also Figure 1.

FIG. 1. *The translation-invariant distance $\rho_i(u_1, u_2) = \rho_i(u_2, u_1)$. The translations $\Phi^I_{\varphi(u_1)}$ and $\Phi^I_{\varphi(u_2)}$ are such that $\rho_i(u_1, u_2) = \|\Phi^I_{\varphi(u_1)}(u_1) - u_2\|_i = \|\Phi^I_{\varphi(u_2)}(u_2) - u_1\|_i$.*

To define a projection of a solution $u(t)$, we choose the wave profile on the MRE with an I-value equal to the I-value of the solution. Next, we define a position for this wave profile. It is obvious to choose the position such that the ρ_1-distance is as small as possible.

DEFINITION 1.1. *Let $u(t)$ be a solution of the damped KdV equation. Define the functions $\gamma(t) \in \mathbb{R}$ and $\varphi(t) \in \mathbb{R}$ such that*

$$\gamma(t) = I(u(t)),$$
$$\|\Phi^I_{-\varphi(t)}(u(t)) - \bar{u}(\gamma)\|_1 = \min_{\varphi\in\mathbb{R}} \|\Phi^I_\varphi(u(t)) - \bar{u}(\gamma)\|_1 = \rho_1(\bar{u}(\gamma), u(t)).$$

Finally, we define $\xi(t)$ to be the difference between $u(t)$ and its projection

$$\xi(t) = \Phi^I_{-\varphi(t)}(u(t)) - \bar{u}(\gamma(t)).$$

The projection of the solution $t \to u(t)$ onto the MRE is the curve $t \to \Phi^I_{\varphi(t)}(\bar{u}(\gamma(t)))$.

An important consequence of the choice of φ as given by Definition 1.1 is that $\|\xi\|_1^2 = \rho_1(\bar{u}(\gamma), u)$. Furthermore, the differential equation for the function $\gamma(t)$ is only in terms of γ and hence can be solved explicitly (see equation (3)):

$$\dot{\gamma} = -2\,\varepsilon\,\gamma \qquad \text{implying} \qquad \gamma(t) = \gamma(0)\, e^{-2\varepsilon t}.$$

The main result of this article can now be formulated.

THEOREM 1.2. *For every $\gamma_0 > 0$, there exists a $K > 0$ and an $\varepsilon_0 > 0$ such that any solution $u(t)$ of the damped KdV equation* (1) *with $\varepsilon \leq \varepsilon_0$ that starts with $\gamma(0) \leq \gamma_0$ and, within a distance ε of a cnoidal wave, stays in a relative ε-neighborhood of the family of cnoidal waves.*

Explicitly, if $u(0)$ is such that $\gamma(0) \leq \gamma_0$ and $\rho_1(\bar{u}(\gamma(0)), u(0)) \leq \varepsilon$, then for all $t \geq 0$,

$$\rho_1(\bar{u}(\gamma(t)), u(t)) \leq K\varepsilon e^{-\varepsilon t} = \bar{K}\varepsilon\|\bar{u}(\gamma(t))\|_0 = \tilde{K}\varepsilon\|\bar{u}(\gamma(t))\|_1, \tag{6}$$

where $\bar{K} = K/\sqrt{2\,\gamma(0)}$.

In (6), we use that on every compact γ-interval $\|\bar{u}(\gamma)\|_0$ and $\|\bar{u}(\gamma)\|_1$ are of the same order. Hence on $[0, \gamma_0]$, the quotient $\|\bar{u}(\gamma)\|_0/\|\bar{u}(\gamma)\|_1$ can be estimated by a constant independent of γ.

Remark 1. Notice that the estimate for the initial condition and the estimate for the time behavior are in the same norm.

Remark 2. From Theorem 1.2, it can be deduced that for every $\gamma_0 > 0$, there exists a $\hat{K}$ and an $\hat{\varepsilon}_0$ such that if $H(u(0)) - H(\bar{u}(\gamma(0))) \leq \hat{\varepsilon}_0$, then $H(u(t)) \leq \hat{K}\, I(u(t))$ for all t. This is sketched in Figure 2.

On the contrary, for the KdV–Burgers equation, i.e., $u_t = -\partial_x\,(\,u_{xx} + u^2\,) + \varepsilon\, u_{xx}$, we observe a "self-organization" towards the MRE. In an H-I-figure, this means that every solution decays to zero tangent to the MRE. Hence asymptotically every solution will be below the tangent line to the MRE at 0, hence below the line $H = I$. This behavior is sketched in Figure 3. This self-organization will not occur for the KdV equation with uniform damping. Hence the situation sketched in Figure 2 is also the best possible one. See [16] for more details.

Remark 3. In [14], the damped KdV equation with an additional forcing is considered and the existence of finite-dimensional attractors is investigated. In case there is no forcing, the attractor is trivial. The result in Theorem 1.2 gives more information than the existence of an attractor. It describes an approximation for the intermediate and asymptotic states. The asymptotic result also shows how the solution decays to the attractor 0.

In the next sections, we will prove Theorem 1.2. The proof uses the variational principle which underlies the stability result of the cnoidal waves (see [4]). More explicit, to prove the stability of the cnoidal waves, we can use the (Lyapunov) functional $L(u) = H(u) - H(\bar{u}(I(u)))$. This functional is also similar to the so-called amended Hamiltonian or energy-momentum functional as used in [28, 29]. To prove Theorem 1.2, we will analyze the time behavior of the function $L(u(t))$, where $u(t)$ is a solution of the damped KdV equation, and derive a Gronwall-type inequality for $L(u(t))$. However, it turns out that this inequality is not optimal. To obtain optimal results in time asymptotics, a shift of the MRE to a neighboring ($\mathcal{O}(\varepsilon)$) set has to be performed. The use of such a shift can also be found in [22]. However, in that article, only equilibria of finite-dimensional perturbed Hamiltonian systems are investigated on a finite time scale.

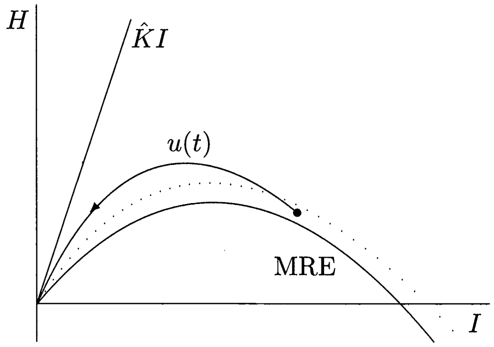

FIG. 2. *Sketch of the projection of a solution of the uniformly damped KdV equation, which starts near the MRE, in the H-I-plane.*

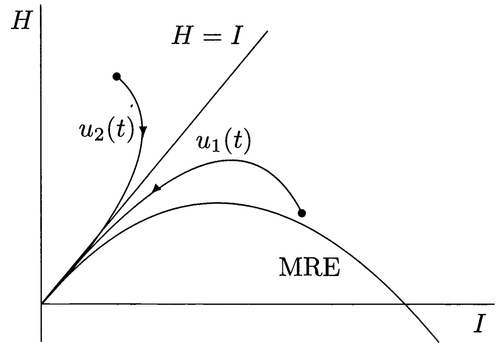

FIG. 3. *Sketch of the projection of two solutions $u_1(t)$ and $u_2(t)$ of the KdV–Burgers equation in the H-I-plane. Note the tangent behavior near zero.*

Remark 4. The shift of the MRE gives rise to an interesting question. The family of cnoidal waves is not invariant for the damped KdV equation. We will see that at every instance there is a forcing that drives a solution away from the MRE.

Keeping in mind the behavior as sketched in Figure 2, it is very unlikely that the MRE is stable for fixed values of ε. In other words, we cannot expect that for a fixed value of ε it yields that for every $\delta > 0$ there exist a $\delta_0 > 0$ and a $T > 0$ such that for every solution $u(t)$ which satisfies $\rho_1(u(0), \bar{u}(\gamma(0))) < \delta_0$, it holds that $\rho_1(u(t), \bar{u}(\gamma(t))) < \delta$ for all $t \geq T$.

The question remains as to if there is another manifold near the MRE that is stable in this sense. A possible candidate could be the shift of the MRE, but we will see later that it has a disadvantage similar to that of the MRE, although it approximates the solution up to higher order in ε. However, that does not help for fixed values of ε. Another possibility could be an iterated shift of the MRE. If it exists, it would give an invariant manifold. However, this question regarding existence is not obvious to answer.

In [13], ideas similar to those used in this article are exploited to analyze the relevance of a two-dimensional family of relative equilibria of a finite-dimensional mechanical system with one cyclic coordinate to which uniform friction is added. An extension to higher-dimensional manifolds of relative equilibria of (finite-dimensional) Hamiltonian systems with symmetries and their relevance under a dissipative perturbation was recently established in [12].

2. A first analysis of the damped KdV equation. As seen in §1, the time behavior of the additional first integral $\gamma(t) = I(u(t))$, where $u(t)$ is a solution of the damped KdV equation, is given by

$$\gamma(t) = I(u(t)) = I(u(0))e^{-2\varepsilon t} = \gamma(0)e^{-2\varepsilon t}.$$

This implies that every solution converges to 0 and hence to the MRE. By Definition 1.1 it holds that $I(\bar{u}(\gamma) + \xi) = I(\bar{u}(\gamma))$, implying that

$$(7) \qquad -\int_0^{2\pi} \bar{u}\,\xi = \frac{1}{2}\int_0^{2\pi} \xi^2;$$

therefore,

$$\|\xi(t)\|_0^2 = 2|(\bar{u}(\gamma(t)), \xi(t))| \le 2\|\bar{u}(\gamma(t))\|_0 \|\xi(t)\|_0,$$

and hence

$$(8) \qquad \|\xi(t)\|_0 \le 2\sqrt{2\gamma(0)}\, e^{-\varepsilon t}.$$

This implies that the translation-invariant L^2-distance between a solution and the MRE is less than or equal to a constant times the L^2-norm of the solution.

As we stated previously, to prove Theorem 1.2, we will make use of a similar (Lyapunov) functional as featured in the energy-momentum method to determine the stability of relative equilibria in an unperturbed Hamiltonian system (see [28, 29] or (for the KdV equation) [4]). To prove the stability of the cnoidal waves with such a technique, it is essential that the cnoidal wave $\bar{u}(\gamma)$ with minimal period 2π is a constrained minimum of the Hamiltonian of the (unperturbed) KdV equation on the level set with $I = \gamma$. This property is proved in Lemma A.1 in the appendix. This lemma implies that the following functional acts as a Lyapunov functional for a cnoidal wave in the case of the unperturbed KdV equation.

DEFINITION 2.1. *Let $u \in H^1_{\mathrm{per},0}$. Define the functional $L(u)$ on $H^1_{\mathrm{per},0}$ as*

$$(9) \qquad L(u) = H(u) - H(\bar{u}(\gamma)) = H_\gamma(u) - H_\gamma(\bar{u}(\gamma))$$

with $\gamma = I(u)$.

Furthermore, define the self-adjoint operator $\tilde{Q}(\gamma)$ on H^1_{per} as

$$\tilde{Q}(\gamma) = D^2\hat{L}(\bar{u}(\gamma)) = D^2H_\gamma(\bar{u}(\gamma))| = -D_{xx} - \lambda(\gamma) - 2\bar{u}(\gamma),$$

and let $Q(\gamma)$ be its restriction on $H^1_{\mathrm{per},0}$; hence

$$Q(\gamma) = D^2\hat{L}(\bar{u}(\gamma))|_{H^1_{\mathrm{per},0}} = D^2H_\gamma(\bar{u}(\gamma))|_{H^1_{\mathrm{per},0}}.$$

The Euler–Lagrange equation (2), i.e., $(\bar{u}_{xx} + \bar{u}^2 + \lambda\,\bar{u})$ is constant, the notation of Definition 1.1, and identity (8) imply that $L(u)$ can be written as

$$\begin{aligned} L(u) = H(\bar{u}+\xi) - H(\bar{u}) &= \int_0^{2\pi}\left[\bar{u}_x\,\xi_x + \frac{1}{2}\xi_x^2 - \bar{u}^2\,\xi - \bar{u}\,\xi^2 - \frac{1}{3}\,\xi^3\right] \\ &= \int_0^{2\pi} \xi\,[-\bar{u}_{xx} - \bar{u}^2 - \lambda\,\bar{u}] + \int_0^{2\pi}\left[\frac{1}{2}\,\xi_x^2 - \bar{u}\,\xi^2 + \lambda\,\bar{u}\,\xi - \frac{1}{3}\,\xi^3\right] \\ &= \int_0^{2\pi}\left[\frac{1}{2}\,\xi_x^2 - \bar{u}\,\xi^2 - \frac{1}{2}\lambda\,\xi^2 - \frac{1}{3}\,\xi^3\right] = \frac{1}{2}\,(Q(\gamma)\xi, \xi) - \frac{1}{3}\int_0^{2\pi}\xi^3. \end{aligned}$$

Define $\tilde{\mathbb{Y}}(\gamma)$ as the subspace of the tangent space to the I-level set that is orthogonal to the direction of the I-flow in H^1_{per}, and define $\mathbb{Y}(\gamma)$ to be the restriction to $H^1_{\text{per},0}$:

$$\tilde{\mathbb{Y}}(\gamma) = \{y \in H^1_{\text{per}} \mid (y, X_I(\bar{u}(\gamma))) = 0 \ \wedge \ (y, I'(\bar{u}(\gamma))) = 0\},$$
$$\mathbb{Y}(\gamma) = \{y \in H^1_{\text{per},0} \mid (y, X_I(\bar{u}(\gamma))) = 0 \ \wedge \ (y, I'(\bar{u}(\gamma))) = 0\}.$$

From the minimality of the cnoidal waves, it follows that $Q(\gamma)$ is strictly positive definite on $\mathbb{Y}(\gamma)$ for a fixed value of $\gamma > 0$.

For our purpose, we need a bit stronger property, namely that L is equivalent with the translation-invariant H^1_{per}-distance on every $L^2_{\text{per},0}$-compact set, which includes 0.

LEMMA 2.2. *For every compact interval $\mathcal{G} \in \mathbb{R}^+_0$ with $0 \in \mathcal{G}$, there exist $C \geq c > 0$ and a neighborhood $\mathcal{U} \subset H^1_{\text{per},0}$ of the MRE such that for all $u \in \mathcal{U}$ with $I(u) \in \mathcal{G}$, it holds that*

$$c\,\rho_1^2(\bar{u}(\gamma), u) \leq L(u) \leq C\,\rho_1^2(\bar{u}(\gamma), u) \tag{10}$$

with $\gamma = I(u)$.

Proof. Let $\gamma > 0$. First, we prove that L is bounded from above. Let $u \in H^1_{\text{per},0}$ and write $u = \Phi^I_\varphi(\bar{u}(\gamma) + \xi)$ as in Definition 1.1. Using the Poincarè inequalities (4) and (5), it is easy to calculate that there exists some $C_1(\gamma) > 0$ such that

$$\begin{aligned} L(u) &= \int_0^{2\pi} \left[\frac{1}{2}\xi_x^2 - \bar{u}\xi^2 - \frac{1}{2}\lambda\,\xi^2 - \frac{1}{3}\xi^3\right] \\ &\leq \frac{1}{2}\|\xi\|_1^2 + \|\bar{u}\|_\infty \|\xi\|_0^2 + \frac{1}{2}|\lambda|\|\xi\|_0^2 + \frac{1}{3}\|\xi\|_\infty\|\xi\|_0^2 \\ &\leq 2\,\pi^2\,\|\xi\|_1^2\left[\frac{1}{4\,\pi^2} + 2\,\|\bar{u}\|_\infty + |\lambda| + \frac{2\sqrt{2\pi}}{3}\|\xi\|_1\right] \\ &\leq C_1(\gamma)\|\xi\|_1^2 \end{aligned} \tag{11}$$

in a neighborhood of the MRE, e.g., if $\|\xi\|_1 \leq 1$. By definition, $\|\xi\|_1^2 = \rho_1(u, \bar{u})$; hence equation (11) implies that

$$L(u) \leq C_1(\gamma)\rho_1^2(u, \bar{u}(\gamma)) \tag{12}$$

and $C_1(\gamma)$ is bounded if $\gamma \to 0$.

Lemma A.3 in the appendix yields that $Q(\gamma)$ is strictly positive definite on $\mathbb{Y}(\gamma)$; explicitly,

$$(Q(\gamma)\,y, y) \geq c_1(\gamma)\|y\|_1^2 \quad \text{for all } y \in \mathbb{Y}(\gamma)$$

with $c_1(\gamma) > 0$ and $\lim_{\gamma\to 0} c_1(\gamma) > 0$ as well.

This inequality implies a lower bound on L. To see this, write $\xi = a\,X_I(\bar{u}) + b\,I'(\bar{u}) + y$, where $y \in \mathbb{Y}(\gamma)$. We will show that a and b are of the order $\|\xi\|_1^2$ if $\|\xi\|_1$ is small. First, we estimate a. We know that $(\,\xi, X_I(\Phi^I_{\varphi(u)}(u))\,) = 0$; therefore,

$$\begin{aligned} 0 &= (\xi, X_I(\Phi^I_{\varphi(u)}(u))) = (\xi, X_I(\bar{u})) + \mathcal{O}(\|\xi\|_0^2) \\ &= a\|X_I(\bar{u})\|_0^2 + \mathcal{O}(\|\xi\|_1^2). \end{aligned}$$

Next we estimate b, using the fact that $I(\Phi^I_{\varphi(u)}(u)) = I(u) = I(\bar{u})$, by

$$\begin{aligned} 0 &= I(\Phi^I_{\varphi(u)}(u)) - I(\bar{u}) = (I'(\bar{u}), \xi) + \mathcal{O}(\|\xi\|_0^2) \\ &= b\|I'(\bar{u})\|_0^2 + \mathcal{O}(\|\xi\|_1^2). \end{aligned}$$

Now we know that the "largest" part of ξ is in $\mathbb{Y}(\gamma)$, and we can derive a relation between $L(u)$ and $\|\xi\|_1^2$ for $\|\xi\|_1$ small:

$$\begin{aligned} L(u) &= L(\Phi^I_{\varphi(u)}(u)) = L(\bar{u}) + \frac{1}{2}(Q(\gamma)\xi,\xi) + \mathcal{O}(\|\xi\|_0^3) \\ &= \frac{1}{2}(Q(\gamma)y,y) + \mathcal{O}(|b|\|\xi\|_0 + |b|^2 + \|\xi\|_0^3) \\ &\geq \frac{1}{2}c_1(\gamma)\|y\|_1^2 + \mathcal{O}(\|\xi\|_0^3) = \frac{1}{2}c_1(\gamma)\|\xi\|_1^2 + \mathcal{O}(\|\xi\|_0^3). \end{aligned}$$

This means that there exists a $\delta_0 > 0$ such that for all u with $\rho_1(\bar{u},u) < \delta_0$ (recall that $\|\xi\|_1^2 = \rho_1(u,\bar{u})$),

$$L(u) \geq \frac{1}{4}c_1(\gamma)\rho_1(\bar{u},u).$$

To prove equation (10), we use the facts that $\lim_{\gamma\to 0} c_1(\gamma) \neq 0$ and $C_1(\gamma)$ is bounded. Hence in every compact interval $\mathcal{G}$ that includes 0, there exist $0 < c \leq C$ such that (10) holds. □

After these observations about the unperturbed KdV equation, we return to the damped KdV equation. The time behavior of the difference function $\xi(t)$ gives an idea about what causes the deviation of solutions of the damped KdV equation of the MRE. Using Definition 1.1, we see that

$$\begin{aligned} \dot{\xi} &= \frac{\mathrm{d}}{\mathrm{d}t}\left[\Phi^I_{-\varphi(t)}(u(t))\right] - \dot{\bar{u}}(\gamma(t)) \\ &= -\partial_x[\bar{u}_{xx} + \xi_{xx} + 2(\bar{u}+\xi)^2] - \varepsilon(\bar{u}+\xi) - \dot{\bar{u}} - \dot{\varphi}\partial_x(\bar{u}+\xi). \end{aligned}$$

To recognize more structure in this equation, we will rewrite it. By using the Euler–Lagrange equation (27) (in the appendix) and the differential equation for γ, it follows that

$$\begin{aligned} \dot{\xi} &= \partial_x[\xi_{xx} + 2\bar{u}\xi + \lambda\xi + \xi^2] + (\lambda - \dot{\varphi})\partial_x(\bar{u}+\xi) - \varepsilon[2\gamma\bar{u}'(\gamma) - \bar{u}] - \varepsilon\xi \\ &= \partial_x H_\gamma{}'(\bar{u}+\xi) + (\lambda - \dot{\varphi})\partial_x(\bar{u}+\xi) - \varepsilon\xi + R(\bar{u}(\gamma),\varepsilon) \end{aligned}$$

with the so-called residual

$$R(\bar{u}(\gamma),\varepsilon) = -\varepsilon[2\gamma\bar{u}'(\gamma) - \bar{u}]. \tag{13}$$

The first two terms of the equation for $\dot{\xi}$ have a Hamiltonian origin. The first term is the modified KdV Hamiltonian. The second term induces a translation of the wave profile; hence this term will be irrelevant for our analysis. The third and fourth terms are the most relevant for our analysis. The third term represents the damping. The fourth term does not depend on ξ. It is called the residual because it shows the effect of the damped KdV equation on the MRE, except for some irrelevant influence in the translation direction $X_I(\bar{u})$. The residual is an element of $\mathbb{Y}(\gamma)$; hence if the residual is not equal to 0, then a solution that starts on the MRE will soon deviate from it. This implies that the residual acts like a forcing in the ξ-equation. In other words, the third and fourth terms show a competition between a dissipation directed towards the MRE and a forcing away from the MRE.

We have seen that the functional L is equivalent to the H_1-norm of ξ. Therefore, we look at the time behavior of this functional to see how fast ξ can grow. Using the translation invariance of H and I, it follows immediately that $L(u) = L(\bar{u}+\xi)$. Using the second expression in (9) and the equation for $\dot{\xi}$, it follows that

$$\frac{\mathrm{d}}{\mathrm{d}t}L(u(t)) = \dot{\lambda}[I(\bar{u}+\xi) - I(\bar{u})] + (H_\gamma{}'(\bar{u}+\xi), -\varepsilon\xi + R(\bar{u},\varepsilon) - \dot{\bar{u}}).$$

The first term is zero because $I(\bar{u}+\xi) = I(\bar{u})$. Note that $H'_\gamma(\bar{u}+\xi) = Q(\gamma)\xi - \xi^2$; hence $(H_\gamma{}'(\bar{u}+\xi), -\varepsilon\xi) = -2\varepsilon L(u) + \frac{1}{3}(\xi^2, \xi)$. We again use the Euler–Lagrange equation to rewrite the inner product with $(R(\bar{u},\varepsilon) - \dot{\bar{u}})$. This yields

$$\frac{\mathrm{d}}{\mathrm{d}t}L(u(t)) = -2\varepsilon L(\gamma,\xi) + \varepsilon\int_0^{2\pi} \bar{u}^2\xi + \varepsilon\int_0^{2\pi} \bar{u}\xi^2 + \frac{1}{3}\varepsilon\int_0^{2\pi} \xi^3. \tag{14}$$

Note that in expression (14), for the time behavior of L, the first term is dissipative, the second is a forcing-like component, and the last two terms are small compared to the first two terms (if ξ and γ are small).

With this expression for $\frac{\mathrm{d}}{\mathrm{d}t}L(u(t))$, we derive a preliminary estimate for the functional L.

PROPOSITION 2.3. *For every $\varepsilon > 0$, there exist a $\delta > 0$ and a constant K_0, both depending on $\gamma(0)$, such that*

$$\sqrt{L(u(t))} \le K_0\left[\sqrt{L(u(0))} + 2\sqrt{2\pi}\gamma(0)\right]e^{-\varepsilon t} \tag{15}$$

as long as $\|\xi(t)\|_1 < \delta$.

Proof. For the last three terms in equation (14), it holds that

$$\left|\int_0^{2\pi} \bar{u}^2\xi\right| \le \|\xi\|_\infty \int_0^{2\pi} \bar{u}^2 \le 2\sqrt{2\pi}\gamma\|\xi\|_1,$$

$$\left|\int_0^{2\pi} \bar{u}\xi^2\right| \le \|\xi\|_\infty \int_0^{2\pi} \xi\bar{u} \le \sqrt{2\pi}\|\xi\|_1\|\bar{u}\|_0\|\xi\|_0 \le 4\pi\sqrt{\pi}\sqrt{\gamma}\|\xi\|_1^2,$$

$$\left|\int_0^{2\pi} \xi^3\right| \le \|\xi\|_\infty \int_0^{2\pi} \xi^2 \le \sqrt{2\pi}\|\xi\|_1\|\xi\|_0^2 \le 8\pi\sqrt{\pi}\sqrt{\gamma}\|\xi\|_1^2.$$

In these estimates, we use that $\|\xi\|_0 \le 2\sqrt{2\gamma}$ and the Poincaré inequalities (4) and (5).

To be able to switch from $\|\xi\|_1$ to the functional L, we will use Lemma 2.2. Let δ be such that the equivalence relation (10) holds for all $\|\xi\|_1 < \delta$. Substituting the relations above into (14) and using (10) gives the following estimate for the time behavior of L:

$$\frac{\mathrm{d}}{\mathrm{d}t}L \le \left[-2\varepsilon + \varepsilon\frac{20\sqrt{\gamma\pi\sqrt{\pi}}}{3c}\right]L + \varepsilon\frac{2\sqrt{2\pi}\gamma}{\sqrt{c}}\sqrt{L}.$$

Define $N(t) = e^{\varepsilon t}\sqrt{L}$; then this inequality implies that $N(t) = 0$ or

$$\dot{N} \le \left[\varepsilon\frac{10\sqrt{\gamma\pi\sqrt{\pi}}}{3c}\right]N + \varepsilon\frac{\sqrt{2\pi}\gamma}{\sqrt{c}}e^{\varepsilon t}.$$

Applying Gronwall's lemma to this equation gives

$$N(t) \le K_0 N(0) + \varepsilon K_0\int_0^t \frac{\sqrt{2\pi}e^{-\varepsilon\tau}\gamma(0)}{\sqrt{c}}d\tau = K_0\left[N(0) + \frac{\sqrt{2\pi}\gamma(0)}{\sqrt{c}}(1 - e^{-\varepsilon t})\right],$$

where $K_0 = \exp\left[\frac{10\pi\sqrt{\pi}\sqrt{\gamma(0)}}{3c}\right]$. □

The estimate of Proposition 2.3 only provides information about the approximation on a finite time scale. Even if we start on the MRE, hence with $\|\xi(0)\|_1 = 0$, after some time the norm of the right-hand side of estimate (15) is of order $\sqrt{\gamma}$ instead of order $\varepsilon\sqrt{\gamma}$. This effect is induced by the residual, which after an integration becomes of order 1 instead of order ε. In other words, we need a smaller residual. The present residual is induced by the projection on the MRE, which approximates the solution in zeroth order. If we have a better approximation than this projection, we can expect a smaller residual. In the next section, we will derive such a better approximation and prove Theorem 1.2 by using a functional related to this better approximation.

3. Justification of the approximation. The residual $R(\bar{u}(\gamma), \varepsilon)$ measures how well the curve $\bar{u}(\gamma(t))$ obeys the damped KdV equation. The function $t \to \bar{u}(\gamma(t))$ is a zeroth-order approximation of the damped KdV equation and therefore gives a residual of order ε. It can be expected that the residual for a first-order approximation of the damped KdV equation is smaller, of order ε^2. Using the knowledge that the L^2-norm $I(u)$ is $\gamma(0)e^{-2\varepsilon t}$, which is a slow time behavior, we try to find a better approximation of the form

$$u(t) = \Phi^I_{\lambda(\varepsilon)t}(\bar{u}(\gamma(t)) + \varepsilon\bar{v}_1(\gamma(t), \varepsilon)).$$

Substitution of this expression in the dynamical system (1) gives

$$\partial_x[H'(\bar{u} + \varepsilon\bar{v}_1) - \lambda(\varepsilon)I'(\bar{u} + \varepsilon\bar{v}_1)] - \varepsilon[(\bar{u} + \varepsilon\bar{v}_1) - 2\gamma(\bar{u}'(\gamma) + \bar{v}_1'(\gamma, \varepsilon))] = 0.$$

After taking first-order terms in ε of this equation, it remains (up to order-ε^2 terms)

$$H'(\bar{u} + \varepsilon\bar{v}_1) - \lambda(\varepsilon)I'(\bar{u} + \varepsilon\bar{v}_1) = \partial_x^{-1}[R(\bar{u}, \varepsilon)] + \alpha(\varepsilon). \tag{16}$$

(The operator ∂_x^{-1} is defined to act on the space $H^1_{\text{per},0}$ and $\alpha(\varepsilon)$ is a constant which is introduced by the integration.) If we can find a solution $(\bar{u}_1(\gamma, \varepsilon), \lambda(\varepsilon), \alpha(\varepsilon))$ of equation (16) (with $\bar{u}_1(\gamma, \varepsilon) = \bar{u}(\gamma) + \varepsilon\bar{v}_1(\gamma, \varepsilon)$), then we expect that the residual in $\bar{u}_1(\gamma, \varepsilon)$ is of order ε^2, an improvement compared to the residual in $\bar{u}(\gamma)$, which is of order ε.

Another way to interpret the definition of the function $\bar{u}_1(\gamma, \varepsilon)$ is by noticing that $\bar{u}_1(\gamma, \varepsilon)$ is a constrained critical point of a new Hamiltonian

$$H_{\text{new}}(u, \gamma, \varepsilon) = H(u) - (\partial_x^{-1}R(\bar{u}(\gamma), \varepsilon),\, u)$$

on the level set of $I(u) = \gamma$. Hence $\bar{u}_1$ is a kind of new relative equilibrium. However, the new Hamiltonian H_{new} is not translation invariant; hence neither can we find a two-parameter family of constrained critical points nor is $\Phi^I_{\lambda(\varepsilon)t}(\bar{u}_1)$ a solution of the new Hamiltonian system. Because we ignore all shifts in the solution, a curve of new relative equilibria $\bar{u}_1(\gamma, \varepsilon)$ is sufficient to give a better approximation for a solution of the damped KdV equation.

Remark 5. It is possible to define a new translation-invariant Hamiltonian which possesses a two-dimensional family of relative equilibria that give a residual of order ε^2. Analogously to the definition of the translation-invariant distance, we define this new Hamiltonian as

$$\tilde{H}_{\text{new}}(u, \gamma, \varepsilon) = H(u) - (\partial_x^{-1}R(\bar{u}, \varepsilon), \Phi^I_{\psi(u)}(u))$$

with the functional $\psi : H^1_{\text{per},0} \to [0, 2\pi)$ such that

$$(17) \qquad (\partial_x^{-1} R(\bar{u}, \varepsilon), \Phi^I_{\psi(u)}(u)) = \min_{\varphi \in [0,2\pi)} (\partial_x^{-1} R(\bar{u}, \varepsilon), \, \Phi^I_\varphi(u)).$$

If the minimum in (17) is attained at more than one value $\varphi \in [0, 2\pi)$, then $\psi(u)$ is the smallest one. Now H_{new} is a translation-invariant functional and its derivative with respect to u is

$$\tilde{H}'_{\text{new}}(u, \gamma, \varepsilon) = H'(u) - \Phi^I_{-\psi(u)}(\partial_x^{-1} R(\bar{u}, \varepsilon)).$$

Hence the constrained critical points $\tilde{u}_1$ of $\tilde{H}_{\text{new}}$ on the level set $I = \gamma$ satisfy

$$0 = H'(\tilde{u}_1) - \tilde{\lambda}_1 I'(\tilde{u}_1) - \Phi^I_{-\psi(u)}(\partial_x^{-1} R(\bar{u}, \varepsilon)).$$

Because $\psi(\bar{u}) = 0$, the approximation $\bar{u}_1$ gives rise to a residual of order ε^2. See [10] for more details.

First, we show that there indeed exists a curve of new relative equilibria $\bar{u}_1(\gamma, \varepsilon)$ in the neighborhood of $\varepsilon = 0$ by applying the implicit-function theorem to H_{new}, which is a perturbation of the original Hamiltonian H. To be able to apply the implicit-function theorem, it is important that $\partial_x^{-1} R(\bar{u}(\gamma), \varepsilon)$ is orthogonal to the kernel of $Q(\gamma)$ and hence orthogonal to $X_I(\bar{u})$. This will be shown in the proof of the next lemma. By taking the inner product with $X_I(\bar{u}_1)$ in equation (16), it follows that $\bar{u}_1$ is orthogonal to $R(\bar{u}(\gamma), \varepsilon)$.

LEMMA 3.1. *For every $\gamma > 0$ there exists an $\varepsilon_0(\gamma)$ and a unique curve*

$$\{\bar{u}_1(\gamma, \varepsilon) \mid |\varepsilon| \le \varepsilon_0(\gamma)\}$$

of minimal points of the Hamiltonian H_{new} on the level set $I = \gamma$ in $H^1_{\text{per},0}$. Explicitly, for every $|\varepsilon| \le \varepsilon_0(\gamma)$, there exist unique Lagrange multipliers $\lambda_1(\gamma, \varepsilon)$ and $\alpha_1(\gamma, \varepsilon)$ such that

$$(18) \qquad \begin{aligned} 0 &= H'_{\text{new}}(\bar{u}_1(\gamma, \varepsilon), \gamma, \varepsilon) - \lambda_1(\gamma, \varepsilon) I'(\bar{u}_1(\gamma, \varepsilon)) - \alpha_1(\gamma, \varepsilon), \\ 0 &= I(\bar{u}_1(\gamma, \varepsilon)) - \gamma. \end{aligned}$$

Furthermore, there exists a $K(\gamma) > 0$ such that for all $|\varepsilon| \le \varepsilon_0(\gamma)$, it holds that

$$\begin{aligned} \|\bar{u}(\gamma) - \bar{u}_1(\gamma, \varepsilon)\|_1 &\le K(\gamma) \|\partial_x^{-1} R(\bar{u}(\gamma), \varepsilon)\|_0 = \mathcal{O}(\varepsilon \|\bar{u}(\gamma)\|_0), \\ |\lambda(\gamma) - \lambda_1(\gamma, \varepsilon)| \; &\le K(\gamma) \|\partial_x^{-1} R(\bar{u}(\gamma), \varepsilon)\|_0 = \mathcal{O}(\varepsilon \|\bar{u}(\gamma)\|_0). \end{aligned}$$

Finally, $\lim_{\gamma \to 0} K(\gamma)$ and $\lim_{\gamma \to 0} \varepsilon_0(\gamma)$ exist and $\varepsilon_0(0) > 0$.

Proof. Let $\gamma > 0$. As we stated previously, we use the implicit-function theorem (see, e.g., [9]) to prove this lemma. First, we reformulate the problem. Instead of looking for a 2π-periodic solution of (18) with mean value, it is more convenient to add the mean-value zero condition to the equations and consider the problem in the space of all 2π-periodic functions. Hence we look for a 2π-periodic solution of

$$(19) \qquad 0 = \begin{pmatrix} H'(u) - \lambda I'(u) - \alpha \mathbf{1} \\ I(u) - \gamma \\ M(u) \end{pmatrix} - \begin{pmatrix} \partial_x^{-1} R(\bar{u}(\gamma), \varepsilon) \\ 0 \\ 0 \end{pmatrix},$$

where $\mathbf{1}$ is the function that equals 1 for all $x \in [0, 2\pi]$ and $M(u) = \int_0^{2\pi} u$. For $\varepsilon = 0$ (the unperturbed case), this problem does not have a unique solution in H^1_{per}. We have seen that a one-dimensional manifold of solutions can be formed: all translates of the cnoidal wave $\bar{u}(\gamma)$, hence $\{(\Phi^I_\varphi(\bar{u}(\gamma)), \lambda(\gamma), \alpha(\gamma)) \mid \varphi \in [0, 2\pi)\}$. Hence this will cause a problem in the application of the implicit-function theorem to these equations in H^1_{per}. To avoid this problem, we will use the fact that $\bar{u}_1$ is orthogonal to $R(\bar{u}, \varepsilon)$.

We distinguish two cases.

1. If $(R(\bar{u}, \varepsilon), \bar{u}_x)) \neq 0$, then we add the equation

$$0 = (\partial_x^{-1} R(\bar{u}, \varepsilon), \partial_x u) = -(R(\bar{u}, \varepsilon), u) \tag{20}$$

to our set of equations (19), and we add the term $\beta X_I(u)$ with the extra unknown β to the first equation. Explicitly, for $\varepsilon \geq 0$, we introduce the functions F and F_0 on $H^1_{\text{per}} \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}$:

$$F(u, \lambda, \alpha, \beta; \varepsilon) = \begin{pmatrix} H'(u) - \lambda I'(u) - \alpha \mathbf{1} - \beta X_I(u) - \partial_x^{-1} R(\bar{u}(\gamma), \varepsilon) \\ I(u) - \gamma \\ M(u) \\ (R(\bar{u}, \varepsilon), u) \end{pmatrix}$$

and $F_0(u, \lambda, \alpha, \beta) = F(u, \lambda, \alpha, \beta; 0)$ for all $u \in H^1_{\text{per}}$ and $\lambda, \alpha, \beta \in \mathbb{R}$. A solution of the equation

$$F(u, \lambda, \alpha, \beta; \varepsilon) = 0$$

gives a constrained critical point of the new Hamiltonian H_{new} on level sets of I. Indeed, take the inner product of $X_I(u)$ with the first equation in $F = 0$; then it follows that $\beta = 0$. In other words, the first equation in $F = 0$ is the Euler–Lagrange equation for the critical-point problem. Furthermore, if $\varepsilon = 0$, the critical-point problem for the KdV equation reappears; hence $F_0(\bar{u}(\gamma), \lambda(\gamma), \alpha(\gamma), 0) = 0$ and this solution is unique for $\varepsilon = 0$ in $H^1_{\text{per}} \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}$ thanks to the last equation.

The function F_0 satisfies the following properties:

(i) F_0 is continuously differentiable. Indeed, it is a straightforward calculation to see that for all $(u, \lambda, \alpha, \beta), (\hat{u}, \hat{\lambda}, \hat{\alpha}, \hat{\beta}) \in H^1_{\text{per}} \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}$,

$$F_0(u, \lambda, \alpha, \beta) = F_0(\hat{u}, \hat{\lambda}, \hat{\alpha}, \hat{\beta}) + DF_0(\hat{u}, \hat{\lambda}, \hat{\alpha}, \hat{\beta}) \begin{pmatrix} u - \hat{u} \\ \lambda - \hat{\lambda} \\ \alpha - \hat{\alpha} \\ \beta - \hat{\beta} \end{pmatrix} - \begin{pmatrix} G(u, \hat{u}, \lambda, \hat{\lambda}) \\ 0 \\ 0 \\ 0 \end{pmatrix},$$

where $G(u, \hat{u}, \lambda, \hat{\lambda}) = (u - \hat{u})^2 + (\lambda - \hat{\lambda})(u - \hat{u})$. This implies that

$$\begin{aligned} &\left\| F_0(u, \lambda, \alpha, \beta) - F_0(\hat{u}, \hat{\lambda}, \hat{\alpha}, \hat{\beta}) - DF_0(\hat{u}, \hat{\lambda}, \hat{\alpha}, \hat{\beta}) \begin{pmatrix} u - \hat{u} \\ \lambda - \hat{\lambda} \\ \alpha - \hat{\alpha} \\ \beta - \hat{\beta} \end{pmatrix} \right\|_0 \\ &\quad \leq \|(\lambda - \hat{\lambda})(u - \hat{u})\|_0 + \|(u - \hat{u})^2\|_0 \\ &\quad \leq 2\pi |\lambda - \hat{\lambda}| \|u - \hat{u}\|_1 + 8\pi^3 \|u - \hat{u}\|_1^2. \end{aligned}$$

Hence F_0 is continuously differentiable.

(ii) $DF_0(\bar{u}(\gamma), \lambda(\gamma), \alpha(\gamma), 0)$ is injective and surjective. We prove this property in Lemma A.5 in the appendix.

(iii) $DF_0(\bar{u}(\gamma),\lambda(\gamma),\alpha(\gamma),0)^{-1}[F(u,\lambda,\alpha,\beta;\varepsilon)-F_0(u,\lambda,\alpha,\beta)]$ is Lipschitz continuous. This last property follows from the facts that F and F_0 are Lipschitz continuous and $DF_0(\bar{u}(\gamma),\lambda(\gamma),\alpha(\gamma),0)^{-1}$ is bounded. This last observation is a consequence of the minimality of the cnoidal waves and hence of Lemma 2.2.

With (i)–(iii), all conditions for the application of the implicit-function theorem to the equation $F=0$ are satisfied.

2. If $(R(\bar{u},\varepsilon),\bar{u}_x))=0$, then we consider the equations (19) on a subspace of H^1_{per}, namely

$$\mathbb{X}(\gamma)=\{u\in H^1_{\text{per}}\mid (u,X_I(\bar{u}(\gamma)))=0\}.$$

Also, in a way similar to case 1, we can prove that all conditions for the application of the implicit-function theorem to equation (19) are satisfied.

The application of the implicit-function theorem implies that there exists a neighborhood $\mathcal{U}_1(\gamma)\subset H^1_{\text{per}}\times\mathbb{R}\times\mathbb{R}$ around the relative equilibrium $(\bar{u}(\gamma),\lambda(\gamma),\alpha(\gamma))$, a positive number $\varepsilon_0(\gamma)$, and a curve of points $\big((\bar{u}_1(\gamma,\varepsilon),\lambda_1(\gamma,\varepsilon),\alpha_1(\gamma,\varepsilon))\big)_{|\varepsilon|\le\varepsilon_0(\gamma)}$ in $\mathcal{U}_1(\gamma)$ such that

$$\begin{aligned}0&=H'(\bar{u}_1)-\lambda_1 I'(\bar{u}_1)-\alpha_1-\partial_x^{-1}R(\bar{u},\varepsilon),\\ 0&=I(\bar{u}_1)-\gamma,\\ 0&=M(\bar{u}_1).\end{aligned}\tag{21}$$

Furthermore, it follows also that

$$\begin{aligned}\|\bar{u}_1(\gamma,\varepsilon)-\bar{u}(\gamma)\|_1&=\mathcal{O}(\|\partial_x^{-1}R(\bar{u},\varepsilon)\|_0),\\ |\lambda_1(\gamma,\varepsilon)-\lambda(\gamma)|&=\mathcal{O}(\|\partial_x^{-1}R(\bar{u},\varepsilon)\|_0),\\ |\alpha_1(\gamma,\varepsilon)-\alpha(\gamma)|&=\mathcal{O}(\|\partial_x^{-1}R(\bar{u},\varepsilon)\|_0).\end{aligned}\tag{22}$$

From the definition of the residual $R(\bar{u},\varepsilon)$ (see (13)) and by using properties of elliptic functions (see [8]), it follows that there is a constant K_2 (independent of γ) such that $\|R(\bar{u}(\gamma),\varepsilon)\|_0\le\varepsilon K_2\sqrt{\gamma}$.

We must still show that $\bar{u}_1(\gamma,\varepsilon)$ is a constrained *minimum* on the level set with $I=\gamma$. Consider the linearization of $H'(u)-\lambda_1 I'(u)-\partial_x^{-1}R(\bar{u},\varepsilon)$ around $\bar{u}_1$:

$$\tilde{Q}_1(\gamma,\varepsilon)=D^2H(\bar{u}_1)-\lambda_1 D^2I(\bar{u}_1)=Q(\gamma)-(\lambda_1-\lambda)Id-2(\bar{u}_1-\bar{u}).$$

Using the fact that $Q(\gamma)$ is strictly positive definite on $\mathbb{Y}(\gamma)$ and (22), we will show that $\tilde{Q}_1(\gamma)$ is strictly positive definite on $\tilde{\mathbb{Y}}_1(\gamma)=\{\eta\in H^1_{\text{per}}\mid (\eta,X_I(\bar{u}_1))=0,(\eta,I'(\bar{u}_1))=0\}$.

Let $\eta\in\tilde{\mathbb{Y}}_1(\gamma)$. Then we have

$$\begin{aligned}(\tilde{Q}_1(\gamma)\eta,\eta)&=(Q(\gamma)\eta,\eta)-(\lambda_1-\lambda_0)\|\eta\|_0^2-2((\bar{u}_1-\bar{u})\eta,\eta)\\ &\ge(Q(\gamma)\eta,\eta)-|\lambda_1-\lambda_0|\|\eta\|_0^2-2\|\bar{u}_1-\bar{u}\|_1\|\eta\|_0^2\\ &\ge(Q(\gamma)\eta,\eta)-3K\|\partial_x^{-1}R_3(\bar{u},\varepsilon)\|_0\|\eta\|_0^2.\end{aligned}$$

From the minimality of the cnoidal waves, it follows that there exists a $c(\gamma)$ such that $(Q(\gamma)\xi,\xi)\ge c(\gamma)\|\xi\|_1^2$ for all $\xi\in\mathbb{Y}(\gamma)$. We will use this to prove that $(Q(\gamma)\eta,\eta)$ is strictly positive. Write

$$\eta=aX_I(\bar{u})+bI'(\bar{u})+y$$

with $y \in \mathbb{Y}(\gamma)$. Then we have

$$\begin{array}{lclclcl} |a| & = & |(\eta, X_I(\bar{u}))| & = & |0 + (\eta, \partial_x(\bar{u} - \bar{u}_1))| & \leq & K\|\partial_x^{-1}R_3(\bar{u},\varepsilon)\|_0\|\eta\|_0, \\ |b| & = & |(\eta, I'(\bar{u}))| & = & |0 + (\eta, (\bar{u} - \bar{u}_1))| & \leq & K\|\partial_x^{-1}R_3(\bar{u},\varepsilon)\|_0\|\eta\|_0. \end{array}$$

This implies that there exists some $\tilde{K} > 0$ such that

$$\begin{aligned} (Q(\gamma)\eta,\eta) &= b^2(Q(\gamma)\bar{u},\bar{u}) + (Q(\gamma)y,y) \\ &\geq c(\gamma)\|y\|_0^2 - K^2\|\partial_x^{-1}R_3(\bar{u},\varepsilon)\|_0^2\|\eta\|_0^2\|Q(\gamma)\|_0, \|\bar{u}\|_0^2 \\ &\geq \left(c(\gamma) - \tilde{K}\varepsilon\sqrt{\gamma}\right)\|\eta\|_0^2 \\ &\geq \frac{1}{2}c(\gamma)\|\eta\|_0^2 \end{aligned}$$

for ε sufficiently small and γ bounded. Hence

$$\begin{aligned} (\tilde{Q}_1(\gamma)\eta,\eta) &\geq \frac{1}{2}c(\gamma)\|\eta\|_0^2 - 3K\|\partial_x^{-1}R_3(\bar{u},\varepsilon)\|_0\|\eta\|_0^2 \\ &\geq \frac{1}{4}c(\gamma)\|\eta\|_0^2 \end{aligned}$$

for ε sufficiently small. With Lemma A.4, this implies that

$$(\tilde{Q}_1(\gamma)\eta,\eta) \geq \tfrac{1}{4}\tilde{c}_1(\gamma)\|\eta\|_1^2 \tag{23}$$

for some $\tilde{c}_1(\gamma) > 0$ with $\tilde{c}_1(0) > 0$. We can conclude that $\bar{u}_1(\gamma)$ is a constrained minimum of the new Hamiltonian H_{new}.

Finally, we consider the problem of the uniformness in γ. The procedure of the implicit-function theorem can be continued until the invertibility of the linearization fails. Because the lower bound on $\tilde{Q}(\gamma)$ is also strictly positive in the limit for $\gamma \to 0$, there is a uniform (in γ) neighborhood around the MRE near 0 for which a unique solution of (18) exists. In other words, the limit for $\gamma \to 0$ of $\varepsilon_0(\gamma)$ and $K(\gamma)$ exist and $\varepsilon_0(0) = 0$. □

Remark 6. At the new relative equilibrium $\bar{u}_1(\gamma,\varepsilon)$, the adapted residual is of order $\varepsilon^2\|\bar{u}(\gamma)\|_0$. Indeed,

$$\begin{aligned} R(\bar{u}_1(\gamma,\varepsilon),\varepsilon) &= \dot{\gamma}\bar{u}_1'(\gamma,\varepsilon) - \partial H_{\text{new}}'(\bar{u}_1,\gamma,\varepsilon) - R(\bar{u},\varepsilon) - \varepsilon P(\bar{u}_1) \\ &= -2\varepsilon\gamma[\bar{u}_1'(\gamma,\varepsilon) - \bar{u}'(\gamma)] - \varepsilon[\bar{u}_1 - \bar{u}] - \lambda_1 X_I(\bar{u}_1). \end{aligned}$$

With $\|\bar{u}(\gamma) - \bar{u}_1(\gamma,\varepsilon)\|_1 = \mathcal{O}(\varepsilon\|\bar{u}(\gamma)\|_0)$, we immediately see that $\|R(\bar{u}_1(\gamma,\varepsilon),\varepsilon)\|_1 = \mathcal{O}(\varepsilon^2\|\bar{u}(\gamma)\|_0)$.

With the new Hamiltonian and the new minima, we can define a functional to "measure" the distance to the new minima:

$$L_{\text{new}}(u,\varepsilon) = H_{\text{new}}(u,\gamma,\varepsilon) - H_{\text{new}}(\bar{u}_1(\gamma,\varepsilon),\gamma,\varepsilon)$$

with $\gamma = I(u)$. The functional L_{new} is equivalent to the translation-invariant H^1-distance between u and $\bar{u}_1(\gamma,\varepsilon)$ with $\gamma = I(u)$.

LEMMA 3.2. *For every $\gamma > 0$, there exist $C(\gamma) \geq c(\gamma) > 0$, $\delta(\gamma) > 0$, and $\varepsilon_0(\gamma) > 0$, such that for all ε with $|\varepsilon| \leq \varepsilon_0(\gamma)$ and for all η with $(\eta, X_I(\bar{u}_1 + \eta)) = 0$ and $I(\bar{u}_1(\gamma) + \eta) = \gamma$, it holds that*

$$c(\gamma)\|\eta\|_1^2 \leq L_{\text{new}}(\bar{u}_1(\gamma,\varepsilon) + \eta, \varepsilon) \leq C(\gamma)\|\eta\|_1^2$$

as long as $\|\eta\|_1 \leq \delta(\gamma)$.

For every compact γ*-interval* $\mathcal{G}$, *there exist* $C \geq c > 0$, $\delta > 0$, *and* $\varepsilon_0 > 0$ *such that for all* ε *with* $|\varepsilon| \leq \varepsilon_0$, *for all* $\gamma \in \mathcal{G}$, *and for all* η *with* $(\eta, X_I(\bar{u}_1 + \eta)) = 0$ *and* $I(\bar{u}_1(\gamma) + \eta) = \gamma$, *it holds that*

$$c\|\eta\|_1^2 \leq L_{\text{new}}(\bar{u}_1(\gamma, \varepsilon) + \eta, \varepsilon) \leq C\|\eta\|_1^2$$

as long as $\|\eta\|_1 \leq \delta$.

Proof. In the proof of Lemma 3.1, it is shown that $\tilde{Q}_1(\gamma, \varepsilon) = D_\eta^2 L_{\text{new}}(\bar{u}_1(\gamma, \varepsilon), \varepsilon)$ is bounded from below on $\tilde{\mathbb{Y}}(\gamma) = \{\eta \in L^2 \mid (\eta, X_I(\bar{u}_1)) = 0, (\eta, X_I(\bar{u}_1)) = 0\}$ (see equation (23)) and that this lower bound remains strictly positive if $\gamma \longrightarrow 0$. As in the proof of Lemma 2.2, we can show that (23) implies that there is some $c(\gamma) > 0$ such that

$$L_{\text{new}}(\bar{u}_1(\gamma, \varepsilon) + \eta, \varepsilon) \geq c(\gamma)\|\eta\|_1^2$$

with $c(0) > 0$.

For the upper bounds, we rewrite L_{new}:

$$\begin{aligned} L_{\text{new}}(\bar{u}_1(\gamma, \varepsilon) + \eta, \varepsilon) &= H_{\text{new}}(\bar{u}_1(\gamma) + \eta, \gamma, \varepsilon) - \lambda_1(\gamma, \varepsilon) I(\bar{u}_1(\gamma) + \eta) \\ &\quad - [H_{\text{new}}(\bar{u}_1(\gamma), \gamma, \varepsilon) - \lambda_1(\gamma, \varepsilon) I(\bar{u}_1(\gamma))] \\ &= (H'_{\text{new}}(\bar{u}_1(\gamma)) - \lambda_1(\gamma, \varepsilon) I'(\bar{u}_1(\gamma)), \eta) \\ &\quad + \frac{1}{2}(\tilde{Q}_1(\gamma, \varepsilon)\eta, \eta) - \frac{1}{3}\int_0^{2\pi} \eta^3(x, t)\,dx. \end{aligned}$$

It is a straightforward calculation to derive the following estimates for $\|\eta\|_1 \leq \delta$:

$$\begin{aligned} &(Q_1(\gamma, \varepsilon)\eta, \eta) \leq \|\eta_x\|_0^2 + (2\|\bar{u}_1\|_\infty + |\lambda_1|)\|\eta\|_0^2 \leq C_1(\gamma)\|\eta\|_1^2, \\ &\int_0^{2\pi} \eta^3(x, t)\,dx \leq \|\eta\|_\infty \|\eta\|_0^2 \leq \sqrt{2\pi}4\pi^2\delta\|\eta\|_1^2. \end{aligned} \tag{24}$$

Note that $C_1(\gamma)$ is bounded from above if $\gamma \longrightarrow 0$ and that the second estimate in (24) does not depend on γ at all. Substitution of the estimates in (24) gives the upper bounds in the lemma. □

With L_{new}, we investigate the time behavior of the distance between a solution $u(t)$ of the damped KdV equation and the new relative equilibrium $\bar{u}_1(\gamma(t), \varepsilon)$. For a solution of the damped KdV equation, we define

$$\eta(t) = \Phi^I_{\phi(t)}(u(t)) - \bar{u}_1(\gamma(t), \varepsilon)$$

or, equivalently,

$$u(t) = \Phi^I_{\phi(t)}(\bar{u}_1(\gamma(t), \varepsilon) + \eta(t))$$

with $\phi(t)$ such that $\|\eta(t)\|^2 = \rho_1(u(t), \bar{u}_1(\gamma(t)), \varepsilon))$. (This implies the property that $(\eta, X_I(\bar{u}_1 + \eta)) = 0$.) With this definition, the dynamical equation for η is

$$\dot{\eta} + \dot{\bar{u}}_1 = \partial_x H'_{\text{new}}(\bar{u}_1 + \eta, \gamma, \varepsilon) - \dot{\phi} X_I(\bar{u}_1 + \eta) + [\varepsilon P(\bar{u}_1 + \eta) + R(\bar{u}, \varepsilon)].$$

Next, we give an estimate for the growth of L_{new} which is essentially better than the one we derived for L in the previous section.

PROPOSITION 3.3. *For every $\gamma(0)$, there exists a constant K (depending on $\gamma(0)$) such that for all $t \geq 0$ and $|\varepsilon| \leq \varepsilon_0$, it holds that*

$$L_{\text{new}}(u(t),\varepsilon) \leq K L_{\text{new}}(u(0),\varepsilon)e^{-2\varepsilon t} + K\varepsilon e^{-2\varepsilon t}$$

as long as $\|\eta(t)\|_1 \leq \delta$ (δ is given by Lemma 3.2).

Proof. To prove this proposition, we consider the time derivative of L_{new}:

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}[L_{\text{new}}(u(t),\varepsilon)] &= (H'_{\text{new}}(\bar{u}_1+\eta,\gamma,\varepsilon) - \lambda_1 I'(\bar{u}_1+\eta), \dot{\bar{u}}_1 + \dot{\eta}) \\ &\quad + \dot{\gamma}\left[\frac{\partial}{\partial\gamma}H_{\text{new}}(\bar{u}_1+\eta,\gamma,\varepsilon)) - \frac{\partial}{\partial\gamma}H_{\text{new}}(\bar{u}_1,\gamma,\varepsilon))\right] \\ &= \text{(I)} + \text{(II)}.\end{aligned} \tag{25}$$

We will elaborate the terms (I) and (II) separately.

$$\begin{aligned}\text{(I)} &= -\varepsilon\left(H'_{\text{new}}(\bar{u}_1+\eta,\gamma,\varepsilon) - \lambda_1 I'(\bar{u}_1+\eta), \bar{u}_1 + \eta - \frac{1}{\varepsilon}R(\bar{u},\varepsilon)\right) \\ &= -\varepsilon\left(\tilde{Q}_1(\gamma,\varepsilon)\eta - \eta^2, \bar{u}_1 + \eta - \frac{1}{\varepsilon}R(\bar{u},\varepsilon)\right) \\ &= -2\varepsilon L_{\text{new}} + \frac{\varepsilon}{3}\int_0^{2\pi}\eta^3 + (\eta^2,[\varepsilon\bar{u}_1 - R(\bar{u},\varepsilon)]) \\ &\quad -\varepsilon\left(\eta, \tilde{Q}_1(\gamma,\varepsilon)\left[\bar{u}_1 - \frac{1}{\varepsilon}R(\bar{u},\varepsilon)\right]\right).\end{aligned} \tag{26}$$

In the same way as we showed that $\|\xi(t)\|_0 \leq 2\sqrt{2\gamma(t)}$ (see (8)), it can be seen that $\|\eta(t)\|_0 \leq 2\sqrt{2\gamma(t)}$. Just as in the proof of Proposition 2.3, this implies that $\int_0^{2\pi}\eta^3 \leq 8\pi\sqrt{\pi}\sqrt{\gamma}\|\eta\|_1^2 = \mathcal{O}(\varepsilon^2\sqrt{\gamma}+\varepsilon\sqrt{\gamma})$.

Furthermore, $\varepsilon\bar{u}_1 - R(\bar{u},\varepsilon) = \varepsilon(\bar{u}_1 - \bar{u}) - \dot{\bar{u}}$; hence $\|\varepsilon\bar{u}_1 - R(\bar{u},\varepsilon)\|_0 \leq \varepsilon\|\bar{u}_1 - \bar{u}\|_0 + \|\dot{\bar{u}}\|_0$. In this estimate, we use the explicit expression for the cnoidal waves in terms of the Jacobi elliptic functions to conclude that $\|\dot{\bar{u}}\|_0 = 2\varepsilon\gamma\|\bar{u}'(\gamma)\| = \mathcal{O}(\varepsilon\sqrt{\gamma})$.

Using these estimates, we see that the second and third terms in (26) are bounded by $\varepsilon K_4\sqrt{\gamma}\|\eta\|_1^2$ (K_4 is a constant independent of γ and of ε). We will give more attention to the estimate of the last term because it will improve the estimate of Proposition 2.3. By definition,

$$\varepsilon\left(\eta, \tilde{Q}_1(\gamma,\varepsilon)\left[\bar{u}_1 - \frac{1}{\varepsilon}R(\bar{u},\varepsilon)\right]\right) = \varepsilon(\eta, \tilde{Q}_1(\gamma,\varepsilon)[(\bar{u}_1 - \bar{u}) - 2\gamma\bar{u}'(\gamma)]).$$

Furthermore (see Lemma A.2(ii) in the appendix),

$$\begin{aligned}\tilde{Q}_1(\gamma,\varepsilon)\bar{u}'(\gamma) &= Q(\gamma)\bar{u}'(\gamma) + 2(\bar{u} - \bar{u}_1)\bar{u}'(\gamma) \\ &= \lambda'(\gamma)\bar{u}_1 + (\bar{u} - \bar{u}_1)[\lambda'(\gamma) + 2\bar{u}'(\gamma)].\end{aligned}$$

Hence

$$\begin{aligned}\varepsilon\left(\eta, \tilde{Q}_1(\gamma,\varepsilon)\left[\bar{u}_1 - \frac{1}{\varepsilon}R(\bar{u},\varepsilon)\right]\right) &= \varepsilon(\eta, [\tilde{Q}_1(\gamma,\varepsilon) - 2\gamma(\lambda'(\gamma) + 2\bar{u}'(\gamma))](\bar{u}_1 - \bar{u})) \\ &\quad - 2\varepsilon\gamma\lambda'(\gamma)(\eta,\bar{u}_1).\end{aligned}$$

By using the facts that $2(\eta, \bar{u}_1) = -\|\eta\|_0^2$ (this follows from $I(\bar{u}_1 + \eta) = I(\bar{u}_1)$), $\gamma\lambda'(\gamma) = \mathcal{O}(\sqrt{\gamma})$, and $\|\bar{u}(\gamma) - \bar{u}_1(\gamma, \varepsilon)\|_1 = \mathcal{O}(\varepsilon\sqrt{\gamma})$ (see Lemma 3.1), it follows that there exist constants K_5 and K_6 such that

$$\varepsilon\left(\eta, \tilde{Q}_1(\gamma)\left[\bar{u}_1 - \frac{1}{\varepsilon}R(\bar{u}, \varepsilon)\right]\right) \leq \varepsilon^2 K_5\sqrt{\gamma}\|\eta\|_1 + \varepsilon K_6\sqrt{\gamma}\|\eta\|_1^2.$$

Next, we estimate the second term of equation (25). Using the definitions of H_{new} and $R(\bar{u}, \varepsilon)$, it follows that

$$\begin{aligned}(\text{II}) &= \dot{\gamma}\left(\eta, \partial_x^{-1}\frac{\partial}{\partial\gamma}(2\varepsilon\gamma\bar{u}'(\gamma) + \varepsilon\bar{u}(\gamma)\right) \\ &= -2\varepsilon^2\gamma\|\eta\|_0\|\partial_x^{-1}(3\bar{u}'(\gamma) + 2\gamma\bar{u}''(\gamma))\|_0 \\ &\leq K_7\varepsilon^2\|\eta\|_1\sqrt{\gamma}.\end{aligned}$$

(Again, we use the explicit expression for $\bar{u}$ in terms of the Jacobi elliptic functions.)

Finally, using the fact that $\|\eta\|^2 \leq L_{\text{new}}/c$ (for $\|\eta\|_1 \leq \delta$), we can estimate $\frac{\mathrm{d}}{\mathrm{d}t}L_{\text{new}}$ by

$$\frac{\mathrm{d}}{\mathrm{d}t}L_{\text{new}} \leq -2\varepsilon L_{\text{new}} + K_0\varepsilon\sqrt{\gamma}L_{\text{new}} + K_0\varepsilon^2\gamma\sqrt{L_{\text{new}}}$$

for some constant K_0. Integrating this equation and applying Gronwall's lemma, we have that there exists some constant K such that

$$L_{\text{new}}(u(t), \varepsilon) \leq KL_{\text{new}}(\gamma(0), \eta(0), \varepsilon)e^{-2\varepsilon t} + K\varepsilon e^{-2\varepsilon t}. \qquad \square$$

The proof of Theorem 1.2 is a corollary of Proposition 3.3.

Proof of Theorem 1.2. From Lemmas 3.2 and 3.3 and the fact that $\|\eta(t)\|^2 = \rho_1(u(t), \bar{u}_1(\gamma(t)), \varepsilon))$, it follows that

$$\rho_1(u(t), \bar{u}_1(\gamma(t)), \varepsilon)) \leq K\rho_1(u(0), \bar{u}_1(\gamma(0)), \varepsilon))e^{-\varepsilon t} + K\varepsilon e^{-\varepsilon t}$$

if $\|\eta(0)\|_1$ is sufficiently small.

Now we use the fact that $\|\bar{u}_1(\gamma, \varepsilon) - \bar{u}(\gamma)\|_1 \leq \hat{K}\varepsilon\|\bar{u}\|_0$ for some constant $\hat{K}$ (see Lemma 3.1), which yields

$$\begin{aligned}\rho_1(u(t), \bar{u}(\gamma(t))) &\leq \rho_1(u(t), \bar{u}_1(\gamma(t)), \varepsilon)) + \|\bar{u}_1(\gamma(t), \varepsilon) - \bar{u}(\gamma(t))\|_1 \\ &\leq K\rho_1(u(0), \bar{u}_1(\gamma(0)), \varepsilon))e^{-\varepsilon t} + \tilde{K}\varepsilon e^{-\varepsilon t}(1 + \sqrt{2\gamma(0)}) \\ &\leq K\rho_1(u(0), \bar{u}(\gamma(0)))e^{-\varepsilon t} + \tilde{K}\varepsilon e^{-\varepsilon t}(1 + \sqrt{2\gamma(0)}) \\ &\quad + K\|\bar{u}_1(\gamma(0), \varepsilon) - \bar{u}(\gamma(0))\|_1 e^{-\varepsilon t} \\ &\leq K\rho_1(u(0), \bar{u}(\gamma(0)))e^{-\varepsilon t} + \bar{K}\varepsilon e^{-\varepsilon t}\end{aligned}$$

for some constant $\bar{K}$. This completes the proof of Theorem 1.2. □

Appendix. Some properties of the unperturbed KdV equation and cnoidal waves. As indicated in [4], the cnoidal waves are constrained minima of the Hamiltonian on level sets of I.

LEMMA A.1. *Let* $\gamma > 0$. *For all* 2π*-periodic functions* u *with mean value zero that satisfy* $I(u) = \gamma$, *it holds that*

$$H(u) \geq H(\bar{u}(\gamma)).$$

If $H(u) = H(\bar{u}(\gamma))$ and $I(u) = \gamma$, then u is a cnoidal wave with 2π as a minimal period. Explicitly, we have

$$(I(u) = \gamma \wedge H(u) = H(\bar{u}(\gamma))) \Rightarrow \exists_{\phi \in \mathbb{R}}[u = \Phi^I_\phi(\bar{u}(\gamma))].$$

Furthermore, all cnoidal waves $\bar{u}(\gamma)$ satisfy the Euler–Lagrange equation

$$\partial_x(H'(u) - \lambda I'(u)) = \partial_x(\bar{u}_{xx} + \bar{u}^2 + \lambda \bar{u}) = 0, \tag{27}$$

and the cnoidal wave $\bar{u}(\gamma)$ is an unconstrained minimum of the modified KdV Hamiltonian $H_\gamma(u) = H(u) - \lambda(\gamma)I(u)$.

Proof. Let $\gamma > 0$. We start by proving that the minimum of H on the level set $I = \gamma$ exists. For this proof, we show that H is a weakly lower semicontinuous (w.l.s.c.) functional that is coercive on the level set $I = \gamma$.

(i) First, we show coerciveness. For all $u \in H^1_{\text{per},0}$ with $I(u) = \gamma$, it holds that

$$\left| \int_0^{2\pi} u^3(x)dx \right| \leq \|u\|_\infty \int_0^{2\pi} u^2(x)dx \leq \sqrt{2\pi}\|u\|_1 2\gamma \tag{28}$$

(we used the Poincaré inequalities (4) and (5)). This gives

$$H(u) \geq \frac{1}{2}\int_0^{2\pi} u_x^2(x)dx - \frac{1}{3}\left|\int_0^{2\pi} u^3(x)dx\right| \geq \|u\|_1 \left[\frac{1}{2}\|u\|_1 - \frac{\sqrt{2\pi}}{3}\gamma\right]. \tag{29}$$

The last expression grows to infinity for $\|u\|_1 \to \infty$.

(ii) Next, we prove weak lower semicontinuity. The norm is a w.l.s.c. functional; hence $\int_0^{2\pi} u_x^2(x)dx = \|u\|_1^2$ is w.l.s.c. The term $\int_0^{2\pi} u^3(x)dx$ is a functional that is even weakly continuous. To prove this, we use the fact that $H^1_{\text{per},0}$ is embedded in C^0 and the embedding operator is strongly continuous. (See [30, p. 82].) Hence if the sequence $(u_n)_{n\in\mathbb{N}}$ converges weakly to u in $H^1_{\text{per},0}$, then this sequence is uniformly convergent to u. This implies that

$$\lim_{n\to\infty} \int_0^{2\pi} u_n^3(x)dx = \int_0^{2\pi} u^3(x)dx, \tag{30}$$

which shows that the functional $\int_0^{2\pi} u^3(x)dx$ is weakly continuous. In the same way, it is proved that the set $\{u \in H^1_{\text{per},0} \mid \int_0^{2\pi} u^2(x)dx = 2\gamma\}$ is weakly closed.

A coercive w.l.s.c. functional defined on a (sequentially) weakly closed set attains its infimum on this set. (See [6, §6.1] and [31, Chap. 38].) This completes the proof that H has a minimum on the level set with $I = \gamma$.

From variational calculus, it follows that this minimum satisfies the Euler–Lagrange equation

$$H'(u) - \lambda I'(u) = \alpha \tag{31}$$

for some Lagrange multipliers λ and α. Using properties of elliptic functions (see, e.g., [8] or [10]), it follows that the cnoidal waves with minimal period are unique solutions of such a equation with minimal value of H. □

In several places, we use properties of the operators $Q(\gamma)$ and $\tilde{Q}(\gamma)$ and the cnoidal waves. We list some important ones.

LEMMA A.2. *The operators $Q(\gamma)$ and $\tilde{Q}(\gamma)$ and the cnoidal waves satisfy the following properties:*

(i) $Q(\gamma)\bar{u}_x(\gamma) = \tilde{Q}(\gamma)\bar{u}_x(\gamma) = 0$;
(ii) $Q(\gamma)\bar{u}'(\gamma) = \tilde{Q}(\gamma)\bar{u}'(\gamma) = \lambda'(\gamma)\bar{u}(\gamma) + \alpha'(\gamma)\mathbf{1}$ *and* $\alpha'(\gamma) = \frac{1}{\pi}$;
(iii) $\tilde{Q}(\gamma)\mathbf{1} = -2\bar{u} - \lambda(\gamma)\mathbf{1}$;
(iv) $\lambda'(\gamma) < 0$;
(v) $\operatorname{range}[\tilde{Q}(\gamma)] = \{u \in H^1_{\text{per}} \mid (X_I(\bar{u}), u) = 0\}$.

Proof. (i) The translation invariance of both H and I implies that $\tilde{Q}(\gamma)X_I(\bar{u}) = 0$; hence $\tilde{Q}(\gamma)\bar{u}_x(\gamma) = 0$. Also, because $\bar{u}_x \in H^1_{\text{per},0}$, $Q(\gamma)\bar{u}_x(\gamma) = 0$.

(ii) Differentiation of the Euler–Lagrange equation for the cnoidal waves, i.e.,

$$-\bar{u}_{xx}(\gamma) - \bar{u}^2 - \lambda(\gamma)\bar{u}(\gamma) - \alpha(\gamma) = 0,$$

with respect to γ shows statement (ii) of the lemma. Integration of this Euler–Lagrange equation yields $\alpha(\gamma) = \frac{1}{\pi}\gamma$ and hence $\alpha'(\gamma) = \frac{1}{\pi}$.

(iii) The equation follows immediately from the definition of $\tilde{Q}(\gamma)$.

(iv) The proof of this property can be found in [11].

(v) $\tilde{Q}(\gamma)$ is a self-adjoint operator, and in Lemma A.3 it is proved that $X_I(\bar{u})$ is the only eigenvector with eigenvalue 0. □

The cnoidal waves are minima of the modified KdV Hamiltonian H_γ. This implies that $Q(\gamma)$ is positive definite on $\mathbb{Y}(\gamma)$. In Lemma A.3, we show that a slightly stronger property holds.

LEMMA A.3. *The operator $Q(\gamma)$ is strictly positive definite on $\mathbb{Y}(\gamma)$. To be explicit, there is some $c_1(\gamma) > 0$ such that*

$$(Q(\gamma)y, y) \geq c_1(\gamma)\|y\|_1^2 \qquad \textit{for all } y \in \mathbb{Y}(\gamma) \tag{32}$$

and $\lim_{\gamma\to 0} c_1(\gamma) > 0$.

Proof. To prove this boundedness from below, we consider the eigenvalues of $Q(\gamma)$. These eigenvalues form a monotonically nondecreasing sequence in $\mathbb{R}$:

$$\lambda_0 \leq \lambda_1 \leq \lambda_2 \leq \cdots \qquad \text{with } \lim_{n\to\infty} \lambda_n = \infty. \tag{33}$$

For the smallest eigenvalue λ_0, it holds that

$$\lambda_0 = \min\left\{(Q(\gamma)\xi, \xi) \mid \xi \in H^1_{\text{per},0}, \int_0^{2\pi} \xi^2 = 1\right\}. \tag{34}$$

This number is negative because

$$(Q(\gamma)\bar{u}(\gamma), \bar{u}(\gamma)) = -\int_0^{2\pi} \bar{u}(\gamma)^3 < 0. \tag{35}$$

The last inequality is based on the fact that $I(\bar{u}) = I(-\bar{u})$ and $H(\bar{u}) < H(-\bar{u})$ because of the minimality of $H(\bar{u})$ on the level set with $I = \gamma$. This implies that $-\frac{1}{3}\int_0^{2\pi}\bar{u}^3 < \frac{1}{3}\int_0^{2\pi}\bar{u}^3$; in other words, $-\frac{2}{3}\int_0^{2\pi}\bar{u}^3 < 0$.

The translation invariance of H and I implies that $Q(\gamma)\bar{u}_x = 0$; hence $Q(\gamma)$ has at least one eigenvalue which equals zero for all $\gamma > 0$.

At $\gamma = 0$, the operator $Q(0)$ is equal to $-(D_{xx} + Id)$. The eigenvalues of this operator on $H^1_{\text{per},0}$ are (k^2-1), $k \in \mathbb{N}$. All these eigenvalues are double. The continuity of $Q(\gamma)$ in γ implies that for $\gamma > 0$ in a neighborhood of 0, it holds that

$$\lambda_0(\gamma) < 0, \qquad \lambda_1(\gamma) = 0, \qquad \lambda_2(\gamma) > 0. \tag{36}$$

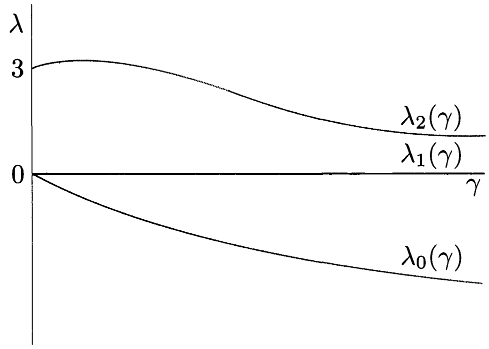

FIG. 4. *Sketch of the behavior of the eigenvalues* $\lambda_0(\gamma)$, $\lambda_1(\gamma)$, *and* $\lambda_2(\gamma)$.

See also Figure 4.

We prove $\lambda_2(\gamma) > 0$ for all $\gamma \geq 0$ by using a contradiction argument and $\tilde{Q}(\gamma)$, the extension of $Q(\gamma)$ on H^1_{per}. Assume that there is some $\gamma_0 > 0$ such that $\lambda_2(\gamma_0) = 0$. Then the operator $\tilde{Q}(\gamma)$ has a double eigenvalue zero. The differential equation for the eigenvalues and 2π-periodic eigenvectors of $\tilde{Q}(\gamma)$ is called Lamé's equation; see, e.g., [24]. It follows from Sturm–Liouville theory that zero is the second or the third eigenvalue of this equation because $\bar{u}_x$ is an eigenvector at zero. In [2], it is proved that the first three eigenvalues of this equation are single. Hence zero has to be a single eigenvalue of $\tilde{Q}(\gamma)$. This contradicts our assumption that $\lambda_2(\gamma_0) = 0$ and implies that $\lambda_2(\gamma_0) > 0$ for all $\gamma_0 \geq 0$. We have seen that $\lambda_2(0) = 3$; hence on every compact γ-interval, there is a positive lower bound for $\lambda_2(\gamma)$.

Using ideas similar to those of [23], this behavior of the eigenvalues of $Q(\gamma)$ implies that there is a $c_0(\gamma) > 0$ such that

$$\int_0^{2\pi} [y_x^2(x) - (2\bar{u}(x) - \lambda)y^2(x)]dx = (Q(\gamma)y, y) \geq c_0(\gamma)\|y\|_0^2 \tag{37}$$

for all $y \in \mathbb{Y}(\gamma)$. In Lemma A.4, we will prove that (37) implies that

$$(Q(\gamma)y, y) \geq c_1(\gamma)\|y\|_1^2 \qquad \text{for all } y \in \mathbb{Y}(\gamma)$$

with $c_1(\gamma) = \frac{c_0(\gamma)}{c_0(\gamma)+\|2\bar{u}(\gamma)+\lambda(\gamma)\|_\infty}$. □

In the proof of Lemma A.3, we used the fact that if $(Q(\gamma)y, y)$ is bounded from below in the L^2-norm for all $y \in \mathbb{Y}(\gamma)$, then it is bounded from below in the H^1-norm as well. This property can be concluded immediately from the following lemma.

LEMMA A.4. *Let* $p(x)$ *be a continuous function on* $[-\pi, \pi]$. *If for some* $\xi \in H^1_{\text{per},0}$ *it holds that*

$$\int_0^{2\pi} [\xi_x^2(x) + p(x)\xi^2(x)]dx \geq c\|\xi\|_0^2, \tag{38}$$

then

$$\int_0^{2\pi} [\xi_x^2(x) + p(x)\xi^2(x)]dx \geq c_1\|\xi\|_1^2 \tag{39}$$

with $c_1 = \frac{c}{c+\|p\|_\infty}$.

Proof. Assume that (38) holds for some $\xi \in H^1_{\mathrm{per},0}$. By rewriting the integral in equation (40), we see that

$$\begin{aligned}\int_0^{2\pi}[\xi_x^2(x)+p(x)\xi^2(x)]dx &= c_1\int_0^{2\pi}\xi_x^2(x)dx+(1-c_1)\int_0^{2\pi}\xi_x^2(x)dx\\ &\quad+\int_0^{2\pi}p(x)\xi^2(x)dx.\end{aligned}\tag{40}$$

Now we use inequality (38); it follows that

$$\begin{aligned}&\int_0^{2\pi}[\xi_x^2(x)+p(x)\xi^2(x)]dx\\ &\quad\geq c_1\int_0^{2\pi}\xi_x^2(x)dx+(1-c_1)c\|\xi\|_0^2-c_1\|p\|_\infty\|\xi\|_0^2\\ &\quad= c_1\int_0^{2\pi}\xi_x^2(x)dx+c\|\xi\|_0^2-c_1(c+\|p\|_\infty)\|\xi\|_0^2\\ &\quad= c_1\|\xi\|_1^2. \qquad \square\end{aligned}\tag{41}$$

The last subject in this appendix is the operator $DF_0(\bar{u}(\gamma),\lambda(\gamma),\alpha(\gamma),0)$ as defined in the proof of Lemma 3.1.

LEMMA A.5. *The operator $DF_0(\bar{u}(\gamma),\lambda(\gamma),\alpha(\gamma),0)$ is injective and surjective, for all $\gamma > 0$.*

Proof. Let $\gamma > 0$. Define A_0 on $H^1_{\mathrm{per}}\times\mathbb{R}\times\mathbb{R}\times\mathbb{R}$ as

$$A_0 = DF_0(\bar{u}(\gamma),\lambda(\gamma),\alpha(\gamma),0) = \begin{pmatrix} \tilde{Q}(\gamma) & -\bar{u}(\gamma) & -\mathbf{1} & -\bar{u}_x(\gamma)\\ \bar{u}(\gamma) & 0 & 0 & 0\\ \mathbf{1} & 0 & 0 & 0\\ R(\bar{u}(\gamma),\varepsilon) & 0 & 0 & 0 \end{pmatrix}.$$

(i) First, we prove that A_0 is an injective map. Assume that $A_0(v,l,a,b)=0$ for some $(v,l,a,b)\in H^1_{\mathrm{per}}\times\mathbb{R}\times\mathbb{R}\times\mathbb{R}$; hence

$$0=\tilde{Q}(\gamma)v-l\bar{u}(\gamma)-a\mathbf{1}-b\bar{u}_x(\gamma),\tag{42}$$

$$0=(\bar{u}(\gamma),v),\tag{43}$$

$$0=(\mathbf{1},v),\tag{44}$$

$$0=(R(\bar{u}(\gamma),\varepsilon),v).\tag{45}$$

Taking the inner product of (42) with $\bar{u}_x$ yields $b\|\bar{u}_x\|_0^2=0$ and hence $b=0$. Write $v = c_1\bar{u}'(\gamma)+c_2\bar{u}_x+y$, with $y\in\tilde{\mathbb{Y}}(\gamma)$. This decomposition is unique because $(\bar{u}'(\gamma),\bar{u}) = \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}\gamma}\|\bar{u}\|_0^2 = 1$ and hence $\bar{u}'(\gamma)\notin\tilde{\mathbb{Y}}(\gamma)$. From (43), it follows that $c_1=(v,\bar{u})=0$. Taking the inner product of (42) with v shows that $0=(\tilde{Q}(\gamma)v,v)=(\tilde{Q}(\gamma)y,y)$. Hence $y=0$ because $\tilde{Q}(\gamma)$ is strictly positive definite on $\tilde{\mathbb{Y}}(\gamma)$. From (45), it follows that $0=c_2(R(\bar{u}(\gamma),\varepsilon),\bar{u}_x)$. Because of the assumption that $(R(\bar{u}(\gamma),\varepsilon),\bar{u}_x)\neq 0$, this implies that $c_2=0$ and hence $v=0$. Finally, substituting $v=0$ and $b=0$ in (42) yields $l\bar{u}(\gamma)+a\mathbf{1}=0$. Because $\bar{u}(\gamma)$ and $\mathbf{1}$ are linearly independent, this implies that $l=0$ and $a=0$.

(ii) Next, we show that A_0 is surjective. Assume that $A_0(v,l,a,b) = (w,m,c,d)$ for some $(v,l,a,b), (w,m,c,d) \in H^1_{\text{per}} \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}$; hence

$$w = \tilde{Q}(\gamma)v - l\bar{u}(\gamma) - a\mathbf{1} - b\bar{u}_x(\gamma), \tag{46}$$

$$m = (\bar{u}(\gamma), v), \tag{47}$$

$$c = (\mathbf{1}, v), \tag{48}$$

$$d = (R(\bar{u}(\gamma), \varepsilon), v). \tag{49}$$

Taking the inner product of (46) with $\bar{u}_x$ yields $b\|\bar{u}_x\|_0^2 = (w, \bar{u}_x)$. This defines b because $\|\bar{u}_x\|_0^2 \neq 0$. Take the inner product of (46) with $\mathbf{1}$ and use Lemma A.2(iii), which yields $2\pi a = -(w,\mathbf{1}) - 2m - \lambda c$. This defines a. Take the inner product of (46) with $\bar{u}'(\gamma)$ and use Lemma A.2(ii), which yields $l = -(w, \bar{u}'(\gamma)) - b(\bar{u}_x, \bar{u}'(\gamma)) + \lambda'(\gamma)m + \alpha'(\gamma)c$. This defines l. From Lemma A.2(v), it follows that $\tilde{Q}(\gamma)$ is invertible on $\{\bar{u}_x\}^{\perp}$; hence

$$v = \tilde{Q}(\gamma)^{-1}[w + l\bar{u} + a\mathbf{1} + b\bar{u}_x] + f\bar{u}_x.$$

The value of f follows from (49). □

A REFINED WIENER–LEVINSON METHOD IN FREQUENCY ANALYSIS*

K. PAN†

Abstract. This paper is concerned with the problem of determining unknown frequencies $\omega_1, \ldots, \omega_I$, using the first N observed values of a discrete-time signal $\{x(m)\}_{m=0}^{N-1}$ arising from a continuous waveform that is the superposition of a finite number of sinusoidal waves with well-defined frequencies ω_j, $j = 1, 2, \ldots, I$. In [K. Pan and E. B. Saff, *J. Approx. Theory*, 71 (1992), pp. 239–251] (see also [W. B. Jones, O. Njåstad, W. J. Thron, and H. Waadeland, *J. Comput. Appl. Math.*, 46 (1993), pp. 217–228]), we proved that unknown frequencies ω_j, $j = 1, 2, \ldots, I$, in a periodic discrete-time signal can be determined by zeros of Szegö polynomials with respect to some distribution function by using the first N samples with a rate of convergence of $1/N$. We introduce a refined way to obtain a rate of convergence of $1/N^p$ by using about pN samples of the signals, where p is any given positive integer.

Key words. frequency analysis, orthogonal polynomials

AMS subject classifications. 33C45, 40A15, 41A21

1. Introduction.

We denote a doubly infinite sequence $x = \{x(m)\}_{-\infty}^{\infty}$ of real numbers as a signal. We consider signals of the form

$$x(m) = \sum_{j=-I}^{I} \alpha_j e^{i\omega_j m}, \quad x(0) \neq 0, \tag{1.1}$$

where

$$\alpha_0 \geq 0, \quad \alpha_{-j} = \bar{\alpha}_j, \quad \omega_{-j} = -\omega_j, \quad 0 = \omega_0 < \omega_1 < \cdots < \omega_I < \pi. \tag{1.2}$$

The problem of determining the frequencies ω_j from the first N samples $\{x(m)\}_{m=0}^{N-1}$ has important applications to science and engineering. Recently, a method for solving this problem was introduced by Jones, Njåstad, and Saff based upon the techniques of Wiener and Levinson. The starting points for this method are the autocorrelation coefficients

$$\mu_k^{(N)} := \sum_{m=0}^{N-1-k} x(m)\overline{x(m+k)}, \quad k = 0, 1, 2, \ldots, \quad \text{and } \mu_{-k} = \mu_k.$$

They form a positive definite Hermitian sequence (cf. [JNS]); that is,

$$D_n^{(N)} := \det(\mu_{i-j}^{(N)})_0^n > 0, \quad n = 0, 1, 2, \ldots.$$

We consider the monic Szegö polynomials $\phi_{n,N}(z), n \geq 1$, as follows,

$$\phi_{n,N}(z) := \frac{1}{D_{n-1}^{(N)}} \begin{vmatrix} \mu_0^{(N)} & \mu_{-1}^{(N)} & \cdots & \mu_{-n}^{(N)} \\ \mu_1^{(N)} & \mu_0^{(N)} & \cdots & \mu_{-n+1}^{(N)} \\ \vdots & \vdots & \cdots & \vdots \\ \mu_{n-1}^{(N)} & \mu_{n-2}^{(N)} & \cdots & \mu_{-1}^{(N)} \\ 1 & z & \cdots & z^n \end{vmatrix}.$$

* Received by the editors September 7, 1994; accepted for publication (in revised form) April 14, 1995.

† Department of Mathematics, Barry University, Miami Shores, FL 33161.

The following conjecture on the asymptotics of zeros of $\phi_{n,N}(z)$ was introduced in [JNS].

CONJECTURE (see [JNS]). *As $n \to \infty$ and $N \to \infty$, the $2I + L$ zeros of $\phi_{n,N}(z)$ of largest modulus approach the point $e^{i\omega_j}$, $j = \pm 1, \pm 2, \ldots, \pm I$, and also* 1 *if $L = 1$. Here $L = 1$ if $\alpha_0 > 0$ and $L = 0$ if $\alpha_0 = 0$.*

This conjecture has recently been verified by the results of [PS] and [JNTW] for n fixed, $n \geq 2I + L$, and $N \to \infty$. In [PS] (see also [JNTW]), we proved that the rate of convergence is $\mathcal{O}(1/N)$ for $n = 2I + L$. That is, let $\alpha_{N,j,n}$ denote the zero of $\phi_{n,N}(z)$ that is closest to $e^{i\omega_j}$; then $|\alpha_{N,j,n} - e^{i\omega_j}| = \mathcal{O}(1/N)$ as $N \to \infty$ and $1/N$ is the best possible. Thus, for N large enough, those zeros of $\phi_{n,N}(z)$ can be used to approximate the unknown frequencies.

From numerical experiments (cf. [JNS]), we can see that it may take 1000 samples to get only two significant digits. We want to find some alternative ways to improve this method.

In this paper, we introduce a new idea to approximate the unknown frequencies by creating a "window" to compute the autocorrelation coefficients. This method will give us an asymptotic rate of convergence of $1/N^p$ by using about pN samples of x for any positive integer $p \geq 1$.

The outline of the paper is as follows. In §2, we state our main results, and the proofs of these results are given in §3. The numerical results can be found in §4.

2. Main theorems. For convenience we let $\beta_j := e^{i\omega_j}, j = -I, \ldots, I$. Set

$$\mu_k := \sum_{-I}^{I} |\alpha_j|^2 \beta_j^k, \quad k = 0, \pm 1, \ldots.$$

Then the sequence $\{\mu_k\}_{-\infty}^{\infty}$ is a positive $(2I + L)$-definite hermitian sequence (cf. [PS]). This means that

$$b_n > 0 \quad \text{for} \quad 0 \leq n \leq 2I + L - 1, \qquad b_{2I+L} = 0,$$

where

$$b_n := \det(\mu_{i-j})_0^n.$$

For any integers $N > 0$ and $p \geq 1$, we define $a(N, p, k)$, $k = 0, \ldots, pN$, as follows:

$$\left(\frac{1 - R^{N+1}}{1 - R}\right)^p = (1 + R + \cdots + R^N)^p = \sum_{k=0}^{pN} a(N, p, k) R^k.$$

Also, we define

$$\nu_m^{(N,p)} := \sum_{k=0}^{pN} a(N, p, k) x(k) \overline{x(k + m)}, \nu_{-m}^{(N,p)} = \overline{\nu_m^{(N,p)}}, \quad m = 0, 1, 2, \ldots.$$

Although we cannot prove that $\{\nu_m^{(N,p)}\}$ is a positive definite hermitian sequence, we can prove the following.

THEOREM 2.1. *For $N \to \infty$, we have*

$$c_n^{(N,p)} := \det(\nu_{i-j}^{(N,p)})_{i,j=0}^n > 0, \quad n = 0, 1, \ldots, 2I + L - 1.$$

Furthermore, we have

$$\frac{1}{(N+1)^{p(n+1)}}\, c_n^{(N,p)} = b_n + \mathcal{O}\left(\frac{1}{N^p}\right), \quad n = 0, 1, \ldots, 2I+L-1.$$

Next, set

$$\psi_{2I+L,N,p}(z) := \frac{1}{c_{2I+L-1}^{(N,p)}} \begin{vmatrix} \nu_0^{(N,p)} & \nu_{-1}^{(N,p)} & \cdots & \nu_{-(2I+L)}^{(N,p)} \\ \nu_1^{(N,p)} & \nu_0^{(N,p)} & \cdots & \nu_{-(2I+L)+1}^{(N,p)} \\ \vdots & \vdots & \cdots & \vdots \\ \nu_{(2I+L)-1}^{(N,p)} & \nu_{(2I+L)-2}^{(N,p)} & \cdots & \nu_{-1}^{(N,p)} \\ 1 & z & \cdots & z^{2I+L} \end{vmatrix}.$$

THEOREM 2.2. *For any integer $p \geq 1$, we have*

$$\lim_{N\to\infty} \psi_{2I+L,N,p}(z) = \phi_{2I+L}(z) := (z-1)^L \sum_{j=1}^{I} (z-\beta_j)(z-\beta_{-j}), \quad z \in C.$$

The convergence is uniform on compact subsets of $\mathbf{C}$. *More precisely, we have for each compact set $K \subset \mathbf{C}$,*

$$|\psi_{2I+L,N,p}(z) - \phi_{2I+L}(z)| \leq \frac{A}{N^p}, \quad z \in K, \quad N \to \infty,$$

where A is a constant that depends on K.

COROLLARY 2.3. *For each N large, let $\beta_{N,j,p}$ denote the zero of $\psi_{2I+L,N,p}(z)$ that is closest to β_j. Then for $j = \pm 1, \pm 2, \ldots, \pm I$ and $j = 0$ if $L = 1$,*

$$|\beta_{N,j,p} - \beta_j| = \mathcal{O}\left(\frac{1}{N^p}\right), \quad N \to \infty.$$

Remark 1. The rate of convergence in the corollary is the best possible. This can be seen from the following example for the case when $\alpha_0 = 0$.

Let

$$x(m) := \beta_1^m + \beta_{-1}^m = 2\cos(\pi m/2),$$

where $\beta_1 = i$, and $\phi_2(z) = z^2 + 1$. On computing the moments $\nu_k^{(N,p)}$ and using the determinant representation for the orthogonal polynomial $\psi_{2,N,p}(z)$, we find

$$\psi_{2,N,p}(z) = z^2 + 1 \quad \text{for } N \text{ even}$$

and

$$\psi_{2,N,p}(z) = z^2 + 1 + \frac{1}{N^p} \quad \text{for } N \text{ odd}.$$

Thus the zeros of $\psi_{2,N,p}(z)$ approach $\pm i$ with exact rate $1/N^p$.

Remark 2. From this example, we can see that the zeros of $\psi_{2I+L,N,p}(z)$ do not lie in $|z| < 1$ since $\{\nu_m^{(N,p)}\}$ is not a positive definite hermitian sequence.

3. Proofs of theorems. Before we give the proof of Theorem 2.1, we need the following lemma.

LEMMA 3.1. *For $N \to \infty$, we have*

$$\frac{1}{(N+1)^p}\nu_m^{(N,p)} = \mu_m + \mathcal{O}\left(\frac{1}{N^p}\right), \quad m = 0, \quad \pm 1, \ldots.$$

Proof. Notice that

$$\begin{aligned}
\nu_m^{(N,p)} &= \sum_{k=0}^{pN} a(N,p,k)x(k)\overline{x(k+m)} = \sum_{k=0}^{pN} a(N,p,k) \sum_{j=-I}^{I} \alpha_j \beta_j^k \sum_{l=-I}^{I} \overline{\alpha}_l \overline{\beta}_l^{k+m} \\
&= \sum_{j,l=-I}^{I} \alpha_j \overline{\alpha}_l \overline{\beta}_l^m \sum_{k=0}^{pN} a(N,p,k)\beta_j^k \overline{\beta}_l^k \\
&= \sum_{j=-I}^{I} |\alpha_j|^2 \overline{\beta}_j^m \sum_{k=0}^{pN} a(N,p,k) + \sum_{j \neq l} \alpha_j \overline{\alpha}_l \overline{\beta}_l^m \sum_{k=0}^{pN} a(N,p,k)\beta_j^k \overline{\beta}_l^k \\
&= \sum_{j=-I}^{I} |\alpha_j|^2 \overline{\beta}_j^m (N+1)^p + \sum_{j \neq l} \alpha_j \overline{\alpha}_l \overline{\beta}_l^m \left[\frac{1-(\beta_j\overline{\beta}_l)^{N+1}}{1-\beta_j\overline{\beta}_l}\right]^p.
\end{aligned}$$

Thus we have

$$\frac{1}{(N+1)^p}\,\nu_m^{(N,p)} = \mu_m + \mathcal{O}\left(\frac{1}{N^p}\right). \qquad \square$$

Proof of Theorem 2.1. It follows from Lemma 3.1. □

Proof of Theorem 2.2. From Lemma 3.1, we have

$$\begin{aligned}
&\psi_{2I+L,N,p}(z) \\
&= \frac{1}{c_{2I+L-1}^{(N,p)}} \begin{vmatrix} \nu_0^{(N,p)} & \nu_{-1}^{(N,p)} & \cdots & \nu_{-(2I+L)}^{(N,p)} \\ \nu_1^{(N,p)} & \nu_0^{(N,p)} & \cdots & \nu_{-(2I+L)+1}^{(N,p)} \\ \vdots & \vdots & \cdots & \vdots \\ \nu_{(2I+L)-1}^{(N,p)} & \nu_{(2I+L)-2}^{(N,p)} & \cdots & \nu_{-1}^{(N,p)} \\ 1 & z & \cdots & z^{2I+L} \end{vmatrix} \\
&= \frac{1}{b_{2I+L-1} + \mathcal{O}(1/N^p)} \left\{ \begin{vmatrix} \mu_0 & \mu_{-1} & \cdots & \mu_{-(2I+L)} \\ \mu_1 & \mu_0 & \cdots & \mu_{-(2I+L)+1} \\ \vdots & \vdots & \cdots & \vdots \\ \mu_{(2I+L)-1} & \mu_{(2I+L)-2} & \cdots & \mu_{-1} \\ 1 & z & \cdots & z^{2I+L} \end{vmatrix} \right\} + \mathcal{O}(1/N^p) \\
&= \phi_{2I+L}(z) + \mathcal{O}(1/N^p),
\end{aligned}$$

where $\mathcal{O}(1/N^p)$ is uniform in z on any compact subset of $\mathbf{C}$. Here we use the fact that (see [PS])

$$\frac{1}{b_{2I+L-1}}\begin{vmatrix} \mu_0 & \mu_{-1} & \cdots & \mu_{-(2I+L)} \\ \mu_1 & \mu & \cdots & \mu_{-(2I+L)+1} \\ \vdots & \vdots & \cdots & \vdots \\ \mu_{(2I+L)-1} & \mu_{(2I+L)-2} & \cdots & \mu_{-1} \\ 1 & z & \cdots & z^{2I+L} \end{vmatrix} = \phi_{2I+L}(z).$$

This completes the proof of Theorem 2.2. □

Proof of Corollary 2.3. From the proof of Theorem 2.2, we obtain that

$$\psi_{2I+L,N,p}(\beta_j) = \mathcal{O}(1/N^p), \quad j = \pm 1, \dots, \pm I \text{ and } j = 0 \text{ if } L = 1.$$

As previously remarked, $\beta_{N,j,p} \to \beta_j$. Thus for $N \to \infty$, we have

$$|\beta_j - \beta_{N,j,p}| = \left| \frac{\psi_{2I+L,N,p}(\beta_j)}{\Pi_{s \neq j}(\beta_j - \beta_{N,s})} \right| = \mathcal{O}(1/N^p), \quad N \to \infty,$$

for $j = \pm 1, \dots, \pm I$ and $j = 0$ if $L = 1$. □

4. Numerical results. We can use Levinson's algorithm to compute $\psi_{2I+L,N,p}(z)$. After we find $\nu_0^{(N,p)}$, $\nu_1^{(N,p)}, \dots, \nu_{2I+L}^{(N,p)}$, we compute δ_0, E_0, δ_1, $E_1, \dots, \delta_{2I+L}$, E_{2I+L} successively. Initially, set

$$\delta_0 = 1, \qquad E_0 = \nu_0^{(N,p)}, \qquad \delta_1 = -\nu_1^{(N,p)}/\nu_0^{(N,p)}, \qquad q_0^{(1)} = \delta_1, \qquad q_1^{(1)} = 1.$$

Then for $k = 2, 3, \dots, 2I + L$, compute

$$E_{k-1} = \sum_{j=0}^{k-1} q_j^{(k-1)} \nu_{k-1-j}^{(N,p)},$$

$$\delta_k = -\frac{\sum_{j=0}^{k-1} q_j^{(k-1)} \nu_{j+1}^{(N,p)}}{E_{k-1}},$$

$$q_j^{(k)} = \delta_k q_{k-1}^{(k-1)} + q_{j-1}^{(k-1)}, \qquad j = 1, 2, \dots, k-1,$$

$$q_k^{(k)} = 1, \qquad q_0^{(k)} = \delta_k.$$

Finally,

$$E_k = \sum_{j=0}^{2I+L} q_j^{(k)} \nu_{2I+L-j}^{(N,p)}.$$

Then $\psi_{2I+L,N,p}(z) = \sum_{j=0}^{2I+L} q_j^{(2I+L)} z^j$.

Example 1. (See Table 1.)

$$x(m) = \beta_{-1}^m + \beta_1^m = 2\cos(m\pi/7), \quad \beta_1 = e^{i\pi/7} = 0.9009688680 + 0.4338837393i.$$

$$\beta_{N,1,p} := \text{ the zero of } \psi_{2,N,p}(z) \text{ that is closest to } \beta_1.$$

TABLE 1

	p	$\beta_{N,1,p}$	$\|\beta_{N,1,p} - \beta_1\|$

FAMILIES OF ORTHOGONAL TWO-DIMENSIONAL WAVELETS*

PETER MAASS†

Abstract. We construct orthonormal wavelet bases of $L^2(\mathbb{R}^2)$ with compact support for dilation matrices of determinant 2. The key idea is to describe the set $\mathcal{H}_2$ of all two-dimensional (2D) scaling coefficients satisfying the orthogonality condition as an implicit function. This set includes the scaling coefficients for induced 1D wavelets. We compute the tangent space of $\mathcal{H}_2$ at H_N, the scaling coefficients for induced 1D Daubechies wavelets. The structure of the tangent space allows us to build nonseparable wavelets by starting at H_N and tracing $\mathcal{H}$ along its tangent lines. Various families of compactly supported orthogonal 2D wavelets for the quincunx grid are explicitly given.

Key words. wavelets, dilation equations, multiresolution analysis

AMS subject classifications. 42A52, 65D20

1. Introduction.

The wavelet transform has by now proved to be a reliable tool for a wide range of applications in signal processing. The success of this method often relies on the special properties of orthogonal wavelets with compact support. In short, an orthogonal one-dimensional (1D) wavelet is a function ψ such that

$$\{\psi_{mk}(x) = 2^{-m/2}\psi(2^{-m}x - k) \mid k, m \in \mathbb{Z}\}$$

forms an orthonormal basis for $L^2(\mathbb{R})$. Fast algorithms require compactly supported wavelets. Besides the Haar wavelets

$$\psi(x) = \chi_{[0,1/2]}(x) - \chi_{[1/2,1]}(x),$$

no compactly supported orthogonal wavelets were known before I. Daubechies [6] succeeded in merging the wavelet idea, originally defined via group representations on the affine group [10], with the concept of a multiresolution analysis, stemming from signal processing [12]. The outcome was a family $\{\psi_N\}$ of compactly supported orthogonal wavelets with linearily increasing regularity. This family of functions has found applications in such diverse fields as data compression, numerical solutions of partial differential equations, the construction of multigrid methods [15], the examination of electrocardiograms, and many more. For a long but still incomplete list of applications, see the references in [7, 17, 2, 16].

When constructing orthogonal 2D wavelets, the dilation parameter 2 is replaced by a matrix A satisfying certain restrictions. For example, tensor products of orthogonal 1D wavelets lead to 2D wavelets for $A = \mathrm{diag}(2,2)$. In applications such as image compression, these wavelet bases lead to artifacts in directions parallel to the coordinate axis. In other words, these separable wavelets are not isotropic. Moreover, we need $|\det(A)| - 1 = 3$ wavelets in order to obtain a basis of $L^2(\mathbb{R}^2)$. Hence we are lead to study dilation matrices with $\det(A) = 2$. Here the standard example is

$$A = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix},$$

which corresponds to a rotation of $\pi/4$. Thus far, three types of orthogonal 2D wavelets are known. First of all, a beautiful generalization of the Haar wavelet leads

* Received by the editors April 2, 1993; accepted for publication (in revised form) May 30, 1995. This work was partially supported by Deutsche Forschungsgemeinschaft grant MA 1657/1–1.

† Fachbereich Mathematik, Universität Potsdam, Postfach 60 15 53, D-14415 Potsdam, Germany.

to 2D wavelets which are characteristic functions of certain sets [9]. Besides the tensor-product wavelets for diagonal dilation matrices one can also lift 1D wavelets to higher-dimensional wavelets for dilation matrices A with $|\det(A)| = 2$ [4]. Both types are called separable, they have an inherent 1D structure. Moreover, nonseparable quadrature mirror filters (QMFs) have been constructed in [11]; they lead to continuous 2D wavelets [18].

Our aim is to develop a general construction procedure for nonseparable compactly supported orthogonal 2D wavelets for dilation matrices with $|\det(A)| = 2$. As usual, we exploit the connection between wavelets and multiresoluton analysis. This leads us to study the Fourier series H of the coefficients of finite scaling equations. Instead of constructing a particular H, we examine the set $\mathcal{H}_2$ of all trigonometric polynomials H satisfying the orthogonality condition. The key idea is to use the description of $\mathcal{H}_2$ as an implicit function. Starting at a known point on $\mathcal{H}_2$, namely the Fourier series H_N associated with the lifted 1D Daubechies wavelet ψ_N, we can trace part of $\mathcal{H}_2$ via its tangential space.

In this paper, we are primarily interested in constructing wavelets. Hence the problem of investigating the regularity or the number of vanishing moments of these wavelets will only be touched upon in §4.

The paper is organized as follows. Section 2 contains the relevant theory for 1D wavelets and multiresolution analysis. Section 3 starts from the 2D scaling equation and constructs the tangent space of $\mathcal{H}_2$ at H_N. The structure of the tangent space allows us to examine $\mathcal{H}_2$ by starting at H_N and tracing $\mathcal{H}$ along its tangent lines. In order to ensure that such an $H \in \mathcal{H}_2$ actually leads to an orthogonal wavelet, we also have to check the Cohen criterion. This is done in §4, leading to families of nonseparable orthogonal wavelets.

2. Multiresolution analysis and orthogonal 1D wavelets.

Wavelets are most conveniently described within the framework of multiresolution analysis. This concept was introduced in 1986 by Y. Meyer and S. Mallat; since then, it has become the main tool for constructing compactly supported wavelets. A multiresolution analysis in $\mathbb{R}^d$ for a dilation matrix A consists of a series of nested linear spaces $\{V_m | m \in \mathbb{Z}\}$

$$\cdots \subset V_2 \subset V_1 \subset V_0 \subset V_{-1} \subset \cdots$$

such that

$$\overline{\cup V_m} = L^2(\mathbb{R}^d), \qquad \cap V_m = \{0\},$$

$$f(x) \in V_m \Longleftrightarrow f(Ax) \in V_{m-1},$$

where A, the dilation matrix, is a matrix whose eigenvalues λ have modulus greater than 1, $|\lambda| > 1$, and which maps the integer vectors $k \in \mathbb{Z}^d$ to integer vectors, i.e.,

$$\Gamma = A\mathbb{Z}^d \subset \mathbb{Z}^d.$$

The decisive condition that makes this scheme work is the requirement that there exists a function φ such that

$$\{\varphi(x-k) \mid k \in \mathbb{Z}^d\} \text{ is an orthonormal basis of } V_0.$$

The requirement that φ and its integer translates are orthonormal can be replaced by alternative conditions [7], e.g., by the stability requirement that

$$\{\varphi(x-k) \mid k \in \mathbb{Z}^d\} \text{ forms a Riesz basis of } V_0.$$

Note that the subspace V_m is spanned by $\{\varphi(A^{-m}x-k) \mid k \in \mathbb{Z}^d\}$. The name *multiresolution analysis* stems from the interpretation that different subspaces V_m contain functions representing details of increasing size as $m \longrightarrow \infty$. The projection of a signal f onto V_m can thus be interpreted as applying a low-pass filter with diminishing bandwidth as $m \longrightarrow \infty$. From $\varphi \in V_0 \subset V_{-1}$, it follows that φ satisfies a scaling equation

$$\varphi(x) = |\det(A)| \sum h_k \varphi(Ax-k). \tag{1}$$

The set of scaling coefficients $\{h_k\}$ is called the associated discrete filter. Most of this article deals with properties of the Fourier series of such discrete filters.

The Fourier series of the scaling coefficients is denoted by $H(\omega)$, $\omega \in \mathbb{R}^d$:

$$H(\omega) = sum_{k\in\mathbb{Z}^d} h_k e^{-ik\cdot\omega}, \tag{2}$$

where $\omega \cdot k$ denotes the standard scalar product.

Let A^{-t} denote the transpose of the inverse matrix A^{-1} and define the Fourier transform of a function $f \in L^2(\mathbb{R}^d)$ by

$$\hat{f}(\omega) = (2\pi)^{-d/2} \int\limits_{\mathbb{R}^d} f(x) e^{-i\omega\cdot x}\, dx.$$

Then taking the Fourier transform on both sides of the scaling equation (1) leads to

$$\begin{aligned} \hat{\varphi}(\omega) &= H(A^{-t}\omega)\hat{\varphi}(A^{-t}\omega) \\ &= \prod_{m\geq 1} H((A^{-t})^m\omega). \end{aligned} \tag{3}$$

By W_m we denote the orthogonal component of V_m in V_{m-1}:

$$V_m \oplus W_m = V_{m-1}.$$

In other words, W_m is the complement of a low-pass filtered function space V_m in a space V_{m-1} of functions with a larger bandwidth, i.e., the projection of a signal onto W_m amounts to applying a band-pass filter. Y. Meyer [13] proved that there exist functions $\psi_1, \ldots, \psi_{|\det(A)|-1} \in L^2(\mathbb{R})$, the associated wavelets, with mean value 0 such that

$$\overline{\operatorname{span}\{\psi_j(x-k) \mid k \in \mathbb{Z}^d,\ j = 1, \ldots, |\det(A)|-1\}} = W_0,$$

$$\langle \psi_i(\cdot), \psi_j(\cdot - k)\rangle_{L^2(\mathbb{R}^d)} = \delta_{0k}\delta_{ij}.$$

In other words, only dilation matrices with $|\det(A)| = 2$ allow the construction of a single function ψ such that

$$\{\psi_{mk}(x) = 2^{-m/2}\, \psi(A^{-m}x-k) \mid m \in \mathbb{Z}, k \in \mathbb{Z}^2\} \tag{4}$$

forms an orthonormal basis for $L^2(I\!R^d)$.

The most interesting dilation matrix in the 1D case, $d = 1$, is therefore $A = 2$, and ϕ satisfies the scaling relation

$$\varphi(x) = 2\sum h_k \; \varphi(2x - k). \tag{5}$$

An orthogonal wavelet ψ can then be constructed explicitly from a given orthogonal scaling function ϕ, i.e., $\phi(x) \perp \phi(x-k)$ if $k \neq 0$, by, e.g.,

$$\psi(x) = 2\sum g_k \varphi(2x - k), \tag{6}$$

$$g_k = (-1)^k h_{1-k}. \tag{7}$$

All properties of ψ can be deduced from the scaling coefficients $\{h_k\}$ [6]. For example, in our search for compactly supported wavelets, we need only look at scaling equations with a finite number of nonzero scaling coefficients. After introducing the Fourier series

$$H(\omega) = \sum_{k=0}^{n} h_k e^{-ik\omega}, \qquad G(\omega) = \sum_{k=0}^{n} g_k e^{-ik\omega},$$

the main step in constructing compactly supported orthogonal wavelets requires us to find a trigonometric polynomial H satisfying the orthogonality condition [6].

THEOREM 2.1. *If $\varphi \in L^2(I\!R)$ is a solution of* (5) *which is orthogonal to its integer translates, i.e.,*

$$k \neq 0 : \varphi(x) \perp \varphi(x - k),$$

then

$$|H(\omega)|^2 + |H(\omega + \pi)|^2 = 1, \qquad H(0) = 1. \tag{8}$$

A set of coefficients $\{h_k, g_k\}$ satisfying $(3, 4)$ is called a QMF in the language of signal processing. A QMF is the discrete analogue of the function pair (φ, ψ). Thus far, we have reviewed the procedure which starts with a multiresolution analysis and the related scaling function φ (resp. the wavelets ψ) and ends at a QMF, i.e., a set of discrete coefficients $\{h_k\}$ satisfying an orthogonality condition (8). The construction of orthogonal wavelets proceeds in the reverse direction. However, there exist pathological examples of QMFs where the corresponding solutions φ (resp. ψ) of (5) (resp. (6)) are not orthogonal to there integer translates [6]. This can be avoided, e.g., by checking the following Cohen criterion, which we state for dimensions $d = 1$ and $d = 2$.

CRITERION 2.2 (Cohen criterion). *The Fourier series $H(\omega) = \sum_{k \in Z\!\!\!Z} h_k \; e^{-ik\omega}$, $\omega \in I\!R$, satisfies the 1D Cohen criterion if there exists a set $K \subset I\!R$ such that*

- *K contains a neighborhood of the origin,*
- *$|K| = 2\pi$ and for all ω in $[-\pi, \pi]$, there exists a $k \in Z\!\!\!Z$ such that $\omega + 2k\pi \in K$,*
- *for all $m > 0$, $H(2^{-m}\omega)$ does not vanish on K.*

The Fourier series $H(\omega) = \sum_{k \in Z\!\!\!Z^2} h_k \; e^{-ik\cdot\omega}$, $\omega = (\omega_1, \omega_2) \in I\!R^2$, satisfies the 2D Cohen criterion if there exists a set $K \subset I\!R^2$ such that

- *K contains a neighborhood of the origin,*

- $|K| = 4\pi^2$ *and for all* ω *in* $[-\pi,\pi]^2$, *there exists a* $k \in \mathbb{Z}^2$ *such that* $\omega + 2\pi k \in K$,
- *for all* $m > 0$, $H(A^{-m}\omega)$ *does not vanish on* K.

In [3], it was proved that this criterion in addition to the orthogonality condition (8) is necessary and sufficient for the L^2 convergence of the infinite product (3) and the orthogonality of the limit function.

THEOREM 2.3. *Suppose* $H(\omega) = \sum_{k\in\mathbb{Z}} h_k\, e^{ik\omega}$ *satisfies* (8). *Then the infinite product* (3) *converges in* $L^2(\mathbb{R})$ *to an orthogonal solution of* (5) *if and only if* H *satisfies the Cohen criterion* (*Criterion* 2.2).

Our approach for constructing orthogonal wavelets starts by introducing $\mathcal{H}_1$, the set of all trigonometric polynomials in one variable satisfying the orthogonality condition (8), and its subset $\mathcal{H}_1^N \subset \mathcal{H}_1$,

$$\mathcal{H}_1^N = \left\{ H(\omega) = \sum_{k=0}^{2N-1} h_k e^{-ik\omega} \mid H \text{ satifies } (8) \right\},$$

consisting of the polynomial solutions of (8) of degree $(2N-1)$. We choose to label the subspaces by N instead of using the filter length $n = 2N-1$ because the Daubechies wavelets ψ_N obey scaling relations with $2N$ coefficents and their related Fourier series H_N are therefore elements of H_1^N. These polynomials have $2N$ coefficients; hence $\mathcal{H}_1^N$ can be viewed as a manifold in $\mathbb{R}^{2N}$.

Let us further define

$$q(\omega) = |H(\omega)|^2. \tag{9}$$

For any $H \in \mathcal{H}_1$, the corresponding q is an even positive trigonometric polynomial with $q(0) = 1$ solving the simple equation

$$q(\omega) + q(\omega + \pi) = 1. \tag{10}$$

This is a linear equation with the general solution

$$\mathcal{K}_1 = \left\{ q(\omega) = 1/2 + \sum_{k\in\mathbb{Z}} \alpha_k \cos\left((2k+1)\omega\right) \mid \sum \alpha_k = 1/2,\ q \geq 0 \right\}.$$

$\mathcal{K}_1$ is the intersection of a linear affine space with the convex cone of positive functions, i.e., $\mathcal{K}_1$ is a convex set. We introduce the map

$$q : \mathcal{H}_1 \longrightarrow \mathcal{K}_1 \tag{11}$$

$$H \longmapsto |H|^2. \tag{12}$$

We will often use the shorthand notation $q(\omega)$ for $(q(H))(\omega)$; we will identify the trigonometric polynomial H with the set of its coefficients whenever appropriate. $\mathcal{K}_1$ has a simple structure; hence our construction follows a four-step procedure:

1. choose a $q \in \mathcal{K}_1$;
2. solve $|H|^2 = q$;
3. check the Cohen criterion;
4. solve the scaling equations (5) and (6).

In general, it is not possible to give a solution of (1) in closed form, but the graphical iteration process described in [6] converges to a solution under rather general conditions. Moreover, the values of φ and ψ at dyadic values can be computed efficiently

[7]. This solves step 4. Step 2, i.e., the question of inverting the map q, is answered by the following theorem.

THEOREM 2.4 (Fejer–Riesz theorem). *Let q be a real positive polynomial in $\cos(\omega)$, i.e.,*

$$q(\omega) = \sum_{k=0}^{n} \alpha_k \cos(k\omega), \quad q(\omega) \geq 0.$$

Then there exists a trigonometric polynomial H of the same degree, i.e.,

$$H(\omega) = \sum_{k=0}^{n} h_k e^{-ik\omega},$$

with real coefficients, such that

$$q(\omega) = |H(\omega)|^2. \tag{13}$$

This result is due to Riesz. The proof is based on the ability to factorize polynomials in one variable, i.e.,

$$q(\omega_0) = 0 \Longrightarrow (\omega - \omega_0) \mid q(\omega);$$

see [14]. This is not possible for polynomials in more than one variable. The major step in constructing orthogonal 2D wavelets will be a characterization of some trigonometric polynomials in two variables which allow taking the root in the sense of the above theorem.

The Fejer–Riesz theorem (Theorem 2.4) implies that any $q \in \mathcal{K}_1$ has a root in the sense of (13). Another way to view this result is as follows.

COROLLARY 2.5. $q(\mathcal{H}_1) = \mathcal{K}_1$.

The main advantage of investigating $\mathcal{K}_1$ instead of $\mathcal{H}_1$ is that $\mathcal{K}_1$ is a flat linear manifold while $\mathcal{H}_1$ is defined by a set of quadratic equations. Moreover, $\mathcal{K}_1$ is convex. To end this section, we determine a special set of extremal points of $\mathcal{K}_1$ by constructing a set of supporting hyperplanes. This will lead to the well-known family of orthogonal 1D Daubechies wavelets. We define the subset of trigonometric polynomials of degree $2N-1$:

$$\mathcal{K}_1^N := \{q \in \mathcal{K}_1 \mid \deg(q) \leq 2N - 1\}.$$

LEMMA 2.6. *For fixed N, let $\{d_k \mid k = 0, \ldots, 2N-1\}$ denote the scaling coefficients associated with the Daubechies wavelets ψ_N and let*

$$H_N(\omega) = \sum_{k=0}^{2N-1} d_k \; e^{-ik\omega}$$

denote the corresponding Fourier series. Then

$$|H_N(\omega)|^2 = q_N(\omega) = 1 - c_N \int_0^{\omega} \sin(t)^{2N-1} \, dt,$$

$$c_N^{-1} = \int_0^{\pi} \sin^{2N-1}(t) dt$$

is an extremal point of $\mathcal{K}_1^N$.

Proof. Define

$$u(\omega) = 1 - c_N \int_0^\omega \sin(t)^{2N-1} dt.$$

We begin by establishing that

$$q_N(\omega) = \sum_{k=0}^{N-1} \begin{pmatrix} N-1+k \\ k \end{pmatrix} (\sin(\omega/2))^{2k},$$

as defined in [6], is indeed equal to $u(\omega)$. With the above definition of c_N, we have

$$\begin{aligned} u(\omega+\pi) &= -c_N \int_\pi^{\pi+\omega} \sin(t)^{2N-1}\, dt \\ &= c_N \int_0^\omega \sin^{2N-1}(t) dt. \end{aligned}$$

u is a positive polynomial of degree $2N-1$ in $\cos(t)$ which solves (10); therefore, $u \in \mathcal{K}_1^N$. Moreover,

$$u'(\omega) = -c_N \ \sin^{2N-1}(\omega),$$

which implies that u is the unique element in $\mathcal{K}_1^N$ with

$$u^{(k)}(\pi) = 0, \qquad k = 0, 1, \ldots, 2N-1.$$

On the other hand, the Daubechies wavelet ψ_N was constructed by requiring that $H_N \in \mathcal{H}_1^N$ or, equivalently, $q_N = |H_N|^2 \in \mathcal{K}_1^N$ has a zero at $\omega = \pi$ of the highest possible order. It follows that $u = q_N$. This part of the lemma, with a different reasoning, can be found in [13].

It remains to show that u is an extremal point of $\mathcal{K}_1^N$. We construct supporting hyperplanes. Any

$$q(\omega) \ = \ 1/2 + \sum_{k=1}^{2N-1} \alpha_k \ \cos((2k-1)\omega) \in \mathcal{K}_1^N$$

is an even positive smooth function which solves (10); therefore, $0 \le q(\omega) \le 1$. Since $q(0) = 1$, we immediately have

$$q'(0) = 0, \qquad q''(0) = \sum_{k=1}^{2N-1} (2k-1)^2 \alpha_k \le 0.$$

Hence the condition $q''(0) = 0$ defines a supporting hyperplane $\mathcal{E}_1$:

$$\mathcal{E}_1 : \sum_{k=1}^{N} (2k-1)^2 \alpha_k = 0.$$

Note that $q(H_N) = q_N$ lies on this hyperplane.

$\mathcal{K}_1^N \cap \mathcal{E}_1$ is again a convex set. Among the elements $q \in \mathcal{K}_1 \cap \mathcal{E}_1$, we select the functions on the plane $\mathcal{E}_2$ defined by $q^{(4)}(0) = 0$. This again gives a condition on $\{\alpha_k\}$:

$$\mathcal{E}_2 : \sum_{k=1}^{N} (2k-1)^4 \alpha_k = 0.$$

We can continue in this vein, defining successive $\mathcal{E}_\ell$, $\ell = 1, \dots, N$, each defined by

$$\mathcal{E}_\ell : \sum_{k=1}^{N} (2k-1)^{2\ell} \alpha_k = 0,$$

and each $\mathcal{E}_\ell$ is a supporting hyperplane for

$$\mathcal{K}_1 \cap \mathcal{K}_2 \cap \cdots \cap \mathcal{K}_{\ell-1}.$$

The corresponding linear equations for $\{\alpha_k\}$ are linearly independent. Hence there is a unique element in $\mathcal{K}_1^N$ lying in the intersection of all hyperplanes

$$q \in \cap_{k=1}^{N} \mathcal{E}_k.$$

By construction, $q_N \in \cap_{k=1}^{N} \mathcal{E}_k$, so that q_N is this unique element. □

3. 2D wavelets. Our aim is to construct compactly supported orthogonal 2D wavelets, i.e., we search for functions $\psi \in L^2(\mathbb{R}^2)$ such that

$$\{\psi_{mk}(x) = 2^{-m/2}\ \psi(A^{-m}x - k) \mid m \in \mathbb{Z},\ k \in \mathbb{Z}^2\}$$

forms an orthonormal basis for $L^2(\mathbb{R}^2)$. Hence we consider dilation matrices A with $|\det(A)| = 2$. Obviously, the scaling function φ and the related wavelet ψ depend very much on the dilation matrix A; see (3). For example, the same set of coefficients $\{h_k\}$ may lead to a wavelet with arbitrary high regularity for one dilation matrix A and to a discontinuous wavelet for another A [4].

However, the 2D equivalent to the 1D orthogonality condition of Theorem 2.1 depends only on a set of representatives of the cosets of the adjoint grid

$$\tilde{\Gamma} = A^t \mathbb{Z}^2;$$

see Lemma 3.1 below. If $|\det(A)| = 2$, then the set of representatives consists of a single vector $z \in \mathbb{Z}^2 \backslash \tilde{\Gamma}$. There are exactly three different grids Γ stemming from dilation matrices A with $|\det(A)| = 2$:

- the line grid, i.e., $m = (m_1, m_2) \in \Gamma \Longleftrightarrow m_2$ is even;
- the column grid, i.e., $m = (m_1, m_2) \in \Gamma \Longleftrightarrow m_1$ is even;
- the quincunx grid, i.e., $m = (m_1, m_2) \in \Gamma \Longleftrightarrow m_1 + m_2$ is even.

Since the first two grids—and their adjoint grids $\tilde{\Gamma}$—are related to each other by a simple exchange of variables, we may assume without loss of generality that

$$z = \begin{pmatrix} 1 \\ 0 \end{pmatrix}.$$

As in the 1D case, the construction of orthogonal wavelets centers around the Fourier series H of the scaling coefficients. The following results treat all dilation matrices with $|\det(A)| = 2$, but to illustrate the construction, we will always refer to the standard example where A incorporates a rotation by $\pi/4$:

$$A = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}.$$

This matrix has been discussed, e.g., in [4], [17]. It is the most basic dilation matrix with two complex eigenvalues; hence it produces nonseparable wavelets.

3.1. Orthogonality relation. As in the 1D case, the orthogonality of $\{\varphi(x-m)\}$ leads to an orthogonality condition expressed in terms of the Fourier series (2). The proof of the following lemma is a straightforward generalization of the corresponding result in $L^2(\mathbb{R})$; see [13].

LEMMA 3.1. *Given a dilation matrix A with an arbitrary value of $|\det(A)|$, choose a complete set of representatives of $\tilde{\Gamma}$*

$$\{z_1 = 0, z_2, \dots, z_{|\det(A)|}\},$$

i.e.,

$$\mathbb{Z}^2 = \bigcup_{k=1}^{|\det(A)|} (z_k + \tilde{\Gamma}).$$

Suppose the scaling equation (1) has a solution $\varphi \in L^2(\mathbb{R}^d)$ which is orthogonal to its integer translates

$$\varphi(x) \perp \varphi(x-m) \quad \textit{for all} \quad m \neq 0 \in \mathbb{Z}^d.$$

Let $z \in \mathbb{Z}^2$ be a representative of the coset of the grid $\tilde{\Gamma}$, i.e., $(z+\tilde{\Gamma}) \cup \tilde{\Gamma} = \mathbb{Z}^2$.

Then the Fourier series H satisfies the orthogonality relation

$$|H(\omega)|^2 + |H(\omega + 2\pi A^{-t}z)|^2 = 1, \qquad H(0) = 1. \tag{14}$$

If we specify this result, then we may choose a representative z such that

$$2\pi A^{-1} z = \begin{pmatrix} \pi \\ \pi \end{pmatrix}.$$

COROLLARY 3.2. *For $d = 2$ and $|\det(A)| = 2$, the orthogonality condition of Lemma 3.1 is given by*

$$|H(\omega)|^2 + \left| H\left(\omega + \begin{pmatrix} \pi \\ \pi \end{pmatrix}\right)\right|^2 = 1, \qquad H(0) = 1. \tag{15}$$

The 2D orthogonality condition is very similar to its 1D counterpart, and we can easily lift Fourier series which satisfy (8) to higher dimensions.

COROLLARY 3.3. *If $H_1(\omega)$ satisfies the 1D orthogonality condition, then*

$$H(\omega_1, \omega_2) = H_1(\omega_1)$$

obeys (15).

This leads to so-called induced wavelets, which have been studied in [4]. They are not suitable for application since they are not isotropic and have a poor smoothness.

As in the 1D case, we have to check in addition the Cohen criterion, which insures that an H satisfying (15) leads to an orthogonal scaling function which generates a multiresolution analysis [4]. Moreover, we still need to know how to construct the wavelet ψ given the scaling function φ.

LEMMA 3.4. *Let A denote a dilation matrix with $|\det(A)| = 2$ and let z be a representative of the coset of $\tilde{\Gamma}$. Given an orthogonal scaling function φ with scaling coefficients $\{h_k \mid k \in \mathbb{Z}^2\}$, define*

$$g_k = (-1)^{e(k)} h_{z-k}, \quad k \in \mathbb{Z}^2,$$

where the exponent $e(k)$ is given by

$$e(k) = \begin{cases} 0 & \text{if} \quad k \in \tilde{\Gamma}, \\ 1 & \text{if} \quad k \in \mathbb{Z}^2 \backslash \tilde{\Gamma}, \end{cases}$$

e.g., for the quincunx grid, we may choose $e(k) = k_1 + k_2$. Then

$$\psi(x) := 2 \sum g_k \varphi(Ax - k)$$

defines an orthogonal 2D wavelet, i.e.,

$$\{2^{-m/2} \ \psi(A^{-m}x - k) \mid m \in \mathbb{Z}, k \in \mathbb{Z}^2\}$$

is an orthonormal basis for $L^2(\mathbb{R}^2)$.

Proof. The proof proceeds analogously to the 1D-case. □

3.2. The implicit-function approach. As in the 1D case, we examine the set of trigonometric polynomials H which solve (15):

$$\mathcal{H}_2 := \{H \mid H \text{ solves (17), } H \text{ is a trigonometric polynomial}\}.$$

By $\mathcal{H}_2^N \subset \mathcal{H}_2$ we denote the subspace of trigonometric polynomials of degree $\deg(H) \leq 2N - 1$. We define

$$q(\omega) = |H(\omega)|^2. \tag{16}$$

The general solution of $q(\omega) + q(\omega + \pi \begin{pmatrix}1\\1\end{pmatrix}) = 1$ is given by

$$\mathcal{K}_2 = \left\{ q(\omega) = 1/2 + \sum_{\substack{k \in \mathbb{Z}^2 \\ k_1+k_2 \text{ odd}}} \alpha_k \cos(k \cdot \omega) \mid q(0) = 1, \ q \geq 0 \right\}. \tag{17}$$

$\mathcal{K}_2$ is the intersection of an affine linear space with the convex cone of positive functions, i.e., $\mathcal{K}_2$ is a convex set. In contrast to the 1D case, not every $q \in \mathcal{K}_2$ has a polynomial root in the sense of (16). We define the subset

$$q(\mathcal{H}_2) = \mathcal{K}_{\text{orth}},$$

$$\mathcal{K}_{\text{orth}} = \{q \in \mathcal{K}_2 \mid q = |H|^2, \ H \text{ is a trigonometric polynomial}\}.$$

In a slight abuse of notation, we write H for the set of scaling coefficients $\{h_k^N \mid k \in \mathbb{Z}^2\}$ and we use the same symbol for the Fourier series

$$H(\omega) = \sum_{k \in \mathbb{Z}^2} h_k e^{-ik \cdot \omega}.$$

As described in Corollary 3.3, we can lift elements $q_1 \in \mathcal{K}_1$ (resp. $H_1 \in \mathcal{H}_1$) to higher dimensions:

$$q_1 \in \mathcal{K}_1 : q(\omega_1, \omega_2) = q_1(\omega_1) \in \mathcal{K}_{\text{orth}}.$$

For example, we can lift the scaling coefficients $\{d_k \mid k = 0, \dots, 2N-1\}$ of the Daubechies wavelet ψ_N:

$$H_N = \{h_k^N \mid k = (k_1, k_2),\ 0 \le k_1,\ k_2 \le 2N-1\}. \tag{18}$$

Note that

$$h^N_{(k_1,0)} = d_{k_1},$$

$$h^N_{(k_1,k_2)} = 0 \quad \text{if} \quad k_2 \neq 0.$$

Notational remark. The length of the filters is generally denoted by n, but in most cases, we deal with the dimension $n = 2N-1$ related to the Daubechies filters.

The starting point for the following is the observation

$$H_N \in \mathcal{H}_1 \subset \mathcal{H}_2. \tag{19}$$

$$q(H_N) \in \mathcal{K}_1 \subset \mathcal{K}_{\text{orth}} \subset \mathcal{K}_2. \tag{20}$$

As in the 1D case, we expect that $\mathcal{K}_{\text{orth}}$ has a more convenient structure than $\mathcal{H}_2$, at least $\mathcal{K}_{\text{orth}}$ contains the flat subset $\mathcal{K}_1$.

Our procedure for investigating $\mathcal{H}_2$ and $\mathcal{K}_2$ proceeds as follows:

1. Describe $\mathcal{H}_2$ as an implicit function, i.e.,

$$H(\omega) = \sum_{0 \le k_1, k_2 \le n} h_k e^{-ik\cdot\omega} \in \mathcal{H}_2 \Longleftrightarrow F(H) = 0.$$

The function $F : I\!R^{(n+1)^2} \to I\!R^{(n+1)^2-n+1}$ is determined either via the description (17) of $\mathcal{K}_2$ or by expressing the orthogonality condition (15) directly in terms of the coefficients $\{h_k\}$.

2. Choose $n = 2N-1$ and apply the implicit-function theorem to compute the tangent space of $\mathcal{H}_2^N$ at H_N. This requires three steps:

(a) Compute the Jacobian J of F at H_N.

(b) Split the coefficients in two sets $x \in I\!R^{n-1}$ and $y \in I\!R^{(n+1)^2}$ such that

$$\frac{\partial F}{\partial y}(H_N) \text{ is not singular.}$$

(c) Compute the tangent vectors of $\mathcal{H}_2$ at H_N with the help of

$$\left(\frac{\partial F}{\partial y}(H_N)\right)^{-1} \frac{\partial F}{\partial x}(H_N) = -\nabla g,$$

where $g(x)$ is the function implicitly defined by $F(x, g(x)) = 0$.

3. Choose $n = 2N-1$, start at $H_N \in \mathcal{H}_2$, follow a tangent vector t_N, and add a correction term in order to stay on $\mathcal{H}_2$:

$$H = H_N + s\, t_N + \text{correction term}.$$

We begin by writing out the defining equations for $\mathcal{H}_2$ and $\mathcal{K}_{\mathrm{orth}}$ in detail. We are interested in compactly supported wavelets. Hence we investigate scaling equations with a finite number of scaling coefficients $\{h_k\}$. Let

$$H(\omega) = \sum_{k_1,k_2=0}^{n} h_k \, e^{-ik\cdot\omega} \tag{21}$$

be a trigonometric polynomial of degree n with $(n+1)^2$ coefficients. The grid points corresponding to coefficients of the polynomial are marked in Figure 1. From (15), we get the first condition for the coefficients $\{h_k\}$: $H(0) = 1$, i.e.,

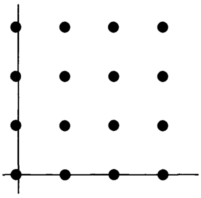

FIG. 1.

$$\sum_k h_k = 1. \tag{22}$$

The coefficients of $q = |H|^2$ are given by

$$\begin{aligned} q(\omega) &= \sum_{k,l} h_k h_l \, e^{-i(k-l)\cdot\omega} = \sum_m \left\{ \sum_k h_k h_{k-m} \right\} e^{-im\cdot\omega} \\ &= \sum_k h_k^2 + 2 \sum_{m_1=1}^{n} \left\{ \sum_{k_1=0}^{n} h_{(k_1,0)} h_{(k_1-m_1,0)} \right\} \cos(m_1\omega_1) \\ &\quad + 2 \sum_{m_1=-n}^{n} \sum_{m_2=1}^{n} \left\{ \sum_k h_k h_{k-m} \right\} \cos(m\cdot\omega). \end{aligned}$$

$q \in \mathcal{K}_2$ implies that the coefficients of $\cos(m\cdot\omega)$, m_1+m_2 even, have to vanish and that the constant term has to equal $1/2$; see (17). Together with (22), this poses n^2+n+2 conditions. In other words, the coefficients $H = \{h_k\}$ satisfying (15) are the zeros of

$$F : \mathbb{R}^{(n+1)^2} \longrightarrow \mathbb{R}^{n^2+n+2},$$

where the n^2+n+2 equations are given by

$$F_1(H) = \sum_k h_k - 1,$$

$$F_2(H) = \sum_k h_k^2 - 1/2,$$

$$F_m(H) = \sum_k h_k h_{k-m} \quad \text{for } m \neq (0,0),\ m_1+m_2 \text{ even}.$$

We are interested in filters of length $n = 2N - 1$; $\mathcal{H}_2^N$ is therefore given here as an implicitly defined function

$$\mathcal{H}_2^N = \{H \in I\!R^{(2N)^2} \mid F(H) = 0\}.$$

The next step requires us to compute the Jacobian of F evaluated at the scaling coefficients $\{h_k^N\}$ for the induced 1D Daubechies wavelets (18). These coefficients vanish if $k_2 \neq 0$; in order to distinguish between the 2D array of coefficients h_k^N and its 1D vector of nonzero coefficients, we define for fixed N

$$d_k = h^N_{(k,0)}, \quad k = 0, \dots, 2N-1. \tag{23}$$

The partial derivatives of F_1 and F_2 are given by

$$\frac{\partial F_1}{\partial h_k}(H_N) = 1, \qquad \frac{\partial F_2}{\partial h_k}(H_N) = 2h_k^N = \begin{cases} 2d_{k_1} : k_2 = 0, \\ \ \ 0 \ \ : k_2 \neq 0. \end{cases}$$

For $m = (m_1, 0)$, $m_1 \neq 0$ even, we obtain

$$\frac{\partial F_m}{\partial h_k}(H_N) = \begin{cases} d_{k_1 - m_1} + d_{k_1 + m_1} : k_2 = 0, \\ \qquad 0 \qquad\quad : \text{otherwise}. \end{cases}$$

We combine these partial derivatives in an $(N-1) \times (2N)$ submatrix J_0 with coefficients $(J_1)_{ij}$, $1 \le i \le (N-1)$, $0 \le j \le (2N-1)$:

$$(J_0)_{ij} = \frac{\partial F_{(2i,0)}}{\partial h_{(j,0)}}(H_N) = d_{j-2i} + d_{j+2i}. \tag{24}$$

For example, for $N = 2$, i.e., $n = 3$, this submatrix is simply

$$J_0 = (d_2, d_3, d_0, d_1).$$

The remaining partial derivatives for $1 \le m_2 \le n$, $-n \le m_1 \le n$, $m_1 + m_2$ even, are determined by

$$\frac{\partial F_m}{\partial h_k}(H_N) = \begin{cases} d_{k_1 - m_1} : \text{if } k_2 = m_2,\ m_1 \le k_1 \le n + m_1, \\ \ \ 0 \ \ \ : \text{otherwise}. \end{cases}$$

For a fixed $m_2 > 0$, m_2 odd, we gather the relevant derivatives in a $(2N) \times (2N)$ submatrix J_1 with coefficients $(J_1)_{ij}$, $0 \le i, j \le (2N-1)$:

$$(J_1)_{ij} = \frac{\partial F_{(-n+2i, m_2)}}{\partial h_{(j, m_2)}}(H_N) = d_{j+n-2i}, \tag{25}$$

$$J_1 = \begin{pmatrix} d_n & 0 & 0 & 0 \cdots 0 \\ d_{n-2} & d_{n-1} & d_n & 0 \cdots 0 \\ & \cdot & & \cdot \\ & \cdot & & \cdot \\ d_1 & d_2 & \cdots & d_n & 0 \\ 0 & d_0 & d_1 & \cdots & d_{n-1} \\ & \cdot & & & \cdot \\ & \cdot & & & \cdot \\ 0 & \cdots & 0 & 0 & d_0 \end{pmatrix};$$

for a fixed $m_2 > 0$, m_2 even, we obtain a $(2N-1)\times(2N)$ submatrix J_2 with coefficients $(J_2)_{ij},\ 0 \le i \le (2N-2),\ 0 \le j \le (2N-1)$:

$$(J_2)_{ij} = \frac{\partial F_{(-n+1+2i,m_2)}}{\partial h_{(j,m_2)}}(H_N) = d_{j+n-1-2i}, \tag{26}$$

$$J_2 = \left(\begin{array}{cccccc} d_{n-1} & d_n & 0 & 0 & 0 & \cdots 0 \\ d_{n-3} & \cdots & d_{n-1} & d_n & 0 & \cdots 0 \\ & \cdot & & & & \cdot \\ & \cdot & & & & \cdot \\ d_0 & d_1 & \cdots & \cdots & \cdots & d_n \\ 0 & 0 & d_0 & \cdots & d_{n-3} & d_{n-2} \\ & \cdot & & & & \cdot \\ & \cdot & & & & \cdot \\ 0 & \cdots & \cdots & 0 & d_0 & d_1 \end{array}\right).$$

For $N = 2$, these matrices reduce to

$$J_1 = \begin{pmatrix} d_3 & 0 & 0 & 0 \\ d_1 & d_2 & d_3 & 0 \\ 0 & d_0 & d_1 & d_2 \\ 0 & 0 & 0 & d_0 \end{pmatrix}, \qquad J_2 = \begin{pmatrix} d_2 & d_3 & 0 & 0 \\ d_0 & d_1 & d_2 & d_3 \\ 0 & 0 & d_0 & d_1 \end{pmatrix}.$$

If we arrange the 2D array of coefficients $\{h_k\}$ in a vector $h'_{k'}$ by

$$h_{(k_1,k_2)} = h'_{k'}, \quad k' = k_1 + (n+1)k_2,$$

i.e., the subvectors of length $n+1$ correspond to coefficents h_k on the same line in Figure 1, then the full Jacobian J has the following block structure:

$$J = \left(\begin{array}{ccccccc} 1 & \cdots & \cdots & \cdots & \cdots & \cdots & 1 \\ 2D_0,\ldots,2D_n & 0 & \cdots & \cdots & \cdots & \cdots & 0 \\ & & & & & & \\ J_0 & & & & & & \\ & J_1 & & & & & \\ & & J_2 & & & & \\ & & & J_1 & & & \\ & & & \cdots & \cdots & \cdots & \\ & & & & & J_2 & \\ & & & & & & J_1 \end{array}\right).$$

For $N = 2$, we obtain a 14×16 matrix. We collect some results concerning J_1 and J_2. Similar matrices occur in the dyadic construction of $\varphi(x)$ [5].

LEMMA 3.5. *Let J_1 and J_2 be defined as above, $n = 2N-1$.*

(a) *J_1 is a regular matrix, and*

(b) *J_2 has rank n and $x = (x_j)_{j=0,\ldots,n}$, $x_j = (-1)^j d_{n-j}$, satisfies*

$$J_2 x = 0.$$

Proof. Let b^j, $j = 1,\ldots,(n+1)/2$, denote the jth line vector of J_1. Since $d_n \neq 0$, these vectors are linearly independent. Since $d_0 \neq 0$, we conclude that the other line vectors, where c^j, $j = 1, \ldots, (n+1)/2$, denotes the $(n+2-j)$th line vector of J_1, are also linearly independent.

The spans of the two sets of vectors are orthogonal since ($d_\ell = 0$ if $\ell < 0$ or $\ell > n$)

$$\begin{aligned}\langle b^j, c^i \rangle &= \sum_{k=0}^{n} d_{k+n-2(j-1)} d_{k+n-2(n+1-i)} \\ &= \sum_{k=0}^{n} d_k d_{k+2(j-1-n-1+i)},\end{aligned}$$

and the orthogonality of the Daubechies scaling function gives ($\ell \neq 0$)

$$\begin{aligned}0 &= \langle \varphi_N(\cdot), \varphi_N(\cdot - \ell) \rangle \\ &= 4 \sum_{k,m=0}^{n} d_k d_m \langle \varphi_N(2 \cdot -k), \varphi_N(2 \cdot -2\ell - m) \rangle \\ &= 4 \sum_{k=0}^{n} d_k d_{k-2\ell}.\end{aligned}$$

The indices i and j run between 1 and $(n+1)/2$; hence $\ell = j - n + i - 2 \leq -1$ and

$$\langle b^j, c^i \rangle = 0.$$

Hence the $(n+1)$ line vectors $\{b^j, c^j\}$ of J_1 are linearly independent; this proves (a).

In the same manner, we prove that the line vectors of J_2 are linearly independent. It remains to construct a nonzero vector in the kernel of J_2. Here we exploit the fact that

$$\forall \ell : \langle \varphi_N(\cdot),\ \psi_N(\cdot - \ell) \rangle = 0.$$

Inserting the 1D scaling relations yields

$$\begin{aligned}0 &= \sum_{m,k} d_k (-1)^m d_{1-m} \langle \varphi_N(2 \cdot -k), \varphi_N(2 \cdot -2\ell - m) \rangle \\ &= \sum (-1)^k d_k d_{1+2\ell-k}.\end{aligned}$$

The ith coefficient of $J_2 x$ is

$$\begin{aligned}(J_2 x)_i &= \sum d_{k+n-1-2i} (-1)^k d_{n-k} \\ &= \sum_{k=0}^{n} (-1)^{n-k} d_{-k+2n-2i-1} d_k \\ &= 0.\end{aligned}$$

This proves (b). □

In order to apply the implicit-function theorem to

$$F : I\!R^{(n+1)^2} \longrightarrow I\!R^{n^2+n+2}, \qquad F(H_N) = 0,$$

we need to find $n-1$ "free" coefficients $x = (h_{f_1}, \ldots, h_{f_{N-1}})$ such that the remaining "dependent" coefficients $y = (h_{e_1}, \ldots, h_{e_{N^2+N+2}})$ have a regular Jacobian $\frac{\partial F}{\partial y}(H_N)$. Unfortunately, this is not possible.

LEMMA 3.6. *For any choice of $(n-1)$ coefficients $x = (h_{f_1}, \dots, h_{f_{N-1}})$, the Jacobian of F at H_N with respect to the remaining dependent coefficients $y = (h_{d_1}, \dots, h_{d_{N^2+N+2}})$ is singular.*

Proof. $H_N(\omega)$ satisfies the orthogonality condition (15); hence $H(0) = 1$ and

$$H_N(\pi) = \sum_{k=0}^{n} d_k e^{-ik\pi} = 0.$$

It follows that the odd and even coefficients of H_N both sum up to $1/2$.

In each column of J_1 and J_2, either all odd or all even d_n's occur exactly once. Therefore, the sum of the line vectors of J_1 or J_2 is the vector $(1/2, \dots, 1/2)$. The same is true if we combine the second row of J with J_0. We see that the first row vector of J equals the sum of the other rows.

But $\frac{\partial F}{\partial y}(H_N)$ is the submatrix of J formed by those columns of F which correspond to coefficients in y. This does not change the sum of the rows of $\frac{\partial F}{\partial y}(H_N)$, i.e., the first row of $\frac{\partial F}{\partial y}(H_N)$ is a linear combination of the other rows and $\frac{\partial F}{\partial y}(H_N)$ cannot be regular. □

Nevertheless, the hard implicit-function theorem [1] ensures the existence of the implicit function under the given conditions. However, the hard implicit-function theorem is not constructive, i.e., it does not help to compute the tangent vectors of the implicit function. To circumvent this problem, we first solve for the implicit function without the first condition $F_1 : \sum h_k = 1$. $\tilde{F}$ denotes F without the first equation, i.e., we examine

$$\tilde{F} : I\!R^{(n+1)^2} \longrightarrow I\!R^{n^2+n+1} \tag{27}$$

and compute the tangent space at $H_N \in \mathcal{H}_2^N$ of the implicit function defined by

$$\tilde{F}(h) = 0.$$

If we later intersect this tangent space with the hyperplane $\sum h_k = 1$, we will obtain the tangent space of $\mathcal{H}_2$ at H_N.

There is not much choice for the n free coefficients: J_2 occurs $(n-1)/2$ times in J. J_2 has rank deficit 1, i.e., we need to choose one free coefficient for each occurrence of J_2. Combining the first $(n+1)$ entries of the first row of $\tilde{J}$ with J_0 gives a $(n+1)/2$-by-$(n+1)$ matrix, i.e., we have at least $(n+1)/2 = N$ free coefficients among the first $(n+1) = 2N$ coefficients. With our convention for numbering, the first $(n+1)$ coefficients are $m = (m_1, 0), m_1 = 0, \dots, n$. As free coefficients, we choose

$$x = (h_{(0,0)}, \dots, h_{N,0)}, h_{(0,2)}, h_{(0,4)}, \dots, h_{(0,2N-2)});$$

the remaining coefficients are collected in y. Let J_2' denote the matrix J_2 without the first column, and let J_0' denote J_0 without the first N columns: J_0' is an $(N-1) \times N$ matrix; J_2' is a $(2N-1) \times (2N-1)$ matrix; $\frac{\partial \tilde{F}}{\partial y}(H_N)$ is a square matrix with dimension

$4N^2 - 2N + 1 = n^2 + n + 1$:

$$
(28) \qquad \frac{\partial \tilde{F}}{\partial y}(H_N) = \left(\begin{array}{cccccccc}
d_{(n+1)/2}, \dots, d_n & 0 & \cdots & \cdots & \cdots & \cdots & & 0 \\
J_0' & & & & & & & \\
 & J_1 & & & & & & \\
 & & J_2' & & & & & \\
 & & & J_1 & & & & \\
 & & & \cdots & \cdots & \cdots & & \\
 & & & & & & J_2' & \\
 & & & & & & & J_1
\end{array} \right).
$$

We now consider the function

$$g : I\!R^n \longrightarrow I\!R^{n^2+n+1}$$

implicitly defined by $\tilde{F}(x, g(x)) = 0$. In order to obtain the tangent vectors of $\mathcal{H}_2$ at H_N, we compute the Jacobian g according to

$$\nabla g = -\left(\frac{\partial \tilde{F}}{\partial y}\right)^{-1} \frac{\partial \tilde{F}}{\partial x}.$$

$\frac{\partial \tilde{F}}{\partial x}$ consists of those columns of the Jacobian of $\tilde{F}$ which were not used in $\frac{\partial \tilde{F}}{\partial y}$; hence $\frac{\partial \tilde{F}}{\partial x}$ and ∇g are $(n^2 + n + 1) \times n$ matrices. We observe that $\frac{\partial \tilde{F}}{\partial x}$ does not use any columns involving the submatrix J_1, i.e., the rows of $\frac{\partial \tilde{F}}{\partial x}$ corresponding to coefficinets h_k with $k = (k_1, k_2)$, k_2 odd, are all zero. For $N = 2$, we obtain

$$J_2' = \begin{pmatrix} d_3 & 0 & 0 \\ d_1 & d_2 & d_3 \\ 0 & d_0 & d_1 \end{pmatrix},$$

$$\frac{\partial \tilde{F}}{\partial y} = \begin{pmatrix} d_2\, d_3 & 0 & 0 & 0 \\ d_0\, d_1 & 0 & 0 & 0 \\ 0 & J_1 & 0 & 0 \\ 0 & 0 & J_2' & 0 \\ 0 & 0 & 0 & J_1 \end{pmatrix}, \qquad \frac{\partial \tilde{F}}{\partial x} = \begin{pmatrix} d_0 & d_1 & 0 \\ d_2 & d_3 & 0 \\ & \mathcal{O} & \\ 0 & 0 & d_2 \\ 0 & 0 & d_0 \\ 0 & 0 & 0 \\ & \mathcal{O} & \end{pmatrix};$$

here $\mathcal{O}$ denotes a 4×3 matrix with zero entries.

Once we have computed ∇g, the tangent vectors t of $\mathcal{H}_1^N$ at H_N are obtained in the following way. We write the vector t naturally as an array $t = \{t_k \mid k = (k_1, k_2),\ 0 \leq k_1, k_2 \leq (2N-1)\}$. Then $dx = (dx_1, \dots, dx_n)$ corresponds to an array $dx = \{dx_k \mid k = (k_1, k_2),\ 0 \leq k_1, k_2 \leq (2N-1)\}$ whose entries are zero whenever its index k corresponds to a dependent variable y; similarly, the $(n^2 + n + 1)$ vector $\nabla g dx$ corresponds to an array whose entries are zero whenever its index corresponds to a free variable x. With this convention,

$$t = dx + \nabla dx$$

gives a desired tangent vector. In addition, we have to obey the omitted equation $0 = F_1(h) = \sum h_k - 1$. This is satisfied if we restrict the tangent vectors t to the hyperplane

$$\sum_{k\in\mathbb{Z}^2} t_k = 0.$$

LEMMA 3.7. *The tangent vectors $t = \{t_k \mid k = (k_1, k_2)\}$ of $\mathcal{H}_2$ at H_N satisfy*

$$t_k = 0 \quad \textit{if } k_2 \textit{ is odd.}$$

Proof. The derivatives of the implicit function g are the solution of the linear system

$$-\frac{\partial\tilde{F}}{\partial y}\,\nabla g = \frac{\partial\tilde{F}}{\partial x}.$$

(The columns of ∇g are the tangent vectors of g.) This large linear system splits up into smaller linear systems with matrices

$$\begin{pmatrix} d_{\frac{n+1}{2}},\ldots,d_n \\ J_0' \end{pmatrix},\ J_1,\ J_2'.$$

The components of the tangent vectors of g corresponding to odd lines—i.e., k_2 odd—are the solution of the subsystem

$$J_1 z = \mathcal{O}.$$

Lemma 3.6 proves $z = 0$, and hence $t = dx + \nabla g dx$ has zero entries whenever $k = (k_1, k_2)$, k_2 odd. □

Moreover, we can solve the linear systems with matrix J_2' explicitly. This gives the components of the tangent vectors corresponding to coefficients on even lines (k_2 even).

LEMMA 3.8. *Let $z = (z_1, \ldots, z_n)$ denote the solution vector of*

$$J_2' z = \begin{pmatrix} d_{n-1} \\ d_{n-3} \\ \cdot \\ d_0 \\ 0 \\ \cdot \\ \cdot \\ 0 \end{pmatrix}.$$

Then $z_k = (-1)^{k-1}(d_{n-k}/d_n)$, $k = 1, \ldots, n$.

Proof. The Daubechies wavelet ψ_N is orthogonal to the scaling function φ_N:

$$\begin{aligned} 0 &= \langle\psi_N,\ \varphi_N(\cdot-\ell)\rangle \\ &= 4\sum_{m,k} d_k\ (-1)^m d_{1-m}\ \ \langle\varphi_N(2\cdot-m),\ \varphi_N(2\cdot-2\ell-k)\rangle \\ &= 2\sum_{k=0}^{n}(-1)^k d_k d_{1-2\ell-k}. \end{aligned}$$

On the other hand, the entries of the $n \times n$ matrix J_2' are given by

$$(J_2')_{\ell k} = d_{n+1-2\ell+k}, \quad 1 \leq \ell,\ k \leq n.$$

Let z be defined as above:

$$\begin{aligned}(d_n\ J_2'\ z)_\ell &= \sum_{k=1}^{n} d_{n+1-2\ell+k}(-1)^{k-1} d_{n-k} \\ &= \sum_{k=0}^{n-1}(-1)^k\ d_k d_{1-2(\ell-n)-k} \\ &= (-1)^{n+1} d_n d_{1-2(\ell-n)-n} = d_n d_{1+n-2\ell}.\end{aligned}$$

This gives—up to the factor d_n—the desired right-hand side. □

Thus far, we have obtained a complete description of the tangent vectors of the implicit function $g(x)$, i.e., the tangent directions of $\mathcal{H}_2$ at H_N are given by $dx + \nabla g dx$.

THEOREM 3.9. *Let $\mathcal{H}_2^N$ denote the set of coefficients*

$$h = \{h_k \mid k = (k_1, k_2),\ 0 \leq k_1, k_2 \leq n)$$

satisfying the 2D orthogonality relation. Let H_N denote the scaling coefficients associated with the induced 1D Daubechies wavelet ψ_N. The tangent space $\mathcal{T}_N$ of $\mathcal{H}_2^N$ at H_N is the direct sum

$$\mathcal{T}_N = T_1 \bigoplus T_2$$

of the linear spaces T_1 and T_2. T_1 is the induced tangent space of $\mathcal{H}_1^N$, i.e., it contains tangent vectors $t = \{t_k\}$ with $t_{(k_1,k_2)} = 0$ for $k_2 \neq 0$. T_2 is spanned by $(n-1)/2$ vectors t^m, $m = 1, \ldots, (n-1)/2$:

$$t^m = \left\{ t_{(k_1,k_2)} \mid t_{(k_1,k_2)} = \left\{ \begin{array}{cc} (-1)^{k_1-1} d_{n-k_1}, & k_2 = 2m, \\ 0 & elsewhere \end{array} \right\} \right\}.$$

COROLLARY 3.10. *In terms of Fourier polynomials, the tangent vectors at H_N, which are orthogonal to the induced 1D tangent vectors, are linear combinations of*

$$e^{-i2m\omega_2} \cdot G_N(\omega_1), \quad m = 1, \ldots, (n-1)/2,$$

where $G_N(\omega) = \sum_{k=0}^{n}(-1)^k d_{n-k} e^{-ik\omega}$ is the Fourier polynomial of the Daubechies wavelet coefficients.

For $N = 2$, the Daubechies scaling coefficients are explicitly given as

$$8 \begin{pmatrix} d_0 \\ d_1 \\ d_2 \\ d_3 \end{pmatrix} = \begin{pmatrix} 1 \\ 3 \\ 3 \\ 1 \end{pmatrix} + \sqrt{3} \begin{pmatrix} -1 \\ -1 \\ 1 \\ 1 \end{pmatrix}.$$

Remark. These are the coefficients of the scaling equation for the scaling function φ_2. The scaling equation for the wavelet ψ has coefficients $g_k = (-1)^k d_{1-k}$. The connection between wavelet coefficients and central difference quotients can be seen here. The g_k's are a simple combination of the central difference quotient of order 3 and the central difference quotient of order 2 on four points. In a similar way, one can easily parametrize all orthogonal 1D-wavelets by difference quotients.

The tangent vectors of $\mathcal{H}_2$ at H_2 are given by the induced tangent vectors s^1 and s^2,

$$s^1 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & -\sqrt{3} & 1+\sqrt{3} \end{pmatrix}, \quad s^2 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & -1 & 1-\sqrt{3} & \sqrt{3} \end{pmatrix},$$

and the additional tangent vector t^1,

$$t^1 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ -1-\sqrt{3} & 3+\sqrt{3} & -3+\sqrt{3} & 1-\sqrt{3} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

The tangent vectors are given as arrays, with the convention that, e.g., $s^1_{(0,3)} = -t^1_{(2,0)} = 1+\sqrt{3}$, $s^2_{(0,2)} = t^1_{(2,3)} = 1-\sqrt{3}$.

For the proofs of the results above, we used only that H_N satisfies the orthogonality condition (8). Hence the tangent spaces look the same for any induced $H \subset \mathcal{H}_1 \subset \mathcal{H}_2$ with $h_0 \neq 0 \neq h_n$, n odd. No further properties of the Daubechies wavelets were necessary.

Now we start computing the tangent vectors at

$$q(H_N) \in q(\mathcal{H}_2) = \mathcal{K}_{\text{orth}} \subset \mathcal{K}_2,$$

where q is defined by $q(H) = |H|^2$. The tangent vectors of $\mathcal{K}_{\text{orth}}$ at $q(H_N)$ are therefore computed as the linearization of

$$q(H_N(\omega_1) + se^{-i2k\omega_2}\, G_N(\omega_1)).$$

Since $\mathcal{K}_1$ is a flat subset of $\mathcal{K}_{\text{orth}}$, it follows that the Fourier polynomials of the induced 1D tangent vectors are linear combinations of

$$\cos(n\omega_1) - \cos((n-2m)\omega_1), \quad m = 1, \dots, (N-1)/2.$$

THEOREM 3.11. *Let $\{d_k\}$ denote the scaling coefficients of the Daubechies wavelet ψ_N, and define*

$$H_N(\omega_1) = \sum_{k=0}^{n} d_k e^{-ik\omega_1}, \qquad G_N(\omega_1) = \sum_{k=0}^{n} (-1)^k d_{n-k} e^{-ik\omega_1} = e^{-in\omega_1}\overline{H}_N(\omega_1).$$

The Fourier polynomials of the tangent vectors of $\mathcal{K}_{\text{orth}}$ at $q(H_N)$ are linear combinations of the induced 1D tangent vectors with

$$e^{i2k\omega_2}[H_N(\omega_1)\overline{G}_N(\omega_1)] + e^{-i2k\omega_2}[\overline{H}_N(\omega_1)G_N(\omega_1)], \quad k = 1, \dots, (n-1)/2.$$

Our idea was to compute the tangent spaces of $\mathcal{K}_{\text{orth}}$ with the hope that $\mathcal{K}_1$ is not the only flat subspace of $\mathcal{K}_{\text{orth}}$. But numerical tests did not reveal any other flat subspaces. Nevertheless, the simple structure of the tangents at $H_N \in \mathcal{H}_2$ allows us to trace part of H_2 by following the tangent lines.

4. Families of orthogonal 2D wavelets. In the last section, we studied the tangent space of the set $\mathcal{H}_2$ of coefficients $\{h_k\}$ satisfying the 2D orthogonality condition (15). $\mathcal{H}_2$ is not a flat manifold; therefore, starting at $H_N \in \mathcal{H}_2$ and following a tangent t does not lead directly to new wavelets. In this section, we discuss different correction terms c such that

$$H(\omega_1, \omega_2) = H_N(\omega_1) + \mu t + \mu c(\omega_1, \omega_2) \text{ correction term} \in \mathcal{H}_2.$$

Moreover, the orthogonality condition ensures only discrete orthogonality of the coefficient set. In order to prove that the solution of the scaling equation with coefficients $H = \{h_k\} \in \mathcal{H}_2$ is orthogonal to its translates, we also need to check the condition stated in Criterion 2.2; see [4]. However, not only do the Fourier series H_N of the scaling coefficients for the 1D Daubechies wavelets satisfy the 1D Cohen criterion with $K = [-\pi, \pi]$, but we also have

$$\forall m > 0,\ 0 \leq \epsilon < \pi : H_N(2^{-m}\omega_1) \text{ does not vanish on } [-\pi - \epsilon, \pi + \epsilon].$$

This follows directly from Lemma 2.6. This implies for our construction that the 2D Cohen criterion will be satisfied at least for small μ. For a special class of wavelets, see Lemma 4.3, we will check the orthogonality directly.

4.1. Twisted wavelets. Let $n = 2N - 1$ be an odd integer and let $H_0(\omega) \in \mathcal{H}_2$ denote the Fourier polynomial of an orthogonal 1D wavelet with $(n+1)$ coefficients, e.g., the Daubechies wavelets H_N. As shown in the previous section, the Fourier filter of the tangent vector is given by

$$G_0(\tau) = e^{-in\tau}\overline{H}_0(\pi + \tau)$$

—this denotes complex conjugation. The linear combination $H_0(\omega_1) + \mu e^{-i2k\omega_2}G_0(\omega_1)$ proceeds along a tangent line of $\mathcal{H}_2$. In order to stay on $\mathcal{H}_2$, we must add a correction term.

LEMMA 4.1. *Let H_0 and G_0 be defined as above. Define H_1 and G_1 by*

$$H_1(\tau) = (1/2)e^{-in\tau}\{e^{-i\tau}[\overline{H}_0(\tau) - \overline{H}_0(\pi + \tau)] + e^{i\tau}[\overline{H}_0(\tau) + \overline{H}_0(\pi + \tau)]\},$$

$$G_1(\tau) = (1/2)\{e^{i\tau}[H_0(\pi + \tau) - H_0(\tau)] \ + \ e^{-i\tau}[H_0(\pi + \tau) + H_0(\tau)]\}.$$

For any $k \in \mathbb{Z}$, $\mu \in \mathbb{R}$, the Fourier filter $m(\omega_1, \omega_2)$ defined by

$$(1 + \mu^2)\ m(\omega_1, \omega_2) = H_0(\omega_1) + \mu e^{-i2k\omega_2}G_0(\omega_1) - \mu\{G_1(\omega_1) - \mu e^{-i2k\omega_2}H_1(\omega_1)\}$$

is a solution of the 2D orthogonality condition, i.e., it constitutes a QMF.

Remark. H_1 also satisfies the 1D orthogonality condition, and G_1 is the corresponding tangent vector. The coefficients of H_1 come from a simple twist of the coefficients of H_0: if we pair the coefficients of H_0, i.e., $(h_{(0,0)}, h_{(1,0)}), (h_{(2,0)}, h_{(3,0)}), \ldots,$ $(h_{(n-1,0)}, h_{(n,0)})$, and reverse these pairs and their order, i.e.,

$$(h_{(n-1,0)}, h_{(n,0)}),\ (h_{(n-3,0)}, h_{(n-2,0)}), \ldots, (h_{(0,0)}, h_{(1,0)}),$$

then we obtain the coefficients of H_1.

Proof. It is a lengthy but easy calculation to show that m obeys the 2D orthogonality relation: the summands of $|m|^2$ are, e.g., of the form

$$2G_0\overline{H}_1(\tau) = e^{i\tau}\{H_0(\tau)\overline{H}_0(\pi+\tau) + |H_0(\pi+\tau)|^2\} + e^{-i\tau}\{H_0(\tau)\overline{H}_0(\pi+\tau) - |H_0(\pi+\tau)|^2\}.$$

It follows that

$$(G_0\overline{H}_1 + \overline{G}_0 H_1)(\tau) + (G_0\overline{H}_1 + \overline{G}_0 H_1)(\tau + \pi) = 0.$$

The other terms are treated in the same way. □

For these Fourier series, the coefficients are concentrated on two lines, namely $(m_1, 0)$ and $(m_1, 2k)$. Alterations of the above procedure lead to more equally spread coefficients, e.g.,

$$\begin{aligned}&(1+\mu^2)m(\omega_1,\omega_2)\\ &\quad = H_0(\omega_1) + \mu e^{-i(3\omega_2+\omega_1)}G_0(\omega_1) - \mu\{e^{-i(\omega_1+\omega_2)}G_1(\omega_1) - \mu e^{-i2\omega_2}H_1(\omega_1)\}.\end{aligned}$$

These series also solve the orthogonality relation.

Another class of trigonometric polynomials satisfying the orthogonality condition with a more convenient description can be found as follows.

THEOREM 4.2. *Let $H(\omega) \in \mathcal{H}_1$ denote the Fourier series of the scaling coefficients $\{h_k \mid k = 0, \dots, n\}$, n odd, for an orthogonal 1D wavelet. Denote the tangent vector by $G(\tau)$. Let P and Q be (π, π)-periodic trigonometric polynomials in (ω_1, ω_2) satisfying*

$$|P|^2 + |Q|^2 = 1, \qquad P(0) = 1.$$

Then

$$m(\omega_1, \omega_2) = P(\omega_1, \omega_2)\ H(\omega_1) \ +\ Q(\omega_1, \omega_2) G(\omega_1)$$

satisfies the 2D orthogonality relation, i.e., m constitutes a QMF.

Proof. Obviously

$$|m|^2 = |P|^2|H|^2 + |Q|^2|G|^2 + PH\overline{QG} + \overline{PH}QG.$$

Therefore, exploiting the periodicity of P and Q and the orthogonality of H leads to

$$\begin{aligned}&|m(\omega_1,\omega_2)|^2 + |m(\omega_1+\pi,\omega_2+\pi)|^2\\ &\quad = |P(\omega_1,\omega_2)|^2 + |Q(\omega_1,\omega_2)|^2 + (P\overline{Q})(\omega_1,\omega_2)[H\overline{G}(\omega_1) + H\overline{G}(\pi+\omega_1)]\\ &\qquad\qquad + (\overline{P}Q)(\omega_1,\omega_2)[\overline{H}G(\omega_1) + \overline{H}G(\pi+\omega_1)].\end{aligned}$$

n is odd and $G(\tau) = e^{-in\tau}\overline{H}(\pi + \tau)$. Therefore, the terms in the brackets vanish. □

Of course, this family of nonseparable QMF filters could have been found directly, but the structure of the tangent space inspired this choice. The relation for P and Q looks rather similar to the 2D orthogonality condition, but P and Q do not have to be related by a shift of the argument. For example, we can choose $|P|^2$ to be a power of $\cos(x)$ and construct the corresponding Q with the help of the Fejer–Riesz theorem (Theorem 2.4). This opens a way of controlling the zeros of m and might be helpful in constructing smooth wavelets for the quincunx grid.

We have to show that these Fourier series satisfy the 2D Cohen criterion. We will single out a special class and prove the orthogonality of the wavelets directly.

LEMMA 4.3. *Let H_N denote the Fourier series of the scaling coefficients for the 1D Daubechies wavelet ψ_N. As usual, $G_N(\omega)$ denotes the tangent vector. Let*

$$P(\omega_2) = H_N(2\omega_2) \quad \textit{and} \quad Q(\omega_1, \omega_2) = e^{i(\omega_1+\omega_2)}G_N(2\omega_2).$$

Then

$$m(\omega_1,\omega_2) = P(\omega_2)H_N(\omega_1) \ + \ Q(\omega_1,\omega_2)G_N(\omega_1)$$

is the Fourier series of the scaling coefficients for a compactly supported orthogonal 2D wavelet for the dilation matrix $A = \left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$.

Remarks. The exponential factor $e^{i(\omega_1+\omega_2)}$ can be replaced by any $e^{i(k_1\omega_1+k_2\omega_2)}$, where $k_1, k_2 \in \mathbb{Z}$, $k_1 + k_2$ are even, and $2k_1 - k_2 = 1$ or 2. Moreover, generalizations to other dilation matrices A with $|\det(A)| = 2$ are obvious.

Proof. We have to check the Cohen criterion. m has a set of trivial zeros at

$$(2n\pi, \pi/2 \ + k\pi), \ ((2n+1)\pi, \ k\pi), \quad k, n \in \mathbb{Z}.$$

If (ω_1, ω_2) is a nontrivial zero of m, then

$$|H_N(2\omega_2)|^2 |H_N(\omega_1)|^2 = |H_N(\pi + 2\omega_2)|^2 |H_N(\pi + \omega_1)|^2$$

or

$$\frac{|H_N(2\omega_2)|^2}{|H_N(\pi + 2\omega_2)|^2} = \frac{|H_N(\pi + \omega_1)|^2}{|H_N(\omega_1)|^2}.$$

$q = |H_N|^2$ is monotonically decreasing on $[0, \pi]$, $q(0) = 1$, $q(\pi) = 0$, q is an even function, and q' is a multiple of $\sin^{2N-1}(\omega)$. Hence there is no zero outside the lines

$$\omega_2 = \pm(1/2)(\omega_1 - \pi) + k\pi, \quad k \in \mathbb{Z}.$$

The lines $\omega_2 = -(1/2)(\omega_1 - \pi) + k\pi$ may be excluded since N is odd, $\overline{H}(\omega) = H(-\omega)$:

$$m(\omega_1, -(1/2)(\omega_1 - \pi) + k\pi) = H_N(\omega_1)H_N(\pi - \omega_1)[1 - e^{i(\omega_1/2+\pi/2+k\pi)}],$$

which is nonzero unless ω_1 is an odd multiple of π.

We have to find a set K congruent to $[-\pi, \pi]^2$ where $\hat{\varphi}$, a solution of the scaling equation with coefficients given by m, does not vanish. The Fourier transform of the scaling equation gives

$$\hat{\varphi}(\omega_1, \omega_2) = \prod_{j>0} m\left((A^t)^{-j} \begin{pmatrix} \omega_1 \\ \omega_2 \end{pmatrix}\right). \tag{29}$$

The previous consideration restricts zeros to lines

$$\omega_2 = (1/2)(\omega_1 - \pi) + k\pi$$

and their images under $(A^t)^j$. These lines intersect $[-\pi, \pi]^2$ at four line segments. Translating those line segments by $(0, 2\pi)$ yields a set K such that m does not vanish on $(A^t)^{-j}K$ with the possible exception of the critical points

$$\left(\frac{4}{5}\pi, \frac{2}{5}\pi\right), \ \left(\frac{2}{5}\pi, -\frac{4}{5}\pi\right), \ \left(-\frac{2}{5}\pi, \frac{4}{5}\pi\right), \ \left(-\frac{4}{5}\pi, -\frac{2}{5}\pi\right). \tag{30}$$

At these points,

$$|P(\omega_2)H_N(\omega_1)| \neq |Q(\omega_1, \omega_2)G(\omega_1)|, \quad \text{i.e.,} \quad m \neq 0.$$

Hence we have constructed a set K where $\hat{\varphi}$ does not vanish. A standard argument as in the proof of Lemma 3.1 of [6] shows that $\hat{\varphi}$ is bounded away from 0 on K. □

Naturally, we are interested in differentiable wavelets. The critical points in (30) form an orbit under the action of $A = \left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$. Hence we can obtain upper bounds for the smoothness of φ by applying the techniques of [4, Chaps. II.3.b and IV.3.b]. Also, generalizations of the methods introduced by T. Eirola [8] and L. Villemoes [18] to higher dimension will lead to Sobolev estimates for φ. However, preliminary calculation did not reveal any canonical candidates for smooth wavelets among the members of the family of wavelets described above. However, following Theorem 4.2, we have some freedom in choosing P and Q such that, e.g., m has a zero of a specified order at (π, π).

4.2. α-wavelets. In this section, we develop an iterative procedure for constructing QMFs, i.e., solutions of the 2D orthogonality condition. We again begin with an induced 1D wavelet and proceed along the tangential direction at this point. This implies that we obtain orthogonal wavelets for at least small values of the tangent parameter.

We begin by investigating Fourier filters with 16 coefficients $\{h_m \mid m = (m_1, m_2),\ 0 \le m_1, m_2 \le 3\}$. The results of §3 show that if we proceed along the tangential directions t, then

$$t_m = 0 \quad \text{if } m_1 \text{ is odd.}$$

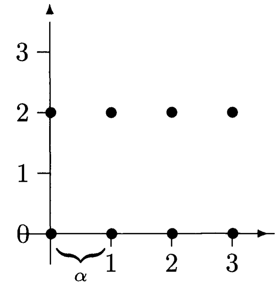

FIG. 2.

The position of the remaining eight coefficients in the grid $\mathbb{Z}^2$ are marked in Figure 2. These eight coefficients are grouped in pairs of two. In particular, the first two coefficicients on the baseline form the pair $\alpha = (h_{(0,0)}, h_{(1,0)})$.

Up to normalization the four coefficients on the baseline should satisfy the 1D orthogonality condition; this implies

$$(h_{(2,0)}, h_{(3,0)}) = \lambda\ \alpha^{\perp} = \lambda(-h_{(1,0)}, h_{(0,0)}).$$

Now we add a multiple of the tangent vector in line $m_2 = 2k$ and adjust α in order to satisfy the 2D orthogonality condition.

THEOREM 4.4. *Let $\alpha = (h_{(0,0)}, h_{(1,0)})$ and $\lambda, \mu \in \mathbb{R} \cup \{\pm\infty\}$ and define $\alpha^{\perp} = (-h_{(1,0)}, h_{(0,0)})$,*

$$h_2^{\alpha} = \begin{pmatrix} 0 & 0 \\ -\lambda\mu\alpha & \mu\alpha^{\perp} \\ 0 & 0 \\ \alpha & \lambda\alpha^{\perp} \end{pmatrix}. \tag{31}$$

If

$$\alpha = \frac{1}{2(1+\lambda^2)(1+\mu^2)}(1-\lambda\mu+\lambda+\mu,\ 1-\lambda\mu-\lambda-\mu),$$

then the Fourier series of h satisfies the 2D orthogonality relation.

Proof. Let H denote the Fourier filter of h and let $q = |H|^2$. We have to check that $q \in \mathcal{K}_2$, i.e., the coefficients of $\cos(k \cdot \omega)$, $k = (k_1, k_2) \neq (0,0)$ even, have to vanish. We can phrase this condition differently: the discrete convolution of h_2^α with itself has to vanish except at the origin. Since $\alpha \cdot \alpha^\perp = 0$, this is obviously the case.

We have two degrees of freedom left, i.e., $(h_{(0,0)}, h_{(1,0)})$, and we have to satisfy two more conditions:

$$\sum_m h_m = 1, \qquad \sum_m h_m^2 = 1/2.$$

The first conditon restricts $(h_{(0,0)}, h_{(1,0)})$ to a line in $\mathbb{R}^2$:

$$h_{(0,0)}(1-\lambda\mu+\lambda+\mu) + h_{(1,0)}(1-\lambda\mu-\lambda-\mu) = 1;$$

the second condition restricts $(h_{(0,0)}, h_{(1,0)})$ to a circle:

$$(h_{(0,0)}^2 + h_{(1,0)}^2)(1+\lambda^2)(1+\mu^2) = 1/2.$$

We show that the line is a tangent to the circle, i.e., the point on the line with minimal distance from the origin is also a point on the circle. Obviously, the α given in the theorem is the point on the line with minimal distance from the origin. We compute its norm:

$$\begin{aligned} \| \alpha \|_2^2 &= \frac{1}{4(1+\lambda^2)^2(1+\mu^2)^2}\{(1-\lambda\mu+\lambda+\mu)^2 + (1-\lambda\mu-\lambda-\mu)^2\} \\ &= \frac{1}{2(1+\lambda^2)(1+\mu^2)}. \qquad \square \end{aligned}$$

The pair of parameters $(\lambda, \mu) = (2+\sqrt{3}, 0)$ leads to the Daubechies wavelet ψ_2.

Remark. We can generate more QMFs by shifting the indices of the coefficients $(-\lambda\mu\alpha, \mu\alpha^\perp)$ in the line $m_2 = 2$ of h_2^α. Shifts of $\ell = (\ell_1, \ell_2)$ lead to coefficients satisfying the orthogonality relation as long as $\ell \neq (-2, 2k)$ and $\ell_1 + \ell_2$ is even. For example, let $\alpha = (\alpha_1, \alpha_2)$ and $\ell = (-1, 1)$; then

$$h = \begin{pmatrix} 0 & -\lambda\mu\alpha_1 & -\lambda\mu\alpha_2 & -\mu\alpha_2 & \mu\alpha_1 \\ \alpha_1 & \alpha_2 & -\lambda\alpha_2 & \lambda\alpha_1 & 0 \end{pmatrix}$$

defines a QMF. More possibilities arise from splitting $(-\lambda\mu\alpha, \mu\alpha^\perp)$ into its two components

$$\beta = -\lambda\mu\alpha \quad \text{and} \quad \gamma = \mu\alpha^\perp$$

and shifting both components separately by ℓ_β and ℓ_γ. The resulting set of coefficients h still satisfies the 2D orthogonality condition as long as $\ell_\beta \neq (-2, 2k)$, $\ell_\gamma \neq (-2, 2k)$, $\ell_\beta \neq \ell_\gamma + (2, 0)$. For example, $\ell_\beta = (1, -1)$ and $\ell_\gamma = (-1, -3)$ lead to

$$\tilde{h} = \begin{pmatrix} 0 & -\lambda\mu\alpha_1 & -\lambda\mu\alpha_2 & 0 \\ \alpha_1 & \alpha_2 & -\lambda\alpha_2 & \lambda\alpha_1 \\ 0 & -\mu\alpha_2 & \mu\alpha_1 & 0 \end{pmatrix}.$$

COROLLARY 4.5. *This set of coefficients $\tilde{h}$ is—up to normalization—identical to the family of QMF filters studied in* [11]. *In particular, the choice $(\lambda,\mu) = (-2+\sqrt{3}, -\sqrt{3})$ leads to a wavelet for the quincunx grid which is known to be continuous* [18].

Now we start iterating the procedure above. First, we choose arbitrary nonzero values for $\lambda = \mu_1, \mu_2, \ldots, \mu_l$ and compute. Let $h_2^\alpha = [h_2^0, h_2^1]$ denote the full set of coefficients, where $h_2^0 = (\alpha, \lambda\alpha^\perp)$ denotes the set of coefficients on the baseline and $h_2^1 = (-\mu_2\lambda\alpha, \mu_2\alpha^\perp)$ denotes the coefficients on the line $m_2 = 2k$. The iteration produces a family of coefficient sets $\{h_l^\alpha = [h_l^0, \mu_l h_l^1] \mid l \in N\}$ by

$$h_l^0 = (h_{l-1}^0,\ h_{l-1}^1),$$

$$h_l^1 = \left(-\mu_{l-1}\mu_l h_{l-1}^0, \frac{\mu_l}{\mu_{l-1}} h_{l-1}^1\right).$$

It follows by induction that

$$\begin{aligned} \|h_l^1\|_2^2 &= \mu_{l-1}^2\mu_l^2\|h_{l-1}^0\|_2^2 + \frac{\mu_l^2}{\mu_{l-1}^2}\|h_{l-1}^1\|_2^2 \\ &= \mu_l^2\|h_{l-1}^1\|_2^2 + \mu_l^2\|h_{l-1}^0\|_2^2 && (32) \\ &= \mu_l^2\|h_l^0\|_2^2. && (33) \end{aligned}$$

The question remains of how to choose values for $\alpha = (\alpha_1, \alpha_2)$. To this end, we introduce the auxiliary values

$$n_l^{01}, n_l^{02}, n_l^{11}, n_l^{12},$$

recursively defined by

$$n_1^{01} = 1, \qquad n_1^{02} = 1, \qquad n_1^{11} = \lambda, \qquad n_1^{12} = -\lambda,$$

$$n_l^{01} = n_{l-1}^{01} + n_{l-1}^{11}, \qquad n_l^{02} = n_{l-1}^{02} + n_{l-1}^{12},$$

$$n_l^{11} = \mu_l\left(-\mu_{l-1}n_{l-1}^{01} + \frac{1}{\mu_{l-1}}n_{l-1}^{11}\right), \qquad n_l^{12} = \mu_l\left(-\mu_{l-1}n_{l-1}^{02} + \frac{1}{\mu_{l-1}}n_{l-1}^{12}\right).$$

Then we define the vectors n_l and α by

$$n_l = \begin{pmatrix} n_l^{01} + n_l^{11} \\ n_l^{02} + n_l^{12} \end{pmatrix}, \qquad \alpha = \frac{n_l}{\|\, n_l \,\|_2^2}.$$

The procedure for constructing h_l^α starts by choosing arbitrary values $\lambda = \mu_1, \mu_2, \ldots, \mu_l$; then n_l, α, h_l^0, and h_l^1 are computed.

THEOREM 4.6. *The set of coefficients h_l^α satisfies the 2D orthogonality condition.*

Proof. The proof requires several induction arguments.

First, we have to check whether

$$\sum_{m\in\mathbb{Z}} (h_l^\alpha)_m = 1, \qquad \sum_{m\in\mathbb{Z}} (h_l^\alpha)_m^2 = 1/2. \tag{34}$$

From the definitions of $h_l^0, h_l^1, n_l^{01}, n_l^{02}, n_l^{11}$, and n_l^{12}, we easily deduce by induction that for any choice of $\alpha = (\alpha_1, \alpha_2)$, we have

$$\sum (h_l^0)_m = n_l^{01}\alpha_1 + n_l^{02}\alpha_2,$$

$$\sum (h_l^1)_m = n_l^{11}\alpha_1 + n_l^{12}\alpha_2.$$

Therefore, we easily obtain

$$\sum_{m\in\mathbb{Z}} (h_l^\alpha)_m = \sum (h_l^0)_m + \sum (h_l^1)_m = \alpha \cdot n_l = 1.$$

With the help of (32), we see that

$$\begin{aligned}\sum_{m\in\mathbb{Z}} (h_l^\alpha)_m^2 &= \sum (h_l^0)_m^2 + \sum (h_l^1)_m^2 \\ &= (1+\mu_l^2\mu_{l-1}^2)\sum (h_{l-1}^0)_m^2 + (1+\mu_l^2/\mu_{l-1}^2)\sum (h_{l-1}^1)_m^2 \\ &= (1+\mu_l^2)\sum_{m\in\mathbb{Z}} (h_{l-1}^\alpha)_m^2 \\ &= (1+\mu_l^2)\cdot\dots\cdot(1+\mu_2^2)(1+\lambda^2)(\alpha_1^2+\alpha_2^2) \\ &= (1+\mu_l^2)\cdot\dots\cdot(1+\mu_2^2)(1+\lambda^2)/\parallel n_l \parallel_2^2.\end{aligned}$$

The auxiliary values have been chosen such that (proof by induction)

$$n_l^{11} = \mu_l n_l^{02}, \qquad n_l^{12} = -\mu_l n_l^{01},$$

$$\parallel n_l \parallel_2^2 = (1+\mu_l^2) \parallel n_{l-1} \parallel_2^2, \qquad \parallel n_1 \parallel_2^2 = 2(1+\lambda^2).$$

The geometric interpretation of the above says that the equations in (34) restrict the choice of $\alpha = (\alpha_1, \alpha_2)$ to the intersection of a straight line with a circle. Incidentially, the line is tangential to the circle as in Theorem 4.5.

Finally, we have to check that the expansion of $|H|^2$ contains no even cos terms. However, let q denote the square modulus of the Fourier series associated with h_l^α. The terms $\cos(m\cdot\omega)$ for an even $m \neq (0,0)$ vanish by the same convolution argument as in the proof of Theorem 4.5. The only critical term is the coefficient of $\cos(2k\omega_2)$. The coefficient of $\cos(2k\omega_2)$ is given by

$$\langle h_l^1, h_l^0\rangle = -\mu_l\mu_{l-1}\langle h_{l-1}^0, h_{l-1}^0\rangle + \frac{\mu_l}{\mu_{l-1}}\langle h_{l-1}^1, h_{l-1}^1\rangle = 0.$$

The last equality follows from (32). □

Acknowledgments. The author would like to thank the referees for their careful reading of the manuscript and their suggestions for improving this paper.

DIMENSION AND LOCAL BASES OF HOMOGENEOUS SPLINE SPACES*

PETER ALFELD†, MARIAN NEAMTU‡, AND LARRY L. SCHUMAKER§

Abstract. Recently, we have introduced spaces of splines defined on triangulations lying on the sphere or on sphere-like surfaces. These spaces arose out of a new kind of Bernstein–Bézier theory on such surfaces. The purpose of this paper is to contribute to the development of a constructive theory for such spline spaces analogous to the well-known theory of polynomial splines on planar triangulations. Rather than working with splines on sphere-like surfaces directly, we instead investigate more general spaces of homogeneous splines in $\mathbb{R}^3$. In particular, we present formulas for the dimensions of such spline spaces, and construct locally supported bases for them.

Key words. multivariate splines, piecewise polynomial functions, homogeneous spline spaces, dimensions, sphere-like surfaces, sphere, interpolation, approximation, data fitting

AMS subject classifications. 41A63, 41A15, 65D07

1. Introduction. Let $\Delta := \{T^{[i]}\}_1^N$ be a planar triangulation of a set Ω, and let $0 \leq r \leq d$ be integers. The classical *space of splines of degree d and smoothness r* is defined by

$$\mathcal{S}_d^r(\Delta) := \{s \in C^r(\Omega) \ : \ s|_{T^{[i]}} \in \mathcal{P}_d, \quad i = 1, \ldots, N\}, \tag{1}$$

where $\mathcal{P}_d$ is the space of bivariate polynomials of degree at most d. These spaces of spline functions have found numerous applications in interpolation, data fitting, finite element solutions of boundary-value problems, computer aided geometric design, image processing, and elsewhere.

There is a well-developed (albeit incomplete) constructive theory for the polynomial spline spaces $\mathcal{S}_d^r(\Delta)$ which includes

(1) dimension formulas,
(2) construction of local bases,
(3) estimates on the approximation power,
(4) algorithms for manipulating the splines,
(5) algorithms for interpolation, data fitting, etc.

Recently [4], we introduced analogous spaces of splines defined on a triangulation on the sphere or on a sphere-like surface. As suggested by our companion paper [6], we believe that such spaces have important applications, and hence it is important to develop the analogous constructive theory.

Following [4], we will analyze spherical splines by investigating a more general class of splines associated with a *trihedral decomposition* $\mathcal{T} := \{T^{[i]}\}_1^N$ of a set $\Omega \subseteq \mathbb{R}^3$

(see §2 below). Given such a decomposition, the associated spaces of *homogeneous splines* are defined by

$$\mathcal{H}_d^r(\mathcal{T}) := \{s \in C^r(\Omega) : s|_{T^{[i]}} \in \mathcal{H}_d, \quad i = 1, \dots, N\}, \tag{2}$$

where $\mathcal{H}_d$ denotes the space of trivariate polynomials of degree d which are homogeneous of degree d (recall that a function f defined on $\mathbb{R}^3$ is *homogeneous of degree* d provided $f(\alpha v) = \alpha^d f(v)$ for all real numbers α and all $v \in \mathbb{R}^3$). Splines on the sphere or on a sphere-like surface S are then obtained by restricting $\mathcal{H}_d^r(\mathcal{T})$ to S.

The main purpose of this paper is to establish dimension formulas for spaces of homogeneous splines and to show how to construct bases of locally supported splines. Homogeneous splines can be stored and evaluated using the algorithms presented in [4] for homogeneous polynomials. The question of the approximation power of homogeneous and spherical splines will be dealt with elsewhere. Applications to the interpolation and fitting of scattered data on the sphere or on a sphere-like surface are discussed in [6]. Even though we are working in $\mathbb{R}^3$, because of the nature of homogeneous polynomials—which are essentially bivariate functions—the entire development is closely modelled after the analysis of the bivariate spaces of splines $\mathcal{S}_d^r(\Delta)$ carried out in [8, 15, 16, 17].

2. Homogeneous spline spaces. We begin by introducing some notation, closely following [4].

DEFINITION 1. *Let $\{v_1, v_2, v_3\}$ be a set of linearly independent unit vectors in $\mathbb{R}^3$. We call*

$$T = \{v \in \mathbb{R}^3 : v = b_1 v_1 + b_2 v_2 + b_3 v_3 \quad \textit{with} \quad b_i \geq 0\} \tag{3}$$

the trihedron generated by $\{v_1, v_2, v_3\}$. *As in* [4], *we call the real numbers b_1, b_2, b_3 the* trihedral coordinates *of v with respect to T. They are homogeneous linear functions in the coordinates of v.*

We call the set $\{v \in T : b_i = 0\}$ the (ith) *face* of T, and the set $\{\alpha v_i : \alpha \geq 0\}$ the (ith) *ray* of T (or the ray generated by v_i). To avoid awkward repetitions, we abuse our notation slightly: in addition to writing v for a unit vector, we also use v to denote the associated point in $\mathbb{R}^3$ and the associated ray generated by v.

DEFINITION 2. *Let $\mathcal{T} = \{T^{[i]}\}_{i=1}^N$ be a nonempty set of trihedra, and let $\Omega := \cup T^{[i]}$. Then we call $\mathcal{T}$ a* trihedral decomposition of Ω *provided that*

(1) *the interiors of the trihedra in $\mathcal{T}$ are pairwise disjoint*;

(2) *the set $\Omega \cap S$ is homeomorphic to a two-dimensional disk or equals S, where S is the unit sphere*;

(3) *each face of a trihedron in $\mathcal{T}$ is either on the boundary of Ω or it is a common face of precisely two trihedra in $\mathcal{T}$.*

Each of the $T^{[i]} \cap S$ is a spherical triangle, and $\Delta = \{T^{[i]} \cap S\}_{i=1}^N$ is a *spherical triangulation*; cf. [19]. We say a trihedral decomposition $\mathcal{T}$ is *total* if $\Omega = \mathbb{R}^3$. Otherwise, we say that it is *partial.*

It will be convenient to denote the set of unit vectors defining the rays of the trihedra in $\mathcal{T}$ by $\mathcal{V}$. If $\mathcal{T}$ is a partial trihedral decomposition, it is natural to define rays to be *boundary rays* of $\mathcal{T}$ provided they are associated with vectors $v \in \mathcal{V}$ which lie on the boundary of Ω. All other rays will be called *interior rays.* We denote the sets of boundary and interior rays in $\mathcal{T}$ by $\mathcal{V}_B$ and $\mathcal{V}_I$, respectively. Clearly, all rays of a total trihedral decomposition are interior rays. Following the notation used for planar triangulations, we denote the number of boundary and interior rays of $\mathcal{T}$ by

V_B and V_I, respectively. Similarly, we denote the number of boundary and interior faces of $\mathcal{T}$ by E_B and E_I. For a partial decomposition, the number of rays is given by $V := V_B + V_I$, and the number of faces is given by $E := E_B + E_I$. For a total decomposition, $V = V_I$ and $E = E_I$.

Let T be a trihedron generated by $\{v_1, v_2, v_3\}$, and let b_1, b_2, b_3 denote the corresponding trihedral coordinates as functions of $v \in \mathbb{R}^3$. The *homogeneous Bernstein basis polynomials of degree d associated with* T are the polynomials

$$B^d_{ijk}(v) := \frac{d!}{i!j!k!} b_1^i b_2^j b_3^k, \qquad i+j+k=d, \tag{4}$$

which closely resemble bivariate Bernstein basis polynomials [12, 13, 14].

The space $\mathcal{H}_d$ of trivariate homogeneous polynomials is a $\binom{d+2}{2}$-dimensional linear space, and, as observed in [4], it is spanned by the set of $\binom{d+2}{2}$ Bernstein basis polynomials defined in (4). Thus each $p \in \mathcal{H}_d$ can be written uniquely in the form

$$p(v) = \sum_{i+j+k=d} c_{ijk} B^d_{ijk}(v). \tag{5}$$

In [4], p is referred to as a *homogeneous Bernstein–Bézier (HBB) polynomial of degree d.*

It will be convenient to define the *domain points* associated with T to be the points

$$P_{ijk} := \frac{iv_1 + jv_2 + kv_3}{d}, \qquad i+j+k=d. \tag{6}$$

In contrast to the case of polynomial splines on planar triangles, this definition of P_{ijk} is not the only natural one (see Remark 24 in §9).

If we look at all of the domain points for all of the trihedra in a trihedral decomposition, it is clear that the domain points associated with a common face of two trihedra coincide. If we eliminate such repetitions, we see that for a given trihedral decomposition $\mathcal{T}$, there are one point associated with each ray, $d-1$ points associated with each face, and $\binom{d-1}{2}$ associated with the interior of each trihedron. Thus the set $\mathcal{G}$ of distinct domain points has cardinality

$$\#(\mathcal{G}) = V + (d-1)E + \binom{d-1}{2} N. \tag{7}$$

The importance of the HBB form of homogeneous polynomials is that it provides a simple way to describe when two such polynomials defined on adjoining trihedra join together smoothly. Indeed, suppose $T^{[1]}$ and $T^{[2]}$ are two trihedra generated by the sets $\{v_1, v_2, v_3\}$ and $\{v_1, v_3, v_4\}$, respectively. Then as shown in [4], the two associated homogeneous polynomials $p^{[1]}$ and $p^{[2]}$ of degree d agree on the face shared by $T^{[1]}$ and $T^{[2]}$ in value and all derivatives up to order r if and only if

$$c^{[2]}_{ijk} = \sum_{\mu+\nu+\kappa=k} c^{[1]}_{i+\mu,\nu,j+\kappa} B^k_{\mu\nu\kappa}(v_4) \quad \text{for all} \quad k \le r, \quad i+j+k=d, \tag{8}$$

where $B^k_{\mu\nu\kappa}$ are the Bernstein basis polynomials of degree k associated with $T^{[1]}$.

By (8), $p^{[1]}$ and $p^{[2]}$ join *continuously* across their common face if and only if

$$c^{[2]}_{ij0} = c^{[1]}_{i0j}, \qquad i + j = d. \tag{9}$$

We conclude that a spline $s \in \mathcal{H}^0_d(\mathcal{T})$ is uniquely defined by a set of $\#(\mathcal{G})$ coefficients, one associated with each point $P \in \mathcal{G}$. This implies that the space $\mathcal{H}^0_d(\mathcal{T})$ has dimension $\#(\mathcal{G})$.

For later use, for each $P \in \mathcal{G}$, it will be convenient to define a linear functional λ_P defined on $\mathcal{H}^0_d(\mathcal{T})$ with the property that for any $s \in \mathcal{H}^0_d(\mathcal{T})$,

$$\lambda_P s = c_P, \tag{10}$$

where c_P is the coefficient associated with the point P. We denote the set of all such linear functionals by Λ. Clearly, $\#(\Lambda) = \#(\mathcal{G})$.

For each $\lambda \in \Lambda$, there is a unique spline $s_\lambda \in \mathcal{H}^0_d(\mathcal{T})$ such that

$$\gamma s_\lambda = \delta_{\gamma,\lambda}, \quad \text{all } \gamma \in \Lambda. \tag{11}$$

The spline s_λ has all coefficients equal to 0 except for the coefficient λs_λ which has value 1. By construction, s_λ has one of the following supports:

(1) a single trihedron T if the coefficient λs_λ is associated with a domain point in the interior of T;

(2) a pair of adjoining trihedra if the coefficient λs_λ is associated with a domain point in the interior of a face separating two trihedra;

(3) the union of all trihedra which share the ray v if the coefficient λs_λ is associated with the domain point v.

In view of these properties, we say that such splines have *local support*. The duality property (11) assures that the splines s_λ for $\lambda \in \Lambda$ are linearly independent, and since there are precisely $\#(\mathcal{G})$ of them, they form a basis for $\mathcal{H}^0_d(\mathcal{T})$.

To obtain analogous results for $\mathcal{H}^r_d(\mathcal{T})$, we follow [8, 15, 17]. To get an upper bound on dimension, we construct a *determining set* $\Gamma \subset \Lambda$ such that if $s \in \mathcal{H}^r_d(\mathcal{T})$,

$$\gamma s = 0 \quad \text{for all} \quad \gamma \in \Gamma \qquad \text{implies} \qquad s \equiv 0. \tag{12}$$

Then as shown in [8], $\dim \mathcal{H}^r_d(\mathcal{T})$ is bounded above by the cardinality of Γ. We can get a lower bound for the dimension (and construct a basis at the same time) if Γ is chosen so that for each $\lambda \in \Gamma$, there exists a spline $s_\lambda \in \mathcal{H}^r_d(\mathcal{T})$ satisfying

$$\gamma s_\lambda = \delta_{\gamma,\lambda}, \quad \text{all } \gamma \in \Gamma. \tag{13}$$

This duality implies that the splines $\{s_\lambda\}$ are linearly independent, and it follows that the dimension of $\mathcal{H}^r_d(\mathcal{T})$ is equal to the cardinality of Γ and that these splines form a basis. Such a set Γ is called a *minimal determining set.*

We close this section by presenting the main result of the paper. Its proof will be developed in the following sections.

THEOREM 3. *Let* $r \geq 0$ *and* $d \geq 3r + 2$. *Suppose* $\mathcal{T}$ *is a trihedral decomposition of a set* $\Omega \subseteq \mathbb{R}^3$. *Let*

$$\sigma := \sum_{v \in \mathcal{V}_I} \sigma_v, \quad \textit{where} \quad \sigma_v := \sum_{m=1}^{d-r} (r + m + 1 - me_v)_+ \tag{14}$$

and e_v is the number of distinct planes containing the faces that meet at the ray v. Then

$$\dim \mathcal{H}_d^r(\mathcal{T}) = (d-r)(d-2r)V - 2d^2 + 6dr - 3r^2 + 3r + 2 + \sigma \tag{15}$$

if $\mathcal{T}$ is a total decomposition, and

$$\begin{aligned} \dim \mathcal{H}_d^r(\mathcal{T}) =& \frac{(d-r+1)(d-r)}{2} V_B + (d-r)(d-2r)V_I \\ & - \frac{2d^2 - 6dr + 3r^2 - 3r - 2}{2} + \sigma \end{aligned} \tag{16}$$

if $\mathcal{T}$ is a partial decomposition. In either case, there exists a basis for $\mathcal{H}_d^r(\mathcal{T})$ consisting of splines such that the support of each spline is either a single trihedron, an adjoining pair, or the set of trihedra containing a single ray.

3. Minimal determining sets for splines on oranges.

In [8, 15], the key to analyzing the dimension of bivariate spline spaces was first to examine the special case of a *cell* consisting of a set of triangles sharing one vertex. In this section, we construct minimal determining sets for spline spaces on the trihedral analog of cells. In the context of tetrahedral decompositions, these were called oranges in [10, 20]. Throughout this section, we assume only that $0 \le r < d$.

DEFINITION 4. *A trihedral decomposition $\mathcal{O}$ consisting of a set of trihedra sharing one ray v is called an* orange. *We call v the axis of the orange*; *see Fig.* 1.

Suppose the trihedra in $\mathcal{O}$ are labeled in counterclockwise order as $T^{[1]}, T^{[2]}, \dots, T^{[N]}$ as we move around the axis v, where the rays of $T^{[\ell]}$ are v, v_ℓ, and $v_{\ell+1}$. If v is an interior ray, we have $v_{N+1} = v_1$. We can label the domain points in these trihedra as

$$P_{ijk}^{[\ell]} := \frac{iv + jv_\ell + kv_{\ell+1}}{d}, \qquad i+j+k = d. \tag{17}$$

THEOREM 5. *If $\mathcal{O}$ is an orange associated with a boundary ray v, then*

$$\dim H_d^r(\mathcal{O}) = \binom{d+2}{2} + (N-1)\binom{d-r+1}{2}. \tag{18}$$

If $\mathcal{O}$ is an orange associated with an interior ray v, then

$$\dim \mathcal{H}_d^r(\mathcal{O}) = \binom{r+2}{2} + N\binom{d-r+1}{2} + \sum_{m=1}^{d-r} (r+m+1-me)_+, \tag{19}$$

where e denotes the number of distinct planes shared by trihedra in $\mathcal{O}$.

Proof. Let Π be a plane which intersects the axis of $\mathcal{O}$ at a point w which is not the origin, and so that Π is perpendicular to the axis. The intersections with Π of those faces of $\mathcal{O}$ which contain the axis are rays in Π emanating from w. If we replace them with unit line segments with one end at w and then connect their endpoints in order, we get a planar triangulation Δ consisting of a set of triangles sharing the vertex w. Clearly, the restriction of a spline in $\mathcal{H}_d^r(\mathcal{O})$ to Δ is a spline in $\mathcal{S}_d^r(\Delta)$. Conversely, by the homogeneity of the splines in $\mathcal{H}_d^r(\mathcal{O})$, a spline in $\mathcal{S}_d^r(\Delta)$ extends uniquely to a spline in $\mathcal{H}_d^r(\mathcal{O})$. The two spaces $\mathcal{S}_d^r(\Delta)$ and $\mathcal{H}_d^r(\mathcal{O})$ are therefore isomorphic, and the dimension assertion follows from Theorem 2.2 in [17]. □

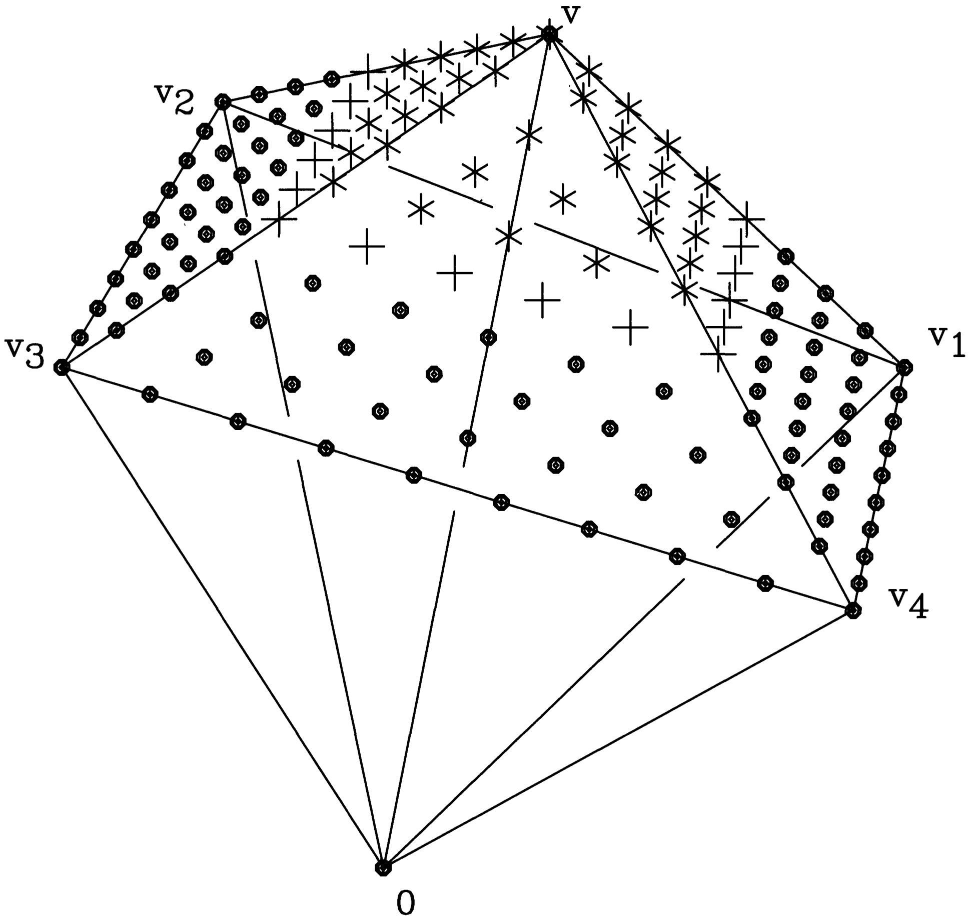

FIG. 1. *An orange with axis v.*

Following the proofs of Lemma 3.1 in [15] and Lemma 3.1 in [8], we now construct minimal determining sets for $\mathcal{H}_d^r(\mathcal{O})$ when $\mathcal{O}$ is an orange. We need the concept of a ring of domain points around a ray v.

DEFINITION 6. *Let $\mathcal{O}$ be an orange as above. Then given an integer d, the* mth ring *of $\mathcal{O}$ is the set of domain points*

$$\left\{P^{[\ell]}_{d-m,j,k} : j+k=m,\ \ell=1,2,\ldots,N\right\}. \tag{20}$$

*The m-*disk *in $\mathcal{O}$ is the union of the* 0*th through mth rings.*

The concepts of ring and disk are illustrated in Fig. 1. In particular, the domain points in the 5-ring around the vertex v in the figure are marked with + signs. The domain points in the 5-disk include all points marked with * or with +. To avoid cluttering the picture, the domain points in the far face (with vertices v, v_1, and v_2) have been omitted.

THEOREM 7. *Suppose $\mathcal{O}$ is an orange associated with a boundary ray v. Then the set*

$$\left\{P^{[1]}_{ijk} : i+j+k=d\right\} \cup \bigcup_{\ell=2}^{N} \left\{P^{[\ell]}_{ijk} : k \geq r+1\right\} \tag{21}$$

is a minimal determining set for $\mathcal{H}^r_d(\mathcal{T})$. Suppose $\mathcal{O}$ is an orange surrounding an interior ray v, and let e be as in Theorem 5. *Let*

$$\mu_{N-e+1} < \mu_{N-e+2} < \cdots < \mu_{N-1} = N, \quad \mu_N = N+1, \tag{22}$$

be such that the associated edges are pairwise noncollinear, and let

$$\mu_1 < \mu_2 < \cdots < \mu_{N-e} \tag{23}$$

be the complementary set so that

$$\{\mu_1, \mu_2, \ldots, \mu_N\} = \{2, 3, \ldots, N+1\}. \tag{24}$$

Let $\Gamma_0 \subseteq \Lambda$ be the set of functionals corresponding to domain points in the trihedron $T^{[1]}$. In addition, for each $m = 1, \ldots, d-r$, let Γ_m be the set of functionals corresponding to the first $Nm - (r+m+1) + (r+m+1-me)_+$ points in the ordered set

$$\{P^{[\mu_1]}_{d-m-r,m-1,r+1}, \ldots, P^{[\mu_1]}_{d-m-r,0,m+r}, \ldots, P^{[\mu_N]}_{d-m-r,m-1,r+1}, \ldots, P^{[\mu_N]}_{d-m-r,0,m+r}\}. \tag{25}$$

Then

$$\Gamma = \bigcup_{m=0}^{d-r} \Gamma_m \tag{26}$$

is a minimal determining set for $H^r_d(\mathcal{O})$.

Proof. We prove the result only for the case where the axis of the orange is an interior ray; the other case is similar. It is easy to check that the cardinality of Γ is given by the formula (19), and so we only need to show that Γ is a minimal determining set. To that end, consider the plane Π that is perpendicular to the vector v and passes through the point v. Explicitly,

$$\Pi = \left\{u \in \mathbb{R}^3 : (u-v)\cdot v = 0\right\}, \tag{27}$$

where $\cdot$ denotes the ordinary dot product. Let w_ℓ denote the orthogonal projection of v_ℓ onto Π, i.e.,

$$w_\ell = v_\ell + \left(1 - \frac{v_\ell \cdot v}{v \cdot v}\right) v, \quad \ell = 1, 2, \ldots, N. \tag{28}$$

The intersection of $\mathcal{O}$ with Π forms a two-dimensional cell Δ in the sense of [17]. Let Γ_Δ denote the functionals defined on $S^r_d(\Delta)$ corresponding to the projections of the points defining Γ. In view of the correspondence between bivariate polynomials and trivariate homogeneous polynomials, by Theorem 3.3 of [17], Γ_Δ is a (minimal) determining set of $S^r_d(\Delta)$. The fact that Γ is a determining set for $\mathcal{H}^r_d(\mathcal{O})$ now follows from a careful comparison of the smoothness conditions for $S^r_d(\Delta)$ and $\mathcal{H}^r_d(\mathcal{O})$. Any spline $s \in \mathcal{H}^0_d(\mathcal{O})$ can be expressed on the trihedron $T^{[\ell]}$ in the form (5) with $c_{ijk} = c^{[\ell]}_{ijk}$. To obtain the smoothness conditions for $\mathcal{H}^r_d(\mathcal{O})$, we write

$$v_{\ell+1} = r_\ell v + s_\ell v_{\ell-1} + t_\ell v_\ell, \tag{29}$$

where for convenience we treat all rays, domain points, and coefficients cyclically as we move around v (so that $v_0 = v_N$ for example). By (8), a spline in $H_d^0(\mathcal{O})$ belongs to $H_d^r(\mathcal{O})$ if and only if for all $\ell = 1, 2, \ldots, N$,

$$c_{ijk}^{[\ell+1]} = \sum_{\mu+\nu+\kappa=k} c_{i+\mu,\nu,j+\kappa}^{[\ell]} \frac{k!}{\mu!\nu!\kappa!} r_\ell^\mu s_\ell^\nu t_\ell^\kappa \tag{30}$$

for $k \leq r$ and $i + j + k = d$. Consider now the corresponding smoothness conditions for $S_d^r(\Delta)$. It can be checked that the projections of the v_ℓ satisfy

$$w_{\ell+1} = \tilde{r}_\ell v + s_\ell w_{\ell-1} + t_\ell w_\ell, \tag{31}$$

where

$$\tilde{r}_\ell := 1 - s_\ell - t_\ell. \tag{32}$$

Using a tilde to denote the coefficients of a spline in $S_d^r(\Delta)$, we obtain the conditions

$$\tilde{c}_{ijk}^{[\ell+1]} = \sum_{\mu+\nu+\kappa=k} \tilde{c}_{i+\mu,\nu,j+\kappa}^{[\ell]} \frac{k!}{\mu!\nu!\kappa!} \tilde{r}_\ell^\mu s_\ell^\nu t_\ell^\kappa, \qquad \ell = 1, \ldots, N. \tag{33}$$

We now show that Γ is a determining set for $\mathcal{H}_d^r(\mathcal{O})$. Consider a spline $s \in \mathcal{H}_d^r(\mathcal{O})$. We work our way through the rings of the orange. The 0th ring is v itself. It is in Γ and therefore the coefficient corresponding to it must be zero. Suppose now that the coefficients corresponding to the first m rings are all zero and consider the $(m+1)$th ring and the smoothness conditions (30) and (33) for $k = m$. In spite of r_ℓ and $\tilde{r}_\ell$ being different, these equations are equivalent since the terms where $r_\ell \neq 0$ and $\tilde{r}_\ell \neq 0$ contain coefficients which are zero by the induction hypothesis. Thus the coefficients of s must vanish on the $(m+1)$th ring and it follows that Γ is a determining set. Since it has cardinality equal to the dimension of $H_d^r(\mathcal{O})$, it follows that Γ is minimal. □

Remark 8. The argument used in the proof of Theorem 7 applies to all minimal determining sets which have $\#\Gamma_m$ points on the $(r+m)$th ring for $m = 1, \ldots, d-r$. However, it is not true in general that the analogue of a minimal determining set for a two-dimensional cell is also a minimal determining set for a corresponding orange as is shown in the following example.

Example 9. Let $\mathcal{O}$ be an orange with $N = 4$, $v_3 = -v_1$ and $v_4 = -v_2$.

Discussion. Figure 2 shows a minimal determining set for $S_2^1(\Delta)$ that is not determining for $H_2^1(\mathcal{O})$, where points corresponding to functionals not in the set are marked with a dot, and the functionals corresponding to all other points are in the set. Note that in particular the functional corresponding to the center point (which is at v) is *not* in the set. Clearly, in the two-dimensional cell, the coefficients at the points marked with a crosshair ($\oplus$) or a triangle ($\triangle$) determine the coefficient at v. In fact, we have

$$\bar{c}_v = \frac{\bar{c}_\oplus + c_\triangle}{2}. \tag{34}$$

On the other hand, the relevant smoothness condition for $H_2^1(\mathcal{O})$ is

$$c_\oplus = -c_\triangle, \tag{35}$$

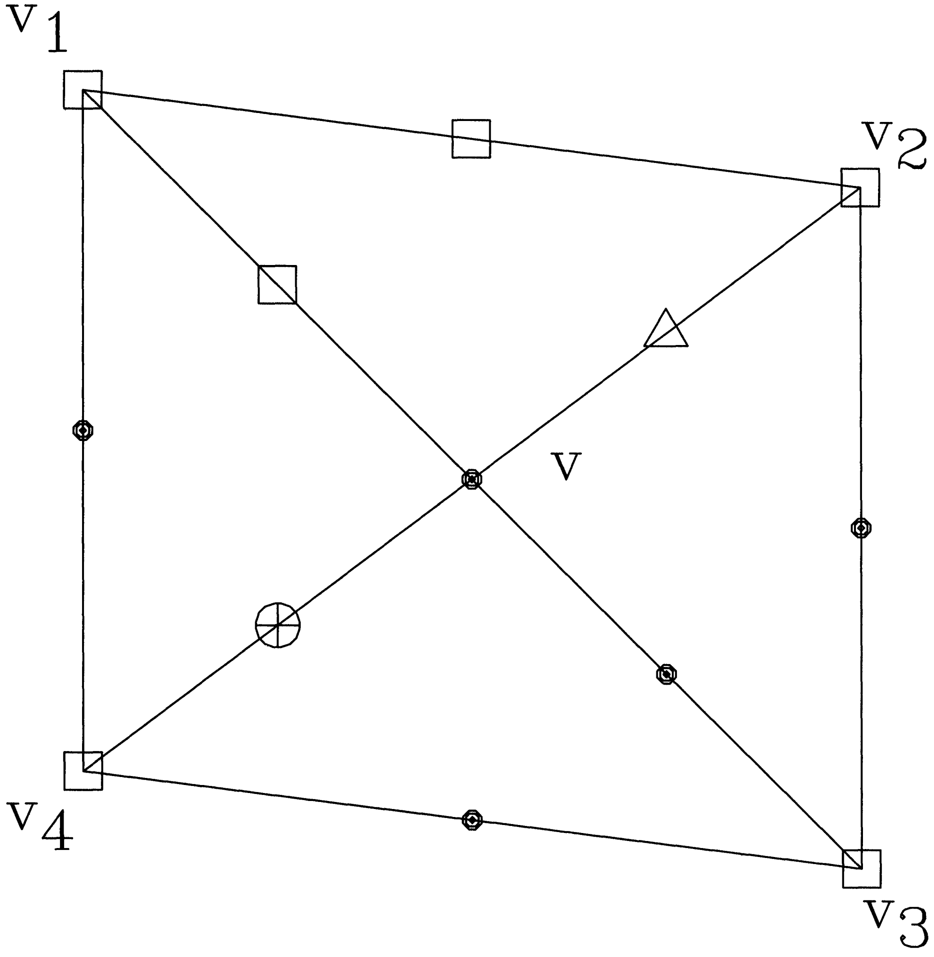

FIG. 2. *A nondetermining set.*

and so the two points marked with $\oplus$ or $\triangle$ cannot both be in the minimal determining set. It is of course easy to construct sets that are minimal determining for both $S_2^1(\Delta)$ and $H_2^1(\mathcal{O})$. An example (conforming to Theorem 7) can be obtained from Fig. 2 by replacing the point marked with $\oplus$ with v. □

4. A minimal determining set for $\mathcal{H}_d^r(\mathcal{T})$ when $d \geq 3r+2$. In this section, we construct a minimal determining set Γ for $\mathcal{H}_d^r(\mathcal{T})$ in the case where $d \geq 3r+2$. As in the bivariate case [8, 15], the key to the construction is to partition the Bézier coefficients into suitable subsets. Consider a trihedron T generated by the vectors v_1, v_2, v_3, and let $\mathcal{P} := \{P_{ijk}\}_{i+j+k=d}$ be the associated set of Bézier coefficients. To make the description of Γ easier, we recall the correspondence between coefficients, domain points, and the associated linear functionals,

$$c_{ijk} \sim P_{ijk} \sim \lambda_{P_{ijk}}, \tag{36}$$

and work only with domain points P_{ijk} here. We define the *distance of P_{ijk} from the* *ray* v to be

$$\text{dist}\,(P_{ijk}, v) := \begin{cases} d-i & \text{if } v = v_1, \\ d-j & \text{if } v = v_2, \\ d-k & \text{if } v = v_3. \end{cases} \tag{37}$$

For $i = 1, 2, 3$, let

$$\begin{aligned} \text{‘}\mathcal{D}_\mu(v_i) &:= \big\{P \in \mathcal{P} : \text{dist}(P, v_i) \le \mu\big\}, \\ \mathcal{A}(v_i) &:= \big\{P \in \mathcal{P} : \text{dist}(P, v_i) > \mu,\ \text{dist}(P, v_{i+1}) \ge d - r, \\ &\qquad\qquad \text{dist}(P, v_{i+2}) \ge d - r\big\}, \\ \mathcal{F}(v_i) &:= \big\{P \in \mathcal{P} : \text{dist}(P, v_i) \ge d - r\big\}, \\ \mathcal{E}(v_i) &:= \big\{P \in \mathcal{F}(v_i) : |\text{dist}(P, v_{i+1}) - \text{dist}(P, v_{i+2})| \le d - 3r - 2\big\}, \\ \mathcal{B}_L(v_i) &:= [\mathcal{F}(v_i) \cap \mathcal{D}_{2r}(v_{i+1})] \setminus [\mathcal{D}_\mu(v_{i+1}) \cup \mathcal{A}(v_{i+1}) \cup \mathcal{E}(v_i)], \\ \mathcal{B}_R(v_i) &:= [\mathcal{F}(v_i) \cap \mathcal{D}_{2r}(v_{i+2})] \setminus [\mathcal{D}_\mu(v_{i+2}) \cup \mathcal{A}(v_{i+2}) \cup \mathcal{E}(v_i)], \\ \mathcal{C} &:= \big\{P \in \mathcal{P} : \text{dist}(P, v_j) < d - r,\ \ j = i, i+1, i+2\big\}, \end{aligned} \tag{38}$$

where

$$\mu := r + \left\lfloor \frac{r+1}{2} \right\rfloor, \tag{39}$$

and we identify $v_4 = v_1$ and $v_5 = v_2$.

The set $\mathcal{D}_\mu(v_i)$ contains the points in a disk around v_i of radius μ. $\mathcal{A}(v_i)$ (called a *cap* in [15]) is the set of points not in $\mathcal{D}_\mu(v_i)$ but whose corresponding coefficients are involved in smoothness conditions of order up to r across the two faces sharing v_i. The sets $\mathcal{E}(v_i)$, $\mathcal{B}_L(v_i)$, and $\mathcal{B}_R(v_i)$ include only domain points whose corresponding coefficients are involved in smoothness conditions across the face opposite the ray v_i. Finally, $\mathcal{C}$ corresponds to coefficients which do not enter any smoothness conditions.

In Fig. 3, we have marked the domain points associated with one trihedron for the case $d = 23$ and $r = 6$ to show which of the above sets they belong to. Dots correspond to points in the sets $\mathcal{D}_\mu(v_i)$, circles to points in the sets $\mathcal{E}(v_i)$, asterisks to points in the caps $\mathcal{A}(v_i)$, plus signs to points in the sets $\mathcal{B}_L(v_i)$ and $\mathcal{B}_R(v_i)$, and ×'s to points in the set $\mathcal{C}$.

As in the bivariate case, in order to describe a minimal determining set for $\mathcal{H}_d^r(\mathcal{T})$, we have to take account of certain degenerate faces. In [15], an edge F of a planar triangulation is defined to be degenerate at one of its endpoints v if the edges preceding and succeeding F and connected to v are collinear. We require a similar concept for trihedral decompositions.

Definition 10. *Let F be an interior face of a trihedral decomposition $\mathcal{T}$, and let v be one of the two rays generating it. We say that F is* degenerate *at v if the faces other than F of the two trihedra sharing F and meeting in v are coplanar.*

We also need to adapt the familiar concept of a singular vertex.

Definition 11. *An interior ray v of a trihedral decomposition $\mathcal{T}$ is said to be* singular *if it has precisely four faces meeting at v which lie in two distinct planes.*

In contrast to the planar case where an edge can be degenerate at only one endpoint, for trihedral decompositions, it is possible for a face to be degenerate at both of the rays defining it, see Example 19 below. We are now ready to describe a minimal determining set Γ for $\mathcal{H}_d^r(\mathcal{T})$ in the case $d \ge 3r + 2$.

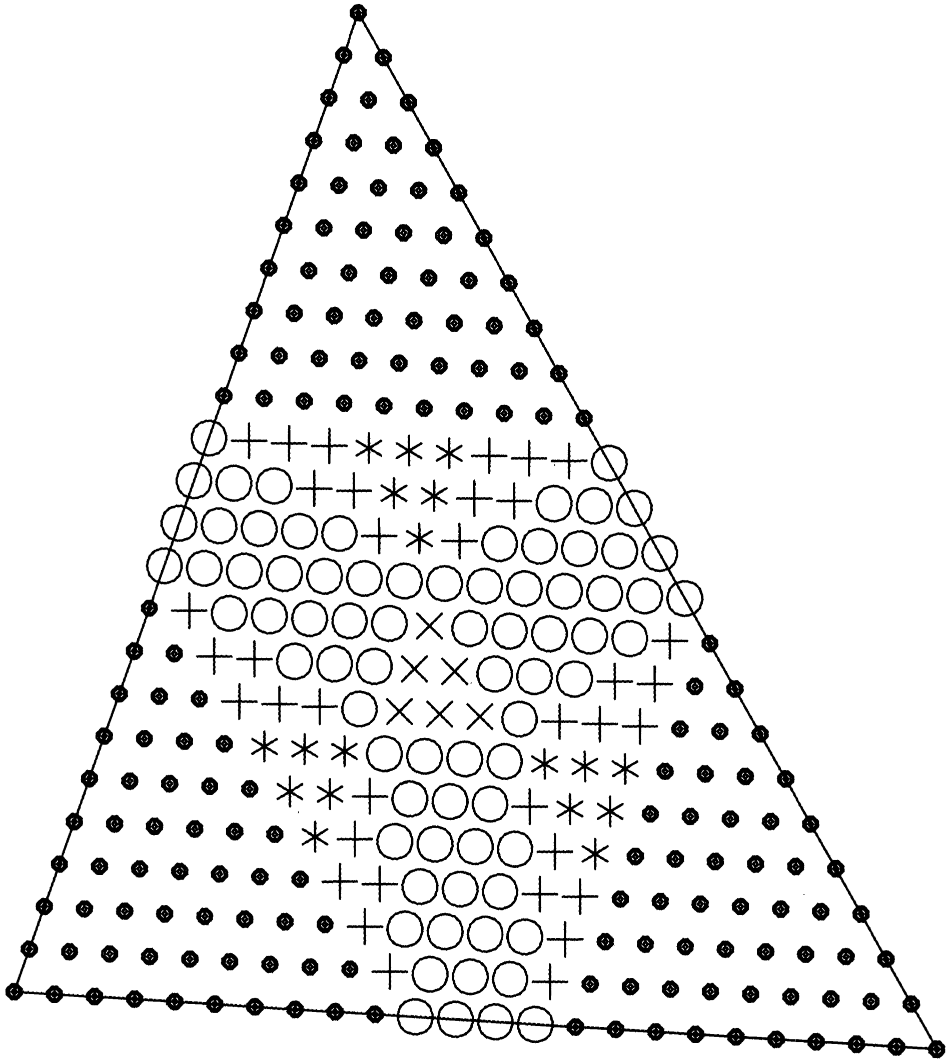

FIG. 3. *Division of domain points by Algorithm* 12; $d = 23$, $r = 6$, $\mu = 9$.

ALGORITHM 12. If $d \geq 3r + 2$, choose the set Γ as follows:

(1) For each *interior ray* v of $\mathcal{T}$, choose a minimal determining set as described in Theorem 7 for the space $\mathcal{H}_d^r(\mathcal{T})$ restricted to the μ-disk of $\mathcal{O}_v$, where $\mathcal{O}_v$ is the orange surrounding v.

(2) For each *boundary ray* v of $\mathcal{T}$, choose a minimal determining set as described in Theorem 7 for the space $\mathcal{H}_d^r(\mathcal{T})$ restricted to the μ-disk of $\mathcal{O}_v$, where $\mathcal{O}_v$ is the orange containing v.

(3) For each *trihedron* T in $\mathcal{T}$, choose the functionals corresponding to $\mathcal{C}$ and all three of the sets $\mathcal{A}(v_i)$ associated with T.

(4) For each *face* F in T, include the functionals corresponding to the set $\mathcal{E}(v)$ associated with a ray v in an adjoining trihedron and opposite to F. If F is a boundary face, there is only one such trihedron, while if it is an interior face, we can work with either of the two trihedra sharing it. If F is a boundary face, also include

the functionals associated with the two sets $\mathcal{B}_L(v)$ and $\mathcal{B}_R(v)$.

(5) Suppose that v is an interior vertex and that m of the faces attached to v are degenerate at v. Then for each such face F, remove the functionals corresponding to the cap nearest to v in the triangle preceding F (in counterclockwise order), and replace them by the functionals in the set $\mathcal{B}_L$ associated with F and lying in the same triangle. If F is degenerate at both of its ends, carry out this step at each end. It is easy to see that m can only be 1, 2, or 4. For an illustration of this step in the case $m = 1$, see Figs. 1 and 2 in [15]).

(6) If v is singular, add the functionals corresponding to one cap $\mathcal{A}(v)$ in one of the trihedra containing v.

THEOREM 13. *Let $\mathcal{T}$ be a trihedral decomposition and let $d \geq 3r+2$ and $r \geq 0$. Then the set Γ constructed in Algorithm* 12 *is a minimal determining set for $\mathcal{H}_d^r(\mathcal{T})$, and its cardinality is given by* (15) *if $\mathcal{T}$ is total and by* (16) *if $\mathcal{T}$ is partial. For each $\lambda \in \Gamma$, there exists a unique spline $s_\lambda \in \mathcal{H}_d^r(\mathcal{T})$ such that* (13) *holds. Then $\{s_\lambda\}_{\lambda\in\Gamma}$ forms a basis for $\mathcal{H}_d^r(\mathcal{T})$ such that the support of each spline is either a single trihedron, an adjoining pair, or an orange.*

Proof. We give the proof only in the case where $\mathcal{T}$ is total since the case where it is partial is very similar. First, we observe that the cardinalities of the sets defined in (38) are as follows:

$$\begin{aligned}
\#\mathcal{D}_\mu(v_i) &= \binom{\mu+2}{2},\\
\#\mathcal{A}(v_i) = \#\mathcal{B}_L(v_i) = \#\mathcal{B}_R(v_i) &= \binom{2r-\mu+1}{2},\\
\#\mathcal{E}(v_i) &= dr+d-12\mu r-3\mu-1+6r^2+4\mu^2,\\
\#\mathcal{C} &= \binom{d-3r-1}{2}.
\end{aligned} \tag{40}$$

Moreover, the sets are pairwise disjoint and their union is the set of all domain points in the trihedron $\mathcal{T}$.

Next, we show that the cardinality of the set Γ is given by (15) when $\mathcal{T}$ is total. It can be shown that in this case

$$N = 2(V-2) \quad\text{and}\quad E = 3(V-2), \tag{41}$$

where E is the number of faces of $\mathcal{T}$. Note that step 5 of Algorithm 12 does not change the cardinality of Γ, and that step 2 does not contribute since there are no boundary rays. With these observations, it follows from Algorithm 12 and Theorem 7 that

$$\begin{aligned}
\#\Gamma = {} & \sum_{v\in\mathcal{V}}\left[\binom{r+2}{2}+E_v\binom{\mu-r+1}{2}+\tilde{\sigma}_v\right] && \text{(step 1)}\\
+ {} & N\left[\binom{d-3r-1}{2}+3\binom{2r-\mu+1}{2}\right] && \text{(step 3)}\\
+ {} & E\left[dr+d-12\mu r-3\mu-1+6r^2+4\mu^2\right] && \text{(step 4)}\\
+ {} & K\binom{2r-\mu+1}{2}, && \text{(step 6)}
\end{aligned} \tag{42}$$

where E_v is the number of interior faces meeting at the ray v, K is the number of singular rays, and

$$\tilde{\sigma}_v := \sum_{m=1}^{\mu-r}(r+m+1-me_v)_+\,. \tag{43}$$

Using

$$\sum_{v\in\mathcal{T}} E_v = 2E \tag{44}$$

and (41), the equality of the right-hand sides of (42) and (15) follows after a straightforward manipulation. (Note that for singular rays, the $\tilde{\sigma}_v$ and the factor multiplying K combine to produce σ_v.)

We now show that Γ is a determining set for $\mathcal{H}_d^r(\mathcal{T})$. In the absence of degenerate faces, this follows as in [15]. For a degenerate face, note that the coefficients corresponding to points in the cap moved in step 5 of Algorithm 12 are implied to be zero by the smoothness conditions (8) across the degenerate face, independent of the possible relocation of other caps.

To complete the proof, we now construct a basis for $\mathcal{H}_d^r(\mathcal{T})$ satisfying (13). Clearly, for a given $\lambda \in \Gamma$, we can set the coefficient $\lambda s = 1$ and all other coefficients corresponding to $\gamma \in \Gamma$ with $\gamma \neq \lambda$ to zero, we can solve for the remaining coefficients using the smoothness conditions. If the domain point P corresponding to λ is contained in a set $\mathcal{C}$, then the resulting spline s_λ has support on the trihedron T containing P. If P is in a set of the form $\mathcal{E}(v_i)$, then s_λ has support on the union of the two trihedra containing the face opposite v_i. In all other cases, s_λ has support on an orange. □

Remark 14. Instead of constructing an explicit basis, it is also possible to prove the dimension statement in Theorem 13 by showing that the expressions in (15) provides a *lower bound* on $\dim \mathcal{H}_d^r(\mathcal{T})$ as was done in [1] in the planar case. This is done by thinking of $\mathcal{H}_d^r(\mathcal{T})$ as a subspace of $\mathcal{H}_d^0(\mathcal{T})$, enforcing the smoothness conditions in the μ-disks via Theorem 7, and then subtracting the number of appropriate smoothness conditions (8) needed to enforce smoothness across the interior faces of $\mathcal{T}$.

5. A minimal determining set for $\mathcal{H}_d^r(\mathcal{T})$ when $d \geq 4r+1$. As in the case of splines defined on a planar triangulation [8], the construction of a minimal determining set can be greatly simplified if $d \geq 4r+1$. In this case, the disks of radius $2r$ around rays of T do not overlap, and the remaining smoothness conditions across faces of $\mathcal{T}$ decouple. In that case, the following much simpler algorithm can be used:

ALGORITHM 15. If $d \geq 4r+1$, choose the set Γ as follows:

(1) For each *interior ray* v of $\mathcal{T}$, choose a minimal determining set for $\mathcal{H}_{2r}^r(\mathcal{O}_v)$ as described in Theorem 7, where $\mathcal{O}_v$ is the orange surrounding v.
(2) For each *boundary ray* v of $\mathcal{T}$, choose a minimal determining set for $\mathcal{H}_{2r}^r(\mathcal{O}_v)$ as described in Theorem 7. where $\mathcal{O}_v$ is the orange containing v.
(3) For each *trihedron* T in $\mathcal{T}$, choose $\mathcal{C}$.
(4) For each *face* in $\mathcal{T}$, choose

$$\tilde{\mathcal{E}}(v_1) = \mathcal{F}(v_1) \setminus [\mathcal{D}_{2r}(v_2) \cup \mathcal{D}_{2r}(v_3)], \tag{45}$$

where v_1, v_2, v_3 define a trihedron such that v_2 and v_3 span the face.

For the case $d = 23$ and $r = 5$, Fig. 4 shows the choice of the domain points for a single trihedron T using Algorithm 15. As in Fig. 3, dots correspond to points in sets of the form $\mathcal{D}_{2r}(v_i)$ and circles correspond to points in $\tilde{\mathcal{E}}(u_i)$, while ×'s mark the points in $\mathcal{C}$.

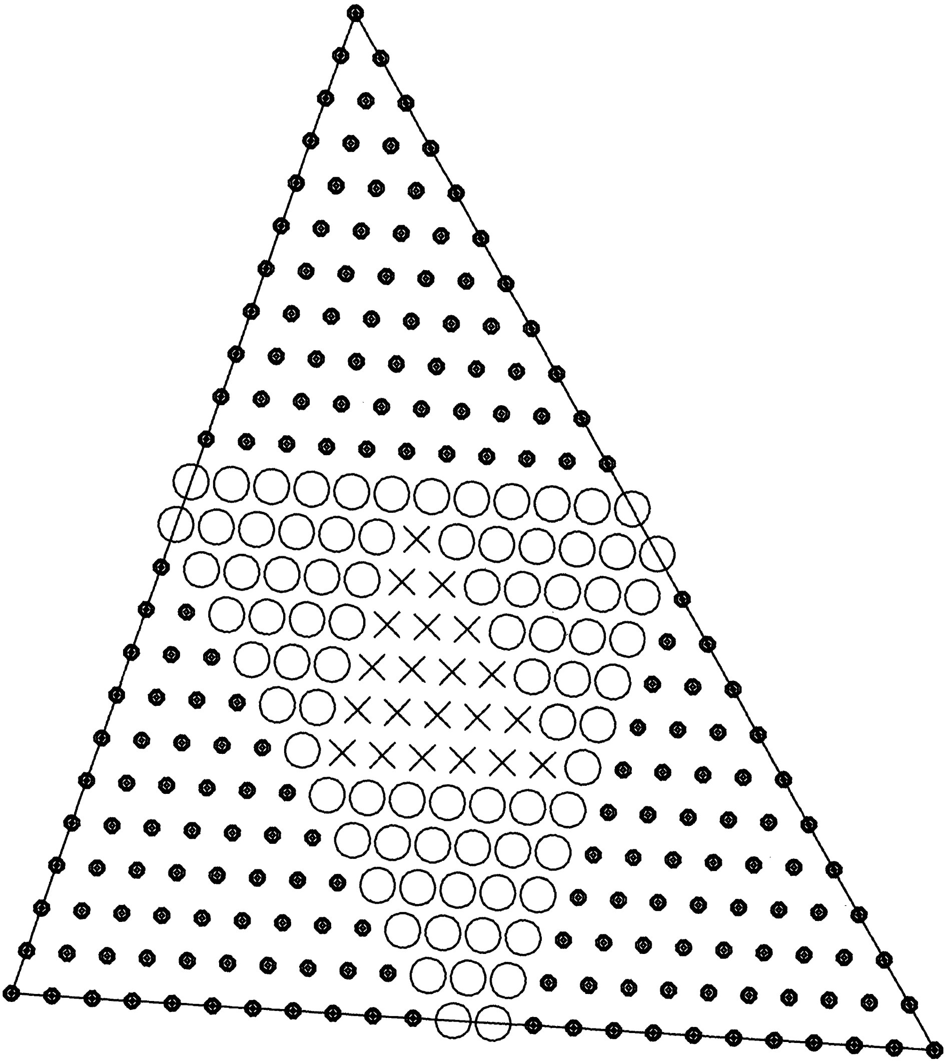

FIG. 4. *Division of domain points by Algorithm* 15; $d = 23$, $r = 5$.

6. The case $d \leq 3r+1$. As in the planar case, it is also possible to treat spline spaces for $d \leq 3r+1$ provided we restrict the class of trihedral decompositions somewhat.

THEOREM 16. *Let $d = 3r+1$, and suppose that the trihedral decomposition $\mathcal{T}$ does not possess any degenerate faces. Then the dimension of $H_{3r+1}^r(\mathcal{T})$ is given by* (15) *or* (16), *depending on whether $\mathcal{T}$ is total or partial. Moreover, there exists a basis with local supports as in Theorem* 13.

Proof. A minimal determining set can be constructed by an obvious adaptation of the prescription given in [9] for the planar case. □

It is also of interest to consider certain generic decompositions; see [11] for the planar case.

DEFINITION 17. *A trihedral decomposition $\mathcal{T}$ is said to be* generic with respect to r and d *provided that for all sufficiently small perturbations of the rays of $\mathcal{T}$, the* *resulting trihedral decomposition* $\tilde{\mathcal{T}}$ *satisfies*

$$\dim H_d^r(\tilde{\mathcal{T}}) = \dim H_d^r(\mathcal{T}). \tag{46}$$

THEOREM 18. *Fix* $d \in \{2,3,4\}$, *and suppose* $\mathcal{T}$ *is a generic trihedral decomposition with respect to* $r = 1$ *and* d. *Then the dimension of* $H_d^1(\mathcal{T})$ *is given by* (15) *or* (16), *depending on whether* $\mathcal{T}$ *is total or not.*

Proof. The space $H_d^1(\mathcal{T})$ is isomorphic to the space $\mathcal{S}_d^1(\Delta)$, where Δ is the generalized triangulation (see [11]) obtained by projecting the points in $\mathcal{V}$ through the origin onto a plane that does not contain the origin and is not parallel to any of the rays in $\mathcal{T}$. The result then follows from Theorems 27 and 33 in [11]. □

The proof of Theorem 18 does not involve finding a minimal determining set. For $d = 4$, it may be possible to construct one using the techniques in [7]. However, in the case $d \in \{2,3\}$, no general procedure for finding a minimal determining set is known even in the (generic) planar case.

7. Doubly degenerate faces. While the structure of bivariate splines on planar triangulations and homogeneous splines on trihedral decompositions in $\mathbb{R}^3$ are very similar, there is a situation which can occur in the homogeneous case but cannot occur in the planar case: it is possible for a face to be degenerate at both rays. We illustrate this in the following example.

Example 19. Let

$$v_i = -v_{i+3} = e_i, \quad i = 1,2,3, \tag{47}$$

where e_i denote the standard unit vectors, and let $\mathcal{T}^*$ be the set of trihedra generated by the sets

$$\begin{array}{llll} \{v_1,v_2,v_3\}, & \{v_1,v_2,v_6\}, & \{v_1,v_3,v_5\}, & \{v_1,v_5,v_6\}, \\ \{v_2,v_3,v_4\}, & \{v_2,v_4,v_6\}, & \{v_3,v_4,v_5\}, & \{v_4,v_5,v_6\}. \end{array} \tag{48}$$

The convex hull of these points forms a regular octahedron; see Fig. 5. In the resulting trihedral decomposition, each face is degenerate at each of its two rays, and at each ray each face sharing the ray is contained in one of only two planes. Thus all rays of $\mathcal{T}^*$ are singular.

As a check on our formulas and to provide actual numbers for comparison purposes, we have computed the dimensions of $H_d^r(\mathcal{T}^*)$ in Example 19 for $1 \le r \le 5$ and $1 \le d \le 15$ by setting up the smoothness conditions and numerically computing the rank of the matrix describing the smoothness conditions using the Goliath package [2, 3] and other special purpose software. For the trihedral decomposition $\mathcal{T}^*$, there are six singular rays. Thus for $d \ge 2r$, the expression (15) becomes

$$\begin{aligned} \phi_d^r &:= 4d^2 - 12dr + 9r^2 + 3r + 2 + 6\sum_{m=1}^{d-r}(r+1-m)_+ \\ &= 2\,(2d^2 - 6dr + 6r^2 + 3r + 1). \end{aligned} \tag{49}$$

This gives

$$\phi_d^r = \begin{cases} 4d^2 - 12d + 20 & \text{if } d \ge 2 \text{ and } r = 1, \\ 4d^2 - 24d + 62 & \text{if } d \ge 4 \text{ and } r = 2, \\ 4d^2 - 36d + 128 & \text{if } d \ge 6 \text{ and } r = 3, \\ 4d^2 - 48d + 218 & \text{if } d \ge 8 \text{ and } r = 4, \\ 4d^2 - 60d + 252 & \text{if } d \ge 10 \text{ and } r = 5. \end{cases} \tag{50}$$

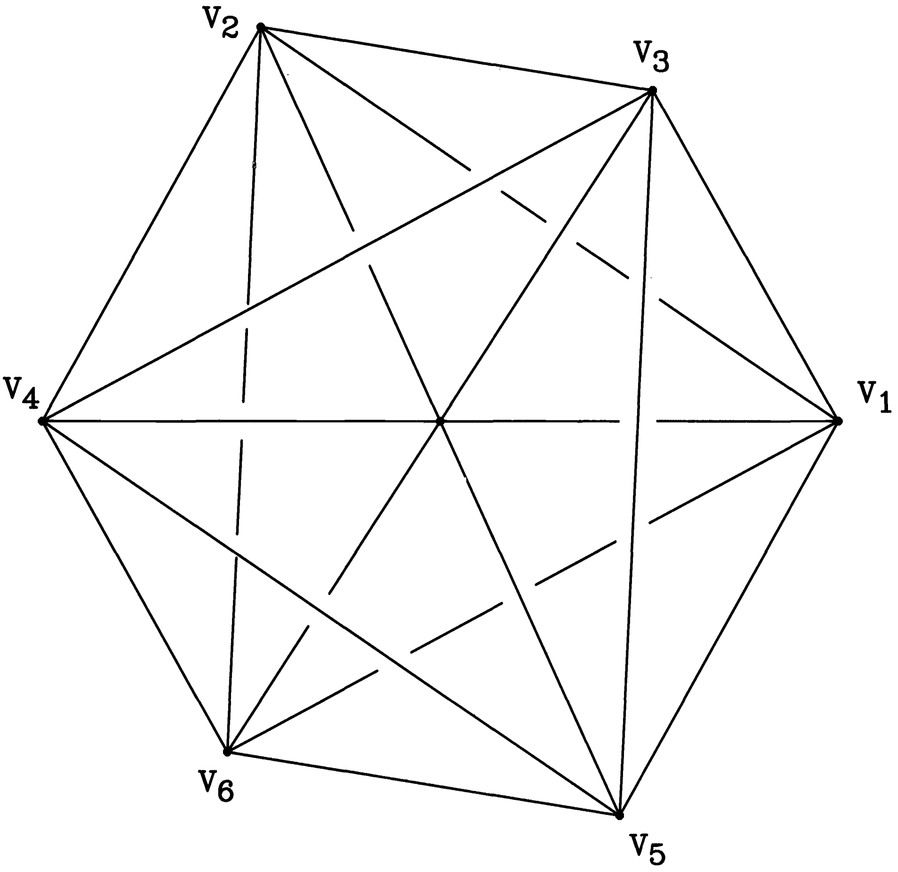

FIG. 5. *The regular octahedron.*

In Table 1, we have used an asterisk to mark those cases where the computed dimensions of $H_d^r(\mathcal{T}^*)$ differ from the values of ϕ_d^r. As a curiosity, we note that for the trihedral decomposition $\mathcal{T}^*$, the formulas are in fact correct for $d = 3r + 1$ (and of course all larger values) but not for $d \le 3r$, even though $\mathcal{T}^*$ is not generic and all faces are degenerate.

TABLE 1

Dimensions of $H_d^r(\mathcal{T}^*)$ *on the regular octahedron.*

d:	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
$r = 1$:	3*	9*	19*	36	60	92	132	180	236	300	372	452	540	636	740
$r = 2$:	3*	6*	13*	24*	39*	61*	90	126	170	222	282	350	426	510	602
$r = 3$:	3*	6*	10*	18*	30*	46*	66*	93*	127*	168	216	272	336	408	488
$r = 4$:	3*	6*	10*	15*	24*	37*	54*	75*	100*	132*	171*	217*	270	330	398
$r = 5$:	3*	6*	10*	15*	21*	31*	45*	63*	85*	111*	141*	178*	222*	273*	331*

8. Super splines. As in the planar case [15], the methods above can also be used to compute the dimension and to construct locally supported bases for spaces of homogeneous *super splines*:

$$\mathcal{H}_d^{r,\theta}(\mathcal{T}) := \{s \in \mathcal{H}_d^r(\mathcal{T}) : s \in C^{\rho_v}(v), \quad v \in \mathcal{V}\}, \tag{51}$$

where $\theta := \{\rho_v\}_{v \in \mathcal{V}}$ and $r \le \rho_v < d$ for all v. Here $s \in C^{\rho_v}(v)$ means that all of the derivatives up to order ρ_v of the pieces of s which join at v have a common value at v. We assume throughout that the μ- and ρ_v-disks around neighboring rays do not overlap, i.e.,

$$\max\{\mu, \rho_u\} + \max\{\mu, \rho_v\} < d \tag{52}$$

for all pairs of vertices u and v which generate a face of $\mathcal{T}$, where μ is defined in (39).

THEOREM 20. *Let $\mathcal{T}$ be a partial trihedral decomposition and suppose that $d \ge 3r + 2$ and that* (52) *holds. Then*

$$\begin{aligned}\dim \mathcal{H}_d^{r,\theta}(\mathcal{T}) = {} & \left[(d-r)(d-2r) - \binom{r+2}{2}\right] V + \sum_{v \in \mathcal{V}} \binom{\rho_v + 2}{2} \\ & - \sum_{v \in \mathcal{V}} \left[E_v \binom{\rho_v - r + 1}{2}\right] - 2d^2 + 6dr - 3r^2 + 3r + 2 \\ & + \sum_{v \in \mathcal{V}} \sum_{m=\rho_v - r+1}^{d-r} (r + m + 1 - m e_v)_+ \end{aligned} \tag{53}$$

if $\mathcal{T}$ is a total trihedral partition, and

$$\begin{aligned}\dim \mathcal{H}_d^{r,\theta}(\mathcal{T}) = {} & \frac{(d-r+1)(d-r)}{2} V_B + \left[(d-r)(d-2r) - \binom{r+2}{2}\right] V_I \\ & - \frac{2d^2 - 6dr + 3r^2 - 3r - 2}{2} \\ & - \sum_{v \in \mathcal{V}} \left[E_v \binom{\rho_v - r + 1}{2}\right] + \sum_{v \in \mathcal{V}_I} \binom{\rho_v + 2}{2} \\ & + \sum_{v \in \mathcal{V}_I} \sum_{m=\rho_v - r+1}^{d-r} (r + m + 1 - m e_v)_+ \end{aligned} \tag{54}$$

if $\mathcal{T}$ is a partial trihedral decomposition. Here E_v is the number of interior faces attached to the vertex v for each $v \in \mathcal{V}$. Moreover, there exists a basis of splines for $\mathcal{H}_d^{r,\theta}(\mathcal{T})$ such that the support of each spline is either a single trihedron, an adjoining pair, or an orange.

Proof. nWe give the proof for the case of a partial trihedral decomposition. The proof when the decomposition is total is similar (and simpler). The key observation is that the set of points chosen by Algorithm 12 and lying inside the disk $\mathcal{D}_{\rho_v}(v)$ is a minimal determining set for $\mathcal{H}_{\rho_v}^r(\mathcal{O}_v)$, where $\mathcal{O}_v$ is the orange with axis v. Thus, if we now impose C^{ρ_v} continuity at v, then we can replace those $\dim \mathcal{H}_{\rho_v}^r(\mathcal{O}_v)$ points by $\binom{\rho_v+2}{2}$ points lying in one trihedron in $\mathcal{O}_v$. This shows that for each ray v, the change in the number of points in the minimal determining set Γ constructed by Algorithm 12 is given by

$$\dim H_{\rho_v}^r(\mathcal{O}_v) - \dim H_{\rho_v}^{\rho_v}(\mathcal{O}_v) = \dim H_{\rho_v}^r(\mathcal{O}_v) - \binom{\rho_v + 2}{2}. \tag{55}$$

Thus

$$\begin{aligned}\dim\mathcal{H}_d^{r,\theta}(\mathcal{T}) &= \dim\mathcal{H}_d^r(\mathcal{T}) - \sum_{v\in\mathcal{V}}\left[\dim H^r_{\rho_v}(\mathcal{O}_v) - \binom{\rho_v+2}{2}\right]\\ &= \frac{(d-r+1)(d-r)}{2}V_B + (d-r)(d-2r)V_I\\ &\quad - \frac{2d^2-6dr+3r^2-3r-2}{2} + \sum_{v\in\mathcal{V}}\sum_{m=1}^{d-r}(r+m+1-me_v)_+\\ &\quad - \sum_{v\in\mathcal{V}_I}\left[\binom{r+2}{2} + E_v\binom{\rho_v-r+1}{2} + \sum_{m=1}^{\rho_v-r}(r+m+1-me_v)_+\right]\\ &\quad - \sum_{v\in\mathcal{V}_B}\left[\binom{\rho_v+2}{2} + E_v\binom{\rho_v-r+1}{2}\right] + \sum_{v\in\mathcal{V}}\binom{\rho_v+2}{2}.\end{aligned}\tag{56}$$

Now, combining terms, we get (54).

Our new minimal determining set can now be used to construct a basis of locally supported splines as was done in the proof of Theorem 3. □

The case where all ρ_v are equal is of particular interest.

COROLLARY 21. *Suppose that*

$$\rho_v = \rho \geq r, \quad v \in \mathcal{V},\tag{57}$$

and that $2\rho < d$. *Then*

$$\begin{aligned}\dim\mathcal{H}_d^{r,\theta}(\mathcal{T}) &= \frac{(2d^2-6dr-3r^2+12r\rho+3r-5\rho^2-3\rho)}{2}V\\ &\quad + (-2d^2+6rd+3r^2-3r+6\rho^2-12r\rho+6\rho+2)\\ &\quad + \sum_{v\in\mathcal{V}}\sum_{m=\rho-r+1}^{d-r}(r+m+1-me_v)_+\end{aligned}\tag{58}$$

if $\mathcal{T}$ *is a total trihedral partition, and*

$$\begin{aligned}\dim\mathcal{H}_d^{r,\theta}(\mathcal{T}) &= \frac{(d^2-2rd-r^2+d+r-2\rho^2+4\rho r-2\rho)}{2}V_B\\ &\quad + \frac{(2d^2-6rd-3r^2+12\rho r+3r-5\rho^2-3\rho)}{2}V_I\\ &\quad + \frac{(-2d^2+6rd+3r^2-3r+6\rho^2-12r\rho+6\rho+2)}{2}\\ &\quad + \sum_{v\in\mathcal{V}_I}\sum_{m=\rho-r+1}^{d-r}(r+m+1-me_v)_+\end{aligned}\tag{59}$$

if $\mathcal{T}$ *is a partial trihedral decomposition. Moreover, there exists a basis of splines for* $\mathcal{H}_d^{r,\theta}(\mathcal{T})$ *such that the support of each spline is either a single trihedron, an adjoining pair, or an orange.*

Proof. Substituting (57) in (53) and using (41) and (44) leads to (58). For a partial decomposition, the classical Euler relations for a triangulation imply

$$\sum_{v\in\mathcal{V}} E_v = 2E_I = 2(V_B+3V_I-3).\tag{60}$$

Now, substituting (57) in (54) and using (60) leads to (59). □

In both Theorem 20 and Corollary 21, the formula for a total trihedral decomposition can be obtained from the formula for a partial one by dropping the term with V_B and doubling the constant term. Moreover, if we set $\rho = r$ in the corollary, of course, we recover the formulas in Theorem 3.

9. Remarks.

Remark 22. The proof of Theorem 7 is based on the proof of Theorem 3.3 of [17] for polynomial splines on planar triangulations. The description of the minimal determining set for a cell given there is not quite correct in that it allows $\mu_{N-1} < N$, which could lead to the same point being included in Γ twice. This is easily fixed by requiring that $\mu_{N-1} = N$, as we have done here.

Remark 23. As in our paper [5], it is possible to develop a theory of homogeneous splines defined on a (total or partial) decomposition of $\mathbb{R}^2$ by wedges (the two-dimensional analogs of trihedra). Such splines can be restricted to a circle or a similar curve to obtain univariate functions along the curve. The corresponding dimensions and minimal determining sets can be obtained in a straightforward manner by considering a single ring in Theorem 7.

Remark 24. In the bivariate polynomial spline case, there is no question that the right way to define domain points P_{ijk} associated with the Bernstein–Bézier coefficients of a polynomial is by the formula in (6). In that case, the set of pairs $\{P, c_P\}_{P\in\mathcal{G}}$ is called the *Bézier net* of s and has an important geometric interpretation. However, in the trihedral setting, it is not so clear what the best way is to define the analogous points. As discussed in [4], there are reasonable alternatives, although it appears that there is no definition which carries the full geometric significance of the domain points in the planar case. Our choice here is a useful way to label control coefficients.

Remark 25. For polynomial spline spaces on planar triangulations, there are well-known lower and upper bounds on the dimension of $\mathcal{S}_d^r(\Delta)$ which are of interest for $d < 3r + 2$; see, e.g., [18] and references therein. Similar bounds can be derived for our homogeneous spline spaces and will be treated elsewhere.

Remark 26. The formula (54) given in Theorem 20 for a partial trihedral decomposition is much simpler than the corresponding formula in Theorem 2.4 of [15]. Since our proof of Theorem 20 can also be used in the bivariate case, the simpler formula (54) is also valid there.

ON A REPRESENTATION FORMULA FOR B. TEMPLE SYSTEMS*

S. BENZONI-GAVAGE†

Abstract. The author gives an inf-sup representation formula associated with genuinely nonlinear characteristic fields of B. Temple systems of conservation laws which reduces to the Lax formula in the convex scalar case. The proof is derived by means of geometrical arguments together with a method of characteristics. It holds for piecewise-smooth entropy solutions to the Cauchy problem for a large variety of initial data including Riemann data.

Key words. systems of conservation laws, B. Temple systems, weak entropy solutions

AMS subject classifications. 35L45, 35L60, 35L65, 35L67

1. Introduction.

In the theory of hyperbolic systems of conservation laws, the class of B. Temple systems [7] is known to generalize the properties of scalar conservation laws to a certain extent. Indeed, let $f : \Omega$ convex domain $\subset \mathbb{R}^n \longrightarrow \mathbb{R}^n$ be a $\mathcal{C}^2$ strictly hyperbolic flux function, i.e., such that for all $u \in \Omega$, the Jacobian matrix $df(u)$ has n distinct real eigenvalues [2].

DEFINITION 1. *We say that a characteristic field associated with a given eigenvalue belongs to the B. Temple class if the associated left eigenvector field is orthogonal to a foliation by hyperplanes of Ω. By B. Temple system, we mean that every characteristic field belongs to the B. Temple class.*

This is a very strong requirement which implies two "scalar-like properties" for B. Temple systems. First, the elementary wave curves are straight lines. This result was part of the original paper by Temple [7]. Second, Serre [5] has shown that such systems are *rich*, that is, one can construct an infinite number of entropies. In [6], Serre proved several integrability properties of such systems. More precisely, he showed that if $v_x = u$ and $v_t = -f(u)$ with f a B. Temple flux function according to Definition 1, then the graph $\mathcal{G} = \{x, t, v(x,t)\}$ of v lies in a surface $\Sigma \subset \mathbb{R}^{n+2}$ given by the intersection of n envelopes of hyperplanes. This result is not complete, however. It does not enable us to distinguish entropy solutions from other weak solutions. This means that Σ may contain loops—corresponding to the occurrence of shocks (in the genuinely nonlinear case)—that should be eliminated from $\mathcal{G}$ (which in principle is the graph of a Lipschitz-continuous function). The inf-sup representation formula presented in this paper does involve some entropy criteria. Since it reduces to the Lax formula [2] in the convex scalar case, it may be a way to erase the irrelevant parts of the graph in all cases.

It is well known that shocks are closely related to genuinely nonlinear fields.

DEFINITION 2 (Lax). *A characteristic field associated with an eigenvalue λ and a right eigenvector r is genuinely nonlinear if $d\lambda \cdot r$ never vanishes on Ω.*

The aim of this paper is to produce as many representation formulas as there are genuinely nonlinear fields in a given B. Temple system. Thus for any λ-shock in an entropy solution of $u_t + f(u)_x = 0$, the ambiguity regarding the location of v in the envelope may be eliminated through the scalar representation formula associated with the λ-field.

In order to prove those formulas, we shall first show that for each genuinely nonlinear field, certain kinds of generalized convexity inequalities are satisfied. Then it

* Received by the editors June 1, 1994; accepted for publication (in revised form) August 1, 1995.

† Unité de Mathématiques Pures et Appliquées (CNRS UMR 128), École Normale Supérieure de Lyon, 46 Allée d'Italie, F-69364 Lyon cedex 07, France (benzoni@umpa.ens-lyon.fr).

follows rather easily from a method of characteristics that the involved "inf-suprema" are nonpositive. It is a somewhat awkward task to see they are actually equal to zero. We shall prove them to be so for a large variety of initial data, including "monotone" (in a sense that we will specify) and especially Riemann data. The result remains a conjecture for general bounded-variation (BV) initial data.

2. Statement of the problem. As mentioned above, we consider the system of conservation laws

$$(1) \qquad u_t + f(u)_x = 0, \qquad u(x,t) \in \mathbb{R}^n, \quad x \in \mathbb{R},\ t > 0,$$

which is assumed to be strictly hyperbolic, the eigenvalues being denoted by $\lambda_1(u), \dots, \lambda_n(u)$ for each state $u \in \Omega \subset \mathbb{R}^n$. This is assumed to be a B. Temple system. It is now classical that this implies the existence of a set $\{w_1, \dots, w_n\}$ of n independent strong Riemann invariants (i.e, for all u, the forms $dw_1(u), \dots, dw_n(u)$ are left eigenvectors of $df(u)$ associated, respectively, with $\lambda_1(u), \dots, \lambda_n(u)$). And this ensures the existence [3], [4] and the uniqueness [1] of a BV entropy solution to the Cauchy problem

$$(1) \qquad u_t + f(u)_x = 0,$$

$$(2) \qquad u(x,0) = u_0(x) \in \Omega, \quad x \in \mathbb{R}$$

provided that $u_0 \in \mathrm{BV}(\mathbb{R})$. Initially (through §3), these results are sufficient for our analysis. We do not need to assume that *each* characteristic field belongs to the B. Temple class. However, this will be used explicitly in Lemma 4.1 which suggests that certain strong interactions between all the fields are involved in formula (5). This point is not completely clear since this assumption is not used in the results of §§4.1 and 4.2.

Henceforth, we suppose that (λ, r) (r being a right eigenvector associated with λ) is a genuinely nonlinear B. Temple field of system (1). (Note that in the absence of genuine nonlinearity, it is impossible to derive any kind of Lax formula.) Since $d\lambda \cdot r$ does not vanish on Ω, we may choose, for instance, r such that

$$\text{(i)} \qquad d\lambda(u) \cdot r(u) \ > \ 0, \quad \forall u \in \Omega.$$

Let w be a strong Riemann invariant associated with this field. By the strict hyperbolicity of system (1), we know that $dw \cdot r$ cannot vanish. Let us assume, possibly changing w into $-w$, that

$$\text{(ii)} \qquad dw(u) \cdot r(u) \ > \ 0, \quad \forall u \in \Omega.$$

By Definition 1, we know that the family of characteristic submanifolds $\{u \in \Omega; w(u) = a\}$ consists of a foliation by hyperplanes of Ω. Thus for all $a \in w(\Omega)$, there exists a hyperplane $\Pi_a \subset \mathbb{R}^n$ such that

$$\{u \in \Omega; w(u) = a\} = \Pi_a \cap \Omega.$$

The one-parameter family of hyperplanes $(\Pi_a)_{a \in w(\Omega)}$ may be described by means of their affine equations

$$\Pi_a = \{u \in \mathbb{R}^n; e_a \cdot u = m_a\},$$

where the e_a's are linear forms and the m_a's are scalar quantities. Clearly,

$$e_a \parallel dw(u) \quad \forall u \in \Pi_a \cap \Omega$$

so that we can choose e_a pointing into the same half-space as $dw(u)$ for $u \in \Pi_a \cap \Omega$. This means we also have

$$\text{(iii)} \qquad e_a \cdot r(u) \ > \ 0 \quad \forall u \in \Pi_a \cap \Omega.$$

It is not difficult to see that $e_a \cdot f(u)$ is also a constant on $\Pi_a \cap \Omega$, which we shall denote by q_a:

$$e_a \cdot f(u) = q_a \quad \forall u \in \Pi_a \cap \Omega.$$

DEFINITION 3. *We refer to a genuinely nonlinear B. Temple field* (λ, r) *with its related objects* w, e_a, m_a, *and* q_a *as a* GNLBT field.

We now assume the entropy solution u of the Cauchy problem (1)–(2) to be piecewise smooth. Thus it can be expressed as the space derivative of v such that

$$v_t + f(v_x) = 0, \tag{3}$$

$$v(x,0) = v_0(x) = \int_0^x u_0(\eta)d\eta. \tag{4}$$

With these assumptions, the conjectured representation formula reads as follows:

$$\inf_y \sup_a \{e_a \cdot v_0(y) - e_a \cdot v(x,t) + (x-y)\, m_a - t\, q_a\} = 0. \tag{5}$$

This formula clearly reduces to a Lax formula in the strictly convex scalar case. Indeed, in that case, there is just one field which is obviously of the B. Temple class and is genuinely nonlinear by the strict convexity. Inequalities (i)–(iii) are satisfied with $\lambda(u) = f'(u)$, $r \equiv 1$, $w(u) = u$, $e_a = 1$, $m_a = a$, and $q_a = f(a)$. Substituting into (5), we obtain

$$\inf_y \sup_a \{v_0(y) - v(x,t) + (x-y)a - tf(a)\} = 0$$

or, equivalently,

$$\inf_y \left\{ v_0(y) + \sup_a [(x-y)a - tf(a)] \right\} = v(x,t),$$

i.e., for $t > 0$,

$$v(x,t) = \inf_y \left\{ v_0(y) + tf^* \left(\frac{x-y}{t} \right) \right\}.$$

This is the well-known Lax formula [2].

Formula (5) was motivated by a result of Serre, who proved [6] that $\mathcal{L}(y,a;x,t) := e_a(v_0(y)) - e_a(v(x,t)) + (x-y)m_a - tq_a$ vanishes when y is given by the bottom of the λ-characteristic passing through (x,t) and a is the constant value $w \circ u(x,t) = w \circ u_0(y)$ of $w \circ u$ along this characteristic. Actually, (5) is meant to clarify the point concerning

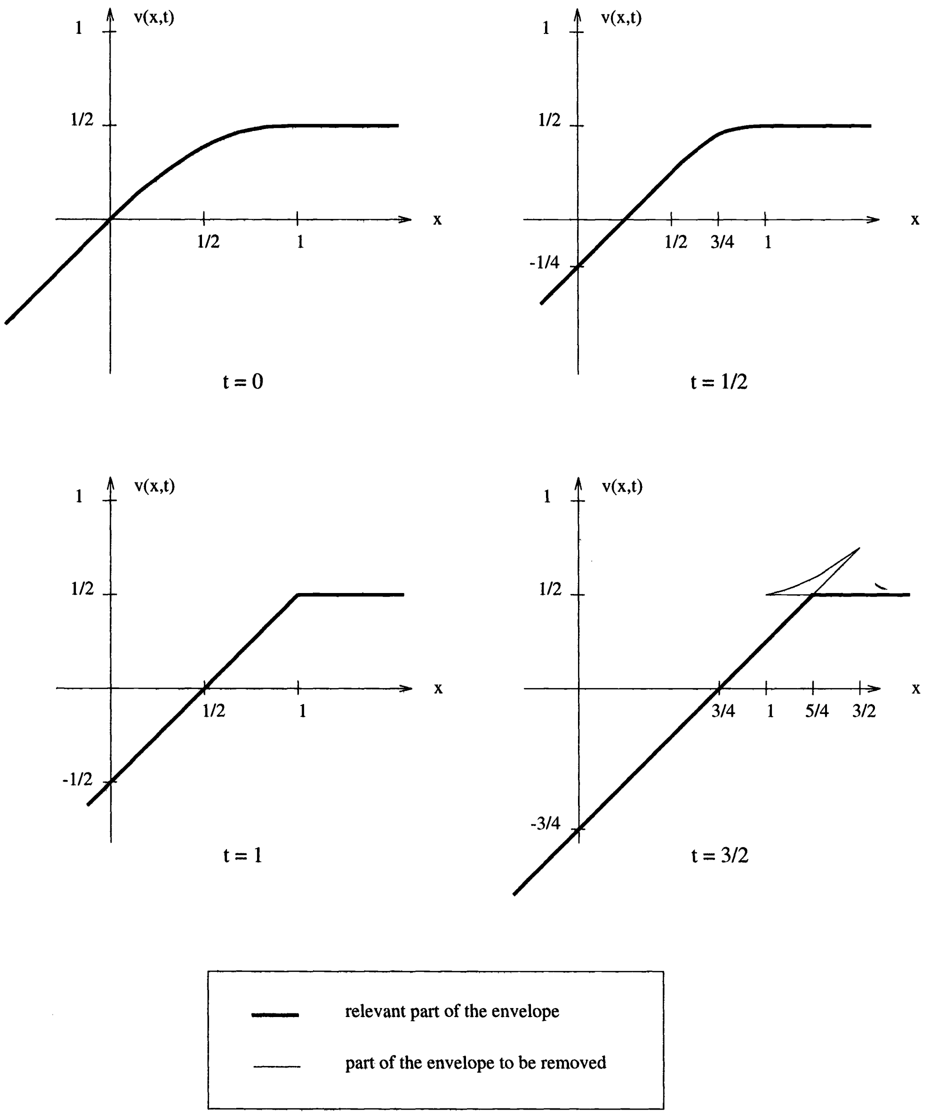

FIG. 1.

shocks in Serre's work. Indeed, his result says that the graph $\mathcal{G} \subset \mathbb{R}^{n+2}$ of v is included in the envelope of the hyperplanes

$$P_y = \{X, T, V; e_{w\circ u_0(y)} \cdot V - X\, m_{w\circ u_0(y)} + T\, q_{w\circ u_0(y)} = e_{w\circ u_0(y)} \cdot v_0(y) - y\, m_{w\circ u_0(y)}\}.$$

If there are shocks, some parts of this envelope should be removed because they should not be attained by $\mathcal{G}$.

Example 1. We can examine the Burgers equation with initial data generating a shock in finite time (at time $t = 1$ on Figure 1). We see that the envelope does contain a loop which is eliminated by the Lax formula.

The next section is devoted to proving the first "half-result":

$$\inf_y \sup_a \{e_a \cdot v_0(y) - e_a \cdot v(x,t) + (x-y)m_a - tq_a\} \leq 0.$$

This will be achieved through a very similar method to that of the scalar case using a sort of "generalized convexity inequality."

3. A first result. Let (λ, r) be a GNLBT field. Then we have the following.

THEOREM 3.1. *If* (i)–(iii) *hold, then for all $a \in w(\Omega)$ and for all $u \in \Omega$,*

$$e_a \cdot f(u) - q_a - \lambda(u)(e_a \cdot u - m_a) \leq 0. \tag{6}$$

Note that in the scalar case, this is merely the classical convexity inequality

$$f(u) - f(a) - f'(u)(u-a) \leq 0,$$

which implies that the graph of f lies above its tangents.

We will use the following lemma in the proof of Theorem 3.1.

LEMMA 3.2. *Let (λ, r) be a GNLBT field such that* (i)–(iii) *hold. Let $s \in I \mapsto u(s)$ be the integral curve of r passing through a given state b at $s = 0$ (with $0 \in I$). Then the real-valued function $s \in I \mapsto \mathcal{F}(u(s); b) := dw(b) \cdot (f(u(s)) - f(b) - \lambda(u(s))(u(s) - b))$ admits a strict global maximum at $s = 0$.*

Proof. Using the identity $df \cdot r \equiv \lambda r$, we immediately compute the first derivative

$$\frac{d}{ds}\mathcal{F}(u(s); b) = -(d\lambda(u(s)) \cdot r(u(s)))\, dw(b) \cdot (u(s) - b)$$

since $du/ds = r(u(s))$. Now by (i), we see that $(d/ds)\mathcal{F}(u(s); b)$ and $dw(b) \cdot (u(s) - b)$ vanish simultaneously at $s = 0$ and take opposite signs elsewhere. Moreover, the integral curve of r passing through b encounters the hyperplane $\Pi_{w(b)}$ only at the point b (corresponding to $s = 0$). Therefore, by (ii), we get that $dw(b) \cdot (u(s) - b) > 0$ for $s > 0$ and $dw(b) \cdot (u(s) - b) < 0$ for $s < 0$. □

Proof of Theorem 3.1. Relation (6) is equivalent to

$$dw(b) \cdot (f(u) - f(b) - \lambda(u)(u - b)) \leq 0 \tag{7}$$

for all states $u, b \in \Omega$. However, $\mathcal{F}(u; b) = dw(b) \cdot (f(u) - f(b) - \lambda(u)(u - b))$ has the same sign for all $b \in \Pi_a \cap \Omega$ so it is sufficient to show (7) for just one $b \in \Pi_a \cap \Omega$ (depending on u). We can choose b to lie on the integral curve of r passing through u. This curve is transverse to the hyperplanes Π_a (since $dw \cdot r \neq 0$) and thus encounters all of them. Then the trick is in considering the opposite point of view, which will make our computations much easier. We take $b \in \Pi_a \cap \Omega$ and examine $\mathcal{F}(u(s); b)$, where $s \mapsto u(s)$ is the integral curve of r passing through b (such that $u(0) = b$). Now Lemma 3.2 and the fact that $\mathcal{F}(u; u) = 0$ imply that $\mathcal{F}(u(s); b) \leq 0$ for all s. This completes the proof. □

Now it is quite easy to prove the following.

THEOREM 3.3. *Let (λ, r) be a GNLBT field such that* (i)–(iii) *hold. If v satisfies equations* (3) *and* (4) *and is such that $u = v_x$ is piecewise smooth and is the entropy solution to equations* (1) *and* (2), *then for all $(x,t) \in \mathbb{R} \times \mathbb{R}^+$,*

$$\inf_y \sup_a \{e_a \cdot v_0(y) - e_a \cdot v(x,t) + (x-y)\, m_a - t\, q_a\} \leq 0. \tag{8}$$

Proof. Let us denote by $\mathcal{L}$ the function

$$\mathcal{L}(y, a; x, t) = e_a \cdot v_0(y) - e_a \cdot v(x, t) + (x - y)m_a - tq_a.$$

This is a Lipschitz-continuous function with respect to x and t. Moreover, $\mathcal{L}(y, a;\ .\,,.)$ is a nonincreasing function of time along any λ-characteristic for every y and a. This is a straightforward consequence of Theorem 3.1 since the relations

$$\mathcal{L}_t(y, a; x, t) = e_a \cdot f(u(x, t)) - q_a, \tag{9}$$

$$\mathcal{L}_x(y, a; x, t) = -\, e_a \cdot u(x, t) + m_a \tag{10}$$

imply that

$$\mathcal{L}_t(y, a; x, t) + \lambda(u(x, t))\mathcal{L}_x(y, a; x, t)$$

$$= e_a \cdot f(u(x, t)) - q_a - \lambda(u(x, t))(e_a \cdot u(x, t) - m_a) \leq 0$$
$$\forall a \in w(\Omega), \quad \forall y \in \mathbb{R}.$$

Serre pointed out in [6] that the Lax entropy inequalities enable us to go *backward* along any λ-characteristic. Therefore, for any point $(x, t) \in \mathbb{R} \times \mathbb{R}^+$, there is at least one point of intersection between the λ-characteristic passing through (x, t) and the space axis, which will be denoted by $(y(x, t), 0)$ and referred to as the "(x, t)-foot." Note that if (x, t) lies on a λ-shock curve, there may be two "feet," which we will then denote by $y_l(x, t)$ on the left and $y_r(x, t)$ on the right. In this case, $y(x, t)$ refers to either one.

DEFINITION 4. *For any point $(x, t) \in \mathbb{R} \times \mathbb{R}^+$, we define* (x, t)-foot *to be a point $(y(x, t), 0)$ of intersection between the λ-characteristic passing through (x, t) and the space axis. If there is a λ-shock passing through (x, t), we denote by $(y_l(x, t), 0)$ (respectively, $(y_r(x, t), 0)$) the intersection point lying on the left (respectively, on the right) of the shock.*

Here we have

$$\mathcal{L}(y(x, t), a; x, t) \leq \mathcal{L}(y(x, t), a; y(x, t), 0) = 0 \quad \forall a \in w(\Omega),$$

which proves (8). □

Remark 1. Let us note that for all $a \neq w \circ u(x, t)$, $\mathcal{L}(y, a; x, t)$ is a *strictly* decreasing function of time along the λ-characteristics while $\mathcal{L}(y, w \circ u(x, t);\, .\,,.)$ is constant along the λ-characteristic passing through (x, t). (We recall that $w \circ u(x, t)$ is also a constant along such a characteristic.) Indeed, the inequality in Theorem 3.1 is strict unless $w(u) = a$ (cf. Lemma 3.2). This implies

$$\sup_a \mathcal{L}(y(x, t), a; x, t) = 0,$$

where the supremum is actually a strict maximum attained at $a = w \circ u(x, t) = w \circ u_0(y(x, t))$.

Therefore, if the conjectured formula is true, it amounts to saying that the "worst" situation appears at the foot $y = y(x, t)$ in the sense that the infimum

$$\inf_y [\sup_a \mathcal{L}(y, a; x, t)]$$

is, in fact, a minimum attained at $y = y(x, t)$.

4. The reverse inequality. In this section, we discuss the situation in which

$$\sup_a \mathcal{L}(y,a;x,t) \geq 0 \quad \forall y \in \mathbb{R}. \tag{11}$$

In the scalar case, inequality (11) is true due to another monotonic property of $\mathcal{L}$ which states that $\mathcal{L}(y,a;y+f'(a)t,t)$ is a nondecreasing function in time. It is not difficult to show that this is a consequence of the "reverse" convexity inequality

$$f(u)-f(a)-f'(a)(u-a) \geq 0.$$

Thus we have

$$\mathcal{L}(y,a;x,t) \geq \mathcal{L}(y,a;y,0) = 0$$

for a such that $f'(a)=(x-y)/t$. (If $(x-y)/t$ does not belong to the range of f', then y does not contribute to the infimum since $\sup_a[((x-y)/t)a - f(a)] = +\infty$.) In fact, $a = f^*((x-y)/t)$, f^* denoting the convex conjugate function of f.

In the case of a B. Temple system, we have a kind of "reverse" inequality to (7).

LEMMA 4.1. *We assume that all of system* (1) *is of the B. Temple class. Let* (λ, r) *be a GNLBT field such that* (i)–(iii) *hold. Let* $s \in I \mapsto u(s)$ *be the integral curve of* r *passing through a given state* b *at* $s=0$ (*with* $0 \in I$). *Then the real-valued function* $s \in I \mapsto \mathcal{G}(u(s);b) := dw(b)\cdot(f(u(s)) - f(b) - \lambda(b)(u(s)-b))$ *admits a strict global minimum at the point* $s=0$. *In other words, whenever the states* u *and* b *lie on the same integral curve of* r, *they satisfy*

$$dw(b)\cdot(f(u)-f(b)-\lambda(b)(u-b)) \geq 0. \tag{12}$$

Proof. Our computations are even easier than in Lemma 3.2. We have

$$\frac{d}{ds}\mathcal{G}(u(s);b) = (\lambda(u(s)) - \lambda(b))dw(b)\cdot r(u(s)),$$

which clearly vanishes at $s=0$. Moreover, from (i), we know that $\lambda(u(s)) > \lambda(b)$ for $s>0$ and $\lambda(u(s)) < \lambda(b)$ for $s<0$. However, integral curves of r are, in fact, straight lines. (This is where we use the property of the whole system belonging to the B. Temple class; see [7].) Therefore, $dw(b)\cdot r(u(s))$ cannot vanish and remains positive since $dw(b)\cdot r(b) > 0$ (ii). □

Unlike (7), which is equivalent to (6), inequality (12) cannot in general be written just in terms of a. There is one particular case in which Lemma 4.1 enables us to prove equation (5); that is when $\lambda(b)$ depends only on $w(b)$ (which, of course, includes the scalar case).

PROPOSITION 4.2. *Assume that all of system* (1) *is of the B. Temple class,* (λ, r) *is a GNLBT field such that* (i)–(iii) *hold, and*

$$d\lambda \wedge dw = 0 \quad \textit{in } \Omega.$$

If v *satisfies equations* (3) *and* (4) *and is such that* $u = v_x$ *is piecewise smooth and is the entropy solution to equations* (1) *and* (2), *then for all* $(x,t) \in \mathbb{R}\times\mathbb{R}^+$,

$$\inf_y \sup_a \{e_a\cdot v_0(y) - e_a\cdot v(x,t) + (x-y)\,m_a - t\,q_a\} = 0.$$

Proof. Indeed, λ is then constant on $\Pi_a \cap \Omega$. Let us denote its value by λ_a. From Lemma 4.1 (with b the intersection of Π_a and the integral curve of r passing through u), we have for all states $u \in \Omega$ and for all values of $a \in w(\Omega)$,

$$e_a \cdot f(u) - q_a - \lambda_a(e_a \cdot u - m_a) \geq 0. \tag{13}$$

This enables us to work out the formula in the same way as in the scalar case.

Let y be any point in $\mathbb{R}$. From (13), it is easy to see that $\mathcal{L}(y, a; y + \lambda_a t, t)$ is a nondecreasing function of time. If $c = (x - y)/t_0$ is in the range of λ_a, let a such that $\lambda_a = c$. We get

$$\mathcal{L}(y, a; x, t_0) \geq \mathcal{L}(y, a; y, 0) = 0.$$

Now, if $c > \sup\limits_a \lambda_a$, let a_M be an upper bound for $w \circ u$. Then $c > \lambda_{a_M}$ and we have

$$\frac{d}{dt}\mathcal{L}(y, a_M; y + ct, t) = e_{a_M} \cdot f(u(y + ct, t)) - q_{a_M} - c(e_{a_M} \cdot u(y + ct, t) - m_{a_M})$$

with $e_{a_M} \cdot u(y + ct, t) - m_{a_M} \leq 0$. Thus $(d/dt)\mathcal{L}(y, a_M; y + ct, t) \geq 0$ and therefore

$$\mathcal{L}(y, a_M; x, t_0) \geq \mathcal{L}(y, a_M; y, 0) = 0.$$

Of course, if $c < \inf_a \lambda_a$, the same holds with a lower bound a_m. Thus we have (11), which with Theorem 3.3 completes the proof. □

Note that this case is very similar to the scalar case since λ-characteristics are straight lines.

In the general case, the eigenvalue λ is not a constant on the hyperplanes Π_a. Lemma 4.1 states that $\mathcal{L}(y, a; X_a(t), t)$ is nondecreasing along curves that are no longer straight lines but are defined as

$$\frac{dX_a}{dt} = \lambda(b_a(\, u(X_a(t), t))),$$

where $b_a(u)$ denotes the intersection of the integral curve of r passing through u (that is, $u + \mathbb{R}r(u)$) with Π_a. These curves are not easy to handle. Unlike the λ-characteristics, they do not have to intercept the x-axis. Indeed, in order to use the Lax entropy inequalities $\lambda(u_r) < \sigma < \lambda(u_l)$, we need some information on b_a, such as

$$\lambda(b_a(u_r)) \leq \lambda(u_r)$$

and

$$\lambda(b_a(u_l)) \geq \lambda(u_l).$$

There is no obvious way to derive such inequalities unless $w(u_r) \leq a \leq w(u_l)$ (which is undoubtedly related to Lemma 4.9 in §4.2). In any case, the existence of such points of intersection would not even solve the problem. For a given a and a possible corresponding point $y_a(x, t)$, the quantity $\mathcal{L}(y, a; y_a(x, t), 0)$ does not have to be nonnegative.

These remarks are meant to point out the kind of difficulties encountered when we try to check whether or not inequality (11) holds for all y (and especially for $y \neq y(x, t)$). Nevertheless, we conjecture this inequality—and thus also the representation formula (5)—to be true. The proof is now given for several particular cases when the initial data are "nice enough" so that it is possible to produce at least one a (depending on $(x,t;y)$) such that $\mathcal{L}(y,a;x,t) \geq 0$.

Before going further, let us show that (11) holds at $t = 0$ for any initial data of bounded variation. Indeed,

$$\mathcal{L}(y,a;x,0) = e_a \cdot (v_0(y) - v_0(x)) + (x-y)m_a,$$

which is equal to zero if $y = x$ (for all $a \in w(\Omega)$) or, for $y \neq x$,

$$\mathcal{L}(y,a;x,0) = (y-x)\left[e_a \cdot \left(\frac{1}{y-x}\int_x^y u_0\right) - m_a\right],$$

which is equal to zero for $\boldsymbol{a} = \boldsymbol{w}\ ((1/(y-x))\int_x^y \boldsymbol{u}_o)$. (The mean value $(1/(y-x))\int_x^y u_0$ still lies in the convex set Ω.)

4.1. Proof of equation (5) for special initial data. For $t > 0$, let us begin with a very simple case.

THEOREM 4.3. *Let* (λ, r) *be a GNLBT field such that* (i)–(iii) *hold. Assume that* $w \circ u_0$ *is* nondecreasing. *If* v *satisfies equations* (3) *and* (4) *and is such that* $u = v_x$ *is piecewise smooth and is the entropy solution to equations* (1) *and* (2), *then for all* $(x,t) \in \mathbb{R} \times \mathbb{R}^+$,

$$\inf_y \sup_a \{e_a \cdot v_0(y) - e_a \cdot v(x,t) + (x-y)\, m_a - t\, q_a\} = 0.$$

Proof. This is a simple case in the sense that there is no λ-shock in the solution with such initial data. In addition, the proof works out almost immediately. Indeed, let $\boldsymbol{a}_{(x,t)} = \boldsymbol{w} \circ \boldsymbol{u}(\boldsymbol{x},\boldsymbol{t}) = \boldsymbol{w} \circ \boldsymbol{u}_o(\boldsymbol{y}(\boldsymbol{x},\boldsymbol{t}))$. Then $\mathcal{L}(y, a_{(x,t)}; \cdot, \cdot)$ is constant along the λ-characteristic passing through (x,t) (see Remark 1) and thus

$$\mathcal{L}(y, a_{(x,t)}; x, t) = \mathcal{L}(y, a_{(x,t)}; y(x,t), 0) \quad \forall y \in \mathbb{R}.$$

Now let us compare $\mathcal{L}(y, a_{(x,t)}; y(x,t), 0)$ to $\mathcal{L}(y, a_{(x,t)}; y, 0) = 0$ for any $y \in \mathbb{R}$. From equation (10), (ii), and (iii), we know that

$$\operatorname{sgn} \mathcal{L}_x(y,a;x,t) = \operatorname{sgn}(a - w \circ u(x,t)). \tag{14}$$

Therefore,

- if $y \leq y(x,t)$, then $w \circ u_0(z) \leq a_{(x,t)}$ for all $z \in [y, y(x,t)]$ and $\mathcal{L}(y, a_{(x,t)}; z, 0)$ is nondecreasing for $z \in [y, y(x,t)]$;
- if $y \geq y(x,t)$, then $w \circ u_0(z) \geq a_{(x,t)}$ for all $z \in [y(x,t), y]$ and $\mathcal{L}(y, a_{(x,t)}; z, 0)$ is nonincreasing for $z \in [y(x,t), y]$.

In both situations, we see that

$$0 = \mathcal{L}(y, a_{(x,t)}; y, 0) \leq \mathcal{L}(y, a_{(x,t)}; y(x,t), 0) = \mathcal{L}(y, a_{(x,t)}; x, t). \qquad \square$$

Let us now take some rather simple initial data which may give rise to a λ-shock. Let $X_0 \in \mathbb{R}$.

THEOREM 4.4. *Let* (λ, r) *be a GNLBT field such that* (i)–(iii) *hold. Assume that* $w \circ u_0$ *reads*

$$w \circ u_0(z) = \begin{cases} w_l & \textit{if } z < X_0, \\ w_r & \textit{if } z > X_0. \end{cases}$$

If v satisfies equations (3) *and* (4) *and is such that $u = v_x$ is piecewise smooth and is the entropy solution to equations* (1) *and* (2), *then for all $(x,t) \in \mathbb{R} \times \mathbb{R}^+$,*

$$\inf_y \sup_a \{e_a \cdot v_0(y) - e_a \cdot v(x,t) + (x-y)\, m_a - t\, q_a\} = 0.$$

Note that this case contains the Riemann problems but is more general in the sense that u_0 is only required to stay in a given hyperplane (Π_{w_l} or Π_{w_r}) on each interval instead of being a constant. However, there is no additional difficulty in the proof.

Proof. If $w_l \leq w_r$ (i.e., a λ-rarefaction wave appears for $t > 0$), then, in fact, Theorem 4.3 holds. Henceforth, we assume that $w_l > w_r$. Then a λ-shock takes place for $t > 0$. However, due to the Lax entropy inequalities, the λ-characteristic passing through (x,t) cannot cross this shock at any time $s \leq t$. For example, let us assume that the λ-characteristic passing through (x,t) lies to the right (of the λ-shock curve initiated at X_0) until time t. Let us split the study of $\sup_a \mathcal{L}(y,a;x,t)$ into two cases depending on whether the point $(y,0)$ lies on the same side as the λ-shock curve or the opposite one.

1. Let us take $y \geq X_0$. Then the proof does not depend on $w \circ u_0(Y)$ for $Y < X_0$. Indeed, let $\boldsymbol{a = w \circ u(x,t) = w \circ u_0(y(x,t)) = w \circ u_0(y) = w_r}$. Then we have

$$0 = \mathcal{L}(y,a;y,0) = \mathcal{L}(y,a;y(x,t),0) = \mathcal{L}(y,a;x,t),$$

which proves that $\sup_a \mathcal{L}(y,a;x,t) \geq 0$.

2. Now let us take $y < X_0$. We will see that $\boldsymbol{a = w \circ u_0(y)}$ still gives the desired estimate. We denote by $X(t)$ the position of the λ-shock at time t. Then going backwards along the λ-characteristics, we see that $w \circ u(\xi,t) = w_r < w_l = w \circ u_0(y) = a$ for all $\xi \in]X(t), x]$. Therefore, using (14), we have

$$\mathcal{L}(y,a;x,t) \geq \mathcal{L}(y,a;X(t),t).$$

Now we consider $y_l(X(t),t)$ the "$(X(t),t)$-left-foot" as in Definition 4. Then, applying case 1 to $(X(t),t)$ instead of (x,t) and w_l instead of w_r, we get

$$0 = \mathcal{L}(y,a;y,0) = \mathcal{L}(y,a;y_l(X(t),t),0) = \mathcal{L}(y,a;X(t),t)$$

since $a = w_l = w \circ u(X(t)-0,t) = w \circ u_0(y_l(X(t),t))$. □

Remark 2. In case 1 of the proof, we may weaken the assumption on $w \circ u_0$. Indeed, let us assume that $w \circ u_0(z)$ is only nondecreasing for any $z > X_0$. Let $\boldsymbol{a = w \circ u(x,t) = w \circ u_0(y(x,t))}$ (which is possibly no longer equal to $w \circ u_0(y)$). Then we have (see the proof of Theorem 4.3)

$$0 = \mathcal{L}(y,a;y,0) \leq \mathcal{L}(y,a;y(x,t),0) = \mathcal{L}(y,a;x,t),$$

which still proves $\sup_a \mathcal{L}(y,a;x,t) \geq 0$.

Remark 3. We have seen in case 2 that the proof does not always work with the "simple" value $a = w \circ u(x,t)$. This is not surprising. For the scalar case, the "working value" is $a = f^*((x-y)/t)$. For systems, we do not have a tool similar to f^*, which explains the difficulties related to the derivation of more general results.

Remark 2 prompts us to try the following generalization of Theorems 4.3 and 4.4. Let us take $X_0 \in \mathbb{R}$.

THEOREM 4.5. *Let* (λ, r) *be a GNLBT field such that* (i)–(iii) *hold. Assume that* $w \circ u_0$ *is a nondecreasing function on each of the intervals* $]-\infty, X_0)$ *and* $(X_0, +\infty[$*. If* v *satisfies equations* (3) *and* (4) *and is such that* $u = v_x$ *is piecewise smooth and is the entropy solution to equations* (1) *and* (2)*, then for all* $(x,t) \in \mathbb{R} \times \mathbb{R}^+$,

$$\inf_y \sup_a \{e_a \cdot v_0(y) - e_a \cdot v(x,t) + (x-y)m_a - tq_a\} = 0.$$

We shall only consider the case when

$$w \circ u_0(X_0 - 0) > w \circ u_0(X_0 + 0).$$

(Otherwise Theorem 4.3 holds and gives the result.) This generates a single λ-shock wave. More precisely, we need the following lemma.

LEMMA 4.6. *Let* u_0 *be of bounded variation such that* $w \circ u_0$ *is a nondecreasing function on* $]-\infty, X_0)$ *and* $(X_0, +\infty[$ *and* $w \circ u_0(X_0 - 0) > w \circ u_0(X_0 + 0)$*. Then the entropy solution to equations* (1) *and* (2) *consists of a* λ*-shock wave* $t \mapsto X(t)$ *and* $w \circ u(x,t)$ *is a nondecreasing function of* x *for* $x < X(t)$ *and for* $x > X(t)$*. Moreover, let*

$$w_l(t) = w \circ u(X(t) - 0, t)$$

and

$$w_r(t) = w \circ u(X(t) + 0, t).$$

Then $w_l(t)$ (*respectively,* $w_r(t)$) *is a continuous nonincreasing* (*respectively, nondecreasing*) *function of* $t > 0$.

Proof. The monotonic properties are derived by going backward along the λ-characteristics and using the properties of $w \circ u_0$. If $w \circ u_0$ has some points of discontinuity apart from X_0, then they generate rarefaction waves; hence we have the continuity of $w_{l,r}(t)$. □

In particular, Lemma 4.6 implies the existence of $w_{l,r}^\infty = \lim_{t \to +\infty} w_{l,r}(t)$ such that

$$w_l(0) \geq w_l^\infty \geq w_r^\infty \geq w_r(0). \tag{15}$$

Proof of Theorem 4.5. If $(y, 0)$ lies on the same side of the λ-shock as (x,t), the proof of equation (5) is the same as the proof of Theorem 4.3 (see Remark 2).

The remaining problem is when (x,t) and $(y,0)$ lie on opposite sides. Let us assume, for instance, that (x,t) lies on the left, i.e., $x < X(t)$ and thus $y(x,t) < X_0$. Let us take $y > X_0$. We shall discuss different cases concerning the location of $y(x,t)$. Let us define

$$\begin{aligned} Y_l^\infty &= \sup\{Y \leq X_0; w \circ u_0(Y) \leq w_l^\infty\}, \\ Y_r^\infty &= \sup\{Y \leq X_0; w \circ u_0(Y) \leq w_r^\infty\}, \\ Y_r^0 &= \sup\{Y \leq X_0; w \circ u_0(Y) \leq w_r(0)\}. \end{aligned}$$

Clearly, from (15), these points (possibly equal to $-\infty$) are in the following order:

$$Y_r^0 \leq Y_r^\infty \leq Y_l^\infty \leq X_0.$$

1. If $y(x,t) \leq Y_r^0$, then $w \circ u(x,t) = w \circ u_0(y(x,t)) \leq w_r(0)$. In this case, the proof is the same as if $w \circ u_0$ were nondecreasing on the whole interval $[y(x,t), y]$ (whereas there is a "bump" between Y_r^0 and X_0). Indeed, let $\boldsymbol{a = w \circ u(x, t)}$. Then $w \circ u_0(z) \geq a$ for any $z \in [y(x,t), y]$. Therefore, due to (14), $\mathcal{L}(y, a; z, 0)$ is a nonincreasing function of z for any $z \in [y(x,t), y]$, which gives

$$0 = \mathcal{L}(y, a; y, 0) \leq \mathcal{L}(y, a; y(x,t), 0) = \mathcal{L}(y, a; x, t).$$

2. If $Y_r^0 < y(x,t) \leq Y_r^\infty$, then $w_r(0) \leq w \circ u(x,t) \leq w_r^\infty$. Now if $w \circ u(x,t) < w_r^\infty$, there exists a $T \geq 0$ such that $w \circ u(x,t) = w_r(T)$. Let $\boldsymbol{a = w \circ u(x, t)}$. Let us consider $y_r(X(T), T)$ to be the $(X(T), T)$-right-foot. There are two possibilities:

- If the shock has already canceled at time T, then $w_r(T) = w_l(T)$ and we have

$$0 = \mathcal{L}(y, a; y, 0) \leq \mathcal{L}(y, a; y_r(X(T), T), 0); = \mathcal{L}(y, a; X(T), T) = \mathcal{L}(y, a; x, t).$$

- If we have $w_r(T) < w_l(T)$, then the λ-characteristic passing through (x,t) cannot have encountered the λ-shock at time T. Indeed, from Lemma 4.6, we have $w \circ u(x,t) = w_r(T) < w_l(T) \leq w_l(\tau)$ for all $\tau \leq T$. Therefore, let χ be the position of this characteristic at time T.

On one hand, $a = w \circ u(x,t)$ forces $\mathcal{L}(y, a; ., .)$ to be a constant along the λ-characteristic passing through (x,t) while $a = w_r(T)$ forces $\mathcal{L}(y, a; ., .)$ to be a constant along the λ-characteristic(s) passing through $(X(T), T)$. On the other hand, since $w \circ u_0(z) \geq w \circ u_0(y(x,t))$ for $z \in [y(x,t), X_0]$ and due to (14), $\mathcal{L}(y, a; ., T)$ is nonincreasing on $[\chi, X(T)]$. Thus we can write

$$\begin{aligned} 0 = \mathcal{L}(y, a; y, 0) &\leq \mathcal{L}(y, a; y_r(X(T), T), 0) = \mathcal{L}(y, a; X(T), T) \\ &\leq \mathcal{L}(y, a; \chi, T) = \mathcal{L}(y, a; x, t). \end{aligned}$$

The limit case $w \circ u(x,t) = w_r^\infty$ follows from the continuity of $\mathcal{L}$, which gives

$$0 \leq \mathcal{L}(y, w_r^\infty; x, t).$$

3. If $Y_l^\infty \leq y(x,t) < X_0$, then $w_l^\infty \leq w \circ u(x,t) \leq w_l(0) = w \circ u_0(X_0 - 0)$. Now, if $w \circ u(x,t) > w_l^\infty$, there exists a $T \geq 0$ such that $w \circ u(x,t) = w_l(T)$. Then the λ-characteristic passing through (x,t) encounters the shock curve at time T and, of course, $t \leq T$. Let $\boldsymbol{a = w_r(T)}$. Let us consider $y_r(X(T), T)$ to be the $(X(T), T)$-right-foot. Since $\mathcal{L}(y, a; ., .)$ is a nonincreasing function of time along λ-characteristics and is constant iff a is the constant value of $w \circ u$ along such characteristics, we have

$$\begin{aligned} 0 = \mathcal{L}(y, a; y, 0) &\leq \mathcal{L}(y, a; y_r(X(T), T), 0) = \mathcal{L}(y, a; X(T), T) \\ &\leq \mathcal{L}(y, a; x, t). \end{aligned}$$

The limit case $w \circ u(x,t) = w_l^\infty$ follows from the continuity of $\mathcal{L}$, which again gives

$$0 \leq \mathcal{L}(y, w_r^\infty; x, t).$$

4. If $Y_r^\infty < y(x,t) < Y_l^\infty$, then $w_r^\infty \leq w \circ u(x,t) \leq w_l^\infty$. The λ-characteristics issued from any point in $[Y_r^\infty, Y_l^\infty]$ are necessarily defined for any time. Let $\xi_{l,r}$ be the location at time t of the λ-characteristic issued from $Y_{l,r}^\infty$. We have $\xi_r < x < \xi_l$ and $w \circ u(., t) \geq w_r^\infty$ on $]x, \xi_l]$. Therefore, let $\boldsymbol{a = w_r^\infty}$. The function $\mathcal{L}(y, a; ., t)$ is nonincreasing on $[x, \xi_l]$ and we have

$$0 \leq \mathcal{L}(y, a; \xi_l, t) \leq \mathcal{L}(y, a; x, t).$$

This ends the proof of Theorem 4.5. $\square$

Before going further, it may be interesting to notice that there is a kind of paradox in this proof, which actually throws light on the asymptotic behavior of the solution. This is summed up in the following statement.

COROLLARY 4.7. *Let u_0 be of bounded variation such that $w \circ u_0$ is a nondecreasing function on $]-\infty, X_0)$ and $(X_0, +\infty[$ and $w \circ u_0(X_0 - 0) > w \circ u_0(X_0 + 0)$. We denote by $t \mapsto X(t)$ the generated λ-shock wave in the entropy solution to equations* (1) *and* (2) *and*

$$w_l(t) = w \circ u(X(t) - 0, t),$$

$$w_r(t) = w \circ u(X(t) + 0, t).$$

If $w \circ u_0(-\infty) < w \circ u_0(+\infty)$, then

$$\lim_{t \to +\infty} w_l(t) = \lim_{t \to +\infty} w_r(t).$$

If $w \circ u_0(-\infty) \geq w \circ u_0(+\infty)$, then

$$\lim_{t \to +\infty} w_l(t) = w \circ u_0(-\infty) \quad \text{and} \quad \lim_{t \to +\infty} w_r(t) = w \circ u_0(+\infty).$$

Proof. We are going to show that case 4 in the proof of Theorem 4.5 is void. In other words, there are no points (x, t) such that

$$w_r^\infty < w \circ u(x, t) < w_l^\infty. \tag{16}$$

Indeed, if (x, t) were such a point and were lying on the left of the shock, we would have from case 4 that

$$\mathcal{L}(y, w_r^\infty; x, t) \geq 0.$$

Since $w \circ u(x,t) < w_l^\infty$, the λ-characteristic passing through (x, t) could not encounter the shock in finite time, and because $w \circ u(x, t) > w_r^\infty$, the function $\mathcal{L}(y, w_r^\infty; ., .)$ would be strictly decreasing along this characteristic. Thus this function would have a finite nonnegative limit as $t \to +\infty$ and its derivative would tend to zero. However, this derivative is

$$e_{w_r^\infty} \cdot f(u(x, t)) - q_{w_r^\infty} - \lambda(u(x, t))(e_{w_r^\infty} \cdot u(x, t) - m_{w_r^\infty})$$

and cannot tend to zero unless $w \circ u(x, t)$ tends to w_r^∞ (see Remark 2). This is impossible since $w \circ u(x, t)$ is a constant along the λ-characteristic and is not equal to w_r^∞ by assumption.

If (x, t) were a point lying on the right of the shock, we could show in exactly the same way (taking $(y, 0)$ on the left) that (16) cannot hold.

Thus we have either $]w_r^\infty, w_l^\infty[= \emptyset$, which means

$$w_r^\infty = w_l^\infty, \tag{17}$$

or

$$w_l^\infty = w \circ u_0(-\infty) \quad \text{and} \quad w_r^\infty = w \circ u_0(+\infty). \tag{18}$$

If $w \circ u_0(-\infty) < w \circ u_0(+\infty)$, equation (18) is impossible since we always have $w_r^\infty \leq w_l^\infty$, so equation (17) must hold. □

Therefore, the asymptotic behavior of the solution consists of either the cancellation of the shock or its adaptation to the profile given by $w \circ u_0(-\infty)$ and $w \circ u_0(+\infty)$. This is a rather nontrivial consequence of our analysis.

Using Theorems 4.3, 4.4, and 4.5, we can easily obtain the following results concerning "piecewise-constant" initial data (which may be interesting in relation to finite difference schemes).

THEOREM 4.8. *Let (λ, r) be a GNLBT field such that* (i)–(iii) *hold. Assume that $w \circ u_0$ is* piecewise constant *and is such that*

1. *$w \circ u_0$ is nondecreasing,*
2. *$w \circ u_0$ is nonincreasing, or*
3. *the "mesh" contains at most three intervals.*

If v satisfies equations (3) *and* (4) *and is such that $u = v_x$ is piecewise smooth and is the entropy solution to equations* (1) *and* (2), *then for all $(x,t) \in \mathbb{R} \times \mathbb{R}^+$,*

$$\inf_y \sup_a \{e_a \cdot v_0(y) - e_a \cdot v(x,t) + (x-y)\, m_a - t\, q_a\} = 0.$$

Proof. Case 1 is contained in Theorem 4.3. Case 2 can be proved similarly to Theorem 4.4 with $a = w \circ u_0(y)$. Actually, it will follow from the next section that $a = w \circ u_0(y)$ gives the desired estimate for *any* nonincreasing initial data. As for case 3, the initial data takes at most three values. In any case, we can apply either cases 1 or 2 or Theorem 4.5. Unfortunately, with more than three intervals, our method would become too complicated. □

4.2. Attempt to extend the proof to any initial data. One attempt to extend the proof to any kind of initial data proceeds as follows. Drawing inspiration from Theorems 4.3 and 4.4, we may consider the following situation. Let $(x,t) \in \mathbb{R} \times \mathbb{R}^{+*}$ and $(y(x,t),0)$ be its foot. Let $y < y(x,t)$. Consider a point $z(y;x,t) \in [y, y(x,t)]$ such that $w \circ u_0(z) \leq w \circ u_0(z(y;x,t))$ for all $z \in [y, y(x,t)]$.

Assume that the λ-characteristic issued from $z(y;x,t)$ attains time t. We denote by $Z(y;x,t)$ its location at that time. Let $\boldsymbol{a = w \circ u_0(z(y;x,t))}$. By the definition of a, we have that $w \circ u_0(z) \leq a$, for all $z \in [y, z(y;x,t)]$ and also that

$$w \circ u(Z,t) \leq w \circ u(Z(y;x,t),t) = w \circ u_0(z(y;x,t)) = a$$

for all $Z \in [Z(y;x,t), x]$. Therefore, we get from equation (14) that

$$\mathcal{L}(y,a;x,t) \geq \mathcal{L}(y,a;Z(y;x,t),t) = \mathcal{L}(y,a;z(y;x,t),0) \geq \mathcal{L}(y,a;y,0) = 0.$$

In the case where the λ-characteristic issued from $z(y;x,t)$ encounters a λ-shock *before* time t, the preceding argument fails in general. However, it does work in the following situation. If $w \circ u_0$ is nonincreasing, then the proof is based on an additional monotonic property of $\mathcal{L}$ which we state in the following lemma.

LEMMA 4.9. *Let (λ, r) be a GNLBT field such that* (i)–(iii) *hold. Let $t \mapsto X(t)$ be a λ-shock wave. Moreover, let us denote by*

$$w \circ u(X(t)-0,t) = w_l(t), \qquad w \circ u(X(t)+0,t) = w_r(t).$$

Then $t \mapsto \mathcal{L}(y,a;X(t),t)$ is a nondecreasing function of t on any interval $[t_0,t_1]$ provided that

$$\sup_{[t_0,t_1]} \boldsymbol{w_r} \leq \boldsymbol{a} \leq \inf_{[t_0,t_1]} \boldsymbol{w_l}.$$

Proof. We look at the first derivative of the Lipschitz-continuous function $t \mapsto \mathcal{L}(y, a; X(t), t)$. Equations (9) and (10) imply that

$$\begin{aligned}\frac{d}{dt}\mathcal{L}(y, a; X(t), t) &= \mathcal{L}_t(y, a; X(t), t) + \sigma(t)\mathcal{L}_x(y, a; X(t), t)\\ &= e_a \cdot f(u_{l,r}(t)) - q_a - \sigma(t)(e_a \cdot u_{l,r}(t) - m_a).\end{aligned}$$

(Both values give the same result owing to the Rankine–Hugoniot condition.) Now we appeal to the classical convex entropy of (1),

$$u \mapsto |e_a \cdot u - m_a|,$$

whose entropy flux is $u \mapsto \operatorname{sgn}(e_a \cdot u - m_a)(e_a \cdot f(u) - q_a)$. The associated entropy inequality along the shock curve reads

$$\sigma(|e_a \cdot u_r - m_a| - |e_a \cdot u_l - m_a|)$$

$$\geq \operatorname{sgn}(e_a \cdot u_r - m_a)(e_a \cdot f(u_r) - q_a) - \operatorname{sgn}(e_a \cdot u_l - m_a)(e_a \cdot f(u_l) - q_a).$$

Note that due to the Rankine–Hugoniot condition, this inequality would be trivial if we had $(e_a \cdot u_r - m_a)(e_a \cdot u_l - m_a) > 0$. However, the assumption $(w(u_r) \leq a \leq w(u_l))$, (ii), and (iii) imply that

$$e_a \cdot u_r - m_a \leq 0 \leq e_a \cdot u_l - m_a.$$

These quantities cannot vanish simultaneously. (Otherwise, there would be no shock at all.) Therefore the entropy inequality together with the Rankine–Hugoniot condition imply that

$$-2\sigma(e_a \cdot u_l - m_a) \geq -2(e_a \cdot f(u_l) - q_a)$$

or, symmetrically,

$$-2\sigma(e_a \cdot u_r - m_a) \geq -2(e_a \cdot f(u_r) - q_a).$$

This proves that $(d/dt)\mathcal{L}(y, a; X(t), t)$ is nonnegative. □

THEOREM 4.10. *Let* (λ, r) *be a GNLBT field such that* (i)–(iii) *hold. Assume that* $w \circ u_0$ *is nonincreasing. If* v *satisfies equations* (3) *and* (4) *and is such that* $u = v_x$ *is piecewise smooth and is the entropy solution to equations* (1) *and* (2), *then for all* $(x, t) \in \mathbb{R} \times \mathbb{R}^+$,

$$\inf_y \sup_a \{e_a \cdot v_0(y) - e_a \cdot v(x, t) + (x - y)\, m_a - t\, q_a\} = 0.$$

Proof. Let $(x, t) \in \mathbb{R} \times \mathbb{R}^{+*}$ and $(y(x, t), 0)$ be its foot. Let, for example, $y < y(x, t)$. We again consider a point $z(y; x, t) \in [y, y(x, t)]$ such that $w \circ u_0(z) \leq w \circ u_0(z(y; x, t))$ for all $z \in [y, y(x, t)]$. The assumption on $w \circ u_0$ enables us to take $z(y; x, t) = y$. If the λ-characteristic issued from $z(y; x, t) = y$ attains time t, we can stick to the preceding argument. If the λ-characteristic issued from $z(y; x, t) = y$ encounters a λ-shock at some time $t_0 < t$, we denote by $s \mapsto X(s)$ this λ-shock curve and

$$w \circ u(X(t) - 0, t) = w_l(t), \qquad w \circ u(X(t) + 0, t) = w_r(t).$$

By definition, we have either $w \circ u_0(y) = w_l(t_0)$ or $w \circ u_0(y) = w_r(t_0)$. Moreover, by a lemma similar to Lemma 4.6, we have that w_l is a nondecreasing function of time whereas w_r is nonincreasing. Let $\boldsymbol{a} = \boldsymbol{w} \circ \boldsymbol{u}_0(\boldsymbol{y})$. In any case, we get

$$\sup_{[t_0,t]} w_r \leq a \leq \inf_{[t_0,t]} w_l.$$

Applying Lemma 4.9 and equation (14), we get

$$\mathcal{L}(y,a;x,t) \geq \mathcal{L}(y,a;X(t),t) \geq \mathcal{L}(y,a;X(t_0),t_0) = \mathcal{L}(y,a;y,0) = 0. \qquad \square$$

Eventually, we will have proved the formula in both monotonic cases for $w \circ u_0$. That is one of the reasons why we make the following conjecture.

CONJECTURE 1. *Let* (λ, r) *be a GNLBT field such that* (i)–(iii) *hold. Let* u_0 *belong to* BV($\mathbb{R}$). *If* v *satisfies equations* (3) *and* (4) *and is such that* $u = v_x$ *is piecewise smooth and is the entropy solution to equations* (1) *and* (2), *then for all* $(x,t) \in \mathbb{R} \times \mathbb{R}^+$,

$$\inf_y \sup_a \{e_a \cdot v_0(y) - e_a \cdot v(x,t) + (x-y)m_a - tq_a\} = 0. \tag{5}$$

Remark 4. We can prove that $\sup_a \mathcal{L}(y,a;x,t) \geq 0$ for points (x,t) lying outside a cone with vertex y. Indeed, let $a_{m,M}$ be such that

$$a_m \leq w \circ u_0 \leq a_M.$$

It is sufficient to prove that

$$\sup_{a \in [a_m,a_M]} \mathcal{L}(y,a;x,t) \geq 0.$$

Since $\mathcal{L}$ is continuous with respect to a (in fact, it is at least $\mathcal{C}^1$) and is Lipschitz continuous with respect to $(y;x,t)$, the upper envelope

$$L_0(y;x,t) = \sup_{a \in [a_m,a_M]} \mathcal{L}(y,a;x,t) = \max_{a \in [a_m,a_M]} \mathcal{L}(y,a;x,t)$$

is Lipschitz continuous. We shall easily prove that there exists some nonnegative constant C such that $L_0(y;x,t) \geq 0$ if $|(x-y)/t| \geq C$.

Indeed, suppose that we have some compact and convex *invariant domain* $K \subset \Omega$ that contains u_0. For each $a \in [a_m, a_M]$, let

$$\delta_a(u) = \begin{cases} \dfrac{e_a \cdot f(u) - q_a}{e_a \cdot u - m_a} & \text{if } u \notin \Pi_a \cap \Omega, \\ \lambda(u) & \text{if } u \in \Pi_a \cap \Omega. \end{cases}$$

This gives a continuous function of the two arguments a and u. Then let $C = \min_{[a_m,a_M]\times K} |\delta_a(u)|$. We have—among other things—that

$$\mathcal{L}_t(y,a;x,t) = e_a \cdot f(u(x,t)) - q_a \geq -C|\, m_a - e_a \cdot u(x,t)\,| = -C|\,\mathcal{L}_x(y,a;x,t)\,|.$$

In particular, this gives, for $x < y$,

$$\mathcal{L}_t(y,a_m;x,t) \geq +C\mathcal{L}_x(y,a_m;x,t)$$

and, for $x > y$,

$$\mathcal{L}_t(y, a_M; x, t) \geq -C\mathcal{L}_x(y, a_M; x, t).$$

After integrating these inequalities along the lines with "slopes" $-C$ and $+C$, respectively, we obtain that $\mathcal{L}$ is nondecreasing along those lines. Since equation (14) implies that

$$\mathcal{L}(y, a_m; Y, 0) \geq 0, \quad Y < y,$$

and that

$$\mathcal{L}(y, a_M; Y, 0) \geq 0, \quad Y > y,$$

we must have that $L_0(y; x, t) \geq 0$ for all (x, t) such that $|(x - y)/t| \geq C$.

5. Conclusion. Formula (5) has been proved for a large variety of initial data, including Riemann data and more generally monotone initial data (in the coordinates of Riemann invariants). For general initial data of bounded variation, its proof should rely on

$$L_0(y; x, t) \geq 0 \quad \forall y \in \mathbb{R} \tag{11}$$

for all $(x, t) \in \mathbb{R} \times \mathbb{R}^+$. It was noted that inequality (11) holds at $t = 0$ and also for $(y; x, t)$ such that $|(x - y)/t| \geq C > 0$. However, there is still a great deal of analysis to do in order to remove all the restrictions.

Acknowledgments. This study was suggested to me by D. Serre. I would especially like to thank him for his constant encouragement. A. Heibig also took an interest in my work for which I thank him sincerely.

CONVERGENCE OF THE HOMOGENIZATION PROCESS FOR A DOUBLE-POROSITY MODEL OF IMMISCIBLE TWO-PHASE FLOW*

ALAIN BOURGEAT†, STEPHAN LUCKHAUS‡, AND ANDRO MIKELIĆ§

Abstract. In this paper, we justify by periodic homogenization the double-porosity model for immiscible incompressible two-phase flow. The volume fraction of the fissured part and the nonfissured part are kept positive constants and of the same order. The scaling is such that, in the final homogenized equations, the less permeable part of the matrix contributes as a nonlinear memory term. To prove the convergence of the total velocity and of the "reduced" pressure, we use the two-scale convergence since it seems to be appropriate for the problem, even though it would be possible to work with periodic modulation. However, in the final step, the degenerate ellipticity prevents the use of the two-scale convergence method and leads us to use periodic modulation.

Key words. flow in porous medium, double porosity, fractured reservoir, homogenization, dilation

1. Introduction.

Naturally fractured reservoirs may contain many fractures that permeate different regions of the reservoir and are characterized by the existence of a system of high-conductivity fissures together with a large number of matrix blocks containing most of the oil. The fractures serve as highly conductive flow paths for the reservoir's fluid, increasing the reservoir's effective permeability significantly over the permeability corresponding only to the rock matrix. The reservoir mechanism of fractured systems is significantly different from that of a so-called single-porosity system; see, for instance, [15, 17, 18, 23, 26]. To describe the flow of the fluid in such a fractured reservoir, several authors in the engineering literature [8, 16, 19, 31] showed that if there are many well-connected fractures, the network of fractures behaves as an equivalent porous medium, described by the so-called "dual-porosity" model.

In Barenblatt's dual-porosity model of the fractures, the width is considerably greater than the characteristic dimensions of the pores and the permeability K^* of the fissure system considerably exceeds the permeability k of the individual blocks of porous media. At the same time, the fissures occupy a smaller volume than the pores, so the ratio of the volume of the fissures to the total volume is smaller than the porosity of any individual block of porous media.

To obtain the dual-porosity model, the fracture system's local properties are averaged over a volume containing both the fractures and a matrix. The so-called dual-porosity model for a porous medium consists of an equivalent coarse-grained porous medium in which the fissures play the role of "pores" and the blocks of porous media play the role of "grains."

While no flow is allowed between blocks, only matrix–fractures flow is possible,

and the porous-rock matrix system plays the role of a global source term macroscopically distributed over the entire equivalent coarse-grained porous medium.

Since flow in the fractures is much more rapid than inside the matrix, the fluid does not flow directly from one matrix block to another. Rather it first flows into the fractures system and then can pass into a block or remain in the fractures.

Denote by ε the ratio between the size of one block of porous media Ω_m^ε to the size of the whole domain of calculation Ω; then the characteristic time scale for any parabolic evolution in one block Ω_m^ε will be of order ε^{-2}.

In our case, the parabolic evolution is driven by the system of continuity (2.1)–(2.6) below. On the other hand, to have a permeability ratio of order ε^2 between the system of equations in the blocks of porous media and the system of equations in the fissures means that the ratio of the characteristic time for the rescaled flow (by $y = x/\varepsilon$) in a single block and the characteristic time for the flow through the entire system of fractures is of order ε^{-2}. Roughly speaking, we may say that a time ratio of ε^2 between the fractures and the porous block will give a time scaling allowing at the global level (i.e., $\varepsilon \to 0$) the matrix–fracture interaction phenomena described before and will lead to the dual-porosity model. At a time $t \ll 1$, a large fraction of the reserves is extracted from the fractures; then at time $t \sim 0(1)$, the exchange between porous blocks and fissures as described in [25] begins. This effect has already been observed in the case of a diffusion equation coupled with Darcy flow in the paper of Vogt [30]. It should also be noticed that this ε^2 time scaling is done in the engineering literature, as, for instance, in [27, 28], but is motivated by introducing a geometrical factor of transmissibility. If one takes the ratio of the two permeabilities of order one, then by the usual theory of homogenization the limit model will be, as, for instance, in [11, 12], a single-porosity model. If the ratio is smaller than of order ε^2, then there is no contribution from the blocks to the global continuity system of equations in the limit model, which then corresponds to the homogenization of only the system of fissures.

The precise physical assumptions made before averaging for the system of porous blocks and fissures are as follows. The medium is of "dual-porosity" type; i.e., the two parts of this medium, the fissures and the blocks, both behave like porous media and obey the generalized Darcy law. They differ only by their porosity and absolute permeability. Moreover, the two phases—the wetting and the nonwetting—are assumed to be incompressible and in capillary equilibrium at the pore level. This last assumption means that the faster time scale (or order ε^2 as discussed before) is sufficiently large to be bigger than the required time to establish pore equilibrium in both parts of the porous medium; moreover, we assume that there are no capillary hysteresis effects, which means this capillary equilibrium is unique. These last two assumptions lead in both parts of the medium to capillary pressure and relative permeability curves depending only on saturation and space and, finally, to the two-phase immiscible-flow parabolic-elliptic system of equations with a degeneracy. In this we follow the existing engineering literature.

It should be noticed that in some experimental situations as described in [9] or [10], the physical assumptions above are not valid; some other models of fissured porous media must be used. Some of these models in which the capillary pressure in the fissured part is neglected lead to a system with a purely convective equation instead of the degenerate one. This type of purely convective equation is outside the scope of this paper and of the homogenization methods presented herein.

The main objective of this paper is to derive rigorously (from the mathematical point of view) the dual-porosity model for incompressible two-phase flow. Rigorous mathematical proof of this dual-porosity model has been obtained before only for the single-phase flow in [6], i.e., when the equations are linear. For the case of two-phase flow, where the leading equations are much more complicated (a nonlinear system of coupled equations with parabolic degeneracy), the authors of [6] were able only to derive this model by formal asymptotic expansion in [7].

To prove our result, we use the two-scale convergence method defined in [3] and [24] to prove convergence of the total velocity and of the "reduced" pressure, but the difficulty added by the degenerate ellipticity prevents the use of two-scale convergence of the saturation and leads to the use of periodic modulation as defined in [6] or [30].

For the sake of simplicity, as usual in the engineering literature (see, for instance [25, 28, 31]), we assume periodic distribution of the cells; each cell contains only one matrix. However, the two-scale method could also be used with randomly distributed cells as in [3], and although the periodic modulation is used herein under periodic assumptions, we think that it could certainly be extended to some type of randomly distributed media.

The remainder of the paper is as follows.

In the next section, we present the equations that describe the microscopic nature of the two-phase flow in a naturally fractured reservoir. These equations are spacially scaled by ε, the ratio between the size of the blocks and the size of the domain Ω, and are time scaled as explained above by ε^2. After extension of the solution and the pressure from the fissured part to the whole domain Ω, we obtain from the a priori estimates in §3 the convergence to the homogenized macroscopic model in §4.

2. The microscopic model. The system of small fractures surrounding the block of porous medium is considered itself as a porous medium with dimensionless absolute permeability K^* and porosity ϕ^*. For this medium, the relative permeability curves are denoted $K_{ri}(S)$, $i = o, w$, and the capillary pressure curve is denoted $P_c(S)$.

In each individual cell Y, the matrix block of porous medium Y_m has dimensionless absolute permeability k and porosity φ with relative permeability $k_{ri}(s)$, $i = o, w$, and capillary pressure curve $p_c(s)$.

Denoting by Ω_m^ε the blocks of porous media, by Ω_f^ε the fissures surrounding Ω_m^ε, and by Γ^ε the boundary between Ω_m^ε and Ω_f^ε, with $(0, T)$ a time interval, we write the conservation of mass in each phase, combined with the generalized Darcy law, as

$$\phi^*(x)\frac{\partial S_o^\varepsilon}{\partial t} - \operatorname{div}\left\{\frac{K^*(x)K_{ro}(S_o^\varepsilon)}{\mu_o}[\nabla P_o^\varepsilon - \rho_o g]\right\} = f_o(x,t) \tag{2.1}$$

and

$$\phi^*(x)\frac{\partial S_w^\varepsilon}{\partial t} - \operatorname{div}\left\{\frac{K^*(x)K_{rw}(S_w^\varepsilon)}{\mu_w}[\nabla P_w^\varepsilon - \rho_w g]\right\} = f_w(x,t) \quad \text{in} \quad \Omega_f^\varepsilon \times (0,T), \tag{2.2}$$

$$\varphi^\varepsilon(x)\frac{\partial s_o^\varepsilon}{\partial t} - \varepsilon^2\operatorname{div}\left\{\frac{k^\varepsilon(x)k_{ro}(s_o^\varepsilon)}{\mu_o}[\nabla p_o^\varepsilon - \rho_o g]\right\} = f_o(x,t) \tag{2.3}$$

and

$$\varphi^\varepsilon(x)\frac{\partial s_w^\varepsilon}{\partial t} - \varepsilon^2\operatorname{div}\left\{\frac{k^\varepsilon(x)k_{rw}(s_w^\varepsilon)}{\mu_w}[\nabla p_w^\varepsilon - \rho_w g]\right\} = f_w(x,t) \quad \text{in} \quad \Omega_m^\varepsilon \times (0,T), \tag{2.4}$$

$$\frac{K^* K_{ro}(S_o^\varepsilon)}{\mu_o} \, [\nabla P_o^\varepsilon - \rho_o g] \cdot \nu = \varepsilon^2 \frac{k^\varepsilon k_{ro}(s_w^\varepsilon)}{\mu_o} \, [\nabla p_o^\varepsilon - \rho_o g] \cdot \nu, \tag{2.5}$$

$$\frac{K^* K_{rw}(S_w^\varepsilon)}{\mu_w} \, [\nabla P_w^\varepsilon - \rho_w g] \cdot \nu = \varepsilon^2 \frac{k^\varepsilon k_{rw}(s_w^\varepsilon)}{\mu_w} \, [\nabla p_w^\varepsilon - \rho_w g] \cdot \nu \quad \text{on} \quad \Gamma^\varepsilon \times (0,T); \tag{2.6}$$

$$P_o^\varepsilon = p_o^\varepsilon \quad \text{on} \quad \Gamma^\varepsilon \times (0,T), \tag{2.7}$$

$$P_w^\varepsilon = p_w^\varepsilon \quad \text{on} \quad \Gamma^\varepsilon \times (0,T); \tag{2.8}$$

$$S_o^\varepsilon(x,0) = S_o^0(x) \quad \text{in} \quad \Omega_f^\varepsilon, \qquad s_o^\varepsilon(x,0) = s_o^0(x) \quad \text{in} \quad \Omega_m^\varepsilon; \tag{2.9}$$

$$S_w^\varepsilon(x,0) = S_w^0(x) \quad \text{in} \quad \Omega_f^\varepsilon, \qquad s_w^\varepsilon(x,0) = s_w^0(x) \quad \text{in} \quad \Omega_m^\varepsilon; \tag{2.10}$$

$$S_o^\varepsilon + S_w^\varepsilon = 1 \quad \text{in} \quad \Omega_f^\varepsilon, \qquad s_o^\varepsilon + s_w^\varepsilon = 1 \quad \text{in} \quad \Omega_m^\varepsilon \times (0,T); \tag{2.11}$$

$$\begin{aligned} P_w^\varepsilon - P_o^\varepsilon &= P_c(S_w^\varepsilon) \quad \text{in} \quad \Omega_f^\varepsilon \times (0,T), \\ p_w^\varepsilon - p_o^\varepsilon &= p_c(s_w^\varepsilon) \quad \text{in} \quad \Omega_m^\varepsilon \times (0,T), \end{aligned} \tag{2.12}$$

where ν denotes the outward normal to Γ^ε.

Also, we define the boundary conditions

$$P_o^\varepsilon = P_o^D \quad \text{on} \quad \Gamma^1 \times (0,T), \qquad P_w^\varepsilon = P_w^D \quad \text{on} \quad \Gamma^1 \times (0,T) \tag{2.13}$$

(i.e., Γ^1 represents the part of the boundary $\partial\Omega$ that is in contact with a liquid continuum).

$$\frac{K^* K_{ro}(S_o^\varepsilon)}{\mu_o} \, [\nabla P_o^\varepsilon - \rho_o g] \cdot \nu = g_o \quad \text{on} \quad \Gamma^2 \times (0,T), \tag{2.14}$$

$$\frac{K^* K_{rw}(S_w^\varepsilon)}{\mu_w} \, [\nabla P_w^\varepsilon - \rho_w g] \cdot \nu = g_w \quad \text{on} \quad \Gamma^2 \times (0,T) \tag{2.15}$$

(i.e., a prescribed flow rate is assumed through the pervious boundary Γ^2).

At this point, we state a number of assumptions on data.

(A1) To avoid too much notation, let $\Omega = \Omega_f^\varepsilon \cup \Omega_m^\varepsilon \cup \Gamma^\varepsilon$ be a cube and $Y =]0,1[^n$ be a cell. Let $\partial\Omega = \overline{\Gamma^1} \cup \overline{\Gamma^2}$, $\Gamma^1 \cap \Gamma^2 = \emptyset$, where each Γ^1 and Γ^2 is an $(n-1)$-dimensional manifold (with boundary).

(A2) Let $\phi^* \in L^\infty(\Omega)$ and $\phi^*(x) \geq \phi_* > 0$. Furthermore, let $\varepsilon^{-1} \in I\!N$ and $\varphi^\varepsilon(x) = \varphi^0\left(\frac{x}{\varepsilon}\right) \in L^\infty(\Omega)$, where φ^0 is a Y-periodic function and $\varphi^\varepsilon(x) \geq \varphi_* > 0$.

(A3) Let $k^\varepsilon(x) = k\left(\frac{x}{\varepsilon}\right)$, where k is a Y-periodic tensor, $k^\varepsilon \in L^\infty(\Omega)^{n^2}$, and

$$0 < k_*|\xi|^2 \leq k^\varepsilon \xi \xi \leq k^*|\xi|^2 \quad \forall \xi \in I\!R^n, \ \xi \neq 0;$$

furthermore, let $K^* \in L^\infty(\Omega)$ and $K^*(x) \geq k_* > 0$.

(A4) The capillary pressures P_c and p_c are strictly monotone increasing and locally Lipschitz continuous in $(0,1)$.

(A5) The saturations $S_i(x,Z)$ and $s_i(x,Z)$, considered as functions of the capillary pressure Z, are measurable in $x \in \Omega$ and continuous in $Z \in [0,1]$. Furthermore, $S_w(x,Z) = 0 = s_w(x,z)$ for $Z \leq P_{\min}$ (for $z \leq p_{\min}$, respectively) and $S_o(x,Z) = 0 = s_o(x,z)$ for $Z \geq P_{\max}$ (for $z \geq p_{\max}$, respectively); $-\infty \leq p_{\min} < 0 < p_{\max} < +\infty$ and $-\infty \leq P_{\min} < 0 < P_{\max} < +\infty$. Finally, S_o and s_o are monotone decreasing and S_w and s_w are monotone increasing in $Z \in [P_{\min}, P_{\max}]$ and in $z \in [p_{\min}, p_{\max}]$, respectively.

Now following [4] and [15], we transform our system (2.1)–(2.15) to a system formulated as an elliptic-parabolic problem for the "reduced" pressure, the total velocity, and the saturation of the w-phase.

Adding (2.1) and (2.2) gives

$$\operatorname{div}\{\varphi_o^\varepsilon + \varphi_w^\varepsilon\} = f_o + f_w \quad \text{in} \quad \Omega_f^\varepsilon \times (0,T), \tag{2.16}$$

where

$$\varphi_o^\varepsilon = -\frac{K^* K_{ro}(S_w^\varepsilon)}{\mu_o}\,[\nabla P_o^\varepsilon - \rho_o g],$$
$$\varphi_w^\varepsilon = -\frac{K^* K_{rw}(S_w^\varepsilon)}{\mu_w}\,[\nabla P_w^\varepsilon - \rho_w g].$$

Now we denote by K_{ro} and K_{rw} the relative permeability curves as functions of S_w^ε, and we define the "reduced" pressure as in [15]:

$$P^\varepsilon = \frac{1}{2}(P_o^\varepsilon + P_w^\varepsilon) + \int_0^{S_w^\varepsilon} \left(\frac{K_{rw}/\mu_w}{K_{ro}/\mu_0 + K_{rw}/\mu_w} - \frac{1}{2}\right)\frac{\partial P_c}{dS}dS. \tag{2.17}$$

We then have with definition (2.17) that

$$\nabla P^\varepsilon = \frac{K_{ro}(S_w^\varepsilon)/\mu_o}{K_{ro}(S_w^\varepsilon)/\mu_o + K_{rw}(S_w^\varepsilon)/\mu_w}\nabla P_o^\varepsilon + \frac{K_{rw}(S_w^\varepsilon)/\mu_w}{K_{ro}(S_w^\varepsilon)/\mu_o + K_{rw}(S_w^\varepsilon)/\mu_w}\nabla P_w^\varepsilon$$

and

$$\begin{aligned}&\varphi_o^\varepsilon + \varphi_w^\varepsilon\\ &= -K^*\left[\frac{K_{ro}(S_w^\varepsilon)}{\mu_o} + \frac{K_{rw}(S_w^\varepsilon)}{\mu_w}\right]\left\{\nabla P^\varepsilon - \frac{(K_{ro}(S_w^\varepsilon)/\mu_o)\rho_o g + (K_{rw}(S_w^\varepsilon)/\mu_w)\rho_w g}{K_{ro}(S_w^\varepsilon)/\mu_o + K_{rw}(S_w^\varepsilon)/\mu_w}\right\}.\end{aligned}$$

For simplicity, we suppose $f_o = 0$ and $f_w = 0$. Then (2.16) and (2.17) imply

$$\begin{aligned}&\operatorname{div}\left\{K^*\left[\frac{K_{ro}(S_w^\varepsilon)}{\mu_o} + \frac{K_{rw}(S_w^\varepsilon)}{\mu_w}\right]\right.\\ &\qquad\left.\cdot\left[\nabla P^\varepsilon - \frac{(K_{ro}(S_w^\varepsilon)/\mu_o)\rho_o + (K_{rw}(S_w^\varepsilon)/\mu_w)\rho_w}{K_{ro}(S_w^\varepsilon)/\mu_o + K_{rw}(S_w^\varepsilon)/\mu_w}g\right]\right\} = 0.\end{aligned} \tag{2.18}$$

Furthermore, we use the identity

$$\left[\frac{K_{ro}(S_w^\varepsilon)}{\mu_o} + \frac{K_{rw}(S_w^\varepsilon)}{\mu_w}\right]\varphi_w^\varepsilon = \frac{-K_{rw}(S_w^\varepsilon)}{\mu_w}\varphi_o^\varepsilon + \frac{K_{ro}(S_w^\varepsilon)}{\mu_o}\varphi_w^\varepsilon + \frac{K_{rw}(S_w^\varepsilon)}{\mu_w}(\varphi_o^\varepsilon + \varphi_w^\varepsilon),$$

which gives

$$\begin{aligned}\varphi_w^\varepsilon = &-\frac{K_{rw}(S_w^\varepsilon)/\mu_w}{K_{ro}(S_w^\varepsilon)/\mu_o + K_{rw}(S_w^\varepsilon)/\mu_w}\,\varphi_o^\varepsilon + \frac{K_{ro}(S_w^\varepsilon)/\mu_o}{K_{ro}(S_w^\varepsilon)/\mu_o + K_{rw}(S_w^\varepsilon)/\mu_w}\,\varphi_w^\varepsilon\\ &+\frac{K_{rw}(S_w^\varepsilon)/\mu_w}{K_{ro}(S_w^\varepsilon)/\mu_o + K_{rw}(S_w^\varepsilon)/\mu_w}\,(\varphi_o^\varepsilon + \varphi_w^\varepsilon).\end{aligned}$$

Now combining the last equality with (2.2) gives

$$\begin{aligned}\phi^*\frac{\partial S_w^\varepsilon}{\partial t} - \operatorname{div}\left\{K^*\frac{K_{rw}K_{ro}}{\mu_w\mu_o(K_{rw}/\mu_w + K_{ro}/\mu_o)}\left[\frac{\partial P_c}{dS}\nabla S_w^\varepsilon + (\rho_o - \rho_w)g\right]\right.\\ \left. - \frac{K_{rw}/\mu_w}{K_{ro}/\mu_o + K_{rw}/\mu_w}(\varphi_o^\varepsilon + \varphi_w^\varepsilon)\right\} = 0.\end{aligned} \tag{2.19}$$

Following Alt and DiBenedetto [4], we introduce the saturations of the wetting fluid as

$$S^\varepsilon(x,t) = S^\varepsilon_w\,(x, P^\varepsilon_w - P^\varepsilon_o) = S^\varepsilon_w\,(x, P_c(x,t)),$$
$$s^\varepsilon(x,t) = s^\varepsilon_w\,(x, p_c\,(x,t));$$

the "reduced" pressures as

$$P^\varepsilon(x,t) = \frac{1}{2}\,(P^\varepsilon_o + P^\varepsilon_w) + \int_0^{S^\varepsilon_w} \left(\frac{K_{rw}/\mu_w}{K_{ro}/\mu_o + K_{rw}/\mu_w} - \frac{1}{2}\right)\frac{\partial P_c}{\partial S}dS,$$
$$p^\varepsilon(x,t) = \frac{1}{2}\,(p^\varepsilon_o + p^\varepsilon_w) + \int_0^{s^\varepsilon_w} \left(\frac{k_{rw}/\mu_w}{k_{ro}/\mu_o + k_{rw}/\mu_w} - \frac{1}{2}\right)\frac{\partial p_c}{\partial s}ds;$$

and the total velocities as

$$V^\varepsilon(x,t) = -K^*(x)\,\Lambda\,(S^\varepsilon)[\nabla P^\varepsilon - E\,(S^\varepsilon)\,g],$$
$$v^\varepsilon(x,t) = -\varepsilon^2 k^\varepsilon(x)\,\lambda\,(s^\varepsilon)[\nabla p^\varepsilon - e\,(s^\varepsilon)\,g],$$

where

$$\Lambda(S) = \frac{K_{ro}(S)}{\mu_o} + \frac{K_{rw}(S)}{\mu_w},$$
$$\lambda(S) = \frac{k_{ro}(S)}{\mu_o} + \frac{k_{rw}(S)}{\mu_w},$$
$$E(S) = \frac{1}{\Lambda(S)}\left[\frac{K_{ro}(S)}{\mu_o}\rho_o + \frac{K_{rw}(S)}{\mu_w}\rho_w\right],$$
$$e(S) = \frac{1}{\lambda(S)}\left[\frac{k_{ro}(S)}{\mu_o}\rho_o + \frac{k_{rw}(S)}{\mu_w}\rho_w\right].$$

To simplify the notation inside (2.19), we introduce the notation

$$A(S) = \frac{K_{rw}(S)K_{ro}(S)}{\mu_o\mu_w\Lambda(S)}\frac{dP_c(S)}{dS},$$
$$a(S) = \frac{k_{rw}(S)k_{ro}(S)}{\mu_o\mu_w\lambda(S)}\frac{dp_c(S)}{dS},$$
$$B(S) = \frac{K_{rw}(S)K_{ro}(S)}{\mu_o\mu_w\Lambda(S)}(\rho_o - \rho_w),$$
$$b(S) = \frac{k_{rw}(S)k_{ro}(S)}{\mu_o\mu_w\lambda(S)}(\rho_o - \rho_w),$$
$$D(S) = \frac{K_{rw}(S)}{\mu_w\Lambda(S)},$$
$$d(S) = \frac{k_{rw}(S)}{\mu_w\lambda(S)}.$$

With this new notation, we have transformed the system (2.1)–(2.6), (2.11), (2.12) into

$$\phi^*\frac{\partial S^\varepsilon}{\partial t} - \operatorname{div}\{K^*A(S^\varepsilon)\nabla S^\varepsilon + K^*B(S^\varepsilon)g - D(S^\varepsilon)V^\varepsilon\} = 0 \quad \text{in } \Omega^\varepsilon_f \times (0,T), \tag{2.20}$$

$$V^\varepsilon = -K^*\Lambda(S^\varepsilon)[\nabla P^\varepsilon - E(S^\varepsilon)g] \quad \text{in } \Omega^\varepsilon_f \times (0,T), \tag{2.21}$$

$$\text{div} V^\varepsilon = 0 \quad \text{in} \quad \Omega_f^\varepsilon \times (0,T), \tag{2.22}$$

$$\varphi^\varepsilon(x)\frac{\partial s^\varepsilon}{\partial t} - \text{div}\,\{\varepsilon^2 k^\varepsilon a(s^\varepsilon)\nabla s^\varepsilon + k^\varepsilon \varepsilon^2 b(s^\varepsilon)g - d(s^\varepsilon)v^\varepsilon\} = 0 \quad \text{in} \quad \Omega_m^\varepsilon \times (0,T), \tag{2.23}$$

$$v^\varepsilon = -\varepsilon^2 k^\varepsilon \lambda(s^\varepsilon)\,[\nabla p^\varepsilon - e(s^\varepsilon)g] \quad \text{in} \quad \Omega_m^\varepsilon \times (0,T), \tag{2.24}$$

$$\text{div}\, v^\varepsilon = 0 \quad \text{in} \quad \Omega_m^\varepsilon \times (0,T), \tag{2.25}$$

where the following assumptions have been made.

(A6) The functions of S_w^ε, K_{ro}, K_{rw}, k_{rw}, and k_{ro} are continuous in $[0,1]$ and strictly positive in $(0,1)$, $K_{ro}(0) > 0$, $K_{rw}(1) > 0$, $k_{rw}(1) > 0$, $k_{ro}(0) > 0$, and $K_{rw}(0) = k_{rw}(0) = K_{ro}(1) = k_{ro}(1) = 0$. Furthermore, the functions Λ and λ satisfy

$$0 < \lambda_* \leq \min\{\Lambda(S),\ \lambda(S)\} < \max\{\Lambda(S),\ \lambda(S)\} \leq \lambda^* < +\infty.$$

(A7) A and a are continuous functions defined on $[0,1]$,

$$A(0) = A(1) = a(0) = a(1) = 0, \qquad A,\ a > 0 \quad \text{on} \quad (0,1).$$

(A8) B and b are continuous functions defined on $[0,1]$,

$$B(0) = B(1) = b(0) = b(1) = 0.$$

(A9) $D, d \in C[0,1]$ and $D(0) = d(0) = 0$.

(A10) $E, e \in C\,[0,1]$ and E and e are strictly positive.

After having derived in (2.20)–(2.25) the equations for P^ε, p^ε, S^ε, s^ε, V^ε, and v^ε, we turn to the boundary conditions (2.7) and (2.8) together with (2.12). The assumptions (A4)–(A5) imply

$$S^\varepsilon = s^\varepsilon \quad \text{on} \quad \Gamma^\varepsilon \times (0,T), \tag{2.26}$$

$$P^\varepsilon = p^\varepsilon \quad \text{on} \quad \Gamma^\varepsilon \times (0,T). \tag{2.27}$$

Finally, (2.5)–(2.6) and (2.22)–(2.24) imply

$$V^\varepsilon \cdot \nu = v^\varepsilon \cdot \nu \quad \text{on} \quad \Gamma^\varepsilon \times (0,T), \tag{2.28}$$

$$K^*[A(S^\varepsilon)\nabla S^\varepsilon + B(S^\varepsilon)g] \cdot \nu = k^\varepsilon[\varepsilon^2 a(s^\varepsilon)\nabla s^\varepsilon + \varepsilon^2 b(s^\varepsilon)g] \cdot \nu \quad \text{on} \quad \Gamma^\varepsilon \times (0,T). \tag{2.29}$$

It remains to write the boundary conditions on the outer boundary $\partial\Omega$ as

$$\left\{\begin{array}{l} V^\varepsilon \cdot \nu = g_o + g_w = 0 \quad \text{on} \quad \Gamma^2 \times (0,T), \\ K^*[A(S^\varepsilon)\nabla S^\varepsilon + B(S^\varepsilon)g] \cdot \nu = g_w \quad \text{on} \quad \Gamma^2 \times (0,T), \\ S^\varepsilon = S_w^\varepsilon(x, P_w^D - P_o^D) \quad \text{on} \quad \Gamma^1 \times (0,T). \end{array}\right. \tag{2.30}$$

To simplify the manipulations, we suppose that $S_w^\varepsilon(x, P_w^D - P_o^D) = 0$, i.e.,

$$S^\varepsilon = 0, P^\varepsilon = \frac{P_o^D + P_w^D}{2} = P_T^D \quad \text{on} \quad \Gamma^1 \times (0,T). \tag{2.31}$$

The initial conditions are

$$(2.32)\qquad S^\varepsilon(x,0)=S_w^0(x)\quad\text{in}\quad \Omega_f^\varepsilon,\qquad s^\varepsilon(x,0)=s_w^0(x)\quad\text{in}\quad \Omega_m^\varepsilon.$$

Now we define a weak solution to the problem (2.20)–(2.32).

DEFINITION (see Antontsev, Kazhikhov, and Monakhov [5]). *The measurable functions P^ε, p^ε, S^ε, s^ε, V^ε, and v^ε are a weak solution to the problem* (2.20)–(2.32) *if the following hold.*

(a) $0\le S^\varepsilon(x,t)\le 1$ *(a.e.) in* $\Omega_f^\varepsilon\times(0,T)$; $0\le s^\varepsilon(x,t)\le 1$ *(a.e.) in* $\Omega_m^\varepsilon\times(0,T)$.

(b) $\nabla P^\varepsilon\in L^\infty((0,T)\ ;\ L^2(\Omega_f^\varepsilon)^n)$, $\nabla p^\varepsilon\in L^\infty((0,T)\ ;\ L^2(\Omega_m^\varepsilon)^n)$,

$$A(S^\varepsilon)\nabla S^\varepsilon\in L^2(\Omega_f^\varepsilon\times(0,T))^n,\qquad \varepsilon a(s^\varepsilon)\nabla s^\varepsilon\in L^2(\Omega_m^\varepsilon\times(0,T))^n.$$

(c) *The boundary conditions* (2.31) *hold on* $\Gamma^1\times(0,T)$.

(d) *Conditions* (2.26) *and* (2.27) *are satisfied.*

(e) *For every* $\varphi\in H^1(\Omega\times(0,T))$ *and every* $\Psi\in H^1(\Omega)$ *satisfying* $\varphi=0$ *on* $\Gamma^1\times(0,T)$ *and* $\Psi=0$ *on* Γ^1, *we have*

$$(2.33)\qquad \int_0^t\int_{\Omega_f^\varepsilon}\phi^*S^\varepsilon\frac{\partial\varphi}{\partial t}+\int_0^t\int_{\Omega_m^\varepsilon}\varphi^\varepsilon s^\varepsilon\frac{\partial\varphi}{\partial t}-\int_0^t\int_{\Omega_f^\varepsilon}A(S^\varepsilon)K^*\nabla S^\varepsilon\nabla\varphi$$
$$-\int_0^t\int_{\Omega_m^\varepsilon}\varepsilon^2k^\varepsilon a(s^\varepsilon)\nabla s^\varepsilon\nabla\varphi-\int_0^t\int_{\Omega_f^\varepsilon}B(S^\varepsilon)K^*g\nabla\varphi-\int_0^t\int_{\Omega_m^\varepsilon}\varepsilon^2b(s^\varepsilon)k^\varepsilon g\nabla\varphi$$
$$+\int_0^t\int_{\Omega_f^\varepsilon}D(S^\varepsilon)V^\varepsilon\nabla\varphi+\int_0^t\int_{\Omega_m^\varepsilon}d(s^\varepsilon)v^\varepsilon\nabla\varphi=\int_{\Omega_f^\varepsilon}\phi^*S^\varepsilon(\cdot,t)\varphi(\cdot,t)dx$$
$$+\int_{\Omega_m^\varepsilon}\varphi^\varepsilon s^\varepsilon(\cdot,t)\varphi(\cdot,t)dx-\int_{\Omega_f^\varepsilon}\phi^*S_w^0\varphi(\cdot,0)-\int_{\Omega_f^\varepsilon}\varphi^\varepsilon s_w^0\varphi(\cdot,0)-\int_0^t\int_{\Gamma^2}g_w\varphi$$

for (a.e.) $t\in(0,T)$ *and*

$$(2.34)\qquad \int_{\Omega_f^\varepsilon}V^\varepsilon\nabla\Psi dx+\int_{\Omega_m^\varepsilon}v^\varepsilon\nabla\Psi dx=0\quad \textit{for (a.e.)}\quad t\in(0,T),$$

where V^ε *and* v^ε *are given by* (2.22) *and* (2.24).

Following Antontsev, Kazhikhov, and Monakhov [5, pp. 203–204], we make the following assumptions:

$$(2.35)\qquad 0\le S_w^0\le 1\quad\text{in}\quad\Omega\quad\text{and}\quad 0\le s_w^0\le 1\quad\text{in}\quad\Omega;$$
$$(2.36)\qquad P_T^D\in L^\infty(0,T\ ;\ H^1(\Omega)),\qquad g_w\in L^\infty((0,T)\times\Gamma^2).$$

Then the existence theory (see Alt and DiBenedetto [4], Antontsev, Kazhikhov, and Monakhov [5], or Kröner and Luckhaus [21]) gives the existence of at least one weak solution for all $\varepsilon>0$.

3. A priori estimates and extensions.

As a simple consequence of the construction of the weak solution, we get the estimates

$$(3.1)\qquad \int_0^T\int_{\Omega_f^\varepsilon}A(S^\varepsilon)|\nabla S^\varepsilon|^2\le C,$$

$$\int_0^T \int_{\Omega_m^\varepsilon} a(s^\varepsilon)|\nabla s^\varepsilon|^2 \le \frac{C}{\varepsilon^2}, \tag{3.2}$$

$$0 \le S^\varepsilon \le 1 \quad \text{(a.e.) in} \quad \Omega_f^\varepsilon \times (0,T), \tag{3.3}$$

$$0 \le s^\varepsilon \le 1 \quad \text{(a.e.) in} \quad \Omega_m^\varepsilon \times (0,T), \tag{3.4}$$

$$\int_0^T \int_{\Omega_f^\varepsilon} |\nabla P^\varepsilon|^2 \le C, \tag{3.5}$$

$$\int_0^T \int_{\Omega_m^\varepsilon} |\nabla p^\varepsilon|^2 \le \frac{C}{\varepsilon^2}, \tag{3.6}$$

$$\int_0^T \int_{\Omega_f^\varepsilon} |V^\varepsilon|^2 \le C, \tag{3.7}$$

$$\int_0^T \int_{\Omega_m^\varepsilon} |v^\varepsilon|^2 \le C\varepsilon^2. \tag{3.8}$$

To get some additional a priori estimates and to homogenize the ε-problem we need to extend S^ε and P^ε to the whole domain $\Omega = \Omega_m^\varepsilon \cup \Omega_f^\varepsilon \cup \Gamma^\varepsilon$.

We assume then the geometry of the cell Y defined as follows.

(A11) Y_m, the matrix part, is a connected open subset of $I\!R^n$; $\overline{Y_m} \subset Y^0$, with Lipschitz boundary; $Y_f = Y \setminus \overline{Y_m}$, the fissure part, is connected.

Now defining $\Omega_f^\varepsilon = \Omega \cap \bigcup_{k\in \mathbb{Z}^n}(Y_f + k)$ from Acerbi et al. [1], there exist three constants $k_i = k_i(Y_f, n, q) > 0$, $i = 0,1,2$, and a linear and continuous extension operator

$$\Pi_\varepsilon \ : W^{1,q}(\Omega_f^\varepsilon) \to W^{1,q}_{\text{loc}}(\Omega) \tag{3.9}$$

such that

$$\Pi_\varepsilon u = u \quad \text{(a.e.) in} \quad \Omega_f^\varepsilon, \tag{3.10}$$

$$\int_{\Omega(\varepsilon k_0)} |\Pi_\varepsilon u|^q dx \le k_1 \int_{\Omega_f^\varepsilon} |u|^q dx, \tag{3.11}$$

$$\int_{\Omega(\varepsilon k_0)} |\nabla(\Pi_\varepsilon u)|^q dx \le k_2 \int_{\Omega_f^\varepsilon} |\nabla u|^q dx \tag{3.12}$$

for all $u \in W^{1,q}(\Omega_f^\varepsilon)$ and where $\Omega(\varepsilon k_0) = \{x \in \Omega \ : \text{dist}(x, \partial\Omega) > \varepsilon k_0\}$.

To avoid dealing with boundary layers, we make the following additional assumption on the structure of the whole domain Ω.

(A12) $\Omega_m^\varepsilon = \Omega(\varepsilon k_0) \cap (\bigcup_{k\in\mathbb{Z}^n} \varepsilon(Y_m + k))$ and $\Omega_f^\varepsilon = \Omega \setminus \overline{\Omega_m^\varepsilon}$.

Now let us derive L^2-estimates for P^ε and p^ε. Supposing that the blocks are removed in an εk_0-neighborhood of $\partial\Omega$, (3.11), (3.12), and (3.5) imply

$$\int_0^T \int_\Omega |\nabla(\Pi_\varepsilon P^\varepsilon)|^2 \le C. \tag{3.13}$$

Using the boundary condition on Γ^1, we get

$$\int_0^T \int_\Omega |\Pi_\varepsilon P^\varepsilon|^2 \le C. \tag{3.14}$$

Furthermore, by the continuity of pressures, we have

$$\int_0^T \int_{\Omega_m^\varepsilon} |p^\varepsilon - \Pi_\varepsilon P^\varepsilon|^2 dxdt \leq C\varepsilon^2 \int_0^T \int_{\Omega_m^\varepsilon} |\nabla(p^\varepsilon - \Pi_\varepsilon P^\varepsilon)|^2 dxdt,$$

which implies

$$\| p^\varepsilon - \Pi_\varepsilon P^\varepsilon \|_{L^2(\Omega_m^\varepsilon \times (0,T))} \leq C\varepsilon \| \nabla p^\varepsilon \|_{L^2(\Omega_m^\varepsilon \times (0,T))^n} + C\varepsilon \| \nabla P^\varepsilon \|_{L^2(\Omega_f^\varepsilon \times (0,T))^n} \leq C$$

and

$$\int_0^T \int_{\Omega_m^\varepsilon} |p^\varepsilon|^2 dxdt \leq C. \tag{3.15}$$

Now we plug a test function $\psi^\varepsilon = p^\varepsilon - \Pi_\varepsilon P^\varepsilon$ in Ω_m^ε and 0 in Ω_f^ε into the variational equation (2.34).

Equation (2.34) and the a priori estimates (3.13)–(3.14) give

$$\| \nabla p^\varepsilon \|_{L^2(\Omega_m^\varepsilon \times (0,T))^n} \leq C. \tag{3.16}$$

We define $\widetilde{p}^\varepsilon$ by

$$\widetilde{p}^\varepsilon = \begin{cases} p^\varepsilon(x,t) & \text{if} \quad x \in \overline{\Omega}_m^\varepsilon, \\ P^\varepsilon(x,t) & \text{if} \quad x \in \Omega_f^\varepsilon \end{cases}$$

and get

$$\begin{cases} \int_0^T \int_\Omega |\widetilde{p}^\varepsilon|^2 dxdt \leq C, \\ \int_0^T \int_\Omega |\nabla \widetilde{p}^\varepsilon|^2 dxdt \leq C. \end{cases} \tag{3.17}$$

Now we define $Z(S) = \int_0^S \sqrt{A(\eta)} d\eta$. Obviously, Z is a monotone function of S. Furthermore, we set $Z^\varepsilon = Z(S^\varepsilon)$.

Then

$$0 \leq Z^\varepsilon \leq M_Z = \max_{\eta \in [0,1]} \sqrt{A(\eta)} \quad \text{(a.e.) in} \quad \Omega_f^\varepsilon \times (0,T),$$

$$\nabla Z^\varepsilon = \sqrt{A(S^\varepsilon)} \nabla S^\varepsilon \in L^2(\Omega_f^\varepsilon \times (0,T)).$$

Hence

$$\int_0^T \int_\Omega |\nabla(\Pi_\varepsilon Z^\varepsilon)|^2 dxdt \leq C, \tag{3.18}$$

$$0 \leq \Pi_\varepsilon Z^\varepsilon \leq M_Z \quad \text{(a.e.) in} \quad \Omega \times (0,T). \tag{3.19}$$

Introducing $\overline{S}^\varepsilon$ as $\overline{S}^\varepsilon = (Z)^{-1}(\Pi_\varepsilon Z^\varepsilon)$ leads to

$$\nabla \overline{S}^\varepsilon = \frac{1}{dZ/dS} \nabla(\Pi_\varepsilon Z^\varepsilon) = \frac{1}{\sqrt{a(\overline{S}^\varepsilon)}} \nabla(\Pi_\varepsilon Z^\varepsilon)$$

and to the estimate

$$\int_0^T \int_\Omega a(\overline{S}^\varepsilon) |\nabla \overline{S}^\varepsilon|^2 dxdt \leq C, \tag{3.20}$$

$$0 \le \overline{S}^\varepsilon \le 1 \quad \text{(a.e.) in} \quad \Omega \times (0,T). \tag{3.21}$$

To extend s^ε, we introduce as before $z = \int_0^s \sqrt{a(\eta)}d\eta$.
Since $dz/ds = \sqrt{a(s)} \ge 0$, z is monotone.
Once again, we have

$$0 \le z^\varepsilon \le M_z = \max_{\eta\in[0,1]} \sqrt{a(\eta)} \quad \text{(a.e.) in} \quad \Omega_m^\varepsilon \times (0,T),$$

$$\nabla z^\varepsilon = \sqrt{a(s^\varepsilon)}\nabla s^\varepsilon \in L^2(\Omega_m^\varepsilon \times (0,T)).$$

Hence for

$$\widetilde{z}^\varepsilon = \begin{cases} z^\varepsilon(x,t) & \text{for} \quad x \in \overline{\Omega}_m^\varepsilon, \\ Z^\varepsilon(x,t) & \text{for} \quad x \in \overline{\Omega}_f^\varepsilon, \end{cases}$$

we have

$$\int_0^T \int_\Omega |\nabla \widetilde{z}^\varepsilon|^2 dxdt \le C/\varepsilon^2, \tag{3.22}$$

$$0 \le \widetilde{z}^\varepsilon \le \max\{M_Z, M_z\} \quad \text{(a.e.) on} \quad \Omega \times (0,T). \tag{3.23}$$

Finally, we set

$$\widetilde{s}^\varepsilon = \begin{cases} s^\varepsilon(x,t) & \text{for} \quad x \in \overline{\Omega}_m^\varepsilon, \\ S^\varepsilon(x,t) & \text{for} \quad x \in \Omega_f^\varepsilon. \end{cases}$$

Then

$$0 \le \widetilde{s}^\varepsilon \le 1 \quad \text{(a.e.) on} \quad \Omega \times (0,T). \tag{3.24}$$

After deriving the estimates for the spatial derivatives, we turn to the behavior in time. In the case of nondegenerate nonlinear problems, one method is to formulate an estimate for the time derivative of a fractional order (see Aganović and Mikelić [2]). For this degenerate parabolic-elliptic system, we use a similar but more direct approach.

We start with the variational formulation (2.33) and define

$$B_1^\varepsilon(x,t) = A(S^\varepsilon)K^*\nabla S^\varepsilon + B(S^\varepsilon)K^*g - D(S^\varepsilon)V^\varepsilon \quad \text{in} \quad \Omega_f^\varepsilon \times (0,T),$$

$$B_2^\varepsilon(x,t) = a(s^\varepsilon)k^*\nabla s^\varepsilon + b(s^\varepsilon)k^*g - \varepsilon^{-2}v^\varepsilon d(s^\varepsilon) \quad \text{in} \quad \Omega_m^\varepsilon \times (0,T).$$

It is natural to set $B_i^\varepsilon = 0$ for $t \notin (0,T)$. Then

$$\int_{I\!R} \int_{\Omega_f^\varepsilon} |B_1^\varepsilon|^2 < +\infty \quad \text{and} \quad \int_{I\!R} \int_{\Omega_f^\varepsilon} \varepsilon^2 |B_2^\varepsilon|^2 < +\infty.$$

Let us take $\varphi\ (x,t) = \eta(t)\xi(x)$, $\eta \in C_0^\infty((0,T))$, $\xi \in H_0^1(\Omega)$ as a test function in (2.33). We get

$$\int_0^T \left\{ \frac{\partial \eta}{\partial t} \left[\int_{\Omega_f^\varepsilon} \phi^* S^\varepsilon \xi + \int_{\Omega_w^\varepsilon} \varphi^\varepsilon s^\varepsilon \xi \right] - \eta \left[\int_{\Omega_m^\varepsilon} B_1^\varepsilon \nabla \xi + \int_{\Omega_m^\varepsilon} \varepsilon^2 B_2^\varepsilon \nabla \xi \right] \right\} dt = 0,$$

which implies

$$-\frac{d}{dt}\left[\int_{\Omega_f^\varepsilon} \phi^* S^\varepsilon \xi + \int_{\Omega_m^\varepsilon} \varphi^\varepsilon s^\varepsilon \xi\right] = \int_{\Omega_f^\varepsilon} B_1^\varepsilon \nabla \xi + \int_{\Omega_m^\varepsilon} \varepsilon^2 B_2^\varepsilon \nabla \xi. \tag{3.25}$$

Now we choose an interval $[\tau, \tau + \Delta\tau] \subset (0, T)$, $\tau > 0, \Delta\tau > 0$, and after integrating (3.25) over that interval we find the equality

$$-\int_{\Omega_f^\varepsilon} \phi^* \xi \Delta_\tau S^\varepsilon - \int_{\Omega_m^\varepsilon} \varphi^\varepsilon \xi \Delta_\tau s^\varepsilon = \int_\tau^{\tau+\Delta\tau} \int_{\Omega_f^\varepsilon} B_1^\varepsilon \nabla \xi + \int_\tau^{\tau+\Delta\tau} \int_{\Omega_m^\varepsilon} \varepsilon^2 B_2^\varepsilon \nabla \xi, \tag{3.26}$$

where $\Delta_\tau u = u(\cdot, \tau + \Delta\tau) - u(\cdot, \tau)$. Noting that τ is a parameter in (3.26), we choose $\xi = \Delta_\tau \widetilde{z}^\varepsilon$ as a test function in (3.26). We get

$$\begin{aligned}
&\int_{\Omega_f^\varepsilon} \phi^* \Delta_\tau Z^\varepsilon \Delta_\tau S^\varepsilon + \int_{\Omega_m^\varepsilon} \varphi^\varepsilon \Delta_\tau z^\varepsilon \Delta_\tau s^\varepsilon \\
&\leq \left| \int_\tau^{\tau+\Delta\tau} \int_{\Omega_f^\varepsilon} B_1^\varepsilon(x,t) \cdot \nabla \Delta_\tau Z^\varepsilon dx dt \right| + \left| \int_\tau^{\tau+\Delta\tau} \int_{\Omega_m^\varepsilon} \varepsilon^2 B_2^\varepsilon(x,t) \nabla \Delta_\tau z^\varepsilon dx dt \right| \\
&\leq \left| \int_0^1 \int_{\Omega_f^\varepsilon} B_1^\varepsilon(x, \tau + \sigma\Delta\tau) \nabla \Delta_\tau Z^\varepsilon d\sigma dx \right| |\Delta\tau| + |\Delta\tau| \\
&\quad \cdot \left| \int_0^1 \int_{\Omega_m^\varepsilon} \varepsilon^2 B_2^\varepsilon(x, \tau + \sigma\Delta\tau) \nabla \Delta_\tau z^\varepsilon d\sigma dx \right|.
\end{aligned}$$

Integration in time over $[0, T - \Delta\tau]$ and Hölder's inequality give

$$\begin{aligned}
&\int_0^{T-\Delta\tau} \int_{\Omega_f^\varepsilon} \phi^* \Delta_\tau Z^\varepsilon \Delta_\tau S^\varepsilon + \int_0^{T-\Delta\tau} \int_{\Omega_m^\varepsilon} \varphi^\varepsilon \Delta_\tau z^\varepsilon \Delta_\tau s^\varepsilon \leq |\Delta\tau|, \\
&\{\|B_1^\varepsilon \|_{L^2(\Omega_f^\varepsilon \times (0,T))^n} \cdot \| \nabla \Delta_\tau Z^\varepsilon \|_{L^2(\Omega_f^\varepsilon \times [0, T-\Delta\tau])^n} \\
&\quad + \| B_2^\varepsilon \|_{L^2(\Omega_w^\varepsilon \times (0,T))^n} \| \varepsilon \nabla \Delta_\tau z^\varepsilon \|_{L^2(\Omega_m^\varepsilon \times [0, T-\Delta\tau])^n} \} \leq C|\Delta\tau|.
\end{aligned}$$

Using monotonicity, we get

$$\int_0^{T-\Delta\tau} \int_\Omega [\widetilde{z}^\varepsilon(\cdot, \cdot + \Delta\tau) - \widetilde{z}^\varepsilon(\cdot, \cdot)] [\widetilde{s}^\varepsilon(\cdot, \cdot + \Delta\tau) - \widetilde{s}^\varepsilon(\cdot, \cdot)] \leq C|\Delta\tau| \tag{3.27}$$

and

$$\int_0^{T-\Delta\tau} \int_\Omega |\widetilde{z}^\varepsilon(\cdot, \cdot + \Delta\tau) - \widetilde{z}^\varepsilon(\cdot, \cdot)|^2 \leq C|\Delta\tau|. \tag{3.28}$$

For Z^ε, we get

$$\int_0^{T-\Delta\tau} \int_{\Omega_f^\varepsilon} |Z^\varepsilon(\cdot, \cdot + \Delta\tau) - Z^\varepsilon(\cdot, \cdot)|^2 \leq C|\Delta\tau|,$$

and since our extension is by reflection, we conclude
(3.29)

$$\int_0^{T-\Delta\tau} \int_\Omega [(\Pi_\varepsilon Z^\varepsilon)(\cdot, \cdot + \Delta\tau) - (\Pi_\varepsilon Z^\varepsilon)(\cdot, \cdot)] \left[\overline{S}^\varepsilon(\cdot, \cdot + \Delta\tau) - \overline{S}^\varepsilon(\cdot, \cdot)\right] \leq C|\Delta\tau|$$

and

$$\int_0^{T-\Delta\tau}\int_\Omega |(\Pi_\varepsilon Z^\varepsilon)(\cdot,\cdot+\Delta\tau)-(\Pi_\varepsilon Z^\varepsilon)(\cdot,\cdot)|^2 \le C|\Delta\tau|. \tag{3.30}$$

4. Compactness and convergence results. Using the a priori estimates derived in §3 and the concept of two-scale convergence as in [13] and [24], we get the following compactness results.

PROPOSITION 4.1. *There exists a subsequence such that*

(4.1) $\Pi_\varepsilon P^\varepsilon \longrightarrow P \in L^2((0,T);H^1(\Omega))$ *in the two-scale sense*;

(4.2) $\nabla(\Pi_\varepsilon P^\varepsilon) \longrightarrow \nabla P + \nabla_y P_1(t,x,y)$ *in the two-scale sense, where*

$$P_1 \in L^2((0,T)\times\Omega\ ;\ H^1_{\text{per}}(Y));$$

(4.3) $\widetilde{p}^\varepsilon \longrightarrow p \in L^2((0,T);H^1(\Omega))$ *in the two-scale sense*;

(4.4) $\Pi_\varepsilon Z^\varepsilon \longrightarrow Z \in L^2((0,T);\ H^1(\Omega))$ *in the two-scale sense*;

(4.5) $\nabla(\Pi_\varepsilon Z^\varepsilon) \longrightarrow \nabla Z + \nabla_y Z_1(t,x,y)$ *in the two-scale sense, where*

$$Z_1 \in L^2((0,T)\times\Omega\ ;\ H^1_{\text{per}}(Y));$$

(4.6) $\Pi_\varepsilon Z^\varepsilon \longrightarrow Z$ *strongly in* $L^q((0,T)\times\Omega)$ $\forall q < +\infty$;

(4.7) $\overline{S}^\varepsilon \longrightarrow S$ *strongly in* $L^q((0,T)\times\Omega)$ $\forall q < +\infty$;

(4.8) $\widetilde{s}^\varepsilon \longrightarrow s \in L^2((0,T)\times\Omega\times Y)$ *in the two scale-sense*;

(4.9) $\widetilde{z}^\varepsilon \longrightarrow z \in L^2((0,T)\times\Omega\ ;H^1_{\text{per}}(Y))$ *in the two scale-sense*;

(4.10) $\varepsilon\nabla\widetilde{z}^\varepsilon \longrightarrow \nabla_y z \in L^2((0,T)\times\Omega\times Y)$ *in the two scale-sense.*

Furthermore, let $\widetilde{V}^\varepsilon$ *be equal to* V^ε *in* $\Omega_f^\varepsilon\times(0,T)$ *and* v^ε *in* $\Omega_m^\varepsilon\times(0,T)$. *Then we have*

(4.11) $\widetilde{V}^\varepsilon \longrightarrow V \in L^2((0,T)\times\Omega\times Y)$ *in the two scale-sense*;

(4.12) $\text{div}_y V = 0$ *and* $\text{div}_x \int_Y V(x,y)dy = 0$.

Proof. The proof is a direct consequence of the a priori estimates and of Theorem 1.2 and Proposition 1.4 in Allaire [3]. □

Again as in Allaire [3], we plug into (2.34) a test function of the form

$$\varphi(x,t)+\varepsilon\varphi_1(x,x/\varepsilon,t)+\Psi(x,x/\varepsilon,t),$$

where $\varphi\in\mathcal{D}(Q_T)$, $\varphi_1\in\mathcal{D}(Q_T\ ;C^\infty_{\text{per}}(Y))$, and $\Psi\in\mathcal{D}(Q_T\ ;C^\infty_{\text{per}}(Y))$ with $\Psi=0$ for $y\in Y_f$.

We get

$$\int_0^T\int_{\Omega_f^\varepsilon} K^*\Lambda(S^\varepsilon)[\nabla P^\varepsilon - E(S^\varepsilon)g][\nabla\varphi+\varepsilon\nabla_x\varphi_1^\varepsilon+\nabla_y\varphi_1^\varepsilon]$$
$$+\int_0^T\int_{\Omega_m^\varepsilon}\varepsilon^2 k^\varepsilon\lambda(s^\varepsilon)[\nabla p^\varepsilon - e(s^\varepsilon)g]\left[\nabla\varphi+\varepsilon\nabla_x\varphi_1^\varepsilon+\nabla_y\varphi_1^\varepsilon+\nabla_x\Psi^\varepsilon+\frac{1}{\varepsilon}\nabla_y\Psi^\varepsilon\right]=0.$$

Passing to the two-scale limit yields

$$\int_0^T\int_\Omega\int_{Y_f} K^*\Lambda(S)[\nabla P+\nabla_y P_1 - E(S)g][\nabla\varphi(x,t)+\nabla_y\varphi_1(x,y,t)]$$
$$+\lim_{\varepsilon\to 0}\int_0^T\int_{\Omega_m^\varepsilon} k^\varepsilon\lambda(s^\varepsilon)\varepsilon\nabla p^\varepsilon\nabla_y\Psi^\varepsilon=0.$$

Choosing $\Psi = 0$ gives

$$-\mathrm{div}_x \left\{ \int_{Y_f} K^*(x)\Lambda(S)[\nabla P + \nabla_y P_1 - E(S)g] \right\} = 0 \quad \text{in} \quad Q_T \tag{4.13}$$

and

$$-\mathrm{div}_y \left\{ K^*(x)\Lambda(S)[\nabla P + \nabla_y P_1 - E(S)g] \right\} = 0 \quad \text{in} \quad Y_f$$

with

$$K^*(x)\Lambda(S)[\nabla P + \nabla_y P_1 - E(S)g] \cdot \nu = 0 \quad \text{on} \quad \partial Y_m$$

for a.e. $x, t \in Q_T$.

We shall use Θ, the tensor whose (i,j) component is $\partial\xi_j/\partial y_i$, where ξ_j is a periodic solution in Y of the auxiliary problem

$$\begin{cases} \Delta_y \xi_j = 0 & \text{in} \quad Y_f, \\ \nabla_y \xi_j \cdot \nu = -e_j \cdot \nu & \text{on} \quad \partial Y_m. \end{cases} \tag{4.14}$$

Since S is independent of y from (4.6) and (4.7), P_1 is given by the product

$$P_1 = \sum_j \xi_j(y) \left(\frac{\partial P}{\partial x_j} - E(S)g\delta_{j3} \right).$$

Finally, (4.13) reduces to

$$\begin{cases} \overline{V} = K^{*H} A(S) \left[\nabla_x P - E(S)g \right] = \dfrac{1}{|Y|} \displaystyle\int_Y V dy, \\ -\mathrm{div}_x \overline{V} = 0 \quad \text{in} \quad Q_T \end{cases} \tag{4.15}$$

with

$$K^{*H} = \frac{1}{|Y|} \int_{Y_f} K^*(I + \Theta) dy = \frac{|Y_f|}{|Y|} K^* \left(I + \frac{1}{|Y_f|} \int_{Y_f} \Theta(y) dy \right).$$

In our next step, we plug in a test function of the same form as above into (2.33). We have

$$\begin{aligned}
&\int_0^T \int_{\Omega_f^\varepsilon} \phi^* S^\varepsilon \left[\frac{\partial \varphi}{\partial t} + \varepsilon \frac{\partial \varphi_1^\varepsilon}{\partial t} \right] + \int_0^T \int_{\Omega_m^\varepsilon} \varphi^\varepsilon s^\varepsilon \left[\frac{\partial \varphi}{\partial t} + \varepsilon \frac{\partial \varphi_1^\varepsilon}{\partial t} + \frac{\partial \Psi}{\partial t} \right] \\
&- \int_0^T \int_{\Omega_f^\varepsilon} \sqrt{A(S^\varepsilon)} K^* \nabla Z^\varepsilon [\nabla \varphi + \varepsilon \nabla_x \varphi_1^\varepsilon + \nabla_y \varphi_1^\varepsilon] \\
&- \int_0^T \int_{\Omega_m^\varepsilon} \varepsilon \sqrt{a(s^\varepsilon)} K^* \varepsilon \nabla z^\varepsilon \left[\nabla \varphi + \varepsilon \nabla_x \varphi_1^\varepsilon + \nabla_y \varphi_1^\varepsilon + \nabla_x \Psi^\varepsilon + \frac{1}{\varepsilon} \nabla_y \Psi^\varepsilon \right] \\
&- \int_0^T \int_{\Omega_f^\varepsilon} B(S^\varepsilon) K^* g [\nabla \varphi + \varepsilon \nabla_x \varphi_1^\varepsilon + \nabla_y \varphi_1^\varepsilon] \\
&- \int_0^T \int_{\Omega_m^\varepsilon} \varepsilon^2 b(s^\varepsilon) k^\varepsilon g \left[\nabla \varphi + \varepsilon \nabla_x \varphi_1^\varepsilon + \nabla_y \varphi_1^\varepsilon + \nabla_x \Psi^\varepsilon + \frac{1}{\varepsilon} \nabla_y \Psi^\varepsilon \right] \\
&+ \int_0^T \int_{\Omega_m^\varepsilon} d(s^\varepsilon) v^\varepsilon \left[\nabla \varphi + \varepsilon \nabla_x \varphi_1^\varepsilon + \nabla_y \varphi_1^\varepsilon + \nabla_x \Psi^\varepsilon + \frac{1}{\varepsilon} \nabla_y \Psi^\varepsilon \right] \\
&+ \int_0^T \int_{\Omega_f^\varepsilon} D(S^\varepsilon) V^\varepsilon [\nabla \varphi + \varepsilon \nabla_x \varphi_1^\varepsilon + \nabla_y \varphi_1^\varepsilon] = 0.
\end{aligned}$$

Passing to the two-scale limit yields

$$\int_0^T \int_\Omega \int_{Y_f} \phi^* S \frac{\partial \varphi(x,t)}{\partial t} + \int_0^T \int_\Omega \int_{Y_m} \varphi^0(x) s(x,y) \cdot \left[\frac{\partial \varphi(x,t)}{\partial t} + \frac{\partial}{\partial t} \Psi(x,y,t) \right]$$
$$- \int_0^T \int_\Omega \int_{Y_f} \sqrt{A(S)} K^* [\nabla Z + \nabla_y Z_1][\nabla \varphi + \nabla_y \varphi_1(x,y,t)]$$
$$- \lim_{\varepsilon \to 0} \int_0^T \int_{\Omega_m^\varepsilon} \sqrt{a(s^\varepsilon)} K^* \varepsilon \nabla z^\varepsilon \nabla_y \Psi^\varepsilon - \int_0^T \int_\Omega \int_{Y_f} B(S) K^* g [\nabla \varphi + \nabla_y \varphi_1(x,y)]$$
$$- \int_0^T \int_\Omega \int_{Y_f} D(S) V [\nabla \varphi + \nabla_y \varphi] + \lim_{\varepsilon \to 0} \int_0^T \int_{\Omega_m^\varepsilon} d(s) \frac{v^\varepsilon}{\varepsilon} \nabla_y \Psi^\varepsilon = 0.$$

The choice $\Psi = 0$ gives

$$|Y_f| \phi^* \frac{\partial S(x,t)}{\partial t} + \int_{Y_m} \varphi^0(y) \frac{\partial s(x,y,t)}{\partial t} dy$$
$$- \mathrm{div}_x \left\{ \sqrt{A(S)} \int_{Y_f} K^*(x) [\nabla_x Z + \nabla_y Z_1] dy + |Y_f| B(S) K^* g - D(S) \int_{Y_f} V(x,y) dy \right\}$$
$$= 0 \quad \text{in} \quad Q_T \tag{4.16}$$

and

$$\left\{ \begin{array}{c} \mathrm{div}_y \{ \sqrt{A(S)} K^*(x) [\nabla_x Z + \nabla_y Z_1] + B(S) K^* g - D(S) V(x,y) \} = 0 \\ \text{in} \quad Y_f \quad \text{for (a.e.)} \quad x,t \in Q_T, \\ \sqrt{A(S)} K^* [\nabla_x Z + \nabla_y Z_1] \nu + B(S) K^* g \cdot \nu = 0 \quad \text{on} \quad \partial Y_m \end{array} \right. \tag{4.17}$$

since

$$V \cdot \nu = K^* \Lambda(S) [\nabla P + \nabla_y P_1 + E(S) g] \cdot \nu = 0 \quad \text{on} \quad \partial Y_m.$$

Using (as for the pressure equation (4.15)) Θ defined by (4.14) and

$$K^{*H} = \frac{1}{|Y|} \int_{Y_f} K^* (I + \Theta) dy = \frac{|Y_f|}{|Y|} K^* \left(I + \frac{1}{|Y_f|} \int_{Y_f} \Theta(y) dy \right), \tag{4.18}$$

we obtain $Z_1 = \sum_j \xi_j(y) \big(\partial Z / \partial x_j + B(S) / \sqrt{A(S)} g \delta_{j3} \big)$.

Finally, (4.16) reduces to

$$\frac{|Y_f|}{|Y|} \phi^* \frac{\partial S}{\partial t} - \mathrm{div}_x \left\{ K^{*H} \left(A(S) \nabla_x S + B(S) g \right) - D(S) \overline{V} \right\}$$
$$= - \frac{1}{|Y|} \int_{Y_m} \varphi^0(y) \frac{\partial s(x,y,t)}{\partial t} \quad \text{in} \quad Q_T. \tag{4.19}$$

However, in (4.16) we have the term

$$\frac{\partial}{\partial t} \int_{Y_m} \varphi^0(y) s(x,y,t) dy,$$

which belongs to $H^{-1}(Q_T)$ a priori.

In fact, we will show that this term is more regular.

LEMMA 4.2.

$$\partial_t \int_{Y_m} \varphi^0(y) s(x,y,t) dy \in L^2(Q_T).$$

Proof. We introduce F_ε as

$$F_\varepsilon = \varepsilon^2 \sqrt{a(s^\varepsilon)} k^\varepsilon(x) \nabla z^\varepsilon - d(s^\varepsilon) v^\varepsilon = \varepsilon \overline{F}_\varepsilon$$

with $\| \overline{F}_\varepsilon \|_{L^2(\Omega^\varepsilon_m \times (0,T))^n} \leq C$.

Obviously, $\overline{F}_\varepsilon \longrightarrow F^*$ in the two-scale sense and

$$\varphi^0(y) \partial_t s - \operatorname{div}_y F^*(x,y) = 0 \quad \text{in} \quad H^{-1}(Q_T \times Y_m).$$

Consequently, for all $\xi \in H^1_0(0,T)$, we have

$$-\int_0^T \varphi^0(y) s \partial_t \xi - \operatorname{div}_y \left\{ \int_0^T F^* \xi \right\} = 0 \quad \text{in} \quad H^{-1}(\Omega \times Y_m),$$

which gives

$$-\operatorname{div}_y \left\{ \int_0^T F^* \xi \right\} \in L^\infty(Y_m) \quad \text{for (a.e)} \quad x \in \Omega$$

and for all $\xi \in H^1_0(0,T)$.

Hence

$$\int_0^T \xi F^* \in L^2(\Omega \times Y_m)^n \quad \text{and} \quad \operatorname{div}_y \left\{ \int_0^T \xi F^* \right\} \in L^2(\Omega \times Y_m),$$

and we conclude that $\int_0^T \xi F^* \cdot \nu \in L^2\left(\Omega\, ; H^{-1/2}(\partial Y_m)\right)$.

Now we obtain

$$-\int_0^T \left[\int_{Y_m} \varphi^0(y) s(x,y,t) \right] \partial_t \xi dt = \int_0^T \int_{\partial Y_m} \xi F^* \cdot \nu \in L^2(\Omega).$$

The right-hand side is well defined for all $\xi \in L^2(0,T)$. Therefore,

$$\partial_t \int_{Y_m} \varphi^0(s) s(x,y,t) dy \in L^2(Q_T). \qquad \square$$

Our next step is to show that $p = P$. We have the following result.

LEMMA 4.3. *Let P and p be defined by* (4.1)–(4.2) *and* (4.3), *respectively. Then we have*

$$P(x,t) = p(x,t) \quad \textit{for (a.e.)} \quad (x,t) \in Q_T. \tag{4.20}$$

Proof. By the continuity of the pressures we have

$$\int_0^T \int_{\Omega^\varepsilon_m} |p^\varepsilon - \Pi_\varepsilon P^\varepsilon|^2 dx\, dt \leq C\varepsilon^2 \int_0^T \int_{\Omega^\varepsilon_m} |\nabla(P^\varepsilon - \Pi_\varepsilon P^\varepsilon)|^2 dx\, dt \leq C\varepsilon^2. \tag{4.21}$$

Passing to the limit $\varepsilon \to 0$ yields (4.20). $\square$

It remains to find the equations satisfied by s and z. The first result is the identification of initial conditions.

LEMMA 4.4. *Let S and s be defined by* (4.8) *and* (4.9), *respectively. Then we have*

$$|Y_f|\phi^* S(x,0) + \int_{Y_m} \varphi^0(y) s(x,y,0)\,dy \\ = \phi^* S_w^0(x)|Y_f| + s_w^0(x) \int_{Y_m} \varphi^0(y)dy \quad (a.e.) \quad x \in \Omega \tag{4.22}$$

and

$$s(x,y,0) = s_w^0(x) \quad (a.e.) \quad (x,y) \in \Omega \times Y_m. \tag{4.23}$$

Our next step is to look for an equation for s. First, it should be noticed that by (2.24) and (3.16),

$$\| v^\varepsilon \|_{L^2(\Omega_m^\varepsilon \times (0,T))} \leq C\varepsilon^2 \tag{4.24}$$

and

$$\left| \int_0^T \int_{\Omega_m^\varepsilon} d(s^\varepsilon) v^\varepsilon \nabla \Psi \right| \leq C\varepsilon. \tag{4.25}$$

Consequently, there will be no transport term in the equation for s. The remaining nonlinear term in (2.23) is monotone. Therefore, it would be natural to try passing to the limit using monotonicity. This approach would work nicely if the nonlinearity was not degenerate. The degeneration makes the standard monotonicity argument (see, e.g., Lions [22, pp. 190–204]) fairly complicated if not impossible, and we have chosen a different approach, that is, the periodic modulation. The approach through the periodic modulation makes it possible to go to the limit in the degenerate terms that depend nonlinearly on s^ε.

DEFINITION 4.5. *For a given $\varepsilon > 0$, we define a dilation operator D^ε mapping measurable functions on $\Omega_m^\varepsilon \times (0,T)$ to measurable functions on $\Omega \times Y_m \times (0,T)$ by*

$$(D^\varepsilon u)(x,y,t) = u(c^\varepsilon(x) + \varepsilon y, t), \qquad y \in Y_m, \quad (x,t) \in \Omega \times (0,T), \tag{4.26}$$

where $c^\varepsilon(x)$ denotes the lattice translation point of the ε-cell domain containing x. We extend $(D^\varepsilon u)$ from Y_m to $\bigcup_k (Y_m + k)$ periodically.

It is easy to see that

$$\begin{cases} \| D^\varepsilon u \|_{L^q(Q_T \times Y_m)} = \| u \|_{L^q(Q_T)}, & 1 \leq q < +\infty, \\ \nabla_y D^\varepsilon u = \varepsilon D^\varepsilon \nabla_x u \quad \text{(a.e.)} & \text{in } Q_T \times Y_m \end{cases} \tag{4.27}$$

for all $u \in L^2(0,T\ ; W^{1,q}\ (\Omega_m^\varepsilon))$. For more properties of the dilation operator D^ε, we refer to Arbogast, Douglas, and Hornung [6, pp. 828–831].

The connection between the periodic modulation and H-measures is discussed in Tartar [29, pp. 203–204].

To proceed, we have to establish in the following proposition the link between the two-scale convergence and the weak convergence of a periodically modulated sequence.

PROPOSITION 4.6. *Let $\{u^\varepsilon\}$ be a uniformly bounded sequence in $L^2(\Omega^\varepsilon_m \times (0,T))$ that satisfies the conditions*

$$D^\varepsilon u^\varepsilon \rightharpoonup u^0 \quad \textit{weakly in} \quad L^2(Q_T; L^2_{\mathrm{per}}(Y_m))$$

and

$$\chi_{\Omega^\varepsilon_m} u^\varepsilon \longrightarrow u^* \in L^2(Q_T\ ; L^2_{\mathrm{per}}(Y)) \quad \textit{in the two-scale sense.}$$

Then we have

$$u^0 = u^* \quad \textit{(a.e.) in} \quad Q_T \times Y_m. \tag{4.28}$$

Proof. Let $\psi \in C^\infty_0(Q_T)$ and $h \in C^\infty_{\mathrm{per}}(\overline{Y}_m)$. Then we have

$$\begin{aligned}
&\int_{Q_T}\int_{Y_m} (D^\varepsilon u^\varepsilon)(x,y,t)\psi(x,t)h(y)dydxdt \\
&\quad = \int_{Q_T}\int_{Y_m} u^\varepsilon(c^\varepsilon(x)+\varepsilon y,t)\psi(x,t)h(y)dydxdt \\
&\quad = \sum_k \int_0^T \left\{\int_{\varepsilon(Y+k)}\int_{Y_m} \psi(x,t)u^\varepsilon(\varepsilon k+\varepsilon y,t)h(y)dydx\right\} dt.
\end{aligned}$$

Now we use the estimate

$$\left|\varepsilon^{-n}\int_{\varepsilon(Y+k)} \psi(x,t)dx - \psi(z,t)J\right| \le C\varepsilon \quad \forall z \in \varepsilon(Y_m+k)$$

and get

$$\begin{aligned}
&\int_{Q_T}\int_{Y_m} (D^\varepsilon u^\varepsilon)(x,y,t)\psi(x,t)h(y)dy\ dx\ dt = \sum_k \int_0^T \left[\int_{\varepsilon(Y+k)} \psi(x,t)dx\right], \\
&\quad \left\{\varepsilon^{-n}\int_{\varepsilon(Y_m+k)} u^\varepsilon(z,t)h(z/\varepsilon)dz\right\} dt = O(\varepsilon) + \sum_k \int_0^T \int_{\varepsilon(Y_m+k)} u^\varepsilon(z,t), \\
&\quad h(z/\varepsilon)\psi(z,t)dz\ dt = O(\varepsilon) + \int_{Q_T} u^\varepsilon(z,t)h(z/\varepsilon)\chi_{\Omega^\varepsilon_m}(z)\psi(z,t)dzdt \\
&\quad \to \int_{Q_T}\int_{Y_m} u^*(z,y,t)h(y)\psi(z,t)dz\ dy\ dt = \int_{Q_T}\int_{Y_m} u^0(x,y,t)h(y)\psi(x,t)dx\ dy\ dt.
\end{aligned}$$

Hence $u^0 = u^*$ (a.e.) in $Q_T \times Y_m$. □

Some additional useful properties of the dilation operator are given by the following lemma and corollary from Arbogast, Douglas, and Hornung [6].

LEMMA 4.7. *Let $\varphi,\ \psi \in L^2(0,T\ ; H^1(\Omega^\varepsilon_m))$. Then*

$$\begin{aligned}
(D^\varepsilon\varphi, D^\varepsilon\psi)_{L^2(Q_T\times Y_m)} &= (\varphi,\psi)_{L^2(\Omega^\varepsilon_m\times(0,T))}, \\
\| \nabla_y D^\varepsilon\varphi \|_{L^2(Q_T\times Y_m)^n} &= \varepsilon \ \| D^\varepsilon \nabla_x\varphi \|_{L^2(\Omega^\varepsilon_m\times(0,T))^n}, \\
(D^\varepsilon\varphi,\psi)_{L^2(Q_T\times Y)} &= (\varphi, D^\varepsilon\psi)_{L^2(Q_T\times Y)}.
\end{aligned}$$

COROLLARY 4.8. *With the above notation, we have*

$$\| D^\varepsilon s^\varepsilon \|_{L^2(Q_T;\ L^2_{\mathrm{per}}(Y_m))} \leq C,$$
$$\| D^\varepsilon z^\varepsilon \|_{L^2(Q_T;\ L^2_{\mathrm{per}}(Y_m))} \leq C.$$

Having established the link between the two-scale convergence and the weak convergence of the periodically modulated sequence $\{s^\varepsilon\}$, our strategy is simple; we find an equation for $D^\varepsilon s^\varepsilon$ and pass to the limit.

Now from assumptions (A11) on the geometry of the cell, we may prove the following proposition.

PROPOSITION 4.9. *Let* $\varepsilon > 0$ *and let* $D^\varepsilon s^\varepsilon$ *be defined by* (4.26). *Then* $D^\varepsilon s^\varepsilon = \overline{s}^\varepsilon$ *satisfies the equation*

$$\varphi^0(y)\partial_t(D^\varepsilon s^\varepsilon) - \mathrm{div}_y\{k(y)\nabla_y \mathcal{A}(\overline{s}^\varepsilon)\} = \tag{4.29}$$
$$\varepsilon \mathrm{div}_y\{k(y)b(\overline{s}^\varepsilon)g\} - \varepsilon^{-1}\mathrm{div}_y\{d(\overline{s}^\varepsilon)D^\varepsilon v^\varepsilon\} \ \ \textit{in}\ \ L^2(0,T;H^{-1}(Y_m))\ \ \textit{for (a.e.)}\ x \in \Omega^\varepsilon_m.$$

Proof. Let $\xi \in H^{-1}(0,T\ ;\ L^2(Y_m)) \cap L^2(0,T\ ;\ C^\infty_0(Y_m))$. Then we define

$$(D^\varepsilon \xi)^\tau(x,z,t) = \begin{cases} \xi\left(\frac{z-c^\varepsilon(x)}{\varepsilon}, t\right) & \text{for } z \in \varepsilon Y_m + c^\varepsilon(x), \\ 0 & \text{otherwise.} \end{cases} \tag{4.30}$$

Let $\xi_k(y,t) = \xi(y+k,t), k \in \mathbb{Z}^n$. Obviously, ξ_k is defined on $Y_m + k$ and $\xi_k \in H^1(0,T\ ;\ L^2(Y_m+k)) \cap L^2(0,T\ ;\ C^\infty_0(Y_m+k))$. □

Now we plug $(D^\varepsilon \xi_k)^\tau(x,x,t)$ into (2.33) as a test function. Since supp $(D^\varepsilon \xi_k)^\tau \subset \varepsilon(Y_m+k) \times (0,T)$ and the components of Ω^ε_m are strictly separated, we get

$$\int_0^T \int_{\varepsilon(Y_m+k)} \varphi^\varepsilon s^\varepsilon \partial_t((D^\varepsilon \xi_k)^\tau) - \int_0^T \int_{\varepsilon(Y_m+k)} \varepsilon^2 k^\varepsilon a(s^\varepsilon)\nabla s^\varepsilon \nabla (D^\varepsilon \xi_k)^\tau$$
$$- \int_0^T \int_{\varepsilon(Y_m+k)} \varepsilon^2 b(s^\varepsilon) k^\varepsilon g \nabla (D^\varepsilon \xi_k)^\tau + \int_0^T \int_{\varepsilon(Y_m+k)} d(s^\varepsilon) v^\varepsilon \nabla (D^\varepsilon \xi_k)^\tau$$
$$= \int_{\varepsilon(Y_m+k)} \varphi^\varepsilon s^\varepsilon(\cdot,T)(D^\varepsilon \xi_k)^\tau(\cdot,T)dx - \int_{\varepsilon(Y_m+k)} \varphi^\varepsilon s^0_w (D^\varepsilon \xi_k)^\tau(\cdot,0)dx.$$

Moreover, for $x \in \varepsilon(Y_m+k)$, $c^\varepsilon(x) = \varepsilon k$, and the change of variables $y = \varepsilon^{-1}(x - c^\varepsilon(x))$ gives

$$\int_0^T \int_{Y_m} \varphi^0(y)(D^\varepsilon s^\varepsilon)(x,y,t)\partial_t \xi_k(y,t)dy\,dt \tag{4.31}$$
$$- \int_0^T \int_{Y_m} k(y)a(D^\varepsilon s^\varepsilon)\nabla_y(D^\varepsilon s^\varepsilon)\nabla_y \xi_k - \int_0^T \int_{Y_m} \varepsilon b(D^\varepsilon s^\varepsilon)k(y)g\nabla_y \xi_k$$
$$+ \int_0^T \int_{Y_m} \varepsilon^{-1} d(D^\varepsilon s^\varepsilon) D^\varepsilon v^\varepsilon \nabla_y \xi_k$$
$$= \int_{Y_m} \varphi^0(y)(D^\varepsilon s^\varepsilon)(\cdot,T)\xi_k(\cdot,T) - \int_{Y_m} \varphi^0(y) D^\varepsilon s^0_w \xi_k(\cdot,0)dy$$

for (a.e.) $x \in \varepsilon(Y_m+k)$. (4.29) is a simple consequence of (4.31). □

Remark. It should be noticed that

$$D^\varepsilon Z^\varepsilon = D^\varepsilon z^\varepsilon \ \text{ in } \ H^{1/2}(\partial Y_m) \quad \text{for (a.e.)} \quad (x,t) \in \Omega^\varepsilon_m \times (0,T), \tag{4.32}$$

where $D^\varepsilon z^\varepsilon = \int_0^{D^\varepsilon s^\varepsilon} \sqrt{a(\eta)}d\eta$.

Having obtained the equations for $D^\varepsilon s^\varepsilon$ we are now able to establish the a priori estimates for $D^\varepsilon z^\varepsilon$ and $D^\varepsilon s^\varepsilon$, analogous to those obtained for Z^ε and S^ε for all $k \in \mathbb{Z}^n$. Then we could pass to the limit for fixed k and, finally, by a density argument the limit equations for s would have been obtained. However, the limit equation for s has already been obtained in Arbogast, Douglas, and Hornung [6] by formal asymptotic expansion, and since it is decoupled from the pressure equation, we prefer comparing the formal limit equation with the equation for the $D^\varepsilon s^\varepsilon$.

We consider the following problem. Find $s^* \in L^2(Q_T\ ;\ L^2_{\text{per}}(Y_m)) \cap L^\infty(Q_T \times Y_m)$, $0 \le s^* \le 1$ (a.e.) on $Q_T \times Y_m$, $a(s^*)\nabla s^* \in L^2(Q_T\ ;\ L^2_{\text{per}}(Y_m))^n$, $\partial_t s^* \in L^2(Q_T; H^{-1}_{\text{per}}(Y_m))$ such that

$$\tag{4.33} \begin{gathered} \int_0^t\int_{Y_m} \varphi^0(y)s^*(x,y,\tau)\partial_t\psi - \int_0^t\int_{Y_m} k(y)a(s^*)\nabla_y s^*\nabla_y\psi \\ = \int_{Y_m} \varphi^0(y)s^*(x,y,t)\psi(y,t)dy - \int_{Y_m} \varphi^0(y)s^0_w(x)\psi(y,0)dy \\ \text{(a.e)}\ (x,t) \in Q_T \quad \forall\psi \in H^1(Q_T \times Y_m), \end{gathered}$$

$$\tag{4.34} z^* = \int_0^{s^*} \sqrt{a(\eta)}d\eta = Z = \int_0^S \sqrt{a(\eta)}d\eta \text{ in } L^2(0,T\ ;\ H^{1/2}(\partial Y_m))$$

for (a.e.) $x \in \Omega$.

For fixed $Z \in L^2(0,T;\ H^1(\Omega))$, $S \in L^\infty(Q_T)$, $0 \le S \le 1$ (a.e.) on Q_T and $S^0_w \in L^\infty(\Omega)$, $0 \le S^0_w \le 1$ (a.e.) on Ω, the classical theory (see, e.g., Lions [22]) gives existence of a unique solution s^* for (4.33)–(4.34).

Our final step is to compare the problems (4.33)–(4.34) and (4.31)–(4.32). We have the following result.

PROPOSITION 4.10. *Let $D^\varepsilon s^\varepsilon$ be defined by* (4.26), *and let s^* be a solution for* (4.33)–(4.34). *Then we have*

$$\tag{4.35} D^\varepsilon s^\varepsilon \longrightarrow s^* \quad in \quad L^2(\Omega \times Y_m \times (0,T))$$

and

$$s^* = s \quad (a.e.)\ on \quad \Omega \times Y_m \times (0,T),$$

where s is defined by assumptions (A11)–(A12).

Proof. Since a can vanish for $D^\varepsilon s^\varepsilon = 0$ or 1, we choose the test function by a change of pivot. Therefore, we introduce w^ε by

$$\tag{4.36} \begin{cases} -\text{div}_y\{k(y)\nabla_y w^\varepsilon\} &= \varphi^0(y)\{D^\varepsilon s^\varepsilon - s^*\} \text{ in } Y_m, \\ w^\varepsilon &= 0 \text{ on } \partial Y_m \end{cases}$$

for (a.e.) $(x,t) \in Q_T$.

Obviously, $w^\varepsilon \in H^1(Q_T \times Y_m)$,

$$\|\ \nabla_y w^\varepsilon\ \|_{L^2(Q_T;L^2(Y_m))} \le C \ \|\ D^\varepsilon s^\varepsilon - s^*\ \|_{L^2(Q_T\times Y_m)},$$

and

$$\tag{4.37} \begin{cases} -\text{div}_y\{k\nabla_y w^\varepsilon(x,y,0)\} &= \varphi^0(y)\{D^\varepsilon s^0_w - s^0_w\}, \\ w^\varepsilon(x,\cdot,0) &= 0 \text{ on } \partial Y_m. \end{cases}$$

Now we introduce the function ζ^ε by $\zeta^\varepsilon = D^\varepsilon s^\varepsilon - s^*$ and $\mathcal{A}$ by $\mathcal{A}(s) = \int_0^s a(\eta)\ d\eta$.

Obviously, ζ^ε satisfies the variational equation

$$\begin{aligned}(4.38)\quad &\int_0^T\int_{Y_m}\int_\Omega \varphi^0(y)\zeta^\varepsilon\partial_t\Psi - \int_{Q_T}\int_{Y_m} k(y)\nabla_y\{\mathcal{A}(D^\varepsilon s^\varepsilon)-\mathcal{A}(s^*)\}\nabla_y\Psi\\ &-\int_\Omega\int_{Y_m}\varphi^0(y)\zeta^\varepsilon(\cdot,T)\Psi\,(\cdot,T)+\int_\Omega\int_{Y_m}\varphi^0(y)\{D^\varepsilon s^0_w - s^0_w\}\Psi(\cdot,0)\\ &=\varepsilon\int_{Q_T}\int_{Y_m}k(y)b(D^\varepsilon s^\varepsilon)g\nabla_y\Psi - \varepsilon^{-1}\int_{Q_T}\int_{Y_m}d(D^\varepsilon s^\varepsilon)(D^\varepsilon v^\varepsilon)\nabla_y\Psi\\ &\qquad\forall\Psi\in H^1(Q_T\times Y_m),\quad \Psi=0\quad\text{on}\quad\partial Y_m\end{aligned}$$

and the boundary condition

$$(4.39)\quad \int_0^{\zeta^\varepsilon}\sqrt{a(\eta)}d\eta=\int_{S(x,t)}^{D^\varepsilon S^\varepsilon}\sqrt{a(\eta)}d\eta\ \text{ in } L^2(0,T\ ;\ H^{1/2}(\partial Y_m))\ (\text{a.e.})\,x\in\Omega.$$

To estimate the L^2-norm of ζ^ε we choose $\Psi=w^\varepsilon$ as the test function. We have

$$\begin{aligned}(4.40)\quad &\int_{Q_T}\int_{Y_m}\varphi^0(y)\zeta^\varepsilon\partial_t w^\varepsilon-\int_\Omega\int_{Y_m}\varphi^0(y)\zeta^\varepsilon(\cdot,T)w^\varepsilon(\cdot,T)\\ &+\int_\Omega\int_{Y_m}\varphi^0(y)\{D^\varepsilon s^0_w-s^0_w\}w^\varepsilon(\cdot,0)-\int_{Q_T}\int_{Y_m}k(y)\nabla_y\{\mathcal{A}(D^\varepsilon s^\varepsilon)-\mathcal{A}(s^*)\}\nabla_y w^\varepsilon\\ &=\varepsilon\int_{Q_T}\int_{Y_m}k(y)b(D^\varepsilon s^\varepsilon)g\nabla_y w^\varepsilon-\varepsilon^{-1}\int_{Q_T}\int_{\Omega_\varepsilon}d(D^\varepsilon s^\varepsilon)(D^\varepsilon v^\varepsilon)\nabla_y w^\varepsilon.\end{aligned}$$

Using the uniform boundedness of $\nabla_y w^\varepsilon$ in $L^2(Q_T\times Y_m)$ we find out that the right-hand side is bounded by $C\varepsilon$.

Furthermore,

$$\begin{aligned}\int_{Q_T}\int_{Y_m}\varphi^0(y)\partial_t w^\varepsilon\zeta^\varepsilon&=\int_{Q_T}\int_{Y_m}k\nabla_y w^\varepsilon\nabla_y\partial_t w^\varepsilon\\ &=\frac12\int_\Omega\int_{Y_m}k|\nabla_y w^\varepsilon(\cdot,T)|^2-\frac12\int_\Omega\int_{Y_m}k|\nabla_y w^\varepsilon(\cdot,0)|^2,\end{aligned}$$

$$\int_\Omega\int_{Y_m}\varphi(y)\zeta^\varepsilon(\cdot,T)w^\varepsilon(\cdot,T)=\int_\Omega\int_{Y_m}k|\nabla_y w^\varepsilon(\cdot,T)|^2,$$

and

$$\int_\Omega\int_{Y_m}\varphi(y)\zeta^\varepsilon(\cdot,0)w^\varepsilon(\cdot,0)=\int_\Omega\int_{Y_m}k|\nabla_y w^\varepsilon(\cdot,0)|^2.\qquad\square$$

Therefore, we write (4.40) in the form

$$\begin{aligned}&\left|\int_{Q_T}\int_{Y_m}k(y)\nabla_y\{\mathcal{A}(D^\varepsilon s^\varepsilon)-\mathcal{A}(s^*)\}\nabla_y w^\varepsilon\right|\\ &\le C\varepsilon+\frac12\int_\Omega\int_{Y_m}|\nabla_y w^\varepsilon(\cdot,0)|^2\le C\left\{\varepsilon+\parallel D^\varepsilon s^0_w-s^0_w\parallel_{L^2(\Omega\times Y_m)}\right\}.\end{aligned}$$

It remains to find an estimate from below for the diffusion term. We have

$$\begin{aligned}0\le&\int_{Q_T}\int_{Y_m}k(y)\nabla_y\{\mathcal{A}(D^\varepsilon s^\varepsilon)-\mathcal{A}(s^*)\}\nabla_y w^\varepsilon=\int_{Q_T}\int_{\partial Y_m}\{\mathcal{A}(D^\varepsilon s^\varepsilon)\\ &-\mathcal{A}(S)\}k(y)\nabla_y w^\varepsilon\cdot\nu-\int_{Q_T}\int_{Y_m}\{\mathcal{A}(D^\varepsilon s^\varepsilon)-\mathcal{A}(S)\}\mathrm{div}_y\{k(y)\nabla_y w^\varepsilon\}\\ &=\int_{Q_T}\int_{Y_m}\nabla_y\mathcal{A}(\Pi_\varepsilon D^\varepsilon S^\varepsilon)k(y)\nabla_y w^\varepsilon+\int_{Q_T}\int_{Y_m}\{\mathcal{A}(D^\varepsilon s^\varepsilon)-\mathcal{A}(s^*)\}\varphi^0(y)\zeta^\varepsilon.\end{aligned}$$

Therefore,

$$\begin{aligned}
&\int_{Q_T}\int_{Y_m} \{\mathcal{A}(D^\varepsilon s^\varepsilon) - \mathcal{A}(s^*)\}\{D^\varepsilon s^\varepsilon - s^*\} \\
&\leq C\varepsilon + C \parallel D^\varepsilon s_w^0 - s_w^0 \parallel_{L^2(\Omega\times Y_m)} + C \parallel \nabla_y \mathcal{A}(\Pi_\varepsilon D^\varepsilon S^\varepsilon) \parallel_{L^2(Q_T\times Y_m)^n} \\
&= C\varepsilon + C \parallel D^\varepsilon s_w^0 - s_w^0 \parallel_{L^2(\Omega\times Y_m)} + C\varepsilon \parallel \nabla_x \mathcal{A}(\Pi_\varepsilon D^\varepsilon S^\varepsilon) \parallel_{L^2(Q_T\times Y_m)^n}
\end{aligned}$$

and consequently,

$$\{\mathcal{A}(D^\varepsilon s^\varepsilon) - \mathcal{A}(s^*)\}\{D^\varepsilon s^\varepsilon - s^*\} \to 0 \quad \text{(a.e.) in} \quad Q_T \times Y_m.$$

Hence $D^\varepsilon s^\varepsilon - s^* \to 0$ (a.e.) in $Q_T \times Y_m$ and $D^\varepsilon s^\varepsilon - s^* \to 0$ (a.e.) in $L^q(Q_T \times Y_m)$ for all $q \in [1, +\infty[$ by Lebesgue's dominated convergence theorem. □

We summarize our results in Theorem 4.11.

THEOREM 4.11 (convergence theorem). *Let the assumptions* (A1)–(A10) *be satisfied. Let* $\{P^\varepsilon, p^\varepsilon, S^\varepsilon, s^\varepsilon, V^\varepsilon, v^\varepsilon\}_{\{\varepsilon>0\}}$ *be weak solutions to the problem* (2.20)–(2.32). *Then there exists a subsequence, denoted by the same subscript, such that*

$$\Pi_\varepsilon P^\varepsilon \to P \in L^2(0,T\,; H^1(\Omega)) \quad \textit{in the two-scale sense};\tag{4.41}$$

$$\nabla(\Pi_\varepsilon P^\varepsilon) \to \nabla P + \nabla_y P_1 \quad \textit{in the two-scale sense};\tag{4.42}$$

$$\Pi_\varepsilon Z^\varepsilon = \Pi_\varepsilon \int_0^{S^\varepsilon} \sqrt{A(\eta)}d\eta \to Z \in L^2(0,T\,; H^1(\Omega)) \quad \textit{in the two-scale sense};\tag{4.43}$$

$$\nabla(\Pi_\varepsilon Z^\varepsilon) \to \nabla Z + \nabla_y Z_1 \quad \textit{in the two-scale sense}\tag{4.44}$$

with $Z_1, P_1 \in L^2(Q_T\ ;\ H^1_{\text{per}}(Y))$;

$$\overline{S}^\varepsilon = (Z^\varepsilon)^{-1}(\Pi_\varepsilon Z^\varepsilon) \to S \quad \textit{strongly in} \quad L^q(Q_T) \quad \forall q \in [1, +\infty[;\tag{4.45}$$

$$\Pi_\varepsilon Z^\varepsilon \to Z \quad \textit{strongly in} \quad L^q(Q_T) \quad \forall q \in [1, +\infty[;\tag{4.46}$$

$$\widetilde{s}^\varepsilon \to s \in L^2(Q_T \times Y) \quad \textit{in the two-scale sense};\tag{4.47}$$

$$D^\varepsilon s^\varepsilon \to s \quad \textit{strongly in} \quad L^q(Q_T \times Y_m),\tag{4.48}$$

where the extension operator Π_ε *is defined by* (3.10)–(3.12), $\widetilde{s}^\varepsilon$ *is equal to* s^ε *in* $\Omega_m^\varepsilon \times]0,T[$ *and to* S^ε *in* $\Omega_f^\varepsilon \times]0,T[$, $D^\varepsilon s^\varepsilon$ *is defined by* (4.26), *and* $\{P, S, s, V\}$ *are solutions to the nonlinear system*

$$\left\{\begin{aligned}
&\frac{1}{|Y|}\int_Y V dy = \overline{V} = -K^{*H}\Lambda(S)[\nabla_x P - E(S)g] \quad \textit{in} \quad Q_T, \\
&\qquad\qquad -\text{div}_x \overline{V} = 0 \quad \textit{in} \quad Q_T, \\
&\overline{V}\cdot\nu = 0 \quad \textit{on} \quad \Gamma^2 \times (0,T), \qquad P = P_T^D = \tfrac{P_w^D + P_o^D}{2} \quad \textit{on} \quad \Gamma^1 \times (0,T);
\end{aligned}\right.\tag{4.49}$$

$$\left\{\begin{aligned}
&S(x,0) = S_w^0(x) \quad \textit{(a.e.) in} \quad \Omega, \qquad S = 0 \quad \textit{(a.e.) on} \quad \Gamma^1 \times (0,T), \\
&\frac{|Y_f|}{|Y|}\phi^*\partial_t S - \text{div}_x\left\{K^{*H}(A(S)\nabla_x S + B(S)g) - D(S)\overline{V}\right\} \\
&\qquad = -\frac{1}{|Y|}\int_{\partial Y_m} k(y)a(s)\nabla_y s\cdot\nu d\eta \quad \textit{in} \quad Q_T, \\
&K^{*H}(A(S)\nabla_x S + B(S)g)\cdot\nu = g_w \quad \textit{on} \quad \Gamma^2 \times (0,T)
\end{aligned}\right.\tag{4.50}$$

with K^{*H} *defined by* (4.18).

For (a.e.) $x \in \Omega$, *the right-hand side of* (4.50) *is defined from*

$$(4.51)\quad \begin{cases} z = \int_0^s \sqrt{a(\eta)}d\eta = Z = \int_0^S \sqrt{A(\eta)}d\eta \quad \textit{on} \quad \partial Y_m, \\ \varphi^0(y)\partial_t s - \operatorname{div}_y\{k(y)a(s)\nabla_y s\} = 0 \quad \textit{in} \quad Q_T \times Y_m, \\ s(x,y,0) = s_w^0(x) \quad \textit{in} \quad \Omega \times Y_m. \end{cases}$$

From (4.49)–(4.51) above, due to the strong convergence of S^ε and hence of all functions of S^ε, doing the inverse of what we have done in §2, we conclude the following:

- There is a macroscopic fracture system driven by equations in all $\Omega \times (0,T)$ similar to (2.1), (2.2) and with an effective absolute rock permeability K^{*H} given by (4.18) and an effective porosity $\frac{|Y_f|}{|Y|}\Phi^*$ but with an additional right-hand side source-like term $\frac{1}{|Y|}\int_{Y_m} \varphi^0(y)\partial_t s dy = \frac{1}{|Y|}\int_{\partial Y_m} k(y)a(s)\nabla_y s \cdot \eta d\eta$.
- For each $x \in \Omega$ there is a matrix block, the flow in which is described by (4.51) and produces the source-like term.

Remark. In the definition (4.18) of K^{*H}, the effective permeability, the term $I + \frac{1}{|Y_f|}\int_{Y_f} \Theta(y)dy$ plays the role of a tortuosity factor like that defined in [14] or [20].

TRAVELING WAVES AS LIMITS OF SOLUTIONS ON BOUNDED DOMAINS*

GIORGIO FUSCO[†], JACK K. HALE[‡], AND JIANPING XUN[§]

Abstract. This paper is concerned with the asymptotic behavior as $\epsilon \to 0$ of solutions of the reaction-diffusion equation $u_t = \epsilon^2 u_{xx} - (u+a)(u^2-1)$ defined in $(-1,1)$ with Neumann boundary conditions. For $a = 0$, this equation has a monotone equilibrium solution u^ϵ with the property that $u^\epsilon(x) \to -1$ (resp. $+1$) on $[-1,0)$ (resp. $(0,1]$) as $\epsilon \to 0$; that is, the solution has a sharp transition layer if $a = 0$. Also, it is known that u^ϵ has a one-dimensional unstable manifold $\mathcal{M}(u^\epsilon)$. Solutions near $\mathcal{M}(u^\epsilon)$ decrease exponentially to $\mathcal{M}(u^\epsilon)$ and move with a speed $O(e^{-c/\epsilon})$ along $\mathcal{M}(u^\epsilon)$.

This paper considers the case where a is small and fixed. For each fixed ϵ, $a \neq 0$, small, there is an equilibrium solution $u^{\epsilon a}$ with unstable manifold of dimension one, but $u^{\epsilon a}$ approaches either the function 1 or -1 as $\epsilon \to 0$; that is, there is no monotone equilibrium solution with a sharp transition layer. If we rescale x to ϵx and consider the rescaled equation on $(-\infty, \infty)$, then there is a unique (except for translation) monotone traveling-wave solution on $(-\infty,\infty)$ with wave speed $-\sqrt{2}a$. Using a geometric approach, we prove that there are positive constants ϵ_0 and a_0 such that, for $0 < \epsilon < \epsilon_0$ and $|a| < a_0$, solutions of the rescaled equations on $(-\frac{1}{\epsilon}, \frac{1}{\epsilon})$ in a neighborhood of size $C\sqrt{a_0}$ of a monotone traveling-wave solution decrease exponentially fast before they enter a neighborhood of size $O(\epsilon^k)$ of such a solution, where k can be any positive integer. Along the traveling-wave direction, solutions move with the traveling-wave speed plus an error term $O(\epsilon^k)$. It also is proved that the L^∞-norm between the solution and a translation of the traveling wave is of order $O(\epsilon^k)$ for $C_1 k \log \frac{1}{\epsilon} < t < \frac{C_2}{\epsilon}$.

Key words. transition layers, phase separation, unstable invariant manifold, traveling-wave solutions

1. Introduction.

It is generally accepted folklore that traveling-wave solutions of parabolic partial differential equations are representative of typical behavior of solutions of the same partial differential equation on a large unbounded domain. The intent of this paper is to make this rigorous for a scalar reaction-diffusion equation in one space variable. More specifically, we consider the equation

$$u_t = \epsilon^2 u_{xx} - f_a(u), \quad x \in (-1,1), \tag{1}$$

with homogeneous Neumann boundary conditions

$$u_x = 0, \quad x = \pm 1. \tag{2}$$

In this equation, $\epsilon > 0$ is a small parameter, a is a small parameter independent of ϵ, and

$$f_a(u) =: (u+a)(u^2-1) =: f_0(u) + ag(u), \tag{3}$$

$$f_0(u) =: u(u^2-1), \qquad g(u) =: u^2-1. \tag{4}$$

Equation (1) is a gradient system corresponding to the Liapunov functional

$$J(u) =: \int_{-1}^{1} \left(\frac{\epsilon^2}{2} u_x^2 + F(u) \right) dx,$$

where $F(u)$ is a function such that $f_a(u) = F'(u)$. Equation (1) is perhaps the simplest mathematical model for the dynamical phase transition. In this context, u is an order–disorder parameter which is related to the microscopic structure of the matter in such a way that u near -1 corresponds to one of the two phases (solid) and u near 1 corresponds to the other phase (liquid). The parameter a corresponds to the temperature. For $a < 0$, the constant solution $u = -1$ (solid) is the unique global minimizer of $J(u)$. If $a = 0$, then both $u = \mp 1$ minimize $J(u)$ and this corresponds to the situation where two phases of the same substance can coexist at the transition temperature. For $a > 0$, $u = 1$ (liquid) is the unique global minimizer of $J(u)$.

It is known that equation (1) generates a dissipative semiflow in several function spaces and that it possesses a global attractor $\mathcal{A}_\epsilon$ (see [H]).

If $a = 0$, the number of fixed points (stationary solutions of (1)) increases without bounds as $\epsilon \to 0$. When the equilibria are hyperbolic, the attractor $\mathcal{A}_\epsilon$ is the set of equilibria together with their unstable manifolds. In the view of [F-H] (or [C-P]), the solution quickly "*lands*" near $\mathcal{A}_\epsilon$ and there it is strongly attracted toward an unstable manifold; it then enters a slow stage during which it moves along the unstable manifold and, when it gets close to the boundary of this unstable manifold, the motion is quick, to be followed again by slow movement along another unstable manifold, etc. This phenomenon has been observed numerically and studied rigorously by Carr and Pego [C-P], Fusco and Hale [F-H], Fusco [F], and Bronsard and Kohn [B-K].

For $a = 0$, there is an $\epsilon_1 > 0$ such that, for $0 < \epsilon < \epsilon_1$, there is an equilibrium solution u^ϵ of (1) which is monotone increasing on $(-1, 1)$ and, for ϵ very small, is in an ϵ-neighborhood of $+1$ in $(\epsilon \log \frac{1}{\epsilon}, 1)$ and in an ϵ-neighborhood of -1 in $(-1, -\epsilon \log \frac{1}{\epsilon})$.

It is known [C-P], [F-H], [F] that, for $\epsilon \ll 1$, the stationary solution u^ϵ is hyperbolic and unstable with the unstable manifold $\mathcal{M}^\epsilon$ having dimension one. Moreover, as $\epsilon \to 0$, any compact part of $\mathcal{M}^\epsilon$ approaches the manifold defined by the translates of the standing waves of the equation

$$u_t = \epsilon^2 u_{xx} - f_0(u), \quad x \in (-\infty, \infty), \tag{5}$$

and the flow on $\mathcal{M}^\epsilon$ is extremely slow (speed of $O(e^{-c/\epsilon})$). More precisely, the manifold $\mathcal{M}^\epsilon$ approaches the manifold $\mathcal{M}^0$ defined by the map

$$h \to U\left(\frac{\cdot - h}{\epsilon}\right),$$

where U is the unique solution of the problem

$$\begin{cases} U_{xx} - f_0(U) = 0, \\ \lim\limits_{x \to \pm\infty} U(x) = \pm 1, \\ U(0) = 0. \end{cases} \tag{6}$$

Since the equilibrium point referred to above is hyperbolic, we can find a function $a = a(\epsilon)$ approaching zero as $\epsilon \to 0$ such that there is an equilibrium point $u^{\epsilon a}$ of (1) which is monotone increasing with a profile which is close to a step function if ϵ is sufficiently small. The dynamics in this case will be similar to those when $a = 0$.

On the other hand, if we fix $a > 0$ small but independent of ϵ and let $\epsilon \to 0$, the equilibrium solution $u^{\epsilon a}$ will not develop an interior layer and approach a step function but instead will develop a boundary layer at $x = 1$ and approach -1 uniformly in any compact interval in $[-1, 1)$. On the other hand, the dimension of the unstable manifold of $u^{\epsilon a}$ is one and it is exponentially attracting. Thus we would expect that this one-dimensional manifold $\mathcal{M}^{\epsilon a}$ would converge to some one-dimensional stable object as $\epsilon \to 0$. This object should correspond to the invariant manifold $\mathcal{M}^{0a}$ of the monotone traveling wave (and its translates) for equation (5) with f_a replacing f_0. To give a complete proof of this conjecture is beyond the scope of this paper. However, we prove in the following that, if $\epsilon > 0$ is small, solutions of (1) and (2) with initial condition close in a certain sense to $\mathcal{M}^{0a}$ are attracted to a very small neighborhood of $\mathcal{M}^{0a}$ and remain near $\mathcal{M}^{0a}$ for a time of $O(\epsilon^{-1})$ drifting along $\mathcal{M}^{0a}$ with a speed which is almost exactly that of the traveling wave. We now make this more precise.

If we rescale the space variable $x \to \epsilon x$, then we obtain an equation with diffusion coefficient 1 but defined on the interval $(-\frac{1}{\epsilon}, \frac{1}{\epsilon})$:

$$u_t = u_{xx} - f_a(u), \quad x \in \left(-\frac{1}{\epsilon}, \frac{1}{\epsilon}\right), \tag{1'}$$

and

$$u_x = 0 \quad \text{for } x = \pm\frac{1}{\epsilon}. \tag{2'}$$

It is known that, for given initial data $u_0(x)$ which is less than a in $I_1 =: [-1, \xi)$ and greater than a in $I_2 =: (\xi, 1]$, where ξ is some number between -1 and 1, the solution $u(x,t)$ of (1) and (2) which begins at $t = 0$ with this initial data will be attracted to -1 in I_1 and 1 in I_2 in a short time and a sharp interface will be formed near $x = \xi$. This is the so-called phase-generation stage. In the next stage, the configuration of the solution generated in the first stage will stay almost the same but the interface will drift slowly toward the boundary (see [A-B-F], [A-Mc], [B-F1], [B-F2], [C-P], [D-S], [F-H], [B-X1], and [B-X2]).

The main interest of this paper is the limiting behavior of the solutions of (1) and (2) as $\epsilon \to 0$ for large but finite t. In other words, we are interested in the second stage of the motion described above.

Let $U(x + \sqrt{2}at)$ be the unique (except for translation) monotone traveling-wave solution of (1′) on $(-\infty, \infty)$. Our main goal in this paper is to prove the following theorem.

THEOREM. *There exist positive constants C and a_0 such that, for any integer k, there are positive constants ϵ_0, C_1, C_2, and C_3 such that, if $0 < \epsilon \leq \epsilon_0$ and $|a| \leq a_0$, then, for any solution $u^\epsilon(x,t)$ of (1′) and (2′) with initial data in a $C\sqrt{a_0}$ L^∞-neighborhood of $U(\cdot)$, there is a positive constant h_0 such that*

$$\left|u(x,t) - U(x + \sqrt{2}at - h_0)\right| \leq C_1\epsilon^{k-2}$$

for $x \in [-\frac{1}{\epsilon}, \frac{1}{\epsilon}]$, $t \in (C_2 k \log\frac{1}{\epsilon}, \frac{C_3}{\epsilon})$.

We organize the paper as follows. In §2, we construct an approximate manifold such that the traveling-wave solution of (1) is nearby. We also give some estimates about the base manifold and derive equation (1) in the new coordinate system. In §3, we give an estimate of the motion speed of a solution of (1) and (2). In §4, we prove that the approximate manifold attracts solutions which start in a small neighborhood of size independent of ϵ. Finally, in §5, we prove that solutions of (1′) with initial data in a small neighborhood of the approximate manifold approach the traveling-wave solution of (1′) as $\epsilon \to 0$.

2. The tubular coordinates and the equations of motion. We consider equation (1) together with the Neumann boundary conditions (2), assuming throughout that a in equation (1) is small but independent of ϵ. We study the limiting behavior of the solutions of equation (1) when $\epsilon \to 0$. We construct the approximate manifold by patching together solutions $\phi(x, \ell, \pm 1)$ of the equation

$$\begin{cases} \epsilon^2 \phi_{xx} - f_0(\phi) = 0, & |x| < \dfrac{\ell}{2}, \\ \phi = 0, \quad x = \pm\dfrac{\ell}{2}, \end{cases} \tag{7}$$

as was done in [C-P], where it was proved that, if $\frac{\epsilon}{\ell}$ is small, (7) has a unique positive solution $\phi(x, \ell, +1)$ which is exponentially close (in terms of ϵ) to 1 at $x = 0$ and a unique negative solution $\phi(x, \ell, -1)$ which is exponentially close to -1 at 0.

Let $\chi : R \to [0, 1]$ be a C^∞ cutoff function with $\chi(x) = 0$ for $x \leq -1$ and $\chi(x) = 1$ for $x \geq 1$.

We define

$$\Omega_{\rho_0} =: \{h \in R : \rho_0 - 1 < h < 1 - \rho_0\}, \tag{8}$$

where ρ_0 is a small but fixed positive number. For any $h \in \Omega_{\rho_0}$, let

$$\begin{aligned} u^h(x) =: &\left[1 - \chi\left(\frac{x-h}{\epsilon}\right)\right] \phi\left(x+1, 2(h+1), -1\right) \\ &+ \chi\left(\frac{x-h}{\epsilon}\right) \phi\left(x-1, 2(1-h), 1\right), \end{aligned} \tag{9}$$

and we take the approximate manifold to be

$$\mathcal{M} =: \{u^h : h \in \Omega_{\rho_0}\}. \tag{10}$$

Remark. From our definition of the approximate manifold, it is clear that $\mathcal{M}$ does not depend on a. This may look strange at first but becomes reasonable when one takes into account that the special nonlinearity f_a that we are considering has the remarkable property that, as a varies, the speed of the traveling wave changes but its profile remains unchanged and coincides with the standing wave corresponding to $a = 0$. On the other hand, as we discuss in Propositions 4 and 5 below, if ϵ is small, the function ϕ we used for constructing the approximate manifold is extremely close to the standing wave.

It is not necessary to assume that the function f_a has the particular form (3). In fact, we could have considered a more general double-well potential $F_a(u)$ depending smoothly upon a parameter a with the property that $F_0(u)$ has only three critical points—two nondegenerate minima u_0^- and u_0^+ with $F_0(u_0^-) = F_0(u_0^+)$ and a nondegenerate maximum at u_0^0. The same type of result as above is true. Of course, in this case, it is not possible to use such a simple approximate manifold. An appropriate one can be chosen following the approach in Fusco and Hale [F-H]. We have chosen to present only the simplest case.

The following notation will be used throughout the paper:

$\mathcal{L}_a(\phi) =: \epsilon^2\phi_{xx} - f_a(\phi)$;

$L_a^h(\phi) =: \epsilon^2\phi_{xx} - f_a'(u^h)\phi$; that is, L_a^h is $\mathcal{L}_a^h$ linearized at u^h;

$\tau^h(x) =: -[\chi((x-\epsilon+1)/\epsilon)(x)\chi((1-x-\epsilon)/\epsilon)(x)]u_x^h(x)$;

where $\langle\cdot,\cdot\rangle$ is the inner product in $L^2(-1,1)$. Also, we let $\|\cdot\|$ be the norm in $L^2(-1,1)$ induced by $\langle\cdot,\cdot\rangle$

It is possible to show (cf. Lemmas 7.8 and 7.9 and Proposition 3.4 in [C-P]) that the tangent vector u_h^h to $\mathcal{M}$, aside from a small term of $O(e^{-c/\epsilon})$, coincides with $-u_x^h$. On the other hand τ^h and $-u_x^h$ are different only in intervals of size 2ϵ near the boundary, where u_x^h is $O(e^{-c/\epsilon})$. Therefore, τ^h is almost tangent to $\mathcal{M}$ and unlike u_h^h satisfies Neumann boundary conditions.

Our objective is to show that, in a very precise sense, $\mathcal{M}$ can be considered as an approximate invariant manifold. To do this, we employ a new coordinate system

$$u \longrightarrow (h,v) \quad \text{meaning} \quad u = u^h + v, \quad \text{where } u^h \in \mathcal{M},$$

$$\langle v, \tau^h\rangle = 0, \qquad v_x = 0 \quad \text{at } x = 0, 1. \tag{11}$$

If we define

$$\mathcal{B}_\sigma =: \left\{ u \in L^\infty : \inf_{h\in\Omega_{\rho_0}} \|u - u^h\|_\infty < \sigma \right\}, \tag{12}$$

it is proved in [C-P] that, if $u \in \mathcal{B}_{\sigma_0}$, the coordinate representation (11) is valid for some fixed σ_0.

Now let $u(x,t)$ be a classical solution of (1) and (2) having the coordinate representation

$$u(x,t) = u^{h(t)}(x) + v(x,t). \tag{13}$$

If we differentiate the identity $\langle v(\cdot,t), \tau^{h(t)}\rangle = 0$ with respect to t and use the expression for v_t which is obtained by inserting (13) into (1), we obtain the equations

$$[\langle u_h^h, \tau^h\rangle - \langle v, \tau_h^h\rangle]h' = \langle \mathcal{L}_a(u^h + v), \tau^h\rangle, \tag{14}$$

$$v_t = \mathcal{L}_a(u) - u_h^h h', \tag{15}$$

where, for simplicity of notation, we suppress the dependence on t. Equations (14) and (15) will be of primary concern in the remainder of this paper.

In the next section, we will need some estimates about the approximate manifold that we have just constructed explicitly. Here we list some results, the proofs of which can be found in [C-P] (cf. Proposition 2.3 and Theorem 5.2).

PROPOSITION 1. *There are constants $A_0 > 0$, C, c, and $\epsilon_0 > 0$ such that, if $\epsilon < \epsilon_0$, we have, for $h \in \Omega_{\rho_0}$,*

$$\begin{aligned} A_0\epsilon^{-1/2} &\le \|u_h^h\| \le 2A_0\epsilon^{-1/2}, \\ A_0\epsilon^{-1/2} &\le \|\tau^h\| \le 2A_0\epsilon^{-1/2}, \\ A_0\epsilon^{-1} &\le \langle u_h^h, \tau^h\rangle \le 2A_0\epsilon^{-1}, \\ \|\tau_h^h\| &\le C\epsilon^{-3/2}, \\ \|\tau_h^h\|_{L^1} &\le C\epsilon^{-1}, \\ \|\mathcal{L}_0(u^h)\| &= O\left(\exp\left(-\frac{c}{\epsilon}\right)\right), \\ \|L_0^h(\tau^h)\| &= O\left(\exp\left(-\frac{c}{\epsilon}\right)\right). \end{aligned} \tag{16}$$

As was proved in [C-P] or in the appendix of [ABF], the last estimate in (16) is a consequence of the fact that τ^h is exponentially close to the first eigenfunction of L_0^h and the first eigenvalue is exponentially small.

PROPOSITION 2. *There exist constants Λ and ϵ_1 such that, for $h \in \Omega_{\rho_0}$ and $\epsilon < \epsilon_1$, the following assertions hold:*

(i) *if $v \in H^1$ and $\langle v, \tau^h\rangle = 0$, then*

$$\Lambda\epsilon\|v\|_{L^\infty}^2 \le 2\Lambda\int_{-1}^{1}(\epsilon^2 v_x^2 + v^2)dx \le 2\int_0^1(\epsilon^2 v_x^2 + f_0'(u^h)v^2)dx; \tag{17}$$

(ii) *if $v \in H^2$, $v_x = 0$ at $x = 0, 1$, and $\langle v, \tau^h\rangle = 0$, then*

$$\Lambda\int_{-1}^{1}(\epsilon^2 v_x^2 + f_0'(u^h)v^2)dx = \Lambda\langle v, -L_0^h v\rangle \le \|L_0^h v\|^2. \tag{18}$$

3. Estimate on $h'(t)$. The goal of this section is to give an estimate on $h' =: h'(t)$. Later, we will refine this estimate and show that h' approaches the speed of the monotone traveling-wave solution of (1) on $(-\infty, \infty)$. Throughout the remainder of the paper, C will designate a generic constant independent of ϵ and a.

We estimate $\langle v, \tau_h^h\rangle$ first. In the following, we take $0 < \epsilon \le \epsilon_0$ and $|a| \le a_0$ with ϵ_0 and a_0 fixed small constants and assume the following:

I. $u(x,t)$ is a classical solution of (1) and (2) such that $u(\cdot, 0) \in \mathcal{B}_{\sigma_0}$ so that the coordinate representation (13) is valid in a neighborhood of $t = 0$.

II. The function $v(x,t)$ defined in (13) satisfies

$$\|v(\cdot, t)\|_{L^\infty} < C\sqrt{a_0}.$$

The continuity of the representation (13) and the continuity of the solution of (1) and (2) with respect to the initial data imply that this inequality holds for t in some interval $[0, T)$ provided that it holds at $t = 0$. We shall see that, if ϵ_0 and a_0 are small enough, it holds until $h(t)$ leaves Ω_{ρ_0}. We will prove this by obtaining a priori estimates under this assumption and then show that our estimates imply that we can choose ϵ_0 and a_0 so that II is always satisfied.

By assumption II and Proposition 1, we obtain the inequality

$$|\langle v, \tau_h^h\rangle| \le C\|v\|_{L^\infty}\|\tau_h^h\|_{L^1} \le C\sqrt{a_0}\epsilon^{-1}. \tag{19}$$

From this estimate and Proposition 1, we see that

$$\langle u_h^h, \tau^h\rangle - \langle v, \tau_h^h\rangle > C\epsilon^{-1}. \tag{20}$$

From (19) and (20), we can see that the coefficient of h' in formula (14) is nonzero. Therefore, we can rewrite (14) as

$$h' = X(h, v), \tag{14$'$}$$

where

$$X(h, v) =: \frac{\langle \mathcal{L}_a(u^h + v), \tau^h\rangle}{\langle u_h^h, \tau^h\rangle - \langle v, \tau_h^h\rangle}. \tag{14$''$}$$

We estimate $\langle \mathcal{L}_a(u), \tau^h\rangle$ as follows:

$$\begin{aligned}\langle \mathcal{L}_a(u), \tau^h\rangle &= \langle \mathcal{L}_0(u^h), \tau^h\rangle + \langle \epsilon^2 v_{xx} - f_0'(u^h)v, \tau^h\rangle \\ &\quad - \left\langle \frac{1}{2}f_0''v^2 + ag(u^h) + ag'v, \tau^h\right\rangle \\ &=: \mathrm{I} + \mathrm{II} + \mathrm{III},\end{aligned} \tag{21}$$

where f_0'' and g' are evaluated at points between u and u^h.

By using Proposition 1, we have

$$|\mathrm{I}| = O(e^{-c/\epsilon}); \tag{22}$$

$$\begin{aligned}|\mathrm{II}| &= |\langle v, L_0^h \tau^h\rangle| \\ &= O(e^{-c/\epsilon}).\end{aligned} \tag{23}$$

On the other hand, if a_0 is sufficiently small, assumption II implies that, for $|a| \le a_0$,

$$|\mathrm{III}| \le Ca_0 \|\tau^h\|_{L_1},$$

and therefore

$$|\mathrm{III}| \le Ca_0. \tag{24}$$

In fact, the definition of τ^h implies that

$$\|\tau^h\|_{L^1} = \|u_x^h\|_{L^1} + O(e^{-c/\epsilon}) < C.$$

Combining formulas (19) through (24) yields the following proposition.

PROPOSITION 3. *If assumptions* I *and* II *hold,* $0 < \epsilon \le \epsilon_0$, *and* $|a| \le a_0$, *then there is a constant* $C > 0$ *such that the following estimate is valid:*

$$|h'| \le Ca_0\epsilon.$$

4. Estimates in the direction orthogonal to $\mathcal{M}$. In the previous section, we gave an estimate in the direction tangential to $\mathcal{M}$. In this section, we obtain an estimate in the direction orthogonal to $\mathcal{M}$. In order to do this, we need a number of estimates on the functions $\phi(x, \ell, \pm 1)$ that we used for constructing $\mathcal{M}$. We present the estimates in a sequence of propositions.

PROPOSITION 4. *For any integer k, there exist positive constants ϵ_1 and C such that, for $0 < \epsilon < \epsilon_1$, we have*

$$|\phi(x, 2\ell, -1) - \Phi(x-\ell)| \leq C\epsilon^k, \quad x \in [0, \ell],$$

$$|\phi(x, 2\ell, 1) + \Phi(x-\ell)| \leq C\epsilon^k, \quad x \in [0, \ell],$$

where $\phi(x, 2\ell, \pm 1)$ are solutions of equation (7) *with ℓ replaced by 2ℓ and $\Phi(x) = U(\frac{x}{\epsilon})$ is the standing-wave solution of*

$$\begin{cases} \epsilon^2 \Phi_{xx}(x) = f_0(\Phi(x)) & \text{for } x \in (-\infty, \infty) \\ \Phi(x) \to \pm 1 & \text{as } x \to \pm\infty \\ \Phi(0) = 0. \end{cases} \tag{25}$$

Proof: Step 1. Let δ be a fixed positive number such that

$$q^2 =: \min\{f_0'(s) : |s \pm 1| < 2\delta\} > 0. \tag{26}$$

If $\phi(x)$ is either $\phi(x, 2\ell, +1)$ or $\phi(x, 2\ell, -1)$, then ϕ depends on ϵ and ℓ through the ratio $\frac{\epsilon}{\ell} =: r$ and there is a positive number $H = H(\delta)$ such that

$$|\phi(x) - \phi(0)| < \delta \quad \text{for } x \in [0, \ell - \epsilon H). \tag{27}$$

Let $\alpha =: \alpha(r) =: F(\phi(0))$, where F is defined by $F' = f_0$, $F \geq 0$ and $F(\pm 1) = 0$. It is known and actually not hard to show that $\phi(0) + 1 = O(e^{-c/\epsilon})$ and therefore that $\alpha(r) = O(e^{-c/r})$(see [C-P]).

Let $\tilde{H} > H$ be such that

$$|\Phi(x-\ell) + 1| < \delta \quad \text{for } x \in (-\infty, \ell - \epsilon\tilde{H}] \tag{28}$$

and $\epsilon > 0$ sufficiently small. This is possible since $\Phi(-\epsilon\tilde{H})$ is ϵ independent and approaches -1 as $\tilde{H} \to \infty$. If we define $p =: \phi(\ell - \epsilon\tilde{H})$ and $\bar{p} =: \Phi(-\epsilon\tilde{H})$, then $\bar{p}$ is ϵ independent.

Using the fact that

$$\int_p^0 \frac{du}{\sqrt{2(F(u) - \alpha(r))}} = \int_{\bar{p}}^0 \frac{du}{\sqrt{2F(u)}} = \epsilon\tilde{H}$$

and $\alpha(r) > 0$, we know that $-1 < \bar{p} < p \leq \phi(x) \leq 0$ for $x \in [\ell - \epsilon\tilde{H}, \ell]$. Therefore, for $x \in [\ell - \epsilon\tilde{H}, \ell]$, we have $F(\phi(x)) \geq C > 0$ for some constant C depending only on F and $\tilde{H}$. It follows that if we let $\bar{V}(x) =: \phi(x) - \Phi(x-\ell)$, then, for $x \in [\ell - \epsilon\tilde{H}, \ell]$,

$$\begin{cases} \epsilon\bar{V}_x(x) = \sqrt{2}((F(\phi(x)) - \alpha)^{1/2} - F(\Phi(x))^{1/2}) \geq -C(\alpha + \bar{V}), \\ \bar{V}(\ell) = 0, \quad \bar{V}(x) \geq 0, \end{cases}$$

where C is a positive constant depending only on F.

By integration, we deduce that $|\Phi(x-\ell) - \phi(x)| \leq C_1\alpha(r)$ for $x \in [\ell - \epsilon\tilde{H}, \ell]$, where $C_1 = e^{C\tilde{H}}$. Therefore, using the fact that $\alpha(r)$ is exponentially small, we obtain

$$|\Phi(x-\ell) - \phi(x)| \leq C_1'\epsilon^k \quad \text{for } x \in [\ell - \epsilon\tilde{H}, \ell] \tag{29}$$

and any fixed $C_1' \ge 1$ provided that $\epsilon > 0$ is sufficiently small.

Step 2. In this step, we will prove (29) in the interval $\mathrm{I} =: [0, \ell - \tilde{H}\epsilon]$. We denote $\bar{V}(x) = \phi(x) - \Phi(x - \ell)$ as in Step 1.

Let $\tilde{v} =: \Phi(x - \ell) + 1$. Using (28) and the definition of q in (26), we can compare $\tilde{v}$ with the solution of

$$\begin{cases} \epsilon^2 y_{xx} = q^2 y & \text{for } x \in (-\infty, \ell - \epsilon\tilde{H}), \\ y(-\infty) = 0, & y(\ell - \epsilon\tilde{H}) = \delta, \end{cases}$$

to obtain

$$0 \le \tilde{v}(x) \le y(x) = \delta e^{(x - (\ell - \epsilon\tilde{H}))\frac{q}{\epsilon}}.$$

This is bounded above by $C\epsilon^k$ provided that $x \le \ell - \tilde{C}_1 \epsilon k \log \frac{1}{\epsilon}$ for ϵ sufficiently small and where $\tilde{C}_1' = \frac{2}{q}$.

Then, for $x \in \mathrm{I} = [0, \ell - \epsilon\tilde{H}]$, we have

$$\begin{aligned} \epsilon^2 \bar{V}_{xx} &= F'(\phi(x)) - F'(\Phi(x - \ell)) \\ &= F''(\xi)\bar{V}(x) \ge q^2 \bar{V}(x), \end{aligned}$$

where (27) and (28) are used.

At the endpoints of I, we have $\bar{V}(0) = \tilde{a}$ and $\bar{V}(\ell - \tilde{H}\epsilon) = \tilde{b}$. We have already recalled in Step 1 that $\phi(0) + 1 = O(e^{-c/\epsilon})$. Moreover, $\Phi(0) + 1 = O(e^{-c/\epsilon})$. It follows that, for $\epsilon > 0$ small,

$$|\tilde{a}| = |[\phi(0) + 1)] - [\Phi(-\ell) + 1]| \le C\epsilon^k.$$

On the other hand, by (29), $|\tilde{b}| \le C\epsilon^k$ for ϵ sufficiently small.

If we solve

$$\begin{cases} \epsilon^2 y'' = q^2 y & \text{for } x \in \mathrm{I}, \\ y(0) = \tilde{a}, & y(\ell - \tilde{H}\epsilon) = \tilde{b}, \end{cases}$$

and use a comparison argument, it is not hard to conclude that

$$|\Phi(x - \ell) - \phi(x)| = |\bar{V}(x)| \le |y| \le \max\left\{|\tilde{a}|, |\tilde{b}|\right\} \le C_1'\epsilon^k$$

for $x \in [0, \ell - \epsilon\tilde{H}]$. The proof follows if we adjust the constant $\tilde{C}_1$. □

PROPOSITION 5. *For any positive integer k, positive constants ϵ_1 and C as in Proposition* 4, *and any positive integer $0 < n < k$, there exists $C_1 > 0$, which may depend on n, such that, for $0 < \epsilon < \epsilon_1$, we have*

$$|\phi^{(n)}(x) - \Phi^{(n)}(x - \ell)| \le C_1 \epsilon^{k-n} \quad \textit{for } x \in [0, \ell]. \tag{30}$$

Proof. We give the proof only for $n = 1$, and the general case follows immediately from the following formula:

$$\frac{d^n}{dx^n} f(g) = \sum_{\substack{\alpha_j \ge 0 \\ \sum \alpha_j = n}} c^\alpha(g) \frac{d^{\alpha_1}}{dx^{\alpha_1}} g \frac{d^{\alpha_2}}{dx^{\alpha_2}} g \cdots \frac{d^{\alpha_n}}{dx^{\alpha_n}} g,$$

where f and g can be any smooth functions and the $c^\alpha(g)$'s in the sum are functions of g.

For $x \in [0, \ell]$, we start with the relation

$$\epsilon^2[\phi_{xx}(x) - \Phi_{xx}(x-\ell)] = F'(\phi) - F'(\Phi).$$

Integrating, we obtain

$$\epsilon^2[\phi_x(x) - \Phi_x(x-\ell)] = \int_0^x [F'(\phi) - F'(\Phi)]dx + \epsilon^2 O(\epsilon^{k-1}).$$

As a consequence,

$$\begin{aligned}\epsilon^2|\phi_x(x) - \Phi_x(x-\ell)| &\leq \epsilon C_1'' k \log\frac{1}{\epsilon}[|F''(\xi)||\phi - \Phi|] + O(\epsilon^{k+1})\\ &\leq C_1'\epsilon^{k+1}\log\frac{1}{\epsilon}\end{aligned}$$

and the proposition now follows. □

We now show that $\mathcal{M}$ is "*close*" to being invariant under the flow generated by equations (1) and (2). Actually, the following propositions show that $\mathcal{M}$ attracts nearby solutions exponentially fast into a neighborhood of $\mathcal{M}$ of size $O(\epsilon^k)$, where k can be any positive integer provided $0 < \epsilon < \epsilon^0$ and ϵ_0 is small.

To make the above statement rigorous, we denote

$$\tilde{h}(t) =: -\sqrt{2}a\epsilon t, \qquad \zeta(x,t) =: u^{\tilde{h}(t)}(x). \tag{31}$$

Note that we need to require that the t in (31) is such that $\tilde{h}(t) \in \Omega_{\rho_0}$ and therefore $0 < t < \frac{C}{\epsilon}$.

PROPOSITION 6. *There is a positive constant a_0 such that, for any positive integer k, there are positive constants ϵ_0 and C_1 such that, for $0 < \epsilon < \epsilon_0$ and $|a| \leq a_0$, we have*

$$\left|\frac{\partial}{\partial t}\zeta(x,t) = \mathcal{L}_a(\zeta(x,t))\right| \leq C_1\epsilon^k\log\frac{1}{\epsilon} \tag{32}$$

for $x \in [-1,1]$ and $0 < t < \frac{C}{\epsilon}$.

Proof. For simplicity, we denote the function $\chi(\frac{x-h}{\epsilon})$ by $\chi^\epsilon(x-h)$. We have (cf. Lemma 7.8 in [C-P])

$$u^h = (1-\chi^\epsilon(x-h))\phi(x+1, 2(h+1), -1) + \chi^\epsilon(x-h)\phi(x-1, 2(h-1), 1), \tag{33}$$

$$\begin{aligned}u_h^h = &-[(1-\chi^\epsilon(x-h))\phi_x(x+1, 2(h+1), -1)\\ &+ \chi^\epsilon(x-h)\phi_x(x-1, 2(h-1), 1)] + O(e^{-c/\epsilon}),\end{aligned} \tag{34}$$

and

$$\begin{aligned}u_{xx}^h = &(1-\chi^\epsilon(x-h))\phi_{xx}(x+1, 2(h+1), -1)\\ &+ \chi^\epsilon(x-h)\phi_{xx}(x-1, 2(h-1), 1) + O(e^{-c/\epsilon}).\end{aligned} \tag{35}$$

The traveling-wave solution $U(x,t)$ of equation (1) on $(-\infty, \infty)$ can be calculated explicitly as

$$\tilde{\Phi}(x,t) =: U\left(\frac{x}{\epsilon} + \sqrt{2}at\right) =: \frac{-1 + \exp(\sqrt{2}(\frac{x}{\epsilon} + \sqrt{2}at))}{1 + \exp(\sqrt{2}(\frac{x}{\epsilon} + \sqrt{2}at))}. \tag{36}$$

Then we have the following estimates:

$$\begin{aligned}|U(x,t)-\zeta(x,t)| &\leq (1-\chi^{\epsilon})|\tilde{\Phi}(x,t)-\phi(x+1,2(\tilde{h}+1),-1)| \\ &\quad +\chi^{\epsilon}|\tilde{\Phi}(x,t)-\phi(x-1,2(\tilde{h}-1),1)| \\ &\leq C\epsilon^{k},\end{aligned} \tag{37}$$

where we have used the fact that $\tilde{\Phi}$ is simply the translation of the standing wave of (1) with $a=0$, and therefore Proposition 4 applies. Similarly, using Propositions 4 and 5 and formulas (34) and (35), we obtain

$$\epsilon^2|\tilde{\Phi}_{xx}(x,t)-\zeta_{xx}(x,t)| \leq C\epsilon^k \log\frac{1}{\epsilon},$$

$$|\tilde{\Phi}_t(x,t)-\zeta_t(x,t)| \leq Ca_0\ \epsilon^k \log\frac{1}{\epsilon}. \tag{38}$$

The proof of the proposition follows from (37), (38), and the fact that $\tilde{\Phi}$ is a traveling-wave solution of (1). □

We need an estimate on the Fréchet derivative of the function $X(h,v)$ defined by

$$X(h,v)=\frac{\langle\mathcal{L}_a(u^h+v),\tau^h\rangle}{\langle u^h_h,\tau^h\rangle-\langle v,\tau^h_h\rangle}. \tag{39}$$

PROPOSITION 7. *If v satisfies assumption* II, *then there is a positive constant C such that*

$$\left\|\frac{\partial}{\partial v}X(h,v)\right\| \leq C\sqrt{a_0}\epsilon^{1/2}. \tag{40}$$

Proof. If μ is a smooth function satisfying boundary condition (2), then it can be verified that

$$\frac{\partial}{\partial v}X(h,v)\mu=\frac{\mathrm{I}+\mathrm{II}}{(\langle u^h_h,\tau^h\rangle-\langle v,\tau^h_h\rangle)^2}, \tag{41}$$

where

$$\mathrm{I}=:[\langle u^h_h,\tau^h\rangle-\langle v,\tau^h_h\rangle]\langle\epsilon^2\mu_{xx}-f_a'(u^h+v)\mu,\tau^h\rangle,$$
$$\mathrm{II}=:\langle\mu,\tau^h_h\rangle\langle\epsilon^2(u^h+v)_{xx}-f_a(u^h+v),\tau^h\rangle.$$

Using (20) and (41), we obtain

$$\left|\frac{\partial}{\partial v}X(h,v)\mu\right| \leq C\epsilon^2[|\mathrm{I}|+|\mathrm{II}|]. \tag{42}$$

We have

$$\begin{aligned}|\mathrm{I}| &= |\langle u^h,\tau^h\rangle-\langle v,\tau^h_h\rangle||\langle\mu,\epsilon^2\tau_{xx}-f_a'(u^h+v)\tau\rangle| \\ &\leq C\epsilon^{-1}\|\mu\|\|\epsilon^2\tau_{xx}-f_a'(u^h+v)\tau\| \\ &\leq C\epsilon^{-1}\|\mu\|\|L_0^h(\tau^h)+ag'(u^h)\tau^h-f_a''v\tau^h\| \\ &\leq C\epsilon^{-1}\|\mu\|[Ce^{-c/\epsilon}+Ca_0\epsilon^{-1/2}+C\sqrt{a_0}\epsilon^{-1/2}] \\ &\leq C\sqrt{a_0}\epsilon^{-3/2}\|\mu\|,\end{aligned} \tag{43}$$

where we have used the fact that $\|L_0^h(\tau^h)\| = O(e^{-c/\epsilon})$ by Proposition 1.

Similarly, we derive the following estimate for II:

$$\begin{aligned}|\mathrm{II}| &= |\langle \mathcal{L}_0^h(u^h), \tau^h\rangle + \langle v, L_0^h \tau^h\rangle + \langle -ag(u^h) - ag'(u^h)v \\ &\qquad + \frac{1}{2} f_a'' v^2, \tau^h\rangle||\langle \mu, \tau_h^h\rangle| \\ &\leq [Ce^{-c/\epsilon} + Ca_0\|\tau^h\|_{L^1}]\epsilon^{-3/2}\|\mu\| \\ &\leq C\sqrt{a_0}\epsilon^{-3/2}\|\mu\|.\end{aligned} \tag{44}$$

The proof of the proposition follows from (42), (43), and (44). □

PROPOSITION 8. *There exists a positive constant* a_0 *such that, for any integer* k, *there are positive constants* ϵ_0 *and* C *such that, if* $0 < \epsilon \leq \epsilon_0$ *and* v *satisfies assumption* II, *then*

$$\|v(\cdot, t)\|^2 \leq \|v(\cdot, 0)\|^2 e^{-\Lambda t} + C\epsilon^k \tag{45}$$

for $x \in [-1, 1]$ *and* $0 < t < \frac{C}{\epsilon}$.

Proof. We have

$$\begin{aligned}\frac{1}{2}\frac{\partial}{\partial t}\|v\|^2 &= \langle v, v_t\rangle \\ &= \langle v, \mathcal{L}_a(u) - u_h^h h'\rangle \\ &= \Big\langle v, [\mathcal{L}_a(u^h) - u_h^h X(h, 0)] + L_0^h v - ag'(u^h)v \\ &\qquad + \frac{1}{2} f_a'' v^2 + u_h^h [X(h, 0) - X(h, v)]\Big\rangle \\ &=: \mathrm{I} + \mathrm{II} + \mathrm{III} + \mathrm{IV} + \mathrm{V}.\end{aligned}$$

By Propositions 4 and 5 and the fact that $\tilde{\Phi}_t = \mathcal{L}_a(\tilde{\Phi}) = -\sqrt{2}at\epsilon$, it follows that $X(h, 0) = -\sqrt{2}a\epsilon + O(\epsilon^{k+1})$ for any h. Therefore, if we let $s =: h/(-\sqrt{2}a\epsilon)$, then $h(t) = \tilde{h}(s)$, where $\tilde{h}$ is defined in (31), and

$$\mathcal{L}_a(u^h) - u_h^h X(h, 0) = \mathcal{L}_a(u^{\tilde{h}}) - \frac{\partial}{\partial s} u^{\tilde{h}} + O(e^{-c/\epsilon}).$$

From this, Proposition 6, and assumption II, it follows that $|\mathrm{I}| \leq C\epsilon^k$. By Proposition 2, $-\mathrm{II} \geq \Lambda\|v\|^2$.

Using assumption II, we have $|\mathrm{III}|, |\mathrm{IV}| \leq C\sqrt{a_0}\|v\|^2$.

For V, we use Proposition 7 to deduce that

$$\begin{aligned}|\mathrm{V}| \leq \|v\|^2 \|u_h^h\| \left\|\frac{\partial}{\partial v} X(h, \bar{v})\right\| &\leq C\epsilon^{-1/2}\|v\|^2 \sqrt{a_0}\epsilon^{1/2} \\ &= C\sqrt{a_0}\|v\|^2,\end{aligned}$$

where $\bar{v}(x, t)$ is a suitable value between 0 and $v(x, t)$.

Combining all of these estimates, we obtain

$$\frac{\partial}{\partial t}\|v\|^2 + \Lambda\|v\|^2 \leq C\epsilon^k$$

provided that a_0 is chosen sufficiently small. The proof of the proposition follows immediately from Gronwall's inequality. □

In order to obtain an L^∞ estimate on v, we need the following proposition.

PROPOSITION 9. *There is a positive constant a_0 such that, for any integer k, there are positive constants ϵ_0, C, C_1, and C_2 such that, if $0 < \epsilon < \epsilon_0$ and assumption* II *is satisfied, we have*

$$\langle -L_0^h v(\cdot,t), v(\cdot,t)\rangle \le C\epsilon^k \tag{46}$$

for $x \in [-1,1]$ and $C_1 k \log\frac{1}{\epsilon} < t < \frac{C_2}{\epsilon}$.

Proof. We have

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\langle -L_0^h v, v\rangle = &-\|L_0^h v\|^2 + \langle -L_0^h v, \mathcal{L}_0(u^h)\rangle \\ &+ \left\langle L_0^h v, \frac{1}{2}(f_0'' + ag'')v^2\right\rangle + \langle L_0^h v, ag(u^h)\rangle \\ &+ \langle L_0^h v, ag'(u^h)v\rangle + \langle L_0^h v, u_h^h h'\rangle \\ &+ \frac{1}{2}\langle f_0''(u^h)u_h^h h' v, v\rangle \\ =:& -\|L_0^h v\|^2 + \mathrm{I} + \mathrm{II} + \mathrm{III} + \mathrm{IV} + \mathrm{V} + \mathrm{VI}.\end{aligned} \tag{47}$$

There exist positive constants $b_i, i = 1, \ldots, 4$, whose sum is $\frac{1}{2}$ such that the six terms in (47) are estimated as follows:

$$\begin{aligned}|\mathrm{I}| &\le \|L_0^h v\|\|\mathcal{L}_0(u^h)\| \le b_1\|L_0^h v\|^2 + C\|\mathcal{L}_0(u^h)\|^2 \\ &\le b_1\|L_0^h v\|^2 + O(e^{-c/\epsilon}),\end{aligned}$$

where, in the last inequality, we have used Proposition 1.

By the second part of (17), we know that $\|v\|^2 \le C\|L_0^h v\|\|v\|$ and therefore $\|v\|^2 \le C\|L_0^h\|^2$, and it follows from this that

$$|\mathrm{II}| \le C\|v\|_\infty\|L_0^h v\|^2 \le b_2\|L_0^h v\|^2.$$

We estimate III by integration by parts. Noticing that the boundary term contribution is $O(e^{-c/\epsilon})$, we obtain using Proposition 8 that for $0 \le t \le T$, T such that assumption II is satisfied in $[0,T]$,

$$\begin{aligned}|\mathrm{III}| &\le |\langle L_0^h(ag(u^h)), v\rangle| + Ce^{-c/\epsilon} \\ &\le C|a|\|v(\cdot,t)\| \\ &\le C|a| + Ce^{-c/\epsilon}\left(\|v(\cdot,0)\|e^{-\Lambda t/2} + C\epsilon^{k/2}\right).\end{aligned}$$

Therefore, we can take ϵ small such that

$$|\mathrm{III}| \le C|a|\left(\|v(x,0)\|e^{-\Lambda t/2} + \epsilon^k\right).$$

$$|\mathrm{IV}| \le C|a|\|v\|\|L_0^h v\| \le b_3\|L_0^h v\|^2.$$

Similarly to estimating III, we have

$$|\mathrm{V}| \le C|a|\left(\|v(x,0)\|e^{-\Lambda t/2} + \epsilon^k\right).$$

By using Propositions 2 and 3 and assuming that a_0 is sufficiently small, we estimate VI as follows:

$$|\mathrm{VI}| \leq Ca_0\|v\|^2 \leq Ca_0\|L_0^h v\|^2.$$

Combining (47) and the above estimates, we have

$$\frac{d}{dt}\langle -L_0^h v, v\rangle \leq -\|L_0^h v\|^2 + C\left(\|v(x,0)\|e^{-\Lambda t/2} + \epsilon^k\right).$$

This inequality together with Proposition 2 implies that

$$\frac{d}{dt}\langle -L_0^h v, v\rangle + \Lambda\langle -L_0^h v, v\rangle \leq C\left(\|v(x,0)\|e^{-\Lambda t/2} + \epsilon^k\right),$$

and, from an application of Gronwall's lemma, we conclude that

$$\langle -L_0^h v(\cdot,t), v(\cdot,t)\rangle \leq \langle -L_0^h v(\cdot,0), v(\cdot,0)\rangle e^{-\Lambda t} + C\left(\|v(x,0)\|e^{-\Lambda t/2} + \epsilon^k\right),$$

and the proof follows. □

5. Solutions in bounded domain approach the traveling-wave solution. In this section, we prove the theorem stated in §1. After all the work in the previous sections, this is a fairly easy task.

We may choose C_1 such that $\Lambda C_1 \geq 1$; now, using inequality (45), we see that $C_1 k \log\frac{1}{\epsilon} < t < \frac{C_2}{\epsilon}$ implies that $\|v(\cdot,t)\| \leq C\epsilon^k$. From (14′) and (14″), we have

$$\begin{aligned} h'(t) &= \frac{\langle \mathcal{L}_0(u^h) + ag(u^h) + f_a'v, \tau^h\rangle + \langle v, L_a^h\tau^h\rangle}{\langle u^h, \tau^h\rangle - \langle v, \tau_h^h\rangle} \\ &= \frac{-aA + O(\epsilon^{(k-1)/2})}{\frac{A}{\epsilon\sqrt{2}} + O(\epsilon^{(k-3)/2})} \\ &= -a\epsilon\sqrt{2} + O(\epsilon^{(k+1)/2}), \end{aligned}$$

where A is a constant which can be calculated explicitly.

Therefore, by choosing a different k, we have $h'(t) = -a\epsilon\sqrt{2} + O(\epsilon^k)$ for $t_0 =: C_1 k\log\frac{1}{\epsilon} < t < \frac{C^2}{\epsilon} =: t_1$. Thus, if we let $h_0 =: h(t_0)\epsilon^{-1}$, then

$$h(t) = -a\epsilon\sqrt{2}t + h_0\epsilon + O(\epsilon^{(k-1)}). \tag{48}$$

Also from (46), it is easy to deduce that there is a positive constant C_3 such that

$$\|v(\cdot,t)\|_{L^\infty} \leq C_3\epsilon^{k-2} \tag{49}$$

for $C_1 k\log\frac{1}{\epsilon} < t < \frac{C_2}{\epsilon}$. Estimate (49) was obtained under hypothesis II; that is, as long as II is satisfied, inequality (49) is satisfied. Therefore, if we choose ϵ_0 so that $C_3\epsilon_0^{k-2} \leq C\sqrt{a_0}$, where C is the constant in II, then II will be satisfied for $0 < \epsilon \leq \epsilon_0$ and $|a| \leq a_0$.

Applying Propositions 4 and 5 and formulas (36), (48), and (49), we obtain

$$\begin{aligned} &|u(x,t) - \Phi(x + \epsilon\sqrt{2}at - h_0\epsilon)| \\ &\qquad \leq |u^h - \Phi(x + \epsilon\sqrt{2}at - h_0\epsilon)| + |v| \leq C\epsilon^{k-2} \end{aligned}$$

for $t_0 < t < t_1$, where Φ is the solution of equation (25). Therefore, we have proved the following proposition.

PROPOSITION 10. *There is a positive constant a_0 such that, for any positive integer k, there are positive constants ϵ_0, C, C_1, and C_2 such that if $0 < \epsilon < \epsilon_0$ and $|a| \leq a_0$, then*

$$|u(x,t) - \Phi(x + \epsilon\sqrt{2}at - h_0\epsilon)| \leq C\epsilon^{k-2}$$

for $x \in [-1, 1]$ and $C_1 k \log\frac{1}{\epsilon} < t < \frac{C_2}{\epsilon}$.

The theorem stated in §1 is a direct result of this proposition using the rescaling $x \longrightarrow \epsilon x$.

ASYMPTOTIC BEHAVIOR OF TWO INTERREACTING CHEMICALS IN A CHROMATOGRAPHY REACTOR*

DANIEL N. OSTROV†

Abstract. The chromatographic separation of two chemical species (c_1 and c_2) that transform into each other with first-order kinetics as they pass through a Langmuir isotherm reactor is governed by the following system of nonlinear hyperbolic conservation equations:

$$\begin{aligned} &\frac{\partial c_1}{\partial x} + \frac{\partial}{\partial t}\left(\frac{c_1}{1+c_1+c_2}\right) = -kc_1 + k'c_2 \\ \text{and}\quad &\frac{\partial c_2}{\partial x} + \frac{\partial}{\partial t}\left(\frac{\gamma c_2}{1+c_1+c_2}\right) = \gamma(kc_1 - k'c_2), \end{aligned}$$

$$\text{where } t \in (-\infty, \infty).$$

An analysis is presented of the two species' asymptotic behavior as they progress down a semiinfinite (i.e., $x \in [0,\infty)$) separation reactor with cyclic (periodic) entering feed concentrations. First it is shown that the method of generalized characteristics can be extended to describe the above system of equations. Then generalized characteristics are applied to show that the ω-limit set for the species concentrations is comprised of a single determined point on the curve of chemical equilibrium and that this point is approached at an exponential rate.

Key words. chromatography, hyperbolic conservation laws, generalized characteristics

AMS subject classification. 35

1. Introduction.

Chromatography is a process used by chemists and engineers to separate two chemical components in a fluid phase. The two components are passed through a tubular reactor packed with solid particles. Even though the fluid velocity may be constant, the fact that the solid will absorb different amounts of the two chemical components will cause the two concentration distributions to move down the reactor at different rates.

When a reaction allowing the two components to transform into each other occurs in the fluid, the separation caused by the chromatographic reactor will be inhibited. We will consider the most common case where the kinetics of this transformation are first order (i.e., the rate of a component's transformation is proportional to the component's concentration). A simple example of chromatography with a first-order transformation is provided by considering a separation of the cis and trans isomeric forms of an organic compound. When the temperature of the chromatography reactor provides enough activation energy to allow the isomers' chemical bonds to break and reconnect, each isomer will transform into the other at a rate proportional to its concentration.

When the solid phase consists of small, densely packed particles and the fluid velocity is relatively slow, each chemical species approaches an equilibrium between its fluid and solid phases at each point in the reactor. If the temperature within the reactor is assumed to be uniformly constant in time and space, this equilibrium allows us to express each species' solid concentration strictly as a function of both species' fluid concentrations. The function describing this relation is called an *adsorption isotherm.* The *Langmuir isotherm* is the most common type of adsorption isotherm

used by chemical engineers. It corresponds to a simple kinetic model for adsorption that effectively describes a large range of observed solid–liquid kinetic behavior [7]. For a chromatography reactor in which the two components interreact with first-order kinetics and the solid–liquid equilibrium is governed by the Langmuir isotherm, the mass balances for the two species are

$$\frac{\partial c_1}{\partial x} + \frac{\partial}{\partial t}\left(\frac{c_1}{1+c_1+c_2}\right) = -kc_1 + k'c_2 \tag{1.1a}$$

$$\text{and}\quad \frac{\partial c_2}{\partial x} + \frac{\partial}{\partial t}\left(\frac{\gamma c_2}{1+c_1+c_2}\right) = \gamma(kc_1 - k'c_2), \tag{1.1b}$$

$$\text{where } t \in (-\infty,\infty), \quad x \in [0,\infty).$$

In these balances, c_1 and c_2 are proportional to the two species' concentrations in the liquid phase, k and k' are proportional to the rate constants in the reaction, x is proportional to the length down the reactor, t is related to the time, and γ is a known constant between 0 and 1 dependent on the nature of the Langmuir isotherm. To avoid potential confusion, it should be noted that the mathematical roles played by x and t in the above chromatography equations are the opposite of the mathematical roles that x and t typically play in physical hyperbolic systems (e.g., gas dynamics) and in most hyperbolic systems literature.

It is not immediately clear how the species concentrations will behave as the reactor gets progressively longer (i.e., as $x \to \infty$). On one hand, the chemical reaction will tend to push the concentrations toward chemical equilibrium ($c_2/c_1 = k/k'$); on the other hand, the separation caused by the chromatographic effect will tend to push the concentrations away from equilibrium. Even in cases where the concentrations do approach equilibrium, the fact that the equilibrium is defined by a curve, as opposed to one point, means that the nature of the ω-limit set is still uncertain. Further, we would like to know at what rate the ω-limit set is approached. This rate of approach can be useful in designing reactors of this nature.

In §2, we will start to approach these questions by translating the physical conditions of the reactor into an appropriate mathematical problem. We will begin by deriving the mass balances given in (1.1). It is more convenient to describe the behavior of c_1 and c_2 when these concentrations are transformed into two special state vector coordinates called the Riemann invariants, z and w. We will determine the Riemann invariant forms of the mass balances in (1.1) and also determine which regions of the (z, w) graph are physically possible. Finally, we will note some of the properties of the equilibrium curve on the (z, w) phase portrait.

Section 3 will describe the method of generalized characteristics, which will be the tool used to determine the evolution of z and w. Classical characteristics are curves in the (t, x) plane where the shape of the curve and the evolution of the solution along the curve are defined by a characteristic system of ordinary differential equations (ODEs). For a system of n equations with n unknown functions, there are n families of these characteristic curves. Classical characteristics can be used to solve nonlinear differential equations in the region between their initial condition ($x = 0$) and the value of x corresponding to the first shock formation. At the shock formation, characteristic curves of the same family cross each other, leading to multiple possible solutions.

The method of generalized characteristics allows the characteristic system of ODEs to be extended past shocks to *all* $x \in [0, \infty)$. This is accomplished by considering any specific point in the (t, x) plane and looking at the funnel of all classical characteristic curves and shock curves of each family that emanate backward in x from that point to the initial condition $x = 0$. Each funnel is bounded by a minimal and maximal backward characteristic. For genuinely nonlinear systems (such as chromatography reactors with Langmuir isotherms), the minimal and maximal backward characteristics are not shocks; they propagate with classical characteristic speed. This fact, along with the standard entropy condition (which corresponds, physically, to requiring the concentration c_1 at a fixed location to increase as shocks pass through the location), will allow us to study the solution in regions of the (t, x) plane with shocks.

The nonlinearity caused by the Langmuir isotherm will identify the system in (1.1) as part of a special class of equations defined by Temple in 1983 [9]. This class of equations is remarkable in the sense that shocks formed by the characteristics associated with the family of one Riemann invariant will not induce discontinuities in the other Riemann invariants. This property has the powerful effect of preventing rarefaction waves from occurring when $x \neq 0$. In other words, there can only be one generalized characteristic (classical or shock) from each family emanating in the forward direction from any point (t, x), where $x > 0$.

Section 3 will show how basic properties of the minimal and maximal characteristics can be used to derive one-sided Lipschitz bounds on the variation of the solution in the t direction. These bounds will be used to prove that the Riemann invariants exhibit the properties of Temple equations even though (1.1) contains inhomogeneous reaction terms. From these properties, we will be able to determine the structure of the solution. The approach used in this section will involve modifying the method used by Dafermos and Geng to describe the behavior of characteristics for the homogeneous form of (1.1) [2].

With the tools of generalized characteristics in place, we will be able to explore the long-term behavior of (1.1) in §4. We will consider the case of periodic initial conditions since they physically correspond to the conditions under which a continuously run chromatography reactor would operate. First, we will define regions of the (z, w) phase plane that are invariant (i.e., if the solution is contained by the region at $x = x_o$, then the solution is contained by the region for all $x > x_o$). We will then establish that under periodic conditions the smallest invariant region containing the solution shrinks in proportion to its own size as x increases. It immediately follows from this conclusion that the ω-limit set is comprised of a single point on the chemical equilibrium curve and that this point is approached exponentially as x increases. Finally, by using an integrated form of the mass balances in (1.1), we will determine precisely which point on the equilibrium curve is being approached.

2. Mathematical modeling of the chromatography reactor.

We begin with the mass balances of the two components in the chromatography reactor

$$\frac{\partial c_1}{\partial x} + \frac{\partial n_1}{\partial t} = -kc_1 + k'c_2, \tag{2.1a}$$

$$\frac{\partial c_2}{\partial x} + \frac{\partial n_2}{\partial t} = kc_1 - k'c_2. \tag{2.1b}$$

where c_1, c_2 and n_1, n_2 are the component concentrations in the reactor's liquid and solid phases, respectively, x is the location down the reactor, t is related to time, and

k and k' are the first-order reaction rate constants. The derivation of this system is detailed by Rhee, Aris, and Amundson in [7].

The Langmuir isotherm expresses each solid concentration as a function of the liquid concentrations:

$$n_i = \frac{NK_i c_i}{1 + K_1 c_1 + K_2 c_2}, \qquad i = 1, 2, \tag{2.2}$$

where N, K_1 and K_2 are experimentally determined constants. Inserting (2.2) into (2.1), rescaling t, x, the concentrations, and the rate constants, and defining $\gamma \equiv K_2/K_1$ leads to the forms of the mass balances shown in §1:

$$\frac{\partial c_1}{\partial x} + \frac{\partial}{\partial t}\left(\frac{c_1}{1 + c_1 + c_2}\right) = -kc_1 + k'c_2 \tag{1.1a}$$

and

$$\frac{\partial c_2}{\partial x} + \frac{\partial}{\partial t}\left(\frac{\gamma c_2}{1 + c_1 + c_2}\right) = \gamma(kc_1 - k'c_2), \tag{1.1b}$$

$$\text{where } t \in (-\infty, \infty), \quad x \in [0, \infty).$$

We can label the two chemical components so that $K_1 \geq K_2$ and therefore state that $\gamma \in (0, 1]$. We will consider $\gamma \in (0, 1)$ since the case where $\gamma = 1$ can be solved with the aid of the single homogeneous expression for $c_1 + c_2$ obtained by adding the two equations in (1.1) together. Again, we point out that the mathematical roles played by x and t in (1.1) are the reverse of the mathematical roles that x and t typically play in hyperbolic-systems literature.

The Riemann-invariant form of the system in (1.1) partially decouples the behavior of the two components. This form can be obtained by first transforming (1.1) into a system investigated by Dafermos and Geng [2] by making a change in the state variable coordinates

$$u \equiv (c_1 + c_2 + 1)/\gamma, \qquad v \equiv (\gamma c_1 + c_2 + 1 + \gamma)/\gamma$$

and also making a scale change in the independent variable by defining x/γ to be equal to a new variable x, which yields

$$\frac{\partial u}{\partial x} - \frac{\partial (v/u)}{\partial t} = -au + bv - c, \tag{2.3a}$$

$$\frac{\partial v}{\partial x} - \frac{\partial (1/u)}{\partial t} = 0, \tag{2.3b}$$

$$\text{where } a \equiv \gamma(k + k'\gamma), \quad b \equiv \gamma(k + k'), \quad \text{and } c \equiv (k' + k\gamma).$$

It should be noted that the constants in (2.3) are all positive and have the property that $b^2 - ac = -\gamma kk'(1 - \gamma)^2 < 0$.

The Riemann invariants z and w for the system in (2.3) are

$$z \equiv \frac{1}{\lambda u} \quad \text{and} \quad w \equiv \frac{1}{\mu u}, \tag{2.4}$$

where λ and μ are the characteristic speeds of the system, which can be expressed in (u, v) coordinates or (z, w) coordinates:

$$\lambda = \frac{v - \sqrt{v^2 - 4u}}{2u^2} = \frac{1}{z^2 w}, \qquad \mu = \frac{v + \sqrt{v^2 - 4u}}{2u^2} = \frac{1}{zw^2}. \tag{2.5}$$

In regions where the solution to (2.3) is smooth, the system can be transformed into the desired Riemann-invariant form:

$$\frac{\partial z}{\partial x} + \lambda \frac{\partial z}{\partial t} = g(z, w), \tag{2.6a}$$

$$\frac{\partial w}{\partial x} + \mu \frac{\partial w}{\partial t} = -g(z, w), \tag{2.6b}$$

$$\text{where } g(z, w) \equiv \frac{a(zw) - b(z + w) + c}{z - w}.$$

We will assume in any solution to (2.6) that the Riemann invariants do not stray, for some constant M, from the following restricted ranges:

$$z \in \left[\frac{1}{\gamma}, M\right] \quad \text{and} \quad w \in \left[1, \frac{1}{\gamma}\right]. \tag{2.7}$$

These restrictions physically correspond to requiring that the concentrations, c_1 and c_2, are nonnegative and do not approach infinity.

Further, we assume that the solution remains bounded away from the umbilic point $z = w = 1/\gamma$, which implies that the system is strictly hyperbolic since $0 < \lambda < \mu$.

Both characteristic fields are genuinely nonlinear since

$$\frac{\partial \lambda}{\partial z} < 0 \quad \text{and} \quad \frac{\partial \mu}{\partial w} < 0, \tag{2.8}$$

which is immediately seen from (2.5) and (2.7).

The chemical equilibrium curve ($c_2/c_1 = k/k'$) for (1.1) corresponds in the Riemann-invariant system to the curve defined by $g(z, w) = 0$. If we define

$$z_e(w) \equiv \frac{c - bw}{b - aw} \quad \text{and} \quad w_e(z) \equiv \frac{c - bz}{b - az}, \tag{2.9}$$

then we have that $g(z_e(w), w) = g(z, w_e(z)) \equiv 0$ from the definition of g. Therefore, both z_e and w_e define the equilibrium curve in the Riemann-invariant plane.

We wish to note some of the properties of g and z_e. From (2.7) we see that $z_e(w)$ is defined only for $w \in [1, \frac{c-bM}{b-aM}]$. This restricted domain of z_e implies that the expressions for the first and second derivatives of z_e must be positive:

$$\frac{dz_e}{dw} = \frac{ac - b^2}{(aw - b)^2} > 0, \tag{2.10a}$$

$$\frac{d^2 z_e}{dw^2} = \frac{-2a(ac - b^2)}{(aw - b)^3} > 0. \tag{2.10b}$$

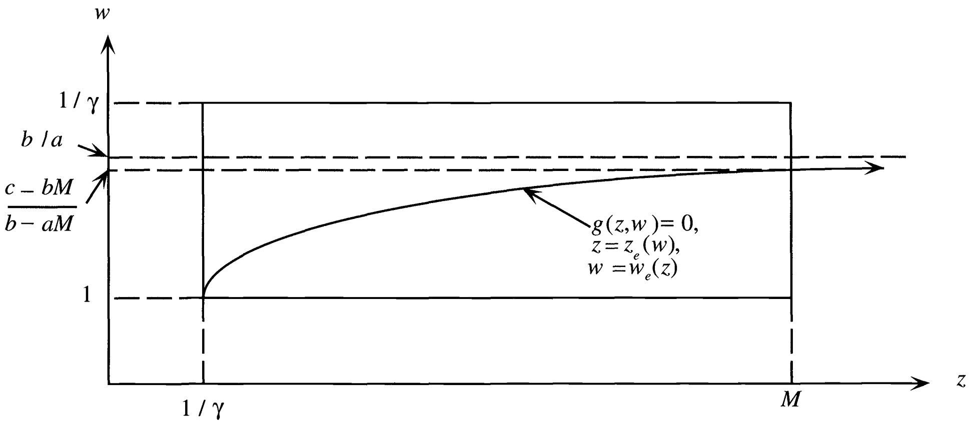

FIG. 1. *The Riemann-invariant phase plane. The invariants can only take values inside the solid rectangle shown above. As $z \longrightarrow \infty$, the equilibrium curve asymptotically approaches $w = b/a$.*

These properties of $z_e(w)$ along with (2.7) allow us to construct the phase plane shown in Fig. 1. Finally, we have that

$$\frac{\partial g}{\partial w} = \frac{az^2 - 2bz + c}{(w-z)^2} > 0, \tag{2.11a}$$

$$\frac{\partial g}{\partial z} = \frac{aw^2 - 2bw + c}{-(w-z)^2} < 0. \tag{2.11b}$$

The speed of shock propagation σ is given by the Rankine–Hugoniot conditions as applied to (2.3). These can be expressed in terms of the Riemann invariants by using the fact that $v = z + w$ and $u = zw$:

$$\sigma(z_+w_+ - z_-w_-) + z_+^{-1} + w_+^{-1} - z_-^{-1} - w_-^{-1} = 0, \tag{2.12a}$$

$$\sigma(z_+ + w_+ - z_- - w_-) + z_+^{-1}w_+^{-1} - z_-^{-1}w_-^{-1} = 0, \tag{2.12b}$$

where the subscripts "+" and "−" refer to the limit as t approaches the shock from the right and the left, respectively. Solving (2.12) leads to two possible shock speeds: 1-shocks, where $z_- \neq z_+$, $w_- = w_+$, and

$$\sigma = z_-^{-1}z_+^{-1}w_\pm^{-1}; \tag{2.13a}$$

and 2-shocks, where $w_- \neq w_+$, $z_- = z_+$, and

$$\sigma = w_-^{-1}w_+^{-1}z_\pm^{-1}. \tag{2.13b}$$

From (2.13), it is clear that shocks associated with one Riemann-invariant family do not induce discontinuities in the other invariant family, and so our system belongs to the class of equations defined by Temple.

The initial-value problem for (2.3) may have many solutions whose shocks satisfy the Rankine–Hugoniot conditions. By using the *entropy*, η, and the *entropy flux*, q, we are able to remove solutions that are physically irrelevant. The entropy conditions used in chromatography are completely analogous to the entropy conditions discussed in the context of gas dynamics [7]. η and q are any two functions satisfying

$$\frac{\partial q}{\partial z} = \lambda \frac{\partial \eta}{\partial z} \quad \text{and} \quad \frac{\partial q}{\partial w} = \mu \frac{\partial \eta}{\partial w}. \tag{2.14}$$

In §3, we will make use of the solution pair $(\eta,\ q)$ to (2.14) of the Lax type considered by Dafermos and Geng [2]:

$$\eta(z,w) = \left[1 - \frac{w}{z} + \frac{2}{l}w - \frac{2}{l^2}zw\right] \exp\left(\frac{l}{z}\right), \tag{2.15a}$$

$$q(z,w) = \left[\left(\frac{1}{z^2 w} - \frac{1}{z^3}\right) - \frac{2}{l}\left(\frac{1}{zw} - \frac{2}{z^2}\right) + \frac{2}{l^2}\left(\frac{1}{w} - \frac{5}{z}\right) + \frac{12}{l^3}\right] \exp\left(\frac{l}{z}\right). \tag{2.15b}$$

In particular, we will use the following two equations, which are determined directly from (2.15):

$$q(z,w) - \lambda(z,w)\eta(z,w) = -\frac{2}{l}\left[\frac{1}{zw}\left(1 - \frac{w}{z}\right) + O\left(\frac{1}{l}\right)\right] \exp\left(\frac{l}{z}\right), \tag{2.16a}$$

$$q(z,w) - [\lambda(z,w) + \varepsilon]\eta(z,w) = -\left[\varepsilon\left(1 - \frac{w}{z}\right) + O\left(\frac{1}{l}\right)\right] \exp\left(\frac{l}{z}\right). \tag{2.16b}$$

Entropies of the type considered by Lax [5] are generally convex only when l is large in one direction. However, the entropies for Temple-class systems are special in that they are convex when l is large in either direction.

Entropy–entropy flux solution pairs also exist that look similar to (2.15) with the roles of z and w interchanged.

Existence of entropy solutions to homogeneous systems of conservation laws in Temple's class under any initial condition with bounded variation has been shown by Serre [8]. Existence for the inhomogeneous system in Temple's class examined in this paper may be established through a routine extension of these methods. The issue of uniqueness of the entropy solution, even in the homogeneous case, has only been partially resolved, and in the inhomogeneous case, the problem is open.

3. Generalized characteristics. We consider a (weak) solution $(c_1(t,x), c_2(t,x))$ of locally bounded variation (BV) to (1.1) defined for $(t,x) \in (-\infty,\infty) \times [0,\infty)$. We assume that the Riemann-invariant fields $(z(t,x), w(t,x))$ induced by this solution take values in a small neighborhood of some fixed state (z_o, w_o) and that the two characteristic fields have well-separated speeds.

We assume that for any fixed $x \geq 0$, the concentrations $c_1(.,x)$ and $c_2(.,x)$—and thereby also the functions $z(.,x)$ and $w(.,x)$—have bounded variation locally on $(-\infty,\infty)$. This ensures that limits of the solution from the left and the right (i.e., $c_1(t\pm,x)$, $c_2(t\pm,x)$, $z(t\pm,x)$, and $w(t\pm,x)$) always exist. If we wish, we can normalize the solution by requiring that the solution always equals its left (or right) limit. This will define the value of the solution on the set of all shocks and, therefore, will require an alteration of the solution on no more than a set of measure zero since BV solutions can have no more than a countable number of shock curves.

We will require that the solution satisfies the standard entropy condition, which can be written in terms of the characteristic speeds

$$\lambda(z(t-,x),w(t-,x)) \geq \lambda(z(t+,x),w(t+,x)),$$

$$\mu(z(t-,x),w(t-,x)) \geq \mu(z(t+,x),w(t+,x)) \tag{3.1}$$

or, equivalently, in terms of the Riemann invariants

$$z(t-,x) \leq z(t+,x), \qquad w(t-,x) \leq w(t+,x). \tag{3.2}$$

These conditions imply that for any convex entropy function, η, and its associated entropy flux, q, the relation

$$\frac{\partial \eta}{\partial x} + \frac{\partial q}{\partial t} \leq g(z,w)\left(\frac{\partial \eta}{\partial z} - \frac{\partial \eta}{\partial w}\right) \tag{3.3}$$

holds in the sense of measures.

The entropy condition in (3.1) has been previously applied to chromatography equations in [7]. It corresponds (see [2]) to the physical requirement

$$c_1(t-,x) \leq c_1(t+,x). \tag{3.4}$$

In other words, as a shock passes through any fixed location in the reactor, c_1, the concentration of the species that can induce higher concentrations in the solid phase (see (2.2)) will increase.

A *classical* 1-characteristic on the interval $[x_1, x_2]$ for the system being studied is an integral curve of the ODE

$$\frac{dt}{dx} = \lambda(z(t,x),w(t,x)). \tag{3.5}$$

Classical characteristics determine the solution in regions where the solution is smooth. To extend characteristics to regions with shocks, it is necessary to consider them as integral curves of (3.5) in the sense of Filippov [3] since the right-hand side of (3.5) can now be discontinuous. It follows that a *generalized* 1-characteristic is defined as a Lipschitz curve $\tau(x)$ such that

$$\tau'(x) \in [\lambda(z(\tau(x)+,x),w(\tau(x)+,x)),\lambda(z(\tau(x)-,x),w(\tau(x)-,x))] \quad \text{a.e.} \tag{3.6}$$

Similarly, a classical 2-characteristic satisfies

$$\frac{dt}{dx} = \mu(z(t,x),w(t,x)), \tag{3.7}$$

and a generalized 2-characteristic is a Lipschitz curve $v(x)$, where

$$v'(x) \in [\mu(z(v(x)+,x),w(v(x)+,x)),\mu(z(v(x)-,x),w(v(x)-,x))] \quad \text{a.e.} \tag{3.8}$$

We state some elementary properties of characteristics which can be determined by extending the proofs in [1]. Every generalized i-characteristic ($i = 1, 2$) propagates with either classical characteristic speed or with the shock speed associated with the i family. From any point (T, X) in the upper half-plane, there emanates in the backward (i.e., decreasing-x) direction a 1-characteristic funnel and a 2-characteristic funnel, which only intersect at (T, X). Each funnel is bounded by minimal and maximal i-characteristics (which may or may not be distinct). These minimal and maximal characteristics always propagate with classical characteristic speed; specifically, we have the following.

LEMMA 3.1. *Consider* $(T, X) \in (-\infty, \infty) \times (0, \infty)$. *If* τ *is the minimal or maximal backward* 1*-characteristic emanating from* (T, X), *then for almost every* $x \in [0, X]$,

$$z(\tau(x)-, x)) = z(\tau(x)+, x)), \qquad w(\tau(x)-, x)) = w(\tau(x)+, x)), \tag{3.9}$$

$$\tau'(x) = \lambda(z(\tau(x)\pm, x), w(\tau(x)\pm, x)). \tag{3.10}$$

If v *is the minimal or maximal backward* 2*-characteristic emanating from* (T, X), *then for almost every* $x \in [0, X]$,

$$z(v(x)-, x)) = z(v(x)+, x)), \qquad w(v(x)-, x)) = w(v(x)+, x)), \tag{3.11}$$

$$v'(x) = \mu(z(v(x)\pm, x), w(v(x)\pm, x)). \tag{3.12}$$

Now we consider the behavior of the Riemann invariants on these minimal and maximal characteristics. Over a classical 1-characteristic, we have that $\frac{dz}{dx} = g(z, w)$, and over a classical 2-characteristic, we have that $\frac{dw}{dx} = -g(z, w)$. We begin to derive similar results for the extremal characteristics by using entropy.

LEMMA 3.2. *Let* τ *and* v *be the minimal and maximal backward* 1*-characteristics emanating from any point* (T, X) *of the upper half-plane. Then for all* $0 \le \xi \le \chi \le X$,

$$z(\tau(\chi)-, \chi) - z(\tau(\xi)-, \xi) \le \int_{\xi}^{\chi} g(z(\tau(x)-, x), w(\tau(x)-, x))dx, \tag{3.13}$$

$$z(v(\chi)+, \chi) - z(v(\xi)+, \xi) \ge \int_{\xi}^{\chi} g(z(v(x)+, x), w(v(x)+, x))dx. \tag{3.14}$$

Similarly, if τ *and* v *are the minimal and maximal backward* 2*-characteristics emanating from the point* (T, X), *then for all* $0 \le \xi \le \chi \le X$,

$$w(\tau(\chi)-, \chi) - w(\tau(\xi)-, \xi) \le \int_{\xi}^{\chi} -g(z(\tau(x)-, x), w(\tau(x)-, x))dx, \tag{3.15}$$

$$w(v(\chi)+, \chi) - w(v(\xi)+, \xi) \ge \int_{\xi}^{\chi} -g(z(v(x)+, x), w(v(x)+, x))dx. \tag{3.16}$$

Proof. We will only show the proof of (3.13), since the proofs of the other three relations are similar.

First, we define τ_ε, an integral curve in the sense of Filippov of the differential equation

$$\frac{dt}{dx} = \lambda(z(t, x), w(t, x)) + \varepsilon \tag{3.17}$$

which emanates from the point $(T-\varepsilon, X)$, where ε is a small, positive, fixed number. It follows that

$$\tau_\varepsilon'(x) \geq \lambda(z(\tau_\varepsilon(x)+, x), w(\tau_\varepsilon(x)+, x)) + \varepsilon \tag{3.18}$$

for almost every $x \in [0, X]$ and that $\tau_\varepsilon(x) < \tau(x)$ for all $x \in [0, X]$. Further, $\tau_\varepsilon(x)$ converges uniformly on $[0, X]$ to $\tau(x)$ as $\varepsilon \to 0$.

We now integrate the entropy inequality in (3.3) over the domain $\{(t,x) : \xi \leq x \leq \chi, \tau_\varepsilon(x) \leq t \leq \tau(x)\}$ and apply the Gauss–Green theorem to obtain

$$\begin{aligned} &\int_{\tau_\varepsilon(\chi)}^{\tau(\chi)} \eta(z(t,\chi), w(t,\chi))dt - \int_{\tau_\varepsilon(\xi)}^{\tau(\xi)} \eta(z(t,\xi), w(t,\xi))dt \\ &+ \int_\xi^\chi q(z(\tau(x)-, x), w(\tau(x)-, x)) - \tau'(x)\eta(z(\tau(x)-, x), w(\tau(x)-, x))dx \\ &- \int_\xi^\chi q(z(\tau_\varepsilon(x)+, x), w(\tau_\varepsilon(x)+, x)) - \tau_\varepsilon'(x)\eta(z(\tau_\varepsilon(x)+, x), w(\tau_\varepsilon(x)+, x))dx \\ &\leq \int_\xi^\chi \int_{\tau_\varepsilon(x)}^{\tau(x)} g(z,w)\left(\frac{\partial \eta}{\partial z} - \frac{\partial \eta}{\partial w}\right) dtdx. \end{aligned} \tag{3.19}$$

By using the expressions for η and q given in (2.15) with l very large and negative, we can use (2.16), (3.10), and (3.18) to show that the last two integrals on the left-hand side of (3.19) are nonnegative and nonpositive respectively. Therefore, both integrals can be removed from (3.19) and the inequality is preserved:

$$\begin{aligned} &\int_{\tau_\varepsilon(\chi)}^{\tau(\chi)} \eta(z(t,\chi), w(t,\chi))dt - \int_{\tau_\varepsilon(\xi)}^{\tau(\xi)} \eta(z(t,\xi), w(t,\xi))dt \\ &\leq \int_\xi^\chi \int_{\tau_\varepsilon(x)}^{\tau(x)} -\frac{lg(z(t,x), w(t,x))}{z^2} \exp\left(\frac{l}{z}\right)\left(1 - \frac{w}{z} + O\left(\frac{1}{l}\right)\right) dtdx. \end{aligned} \tag{3.20}$$

If we define $\bar{z}(x) \equiv \operatorname{ess\,inf}_{[\tau_\varepsilon(x), \tau(x)]} z(.,x)$, $\bar{g}(x) \equiv \operatorname{ess\,sup}_{[\tau_\varepsilon(x), \tau(x)]} g(z(.,x), w(.,x))$, and $\Phi(x) \equiv \int_{\tau_\varepsilon(x)}^{\tau(x)} \eta dt$, we can express (3.20) in terms of Φ:

$$\Phi(\chi) - \Phi(\xi) \leq \int_\xi^\chi \frac{-l\bar{g}(x)}{\bar{z}^2(x)}(1 + O(1/l))\Phi(x)dx. \tag{3.21}$$

Since the integrand in (3.21) is finite, it immediately follows that $\Phi(x)$ is upper Lipschitz continuous. Any upper-Lipschitz-continuous function $f(x)$ is differentiable almost everywhere and $\int_a^b \frac{df(x)}{dx}dx \geq f(b) - f(a)$. Therefore, when we divide (3.21) by $\chi - \xi$ and let $\xi \to \chi$, we get an expression for the derivative of Φ almost everywhere. Further, after rearranging the resulting expression and applying the chain rule, we can integrate between new ξ and χ points and—since $\ln(\Phi(x))$ is upper Lipschitz continuous—we preserve the inequality

$$\ln\left(\frac{\Phi(\chi)}{\Phi(\xi)}\right) \leq \int_\xi^\chi \frac{d\ln(\Phi(x))}{dx}dx \leq \int_\xi^\chi \frac{-l\bar{g}(x)}{\bar{z}^2(x)}(1 + O(1/l))dx. \tag{3.22}$$

Now we multiply (3.22) by $-1/l$ and let $l \to -\infty$, which causes the Φ terms to converge to the L^∞ norm of the exponentials in their entropy expressions given in (2.15), which leads to

$$-\frac{1}{\tilde{z}(\chi)} + \frac{1}{\tilde{z}(\xi)} \leq \int_\xi^\chi \frac{\bar{g}(x)}{\tilde{z}^2(x)} dx, \tag{3.23}$$

where $\tilde{z}(x) \equiv \operatorname{ess\,sup}_{[\tau_\varepsilon(x),\tau(x)]} z(.,x)$. Letting $\varepsilon \to 0$ forces the z terms on both sides of the inequality to converge to the limit of z from the left of the $\tau(x)$ curve:

$$-\frac{1}{\hat{z}(\chi)} + \frac{1}{\hat{z}(\xi)} \leq \int_\xi^\chi \frac{\hat{g}(x)}{\hat{z}^2(x)} dx, \tag{3.24}$$

where $\hat{z}(x) \equiv z(\tau(x)-,x)$ and $\hat{g}(x) \equiv g(z(\tau(x)-,x), w(\tau(x)-,x))$. From the upper-Lipschitz-function argument used to establish (3.22), we can "differentiate" (3.24), cancel terms, and then integrate while still preserving the inequality. This yields

$$\hat{z}(\chi) - \hat{z}(\xi) \leq \int_\xi^\chi \hat{g}(x) dx, \tag{3.25}$$

which is identical to (3.13).

An almost identical method is used to show (3.14), but instead of using a characteristic τ_ε, which is displaced slightly to the left of τ, one uses a characteristic v_ε, which is displaced slightly to the right of v. Also, we let l (as opposed to $-l$) be large. In the proofs of (3.15) and (3.16), we follow the proofs of (3.13) and (3.14) but use the form of the entropy which is similar to (2.15) with the roles of z and w switched.

The next lemma establishes bounds on the widening of extremal backward characteristics of a family. These bounds depend on the total variation of the Riemann invariant associated with the other family along this extremal curve. We will assume in any x interval of finite length that this variation is bounded uniformly over the extremal characteristics; specifically, for any $x_1 < \infty$, we have that

$$K_z(x_1) \equiv \sup_v \left[TV_{x\in[0,x_1]} z(v(x)-,x)\right] < \infty \tag{3.26a}$$

and

$$K_w(x_1) \equiv \sup_\tau \left[TV_{x\in[0,x_1]} w(\tau(x)-,x)\right] < \infty, \tag{3.26b}$$

where v is any extremal 2-characteristic and τ any extremal 1-characteristic that emanates from the line $x = x_1$.

LEMMA 3.3. *Let $-\infty < S \leq T < \infty$ and $X > 0$. If τ is the minimal backward 1-characteristic emanating from (S, X) and v is the maximal backward 1-characteristic emanating from (T, X), then there exist positive constants D, δ, β, α, and L such that for $x \in \{[0, X] : X - x \leq L\}$,*

$$\begin{aligned} v(x) - \tau(x) \leq{} & 2[T-S] \exp\left(\frac{D}{\delta}(\Theta(X) - \Theta(x))\right) \\ & + 2\beta[z(T+,X) - z(S-,X)] \int_x^X \exp\left(\frac{D}{\delta}(\Theta(y) - \Theta(x)) + \alpha(X-y)\right) dy, \end{aligned} \tag{3.27}$$

where $\Theta(\xi) \equiv TV_{x\in[0,\xi]}w(\tau(x)-,x)+\xi$. *Similarly, if* τ *is the minimal backward* 2*-characteristic emanating from* (S,X) *and* v *is the maximal backward* 2*-characteristic emanating from* (T,X)*, then there exist positive constants* D*,* δ*,* β*,* α*, and* L *such that for* $x \in \{[0,X] : X-x \le L\}$*,*

$$\begin{aligned} v(x)-\tau(x) &\le 2[T-S]\exp\left(\frac{D}{\delta}(\Theta(X)-\Theta(x))\right) \\ &\quad + 2\beta[w(T+,X)-w(S-,X)]\int_x^X \exp\left(\frac{D}{\delta}(\Theta(y)-\Theta(x))+\alpha(X-y)\right)dy, \end{aligned} \tag{3.28}$$

where $\Theta(\xi) \equiv TV_{x\in[0,\xi]}z(\tau(x)-,x)+\xi$.

Proof. We will only show (3.27) since the proof for (3.28) is essentially identical. The proof for (3.27) is somewhat involved, so we will employ the following simplifying notation:

$$z(x) \equiv z(\tau(x)-,x), \qquad w(x) \equiv w(\tau(x)-,x),$$

$$Z(x) \equiv z(v(x)+,x), \qquad W(x) \equiv w(v(x)+,x),$$

$$\zeta(x) \equiv z(x)-Z(x), \qquad \omega(x) \equiv w(x)-W(x),$$

$$\phi(x) \equiv v(x)-\tau(x).$$

Since we are looking for bounds on the characteristics' widening, we begin with the expressions for the characteristics' slopes given in (3.10) and (3.12):

$$\phi'(x) = \frac{1}{Z^2W}-\frac{1}{z^2w} = \frac{z+Z}{WZ^2z^2}\zeta(x)+\frac{1}{z^2Ww}\omega(x) \quad \text{a.e.,} \tag{3.29}$$

where z, Z, w, and W are all functions of x. From (2.7), it is clear that the fractions in front of ζ and ω are bounded away from both 0 and ∞, so we next concentrate on looking for bounds on the behavior of ζ and ω.

Lemma 3.2 gives an expression bounding ζ:

$$\begin{aligned} \zeta(y)-\zeta(x) &\le \int_x^y -\frac{aZW-b(Z+W)+c}{Z-W}+\frac{azw-b(z+w)+c}{z-w}d\xi \\ &= \int_x^y \frac{-aW^2+2bW-c}{(Z-W)(z-W)}\zeta(\xi)-\frac{-az^2+2bz-c}{(z-W)(z-w)}\omega(\xi)d\xi, \end{aligned} \tag{3.30}$$

where z, Z, w, and W are all functions of ξ. Since we are bounded away from the umbilic point where $w(t,x)=z(t,x)$, the denominators in the fractions of (3.30) are bounded away from zero. The numerators in the fractions of (3.30) are also bounded from zero since $b^2-ac<0$. Therefore, there are positive, finite constants a_1, a_2, and b_1 such that $a_1 > a_2$ and

$$\zeta(y)-\zeta(x) \le \int_x^y [-a(\xi)\zeta(\xi)+b_1|\omega(\xi)|]\,d\xi, \tag{3.31}$$

$$\text{where } a(\xi) \equiv \begin{cases} a_1 & \text{if } \zeta(\xi) < 0, \\ a_2 & \text{if } \zeta(\xi) \geq 0. \end{cases}$$

As in Lemma 3.2, the properties of upper-Lipschitz-continuous functions allow us to "differentiate" (3.31), multiply the result by an appropriate integrating factor, and preserve the inequality upon integration between x and X, leading to

$$\zeta(x) \geq \zeta(X) \exp\left(\int_x^X a(\xi)d\xi\right) - b_1 \int_x^X |\omega(\xi)| \exp\left(\int_x^\xi a(\chi)d\chi\right) d\xi, \quad x \in [0, X]. \tag{3.32}$$

From (3.32), we obtain our final form of the bound on $\zeta(x)$:

$$\zeta(x) \geq \zeta(X)e^{\alpha(X-x)} - b_1 e^{a_1(X-x)} \int_x^X |\omega(\xi)| d\xi, \tag{3.33}$$

$$\text{where } \alpha \equiv \begin{cases} a_1 & \text{if } \zeta(X) \leq 0, \\ a_2 & \text{if } \zeta(X) > 0. \end{cases}$$

Next, we derive the following bound on the integral of $\omega(x)$:

$$\int_x^X |\omega(y)| dy \leq \delta\phi(x) + D \int_x^X \phi(y) d\Theta(y). \tag{3.34}$$

We require a somewhat intricate construction to establish (3.34). First, we define the function $P(y)$ in the case where $\omega(y) \leq 0$ to be the x coordinate of the point of intersection of τ with the *minimal* backward 2-characteristic emanating from $(v(y), y)$. In the case where $\omega(y) > 0$, $P(y)$ is defined to be the x coordinate of the point of intersection of τ with the *maximal* backward 2-characteristic emanating from $(v(y), y)$. Next, we define $p(y) \equiv \inf_{\xi \in [y,X]} P(\xi)$ on the domain $y \in (\bar{y}, X]$, where $\bar{y} \equiv \inf\{y \in [0, X] : P(y) \text{ is defined}\}$. The domain of definition of p is extended to the point $\bar{y}$ by using $p(\bar{y}) \equiv \inf_{[\bar{y},X]} P(\xi)$ when $P(\bar{y})$ is defined or $p(\bar{y}) \equiv \inf_{(\bar{y},X]} P(\xi)$ when $P(\bar{y})$ is not defined. p is a monotonically increasing function with the property that $p(y) \leq y$ since the characteristic speeds are positive. We also define an "inverse" for p: $h(\xi) \equiv \sup\{y : p(y-) \leq \xi \leq p(y)\}$.

Now we fix $x \in [0, X]$ and define $\hat{y}$ by $\hat{y} \equiv \bar{y}$ if $x \in [0, p(\bar{y})]$, $\hat{y} \equiv h(x)$ if $x \in (p(\bar{y}), p(X)]$, and $\hat{y} \equiv X$ if $x \in (p(X), X]$.

Since the characteristic speeds are well separated, there is a constant C such that $0 \leq \hat{y} - x \leq C\phi(x)$. Combining this with the requirement that w stays in a small neighborhood of some fixed state yields

$$\int_x^{\hat{y}} |\omega(y)| dy \leq \delta\phi(x), \quad \text{where } \delta \ll 1. \tag{3.35}$$

This estimate also holds, with $\hat{y} = X$, when $\bar{y}$ is undefined.

Now we consider the integral of $|\omega(y)|$ over the remaining region: $y \in (\hat{y}, X]$. Using Lemma 3.2, we can establish that

$$|\omega(y)| \leq \Lambda(y) - \Lambda(P(y)) + ||g||_{L^\infty}(y - P(y)), \tag{3.36}$$

where $\Lambda(y) \equiv TV_{\xi \in [0,y]} w(\tau(\xi)-, \xi)$. $||g||_{L^\infty}$ must exist since the ranges of z and w are restricted by (2.7). From the definition of $p(y)$, it is obvious that $p(y) \leq P(y)$. Using this and the fact that the separation of speeds implies that $y - P(y) \leq C\phi(y)$ allows the integral of (3.36) to be expressed as

$$\int_{\hat{y}}^{X} |\omega(y)|dy \leq \int_{\hat{y}}^{X} \Lambda(y) - \Lambda(p(y))dy + C\|g\|_{L^\infty} \int_{\hat{y}}^{X} \phi(y)dy. \tag{3.37}$$

We wish to reexpress the integral of the total variations in (3.37). This is accomplished by constructing a sequence $\{\Lambda_n\}$ of nondecreasing, absolutely continuous functions which converge pointwise to $\Lambda(y)$ on $[0, X]$ so that we have

$$\int_{\hat{y}}^{X} [\Lambda_n(y) - \Lambda_n(p(y))]dy = \int_{\hat{y}}^{X} \int_{p(y)}^{y} \Lambda_n'(\xi)d\xi dy \tag{3.38}$$

$$= \int_{p(\hat{y})}^{\hat{y}} [h(\xi) - \hat{y}]\Lambda_n'(\xi)d\xi + \int_{\hat{y}}^{p(X)} [h(\xi) - \xi]\Lambda_n'(\xi)d\xi + \int_{p(X)}^{X} [X - \xi]\Lambda_n'(\xi)d\xi.$$

From the separation of the characteristic speeds and the definition of h, we infer that

$$h(\xi) - \hat{y} \leq C\phi(\xi), \qquad \xi \in [p(\hat{y}), \hat{y}],$$

$$h(\xi) - \xi \leq C\phi(\xi), \qquad \xi \in (\hat{y}, p(X)],$$

$$X - \xi \leq C\phi(\xi), \qquad \xi \in (p(X), X].$$

Moreover, by the construction of $\hat{y}$, it follows that $p(\hat{y}) \geq x$. Therefore, (3.38) yields

$$\int_{\hat{y}}^{X} [\Lambda_n(y) - \Lambda_n(p(y))]dy \leq C \int_{x}^{X} \phi(\xi)d\Lambda_n(\xi). \tag{3.39}$$

Passing to the limit as $n \to \infty$ causes (3.39) to converge to

$$\int_{\hat{y}}^{X} [\Lambda(y) - \Lambda(p(y))]dy \leq C \int_{x}^{X} \phi(\xi)d\Lambda(\xi). \tag{3.40}$$

Substitution of (3.40) into (3.37) yields

$$\int_{\hat{y}}^{X} |\omega(y)|dy \leq D \int_{x}^{X} \phi(y)d\Theta(y), \tag{3.41}$$

where D is a constant and $d\Theta(y) \equiv d\Lambda(y) + dy$. This combined with (3.35) establishes (3.34).

With the bounds on ζ and ω established in (3.33) and (3.34), we return to the bound on ϕ in (3.29). Substitution of (3.33) into (3.29) yields

$$\phi'(y) \geq -A|\omega(y)| + \beta\zeta(X)e^{\alpha(X-y)} - Be^{a_1(X-y)} \int_{y}^{X} |\omega(\xi)|d\xi \quad \text{a.e.}, \tag{3.42}$$

where A, B, and β are all positive constants. Now we integrate (3.42) between x and X. The double integral in the resulting relation can be reexpressed by the following change in the order of integration:

$$\int_{x}^{X} \int_{y}^{X} |\omega(\xi)|e^{a_1(X-y)}d\xi dy = \int_{x}^{X} |\omega(\xi)| \int_{x}^{\xi} e^{a_1(X-y)}dyd\xi$$

$$\leq (1/a_1)(e^{a_1(X-x)}-1)\int_x^X |\omega(\xi)|d\xi \tag{3.43}$$

so that (3.42) yields

$$\phi(x) \leq \phi(X) - (\beta/\alpha)\zeta(X)(e^{\alpha(X-x)}-1) + [A + (B/a_1)(e^{a_1(X-x)}-1)]\int_x^X |\omega(\xi)|d\xi. \tag{3.44}$$

Next, we substitute (3.34) into (3.44). Further, we restrict $X-x \leq L$, where L is some positive constant such that the bracketed term in (3.44) is less than $1/(2\delta)$ whenever $X-x \leq L$. This process yields

$$\phi(x) \leq 2\phi(X) - 2(\beta/\alpha)\zeta(X)(e^{\alpha(X-x)}-1) + \frac{D}{\delta}\int_x^X \phi(y)d\Theta(y). \tag{3.45}$$

Application of a generalized form of Gronwall's inequality [2], [4] to (3.45) leads to

$$\begin{aligned}\phi(x) &\leq 2\phi(X)\exp\left[\frac{D}{\delta}(\Theta(X)-\Theta(x))\right] \\ &\quad - \zeta(X)2\beta\int_x^X \exp\left[\frac{D}{\delta}(\Theta(y)-\Theta(x)) + \alpha(X-y)\right]dy,\end{aligned} \tag{3.46}$$

which is equivalent to (3.27), the claim of the lemma.

From Lemma 3.3, we can quickly deduce the following.

LEMMA 3.4. *If (T,X) is any point of the upper half-plane where $z(T-,X) = z(T+,X)$, then a unique backward 1-characteristic, τ, emanates from (T,X) and*

$$z(\tau(x)\pm,x) = z(T\pm,X) - \int_x^X g(z(\tau(y)\pm,y),w(\tau(y)\pm,y))dy, \quad x \in (0,X]. \tag{3.47}$$

Similarly, if $w(T-,X) = w(T+,X)$, then a unique backward 2-characteristic v emanates from (T,X) and

$$w(v(x)\pm,x) = w(T\pm,X) + \int_x^X g(z(v(y)\pm,y),w(v(y)\pm,y))dy, \quad x \in (0,X]. \tag{3.48}$$

Proof. Since $z(T+,X) = z(T-,X)$, (3.27) clearly implies that the minimal and maximal backward characteristics must be the same curve, $\tau(y)$, for all $y \in [0,X]$. From (3.9) of Lemma 3.1, we have that

$$\int_x^X g(z(\tau(y)-,y),w(\tau(y)-,y))dy = \int_x^X g(z(\tau(y)+,y),w(\tau(y)+,y))dy; \tag{3.49}$$

therefore, Lemma 3.2 implies that

$$z(\tau(x)+,x) \leq z(T\pm,X) - \int_x^X g(z(\tau(y)\pm,y),w(\tau(y)\pm,y))dy \leq z(\tau(x)-,x). \tag{3.50}$$

However, the entropy condition in (3.2) states that $z(\tau(x)+,x) \geq z(\tau(x)-,x)$, so (3.50) must hold as an equality, which establishes (3.47).

The proof for (3.48) is completely analogous.

Lemma 3.3 also gives us the following one-sided Lipschitz conditions.

LEMMA 3.5. *There are functions $H(X) > 0$ and $\hat{H}(X) > 0$ which are unbounded only as $X \to 0$ such that*

$$\frac{z(T,X) - z(S,X)}{T - S} \geq -H(X), \quad -\infty < S < T < \infty, \quad X > 0, \tag{3.51}$$

$$\frac{w(T,X) - w(S,X)}{T - S} \geq -\hat{H}(X), \quad -\infty < S < T < \infty, \quad X > 0. \tag{3.52}$$

Proof. It suffices to establish (3.51) under the assumptions $z(T-,X) = z(T+,X)$, $z(S-,X) = z(S+,X)$, and $z(S,X) > z(T,X)$. Since the left-hand side of (3.27) is nonnegative, we immediately have for any $x \in [0,X]$, where $x \geq X - L$, that

$$\frac{z(T,X) - z(S,X)}{T - S} \geq \frac{-\exp\left(-\frac{D}{\delta}(\Theta(x) - \Theta(X))\right)}{\beta \int_x^X \exp\left(-\frac{D}{\delta}(\Theta(x) - \Theta(y)) + \alpha(X - y)\right) dy}$$

$$= -\left[\beta \int_x^X \exp\left(-\frac{D}{\delta}(\Theta(X) - \Theta(y)) + \alpha(X - y)\right) dy\right]^{-1}. \tag{3.53}$$

By choosing x judiciously and exploiting the uniform bounds on the total variation of w given in (3.26), we define $H(X)$:

$$H(X) \equiv \begin{cases} \left[\beta \int_{X-L}^X \exp\left(-\frac{D}{\delta}K_w(X) + \left(\alpha - \frac{D}{\delta}\right)(X - y)\right) dy\right]^{-1} & \text{if } X > L \\ \left[\beta \int_0^X \exp\left(-\frac{D}{\delta}K_w(X) + \left(\alpha - \frac{D}{\delta}\right)(X - y)\right) dy\right]^{-1} & \text{if } X \leq L. \end{cases} \tag{3.54}$$

The proof for (3.52) is completely analogous.

The conclusions of Lemmas 3.1–3.5 are collected in the following theorem, which states that forward characteristics are unique and summarizes the properties of minimal and maximal backward characteristics. In particular, we see the classical 1-characteristic behavior ($\frac{dz}{dx} = g(z,w)$) on extremal 1-characteristics (except possibly at the characteristics' endpoints) and the classical 2-characteristic behavior ($\frac{dw}{dx} = -g(z,w)$) on the extremal 2-characteristics (except possibly at the endpoints).

THEOREM 3.1. *Let (T,X) be any point of the upper half-plane, with $X > 0$. A unique forward* 1*-characteristic emanates from the point. Further, if we define τ and v to be the minimal and maximal backward* 1*-characteristics emanating from (T,X), then for $x \in (0,X)$,*

$$z(\tau(0)+,0) + \int_0^x g(z(\tau(y)\pm,y),w(\tau(y)\pm,y))dy \leq z(\tau(x)+,x)$$

$$= z(T-,X) - \int_x^X g(z(\tau(y)\pm,y),w(\tau(y)\pm,y))dy$$

$$= z(\tau(x)-,x) \leq z(\tau(0)-,0) + \int_0^x g(z(\tau(y)\pm,y),w(\tau(y)\pm,y))dy, \tag{3.55}$$

$$z(v(0)+,0)+\int_0^x g(z(v(y)\pm,y),w(v(y)\pm,y))dy \le z(v(x)+,x)$$

$$= z(T+,X)-\int_x^X g(z(v(y)\pm,y),w(v(y)\pm,y))dy$$

$$= z(v(x)-,x) \le z(v(0)-,0)+\int_0^x g(z(v(y)\pm,y),w(v(y)\pm,y))dy. \tag{3.56}$$

When $z(T-,X)=z(T+,X)$, τ and v coincide.

Similarly, a unique forward 2*-characteristic emanates from (T,X), and if we now define τ and v to be the minimal and maximal backward* 2*-characteristics emanating from (T,X), then for $x\in(0,X)$,*

$$w(\tau(0)+,0)-\int_0^x g(z(\tau(y)\pm,y),w(\tau(y)\pm,y))dy \le w(\tau(x)+,x)$$

$$= w(T-,X)+\int_x^X g(z(\tau(y)\pm,y),w(\tau(y)\pm,y))dy$$

$$= w(\tau(x)-,x) \le w(\tau(0)-,0)-\int_0^x g(z(\tau(y)\pm,y),w(\tau(y)\pm,y))dy \tag{3.57}$$

$$w(v(0)+,0)-\int_0^x g(z(v(y)\pm,y),w(v(y)\pm,y))dy \le w(v(x)+,x)$$

$$= w(T+,X)+\int_x^X g(z(v(y)\pm,y),w(v(y)\pm,y))dy$$

$$= w(v(x)-,x) \le w(v(0)-,0)-\int_0^x g(z(v(y)\pm,y),w(v(y)\pm,y))dy. \tag{3.58}$$

When $w(T-,X)=w(T+,X)$, τ and v coincide.

Proof. From (3.51) and (3.52) in Lemma 3.5 and the expressions for λ and μ in (2.5), we determine that

$$\frac{\lambda(z(t,x),w(t,x))-\lambda(z(s,x),w(s,x))}{t-s} \le AH(x)+B\hat{H}(x), \tag{3.59}$$

$$\frac{\mu(z(t,x),w(t,x))-\mu(z(s,x),w(s,x))}{t-s} \le AH(x)+B\hat{H}(x). \tag{3.60}$$

Since H and $\hat{H}$ are bounded everywhere except at $x=0$, it follows from Filippov's theory [3] that the initial-value problems in (3.5) and (3.7) with datum (T,X) have *unique* solutions in the forward spatial direction if $X>0$. In other words, unique forward 1- and 2-characteristics emanate from (T,X).

We now establish (3.55). From Lemma 3.1, we have that $z(\tau(x)+,x) = z(\tau(x)-,x)$ for almost every x. Combining this fact with (3.47) of Lemma 3.4 implies that $z(\tau(x)+,x) = z(\tau(x)-,x)$ is true for all $x \in (0,X)$. Combining this new result with Lemma 3.4, we see that τ is both the minimal and maximal characteristic emanating from $(\tau(x),x)$ for any $x \in (0,X)$. The last inequality in (3.55) now follows directly from (3.13) of Lemma 3.2, and the first inequality in (3.55) follows directly from (3.14) of Lemma 3.2.

All that remains to be proven in (3.55) is that

$$z(\tau(x)-,x) = z(T-,X) - \int_x^X g(z(\tau(y)\pm,y),w(\tau(y)\pm,y))dy. \tag{3.61}$$

This is established by considering an increasing sequence $\{t_n\}$ such that t_n converges to T and $z(t_n-,X) = z(t_n+,X)$ for all n. We let τ_n denote the unique backward 1-characteristic emanating from (t_n,X). From Lemma 3.4, we know that

$$z(\tau_n(x)\pm,x) = z(t_n,X) - \int_x^X g(z(\tau_n(y)\pm,y),w(\tau_n(y)\pm,y))dy, \quad x \in (0,X]. \tag{3.62}$$

As $n \to \infty$, $z(t_n,X) \to z(T-,X)$ and $\tau_n(x) \to \tau(x)$ uniformly on $(0,X]$. The uniform convergence of τ_n establishes the convergence of the integral:

$$\lim_{n\to\infty} \int_x^X g(z(\tau_n(y)\pm,y),w(\tau_n(y)\pm,y))dy = \int_x^X g(z(\tau(y)-,y),w(\tau(y)-,y))dy. \tag{3.63}$$

The uniform convergence also allows us to state that

$$\lim_{n\to\infty} z(\tau_n(y)\pm,y) = z(\tau(y)-,y). \tag{3.64}$$

Therefore, taking the limit as $n \to \infty$ of (3.62) yields (3.61).

The proofs of (3.56), (3.57), and (3.58) are quite similar and therefore are omitted.

The knowledge we have collected concerning the nature of characteristics is applied to the following three theorems, which describe the structure of solutions to our system. The reader can find the explicit proofs of these theorems in [6]; however, they are omitted here due to their similarity to the proofs used in [2] by Dafermos and Geng for the homogeneous form of (1.1).

THEOREM 3.2. *Let (T,X) be any point on the upper half-plane with $X > 0$. Consider the (unique) forward 1-characteristic σ and the (not necessarily distinct) minimal and maximal backward 1-characteristics, τ_- and τ_+, emanating from (T,X). Define the sets*

$$S_- \equiv \{(t,x) : 0 \le x < X,\ t \le \tau_-(x) \text{ or } x \ge X,\ t \le \sigma(x)\}$$

and

$$S_+ \equiv \{(t,x) : 0 \le x < X,\ t \ge \tau_+(x) \text{ or } x \ge X,\ t \ge \sigma(x)\}.$$

Then the restriction of $z(t-,x)$ to S_- and the restriction of $z(t+,x)$ to S_+ are continuous at (T,X). In particular, z is continuous at (X,T) if and only if $z(T-,X) = z(T+,X)$.

Similarly, if σ is the forward 2-characteristic and τ_- and τ_+ are the minimal and maximal backward 2-characteristics emanating from (T,X), then the restriction of $w(t-,x)$ to the set

$$\Sigma_- \equiv \{(t,x) : 0 \le x < X,\ t \le \tau_-(x) \text{ or } x \ge X,\ t \le \sigma(x)\}$$

and the restriction of $w(t+,x)$ to the set

$$\Sigma_+ \equiv \{(t,x) : 0 \le x < X,\ t \ge \tau_+(x) \text{ or } x \ge X,\ t \ge \sigma(x)\}$$

are continuous at (T,X). In particular, w is continuous at (X,T) if and only if $w(T-,X) = w(T+,X)$.

The next proposition states that once a discontinuity develops, it has to propagate all the way to infinity as a shock.

THEOREM 3.3. *If σ is the (unique) forward 1-characteristic emanating from a point (T,X) of the upper half-plane with $z(T-,X) < z(T+,X)$, then $z(\sigma(x)-,x) < z(\sigma(x)+,x)$ for $0 \le X < x < \infty$.*

Similarly, if σ is the forward 2-characteristic emanating from (T,X), where $w(T-, X) < w(T+,X)$, then $w(\sigma(x)-,x) < w(\sigma(x)+,x)$ for $X < x < \infty$.

A point (T,X) of the upper half-plane will be called a *1-shock generation point* if a forward 1-characteristic σ emanating from (T,X) satisfies $z(\sigma(x)-,x) < z(\sigma(x)+,x)$ for $x \in (X,\infty)$ and none of the backward 1-characteristics emanating from (T,X) contains any point of discontinuity of z. The definition of a 2-shock generation point is completely analogous. By virtue of Theorem 3.3, it is easily seen that if (T,X) is a point of discontinuity of z (or w), then at least one backward 1-characteristic (or 2-characteristic) emanating from (T,X) must pass through a 1-shock (or a 2-shock) generation point.

When (T,X) is a 1-shock generation point, either $z(T-,X) = z(T+,X)$ or $z(T-,X) < z(T+,X)$. In the latter case (T,X) is the *focus* of a *1-compression wave.* Similarly, 2-shock generation points (T,X) may be either points of continuity of w, $w(T-,X) = w(T+,X)$, or foci of 2-compression waves when $w(T-,X) < w(T+,X)$.

The following proposition describes the structure of shocks.

THEOREM 3.4. *Let σ be a 1-shock generated at the point $(\sigma(X),X)$. Consider the four functions $z_\pm(x) \equiv z(\sigma(x)\pm,x)$, $w_\pm(x) \equiv w(\sigma(x)\pm,x)$, defined on $[X,\infty)$. Then the following hold:*

(i) *$z_\pm$ are right-continuous functions with bounded variation locally. For $x > X$,*

$$z_-(x) < z_+(x), \qquad z_-(x-) \ge z_-(x+), \qquad z_+(x-) \le z_+(x+). \tag{3.65}$$

When $z_-(x-) = z_-(x+)$, $(\sigma(x),x)$ is a point of continuity of the restriction of z to the set $\{(t,\xi) : \xi > X, t < \sigma(\xi)\}$; otherwise, $(\sigma(x),x)$ is a point of interaction of σ with another 1-shock or it is the focus of a 1-compression wave impinging from the left. When $z_+(x-) = z_+(x+)$, $(\sigma(x),x)$ is a point of continuity of the restriction of z to the set $\{(t,\xi) : \xi > X,\ t > \sigma(\xi)\}$; otherwise, $(\sigma(x),x)$ is a point of interaction of σ with another 1-shock or it is the focus of a 1-compression wave impinging from the right.

(ii) *$w_\pm$ are functions of bounded variation locally*; *w_- is right-continuous while w_+ is left-continuous. For $x > X$,*

$$w_-(x-) \ge w_-(x+), \quad w_+(x-) \ge w_+(x+),$$

$$w_-(x-) = w_+(x-), \quad w_-(x+) = w_+(x+). \tag{3.66}$$

x is point of discontinuity of $w_\pm$ if $(\sigma(x),x)$ is a point of interaction of σ with a 2-shock.

(iii) *σ is right-differentiable at every $x \ge X$ and*

$$\frac{d^+}{dx}\sigma(x) = \frac{1}{z_-(x)z_+(x)w_-(x)}, \quad X \le x < \infty. \tag{3.67}$$

(iv) *If x is a point of continuity of $z_\pm$ and $w_\pm$, then σ is differentiable at x.*

A similar statement holds for 2-shocks with the roles of z and w appropriately interchanged.

Proof. We present a proof of the claim that $z_\pm$ and $w_\pm$ are functions of bounded variation locally since the proofs given in [2] cannot be extended to the inhomogeneous case considered here.

To show that z_- has bounded variation, we first prove that for any $Y \in [0,\infty)$,

$$TV_{t\in(-\infty,\infty)}w(t,Y) + TV_{t\in(-\infty,\infty)}z(t,Y)$$

$$\le [TV_{t\in(-\infty,\infty)}w(t,0) + TV_{t\in(-\infty,\infty)}z(t,0)]e^{2KY}, \tag{3.68}$$

$$\text{where } K \equiv \max\left[\left\|\frac{\partial g}{\partial w}\right\|_{L^\infty}, \left\|\frac{\partial g}{\partial z}\right\|_{L^\infty}\right].$$

We know that K is finite from the expressions for the partial derivatives for g given in (2.11) combined with the restricted variation of z and w in (2.7) and the fact that we are bounded away from the umbilic point where $w = z$. To show (3.68), we pick any mesh $\cdots s_{i-1} < S_{i-1} < s_i < S_i < s_{i+1} < S_{i+1}\cdots$ with the property that $\cdots z(s_i,Y) > z(S_i,Y) < z(s_{i+1},Y)\cdots$. By virtue of (3.9), it suffices to consider only meshes with $z(s_i-,Y) = z(s_i+,Y)$ and $z(S_i-,Y) = z(S_i+,Y)$. Now define τ_i to be the (unique) backward 1-characteristic emanating from (s_i,Y) and v_i to be the (unique) backward 1-characteristic emanating from (S_i,Y). From Theorem 3.1, we know that

$$z(s_i,Y) - z(S_i,Y) \le z(\tau_i(0)-,0) - z(v_i(0)+,0)$$

$$+\int_0^Y g(z(\tau_i(x),x),w(\tau_i(x),x)) - g(z(v_i(x),x),w(v_i(x),x))dx \tag{3.69}$$

and

$$z(s_i,Y) - z(S_{i-1},Y) \le z(\tau_i(0)-,0) - z(v_{i-1}(0)+,0)$$

$$+\int_0^Y g(z(\tau_i(x),x),w(\tau_i(x),x)) - g(z(v_{i-1}(x),x),w(v_{i-1}(x),x))dx. \tag{3.70}$$

Since forward characteristics are unique, we know that $\cdots\tau_i(0) \le v_i(0) \le \tau_{i+1}(0)\cdots$. Therefore, when we sum (3.69) and (3.70) for all i and apply the chain rule to the resulting equation's integrands, we obtain

$$TVz(Y) \le TVz(0) + \int_0^Y K(TVz(x) + TVw(x))dx, \tag{3.71}$$

where $TVz(x) \equiv TV_{t\in(-\infty,\infty)}z(t,x)$ and $TVw(x) \equiv TV_{t\in(-\infty,\infty)}w(t,x)$. We can repeat this entire process for w(.,Y) and add the result to (3.71), yielding

$$TVz(Y) + TVw(Y) \le TVz(0) + TVw(0) + \int_0^Y 2K[TVz(x) + TVw(x)]dx. \tag{3.72}$$

(3.68) follows from (3.72) by Gronwall's inequality.

Now we perform a similar process on σ. We pick any mesh $\cdots y_{i-1} < \xi_{i-1} < y_i < \sigma_i < y_{i+1} < \xi_{i+1} \cdots$ with the property that $z_-(y_i) > z_-(\xi_i) < z_-(y_{i+1})$. We redefine τ_i to be the minimum backward 1-characteristic emanating from $(\sigma(y_i), y_i)$ and v_i to be the minimum backward 1-characteristic emanating from $(\sigma(\xi_i), \xi_i)$. From Theorem 3.1, we know that

$$z_-(y_i) - z_-(\xi_i) \leq z(\tau_i(0)-, 0) - z(v_i(0)+, 0)$$

$$+ \int_0^{y_i} g(z(\tau_i(x), x), w(\tau_i(x), x)) - g(z(v_i(x), x), w(v_i(x), x))dx$$

$$+ \int_{y_i}^{\xi_i} g(z(\tau_i(x), x), w(\tau_i(x), x))dx \tag{3.73}$$

and

$$z_-(y_i) - z_-(\xi_{i-1}) \leq z(\tau_i(0)-, 0) - z(v_{i-1}(0)+, 0)$$

$$+ \int_0^{y_i} g(z(\tau_i(x), x), w(\tau_i(x), x)) - g(z(v_{i-1}(x), x), w(v_{i-1}(x), x))dx$$

$$+ \int_{y_i}^{\xi_i} g(z(\tau_i(x), x), w(\tau_i(x), x))dx. \tag{3.74}$$

As before, we have that $\cdots \tau_i(0) \leq v_i(0) \leq \tau_{i+1}(0) \cdots$, so when we sum (3.73) and (3.74) for all i and apply the chain rule, we obtain

$$TV_{x \in [0,Y]} z_-(x) \leq TVz(0) + \int_0^Y K(TVz(x) + TVw(x))dx + Y||g||_{L^\infty}. \tag{3.75}$$

Now we use (3.68), yielding

$$TV_{x \in [0,Y]} z_-(x) \leq TVz(0) + \frac{1}{2}(e^{2KY} - 1)[TVz(0) + TVw(0)] + Y||g||_{L^\infty}. \tag{3.76}$$

Therefore, the total variation of z_- is bounded locally.

The proofs showing that z_+, w_-, and w_+ have local bounded variation are similar and thus will be omitted.

The proofs of the remaining assertions follow [2] closely and are thus omitted. Again, the reader is directed to [6] for the exact form of these proofs.

4. Asymptotic behavior of the periodic case. With our knowledge of generalized characteristics and the structure of the solution from §3, we are now prepared to establish the asymptotic behavior of the chemical concentrations. We will begin by locating invariant regions of the (z, w) phase plane. Then we will show that these invariant regions shrink exponentially to a single point located on the equilibrium curve when the chemical components are cyclically fed into the chromatography reactor (i.e., periodic conditions at $x = 0$). Finally, we use an integrated form of the mass balance to show which point of the equilibrium curve is approached under these periodic conditions.

We start with the assumption that there exists some spatial location X where $\sup_{t\in(-\infty,\infty)} w(t,X) < b/a$. This assumption allows us to state that $w(t,X)$ is in the domain of the equilibrium curve function $z_e(w)$ given in (2.9). Once we establish the invariant regions, this assumption will also imply that $w(t,x)$ is also in the domain of $z_e(w)$ for all $x > X$.

To determine these invariant regions, we will need the following lemma, which states that as an extremal 1-characteristic passes through a spatial interval where w is constant, the value of z on the 1-characteristic exponentially approaches the equilibrium value associated with that constant state. An analogous result holds for the 2-characteristic.

LEMMA 4.1. *Define $z(x) \equiv z(\tau(x)-,x)$ and $w(x) \equiv w(\tau(x)-,x)$, where τ is the minimal backward 1-characteristic which emanates from a point (T,X) in the upper half plane. If $0 < y \leq Y \leq X$ and there is a constant $W < b/a$ such that $w(x) = W$ for all $x \in [y,Y]$, then there are positive constants $\alpha_1 < \alpha_2$ such that*

$$z(y) \geq z_e(W)$$

implies

$$z_e(W)+(z(y)-z_e(W))e^{-\alpha_2(Y-y)} \leq z(Y) \leq z_e(W)+(z(y)-z_e(W))e^{-\alpha_1(Y-y)} \tag{4.1a}$$

and

$$z(y) \leq z_e(W)$$

implies

$$z_e(W)+(z(y)-z_e(W))e^{-\alpha_1(Y-y)} \leq z(Y) \leq z_e(W)+(z(y)-z_e(W))e^{-\alpha_2(Y-y)}. \tag{4.1b}$$

The above equations also hold if we define $z(x) \equiv z(\tau(x)+,x)$ and $w(x) \equiv w(\tau(x)+,x)$ and if τ is the maximal backward 1-characteristic which emanates from (T,X).

Similarly, if we define $z(x) \equiv z(v(x)-,x)$ and $w(x) \equiv w(v(x)-,x)$, where v is the minimal backward 2-characteristic which emanates from (T,X), and if there is a constant, Z, such that $z(x) = Z$ for $0 < y < x < Y \leq X$, then

$$w(y) \geq w_e(Z)$$

implies

$$w_e(Z)+(w(y)-w_e(Z))e^{-\alpha_2(Y-y)} \leq w(Y) \leq w_e(Z)+(w(y)-w_e(Z))e^{-\alpha_1(Y-y)} \tag{4.1c}$$

and

$$w(y) \leq w_e(Z)$$

implies

$$w_e(Z)+(w(y)-w_e(Z))e^{-\alpha_1(Y-y)} \leq w(Y) \leq w_e(Z)+(w(y)-w_e(Z))e^{-\alpha_2(Y-y)}. \tag{4.1d}$$

As before, the above equations also hold if we define $z(x) \equiv z(v(x)+,x)$ and $w(x) \equiv w(v(x)+,x)$ and if v is the maximal backward 2-characteristic which emanates from (T,X).

Proof. We establish (4.1a). From Theorem 3.1, we know that

$$z(Y) = z(y) + \int_y^Y g(z(x), w(x))dx, \tag{4.2}$$

and therefore, after substituting the definitions of $g(z, w)$ and $z_e(w)$, we have

$$z(Y) = z(y) + \int_y^Y \frac{aW - b}{z(x) - W}[z(x) - z_e(W)]dx. \tag{4.3}$$

From the range of z and w given in (2.7) and the constraint that $W < b/a$, we know that there exist positive constants $C_1 < C_2$, where $-C_2 \le (aW - b)/(z(x) - W) \le -C_1$. If we differentiate (4.3), insert these bounding constants, and solve the resulting differential inequality, we obtain (4.1a) with C_1 and C_2 instead of α_1 and α_2.

We use this same method to obtain (4.1b)–(4.1d) (each with different C_1 and C_2 values in place of α_1 and α_2). Finally, we define α_1 as the minimum of the four C_1's and α_2 as the maximum of the four C_2's.

This same proof (with the same values for α_1 and α_2) holds for the maximal characteristic cases.

Now we can establish the invariant region.

THEOREM 4.1. *When there exists an X such that $\sup_{t\in(-\infty,\infty)} w(t, X) < b/a$, then we can define a closed rectangle I in the (z, w) phase plane which encloses the solution at $x = X$ and is bounded by the lines*

$$w = W_1 \equiv \max\left[\sup_t w(t, X), w_e\left(\sup_t z(t, X)\right)\right],$$

$$w = W_0 \equiv \min\left[\inf_t w(t, X), w_e\left(\inf_t z(t, X)\right)\right],$$

$$z = Z_1 \equiv z_e(W_1) = \max\left[\sup_t z(t, X), z_e\left(\sup_t w(t, X)\right)\right],$$

$$z = Z_0 \equiv z_e(W_0) = \min\left[\inf_t z(t, X), z_e\left(\inf_t w(t, X)\right)\right].$$

This rectangle is invariant. That is, $(z(t, x), w(t, x)) \in I$ for all $x \ge X$.

Proof. We will prove the invariance of the open rectangles $I_n \equiv \{(z, w) : z \in (Z_0 - 1/n, Z_1 + 1/n),\ w \in (w_e(Z_0 - 1/n), w_e(Z_1 + 1/n))\}$. The invariance of I_n implies the invariance of I since $I \subset I_n$ and $I = \bigcap_{n=1}^{\infty} I_n$.

If I_n is not invariant, then there is a point (T, Y), where $Y > X$, such that $(z(t, x), w(t, x)) \in I_n$ for $x \in [X, Y)$ but $(z(T, Y), w(T, Y)) \in \partial I_n$. Without loss of generality, we will assume the case $z(T, Y) = Z_0 - 1/n$. From Theorem 3.1 we know that

$$z(Y) = z(X) + \int_X^Y g(z(\xi), w(\xi))d\xi, \tag{4.4}$$

where τ is the minimal backward 1-characteristic emanating from (T, Y), $z(x) \equiv z(\tau(x)-, x)$, and $w(x) \equiv w(\tau(x)-, x)$. From (2.11a), we know that $\frac{\partial g}{\partial w} > 0$; therefore, decreasing $w(\xi)$ decreases the right-hand side of (4.4):

$$z(Y) \ge z(X) + \int_X^Y g\left(z(\xi), w_e\left(Z_0 - \frac{1}{n}\right)\right) d\xi. \tag{4.5}$$

The right-hand side of (4.5) is equal to the value that $Z(Y)$ would have to take if $\forall x \in [X,Y], w(x) = w_e(Z_0 - 1/n)$. Since $Z(X) \geq Z_0 - 1/n$, we can apply Lemma 4.1 to the right-hand side of 4.5 to obtain

$$z(Y) \geq Z_0 - \frac{1}{n} + \left[z(X) - \left(Z_0 - \frac{1}{n}\right)\right] e^{-\alpha_2(Y-X)}. \tag{4.6}$$

Since, from entropy, we must have that $z(T,Y) \geq z(T-,Y) \equiv z(Y)$, we conclude from (4.6) that $Z_0 - 1/n = z(X)$. But this contradicts the fact that $z(X) \geq Z_0$. Therefore, I_n and thereby I are invariant.

The fact that I is invariant is not particularly surprising given the nature of the vector fields $\frac{dz}{dx} = g(z,w)$ and $\frac{dw}{dx} = -g(z,w)$ shown in Fig. 2.

We now consider the case where the conditions at $x = 0$ are periodic in t with period L, which, of course, induces a solution which is periodic in t for any fixed x. We will show that over a fixed interval of space, the invariant region associated with this solution shrinks in proportion to its own size, which implies that the solution must exponentially approach a single point on the equilibrium curve.

We assume that at some location X, the solution is close enough to the equilibrium curve so that $\sup_{t\in(-\infty,\infty)} w(t,X) < b/a$, and therefore, from Theorem 4.1, we can define an invariant region bounded by the lines $w = W_0$, $w = W_1$, $z = Z_0 = z_e(W_0)$, and $z = Z_1 = z_e(W_1)$. We also consider some arbitrary number $x_0 > X$ and define the lines that bound the (smaller) invariant region at $x = x_0$: $w = w_0$, $w = w_1$, $z = z_0 = z_e(w_0)$, and $z = z_1 = z_e(w_1)$.

In the beginning of §3, we assumed that the characteristic speeds have small oscillations and are well separated. We reexpress this condition by defining s_1, s_2, s_3, and s_4 as explicit bounds on the speeds:

$$\lambda \in [s_1, s_2], \qquad \mu \in [s_3, s_4],$$

$$\text{where } 0 < s_1 \leq s_2 < s_3 \leq s_4 \quad \text{and} \quad \frac{(s_2 - s_1) + (s_4 - s_3)}{s_3 - s_2} \ll 1. \tag{4.7}$$

From this, we can define the spatial interval $H \equiv L/(s_3 - s_2)$, which will be of particular interest to us. H has the property that any backward 1-characteristic emanating from an arbitrary point $(t, x+H)$ must intersect each backward 2-characteristic emanating from the period of points between $(t, x+H)$ and $(t+L, x+H)$ as the 1-characteristic passes through the $[x, x+H]$ region.

We will show that as x progresses through the interval $[x_0, x_0 + 7H + \ln 2/\alpha_2]$, the invariant region must proportionally shrink. To simplify notation, we translate the x-coordinate system so as to set $x_0 = -4H$. (Therefore, the original invariant region is now located at $x = -(x_0 + 4H - X)$ and we wish to show proportional shrinkage as we pass through the interval $[-4H, 3H + \ln 2/\alpha_2]$.)

Our proof is basically by contradiction. If there is no proportional shrinking, then there is at least one backward 1-characteristic emanating from the line $x = 3H$ that stays near the equilibrium point (z_1, w_1) on the phase plane as the trajectory travels back to $x = -4H$, and there is a second backward 1-characteristic emanating from a later time on the $x = 3H$ line that stays near the equilibrium point (z_0, w_0) as it travels back to $x = -4H$. The value of w on a 2-characteristic will not be able to change too drastically as the 2-characteristic progresses between these 1-characteristics. Therefore, the 2-characteristics with the property that w is near

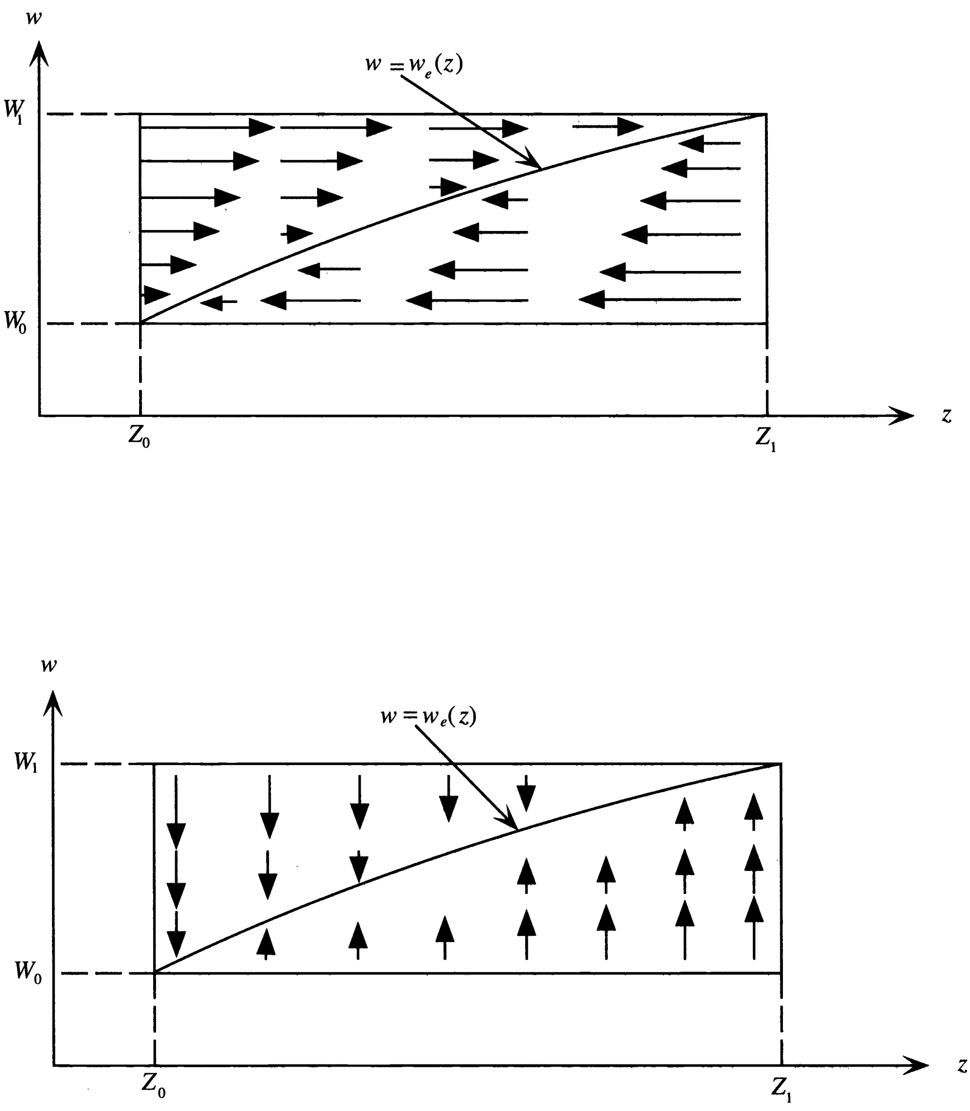

FIG. 2. *The vector fields for classical characterisic behavior. In* (2a)*, we have the vector field* $\frac{dz}{dx} = g(z, w)$*. In* (2b)*, we have the vector field* $\frac{dw}{dx} = -g(z, w)$*.*

w_0 as they cross the first 1-characteristic must significantly expand in measure before they reach the second 1-characteristic. By comparing the slopes over the region $x \in [-4H, 3H]$ of 2-characteristics where w is near w_0 to 2-characteristics where w is near w_1, we will see that this expansion cannot occur. We will conclude in Theorem 4.2 that the range of z values must proportionally shrink over the spatial interval $7H$. This shrinkage of z will induce a proportional shrinkage of the range of w values as we progress through an additional interval of length $\ln 2/\alpha_2$, as will be shown in Theorem 4.3.

We begin to formalize these ideas. First, we label the bounds on the range of values that z takes on the line $x = 3H$:

$$z_M \equiv \sup_t z(t,3H), \qquad z_m \equiv \inf_t z(t,3H). \tag{4.8}$$

We wish to show that there exists some constant $\varepsilon' > 0$ that depends *only* on the period L, the bounds on the characteristic speeds s_i, and the reference invariant region (i.e. Z_0, Z_1, W_0, and W_1) such that $(z_M - z_m)/(z_1 - z_0) < 1 - \varepsilon'$.

To select the appropriate backward 1-characteristics that we wish to analyze, we first choose any two points t_m and t_M which satisfy the conditions

$$\lim_{t\to t_M^+} z(t,3H) = z_M, \qquad \lim_{t\to t_m^-} z(t,3H) = z_m,$$

$$\text{and } t_m - t_M \in (L, 2L]. \tag{4.9}$$

Now we define τ_M as the maximal backward 1-characteristic emanating from $(t_M, 3H)$ and τ_m as the minimal backward 1-characteristic emanating from $(t_m, 3H)$. We also define v_m, the minimal backward 2-characteristic emanating from $(t_m, 3H)$, and v_M, the (unique) forward 2-characteristic emanating from $(\tau_M(0), 0)$. From this construction, we find that the location $\tilde{\xi}$, where $\tau_M(\tilde{\xi}) = v_m(\tilde{\xi})$ (i.e., the two characteristics cross), must have the property that $\tilde{\xi} \geq H$. We also find that the location $\hat{\xi}$, which corresponds to the x coordinate where the τ_m and v_M characteristics cross, must have the property that $3H - \hat{\xi} \geq H$. This implies that the measure of the space under which τ_M is influenced by the 2-characteristics located between v_M and v_m must be no smaller than H; similarly, the measure of the space under which τ_m is influenced by the 2-characteristics between v_M and v_m is also no smaller than H (see Fig. 3).

To investigate how requiring z_M to be close to z_1 affects $w(\tau_M(x), x)$, we will require a lemma whose result is dependent on the nature of the equilibrium curve. From (2.10a), it is clear that there are constants $E_2 \geq E_1 > 0$ that bound the slope of the equilibrium curve: $E_1 \leq \frac{dz_e}{dw} \leq E_2$. The values of these constants depend only on Z_0, Z_1, W_0, and W_1. Since w_e is the inverse of z_e, we also have that $1/E_1 \geq \frac{dw_e}{dz} \geq 1/E_2$. Finally, it will be convenient to define $E \equiv E_1/E_2$. Now we present a lemma whose proof will be used to establish a number of useful results.

LEMMA 4.2. *If we define the function $\gamma(x) \in [0,1]$ by the relation $w(\tau_M(x)+, x) \equiv w_1 - \gamma(x)(w_1 - w_0)$ and define $z(x) \equiv z(\tau_M(x)+, x)$, then*

$$\frac{z_1 - z(X_2)}{z_1 - z_0} \geq E\alpha_1 \int_{X_1}^{X_2} \gamma(x) e^{-\alpha_2(X_2 - x)} dx, \tag{4.10}$$

where $-4H \leq X_1 \leq X_2$. This implies that if $z(X_2)$ is near z_1, then the measure of x values where $w(\tau_M(x)+, x)$ fails to be close to w_1 is small.

Proof. We begin by comparing the actual solution $z(x)$ of (3.56), where τ_M is under the influence of $\gamma(x)$, with the solution $z_I(x)$ of (3.56) that would occur if τ_M were under the influence of a function $\gamma_I(x)$, where $\gamma_I(x) \leq \gamma(x)$. If both solutions start at the same point, $z(X_1) = z_I(X_1) = Z$, then the fact from (2.11a) that $\frac{\partial g}{\partial w} > 0$ implies that $z(x) \leq z_I(x)$ for all $x \geq X_1$. In other words, making $\gamma(x)$ smaller makes $z(x)$ bigger as x increases.

With this in mind, we divide the region $[X_1, X_2]$ into pieces of length Δx and define

$$\gamma^j \equiv \inf\{\gamma(x) : x \in [X_1 + (j-1)\Delta x, X_1 + j\Delta x]\}. \tag{4.11}$$

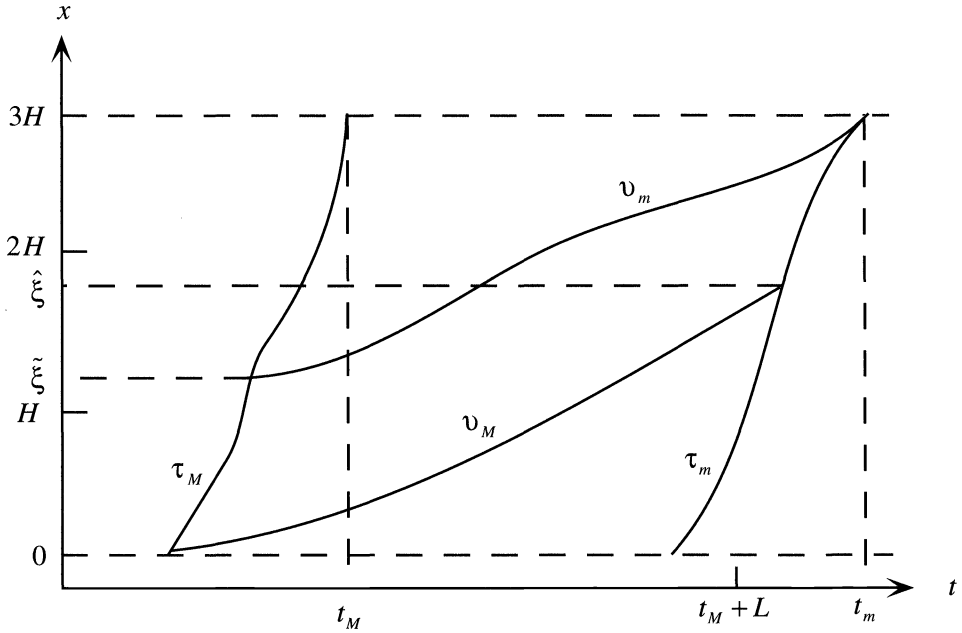

FIG. 3. *The characteristics τ_M, τ_m, v_M, and v_m on the (t, x) plane. We will monitor the variation of z in the regions of τ_M and τ_m located between v_M and v_m.*

We also define

$$z_e^j \equiv z_e(w_1 - \gamma^j(w_1 - w_0)), \tag{4.12}$$

$$z^j \equiv z(X_1 + j\Delta x), \tag{4.13}$$

$$\text{and } \alpha^j \equiv \begin{cases} \alpha_1 & \text{if } z^{j-1} - z_e^j \geq 0, \\ \alpha_2 & \text{if } z^{j-1} - z_e^j < 0, \end{cases} \tag{4.14}$$

where α_1 and α_2 are defined in Lemma 4.1 and depend only on Z_0, Z_1, W_0, and W_1. We use Lemma 4.1 combined with the fact that making $\gamma(x)$ smaller makes $z(x)$ bigger to obtain

$$z^1 \leq z_e^1 + (Z - z_e^1)e^{-\alpha^1 \Delta x}. \tag{4.15}$$

Using the fact that $Z \leq z_1$, which follows from Theorem 4.1, and that $z_e^j \leq z_1 - E\gamma^j(z_1 - z_0)$, we can transform (4.15) into

$$z^1 \leq z_1 - E\gamma^1(z_1 - z_0)(1 - e^{-\alpha^1 \Delta x}). \tag{4.16}$$

Repeating this method and using (4.16), we can obtain an expression for z^2:

$$z^2 \leq z_1 - E(z_1 - z_0)[\gamma^2(1 - e^{-\alpha^2 \Delta x}) + \gamma^1(1 - e^{-\alpha^1 \Delta x})e^{-\alpha^2 \Delta x}] \tag{4.17}$$

and, continuing in this fashion, we obtain an expression for z^n:

$$z^n \leq z_1 - E(z_1 - z_0) \sum_{i=1}^{n} \left[\gamma^i (1 - e^{-\alpha^i \Delta x}) \exp\left[-\Delta x \sum_{j=1}^{n-i} \alpha^{(n-j+1)} \right] \right]. \tag{4.18}$$

By using the definition of α^j, we can simplify (4.18):

$$z^n \leq z_1 - E(z_1 - z_0) \sum_{i=1}^{n} \left[\gamma^i(1 - e^{-\alpha_1 \Delta x}) \exp[-\Delta x \alpha_2 (n-i)]\right]. \tag{4.19}$$

By the nature of BV solutions, the number of 2-shocks is countable; therefore, $\gamma(x)$ can be discontinuous only on a set of measure zero, which implies that $\gamma(x)$ is Riemann integrable. Therefore, as $\Delta x \to 0$, (4.19) yields the desired integral, and, after some simple algebra, we obtain (4.10).

Now we are prepared to quantify the effect on $w(\tau_M(x)+, x)$ when z_M is near z_1.

LEMMA 4.3. *If we define* $\varepsilon_M \equiv \sqrt{(z_1 - z_M)/(z_1 - z_0)}$ *and define the region of* τ_M *between* v_M *and* v_m *where* w *is bounded away from* w_1 *by* $A_{\varepsilon_M} \equiv \{x \in [0, \tilde{\xi}] : w(\tau_M(x)+, x) \in [w_0, w_1 - \varepsilon_M(w_1 - w_0)]\}$, *then the Lebesgue measure,* m, *of* A_{ε_M} *is bounded by* ε_M; *specifically,*

$$\frac{e^{3H\alpha_2}}{E\alpha_1} \varepsilon_M \geq m(A_{\varepsilon_M}). \tag{4.20}$$

Proof. From Lemma 4.2, we have that

$$(\varepsilon_M)^2 = \frac{z_1 - z_M}{z_1 - z_0} \geq E\alpha_1 e^{-3H\alpha_2} \int_0^{3H} \gamma(x)dx. \tag{4.21}$$

By the definition of A_{ε_M}, we have that $\int_0^{3H} \gamma(x)dx \geq \varepsilon_M m(A_{\varepsilon_M})$, and therefore, (4.21) yields

$$\frac{e^{3H\alpha_2}}{E\alpha_1} (\varepsilon_M)^2 \geq \varepsilon_M m(A_{\varepsilon_M}), \tag{4.22}$$

and the result of the lemma is obvious.

Using a similar process, we can analyze the behavior on τ_m.

LEMMA 4.4. *If we define* $\varepsilon_{\bar{m}} \equiv \sqrt{(z_m - z_0)/(z_1 - z_0)}$ *and define the region of* τ_m *between* v_M *and* v_m *where* w *is close to* w_0 *by* $A_{\varepsilon_m} \equiv \{x \in [\hat{\xi}, 3H] : w(\tau_m(x)+, x) \in [w_0, w_0 + \varepsilon_m(w_1 - w_0)]\}$, *then the parameter* ε_m *is bounded by* $\varepsilon_{\bar{m}}$; *specifically,*

$$\frac{e^{3H\alpha_2}}{E\alpha_1(H - m(A_{\varepsilon_m}))} (\varepsilon_{\bar{m}})^2 \geq \varepsilon_m. \tag{4.23}$$

Proof. The proof is similar to the proof of Lemma 4.3. The method used to establish Lemma 4.2 can be reemployed to verify the following analogous result:

$$(\varepsilon_{\bar{m}})^2 = \frac{z_m - z_0}{z_1 - z_0} \geq E\alpha_1 e^{-3H\alpha_2} \int_0^{3H} \gamma(x)dx, \tag{4.24}$$

where $\gamma(x)$ is defined by $w(\tau_m(x)+, x) \equiv w_0 + \gamma(x)(w_1 - w_0)$. By the definition of A_{ε_m}, we have that

$$\int_0^{3H} \gamma(x)dx \geq \varepsilon_m(3H - \hat{\xi} - m(A_{\varepsilon_m})), \tag{4.25}$$

which, when combined with the fact that $3H - \hat{\xi} \geq H$, can be inserted into (4.24) to yield the result of the theorem.

With the above definition of ε_M and $\varepsilon_{\bar{m}}$, we see that our goal of finding $\varepsilon' > 0$ such that $(z_M - z_m)/(z_1 - z_0) < 1 - \varepsilon'$ is equivalent to finding $\varepsilon' > 0$ such that $\varepsilon_M^2 + \varepsilon_{\bar{m}}^2 > \varepsilon'$.

Next, we use Lemma 4.1 to determine some bounds on the evolution of a Riemann invariant as it progresses on an extremal characteristic of its own family.

LEMMA 4.5. *Consider any maximal backward* 2*-characteristic v which emanates from a point (T, X), where $X > -4H$. If we define $w(x) \equiv w(v(x)+, x)$, then for $-4H \leq y \leq Y \leq X$, we have*

$$w(Y) \geq w_0 + (w(y) - w_0)e^{-\alpha_2(Y-y)}, \tag{4.26a}$$

$$w(Y) \leq w_1 + (w(y) - w_1)e^{-\alpha_2(Y-y)}. \tag{4.26b}$$

(4.26) *also holds if v is a minimal backward* 2*-characteristic and $w(x) \equiv w(v(x)-, x)$.*

Similarly, if we consider any maximal backward 1*-characteristic τ which emanates from the point (T, X) and we define $z(x) \equiv z(\tau(x)+, x)$, then for $-4H \leq y \leq Y \leq X$, we have*

$$z(Y) \geq z_0 + (z(y) - z_0)e^{-\alpha_2(Y-y)}, \tag{4.27a}$$

$$z(Y) \leq z_1 + (z(y) - z_1)e^{-\alpha_2(Y-y)}. \tag{4.27b}$$

(4.27) *also holds if τ is a minimal backward* 1*-characteristic and $z(x) \equiv z(\tau(x)-, x)$.*

Proof. We prove (4.26a). From Theorem 3.1, we know that

$$w(Y) = w(y) - \int_y^Y g(z(v(x)+, x), w(x))dx. \tag{4.28}$$

From (2.11b), we know that $\frac{\partial g}{\partial z} < 0$; therefore, decreasing $z(v(x)+, x)$ in (4.28) decreases the right-hand side of (4.28):

$$w(Y) \geq w(y) - \int_y^Y g(z_0, w(x))dx. \tag{4.29}$$

Lemma 4.1 implies that

$$w(y) - \int_y^Y g(z_0, w(x))dx \geq w_0 + (w(y) - w_0)e^{-\alpha_2(Y-y)}, \tag{4.30}$$

which we combine with (4.29) to obtain (4.26a).

The remaining statements in the lemma have analogous proofs.

To prove the proportional shrinkage of the invariant regions (i.e., to find an $\varepsilon' > 0$ such that $\varepsilon_M^2 + \varepsilon_{\bar{m}}^2 > \varepsilon'$), we require only one more result, which will be the goal of Lemmas 4.6 and 4.7: we need to show that if ε_M and ε_m are in a sufficiently small neighborhood of zero, which we will call $[0, \bar{\varepsilon}]$, then there is a constant C such that $m(A_{\varepsilon_M}) \geq Cm(A_{\varepsilon_m})$. In other words, the measure of the x values where $w(\tau_M(x)+, x)$ is not near w_1 bounds the measure of the x values where $w(\tau_m(x)+, x)$ is near w_0.

The proofs of Lemmas 4.6 and 4.7 will make use of two new small-valued variables, ε_1 (which will be closely related to ε_m) and ε_2 (which will be closely related to ε_M).

The proofs will also require the following construction, which divides the region of the (t, x) plane bounded by τ_M, τ_m, $x = 0$, and $x = 3H$ into a countable number of "blocks."

We start with $x_1^t \equiv \max\{x : x \leq 3H \text{ and } x \in A_{\varepsilon_m}\}$. The point $(\tau_m(x_1^t), x_1^t)$ is (generally) located near the top of the τ_m characteristic. We define v_1^t to be the maximal backward 2-characteristic emanating from $(\tau_m(x_1^t), x_1^t)$ and follow it back until it intersects τ_M. We define the x coordinate of this point of intersection as X_1^t. Now we move down τ_M until we hit the point $(\tau_M(X_1^c), X_1^c)$, where $X_1^c \equiv \sup\{x : x < X_1^t \text{ and } x \in \text{the complement of } A_{\varepsilon_M}\}$. Next, we follow v_1^c, the forward characteristic emanating from $(\tau_M(X_1^c), X_1^c)$, until it intersects τ_m, and we define x_1^c as the x coordinate of the point of intersection. This completes the first block. Now we define $x_2^t \equiv \max\{x : x \leq x_1^c \text{ and } x \in A_{\varepsilon_m}\}$ and continue constructing these blocks until we reach $x = 0$. Because the variation of w on 1-characteristics is locally bounded, there can be at most a countably infinite number of these blocks.

Since $x_i^t \in A_{\varepsilon_m}$, we can use (4.26a) of Lemma 4.5 to obtain

$$w(\tau_M(X_i^t)+, X_i^t) \leq w_0 + \varepsilon_1^2(w_1 - w_0), \tag{4.31}$$

where $\varepsilon_1 \equiv \sqrt{\varepsilon_m e^{3H\alpha_2}}$. The form of the construction also provides the following facts:

$$A_{\varepsilon_m} \subset \bigcup_i [x_i^c, x_i^t], \qquad \bigcup_i [X_i^c, X_i^t] \subset A_{\varepsilon_M}, \tag{4.32}$$

$$x_i^c < x_i^t, \qquad X_i^c < X_i^t. \tag{4.33}$$

We wish to find some constant C, where $x_i^t - x_i^c \leq C(X_i^t - X_i^c)$. This will allow us to use (4.32) to show that the measure of A_{ε_M} bounds the measure of A_{ε_m}. To find C, we will need to add some additional elements to our construction. We define $X_i^b \equiv \sup\{x : x < X_i^c \text{ and } w(\tau_M(x)+, x) \leq w_0 + \varepsilon_1(w_1 - w_0)\}$. X_i^b has the property $X_{i+1}^t < X_i^b < X_i^c$. We also define $v_i^b(x)$ as the forward 2-characteristic emanating from $(\tau_M(X_i^b), X_i^b)$ when $x \geq X_i^b$ and as the maximal backward 2-characteristic emanating from $(\tau_M(X_i^b), X_i^b)$ when $x < X_i^b$. The x coordinate of the point of intersection of $v_i^b(x)$ with $\tau_m(x)$ will be called x_i^b. Finally, we extend the previous definition of v_i^c by defining v_i^c as the maximal backward 2-characteristic emanating from $(\tau_M(X_i^c), X_i^c)$ when $x \leq X_i^c$.

Note that in this construction, the capital letter X is used to denote locations that are significant on the τ_M characteristic, and the lower-case letter x denotes important locations on the τ_m characteristic. The superscripts t, c, and b refer to the "top," "center," and "bottom" of a block. A constructed block along with some of its properties is shown in Fig. 4.

By analyzing v_i^c and v_i^b, we will determine bounds on the slope of v_i^c. With these bounds in place, we will analyze v_i^t and v_i^c, which will yield the desired relationship: $x_i^t - x_i^c \leq C(X_i^t - X_i^c)$. The bounds on the slope of v_i^c will come from the following lemma.

LEMMA 4.6. *If ε_m and ε_M are sufficiently small, then $v_i^c(x)$ cannot intersect $v_i^b(x)$ at any $x \in [-4H, 3H]$.*

Proof. We wish to show that the minimum possible value of $v_i^c(x) - v_i^b(x)$ is bounded away from zero in the region $x \in [0, 3H]$. To accomplish this, we consider the largest possible values for the slope (i.e., derivative) of $v_i^c(x)$ and the smallest possible values for the slope of $v_i^b(x)$ in the region $x \in [-4H, 3H]$.

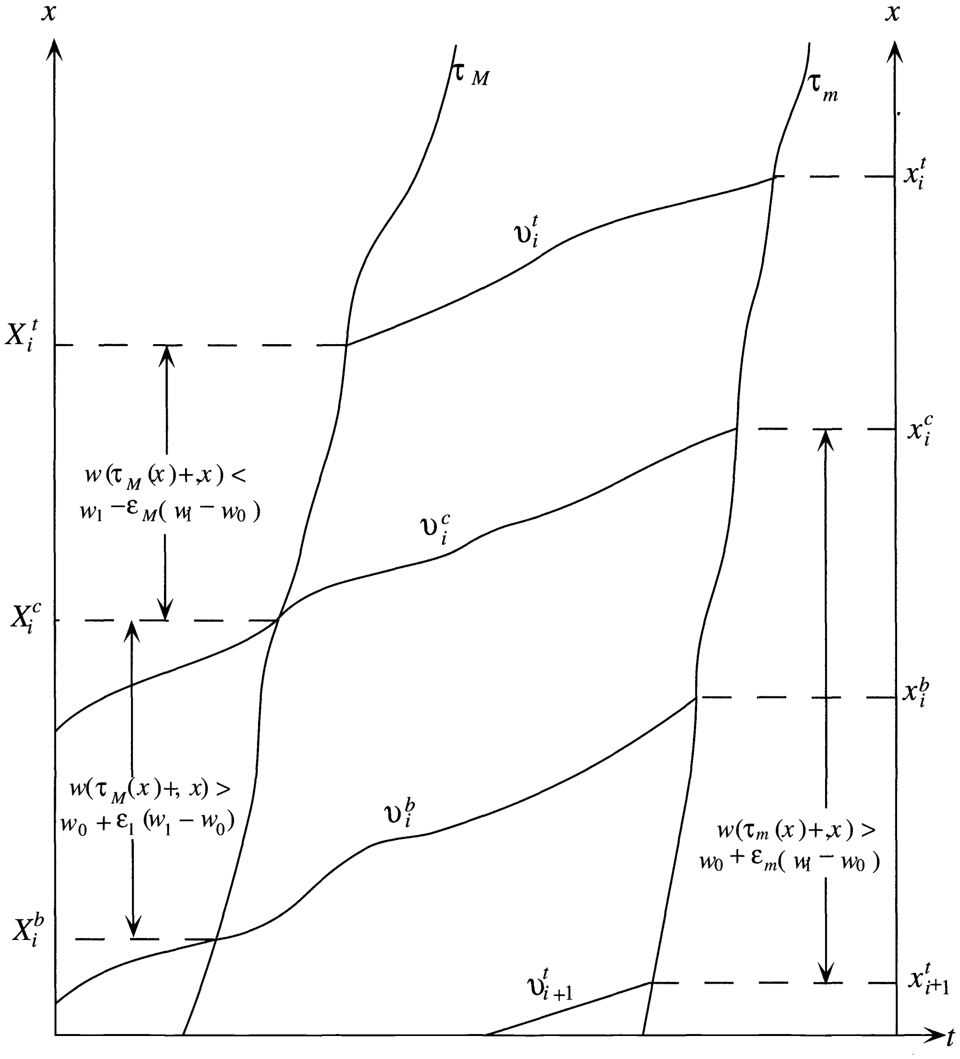

FIG. 4. *A constructed block in the region between τ_M and τ_m. w is bounded away from w_1 in the region of τ_M located between v_i^t and v_i^c, whereas w is bounded away from w_0 in the region of τ_M located between v_i^c and v_i^b. w is also bounded away from w_0 in the region of τ_m located between v_i^c and v_{i+1}^t.*

First, we analyze $v_i^c(x)$ in the region $x \in [-4H, X_i^c]$. From (2.5) and (3.12), we have

$$v_i^c(X_i^c) - v_i^c(-4H) = \int_{-4H}^{X_i^c} \frac{1}{w^2(x)z(x)}dx, \tag{4.34}$$

where $w(x) \equiv w(v_i^c(x)\pm, x)$ and $z(x) \equiv z(v_i^c(x)\pm, x)$. Adding and subtracting $1/(w_1^2 z_1)$ to the integrand of (4.34) and manipulating the result yields

$$v_i^c(X_i^c) - v_i^c(-4H) = \frac{1}{w_1^2 z_1}(X_i^c + 4H)$$

$$+\int_{-4H}^{X_i^c}\frac{w_1+w(x)}{w^2(x)w_1^2z_1}(w_1-w(x))dx+\int_{-4H}^{X_i^c}\frac{1}{w^2(x)z(x)z_1}(z_1-z(x))dx. \tag{4.35}$$

We can use the reference invariant region to partially bound the integrals in (4.35):

$$\int_{-4H}^{X_i^c}\frac{w_1+w(x)}{w^2(x)w_1^2z_1}(w_1-w(x))dx+\int_{-4H}^{X_i^c}\frac{1}{w^2(x)z(x)z_1}(z_1-z(x))dx$$

$$\leq\frac{2W_1}{W_0^4Z_0}\int_{-4H}^{X_i^c}(w_1-w(x))dx+\frac{1}{W_0^2Z_0^2}\int_{-4H}^{X_i^c}(z_1-z(x))dx; \tag{4.36}$$

however, we still require bounds on the integrals which appear on the right-hand side of (4.36).

Since $w(\tau_M(x)+,x)$ is left-continuous (from Theorem 3.2), we know from the definition of X_i^c that

$$w(v_i^c(X_i^c)+,X_i^c)\geq w_1-\varepsilon_M(w_1-w_0). \tag{4.37}$$

Therefore, Lemma 4.5 implies that

$$w(v_i^c(x)+,x)\geq w_1-\varepsilon_2(w_1-w_0),\quad x\in[-4H,X_i^c], \tag{4.38}$$

where $\varepsilon_2\equiv\varepsilon_M\exp[7H\alpha_2]$. This allows us to bound the first integral on the right-hand side of (4.36):

$$\int_{-4H}^{X_i^c}(w_1-w(x))dx\leq\int_{-4H}^{X_i^c}\varepsilon_2(w_1-w_0)dx\leq 7H\varepsilon_2(w_1-w_0). \tag{4.39}$$

The value of $z(x)$ cannot be too small in the region $x\in[-4H,X_i^c]$ or (4.37) will fail to be satisfied. By applying the logic used in Lemma 4.2, we can explicitly express this bound on the behavior of $z(x)$ as

$$\frac{\varepsilon_2}{E\alpha_1}\geq\int_{-4H}^{X_i^c}\gamma(x)dx, \tag{4.40}$$

where $\gamma(x)$ is defined by the equation $z(x)\equiv z_1-\gamma(x)(z_1-z_0)$. This allows us to bound the second integral on the right-hand side of (4.36):

$$\int_{-4H}^{X_i^c}(z_1-z(x))dx=(z_1-z_0)\int_{-4H}^{X_i^c}\gamma(x)dx\leq\frac{\varepsilon_2}{E\alpha_1}(z_1-z_0). \tag{4.41}$$

We combine (4.39) and (4.41) with (4.35) and (4.36) and use the fact that $(z_1-z_0)\leq E_2(w_1-w_0)$ to obtain the final form of the bound on $v_i^c(x)$:

$$v_i^c(X_i^c)-v_i^c(-4H)\leq\frac{1}{w_1^2z_1}(X_i^c+4H)+K\varepsilon_2(w_1-w_0). \tag{4.42}$$

In the above equation—and throughout the rest of this paper—K will be used to denote any positive constant that depends strictly on the period, the bounds on the characteristic speeds, and the reference invariant region.

Using analogous steps, we can establish a similar bound on $v_i^b(x)$ in the region $x \in [-4H, X_i^b]$:

$$v_i^b(X_i^b) - v_i^b(-4H) \geq \frac{1}{w_0^2 z_0}(X_i^b + 4H) - K\varepsilon_1(w_1 - w_0). \tag{4.43}$$

Now we turn our attention to the region past the τ_M characteristic. Because (4.42) and (4.43) pull v_i^c and v_i^b so far away from each other, we can let the two characteristics approach each other as quickly as possible in this region. From (2.5) and (3.12), we have

$$v_i^c(x) - v_i^c(X_i^c) = \int_{X_i^c}^{x} \frac{dy}{w_0^2(v_i^c(y), y) z_0(v_i^c(y), y)} \leq \frac{1}{w_0^2 z_0}(x - X_i^c), \quad x \in [X_i^c, 3H], \tag{4.44}$$

$$v_i^b(x) - v_i^b(X_i^b) = \int_{X_i^b}^{x} \frac{dy}{w_0^2(v_i^b(y), y) z_0(v_i^b(y), y)} \geq \frac{1}{w_1^2 z_1}(x - X_i^b), \quad x \in [X_i^b, 3H]. \tag{4.45}$$

We now have bounds for v_i^c and v_i^b throughout our region of interest. Since backward 2-characteristics cannot cross, we know that $v_i^c(x)$ and $v_i^b(x)$ cannot cross in the region $x \in [-4H, X_i^c]$. We now show that $v_i^c(x)$ and $v_i^b(x)$ cannot cross in the region $x \in [X_i^c, 3H]$. First, we combine (4.42) with (4.44) and use the fact that $X_i^c \geq 0$ to obtain

$$\begin{aligned} v_i^c(x) - v_i^c(-4H) &\leq \frac{X_i^c + 4H}{w_1^2 z_1} + \frac{x - X_i^c}{w_0^2 z_0} + K\varepsilon_2(w_1 - w_0) \\ &\leq \frac{4H}{w_1^2 z_1} + \frac{x}{w_0^2 z_0} + K\varepsilon_2(w_1 - w_0). \end{aligned} \tag{4.46}$$

Similarly, we combine (4.43) with (4.45) and use the fact that $X_i^b \geq 0$ to obtain

$$\begin{aligned} v_i^b(x) - v_i^b(-4H) &\geq \frac{X_i^b + 4H}{w_0^2 z_0} + \frac{x - X_i^b}{w_1^2 z_1} - K\varepsilon_1(w_1 - w_0) \\ &\geq \frac{4H}{w_0^2 z_0} + \frac{x}{w_1^2 z_1} - K\varepsilon_1(w_1 - w_0). \end{aligned} \tag{4.47}$$

Subtracting (4.46) from (4.47) and using the fact that $v_i^b(-4H) - v_i^c(-4H) > 0$ yields

$$v_i^b(x) - v_i^c(x) \geq \left[\frac{1}{w_0^2 z_0} - \frac{1}{w_1^2 z_1}\right](4H - x) - K(w_1 - w_0)(\varepsilon_1 + \varepsilon_2). \tag{4.48}$$

Using the reference invariant region, the fact that $x \leq 3H$, and the bounds on the slope of the equilibrium curve, we can rearrange and minimize the right-hand side of (4.48) so as to obtain

$$\begin{aligned} v_i^b(x) - v_i^c(x) &\geq \left[\frac{2W_0 H}{W_1^4 Z_1} + \frac{E_1 H}{W_1^2 Z_1^2} - K(\varepsilon_1 + \varepsilon_2)\right](w_1 - w_0) \\ &= [K - K(\varepsilon_1 + \varepsilon_2)](w_1 - w_0). \end{aligned} \tag{4.49}$$

For sufficiently small ε_m and ε_M, ε_1 and ε_2 become small enough to cause the $K(\varepsilon_1 + \varepsilon_2)$ term in (4.49) to be small compared to the K term. Therefore, for sufficiently small ε_m and ε_M, we have that

$$v_i^b(x) - v_i^c(x) \geq K(w_1 - w_0), \quad x \in [X_i^c, 3H]. \tag{4.50}$$

We conclude from (4.50) that the v_i^b and v_i^c characteristics never cross. This conclusion, of course, assumes that $w_1 > w_0$, but this is not a problem since $w_1 = w_0$ is just the trivial case where the invariant region is already a single point on the chemical-equilibrium curve, leaving nothing more to prove.

From Lemma 4.6, we get the following useful fact.

COROLLARY 4.1. *For sufficiently small ε_m and ε_M, the limit of w from the right of v_i^c is bounded away from w_0; specifically,*

$$w(v_i^c(x)+, x) \geq w_0 + \varepsilon_1 e^{-3H\alpha_2}(w_1 - w_0), \tag{4.51}$$

where $x \in [X_i^c, x_i^c]$.

Proof. Consider any $Y \in [X_i^c, x_i^c]$. Define v as the maximal backward 2-characteristic emanating from $(v_i^c(Y), Y)$, and define y as the x-coordinate of the point where v and τ_M cross. From Lemma 4.6, we have that $X_i^b < y \leq X_i^c$. Therefore, the nature of the construction implies that

$$w(v(y)+, y) \geq w_0 + \varepsilon_1(w_1 - w_0). \tag{4.52}$$

We can relate $w(v(y)+, y)$ to $w(v(Y)+, Y)$ by using (4.26a) of Lemma 4.5:

$$w(v(Y)+, Y) \geq w_0 + (w(v(y)+, y) - w_0)e^{-\alpha_2(Y-y)}. \tag{4.53}$$

Combining (4.52) and (4.53) with the fact that $Y - y \leq 3H$ establishes the claim of the corollary.

Now we analyze how wide the distance between the v_i^t and v_i^c characteristics can become as x increases. Specifically, we wish to relate $x_i^t - x_i^c$ to $X_i^t - X_i^c$.

LEMMA 4.7. *There is a constant $C > 0$ that depends strictly on the bounds on the characteristic speeds s_i such that*

$$x_i^t - x_i^c \leq C(X_i^t - X_i^c). \tag{4.54}$$

Proof. To obtain the lemma's claim, we must consider the behavior of v_i^t and v_i^c in three separate regions: $x \in [X_i^c, X_i^t]$, $x \in [X_i^t, x_i^c]$, and $x \in [x_i^c, x_i^t]$.

Since we have bounds on the characteristic speeds, it is straightforward to use (4.7) to express explicit bounds on the widening of the characteristics in the regions $x \in [X_i^c, X_i^t]$ and $x \in [x_i^c, x_i^t]$:

$$(X_i^t - X_i^c)(s_4 - s_1) \geq v_i^c(X_i^t) - v_i^t(X_i^t), \tag{4.55}$$

$$(x_i^t - x_i^c)(s_3 - s_2) \leq v_i^c(x_i^c) - v_i^t(x_i^c). \tag{4.56}$$

Now we consider the range $x \in [X_i^t, x_i^c]$. We can apply the method used to obtain (4.43) in Lemma 4.6 to establish an analogous result for the backward characteristic v_i^t in this region:

$$v_i^t(x_i^c) - v_i^t(X_i^t) \geq \frac{1}{w_0^2 z_0}(x_i^c - X_i^t) - K\varepsilon_1^2(w_1 - w_0). \tag{4.57}$$

The forward characteristic $v_i^c(x)$ can propagate with either classical or shock speed. Either way, we have from (2.13b) and (3.6) that

$$v_i^c(x_i^c) - v_i^c(X_i^t) = \int_{X_i^t}^{x_i^c} \frac{dx}{z(v_i^c(x)\pm, x)w(v_i^c(x)-, x)w(v_i^c(x)+, x)}. \tag{4.58}$$

Now we use Corollary 4.1 to obtain the bound

$$v_i^c(x_i^c) - v_i^c(X_i^t) \le \int_{X_i^t}^{x_i^c} \frac{dx}{z_0 w_0 (w_0 + \varepsilon_1 (w_1 - w_0)\exp(-3H\alpha_2))}. \tag{4.59}$$

Using the reference invariant region, the bound in (4.59) can be manipulated into the following form:

$$v_i^c(x_i^c) - v_i^c(X_i^t) \le \frac{1}{w_0^2 z_0}(x_i^c - X_i^t) - \frac{\varepsilon_1 (w_1 - w_0)\exp(-3H\alpha_2)}{W_1^3 Z_1}(x_i^c - X_i^t). \tag{4.60}$$

We claim that $x_i^c - X_i^t$ cannot be too small. This comes from the requirement that τ_M and τ_m be at least one period apart from each other. Since $v_i^c(x_i^c) - v_i^c(X_i^c) \ge L$, we know that $x_i^c - X_i^c \ge L/s_4$. From Lemma 4.3 and (4.32), we see that $X_i^c - X_i^t \to 0$ as $\varepsilon_M \to 0$; therefore, $x_i^c - X_i^t \ge L/(2s_4)$ and $x_i^c - X_i^t$ cannot be too small for sufficiently small ε_M. This allows us to express (4.60) as

$$v_i^c(x_i^c) - v_i^c(X_i^t) \le \frac{1}{w_0^2 z_0}(x_i^c - X_i^t) - K\varepsilon_1 (w_1 - w_0). \tag{4.61}$$

We combine (4.57) with (4.61) to obtain

$$v_i^c(x_i^c) - v_i^t(x_i^c) \le v_i^c(X_i^t) - v_i^t(X_i^t) - (w_1 - w_0)(K\varepsilon_1 - K\varepsilon_1^2). \tag{4.62}$$

Therefore, for ε_1 sufficiently small, we have

$$v_i^c(x_i^c) - v_i^t(x_i^c) \le v_i^c(X_i^t) - v_i^t(X_i^t). \tag{4.63}$$

(4.63) can now be combined with the bounds in the other regions, (4.55) and (4.56), to yield

$$x_i^t - x_i^c \le \frac{s_4 - s_1}{s_3 - s_2}(X_i^t - X_i^c), \tag{4.64}$$

which, by defining $C \equiv (s_4 - s_1)/(s_3 - s_2)$, establishes the claim of the lemma.

We are now ready to show proportional shrinkage of the invariant region. We begin by showing that the range of z values in the solution must shrink in proportion to $z_1 - z_0$ as the solution progresses through a spatial interval of length $7H$.

THEOREM 4.2. *There is a constant $\varepsilon' > 0$ that depends* only *on the period L, the bounds on the characteristic speeds s_1, s_2, s_3, and s_4, and the reference invariant region Z_0, Z_1, W_0, and W_1 such that*

$$\frac{z_M - z_m}{z_1 - z_0} \le 1 - \varepsilon'. \tag{4.65}$$

Proof. From Lemmas 4.6 and 4.7, we know that there exists some sufficiently small $\bar{\varepsilon} > 0$ that depends only on the period, the bounds on the characteristic speeds, and the reference invariant region such that for all $\varepsilon_m \le \bar{\varepsilon}$ and $\varepsilon_M \le \bar{\varepsilon}$, we have that

$x_i^t - x_i^c \leq C(X_i^t - X_i^c)$. We sum this relation over all the i-blocks and use (4.32) to obtain

$$m(A_{\varepsilon_m}) \leq \sum_i (x_i^t - x_i^c) \leq C \sum_i (X_i^t - X_i^c) \leq Cm(A_{\varepsilon_M}). \tag{4.66}$$

Therefore, the measure of the set of x values on τ_M where $w(\tau_M(x)+, x)$ is bounded away from w_1 bounds the measure of the set of x values on τ_m where $w(\tau_M(x)+, x)$ is close to w_0.

Now we set $\varepsilon_m \equiv \bar{\varepsilon}$. From Lemma 4.3 and (4.66), it is clear that $\varepsilon_M \geq Km(A_{\bar{\varepsilon}})$. Therefore, there is a constant $\delta \in (0, \bar{\varepsilon}]$ that depends only on the period, the bounds on the characteristic speeds, and the reference invariant region such that $(\varepsilon_M)^2 \leq \delta$ implies $m(A_{\bar{\varepsilon}}) \leq H/2$. This allows us to use Lemma 4.4 to conclude that $(\varepsilon_{\bar{m}})^2 \geq K\bar{\varepsilon}$ whenever $(\varepsilon_M)^2 \leq \delta$. Therefore, $(\varepsilon_M)^2 + (\varepsilon_{\bar{m}})^2 \geq \varepsilon'$, where $\varepsilon' \equiv \min[\delta, K\bar{\varepsilon}]$. However, by the definitions of ε_M and $\varepsilon_{\bar{m}}$, we know that

$$\frac{z_M - z_m}{z_1 - z_0} = 1 - (\varepsilon_M)^2 - (\varepsilon_{\bar{m}})^2, \tag{4.67}$$

which immediately implies (4.65).

Now we look at the shrinkage in the range of values of w as we proceed through an additional interval of length $\ln 2/\alpha_2$.

THEOREM 4.3. *There is a constant $\varepsilon > 0$ that depends only on the period, the bounds on the characteristic speeds, and the reference invariant region and there are also constants w_M and w_m such that*

$$\frac{w_M - w_m}{w_1 - w_0} \leq 1 - \varepsilon, \tag{4.68}$$

$$w_m \leq w(t, 3H + (\ln 2)/\alpha_2) \leq w_M \quad \forall t \in (-\infty, \infty), \tag{4.69}$$

$$\text{and } z_e(w_m) \leq z(t, 3H + \ln 2/\alpha_2) \leq z_e(w_M) \quad \forall t \in (-\infty, \infty). \tag{4.70}$$

Proof. From Theorem 4.2, we know that there is an $r \in [0, 1]$ such that $z_1 - z_M \geq r\varepsilon'(z_1 - z_0)$ and $z_m - z_0 \geq (1 - r)\varepsilon'(z_1 - z_0)$. From Theorem 4.5, we know that if $x \in [3H, 3H + \ln 2/\alpha_2]$, then $z(t, x) \leq z_M + (r\varepsilon'/2)(z_1 - z_0)$ and therefore $z(t, x) \leq z_1 - (r\varepsilon'/2)(z_1 - z_0)$. The method of the proof of Theorem 4.5 can also be used to show that since z is bounded away from z_1 in the region $x \in [3H, 3H + \ln 2/\alpha_2]$, w must be drawn away from w_1 as the solution progresses through this region. Specifically,

$$\sup_t w(t, 3H + (\ln 2)/\alpha_2) \leq w_M, \tag{4.71}$$

where

$$w_M \equiv w_e\left(z_1 - \frac{r\varepsilon'}{2}(z_1 - z_0)\right) + \left[w_1 - w_e\left(z_1 - \frac{r\varepsilon'}{2}(z_1 - z_0)\right)\right] e^{-\frac{\alpha_1}{\alpha_2}\ln 2}. \tag{4.72}$$

The definition in (4.72) can be transformed using the bounds on the derivative of $w_e(z)$ to yield

$$\frac{w_1 - w_M}{w_1 - w_0} \geq \frac{r\varepsilon' E}{2}\left(1 - 2^{-\frac{\alpha_1}{\alpha_2}}\right). \tag{4.73}$$

Further, if we take z_e of both sides of (4.72), we see that

$$\sup_t z(t, 3H + \ln 2/\alpha_2) \leq z_e(w_M). \tag{4.74}$$

Similarly, we also have that $z(t,x) \geq z_m - ((1-r)\varepsilon'/2)(z_1 - z_0) \geq z_0 + ((1-r)\varepsilon'/2)(z_1 - z_0)$ for $x \in [3H, 3H + \ln 2/\alpha_2]$, and this leads to

$$\inf_t w(t, 3H + (\ln 2)/\alpha_2) \geq w_m, \tag{4.75}$$

where

$$w_m \equiv w_e\left(z_0 + \frac{(1-r)\varepsilon'}{2}(z_1 - z_0)\right) + \left[w_1 - w_e\left(z_0 + \frac{(1-r)\varepsilon'}{2}(z_1 - z_0)\right)\right] e^{-\frac{\alpha_1}{\alpha_2}\ln 2}. \tag{4.76}$$

We also have that

$$\frac{w_m - w_0}{w_1 - w_0} \geq \frac{(1-r)\varepsilon' E}{2}\left(1 - 2^{-\frac{\alpha_1}{\alpha_2}}\right) \tag{4.77}$$

and

$$\inf_t z(t, 3H + \ln 2/\alpha_2) \geq z_e(w_m). \tag{4.78}$$

Adding (4.73) to (4.77) and defining $\varepsilon \equiv (\varepsilon' E/2)(1 - 2^{-\alpha_1/\alpha_2})$ establishes the claim of the lemma.

Theorem 4.3 allows us to ascertain the asymptotic behavior of the periodic case.

COROLLARY 4.2. *The invariant set containing the solution shrinks exponentially to a single point on the equilibrium curve as $x \to \infty$.*

Proof. First, we redefine our coordinate system so that $x = 0$ corresponds to a location where the solution lies within the reference invariant region. By repeatedly applying Theorem 4.3, we have that for any nonnegative integer n,

$$\sup_{(t,x)\in X_n} w(t,x) - \inf_{(t,x)\in X_n} w(t,x) \leq (W_1 - W_0)\exp[n \ln(1-\varepsilon)] \tag{4.79}$$

and

$$w_e\left(\sup_{(t,x)\in X_n} z(t,x)\right) - w_e\left(\inf_{(t,x)\in X_n} z(t,x)\right) \leq (W_1 - W_0)\exp[n\ln(1-\varepsilon)], \tag{4.80}$$

where $X_n \equiv \{(t,x) : n(7H + \ln 2/\alpha_2) \leq x < (n+1)(7H + \ln 2/\alpha_2)\}$. Therefore, the solution lies in invariant rectangles that shrink exponentially in size to a single point as $x \to \infty$. Further, since the lower left-hand corner and the upper right-hand corner of the rectangle are on the equilibrium curve, we conclude that the point to which the invariant regions shrink must also be on the equilibrium curve.

Finally, we determine which point on the equilibrium curve is approached as $x \to \infty$ by using the form of the mass balance for the two chemical components given in (2.3b).

THEOREM 4.4. *Under periodic conditions, the solution exponentially shrinks to the point (Z, W) on the equilibrium curve defined by*

$$Z \equiv \frac{M}{2} + \sqrt{\frac{M^2}{4} - \frac{bM - c}{a}} \quad \textit{and} \quad W \equiv w_e(Z), \tag{4.81}$$

where a, b, and c are defined in (2.3), $M \equiv (1/L)\int_{t_0}^{t_0+L} z(t,0) + w(t,0)dt$, *and* t_0 *is any arbitrary number.*

Proof. Combining the mass balance in (2.3b) with the fact that $v = z + w$ and $u = zw$ yields

$$\frac{\partial}{\partial x}\left(z(t,x) + w(t,x)\right) - \frac{\partial}{\partial t}\left(\frac{1}{z(t,x)w(t,x)}\right) = 0. \tag{4.82}$$

We integrate (4.82) over the region $\{(t,x) : t_0 \le t \le t_0 + L,\ 0 \le x \le x_1\}$. Since the solution is periodic, the integral of the term in (4.82) with the partial derivative with respect to t equals zero. If we let $x_1 \to \infty$ and apply Corollary 4.2, we obtain from the integrated form of (4.82) that

$$\int_{t_0}^{t_0+L} [z(t,0) + w(t,0)]dt = L(Z + W), \tag{4.83}$$

where $W = w_e(Z)$. After substituting the definition of $w_e(z)$ given in (2.9) into (4.83), we explicitly solve for Z, which yields the result in (4.81).

Acknowledgments. This paper was originally part of the author's Ph.D. dissertation at Brown University, which was supervised by Professor Constantine Dafermos, whom I wish to thank for supplying invaluable advice throughout this paper's development. I would also like to thank the anonymous referee of this paper for providing so many helpful comments and suggestions.

ON THE SOLUTION OF TIME-HARMONIC SCATTERING PROBLEMS FOR MAXWELL'S EQUATIONS*

CHRISTOPHE HAZARD† AND MARC LENOIR†

Abstract. This paper deals with the scattering of a monochromatic electromagnetic wave by a perfect conductor surrounded by a locally inhomogeneous medium. The direct numerical solution of this problem by a finite-element method requires special edge elements. The aim of the present paper is to give an equivalent formulation of the problem well suited for both easy theoretical investigation and numerical implementation. Following a well-known idea, this formulation is obtained by adding a regularizing term such as "grad div" in the time-harmonic Maxwell equations, which leads us to solve an elliptic problem similar to the vector Helmholtz equation instead of Maxwell's equation. The numerical treatment of this new formulation requires only standard Lagrange finite elements.

A unified approach, which is valid for the equations satisfied by either the electric or the magnetic field, is presented. It applies for a conductor with a Lipschitz-continuous boundary surrounded by a dissipative or nondissipative medium whose electromagnetic coefficients (permittivity and permeability) may be irregular. A family of scattering problems is defined, that is, the classical problem (which follows from Maxwell's equations) and the so-called "regularized problem" obtained by adding a regularizing term in Maxwell's equations. These problems are shown to be well posed and to have the same solution. An integral representation technique is described.

Key words. Maxwell's equations, scattering by obstacles, integral representation

1. Introduction.

1.1. Motivation.

Consider a perfect conductor surrounded by a medium whose electromagnetic coefficients (permittivity and permeability) are assumed constant outside a bounded domain. We are concerned with the scattering of a time-harmonic electromagnetic wave by this inhomogeneity of the space. (Let us mention that the presence of the perfect conductor is not essential; the same holds for the scattering by a dielectric obstacle.) The direct numerical solution of such a problem has been extensively studied. In particular, the use of Nédélec's curl-conforming finite elements [20] seems to be widely held (see, e.g., Levillain [16]), although there remain some open questions regarding the proof of the convergence properties of the numerical schemes involving high-order Nédélec finite elements (see Kikuchi [12]). Our aim is to propose an alternative approach that allows the use of standard Lagrange finite elements. It consists of replacing the classical Maxwell equations by an elliptic problem that has the same solution.

The main idea to construct this "regularized problem" is not new and may be found, for instance, in the papers from Werner [25], Leis [15], Knauff and Kress [13], or, more recently, Bamberger and Bonnet [3] and Mayergoyz and D'Angelo [17]. It is based on the simple fact that a three-dimensional field U that is a solution to

$$\operatorname{curl}(\operatorname{curl} U) - k^2 U = 0, \quad k \neq 0, \tag{1.1}$$

in an open set of $\mathbb{R}^3$ satisfies $\operatorname{div} U = 0$. As a consequence, it is also a solution to the vector Helmholtz equation

$$-\Delta U - k^2 U = 0 \tag{1.2}$$

* Received by the editors July 18, 1994; accepted for publication July 26, 1995.

† Laboratoire de Simulation et Modélisation des Phénomènes de Propagation (Associé au Centre National de la Recherche Scientifique et à l'Université Pierre et Marie Curie), École Nationale Supérieure de Techniques Avancées, Chemin de la Hunière, 91120 Palaiseau, France.

by virtue of the relation $\operatorname{curl}(\operatorname{curl} U) - \operatorname{grad}(\operatorname{div} U) = -\Delta U$. The converse is of course wrong if no additional condition is given, but it becomes true in the context of the scattering of electromagnetic waves by an obstacle with additional boundary conditions on the obstacle and at infinity. This may be easily understood as follows. Let U be a solution to (1.2) and assume that U satisfies the well-known Sommerfeld radiation condition at infinity. It is readily seen that its divergence $\varphi = \operatorname{div} U$ satisfies the scalar Helmholtz equation $-\Delta\varphi - k^2\varphi = 0$ as well as the scalar Sommerfeld radiation condition. Consequently, if we add a condition such as $\varphi = 0$ on the boundary of the obstacle (which has to be assumed regular), we deduce from classical results (Rellich [21]) that φ vanishes everywhere outside the obstacle, which shows that U is a solution to (1.1).

Our purpose is to extend this result to the general case of variable (discontinuous) electromagnetic coefficients and irregular boundaries for which this simple proof does not apply anymore. In this situation, (1.1) is replaced by the time-harmonic Maxwell equation

$$\operatorname{curl}(\zeta^{-1} \operatorname{curl} U) - \omega^2 \xi\, U = 0. \tag{1.3}$$

Noticing that every solution to this equation satisfies $\operatorname{div} \xi U = 0$, we will see that instead of solving (1.3) we can equivalently solve its regularized form

$$\operatorname{curl}(\zeta^{-1} \operatorname{curl} U) - \bar{\xi} \operatorname{grad}(\tau^{-1} \operatorname{div} \xi U) - \omega^2 \xi\, U = 0, \tag{1.4}$$

which has the advantage of involving an elliptic second-order differential operator. To prove the equivalence between the classical and regularized scattering problems (related, respectively, to (1.3) and (1.4)), we cannot study the equation satisfied by $\operatorname{div} \xi U$ as described above. The method we propose consists of proving the well-posedness of both problems and noticing that the solution to the classical problem solves the regularized equations since it is divergence-free.

From a numerical point of view, the regularized problem has a twofold interest compared with the classical problem. On one hand, its associated fundamental solution (Green tensor) has a weaker singularity (order 1 instead of 3), which is essential as far as integral representations are concerned. On the other hand, we will see that the regularized problem comes within the classical framework of approximation of Fredholm operators, which allows us in particular to use a standard discretization by Lagrange finite elements.

1.2. Outline of the paper. In §2.1, we present the classical equations that model the scattering of a time-harmonic wave by an inhomogeneous medium. We deal simultaneously with the equations satisfied by the electric or magnetic fields in the cases of dissipative or nondissipative media. Then, in §2.2, we introduce the regularizing term $\bar{\xi} \operatorname{grad}(\tau^{-1} \operatorname{div} \xi U)$ mentioned above. By suitable modifications of the boundary conditions as well as the radiation condition at infinity, we thus define a "regularized problem." Section 2.3 is devoted to the description of the functional framework associated with this problem. We finally state in §2.4 the main result of this paper, which consists of the equivalence between the classical and regularized formulations; the introduction of the regularizing term (which depends on the choice of function τ) does not affect the solution to the problem. The proof of this statement is the object of the remainder of the paper, where we develop a method that is well adapted for the numerical solution to the regularized problem by means of standard finite elements.

Section 3 consists of the proof of the uniqueness of the solution to the scattering problems (classical and regularized). The method we use is rather classical. The treatment of infinity (which is assumed homogeneous) is based on the well-known asymptotic behavior of the solutions to the scalar Helmholtz equation (Rellich [21]). Then, the treatment of the remainder of the space (containing all the inhomogeneities) follows by a unique continuation technique; here appear some restrictions concerning the regularity of the electromagnetic coefficients. Indeed, we will see that these coefficients have to be assumed piecewise Lipschitz continuous in the part of the domain where the medium is not dissipative.

Section 4 is devoted to the proof of the existence of a solution for the classical or regularized problem. The technique we present is similar to integral equation techniques [5]; it actually is an adaptation of the so-called "method of coupling between variational formulation and integral representation" introduced by Jami and Lenoir [9] in linear hydrodynamics. This method consists of replacing the initial problem by an equivalent problem (set in a bounded domain) that is obtained by means of an integral representation formula. We show that the existence and the uniqueness of the solution to this latter problem are a matter for Fredholm alternative; by virtue of the uniqueness proved in §3, the existence property for the initial problem follows. Let us point out that for the regularized problem, the same results may be obtained by a standard integral equation approach. Our method simply has the advantage of leading to an integral operator that involves a nonsingular kernel.

Finally, we have postponed until Appendices A and B some technical but essential results that concern, respectively, the statement of integral representation formulas and compactness properties.

1.3. Notation. In this section, we recall some usual notation concerning the function spaces that are used in the context of Maxwell's equations; we refer, for instance, to Girault and Raviart [8] for a detailed study of these spaces.

Let $\mathcal{O}$ be a bounded open set in $\mathbb{R}^3$. We define $\mathcal{D}(\mathcal{O})$ to be the space of infinitely differentiable functions with compact support in $\mathcal{O}$, $\mathcal{D}(\overline{\mathcal{O}}) = \{\varphi_{|\mathcal{O}} \mid \varphi \in \mathcal{D}(\mathbb{R}^3)\}$, and $\mathcal{D}'(\mathcal{O})$ is the dual space of $\mathcal{D}(\mathcal{O})$ (space of distributions). We use the notation $H^s(\mathcal{O})$, $s \in \mathbb{R}$, for the classical Sobolev spaces and $H_0^s(\mathcal{O})$ for the completion of $\mathcal{D}(\mathcal{O})$ in $H^s(\mathcal{O})$. We denote by $H(\mathrm{curl};\mathcal{O})$ and $H(\mathrm{div};\mathcal{O})$ the Hilbert spaces

$$H(\mathrm{curl};\mathcal{O}) = \{V \in L^2(\mathcal{O})^3 \mid \mathrm{curl}\, V \in L^2(\mathcal{O})^3\},$$
$$H(\mathrm{div};\mathcal{O}) = \{V \in L^2(\mathcal{O})^3 \mid \mathrm{div}\, V \in L^2(\mathcal{O})\}.$$

If $\mathcal{O}$ has a Lipschitz-continuous boundary $\partial\mathcal{O}$, then for every function $V \in H(\mathrm{curl};\mathcal{O})$ (respectively, $V \in H(\mathrm{div};\mathcal{O})$), the quantity $(V \wedge n)_{|\partial\mathcal{O}}$ (respectively, $(V \cdot n)_{|\partial\mathcal{O}}$) is defined by Green's formula as an element of $H^{-1/2}(\partial\mathcal{O})^3$ (respectively, $H^{-1/2}(\partial\mathcal{O})$). Let $H_0(\mathrm{curl};\mathcal{O})$ and $H_0(\mathrm{div};\mathcal{O})$ be the completions of $\mathcal{D}(\mathcal{O})^3$ in $H(\mathrm{curl};\mathcal{O})$ and $H(\mathrm{div};\mathcal{O})$. We have

$$H_0(\mathrm{curl};\mathcal{O}) = \{V \in H(\mathrm{curl};\mathcal{O}) \mid V \wedge n = 0 \text{ on } \partial\mathcal{O}\},$$
$$H_0(\mathrm{div};\mathcal{O}) = \{V \in H(\mathrm{div};\mathcal{O}) \mid V \cdot n = 0 \text{ on } \partial\mathcal{O}\}.$$

For an unbounded domain $\Omega \subset \mathbb{R}^3$, $H_{\mathrm{loc}}(\mathrm{curl};\Omega)$ (respectively, $H_{\mathrm{loc}}(\mathrm{div};\Omega)$) denotes the Frechet space of functions $V \in L^2_{\mathrm{loc}}(\Omega)$ such that $V_{|\mathcal{O}} \in H(\mathrm{curl};\mathcal{O})$ (respectively, $V_{|\mathcal{O}} \in H(\mathrm{div};\mathcal{O})$) for every bounded set $\mathcal{O} \subset \Omega$.

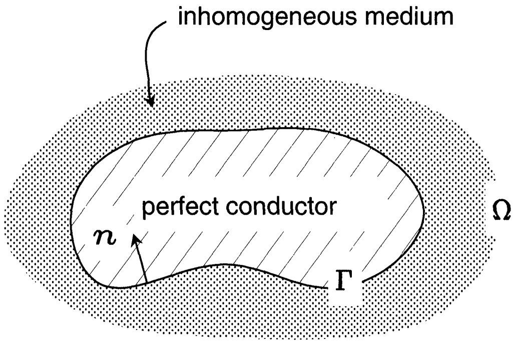

FIG. 2.1. *Scattering by a perfect conductor.*

2. The classical and regularized scattering problems.

2.1. Classical formulation. Let $\Omega \subset \mathbb{R}^3$ be an unbounded connected domain (the complement of a compact set of $\mathbb{R}^3$) with a Lipschitz-continuous boundary Γ. We denote by n the unit outward normal on Γ. The domain Ω is filled by an isotropic medium that may be inhomogeneous in a bounded part of Ω (see Fig. 2.1). Let us mention that the assumption of isotropy is not essential; the same study may be easily extended to anisotropic media.

2.1.1. Maxwell's equations. For a given frequency $\omega > 0$, the electric and magnetic fields E and H satisfy in Ω the time-harmonic Maxwell equations

$$-i\omega \begin{pmatrix} E \\ H \end{pmatrix} = \begin{pmatrix} 0 & \varepsilon^{-1}\operatorname{curl} \\ -\mu^{-1}\operatorname{curl} & 0 \end{pmatrix} \begin{pmatrix} E \\ H \end{pmatrix},$$

where the functions ε and μ are, respectively, the electric permittivity and the magnetic permeability of the medium. By eliminating E or H, Maxwell's equations turn into the second-order equation

$$\operatorname{curl}(\zeta^{-1}\operatorname{curl} U) - \omega^2 \xi\, U = 0 \quad \text{in } \Omega, \tag{2.1}$$

where U denotes either the electric or the magnetic field, and

$$\begin{aligned} \zeta = \mu \quad &\text{and} \quad \xi = \varepsilon \quad \text{if } U = E, \\ \zeta = \varepsilon \quad &\text{and} \quad \xi = \mu \quad \text{if } U = H. \end{aligned} \tag{2.2}$$

In the case of a nondissipative medium, these functions are real and positive. The effect of dissipation is taken into account by adding to ε or μ a positive imaginary part that corresponds to the electric or magnetic conductivity of the medium (see, e.g., [10]). In the present paper, we assume that ζ and ξ are $L^\infty(\Omega)$ complex-valued functions such that

$$\begin{aligned} \mathfrak{Re}\,\zeta(x) \geq \alpha \quad &\text{and} \quad \mathfrak{Im}\,\zeta(x) \geq 0, \\ \mathfrak{Re}\,\xi(x) \geq \alpha \quad &\text{and} \quad \mathfrak{Im}\,\xi(x) \geq 0 \end{aligned} \tag{2.3}$$

almost everywhere in Ω (α is a real positive constant). Moreover, the medium is assumed homogeneous in a vicinity of infinity; we thus suppose that there exists r_0 such that

$$\zeta(x) = \zeta_0 \quad \text{and} \quad \xi(x) = \xi_0 \quad \text{for } \|x\| \geq r_0 > 0. \tag{2.4}$$

Note that outside such a ball, (2.1) simplifies to

$$\operatorname{curl}(\operatorname{curl} U) - k_s^2 U = 0, \quad \text{where } \; k_s = \omega\sqrt{\zeta_0 \xi_0}. \tag{2.5}$$

We use the notation "k_s" because of the similarity with the so-called S-waves in linear elasticity that are characterized by a divergence-free displacement field (since solutions to (2.5) are infinitely differentiable [18], every solution to (2.5) clearly satisfies $\operatorname{div} U = 0$).

Remark 2.1. Assuming the choice of the principal determination for the square root in (2.5), assumptions (2.3) imply that

$$\Re e\, k_s > 0, \qquad \Im m\, k_s \geq 0, \quad \text{and} \tag{2.6}$$

$$k_s \in \mathbb{R}^+ \Leftrightarrow \big(\zeta_0 \in \mathbb{R}^+ \text{ and } \xi_0 \in \mathbb{R}^+\big). \tag{2.7}$$

2.1.2. Boundary conditions. The behavior of U in the vicinity of the perfect conductor depends on whether U represents the electric or the magnetic field. These boundary conditions read classically as

$$U \wedge n = 0 \quad \text{on } \Gamma \;\; \text{(electric boundary condition)} \quad \text{or} \tag{2.8}$$

$$\operatorname{curl} U \wedge n = 0 \quad \text{on } \Gamma \;\; \text{(magnetic boundary condition)}. \tag{2.9}$$

They will be denoted, respectively, by $\mathcal{B}_\infty^E$ and $\mathcal{B}_\infty^H$ in what follows. (The index ∞ refers to the classical Maxwell equation in this paper.)

Remark 2.2. It is well known that the boundary condition $\mathcal{B}_\infty^E$ implies that the quantity $\operatorname{curl} U \cdot n$ vanishes on Γ. On the other hand, the boundary condition $\mathcal{B}_\infty^H$ together with Maxwell's equation (2.1) implies $U \cdot n = 0$ on Γ.

2.1.3. Radiation condition. Since we are concerned with a scattering problem, the field U actually represents the superposition of a given monochromatic incident wave U_I (i.e., a solution to (2.5) in $\mathbb{R}^3$) and an unknown scattered wave U_S, i.e.,

$$U = U_I + U_S. \tag{2.10}$$

The asymptotic behavior of U_S at infinity is specified by means of a radiation condition, which expresses that the energy associated with the scattered wave radiates toward infinity (see §3.2). The expression of this condition depends on k_s (defined in (2.5)):

$$\begin{aligned} &\lim_{R\to\infty} \int_{\Sigma_R} \|\operatorname{curl} U_S \wedge n - ik_s U_S\|^2 \, d\gamma = 0 && \text{if } \Im m\, k_s = 0, \\ &\lim_{R\to\infty} \int_{\Sigma_R} \Big[\|\operatorname{curl} U_S \wedge n\|^2 + |k_s|^2 \, \|U_S\|^2\Big] \, d\gamma = 0 && \text{if } \Im m\, k_s > 0, \end{aligned} \tag{2.11}$$

where $\Sigma_R = \big\{x \in \mathbb{R}^3 \mid \|x\| = R\big\}$. The first condition is the well-known outgoing Silver–Müller radiation condition (see [10] or [18]); the second one is a decay condition for U_S at infinity. They will be referred to as $\mathcal{R}_\infty$ in what follows.

2.1.4. The scattering problems. For a given incident wave U_I (i.e., a given solution to Maxwell's equation (2.5) in the whole space $\mathbb{R}^3$), we consider the two kinds of scattering problems, denoted, respectively, by $\mathcal{P}_\infty^E$ or $\mathcal{P}_\infty^H$ according to the choice of the boundary condition on Γ:

$$(\mathcal{P}_\infty^{E/H}) \qquad \begin{aligned} &\operatorname{curl}(\zeta^{-1} \operatorname{curl} U) - \omega^2 \xi U = 0 \quad \text{in } \Omega, \\ &U \text{ satisfies the boundary condition } \mathcal{B}_\infty^{E/H} \text{ (i.e., (2.8) or (2.9))}, \\ &U_S = U - U_I \text{ satisfies the radiation condition } \mathcal{R}_\infty, \text{ (i.e., (2.11))}. \end{aligned}$$

The aim of the present paper is to show a practical method for solving these problems.

2.2. The regularized formulation. When the medium is homogeneous, there is a close connection between the equations of linear elasticity and Maxwell's equations. If $\mathcal{U}(x,t) = \Re e\left(U(x)e^{-i\omega t}\right)$ is the time-periodic displacement field in a medium with Lamé coefficients λ and μ and density ρ, it satisfies

$$-\sigma_{ij,j}(U) - \omega^2 \rho U = 0, \quad \text{where } \sigma_{ij} = \lambda(\operatorname{div} U)\delta_{ij} + \mu(U_{i,j} + U_{j,i}),$$

which can be written as

$$\mu \operatorname{curl}\,(\operatorname{curl} U) - (\lambda + 2\mu) \operatorname{grad}(\operatorname{div} U) - \omega^2 \rho U = 0.$$

For $\lambda = -2\mu$, this is actually Maxwell's equation (2.5), but even when $\lambda \neq 2\mu$, it is satisfied by any solution to Maxwell's equation since it is divergence-free. For $\mu > 0$ and $\lambda \geq 0$, the above equation is known to be strongly elliptic, which makes it attractive for discretization instead of Maxwell's equations provided that its solution actually is divergence-free.

2.2.1. Regularized equation. The generalization of this remark to nonhomogeneous media leads to

$$\operatorname{curl}(\zeta^{-1} \operatorname{curl} U) - \bar{\xi} \operatorname{grad}(\tau^{-1} \operatorname{div} \xi U) - \omega^2 \xi U = 0, \tag{2.12}$$

where τ is a given function (which has no particular physical meaning as far as electromagnetism is concerned). If τ is assumed to be infinite in the whole domain Ω (i.e., $\tau^{-1} = 0$), this equation reduces to Maxwell's equation (2.1). If τ and τ^{-1} are bounded in Ω, it will be referred to as the "regularized Maxwell equation" in what follows. In the case of a real-valued function ξ, it can be considered as obtained by eliminating E or H in the first-order system

$$-i\omega \begin{pmatrix} E \\ H \\ \varphi \\ \psi \end{pmatrix} = \begin{pmatrix} 0 & \varepsilon^{-1} \operatorname{curl} & \operatorname{grad} \lambda^{-1} & 0 \\ -\mu^{-1} \operatorname{curl} & 0 & 0 & \operatorname{grad} \nu^{-1} \\ \operatorname{div} \varepsilon & 0 & 0 & 0 \\ 0 & \operatorname{div} \mu & 0 & 0 \end{pmatrix} \begin{pmatrix} E \\ H \\ \varphi \\ \psi \end{pmatrix},$$

where $\tau = \lambda$ if $U = E$ and $\tau = \nu$ if $U = H$.

We choose for τ to satisfy conditions similar to (2.3)–(2.4), i.e., $\tau \in L^\infty(\Omega)$ and

$$\Re e\, \tau(x) \geq \alpha > 0 \quad \text{and} \quad \Im m\, \tau(x) \geq 0 \quad \text{a.e. in } \Omega, \quad \text{with} \tag{2.13}$$

$$\tau(x) = \tau_0 \quad \text{for } \|x\| \geq r_0 > 0. \tag{2.14}$$

For sufficiently large $\|x\|$, (2.12) thus simplifies to

$$\operatorname{curl}(\operatorname{curl} U) - t^{-1} \operatorname{grad}(\operatorname{div} U) - k_s^2 U = 0 \quad \text{with } t = \tau_0 \zeta_0^{-1} |\xi_0|^{-2}. \tag{2.15}$$

In what follows, we will assume that either τ satisfies the conditions stated above or $\tau^{-1} = 0$ in Ω (in other words, $\tau \equiv \infty$). In this latter case, (2.12) corresponds to the classical Maxwell equation, and the simplified form (2.15) is merely (2.5) (since $t = \infty$ for $\tau_0 = \infty$).

Just as the notation k_s was related to S-waves in linear elasticity, we denote

$$k_p = k_s \sqrt{t} = \omega \sqrt{\tau_0 / \overline{\xi_0}} \quad \text{if } \tau_0 \neq \infty, \tag{2.16}$$

which corresponds to the wave number of P-waves (i.e., the irrotational displacement fields).

Remark 2.3. As in Remark 2.1, if τ_0 is finite, the assumptions concerning τ and ξ yield

$$\mathfrak{Re}\, k_p > 0, \qquad \mathfrak{Im}\, k_p \geq 0, \quad \text{and} \tag{2.17}$$

$$k_p \in \mathbb{R}^+ \Leftrightarrow \left(\xi_0 \in \mathbb{R}^+ \text{ and } \tau_0 \in \mathbb{R}^+\right). \tag{2.18}$$

2.2.2. Extended boundary conditions. Taking into account the regularizing term in (2.12) leads to an extended expression of the boundary conditions near the perfect conductor. The fact that the regularized equation does not imply the divergence-free condition requires us to complete the classical conditions as follows:

$$U \wedge n = 0, \quad \tau^{-1} \operatorname{div} \xi U = 0 \quad \text{on } \Gamma \quad \text{(electric boundary condition)} \quad \text{or} \tag{2.19}$$

$$\operatorname{curl} U \wedge n = 0, \quad \tau^{-1} U \cdot n = 0 \quad \text{on } \Gamma \quad \text{(magnetic boundary condition)}, \tag{2.20}$$

where the notation $\tau^{-1} \operatorname{div} \xi U = 0$ simply means that we add the condition $\operatorname{div} \xi U = 0$ to the classical electric boundary condition only when the regularized equation is considered (and the same holds for the boundary condition $\tau^{-1} U \cdot n = 0$). These new conditions are denoted in what follows by $\mathcal{B}_\tau^E$ and $\mathcal{B}_\tau^H$, respectively.

2.2.3. Extended radiation conditions. Similar to elasticity, the radiation condition associated with (2.15) (for $t \neq \infty$) involves two relations, respectively, concerning the behavior at infinity of the transverse and radial components of the scattered wave. Their expressions, which depend on k_s and k_p, are

$$\begin{aligned} &\lim_{R\to\infty} \int_{\Sigma_R} \left\| \operatorname{curl} U_S \wedge n - i k_s n \wedge (U_S \wedge n) \right\|^2 d\gamma = 0 && \text{if } \mathfrak{Im}\, k_s = 0, \\ &\lim_{R\to\infty} \int_{\Sigma_R} \left[\left\| \operatorname{curl} U_S \wedge n \right\|^2 + |k_s|^2 \left\| n \wedge (U_S \wedge n) \right\|^2 \right] d\gamma = 0 && \text{if } \mathfrak{Im}\, k_s > 0 \end{aligned} \tag{2.21}$$

and

$$\begin{aligned} &\lim_{R\to\infty} \int_{\Sigma_R} \left| \sqrt{t^{-1}} \operatorname{div} U_S - i k_s\, U_S \cdot n \right|^2 d\gamma = 0 && \text{if } \mathfrak{Im}\, k_p = 0, \\ &\lim_{R\to\infty} \int_{\Sigma_R} \left[\left| t^{-1} \right| \left| \operatorname{div} U_S \right|^2 + |k_s|^2 \left| U_S \cdot n \right| \right] d\gamma = 0 && \text{if } \mathfrak{Im}\, k_p > 0. \end{aligned} \tag{2.22}$$

The conjunction of these two conditions will be denoted by $\mathcal{R}_t$ in what follows.

Remark 2.4. Note that for $t \neq \infty$, the radial radiation condition (2.22) may be written as

$$\begin{aligned} &\lim_{R\to\infty} \int_{\Sigma_R} \left| \operatorname{div} U_S - i k_p\, U_S \cdot n \right|^2 d\gamma = 0 && \text{if } \mathfrak{Im}\, k_p = 0, \\ &\lim_{R\to\infty} \int_{\Sigma_R} \left[\left| \operatorname{div} U_S \right|^2 + |k_p|^2 \left| U_S \cdot n \right|^2 \right] d\gamma = 0 && \text{if } \mathfrak{Im}\, k_p > 0, \end{aligned} \tag{2.23}$$

and for $t = \infty$, it reduces to

$$\lim_{R\to\infty} \int_{\Sigma_R} \left| U_S \cdot n \right|^2 d\gamma = 0. \tag{2.24}$$

By virtue of the relation $\|V\|^2 = \|V \wedge n\|^2 + |V \cdot n|^2$, this latter condition together with the transverse radiation condition (2.21) clearly amounts to (2.11). The formulation (2.21)–(2.22) of $\mathcal{R}_t$ for $t = \infty$ is thus consistent with the classical radiation condition $\mathcal{R}_\infty$.

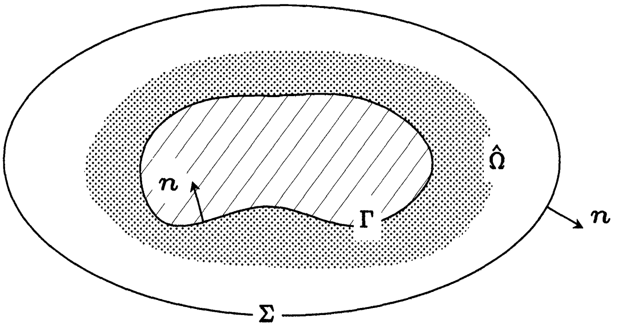

FIG. 2.2.

2.2.4. The new scattering problems. For every function τ that satisfies the assumptions stated above, we thus consider the following problem instead of problem $\mathcal{P}_\infty^{E/H}$:

$$(\mathcal{P}_\tau^{E/H})\quad \begin{array}{c} \operatorname{curl}(\zeta^{-1}\operatorname{curl} U) - \bar{\xi}\operatorname{grad}(\tau^{-1}\operatorname{div}\xi U) - \omega^2\xi U = 0 \quad \text{in } \Omega, \\ U \text{ satisfies the boundary condition } \mathcal{B}_\tau^{E/H} \text{ (i.e., (2.19) or (2.20))}, \\ U_S = U - U_I \text{ satisfies the radiation condition } \mathcal{R}_t \text{ (i.e., (2.21) and (2.22))}, \end{array}$$

where we recall that the incident wave U_I is a solution to Maxwell's equation (2.5) in the whole space $\mathbb{R}^3$. The two cases $\tau \equiv \infty$ and $\tau \in L^\infty(\Omega)$ correspond, respectively, to the classical and regularized equations.

2.3. Functional framework. In this paragraph, we make the exact significance of (2.12) precise as well as the associated functional framework in the classical or regularized situation. The interpretation of (2.12) used in the present paper consists of a weak formulation that involves a function space containing a divergence-free condition. This formulation is unusual as far as the classical Maxwell equation is concerned; we will show that it actually is consistent with the usual interpretation (in the sense of distributions). The main advantage of this formulation will appear in §4. It allows us to express problem $\mathcal{P}_\tau^{E/H}$ as a Fredholm equation.

2.3.1. Weak formulation. Consider the Frechet spaces

$$(2.25)\quad \begin{array}{l} \mathcal{F}_\tau^E(\Omega) = \{V \in H_{\text{loc}}(\text{curl};\Omega) \mid \operatorname{div}\xi V \in L^2_{\text{loc}}(\Omega), \\ \qquad\qquad \operatorname{div}\xi V = 0 \text{ in } \Omega \text{ if } \tau \equiv \infty, \text{ and } V \wedge n = 0 \text{ on } \Gamma\}, \\ \mathcal{F}_\tau^H(\Omega) = \{V \in H_{\text{loc}}(\text{curl};\Omega) \mid \operatorname{div}\xi V \in L^2_{\text{loc}}(\Omega), \\ \qquad\qquad \operatorname{div}\xi V = 0 \text{ in } \Omega \text{ if } \tau \equiv \infty, \text{ and } \xi V \cdot n = 0 \text{ on } \Gamma\}. \end{array}$$

When there is no ambiguity about the domain, we will simply denote these spaces by $\mathcal{F}_\tau^{E/H}$ (the case of a subdomain $\hat{\Omega}$ of Ω is used in Definition 2.5 below). In these spaces, the interpretation of the classical ($\tau \equiv \infty$) or regularized ($\tau \in L^\infty(\Omega)$) Maxwell equation is given by the following statement.

DEFINITION 2.5. *Let Σ be a closed regular surface surrounding the inhomogeneous medium and delimiting a bounded domain $\hat{\Omega} \subset \Omega$ (see Fig. 2.2). A function $U \in \mathcal{F}_\tau^E(\Omega)$ (respectively, $U \in \mathcal{F}_\tau^H(\Omega)$) is said to satisfy* (2.12) *and the electric boundary condition $\mathcal{B}_\tau^E$, i.e.,* (2.19) *(respectively, the magnetic boundary condition $\mathcal{B}_\tau^H$, i.e.,* (2.20)) *if the following conditions hold.*

(i) *In the region where the coefficients ξ, ζ, and τ are constant (in particular outside Σ), U satisfies in the sense of distributions the simplified equation* (2.15).

(ii) *For every field* $V \in \mathcal{F}_\tau^{E/H}(\hat{\Omega})$, *we have*

$$\begin{aligned}(2.26)\qquad &\int_{\hat\Omega} \zeta^{-1} \operatorname{curl} U \cdot \overline{\operatorname{curl} V} + \int_{\hat\Omega} \tau^{-1} \operatorname{div} \xi U \, \overline{\operatorname{div} \xi V} - \omega^2 \int_{\hat\Omega} \xi U \cdot \overline{V} \\ &+ \zeta_0^{-1} \int_\Sigma \operatorname{curl} U \cdot \overline{(V \wedge n)}\, d\gamma - t^{-1} \zeta_0^{-1} \int_\Sigma \operatorname{div} U \, \overline{(V \cdot n)}\, d\gamma = 0.\end{aligned}$$

This definition requires some comments in particular about the boundary integrals in (2.26). Let us first recall the following property about the regularity of U.

PROPOSITION 2.6. *If* $U \in \mathcal{F}_\tau^{E/H}(\Omega)$ *satisfies* (i), *then* U *is infinitely differentiable in the region where the coefficients* ξ, ζ, *and* τ *are constant and satisfies in the strong sense the simplified equation* (2.15).

Proof. This follows from standard results of interior regularity for elliptic equations. □

Remark 2.7. In (2.26), the integrals on Σ should be written as duality products between $H^{1/2}(\Sigma)$ and $H^{-1/2}(\Sigma)$ since $V \wedge n \in H^{-1/2}(\Sigma)^3$, $V \cdot n \in H^{-1/2}(\Sigma)$, and U is regular in the vicinity of Σ (by virtue of Proposition 2.6). For the sake of simplicity, we keep the integral notation.

At first glance, Definition 2.5 may seem intricate. As we will see below, the regularized equation cannot be interpreted in the sense of distributions when ξ is not regular enough (simply because $\mathcal{D}(\Omega)$ is not contained in $\mathcal{F}_\tau^{E/H}$). This explains why we need a weak formulation such as (2.26). The remainder of this section shows that Definition 2.5 agrees with the other possible interpretations of the problem.

2.3.2. Usual formulation in the classical case. The classical Maxwell equation (2.1) is usually interpreted in the sense of distributions. Indeed, for every function $U \in H_{\mathrm{loc}}(\mathrm{curl}; \Omega)$, we can define the distribution $\operatorname{curl}(\zeta^{-1} \operatorname{curl} U) \in \mathcal{D}'(\Omega)^3$ by setting

$$\langle \operatorname{curl}(\zeta^{-1} \operatorname{curl} U), V \rangle = \int_\Omega \zeta^{-1} \operatorname{curl} U \cdot \operatorname{curl} V \quad \forall V \in \mathcal{D}(\Omega)^3.$$

As a consequence, by considering the Frechet spaces

$$\begin{aligned}\mathcal{F}^E(\Omega) &= \{V \in H_{\mathrm{loc}}(\mathrm{curl}; \Omega) \mid V \wedge n = 0 \text{ on } \Gamma\}, \\ \mathcal{F}^H(\Omega) &= H_{\mathrm{loc}}(\mathrm{curl}; \Omega)\end{aligned}$$

that contain $\mathcal{F}_\infty^E(\Omega)$ and $\mathcal{F}_\infty^H(\Omega)$, respectively, defined by (2.25), we are led to a definition that is different from Definition 2.5.

DEFINITION 2.8. *A function* $U \in \mathcal{F}^E(\Omega)$ (*respectively,* $U \in \mathcal{F}^H(\Omega)$) *is said to satisfy the classical Maxwell equation* (2.1) *and the electric boundary condition* $\mathcal{B}_\infty^E$ (*respectively, the magnetic boundary condition* $\mathcal{B}_\infty^H$) *if*

$$(2.27)\qquad \int_\Omega \zeta^{-1} \operatorname{curl} U \cdot \overline{\operatorname{curl} V} - \omega^2 \int_\Omega \xi U \cdot \overline{V} = 0$$

for every field $V \in \mathcal{F}^E(\Omega)$ (*respectively,* $V \in \mathcal{F}^H(\Omega)$) *with compact support.*

Remark 2.9. A function $U \in \mathcal{F}^{E/H}(\Omega)$ that satisfies (2.27) obviously satisfies the divergence-free condition $\operatorname{div} \xi U = 0$ in the sense of distributions. Indeed, taking $V = \operatorname{grad} \overline{\varphi}$ for $\varphi \in \mathcal{D}(\Omega)$ in (2.27) yields

$$(2.28)\qquad \int_\Omega \xi U \cdot \operatorname{grad} \varphi = 0 \quad \forall \varphi \in \mathcal{D}(\Omega)$$

(which can be extended by density to every function $\varphi \in H_0^1(\Omega)$). Note that in the case of the magnetic field, this relation is also valid for every $\varphi \in \mathcal{D}(\overline{\Omega})$ (since $\operatorname{grad}\varphi \in \mathcal{F}^H(\Omega)$). By Green's formula, this implies that $\xi U \cdot n = 0$ on Γ. In short, a function $U \in \mathcal{F}^{E/H}(\Omega)$ that satisfies (2.27) belongs to $\mathcal{F}_\infty^{E/H}(\Omega)$.

Let $U \in \mathcal{F}^{E/H}(\Omega)$ satisfy (2.27). As in Proposition 2.6, we know from interior regularity results that outside the inhomogeneous medium, U is infinitely differentiable. Equation (2.5) is thus satisfied in the strong sense. Consider then the subdomain $\hat{\Omega}$ of Ω defined in Definition 2.5. Using Green's formula outside Σ in (2.27) shows that relation (2.26) (with $\tau \equiv \infty$) is valid for every field $V \in \mathcal{F}^{E/H}(\hat{\Omega})$.

We can now show in the classical case the equivalence between Definitions 2.5 and 2.8, which is a straightforward consequence of the following proposition.

PROPOSITION 2.10. *If $\tau \equiv \infty$, the following statements are equivalent:*

(i) $U \in \mathcal{F}^{E/H}(\Omega)$ *satisfies* (2.26) *for every* $V \in \mathcal{F}^{E/H}(\hat{\Omega})$;

(ii) $U \in \mathcal{F}_\infty^{E/H}(\Omega)$ *satisfies* (2.26) *for every* $V \in \mathcal{F}_\infty^{E/H}(\hat{\Omega})$.

Proof. The fact that (i) $\Rightarrow$ (ii) is obvious. If (i) is satisfied, then U clearly belongs to $\mathcal{F}_\infty^{E/H}(\Omega)$ (see Remark 2.9). The proof of the converse is based on a decomposition of vector fields given in Appendix B. Suppose that $U \in \mathcal{F}_\infty^{E/H}(\Omega)$ satisfies (2.26) for every function $V' \in \mathcal{F}_\infty^{E/H}(\hat{\Omega})$. Let $V \in \mathcal{F}^{E/H}(\hat{\Omega})$; by Lemma B.6 (taking $\mathcal{O} = \hat{\Omega}$ and $F_0 = \Gamma \cup \Sigma$, $F_1 = \emptyset$ if $V \in \mathcal{F}^E(\hat{\Omega})$, or $F_0 = \Sigma$ and $F_1 = \Gamma$ if $V \in \mathcal{F}^H(\hat{\Omega})$), we have

$$V = \operatorname{grad}\varphi + V'$$

where

$$\varphi \in \mathcal{H}^{E/H} \quad \text{with} \quad \begin{cases} \mathcal{H}^E = H_0^1(\hat{\Omega}), \\ \mathcal{H}^H = \left\{\psi \in H^1(\hat{\Omega}) \mid \psi_{|\Sigma} = 0\right\} \end{cases}$$

and $V' \in \mathcal{F}_\infty^{E/H}(\hat{\Omega})$. Since relation (2.26) is assumed to be satisfied for V', we deduce

$$\begin{aligned} \int_{\hat{\Omega}} \zeta^{-1} \operatorname{curl} U \cdot \overline{\operatorname{curl} V} - \omega^2 \int_{\hat{\Omega}} \xi U \cdot \overline{V} + \zeta_0^{-1} \int_\Sigma \operatorname{curl} U \cdot \overline{(V \wedge n)}\, d\gamma \\ = -\omega^2 \int_{\hat{\Omega}} \xi U \cdot \overline{\operatorname{grad}\varphi} + \zeta_0^{-1} \int_\Sigma \operatorname{curl} U \cdot \overline{(\operatorname{grad}\varphi \wedge n)}\, d\gamma. \end{aligned}$$

In the right-hand side of this equality, the integral on Σ vanishes since $\operatorname{grad}\varphi \wedge n = 0$ on Σ (see Lemma B.6). The integral on $\hat{\Omega}$ also vanishes; indeed, by Green's formula,

$$\int_{\hat{\Omega}} \xi U \cdot \overline{\operatorname{grad}\varphi} = -\int_{\hat{\Omega}} (\operatorname{div}\xi U)\, \overline{\varphi} + \int_{\Gamma \cup \Sigma} (\xi U \cdot n)\, \overline{\varphi}\, d\gamma,$$

where $\operatorname{div}\xi U = 0$. Moreover, in the case of the electric (respectively, magnetic) field, we have $\varphi = 0$ on $\Gamma \cup \Sigma$ (respectively, $\xi U \cdot n = 0$ on Γ and $\varphi = 0$ on Σ). This completes the proof. □

2.3.3. Some remarks about the regularized situation. Unlike the quantity $\operatorname{curl}(\zeta^{-1} \operatorname{curl} U)$, the term $\bar{\xi} \operatorname{grad}(\tau^{-1} \operatorname{div}\xi U)$ cannot be interpreted in the sense of distributions unless the coefficients are regular enough. In particular, if ξ is assumed Lipschitz continuous in Ω, then for every function $U \in H_{\mathrm{loc}}(\operatorname{div};\Omega)$, we can define the distribution $\bar{\xi} \operatorname{grad}(\tau^{-1} \operatorname{div}\xi U) \in \mathcal{D}'(\Omega)^3$ by the relation

$$\langle \bar{\xi} \operatorname{grad}(\tau^{-1} \operatorname{div}\xi U), V \rangle = -\int_\Omega \tau^{-1} \operatorname{div}\xi U \operatorname{div}\bar{\xi} V \quad \forall V \in \mathcal{D}(\Omega)^3.$$

In this case, Definition 2.5 agrees with this interpretation: since every field $V \in \mathcal{D}(\hat{\Omega})^3$ belongs to $\mathcal{F}_\tau^{E/H}(\hat{\Omega})$, relation (2.26) implies that U satisfies the regularized Maxwell equation (2.12) in Ω in the sense of distributions.

Remark 2.11. Definition 2.5 implies some transmission conditions on a surface of discontinuity of the coefficients. Indeed, the quantities $U \wedge n$ and $\xi U \cdot n$ must be continuous across this boundary for $\operatorname{curl} U \in L^2_{\text{loc}}(\Omega)$ and $\operatorname{div} \xi U \in L^2_{\text{loc}}(\Omega)$. Moreover, if this boundary is $C^{1,1}$ and if ξ is Lipschitz continuous on both sides, it is readily seen that the quantity $\zeta^{-1} \operatorname{curl} U \wedge n + n \tau^{-1} \operatorname{div} \xi U$ (defined in $H^{-1/2}$ by means of Green's formula) is also continuous.

2.4. Equivalence between the classical and regularized problems.

Let $U \in \mathcal{F}_\infty^{E/H}$ be a solution of the classical scattering problem $\mathcal{P}_\infty^{E/H}$. For every function τ that satisfies the assumptions stated in §2.2, U belongs to $\mathcal{F}_\tau^{E/H}$ and satisfies in the sense of Definition 2.5 the regularized Maxwell equation as well as the boundary conditions $\mathcal{B}_\tau^{E/H}$ (see Proposition 2.10). Moreover, the associated scattered wave $U_S = U - U_I$ clearly satisfies the transverse and radial radiation conditions $\mathcal{R}_t$ since $\operatorname{div} U_I = 0$. This shows that every solution to the classical scattering problem $\mathcal{P}_\infty^{E/H}$ is also a solution to problem $\mathcal{P}_\tau^{E/H}$ (for the same incident wave).

The aim of the present paper is to prove the converse of this statement and to present a convenient method for its numerical solution. More precisely, by adding some suitable conditions on the coefficients ξ, ζ, and τ (which ensure the uniqueness of the solution to $\mathcal{P}_\tau^{E/H}$ (see §3.1)), we will prove the following result.

THEOREM 2.12. *Let ξ, ζ, and τ be chosen such that $\mathcal{P}_\tau^{E/H}$ admits at most one solution. Let U_I be a given divergence-free incident wave, i.e., a solution to Maxwell equation* (2.5) *in the whole space* $\mathbb{R}^3$.

(i) *The scattering problem $\mathcal{P}_\tau^{E/H}$ has exactly one solution in $\mathcal{F}_\tau^{E/H}$.*

(ii) *This solution does not depend on τ.*

The last statement actually amounts to saying that the solution to $\mathcal{P}_\tau^{E/H}$ satisfies the divergence-free condition $\operatorname{div} \xi U = 0$ in Ω. It is a straightforward consequence of the well-posedness of $\mathcal{P}_\tau^{E/H}$ (i.e., point (i)) and the fact that a solution to $\mathcal{P}_\infty^{E/H}$ is also a solution to $\mathcal{P}_\tau^{E/H}$. The remainder of the paper consists of proving (i).

3. Uniqueness.

The aim of this section is to prove that for every function τ, problem $\mathcal{P}_\tau^{E/H}$ has at most one solution. By linearity, this amounts to proving that if the incident wave vanishes, the only solution to $\mathcal{P}_\tau^{E/H}$ is 0.

3.1. Some restrictions for uniqueness.

Thus far, we did not make any assumption regarding the regularity of the coefficients ξ, ζ, and τ (they were just assumed bounded). In this general framework, the uniqueness of the solution to problem $\mathcal{P}_\tau^{E/H}$ cannot be ensured. We thus have to add some restrictive conditions that allow us to prove uniqueness. These assumptions depend on whether the coefficients are real-valued or not.

More precisely, we will suppose in this section that the domain Ω can be decomposed as shown in Fig. 3.1 into several disjointed (and nonempty) open sets $\{\Omega_n \mid n = \overline{0,N}\}$ with piecewise $C^{1,1}$ boundaries; Ω then appears as the interior of $\bigcup_{n=\overline{0,N}} \overline{\Omega_n}$ (where $\overline{\Omega_n}$ denotes the closure of Ω_n). For the convenience of the presentation (and because of the particular role of infinity), we define one of these sets, say Ω_0, to be the exterior of a ball containing all the inhomogeneities. In addition to the hypotheses stated in §2, we will assume that in every subdomain Ω_n, each of the

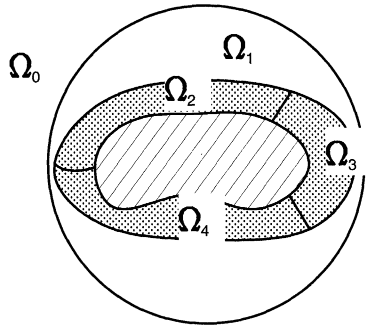

FIG. 3.1. *Decomposition of Ω into subdomains.*

coefficients ξ, ζ, and τ satisfies one of the following conditions.

1. Its restriction to Ω_n is real-valued and defines a Lipschitz-continuous function in Ω_n.

2. Its restriction to Ω_n is a Lipschitz-continuous complex-valued function whose imaginary part is positive almost everywhere in Ω_n.

3. An exceptional condition for τ only: $\tau \equiv \infty$ in the whole domain Ω.

Of course, these conditions can be satisfied independently by each coefficient; in a given subdomain Ω_n, ξ may satisfy 1 whereas ζ satisfies 2 and τ satisfies 3.

Let us mention that the assumption concerning the Lipschitz regularity in the second condition may be removed for the coefficients ζ and τ but not for ξ (since it is involved in the definition of the function space $\mathcal{F}_\tau^{E/H}$).

Our purpose now is to prove the following uniqueness result.

THEOREM 3.1. *Let ξ, ζ, and τ satisfy the hypotheses stated above. If $U \in \mathcal{F}_\tau^{E/H}$ is a solution to $\mathcal{P}_\tau^{E/H}$ with no incident wave (i.e., $U_I \equiv 0$), then $U \equiv 0$.*

The main tools for the proof of this statement are on one hand the energy conservation law presented in §3.2 and on the other hand some results concerning the unique continuation principle for elliptic (or subelliptic) equations. The detailed proof is given in §§3.3 and 3.4.

3.2. Energy flux and radiation conditions. Let $R > 0$ be chosen such that the coefficients ξ, ζ, and τ are constant outside $\Sigma_R = \{x \in \mathbb{R}^3 \mid \|x\| = R\}$. We denote $\hat{\Omega}_R = \{x \in \Omega \mid \|x\| < R\}$. Let $U \in \mathcal{F}_\tau^{E/H}$ satisfy (2.12) and the boundary condition $\mathcal{B}_\tau^{E/H}$ (in the sense of Definition 2.5). By taking the imaginary part of (2.26) with $V = \bar{U}$, $\Sigma = \Sigma_R$, and $\hat{\Omega} = \hat{\Omega}_R$, we obtain

$$\mathcal{F}_R(U) + \mathcal{J}_R(U) = 0, \quad \text{where} \tag{3.1}$$

$$\mathcal{F}_R(U) = \mathcal{F}_R^s(U) + \mathcal{F}_R^p(U) \quad \text{with} \tag{3.2}$$

$$\mathcal{F}_R^s(U) = -\mathfrak{Im}\left\{\zeta_0^{-1} \int_{\Sigma_R} \operatorname{curl} U \cdot \overline{(U \wedge n)}\, d\gamma\right\}, \tag{3.3}$$

$$\mathcal{F}_R^p(U) = \mathfrak{Im}\left\{t^{-1}\zeta_0^{-1} \int_{\Sigma_R} \operatorname{div} U\, \overline{(U \cdot n)}\, d\gamma\right\}, \quad \text{and} \tag{3.4}$$

$$\mathcal{J}_R(U) = \mathfrak{Im} \int_{\hat{\Omega}_R} \left[\omega^2 \xi \|U\|^2 - \zeta^{-1} \|\operatorname{curl} U\|^2 - \tau^{-1} |\operatorname{div} \xi U|^2\right]. \tag{3.5}$$

For the classical Maxwell equation ($\tau \equiv \infty$), $\mathcal{F}_R(U)$ and $\mathcal{J}_R(U)$, respectively, represent (up to a factor $(2\omega)^{-1}$) the mean outgoing energy flux (per time period) through the boundary Σ_R and the energy loss by Joule effect in $\hat{\Omega}_R$. Equation (3.1) stands for energy conservation. We keep the same terminology for the regularized formulation.

The radiation conditions allow us to express the energy flux at infinity as follows.

LEMMA 3.2. *If U satisfies the outgoing radiation conditions* (2.21) *and* (2.22), *then the outgoing energy flux at infinity is given by*

$$\lim_{R\to\infty} \mathcal{F}_R(U) = \mathcal{F}^s_\infty(U) + \mathcal{F}^p_\infty(U),$$

where $\mathcal{F}^s_\infty$ if $\mathfrak{Im}\, k_s = 0$ is defined as

$$\mathcal{F}^s_\infty(U) = \frac{1}{2k_s\zeta_0} \lim_{R\to\infty} \int_{\Sigma_R} \left\{ \|\operatorname{curl} U \wedge n\|^2 + |k_s|^2 \, \|n \wedge (U \wedge n)\|^2 \right\} d\gamma$$

and $\mathcal{F}^s_\infty(U) = 0$ otherwise. Similarly, if $t \neq 0$ and $\mathfrak{Im}\, k_p = 0$, then $\mathcal{F}^p_\infty(U)$ reads

$$\mathcal{F}^p_\infty(U) = \frac{1}{2tk_p\zeta_0} \lim_{R\to\infty} \int_{\Sigma_R} \left\{ |\operatorname{div} U|^2 + |k_p|^2 \, |U \cdot n|^2 \right\} d\gamma;$$

otherwise, $\mathcal{F}^p_\infty(U) = 0$.

Proof. If k_s is real (respectively, $t \neq \infty$ and $k_p \in \mathbb{R}^+$), this follows from the radiation conditions and the formulas

$$\begin{aligned} \|\operatorname{curl} U \wedge n - ik_s\, n \wedge (U \wedge n)\|^2 &= \|\operatorname{curl} U \wedge n\|^2 + |k_s|^2 \, \|n \wedge (U \wedge n)\|^2 \\ &\quad + 2k_s \,\mathfrak{Im}\{\operatorname{curl} U \cdot \overline{(U \wedge n)}\}, \\ |\operatorname{div} U - ik_p\, U \cdot n|^2 &= |\operatorname{div} U|^2 + |k_p|^2 \, |U \cdot n|^2 - 2k_p \,\mathfrak{Im}\{\operatorname{div} U\, \overline{(U \cdot n)}\}. \end{aligned}$$

If $\mathfrak{Im}\, k_s \neq 0$ (or $\mathfrak{Im}\, k_p \neq 0$, or $t = \infty$), this result readily follows from the radiation conditions using the Schwarz inequality. □

PROPOSITION 3.3. *If $U \in \mathcal{F}^{E/H}_\tau$ is a solution to problem $\mathcal{P}^{E/H}_\tau$ with $U_I \equiv 0$, then*

$$\lim_{R\to\infty} \mathcal{F}_R(U) = \lim_{R\to\infty} \mathcal{J}_R(U) = 0. \tag{3.6}$$

Proof. First notice that $\mathcal{J}_R(U)$ is a nonnegative and nondecreasing function of R. Moreover, by Lemma 3.2, $\lim_{R\to\infty} \mathcal{F}_R(U)$ is also nonnegative. The conclusion follows from relation (3.1). □

A straightforward. consequence of this result and of the definition (3.5) of $\mathcal{J}_R$ follows.

COROLLARY 3.4. *For every open subset $\mathcal{O} \subset \Omega$, we have the properties*

$$\mathfrak{Im}\,\xi \geq 0 \quad \text{a.e.} \quad \text{in } \mathcal{O} \quad \Longrightarrow \quad U_{|\mathcal{O}} = 0, \tag{3.7}$$

$$\mathfrak{Im}\,\zeta \geq 0 \quad \text{a.e.} \quad \text{in } \mathcal{O} \quad \Longrightarrow \quad (\operatorname{curl} U)_{|\mathcal{O}} = 0, \tag{3.8}$$

$$\mathfrak{Im}\,\tau \geq 0 \quad \text{a.e.} \quad \text{in } \mathcal{O} \quad \Longrightarrow \quad (\operatorname{div} \xi U)_{|\mathcal{O}} = 0. \tag{3.9}$$

3.3. First step of the proof of Theorem 3.1: The particular case of Ω_0. We prove in this paragraph that *if $U \in \mathcal{F}^{E/H}_\tau$ is a solution to $\mathcal{P}^{E/H}_\tau$ with $U_I \equiv 0$, then U vanishes in Ω_0.*

Recall that Ω_0 is the exterior of a ball containing all the inhomogeneities. In this subdomain, the field U satisfies (see Proposition 2.6)

$$\operatorname{curl}(\operatorname{curl} U) - t^{-1} \operatorname{grad}(\operatorname{div} U) - k_s^2 U = 0. \tag{3.10}$$

First, notice that if $\mathfrak{Im}\,\xi_0 \neq 0$, the result follows from property (3.7). In what follows, we thus assume that ξ_0 is real.

3.3.1. A scalar result. Let us prove that $\operatorname{div} U = 0$ in Ω_0. This is obvious if $\tau_0 = \infty$ (since the condition $\operatorname{div} \xi U = 0$ in Ω is contained in the definition of the space $\mathcal{F}_\tau^{E/H}$). Moreover, if $\mathfrak{Im}\, \tau_0 \neq 0$, this results from property (3.9). Consequently, we suppose below that $\tau_0 \in \mathbb{R}^+$.

Setting $\varphi = \operatorname{div} U$ and taking the divergence of (3.10) yields

$$\Delta\varphi + k_p^2\varphi = 0, \quad \text{where } k_p = \omega\sqrt{\tau_0/\xi_0} \in \mathbb{R}^+.$$

The fact that φ vanishes is based on the following lemma (due to Rellich [21]), which concerns the asymptotic behavior at infinity of the solutions to the Helmholtz equation.

LEMMA 3.5. *Let φ be a solution to equation $\Delta\varphi + k^2\varphi = 0$ outside a sphere Σ_{R_0} of radius R_0 (where k is a positive constant). If φ satisfies the condition*

$$\lim_{R\to\infty} \int_{\Sigma_R} |\varphi|^2 d\gamma = 0, \tag{3.11}$$

then $\varphi \equiv 0$ outside Σ_{R_0}.

From (3.6) and the expression of $\lim_{R\to\infty} \mathcal{F}_R$ given in Lemma 3.2, we see that condition (3.11) is satisfied. As a consequence, $\varphi = \operatorname{div} U$ vanishes in Ω_0.

3.3.2. Back to the vector problem. If $\mathfrak{Im}\, \zeta_0 \neq 0$, property (3.8) implies moreover that $\operatorname{curl} U = 0$ in Ω_0. By (3.10), we deduce that U vanishes. On the other hand, if $\zeta_0 \in \mathbb{R}^+$, the fact that $\operatorname{div} U = 0$ allows us to replace t^{-1} by any other value in (3.10). In particular, by choosing $t = 1$, we see that U satisfies the vector Helmholtz equation

$$\Delta U + k_s^2 U = 0, \quad \text{where } k_s = \omega\sqrt{\zeta_0\xi_0} \in \mathbb{R}^+.$$

And here again, using (3.6) and the expression of $\lim_{R\to\infty} \mathcal{F}_R$ given in Lemma 3.2, we have

$$\lim_{R\to\infty} \int_{\Sigma_R} \|U\|^2 d\gamma = 0$$

by virtue of the relation $\|U\|^2 = \|n \wedge (U \wedge n)\|^2 + |U \cdot n|^2$. (Note that if $\tau_0 = \infty$, the fact that $\lim_{R\to\infty} \int_{\Sigma_R} |U \cdot n|^2 d\gamma = 0$ is contained in the radiation conditions.) We can thus apply Lemma 3.5 to each component of U. The conclusion follows as $U = 0$ in Ω_0.

3.4. Second step of the proof: The other subdomains. To prove that U vanishes in every subdomain Ω_n, $n > 0$, we will use either the results of Corollary 3.4 or a unique continuation technique, which is the object of Proposition 3.6 below, depending on whether the coefficients ξ, ζ, and τ are real-valued or not.

3.4.1. The unique continuation principle. Consider a given subdomain Ω_n $(n > 0)$ of Ω, and suppose that in Ω_n the coefficients ξ, ζ, and τ all satisfy condition 1 given in §3.1. These are Lipschitz-continuous real-valued functions. In this case, we have seen in §2.3 that a solution $U \in \mathcal{F}_\tau^{E/H}$ to $\mathcal{P}_\tau^{E/H}$ satisfies

$$\operatorname{curl}(\zeta^{-1} \operatorname{curl} U) - \xi \operatorname{grad}(\tau^{-1} \operatorname{div} \xi U) - \omega^2 \xi U = 0 \quad \text{in } \Omega_n \tag{3.12}$$

in the sense of distributions. Our aim is to prove the following statement.

PROPOSITION 3.6. *Let ξ, ζ, and τ all satisfy condition* 1 *of* §3.1. *If a solution $U \in \mathcal{F}_\tau^{E/H}$ to* (3.12) *vanishes in a (arbitrary small) ball $B \subset \Omega_n$, then $U = 0$ in the whole domain Ω_n.*

Proof. We first prove that $\operatorname{div} \xi U = 0$ in Ω_n, from which we will be able to deduce that $U \equiv 0$.

(i) Consider the scalar function $\varphi = \tau^{-1} \operatorname{div} \xi U \in L^2(\Omega_n)$. By taking the divergence of (3.12), we see that φ satisfies

$$\operatorname{div}(\xi \operatorname{grad} \varphi) + \omega^2 \tau \varphi = 0 \quad \text{in } \Omega_n$$

in the sense of distributions. From interior regularity for (very weak) solutions to elliptic equations (see, e.g., Nečas [19]), we infer that in every open set $\mathcal{O}$ such that $\overline{\mathcal{O}} \subset \Omega_n$, we have $\varphi_{|\mathcal{O}} \in H^2(\mathcal{O})$. The classical results of unique continuation for second-order elliptic scalar equations (see, e.g., Kenig [11]) then show that if $\varphi = 0$ in a ball $B \subset \Omega_n$, then φ vanishes everywhere in Ω_n. We have thus proved that $\operatorname{div} \xi U \equiv 0$.

(ii) This result implies in particular that U is a solution to the classical Maxwell equation

$$\operatorname{curl}(\zeta^{-1} \operatorname{curl} U) - \omega^2 \xi U = 0 \quad \text{in } \Omega_n. \tag{3.13}$$

To see that U vanishes, we use the strong unique continuation principle proved by Vogelsang [23], who deals with the original first-order system of Maxwell's equations instead of (3.13). By setting, for instance,

$$H = U \quad \text{and} \quad E = \frac{-1}{i\omega\zeta} \operatorname{curl} U,$$

we clearly have

$$\operatorname{curl} E = i\omega\xi H \quad \text{and} \quad \operatorname{curl} H = -i\omega\zeta E,$$

where both fields E and H obviously belong to $H(\operatorname{curl}; \Omega_n)$. To apply [23], we simply have to check that E and H actually belong to $H^1(\mathcal{O})^3$ for every open set $\mathcal{O}$ such that $\overline{\mathcal{O}} \subset \Omega_n$. From [23], we know in this case that if E and H vanish in a ball $B \subset \mathcal{O}$, then they vanish in the whole domain $\mathcal{O}$. To prove that $(E, H) \in H^1(\mathcal{O})^3$, note that $\operatorname{div} \zeta E = 0$ and $\operatorname{div} \xi H = 0$, which shows that E and H also belong to $H(\operatorname{div}; \Omega_n)$ since ζ and ξ are Lipschitz continuous. The conclusion follows from the H^1 interior regularity of functions of $H(\operatorname{curl}) \cap H(\operatorname{div})$ (see [8]). □

3.4.2. End of the proof of Theorem 3.1. We now come back to the general situation where ξ, ζ, and τ satisfy one of the three conditions stated in §3.1. Let Ω_n ($n > 0$) be a given subdomain of Ω. We prove below that *if a solution U to $\mathcal{P}_\tau^{E/H}$ vanishes in some subdomain $\Omega_{n'}$ adjacent to Ω_n, then it also vanishes in Ω_n.* The statement of Theorem 3.1 follows, for we already know that $U = 0$ in Ω_0 (§3.3) and Ω is assumed connected (every subdomain Ω_n is linked to Ω_0 by a path contained in Ω).

(i) First, note that if ξ satisfies condition 2 of §3.1 in Ω_n (i.e., its imaginary part is positive almost everywhere), the result obviously follows from property (3.7). We assume now that ξ is a real-valued and Lipschitz-continuous function (condition 1).

(ii) If τ satisfies condition 2 in Ω_n, we know that $\operatorname{div}\xi U = 0$ in Ω_n (property (3.9)) and, consequently, U satisfies the regularized Maxwell equation (3.12) in Ω_n for any other function τ. The same holds if τ is infinite (condition 3). Therefore, it is enough to deal with the case of condition 1 for τ.

(iii) Similarly, if ζ satisfies condition 2, we know that $\operatorname{curl} U = 0$ in Ω_n, which shows that we can modify (3.12) by replacing ζ by any other function; U will always be a solution to the modified equation. Here again, we can suppose that ζ satisfies condition 1.

(iv) We are finally in the context of Proposition 3.6. Assume that in one of the subdomains adjacent to Ω_n, say $\Omega_{n'}$, the field U vanishes. To apply Proposition 3.6, consider the domain $\tilde{\Omega}_n = \Omega_n \cup B$, where B is a small ball centered at a point of a regular part (i.e., $C^{1,1}$) of $\partial\Omega_n \cap \partial\Omega_{n'}$. Let $\tilde{\xi}$, $\tilde{\zeta}$, and $\tilde{\tau}$ denote, respectively, Lipschitz-continuous (and real-valued) extensions of $\xi_{|\Omega_n}$, $\zeta_{|\Omega_n}$, and $\tau_{|\Omega_n}$ in $\tilde{\Omega}_n$ (these extensions are built for instance by the standard reflection technique). It is then clear that if we replace in $\tilde{\Omega}_n$ these three functions by $\tilde{\xi}$, $\tilde{\zeta}$, and $\tilde{\tau}$, the field U still remains a solution to (3.12) in $\tilde{\Omega}_n$ in the sense of distributions (see Remark 2.11). The statement of Proposition 3.6 then applies in the new subdomain $\tilde{\Omega}_n$. This completes the proof.

4. Existence of a solution.

4.1. The method of coupling by integral representation.

We present in this paragraph the so-called "method of coupling between variational formulation and integral representation," which consists of reducing problem $\mathcal{P}_\tau^{E/H}$ to an equivalent problem set in a bounded domain. This will allow us to use the Fredholm alternative to prove the existence result. The cases of classical or regularized equation are dealt with simultaneously.

Let F be a closed regular surface surrounding the perfect conductor and located in the region where the coefficients ξ, ζ, and τ are constant (see Fig. 4.1). If U is a solution to $\mathcal{P}_\tau^{E/H}$, we know (see Proposition 2.6) that outside F, the scattered wave $U_S = U - U_I$ satisfies the simplified equation

$$\operatorname{curl}(\operatorname{curl} U_S) - t^{-1}\operatorname{grad}(\operatorname{div} U_S) - k_s^2 U_S = 0 \tag{4.1}$$

as well as the radiation condition $\mathcal{R}_t$, i.e., (2.21) and (2.22). We prove in Appendix A (Proposition A.7) that U_S consequently satisfies the following integral representation outside F:

$$\begin{aligned} U_S(x) = &\int_F \mathbb{G}_t(x-y)\left\{\operatorname{curl} U_S(y) \wedge n_y + t^{-1} n_y \operatorname{div} U_S(y)\right\} d\gamma_y \\ &- \int_F (\operatorname{curl}_y \mathbb{G}_t(x-y))\left\{U_S(y) \wedge n_y\right\} d\gamma_y \\ &- t^{-1}\int_F (\operatorname{div}_y \mathbb{G}_t(x-y))^T\left\{U_S(y)\cdot n_y\right\} d\gamma_y, \end{aligned} \tag{4.2}$$

where $\mathbb{G}_t$ is the outgoing Green tensor associated with (4.1) (see Proposition A.1). In what follows, this formula will be written in the form

$$U_S = \mathcal{I}_t[F; U_S] \quad \text{outside } F. \tag{4.3}$$

Notice that since U_I is a solution to

$$\operatorname{curl}(\operatorname{curl} U_I) - k_s^2 U_I = 0 \quad \text{in } \mathbb{R}^3,$$

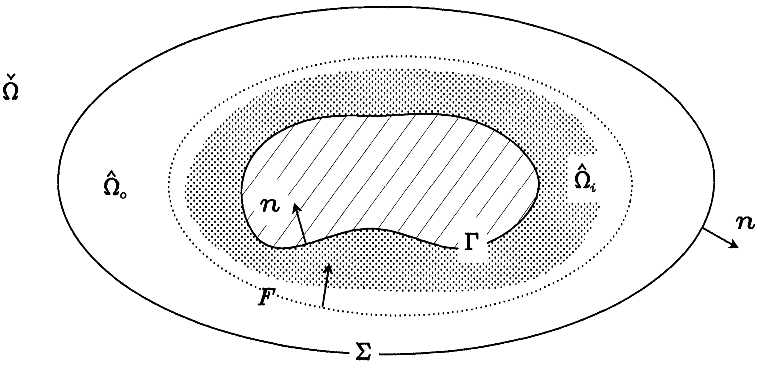

FIG. 4.1. *Reduction to a bounded domain.*

it satisfies in particular (4.1) inside F. We deduce from the integral representation formula in a bounded domain (Proposition A.5) that

$$0 = \mathcal{I}_t[F; U_I] \quad \text{outside } F. \tag{4.4}$$

As a consequence, the integral representation (4.3) can be written in terms of the total field U as

$$U = U_I + \mathcal{I}_t[F; U] \quad \text{outside } F. \tag{4.5}$$

Consider then a closed regular surface Σ surrounding F (and which has no point in common with F). We denote by $\hat{\Omega}$ the bounded part of Ω delimited by Σ, $\hat{\Omega}_i$ and $\hat{\Omega}_o$ the parts of $\hat{\Omega}$ located, respectively, inside and outside F and finally $\check{\Omega}$ the exterior of Σ. The orientation of the unit normal on the surfaces Γ, F, and Σ is shown in Fig. 4.1. Let us define two boundary operators on Σ that involve, respectively, the tangential and normal components of the field as

$$\begin{aligned} T_\lambda U &= \{\operatorname{curl} U \wedge n + \lambda\, n \wedge (U \wedge n)\}_{|\Sigma} \quad \text{and} \\ N_\nu U &= \{\operatorname{div} U + \nu\, U \cdot n\}_{|\Sigma}, \end{aligned} \tag{4.6}$$

where λ and ν are complex parameters. If U is a solution to $\mathcal{P}_\tau^{E/H}$, it clearly satisfies $T_\lambda U = T_\lambda\,(U_I + \mathcal{I}_t[F; U])$ and $N_\nu U = N_\nu\,(U_I + \mathcal{I}_t[F; U])$ by virtue of (4.5). It follows that the restriction $\hat{U}$ of U to $\hat{\Omega}$ is a solution to the problem (set in the bounded domain $\hat{\Omega}$)

$$\begin{gathered} \operatorname{curl}(\zeta^{-1} \operatorname{curl} \hat{U}) - \bar{\xi} \operatorname{grad}(\tau^{-1} \operatorname{div} \xi \hat{U}) - \omega^2 \xi \hat{U} = 0 \quad \text{in } \hat{\Omega}, \\ \hat{U} \text{ satisfies } \mathcal{B}_\tau^{E/H} \quad \text{on } \Gamma, \\ T_\lambda(\hat{U} - \mathcal{I}_t[F; \hat{U}]) = T_\lambda U_I \quad \text{and} \quad t^{-1} N_\nu(\hat{U} - \mathcal{I}_t[F; \hat{U}]) = t^{-1} N_\nu U_I \quad \text{on } \Sigma. \end{gathered} \tag{4.7}$$

Note that in the condition on Σ, called the "coupling condition," the relation that involves N_ν is taken into account only if $t \neq \infty$.

The natural function space associated with this problem is obtained by taking the functions of $\mathcal{F}_\tau^{E/H}(\hat{\Omega})$ that are regular enough in the vicinity of Σ (because of the coupling condition on this surface). We thus define the Hilbert spaces

$$\begin{aligned} \mathcal{H}_\tau^E = \{ & V \in H(\operatorname{curl}; \hat{\Omega}) \mid \operatorname{div} \xi V \in L^2(\hat{\Omega}),\ \operatorname{div} \xi V = 0 \text{ in } \hat{\Omega} \text{ if } \tau \equiv \infty, \\ & (V \wedge n)_{|\Gamma} = 0,\ (V \wedge n)_{|\Sigma} \in L^2(\Sigma)^2 \text{ and } t^{-1}(V \cdot n)_{|\Sigma} \in L^2(\Sigma)\}, \\ \mathcal{H}_\tau^H = \{ & V \in H(\operatorname{curl}; \hat{\Omega}) \mid \operatorname{div} \xi V \in L^2(\hat{\Omega}),\ \operatorname{div} \xi V = 0 \text{ in } \hat{\Omega} \text{ if } \tau \equiv \infty, \\ & (\xi V \cdot n)_{|\Gamma} = 0,\ (V \wedge n)_{|\Sigma} \in L^2(\Sigma)^2 \text{ and } t^{-1}(V \cdot n)_{|\Sigma} \in L^2(\Sigma)\}. \end{aligned} \tag{4.8}$$

To write a variational formulation of problem (4.7) in these spaces, we have to modify the coupling condition on Σ and, more precisely, the expression of the integral representation $\mathcal{I}_t[F;\hat{U}]$. Indeed, the quantity $\mathcal{I}_t[F;V]$ is not defined for every function $V \in \mathcal{H}_\tau^{E/H}$ because of the term $(\operatorname{curl} V \wedge n + t^{-1} n \operatorname{div} V)_{|F}$ whose definition requires an additional condition such as $\operatorname{curl}(\operatorname{curl} V) - t^{-1}\operatorname{grad}(\operatorname{div} V) \in L^2(\hat{\Omega}_o)$ (see Remark A.6). To remove this term, consider a regular right inverse R of the trace operator from $\hat{\Omega}_o$ to F, i.e., a linear operator that maps every regular function φ defined on F onto a regular function $R\varphi$ defined in $\hat{\Omega}_o$ that satisfies $(R\varphi)_{|F} = \varphi$. Suppose in addition that R vanishes on Σ (i.e., $(R\varphi)_{|\Sigma} = 0$ for every φ). Integrating by parts the embarrassing term in (4.2) yields

$$\begin{aligned}\int_F \mathbb{G}_t(x,\cdot)\left\{\operatorname{curl} U_S \wedge n + t^{-1} n \operatorname{div} U_S\right\} d\gamma \\ = -\int_{\hat{\Omega}_o} R\mathbb{G}_t(x,\cdot)\left\{\operatorname{curl}\operatorname{curl} U_S - t^{-1}\operatorname{grad}\operatorname{div} U_S\right\} \\ + \int_{\hat{\Omega}_o}(\operatorname{curl} R\mathbb{G}_t(x,\cdot))\operatorname{curl} U_S + t^{-1}\int_{\hat{\Omega}_o}(\operatorname{div} R\mathbb{G}_t(x,\cdot))^T \operatorname{div} U_S\end{aligned}$$

for x located outside F, where we have denoted $\mathbb{G}_t(x,y) = \mathbb{G}_t(x-y)$. Using the fact that U_S satisfies (4.1) in $\hat{\Omega}_o$, the integral representation (4.2) can be written equivalently as $U_S = \mathcal{I}_t^R[F;U_S]$ outside F, where

$$\begin{aligned}\mathcal{I}_t^R[F;U_S](x) = -k_s^2 \int_{\hat{\Omega}_o} R\mathbb{G}_t(x,\cdot)\, U_S \\ + \int_{\hat{\Omega}_o}(\operatorname{curl} R\mathbb{G}_t(x,\cdot))\operatorname{curl} U_S + t^{-1}\int_{\hat{\Omega}_o}(\operatorname{div} R\mathbb{G}_t(x,\cdot))^T \operatorname{div} U_S \\ - \int_F(\operatorname{curl}\mathbb{G}_t(x,\cdot))\left\{U_S \wedge n\right\} d\gamma - t^{-1}\int_F(\operatorname{div}\mathbb{G}_t(x,\cdot))^T\left\{U_S\cdot n\right\} d\gamma.\end{aligned} \tag{4.9}$$

More generally, for every field U that satisfies (4.1) in $\hat{\Omega}_o$, we clearly have

$$\mathcal{I}_t[F;U] = \mathcal{I}_t^R[F;U] \quad \text{outside } F. \tag{4.10}$$

Substituting this relation in the coupling condition on Σ in (4.7), we are now able to define the reduced problem, denoted by $\hat{\mathcal{P}}_\tau^{E/H}$ in what follows, as

$$(\hat{\mathcal{P}}_\tau^{E/H}) \quad \begin{array}{c}\text{Find } \hat{U} \in \mathcal{H}_\tau^{E/H} \text{ such that} \\ \operatorname{curl}(\zeta^{-1}\operatorname{curl}\hat{U}) - \bar{\xi}\operatorname{grad}(\tau^{-1}\operatorname{div}\xi\hat{U}) - \omega^2\xi\hat{U} = 0 \quad \text{in } \hat{\Omega}, \\ \hat{U} \text{ satisfies } \mathcal{B}_\tau^{E/H} \quad \text{on } \Gamma, \\ T_\lambda(\hat{U} - \mathcal{I}_t^R[F;\hat{U}]) = T_\lambda U_I \quad \text{and} \quad t^{-1}N_\nu(\hat{U} - \mathcal{I}_t^R[F;\hat{U}]) = t^{-1}N_\nu U_I \quad \text{on } \Sigma,\end{array}$$

where we recall that the classical or regularized equation in $\hat{\Omega}$ has to be understood in the sense of Definition 2.5.

4.2. Equivalence between the initial and the reduced problems. The link between the initial problem $\mathcal{P}_\tau^{E/H}$ and the new one $\hat{\mathcal{P}}_\tau^{E/H}$ may be stated as follows.

PROPOSITION 4.1. *Let λ and ν be two complex parameters chosen such that $\mathfrak{Im}(\lambda k_s^{-2}) < 0$ and $\mathfrak{Im}(\nu k_p^{-2}) < 0$ (if $t \neq \infty$). Problem $\mathcal{P}_\tau^{E/H}$ admits at least (respectively, at most) one solution if and only if the same holds for $\hat{\mathcal{P}}_\tau^{E/H}$. Moreover,*

(i) *if U is a solution to $\mathcal{P}_\tau^{E/H}$, then $\hat{U} = U_{|\hat{\Omega}}$ is a solution to $\hat{\mathcal{P}}_\tau^{E/H}$;*

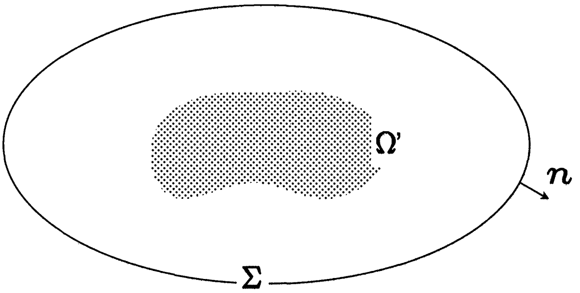

FIG. 4.2.

(ii) *if $\hat{U}$ is a solution to $\hat{\mathcal{P}}_T^{E/H}$, then the field U defined by*

$$U = \hat{U} \quad \textit{in } \hat{\Omega} \quad \textit{and} \quad U = U_I + \mathcal{I}_t[F;\hat{U}] \quad \textit{in } \check{\Omega} \tag{4.11}$$

is a solution to $\mathcal{P}_T^{E/H}$.

Proof. First, note that it is enough to prove the equivalence of $\mathcal{P}_T^{E/H}$ and $\hat{\mathcal{P}}_T^{E/H}$ for the existence of a solution. The equivalence for the uniqueness readily follows using the uniqueness of the continuation of U outside F. (A solution to $\mathcal{P}_T^{E/H}$ that vanishes in a vicinity of F must vanish everywhere outside F by virtue of the integral representation (4.2).)

(i) If U is a solution to $\mathcal{P}_T^{E/H}$, it satisfies by construction the coupling condition on Σ, and consequently $U_{|\hat{\Omega}}$ is a solution to $\hat{\mathcal{P}}_T^{E/H}$ (for every pair $(\lambda,\nu) \in \mathbb{C}^2$).

(ii) Conversely, let $\hat{U}$ be a solution to $\hat{\mathcal{P}}_T^{E/H}$. If $\hat{U}$ matches analytically the function $U_I + \mathcal{I}_t[F;\hat{U}]$ defined in $\check{\Omega}$, then the field U given by (4.11) is clearly a solution to $\mathcal{P}_T^{E/H}$. To prove this analytical matching, we show below that

$$\hat{U} = U_I + \mathcal{I}_t[F;\hat{U}] \quad \text{in } \hat{\Omega}_o.$$

The integral representation of $\hat{U}$ in $\hat{\Omega}_o$ reads (see Proposition A.5)

$$\hat{U} = \mathcal{I}_t[F;\hat{U}] + V \quad \text{in } \hat{\Omega}_o, \quad \text{where } V = \mathcal{I}_t[\Sigma;\hat{U}];$$

we thus have to verify that $V = U_I$ in $\hat{\Omega}_o$. The expression $\mathcal{I}_t[\Sigma;\hat{U}]$ (which is nothing but $\mathcal{I}_t^R[\Sigma;\hat{U}]$ by (4.10)) actually defines a field in the whole domain Ω' located inside Σ (see Fig. 4.2). This field is obviously a solution to

$$\begin{array}{ll} \operatorname{curl}(\operatorname{curl} V) - t^{-1}\operatorname{grad}(\operatorname{div} V) - k_s^2 V = 0 & \text{in } \Omega', \\ T_\lambda V = T_\lambda U_I \quad \text{and} \quad t^{-1}N_\nu V = t^{-1}N_\nu U_I & \text{on } \Sigma. \end{array}$$

To see that U_I is the only solution to this problem, note that its solution for $U_I = 0$ satisfies

$$\int_{\Omega'} \|\operatorname{curl} V\|^2 + t^{-1}\int_{\Omega'} |\operatorname{div} V|^2 - k_s^2 \int_{\Omega'} \|V\|^2 \\ + \lambda \int_\Sigma \|V \wedge n\|^2 d\gamma + t^{-1}\nu \int_\Sigma |V \cdot n|^2 d\gamma = 0,$$

from which we deduce

$$\Im m\, k_s^{-2} \int_{\Omega'} \|\operatorname{curl} V\|^2 + \Im m\, k_p^{-2} \int_{\Omega'} |\operatorname{div} V|^2 \\ + \Im m(\lambda k_s^{-2}) \int_\Sigma \|V \wedge n\|^2 d\gamma + \Im m(\nu k_p^{-2}) \int_\Sigma |V \cdot n|^2 d\gamma = 0,$$

where the terms that involve k_p have to be removed if $t = \infty$. We know that $\mathfrak{Im}\, k_s^{-2} \le 0$ and $\mathfrak{Im}\, k_p^{-2} \le 0$ (see §2). Consequently, if λ and ν are chosen such that $\mathfrak{Im}(\lambda k_s^{-2}) < 0$ and $\mathfrak{Im}(\nu k_p^{-2}) < 0$, we have $V \wedge n = 0$ and $t^{-1} V \cdot n = 0$ on Σ, and thus $\operatorname{curl} V \wedge n = 0$ and $t^{-1} \operatorname{div} V = 0$ on Σ (for $T_\lambda V = 0$ and $t^{-1} N_\nu V = 0$). It follows that V vanishes in Ω' (since $V = \mathcal{I}_t[\Sigma; V]$), which completes the proof. □

4.3. Fredholm alternative: An existence result. Our aim now is to show that problem $\hat{\mathcal{P}}_\tau^{E/H}$ can be written as a Fredholm equation, from which we will be able to deduce that it is well posed. Let us first write a variational formulation of $\hat{\mathcal{P}}_\tau^{E/H}$. By Definition 2.5, it may be easily seen that this problem is equivalent to

$$(4.12) \qquad \begin{array}{c} \text{Find } \hat{U} \in \mathcal{H}_\tau^{E/H} \text{ such that} \\ a_\tau(\hat{U}, V) = l_\tau(V) \quad \forall V \in \mathcal{H}_\tau^{E/H}, \end{array}$$

where $a_\tau(\cdot\,,\cdot)$ is the sesquilinear form defined on $\mathcal{H}_\tau^{E/H} \times \mathcal{H}_\tau^{E/H}$ by

$$\begin{aligned} a_\tau(\hat{U}, V) = & \int_{\hat{\Omega}} \zeta^{-1} \operatorname{curl} \hat{U} \cdot \overline{\operatorname{curl} V} + \int_{\hat{\Omega}} \tau^{-1} \operatorname{div} \xi \hat{U}\, \overline{\operatorname{div} \xi V} \\ & - \omega^2 \int_{\hat{\Omega}} \xi \hat{U} \cdot \overline{V} + \zeta_0^{-1} \int_\Sigma \left\{ \lambda (\hat{U} \wedge n) \cdot \overline{(V \wedge n)} + t^{-1} \nu (\hat{U} \cdot n)\, \overline{(V \cdot n)} \right\} d\gamma \\ & - \zeta_0^{-1} \int_\Sigma \left\{ T_\lambda \mathcal{I}_t^R[F; \hat{U}] \cdot \overline{V} + t^{-1} N_\nu \mathcal{I}_t^R[F; \hat{U}]\, \overline{V \cdot n} \right\} d\gamma, \end{aligned}$$

and $l_\tau(\cdot)$ is the semilinear form given by

$$l_\tau(V) = \zeta_0^{-1} \int_\Sigma \left\{ T_\lambda U_I \cdot \overline{V} + t^{-1} N_\nu U_I\, \overline{V \cdot n} \right\} d\gamma.$$

Consider then the operators $\mathbb{J}_\tau$ and $\mathbb{K}_\tau$ defined on $\mathcal{H}_\tau^{E/H}$ by

$$(4.13) \qquad \begin{aligned} (\mathbb{J}_\tau \hat{U}, V)_{\mathcal{H}_\tau^{E/H}} = & \int_{\hat{\Omega}} \zeta^{-1} \operatorname{curl} \hat{U} \cdot \overline{\operatorname{curl} V} + \int_{\hat{\Omega}} \tau^{-1} \operatorname{div} \xi \hat{U}\, \overline{\operatorname{div} \xi V} \\ & + \omega^2 \xi_0 \int_{\hat{\Omega}} \hat{U} \cdot \overline{V} + \zeta_0^{-1} \int_\Sigma \left\{ \lambda (\hat{U} \wedge n) \cdot \overline{(V \wedge n)} + t^{-1} \nu (\hat{U} \cdot n)\, \overline{(V \cdot n)} \right\} d\gamma \end{aligned}$$

and

$$(4.14) \qquad \begin{aligned} (\mathbb{K}_\tau \hat{U}, V)_{\mathcal{H}_\tau^{E/H}} = & -\omega^2 \int_{\hat{\Omega}} (\xi + \xi_0)\, \hat{U} \cdot \overline{V} \\ & - \zeta_0^{-1} \int_\Sigma \left\{ T_\lambda \mathcal{I}_t^R[F; \hat{U}] \cdot \overline{V} + t^{-1} N_\nu \mathcal{I}_t^R[F; \hat{U}]\, \overline{V \cdot n} \right\} d\gamma, \end{aligned}$$

and let L_τ be the vector of $\mathcal{H}_\tau^{E/H}$ associated with the semilinear form $l_\tau(\cdot)$ by the relation

$$(4.15) \qquad (L_\tau, V)_{\mathcal{H}_\tau^{E/H}} = l_\tau(V) \quad \forall V \in \mathcal{H}_\tau^{E/H}.$$

In these definitions, $(\cdot\,,\cdot)_{\mathcal{H}_\tau^{E/H}}$ denotes the natural scalar product in $\mathcal{H}_\tau^{E/H}$ as

$$(4.16) \qquad \begin{aligned} (U, V)_{\mathcal{H}_\tau^{E/H}} = & \int_{\hat{\Omega}} \{ \operatorname{curl} U \cdot \overline{\operatorname{curl} V} + U \cdot \overline{V} \} + |t^{-1}| \int_{\hat{\Omega}} \operatorname{div} \xi U\, \overline{\operatorname{div} \xi V} \\ & + \int_\Sigma (\hat{U} \wedge n) \cdot \overline{(\hat{V} \wedge n)}\, d\gamma + |t^{-1}| \int_\Sigma (\hat{U} \cdot n)\, \overline{(\hat{V} \cdot n)}\, d\gamma. \end{aligned}$$

The variational formulation (4.12) clearly amounts to the equation

$$(\mathbb{J}_\tau + \mathbb{K}_\tau)\hat{U} = L_\tau \quad \text{in } \mathcal{H}_\tau^{E/H}. \tag{4.17}$$

We are now able to state the main result of this section.

THEOREM 4.2. *Suppose that the coefficients ξ, ζ, and τ satisfy the conditions given in* §3.1. *Let $(\lambda,\nu) \in \mathbb{C}^2$ be chosen such that $\Im m(\lambda k_s^{-2}) < 0$ and $\Im m(\nu k_p^{-2}) < 0$ (if $t \neq \infty$). The reduced problem $\hat{\mathcal{P}}_\tau^{E/H}$ has a unique solution in $\mathcal{H}_\tau^{E/H}$.*

Proof. We prove in §4.4 that $\mathbb{J}_\tau$ and $\mathbb{K}_\tau$ are, respectively, an automorphism and a compact operator in $\mathcal{H}_\tau^{E/H}$. The Fredholm alternative shows that if the only solution to (4.17) with $L_\tau = 0$ is the trivial solution $\hat{U} = 0$, then (4.17) has exactly one solution for every $L_\tau \in \mathcal{H}_\tau^{E/H}$. And the required uniqueness property simply follows from the uniqueness of the solution to problem $\mathcal{P}_\tau^{E/H}$ (Theorem 3.1) and the equivalence between this latter problem and $\hat{\mathcal{P}}_\tau^{E/H}$ for this uniqueness property (Proposition 4.1). □

Remark 4.3. This theorem together with the equivalence between $\mathcal{P}_\tau^{E/H}$ and $\hat{\mathcal{P}}_\tau^{E/H}$ for the existence property (Proposition 4.1) complete the proof of (i) in Theorem 2.12. Problem $\mathcal{P}_\tau^{E/H}$ is well-posed, which implies that its solution is independent of τ (since $\operatorname{div} \xi U = 0$, see §2.4). This shows in particular that the same holds for the solution to $\hat{\mathcal{P}}_\tau^{E/H}$.

4.4. Two technical lemmas. We prove below that operators $\mathbb{J}_\tau$ and $\mathbb{K}_\tau$ given by (4.13) and (4.14) define, respectively, an automorphism and a compact operator in $\mathcal{H}_\tau^{E/H}$.

LEMMA 4.4. *Let $(\lambda,\nu) \in (\mathbb{C}^*)^2$ be chosen such that $\Im m(\lambda k_s^{-2}) < 0$ and $\Im m(\nu k_p^{-2}) < 0$ (if $t \neq \infty$). Then $\mathbb{J}_\tau$ is a bounded invertible operator in $\mathcal{H}_\tau^{E/H}$ with bounded inverse.*

Proof. By virtue of the Lax–Milgram theorem, it is enough to prove that the sesquilinear form associated with $\mathbb{J}_\tau$ in (4.13) is coercive in $\mathcal{H}_\tau^{E/H}$, i.e.,

$$\left|(\mathbb{J}_\tau V, V)_{\mathcal{H}_\tau^{E/H}}\right| \geq \alpha \|V\|^2_{\mathcal{H}_\tau^{E/H}} \quad \forall V \in \mathcal{H}_\tau^{E/H}$$

for some positive constant α. Intuitively, this results from the fact that the functions ζ^{-1}, τ^{-1}, $\omega^2\xi_0$, $\lambda\zeta_0^{-1}$, and $t^{-1}\nu\zeta_0^{-1}$ involved in the different integrals in (4.13) take their values in a sector of the complex plane (with vertex 0) whose opening angle is less than π. More precisely, by dividing these functions by $\omega^2\xi_0$, we infer that there exists $\theta \in]-\pi, 0[$ such that

$$\begin{gathered} \theta \leq \arg(\omega^2\xi_0\zeta)^{-1} \leq 0 \quad \text{a.e.} \quad \text{in } \hat{\Omega}, \\ \theta \leq \arg(\omega^2\xi_0\tau)^{-1} \leq 0 \quad \text{a.e.} \quad \text{in } \hat{\Omega}, \\ \theta \leq \arg(\lambda k_s^{-2}) \leq 0 \quad \text{and} \quad \theta \leq \arg(\nu k_p^{-2}) \leq 0 \quad (\text{if } t \neq \infty). \end{gathered}$$

The two former statements follow from hypotheses (2.3) and (2.13), and the latter from the choice of the parameters λ and ν. By noticing moreover that functions ζ^{-1} and τ^{-1} are bounded from below, we deduce that there exists a positive constant C such that

$$\begin{gathered} \Re e\left\{(\omega^2\xi_0\zeta)^{-1} e^{-i\theta/2}\right\} \geq C \quad \text{a.e.} \quad \text{in } \hat{\Omega}, \\ \Re e\left\{(\omega^2\xi_0\tau)^{-1} e^{-i\theta/2}\right\} \geq C \quad \text{a.e.} \quad \text{in } \hat{\Omega}, \\ \Re e\left\{\lambda k_s^{-2}\, e^{-i\theta/2}\right\} \geq C \quad \text{and} \quad \Re e\left\{\nu k_p^{-2}\, e^{-i\theta/2}\right\} \geq C \quad (\text{if } t \neq \infty). \end{gathered}$$

Hence we have

$$\Re e\left\{(\omega^2\xi_0)^{-1}\, e^{-i\theta/2}\, (\mathbb{J}_\tau V, V)_{\mathcal{H}_\tau^{E/H}}\right\} \ge C\int_{\hat\Omega} \|\operatorname{curl} V\|^2 + C\left|t^{-1}\right| \int_{\hat\Omega} |\operatorname{div} \xi V|^2$$
$$+\cos\theta/2 \int_{\hat\Omega} \|V\|^2 + C\int_\Sigma \|V\wedge n\|^2 d\gamma + C\left|t^{-1}\right|\int_\Sigma |V\cdot n|^2 d\gamma$$

and consequently

$$\Re e\left\{(\omega^2\xi_0)^{-1}\, e^{-i\theta/2} (\mathbb{J}_\tau V, V)_{\mathcal{H}_\tau^{E/H}}\right\} \ge \min(C, \cos\theta/2)\|V\|^2_{\mathcal{H}_\tau^{E/H}}$$

for every $V \in \mathcal{H}_\tau^{E/H}$. The coerciveness of the form follows. □

LEMMA 4.5. *$\mathbb{K}_\tau$ is a compact operator in $\mathcal{H}_\tau^{E/H}$.*

Proof. We study separately the two terms that define operator $\mathbb{K}_\tau$ in (4.14) by writing it as $\mathbb{K}_\tau = -\omega^2\mathbb{K}^{\hat\Omega} - \zeta_0^{-1}\mathbb{K}_\tau^\Sigma$, where

$$(\mathbb{K}^{\hat\Omega} U, V)_{\mathcal{H}_\tau^{E/H}} = \int_{\hat\Omega} (\xi + \xi_0)\; U\cdot \overline{V},$$
$$(\mathbb{K}_\tau^{\Sigma} U, V)_{\mathcal{H}_\tau^{E/H}} = \int_\Sigma \left\{T_\lambda \mathcal{I}_t^R[F;U]\cdot\overline{V} + t^{-1} N_\nu \mathcal{I}_t^R[F;U]\;\overline{V\cdot n}\right\} d\gamma.$$

(i) To see that $\mathbb{K}^{\hat\Omega}$ is compact, first notice from the Schwarz inequality that

$$\left|(\mathbb{K}^{\hat\Omega} U, V)_{\mathcal{H}_\tau^{E/H}}\right| \le C\|U\|_{L^2(\hat\Omega)}\|V\|_{L^2(\hat\Omega)}$$

since $\xi \in L^\infty(\Omega)$. As a consequence, we have

$$\left\|\mathbb{K}^{\hat\Omega} U\right\|_{\mathcal{H}_\tau^{E/H}} = \sup_{V\in\mathcal{H}_\tau^{E/H},\ V\neq 0} \frac{\left|(\mathbb{K}^{\hat\Omega} U, V)_{\mathcal{H}_\tau^{E/H}}\right|}{\|V\|_{\mathcal{H}_\tau^{E/H}}} \le C\|U\|_{L^2(\hat\Omega)}$$

for every $U \in \mathcal{H}_\tau^{E/H}$. Thus $\mathbb{K}^{\hat\Omega}$ appears as a continuous operator from $L^2(\hat\Omega)$ into $\mathcal{H}_\tau^{E/H}$. The conclusion follows from the compactness of the canonical injection from $\mathcal{H}_\tau^{E/H}$ into $L^2(\hat\Omega)$ (see Corollary B.5).

(ii) Let us prove now that $\mathbb{K}_\tau^\Sigma$ is compact. From the definition (4.9) of $\mathcal{I}_t^R[F;U]$, it is easy to see that this function is infinitely differentiable in a vicinity of Σ, and if D denotes any derivative operator on Σ (of any order), we have

$$\left|D\mathcal{I}_t^R[F;U](x)\right| \le C_D\Big(\|\operatorname{curl} U\|_{L^2(\hat\Omega_o)} + \left|t^{-1}\right| \|\operatorname{div} U\|_{L^2(\hat\Omega_o)}$$
$$+\ \|U\|_{L^2(\hat\Omega_o)} + \|U\wedge n\|_{H^{-1/2}(F)} + \left|t^{-1}\right| \|U\cdot n\|_{H^{-1/2}(F)}\Big)$$

at every point $x \in \Sigma$ (C_D is a positive constant which depends on D). We thus have

$$\left|D\mathcal{I}_t^R[F;U](x)\right| \le C_D\|U\|_{\mathcal{H}_\tau^{E/H}} \quad \forall x\in\Sigma.$$

This implies in particular that for every $s\ge 0$,

$$\left\|T_\lambda \mathcal{I}_t^R[F;U]\right\|_{H^s(\Sigma)} \le C_s\|U\|_{\mathcal{H}_\tau^{E/H}},$$

as well as the same inequality for $N_\nu \mathcal{I}_t^R[F;U]$. We deduce from these properties that

$$\left|(\mathbb{K}_\tau^\Sigma U, V)_{\mathcal{H}_\tau^{E/H}}\right| \le C_s\ \|U\|_{\mathcal{H}_\tau^{E/H}}\ \left\|n\wedge(V\wedge n) + t^{-1} n(V\cdot n)\right\|_{H^{-s}(\Sigma)^3}\cdot$$

Hence the adjoint $(\mathbb{K}_\tau^\Sigma)^*$ of operator $\mathbb{K}_\tau^\Sigma$ satisfies

$$\begin{aligned}\left\|(\mathbb{K}_\tau^\Sigma)^* V\right\|_{\mathcal{H}_\tau^{E/H}} &= \sup_{U\in\mathcal{H}_\tau^{E/H},\ U\neq 0} \frac{\left|(\mathbb{K}_\tau^\Sigma U, V)_{\mathcal{H}_\tau^{E/H}}\right|}{\|U\|_{\mathcal{H}_\tau^{E/H}}} \\ &\leq C_s \ \left\|n\wedge(V\wedge n)+t^{-1}n(V\cdot n)\right\|_{H^{-s}(\Sigma)^3}\end{aligned}$$

for every $s\geq 0$. As a consequence, $(\mathbb{K}_\tau^\Sigma)^*$ appears as a continuous operator from $H^{-s}(\Sigma)^3$ into $\mathcal{H}_\tau^{E/H}$. The trace operator $V\to\big(n\wedge(V\wedge n)+t^{-1}n(V\cdot n)\big)_{|\Sigma}$ is obviously continuous from $\mathcal{H}_\tau^{E/H}$ into $L^2(\Sigma)^3$; the compactness of $(\mathbb{K}_\tau^\Sigma)^*$ (and consequently the compactness of $\mathbb{K}_\tau^\Sigma$) then results from the compactness of the canonical injection from $L^2(\Sigma)$ into $H^{-s}(\Sigma)$ (with $s>0$). □

5. Conclusion. Let us first notice that from a theoretical point of view, the method of "coupling between variational formulation and integral representation" described above provides a direct proof for the existence of a solution to the classical scattering problem. Indeed, the separation between the boundary F (on which the integral representation is written) and the boundary Σ (where this integral representation is used) leads to the compactness of the corresponding operator and, consequently, allows us to write the problem as a Fredholm equation. This differs from usual integral techniques (see, e.g., [5], [13]) that deduce the existence result for the classical problem from the existence of a solution to the regularized problem by studying the equations satisfied by the divergence of the field (this requires a sufficient regularity of the electromagnetic coefficients as well as of the boundary of the obstacle). Let us mention two other methods for proving the existence of a solution, which both consist of introducing a sequence of well-posed scattering problems, and studying the limit of their solutions. First, the so-called "limiting absorption principle" applies in the nondissipative case, which actually is considered as the limit of dissipative problems. (Bendali [4] presents this method for the vector Helmholtz equation outside a regular boundary, but it is probably easy to extend it to the case of Maxwell's equations and for irregular boundaries.) Second, the original proof of Abboud [1] is based on a sequence of regular boundaries, which tends to an irregular one.

To a certain extent, our method of regularization of Maxwell equations can be compared with the work of Abboud and Nédélec [2], who obtained an H^1-formulation of the problem (using a series expansion of the field by means of spherical harmonics instead of an integral representation). Their "regularized problem" (which also comes within the context of the Fredholm alternative) is, however, different; in particular, its variational formulation involves a boundary sesquilinear form on every surface of discontinuity of the electromagnetic coefficients (this form depends on the curvature tensor of the surface, which requires regular enough boundaries).

From a numerical point of view, let us recall the two main advantages of the regularized problem compared with the classical one.

(i) On one hand, the integral representations involve a less singular kernel (order 1 instead of 3); our approach agrees with the integral equation technique developed in the case of a regular boundary by Bendali [4]. (The singularity of the kernel is also of order 1 in its integral equation.)

(ii) On the other hand, the approximation of the function spaces appearing in the regularized formulation is a matter for a standard discretization by Lagrange finite elements. Note, however, that one must be careful if the coefficients of the medium or the boundary of the obstacle are irregular. Indeed the spaces to be discretized contain transmission conditions on the surfaces of discontinuity of the coefficients (following from the condition $\operatorname{div}\xi U \in L^2$), which leads us to "split" the degrees of freedom located on these surfaces. Moreover, the solution to the scattering problem may be singular in the vicinity of the singularities of the boundary (for instance, the corners and edges for a piecewise regular boundary). More precisely, this solution can be decomposed (see Costabel [7]) as the sum of a "regular" part (which belongs to H^1 and can thus be approximated by Lagrange finite elements) and a "singular" part (which is orthogonal to H^1 and must be taken into account explicitly).

The numerical implementation of our method is in progress and will be presented in the near future.

Appendix A. Integral representation. We have pointed out in §2.2 the analogy between the regularized Maxwell equation and linear elasticity. Actually, part of the results given in this appendix comes within the classical framework of potential theory in elasticity (see, e.g., Kupradze [14]). However, for the sake of consistency, we present below a complete and concise method of working out the integral representation formulas that are used in the present paper. In §A.1, we exhibit the expression of the Green tensors associated with the classical and regularized equations. Then, in §A.2, we prove an integral representation formula in a bounded domain, using elementary properties of distributions. We finally generalize this formula in §A.3 to the case of an exterior domain.

A.1. The Green tensors. A 3×3 matrix of distributions $\mathbb{G}_t$ is said to be a Green tensor (or a tensor of fundamental solutions) of the classical ($t = \infty$) or the regularized ($0 < t < \infty$) Maxwell equation if

$$\text{(A.1)} \qquad \operatorname{curl}(\operatorname{curl}\mathbb{G}_t) - t^{-1}\operatorname{grad}(\operatorname{div}\mathbb{G}_t) - k_s^2\mathbb{G}_t = \delta\mathbb{I} \quad \text{in } \mathbb{R}^3,$$

where δ denotes the Dirac measure at point $x = 0$ and $\mathbb{I}$ is the identity matrix. In other words, if we denote by $\mathbb{G}_t^{(i)}$ for $i = 1, \dots, 3$ the column vectors of $\mathbb{G}_t$, this amounts to the relations (to be understood in the sense of distributions)

$$\text{(A.2)} \qquad \operatorname{curl}(\operatorname{curl}\mathbb{G}_t^{(i)}) - t^{-1}\operatorname{grad}(\operatorname{div}\mathbb{G}_t^{(i)}) - k_s^2\mathbb{G}_t^{(i)} = \delta x^{(i)}, \quad i = 1, \dots, 3,$$

where $(x^{(1)}, x^{(2)}, x^{(3)})$ is the canonical basis of $\mathbb{R}^3$. Such a Green tensor $\mathbb{G}_t$ is said to be outgoing if each column vector $\mathbb{G}_t^{(i)}$ satisfies the outgoing transverse and radial radiation conditions:

$$\text{(A.3)} \qquad \begin{aligned} &\lim_{R\to\infty} \int_{\Sigma_R} \left\| \operatorname{curl}\mathbb{G}_t^{(i)} \wedge n - ik_s n \wedge (\mathbb{G}_t^{(i)} \wedge n) \right\|^2 d\gamma = 0 && \text{if } \Im m\, k_s = 0, \\ &\lim_{R\to\infty} \int_{\Sigma_R} \left[\left\| \operatorname{curl}\mathbb{G}_t^{(i)} \wedge n \right\|^2 + |k_s|^2 \left\| n \wedge (\mathbb{G}_t^{(i)} \wedge n) \right\|^2 \right] d\gamma = 0 && \text{if } \Im m\, k_s > 0, \end{aligned}$$

$$\text{(A.4)} \qquad \begin{aligned} &\lim_{R\to\infty} \int_{\Sigma_R} \left| \sqrt{t^{-1}} \operatorname{div}\mathbb{G}_t^{(i)} - ik_s\, \mathbb{G}_t^{(i)} \cdot n \right|^2 d\gamma = 0 && \text{if } \Im m\, k_p = 0, \\ &\lim_{R\to\infty} \int_{\Sigma_R} \left[\left|t^{-1}\right| \left| \operatorname{div}\mathbb{G}_t^{(i)} \right|^2 + |k_s|^2 \left| \mathbb{G}_t^{(i)} \cdot n \right| \right] d\gamma = 0 && \text{if } \Im m\, k_p > 0, \end{aligned}$$

where we recall that $k_p = k_s\sqrt{t}$ if $t \neq \infty$.

PROPOSITION A.1. *The outgoing Green tensor $\mathbb{G}_t$ associated with the classical* (*respectively, regularized*) *Maxwell equation is uniquely defined by*

$$\text{(A.5)} \qquad \begin{aligned} \mathbb{G}_\infty &= g_{k_s}\mathbb{I} + k_s^{-2}\operatorname{Hess} g_{k_s}, \\ \mathbb{G}_t &= g_{k_s}\mathbb{I} + k_s^{-2}\operatorname{Hess}(g_{k_s} - g_{k_p}) \quad \textit{if } t \neq \infty, \end{aligned}$$

where $\mathbb{I}$ *is the identity matrix,* Hess *stands for the Hessian operator, and* g_k *denotes the function defined on* $\mathbb{R}^3$ *by*

$$g_k(x) = \frac{e^{ik\|x\|}}{4\pi\|x\|}. \tag{A.6}$$

Remark A.2. For every k such that $\Re e\, k > 0$ and $\Im m\, k \geq 0$, function g_k is nothing but the outgoing Green function of operator $-\triangle - k^2$ (see, e.g., Wilcox [26]), i.e., the only function that satisfies

$$-\triangle g_k - k^2 g_k = \delta \;\text{ in } \mathbb{R}^3, \tag{A.7}$$

and the well-known Sommerfeld outgoing radiation condition

$$\begin{aligned} &\lim_{R\to\infty}\int_{\Sigma_R} |\partial_n g_k - ikg_k|^2\, d\gamma = 0 && \text{if } \Im m\, k = 0,\\ &\lim_{R\to\infty}\int_{\Sigma_R} \left[|\partial_n g_k|^2 + |k|^2\, \|g_k\|^2\right] d\gamma = 0 && \text{if } \Im m\, k > 0. \end{aligned} \tag{A.8}$$

Remark A.3. By (A.7) and noticing that $\operatorname{Hess} g_k = \operatorname{grad}\operatorname{div}(g_k\mathbb{I})$, we see that (A.5) can be equivalently expressed as

$$\begin{aligned} \mathbb{G}_\infty &= k_s^{-2}\left(\operatorname{curl}\operatorname{curl}(g_{k_s}\mathbb{I}) - \delta\mathbb{I}\right),\\ \mathbb{G}_t &= k_s^{-2}\left(\operatorname{curl}\operatorname{curl}(g_{k_s}\mathbb{I}) - \operatorname{grad}\operatorname{div}(g_{k_p}\mathbb{I}) - \delta\mathbb{I}\right) \quad \text{if } t \neq \infty\\ &= k_s^{-2}\operatorname{curl}\operatorname{curl}((g_{k_s} - g_{k_p})\mathbb{I}) + tg_{k_p}\mathbb{I}), \end{aligned} \tag{A.9}$$

where the two first formulas may be seen as the decompositions of $\mathbb{G}_\infty$ and $\mathbb{G}_t$ into "S" and "P" waves.

Remark A.4. The singularity of $\mathbb{G}_\infty$ in the vicinity of $x = 0$ is of order 3 (i.e., it has an asymptotic behavior such as $\|x\|^{-3}$). The singularity of $\mathbb{G}_t$ is only of order 1; this is obvious in the particular case $t = 1$ since $\mathbb{G}_1$ is simply the diagonal operator $g_{k_s}\mathbb{I}$).

Proof. We first show that (A.1) has at most one outgoing solution and then that the tensor $\mathbb{G}_t$ given by (A.5) is this solution.

(i) The uniqueness of $\mathbb{G}_t$ follows from the same arguments as those developed in §3.3 for the proof of Theorem 3.1. Indeed, if U is a solution to the homogeneous equation

$$\operatorname{curl}(\operatorname{curl} U) - t^{-1}\operatorname{grad}(\operatorname{div} U) - k_s^2 U = 0$$

in the whole space $\mathbb{R}^3$ and satisfies the radiation conditions (A.3) and (A.4), it may be readily verified that the energy flux at infinity vanishes, which implies $U = 0$. Note that the uniqueness of $\mathbb{G}_\infty$ results from that of $\mathbb{G}_t$ ($t \neq \infty$).

(ii) It may be easily seen that

$$\begin{aligned} \operatorname{curl}\mathbb{G}_\infty = \operatorname{curl}(g_{k_s}\mathbb{I}) \quad &(\text{and} \quad \operatorname{div}\mathbb{G}_\infty = -k_s^{-2}\operatorname{div}(\delta\mathbb{I})),\\ \operatorname{curl}\mathbb{G}_t = \operatorname{curl}(g_{k_s}\mathbb{I}) \quad &\text{and} \quad \operatorname{div}\mathbb{G}_t = t\operatorname{div}(g_{k_p}\mathbb{I}). \end{aligned} \tag{A.10}$$

These relations together with the expressions (A.9) show that $\mathbb{G}_\infty$ and $\mathbb{G}_t$ are solution to (A.1).

(iii) It remains to verify that the column vectors of $\mathbb{G}_\infty$ and $\mathbb{G}_t$ satisfy the radiation conditions. Let $\Sigma_R = \left\{x \in \mathbb{R}^3 \mid \|x\| = R\right\}$, and let n denote the outer unit normal on Σ_R. From (A.10), we deduce that on Σ_R we have

$$\begin{aligned} \operatorname{curl} \mathbb{G}_\infty^{(i)} \wedge n &= d_r g_{k_s}\; n \wedge (x^{(i)} \wedge n) \quad (\text{and } \operatorname{div} \mathbb{G}_\infty^{(i)} = 0), \\ \operatorname{curl} \mathbb{G}_t^{(i)} \wedge n &= d_r g_{k_s}\; n \wedge (x^{(i)} \wedge n) \quad \text{and} \quad \operatorname{div} \mathbb{G}_t^{(i)} = t\, d_r g_{k_p}\; x^{(i)} \cdot n. \end{aligned} \tag{A.11}$$

Moreover, by noticing that for large R

$$d_r g_k(R) = O(R^{-1}) \quad \text{and} \quad d_r^2 g_k(R) = -k^2 g_k(R) + O(R^{-2}),$$

we see that

$$\operatorname{grad} \operatorname{div}(g_k x^{(i)}) = -k^2 g_k\; (x^{(i)} \cdot n) n + O(R^{-2}).$$

Hence, we infer from (A.5) that

$$\begin{aligned} \mathbb{G}_\infty^{(i)} &= g_{k_s}\; n \wedge (x^{(i)} \wedge n) + O(R^{-2}), \\ \mathbb{G}_t^{(i)} &= g_{k_s}\; n \wedge (x^{(i)} \wedge n) + t\, g_{k_p}\; (x^{(i)} \cdot n) n + O(R^{-2}). \end{aligned} \tag{A.12}$$

The conclusion follows from these formulas together with (A.11) and the fact that g_k satisfies the radiation condition (A.8). For instance, if $k_s \in \mathbb{R}^+$, we have

$$\operatorname{curl} \mathbb{G}_t^{(i)} \wedge n - i k_s\; n \wedge (\mathbb{G}_t^{(i)} \wedge n) = (d_r g_{k_s} - i k_s g_{k_s})\; n \wedge (x^{(i)} \wedge n) + O(R^{-2})$$

for $t = \infty$ or $t \neq \infty$, which shows that each $\mathbb{G}_t^{(i)}$ satisfies the transverse radiation condition (A.3). □

A.2. Integral representation in a bounded domain. Let $\mathcal{O}$ be a bounded open set of $\mathbb{R}^3$ with Lipschitz-continuous boundary F. We denote by n the unit outward normal on F and by $\mathcal{O}'$ the exterior of $\mathcal{O}$, i.e., $\mathcal{O}' = \mathbb{R}^3 \setminus \overline{\mathcal{O}}$. Let $U \in H(\text{curl}; \mathcal{O}) \cap H(\text{div}; \mathcal{O})$ be a function that satisfies (in the sense of distributions) the classical ($t = \infty$) or regularized ($t \neq \infty$) Maxwell equation

$$\operatorname{curl}(\operatorname{curl} U) - t^{-1} \operatorname{grad}(\operatorname{div} U) - k_s^2 U = 0 \tag{A.13}$$

in $\mathcal{O}$. Consider the function $\mathcal{U} \in L^2(\mathbb{R}^3)$ defined by $\mathcal{U} = U$ in $\mathcal{O}$ and $\mathcal{U} = 0$ in $\mathcal{O}'$.

PROPOSITION A.5. *In $\mathcal{O} \cup \mathcal{O}'$, the function $\mathcal{U}$ satisfies the integral representation*

$$\begin{aligned} \mathcal{U}(x) = &\int_F \mathbb{G}_t(x-y) \left\{\operatorname{curl} U(y) \wedge n_y + t^{-1} n_y \operatorname{div} U(y)\right\} d\gamma_y \\ &- \int_F (\operatorname{curl}_y \mathbb{G}_t(x-y)) \left\{U(y) \wedge n_y\right\} d\gamma_y \\ &- t^{-1} \int_F (\operatorname{div}_y \mathbb{G}_t(x-y))^T \left\{U(y) \cdot n_y\right\} d\gamma_y \end{aligned} \tag{A.14}$$

(*where the exponent T denotes the transposed of a matrix*).

Note that by virtue of (A.10), this integral representation can be expressed in the form

$$\begin{aligned} \mathcal{U}(x) = &\int_F \mathbb{G}_t(x-y) \left\{\operatorname{curl} U(y) \wedge n_y + t^{-1} n_y \operatorname{div} U(y)\right\} d\gamma_y \\ &- \int_F \operatorname{grad}_y g_{k_s}(x-y) \wedge \left\{U(y) \wedge n_y\right\} d\gamma_y \\ &- \int_F \operatorname{grad}_y g_{k_p}(x-y) \left\{U(y) \cdot n_y\right\} d\gamma_y, \end{aligned} \tag{A.15}$$

where the last integral has to be removed in the case $t = \infty$.

Remark A.6. In these formulas, all the integrals should be written as a duality product between $H^{-1/2}(F)$ and $H^{1/2}(F)$. Indeed, we know from the hypothesis $U \in H(\mathrm{curl}; \mathcal{O}) \cap H(\mathrm{div}; \mathcal{O})$ that the quantities $(U \wedge n)_{|F}$ and $(U \cdot n)_{|F}$ are defined as elements of $H^{-1/2}(F)$ (see, e.g., [8]). Moreover, with the additional condition $\mathrm{curl}(\mathrm{curl}\, U) - t^{-1}\,\mathrm{grad}(\mathrm{div}\, U) \in L^2(\mathcal{O})$ that follows from (A.13), the quantity $(\mathrm{curl}\, U \wedge n + t^{-1} n\, \mathrm{div}\, U)_{|F}$ also appears as a distribution of $H^{-1/2}(\Sigma)$. However, for the sake of simplicity, we retain the integral notation.

Proof. We show below that the integral representation (A.14) is nothing but the convolution between the Green tensor $\mathbb{G}_t$ and the distribution

$$S = \mathrm{curl}(\mathrm{curl}\mathcal{U}) - t^{-1}\,\mathrm{grad}(\mathrm{div}\mathcal{U}) - k_s^2 \mathcal{U} \tag{A.16}$$

whose restriction to $\mathcal{O}$ and $\mathcal{O}'$ is obviously 0 by construction of $\mathcal{U}$; the support of S is thus contained in F.

(i) Let us first prove that

$$\mathcal{U} = \mathbb{G}_t * S, \tag{A.17}$$

where the convolution is defined similarly to the corresponding matrix product, i.e.,

$$(\mathbb{G}_t * S)^{(i)} = \sum_{j=1}^{3} \mathbb{G}_t^{(i,j)} * S^{(j)}.$$

With this definition, it may be easily seen that the operators curl, grad, and div can be expressed as

$$\mathrm{curl}\, V = (\mathrm{curl}\, \delta \mathbb{I}) * V, \quad \mathrm{grad}\, v = (\mathrm{grad}\, \delta) * v, \quad \text{and} \quad \mathrm{div}\, V = (\mathrm{grad}\, \delta)^T * V,$$

and we have the transposition relation $(A * B)^T = B^T * A^T$ (note that $(\mathrm{curl}\, \delta \mathbb{I})^T = -\,\mathrm{curl}\, \delta \mathbb{I}$). We deduce

$$\begin{aligned} &\mathbb{G}_t^T * \left\{\mathrm{curl}(\mathrm{curl}\mathcal{U}) - t^{-1}\,\mathrm{grad}(\mathrm{div}\mathcal{U}) - k_s^2 \mathcal{U}\right\} \\ &\qquad = \left\{\mathrm{curl}(\mathrm{curl}\, \mathbb{G}_t) - t^{-1}\,\mathrm{grad}(\mathrm{div}\, \mathbb{G}_t) - k_s^2 \mathbb{G}_t\right\}^T * \mathcal{U}, \end{aligned}$$

where the right-hand side is nothing but $(\delta \mathbb{I}) * \mathcal{U} = \mathcal{U}$ by virtue of (A.1). Property (A.17) follows.

(ii) The second step consists of calculating the distribution S. For every $V \in \mathcal{D}(\mathbb{R}^3)^3$, we have

$$\langle S, V \rangle = \int_{\mathcal{O}} U \cdot \left\{\mathrm{curl}(\mathrm{curl}\, V) - t^{-1}\,\mathrm{grad}(\mathrm{div}\, V) - k_s^2 V\right\}.$$

Integrating by parts and using the fact that U satisfies Maxwell's equation in $\mathcal{O}$ yields

$$\begin{aligned} \langle S, V \rangle = &\int_F \left\{\mathrm{curl}\, U \wedge n + t^{-1} n\, \mathrm{div}\, U\right\} \cdot V\, d\gamma \\ &+ \int_F \{U \wedge n\} \cdot \mathrm{curl}\, V\, d\gamma - t^{-1} \int_F \{U \cdot n\}\, \mathrm{div}\, V\, d\gamma, \end{aligned}$$

which can be expressed in the form

$$S = \left\{\mathrm{curl}\, U \wedge n + t^{-1} n\, \mathrm{div}\, U\right\} \delta_F + \mathrm{curl}\left\{(U \wedge n)\delta_F\right\} + t^{-1}\,\mathrm{grad}\left\{(U \cdot n)\delta_F\right\}, \tag{A.18}$$

where we denote by $f\delta_F$ the distribution of $\mathcal{D}'(\mathbb{R}^3)$ given by

$$\langle f\delta_F, \varphi \rangle = \int_F f \varphi\, d\gamma \quad \forall \varphi \in \mathcal{D}(\mathbb{R}^3).$$

(iii) Substituting the expression (A.18) of S in (A.17), we finally have

$$\begin{aligned}\mathcal{U} = \mathbb{G}_t * \left\{\operatorname{curl} U \wedge n + t^{-1} n \operatorname{div} U\right\} \delta_F \\ + (\operatorname{curl} \mathbb{G}_t) * \{(U \wedge n)\delta_F\} + t^{-1}(\operatorname{div} \mathbb{G}_t)^T * \{(U \cdot n)\delta_F\}.\end{aligned}$$

Each term of the right-hand side is a convolution between a function that is infinitely differentiable outside 0 and a measure with compact support (on F). Outside the support of this measure, it thus defines an infinitely differentiable function that can be expressed in an integral form (see, e.g., Schwartz [22]); this form is simply the integral representation formula (A.14). □

A.3. The case of an exterior domain. Let $\mathcal{O}$, $\mathcal{O}'$, and F be defined as in the previous section, and let n denote now the unit normal on F oriented toward $\mathcal{O}$. Consider a function $U \in H_{\text{loc}}(\text{curl}; \mathcal{O}') \cap H_{\text{loc}}(\text{div}; \mathcal{O}')$ that satisfies (in the sense of distributions) the classical or regularized Maxwell equation (A.13) in $\mathcal{O}'$. Define the function $\mathcal{U} \in L^2(\mathbb{R}^3)$ by $\mathcal{U} = 0$ in $\mathcal{O}$ and $\mathcal{U} = U$ in $\mathcal{O}'$.

PROPOSITION A.7. *If U satisfies the outgoing radiation conditions* (A.3) *and* (A.4), *then the statement of Proposition* A.5 *holds*; *formulas* (A.14) *or* (A.15) *are still valid.*

The main ingredients of the proof are the integral representation in a bounded domain (Proposition A.5), the uniqueness of the Green tensor (Proposition A.1), and the following lemma.

LEMMA A.8. *Let A, B, and c be three functions defined on the boundary F of $\mathcal{O}$* (*where A and B are vector-valued and c is scalar-valued*). *Then the function $\mathcal{U}$ given by*

$$\begin{aligned}\mathcal{U}(x) = \int_F \mathbb{G}_t(x-y)\, A(y)\, d\gamma_y \\ - \int_F (\operatorname{curl}_y \mathbb{G}_t(x-y))\, B(y)\, d\gamma_y - t^{-1} \int_F (\operatorname{div}_y \mathbb{G}_t(x-y))^T c(y)\, d\gamma_y,\end{aligned} \tag{A.19}$$

satisfies Maxwell's equation (A.13) *separately in $\mathcal{O}$ and $\mathcal{O}'$ as well as the radiation conditions* (A.3) *and* (A.4).

Proof. To see that Maxwell's equation (A.13) is satisfied, just notice that as in the proof of Proposition A.5, the definition (A.19) of $\mathcal{U}$ can be expressed equivalently as

$$\mathcal{U} = \mathbb{G}_t * (A\delta_F) + (\operatorname{curl} \mathbb{G}_t) * (B\delta_F) + t^{-1}(\operatorname{div} \mathbb{G}_t)^T * (c\delta_F),$$

from which we deduce

$$\begin{aligned}&\operatorname{curl}(\operatorname{curl} \mathcal{U}) - t^{-1} \operatorname{grad}(\operatorname{div} \mathcal{U}) - k_s^2 \mathcal{U} \\ &\quad = (\delta\mathbb{I}) * (A\delta_F) + (\operatorname{curl} \delta\mathbb{I}) * (B\delta_F) + t^{-1}(\operatorname{div} \delta\mathbb{I})^T * (c\delta_F) \\ &\quad = A\delta_F + \operatorname{curl}(B\delta_F) + t^{-1} \operatorname{grad}(c\delta_F).\end{aligned}$$

This distribution vanishes outside F.

To see that $\mathcal{U}$ satisfies the radiation conditions, we simply have to exhibit the asymptotic behavior of (A.19) when $\|x\|$ tends to infinity. The conclusion follows from the fact that the columns of $\mathbb{G}_t$ and $\operatorname{curl} \mathbb{G}_t$, as well as $(\operatorname{div} \mathbb{G}_t)^T$ if $t \neq \infty$, satisfy the radiation conditions (the proof of this result, which does not raise any particular difficulty, is left to the reader). □

Proof of Proposition A.7. Let Σ be the boundary of an open ball B whose radius is chosen large enough so that it contains F. Using the simplified notation $\mathcal{U} = \mathcal{I}_t[F; U]$

for the integral representation (A.14), we deduce from Proposition A.5 (applied in the bounded domain $\mathcal{O}' \cap B$) that

$$\mathcal{I}_t[F;U] + \mathcal{I}_t[\Sigma;U] = \begin{cases} U & \text{in } \mathcal{O}' \cap B, \\ 0 & \text{in } \mathcal{O} \cup (\mathbb{R}^3 \setminus \overline{B}). \end{cases} \tag{A.20}$$

We thus have to prove that $\mathcal{I}_t[\Sigma;U] = 0$ in $\mathcal{O}' \cap B$. First notice that from Lemma A.8, $\mathcal{I}_t[\Sigma;U]$ defines a function that satisfies Maxwell's equation separately in B and $\mathbb{R}^3 \setminus \overline{B}$ as well as the radiation conditions. Consider then the function V given by

$$V = \mathcal{I}_t[\Sigma;U] \text{ in } B, \quad \text{and} \quad V = U - \mathcal{I}_t[F;U] \text{ in } \mathbb{R}^3 \setminus \overline{B}.$$

Noticing that in $\mathcal{O}' \cap B$ we have $V = U - \mathcal{I}_t[F;U]$ by virtue of (A.20), we infer that V is regular in the vicinity of Σ. Hence V satisfies Maxwell's equation in the whole space $\mathbb{R}^3$ and the radiation conditions. The uniqueness of $\mathbb{G}_t$ (Proposition A.1) ensures that $V \equiv 0$. □

Appendix B. Compactness results. For the sake of completeness, we sum up in this appendix the compactness results that are available to our knowledge regarding the embedding of

$$H(\operatorname{curl}, \operatorname{div}\xi; \mathcal{O}) = \left\{U \in L^2(\mathcal{O})^3 \;\middle|\; \operatorname{curl} U \in L^2(\mathcal{O})^3 \text{ and } \operatorname{div} \xi U \in L^2(\mathcal{O})\right\}$$

into $L^2(\mathcal{O})$ for a bounded open set $\mathcal{O} \subset \mathbb{R}^3$ and a bounded function ξ.

B.1. Statement of the results and consequences. Let us first point out that the embedding of $H(\operatorname{curl}, \operatorname{div}\xi; \mathcal{O})$ into $L^2(\mathcal{O})$ is not compact; we have to add some boundary condition to ensure compactness. In this paragraph, we assume that $\mathcal{O}$ is a bounded simply connected open set in $\mathbb{R}^3$ with Lipschitz-continuous boundary $\partial\mathcal{O}$. The following result may be found in Costabel [6]; it is related to the case of a constant function ξ.

PROPOSITION B.1. *The embedding of each of the following spaces into $L^2(\mathcal{O})$ is compact:*

$$\left\{U \in H(\operatorname{curl}, \operatorname{div}; \mathcal{O}) \;\middle|\; U \wedge n \in L^2(\partial\mathcal{O})^3\right\}, \tag{B.1}$$

$$\left\{U \in H(\operatorname{curl}, \operatorname{div}; \mathcal{O}) \;\middle|\; U \cdot n \in L^2(\partial\mathcal{O})\right\}. \tag{B.2}$$

These properties can be readily extended to the case of a bounded function ξ with bounded gradient. Indeed, we have in this case $H(\operatorname{curl}, \operatorname{div}\xi; \mathcal{O}) = H(\operatorname{curl}, \operatorname{div}; \mathcal{O})$. The case of a function ξ that is only assumed bounded has been dealt with by Weber [24] for homogeneous boundary conditions, which may be summarized as follows.

PROPOSITION B.2. *Let $\xi \in L^\infty(\mathcal{O})$ such that $\Re e\, \xi > \alpha$ a.e. in $\mathcal{O}$ ($\alpha > 0$ fixed). The embedding of each of the following spaces into $L^2(\mathcal{O})$ is compact:*

$$\{U \in H(\operatorname{curl}, \operatorname{div}\xi; \mathcal{O}) \mid U \wedge n = 0 \text{ on } \partial\mathcal{O}\}, \tag{B.3}$$

$$\{U \in H(\operatorname{curl}, \operatorname{div}\xi; \mathcal{O}) \mid \xi U \cdot n = 0 \text{ on } \partial\mathcal{O}\}. \tag{B.4}$$

In view of these propositions, it seems natural to wonder whether these latter compactness properties hold if we replace the homogeneous boundary conditions by $U \wedge n \in L^2(\partial\mathcal{O})^3$ or $\xi U \cdot n \in L^2(\partial\mathcal{O})$. The answer is given in the following proposition, which is proved in the next paragraph.

PROPOSITION B.3. *Let $\xi \in L^\infty(\mathcal{O})$ such that $\Re e\, \xi > \alpha$ a.e. in $\mathcal{O}$ ($\alpha > 0$ fixed).*

(i) *The embedding of the following space into* $L^2(\mathcal{O})$ *is compact:*

$$\{U \in H(\text{curl}, \text{div}\,\xi; \mathcal{O}) \mid \xi U \cdot n \in L^2(\partial\mathcal{O})\}. \tag{B.5}$$

(ii) *Suppose that* $\partial\mathcal{O}$ *is regular enough so that the following* ε*-regularity condition is satisfied for some* $\varepsilon > 0$. *The solution* φ *to*

$$\begin{aligned} \Delta\varphi &= 0 \quad \text{in } \mathcal{O}, \\ \partial_n\varphi &= f \quad \text{on } \partial\mathcal{O} \end{aligned}$$

belongs to $H^{3/2+\varepsilon}(\mathcal{O})/\mathbb{R}$ *for every* $f \in H^{1/2}(\mathcal{O})$ *such that* $\int_{\partial\mathcal{O}} f\,d\gamma = 0$. *Then the embedding of*

$$\{U \in H(\text{curl}, \text{div}\,\xi; \mathcal{O}) \mid U \wedge n \in L^2(\partial\mathcal{O})^3\} \tag{B.6}$$

into $L^2(\mathcal{O})$ *is compact.*

Remark B.4. In case (ii), the boundary $\partial\mathcal{O}$ must be more regular than Lipschitz continuous. For instance, we can choose a surface of class $C^{1,1}$ since a solution to the Laplace equation with a $H^{1/2}(\partial\mathcal{O})$ normal derivative belongs in this case to $H^2(\mathcal{O})$.

As we will see in the proof of Corollary B.5, we can manage without these latter properties for the problem studied in the present paper. However, they become necessary if the boundary condition on the perfect conductor is replaced by an impedance condition.

COROLLARY B.5. *Let* $\mathcal{H}_T^{E/H}$ *be the Hilbert spaces defined in* (4.8), *where the domain* $\hat{\Omega}$ *is assumed to have a Lipschitz-continuous boundary* $\Gamma \cup \Sigma$, *and* $\xi \in L^\infty(\hat{\Omega})$ *satisfies assumptions* (2.3) *and* (2.4). *The embedding of* $\mathcal{H}_T^{E/H}$ *into* $L^2(\hat{\Omega})$ *is compact.*

Proof. Let $\{\mathcal{S}^{(i)} \mid 1 \le i \le I\}$ be a finite family of regular open sets that covers $\overline{\hat{\Omega}}$ (i.e., $\overline{\hat{\Omega}} \subset \bigcup_{1\le i\le I} \mathcal{S}^{(i)}$) such that each $\mathcal{O}^{(i)} = \mathcal{S}^{(i)} \cap \hat{\Omega}$ is a simply connected domain with a Lipschitz-continuous boundary. Suppose that this family is chosen so that no $\mathcal{O}^{(i)}$ contains simultaneously a part of the boundary Σ and a part of the inhomogeneous medium (which is possible because of the assumptions on Σ; see Fig. 4.1). Consider then a partition of unity $\{\alpha^{(i)} \mid 1 \le i \le I\}$ associated with this family, i.e., a family of functions $\alpha^{(i)}$ that satisfy

$$\alpha^{(i)} \in \mathcal{D}(\mathcal{S}^{(i)}), \quad 0 \le \alpha^{(i)} \le 1, \quad \text{and} \quad \sum_{i=1}^{I} \alpha^{(i)} = 1 \quad \text{in } \hat{\Omega}.$$

Let $\{U_k \mid k \in \mathbb{N}\}$ be a bounded sequence of $\mathcal{H}_T^{E/H}$; let us prove that there exists a subsequence of U_k that converges in $L^2(\hat{\Omega})$.

We clearly have $U_k = \sum_{1\le i\le I} \alpha^{(i)} U_k$. Let $U_k^{(i)}$ denote the restriction of $\alpha^{(i)} U_k$ to $\mathcal{O}^{(i)}$. By virtue of the assumptions stated above, it is readily seen that each $\{U_k^{(i)} k \in \mathbb{N}\}$ defines a bounded sequence in one of the spaces given in Propositions B.1 or B.2. Starting for instance with $U_k^{(1)}$, we can extract a subsequence (still denoted by $U_k^{(1)}$) that converges in $L^2(\mathcal{O}^{(1)})$. Going on with the associated subsequence of $U_k^{(2)}$, we can extract from it a subsequence (still denoted by $U_k^{(2)}$) that converges in $L^2(\mathcal{O}^{(2)})$, and so on, in a finite number of steps; the resulting subsequences $U_k^{(i)}$, respectively, converge in $L^2(\mathcal{O}^{(i)})$, which shows that U_k converges in $L^2(\hat{\Omega})$. □

B.2. Proof of Proposition B.3. The presentation of the proof follows the lines of [24]; however, it is shorter since we use some classical decomposition results (given, for instance, in [8]).

We denote by U_k a bounded sequence in (B.5) or (B.6). Our aim is to prove that some subsequence of U_k converges in $L^2(\mathcal{O})$.

B.2.1. Normal boundary conditions. First consider the case of (B.5), that is, $\xi U_k \cdot n$ is bounded in $L^2(\partial\mathcal{O})$. From Lemma B.6 (with $F_0 = \emptyset$ and $F_1 = \partial\mathcal{O}$), we see that U_k has the decomposition $U_k = \operatorname{grad}\varphi_k + W_k$ where $\varphi_k \in H^1(\mathcal{O})/\mathbb{R}$ is defined by

$$\int_{\mathcal{O}} \xi \operatorname{grad}\varphi_k \cdot \overline{\operatorname{grad}\psi} = \int_{\mathcal{O}} \xi U_k \cdot \overline{\operatorname{grad}\psi} \quad \forall \psi \in H^1(\mathcal{O})/\mathbb{R},$$

and W_k is such that

$$\operatorname{curl} W_k = \operatorname{curl} U_k, \quad \operatorname{div} \xi W_k = 0, \quad \text{and} \quad (\xi W_k \cdot n)_{|\partial\mathcal{O}} = 0.$$

Let us prove separately that some subsequences of $\operatorname{grad}\varphi_k$ and W_k converge in $L^2(\mathcal{O})$.

(i) Set $U_{lk} = U_l - U_k$ and $\varphi_{lk} = \varphi_l - \varphi_k$. From the definition of φ_k, we readily have (integrating by parts)

$$\int_{\mathcal{O}} \xi \left\|\operatorname{grad}\varphi_{lk}\right\|^2 = \int_{\mathcal{O}} \xi U_{lk} \cdot \overline{\operatorname{grad}\varphi_{lk}} = -\int_{\mathcal{O}} \operatorname{div}(\xi U_{lk})\, \overline{\varphi_{lk}} + \int_{\partial\mathcal{O}} (\xi U_{lk} \cdot n) \overline{\varphi_{lk}}\, d\gamma.$$

As φ_k is bounded in $H^1(\mathcal{O})/\mathbb{R}$, we can extract a subsequence (still denoted φ_k) that converges in $L^2(\mathcal{O})/\mathbb{R}$ and whose trace on $\partial\mathcal{O}$ converges in $L^2(\partial\mathcal{O})/\mathbb{R}$. The convergence of $\operatorname{grad}\varphi_k$ in $L^2(\mathcal{O})$ follows. (Note that we use here the fact that $\xi U_k \cdot n$ is bounded in $L^2(\partial\mathcal{O})$.)

(ii) To deal with W_k, we apply [8, Thm. 3.6, p. 48], which shows the existence of Ψ_k in $H(\operatorname{curl};\mathcal{O})$ such that

$$\operatorname{curl}\Psi_k = \xi W_k, \quad \operatorname{div}\Psi_k = 0, \quad \text{and} \quad (\Psi_k \wedge n)_{|\partial\mathcal{O}} = 0.$$

From Costabel [6, Thm. 2], we deduce that $\Psi_k \in H^{1/2}(\mathcal{O})^3$ and $\left\|\Psi_k\right\|_{H^{1/2}(\mathcal{O})^3} \leq C \left\|\xi W_k\right\|_{L^2(\mathcal{O})^3}$ and thus deduce the existence of a subsequence, still denoted Ψ_k, converging in $L^2(\mathcal{O})^3$. Since

$$\int_{\mathcal{O}} \xi \left\|W_{lk}\right\|^2 = \int_{\mathcal{O}} \operatorname{curl}\Psi_{lk} \cdot \overline{W_{lk}} = \int_{\mathcal{O}} \Psi_{lk} \cdot \overline{\operatorname{curl} W_{lk}}$$

(where $W_{lk} = W_l - W_k$ and $\Psi_{lk} = \Psi_l - \Psi_k$), W_k converges in $L^2(\mathcal{O})^3$.

B.2.2. Tangential boundary conditions. Consider now a sequence U_k bounded in (B.6) ($U_k \wedge n$ is bounded in $L^2(\partial\mathcal{O})$). From Lemma B.6 (with $F_0 = \partial\mathcal{O}$ and $F_1 = \emptyset$), we have the decomposition $U_k = \operatorname{grad}\varphi_k + W_k$, where $\varphi_k \in H_0^1(\mathcal{O})$ is now defined by

$$\int_{\mathcal{O}} \xi \operatorname{grad}\varphi_k \cdot \overline{\operatorname{grad}\psi} = \int_{\mathcal{O}} \xi U_k \cdot \overline{\operatorname{grad}\psi} \quad \forall \psi \in H_0^1(\mathcal{O}),$$

and W_k is such that

$$\operatorname{curl} W_k = \operatorname{curl} U_k, \quad \operatorname{div} \xi W_k = 0, \quad \text{and} \quad (W_k \wedge n)_{|\partial\mathcal{O}} = (U_k \wedge n)_{|\partial\mathcal{O}}.$$

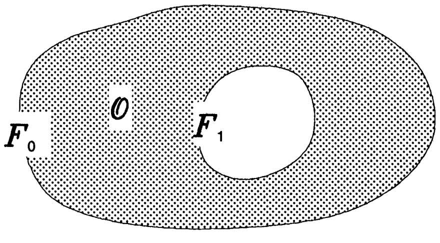

FIG. B.1.

(i) To see that some subsequence of $\operatorname{grad}\varphi_k$ converges in $L^2(\mathcal{O})$, we proceed exactly as above (no boundary term appears in the integration by parts since $\varphi_k = 0$ on $\partial\mathcal{O}$).

(ii) For W_k, we apply [8, Thm. 3.5, p. 47] which shows the existence of Φ_k in $H(\operatorname{curl};\mathcal{O})$ such that

$$\operatorname{curl}\Phi_k = \xi W_k, \quad \operatorname{div}\Phi_k = 0, \quad \text{and} \quad (\Phi_k \cdot n)_{|\partial\mathcal{O}} = 0.$$

Provided $\partial\mathcal{O}$ satisfies the ε-regularity condition, we deduce from Lemma B.8 that $\Phi_k \in H^{1/2+\varepsilon}(\mathcal{O})^3$ and $\|\Phi_k\|_{H^{1/2+\varepsilon}(\mathcal{O})^3} \leq C\,\|\xi W_k\|_{L^2(\mathcal{O})^3}$. Consequently, there exists a subsequence Φ_k converging in $L^2(\mathcal{O})^3$ such that $(\Phi_k \wedge n)_{|\partial\mathcal{O}}$ converges in $L^2(\partial\mathcal{O})^2$. Since

$$\int_{\mathcal{O}} \xi\,\|W_{lk}\|^2 = \int_{\mathcal{O}} \Phi_{lk}\cdot\overline{\operatorname{curl} W_{lk}} + \int_{\partial\mathcal{O}} \Phi_{lk}\cdot\overline{W_{lk}\wedge n}\,d\gamma,$$

the convergence of W_k in $L^2(\mathcal{O})^3$ follows.

B.3. Auxiliary lemmas. The following lemma concerns a decomposition of vector fields that allows adding the divergence-free condition in the function spaces related to the classical Maxwell equation (see §2.3). It is also used for the compactness results shown above.

LEMMA B.6. *Let $\mathcal{O}$ be an open set of $\mathbb{R}^3$ with a Lipschitz-continuous boundary that consists of two disjointed parts F_0 and F_1 as shown in Fig.* B.1 (*where one of them may be $\emptyset$*). *Let $\xi \in L^\infty(\mathcal{O})$ such that $\Re e\,\xi > \alpha$ a.e. in $\mathcal{O}$ ($\alpha > 0$ fixed). Then every function $V \in L^2(\mathcal{O})^3$ has the decomposition*

$$\text{(B.7)}\qquad \begin{gathered} V = \operatorname{grad}\varphi + V' \quad \textit{where} \\ \varphi \in H^1(\mathcal{O}), \quad \varphi = 0 \textit{ on } F_0, \quad \textit{and} \\ V' \in L^2(\mathcal{O})^3, \quad \operatorname{div}\xi V' = 0 \quad \textit{in } \mathcal{O}, \quad \textit{and} \quad \xi V'\cdot n = 0 \quad \textit{on } F_1. \end{gathered}$$

Moreover, $\operatorname{curl} V' = \operatorname{curl} V$ *and* $\operatorname{grad}\varphi \wedge n = 0$ *on* F_0.

Remark B.7. Note that $\xi V' \cdot n$ and $\operatorname{grad}\varphi \wedge n$ are defined, respectively, in $H^{-1/2}(\partial\mathcal{O})$ and $H^{-1/2}(\partial\mathcal{O})^3$ since $\operatorname{div}\xi V' = 0$ and $\operatorname{curl}(\operatorname{grad}\varphi) = 0$.

Proof. Let $\mathcal{H}$ denote the Hilbert space $\{\psi \in H^1(\mathcal{O}) \mid \psi_{|F_0} = 0\}$ if $F_0 \neq \emptyset$ and $\mathcal{H} = H^1(\mathcal{O})/\mathbb{R}$ if $F_0 = \emptyset$. Let V be a given function of $L^2(\mathcal{O})^3$. First, notice that there exists a unique function $\varphi \in \mathcal{H}$ such that

$$\int_{\mathcal{O}} \xi \operatorname{grad}\varphi\cdot\overline{\operatorname{grad}\psi} = \int_{\mathcal{O}} \xi V\cdot\overline{\operatorname{grad}\psi} \quad \forall\psi \in \mathcal{H}.$$

This follows from the Lax–Milgram theorem (by virtue of the assumptions on ξ, the left-hand side of this relation defines a continuous and coercive form in $\mathcal{H}$). In other words, φ is formally the only solution to

$$\begin{aligned} \operatorname{div}(\xi \operatorname{grad} \varphi) &= \operatorname{div} \xi V \quad \text{in } \mathcal{O}, \\ \varphi &= 0 \quad \text{on } F_0, \\ \partial_n \varphi &= V \cdot n \quad \text{on } F_1. \end{aligned}$$

Consider then the function $V' = (V - \operatorname{grad} \varphi) \in L^2(\mathcal{O})^3$ that satisfies by construction of φ the divergence-free condition $\operatorname{div} \xi V' = 0$ (in the sense of distributions) as well as the boundary condition $\xi V' \cdot n = 0$ on F_1. We readily have $\operatorname{curl} V' = \operatorname{curl} V$. It remains to prove that $\operatorname{grad} \varphi \wedge n = 0$ on F_0, which amounts to showing that

$$\int_{\mathcal{O}} \operatorname{grad} \varphi \cdot \operatorname{curl} W = 0$$

for every $W \in \mathcal{D}(\overline{\mathcal{O}})^3$ whose support is localized in a vicinity of F_0 ($W \equiv 0$ near F_1). This property simply follows from Green's formula:

$$\int_{\mathcal{O}} \operatorname{grad} \varphi \cdot \operatorname{curl} W = -\int_{\mathcal{O}} \varphi \operatorname{div}(\operatorname{curl} W),$$

where the boundary integral vanishes since $\varphi = 0$ on F_0. □

The following regularity lemma is derived from Costabel [6].

LEMMA B.8. *Let $\mathcal{O}$ be a simply connected bounded open set satisfying the ε-regularity condition stated in point* (ii) *of Proposition* B.3. *Then the space*

$$\mathcal{V} = \left\{ U \in H(\operatorname{curl}; \mathcal{O}) \,\middle|\, \operatorname{div} U = 0 \;\; \textit{and} \;\; (U \cdot n)_{|\partial\mathcal{O}} = 0 \right\}$$

is embedded in $H^{1/2+\varepsilon}(\mathcal{O})^3$. Moreover, there exists a constant $C > 0$ such that for every $U \in \mathcal{V}$, we have

$$\|U\|_{H^{1/2+\varepsilon}(\mathcal{O})^3} \leq C \|U\|_{\mathcal{V}}.$$

Proof. We proceed exactly as in [6].

(i) Let $U \in \mathcal{V}$. From [8, Thm. 3.4, p. 45], we deduce the existence of $\Phi \in H^1(\mathcal{O})^3$ such that

$$\operatorname{curl} \Phi = \operatorname{curl} U \quad \text{and} \quad \operatorname{div} \Phi = 0.$$

Let $\Psi = U - \Phi$; we have $\Psi \in L^2(\mathcal{O})^3$ with $\operatorname{curl} \Psi = 0$ and by the Stokes theorem [8, Thm. 2.9, p. 31] the existence of $q \in H^1(\mathcal{O})$ such that $\Psi = \operatorname{grad} q$. It follows that q satisfies

$$\begin{aligned} \Delta q &= 0 \quad \text{in } \mathcal{O}, \\ \partial_n q &= -(\Phi \cdot n)_{|\partial\mathcal{O}} \;\in\; H^{1/2}(\partial\mathcal{O}). \end{aligned}$$

By the ε-regularity hypothesis, $q \in H^{3/2+\varepsilon}(\mathcal{O})$, and consequently $U \in H^{1/2+\varepsilon}(\mathcal{O})^3$.

(ii) The estimation follows from the closed graph theorem. We denote by I the identity in $L^2(\mathcal{O})^3$ and by J its restriction to $\mathcal{V}$ considered as an application between $\mathcal{V}$ and $H^{1/2+\varepsilon}(\mathcal{O})^3$. Let (U_n, JU_n) be a sequence that converges in $\mathcal{V} \times H^{1/2+\varepsilon}(\mathcal{O})^3$, say to (U, Y). Considered as a sequence in $L^2(\mathcal{O}) \times L^2(\mathcal{O})$, $(U_n, JU_n) = (U_n, IU_n)$ converges to (U, IU), from which we deduce that $Y = IU = JU$; that is, the graph of J is closed. As a consequence, the natural embedding $\mathcal{V} \longrightarrow H^{1/2+\varepsilon}(\mathcal{O})^3$ is continuous. □

SPECTRAL ANALYSIS OF A MULTISTRATIFIED ACOUSTIC STRIP PART II: ASYMPTOTIC BEHAVIOR OF SOLUTIONS FOR A SIMPLE STRATIFICATION*

ELISABETH CROC† AND YVES DERMENJIAN†

Abstract. We consider the acoustic propagator $A = -\nabla.c^2\nabla$ in $\Omega = \{(x,z) \in \mathbb{R}^2 \; / \; 0 < z < H\}$. The velocity c, which describes the stratification of the strip Ω, depends only on the variable z: it is assumed to be a function in $L^\infty((0,H))$ bounded from below by $c_m > 0$. Let A be the self-adjoint operator associated with the Neumann or Dirichlet condition at $z = 0$ and $z = H$; let μ be a real number in the spectrum of A; and let u be the solutions of the equation $(A - \mu I)u = f$ locally in the domain of A, which are determined by the limiting absorption principle in [E. Croc and Y. Dermenjian, *SIAM J. Math. Anal.*, 26 (1995), pp. 880–924] and made explicit with trace operators. Thanks to accurate Hölder properties for the trace operators, we control the asymptotic behavior of u with so-called "zero-trace" conditions for f.

Key words. stratified medium, acoustic waves, self-adjoint operator, resolvent, limiting absorption principle, bootstrap theorem

AMS subject classifications. 35L05, 35P, 47A70

1. Introduction.

This article is the continuation of [CD95a]. Let us recall the problem: the modeling of a particular seismic problem leads to a scalar wave equation written as

$$(\partial_t)^2 v + Av = S$$

in the strip

$$\Omega = \{(x,z) \in \mathbb{R}^2 \; / \; 0 < z < H\}.$$

The unknown function $v(t,x,z)$ is the displacement in the medium: it is a real-valued function defined for t in $\mathbb{R}$ and (x,z) in Ω.

The spatial operator is the differential operator $A = -\nabla.c^2\nabla = -\partial_x(c^2(x,z)\partial_x) - \partial_z(c^2(x,z)\partial_z)$ acting in Ω. The coefficient $c(x,z)$ characterizes the medium celerity: it is a measurable function in Ω which satisfies $0 < c_m \leq c(x,z) \leq c_M$ for almost every (x,z) in Ω and with some real numbers $c_m, c_M > 0$. Our goal is to deal with media stratified differently according to whether $x < 0$ or $x > 0$: it means that the celerity function is such that $c(x,z) = c_-(z)$ if $x < 0$ and $c(x,z) = c_+(z)$ if $x > 0$.

The right-hand side, $S(t,x,z)$, is a given source. It is a function in $L^2(\Omega)$, the Hilbert space of complex-valued functions defined on Ω which are Lebesgue measurable and square integrable.

The boundary conditions (BC) for the displacement $v(t,x,z)$ are the Neumann or the Dirichlet conditions in $z = 0$ and $z = H$. For instance, geophysical problems lead to the following boundary conditions:

$$c^2 \partial_z v|_{z=0} = 0 \quad \text{and} \quad v|_{z=H} = 0. \tag{1.1}$$

Choosing a constructive stationary approach, we intend to obtain the spectral and scattering theory for the acoustic propagator, that is, the self-adjoint operator

* Received by the editors July 18, 1994; accepted for publication July 24, 1995.

† U.F.R. Mathématiques Informatique Mécanique, Université de Provence, Case V, 3 Place Victor-Hugo, F-13331 Marseille cedex 3, France (ecroc@gyptis.univ-mrs.fr, dermenji@gyptis.univ-mrs.fr).

$(D(A), A)$ acting in $L^2(\Omega)$ that we associate with the problem. The domain $D(A)$ is included in the Sobolev space

$$H^1(\Omega) = \{u \in L^2(\Omega) \;/\; \partial_x u,\ \partial_z u \in L^2(\Omega)\}$$

and is equal to

$$D(A) = \{u \in H^1(\Omega) \;/\; -\nabla.c^2\nabla u \in L^2(\Omega),\ u \text{ satisfies (BC)}\}. \tag{1.2}$$

We call free or unperturbed problem the case where the strip is only stratified in the z direction. Therefore, the celerity c is a function of the single variable z in $(0, H)$ such that $c_-(z) = c_+(z) = c(z)$. The free differential operator is written as

$$A = -c^2(z)(\partial_x)^2 - \partial_z(c^2(z)\partial_z). \tag{1.3}$$

A particular case that could serve as a typical problem is the case of a two-valued function

$$c(z) = c_1 \quad \text{if } 0 < z < h \quad \text{and} \quad c(z) = c_2 \quad \text{if } h < z < H \tag{1.4}$$

with $0 < h < H$ and $0 < \text{Min}(c_1, c_2)$. More generally, we consider a celerity $c(z)$ which satisfies the assumption

$$c \in L^\infty((0, H)) \quad \text{and} \quad \text{Min}\, c(z) \geq c_m > 0. \tag{H}$$

In [CD95a], we developed an explicit spectral analysis of the free operator (1.2)–(1.3) with boundary conditions (1.1) or (BC), and then we deduced a limiting absorption principle for the resolvent operator $R_A(\mu + i\varepsilon) = (A - (\mu + i\varepsilon)I)^{-1}$ when ε goes to 0 and μ is in the spectrum of A.

In this article, the results concern $u^\pm = R_A^\pm(\mu)f$, the solutions of the equation $(A - \mu I)u = f$ which are obtained with an appropriate f by this limiting absorption principle. The article is organized as follows.

In §2, we fix our notation and recall the results of [CD95a]. Then we present our main results. These are the so-called division or bootstrap theorems (Theorems 2.1 and 2.2) for the free operator (1.2)–(1.3) under assumption (H). Under some assumptions on the function f, these division theorems specify the asymptotic behavior of $u^\pm$ when (x, z) tends to infinity in Ω. Moreover, the stated and used results allow us to again visit the limiting absorption principle at thresholds (Theorem 2.3).

In §3, we look for the basic estimates needed to prove the previous theorems. These estimates are essentially derived from Agmon's results, specifically from Lemma B.2 of [A]. They concern the terms that arise in the explicit formula of the resolvent and rely on a thorough study of trace operators. On one hand, we state Sobolev properties and differentiability (see Propositions 3.2–3.5) of the generalized Fourier coefficients (equation (2.5) in §2) of a function in $L^2(\Omega)$. These coefficients are associated with the spectral representation of A obtained in [CD95a]. On the other hand, we collect some Hölder estimates (see Propositions 3.8 and 3.9) scattered throughout [CD95a] and based on Theorem 3.7. Finally, we use [A, Lem. B.2] and Corollary 3.1 to state new estimates (see Propositions 3.10 and 3.11).

In §4, we complete the proofs of Theorems 2.1 and 2.2. We use the limiting absorption principles from [CD95a], called LAP1 and LAP2.

In §5, we prove Theorem 2.3, also called LAP3. The thresholds are the eigenvalues $\lambda(0, m)$, $m \geq 1$ (see equation (2.2) in §2), of the transverse operator $B = -d_z(c^2(z)d_z)$

on $(0,H)$ with domain $D(B) = \{u \in H^1((0,H)) \ / \ Bu \in L^2((0,H)),\ u$ satisfies (BC)$\}$. The statement of LAP3 is the convergence in the space $L^2_{-s}(\Omega) = \{f \ / \ (1+x^2)^{-s/2} f \in L^2(\Omega)\}$ of $R_A(\zeta)f$ when ζ, $\pm\text{Im}\zeta > 0$, tends to a threshold $\mu = \lambda(0,m)$. Sufficient conditions for such a convergence are as follows: $s > 3/2$ and f is in the space $E_s(\mu) = NL^2_s(m,1)$. This space, appearing in Theorem 2.2 and considered in Proposition 3.6, has codimension 2 in $L^2_s(\Omega)$.

We now call the perturbed problem the case of the strip where the celerity is such that $c(x,z) = c_-(z)$ if $x < 0$ and $c(x,z) = c_+(z)$ if $x > 0$ with two distinct functions c_- and c_+ satisfying the assumption (H). With the limiting absorption principles and division theorems for the both free operators associated with the celerities c_- and c_+, we are in a position to deduce a limiting absorption principle for the associated perturbed operator. There are many examples of such a path from free operators to perturbed operators with short range perturbations (see, for example, [A], [DG], [H], [V], and [We]) or long-range perturbations (see, for example, [T81a] and [T81b]). The particularity of the problem under consideration is the radical difference between the behavior of the celerity when x goes to $-\infty$ and when x goes to $+\infty$. It will be studied in a third paper.

2. Notation, review, and results. The operator $(D(A),A)$ is defined by (1.2) and (1.3). The celerity c is a function of z and satisfies assumption (H).

We now present some notation and useful results from [CD95a].

For any real number s, let $L^2_s(\Omega)$ be the weighted space $L^2_s(\Omega) = \{f \ / \ (1+x^2)^{s/2} f \in L^2(\Omega)\}$ equipped with the Hilbertian norm

$$\|f\|_{L^2_s(\Omega)} = \|(1+x^2)^{s/2} f\|_{L^2(\Omega)} = \left(\int_\Omega (1+x^2)^s |f(x,z)|^2 dxdz\right)^{1/2}.$$

The dual $L^2_s(\Omega)'$ and the space $L^2_{-s}(\Omega)$ are isometric. They are identified through the duality bracket

$$\langle f,g\rangle_{L^2_s(\Omega),\ L^2_{-s}(\Omega)} = \int_\Omega f(x,z)g(x,z)dxdz.$$

Let $u \mapsto \mathcal{F}u(\xi) = (2\pi)^{-1/2}\int_{\mathbb{R}} e^{-i\xi x}u(x)dx$ be the Fourier transform on $L^2(\mathbb{R})$. The partial Fourier transform with respect to the variable x on $L^2(\Omega)$ is also denoted $\mathcal{F}$.

For any real number ξ, let $(V(\xi,n,.))_{n\geq 1}$ be an orthonormal basis of the space $L^2((0,H))$ which satisfies the eigenvalue problem

$$-(c^2V')' + c^2\xi^2 V = \lambda V \text{ on } (0,H), \quad V \text{ satisfies (BC)}. \tag{2.1}$$

This problem is studied in §4.2 of [CD95a]. The eigenfunctions $V(\xi,n,.)$ can be chosen real. The eigenvalues λ are simple and strictly positive. For each real number ξ, they define an unbounded real sequence $(\lambda(\xi,n))_{n\geq 1}$, increasingly ordered with n.

The operator $(D(A),A)$ is self-adjoint in the space $L^2(\Omega)$. The spectrum $\sigma(A)$ of the operator A is the half-line $[\lambda(0,1),+\infty) \subseteq [(\pi^2/4H^2)c^2_m,+\infty)$. The eigenvalues of (2.1) for $\xi = 0$ appear as exceptional values or thresholds, and we set

$$\Gamma(A) = \{\lambda(0,n) \ / \ n \geq 1\}. \tag{2.2}$$

The properties of the dispersion curves

$$\xi \mapsto \lambda(\xi,n), \quad n \geq 1, \tag{2.3}$$

are described in Theorem 4.5 of [CD95a]. They are strictly increasing on $[0,+\infty)$ and even and analytic on $\mathbb{R}$, and there exist functions $\xi \mapsto a_n(\xi)$ such that

$$(2.4)\qquad \lambda(\xi,n) = \lambda(0,n) + \xi^2 a_n(\xi) \quad \text{with } c_m^2 \le a_n(\xi) \le \|c\|^2_{L^\infty((0,H))}.$$

Looking at the restriction of $\xi \mapsto \lambda(\xi,n)$ to the interval $[0,+\infty)$, $\lambda \mapsto \xi(\lambda,n)$ is the monotone inverse function which maps $[\lambda(0,n),+\infty)$ onto $[0,+\infty)$.

For any function f in the space $L^2(\Omega)$, any integer $n \ge 1$, for $j = 1$ or 2, the generalized Fourier coefficients are the complex-valued functions defined for almost every real number ξ and for almost every real number λ in the interval $(\lambda(0,n),+\infty)$ by

$$(2.5)\quad \widetilde{f}(\xi,n) = (2\pi)^{-1/2}\int_\Omega f(x,z)e^{-i\xi x}V(\xi,n,z)dxdz = \int_0^H \mathcal{F}f(\xi,z)V(\xi,n,z)dz,$$

$$(2.6)\qquad f^j(\lambda,n) = (\partial_\lambda \xi(\lambda,n))^{1/2}\,\widetilde{f}((-1)^j\xi(\lambda,n),n).$$

The coefficients (2.5) and (2.6), respectively, are associated with the spectral representation of the self-adjoint operator $(D(A),A)$, which is made explicit in Theorems 3.1 and 3.2, respectively, of [CD95a]. The functions $\widetilde{f}(.,n)$ and $f^j(.,n)$ satisfy

$$(2.7)\qquad \sum_{n\ge1}\int_{-\infty}^{+\infty}|\widetilde{f}(\xi,n)|^2d\xi = \sum_{n\ge1}\sum_{j=1}^{2}\int_{\lambda(0,n)}^{+\infty}|\,f^j(\lambda,n)|^2d\lambda < +\infty.$$

The function f in the space $L^2(\Omega)$ and the scalar product $(f \mid g)_{L^2(\Omega)}$ with a function g in $L^2(\Omega)$ can be written as

$$(2.8)\qquad f(x,z) = \sum_{n\ge1}(2\pi)^{-1/2}\int_{-\infty}^{+\infty}\widetilde{f}(\xi,n)e^{i\xi x}V(\xi,n,z)\,d\xi,$$

$$(2.9)\quad (f \mid g)_{L^2(\Omega)} = \sum_{n\ge1}\int_{-\infty}^{+\infty}\widetilde{f}(\xi,n)\overline{\widetilde{g}(\xi,n)}\,d\xi = \sum_{n\ge1}\sum_{j=1}^{2}\int_{\lambda(0,n)}^{+\infty}f^j(\lambda,n)\overline{g^j(\lambda,n)}\,d\lambda.$$

Let s be a real number such that $s > 1/2$.

For any real number ξ and any integer $n \ge 1$, the trace operator $\widetilde{\tau}_n(\xi)$, defined by

$$(2.10)\quad f \in L^2_s(\Omega) \mapsto \widetilde{\tau}_n(\xi)f = \widetilde{f}(\xi,n) = (2\pi)^{-1/2}\int_\Omega f(x,z)e^{-i\xi x}V(\xi,n,z)dxdz,$$

is a continuous linear form on $L^2_s(\Omega)$ with Hölder properties in the variable ξ stated in Proposition 3.2 of [CD95a]. Specifically, for a real number δ in $[0,1]$, $\delta < s - 1/2$, there exists a function $M(\xi,\xi') = M_n(s,\delta,\xi,\xi')$, continuous with respect to ξ and ξ', such that

$$(2.11)\qquad \forall f \in L^2_s(\Omega),\quad |\widetilde{\tau}_n(\xi)f - \widetilde{\tau}_n(\xi')f| \le M(\xi,\xi')|\xi-\xi'|^\delta\|f\|_{L^2_s(\Omega)}.$$

The space

$$(2.12)\qquad NL^2_s(n) = \{f \in L^2_s(\Omega)\ /\ \widetilde{\tau}_n(0)f = 0\}$$

is a closed subspace of $L^2_s(\Omega)$ with codimension one. Referring to Proposition 3.3 of [CD95a]), the space

$$W(n) = NL^2_s(n) \cap C^\infty_0(\Omega) \tag{2.13}$$

is dense in $NL^2_s(n)$ and therefore not dense in $L^2_s(\Omega)$. However, the space $W(n)$ is dense in $L^2_t(\Omega)$ for $t \leq 1/2$.

For any real number λ in $\sigma(A)$, any integer $n \geq 1$, and $j = 1$ or 2, the trace operator $\tau^j_n(\lambda)$ is then defined on $L^2_s(\Omega)$ by

$$\tau^j_n(\lambda)f \; = 0 \quad \text{if } \lambda = \lambda(0,n), \tag{2.14a}$$

$$\tau^j_n(\lambda)f = f^j(\lambda,n) = (\partial_\lambda \xi(\lambda,n))^{1/2}\, \widetilde{\tau}_n((-1)^j \xi(\lambda,n))f \quad \text{if } \lambda > \lambda(0,n). \tag{2.14b}$$

The function $\lambda \mapsto \tau^j_n(\lambda)$ maps $[\lambda(0,n),+\infty)$ in $L^2_s(\Omega)' = L^2_{-s}(\Omega)$. Its properties are stated in Proposition 3.4 of [CD95a]. Far from $\lambda(0,n)$, the function $\lambda \mapsto (\partial_\lambda \xi(\lambda,n))^{1/2}$ is analytic, and the function $\lambda \mapsto \tau^j_n(\lambda)$ has Hölder properties identical to those of the function $\xi \mapsto \widetilde{\tau}_n(\xi)$ (see (2.11)) and, in particular, the same Hölder order δ. Due to the vanishing of $\partial_\xi \lambda(.,n)$ in $\xi = 0$, the function $\lambda \mapsto \tau^j_n(\lambda)$ fails to be continuous in $\lambda(0,n)$. However, there exists a function $C(\lambda) = C_n(s,\lambda)$, continuous with respect to $\lambda \geq \lambda(0,n)$, such that

$$\forall f \in L^2_s(\Omega), \quad |\tau^j_n(\lambda)f| \leq C(\lambda)|\lambda - \lambda(0,n)|^{-1/4}\|f\|_{L^2_s(\Omega)}. \tag{2.15}$$

In the neighborhood of $\lambda(0,n)$, to get Hölder conditions for $\lambda \mapsto \tau^j_n(\lambda)$, we have to consider the restriction of $\tau^j_n(\lambda)$ to $NL^2_s(n)$ and to assume that $s > 1$. Specifically, for $s > 1$ and for a real number δ in $[0,1/4]$, $\delta < (s-1)/2$, there exists a function $M(\lambda,\lambda') = M_n(s,\delta,\lambda,\lambda')$, continuous with respect to $\lambda, \lambda' \geq \lambda(0,n)$, such that

$$\forall f \in NL^2_s(n), \quad |\tau^j_n(\lambda)f - \tau^j_n(\lambda')f| \leq M(\lambda,\lambda')|\lambda - \lambda'|^\delta \|f\|_{L^2_s(\Omega)}. \tag{2.16}$$

The following useful formulas are derived from (2.4) and are used in the proof of Proposition 3.4 of [CD95a]:

$$\partial_\xi \lambda(\pm\xi,n) = \pm\xi\; b_n(\xi), \tag{2.17a}$$

$$\xi = \xi(\lambda,n) = (\lambda - \lambda(0,n))^{1/2}\; G_n(\xi), \tag{2.17b}$$

$$\partial_\lambda \xi(\lambda,n) = (\lambda - \lambda(0,n))^{-1/2}\; H_n(\xi), \tag{2.17c}$$

$$\tau^j_n(\lambda)f = (\lambda - \lambda(0,n))^{-1/4}\; H_n(\xi)^{1/2}\; \widetilde{\tau}_n((-1)^j\; \xi)f, \tag{2.17d}$$

where $\xi \geq 0$ and the functions b_n, G_n, and H_n are strictly positive and analytic on $[0,+\infty)$.

The limiting absorption principle is valid when the real number μ is in $\sigma(A)$, that is, we can determine

$$R^\pm_A(\mu) = \lim_{\zeta \to \mu,\; \pm\mathrm{Im}\zeta > 0} (A - \zeta I)^{-1}. \tag{2.18}$$

Then the function $R^\pm_A$ defined on $\mathbb{C}^\pm = \{\zeta \in \mathbb{C} \; / \; \pm \mathrm{Im}\zeta > 0\}$ by $\zeta \mapsto R^\pm_A(\zeta) = (A - \zeta I)^{-1}$ can be continued on $\sigma(A)$. Theorem 3.4 of [CD95a] claims the following results, called LAP1 and LAP2.

- LAP1.

$$\text{If } \mu \notin \Gamma(A) = \{\lambda(0,n) \ / \ n \geq 1\} \quad \text{and} \quad s > 1/2, \tag{2.19}$$

then the limits in (2.18) exist in the uniform-operator topology on the space $B(L^2_s(\Omega), L^2_{-s}(\Omega))$. Moreover, each function $R^{\pm}_A$ is locally Hölder continuous on $\overline{\mathbb{C}^{\pm}} \setminus \Gamma(A)$ with order δ_1 in $[0, \mathrm{Min}(1, s - 1/2))$.

- LAP2.

$$\text{If } \mu = \lambda(0,n) \quad \text{and} \quad s > 1, \tag{2.20}$$

then the limits in (2.18) exist in the uniform operator topology on the space $B(NL^2_s(n), NL^2_s(n)')$. Moreover, each function $R^{\pm}_A$ is locally Hölder continuous on $J^{\pm}_n = \{\zeta \in \overline{\mathbb{C}^{\pm}} \ / \ \lambda(0, n-1) < \mathrm{Re}\zeta < \lambda(0, n+1)\}$ with order δ_2 in $[0, \mathrm{Min}(1/4, (s-1)/2))$.
Let us recall that $NL^2_s(n)$ is not dense in $L^2_s(\Omega)$, $s > 1/2$. Therefore, $L^2_{-s}(\Omega)$ cannot be identified with a subspace of $NL^2_s(n)'$.

With the above definitions and notations, we have the following statements.

THEOREM 2.1 (division theorem outside of $\Gamma(A)$). *Let $m \geq 2$ be an integer, I_m be the interval $(\lambda(0, m-1), \lambda(0, m))$, and $\mu \in I_m$. Let $s > 1/2$ be a real number and f be a function in $L^2_s(\Omega)$ such that*

$$\tau^j_n(\mu) f = 0, \quad j = 1 \, or \, 2, \quad 1 \leq n < m. \tag{2.21}$$

Then $R^+_A(\mu)f = R^-_A(\mu)f = u$, which is in $L^2_{-s}(\Omega)$ by LAP1, *belongs to $L^2_{-\tilde{s}}(\Omega)$ with $\tilde{s} = \mathrm{Max}(0, 1-s)$. Moreover, there exists a function $C = C_m(\mu, s)$, continuous with respect to the variable μ on I_m, such that for every f in $L^2_s(\Omega)$ satisfying* (2.21), *we have*

$$\|u\|_{L^2_{-\tilde{s}}(\Omega)} \leq C \|f\|_{L^2_s(\Omega)}. \tag{2.22}$$

THEOREM 2.2 (division theorem at thresholds). *Let $m \geq 1$ be an integer and $\mu = \lambda(0, m)$ be the corresponding threshold of A. Let $s > 3/2$ be a real number and f be a function in $L^2_s(\Omega)$ satisfying* (2.21) *and such that*

$$\int_\Omega f(x,z) V(0,m,z) dx dz = \int_\Omega x f(x,z) V(0,m,z) dx dz = 0. \tag{2.23}$$

Then $R^+_A(\mu)f = R^-_A(\mu)f = u$, which is in $NL^2_s(m)'$ by LAP2, *belongs to $L^2_{-\tilde{s}}(\Omega)$ with $\tilde{s} = \mathrm{Max}(0, 2-s)$. Moreover, there exists a constant $C = C(\mu, s)$ such that for every f in $L^2_s(\Omega)$ satisfying* (2.21) *and* (2.23), *we have*

$$\|u\|_{L^2_{-\tilde{s}}(\Omega)} \leq C \|f\|_{L^2_s(\Omega)}. \tag{2.24}$$

Remark 2.1. The space $L^2_{-\tilde{s}}(\Omega)$ is a strict subspace of $NL^2_s(m)'$. Indeed, the real number $\tilde{s} = \mathrm{Max}(0, 2-s)$, $s > 3/2$, is in the interval $[0, 1/2)$. Therefore, the space $W(m) = NL^2_s(m) \cap C^\infty_0(\Omega)$ is dense in the space $L^2_{\tilde{s}}(\Omega)$, and we have the injective maps

$$NL^2_s(m) \subset L^2_{\tilde{s}}(\Omega) \subseteq L^2(\Omega) \subseteq L^2_{-\tilde{s}}(\Omega) \subset NL^2_s(m)'.$$

For $s > 3/2$, according to condition (2.23), we define the space

$$NL^2_s(m,1) = \left\{ f \in NL^2_s(m) \ / \ \int_\Omega x f(x,z) V(0,m,z) dx dz = 0 \right\}. \tag{2.25}$$

We consider this closed hyperplane of $NL^2_s(m)$ in Proposition 3.6 in §3. There we get some properties of nullity and Hölder continuity in $\lambda = \lambda(0,m)$ for the trace functions $\lambda \mapsto f^j(\lambda, m)$, $j = 1$ or 2. They are sufficient to get the following "strong" limiting absorption principle in $L^2_{-s}(\Omega)$.

THEOREM 2.3 (LAP3). *Let $m \geq 1$ be an integer and $\mu = \lambda(0,m)$ be the corresponding threshold of A. We set $J_m = (\lambda(0,m-1), \lambda(0,m+1))$ with $\lambda(0,0) < \lambda(0,1)$. Let $s > 3/2$ be a real number and $NL^2_s(m,1)$ be the Banach space* (2.25) *equipped with the norm of $L^2_s(\Omega)$. Then the following hold:*

(i) *For μ in J_m, the limits in* (2.18) *exist in the uniform operator topology on the space $B(NL^2_s(m,1), L^2_{-s}(\Omega))$.*

(ii) *Each function $\zeta \mapsto R^{\pm}_A(\zeta)$, defined on $J^{\pm}_m = \{\zeta \in \overline{\mathbb{C}^{\pm}} \ / \ \mathrm{Re}\zeta \in J_m\}$ and valued in $B(NL^2_s(m,1), L^2_{-s}(\Omega))$, is locally Hölder continuous with order δ in $[0,1/2]$, $\delta < (s-3/2)/2$. Specifically, there exists a function $C_m(\zeta,\zeta') = C_m(s,\delta,\zeta,\zeta')$, continuous with respect to ζ and ζ' in $J^{\pm}_m$, such that*

(2.26)
$$\forall f \in L^2_s(m,1), \quad \|R^{\pm}_A(\zeta)f - R^{\pm}_A(\zeta')f\|_{L^2_{-s}(\Omega))} \leq C_m(\zeta,\zeta')|\zeta-\zeta'|^{\delta}\|f\|_{L^2_s(\Omega)}.$$

The same properties hold for the functions $\zeta \mapsto \nabla R^{\pm}_A(\zeta)$.

(iii) *Let f be a function in $NL^2_s(m,1)$ and*

$$U^{\pm} = R^{\pm}_A(\mu)f = \lim_{\zeta \to \mu,\ \pm\mathrm{Im}\zeta\ >0} R_A(\zeta)f.$$

With the notation in (2.10) *and* (2.14), *we have*

$$(2.27) \qquad \langle U^{\pm}, g\rangle_{L^2_{-s}(\Omega),\, L^2_s(\Omega)} = \begin{cases} \displaystyle\sum_{n \geq m} \int_{-\infty}^{+\infty} \frac{\tilde{f}(\xi,n)\overline{\tilde{g}(\xi,n)}}{\lambda(\xi,n)-\mu}d\xi \\ \displaystyle\quad + \sum_{n<m} \mathrm{p.v.} \int_{-\infty}^{+\infty} \frac{\tilde{f}(\xi,n)\overline{\tilde{g}(\xi,n)}}{\lambda(\xi,n)-\mu}d\xi \\ \displaystyle\quad \pm i\pi \sum_{n<m}\sum_{j=1}^{2} f^j(\mu,n)\overline{g^j(\mu,n)}. \end{cases}$$

The distributions $\partial_x U^{\pm}$ and $\partial_z U^{\pm}$ are in $L^2_{-s}(\Omega)$. Each function $U^{\pm} = R^{\pm}_A(\mu)f$ is in $D(A)_{\mathrm{loc}}$ and satisfies the differential equation

$$(2.28) \qquad (A - \mu I)U^{\pm} = f \quad in\ \mathcal{D}'(\Omega).$$

Remark 2.2. The restriction of $U^{\pm}$ to $NL^2_s(m)$ is $u^{\pm} = R^{\pm}_A(\mu)f$, the limit form on $NL^2_s(m)$ defined by LAP2. When $s > 3/2$, $NL^2_s(m)$ is not dense in $L^2_s(\Omega)$. Thus the identification of $U^{\pm}$ and $u^{\pm}$ through $R^{\pm}_A(\mu)f$ is not valid. To be more precise, $U^{\pm}$ is the particular continuation of $u^{\pm}$ on $L^2_s(\Omega)$ given by formula (2.27).

Remark 2.3. Theorem 2.3 improves LAP2 since $R^{\pm}_A(\mu)f$ is a form defined on $L^2_s(\Omega)$, a larger space than $NL^2_s(m)$. However, we have to choose larger s and f in an hyperplane of $NL^2_s(m)$. In a future paper, we will examine the question of whether there exist functions f_μ in the space $NL^2_s(m)$ with $s > 1$ such that

$$(2.29) \qquad \lim_{\zeta \to \mu,\ \zeta \notin \sigma(A)} \|R_A(\zeta)f_\mu\|_{L^2_{-s}(\Omega)} = +\infty.$$

Remark 2.4. The Hölder order δ in $[0, 1/2]$, $\delta < (s - 3/2)/2$, obtained in LAP3, has to be compared with the order δ_2 in $[0, \mathrm{Min}(1/4, (s-1)/2))$, obtained in LAP2. In the case where $s > 3/2$, Corollary 3.4 together with Theorem 3.7 (both in §3) allows us to increase the order δ_2 in LAP2 up to δ (see Remark 3.1, also in §3).

3. Basic estimates. For any real number s, $H^s(\mathbb{R})$ denotes the Sobolev space with exponent s, the space of tempered distributions v such that $\mathcal{F}v$ is in $L^2_s(\mathbb{R})$. It is a Hilbert space with the norm $\|v\|_{H^s(\mathbb{R})} = \|\mathcal{F}v\|_{L^2_s(\mathbb{R})}$.

3.1. Agmon's result. We return to a basic result of Agmon. We use it in dimension one.

LEMMA B.2 FROM [A]. *Let $s > 1/2$ be a real number. Let v be a function in $H^s(\mathbb{R})$ such that $v(0) = 0$. Then the function $V(\xi) = (v(\xi)/\xi)$ is in $H^{s-1}(\mathbb{R}) \cap L^1_{\mathrm{loc}}(\mathbb{R})$, and there exists a constant $C = C(s)$, independent of v in $H^s(\mathbb{R})$, such that*

$$\|V\|_{H^{s-1}(\mathbb{R})} \leq C\|v\|_{H^s(\mathbb{R})}. \tag{3.1}$$

Proof. We refer to [A, pp. 209–211]. □

COROLLARY 3.1. *Let $s > 3/2$ be a real number. Let v be a function in $H^s(\mathbb{R})$ such that $v(0) = v'(0) = 0$. Then $V(\xi) = (v(\xi)/\xi^2)$ is a function in $H^{s-2}(\mathbb{R}) \cap L^1_{\mathrm{loc}}(\mathbb{R})$, and there exists a constant $C = C(s)$, independent of v in $H^s(\mathbb{R})$, such that*

$$\|V\|_{H^{s-2}(\mathbb{R})} \leq C\|v\|_{H^s(\mathbb{R})}. \tag{3.2}$$

Proof. Lemma B.2 gives the function $\xi \longmapsto v_1(\xi) = (v(\xi)/\xi)$ in the space $H^{s-1}(\mathbb{R}) \cap L^1_{\mathrm{loc}}(\mathbb{R})$. Since $v_1(0) = \lim_{\xi\to 0} v_1(\xi) = \lim_{\xi\to 0}(v(\xi)/\xi) = v'(0) = 0$, Lemma B.2 can be applied to v_1. This yields the corollary. □

3.2. Accurate properties of the trace operators. First, we give results about the Sobolev regularity, with respect to the variable ξ, of the generalized Fourier coefficients $\widetilde{u}(\xi, n)$ defined by (2.5) for functions u in $L^2(\Omega)$.

PROPOSITION 3.2. *Let $s \geq 0$ be a real number. Let $n \geq 1$ be an integer, M be a real number, and Φ be a function in $C_0^\infty(\mathbb{R})$ with support in the interval $[-M, M]$. Then the continuous map from $L^2(\Omega)$ in $L^2(\mathbb{R})$ defined by $u \mapsto \Phi\widetilde{u}(., n)$ satisfies the inequality*

$$\|\Phi\widetilde{u}(., n)\|_{H^{-s}(\mathbb{R})} \leq C\|u\|_{L^2_{-s}(\Omega)}, \tag{3.3}$$

where the constant $C = C_n(s, \Phi)$ is independent of u in $L^2(\Omega)$. Moreover, if u is in $L^2_s(\Omega)$, we have

$$\Phi\widetilde{u}(., n) \in H^s(\mathbb{R}) \quad \text{and} \quad \|\Phi\widetilde{u}(., n)\|_{H^s(\mathbb{R})} \leq C\|u\|_{L^2_s(\Omega)}. \tag{3.4}$$

The constant $C = C_n(s, \Phi)$ can be chosen continuously dependent on M and on the norms $\|\Phi^{(l)}\|_{L^\infty(\mathbb{R})}, l \leq s + 1$.

Proof. Using the eigenfunctions $V(\xi, n, z)$ introduced in (2.1), we define

$$w(., z) = \mathcal{F}^{-1}(\Phi V(., n, z)). \tag{3.5}$$

Thanks to the C^∞ regularity of $\xi \mapsto V(\xi, n, .)$ from $\mathbb{R}$ in $L^2((0, H))$, for every integer k, the function w satisfies

$$\int_\Omega |\partial_\xi^k(\mathcal{F}w)(\xi, z)|^2 d\xi dz = \int_\Omega \left|\sum_{l=0}^{k} \binom{k}{l} \Phi^{(l)}(\xi)\partial_\xi^{k-l} V(\xi, n, z)\right|^2 d\xi dz \leq c_n(k, \Phi).$$

Therefore, for every real $r \geq 0$, we have

$$\|w\|_{L^2_r(\Omega)} \leq \widetilde{c}_n(r, \Phi) = \text{Max}\{c_n(k, \Phi) \ / \ k \in \mathbb{N},\ 0 \leq k \leq r+1\}. \tag{3.6}$$

Let u be a function in $L^2(\Omega)$. With the definition (2.5) of $\widetilde{u}$ and with the property of the Fourier transform $\mathcal{F}$ with regard to convolution, we have

$$\Phi(\xi)\widetilde{u}(\xi, n) = \int_0^H \mathcal{F}u(\xi, z)\Phi(\xi)V(\xi, n, z)dz = (2\pi)^{-1/2}\mathcal{F}\left(\int_0^H u(., z) * w(., z)dz\right)$$

and

$$\|\Phi\widetilde{u}(., n)\|_{H^{\pm s}(\mathbb{R})} = (2\pi)^{-1/2}\left\|\int_0^H u(., z) * w(., z)dz\right\|_{L^2_{\pm s}(\mathbb{R})}.$$

Let us set $t = \pm s$. From $(1+x^2)^t \leq c(s)(1+(x-X)^2)^t(1+X^2)^s$, the Schwarz inequality, and the Fubini theorem, we deduce the following estimates:

$$\begin{aligned}
&\left\|\int_0^H u(., z) * w(., z)dz\right\|^2_{L^2_t(\mathbb{R})} \\
&= \int_{-\infty}^{+\infty} (1+x^2)^t \left|\int_0^H \int_{-\infty}^{+\infty} u(x-X, z)w(X, z)dXdz\right|^2 dx \\
&\leq c(s)\int_{-\infty}^{+\infty}\left|\int_{-\infty}^{+\infty}\int_0^H (1+(x-X)^2)^{t/2}u(x-X, z)(1+X^2)^{s/2}w(X, z)dzdX\right|^2 dx \\
&\leq c(s)\int_{-\infty}^{+\infty}\left[\int_{-\infty}^{+\infty}\left(\int_0^H (1+(x-X)^2)^t|u(x-X, z)|^2dz\right)^{1/2}\right. \\
&\qquad\qquad \left.\left(\int_0^H (1+X^2)^s|w(X, z)|^2dz\right)^{1/2} dX\right]^2 dx \\
&\leq c(s)\int_{-\infty}^{+\infty}\left[\int_{-\infty}^{+\infty}\int_0^H (1+X^2)^{-1}(1+(x-X)^2)^t|u(x-X, z)|^2dzdX\right] \\
&\qquad\qquad \left[\int_{-\infty}^{+\infty}\int_0^H (1+X^2)^{s+1}|w(X, z)|^2dzdX\right] dx \\
&\leq c(s)\|w\|^2_{L^2_{s+1}(\Omega)}\int_{\mathbb{R}\times\Omega}(1+X^2)^{-1}(1+(x-X)^2)^t|u(x-X, z)|^2dXdxdz.
\end{aligned}$$

Using (3.6) with $r = s+1$, we obtain the estimate

$$\forall u \in L^2(\Omega), \quad \|\Phi\widetilde{u}(., n)\|_{H^t(\mathbb{R})} \leq C\|u\|_{L^2_t(\Omega)} \tag{3.7}$$

with a constant $C = C_n(t, \Phi) \leq \widetilde{c}(s)\widetilde{c}_n(s+1, \Phi)$. The Φ dependence of the constant C appears in the constant $\widetilde{c}_n(s+1, \Phi)$ of (3.6). The proof is then complete. □

Choosing a larger s, we can improve the description of $\Phi\widetilde{u}(., n)$ with the help of Lemma B.2.

PROPOSITION 3.3. *Let $s > 3/2$ be a real number. Let $n \geq 1$ be an integer, f be a function in $NL^2_s(n)$, and Φ be a function in $C_0^\infty(\mathbb{R})$. Then there exists $\rho = \rho_{\Phi,f}$ in $H^{s-1}(\mathbb{R}) \cap L^1(\mathbb{R})$ such that*

$$\Phi(\xi)\widetilde{f}(\xi,n) = \xi\,\rho(\xi), \quad \xi \in \mathbb{R}. \tag{3.8}$$

Moreover, there exist constants $c(s), C = C_n(s,\Phi)$, $\delta \in [0,1]$ and $\delta < s - 3/2$, and $M = M_n(s,\Phi,\delta)$, independent of f in $NL^2_s(n)$ and of the real numbers ξ and ξ', such that

$$|\rho(\xi)| \leq c(s)\|\rho\|_{H^{s-1}(\mathbb{R})} \leq C\|f\|_{L^2_s(\Omega)}, \tag{3.9}$$

$$|\rho(\xi) - \rho(\xi')| \leq M|\xi - \xi'|^\delta \|f\|_{L^2_s(\Omega)}. \tag{3.10}$$

The constants $C = C_n(s,\Phi)$ and $M = M_n(s,\Phi,\delta)$ can be chosen with the same dependence on Φ as in Proposition 3.2.

Proof. Let us recall (2.12): $NL^2_s(n) = \{f \in L^2_s(\Omega) \ / \ \widetilde{f}(0,n) = 0\}$. Using Proposition 3.2, the function $\xi \longmapsto v(\xi) = \Phi(\xi)\widetilde{f}(\xi,n)$ is in $H^s(\mathbb{R})$ and is compactly supported, and $\|v\|_{H^s(\mathbb{R})} \leq c_n(s,\Phi)\|f\|_{L^2_s(\Omega)}$. Then we apply Lemma B.2 to get $\rho(\xi) = (v(\xi)/\xi)$ in $H^{s-1}(\mathbb{R}) \cap L^1(\mathbb{R})$ and $\|\rho\|_{H^{s-1}(\mathbb{R})} \leq \tilde{c}_n(s,\Phi)\|f\|_{L^2_s(\Omega)}$. Estimates (3.9) and (3.10) are then derived from classical ones for functions in $H^t(\mathbb{R})$. Specifically,

$$\begin{aligned}
|\rho(\xi)| &= (2\pi)^{-1/2}\left|\int_{-\infty}^{+\infty} \mathcal{F}\rho(x)e^{ix\xi}dx\right| \\
&\leq (2\pi)^{-1/2}\left(\int_{-\infty}^{+\infty} (1+x^2)^{-t}dx\right)^{1/2}\left(\int_{-\infty}^{+\infty} |\mathcal{F}\rho(x)|^2(1+x^2)^t dx\right)^{1/2} \quad \text{with } t > 1/2
\end{aligned}$$

so that $|\rho(\xi)| \leq c(t)\|\rho\|_{H^t(\mathbb{R})}$, and

$$\begin{aligned}
|\rho(\xi) - \rho(\xi')| &= (2\pi)^{-1/2}\left|\int_{-\infty}^{+\infty} \mathcal{F}\rho(x)(e^{ix\xi} - e^{ix\xi'})dx\right| \\
&\leq (2\pi)^{-1/2}\int_{-\infty}^{+\infty} |\mathcal{F}\rho(x)|\ 2^{1-\delta}|\xi - \xi'|^\delta|x|^\delta dx \quad \text{with } \delta \in [0,1]
\end{aligned}$$

so that $|\rho(\xi) - \rho(\xi')| \leq c(t,\delta)|\xi - \xi'|^\delta\|\rho\|_{H^t(\mathbb{R})}$ with $\delta < t - 1/2$. □

Precise results follow about the behavior of the trace functions near thresholds.

COROLLARY 3.4. *Let $s > 3/2$ be a real number, $n \geq 1$ be an integer, and $j = 1$ or 2. Let f be a function in $NL^2_s(n)$. Then there exist locally Hölder continuous functions $\widetilde{F}(.,n) = \widetilde{F}_f(.,n)$ defined on $I\!R$ and $F^j(.,n) = F^j_f(.,n)$ defined on $I_n = [\lambda(0,n), +\infty)$ such that*

$$\widetilde{f}(\xi,n) = \xi\widetilde{F}(\xi,n) \quad \textit{and} \quad f^j(\lambda,n) = (\lambda - \lambda(0,n))^{1/4}\, F^j(\lambda,n). \tag{3.11}$$

Specifically, for δ in $[0,1]$, $\delta < s - 3/2$, there exist a function $\widetilde{M}(\xi,\xi') = \widetilde{M}_n(s,\delta,\xi,\xi')$, continuous with respect to ξ and ξ', and a function $M(\lambda,\lambda') = M_n(s,\delta,\lambda,\lambda')$, continuous with respect to $\lambda, \lambda' \geq \lambda(0,n)$, such that

$$\forall f \in NL^2_s(n), \quad |\widetilde{F}(\xi,n) - \widetilde{F}(\xi',n)| \leq \widetilde{M}(\xi,\xi')|\xi - \xi'|^\delta\|f\|_{L^2_s(\Omega)}. \tag{3.12a}$$

$$\forall f \in NL^2_s(n), \quad |F^j(\lambda,n) - F^j(\lambda',n)| \leq M(\lambda,\lambda')|\lambda - \lambda'|^{\delta/2}\|f\|_{L^2_s(\Omega)}. \tag{3.12b}$$

Proof. Note that we already have the Hölder continuity (2.11) for $\widetilde{f}(.,n)$. From Proposition 3.3, we deduce $\widetilde{f}(\xi,n) = \xi\widetilde{F}(\xi,n)$ and (3.12a) with δ in $[0,1]$, $\delta < s-3/2$. Let $\lambda, \lambda' \geq \lambda(0,n)$ and $\xi, \xi' \geq 0$ be connected by $\xi = \xi(\lambda,n)$ and $\xi' = \xi(\lambda',n)$. From (2.6), (2.17c), and (2.17b) and setting $\varepsilon_j = (-1)^j$, we get

$$\begin{aligned} f^j(\lambda,n) &= (\partial_\lambda\xi(\lambda,n))^{1/2}\,\widetilde{f}(\varepsilon_j\xi,n) = (\lambda-\lambda(0,n))^{-1/2}H_n(\xi)^{1/2}\varepsilon_j\xi\,\widetilde{F}(\varepsilon_j\xi,n) \\ &= (\lambda-\lambda(0,n))^{-1/4}H_n(\xi)^{1/2}\,\varepsilon_j(\lambda-\lambda(0,n))^{1/2}G_n(\xi)\widetilde{F}(\varepsilon_j\xi,n). \end{aligned}$$

Thus $f^j(\lambda,n) = (\lambda-\lambda(0,n))^{1/4}F^j(\lambda,n)$ with

$$F^j(\lambda,n) = (-1)^j H_n(\xi)^{1/2}G_n(\xi)\,\widetilde{F}((-1)^j\xi,n). \tag{3.13}$$

The analyticity and strict positivity of H_n and G_n and the Hölder continuity (3.12a) of $\widetilde{F}(.,n)$ imply

$$|F^j(\lambda,n) - F^j(\lambda',n)| \leq M(\xi,\xi')|\xi-\xi'|^\delta \|f\|_{L^2_s(\Omega)}.$$

Again with (2.17b), we get (3.12b). □

Propositions 3.2 and 3.3 imply particular differentiability properties for the functions $\widetilde{f}(.,n) = \widetilde{\tau}_n(.)f$. Such properties are made explicit in the next proposition.

PROPOSITION 3.5 (derivatives of the trace operators and the spaces $NL^2_s(m,k)$). *Let $s > 1/2$ be a real number and $n \geq 1$ and $k \geq 0$ be integers with $k < s-1/2$. Then the function $\xi \longrightarrow \widetilde{\tau}_n(\xi)$ defined on $\mathbb{R}$ and valued in $L^2_s(\Omega)'$ has a derivative $(d^k\widetilde{\tau}_n/d\xi^k)$. There exists a function $C(\xi) = C_n(s,\xi)$, continuous with respect to ξ, such that*

$$\forall f \in L^2_s(\Omega), \quad \left|\frac{d^k\widetilde{\tau}_n}{d\xi^k}(\xi)f\right| \leq C(\xi)\|f\|_{L^2_s(\Omega)}. \tag{3.14}$$

This derivative is locally Hölder continuous with order δ in $[0,1]$, $\delta < s-1/2-k$. Specifically, there exists a function $M(\xi,\xi') = M_n(s,\delta,\xi,\xi')$, continuous with respect to ξ and ξ', such that

$$\forall f \in L^2_s(\Omega), \quad \left|\frac{d^k\widetilde{\tau}_n}{d\xi^k}(\xi)f - \frac{d^k\widetilde{\tau}_n}{d\xi^k}(\xi')f\right| \leq M(\xi,\xi')|\xi-\xi'|^\delta\|f\|_{L^2_s(\Omega)}. \tag{3.15}$$

The space

$$NL^2_s(n,k) = \left\{f \in L^2_s(\Omega)\ /\ \frac{d^l\widetilde{\tau}_n}{d\xi^l}(0)f = 0,\ 0 \leq l \leq k\right\} \tag{3.16}$$

is a closed subspace of $L^2_s(\Omega)$ with codimension $k+1$. In particular, we have

$$NL^2_s(n,0) = NL^2_s(n) = \left\{f \in L^2_s(\Omega)\ /\ \int_\Omega f(x,z)V(0,n,z)dxdz = 0\right\}. \tag{3.17}$$

Proof. The existence and continuity of the trace operator $\xi \longmapsto \widetilde{\tau}_n(\xi)$ and estimate (3.15) with $s > 1/2$ and $k = 0$ have been proved in Proposition 3.2 of [CD95a]. Let us now assume that $s > 3/2$. Let k be an integer such that $0 < k < s-3/2$. We consider a function f in $L^2_s(\Omega)$ and its Fourier transform $\mathcal{F}f$ with respect to the variable x. Since $k < s-1/2$, the function $\mathcal{F}f(.,z)$ is in the space $C^k(\mathbb{R})$ for almost every z in

$(0, H)$. For any integer l in $[0, k]$, we have

$$\begin{aligned}|\partial_\xi^l(\mathcal{F}f)(\xi, z)| &= (2\pi)^{-1/2}\left|\int_{-\infty}^{+\infty} x^l e^{-i\xi x} f(x, z)dx\right| \\ &\leq (2\pi)^{-1/2}\left(\int_{-\infty}^{+\infty}(1+x^2)^{-s+l}dx\right)^{1/2}\left(\int_{-\infty}^{+\infty}|f(x,z)|^2(1+x^2)^s dx\right)^{1/2} \\ &\leq C(s,k)\|f\|_{L^2_s(\Omega)}.\end{aligned}$$

The differentiability of the trace function $\xi \mapsto \widetilde{f}(\xi, n) = (\mathcal{F}f(\xi, .)\ /\ V(\xi, n, .))_{L^2((0,H))}$ follows from the differentiability of $\xi \mapsto V(\xi, n, .)$. Therefore, the trace map $\widetilde{\tau}_n$ has a derivative of order k such that

$$\frac{d^k\widetilde{\tau}_n}{d\xi^k}(\xi)f = \sum_{l=0}^{k}\binom{k}{l}\int_0^H \partial_\xi^l(\mathcal{F}f)(\xi, z)\partial_\xi^{k-l}V(\xi, n, z)dz. \tag{3.18}$$

As in Proposition 3.2 of [CD95a], estimates (3.14) and (3.15) are deduced from

$$\|\partial_\xi^l V(\xi, n, .) - \partial_\xi^l V(\xi', n, .)\|_{L^2((0,H))} \leq C_n(l, \xi, \xi')|\xi - \xi'|$$

and from

$$|e^{-i\xi x} - e^{-i\xi' x}| \leq 2^{1-\delta}|\xi - \xi'|^\delta |x|^\delta.$$

Now the forms $(d^l\widetilde{\tau}_n/d\xi^l)(0)$, $0 \leq l \leq k$, are continuous on $NL_s^2(m)$, and the properties of the spaces $NL_s^2(m, k)$ are clear. □

When f is a function in $NL_s^2(n)$, $s > 3/2$, we can determine Hölder continuous functions $\widetilde{F}_f(., n)$ and $F_f^j(., n)$, $j = 1$ or 2, through $\widetilde{f}(., n)$ and $f^j(., n)$ with the help of (3.11). When f is in $NL_s^2(n, 1)$, these functions have supplementary properties of nullity.

Proposition 3.6 (the space $NL_s^2(n, 1)$). *Let $s > 3/2$ be a real number and $n \geq 1$ be an integer. Then the space $NL_s^2(n, 1)$ defined by* (3.16) *is a closed hyperplane of $NL_s^2(n)$ such that*

$$\begin{aligned}NL_s^2(n, 1) &= \{f \in NL_s^2(n)\ /\ \widetilde{F}_f(0, n) = 0\} \\ &= \{f \in NL_s^2(n)\ /\ F_f^j(0, n) = 0,\ j = 1, 2\} \\ &= \left\{f \in NL_s^2(n)\ /\ \int_\Omega x f(x, z)V(0, n, z)dxdz = 0\right\}.\end{aligned} \tag{3.19}$$

Moreover, for δ in $[0, 1/2]$, $\delta < (s-3/2)/2$, there exists a function $C(\lambda) = C_n(s, \delta, \lambda)$, continuous with respect to $\lambda \geq \lambda(0, n)$, such that

$$\forall f \in NL_s^2(n, 1), \quad |f^j(\lambda, n)| \leq C(\lambda)(\lambda - \lambda(0, n))^{1/4+\delta}\|f\|_{L_s^2(\Omega)}. \tag{3.20}$$

Proof. When f is in $NL_s^2(n)$, $s > 3/2$, we have $\widetilde{f}(0, n) = 0$, and $\widetilde{F}_f(\xi, n) = \widetilde{f}(\xi, n)/\xi$ is locally Hölder continuous with respect to ξ. Therefore, $\widetilde{F}_f(0, n) = \lim_{\xi\to 0}\widetilde{f}(\xi, n)/\xi = (d\widetilde{\tau}_n/d\xi)(0)f$. Since $\xi \mapsto V(\xi, n, .)$ is even, $\partial_\xi V(0, n, .) = 0$. From this and from (3.18) with $k = 1$, we derive

$$\frac{d\widetilde{\tau}_n}{d\xi}(0)f = \int_0^H \partial_\xi(\mathcal{F}f)(0, z)V(0, n, z)dz = -i(2\pi)^{-1/2}\int_\Omega x f(x, z)V(0, n, z)dxdz.$$

The description (3.19) of $NL_s^2(n, 1)$ follows. Estimate (3.12b) yields (3.20). □

3.3. Investigations of the terms of the resolvent. Let μ be a real number in $\sigma(A) = [\lambda(0,1), +\infty)$. We fix $\lambda(0,0) = 0$. Let $m \geq 1$ be the integer such that μ is in the interval $(\lambda(0, m-1), \lambda(0,m)]$ and let $n \geq 1$ be an integer. The following quantities B_n and r_n are defined in [CD95a]:

If $n \geq 1$ and $\zeta \notin \sigma(A)$,

$$B_n(\zeta, f, \varphi) = \int_{-\infty}^{+\infty} \frac{\widetilde{f}(\xi,n)\,\overline{\widetilde{\varphi}(\xi,n)}}{\lambda(\xi,n)-\zeta} d\xi = \sum_{j=1}^{2} \int_{\lambda(0,n)}^{+\infty} \frac{f^j(\lambda,n)\,\overline{\varphi^j(\lambda,n)}}{\lambda-\zeta} d\lambda \tag{3.21a}$$

$$\text{with } f \text{ and } \varphi \text{ in } L^2(\Omega). \tag{3.21b}$$

If $n \geq m$ (which is equivalent to $\lambda(0,n) \geq \mu$),

$$B_n(\mu, f, \varphi) = \int_{-\infty}^{+\infty} \frac{\widetilde{f}(\xi,n)\,\overline{\widetilde{\varphi}(\xi,n)}}{\lambda(\xi,n)-\mu} d\xi = \sum_{j=1}^{2} \int_{\lambda(0,n)}^{+\infty} \frac{f^j(\lambda,n)\,\overline{\varphi^j(\lambda,n)}}{\lambda-\mu} d\lambda \tag{3.22a}$$

$$\text{with } f \text{ and } \varphi \text{ in } L^2(\Omega) \quad \text{if } n > m \text{ (and } \lambda(0,n) > \mu) \tag{3.22b}$$

$$\text{with } f \text{ and } \varphi \text{ in } NL^2_s(m), \quad s > 1, \quad \text{if } n = m \text{ (and } \mu = \lambda(0,m)). \tag{3.22c}$$

If $n < m$ (which is equivalent to $\lambda(0,n) < \mu$),

(3.23a)

$$B_n(\mu, f, \varphi) = \text{p.v.} \int_{-\infty}^{+\infty} \frac{\widetilde{f}(\xi,n)\,\overline{\widetilde{\varphi}(\xi,n)}}{\lambda(\xi,n)-\mu} d\xi = \sum_{j=1}^{2} \text{p.v.} \int_{\lambda(0,n)}^{+\infty} \frac{f^j(\lambda,n)\,\overline{\varphi^j(\lambda,n)}}{\lambda-\mu} d\lambda,$$

$$r_n(\mu, f, \varphi) = \sum_{j=1}^{2} f^j(\mu,n)\,\overline{\varphi^j(\mu,n)} \tag{3.23b}$$

$$\text{with } f \text{ and } \varphi \text{ in } L^2_s(\Omega), \quad s > 1/2. \tag{3.23c}$$

The existence of the following limits $B_n^{\pm}$ is used in [CD95a]:

If $n \geq m$ and if both f and φ satisfy (3.22b) in the case where $n > m$ or (3.22c) in the case where $n = m$,

$$B_n^+(\mu, f, \varphi) = B_n^-(\mu, f, \varphi) = \lim_{\zeta \to \mu,\ \pm \mathrm{Im}\zeta > 0} B_n(\zeta, f, \varphi) = B_n(\mu, f, \varphi). \tag{3.24}$$

If $n < m$ and if both f and φ satisfy (3.23c),

$$B_n^{\pm}(\mu, f, \varphi) = \lim_{\zeta \to \mu,\ \pm \mathrm{Im}\zeta > 0} B_n(\zeta, f, \varphi) = B_n(\mu, f, \varphi) \ \pm\ i\,\pi\, r_n(\mu, f, \varphi). \tag{3.25}$$

For $\zeta \in \overline{\mathbb{C}^{\pm}} = \{\zeta \in \mathbb{C} \ / \ \pm \mathrm{Im}\zeta \geq 0\}$, $\zeta \notin \sigma(A)$, with f and $\varphi \in L^2(\Omega)$, we set

$$B_n^{\pm}(\zeta, f, \varphi) = B_n(\zeta, f, \varphi). \tag{3.26}$$

The limiting absorption principle and the properties of the resolvent on $\overline{\mathbb{C}^{\pm}}$ are based on a detailed study of the functions $\zeta \mapsto B_n^{\pm}(\zeta, n, \varphi)$ near the spectrum $\sigma(A)$. This study is presented in Propositions 3.6 and 3.7 of [CD95a] and consists of proving particular properties for the Hilbert transform of a Hölder continuous function. The main result—namely, the Hölder continuity of the Hilbert transform—is also proved by Muskhelishvili [Mu] in a theorem on the behavior of a Cauchy integral near the boundary. We now give these properties in the form which we use for the proof of Theorem 2.3.

THEOREM 3.7. *Let a, b $(a < b)$, and $\delta \in [0,1)$ be three real numbers. Let h be a function that is Hölder continuous on $[a,b]$ with order δ. We suppose that $h(a) = h(b) = 0$ and that there exists a constant $A(h)$ such that*

$$\forall \lambda, \lambda' \in [a,b], \quad |h(\lambda) - h(\lambda')| \le A(h)|\lambda - \lambda'|^{\delta}. \tag{3.27}$$

For ζ in $\mathbb{C}^{\pm} = \{\zeta \in \mathbb{C} \ / \ \pm \mathrm{Im}\zeta > 0\}$, we set $\mathcal{H}h^{\pm}(\zeta) = \int_a^b (h(\lambda)/(\lambda - \zeta))d\lambda$. Then the following hold:

(i) *For a real number μ in $[a,b]$, the following limits exist:*

$$\text{if } h(\mu) \neq 0, \quad \mathcal{H}h^{\pm}(\mu) = \lim_{\zeta \to \mu, \ \pm\mathrm{Im}\zeta > 0} \mathcal{H}h^{\pm}(\zeta) = \text{p.v.} \int_a^b \frac{h(\lambda)}{\lambda - \mu} d\lambda \pm i\pi h(\mu); \tag{3.28}$$

$$\text{if } h(\mu) = 0, \quad \mathcal{H}h^{+}(\mu) = \mathcal{H}h^{-}(\mu) = \lim_{\zeta \to \mu, \ \pm\mathrm{Im}\zeta > 0} \mathcal{H}h^{\pm}(\zeta) = \int_a^b \frac{h(\lambda)}{\lambda - \mu} d\lambda. \tag{3.29}$$

(ii) *The extended functions $\mathcal{H}h^{\pm}$ on $V^{\pm} = \{\zeta \in \overline{\mathbb{C}^{\pm}} \ / \ a \le \mathrm{Re}\zeta \le b\}$, are Hölder continuous on $V^{\pm}$ with order δ. Specifically, there exist functions $C(\zeta, \zeta') = C(a, b, \delta, \zeta, \zeta')$ and $D(\zeta) = D(a, b, \delta, \zeta)$, continuous with respect to ζ and ζ' and independent of h, such that for ζ and ζ' in $V^{\pm}$, we have*

$$|\mathcal{H}h^{\pm}(\zeta) - \mathcal{H}h^{\pm}(\zeta')| \le A(h)C(\zeta, \zeta')|\zeta - \zeta'|^{\delta}, \tag{3.30}$$

$$|\mathcal{H}h^{\pm}(\zeta)| \le A(h)D(\zeta). \tag{3.31}$$

Proof. We refer to [Mu, Chap. 2, §22] (see also [G, Chap. I, §5]). Note that the use of the maximum-modulus theorem allows us to increase the Hölder order for $\mathcal{H}h^{\pm}$ up to $\delta < 1$ and not only to any δ', $\delta' < \delta$. An attentive reading of the proof shows the precise dependence on h in (3.30) and (3.31), as in our proofs of Propositions 3.6 or 3.7 of [CD95a]. □

The next two propositions collect estimates that can be found more or less explicitly in §3 of [CD95a].

PROPOSITION 3.8 (Hölder continuity and bounds for $B_n^{\pm}$ and r_n outside of $\Gamma(A)$). *Let $m \ge 2$ be an integer, I_m be the interval $(\lambda(0, m-1), \lambda(0, m))$, and $I_m^{\pm} = \{\zeta \in \overline{\mathbb{C}^{\pm}} \ / \ \mathrm{Re}\zeta \in I_m\}$. Let s and δ be real numbers such that*

$$s > 1/2 \quad \text{and} \quad \delta \in [0, \mathrm{Min}(1, s - 1/2)). \tag{3.32}$$

Then there exist functions $C(\zeta, \zeta') = C_m(s, \delta, \zeta, \zeta')$ and $D(\zeta) = D_m(s, \delta, \zeta)$, continuous with respect to ζ and ζ', such that for any functions f and φ in $L_s^2(\Omega)$,

(i) *for any complex numbers* ζ *and* ζ' *in* $I_m^{\pm}$, *we have*

$$\sum_{n\geq m} |B_n^{\pm}(\zeta,f,\varphi) - B_n^{\pm}(\zeta',f,\varphi)| \leq C(\zeta,\zeta')|\zeta-\zeta'| \, \|f\|_{L^2(\Omega)} \, \|\varphi\|_{L^2(\Omega)}, \tag{3.33}$$

$$\sum_{n\geq m} |B_n^{\pm}(\zeta,f,\varphi)| \leq D(\zeta)\|f\|_{L^2(\Omega)}\|\varphi\|_{L^2(\Omega)}, \tag{3.34}$$

$$\sum_{1\leq n<m} |B_n^{\pm}(\zeta,f,\varphi) - B_n^{\pm}(\zeta',f,\varphi)| \leq C(\zeta,\zeta')|\zeta-\zeta'|^{\delta}\|f\|_{L^2_s(\Omega)}\|\varphi\|_{L^2_s(\Omega)}, \tag{3.35}$$

$$\sum_{1\leq n<m} |B_n^{\pm}(\zeta,f,\varphi)| \leq D(\zeta)\|f\|_{L^2_s(\Omega)}\|\varphi\|_{L^2_s(\Omega)}; \tag{3.36}$$

(ii) *for any real numbers* λ *and* λ' *in* I_m, *we have*

$$\sum_{1\leq n<m} |r_n(\lambda,f,\varphi) - r_n(\lambda',f,\varphi)| \leq C(\lambda,\lambda')|\lambda-\lambda'|^{\delta}\|f\|_{L^2_s(\Omega)}\|\varphi\|_{L^2_s(\Omega)}, \tag{3.37}$$

$$\sum_{1\leq n<m} |r_n(\lambda,f,\varphi)| \leq D(\lambda)\|f\|_{L^2_s(\Omega)}\|\varphi\|_{L^2_s(\Omega)}. \tag{3.38}$$

Moreover, in (3.37), *the order* δ *can go up to* 1 *if* $s > 3/2$.

PROPOSITION 3.9 (Hölder continuity and bounds for $B_n^{\pm}$ and r_n near $\Gamma(A)$). *Let* $m \geq 1$ *be an integer and* $\lambda(0,m)$ *be the corresponding threshold of* A. *Let* J_m *be the interval* $(\lambda(0,m-1),\lambda(0,m+1))$ *and* $J_m^{\pm} = \{\zeta \in \overline{\mathbb{C}^{\pm}} \ / \ \mathrm{Re}\zeta \in J_m\}$.

(i) *Let* s *and* δ *be real numbers satisfying* (3.32). *Then there exist functions* $C(\zeta,\zeta') = C_m(s,\delta,\zeta,\zeta')$ *and* $D(\zeta) = D_m(s,\delta,\zeta)$, *continuous with respect to* ζ,ζ', *such that for any functions* f *and* φ *in* $L^2_s(\Omega)$ *and for any complex numbers* ζ *and* ζ' *in* $J_m^{\pm}$, *we have on the one hand*

$$\sum_{n>m} |B_n^{\pm}(\zeta,f,\varphi) - B_n^{\pm}(\zeta',f,\varphi)| \leq C(\zeta,\zeta')|\zeta-\zeta'| \, \|f\|_{L^2(\Omega)} \, \|\varphi\|_{L^2(\Omega)}, \tag{3.39}$$

$$\sum_{n>m} |B_n^{\pm}(\zeta,f,\varphi)| \leq D(\zeta)\|f\|_{L^2(\Omega)}\|\varphi\|_{L^2(\Omega)}, \tag{3.40}$$

and on the other hand, for $1 \leq n < m$, *estimates* (3.35) *and* (3.36) *and estimates* (3.37) *and* (3.38) *for any real numbers* λ *and* λ' *in* J_m.

(ii) *Let* s *and* δ *be real numbers such that*

$$s > 1 \quad \text{and} \quad \delta \in [0, \mathrm{Min}(1/4,(s-1)/2)). \tag{3.41}$$

Then there exist functions $C(\zeta,\zeta') = C_m(s,\delta,\zeta,\zeta')$ *and* $D(\zeta) = D_m(s,\delta,\zeta)$, *continuous with respect to* ζ *and* ζ', *such that for any complex numbers* ζ *and* ζ' *in* $J_m^{\pm}$ *and for any functions* f *and* φ *in* $NL^2_s(m)$, *one has*

$$|B_m^{\pm}(\zeta,f,\varphi) - B_m^{\pm}(\zeta',f,\varphi)| \leq C(\zeta,\zeta')|\zeta-\zeta'|^{\delta}\|f\|_{L^2_s(\Omega)}\|\varphi\|_{L^2_s(\Omega)}, \tag{3.42}$$

$$|B_m^{\pm}(\zeta,f,\varphi)| \leq D(\zeta)\|f\|_{L^2_s(\Omega)}\|\varphi\|_{L^2_s(\Omega)}. \tag{3.43}$$

Remark 3.1. If $s > 3/2$, we prove in Theorem 5.2 in §5 that the Hölder order in point (ii) can be improved up to δ in $[0,1/2]$, $\delta < (s-3/2)/2$.

We now use Agmon's result from §3.1.

PROPOSITION 3.10 (a new estimate for B_n). *Let $m \geq 2$ and $n \geq 1$ be integers such that $n < m$. Let μ be a real number in $\sigma(A)$ such that $\lambda(0, m-1) < \mu \leq \lambda(0,m)$. Let $s > 1/2$ be a real number. Then for any function f such that*

$$f \in L^2_s(\Omega), \qquad \tilde{f}(\pm\xi(\mu,n),n) = 0 \tag{3.44}$$

and for any function $\varphi \in L^2_s(\Omega)$, the principal-value integral (3.23a) *is an ordinary integral written as*

$$B_n(\mu,f,\varphi) = \int_{-\infty}^{+\infty} \frac{\tilde{f}(\xi,n)\,\overline{\tilde{\varphi}(\xi,n)}}{\lambda(\xi,n)-\mu}d\xi. \tag{3.45}$$

With a constant $C = C(\mu,s)$ independent of f and φ, it satisfies the estimate

$$|B_n(\mu,f,\varphi)| \leq C\|f\|_{L^2_s(\Omega)}\|\varphi\|_{L^2_{\tilde{s}}(\Omega)} \quad \textit{with } \tilde{s} = \mathrm{Max}(0, 1-s). \tag{3.46}$$

Moreover, if $s \geq 1$, for any function f satisfying (3.44) *and for any function φ in $L^2(\Omega)$, the integral* (3.45) *is still defined and the estimate* (3.46) *holds with $\tilde{s} = 0$.*

Proof. When $n < m$, the equation $\lambda(\xi,n) - \mu = 0$ has two roots $\xi = \pm\xi(\mu,n)$ which are of order 1. We fix a real number $\delta = \delta(\mu,n) > 0$ such that $\pm\xi(\mu,n)$ is the only root for $\lambda(\xi,n)-\mu = 0$ in the interval $J_n^\pm = (\pm\xi(\mu,n)-2\delta,\ \pm\xi(\mu,n)+2\delta)$. Then we choose a function $\Phi = \Phi_{n,\mu}$ in $C_0^\infty(\mathbb{R})$ equal to 1 on $(\pm\xi(\mu,n)-\delta,\ \pm\xi(\mu,n)+\delta)$ with support in $J_n^\pm$ and valued in $[0,1]$. In order to study the integral in (3.23a), we rewrite it in the form $B_n(\mu,f,\varphi) = b_n(\mu,f,\varphi) + s_n(\mu,f,\varphi)$ with

$$b_n(\mu,f,\varphi) = \int_{-\infty}^{+\infty} \frac{(1-\Phi(\xi)^2)\tilde{f}(\xi,n)\,\overline{\tilde{\varphi}(\xi,n)}}{\lambda(\xi,n)-\mu}d\xi, \tag{3.47}$$

$$s_n(\mu,f,\varphi) = \int_{-\infty}^{+\infty} \frac{\Phi(\xi)\tilde{f}(\xi,n)\,\overline{\Phi(\xi)\tilde{\varphi}(\xi,n)}}{\lambda(\xi,n)-\mu}d\xi. \tag{3.48}$$

The integral in the right-hand side of (3.47) is well defined when f and φ are in $L^2(\Omega)$. From (2.9), we get a bound for b_n with a constant $C = C(\mu)$,

$$|b_n(\mu,f,\varphi)| \leq C\int_{-\infty}^{+\infty} |\tilde{f}(\xi,n)\overline{\tilde{\varphi}(\xi,n)}|d\xi \leq C\|f\|_{L^2(\Omega)}\|\varphi\|_{L^2(\Omega)}. \tag{3.49}$$

Let us now consider the term $s_n(\mu,f,\varphi)$. Using Proposition 3.2, we have the function $\Phi\tilde{f}(.,n)$ in $H^s(\mathbb{R})$ and the estimate $\|\Phi\tilde{f}(.,n)\|_{H^s(\mathbb{R})} \leq C(s,n,\Phi)\ \|f\|_{L^2_s(\mathbb{R})}$. Moreover, since $\tilde{f}(\pm\xi(\mu,n),n) = 0$, with the help of Lemma B.2, we get the function $V = (\Phi\tilde{f}(.,n))/(\lambda(.,n)-\mu)$ in $H^{s-1}(\mathbb{R}) \cap L^1(\mathbb{R})$ and the estimate

$$\|V\|_{H^{s-1}(\mathbb{R})} \leq C(s,n)\|\Phi\tilde{f}(.,n)\|_{H^s(\mathbb{R})} \leq C(s,n,\Phi)\|f\|_{L^2_s(\Omega)}. \tag{3.50}$$

When φ is in $L^2_s(\Omega)$, $s > 1/2$, the function $\tilde{\varphi}(.,n)$ is continuous. From this and from our conditions on s, f, and φ, it follows that the function $V\overline{\Phi\tilde{\varphi}(.,n)}$ is in $L^1(\mathbb{R})$. Then the integral in the right-hand side of (3.48) is well defined, and (3.45) is valid.

Moreover, as φ belongs to $L^2_{\tilde{s}}(\Omega) \subseteq L^2_{1-s}(\Omega)$, again from Proposition 3.2, it follows that $\Phi\widetilde{\varphi}(.,n)$ in $H^{1-s}(\mathbb{R})$ and

$$\|\Phi\widetilde{\varphi}(.,n)\|_{H^{1-s}(\mathbb{R})} \leq C(s,n,\Phi)\ \|\varphi\|_{L^2_{1-s}(\Omega)}. \tag{3.51}$$

When φ is in $\mathcal{S}(\mathbb{R})$, the integral in (3.48) can be written as the duality brackets

$$s_n(\mu,f,\varphi) = \langle V, \overline{\Phi\widetilde{\varphi}(.,n)}\rangle_{\mathcal{S}'(\mathbb{R}),\,\mathcal{S}(\mathbb{R})} = \langle \mathcal{F}V, \mathcal{F}^{-1}(\overline{\Phi\widetilde{\varphi}(.,n)})\rangle_{L^2_{s-1}(\Omega),\ L^2_{1-s}(\Omega)}.$$

By a density argument, for any φ in $L^2_{\tilde{s}}(\Omega)$ if $1/2 < s < 1$ and $t = 1-s$ or for any φ in $L^2(\Omega)$ if $s \geq 1$ and $t = 0$, we get

$$|s_n(\mu,f,\varphi)| \ \leq\ C\|f\|_{L^2_s(\Omega)}\|\varphi\|_{L^2_t(\Omega)} \tag{3.52}$$

with $C = C(\mu,s)$. Estimate (3.46) follows from (3.49) and (3.52). □

PROPOSITION 3.11 (a new estimate for B_m at the threshold $\mu = \lambda(0,m)$). *Let $m \geq 1$ be an integer, $\mu = \lambda(0,m)$ be the corresponding threshold of A, and $s > 3/2$ be a real number. Then for any function f in $NL^2_s(m,1)$, the integral*

$$I_m(\mu,f,\varphi) = \int_{-\infty}^{+\infty} \frac{\widetilde{f}(\xi,m)\ \overline{\widetilde{\varphi}(\xi,m)}}{\lambda(\xi,m)-\mu}d\xi \tag{3.53}$$

is defined for any function φ in $L^2_{\tilde{s}}(\Omega)$ or, if $s \geq 2$, for any function φ in $L^2(\Omega)$. It satisfies the estimate

$$|I_m(\mu,f,\varphi)| \leq C\|f\|_{L^2_s(\Omega)}\|\varphi\|_{L^2_{\tilde{s}}(\Omega)} \quad \textit{with } \tilde{s} = \operatorname{Max}(0, 2-s) \tag{3.54}$$

with a constant $C = C(\mu,s)$ independent of f and φ. Moreover, if φ is a function in $NL^2_s(m)$, we have $I_m(\mu,f,\varphi) = B_m(\mu,f,\varphi)$.

Proof. We proceed in the same way as in the proof of Proposition 3.10. We have (2.4), that is, $\lambda(\xi,m) - \mu = \xi^2 a_m(\xi)$ with $a_m(\xi)$ an analytical function on $\mathbb{R}$ which does not vanish. With the help of a function $\Phi = \Phi_\mu$ in $C_0^\infty(\mathbb{R})$ equal to 1 in a neighborhood of $\xi = 0$ and valued in $[0,1]$, we again represent the integral in the form of the sum

$$B_m(\mu,f,\varphi) = b_m(\mu,f,\varphi) + s_m(\mu,f,\varphi) \tag{3.55}$$

with b_m and s_m defined by (3.47) and (3.48). Estimate (3.49) is still valid for b_m. Since $s > 3/2$ and f is in $NL^2_s(m,1)$, according to the definition of $NL^2_s(m,1)$ in (3.16), the function $\widetilde{f}(.,m)$ and its first derivative vanish at $\xi = 0$. With the help of Proposition 3.2 and Corollary 3.1, we get $\Phi\widetilde{f}(.,m)$ in $H^s(\mathbb{R})$, $V = (\Phi\widetilde{f}(.,m))/(\xi^2 a_m(\xi))$ in $H^{s-2}(\mathbb{R}) \cap L^1(\mathbb{R})$, and the estimate

$$\|V\|_{H^{s-2}(\mathbb{R})} \leq C(s,m)\|\Phi\widetilde{f}(.,m)\|_{H^s(\mathbb{R})} \leq C(s,m,\Phi)\|f\|_{L^2_s(\Omega)}.$$

The end of the proof is similar to the end of the proof of Proposition 3.10. □

4. Proofs of the division theorems. These theorems concern the operators $R^{\pm}_A(\mu)$ defined by LAP1 or LAP2. We refer to Proposition 3.8 of [CD95a] for their explicit calculations. We recall that they are obtained by studying the limits of

$$(R^{\pm}_A(\zeta)f \mid \varphi)_{L^2(\Omega)} \ =\ ((A-\zeta I)^{-1} \mid \varphi)_{L^2(\Omega)} \ =\ \sum_{n\geq 1} B^{\pm}_n(\zeta,f,\varphi) \tag{4.1}$$

when $\zeta \in \mathbb{C}^{\pm} = \{\zeta \in \mathbb{C} \;/\; \pm \mathrm{Im}\zeta > 0\}$, $\zeta \notin \sigma(A)$, and ζ tends to $\mu \in \sigma(A)$. Here the quantities $B_n^{\pm}$ are given by (3.26) and (3.21).

Let μ be a real number in $\sigma(A) = [\lambda(0,1), +\infty)$. We set $\lambda(0,0) = 0$. Let $m \geq 1$ be the integer such that μ is in the interval $(\lambda(0,m-1), \lambda(0,m)]$. Let s be a real number and $E_s(\mu)$ be the space of functions defined on Ω such that $s > 1/2$ and $E_s(\mu) = L^2_s(\Omega)$ if $\mu \neq \lambda(0,m)$, $s > 1$, and $E_s(\mu) = NL^2_s(m)$ if $\mu = \lambda(0,m)$. With such a μ, m, and s and with f and φ in $E_s(\mu)$, we have

$$\begin{aligned} \langle R_A^{\pm}(\mu)f, \overline{\varphi}\rangle_{E_s(\mu)',\, E_s(\mu)} &= \lim_{\zeta \to \mu,\ \pm\mathrm{Im}\zeta > 0} (R_A^{\pm}(\zeta)f \mid \varphi)_{L^2(\Omega)} \\ &= \sum_{n \geq 1} B_n(\mu, f, \varphi) \;\pm\; i\pi \sum_{n<m} r_n(\mu, f, \varphi), \end{aligned} \tag{4.2}$$

where the quantities B_n and r_n are given by (3.22a)–(3.23b). When the zero-trace conditions (2.21) are fulfilled, we have the simpler formula

$$\langle R_A^{+}(\mu)f, \overline{\varphi}\rangle_{E_s(\mu)',E_s(\mu)} = \langle R_A^{-}(\mu)f, \overline{\varphi}\rangle_{E_s(\mu)',\, E_s(\mu)} = \sum_{n \geq 1} B_n(\mu, f, \varphi). \tag{4.3}$$

Proof of Theorem 2.1. Let μ be in $I_m = (\lambda(0,m-1), \lambda(0,m))$. Let s and f satisfy the assumptions of Theorem 2.1. The function f is in $L^2_s(\Omega)$ and satisfies the zero-trace conditions (2.21). Formula (4.3) defines $u = R_A^{\pm}(\mu)f$ and holds in particular with φ in $C_0^{\infty}(\Omega)$. We apply Proposition 3.8 and Proposition 3.10 with $\tilde{s} = \mathrm{Max}(0, 1-s)$. We get

$$|\langle u, \overline{\varphi}\rangle_{\mathcal{D}'(\Omega), C_0^{\infty}(\Omega)}| = \left| \sum_{n \geq 1} B_n(\mu, f, \varphi) \right| \leq C \|f\|_{L^2_s(\Omega)} \|\varphi\|_{L^2_{\tilde{s}}(\Omega)} \tag{4.4}$$

with $C = C(\mu, s)$ independent of f in $L^2_s(\Omega)$, with φ in $C_0^{\infty}(\Omega)$, and continuous with respect to μ in I_m. Therefore, u is in $L^2_{-\tilde{s}}(\Omega)$ and satisfies (2.22). □

Proof of Theorem 2.2. Let $\mu = \lambda(0,m)$ and let s and f satisfy the assumptions of Theorem 2.2. The function f is in $NL^2_s(m,1)$, a closed hyperplane of $NL^2_s(m)$, and LAP2 is valid. With the zero-trace conditions (2.21), formula (4.3) defines $u = R_A^{\pm}(\mu)f$ and holds in particular with φ in $W(m) = NL^2_s(m) \cap C_0^{\infty}(\Omega)$. We apply Propositions 3.9, 3.10, and 3.11. The last of these requires f to be in $NL^2_s(m,1)$. We get

$$|\langle u, \overline{\varphi}\rangle_{NL^2_s(m)', NL^2_s(m)}| = \left| \sum_{n \geq 1} B_n(\mu, f, \varphi) \right| \leq C \|f\|_{L^2_s(\Omega)} \|\varphi\|_{L^2_{\tilde{s}}(\Omega)}, \tag{4.5}$$

where $\tilde{s} = \mathrm{Max}(0, 2-s)$ and $C = C(\mu, s)$ independent of f in $NL^2_s(m,1)$ and φ in $W(m)$. A density argument ends the proof: as $s > 3/2$, we have $\tilde{s}$ in $[0, 1/2)$, and the space $W(m)$ is dense in $L^2_{\tilde{s}}(\Omega)$. Therefore, u is in $L^2_{-\tilde{s}}(\Omega)$ and satisfies (2.24). □

Remark 4.1. The density argument about $W(m)$ can be omitted. Let us consider the form $U(\varphi) = \sum_{n \geq 1} B_n(\mu, f, \varphi)$ occuring in the right-hand side of (4.3). We apply point (i) of Proposition 3.9 if $n > m$, Proposition 3.10 if $n < m$, and Proposition 3.11 if $n = m$. With f in $NL^2_s(m,1)$ and φ in $C_0^{\infty}(\Omega)$, we get

$$|U(\varphi)| \leq C \|f\|_{L^2_s(\Omega)} \|\varphi\|_{L^2_{\tilde{s}}(\Omega)}.$$

The form U—and therefore u—is in $L^2_{-\tilde{s}}(\Omega)$.

5. Returning to the limiting absorption principle at thresholds. Let $m \geq 1$ be an integer and $\mu = \lambda(0, m)$ be the corresponding threshold of A. For $s > 1$ and f in $NL^2_s(m)$, the limit form $u^{\pm} = R^{\pm}_A(\mu)f$ in LAP2 is not defined on $L^2_{\tilde{s}}(\Omega)$. The trouble is caused by the following fact: when φ is in $L^2_{\tilde{s}}(\Omega) \setminus NL^2_s(m)$ and when ζ is not in $\sigma(A)$ and tends to μ, the modulus of $B_m(\zeta, f, \varphi)$ defined by (3.22) can tend to $+\infty$.

Let us consider the form $B_m(\mu, f, .)$ defined by (3.22) on $NL^2_s(m)$ when $s > 1$ and f is in $NL^2_s(m)$. On the basis of Proposition 3.11, this form can be extended to $L^2_{\tilde{s}}(\Omega)$, $\tilde{s} = \text{Max}(0, 2 - s)$, when $s > 3/2$ and f is in $NL^2_s(m, 1)$. On the subspace $L^2_s(\Omega)$ of $L^2_{\tilde{s}}(\Omega)$, this continuation is given by the integral in (3.53).

Let us now fix $s > 3/2$, f in $NL^2_s(m, 1)$, and φ in $L^2_s(\Omega)$. The question with respect to the prospect of a "better" limiting absorption principle at thresholds is whether the limit in (3.24) is still valid and if this limit is equal to $I_m(\mu, f, \varphi)$. A quick answer can be obtained. For ζ not in $\sigma(A)$, we consider

$$B_m(\zeta, f, \varphi) = \int_{-\infty}^{+\infty} \frac{\widetilde{f}(\xi, m)\, \overline{\widetilde{\varphi}(\xi, m)}}{\xi^2 a_m(\xi) - (\zeta - \mu)} d\xi. \tag{5.1}$$

As seen in Proposition 3.11, the function $\xi \mapsto (\widetilde{f}(\xi, m))/(\xi^2 a_m(\xi))$ is in $L^1_{\text{loc}}(\mathbb{R})$, and the function $\xi \mapsto \widetilde{\varphi}(\xi, m)$ is continuous on $\mathbb{R}$. Then with the condition $\text{Re}\zeta \leq \mu$, we may apply the Lebesgue dominated-convergence theorem and get

$$\lim_{\zeta \to \mu,\ \text{Re}\zeta\ \leq\ \mu,\ \zeta \notin \sigma(A)} B_m(\zeta, f, \varphi) = I_m(\mu, f, \varphi). \tag{5.2}$$

In fact, the restriction $\text{Re}\zeta \leq \mu$ in (5.2) can be raised. To do this, we have to use the finer properties of the trace functions, which are contained in Corollary 3.4 and Proposition 3.6. They allow us to apply Theorem 3.7.

5.1. Analysis of the term B_m near $\lambda(0, m)$.

It is more convenient to use the spectral variable λ in order to study the integral (3.22). For $j = 1$ or 2, for ζ not in $\sigma(A)$, and for f in $NL^2_s(m, 1)$ and φ in $L^2_s(\Omega)$, $s > 3/2$, we consider

$$B^j_m(\zeta, f, \varphi) = \int_{\lambda(0,m)}^{+\infty} \frac{f^j(\lambda, m)\, \overline{\varphi^j(\lambda, m)}}{\lambda - \zeta} d\lambda. \tag{5.3}$$

In view of (3.11), for $\lambda \in \overline{I_m} = [\lambda(0, m), +\infty)$, we set

$$h^j(\lambda) = f^j(\lambda, m)\, \overline{\varphi^j(\lambda, m)} = (\lambda - \lambda(0, m))^{1/4} F^j(\lambda, m) \overline{\varphi^j(\lambda, m)}. \tag{5.4}$$

It follows from Corollary 3.4 and Proposition 3.6 that the function $F^j(., m)$ is locally Hölder continuous on $\overline{I_m}$ with order δ in $[0, 1/2]$, $\delta < (s - 3/2)/2$, and vanishes at $\lambda = \lambda(0, m)$. We now specify the behavior of $\Phi^j(\lambda, m) = (\lambda - \lambda(0, m))^{1/4} \varphi^j(\lambda, m)$.

PROPOSITION 5.1. *Let $m \geq 1$ be an integer. Let $s > 1/2$ be a real number and φ be a function in $L^2_s(\Omega)$. Then the function $\Phi^j(., m)$ defined on $\overline{I_m} = [\lambda(0, m), +\infty)$ by*

$$\Phi^j(\lambda, m) = (\lambda - \lambda(0, m))^{1/4} \varphi^j(\lambda, m) \tag{5.5}$$

is locally Hölder continuous with order δ in $[0, 1/2]$, $\delta < (s - 1/2)/2$. Specifically, there exists a function $C(\lambda, \lambda') = C_m(s, \delta, \lambda, \lambda')$, continuous with respect to $\lambda, \lambda' \geq \lambda(0, m)$, such that

$$\forall \varphi \in L^2_s(\Omega), \quad |\Phi^j(\lambda, m) - \Phi^j(\lambda', m)| \leq C(\lambda, \lambda') |\lambda - \lambda'|^{\delta} \|\varphi\|_{L^2_s(\Omega)}. \tag{5.6}$$

In particular, if $s > 3/2$, $\Phi^j(.,m)$ *is locally Hölder continuous with order* $1/2$.

Proof. It is similar to the one concerning $F^j(.,m)$ in Corollary 3.4. Let $\lambda, \lambda' \geq \lambda(0,m)$ and let $\xi, \xi' \geq 0$ be connected by $\xi = \xi(\lambda, m)$ and $\xi' = \xi(\lambda', m)$. Estimate (2.15) already shows that $\Phi^j(.,m)$ is bounded. From (2.17d), we get

$$\Phi^j(\lambda, m) = H_m(\xi)^{1/2}\widetilde{\varphi}((-1)^j\xi, m).$$

The analyticity and strict positivity of H_m, the Hölder condition (2.11) of $\widetilde{\varphi}(.,m)$, with order δ' in $[0,1]$, $\delta' < s - 1/2$, imply

$$|\Phi^j(\lambda,m) - \Phi^j(\lambda',m)| \leq M(\xi,\xi')|\xi - \xi'|^{\delta'} \|\varphi\|_{L^2_s(\Omega)}.$$

With (2.17b), we get (5.6). □

We are now in a position to state the main result that will allow us to prove Theorem 2.3. This result has to be compared with point (ii) of Proposition 3.9.

First, we recall and fix some notation. According to (3.26), (3.24), (3.25), and (3.53), for a function f in $NL^2_s(m,1)$ and a function φ in $L^2_s(\Omega)$, we can define the function $B^{\pm}_m(.,f,\varphi)$ on $\overline{\mathbb{C}^{\pm}}$ by

$$B^{\pm}_m(\zeta, f, \varphi) = B_m(\zeta, f, \varphi) \quad \text{if } \pm\text{Im}\zeta > 0, \tag{5.7a}$$

$$B^{\pm}_m(\lambda, f, \varphi) = B_m(\lambda, f, \varphi) \quad \text{if } \lambda < \lambda(0,m), \tag{5.7b}$$

$$B^{\pm}_m(\lambda, f, \varphi) = B_m(\lambda, f, \varphi) \pm i\,\pi\, r_m(\lambda, f, \varphi) \quad \text{if } \lambda > \lambda(0,m), \tag{5.7c}$$

$$B^{\pm}_m(\lambda(0,m), f, \varphi) = I_m(\lambda(0,m), f, \varphi). \tag{5.7d}$$

THEOREM 5.2 (Hölder continuity and bounds for $B^{\pm}_m$ near $\lambda(0,m)$). *Let* $m \geq 1$ *be an integer and* $\lambda(0,m)$ *be the corresponding threshold of* A. *Let* J_m *be the interval* $(\lambda(0,m-1), \lambda(0,m+1))$ *and* $J^{\pm}_m = \{\zeta \in \overline{\mathbb{C}^{\pm}}\ /\ \text{Re}\zeta \in J_m\}$. *Let* s *and* δ *be real numbers such that*

$$s > 3/2 \quad \textit{and} \quad \delta \in [0,1/2], \quad \delta < (s - 3/2)/2. \tag{5.8}$$

Then there exist functions $C(\zeta,\zeta') = C_m(s,\delta,\zeta,\zeta')$ *and* $D(\zeta) = D_m(s,\delta,\zeta)$, *continuous with respect to* ζ *and* ζ', *such that for any complex numbers* ζ *and* ζ' *in* $J^{\pm}_m$ *and for any functions* f *in* $NL^2_s(m,1)$ *and* φ *in* $L^2_s(\Omega)$, *we have*

$$|B^{\pm}_m(\zeta, f, \varphi) - B^{\pm}_m(\zeta', f, \varphi)| \leq C(\zeta,\zeta')|\zeta - \zeta'|^{\delta}\|f\|_{L^2_s(\Omega)}\|\varphi\|_{L^2_s(\Omega)}, \tag{5.9}$$

$$|B^{\pm}_m(\zeta, f, \varphi)| \leq D(\zeta)\|f\|_{L^2_s(\Omega)}\|\varphi\|_{L^2_s(\Omega)}. \tag{5.10}$$

In particular, we have

$$\lim_{\zeta \to \lambda(0,m),\ \pm\text{Im}\zeta \geq 0} B^{\pm}_m(\zeta, f, \varphi) = I_m(\lambda(0,m), f, \varphi). \tag{5.11}$$

Proof. Let ζ be in $J^{\pm}_m$ and be not in $\sigma(A)$. We have $B^{\pm}_m(\zeta, f, \varphi) = B_m(\zeta, f, \varphi) = \sum_{j=1}^{2} B^j_m(\zeta, f, \varphi)$ with B^j_m defined in (5.3). We fix $\Lambda > 0$ and set $K = [\lambda(0,m), \lambda(0,m) + \Lambda]$. First, using (2.9), we easily get estimates similar to (5.9) with $\delta = 1$ and to (5.10) for the quantity $J(\zeta, f, \varphi) = \sum_{j=1}^{2} \int_{\lambda(0,m)+\Lambda}^{+\infty} (f^j(\lambda, m)\, \overline{\varphi^j(\lambda, m)})/(\lambda - \zeta) d\lambda$. Second, for $j = 1$ or 2, we study

$$I^j(\zeta, f, \varphi) = \int_K \frac{f^j(\lambda, m)\, \overline{\varphi^j(\lambda, m)}}{\lambda - \zeta} d\lambda = \int_K \frac{h^j(\lambda)}{\lambda - \zeta} d\lambda.$$

Our comments preceding Proposition 5.1 and the proposition itself imply that the function h^j is Hölder continuous on K with order δ in $[0, 1/2]$, $\delta < (s - 3/2)/2$, and there exists a constant $C_m = C_m(s, \delta, \Lambda)$ such that

(5.12)

$$\forall \lambda, \lambda' \in K, \quad \forall \varphi \in L_s^2(\Omega), \quad |h^j(\lambda) - h^j(\lambda')| \leq C|\lambda - \lambda'|^\delta \|f\|_{L_s^2(\Omega)} \|\varphi\|_{L_s^2(\Omega)}.$$

Moreover, the choice of f in $NL_s^2(m, 1)$ implies $F^j(\lambda(0, m), m) = 0$ so that $h^j(\lambda(0, m)) = 0$. Theorem 3.7 is then valid and gives the needed results to end the proof. □

5.2. Proof of Theorem 2.3. Let $\mu = \lambda(0, m)$ and let s and f satisfy the assumptions of Theorem 2.3. Since f is in $NL_s^2(m)$, $s > 3/2 > 1$, LAP2 is valid and formula (4.2) defines $u^\pm = R_A^\pm(\mu) f$ in the dual $NL_s^2(m)'$.

We proceed as in §3.2 of [CD95a].

Using Proposition 3.9 and Theorem 5.2, we get the limits in (2.18) in the norm topology on $B(NL_s^2(m, 1), L_{-s}^2(\Omega))$ and the Hölder conditions in (2.26) for $R_A^\pm$ under condition (5.8) for s and δ.

Formula (2.27) for $\langle R_A^\pm(\mu) f, \varphi \rangle_{L_{-s}^2(\Omega), L_s^2(\Omega)}$, is a consequence of formulas (3.53) and (5.11) for I_m, (3.22) for B_n if $n > m$, and (3.23) and (3.25) for B_n and r_n if $n < m$. When φ is in $NL_s^2(m)$, we again find $\langle u^\pm, \varphi \rangle_{NL_s^2(m)', NL_s^2(m)}$.

Let us now look at the gradient of $R_A^\pm(\zeta) f$. First, we recall a property already used in [CD95a] concerning ∇v when v in $D(A)$. Let t be a real number and v be a function in $D(A) \cap L_t^2(\Omega)$ such that Av is also in $L_t^2(\Omega)$. Then there exists a constant $C = C(t, A)$ such that

$$\|\nabla v\|_{L_t^2(\Omega)} \leq C\, (\|v\|_{L_t^2(\Omega)} + \|Av\|_{L_t^2(\Omega)}).$$

Therefore, when ζ is not in $\sigma(A)$, with $t = -s$ and $v = R_A^\pm(\zeta) f - R_A^\pm(\zeta') f$, we get an estimate similar to (2.26) for $\nabla R_A^\pm(\zeta)$ since $Av = \zeta R_A^\pm(\zeta) f - \zeta' R_A^\pm(\zeta') f$.

Finally, the fact that $U^\pm$ belongs to $D(A)_{\text{loc}}$ and the differential equation (2.28) follow from $\nabla .\, c^2 \nabla R_A(\zeta) = I + \zeta R_A(\zeta)$. □

We are now ready to study the perturbed operator presented in the introduction. We shall develop a perturbative method with ingredients adapted from Majda [Ma]. Preliminary results are presented in [BCD] and detailed and completed in [CD95b].

SEMILINEAR ELLIPTIC EQUATIONS IN $\mathbb{R}^N$ WITH ALMOST PERIODIC OR UNBOUNDED FORCING TERM[*]

GILLES FOURNIER[†], ANDRZEJ SZULKIN[‡], AND MICHEL WILLEM[§]

Our colleague and friend, Gilles Fournier, died untimely on August 13, 1995.
A. Szulkin, M. Willem

Abstract. This work is devoted to the existence and uniqueness of almost periodic solutions in $\mathbb{R}^N$ of the equation $-\Delta u + \sum_{j=1}^N c_j\partial_j u + g(u) = h(x)$. We also prove the existence of solutions with the same growth as some unbounded forcing terms. Under a local monotonicity assumption, the method of upper and lower solutions is used.

Key words. semilinear elliptic equations, almost periodic functions, upper and lower solutions, unbounded forcing term

AMS subject classifications. 34C27, 35B15, 58G20.

1. Introduction.

Let us consider the problem

$$-\Delta u + \sum_{j=1}^{N} c_j\partial_j u + g(u) = h(x), \quad x \in \mathbb{R}^N. \tag{1.1}$$

Many papers are devoted to semilinear elliptic problems of this type; see, e.g., [10]. If h has some additional properties, one may look for solutions of (1.1) which also have such properties. In particular, if h is almost periodic, the existence of almost periodic oscillations for (1.1) is a natural problem (see [2], [5], [7], [12]). The method of [1]–[4] and [7] in treating (1.1) is to use minimization on a Besicovitch–Sobolev space of almost periodic functions. It is then a delicate (and in most cases unsolved) problem to show that the minimizing Besicovitch–Sobolev class contains a function which is a solution of (1.1) in the usual sense. Moreover, in [1]–[5] and [7], only ordinary differential equations are considered, and the variational approach there excludes the possibility of having first-order terms in (1.1).

In this paper, we use the method of upper and lower solutions. In §2, we prove the existence of a locally bounded solution of (1.1) and obtain a basic estimate. In §3, we show that (1.1) has a unique almost periodic solution if g is increasing and h almost periodic. We would like to emphasize here that while in [1]–[5] and [7] it is essential that one has an ordinary differential equation without first-order terms, our method makes it possible to also treat problems *with* first-order terms (like the pendulum with friction—see Example 3.3 below—with $x = t$ and $N = 1$) and *partial* differential equations with almost periodic forcing.

In §4, we consider equation (1.1) with forcing term h having polynomial or subexponential growth. Using appropriate upper and lower solutions, we prove the existence of solutions, with the same growth rate as h.

2. Upper and lower solutions. We first consider the Dirichlet problem

$$\text{(2.1)}\qquad \begin{cases} -\Delta u + \sum_{j=1}^{N} c_j \partial_j u + f(x,u) = h(x), & x \in \Omega \\ u(x) = \gamma(x), \quad x \in \Gamma, \end{cases}$$

where Ω is an open-bounded domain in $\mathbb{R}^N$, $\Gamma := \partial\Omega$ is a smooth submanifold, the c_j's are real constants, $f \in \mathcal{C}(\bar{\Omega} \times \mathbb{R})$, $h \in L^\infty(\Omega)$, and $\gamma \in H^{1/2}(\Gamma)$.

DEFINITION 2.1. *The function $\alpha \in H^1(\Omega) \cap L^\infty(\Omega)$ is a lower solution of* (2.1) *if, for every $v \in \mathcal{D}(\Omega)$,*

$$\text{(2.2)}\qquad v \geq 0 \Rightarrow \int_\Omega \sum_{j=1}^{N} \partial_j \alpha (\partial_j v + c_j v)\, dx + \int_\Omega f(x,\alpha) v\, dx \leq \int_\Omega hv\, dx$$

and, for almost every $x \in \Gamma$,

$$\alpha(x) \leq \gamma(x).$$

The function $\beta \in H^1(\Omega) \cap L^\infty(\Omega)$ is an upper solution of (2.1) *if, for every $v \in \mathcal{D}(\Omega)$,*

$$\text{(2.3)}\qquad v \geq 0 \Rightarrow \int_\Omega \sum_{j=1}^{N} \partial_j \beta (\partial_j v + c_j v)\, dx + \int_\Omega f(x,\beta) v\, dx \geq \int_\Omega hv\, dx$$

and, for almost every $x \in \Gamma$,

$$\beta(x) \geq \gamma(x).$$

Remark 2.2. It is easy to verify that (2.2) and (2.3) hold for every $v \in H_0^1(\Omega)$ if α is a lower and β an upper solution.

The following result is contained in a theorem of Deuel and Hess [8]. We give a sketch of the proof for the sake of completeness.

THEOREM 2.3. *Assume that α is a lower and β an upper solution of* (2.1) *and that $\alpha \leq \beta$. Then problem* (2.1) *has a weak solution $u \in H^1(\Omega)$ such that $\alpha \leq u \leq \beta$. Moreover, $u \in \mathcal{C}^1(\Omega)$.*

Proof. 1. Consider the modified problem

$$\text{(2.4)}\qquad \begin{cases} -\Delta u + \sum_{j=1}^{N} c_j \partial_j u = -F(x,u) + h(x), & x \in \Omega, \\ u(x) = \gamma(x), \quad x \in \Gamma, \end{cases}$$

where F is defined on $\bar{\Omega} \times \mathbb{R}$ by

$$\begin{aligned} F(x,u) &:= f(x,\alpha(x)) \quad \text{if } u < \alpha(x), \\ &:= f(x,u) \quad \text{if } \alpha(x) \leq u \leq \beta(x), \\ &:= f(x,\beta(x)) \quad \text{if } \beta(x) < u. \end{aligned}$$

Since the linear operator in (2.4) is invertible, (2.4) is equivalent to the fixed-point problem

$$\text{(2.5)}\qquad u = Au, \quad u \in K = \{w \in H^1(\Omega) : w|\Gamma = \gamma\}.$$

Since A is completely continous and has a bounded range, problem (2.5) has a solution u by the Schauder fixed-point theorem. Moreover, $u \in W^{2,p}_{\text{loc}}(\Omega)$ for $1 < p < \infty$. In particular, $u \in \mathcal{C}^{1,\alpha}_{\text{loc}}(\Omega)$ for $0 < \alpha < 1$.

2. It remains only to prove that $\alpha \le u \le \beta$ on Ω. Since $v := (\alpha - u)^+ \in H_0^1(\Omega)$, we obtain, from (2.2) and (2.4),

$$\int_\Omega \sum_{j=1}^N \partial_j(\alpha - u)(\partial_j v + c_j v)\, dx \le \int_\Omega (F(x,u) - f(x,\alpha))v\, dx = 0$$

so that

$$\int_\Omega \sum_{j=1}^N (\partial_j(\alpha - u)^+)^2\, dx = 0.$$

Hence $(\alpha - u)^+$ is constant on Ω and, necessarily, $(\alpha - u)^+ = 0$ on Ω. Similarly, we have that $(u - \beta)^+ = 0$ on Ω. □

We now consider the problem

$$-\Delta u + \sum_{j=1}^N c_j \partial_j u + f(x,u) = h(x), \quad x \in \mathbb{R}^N, \tag{2.6}$$

where $f \in \mathcal{C}(\mathbb{R}^N \times \mathbb{R})$ and $h \in L^\infty_{\text{loc}}(\mathbb{R}^N)$.

DEFINITION 2.4. *The function $\alpha \in H^1_{\text{loc}}(\mathbb{R}^N) \cap L^\infty_{\text{loc}}(\mathbb{R}^N)$ is a lower solution of* (2.6) *if, for every $v \in \mathcal{D}(\mathbb{R}^N)$,* (2.2) *holds with $\Omega = \mathbb{R}^N$.*

The function $\beta \in H^1_{\text{loc}}(\mathbb{R}^N) \cap L^\infty_{\text{loc}}(\mathbb{R}^N)$ is an upper solution of (2.6) *if, for every $v \in \mathcal{D}(\mathbb{R}^N)$,* (2.3) *holds with $\Omega = \mathbb{R}^N$.*

THEOREM 2.5. *Assume that α is a lower and β an upper solution of* (2.6) *and $\alpha \le \beta$. Then equation* (2.6) *has a weak solution $u \in \mathcal{C}^1(\mathbb{R}^N)$ such that $\alpha \le u \le \beta$.*

Proof. 1. Let $n \ge 1$ be a fixed integer. Theorem 2.3, applied to $\Omega_n := B(0,n)$, implies the existence of a solution $u_n \in H^1(\Omega_n) \cap \mathcal{C}^1(\Omega_n)$ of

$$\begin{gathered} -\Delta u + \textstyle\sum_{j=1}^N c_j \partial_j u + f(x,u) = h(x), \quad |x| < n, \\ u(x) = \alpha(x), \quad |x| = n, \end{gathered}$$

such that $\alpha \le u_n \le \beta$ on Ω_n.

2. By construction, $(u_n)_{n\ge 2}$ and $(Lu_n)_{n \ge 2}$, where $L = -\Delta + \sum_{j=1}^N c_j \partial_j$, are bounded in $L^\infty(\Omega_2)$. Inequality (4.6) in [11] implies that $(u_n)_{n\ge 2}$ is bounded in $H^1(\Omega_1)$. Thus there exists a subsequence (u_n^1) such that, in $H^1(\Omega_1)$,

$$u_n^1 \rightharpoonup u^1, \quad n \to \infty.$$

By a repeated selection of subsequences, we obtain a sequence (u_n^k) such that in $H^1(\Omega_k)$,

$$u_n^k \rightharpoonup u^k, \quad n \to \infty.$$

It is clear that $u^{k-1} = u^k$ on Ω_{k-1}. Since by the Rellich theorem, in $L^2(\Omega_k)$,

$$u_n^k \to u^k, \quad n \to \infty,$$

it is clear that $\alpha \le u^k \le \beta$ and u^k is a weak solution of

$$-\Delta u + \sum_{j=1}^N c_j \partial_j u + f(x,u) = h(x)$$

on Ω_k. Let us define $u \in H^1_{\text{loc}}(\mathbb{R}^N)$ by $u = u^k$ on Ω_k. Then u is a weak solution of (2.6), $u \in \mathcal{C}^1(\mathbb{R}^N)$, and $\alpha \le u \le \beta$. □

Remark 2.6. The above result generalizes Theorem 2.10 in [10], where it is assumed that $c_1 = \cdots = c_N = 0$, f is a locally Hölder continuous function which is locally Lipschitz continuous in u, and $h = 0$.

We shall now prove a basic estimate.

THEOREM 2.7. *Let $h_1, h_2, \alpha, \beta \in L^\infty(\mathbb{R}^N)$. Assume that there exists $\delta > 0$ such that*

$$\alpha(x) \le s \le t \le \beta(x) \Rightarrow f(x,t) - f(x,s) \ge \delta(t-s). \tag{2.7}$$

If, for $j = 1, 2$, $u_j \in \mathcal{C}^1(\mathbb{R}^N)$ is a weak solution of

$$-\Delta u + \sum_{j=1}^N c_j \partial_j u + f(x,u) = h_j(x)$$

such that $\alpha \le u_j \le \beta$, then

$$|u_1 - u_2|_\infty \le \delta^{-1} |h_1 - h_2|_\infty.$$

Proof. Let us define $c := \delta^{-1}|h_1 - h_2|_\infty$, $v := u_2 - u_1 - c$, and $\Omega := \{x \in \mathbb{R}^N : v(x) > 0\}$. It follows from (2.7) that on Ω,

$$\begin{aligned} -\Delta v + \delta v + \sum_{j=1}^N c_j \partial_j v &= f(x,u_1) - f(x,u_2) + h_2 - h_1 + \delta v \\ &\le -\delta(u_2 - u_1) + |h_2 - h_1|_\infty + \delta v \\ &= |h_2 - h_1|_\infty - \delta c = 0. \end{aligned} \tag{2.8}$$

Let $\omega := v/\psi$, where $\psi(x) = \Pi_{j=1}^N \cosh \alpha x_j$, $\alpha > 0$, and

$$\alpha^2 N + \sum_{j=1}^N \alpha |c_j| < \delta.$$

A simple computation using (2.8) shows that on Ω,

$$-\Delta\omega + \sum_{j=1}^N \partial_j \omega (c_j - 2\alpha \tanh \alpha x_j) + \left(\delta - \alpha^2 N + \sum_{j=1}^N \alpha c_j \tanh \alpha x_j\right) \omega \le 0. \tag{2.9}$$

Assume that $\Omega \ne \phi$ and let $\Omega_R := \Omega \cap B(0,R)$. Since $v \in L^\infty(\mathbb{R}^N)$, $\omega(x) \to 0$ as $|x| \to \infty$. Therefore, for R large enough, there exists $\epsilon > 0$ such that

$$\max_{\partial\Omega_R} \omega < \epsilon < \max_{\Omega_R} \omega.$$

Multiplying (2.9) by $h := (\omega - \epsilon)^+ \in H^1_0(\Omega_R)$ and integrating by parts, we obtain

$$\begin{aligned} \int_{\Omega_R} |\nabla h|^2 \, dx + \alpha^2 \sum_{j=1}^N \int_{\Omega_R} h^2/\cosh^2 \alpha x_j \, dx \\ + \int_{\Omega_R} \left(\delta - \alpha^2 N + \sum_{j=1}^N \alpha c_j \tanh \alpha x_j\right)(h+\epsilon) h \, dx \le 0. \end{aligned}$$

Hence $h = 0$ and $\omega \le \epsilon$ on Ω_R—a contradiction. Thus $u_2 - u_1 \le c$. Interchanging u_1 and u_2 gives $u_1 - u_2 \le c$. □

Remark 2.8. The growth-damping factor ψ has been used to study linear elliptic equations on $\mathbb{R}^N$ (see, e.g., [9, p. 187]).

COROLLARY 2.9. *Suppose that $f(x,t) - f(x,s) \ge \delta(t-s)$ for some $\delta > 0$ and all $t \ge s$. Then equation* (2.6) *has at most one weak solution $u \in \mathcal{C}^1(\mathbb{R}^N)$ which is subexponential in the sense that $u(x)/\prod_{j=1}^N \cosh \alpha x_j$ is bounded for each $\alpha > 0$.*

Proof. In the proof of Theorem 2.7, we now have $c = 0$ and $v = u_2 - u_1$. Since v is subexponential, $\omega(x) = v(x)/\psi(x) \to 0$ as $|x| \to \infty$ and the argument of Theorem 2.7 gives $u_2 - u_1 \le 0$. Similarly, $u_1 - u_2 \le 0$. □

3. Uniformly almost periodic solutions. Let us recall that the translate of a function is defined by $\tau_c u(x) := u(x-c)$.

The following definition is due to Bochner (see, e.g., [6]).

DEFINITION 3.1. *A function $u \in \mathcal{BC}(\mathbb{R}^N)$ is uniformly almost periodic (UAP) if for every sequence $(c_n) \subset \mathbb{R}^N$, $(\tau_{c_n} u)$ contains a uniformly convergent subsequence on $\mathbb{R}^N$.*

We now consider the problem

$$\begin{cases} -\Delta u + \sum_{j=1}^N c_j \partial_j u + g(u) = h(x), & x \in \mathbb{R}^N, \\ u \in \mathcal{BC}(\mathbb{R}^N), \end{cases} \tag{3.1}$$

where $g \in \mathcal{C}(\mathbb{R})$ and $h \in L^\infty(\mathbb{R}^N)$.

THEOREM 3.2. *Assume that $\alpha \in H^1_{\text{loc}}(\mathbb{R}^N) \cap L^\infty(\mathbb{R}^N)$ is a lower and $\beta \in H^1_{\text{loc}}(\mathbb{R}^N) \cap L^\infty(\mathbb{R}^N)$ an upper solution of* (3.1) *and $\alpha \le \beta$. If there exists $\delta > 0$ such that*

$$\inf \text{ess}\, \alpha \le s \le t \le \sup \text{ess}\, \beta \Rightarrow g(t) - g(s) \ge \delta(t-s),$$

then problem (3.1) *has a unique weak solution $u \in \mathcal{C}^1(\mathbb{R}^N)$ such that $\alpha \le u \le \beta$. Moreover, if h is UAP, then u is also UAP.*

Proof. Theorem 2.5 implies the existence of a solution $u \in \mathcal{C}^1(\mathbb{R}^N)$ of (3.1) such that $\alpha \le u \le \beta$. Uniqueness follows from Theorem 2.7.

Now assume that h is UAP and consider a sequence $(c_n) \subset \mathbb{R}^N$. For simplicity, we write

$$h_n := \tau_{c_n} h, \qquad u_n := \tau_{c_n} u.$$

Going if necessary to a subsequence, we can assume that (h_n) converges uniformly on $\mathbb{R}^N$. It is clear that

$$-\Delta u_n + \sum_{j=1}^N c_j \partial_j u_n + g(u_n) = h_n.$$

Theorem 2.7 implies that

$$|u_j - u_k|_\infty \le \delta^{-1} |h_j - h_k|_\infty \to 0, \quad j, k \to \infty.$$

Hence (u_n) converges uniformly on $\mathbb{R}^N$ and u is UAP. □

Example 3.3. Consider the equation

$$-\Delta u + \sum_{j=1}^N c_j \partial_j u - \sin u = h(x), \tag{3.2}$$

where h is UAP. If $\|h\|_\infty < 1$, then equation (3.2) has a unique UAP solution such that $\pi/2 < u < 3\pi/2$. Indeed, for ϵ and δ positive and small enough, $\pi/2 + \epsilon$ is a lower solution, $3\pi/2 - \epsilon$ an upper solution, and

$$\sin s - \sin t \geq \delta(t - s)$$

for $\pi/2 + \epsilon \leq s \leq t \leq 3\pi/2 - \epsilon$. The particular case

$$-\ddot{u} = \sin u + h(x)$$

is treated in [7]. Assuming that $\|h\|_\infty < 1$, uniqueness is proved there for every h and existence for a dense set of h. See also [1]–[4] for the existence of generalized solutions.

Example 3.4. Consider the equation

$$-\Delta u + \sum_{j=1}^{N} c_j \partial_j u + u + u^3 = h(x), \tag{3.3}$$

where h is UAP. Using Theorem 3.2, it is easy to verify that equation (3.3) has a unique UAP solution. The particular case

$$-\ddot{u} + u + u^3 = h(x)$$

is treated in [5].

4. Unbounded forcing term. In this section, we consider problem (2.6) with a measurable function h having polynomial or subexponential growth.

DEFINITION 4.1. *A function h is said to be of polynomial growth if there is an integer $m \geq 0$ and a constant C such that*

$$|h(x)| \leq C\left(1 + \sum_{j=1}^{N} |x_j|^m\right) \quad \textit{for almost all } x \in \mathbb{R}^N, \tag{4.1}$$

and h is of subexponential growth if for each $\gamma > 0$, there is a C_γ such that

$$|h(x)| \leq C_\gamma \prod_{j=1}^{N} \cosh \gamma x_j \quad \textit{for almost all } x \in \mathbb{R}^N.$$

THEOREM 4.2. *Suppose that there are $\delta > 0$ and $R > 0$ such that $f(x,t)t \geq \delta t^2$ whenever $|t| \geq R$. If h is a measurable function which satisfies* (4.1) *for some integer $m \geq 0$, then* (2.6) *has a weak solution $u \in C^1(\mathbb{R}^N)$ which also satisfies* (4.1) (*with the same m*).

Proof. Let $\varphi(x) := D(1 + \gamma \sum_{j=1}^{N} |x_j|^m)$, where $\gamma > 0$, $D \geq R$, and $m \geq 2$. Then

$$-\Delta\varphi + \sum_{j=1}^{N} c_j \partial_j \varphi + f(x, \varphi) \geq -\gamma m(m-1) D \sum_{j=1}^{N} |x_j|^{m-2}$$
$$+ \gamma m D \sum_{j=1}^{N} c_j |x_j|^{m-2} x_j + \delta D\left(1 + \gamma \sum_{j=1}^{N} |x_j|^m\right).$$

Choosing γ small enough, we obtain

$$-\Delta\varphi + \sum_{j=1}^{N} c_j \partial_j \varphi + f(x, \varphi) \geq \epsilon D \left(1 + \sum_{j=1}^{N} |x_j|^m\right) \tag{4.2}$$

for some $\epsilon > 0$. Hence $\alpha := -\varphi$ is a lower and $\beta := \varphi$ an upper solution if D is large enough. Therefore, the conclusion follows from Theorem 2.5.

If $m = 1$, let $\varphi_0(x) := D(1 + \gamma \sum_{j=1}^{N} |x_j|)$, where $D \geq R$, and let φ be obtained from φ_0 by "rounding off the corner" in each $|x_j|$. Then it is easy to see that (4.2) is satisfied (with $m = 1$) whenever γ is small enough. Finally, if $m = 0$, there is a constant lower and a constant upper solution. □

THEOREM 4.3. *If f satisfies the hypotheses of Theorem* 4.2 *and h is a measurable function of subexponential growth, then* (2.6) *has a weak solution $u \in C^1(\mathbb{R}^N)$ which is also of subexponential growth.*

Proof. Let $\varphi(x) := D \prod_{j=1}^{N} \cosh \gamma x_j$, where $\gamma > 0$ and $D \geq R$. Choosing γ sufficiently small, we obtain

$$-\Delta\varphi + \sum_{j=1}^{N} c_j \partial_j \varphi + f(x, \varphi) \geq \epsilon\varphi$$

for some $\epsilon > 0$, and again we can take $\alpha := -\varphi$ and $\beta := \varphi$ with D large enough. □

THEOREM 4.4. *Suppose that $f(x,t) - f(x,s) \geq \delta(t - s)$ for some $\delta > 0$ and all $t \geq s$, $x \in \mathbb{R}^N$. Then the solution of* (2.6) *which was obtained in Theorems* 4.2 *and* 4.3 *is unique in the class of all functions $u \in C^1(\mathbb{R}^N)$ having subexponential growth.*

Proof. This is an immediate consequence of Corollary 2.9. □

Remark 4.5. (i) Under the hypotheses of Theorem 4.4, equation (2.6) may have many solutions as is demonstrated by the example $-u'' + u = 0$, but only one solution is subexponential.

(ii) In [13], it was shown that if $f(x,t)t \geq \delta|t|^{p+1}$ for large $|t|$ and $h \in L^1_{\text{loc}}(\mathbb{R}^N)$, then (2.6) has a solution $u \in L^p_{\text{loc}}(\mathbb{R}^N)$. Moreover, this solution is unique in $L^p_{\text{loc}}(\mathbb{R}^N)$ if f satisfies a suitable monotonicity assumption.

Acknowledgments. This work was done while the first and second authors were visiting Louvain-la-Neuve. They would like to thank the members of the Department of Mathematics at Universite Catholique de Louvain for their hospitality. The second author would also like to thank Jan Chabrowski, from whom he learned the method of introducing the growth damping factor.

WHAT IS THE SUBDIFFERENTIAL OF THE CLOSED CONVEX HULL OF A FUNCTION?*

J. BENOIST† AND J.-B. HIRIART-URRUTY‡

Abstract. Given a function $f : \mathbb{R}^n \to (-\infty, +\infty]$ and its closed convex hull $\overline{\text{co}}f$, we consider the question of expressing the subdifferential of $\overline{\text{co}}f$ in terms of the subdifferential of f. Under a fairly general assumption on the behavior of f at infinity, we obtain an explicit formula of the subdifferential of $\overline{\text{co}}f$ from that of f and its asymptotic function.

Key words. convex hull, subdifferential, asymptotic function

AMS subject classifications. 26B05, 26B25, 49H05

1. Introduction.

Let $f : \mathbb{R}^n \to (-\infty, +\infty]$ be any function. The *closed convex hull* (or closed convex envelope) $\overline{\text{co}}f$ of f can be defined in various ways such as the following: $\overline{\text{co}}f$ is the greatest closed convex function maximized by f on $\mathbb{R}^n$; or (when f is minimized by some affine function) $\overline{\text{co}}f$ is the Legendre–Fenchel biconjugate of f. In view of the generality of the class of functions f that we are considering, the calculation of $(\overline{\text{co}}f)(x)$ is, as a general rule, extremely complicated. However, we should be able to derive qualitative properties on $\overline{\text{co}}f$ from the corresponding properties of f without having to compute $(\overline{\text{co}}f)(x)$ for all x. For example, is $\overline{\text{co}}f$ differentiable whenever f is differentiable? The answer is, in general, no: there are C^∞ functions $f : \mathbb{R}^2 \to \mathbb{R}$ whose closed convex hulls are not (even once) differentiable. However, the answer is yes under a fairly general assumption on the behavior of f at infinity, as will be shown in §4. One of the key ingredients for studying such differentiability properties is *a formula linking the subdifferential of f and that of $\overline{\text{co}}f$*. To derive such an explicit formula is precisely the aim of this paper. This paper is organized as follows. General assumptions on f and properties of $\overline{\text{co}}f$ as well as preliminary results from subdifferential theory are presented in §2. The case where f is 1-coercive (i.e., f satisfies $\lim_{\|x\| \to +\infty} f(x)/\|x\| = +\infty$) is recalled in §3 from [9, Chap. X, §1.5]. This is motivated by the importance of 1-coercive functions f in the context of calculating $\overline{\text{co}}f$ as well as by the necessity of preparing the more general situation treated in §4. When f is no longer 1-coercive, to calculate $\overline{\text{co}}f$, the behavior of f at infinity must somehow be taken into account. This is done via the so-called asymptotic function f_∞ of f whose essential properties are displayed at the beginning of §4. Under a general assumption on f_∞, in §4, we give an explicit formula of the subdifferential of $\overline{\text{co}}f$ in terms of the subdifferentials of f and f_∞.

2. Preliminaries.

2.1. From a function to its closed convex hull.

We assume throughout that $\mathbb{R}^n$ is equipped with the standard inner product denoted by $\langle .,. \rangle$, and $f : \mathbb{R}^n \to (-\infty, +\infty]$ satisfies (at least)

$$\text{dom} f := \{x \in \mathbb{R}^n \mid f(x) < +\infty\} \text{ is nonempty;} \tag{1}$$

$$\text{there is an affine function minimizing } f \text{ on } \mathbb{R}^n. \tag{2}$$

Such an f is convex if and only if its epigraph $\text{epi}f := \{(x,r) \in \mathbb{R}^n \times \mathbb{R} \mid f(x) \leq r\}$ is convex. If not, a natural way to "convexify" f is to take the convex hull $\text{co}(\text{epi}f)$ of $\text{epi}f$. This gives a convex set, which is not necessarily an epigraph (consider $x \in \mathbb{R} \mapsto f(x) = \sqrt{|x|}$), but which can be made so by "closing its bottom"; we thus define the *convex hull* $\text{co}f$ of f by

$$(3) \qquad x \in \mathbb{R}^n \ \mapsto \ (\text{co}f)(x) = \inf\{r \in \mathbb{R} \ \mid \ (x,r) \in \text{co}(\text{epi}f)\}$$

($\inf \emptyset = +\infty$ by convention).

There are several ways of getting at $(\text{co}f)(x)$ (cf. [14], for example); statements (4) and (5) recall them. By the unit simplex of $\mathbb{R}^{n+1}$, we mean

$$\Delta_{n+1} := \left\{(\alpha_1, \ldots, \alpha_{n+1}) \ \in \ \mathbb{R}^{n+1} \mid \sum_{i=1}^{n+1} \alpha_i = 1, \quad \alpha_i \geq 0 \quad \text{for } i = 1, \ldots, n+1\right\}.$$

For all $x \in \mathbb{R}^n$, we have

$$(4) \qquad (\text{co}f)(x) = \sup\{g(x) \mid g : \mathbb{R}^n \to (-\infty, +\infty] \text{ convex}, \quad g \leq f\}$$

$$(5) \qquad (\text{co}f)(x) = \inf\left\{\sum_{i=1}^{n+1} \alpha_i f(x_i) \mid (\alpha_1, \ldots, \alpha_{n+1}) \in \Delta_{n+1}, \quad x_i \in \text{dom}\, f, \sum_{i=1}^{n+1} \alpha_i x_i = x\right\}.$$

Instead of $\text{co}(\text{epi}f)$, we can take the closed convex hull $\overline{\text{co}}($
epif) of $\text{epi}f$; we obtain a closed set, which is now always an epigraph. The so-called *closed convex hull* $\overline{\text{co}}f$ of f is thus defined by

$$(6) \qquad x \ \in \ \mathbb{R}^n \ \mapsto \ (\overline{\text{co}}f)(x) \ = \ \min\{r \in \mathbb{R} \mid (x,r) \in \overline{\text{co}}(\text{epi}f)\}.$$

Similarly to (4), for all $x \in \mathbb{R}^n$, we have

$$(7) \qquad (\overline{\text{co}}f)(x) = \sup\{g(x) \ \mid \ g : \mathbb{R}^n \to (-\infty, +\infty] \text{ closed convex}, \ g \leq f\}.$$

More interesting to note is the following:

$$(8) \qquad (\overline{\text{co}}f)(x) = \sup\{\langle s, x\rangle - b \mid \langle s, y\rangle - b \ \leq \ f(y) \quad \text{for all } y \in \mathbb{R}^n\},$$

or, equivalently, $\overline{\text{co}}f$ is the Legendre–Fenchel biconjugate of f:

$$(9) \qquad \overline{\text{co}}f \ = \ f^{\star\star}$$

(Recall that the Legendre–Fenchel conjugate $f^\star$ of f is defined by $s \in \mathbb{R}^n \mapsto f^\star(s) = \sup_x[\langle s, x\rangle - f(x)]$ and that $f^{\star\star}$ stands for $(f^\star)^\star$.)

In view of (5), it is clear that $\text{dom}(\text{co}f) = \text{co}(\text{dom}\, f)$. By construction, the closure of the convex function $\text{co}f$ is precisely $\overline{\text{co}}f$. Thus both functions coincide at least on the relative interior of $\text{co}(\text{dom}\, f)$. In many cases, we have $\text{co}f = \overline{\text{co}}f$ (cf. §3 below, for example), but there are important instances where $\text{co}f$ is not a closed function.

The convex-hull and closed-convex-hull operations are *global* in the sense that they require to know—a priori—the behavior of f on the whole of $\mathbb{R}^n$. That is the main source of difficulties in the calculation of $(\overline{\text{co}}f)(x)$. Actually, the calculus rules on the closed-convex-hull operation rely mainly on (9), twice using the transformation rules for the Legendre–Fenchel conjugacy.

2.2. The subdifferential theory. At a point x where f is finite, the *subdifferential* $\partial f(x)$ of f at x is the set of $s \in \mathbb{R}^n$ satisfying

$$f(y) \geq f(x) + \langle s, y - x\rangle \quad \text{for all } y \in \mathbb{R}^n. \tag{10}$$

From this definition and the construction (8) of $\overline{\text{co}}f$, it is clear that $\partial(\overline{\text{co}}f)(x) = \partial f(x)$ whenever $(\overline{\text{co}}f)(x) = f(x)$.

The following are classical results (cf. [14, Part V] or [9, Chap. X, §1.4]) and will be used in what follows. First,

$$\partial f(x) \text{ nonempty} \Longrightarrow (\overline{\text{co}}f)(x) = f(x); \tag{11}$$

$$\begin{matrix}(\overline{\text{co}}f)(x) = f(x) \text{ and} \\ f \text{ finite in a neighborhood of } x\end{matrix} \Longrightarrow \partial f(x) \text{ is nonempty.} \tag{12}$$

In particular, if f is Gâteaux differentiable at x, having a nonempty $\partial f(x)$ is equivalent to having $(\overline{\text{co}}f)(x) = f(x)$, and in such a case,

$$\partial f(x) = \partial(\overline{\text{co}}f)(x) = \{\nabla f(x)\}. \tag{13}$$

Consider the example $x \in \mathbb{R} \mapsto f(x) = e^{-x^2}$ and realize that one may have $(\overline{\text{co}}f)(x) < f(x)$ (i.e., $\partial f(x) = \emptyset$) for all x.

If f is convex, $\partial f(x)$ is nonempty for (at least) all the x's in the relative interior of $\operatorname{dom} f$. When f is not convex, $\partial f(x) \neq \emptyset$ occurs at very peculiar points x of $\operatorname{dom} f$ (as seen from (11) and (12)).

An equivalent way of expressing (10) is

$$s \in \partial f(x) \text{ if and only if } f^\star(s) + f(x) - \langle s, x\rangle = 0 \text{ (or } \leq 0). \tag{14}$$

This is a very useful characterization of the elements of $\partial f(x)$, especially since $(\overline{\text{co}}f)^\star = f^\star$. Concerning the minimization of f and $\overline{\text{co}}f$, we recall that

$$\begin{aligned} \inf_{y \in \mathbb{R}^n} f(y) &= \inf_{y \in \mathbb{R}^n} (\overline{\text{co}}f)(y) \quad \text{and} \\ \operatorname{Argmin}(\overline{\text{co}}f) &:= \{x \in \mathbb{R}^n \mid (\overline{\text{co}}f)(x) = \inf_{y \in \mathbb{R}^n} (\overline{\text{co}}f)(y)\} \\ &= \{x \in \mathbb{R}^n \mid 0 \in \partial(\overline{\text{co}}f)(x)\}. \end{aligned} \tag{15}$$

Finally, for differentiability purposes, we keep in mind the following:

$$\begin{matrix}\text{co}f \text{ and } \overline{\text{co}}f \text{ coincide on the interior of } \text{co}(\operatorname{dom} f), \text{and } \text{co}f \text{ is} \\ \text{differentiable at } x \in \operatorname{int}(\text{co}(\operatorname{dom} f)) \text{ if and only if } \partial(\text{co}f)(x) \\ \text{contains a single element (which is therefore } \nabla(\text{co}f)(x)).\end{matrix} \tag{16}$$

3. The subdifferential of $\overline{\text{co}}f$ for 1-coercive f.

In this section, we assume that $f : \mathbb{R}^n \to (-\infty, +\infty]$ satisfies (1) and

$$f \text{ is closed on } \mathbb{R}^n \text{(i.e., epi} f \text{ is a closed set of } \mathbb{R}^{n+1}); \tag{17}$$

$$f \text{ is 1-coercive on } \mathbb{R}^n, \quad \text{that is,} \quad \lim_{\|x\| \to +\infty} \frac{f(x)}{\|x\|} = +\infty. \tag{18}$$

As far as the closed-convex-hull operation is concerned, assumption (17) is not severe: indeed, both f and its closure $\overline{f}$ yield the same closed convex hull ($\overline{\text{co}}f = \overline{\text{co}}\overline{f}$).

Assumption (18) (which, in particular, implies (2) for closed functions) is more restrictive and will be removed in the next section. There are, however, many situations where it holds.

Example 3.1. Let S be a nonempty compact subset of $\mathbb{R}^n$ and $f : S \to \mathbb{R}$ a continuous function. Then the function f, extended to the whole $\mathbb{R}^n$ setting $f(x) = +\infty$ if $x \notin S$, satisfies (17) and (18). This is actually the most frequent case in applications where $\overline{\text{co}}f$ must be explicitly calculated (see [10, Chap. IV, §4.3] and [15]).

Example 3.2. Let f satisfy only (1) and (17). Then the "restricted" function

$$f_k : x \in \mathbb{R}^n \mapsto f(x) \quad \text{if } \|x\| \leq k, \quad +\infty \text{ if not,}$$

verifies (for k large enough) assumptions (1), (17), and (18). Indeed, $\overline{\text{co}}f_k$ ($=\text{co}f_k$ as will seen below) is an approximation of co$f$ since $(\overline{\text{co}}f_k)_k$ is a decreasing sequence of closed convex functions converging to co$f$ when $k \to +\infty$ (cf. (5)). The first important property of 1-coercive functions is the following.

LEMMA 3.3. *Let f satisfy* (1), (17), *and* (18). *Then the following hold:*

(i) co(epi$f$) *is a closed set.*

(ii) *For any $x \in$ dom(co$f$) $=$ co(dom$f$), there are $x_i \in$ dom f and $(\alpha_1, \ldots, \alpha_{n+1}) \in \Delta_{n+1}$ such that*

$$x = \sum_{i=1}^{n+1} \alpha_i x_i \quad \text{and} \quad (\text{co}f)(x) = \sum_{i=1}^{n+1} \alpha_i f(x_i). \tag{19}$$

Part (i) of the lemma is due to Valadier [17, p. 69]; a more readable and detailed proof can be found in [9, Chap. X, §1.5]. Part (ii) is simply a consequence of (i): it suffices to express $(x, (\text{co}f)(x))$—which lies on the boundary of co(epi$f$)—as a convex combination of $n+1$ elements (x_i, y_i) in epi$f$ and to realize that the y_i's have to be $f(x_i)$. To directly prove that the infimum in the definition of $(\text{co}f)(x)$ in (5) is achieved may be arduous, as exemplified in [8, Thm. 2.1].

We are thus in a situation where $\overline{\text{co}}f = \text{co}f$. Given $x \in$ dom(co$f$) $=$ co(dom f), we dub "called by x" the subfamily $\{x_i\}_{i \in I}$ of the family $\{x_1, \ldots, x_{n+1}\}$ as described in Lemma 3.3(ii) corresponding to strictly positive α_i's ($i \in I$ whenever $\alpha_i > 0$). Where do the x_i's called by a given x lie? As a general rule, this is very difficult to answer. In view of their definition, however, we can say that

$$\begin{gathered} \text{the } x_i\text{'s called by } x \text{ belong to dom} f \\ \text{and} \\ \text{to the smallest face of co(dom} f\text{)containing } x. \end{gathered} \tag{20}$$

For example, if x is an extreme point of co(dom f), then $x \in$ dom f and the smallest face containing x is $\{x\}$; hence the only possibility for x is to call itself. Consequently, $(\text{co}f)(x) = f(x)$.

Note also that, due to the 1-coerciveness assumption on f, the x_i's called by x remain in a compact set when the x's lie in a compact set.

Remark 3.4. Even if the original function f has a very "regular" behavior on (a convex) dom $f(:= C)$, the resulting co$f$ may not be continuous on C. To see this, let us recall the counterexample by Kruskal [12]. In $\mathbb{R}^3$, let C be the convex hull of the circle $\{(a,b,c) \mid c = 0 \text{ and } a^2 + (b-1)^2 = 1\} =: \Gamma$ and the line segment $\{(0,0,c) \mid -1 \leq c \leq 1\} =: L$ (see Fig. 1). Now let $f : (a,b,c) \in \mathbb{R}^3 \mapsto f(a,b,c) = -c^2$ if $(a,b,c) \in C$ and $+\infty$ if not. Clearly, f satisfies all the assumptions invoked in this section. What is $(\mathrm{co} f)(x)$, $x = (a, b, c)$? If $x \in \Gamma \setminus \{(0,0,0)\}$, $(\mathrm{co} f)(x) = f(x) = 0$; if $x = (0,0,1)$ or $(0,0,-1)$, $(\mathrm{co} f)(x) = f(x) = -1$. Let $x = (0,0,0)$. The smallest face of C containing x is the line segment L, and the x_i's called by such an x are $x_1 = (0,0,1)$ and $x_2 = (0,0,-1)$; whence $(\mathrm{co} f)(x) = (1/2)[f(x_1) + f(x_2)] = -1$. Thus $\mathrm{co} f$ is not continuous on Γ (contained in the boundary of C). We know that $\mathrm{co} f$, being a convex function, is continuous on the interior of C. As for the differentiability properties, the answer will be provided by a subdifferential relationship linking ∂f to $\partial(\mathrm{co} f)$.

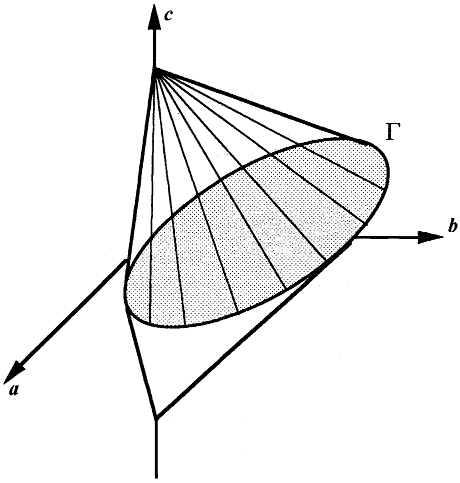

FIG. 1.

LEMMA 3.5. *For a given $x \in \mathrm{co}(\mathrm{dom} f)$, consider a family $\{x_i\}_{i\in I}$ called by x. Then the following hold:*

(i) *$f(x_i) = (\mathrm{co} f)(x_i)$ for all $i \in I$;*

(ii) *$\mathrm{co} f$ is affine on the compact convex polyhedron $\mathrm{co}\{x_i \mid i \in I\}$.*

Proof. See [8, p. 697] or [9, Chap. 10, §1.5]. □

The fact that $\mathrm{co} f$ is affine on $\mathrm{co}\{x_i \mid i \in I\}$ is easy to imagine and visualize (for $n = 1$ or 2). The coincidence property (i) shows that the points x_i that are called are very particular: not all the points x_i, even those satisfying (20), are going to be called.

We now are ready to obtain the subdifferential formula of $\mathrm{co} f$ from that of f.

THEOREM 3.6. *Let f satisfy (1), (17), and (18). For a given $x \in \mathrm{co}(\mathrm{dom} f)$, consider a collection of $\{x_i\}_{i\in I}$ called by x. Then*

$$\partial(\mathrm{co} f)(x) = \bigcap_{i\in I} \partial f(x_i). \tag{21}$$

For any $s \in \partial(\mathrm{co} f)(x)$,

$$\langle s, x\rangle - (\mathrm{co} f)(x) = \langle s, x_i\rangle - f(x_i) \quad \text{for all } i \in I. \tag{22}$$

Proof. See [9, Chap. X, §1.5]; a proof of a different kind and covering a more general situation will be given later (the proof of Theorem 4.6 in §4). □

Relation (22) expresses an "equilibrium property" achieved between $(\mathrm{co} f)(x)$ and the $f(x_i)$'s at the x_i's that the point x calls; it reminds us of the affinity property of $\mathrm{co} f$ on the convex compact polyhedron generated by the x_i's (cf. Lemma 3.5(ii)). Actually, the following explains (22): if $\partial(\mathrm{co} f)(x)$ is nonempty and $s \in \partial(\mathrm{co} f)(x)$, then $(x, (\mathrm{co}f)(x))$ belongs to the subset of epi(co$f$) that maximizes the linear form $\langle (s, -1), . \rangle$.

Comment 3.7. 1. It is surprising that f enters the subdifferential formula (21) via its subdifferential in the sense of convex analysis (i.e., the stringent condition (10)) since we know that for a nonconvex function f, this subdifferential is empty more often than not. However, the x_i's considered are "called points," and at such points f and co$f$ coincide, so there is a good chance that the $\partial f(x_i)$'s are nonempty (cf. (12)).

2. If x lies in the relative interior of co(dom f), the subdifferential of co$f$ at x is nonempty, which implies (by (21)) that the subdifferential of f at the x_i's called by x is necessarily nonempty. This again restricts the set of possible candidates $x_i \in \mathrm{dom}\, f$ to be called.

3. In view of subdifferential theory as recalled in §2.2 (especially (16)), the differentiability of co$f$ at $x \in \mathrm{int}(\mathrm{co}(\mathrm{dom}\, f))$ is secured whenever $\partial f(x_i)$ contains a single element for just one of the x_i's called by x. In fact, all of the conditions on the geometry of dom f near x_i and the behavior of f around x_i, which have been carefully studied by Griewank and Rabier in [8, §3] to ensure the differentiability of co$f$ on int(co(dom f)), are sufficient for $\partial(\mathrm{co}f)$ to be single valued; formula (21) clearly shows what to expect about $\partial(\mathrm{co}f)(x)$ from information about $\partial f(x_i)$ at points x_i called by x. To illustrate, consider f (satisfying (1), (17), and (18)) such that

$$\text{(23)}\quad \begin{array}{l}\partial f(x_i) \text{ is empty for all } x_i \text{ on the boundary of } \mathrm{dom}\, f, \text{and } \partial f(x_i)\\ \text{is a singleton at any } x_i \in \mathrm{int}(\mathrm{dom}\, f) \text{ where } \partial f(x_i) \text{ is nonempty}\end{array}$$

(for example, if dom f is open and f is Gâteaux differentiable on dom f). Then it immediately follows from (21) that co$f$ is differentiable (and, therefore, continuously differentiable) on the interior of its domain.

4. For f satisfying (1), (17), and (18), the set Argmin$f$ of its minimum points is a nonempty compact set. It then follows from (15) and (21) that

$$\text{(24)}\qquad \mathrm{Argmin}(\mathrm{co}f) = \mathrm{co}(\mathrm{Argmin}f).$$

5. Even if we impose greater regularity on f (say C^k, $k \geq 2$), co$f$ as a rule is not C^2. However, if f is locally $C^{1,\alpha}$, $0 < \alpha \leq 1$, then so is co$f$ (under some additional technical assumptions on f that are explained in detail in [8, §4]). See also [13, Prop. 3.1] for an ellipticity condition on $\overline{\mathrm{co}}f$ when f is C^2 on $\mathbb{R}^n$ and [11, §5] for a study of what regularity (between C^1 and C^2) co$f$ must have.

Remark 3.8. In connection with the end of Comment 3.7(3), let us note that even if C is a compact convex set and f a C^∞ function on int$C$, the resulting $\overline{\mathrm{co}}f$ need not be differentiable on int$C$. The following is a counterexample in that respect. Let C be the convex hull of the five points $(1,0), (1,2), (0,3), (-1,2)$, and $(-1,0)$ in $\mathbb{R}^2$ and let $f : (a,b) \in \mathbb{R}^2 \mapsto f(a,b) = 1 - a^2$ if $(a,b) \in C$ and $+\infty$ if not. Then $\overline{\mathrm{co}}f$ is not differentiable on the line segment L joining $(1,2)$ and $(-1,2)$. The reason is that for any x lying in the relative interior of L, the points called by x are $x_1 = (1,2)$ and $x_2 = (-1,2)$ so that $\partial f(x_1)$ $(= \partial(\overline{\mathrm{co}}f)(x_1))$ and $\partial f(x_2)$ $(= \partial(\overline{\mathrm{co}}f)(x_2))$ have more than one element in common. The situation would be different if x_1 and x_2 were "smooth" boundary points of C. See Fig. 2.

4. The subdifferential of $\overline{\mathrm{co}}f$ for epi-pointed f. If we assume only (1) and (17) for f, can we express the subdifferential of $\overline{\mathrm{co}}f$ in terms of that of f only (as in (21))? The answer is, in general, no, as shown by the next example.

Example 4.1. Let $f : \mathbb{R}^2 \to \mathbb{R}$ be defined by

$$(a,b) \in \mathbb{R}^2 \mapsto f(a,b) = \sqrt{a^2 + e^{-b^2}}.$$

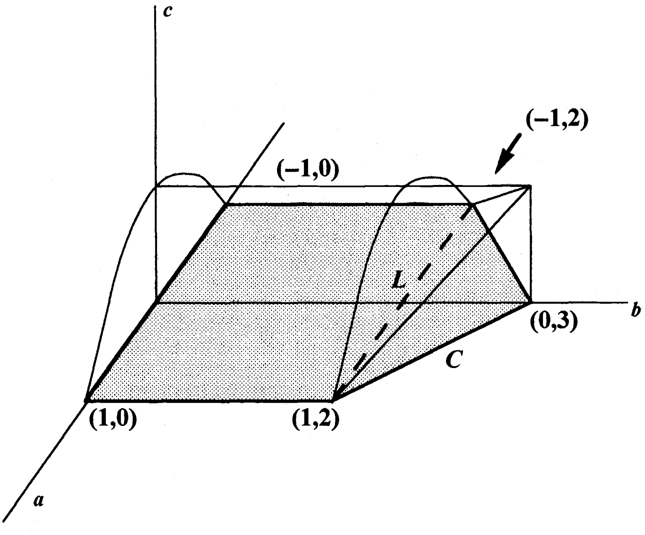

FIG. 2.

f is C^∞ on $\mathbb{R}^2$, and it is easy to verify that

$$(\text{co}f =) \quad \overline{\text{co}}f : (a,b) \longmapsto (\overline{\text{co}}f)(a,b) = |a|.$$

Should a formula like (21) hold true, the differentiability of f would induce that of $\overline{\text{co}}f$, which is not the case.

To obtain a formula similar to (21)—at least for a large class of functions that we call "epi-pointed" (the definition comes later)—we must somehow take into account the behavior of f at infinity. This is done via the asymptotic function of f.

4.1. The asymptotic cone of a set and the asymptotic function of a function. Given a nonempty closed set S (the closedness is not so important since the proposed concepts are blind to the closure operation on sets), the *asymptotic cone* S_∞ of S is defined as follows:

$$S_\infty := \{d \in \mathbb{R}^n \mid \exists (x_k)_k \text{ in } S,\ \exists (t_k)_k \text{ in } \mathbb{R}_+ \text{ with } \lim_{k\to+\infty} t_k = 0 \text{ such that } d = \lim_{k\to+\infty} t_k x_k\}. \tag{25}$$

S_∞ is a *closed cone* (with apex 0), and, moreover, if S is convex, S_∞ coincides with the asymptotic cone (or recession cone or characteristic cone) of S used in the context of convex analysis (cf. [14, §8] or [16, p. 107]). If K is already a nonempty closed cone, then clearly $K_\infty = K$; in particular, $(S_\infty)_\infty = S_\infty$. Before going further, we comment on the introduction and use of asymptotic cones for nonconvex sets. To our knowledge, it is Debreu [3, p. 26] who first proposed the current definition (under a different but equivalent form) of the asymptotic cone and gave (without proofs) some of its uses—for example, sufficient conditions for the sum of closed sets to be closed. Later, the concept was proposed again by Dedieu [4, 5, 6], who studied it in full detail (and even in a more general setting—that of a real topological vector space). The definition has been rediscovered several times since then, and it has proved useful in various areas such as nonconvex optimization, existence theory in variational problems, mathematical economics, etc.

DEFINITION 4.2. *A closed cone K of* $\mathbb{R}^n$ *is said to be* pointed *if*

$$\text{(26)}\qquad \left.\begin{array}{l} m \in \mathbb{N}^\star, \\ c_i \in K \quad \textit{for all } i = 1, \dots, m, \\ \displaystyle\sum_{i=1}^{m} c_i = 0 \end{array}\right\} \Longrightarrow (c_i = 0 \quad \textit{for all } i = 1, \dots, m).$$

Note that as in Carathéodory's theorem (and its proof), we might well limit ourselves to the integers $m \leq n+1$ in (26). Indeed, suppose that there is a family $\{c_i\}_{i \in I} \subset K \setminus \{0\}$ with card$I > n+1$ and $\sum_{i \in I} c_i = 0$ and that property (26) holds true with $1 \leq m \leq n+1$. From the equality $0 = \sum_{i \in I} \frac{1}{\text{card} I} c_i$, with Carathéodory's theorem, we deduce that there exist $J \subset I$ and $\{\beta_j\}_{j \in J}$ such that

$$1 \leq \text{card} J \leq n+1, \qquad \beta_j > 0 \quad \text{for all } j \in J,$$

$$\sum_{j \in J} \beta_j = 1 \quad \text{and} \quad \sum_{j \in J} \beta_j c_j = 0.$$

Now, however, the $\{c'_j := \beta_j c_j\}_{j \in J}$'s form a family of at most $n+1$ elements of K, and property (26) would induce that $c'_j = 0$, and hence $c_j = 0$ for all $j \in J$. This contradicts the initial assumption on c_j, namely, $c_j \in K \setminus \{0\}$.

It is also easy to check that a nonempty closed cone K is pointed if and only if

$$\text{(27)}\qquad (\text{co}K) \cap (-\,\text{co}\,K) = \{0\};$$

this expresses the pointedness property of the convex cone co$K$.

The following result plays a key role in what follows.

PROPOSITION 4.3. *Let S be a nonempty closed set and assume that S_∞ is pointed; then*

(i) $\overline{\text{co}}S = \text{co}S + \text{co}(S_\infty)$ $(= \text{co}(S + S_\infty))$;

(ii) $\text{co}(S_\infty) = (\overline{\text{co}}S)_\infty$ *and thus* $\text{co}(S_\infty)$ *is closed.*

To our knowledge, this statement first appeared in McFadden [7]; see the appendix for an alternate proof.

It is now natural to consider closed functions f and define their asymptotic functions via the asymptotic cones of their epigraphs. Let $f : \mathbb{R}^n \to (-\infty, +\infty]$ satisfy (1), (2), and (17) (although all these requirements are not necessary for the definition to hold); then epi$f$ is a nonempty closed set in $\mathbb{R}^{n+1}$ and we can define (geometrically) the *asymptotic function* f_∞ of f by

$$\text{(28)}\qquad \text{epi}(f_\infty) = (\text{epi}f)_\infty.$$

Clearly, f_∞ is a *positively homogeneous closed function* satisfying $f_\infty(0) = 0$. Indeed, if f is minimized by the affine function $\langle s, . \rangle - r$, the asymptotic function f_∞ of f is minimized by the linear function $\langle s, . \rangle$. In fact, we have an *analytical* definition of f_∞ (suggested in [5, p. 943]) as follows.

PROPOSITION 4.4. *For all $d \in \mathbb{R}^n$,*

$$\text{(29)}\qquad f_\infty(d) = \liminf_{t \to 0^+, d' \to d} t f\left(\frac{d'}{t}\right).$$

Proof. See the appendix. □

At this stage, one may wonder what class of positively homogeneous closed functions one obtains when taking asymptotic functions. Actually, one obtains all of them since $(f_\infty)_\infty = f_\infty$. The following result, whose proof relies on specific approximation and regularization techniques from [1], goes even further: if $g : \mathbb{R}^n \longrightarrow (-\infty, +\infty]$ is a positively homogeneous closed function with a nonempty domain, there exists a C^1 function $f : \mathbb{R}^n \to \mathbb{R}$ such that $f_\infty = g$.

4.2. Epi-pointed closed functions. We say that a function $f : \mathbb{R}^n \to (-\infty, +\infty]$ satisfying (1), (2), and (17) is *epi-pointed* (or asymptotically epi-pointed) when $(\operatorname{epi} f)_\infty$ is pointed. The following gives various characterizations of epi-pointed functions.

PROPOSITION 4.5. *Assume that f satisfies* (1), (2), *and* (17). *Then the epi-pointedness of f is equivalent to one of the following properties:*

(i) *f is minimized by $n+1$ affine functions $\langle s_i, . \rangle - r_i$ with affinely independent slopes s_i*;

(ii) $\operatorname{dom} f^\star$ *has a nonempty interior*;

(iii) *there exist $s \in \mathbb{R}^n$, $\sigma > 0$, and $r \in \mathbb{R}$ such that*

$$f(x) \geq \langle s, x\rangle + \sigma\|x\| - r \quad \textit{for all } x \in \mathbb{R}^n; \tag{30}$$

(iv) *there exists $s \in \mathbb{R}^n$ such that*

$$\liminf_{\|x\| \to +\infty} \frac{f(x) - \langle s, x\rangle}{\|x\|} > 0. \tag{31}$$

Proof. See the appendix. □

The following are easy consequences of the characterizations above (the functions f and g below are assumed to satisfy (1), (2), and (17)):

- If f is epi-pointed, so is $f + \langle s, . \rangle + r$, where $s \in \mathbb{R}^n$ and $r \in \mathbb{R}$.
- If $f \geq g$ and g is epi-pointed ($g = \sigma\|.\| + r$ with $\sigma > 0$, $r \in \mathbb{R}$, for example), then f is epi-pointed.
- If f or g is epi-pointed and if $\operatorname{dom} f \cap \operatorname{dom} g$ is nonempty, then $\max(f, g)$ is epi-pointed (use characterization (iii)).

In spite of the exact formula $h_\infty = \min(f_\infty, g_\infty)$ for $h := \min(f, g)$, the epi-pointedness of f and g does not ensure that of h; however, note that if f is 1-coercive and g is epi-pointed (resp. 1-coercive), then h is epi-pointed (resp. 1-coercive).

- Consider f and g with g epi-pointed and $\operatorname{dom} f \cap \operatorname{dom} g$ nonempty. Then $f + g$ is epi-pointed (use characterization (iii)).
- If S is a nonempty closed set and I_S its indicator function ($I_S(x) = 0$ if $x \in S$, $+\infty$ if not), then $(I_S)_\infty = I_{S_\infty}$, whence S is pointed if and only if I_S is epi-pointed.

4.3. The main result. The theorem below gives an explicit formula for the subdifferential of $\overline{\text{co}} f$ in terms of those of f and f_∞ for the class of epi-pointed functions.

THEOREM 4.6. *Assume that the closed function $f : \mathbb{R}^n \to (-\infty, +\infty]$ is epi-pointed. Then the following hold:*

(i) *For all* $x \in \operatorname{dom}(\overline{\text{co}} f)$*, there are points* $x_1, \ldots, x_p$ *in* $\operatorname{dom} f$*, real numbers* $\alpha_1, \ldots, \alpha_p$ $(p \in \mathbb{N}^\star)$*, and possibly points* $y_1, \ldots, y_q$ *in* $\operatorname{dom} f_\infty \setminus \{0\}$ $(q \in \mathbb{N})$ *such that*

$$(32)\qquad \begin{cases} \alpha_i > 0 \quad \textit{for all } i = 1, \ldots, p, \quad \sum_{i=1}^{p} \alpha_i = 1; \\ x = \sum_{i=1}^{p} \alpha_i x_i + \sum_{j=1}^{q} y_j; \\ (\overline{\text{co}} f)(x) = \sum_{i=1}^{p} \alpha_i f(x_i) + \sum_{j=1}^{q} f_\infty(y_j). \end{cases}$$

Moreover, one may choose a decomposition of the above type with

$$(33)\qquad q \leq n \quad \textit{and} \quad p + q \leq n + 1.$$

(ii) *For any decomposition of the type described in* (i)*, we have*

$$(34)\qquad \partial(\overline{\text{co}} f)(x) = \left[\bigcap_{i=1}^{p} \partial f(x_i)\right] \bigcap \left[\bigcap_{j=1}^{q} \partial f_\infty(y_j)\right].$$

Proof. See the appendix. □

In the above statements, $q = 0$ means that there is no y_j in the decomposition of x. In accordance with our earlier appellation, we term "called by x" a family $\{x_i, y_j\}$ of points as described in (i). We exclude the null y_j's because they add nothing in (32) (since $f_\infty(0) = 0$) or (34) (since, as seen in the course of the proof, $\partial f(x_i) \subset \partial f_\infty(0)$ for any $x_i \in \operatorname{dom} f$ and $\partial f_\infty(y_j) \subset \partial f_\infty(0)$ for any $y_j \in \operatorname{dom} f_\infty$). A given $x \in \operatorname{dom}(\overline{\text{co}} f)$ may call only x_i points or both x_i and y_j points for (32) to hold.

The 1-coercive case, recalled in §3, falls into this more general one. Indeed, if f is closed and 1-coercive, then f is epi-pointed (use Proposition 4.5(iv) with $s = 0$ or Proposition 4.5(ii) since $\operatorname{dom} f^\star = \mathbb{R}^n$ in that case) and $f_\infty = I_{\{0\}}$, i.e., $f_\infty : d \mapsto f_\infty(d) = 0$ if $d = 0$, $+\infty$ if not. Thus $\operatorname{epi}(\overline{\text{co}} f) = \operatorname{co}(\operatorname{epi} f) + \{0\} \times \mathbb{R}_+ = \operatorname{co}(\operatorname{epi} f)$, whence we recover $\overline{\text{co}} f = \text{co} f$. The points $x \in \operatorname{dom}(\text{co} f)$ are necessarily of the x_i type. Before going further, let us illustrate Theorem 4.6 with a simple example.

Example 4.7. Let $f : \mathbb{R} \to \mathbb{R}$ be defined as follows:

$$f(x) = \begin{cases} \sqrt{|x+1|} & \text{if } x \leq -1, \\ 1 - |x| & \text{if } -1 \leq x \leq 1 \\ (x-1)(1+e^{-x}) & \text{if } x \geq 1. \end{cases} \quad \text{(see Fig. 3)},$$

Then $f_\infty(d) = d^+$, and $(\overline{\text{co}} f)(x) = 0$ if $x \leq 1$ and $x - 1$ if $x \geq 1$. The assumptions of Theorem 4.6 are obviously satisfied by f. The point $x = 2$ can call only $x_1 = 1$ and $y_1 = 1$; as a result (see (34)),

$$(\{1\} =) \quad \partial(\overline{\text{co}} f)(x) = \partial f(x_1) \cap \partial f_\infty(y_1) = [0, 1] \cap \{1\}.$$

This also shows that the bounds in (33) are sharp. On the other hand, $x = 0$ can call only $x_1 = 1$ and $x_2 = -1$; then

$$(\{0\} =) \quad \partial(\overline{\text{co}} f)(x) = \partial f(x_1) \cap \partial f(x_2) = [0, 1] \cap \{0\}.$$

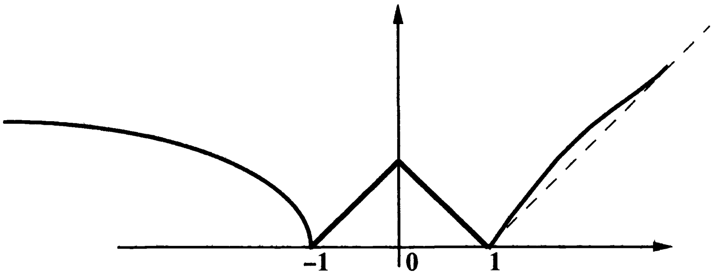

FIG. 3.

Comment 4.8 (under the assumptions of Theorem 4.6). 1. Since $(\overline{\text{co}}(\text{epi}f))_\infty$ equals $\text{co}((\text{epi}f)_\infty)$ (cf. Proposition 4.3(ii)), its "functional" counterpart is:

$$(\overline{\text{co}}f)_\infty = \text{co}(f_\infty) \quad (= \overline{\text{co}}(f_\infty)). \tag{35}$$

It goes without saying that f_∞ itself satisfies the assumptions of Theorem 4.6: it is closed and epi-pointed.

2. Similarly to the 1-coercive case (cf. Lemma 3.5), we note the following properties of $\overline{\text{co}}f$: if $x_1, \dots, x_p$ and $y_1, \dots, y_q$ are points called by a given $x \in \text{dom}(\overline{\text{co}}f)$, then

$$\begin{gathered} f(x_i) = (\overline{\text{co}}f)(x_i) \quad \text{for all } i = 1, \dots, p \\ \text{and} \\ f_\infty(y_j) = (\text{co}f_\infty)(y_j) \quad \text{for all } j = 1, \dots, q; \end{gathered} \tag{36}$$

$$\begin{gathered} \overline{\text{co}}f \text{ is affine on the closed convex polyhedron} \\ P = \text{co}\{x_1, \dots, x_p\} + \mathbb{R}_+ y_1 + \cdots + \mathbb{R}_+ y_q. \end{gathered} \tag{37}$$

To prove (36), we first note that

$$(\overline{\text{co}}f)(x) \le (\overline{\text{co}}f)\left(\sum_{i=1}^{p} \alpha_i x_i\right) + (\overline{\text{co}}f)_\infty \left(\sum_{j=1}^{q} y_j\right). \tag{38}$$

(This is a property of asymptotic functions for convex functions; see [14, p. 66].) Second, $\overline{\text{co}}f$ is convex and $(\overline{\text{co}}f)_\infty$ subadditive, so

$$(\overline{\text{co}}f)(x) \le \sum_{i=1}^{p} \alpha_i \, (\overline{\text{co}}f)(x_i) + \sum_{j=1}^{q} (\overline{\text{co}}f)_\infty(y_j). \tag{39}$$

Now $\overline{\text{co}}f$ (resp. $(\overline{\text{co}}f)_\infty$ ($= \text{co}f_\infty$ from (35))) minimizes f (resp. f_∞); hence the right-hand side of (39) is maximized by $\sum_{i=1}^p \alpha_i f(x_i) + \sum_{j=1}^q f_\infty(y_j) = (\overline{\text{co}}f)(x)$. Combining this with (39) yields (36).

To prove (37), we let $P = \text{co}\{x_1, \dots, x_p\} + \mathbb{R}_+ y_1 + \cdots + \mathbb{R}_+ y_q$; x lies in the relative interior *riP* of P. (Recall that $riP = \{\sum_{i=1}^p \alpha_i' x_i + \sum_{j=1}^q \beta_j' y_j : \alpha_i' > 0 \text{ for all } i, \sum_{i=1}^p \alpha_i' = 1, \beta_j' > 0 \text{ for all } j\}$.) Consider $g(x) = (\overline{\text{co}}f)(x)$ if $x \in P$ and $+\infty$ otherwise. It is a closed convex function whose domain is P; indeed,

$$\begin{aligned} \left(\overline{\text{co}}f)(\sum_{i=1}^{p} \alpha_i' x_i + \sum_{j=1}^{q} \beta_j' y_j\right) &\le (\overline{\text{co}}f)\left(\sum_{i=1}^{p} \alpha_i' x_i\right) + (\overline{\text{co}}f)_\infty \left(\sum_{j=1}^{q} \beta_j' y_j\right) \\ &\le \sum_{i=1}^{p} \alpha_i' (\overline{\text{co}}f)(x_i) + \sum_{j=1}^{q} \beta_j' (\overline{\text{co}}f)_\infty(y_j). \end{aligned}$$

Since $x \in ri\,\mathrm{dom}\, g$, we can choose s in the nonempty $\partial g(x)$ and define $\ell(x') := (\overline{\mathrm{co}}f)(x) + \langle s, x' - x\rangle$.

Step 1. The affine function ℓ minorizes $(\overline{\mathrm{co}}f)$ on P and coincides with $(\overline{\mathrm{co}}f)$ at x.

Step 2. Since $\ell \leq \overline{\mathrm{co}}f$ on P, we easily deduce that

$$\begin{cases} \ell(x_i) \leq \overline{\mathrm{co}}f(x_i) & \text{for all } i \in \{1,\dots,p\}; \\ \ell_\infty(y_j) = \langle s, y_j\rangle \leq (\overline{\mathrm{co}}f)_\infty(y_j) & \text{for all } j \in \{1,\dots,q\}. \end{cases}$$

Step 3. From the following chain of equalities and inequalities,

$$\begin{aligned} \overline{\mathrm{co}}f(x) &= \ell(x) \\ &= \sum_{i=1}^{p} \alpha_i \ell(x_i) + \sum_{j=1}^{q} \langle s, y_j\rangle && \text{[since } \ell \text{ is affine]} \\ &\leq \sum_{i=1}^{p} \alpha_i (\overline{\mathrm{co}}f)(x_i) + \sum_{j=1}^{q} (\overline{\mathrm{co}}f)_\infty(y_j) && \text{[see Step 2]} \\ &= \sum_{i=1}^{p} \alpha_i f(x_i) + \sum_{j=1}^{q} f_\infty(y_j) && \text{[from (36)]} \\ &= \overline{\mathrm{co}}f(x) && \text{[from (32)],} \end{aligned}$$

we deduce that

$$\begin{cases} \ell(x_i) = \overline{\mathrm{co}}f(x_i) & \text{for all } i \in \{1,\dots,p\}; \\ \langle s, y_j\rangle = (\overline{\mathrm{co}}f)_\infty(y_j) & \text{for all } j \in \{1,\dots,q\}. \end{cases}$$

Step 4. Let $x' = \sum_{i=1}^{p} \alpha'_i x_i + \sum_{j=1}^{q} \beta'_j y_j \in P$. We have

$$\begin{aligned} \overline{\mathrm{co}}f(x') &\leq (\overline{\mathrm{co}}f)\left(\sum_{i=1}^{p} \alpha'_i x_i\right) + (\overline{\mathrm{co}}f)_\infty \left(\sum_{j=1}^{q} \beta'_j y_j\right) \\ &\leq \sum_{i=1}^{p} \alpha'_i (\overline{\mathrm{co}}f)(x_i) + \sum_{j=1}^{q} \beta'_j (\overline{\mathrm{co}}f)_\infty(y_j) \\ &= \sum_{i=1}^{p} \alpha'_i \ell(x_i) + \sum_{j=1}^{q} \beta'_j \langle s, y_j\rangle && \text{[see Step 3]} \\ &= \ell(x') && \text{[since } \ell \text{ is affine]} \\ &\leq \overline{\mathrm{co}}f(x'). \end{aligned}$$

Then all of these inequalities are equalities and, in particular, $\ell = \overline{\mathrm{co}}f$ on P.

3. Concerning the comparison of $\mathrm{Argmin}(\overline{\mathrm{co}}f)$ with similar sets associated with f and f_∞, we have the following:

$$\begin{aligned} \mathrm{Argmin}(\overline{\mathrm{co}}f) &= \mathrm{co}(\mathrm{Argmin} f) + \mathrm{co}(\mathrm{Argmin} f_\infty) \\ &\quad (= \mathrm{co}(\mathrm{Argmin} f + \mathrm{Argmin} f_\infty)). \end{aligned} \tag{40}$$

For this, it suffices to combine the characterization (15) of $\mathrm{Argmin}(\overline{\mathrm{co}}f)$ with formula (34). When f is 1-coercive, $\mathrm{Argmin} f_\infty = \{0\}$ and we obtain (24).

4. The "equilibrium property" (22) of Theorem 3.6 has also its counterpart: if $x_1, \dots, x_p$ and $y_1, \dots, y_q$ are points called by a given $x \in \mathrm{dom}(\overline{\mathrm{co}}f)$, then for any $s \in \partial(\overline{\mathrm{co}}f)(x)$,

$$f_\infty(y_j) = \langle s, y_j\rangle \quad \text{for all } j = 1, \dots, q \tag{41}$$

and

$$\langle s, x\rangle - (\overline{\text{co}} f)(x) = \langle s, x_i\rangle - f(x_i) \quad \text{for all } i = 1, \dots, p. \tag{42}$$

To see that, observe that $s \in \partial f_\infty(y_j)$ $(= \partial(\text{co} f_\infty)(y_j))$ implies

$$s \in \partial f_\infty(0)\ (= \partial(\text{co} f_\infty)(0)) \quad \text{and} \quad f_\infty(y_j) = \langle s, y_j\rangle \quad \text{for all } j = 1, \dots, q. \tag{43}$$

(This is due to the fact that $\text{co} f_\infty$ $(= (\overline{\text{co}} f)_\infty)$ is a closed positively homogeneous function.) Next, $s \in \partial(\overline{\text{co}} f)(x)$ (resp. $s \in \partial f(x_i)$) is characterized by the equality $(\overline{\text{co}} f)(x) - \langle s, x\rangle = -(\overline{\text{co}} f)^\star(s)$ (resp. $f(x_i) - \langle s, x_i\rangle = -f^\star(s)$), whence we have (42) since $(\overline{\text{co}} f)^\star = f^\star$.

COROLLARY 4.9. *In addition to the assumptions of Theorem* 4.6 *on f suppose the following:*

The subdifferential of f is empty on the boundary of $\text{dom}\, f$;
f is Gâteaux differentiable on the interior of $\text{dom}\, f$.

(*A Fréchet-differentiable epi-pointed $f : \mathbb{R}^n \to \mathbb{R}$ satisfies all these requirements*). *Then $\overline{\text{co}} f$ is* (*continuously*) *differentiable on the interior of its domain.*

Indeed, the x_i's called by $x \in \text{int}\,\text{dom}(\overline{\text{co}} f)$—and there necessarily are such x_i's (see Theorem 4.6(i))—lie in the interior of $\text{dom}\, f$ and, at these points, $\partial f(x_i) = \{\nabla f(x_i)\}$. It then follows from (34) that

$$\nabla(\overline{\text{co}} f)(x) = \nabla f(x_i) \quad \text{for all } i = 1, \dots, p. \tag{44}$$

The function f exhibited in Example 4.1 is not epi-pointed. It is minimized by (at most) two affine functions with affinely independent slopes, while three would be necessary to make it epi-pointed (cf. Proposition 4.5(i)). Should the result of Theorem 4.6 hold, the differentiability of f would induce that of $\overline{\text{co}} f$, which is not the case. Thus the epi-pointedness assumption on f cannot be completely removed in Theorem 4.6.

Remark 4.10. This is also the place where the extended subdifferential calculus for nonconvex functions [2] can be useful. Suppose, for example, that we want to convexify the restriction of some closed function $g : \mathbb{R}^n \to (-\infty, +\infty]$ on a closed subset S, i.e., convexify $f = g + I_S : x \mapsto f(x) = g(x)$ if $x \in S$ and $+\infty$ if not. Various conditions on g or S guarantee that f is closed and epi-pointed (the assumptions of Theorem 4.6). At a point x_i called by x, under fairly general assumptions on g and S [2, pp. 95–109],

$$\partial^{cl} f(x_i) \subset \partial^{cl} g(x_i) + N_S^{cl}(x_i)$$

($\partial^{cl} g$ (resp. N_S^{cl}) denote the generalized subdifferential of g (resp. normal cone to S) in Clarke's sense), whence an *outer estimate* of $\partial f(x) \subset \partial f(x_i)$ (since $\partial f(x_i)$ is always included in $\partial^{cl} f(x_i)$) in terms of the behavior of g around x_i (via $\partial^{cl} g(x_i)$) and the geometry of S around x_i (via $N_S^{cl}(x_i)$).

Remark 4.11. As is clear from the proof of Theorem 4.6 (see the appendix), all the conclusions of Theorem 4.6, especially formula (34), hold provided that

$$\overline{\text{co}}(\text{epi} f) = \text{co}(\text{epi} f) + \text{co}(\text{epi} f_\infty) \tag{45}$$

for the function f considered. To ensure this, the epi-pointedness of f was specifically a general assumption. However, a function like $x \in \mathbb{R}^n \mapsto \sqrt{\|x\|}$ satisfies (45) without being epi-pointed.

5. Appendix.

5.1. Proof of Proposition 4.3.

Proof of (i). Let $x \in S$, $d \in S_\infty$; then for some $(x_k)_k$ in S and $(t_k)_k$ in $\mathbb{R}_+$ with $\lim_{k\to+\infty} t_k = 0$,

$$x + d = \lim_{k\to+\infty} (x + t_k x_k) = \lim_{k\to+\infty} ((1 - t_k)x + t_k x_k),$$

whence $x + d \in \overline{\text{co}}S$. Therefore, $S + S_\infty \subset \overline{\text{co}}S$ and

$$\text{co}S + \text{co}S_\infty = \text{co}(S + S_\infty) \subset \overline{\text{co}}S. \tag{46}$$

For the converse inclusion, consider $v \in \overline{\text{co}}S$; then $v = \lim_{k\to+\infty} v_k$ with

$$v_k = \alpha_k^1 x_k^1 + \cdots + \alpha_k^{n+1} x_k^{n+1} \tag{47}$$

for some $\alpha_k = (\alpha_k^1, \ldots, \alpha_k^{n+1}) \in \Delta_{n+1}$ and $x_k^1, \ldots, x_k^{n+1}$ in S.

Subsequencing if necessary, we may assume that, for all i, $\alpha_k^i \to \alpha^i$ when $k \to +\infty$. Since $(\alpha^1, \ldots, \alpha^{n+1}) \in \Delta_{n+1}$, we set $I := \{i \mid \alpha^i > 0\}$ and $J := \{i \mid \alpha^i = 0\}$. Suppose that one of the sequences $(\alpha_k^i x_k^i)_k$ is unbounded. Without loss of generality, we may consider that

(a) $\|\alpha_k^1 x_k^1\| = \max_{i=1,\ldots,n+1} \|\alpha_k^i x_k^i\|$ for all k;

(b) $\|\alpha_k^1 x_k^1\| \to +\infty$ when $k \to +\infty$.

According to (a), each sequence $(\alpha_k^i x_k^i / \|\alpha_k^1 x_k^1\|)_k$ is bounded and may thus be assumed to converge to some d^i which—due to (b)—lies in S_∞. Again from (b), dividing both sides of (47) by $\|\alpha_k^1 x_k^1\|$ and letting $k \to +\infty$ yields $0 = \sum_{i=1}^{n+1} d^i$. However, since $\|d^1\| = 1$, this contradicts the pointedness property of S_∞.

Thus all of the sequences $(\alpha_k^i x_k^i)_k$ are bounded and, subsequencing in an appropriate way, we can pass to the limit in (47) and obtain

$$v = \sum_{i\in I} \alpha^i x_i + \sum_{j\in J} d^j \in \text{co}\, S + \text{co}S_\infty,$$

whence the converse inclusion in (46) is proved.

Proof of (ii). Since the asymptotic cone of $\overline{\text{co}}S$ is the same as that of co$S$, what we have to prove is actually $\text{co}(S_\infty) = (\text{co}S)_\infty$.

From $S \subset \text{co}S$, we infer that $S_\infty \subset (\text{co}S)_\infty$, and since the latter is convex, we have $\text{co}(S_\infty) \subset (\text{co}S)$.

Conversely, let $v \in (\text{co}S)_\infty$. According to (25) and the definition of co$S$, there exist sequences $(t_k)_k$ in $\mathbb{R}_+$, $(\beta_k)_k$ in Δ_{n+1} with $\beta_k = (\beta_k^1, \ldots, \beta_k^{n+1})$, and $(x_k^1)_k, \ldots, (x_k^{n+1})_k$ in S such that

$$\lim_{k\to+\infty} t_k = 0, \qquad v = \lim_{k\to+\infty} t_k(\beta_k^1 x_k^1 + \cdots + \beta_k^{n+1} x_k^{n+1}).$$

Setting $\alpha_k^i = t_k \beta_k^i$ and $v_k = \alpha_k^1 x_k^1 + \cdots + \alpha_k^{n+1} x_k^{n+1}$, we continue the same reasoning as in the proof of (i) above ($I = \emptyset$ here) to get $v = \sum_{j=1}^{n+1} d^j$ with $d^j \in S_\infty$ for all $j \in J$. Whence $v \in \text{co}(S_\infty)$.

As the asymptotic cone of $\overline{\text{co}}S$, $\text{co}(S_\infty)$ is closed. This can also be viewed as a direct consequence of (i): apply the result of (i) to S_∞ and the relation $\overline{\text{co}}(S_\infty) = \text{co}(S_\infty)$ results. □

5.2. Proof of Proposition 4.4. Define

$$g : d \in \mathbb{R}^n \mapsto g(d) = \liminf_{t \to 0^+, d' \to d} tf\left(\frac{d'}{t}\right).$$

To prove $f_\infty = g$, it suffices to verify that epi $g = (\text{epi} f)_\infty$.

First, let $(v, \mu) \in (\text{epi} f)_\infty$; there exist sequences $((x_k, \mu_k))_k$ in epi$f$ and $(t_k)_k$ in $\mathbb{R}_+$ converging to 0 such that $(v, \mu) = \lim_{k \to +\infty} t_k(x_k, \mu_k)$. Therefore, $v = \lim_{k \to +\infty} t_k x_k$ and $\mu = \lim_{k \to +\infty} t_k \mu_k$ with $f(x_k) \leq \mu_k$ for all k so that

$$g(v) \leq \liminf_{k \to +\infty} t_k f\left(\frac{t_k x_k}{t_k}\right) \leq \liminf_{k \to +\infty} t_k \mu_k = \mu.$$

We thus have proved that $(v, \mu) \in$ epi g.

Conversely, let $(v, \mu) \in$ epi g. Following the definition of $g(v)$, there exist $(t_k)_k$ in $\mathbb{R}_+^\star$ converging to 0 and $(v_k)_k$ converging to v such that $(t_k f(v_k/t_k))_k$ converges and $\lim_{k \to +\infty} t_k f(v_k/t_k) \leq \mu$. Given $\epsilon > 0$, we have $t_k f(v_k/t_k) \leq \mu + \epsilon$ for k large enough. Then $(v, \mu + \epsilon) = \lim_{k \to +\infty} t_k(v_k/t_k, (\mu + \epsilon)/t_k)$ with $(v_k/t_k, (\mu + \epsilon)/t_k) \in$ epi$f$ for k large enough. This means that $(v, \mu + \epsilon) \in (\text{epi} f)_\infty$, and since this holds true for all $\epsilon > 0$, we have $(v, \mu) \in (\text{epi} f)_\infty$. □

5.3. Proof of Proposition 4.5.

(*f is epi-pointed*) $\Rightarrow$ (i). We make use of the following classical result on closed convex cones (deduced from [14, Cor. 14.6.1] or [16, §2.10], for example): if K is a nonempty closed convex cone,

$$(48) \qquad (K \text{ pointed}) \Longleftrightarrow (\text{polar cone } K^\circ \text{of } K \text{ has a nonempty interior});$$

$$(49) \qquad (v \in \text{int} K^\circ) \Longleftrightarrow (\langle v, d \rangle < 0 \quad \text{for all nonnull } d \text{ of } K).$$

Set $K = \text{co}(\text{epi} f_\infty)$; K is a pointed closed convex cone (cf. Proposition 4.3(ii)). Since $\text{int} K^\circ \neq \emptyset$ and since we know that $K^\circ \subset \mathbb{R}^n \times \mathbb{R}_-$, we may choose $n+1$ affinely independent s_i's such that $(s_i, -1) \in \text{int} K^\circ$ (a similar device was used in [17, p. 59]). We want to show that s_i is the slope of some affine function minimizing f. For a given i, suppose that for all k there exists $u_k \in$ epi$f$ such that

$$(50) \qquad \langle (s_i, -1), u_k \rangle \geq k.$$

Subsequencing if necessary, we may assume that $(u_k/\|u_k\|)_k$ converges to an element d which by construction lies in $(\text{epi} f)_\infty \setminus \{(0,0)\}$. Dividing (50) by $\|u_k\|$ and letting $k \to +\infty$ yields $\langle (s_i, -1), d \rangle \geq 0$, which contradicts $(s_i, -1) \in \text{int} K^\circ$ (cf. (49)). Thus for all i, there exists $r_i \in \mathbb{R}$ such that

$$\sup_{x \in \mathbb{R}^n} \langle (s_i, -1), (x, f(x)) \rangle = \sup_{u \in \text{epi} f} \langle (s_i, -1), u \rangle \leq r_i.$$

This is written as

$$\langle s_i, x \rangle - r_i \leq f(x) \quad \text{for all } x \in \mathbb{R}^n.$$

(i) $\Leftrightarrow$ (ii). From the definition of $f^\star$, f is minimized by the affine function $\langle s, . \rangle - r$ if and only if the slope s lies in dom $f^\star$. (i) expresses that there are $n+1$ affinely independent points in dom $f^\star$; this means that int(dom $f^\star$) is nonempty.

(ii) $\Rightarrow$ (iii). Let $s \in \operatorname{int}(\operatorname{dom} f^\star)$; we take $\sigma > 0$ such that the compact ball $\bar{B}(s,\sigma)$ is contained in $\operatorname{int}(\operatorname{dom} f^\star)$. Since $f^\star$ is continuous on $\operatorname{int}(\operatorname{dom} f^\star)$ [14, §10], it is bounded above on $\bar{B}(s,\sigma)$; we choose an $r \in \mathbb{R}$ for which

$$f^\star(s') \leq r \quad \text{for all } s' \in \bar{B}(s,\sigma)$$

or, equivalently,

$$-r + \langle s', x\rangle \leq f(x) \quad \text{for all } x \in \mathbb{R}^n \text{ and } s' \in \bar{B}(s,\sigma).$$

By considering $s' = s + \sigma(x/\|x\|)$ if $x \neq 0$ (and any $s' \in \bar{B}(s,\sigma)$ if $x = 0$), we conclude that

$$-r + \langle s, x\rangle + \sigma\|x\| \leq f(x) \quad \text{for all } x \in \mathbb{R}^n.$$

(iii) $\Leftrightarrow$ (iv). This is clear.

(iv) $\Rightarrow$ (*f is epi-pointed*). There is $\sigma > 0$ such that for $\|x\|$ large enough,

$$f(x) \geq \sigma\|x\| + \langle s, x\rangle.$$

The function $x \mapsto \sigma\|x\| + \langle s, x\rangle$ is epi-pointed; hence so is f. □

5.4. Proof of Theorem 4.6.

Proof of (i). Since $(\operatorname{epi} f)_\infty$ is pointed by assumption, it follows from Proposition 4.3 (i) that

$$(\operatorname{epi}(\overline{\operatorname{co}} f) =)\ \overline{\operatorname{co}}(\operatorname{epi} f) = \operatorname{co}(\operatorname{epi} f) + co(\operatorname{epi} f_\infty). \tag{51}$$

For $x \in \operatorname{dom}(\overline{\operatorname{co}} f)$, the point $(x, (\overline{\operatorname{co}} f)(x))$ lies in the epigraph of $(\overline{\operatorname{co}} f)$; according to the decomposition (51), there exist real numbers $\alpha_1, \ldots, \alpha_p$, points $(x_1, r_1), \ldots, (x_p, r_p)$ in $\operatorname{epi} f$, and points $(y_1, \rho_1), \ldots, (y_{q'}, \rho_{q'})$ in $\operatorname{epi} f_\infty$ such that

$$\begin{aligned} &\alpha_i > 0 \quad \text{for all } i = 1, \ldots, p, \quad \sum_{i=1}^p \alpha_i = 1; \\ &(x, (\overline{\operatorname{co}} f)(x)) = \sum_{i=1}^p \alpha_i (x_i, r_i) + \sum_{j=1}^{q'} (y_j, \rho_j) \end{aligned} \tag{52}$$

(remember that $\operatorname{epi} f_\infty$ is a cone). Actually, due to the definition of $(\overline{\operatorname{co}} f)(x)$ as the infimum of those r such that $(x, r) \in \operatorname{epi}(\overline{\operatorname{co}} f)$, each r_i (resp. each ρ_j) has to be $f(x_i)$ (resp. $f_\infty(y_j)$). Now since $f_\infty(0) = 0$, all the null y_j's can be removed in (52); there are thus real numbers $\alpha_1, \ldots, \alpha_p$ ($p \in \mathbb{N}^\star$), points $x_1, \ldots, x_p$ in $\operatorname{dom} f$, and possibly points $y_1, \ldots, y_q$ in $\operatorname{dom} f_\infty \setminus \{0\}$ ($q \in \mathbb{N}$) such that

$$\begin{aligned} &\alpha_i > 0 \quad \text{for all } i = 1, \ldots, p, \quad \sum_{i=1}^p \alpha_i = 1; \\ &(x, (\overline{\operatorname{co}} f)(x)) = \sum_{i=1}^p \alpha_i (x_i, f(x_i)) + \sum_{j=1}^{q} (y_j, f_\infty(y_j)). \end{aligned} \tag{53}$$

Hence the first part of Theorem 4.6(i) is proved.

To continue, we need the following variant of Carathéodory's theorem.

LEMMA 5.1. *Let $x_1, \dots, x_r$ be r points of $\mathbb{R}^n$, and let x be on the boundary of the closed convex cone $\mathbb{R}_+x_1 + \cdots + \mathbb{R}_+x_r$. Then there exists $\Gamma(x) \subset \{1, \dots, r\}$ with* $\mathrm{card}\Gamma(x) \leq n-1$ *such that* $x \in \sum_{\gamma \in \Gamma(x)} \mathbb{R}_+x_\gamma$.

Proof. Because x lies on the boundary of $K := \mathbb{R}_+x_1 + \cdots + \mathbb{R}_+x_r$, there exists a hyperplane $H_{s,r}$ supporting K at x: for some $s \neq 0$ and $r \in \mathbb{R}$,

$$\langle s, x \rangle - r = 0, \tag{54}$$

$$\langle s, d \rangle - r \leq 0 \quad \text{for all } d \in K. \tag{55}$$

Relabelling the indices if necessary, we may assume that x is a positive combination of the first δ elements $x_1, \dots, x_\delta$:

$$x = \alpha_1 x_1 + \cdots + \alpha_\delta x_\delta, \quad \alpha_i > 0 \quad \text{for all } i = 1, \dots, \delta \text{ and } \delta \leq r.$$

Setting $d = x_i$ successively in (55), using (54), we obtain

$$0 = \langle s, x \rangle - r = \sum_{i=1}^{\delta} \alpha_i [\langle s, x_i \rangle - r] \leq 0,$$

so each $\langle s, x_i \rangle - r$ is actually 0: each x_i is in $H_{s,r}$. Then Carathéodory's theorem for cones tells us that

$$x \in (\mathbb{R}_+x_1 + \cdots + \mathbb{R}_+x_\delta) \cap H_{s,r}$$

can be described as positive combination of only $n-1$ elements x_i. □

We begin with a decomposition of $(x, (\overline{\mathrm{co}}f)(x))$ as in (53),

$$(x, (\overline{\mathrm{co}}f)(x)) = \sum_{i=1}^{p} \alpha_i (x_i, f(x_i)) + \sum_{j=1}^{q} (y_j, f_\infty(y_j)),$$

and we set (in $\mathbb{R}^{n+2}$) $X = (x, (\overline{\mathrm{co}}f)(x), 1)$, $X_i = (x_i, f(x_i), 1)$ for $i = 1, \dots, p$, and, possibly, $X_{p+j} = (y_j, f_\infty(y_j), 0)$ for $j = 1, \dots, q$. It is clear that X lies on the boundary of the closed convex cone $\sum_{i=1}^{p+q} \mathbb{R}_+X_i$ (of $\mathbb{R}^{n+2}$). Thus according to Lemma 5.1, there exists an index set $\Gamma(X) = I \cup J$ ($I \subset \{1, \dots, p\}$ and $J \subset \{p+1, \dots, p+q\}$) with $\mathrm{card}\Gamma(X) \leq n+1$ such that

$$X = \sum_{i \in I} \mathbb{R}_+X_i + \sum_{j \in J} \mathbb{R}_+X_j.$$

This yields

$$(x, (\overline{\mathrm{co}}f)(x)) = \sum_{i \in I} \alpha_i (x_i, f(x_i)) + \sum_{j \in J} \beta_j (y_{j-p}, f_\infty(y_{j-p}))$$

$$\text{with } \sum_{i \in I} \alpha_i = 1, \qquad \alpha_i \geq 0 \quad \text{for all } i \in I, \quad \beta_j \geq 0 \quad \text{for all } j \in J.$$

However, since f_∞ is positively homogeneous, we can rewrite

$$\beta_j (y_{j-p}, f_\infty(y_{j-p})) = (y'_j, f_\infty(y'_j)),$$

where $y'_j = \beta_j y_{j-p}$ for all $j \in J$.

As for the bound on q, it suffices to note that $\sum_{j \in J}(y'_j, f_\infty(y'_j))$ lies on the boundary of $\mathrm{co}(\mathrm{epi} f_\infty)$ and again apply Lemma 4.12.

Proof of (ii). Recall that for a nonempty $S \subset \mathbb{R}^n$ and $u \in S$, the normal cone $N_S(u)$ to S at u is defined as the set of d such that $\langle d, v-u\rangle \leq 0$ for all $v \in S$. Its relationship with the subdifferential of a function is as follows:

$$s \in \partial g(x) \quad \text{if and only if } (s, -1) \in N_{\mathrm{epi}\, g}((x, g(x))). \tag{56}$$

For normal cones, the following calculus rules are useful.

LEMMA 5.2.

(i) *If* $u_1 \in S_1$ *and* $u_2 \in S_2$, *then*

$$N_{S_1+S_2}(u_1+u_2) = N_{S_1}(u_1) \cap N_{S_2}(u_2).$$

(ii) *For* $u \in \mathrm{co}\, S$ ($u = \sum_{i=1}^r \alpha_i u_i$ *with* $\sum_{i=1}^r \alpha_i = 1$, $\alpha_i > 0$, *and* $u_i \in S$ *for all* $i = 1, \dots, r$),

$$N_{\mathrm{co}\, S}(u) = \bigcap_{i=1}^r N_S(u_i).$$

(iii) *For a closed subset* S *and any* $u \in S$, *we have*

$$N_S(u) \subset N_{S_\infty}(0).$$

Proof. (i) This is immediate from the definition of normal cones.

(ii) First, note that $N_{\mathrm{co}\, S}(u) = N_S(u)$. If $d \in \bigcap_{i=1}^r N_S(u_i)$, we infer from the r inequalities

$$\langle d, v - u_i\rangle \leq 0 \quad \text{for all } v \in S \ \ (i = 1, \dots, r)$$

that $\langle d, v-u\rangle \leq 0$ for all $v \in S$, whence $d \in N_S(u)$.

Conversely, let $d \in N_{\mathrm{co}\, S}(u)$. Fix $i_0 \in \{1, \dots, r\}$ and for an arbitrary $w \in S$, set $v = \alpha_{i_0} w + \sum_{i \neq i_0} \alpha_i u_i$. Since $v \in \mathrm{co}\, S$,

$$\alpha_{i_0}\langle d, w - u_{i_0}\rangle = \langle d, v - u\rangle \leq 0;$$

that is, $d \in N_S(u_{i_0})$.

(iii) Let $d \in N_S(u)$ and consider $d' \in S_\infty$. For sequences $(x_k)_k$ in S and $(t_k)_k$ in $\mathbb{R}_+$ that give rise to d' (cf. the definition in (25)), we have

$$\langle d, t_k x_k - t_k u\rangle = t_k \langle d, x_k - u\rangle \leq 0 \quad \text{for all } k.$$

Then passing to the limit $k \to +\infty$ yields $\langle d, d'\rangle \leq 0$. □

In a decomposition like (53), we set $y_{q+1} = 0$ if $q = 0$ (i.e., there is no nonnull y_j involved). We have

$$\begin{aligned}
&N_{\overline{\mathrm{co}}(\mathrm{epi} f)}((x, (\overline{\mathrm{co}} f)(x))) \\
&= N_{\mathrm{co}(\mathrm{epi} f)+\mathrm{co}(\mathrm{epi} f_\infty)}\left(\sum_i \alpha_i(x_i, f(x_i)) + \sum_j (y_j, f_\infty(y_j))\right) \\
&= \left[N_{\mathrm{co}(\mathrm{epi} f)}\left(\sum_i \alpha_i(x_i, f(x_i))\right)\right] \cap \left[N_{\mathrm{co}(\mathrm{epi} f_\infty)}\left(\sum_j (y_j, f_\infty(y_j))\right)\right] \\
&\quad \text{(according to Lemma 5.2 (i))} \\
&= [\cap_i N_{\mathrm{epi} f}((x_i, f(x_i)))] \cap [\cap_j N_{\mathrm{epi} f_\infty}((y_j, f_\infty(y_j)))] \\
&\quad \text{(according to Lemma 5.2(ii)).}
\end{aligned}$$

According to Lemma 5.2 (iii), we can now remove all the null y_j's. With (56), we then have

$$\begin{aligned} s \in \partial(\overline{\text{co}}f)(x) &\Leftrightarrow (s,-1) \in N_{\text{epi}(\overline{\text{co}}f)}((x,(\overline{\text{co}}f)(x))) \\ &\Leftrightarrow \begin{cases} (s,-1) \in N_{\text{epi}f}((x_i,f(x_i))) & \text{for all } i \\ \text{and} \\ (s,-1) \in N_{\text{epi}f_\infty}((y_j,f_\infty(y_j))) & \text{for all } j \end{cases} \\ &\Leftrightarrow s \in \partial f(x_i) \quad \text{for all } i \quad \text{and} \quad s \in \partial f_\infty(y_j) \quad \text{for all } j. \qquad \square \end{aligned}$$

Acknowledgment. The authors would like to thank the referee for his careful study of the script and for pointing out that our original proof of (37) was somewhat questionable.

INVERSION DE CERTAINS OPÉRATEURS ELLIPTIQUES À COEFFICIENTS VARIABLES[*]

PHILIPPE TCHAMITCHIAN[†]

Abstract. We consider elliptic operators in divergence form with variable coefficients defined through an accretive sesquilinear form on the whole space. The coefficients of leading order are supposed to be lipschitzian. We show how wavelets bases allow us to explicitly compute the inverse of such operators. The first main ingredient is a detailed study, of independant interest, of the convergence of the usual Galerkin approximations. The second main ingredient is the notion of paraproduct, suitably adapted to our context.

Key words. elliptic operators, wavelets, Galerkin approximation, paraproducts

AMS subject classifications. 35A35, 35C10, 35J15, 65M60, 65M70

1. Introduction et exemples.

Cet article présente une analyse de certains opérateurs aux dérivées partielles à coefficients variables, à l'aide des analyses multirésolution et des bases d'ondelettes qui leur sont attachées.

Les opérateurs que nous traitons sont de la forme

$$L = -\operatorname{div} A\nabla + b,$$

vérifiant les hypothèses suivantes:

- ils sont définis sur $\mathbb{R}^n$ (le traitement de problèmes avec conditions au bord étant l'un des principaux problèmes ouverts à l'emploi des ondelettes);
- ils sont associés à une forme sesquilinéaire continue sur $H^1(\mathbb{R}^n)$ et strictement accrétive;
- enfin A est lipschitzienne, ce qui implique que le domaine de L soit l'espace $H^2(\mathbb{R}^n)$.

Notre but est de calculer le plus explicitement possible l'opérateur L^{-1}, au sens de la meilleure topologie possible, c'est-à-dire en tant qu'opérateur continu de L^2 dans H^2, et d'une façon qui soit utilisable en analyse numérique.

Nous avons proposé une première solution à ce problème dans [8]. Mais, reposant sur l'emploi de bases d'ondelettes trop particulières, elle n'était pas très utile et nous ne l'avons pas publiée. Néanmoins, certains ingrédients en sont repris ici.

Une deuxième solution a ensuite été proposée par Bénassi, Jaffard, et Roux, qui consiste à construire une famille de "vaguelettes" orthogonales pour la forme associée à l'opérateur. Mais, bien que constructive, la preuve présente de nombreuses étapes qui, à notre avis, rendent difficile la transposition de ce résultat en situation numérique.

D'un point de vue plus directement algorithmique, on peut penser à partir des idées développées par Beylkin, Coifman, et Rokhlin (BCR) pour la résolution de problèmes intégraux ou différentiels. Cependant, une hypothèse essentielle dans leurs travaux nous fait défaut.

En effet, pour que les algorithmes BCR donnent de bons résultats, ils doivent être appliqués à un opérateur dont le noyau est régulier en dehors de la diagonale, et d'autant plus décroissant à l'infini qu'il est dérivé. L'exemple typique est $K(x,y) = |x-y|^{-n+2}$. Avec un opérateur du type que nous considérons, une telle hypothèse

[*] Received by the editors April 16, 1994; accepted for publication July 31, 1995.

n'est satisfaite que si les coefficients sont suffisamment réguliers, bien plus que ce que nous voulons supposer.

La question des hypothèses faites sur la régularité des coefficients n'est pas gratuite, même pour le numéricien. Car, outre son intérêt mathématique intrinsèque, elle est directement liée à la stabilité des algorithmes. Par exemple, dans notre calcul de L^{-1}, les quantités importantes sont le conditionnement de A, celui de la forme associée à L, et enfin la norme lipschitz de A. Cela implique que tout algorithme dérivé de nos résultats dépendra de ces constantes, et sera d'autant mieux conditionné qu'elles seront d'un ordre de grandeur raisonnable, et ce indépendamment de la taille des dérivées d'ordre supérieur des coefficients.

Les deux approches, de Benassi, Jaffard, Roux et de Beylkin, Coifman, et Rokhlin, utilisent la forme associée à L et les opérateurs de Galerkin qui approchent L^{-1}. Notre solution repose en partie également sur ces opérateurs, que nous sommes ainsi amenés à étudier. Nous prouvons que ces opérateurs permettent d'approcher L^{-1} pour la topologie forte de H^2, et non pas seulement celle de H^1: c'est là un premier résultat, qui montre que, même si la précision est du même ordre, la méthode de Galerkin converge plus finement dans des espaces associés à une analyse multi–résolution qu'en situation générale.

Ce résultat repose sur des inégalités a priori précisées,[1] que nous établissons en imitant, à l'intérieur de chaque espace d'approximation donné par l'analyse multi–résolution, le calcul fonctionnel de Calderón. Nous définissons en particulier une notion adaptée de transformées de Riesz, et étudions les commutateurs entre ces transformées et les opérateurs de multiplication ponctuelle par les fonctions lipschitziennes.

Il faut cependant souligner, comme nous l'a fait remarquer D. Gottlieb, que nous remercions, que le même résultat est vrai pour les méthodes spectrales, dans le cadre périodique. En revanche, alors que la multiplication par des coefficients variables est peu agréable en Fourier, les bases d'ondelettes permettent de presque diagonaliser les opérateurs de multiplication ponctuelle par des fonctions un peu régulières. C'est là le deuxième ingrédient de notre construction, le paraproduit, issu du calcul paradifférentiel de J. M. Bony, sous la forme simple qu'on peut lui donner avec une base d'ondelettes, qui a été explicitée par Y. Meyer [7].

Combinant les approximations fournies par la méthode de Galerkin et par le calcul paradifférentiel, nous inversons L, en suivant un schéma abstrait qui est expliqué dans la première partie de l'article. Nous y énonçons à la suite notre résultat principal.

Dans la deuxième partie, nous démontrons les inégalités précisées dont nous avons besoin dans la troisième. Celle-ci est consacrée à la preuve de nos résultats sur la qualité de l'approximation par la méthode de Galerkin dans une analyse multi-résolution et sur le calcul de L^{-1}.

L'ensemble de l'article utilise, en plusieurs points cruciaux, les propriétés essentielles des ondelettes. C'est pourquoi nous rappelons, à la fin de la première partie, le lemme fondamental qui régit (jusqu'à présent) l'emploi de ces bases en théorie des opérateurs.

2. Le schéma d'inversion.

2.1. Généralités. Nous le présentons d'abord de manière abstraite, avant de considérer des opérateurs plus concrets.

[1] Ce sont ces inégalités qui nous permettent de généraliser le théorème écrit dans [8] à toutes les analyses multi-résolution raisonnables de $L^2(\mathbb{R}^n)$, et en font ainsi un résultat à notre avis intéressant.

Soit L un opérateur non borné sur un espace de Hilbert $\mathcal{H}$, de domaine dense $D(L)$, réalisant un isomorphisme de $D(L)$ sur $\mathcal{H}$.

Soit également une suite $(V_j)_{j\in\mathbb{Z}}$ d'espaces d'approximation, fermés dans $\mathcal{H}$, emboîtés ($V_j \subset V_{j+1}$) et définissant une approximation de l'identité: $\bigcup_{j\in\mathbb{Z}} V_j$ est dense dans $\mathcal{H}$, et dans $D(L)$ muni de la topologie du graphe. On note

$$\pi_j : \mathcal{H} \to V_j$$

l'opérateur de restriction par projection orthogonale (pour le produit scalaire sur $\mathcal{H}$), et l'adjoint π_j^*, de V_j dans $\mathcal{H}$, est l'opérateur d'extension naturel. On note également $\pi_j^\perp$ la projection orthogonale de $\mathcal{H}$ sur $V_j^\perp$.

On suppose que sont satisfaites les hypothèses suivantes.

Hypothèse (H1). Pour tout $j \in \mathbb{Z}$, l'opérateur

$$\pi_j L \pi_j^* \ : \ V_j \to V_j$$

est inversible.

On note alors Γ_j l'opérateur inverse prolongé à $\mathcal{H}$:

$$\Gamma_j = \pi_j^* (\pi_j L \pi_j^*)^{-1} \pi_j.$$

Les opérateurs Γ_j sont appelés opérateurs de Galerkin.

Hypothèse (H2). Les opérateurs $L\Gamma_j$ sont uniformément bornés.

Remarquer que, par définition, on a

$$\pi_j L \Gamma_j = \pi_j. \tag{1}$$

L'hypothèse porte donc en réalité sur les opérateurs $\pi_j^\perp L \Gamma_j$: ils mesurent le résidu associé à la résolution approchée d'une équation $Lu = f$, où $f \in V_j$, par $u_j = \Gamma_j f$.

Enfin, on suppose qu'on sait approximativement inverser L sur $V_j^\perp$, au sens suivant.

Hypothèse (H3). Pour tout j, il existe un opérateur P_j, continu de $\mathcal{H}$ dans $D(L)$, tel que, si R_j est défini par la relation

$$L P_j = \pi_j^\perp - R_j, \tag{2}$$

alors on a

$$\lim_{j\to+\infty} \|R_j\| = 0.$$

Par exemple, si L admet une parametrix P, c'est-à-dire un opérateur continu de $\mathcal{H}$ dans $D(L)$ tel que

$$L P = I - K, \tag{3}$$

où K est compact, alors $P_j = P\pi_j^\perp$ convient. On aura en effet $R_j = K\pi_j^\perp$, et la compacité de K entraine $\lim_{j\to+\infty} \|R_j\| = 0$. Naturellement, si la relation (3) est satisfaite, il suffit d'inverser $I - K$ pour inverser L. La portée de cette remarque est cependant limitée, premièrement parce qu'il est souvent à peu près aussi ardu de construire une parametrix que de calculer L^{-1}, et deuxièmement parce que l'inversion d'une perturbation compacte de l'identité n'est pas, en pratique, facile a priori.

Le schéma que nous proposons, plus flexible, est fondé sur l'emploi conjugué des opérateurs de Galerkin Γ_j et des parametrix généralisées P_j.

THÉORÈME 2.1. *Avec les notations précédentes, et sous les hypothèses* (H1), (H2), *et* (H3), *si on définit les opérateurs* U_j *par*

$$L(\Gamma_j + P_j) = I - U_j,$$

alors on a

$$\lim_{j\to+\infty} \|U_j^2\| = 0.$$

Par conséquent, la série de Neumann $\sum_{p=0}^{+\infty} U_j^p$ *est normalement convergente pour j assez grand, et on peut écrire*

$$L^{-1} = (\Gamma_j + P_j) \sum_{p=0}^{+\infty} U_j^P.$$

L'argument repose sur une relation d'orthogonalité. On commence par calculer $L(\Gamma_j + P_j)$. Utilisant (1) et (2), il vient

$$\begin{aligned} L(\Gamma_j + P_j) &= \pi_j L\Gamma_j + \pi_j^\perp L\Gamma_j + \pi_j^\perp - R_j \\ &= I + \pi_j^\perp L\Gamma_j - R_j, \end{aligned}$$

c'est-à-dire

$$U_j = R_j - \pi_j^\perp L\Gamma_j.$$

L'opérateur U_j n'est pas petit, il est seulement contrôlé uniformément en norme, grâce à (H2). Mais il faut se rappeler que Γ_j est nul sur $V_j^\perp$, autrement dit que $\Gamma_j = \Gamma_j \pi_j^* \pi_j$. Par conséquent, $\pi_j^\perp L\Gamma_j$ est de carré nul. On a donc

$$U_j^2 = R_j^2 - R_j \pi_j^\perp L\Gamma_j - \pi_j^\perp L\Gamma_j R_j.$$

On conclut alors grâce à (H2) et (H3).

2.2. Enoncé des principaux résultats. Ce schéma sera utilisé dans le cas des opérateurs

$$L = -\operatorname{div} A\nabla + b,$$

définis sur $\mathbb{R}^n$, sous les hypothèses suivantes:

- $A = A(x) = (a_{\alpha\beta}(x))_{1\le\alpha,\beta\le n}$ et $b = b(x)$ sont bornées.
- La forme sesquilinéaire

$$B(f,g) = \int A\nabla f\cdot\nabla\bar{g} + \int b f\bar{g},$$

continue sur $H^1(\mathbb{R}^n)$, est strictement accrétive. Cela signifie qu'il existe $\delta > 0$ tel que

$$\forall f \in H^1, \quad \operatorname{Re} B(f,f) \ge \delta\|f\|_{H^1}^2,$$

ou encore, de façon équivalente,

$$\begin{aligned} \forall x,\xi \in \mathbb{R}^n, \quad &\operatorname{Re} A(x)\xi\cdot\bar{\xi} \ge \delta|\xi|^2. \\ &\operatorname{Re} b(x) \ge \delta. \end{aligned}$$

- La matrice A est lipschitzienne.

L'espace de Hilbert $\mathcal{H}$ est naturellement $L^2(\mathbb{R}^n)$. On note simplement $\|\cdot\|$ sa norme, ainsi que la norme d'opérateur induite.

Les espaces d'approximation V_j seront fournis par une analyse multirésolution tensorielle (AMR)[2] de régularité $r \geq 3$.

Cela signifie que:

- les espaces V_j sont engendrés par les fonctions $\varphi_{jk}(x) = 2^{jn/2}\,\varphi(2^j x - k)$, $k \in \mathbb{Z}^n$, orthonormales entre elles, déduites par translation et dilatation d'une fonction φ;
- cette fonction φ est construite par produit tensoriel à partir d'une fonction d'une variable, notée ϕ:

$$\varphi(x) = \phi(x_1) \cdots \phi(x_n);$$

- la fonction ϕ est au moins de classe C^{r-1} et à dérivée d'ordre $r-1$ lipschitzienne, avec $r \geq 3$, chaque dérivée de ϕ étant à décroissance rapide;
- pour tout $\varepsilon \in \{0,1\}^n$, $\varepsilon \neq 0$, il existe une fonction ψ_ε, de sorte que l'ensemble des $2^{jn/2}\,\psi_\varepsilon(2^j\,x - k)$, $k \in \mathbb{Z}^n$, forme une base orthonormée de W_j, le supplémentaire orthogonal de V_j dans V_{j+1};
- chaque ψ_ε, comme φ, est au moins de classe C^{r-1}, chaque dérivée d'ordre $r-1$ est au moins lipschitzienne, et chaque dérivée de ψ_ε est à décroissance rapide.
- On aura besoin de la description plus précise suivante. Il existe une ondelette d'une variable, Ψ, ayant les mêmes propriétés que ϕ, et telle qu'il existe un entier $N \geq r$ pour lequel on a

$$\forall k \leq N, \quad \int_{\mathbb{R}} t^k\,\Psi(t)\,dt = 0. \tag{4}$$

En convenant de noter $\psi_0 = \phi$ et $\psi_1 = \Psi$, et si $\varepsilon = (\varepsilon_1, \ldots, \varepsilon_n)$, alors on a

$$\psi_\varepsilon(x) = \psi_{\varepsilon_1}(x_1) \cdots \psi_{\varepsilon_n}(x_n).$$

On écrit

$$2^{jn/2}\,\psi_\varepsilon(2^j x - k) = \psi_\lambda(x),$$

où $\lambda = (k + \frac{1}{2}\varepsilon)\,2^{-j}$, et on désigne par D l'ensemble des λ. La correspondance

$$\lambda \mapsto (j,\, k,\, \varepsilon)$$

est biunivoque, et on notera parfois $j(\lambda)$, $k(\lambda)$, $\varepsilon(\lambda)$ les indices associés à λ.

La collection des ψ_λ, $\lambda \in \Lambda$, est une base orthonormée de $L^2(\mathbb{R}^n)$, et une base inconditionnelle des espaces de Sobolev $H^s(\mathbb{R}^n)$, $|s| < 3$.

Nous renvoyons le lecteur à [3] et [5] pour les connaissances de base sur les ondelettes. Nous nous contenterons d'indiquer que l'intuition avec laquelle on peut comprendre ce qui suit est que les fonctions φ_{jk} et ψ_λ se comportent comme si elles étaient supportées dans le cube dyadique $k2^{-j} + 2^{-j}\,[0,1]^n$, et, dans l'espace de Fourier, dans

[2] Une remarque de P. Auscher, que nous remercions, a permis de généraliser notre preuve au cas des AMR de régularité $r \geq 3$ quelconques. Cependant, ces analyses sont, à notre connaissance, peu utilisées. Nous nous contenterons donc d'indiquer rapidement les modifications à apporter, sans les détailler. Ces modifications sont, de toute façon, de nature technique et s'insèrent dans la stratégie générale de la preuve.

la boule $|\omega| \leq 2^j$ pour ce qui concerne φ_{jk}, et dans la couronne $2^{j-1} \leq |\omega| \leq 2^{j+1}$ pour ce qui concerne ψ_λ.

Nous démontrerons le théorème suivant.

THÉORÈME 2.2. *L'opérateur L et l'AMR (V_j) satisfont aux hypothèses* (H1), (H2), *et* (H3), *et avec les notations du Théorème* 2.1, *on a plus précisément*

$$\|U_j^2\| \leq C\,2^{-j}, \tag{5}$$

où C est une constante indépendante de j.

Remarquons que, L étant associé à une forme strictement accrétive, l'hypothèse (H1) est classiquement satisfaite. La difficulté est de prouver (H2) et (H3). Si la preuve de (H3) emploie des ingrédients plus ou moins déjà connus, celle de (H2) va nécessiter quelques développements assez nouveaux, croyons-nous, et qui conduisent à un résultat intéressant par lui-même, que nous énonçons maintenant.

THÉORÈME 2.3. *Reprenant les notations du paragraphe* 2.1, *on a*

$$\forall f \in L^2, \quad \lim_{j\to+\infty} \|L^{-1} f - \Gamma_j\, f\|_{H^2} = 0.$$

Autrement dit, les approximations u_j de la solution du problème $Lu = f$, données par $u_j = \Gamma_j f$ convergent non seulement en norme H^1 vers u, mais aussi en norme H^2.

Les AMR conduisent donc à des schémas de Galerkin plus précis, au sens que la convergence a lieu pour une topologie plus fine que la topologie habituelle, même si l'ordre de précision est inchangé.

Ainsi que nous l'avons annoncé, ces théorèmes sont une conséquence de l'existence des bases d'ondelettes. La base des φ_{jk}, $k \in \mathbb{Z}^n$, dans V_j, nous sera de faible utilité, et nous utiliserons presque constamment les ondelettes ψ_λ.

Rappelons donc de quelle façon on emploie ces fonctions en théorie des opérateurs.

2.3. Le lemme fondamental. Jusqu'à présent, les bases d'ondelettes ont servi à prouver la continuité de certains opérateurs, le plus souvent sur L^2. La démarche suivie consiste, à partir d'une analyse adéquate de l'opérateur étudié, à se ramener à une classe d'opérateurs définis à travers les images de chaque ondelette de base, qui soient des fonctions imitant le comportement des ondelettes (et qu'on appelle vaguelettes pour cette raison).

Or, la continuité des opérateurs de cette classe est entièrement caractérisée.

LEMME FONDAMENTAL. *Soit U un opérateur linéaire défini par $U(\psi_\lambda) = f_\lambda$, où les fonctions f_λ satisfont aux hypothèses suivantes:*

$$\forall x \in \mathbb{R}^n, \quad |f_\lambda(x)| \leq C\,2^{jn/2}\,(1 + 2^j|x-\lambda|)^{-n-s}, \tag{6}$$

$$\forall x \in \mathbb{R}^n, \quad |\nabla f_\lambda(x)| \leq C\,2^{jn/2}\,2^j\,(1 + 2^j|x-\lambda|)^{-n-s}, \tag{7}$$

où s est un réel > 0 indépendant de λ, ainsi que la constante C.

Alors, U est continu sur $L^2(\mathbb{R}^n)$ si et seulement si les scalaires $\int f_\lambda$ satisfont à la condition de Carleson:

$$\exists C > 0, \quad \forall \lambda \in D, \quad \sum_{Q_\mu \subset Q_\lambda} \left|\int f_\mu\right|^2 \leq C^2\,|Q_\lambda|,$$

où Q_λ est le cube dyadique contenant λ dont le côté est de longueur $2^{-j(\lambda)}$.

Si cette condition est satisfaite, la norme d'opérateur de U est contrôlée par la meilleure constante C possible dans les trois inégalités précédentes.

Le lecteur intéressé pourra trouver une preuve de ce résultat dans [6], sous une forme d'ailleurs un peu plus générale (c'est-à-dire avec des hypothèses (6) et (7) plus faibles). L'énoncé que nous en donnons est celui dont nous avons besoin. Signalons enfin qu'un argument court, mais sophistiqué, qui démontre le lemme fondamental est de remarquer que U est un opérateur d'intégrale singulière, dont le noyau est de Calderón–Zygmund, puis d'appliquer le critère de David et Journé, autrement dit le théorème T(1). On vérifie alors que tout se ramène à savoir si la fonction

$$\sum_\lambda \overline{\left(\int f_\lambda\right)}\, \psi_\lambda = U^*(1)$$

appartient ou non à BMO (bounded mean oscillation). Or, cette appartenance est équivalente à la condition de Carleson.

On convient, dans toute la suite, d'appeler *estimations standard de paramètre s* les estimations (6) et (7). On dira parfois qu'une famille (f_λ) vérifie les estimations standard, ce qui voudra dire qu'il existe $s > 0$ pour lequel les estimations de paramètre s sont vraies.

L'exemple le plus caractéristique d'emploi du lemme fondamental, et qui est le prototype de l'usage que nous en ferons, est donné par la preuve suivante du célèbre théorème du premier commutateur de Calderón, dont nous rappelons la teneur.

On se donne $a(x)$, $x \in \mathbb{R}$, une fonction lipschitzienne d'une variable; on note H la transformée de Hilbert. Il s'agit de montrer que le commutateur $[a, H]$ est régularisant d'ordre un, c'est-à-dire que l'opérateur $[a, H]\, \frac{d}{dx}$ est borné sur L^2.

Calculons l'image d'une ondelette ψ_λ par cet opérateur. Elle s'écrit

$$a(x)\, 2^j\, (H\, \psi')_\lambda(x) - H\{2^j a\, (\psi')_\lambda\}\, (x),$$

avec $(H\psi')_\lambda(x) = 2^{j/2}\, (H\, \psi')\, (2^j\, x - k)$, et de même pour $(\psi')_\lambda$.

Mais on peut soustraire à $a(x)$ n'importe quelle constante sans changer l'image de ψ_λ : on remplace donc $a(x)$ par $a(x) - a(\lambda)$.

Soient alors U_1 et U_2 les deux opérateurs définis par

$$U_1\, \psi_\lambda(x) = 2^j\, [a(x) - a(\lambda)]\, (H\, \psi')_\lambda(x),$$
$$U_2\, \psi_\lambda(x) = 2^j\, [a(x) - a(\lambda)]\, (\psi')_\lambda(x),$$

de sorte que

$$[a, H]\, \frac{d}{dx} = U_1 - H\, U_2.$$

Il suffit de prouver que U_1 et U_2 sont continus sur L^2 pour prouver le théorème de Calderón. Pour cela, on applique le lemme fondamental.

On vérifie aisément que U_1 et U_2 en satisfont les hypothèses. On calcule donc:

$$\begin{aligned} \int U_1\, (\psi_\lambda) &= - \int a'\, (H\psi)_\lambda \\ &= - \int (Ha')\, \psi_\lambda \\ \text{et } \int U_2\, (\psi_\lambda) &= - \int a'\, \psi_\lambda\, . \end{aligned}$$

Les deux conditions de Carleson sont remplies, parce que $a' \in L^\infty$ par hypothèse, ce qui entraîne que $H\,a' \in \mathrm{BMO}$, et permet de conclure.

Nous en venons maintenant à la preuve des Théorèmes 1.2 et 1.3, et commençons par la démonstration de quelques inégalités a priori.

3. Une inégalité précisée.

3.1. Enoncé du théorème. Soit $B = B(x) = (b_{\alpha\beta}(x))$ une fonction à valeurs matricielles, supposée bornée et lipschitzienne. On notera $\|B\|$ le supremum des normes $\|B(x)\|_{2,2}$, induites par la norme euclidienne sur $\mathbb{R}^n$, et $\|B\|_{\mathrm{lip}}$ la quantité $\sum_{\alpha,\beta}\|\nabla\, b_{\alpha\beta}\|_\infty$.

L'opérateur $b_{\alpha\beta}\,\partial_\alpha\,\partial_\beta$ (où la sommation sur tous les indices α et β est sous-entendue) est bien défini de H^2 dans L^2, et il existe une constante C telle que

$$\forall f \in H^2, \quad \|b_{\alpha\beta}\,\partial_a\,\partial_\beta\, f\| \leq C\|\Delta f\|$$

(où $\|\cdot\|$ désigne la norme L^2).

Dans le cas où B est en fait constante, la meilleure constante C est exactement $\|B\|$. Dans le cas général, cette observation reste vraie, à un terme d'ordre 1 près.

LEMME 3.1. *Il existe une constante absolue $C = C(n)$ telle que*

$$\forall f \in H^2, \quad \|b_{\alpha\beta}\,\partial_\alpha\,\partial_\beta\, f\| \leq \|B\|\;\|\Delta\, f\| + C\,\|B\|_{\mathrm{lip}}\;\|\nabla\, f\|.$$

La preuve de ce résultat est très simple, mais repose sur le résultat profond de Calderón que nous avons déjà mentionné: si b est lipschitzienne et si R_α est une transformée de Riesz, alors le commutateur $[b,\, R_\alpha]$ est régularisant d'ordre 1 (exactement, c'est la généralisation à plusieurs dimensions du théorème de Calderón que nous utilisons).

Soit $f \in H^2$. On a

$$\begin{aligned} b_{\alpha\beta}\,\partial_\alpha\,\partial_\beta\, f &= b_{\alpha\beta}\,R_\alpha\,R_\beta\,(\Delta f) \\ &= R_\alpha\,b_{\alpha\beta}\,R_\beta\,(\Delta f) \\ &\quad + [b_{\alpha\beta},\, R_\alpha]\,R_\beta\,(\Delta f). \end{aligned}$$

Le deuxième terme est celui auquel on applique le résultat de Calderón: il se majore par $C\|B\|_{lip}\,\|\nabla f\|$. Pour estimer le premier, il suffit de se donner $g \in L^2$; on a alors

$$\tag{8} \begin{aligned} |\langle R_\alpha\, b_{\alpha\beta}\, R_\beta\,\Delta f,\, g\rangle| &= |\langle b_{\alpha\beta}\, R_\beta\,\Delta f, R_\alpha\, g\rangle| \\ &\leq \|B\| \left\| \left(\sum |R_\beta\,\Delta f|^2\right)^{1/2} \right\| \left\| \left(\sum |R_\alpha g|^2\right)^{1/2} \right\| \\ &\leq \|B\|\|\Delta f\|\|g\|. \end{aligned}$$

(Remarquons que le choix de la matrice B, définissant l'opérateur $b_{\alpha\beta}\,\partial_\alpha\,\partial_\beta$, n'est pas unique. Si B est réelle, c'est en imposant à B d'être symétrique qu'on minimise la norme $\|B\|$.)

Le but de cette deuxième partie est d'établir une version plus forte du Lemme 3.1, où l'espace de départ est un espace d'approximation V_j, au lieu de H^2.

THÉORÈME 3.2. *On désigne par π_j la projection orthogonale de L^2 sur l'espace V_j. Alors, il existe une constante C, ne dépendant que de l'AMR, telle que*

$$\tag{9} \begin{gathered} \forall j \in \mathbb{Z}, \quad \forall f \in V_j, \\ \|\pi_j b_{\alpha\beta}\,\partial_\alpha\,\partial_\beta\, f\| \leq \|B\|\;\|\pi_j\,\Delta f\| + C\|B\|_{\mathrm{lip}}\,\|\nabla f\|. \end{gathered}$$

Noter que le passage à la limite $j \to +\infty$ permet de retrouver le Lemme 3.1.

L'uniformité par rapport à j dans l'inégalité précédente résulte simplement de son invariance par scaling. Ce théorème est donc en réalité un résultat sur l'espace V_0. Néanmoins, la structure d'AMR sera utilisée dans la preuve, de sorte que nous ne savons pas pour quels espaces V, en toute généralité, ce résultat reste vrai.

Remarquons cependant que, suivant D. Gottlieb, dans le cas des approximations de Fourier, on a $\pi_j \Delta f = \Delta f$ si $f \in V_j$. Le Lemme 3.1 implique alors aussitôt l'inégalité (9), puisque π_j est une projection orthogonale.

Pour prouver le Théorème 3.2, nous nous plaçons dans V_0. La démonstration suit alors à peu près le même schéma que celle du Lemme 3.1. Elle repose sur l'emploi de transformées de Riesz adaptées à l'espace V_0, qui permettent de passer de $\pi_0 \, \Delta f$ à $\pi_0 \, \partial_\alpha \, \partial_\beta \, f$, pour toute $f \in V_0$. En particulier, nous éviterons entièrement le recours aux commutateurs de la forme $[\pi_0, \, \partial_\alpha]$.

La section suivante est consacré à l'étude de ces transformées, avant de donner la preuve du Théorème 3.2.

3.2. Transformées de Riesz adaptées à l'espace V_0.

3.2.1. Opérateurs à coefficients constants et transformées de Riesz adaptées. On oublie ici, et jusqu'à la fin de cette deuxième partie, l'indice 0, et on note V, π au lieu de V_0, π_0. On rappelle que π est défini comme étant un opérateur de L^2 dans V, et son adjoint π^* de V dans L^2.

V étant invariant par translation selon $\mathbb{Z}^n$, les calculs se font, dans cette section, avec la transformée de Fourier. Rappelons que ([3], [5]) tout élément f de V est donné par

$$\hat{f}(\omega) = m(\omega) \, \hat{\varphi}(\omega),$$

où m est $2\pi \, \mathbb{Z}^n$-périodique et de carré intégrable (il suffit d'écrire $f(x) = \sum c_k \, \varphi(x - k)$ pour le voir). De plus, l'orthonormalité des fonctions $\varphi(\cdot - k)$ est équivalente à la relation

$$\sum_{k \in \mathbb{Z}^n} |\hat{\varphi}(\omega + 2\pi k)|^2 = 1, \tag{10}$$

qui est vraie en tout $\omega \in \mathbb{R}^n$. Finalement, si f est quelconque dans L^2, sa projection orthogonale sur V est donnée par

$$(\pi f)^\wedge(\omega) = m(\omega) \, \hat{\varphi}(\omega), \tag{11}$$

avec

$$m(\omega) = \sum_{k \in \mathbb{Z}^n} \hat{f}(\omega + 2\pi k) \, \overline{\hat{\varphi}(\omega + 2\pi k)}.$$

Soit maintenant $P(D)$ un opérateur aux dérivées partielles à coefficients constants, d'ordre 2 pour fixer les idées, et de symbole $\sigma(\omega)$:

$$(P(D) \, f)^\wedge(\omega) = \sigma(\omega) \, \hat{f}(\omega).$$

Il résulte de (11) que, si $f \in V$, avec $\hat{f}(\omega) = m(\omega) \, \hat{\varphi}(\omega)$, alors on a

$$(\pi \, P(D) \, f)^\wedge(\omega) = \sigma^V(\omega) \, m(\omega) \, \hat{\varphi}(\omega), \tag{12}$$

où

$$\sigma^V(\omega) = \sum_{k \in \mathbb{Z}^n} \sigma(\omega + 2\pi k)\, |\hat{\varphi}(\omega + 2\pi k)|^2$$

(l'hypothèse de régularité sur φ assure l'existence de σ^V).

En d'autres termes, l'opérateur $\pi\, P(D)\, \pi^*$ est l'opérateur de convolution associé au symbole σ^V.

En particulier, on a, si $f \in V$,

$$(\pi\, \Delta f)^\wedge(\omega) = -\left(\sum_{k \in \mathbb{Z}^n} |\omega + 2\pi k|^2\, |\hat{\varphi}(\omega + 2\pi k)|^2 \right) \hat{f}(\omega).$$

On définit alors l'opérateur Λ^V, de V dans lui-même, par

$$\forall f \in V, \quad (\Lambda^V f)^\wedge(\omega) = \left(\sum_k |\omega + 2\pi k|^2\, |\hat{\varphi}(\omega + 2\pi k)|^2 \right)^{1/2} \hat{f}(\omega),$$

de sorte que

$$(\Lambda^V)^2 = -\pi \Delta \pi^*.$$

On définit ensuite les transformées de Riesz adaptées à V, notées R^V_α et $R^V_{\alpha,\beta}$, par les formules

$$\begin{aligned} R^V_\alpha &= -i(\pi\, \partial_\alpha\, \pi^*)\, (\Lambda^V)^{-1}, \\ R^V_{\alpha,\beta} &= (\pi\, \partial_\alpha\, \partial_\beta\, \pi^*)\, (\pi\, \Delta \pi^*)^{-1}. \end{aligned}$$

Si on pose

$$k^V_\alpha(\omega) = -i\, \frac{\displaystyle\sum_k (\omega_\alpha + 2\pi k_\alpha)\, |\hat{\varphi}(\omega + 2\pi k)|^2}{\left(\displaystyle\sum_k |\omega + 2\pi k|^2\, |\hat{\varphi}(\omega + 2\pi k)|^2 \right)^{1/2}}$$

et

$$k^V_{\alpha,\beta}(\omega) = \frac{\displaystyle\sum_k (\omega_\alpha + 2\pi k_\alpha)\, (\omega_\beta + 2\pi k_\beta)\, |\hat{\varphi}(\omega + 2\pi k)|^2}{\displaystyle\sum_k |\omega + 2\pi k|^2\, |\hat{\varphi}(\omega + 2\pi k)|^2}$$

(ces fonctions sont $2\pi\mathbb{Z}^n$-périodiques, définies en tout $\omega \notin 2\pi\mathbb{Z}^n$ et bornées par 1), alors R^V_α et $R^V_{\alpha,\beta}$ sont les restrictions à V des opérateurs de convolution de symboles k^V_α et $k^V_{\alpha,\beta}$:

$$\begin{aligned} (R^V_\alpha\, f)^\wedge\, (\omega) &= k^V_\alpha(\omega)\, \hat{f}(\omega), \\ (R^V_{\alpha,\beta}\, f)^\wedge\, (\omega) &= k^V_{\alpha,\beta}(\omega)\, \hat{f}(\omega). \end{aligned}$$

Par construction, si $f \in V$, on a

$$\pi\, \partial_\alpha\, \partial_\beta\, f = R^V_{\alpha,\beta}\, (\pi \Delta f). \tag{13}$$

Dans $L^2(\mathbb{R}^n)$, on a l'identité algébrique

$$R_{\alpha,\beta} = R_\alpha \, R_\beta \ ,$$

qui, toute élémentaire qu'elle soit, est essentielle dans la preuve du Lemme 3.1. Ici, on n'a pas a priori la même relation entre $R^V_{\alpha,\beta}$, R^V_α, et R^V_β. Cependant, la structure de produit tensoriel de V nous donne le lemme suivant.

LEMME 3.3. *Si $\alpha \neq \beta$, $R^V_{\alpha,\beta} = R^V_\alpha \, R^V_\beta$.*

Cela provient des identités

$$\hat{\varphi}(\omega) = \hat{\phi}(\omega_1) \cdots \hat{\phi}(\omega_n)$$

et

$$\sum_{k_\alpha \in \mathbb{Z}} |\hat{\phi}(\omega_\alpha + 2\pi\, k_\alpha)|^2 = 1, \quad \alpha = 1, \dots, n,$$

d'où

$$\sum_k (\omega_\alpha + 2\pi k_\alpha)\,(\omega_\beta + 2\pi k_\beta)\,|\hat{\varphi}(\omega + 2\pi\, k)|^2$$
$$= \left(\sum_k (\omega_\alpha + 2\pi k_\alpha) |\hat{\varphi}(\omega + 2\pi\, k)|^2 \right) \left(\sum_k (\omega_\beta + 2\pi k_\beta) |\hat{\varphi}(\omega + 2\pi\, k)|^2 \right).$$

En termes de dérivées partielles, le Lemme 3.3 signifie que

$$\forall \alpha \neq \beta, \quad \forall f \in V, \quad \pi\, \partial_\alpha\, \partial_\beta\, f = (\pi\, \partial_\alpha\, \pi^*)\,(\pi\, \partial_\beta\, f).$$

En revanche, quand $\alpha = \beta$, l'identité du Lemme 3.3 est fausse. Il en subsiste cependant une forme plus faible.

LEMME 3.4. *L'opérateur $R^V_{\alpha,\alpha} - (R^V_\alpha)^2$ est positif.*

En effet, de (10) et par Cauchy–Schwarz, on a l'inégalité

$$k^V_\alpha(\omega)^2 \leq k^V_{\alpha,\alpha}(\omega).$$

On peut donc poser

$$S^V_\alpha = \left(R^V_{\alpha,\alpha} - (R^V_\alpha)^2\right)^{1/2},$$

qui est le multiplicateur de symbole

$$\left(k^V_{\alpha,\alpha}(\omega) - k^V_\alpha(\omega)^2\right)^{1/2}.$$

On a alors le lemme suivant.

LEMME 3.5. *Pour toute $f \in V$,*

$$\int \sum_\alpha |R^V_\alpha\, f|^2 + \sum_\alpha |S^V_\alpha\, f|^2 = \int |f|^2.$$

C'est une conséquence directe de la définition de S^V_α, chacun des deux membres de l'égalité étant égal à $\int \sum_\alpha |R^V_{\alpha,\alpha}\, f|^2$.[3]

[3] (P. Auscher) Dans le cas où l'AMR n'a pas une structure de produit tensoriel, la construction précédente doit être modifiée en définissant la matrice des opérateurs $(S^V_{\alpha,\beta})$ comme étant la racine carrée de la matrice $(R^V_{\alpha,\beta})$. Tous les résultats que nous prouverons sur les R^V_α seront également vrais pour les $S^V_{\alpha,\beta}$, et ce jusqu'à la preuve du Théorème 3.2. Nous laissons au lecteur l'écriture du cas général, ne traitant en détail que le cas tensoriel.

3.2.2. Images des ondelettes. Après l'étude algébrique précédente, venons-en à l'analyse des opérateurs adaptés à V. Ils sont les restrictions à V d'opérateurs de convolution, dont les symboles sont des fonctions bornées $2\pi\,\mathbb{Z}^n$-périodiques. Faire leur analyse signifie pour nous en calculer les images des ondelettes ψ_λ, avec $j(\lambda) \leq -1$, qui forment une base de V: ces opérateurs présentent alors trois types de comportement.

L'opérateur Λ^V, de symbole

$$\ell^V(\omega) = \left(\sum_k |\omega + 2\pi k|^2\, |\hat{\varphi}(\omega + 2\pi k|^2\right)^{1/2},$$

s'apparente à l'opérateur de Calderón $\Lambda = \sqrt{-\Delta}$, de symbole $|\omega|$, parce que $\ell^V(\omega)$ est équivalent à $|\omega|$ au voisinage de 0.

Les opérateurs R^V_α et $R^V_{\alpha,\beta}$ s'apparentent aux transformées de Riesz, parce que leurs symboles vérifient

$$k^V_\alpha(\omega) \sim -i\frac{\omega_\alpha}{|\omega|}$$

et

$$k^V_{\alpha,\beta}(\omega) \sim \frac{\omega_\alpha\,\omega_\beta}{|\omega|^2}$$

au voisinage de 0. Quant aux opérateurs S^V_α, leur symbole n'est pas singulier, comme on le verra, et leur action est triviale.

Les opérateurs Λ ou R_α agissent d'une façon bien connue sur les ondelettes, et nous allons démontrer que les opérateurs adaptés à V agissent de façon équivalente. La difficulté provient du caractère périodique de leur symbole: par exemple, k^V_α est singulier en tout point de $2\pi\mathbb{Z}^n$, et pas seulement en l'origine. C'est pourquoi il faut comparer Λ^V à $\pi\Lambda\pi^*$ et R^V_α à $\pi\, R_\alpha\, \pi^*$: la projection π a pour effet de périodiser les symboles de Λ et de R_α et ainsi d'imiter les symboles ℓ^V et k^V_α.

A cet effet, nous définissons les opérateurs T^V_0 et T^V_α, $\alpha = 1, \ldots, n$, agissant dans V, par les relations

$$\Lambda^V = T^V_0\, \pi\Lambda\pi^*, \tag{14}$$

où, rappelons-le, $\Lambda = \sqrt{-\Delta}$, et

$$R^V_\alpha = T^V_\alpha + \pi\, R_\alpha\, \pi^*. \tag{14'}$$

Ce sont des opérateurs de convolution, de symboles respectifs

$$\tau_0(\omega) = \frac{\left(\sum_k |\omega + 2\pi\, k|^2\, |\hat{\varphi}(\omega + 2\pi k)|^2\right)^{1/2}}{\sum_k |\omega + 2\pi\, k|\, |\hat{\varphi}(\omega + 2\pi k)|^2}$$

et

$$\tau_\alpha(\omega) = k^V_\alpha(\omega) - \sum_k \frac{\omega_\alpha + 2\pi k_\alpha}{|\omega + 2\pi k|}\, |\hat{\varphi}(\omega + 2\pi k)|^2.$$

L'opérateur S_α^V a un symbole du même type, noté $\sigma_\alpha(\omega)$, égal à $\left(k_{\alpha,\alpha}^V(\omega) - k_\alpha^V(\omega)^2\right)^{1/2}$.

Tous ces symboles sont des fonctions $2\pi\mathbb{Z}^n$-périodiques de classe au moins C^{2N-1}, où N est défini par les propriétés d'oscillation des ondelettes: voir (4). On démontre en fait le résultat suivant.

LEMME 3.6. *Pour chacun des symboles τ_0, τ_α, σ_α, notés génériquement τ, il existe une constante C telle que*

$$\forall k \in \mathbb{Z}^n, \quad |\hat{\tau}\,(k)| \le \frac{C}{1+|k|^{n+2N-1}}.$$

Nous ne faisons qu'en esquisser la démonstration, de nature technique sans être difficile.

Il suffit de prouver que $\partial^\alpha \tau$ est intégrable sur $[-\pi, \pi]^n$ pour tout α de longueur inférieure ou égale à $n + 2N - 1$, et pour cela, il est également suffisant de montrer que

$$\tau(\omega) = \tau(0) + O(|\omega|^{2N}) \tag{15}$$

au voisinage de 0, puisque τ est C^∞ en–dehors de 0. Finalement, tout se ramène à connaître le comportement de $|\hat{\varphi}(\omega + 2\pi k)|^2$ au voisinage de 0, pour tout $k \in \mathbb{Z}^n$.

On écrit alors

$$\hat{\varphi}\,(\omega) = \hat{\phi}(\omega_1)\cdots\hat{\phi}(\omega_n),$$

et il est connu que

$$\hat{\phi}(\xi) = \prod_{j=1}^{+\infty} m_0(2^{-j}\xi),$$

pour une certaine fonction C^∞ 2π–périodique m_0, satisfaisant entre autres à l'identité

$$|m_0(\xi)|^2 + |m_0(\xi+\pi)|^2 = 1.$$

Par définition de ϕ et de N, on a

$$m_0(\xi+\pi) = O(\xi^{N+1})$$

au voisinage de 0, d'où on déduit que

$$|\hat{\phi}(\xi)|^2 = 1 + O(\xi^{2N+2})$$

et que

$$|\hat{\varphi}(\omega)|^2 = 1 + O(|\omega|^{2N+2}).$$

Si maintenant $k \in \mathbb{Z}^n$, $k \neq 0$, il existe $m \ge 0$ tel que $k \in 2^m\,\mathbb{Z}^n$ et $k \notin 2^{m+1}\,\mathbb{Z}^n$. Le lecteur intéressé pourra montrer qu'on a alors

$$|\hat{\varphi}(\omega + 2\pi k)|^2 \le C\,2^{-(2N+2)m}\,|\omega|^{2N+2}\,|\hat{\varphi}(2^{-m-1}\,[\omega + 2\pi k])|^2,$$

uniformément par rapport à $k \in \mathbb{Z}^n$ et ω dans un voisinage de 0. Cette formule implique que, si $\sigma(\omega)$ est une fonction homogène de ω, d'ordre strictement inférieur à $2N + 2$, et telle que

$$\sum_k |\sigma(\omega + 2\pi k)|\,|\hat{\varphi}\,(\omega + 2\pi k)|^2 \in L^\infty,$$

alors, au voisinage de 0, on a

$$\sum_k \sigma(\omega + 2\pi k)\,|\hat{\varphi}\,(\omega + 2\pi k)|^2 = \sigma(\omega) + 0(|\omega|^{2N+2}).$$

Puisque, dans l'application au Lemme 3.6, σ n'est jamais de degré supérieur à 2, on en déduit l'estimation (15).

L'action des opérateurs S^V_α, T^V_0, et T^V_α s'analyse alors simplement grâce au lemme suivant.

LEMME 3.7. *Si f_λ est une fonction satisfaisant les estimations standard* (6) *et* (7), *avec un paramètre s, une constante C_0, et $j(\lambda) \leq -1$, et si (c_k) est une suite de scalaires tels que*

$$\forall k \in \mathbb{Z}^n, \quad |c_k| \leq \frac{1}{1 + |k|^{n+s}},$$

alors la fonction

$$g_\lambda(x) = \sum_k c_k\, f_\lambda(x - k)$$

satisfait également à (6) *et* (7), *avec le même paramètre s, et une constante C ne dépendant que de C_0.*

Notant $j = j(\lambda)$, on décompose g_λ en

$$g_\lambda = \sum_{|k| \leq 2^{-j}} + \sum_{|k| > 2^{-j}} .$$

Le premier terme est majoré par

$$\begin{aligned} &C_0 \sum_{|k| \leq 2^{-j}} |c_k|\, 2^{jn/2}\,(1 + 2^j |x - k - \lambda|)^{-n-s} \\ &\leq C(n+s)\, C_0\, \|c_k\|_1\, 2^{jn/2}\,(1 + 2^j\,|x - \lambda|)^{-n-s}. \end{aligned}$$

Le second se majore par

$$\begin{aligned} &2C_0 \sum_{|k| > 2^{-j}} \frac{2^{j(n+s)}}{1 + |2^j\, k|^{n+s}}\, 2^{jn/2}\,(1 + 2^j |x - k - \lambda|)^{-n-s} \\ &\leq C'(s)\, C_0\, 2^{js}\, 2^{jn/2}\,(1 + 2^j\,|x - \lambda|)^{-n-s}. \end{aligned}$$

Puisque $j \leq -1$, ce terme est du même ordre que le premier, voire négligeable devant lui.

Les estimations sur $\nabla\, g_\lambda$ se prouvent de la même façon.

Il nous faut maintenant étudier l'action de $\pi\Lambda\pi^*$ et de $\pi\, R_\alpha\, \pi^*$ sur une ondelette ψ_λ appartenant à V. Rappelons d'abord comment agissent Λ et R_α, en partant du résultat classique suivant [6].

LEMME 3.8. *Soit $G(x)$ une fonction C^∞ sur $\mathbb{R}^n \backslash \{0\}$, telle que, pour tout multi-indice γ, il existe une constante C_γ vérifiant*

$$\forall x \in \mathbb{R}^n \backslash \{0\}, \quad |\partial^\gamma G(x)| \leq C_\gamma\, |x|^{-n+m-|\gamma|}, \tag{16}$$

pour un certain entier $m \geq 1$. Il existe alors, si $N \geq m$, une constante C telle que, pour tout $\lambda \in D$, on ait

$$\forall x \in \mathbb{R}^n, \quad |G * \psi_\lambda(x)| \leq C\, 2^{-jm}\, 2^{jn/2}\,(1 + 2^j\,|x - \lambda|)^{-n+m-N-1},$$

et plus généralement, pour tout multi-indice γ, $|\gamma| \leq m + r - 1$,

$$\forall x \in \mathbb{R}^n, \quad |\partial^\gamma G * \psi_\lambda(x)| \leq C'_\gamma\, 2^{-jm+j|\gamma|}\, 2^{jn/2}(1 + 2^j\,|x - \lambda|)^{-n+m-N-1-|\gamma|}.$$

Pour la commodité du lecteur, nous en donnons une démonstration, puis nous en déduirons les estimations sur $R_\alpha\,\psi_\lambda$ et $\Lambda\psi_\lambda$.

On commence par se ramener au cas $j(\lambda) = k(\lambda) = 0$, par homogénéité et invariance par translation, de sorte qu'il s'agit de décrire la décroissance à l'infini de $G * \psi_\varepsilon$.

Celle-ci provient des oscillations de l'ondelette ψ_ε.

En effet, on se rappelle que ψ_ε est un produit tensoriel $\Psi_{\varepsilon_1}(x_1)\cdots\Psi_{\varepsilon_n}(x_n)$, où $\varepsilon_i = 1$ ou 0, $\Psi_1 = \Psi$ et $\Psi_0 = \phi$, l'un au moins des ε_i étant non nul.

Traitons en détail le cas $\varepsilon = (1, 0, \dots, 0)$, les autres cas se traitant de même. Par définition de N, il existe $\Psi^{-(N+1)}$, primitive d'ordre $N+1$ de Ψ, qui soit à décroissance rapide. Soit θ la fonction

$$\theta(x) = \Psi^{-(N+1)}(x_1)\,\phi(x_2)\cdots\phi(x_n).$$

Par construction, $\partial_1^{N+1}\,\theta = \psi_\varepsilon$, et θ est à décroissance rapide.

On se donne maintenant une fonction $\mathcal{X}$ régulière engendrant une partition de l'unité: $\mathcal{X}$ est C^∞, Supp $\mathcal{X} \subset [-10, 10]^n$, et $\sum_{k \in \mathbb{Z}^n} \mathcal{X}(x - k) = 1$ pour tout $x \in \mathbb{R}^n$. On découpe θ en

$$\theta = \sum_{k \in \mathbb{Z}^n} \theta_k,$$

où $\theta_k(x) = \theta(x)\,\mathcal{X}(x - k)$. Ainsi, on a

$$G * \psi_\varepsilon = \sum_{k \in \mathbb{Z}^n} (\partial_1^{N+1}\,\theta_k) * G.$$

Soient $x \in \mathbb{R}^n$, $k \in \mathbb{Z}^n$. Si $|x - k| \leq 20$, on écrit

$$\begin{aligned}|\partial_1^{N+1}\,\theta_k * G(x)| &\leq \int |\partial_1^{N+1}\,\theta_k(y)|\,|G(x - y)|\,dy \\ &\leq C_p\,(1 + |k|)^p\end{aligned}$$

pour tout $p \in \mathbb{N}$, puisque G est localement intégrable.

Si $|x - k| > 20$, alors $|x - y| > \frac{1}{2}\,|x - k|$ quand $y \in$ Supp θ_k. On en déduit

$$\begin{aligned}|\partial_1^{N+1}\,\theta_k * G(x)| &\leq \int |\theta_k(y)|\,|\partial_1^{N+1}\,G(x - y)|\,dy \\ &\leq C_p\,(1 + |k|)^p\,|x - k|^{-n+m-N-1}.\end{aligned}$$

Finalement, on obtient pour tout x

$$|G * \psi_\varepsilon(x)| \leq C_p \sum_{k \in \mathbb{Z}^n} (1 + |k|)^{-p}\,(1 + |x - k|)^{-n+m-N-1}.$$

Choisissant $p \geq n - m + N + 1$, et pourvu que $N \geq m$, il vient

$$|G * \psi_\varepsilon(x)| \leq C\,(1+|x|)^{-n+m-N-1}.$$

Les estimations sur les dérivées de $G * \psi_\varepsilon$ s'obtiennent de façon analogue, quitte à remplacer G par l'une de ses dérivées partielles. Un examen attentif de l'argument montre que l'ordre maximal autorisé de dérivation est égal à $m + r - 1$. Ceci achève la preuve du lemme.

On l'applique alors à $G(x) = |x|^{-n+1}$, ce qui permet d'estimer $\Lambda^{-1}\,\psi_\lambda$. Puisque $R_\alpha = -\partial_\alpha\,\Lambda^{-1}$, et $\Lambda = \sum_\alpha \partial_\alpha\,R_\alpha = -\Delta\,\Lambda^{-1}$, on retrouve les estimations bien connues sur $R_\alpha\,\psi_\lambda$ et $\Lambda\,\psi_\lambda$, qui s'écrivent

(17) si $|\gamma| \leq r - 1$, il existe C_γ telle que

$$\forall\, x \in \mathrm{I\!R}^n, \quad |\partial^\gamma\, R_\alpha\,\psi_\lambda\,(x)| \leq C_\gamma\, 2^{jn/2}\, 2^{j|\gamma|}\,(1+2^j|x-\lambda|)^{-n-N-1-|\gamma|},$$

(18) si $|\gamma| \leq r - 2$, il existe C_γ telle que

$$\forall x \in \mathrm{I\!R}^n, \quad |\partial^\gamma\,\Lambda\,\psi_\lambda\,(x)| \leq C_\gamma\, 2^{jn/2}\, 2^{j(1+|\gamma|)}\,(1+2^j|x-\lambda|)^{-n-N-2-|\gamma|}.$$

Pour finalement obtenir les estimations sur $\pi(R_\alpha\,\psi_\lambda)$ et $\pi(\Lambda\,\psi_\lambda)$, on utilise le lemme suivant, qui décrit l'action de la projection π sur des fonctions "basses fréquences."

LEMME 3.9. *Soient f_λ, où $\lambda \in D$ et $j(\lambda) \leq -1$, une famille de fonctions telle que pour tout $|\gamma| \leq q$, où q est un entier $\leq r$, il existe une constante C_γ et un réel $s_\gamma >$ 0 vérifiant les estimations:*

$$\forall x \in \mathrm{I\!R}^n, \quad |\partial^\gamma\, f_\lambda\,(x)| \leq C_\gamma\, 2^{jn/2}\, 2^{j|\gamma|}\,(1+2^j|x-\lambda|)^{-n-s_\gamma}.$$

Alors, la famille des projections $\pi(f_\lambda)$ vérifient des estimations analogues, où seules les constantes C_γ sont changées.

On commence par montrer l'estimation sur $\pi(f_\lambda)$, qu'on écrit

$$\pi(f_\lambda)(x) = \sum_k \int f_\lambda(y)\,\overline{\varphi(y-k)}\,dy \quad \varphi(x-k).$$

Le noyau intégral de la projection, $\sum_k \overline{\varphi(y-k)}\,\varphi(x-k)$, est majoré en module par $C_p\,(1+|x-y|)^{-p}$, quel que soit $p > 0$. On a donc, choisissant $p = n + s_0$,

$$\begin{aligned}|\pi(f_\lambda)(x)| &\leq C\,2^{jn/2} \int (1+2^j|y-\lambda|)^{-n-s_0}\,(1+|x-y|)^{-n-s_0}\,dy\\ &\leq C\,2^{jn/2}\,(1+2^j|x-\lambda|)^{-n-s_0},\end{aligned}$$

puisque $j \leq -1$.

Pour montrer l'estimation voulue sur $\partial^\gamma\,\pi(f_\lambda)$, où $|\gamma| \leq q$, on utilise le résultat de commutation de Lemarié [4], qui s'écrit

(19) $$\partial^\gamma \pi = \pi_\gamma\,\partial^\gamma,$$

où π_γ est une projection sur un sous–espace V_γ, non orthogonale. Plus précisément, il existe φ_γ et $\widetilde{\varphi}_\gamma$, deux fonctions à décroissance rapide (et qui engendrent deux AMR biorthogonales), telles que

$$\pi_\gamma\, f(x) = \sum_k \int f(y)\overline{\widetilde{\varphi}_\gamma(y-k)}\,dy \quad \varphi_\gamma(x-k).$$

Ceci permet de reproduire les estimations précédentes, et ainsi de terminer la preuve du Lemme 3.9.

Partant des décompositions (14) et (14'), et appliquant les Lemmes 2.6, 2.7, 2.8, et 2.9, on obtient le lemme suivant.

LEMME 3.10. *Les familles de fonctions* $R^V_\alpha\,\psi_\lambda$ *et* $\Lambda^V\,\psi_\lambda$, *avec* $j(\lambda) \le -1$, *vérifient les estimations* (17) *et* (18), *respectivement. La famille des fonctions* $S^V_\alpha\,\psi_\lambda$, *avec* $j(\lambda) \le -1$, *vérifie les estimations suivantes:*
(20)
pour tout γ, $|\gamma| \le r$, *il existe une constante* C_γ *telle que, pour presque tout* $x \in \mathbb{R}^n$,

$$|\partial^\gamma\, S^V_\alpha\,\psi_\lambda(x)| \le C_\gamma\, 2^{jn/2}\, 2^{j|\gamma|}\,(1 + 2^j|x-\lambda|)^{-n-2N+1}.$$

On obtiendrait un résultat analogue sur les $R^V_{\alpha,\beta}\,\psi_\lambda$, que nous n'utiliserons pas. Remarquons, pour terminer cette section, que les opérateurs étudiés étant des convolutions, les fonctions images des ondelettes ψ_λ annulent les mêmes moments, sous la condition que ces moments existent.

3.2.3. Commutateurs. Les commutateurs dont nous avons besoin sont $[R^V_\alpha,\ \pi\, b\, \pi^*]$ et $[S^V_\alpha,\ \pi\, b\, \pi^*]$. Comme ce sont des opérateurs de V dans lui-même et que V est inclus dans H^1 (et même H^2), affirmer qu'ils sont régularisants d'ordre 1 n'a pas un sens très clair. C'est pourquoi l'analogue du théorème de Calderón prend la forme suivante.

LEMME 3.11. *Les opérateurs* $[R^V_\alpha,\ \pi\, b\, \pi^*]\,\Lambda^V$ *et* $[S^V_\alpha,\ \pi\, b\, \pi^*]\,\Lambda^V$, *agissant de* V *dans* V, *ont une norme majorée par* $C\,\|\nabla b\|_\infty$, *où* C *est une constante ne dépendant que de* V.

(Noter que, par scaling, ce lemme se transpose à V_j, pour tout j, avec la même constante C.)

La stratégie de la preuve est la même que pour étudier le premier commutateur de Calderón. On munit V de sa base d'ondelettes (ψ_λ), où $j(\lambda) \le -1$. Si $\Gamma = [T,\ \pi\, b\, \pi^*]\,\Lambda^V$ est le commutateur considéré, $T = R^V_\alpha$ ou S^V_α, on calcule l'image de chaque ψ_λ:

$$T(\pi\, b\,\Lambda^V(\psi_\lambda)) - \pi\, b\, T\,\Lambda^V(\psi_\lambda).$$

Remplaçant b par $b - b(\lambda)$, on obtient

$$\begin{aligned}\Gamma(\psi_\lambda) &= T\pi([b-b(\lambda)]\,\Lambda^V\,(\psi_\lambda))\\ &\quad - \pi[b-b(\lambda)]\,T\,\Lambda^V\,(\psi_\lambda).\end{aligned}$$

Soient alors les opérateurs U et U_T définis par

$$U(\psi_\lambda) = [b-b(\lambda)]\,\Lambda^V\,(\psi_\lambda)$$

et

$$U_T(\psi_\lambda) = [b-b(\lambda)]\,T\,\Lambda^V\,(\psi_\lambda).$$

L'estimation sur la norme de Γ résultera de l'estimation analogue sur les normes de U et de U_T, obtenue en appliquant le lemme fondamental.

Commençons par vérifier les estimations standard.

Grâce à la majoration

$$|b(x) - b(\lambda)| \leq \|\nabla b\|_\infty \, |x - \lambda|, \tag{21}$$

celles-ci découlent, pour la famille des $U(\psi_\lambda)$, des inégalités (18) sur les $\Lambda^V(\psi_\lambda)$, démontrées au Lemme 3.10.

Si $T = R^V_\alpha$, on a $T\,\Lambda^V = -i\,\pi\,\partial_\alpha\,\pi^*$, et les estimations standard sur les $U_T\,(\psi_\lambda)$ proviennent de (21) et du Lemme 3.9.

Si enfin $T = S^V_\alpha$, on applique les Lemmes 3.6 et 3.7 aux fonctions $\Lambda^V\,(\psi_\lambda)$.

Il faut maintenant estimer les intégrales des fonctions $U(\psi_\lambda)$ et $U_T(\psi_\lambda)$, et les constantes de Carleson associées.

Avec $T = Id$, R^V_α ou S^V_α, on calcule donc

$$\int b\,T\,\Lambda^V\,(\psi_\lambda).$$

Utilisant (14) et le fait que T, T^V_0 et $\pi\,\Lambda\,\pi^*$ commutent, cette intégrale se réécrit

$$\int \Lambda(\pi b)\,T^V_0\,T(\psi_\lambda). \tag{22}$$

Or, des relations (19) de Lemarié, on déduit que πb est lipschitzienne, de norme lipschitz contrôlée par celle de b. Comme on a

$$\Lambda(\pi b) = \sum_\alpha R_\alpha\,\partial_\alpha\,\pi b,$$

$\Lambda(\pi b)$ appartient à BMO, de norme majorée par $C\|\nabla b\|_\infty$, où C ne dépend que de V.

D'autre part, grâce aux Lemmes 3.6, 3.7, et 3.10, les fonctions $T^V_0\,T(\psi_\lambda)$ vérifient les estimations standard, et sont de plus d'intégrale nulle.

Il est alors très classique de montrer que les intégrales (22) vérifient l'inégalité de Carleson requise par le lemme fondamental, avec une constante contrôlée par la norme de $\Lambda(\pi b)$ dans BMO (voir [5]).

Ceci permet d'achever la preuve du Lemme 3.11, et conclut notre étude des transformées de Riesz adaptées à V.

3.3. Preuve du Théorème 3.2. Considérons maintenant $f \in V\,(= V_0)$, et estimons la norme de $\pi\,b_{\alpha\beta}\,\partial_\alpha\,\partial_\beta\,f$. Elle se laisse trivialement dominer par $C\|\Delta f\|$, mais nous voulons comparer à $\pi\Delta f$ au lieu de Δf d'une part, et d'autre part obtenir la meilleure constante C, c'est-à-dire $\|B\|$, quitte à ajouter au majorant un terme d'ordre 1.

On commence par échanger la projection et la multiplication, en écrivant

$$\begin{aligned}\pi\,b_{\alpha\beta}\,\partial_\alpha\,\partial_\beta\,f = {}& \pi\,b_{\alpha\beta}\,\pi^*\,\pi\,\partial_\alpha\,\partial_\beta\,f \\ & - [b_{\alpha\beta},\,\pi^*\,\pi]\,\partial_\alpha\,\partial_\beta\,f.\end{aligned}$$

Le second terme se traite facilement.

LEMME 3.12. *Pour toute fonction b lipschitzienne et pour tout α, l'opérateur $[b,\,\pi^*\pi]\,\partial_\alpha$ est continu, de norme contrôlée par $C\,\|\nabla b\|_\infty$, où C ne dépend que de V.*

Ce résultat se démontre exactement comme le Lemme 3.11, avec d'ailleurs un peu moins de complications techniques. Nous en laissons donc l'écriture au lecteur.

On a ainsi

$$\|[b_{\alpha\beta},\pi^*\pi]\,\partial_\alpha\,\partial_\beta\,f\| \leq C\,\|B\|_{\mathrm{lip}}\,\|\nabla f\|.$$

Le terme principal $\pi\, b_{\alpha\beta}\, \pi^*\pi\, \partial_\alpha\, \partial_\beta\, f$ s'écrit en utilisant les transformées de Riesz adaptées à V:

$$\begin{aligned}\pi\, b_{\alpha\beta}\, \pi^*\pi\, \partial_\alpha\, \partial_\beta\, f &= \pi\, b_{\alpha\beta}\, \pi^*\, R^V_{\alpha\beta}\, (\pi\Delta f)\\ &= \pi\, b_{\alpha\beta}\, \pi^*\, R^V_\alpha\, R^V_\beta\, (\pi\Delta f)\\ &\quad + \pi\, b_{\alpha\alpha}\, \pi^*\, (S^V_\alpha)^2\, (\pi\Delta f).^4\end{aligned}$$

Comme dans la preuve du Lemme 3.1, on a maintenant

$$\begin{aligned}\pi\, b_{\alpha\beta}\, \pi^*\pi\, \partial_\alpha\, \partial_\beta\, f &= R^V_\alpha\, (\pi\, b_{\alpha\beta}\, \pi^*)\, R^V_\beta\, (\pi\Delta f)\\ &\quad + S^V_\alpha\, (\pi\; b_{\alpha\alpha}\, \pi^*)\, S^V_\beta\, (\pi\Delta f)\\ &\quad + [\pi\, b_{\alpha\beta}\, \pi^*,\; R^V_\alpha]\, R^V_\beta (\pi\Delta f)\\ &\quad + [\pi\, b_{\alpha\alpha}\, \pi^*,\; S^V_\alpha]\, S^V_\alpha (\pi\Delta f).\end{aligned}$$

D'après le Lemme 3.11, les deux derniers termes sont majorés en norme par $C\|B\|_{\text{lip}}\, \|\nabla f\|$.

Pour estimer les deux premiers, on définit la matrice $\widetilde{B}$, dans $M_{2n}(\mathbb{C})$, par

$$\widetilde{B} = \left(\begin{array}{cccccc} b_{11} & & 0 & \vdots & & \\ & \ddots & & \vdots & & 0 \\ 0 & & b_{nn} & \vdots & & \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & & & \vdots & & B \\ & & & \vdots & & \end{array}\right).$$

On démontre, exactement comme dans (8), que l'opérateur

$$R^V_\alpha\, (\pi\, b_{\alpha\beta}\, \pi^*)\, R^V_\beta + S^V_\alpha\, (\pi\, b_{\alpha\alpha}\, \pi^*)\, S^V_\alpha$$

est de norme majorée par $\|\widetilde{B}\|$: on utilise pour cela le Lemme 3.5, et le fait que la projection π, étant orthogonale, est de norme 1. A ce stade, nous avons obtenu l'estimation

$$\|\pi\, b_{\alpha\beta}\, \partial_\alpha\, \partial_\beta\, f\| \leq \|\widetilde{B}\|\, \|\pi\Delta f\| + C\, \|B\|_{\text{lip}}\, \|\nabla f\|.$$

Pour conclure, il ne reste plus qu'à remarquer le résultat amusant suivant.

LEMME 3.13.

$$\|\widetilde{B}\| = \|B\|.$$

Le Théorème 3.2 est maintenant complètement démontré. Remarquons qu'il se généralise directement au cas où les coefficients $b_{\alpha\beta}$ sont de régularité $\varepsilon > 0$. On obtient alors

$$\|\pi\, b_{\alpha\beta}\, \partial_\alpha\, \partial_\beta\, f\| \leq \|B\|\, \|\pi\Delta f\| + C\, \|B\|_{C^\varepsilon}\, \|f\|_{\dot{H}^{2-\varepsilon}},$$

où $\dot{H}^{2-\varepsilon}$ désigne l'espace de Sobolev homogène d'ordre $2-\varepsilon$.

[4] Dans le cas des AMR non tensorielles, l'algèbre est légèrement plus compliquée, mais sans que la preuve change de nature.

4. Inversion des opérateurs strictement accrétifs du second ordre à coefficients dominants lipschitziens. Revenons à l'opérateur $L = -\mathrm{div}A\nabla + b$, satisfaisant toutes les hypothèses exposées à la première partie: nous devons prouver que sont également satisfaites (H2) et (H3), afin d'appliquer le schéma d'inversion du Théorème 1.1, et démontrer les Théorèmes 2.2 et 2.3.

Rappelons que la stratégie générale d'inversion de L que nous suivons consiste à découpler les basses et les hautes fréquences, en écrivant

$$L^2 = V_{j_0} \oplus \bigoplus_{j \geq j_0} W_j,$$

et en approchant l'opérateur L par la méthode de Galerkin sur V_{j_0}, par une parametrix sur $V_{j_0}^{\perp}$.

Nous étudions d'abord les approximations Galerkin, prouvant notamment le Théorème 2.3, puis nous construisons la parametrix. Nous supposons donnée une AMR (V_j) satisfaisant aux hypothèses du Théorème 2.2.

4.1. Action de L sur V_j et opérateurs de Galerkin. Reprenant les notations du Théorème 2.1, nous désignons par $\pi_j : L^2 \to V_j$ et $\pi_j^* : V_j \to L^2$ les opérateurs de restriction (par projection orthogonale) et de prolongement associés à V_j. Par hypothèse, l'opérateur $\pi_j L \pi_j^*$, de V_j dans lui-même, est inversible: nous notons Γ_j l'extension naturelle à L^2 de son inverse $(\pi_j L \pi_j^*)^{-1}$. Γ_j est l'opérateur de Galerkin associé à L et à V_j.

On a classiquement

$$\forall f \in L^2, \quad \lim_{j \to +\infty} \|L^{-1}f - \Gamma_j f\|_{H^1} = 0,$$

et le Théorème 2.3 affirme que la même relation est vraie pour la norme H^2. Ce résultat est plus fort que l'hypothèse (H2), qui affirme seulement que les opérateurs $L\Gamma_j$ sont uniformément bornés.

Ces propriétés vont résulter du corollaire suivant du Théorème 3.2.

THÉORÈME 4.1. *Il existe une constante C, ne dépendant que de L et de l'AMR (V_j), telle que pour tout $j \in \mathbb{Z}$ et pour toute $f \in V_j$, on ait*

$$\|Lf\| \leq C\,(\|\pi_j L f\| + \|f\|_{H^1}) \tag{23}$$

En termes plus intuitifs, cette inégalité signifie que la régularité des coefficients est suffisante pour que l'action de L sur V_j n'induise pas un "éclatement" incontrôlé par $\pi_j L f$, c'est-à-dire sa projection basses fréquences.

Pour démontrer ce résultat, on commence par l'établir dans le cas où les coefficients sont constants, qui se réduit à l'observation suivante.

LEMME 4.2. *Si A est constante, $j \in \mathbb{Z}$ et $f \in V_j$, alors*

$$\|L_0 f\| \leq C\|\pi_j L_0 f\|,$$

où $L_0 = -\mathrm{div}A\,\nabla$, et où C ne dépend que de A et de l'AMR.

Il suffit de faire le calcul avec la transformée de Fourier, en utilisant les résultats du paragraphe 3.2.1, pour prouver ce lemme.

Dans le cas général, on commence par renormaliser A: si

$$t = \frac{\delta}{\|A\|^2}, \qquad \|I - tA\| \leq \left(1 - \frac{\delta^2}{\|A\|^2}\right)^{1/2},$$

où δ est la constante d'accrétivité de A. On peut donc se ramener au cas où $A = I - B$, avec $\|B\| < 1$.

Notant toujours L_0 l'opérateur $-\mathrm{div} A\,\nabla$, le Théorème 3.2 donne l'inégalité

$$\|\pi_j\, L_0\, f\| \geq (1 - \|B\|)\, \|\pi_j\, \Delta\, f\| - C\, \|B\|_{\text{lip}}\, \|\nabla\, f\|.$$

Comme on a d'autre part

$$\|L_0 f\| \leq C\, \|\Delta f\| \leq C'\, \|\pi_j\, \Delta\, f\|,$$

on obtient le Théorème 3.2 pour L_0, et donc pour L. Une version précisée en est d'ailleurs

$$\|L_0\, f\| \leq C\, \frac{\|A\|^2}{\delta^2}\, (\|\pi_j\, L_0\, f\| + \|A\|_{\text{lip}} \|\nabla\, f\|),$$

où C ne dépend que de l'AMR. Si A est auto-adjointe, $\frac{\|A\|}{\delta}$ n'est autre que le conditionnement de A, $K(A) = \|A\|\|A^{-1}\|$, à condition bien sûr que δ soit la meilleure constante d'accrétivité, et dans le cas général, on a seulement l'inégalité $\frac{\|A\|}{\delta} \geq K(A)$.

Enfin, comme le Théorème 3.2, le Théorème 4.1 se généralise au cas où L s'écrit

$$L = -a_{\alpha\beta}\, \partial_\alpha\, \partial_\beta + b_\alpha\, \partial_\alpha + b,$$

avec $a_{\alpha\beta} \in C^\varepsilon$, $\varepsilon > 0$.

Le Théorème 4.1 implique immédiatement que les opérateurs $L\,\Gamma_j$ sont uniformément bornés. Si $f \in V_j$, on applique l'inégalité (23) à $g_j = \Gamma_j\, f$: on sait que $\|g_j\|_{H^1} \leq C\, \|f\|$, où C ne dépend que de L, et on a d'autre part $\pi_j\, L\, g_j = f$, d'où finalement $\|L\, g_j\| \leq C\, \|f\|$, qui est le résultat désiré.

La démonstration du Théorème 2.3 est à peine moins difficile. On se donne $f \in L^2$, on pose $g = L^{-1}\, f$, $g_j = \Gamma_j\, f$ et il s'agit de montrer que

$$\lim_{j \to +\infty} \|g - g_j\|_{H^2} = 0.$$

Décomposons $g - g_j$ en $\pi_j^\perp\, g + \pi_j g - g_j$, où $\pi_j^\perp$ est la projection orthogonale sur $V_j^\perp$.

Puisque $g \in H^2$ et que les ondelettes choisies sont base inconditionnelle de H^2, on a

$$\lim_{j \to +\infty} \|\pi_j^\perp g\|_{H^2} = 0. \tag{24}$$

Il reste à estimer la norme H^2 de $\pi_j g - g_j$, qui est équivalente à la norme L^2 de $L(\pi_j g - g_j)$ (nous laissons au lecteur la preuve de cette remarque). Mais l'inégalité (23) nous donne

$$\|L(\pi_j g - g_j)\| \leq C\, (\|\pi_j L(\pi_j g - g_j)\| + \|\pi_j g - g_j\|_{H^1}).$$

On a

$$\lim_{j \to +\infty} \|\pi_j g - g_j\|_{H^1} = 0.$$

D'autre part, par construction, $\pi_j\, L\, g_j = \pi_j\, f = \pi_j\, L\, g$, d'où

$$\pi_j\, L\, (\pi_j g - g_j) = -\pi_j\, L\, \pi_j^\perp\, g.$$

On déduit alors de (24) que

$$\lim_{j \to +\infty} \|\pi_j\, L\, (\pi_j g - g_j)\| = 0,$$

ce qui termine la preuve du Théorème 2.3.

4.2. Construction d'une parametrix. Pour conclure, c'est-à-dire démontrer le Théorème 2.2, il faut établir (H3), sous une forme suffisamment précise pour pouvoir en déduire l'inégalité (5).

La parametrix que nous allons construire est définie sur $V_{j_0}^{\perp}$, où j_0 est fixé, en associant à chaque ondelette de base ψ_λ, $j(\lambda) \geq j_0$, la fonction θ_λ, définie par

$$-\mathrm{div} A(\lambda) \nabla \theta_\lambda = \psi_\lambda.$$

THÉORÈME 4.3. *Si j_0 est fixé, l'opérateur P_{j_0} (dépendant de j_0), défini par*

$$P_{j_0}(\psi_\lambda) = \theta_\lambda \quad si\; j(\lambda) \geq j_0,$$
$$P_{j_0}(f) = 0 \quad si\; f \in V_{j_0},$$

est une parametrix à droite de L, au sens suivant.

(i) *L'opérateur P_{j_0} est continu de L^2 dans H^2, et sa norme est uniformément majorée par rapport à j_0;*

(ii) *l'opérateur $L\,P_{j_0}$ se décompose en*

$$L\,P_{j_0} = \pi_{j_0}^{\perp} - R_{j_0},$$

où $\pi_{j_0}^{\perp}$ est la projection orthonormale sur $V_{j_0}^{\perp}$, et où l'opérateur R_{j_0} est borné sur L^2 en norme par $C\,2^{-j_0}$, la constante C ne dépendant pas de j_0.

Ce théorème implique que L vérifie l'hypothèse (H3), l'inégalité (5) provenant de l'estimation sur la norme de R_{j_0}, et de la preuve du Théorème 2.1.

La définition de P_{j_0} est fondée sur l'idée classique du gel des coefficients dominants. On tire ici partie de la localisation des ψ_λ, qui permet de bien adapter le point de collocation des coefficients.

Il est cependant important de comprendre que la seule localisation des ondelettes dans l'espace physique $\mathbb{R}^n$ n'est pas suffisante. En effet, pour que le Théorème 4.3 puisse être vrai, il est au moins nécessaire que chaque θ_λ approche la fonction $L^{-1}(\psi_\lambda)$: c'est le cas, comme on va le voir, grâce aux propriétés d'oscillation des ψ_λ. (En d'autres termes, le même procédé appliqué aux fonctions $\varphi_{j_0 k}$ ne donnerait pas du tout le même résultat.)

Enfin, soulignons que P_{j_0} est une parametrix en un sens plutôt faible. En l'absence de régularité des coefficients $\partial_\alpha\, a_{\alpha\beta}$ et b, le reste R_{j_0} n'est pas régularisant. Néanmoins, nous verrons qu'il se décompose en

$$R_{j_0} = R_{j_0,0} + \partial_\alpha(a_{\alpha\beta}) R_{j_0,\beta} + bP_{j_0},$$

où les opérateurs $R_{j_0,0}$ et $R_{j_0,\beta}$ sont régularisants d'ordre 1, et P_{j_0}, d'après le théorème, est régularisant d'ordre 2.

Démontrons maintenant le Théorème 4.3 et, pour commencer, décrivons les θ_λ (soulignons que, dans cette notation, λ a la signification usuelle d'un indice, et ne signifie pas qu'il existe θ_ε telle que $\theta_\lambda(x) = 2^{jn/2}\,\theta_\varepsilon(2^j x - k)$).

LEMME 4.4. *Il existe une constante C telle que, pour tout λ et pour tout x,*

$$|\theta_\lambda(x)| \leq C\,2^{jn/2}\,4^{-j}\,(1 + 2^j|x-\lambda|)^{-n-N+1},$$

et plus généralement, pour tout multi-indice γ, $|\gamma| \leq r+1$, il existe C_γ telle que

$$|\partial^\gamma \theta_\lambda(x)| \leq C_\gamma\,2^{jn/2}\,2^{j(|\gamma|-2)}\,(1 + 2^j|x-\lambda|)^{-n-N+1-|\gamma|}.$$

Ce n'est qu'une conséquence directe du Lemme 3.8, puisque $\theta_\lambda = G_\lambda * \psi_\lambda$, où G_λ est la fonction de Green de l'opérateur $-\mathrm{div} A(\lambda)\,\nabla$, qui vérifie, uniformément en λ, les estimations (16), avec $m = 2$.

En utilisant le lemme fondamental, on en déduit sans difficulté la continuité de l'opérateur P_{j_0} de L^2 dans H^2, uniformément par rapport à j_0.

Calculons alors $L\,P_{j_0}$. Si ψ_λ est une ondelette, telle que $j(\lambda) \geq j_0$ (parce que sinon $P_{j_0}\,\psi_\lambda = 0$), on a

$$\begin{aligned} L\,P_{j_0}\,\psi_\lambda &= L\,\theta_\lambda \\ &= \psi_\lambda - R_{j_0}(\psi_\lambda), \end{aligned}$$

avec

$$\begin{aligned} R_{j_0}\,(\psi_\lambda) = [a_{\alpha\beta} - a_{\alpha\beta}(\lambda)]\,\partial_\alpha\,\partial_\beta\,\theta_\lambda \\ - \partial_\alpha(a_{\alpha\beta})\,\partial_\beta\,\theta_\lambda + b\,\theta_\lambda. \end{aligned}$$

Les opérateurs qui à ψ_λ associent, respectivement, $\partial_\beta\,\theta_\lambda$ et θ_λ sont continus sur L^2 et majorés en norme par $C\,2^{-j_0}$ et $C\,4^{-j_0}$ (appliquer le lemme fondamental et les estimations du Lemme 4.4).

Quant à l'opérateur qui à ψ_λ associe $[a_{\alpha\beta}(\lambda) - a_{\alpha\beta}]\,\partial_\alpha\,\partial_\beta\,\theta_\lambda$, il est régularisant d'ordre 1, et continu sur L^2 de norme majorée par $C\,2^{-j_0}$: ceci se démontre à nouveau grâce au lemme fondamental, en suivant la même démarche que pour l'étude des commutateurs. Nous laissons au lecteur l'adaptation des arguments utilisés à ce cas particulier.

Finalement, l'opérateur R_{j_0} est borné, et de norme majorée par $C\,2^{-j_0}$, ce qui achève de démontrer le Théorème 4.3, donc le Théorème 2.2. Le Théorème 2.1 s'applique, et permet d'inverser L, au sens de la meilleure topologie possible.

5. Conclusion. Quelques considérations orientées vers les applications numériques pour conclure.

Les méthodes spectrales, très précises, sont d'un emploi mal commode dès qu'il y a des coefficients variables à contenu spectral assez riche dans les équations à résoudre. Même s'il est possible, en théorie, d'utiliser une méthode de Galerkin, le calcul effectif de la matrice associé à l'opérateur $\pi_j L \pi_j^*$ pose de sérieux problèmes.

C'est pourquoi nous pensons que, remplaçant les fonctions spectrales par les ondelettes, il est peut-être possible de tirer partie de la double localisation des ondelettes d'une façon numériquement efficace.

La formule d'inversion du Théorème 2.1 peut servir de base à un algorithme, de nature itérative à cause de la série de Neumann qui intervient. Les résultats d'une première tentative dans ce sens seront ultérieurement publiés. Nous voudrions souligner ici quelques points qui justifient a priori l'intérêt numérique de cette formule:

(i) le seuil de séparation j_0 est indépendant du second membre de l'équation à résoudre et de la précision cherchée;

(ii) de plus, le nombre d'itérations nécessaires à atteindre un gain donné en précision ne dépend pas de la taille de la grille;

(iii) à cause de la forme de la paramétrix P_{j_0}, une version adaptative d'un algorithme d'inversion est possible en principe;

(iv) enfin, la formule d'inversion étant fondée sur un calcul perturbatif, il ne sera pas nécessaire de calculer avec une grande précision les opérateurs Γ_{j_0} et P_{j_0}: l'opérateur

$$L\,(\widetilde{\Gamma}_{j_0} + \widetilde{P}_{j_0}),$$

où le tilde désigne les opérateurs effectivement calculés, reste une perturbation de l'identité.

Malgré d'évidentes différences géométriques, ces quatre propriétés rapprochent notre méthode des méthodes multi-grilles: nous espérons pouvoir prochainement développer la comparaison.

ON QUASI-PERIODIC PERTURBATIONS OF ELLIPTIC EQUILIBRIUM POINTS*

ÀNGEL JORBA[†] AND CARLES SIMÓ[‡]

Abstract. This work focuses on quasi-periodic time-dependent perturbations of ordinary differential equations near elliptic equilibrium points. This means studying

$$\dot{x} = (A + \varepsilon Q(t, \varepsilon))x + \varepsilon g(t, \varepsilon) + h(x, t, \varepsilon),$$

where A is elliptic and h is $\mathcal{O}(x^2)$. It is shown that, under suitable hypothesis of analyticity, nonresonance and nondegeneracy with respect to ε, there exists a Cantorian set $\mathcal{E}$ such that for all $\varepsilon \in \mathcal{E}$ there exists a quasi-periodic solution such that it goes to zero when ε does. This quasi-periodic solution has the same set of basic frequencies as the perturbation. Moreover, the relative measure of the set $[0, \varepsilon_0] \setminus \mathcal{E}$ in $[0, \varepsilon_0]$ is exponentially small in ε_0. The case $g \equiv 0$, $h \equiv 0$ (quasi-periodic Floquet theorem) is also considered.

Finally, the Hamiltonian case is studied. In this situation, most of the invariant tori that are near the equilibrium point are not destroyed but only slightly deformed and "shaken" in a quasi-periodic way. This quasi-periodic "shaking" has the same basic frequencies as the perturbation.

Key words. quasi-periodic perturbations, elliptic points, quasi-periodic solutions, small divisors, quasi-periodic Floquet theorem, Kolmogorov–Arnold–Moser (KAM) theory

1. Introduction.

In this work, we will consider autonomous differential equations under quasi-periodic time-dependent perturbations near an elliptic equilibrium point. The kind of equation with which we shall deal is

$$\dot{x} = (A + \varepsilon Q(t, \varepsilon))x + \varepsilon g(t, \varepsilon) + h(x, t, \varepsilon),$$

where A is assumed to be elliptic (that is, all the eigenvalues are purely imaginary and nonzero), h is of second order in x, and the system is autonomous when $\varepsilon = 0$. At this point, we recall the definition of a quasi-periodic function.

DEFINITION 1.1. *A function f is a quasi-periodic function with basic frequencies $\omega_1, \ldots, \omega_r$ if $f(t) = F(\theta_1, \ldots, \theta_r)$, where F is 2π periodic in all its arguments and $\theta_j = \omega_j t$ for $j = 1, \ldots, r$.*

We assume that the quasi-periodic functions appearing in our equations are analytical. For definiteness we give the following definition.

DEFINITION 1.2. *A function f is analytic quasi-periodic on a strip of width ρ if it is quasi-periodic and F (see Definition 1.1) is analytical for $|\mathrm{Im}\ \theta_j| \le \rho$ for $j = 1, \ldots, r$. In this case, we denote by $\|f\|_\rho$ the norm*

$$\sup\{|F(\theta_1, \ldots, \theta_r)| \text{ with } |\mathrm{Im}\ \theta_j| \le \rho,\ 1 \le j \le r\}.$$

This kind of equation appears in many problems. As an example, we can consider the equations of the motion near the equilateral libration points of the earth–moon system, including (quasi-periodic) perturbations coming from the noncircular motion

of the moon and the effect of the sun. See [13], [5], [11], [12], [10], and [15]. In these works, some seminumerical methods were applied to compute a quasi-periodic orbit replacing the equilateral relative equilibrium point (which means that, when the perturbation tends to zero, quasi-periodic orbit tends to the libration point), but there is a lack of theoretical support to ensure that the methods used are really convergent and the computed quasi-periodic orbit really exists. In §2, the existence of that dynamical equivalent is shown for a Cantorian set (of positive measure) of values of ε. Another problem related to this is the study of the stability of that quasi-periodic solution. In order to do this, a kind of Floquet theory is available (see [16]) which now can be obtained as a result of the more general study presented here (see §2).

We also want to note that the Floquet theorem for the quasi-periodic case has already been considered in many papers. An approach similar to ours (based on Kolmogorov–Arnold–Moser (KAM) techniques) can be found in [3]. There the reducibility to constant coefficients is studied for the case in which A is a hyperbolic matrix. For the case in which A is elliptic, some bounds are given on the measure of the set of matrices Q for which the system can be reduced to constant coefficients. The bounds on that measure, however, are not as good as those that can be derived from the work presented here.

Another approach to the reducibility of quasi-periodic linear equations can be found in [14]. The methods used there are not based on KAM techniques, and the results can be applied to systems that are not close to constant coefficients. The main drawback is that the hypotheses used are quite restrictive[1] and are very difficult to check in a practical example.

Finally, it is interesting to consider the Hamiltonian case. In §3, we show that most of the KAM tori of the autonomous system still persist when the quasi-periodic time-dependent perturbation is added.

Studies of this kind for the case of the one-dimensional Schrödinger equation can be found in the literature—see, for instance, [6], [18], [4], or [8]—and some of the methods and ideas used here are already contained in these papers. Note that since the "unperturbed" problem is a harmonic oscillator, it is possible to obtain better results (see, e.g., [8]). Some of the ideas of this paper could be already found in [17] and [7], although they deal with slightly different problems.

2. A dynamical equivalent to elliptic equilibrium points.

In this section, we focus on the equation

$$\dot{x} = (A + \varepsilon Q(t, \varepsilon))x + \varepsilon g(t, \varepsilon) + h(x, t, \varepsilon), \tag{1}$$

where the time dependence is quasi-periodic with vector of basic frequencies $\omega = (\omega_1, \ldots, \omega_r)$ and analytic on a strip of width $\rho_0 > 0$. The reader should recall that h is of second order in x. We want to stress that the equations are not required to be Hamiltonian. (The Hamiltonian case will be considered in §3.)

2.1. The inductive scheme.

To study (1), let us perform some changes to simplify it. First of all, we shall try to eliminate the independent term $g(t)$ by means of quasi-periodic changes of variables. To do this, we shall need a scheme with quadratic convergence. (Otherwise, the small-divisors effect would make the method divergent.) This kind of scheme is based on the Newton method, that is, to linearize the problem

[1] For instance, the system $\dot{x} = (A + \varepsilon Q(t, \varepsilon))x$, where A is elliptic and ε is small, does not satisfy the required hypothesis.

in a known approximation of the solution, solve this linear problem, and take this solution as a new (better) approximation to the solution for which we are looking. These algorithms can overcome the effect of the small divisors and ensure convergence on certain regions. To apply this method to our problem, we must consider the following linearized problem. (We take as an initial guess the zero solution, and we linearize around this point.)

$$\dot{x} = (A + \varepsilon Q(t,\varepsilon))x + \varepsilon g(t,\varepsilon).$$

We are looking for a quasi-periodic solution $\underline{x}(t,\varepsilon)$ whose basic frequencies are those of g and Q such that $\lim_{\varepsilon\to 0} \underline{x}(t,\varepsilon) = 0$. At this point, we note that we do not need to know $\underline{x}(t,\varepsilon)$ exactly because an approximation of order ε is enough. This is another property of the Newton method; we do not need to know the Jacobian matrix exactly but just some approximation of it, and it is enough that this approximation be of the order of the independent term that we want to make zero. In our case, this can be easily done by considering the linear system

$$\dot{x} = Ax + \varepsilon g(t,\varepsilon). \tag{2}$$

Here we need a nonresonance condition. The usual one is

$$|(k,\omega)\sqrt{-1} - \lambda_i| > \frac{c}{|k|^{\gamma_0}}, \tag{3}$$

where λ_i are the eigenvalues of A and $|k| = |k_1| + \cdots + |k_r|$. Condition (3) as well as condition (7), an additional diophantine condition needed later, will be discussed in detail throughout §2.2.

Let us call $\underline{x}(t,\varepsilon)$ the solution of (2) that is quasi-periodic with respect to t (and whose basic frequencies are those of g) and of order ε. The existence of this solution will be shown by Lemma 2.10. Now we can perform the change of variables $x = \underline{x}(t,\varepsilon) + y$ to (1) to obtain

$$\dot{y} = (A + \varepsilon Q_1(t,\varepsilon))y + \varepsilon^2 g_1(t,\varepsilon) + h_1(y,t,\varepsilon), \tag{4}$$

where if $\varepsilon \neq 0$,

$$\begin{aligned}
Q_1(t,\varepsilon) &= Q(t,\varepsilon) + \frac{1}{\varepsilon} D_x h(\underline{x}(t,\varepsilon),t,\varepsilon),\\
g_1(t,\varepsilon) &= \frac{1}{\varepsilon^2} h(\underline{x}(t,\varepsilon),t,\varepsilon) + \frac{1}{\varepsilon} Q(t,\varepsilon)\underline{x}(t,\varepsilon),\\
h_1(y,t,\varepsilon) &= h(\underline{x}(t,\varepsilon) + y,t,\varepsilon) - h(\underline{x}(t,\varepsilon),t,\varepsilon) - D_x h(\underline{x}(t,\varepsilon),t,\varepsilon)y.
\end{aligned}$$

Note that this process cannot be (successfully) iterated. Now we need a solution of

$$\dot{y} = (A + \varepsilon Q_1(t,\varepsilon))y + \varepsilon^2 g_1(t,\varepsilon) \tag{5}$$

with an accuracy of order ε^2; and if we take the kind of approximation given by (2) (that is, dropping Q_1), we will have a divergent scheme. This is because, in this way, one obtains linear convergence in ε, which is overcome by the effect of the small divisors.

To deal with this difficulty, we perform a new change of variables to get something like $\varepsilon^2 Q_2$ instead of εQ_1. This can be done as follows. Let us define the average of Q_1 as

$$\overline{Q}_1(\varepsilon) = \lim_{T\to\infty} \frac{1}{2T} \int_{-T}^{T} Q_1(t,\varepsilon)\,dt.$$

For the existence of the limit, see, for instance, [9]. Now consider now (5) after averaging with respect to t and some rearrangement:

$$\dot{y} = (\overline{A}(\varepsilon) + \varepsilon\widetilde{Q}_1(t,\varepsilon))y + \varepsilon^2 g_1(t,\varepsilon),$$

where $\widetilde{Q}_1(t,\varepsilon) = Q_1(t,\varepsilon) - \overline{Q}_1(\varepsilon)$, $\overline{A}(\varepsilon) = A + \varepsilon\overline{Q}_1(\varepsilon)$. Now we need to find a quasi-periodic solution of

$$\dot{P} = \overline{A}P - P\overline{A} + \widetilde{Q}_1 \tag{6}$$

with the same basic frequencies as $\widetilde{Q}_1$. This can be done if the eigenvalues of $\overline{A}$ satisfy a diophantine condition. The one used in [16] was

$$|(k,\omega)\sqrt{-1} - \overline{\lambda}_i + \overline{\lambda}_j| > \frac{c}{|k|^{\gamma_0}}. \tag{7}$$

Then, making the change of variables $y = (I + \varepsilon P)z$ (I denotes the identity matrix) to (4) (these changes of variables have already been considered in [3], [16], and [15]), we obtain the equation

$$\dot{z} = (\overline{A}(\varepsilon) + \varepsilon^2 Q_2(t,\varepsilon))z + \varepsilon^2 g_2(t,\varepsilon) + h_2(z,t,\varepsilon), \tag{8}$$

where $Q_2(t,\varepsilon) = (I + \varepsilon P(t,\varepsilon))^{-1}\widetilde{Q}_1 P(t,\varepsilon)$, $g_2(t,\varepsilon) = (I + \varepsilon P(t,\varepsilon))^{-1}g_1(t,\varepsilon)$, and $h_2(z,t,\varepsilon) = (I + \varepsilon P(t,\varepsilon))^{-1}h_1((I + \varepsilon P(t,\varepsilon))z,t,\varepsilon)$. Now, using $\dot{z} = \overline{A}z + \varepsilon^2 g_2(t)$, we are able to find an approximate solution of (8) with an accuracy of order ε^2 that allows us to proceed with the Newton method. In this way, after n steps (each step is composed of the two changes of variables as explained above), the equation will look like

$$\dot{x}_n = (A_n(\varepsilon) + \varepsilon^{2^n} Q_n(t,\varepsilon))x_n + \varepsilon^{2^n} g_n(t,\varepsilon) + h_n(x_n,t,\varepsilon).$$

Then if the norms of A_n, Q_n, g_n, and h_n do not grow too fast with n, the scheme will be convergent to an equation like

$$\dot{y} = A_\infty(\varepsilon)y + h_\infty(y,t,\varepsilon).$$

This equation has the trivial solution $y = 0$, and this shows that in the original system of equations, the origin is replaced by a quasi-periodic orbit whose basic frequencies are those of the perturbation. Note that we have also obtained the linearized flow (given by the "Floquet" matrix A_∞) around this quasi-periodic solution.

2.2. The resonances. We recall that the small divisor conditions needed at each step (to compute the changes of variables) are

$$|(k,\omega)\sqrt{-1} - \lambda_i| > \frac{c}{|k|^{\gamma_0}}, \qquad |(k,\omega)\sqrt{-1} - \lambda_i + \lambda_j| > \frac{c}{|k|^{\gamma_0}}. \tag{9}$$

The first condition is needed to solve equations like (2) and the second one to solve equations like (6). Note that the eigenvalues λ_i are changed at each step of the process (because A is changed), and this implies that we do not know in advance if they will satisfy the diophantine conditions for all the steps.

To deal with this problem, we need to have some control on the variation of the eigenvalues at each step. To explain the main idea, let us focus on (2). Since we are assuming that the eigenvalues of A verify condition (3), at the first step, we can solve the equation and proceed. In the second step, when we need to solve the same equation, we find that the matrix has been (slightly) changed. Now it is $\overline{A}(\varepsilon) = A + \varepsilon\overline{Q}_1(\varepsilon)$. Therefore, since the eigenvalues of $\overline{A}$ are different from those of A, we cannot assure that they satisfy condition (3).

To explain how to overcome this difficulty, let us denote by $\overline{\lambda}_i(\varepsilon)$, $i = 1, \dots, d$, the eigenvalues of the matrix $\overline{A}(\varepsilon)$. Let us write $\overline{\lambda}_i(\varepsilon)$ as

$$\overline{\lambda}_i(\varepsilon) = \lambda_i + \lambda_i^{(1)}\varepsilon + \lambda_i^{(2)}\varepsilon^2 + \cdots, \tag{10}$$

where λ_i is an eigenvalue of the unperturbed matrix A. If we look at $\overline{\lambda}_i(\varepsilon)$ as a function of ε, we can avoid the resonant values of $\overline{\lambda}_i(\varepsilon)$ by avoiding the corresponding values of ε. This implies that taking out a (Cantor-like) set of resonant values of $\overline{\lambda}_i(\varepsilon)$ (this set is the usual union of small intervals centered in the values (k, ω)) is equivalent to taking out the corresponding (by (10)) values of ε. To bound the measure of the "resonant" values of ε, we will require that relation (10) be Lipschitz from below with respect to ε. We also want to note that we need to take out values of ε at each step of the inductive process, so we need to have this condition at each step. Let us examine this. At first sight, it seems enough to ask for $\lambda_i^{(1)} \neq 0$ because this value is produced by the first averaging. Therefore,

1. it is left unchanged by all the others steps of the inductive procedure;
2. it can be computed easily at the beginning (it is a verifiable hypothesis).

The problem is that if we take out a Cantor-like set at each step, the dependence of $\overline{\lambda i}(\varepsilon)$ on ε is not differentiable (because $\overline{\lambda}_i(\varepsilon)$ is defined only on a set with empty interior), and we do not even know if it is continuous. Therefore, it is not obvious how to derive the Lipschitz condition that we need.

To deal with the latter difficulty, we will show explicitly that at each step, relation (10) is Lipschitz. (Note that the definition of Lipschitz holds perfectly on sets with empty interior.) This will allow us to control the measure of the set of ε that we are taking out.

Finally, we want to note that this technique has to be applied twice at each step—once for equations like (2) and once for equations like (6).

2.3. The measure of the resonant set. Another important point is to bound the measure of the set of values of ε too close to resonance. To do this, we will assume that ε belongs to an interval $[0, \varepsilon_0]$, where ε_0 is small enough. We will show is that it is possible to bound the measure of the set of resonant values of ε by a quantity exponentially small in ε_0. To simplify the discussion, we will again focus on (2), so the corresponding small denominator is $(k, \omega)\sqrt{-1} - \lambda_i$.

The usual procedure is to use the bound given by (3) because it is good enough to produce convergence and to give a positive measure set of admissible frequencies. (This has been done in [15] and [16].) Note that the size of the set of resonant values of λ is given by the bound of the small divisors.[2] This implies that we should try to choose that value as small as possible. On the other hand, however, this value will appear in the denominators of the Fourier series. Therefore, if it is too small, we will not be able to prove convergence.

[2] For instance, in the case of (3), the set of resonant values of λ is

$$\bigcup_{|k|\neq 0} B\left((k, \omega)\sqrt{-1}, \frac{c}{|k|^{\gamma_0}}\right),$$

where $B(a, r)$ denotes the ball (in the complex plane) centered in a with radius r.

The condition that we have used is

$$|(k,\omega)\sqrt{-1}-\lambda_i| > \frac{c}{|k|^{\gamma_n}}e^{-\nu_n|k|} = D(k,n),$$

where γ_n has been taken to be equal to $\gamma_0 z^n$ $(1 < z < 2)$ and ν_n is $\frac{\nu_0}{(n+1)^2}$. Here n denotes the actual step of the inductive process. To begin the discussion of this expression, let us remark that the measure of the resonant set of λ at each step n is given by $\sum_{k\neq 0} 2D(k,n)$, $k \in \mathbb{Z}^r$, and the total measure is

$$\sum_{n\geq 0}\sum_{k\in\mathbb{Z}^r\setminus\{0\}} 2\frac{c}{|k|^{\gamma_n}}e^{-\nu_n|k|}. \tag{11}$$

Therefore, a first condition that we need is that those sums are convergent.

Before continuing with the discussion of $D(k,n)$, let us first explain where the exponentially small character (of the set of resonant values of ε) comes from. This will (hopefully) make clear the reasons to choose an expression like $D(k,n)$.

As we stated before, the eigenvalues of the matrix A move at each step of the inductive process by an amount of $\mathcal{O}(\varepsilon)$. Let us call $I_i(\varepsilon)$ the interval (with diameter $\mathcal{O}(\varepsilon)$) where the eigenvalue number i moves. This implies that if the eigenvalues of the unperturbed matrix satisfy a condition like (3), the values (k,ω) are outside $I_i(\varepsilon)$ if $|k| < N(\varepsilon)$ for a suitable value $N(\varepsilon)$. (Another way of saying this is that the values (k,ω) cannot approach λ_i too fast because of (3).) For that reason, we do not need to take out resonances with $|k| < N(\varepsilon)$; and this leads to the fact that in (11) it is enough to start the sum in k when $|k| \geq N(\varepsilon)$. This in turn implies that if the expression $D(k,n)$ decays exponentially with $|k|$, we will obtain something exponentially small with ε_0.

This is the reason for putting something like $\exp(-\nu|k|)$ in $D(k,n)$. Since this value will appear in the denominators of the corresponding Fourier series, we will have the factor $\exp(\nu|k|)$ multiplying the coefficients of those series. This will produce a reduction of the analyticity strip of the series; the width will go from ρ to $\rho-\nu$. Of course, after a few steps, the functions will not be analytic. Thus the entire inductive process will be over. To avoid this problem, we have chosen ν depending on the actual step $\nu_n = \frac{\nu_0}{(n+1)^2}$ in such a way that the total reduction on the analyticity strip remains bounded. (Of course, other selections of ν_n are possible, but they do not change the final result.)

The next step is to realize that with this selection of ν_n, the exponential goes to 1 when n goes to infinity. Thus we need to add some factor in front of the exponential to ensure that the sum with respect to n is still exponentially small. For this reason, we have added the factor $c/|k|^{\gamma_n}$. The selection $\gamma_n = \gamma_0 z^n$ is not the only one (one can use, for instance, $\gamma_n = \gamma_0 n^j$ for some j), but the results with the present choice seem to be better than for other choices. Finally, the value z has to be taken between 1 and 2. If it is taken equal to 2, then the divisor is too small and we are not able to guarantee convergence. This is seen more clearly in the proofs.

Finally, this entire procedure is applied (at each step) in the same way for (6) using the same exponential bound for the denominators.

2.4. Some remarks. Before finishing the overview of this paper, it is interesting to remark that since the equations with which we deal are not necessarily Hamiltonian, it is possible that in some step of the inductive process, the eigenvalues of the matrix A leave the imaginary axis. In this case, we do not need to worry about resonances from this step onward. Since we cannot know in advance if this is going to happen, we have considered the worst case during all of the proofs; that is, the eigenvalues are always on the imaginary axis. On the other hand, if the initial matrix A is partially elliptic and partially hyperbolic, the results are still valid. In the hyperbolic case, they are of course much better; that is, they hold for a full interval $[0, \varepsilon_0]$.

In some cases, it is possible that at the first step of the inductive process the eigenvalues leave the imaginary axis. (This is really the general case.) Theorem 2.4 ensures that this case can be detected when averaging the original system and looking for the new equilibrium point of this autonomous system. The linearized equations around that point and the "Floquet" matrix (A_∞) of the quasi-periodic orbit differ in $\mathcal{O}(\varepsilon^2)$.

Another interesting point is to compare what we are doing here with the proof of the KAM theorem. In the proof of the KAM theorem (see, for instance, [1]), we use the action variables as parameters to avoid resonances. Here we use the eigenvalues of the matrix A, but since we cannot move them directly, we move them by means of the single parameter ε. Note that the nondegeneracy condition of the KAM (nonzero Jacobian of the frequencies with respect to the actions) says basically that we can control the frequencies through the actions. Here we want to control the eigenvalues by means of ε, so we ask for a suitable Lipschitz condition. As is well known (see, for instance, [2]), the nondegeneracy condition of the KAM theorem can be relaxed to a second-order condition. Here it is possible to do something similar (instead of asking for $\lambda_i^{(1)} \neq 0$ in (10), we can allow $\lambda_i^{(1)} = 0$ but ask for $\lambda_i^{(2)} \neq 0$ or even a higher-order condition), and the estimates on the measure of the Cantorian set of ε are obtained in a similar way. (In fact, the estimates can be even better.) It is also remarkable that the scheme of the proof that we are using is quite similar to that of the KAM theorem [1].

Finally, note that if the nonlinearity h and the independent term g of the initial equation (1) are both equal to zero, we have a Floquet theorem. Now the result obtained is better than that contained in [16]. There it was shown that the measure of the set of "resonant" $\varepsilon \in [0, \varepsilon_0]$ is $o(\varepsilon_0)$, and here it is proved to be exponentially small with ε_0.

2.5. Theorems. From now on, if $x \in \mathbb{R}^n$, we denote by $\|x\|$ the sup norm of x. If A is a matrix, $\|A\|$ denotes the corresponding sup norm.

THEOREM 2.1. *Consider the differential equation*

$$\dot{x} = (A + \varepsilon Q(t, \varepsilon))x + \varepsilon g(t, \varepsilon) + h(x, t, \varepsilon), \tag{12}$$

where $Q(t, \varepsilon)$, $g(t, \varepsilon)$, and $h(x, t, \varepsilon)$ depend on time in a quasi-periodic way with basic frequencies $(\omega_1, \dots, \omega_r)^t$, $r \geq 2$, and $|\varepsilon| < \varepsilon_0$. We assume that A is a constant $d \times d$ matrix with d different eigenvalues λ_i and $\det A \neq 0$. *Let us suppose that $h(x, t, \varepsilon)$ is analytic with respect to x on the ball $B_r(0)$, $h(0, t, \varepsilon) = 0$ and $D_x h(0, t, \varepsilon) = 0$. Moreover, we assume the following:*

1. *Q, g, and h are analytic with respect to t on a strip of width $\rho_0 > 0$, and they depend on ε in a Lipschitz way.*

2. *$\|D_{xx} h(x, t, \varepsilon)\| \leq K$, where $\|x\| \leq r$, $|\varepsilon| \leq \varepsilon_0$, and t belongs to the strip defined in* 1.

3. *The vector $(\lambda_1, \dots, \lambda_d, \sqrt{-1}\omega_1, \dots, \sqrt{-1}\omega_r)$ satisfies the nonresonance conditions*

$$|(k, \omega)\sqrt{-1} - \lambda_i| > \frac{2c}{|k|^{\gamma_0}}, \qquad |(k, \omega)\sqrt{-1} - \lambda_i + \lambda_j| > \frac{2c}{|k|^{\gamma_0}}$$

for all $1 \le i, j \le d$, $k \in \mathbb{Z}^r \setminus \{0\}$, $c > 0$, *and* $\gamma_0 \ge r - 1$. *As usual,* $|k|$ *is taken as* $|k| = |k_1| + \cdots + |k_r|$.

4. *Let us denote by* $\underline{x}(t, \varepsilon)$ *the unique analytical quasi-periodic solution of* $\dot{x} = Ax + \varepsilon g(t, \varepsilon)$ *such that* $\lim_{\varepsilon \to 0} \underline{x}(t, \varepsilon) = 0$ (*the existence of this solution is shown by Lemma* 2.10), *and let us define*

$$\underline{A}(\varepsilon) = A + \varepsilon \overline{Q}(\varepsilon) + \overline{D_x h(\underline{x}(t, \varepsilon), t, \varepsilon)}.$$

Let $\lambda_j^0(\varepsilon)$, $j = 1, \dots, d$, *be the eigenvalues of* $\underline{A}$. *We require the existence of* $\overline{\delta}$, $\delta > 0$ *such that*

$$\frac{\overline{\delta}}{2} |\varepsilon_1 - \varepsilon_2| > |\lambda_i^0(\varepsilon_1) - \lambda_j^0(\varepsilon_1) - (\lambda_i^0(\varepsilon_2) - \lambda_j^0(\varepsilon_2))| > 2\delta |\varepsilon_1 - \varepsilon_2| > 0,$$

$$\frac{\overline{\delta}}{2} |\varepsilon_1 - \varepsilon_2| > |\lambda_k^0(\varepsilon_1) - \lambda_k^0(\varepsilon_2)| > 2\delta |\varepsilon_1 - \varepsilon_2| > 0$$

for all i, j, and k satisfying $1 \le i < j \le d$ *and* $1 \le k \le d$ *and provided that* $|\varepsilon_1|$ *and* $|\varepsilon_2|$ *are less than some small value* ε_0.

Then there exists a Cantorian set $\mathcal{E} \subset (0, \varepsilon_0)$ *with positive Lebesgue measure such that* (12) *can be transformed by means of a change of variables into*

$$\dot{y} = A_\infty(\varepsilon) y + h_\infty(y, t, \varepsilon),$$

where A_∞ *is a constant matrix and* $h_\infty(y, t, \varepsilon)$ *is of second order in* y. *If* ε_0 *is small enough, the relative measure of* $(0, \varepsilon_0) \setminus \mathcal{E}$ *in* $(0, \varepsilon_0)$ *is less than* $\exp(-c_1/\varepsilon_0^{c_2})$ *for* $c_1 > 0$ *and* $c_2 > 0$ (*independent of* ε_0), *where* c_2 *is any number such that* $c_2 < \frac{1}{\gamma_0}$. *Furthermore, the quasi-periodic change of variables that performs this transformation is analytic with respect to t, and it has the same basic frequencies as Q, g, and h.*

Remark 1. In hypothesis 3, we use $2c$ instead of the usual c in the diophantine condition to simplify the notation inside the proofs.

Remark 2. During the proof of this theorem, we will suppose that $\rho_0 \ge 1 + \frac{\pi^2}{6}$. This condition can be achieved by introducing a new time $\tau = st$, where

$$s = \max \left\{ \frac{1 + \frac{\pi^2}{6}}{\rho_0}, 1 \right\}.$$

This scaling may change the constant c; therefore, the set $\mathcal{E}$ is scaled by the same factor.

Remark 3. For fixed values of λ_i, $i = 1, \dots, d$, $\lambda_i \ne \lambda_j$ if $i \ne j$, hypothesis 3 is not satisfied for any c only for a set of values of ω of zero measure if $\gamma_0 > r - 1$.

Remark 4. If $r = 1$, that is, if the perturbation is periodic, no small divisors appear if ε is small enough and the results hold for all $\varepsilon \in (0, \varepsilon_0)$. The proof is classical. We shall assume without explicit mention that $r \ge 2$ in what follows.

COROLLARY 2.2. *Under the hypothesis of Theorem* 2.1, *there exists a Cantorian set* $\mathcal{E} \subset (0, \varepsilon_0)$ *with positive Lebesgue measure* (*and with the complementary being exponentially small*) *such that* (12) *has a quasi-periodic solution* $x_\varepsilon(t)$ *with basic frequencies* $(\omega_1, \dots, \omega_r)$ *such that*

$$\lim_{\substack{\varepsilon \to 0 \\ \varepsilon \in \mathcal{E}}} \|x_\varepsilon\| = 0.$$

COROLLARY 2.3 (a Floquet theorem). *Consider the linear differential equation*

$$\dot{x} = (A + \varepsilon Q(t,\varepsilon))x, \tag{13}$$

where $Q(t,\varepsilon)$ depends quasi-periodically on time with basic frequencies $(\omega_1, \dots, \omega_r)^t$, $r \geq 2$, and $|\varepsilon| < \varepsilon_0$. We assume that A is a constant $d \times d$ matrix with d different eigenvalues λ_i and $\det A \neq 0$. Moreover, we assume the following:

1. *Q is analytic with respect to t on a strip of width $\rho_0 > 0$ and depends on ε in a Lipschitz way.*

2. *The vector $(\lambda_1, \dots, \lambda_d, \sqrt{-1}\omega_1, \dots, \sqrt{-1}\omega_r)$ satisfies the nonresonance condition*

$$|(k,\omega)\sqrt{-1} - \lambda_i + \lambda_j| > \frac{2c}{|k|^{\gamma_0}}$$

for all $1 \leq i,\ j \leq d$, $k \in \mathbb{Z}^r \setminus \{0\}$, $c > 0$, and $\gamma_0 \geq r - 1$.

3. *Let us define*

$$\underline{A}(\varepsilon) = A + \varepsilon\overline{Q}(\varepsilon).$$

Let $\lambda_j^0(\varepsilon)$, $j = 1, \dots, d$, be the eigenvalues of $\underline{A}$. We require the existence of $\overline{\delta}$, $\delta > 0$ such that

$$\frac{\overline{\delta}}{2}|\varepsilon_1 - \varepsilon_2| > |\lambda_i^0(\varepsilon_1) - \lambda_j^0(\varepsilon_1) - (\lambda_i^0(\varepsilon_2) - \lambda_j^0(\varepsilon_2))| > 2\delta|\varepsilon_1 - \varepsilon_2| > 0$$

for all i, j, and k satisfying $1 \leq i < j \leq d$ and $1 \leq k \leq d$ and provided that $|\varepsilon_1|$ and $|\varepsilon_2|$ are less than some small value ε_0.

Then there exists a Cantorian set $\mathcal{E} \subset (0, \varepsilon_0)$ with positive Lebesgue measure such that (13) *can be reduced to a system with constant coefficients*

$$\dot{y} = A_\infty(\varepsilon)y$$

by means of a change of variables $x = (I + \varepsilon P(t,\varepsilon))y$, where I is the identity matrix and P is analytic and quasi-periodic with respect to t with ω as a vector of basic frequencies. If ε_0 is small enough, the relative measure of $(0,\varepsilon_0) \setminus \mathcal{E}$ in $(0,\varepsilon_0)$ is less than $\exp(\frac{-c_1}{\varepsilon_0^{c_2}})$ for $c_1 > 0$ and $c_2 > 0$ (independent of ε_0), where c_2 is any number such that $c_2 < \frac{1}{\gamma_0}$.

Remark. This corollary is the result of taking $g \equiv h \equiv 0$ in Theorem 2.1. We have also weakened the nonresonance condition. This fact becomes clear by looking into the proof for that theorem.

THEOREM 2.4. *Let us consider* (12), *and let us assume that all the hypotheses of Theorem* 2.1 *hold. Moreover, let us assume that the nonlinear part $h(x,t,\varepsilon)$ is of class C^2 with respect to ε and $h(x,t,0) \equiv h(x)$. Then if ε is sufficiently small, the averaged system*

$$\dot{y} = (A + \varepsilon\overline{Q})y + \varepsilon\overline{g} + \overline{h}(y,\varepsilon)$$

has an equilibrium point $x_0(\varepsilon)$ such that

1. $\lim_{\varepsilon\to 0} \|x_0(\varepsilon)\| = 0$;

2. *the matrix A_{x_0} of the linearized system around $x_0(\varepsilon)$ and the matrix A_∞ obtained in Theorem* 2.1 *satisfy $\|A_{x_0} - A_\infty\| = \mathcal{O}(\varepsilon^2)$.*

COROLLARY 2.5. *Let us define $\lambda_i^{x_0}$, $1 \le i \le d$, as the eigenvalues of the matrix A_{x_0} defined in Theorem 2.4. Then, under the hypothesis of Theorem 2.4, an equivalent version of hypothesis 4 in Theorem 2.1 is obtained if λ_i^0 are replaced by $\lambda_i^{x_0}$.*

The proofs of the results above have been split into several parts to simplify the reading. Section 2.6 contains lemmas needed to show the convergence of the iterative scheme used to obtain Theorem 2.1. Section 2.7 presents the convergence proof. Up to this point, we do not worry about the measure of the set of values of ε that must be taken out. Section 2.8 includes the lemmas used to prove that matrix A depends on ε in a Lipschitz way at each step of the procedure. The lemma used to bound the measure of the Cantorian set where Theorem 2.1 holds is given in §2.9. Section 2.10 actually states the bounds for that measure, and, finally, §2.11 is devoted to Theorem 2.4.

2.6. Convergence lemmas. In what follows, we will use the fact that an analytic quasi-periodic function $f(t)$ on a strip of width ρ with $\omega = (\omega_1, \dots, \omega_r)$ as a vector of basic frequencies has Fourier coefficients defined by

$$f_k = \frac{1}{(2\pi)^r} \int_{\mathbb{T}^r} F(\theta_1, \dots, \theta_r) e^{-(k,\theta)\sqrt{-1}}\, d\theta$$

(F is defined in Definition 1.1) such that f can be expanded as

$$f(t) = \sum_{k \in \mathbb{Z}^r} f_k e^{(k,\omega)\sqrt{-1}t}$$

for all t such that $|\mathrm{Im}\ t| < \frac{\rho}{\|\omega\|}$. Moreover, the analyticity of f implies that

$$|f_k| \le \|f\|_\rho e^{-\rho|k|}.$$

LEMMA 2.6. *Let $\delta \in]0, 1]$, $\alpha \ge 1$. Let us define the function*

$$\chi(s) = \left(\frac{s-1}{e}\right)^{s-1} \sqrt{s-1}.$$

Then

$$\sum_{k \in \mathbb{Z}^r} |k|^\alpha e^{-\delta|k|} \le \frac{20r}{3\delta^{r+\alpha}} \chi(r+\alpha).$$

Proof. We shall use the fact that $\#\{k \in \mathbb{Z}^r \ / \ |k| = m\} \le 2rm^{r-1}$. This is checked immediately for $m = 1$ or for $r \le 3$. Then we use induction with respect to r for $m \ge 2$. We then obtain

$$\sum_{k \in \mathbb{Z}^r} |k|^\alpha e^{-\delta|k|} \le 2r \sum_{m=0}^{\infty} m^{r+\alpha-1} e^{-\delta m} = (\triangle).$$

Since the unique maximum of $g(x) = x^{r+\alpha-1}e^{-\delta x}$ is reached when $x = \frac{r+\alpha-1}{\delta}$, we can bound the sum above by this maximum plus the integral as

$$(\triangle) \le 2r \left[\left(\frac{r+\alpha-1}{\delta e}\right)^{r+\alpha-1} + \frac{1}{\delta^{r+\alpha}} \Gamma(r+\alpha) \right]$$

$$= \frac{2r}{\delta^{r+\alpha}}\left(\frac{r+\alpha-1}{e}\right)^{r+\alpha-1}\left[\delta+\left(\frac{e}{r+\alpha-1}\right)^{r+\alpha-1}\Gamma(r+\alpha)\right]$$

$$< \frac{2r}{\delta^{r+\alpha}}\left(\frac{r+\alpha-1}{e}\right)^{r+\alpha-1}\frac{10}{3}\sqrt{r+\alpha-1} = \frac{20r}{3}\frac{\chi(r+\alpha)}{\delta^{r+\alpha}}. \qquad \square$$

LEMMA 2.7. *Let $h : U \subset \mathbb{R}^d \longrightarrow \mathbb{R}^d$ be a function of class $\mathcal{C}^2$ on a ball $B_r(0)$ that satisfies $h(0) = 0$, $D_x h(0) = 0$, and $\|D_{xx}h(x)\| \le K$, where $x \in B_r(0)$. Then $\|h(x)\| \le \frac{K}{2}\|x\|^2$ and $\|D_x h(x)\| \le K\|x\|$.*

The proof follows from Taylor's formula.

LEMMA 2.8. *Let M be a diagonal matrix with d different nonzero eigenvalues μ_j, $j = 1,\dots,d$, and $\alpha = \min\{\min_{i,j;\, i\ne j}|\mu_i-\mu_j|, \min_i|\mu_i|\}$. Let N be a matrix such that $(d+1)\|N\| < \alpha$. Let σ_j, $j=1,\dots,d$, be the eigenvalues of $M+N$, and let B a suitable matrix such that $B^{-1}(M+N)B = D = \operatorname{diag}(\sigma_j)$ with condition number $C(B)$. Then the following hold:*

1. $\beta = \min\{\min_{i,j;\, i\ne j}|\sigma_i-\sigma_j|, \min_i|\sigma_i|\} \ge \alpha - 2\|N\|$.
2. $C(B) \le \frac{\alpha+(d-3)\|N\|}{\alpha-(d+1)\|N\|}$. *In particular, if* $\|N\| < \frac{\alpha}{3d-1}$, *then* $C(B) < 2$.

Proof. The proof can be found in [16] or [15]. □

LEMMA 2.9. *Let A_0 be a $d\times d$ matrix such that* $\operatorname{Spec}(A_0) = \{\lambda_1^0,\dots,\lambda_d^0\}$, *$|\lambda_i^0| > 2\mu$, $|\lambda_i^0-\lambda_j^0| > 2\mu$, $i\ne j$, where $\mu > 0$. Let B_0 be a regular matrix such that $B_0^{-1}A_0B_0 = D_0 = \operatorname{diag}(\lambda_1^0,\dots,\lambda_d^0)$. Let us define $\beta_0 = \max\{\|B_0\|, \|B_0^{-1}\|\}$, and let α be a value such that $0 < \alpha < \frac{2\mu}{(3d-1)\beta_0^2}$. Then if A verifies $\|A-A_0\| < \alpha$, the following conditions hold:*

1. $\operatorname{Spec}(A) = \{\lambda_1,\dots,\lambda_d\}$, *and* $|\lambda_i| > \mu$, $|\lambda_i-\lambda_j| > \mu$, $i\ne j$.
2. *There exists a nonsingular matrix B such that $B^{-1}AB = \operatorname{diag}(\lambda_1,\dots,\lambda_d)$, which satisfies $\|B\|\le\beta$ and $\|B^{-1}\|\le\beta$, with $\beta = 2\beta_0$.*

Proof. Let A be a matrix, and we write $A = A_0 + (A-A_0)$. Then $B_0^{-1}AB_0 = D_0 + N$, where $N = B_0^{-1}(A-A_0)B_0$. Here we can apply Lemma 2.8 to obtain 1 if $\|A-A_0\| \le \frac{2\mu}{(d+1)\beta_o^2}$. Note that Lemma 2.8 states that the condition number of the matrix C that diagonalizes D_0+N is less than 2 provided that $\|A-A_0\| < \frac{2\mu}{(3d-1)\beta_0^2}$. In this case, the matrix that diagonalizes A can be obtained by multiplying B_0 by C. Hence its norm can be bounded by $2\beta_0$. □

In the next lemmas, the parameters γ and ν are assumed to be positive.

LEMMA 2.10. *Let us consider the equation $\dot{x} = Ax + \varepsilon g(t)$, where A is a $d\times d$ matrix belonging to the ball $B_\alpha(A_0) \subset \mathcal{L}(\mathbb{R}^d,\mathbb{R}^d)$ with α as given by Lemma 2.9, $g(t) = (g_i(t))_{1\le i\le d}$, and $g_i(t)$ is an analytic quasi-periodic function on a strip of width ρ_1 and is expressed as*

$$g_i(t) = \sum_{k\in\mathbb{Z}^r} g_i^k e^{(k,\omega)\sqrt{-1}t}.$$

Let us assume that $|(k,\omega)\sqrt{-1}-\lambda_i| > \frac{c}{|k|^\gamma}e^{-\nu|k|}$ $\forall\lambda_i \in \operatorname{Spec}(A)$. Let ρ_2 be such that $0 < \rho_2 < \rho_1 - \nu$ and $\delta = \rho_1-\rho_2-\nu \le 1$. Then there exists a unique quasi-periodic solution of $\dot{x} = Ax+\varepsilon g(t)$ that has the same basic frequencies as g and that satisfies

$$\|x\|_{\rho_2} \le \varepsilon\|g\|_{\rho_1}L_1,$$

where $L_1 = 4\beta_0^2[\frac{1}{\mu} + \frac{20r}{3c}\frac{\chi(r+\gamma)}{\delta^{r+\gamma}}]$ and μ and β_0 are defined in Lemma 2.9.

Remark. In this and forthcoming lemmas, we consider A, Q, g, and h depending also on ε (see Theorem 2.1), but, for simplicity, we do not write this explicitly.

Proof. Let B be the matrix found in Lemma 2.9. Making the change of variables $x = By$ and defining $h(t) = B^{-1}g$, the equation becomes

$$\dot{y} = Dy + \varepsilon h(t).$$

Since D is a diagonal matrix, we can handle this equation as d unidimensional equations, which can easily be solved. If $y = (y_i)_{1\leq i \leq d}$ and

$$y_i(t) = \sum_{k\in\mathbb{Z}^r} y_i^k e^{(k,\omega)\sqrt{-1}t},$$

the coefficients must be $y_i^k = \varepsilon \frac{h_i^k}{(k,\omega)\sqrt{-1}-\lambda_i}$, and they can be bounded by

$$|y_i^k| \leq \begin{cases} \varepsilon\frac{\|h\|_{\rho_1}}{\mu} & \text{if } k=0,\\ \varepsilon\|h\|_{\rho_1}\frac{|k|^\gamma}{c}e^{-(\rho_1-\nu)|k|} & \text{if } k\neq 0.\end{cases}$$

Now we need to bound the norm $\|y\|_{\rho_2}$. Let t be a complex value such that $|\text{Im } \omega_i t| \leq \rho_2$ (for all i). Then

$$|y_i(t)| \leq \sum_{k\in\mathbb{Z}^r} |y_i^k|\,|e^{(k,\omega t)\sqrt{-1}}| \leq \varepsilon\frac{\|h\|_{\rho_1}}{\mu} + \sum_{k\neq 0}\varepsilon\|h\|_{\rho_1}\frac{|k|^\gamma}{c}e^{-(\rho_1-\nu)|k|}e^{\rho_2|k|}.$$

Setting $\delta = \rho_1 - \rho_2 - \nu$, we can use Lemma 2.6 to bound the sum above as

$$|y_i(t)| \leq \varepsilon\|h\|_{\rho_1}\left[\frac{1}{\mu} + \frac{20r\chi(r+\gamma)}{3c\delta^{r+\gamma}}\right].$$

Since $\|h\|_{\rho_1} \leq \|B^{-1}\|\|g\|_{\rho_1}$ and $\|x\|_{\rho_2} \leq \|B\|\|y\|_{\rho_2}$, the result follows. □

LEMMA 2.11. *Let us consider the equation $\dot{P} = AP - PA + Q$, where $A \in B_\alpha(A_0)$ and $Q = (q_{ij})$, where $q_{ij}(t)$ are analytic quasi-periodic functions on a strip of width ρ_1 and are expressed as*

$$q_{ij}(t) = \sum_{k\in\mathbb{Z}^r} q_{ij}^k e^{(k,\omega)\sqrt{-1}t}.$$

We also assume that Q has average equal to zero and that $|(k,\omega)\sqrt{-1} - \lambda_i + \lambda_j| > \frac{c}{|k|^\gamma}e^{-\nu|k|}$ $\forall\lambda_i \in \text{Spec}(A)$. Let ρ_2 be such that $0 < \rho_2 < \rho_1 - \nu$ and $\delta = \rho_1 - \rho_2 - \nu \leq 1$. Then there exists a unique quasi-periodic solution of $\dot{P} = AP - PA + Q$ that has the same basic frequencies as Q and that satisfies

$$\|P\|_{\rho_2} \leq \|Q\|_{\rho_1} L_2,$$

where $L_2 = 16\beta_0^2\frac{20r\chi(r+\gamma)}{3c\delta^{r+\gamma}}$ and β_0 is defined in Lemma 2.9.

Proof. Let B be the matrix found in Lemma 2.9. Making the change of variables $P = BSB^{-1}$ and defining $R = B^{-1}QB$, the equation becomes

$$\dot{S} = DS - SD + R,$$

where the matrix R has zero average. Since D is a diagonal matrix, we can handle this equation as d^2 unidimensional equations, which can be solved easily. If $S = (s_{ij})$ and

$$s_{ij}(t) = \sum_{k\in\mathbb{Z}^r\setminus\{0\}} s_{ij}^k e^{(k,\omega)\sqrt{-1}t},$$

the coefficients must be $s_{ij}^k = \frac{r_{ij}^k}{(k,\omega)\sqrt{-1}-\lambda_i+\lambda_j}$, and they can be bounded by

$$|s_{ij}^k| \leq \|r_{ij}\| \frac{|k|^\gamma}{c} e^{-(\rho_1-\nu)|k|}.$$

Now we need to bound the norm $\|S\|_{\rho_2}$. Let t be a complex value such that $|\mathrm{Im}\ \omega_i t| \leq \rho_2$ (for all i). Then

$$|s_{ij}(t)| \leq \sum_{k\in\mathbb{Z}^r} |s_{ij}^k|\ |e^{(k,\omega t)\sqrt{-1}}| \leq \sum_{k\neq 0} \|r_{ij}\|_{\rho_1} \frac{|k|^\gamma}{c} e^{-(\rho_1-\nu)|k|} e^{\rho_2|k|}.$$

Now we can use Lemma 2.6, setting $\delta = \rho_1 - \rho_2 - \nu$, to bound the sum above as

$$|s_{ij}(t)| \leq \frac{\|r_{ij}\|_{\rho_1}}{c} \left[\frac{20r\chi(r+\gamma)}{3\delta^{r+\gamma}}\right].$$

Since $\|P\|_{\rho_2} \leq \|B\|\|S\|_{\rho_2}\|B^{-1}\|$, we can use $\|R\|_{\rho_1} \leq \|B^{-1}\|\|Q\|_{\rho_1}\|B\|$ to obtain the result. □

LEMMA 2.12. *Let us consider $\dot{x} = (A + \varepsilon Q(t))x + \varepsilon g(t) + h(x,t)$, where the time dependence is assumed to be analytic quasi-periodic on a strip of width ρ_1. We also assume that $h(x,t)$ is analytic with respect to x on the ball $B_\tau(0)$ and satisfies $\|D_{xx}h(x,t)\|_{\rho_1} \leq K$ $\forall x \in B_\tau(0)$. Moreover, $A \in B_\alpha(A_0)$ and $|(k,\omega)\sqrt{-1} - \lambda_i| > \frac{c}{|k|^\gamma}e^{-\nu|k|}$ $\forall \lambda_i \in \mathrm{Spec}(A)$. Let ρ_2 be such that $0 < \rho_2 < \rho_1 - \nu$ and $\delta = \rho_1 - \rho_2 - \nu \leq 1$. Then there exists a change of variables $x = y + \underline{x}(t)$ that transforms the initial equation into*

$$\dot{y} = (\overline{A} + \varepsilon\widetilde{Q}_1)y + \varepsilon^2 g_1(t) + h_1(x,t),$$

where $\widetilde{Q}$ has zero average and the following bounds hold.

1. $\|\widetilde{Q}_1\|_{\rho_2} \leq 2\|Q\|_{\rho_1} + 2KL_1\|g\|_{\rho_1}$, *where L_1 was defined in Lemma* 2.10.
2. $\|g_1\|_{\rho_2} \leq KL_1^2\|g\|_{\rho_1}^2/2 + L_1\|Q\|_{\rho_1}\|g\|_{\rho_1}$.
3. $\|\overline{A}\| \leq \|A\| + \varepsilon(\|g\|_{\rho_1}KL_1 + \|Q\|_{\rho_1})$.
4. $\|D_{yy}h_1(y,t)\|_{\rho_2} \leq K$.
5. $\|\underline{x}\|_{\rho_2} \leq \varepsilon\|g\|_{\rho_1}L_1$.

Here $y \in B_{\tau_1}(0)$, $\tau_1 = \tau - \|\underline{x}\|_{\rho_2}$, and ε is small enough.

Proof. Let $\underline{x}$ be such that $\dot{\underline{x}} = A\underline{x} + \varepsilon g$. In Lemma 2.10, we obtained

$$\|\underline{x}\|_{\rho_2} \leq \varepsilon\|g\|_{\rho_1}L_1.$$

Making the change of variables $x = y + \underline{x}(t)$, we get

$$\dot{y} = (A + \varepsilon Q + D_x h(\underline{x}(t),t))y + h(\underline{x}(t),t) + \varepsilon Q\underline{x}(t) + h_1(y,t),$$

where $h_1(y,t) = h(\underline{x}(t) + y,t) - h(\underline{x}(t),t) - D_x h(\underline{x}(t),t)y$. Defining $Q_1 = Q + \frac{1}{\varepsilon}D_x h(\underline{x}(t),t)$ and $g_1 = \frac{1}{\varepsilon^2}h(\underline{x}(t),t) + \frac{1}{\varepsilon}Q\underline{x}(t)$ ($\varepsilon \neq 0$), the equation is then

$$\dot{y} = (A + \varepsilon Q_1(t))y + \varepsilon^2 g_1(t) + h_1(y,t).$$

To finish, the terms of this equation must be bounded. Let us start with Q_1. Using Lemma 2.7, we get

$$\|Q_1\|_{\rho_2} \leq \|Q\|_{\rho_2} + \frac{1}{\varepsilon}K\|\underline{x}\|_{\rho_2} \leq \|Q\|_{\rho_1} + \|g\|_{\rho_1}KL_1.$$

Now let us bound $\|g_1\|_{\rho_2}$, again by means of Lemma 2.7, as

$$\|g_1\|_{\rho_2} \leq \frac{1}{\varepsilon^2}\frac{K}{2}\|\underline{x}\|_{\rho_2}^2 + \frac{1}{\varepsilon}\|Q\|_{\rho_1}\|\underline{x}\|_{\rho_2} \leq \frac{KL_1^2\|g\|_{\rho_1}^2}{2} + \|Q\|_{\rho_1}\|g\|_{\rho_1}L_1.$$

Now it is $D_{yy}h_1(y,t)$'s turn, that is,

$$\|D_{yy}h_1\|_{\rho_2} = \|D_{xx}h(\underline{x}(t)+y,t)\| \leq K.$$

To do this, we must require that $y \in B_{\tau_1}(0)$, where $\tau_1 = \tau - \|\underline{x}\|_{\rho_2}$. ($\varepsilon$ is assumed to be small enough.) Now, using that $Q_1(t) = \overline{Q}_1 + \widetilde{Q}_1(t)$ and defining $\overline{A} = A + \varepsilon\overline{Q}_1$, we obtain

$$\dot{y} = (\overline{A} + \varepsilon\widetilde{Q}_1(t))y + \varepsilon^2 g_1(t) + h_1(y,t).$$

Finally,

$$\|\overline{A}\| \leq \|A\| + \varepsilon\|\overline{Q}_1\|_{\rho_2},$$

and taking into account that $\|\overline{Q}_1\|_{\rho_2} \leq \|Q_1\|_{\rho_2}$ and that $\|\widetilde{Q}_1(t)\|_{\rho_2} \leq 2\|Q_1\|_{\rho_2}$ the proof is finished. □

LEMMA 2.13. *Let us consider $\dot{x} = (A + \varepsilon Q(t))x + \varepsilon^2 g(t) + h(x,t)$, where the time dependence is assumed to be analytic quasi-periodic on a strip of width ρ_1 and Q has zero average. We also assume that $h(x,t)$ is analytic with respect to x on the ball $B_\tau(0)$ and that it satisfies $\|D_{xx}h(x,t)\|_{\rho_1} \leq K$ $\forall x \in B_\tau(0)$. Moreover, $A \in B_\alpha(A_0)$ and $|(k,\omega)\sqrt{-1} - \lambda_i + \lambda_j| > \frac{c}{|k|^\gamma}e^{-\nu|k|}$ $\forall \lambda_i$, $\lambda_j \in$ Spec(A). Let ρ_2 be such that $0 < \rho_2 < \rho_1 - \nu$ and $\delta = \rho_1 - \rho_2 - \nu \leq 1$. Then there exists a change of variables $x = (I + \varepsilon P(t))y$, where I is the identity $d \times d$ matrix and $P(t)$ is analytic quasi-periodic on a strip of width ρ_2, which transforms the initial equation into*

$$\dot{y} = (\overline{A} + \varepsilon^2\widetilde{Q}_1)y + \varepsilon^2 g_1(t) + h_1(y,t),$$

where $\widetilde{Q}_1$ has zero average and the following bounds hold.

1. $\|\widetilde{Q}_1\|_{\rho_2} \leq \frac{2\|P\|_{\rho_2}}{1-\varepsilon\|P\|_{\rho_2}}\|Q\|_{\rho_1}$, *where $\|P\|_{\rho_2} \leq \|Q\|_{\rho_1}L_2$ and L_2 was defined in Lemma* 2.11.
2. $\|g_1\|_{\rho_2} \leq \frac{1}{1-\varepsilon\|P\|_{\rho_2}}\|g\|_{\rho_1}$.
3. $\|D_{yy}h_1\|_{\rho_2} \leq K\frac{(1+\varepsilon\|P\|_{\rho_2})^2}{1-\varepsilon\|P\|_{\rho_2}}$.
4. $\|\overline{A}\| \leq \|A\| + \varepsilon^2\frac{\|P\|_{\rho_2}}{1-\varepsilon\|P\|_{\rho_2}}\|Q\|_{\rho_1}$.

Here $y \in B_{\tau_1}(0)$, $\tau_1 = \frac{\tau}{1+\varepsilon\|P\|_{\rho_2}}$, and ε is small enough.

Proof. Using Lemma 2.11 we can solve $\dot{P} = AP - PA + Q$. The solution that we have found verifies

$$\|P\|_{\rho_2} \leq \|Q\|_{\rho_1}L_2.$$

Now, by means of the change of variables $x = (I+\varepsilon P)y$ and introducing the notation $Q_1 = (I+\varepsilon P)^{-1}QP$, $g_1 = (I+\varepsilon P)^{-1}g$, and $h_1(y,t) = (I+\varepsilon P)^{-1}h((I+\varepsilon P)y,t)$, we obtain the equation

$$\dot{y} = (A + \varepsilon^2 Q_1(t))y + \varepsilon^2 g_1(t) + h_1(y,t).$$

Next, we are going to bound the terms of this equation. For this purpose, we need the bound of $\|P\|_{\rho_2}$ provided by Lemma 2.11 and displayed above, that is,

$$\|Q_1\|_{\rho_2} \le \left(\sum_{i=0}^{\infty} \varepsilon^i \|P\|_{\rho_2}^i\right) \|Q\|_{\rho_2}\|P\|_{\rho_2} \le \frac{\|P\|_{\rho_2}}{1-\varepsilon\|P\|_{\rho_2}}\|Q\|_{\rho_1},$$

$$\|g_1\|_{\rho_2} \le \frac{1}{1-\varepsilon\|P\|_{\rho_2}}\|g\|_{\rho_1},$$

$$\|D_{yy}h_1\|_{\rho_2} \le \frac{1}{1-\varepsilon\|P\|_{\rho_2}}K\|I+\varepsilon P\|_{\rho_2}^2 \le K\frac{(1+\varepsilon\|P\|_{\rho_2})^2}{1-\varepsilon\|P\|_{\rho_2}}.$$

Of course, we require $y \in B_{r_1}(0)$, where $r_1 = r/(1+\varepsilon\|P\|_{\rho_2})$, and ε is small enough. To finish this, we rewrite the equation using $Q_1(t) = \overline{Q}_1 + \widetilde{Q}_1(t)$, and $\overline{A} = A + \varepsilon^2\overline{Q}_1$, and we obtain

$$\dot{y} = (\overline{A} + \varepsilon^2\widetilde{Q}_1)y + \varepsilon^2 g_1(t) + h_1(y,t),$$

and we only need to bound $\overline{A}$ as

$$\|\overline{A}\| \le \|A\| + \varepsilon^2\|Q_1\|_{\rho_2}. \qquad \square$$

Thus far, we have the main tools to carry out one step of the inductive process. Now we present a lemma that will be used to show the convergence.

LEMMA 2.14. *Let η_n be a sequence of real positive numbers such that*

$$\eta_{n+1} \le (\overline{\gamma}z^n)^{\overline{\gamma}z^n}\eta_n^2$$

for all $n \ge 0$, where $\overline{\gamma} > 0$, $1 < z < 2$. Then

$$\eta_n \le \left[\left(\overline{\gamma}z^{\frac{z}{2-z}}\right)^{\frac{\overline{\gamma}}{2-z}}\eta_0\right]^{2^n}.$$

Proof. Taking logarithms, we have

$$\begin{aligned}\log\eta_{n+1} &\le (\overline{\gamma}z^n)\log(\overline{\gamma}z^n) + 2\log\eta_n\\ &\le (\overline{\gamma}z^n)\log(\overline{\gamma}z^n) + 2\overline{\gamma}z^{n-1}\log(\overline{\gamma}z^{n-1}) + 4\log\eta_{n-1} \le \cdots\\ &\le \overline{\gamma}\sum_{j=0}^{n} 2^j z^{n-j}(\log\overline{\gamma} + (n-j)\log z) + 2^{n+1}\log\eta_0\\ &= \overline{\gamma}\,2^{n+1}\log\overline{\gamma}\sum_{l=0}^{n}\frac{z^l}{2^{l+1}} + \overline{\gamma}\,2^{n+1}\log z\sum_{l=1}^{n} l\frac{z^l}{2^{l+1}} + 2^{n+1}\log\eta_0\\ &\le \overline{\gamma}\,2^{n+1}\frac{1}{2-z}\log\overline{\gamma} + \overline{\gamma}\,2^{n+1}\frac{z}{(2-z)^2}\log z + 2^{n+1}\log\eta_0.\end{aligned}$$

The result follows by exponentiation. $\square$

LEMMA 2.15. *Let $\{a_n\}_n$ be a sequence of positive real numbers that satisfies $a_n \in\ ]0,1]$, $\prod_{n=0}^{\infty} a_n = a \in\ ]0,1]$. Let $\{b_n\}_n$ be another sequence of positive real numbers that satisfies $\sum_{n=0}^{\infty} b_n = b < +\infty$. Consider the new sequence $\{r_n\}_n$ defined* *by $\tau_{n+1} = a_n\tau_n - b_n$. Then the sequence $\{\tau_n\}_n$ converges to a limit value τ_∞ that satisfies $\tau_\infty \geq a\tau_0 - b$.*

Proof. It is easy to see that

$$\tau_{n+1} = \left(\prod_{i=0}^{n} a_i\right)\tau_0 - \sum_{i=0}^{n-1}\left[\left(\prod_{j=i+1}^{n} a_j\right) b_i\right] - b_n.$$

As all the terms appearing in this expression converge, so does τ_n. Moreover, using that

$$\prod_{j=i+1}^{n} a_j \leq 1$$

for all n, the result follows. □

2.7. Proof of Theorem 2.1 (part I). Here we will present the proof without worrying about resonances, and then in §2.10, we will take out the values of ε for which the proof fails.

First of all, let us denote by A_0 the initial matrix A (see Theorem 2.1) corresponding to the averaged linear part of the differential system. Let μ be a real value such that if $\mathrm{Spec}(A_0) = \{\lambda_1^0, \dots, \lambda_d^0\}$, then $|\lambda_i^0| > 2\mu$ and $|\lambda_i^0 - \lambda_j^0| > 2\mu$ for all $i \neq j$. Then Lemma 2.9 can be applied to obtain values α and β such that all the matrices contained inside the ball $B_\alpha(A_0) = \{\frac{A}{\|A-A_0\|} < \alpha\}$ can be diagonalized. Moreover, the matrix B of the diagonalizing change of variables satisfies $\|B\| < \beta$ and $\|B^{-1}\| < \beta$. During the proof, we shall see that if ε is small enough, all the matrices A_n that appear during the inductive process are inside that ball.

Since we assume that the dependence of Q, g, and h with respect to ε is Lipschitz, every time we compute some norm, we mean without explicit mention that we look for the maximum not only with respect to t in the suitable strip but also with respect to ε in the allowed range.

To begin the proof, we suppose that we have applied the method presented previously up to step n, and we will see that we can apply it again to get the $n+1$ step. In this way, we shall obtain bounds for the quasi-periodic part at the nth step and for the transformation at this step, and this allows us to prove the convergence.

We note that in the first step (that is, when the current data are the initial ones) the index n is equal to 0.

Now suppose that we are at the nth step. This means that the equation we have is

$$\dot{x}_n = (A_n(\varepsilon) + \varepsilon^{2^n} Q_n(t,\varepsilon))x_n + \varepsilon^{2^n} g_n(t,\varepsilon) + h_n(x_n,t,\varepsilon), \tag{14}$$

where A_n belongs to $B_\alpha(A_0)$; its eigenvalues λ_i verify the nonresonance condition

$$|(k,\omega)\sqrt{-1} - \lambda_i| > \frac{c}{|k|^{\gamma_n}} e^{-\nu_n|k|},$$

where $\gamma_n = \gamma_0 z^n$ $(1 < z < 2)$ and $\nu_n = \frac{\nu_0}{(n+1)^2}$, with $0 < \nu_0 < \frac{1}{4}$. Since we need to reduce the width of the analyticity strip of the quasi-periodic functions, we define $\rho_{n+1} = \rho_n - \frac{1}{(n+1)^2}$ and $\sigma_n = \rho_n - \frac{1}{2(n+1)^2}$, with $\rho_0 = 1 + \frac{\pi^2}{6}$. During the proof, we shall see that the analyticity ball (with respect to x) of $h_n(x,t)$ must be reduced at each step of the inductive process; and we shall find that by selecting ε small enough, the limit radius of this ball is positive. Let us define τ_n as this radius at step n. Now we can apply Lemma 2.12 to transform (14) into

$$\dot{y}_n = (\widehat{A}_n(\varepsilon) + \varepsilon^{2^n}\widehat{Q}_n(t,\varepsilon))y_n + \varepsilon^{2^{n+1}}\widehat{g}_n(t,\varepsilon) + \widehat{h}_n(y_n,t,\varepsilon), \tag{15}$$

where the width of the analyticity strip has been reduced to σ_n. Now, assuming that the nonresonance condition

$$|(k,\omega)\sqrt{-1} - \lambda_i + \lambda_j| > \frac{c}{|k|^{\gamma_n}}e^{-\nu_n|k|}$$

holds for all λ_i, $\lambda_j \in \operatorname{Spec}(\widehat{A}_n(\varepsilon))$, we can apply Lemma 2.13 to (15) and get

$$\dot{x}_{n+1} = (A_{n+1}(\varepsilon) + \varepsilon^{2^{n+1}}Q_{n+1}(t,\varepsilon))x_{n+1} + \varepsilon^{2^{n+1}}g_{n+1}(t,\varepsilon) + h_{n+1}(x_{n+1},t,\varepsilon). \tag{16}$$

Now the width of the analyticity strip has been reduced to ρ_{n+1}. The next step of the proof is to obtain bounds of the terms appearing in (16) depending on the bounds of the terms of (14).

In what follows, $L_{1,n}$ and $L_{2,n}$ denote the values of L_1 and L_2 as introduced in Lemmas 2.10 and 2.11, where γ, ν, and δ are replaced by γ_n, ν_n, and $\frac{1/2-\nu_0}{(n+1)^2}$, respectively.

Using Lemma 2.13 and the condition $\varepsilon^{2^n}\|P_n\|_{\rho_{n+1}} \leq \frac{1}{2}$ (see below), we get

$$\|Q_{n+1}\|_{\rho_{n+1}} \leq 4L_{2,n}\|\widehat{Q}_n\|^2_{\sigma_n}.$$

Here we need Lemma 2.12 to bound the expression above, but the bound provided by this lemma has a "still unknown" term, that is, the bound of the second derivative of h_n. Let us call this value K_n. Note that it is "modified" at each step by Lemma 2.13. In order to bound it, we shall assume that ε is small enough to ensure that $\varepsilon^{2^n}\|P_n\|_{\rho_{n+1}}$ is less than $\frac{1}{2}$. This implies that the value of ε will be reduced at each step, if necessary, to guarantee that condition. We will see that this condition is achieved from a certain step onward, without modifying ε anymore. Therefore, we assume that $K_n \leq (\frac{9}{2})^n K_0$ (when the convergence is proved, we shall give a more realistic bound of K_n that converges to a real number), and Lemma 2.12 states that

$$\|\widehat{Q}_n\|_{\sigma_n} \leq 2\|Q_n\|_{\rho_n} + 2K_nL_{1,n}\|g_n\|_{\rho_n}.$$

Now we bound the norm of g_{n+1} as

$$\|g_{n+1}\|_{\rho_{n+1}} \leq 2\|\widehat{g}_n\|_{\sigma_n},$$

and, from Lemma 2.12,

$$\|g_{n+1}\|_{\rho_{n+1}} \leq K_nL^2_{1,n}\|g_n\|^2_{\rho_n} + 2L_{1,n}\|Q_n\|_{\rho_n}\|g_n\|_{\rho_n}.$$

For simplicity, let us denote $\alpha_n = \|Q_n\|_{\rho_n}$ and $\beta_n = \|g_n\|_{\rho_n}$. This means that we have obtained the bounds

$$\alpha_{n+1} \leq 16L_{2,n}\left(\alpha_n + \left(\frac{9}{2}\right)^n L_{1,n}\beta_n\right)^2,$$

$$\beta_{n+1} \leq \left(\frac{9}{2}\right)^n L^2_{1,n}\beta^2_n + 2L_{1,n}\alpha_n\beta_n.$$

To bound α_n and β_n, we define, $\eta_n = \max\{\alpha_n, \beta_n\}$. Since $L_{2,n} < 4L_{1,n}$, after some rearranging, we get

$$\alpha_{n+1} \leq 64 L_{1,n} \left(1 + \left(\frac{9}{2}\right)^n L_{1,n}\right)^2 \eta_n^2,$$
$$\beta_{n+1} \leq \left(\left(\frac{9}{2}\right)^n L_{1,n}^2 + 2L_{1,n}\right) \eta_n^2.$$

Since we can assume $c \leq 1$ without adding any additional constraint on the small divisors, we have $L_{1,n} > 1$. Hence

$$\eta_{n+1} < 128 \left(\frac{9}{2}\right)^n L_{1,n}^3 \eta_n^2.$$

It is immediate to check that there exists $\overline{\gamma}$ (depending on γ_0, r, β_0, c, ν_0, and z) such that

$$128 \left(\frac{9}{2}\right)^n L_{1,n}^3 < (\overline{\gamma} z^n)^{\overline{\gamma} z^n} \quad \forall n \geq 0.$$

Using Lemma 2.14, we have $\eta_n \leq M_1^{2^n}$, where $M_1 = (\overline{\gamma} z^{\frac{z}{2-z}})^{\frac{\overline{\gamma}}{2-z}} \eta_0$. With this, we have proved that

$$\|Q_n\|_{\rho_n} \leq M_1^{2^n}, \qquad \|g_n\|_{\rho_n} \leq M_1^{2^n}.$$

Note that this bound allows us to ensure that if $\varepsilon < \varepsilon_1 = M_1^{-1}$, then

$$\lim_{n \to \infty} \varepsilon^{2^n} \|Q_n\|_{\rho_n} = \lim_{n \to \infty} \varepsilon^{2^n} \|g_n\|_{\rho_n} = 0.$$

The next step is to bound $\|P_n\|_{\rho_{n+1}}$. For this purpose, we first use Lemma 2.13 and then Lemma 2.12 to obtain

$$\|P_n\|_{\rho_{n+1}} \leq 2L_{2,n}(\|Q_n\|_{\rho_n} + K_n L_{1,n} \|g_n\|_{\rho_n}) \leq 4 \left(\frac{9}{2}\right)^n L_{1,n} L_{2,n} \eta_n.$$

Now it is not difficult to prove that $L_{1,n} \leq M_2^{2^n}$ and $L_{2,n} \leq M_2^{2^n}$ for a suitable constant M_2. (This is easily shown by taking logarithms.) Hence we can derive

$$\|P_n\|_{\rho_{n+1}} \leq M_3^{2^n}$$

for a suitable constant M_3. This means that if $\varepsilon < \varepsilon_1 = \min\{M_1^{-1}, M_3^{-1}\}$, we have

$$\lim_{n \to \infty} \varepsilon^{2^n} \|P_n\|_{\rho_{n+1}} = 0.$$

This allows the condition $\varepsilon^{2^n} \|P_n\|_{\rho_{n+1}} < \frac{1}{2}$ without reducing the value of ε at each step. Now we will bound $\|\underline{x}_n\|_{\sigma_n}$ as

$$\|\underline{x}_n\|_{\sigma_n} \leq \varepsilon^{2^n} L_{1,n} \|g_n\|_{\rho_n} < \varepsilon^{2^n} M_4^{2^n}$$

for a suitable M_4. When the changes of coordinates have been bounded, we can estimate the decrease of the radius τ_n of the ball where h_n is analytic with respect to x. It has been shown that

$$\tau_{n+1} = \frac{\widehat{\tau}_n}{1 + \varepsilon^{2^n} \|P_n\|_{\rho_{n+1}}} = \frac{1}{1 + \varepsilon^{2^n} \|P_n\|_{\rho_{n+1}}} \tau_n - \frac{\|\underline{x}_n\|_{\rho_n}}{1 + \varepsilon^{2^n} \|P_n\|_{\rho_{n+1}}}.$$

Now we define

$$a_n = \frac{1}{1+\varepsilon^{2^n}\|P_n\|_{\rho_{n+1}}}, \qquad b_n = \frac{\|\underline{x}_n\|_{\rho_n}}{1+\varepsilon^{2^n}\|P_n\|_{\rho_{n+1}}}.$$

It is easy to prove that $\prod_{n=0}^{\infty} a_n$ converges by

$$\left|\ln \prod_{n=0}^{N} a_n\right| \le \sum_{n=0}^{N} |\ln a_n| < \sum_{n=0}^{N} \varepsilon^{2^n}\|P_n\|_{\rho_{n+1}} < \infty \quad \forall N \in \mathbb{N}.$$

Because $\sum b_n$ is also convergent, we can apply Lemma 2.15 to get $r_\infty \ge a r_0 - b$, which is positive if ε is taken small enough.

Now let us bound $\|A_n\|$ as

$$\begin{aligned}\|A_{n+1}\| &\le \|\widehat{A}_n\| + \varepsilon^{2^n}\frac{\|P_n\|_{\rho_{n+1}}}{1-\varepsilon^{2^n}\|P_n\|_{\rho_{n+1}}} \\ &\le \|\widehat{A}_n\| + \varepsilon^{2^n}\|Q_n\|_{\rho_n} + \varepsilon^{2^n}\frac{\|P_n\|_{\rho_{n+1}}}{1-\varepsilon^{2^n}\|P_n\|_{\rho_{n+1}}}.\end{aligned}$$

Using the bounds found above we can write that

$$\|A_{n+1}\| \le \|A_n\| + \kappa_n,$$

where $\kappa_n \le \varepsilon^{2^n} M_5^{2^n}$ for a suitable M_5. Because $\sum \kappa_n$ is convergent we can ensure that if ε is selected small enough, the matrices A_n are always inside the ball $B_\alpha(A_0)$ defined before.

Now consider the value K_n. Above we have used the pessimistic bound $K_n \le (\frac{9}{2})^n K_0$. Note that this bound does not allow us to guarantee the convergence of the functions $h_n(x_n, t)$ to an analytic function $h_\infty(x_\infty, t)$ with respect to x. Now we can use a more accurate bound of that value to get this. From Lemma 2.13, we know that

$$K_{n+1} \le K_n \frac{(1+\varepsilon^{2^n}\|P_n\|_{\rho_{n+1}})^2}{1-\varepsilon^{2^n}\|P_n\|_{\rho_{n+1}}};$$

by means of the inequality $\frac{1}{1-x} \le 1 + 2x$ if $0 \le x \le \frac{1}{2}$, we get

$$K_{n+1} \le \left(1 + 2\varepsilon^{2^n}\|P_n\|_{\rho_{n+1}}\right)^3 K_n.$$

And, using the bounds of $\|P_n\|_{\rho_{n+1}}$ that we already know, it is easy to see that the (bound of the) value K_n converges.

Hence we have obtained the convergence proof for all $|\varepsilon| < \varepsilon_0$ for a suitable ε_0 without taking into account the "bad set" of values of ε for which the diophantine conditions at some step n are not satisfied.

2.8. Lipschitz lemmas. In this section, we present the lemmas needed to show that at each step of the inductive process, the dependence on ε of the eigenvalues of the matrix A_n is Lipschitz.

LEMMA 2.16. *Let $f : [-\varepsilon, \varepsilon] \to \mathbb{C}$ be a Lipschitz function from above (with constant L) and from below (with constant l), that is,*

$$|f(x) - f(y)| \le L|x-y|, \qquad |f(x) - f(y)| \ge l|x-y|.$$

Let $g : [-\varepsilon, \varepsilon] \to \mathbb{C}$ be another Lipschitz function from above with constant $\alpha < l$, that is,

$$|g(x) - g(y)| \leq \alpha|x - y|.$$

Then $h = f + g$ is Lipschitz from above with constant $L + \alpha$ and from below with constant $l - \alpha$, that is,

$$|h(x) - h(y)| \leq (L + \alpha)|x - y|, \qquad |h(x) - h(y)| \geq (l - \alpha)|x - y|.$$

Proof. The proof is elementary. □

Remark. Henceforth, all Lipschitz functions appearing in the text will be Lipschitz from above unless otherwise stated. Moreover, we will sometimes use $\mathcal{L}(f)$ to denote the Lipschitz constant (always with respect to ε) of a Lipschitz function f. The set on which this constant is taken should be clear from the context. For instance, if $f(t, \varepsilon)$ is known to be defined for $|\text{Im } t| \leq \rho$ and $\varepsilon \in E \subset \mathbb{R}$ and is Lipschitz with respect to ε in E, then $|f(t, \varepsilon_2) - f(t, \varepsilon_1)| \leq \mathcal{L}(f)|\varepsilon_2 - \varepsilon_1|$ for all t, ε_1, and ε_2 in the allowed domain.

In what follows, we shall denote by $\overline{\mathbb{N}}$ the set of nonnegative integers, that is, $\mathbb{N} \cup \{0\}$.

LEMMA 2.17. *Let us define*

$$f(z, \varepsilon) = \sum_{|k| \geq 2} a_k(\varepsilon) z^k, \quad k \in \overline{\mathbb{N}}^d,$$

and assume that the sum is convergent $\forall z \in D = D_1 \times \cdots \times D_d \subset \mathbb{C}^d$, where D_j are fixed disks of $\mathbb{C}$. Moreover, we suppose that f depends on ε in a Lipschitz way with Lipschitz constant L. Let us take $\widehat{D} \subset D$ such that $\widehat{D} = \widehat{D}_1 \times \cdots \times \widehat{D}_d$ and satisfying $\text{radius}(\widehat{D}_j) \leq \alpha \, \text{radius}(D_j) = \alpha r_j$, $0 < \alpha < 1$. *Then if $z \in \widehat{D}$, it holds that*

1. $|f(z, \varepsilon_1) - f(z, \varepsilon_2)| \leq K_2(\alpha) L |\varepsilon_1 - \varepsilon_2| \alpha^2$,
2. $\|D_z f(z, \varepsilon_1) - D_z f(z, \varepsilon_2)\| \leq K_1(\alpha) L |\varepsilon_1 - \varepsilon_2| \alpha$,

where both $K_i(\alpha)$, $i = 1, 2$, defined for $\alpha < 1$, are continuous and increasing functions.

Proof Let $\partial_0 D$ be $\partial D_1 \times \cdots \times \partial D_d$, where ∂ stands for the boundary of the corresponding sets. Since

$$a_k(\varepsilon) = \frac{1}{(2\pi\sqrt{-1})^d} \int_{\partial_0 D} \frac{f(z, \varepsilon)}{z_1^{k_1+1} \cdots z_d^{k_d+1}} \, dz_1 \cdots dz_d,$$

we have that

$$\begin{aligned} |a_k(\varepsilon_1) - a_k(\varepsilon_2)| &\leq \frac{1}{(2\pi)^d} \int_{\partial_0 D} \frac{|f(z, \varepsilon_1) - f(z, \varepsilon_2)|}{|z_1|^{k_1+1} \cdots |z_d|^{k_d+1}} |dz_1 \cdots dz_d| \\ &\leq \frac{L|\varepsilon_1 - \varepsilon_2|}{(2\pi)^d} \int_{\partial_0 D} \frac{|dz_1| \cdots |dz_d|}{r_1^{k_1+1} \cdots r_d^{k_d+1}} = \frac{L}{r^k} |\varepsilon_1 - \varepsilon_2|. \end{aligned}$$

On the other hand,

$$\begin{aligned} |f(z, \varepsilon_1) - f(z, \varepsilon_2)| &\leq \sum_{|k| \geq 2} |a_k(\varepsilon_1) - a_k(\varepsilon_2)| |z^k| \\ &\leq L|\varepsilon_1 - \varepsilon_2| \sum_{|k| \geq 2} \frac{|z_1|^{k_1} \cdots |z_d|^{k_d}}{r_1^{k_1} \cdots r_d^{k_d}} = (\diamond). \end{aligned}$$

Now, using $z \in \widehat{D}$ (that is, $|z_j| \leq \alpha r_j$) and $\#\{k \in \overline{\mathbb{N}}^d \;/\; |k| = m\} \leq dm^{d-1}$ if $m \geq 1$ (which can be obtained by induction with respect to d), we obtain

$$(\diamond) \leq L|\varepsilon_1 - \varepsilon_2| \sum_{|k|\geq 2} \alpha^{|k|} \leq L|\varepsilon_1 - \varepsilon_2| \sum_{m=2}^{\infty} dm^{d-1}\alpha^m = K_2(\alpha)L|\varepsilon_1 - \varepsilon_2|\alpha^2,$$

where $K_2(\alpha) = d\sum_{m=2}^{\infty} m^{d-1}\alpha^{m-2}$. Finally, it is not difficult to see that $K_2(\alpha)$ is convergent if $|\alpha| < 1$. This completes the proof of 1.

Since

$$\frac{\partial f}{\partial z_j}(z, \varepsilon) = \sum_{|k|\geq 2} k_j a_k(\varepsilon) z^{k-e_j},$$

we can proceed in the same way as before, that is,

$$\begin{aligned}
\left| \frac{\partial f}{\partial z_j}(z, \varepsilon_1) - \frac{\partial f}{\partial z_j}(z, \varepsilon_2) \right| &\leq \sum_{|k|\geq 2} k_j |a_k(\varepsilon_1) - a_k(\varepsilon_2)||z|^{k-e_j} \\
&\leq \sum_{|k|\geq 2} k_j \frac{L}{r^k} |\varepsilon_1 - \varepsilon_2||z|^{k-e_j} \leq \frac{L|\varepsilon_1 - \varepsilon_2|}{r_j} \sum_{|k|\geq 2} k_j \alpha^{k-e_j} \\
&\leq \frac{L|\varepsilon_1 - \varepsilon_2|}{r_j} \sum_{m=2}^{\infty} dm^d \alpha^{m-1} \leq K_1(\alpha)L|\varepsilon_1 - \varepsilon_2|\alpha,
\end{aligned}$$

where $K_1(\alpha) = \frac{d}{r_\infty} \sum_{m=2}^{\infty} m^d \alpha^{m-2}$ and r_∞ is a lower bound of the values r_j (see §2.7). Here, we note that $K_1(\alpha)$ is convergent if $|\alpha| < 1$. To complete the proof, we only need to take the sup norm of the vector of components

$$\frac{\partial f}{\partial z_j}(z, \varepsilon_1) - \frac{\partial f}{\partial z_j}(z, \varepsilon_2). \qquad \square$$

LEMMA 2.18. *Let us suppose that $P(t, \varepsilon)$ is a matrix depending on ε in a Lipschitz way with constant L. If $\|P\| \leq \frac{1}{2}$, then $(I + P(t, \varepsilon))^{-1}$ is Lipschitz with respect to ε with constant $4L$.*

Proof. It is known that

$$(I + P)^{-1} = I - P + P^2 - P^3 + \cdots,$$

and then it is easy to see that

$$\begin{aligned}
\mathcal{L}((I + P)^{-1}) &\leq \mathcal{L}(P) + \mathcal{L}(P^2) + \mathcal{L}(P^3) + \cdots \leq \sum_{n=1}^{\infty} \left[n\|P\|^{n-1}L \right] \\
&= \frac{1}{(1 - \|P\|)^2} L \leq 4L. \qquad \square
\end{aligned}$$

LEMMA 2.19. *Let $q(t, \varepsilon)$ be an analytic quasi-periodic function on a strip of width ρ_1. We write*

$$q(t, \varepsilon) = \sum_{k \in \mathbb{Z}^r} q^k(\varepsilon) e^{(k,\omega)\sqrt{-1}t},$$

and we assume that all the coefficients $q^k(\varepsilon)$ depend on ε in a Lipschitz way with constant L_k. Moreover, we suppose that $L_k \leq L|k|^\alpha e^{-\rho_1|k|}$ if $k \neq 0$, where L is a positive constant. Let us take $\rho_2 \in]0, \rho_1[$. Then if $q(t,\varepsilon)$ is restricted to a strip of width ρ_2, it depends on ε in a Lipschitz way with constant

$$L' = L_0 + L\frac{20r}{3\delta^{r+\alpha}}\chi(r+\alpha),$$

where $L_0 = L_{k=0}$, $\delta = \rho_1 - \rho_2$, and χ is as defined in Lemma 2.6.

Proof.

$$\begin{aligned} |q(t,\varepsilon_1) - q(t,\varepsilon_2)| &\leq \sum_{k\in\mathbb{Z}^r} |q^k(\varepsilon_1) - q^k(\varepsilon_2)||e^{(k,\omega)\sqrt{-1}t}| \\ &\leq \left[L_0 + L\sum_{k\neq 0} |k|^\alpha e^{-\delta|k|} \right] |\varepsilon_1 - \varepsilon_2|. \end{aligned}$$

Here we can apply Lemma 2.6 to obtain the desired result. □

LEMMA 2.20. *Let $q(t,\varepsilon)$ be an analytic quasi-periodic function on a strip of width ρ,*

$$q(t,\varepsilon) = \sum_{k\in\mathbb{Z}^r} q^k(\varepsilon) e^{(k,\omega)\sqrt{-1}t}.$$

Let us assume that $q(t,\varepsilon)$ depends on ε in a Lipschitz way with constant L. Then the coefficients $q^k(\varepsilon)$ depend on ε in a Lipschitz way since

$$|q^k(\varepsilon_1) - q^k(\varepsilon_2)| \leq L_k|\varepsilon_1 - \varepsilon_2|,$$

where $L_k = Le^{-\rho|k|}$.

Proof. Let us fix ε_1 and ε_2 and define $p(t) = q(t,\varepsilon_1) - q(t,\varepsilon_2)$. Since $\|p\|_\rho \leq L|\varepsilon_1 - \varepsilon_2|$, the Fourier coefficients of p satisfy

$$|p^k| \leq L|\varepsilon_1 - \varepsilon_2|e^{-\rho|k|},$$

and using the fact that $|p^k| = |q^k(\varepsilon_1) - q^k(\varepsilon_2)|$, the result follows. □

LEMMA 2.21. *Let us define*

$$f(\varepsilon) = \frac{g(\varepsilon)}{\sigma - \lambda(\varepsilon)},$$

where $|\sigma - \lambda(\varepsilon)| \geq u$ and g and λ are Lipschitz functions with constants L_g and L_λ, respectively. Then f is Lipschitz with constant

$$L_f = \frac{L_g}{u} + \|g\|_\infty \frac{L_\lambda}{u^2}.$$

Proof. The proof is straightforward. □

LEMMA 2.22. *Let A_0 be a $d \times d$ matrix such that* $\operatorname{Spec}(A_0) = \{\lambda_1^0, \ldots, \lambda_d^0\}$, *$|\lambda_i^0| > 2\mu$, $|\lambda_i^0 - \lambda_j^0| > 2\mu$, $i \neq j$, where $\mu > 0$. Let $A(\varepsilon)$ be a matrix-valued function such that $\|A(\varepsilon) - A_0\| < \alpha$ if $|\varepsilon| < \varepsilon_0$ and dependent on ε in a Lipschitz way, with constant L_A.*

Let $B(\varepsilon)$ be the change of variables that diagonalizes $A(\varepsilon)$ (see Lemma 2.9). Then there exist $\tau_1 = \tau_1(A_0, \alpha, \beta)$ and $\tau_2 = \tau_2(A_0, \alpha, \beta)$ such that

$$\begin{aligned} \|B(\varepsilon_1) - B(\varepsilon_2)\| &\le \tau_1 L_A |\varepsilon_1 - \varepsilon_2|, \\ \|B^{-1}(\varepsilon_1) - B^{-1}(\varepsilon_2)\| &\le \tau_1 L_A |\varepsilon_1 - \varepsilon_2|, \\ |\lambda_j(\varepsilon_1) - \lambda_j(\varepsilon_2)| &\le \tau_2 L_A |\varepsilon_1 - \varepsilon_2|, \end{aligned}$$

where $\lambda_j(\varepsilon)$ are the eigenvalues of $A(\varepsilon)$ and the definition of values α and β can be found in Lemma 2.9.

Proof. This result is essentially contained in [19, pp. 66–67], but for an analytic dependence on ε. The result for a Lipschitz dependence on ε can be obtained as follows.

1. Let us consider the matrix A as a function of all its elements a_{ij}. This implies that if the elements are close enough to those of A_0, the eigenvalues and eigenvectors depend on a_{ij} in an analytic way. Hence in any compact set inside the domain of analyticity, they also depend in a Lipschitz way.

2. The elements $a_{ij}(\varepsilon)$ of $A(\varepsilon)$ also depend on ε in Lipschitz way with the same constant since

$$\begin{aligned} |a_{ij}(\varepsilon_1) - a_{ij}(\varepsilon_2)| &\le \max_{1 \le i \le n} \sum_{j=1}^{n} |a_{ij}(\varepsilon_1) - a_{ij}(\varepsilon_2)| \\ &= \|A(\varepsilon_1) - A(\varepsilon_2)\| \le L|\varepsilon_1 - \varepsilon_2|. \end{aligned}$$

3. Finally, we compose the Lipschitz dependence (of the eigenvalues and eigenvectors) on a_{ij} with the Lipschitz dependence of a_{ij} on ε. □

LEMMA 2.23. *Let us consider the equation*

$$\dot{x} = A(\varepsilon)x + g(t, \varepsilon)$$

under the same hypothesis as in Lemma 2.10. Let ρ_2 be such that $0 < \rho_2 < \rho_1 - 2\nu$ and $\delta = \rho_1 - \rho_2 - 2\nu \le 1$. Moreover, we assume that $A(\varepsilon)$ and $g(t, \varepsilon)$ depend on ε in a Lipschitz way with constants L_A and L_g, respectively. Then the solution $x(t, \varepsilon)$ of this equation (see Lemma 2.10) depends on ε in a Lipschitz way for t belonging to the strip of width ρ_2 with constant

$$L_x \le \frac{\chi(r + 2\gamma)}{\delta^{r+2\gamma}} (E_1 L_A \|g\|_{\rho_1} + E_2 L_g),$$

where E_1 and E_2 are positive constants that do not depend on the actual step of the inductive process of §2.7.

Proof. First of all, let us make the change of variables $x = B(\varepsilon)y$ (the matrix $B(\varepsilon)$ is given by Lemma 2.22) in order to diagonalize the matrix $A(\varepsilon)$. With this, the equation becomes

$$\dot{y} = D(\varepsilon)y + h(t, \varepsilon),$$

where $D(\varepsilon)$ is a diagonal matrix and $h(t, \varepsilon) = B^{-1}(\varepsilon)g(t, \varepsilon)$. Lemma 2.22 ensures that $L_D \equiv \mathcal{L}(D) \equiv \max_i L_{\lambda_i} = \tau_2 L_A$ and $L_h \equiv \mathcal{L}(h) = \tau_1 L_A \|g\|_{\rho_1} + \beta L_g$. Moreover, since

$$h(t, \varepsilon) = \sum_{k \in \mathbb{Z}^r} h^k(\varepsilon) e^{(k,\omega)\sqrt{-1}t},$$

we have by Lemma 2.20 that $L_{h^k} \equiv \mathcal{L}(h^k) = L_h e^{-\rho_1|k|}$.

As shown in Lemma 2.10, the solution in which we are interested is given by

$$y_i^k(\varepsilon) = \frac{h_i^k(\varepsilon)}{(k,\omega)\sqrt{-1} - \lambda_i(\varepsilon)}.$$

Now let us compute $L_{y_i^k} \equiv \mathcal{L}(y_i^k)$. We distinguish two cases and use Lemma 2.21 in both.

Case 1: $k = 0$.

$$\begin{aligned} L_{y_i^0} &= \frac{L_{h^0}}{\mu} + |h^0|\frac{L_{\lambda_i}}{\mu^2} \le \frac{\tau_1 L_A\|g\|_{\rho_1} + \beta L_g}{\mu} + \|g\|_{\rho_1}\beta\frac{\tau_2 L_A}{\mu^2} \\ &= \left(\frac{\tau_1}{\mu} + \frac{2\beta_0\tau_2}{\mu^2}\right) L_A\|g\|_{\rho_1} + \frac{2\beta_0}{\mu}L_g \equiv C_1 L_A\|g\|_{\rho_1} + C_2 L_g, \end{aligned}$$

where μ has been defined in Lemma 2.9 and C_1 and C_2 do not depend on the step of the iterative process.

Case 2: $k \neq 0$.

$$\begin{aligned} L_{y_i^k} &= \frac{L_{h^k}}{\frac{c}{|k|^\gamma}e^{-\nu|k|}} + |h^k|\frac{L_{\lambda_i}}{\left(\frac{c}{|k|^\gamma}e^{-\nu|k|}\right)^2} \\ &\le \frac{|k|^\gamma e^{\nu|k|}}{c} L_h e^{-\rho_1|k|} + \frac{|k|^{2\gamma}e^{2\nu|k|}}{c^2}\|h\|_{\rho_1} e^{-\rho_1}\tau_2 L_A \\ &\le |k|^{2\gamma} e^{-(\rho_1 - 2\nu)|k|}\left[\frac{\tau_1}{c}\|g\|_{\rho_1} L_A + \frac{\beta}{c}L_g + \frac{\beta\tau_2}{c^2}\|g\|_{\rho_1} L_A\right] \\ &\equiv |k|^{2\gamma} e^{-(\rho_1 - 2\nu)|k|}\left[C_3\|g\|_{\rho_1} L_A + C_4 L_g\right], \end{aligned}$$

where now C_3 and C_4 do not depend on the step of the iterative process.

Now we can apply this to bound the Lipschitz constant L_y corresponding to $y(t,\varepsilon) = \sum_k y_i^k(\varepsilon)e^{(k,\omega)\sqrt{-1}t}$. From Lemma 2.19, we obtain

$$L_y = C_1 L_A\|g\|_{\rho_1} + C_2 L_g + (C_3 L_A\|g\|_{\rho_1} + C_4 L_g)\frac{20r}{3\delta^{r+2\gamma}}\chi(r+2\gamma),$$

where $0 < \rho_2 < \rho_1 - 2\nu$ such that $\delta = \rho_1 - \rho_2 - 2\nu \le 1$. To simplify the following steps, we note that

$$L_y \le \frac{\chi(r+2\gamma)}{\delta^{r+2\gamma}}(C_5 L_A\|g\|_{\rho_1} + C_6 L_g)$$

for suitable constants C_5 and C_6, both independent on the actual step of the inductive process.

Since $x = B(\varepsilon)y$, we have $L_x \equiv \mathcal{L}(x) \le \tau_1 L_A\|y\|_{\rho_2} + \beta L_y$, which allows us (using the bound on $\|y\|_{\rho_2}$ given inside the proof of Lemma 2.10) to establish the bound

$$L_x \le \tau_1 L_A\left[\frac{1}{\mu} + \frac{20r\chi(r+\gamma)}{3c\delta^{r+\gamma}}\right]\beta\|g\|_{\rho_1} + \beta\frac{\chi(r+2\gamma)}{\delta^{r+2\gamma}}(C_5 L_A\|g\|_{\rho_1} + C_6 L_g).$$

This can easily be rearranged to

$$L_x \le \frac{\chi(r+2\gamma)}{\delta^{r+2\gamma}}(E_1 L_A\|g\|_{\rho_1} + E_2 L_g),$$

where E_1 and E_2 are suitable constants not dependent on the actual step of the inductive process. □

2.9. Measure lemma. Here we give the basic lemma used to bound the measure of the resonances.

LEMMA 2.24. *Let $\omega \in \mathbb{R}^r$ and $v \in \sqrt{-1}\mathbb{R}$ such that*

$$|v - \sqrt{-1}(k,\omega)| \geq \frac{2c}{|k|^{\gamma_0}}$$

for all $k \in \mathbb{Z}^r \setminus \{0\}$, where $c > 0$ and $\gamma_0 > 0$. We define the nth resonant subset $\mathcal{R}_\mu^{(n)} = \mathcal{R}_\mu^{(n)}(v)$ as

$$\mathcal{R}_\mu^{(n)} = \Big\{\varphi \in \sqrt{-1}\mathbb{R},\ |\varphi| < \mu \ / \ \exists k' \in \mathbb{Z}^r \setminus \{0\}$$

$$\text{such that } |\varphi + v - \sqrt{-1}(k',\omega)| < \frac{c}{|k'|^{\gamma_n}} e^{-\nu_n |k'|}\Big\},$$

where $\nu_n = \frac{\nu_0}{(n+1)^2}$, $0 < \nu_0 < \frac{1}{4}$, $\gamma_n = \gamma_0 z^n$, $1 < z < 2$, and $\gamma_0 \geq r - 1$. Let $\mathcal{R}_\mu = \cup_{n\geq 0}\mathcal{R}_\mu^{(n)}$ and $\psi(\mu) = \frac{m(\mathcal{R}_\mu)}{2\mu}$, where m denotes the Lebesgue measure. Then $\psi(\mu) \leq \exp(-c_1/\mu^{c_2})$ for some positive constants c_1 and c_2, where $c_2 < \frac{1}{\gamma_0}$, provided μ is small enough.

Proof. Let k' and φ be such that

$$|\varphi + v - \sqrt{-1}(k',\omega)| < \frac{c}{|k'|^{\gamma_n}} e^{-\nu_n |k'|}.$$

Since

$$|v - \sqrt{-1}(k',\omega)| \geq \frac{2c}{|k'|^{\gamma_0}},$$

we have

$$\mu > |\varphi| > \frac{2c}{|k'|^{\gamma_0}} - \frac{c}{|k'|^{\gamma_n} \exp(\nu_n |k'|)} > \frac{c}{|k'|^{\gamma_0}},$$

and hence $|k'| \geq \lceil (\frac{c}{\mu})^{1/\gamma_0} \rceil \equiv M(\mu)$, where for $\alpha \in \mathbb{R}$, $\lceil \alpha \rceil$ denotes the lowest integer greater than or equal to α. Now let us add for all $|k'| \geq M(\mu)$ and all $n \geq 0$ to have an upper bound on $m(\mathcal{R}_\mu)$. Adding for all $|k'| \geq M(\mu)$ and for a fixed n, we obtain

$$\sum_{|k'| \geq M(\mu)} \frac{2c}{|k'|^{\gamma_n} \exp(\nu_n |k'|)} 2c \sum_{j \geq M(\mu)} \frac{2rj^{r-1}}{j^{\gamma_n}} e^{-\nu_n j}$$

$$< 4crM(\mu)^{r-1-\gamma_n} \frac{e^{-\nu_n M(\mu)}}{1 - e^{-\nu_n}} < \frac{5cr}{\nu_0} M(\mu)^{r-1-\gamma_n} (n+1)^2 e^{-\nu_n M(\mu)}$$

because $r - 1 - \gamma_n \leq 0$ and $1 - e^{-\alpha} > 0.8\alpha$ if $0 \leq \alpha \leq \frac{1}{4}$. Adding for all n, we have

$$m(\mathcal{R}_\mu) \leq \frac{5cr}{\nu_0} M(\mu)^{r-1} \sum_{n\geq 0} (n+1)^2 M(\mu)^{-\gamma_0 z^n} \exp\left(-\frac{\nu_0}{(n+1)^2} M(\mu)\right).$$

For our purposes, a rough bound is enough. Let $n_* = \log(\nu_0 M(\mu))/\log z$. We split $\sum_{n\geq 0}$ as $\sum_{n=0}^{n_*} + \sum_{n > n_*}$ and assume μ small enough so that

$$\frac{(n+2)^2 M(\mu)^{-\gamma_0 z^{n+1}}}{(n+1)^2 M(\mu)^{-\gamma_0 z^n}} \leq \frac{1}{2} \quad \forall n \geq 0.$$

Then

$$\sum_{n\geq 0}(n+1)^2 M(\mu)^{-\gamma_0 z^n}\exp\left(-\frac{\nu_0}{(n+1)^2}M(\mu)\right)$$
$$\leq 2M(\mu)^{-\gamma_0}\exp\left(-\frac{\nu_0}{(n_*+1)^2}M(\mu)\right)+(n_*+1)^2 M(\mu)^{-\gamma_0 z^{n_*}}.$$

To finish the proof, after selecting any value of c_1 and $c_2 < \frac{1}{\gamma_0}$, we want to show that each term is less than $\frac{1}{2}\exp(-\frac{c_1}{\mu^{c_2}})$. To this end, we take logarithms. We have to prove

$$\log A - \log\left(\frac{c}{\mu}\right) - \frac{\nu_0}{\left[\frac{\log\left(\nu_0\left(\frac{c}{\mu}\right)^{\frac{1}{\gamma_0}}\right)}{\log z}+1\right]^2}\left(\frac{c}{\mu}\right)^{\frac{1}{\gamma_0}} < -\log 4 - \frac{c_1}{\mu^{c_2}},$$

$$\log A + 2\log\left[\frac{\log\left(\nu_0\left(\frac{c}{\mu}\right)^{\frac{1}{\gamma_0}}\right)}{\log z}+1\right] - \nu_0\left(\frac{c}{\mu}\right)^{\frac{1}{\gamma_0}}\log\left(\frac{c}{\mu}\right) < -\log 2 - \frac{c_1}{\mu^{c_2}},$$

where $A = \frac{5cr}{\nu_0}(\frac{c}{\mu})^{(r-1)/\gamma_0}$. Both inequalities are true if μ is small enough or, equivalently, for μ in a fixed range if c_1 is big enough. □

2.10. Proof of Theorem 2.1 (part II). Thus far, we have shown the convergence of the iterative scheme provided that some nonresonance conditions hold at each step n (see §2.7). Now our purpose is to show that all the matrices $A_n(\varepsilon)$ are Lipschitz (with respect to ε) from above and below and that their Lipschitz constants are bounded (from above and below, respectively) by constants that do not depend on n. As we shall see later, this allows us to take out a dense set (with small relative measure) of values of ε for which the resonance conditions assumed during §2.7 might not hold at some step (i.e., for some n) of the proof.

To prove that $A_n(\varepsilon)$ is Lipschitz from below, we shall proceed in the following way. Since $A_0(\varepsilon)$ is Lipschitz from above and below (by hypothesis), it is enough to show that $A_n(\varepsilon)$ is Lipschitz from above and $\mathcal{L}(A_0) - \mathcal{L}(A_n) = \mathcal{O}(\varepsilon)$ since Lemma 2.16 implies that if ε is sufficiently small, $A_n(\varepsilon)$ is also Lipschitz from below. For this reason, we will focus on Lipschitz constants from above, which for simplicity will simply be called Lipschitz constants. The notation used will be

$$\mathcal{L}(A_n(\varepsilon)) = L_{A_n}, \quad \mathcal{L}(\widehat{A}_n(\varepsilon)) = L_{\widehat{A}_n}, \quad \mathcal{L}(\varepsilon^{2^n}Q_n(t,\varepsilon)) = L_{Q_n},$$
$$\mathcal{L}(\varepsilon^{2^n}\widehat{Q}_n(t,\varepsilon)) = L_{\widehat{Q}_n}, \quad \mathcal{L}(\varepsilon^{2^n}g_n(t,\varepsilon)) = L_{g_n}, \quad \mathcal{L}(\varepsilon^{2^n}\widehat{g}_n(t,\varepsilon)) = L_{\widehat{g}_n},$$
$$\mathcal{L}(\varepsilon^{2^n}P_n(t,\varepsilon)) = L_{P_n}, \quad \mathcal{L}(h_n(x,t,\varepsilon)) = L_{h_n}, \quad \mathcal{L}(\widehat{h}_n(x,t,\varepsilon)) = L_{\widehat{h}_n}.$$

Our purpose now is to bound the Lipschitz constants of the equation terms at step $n+1$ as a function of the Lipschitz constants at step n. Let us assume that the scheme of §2.7 has been applied up to step n. Then the following bounds can be established:

$$\|\widehat{Q}_n\|_{\sigma_n} \leq N_1^{2^n},$$
$$\|P_n\|_{\rho_{n+1}} \leq N_1^{2^n},$$

$$\|\underline{x}_n\|_{\sigma_n} \leq (\varepsilon_0 N_1)^{2^n},$$
$$\|\widehat{g}_n\|_{\sigma_n} \leq N_1^{2^{n+1}},$$

where N_1 is a positive constant and ε_0 is as defined at the end of §2.7 and is also assumed to satisfy $\varepsilon_0 N_1 < 1$. Using the bounds given in §2.7, the proofs are not difficult.

We shall also use the bounds $\|Q_n\|_{\rho_n} \leq N_1^{2^n}$ and $\|g_n\|_{\rho_n} \leq N_1^{2^n}$ (see §2.7) when needed. The constant N_1 can be easily obtained from the constants M_i, $i = 1, \ldots, 4$, introduced in §2.7.

Now let us bound $L_{Q_{n+1}}$. It is easy to obtain

$$\varepsilon^{2^{n+1}} Q_{n+1} = (I + \varepsilon^{2^n} P_n(t,\varepsilon))^{-1} (\varepsilon^{2^n} \widehat{Q}_n(t,\varepsilon))(\varepsilon^{2^n} P_n(t,\varepsilon)),$$

and this implies

$$\begin{aligned} L_{Q_{n+1}} \leq\ & 4L_{P_n} \varepsilon_0^{2^n} \|\widehat{Q}_n\|_{\sigma_n} \varepsilon_0^{2^n} \|P_n\|_{\rho_{n+1}} + \|(I + \varepsilon^{2^n} P_n)^{-1}\|_{\rho_{n+1}} L_{\widehat{Q}_n} \varepsilon_0^{2^n} \|P_n\|_{\rho_{n+1}} \\ & + \|(I + \varepsilon^{2^n} P_n)^{-1}\|_{\rho_{n+1}} \varepsilon_0^{2^n} \|\widehat{Q}_n\|_{\sigma_n} L_{P_n}. \end{aligned}$$

Using the fact that $\|(I + \varepsilon^{2^n} P_n)^{-1}\|_{\rho_{n+1}} \leq 2$ (see §2.7), we obtain

$$\begin{aligned} L_{Q_{n+1}} &\leq 4L_{P_n} (\varepsilon_0 N_1)^{2^n} (\varepsilon_0 N_1)^{2^n} + 2L_{\widehat{Q}_n} (\varepsilon_0 N_1)^{2^n} + 2(\varepsilon_0 N_1)^{2^n} L_{P_n} \\ &< 6(\varepsilon_0 N_1)^{2^n} L_{P_n} + 2(\varepsilon_0 N_1)^{2^n} L_{\widehat{Q}_n}. \end{aligned}$$

Now we consider $L_{\underline{x}_n}$. From Lemma 2.23, it is not difficult to obtain

$$L_{\underline{x}_n} \leq \frac{\chi(r + 2\gamma_n)}{\delta_n^{r+2\gamma_n}} (E_1 L_{A_n} \varepsilon_0^{2^n} \|g_n\|_{\rho_n} + E_2 L_{g_n}),$$

where δ_n is now $\frac{1/2 - 2\nu_0}{(n+1)^2}$. Introducing $L_{3,n} = \frac{\chi(r+2\gamma_n)}{\delta_n^{r+2\gamma_n}} \max\{E_1, E_2\}$, we can write

$$L_{\underline{x}_n} \leq L_{3,n} \left(L_{A_n} (\varepsilon_0 N_1)^{2^n} + L_{g_n} \right). \tag{17}$$

Let us consider now $L_{\widehat{Q}_n}$. We recall that $\widehat{Q}_n$ was defined as

$$\varepsilon^{2^n} \widehat{Q}_n = \varepsilon^{2^n} Q_n(t,\varepsilon) + D_x h_n(\underline{x}_n(t,\varepsilon), t, \varepsilon).$$

This allows us to write

$$L_{\widehat{Q}_n} \leq L_{Q_n} + \|D_{xx} h_n(\underline{x}_n(t,\varepsilon), t, \varepsilon)\| L_{\underline{x}_n} + \mathcal{L}(D_x h_n(\underline{x}, t, \varepsilon)).$$

Here we can use the fact that $\|D_{xx} h_n(\underline{x}(t,\varepsilon), t, \varepsilon)\| \leq K_\infty$ (see §2.7), Lemma 2.17, and (17) to write

$$L_{\widehat{Q}_n} \leq L_{Q_n} + K_\infty L_{3,n} \left(L_{A_n} (\varepsilon_0 N_1)^{2^n} + L_{g_n} \right) + K_1(\alpha) L_{h_n} (\varepsilon_0 N_1)^{2^n},$$

where $\alpha = \frac{\|\underline{x}_n\|_{\sigma_n}}{r_\infty}$. Moreover, note that α goes to zero when $\|\underline{x}_n\|_{\sigma_n}$ does. This implies that if ε is small enough, we can assume that $K_1(\alpha)$ is less than, for instance, $K_1(\frac{1}{2})$.

Now we focus on L_{P_n}. The definition of P_n is

$$\varepsilon^{2^n}\dot{P}_n(t,\varepsilon) = \widehat{A}_n(\varepsilon^{2^n}P_n(t,\varepsilon)) - (\varepsilon^{2^n}P_n(t,\varepsilon))\widehat{A}_n + \varepsilon^{2^n}\widehat{Q}_n(t,\varepsilon).$$

Since this is a linear system of differential equations, we can apply a lemma that is essentially like Lemma 2.23 but for the actual system of equations and with new constants $\overline{E}_1$ and $\overline{E}_2$ to get

$$\begin{aligned} L_{P_n} &\leq \frac{\chi(r+2\gamma_n)}{\delta_n^{r+2\gamma_n}}\left(\overline{E}_1\|\varepsilon_0^{2^n}\widehat{Q}_n\|_{\sigma_n}L_{A_n} + \overline{E}_2L_{\widehat{Q}_n}\right) \\ &\leq \frac{\chi(r+2\gamma_n)}{\delta_n^{r+2\gamma_n}}\left(\overline{E}_1(\varepsilon_0N_1)^{2^n}L_{\widehat{A}_n} + +\overline{E}_2L_{\widehat{Q}_n}\right) \leq L_{3,n}\left((\varepsilon_0N_1)^{2^n}L_{\widehat{A}_n} + L_{\widehat{Q}_n}\right), \end{aligned}$$

where $L_{3,n}$ has been redefined as $L_{3,n} = \frac{\chi(r+2\gamma_n)}{\delta_n^{r+2\gamma_n}}\max\{E_1, E_2, \overline{E}_1, \overline{E}_2\}$.

Let us consider $L_{g_{n+1}}$. From

$$\varepsilon^{2^{n+1}}g_{n+1}(t,\varepsilon) = (I + \varepsilon^{2^n}P_n(t,\varepsilon))^{-1}(\varepsilon^{2^{n+1}}\widehat{g}_n(t,\varepsilon)),$$

it follows that

$$\begin{aligned} L_{g_{n+1}} &\leq 4L_{P_n}\varepsilon_0^{2^{n+1}}\|\widehat{g}_n\|_{\sigma_n} + \|(I + \varepsilon^{2^n}P_n(t,\varepsilon))^{-1}\|_{\rho_{n+1}}L_{\widehat{g}_n} \\ &\leq 4L_{P_n}(\varepsilon_0N_1)^{2^{n+1}} + 2L_{\widehat{g}_n}. \end{aligned}$$

Now consider now $L_{\widehat{A}_n}$. Since we have

$$\widehat{A}_n(\varepsilon) = A_n(\varepsilon) + \varepsilon^{2^n}\overline{\widehat{Q}}_n(\varepsilon),$$

it follows that

$$L_{\widehat{A}_n} = L_{A_n} + L_{\widehat{Q}_n}.$$

Moreover, since $A_{n+1} = \widehat{A}_n$, we also have

$$L_{A_{n+1}} = L_{\widehat{A}_n}.$$

Now let us bound $L_{\widehat{g}_n}$. Recall that

$$\varepsilon^{2^{n+1}}\widehat{g}_n(t,\varepsilon) = h_n(\underline{x}_n(t,\varepsilon),t,\varepsilon) + \varepsilon^{2^n}Q_n(t,\varepsilon)\underline{x}_n(t,\varepsilon),$$

which implies

$$\begin{aligned} L_{\widehat{g}_n} &\leq \|D_xh_n(\underline{x}_n(t,\varepsilon),t,\varepsilon)\|_{\sigma_n}L_{\underline{x}_n} + L_{h_n(\underline{x}_n,t,\varepsilon)} \\ &\quad + L_{Q_n}\|\underline{x}_n(t,\varepsilon)\|_{\sigma_n} + \|\varepsilon^{2^n}Q_n(t,\varepsilon)\|_{\rho_n}L_{\underline{x}_n} \\ &\leq [K_\infty\|\underline{x}_n(t,\varepsilon)\|_{\sigma_n} + \|\varepsilon^{2^n}Q_n(t,\varepsilon)\|_{\rho_n}]L_{\underline{x}_n} \\ &\quad + K_2\left(\frac{1}{2}\right)\|\underline{x}_n(t,\varepsilon)\|_{\sigma_n}^2L_{h_n} + \|\underline{x}_n(t,\varepsilon)\|_{\sigma_n}L_{Q_n}, \end{aligned}$$

where we have used the fact that $L_{h_n(\underline{x}_n,t,\varepsilon)} \leq K_2(\alpha)L_{h_n}\|\underline{x}_n\|^2$ and, as before, that $K_2(\alpha) \leq K_2(\frac{1}{2})$ if ε_0 is small enough. On the other hand,

$$K_\infty\|\underline{x}_n(t,\varepsilon)\|_{\sigma_n} + \|\varepsilon^{2^n}Q_n(t,\varepsilon)\|_{\rho_n} \leq (K_\infty + 1)(\varepsilon_0N_1)^{2^n}.$$

This implies

$$L_{\widehat{g}_n} \le K_3 L_{3,n} (\varepsilon_0 N_1)^{2^n} (L_{A_n} + L_{g_n} + L_{h_n} + L_{Q_n}),$$

where $K_3 = \max\{K_\infty + 1,\ K_2(\frac{1}{2})\}$ and we have used $\varepsilon_0 N_1 < 1$ and $L_{3,n} > 1$.

Let us follow with $L_{h_{n+1}}$. Since

$$h_{n+1}(x_{n+1}, t, \varepsilon) = (I + \varepsilon^{2^n} P_n(t,\varepsilon))^{-1} \widehat{h}_n((I + \varepsilon^{2^n} P_n(t,\varepsilon)) x_{n+1}, t, \varepsilon),$$

we have

$$\begin{aligned} L_{h_{n+1}} &\le 4 L_{P_n} \|\widehat{h}_n((I + \varepsilon^{2^n} P_n) x_{n+1}, t, \varepsilon)\|_{\rho_{n+1}} \\ &\quad + \|(I + \varepsilon^{2^n} P_n)^{-1}\|_{\rho_{n+1}} \|D_x \widehat{h}_n\|_{\rho_{n+1}} L_{P_n} + \|(I + \varepsilon^{2^n} P_n)^{-1}\|_{\rho_{n+1}} L_{\widehat{h}_n} \\ &\le 4 L_{P_n} \frac{K_\infty}{2} \tau_\infty + 2 K_\infty \tau_\infty L_{P_n} + 2 L_{\widehat{h}_n}, \end{aligned}$$

which allows us to write

$$L_{h_{n+1}} \le 4 K_\infty \tau_\infty L_{P_n} + 2 L_{\widehat{h}_n}.$$

Finally, let us consider $L_{\widehat{h}_n}$. We recall that

$$\widehat{h}_n(y_n, t, \varepsilon) = h_n(\underline{x}_n(t,\varepsilon) + y_n, t, \varepsilon) - h_n(\underline{x}_n(t,\varepsilon), t, \varepsilon) - D_x h_n(\underline{x}_n(t,\varepsilon), t, \varepsilon) y_n,$$

which implies

$$\begin{aligned} L_{\widehat{h}_n} &\le \|D_x h_n(\underline{x}_n(t,\varepsilon) + y_n, t, \varepsilon)\| L_{\underline{x}_n} + L_{h_n} + \|D_x h_n(\underline{x}_n(t,\varepsilon), t, \varepsilon)\| L_{\underline{x}_n} \\ &\quad + L_{h_n} + \|D_{xx} h_n(\underline{x}_n(t,\varepsilon), t, \varepsilon)\| \|y_n\| L_{\underline{x}_n} + \|y_n\| L_{D_x h_n} \\ &\le K_\infty \tau_\infty L_{\underline{x}_n} + L_{h_n} + K_\infty \tau_\infty L_{\underline{x}_n} + L_{h_n} + K_\infty \tau_\infty L_{\underline{x}_n} + \tau_\infty K_1(\alpha) \alpha L_{h_n}. \end{aligned}$$

Furthermore, if ε is small enough, we have $\tau_\infty K_1(\alpha)\alpha \le 1$, and the following bound can be obtained:

$$L_{\widehat{h}_n} \le 3 K_\infty \tau_\infty L_{\underline{x}_n} + 3 L_{h_n}.$$

Thus far, we have stated some bounds on the Lipschitz constants. The next step is to relate (in closed formulas) the bounds of step $n+1$ with bounds of step n.

Let us define $a_n = L_{A_n}$, $b_n = \max\{L_{Q_n}, L_{g_n}\}$, and $c_n = L_{h_n}$; and let $e_n = (\varepsilon_0 N_1)^{2^n}$. Furthermore, let $L_{4,n} = L_{3,n} \max\{K_\infty, 6, 2K_3, 6K_\infty \tau_\infty\}$. After some rearrangement, we can write the bounds on the recurrences as

$$\begin{aligned} a_{n+1} &\le a_n + b_n + L_{4,n}(a_n e_n + b_n) + K_1(\alpha) e_n c_n, \\ b_{n+1} &\le 5 L_{4,n}^2 e_n a_n + 8 L_{4,n}^2 e_n b_n + (4K_1(\alpha) + 1) L_{4,n} e_n c_n, \\ c_{n+1} &\le 3 L_{4,n}^2 e_n a_n + 4 L_{4,n}^2 b_n + (6 + 2K_1(\alpha) L_{4,n}) c_n. \end{aligned} \tag{18}$$

Let $d_n = \max\{a_n, b_n, c_n\}$. It is immediate (recalling that $e_n < 1$ and $L_{4,n} > 1$) to obtain

$$d_{n+1} \le R L_{4,n}^2 d_n,$$

where $R = 14+4K_1(\alpha)$. As before, it is easy to obtain $RL_{4,n}^2 \leq M_6^{2^n}$ for some suitable M_6 independent of n. Therefore,

$$d_n \leq \prod_{j=0}^{n} M_6^{2^j} d_0 < M_6^{2^{n+1}} d_0.$$

Going back to (18), we have

$$\begin{aligned} b_{n+1} \leq \frac{5}{14} M_6^{2^n} (\varepsilon_0 N_1)^{2^n} M_6^{2^{n+1}} d_0 + \frac{8}{14} M_6^{2^n} (\varepsilon_0 N_1)^{2^n} M_6^{2^{n+1}} d_0 \\ + M_6^{2^n} (\varepsilon_0 N_1)^{2^n} M_6^{2^{n+1}} d_0 \leq 2d_0 \left(N_1 M_6^3\right)^{2^n} \varepsilon_0^{2^n} \leq (\varepsilon_0 S)^{2^n}, \end{aligned}$$

where S is a constant independent of n and ε_0. Taking $\varepsilon_0 < S^{-1}$, we have $b_n \longrightarrow 0$ as $n \longrightarrow 0$. Furthermore, we also obtain

$$a_{n+1} - a_n < (\varepsilon_0 T)^{2^n}$$

for a suitable constant T independent of n and ε_0. We also require $\varepsilon_0 < T^{-1}$. Then

$$a_n - a_0 < \sum_{j=0}^{n-1} (\varepsilon_0 T)^{2^j} < 2T\varepsilon_0$$

for all n provided that $\varepsilon_0 < \min\{S^{-1}, \frac{1}{2}T^{-1}\}$.

This is the bound we were looking for; it shows that $A_n(\varepsilon)$ is a Lipschitz function of ε and that $\mathcal{L}(A_n) - \mathcal{L}(A_0) = \mathcal{O}(\varepsilon)$. This means that, using Lemmas 2.16 and 2.22, the eigenvalues λ_j^n and the differences $\lambda_{j_1}^n - \lambda_{j_2}^n$ are Lipschitz from above and from below if ε is small enough.

To complete the proof, we take into account the resonances. Since we want to skip the possible resonances due to λ_j^n and $\lambda_{j_1}^n - \lambda_{j_2}^n$ at the nth step, we have to apply Lemma 2.24 for each one of the eigenvalues and couples. This amounts to skipping a measure at most d^2 times that we skipped in the frequency space. To go back to the parameter space, that is, to ε, we use the Lipschitz constant from below. In this way, we obtain the Cantorian $\mathcal{E}$ with the desired properties. □

2.11. Proof of Theorem 2.4. Since $\det A \neq 0$, the contraction lemma ensures that if ε is small enough, there exists a function $x_0(\varepsilon)$ such that

$$(A + \varepsilon\overline{Q})x_0(\varepsilon) + \varepsilon\overline{g} + \overline{h}(x_0(\varepsilon), \varepsilon) = 0,$$

and it verifies that $x_0(\varepsilon) = \mathcal{O}(\varepsilon)$. Let us define

$$A_{x_0} = A + \varepsilon\overline{Q} + D_x\overline{h}(x_0(\varepsilon), \varepsilon),$$

and let $\underline{x}(t, \varepsilon)$ be such that

$$\dot{\underline{x}} = A\underline{x} + \varepsilon g(t, \varepsilon). \tag{19}$$

(The existence of this solution was shown in Lemma 2.10, and we recall that it was proved to be $\mathcal{O}(\varepsilon)$.) The terms of order ε of the matrix A_∞ are provided by Lemma 2.12 at the first step of the inductive process. This modified matrix $\widehat{A}$ is

$$\widehat{A} = A + \varepsilon\overline{Q} + \overline{D_x h(\underline{x}, t, \varepsilon)}.$$

Then

$$\|A_{x_0}-\widehat{A}\| = \|D_x\overline{h}(x_0(\varepsilon),\varepsilon) - \overline{D_xh(\underline{x}(t,\varepsilon),t,\varepsilon)}\|.$$

However,

$$\overline{D_xh(\underline{x}(t,\varepsilon),t,\varepsilon)} = \overline{(C+\varepsilon R(t))\underline{x}(t)} + \mathcal{O}(\varepsilon^2) = C\overline{\underline{x}} + \mathcal{O}(\varepsilon^2),$$

where $C = \frac{1}{2}D_{xx}h(0,t,0)$ is a constant matrix by hypothesis. Moreover, it is also easy to obtain that

$$D_x\overline{h}(x_0(\varepsilon),\varepsilon) = (C+\varepsilon\overline{R})x_0(\varepsilon) + \mathcal{O}(\varepsilon^2) = Cx_0(\varepsilon) + \mathcal{O}(\varepsilon^2).$$

We have obtained that

$$\|A_{x_0}-\widehat{A}\| = C(x_0(\varepsilon)-\overline{\underline{x}}) + \mathcal{O}(\varepsilon^2).$$

Now, averaging (19), we get that $A\overline{\underline{x}}+\varepsilon\overline{g}=0$, and using $Ax_0(\varepsilon)+\varepsilon\overline{g} = -(\varepsilon\overline{Q}x_0(\varepsilon)+\overline{h}(x_0(\varepsilon),\varepsilon)) = \mathcal{O}(\varepsilon^2)$, we obtain $\|x_0(\varepsilon)-\overline{\underline{x}}\| = \mathcal{O}(\varepsilon^2)$, which completes the proof. □

3. The neighborhood of an elliptic equilibrium point of a Hamiltonian system. Let us consider the Hamiltonian

$$H^0(p,q,t) = H_0(p) + H_1(p,q,t),$$

where $|H_1|$ is small and depends on time in a quasi-periodic way, with $\varphi = (\varphi_1,\dots,\varphi_r)$ as a vector of basic frequencies. To obtain an autonomous system we define $q_2 = q$, $p_2 = p$, and $q_1 = \varphi t$. Therefore, the Hamiltonian takes the form

$$H(p_1,p_2,q_1,q_2) = (\varphi,p_1) + H_0(p_2) + H_1(p_2,q_2,q_1),$$

where p_1 are the actions corresponding to q_1. (Obviously, they are not relevant in this problem and have only been added to obtain a Hamiltonian form.) We are interested in the invariant tori that the unperturbed system $H = H_0(p_2)$ had. Note that the KAM theorem (see [1]) cannot be applied directly due to the degeneracy of this case.[3]

We have considered this case in Theorem 3.1, and we have found that the proof of the classical KAM theorem (see [1]) still works because the perturbing frequencies are not modified in any step of the inductive process, and we only have to worry about the proper frequencies of the Hamiltonian, which can be controlled provided that the nondegeneracy condition

$$\det\left(\frac{\partial^2 H_0}{\partial(p_2)^2}\right) \neq 0$$

holds. The result obtained is that there exist invariant tori near the origin for ε small enough. The frequencies of these tori are those of the unperturbed tori plus those of the perturbation. This can be described by saying that the unperturbed tori are "quasi-periodically dancing" to the "rhythm" of the perturbation. The tori whose frequencies are in resonance with those of the perturbation are destroyed.

Finally, in the case where the origin is not a fixed point of the perturbed Hamiltonian, we can reduce to this case by performing a change of variables, transforming

[3] However, see the comments in [2, pp. 193–194] for a related result.

the quasi-periodic orbit that replaces the equilibrium point (we recall that this orbit exists for a Cantorian set of values of ε) in a fixed point.

THEOREM 3.1. *Let us consider the Hamiltonian*

$$H(p_1, p_2, q_1, q_2) = (\varphi, p_1) + H_0(p_2) + \varepsilon H_1(p_2, q_1, q_2),$$

where q_1 are the angles of the perturbation, p_1 are the corresponding actions, q_2 and p_2 are the angles and actions of the unperturbed system, and $\varphi = (\varphi_1, \ldots, \varphi_{n_1})$ is a constant vector of frequencies that satisfies the nonresonance condition

$$|(k, \varphi)| > \frac{c}{|k|^\gamma} \quad \forall k \in \mathbb{Z}^{n_1} \setminus \{0\}, \quad \gamma > n_1 - 1.$$

Let G^1 be a compact domain of $\mathbb{R}^{n_1}$, let G^2 be a compact domain of $\mathbb{R}^{n_2}$, and let G be $G^1 \times G^2$. Now suppose that this Hamiltonian function $H(p_1, p_2, q_1, q_2) = H(p, q)$ is analytic on the domain $F = \{(p, q) \,/\, p = (p_1, p_2) \in G, |\mathrm{Im}\, q| \le \rho\}$ and has period 2π with respect to the variables q. Let us assume that in the domain F,

$$\det \left| \frac{\partial^2 H_0}{\partial (p_2)^2} \right| \neq 0.$$

Then if ε is small enough, the motion defined by the Hamiltonian equations

$$\begin{aligned} \dot{p}_1 &= -\frac{\partial H}{\partial q_1}, & \dot{q}_1 &= \varphi, \\ \dot{p}_2 &= -\frac{\partial H}{\partial q_2}, & \dot{q}_2 &= \frac{\partial H}{\partial p_2}, \end{aligned} \tag{20}$$

has the following properties.

1. *There exists a decomposition* $\mathrm{Re}\, F = F_1 + F_2$, *where F_1 is invariant and F_2 is small:* $\mathrm{mes}\, F_2 \le \kappa_1(\varepsilon)\, \mathrm{mes}\, F$, *where $\kappa_1(\varepsilon)$ is $o(\varepsilon)$.*

2. *F_1 is composed of invariant n-dimensional analytic tori I_ϕ, defined parametrically by the equations*

$$p = p_\phi + f_\phi(Q), \qquad q = Q + g_\phi(Q),$$

where f_ϕ and g_ϕ are analytic functions of period 2π in the variables Q and ϕ is a parameter determining the torus I_ϕ. In fact, ϕ consists of all the frequencies, i.e., those of the external excitation and the proper frequencies, $\phi = (\varphi_1, \ldots, \varphi_{n_1}, \omega_1, \ldots, \omega_{n_2})$.

3. *The invariant tori I_ϕ differ little from the tori $p = p_\phi$, namely,*

$$|f_\phi(Q)| < \kappa_2(\varepsilon), \qquad |g_\phi(Q)| < \kappa_2(\varepsilon),$$

where $\kappa_2(\varepsilon)$ is $o(\varepsilon)$.

4. *The motion* (20) *on the invariant torus I_ϕ is quasi-periodic with n frequencies $\varphi_1, \ldots, \varphi_{n_1}, \omega_1, \ldots, \omega_{n_2}$ $(n = n_1 + n_2)$, namely,*

$$\dot{Q} = \phi, \qquad \omega = \left. \frac{\partial H_0}{\partial p_2} \right|_{p_\phi}.$$

3.1. Sketch of the proof of Theorem 3.1. The proof of this theorem is essentially the same as that of the KAM theorem contained in [1], and its technical details can be found in [15]. Here we show the idea of this proof.

Let us define p and q as the vectors p_1, p_2 and q_1, q_2, respectively. Now the Hamiltonian that we have is

$$H^\varepsilon = (\varphi, p_1) + H_0(p_2) + \varepsilon \overline{H}_1(p_2) + \varepsilon \widetilde{H}_1(p_2, q), \tag{21}$$

and let us consider the generating function $S(P,q) = Pq + \sum_{k \neq 0} S^k(P_2) e^{(k,q)\sqrt{-1}}$. If we perform the canonical change of variables

$$\begin{aligned} p_1 &= P_1 + \varepsilon \frac{\partial S}{\partial q_1}, \\ p_2 &= P_2 + \varepsilon \frac{\partial S}{\partial q_2}, \\ Q_1 &= q_1, \\ Q_2 &= q_2 + \varepsilon \frac{\partial S}{\partial P_2} \end{aligned}$$

on (21), we obtain

$$H^\varepsilon = (\varphi, P_1) + H_0(P_2) + \varepsilon \overline{H}_1(P_2) + \varepsilon F + \varepsilon^2 R(P_2, q),$$

where $F = (\varphi, S_{q_1}) + (\omega(P_2), S_{q_2}) + \widetilde{H}_1(P_2, q)$ and $\omega(p_2) = \frac{\partial H_0}{\partial p_2}(p_2)$. Let $\phi(P_2)$ be the vector $\varphi, \omega(P_2)$. We require $F = 0$, namely,

$$(\phi(P_2), S_q) + \widetilde{H}_1(P_2, q) = 0.$$

Now, using the fact that $\widetilde{H}_1(P_2, q) = \sum_{k \neq 0} h_1^k(P_2) e^{(k,q)\sqrt{-1}}$, the coefficients of the Fourier expansion for the generating function S can be obtained easily as

$$S^k(P_2) = \frac{h_1^k}{(\phi(P_2), k)} \sqrt{-1}.$$

To ensure the convergence of this series, it is sufficient to use the usual nonresonance condition

$$|(\phi(P_2), k)| \geq \frac{c}{|k|^\gamma}, \tag{22}$$

which allows us to prove the convergence in a smaller strip than that on which $\widetilde{H}_1$ is analytic. With this, the Hamiltonian takes the form

$$H^\varepsilon = (\varphi, P_1) + H_1^\varepsilon(P_2) + \varepsilon^2 \overline{H}_3(P_2) + \varepsilon^2 \widetilde{H}_3(P_2, Q).$$

This new Hamiltonian is very similar to (21) but with ε^2 instead of ε. Note that the difference between this proof and the one in [1] is condition (22). Due to the fact that the first components of $\phi(P_2)$ are those of φ, *which are constant throughout the inductive process*, we only have to worry about the last ones, $\omega(P_2)$. These components are different at each step of the process, but they can be controlled by the nondegeneracy condition

$$\det\left(\frac{\partial^2 H_0}{\partial (p_2)^2}\right) \neq 0.$$

This is done exactly as shown in [1]. Note that to get a rigorous proof of this theorem, we need only copy the proof contained in [1] and add the "parameter" φ. The unique difference is that now the nonresonance condition is stronger in the sense that we must eliminate a bigger set of (resonant) tori.

PERIODIC MONOTONE SYSTEMS WITH AN INVARIANT FUNCTION[*]

JIANG JI-FA[†]

Abstract. The author studies the periodic time-dependent type-K monotone system

$$\dot{x}_i = F_i(t, x_1, \ldots, x_n) \quad (i = 1, \ldots, n)$$

in the interior of the nonnegative orthant in n-space satisfying the following conditions: (i) if $x \neq y$, $x_i = y_i$, and $x_j \leq y_j$ for $j \neq i$, then $F_i(t,x) \leq F_i(t,y)$; (ii) $F(t,x)$ is periodic in t of period $\tau > 0$; (iii) F possesses an invariant function with positive gradient. It is proved that every solution to such a system either converges to a periodic solution or eventually leaves any compact set. This result gives an affirmative answer to the conjecture recently proposed by B. R. Tang, Y. Kuang, and H. Smith in [*SIAM J. Math. Anal.*, 24 (1993), pp. 1331–1339] for periodic type-K monotone systems.

1. Introduction.

Consider the system of ordinary differential equations

$$\dot{x} = F(t, x), \tag{1}$$

where $F : \mathbf{R} \times P \to \mathbf{R}^n$ is continuous with $P = \{p \in \mathbf{R}^n : p_i > 0 \text{ for all } i,\ 1 \leq i \leq n\}$ and satisfies the following conditions:

(i) $F(t,x)$ is periodic in t of period $\tau > 0$, that is, $F(t+\tau, x) = F(t,x)$ for all $t \in \mathbf{R}$ and all $x \in P$;

(ii) system (1) has the uniqueness property for the initial-value problems on $\mathbf{R} \times P$ and every solution of (1) can be extended into the future;

(iii) for each fixed t, the vector function $F(t,x)$ is of type K in P, i.e., $F_i(t,x) \leq F_i(t,y)$ for any two distinct points $x = (x_1, x_2, \ldots, x_n)$ and $y = (y_1, y_2, \ldots, y_n)$ in P with $x_i = y_i$ and $x_k \leq y_k (k = 1, 2, \ldots, n;\ k \neq i)$;

(iv) (1) possesses an order-increasing invariant function, i.e., there exists a C^1 function $H : P \to \mathbf{R}$ such that grad $H(x) \gg O$ for each $x \in P$ and

$$\langle \text{grad } H(x), F(t,x) \rangle = 0 \tag{2}$$

for all $t \in \mathbf{R}$ and all $x \in P$. The autonomous system (1) has been studied extensively in the econometria lectures [17, 18] and the papers [4, 13, 19]. The limiting behavior of these systems is well understood. However, if one wishes to build a theory of such systems which reflects changes due to seasonal adjustments, then it is important to study time-dependent systems. In the case $H(x) = \sum_{i=1}^{n} x_i$, (1) is the generalized gross-substitute system which was studied by Nakajima [2] and Sell and Nakajima [3]. Their results show that every compact solution to such a system is asymptotically periodic (almost periodic). When $F(t,x)$ is independent of t and $F_i(x_1, x_2, \ldots, x_n)$ is strictly increasing in x_k for all $k \neq i$, the flow generated by (1) is strongly monotone. Mierczyński [4] proved that every solution either converges to an equilibrium or eventually leaves any compact set. The author's paper [13] investigates the case where $F_i(x_1, x_2, \ldots, x_n)$ is nondecreasing in x_k for all $k \neq i$ and proves the

same result. Assume that $F(t,x)$ is continuously differentiable in $x \in P$, $D_xF(t,x)$ is irreducible, and all its off-diagonal terms are nonnegative. If every solution of (1) is compact, then the abstract results of Takáč [6] and Dancer and Hess [9] imply that every solution is asymptotically periodic of period τ. In the recent paper [1], B. R. Tang, Y. Kuang, and H. Smith conjectured that for the periodic (almost periodic) system (1), if conditions (ii)–(iv) hold, then every solution either converges to a periodic solution (an almost periodic solution) or eventually leaves any compact set. Meanwhile, they partly proved this conjecture. More precisely, assuming that H is C^2 with cooperative Hessian matrix, the inequality in (iii) is strict, and some additional conditions for H hold, they cleverly constructed a Liapunov function and proved the above conjecture is true by the theory of skew-product flow.

The object of this paper is to prove that the conjecture proposed by B. R. Tang, Y. Kuang, and H. Smith [1] holds in the case where $F(t,x)$ is periodic in t. We shall prove the following.

THEOREM A. *If system* (1) *satisfies conditions* (i)–(iv), *then every compact solution is asymptotically periodic of period* τ.

This result naturally generalizes that of [2] to the case of a not-necessarily linear-invariant function and drops the strict monotonicity condition in [1, 4] and the irreducibility condition in [6, 9, 14], each of which is needed to guarantee that the system is strongly monotone. Using the ideas in [14], we can prove that the set of fixed points for the Poincaré map T is a curve totally ordered by $\ll$ if the strict monotonicity or irreducibility condition is satisfied. However, if we assume that the system is monotone without strict assumption, then other cases can occur. For example, consider the system

$$\begin{aligned} \dot{x} &= -x + y + z^2, \\ \dot{y} &= x - y + (3 + 2\sin t)z^2, \\ \dot{z} &= -(2 + \sin t)z, \end{aligned} \tag{3}$$

which is defined in $x \geq 0$, $y \geq 0$, and $z \geq 0$ and possesses an invariant function $H = x + y + z^2$. By solving the nonlinear equations in (3), we can easily prove that for any solution $(x(t),\ y(t),\ z(t))$ of (3), there exists a constant $c \geq 0$ such that $(x(t), y(t), z(t)) \to (c, c, 0)$ as $t \to +\infty$ and the set of periodic points for (3) is $\{(c, c, 0) : c \geq 0\}$, which is totally ordered by $\leq$ but not by $\ll$. Moreover, if we add an equation $\dot{w} = 0$ to the system (3), then it becomes a four-dimensional one in which the set of periodic points is $\{(c, c, 0, d) : c \geq 0, d \geq 0\}$. This set is not ordered by $\leq$.

Next, we consider the system

$$\begin{aligned} \dot{x}_1 &= (2 + \cos t)e^{x_1}x_2 - e^{x_1} + 1, \\ \dot{x}_2 &= 1 - e^{-x_1} - (2 + \cos t)x_2 \end{aligned} \tag{4}$$

for $x_1 \geq 0$, $x_2 \geq 0$. System (4) has an invariant function $H(x_1, x_2) = 1 - e^{-x_1} + x_2$. We calculate the corresponding Liapunov function $V(x,y) : \mathbf{R}^2_+ \times \mathbf{R}^2_+ \to \mathbf{R}_+$, which is defined in [1, p. 1334]:

$$V(x,y) = |e^{-x_1} - e^{-y_1}| + |x_2 - y_2|.$$

It is easy to see that $\lim_{|x-y| \to +\infty} V(x,y) = +\infty$ does not hold. Therefore, Theorem 3.1 in [1] cannot be applied to system (4). However, Theorem A can be applied.

2. Definitions and preliminary lemmas. Let x, $y \in \mathbf{R}^n$. There exists a partial order in $\mathbf{R}^n$ given by $x \leq y$ ($x \ll y$) if and only if $x_i \leq y_i$ ($x_i < y_i$) for $i = 1, 2, \ldots, n$. We write $x < y$ to signify that $x \leq y$ and $x \neq y$. If x and y are two vectors with $x \ll y$, let $[[x, y]] = \{z : x \ll z \ll y\}$, $[x, y]] = \{z : x \leq z \ll y\}$, and $[[x, y] = \{z : x \ll z \leq y\}$. If x and y are two vectors with $x < y$, let $[x, y] = \{z : x \leq z \leq y\}$. $[p, \infty]]$ is the set $\{x : x \geq p\}$. If $A \subset P$ is a set, then $a \leq A$ ($A \leq a$) means $a \leq x$ ($x \leq a$) for all $x \in A$; similar notation holds for $a < A$, etc.

We denote by $\varphi(t, x)$ the solution of (1) satisfying $\varphi(0, x) = x$. For $x \in P$, we also write $x(t)$ for $\varphi(t, x)$.

Fundamental to our study is Kamke's theorem, which is stated as follows.

KAMKE'S THEOREM. *Assume* (ii) *and* (iii) *hold. Let $x(t)$ and $y(t)$ be solutions of* (1) *defined for $a \leq t \leq b$ such that $x(a) \ll y(a)$ (resp., $x(a) \leq y(b)$). Then $x(t) \ll y(t)$ (resp., $x(t) \leq y(t)$) for all $t \in [a, b]$.*

W. A. Coppel [10. p. 30] discussed the following question: assuming that $x(a) \leq y(a)$, under what conditions can we have the equality $x_i(b) = y_i(b)$? His argument shows that if (ii) and (iii) hold, then $x_i(b) = y_i(b)$ if and only if $x_i(t) = y_i(t)$ for any $t \in [a, b]$.

Define the Poincaré map $T : P \to P$ by

$$Tx = \varphi(\tau, x).$$

Then T is continuous and $T^k x = \varphi(k\tau, x)$ for any positive integer k. Let $T_i^k x$ denote the ith component of $T^k x$. If the dimension n of Euclidean space $\mathbf{R}^n$ is fixed, we let $N = \{1, 2, \ldots, n\}$. If $I \subset N$, we denote by $C(I)$ the complement of I in N, $C(I) = N - I$. From Kamke's theorem and the argument discussed by Coppel in [10, p. 30], we obtain the following.

LEMMA 2.1. *If $x < y$ with $x_i < y_i$ for $i \in I$, then $T^k x < T^k y$ and $T_i^k x < T_i^k y$ for $i \in I$ and any fixed positive integer k.*

DEFINITION. *Let $x(t)$ be a solution of system* (1) *defined on $[t_o, +\infty)$ for some $t_o \in \mathbf{R}$. $x(t)$ is said to be* compact *if there exist two positive vectors $a, b \in P$ such that $a \leq x(t) \leq b$ for all $t \geq t_o$.*

A compact solution $x(t)$ is said to be *asymptotically periodic of period τ* if there is a periodic solution $y(t)$, $y(t + \tau) = y(t)$, such that $x(t) - y(t) \to O$ as $t \to +\infty$.

Suppose $\varphi(t, x)$ is a compact solution of (1). The positive semiorbit of x is defined by $O^+(x) = \{T^k x : k \in \mathbf{Z}_+\}$, where $\mathbf{Z}_+ = \{0, 1, 2, \ldots\}$ and the ω-limit set of x is defined by $\omega(x) = \{y : T^{n_k} x \to y (k \to \infty)$ for some sequence $n_k \to \infty$ in $\mathbf{Z}_+\}$. Then $\omega(x)$ is fully invariant, i.e., $T\omega(x) = \omega(x)$.

LEMMA 2.2. *Assume that $\varphi(t, x)$ is a compact solution of* (1) *and $\omega(x)$ is the ω-limit set of x. Then for any $y \in \omega(x)$, $\varphi(t, y)$ is also a compact solution of* (1).

Proof. By the definition of $\omega(x)$, there exists some sequence $n_k \to \infty (k \to \infty)$ such that $\lim_{k \to \infty} T^{n_k} x = y$, i.e., $\varphi(n_k \tau, x) \to y$, as $k \to \infty$. Since the solutions of (1) are continuous with respect to initial conditions (see [11, p. 94]), for any fixed $t > 0$, $\varphi(t, y) = \lim_{k \to \infty} \varphi(t, \varphi(n_k \tau, x))$. By condition (i), $F(t, x)$ is periodic in t of period τ. Therefore, $\varphi(t, \varphi(n_k \tau, x)) = \varphi(t + n_k \tau, x)$. The compactness of $\varphi(t, x)$ implies that there exist two positive vectors a, $b \in P$ such that $a \leq \varphi(t, x) \leq b$ for any $t \geq 0$. It follows that

$$a \leq \varphi(t, \varphi(n_k \tau, x)) \leq b.$$

Letting $k \to \infty$, we have

$$a \leq \varphi(t, y) \leq b,$$

i.e., $\varphi(t, y)$ is compact. This completes the proof.

Finally, let $E = \{p \in P : Tp = p\}$ denote the set of all fixed points for T.

3. Proof of Theorem A.

It is convenient to establish some preliminary results before proceeding to the proof of Theorem A. In all of these, we assume the hypotheses of the theorem hold.

LEMMA 3.1. *Suppose $p \in E$. Then for any neighborhood W of p in P, there exists another neighborhood $U \subset W$ of p such that $T^k U \subset U$ for any positive integer k. Therefore, the fixed point p of T is Liapunov stable.*

Proof. Fix a, $b \in W$ with $a \ll p \ll b$ and $[a, b] \subset W$. Then we may choose c, $d \in [[a, b]]$ so that $c \ll p \ll d$. Let $h_1 = H(c)$ and $h_2 = H(d)$. Then we define the sets

$$A = H^{-1}(h_1) \bigcap [[O, p], \qquad B = H^{-1}(h_2) \bigcap [p, \infty]], \quad \text{and} \quad U = \bigcup_{(u,v) \in A \times B} [[u, v]].$$

It is easy to see that A, $B \subset [a, b]$ if $\|p - c\|$ and $\|p - d\|$ are sufficiently small. Clearly, $U \subset [a, b]$ is open.

Since H is an invariant function of system (1), $H(\varphi(t, x)) \equiv$ const for a fixed $x \in P$ and all $t \geq 0$. Thus $H(T^k u) = H(u) = h_1$ and $H(T^k v) = H(v) = h_2$ for any positive integer k. From $p \in E$ and Kamke's theorem, it follows that $T^k u \leq p \leq T^k v$. This proves that $T^k u \in A$ and $T^k v \in B$. Therefore,

$$T^k U = \bigcup_{(u,v) \in A \times B} [[T^k u, T^k v]] \subset U \subset W$$

for each positive integer k. The proof of the lemma is complete.

LEMMA 3.2. *There cannot exist two points p, $q \in E$ such that $p < q$ and $[p, q] \cap E = \{p, q\}$.*

Proof. Suppose the contrary, that is, there exist p, $q \in E$ with $p < q$ such that there is no fixed point between p and q. Lemma 2.1 implies that $Tx < Ty$ for any x, $y \in P$ with $x < y$. Following Dancer and Hess [9], such a map T is strictly order preserving. Applying [9, Prop. 1], we obtain that there is a monotone entire orbit $(x_k)_{k \in \mathbf{Z}}$ in $[p, q]$ connecting p and q, where $\mathbf{Z}$ denotes the set of all integers. Then either $\lim_{k \to -\infty} x_k = p$ and $\lim_{k \to \infty} x_k = q$ or $\lim_{k \to -\infty} x_k = q$ and $\lim_{k \to \infty} x_k = p$. Because H is an invariant function, $H(x_k) = c$ for any $k \in \mathbf{Z}$. The continuity of H implies that $H(p) = H(q) = c$. But from $p < q$ and grad $H(x) \gg O$ for any $x \in P$, it follows that $H(p) < H(q)$, a contradiction. This proves Lemma 3.2.

LEMMA 3.3. *Suppose that $\varphi(t, x)$ is a compact solution of* (1) *and $q \in \omega(x)$ is a stable fixed point of T. Then $\omega(x) = \{q\}$.*

This lemma is adapted from [9, p. 130].

LEMMA 3.4. *Assume that $\varphi(t, x)$ is a compact solution of* (1). *If p and q are the greatest lower bound and the least upper bound of $\omega(x)$, respectively, then p and q are the fixed points of T.*

Proof. Since $\varphi(t, x)$ is a compact solution of (1), there are two positive vectors a, $b \in P$ such that $a \leq \varphi(t, x) \leq b$ for any $t \geq 0$. Hence $a \leq \omega(x) \leq b$. It follows that $a \leq p \leq q \leq b$. Suppose that the conclusion is false. Then, for example, $Tp \neq p$. By the definition of p, $p \leq \omega(x)$. Kamke's theorem and the full invariance of $\omega(x)$ imply that $Tp \leq \omega(x)$. By definition, Tp is also a lower bound for $\omega(x)$, whence $Tp < p$. Because grad $H(x) \gg O$ for each $x \in P$, $H(Tp) < H(p)$. But it follows from (2) that $H(Tp) = H(p)$—a contradiction. This proves the lemma.

LEMMA 3.5. *If $\varphi(t,x)$ is a compact solution of* (1) *and $\omega(x) = \{p\}$, then $\varphi(t,x) - \varphi(t,p) \to O$ as $t \to \infty$.*

This lemma is well known, so its proof is omitted.

Suppose that $\varphi(t,x)$ is a compact solution of (1) and $\omega(x)$ is the ω-limit set of x. Let $p = (p_1, p_2, \ldots, p_n)$ and $q = (q_1, q_2, \ldots, q_n)$ be the greatest lower bound and the least upper bound of $\omega(x)$, respectively. For $y = (y_1, y_2, \ldots, y_n)$, we define

$$\sigma_p(y) = \sharp\{i : y_i \neq p_i\}.$$

Here, $\sharp$ denotes the cardinality of the set. Furthermore, we define

$$M(x,p) = \max\{\sigma_p(y) \ : \ y \in \omega(x)\}.$$

From Lemma 2.2, for any $y \in \omega(x)$, $\varphi(t,y)$ is compact. Therefore, we can also define $M(y,u)$, where u is the greatest lower bound of $\omega(y)$.

Proof of Theorem A. Suppose that $\varphi(t,x)$ is a compact solution of (1) and $\omega(x)$ is the ω-limit set of x. In order to prove the theorem, by Lemma 3.5, we have only to prove that $\omega(x)$ is a singleton. Lemma 3.1 tells us that p is Liapunov stable for any $p \in E$. Therefore, by Lemma 3.3, we have only to prove that $\omega(x) \cap E \neq \phi$. Therefore, suppose $\omega(x) \cap E = \phi$, and we shall prove the following two facts:

(I) $M(x,p) \leq n-1$; and

(II) there exists $y \in \omega(x)$ such that $M(y,u) < M(x,p)$, where u is the greatest lower bound of $\omega(y)$.

First, we prove (I). By Lemma 3.4, the greatest lower bound p of $\omega(x)$ is a fixed point of T. Since $\omega(x) \cap E = \phi$, $p \,\overline{\in}\, \omega(x)$, hence $p < \omega(x)$. If (I) is not true, then $M(x,p) = n$, i.e., there is a point $y \in \omega(x)$ such that $\sigma_p(y) = n$, which implies that $p \ll y$. We claim that $[p,y]] \cap E = \{p\}$ must hold. If this equality is false, then there is a fixed point $p_o \in E$ such that $p < p_o \ll y$. Since $y \in \omega(x)$, there is an integer $k_o > 0$ such that $p_o \ll T^{k_o}x$. Kamke's theorem implies that $p_o \ll T^k x$ for $k \geq k_o$. It immediately follows that $p_o \leq \omega(x)$, i.e., p_o is a lower bound of $\omega(x)$, whence $p_o \leq p$, contradicting $p < p_o$. This proves that $[p,y]] \cap E = \{p\}$. Let q denote the least upper bound of $\omega(x)$. Then, by Lemma 3.4, $q \in E$. $\omega(x) \cap E = \phi$ implies that $p < \omega(x) < q$. Since $p \ll y$ and $y \in \omega(x)$, $p \ll q$. Obviously, $[p,q] \cap E$ is a compact set. Since $[p,y]] \cap E = \{p\}$, it is easy to prove that $B := ([p,q] \cap E) \backslash \{p\}$ is also a compact set. By Zorn's lemma, B contains a minimal element p_o. It is not difficult to see that $p < p_o$. The minimality of p_o implies that there exists no fixed point between p and p_o, that is, $[p, p_o] \cap E = \{p, p_o\}$, contradicting Lemma 3.2. (I) is proved.

Second, we prove (II). Let $M(x,p) = m \leq n-1$ and choose $y \in \omega(x)$ such that $\sigma_p(y) = m$. Without loss of generality, we may assume that $y_i \neq p_i$ (hence, $y_i > p_i$) for $i = 1, 2, \ldots, m$. The maximality of m implies that $y_j = p_j$ for $j = m+1, \ldots, n$. For any integer $k > 0$, applying Lemma 2.1, we have $p_i < T_i^k y$ for $i = 1, 2, \ldots, m$. Since $T^k y \in \omega(x)$, the maximality of m implies that $p_j = T_j^k y$ for $j = m+1, \ldots, n$.

Let $\pi^m = \{(x_1, x_2, \ldots, x_m, 0, 0, \ldots, 0) \ : \ x_i \geq 0 \text{ for } i = 1, 2, \ldots, m\}$. Then $O^+(y) \subset p + \pi^m$, which implies that $\omega(y) \subset p + \pi^m$. For an n-dimensional vector $z = (z_1, z_2, \ldots, z_n)$, we define an m-dimensional vector $\tilde{z} = (z_1, z_2, \ldots, z_m)$, and we also use the same symbols $\leq$, $<$, and $\ll$ to denote the order relation in $\mathbf{R}^m$. Suppose u and v are the greatest lower bound and the least upper bound of $\omega(y)$, respectively. Obviously, $u_j = v_j = p_j$ for $j = m+1, \ldots, n$. Therefore, $M(y,u) \leq m$.

We assert that $M(y,u) < m$. If not, $M(y,u) = m$. By the definition of $M(y,u)$, there is a point $z \in \omega(y)$ such that $\sigma_u(z) = m$, i.e., $\tilde{u} \ll \tilde{z}$. We claim that there exists a relative open set V in $[u,v]$ containing u such that $V \cap E = \{u\}$. If the claim is false, then there is a sequence $\{w_k\} \subset E$ such that $u < w_k$ for any $k > 0$ and $\lim_{k\to\infty} w_k = u$. Hence $\lim_{k\to\infty} \tilde{w}_k = \tilde{u} \ll \tilde{z}$ and there exists a $k_0 > 0$ such that $\tilde{w}_k \ll \tilde{z}$ for $k \geq k_0$. Let $w = w_{k_0}$. Then $w_j = u_j = v_j = p_j$ for $j = m+1, \dots, n$. Since $z \in \omega(y)$, there exists an integer $k_1 > 0$ such that $\tilde{w} \ll \widetilde{T^{k_1}y}$. Because $w_j = T_j^k y = p_j$ for $j = m+1, \dots, n, w < T^{k_1}y$. Lemma 2.1 implies that $w < T^k y$ for $k \geq k_1$. Hence $w \leq \omega(y)$, i.e., w is a lower bound of $\omega(y)$, whence $w \leq u$, contradicting $u < w$. This contradiction shows that our claim is true, i.e., $V \cap E = \{u\}$. Therefore, $C := ([u,v] \cap E)\backslash\{u\}$ is a compact set. Zorn's lemma implies that C contains a minimal element u_0. Obviously, $u < u_0$ and $[u, u_0] \cap E = \{u, u_0\}$, contradicting Lemma 3.2. This proves that our assertion holds, i.e., $M(y,u) < M(x,p)$.

For any $y \in \omega(x), \omega(y) \cap E = \phi$. Let $y_0 = y$ and $u_0 = u$. Then, repeatedly using (II) $m+1$ times, we have $\{y_0, y_1, \dots, y_m\} \subset \omega(x)$ such that

$$M(y_i, u_i) < M(y_{i-1}, u_{i-1}) \tag{5}$$

for $i = 1, 2, \dots, m$, where u_i is the greatest lower bound of $\omega(y_i)$. Since $M(y_0, u_0) = M(y,u) < m$, it follows from (5) that $M(y_i, u_i) < m - i$ for $i = 0, 1, 2, \dots, m$. Therefore, $M(y_m, u_m) < 0$. But by the definition of $M(y_m, u_m)$, it is a nonnegative integer—a contradiction. This shows that $\omega(x) \cap E \neq \phi$. The proof is complete.

Remark 1. For infinite-dimensional strongly monotone systems satisfying a much more general conservation law than the one used in this paper, analogous results are proved by Takáč in [7, 8]. All these systems have a common characteristic: every fixed point (equilibrium) is Liapunov stable. The author [12, 15, 16] proves the results of convergence to fixed point without the *strongly* assumption.

Remark 2. J. Mierczyński [5] proved that if (iii) and (iv) hold and $F(t,x)$ satisfies the carathéodory conditions, then the solutions of (1) uniquely exist for the initial value problem on $\mathbf{R} \times P$. Assuming further that (i) holds, we can conclude that every compact solution is asymptotically periodic of period τ under the above hypotheses.

Acknowledgments. The author is indebted to the referees for their valuable suggestions.

NONSTATIONARY SUBDIVISION SCHEMES AND MULTIRESOLUTION ANALYSIS*

ALBERT COHEN† AND NIRA DYN‡

Abstract. Nonstationary subdivision schemes consist of recursive refinements of an initial sparse sequence with the use of masks that may vary from one scale to the next finer one. This paper is concerned with both the convergence of nonstationary subdivision schemes and the properties of their limit functions. We first establish a general result on the convergence of such schemes to C^∞ compactly supported functions. We show that these limit functions allow us to define a multiresolution analysis that has the property of spectral approximation. Finally, we use these general results to construct C^∞ compactly supported cardinal interpolants and also C^∞ compactly supported orthonormal wavelet bases that constitute Riesz bases for Sobolev spaces of any order.

Key words. subdivision schemes, multiresolution analysis, spectral approximation, dyadic interpolation, wavelets.

AMS subject classifications. 41A28, 41A30, 41A10, 42C15

1. Introduction. Subdivision schemes constitute a useful tool for the fast generation of smooth curves and surfaces from a set of control points by means of iterative refinements. In the most-often-considered binary univariate case, one starts from a sequence $s_0(k)$ and obtains at step j a sequence $s_j(2^{-j}k)$ generated from the previous one by linear rules:

$$s_j(2^{-j}k) = 2 \sum_{n\in k+2\mathbb{Z}} c_{j,k}(n) s_{j-1}(2^{-j}(k-n)). \tag{1.1}$$

The masks $c_{j,k} = \{c_{j,k}(n)\}_{n\in\mathbb{Z}}$ are, in general, finite sequences, a property that is clearly useful for the practical implementation of (1.1).

A natural problem is then to study the convergence of such an algorithm to a limit function. In particular, the scheme is said to be strongly convergent if and only if there exists a continuous function $f(x)$ such that $\lim_{j\to+\infty}(\sup_k |s_j(2^{-j}k) - f(2^{-j}k)|) = 0$. One can study more general types of convergence with the use of a smooth function g that is well localized in space (for example, compactly supported) and satisfies the interpolation property $g(k) = \delta_k$. One can then define $f_j(x) = \sum_k s_j(2^{-j}k) g(2^j x - k)$ and study the convergence of f_j to f in a functional sense.

A subdivision scheme is said to be stationary and uniform when the masks $c_{j,k}(n) = c_n$ are independent of the parameters j and k. In that case, one can rewrite (1.1) as

$$s_j(2^{-j}k) = 2\sum_n c_{k-2n} s_{j-1}(2^{-j+1}n). \tag{1.2}$$

Note that (1.2) is equivalent to filling in the sequence s_{j-1} with zeros at the intermediate points $2^{-j}(2k+1)$ and applying a discrete convolution with the sequence (c_k). Detailed reviews of stationary subdivision have been done by Cavaretta, Dahmen, and Micchelli (1991) and Dyn (1992).

These algorithms apply in a natural way to computer-aided geometric design. Moreover, the interest in stationary subdivision schemes has grown in the digital-image-processing and numerical-analysis communities since they have been connected to multiresolution analysis and wavelet bases.

A multiresolution analysis consists of a nested sequence of approximation subspaces

$$\{0\} \to \cdots V_{-2} \subset V_{-1} \subset V_0 \subset V_1 \subset V_2 \cdots \to L^2(\mathbb{R}) \tag{1.3}$$

that are generated by a "scaling function" $\varphi \in V_0$ in the sense that the set $\{\varphi(2^j x - k)\}_{k\in\mathbb{Z}}$ constitutes a Riesz basis for V_j. By $V_j \to L^2(\mathbb{R})$, we mean here that for any f in $L^2(\mathbb{R})$, $\lim_{j\to+\infty} \|P_j f - f\|_0 = 0$, where $P_j f$ is the L^2-projection of f onto V_j and $\|\cdot\|_0$ is the L^2 norm (we shall use the notation $\|\cdot\|_s$ for the Sobolev $H^s = W_2^s$ norm). Here again, many generalizations are possible (see Meyer (1990) or Daubechies (1992) for a detailed review of this concept).

Since the spaces V_j are embedded, the scaling function satisfies an equation of the type

$$\varphi(x) = 2\sum_n c_n \varphi(2x - n). \tag{1.4}$$

We shall assume here that φ is compactly supported so that the c_n's are finite in number. In that case, φ is also an L^1 function and by taking the Fourier transform of (1.4), we have

$$\hat{\varphi}(\omega) = m(\omega/2)\hat{\varphi}(\omega/2), \tag{1.5}$$

where $m(\omega) = \sum_{n\in\mathbb{Z}} c_n e^{-in\omega}$. Assuming that φ is normalized in the sense that $\int \varphi = \hat{\varphi}(0) = 1$, by iterating (1.5), we obtain

$$\hat{\varphi}(\omega) = \prod_{k=1}^{+\infty} m(2^{-k}\omega). \tag{1.6}$$

This formula indicates that φ is the limit in the weak (or distribution) sense of a stationary subdivision scheme since it represents in the Fourier domain the refinement of an initial Dirac sequence by iterative convolutions with c_n. Note also that the support of φ is contained in the convex hull of the support of the mask (c_k). Conversly, any refinable function, i.e., weak limit of such a scheme, satisfies a "refinement equation" of the type described above and is a potential candidate to generate a multiresolution analysis (see also Derfel, Dyn, and Levin (1995)).

Given a stationary subdivision scheme, we see here that two questions are relevant:

- Is the scheme convergent and in what sense?
- What are the properties of the limit functions?

By the last question, we mean in particular the approximation properties of the spaces V_j (can we approximate in norms other than L^2, in particular in Sobolev spaces H^s, with specific rates...), the exact regularity of the scaling function, and other properties of φ such as cardinal interpolation or orthonormality of its integer shifts.

Numerous contributions have been made to these two problems. The convergence of the subdivision and the approximation properties of the multiresolution spaces are strongly linked: in particular, one can prove (see Dyn and Levin (1990); Cavaretta, Dahmen, and Micchelli (1992); and Daubechies and Lagarias (1991)) that both the convergence of the subdivision scheme to a C^r function for some $r \geq 0$ and the property that $\lim_{j \to +\infty} 2^{js} \|P_j f - f\|_0 = 0$ for all $f \in H^s$ $(s \leq r)$ imply that the scaling function satisfies the Strang–Fix conditions of order N, where N is an integer such that $N \leq r < N+1$. These conditions can be expressed by three equivalent statements:

- Any polynomial of degree not exceedding N can be expressed as a combination of the integer shifts of φ.
- For all $p \leq N$ and $n \in \mathbb{Z} - \{0\}$, $(\frac{d}{d\omega})^p \hat{\varphi}(2n\pi) = 0$, $\hat{\varphi}(0) = 1$.
- For all $p \leq N$, $(\frac{d}{d\omega})^p m(\pi) = 0$ or, equivalently, $\sum_n (-1)^n n^p c_n = 0$.

Note that this last statement reveals that $m(\omega)$ can be written as

$$m(\omega) = \left(\frac{1+e^{-i\omega}}{2}\right)^{N+1} q(\omega), \tag{1.7}$$

where $q(\omega)$ is a trigonometric polynomial. (1.7) implies that there are at least $N+2$ nonzero c_n's, and thus the support length of φ is at least $N+1$. This leads to the observation that very good approximation rates for regular functions, as well as convergence of the subdivision in a smooth norm, can only be achieved if one accepts the loss of some space localization (in particular, one cannot build a refinable function that is both compactly supported and in C^∞).

More recently, attention has been given to subdivision schemes that are nonstationary in scale, i.e., for which the masks may vary from one step of the refinement process to the next. A model case is the scheme that uses at step k the same mask $c_n^k = \binom{k}{n} 2^{-k+1}$ $(0 \leq n \leq k)$ that would give rise in the stationary subdivision case to B-splines of degree $k-1$. It was proved by Derfel, Dyn, and Levin (1995) that such a scheme converges strongly to the "up-function" introduced by Rvachev and Rvachev (1971) (see also Rvachev (1990)). The limit function can thus be written in the Fourier domain as

$$\hat{\varphi}(\omega) = \prod_{k=1}^{+\infty} \left(\frac{1+e^{-i2^{-k}\omega}}{2}\right)^k. \tag{1.8}$$

The length of its support is given by $L = \sum_{k>0} k2^{-k} = 2 < +\infty$. Such a function cannot satisfy a refinement equation of the type of (1.4). However, note that the product (1.8) can also be written as

$$\begin{aligned}\prod_{k=1}^{+\infty} \left(\frac{1+e^{-i2^{-k}\omega}}{2}\right)^k &= \prod_{n=0}^{+\infty} \prod_{k=n+1}^{+\infty} \frac{1+e^{-i2^{-k}\omega}}{2} \\ &= \prod_{n=0}^{+\infty} \frac{1+e^{-i2^{-n}\omega}}{-i2^{-n}\omega} \\ &= \prod_{n=0}^{+\infty} \hat{\chi}_{[0,1]}(2^{-n}\omega).\end{aligned}$$

It follows that

$$\varphi = \chi_{[0,1]} * 2\chi_{[0,1/2]} * \cdots * 2^j \chi_{[0,2^{-j}]} * \cdots$$

is a C^∞ function that satisfies a "continuous-refinement equation" of the type

$$\varphi(x) = 2\chi_{[0,1]} * \varphi(2\cdot) = \int_0^2 \varphi(2x-y)dy. \tag{1.9}$$

The idea of using iterative convolutions to build C^∞ compactly supported test functions is older than Rvachev's work: it can be found in Mandelbrojt (1942).

Returning to subdivision schemes, we see that by letting the masks grow linearly, it is possible to obtain a C^∞ function while preserving the compact-support property. It was also shown by Dyn and Ron (1995) that a "semimultiresolution analysis" can be derived by defining, for all $j \geq 0$, $V_j = \text{Span}\{\varphi_j(2^j x - k)\}_{k\in\mathbb{Z}}$ with

$$\hat{\varphi}_j(\omega) = \prod_{k=1}^{+\infty} \left(\frac{1+e^{-i2^{-k}\omega}}{2}\right)^{k+j} \tag{1.10}$$

and that these spaces have the property of spectral approximation in L^2: for any $r \geq 0$ and for all $f \in H^r$, $\lim_{j\to+\infty} 2^{jr}\|P_j f - f\|_0 = 0$.

Our goal in this paper is to generalize these results to a large class of nonstationary subdivision schemes.

Assuming that such a scheme converges at least in the sense of tempered distributions, the general form of its limit function will be given in the Fourier domain by

$$\hat{\varphi}(\omega) = \prod_{k=1}^{+\infty} m_k(2^{-k}\omega), \tag{1.11}$$

where m_k is the sequence of trigonometric polynomials associated with the masks of the subdivision. Note that, since we do not assume any particular form for m_k, the function φ will not in general satisfy any type of refinement equation, discrete or continuous, thus making the analysis of its smoothness and approximation properties more difficult.

What is the interest of such a generalization? It is important to remark that the approximation properties of the up-function and its associated multiresolution analysis, very attractive from the theoretical point of view, suffer from a major numerical disadvantage: the computation of the L^2 projection onto V_j is difficult to manage at high scales since the Gram matrix of the basis $\{\varphi^j(2^j x - k)\}_{k\in\mathbb{Z}}$ becomes ill conditioned. More precisely, its condition number $C(j)$ grows exponentially with j:

$$(\sqrt{2})^{j+1} \leq C(j) \leq \text{const}\left(\frac{\pi}{2}\right)^j. \tag{1.12}$$

The upper bound is taken from Dyn and Ron (1995) and the lower bound is obtained here:

$$\begin{aligned} C(j)^2 &= \left(\sup_\omega \sum_k |\hat{\varphi}^j(\omega+2k\pi)|^2\right)\left(\inf_\omega \sum_k |\hat{\varphi}^j(\omega+2k\pi)|^2\right)^{-1} \\ &\geq \left(\inf_\omega \sum_k |\hat{\varphi}^j(\omega+2k\pi)|^2\right)^{-1} \end{aligned}$$

$$\geq \left(\sum_k |\hat{\varphi}^j((2k+1)\pi)|^2\right)^{-1}$$
$$= \left(\sum_k |\cos^{j+1}(\pi/4)\hat{\varphi}^{j+1}((2k+1)\pi/2)|^2\right)^{-1}$$
$$\geq [\cos(\pi/4)]^{-2j-2} = 2^{j+1}.$$

The same problem occurs when one wants to interpolate data on the grid $2^{-j}\mathbb{Z}$ by a function in V_j for j odd: one checks from a similar computation that the condition number $D(j)$ of the system grows exponentially.

In a more general setting, it is possible to keep these condition numbers bounded as j grows. One can even fix one of them to 1 by imposing constraints on the trigonometric polynomials m_k so that the limit functions have orthonormality or cardinal interpolation properties (see §4).

Finally, an important property of multiresolution analysis is the equivalence

$$\|f\|_r^2 \approx \|P_0 f\|_0^2 + \sum_{j>0} 2^{2jr}\|P_{j+1}f - P_j f\|_0^2 \tag{1.13}$$

that is the key to multilevel preconditionning techniques (see Dahmen and Kunoth (1992)) and that can also be expressed in terms of wavelet coefficients. Thus far, we have only been able to prove this equivalence in the orthonormal case for all $r > 0$ (see §4).

Our paper is organized as follows. In §2, we give a general result on the convergence of a nonstationary subdivision scheme in C^∞ under very mild conditions on the masks. In §3, we study the approximation properties of the associated multiresolution spaces and prove that spectral approximation can be achieved for all Sobolev norms. Finally, in §4, we apply these results to dyadic interpolation and to orthonormal wavelets that constitute Riesz bases for all Sobolev spaces. This particular wavelet basis has recently been introduced in a paper by Berkolaiko and Novikov (1992) which was concerned with the existence of a multiscale orthonomal basis of compactly supported C^∞ functions.

For the sake of simplicity, we limit ourselves to the one-dimensional setting and our results are stated in the case where the length of the masks grows at least linearly. We show in the appendix how this can be extended to more general growth rates of the mask length.

2. Nonstationary subdivision schemes. Let $\{m_k\}_{k>0}$ be a sequence of finite masks, i.e., $m_k(n) = 0$ if $|n| > d(k)$. We denote by $m_k(\omega) = \sum_n m_k(n)e^{-in\omega}$ their representation in the Fourier domain, i.e., a sequence of trigonometric polynomials of degree $d(k)$. Let us consider the nonstationary subdivision scheme that is associated with this sequence of masks, i.e., $s_j(2^{-j}k) = 2\sum_n m_j(k-2n)s_{j-1}(2^{-j+1}n)$. If the input is a Dirac sequence $\delta_{m,0}$, one obtains after n steps a sequence of samples on the grid $2^{-n}\mathbb{Z}$ that can be interpolated in a unique way by a function $\varphi^{[n]}$ that is band limited on $[-2^n\pi, 2^n\pi]$. This function is defined by

$$\hat{\varphi}^{[n]}(\omega) = \prod_{k=1}^{n} m_k(2^{-k}\omega)\chi_{[-\pi,\pi]}(2^{-n}\omega). \tag{2.1}$$

Note that the functions $\varphi^{[n]}$ are analytic and thus not compactly supported. We shall use these particular interpolants in order to study the convergence of the subdivision scheme to the limit function defined (if this is possible) by

$$\hat{\varphi}(\omega) = \prod_{k=1}^{+\infty} m_k(2^{-k}\omega). \tag{2.2}$$

After n steps, the result of the subdivision in the space domain is supported in $[-L(n), L(n)]$ with $L(n) = \sum_{k=1}^{n} 2^{-k}d(k)$. A natural condition for the compactly supported limit function is thus

$$L = \sum_{k=1}^{+\infty} 2^{-k}d(k) < +\infty. \tag{2.3}$$

Our first result shows that this condition is also instrumental in the derivation of the convergence in the sense of tempered distributions of the subdivision scheme.

THEOREM 2.1. *Assume that $r_k = 2^{-k}d(k)$ and $s_k = |m_k(0) - 1|$ are both summable sequences and that the functions $|m_k(\omega)|$ are uniformly bounded by some constant $M > 0$. Then $\hat{\varphi}^{[n]}$ converges uniformly on any compact set to $\hat{\varphi}$ and $\varphi^{[n]}$ converges to φ in the sense of tempered distributions. The tempered distribution φ is compactly supported in $[-L, L]$ with $L = \sum_{k>0} r_k$.*

Proof. We first study the convergence of the infinite product (2.2). For a fixed ω, we have to check the summability in k of $t_k(\omega) = |m_k(2^{-k}\omega) - 1|$. If, in addition, $\sum_{k>0} t_k(\omega)$ is uniformly bounded on every compact set, then (2.2) will also converge uniformly on every compact set.

We can write

$$\begin{aligned} t_k(\omega) &\le |m_k(2^{-k}\omega) - m_k(0)| + s_k \\ &\le 2^{-k}|\omega| \sup_{\omega} \left| \frac{d}{d\omega} m_k \right| + s_k. \end{aligned}$$

Using Bernstein's inequality, we obtain the estimate

$$\sup_{\omega} \left| \frac{d}{d\omega} m_k \right| \le Md(k), \tag{2.4}$$

and thus

$$t_k(\omega) \le M|\omega| r_k + s_k, \tag{2.5}$$

which proves the uniform convergence of (2.2) on every compact set.

The same argument shows that for any $n > p \ge 0$, the products

$$P_p^n(\omega) = \prod_{k=p+1}^{n} m_k(2^{-k}\omega), \tag{2.6}$$

are uniformly bounded on $[-2^{p+1}, 2^{p+1}]$ by the same $B > 0$. We can define these products to be equal to 1 whenever $n \le p$ so that this statement makes sense for all $n, p > 0$. This applies in particular to $\hat{\varphi}^{[n]} = P_0^n$ and $\hat{\varphi} = P_0^{\infty}$, which are thus uniformly bounded on $[-2, 2]$.

For $2^p \le |\omega| \le 2^{p+1}$ with $p \ge 0$, we can write

$$\begin{aligned} |\hat{\varphi}^{[n]}(\omega)| &= \left| P_p^n(\omega) \prod_{k=1}^{p} m_k(2^{-k}\omega) \right| \\ &\le BM^p \le BM^{\log_2 |\omega|} \le B|\omega|^b \end{aligned}$$

with $b = \log_2(M)$ (we have assumed here without loss of generality that $M \geq 1$). For all $\omega \in \mathbb{R}$, we thus have the estimate

$$|\hat{\varphi}^{[n]}(\omega)| \leq B(1+|\omega|)^b, \tag{2.7}$$

where the constant B does not depend on n. Consequently, it also holds for the pointwise limit $\hat{\varphi}$.

Now take any test function $g(\omega)$ in the Schwartz class $S(\mathbb{R})$. For any $\varepsilon > 0$, there exists $A > 0$ such that

$$B\int_{|\omega|>A} g(\omega)(1+|\omega|)^b d\omega \ < \ \varepsilon/2. \tag{2.8}$$

By the uniform convergence of $\hat{\varphi}^{[n]}$ to $\hat{\varphi}$ on every compact, there exists N such that for all $n > N$,

$$\left|\int_{|\omega|<A} g(\omega)(\hat{\varphi}(\omega) - \hat{\varphi}^{[n]}(\omega))d\omega\right| \ < \ \varepsilon/2. \tag{2.9}$$

Combining (2.7), (2.8), and (2.9), we immediately obtain the convergence of $\langle\hat{\varphi}^{[n]}|g\rangle$ to $\langle\hat{\varphi}|g\rangle$. □

We are now interested in finding additional hypotheses for stronger convergence of the subdivision scheme to a C^∞ compactly supported function φ. Note that, in contrast to its approximants $\varphi^{[n]}$, the function φ cannot be analytic. Our next result states general conditions for the uniform convergence of $\varphi^{[n]}$ and all its derivatives.

THEOREM 2.2. *Assume that the hypotheses of Theorem* 2.1 *are satisfied and that we have the estimate*

$$|m_k(\omega)| \leq (1+\alpha_k)|m(\omega)|^k \tag{2.10}$$

with $\sum_k |\alpha_k| < +\infty$ *and* $m(\omega) = \cos^\beta(\omega/2)\tilde{m}(\omega)$, *for some* $\beta \geq 0$ *(not necessarily integer), where the function* $\tilde{m}(\omega)$ *is bounded, Hölder continuous at the origin and satisfies* $\tilde{m}(0) = 1$ *and* $\sigma_i = \sup_\omega |\prod_{k=1}^{i} \tilde{m}(2^k\omega)| < 2^{\beta i}$ *for some fixed integer* $i > 0$.

Then φ *is a* C^∞ *compactly supported function and, for all* $s \in \mathbb{Z}_+$, $(\frac{d}{dx})^s\varphi^{[n]}$ *converges uniformly to* $(\frac{d}{dx})^s\varphi$.

Proof. It is sufficient to show that for all $s \in \mathbb{Z}_+$, the functions $|\omega|^s|\hat{\varphi}^{[n]}(\omega)|$ are dominated by an L^1 function $f_s(\omega)$ that does not depend on n: by dominated convergence, this implies

$$\lim_{n\to+\infty}\int |\omega|^s|\hat{\varphi}(\omega) - \hat{\varphi}^{[n]}(\omega)|d\omega \ = \ 0 \tag{2.11}$$

and thus the uniform convergence of all the derivatives of $\varphi^{[n]}$ in the space domain. We shall construct these dominating functions using the additional hypotheses that we have made on the functions $m_k(\omega)$. First, we need a technical estimate that will be useful: for any $q \geq 0$, there exists $C_q > 0$ such that for any sequence $\{a_k\}_{k>0}$ with $0 \leq a_k \leq 1$ and any $n \geq p \geq 0$,

$$\prod_{k=p}^{n} |m_{q+k}(2^{-k}\omega)|^{a_k} \leq C_q(1+|\omega|)^b \tag{2.12}$$

with $b = \log_2(M)$. (As in the previous theorem, we assume without loss of generality that $M \geq 1$.) Indeed, using the same argument (Bernstein's inequality) as in the proof of Theorem 2.1, we observe that $\prod_{k=p}^{n} |m_{q+k}(2^{-k}\omega)|^{a_k}$ is uniformly bounded in $[-1, 1]$ by a constant C_q that does not depend on a_k, p, and n since we have

$$\begin{aligned} |1 - |m_{q+k}(2^{-k}\omega)|^{a_k}| &\leq |m_{q+k}(2^{-k}\omega) - 1| \\ &\leq |m_{q+k}(2^{-k}\omega) - m_{q+k}(0)| + |m_{q+k}(0) - 1| \\ &\leq 2^q M|\omega| r_{q+k} + s_{q+k} \leq 2^q M r_{q+k} + s_{q+k}. \end{aligned}$$

For $2^l \leq |\omega| \leq 2^{l+1}$ with $p \leq l < n$, we now derive

$$\begin{aligned} \prod_{k=p}^{n} |m_{q+k}(2^{-k}\omega)|^{a_k} &= \prod_{k=p}^{l} |m_{q+k}(2^{-k}\omega)|^{a_k} \prod_{k=l+1}^{n} |m_{q+k}(2^{-k}\omega)|^{a_k} \\ &\leq M^l \prod_{k=l+1}^{n} |m_{q+k}(2^{-k}\omega)|^{a_k} \\ &\leq C_q (M)^{\log_2 |\omega|} = C_q |\omega|^b. \end{aligned}$$

In the cases where $l \geq n$, this estimate still holds since $M^n \leq M^l$, while for $l < p$, the bound is C_q. This proves (2.12) for all $\omega \in \mathbb{R}$.

We are now ready to build the dominating functions $f_s(\omega)$. For fixed $s \geq 0$, choose $p \in \mathbb{N}$ such that $p((\log_2 \sigma_i)/i - \beta) + s + b < -1$. (This is always possible since we have assumed $(\log_2 \sigma_i)/i < \beta$.) For $n \geq p$, we can estimate $\hat{\varphi}^{[n]}(\omega)$ on $[-2^n\pi, 2^n\pi]$ by

$$\begin{aligned} |\hat{\varphi}^{[n]}(\omega)| &= \prod_{k=1}^{n} |m_k(2^{-k}\omega)| \\ &\leq M^{p-1} \prod_{k=p}^{n} |m_k(2^{-k}\omega)| \\ &= M^{p-1} \prod_{k=p}^{n} |m_k(2^{-k}\omega)|^{\frac{p}{k}} \prod_{k=p}^{n} |m_k(2^{-k}\omega)|^{\frac{k-p}{k}}. \end{aligned}$$

Using estimate (2.12) and hypothesis (2.10), we thus obtain

$$\begin{aligned} |\hat{\varphi}^{[n]}(\omega)| &\leq M^{p-1} C_p (1 + |\omega|)^b \prod_{k=p}^{n} |m(2^{-k}\omega)|^p \\ &= M^{p-1} C_p (1 + |\omega|)^b \prod_{k=p}^{n} |\cos(2^{-k-1}\omega)|^{\beta p} |\tilde{m}(2^{-k}\omega)|^p \\ &= M^{p-1} C_p (1 + |\omega|)^b \frac{|\mathrm{sinc}(2^{-p}\omega)|^{\beta p}}{|\mathrm{sinc}(2^{-n-1}\omega)|^{\beta p}} \prod_{k=p}^{n} |\tilde{m}(2^{-k}\omega)|^p \\ &\leq A_p (1 + |\omega|)^{b-\beta p} \prod_{k=p}^{n} |\tilde{m}(2^{-k}\omega)|^p, \end{aligned}$$

where A_p depends only on p, since $|\mathrm{sinc}(2^{-n-1}\omega)|^{\beta p}$ is bounded below away from 0 on $[-2^n\pi, 2^n\pi]$ by a constant that does not depend on n but only on p. To estimate the remaining product, we remark that since $\tilde{m}(\omega)$ is bounded and Hölder continuous at the origin and $\tilde{m}(0) = 1$, then for all $n \geq p \geq 0$, the products $\prod_{k=p}^{n} |\tilde{m}(2^{-k}\omega)|^p$ are uniformly bounded on $[-1, 1]$ by a constant B_p that is independent of n. For $2^l \leq |\omega| \leq 2^{l+1}$ with $p \leq l < n$, using the hypothesis on $\tilde{m}$, we obtain

$$\begin{aligned}
\prod_{k=p}^{n} |\tilde{m}(2^{-k}\omega)|^p &= \prod_{k=p}^{l} |\tilde{m}(2^{-k}\omega)|^p \prod_{k=l+1}^{n} |\tilde{m}(2^{-k}\omega)|^p \\
&= \prod_{k=p}^{l} |\tilde{m}(2^{-k}\omega)|^p \prod_{k=1}^{n-l} |\tilde{m}(2^{-k-l}\omega)|^p \\
&\leq B_p \prod_{k=p}^{l} |\tilde{m}(2^{-k}\omega)|^p \\
&\leq B_p \sigma_i^{[\frac{l-p}{i}]p} \left(\sup_{\omega} |\tilde{m}(\omega)|\right)^{(i-1)p} \\
&= D_p \sigma_i^{lp/i} \\
&\leq D_p \sigma_i^{(p/i)\log_2 |\omega|} = A_p |\omega|^{(p/i)\log_2 \sigma_i},
\end{aligned}$$

where D_p depends only on p (again, in the cases where $l \geq n$ or $l < p$, this still holds by replacing the product that does not make sense by 1). Combining this with the previous estimate, we obtain

$$|\hat{\varphi}^{[n]}(\omega)| \leq K_p(1 + |\omega|)^{b+p(\frac{\log_2 \sigma_i}{i} - \beta)}, \tag{2.13}$$

where K_p depends only on p, and thus

$$|\omega|^s |\hat{\varphi}^{[n]}(\omega)| \leq K_p(1 + |\omega|)^{b+s+p(\frac{\log_2 \sigma_i}{i} - \beta)}. \tag{2.14}$$

This also holds trivially for $|\omega| > 2^n\pi$. Since we have assumed that $b+s+p((\log_2 \sigma_i)/i - \beta) < -1$, this gives us the desired uniform L^1 estimate. This concludes the proof of the theorem. □

Remarks. The hypotheses of Theorem 2.2 imply, in particular, that the degree $d(k)$ of m_k grows at least linearly (m_k has a zero of order βk at $\omega = \pi$). This is not strictly necessary: we show in the appendix that it is possible to obtain strongly converging subdivision schemes with a C^∞ limit function as soon as $d(k)$ tends to $+\infty$ without any assumption on its asymptotic behavior (but with the assumption $|m(\omega)| \leq 1$, which removes a lot of technicalities).

These hypotheses can also be weakened by assuming that estimate (2.10) is satisfied only for k sufficiently large: the limit behavior of the subdivision does not depend on the first iterations.

3. Multiresolution approximation. Let $\{m_k\}_{k>0}$ be a sequence of finite masks that satisfy the hypotheses of Theorem 2.2. We define a sequence of C^∞ compactly supported functions by

$$\hat{\varphi}_j(\omega) = \prod_{k=1}^{+\infty} m_{k+j}(2^{-k}\omega), \quad j \geq 0. \tag{3.1}$$

We see that $\varphi_0 = \varphi$ and that φ_j is obtained as the limit of the same subdivision algorithm by cancelling the first j iterations. It follows that φ_j is also in C_0^∞. Since

$\hat{\varphi}_j(\omega) = m_{j+1}(\omega/2)\hat{\varphi}_{j+1}(\omega/2)$, we see that this sequence of functions satisfies a series of recursive refinement equations:

$$\varphi_j(x) = \sum_{|n|\le d(j+1)} m_{j+1}(n)\varphi_{j+1}(2x-n). \tag{3.2}$$

It is thus natural to define a "semimultiresolution analysis" $\{V_j\}_{j\ge 0}$ by $V_j = \mathrm{Span}\{\varphi_j(2^j x - k)\}_{k\in\mathbb{Z}}$. The inclusion $V_j \subset V_{j+1}$ comes from (3.2).

We shall now study the approximation properties of these spaces in Sobolev spaces. Given a function $f \in H^r$, we can define

$$d(f, V_j)_s = \inf_{g\in V_j} \|f-g\|_s \tag{3.3}$$

for $s \le r$, where $\|\cdot\|_s$ is the H^s norm. We are concerned here with the behavior of $d(f, V_j)$ as j goes to $+\infty$. By definition, the spaces V_j have approximation order (resp. density order) r in H^s if $2^{(r-s)j}d(f,V_j)_s$ is bounded (resp. goes to 0) as $j \to +\infty$.

We shall first establish a general result using a technique introduced in a paper by de Boor, DeVore, and Ron (1992) in which the authors are concerned with approximation in the L^2 norm from shift-invariant spaces. Here we adapt their technique to the derivation of density orders in Sobolev norms. Approximation orders in Sobolev norms by shift-invariant spaces are studied in Zao (1995) and Ron (1995).

THEOREM 3.1. *Let $\{\varphi^j\}_{j\ge 0}$ be a sequence of compactly supported functions in H^s for some $s \ge 0$ and define $V_j = \mathrm{Span}\{\varphi_j(2^j x - k)\}_{k\in\mathbb{Z}}$. For $r \ge s$, assume that there exists $t \in]0,\pi]$ such that, for all $0 \le v \le s$,*

$$\sup_{|\omega|<t}\left(|\omega|^{-2r}\frac{\sum_{n\ne 0}|\omega+2n\pi|^{2v}|\hat{\varphi}_j(\omega+2n\pi)|^2}{|\hat{\varphi}_j(\omega)|^2}\right) \to 0 \quad as\ j\to+\infty. \tag{3.4}$$

Then the spaces V_j have density order r in H^s: let P_j be the L^2 projection onto V_j and let S_j be the operator defined by $\mathcal{F}S_jf(\omega) = \hat{f}(\omega)\chi_{[-t,t]}(2^{-j}\omega)$, where $\mathcal{F}$ represents the Fourier-transform operator ($\mathcal{F}f(\omega) = \hat{f}(\omega)$). Then for all $f \in H^r$, we have $d(f,V_j) \le \|P_jS_jf - f\|_s \le C2^{j(s-r)}\|f\|_r\varepsilon(f,j)$ with $0 \le \varepsilon(f,j) \le 1$ and $\lim_{j\to+\infty}\varepsilon(f,j) = 0$.

Proof. First, observe that we can always associate with φ_j a function ϕ^j defined by

$$\hat{\phi}_j(\omega) = \frac{\hat{\varphi}_j(\omega)}{\left(\sum_{n\in\mathbb{Z}}|\hat{\varphi}_j(\omega+2n\pi)|^2\right)^{1/2}} \tag{3.5}$$

such that $\{2^{j/2}\phi_j(2^jx-k)\}_{k\in\mathbb{Z}}$ is an orthonormal basis of V_j: in the case where $\sum_{n\in\mathbb{Z}}|\hat{\varphi}_j(\omega+2n\pi)|^2 = \sum_k\langle\varphi^j(\cdot)|\varphi^j(\cdot-k)\rangle e^{-ik\omega}$ vanishes at some isolated point, we can easily check that ϕ_j is still the L^2 limit when $\varepsilon \to 0$ of $\phi_{j,\varepsilon}$ defined by

$$\hat{\phi}_{j,\varepsilon}(\omega) = \frac{\hat{\varphi}_j(\omega)}{\left(\varepsilon + \sum_{n\in\mathbb{Z}}|\hat{\varphi}_j(\omega+2n\pi)|^2\right)^{1/2}} \tag{3.6}$$

and that $\phi_{j,\varepsilon}$ is an ℓ^2 combination of $\varphi_j(x-k)$.

Consequently, we can write

$$P_jf(x) = 2^j \sum_{k\in\mathbb{Z}} \langle f|\phi_j(2^j\cdot -k)\rangle \phi_j(2^jx-k) \tag{3.7}$$

for any $f \in L^2$. For all $j \geq 0$, we define $Q_j = I - P_j$ and $T_j = I - S_j$. We can thus estimate the approximation error as follows:

$$\begin{aligned}\|P_jS_jf - f\|_s &\leq \|T_jf\|_s + \|P_jS_jf - S_jf\|_s\\ &\leq \|T_jf\|_s + \|S_jP_jS_jf - S_jf\|_s + \|T_jP_jS_jf\|_s\\ &\leq \|T_jf\|_s + \|S_jQ_jS_jf\|_s + \|T_jP_jS_jf\|_s.\end{aligned}$$

Let f be in H^r, i.e., $\|f\|_r^2 = (2\pi)^{-1}\int|\hat{f}(\omega)|^2(1+|\omega|^{2r})d\omega < +\infty$. We shall examine these three quantities separately and prove that they all satisfy the estimate that we want for $d(V_j,f)_s$.

The "truncation error" $\|T_jf\|_s$ is independent of the approximating subspaces V_j. It is clear that we have

$$\begin{aligned}\|T_jf\|_s^2 &= (2\pi)^{-1}\int_{|\omega|>2^jt}|\hat{f}(\omega)|^2(1+|\omega|^{2s})d\omega\\ &\leq (2\pi)^{-1}2^{2j(s-r)}t^{2(s-r)}\int_{|\omega|>2^jt}|\hat{f}(\omega)|^2(1+|\omega|^{2r})d\omega\\ &\leq C2^{2j(s-r)}\|f\|_r^2\varepsilon(f,j),\end{aligned}$$

with $0 \leq \varepsilon(f,j) \leq 1$ and $\varepsilon(f,j) \to 0$ as $j \to +\infty$.

For the second term, we have

$$\begin{aligned}\|S_jQ_jS_jf\|_s^2 &= (2\pi)^{-1}\int_{|\omega|<2^jt}|\mathcal{F}Q_jS_jf(\omega)|^2(1+|\omega|^{2s})d\omega\\ &\leq (2\pi)^{-1}(1+2^{2js}t^{2s})\int_{|\omega|<2^jt}|\mathcal{F}Q_jS_jf(\omega)|^2d\omega\\ &\leq C2^{2js}\|S_jQ_jS_jf\|_0^2.\end{aligned}$$

To estimate $\|S_jQ_jS_jf\|_0^2$, we note that

$$\begin{aligned}\mathcal{F}P_jS_jf(\omega) &= \hat{\phi}_j(2^{-j}\omega)\sum_{k\in\mathbb{Z}}\langle S_jf|\phi_j(2^j\cdot -k)\rangle e^{-i2^{-j}k\omega}\\ &= (2^{j+1}\pi)^{-1}\hat{\phi}_j(2^{-j}\omega)\sum_{k\in\mathbb{Z}}\langle \mathcal{F}S_jf(\cdot)|\hat{\phi}_j(2^{-j}\cdot)e^{i2^{-j}k\cdot}\rangle e^{-i2^{-j}k\omega}.\end{aligned}\tag{3.8}$$

Since the above sum defines a $2^{j+1}\pi$-periodic function which coincides on $[-2^j\pi,2^j\pi]$ with $\hat{f}(\omega)\chi_{[-t,t]}(2^{-j}\omega)\overline{\hat{\phi}(2^{-j}\omega)}$, it follows that, on the interval $[-2^j\pi,2^j\pi]$,

$$\mathcal{F}P_jS_jf(\omega) = |\hat{\phi}_j(2^{-j}\omega)|^2\hat{f}(\omega)\chi_{[-t,t]}(2^{-j}\omega).$$

From this, we derive

$$\|S_jQ_jS_jf\|_0^2 = (2\pi)^{-1}\int_{|\omega|<2^jt}|\hat{f}(\omega) - \mathcal{F}P_jS_jf(\omega)|^2d\omega$$

$$
\begin{aligned}
&= (2\pi)^{-1}\int_{|\omega|<2^jt}|\hat f(\omega)|^2(1-|\hat\phi_j(2^{-j}\omega)|^2)^2d\omega\\
&\leq (2\pi)^{-1}2^{-2jr}\sup_{|\omega|<t}\left(\frac{1-|\hat\phi_j(\omega)|^2}{|\omega|^r}\right)^2\int_{|\omega|<2^jt}|\omega|^{2r}|\hat f(\omega)|^2d\omega\\
&= 2^{-2jr}\|f\|_r^2\sup_{|\omega|<t}\left(\frac{\sum_{n\neq0}|\hat\varphi_j(\omega+2n\pi)|^2}{|\omega|^r\sum_n|\hat\varphi_j(\omega+2n\pi)|^2}\right)^2\\
&\leq 2^{-2jr}\|f\|_r^2\sup_{|\omega|<t}\left(\frac{\sum_{n\neq0}|\hat\varphi_j(\omega+2n\pi)|^2}{|\omega|^r|\hat\varphi_j(\omega)|^2}\right)^2.
\end{aligned}
$$

Combining these estimates with hypothesis (3.4) in the case where $v=0$, we obtain

$$\|S_jQ_jS_jf\|_s^2\leq C2^{2j(s-r)}\|f\|_r^2\varepsilon(j) \tag{3.9}$$

with $0\leq\varepsilon(j)\leq1$ and $\varepsilon(j)\to0$ as $j\to+\infty$.

Finally, for the last term $\|T_jP_jS_jf\|_s$, we note that for ω such that $|\omega-2^{j+1}n\pi|<2^jt$, we have, by (3.8) and the observation following it,

$$\mathcal{F}P_jS_jf(\omega)=\hat\phi_j(2^{-j}\omega)\overline{\hat\phi_j(2^{-j}\omega-2n\pi)}\hat f(\omega-2^{j+1}n\pi), \tag{3.10}$$

and $\mathcal{F}P_jS_jf(\omega)=0$ for $2^jt<|\omega-2^{j+1}n\pi|<2^j\pi$. Consequently, we can estimate this last term as follows:

$$
\begin{aligned}
\|T_jP_jS_jf\|_s^2 &= (2\pi)^{-1}\int_{|\omega|>2^jt}|\mathcal{F}P_jS_jf(\omega)|^2(1+|\omega|^{2s})d\omega\\
&\leq C\sum_{n\neq0}\int_{|\omega|<2^jt}|\mathcal{F}P_jS_jf(\omega+2^{j+1}n\pi)|^2|\omega+2^{j+1}n\pi|^{2s}d\omega\\
&= C\int_{|\omega|<2^jt}|\hat\phi_j(2^{-j}\omega)\hat f(\omega)|^2\sum_{n\neq0}|\omega+2^{j+1}n\pi|^{2s}|\hat\phi_j(2^{-j}\omega+2n\pi)|^2d\omega\\
&\leq C\int_{|\omega|<2^jt}|\hat f(\omega)|^2\left(\sum_{n\neq0}|\omega+2^{j+1}n\pi|^{2s}|\hat\phi_j(2^{-j}\omega+2n\pi)|^2\right)d\omega\\
&\leq C2^{2j(s-r)}\sup_{|\omega|<t}\left(\frac{\sum_{n\neq0}|\omega+2n\pi|^{2s}|\hat\phi_j(\omega+2n\pi)|^2}{|\omega|^{2r}}\right)\int_{|\omega|<2^jt}|\hat f(\omega)|^2|\omega|^{2r}d\omega\\
&\leq C2^{2j(s-r)}\sup_{|\omega|<t}\left(|\omega|^{-2r}\frac{\sum_{n\neq0}|\omega+2n\pi|^{2s}|\hat\varphi_j(\omega+2n\pi)|^2}{|\hat\varphi_j(\omega)|^2}\right)\|f\|_r^2.
\end{aligned}
$$

Combining this estimate with hypothesis (3.4) in the case where $v=s$, we obtain

$$\|T_jP_jS_jf\|_s^2\leq C2^{2j(s-r)}\|f\|_r^2\varepsilon(j) \tag{3.11}$$

with $0\leq\varepsilon(j)\leq1$ and $\varepsilon(j)\to0$ as $j\to+\infty$. This concludes the proof of the theorem. □

We now return to the case of multiresolution spaces generated by the functions φ_j defined by (3.1) with the conditions on the masks stated in Theorem 2.2. The following result shows that, under an additional assumption on these masks, hypothesis (3.4) is satisfied for any $r,v\geq0$.

THEOREM 3.2. *Assume that the family* $\{m_k(\omega)\}_{k>0}$ *satisfies the hypotheses of Theorem* 2.2 *and*

$$|m_k(\omega)| \geq (1-\tilde{\alpha}_k)|a(\omega)|^k, \tag{3.12}$$

where $|\tilde{\alpha}_k| < 1$, $\sum_k |\tilde{\alpha}_k| < +\infty$, $a(\omega)$ *is Hölder continuous at the origin with exponent* $\gamma > 0$ *and* $a(0) = 1$. *Then there exists* $t > 0$ *such that for all* $r, v \geq 0$,

$$\sup_{|\omega|<t} \left(|\omega|^{-2r} \frac{\sum_{n\neq 0} |\omega + 2n\pi|^{2v} |\hat{\varphi}_j(\omega+2n\pi)|^2}{|\hat{\varphi}_j(\omega)|^2} \right) \to 0 \quad \textit{as } j \to +\infty. \tag{3.13}$$

Proof. We shall prove that, for fixed $v > 0$, there exist constants $A, B, C, D, T > 0$ such that if $|\omega| < T$, the following holds:

$$|\hat{\varphi}_j(\omega)|^2 \geq AB^j \tag{3.14}$$

and

$$\sum_{n\neq 0} |\omega + 2n\pi|^{2v} |\hat{\varphi}_j(\omega + 2n\pi)|^2 \leq C|D\omega|^{2\beta j}, \tag{3.15}$$

where β is the exponent that appears in the hypothesis of Theorem 2.2. It will then be sufficient to choose $t \in]0, T[$ such that $(Dt)^{2\beta}/B < 1$ in order to ensure (3.13).

First, we introduce four functions:

$$g_m(\omega) = \prod_{k=1}^{\infty} |m(2^{-k}\omega)|, \qquad h_m(\omega) = \prod_{k=1}^{\infty} |m(2^{-k}\omega)|^k \tag{3.16}$$

and

$$g_a(\omega) = \prod_{k=1}^{\infty} |a(2^{-k}\omega)|, \qquad h_a(\omega) = \prod_{k=1}^{\infty} |a(2^{-k}\omega)|^k. \tag{3.17}$$

The above infinite products are convergent since the functions $m(\omega)$ and $a(\omega)$ are Hölder continuous at the origin, achieving the value 1 there, and hence the logarithm of each of the four infinite products is a convergent series.

By (3.1), (2.10), and (3.12), we have

$$M_a h_a(\omega)[g_a(\omega)]^j \leq |\hat{\varphi}_j(\omega)| \leq M_m h_m(\omega)[g_m(\omega)]^j, \tag{3.18}$$

where

$$M_a = \prod_{k=1}^{\infty} (1 - |\tilde{\alpha}_k|), \qquad M_m = \prod_{k=1}^{\infty} (1 + |\alpha_k|) \tag{3.19}$$

To get an upper bound for the numerator of (3.13), define

$$g_m(\omega) = \operatorname{sinc}^{\beta}(\omega/2)\tilde{g}(\omega) \tag{3.20}$$

with $\tilde{g}(\omega) = \prod_{k=1}^{\infty} |\tilde{m}(2^{-k}\omega)|$. For $l \geq 0$ and $2^l \leq |\omega| \leq 2^{l+1}$, we have, by the hypotheses of Theorem 2.2,

$$\begin{aligned} \tilde{g}(\omega) &= \tilde{g}(2^{-l}\omega) \prod_{k=1}^{l} |\tilde{m}(2^{-k}\omega)| \\ &\leq \sup\nolimits_{|\omega|<2}(\tilde{g}(\omega))(\sup|\tilde{m}|)^{i-1}(\sigma_i)^{[l/i]} \\ &\leq \sup\nolimits_{|\omega|<2}(\tilde{g}(\omega))(\sup|\tilde{m}|)^{i-1}|\omega|^{\frac{\log_2 \sigma_i}{i}} \leq K_1|\omega|^{\beta}. \end{aligned} \tag{3.21}$$

Combining (3.21) with (3.19), we obtain the estimates

$$g_m(\omega) \le K_2(1+|\omega|)^{-\varepsilon} \tag{3.22}$$

with $\varepsilon = \beta - (\log_2 \sigma_i)/i > 0$ and

$$g_m(\omega + 2n\pi) \le K_1|\omega|^{\beta}, \quad n \in \mathbb{Z} - \{0\},\ |\omega| \le \pi. \tag{3.23}$$

In the last inequality, we used the bound

$$\operatorname{sinc}(n\pi + \omega/2) \le |\omega||\omega + 2n\pi|^{-1}, \quad n \in \mathbb{Z} - \{0\}. \tag{3.24}$$

Finally, by (3.22) and since $g_m(\omega)$ is Hölder continuous at the origin with the same exponent as $m(\omega)$, we can also write $h_m(\omega)$ as

$$h_m(\omega) = \prod_{k=0}^{\infty} g_m(2^{-k}\omega). \tag{3.25}$$

For any $\delta \in]0,1[$, choose $\omega_\delta > 0$ such that $g_m(\omega) < \delta$ if $|\omega| > \omega_\delta$. For $l \ge 0$ and $2^l\omega_\delta \le |\omega| < 2^{l+1}\omega_\delta$, we thus have

$$\begin{aligned} h_m(\omega) &= h_m(2^{-l-1}\omega)\prod_{k=0}^{l} g_m(2^{-k}\omega) \\ &\le [\sup_{|\omega|\le\omega_\delta} h_m(\omega)]\delta^{l+1} \\ &\le [\sup_{|\omega|\le\omega_\delta} h_m(\omega)]\delta^{\log_2(|\omega|/\omega_\delta)} \\ &= K_\delta|\omega|^{\log_2\delta}. \end{aligned}$$

Since δ is arbitrary, this shows that $h_m(\omega)$ has rapid decay at infinity. We can thus define

$$K_3 = \sum_{n\in\mathbb{Z}} |\omega + 2n\pi|^{2v}|h_m(\omega + 2n\pi)|^2 < +\infty, \tag{3.26}$$

and conclude estimate (3.15) from (3.18) and (3.22) with $C = M_m^2K_3$ and $D = K_1^{1/\beta}$.

To obtain a lower bound for the denominator of (3.13), we use the fact that $h_a(\omega)$ and $g_a(\omega)$ are Hölder continuous at the origin with the same exponent as $a(\omega)$ and both are 1 at the origin. Thus $h_a(\omega) \ge \theta_1 > 0$ and $g_a(\omega) \ge \theta_2 > 0$ for $|\omega|$ small enough, which together with (3.18) yields (3.14) with $A = M_a^2\theta_1^2$ and $B = \theta_2^2$. □

Combining Theorem 3.1 and 3.2, we immediatly obtain the following corollary.

COROLLARY 3.3. *Let $\{m_k(\omega)\}_{k>0}$ be a family of trigonometric polynomials that satisfy the hypotheses of Theorem* 3.2 *and let $\{\varphi_j\}_{j\ge0}$ be the associated scaling functions defined by* (3.1). *Then the semimultiresolution analysis $\{V_j\}_{j\ge0}$ generated by these functions achieve spectral approximation, i.e., it has density order r in H^s for all $r \ge s \ge 0$.*

Remarks. As in the previous section, the hypotheses here can also be weakened by assuming that the hypotheses on the functions $m_k(\omega)$ hold only for k sufficiently large since only the scaling functions at coarse scales will be affected.

Here we have concentrated on the rate of approximation in Sobolev spaces $H^s(\mathbb{R})$. If we are interested in the approximation of a function $f \in H^r(I)$, where I is a finite interval, we can use the space V_j^I defined by the restriction into I of the functions of V_j. This space has finite dimension, and we can easily check that there exists a constant $C > 0$ such that $\dim(V_j^I) \leq C2^j$. The property that $2^{(r-s)j}d(f, V_j^I)_s$ goes to 0 as $j \to +\infty$ reveals that $\{V_j^I\}_{j\geq 0}$ is a sequence of n-width approximation spaces for Sobolev spaces. In that sense, the V_j spaces are optimal for approximation in all Sobolev spaces.

One may also like to obtain similar optimal results for other types of Besov spaces $B_q^s(L^p)$, e.g., Hölder space $C^s = B_\infty^s(L^\infty)$. The generalizations of the results of this section depend on p in an essential way:

- When $p = 2$, for $H^s = B_2^s(L^2)$ in particular, these spaces can be fully described in the Fourier domain because of the isometry of $f \to \hat{f}$ with respect to the L^2 norm, and Theorem 3.1 can be generalized to $q \neq 1$.
- When $p \neq 2$, this task seems much more difficult since one has to deal with the space domain in which the support of the functions φ_j grows with j, at least linearly. Take, for example, the Hölder space C^s ($s = N + r$, $r \in]0, 1]$): a natural method of approximating $f \in C^s$ by a function in V_j is to approximate f locally by a polynomial of degree N with an L^∞ error of order $(\Delta x)^s$ and to generate these polynomials locally by the functions $\{\varphi_j(2^j x - k)\}_{k\in\mathbb{Z}}$ provided that the Strang–Fix conditions of order N are satisfied. In the case that we consider, due to the particular properties of $m_k(\omega)$, the V_j spaces contain polynomials of arbitrarily high degree as j grows. However, since the support of the functions φ_j grows at least linearly, one can only predict an L^∞ error of order $(j2^{-j})^s$ for arbitrary s. In the standard multiresolution-analysis framework, the error will be of order 2^{-sj} since the generating function is the same at every scale, but only for $s \leq N + 1$, N being the order of the Strang–Fix conditions, which is constant for all $j \geq 0$.

For C^∞ functions, better rates of convergences can be expected. An interesting perspective is the exploration of the approximation properties of the V_j spaces in classes of C^∞ functions defined by the growth of the sup norm of their derivatives (Gevrey classes; see Hormander (1983)).

Finally, let us remark that an important problem—besides knowing the rate of convergence of the best approximation in a fixed norm—is the construction of this best approximation numerically. In the case of Sobolev spaces, we gave an explicit approximation operator that combines truncation in the Fourier domain with L^2 projection onto V_j. An interesting case is when the functions $\{\varphi_j(x - k)\}_{k\in\mathbb{Z}}$ form orthonormal systems for all $j \geq 0$ so that the L^2 projection can be expressed directly in terms of theses compactly supported functions. The next section will focus on an example of such a system, showing that it leads to orthonormal bases of smooth compactly supported wavelets that are Riesz bases for all Sobolev spaces and that the asymptotically best H^s approximation is always achieved by the L^2 projection.

4. Smooth cardinal interpolation and orthonormal wavelet bases with compact support. By definition, a scaling function has the property of cardinal interpolation if

$$\varphi(k) = \delta_{0,k} \tag{4.1}$$

and the property of orthonormality if

$$\langle \varphi(\cdot - k) | \varphi(\cdot - l) \rangle = \delta_{k,l}. \tag{4.2}$$

In the framework of standard multiresolution-analysis and refinement equations, such functions were first studied by Deslauriers and Dubuc (1987) and Dyn, Gregory, and Levin (1987) in the interpolating case and by Daubechies (1988) and Meyer (1990) in the orthonormal case. They can be generated by imposing specific necessary constraints on the coefficients c_n in (1.4) or, equivalently, on the function $m(\omega)$. These constraints are $c_{2n} = (1/2)\delta_{n,0}$ or, equivalently,

$$m(\omega) + m(\omega + \pi) = 1 \tag{4.3}$$

for interpolation and

$$|m(\omega)|^2 + |m(\omega + \pi)|^2 = 1 \tag{4.4}$$

for orthonormality. We recall here the main results of these constructions without proving them since they are now classics and can be found in detail in Daubechies (1992) and Meyer (1990):

- The constraint (4.3) (resp. (4.4)) will be sufficient to ensure (4.1) (resp. (4.2)) if and only if the associated subdivision scheme (i.e., the sequence $\varphi^{[n]}$) converges in C^0 (resp. in L^2) since the functions $\varphi^{[n]}$ that interpolate the subdivision at step n satisfy by recursion the interpolation (resp. orthonormality) property.
- It is clear that a trigonometric polynomial solution of (4.4) leads to one of (4.3) by taking its square modulus. The converse is also true assuming that the solution $M(\omega)$ of (4.3) is a positive, even trigonometric polynomial; then the Riesz lemma ensures the existence of a trigonometric polynomial $m(\omega)$ that satisfies $|m|^2 = M$.
- An important family of solutions of (4.3) is given by

$$M_N(\omega) = \cos^{2N}(\omega/2) \sum_{j=0}^{N-1} \binom{N-1+j}{j} \sin^{2j}(\omega/2) \tag{4.5}$$

for all $N > 0$. It is associated with a family $\{m_N(\omega)\}_{N>0}$ of solutions of (4.4) by the previous argument. It was shown by Daubechies (1988) that the regularity of the associated orthonormal and interpolating scaling functions increases linearly with N in an asymptotical sense.

- Let $\{u(x-k)\}_{k\in\mathbb{Z}}$ be an orthonormal basis of a closed subspace $U \subset L^2(\mathbb{R})$, let $m(\omega)$ be a solution of (4.4), and define $v, w \in U$ by

$$\begin{aligned} \hat{v}(\omega) &= m(\omega/2)\hat{u}(\omega/2), \\ \hat{w}(\omega) &= e^{-i\omega/2}\overline{m(\omega/2+\pi)}\hat{u}(\omega/2). \end{aligned} \tag{4.6}$$

Then $\{2^{-1/2}v(x/2-k)\}_{k\in\mathbb{Z}} \cup \{2^{-1/2}w(x/2-k)\}_{k\in\mathbb{Z}}$ constitutes an orthonormal basis of U. Applying this splitting trick to the refinable orthonormal function detemined by $m(\omega)$, one defines the "mother wavelet" ψ by $\hat{\psi}(\omega) = e^{-i\omega/2}\overline{m(\omega/2+\pi)}\hat{\varphi}(\omega/2)$. The complete system $\{2^{j/2}\psi(2^jx-k)\}_{j,k\in\mathbb{Z}}$ constitutes an orthonormal wavelet basis of $L^2(\mathbb{R})$ and so does $\{\varphi(x-k)\}_{k\in\mathbb{Z}} \cup \{2^{j/2}\psi(2^jx-k)\}_{j\geq 0,k\in\mathbb{Z}}$.

- The function ψ has the same support length and global regularity as φ (in the compactly supported univariate case). The Strang–Fix conditions of order N for φ are equivalent to the property that ψ has $N+1$ vanishing moments, i.e., $\int x^k\psi(x)dx = 0$ for $k = 0, \dots, N$, and hold if φ and ψ are in $H^s(\mathbb{R})$ ($s = N+r$, $r \in]0,1]$). In addition, the wavelet basis is also a Riesz basis for all Sobolev spaces with exponent smaller than s when $\varphi, \psi \in H^s(\mathbb{R})$.

We shall now use the families $\{M_N(\omega)\}_{N>0}$ and $\{m_N(\omega)\}_{N>0}$ described by (4.5) and $|m_N|^2 = M_N$ as the masks of nonstationary subdivision schemes. We will be able to apply the results of the previous sections thanks to an estimate borrowed from Volkmer (1992).

LEMMA 4.1. *The functions $M_N(\omega)$ satisfy*

$$|\cos^2(\omega/2)|^N \leq M_N(\omega) \leq |M(\omega)|^N, \tag{4.7}$$

where $M(\omega)$ is a 2π-periodic function satisfying $M(\omega) = 1$ if $|\omega| \leq \pi/2$ and $M(\omega) = \sin^2(\omega)$ if $\pi/2 \leq |\omega| \leq \pi$. The function $M(\omega)$ can be written as $M(\omega) = \cos^2(\omega/2)\tilde{M}(\omega)$, where $\tilde{M}(\omega)$ is bounded and Hölder continuous and satisfies

$$\sigma_2 = \sup|\tilde{M}(\omega)\tilde{M}(2\omega)| < 2^4 = 16. \tag{4.8}$$

Proof. From (4.5), we clearly have $M_N(\omega) \geq \cos^{2N}(\omega/2)$. The upper estimate is also trivial for $|\omega| \leq \pi/2$ in view of (4.3). For $|\omega| \geq \pi/2$, note that the polynomial $P_N(y) = \sum_{j=0}^{N-1} \binom{N-1+j}{j} y^j$ with $1/2 \leq y \leq 1$ satisfies

$$\begin{aligned} P_N(y) &= \sum_{j=0}^{N-1} \binom{N-1+j}{j}(2y)^j 2^{-j} \leq (2y)^{N-1} \sum_{j=0}^{N-1} \binom{N-1+j}{j} 2^{-j} \\ &= (2y)^{N-1} P_N(1/2) = (4y)^{N-1} \leq (4y)^N. \end{aligned}$$

(We find $P_N(1/2) = 2^{N-1}$ by taking $y = 1/2$ in the equation $(1-y)^N P_N(y) + y^N P_N(1-y) = 1$, which expresses that M_N is a solution of (4.3).) Consequently, we have, for $\pi/2 \leq |\omega| \leq \pi$,

$$\begin{aligned} M_N(\omega) &= \cos^{2N}(\omega/2) P_N(\sin^2(\omega/2) \leq [4\cos^2(\omega/2)\sin^2(\omega/2)]^N \\ &= [\sin^2(\omega)]^N = |M(\omega)|^N. \end{aligned}$$

To prove (4.8), we remark that $\sup_\omega(\tilde{M}(\omega)) = 4$ and that this supremum is attained only at the points $\omega = (2n+1)\pi$. Consequently, $\sup_\omega(\tilde{M}(\omega)\tilde{M}(2\omega)) < \sup_\omega |\tilde{M}(\omega)|^2 = 16$. □

We are now ready to apply the results of the previous sections. For all $j \geq 0$, we define

$$\hat{\Phi}_j(\omega) = \prod_{k=1}^{+\infty} M_{j+k}(2^{-k}\omega) \tag{4.9}$$

and

$$\hat{\varphi}_j(\omega) = \prod_{k=1}^{+\infty} m_{j+k}(2^{-k}\omega). \tag{4.10}$$

THEOREM 4.2. *For all $j > 0$, the subdivision algorithms associated with Φ_j and φ_j converge to these functions in the sense of the uniform convergence of all the derivatives. The functions ϕ^j (resp. φ_j) are in C^∞, are compactly supported in $[-3-2j, 3+2j]$ (resp. $[0, 3+2j]$), and have the property of cardinal interpolation (resp. orthonormality). The families $\{\phi^j\}_{j\geq 0}$ and $\{\varphi_j\}_{j\geq 0}$ both generate multiresolution analyses that have the property of spectral approximation.*

Proof. This result is a simple application of the theorems in the previous sections: Lemma 4.1 indicates that the functions $M_N(\omega)$ and $m_N(\omega)$ satisfy the hypotheses of Theorems 2.1, 2.2, and 3.2. The convergence of the subdivision schemes and the spectral approximation property follow from these results.

Since $M_N(\omega) = \sum_{n=0}^{2N-1} C_n \cos(n\omega)$ and $m_N(\omega) = \sum_{n=0}^{2N-1} c_n e^{-in\omega}$, the supports of ϕ^j and φ_j are, respectively, the intervals $[-L_j, L_j]$ and $[0, L_j]$ with $L_j = \sum_{k>0}(2k+2j-1)2^{-k} = 3+2j$.

Finally, the properties of cardinal interpolation and orthonormality can be derived with the same arguments as in the stationary case: we consider the functions that interpolate the subdivision values after n steps, i.e.,

$$\hat{\Phi}_j^{[n]}(\omega) = \prod_{k=1}^{n} M_{j+k}(2^{-k}\omega)\chi_{[-\pi,\pi]}(2^{-n}\omega) \tag{4.11}$$

and

$$\hat{\varphi}_j^{[n]}(\omega) = \prod_{k=1}^{n} m_{j+k}(2^{-k}\omega)\chi_{[-\pi,\pi]}(2^{-n}\omega). \tag{4.12}$$

The function that is defined by $\hat{\Phi}_j^{[0]} = \hat{\varphi}_j^{[0]} = \chi_{[-\pi,\pi]}$ is clearly both orthonormal and interpolatory. The standard theory (see Daubechies (1992) and Deslauriers and Dubuc (1987)) indicates that the property of cardinal interpolation (resp. orthonormality) of a function u is preserved by the transformation $u \to v$ such that $\hat{v}(\omega) = m(\omega/2)\hat{u}(\omega/2)$ if $m(\omega)$ is a solution of (4.3) (resp. (4.4)).

Consequently, we can easily check by recursion that $\Phi_j^{[n]}$ (resp. $\varphi_j^{[n]}$) is interpolatory (resp. orthonormal) for all $n, j \geq 0$, and the same holds for Φ_j (resp. φ_j) by uniform convergence of the subdivision algorithm. □

Since in the interpolatory case, the subdivision with a finite number of iterations already has the property of cardinal interpolation, it is possible to use these masks to interpolate a sequence on a grid of points $\Gamma = \gamma\mathbb{Z}$ into a sequence on a finer grid $2^{-j}\Gamma$. As j goes to $+\infty$, the limit curve is C^∞ and the influence of a single point in Γ on this curve is limited in space since the limit function from a Dirac sequence is compactly supported. This is clearly a numerical advantage over interpolation with cardinal sines. Figure 1 represents the function Φ_0 obtained after 10 iterations of the subdivision.

For the orthonormal case, in Figure 2, we have represented the function φ_0. In this setting, we can use the "splitting trick" that we have mentionned for the standard case to build orthonormal wavelet bases: for each $j \geq 0$, we define

$$\hat{\psi}_j(\omega) = e^{-i\omega/2}\overline{m_{j+1}(\omega/2+\pi)}\hat{\varphi}_{j+1}(\omega/2) \tag{4.13}$$

so that the family

$$\psi_{j,k} = 2^{j/2}\psi_j(2^j x - k), \quad k \in \mathbb{Z}, \tag{4.14}$$

constitutes an orthonormal basis of the orthogonal complement W_j of V_j in V_{j+1}. Since the spaces V_j approximate any L^2 function with arbitrarily small L^2 error as j grows, the system $\{\varphi(x-k)\}_{k\in\mathbb{Z}} \cup \{\psi_{j,k}(x)\}_{j\geq 0, k\in\mathbb{Z}}$ constitutes an orthonormal basis of $L^2(\mathbb{R})$. Note that the function ψ_j has j vanishing moments and that, although its support grows linearly with j, this growth is dominated by the scaling 2^{-j} so that these wavelets can still be used to analyze and represent the local features of a function.

The last result of this section indicates that this particular system has very good properties with respect to Sobolev spaces.

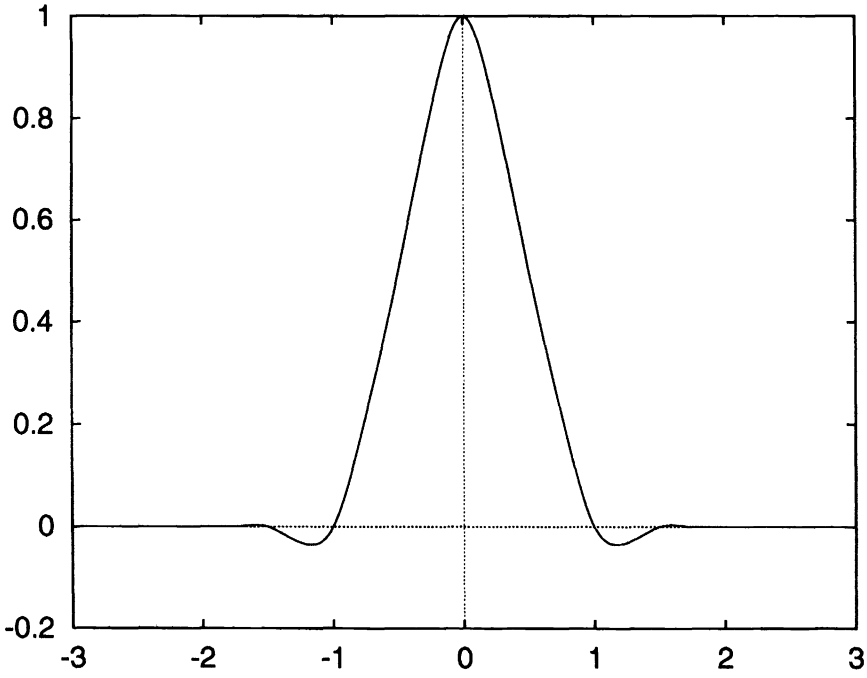

FIG. 1.

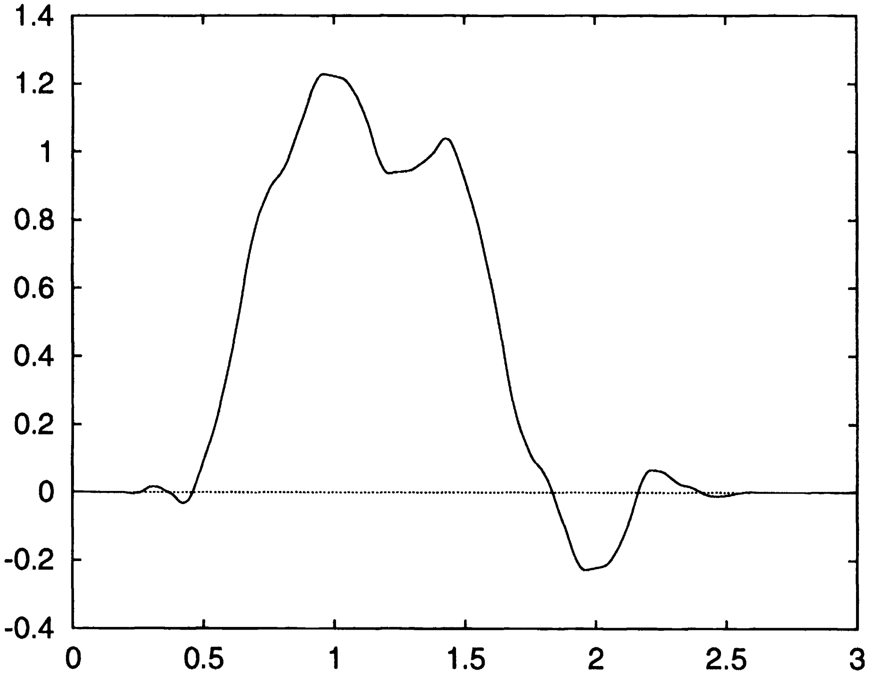

FIG. 2.

THEOREM 4.3. *The system $\{\varphi(x-k)\}_{k\in\mathbb{Z}}\cup\{\psi_{j,k}(x)\}_{j\in\mathbb{N},k\in\mathbb{Z}}$ constitutes a Riesz basis for all Sobolev spaces H^s:*

If $f(x)=\sum_{k\in\mathbb{Z}}c_k\varphi(x-k)+\sum_{j\geq 0,k\in\mathbb{Z}}d_{j,k}\psi_{j,k}(x)$ is a function in H^r, then its wavelet series converges in H^s for $0\leq s\leq r$ and we have the equivalence

$$\|f\|_r^2\approx\sum_k|c_k|^2+\sum_{j,k}2^{2rj}|d_{j,k}|^2=\|P_0(f)\|_0^2+\sum_{j\geq 0}2^{2jr}\|R_j(f)\|_0^2, \tag{4.15}$$

where $R_j=P_{j+1}-P_j$ is the L^2 projector onto W_j. Also, density order r in H^s norm is achieved by the L^2 projection in the sense that $2^{j(r-s)}\|P_jf-f\|_s\to 0$ as $j\to+\infty$ for any $f\in H^r$.

Proof. First, we define a function $u(\omega)$ and a sequence of functions $\{v_n(\omega)\}_{n>0}$ by

$$u(\omega)=\prod_{k=1}^{+\infty}|m(2^{-k}\omega)|^k \tag{4.16}$$

and

$$v_n(\omega)=|m(\omega/2+\pi)|^{n+1}\prod_{k=2}^{+\infty}|m(2^{-k}\omega)|^k, \tag{4.17}$$

where $m(\omega)=\sqrt{M(\omega)}$. The same arguments used for the function $h(\omega)$ in the proof of Theorem 3.2 indicate that $u(\omega)$ and $v_n(\omega)$ have rapid decay at infinity. Using Lemma 4.1 and the fact that $m(\omega)$ is bounded by 1, we obtain

$$|\hat{\varphi}_j(\omega)|\leq u(\omega) \tag{4.18}$$

for all $j\geq 0$ and

$$|\hat{\psi}_j(\omega)|\leq v_n(\omega) \tag{4.19}$$

for all $j\geq n\geq 0$. Now consider a function $f\in H^r$ with $n\leq r<n+1$. We clearly have

$$\|P_0f\|_0^2+\sum_{j=0}^{2n}2^{2rj}\|R_jf\|_0^2\leq C(r)\|f\|_0^2. \tag{4.20}$$

with $C(r)=1+\sum_{j=0}^{2n}2^{2rj}$. For the scales $j>2n$, by Parseval and Poisson identities, we have

$$\begin{aligned}\|R_jf\|_0^2&=\sum_{k\in\mathbb{Z}}|\langle f|\psi_{j,k}\rangle|^2\\&=(2\pi)^{-2}\sum_{k\in\mathbb{Z}}|\langle\hat{f}|\hat{\psi}_{j,k}\rangle|^2\\&=(2\pi)^{-2}2^{-j}\sum_{k\in\mathbb{Z}}\left|\int\hat{f}(\omega)\overline{\hat{\psi}_j(2^{-j}\omega)e^{i2^{-j}k\omega}}d\omega\right|^2\\&=(2\pi)^{-2}2^j\sum_{k\in\mathbb{Z}}\left|\int\hat{f}(2^j\omega)\overline{\hat{\psi}_j(\omega)e^{ik\omega}}d\omega\right|^2\\&=(2\pi)^{-1}2^j\int_{-\pi}^{\pi}\left|\sum_{l\in\mathbb{Z}}\hat{f}(2^j(\omega+2l\pi))\overline{\hat{\psi}_j(\omega+2l\pi)}\right|^2d\omega.\end{aligned}$$

Using (4.20) and the Schwarz inequality, we then obtain

$$\begin{aligned}\|R_jf\|_0^2 &\leq (2\pi)^{-1}2^j\int_{-\pi}^{\pi}\left(\sum_{l\in\mathbb{Z}}|\hat{f}(2^j(\omega+2l\pi))v_{2n+1}(\omega+2l\pi)|\right)^2 d\omega\\ &\leq (2\pi)^{-1}2^jA(r)\int_{-\pi}^{\pi}\left(\sum_{l\in\mathbb{Z}}|\hat{f}(2^j(\omega+2l\pi))|^2v_{2n+1}(\omega+2l\pi)\right)d\omega\\ &\leq (2\pi)^{-1}A(r)\int|\hat{f}(\omega)|^2v_{2n+1}(2^{-j}\omega)d\omega\end{aligned}$$

with $A(r)=\sup_\omega[\sum_{l\in\mathbb{Z}}v_{2n+1}(\omega+2l\pi)]<+\infty$. For $r<n+1$, we can also define $B(r)=\sup_\omega(\sum_{j\in\mathbb{Z}}|2^{-j}\omega|^{-2r}v_{2n+1}(2^{-j}\omega))<+\infty$ (because v_{2n+1} has a zero of order $2n+2$ at the origin). Summing on $j>2n$ our previous estimate with the appropriate weights, we thus obtain

$$\begin{aligned}\sum_{j=2n+1}^{+\infty}2^{2rj}\|R_jf\|_0^2 &= (2\pi)^{-1}A(r)\sum_{j=2n+1}^{+\infty}2^{2rj}\int|\hat{f}(\omega)|^2v_{2n+1}(2^{-j}\omega)d\omega\\ &= (2\pi)^{-1}A(r)\sum_{j=2n+1}^{+\infty}\int|\omega|^{2r}|\hat{f}(\omega)|^2|2^{-j}\omega|^{-2r}v_{2n+1}(2^{-j}\omega)d\omega\\ &\leq A(r)B(r)\|f\|_r^2.\end{aligned}$$

Combining our results for all $j\geq 0$, we finally obtain

$$\sum_k|c_k|^2+\sum_{j,k}2^{2rj}|d_{j,k}|^2\leq[A(r)B(r)+C(r)]\|f\|_r^2. \tag{4.21}$$

For the converse inequality, we first prove the following lemma.

LEMMA 4.4. *For every $r\geq 0$, there exists $K(r)$ such that for all $j\in\mathbb{N}$, the functions $f\in V_j$ satisfy the following Bernstein-type estimate:*

$$f\in V_j\ \Rightarrow\ \|f\|_0\leq\|f\|_r\leq K(r)2^{rj}\|f\|_0. \tag{4.22}$$

Proof. Let $f=\sum_{k\in\mathbb{Z}}a_k\varphi_j(2^j\cdot -k)$, $\sum|a_k|^2<\infty$. Then

$$\|f\|_r^2=\frac{2^{-j}}{2\pi}\int_{\mathbb{R}}\left|\sum_{k\in\mathbb{Z}}a_ke^{-i2^{-j}k\omega}\right|^2|\hat{\varphi}_j(2^{-j}\omega)|^2(1+|\omega|^{2r})d\omega. \tag{4.23}$$

Using (4.1), we get

$$\begin{aligned}\|f\|_r^2 &\leq (2\pi)^{-1}\int\left|\sum_{k\in\mathbb{Z}}a_ke^{-ik\omega}\right|^2|u(\omega)|^2(1+|\omega|^{2r}2^{2rj})d\omega\\ &\leq (2\pi)^{-1}2^{2rj}\int\left|\sum_{k\in\mathbb{Z}}a_ke^{-ik\omega}\right|^2|u(\omega)|^2(1+|\omega|^{2r})d\omega\\ &\leq (K(r))^22^{2rj}(2\pi)^{-1}\int_{-\pi}^{\pi}\left|\sum_{k\in\mathbb{Z}}a_ke^{-ik\omega}\right|^2d\omega\\ &\leq (K(r))^22^{2rj}\|f\|_0^2\end{aligned}$$

with $(K(r))^2 = \sup_\omega \sum_{l\in\mathbb{Z}}(1+|\omega+2\pi l|^{2r})u^2(\omega+2\pi l) < \infty$. □

Returning to the proof of the theorem, to conclude (4.15), we use the following result about Besov spaces (see, for example, Frazier and Jawerth (1985)): for $r > 0$, $1 \leq p, q \leq +\infty$, the norm of a function f in $B^r_{p,q}$ is equivalent to the quantity

$$\inf \left(\sum_{j=0}^{+\infty} \varepsilon_j^q\right)^{1/q}, \tag{4.24}$$

where the infimum is taken over all the sequences of positive numbers $\{\varepsilon_j\}_{j\geq 0}$ such that for some integer $m > r$, there exists a sequence of functions $\{f_j\}_{j\geq 0}$ in W^m_p that satisfies

$$f = \sum_j f_j, \left\|\left(\frac{d}{dx}\right)^m f_j\right\|_{L^p} \leq \varepsilon_j 2^{(m-r)j}, \quad \|f_j\|_{L^p} \leq \varepsilon_j 2^{-rj}. \tag{4.25}$$

It is clear that if $\|P_0(f)\|_0^2 + \sum_j 2^{2jr}\|R_j(f)\|_0^2$ is bounded, $f_0 = P_0 f$ and $f_j = R_{j-1}f$ for $j > 0$ will be a decomposition that satifies (4.25) with $\varepsilon_j = 2^{rj}\|f_j\|_0 K(m)$ in $\ell^2(\mathbb{N})$ since by Lemma 4.4,

$$\left\|\left(\frac{\mathrm{d}}{\mathrm{dx}}\right)^m f_j\right\|_0 \leq \|f_j\|_m \leq K(m)2^{mj}\|f_j\|_0 = \varepsilon_j 2^{(m-r)j}. \tag{4.26}$$

Consequently, we have

$$\|f\|_r^2 \leq D(r)\left(\|P_0(f)\|_0^2 + \sum_j 2^{2jr}\|R_j(f)\|_0^2\right), \tag{4.27}$$

and (4.15) is proved.

Finally, we can use (4.27) and (4.21) to evaluate $\|P_j f - f\|_s^2$ for $f \in H^r$, $r > s$. We obtain

$$\begin{aligned}\|P_j f - f\|_s^2 &\leq D(s)\sum_{l=j}^{+\infty} 2^{2ls}\|R_l(f)\|_0^2\\ &\leq 2^{2j(s-r)}D(s)\sum_{l=j}^{+\infty} 2^{2lr}\|R_l(f)\|_0^2\\ &\leq 2^{2j(s-r)}K(r,s)\|f\|_r^2\varepsilon(j,f),\end{aligned}$$

where $K(r,s) = D(s)(A(r)B(r) + C(r))$, $\varepsilon(j,f) \in [0,1]$ going to 0 as $j \to +\infty$. Spectral approximation is thus achieved by the L^2 projection onto V_j. □

Remarks. One may be interested in the characterization of other Besov spaces, such as Hölder spaces, by the properties of their wavelet coefficients. This task seems difficult for exactly the same reason that was mentioned at the end of the previous section: one would have to deal with the space domain in which the support of ψ^j grows linearly.

In the more general framework of a nonstationary multiresolution analysis $\{V_j\}_{j\geq 0}$ described in the previous section, it would be interesting to prove an equivalence of the type of (4.15),

$$\|f\|_s^2 \approx \|P_0 f\|_0^2 + \sum_{j\geq 0} 2^{2js}\|P_{j+1}f - P_j f\|_0^2, \tag{4.28}$$

since it is the key to multilevel preconditioning techniques (Dahmen and Kunoth (1992)), even when there is no explicit wavelet basis. We do not know so far under which general conditions such an equivalence holds.

5. Conclusions. We have studied the convergence of nonstationary subdivision schemes and the properties of their limit functions in terms of approximation. Some open problems are raised in a natural way:

- the approximation and characterization of functions in spaces other than H^s (more general Besov spaces and Gevrey classes of C^∞ functions);
- the possible generalizations to the multidimensional framework (other than simple tensor products) and to biorthogonal wavelets;
- the search for weaker (if possible, necessary and sufficient) conditions for convergence of the subdivision algorithm, generating C_0^∞ functions.

The orthonormal wavelet basis that we described in the last section gives an answer to an important question in approximation: find a basis that has spectral approximation properties, like the trigonometric system in Sobolev spaces with boundary conditions, and allows us to describe functions locally in space. In particular, we can adapt this system to an interval using for example the approach described in Cohen, Daubechies, and Vial (1993) so that the expansion in the adapted basis asymptotically achieves the n-width in any Sobolev space $H^s(I)$.

The numerical implementation of such an expansion has, of course, the same pyramidal structure as in the standard fast wavelet transform algorithm, using longer filters at the high scales and smaller filters at the coarse scales. This idea is very natural in terms of signal processing since it does not make sense to use a filter with a comparable size to that of the whole signal at the coarse scales. Our results on the convergence of nonstationary subdivision indicate that the regularity of the reconstruction will not be affected by the use of small filters (corresponding to nonregular scaling functions) at the coarsest scales. An interesting perspective is the application of these algorithms in image compression, where both smoothness and space localization of the limit function are required.

Appendix. We want to show here that, under mild conditions, C^∞ scaling functions can be obtained with any type of growth of the mask length in the subdivision.

Let $\{m_k(\omega)\}_{k>0}$ be a family of trigonometric polymomials that satisfies

$$|m_k(\omega)| \le |m(\omega)|^k, \tag{A.1}$$

where $|m(\omega)| = |\cos^\beta(\omega/2)\tilde{m}(\omega)| \le 1$ with $\beta \ge 0$ and $\tilde{m}(\omega)$ is bounded and Hölder continuous at the origin and satisfies $\sigma_i = \sup_\omega |\prod_{k=1}^i \tilde{m}(2^k\omega)| < 2^{\beta i}$ for some $i > 0$.

Now consider a sequence of strictly positive numbers $\{l(k)\}_{k>0}$ with the following properties:

$$\lim_{k\to+\infty} l(k) = +\infty \tag{A.2}$$

and

$$\sum_{k>0} 2^{-k} d(l(k)) < +\infty. \tag{A.3}$$

From Theorem 2.1, we know that we can define a compactly supported tempered distribution φ by

$$\hat{\varphi}(\omega) = \prod_{k=1}^{+\infty} m_{l(k)}(2^{-k}\omega), \tag{A.4}$$

where the product converges uniformly on every compact set.

To study the convergence of the associated subdivision algorithm in the strong sense, we define

$$\hat{\varphi}^{[n]}(\omega) = \prod_{k=1}^{n} m_{l(k)}(2^{-k}\omega)\chi_{[-\pi,\pi]}(2^{-n}\omega), \tag{A.5}$$

$$h_n(\omega) = \prod_{k=1}^{n} |m(2^{-k}\omega)|^{l(k)}\chi_{[-\pi,\pi]}(2^{-n}\omega), \tag{A.6}$$

and

$$g_n(\omega) = \prod_{k=1}^{n} |m(2^{-k}\omega)|\chi_{[-\pi,\pi]}(2^{-n}\omega). \tag{A.7}$$

Now

$$g_n(\omega) = (\mathrm{sinc}(\omega/2))^{\beta}(\mathrm{sinc}(2^{-n-1}\omega))^{-\beta} \prod_{k=1}^{n} |\tilde{m}(2^{-k}\omega)|\chi_{[-\pi,\pi]}(2^{-n}\omega) \tag{A.8}$$

and $\inf_{|\omega|\leq 2^n\pi} |\mathrm{sinc}(2^{-n-1}\omega) = 2/\pi$; hence the same technique used for the estimation of $g(\omega)$ in the proof of Theorem 3.2 yields

$$g_n(\omega) \leq C(1+|\omega|)^{-\varepsilon} \tag{A.9}$$

with $\varepsilon = \beta - (\log_2 \sigma_i)/i > 0$. For a fixed $s > 0$, consider an integer $p > 0$ such that $p\varepsilon \geq s$. Since $l(k)$ goes to $+\infty$, there exists an integer $m \geq 0$ such that $l(k) \geq p$ for all $k > m$. For $n > m$, we can thus estimate $\hat{\varphi}^{[n]}(\omega)$ as follows:

$$\begin{aligned}
|\hat{\varphi}^{[n]}(\omega)| &\leq h_n(\omega)\\
&= \prod_{k=1}^{n} |m(2^{-k}\omega)|^{l(k)}\chi_{[-\pi,\pi]}(2^{-n}\omega)\\
&\leq \prod_{k=m+1}^{n} |m(2^{-k}\omega)|^{l(k)}\chi_{[-\pi,\pi]}(2^{-n}\omega)\\
&\leq \prod_{k=m+1}^{n} |m(2^{-k}\omega)|^{p}\chi_{[-\pi,\pi]}(2^{-n}\omega)\\
&= [g_{n-m}(2^{-m}\omega)]^p\\
&\leq C_s(1+|\omega|)^{-s},
\end{aligned}$$

where $C_s = C^p \sup_\omega((1+|\omega|)/(1+2^{-m}|\omega|))^s$ depends only on s. Since s is arbitrary, we obtain the C^∞ convergence of the subdivision by dominated convergence, as in Theorem 2.2.

This more general result applies in particular to the trigonometric polynomials of §4 since the function $M(\omega)$ of Lemma 4.1 is bounded by 1.

A NONLINEAR OPERATOR RELATED TO SCALING FUNCTIONS AND WAVELETS*

YING HUANG†

Abstract. This paper studies a certain nonlinear operator T from $L^2(\mathbb{R})$ to itself under which every scaling function is a fixed point. The iterations $T^n f$ of T on any L^2-function f with the Riesz basis property are investigated; they turn out to be the subdivision-scheme iterates of f with weights depending on f only. The paper gives conditions for convergence of $T^n f$ to a limit in different topologies and studies the regularity of the limit functions. The results are illustrated with examples.

Key words. scaling functions, wavelets, the Riesz basis property, subdivision schemes

AMS subject classifications. 26A18, 39A10, 42A38

1. Introduction. Orthonormal bases of wavelets $\psi_{j,k}(x) = 2^{-j/2}\psi(2^{-j}x - k)$ $(j, k \in \mathbb{Z})$ for $L^2(\mathbb{R})$ have many useful properties [Ru], [Ch], [I1], [I2], [BF]. The construction of such wavelet bases is well understood; every such basis corresponds to a multiresolution analysis characterized by a *scaling function* $\phi(x)$ (see, e.g., [Dau1]). What makes a randomly chosen ϕ a scaling function? There exist many different possible choices for ϕ. We shall see that scaling functions can all be viewed as the fixed points of a nonlinear operator.

In a multiresolution analysis, for appropriately chosen c_n and d_n, the functions ϕ and ψ satisfy,

$$\phi(x) = \sum_n c_n \phi(2x - n), \qquad \psi(x) = \sum_n d_n \phi(2x - n),$$

and $\psi \perp \phi(\bullet - m)$ for all $m \in \mathbb{Z}$. It follows that $\psi \perp \psi(2\bullet - n)$ for all $n \in \mathbb{Z}$. Now define a nonlinear operator, denoted T, which projects any nonzero function in $L^2(\mathbb{R})$ onto the closed subspace spanned by its own scaled translates. More precisely,

$$T : L^2(\mathbb{R}) \to L^2(\mathbb{R}), \quad Tf := \text{orthorgonal projection of } f \text{ onto } \overline{\text{Span}\{f_{-1,n}; n \in \mathbb{Z}\}},$$

where, as usual, $f_{j,k} = 2^{-j/2}f(2^{-j}x - k)$. It is clear that $T\phi = \phi$ and $T\psi = 0$. This paper studies the properties of T.

The operator T is nonlinear: we have $T(\lambda f) = \lambda\, Tf$ for all $\lambda \in \mathbb{C}$, but there is no a priori reason to expect $T(f+g) = Tf+Tg$, and we shall see explicit counterexamples in §3. Because T is defined as an orthogonal projection, we always have

$$\|Tf\| \leq \|f\|. \tag{1.1}$$

As pointed out above, multiresolution scaling functions ϕ are fixed points of T. We can study the iterations $T^n f$ of T on an arbitrary $f \in L^2(\mathbb{R})$. If these $T^n f$ have a nontrivial limit, then this limit is a fixed point of T and is therefore a candidate of a scaling function. It leads to a multiresolution analysis "naturally" associated with f. When does such a nontrivial limit exist? How stable is the procedure under small perturbations of f? This paper contains answers to these questions. A key observation in our analysis is that T is closely related to subdivision schemes.

The contents of this paper are as follows. We begin with a presentation of the basic properties of T: in §2, we give an explicit formula for Tf for a large class of functions f, and then we discuss the continuity and the fixed point set of T. In §3, we show the connection of $T^n f$ with subdivision schemes. Then §§4 and 5 study sufficient conditions for convergence of T^n (or rescaled iterates of T^n) in different topologies. The final section, §6, consists of examples of functions and their corresponding limit functions, illustrating the results of §§4 and 5.

We conclude this introduction by fixing some notations for the rest of the paper. We normalize the Fourier transform as follows:

$$\hat{f}(\xi) \equiv (f)^\wedge(\xi) := \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} f(x)\, e^{-i\xi x}\, dx. \tag{1.2}$$

Here the integral converges absolutely for all ξ if f is in $L^1(\mathbb{R})$; for general $f \in L^2(\mathbb{R})$, (1.2) should be understood via the standard limiting process. Throughout this paper, the symbol $\| \bullet \|$ (without a subscript) will be reserved for the $L^2(\mathbb{R})$ norm

$$\|f\|^2 = \langle f, f\rangle = \int_{-\infty}^{+\infty} f(x)\, \overline{f(x)}\, dx.$$

With our normalization of the Fourier transform, the Plancherel identity is $\|f\| = \|\hat{f}\|$.

2. Basic properties of T. In this section, we first introduce the definition of the Riesz basis property for an L^2-function f and obtain an explicit formula for the Fourier transform of Tf. With this, we then study the continuity of T and the set of fixed points of T.

2.1. A formula for T. Since Tf is defined by the orthogonal projection of f onto $\overline{\text{Span}\{f_{-1,n}; n \in \mathbb{Z}\}}$, it is tempting to write

$$Tf(x) = \sum_{n\in\mathbb{Z}} \alpha_n \cdot f(2x - n), \tag{2.1}$$

and to try to determine the α_n's in (2.1). This is not always straightforward, however. First of all, the $f(\bullet - n)$ may not be independent, so that several sequences of coefficients α_n in (2.1) would lead to the same answer. An example is given by $f(x) = 1$ for $0 \le x < 2$, $f(x) = 0$ otherwise. For any $x \in \mathbb{R}$, we have $\sum_{n\in\mathbb{Z}}(-1)^n f(x-n) = 0$; since $Tf = f$, we thus have $Tf(x) = f(x) = f(2x) + f(2x-2) + \gamma \cdot \sum_{n\in\mathbb{Z}}(-1)^n f(2x-n)$, where $\gamma \in \mathbb{C}$ is arbitrary. This nonuniqueness of the α_n's can be circumvented by prescribing an algorithm for determining the α_n's. Since $\overline{\text{Span}\{f_{-1,n}; n \in \mathbb{Z}\}} = \overline{\bigcup_{N\in\mathbb{N}} V_{f,N}}$, where $V_{f,N} = \text{Span}\{f_{-1,n}; |n| \le N\}$, and since any finite set of $f_{-1,n}$ is always independent, we have, in general,

$$Tf(x) = \lim_{N\to+\infty} \text{Proj}_{\;V_{f,N}} f(x) = \lim_{N\to+\infty} \sum_{|n|\le N} a_n^N \cdot f(2x-n),$$

where the a_n^N's are now determined uniquely by solving the linear system

$$\left\langle \sum_{|n|\le N} a_n^N \cdot f(2\bullet - n) - f, f(2\bullet - k) \right\rangle = 0 \quad \forall |k| \le N.$$

If, for every fixed n, the a_n^N's tend to a limit as $N \to +\infty$, we could define this limit as α_n, understanding (2.1) in this limiting sense. In the example above, we have

$a_0^N = 1$, $a_2^N = 1$, and all other $a_n^N = 0$ for all $N \geq 2$. However, for general f, the a_n^N need not tend to a limit. A technical example in which the a_n^N's blow up as $N \to +\infty$ is $f(x) = e^{i(\pi/2)x}(2 - |x|)$ for $|x| \leq 2, f(x) = 0$ otherwise. For details, see [Hu].

In the rest of this paper, we shall restrict ourselves to the (very large) class of functions that do not exhibit such problems. We shall say that a function f has the *Riesz basis property* (abbreviated: f is RBP) if $f \in L^2(\mathbb{R})$ and if the set $\{f(x-k)\}_{k\in\mathbb{Z}}$ is a Riesz basis for its closed linear span, i.e., there exist two constants $0 < C_1 \leq C_2 < +\infty$ such that for all finite linear combinations of the $f(x-k)$, we have

$$2\pi C_1 \sum |c_k|^2 \leq \left\| \sum_{k\in\mathbb{Z}} c_k f(x-k) \right\|^2 \leq 2\pi C_2 \sum |c_k|^2.$$

Using Plancherel's formula, this is equivalent to

$$C_1 \leq \sum_{l\in\mathbb{Z}} |\hat{f}(\xi + 2\pi l)|^2 \leq C_2 \quad \text{a.e. in } \xi. \tag{2.2}$$

When f is RBP, any function g in $\overline{\text{Span}\{f(\bullet - n); n \in \mathbb{Z}\}}$ can be uniquely written as $g(x) = \sum_{n\in\mathbb{Z}} \beta_n \cdot f(x-n)$ with l^2-coefficients β_n. One can therefore always write an expression of type (2.1) for Tf. The coefficients α_n can then be found as follows.

PROPOSITION 2.1. *If f is RBP, then $(Tf)^\wedge(\xi) = a(\frac{\xi}{2})\hat{f}(\frac{\xi}{2})$, where*

$$a(\xi) = \frac{\sum_{l\in\mathbb{Z}} \hat{f}(2\xi + 4\pi l)\overline{\hat{f}(\xi + 2\pi l)}}{\sum_{l\in\mathbb{Z}} |\hat{f}(\xi + 2\pi l)|^2}. \tag{2.3}$$

Proof. We can rewrite (2.1) as either $Tf = \sum_{k\in\mathbb{Z}} a_k\, f_{-1,k}$ for some $a_k = \frac{1}{\sqrt{2}}\alpha_k \in \mathbb{C}$ or $(Tf)^\wedge(\xi) = a(\frac{\xi}{2})\hat{f}(\frac{\xi}{2})$, where $a(\xi) = \frac{1}{\sqrt{2}} \sum_{k\in\mathbb{Z}} a_k\, e^{-i\xi k}$. By the definition of T as an orthogonal projection operator, we have $\langle Tf - f, f_{-1,m}\rangle = 0$ for any $m \in \mathbb{Z}$. Thus

$$\langle f, f_{-1,m}\rangle = \langle Tf, f_{-1,m}\rangle = \sum_k a_k^n \langle f_{-1,k}, f_{-1,m}\rangle.$$

Multiplying both sides of this equation by $e^{-i\xi m}$ and summing over $m \in \mathbb{Z}$, we get

$$\sum_{m\in\mathbb{Z}} \langle f, f_{-1,m}\rangle\, e^{-i\xi m} = \sum_{m,k} a_k \langle f_{-1,k}, f_{-1,m}\rangle e^{-i\xi m} = \sqrt{2}\, a(\xi) \sum_{l\in\mathbb{Z}} \langle f, f_{0,l}\rangle e^{-i\xi l}.$$

Hence

$$a(\xi) = \frac{\sum_{m\in\mathbb{Z}} \langle f, f_{-1,m}\rangle\, e^{-i\xi m}}{\sqrt{2}\sum_{l\in\mathbb{Z}} \langle f, f_{0,l}\rangle e^{-i\xi l}}.$$

On the other hand,

$$\begin{aligned}\langle f, f_{-1,m}\rangle &= \sqrt{2} \int_{-\infty}^{+\infty} \hat{f}(\xi) \frac{1}{2} \overline{\hat{f}\left(\frac{\xi}{2}\right)} e^{i\frac{m}{2}\xi} d\xi \\ &= \sqrt{2} \int_0^{2\pi} e^{im\xi} \left(\sum_{l\in\mathbb{Z}} \hat{f}(2\xi + 4\pi l)\overline{\hat{f}(\xi + 2\pi l)} \right) d\xi.\end{aligned}$$

Then

$$\sum_{m\in\mathbb{Z}} \langle f, f_{-1,m}\rangle e^{-im\xi} = 2\pi\sqrt{2} \sum_{l\in\mathbb{Z}} \hat{f}(2\xi + 4\pi l)\overline{\hat{f}(\xi + 2\pi l)}.$$

Similarly, $\sum_{l\in\mathbb{Z}} \langle f, f_{0,l}\rangle e^{-i\xi l} = 2\pi \sum_{l\in\mathbb{Z}} |\hat{f}(\xi + 2\pi l)|^2$. □

2.2. Continuity of T. We already know from (1.1) that T is bounded. This does not immediately imply that T is continuous because T is nonlinear (see §3.1). Thus we need to prove the following.

THEOREM 2.2. *Assume that f is RBP. For any $\varepsilon > 0$, we can find δ, depending only on ε and f, such that if g is RBP and $\|f - g\| \leq \delta$, then $\|Tf - Tg\| \leq \varepsilon$.*

Remark. Here we require that both f and g are RBP because we want to use (2.3). Note that the Riesz basis property for f and $\|f - g\| \leq \delta$ together do *not* necessarily imply that g is RBP.

Proof of Theorem 2.2. Define $f^{\#}$ via its Fourier transform by

$$(f^{\#})^{\wedge}(\xi) = \frac{\hat{f}(\xi)}{\left(2\pi \sum_{l \in \mathbb{Z}} |\hat{f}(\xi + 2\pi l)|^2\right)^{\frac{1}{2}}}. \tag{2.4}$$

This is well defined a.e. in ξ. Then, again a.e. in ξ,

$$\sum_{l \in \mathbb{Z}} |(f^{\#})^{\wedge}(\xi + 2\pi l)|^2 = \frac{1}{2\pi}, \tag{2.5}$$

or, equivalently, the $\{f^{\#}_{-1,k}; k \in \mathbb{Z}\}$'s constitute an orthonormal basis for V_f. Thus by an argument similar to the one that proved Proposition 2.1, we have for any $h \in L^2(\mathbb{R})$ that $(\mathrm{Proj}_{V_{f^{\#}}} h)^{\wedge}(\xi) = a_{f^{\#},h}(\frac{\xi}{2}) \cdot (f^{\#})^{\wedge}(\frac{\xi}{2})$ with

$$a_{f^{\#},h}(\xi) = 2\pi \sum_{l \in \mathbb{Z}} \hat{h}(2\xi + 4\pi l)(f^{\#})^{\wedge}(\xi + 2\pi l).$$

Thus

$$\begin{aligned} &\|\mathrm{Proj}_{V_{f^{\#}}} f - \mathrm{Proj}_{V_{g^{\#}}} f\| = 2\|a_{f^{\#},f} \cdot (f^{\#})^{\wedge} - a_{g^{\#},f} \cdot (g^{\#})^{\wedge}\| \\ &\leq 2(\|(a_{f^{\#},f} - a_{g^{\#},f})(f^{\#})^{\wedge}\| + \|a_{g^{\#},f}((f^{\#})^{\wedge} - (g^{\#})^{\wedge})\|) := 2(I_1 + I_2). \end{aligned}$$

However,

$$\begin{aligned} I_1^2 &= \int_{|\xi| \leq \pi} \sum_l |(f^{\#})^{\wedge}(\xi + 2\pi l)|^2 |a_{f^{\#},f}(\xi) - a_{g^{\#},f}(\xi)|^2 \, d\xi \\ &= \frac{1}{2\pi} \int_{|\xi| \leq \pi} |a_{f^{\#},f}(\xi) - a_{g^{\#},f}(\xi)|^2 \, d\xi \quad \text{(by (2.5))} \\ &\leq 2\pi \int_{|\xi| \leq \pi} \sum_l |\hat{f}(2\xi + 4\pi l)|^2 \sum_k |\hat{f^{\#}}(\xi + 2\pi k) - \hat{g^{\#}}(\xi + 2\pi k)|^2 d\xi \\ &\leq 2\pi C_{2,f} \|f^{\#} - g^{\#}\|^2 \quad (C_{2,f} \text{ is the upper bound for } f \text{ in (2.2)}). \end{aligned}$$

On the other hand,

$$\begin{aligned} I_2^2 &:= \int_{|\xi| \leq \pi} |a_{g^{\#},f}(\xi)|^2 \sum_l |\hat{f^{\#}}(\xi + 2\pi l) - \hat{g^{\#}}(\xi + 2\pi l)|^2 d\xi \\ &\leq \max_{|\xi| \leq \pi} |a_{g^{\#},f}(\xi)|^2 \|f^{\#} - g^{\#}\|^2. \end{aligned}$$

By (2.2), (2.5), and the Cauchy–Schwarz inequality, $|a_{g^{\#},f}|^2 \leq 2\pi C_{2,f}$. Thus

$$\|\mathrm{Proj}_{V_{f^{\#}}} f - \mathrm{Proj}_{V_{g^{\#}}} f\| \leq 4\sqrt{2\pi C_{2,f}} \|f^{\#} - g^{\#}\|.$$

To control $\|f^{\#} - g^{\#}\|$, we define the sequences $b^f(\xi)$ and $b^g(\xi)$ by $b^f_l(\xi) := \hat{f}(\xi + 2\pi l)$ and $b^g_l(\xi) := \hat{g}(\xi + 2\pi l)$; then $b^f(\xi) \in l^2(\mathbb{Z})$ a.e. in ξ, and $\|b^f(\xi)\|_{l^2} \geq C_{1,f} > 0$, $\|b^g(\xi)\|_{l^2} > 0$. We have

$$\begin{aligned}\|f^{\#} - g^{\#}\|^2 &= \int_{|\xi|\leq\pi} \sum_{l\in\mathbb{Z}} \left| \frac{b^f_l(\xi)}{\|b^f(\xi)\|_{l^2}} - \frac{b^g_l(\xi)}{\|b^g(\xi)\|_{l^2}} \right|^2 d\xi \\ &\leq \int_{|\xi|\leq\pi} \left(\frac{2}{\|b^f(\xi)\|_{l^2}} \|b^f(\xi) - b^g(\xi)\|_{l^2} \right)^2 d\xi \\ &\leq \frac{4}{C_{1,f}} \|f - g\|^2 \quad (C_{1,f} \text{ is the lower bound for } f \text{ in (2.2)}).\end{aligned}$$

Therefore,

$$\begin{aligned}\|Tf - Tg\| &\leq \|\mathrm{Proj}_{V_{f^{\#}}} f - \mathrm{Proj}_{V_{g^{\#}}} f\| + \|\mathrm{Proj}_{V_{g^{\#}}} f - \mathrm{Proj}_{V_{g^{\#}}} g\| \\ &\leq 8\sqrt{2\pi C_{2,f}/C_{1,f}} \cdot \|f - g\| + \|f - g\|.\end{aligned}$$

Thus we just need to choose $\delta = \varepsilon/(8\sqrt{2\pi C_{2,f}/C_{1,f}} + 1)$ to obtain $\|Tf - Tg\| \leq \varepsilon$. □

By using a stronger topology, we can avoid the explicit requirement that g be RBP.

COROLLARY 2.3. *Assume that f is RBP and $\int |f(x)|^2(1+|x|^2)dx < \infty$. For any $\varepsilon > 0$, we can find $\delta > 0$ such that if g satisfies $\int |f(x) - g(x)|^2(1 + |x|^2)dx \leq \delta$, then $\|Tf - Tg\| \leq \varepsilon$.*

Proof. 1. Assume that $\int |f(x) - g(x)|^2(1 + |x|^2)dx \leq \delta_1^2$, where the $\delta_1 > 0$ will be determined later. Then

$$\|f - g\|_{L^1} \leq \left(\int |f(x) - g(x)|^2(1 + |x|^2)dx \right)^{\frac{1}{2}} \left(\int \frac{1}{1 + |x|^2} dx \right)^{\frac{1}{2}} \leq \delta_1\sqrt{\pi}.$$

Hence we also have $|\hat{f}(\xi) - \hat{g}(\xi)| \leq \delta_1/\sqrt{2}$.

2. Similarly, $\|f\|_{L^1} \leq M$ and $\|g\|_{L^1} \leq M + \delta_1/\sqrt{2}$ for some constant $M > 0$ depending only on f. Thus $\hat{f}$ and $\hat{g}$ are continuous and $|\hat{f}(\xi) + \hat{g}(\xi)| \leq 2M + \delta_1/\sqrt{2}$. Consequently, $||\hat{f}|^2 - |\hat{g}|^2| \leq (2M + \delta_1/\sqrt{2})\delta_1/\sqrt{2} \leq M_1\delta_1$ if we choose $\delta_1 \leq M\sqrt{2}$ and let $M_1 = 3M/\sqrt{2}$.

3. We are now ready to prove that

$$\sum_{l\in\mathbb{Z}} |\hat{g}(\xi + 2\pi l)|^2 \geq C_{1,f}/4 \quad \text{for any} \quad \xi \in [-\pi, \pi].$$

(Here $C_{1,f}$ is the lower bound for f in (2.2).) By the same argument (due to A. Cohen) as in part 1 of the proof of Theorem 6.3.1 in [Dau2], the continuity of $\hat{f}$ implies that there exists $L_0(f) \in \mathbb{N}$, such that for all $\xi \in [-\pi, \pi]$, $\sum_{|l|\leq L_0} |\hat{f}(\xi + 2\pi l)|^2 \geq C_{1,f}/2$. Thus, with the choice $\delta_1 := C_{1,f}/(4(2L_0 + 1)M_1)$,

$$\begin{aligned}\sum_{|l|\leq L_0} |\hat{g}(\xi + 2\pi l)|^2 &\geq \sum_{|l|\leq L_0} |\hat{f}(\xi + 2\pi l)|^2 - (2L_0 + 1)M_1\delta_1 \\ &\geq C_{1,f}/2 - (2L_0 + 1)M_1\delta_1 \geq C_{1,f}/4.\end{aligned}$$

4. On the other hand, since $\int |g(x)|^2(1+|x|^2)dx < \infty$, it follows that $\sum |\hat{g}(\xi + 2\pi l)|^2$ is uniformly continuous in $[-\pi, \pi]$. Thus it is bounded above and g is RBP. We can now use same argument as in the proof of Theorem 2.2. □

2.3. A characterization of fixed points of T. It is obvious from the definition of T that any function f with the Riesz basis property which is also a fixed point of T should be a function satisfying the *refinement equation*

$$f(x) = \sqrt{2} \sum_{k \in \mathbb{Z}} a_k\, f(2x-k), \tag{2.6}$$

where the sequence $\{\sqrt{2}a_k\}$ is called the *mask*. Such functions are called *refinable functions* (see [CDM] for a review). Conversely, if an L^2-function f satisfies (2.6), then f will be a fixed point of T. When—that is, for which a_k—does (2.6) have L^2-solutions?

Formula (2.6) implies, at least formally, that

$$\hat{f}(\xi) = \hat{f}(0) \prod_{j=1}^{\infty} a(2^{-j}\xi), \tag{2.7}$$

where again $a(\xi) = \frac{1}{\sqrt{2}} \sum_{k \in \mathbb{Z}} a_k e^{-ik\xi}$. The following standard result gives a sufficient condition guaranteeing pointwise convergence in ξ of the right-hand side of (2.7).

PROPOSITION 2.4. *If $a(\xi)$ is a 2π-periodic function with $a(0) = 1$ and if for some constant c and $\alpha \in (0,1]$, $|a(\xi) - a(0)| \le c|\xi|^\alpha$ for $\xi \to 0$, then*

$$\hat{\phi}(\xi) = \prod_{j=1}^{\infty} a(2^{-j}\xi) \tag{2.8}$$

is well defined for $\xi \in \mathbb{R}$ and $\hat{\phi}$ is continuous in $\mathbb{R}$.

Next, we address L^2-convergence. In [Her1], Hervé gives the following conditions guaranteeing that ϕ is in $L^2(\mathbb{R})$.

THEOREM 2.5 (Hervé). *Let $a(\xi)$ be a 2π-periodic function with $a(0) = 1$ and suppose that*

$$|a(\xi)| = \left|\cos\frac{\xi}{2}\right|^r \cdot |v(\xi)|, \qquad r > 0, \quad v(\pi) \ne 0,$$

where $|v(\xi) - v(0)| \le c|\xi|^\alpha$ for $\xi \to 0$. Let $P_{|v|^2}$ be the operator which acts on any $F \in C[0,\pi]$ via

$$P_{|v|^2} F(\xi) = \left|v\left(\frac{\xi}{2}\right)\right|^2 \cdot F\left(\frac{\xi}{2}\right) + \left|v\left(\frac{\xi}{2}+\pi\right)\right|^2 \cdot F\left(\frac{\xi}{2}+\pi\right)$$

and let β be the spectral radius of $P_{|v|^2}$ restricted to $C[0,2\pi]$. If $\beta < 2^{2r}$, then $\hat{\phi}$ defined as in (2.8) is in $L^2(\mathbb{R})$.

We give a proof for this result in §4 when we discuss the L^2-convergence of $T^n f$.

This criterion becomes practical when one also has an algorithm for computing the spectral radius of the operator $P_{|v|^2}$. In the same paper [Her1], Hervé also derived a formula for computing this spectral radius; see also [CD2].

Proposition 2.4 requires that $|a(\xi) - a(0)| \le c|\xi|^\alpha$ for ξ near 0, and this condition implies decay for the $\{a_k\}$'s. Interestingly enough, there exist refinement equations without decay (even growth) for the $\{a_k\}$'s which nevertheless have L^2-solutions.

Example 2.6. Consider $f(x) = (1 - \frac{1}{2}|x|) \cdot \chi_{|x| \leq 2}$. Then it is easy to check that $\sum_n 2nf(x-2n) = x$ and $\sum_n (2n - \frac{1}{2}) f(x - 2n + 1) = x$. Thus

$$f(x) = \frac{1}{2} f(2x+2) + f(2x) + \frac{1}{2} f(2x-2) \\ + \sum_n 2nf(2x-2n) - \sum_n \left(2n - \frac{1}{2}\right) f(2x - 2n + 1).$$

Here $|a_k| \sim |k|$, while f is in $L^2(\mathbb{R})$. Of course, this example can be generalized to higher-order B-splines, leading to examples with $|a_k| \sim |k|^l$. Note that these examples also show that a refinable function can be the solution of several different refinement equations.

3. General formula for T^n. It follows from (1.1) that $\|T^{n+1}f\| \leq \|T^n f\| \leq \|f\|$ for all $n \geq 1$. By the weak compactness of the unit ball, we can therefore expect at least weak accumulation points for the sequence $\{T^n f\}_{n \in \mathbb{N}}$. When is this accumulation point unique and nontrivial? Also, when do we have convergence in the L^2-norm as well? We look at an example in §3.1. In §3.2, we derive a general formula for $(Tf)^\wedge$, which will allow us to answer these questions in §4.

3.1. A linear combination of a wavelet and its scaling function. The different orthonormality relations make this example particularly easy. Noting that $T\phi = \phi, T\psi = 0$, we study the action of T on a linear combination of ψ and ϕ:

PROPOSITION 3.1. *Let ϕ, respectively, ψ, be the scaling function, respectively, wavelet, associated with a multiresolution analysis with $|\phi(x)| \leq C(1+|x|)^{-1}$. Define $f := \alpha\phi + \beta\psi$ with $|\alpha|^2 + |\beta|^2 = 1$. Then $\lim_{N\to\infty}(T^N f)^\wedge(\xi) = 0$ a.e. in ξ unless $\beta = 0$, in which case $f = \alpha\phi$ and $T^N f = f$ for all $N \in \mathbb{N}$. Moreover, $T^N f$ converges to 0 weakly in L^2 as well.*

Before starting the proof, let us review some "standard" notations and properties of wavelet analysis. For more details, we refer to [Dau2].

Let $m_0(\xi) = \frac{1}{\sqrt{2}} \sum_{n\in\mathbb{Z}} h_n e^{-in\xi}$ and $m_1(\xi) = \frac{1}{\sqrt{2}} \sum_{n\in\mathbb{Z}} g_n e^{-in\xi}$ with $h_n = \langle \phi, \phi_{-1,n} \rangle$ and $g_n = \langle \psi, \phi_{-1,n} \rangle$. In the following proof, we will use the fact that

$$\text{(3.1)} \qquad \sum_{n\in\mathbb{Z}} h_n \overline{h_{n+2k}} = \delta_{k,0}, \qquad \sum_{n\in\mathbb{Z}} h_n \overline{g_{n+2k}} = 0, \qquad \sum_{n\in\mathbb{Z}} g_n \overline{g_{n+2k}} = \delta_{k,0},$$

$m_0(0) = 1$, and $m_1(0) = 0$. Note that the decay of ϕ ensures that the h_n's are absolutely summable.

Proof of Proposition 3.1. If $\beta = 0$, we are done. We now assume $\beta \neq 0$, so $|\alpha| < 1$. Since the functions $f_{-1,n} = \alpha\phi_{-1,n} + \beta\psi_{-1,n}$ are orthonormal, we have

$$\begin{aligned} f^1 = Tf &= \sum_m \langle \alpha\phi + \beta\psi, \alpha\phi_{-1,m} + \beta\psi_{-1,m} \rangle (\alpha\phi_{-1,m} + \beta\psi_{-1,m}) \\ &= \sum_m (|\alpha|^2 h_m + \overline{\alpha}\beta g_m)(\alpha\phi_{-1,m} + \beta\psi_{-1,m}), \\ f^1(\bullet - m) &= \sum_k (|\alpha|^2 h_k + \overline{\alpha}\beta g_k)(\alpha\phi_{-1,2m+k} + \beta\psi_{-1,2m+k}), \\ \langle f^1, f^1(\bullet - m) \rangle &= \sum_{n,k} (|\alpha|^2 h_n + \overline{\alpha}\beta\, g_n)(|\alpha|^2\, \overline{h_k} + \alpha\overline{\beta}\ \overline{g_k})(|\alpha|^2 + |\beta|^2)\delta_{n,2m+k} \\ &= |\alpha|^2\, \delta_{m,0}. \end{aligned}$$

It follows that T^2f, the projection of $f^1 = Tf$ onto $\overline{\operatorname{Span}\{f^1(2\bullet-n); n \in \mathbb{Z}\}}$, is given by

$$f^2 = T^2 f = |\alpha|^{-2} \sum_m \langle f^1, f^1_{-1,m}\rangle f^1_{-1,m} = \sum_m (|\alpha|^2\, h_m + \overline{\alpha}\beta\, g_m) f^1_{-1,m}.$$

By induction, we then obtain, for all $N \in \mathbb{N}$,

$$\begin{aligned} f^{N+1} &= T^{N+1} f = \sum_m (|\alpha|^2\, h_m + \overline{\alpha}\beta\, g_m) f^N_{-1,m}, \\ \langle f^N, f^N_{-1,m}\rangle &= |\alpha|^{2N}(|\alpha|^2\, h_m + \overline{\alpha}\beta\, g_m), \\ \langle f^N, f^N(\bullet - m)\rangle &= |\alpha|^{2N}\, \delta_{m,0}. \end{aligned} \tag{3.2}$$

Formula (3.2) can be rewritten as

$$\begin{aligned} (f^{N+1})^\wedge(\xi) &= \sum_m (|\alpha|^2 h_m + \overline{\alpha}\beta\, g_m)\sqrt{2}\,(f^N)^\wedge\left(\frac{\xi}{2}\right)\frac{1}{2}e^{-i\frac{m}{2}\xi} \\ &= \left(|\alpha|^2\, m_0\left(\frac{\xi}{2}\right) + \overline{\alpha}\beta\, m_1\left(\frac{\xi}{2}\right)\right)(f^N)^\wedge\left(\frac{\xi}{2}\right) \\ &= \overline{\alpha}^{N+1}\prod_{j=1}^{N+1}(\alpha\, m_0(2^{-j}\xi) + \beta\, m_1(2^{-j}\xi))\hat{f}(2^{-N-1}\xi). \end{aligned} \tag{3.3}$$

Since $\hat{f}(0) = \alpha$ and the h_n's and g_n's are absolutely summable, $[\alpha\, m_0(2^{-j}\xi) + \beta\, m_1(2^{-j}\xi)]$ goes to α pointwise in ξ as $j \to \infty$ with $|\alpha| < 1$, thus the limit of (3.3) for $N \to \infty$ exists, and

$$\lim_{N\to\infty}(T^N f)^\wedge(\xi) = 0 \quad \text{a.e. in } \xi.$$

Now observing that $|\alpha\, m_0(2^{-j}\xi) + \beta\, m_1(2^{-j}\xi)| \le 1$, we have, again from (3.3), that

$$|(T^N f)^\wedge(\xi)| \le |\hat{f}(2^{-N-1}\xi)| \le \frac{1}{\sqrt{2\pi}}\|f\|_{L^1} \le \frac{1}{\sqrt{2\pi}}(|\alpha| + |\beta|)\|\phi\|_{L^1}.$$

Therefore, for the dense set in $L^2(\mathbb{R})$ of u with Fourier transform $\hat{u} \in L^2(\mathbb{R})\bigcap L^1(\mathbb{R})$, we can use Lebesgue's dominated-convergence theorem to get

$$\lim_{N\to\infty}\langle T^N f, u\rangle = \lim_{N\to\infty}\langle (T^N f)^\wedge, \hat{u}\rangle = \left\langle \lim_{N\to\infty}(T^N f)^\wedge, \hat{u}\right\rangle = 0.$$

Since the $T^N f$'s are also uniformly bounded, this implies the weak convergence of $T^N f$ to 0. □

Actually, we shall show below (in Example 4.7) that the convergence holds in the L^2-norm as well. Note that the f^N's are, in fact, linear combinations of *wavelet packets* as introduced by Coifman and Meyer (for a discussion, see, e.g., [CMW]). Note also that this proposition demonstrates the nonlinearity of T since $\alpha\phi = \alpha T\phi + \beta T\psi \neq T(\alpha\phi + \beta\psi)$.

COROLLARY 3.2. *Iterating T on f does* not *necessarily lead to the closest scaling function (in the L^2-sense) $\tilde{\phi}$ to f.*

Proof. Take f as above, $f = \alpha\,\phi + \beta\,\psi$ with $\beta \neq 0$. Then the distance of f to the family of fixed points of T satisfies $\inf\{\|f - \tilde{\phi}\|; T\tilde{\phi} = \tilde{\phi}\} \le \|f - \phi\| = [2 - 2\Re(\alpha)]^{1/2}$. However, by Proposition 3.1, $T^n f \to 0$ so that $\|f - T^n f\| \to 1 > \sqrt{2 - 2\Re(\alpha)}$ if $\Re(\alpha) > \frac{1}{2}$. □

3.2. The general case: Link with subdivision schemes. In our previous examples, $T^n f \to 0$, at least in the distributional sense, unless f is a scaling function, in which case $Tf = f$. Suitable dilations of scaling functions also give fixed points of T. For example, if $f(x) = \chi_{[0,m)}(x)$, where m is an integer ≥ 2, then $f(x) = f(2x) + f(2x - m)$ a.e., so $Tf = f$. On the other hand, if we take $f(x) = \chi_{[0,1/m)}(x)$ with $m \geq 2$, then $T^n f(x) = \chi_{[0,2^{-n}/m)}(x) \to 0$ a.e. in x as $n \to \infty$. What happens to other dilations, such as $f(x) = \chi_{[0,1+\epsilon)}(x), 0 < \epsilon < 1$? Also, more generally, what happens to arbitrary (but nice) functions, such as the Gaussian $e^{-x^2/2}$?

To answer these questions, we need to derive an explicit formula for $T^n f$ valid for general f. We will use formula (2.3) again, not only to compute Tf, but also for the iterates $T^n f$. This means that we shall need the Riesz basis property for f and all the $T^n f$'s. Fortunately, Tf inherits the Riesz basis property from f under some mild additional assumptions on f.

PROPOSITION 3.3. *If f is RBP with continuous $\hat{f}$ satisfying*

$$|\hat{f}(\xi)| \leq C\,(1 + |\xi|)^{-\frac{1}{2}-\epsilon}$$

for some $\epsilon, C > 0$, and if $a(\xi)$, defined by (2.3), *satisfies*

$$|a(\xi)|^2 + |a(\xi + \pi)|^2 > 0, \tag{3.4}$$

then Tf is RBP; *moreover, Tf inherits the other properties of f.*

Proof. 1. We begin by showing that for some $c_1, c_2 > 0$,

$$c_1 \leq |a(\xi)|^2 + |a(\xi + \pi)|^2 \leq c_2. \tag{3.5}$$

By the decay of $\hat{f}$, we can make $\sum_{|l|\geq L} |\hat{f}(\xi + 2\pi l)|^2$ arbitrarily small by choosing the positive integer L large enough. Then the finite sum $\sum_{|l|<L} |\hat{f}(\xi + 2\pi l)|^2$ is continuous because of the continuity of $\hat{f}$. It follows that $\sum_{l\in\mathbb{Z}} |\hat{f}(\xi + 2\pi l)|^2$ is continuous. Similarly, one can prove the continuity of $\sum_{l\in\mathbb{Z}} \hat{f}(2\xi + 4\pi l)\overline{\hat{f}(\xi + 2\pi l)}$. Therefore, the quotient $a(\xi)$ is also continuous. Thus (3.4) implies (3.5).

2. We now prove that Tf is RBP. Using Proposition 2.1, it is easy to check that

$$\begin{aligned}\sum_{l\in\mathbb{Z}} |(Tf)^\wedge(2\xi + 2\pi l)|^2 &= \sum_{l} |a(\xi + \pi l)\hat{f}(\xi + \pi l)|^2 \\ &= |a(\xi)|^2 \sum_{k} |\hat{f}(\xi + 2\pi k)|^2 + |a(\xi + \pi)|^2 \sum_{k} |\hat{f}(\xi + \pi + 2\pi k)|^2,\end{aligned}$$

which implies $0 < c_1 C_{1,f} \leq \sum_l |\hat{T}f(2\xi + 2\pi l)|^2 \leq c_2 C_{2,f} < +\infty$.

3. Since $(Tf)^\wedge(\xi) = a(\xi/2)\hat{f}(\xi/2)$, the continuity of $(Tf)^\wedge$ is obvious. By the Cauchy–Schwarz inequality and (2.3), $|a(\xi)| \leq C_2/C_1$. Therefore, the decay of $\hat{f}$ implies the same type of decay for $(Tf)^\wedge$.

4. Next, we compute $a^1(\xi)$. Now that Tf is RBP, we know, similarly to the case where we obtain a formula for Tf, that $f^2 := T^2 f = \sum_{k\in\mathbb{Z}} a_k^1 f_{-1,k}^1$, or

$$(f^2)^\wedge(\xi) = a^1\left(\frac{\xi}{2}\right)(f^1)^\wedge\left(\frac{\xi}{2}\right)$$

with $a^1(\xi) = \frac{1}{\sqrt{2}} \sum_{k\in\mathbb{Z}} a_k^1 \, e^{-i\xi k}$ defined by replacing $\hat{f}$ by $(Tf)^\wedge$ in (2.3). Furthermore, with

$$\alpha^n(\xi) := \sum_{k\in\mathbb{Z}} \langle f^n, f_{-1,k}^n \rangle \, e^{-i\xi k}, \qquad \beta^n(\xi) := \sum_{k\in\mathbb{Z}} \langle f^n, f_{0,k}^n \rangle \, e^{-i\xi k},$$

we have, for $n = 0, 1$ (we let $a^0 = a$ and $f^0 = f$),

$$a^n(\xi) = \frac{\alpha^n(\xi)}{\sqrt{2}\beta^n(\xi)}.$$

We now show the surprising result that $a^1 = a^0$. In fact, we have

$$\begin{aligned}\beta^1(2\xi) &= \sum_k \langle f^1, f^1_{0,k}\rangle\, e^{-2ki\xi} = \sum_k \sum_{m,l} a^0_m a^0_l \langle f^0_{-1,m}, f^0_{-1,l+2k}\rangle\, e^{-2ki\xi} \\ &= \sum_{k,m,l} a^0_m e^{-im\xi} a^0_l e^{il\xi} \beta^0_{l+2k-m}\, e^{-i(l+2k-m)\xi} \\ &= |a^0(\xi)|^2\beta^0(\xi) + |a^0(\xi+\pi)|^2\beta^0(\xi+\pi).\end{aligned}$$

Similarly, $\alpha^1(2\xi) = a^0(2\xi)\overline{a^0(\xi)}\alpha^0(\xi) + a^0(2\xi)\overline{a^0(\xi+\pi)}\alpha^0(\xi+\pi)$. Hence

$$\begin{aligned}a^1(2\xi) = \frac{\alpha^1(2\xi)}{\sqrt{2}\beta^1(2\xi)} &= \frac{a^0(2\xi)\overline{a^0(\xi)}\alpha^0(\xi) + a^0(2\xi)\overline{a^0(\xi+\pi)}\alpha^0(\xi+\pi)}{\sqrt{2}[|a^0(\xi)|^2\beta^0(\xi) + |a^0(\xi+\pi)|^2\beta^0(\xi+\pi)]} \\ &= \frac{a^0(2\xi)\left\{\overline{a^0(\xi)}\frac{\alpha^0(\xi)}{\sqrt{2}\beta^0(\xi)}\beta^0(\xi) + \overline{a^0(\xi+\pi)}\frac{\alpha^0(\xi+\pi)}{\sqrt{2}\beta^0(\xi+\pi)}\beta^0(\xi+\pi)\right\}}{|a^0(\xi)|^2\beta^0(\xi) + |a^0(\xi+\pi)|^2\beta^0(\xi+\pi)} = a^0(2\xi).\end{aligned}$$

Thus $a^1(\xi)$ also satisfies $|a^1(\xi)|^2 + |a^1(\xi+\pi)|^2 > 0$. □

This proposition motivates the following definition.

DEFINITION 3.4. *We say that f is T-*amenable *if f is RBP, if $\hat{f}$ is continuous and satisfies $|\hat{f}(\xi)| \le C(1+|\xi|)^{-(1/2)-\epsilon}$ for some $\epsilon, C > 0$, and if $a(\xi)$, defined by* (2.3)*, satisfies $|a(\xi)|^2 + |a(\xi+\pi)|^2 > 0$.*

Proposition 3.3 can now simply be rephrased as follows: if f is T-amenable, then so is Tf. By induction, all the successive iterates $T^n f$ will then also be T-amenable; in particular, they will all be RBP. It follows that for some sequence $\{a^n_k\}_{k\in\mathbb{Z}} \in l^2$, $f^{n+1} = T^{n+1}f = \sum_{k\in\mathbb{Z}} a^n_k\, f^n_{-1,k}$; an exact formula for $a^n(\xi) = \frac{1}{\sqrt{2}}\sum_{k\in\mathbb{Z}} a^n_k\, e^{-i\xi k}$ can be found as was done for $a^1(\xi)$. By the same computation that established $a^1 = a^0$, we have $a^n = a^{n-1}$; hence $a^n = a^0$ for all $n \in \mathbb{N}$. Since there will be no confusion hereafter, we will drop the superscript 0 in $a^0(\xi)$. Sometimes we will add a subscript, $a_f(\xi)$, to emphasize the dependence on the original function f.

This observation shows that for T-amenable f, the $T^n f$'s are merely the subdivision-scheme iterates of f with the weights $\{a_k\}$.

THEOREM 3.5. *If f is T-amenable, then the $T^n f$'s are given by*

$$(T^n f)^\wedge(\xi) = \left[\prod_{j=1}^{n} a(2^{-j}\xi)\right] \hat{f}(2^{-n}\xi). \tag{3.6}$$

Formula (3.6) implies, at least formally, that

$$\hat{f}^\infty(\xi) := \lim_{n\to+\infty} (T^n f)^\wedge(\xi) = \hat{f}(0)\prod_{j=1}^{\infty} a(2^{-j}\xi),$$

which can also be rewritten as $\hat{f}^\infty(\xi) = a(\xi/2)\hat{f}^\infty(\xi/2)$, or

$$f^\infty(x) = \sqrt{2}\sum_{k\in\mathbb{Z}} a_k\, f^\infty(2x-k).$$

We have therefore reduced the problem of studying the limit of the $T^n f$ to finding the solution of a refinement equation (also called a dilation equation or a two-scale difference equation) with filter $a(\xi)$. It is not surprising that this limit f^∞ should satisfy a refinement equation since f^∞ is a fixed point of T; it is surprising that the corresponding mask should be given by $a(\xi)$. There exists considerable literature on refinement equations and refinable functions. See, e.g., [CDM], [DL1], [DL2], [Her1], and the papers cited therein for a detailed study with applications to the construction of wavelets and to subdivision schemes in computer-aided geometric design. In the next section, we shall use some of these results and see how they connect with our operator.

4. Sufficient conditions for convergence of T^n. Since the functions $T^n f$ are given by a subdivision scheme, convergence questions boil down to studying the convergence of subdivision schemes, which is studied in the literature on refinable functions. Many of the articles on refinement equations concern the case where $a(\xi)$ is a trigonometric polynomial. Here $a(\xi)$ is usually not a trigonometric polynomial, and we will be particularly interested in the results obtained by Hervé [Her1]–[Her3] which also apply to nonpolynomial $a(\xi)$'s. Other recent results on convergence of the cascade algorithm are in [Du] (mostly the finite case) and in [Her4] and [CD2], which use a different approach. Related results (for another application) can also be found in [DH]. In this section, we shall state and prove several convergence theorems for our iterates $T^n f$. In particular, we study pointwise convergence of $(T^n f)^\wedge(\xi)$, L^2-convergence of $T^n f$, and pointwise convergence of $(T^n f)(x)$.

THEOREM 4.1 (pointwise convergence of $(T^n f)^\wedge$). *Assume that f is T-amenable and that $\hat{f}$ satisfies $\hat{f}(2\pi l) = \delta_{l,0}\hat{f}(0)$ with $\hat{f}(0) \neq 0$. Assume moreover that*

$$|a_f(\xi) - a_f(0)| \leq c|\xi|^\alpha \quad as \quad \xi \to 0, \tag{4.1}$$

where $a_f(\xi)$ is defined as in (2.3). Then $(T^n f)^\wedge$ converges pointwise to a nontrivial continuous limit $\hat{f}(0)\hat{\phi}$ with $\hat{\phi}$ defined as in (2.8).

Note that (4.1) is easy to satisfy. It suffices, e.g., that f has compact support or that $\sum_l |\hat{f}(\xi + 2\pi l) - \hat{f}(2\pi l)|^2 \leq C|\xi|^{2\alpha}$ for sufficiently small ξ.

Theorem 4.1 follows immediately from Proposition 2.4 and the following lemma.

LEMMA 4.2. *For a T-amenable function f, the following are equivalent:*

(1) $a_f(0) = 1$;

(2) $\hat{f}(2\pi l) = \delta_{l,0}\hat{f}(0)$ *with* $\hat{f}(0) \neq 0$, $l \in \mathbb{Z}$;

(3) $\sum_{k\in\mathbb{Z}} f(x-k) =$ *nonzero constant function.*

Proof. 1. We start by proving that (1) ⇒ (2). Assume that $a_f(0) = 1$ or, equivalently (by (2.3)), that $\sum_{l\in\mathbb{Z}} \hat{f}(4\pi l)\overline{\hat{f}(2\pi l)} = \sum_{l\in\mathbb{Z}} |\hat{f}(2\pi l)|^2$. By the Cauchy–Schwarz inequality, this implies that $(\sum_{l\in\mathbb{Z}} |\hat{f}(2\pi l)|^2)^{1/2} \leq (\sum_{l\in\mathbb{Z}} |\hat{f}(4\pi l)|^2)^{1/2}$. However, this can hold only if

$$\begin{cases} \hat{f}((2k+1)2\pi) = 0, & k \in \mathbb{Z}, \\ \hat{f}(4\pi l) = C\hat{f}(2\pi l) & \text{for some constant } C. \end{cases}$$

Since for $k \neq 0$, $k = 2^l(2m+1)$ for some $l \geq 0$ and $m \in \mathbb{Z}$, we find that

$$\hat{f}(2k\pi) = \hat{f}(2 \cdot 2^l(2m+1)\pi) = C^l\hat{f}((2m+1)2\pi) = 0.$$

2. (2) ⇒ (1) is obvious, and (2) ⇔ (3) can be checked by Poisson's summation formula. □

Note that if $a(0) = 1$, then this lemma implies that $a(\pi) = 0$. (We will use this below.) Also note that if $a(\xi)$ is continuous, then the infinite product in (2.8) makes sense only if $a(0) = 1$. Thus (1)–(3) are necessary for the right-hand side of (2.8) to be nontrivial.

Thus far, we have looked only at the weak convergence of $T^n f$ or pointwise convergence of $(T^n f)^\wedge(\xi)$. Before we can speak of convergence in L^2-norm, we need to establish conditions guaranteeing that ϕ is in $L^2(\mathbb{R})$. Note that by using Plancherel's formula and the Poisson summation formula, we can derive, for all $f \in L^2(\mathbb{R}) \bigcap L^1(\mathbb{R})$,

$$\begin{aligned} \|T^n f\|^2 &= \int_{-\infty}^{+\infty} |\hat{f}(2^{-n}\xi)|^2 \prod_{j=1}^{n} |a(2^{-j}\xi)|^2 \, d\xi \\ &= \int_{|\xi| \le 2^n \pi} F(2^{-n}\xi) \prod_{j=1}^{n} |a(2^{-j}\xi)|^2 \, d\xi, \end{aligned} \tag{4.2}$$

where $F(\xi) = \sum_{l \in \mathbb{Z}} |\hat{f}(\xi + 2\pi l)|^2$ is 2π-periodic. In all cases of interest to us, f will have exponential decay or even compact support so that (4.1) is automatically satisfied, and F is continuous. We shall assume this continuity in all that follows.

The right-hand side of formula (4.3) can be computed by using properties of a positive linear operator associated with the continuous 2π-periodic function $a(\xi)$. This operator, which we denoted $P_{|a|^2}$ in §2, is usually called the *Perron–Frobenius operator* or *transfer operator*. Recall that it acts on a continuous 2π-periodic function F as follows:

$$P_{|a|^2} F(\xi) = \left| a\left(\frac{\xi}{2}\right) \right|^2 \cdot F\left(\frac{\xi}{2}\right) + \left| a\left(\frac{\xi}{2} + \pi\right) \right|^2 \cdot F\left(\frac{\xi}{2} + \pi\right).$$

This operator often appears in the study of orthonormal wavelets and in the estimation of the regularity of the scaling functions associated with $a(\xi)$; see, e.g., [CR], [La], [CD1], [CD2], [Vi], [CDM], [Ei], [Gr], and [Her1]–[Her4]. Its connection with (4.3) is given by the following lemma.

LEMMA 4.3. *For any continuous 2π-periodic function F and all $n \in \mathbb{N}$,*

$$\int_{-\pi}^{\pi} P_{|a|^2}^n F(\xi) \, d\xi = \int_{|\xi| \le 2^n \pi} F(2^{-n}\xi) \prod_{j=1}^{n} |a(2^{-j}\xi)|^2 \, d\xi.$$

This lemma (proved by induction; see any of the references above) shows the relation, stated in Theorem 2.5, between L^2-estimates as in (4.3) and the spectral radius of $P_{|a|^2}$. We now give the proof of Theorem 2.5, borrowed from [Co]; see also [Her1]. We include it here because the same technique also proves the technical Lemma 4.4 below that we shall use extensively further on.

Proof of Theorem 2.5. It suffices to prove that

$$\sum_{n \ge 0} \int_{2^{n-1}\pi \le |\xi| \le 2^n \pi} \prod_{j=1}^{\infty} |a(2^{-j}\xi)|^2 \, d\xi < +\infty.$$

Now using the classical formulas

$$\prod_{j=1}^{n} \cos \frac{\xi}{2^{j+1}} = \frac{\sin \frac{\xi}{2}}{2^n \sin(2^{-n-1}\xi)}, \qquad \prod_{j=1}^{\infty} \cos \frac{\xi}{2^{j+1}} = \frac{2 \sin \frac{\xi}{2}}{\xi},$$

we find that

$$\begin{aligned}
I_n &:= \int_{2^{n-1}\pi\le|\xi|\le 2^n\pi} \prod_{j=1}^{\infty} |a(2^{-j}\xi)|^2\, d\xi \\
&= \int_{2^{n-1}\pi\le|\xi|\le 2^n\pi} \left|\frac{2\sin\frac{\xi}{2}}{\xi}\right|^{2r} \prod_{j=1}^{\infty} |v(2^{-j}\xi)|^2\, d\xi \\
&\le C(2^{n-1}\pi)^{-2r} \int_{2^{n-1}\pi\le|\xi|\le 2^n\pi} \prod_{j=1}^{\infty} |v(2^{-j}\xi)|^2\, d\xi.
\end{aligned}$$

Note that if we let $h(\xi) := \prod_{j=1}^{\infty} |v(2^{-j}\xi)|^2 = \prod_{j=1}^{n} |v(2^{-j}\xi)|^2\, h(2^{-n}\xi)$, then because v—and hence $|v|^2$—has Hölder exponent α in 0, we know by Proposition 2.4 that h is continuous. It follows that for $2^{n-1}\pi \le |\xi| \le 2^n\pi$, $|h(2^{-n}\xi)| \le \sup_{\pi/2\le|\zeta|\le\pi} |h(\zeta)| = C$, implying $|h(\xi)| \le C\prod_{j=1}^{n} |v(2^{-j}\xi)|^2$. Hence

$$\begin{aligned}
I_n &\le C(r)\, 2^{-2rn} \int_{2^{n-1}\pi\le|\xi|\le 2^n\pi} \prod_{j=1}^{n} |v(2^{-j}\xi)|^2 d\xi \\
&\le C(r) 2^{-2rn} \int_{|\xi|\le 2^n\pi} \prod_{j=1}^{n} |v(2^{-j}\xi)|^2 d\xi \\
&= C(r)\, 2^{-2rn} \int_{-\pi}^{\pi} P_{|v|^2}^n 1(\xi) d\xi \le C(r)\, 2^{-2rn}(\beta+\epsilon)^n = C(r)\left(\frac{\beta+\epsilon}{2^{2r}}\right)^n.
\end{aligned}$$

Since $\beta < 2^{2r}$, we can choose $\epsilon > 0$ such that $(\beta+\epsilon)/2^{2r} < 1$, so $\sum_{n\ge 0} I_n < +\infty$. □

LEMMA 4.4. *Under the same assumptions as in Theorem* 2.5, *we have, for any* $0 < \alpha \le \pi$,

$$\lim_{n\to\infty} \int_{2^n\alpha\le|\xi|\le 2^n\pi} \prod_{j=1}^{n} |a(2^{-j}\xi)|^2\, d\xi = 0. \tag{4.3}$$

Proof. The only difference between the integral in (4.3) and I_n is that the product now has only n factors instead of infinitely many. We use the estimate, for $2^n\alpha \le |\xi| \le 2^n\pi$,

$$\prod_{j=1}^{n} \left|\cos\frac{\xi}{2^{j+1}}\right|^{2r} = \left|\frac{2\sin\frac{\xi}{2}}{\xi}\right|^{2r} \left|\frac{2^{-n-1}\xi}{\sin(\frac{\xi}{2^{n+1}})}\right|^{2r} \le C(\alpha, r)\, 2^{-2rn}.$$

The rest of the argument is unchanged. □

We are now ready to state the main result of this section.

THEOREM 4.5 (L^2-convergence of $T^n f$). *Assume that f is T-amenable and that f satisfies $\hat{f}(2\pi l) = \delta_{l,0}\hat{f}(0)$. Assume moreover that $|a_f(\xi)| = |\cos\frac{\xi}{2}|^r \cdot |v(\xi)|$ and $r > 0$ with $v(\pi) \ne 0$, where $v(\xi)$ has Hölder exponent α at 0. Let β be the spectral radius of $P_{|v|^2}$ restricted to $C[0, 2\pi]$. If $\beta < 2^{2r}$, then $T^n f$ converges in $L^2(\mathbb{R})$ to $\hat{f}(0)\phi$, where ϕ is defined as in* (2.8).

Proof. Our proof mimics that of Theorem 3.3 in [CD]; our extra condition of the decay of $\hat{f}(\xi)$ is needed here since we do not just consider truncated versions of $T^n f$ as in [CD].

1. By Lemma 4.2, Proposition 2.4, and Theorem 2.5, we know that the assumptions imply that $\hat{\phi}$ is continuous and in $L^2(\mathbb{R})$.

2. Since $\hat{f}$ and $\hat{\phi}$ are continuous in 0 and since $\hat{\phi}(0) = 1$, there exists an $\alpha \in (0, \pi]$ such that

$$|\xi| \le \alpha \Rightarrow |\hat{f}(\xi)| \le C|\hat{\phi}(\xi)| \quad \text{and} \quad |\hat{\phi}(\xi)| \ge C' > 0. \tag{4.4}$$

We now divide $T^n f$ into three parts: $T^n f = \phi_n^1 + \phi_n^2 + \phi_n^3$ with

$$\begin{aligned}
\hat{\phi}_n^1(\xi) &:= (T^n f)^\wedge(\xi)\chi_{|\xi|\le 2^n\alpha}(\xi),\\
\hat{\phi}_n^2(\xi) &:= (T^n f)^\wedge(\xi)[\chi_{|\xi|\le 2^n\pi}(\xi) - \chi_{|\xi|\le 2^n\alpha}(\xi)],\\
\hat{\phi}_n^3(\xi) &:= (T^n f)^\wedge(\xi)\chi_{|\xi|> 2^n\pi}(\xi).
\end{aligned}$$

3. Clearly, $\hat{\phi}_n^1$ converges pointwise to $\hat{f}(0)\hat{\phi}$; by (4.4), $|\hat{\phi}_n^1|$ is dominated by $|\phi|$, $|\hat{\phi}_n^1(\xi)| \le C|\hat{\phi}(2^{-n}\xi)| \cdot \prod_{j=1}^n |a(2^{-j}\xi)| \le C|\hat{\phi}(\xi)|$, which implies the L^2-convergence of ϕ_n^1 to $\hat{f}(0)\phi$.

4. For $\alpha \le |\xi| \le \pi$, $\hat{f}(\xi)$ is bounded above so that

$$\begin{aligned}
\int_{-\infty}^{+\infty} |\hat{\phi}_n^2|^2 d\xi &= \int_{2^n\alpha\le|\xi|\le 2^n\pi} \prod_{j=1}^n |a(2^{-j}\xi)|^2 |\hat{f}(2^{-n}\xi)|^2 \, d\xi\\
&\le C \int_{2^n\alpha\le|\xi|\le 2^n\pi} \prod_{j=1}^n |a(2^{-j}\xi)|^2 \, d\xi.
\end{aligned} \tag{4.5}$$

By Lemma 4.4, (4.5) tends to 0 as $n \to \infty$, i.e., $\phi_n^2 \to 0$ in $L^2(\mathbb{R})$.

5. By formula (4.3),

$$\begin{aligned}
\int_{-\infty}^{+\infty} |\hat{\phi}_n^3|^2 d\xi &= \int_{|\xi|>2^n\pi} \prod_{j=1}^n |a(2^{-j}\xi)|^2 |\hat{f}(2^{-n}\xi)|^2 \, d\xi\\
&= \int_{-\infty}^{+\infty} \prod_{j=1}^n |a(2^{-j}\xi)|^2 |\hat{f}(2^{-n}\xi)|^2 d\xi - \int_{|\xi|\le 2^n\pi} \prod_{j=1}^n |a(2^{-j}\xi)|^2 |\hat{f}(2^{-n}\xi)|^2 \, d\xi\\
&= \int_{|\xi|\le 2^n\pi} \prod_{j=1}^n |a(2^{-j}\xi)|^2 \sum_{l\ne 0} |\hat{f}(2^{-n}\xi + 2l\pi)|^2 \, d\xi = J_1 + J_2,
\end{aligned}$$

where, since $|\hat{f}(\xi)| \le C(1+|\xi|)^{-1/2-\epsilon}$,

$$\begin{aligned}
J_1 &:= \int_{2^n\alpha\le|\xi|\le 2^n\pi} \prod_{j=1}^n |a(2^{-j}\xi)|^2 \sum_{l\ne 0} |\hat{f}(2^{-n}\xi + 2l\pi)|^2 \, d\xi\\
&\le C_2 \int_{2^n\alpha\le|\xi|\le 2^n\pi} \prod_{j=1}^n |a(2^{-j}\xi)|^2 \, d\xi \ \to 0
\end{aligned}$$

by Lemma 4.4 again. It remains to prove that when $n \to \infty$,

$$J_2 := \int_{|\xi|\le 2^n\alpha} G_n(\xi) d\xi = \int_{-\infty}^{+\infty} G_n(\xi)\chi_{|\xi|\le 2^n\alpha}(\xi) d\xi \to 0,$$

where $G_n(\xi) := \prod_{j=1}^n |a(2^{-j}\xi)|^2 \sum_{l\neq 0} |\hat{f}(2^{-n}\xi + 2l\pi)|^2$. By (4.4), we have

$$|G_n(\xi)\chi_{|\xi|\leq 2^n\alpha}(\xi)| \leq \frac{1}{C'}|\hat{\phi}(\xi)|^2 \cdot \sum_{l\neq 0} |\hat{f}(2^{-n}\xi + 2l\pi)|^2 \tag{4.6}$$

$$\leq \frac{C_2}{C'}|\hat{\phi}(\xi)|^2 \quad \text{(by the decay of } f). \tag{4.7}$$

For any fixed ξ, since $\hat{f}(2\pi l) = \hat{f}(0)\delta_{l,0}$ and $|\hat{f}(\xi)| \leq C/(1+|\xi|)^{(1/2)+\epsilon}$, we have

$$\lim_{n\to+\infty} \sum_{l\neq 0} |\hat{f}(2^{-n}\xi + 2l\pi)|^2 = 0.$$

Therefore, by (4.6), $G_n(\xi)\,\chi_{|\xi|\leq 2^n\alpha}(\xi) \to 0$ pointwise. By (4.7) and Lebesgue's theorem, J_2 tends to 0, which implies that $\phi_n^3 \to 0$ in $L^2(\mathbb{R})$. This finishes our proof of L^2 convergence of $T^n f$ to $\hat{f}(0)\phi$. □

Remark. If we consider $P_{|v|} = P_{(\sqrt{|v|})^2}$ and let β_1 be the spectral radius for $P_{|v|}$ restricted to $C[0,2\pi]$, then with the same assumptions except that $\beta_1 < 2^r$ and with $|\hat{f}(\xi)| \leq C(1+|\xi|)^{-1-\epsilon}$ for some $C, \epsilon > 0$, we find that the proofs of the previous lemmas and theorems concerning L^2-convergence can be copied (with small changes) to prove a similar theorem for L^1-convergence of $\hat{Tf}(\xi)$ to $\hat{f}(0)\hat{\phi}(\xi)$, which implies the pointwise convergence of $T^n f(x)$ to $\hat{f}(0)\phi(x)$.

THEOREM 4.6 (pointwise convergence of $T^n f(x)$). *Let $f(x)$ and $a(\xi)$ be as in Theorem 4.5 with the stronger regularity condition $|\hat{f}(\xi)| \leq C\,(1+|\xi|)^{-1-\epsilon}$ for some $\epsilon, C > 0$. Let β_1 be the spectral radius of $P_{|v|}$ restricted to $C[0,2\pi]$. If $\beta_1 < 2^r$, then $(T^n f)^\wedge(\xi)$ converges in $L^1(\mathbb{R})$ to $\hat{f}(0)\hat{\phi}(\xi)$; therefore, $T^n f(x)$ converges pointwise to $\hat{f}(0)\phi(x)$.*

Remark. The proofs of L^2- or L^1-convergence both depend on the property that $\hat{f}(2\pi l) = \hat{f}(0)\delta_{l,0}$. Actually, this is essential for the L^2- (or L^1-) convergence of functions like $\prod_{j=1}^n a(2^{-j}\xi)\hat{f}(2^{-n}\xi)$. We will study this in detail in the next section.

Example 4.7. In §3.1, we looked at the example where $f = \alpha\phi + \beta\psi$ with $|\alpha|^2 + |\beta|^2 = 1$. Let us revisit this example in light of the results of this section. We have

$$\hat{f}(2\pi l) = \alpha\,\hat{\phi}(2\pi l) + \beta\,\hat{\psi}(2\pi l), \quad \hat{\phi}(2\pi l) = \delta_{l,0}\hat{\phi}(0), \quad \hat{\psi}(2\pi l) = e^{i\pi l}\overline{m_0(\pi l + \pi)}\hat{\phi}(\pi l).$$

However, $\hat{\psi}(2\pi l) = e^{i\pi l}\overline{m_0(\pi)}\hat{\phi}(\pi l) = 0$ if $l = 2m$; $\hat{\psi}(2\pi l) = -\hat{\phi}(\pi(2m+1))$ if $l = 2m+1$. Since $\sum_k |\hat{\phi}(2k\pi + \xi)|^2 = \frac{1}{2\pi}$ for all ξ, it follows that $\sum_m |\hat{\phi}(2m\pi + \pi)|^2 \neq 0$ so that $\hat{\psi}(2\pi l)$ cannot be 0 for all $l = 2m+1, m \in \mathbb{Z}$. Thus f can satisfy properties (1), (2), and (3) of Lemma 4.2 only if $\beta = 0$, i.e., $f = \alpha\phi$.

Note also that we can use Lemma 4.3 for a simple proof that $T^N f \to 0$ in $L^2(\mathbb{R})$ for $\beta \neq 0$ (as promised at the end of §3.1). Indeed, we have

$$\|T^N f\|^2 = \int_{-\infty}^{+\infty} |\alpha|^{2N} \prod_{j=1}^N |\alpha\; m_0(2^{-j}\xi) + \beta\; m_1(2^{-j}\xi)|^2 |\hat{f}(2^{-N}\xi)|^2 d\xi$$

$$= |\alpha|^{2N} \int_{|\xi|\leq 2^n\pi} F(2^{-n}\xi) \prod_{j=1}^N |w(2^{-j}\xi)|^2\, d\xi = |\alpha|^{2N} \int_{-\pi}^{\pi} (P_{|w|^2})^N F(\xi) d\xi,$$

where $w(\xi) = \alpha m_0(\xi) + \beta m_1(\xi)$ and $F(\xi) = \sum_l |\hat{f}(\xi + 2\pi l)|^2$. Since the $\{f(\bullet - l)\}_{l\in\mathbb{Z}}$'s are orthonormal, $F(\xi) = \frac{1}{2\pi}$. On the other hand, as a consequence of (3.1), we have $|m_0(\xi)|^2 + |m_1(\xi)|^2 = 1$, which implies that $|w(\xi)|^2 + |w(\xi+\pi)|^2 = 1$. Hence $(P_{|w|^2})^N F(\xi) = F(\xi)$. Therefore, $\lim_{N\to\infty} \|T^N f\|^2 = \lim_{N\to\infty} |\alpha|^{2N} \cdot 2\pi \cdot \frac{1}{2\pi} = 0$, i.e., $T^N f \overset{L^2}{\to} 0$.

We can now answer the questions we raised at the beginning of §3.2.

Example 4.8. First, for $f = \chi_{[0,1+\epsilon)}$, $0 < \epsilon < 1$, we check that $\hat{f}(2k\pi) = (1 - e^{i\epsilon(2k\pi)})/i(2k\pi)$. Therefore, f does not satisfy property (2) of Lemma 4.2; hence $a_f(0) \neq 1$. By the same argument as used in the proof for (1) ⇒ (2) in Lemma 4.2, we even find $|a_f(0)| < 1$. It then follows that $(T^n f)^\wedge \to 0$.

Example 4.9. If $f(x) = e^{-x^2/2}$, then $\hat{f}(\xi) = e^{-\xi^2/2}$. A similar argument shows again that $(T^n f)^\wedge \to 0$.

5. Scaled iteration of T.

Most of our examples go to 0 under the iterations of T, usually because of a systematic "shrinking" of $T^n f$ (see Example 4.7 in the previous section). Can this can be corrected by adjusting the normalization of $T^n f$? Note that although we can control $\|T^n f\|$ (as in Proposition 5.1 below), it is difficult to give a simple formula for $\|T^n f\|$. Therefore, instead of studying the sequence $\{T^n f/\|T^n f\|\}$, we will concentrate on the convergence of the sequence $\Gamma_n = \mu_n \cdot T^n f$ for appropriately chosen μ_n. Our analysis of §3 shows that then $\hat{\Gamma}_n(\xi) = \mu_n \prod_{j=1}^n a(2^{-j}\xi)\hat{f}(2^{-n}\xi)$. Without μ_n, we have several examples where $(T^n f)^\wedge \to 0$ pointwise simply because $|a(0)| < 1$. To remedy this, we define $\mu_n = [a(0)]^{-n}$, i.e.,

$$\Gamma_n = [a(0)]^{-n} \cdot T^n f. \tag{5.1}$$

This makes sense only if $a(0) \neq 0$, which we shall assume whenever we study Γ_n.

We now concentrate on $C^\alpha[0, 2\pi] = \{f \in C[0, 2\pi] \mid \sup_{x\neq y} |f(x) - f(y)|/|x-y|^\alpha < +\infty\}$, $\alpha \in (0, 1]$. The following proposition shows that under some conditions, (5.1) is almost equivalent to simply normalizing the $T^n f$'s to 1.

PROPOSITION 5.1. *Suppose that* $F(\xi) = \sum_{l\in\mathbb{Z}} |\hat{f}(\xi + 2\pi l)|^2$ *and* $|a(\xi)|^2$ *are in* $C^\alpha[0, 2\pi]$ *with* $a(\pi) = 0$ *and* $a(0) \neq 0$. *If, furthermore, f is T-amenable, then there exists* $c_1 > 0$, *and for all* $\epsilon > 0$, *there exists* $c_2 > 0$ *so that* $c_1|a(0)|^n \leq \|T^n f\| \leq c_2|a(0)|^n(1+\epsilon)^n$.

To prove this proposition, we shall need the following result, proved in more generality by Hennion [Hen] and discussed in detail in [Her1].

THEOREM 5.2 (Hennion). *Assume* $|a(\xi)|^2 \in C^\alpha[0, 2\pi]$ *and let* ρ *be the spectral radius for* $P_{|a|^2}$ *restricted to* $C^\alpha[0, 2\pi]$. *Then there exists* $\gamma \geq 0$, $\|\gamma\| \neq 0$, *such that* $P_{|a|^2}\gamma = \rho\gamma$.

Proof of Proposition 5.1. Using results in [Her1], we can check that $a(\pi) = 0 \Rightarrow \rho = |a(0)|^2$. Using the Cauchy–Schwarz inequality and $\lim_{n\to\infty} \|P^n\|^{1/n} = \rho$, we now have

$$\begin{aligned}\|T^n f\|^2 &= \int_{|\xi|\leq 2^n\pi} F(2^{-n}\xi) \prod_{j=1}^n |a(2^{-j}\xi)|^2 \, d\xi = \int_{-\pi}^{\pi} P^n_{|a|^2} F(\xi)\, d\xi. \\ &\leq \sqrt{2\pi}\, \|P^n_{|a|^2} F(\xi)\| \leq C(\rho + \varepsilon)^n, \quad \varepsilon > 0.\end{aligned}$$

Thus we can choose $c_2 > 0$ such that $\|T^n f\| \leq c_2|a(0)|^n(1+\epsilon)^n$.

To prove the other inequality, we use the fact that f is RBP and Theorem 5.2. Take γ in $C^\alpha[0, 2\pi]$. Then we can assume $\gamma \leq M$ for a positive constant M. Hence $0 \leq P^n\gamma \leq MP^n 1$ so that

$$\rho^n\|\gamma\|^2 = \langle\gamma, P^n\gamma\rangle \leq M^2\langle 1, P^n 1\rangle \leq \frac{M^2}{C_1}\int_{-\pi}^{\pi} P^n F(\xi)\, d\xi \quad \text{(by (2.2))},$$

where we have used $\gamma \geq 0$. Thus with $c_1 = M/\sqrt{C_1}$, $\|T^n f\| \geq c_1 |a(0)|^n$. □

Remark. The condition $a(\pi) = 0$ automatically holds if $a(0) = 1$, which reduces to the unscaled case, because $\Gamma_n = T^n f$. However, $a(\pi) = 0$ is also possible when $a(0) \neq 1$. For example, if f is symmetric with respect to the line $x = k + \frac{1}{2}$ with $k \in \mathbb{Z}$, then Tf is also symmetric with respect to the same line, and $a(\pi) = 0$ follows.

Let us now investigate the convergence of the Γ_n's. We begin by considering functions supported in [0,1]. This gives explicit examples where $T^n f$ converages to 0 weakly and for which the Γ_n's converge to a nonzero limit nevertheless.

PROPOSITION 5.3. *Take $f \in L^2(\mathbb{R})$ with support $f \subset [0,1]$ and such that*

$$\int_0^{\frac{1}{2}} f(y)\overline{f(2y)}dy + \int_{\frac{1}{2}}^1 f(y)\overline{f(2y-1)}dy \neq 0. \tag{5.2}$$

Assume that $f|_{[0,1]}$ is not constant a.e. Then $(T^n F)^\wedge(\xi) \to 0$ pointwise for all ξ, but $\hat{\Gamma}_n(\xi)$ converges pointwise to a limit $\hat{\Gamma}_\infty(\xi)$ which may not be 0. This limit is in $L^2(\mathbb{R})$ if and only if

$$\int_0^{\frac{1}{2}} f(y)\overline{f(2y)}dy = \int_{\frac{1}{2}}^1 f(y)\overline{f(2y-1)}dy, \tag{5.3}$$

and in that case Γ_∞ equals $\hat{f}(0)\chi_{[0,1]}$.

Proof. Define $c_0 := \|f\|^{-2} \int_0^{1/2} f(y)\overline{f(2y)}dy$ and $d_0 := \|f\|^{-2} \int_{1/2}^1 f(y)\overline{f(2y-1)}dy$. Because the $f(\bullet - n)$'s are orthonormal, we easily find $a(\xi) = c_0 + d_0 e^{-i\xi}$, so $a(0) = c_0 + d_0$, which explains the assumption in (5.2). We also check that $|c_0|^2 + |d_0|^2 \leq \frac{1}{2}$, so $|a(0)| \leq 1$. Moreover, $|a(0)| = 1$ is only possible if $c_0 = d_0 = \frac{1}{2}$, which would imply (for details, see [Hu]) that $f|_{[0,1]}$ is constant a.e. Since this was excluded by our assumption, it follows that $|a(0)| < 1$, and $(T^n F)^\wedge \to 0$ pointwise. If we let $A(\xi) = a(\xi)/a(0) = (c_0 + d_0 e^{-i\xi})/(c_0 + d_0)$, then by Theorem 4.1, $\hat{\Gamma}_\infty(\xi) = \hat{f}(0)\prod_{j=1}^\infty A(2^{-j}\xi)$, or $\hat{\Gamma}_\infty(\xi) = A(\frac{\xi}{2})\hat{\Gamma}_\infty(\frac{\xi}{2})$. If $\Gamma_\infty \in L^2(\mathbb{R})$, then Γ_∞ is also in $L^1(\mathbb{R})$ and we can apply Theorems 3.1 and 5.1 in [DL1] to conclude $A(\xi) = \frac{1}{2}(1 + e^{-i\xi})$. This implies (5.3) and $\Gamma_\infty = \hat{f}(0)\chi_{[0,1]}$. □

There are many functions supported in [0,1] that satisfy (5.3). For instance, any f symmetric with respect to the line $x = \frac{1}{2}$ will do, as will any $\frac{1}{2}$-periodic function. An example is $f(x) = 6(x - x^2)$; for this function, the graph of Γ_n consists of 2^n arches with amplitude 1.5; this converges to $\chi_{[0,1]}$ in the distributional sense but not in $L^2(\mathbb{R})$ or pointwise. (We will see below that this absence of L^2-convergence holds in more generality.)

If $\hat{f}(2\pi l) = \hat{f}(0)\delta_{l,0}$, then $a(0) = 1$ and Γ_n is just $T^n f$. The next theorem states that the condition $\hat{f}(2\pi l) = \hat{f}(0)\delta_{l,0}$ is *necessary* for L^2- (or L^1-) convergence for $\hat{\Gamma}_n$. This means that, while we have more cases of pointwise convergence for $\hat{\Gamma}_n(\xi)$ than for $(T^n f)^\wedge(\xi)$, nothing is changed for L^2- (or L^1-) convergence: if $(T^n f)^\wedge$ does not converge in L^2 (or L^1), then neither does $\hat{\Gamma}_n$.

THEOREM 5.4. *Assume that $b(\xi)$ is 2π-periodic with Hölder exponent $\beta > 0$ and with $b(0) = 1$. For $g \in L^2(\mathbb{R}) \bigcap L^1(\mathbb{R})$ with $\hat{g}(0) \neq 0$, consider the functions G_n and G defined by $\hat{G_n}(\xi) := \prod_{j=1}^n b(2^{-j}\xi)\,\hat{g}(2^{-n}\xi)$ and $\hat{G}(\xi) := \prod_{j=1}^\infty b(2^{-j}\xi)\,\hat{g}(0)$. If $\hat{G_n}(\xi)$ converges to $\hat{G}(\xi)$ in $L^2(\mathbb{R})$ (or $L^1(\mathbb{R})$) as well as pointwise with $\hat{G} \neq 0$, then $\hat{g}(2\pi l) = \hat{g}(0)\,\delta_{l,0}$.*

Proof. We prove only the case of L^2-convergence; the L^1 case is entirely analogous.

1. Since $\hat{G}$ is continuous and $\hat{G}(0) \neq 0$, there exists an $\alpha \in (0, \pi]$ such that $|\xi| \leq \alpha \Rightarrow |\hat{G}(\xi)| \geq C > 0$. Thus we have $\chi_{|\xi| \leq \alpha}(\xi) \leq \chi_{|\xi| \leq 2^n \alpha}(\xi) \leq \hat{G}(2^{-n}\xi)/C$ for all $n \in \mathbb{N}$.

2. We now consider $\prod_{j=1}^{n} b(2^{-j}\xi)\, \chi_{|\xi| \leq \alpha}(\xi)$, which obviously converges pointwise to $\prod_{j=1}^{\infty} b(2^{-j}\xi) \chi_{|\xi| \leq \alpha}(\xi)$. As in step 3 of the proof of Theorem 4.5,

$$\left| \prod_{j=1}^{n} b(2^{-j}\xi)\, \chi_{|\xi| \leq \alpha}(\xi) \right| \leq \frac{|\hat{G}(\xi)|}{|\hat{g}(0)| C},$$

and so $\lim_{n \to \infty} \int_{|\xi| \leq \alpha} \prod_{j=1}^{n} |b(2^{-j}\xi)|^2 \, d\xi = \int_{|\xi| \leq \alpha} \prod_{j=1}^{\infty} |b(2^{-j}\xi)|^2 \, d\xi > 0$. Thus there exists an n_0 such that for all $n \geq n_0$ (with some constant $C' > 0$),

$$\int_{|\xi| \leq \alpha} \prod_{j=1}^{n} |b(2^{-j}\xi)|^2 \, d\xi \geq \frac{1}{2} \int_{|\xi| \leq \alpha} \prod_{j=1}^{\infty} |b(2^{-j}\xi)|^2 \, d\xi \equiv 2C' \int_{|\xi| \leq \alpha} |\hat{G}(\xi)|^2 d\xi. \tag{5.4}$$

3. Assume $\hat{g}(2\pi l) \neq 0$ for some $l \neq 0$. Then we can choose n_1 such that for all $n \geq n_1$ and all $|\xi| \leq \alpha$, $|\hat{g}(2\pi l + 2^{-n}\xi)|^2 \geq \frac{1}{2} |\hat{g}(2\pi l)|^2$. Consequently,

$$\begin{aligned} \int_{|\xi| \leq \alpha} |\hat{G}_n(2^n 2\pi l + \xi)|^2 d\xi &= \int_{|\xi| \leq \alpha} \prod_{j=1}^{n} |b(2^{-j}\xi)|^2 \, |\hat{g}(2\pi l + 2^{-n}\xi)|^2 d\xi \\ &\geq \frac{1}{2} |\hat{g}(2\pi l)|^2 \int_{|\xi| \leq \alpha} \prod_{j=1}^{n} |b(2^{-j}\xi)|^2 \, d\xi \\ &\geq C' |\hat{g}(2\pi l)|^2 \int_{|\xi| \leq \alpha} |\hat{G}(\xi)|^2 d\xi \quad \text{(by (5.4))}. \end{aligned}$$

4. On the other hand, we have

$$\left(\int_{|\xi| \leq \alpha} |\hat{G}_n(2^n 2\pi l + \xi)|^2 d\xi \right)^{\frac{1}{2}} \leq \|\hat{G}_n - \hat{G}\| + \left(\int_{|\xi| \leq \alpha} |\hat{G}(2^n 2\pi l + \xi)|^2 d\xi \right)^{\frac{1}{2}}.$$

For any $\epsilon > 0$, since we assume $\hat{G}_n \to \hat{G}$ in L^2, we can choose n_3 such that the first term $< \frac{\epsilon}{2}$ for all $n \geq n_3$. Because by a change of variable,

$$\int_{|\xi| \leq \alpha} |\hat{G}(2^n 2\pi l + \xi)|^2 d\xi \leq \int_{|\xi| \geq 2^{n+1}\pi |l| - \alpha} |\hat{G}(\xi)|^2 \, d\xi,$$

we can also choose n_4 so that the second term is bounded by $\frac{\epsilon}{2}$ for all $n \geq n_4$.

5. For $n \geq \max\{n_i | i = 1, 2, 3, 4\}$, we then can combine the above inequalities to get

$$\epsilon^2 \geq C' |\hat{g}(2\pi l)|^2 \int_{|\xi| \leq \alpha} |\hat{G}(\xi)|^2 d\xi > 0.$$

Since ϵ can be made arbitrarily small, this contradicts our assumption that $\hat{g}(2\pi l) \neq 0$. Thus $\hat{g}(2\pi l) = 0$ for all $l \neq 0$. □

Note that the condition $\hat{G}(\xi) \neq 0$ plays a crucial role: if it is not satisfied, then Example 4.7, where $T^n f$ converges in $L^2(\mathbb{R})$ to 0 while $\hat{f}(2\pi l) \neq 0$ for $a \neq 0$, provides a counterexample. Together with Theorem 6.2 from [Her1], Theorem 5.4 can be used to formulate conditions on f that are necessary and sufficient for the L^1- or L^2-convergence of the $(T^n f)^\wedge$'s as well as of the $\hat{\Gamma}_n$'s. (The conditions in Theorems 4.11 and 4.12 are sufficient but not necessary.)

6. Examples illustrating regularity. In this section, we present examples showing that the smoothness of f and its limit function are not related. In the process, these examples also illustrate the results in §§4 and 5. To estimate the regularity of a refinable function f with filter $a(\xi)$, we use theorems in [Her1]–[Her3] that allow us to compute Sobolev exponents s_2 $(:= \sup\{s : \int |\hat{f}(\xi)|^2(1+|\xi|^{2s})d\xi < +\infty\})$ from $|a(\xi)|$. Typically, we need $a(\xi)$ to be factorizable like $|a(\xi)| = |\cos\frac{\xi}{2}|^r|v(\xi)|$.

Example 6.1. Take f to be continuous and supported in [-1,1] with $f(x)+f(x-1) =$ nonzero constant for $x \in [0,1]$. Then f satisfies the conditions in Lemma 4.2 even though f is not necessarily a scaling function. We compare the following two examples:

1. $f_1(x) = \cos^2\frac{\pi x}{2}$, $|x| \le 1$, and $f_1(x) = 0$ otherwise. Then

$$a(\xi) = \cos^2\frac{\xi}{2}\cdot\left[\frac{1-\left(1-\frac{8}{3\pi}\right)\sin^2\frac{\xi}{2}}{1-\frac{1}{2}\sin^2\frac{\xi}{2}}\right]. \tag{6.1}$$

Using the formulas in [Her1], we find $\beta \approx 3.351 < 16$ and $\beta_1 \approx 2.564 < 4$, so $T^n f_1 \overset{L^2}{\rightarrow} f_1^\infty$ and $T^n f_1(x)$ converges pointwise to $f_1^\infty(x)$ (see Theorems 4.5 and 4.6).

2. $f_2(x)|_{[0,1]} = t(1-x)$, $t(y) = y^4(35-84y+70y^2-20y^3)$. Then

$$a(\xi) = \frac{\frac{1549}{12672}+\frac{1}{2}\cos\xi+\frac{4787}{12672}\cos 2\xi}{\frac{1042}{1287}+\frac{245}{1287}\cos\xi} = \cos^2\frac{\xi}{2}\cdot\left(\frac{1-\frac{4787}{1584}\sin^2\frac{\xi}{2}}{1-\frac{245}{2574}\sin^2\frac{\xi}{2}}\right). \tag{6.2}$$

Similar analysis shows that $T^n f_2(x)$ converges pointwise to $f_2^\infty(x)$.

Note that while $f_2(\in C^{4-\epsilon})$ is more regular than $f_1(\in C^{2-\epsilon})$, explicit computation shows that the Sobolev exponents s_2 for the limit functions do not differ much: 1.128 for f_1^∞ and 1.508 for f_2^∞; this is because the regularity of the limit is determined in large part by the number of factors $|\cos\frac{\xi}{2}|$ in $|a(\xi)|$ rather than by the regularity of f itself. For graphs of the limit functions, see [Hu].

Example 6.2. To see a similar situation for the regularity of the limit of Γ_n, we consider $f(x) = e^{-\alpha^2x^2}$, which is C^∞, but the limit of Γ_n can be very irregular depending on the values of α. We have

$$a(\xi) = \left[\sum_{l\in\mathbb{Z}} e^{-\frac{5}{4\alpha^2}(\xi-2\pi l)^2}\right] \Big/ \left[\sum_{l\in\mathbb{Z}} e^{-\frac{1}{2\alpha^2}(\xi-2\pi l)^2}\right].$$

Two extremes are given by $\alpha^2 = \frac{1}{2}$ and $\alpha^2 = 32$. In the first case, $a(\pi) \approx 0.372\times10^{-6}$ so that $a(\xi)$ has "almost" a zero at $\xi = \pi$ and the subdivision scheme produces smooth functions Γ_n that are very similar to f itself, although the true Γ_∞ must be less smooth. For $\alpha^2 = 32$, we find $a(0) \approx 0.63455711$ and $a(\pi) \approx 0.63035395$. Since these are the two extreme values of $a(\xi)$, this shows that $a(\xi)$ is almost "flat." This case is very different from the case $\alpha^2 = \frac{1}{2}$: the limit of Γ_n now is very peaked. Details and graphs can be found in [Hu].

Example 6.3. We study the convergence of the scaled iterates Γ_n for nonsmooth f. We consider $f(x) = 1$ for $-\epsilon < x \le 1+\epsilon$ and $f(x) = 0$ otherwise, which is a dilated and shifted version of $\chi_{(0,1]}$. We shall restrict ourselves to $0 < \epsilon < \frac{2}{3}$. In this case,

$$a(\xi) = \frac{\frac{3\epsilon}{2}(e^{i\xi}+e^{-2i\xi})+(\epsilon+\frac{1}{2})(1+e^{-i\xi})}{4\epsilon\cos\xi+1+2\epsilon} \tag{6.3}$$

and $a(0) = \frac{5\epsilon+1}{6\epsilon+1} < 1$. We therefore have $(T^n f)^\wedge \to 0$. On the other hand, since it is obvious that $a(\xi) \in C^\infty$, the renormalized Γ_n's do have a nontrivial limit. Figure 1 shows the limit function Γ_∞ for a few different ϵ's. Note that the smoothness of Γ_∞ changes with ϵ: an easy computation using (6.3) shows that while $a(\pi) = 0$ and $a'(\pi) \neq 0$ in general, which means that for $0 < \epsilon < \frac{2}{3}$ and $\epsilon \neq \frac{1}{7}$, $|a(\xi)|$ can be divisible only by $|\cos\frac{\xi}{2}|$. The value of $\epsilon = \frac{1}{7}$ is an exception; in this case, $a(\pi) = a'(\pi) = a''(\pi) = 0$. This explains why the graph for Γ_∞ with $\epsilon = \frac{1}{7}$ is the smoothest! This is a typical example of a nonsmooth function leading to a much more regular limit under the scaled iteration.

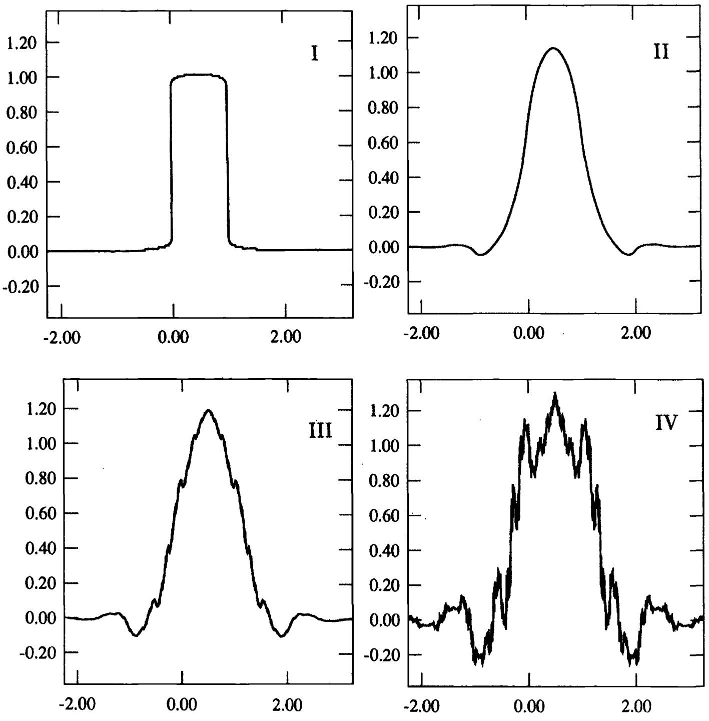

FIG. 1. *The limit function of* Γ_n *for* $f(x) = \chi_{(-\epsilon,1+\epsilon]}(x)$ *for different values of* ϵ: (I) $\epsilon = 0.01$, (II) $\epsilon = \frac{1}{7} \approx 0.14286$, (III) $\epsilon = 0.2$, *and* (IV) $\epsilon = 0.3$. *Their Sobolev exponents* s_2 *are* 1.014, 3.115, 1.138, *and* 1.163, *respectively.*

Acknowledgments. I am pleased to express my gratitude to my advisor, Professor Ingrid Daubechies, for suggesting this topic and being generous with her time and ideas. I also thank Dr. Loic Hervé for providing me with his preprints and for his comments on this paper. Finally, I thank the referees for their valuable suggestions which improved the quality of this paper.

INTERTWINING MULTIRESOLUTION ANALYSES AND THE CONSTRUCTION OF PIECEWISE-POLYNOMIAL WAVELETS*

GEORGE C. DONOVAN[†], JEFFREY S. GERONIMO[†], AND DOUGLAS P. HARDIN[‡]

Abstract. Let (V_p) be a local multiresolution analysis of $L^2(\mathbf{R})$ of multiplicity $r \geq 1$, i.e., V_0 is generated by r compactly supported scaling functions. If the scaling functions generate an orthogonal basis of V_0, then (V_p) is called an *orthogonal multiresolution analysis.* We prove that there exists an orthogonal local multiresolution analysis (V_p') of multiplicity r' such that

$$V_q \subset V_0' \subset V_{q+n}$$

for some integers $q \geq 0$, $n \geq 1$, and $r' > 1$.

In particular, this shows that compactly supported orthogonal polynomial spline wavelets and scaling functions (of multiplicity $r' > 1$) of arbitrary regularity exist, and we give several such examples.

Key words. multiwavelet, intertwining multiresolution analyses, orthogonal wavelet, splines

AMS subject classification. 41A15

1. Introduction.

The starting point for most wavelet constructions is a single function $\phi \in L^2(\mathbf{R})$, called a *scaling function*, whose integer translates form a Riesz basis for a closed linear subspace $V_0 \subset L^2(\mathbf{R})$. If the scaling function is compactly supported and generates an orthogonal basis of V_0, then the associated wavelet will also be compactly supported and generate an orthogonal basis. Daubechies (cf. [5]) constructed scaling functions and associated wavelets that were compactly supported, generated orthogonal bases, and were continuous (or smoother). However, these wavelets do not have closed-form representations; they are defined via a limiting process. Also, it is known that these wavelets cannot have certain other desirable properties (e.g., symmetry). By giving up compact support (cf. [1]) or orthogonality (cf. [4]), symmetric wavelet bases have been constructed using piecewise-polynomial splines. For some applications, the symmetry and simple representation are more important than having both compact support and orthogonality.

Recently, wavelet constructions generated by a finite collection of scaling functions $\Phi = \{\phi^1, \ldots, \phi^r\}$ have been studied (cf. [10], [11], [8], [12], [13], [18], [22]). In [8] and [7], symmetric, compactly supported, continuous, and orthogonal scaling functions (and associated wavelets) were constructed using $r = 2$ scaling functions. As in the case of Daubechies wavelets, these functions do not have closed-form representations. In this paper, using $r > 2$ scaling functions, we construct wavelets that not only have the three properties of compact support, arbitrary regularity, and orthogonality but are also symmetric and piecewise polynomial. In fact, we show that for any multiresolution analysis generated by compactly supported scaling functions, there is an associated intertwining orthogonal multiresolution analysis also generated by compactly supported scaling functions.

More precisely, a *multiresolution analysis of multiplicity* r is a nested sequence of closed linear subspaces (V_p) in $L^2(\mathbf{R})$ satisfying the following:

1. $f \in V_p$ iff $f(2^{-p}\cdot) \in V_0$ for $p \in \mathbf{Z}$.

*Received by the editors October 26, 1994; accepted for publication (in revised form) August 3, 1995. The research of the first author was partially supported by an NSF graduate fellowship. The research of the second and third authors was partially supported by NSF grants.

2. $V_0 \subset V_1$.
3. $\bigcap_{p\in\mathbf{Z}} V_p = \{0\}$.
4. $\bigcup_{p\in\mathbf{Z}} V_p$ is dense in $L^2(\mathbf{R})$.
5. There are r functions $\phi^1, \ldots, \phi^r$ such that the collection of integer translates $\{\phi^s(\cdot - n) \mid s = 1, \ldots, r \text{ and } n \in \mathbf{Z}\}$ is a Riesz basis of V_0.

The functions $\phi^1, \ldots, \phi^r$ are called scaling functions and are said to *generate* the multiresolution analysis (V_p). If there is a set of compactly supported scaling functions whose integer translates form an orthogonal basis of V_0, then we call (V_p) an *orthogonal* multiresolution analysis. The main theorem of this paper is as follows.

THEOREM 1. *If (V_p) is a multiresolution analysis generated by compactly supported scaling functions, then there is some pair of integers (q, n) and some orthogonal multiresolution analysis $(\tilde{V}_p)$ such that*

$$V_q \subset \tilde{V}_0 \subset V_{q+n}.$$

We say that (V_p) and $(\tilde{V}_p)$ are *intertwining multiresolution analyses.*

For the sake of completeness, we note that if the scaling functions are compactly supported, then the intersection property 3 follows from 1 and the fact that V_0 is finitely generated shift-invariant (FSI) space (see §2) [15, Thm. 2.2]. Furthermore, the density property 4 follows from conditions 1 and 2 (see [3] for the single-scaling-function case, which directly generalizes to the multiple-scaling-function case). The Riesz-basis condition 5 may be relaxed: if V_0 is an FSI space with compactly supported generators, then there exists a set of compactly supported generators whose collection of integer translates form a Riesz basis (cf. [2, Thm. 3.38] and [20, Thm. 3.7]). In practice, we will take V_0 to be a classical spline space, in which case it will be elementary to verify conditions 1–5 directly.

If (V_p) is an orthogonal multiresolution analysis, then there is a general procedure (cf. [7], [22], [16], [23]) for calculating compactly supported wavelets $\psi^1, \ldots, \psi^r$ that generate an orthogonal basis of $W_0 = V_1 \ominus V_0$. As in the single-scaling-function case, the work is in finding orthogonal scaling functions.

The structure of this paper is as follows. In §2, we show that, without loss of generality, we can assume that the scaling functions are supported in $[-1, 1]$. The spaces V_p for $p \geq 0$ are examples of FSI spaces, and we develop a necessary and sufficient condition for an FSI space with generators supported in $[-1, 1]$ to be orthogonal. In §3, we give a construction that, under certain conditions, gives an orthogonal intertwining multiresolution analysis. We also provide an example based on continuous piecewise-linear splines.

In §4, we first prove that if certain orthogonal projections are uniformly bounded below, then the construction of §3 works and Theorem 1 holds with $n = 1$. We then use this special case to prove Theorem 1. In §5, we apply the general theory to the piecewise-polynomial spline spaces $\mathcal{S}_{d,r}$ and give an example of orthogonal C^1 cubic spline scaling functions and wavelets.

2. Orthogonal FSI spaces.

If Φ is a subset of $L^2(\mathbf{R})$, let $\tau(\Phi) = \{\phi(\cdot - n) \mid n \in \mathbf{Z}, \phi \in \Phi\}$ denote the set of integer translates of elements in Φ and let $\sigma(\Phi)$ denote the L^2-closure of the linear span of $\tau(\Phi)$. Following [2], we call a space $V \subset L^2(\mathbf{R})$ an FSI space if $V = \sigma(\Phi)$ for some finite set Φ.

Suppose that (V_p) is a multiresolution analysis generated by r scaling functions. Then V_p for $p \geq 0$ is an FSI space with $2^p r$ generators. In particular, if the scaling functions $\{\phi^1, \ldots, \phi^r\}$ are all supported in $[-L, 1]$, then V_1 is generated by the set of

$2r$ scaling functions $\{\phi^s(2\cdot -n), \mid s=1,\ldots,r;\ n=0,1\}$ all supported in $[-L/2,1]$. Hence there is some q such that the multiresolution analysis (V_p') defined by $V_p' = V_{p+q}$ is generated by $2^q r$ scaling functions all supported in $[-1,1]$.

Thus we will be concerned with FSI spaces whose generators $\Phi = \{\phi^1,\ldots,\phi^r\}$ are supported in $[-1,1]$.

Remark 2.1. Certain linear dependencies can be removed as follows: if the restrictions $\phi^s|_{[-1,0]}$ and $\phi^{s'}|_{[-1,0]}$ are linearly dependent on $[-1,0]$, then by taking linear combinations, we can replace one of the generators with a function supported on $[0,1]$. By making such replacements, we can assume that there are k generators $\phi^1,\ldots,\phi^k$ supported in $[-1,1]$ such that

1. they are linearly independent on $[-1,0]$,
2. they are linearly independent on $[0,1]$,
3. the rest of the generators $\phi^{k+1},\ldots,\phi^r$ are supported in $[0,1]$.

Let $H_h(\Phi) = \operatorname{span}\{\phi^s(\cdot-h)\chi_{[0,1]} \mid s=1,\ldots,k\}$ for $h=0,1$. If, in addition to satisfying conditions 1–3 above, we have $H_0(\Phi)\cap H_1(\Phi)=\{0\}$, then

$$\phi^1,\ldots,\phi^k,\phi^1(\cdot-1),\ldots,\phi^k(\cdot-1),\phi^{k+1},\ldots,\phi^r$$

are linearly independent on $[0,1]$, and we say that $\phi^1,\ldots,\phi^r$ are *minimally supported on* $[-1,1]$.

Remark 2.2. In the following, $k=k(\Phi)$ will always represent the number of scaling functions supported on $[-1,1]$ but not supported on $[-1,0]$ or $[0,1]$.

The following lemma, whose proof is delayed until §4, states that any multiresolution analysis generated by compactly supported scaling functions can be converted (as in Remark 2.2) so that it is generated by scaling functions that are minimally supported on $[-1,1]$.

LEMMA 2.1. *Suppose that (V_p) is a multiresolution analysis generated by compactly supported scaling functions. Then there are some n and some set of scaling functions minimally supported on $[-1,1]$ that generate the multiresolution analysis (V_p') given by*

$$V_p' = V_{p+n}.$$

Let V be an FSI space generated by a collection Φ of r scaling functions minimally supported on $[-1,1]$. We say that V is *orthogonal with respect to* $[-1,1]$ if there is some Φ' supported on $[-1,1]$ such that $\tau(\Phi')$ is an orthogonal basis for V' (which is some dilate of V). We will give a necessary and sufficient condition that V be orthogonal with respect to $[-1,1]$. Towards this end, let $\mathcal{A}(V),\mathcal{B}_0(V),\mathcal{B}_1(V)\subset L^2(\mathbf{R})$ be the subspaces defined by

$$\mathcal{A}(V) = \operatorname{span}\{\phi^s \mid s=k+1,\ldots,r\}$$

and

$$\mathcal{B}_h(V) = \operatorname{span}\left(\{\phi^s(\cdot-h)\chi_{[0,1]} \mid s=1,\ldots,k\}\cup\mathcal{A}(V)\right) \text{ for } h=0,1,$$

where $\chi_{[0,1]}$ denotes the characteristic function of $[0,1]$. Finally, define $\mathcal{C}_h(V)$ by $\mathcal{C}_h(V) = \mathcal{B}_h(V)\ominus\mathcal{A}(V)$, the orthogonal complement of $\mathcal{A}(V)$ in $\mathcal{B}_h(V)$.

Remark 2.3.

1. It follows from Remark 2.1 that the spaces $\mathcal{A}(V)$, $\mathcal{B}_0(V)$, and $\mathcal{B}_1(V)$ are independent of the choice of minimally supported generators. For instance, we have

$$\mathcal{A}(V) = \{f \in V \mid \operatorname{supp} f \subset [0,1]\},$$

$$\mathcal{B}_0(V) = \{f\chi_{[0,1]} \mid f\chi_{(-\infty,1]} \in V\}$$

and similarly for $\mathcal{B}_1(V)$.

2. $\mathcal{C}_0(V)$ and $\mathcal{C}_1(V)$ are k dimensional.

LEMMA 2.2. *Suppose that V is an FSI space generated by r functions $\phi^1, \ldots, \phi^r$ minimally supported on $[-1,1]$. Then V is orthogonal with respect to $[-1,1]$ iff $\mathcal{C}_0(V) \perp \mathcal{C}_1(V)$.*

Proof. If V is orthogonal, then it is easy to see directly that $\mathcal{C}_0(V) \perp \mathcal{C}_1(V)$.

Suppose $\mathcal{C}_0(V) \perp \mathcal{C}_1(V)$. By using the Gram–Schmidt procedure, if necessary, we can assume that

- $\phi^s(\cdot - h)$ is orthogonal to $\mathcal{A}(V)$ for $s = 1, \ldots, k$, and $h = 0, 1$;
- $\phi^s \perp \phi^{s'}$ for $s \neq s'$ and $s, s' = 1, \ldots, r$.

Since $\mathcal{C}_0(V) \perp \mathcal{C}_1(V)$, it follows that $\phi^s \perp \phi^{s'}(\cdot - 1)$ for $s, s' = 1, \ldots, k$, and hence $\{\phi^s(\cdot - n) \mid n \in \mathbf{Z}, s = 1, \ldots, r\}$ is an orthogonal basis for V. □

3. Constructing orthogonal multiresolution analyses. The following lemma provides the basic idea we will use to construct orthogonal multiresolution analyses.

LEMMA 3.1. *Let (V_p) be a multiresolution analysis generated by r functions $\phi^1, \ldots, \phi^r$ minimally supported on $[-1,1]$. Suppose there is a subspace $\mathcal{W}$ of $\mathcal{A}(V_1) \ominus \mathcal{A}(V_0)$ such that*

$$(I - P_{\mathcal{W}})\mathcal{C}_0(V_0) \perp (I - P_{\mathcal{W}})\mathcal{C}_1(V_0), \tag{1}$$

where $P_{\mathcal{W}}$ is the orthogonal projection onto $\mathcal{W}$. Let $w_1, \ldots, w_\kappa$ be a basis for $\mathcal{W}$ and let $(\tilde{V}_p)$ be the multiresolution analysis generated by $\phi^1, \ldots, \phi^r, w_1, \ldots, w_\kappa$. Then $(\tilde{V}_p)$ is an orthogonal multiresolution analysis and

$$V_0 \subset \tilde{V}_0 \subset V_1.$$

Proof. Since $\mathcal{W} \subset V_1$, we clearly have $V_0 \subset \tilde{V}_0 \subset V_1$. This implies $V_p \subset \tilde{V}_p \subset V_{p+1}$ for all integers p. It then follows that $(\tilde{V}_p)$ satisfies the first four conditions of a multiresolution analysis.

Observe that $\mathcal{C}_h(\tilde{V}_0) = (I - P_{\mathcal{W}})\mathcal{C}_h(V_0)$ for $h = 0, 1$, and so the result follows from Lemma 2.2. □

Remark 3.1. Let P_h denote the orthogonal projection onto $\mathcal{C}_h(V_0)$ for $h = 0, 1$. Condition (1) can be rewritten as

$$P_0 P_1 = P_0 P_{\mathcal{W}} P_1. \tag{2}$$

Therefore, the rank of $P_{\mathcal{W}}$ must be at least the rank of $P_0 P_1$, which is less than or equal to k. This gives a lower bound on κ, the dimension of $\mathcal{W}$ (which equals the rank of $P_{\mathcal{W}}$). In all of our examples, $P_0 P_1$ has rank k and, it turns out, we can choose κ to be the lower bound k.

We will use the following notation in the rest of this paper:

$$\phi_{l,k}(x) = 2^{l/2}\phi(2^l x - k) \quad \text{for any } \phi \in L^2(\mathbf{R}). \tag{3}$$

3.1. Example: Piecewise-linear orthogonal scaling functions. Let $H : \mathbf{R} \to \mathbf{R}$ be the "hat" function defined by

$$H(x) = \begin{cases} 1 - |x| & \text{if } |x| \leq 1, \\ 0 & \text{otherwise.} \end{cases}$$

Let $\phi^1(x) = \sqrt{3}H(2x)$ and $\phi^2(x) = \sqrt{3}H(2x-1)$ (note that ϕ^1 and ϕ^2 have norm 1) and let (V_p) be the multiresolution analysis generated by $\Phi = \{\phi^1, \phi^2\}$. In this case, V_{-1} is the space of continuous piecewise-linear splines with integer knots. Note that Φ is minimally supported on $[-1,1]$ with $k = k(\Phi) = 1$. Also, $\mathcal{A}(V_0)$, $\mathcal{B}_0(V_0)$, and $\mathcal{B}_1(V_0)$ are spanned by $\{\phi^2_{0,0}\}$, $\{\phi^1_{0,0}\chi_{[0,1]}, \phi^2_{0,0}\}$, and $\{\phi^1_{0,1}\chi_{[0,1]}, \phi^2_{0,0}\}$, respectively. Using

$$c = \langle \phi^1_{0,0}, \phi^2_{0,0} \rangle = 1/4$$

gives the bases $\{\phi^1_{0,0}\chi_{[0,1]} - c\phi^2_{0,0}\}$ and $\{\phi^1_{0,1}\chi_{[0,1]} - c\phi^2_{0,0}\}$ for $\mathcal{C}_0(V_0)$ and $\mathcal{C}_1(V_0)$, respectively.

Note that $\{\phi^1_{1,1}, \phi^2_{1,0}, \phi^2_{1,1}\}$ is a basis for $\mathcal{A}(V_1)$. Direct calculation yields the basis $\{3\phi^1_{1,1} - 5\phi^2_{1,0}, 3\phi^1_{1,1} - 5\phi^2_{1,1}\}$ for $\mathcal{A}(V_1) \ominus \mathcal{A}(V_0)$. Let w be an arbitrary vector in $\mathcal{A}(V_1) \ominus \mathcal{A}(V_0)$:

$$w = a(3\phi^1_{1,1} - 5\phi^2_{1,0}) + b(3\phi^1_{1,1} - 5\phi^2_{1,1}),$$

where we will choose w so that equation (1) is satisfied when $\mathcal{W}$ is the one-dimensional subspace spanned by w. Then

$$\|w\|^2 = (53a^2 + 6ab + 53b^2)/2$$

and equation (1) holds iff

$$\begin{aligned} (4) \qquad & \langle \phi^1_{0,0}\chi_{[0,1]} - c\phi^2_{0,0}, \phi^1_{0,1}\chi_{[0,1]} - c\phi^2_{0,0} \rangle \\ & = \langle \phi^1_{0,0}\chi_{[0,1]} - c\phi^2_{0,0}, w \rangle \langle w, \phi^1_{0,1}\chi_{[0,1]} - c\phi^2_{0,0} \rangle / \|w\|^2. \end{aligned}$$

The left-hand side is easily evaluated to get

$$\langle \phi^1_{0,0}\chi_{[0,1]} - c\phi^2_{0,0}, \phi^1_{0,1}\chi_{[0,1]} - c\phi^2_{0,0} \rangle = -c^2 = -1/16.$$

Using $H(x) = 1/2H(2x+1) + H(2x) + 1/2H(2x-1)$, we find

$$\phi^1_{0,0} = (1/2\sqrt{2})\phi^2_{1,-1} + (1/\sqrt{2})\phi^1_{1,0} + (1/2\sqrt{2})\phi^2_{1,0},$$

$$\phi^2_{0,0} = (1/2\sqrt{2})\phi^2_{1,0} + (1/\sqrt{2})\phi^1_{1,1} + (1/2\sqrt{2})\phi^2_{1,1},$$

which can be used to calculate

$$\langle \phi^1_{0,0}\chi_{[0,1]} - c\phi^2_{0,0}, w \rangle = (3/8\sqrt{2})(b - 9a)$$

and

$$\langle w, \phi^1_{0,1}\chi_{[0,1]} - c\phi^2_{0,0} \rangle = (3/8\sqrt{2})(a - 9b).$$

Thus equation (4) becomes

$$-4(53a^2 + 6ab + 53b^2) = 9(a - 9b)(-9a + b),$$

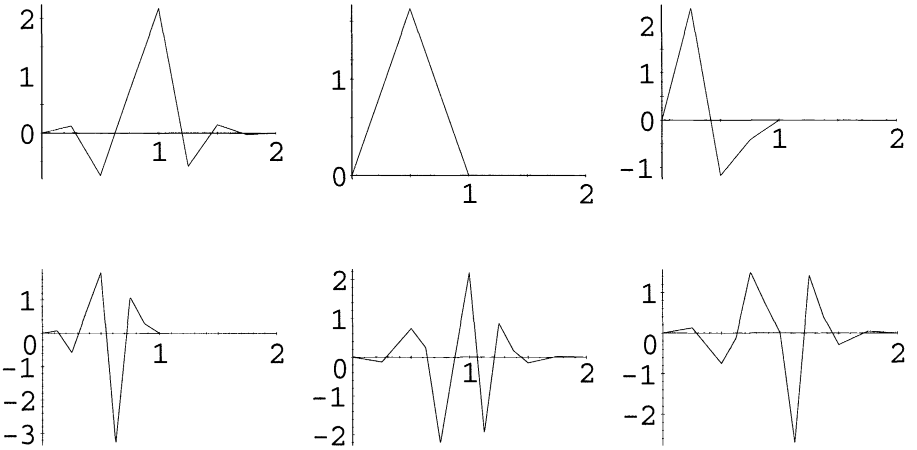

FIG. 1. *Piecewise-linear orthogonal scaling functions (top, right to left: $\tilde\phi^1(\cdot - 1)$, $\tilde\phi^2$, and $\tilde\phi^3$) and wavelets (bottom, right to left: $\tilde\psi^1$, $\tilde\psi^2$, and $\tilde\psi^3(\cdot - 1)$).*

which has the following solutions:

$$b/a = (-762 \pm 320\sqrt{5})/262.$$

We choose $b/a = (-762 + 320\sqrt{5})/262$. Set $\tilde\phi^2 = \phi^2$, $\tilde\phi^3 = w/\|w\|$,

$$y = \phi^1 - \langle \phi^1, \tilde\phi^2\rangle\tilde\phi^2 - \langle \phi^1, \tilde\phi^3\rangle\tilde\phi^3 - \langle \phi^1, \tilde\phi^2(\cdot + 1)\rangle\tilde\phi^2(\cdot + 1) - \langle \phi^1, \tilde\phi^3(\cdot + 1)\rangle\tilde\phi^3(\cdot + 1),$$

and $\tilde\phi^1 = y/\|y\|$; then from the above calculation, we see that $\tilde\Phi = (\tilde\phi^1, \tilde\phi^2, \tilde\phi^3)$ generates the multiresolution analysis $(\tilde V_p)$ with $V_0 \subset \tilde V_0 \subset V_1$. These orthonormal scaling functions and associated wavelets are shown in Figure 1. The wavelets have been constructed so that the techniques used in Theorem 4.4 of [7] lead to a wavelet basis for $L_2[0, 1]$. The interpolation points for these functions are given in Table 1 in Appendix A and the dilation coefficients are given in Table 4 in Appendix B.

3.2. Example: Symmetric piecewise-linear orthogonal scaling functions. We now choose $\tilde V_0$ between V_1 and V_2. Then $\mathcal{A}(V_2) \ominus \mathcal{A}(V_1)$ is $7 - 3 = 4$ dimensional. By applying the intertwining technique twice, we can choose symmetric w_1 and antisymmetric w_2 to obtain scaling functions and wavelets that are either symmetric or antisymmetric, as shown in Figure 2. In this case, $\tilde\Phi = (\tilde\phi^1, \tilde\phi^2, \tilde\phi^3, \tilde\phi^4)$, where $\tilde\phi^2 = \phi^2$, $\tilde\phi_3 = w_1/\|w_1\|$, $\tilde\phi_4 = w_2/\|w_2\|$, and $\tilde\phi^1 = y/\|y\|$. Here

$$y = \phi^1 - \sum_{i=2}^{4} \langle \phi^1, \tilde\phi^i\rangle\tilde\phi^i - \sum_{i=2}^{4} \langle \phi^1, \tilde\phi^i(\cdot + 1)\rangle\tilde\phi^i(\cdot + 1).$$

Because of the symmetry, it is not difficult to generate a wavelet basis for $L_2[0, 1]$ from the wavelets given below [7, Thm. 4.4].

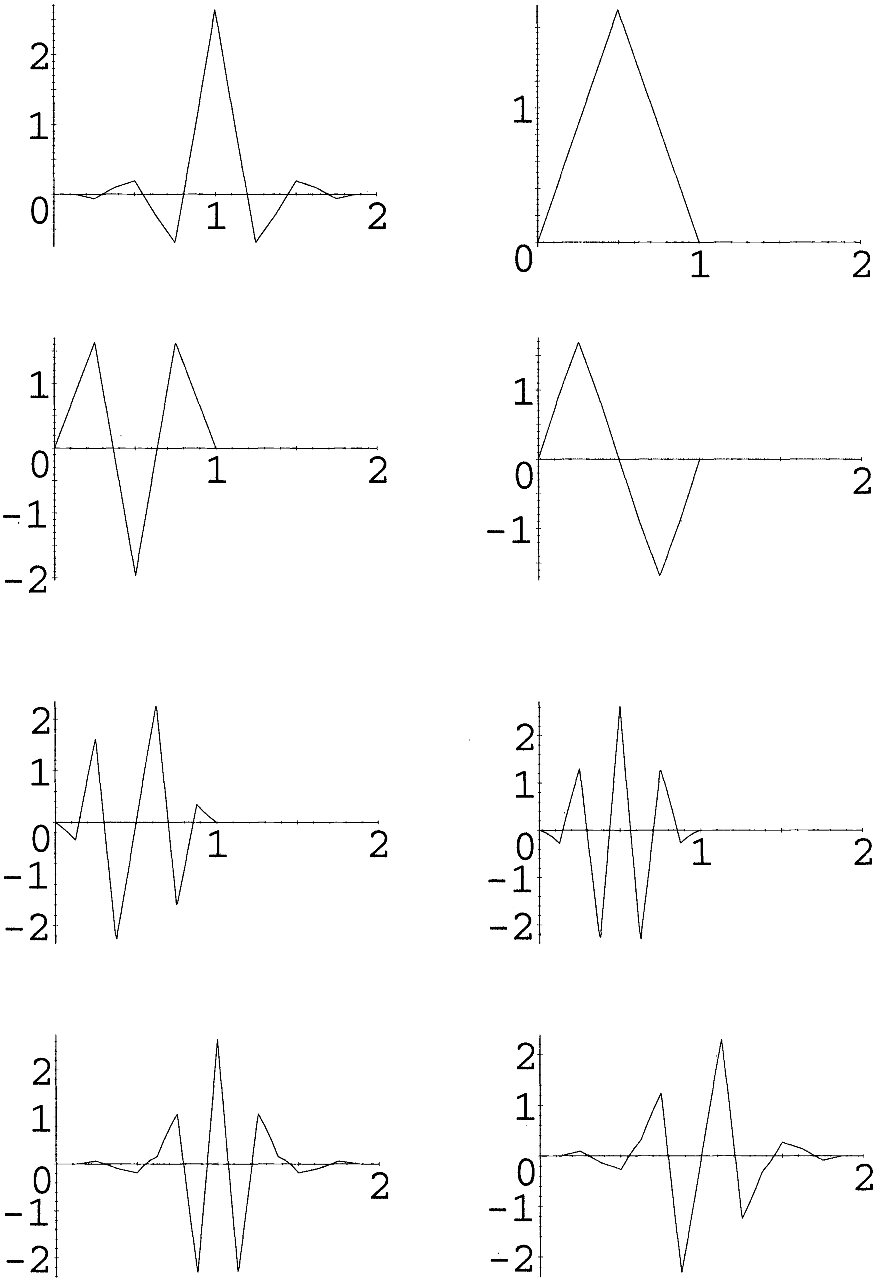

FIG. 2. *Symmetric* (*or antisymmetric*) *piecewise-linear orthogonal scaling functions and wavelets; from top to bottom and left to right:* $\tilde{\phi}^1(\cdot - 1)$, $\tilde{\phi}^2$, $\tilde{\phi}^3$, $\tilde{\phi}^4$, $\tilde{\psi}^1$, $\tilde{\psi}^2$, $\tilde{\psi}^3(\cdot - 1)$, *and* $\tilde{\psi}^4(\cdot - 1)$.

4. Main theorem. We first prove that, with an additional hypothesis, Theorem 1 holds with $n = 1$.

THEOREM 2. *Let (V_p) be a multiresolution analysis generated by r functions $\phi^1, \dots, \phi^r$ minimally supported on $[-1, 1]$. Let Q^l denote the orthogonal projection onto $\mathcal{A}(V_{l+1}) \ominus \mathcal{A}(V_l)$. Suppose there are positive numbers ϵ and l_0 such that $\|Q^l u\| \geq \epsilon\|u\|$ for all $l \geq l_0$ and u in $\mathcal{C}_0(V_l) \cup \mathcal{C}_1(V_l)$. Then there is some integer q and some orthogonal multiresolution analysis $(\tilde{V}_p)$ such that*

$$V_q \subset \tilde{V}_0 \subset V_{q+1}.$$

Proof. As noted in the proof of Lemma 2.2 we can assume that

- $\phi^s(\cdot - h)\chi_{[0,1]}$ is orthogonal to $\mathcal{A}(V_0)$ for $s = 1, \dots, k$ and $h = 0, 1$, and
- $\phi^s \perp \phi^{s'}$ for $s \neq s'$ and $s, s' = 1, \dots, r$.

For $1 \leq s \leq r$ and $l, n \in \mathbf{Z}$, let $\phi^s_{l,n}(x) = 2^{l/2}\phi^s(2^l x - n)$. Then

$$\Lambda = \{\phi^s_{l,n} \mid 1 \leq s \leq k, 1 \leq n \leq 2^l - 1\} \cup \{\phi^s_{l,n} \mid k+1 \leq s \leq r, 0 \leq n \leq 2^l - 1\}$$

is a basis for $\mathcal{A}(V_l)$,

$$\{\phi^s_{l,0}\chi_{[0,1]} \mid 1 \leq s \leq k\} \cup \Lambda$$

is a basis for $\mathcal{B}_0(V_l)$, and

$$\{\phi^s_{l,2^l}\chi_{[0,1]} \mid 1 \leq s \leq k\} \cup \Lambda$$

is a basis for $\mathcal{B}_1(V_l)$. Observe that $\mathcal{A}(V_l)$, $\mathcal{B}_h(V_l)$, and $\mathcal{C}_h(V_l)$ have linear dimensions $2^l r - k$, $2^l r$, and k, respectively.

With $\Phi_{l,n} = (\phi^1_{l,n}, \dots, \phi^k_{l,n})^\top$, we define the overlap matrix, $C = \langle \Phi_{0,0}, \Phi_{0,1}\rangle := (\langle \phi^s_{0,0}, \phi^{s'}_{0,1}\rangle)_{1 \leq s, s' \leq k}$. Let $l_2(\mathbf{R}^k)$ be the Hilbert space of sequences $y = \{y_n\}^{\infty}_{-\infty}$, $y_n \in \mathbf{R}^k$ with $\|y\|_{l_2} = (\sum(y_n, y_n))^{1/2} < \infty$ where (y_n, y_n) is the Euclidean inner product. For $y, x \in l_2(\mathbf{R}^k)$ set $\langle x, y\rangle_{l_2} = \sum(x_n, y_n)$. We first prove the following three lemmas before proceeding with the remainder of the proof of Theorem 2.

LEMMA 4.1. *Let $x = \{x_n\}^{\infty}_{-\infty} \in l_2(\mathbf{R}^k)$ and consider the infinite block-tridiagonal matrix $\mathcal{J} : l_2(\mathbf{R}^k) \to l_2(\mathbf{R}^k)$ given by $\mathcal{J}x = y$, $y = \{y_n\}^{\infty}_{-\infty}$, with $y_i = C^\top x_{i-1} + x_i + Cx_{i+1}$ for all $i \in \mathbf{Z}$. Then $\mathcal{J}$ is a bounded positive operator with* spectrum$\mathcal{J} \subset [a, b]$, *$0 < a$. Consequently, $\mathcal{J}_l = \Pi_l \mathcal{J} \Pi_l$, where $\Pi_l : l_2(\mathbf{R}^k) \to l_2(\mathbf{R}^k)$ is the projection such that $\Pi_l x = \{x_n\}^{2^l-1}_1$ is positive definite with* spectrum$\mathcal{J}_l \subset [a, b]$ *and $|(\mathcal{J}_l)^{-1}_{i,j}| \leq K\lambda^{|i-j|}$. Here K is independent of l, i, and j, and $\lambda = (\sqrt{b/a} - 1)/(\sqrt{b/a} + 1)$.*

Proof. Since $\langle \phi^i, \phi^j\rangle = 0$, $i = 1, \dots, k$, $j = k+1, \dots, r$, and $\langle \phi^i, \phi^j\rangle = 0$, $i = k+1, \dots, r$, $j = k+1, \dots, r$, $i \neq j$, it follows from Theorem 3.2 in [8] (also see [10]) that $\{\phi^i\}^r_{i=1}$ forms a Riesz basis for V_0 iff $(I + C^\top e^{i\theta} + Ce^{-i\theta}) \geq a > 0$, $0 \leq \theta < 2\pi$. Now the symbol of y, $\hat{y} = \widehat{(\mathcal{J}x)} = (I + C^\top e^{i\theta} + Ce^{-i\theta})\hat{x}$, and we find $\langle x, \mathcal{J}x\rangle_{l_2} = (1)/(2\pi)\int_0^{2\pi} \hat{x}^*(I + C^\top e^{i\theta} + Ce^{-i\theta})\hat{x}d\theta \geq a\int_0^{2\pi} \hat{x}^*\hat{x}d\theta = a\|x\|^2_{l_2}$. The upper bound follows in an analogous manner. The min–max principle [19] now implies that spectrum $\mathcal{J}_l \subset [a, b]$ and the decay given in the lemma follows from the exponential decay of elements of inverses of banded matrices (cf. [6], [9]). □

Since Q^l is orthogonal, we can choose $\{u^l_{h,i} \mid 1 \leq i \leq k\}$ to be an orthonormal basis for $\mathcal{C}_h(V_l)$, $h = 0, 1$, such that $\{Q^l u^l_{h,i} \mid 1 \leq i \leq k\}$ is an orthogonal basis for $Q^l\mathcal{C}_h(V_l)$

for $h = 0, 1$. We also define the normalized basis elements $x^l_{h,i} = Q^l u^l_{h,i}/\|Q^l u^l_{h,i}\|$ for $1 \le i \le k$ and $h = 0, 1$.

LEMMA 4.2. *Suppose there is some $\epsilon > 0$ such that $\|Q^l u\| \ge \epsilon\|u\|$ for all l sufficiently large and for u in either $\mathcal{C}_0(V_l)$ or $\mathcal{C}_1(V_l)$. Let $x^l_{h,i}$ and $u^l_{h,i}$ be as above. Then for $1 \le i, j \le k$,*

$$\lim_{l\to\infty} \langle x^l_{0,i}, x^l_{1,j}\rangle = 0 \tag{5}$$

and

$$\lim_{l\to\infty} \frac{\langle u^l_{0,i}, u^l_{1,j}\rangle}{\|Q^l u^l_{0,i}\|\|Q^l u^l_{1,j}\|} = 0. \tag{6}$$

Proof. Observe that

$$\langle \Phi_{l,n}, \Phi_{l,m}\rangle = \begin{cases} C & \text{if } m-n=1, \\ I & \text{if } m=n, \\ C^{\mathrm{T}} & \text{if } m-n=-1. \end{cases}$$

Let $f \in \mathcal{C}_0(V_l)$. Using the bases given above for $\mathcal{A}(V_l)$ and $\mathcal{C}_0(V_l)$, f may be expressed in the form

$$f = \gamma_0^{\mathrm{T}} \Phi_{l,0}\chi_{[0,1]} + \sum_{n=1}^{2^l-1} \gamma_n^{\mathrm{T}} \Phi_{l,n}, \tag{7}$$

where each γ_n is in $\mathbf{R}^k$. Since f is perpendicular to $\mathcal{A}(V_l)$, it follows that $\gamma = (\gamma_1^{\mathrm{T}}, \dots, \gamma_{2^l-1}^{\mathrm{T}})^{\mathrm{T}}$ satisfies the block-tridiagonal system of equations

$$\begin{gathered} \gamma_1 + C\gamma_2 = -C^{\mathrm{T}}\gamma_0, \\ C^{\mathrm{T}}\gamma_{n-1} + \gamma_n + C\gamma_{n+1} = 0, \quad n = 2, 3, \dots, 2^l-2, \\ C^{\mathrm{T}}\gamma_{2^l-2} + \gamma_{2^l-1} = 0. \end{gathered} \tag{8}$$

If we define $\mathcal{J}_l$ to be the matrix representation of the left-hand side of equation (8), we find that $\gamma = \mathcal{J}_l^{-1}(-\gamma_0^{\mathrm{T}} C, 0, \dots, 0)^{\mathrm{T}}$. Thus f is determined by γ_0 (and l) and we denote the dependence of f on γ_0 and l by $f_{\gamma_0,l}$. Let $\lambda = (\sqrt{b/a}-1)/(\sqrt{b/a}+1)$. It follows from Lemma 4.1 that there are positive numbers K and l_0 such that $\|\gamma_n\| \le K\lambda^n$ for $n \ge 0$, $l \ge l_0$, and $\|f_{\gamma_0,l}\| = 1$. Hence

$$\lim_{l\to\infty} \max\{\|f\chi_{[1/2,1]}\| \mid f \in \mathcal{C}_0(V_l), \|f\| = 1\} = 0. \tag{9}$$

Similarly,

$$\lim_{l\to\infty} \max\{\|g\chi_{[0,1/2]}\| \mid g \in \mathcal{C}_1(V_l), \|g\| = 1\} = 0. \tag{10}$$

Equations (9) and (10) then give

$$\lim_{l\to\infty} |\langle u^l_{0,i}, u^l_{1,j}\rangle| \le \lim_{l\to\infty} \|u^l_{0,i}\chi_{[1/2,1]}\|\|u^l_{1,j}\| + \|u^l_{0,i}\|\|u^l_{1,j}\chi_{[0,1/2]}\| = 0.$$

Since Q^l is uniformly bounded below on $\mathcal{C}_h(V_l)$ for $h = 0, 1$ and l large enough, this proves the limit (6).

If $f \in \mathcal{C}_0(V_l)$, then $Q^l f = f-(I-P_{l+1})f$, where P_{l+1} is the orthogonal projection onto $\mathcal{A}(V_{l+1})$, and so $(I-P_{l+1})f$ is in $\mathcal{C}_0(V_{l+1})$. Therefore, both f and $(I-P_{l+1})f$ decay exponentially away from 0. Thus, as above, the limit in (5) follows from equations (9) and (10) and the uniform lower bound on Q^l. □

Let $\mathcal{D}_l$ denote $\operatorname{span}(Q^l\mathcal{C}_0(V_l) \cup Q^l\mathcal{C}_1(V_l))$.

LEMMA 4.3. *There is some q such that for $l \geq q$ there exists a set $\Psi = \{z^{\pm}_{i,j} \mid 1 \leq i,j \leq k\}$ of $2k^2$ functions in $\mathcal{E}_l := (\mathcal{A}(V_{l+1}) \ominus \mathcal{A}(V_l)) \ominus \mathcal{D}_l$ such that if*

$$w^{\pm}_{i,j} = z^{\pm}_{i,j} + (x^l_{0,i} \pm x^l_{1,j})/(4k),$$

then $\{w^{\pm}_{i,j} \mid 1 \leq i,j \leq k\}$ is an orthonormal set.

Proof. Note that $\dim(\mathcal{A}(V_{l+1}) \ominus \mathcal{A}(V_l)) = r2^l$. Let $\{e_i \mid 1 \leq i \leq r2^l\}$ be an orthonormal basis of $\mathcal{A}(V_{l+1}) \ominus \mathcal{A}(V_l)$. Represent $w^{\pm}_{i,j}, z^{\pm}_{i,j}, (x^l_{0,i} \pm x^l_{1,i})/(4k)$ in terms of this basis as column vectors of size $r2^l$. Let W^+_l be the $r2^l \times k^2$ matrix whose $(i-1)k+j$ column is $w^+_{i,j}$. Similarly, define W^-_l and $Z^{\pm}_l$. Let $X^{\pm}_l$ be the $r2^l \times k^2$ matrix whose $(i-1)k+j$ column is $(x^l_{0,i} \pm x^l_{1,j})/(4k)$. In block form, we have

$$W_l := \begin{pmatrix} W^+_l & W^-_l \end{pmatrix} = \begin{pmatrix} X^+_l + Z^+_l & X^-_l + Z^-_l \end{pmatrix} =: X_l + Z_l. \tag{11}$$

Note that $\{w^{\pm}_{i,j} \mid 1 \leq i,j \leq k\}$ is an orthonormal set iff $W_l^{\top} W_l = I$, where I is the $2k^2 \times 2k^2$ identity. Since $z^{\pm}_{i,j} \in \mathcal{D}^{\perp}_l$, we have $X_l^{\top} Z_l = \mathbf{0}$. Hence $W_l^{\top} W_l = I$ iff $Z_l^{\top} Z_l = I - X_l^{\top} X_l$. We can solve this for Z_l (using Cholesky factorization, for instance) if the right-hand side $I - X_l^{\top} X_l$ is positive definite (since it is clearly symmetric).

Let q be large enough so that $|\langle x^l_{0,i}, x^l_{1,j}\rangle| < 1/4$ for $l \geq q$. Then for $l \geq q$, the absolute values of the elements of $X_l^{\top} X_l$ are of the form $|\langle x^l_{0,i} \pm x^l_{1,j}, x^l_{0,m} \pm x^l_{1,n}\rangle|/(16k^2) < 3/(16k^2)$. Thus any row or column sum of the absolute values of the elements of $X_l^{\top} X_l$ is less than $3/8 < 1$, implying that $I - X_l^{\top} X_l$ is diagonally dominant with positive terms on the diagonal and hence is positive definite. □

Let q be as in Lemma 4.3 and $l \geq q$. For $1 \leq i,j \leq k$, let $w^l_{i,j} = \alpha_{i,j} w^+_{i,j} + \beta_{i,j} w^-_{i,j}$, where $\alpha^2_{i,j} + \beta^2_{i,j} = 1$ and $\alpha_{i,j}, \beta_{i,j} \in [0,1]$. Let $\mathcal{W} = \operatorname{span}\{w^l_{i,j} \mid 1 \leq i,j \leq k\}$. Then

$$\begin{aligned}
\langle u^l_{0,i}, P_{\mathcal{W}} u^l_{1,j}\rangle &= \sum_{m,n=1}^{k} \langle u^l_{0,i}, w^l_{m,n}\rangle\langle w^l_{m,n}, u^l_{1,j}\rangle \\
&= \|Q^l u^l_{0,i}\|\|Q^l u^l_{1,j}\| \sum_{m,n=1}^{k} \langle x^l_{0,i}, w^l_{m,n}\rangle\langle w^l_{m,n}, x^l_{1,j}\rangle \\
&= \frac{\|Q^l u^l_{0,i}\|\|Q^l u^l_{1,j}\|}{16k^2} \sum_{m,n=1}^{k} \langle x^l_{0,i}, (\alpha_{m,n}+\beta_{m,n})x^l_{0,m} + (\alpha_{m,n}-\beta_{m,n})x^l_{1,n}\rangle \\
&\quad \cdot\langle(\alpha_{m,n}+\beta_{m,n})x^l_{0,m} + (\alpha_{m,n}-\beta_{m,n})x^l_{1,n}, x^l_{1,j}\rangle \\
&= \frac{\|Q^l u^l_{0,i}\|\|Q^l u^l_{1,j}\|}{16k^2} \Bigg\{ \alpha^2_{i,j} - \beta^2_{i,j} \\
&\quad + \langle x^l_{0,i}, x^l_{1,j}\rangle \left(\sum_{n=1}^{k} (\alpha_{i,n}+\beta_{i,n})^2 + \sum_{m=1}^{k} (\alpha_{m,j}-\beta_{m,j})^2 \right) \\
&\quad + \sum_{m,n=1}^{k} (\alpha^2_{m,n} - \beta^2_{m,n}) \langle x^l_{0,i}, x^l_{1,n}\rangle\langle x^l_{o,m}, x^l_{1,j}\rangle \Bigg\}.
\end{aligned}$$

Let $\gamma_{i,j} = \alpha_{i,j}^2$ and $\underline{\gamma} = (\gamma_{i,j}) \in [0,1]^{k\times k}$. Then $\alpha_{i,j} = \sqrt{\gamma_{i,j}}$ and $\beta_{i,j} = \sqrt{1-\gamma_{i,j}}$. We can rewrite the above calculation as

$$\frac{16k^2}{\|Q^l u_{0,i}^l\| \, \|Q^l u_{1,j}^l\|} \langle u_{0,i}^l, P_{\mathcal{W}} u_{1,j}^l \rangle = 2\gamma_{i,j} - 1 + 2f_{i,j}^l(\underline{\gamma}), \tag{12}$$

where $f_{i,j}^l(\underline{\gamma})$ is continuous for $\underline{\gamma} \in [0,1]^{k\times k}$. Furthermore, if $|\langle x_{0,i}^l, x_{1,n}^l \rangle| < \epsilon$, then $|f_{i,j}^l(\underline{\gamma})| < 4k\epsilon + k^2\epsilon^2$. Let $\theta_{i,j}^l = (1+((16k^2)/(\|Q^l u_{0,i}^l\|\|Q^l u_{1,j}^l\|))\langle u_{0,i}^q, u_{1,j}^q \rangle)/2$. Then equation (2) is equivalent to

$$\theta_{i,j}^l - f_{i,j}^l(\underline{\gamma}) = \gamma_{i,j} \tag{13}$$

or

$$\underline{\theta}^l - \underline{f}^l(\underline{\gamma}) = \underline{\gamma}, \tag{14}$$

where $\underline{\theta}^l = (\theta_{i,j}^l) \in \mathbf{R}^{k\times k}$ and $\underline{f}^l = (f_{i,j}^l) : [0,1]^{k\times k} \to \mathbf{R}^{k\times k}$. Using Lemma 3.1, the proof will be finished once it is shown that equation (14) has a solution.

By Lemma 4.2, we can find l large enough so that $\underline{\theta}^l \in [1/3, 2/3]^{k\times k}$ and so that $\underline{f}^l(\underline{\gamma}) \in [-1/3, 1/3]^{k\times k}$ for $\underline{\gamma} \in [0,1]^{k\times k}$. Then for l large enough,

$$\underline{g} := \underline{\theta}^l - \underline{f}^l$$

maps the compact, convex set $[0,1]^{k\times k}$ into itself continuously. By the Schauder fixed-point theorem, equation (14) has a solution $\underline{\gamma} \in [0,1]^{k\times k}$ and thus Theorem 2 is proved. □

By a suitable modification of the original multiresolution analysis, a new multiresolution analysis $(\hat{V}_p)$ may be constructed with

$$V_0 \subset \hat{V}_0 \subset V_n$$

such that the hypotheses of Lemma 4.2 are satisfied. First note that by Lemma 2.1, any multiresolution analysis generated by compactly supported functions may be assumed to have generators that are minimally supported in $[-1,1]$. Next, let $V_l[a,b] = \{\phi \in V_l : \text{supp}\phi \subset [a,b]\}, T^\infty = \{\phi \in V_0 : \phi \perp V_0(-\infty,0] \oplus V_0[0,\infty)\}, T_0^\infty = \{\phi\chi_{[0,\infty)} : \phi \in T^\infty\}$, and $T_1^\infty = \{\phi\chi_{(-\infty,0]} : \phi \in T^\infty\}$. If all the functions in T^∞ have bounded support, then for l chosen large enough so that $[-2^l, 2^l]$ supports T^∞, $\tilde{V}_0 = V_l$ gives rise to a compactly supported orthogonal multiresolution analysis. Consequently, it is only those functions in T^∞ that have unbounded support that need to be altered. To this end, define $T_0^F = \{\phi \in T_0^\infty : \text{supp}\phi \text{ is bounded}\}, T_1^F = \{\phi \in T_1^\infty : \text{supp}\phi \text{ is bounded}\}, T_0^\omega = T_0^\infty \ominus T_0^F$, and $T_1^\omega = T_1^\infty \ominus T_1^F$ with $k_1 = \dim T_0^F = \dim T_1^F$ and $k_2 = \dim T_0^\omega = \dim T_1^\omega$; also set $\mathcal{C}_0^l = \mathcal{C}_0(V_l)$ and $\mathcal{C}_1^l = \mathcal{C}_1(V_l)$.

The uniform-lower-bound condition of Theorem 2 can be replaced by a simpler one by passing to limits. Using the notation in the proof of Lemmas 4.2 and 4.1, it follows that $2^{-l/2} f_{\gamma_0,l}(2^{-l}\cdot)$ converges in $L^2(\mathbf{R})$ to some $f_{\gamma_0,\infty} \in T_0^\infty$. Furthermore, $2^{-l/2}(Q_l f_{\gamma_0,l})(2^{-l}\cdot)$ converges to $Q^\infty f_{\gamma_0,\infty}$, where Q^∞ is the orthogonal projection onto $V_1[0,\infty)$. We then have the following result.

Lemma 4.4. *If Q^∞ is nonsingular on T_0^∞, then Q^l is uniformly bounded below as in Theorem 2.*

We now complete the proof of Theorem 1 with the following lemma.

LEMMA 4.5. *If (V_p) is a multiresolution analysis generated by compactly supported scaling functions, then there are some integer n and some multiresolution analysis $(\hat{V}_p)$ with $V_0 \subset \hat{V}_0 \subset V_n$, such that for ϕ in the unit sphere of $\mathcal{C}_0(\hat{V}_0)$ or $\mathcal{C}_1(\hat{V}_0)$, $\|2^{-l/2}(\hat{P}^{l+1} - \hat{P}^l)\phi(2^l\cdot)\|$ is bounded away from zero for sufficiently large l. Here $\hat{P}^l$ is the othogonal projection onto $\mathcal{A}(\hat{V}_l)$.*

Proof. To construct $\hat{V}_0$ we will "borrow" functions from $V_1, V_2, \ldots$, taking care not to disturb T_0^F or T_1^F. This will be accomplished first by working with functions in the spaces T_0^∞ and T_1^∞ then approximating these functions by members of $T_0^l = \{\phi(2^{-l}\cdot) : \phi \in \mathcal{C}_0^l\}$ and $T_1^l = \{\phi(2^l\cdot) : \phi \in \mathcal{C}_1^l(\cdot + 1)\}$ for sufficiently large l.

Given $\phi \in T_0^\omega$ of unit length, the fact that (V_p) forms a multiresolution analysis implies that $\lim_{l\to\infty} P_\infty^l \phi = \phi$ and hence that $\lim_{l\to\infty} \|P_\infty^l \phi\| = \|\phi\| = 1$, where P_∞^l is the orthogonal projection onto $V_l(-\infty, 0] \oplus V_l[0, \infty)$. Also, since these projections are onto successively larger spaces, this convergence is monotoncially nondecreasing in l. We have continuous functions converging monotonically to a continuous function (i.e., 1) on a compact set, so the convergence must be uniform. Let n_0 be sufficiently large so that $\|P_\infty^l \phi\| > 1/4$ for all ϕ in the unit sphere of T_0^ω and all $l \geq n_0$. We may choose k_2 orthogonal functions $w_1, \ldots, w_{k_2} \in V_{n_0}[0, \infty)$ with span W_0 such that $\|P_{W_0}\phi\| > 1/4$ for all unit functions $\phi \in T_0^\infty$. Furthermore, we may assume that these functions are compactly supported since if they were not, we could approximate them with arbitrary accuracy by functions that are. Observe that W_0 may be shifted as far to the right as desired without destroying its effectiveness. Indeed, given any $\phi \in T_0^\omega$, $\phi(\cdot + j)\chi_{[0,\infty)}$ is again in T_0^ω for any positive integer, j. Thus for $\phi \in T_0^\omega$, $\|P_{W_0(\cdot - j)}\phi\| = \|P_{W_0}\phi(\cdot + j)\| = \|P_{W_0}(\phi(\cdot + j)\chi_{[0,\infty)})\|$. This last expression is a continuous function of ϕ, which, by the construction of W_0, may not assume the value zero. Therefore, it is bounded away from zero on the unit sphere, say by ϵ_0, where the value of ϵ_0 may depend on j, but will always be positive.

In light of the above observation, shift W_0 so that $\mathrm{supp}W_0 \cap \mathrm{supp}T_0^F = \emptyset$ and $\mathrm{supp}W_0 \cap \mathrm{supp}W_0(1/2\cdot) = \emptyset$. The first condition guarantees that $W_0 \perp T_0^F$, and the second guarantees that "borrowing" the dilates of W_0 will not decrease the magnitudes of projections onto W_0. Similarly choose compactly supported $w_{-1}, \ldots, w_{-k_2} \in V_{n_1}$ with span W_1 so that $\mathrm{supp}W_1 \cap \mathrm{supp}T_1^F = \mathrm{supp}W_1 \cap \mathrm{supp}W_1(1/2\cdot) = \emptyset$ and $\|P_{W_1}\phi\| > \epsilon_1$ for unit $\phi \in T_1^\omega$. Let $n = \max\{n_0, n_1\}$ and $\epsilon = \min\{\epsilon_0, \epsilon_1\}$. Form a new multiresolution analysis $(\hat{V}_p)$ by taking

$$\begin{aligned}\hat{V}_0 = V_l &\oplus \left(\textstyle\bigoplus_{j\in Z} W_0(2^{l-1}\cdot - 2^{l-1}j)\right) \oplus \cdots \oplus \left(\textstyle\bigoplus_{j\in Z} W_0(2^{l-n}\cdot - 2^{l-n}j)\right) \\ &\oplus \left(\textstyle\bigoplus_{j\in Z} W_1(2^{l-1}\cdot - 2^{l-1}j)\right) \oplus \cdots \oplus \left(\textstyle\bigoplus_{j\in Z} W_1(2^{l-n}\cdot - 2^{l-n}j)\right),\end{aligned}$$

where l is chosen sufficiently large so that

1. $\mathrm{supp}(W_0(2^{-1}\cdot) \oplus \cdots \oplus W_0(2^{-n}\cdot) \oplus W_1(2^{-1}\cdot) \oplus \cdots \oplus W_1(2^{-n}\cdot)) \subset [-2^{l-1}, 2^{l-1}]$ and, consequently, $\mathrm{supp}(T_0^F \oplus T_1^F) \subset [-2^{l-1}, 2^{l-1}]$ (we use 2^{l-1} here to assure that W_0 and W_1 do not interfere with each other);
2. T_0^l and T_1^l approximate T_0^∞ and T_1^∞ closely enough so that $\|P_{W_0}\phi\| > (3/4)\epsilon$ for unit $\phi \in T_0^l \ominus T_0^F$ and $\|P_{W_1}\phi\| > (3/4)\epsilon$ for unit $\phi \in T_1^l \ominus T_1^F$, which is possible because the scaling functions form a Riesz basis; and
3. $\|P_{W_0}(I - P_{W_1})\phi\| < \epsilon/2$ for unit $\phi \in \hat{\mathcal{C}}_1^0(\cdot - 1)$ and $\|P_{W_1}(I - P_{W_0})\phi\| < \epsilon/2$ for unit $\phi \in \hat{\mathcal{C}}_0^0$, which is possible because the functions in T_1^ω (respectively, T_0^ω) undergo exponential decay to the left (right), as shown in Lemma 4.1.

Thus we find

$$V_l \subset \hat{V}_0 \subset V_{l+n}.$$

In addition, $\|(\hat{P}^{i+1} - \hat{P}^i)(2^{i/2}\phi(2^i\cdot))\| > \epsilon/4$ for $i \geq 0$ and unit $\phi \in \mathcal{C}_0(\hat{V}_0)$, with an analogous condition holding for $\phi \in \mathcal{C}_1(\hat{V}_0)$. This is true because in the multiresolution analysis $(\hat{V}_p)$, $W_0(2^l\cdot) \oplus W_1(2^l\cdot) \subset \hat{V}_1$, so $(W_0(2^l\cdot))_m \oplus (W_1(2^l\cdot))_m \subset \hat{V}_{m+1}$ for $m \geq 1$. If $u \in \mathcal{C}(\hat{V}_0)$ is a unit vector, then so is $u_{m,0}$, and hence

$$\begin{aligned} \|\hat{P}^{m+1}(I - \hat{P}^m)u_{m,0}\| &\geq \|P_{(W_0(2^l\cdot))_m}(I - \hat{P}^m)u_{m,0}\| \\ &= \|P_{W_0(2^l\cdot)}(I - P_{\hat{V}_0[0,2^m]})u\| \\ &\geq \|P_{W_0(2^l\cdot)}u\| - \|P_{W_0(2^l\cdot)}P_{\hat{V}_0[0,2^m]}u\| \\ &\geq (3/4)\epsilon - (1/2)\epsilon = \epsilon/4, \end{aligned}$$

for all $m \geq 1$. □

Remark 4.1.

1. In the proof of Theorem 2, we took $\mathcal{W}$ to be a k^2-dimensional subspace. In Remark 3.1, it was noted that the rank of P_0P_1 (which is generically k) is a lower bound for dim $\mathcal{W}$. In all of our examples, we achieve the lower bound k.

2. In the case $k = 1$, it is possible to show that the uniform-lower-bound condition of Theorem 2 always holds. In the next section, we show that this is also true for the spline spaces $\mathcal{S}_{d,r}$. Thus Theorem 2 holds in at least the cases of most interest.

We conclude this section with the proof of Lemma 2.1. We restate the lemma for the reader's convenience.

LEMMA 2.1 *Suppose that (V_p) is a multiresolution analysis generated by compactly supported scaling functions. Then there is some n and some set of scaling functions minimally supported on $[-1, 1]$ that generate the multiresolution analysis (V_p') given by*

$$V_p' = V_{p+n}.$$

Proof. Without loss of generality, let V_0 be generated by scaling functions $\Phi = (\phi^1, \ldots, \phi^r)$ as in Remark 2.1. If $f \in H_0(\Phi)$, then f can be expressed uniquely as

$$f = \sum_{s=1}^{k} a_s\phi^s\chi_{[0,1]}. \tag{15}$$

Let $p : H_0(\Phi) \to H_1(\Phi)$ be defined by

$$p(f) = \sum_{s=1}^{k} a_s\phi^s(\cdot - 1)\chi_{[0,1]}. \tag{16}$$

Let $E = H_0(\Phi) \bigcap H_1(\Phi)$ and E' be the maximal p-invariant subspace of E, i.e., $E' = \bigcap_{n=1}^{\infty} p^{-n}(E)$ (where for the purpose of computing E', the range of p is extended to the Minkowski sum of $H_0(\Phi)$ and $H_1(\Phi)$). Since p is nonsingular, $p(E') = E'$. If we consider p as an operator on E', let $\lambda_1, \ldots, \lambda_j$ be the (possibly complex) eigenvalues of p with magnitude less than one and $\lambda_{j+1}, \ldots, \lambda_l$ be its (possibly complex) eigenvalues with magnitude greater than one. The eigenvalues are listed above including multiplicities. We claim that p has no eigenvalues that lie on the unit circle; hence $l = \mathrm{Dim}(E') \leq k$. To see this, suppose that λ is an eigenvalue of p with magnitude one and x an eigenvector associated with this eigenvalue. Let $y = \mathrm{Re}(x)$; then for λ real, set $\kappa = \|y\| = \|p^n(y)\|$; otherwise set $0 < \kappa = \min_{|u|=1}\|x + u\bar{x}\| \leq \|p^n(y)\| \leq \|x\|$. We may define a sequence of functions $\{f_\nu\}_{\nu=0}^{\infty}$ as

$$f_\nu = \sum_{i=0}^{\nu}(-1)^i g_i, \tag{17}$$

where $g_i = (p^i y)(\cdot + i) + (p^{i+1}y)(\cdot + i + 1)$. Note that

1. $g_i = \sum_{s=1}^k a_s^i \phi^s(\cdot + i)$,
2. $A\sum_{s=1}^k (a_s^i)^2 \leq \|g_i\|^2 \leq B\sum_{s=1}^k (a_s^i)^2$,
3. $\|g_i\|^2 = \|p^i y\|^2 + \|p^{i+1}y\|^2$, and
4. $f_\nu = y + (-1)^\nu (p^{\nu+1}y)(\cdot + \nu + 1)$.

Therefore, $\|f_\nu\|^2 = \|y\|^2 + \|p^{\nu+1}y\|^2 \leq 2\|x\|^2$ and $\sum_{i=1}^\nu \sum_{s=1}^k (a_s^i)^2 \geq \sum_{i=1}^\nu \frac{2\kappa^2}{B} = 2\kappa^2\nu/B$, which shows that $\tau(\Phi)$ is not a Riesz basis and thus yields a contradiction.

Let $x_1, \ldots, x_l$ be the generalized eigenvectors associated with $\lambda_1, \ldots, \lambda_l$. In the event that an eigenvalue is complex, its conjugate is also an eigenvalue and we will replace the appropriate generalized eigenvectors by their real and imaginary parts. Note that $x_1, \ldots, x_l$ form a basis for E'. For $y = x_m$, $m = 1, \ldots, j$, we define a sequence of functions $\{f_\nu\}$ as above. In this case, because of the choice of y, $\|p^n y\| \to 0$ since $\lambda_1, \ldots, \lambda_j$ are in magnitude less than one. Therefore, $f_\nu \overset{L^2}{\to} y$. For $y = x_m$, $m = j+1, \ldots, l$, choose the sequence $\{f_\nu\}$ as $f_\nu = \sum_{i=0}^\nu (-1)^i g_i$, where $g_i = (p^{-i}y)(\cdot - i) + (p^{-(i+1)}y)(\cdot - i - 1)$. We again have $f_\nu \overset{L^2}{\to} y$ and so $x_1, \ldots, x_l$ are in V_0. By replacing $\phi^1, \ldots, \phi^k$ by appropriate linear combinations of $\phi^1, \ldots, \phi^k$, we may assume that the right halves (and hence also the shifted left halves) of $\phi^1, \ldots, \phi^l$ are in E'. Since $x_1, \ldots, x_l$ span E', we may replace the generators $\phi^1, \ldots, \phi^l$ by the equivalent set of generators $x_1, \ldots, x_l$. Since $x_1, \ldots, x_l$ have support in $[0,1]$, these may be removed to A. By the linear independence of $\tau(\Phi)$, none of the $\phi^{l+1}, \ldots, \phi^k$ can have their right halves or shifted left halves in E'. If $E \ominus E' = 0$, then $\Phi = \{x_1, \ldots, x_l, \phi^{l+1}, \ldots, \phi^r\}$ is minimally supported and spans V_0.

If there are nonzero functions in $E \ominus E'$, let $E'' = H_0(\Phi) \ominus E'$. For nonzero $x \in E''$, let n_x be such that $p^{n_x}(x) \notin E$ but $p^i(x) \in E$, $1 \leq i < n_x$, and define $n_0 = \infty$. Note that n_x is finite for nonzero x since $x \notin E'$ and that $n_{\alpha x + \beta y} \geq \min\{n_x, n_y\}$ for scalars α, β, and $x, y \in E''$. Now for $i = 1, 2, \ldots$, set $E_i = \{x \in E'' : n_x \geq i\}$. Then E_i is a subspace of E'' and $E_1 = E''$. Also, there is some $\tilde{n}$ such that $E_{\tilde{n}+1} = 0$ and $E_{\tilde{n}} \neq 0$. Let $X_{\tilde{n}}$ be a set of vectors that form a basis for $E_{\tilde{n}}$. By the definition of $\tilde{n}$, if $x \in X_{\tilde{n}}$, then $x \notin E$. Furthermore, $p(X_{\tilde{n}})$ gives a linearly independent set of vectors in $E_{\tilde{n}-1} \bigcap E$. Beginning with the vectors $p(X_{\tilde{n}})$ and $X_{\tilde{n}}$, complete this set to a basis, $X_{\tilde{n}-1}$, for $E_{\tilde{n}-1}$. Now $p(X_{\tilde{n}-1})$ is a linearly independent set of vectors in $E_{\tilde{n}-2}$ and we add a sufficient number of independent vectors to form a basis, $X_{\tilde{n}-2}$, for $E_{\tilde{n}-2}$. Continue this processes until a basis, X_1, for E_1 has been formed. Since X_1 forms a basis for E'', $\{x + p(x)(\cdot + 1) : x \in X_1\}$ may be used to replace $\phi^{l+1}, \ldots, \phi^k \in \Phi$. For $x \in X_1$, set $\phi_x = x + p(x)(\cdot + 1)$. We now consider $\tilde{\phi}_x = \phi_x(\cdot + i - 1)$ for $x \in X_i - X_{i+1}$ (where we set $X_{\tilde{n}+1} = 0$). Since these are just translates of ϕ_x, $x \in X_1$, we may replace ϕ_x by $\tilde{\phi}_x$. For each $x \in X_1$, let

$$\hat{\phi}_x = \sum_{i=0}^{n_x - 1} (-1)^i \tilde{\phi}_{p^i(x)},$$

which is a linear combination of elements from $\{\tilde{\phi}_x : x \in X_1\}$. Then $\{\hat{\phi}_x : x \in X_1\}$ is linearly independent and may be used to replace $\{\tilde{\phi}_x : x \in X_1\}$. Note that the support of $\tilde{\phi}_x$ is $[-n_x, -n_x + 1] \cup [0,1]$ and that $\operatorname{span}\{\hat{\phi}_x(\cdot - a_x)\chi_{[0,1]} x \in X_1\}$ and $\operatorname{span}\{\hat{\phi}(\cdot - b_x)\chi_{[0,1]} : x \in X_1\}$ are linearly independent spaces. The set $\{\phi_x, x \in X_1\} \cup \{x_i\}_{i=1}^l \cup \{\phi^i\}_{i=k+1}^r$ spans V_0. Consequently, there is an integer h, $\log_2 \tilde{n} \leq h < \log_2 \tilde{n} + 1$, such that the above functions, scaled by 2^h, are all supported in $[-1,1]$, and there is a $\tilde{\Phi}$ formed from appropriate translates of these functions such that $\tau(\tilde{\Phi})$ forms a basis for V_h. From the above construction and by Remark 2.1 in §2, appropriate linear combinations of the generators of $\tilde{\Phi}$ may be taken so as to produce a set of generators that is minimally supported. It follows from Theorems 4.3 and 5.3 of [14] that $\tau(\tilde{\Phi})$ is a Riesz basis of V_h. □

5. Orthogonal spline scaling functions. For $h > 0$ and $1 \le r \le d+1$, let $\mathcal{S}_{d,r}(h)$ denote the space of piecewise-polynomial functions on $\mathbf{R}$ of degree d with knots of multiplicity r on $h\mathbf{Z}$. Let $\lceil a \rceil$ denote the least integer greater than or equal to a.

We let (t_i) denote the sequence of knots with multiplicity r for $\mathcal{S}_{d,r}(h)$ given by

$$t_i = h\lceil i/r \rceil, \quad i \in \mathbf{Z}.$$

Also, let N_i^d denote the B-spline in $\mathcal{S}_{d,r}(h)$ with knots $t_i, \ldots, t_{i+d+1}$. Thus N_i^d is supported on $[t_i, t_{i+d+1}] \subset [jh, (j+L)h]$, where $j = \lceil i/r \rceil$ and $L = \lceil (d+1)/r \rceil$. Observe that the support of N_0^d is exactly $[0, Lh]$.

Let q be such that $2^q + 1 \ge L$ and choose $h = 2^{-q}$. Let $R = 2^q r$ and define $\phi^s = N_{s-d-1}^d$ for $s = 1, \ldots, R$. Then $\Phi = (\phi^1, \ldots, \phi^R)^\top$ generates a multiresolution analysis (V_p) with $V_0 = \mathcal{S}_{d,r}(2^{-q}) \cap L^2(\mathbf{R})$ (see Goodman and Lee [11]). It follows from the choice of q that Φ is minimally supported in $[-1, 1]$. Observe that there are exactly $d + 1 - r$ values of i such that 0 is an interior point of $[t_i, t_{i+d+1}]$. Hence $k = k(\Phi) = d + 1 - r$.

In this section, we will show that (V_p) satisfies the hypotheses of Theorem 2 and so there is an orthogonal $\tilde{V}_0$ between $V_{q'}$ and $V_{q'+1}$ for some integer q'. Towards this end, we first develop some results concerning the sign changes of spline functions. We say that $(x_1, \ldots, x_\alpha)$ is a *sign-change sequence* on (a, b) for $f : \mathbf{R} \to \mathbf{R}$ if f is not identically zero on any subinterval (x_j, x_{j+1}), $j = 0, \ldots, \alpha$, where $a = x_0 < x_1 < \cdots < x_\alpha < x_{\alpha+1} = b$, and, for either $k = 0$ or $k = 1$, we have $(-1)^{j+k} f(x) \ge 0$ for all $x \in (x_j, x_{j+1})$ and $j = 0, \ldots, \alpha$. Let i_0, i_1 be given integers and define $\mathcal{P}_{i_0,i_1} = \operatorname{span}\{N_i^d \mid i_0 \le i \le i_1\}$ and $\sigma_i := \{x \mid N_i^d(x) \ne 0\} = (t_i, t_{i+d+1})$ for $i = i_0, \ldots, i_1$. We will need the following result concerning sign changes of B-spline expansions.

LEMMA 5.1. *Let $a, b \in \mathbf{R}$ and i_0, i_1 be integers such that $t_{i_0} < t_{i_1}$ and suppose that $r \le d$ (and thus the B-splines are continuous).*

1. *If $f \in \mathcal{P}_{i_0,i_1}$ and $(x_1, \ldots, x_\alpha)$ is a sign-change sequence for f on (a, b), then for any open interval $G \subset (a, b)$, we have*

$$\operatorname{card}\{x_j \in G\} \le \operatorname{card}\{i \mid \sigma_i \cap G \ne \emptyset\} - 1. \tag{18}$$

2. *If $a < x_1 < x_2 < \cdots < x_\alpha < b$ satisfies*

$$x_i \in \sigma_{i_0+i-1} \cap \sigma_{i_0+i} \quad \textit{for } i = 1, \ldots, \alpha,$$

then there is some $f \in \mathcal{P}_{i_0,i_0+\alpha}$ for which $(x_1, \ldots, x_\alpha)$ is a sign-change sequence on (a, b). Furthermore, f does not vanish on any subinterval of $\bigcup_{i=i_0}^{i_0+\alpha} \sigma_i$.

Proof. Part 1 follows from the variation-diminishing property of B-spline expansions (cf. [21, Thm. 4.76]). Let $x_0 \in \sigma_{i_0}, x_0 \ne x_i$. By [21, Thm. 4.61], there is a unique $f \in \mathcal{P}_{i_0,i_1}$ such that

$$f(x_0) = 1, \qquad f(x_i) = 0, \quad i = 1, \ldots, \alpha.$$

Suppose $\alpha = 1$. Then $f = c_0 N_{i_0}^d + c_1 N_{i_0+1}^d$. Since $f(x_0) = 1$, at least one of c_0 and c_1 are nonzero. Since $x_1 \ne t_k$ for all k, it follows that both c_0 and c_1 are nonzero and so f does not vanish on any subinterval of $\sigma_{i_0} \cup \sigma_{i_1}$. Hence by counting the zeros of f including their multiplicities, it follows from [21, Thm. 4.56] that f changes sign at x_1. It then follows by induction on α that f does not vanish on any subinterval of $(t_{i_0}, t_{i_0+\alpha+d+1}) = \bigcup_{i=i_0}^{i_0+\alpha} \sigma_i$. Hence [21, Thm. 4.56] shows that $(x_1, \ldots, x_\alpha)$ must be all of the zeros of f in $(t_{i_0}, t_{i_0+\alpha+d+1})$ and that all of these zeros must be isolated, simple zeros. Thus $(x_1, \ldots, x_\alpha)$ is a sign-change sequence of f on (a, b). □

LEMMA 5.2. *Let $f \in V_0$ be such that $f\chi_{[0,\infty)} \neq 0$. Then there is some $g \in V_1$ such that supp $g \subset [0,\infty)$ and $\langle f, g\rangle \neq 0$.*

Proof. If $r = d + 1$, then $f\chi_{[0,\infty)} \in V_1$ and we can take $g = f\chi_{[0,\infty)}$.

Suppose $r \leq d$. Let $s_i = t_i/2$ for all i. Note that $n_i^d := N_i^d(2\cdot)$ is the B-spline associated with the knots $s_i, \ldots, s_{i+d+1}$. Let $\sigma'_i = (s_i, s_{i+d+1}) = \{x \mid n_i^d(x) > 0\}$ and $\mathcal{P}'_{i_0,i_1}$ be the span of the B-splines associated with the knots $s_{i_0}, \ldots, s_{i_1+d+1}$.

Let $\hat{f} = f\chi_{[0,\infty)}$. If there exists a σ'_i such that $\sigma'_i \subset \operatorname{supp}\hat{f}$ and f does not change sign on σ'_i, then we can choose $g = n_i^d$. If $\operatorname{supp}\hat{f}$ is not of the form $[0, b]$ or $[0, \infty)$, then some component I of $\operatorname{supp}\hat{f}$ does not contain zero and $\hat{f}\chi_I \in V_1$. In this case, choose $g = \hat{f}\chi_I$. If $\operatorname{supp}\hat{f} = [0, b]$, then by the first part of Lemma 5.1, on $[b - h, b]$, $\hat{f}$ is a polynomial with at most $r - 1$ zeros. Thus on $[b - h, b]$, $\hat{f} = (x - b)^{d-r+1}p(x)$, where $p(x)$ is a polynomial of degree $r - 1$. Consequently, we can choose a function $g \in V_1$ such that on $[b - h, b]$, we have $g = (x - (b - h))^{d-r+1}p(x)$.

Finally, suppose $\operatorname{supp}\hat{f} = [0, \infty)$ and each σ'_i contains a sign change. Suppose there are integers i_0, j_0 and $\alpha \geq 0$ such that

$$\begin{gathered} x_{j_0} \notin \sigma'_{i_0}, \qquad x_{j_0+\alpha+1} \notin \sigma'_{i_0+\alpha}, \quad \text{and} \\ x_{j_0+i} \in \sigma'_{i_0+i-1} \cap \sigma'_{i_0+i} \quad \text{for } i = 1, \ldots, \alpha. \end{gathered} \tag{19}$$

Then part 2 of Lemma 5.1 implies that there is some $g \in V_1$ with support $(a, b) := \bigcup_{i=i_0}^{i_0+\alpha} \sigma'_i$ such that $(x_{j_0+1}, \ldots, x_{j_0+\alpha})$ is a sign-change sequence for g on (a, b). Furthermore, since g does not vanish on any subinterval of (a, b), we have $\langle f, g\rangle \neq 0$.

We now show that there must exist an i_0 and j_0 so that (19) holds. We first show that there do not exist integers i_0 and j_0 such that

$$x_{i_0+l} \in \sigma'_{j_0+l-1} \cap \sigma'_{j_0+l} \tag{20}$$

for all $l \geq 1$. Suppose not; then

$$\operatorname{card}\left\{ x_j \in \bigcup_{l=1}^{2m} \sigma'_{j_0+l} \right\} \geq 2m. \tag{21}$$

Since f is in V_0, it follows from part 1 of Lemma 5.1 that there exists a constant c such that

$$m + c > \operatorname{card}\left\{ x_j \in \bigcup_{l=1}^{2m} \sigma'_{j_0+l} \right\} \tag{22}$$

for all m. This contradicts (21) for m sufficiently large. Thus the above shows that there does not exist an infinite sign-change sequence that satisfies (20).

We now rule out the case where (19) fails for each finite α. Let $0 = x_0 < x_1 < \cdots$ be an infinite sign-change sequence of f on $(0, \infty)$, $n_0 = 1 - r$, and for each $i \geq n_0$, set $k(i) = \min\{j : x_j \in \sigma'_i\} - 1$. Assume that (19) does not hold. Since we have already ruled out (20), it must be that for each i there exists an $n \geq 1$ which depends upon i such that $x_{k(i)+l} \in \sigma'_{i+l-1} \cap \sigma'_{i+l}$, $l = 1, \ldots, n-1$, but $x_{k(i)+n} \notin \sigma'_{i+n-1} \cap \sigma'_{i+n}$ and $x_{k(i)+n} \in \sigma'_{i+n-1}$. Thus $x_{k(i)+n} < \inf \sigma'_{i+n}$, and so from the definition of $k(i+n)$, we find that $k(i+n) > (k(i)+n) - 1$ or $k(i+n) \geq k(i) + n$. Thus for each infinite sign-change sequence not satisfying (19), there exists an infinite sequence $n_0 < n_1 < \cdots$ such that $k(n_{i+1}) \geq k(n_i) + n_{i+1} - n_i$. Since $k(n_0) = 0$, we find that $k(n_l) \geq n_l - n_0$ for all l. From (21) and (22) above, we find that for l large enough, this leads to a contradiction. □

Thus Q_∞, the orthogonal projection onto $V_1[0,\infty)$, is nonsingular on T_0^∞. Then Lemma 4.4 implies that (V_p) satisfies the hypotheses of Theorem 2.

THEOREM 3. *Let r, d, and q be as above and let $V_0 = \mathcal{S}_{d,r}(2^{-q}) \cap L^2(\mathbf{R})$. Then there is some integer $\tilde{q}$ and some orthogonal multiresolution analysis $(\tilde{V}_p)$ such that*

$$V_{\tilde{q}} \subset \tilde{V}_0 \subset V_{\tilde{q}+1}.$$

5.1. Example: $\mathcal{S}_{3,2}$—C^1 cubic scaling functions.

In this case, $L = 2$, $q = 0$, and V_0 is generated by the two B-splines associated with the knot sequences $(-1,-1,0,0,1)$ and $(-1,0,0,1,1)$. As noted in Remark 3.1, we will need $\mathcal{W}$ to have dimension at least 2. Now $\mathcal{A}(V_1) \ominus \mathcal{A}(V_0)$ is two dimensional, which is not large enough to allow for any freedom in the choice of $\mathcal{W}$. Observe that $\mathcal{A}(V_2) \ominus \mathcal{A}(V_1)$ is $6 - 2 = 4$ dimensional. Using Mathematica to aid in the calculations, we find a two-dimensional $\mathcal{W}$ that satisfies equation (1). This gives a total of six scaling functions and six wavelets, as shown in Figure 3.

Scaling Functions

Wavelets

FIG. 3. *Piecewise-cubic C^1 orthogonal scaling functions (from right to left and top to bottom: $\tilde{\phi}^1(\cdot - 1)$, $\tilde{\phi}^2(\cdot - 1)$, $\tilde{\phi}^3$, $\tilde{\phi}^4$, $\tilde{\phi}^5$, $\tilde{\phi}^6$) and wavelets (from top to bottom and right to left: $\tilde{\psi}^1$, $\tilde{\psi}^2$, $\tilde{\psi}^3(\cdot - 1)$, $\tilde{\psi}^4(\cdot - 1)$, $\tilde{\psi}^5(\cdot - 1)$, $\tilde{\psi}^6(\cdot - 1)$).*

Appendix B. Matrix-dilation coefficients. Suppose that (V_p) is an orthogonal multiresolution analysis generated by scaling functions $\phi^1, \ldots, \phi^r$ minimally supported on $[-1, 1]$. Let $\Phi = (\phi^1, \ldots, \phi^r)^{\mathsf{T}}$. Since $V_0 \subset V_1$, it follows that Φ must satisfy a two-scale dilation equation with matrix coefficients:

$$\Phi(x) = \sqrt{2} \sum_{n=-2}^{1} H_n \Phi(2x - n), \tag{23}$$

where each H_n is an $r \times r$ real matrix. The support and orthogonality of the scaling functions imply the given summation limits. In Tables 4–6, we give H_{-2}, H_{-1}, H_0,

TABLE 4

Matrix-dilation coefficients for the piecewise-linear scaling functions and wavelets of the example in §3.1.

and H_1 for the three examples given in §§3.1, 3.2, and 5.1.

The wavelets $\Psi = (\psi^1, \ldots, \psi^r)^T$ constructed from the scaling functions also satisfy a two-scale dilation equation of the form

$$\Psi(x) = \sqrt{2} \sum_{n=-2}^{1} K_n \Phi(2x - n). \tag{24}$$

These matrices are also given in Tables 4–6.

Acknowledgments. The second and third authors thank Gil Strang for his helpful suggestions and encouragement and Amos Ron for pointing out the simplifications in the multiresolution conditions when the scaling functions are compactly supported. We especially thank one of the anonymous referees for a careful reading and for numerous corrections.
