$$\Delta_h^r(v,x) := \sum_{j=0}^{r} (-1)^{r+j} \binom{r}{j} v(x+jh). \tag{3.1}$$

With these differences, we can define the moduli of smoothness

$$\omega_r(v,s)_p := \sup_{0 \le |h| \le s} \|\Delta_h^r(v)\|_{L_p(\mathbb{R}^d)}, \quad s \ge 0,$$

for each $r = 1, 2, \ldots$. The rate at which $\omega_r(v,t)_p$ tends to zero gives information about the smoothness of v in $L_p(\mathbb{R}^d)$.

The Besov spaces are defined for $0 < \alpha < r$ and $0 < p, q \le \infty$ as the set of all functions $v \in L_p(\mathbb{R}^d)$ for which

$$|v|_{B_q^\alpha(L_p(\mathbb{R}^d))} := \begin{cases} \left(\int_0^\infty \left[s^{-\alpha} \omega_r(v,s)_p \right]^q \frac{ds}{s} \right)^{\frac{1}{q}}, & 0 < q < \infty, \\ \sup_{s \ge 0} s^{-\alpha} \omega_r(v,s)_p, & q = \infty, \end{cases} \tag{3.2}$$

is finite. The conditions (3.2) require that $\omega_r(v,s)_p$ behave like $O(s^\alpha)$ as $s \to 0$; the exact requirement on $\omega_r(v,s)_p$ varies with q and becomes stronger as q gets smaller. We define the following "norm" for $B_q^\alpha(L_p(\mathbb{R}^d))$:

$$\|v\|_{B_q^\alpha(L_p(\mathbb{R}^d))} := \|v\|_{L_p(\mathbb{R}^d)} + |v|_{B_q^\alpha(L_p(\mathbb{R}^d))}.$$

Because we allow p and q to be less than 1, this "norm" does not always satisfy the triangle inequality, but it is always a quasinorm, i.e., there exists a constant C such that for all u and v in $B_q^\alpha(L_p(\mathbb{R}^d))$,

$$\|u + v\|_{B_q^\alpha(L_p(\mathbb{R}^d))} \le C(\|u\|_{B_q^\alpha(L_p(\mathbb{R}^d))} + \|v\|_{B_q^\alpha(L_p(\mathbb{R}^d))}).$$

It can be shown that the above definition of Besov spaces does not depend on the choice of r, since all values of $r > \alpha$ give rise to equivalent norms and hence the same space. We note that since $\omega_r(v,t)_p \le 2^r \|v\|_{L_p(\mathbb{R}^d)}$, $1 \le p \le \infty$ (the same inequality holds with 2^r replaced by $2^{r/p}$ when $p < 1$), we obtain an equivalent norm for $B_q^\alpha(L_p(\mathbb{R}^d))$ if we take the integral or supremum in (3.2) over only the interval $[0,1]$. Thus, membership of v in $B_q^\alpha(L_p(\mathbb{R}^d))$ is determined only by the integral or supremum on $[0,1]$.

For certain values of the parameters, the Besov spaces are identical with other smoothness spaces. For example, if $0 < p \le \infty$ and $0 < \alpha$ is not an integer, then $B_\infty^\alpha(L_p(\mathbb{R}^d)) = \mathrm{Lip}(\alpha, L_p(\mathbb{R}^d))$ are the classical Lipschitz spaces. When $\alpha = k$ is an integer, we obtain the generalized Lipschitz spaces, for which $\omega_r(v,s)_p$, $r > k$, is used in place of $\omega_k(v,s)_p$ in the definition of the usual Lipschitz spaces. For $p = 2$ and $\alpha > 0$, the Besov spaces $B_2^\alpha(L_2(\mathbb{R}^d)) = W^\alpha(L_2(\mathbb{R}^d))$ are the Sobolev spaces. The Besov spaces with $q = p$, which we shall denote by $B_p^\alpha := B_p^\alpha(L_p(\mathbb{R}^d))$, are of particular interest. These are sometimes called generalized Sobolev spaces.

The application of Besov spaces to approximation theory and interpolation of linear operators leads to alternate characterizations of these spaces. We shall mention two of these alternate characterizations that hold in the univariate case.

The first characterization describes the Besov spaces in terms of approximation by linear spaces of spline functions. Let $\mathcal{S}_{n,r}$ denote the set of all univariate piecewise polynomials of degree $< r$ that have global smoothness $C^{(r-2)}$ and have break points only at the dyadic integers $j2^{-n}$, $j \in \mathbb{Z}$. For each $f \in L_p(\mathbb{R})$, we define

$$s_n(f)_p := s_{n,r}(f)_p := \inf_{S \in \mathcal{S}_{n,r}} \|f - S\|_{L_p(\mathbb{R})}.$$

Then (see [8]), for $0 < \alpha < r$, a function f is in $B_q^\alpha(L_p(\mathbb{R}))$ if and only if

$$\left(\sum_{n=0}^\infty [2^{n\alpha} s_n(f)_p]^q \right)^{\frac{1}{q}} < \infty, \tag{3.3}$$

with the usual change to a supremum when $q = \infty$. Moreover, (3.3) gives an equivalent seminorm for $B_q^\alpha(L_p(\mathbb{R}))$. It follows directly from (3.3) that $B_\sigma^\alpha(L_p(\mathbb{R}))$ is continuously embedded in $B_\tau^\beta(L_p(\mathbb{R}))$ if $\alpha > \beta$ or $\alpha = \beta$ and $\sigma < \tau$.

Our second characterization describes the Besov spaces in terms of univariate nonlinear approximation. For this, we let $\Sigma_n := \Sigma_{n,r}$ denote the collection of all piecewise-polynomial functions of degree $< r$ on $\mathbb{R}$ that consist of at most $n+1$ pieces. Thus $S \in \Sigma_n$ if and only if there exist n breakpoints $x_1 < x_2 < \cdots < x_n$ such that with $x_0 := -\infty$, $x_{n+1} := \infty$, the function S is a polynomial of degree $< r$ on each of the intervals (x_{i-1}, x_i), $i = 1, \ldots, n$. No assumption is made about the smoothness of S at the breakpoints. The set Σ_n is not a linear space, but it can be considered a nonlinear manifold parameterized by the breakpoints and the coefficients of the polynomial pieces.

We can describe certain Besov spaces in terms of their approximation by the elements of Σ_n. For this, we define for $f \in L_p(\mathbb{R})$, $0 < p \leq \infty$,

$$\sigma_n(f)_p := \sigma_{n,r}(f)_p := \inf_{S \in \Sigma_n} \|f - S\|_{L_p(\mathbb{R})}, \tag{3.4}$$

which is the error in approximating f in the $L_p(\mathbb{R})$ norm by the elements of Σ_n.

Nonlinear spline approximation can be used to characterize certain of the spaces B_τ^α (see [15] and [9]). If $r > \alpha > 0$ and $\tau > 0$ are given, and if there is a p with $0 < p < \infty$ such that $\tau = \tau(\alpha, p) := (\alpha + 1/p)^{-1}$, then $f \in B_\tau^\alpha(L_\tau(\mathbb{R}))$ if and only if

$$\left(\sum_{n=1}^{\infty} [2^{n\alpha} \sigma_{2^n}(f)_p]^\tau\right)^{\frac{1}{\tau}} < \infty \tag{3.5}$$

and (3.5) when added to $\|\cdot\|_{L_\tau(\mathbb{R})}$ gives an equivalent norm for B_τ^α:

$$\|f\|_{B_\tau^\alpha(L_\tau(\mathbb{R}))} \sim \|f\|_{L_\tau(\mathbb{R})} + \left(\sum_{n=1}^{\infty} [2^{n\alpha} \sigma_{2^n}(f)_p]^\tau\right)^{\frac{1}{\tau}}. \tag{3.6}$$

Furthermore, (3.6) implies that $B_{\tau(\alpha,p)}^\alpha$ is continuously embedded in $B_{\tau(\beta,p)}^\beta$ if $\alpha > \beta$. Indeed, $B_{\tau(\alpha,p)}^\alpha$ is continuously embedded in $L_p(\mathbb{R})$ (see [8]), and the family of spaces $B_{\tau(\alpha,p)}^\alpha$ lies on the half-line with slope one emanating from the point $(1/p, 0)$ in Figure 1.

It may be useful to say a few words about the differences in the two characterizations (3.3) and (3.5). The characterization (3.3) describes the space $B_q^\alpha(L_p(\mathbb{R}^d))$ in terms of approximation in $L_p(\mathbb{R}^d)$. Thus the approximation is taking place in the same space ($L_p(\mathbb{R}^d)$) in which the smoothness is measured. In contrast, in (3.5) the approximation takes place in the space $L_p(\mathbb{R}^d)$ but the smoothness is measured in the space $L_\tau(\mathbb{R}^d)$; this is characteristic of nonlinear approximation. Since $\tau < p$, the class of functions that can be approximated by the nonlinear family Σ_n is larger than the class that is approximated by the linear spaces $\mathcal{S}_n$.

4. Rearrangement invariant spaces. In this section, we shall give an elementary approach to finding invariant spaces based on interpolation of operators. We begin by recalling some basic facts about the K-functional and its application to the theory of interpolation of operators.

If (X_0, X_1) is a pair of complete, quasinormed spaces embedded in a Hausdorff space $\mathcal{X}$, then for each $v \in X_0 + X_1$, we form the K-functional

$$K(v,s) := K(v,s;X_0,X_1) := \inf_{v=v_0+v_1} \{\|v_0\|_{X_0} + s\|v_1\|_{X_1}\}, \quad s \geq 0,$$

where the infimum is taken over all decompositions $v = v_0 + v_1$ with $v_i \in X_i$, $i = 0, 1$. It is easy to see that for fixed $s > 0$, $K(\,\cdot\,, s)$ is a quasinorm and for fixed v, $K(v, \,\cdot\,)$ is an increasing concave function on $\mathbb{R}_+$.

The K-functional was introduced by Peetre as a tool for obtaining interpolation spaces X for the pair (X_0, X_1). We recall that a complete quasinormed space X contained in $X_0 + X_1$ is called an *interpolation space* for the pair (X_0, X_1) if each linear operator T that boundedly maps X_0 and X_1 into themselves also maps X boundedly into itself. For such a T, it follows that

$$K(Tv, s; X_0, X_1) \leq M\, K(v, s; X_0, X_1), \quad s > 0,$$

with M the maximum of the norm of T on the two spaces X_0, X_1.

In view of (4.1), we can obtain interpolation spaces for (X_0, X_1) by applying to $K(v, \,\cdot\,)$ a quasinorm defined for functions on $\mathbb{R}_+$. We mention in particular the (θ, q) norms, $0 < \theta < 1$, $0 < q \leq \infty$, which give the spaces $X_{\theta,q}$ that consist of all $v \in X_0 + X_1$ for which

$$(4.1) \qquad |v|_{X_{\theta,q}} := \left(\int_0^\infty [s^{-\theta} K(v,s)]^q \frac{ds}{s} \right)^{1/q}$$

is finite (with the usual change to a supremum when $q = \infty$). It follows from (4.1) that T maps $X_{\theta,q}$ into itself for each $0 < \theta < 1$, $0 < q \leq \infty$, with a norm not exceeding M.

It is not possible to apply this interpolation directly to the operator $E(t)$ associated with (1.1) since it is not linear. However, the following simple remark can be used in place of linearity. We say that an operator T is X_0-Lipschitz on $X_0 + X_1$ if

$$\|T(v_0) - T(v_1)\|_{X_0} \leq M_0 \|v_0 - v_1\|_{X_0}$$

for each $v_0, v_1 \in X_0 + X_1$ for which $v_1 - v_0 \in X_0$.

LEMMA 4.1. *If T is a (possibly nonlinear) operator that is X_0-Lipschitz with constant M_0 on $X_0 + X_1$ and is bounded with norm M_1 on X_1, then T satisfies*

$$(4.2) \qquad K(Tv, s) \leq M\, K(v, s), \quad v \in X_0 + X_1,\ s > 0,$$

with $M := \max(M_0, M_1)$.

Proof. The proof is almost a triviality. Let $s > 0$. For a given $\epsilon > 0$, let $v = v_0 + v_1$ be a decomposition of v that satisfies $\|v_0\|_{X_0} + s\|v_1\|_{X_1} \leq K(v,s) + \epsilon$. Then $Tv = (Tv - Tv_1) + Tv_1$ and $v - v_1 = v_0 \in X_0$. Hence,

$$\|Tv - Tv_1\|_{X_0} + s\|Tv_1\|_{X_1} \leq M_0\|v - v_1\|_{X_0} + sM_1\|v_1\|_{X_1} \leq M(K(f,s) + \epsilon).$$

Since $\epsilon > 0$ is arbitrary, (4.2) follows from the definition of the K-functional. □

We now apply this lemma to the solution operator $E := E(t)$ for the conservation law (1.1). The contractivity of the operator E on $L_1(\mathbb{R}^d)$ has a local variant. For this, we assume that the flux f is in Lip 1. It follows that the transport velocity vector $f'(u)$ satisfies

$$\Lambda := \sup_{u \in \mathbb{R}} \|f'(u)\|_{\ell_1} < \infty,$$

where $\|x\|_{\ell_1} := \sum_{i=1}^d |x_i|$. Under this assumption, we have (see [10]) for any locally integrable functions u_0 and v_0 and any ball $B(x, R)$ of radius $R > 0$ centered at the point x,

$$\int_{B(x,R)} |E(u_0) - E(v_0)| \leq \int_{B(x,R+\Lambda t)} |u_0 - v_0|. \tag{4.3}$$

In particular, if $u_0, v_0 \in L_1(\mathbb{R}^d) + L_\infty(\mathbb{R}^d)$ and $u_0 - v_0 \in L_1(\mathbb{R}^d)$, then taking a limit as $R \to \infty$ in (4.3) shows that E is L_1-Lipschitz on $L_1 + L_\infty$ with constant 1. Since E is a norm-one operator on L_∞, we can apply Lemma 4.1 and find

$$K(E(u_0), s; L_1(\mathbb{R}^d), L_\infty(\mathbb{R}^d)) \leq K(u_0, s; L_1(\mathbb{R}^d), L_\infty(\mathbb{R}^d)). \tag{4.4}$$

The K-functional for the pair $(L_1(\mathbb{R}^d), L_\infty(\mathbb{R}^d))$ can be described in terms of rearrangements of functions. We refer the reader to the book of Bennett and Sharpley [1] and Calderón's paper [2] for a discussion of rearrangements and the material that follows in this section. The rearrangement v^* of a function $v \in L_1(\mathbb{R}^d) + L_\infty(\mathbb{R}^d)$ is a nonincreasing function defined on $\mathbb{R}_+$ that is equimeasurable with v, i.e,

$$\operatorname{meas}\{\, x \in \mathbb{R}^d \mid |v(x)| > y \,\} = \operatorname{meas}\{\, x \in \mathbb{R}_+ \mid |v^*(x)| > y \,\}$$

for all $y \geq 0$. It follows that the rearrangement v^* of any $v \in L_p(\mathbb{R}^d)$ is in $L_p(\mathbb{R}_+)$ and

$$\|v\|_{L_p(\mathbb{R}^d)} = \|v^*\|_{L_p(\mathbb{R}_+)}, \quad 1 \leq p \leq \infty. \tag{4.5}$$

It can readily be verified that the K-functional for (L_1, L_∞) is

$$K(v, s; L_1(\mathbb{R}^d), L_\infty(\mathbb{R}^d)) = \int_0^s v^*(y)\, dy. \tag{4.6}$$

The Hardy–Littlewood maximal function v^{**} of v^* is related to the K-functional $K(v, s; L_1(\mathbb{R}^d), L_\infty(\mathbb{R}^d))$ in the following way:

$$v^{**}(s) := \frac{1}{s} \int_0^s v^*(y)\, dy = \frac{1}{s} K(v, s; L_1(\mathbb{R}^d), L_\infty(\mathbb{R}^d)).$$

Using the functions v^{**}, Calderón defines a normed space $X \subset L^1(\mathbb{R}^d) + L^\infty(\mathbb{R}^d)$ as *rearrangement invariant* if

$$f \in X \text{ and } g^{**}(s) \leq f^{**}(s),\ s \geq 0, \implies g \in X \text{ and } \|g\|_X \leq \|f\|_X.$$

Calderón showed that the interpolation spaces for the pair $(L_1(\mathbb{R}^d), L_\infty(\mathbb{R}^d))$ consist precisely of the set of rearrangement-invariant spaces.

As a consequence, from Lemma 4.1 we obtain the following.

THEOREM 4.2. *If the flux f is in* Lip 1, *then for any $t > 0$, the evolution operator $E = E(t)$ for the conservation law* (1.1) *when applied to an arbitrary function $u_0 \in L_1(\mathbb{R}^d) + L_\infty(\mathbb{R}^d)$ satisfies*

$$E(u_0)^{**}(s) \leq u_0^{**}(s), \quad s \geq 0. \tag{4.7}$$

In particular, E maps every rearrangement-invariant space X on $\mathbb{R}^d$ into itself with norm 1.

Inequality (4.7) gives precise information about the relative sizes of u_0 and Eu_0. For example, if we let $d = 1$, $f(u) = u^2$, u_0 equal the characteristic function of $[0, 1]$,

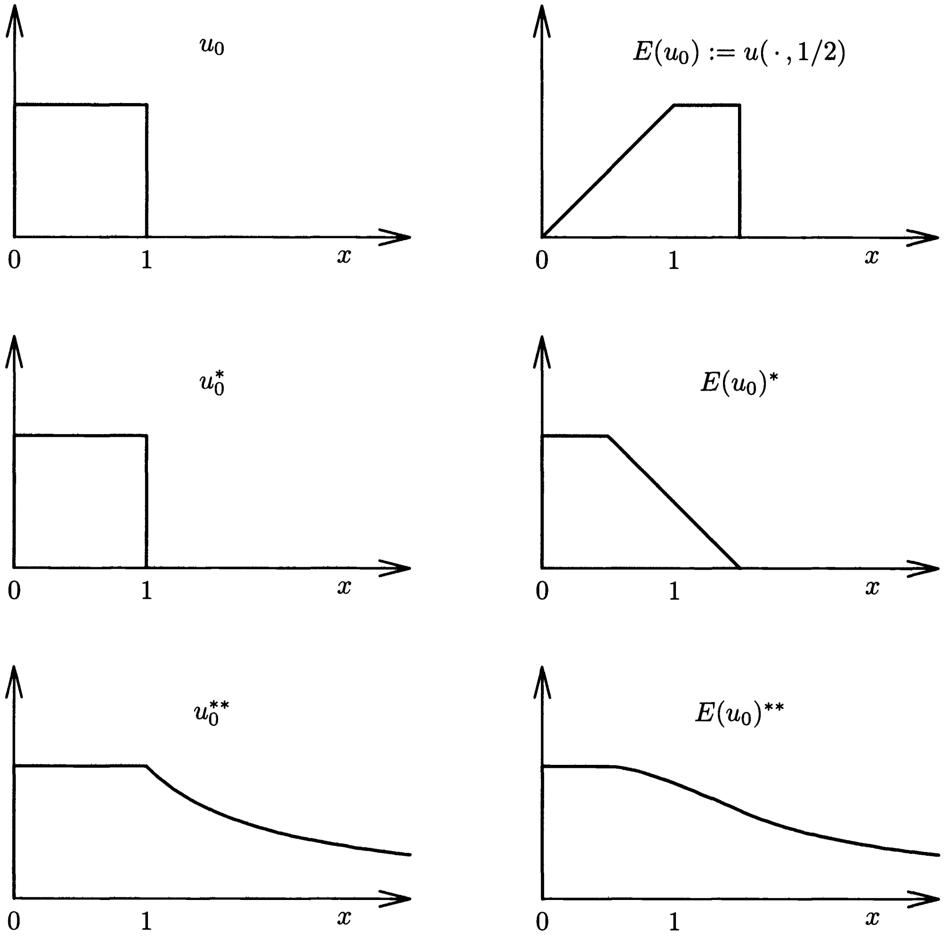

FIG. 2. *For these figures, the flux is $f(u) = u^2$. The initial data $u_0 = \chi_{[0,1]}$, its nonincreasing rearrangement u_0^*, and u_0^{**}, the maximal function of u_0^*. Similarly for $E(u_0) := u(\cdot, 1/2)$.*

and $t = 1/2$, then $u_0 = u_0^*$,

$$E(u_0)(x) = \begin{cases} 0, & x \le 0, \\ x, & 0 \le x \le 1, \\ 1, & 1 \le x \le 3/2, \\ 0, & 1 < x, \end{cases} \quad \text{and} \quad E(u_0)^*(x) = \begin{cases} 0, & x < 0, \\ 1, & 0 \le x \le 1/2, \\ 3/2 - x, & 1/2 \le x \le 3/2, \\ 0, & 3/2 \le x. \end{cases}$$

Note that for $1 < x < 3/2$, $u_0^*(x) < E(u_0)^*(x)$, yet, by Theorem 4.2 (or an easy direct calculation), we have that

$$E(u_0)^{**}(x) \le u_0^{**}(x) \tag{4.8}$$

for all $x > 0$. See Figure 2.

Some examples of rearrangement-invariant spaces are the $L_p(\mathbb{R}^d)$ spaces, $1 \le p \le \infty$, and the Lorentz spaces $L_{p,q}(\mathbb{R}^d)$, $1 \le p \le \infty$, $1 \le q \le \infty$; for $p > 1$, these consist of all $v \in L_1(\mathbb{R}^d) + L_\infty(\mathbb{R}^d)$ for which

$$\|v\|_{L_{p,q}(\mathbb{R}^d)} := \left(\int_0^\infty [s^{1/p}v^{**}(s)]^q \frac{ds}{s}\right)^{\frac{1}{q}}$$

is finite. Other rearrangement-invariant function spaces include $L \log L$ and Orlicz spaces.

We note that this analysis applies to any evolution equation that both satisfies a maximum principle and is a contraction on $L_1(\mathbb{R}^d)$, and, in fact, to any translation-invariant, integral-preserving, contraction semigroup on $L_1(\mathbb{R})$ (see, e.g., [13]).

5. Regularity in Besov spaces, part I: Positive results. The remainder of this paper concerns itself with the regularity of the solution $u(\,\cdot\,,t)$ of (1.1) as measured in Besov spaces. We continue to use the notation $\tau(\alpha,p) := (\alpha + 1/p)^{-1}$ and $B_s^\alpha := B_s^\alpha(L_s(\mathbb{R}^d))$.

It is well known that if the initial data u_0 is of bounded variation, then the solution $u(\,\cdot\,,t)$ of (1.1) is of bounded variation for all positive time t and

$$|u(\,\cdot\,,t)|_{\mathrm{BV}} \le |u_0|_{\mathrm{BV}} \tag{5.1}$$

for all $t > 0$. In addition, we showed in one space dimension [6], [14] that if $f \in C^{r+1}$ is globally Lipschitz continuous and uniformly convex, and $u_0 \in \mathrm{BV} \cap B^\alpha_{\tau(\alpha,1)}$ for some $1 < \alpha < r$, then for all $t > 0$, $u(\,\cdot\,,t) \in \mathrm{BV} \cap B^\alpha_{\tau(\alpha,1)}$ and

$$\|u(\,\cdot\,,t)\|_{B^\alpha_{\tau(\alpha,1)}} \le C(\|u_0\|_{B^\alpha_{\tau(\alpha,1)}} + 1), \tag{5.2}$$

where C depends only on r, t, $\|f^{(r+1)}\|_{L_\infty}$, and $|u_0|_{\mathrm{BV}}$; i.e., $\mathrm{BV} \cap B^\alpha_{\tau(\alpha,1)}$ is a regularity space for (1.1). (For the inviscid Burgers equation,

$$\|u(\,\cdot\,,t)\|_{B^\alpha_{\tau(\alpha,1)}} \le C\|u_0\|_{B^\alpha_{\tau(\alpha,1)}},$$

where C depends only on α.) One can ask whether any other spaces $B_q^\alpha(L_\sigma(\mathbb{R})) \cap \mathrm{BV}(\mathbb{R})$ are also regularity spaces for (1.1). As we have explained in the introduction, this cannot hold for Besov spaces that correspond to points above the line $\mathcal{L}_0$ or below the line $\mathcal{L}_1$ of Figure 1. Thus we can restrict our attention to spaces corresponding to points in the region bounded by $\mathcal{L}_0$, $\mathcal{L}_1$, and the x-axis. Each Besov space in this region is of the form $B_q^\alpha(L_{\tau(\alpha,p)})$ for some p between 1 and infinity, $0 < q \le \infty$, and $\alpha > 0$.

In this section, we show that if $u_0 \in \mathrm{BV} \cap B^\alpha_{\tau(\alpha,p)}$, $\alpha > 1$ and $1 \le p \le \infty$, then $u(\,\cdot\,,t)$ is in $\mathrm{BV} \cap B^\beta_{\tau(\beta,q)}$ for all $1 < q < \infty$ and $\beta < 1 + (\alpha - 1)/q$. The points $(1/\tau(\beta,q), \beta)$, $\beta = 1 + (\alpha - 1)/q$, lie on the line segment joining the points $(1,1)$ and $(1/\tau(\alpha,1), \alpha)$ in Figure 1; i.e., these spaces are intermediate to BV and $B^\alpha_{\tau(\alpha,1)}$. In the next two sections, we show that, in general, $u(\,\cdot\,,t)$ may not be in $\mathrm{BV} \cap B^\beta_{\tau(\beta,q)}$ for $1 < q < \infty$ whenever $\beta > 1 + (\alpha - 1)/q$. In particular, we can say that the $B^\alpha_{\tau(\alpha,p)}$, $\alpha > 1$, are not regularity spaces for (1.1) for any values of $p \ne 1$. As in [7], we can remove the restriction of BV functions if $f(u) = u^2$.

We first prove the following lemma, which holds for general functions v, not necessarily solution of (1.1).

LEMMA 5.1. *If $v \in \mathrm{BV} \cap B^\alpha_{\tau(\alpha,1)}$, $\alpha > 1$, then $v \in B^\beta_\sigma(L_{\tau(\beta,p)})$ for $\beta = 1 + (\alpha - 1)/p$, $1 < p < \infty$, and $\sigma = p\tau(\alpha,1)$.*

Proof. The proof will be based on a standard interpolation argument. We take as the BV-seminorm

$$|v|_{\mathrm{BV}} = \sup_{s>0} \frac{\omega_1(v,s)_1}{s}.$$

Since for any $r \geq 1$, $\omega_r(v,s)_1 \leq 2^{r-1}\omega_1(v,s)_1$, we have

$$\omega_r(v,s)_1 \leq C\omega_1(v,s)_1 \leq C\, s|v|_{\mathrm{BV}}$$

with C depending only on r.

We now assume that $1 < \alpha < r$, and we write $\mu := \tau(\alpha, 1)$ and $\lambda := \tau(\beta, p)$, i.e.,

$$\frac{1}{\mu} = \alpha + 1 \text{ and } \frac{1}{\lambda} = \beta + \frac{1}{p} = \frac{\alpha}{p} + 1.$$

Notice that

$$\Big(\frac{1}{\lambda}, \beta\Big) = \frac{1}{p}\Big(\frac{1}{\mu}, \alpha\Big) + \Big(1 - \frac{1}{p}\Big)(1,1),$$

that is, $(1/\lambda, \beta)$ is a convex combination of $(1/\mu, \alpha)$ and $(1,1)$. We shall estimate $\omega_r(v,s)_\lambda$. We use the abbreviated notation $\Delta(x) := |\Delta_h^r(v,x)|$. We let p' be the conjugate exponent to p, i.e., $1/p + 1/p' = 1$. It follows from Hölder's inequality that

$$\begin{aligned}\int_{\mathbb{R}} \Delta(x)^\lambda\, dx = \int_{\mathbb{R}} \Delta(x)^{\frac{\lambda}{p'}} \Delta(x)^{\frac{\lambda}{p}}\, dx &\leq \Big(\int_{\mathbb{R}} \Delta(x)\, dx\Big)^{\frac{\lambda}{p'}} \Big(\int_{\mathbb{R}} \Delta(x)^{\frac{\lambda}{p}\frac{1}{1-\lambda/p'}}\, dx\Big)^{1-\frac{\lambda}{p'}} \\ &\leq C|v|_{\mathrm{BV}}^{\frac{\lambda}{p'}} |h|^{\frac{\lambda}{p'}} \omega_r(v,|h|)_\mu^{\mu(1-\frac{\lambda}{p'})}\end{aligned}$$

since $\mu = \frac{\lambda}{p}\frac{1}{1-\lambda/p'}$.

By taking a supremum for $|h| \leq s$, we can replace the left side by $\omega_r(v,s)_\lambda^\lambda$ and raise both sides to the power $1/\lambda$ to obtain

$$\omega_r(v,s)_\lambda \leq C|v|_{\mathrm{BV}}^{\frac{1}{p'}} s^{\frac{1}{p'}} \omega_r(v,s)_\mu^{\frac{1}{p}}, \tag{5.3}$$

where we have used the fact that $(\frac{1}{\lambda} - \frac{1}{p'})\mu = \frac{1}{p}$. Therefore,

$$\begin{aligned}\int_0^\infty [s^{-\beta}\omega_r(v,s)_\lambda]^\sigma \frac{ds}{s} &\leq C|v|_{\mathrm{BV}}^{\frac{\sigma}{p'}} \int_0^\infty s^{-\beta\sigma + \frac{\sigma}{p'}} \omega_r(v,s)_\mu^{\frac{\sigma}{p}} \frac{ds}{s} \\ &= C|v|_{\mathrm{BV}}^{\frac{\sigma}{p'}} \int_0^\infty [s^{-\alpha}\omega_r(v,s)_\mu]^\mu \frac{ds}{s}\end{aligned}$$

since $\mu = \tau(\alpha,1) = \sigma/p$ and $\alpha\mu = \beta\sigma - \sigma/p'$. Raising both sides of this inequality to the power $1/\sigma$ shows that

$$|v|_{B_\sigma^\beta(L_{\tau(\beta,p)}(\mathbb{R}))} \leq C|v|_{\mathrm{BV}}^{\frac{1}{p'}} |v|_{B_{\tau(\alpha,1)}^\alpha}^{\frac{1}{p}}. \qquad \square$$

In the next theorem, we apply Lemma 5.1 to solutions of (1.1).

THEOREM 5.2. *Let the flux f be strictly convex and in C^{r+1}. If u_0 is a function of compact support in $B_{\tau(\alpha,p)}^\alpha \cap \mathrm{BV}(\mathbb{R})$ for some $\alpha > 1$ and $1 < p \leq \infty$, then for any later time t the solution $u(\cdot, t)$ to (1.1) is in every Besov space $B_{\tau(\beta,q)}^\beta \cap \mathrm{BV}(\mathbb{R})$ for all $1 \leq q < \infty$ and $0 < \beta < 1 + (\alpha - 1)/q$.*

Proof. It may help the reader to refer to Figure 3 during the course of this proof. We first assume that $1 < q < \infty$ and $1 \leq \beta < 1 + (\alpha - 1)/q$, and we choose auxiliary

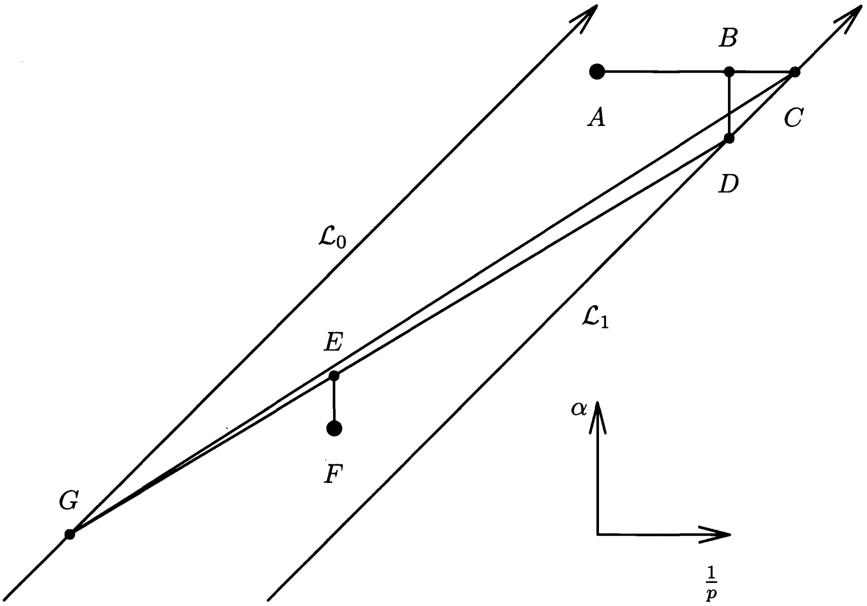

FIG. 3. *The parameters and spaces of Theorem* 5.2. *The points and the spaces are* A: $(\frac{1}{\tau(\alpha,p)},\alpha)$, $B^{\alpha}_{\tau(\alpha,p)}(L_{\tau(\alpha,p)}(\mathbb{R}))$; B: $(\frac{1}{\tau(\alpha',1)},\alpha)$, $B^{\alpha}_{\tau(\alpha,p)}(L_{\tau(\alpha',1)}(\mathbb{R}))$; C: $(\frac{1}{\tau(\alpha,1)},\alpha)$; D: $(\frac{1}{\tau(\alpha',1)},\alpha')$, $B^{\alpha'}_{\tau(\alpha',1)}(L_{\tau(\alpha',1)}(\mathbb{R}))$; E: $(\frac{1}{\tau(\beta',r)},\beta') = (\frac{1}{\tau(\beta,q)},\beta')$, $B^{\beta'}_{r\tau(\alpha',1)}(L_{\tau(\beta',r)}(\mathbb{R}))$; F: $(\frac{1}{\tau(\beta,q)},\beta)$, $B^{\beta}_{\tau(\beta,q)}(L_{\tau(\beta,q)}(\mathbb{R}))$; *and* G: $(1,1)$, $\mathrm{BV}(\mathbb{R})$). *The lines* $\mathcal{L}_0$ *and* $\mathcal{L}_1$ *are as in Figure* 1.

parameters α', β', and s that satisfy $1 < \alpha' < \alpha$, $\beta < \beta' < 1 + (\alpha' - 1)/q$, $\tau(\alpha', 1) < \tau(\alpha, p)$ and

$$\frac{1}{\tau(\beta,q)} = \beta' + \frac{1}{s},$$

i.e., $\tau(\beta, q) = \tau(\beta', s)$. Note that it is always possible to choose these parameters by first choosing α' close enough to α. It follows that $1 < s < \infty$.

We note that because u_0 has compact support, $u_0 \in B^{\alpha}_{\tau(\alpha,p)}(L_{\tau(\alpha,p)}(\mathbb{R}))$ (point A) implies that $u_0 \in B^{\alpha}_{\tau(\alpha,p)}(L_{\tau(\alpha',1)}(\mathbb{R}))$ (point B), since $\tau(\alpha', 1) < \tau(\alpha, p)$. Now, by the embedding theorems mentioned in §3, u_0 is in $B^{\alpha'}_{\tau(\alpha',1)}(L_{\tau(\alpha',1)}(\mathbb{R}))$ (point D), since $\alpha' < \alpha$.

Inequalities (5.1) and (5.2) and the fact that $u_0 \in B^{\alpha'}_{\tau(\alpha',1)}(L_{\tau(\alpha',1)}(\mathbb{R})) \cap \mathrm{BV}(\mathbb{R})$ imply that $u(\cdot\,,t)$ is in the same space for all $t > 0$. We can apply Lemma 5.1 to see that $u(\cdot\,,t)$ is in $B^{\beta'}_{s\tau(\alpha',1)}(L_{\tau(\beta',s)}(\mathbb{R})) = B^{\beta'}_{s\tau(\alpha',1)}(L_{\tau(\beta,q)}(\mathbb{R}))$ (point E). Finally, because $\beta < \beta'$, a standard embedding theorem implies that $u(\cdot\,,t)$ is in $B^{\beta}_{\tau(\beta,q)}(L_{\tau(\beta,q)}(\mathbb{R}))$ (point F), as required.

When $q = 1$ or $\beta < 1$, the theorem follows from what we have already shown and the fact that $B^{\tilde{\beta}}_{\tau(\tilde{\beta},q)}$ is embedded in $B^{\beta}_{\tau(\beta,q)}$ for any $\beta < \tilde{\beta}$. □

6. Regularity in Besov spaces, part II: Limits on regularity. Recall that a smoothness space X is a regularity space for (1.1) if $u_0 \in X \implies u(\cdot\,,t) \in X$ for all $t > 0$. We have remarked that the spaces $\mathrm{BV}(\mathbb{R}) \cap B^{\alpha}_{\tau(\alpha,1)}$ are regularity spaces for (1.1), and we gave simple arguments in the introduction to show that spaces on or above the line $\mathcal{L}_0$ with $\alpha > 1$ or below the line $\mathcal{L}_1$ cannot be regularity spaces for X. We went on to show that if u_0 is in any space $X = B^{\alpha}_{\tau(\alpha,p)} \cap \mathrm{BV}(\mathbb{R})$ for $\alpha > 1$ and $1 < p < \infty$ (i.e., between the lines $\mathcal{L}_0$ and $\mathcal{L}_1$), then the solutions $u(\,\cdot\,,t)$ remained in $B^{\beta}_{\tau(\beta,q)}$ for $1 \le q < \infty$ and $\beta < 1+(\alpha-1)/q$ for all time; we now show that the solution of (1.1) is, in general, not in any space $B^{\beta}_{\tau(\beta,q)}$ with $1 \le q < \infty$ and $\beta > 1+(\alpha-1)/q$. In particular, no Besov space B^{α}_{σ} for $\alpha > 1$ and any $\sigma \ne \tau(\alpha,1)$ is a regularity space for the one-dimensional conservation law (1.1). In this section, we analyze the inviscid Burgers equation, and in the next section we treat general strictly convex fluxes f. In §8, we generalize these results to multivariate problems.

So we consider in this section only $f(u) = u^2/2$, $\alpha > 1$, and $\tau = \tau(\alpha,p) := (\alpha+1/p)^{-1}$ for $1 < p < \infty$. For any α and p, we construct initial data $u_0 \in \mathrm{BV} \cap B^{\alpha}_{\tau(\alpha,p)}$ such that the solution $u(x,1)$ of (1.1) at time 1 is not in any space $B^{\beta}_{\tau(\beta,q)}$ for $1 \le q < \infty$ and $\beta > 1+(\alpha-1)/q$.

It is perhaps easier to first describe the solution $u(x,1)$ that we want to achieve at time 1 and then explain how to find suitable initial data u_0 that yields it. We construct a set of functions ϕ_k, $k = 1,2,\dots$, each of compact support on intervals I_k such that $\sum_k |I_k|$ is finite; our solution will be $u(\,\cdot\,,1) = u_1 := \sum_k \phi_k(\,\cdot - x_k)$, where the increasing sequence of points x_k is chosen such that $u(x,1)$ has bounded support and the supports of $\phi_k(\,\cdot - x_k)$ and $\phi_j(\,\cdot - x_j)$ don't overlap if $j \ne k$. The graph of $\phi_k(x - x_k)$ is given in Figure 4. The rightmost portion of its graph has N_k steps with height $H_k := 2^{-k}$ and width $W_k := 2^{-\alpha k}$; on the left, a linear piece with slope $1/2$ connects the top of the steps with the x axis. Precisely,

$$\phi_k(x) := \begin{cases} 0, & x \le -2N_kH_k, \\ \frac{1}{2}x + N_kH_k, & -2N_kH_k \le x \le 0, \\ (N_k - n)H_k, & nW_k \le x < (n+1)W_k,\ 0 \le n < N_k, \\ 0, & N_kW_k \le x. \end{cases}$$

We choose N_k as the greatest integer such that $N_kH_k \le k^{-r}$. If N_k is zero, then ϕ_k is defined to be zero. If $N_k > 0$ then

$$\frac{1}{2}k^{-r} \le N_kH_k \le k^{-r}. \tag{6.1}$$

The integer r will be given later. We have

$$|I_k| = 2N_kH_k + N_kW_k \le 3N_kH_k \le 3k^{-r}, \tag{6.2}$$

so $\sum_k |I_k| < \infty$ as claimed, and a set of points $\{x_k\}_{k=1}^{\infty}$ can easily be chosen with the required properties.

We obtain $u_0(x)$ by solving the associated backward problem

$$\begin{aligned} &v_t - \left(\frac{1}{2}v^2\right)_x = 0, && x \in \mathbb{R}^d,\ t > 0, \\ &v(x,0) = v_0(x) := u(x,1), && x \in \mathbb{R}^d. \end{aligned}$$

Then we take $u_0 := v(\,\cdot\,,1)$. Each jump in v_0 smooths into a linear rarefaction wave with slope -1, and the linear piece on the left of each ϕ_k evolves into a steeper profile with slope 1, but not yet a shock, at time 1. Thus, $u_0(x) := v(x,1) = \sum_k \psi_k(x - x_k)$,

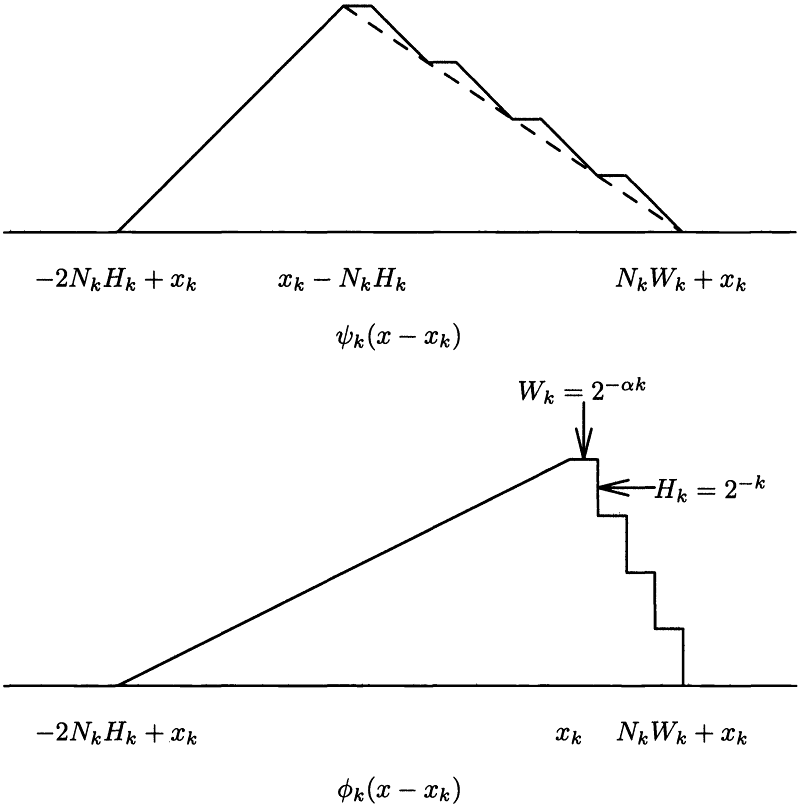

FIG. 4. *The functions $\phi_k(x - x_k)$ and $\psi_k(x - x_k)$, from which $u_0(x) = \sum_k \psi_k(x - x_k)$ and $u(x,1) = \sum_k \phi_k(x - x_k)$. The dashed line indicates the linear approximation to $\psi_k(x - x_k)$ in Theorem* 6.1.

where the continuous function ψ_k takes the values

$$\begin{cases} 0, & x = -2N_kH_k, \\ (N_k - n)H_k, & x = nW_k - (N_k - n)H_k \text{ and} \\ & x = (n+1)W_k - (N_k - n)H_k, \quad 0 \le n < N_k, \\ 0, & x = N_kW_k, \end{cases}$$

is linear between these values, and is zero outside the interval $[-2N_kH_k, N_kW_k]$. Thus, on the right, ψ_k consists of linear pieces with slopes alternating between 0 and -1. See Figure 4. Note that ψ_k has $2N_k + 1$ linear pieces and ϕ_k has $N_k + 1$ linear pieces.

It is easy to justify that u_1 is the solution to (1.1) when $t = 1$ with initial data u_0. For example, in the description of the solution given by Lax (see our §2), for $t < 1$ there is a unique solution $y(x,t)$ to (2.3). When $t = 1$ there is a unique solution to (2.3) except at breakpoints of u_1. These correspond to the jumps in u_1.

We fix $\alpha > 1$ and $1 < p < \infty$ and let r be the smallest integer that satisfies $(r-1)\tau(\alpha,p)/p > 1$, or, equivalently, $r > \alpha p + 2$.

THEOREM 6.1. *Let $1 < p < \infty$ and $\alpha > 1$ be fixed. The function u_0 defined above is in $B^{\alpha}_{\tau(\alpha,p)}$ for $\tau(\alpha,p) := (\alpha + 1/p)^{-1}$, while the function $u_1 = u(\,\cdot\,,1)$ with u the solution to* (1.1) *for this u_0 and $f(u) := u^2/2$ is not in any space $B^{\beta}_{\tau(\beta,q)}$ for any $1 < q < \infty$ and any $\beta > 1 + (\alpha - 1)/q$.*

Proof. (i) We first show that $u_0 \in B^\alpha_{\tau(\alpha,p)}$. For this purpose, we use the seminorm (3.5) for $B^\alpha_{\tau(\alpha,p)}$ that is defined using the approximation errors $\sigma_{2^j}(u_0)_p$. We fix a value of $n \geq 1$ such that $2^n \geq n^r$ and we bound $\sigma_m(u_0)$ for $m := 2^{n+3}$ by constructing a piecewise-linear approximant S to u_0 as follows.

Recall that

$$\operatorname{supp}(\phi_k) = \operatorname{supp}(\psi_k) = I_k = [-2N_kH_k, N_kW_k].$$

Outside of $\bigcup_k(x_k + I_k)$, we define S to be zero. Let $z_k := x_k + N_kW_k$ be the right endpoint of the support interval $x_k + I_k$ of $\psi_k(x - x_k)$. On each $x_k + I_k$ for $1 \leq k < n$ (i.e., where u_0 is largest), we define $S(x) := u_0(x) = \psi_k(x - x_k)$. Then S has at most $\sum_{j=1}^{n-1}(2N_j + 2) \leq 2^{n+1} + 2n \leq 2^{n+2}$ linear pieces to the left of the point z_{n-1}. To the right of z_{n-1}, we define S as follows. On any interval $x_k + I_k$, with $n \leq k \leq 2^n$ (where u_0 is of moderate size), we define S to be the continuous, piecewise-linear function that passes through the points $(x_k - 2N_kH_k, 0)$, $(x_k - N_kH_k, N_kH_k)$, and $(x_k + N_kW_k, 0)$ (the dashed line in Figure 4). To the right of z_{2^n} (where u_0 is smallest), we define S to be identically zero; we call this semi-infinite interval I_∞. Then S has at most $3 \cdot 2^n$ breakpoints to the right of z_{n-1} and hence at most $m = 2^{n+3}$ breakpoints in all.

We consider next the error $E(x) := |u_0(x) - S(x)|$ at points where E is not identically zero. On any interval $x_k + I_k$, $k = n, \dots, 2^n$, the error is no greater than W_k (since the slope of the dashed line in Figure 4 is greater than -1) and E is nonzero on a set of measure at most $N_k(W_k + H_k) \leq 2N_kH_k \leq 2k^{-r}$. Hence

$$\int_{x_k+I_k} E(x)^p\,dx \leq 2W_k^p k^{-r} \leq 2 \cdot 2^{-k\alpha p}k^{-r}. \tag{6.3}$$

On the other hand, on I_∞, $E(x) \leq N_{2^n}H_{2^n} \leq 2^{-nr}$ and E is nonzero on a set of measure not exceeding

$$\sum_{k=2^n}^\infty |I_k| \leq 3\sum_{k=2^n}^\infty \frac{1}{k^r} \leq C2^{-n(r-1)},$$

(see (6.2)) with C (here and later in this proof) depending only on r, since $r > 1$. This gives

$$\int_{I_\infty} E(x)^p\,dx \leq C2^{-nrp}2^{-n(r-1)}. \tag{6.4}$$

Adding the estimates (6.3) and (6.4), we obtain for $m = 2^{n+3}$ and n sufficiently large,

$$\begin{aligned}\sigma_m(u_0)_p^p \leq \|u_0 - S\|_p^p &\leq C2^{-nrp}2^{-n(r-1)} + 2\sum_{k=n}^{2^n} k^{-r}2^{-k\alpha p}\\ &\leq 2^{-nrp}2^{-n(r-1)} + C2^{-n\alpha p}n^{-r}\\ &\leq C2^{-n\alpha p}n^{-r}\end{aligned}$$

since $r \geq \alpha$ and $r > 1$. This inequality also holds (trivially) for all n by simply adjusting the constant C. Using this and the monotonicity of $\sigma_j(u_0)_p$, we obtain that

$$\sum_{n=1}^\infty [2^{n\alpha}\sigma_{2^n}(u_0)_p]^{\tau(\alpha,p)} \leq C\sum_{n=1}^\infty n^{-r\tau(\alpha,p)/p} < \infty$$

since $r\tau(\alpha,p)/p > 1$ by our definition of r. This shows that u_0 is in $B^{\alpha}_{\tau(\alpha,p)}$ and completes the proof of (i).

(ii) We show next that $u_1 = u(\cdot,1) \notin B^{\beta}_{\tau(\beta,q)}$ for any $1 \leq q < \infty$ and $\beta > 1 + (\alpha - 1)/q$ by giving a lower bound on $\omega_{r'}(u_1,t)_{\tau(\beta,q)}$ for any fixed $r' > \beta$. We consider any k for which ϕ_k is not identically zero, and we examine $\Delta_h^{r'}(\phi_k,x)$ for $h := h_k := W_k/r'$ and $\nu W_k - h < x < \nu W_k$, $\nu = 1,\dots,N_k$, i.e., just to the left of each jump of height H_k in ϕ_k. Since $\Delta_h^{r'}(g,x) = 0$ for any constant function g, we have for $\nu W_k - h < x < \nu W_k$,

$$\Delta_h^{r'}(\phi_k,x) = \Delta_h^{r'}(\phi_k - (N_k - \nu)H_k, x) = (-1)^{r'}H_k = (-1)^{r'}2^{-k} \tag{6.5}$$

since all values of $\phi_k(x+jh) - (N_k - \nu)H_k = 0$ in (3.1) except for $j = 0$. This holds for x on a set of measure $N_k h = N_k W_k/r' \geq C2^k k^{-r}2^{-\alpha k} = Ck^{-r}2^{-(\alpha-1)k}$.

From (6.5), we derive for $\tau := \tau(\beta,q) := (\beta + 1/q)^{-1}$,

$$\omega_{r'}(u_1,h_k)_\tau^\tau \geq |H_k|^\tau k^{-r}2^{-(\alpha-1)k} = C2^{k(1-\tau-\alpha)}k^{-r}, \tag{6.6}$$

for all k sufficiently large, say $k \geq k_0$. Using the monotonicity of $\omega_{r'}(u_1,t)_\tau$ in t, dividing the interval of integration in (3.2) into intervals $[h_{k+1},h_k)$ and discretizing the integral yields

$$|u_1|^\tau_{B^\beta_\tau} \geq C\sum_{k=k_0}^{\infty} h_k^{-\beta\tau}\omega_{r'}(u_1,h_k)_\tau^\tau \geq C\sum_{k=k_0}^{\infty} k^{-r}2^{k(\beta\tau\alpha+1-\tau-\alpha)} = \infty \tag{6.7}$$

because

$$\beta\tau\alpha + 1 - \tau - \alpha = \beta\frac{q}{\beta q+1}\alpha + 1 - \frac{q}{\beta q+1} - \alpha = \frac{\beta q + 1 - q - \alpha}{\beta q + 1} > 0.$$

Hence $u_1 \notin B^\beta_{\tau(\beta,q)}$. □

The previous theorem can be used together with embedding theorems for Besov spaces to show that none of the Besov spaces $B^\alpha_s(L_\tau)$ with $(\alpha+1)^{-1} < \tau < \alpha^{-1}$ are regularity spaces. That is, we can allow any value of s. A modification of the construction of the theorem allows this conclusion for $\tau = \alpha^{-1}$. We already remarked that no such space with $\tau > 1/\alpha$ or $\tau < 1/(\alpha+1)$ is a regularity space. We leave these details to the reader.

7. More general fluxes. We shall next show that the results of the previous section are valid for more general fluxes f. We shall assume in this section that f is a strictly convex function on $\mathbb{R}$. Then $a(u) := f'(u)$ is strictly increasing and has an inverse $b := a^{-1}$ under composition of functions. We shall assume that $a(0) = 0$ and therefore $b(0) = 0$ (this assumption could be removed with a suitable change in the construction below).

If $\alpha > 1$, let r, u_0, and u_1 be defined as in the previous section. We consider the solution $v(x,t)$ to (1.1) for the flux f and the initial condition

$$v_0(x) := b(u_0(x)), \quad x \in \mathbb{R}. \tag{7.1}$$

The same argument we have given in §6 can be applied here to show that the solution $v(x,t)$ of (1.1) for $t \leq 1$ with data v_0 is the same as $b(u(x,t))$, where $u(x,t)$ is defined in the previous section.

The next two theorems will show that for every $1 < p < \infty$ and $\alpha > 1$, the function v_0 is in $B^\alpha_{\tau(\alpha,p)}$, but $v(\cdot,1) = v_1$ is not in any space $B^\beta_{\tau(\beta,q)}$ for any $1 < q < \infty$ and

$\beta > 1 + (\alpha - 1)/q$. We shall assume in these theorems that the flux f is in C^{r+1}; it follows that a and b are in C^r.

THEOREM 7.1. *Let α, r, u_0, and $\tau := \tau(\alpha, p)$ be defined as above, and let $1 < p < \infty$. If b is in $C^r[0,1]$, then v_0 is in $B^{\alpha}_{\tau(\alpha,p)}$.*

Proof. This proof is similar to part (i) of Theorem 6.1.

It is reasonable to expect that v_0 will be as smooth as u_0 since b is smooth, but the proof is not completely trivial. We shall estimate the error in approximating v_0 by piecewise polynomials of order r with m pieces. That is, we shall estimate the error $\sigma_m(v_0)_p$ in approximating v_0 by the elements of $\Sigma_{m,r}$ in the $L_p(\mathbb{R})$ norm. We first note that since $b(0) = 0$ and $0 \le u_0(x) \le 1$, for all x, we have $0 \le v_0(x) \le \|b'\|_{L_\infty[0,1]} u_0(x)$ for all $x \in \mathbb{R}$. This implies that $v_0 \in L_p(\mathbb{R})$.

We fix an integer $n \ge 1$ and we estimate $\sigma_m(v_0)_p$ for $m \ge C_0 2^n$ with C_0 an absolute constant that is specified in the course of the proof. We let $\Psi_1 := \sum_{k=1}^{n-1} \psi_k(\,\cdot - x_k)$, $\Psi_2 := \sum_{k=n}^{2^n} \psi_k(\,\cdot - x_k)$, and $\Psi_3 := \sum_{k>2^n} \psi_k(\,\cdot - x_k)$. These functions have disjoint supports. From the definition of v_0, we have

$$v_0 = b(\Psi_1) + b(\Psi_2) + b(\Psi_3) =: b_1 + b_2 + b_3.$$

We first estimate $\sigma_m(b_1)_p$. Recall that Ψ_1 is a piecewise-linear function on $\mathbb{R}$ with no more than $C2^n$ breakpoints. We shall now show that one can add at most an additional $C_0 2^n$ breakpoints so that for any interval I in the resulting partition, $\Psi_1(I)$ is contained in an interval of length 2^{-n}. Indeed, the variation of $\psi_k \le 2/k^r$ for $k = 1, \dots, n$; hence, we need only insert at most $2k^{-r}2^n + 2$ new breakpoints for each $k = 1, \dots, n-1$ to obtain the desired partition. For each of these intervals I, we let P_I be the Taylor polynomial to b of order r expanded at the center of $\Psi_1(I)$. Then $P_I(\Psi_1)$ is a polynomial of order r on I. We define the piecewise-polynomial function S_1 by $S_1 := P_I(\Psi_1)$ for each I. Then,

$$\|b_1 - S_1\|_{L_\infty(I)} = \|b(\Psi_1) - P_I(\Psi_1)\|_{L_\infty(I)} \le \|b^{(r)}\|_{L_\infty[0,1]} 2^{-nr}.$$

Since b_1 and S_1 have compact support, it follows that

$$\sigma_m(b_1)_p \le C2^{-nr}, \quad m \ge C_0 2^n \tag{7.2}$$

with C not depending on n.

We can estimate $\sigma_m(b_2)$ in a similar way. We have shown in the proof of Theorem 6.1 that there is a piecewise-linear function $\tilde{\Psi}_2$ with at most $3 \cdot 2^n$ pieces that satisfies

$$\|\Psi_2 - \tilde{\Psi}_2\|_{L_\infty(\mathbb{R})} \le 2^{-n\alpha}.$$

Moreover, $\tilde{\Psi}_2 = \sum_{k=n}^{2^n} \tilde{\psi}_k(\,\cdot - x_k)$ with each $\tilde{\psi}_k(\,\cdot - x_k)$ a piecewise linear function with 4 pieces and $\mathrm{Var}(\tilde{\psi}_k) = \mathrm{Var}(\psi_k) \le 2k^{-r}$. Therefore, as in the previous case of Ψ_1, we can add new breakpoints and obtain a partition of $\mathbb{R}$ into at most $C_0 2^n$ intervals I such that $\tilde{\Psi}_2$ is linear on I and $\tilde{\Psi}_2(I)$ is contained in an interval of length $\le 2^{-n}$. If P_I denotes the Taylor polynomial of order r of b expanded about the center of $\tilde{\Psi}_2(I)$, then $P_I(\tilde{\Psi}_2)$ is a polynomial of order r on I. The piecewise-polynomial function S_2 is defined to be $P_I(\tilde{\Psi}_2)$ on each I. Then, for each of the intervals I, we have

$$\begin{aligned} \|b_2 - S_2\|_{L_\infty(I)} &\le \|b(\Psi_2) - b(\tilde{\Psi}_2)\|_{L_\infty(I)} + \|b(\tilde{\Psi}_2) - P_I(\tilde{\Psi}_2)\|_{L_\infty(I)} \\ &\le \|b'\|_{L_\infty[0,1]} 2^{-n\alpha} + \|b^{(r)}\|_{L_\infty[0,1]} 2^{-nr} \le C2^{-n\alpha} \end{aligned} \tag{7.3}$$

with C independent of n. Now, by (6.2), b_2 and S_2 vanish outside of a set of measure at most Cn^{-r+1} with C depending only on r. Hence, from (7.3),

$$\|b_2 - S_2\|_{L_p(\mathbb{R})} \leq Cn^{(-r+1)/p}2^{-n\alpha}.$$

It follows that

$$\sigma_m(b_2)_p \leq Cn^{(-r+1)/p}2^{-n\alpha}, \quad m \geq C_0 2^n. \tag{7.4}$$

Since $b(0) = 0$ and $\|\Psi_3\|_{L_\infty(\mathbb{R})} = \sup_{k>2^n} \|\psi_k\|_{L_\infty(\mathbb{R})} \leq 2^{-nr}$, we have

$$\|b_3\|_{L_\infty(\mathbb{R})} \leq \|b'\|_{L_\infty[0,1]}\|\Psi_3\|_{L_\infty(\mathbb{R})} \leq \|b'\|_{L_\infty[0,1]}2^{-nr}.$$

Because b_3 has compact support, we have

$$\sigma_m(b_3)_p \leq C2^{-nr}, \quad m \geq 1. \tag{7.5}$$

Now, $v_0 = b_1 + b_2 + b_3$, and therefore the estimates (7.2), (7.4), and (7.5) give

$$\sigma_m(v_0)_p \leq Cn^{(-r+1)/p}2^{-n\alpha}, \quad m \geq C_0 2^n.$$

From our assumption on r, we have $\tau(r-1)/p > 1$ and therefore

$$\sum_{n=1}^{\infty}[2^{n\alpha}\sigma_{2^n}(v_0)_p]^\tau < \infty.$$

From the characterization (3.5), we obtain that $v_0 \in B^{\alpha}_{\tau(\alpha,p)}$. □

We shall next show that $v_1 := v(\,\cdot\,,1)$ is not in any $B^{\beta}_{\tau(\beta,q)}$, for $1 \leq q < \infty$ and $\beta > (\alpha-1)/q + 1$. For this, we shall assume that

$$b'(x) \geq c, \quad x \in (0,1) \tag{7.6}$$

for some $c > 0$.

THEOREM 7.2. *Under the assumptions of Theorem* 7.1 *and the added assumption* (7.6), *we have* $v_1 \notin B^{\beta}_{\tau(\beta,q)}$ *for all* $1 \leq q < \infty$ *and* $\beta > (\alpha-1)/q + 1$.

Proof. The widths of the constant states in $b(\phi_k)$ are the same as for ϕ_k, and because of assumption (7.6), the heights of the jumps are $\geq c2^{-k}$. Therefore, the same argument as given in the proof of part (ii) of Theorem 6.1 shows that (6.7) holds with $v_1 = b(u_1)$ in place of u_1. Hence v_1 is not in $B^{\beta}_{\tau(\beta,q)}$. □

In summary, Theorems 7.1 and 7.2 give the following results.

THEOREM 7.3. *Given that* $\alpha > 1$ *and* $1 < p \leq \infty$ *and that the flux* f *to the univariate conservation law* (1.1) *has derivative* $a(u) = f'(u)$, *which is strictly increasing and whose inverse function* b *is in* C^r *with* $(r-1)\tau(\alpha,p)/p > 1$, *and also satisfies* (7.6), *the initial condition* $v_0 = b(u_0)$ *is in* $B^{\alpha}_{\tau(\alpha,p)}$ *but the solution* $v(\,\cdot\,,1)$ *to* (1.1) *at time* $t = 1$ *for this initial condition is not in any* $B^{\beta}_{\tau(\beta,q)}$, *for* $1 \leq q < \infty$ *and* $\beta > (\alpha-1)/q + 1$. *Consequently, none of the spaces* $B^{\alpha}_{\tau}(L_\tau)$, $\tau \neq 1/(\alpha+1)$ *are regularity spaces for* (1.1).

8. Regularity in several space dimensions.

We shall next consider the regularity of the solution to the conservation law (1.1) in several space dimensions. The proof that the spaces B^{α}_{τ}, $\tau = (\alpha+1)^{-1}$, are regularity spaces for conservation laws in one space dimension rests on the fact that they arise in the characterization of approximation classes for methods of nonlinear approximation in $L_1(\mathbb{R})$ such as wavelets and free-knot splines. The Besov spaces $B^{\alpha}_{\tau}(L_\tau(\mathbb{R}^d))$, $\tau = (\alpha/d+1)^{-1}$, play the analogous role in nonlinear approximation in several space dimensions. For example, they arise in the characterization of nonlinear approximation by wavelet sums (see [4]). One might expect therefore that they are regularity spaces for conservation laws in several space dimensions. We shall show that this is not the case when $\alpha > 1$.

We assume that $a(u) := f'(u)$ is a continuously differentiable mapping from $\mathbb{R} \to \mathbb{R}^d$ and

$$\text{(i)} \quad a(0) = 0,$$
$$\text{(ii)} \quad a'(0) \neq 0.$$

A slight change in the argument given below would allow the point 0 to be replaced by any other point $x \in \mathbb{R}$.

We write $a(u) =: (a_1(u), \dots, a_d(u))$. Without loss of generality, we can assume that $a_1'(0) \neq 0$ and $a_1'(u) > 0$, in a half-neighborhood $[0, \eta]$ of 0. In order to utilize our previous notation, we shall assume that $a_1(\eta) = 1$. However, a simple modification of the arguments given below would treat the general case of η. We denote by b_1 the inverse function (under composition of functions) to a_1 on $[0, \eta]$. Then, b_1 is defined on $[0, 1]$ and satisfies condition (7.6).

THEOREM 8.1. *Let $\alpha > 1$ and $0 < \tau \leq \infty$. If $b_1 \in C^r[0,1]$ for some sufficiently large integer $r > \max(\alpha, d)$ (described in part (ii) of the proof below), then the space $B^\alpha_\tau(L_\tau(\mathbb{R}^d))$ is not a regularity space for the conservation law (1.1).*

Proof. We shall consider the following three cases.

(i) $\alpha < d(1/\tau - 1)_+$.

In this case, the space $B^\alpha_\tau(L_\tau(\mathbb{R}^d))$ contains functions that are not locally integrable and hence this space cannot be a regularity space for (1.1).

(ii) $\alpha > 1$, $\alpha \geq d(1/\tau - 1)_+$, and $\alpha < 1/\tau$.

We use our previous univariate notation $\tau(\alpha, p) := (\alpha + 1/p)^{-1}$. In this case, we can write $\tau = \tau(\alpha, p)$ for some p with $1 < p < \infty$. We shall show that there is an initial condition w_0 of compact support that is in $B^\alpha_\tau(L_\tau(\mathbb{R}^d))$ but the solution $w(\cdot, 1) = E(1)w_0$ to (1.1) is not in $B^\alpha_\tau(L_\tau(\mathbb{R}^d))$.

We shall utilize the univariate construction of §7 with some modifications. For our fixed values of α and p, we assume that r is chosen as in §§6 and 7. Then, the construction of §6 applies and we let u_0 be the univariate function given in that section. Further, we let $v(\cdot, t)$ be the solution given in §7 to the univariate conservation law (1.1) with initial condition $v_0 := b_1(u_0)$ and transport velocity a_1. We recall that we have shown in §7 that $v_0 \in B^\alpha_\tau(L_\tau(\mathbb{R}))$ but $v_1 := v(\cdot, 1)$ is not in any of the spaces $B^\beta_{\tau(\beta,q)}$ for $1 \leq q < \infty$ and $\beta > 1 + (\alpha - 1)/q$. In particular, v_1 is not $B^\alpha_\tau(L_\tau(\mathbb{R}))$.

We consider now the multivariate conservation law (1.1) with the initial condition

$$w_0(x) := v_0(x_1)\varphi(x_2, \dots, x_d), \quad x = (x_1, \dots, x_d) \in \mathbb{R}^d, \tag{8.1}$$

with $\varphi(x_2, \dots, x_d) = \phi(x_2) \cdots \phi(x_d)$ and ϕ a compactly supported $C^\infty(\mathbb{R})$ function that is one on a sufficiently large (to be chosen momentarily) interval I centered at 0 and satisfying $\|\phi\|_{L_\infty(\mathbb{R})} = 1$. We denote by Q the cube I^d. We let $w = w(x, t)$ denote the solution to (1.1) at time t with initial condition w_0.

Let $\ell \geq 1$ be such that v_0 vanishes outside of $[-\ell, \ell]$. We claim that if the sidelength of Q is chosen sufficiently large, then

$$w(x, t) = v(x_1, t), \quad \text{a.e. } x \in [-2\ell, 2\ell]^d, \ 0 \leq t \leq 1. \tag{8.2}$$

We now prove this claim. Since v_0 (and hence w_0) has compact range, for any $x \in \mathbb{R}^d$, $|a(w_0(x))| \leq C_0$ with C_0 an absolute constant and $|\cdot|$ denoting Euclidean distance. Hence, the transport-velocity vector always has length bounded by C_0.

Now, given $x \in [-2\ell, 2\ell]^d$ and $0 < t < 1$, we consider all points y that can be transported to x, that is, y should satisfy

$$x = y + ta(w_0(y)). \tag{8.3}$$

If y and z are both solutions to (8.3), then when Q is large enough both points y and z would have to come from Q (because of our estimate for the size of the transport velocity). Then, $\varphi(y_2, \dots, y_d) = 1$ and similarly for z. Hence the first components of the vectors in (8.3) give $y_1 + tu_0(y_1) = x_1 = z_1 + tu_0(z_1)$. We have already noted in the univariate analysis of §6 that this implies $y_1 = z_1$. Hence, (8.1) gives $w_0(y) = w_0(z)$ and therefore (8.3) implies $y = z$. Thus, the function $\tilde{w}$ defined by

$$\tilde{w}(x,t) := w_0(y) = v_0(y_1) = v(x_1, t),$$

with y the solution to (8.3), is well defined for $x \in [-2\ell, 2\ell]^d$, and $\tilde{w} := \tilde{w}(x,t)$ satisfies the implicit equation

$$\tilde{w} = w_0(x - ta(\tilde{w})), \quad x \in [-2\ell, 2\ell]^d, \; 0 \le t < 1. \tag{8.4}$$

A direct calculation shows that $\tilde{w}$ is a weak solution to (1.1) on $[-2\ell, 2\ell]^d \times [0,1)$, and since $\tilde{w}$ is continuous and piecewise C^r on subdomains of $[-2\ell, 2\ell]^d \times [0,1)$ with smooth boundaries, $\tilde{w}$ is an entropy solution of (1.1) in this region.

If we let $t \to 1$, then $w(\,\cdot\,, t)$ converges in $L_1(\mathbb{R}^d)$ to $w_1 := w(\,\cdot\,, 1)$. On the other hand, as $t \to 1$, $w(x,t) = v(x_1, t)$ converges to $v_1(x_1)$ a.e. on $[-2\ell, 2\ell]^d$. This shows that $w_1(x) = v_1(x_1)$, a.e. $x \in [-2\ell, 2\ell]^d$, and verifies our claim for $t = 1$.

To complete the proof of the theorem in this case, we shall estimate the Besov norms of w_0 and w_1. We first show that w_1 is not in $B^\alpha_\tau(L_\tau(\mathbb{R}^d))$. It is enough to consider differences $h = h_1 e_1$, $e_1 := (1, 0, \dots, 0)$ in the first coordinate direction, with $0 < h_1 \le 1/r$. Then, $\Delta^r_h(w_1, x) = \Delta^r_{h_1}(v_1, x_1)$ whenever $\Delta^r_{h_1}(v_1, x_1) \ne 0$ and $x \in [-2\ell, 2\ell]^d$. Hence,

$$\|\Delta^r_h(w_1, \cdot)\|_{L_\tau(\mathbb{R}^d)} \ge (4\ell)^{\frac{d-1}{\tau}} \|\Delta^r_{h_1}(v_1, \cdot)\|_{L_\tau(\mathbb{R})}, \quad 0 < h_1 \le 1/r.$$

It follows that $\omega_r(w_1, s)_\tau \ge \omega_r(v_1, s)_\tau$, $0 < s \le 1/r$. Now, we know from Theorem 6.3 that v_1 is not in the Besov space $B^\alpha_\tau(L_\tau(\mathbb{R}))$ and therefore, since $r > \alpha$ (by an earlier remark of §3),

$$\int_0^{1/r} [s^{-\alpha}\omega_r(v_1, s)_\tau]^\tau \frac{ds}{s} = \infty. \tag{8.5}$$

We can replace v_1 by w_1 in (8.5) and conclude that w_1 is not in $B^\alpha_\tau(L_\tau(\mathbb{R}^d))$.

Next, we show that w_0 is in $B^\alpha_\tau(L_\tau(\mathbb{R}^d))$. Let $s > 0$ and let $h = (h_1, \dots, h_d) \in \mathbb{R}^d$ satisfy $|h| \le s$. We define the translation operator $T(h)$ by $T(h)g := g(\,\cdot + h)$, $h \in \mathbb{R}^d$. We define the difference operator D_k by $D_k g := g(\cdot + h_1 e_1 + \cdots + h_k e_k) - g(\cdot + h_1 e_1 + \cdots + h_{k-1} e_{k-1})$ for any function g on $\mathbb{R}^d$. Then, $\Delta_h = \sum_{k=1}^d D_k$. Therefore,

$$\Delta^r_h = \sum D_{k_1} \cdots D_{k_r} \tag{8.6}$$

with the sum taken over all distinct r-tuples $(k_1, \dots, k_r)$ with $k_j \in \{1, \dots, d\}$.

We consider the effect of a general term in (8.6) on w_0. Since all the operators D_k, $k = 1, \dots, d$, and $T(h)$ commute, we can write such a term as

$$D_{k_1} \cdots D_{k_r} = T(\xi) \Delta^j_{h_1 e_1} \Delta^{\lambda_2}_{h_2 e_2} \cdots \Delta^{\lambda_d}_{h_d e_d}, \tag{8.7}$$

with $0 \le \lambda_2, \dots, \lambda_d$ and $\lambda_2 + \cdots + \lambda_d = r - j$ and ξ some point in $\mathbb{R}^d$. The difference operator $\Delta^j_{h_1e_1}$ acts only with respect to x_1, and the remaining difference operators in (8.7) applies only to $x_2, \dots, x_d$. Hence,

$$D_{k_1} \cdots D_{k_r}(w_0) = T(\xi)\Delta^j_{h_1}(v_0, x_1)\Delta^{\lambda_2}_{h_2e_2}(\phi, x_2) \cdots \Delta^{\lambda_d}_{h_de_d}(\phi, x_d).$$

Since $\phi \in C^\infty$, we have for $\mu := \min(1, \tau)$ and for a constant C depending only on d, r, and μ,

$$\omega_r(w_0, s)^\mu_\tau \le C \sum_{j=0}^{r} [s^{r-j}\omega_j(v_0, s)_\tau]^\mu, \tag{8.8}$$

where for the purposes of this formula and the formulas below we define $\omega_0(v_0, s)_\tau := \|v_0\|_{L_\tau(\mathbb{R})}$ for all s. From Marchaud's inequality (see, for example, §8 of Chapter 2 in [5]), the jth term, $j \ne 0, r$, of the sum in (8.8) for $0 < s \le 1$ can be bounded by

$$Cs^{r\mu} \int_s^\infty [\sigma^{-j}\omega_r(v_0, \sigma)_\tau]^\mu \frac{d\sigma}{\sigma} \le Cs^{r\mu} \int_s^1 [\sigma^{-j}\omega_r(v_0, \sigma)_\tau]^\mu \frac{d\sigma}{\sigma} + Cs^{r\mu}\|v_0\|^\mu_{L_\tau(\mathbb{R})}.$$

Returning to (8.8), we obtain for $s \le 1$

$$\begin{aligned} \omega_r(w_0, s)^\mu_\tau &\le Cs^{r\mu}\|v_0\|^\mu_{L_\tau(\mathbb{R})} + \omega_r(v_0, s)^\mu_\tau \\ &\qquad + Cs^{r\mu} \sum_{j=1}^{r-1} \int_s^\infty [\sigma^{-j}\chi_{[0,1]}(\sigma)\omega_r(v_0, \sigma)_\tau]^\mu \frac{d\sigma}{\sigma}. \end{aligned} \tag{8.9}$$

It follows therefore from Hardy's inequality (see, e.g., §3 of Chapter 2 of [5]) that

$$\begin{aligned} &\int_0^\infty \left[s^{-\alpha}\chi_{[0,1]}(s)\omega_r(w_0, s)_\tau\right]^\tau \frac{ds}{s} \\ &\le C\left\{\|v_0\|^\tau_{L_\tau(\mathbb{R})} + \sum_{j=1}^{r} \int_0^\infty \left[s^{r-j-\alpha}\chi_{[0,1]}(s)\omega_r(v_0, s)_\tau\right]^\tau \frac{ds}{s}\right\}. \end{aligned} \tag{8.10}$$

Since $0 \le s \le 1$, the terms $s^{r-j-\alpha}$ can each be replaced by $s^{-\alpha}$. We have remarked earlier that in the definition of the Besov norm, the integral in (3.2) can be taken over $[0, 1]$. Since v_0 is in $B^\alpha_\tau(L_\tau(\mathbb{R}))$, we conclude that the right side of (8.10) is finite, and therefore w_0 is in $B^\alpha_\tau(L_\tau(\mathbb{R}^d))$.

(iii) $\tau \ge 1/\alpha$.

This case can be proved in a similar way to (ii). We let $\tilde{v}$ be the solution to the univariate problem (1.1) with transport velocity a_1 for a compactly supported univariate function $\tilde{v}_0$ in C^∞. We can choose $\tilde{v}_0$ so that no characteristics meet before time $t = 1$ and at time $t = 1$, $\tilde{v}_1 := \tilde{v}(\,\cdot\,, 1)$ has a single downward jump discontinuity at $x = 0$ of size 1. Moreover, we can require that $\tilde{v}_1$ vanishes on $(0, \infty)$ and is continuous on $(-\infty, 0)$.

As in part (ii), we consider the initial condition $w_0 = \tilde{v}_0\varphi$ with φ as in (ii). Then w_0 is in every space $B^\alpha_\tau(L_\tau(\mathbb{R}^d))$. At time $t = 1$, for $h > 0$ sufficiently small, we have

$$|\Delta^r_{he_1}(w_1, x)| \ge 1/2, \quad x = (x_1, \dots, x_d) \in [-1, 1]^d, \quad -h \le x_1 \le 0.$$

Therefore,

$$\omega_r(w_1, s)^\tau_\tau \ge C\,s, \quad s \in [0, 1]. \tag{8.11}$$

This gives that

$$|w_1|^{\tau}_{B^{\alpha}_{\tau}(L_\tau(\mathbb{R}^d))} \geq C \int_0^1 s^{-\alpha\tau}\, ds.$$

Since $\alpha\tau \geq 1$, the last integral diverges and shows that w_1 is not in $B^{\alpha}_{\tau}(L_\tau(\mathbb{R}^d))$. □

NONUNIQUENESS AND UNIQUENESS IN THE INITIAL-VALUE PROBLEM FOR BURGERS' EQUATION*

DANIEL B. DIX†

Abstract. A sharp local existence and uniqueness theory for the initial-value problem for Burgers' equation is given in the Sobolev spaces H^s, $-1/2 < s \leq 0$. It is proved that these results cannot be extended to any $s < -1/2$ because uniqueness fails. A particular nontrivial solution is found which converges to 0 in the H^s-norm as $t \to 0^+$.

Key words. uniqueness, nonuniqueness, initial-value problem, Burgers' equation, Sobolev spaces, distributional solutions

AMS subject classifications. 35A07, 35K55, 35Q53, 35R25

Introduction. It is now an established tradition in the mathematical study of pure initial-value problems for evolutionary partial differential equations to pose these problems for inital data in various Sobolev spaces X and to consider as solutions mappings from a time interval $[0,T]$ into X which may not have sufficient regularity to qualify as classical solutions. The concept of a solution in the distributional sense has been an especially fruitful one in the study of linear problems. And by default, it has become the environment within which nonlinear problems are studied. This is despite the obvious difficulty that there is no generally satisfactory way to multiply two distributions to obtain another distribution. This fact leads us to suspect that if we insist on considering nonlinear initial-value problems with distributional initial data and distributional solutions then eventually, as the distributions become progressively more singular, some departure from the linear pattern will be observed.

As an example of what we mean by the "linear pattern," let us consider how the pure initial-value problem for the linear heat equation (see §1 for an explanation of any unfamiliar notation)

$$\begin{aligned} u_t - u_{xx} &= 0 \qquad &&\text{on } (0,T)\times\mathbb{R}, \\ u(t) &\to u_0 \qquad &&\text{in } \mathcal{S}'(\mathbb{R}) \text{ as } t\to 0^+ \end{aligned}$$

behaves in the scale of Sobolev spaces H^s, $s \in \mathbb{R}$. If $u_0 \in H^s$, then it is not hard to see that there is a solution $u \in C([0,T],H^s)$ for all $T > 0$ ($u(t)\hat{}(k) = e^{-k^2 t}\hat{u}_0(k)$ for all $t \geq 0$). This solution satisfies the equation in the sense that both terms of the equation are in $\mathfrak{D}'((0,T),H^{s-2})$ and add up to zero in that space of distributions. Actually, u is determined by a smooth function on $(0,T)\times\mathbb{R}$ which is a classical solution of the heat equation. Thus local (in fact global) solutions of the heat equation exist for (almost) arbitrarily singular initial data. Furthermore, this solution is the unique one to this problem in a very general sense. In order to make sense out of the initial condition, we should have that the distribution $u \in \mathfrak{D}'((0,T),H^s)$ be given by a mapping in $L^1_{\text{loc}}((0,T),H^s)$. It can be shown (see Theorem 2.1 below) that any such mapping which satisfies the equation in the sense of $\mathfrak{D}'((0,T),H^{s-2})$ is uniquely determined by its initial data (assumed in the topology of $\mathcal{S}'(\mathbb{R})$ as $t\to 0^+$).

*Received by the editors March 12, 1994; accepted for publication September 22, 1994. The existence theory is from the author's Ph.D. thesis directed by Charles Amick at the University of Chicago, 1988. The example of nonuniqueness was found while the author was a Postdoctoral Member of the Institute for Mathematics and Its Applications, 1988–1989. The uniqueness theory was obtained at the University of South Carolina.

†Department of Mathematics, 400E LeConte, University of South Carolina, Columbia, SC 29208 (dix@math.sc.edu).

In this paper, we will explore, by the vehicle of a simple but canonical example, what seems to be emerging as the "nonlinear pattern." Our example will be Burgers' equation,

$$\begin{aligned} u_t + uu_x - u_{xx} &= 0 \qquad \text{on } (0,T) \times \mathbb{R}, \\ u(t) &\to u_0 \qquad \text{in } H^s \text{ as } t \to 0^+. \end{aligned}$$

We will show that in a certain well-defined sense this initial-value problem is locally well posed in H^s for $s > -1/2$ (local existence, uniqueness, and continuous dependence on intial conditions) and that it fails to be well posed (in the same sense) when $s < -1/2$. Although we do not know if local solutions must exist emanating from arbitrary initial data in H^s, for any $s < -1/2$, we do know that the initial-value problem fails to be well posed because such solutions can *fail to be unique*. We will prove this by exhibiting a particular nontrivial solution $v(t)$ of Burgers' equation which converges to zero in the H^s topology as $t \to 0^+$, $s < -1/2$. Obviously, the nonuniqueness is not a result of singular data but rather one of allowing a potential solution to converge to its initial data in a too weak of a topology.

In order to justify our usage of the phrase "nonlinear pattern," we will now compare our results with some obtained by Haraux and Weissler [7] for certain semilinear parabolic equations. One particular case of their results concerned the pure initial-value problem for the semilinear heat equation

$$\begin{aligned} u_t - |u|^4 u - u_{xx} &= 0 \qquad \text{on } (0,T) \times \mathbb{R}, \\ u(t) &\to u_0 \qquad \text{in } L^p(\mathbb{R}) \text{ as } t \to 0^+ \end{aligned}$$

in the scale of Banach spaces L^p, $p \geq 1$. They showed that this initial-value problem is locally well posed in L^p for $p \geq 2$ but that it is not well posed for $1 \leq p < 2$ because, again, uniqueness fails. Their counterexample was a nontrivial self-similar solution which converges to zero as $t \to 0^+$ in the L^p-norm when $1 \leq p < 2$. Our counterexample for Burgers' equation is not (nor could be) a similarity solution. Haraux and Weissler obtained no information about whether or not multiple solutions can arise from any nonzero initial datum. In our example, we find infinitely many solutions emanating (in a weak sense) from general initial data.

Our proof of the existence and uniqueness of solutions of the initial-value problem for Burgers' equation with initial data in H^s, $s > -1/2$, is a robust contraction-mapping argument. The critical Sobolev index $s = -1/2$ is where the argument fails to yield a local solution for data of arbitrary size. This is probably a happy consequence of the simplicity of Burgers' equation and the fact that we set up the argument in the correct norms. But our results do suggest that in other situations, if the proper norms are used, breakdown of the contraction-mapping argument could signal nonuniqueness. Other heuristics might be proposed to explain "why" the critical index is $s = -1/2$. For example, is it merely coincidence that if u solves Burgers' equation, then so does $u^\lambda(x,t) = \lambda u(\lambda x, \lambda^2 t)$ and $\|u^\lambda(\cdot,t)\|_{\dot{H}^s} = \lambda^{s+1/2}\|u(\cdot,\lambda^2 t)\|_{\dot{H}^s}$? Unfortunately, we do not know how to give a generally applicable heuristic to detect the critical index.

In contrast to the robustness of our existence and uniqueness theory, our construction of the counterexample depends on the detailed knowledge of the solutions of Burgers' equation which was furnished by the Hopf–Cole transformation [8]. Although this procedure will not apply to most other equations, the flip side is that we obtain a detailed picture of what happens in the important special case of Burgers' equation. One can only conjecture at this point how much of that detailed picture is generically true. We also remark that the Hopf–Cole transformation naturally yields a local existence theory in L^1 but not in H^s, $s > -1/2$. Our existence and uniqueness theory has nothing to do with the Hopf–Cole transformation.

Lest the reader imagine that consideration of initial-value problems in Sobolev spaces of negative indices is only sensible for parabolic equations, where one is saved, so to speak, by the strong smoothing effect, we would like to point out the recent work of Kenig, Ponce, and Vega [9] concerning the Korteweg–deVries equation

$$\begin{aligned} u_t + uu_x + u_{xxx} &= 0 \qquad \text{on } (0,T) \times \mathbb{R}, \\ u(t) &\to u_0 \qquad \text{in } H^s \text{ as } t \to 0^+. \end{aligned}$$

They showed, using contraction-mapping arguments, that this problem is well posed in H^s for $s > -5/8$. The evidence is not yet compelling enough to identify $s = -5/8$ as the critical Sobolev index for this problem. However, in light of our work, it is not unreasonable to conjecture that there will be a critical index $s_0 \leq -5/8$ and that uniqueness will fail for $s < s_0$.

One feature of any result asserting uniqueness of solutions of a nonlinear initial-value problem lying in $C([0,T], H^s)$ for $s < 0$ is the need to make rigorous sense of the equation for every potential solution. The usual procedure, followed for example by Kenig, Ponce, and Vega, is to prove that a solution exists in a proper subset of $C([0,T], H^s)$ and then to prove that it is unique only with respect to competitors lying in that subset. That is because in order for something to be a competitor, we must be able to decide if it satisfies the equation or not. Since we only know how to multiply functions, not general distributions, this proper subset invariably consists only of functions. So the appearance of generality which results from discussion of the space $C([0,T], H^s)$ of distributions is an illusion, since all the potential solutions are functions.

In this respect, the uniqueness theorem we present is different. We will give a well-defined sense in which every element of $C([0,T], H^s)$ either is or is not a solution of Burgers' equation. Thus we avoid making the a priori restriction to a proper subset of $C([0,T], H^s)$. However, from the standpoint of hindsight, our uniqueness theorem shows that only functions in the proper subset occur as solutions. The idea behind the way we make sense of the equation is derived from some fairly recent advances in the nonlinear theory of generalized functions; c f. Colombeau [3], Biagioni [1], Egorov [6], and Biagioni and Oberguggenburger [2]. The viewpoint of these works is to replace the distributional setting, which has some inadequacies for nonlinear problems, with the more general and more flexible setting of Colombeau generalized functions. In this work, we extract from this above mentioned body of work only the analytical ideas we need to address our problem, and hence we do not need to discuss Colombeau generalized functions directly. In a sequel to this paper [5], we will succeed in repairing the nonuniqueness herein descibed by explicitly adopting the formalism of Colombeau generalized functions.

1. Notation.

- $J = (0, \infty)$.
- $u_t, \partial_x u = u_x$ denote the partial derivatives of u with respect to t and x, respectively.
- $(\mathfrak{F}g)(k) = \hat{g}(k) = \int_{-\infty}^{\infty} e^{-ikx} g(x)\,dx$ is the Fourier transform of g. If $u(x,t)$ is a function of $x \in \mathbb{R}$ and $t \geq 0$, then $u(t)\hat{}(k)$ is the Fourier transform of u in the x variable alone.

- $m(D)$, where $m : \mathbb{R} \to \mathbb{C}$ is a function, is the Fourier multiplier operator defined formally by the rule $[m(D)g]\widehat{\ }(k) = m(k)\hat{g}(k)$. Thus $D = -i\partial_x$.
- $\mathfrak{D}((0,T))$ is the space of Schwartz test functions; $\mathfrak{D}'((0,T),X)$, where X is a topological vector space, is the space of continuous linear maps $\mathfrak{D}((0,T)) \to X$, i.e., the space of X-valued distributions.
- $\mathcal{S}(\mathbb{R})$ is the space of Schwartz tempered test functions; $\mathcal{S}'(\mathbb{R})$ is its dual as a topological vector space, i.e., the space of tempered distributions. $\mathcal{S}'(\mathbb{R},X)$, where X is a topological vector space, is the space of continuous linear maps $\mathcal{S}(\mathbb{R}) \to X$, i.e., the space of X-valued tempered distributions.
- $\|u(x)\|_{L^p(x)} = \|u\|_{L^p}$, where $L^p = L^p(\mathbb{R})$ is the ordinary Lebesgue space.
- $L^1_{\mathrm{loc}}(\Omega, X)$ is the set of measurable functions $\Omega \to X$ (where Ω is a subset of $\mathbb{R}^n$ contained in the closure of its interior and X is a Banach space) that are locally (Bochner) integrable, i.e., they are integrable on every subset of Ω which is compact in $\mathbb{R}^n$. When $X = \mathbb{R}$, we denote $L^1_{\mathrm{loc}}(\Omega,\mathbb{R}) = L^1_{\mathrm{loc}}(\Omega)$.
- $\beta(k) = (1+k^2)^{1/2}$ for all $k \in \mathbb{R}$.
- H^m, where $m \in \mathbb{R}$, is the usual Hilbert–Sobolev space consisting of all tempered distributions u such that $\beta(k)^m\hat{u}(k) \in L^2(k)$. $\|u\|_{H^m} = \|\beta(k)^m\hat{u}(k)\|_{L^2(k)}$.
- $\dot{H}^m$ is the homogeneous Hilbert–Sobolev space of all u such that $|k|^m\hat{u}(k) \in L^2(k)$; $\|u\|_{\dot{H}^m} = \|\,|k|^m\hat{u}(k)\|_{L^2(k)}$.
- L^p_s is the weighted Lebesgue space of all $v(k)$ such that $\beta(k)^s v(k) \in L^p(k)$. $\|u\|_{L^p_s} = \|\beta^s u\|_{L^p}$.
- $C(I,X)$, where $I \subset \mathbb{R}$ is an interval and X is a Banach space, denotes the space of all continuous mappings $I \to X$. $BC(I,X)$ is the Banach space of all bounded continuous mappings $I \to X$. $C^n(I,X)$ is the space of all n-times continuously differentiable mappings $I \to X$.
- $B(a,b) = \int_0^1 (1-x)^{a-1}x^{b-1}\,dx$ is the Beta function, $a>0, b>0$.
- $BC_s((0,T],H^r)$ is defined in §2 before Theorem 2.3. $BC_{s,0}((0,T],H^r)$ is defined at the beginning of §3.
- $F_{s,r}([0,T])$ is defined in §3.
- C_H is defined in Theorem 2.3. C_I is defined in Theorem 3.4.

2. The homogeneous linear equation.

In this section, we will consider the following initial-value problem:

$$u_t - u_{xx} = 0 \qquad \text{on } (0,T)\times\mathbb{R}, \tag{2.1}$$

$$u(t) \to u_0 \qquad \text{in } \mathcal{S}'(\mathbb{R}) \text{ as } t \to 0^+, \tag{2.2}$$

where $u_0 \in \mathcal{S}'(\mathbb{R})$. First we shall show that if a solution to this problem exists in the class $L^1_{\mathrm{loc}}((0,T),H^s)$, where $s \in \mathbb{R}$, then it is the only solution in that class. Then we will show that if $u_0 \in H^s$, then u defined by $u(t)\widehat{\ }(k) = e^{-k^2t}\hat{u}_0(k)$ not only lies in $L^1_{\mathrm{loc}}(J,H^s)$ and satisfies (2.1) and (2.2) but is actually much more regular and satisfies the equation in a classical sense. We will also introduce some natural function spaces which contain the solution.

THEOREM 2.1. *Suppose $s \in \mathbb{R}$, $0 < T \le \infty$, and $u \in L^1_{\mathrm{loc}}((0,T),H^s)$. Since $u \in L^1_{\mathrm{loc}}((0,T),H^{s-2}) \subset \mathfrak{D}'((0,T),H^{s-2})$ and $u_{xx} \in L^1_{\mathrm{loc}}((0,T),H^{s-2})$, we have both*

$$u_t, u_{xx} \in \mathfrak{D}'((0,T),H^{s-2}).$$

If u is such that (2.1) is satisfied in $\mathfrak{D}'((0,T),H^{s-2})$ and (2.2) is satisfied for $u_0 = 0$, then $u = 0$ in $\mathfrak{D}'((0,T),H^s)$.

Proof. Let $\iota : H^s \to H^{s-2}$ be the inclusion and let $[u]$ denote the distribution associated to the mapping u. Let $[\iota u]'$ denote the distributional derivative of $[\iota u] \in \mathfrak{D}'((0,T), H^{s-2})$. Since $\mathfrak{F} : H^{s-2} \to L^2_{s-2}$ is a continuous linear isomorphism, we can apply it to (2.1), which now reads

$$[\iota u]' - [\partial_x^2 u] = 0, \tag{2.3}$$

to obtain $[\mathfrak{F}\iota u]' - [\mathfrak{F}\partial_x^2 u] = 0$ in $\mathfrak{D}'((0,T), L^2_{s-2})$, where we have used the chain rule $\mathfrak{F}([\iota u]') = (\mathfrak{F}[\iota u])'$ and the property $\mathfrak{F}[\iota u] = [\mathfrak{F}\iota u]$, both of which are simple to prove. Since $\mathfrak{F}\iota u \in L^1_{\text{loc}}((0,T), L^2_{s-2})$, we have that $(\mathfrak{F}\iota u)\beta^{s-2} \in L^1_{\text{loc}}((0,T), L^2)$ and thus $(\mathfrak{F}\iota u)\beta^{s-2}$ has a measurable representative which we will denote by $u(t)\hat{}(k)\beta(k)^{s-2}$ for all $(t,k) \in (0,T) \times \mathbb{R}$. $u(t)\hat{}(k)$ is a measurable representative of the mapping $\mathfrak{F}\iota u$. Then $\mathfrak{F}\partial_x^2 u$ has a representative given by $-k^2 u(t)\hat{}(k)$. So the Fourier-transformed equation becomes $[u(t)\hat{}(k)]_t + [k^2 u(t)\hat{}(k)] = 0$ in $\mathfrak{D}'((0,T) \times \mathbb{R})$. Here we have used the isomorphism provided by the Schwartz kernels theorem [11], $\mathfrak{D}'((0,T), \mathfrak{D}'(\mathbb{R})) \cong \mathfrak{D}'((0,T) \times \mathbb{R})$, and the fact that under this isomorphism we have the correspondences

$$\begin{aligned}
[\mathfrak{F}\iota u] &\mapsto [u(t)\hat{}(k)], \\
[\mathfrak{F}\iota u]' &\mapsto [u(t)\hat{}(k)]_t, \\
[\mathfrak{F}\partial_x^2 u] &\mapsto [-k^2 u(t)\hat{}(k)].
\end{aligned}$$

Since $u(t)\hat{}(k)$ and $k^2 u(t)\hat{}(k)$ are in $L^1_{\text{loc}}((0,T) \times \mathbb{R})$, there exists a function $v(t)\hat{}(k) \in L^1_{\text{loc}}((0,T) \times \mathbb{R})$ which is absolutely continuous in $t \in (0,T)$ for every fixed $k \in \mathbb{R}$, $[v(t)\hat{}(k)] = [u(t)\hat{}(k)]$, and if $\partial_t(v(t)\hat{}(k))$ is defined to be the classical t-partial derivative of $v(t)\hat{}(k)$ whenever it exists (almost everywhere on $(0,T) \times \mathbb{R}$) and to be zero elsewhere, then $[\partial_t(v(t)\hat{}(k))] = [u(t)\hat{}(k)]_t$; see [10, Thm. 9.5, p. 24]. Thus we have the equation $\partial_t(v(t)\hat{}(k)) + k^2 v(t)\hat{}(k) = 0$ holding for almost every $(t,k) \in (0,T) \times \mathbb{R}$. So by Fubini's theorem, there exists a conull set $S \subset \mathbb{R}$ such that for every $k \in S$ we have that $\partial_t(v(t)\hat{}(k)) + k^2 v(t)\hat{}(k) = 0$ for almost every $t \in \mathbb{R}$. Since the product of two absolutely continuous functions is absolutely continuous and the product rule for differentiating the product holds, we have that if $k \in S$ then $\partial_t(e^{k^2 t} v(t)\hat{}(k)) = e^{k^2 t}\partial_t(v(t)\hat{}(k)) + k^2 e^{k^2 t} v(t)\hat{}(k) = 0$ for almost every $t \in (0,T)$. So $e^{k^2 t} v(t)\hat{}(k) = h(k)$ for all $(t,k) \in (0,T) \times S$, where $h(k)$ is some function defined for $k \in S$. From this equation, it follows that $h \in L^1_{\text{loc}}(\mathbb{R})$ and hence $[h] \in \mathfrak{D}'(\mathbb{R})$. For every $\theta \in \mathfrak{D}(\mathbb{R})$, we have $\int_{-\infty}^{\infty} v(t)\hat{}(k)\theta(k)\,dk = \int_{-\infty}^{\infty} e^{-k^2 t} h(k)\theta(k)\,dk \to \int_{-\infty}^{\infty} h(k)\theta(k)\,dk$ as $t \to 0^+$ by the dominated-convergence theorem. Let $v \in L^1_{\text{loc}}((0,T), L^2_s)$ be the mapping induced by $v(t)\hat{}(k)$. Then $v(t) \to [h]$ weak-$*$ in $\mathfrak{D}'(\mathbb{R})$ as $t \to 0^+$. On the other hand, $(\mathfrak{F}u)(t) \to 0$ in $\mathcal{S}'(\mathbb{R})$ as $t \to 0^+$. This implies $(\mathfrak{F}u)(t) \to 0$ weak-$*$ in $\mathcal{S}'(\mathbb{R})$ and hence weak-$*$ in $\mathfrak{D}'(\mathbb{R})$ as $t \to 0^+$. If $[h] \neq 0$, then there exist two disjoint weak-$*$ open neighborhoods of $[h]$ and 0, respectively, and hence there exists an $\epsilon > 0$ such that $v(t) \neq (\mathfrak{F}u)(t)$ for all $0 < t < \epsilon$. But $v(t) = (\mathfrak{F}u)(t)$ for almost every $t \in (0,T)$, which is a contradiction. Hence $[h] = 0$. So $v = 0$ and therefore $[u] = [\mathfrak{F}^{-1}v] = 0$ in $\mathfrak{D}'((0,T), H^s)$. □

One should compare our uniqueness theorem for (2.1) to the classical uniqueness theorems for the heat equation (see Widder [12]), which cover even the case where the initial data and the solution are allowed to grow exponentially as $|x| \to \infty$ but concern classical solutions.

THEOREM 2.2. *Suppose $s \in \mathbb{R}$, $u_0 \in H^s$, and $u(t)\hat{}(k) = e^{-k^2 t}\hat{u}_0(k)$ for all $t \in J$ and all $k \in S = \{\xi \in \mathbb{R} \mid |\hat{u}_0(\xi)| < \infty\}$. Then $u(t)\hat{}(k)$ induces a mapping v whose inverse Fourier transform $u = \mathfrak{F}^{-1}v$ satisfies $u \in C^n(J, H^r)$ for all $n \geq 0$ (an integer)* *and $r \geq s$ (a real number). Furthermore, $u(t) \to u_0$ in H^s as $t \to 0^+$ and the unique C^∞ representative of u is a classical solution of* (2.1).

Proof. The set S is conull in $\mathbb{R}$. First we will show that the mapping v induced by $u(t)\hat{\ }(k)$ satisfies $v \in C(J, L^2_r)$ for all real $r \geq s$. The following estimate shows that $v(t) \in L^2_r$ for all $t \in J$:

$$\begin{aligned} \|v(t)\|_{L^2_r} &= \|\beta(k)^{r-s}e^{-k^2t}\beta(k)^s\hat{u}_0(k)\|_{L^2(k)} \\ &\leq \sqrt{2\pi}\|\beta(k)^{r-s}e^{-k^2t}\|_{L^\infty(k)}\|u_0\|_{H^s} \\ &\leq \sqrt{2\pi}\|u_0\|_{H^s}\begin{cases} 1 & \text{if} \quad t \geq (r-s)/2, \\ \left(\frac{r-s}{2t}\right)^{(r-s)/2} e^{t-(r-s)/2} & \text{if} \quad t < (r-s)/2. \end{cases} \end{aligned} \tag{2.4}$$

Now let $t, s \geq \epsilon > 0$. A consequence of the mean-value theorem is the inequality

$$|e^{-k^2t} - e^{-k^2s}| \leq \sqrt{2}k^2e^{-\epsilon k^2}|t-s|.$$

This will imply $v \in C([\epsilon, \infty), L^2_r)$ since

$$\begin{aligned} \|v(t) - v(s)\|_{L^2_r} &= \|\beta(k)^{r-s}[e^{-k^2t} - e^{-k^2s}]\beta(k)^s\hat{u}_0(k)\|_{L^2(k)} \\ &\leq \sqrt{4\pi}\|k^2\beta(k)^{r-s}e^{-\epsilon k^2}\|_{L^\infty(k)}\|u_0\|_{H^s}|t-s|. \end{aligned}$$

So this first result follows since ϵ was arbitrary. This immediately implies that $u = \mathcal{F}^{-1}v \in C(J, H^r)$.

Now we will show that u satisfies (2.1). If $k \in S$, then $\partial_t(u(t)\hat{\ }(k)) = -k^2u(t)\hat{\ }(k)$ for every $t \in J$. $-k^2u(t)\hat{\ }(k)$ induces the mapping $\mathcal{F}\partial_x^2u \in C(J, L^2_{r-2})$. Therefore, $\partial_t(\beta(k)^{r-2}u(t)\hat{\ }(k))$ induces a mapping in $C(J, L^2)$ (namely $(\mathcal{F}\partial_x^2u)\beta^{r-2}$). Also since $u \in C(J, H^r)$, we have that $\iota u \in C(J, H^{r-2})$ and thus $\beta(k)^{r-2}u(t)\hat{\ }(k)$ induces a mapping in $C(J, L^2)$ (namely $(\mathcal{F}\iota u)\beta^{r-2}$). It follows that $[(\mathcal{F}\iota u)\beta^{r-2}]' = [(\mathcal{F}\partial_x^2u)\beta^{r-2}]$ in $\mathfrak{D}'(J, L^2)$. Now multiplication by β^{2-r} is a continuous linear map from L^2 to L^2_{r-2}. So by the chain rule, $[\mathcal{F}\iota u]' = [\mathcal{F}\partial_x^2u]$. Applying the chain rule again for the continuous linear map $\mathcal{F}^{-1} : L^2_{r-2} \to H^{r-2}$, we obtain $[\iota u]' - [\partial_x^2u] = 0$. So u satisfies (2.3). Since both ιu and ∂_x^2u are in $C(J, H^{r-2})$, we have that $\iota u \in C^1(J, H^{r-2})$. Since r is arbitrary, this implies that $u \in C^1(J, H^r)$ for all $r \in \mathbb{R}$. By the chain rule, $\partial_x^2u \in C^1(J, H^{r-2})$. Thus $\iota u \in C^2(J, H^{r-2})$ and this argument may be iterated to show that $u \in C^n(J, H^r)$ for every $n \geq 0$ and $r \in \mathbb{R}$. So there exits a unique C^∞ representative of u. So u satisfies (2.1) in a classical sense.

Finally, we will show that $u(t) \to u_0$ in H^s as $t \to 0^+$.

$$\begin{aligned} \|u(t) - u_0\|_{H^s} &= (2\pi)^{-1/2}\|\beta(k)^s(e^{-k^2t} - 1)\hat{u}_0(k)\|_{L^2} \\ &= \frac{1}{\sqrt{2\pi}}\left(\int_{-\infty}^{\infty} |e^{-k^2t} - 1|^2\beta(k)^{2s}|\hat{u}_0(k)|^2\,dk\right)^{1/2}. \end{aligned}$$

Since $|e^{-k^2t} - 1| \leq 2$ and $\beta(k)^{2s}|\hat{u}_0(k)|^2 \in L^1(k)$, we can apply the dominated-convergence theorem. □

Now we will introduce a family of specially weighted spaces which will be used in our discussion of the initial-value problem for the nonlinear Burgers' equation.

DEFINITION. *Suppose $T > 0, s \leq r$ are real numbers. Let $BC_s((0,T], H^r)$ denote the class of all mappings $u \in C([0,T], H^s) \cap C((0,T], H^r)$ that also satisfy the* *condition*

$$\text{(2.5)} \qquad \|u\|_{BC_s((0,T],H^r)} \overset{\text{def}}{=} \frac{1}{\sqrt{2\pi}} \sup_{t\in[0,T]} \|\beta(k)^s\beta(kt^{1/2})^{r-s}[\mathfrak{F}u(t)](k)\|_{L^2(k)} < \infty.$$

$BC_s((0,T],H^r)$ is a Banach space. This particular time-dependent weighting causes the $r-s$ derivatives higher than the first s derivatives of u to be increasingly deemphasized by the norm (2.5) as $t \to 0^+$. Hence the H^s-norm of $u(t)$ will be bounded absolutely for all $t \in (0,T)$ whereas the H^r-norm will be allowed to blow up as $t \to 0^+$ (assuming $r > s$). The fact that the solutions that we have found have this sort of behavior as $t \to 0^+$ can be seen from estimate (2.4).

THEOREM 2.3. *Suppose* $0 < T < \infty$, $s \in \mathbb{R}$, $u_0 \in H^s$, *and* $u(t)\hat{}(t) = e^{-k^2t}\hat{u}_0(k)$ *for all* $t \in (0,T)$ *and all* $k \in \mathbb{R}$ *such that* $|\hat{u}_0(k)| < \infty$. *Then for any real number* $r \geq s$, *we have* $u \in BC_s((0,T],H^r)$ *and* $\|u\|_{BC_s((0,T],H^r)} \leq C_H\|u_0\|_{H^s}$, *where* $C_H = \|\beta(\omega)^{r-s}e^{-\omega^2}\|_{L^\infty(\omega)}$.

Proof. The indicated continuity follows from Theorem 2.2. For the rest, we estimate

$$\begin{aligned}\|u\|_{BC_s((0,T],H^r)} &= \frac{1}{\sqrt{2\pi}} \sup_{t\in[0,T]} \|\beta(k)^s\beta(kt^{1/2})^{r-s}e^{-k^2t}\hat{u}_0(k)\|_{L^2(k)} \\ &\leq \sup_{t\in[0,T]} \|\beta(kt^{1/2})^{r-s}e^{-k^2t}\|_{L^\infty(k)} \frac{1}{\sqrt{2\pi}}\|\beta(k)^s\hat{u}_0(k)\|_{L^2(k)} \\ &= \|\beta(\omega)^{r-s}e^{-\omega^2}\|_{L^\infty(\omega)}\|u_0\|_{H^s}. \qquad \square\end{aligned}$$

3. The inhomogeneous linear equation. In preparation for consideration of the nonlinear problem (4.1)–(4.2) and to make precise the relation of (4.1) to its associated integral equation, we consider the following inhomogeneous heat equation:

$$\text{(3.1)} \qquad u_t - u_{xx} = f \qquad \text{in } \mathfrak{D}'((0,T),H^{s-2}),$$

$$\text{(3.2)} \qquad u(t) \to 0 \qquad \text{in } \mathcal{S}'(\mathbb{R}) \text{ as } t \to 0^+,$$

where $s \in \mathbb{R}$ and $f \in \mathfrak{D}'((0,T),H^{s-2})$ will be more precisely specified below. The usual procedure would be to specify some class of fs and then derive the properties of the solution u. However, first we will do the opposite: we will define our class of fs by the class where the solution u lives. This class of very general fs will be useful in our uniqueness proof. Then we will show that if g and h live in the same class as u does, then $f = \partial_x(gh)$ is contained in the class of fs. This result will, of course, have immediate applications in the next section.

DEFINITION. *Suppose* $0 < T < \infty$ *and that* $s \leq r$ *are real numbers. Define the class* $BC_{s,0}((0,T],H^r)$ *to consist of those* $u \in BC_s((0,T],H^r)$ *such that* $u(0) = 0$.

We embed $BC_{s,0}((0,T],H^r)$ into $\mathcal{S}'(\mathbb{R},H^s)$ in the following way. Suppose $u \in BC_{s,0}((0,T],H^r)$. Let $v \in BC([0,\infty),H^r)$ be the solution of the initial-value problem (2.1)–(2.2) for the heat equation with initial data given by $u(T)$. Define the mapping $\tilde{u} \in BC(\mathbb{R},H^s)$ by the rule

$$\tilde{u}(t) = \begin{cases} 0 & \text{if } t \leq 0, \\ u(t) & \text{if } t \in [0,T], \\ v(t-T) & \text{if } t \geq T. \end{cases}$$

This mapping $\tilde{u}$ determines an element of $\mathcal{S}'(\mathbb{R},H^s)$ in the usual manner.

DEFINITION. *Suppose $0 < T < \infty$ and that $s \le r$ are real numbers. Define $F_{s,r}([0,T])$ to consist of all $f \in \mathcal{S}'(\mathbb{R}, H^{s-2})$ such that $\tilde{u}_t - \tilde{u}_{xx} = f$ in $\mathcal{S}'(\mathbb{R}, H^{s-2})$ for some $u \in BC_{s,0}((0,T], H^r)$. Define*

$$\|f\|_{F_{s,r}([0,T])} \overset{\text{def}}{=} \|u\|_{BC_s((0,T],H^r)}.$$

If $v \in BC_{s,0}((0,T], H^r)$ also satisfies $\tilde{v}_t - \tilde{v}_{xx} = f$ in $\mathcal{S}'(\mathbb{R}, H^{s-2})$, then $(u-v)_t - (u-v)_{xx} = 0$ and $u(t) - v(t) \to 0$ in H^s as $t \to 0^+$. So by Theorem 2.1 we have $u = v$. Thus the norm in $F_{s,r}([0,T])$ is well defined. Also, the map $BC_{s,0}((0,T], H^r) \to F_{s,r}([0,T]) : u \mapsto \tilde{u}_t - \tilde{u}_{xx}$ is an isometric isomorphism.

Notice that every $f \in F_{s,r}([0,T])$ has compact support contained in $[0,T]$. If $\hat{f}$ denotes the Fourier transform of f in both the x and t variables, then $\hat{f}(k,\tau)$ can be thought of as the restriction to the real line of an entire L^2_{s-2}-valued function of τ. $\hat{u}$ can then be defined as the temperate L^2_s-valued distribution $\hat{u}(k,\tau) = \lim_{\epsilon \to 0^+} \hat{f}(k, \tau - i\epsilon)/(\epsilon + i\tau + k^2)$. u can then be recovered by taking the inverse Fourier transform. This procedure for recovering u from f can be made considerably more concrete when f is known to be in a more restricted class, which we will soon discuss.

First we will need a lemma which will enable us to estimate $f = \partial_x(gh)$ when g and h are in $BC_s((0,T], H^r)$.

LEMMA 3.1. *Suppose $a > 0$, $r \ge 0$ are real numbers, and $g, h \in H^r$. Then*

$$\|\beta(ka)^r [gh]\hat{}\,(k)\|_{L^\infty(k)} \le 2^{r/4} \|\beta(Da)^r g\|_{L^2} \|\beta(Da)^r h\|_{L^2}.$$

Proof. See proof of Lemma 2.3.1 in Dix [4]. □

LEMMA 3.2. *Suppose $0 < T \le 1$, $-1 < s \le 0$ and $r \ge 0$ are real numbers. Then*

$$\begin{aligned}\sup_{t \in (0,T]} t^{|s|/2} \|\beta(Dt^{1/2})^r u(t)\|_{L^2} \le \|u\|_{BC_s((0,T],H^r)} &\le \sup_{t \in (0,T]} t^{|s|/2} \|\beta(Dt^{1/2})^r u(t)\|_{L^2} \\ &\quad + \sup_{t \in [0,T]} \| |D|^s \beta(Dt^{1/2})^r u(t)\|_{L^2}.\end{aligned}$$

Proof. Since $0 \le t \le T \le 1$, we have the estimate $(1 + k^2 t)/(1 + k^2) \ge t$ for all $k \in \mathbb{R}$. Thus $t^{|s|/2} \le \beta(k)^s \beta(kt^{1/2})^{-s} \le |k|^s + t^{|s|/2}$. Now the desired estimates follow directly from the definition of $BC_s((0,T], H^r)$. □

LEMMA 3.3. *Suppose $0 < T < \infty$, $-1 < s \le 0$, and $r < 2s + 1/2$ are real numbers. Then there is a constant such that for every pair of measurable mappings $g, h : (0,T] \to L^2$, both satisfying the estimate*

$$M_g = \sup_{t \in (0,T]} t^{|s|/2} \|g(t)\|_{L^2} < \infty,$$

we have $u(t) \to 0$ in H^r as $t \to 0^+$, where $u : (0,T] \to L^2$ is defined by the rule

$$u(t) = \int_0^t e^{-D^2(t-\tau)} \partial_x [g(\tau) h(\tau)] \, d\tau$$

for all $t \in (0,T]$.

Proof. To see why the Fourier transform in x and the integral in τ commute, consult the proof of Theorem 2.3.3(1) in Dix [4]. Now estimate

$$\begin{aligned}
&\left\|\beta(D)^r \int_0^t \partial_x e^{-D^2(t-\tau)}[g(\tau)h(\tau)]\,d\tau\right\|_{L^2} \\
&= \frac{1}{\sqrt{2\pi}}\left\|\beta(k)^r \int_0^t ik e^{-k^2(t-\tau)}[g(\tau)h(\tau)]^\wedge(k)\,d\tau\right\|_{L^2(k)} \\
&\le \frac{1}{\sqrt{2\pi}}\int_0^t \|\,|k|\beta(k)^r e^{-k^2(t-\tau)}\|_{L^2(k)}\cdot\|[g(\tau)h(\tau)]^\wedge(k)\|_{L^\infty(k)}\,d\tau \\
&\le \frac{1}{\sqrt{2\pi}}M_gM_h\int_0^t \frac{\|\,|k|\beta(k)^r e^{-k^2(t-\tau)}\|_{L^2(k)}}{\tau^{|s|}}\,d\tau.
\end{aligned}\tag{3.3}$$

We have two cases. First of all, if $r \le 0$ then $\beta(k)^r \le |k|^r$. It will be convenient to assume $r > -3/2$. Once proved for such values of r, the result also follows for smaller values. So we see that the integral in (3.3) is bounded by

$$t^{(1/2+2s-r)/2}\|\,|\omega|^{1+r}e^{-\omega^2}\|_{L^2(\omega)}B((1/2+2s-r)/2, 1+s).$$

This tends to 0 as $t \to 0^+$ under our assumptions. The second case is if $r > 0$. This implies that $0 < r < 1/2 + 2s$ and thus $s > -1/4$. But we also have that $r < 2s + 1/2 \le 1/2$, and therefore $\beta(k)^r \le 1 + |k|^r$ for all $k \in \mathbb{R}$. Thus the integral in (3.3) is bounded by

$$\begin{aligned}
&t^{(1/2+2s-r)/2}\|\,|\omega|^{1+r}e^{-\omega^2}\|_{L^2(\omega)}B((1/2+2s-r)/2, 1+s) \\
&+t^{1/4+s}\|\omega e^{-\omega^2}\|_{L^2(\omega)}B(1/4, 1+s).
\end{aligned}$$

Clearly this tends to 0 as $t \to 0^+$. So the lemma is true. □

THEOREM 3.4. *Suppose* $0 < T \le 1$, $-1/2 < s \le 0$, $r \ge 0$, *and* $s \le q < r + 1/2$ *are real numbers. Let* $g, h \in X$, *where* $X = BC_s((0, T], H^r)$. *Then there exists a constant* $C_I > 0$, *depending only on* q, r, *and* s *such that* $\partial_x(gh) \in F_{s,q}([0, T])$ *and*

$$\|\partial_x(gh)\|_{F_{s,q}([0,T])} \le C_I T^{(s+1/2)/2} M_g M_h \le C_I T^{(s+1/2)/2}\|g\|_X\|h\|_X,$$

where $M_g = \sup_{t\in(0,T]} t^{|s|/2}\|\beta(D\sqrt{t})^r g\|_{L^2}$. *Furthermore, if* $u \in BC_{s,0}((0, T], H^r)$ *satisfies* (3.1)–(3.2) *with* $f = \partial_x(gh)$, *then* u *can be recovered from* f *via the formula*

$$u(t) = \int_0^t e^{-D^2(t-\tau)} f(\tau)\,d\tau$$

for all $t \in (0, T]$.

Proof. The plan of the proof is as follows: Let u be defined in terms of g and h by the above formula. First we will show that $u \in BC_{s,0}((0, T], H^q)$. Then we will show that u satisfies (3.1)–(3.2) with $f = \partial_x(gh)$. By Lemma 3.2, $gh \in L^1((0, T), L^1) \subset L^1((0, T), H^{s-1})$, and thus $\partial_x(gh) \in L^1((0, T), H^{s-2})$. So $f = \partial_x(gh)$ is a distribution in $\mathfrak{D}'((0, T), H^{s-2})$ or in $\mathcal{S}'((\mathbb{R}, H^{s-2})$ in the usual way (define f to vanish outside $(0, T)$). So if $u_t - u_{xx} = f$ in $\mathfrak{D}'((0, T), H^{s-2})$ and $u_t = f + u_{xx} \in L^1((0, T), H^{s-2})$, we have that u is absolutely continuous on $[0, T]$ with values in H^{s-2}. Therefore, $\tilde{u}_t - \tilde{u}_{xx} = f$ in $\mathcal{S}'((\mathbb{R}, H^{s-2})$. This shows that $f \in F_{s,q}([0, T])$.

First we will bound the $BC_s((0,T],H^q)$-norm of u. It suffices to do the case where $r \leq q < r+1/2$, since the norm is a nondecreasing function of q. We will use the second estimate of Lemma 3.2 to control u. Since $k^4(t-\tau)\tau \geq 0$, we have the inequality $(1+k^2t) \leq (1+(t-\tau)k^2)(1+\tau k^2)$ holding for all $k \in \mathbb{R}$ and $0 \leq \tau \leq t$. So

$$\beta(k\sqrt{t}) \leq \beta(k\sqrt{t-\tau})\beta(k\sqrt{\tau}).$$

Using this inequality and Lemma 3.1, we have that

$$\begin{aligned} t^{|s|/2}&\left\|\beta(D\sqrt{t})^q \int_0^t \partial_x e^{-D^2(t-\tau)}[g(\tau)h(\tau)]\,d\tau\right\|_{L^2} \\ &= \frac{t^{|s|/2}}{\sqrt{2\pi}}\left\|\int_0^t \beta(k\sqrt{t})^q ike^{-k^2(t-\tau)}[g(\tau)h(\tau)]\hat{}(k)\,d\tau\right\|_{L^2(k)} \\ &\leq \frac{t^{|s|/2}}{\sqrt{2\pi}}\int_0^t \|ik\beta(k\sqrt{t})^{q-r}\beta(k\sqrt{t-\tau})^r e^{-k^2(t-\tau)}\|_{L^2(k)} \\ &\qquad\qquad \cdot \|\beta(k\sqrt{\tau})^r[g(\tau)h(\tau)]\hat{}(k)\|_{L^\infty(k)}\,d\tau \\ &\leq \frac{2^{r/4}t^{|s|/2}}{\sqrt{2\pi}}M_gM_h\int_0^t \frac{\|ik\beta(k\sqrt{t})^{q-r}\beta(k\sqrt{\tau})^r e^{-k^2\tau}\|_{L^2(k)}}{(t-\tau)^{|s|}}\,d\tau \\ &\leq \frac{2^{r/4-1/2}}{\pi^{1/2}}t^{1/4+s/2}M_gM_h\int_0^1 \frac{\|\omega\beta(\omega\sigma^{-1/2})^{q-r}\beta(\omega)^r e^{-\omega^2}\|_{L^2(\omega)}}{\sigma^{3/4}(1-\sigma)^{|s|}}\,d\sigma. \end{aligned}$$

Estimating in a similar way, we get

$$\begin{aligned} &\left\||D|^s\beta(D\sqrt{t})^q \int_0^t \partial_x e^{-D^2(t-\tau)}[g(\tau)h(\tau)]\,d\tau\right\|_{L^2} \\ &= \frac{1}{\sqrt{2\pi}}\left\|\int_0^t |k|^s\beta(k\sqrt{t})^q ike^{-k^2(t-\tau)}[g(\tau)h(\tau)]\hat{}(k)\,d\tau\right\|_{L^2(k)} \\ &\leq \frac{1}{\sqrt{2\pi}}\int_0^t \|\,|k|^{1+s}\beta(k\sqrt{t})^{q-r}\beta(k\sqrt{t-\tau})^r e^{-k^2(t-\tau)}\|_{L^2(k)} \\ &\qquad\qquad \cdot \|\beta(k\sqrt{\tau})^r[g(\tau)h(\tau)]\hat{}(k)\|_{L^\infty(k)}\,d\tau \\ &\leq \frac{2^{r/4}}{\sqrt{2\pi}}M_gM_h\int_0^t \frac{\|\,|k|^{1+s}\beta(k\sqrt{t})^{q-r}\beta(k\sqrt{\tau})^e e^{-k^2\tau}\|_{L^2(k)}}{(t-\tau)^{|s|}}\,d\tau \\ &\leq \frac{2^{r/4-1/2}}{\pi^{1/2}}t^{(s+1/2)/2}M_gM_h\int_0^1 \frac{\|\omega\beta(\omega\sigma^{-1/2})^{q-r}\beta(\omega)^r e^{-\omega^2}\|_{L^2(\omega)}}{\sigma^{3/4+s/2}(1-\sigma)^{-s}}\,d\sigma. \end{aligned}$$

Using Lemma 3.2, we can bound M_g by $\|g\|_X$, and likewise for h. The integrals remaining in these estimates can be shown to be finite when $q-r < 1/2$ by a similar argument to that in the proof of Lemma 2.3.2 in Dix [4]. These two estimates together give the estimate stated in the theorem.

The proof that $u : (0,T] \to H^q$ is continuous is very similar to the proof of Theorem 2.3.3(1) in Dix [4]. The fact that $u(t) \to 0$ in H^s as $t \to 0^+$ follows from Lemma 3.3. Thus we see that $u \in BC_{s,0}((0,T],H^q)$.

The proof that u satisfies (3.1) is almost exactly the same as the proof of Theorem 2.3.3(3) in Dix [4]. □

4. Local existence in $C([0,T],H^s)$, $s>-1/2$. In this section, we prove the existence of a local solution to the initial-value problem

$$u_t+\tfrac{1}{2}\partial_x(u^2)-u_{xx}=f \qquad \text{on } (0,T)\times\mathbb{R}, \tag{4.1}$$

$$u(t)\to u_0 \qquad \text{in } H^s \text{ as } t\to 0^+, \tag{4.2}$$

where $-1/2<s\le 0$, $u_0\in H^s$, and $f\in F_{s,0}([0,T])$. At the same time, we will also consider the nearby problems and how the solution we construct depends on u_0 and f. This viewpoint will then prove to be useful in our discussion of uniqueness in the next section. This initial-value problem for $s>0$ can be done in a similar way to (in fact it is easier than) what we present here.

THEOREM 4.1. *Let $0<T<\infty$, $-1/2<s\le 0\le r$, and constants K and L satisfy the condition*

$$2[C_HK+L]C_IT^{(s+1/2)/2}<1.$$

Let U be the closed ball in H^s centered at 0 and of radius K. Let V be the closed ball in $F_{s,r}([0,T])$ centered at 0 and of radius L. Then for all $u_0\in U$ and all $f\in V$, there exists a unique $u=\mathcal{U}(u_0,f)\in BC_s((0,T],H^r)$ satisfying

$$\|u\|_{BC_s((0,T],H^r)}<\frac{1}{C_IT^{(s+1/2)/2}},$$

(4.1) *in $\mathfrak{D}'((0,T),H^{s-2})$, and* (4.2). *The mapping*

$$\mathcal{U}:U\times V\to BC_s((0,T],H^r):(u_0,f)\mapsto\mathcal{U}(u_0,f)$$

is Lipschitz on $U\times V$ with respect to the metric inherited from $H^s\times F_{s,r}([0,T])$.

Proof. Let X denote the Banach space $BC_s((0,T],H^r)$. Let Y denote the Banach space $F_{s,r}([0,T])$. If $R>0$, consider the complete metric space X_R defined to be the closed ball in X centered at 0 and of radius R. Define $\Lambda=U\times V$. Consider the operator $A:X_R\times\Lambda\to X$ defined for every $(u,u_0,f)\in X\times\Lambda$ by the rule

$$A(u,u_0,f)(t)=e^{-D^2t}u_0+\int_0^t e^{-D^2(t-\tau)}f(\tau)\,d\tau-\frac{1}{2}\int_0^t e^{-D^2(t-\tau)}\partial_x[u(\tau)^2]\,d\tau \tag{4.3}$$

for all $t\in[0,T]$. We are denoting by $\int_0^t e^{-D^2(t-\tau)}f(\tau)\,d\tau$ the solution w of the inhomogeneous heat equation with right-hand side f and zero initial data that is uniquely determined by f. We use this notation even though we have not demonstrated how to make sense of it except for fs in a subclass of V. This will not cause any trouble, though, since we will only be using the fact that the mapping from f to w is an isometric isomorphism from Y onto $BC_{s,0}((0,T],H^r)\subset X$.

If we use Theorems 2.3 and 3.4, we find that

$$\|A(u,u_0,f)\|_X\le C_HK+L+\frac{1}{2}C_IT^{(s+1/2)/2}\|u\|_X^2,$$

$$\|A(u,u_0,f)-A(\tilde{u},u_0,f)\|_X\le\frac{1}{2}C_IT^{(s+1/2)/2}\|u+\tilde{u}\|_X\|u-\tilde{u}\|_X.$$

So the conditions that $A(\cdot,u_0,f)$ map X_R into itself and be a contraction there uniformly for $(u_0,f)\in\Lambda$ are

$$C_HK+L+\frac{1}{2}C_IT^{(s+1/2)/2}R^2\le R,$$

$$\kappa=C_IT^{(s+1/2)/2}R<1.$$

A necessary and sufficient condition that a number $R > 0$ exists satisfying these two inequalities is that

$$2[C_H K + L]C_I T^{(s+1/2)/2} < 1.$$

We are assuming this condition holds, and hence we know that there is a fixed point $u = \mathcal{U}(u_0, f)$ satisfying $u = A(u, u_0, f)$. For all $(u_0, f) \in \Lambda$, the fixed point $u = \mathcal{U}(u_0, f)$ is unique in X_R, where R satisfies both of the above inequalities. In particular, the fixed point satisfies the estimate we stated. On the other hand, any solution u of (4.1)–(4.2) contained in the open ball we stated must first of all be contained in X_R for some R satisfying the necessary inequalities and must also be a fixed point $u = A(u, u_0, f)$ (see Theorem 4.2 below). Hence $u = \mathcal{U}(u_0, f)$. By Theorems 2.2 and 3.4, the fixed point satisfies (4.1) in $\mathfrak{D}'((0,T), H^{s-2})$ and (4.2).

In order to prove the asserted Lipschitz continuity of $\mathcal{U}$, let $u = \mathcal{U}(u_0, f)$ and $v = \mathcal{U}(v_0, g)$ for $(u_0, f), (v_0, g) \in \Lambda$. Then

$$\begin{aligned} \|u - v\|_X &= \|A(u, u_0, f) - A(v, v_0, g)\|_X \\ &\leq \|A(u, u_0, f) - A(v, u_0, f)\|_X + \|A(v, u_0, f) - A(v, v_0, g)\|_X \\ &\leq \kappa \|u - v\|_X + C_H \|u_0 - v_0\|_{H^s} + \|f - g\|_Y. \end{aligned}$$

Since $\kappa < 1$, we therefore have

$$\|\mathcal{U}(u_0, f) - \mathcal{U}(v_0, g)\|_X \leq \frac{1}{1-\kappa}[C_H \|u_0 - v_0\|_{H^s} + \|f - g\|_Y]. \qquad \square$$

The statement of this theorem shows that the local solution is as regular as f is. However, it leaves the false impression that the time interval of existence should shrink as the measured regularity of f increases. The largest time period T of existence which can be obtained via the contraction mapping argument corresponds to $r = 0$. However, the relation between the regularity of f and that of u does not depend on T at all, as the following result shows.

THEOREM 4.2. *Suppose* $0 < T < \infty$, $-1/2 < s \leq 0 \leq r$, $u_0 \in H^s$, $f \in F_{s,r}([0,T])$, *and* $u \in BC_s((0,T], L^2)$ *satisfies* (4.1) *in* $\mathfrak{D}'((0,T), H^{s-2})$ *and* (4.2). *Then u satisfies the integral equation $u = A(u, u_0, f)$, where the operator A is defined in* (4.3) *and* $u \in BC_s((0,T], H^r)$. *In particular, if $f = 0$, then $u \in BC_s((0,T], H^r)$ for all $r \geq 0$ and is represented by a smooth function on $(0,T) \times \mathbb{R}$ which is a classical solution of* (4.1).

Proof. First we will show that $u = A(u, u_0, f)$. This follows because $u - A(u, u_0, f)$ solves the homogeneous heat equation with initial data zero and hence by Theorem 2.1 must vanish. We have $u = A(u, 0, 0) + A(0, u_0, 0) + A(0, 0, f)$. By Theorem 2.3, $A(0, u_0, 0) \in BC_s((0,T], H^r)$. By definition, $A(0, 0, f) \in BC_s((0,T], H^r)$. By Theorem 3.4, $A(u, 0, 0)$ is almost 1/2 of an x-derivative smoother than u is (a priori). Using this smoothing effect, in a finite number of steps, we can infer that u actually lies in $BC_s((0,T], H^r)$.

When $f = 0$, we can iterate this same argument infinitely many times, showing that $u \in BC_s((0,T], H^r)$ for all $r \geq 0$. Using equation (4.1), we can then infer regularity of u in the t-variable (cf. the proof of Theorem 3.1(2) in Dix [4] for the details). Thus we have that u is in fact represented by a smooth function on $(0,T) \times \mathbb{R}$. Since u solves (4.1) in a distributional sense, its smooth representative is a classical solution of (4.1). $\square$

5. Uniqueness of solutions in $C([0, T], H^s)$, $s > -1/2$. Our goal in this section is to show that there is at most one solution u to (4.1)–(4.2) in $C([0,T],H^s)$. Here $0 < T < \infty$ is not necessarily small enough so that we know at least one solution exists via a contraction mapping argument as in the previous section. Our first result shows that solutions in $BC_s((0,T],L^2)$ of (4.1)–(4.2) are unique without restricting the size of the competing solution or the size of T.

THEOREM 5.1. *Suppose* $0 < T < \infty$, $-1/2 < s \leq 0$, $u_0 \in H^s$, $f \in F_{s,0}([0,T])$. *Suppose* $u, v \in BC_s((0,T],L^2)$ *are both solutions of* (4.1) *(in the sense that all three terms are in* $\mathfrak{D}'((0,T),H^{s-2})$ *and sum to zero in that space) and* (4.2). *Then* $u = v$.

Proof. Let T' denote the least upper bound of the set

$$\{T'' \in [0,T] |\ u(t) = v(t) \text{ in } H^s \text{ for all } t \in [0,T'']\}.$$

Since $u, v \in C([0,T],H^s)$, we have $u(T') = v(T')$. Suppose, by way of contradiction, that $T' < T$. Define $u_0' = u(T') = v(T')$. Define $f' \in F_{s,0}([0,T-T'])$ as follows. Let $w \in BC_{s,0}((0,T],L^2)$ be such that $w_t - w_{xx} = f$ (see §3 for the precise sense in which w is uniquely determined). Define $w'(t) = w(t+T') - e^{-D^2t}w(T')$ for all $t \in [0,T-T']$. Clearly, $w' \in BC_{s,0}((0,T-T'],L^2)$. Let this w' be considered as an element of $\mathcal{S}'(\mathbb{R},H^s)$ as in §3 and define $f' = w_t' - w_{xx}'$. We will also use, as a shorthand for this construction, the notation $f'(t) = f(t+T')$ for all $t \in [0,T-T']$. Define $u'(t) = u(t+T')$, $v'(t) = v(t+T')$ for all $t \in [0,T-T']$. Clearly, $u', v' \in BC_s((0,T-T'],L^2)$ are both solutions of the same initial-value problem and hence by Theorem 4.2 satisfy the integral equations $u' = A(u',u_0',f')$ and $v' = A(v',u_0',f')$ on $[0,T-T']$. Following the proof of Theorem 4.1, we can choose a number $T'' \in (0,T-T']$ and a number $R > 0$ such that $A(\cdot,u_0',f')$ maps the closed ball in $BC_s((0,T''],L^2)$ centered at 0 of radius R into itself and is a contraction there, and both u' and v' are in this ball. By the uniqueness of the fixed points of contraction mappings, we have that $u'(t) = v'(t)$ for all $t \in [0,T'']$. This implies that $u(t) = v(t)$ for all $t \in [0,T'+T'']$, which contradicts the definition of T'. Hence $T' = T$ and we are done. □

Our next order of business is to make sense of the equation (4.1) for an arbitrary function in $C([0,T],H^s)$. First we note that $X = BC_s((0,T],L^2)$ is a dense subset of $C([0,T],H^s)$; in fact, it contains the dense subset $C([0,T],L^2)$. Let $Y = F_{s,0}([0,T])$. Define the nonlinear mapping $B : X \to H^s \times Y : u \mapsto (u(0), \tilde{v}_t - \tilde{v}_{xx} + \frac{1}{2}\partial_x(u^2))$, where $v(t) = u(t) - e^{-D^2t}u(0)$ for all $t \in [0,T]$. Since $v \in BC_{s,0}((0,T],L^2)$, we have $\tilde{v}_t - \tilde{v}_{xx} \in Y$. (Note also that $v_t - v_{xx} = u_t - u_{xx}$ in $\mathfrak{D}'((0,T),H^{s-2})$, and so in this sense we henceforth will write $u_t - u_{xx} \in Y$.) Theorem 3.4 shows that $\partial_x(u^2)/2 \in Y$. Thus $B(u)$ is well defined on X with values in $H^s \times Y$. B can be considered to be a densely defined discontinuous nonlinear operator on $C([0,T],H^s)$. Let $\text{gra}(B) \subset X \times H^s \times Y \subset C([0,T],H^s) \times H^s \times Y$ denote the graph of the operator B.

DEFINITION. *Suppose* $(u_0, f) \in H^s \times Y$. *We say* $u \in C([0,T],H^s)$ *satisfies* (4.1)–(4.2) *if* (u, u_0, f) *is contained in the closure of* $\text{gra}(B)$ *with respect to the topology of the ambient space* $C([0,T],H^s) \times H^s \times Y$; *i.e., there exists a family* $\{(u^\epsilon, u_0^\epsilon, f^\epsilon)\}_{\epsilon>0}$ *contained in* $X \times H^s \times Y$ *satisfying*

$$u_t^\epsilon + \frac{1}{2}\partial_x[(u^\epsilon)^2] - u_{xx}^\epsilon = f^\epsilon \qquad \text{in } Y \subset \mathfrak{D}'((0,T),H^{s-2}),$$

$$u^\epsilon(0) = u_0^\epsilon \qquad \text{in } H^s$$

such that

$$\begin{aligned} u^\epsilon &\to u && \text{in } C([0,T],H^s),\\ u_0^\epsilon &\to u_0 && \text{in } H^s,\\ f^\epsilon &\to f && \text{in } Y \end{aligned}$$

as $\epsilon \to 0^+$.

Before we prove the uniqueness of solutions of (4.1)–(4.2) in this above-defined sense, we will comment on the origin of this definition. The primary source of this formulation comes from the theory of generalized functions; cf. Colombeau [3] and Egorov [6]. In those theories, one associates to each distribution $u \in C([0,T],H^s(\mathbb{R}))$ families $\{u^\epsilon\}_{\epsilon>0}$ of smooth approximations which converge to u as $\epsilon \to 0^+$. One then defines $u_0^\epsilon(x) = u^\epsilon(x,0)$ and $f^\epsilon(x,t) = u_t^\epsilon(x,t) + \frac{1}{2}\partial_x[u^\epsilon(x,t)^2] - u_{xx}^\epsilon(x,t)$. Then one has various senses in which one can impose the equation (4.1). The strongest sense is that of equality of Colombeau generalized functions, where one would require that some norm of the difference $f^\epsilon - \tilde{f}^\epsilon$, where $\{\tilde{f}^\epsilon\}_{\epsilon>0}$ is a family of smooth approximations "canonically" associated to the distribution f, tend rapidly to zero as $\epsilon \to 0^+$, where the rate of convergence could be made arbitrarily rapid by choosing a better mollifier to generate the "canonical" smooth approximations. The weakest sense is that f^ϵ should tend to f as distributions as $\epsilon \to 0^+$. The weaker the sense in which the equation is imposed, the more far reaching the uniqueness theorem. Our sense is intermediate between these two extremes in that we require $f^\epsilon \to f$ in the space of distributions Y as $\epsilon \to 0^+$. Since we do not say anything about the rate of convergence, e.g., $O(\epsilon^N)$, we also do not need to say anything about mollifiers or "canonical" smooth approximations. Also, since we do not need u^ϵ to be smooth in order to make sense of the terms in the equation, we only require $u^\epsilon \in X$.

The other source of inspiration for our formulation is the usual theory of densely defined unbounded *linear* operators B between Banach spaces $\mathcal{X}$ and $\mathcal{Y}$. In that theory, the pairs (x,y) in the closure of the graph, provided that closure is itself a graph, are the ones where the equation $Bx = y$ makes sense. The graph of B can be closed in $\mathcal{X} \times \mathcal{Y}$ even if the domain of B is a proper subset of $\mathcal{X}$. However, this domain will in general depend on the space $\mathcal{Y}$. In our application, we chose the target space $H^s \times F_{s,0}([0,T])$ as generally and as naturally as we could see how to. This choice leads to the nice property that the graph of our nonlinear operator B is closed (see Theorem 5.3 below).

THEOREM 5.2. *If* $0 < T \leq 1$, $-1/2 < s \leq 0$, $u_0 \in H^s$, *and* $f \in F_{s,0}([0,T])$, *then there exists only one solution* $u \in C([0,T],H^s)$ *to the initial-value problem* (4.1)–(4.2) *in the above sense.*

Proof. Let $u, v \in C([0,T],H^s)$ be solutions to the initial-value problem (4.1)–(4.2) in the above sense. Arguing as in the proof of Theorem 5.1, we see that it suffices to show that there exists a number $T' \in (0,T]$ such that $u(t) = v(t)$ for all $t \in [0,T']$. Let $Y = F_{s,0}([0,T])$. Define $K = \|u_0\|_{H^s} + 1$ and $L = \|f\|_Y + 1$. Choose $T' \in (0,T]$ such that the condition in Theorem 4.1 is satisfied for T'. Define $\tilde{u} = \mathcal{U}(u_0, f)$. By symmetry, it suffices to show that $u(t) = \tilde{u}(t)$ for all $t \in [0,T']$. Let the family $\{(u^\epsilon, u_0^\epsilon, f^\epsilon)\}_{\epsilon>0}$ be given as above for the solution u. Assume $\epsilon > 0$ is sufficiently small such that $\|u_0^\epsilon\|_{H^s(\mathbb{R})} < K$ and $\|f^\epsilon\|_Y < L$. Define $\tilde{u}^\epsilon = \mathcal{U}(u_0^\epsilon, f^\epsilon) \in BC_s((0,T'],L^2)$ to be the solution whose existence is asserted in Theorem 4.1. By Theorem 5.1, we have $u^\epsilon = \tilde{u}^\epsilon$ on $[0,T']$. By the continuity asserted in Theorem 4.1, we have that

u^ϵ converges to $\tilde{u}$ in $BC_s((0,T'],L^2)$ as $\epsilon \to 0^+$. Since this implies convergence in $C([0,T'],H^s)$, we have that $u = \tilde{u}$ on $[0,T']$. □

THEOREM 5.3. *If* $0 < T \leq 1$, $-1/2 < s \leq 0$, *and the densely defined operator* B *is as we have described above, then the graph* $\operatorname{gra}(B)$ *is closed in*

$$C([0,T],H^s) \times H^s \times F_{s,0}([0,T]).$$

Proof. Let the family $\{(u^\epsilon, u_0^\epsilon, f^\epsilon)\}_{\epsilon>0}$ be given in $\operatorname{gra}(B)$ converging in the above space to (u, u_0, f). By Theorem 5.2, we have that if $0 < T' \leq T$ is sufficiently small, then for all $T_0 \in [0, T-T']$ we have $u(t+T_0) = \mathcal{U}(u(T_0), f(\cdot + T_0))$ for all $t \in [0,T']$. ($f(\cdot + T_0)$ refers to the shorthand notation introduced in the proof of Theorem 5.1.) This implies in a straightforward manner that $u \in BC_s((0,T],L^2)$ and that $(u,u_0,f) \in \operatorname{gra}(B)$. □

6. Nonuniqueness of solutions in $C([0, T], H^s)$, $s < -1/2$.

Consider the well-known "N-wave" solution of Burgers' equation (see Whitham [13])

$$u(x,t) = \frac{x}{t}\frac{\sqrt{a/t}e^{-x^2/(4t)}}{1+\sqrt{a/t}e^{-x^2/(4t)}} = -2\partial_x \ln[1+\sqrt{a/t}e^{-x^2/(4t)}],$$

where $a > 0$. In the above reference, Whitham remarks in passing about the difficulty of interpreting this solution as a solution of an initial-value problem. We make the following assertions about this solution:

(1) for every $\psi \in \mathcal{S}(\mathbb{R})$, we have $\lim_{t\to 0^+} \int_{-\infty}^{\infty} u(x,t)\psi(x)\,dx = 0$, and thus $u(t) \to 0$ in $\mathcal{S}'(\mathbb{R})$ as $t \to 0^+$;

(2) for every $1/4 < s \leq 3/4$, we have $\sup_{t>0} t^s \|u(t)\|_{L^2} < \infty$;

(3) $\lim_{t\to 0^+} t^{1/4}\|u(t)\|_{L^2} = \infty$;

(4) if $s < -1/2$, then $\|u(t)\|_{H^s} \to 0$ as $t \to 0^+$.

To prove assertion (1), we first integrate by parts:

$$\int_{-\infty}^{\infty} u(x,t)\psi(x)\,dx = 2\int_{-\infty}^{\infty} \psi'(x)\ln[1+\sqrt{a/t}e^{-x^2/(4t)}]\,dx.$$

Now define the following function:

$$v(x,t) = \begin{cases} \ln[1+\sqrt{a/t}e^{-x^2/(4t)}] & \text{if } x^2 \geq 2t\ln(a/t) \\ 0 & \text{otherwise.} \end{cases}$$

Thus we have

$$\int_{-\infty}^{\infty} u(x,t)\psi(x)\,dx = 2\int_{-\infty}^{\infty} \psi'(x)v(x,t)\,dx + 2\int_{x^2<2t\ln(a/t)} \psi'(x)\ln[1+\sqrt{a/t}e^{-x^2/(4t)}]\,dx.$$

The first integral in tends to 0 as $t \to 0^+$ by the dominated-convergence theorem since $|v(x,t)| \leq \ln 2$ for all $(x,t) \in \mathbb{R} \times J$, and for every fixed $x \in \mathbb{R} \setminus \{0\}$, we have $v(x,t) \to 0$ as $t \to 0^+$. The second integral can be bounded in absolute value by

$$4\|\psi'\|_{L^\infty(\mathbb{R})} \ln(1+\sqrt{a/t})[2t\ln(a/t)]^{1/2},$$

which also tends to 0 as $t \to 0^+$. Thus (1) is true.

In order to prove (2), we introduce the new variable $\xi = x(4t)^{-1/2}$,

$$t^{2s}\|u(t)\|_{L^2}^2 = c\int_{-\infty}^{\infty}\left|\frac{\xi e^{-\xi^2}}{t^{3/4-s}+t^{1/4-s}a^{1/2}e^{-\xi^2}}\right|^2 d\xi. \tag{6.1}$$

It is an elementary calculation to show that for every $1/4 \le s \le 3/4$, $t > 0$, and $b > 0$, we have

$$t^{3/4-s}+t^{1/4-s}b \ge \frac{1}{2}\left[\frac{b^{3/4-s}}{(3/4-s)^{3/4-s}(s-1/4)^{s-1/4}}\right]^2.$$

Using this estimate in the above with $b = a^{1/2}e^{-\xi^2}$, we obtain

$$t^{2s}\|u(t)\|_{L^2}^2 \le c\int_{-\infty}^{\infty}\left|\frac{\xi e^{-\xi^2}}{[e^{-\xi^2}]^{2(3/4-s)}}\right|^2 dx = c\int_{-\infty}^{\infty}\left|\xi e^{-2\xi^2(s-1/4)}\right|^2 d\xi.$$

This is clearly bounded if $1/4 < s \le 3/4$, and so (2) is true.

To prove (3), we rewrite (6.1) and estimate as follows:

$$\begin{aligned} t^{1/2}\|u(t)\|_{L^2}^2 &= c\int_{-\infty}^{\infty}\left|\frac{\xi}{t^{1/2}e^{\xi^2}+a^{1/2}}\right|^2 d\xi \\ &\ge c\int_{\xi^2\le(1/2)\ln(a/t)}\left|\frac{\xi}{t^{1/2}e^{\xi^2}+a^{1/2}}\right|^2 d\xi \\ &\ge c\int_{\xi^2\le(1/2)\ln(a/t)}\frac{\xi^2}{4a}\,d\xi = c[\ln(a/t)]^{3/2}. \end{aligned}$$

Since this tends to ∞ as $t \to 0^+$, (3) is true.

To prove (4), notice that $u - A(u,0,0)$ solves the heat equation with zero initial data in a distributional sense and hence must be zero. Now use (2) and Lemma 3.3 to yield the result.

Since $a > 0$ can be chosen arbitrarily, we see that there are infinitely many solutions in $C([0,T],H^s)$, $s < -1/2$, to (4.1)–(4.2) with $u_0 = 0$ and $f = 0$. This phenomenon can be understood intuitively as follows. If v solves the heat equation, then $u = -2\partial_x \ln v$ satisfies Burgers' equation. The "N-wave" solution arises from $v = 1 + \sqrt{a/t}e^{-x^2/(4t)}$, which is a solution of the heat equation with initial data $v_0 = 1 + c\delta$, where $c > 0$ depends on a and δ is the Dirac delta distribution. When we apply the function ln, however, the part tending to $c\delta$ makes no contribution in a distributional sense. The number 1 is not special. We could consider the solution of the heat equation with initial data

$$v_0(x) = \exp\left(-\frac{1}{2}\int_{-\infty}^{x} u_0(y)\,dy\right) + c\delta(x)$$

since $u = -2\partial_x \ln v$ would then satisfy Burgers' equation with initial data $u_0 \in L^1$. The initial data would be assumed in the sense of $H^s(\mathbb{R})$, $s < -1/2$, as one can show using the same method as we used to prove (4) above. Thus there are infinitely many nonequivalent solutions emerging from every initial data in L^1. Solutions u of an inhomogeneous Burgers' equation with $f \in L^1([0,T] \times \mathbb{R})$ can also be expressed in terms of solutions v of the heat equation with a potential via the same transformation $u = -2\partial_x \ln v$ [5]. Solutions of this variant of the heat equation can also be written down explicitly using the Feynman–Kac formula. If we use the same initial data v_0 as displayed above in this formula, then we see that there is nonuniqueness of solutions of the inhomogeneous Burgers' equation of the same type. We will omit the details.

Acknowledgment. The author would like to thank Hebe Biagioni for making available various material on Colombeau generalized functions.

ANALYTICITY OF SOLITARY-WAVE SOLUTIONS OF MODEL EQUATIONS FOR LONG WAVES*

YI A. LI[†] AND JERRY L. BONA[‡]

Abstract. It is shown that solitary-wave solutions of model equations for long waves have an analytic extension to a strip in the complex plane that is symmetric about the real axis. The classes of equations to which the analysis applies include equations of Korteweg–de Vries type, the regularized long-wave equations, and particular instances of nonlinear Schrödinger equations.

Key words. nonlinear dispersive wave equations, solitary waves, regularity, analyticity, Korteweg–de Vries-type equations, regularized long-wave-type equations, Schrödinger-type equations

1. Introduction. This note is concerned with solitary-wave solutions of model equations for long waves and aims to cast light on their regularity properties. The prototypical example in view is the well-known travelling-wave solution

$$u(x,t) = \phi_c(x-(c+1)t) = 3c\,\mathrm{sech}^2\left(\frac{c^{1/2}}{2}(x-(c+1)t)\right) \tag{1.1}$$

of the classical Korteweg–de Vries equation

$$u_t + u_x + uu_x + u_{xxx} = 0. \tag{1.2}$$

For any positive value of c, the function of x and t defined in (1.1) via the function ϕ_c of one real variable is an exact solution of (1.2) which is infinitely differentiable and which decays rapidly to zero at $\pm\infty$. These properties are possessed by solitary-wave solutions of a considerable range of evolution equations that feature a balance between nonlinearity and dispersion. As these special travelling-wave solutions of nonlinear, dispersive wave equations are known in many cases to play a significant role in the long-term asymptotics of general classes of solutions, they have come in for detailed study in the last couple of decades. Existence and regularity theory for solitary waves has been developed recently by Benjamin et al. [3] and Weinstein [12]. Their results apply to a broad class of model equations to be introduced presently. The outcome of these theories is that the relevant profiles ϕ_c of the solitary-wave solutions are often positive C^∞-functions having a single maximum and which decay monotonically to zero at infinity, just as does the sech^2 solutions of the Korteweg–de Vries equation displayed above. Moreover, ϕ_c and all its derivatives lie in $L_1 \cap L_\infty$.

In fact, the sech^2-solitary-wave solution of (1.2) has further regularity than just C^∞-smoothness. The function ϕ_c in (1.1) defined on the real axis $\mathbb{R}$ is real analytic and admits an analytic extension to the complex strip $\{z = x+iy : |y| < \pi/c^{1/2}\}$. It is this latter property on which attention will be focused in the present study. While the theory developed here seems to apply to a considerable range of equations, the ideas are most transparently presented in the context of the following relatively concrete

classes of model equations for waves in nonlinear dispersive media:

$$u_t + u_x + u^p u_x - (Mu)_x = 0 \qquad \text{(Korteweg–de Vries type)}, \tag{1.3}$$

$$u_t + u_x + u^p u_x + (Mu)_t = 0 \qquad \text{(regularized long-wave type)}, \tag{1.4}$$

$$iu_t - Mu + |u|^p u = 0 \qquad \text{(Schrödinger type)}. \tag{1.5}$$

In the first two models, p is a positive integer, while p is a positive even integer in (1.5). The linear operator M is a Fourier multiplier operator defined by

$$(\widehat{Mv})(\xi) = \alpha(\xi)\hat{v}(\xi) \tag{1.6}$$

whose nonnegative symbol α satisfies certain growth conditions to be spelled out presently. The linear transformation M is called the dispersion operator and its symbol α is related to the linear dispersion relation for the model in question (see Benjamin [2] or Whitham [13]).

We intend to show that as a rule, solitary-wave solutions of these model equations possess the property of being extensible to an analytic function defined on a strip in the complex plane $\mathbb{C}$, which lies symmetrically about the real axis $\mathbb{R}$ on which the wave profile is ostensibly defined. This fact is interesting in its own right, but in addition, it has implications regarding uniqueness [9] and appears to be useful in assessing whether or not a particular solitary wave is actually a soliton (cf. [5], [6], [8]).

The plan of the paper is as follows. In the next section, a few convenient notational conventions are introduced. In §3, the main result for travelling-wave solutions of Korteweg–de Vries type and regularized long-wave type is enunciated and proved. Section 4 is concerned with the analogous result for nonlinear Schrödinger equations. The paper concludes with a few comments about regularity issues related to those discussed here.

2. Notation. By $L_p = L_p(\mathbb{R})$ for p in the range $1 \le p \le \infty$, we mean the standard class of pth-power Lebesgue-integrable functions on the real line $\mathbb{R}$ with the usual modification if $p = \infty$. The standard norm on L_p will be denoted by $\| \cdot \|_p$. The Fourier transform of a Lebesgue-measurable function ϕ defined on $\mathbb{R}$ is denoted by $\hat{\phi}$ and is defined to be

$$\hat{\phi}(\xi) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \phi(x) e^{i\xi x} dx. \tag{2.1}$$

The convolution of two functions f and g defined on $\mathbb{R}$ is written $f * g$. Multiple convolution of a function with itself will appear frequently, and it is therefore convenient to introduce notation for this operation. If ϕ is a measurable function defined on $\mathbb{R}$ and n is a positive integer, define the function $\mathcal{V}_n\phi$ by the recipe

$$\mathcal{V}_1\phi = \phi,$$

and for $n > 1$,

$$\begin{aligned} \mathcal{V}_n\phi(x) &= (\phi * \mathcal{V}_{n-1}\phi)(x) \\ &= \int_{-\infty}^{\infty} \phi(x-y)\mathcal{V}_{n-1}\phi(y)dy. \end{aligned} \tag{2.2}$$

By a *solitary-wave solution* of (1.3) or (1.4) for a given positive integer p and dispersion symbol α, we shall mean a function $\phi : \mathbb{R} \to \mathbb{R}$ such that ϕ, ϕ', and $M\phi$ all lie in L_2 and such that for some positive constant c, $\phi(x-ct)$ defines an L_2-solution of (1.3) or (1.4). A similar definition will be adopted later for solutions of (1.5). As mentioned already, existence of such solutions for a wide range of symbols α has been dealt with in the recent works of Benjamin et al. [3] and Weinstein [12].

For any $x \in \mathbb{R}$, the greatest integer less than or equal to x is denoted by $\lfloor x \rfloor$.

3. Results for Korteweg–de Vries type and regularized long-wave models.

After a preparatory lemma, the principal result for equations of the types depicted in (1.3) and (1.4) is stated and proved.

LEMMA 1. *Let $c > 1$ be given. Suppose $\phi = \phi(x-ct)$ defines a solitary-wave solution of* (1.3) *or* (1.4) *for a given value of p and symbol α of the dispersion operator M. Suppose also that for some positive constants A and r, $\alpha(\xi) \geq A|\xi|^r$ for all $\xi \in \mathbb{R}$. Then the function*

$$\hat{\psi}(\xi) = \frac{\hat{\phi}(\xi)}{\sqrt{2\pi}[(p+1)(c-1)]^{\frac{1}{p}}} \tag{3.1}$$

lies in $L_1 \cap L_2$ and solves the equation

$$(1+\lambda\alpha(\xi))\,\hat{\psi}(\xi) = \mathcal{V}_{p+1}\hat{\psi}(\xi), \tag{3.2}$$

where $\lambda = 1/(c-1)$ if ϕ is a solution of (1.3) *and $\lambda = c/(c-1)$ if ϕ is a solution of* (1.4).

Proof. Suppose ϕ defines a solitary-wave solution of (1.3) as described in §2. Then

$$(-c+1)\phi' + \phi^p\phi' - M\phi' = 0,$$

from which it follows that, at least in the sense of tempered distributions,

$$[(c-1)+M]\phi - \frac{1}{p+1}\phi^{p+1} = \text{constant}. \tag{3.3}$$

Since each term on the left-hand side is an L_2-function by assumption, the constant on the right-hand side must be zero. Applying the Fourier transform to (3.3) and using (1.6) leads directly to the desired result (3.2) with $\lambda = 1/(c-1)$.

Because $c > 1$ and M has a nonnegative symbol, it follows from (3.3) with the constant equal to zero that

$$\phi = \frac{1}{p+1}[(c-1)+M]^{-1}\phi^{p+1}. \tag{3.3$'$}$$

Since $\phi \in H^1$ by assumption, the product ϕ^{p+1} is also in H^1. For any $s \in \mathbb{R}$, the linear operator $(c-1+M)^{-1}$ maps H^s into H^{s+r}. Hence it transpires from (3.3$'$) that $\phi \in H^{1+r}$. In consequence, $\phi^{p+1} \in H^{1+r}$, whence $\phi \in H^{1+2r}$, and so on. It is thus inferred that $\phi \in H^\infty$, from which it is adduced at once that

$$\int_{-\infty}^{\infty} (1+\xi^2)^m\,|\hat{\psi}(\xi)|^2 d\xi < \infty \tag{3.4}$$

for any m. An immediate consequence of (3.4) is that $\hat{\psi} \in L_1 \cap L_2$, as stated in the lemma.

The same considerations lead to the advertised result when ϕ defines instead a solitary-wave solution of (1.4). □

With this simple lemma in hand, the main issue may be confronted. The idea is to demonstrate that if ϕ defines a solitary-wave solution of (1.3) or (1.4), then its Fourier transform $\hat{\phi}$ has exponential decay at $\pm\infty$. In consequence, the Paley–Wiener theorem assures that ϕ itself is analytic in a complex strip centered about the real axis.

We begin with a special case of the main result, which will prove to be instructive and which contains the essence of the argument that applies to the more general situations.

THEOREM 2. *Let an integer $p \geq 1$ and a wave speed $c > 1$ be given. Suppose that ϕ as in Lemma 1 defines a solitary-wave solution of (1.3) or (1.4) corresponding to the dispersive symbol $\alpha(\xi) = |\xi|^m$ for some real number $m \geq 1$. Then there exists a constant $\sigma > 0$ such that for any μ with $0 < \mu < \sigma$,*

$$\sup_{\xi \in \mathbb{R}} e^{\mu|\xi|} |\hat{\phi}(\xi)| < \infty. \tag{3.5}$$

Proof. By Lemma 1, it suffices to prove (3.5) for the function $\hat{\psi}$ defined in (3.1) that satisfies equation (3.2).

For any k with $0 \leq k \leq m$ and $\lambda > 0$, define the nonnegative function f_k for $\xi \geq 0$ by

$$f_k(\xi) = \frac{\xi^k}{1 + \lambda \xi^m}.$$

It is straightforward to determine that for all $\xi \geq 0$,

$$f_k(\xi) \leq \frac{\delta_k}{\lambda^{\frac{k}{m}}}, \tag{3.6}$$

where $\delta_k = \left(\frac{k}{m}\right)^{\frac{k}{m}} \left(1 - \frac{k}{m}\right)^{1-\frac{k}{m}}$ if $0 < k < m$, and $\delta_m = \delta_0 = 1$.

Case I. $m \geq 1$ is an integer.

Suppose that $\hat{\psi}$ satisfies (3.2) and (3.4). When $0 \leq k \leq m-1$, (3.6) may be used to conclude that

$$\begin{aligned} \left|\xi^k \hat{\psi}(\xi)\right| &= \frac{|\xi|^k}{1 + \lambda|\xi|^m} \left|\mathcal{V}_{p+1} \hat{\psi}(\xi)\right| \\ &\leq \frac{\delta_k}{\lambda^{\frac{k}{m}}} \left|\mathcal{V}_{p+1} \hat{\psi}(\xi)\right| \\ &\leq \frac{1}{\lambda^{\frac{k}{m}}} \mathcal{V}_{p+1} |\hat{\psi}|(\xi) \\ &\leq \frac{1}{\lambda^{\frac{k}{m}}} \left(\frac{kp}{m} + 1\right)^{k-1} \mathcal{V}_{p+1} |\hat{\psi}|(\xi) \end{aligned} \tag{3.7}$$

for any $\xi \in \mathbb{R}$. On the other hand, for any $n \geq 0$ and any $\xi_1 \in \mathbb{R}$, we have

$$
\begin{aligned}
|\xi_1|^{m+n}|\hat{\psi}(\xi_1)| &= \frac{|\xi_1|^{m+n}}{1+\lambda|\xi_1|^m}\left|\mathcal{V}_{p+1}\hat{\psi}(\xi_1)\right| \le \frac{|\xi_1|^n}{\lambda}\mathcal{V}_{p+1}|\hat{\psi}|(\xi_1) \\
&= \frac{1}{\lambda}\int_{-\infty}^{\infty}\left|\hat{\psi}(\xi_1-\xi_2)\right|\int_{-\infty}^{\infty}\left|\hat{\psi}(\xi_2-\xi_3)\right|\int_{-\infty}^{\infty} \\
&\quad \cdots\int_{-\infty}^{\infty}\left|\left(\sum_{i=1}^{p}(\xi_i-\xi_{i+1})+\xi_{p+1}\right)^n\hat{\psi}(\xi_p-\xi_{p+1})\hat{\psi}(\xi_{p+1})\right| d\xi_{p+1}d\xi_p\cdots d\xi_2 \\
&\le \frac{1}{\lambda}\int_{-\infty}^{\infty}\cdots\int_{-\infty}^{\infty}\sum_{\sum_{i=1}^{p+1}r_i=n}\frac{n!}{r_1!\cdots r_{p+1}!} \\
&\quad \cdot\left|\xi_{p+1}^{r_{p+1}}\hat{\psi}(\xi_{p+1})\prod_{i=1}^{p}(\xi_i-\xi_{i+1})^{r_i}\hat{\psi}(\xi_i-\xi_{i+1})\right| d\xi_{p+1}\cdots d\xi_2 \\
&\le \frac{1}{\lambda}\sum_{|r|=n}\binom{n}{r}\left|(\cdot)^{r_1}\hat{\psi}(\cdot)\right| * \left|(\cdot)^{r_2}\hat{\psi}(\cdot)\right| * \cdots * \left|(\cdot)^{r_{p+1}}\hat{\psi}(\cdot)\right|(\xi_1),
\end{aligned}
\tag{3.8}
$$

where $|(\cdot)^{r_i}\hat{\psi}(\cdot)|(\xi) = |\xi^{r_i}\hat{\psi}(\xi)|$ and we have introduced the standard multiindex notation $r = (r_1, \dots, r_{p+1})$, $|r| = r_1 + \cdots + r_{p+1}$, and $\binom{n}{r} = \frac{n!}{r_1!\cdots r_{p+1}!}$. If $0 \le l \le m-1$, then using (3.7) in (3.8) leads to the inequality

$$
\begin{aligned}
|\xi_1|^{m+l}|\hat{\psi}(\xi_1)| &\le \frac{1}{\lambda}\sum_{|r|=l}\binom{l}{r}\left(\prod_{i=1}^{p+1}\frac{1}{\lambda^{\frac{r_i}{m}}}\right)\overbrace{\mathcal{V}_{p+1}|\hat{\psi}| * \cdots * \mathcal{V}_{p+1}|\hat{\psi}|}^{p+1 \text{ copies of } \mathcal{V}_{p+1}|\hat{\psi}|}(\xi_1) \\
&= \frac{1}{\lambda^{1+\frac{l}{m}}}\sum_{|r|=l}\binom{l}{r}\mathcal{V}_{(p+1)^2}|\hat{\psi}|(\xi_1) = \frac{1}{\lambda^{\frac{m+l}{m}}}(p+1)^l\mathcal{V}_{(p+1)^2}|\hat{\psi}|(\xi_1).
\end{aligned}
\tag{3.9}
$$

It follows from (3.7) and (3.9) that for any $\xi \in \mathbb{R}$ and any k with $0 \le k \le 2m-1$, one has

$$
\left|\xi^k\hat{\psi}(\xi)\right| \le \frac{1}{\lambda^{\frac{k}{m}}}\left(\frac{kp}{m}+1\right)^{k-1}\mathcal{V}_{(p+1)(\lfloor\frac{k}{m}\rfloor p+1)}|\hat{\psi}|(\xi),
\tag{3.10}
$$

where, as mentioned previously, $\lfloor\frac{k}{m}\rfloor$ denotes the greatest integer less than or equal to $\frac{k}{m}$.

It is intended to establish (3.10) for all values of k, and to this end we argue by induction, supposing that the inequality (3.10) is true for all k with $0 \le k \le nm-1$ for a fixed integer $n \ge 2$. Let $k = nm + l$ for some integer l in $[0, m-1]$. Then (3.8) and the induction hypothesis allow one to infer the following inequality:

(3.11)

$$\begin{aligned}\left|\xi^k\hat{\psi}(\xi)\right| &\le \frac{1}{\lambda}\sum_{|r|=(n-1)m+l}\binom{(n-1)m+l}{r}\left|(\cdot)^{r_1}\hat{\psi}\right| * \left|(\cdot)^{r_2}\hat{\psi}\right| * \cdots * \left|(\cdot)^{r_{p+1}}\hat{\psi}\right|(\xi)\\ &\le \frac{1}{\lambda}\sum_{|r|=(n-1)m+l}\binom{(n-1)m+l}{r}\left(\prod_{i=1}^{p+1}\frac{\left(\frac{r_ip}{m}+1\right)^{r_i-1}}{\lambda^{\frac{r_i}{m}}}\right)\mathcal{V}_{(p+1)\left(\left\lfloor\frac{r_1}{m}\right\rfloor p+1\right)}|\hat{\psi}| *\\ &\quad * \mathcal{V}_{(p+1)\left(\left\lfloor\frac{r_2}{m}\right\rfloor p+1\right)}|\hat{\psi}| * \cdots * \mathcal{V}_{(p+1)\left(\left\lfloor\frac{r_{p+1}}{m}\right\rfloor p+1\right)}|\hat{\psi}|(\xi)\\ &= \frac{1}{\lambda^{\frac{nm+l}{m}}}\sum_{|r|=(n-1)m+l}\binom{(n-1)m+l}{r}\left(\prod_{i=1}^{p+1}\left(\frac{r_ip}{m}+1\right)^{r_i-1}\right)\mathcal{V}_{\sum_{j=1}^{p+1}(p+1)\left(\left\lfloor\frac{r_j}{m}\right\rfloor p+1\right)}|\hat{\psi}|(\xi).\end{aligned}$$

If inequality (3.10) is specialized to the case $k = 0$, one infers that $|\hat{\psi}| \le \mathcal{V}_{p+1}|\hat{\psi}|$. Using this fact and the elementary formula

$$\begin{aligned}&\sum_{i=1}^{p+1}(p+1)\left(\left\lfloor\frac{r_i}{m}\right\rfloor p+1\right)\\ &= (p+1)\left(p\sum_1^{p+1}\left\lfloor\frac{r_i}{m}\right\rfloor + \sum_1^{p+1}1\right) \le (p+1)\left(p\left\lfloor\sum_1^{p+1}\frac{r_i}{m}\right\rfloor + p + 1\right)\\ &= (p+1)\left(p\left\lfloor\frac{(n-1)m+l}{m}\right\rfloor + p + 1\right) = (p+1)\left(p\left\lfloor\frac{nm+l}{m}\right\rfloor + 1\right)\\ &= (p+1)\left(\left\lfloor\frac{k}{m}\right\rfloor p + 1\right),\end{aligned}$$

one obtains

$$\mathcal{V}_{\sum_1^{p+1}(p+1)(\lfloor r_i/m\rfloor p+1)}|\hat{\psi}| \le \mathcal{V}_{(p+1)\left(\left\lfloor\frac{k}{m}\right\rfloor p+1\right)}|\hat{\psi}|. \tag{3.12}$$

Using a specialization of the multinomial Abel identity (see [11, p. 26]), namely

$$\begin{aligned}&A_N(x_1, x_2, \ldots, x_M)\\ &= \sum_{|k|=N}\binom{N}{k}\prod_{i=1}^{M}(x_i + k_i)^{k_i-1}\\ &= (x_1x_2\cdots x_M)^{-1}\left(\sum_1^M x_i\right)\left(\sum_1^M x_i + N\right)^{N-1},\end{aligned}$$

and the simple relation $\sum_1^{p+1}(r_i - 1) = (n-1)m + l - p - 1$, one obtains

$$\begin{aligned}&\sum_{|r|=(n-1)m+l}\binom{(n-1)m+l}{r}\prod_{i=1}^{p+1}\left(\frac{r_ip}{m}+1\right)^{r_i-1}\\ &= \sum_{|r|=(n-1)m+l}\binom{(n-1)m+l}{r}\left(\frac{p}{m}\right)^{\sum_1^{p+1}(r_i-1)}\prod_1^{p+1}\left(\frac{m}{p}+r_i\right)^{r_i-1}\end{aligned}$$

$$
\begin{aligned}
&= \left(\frac{p}{m}\right)^{(n-1)m+l-p-1} A_{(n-1)m+l}\left(\frac{m}{p}, \frac{m}{p}, \dots, \frac{m}{p}\right) \\
&= \left(\frac{p}{m}\right)^{(n-1)m+l-p-1} \left(\frac{m}{p}\right)^{-(p+1)} \frac{(p+1)m}{p}\left(\frac{(p+1)m}{p} + (n-1)m + l\right)^{(n-1)m+l-1} \\
&= (p+1)\left(\frac{nm+l}{m}p + 1\right)^{(n-1)m+l-1} \\
&= (p+1)\left(\frac{kp}{m} + 1\right)^{k-1-m} \\
&\le \left(\frac{kp}{m} + 1\right)^{k-1}.
\end{aligned}
$$

The latter inequality, when combined with (3.11), (3.12), and the induction hypothesis, yields

$$\left|\xi^k \hat{\psi}(\xi)\right| \le \frac{1}{\lambda^{\frac{k}{m}}}\left(\frac{kp}{m}+1\right)^{k-1} \mathcal{V}_{(p+1)(\lfloor\frac{k}{m}\rfloor p+1)}|\hat{\psi}|(\xi)$$

for any integer $k \ge 0$. It follows that (3.10) holds for any $\xi \in \mathbb{R}$ and any integer $k \ge 0$.

Using the fact that $\hat{\psi} \in L_1(\mathbb{R})$, we infer that

$$
\begin{aligned}
\mathcal{V}_{(p+1)(\lfloor\frac{k}{m}\rfloor p+1)}|\hat{\psi}| &\le \|\hat{\psi}\|_2 \left\|\mathcal{V}_{(p+1)(\lfloor\frac{k}{m}\rfloor p+1)-1}|\hat{\psi}|\right\|_2 \\
&\le \|\hat{\psi}\|_2 \|\hat{\psi}\|_1 \left\|\mathcal{V}_{(p+1)(\lfloor\frac{k}{m}\rfloor p+1)-2}|\hat{\psi}|\right\|_2 \\
&\le \cdots \le \|\hat{\psi}\|_2^2 \|\hat{\psi}\|_1^{(p+1)(\lfloor\frac{k}{m}\rfloor p+1)-2},
\end{aligned}
$$

and so

$$|\xi^k \hat{\psi}(\xi)| \le \frac{\|\hat{\psi}\|_2^2}{\lambda^{k/m}}\left(\frac{kp}{m}+1\right)^{k-1} \|\hat{\psi}\|_1^{(p+1)(\lfloor k/m\rfloor p+1)-2} \tag{3.13}$$

for any $\xi \in \mathbb{R}$.

To complete the proof for Case I, consider the sequence

$$a_k = \frac{1}{k!\,\lambda^{\frac{k}{m}}}\left(\frac{kp}{m}+1\right)^{k-1} \|\hat{\psi}\|_1^{(p+1)(\frac{kp}{m}+1)} \tag{3.14}$$

for $k = 0, 1, 2, \dots$. Because the ratio $\frac{a_{k+1}}{a_k}$ takes the form

$$
\begin{aligned}
\frac{a_{k+1}}{a_k} &= \frac{k!\,\lambda^{\frac{k}{m}}\left(\frac{(k+1)p}{m}+1\right)^{k+1-1} \|\hat{\psi}\|_1^{(p+1)\left(\frac{(k+1)p}{m}+1\right)}}{(k+1)!\,\lambda^{\frac{k+1}{m}}\left(\frac{kp}{m}+1\right)^{k-1} \|\hat{\psi}\|_1^{(p+1)(\frac{kp}{m}+1)}} \\
&= \frac{1}{\lambda^{1/m}} \|\hat{\psi}\|_1^{\frac{(p+1)p}{m}} \left(\frac{p}{m} + \frac{1}{k+1}\right) \left[\left(1 + \frac{p}{m+kp}\right)^{\frac{m+kp}{p}}\right]^{\frac{p(k-1)}{pk+m}},
\end{aligned}
$$

it is readily seen that

$$\lim_{k\to\infty}\frac{a_{k+1}}{a_k}=\frac{ep}{m\ \lambda^{1/m}}\|\hat{\psi}\|_1^{\frac{(p+1)p}{m}}.$$

Hence the power series $\sum_{k=0}^{\infty}a_k\mu^k$ converges for $|\mu|<\frac{m\lambda^{1/m}}{ep}\|\hat{\psi}\|_1^{\frac{-(p+1)p}{m}}$. In consequence of (3.13) and (3.14), it is seen that for any $\xi\in\mathbb{R}$,

$$\begin{aligned}
e^{\mu|\xi|}|\hat{\psi}(\xi)| &= \sum_{k=0}^{\infty}\frac{\mu^k|\xi|^k}{k!}|\hat{\psi}(\xi)| \\
&\le \frac{\|\hat{\psi}\|_2^2}{\|\hat{\psi}\|_1^2}\sum_{k=0}^{\infty}\frac{\mu^k}{k!\ \lambda^{\frac{k}{m}}}\left(\frac{kp}{m}+1\right)^{k-1}\|\hat{\psi}\|_1^{(p+1)(\lfloor k/m\rfloor p+1)} \\
&\le \frac{\|\hat{\psi}\|_2^2}{\|\hat{\psi}\|_1^2}\sum_{k=0}^{\infty}a_k\mu^k<\infty,
\end{aligned}$$

provided $|\mu|<\frac{m\lambda^{1/m}}{ep}\|\hat{\psi}\|_1^{\frac{-(p+1)p}{m}}$. Thus the function $e^{\mu|\xi|}|\hat{\psi}(\xi)|$ appears to be uniformly bounded for such choices of μ, and this is the desired conclusion in case m is a positive integer.

Case II. $m>1$ is not an integer.

If $m_0=\lfloor m\rfloor$ and $\varrho=\max_{0\le\xi<\infty}\frac{1+\lambda\xi^{m_0}}{1+\lambda\xi^{m}}$, then it follows from (3.2) that

$$|\hat{\psi}(\xi)|\le\frac{\varrho}{1+\lambda|\xi|^{m_0}}\mathcal{V}_{p+1}|\hat{\psi}|(\xi). \tag{3.15}$$

Now one may use (3.15) and induction as in the proof of Case I to prove that

$$\left|\xi^k\hat{\psi}(\xi)\right|\le\frac{\varrho^{(p+1)\lfloor k/m_o\rfloor+1}}{\lambda^{k/m_o}}\left(\frac{kp}{m_0}+1\right)^{k-1}\mathcal{V}_{(p+1)\left(\left\lfloor\frac{k}{m_0}\right\rfloor p+1\right)}|\hat{\psi}|(\xi) \tag{3.16}$$

holds for any integer $k\ge0$ and all $\xi\in\mathbb{R}$. In consequence, the following inequality is obtained for integers k and $\xi\in\mathbb{R}$:

$$\left|\xi^k\hat{\psi}(\xi)\right|\le\frac{\varrho^{(p+1)\lfloor k/m_0\rfloor+1}}{\lambda^{k/m_0}}\left(\frac{kp}{m_0}+1\right)^{k-1}\|\hat{\psi}\|_2^2\|\hat{\psi}\|_1^{(p+1)(\lfloor k/m_0\rfloor p+1)-2}.$$

Thus it appears that for all $\xi\in\mathbb{R}$,

$$\begin{aligned}
e^{\mu|\xi|}|\hat{\psi}(\xi)| &= \sum_{k=0}^{\infty}\frac{\mu^k|\xi|^k}{k!}|\hat{\psi}(\xi)| \\
&\le \frac{\|\hat{\psi}\|_2^2}{\|\hat{\psi}\|_1^2}\sum_{k=0}^{\infty}\frac{\mu^k\varrho^{(p+1)\lfloor k/m_0\rfloor+1}}{k!\ \lambda^{k/m_0}}\left(\frac{kp}{m_0}+1\right)^{k-1}\|\hat{\psi}\|_1^{(p+1)(\lfloor k/m_0\rfloor p+1)}<\infty
\end{aligned}$$

for any μ satisfying $0<\mu<\frac{m_0\lambda^{1/m_0}}{ep\varrho^{(p+1)/m_0}}\|\hat{\psi}\|_1^{-(p+1)p/m_0}$.

If the results just obtained for $\hat{\psi}$ are translated into results about $\hat{\phi}$, it appears that if $\phi(x-ct)$ defines a solitary-wave solution of (1.3), then

$$\sup_{\xi\in\mathbb{R}}e^{\mu|\xi|}|\hat{\phi}(\xi)|<\infty \tag{3.17}$$

for any μ satisfying

$$0 < \mu < \frac{m(c-1)^{p/m}(p+1)^{(p+1)/m}(2\pi)^{(p+1)p/2m}}{ep} \|\hat{\phi}\|_1^{\frac{-(p+1)p}{m}} = \rho_1(m,c,\phi)$$

when $1 \le \lfloor m \rfloor = m$, or for any μ satisfying

$$0 < \mu < \frac{m_0(c-1)^{p/m_0}(p+1)^{(p+1)/m_0}(2\pi)^{(p+1)p/2m_0}}{ep\varrho^{(p+1)/m_0}} \|\hat{\phi}\|_1^{\frac{-(p+1)p}{m}} = \rho_1(m,c,\phi)$$

when $1 \le m_0 = \lfloor m \rfloor < m$.

On the other hand, if $\phi(x-ct)$ defines a solitary-wave solution of (1.4), then (3.17) holds for this ϕ for any μ with

$$0 < \mu < \frac{mc^{1/m}(c-1)^{p/m}(p+1)^{(p+1)/m}(2\pi)^{(p+1)p/2m}}{ep} \|\hat{\phi}\|_1^{\frac{-(p+1)p}{m}} = \rho_2(m,c,\phi)$$

when $1 \le \lfloor m \rfloor = m$, or for any μ with

$$0 < \mu < \frac{m_0c^{1/m_0}(c-1)^{p/m_0}(p+1)^{(p+1)/m_0}(2\pi)^{(p+1)p/2m_0}}{ep\varrho^{(p+1)/m_0}} \|\hat{\phi}\|_1^{\frac{-(p+1)p}{m_0}} = \rho_2(m,c,\phi)$$

when $1 \le m_0 = \lfloor m \rfloor < m$.

The theorem is thus seen to be valid if one chooses $\sigma = \rho_1$ for solutions of (1.3) and $\sigma = \rho_2$ for solutions of (1.4). □

An inspection of the proof presented above shows that the specific assumption $\alpha(\xi) = |\xi|^m$ is not needed. Indeed, the presumption that there are positive constants $A > 0$ and $m \ge 1$ such that

$$A|\xi|^m \le \alpha(\xi) \tag{3.18}$$

for all $\xi \in \mathbb{R}$ suffices for our theory. The lower bound in (3.18) implies that the normalized Fourier transform $\hat{\psi}$ satisfies

$$|\hat{\psi}(\xi)| = \frac{1}{1+\lambda\alpha(\xi)}\left|\mathcal{V}_{p+1}\hat{\psi}(\xi)\right| \le \frac{1}{1+\lambda A|\xi|^m}\left|\mathcal{V}_{p+1}\hat{\psi}(\xi)\right|, \tag{3.19}$$

and it is this inequality that is the basis for the estimates appearing in the proof of Theorem 2. In consequence of these remarks, we can assert the following corollary to the proof of Theorem 2.

COROLLARY 3. *Let $u(x,t) = \phi(x-ct)$ be a solitary-wave solution of the equation*

$$u_t + u_x + u^p u_x - (Mu)_x = 0$$

or the equation

$$u_t + u_x + u^p u_x + (Mu)_t = 0,$$

where $p \ge 1$ is an integer and $\widehat{M\phi}(\xi) = \alpha(\xi)\hat{\phi}(\xi)$ with $\alpha(\xi)$ satisfying (3.18) *for some $m \ge 1$ and $A > 0$. Then there exists a constant $\sigma > 0$ such that*

$$\sup_{\xi\in\mathbb{R}} e^{\mu|\xi|}|\hat{\phi}(\xi)| < \infty$$

for any μ with $0 < \mu < \sigma$.

The result concerning analyticity of ϕ now follows immediately from Theorem 2 or Corollary 3 together with the Paley–Wiener theorem.

THEOREM 4. *Let ϕ satisfy the assumptions of Corollary* 3 *and let $\sigma > 0$ be as in the conclusion of this corollary. Then there is a function $\Phi(z)$ defined and holomorphic on the open strip $\{z \in \mathbb{C} : |\Im z| < \sigma\}$ such that $\Phi(x) = \phi(x)$ for all $x \in \mathbb{R}$.*

Proof. Let μ lie in the open interval $(0, \sigma)$. Choose a $\mu_1 > 0$ satisfying $0 < \mu < \mu_1 < \sigma$. Then it follows that

$$\begin{aligned}\int_{-\infty}^{\infty} e^{2\mu|\xi|}|\hat{\phi}(\xi)|^2 d\xi &= \int_{-\infty}^{\infty} e^{-2(\mu_1-\mu)|\xi|}e^{2\mu_1|\xi|}|\hat{\phi}(\xi)|^2 d\xi \\ &\leq \sup_{\xi\in\mathbb{R}} \left(e^{\mu_1|\xi|}|\hat{\phi}(\xi)|\right)^2 \int_{-\infty}^{\infty} e^{-2(\mu_1-\mu)|\xi|} d\xi < \infty.\end{aligned} \tag{3.20}$$

Define the function

$$\Phi(z) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \hat{\phi}(\xi)e^{-iz\xi} d\xi$$

for any $z = x + iy \in \Omega = \{z \in \mathbb{C};\ |\Im z| < \sigma\}$. Using (3.20) and the Paley–Wiener theorem [10], one may conclude that $\Phi(z)$ is a well-defined, analytic function on Ω. Of course, Plancherel's theorem implies that $\Phi(x) = \phi(x)$ for any $x \in \mathbb{R}$. □

An immediate consequence of the analyticity expressed in Theorem 4 is the following interesting result.

COROLLARY 5. *Suppose the hypotheses of Corollary* 3 *to hold and let ϕ be a solitary-wave solution of* (1.3) *or* (1.4). *Then ϕ cannot have compact support, nor can it be the case that in any bounded set $S \subset \mathbb{R}$, there are more than a finite number of points $x_\nu \in S$ such that $\phi(x_\nu) = \nu$. In particular, ϕ has at most finitely many zeros in any bounded subset of* $\mathbb{R}$.

Remarks. It is worth contrasting the last result with that obtained for the evolution equation

$$u_t + u^p u_x + (u^q)_{xxx} = 0, \tag{3.21}$$

where $q > 1$ is an integer. In equation (3.21), the dispersive term is singular, and this fact accounts for the compactly supported travelling-wave solutions (compactons) discovered recently by Rosenau (see Hyman and Rosenau [7]). As Corollary 5 shows, such solutions are not possible when the dispersion is nonsingular.

In case the symbol $\alpha(\xi) = |\xi|^m$, where m is an even integer, one may establish the analyticity of ϕ by recourse to the local theory of ordinary differential equations. It is not immediately transparent even in this case that the real analyticity thereby established extends to analyticity in a complex strip. However, a little work in this context reveals the truth of this assertion. These methods make no impression in case the symbol α does not generate a local operator.

4. Further extensions. It is the purpose of this short section to expand the range of the discussion to include equations of Schrödinger type as depicted in (1.5). In (1.5), it is supposed that M is a dispersion operator with the symbol α as in (1.6) and that $p = 2r$ is an even natural number.

The travelling-wave solutions of (1.5) of interest here have the general form $e^{i\omega t}\psi_{\omega,\theta}(x - \theta t)$, where ω and θ are real numbers with $0 \leq \omega \leq 2\pi$, say, and with $\psi : \mathbb{R} \to \mathbb{C}$ a smooth function lying in $L_1 \cap L_\infty$. Of special interest are the so-called *bound states.* These are standing-wave solutions of (1.5) for which $\theta = 0$, $\omega = \Omega > 0$, and $|\psi|$ tends rapidly to zero at infinity. The function $\psi_{\omega,0} = \phi_\Omega$ defining a bound state $e^{i\Omega t}\phi_\Omega(x)$ satisfies the equation

$$\Omega\phi + M\phi - |\phi|^{2r}\phi = 0. \tag{4.1}$$

In the applications associated to Schrödinger equations, particular importance is attached to *ground states,* which are bound states that minimize energy subject to fixed charge. The associated waveforms ϕ_Ω are analogous to solitary-wave solutions of (1.3) and (1.4) in that they are real valued, even, and rapidly decreasing to zero at infinity. Such solutions fall under the auspices of our previous theory.

THEOREM 6. *Let $\Omega > 0$ and let ϕ_Ω be a ground-state solution of* (1.5) *that lies in $L_1 \cap L_2$. Suppose $p = 2r$, where r is a positive integer, and suppose the symbol α of M to satisfy* (3.18). *Then there exist a $\sigma > 0$ and a function Φ_Ω defined and analytic on the strip $\{z = x + iy : |y| < \sigma\}$ such that $\Phi_\Omega(x) = \phi_\Omega(x)$ for all $x \in \mathbb{R}$.*

The range of applicability of this result may be considerably broadened if the dispersion operator is suitably specialized. Consider, for example, the special case where $\alpha(k) = k^2$, corresponding to the one-dimensional equation

$$iu_t + u_{xx} + |u|^{2r}u = 0, \tag{4.2}$$

with $r = 1$ corresponding to the classical cubic Schrödinger equation. In this case, we have the following simple lemma (cf. Bona and Soyeur [4]) relating bound states to more general travelling-wave solutions. Define $T_\theta : H^1 \to H^1$ by

$$(T_\theta u)(x) = e^{i\frac{1}{2}\theta x}u(x). \tag{4.3}$$

LEMMA 7. *Let ϕ be an H^1-function and let $\psi = T_\theta\phi$ for some $\theta \in \mathbb{R}$. Then ϕ defines a bound state of* (4.2) *corresponding to the parameter $\Omega = \omega - \frac{1}{4}\theta^2 > 0$ if and only if $\psi = \psi_{\omega,\theta}$ defines a travelling-wave solution of* (4.2).

Suppose that $e^{i\omega t}\psi_{\omega,\theta}(x - \theta t)$ is a travelling-wave solution of (4.1) corresponding to a bound state $e^{i\Omega t}\phi_\Omega(x)$ under the transformation in (4.3). Suppose also that ϕ_Ω is actually a ground state. Then according to Theorem 6, ϕ_Ω is the restriction to the real axis of a function Φ_Ω that is analytic in a strip $\{z : |\Im(z)| < \sigma\}$. It follows that $\psi_{\omega,\theta}$ is likewise the restriction to the real axis of a function $\Psi_{\omega,\theta}$ analytic in the same strip, namely the function

$$\Psi_{\omega,\theta}(z) = e^{i\frac{1}{2}\theta z}\phi_\Omega(z).$$

While this result is a consequence of the general theory, such considerations are not required in this special case. Equation (4.1) for ϕ_Ω can be solved explicitly in case $M = -\partial_x^2$, and one readily finds that

$$\phi_\Omega(x) = A\,\mathrm{sech}^{1/r}(Bx),$$

where $A = \sqrt[2r]{(r+1)\Omega}$ and $B = r\sqrt{\Omega}$.

A more challenging situation arises when the symbol $\alpha(k)$ is a perturbation of the Laplacean. Suppose that $\psi_{\omega,\theta}$ defines a travelling-wave solution of (1.5) by the formula

$$u(x,t) = e^{i\omega t}\psi_{\omega,\theta}(x - \theta t).$$

Then $\psi_{\omega,\theta}$ satisfies the equation

$$-\omega\psi - i\theta\psi' - M\psi + |\psi|^{2r}\psi = 0.$$

Guided by the considerations that arose when $M = -\partial_x^2$ in (4.2) and (4.3), we write $\psi_{\omega,\theta}(x) = e^{i\frac{1}{2}\theta x}\phi(x)$. A computation shows ϕ to satisfy the equation

$$(-\omega + \theta^2/2)\phi - i\theta\phi' - \widetilde{M}\phi + |\phi|^{2r}\phi = 0, \tag{4.4}$$

where the symbol $\tilde{\alpha}$ of the operator $\widetilde{M}$ is given by

$$\tilde{\alpha}(\xi) = \alpha(\xi - \theta/2).$$

Assuming that ϕ is real valued, equation (4.4) takes the form

$$\widetilde{M}\phi + i\theta\phi' + (\omega - \theta^2/2)\phi = \phi^{2r+1}, \tag{4.5}$$

or, in Fourier-transformed variables,

$$\left[\alpha(\xi - \theta/2) + \xi\theta + \omega - \theta^2/2\right] \hat{\phi}(\xi) = \widehat{\phi^{2r+1}}(\xi). \tag{4.6}$$

Write $\alpha(\xi) = \xi^2 + \beta(\xi)$, where $\beta(\xi) \geq c|\xi|^m$ for some constants $m \geq 0$ and $c \geq 0$. Then the symbol on the left-hand side of (4.6) may be written as

$$\xi^2 + \beta(\xi - \theta/2) + \omega - \frac{1}{4}\theta^2 \geq \xi^2 + c|\xi - \theta/2|^m + \Omega,$$

where $\Omega = \omega - \frac{1}{4}\theta^2$ as before. If $\Omega > 0$, then obviously we have

$$\xi^2 + \beta(\xi - \theta/2) + \Omega \geq A_1 + A_2|\xi|^2 \tag{4.7}$$

for suitably chosen positive constants A_1 and A_2. Because of (4.7), the theory developed in §3 may be brought to bear, and we ascertain immediately that ϕ has an analytic extension Φ to a strip in $\mathbb{C}$ centered about the real axis. In consequence of the relationship between ϕ and ψ, the same conclusion is drawn about ψ. This result is summarized in our last proposition.

PROPOSITION 8. *Suppose the symbol α of the dispersion operator M to have the form $\alpha(\xi) = \xi^2 + \beta(\xi)$, where $\beta(\xi) \geq c|\xi|^m$ for some $c \geq 0$ and $m \geq 0$. Let $u(x,t) = e^{i\omega t}\psi_{\omega,\theta}(x - \theta t)$ be a travelling-wave solution of* (1.5), *where $\omega - \frac{1}{4}\theta^2 > 0$. Suppose $\psi_{\omega,\theta}(y) = e^{i\frac{1}{2}\theta y}\phi(y)$, where ϕ is real-valued. Then there is a $\sigma > 0$ and a function $\Psi_{\omega,\theta}$ analytic in the strip $\{z : |\Im(z)| < \sigma\}$ such that $\Psi_{\omega,\theta}(x) = \psi_{\omega,\theta}(x)$ for all $x \in \mathbb{R}$.*

Remark. Equation (4.1) arises in more than one space dimension in the form

$$iu_t - Mu + |u|^{2r}u = 0, \tag{4.8}$$

where $u = u(x_1, x_2, \ldots, x_n, t)$ and M is a Fourier multiplier operator defined by

$$\widehat{Mv}(\xi_1, \xi_2, \ldots, \xi_n) = \alpha(\xi_1, \xi_2, \ldots, \xi_n)\, \hat{v}(\xi_1, \xi_2, \ldots, \xi_n).$$

Travelling-wave solutions analogous to those considered in one dimension have the form $e^{i\omega t}\psi_{\omega,\theta}(x - \theta t)$ where $t, \omega \in \mathbb{R}$ and $x, \theta \in \mathbb{R}^n$. Bound states correspond to $\theta = 0$.

It follows readily from the techniques developed in §3 that a ground-state solution ϕ of (4.8) is the restriction to $\mathbb{R}^n$ of a function Φ which is defined in a "strip" $\{(z_1, z_2, \ldots, z_n) \in \mathbb{C}^n : |\Im(z_j)| < \sigma, \text{ for } 1 \le j \le n\}$ and comprises an analytic function of n complex variables there.

In case $M = -\Delta$, then the n-dimensional analog of Lemma 7 allows bound states to be related to general travelling waves via the operator T_θ given by $T_\theta w(x) = e^{i\frac{1}{2}\theta\cdot x}w(x)$ and thereby to extend the results on analyticity to more general travelling-wave solutions.

5. Conclusion. Solitary-wave solutions of the classes (1.3), (1.4), and (1.5) of nonlinear, dispersive wave equations have been shown to possess an analytic extension into a complex strip around their original domain of definition. This further regularity property of such travelling-wave solutions lays the groundwork for a broader use of complex-variable methods in the study of these equations. Such techniques have already proven to be useful in discussing a number of thorny problems connected with uniqueness and soliton behavior (cf. [1], [5], [6], [8], [9]). Perhaps the door now stands ajar to further developments along these lines.

An interesting project for further study would be to determine the type of singularities that arise when a solitary wave is extended into the complex plane. The examples in hand indicate that these extensions will be meromorphic or fractional powers of meromorphic functions. We have conjectured this to be the case under fairly general conditions, but a proof has remained elusive.

THE LINEARIZATION OF THE INITIAL-BOUNDARY VALUE PROBLEM OF THE NONLINEAR SCHRÖDINGER EQUATION*

A. S. FOKAS† AND A. R. ITS‡

Abstract. We consider the nonlinear Schrödinger (NLS) equation in the variable $q(x,t)$ with both x and t in $[0,\infty)$. We assume that $q(x,0)=u(x)$ and $q(0,t)=v(t)$ are given, that $u(0)=v(0)$, and that $u(x)$ *and* $v(t)$ as well as their first two derivatives belong to $L_1 \cap L_2(\mathbb{R}^+)$. We show that the solution of this initial-boundary value problem can be reduced to solving a Riemann–Hilbert (RH) problem in the complex k-plane with jumps on $Im(k^2)=0$. This RH problem is equivalent to a linear integral equation which has a unique global solution. This linear integral equation is uniquely defined in terms of certain functions (scattering data) $b(k)$ and $c(k)$. The function $b(k)$ can be effectively computed in terms of $u(x)$. However, although the analytic properties of $c(k)$ are completely determined, the relationship between $c(k)$, $u(x)$ and $v(t)$ is highly nonlinear. In spite of this difficulty, we can give an effective description of the asymptotic behavior of $q(x,t)$ for large t. In particular, we show that as $t \to \infty$, solitons are generated moving away from the boundary. In addition, our formalism can be used to generate effectively pairs of functions $q(0,t)$ and $q_x(0,t)$ compatible with a given $q(x,0)$ as well as to determine the associated $q(x,t)$. It is important to emphasize that the analysis of this problem, in addition to techniques of exact integrability, requires the essential use of general partial differential equations (PDE) techniques.

1. Introduction.

For integrable equations, a method exists for solving the initial-value problem on the infinite line for decaying initial data. For evolution equations in one spatial variable, this method reduces the solution of the Cauchy problem to the formulation of a certain classical mathematical problem called the Riemann–Hilbert (RH) problem. A RH problem can be solved via a linear integral equation. A distinguished property of integrable equations is that they can be written as the compatibility condition of a pair of linear eigenvalue equations, called the Lax pair [1]. The associated RH problem is essentially determined by the x-part of the Lax pair; the t-part of the Lax pair plays only an auxiliary role. In the case of the nonlinear Schrödinger (NLS) equation, the relevant RH problem is formulated in the complex k-plane with a jump on $Im(k)=0$.

Many physical problems are formulated as initial-boundary value problems. For example, such a problem arises in the modeling of certain ionospheric experiments when one directs a radio frequency wave at the ionosphere. At the reflection point of the wave, a sufficient level of electron plasma waves is excited and nonlinearity becomes important. This problem gives rise to the NLS equation with $x, t\epsilon[0,\infty)$ [2]. Furthermore, several other physical problems can be reduced to initial-boundary value problems. For example, such a problem arises in connection with optical switches [3] and can also be modeled by a NLS. The occurrence of the Korteweg–de Vries (KdV) equation on the quarter-plane is discussed in [21]–[26].

Recently, a new formalism has been developed [4], [5] for studying initial-boundary value problems on the half-infinite line for decaying initial and boundary data. This formalism also reduces the solution of the initial-boundary value problem to the solution of a single RH problem. However, for the formulation of this RH problem, both the x- and the t-parts of the Lax pair play an important role. Actually, it is the t-part which determines where, in the complex k-plane, the jumps occur. In the case of the NLS, the jumps occur on $Im(k^2) = 0$, which is a reflection of the fact that the t-part of the Lax pair contains k^2, which in turn is a consequence of the fact that the NLS involves a second derivative in x. Here we study the initial-boundary value problem for the NLS equation in detail. We show that the analysis of this problem also requires, in addition to techniques from exact integrability, the essential use of more general PDE techniques. In the cases studied so far, the exact methods could be used to establish existence of global solutions as well as to study the properties of these solutions. In contrast, in the problem studied here, exact methods are used only to study the properties of solutions. It shows that a hybrid between exact methods and general PDE techniques can provide a powerful approach for analyzing problems of mathematical and physical significance. We expect that a wide class of problems can be analyzed in a similar manner.

We consider the NLS equation

$$iq_t + q_{xx} - 2\lambda|q|^2 q = 0, \quad x, t \in [0, \infty), \quad \lambda = \pm 1, \tag{1.1}$$

where $q(x,0) = u(x)$ and $q(0,t) = v(t)$ are given. We assume that

$$\begin{gathered} u(x) \in H_2(\mathbb{R}^+), \qquad v(t) \in C_2(\mathbb{R}^+), \qquad u(0) = v(0), \\ xu(x) \;\text{ and }\; x^2u(x) \in L_2(\mathbb{R}^+), v(t) \in L_1 \cap L_2(\mathbb{R}^+), \\ v(t) \in L_1 \cap L_2(\mathbb{R}^+), \qquad v'(t),\;\; tv(t),\;\; tv'(t),\;\; tv''(t) \in L_1(\mathbb{R}^+), \end{gathered} \tag{1.2}$$

where H_2 denotes that a function and its first two derivatives belong to L_2, C_2 denotes that a function is twice differentiable, and prime denotes differentiation.

The cases $\lambda = 1$ and $\lambda = -1$ are usually referred to as the defocusing and focusing cases, respectively. Equation (1.1) is the compatibility condition of the following Lax pair for the 2×2 matrix $w(x,t,k)$ [6]:

$$w_x + ik\sigma_3 w = Qw, \tag{1.3a}$$

$$w_t + Uw = wC(t), \qquad U(x,t,k) \div 2ik^2\sigma_3 + i\lambda|q|^2\sigma_3 - 2kQ + iQ_x\sigma_3, \tag{1.3b}$$

where $\sigma_3 = \text{diag}(1,-1)$, the 2×2 matrix $C(t)$ is an arbitrary function of t, and $Q(x,t)$ is an off-diagonal matrix with 12 and 21 entries given by q and $\lambda\bar{q}$, respectively.

We have developed the following linearization scheme for the solution of the initial-boundary value problem of the NLS. Given $q(x,0)$, construct s_1^+ and s_2^+ by $s_1^+(k) \div \psi_1(0,k)$, $s_2^+(k) \div \psi_2(0,k)$, where $(\psi_1(x,k), \psi_2(x,k))^T$ is the solution of (1.3a) with $q(x,t)$ replaced by $q(x,0)$, satisfying the boundary condition

$$\lim_{x \to \infty} [(\psi_1, \psi_2)^T \exp(-ikx)] = (0,1)^T.$$

Define $b(k)$ by $b = s_1^+/\overline{s_2^+}$. Let $c(k)$, $k \in \mathbb{R}^- \cup i\mathbb{R}^+$ be the boundary value of a function meromorphic for $k \in$ II (I, II, III, and IV denote the first, second, third, and fourth

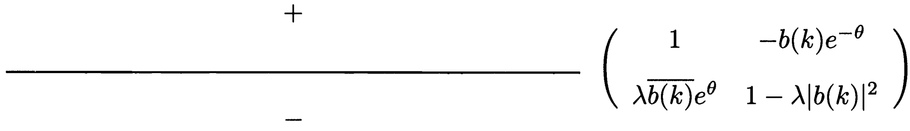
quadrants of the complex k-plane) with poles at the zeros of $s_2^+(k)$ and at the points $\{k_j\}_1^N$, $k_j \in$ II which are assumed to be different than the zeros of $s_2^+(k)$ (generic case); let c_j denote the residues of $c(k)$ at k_j; also, $c(k) \to 0$ as $k \to \infty$. Have $s_1^+(k)$, $s_2^+(k)$, and $c(k)$ solve an RH problem for a 2×2 meromorphic function $\hat{Z}_p$ with possible poles only at $\{k_j\}_1^N$. This RH problem is depicted in Figure 1.1. Finally, determine $q(x,t)$ by $q(x,t) = 2i\lim_{k\to\infty}(k\hat{Z}_p(x,t,k))_{12}$, $k \in$ I, where the subscript 12 denotes the 12 components of the matrix $\hat{Z}_p$. The points $\{k_j\}_1^N$ (which have the meaning of the discrete spectrum of equation (1.3b) evaluated at $x = 0$ and supplemented with the boundary condition $w_1 s_2^+(k) - w_2 s_1^+(k) = 0$ at $t = 0$) give rise to solitons which always move away from the boundary.

In the case of $q(x,0) = 0$, the RH problem reduces to the one depicted in Figure 1.2; it is specified by the boundary values of $c(k)$ on $k \in \mathbb{R}^- \cup i\mathbb{R}^+$, by $\{k_j\}_1^N$, and by $\{c_j\}_1^N$.

Unfortunately, although we have a complete characterization of the analytic properties of $c(k)$, we have not found an effective way of computing $c(k)$ in terms of $q(0,t)$ and $q(x,0)$. (For more details see the discussion below.) In spite of this fact, we can



+
−
$\begin{pmatrix} 1 & -b(k)e^{-\theta} \\ \lambda\overline{b(k)}e^{\theta} & 1-\lambda|b(k)|^2 \end{pmatrix}.$

FIG. 1.3.

give an effective description of the long-time behavior ($\lambda = -1$):

$$q(x,t) = -2\eta_j \frac{\exp[-2i\xi_j x - 4i(\xi_j^2 - \eta_j^2)t - i\varphi_j]}{\cosh[2\eta_j(x + 4\xi_j t) - \Delta_j]} + 0(t^{-\frac{1}{2}}),$$

(1.4)

$$t \to \infty, -\frac{x}{4t} = \xi_j + 0\left(\frac{1}{t}\right), \quad j = 1, \ldots, N,$$

where

(1.5a) $$\eta_j = Im(k_j), \quad \xi_j = Re(k_j),$$

(1.5b)
$$\begin{aligned} \varphi_j = &-\frac{\pi}{2} + \arg c_j \\ &+ \sum_{l=1_{l\neq j}}^{N} [\text{sign}(\xi_l - \xi_j) - 1] \arg\left(\frac{k_j - k_l}{k_j - \bar{k}_l}\right) \\ &+ \frac{1}{\pi}\int_{-\infty}^{-x/4t} \frac{\log[1 + |b(\mu) + \overline{c(\mu)}|^2]}{(\mu - \xi_j)^2 + \eta_j^2}(\mu - \xi_j)d\mu, \end{aligned}$$

(1.5c)
$$\begin{aligned} \Delta_j = &-\log 2\eta_j + \log|c_j| \\ &+ \sum_{l=1_{l\neq j}}^{N} [\text{sign}(\xi_l - \xi_j) - 1] \log\left|\frac{k_j - k_l}{k_j - \bar{k}_l}\right| - \frac{\eta_j}{\pi}\int_{-\infty}^{-x/4t} \frac{\log[1 + |b(\mu) + \overline{c(\mu)}|^2]}{(\mu - \xi_j)^2 + \eta_j^2}d\mu. \end{aligned}$$

All $k_j \in$ II, thus all $\xi_j < 0$ and the solitons move away from the boundary. The summation terms in the above equations describe the interaction among solitons, while the integration terms describe the interaction between solitons and the dispersive part.

Discussion. The linearization scheme developed in this paper can be summarized as follows: Given $q(x, 0)$, construct $b(k)$. Then, if $c(k)$ is *any* suitably decaying function meromorphic for $k \in$ II, the solution of the RH problem of Figure 1.1 generates the solution $q(x,t)$ corresponding to initial data $q(x, 0)$ and *some* boundary data $q(0, t)$. The main limitation of our result is that for given $q(x, 0)$ and $q(0, t)$, we cannot construct $c(k)$ by solving a linear problem. Nevertheless, we claim that for *any* given $q(x, 0)$ and $q(0, t)$ satisfying (1.2), the corresponding function $c(k)$ exists; in other words, the RH problem of Figure 1.1 solves the initial-boundary value problem (1.1) for *general* initial-boundary data.

The above RH problem is quite natural. To appreciate this we first recall the RH problem that corresponds to the NLS with $x \in (-\infty, \infty)$. This RH problem is depicted in Figure 1.3. Comparing the RH problems of Figure 1.1 and Figure 1.3, we see that the jumps for $k \in \mathbb{R}^+$ are identical. The jump for $k \in i\mathbb{R}^+$ cannot have a nonzero entry in the 12 position since $e^{-\theta}$ is unbounded for $k \in i\mathbb{R}^+$. The jump for $k \in i\mathbb{R}^-$ follows by symmetry considerations. Finally, the jump for $k \in \mathbb{R}^-$ follows from the cyclic condition that the product of the jump matrices equals unity (this is a reflection of continuity at $k = 0$). The fact that $c(k)$ has analytic continuation for $k \in \mathrm{II}$ can also be easily understood. At $t = 0$, the RH problem of Figure 1.1 must be reduced to the one that defines $q(x, 0)$. At $t = 0$, the term e^{θ} has analytic continuation in II. Thus the jumps along the imaginary axis can be mapped to a jump on the negative real axis. In this way, at $t = 0$ one finds the RH problem of Figure 1.3 with θ replaced by $2ikx$. This RH problem corresponds precisely to $q(x, 0)$.

The fact that $q(x, 0)$, $q(0, t)$ and $c(k)$ are related in a nonlinear way is a reflection of the fact that $q_x(0, t)$ depends nonlinearly on $q(x, 0)$ and $q(0, t)$. To appreciate this, we first recall the solution of the linearized problem

$$iq_t + q_{xx} = 0, \quad x, t \in [0, \infty), \tag{1.6}$$

where $q(0, t)$ and $q(x, 0)$ are given and decaying for large t and large x. This problem can be solved by the sine transform. However, in order to draw comparisons with the nonlinear problem, we shall use a Fourier transform,

$$\hat{q}(k, t) = \int_0^\infty dx e^{ikx} q(x, t). \tag{1.7}$$

The evolution of the Fourier data $\hat{q}(k, t)$ is given by

$$\hat{q}_t + ik^2 \hat{q} = iq_x(0, t) + kq(0, t). \tag{1.8}$$

In equation (1.8), $q(0, t)$ is known but $q_x(0, t)$ is unknown (the sine transform is precisely used in order to eliminate $q_x(0, t)$). This apparently ominous situation can be bypassed by using the fact that the solution $\hat{q}(k, t)$ of (1.8) is analytic in the upper half of the k complex plane. It turns out that this requirement implies

$$\hat{q}(k, 0) = -\int_0^\infty dt e^{ik^2 t}(iq_x(0, t) + kq(0, t)). \tag{1.9}$$

Given $q(x, 0)$ and $q(0, t)$ and using the substitution $k = e^{i\pi/4}\sqrt{\rho}$, $\rho > 0$, equation (1.9) yields $q_x(0, t)$. It is important to notice that if $q_x(0, t)$ and $q(0, t)$ are arbitrary functions, then the rhs of equation (1.9) will be analytic for $k \in \mathrm{I} \cup \mathrm{III}$. However, in order for $q_x(0, t)$ and $q(0, t)$ to be the boundary values of the solution of equation (1.6), it is necessary and sufficient that the rhs of equation (1.9) has analytic continuation across the positive imaginary k axis ($\hat{q}(k, 0)$ is analytic for $k \in \mathrm{I} \cup \mathrm{II}$).

Before discussing the nonlinear problem, we emphasize that using these type of analyticity arguments, it is possible to solve linear equations for which the standard spectral theory fails. An example of such an equation is the linearized KdV $u_t + u_{xxx} = 0$, for which there does not exist a proper generalization of the sine transform.

We now discuss the nonlinear problem. Let $(\hat{\psi}_1(t, k), \hat{\psi}_2(t, k))^T$ be the solution of the vector equation

$$\hat{\psi}_t + (2ik^2\sigma_3 + i\lambda|q(0, t)|^2\sigma_3 - 2kQ(0, t) + iQ_x(0, t)\sigma_3)\hat{\psi} = 0 \tag{1.10}$$

satisfying the boundary condition $\lim_{t\to\infty}[(\hat{\psi}_1, \hat{\psi}_2)\exp(-2ik^2 t)] = (0, 1)^T$. Let $r(k) \doteqdot \hat{\psi}_1(0, k)/\hat{\psi}_2(0, k)$. It turns out that for arbitrary decaying functions $q(0, t)$ and $q_x(0, t)$,

$r(k)$ is a meromorphic function for $k \in \mathrm{I} \cup \mathrm{III}$ and $r(k) \to 0$ as $k \to \infty$. However, if $q(0,t)$ and $q_x(0,t)$ are the boundary values of the NLS, then in addition $r(k)$ satisfies

$$r(k) = \frac{s_1^+(k)}{s_2^+(k)}, \quad k \in \mathrm{I}, \tag{1.11}$$

where s_1^+ and s_2^+ are determined from $q(x,0)$ and are analytic for $k \in \mathrm{I} \cup \mathrm{II}$. Equation (1.11) is the analogue of equation (1.9). It shows that although the relationship between $q(x,0)$, $q(0,t)$, and $q_x(0,t)$ is highly nonlinear, its reflection in the k-plane (scattering space) is rather simple: $r(k)$ has analytic continuation across the positive imaginary k axis.

There exists an invertible correspondence between the "potential" $\{q(0,t), q_x(0,t)\}$ and the scattering data $r(k)$: Given $q(0,t)$ and $q_x(0,t)$, equation (1.10) implies $r(k)$. Conversely given a meromorphic function $r(k)$, one can find $q(0,t)$ and $q_x(0,t)$ by solving a RH problem with the jump $r(k)$ for $k^2 \in \mathbb{R}$. This provides an effective way for deriving pairs of functions $q(0,t)$ and $q_x(0,t)$ *compatible* with a given $q(x,0)$. Indeed, given $q(x,0)$, one first computes $r(k)$ for $k \in \mathrm{I}$ from equation (1.11). Let $r(k)$, $k \in \mathrm{III}$ be any suitably decaying meromorphic function. Then the solution of the above RH problem yields $q(0,t)$ and $q_x(0,t)$.

Unfortunately, given $q(0,t)$ and $q(x,0)$, we cannot compute $r(k)$ for $k \in \mathrm{III}$ by solving a linear problem. This is a consequence of the fact that now we have a "mixed" problem where one gives "half" the potential, i.e., $q(0,t)$ and "half" the scattering data, i.e., $r(k)$, for $k \in \mathrm{I}$. It turns out that this problem can be formulated as a *nonlinear* RH problem and will be discussed elsewhere.

The study of the large-t behavior of $q(x,t)$ reduces to the study of the large-t behavior of the RH problem of Figure 1.1. Because the x, t dependence of this RH problem is rather simple, it is possible to give an effective asymptotic description of $q(x,t)$ as $t \to \infty$.

It was mentioned earlier that the analysis of equation (1.1) requires an essential use of general PDE techniques. This follows from the fact that in order to study the map between $\{q(0,t), q_x(0,t)\}$ and $r(k)$, one needs a priori estimates for $q_x(0,t)$. The uniqueness and existence of a global solution for the NLS on the quarter-plane is established in [13]. This result makes fundamental use of certain equations which are the analogues of the first three conserved quantities. Therefore, this theory uses L_2 estimates. However, the methods of exact integrability are based on L_1 estimates. It is therefore crucial for us to extend the results of [13] from L_2 to L_1. This poses significant technical difficulties. In this paper, following the ideas of [14], we show how to get L_1 estimates for $q(x,t)$ for all $t \geq 0$. The more difficult problem of obtaining L_1 estimates for $q_x(0,t)$ is discussed in [14].

There exist certain particular boundary conditions for which the difficulties discussed above disappear and the problem can be solved by exact methods. Such cases are discussed in [15]–[20].

It is also worth mentioning that the condition (1.11) is similar to the restrictions on the scattering data that appear in the boundary problem for the elliptic version of the sine-Gordon equation [27].

Notation. We will use the following notation: an overbar denotes complex conjugation; $a^+(k)$ denotes a function analytic for $k \in \mathbb{C}^+$ (upper half of the complex k-plane); $a^-(k)$ denotes a function analytic for $k \in \mathbb{C}^-$; $\hat{a}^+(k)$ denotes a function analytic for $k \in \mathrm{I}$ (first quadrant) $\cup$ III (third quadrant); $\hat{a}^-(k)$ denotes a function analytic for $k \in \mathrm{II}$ (second quadrant) $\cup$ IV (fourth quadrant); the subscript

p denotes meromorphicity instead of analyticity, for example $\hat{a}_p^+(k)$ is meromorphic for $k \in \mathrm{I} \cup \mathrm{III}$; if the matrix A is denoted by $A = (A^+, A^-)$, then $A^+ = (A_1^+, A_2^+)^T$ and $A^- = (A_1^-, A_2^-)^T$, denote the first and the second columns on the matrix A; $\mathrm{I} \doteq \mathrm{diag}(1,1)$.

Summary of results. In §2, we present the relevant formalism. (a) In §2.1, we analyze the x-part of the Lax pair, i.e., equation (1.3a). We define the 2×2 matrices $\varphi(x,t,k)$ and $\psi(x,t,k)$ as the solutions of equation (1.3a) specified by the boundary conditions $\varphi(0,t,k) = \mathrm{I}$, and $\lim_{x\to\infty} \psi(x,t,k)\exp(ikx\sigma_3) = \mathrm{I}$, respectively. We define the matrices $\Phi(x,t,k)$ and $\Psi(x,t,k)$ by the equations $\Phi(x,t,k) = \varphi(x,t,k)\exp(ikx\sigma_3)$ and $\Psi(x,t,k) = \psi(x,t,k)\exp(ikx\sigma_3)$. These functions are analytic in the complex k-plane cut along $Im(k) = 0$, they tend to the unit matrix as $k \to \infty$, and they have unit determinant. Actually, $\Psi = (\Psi^-, \Psi^+)$, and the matrix $\Phi = (\Phi^+, \Phi^-)$ is an entire function with respect to k. The eigenfunctions Φ and Ψ satisfy certain symmetry conditions involving complex conjugation. We define the 2×2 matrix χ_p by

$$\text{(1.12)} \qquad \begin{aligned} \chi_p^-(x,t,k) &= (\Psi^-(x,t,k), \Phi^-(x,t,k)/\overline{\psi_2^+(0,t,\bar{k})}),\\ \chi_p^+(x,t,k) &= (\Phi^+(x,t,k)/\psi_2^+(0,t,k), \Psi^+(x,t,k)), \end{aligned}$$

for $k \in \mathbb{C}^-$ and $k \in \mathbb{C}^+$, respectively. The matrix χ_p has unit determinant and satisfies a certain jump condition

$$\text{(1.13)} \qquad \chi_p^-(x,t,k) = \chi_p^+(x,t,k)F(x,t,k), \quad k \in \mathbb{R},$$

where $F(x,t,k)$ is a 2×2 matrix involving $\psi_1^+(0,t,k)$ and $\psi_2^+(0,t,k)$.

(b) In §2.2, we use the t-part of the Lax pair to analyze $\psi(0,t,k)$. This function satisfies equation (1.3b) evaluated at $x = 0$, where $C(t) = 2ik^2\sigma_3$. We define the 2×2 matrices $\hat{\Phi}(t,k)$ and $\hat{\Psi}(t,k)$ by the requirement that they satisfy the same equation as $\psi(0,t,k)$, and that $\hat{\Phi}(0,k) = \mathrm{I}$, $\lim_{t\to\infty} \hat{\Psi}(t,k) = \mathrm{I}$. These functions are analytic in the complex k-plane cut along $Im(k^2) = 0$, they tend to the unit matrix as $k \to \infty$, and they have unit determinant. Actually $\hat{\Psi} = (\hat{\Psi}^-, \hat{\Psi}^+)$, and the matrix $\hat{\Phi} = (\hat{\Phi}^+, \hat{\Phi}^-)$ is an entire function with respect to k. The eigenfunctions $\hat{\Phi}$ and $\hat{\Psi}$ satisfy the same symmetry condition as those satisfied by Φ and Ψ. We define the matrix $\hat{Y}_p(t,k)$ by

$$\text{(1.14)} \qquad \begin{gathered} \left(\frac{\hat{\Phi}^+(t,k)}{s_2^+(k)}, \psi^+(0,t,k)\right), \left(\frac{\hat{\Psi}^-(t,k)}{\rho(k)}, \psi^+(0,t,k)\right),\\ \left(\psi^-(0,t,k), \frac{\hat{\Psi}^+(t,k)}{\overline{\rho(\bar{k})}}\right), \left(\psi^-(0,t,k), \frac{\hat{\Phi}^-(t,k)}{\overline{s_2^+(\bar{k})}}\right) \end{gathered}$$

for $k \in \mathrm{I}, \ldots, \mathrm{IV}$, where the scalars $s_2^+(k)$ and $\rho(k)$ are defined by

$$\text{(1.15)} \qquad \begin{gathered} s_2^+(k) \doteq \psi_2^+(0,0,k), \quad k \in \mathbb{C}^+; \qquad \rho(k) \doteq \hat{\Psi}_1^-(0,k)s_2^+(k) - \hat{\Psi}_2^-(0,k)s_1^+(k), \quad k \in \mathrm{II};\\ s_1^+(k) \doteq \psi_1^+(0,0,k), \quad k \in \mathbb{C}^+. \end{gathered}$$

The matrix $\hat{Y}_p$ has unit determinant and satisfies a certain jump condition

$$\text{(1.16)} \qquad \hat{Y}_p^-(t,k) = \hat{Y}_p^+(t,k)e^{-2ik^2t\sigma_3}G(k)e^{2ik^2t\sigma_3}, \quad k^2 \in \mathbb{R},$$

where the 2 × 2 matrix $G(k)$ involves the functions $b(k)$ and $c(k)$, which are defined by

$$(1.17) \qquad b(k) \doteqdot \frac{s_1^+(k)}{s_2^+(k)}, \quad k \in \mathbb{R}; \qquad c(k) \doteqdot \frac{\hat{\Psi}_2^-(0,k)}{s_2^+(k)\rho(k)}, \quad k \in i\mathbb{R}^+ \cup \mathbb{R}^-.$$

(c) In §2.3, we formulate an RH problem whose solution gives the solution of the initial-boudnary value problem of the NLS equation. Let the 2 × 2 matrix $\hat{Z}_p(x,t,k)$ be defined by

(1.18)

$$\chi_p(x,t,k)\begin{pmatrix} 1 & 0 \\ \frac{(\hat{Y}_p)_{21}(t,k)}{(\hat{Y}_p)_{22}(t,k)}e^{2ikx} & 1 \end{pmatrix}, \ k \in \mathbb{C}^+; \ \chi_p(x,t,k)\begin{pmatrix} 1 & \frac{(\hat{Y}_p)_{12}(t,k)}{(\hat{Y}_p)_{11}(t,k)}e^{-2ikx} \\ 0 & 1 \end{pmatrix}, \ k \in \mathbb{C}^-.$$

Then the meromorphic function $\hat{Z}_p(x,t,k)$, which has unit determinant, satisfies the RH problem

(1.19)

$$\hat{Z}_p^-(x,t,k) = \hat{Z}_p^+(x,t,k)e^{-i(kx+2k^2t)\sigma_3}G(k)e^{i(kx+2k^2t)\sigma_3}, \quad k^2 \in \mathbb{R}, \ \hat{Z} \to I \text{ as } k \to \infty.$$

The jumps of this RH problem are given in Figure 1.1. The possible poles of $\hat{Z}_p(x,t,k)$ can occur only at the zeros of $\rho(k)$ for $k \in$ II and at the complex conjugates of these zeros. The additional conditions on the residues of $\hat{Z}_p$ have the usual "solitonic" form (equation (2.4.1) in §2.4).

In §3, we discuss rigorous aspects of the formalism developed in §2. This includes finding conditions on $q(x,0)$ and $q(0,t)$ which guarantee the following:

(i) The linear integral equations for $\Phi(x,t,k)$ and $\Psi(x,t,k)$ are uniquely solvable for fixed t and k.

(ii) The linear integral equations for $\hat{\Phi}(t,k)$ and $\hat{\Psi}(t,k)$ are uniquely solvable for fixed k.

(iii) The RH problem of Figure 1.1 is uniquely solvable.

The integral equations for $\Phi(x,t,k)$, $\Psi(x,t,k)$ and for $\hat{\Phi}(t,k)$, $\hat{\Psi}(t,k)$ are of the Volterra type; therefore, they possess global, bounded, continuous solutions provided that $q(x,t)$, with t fixed, and $\{q(0,t), q_x(0,t)\}$ belong in L_1. Furthermore, under certain additional L_2 conditions, $\Phi(0,t,k) - \mathrm{I}$, $\Psi(0,t,k) - \mathrm{I}$, $\hat{\Phi}(t,k) - \mathrm{I}$, and $\hat{\Psi}(t,k) - \mathrm{I} \in H_1$ for fixed t. This implies that the jump matrices of the RH problem of Figure 1.1 belong to H_1. Also, this RH problem satisfies a Schwartz-reflection symmetry. These two facts imply its unique solvability [7].

The most difficult part of the rigorous theory involves deriving L_1 estimates using PDE techniques. In §3, we show how this can be achieved for $q(x,t)$ and $xq(x,t)$, where t is fixed. The analogous but more difficult result for $q_x(0,t)$ is established in [14].

In §4, we use the elegant approach of [11] to study the asymptotic behavior of $q(x,t)$ as $t \to \infty$.

2. The formal analysis. We first study the x-RH problem.

2.1. The x-problem. Let the 2 × 2 matrices $\varphi(x,t,k)$ and $\psi(x,t,k)$ be the solutions of equation (1.3a) specified by the boundary conditions $\varphi(0,t,k) = \mathrm{I}$ and $\lim_{x\to\infty} \exp(ikx\sigma_3)\psi(x,t,k) = \mathrm{I}$, respectively. The matrix $\varphi(x,t,k)$ satisfies the

Volterra integral equation

$$\varphi(x,t,k) = e^{-ikx\sigma_3} + \int_0^x d\xi e^{-ik(x-\xi)\sigma_3} Q(\xi,t)\varphi(\xi,t,k). \tag{2.1.1}$$

The eigenfunction $\psi(x,t,k)$ satisfies a similar equation with $\int_0^x$ replaced by $-\int_x^\infty$. Letting

$$\Phi(x,t,k) = \varphi(x,t,k)e^{ikx\sigma_3}, \qquad \Psi(x,t,k) = \psi(x,t,k)e^{ikx\sigma_3}, \tag{2.1.2}$$

it follows that Φ satisfies the Volterra integral equation

$$\Phi(x,t,k) = I + \int_0^x d\xi e^{-ik(x-\xi)\sigma_3} Q(\xi,t)\Phi(\xi,t,k)e^{ik(x-\xi)\sigma_3}. \tag{2.1.3}$$

This equation, and the analogous equation satisfied by $\Psi(x,t,k)$, imply that

$$\begin{gathered}\Phi = (\Phi^+,\Phi^-) = \begin{pmatrix} \Phi_1^+ & \Phi_1^- \\ \Phi_2^+ & \Phi_2^- \end{pmatrix}, \qquad \Psi = (\Psi^-,\Psi^+) = \begin{pmatrix} \Psi_1^- & \Psi_1^+ \\ \Psi_2^- & \Psi_2^+ \end{pmatrix}, \\ \Phi,\Psi \to \mathrm{I} \text{ as } k\to\infty. \end{gathered} \tag{2.1.4}$$

This notation is explained in the introduction. It is important to notice that, since Φ satisfies a Volterra integral equation with compact support, Φ is an entire function with respect to k.

The eigenfunctions Φ and Ψ have unit determinant. Furthermore, they satisfy certain symmetry conditions. Suppressing for convenience of writing the x,t dependence, these symmetries are

(2.1.5)

$$\overline{\Phi_1^+(k)} = \Phi_2^-(\bar{k}), \qquad \overline{\Psi_1^-(k)} = \Psi_2^+(\bar{k}), \qquad \overline{\Phi_2^+(k)} = \lambda\Phi_1^-(\bar{k}), \qquad \overline{\Psi_2^-(k)} = \lambda\Psi_1^+(\bar{k}).$$

Since the functions φ and ψ are both solutions of equations (1.3), they are related through an x-independent matrix. Hence $\Phi = \Psi\exp(-ikx\sigma_3)(\psi(0,t,k))^{-1}\cdot\exp(ikx\sigma_3)$. Using this equation and defining χ_p by equation (1.12), one finds the jump condition (1.13), where the 2×2 matrix $F(x,t,k)$ is given by

$$\begin{gathered} F_{11} = 1, \qquad F_{22} = \frac{1}{|\psi_2^+(0,t,k)|^2}, \qquad F_{12} = \frac{-\psi_1^+(0,t,k)}{\overline{\psi_2^+(0,t,k)}}\exp(-2ikx), \\ F_{21} = \frac{\lambda\overline{\psi_1^+(0,t,k)}}{\psi_2^+(0,t,k)}\exp(2ikx), \end{gathered} \tag{2.1.6}$$

and $\psi(0,t,k) = \Psi(0,t,k)$.

2.2. The *t*-problem. The eigenfunction $\psi(x,t,k)$ satisfies equation (1.3b). Evaluating this equation as $x\to\infty$, it follows that $C(t) = 2ik^2\sigma_3$. Hence $\psi(0,t,k)$ solves

$$\psi_t(0,t,k) + 2ik^2[\sigma_3,\psi(0,t,k)] = \hat{Q}(t,k)\psi(0,t,k), \tag{2.2.1}$$

where

$$\hat{Q}(t,k) = 2kQ(0,t) - i\lambda|q|^2(0,t)\sigma_3 - iQ_x(0,t)\sigma_3. \tag{2.2.2}$$

The matrix $\hat{Q}(t,k)$ involves $Q(0,t)$, which is known, but it also involves $Q_x(0,t)$, which is unknown. The main idea of [4] and [5] is to solve equation (2.2.1) by formulating an inverse scattering problem. The analysis is similar to that of §2.1. The eigenfunctions $\hat{\Phi}(t,k)$ and $\hat{\Psi}(t,k)$ are the solutions of equation (2.2.1) specified by the boundary conditions $\hat{\Phi}(0,k) = \mathrm{I}$ and $\lim_{t\to\infty}\hat{\Psi}(t,k) = \mathrm{I}$, respectively. In analogy with equation (2.1.3), $\hat{\Phi}$ satisfies the Volterra integral equation

$$\hat{\Phi}(t,k) = \mathrm{I} + \int_0^t d\tau e^{-2ik^2(t-\tau)\sigma_3}\hat{Q}(\tau,k)\hat{\Phi}(\tau,k)e^{2ik^2(t-\tau)\sigma_3}. \tag{2.2.3}$$

This equation, and the analogous equation satisfied by $\hat{\Psi}(x,t,k)$ (where $\int_0^t$ is replaced by $-\int_t^\infty$) imply that

$$\begin{gathered}\hat{\Phi} = (\hat{\Phi}^+,\hat{\Phi}^-) = \begin{pmatrix} \hat{\Phi}_1^+ & \hat{\Phi}_1^- \\ \hat{\Phi}_2^+ & \hat{\Phi}_2^- \end{pmatrix}, \quad \hat{\Psi} = (\hat{\Psi}^-,\hat{\Psi}^+) = \begin{pmatrix} \hat{\Psi}_1^- & \hat{\Psi}_1^+ \\ \hat{\Psi}_2^- & \hat{\Psi}_2^+ \end{pmatrix}, \\ \hat{\Phi},\hat{\Psi} \to \mathrm{I} \quad \text{as} \quad k \to \infty. \end{gathered} \tag{2.2.4}$$

This notation is explained in the introduction. The matrices $\hat{\Phi}$ and $\hat{\Psi}$ have unit determinant, and they satisfy the same symmetry relations as those satisfied by Φ and Ψ (equations (2.1.5)).

It turns out that the following important relationships are valid between $\psi(0,t,k)$, $\hat{\Psi}(t,k)$ and $\hat{\Phi}(t,k)$:

$$\begin{aligned} \psi^+(0,t,k) &= \frac{\psi_2^+(0,0,k)}{\hat{\Psi}_2^+(0,k)}\hat{\Psi}^+(t,k), \quad k \in \mathrm{I}; \\ \psi^-(0,t,k) &= \frac{\psi_1^-(0,0,k)}{\hat{\Psi}_1^-(0,k)}\hat{\Psi}^-(t,k), \quad k \in \mathrm{IV}, \end{aligned} \tag{2.2.5}$$

$$\psi^+(0,t,k) = \psi_2^+(0,0,k)\hat{\Phi}^-(t,k) + \psi_1^+(0,0,k)\hat{\Phi}^+(t,k)\exp(-4ik^2t), \quad k \in \mathbb{C}^+, \tag{2.2.6}$$

$$\psi^-(0,t,k) = \psi_1^-(0,0,k)\hat{\Phi}^+(t,k) + \psi_2^-(0,0,k)\hat{\Phi}^-(t,k)\exp(4ik^2t), \quad k \in \mathbb{C}^-, \tag{2.2.7}$$

where I and IV denote the first and the fourth quadrants of the complex k-plane. To derive these equations, we use the fact that ψ^-E^{-1}, ψ^+E, $\hat{\Psi}^-E^{-1}$, $\hat{\Phi}^-E$, $\hat{\Psi}^+E$, and $\hat{\Phi}^+E^{-1}$, where $E = \exp(2ik^2t)$, are related through equations involving constant coefficients. For example,

$$\psi^+(0,t,k) = \alpha\hat{\Psi}^+(t,k) + \beta\hat{\Psi}^-(t,k)\exp(-4ik^2t), \quad k > 0,$$

where α and β are t-independent scalars. Using $\beta = \det(\psi^+(0,t,k), \hat{\Psi}^+(t,k))\exp(4ik^2t)$ and the fact that the rhs of this equation is a + function going to zero as $t \to \infty$, it follows that $\beta = 0$. Then, evaluating this equation at $t = 0$, equation (2.2.5a) follows. Equations (2.2.5b), (2.2.6), and (2.2.7) are derived in a similar way, where one also uses the fact that $\hat{\Phi}$ is an entire function in the k-complex plane. We also note that equations (2.2.5b) and (2.2.7) follow from equations (2.2.5a) and (2.2.6) using the underlying symmetry conditions.

Let us introduce the notation

$$\psi(0) \doteqdot \psi(0,0,k), \quad \hat{\Psi}(0) \doteqdot \hat{\Psi}(0,k), \quad e = \exp(4ik^2t). \tag{2.2.8}$$

We define the 2×2 matrix $\hat{Y}_p$ by

$$\text{(2.2.9)} \qquad \begin{gathered} \left(\frac{\hat{\Phi}^+(t,k)}{\psi_2^+(0)}, \psi^+(0,t,k)\right), \quad \left(\frac{\hat{\Psi}^-(t,k)}{\rho(k)}, \psi^+(0,t,k)\right), \\ \left(\psi^-(0,t,k), \frac{\hat{\Psi}^+(t,k)}{\nu(k)}\right), \quad \left(\psi^-(0,t,k), \frac{\hat{\Phi}^-(t,k)}{\psi_1^-(0)}\right) \end{gathered}$$

for $k \in \mathrm{I}, \dots, \mathrm{IV}$, respectively, where the scalar functions $\rho(k)$ and $\nu(k)$ are given by

$$\text{(2.2.10)} \qquad \rho(k) \doteqdot \hat{\Psi}_1^-(0)\psi_2^+(0) - \hat{\Psi}_2^-(0)\psi_1^+(0), \quad \nu(k) \doteqdot \hat{\Psi}_2^+(0)\psi_1^-(0) - \hat{\Psi}_1^+(0)\psi_2^-(0).$$

In defining $\hat{Y}_p$, we use when possible $\psi(0,t,k)$ instead of $\hat{\Phi}(t,k)$ and $\hat{\Psi}(t,k)$; the scalars appearing in equation (2.2.9), are chosen by the requirement that $\det \hat{Y}_p = 1$. Since the $\det \hat{Y}_p$ is t-independent, it follows that $\det \hat{Y}_p = 1$ for $k \in \mathrm{II} \cup \mathrm{III}$. For $k \in \mathrm{I}$, the $\det \hat{Y}_p$ is given by

$$\hat{\Phi}_1^+ \frac{\psi_2^+}{\psi_2^+(0)} - \hat{\Phi}_2^+ \frac{\psi_1^+}{\psi_2^+(0)} = \hat{\Phi}_1^+ \frac{\hat{\Psi}_2^+}{\hat{\Psi}_2^+(0)} - \hat{\Phi}_2^+ \frac{\hat{\Psi}_1^+}{\hat{\Psi}_2^+(0)},$$

where we have used equation (2.2.5a). The rhs of this equation simplifies to 1 using the 22 component of the equation $(\hat{\Phi})^{-1}\hat{\Psi} = \exp(-2ik^2t\sigma_3)\hat{\Psi}(0)\exp(2ik^2t\sigma_3)$, i.e., equation (2.2.11b),

$$\text{(2.2.11)} \qquad \begin{aligned} \hat{\Phi}_2^-\hat{\Psi}_1^- - \hat{\Phi}_1^-\hat{\Psi}_2^- &= \hat{\Psi}_1^-(0), & \qquad \hat{\Phi}_1^+\hat{\Psi}_2^+ - \hat{\Phi}_2^+\hat{\Psi}_1^+ &= \hat{\Psi}_2^+(0), \\ \hat{\Phi}_2^-\hat{\Psi}_1^+ - \hat{\Phi}_1^-\hat{\Psi}_2^+ &= \hat{\Psi}_1^+(0)e^{-1}, & \qquad \Phi_1^+\hat{\Psi}_2^- - \hat{\Phi}_2^+\hat{\Psi}_1^- &= \hat{\Psi}_2^-(0)e. \end{aligned}$$

A similar analysis implies that $\det \hat{Y}_p = 1$ for $k \in \mathrm{IV}$.

The matrix $\hat{Y}_p$ satisfies the following jump conditions:

$$\text{(2.2.12)} \qquad \hat{Y}_p^-(t,k) = \hat{Y}_p^+(t,k)\hat{G}(t,k), \quad k^2 \in \mathbb{R};$$

$$\text{(2.2.13)} \qquad k \in i\mathbb{R}^+ : \quad \hat{G}_{11} = \hat{G}_{22} = 1, \qquad \hat{G}_{12} = 0, \qquad \hat{G}_{21} = \frac{\hat{\Psi}_2^-(0)}{\psi_2^+(0)\rho}e;$$

$$\text{(2.2.14)} \qquad k \in i\mathbb{R}^- : \quad \hat{G}_{11} = \hat{G}_{12} = 1, \qquad \hat{G}_{21} = 0, \qquad \hat{G}_{12} = -\frac{\hat{\Psi}_1^+(0))}{(\psi_1^-(0))\overline{\rho(\bar{k})}}e^{-1};$$

(2.2.15)

$$k \in \mathbb{R}^+ : \quad \hat{G}_{11} = 1, \quad \hat{G}_{22} = \frac{1}{\psi_2^+(0)\psi_1^-(0)}, \quad \hat{G}_{12} = -\frac{\psi_1^+(0)}{\psi_1^-(0)}e^{-1}, \quad \hat{G}_{21} = \frac{\psi_2^-(0)}{\psi_2^+(0)}e;$$

(2.2.16)

$$k \in \mathbb{R}^- : \quad \hat{G}_{11} = 1 - R_1R_2, \qquad \hat{G}_{22} = 1, \qquad \hat{G}_{12} = -R_1e^{-1}, \qquad G_{21} = R_2e,$$

where the scalar functions $R_1(k)$ and $R_2(k)$ are defined by

$$\text{(2.2.17)} \quad R_1 = \frac{\psi_1^+(0)\hat{\Psi}_2^+(0) - \psi_2^+(0)\hat{\Psi}_1^+(0)}{\psi_2^-(0)\hat{\Psi}_1^+(0) - \psi_1^-(0)\hat{\Psi}_2^+(0)}, \qquad R_2 \doteqdot \frac{\psi_1^-(0)\hat{\Psi}_2^-(0) - \psi_2^-(0)\hat{\Psi}_1^-(0)}{\hat{\Psi}_1^-(0)\psi_2^+(0) - \hat{\Psi}_2^-(0)\psi_1^+(0)}.$$

We now indicate how these jump conditions can be derived.

$k \in R^+$. Substituting the expression for $\hat{Y}_p$ in equation (2.2.12) and using $\det \psi = \det \hat{\Phi} = 1$, one finds $\hat{G}_{11} = 1$, $\hat{G}_{22} = 1/\psi_2^+(0)\psi_1^-(0)$, and

$$\hat{G}_{12} = \hat{\Phi}_1^- \frac{\psi_2^+}{\psi_1^-(0)} - \hat{\Phi}_2^- \frac{\psi_1^+}{\psi_1^-(0)}, \qquad \hat{G}_{21} = \hat{\Phi}_1^+ \frac{\psi_2^-}{\psi_2^+(0)} - \hat{\Phi}_2^+ \frac{\psi_1^-}{\psi_2^+(0)}.$$

Using equations (2.2.5) to eliminate $\psi_2^+, \psi_1^+, \psi_2^-$, and ψ_1^- and then using (2.2.11c) and (2.2.11d), these equations become

$$\hat{G}_{12} = -\frac{\psi_2^+(0)\hat{\Psi}_1^+(0)}{\psi_1^-(0)\hat{\Psi}_2^+(0)} e^{-1}, \qquad \hat{G}_{21} = \frac{\psi_1^-(0)\hat{\Psi}_2^-(0)}{\psi_2^+(0)\hat{\Psi}_1^-(0)} e.$$

Using equation (2.2.5) evaluated at $t = 0$, these expressions yield the expression for $\hat{G}_{12}$ and $\hat{G}_{21}$ given in equation (2.2.15).

$k \in iR^+$. Substituting the expressions for $\hat{Y}_p$ in equation (2.2.12), one finds $\hat{G}_{11} = 1$, $\hat{G}_{12} = 0$, and

$$\hat{G}_{22} = \hat{\Phi}_1^+ \frac{\psi_2^+}{\psi_2^+(0)} - \hat{\Phi}_2^+ \frac{\psi_1^+}{\psi_2^+(0)}, \qquad \hat{G}_{21} = \frac{\hat{\Phi}_1^+ \hat{\Psi}_2^- - \hat{\Phi}_2^+ \hat{\Psi}_1^-}{\rho \psi_2^+(0)}.$$

Using equation (2.2.5a) to eliminate ψ_2^+ and ψ_1^+ and then using equation (2.2.11b), it follows that $\hat{G}_{22} = 1$. Using equation (2.2.11d), it follows that $\hat{G}_{21} = \hat{\Psi}_2^-(0)e/\rho\psi_2^+(0)$.

$k \in iR^-, k \in R^-$. The derivation of the jump matrices defined in equations (2.2.14) and (2.2.16) is similar to the above and hence is omitted.

The number of independent functions appearing in the above jumps can be reduced by using the underlying symmetry conditions. Some of these functions can be computed effectively in terms of initial data, while the rest, although dependent in a nonlinear way on the boundary data, can be given an effective characterization in the k-complex plane.

Let us summarize the main formal results of this subsection.

PROPOSITION 2.1. *Let the* 2×2 *matrix value function* $\hat{Y}_p(t, k)$ *be defined by equation* (1.14). *Then* $\hat{Y}_p$ *satisfies equation* (1.16), *where the jump matrices are depicted in Figure* 1.1 *with* θ *replaced by* $4ik^2t$.

The functions $s_1^+(k)$ *and* $s_2^+(k)$ *defined in* (1.15) *can be computed in terms of the initial data* $q(x, 0)$. *The function* $c(k)$ *defined in* (1.17) *depends in a nonlinear way on the boundary data* $q(0, t)$. *These functions, which are called the scattering data, have the following properties:*

1. $s_1^+(k)$ *and* $s_2^+(k)$ *are analytic for* $k \in \mathbb{C}^+$; $s_1^+(k) \to 0$ *and* $s_2^+(k) \to 1$ *as* $k \to \infty$.
2.

(2.2.18)
$$|s_2^+(k)|^2 - \lambda |s_1^+(k)|^2 = 1, \quad k \in \mathbb{R}.$$

3. $c(k)$ *is analytic in* II *except for possible poles, which can occur at the zeros of* $s_2^+(k)$ *and at the points* $\{k_j\}_1^N$, $k_j \in$ II, *which are the zeros of the function* $\rho(k)$ *defined in* (1.15); $c(k) \to 0$ *as* $k \to \infty$.

Proof. It is straightforward to derive the jump matrices appearing in Figure 1.1 from equations (2.2.13)–(2.2.16). The jumps on R^+, $i\mathbb{R}^+$ follow from the notations introduced in (1.15), (1.17), the underlying symmetry, and the relation $|s_2^+|^{-2} =$

$1-\lambda|b|^2$, which in turn follows from $\det\psi(0)=1$ and the underlying symmetry. The jump on iR^- follows from the underlying symmetry. Taking again into account the underlying symmetry and the relation $\det\psi(0)=1$, it follows that for $k\in\mathbb{R}^-$,

$$b(k)-\lambda\overline{c(k)}=\frac{\psi_1^+(0)}{\psi_1^-(0)}-\frac{\hat{\Psi}_1^+(0)}{\psi_1^-(0)[\hat{\Psi}_2^+(0)\psi_1^-(0)-\hat{\Psi}_1^+(0)\psi_2^-(0)]}=$$

$$\frac{\psi_1^+(0)\hat{\Psi}_2^+(0)\psi_1^-(0)-\hat{\Psi}_1^+(0)(1+\psi_1^+(0)\psi_2^-(0))}{\psi_1^-(0)[\hat{\Psi}_2^+(0)\psi_1^-(0)-\hat{\Psi}_1^+(0)\psi_2^-(0)]}=\frac{\psi_1^+(0)\hat{\Psi}_2^+(0)-\hat{\Psi}_1^+(0)\psi_2^+(0)}{\hat{\Psi}_2^+(0)\psi_1^-(0)-\hat{\Psi}_1^+(0)\psi_2^-(0)}=-R_1.$$

Since $R_2=\lambda\bar{R}_1$, this implies the jump on $\mathbb{R}^-$ indicated in Figure 1.1.

The initial data $q(x,0)$ can be used to compute $\psi(x,0,k)$, which in turn implies $\psi(0,0,k)$. Hence all of the components of $\psi(0,0,k)$ can be effectively calculated in terms of $q(x,0)$. Equation (2.2.18) follows from $\det\psi(0)=1$. Although the scattering data $c(k)$ depends in a nonlinear way on the boundary data $q(0,t)$, its analytic structure can be characterized explicitly. The large-k behavior of s_1^+, s_2^+, and $c(k)$ follows from the large-k behavior of $\psi_1^+(0,0,k)$, $\psi_2^+(0,0,k)$, $\hat{\Psi}_2^-$, and $\hat{\Psi}_1^-$. The possible poles for $c(k)$ appear at the possible zeros of $s_2^+(k)$ and of $\rho(k)$. This completes the proof of Proposition 2.1.

Remark. If one investigates the direct and inverse problems associated with equation (1.3b) without assuming a relationship between $q(0,t)$ and $q_x(0,t)$, one finds that the basic scattering data is the reflection coefficient $r(k)$ defined by

$$r(k)=\frac{\hat{\Psi}_1^+(0,k)}{\hat{\Psi}_2^+(0,k)}. \tag{2.2.19}$$

The only analytic restriction on $r(k)$ is that it is meromorphic in $\mathrm{I}\cup\mathrm{III}$. However, in our case, since $q(0,t)$ and $q_x(0,t)$ are the boundary values of the NLS equation, there exists a relationship between $q(0,t)$ and $q_x(0,t)$. It is quite interesting that although this relationship is highly nonlinear, its representation in the scattering space is very simple: $r(k)$ has analytic continuation for $k\in\mathrm{II}$. Indeed, equation (2.2.5a) evaluated at $t=0$ becomes

$$\frac{\psi_1^+(0,0,k)}{\psi_2^+(0,0,k)}=\frac{\hat{\Psi}_1^+(0,k)}{\hat{\Psi}_2^+(0,k)},\quad k\in\mathrm{I}.$$

But $\psi^+(0,0,k)$ is analytic in $\mathrm{I}\cup\mathrm{II}$, hence $r(k)$ has an analytic continuation across $i\mathbb{R}^+$. The function $c(k)$ is related to $r(k)$ through the equation

$$c(k)=\frac{\lambda\overline{r(\bar{k})}}{(s_2^+(k))^2(1-\lambda\frac{s_1^+(k)}{s_2^+(k)}\overline{r(\bar{k})})}. \tag{2.2.20}$$

2.3. The RH problem. In this section, we formulate a RH problem, whose solution gives the solution of the initial boundary value problem of the NLS equation.

PROPOSITION 2.2. *Let the* 2×2 *matrix* $\hat{Z}_p(x,t,k)$ *be defined by equation* (1.18). *Then the following hold:*

(i) $\hat{Z}_p(x,t,k)$ *has unit determinant and it satisfies the RH problem* (1.19).

(ii) $\hat{Z}_p(x,t,k)$ *is a meromorphic function in the complex* k*-plane cut along* $Im(k^2)=0$. *Its possible poles can occur only at the zeros of* $\rho(k)$ *for* $k\in\mathrm{II}$ *and at the complex conjugate of these zeros.*

(iii) *The eigenfunction* $\Psi^+(x,t,k)$ *and the potential* $q(x,t)$ *can be obtained from* $\hat{Z}_p(x,t,k)$ *by*

(2.3.1)
$$\Psi^+(x,t,k) = \hat{Z}_p(x,t,k)(0,1)^T, \quad k \in \mathbb{C}^+; \quad q(x,t) = 2i \lim_{k\to\infty} (k\hat{Z}_p(x,t,k))_{12}, \quad k \in \mathrm{I},$$

where the subscript 12 *denotes the* 12 *components of* $\hat{Z}_p$.

Proof. For convenience of writing, we drop the subscript p in $\hat{Y}$.

(i). We first note that the jump matrix $F(x,t,k)$ defined in equation (2.1.6) can be written as

$$F(x,t,k) = \begin{pmatrix} 1 & 0 \\ \frac{\hat{Y}_{21}^{\mp}(t,k)}{\hat{Y}_{22}^{\pm}(t,k)} e^{2ikx} & 1 \end{pmatrix} \begin{pmatrix} 1 & -\frac{\hat{Y}_{12}^{\pm}(t,k)}{\hat{Y}_{11}^{\mp}(t,k)} e^{-2ikx} \\ 0 & 1 \end{pmatrix}, \quad k \gtrless 0. \tag{2.3.2}$$

Now consider the jump conditions for $\hat{Z}_p(x,t,k)$.

$k \in \mathbb{R}^+$. Equations (1.18), (1.13), and (2.3.2) yield

$$\begin{aligned}[\hat{Z}_p^+(x,t,k)]^{-1}\hat{Z}_p^-(x,t,k) &= \begin{pmatrix} 1 & 0 \\ -\frac{\hat{Y}_{21}^+}{\hat{Y}_{22}^+} e^{2ikx} & 1 \end{pmatrix} F(x,t,k) \begin{pmatrix} 1 & \frac{\hat{Y}_{12}^-}{\hat{Y}_{11}^-} e^{-2ikx} \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & 0 \\ \frac{\hat{Y}_{21}^- - \hat{Y}_{21}^+}{\hat{Y}_{22}^+} e^{2ikx} & 1 \end{pmatrix} \begin{pmatrix} 1 & \frac{\hat{Y}_{12}^- - \hat{Y}_{12}^+}{\hat{Y}_{11}^-} e^{-2ikx} \\ 0 & 1 \end{pmatrix},\end{aligned}$$

where $\hat{Y}_{jl}^{\pm} \equiv \hat{Y}_{jl}^{\pm}(t,k)$. Equation (1.16) implies

$$\hat{Y}_{21}^- - \hat{Y}_{21}^+ = \hat{Y}_{22}^+ \hat{G}_{21}(t,k), \qquad \hat{Y}_{12}^- - \hat{Y}_{12}^+ = \hat{Y}_{11}^- \hat{G}_{12}(t,k).$$

Using these equations it follows that

$$\begin{aligned}[\hat{Z}_p^+(x,t,k)]^{-1}\hat{Z}_p^-(x,t,k) &= \begin{pmatrix} 1 & 0 \\ \hat{G}_{21}(t,k)e^{2ikx} & 1 \end{pmatrix} \begin{pmatrix} 1 & \hat{G}_{12}(t,k)e^{-2ikx} \\ 0 & 1 \end{pmatrix} \\ &= e^{-i(kx+2k^2t)\sigma_3} G(k) e^{i(kx+2k^2t)\sigma_3}.\end{aligned}$$

$k \in i\mathbb{R}^+$. Equation (1.18) yields

$$[\hat{Z}_p^+((x,t,k)]^{-1}\hat{Z}_p^-(x,t,k) = \begin{pmatrix} 1 & 0 \\ \left(\frac{\hat{Y}_{21}^-}{\hat{Y}_{22}^-} - \frac{\hat{Y}_{21}^+}{\hat{Y}_{22}^+}\right) e^{2ikx} & 1 \end{pmatrix}.$$

Equation (1.16) implies

$$\hat{Y}_{22}^- = \hat{Y}_{22}^+, \quad \hat{Y}_{21}^- - \hat{Y}_{21}^+ = \hat{Y}_{22}^+ \hat{G}_{21}(t,k).$$

Using these equations, it follows that

$$[\hat{Z}_p^+(x,t,k)]^{-1}\hat{Z}_p^-(x,t,k) = \begin{pmatrix} 1 & 0 \\ \hat{G}_{21}(t,k)e^{2ikx} & 1 \end{pmatrix} = e^{-i(kx+2k^2t)\sigma_3} G(k) e^{i(kx+2k^2t)\sigma_3}.$$

The derivation of the jump conditions for $k \in \mathbb{R}^-$ and $k \in i\mathbb{R}^-$ is similar to the above and hence is omitted.

(ii). Let $k \in \mathrm{I}$. Using the definitions of $\chi_p(x,t,k)$ and $\hat{Y}_p(t,k)$ for $k \in \mathrm{I}$, i.e.,

$$\chi_p(x,t,k) = \left(\frac{\Phi^+(x,t,k)}{\psi_2^+(0,t,k)}, \Psi^+(x,t,k)\right), \ \hat{Y}_{21}(t,k) = \frac{\hat{\Phi}_2^+(t,k)}{s_2^+(k)}, \ \hat{Y}_{22}(t,k) = \psi_2^+(0,t,k),$$

equation (1.18) yields

$$\hat{Z}_p(x,t,k) = \left(\tfrac{1}{\psi_2^+(0,t,k)}\left(\Phi^+(x,t,k) + \tfrac{\hat{\Phi}_2^+(t,k)}{s_2^+(k)}\Psi^+(x,t,k)e^{2ikx}\right), \Psi^+(x,t,k)\right), \quad k \in \mathrm{I}. \tag{2.3.3}$$

We will show that at the possible zeros of $\psi_2^+(0,t,k)$, denoted by k_0,

$$\Phi^+(x,t,k_0) + \frac{\hat{\Phi}_2^+(t,k_0)}{s_2^+(k_0)}\Psi^+(x,t,k_0)e^{2ik_0x} = 0, \quad k_0 \in \mathrm{I}, \tag{2.3.4}$$

hence the possible poles of $\hat{Z}_p(x,t,k)$ for $k \in \mathrm{I}$ can occur only at the fixed possible zeros of $s_2^+(k)$.

To derive equation (2.3.4), we first relate $\Phi^+(x,t,k)$ to $\Psi^+(x,t,k)e^{2ikx}$, and to $\Phi^-(x,t,k)e^{2ikx}$ through an equation with x-independent coefficients. Evaluating this equation at $x = 0$ it follows that

$$\Phi^+(x,t,k) = \frac{\Psi^+(x,t,k)}{\psi_1^+(0,t,k)}e^{2ikx} - \frac{\psi_2^+(0,t,k)}{\psi_1^+(0,t,k)}\Phi^-(x,t,k)e^{2ikx}, \quad k \in \mathbb{C}^+. \tag{2.3.5}$$

Equation (2.3.4) follows from equation (2.3.5) evaluated at $k = k_0$. Indeed, when $k = k_0$, $\psi_2^+(0,t,k_0) = 0$, hence equation (2.2.6) yields

$$\psi_1^+(0,t,k_0) = s_2^+(k_0)\hat{\Phi}_1^-(t,k_0) + s_1^+(k_0)\hat{\Phi}_1^+(t,k_0)e^{-4ik_0^2t},$$

$$0 = s_2^+(k_0)\hat{\Phi}_2^-(t,k_0) + s_1^+(k_0)\hat{\Phi}_2^+(t,k_0)e^{-4ik_0^2t}, \quad k_0 \in \mathrm{I}. \tag{2.3.6}$$

These equations together with $\det\hat{\Phi} = 1$ imply $\psi_1^+(0,t,k_0)\hat{\Phi}_2^+(t,k_0) = -s_2^+(k_0)$.

Let $k \in \mathrm{II}$. Instead of equation (2.3.3) we now find

$$\hat{Z}_p(x,t,k) = \left(\tfrac{1}{\psi_2^+(0,t,k)}\left(\Phi^+(x,t,k) + \tfrac{\hat{\Psi}_2^-(t,k)}{\rho(k)}\Psi^+(x,t,k)e^{2ikx}\right), \Psi^+(x,t,k)\right), \quad k \in \mathrm{II}. \tag{2.3.7}$$

Again it can be shown that if $\psi_2^+(0,t,k_0) = 0$, $k_0 \in \mathrm{II}$, then

$$\Phi^+(x,t,k_0) + \frac{\hat{\Psi}_2^-(t,k_0)}{\rho(k_0)}\Psi^+(x,t,k_0)e^{2ik_0x} = 0, \quad k_0 \in \mathrm{II}; \tag{2.3.8}$$

hence the possible poles of $\hat{Z}_p(x,t,k)$ for $k \in \mathrm{II}$ can occur only at the fixed possible zeros of $\rho(k)$. Equation (2.3.8) follows from equation (2.3.5) using $\det\hat{Y}_p = 1$, $k \in \mathrm{II}$, i.e.,

$$\rho(k) = \hat{\Psi}_1^-(t,k)\psi_2^+(0,t,k) - \hat{\Psi}_2^-(t,k)\psi_1^+(0,t,k).$$

The absence of singularities of $\hat{Z}_p(x,t,k)$ at the possible zeros of $\psi_1^-(0,t,k)$ can be proven in a similar manner; alternatively, one can use the underlying symmetry.

To conclude the proof of statement (ii) it remains to notice that $s_2^+(k)$ cannot have zeros in I. In fact, if $s_2^+(k_0) = 0$ for $k_0 \in \mathrm{I}$, equation (2.2.6) implies

$$e^{4ik_0^2t}\psi^+(0,t,k_0) = s_1^+(k_0)\hat{\Phi}^+(t,k_0), \quad k_0 \in \mathrm{I}.$$

This means

$$\hat{\Phi}^+(t,k_0) \to 0, \quad t \to +\infty,$$

which contradicts $\det\hat{\Phi} = 1$ for all $t > 0$. Taking into account that $s_2^+(k)$ participates in the definition of $\hat{Z}_p$ only in the first quadrant I, we conclude that the function $\hat{Z}_p(x,t,k)$ can have poles only in the quadrants II and III and that these poles occur at the zeros of $\rho(k)$ and $\overline{\rho(\bar{k})}$, respectively. As we will see in §4, this fact implies that the possible solitons of the initial-boundary value problem (1.1) move away from the boundary.

(iii). Equation (2.3.1b) follows from the large-k asymptotics of equation (1.3).

We conclude this subsection with a discussion of the appropriate data needed to solve the RH problem.

PROPOSITION 2.3. *The RH problem for $\hat{Z}_p$ is uniquely specified by the following data, called scattering data:* (i) *$c(k)$ for $k \in \mathbb{R}^- \cup i\mathbb{R}^+$;* (ii) *$s_1^+(k)$ for $k \in \mathbb{R}$;* (iii) *the zeros of $s_2^+(k)$ for $k \in \mathbb{C}^+$;* (iv) *the zeros $\{k_j\}_1^N$ of $\rho(k)$ and the residues $\{c_j\}_1^N$ of $c(k)$ at these poles.*

Proof. Indeed, (ii) and (iii) together with equation (2.2.18) yield s_2^+ through the solution of a scalar RH problem. Then, $c(k)$, s_1^+, and s_2^+ specify all the jump conditions. The possible poles of $\hat{Z}_p$ can occur at the possible zeros of $\rho(k)$. The additional conditions on the residues of $\hat{Z}_p$ are given in the next section (equation 2.4.1)).

It is worth mentioning that $\rho(k) \neq 0$ for $k \in i\mathbb{R}^+$. Indeed, equation (2.2.5a) implies that for $k \in i\mathbb{R}^+$, $s_1^+(k) = \rho(k)\hat{\Psi}_1^+(0,k)$ and $s_2^+(k) = \rho(k)\hat{\Psi}_2^+(0,k)$. Thus $\rho(k) \neq 0$ since s_1^+ and s_2^+ cannot vanish simultaneously.

Remark 1. The above analysis is valid for the generic situation, i.e., we assume that all zeros of $\psi_2^+(0,t,k)$, of $s_2^+(k)$, and of $\rho(k)$ are simple, they do not coincide with each other, they do not lie on the cross $Imk^2 = 0$, and there is a finite number of them.

Remark 2. The function $c(k)$, $k \in \mathbb{R}^- \cup i\mathbb{R}^+$, satisfies certain restrictions. Indeed, since it is the boundary value of a function meromorphic in II and decreasing as $k \to \infty$, $c(k)$ satisfies the following infinite set of conditions:

$$\text{(2.3.9)} \qquad \frac{1}{2\pi i}\int_{\mathbb{R}^-\cup i\mathbb{R}^+} \frac{c(k')}{k'-k}dk' = \sum_{j=1}^{N} \frac{c_j}{k_j - k} + \sum_{j=1}^{M} \frac{c_j^+}{k_j^+ - k} \quad \forall k \notin \mathrm{II}$$

or

$$\text{(2.3.10)} \qquad \frac{1}{2\pi i}\int_{\mathbb{R}^-\cup i\mathbb{R}^+} c(k)(k-1)^{-n}dk = \sum_{j=1}^{N} c_j(k_j - 1)^{-n} + \sum_{j=1}^{M} c_j^+(k_j^+ - 1)^{-n},$$

where $k_j^+, j = 1, \ldots, M$ are the zeros of $s_2^+(k)$, and c_j^+ are the corresponding residues of $c(k)$. As a set of independent parameters for $c(k)$, one can take the *whole* set of its poles and the corresponding residues $\{k_j, k_j^+, c_j, c_j^+\}$ supplemented by

$$\alpha(k) \doteq Re\left\{ c(k) - \sum_{j=1}^{N} \frac{c_j}{k-k_j} - \sum_{j=1}^{M} \frac{c_j^+}{k-k_j^+} \right\}, \quad k \in \mathbb{R}^- \cup i\mathbb{R}^+.$$

Having $\{\alpha(k); k_j, k_j^+, c_j, c_j^+\}$, one can reconstruct $c(k)$ in *closed form.* Also, in order to reconstruct $s_1^+(k)$, one needs to know $\beta(k) \doteq Res_1^+(k)$. Thus the set of independent parameters for our RH problem are

$$\{\alpha(k); \beta(k); k_j, k_j^+, c_j, c_j^+\},$$

where $\alpha(k)$ and $\beta(k)$ are real-valued decreasing functions defined on the whole line, k_j, $k_j^+ \in \mathrm{II}$, c_j, $c_j^+ \in \mathbb{C}\backslash\{0\}$. In particular, this means that the functional dimension of the set can be represented by two complex-valued functions defined on the half-line.

2.4. Solitons. It turns out that the zeros of $\rho(k)$ give rise to solitons.

PROPOSITION 2.4. *Assume that $\rho(k)$ has a finite number of simple zeros for $k \in \mathrm{II}$. Let these zeros be denoted by $\{k_j\}_1^N$. Let $\{c_j\}_1^N$ be the corresponding residues of $c(k)$. Then the following hold:*

(i) *The first column $\hat{Z}_p^{(1)}(x,t,k)$ of $\hat{Z}_p(x,t,k)$ has a simple pole at k_j, $j = 1,\dots,N$, and the second column $\hat{Z}_p^{(2)}(x,t,k)$ of $\hat{Z}_p(x,t,k)$ has a simple pole at $\bar{k}_j$, $j = 1,\dots,N$; the corresponding residues satisfy the equations*

$$\begin{aligned} &\operatorname*{res}_{k_j} \hat{Z}_p^{(1)}(x,t,k) = c_j e^{\theta(k_j)} \hat{Z}_p^{(2)}(x,t,k_j), \qquad \theta(k) \doteq 2i(kx+2k^2t), \\ &\operatorname*{res}_{\bar{k}_j} \hat{Z}_p^{(2)}(x,t,k) = \lambda \bar{c}_j e^{-\theta(\bar{k}_j)} \hat{Z}_p^{(1)}(x,t,\bar{k}_j). \end{aligned} \tag{2.4.1}$$

(ii) *Equations* (2.4.1) *together with the jump condition* (1.19a) *and the asymptotic condition* (1.19b) *characterize the function $\hat{Z}_p(x,t,k)$ uniquely.*

(iii) *The RH problem* (1.19), (2.4.1) *can be solved as follows: Let $\hat{Z}(x,t,k)$ be the solution of an RH problem satisfying the same jump conditions as $\hat{Z}_p(x,t,k)$, but with $c(k)$ and $b(k)$ replaced by $c_0(k) \doteq c(k)\Pi_{j=1}^N(k-k_j)/(k-\bar{k}_j)$ and $b_0(k) = b(k)\Pi_{j=1}^N(k-\bar{k}_j)/(k-k_j)$. This RH problem is regular, i.e., $\hat{Z}(x,t,k)$ has no singularities in the complex k-plane. Then $\hat{Z}_p(x,t,k)$ can be found from $\hat{Z}$ through the equation*

(2.4.2)

$$\begin{aligned} &\hat{Z}_p(x,t,k) \\ &\quad = (kI+B_N)(kI+B_{N-1})\cdots(kI+B_1)\hat{Z}(x,t,k) \begin{pmatrix} \frac{1}{\Pi_{j=1}^N(k-k_j)} & 0 \\ 0 & \frac{1}{\Pi_{j=1}^N(k-\bar{k}_j)} \end{pmatrix}, \end{aligned}$$

where the 2×2 matrices $B_1,\dots,B_N$ are independent of k. These matrices can be determined recursively by solving the algebraic *equations*

$$\begin{aligned} &(k_j\mathrm{I} + B_j)\hat{Z}_{j-1}(x,t,k_j)\begin{pmatrix} 1 \\ -d_j(x,t) \end{pmatrix} = 0, \\ &(\bar{k}_jI + B_j)\hat{Z}_{j-1}(x,t,\bar{k}_j)\begin{pmatrix} -\lambda\bar{d}_j(x,t) \\ 1 \end{pmatrix} = 0, \end{aligned} \tag{2.4.3}$$

where

$$\hat{Z}_j(x,t,k) = (k\mathrm{I} + B_j)\hat{Z}_{j-1}(x,t,k), \quad j = 1,\dots,N-1, \quad \hat{Z}_0 = \hat{Z},$$

$$d_j(x,t) = c_j \frac{\Pi_{l=1,l\neq j}^{N}(k_j - k_l)}{\Pi_{l=1}^{N}(k_j - \bar{k}_l)} \exp(2ik_jx + 4ik_j^2 t). \tag{2.4.4}$$

The RH problem for $\hat{Z}$, and the algebraic equations for $B_1,\dots,B_N$ in the focusing case $\lambda = -1$, are always solvable.

Proof. $\hat{Z}_p(x,t,k)$ is given by equations (2.3.3) and (2.3.7) for k in the first and second quadrants, respectively. Since $s_2^+(k)$ has no zeros in I, $\hat{Z}_p$ is analytic for $k \in$ I, while the first column of $\hat{Z}_p$ has poles for $k \in$ II at the zeros of $\rho(k)$, i.e., at the points $k_1,\dots,k_N$, which are simultaneously the poles of $c(k)$. For $k \in i\mathbb{R}^+$,

$$\hat{Z}_p^-(x,t,k)\begin{pmatrix} 1 & 0 \\ -c(k)e^{\theta} & 1 \end{pmatrix} = \hat{Z}_p^+(x,t,k). \tag{2.4.5}$$

Because $\hat{\Phi}(t,k)$ is an entire function, both sides of equation (2.4.5) have an analytic continuation into the second quadrant of the complex k-plane; moreover, $\hat{Z}_p^+(x,t,k)$ has no singularities at $k_1,\dots,k_N$. This shows that the lhs of equation (2.4.5) has no singularities at $k_1,\dots,k_N$ as well. Similar considerations apply for $k \in$ III; thus

$$\hat{Z}_p(x,t,k)\begin{pmatrix} 1 \\ -c(k)e^{\theta} \end{pmatrix} \quad \text{and} \quad \hat{Z}_p(x,t,k)\begin{pmatrix} -\lambda\overline{c(\bar{k})}e^{-\theta(k)} \\ 1 \end{pmatrix}$$

have no singularities at k_j and $\bar{k}_j$, respectively. This implies equations (2.4.1).

In order to prove statement (ii), we suppose that $\hat{z}_p(x,t,k)$ is another solution of the RH problem (1.19), (2.4.1). The function $\hat{R}(k)$,

$$\hat{R} = \hat{z}_p\hat{Z}_p^{-1},$$

has no jumps at $k^2 \in \mathbb{R}$. Its only possible singularities ($\det \hat{Z}_p = 1$) are at the points k_j and $\bar{k}_j$. For $k \in$ II, one can rewrite $\hat{R}$ as

$$\hat{R}(k) = \hat{z}_p(k)\begin{pmatrix} 1 & 0 \\ -c(k)e^{\theta} & 1 \end{pmatrix}\left[\hat{Z}_p^-(k)\begin{pmatrix} 1 & 0 \\ -c(k)e^{\theta} & 1 \end{pmatrix}\right]^{-1},$$

which shows that $\hat{R}(k)$ has actually no singularities at k_j. Similar considerations for $k \in$ III show that $\hat{R}(k)$ has no singularities at $\bar{k}_j$ either. These facts together with (1.19b) imply that $\hat{R} = \mathrm{I}$.

The essence of deriving the statement (iii) is the usual idea of using Darboux transformations to solve an RH problem with singularities. We need to show that the function $\hat{Z}_p$ defined through (2.4.2)–(2.4.4) satisfies the RH problem (1.19), (2.4.1). In fact, by construction, the matrix $\hat{Z}_p$ satisfies the correct jump condition, and $\hat{Z}_p \to \mathrm{I}$ as $k \to \infty$. Also,

$$\underset{k_j}{res}\ \hat{Z}_p^{(1)}(x,t,k) = P_j(k_j)(k_j\mathrm{I} + B_j)\hat{Z}_{j-1}(x,t,k_j)\begin{pmatrix} 1 \\ 0 \end{pmatrix}\frac{1}{\Pi_{l=1,l\neq j}^{N}(k_j - k_l)},$$

$$\hat{Z}_p^{(2)}(x,t,k_j) = P_j(k_j)(k_j\mathrm{I} + B_j)\hat{Z}_{j-1}(x,t,k_j)\begin{pmatrix} 0 \\ 1 \end{pmatrix}\frac{1}{\Pi_{l=1}^{N}(k_j - \bar{k}_l)},$$

where

$$P_j(k) = (k\mathrm{I} + B_N)(k\mathrm{I} + B_{N-1}) \cdots (k\mathrm{I} + B_{j+1}).$$

This yields equation (2.4.1a) as a direct consequence of equation (2.4.3a); actually, since $\det P_j(k_j) \neq 0$, these two equations are equivalent. Similarly, equation (2.4.1b) follows from (2.4.3b).

Due to the underline symmetry of the jump conditions, the regular RH problem for $Z(x,t,k)$ is always solvable (i.e., there exists a vanishing lemma [7]). In order to discuss the solvability of the algebraic equations (2.4.3), we rewrite them in the form

$$B_j = -W_j \begin{pmatrix} k_j & 0 \\ 0 & \bar{k}_j \end{pmatrix} W_j^{-1},$$

$$W_j \doteqdot \left(\hat{Z}_{j-1}(x,t,k_j) \begin{pmatrix} 1 \\ -d_j(x,t) \end{pmatrix}, \ \hat{Z}_{j-1}(x,t,\bar{k}_j) \begin{pmatrix} -\lambda \overline{d_j}(x,t) \\ 1 \end{pmatrix} \right).$$

This implies that the system of the algebraic equations for the matrices $B_1, \ldots, B_N$ is solvable iff

$$\det W_j \neq 0, \quad j = 1, \ldots, N, \quad \forall x, t > 0. \tag{2.4.6}$$

For $\lambda = -1$ (focusing case), equations (2.4.6) are always valid. Indeed, the symmetry

$$\hat{Z}(x,t,k) = \sigma_2 \overline{\hat{Z}(x,t,\bar{k})} \sigma_2 \tag{2.4.7}$$

yields the formula

$$W_1 = \sigma_2 \bar{W}_1 \sigma_2, \tag{2.4.8}$$

or

$$\det W_1 = |(W_1)_{11}|^2 + |(W_1)_{21}|^2, \tag{2.4.9}$$

where $(W_1)_{11}$ and $(W_1)_{21}$ denote the 11 and 21 components of W_1. Since $\det \hat{Z} = 1$, $(W_1)_{11}$ and $(W_1)_{21}$ cannot be zero simultaneously, and equation (2.4.6) is valid for $j = 1$. The function $\hat{Z}_1$ satisfies the same symmetry condition (2.4.7) as $\hat{Z}$, and $\det \hat{Z}_1(x,t,k) = (k - k_1)(k - \bar{k}_1) \neq 0$ for $k = k_2, \bar{k}_2$; repeating the above arguments, it follows that (2.4.6) is valid for $j = 2$ together with the symmetry condition for $\hat{Z}_2$. Similar considerations apply to $j = 3, \ldots, N$. This completes the proof of Proposition 2.4.

In the defocusing case, $\lambda = 1$, the above arguments regarding the solvability of the algebraic system (2.4.3) are not valid. In this case one has to replace σ_2 in equations (2.4.7) and (2.4.8) by σ_1. This implies that the + sign in (2.4.9) is replaced by the − sign. Actually, the asymptotic analysis of §4 suggests that the solvability condition (2.4.6) does not hold in the defocusing case. In other words, solitons do not exist for $\lambda = 1$.

3. Rigorous considerations. We first discuss the x-problem. Let $\Phi(x,t,k)$ be defined by the integral equation (2.1.3). Let $\Psi(x,t,k)$ be defined by a similar integral equation with $\int_0^x$ replaced by $\int_\infty^x$. If $q(x,t) \in L_1(\mathbb{R}^+)$ in x, these integral equations have continuous and bounded solutions for fixed t and k. Furthermore,

Φ and Ψ have the analytic dependence in k indicated in equation (2.1.4). Also the Riemann–Lebesgue lemma implies that Φ, $\Psi \to \mathrm{I}$ as $k \to \infty$. If $q(x,t)$, $xq(x,t) \in L_1(\mathbb{R}^+) \cap L_2(\mathbb{R}^+)$ in x, then $\psi(0,t,k) \in H_1(\mathbb{R})$ in k.

In summary, if

$$(3.1) \qquad q(x,t), \;\; xq(x,t) \in L_1(\mathbb{R}^+) \cap L_2(\mathbb{R}^+) \;\text{ in }\; x,$$

then the formal results of §2.1 are justified. In particular the jump condition (1.13) is valid and the coefficients $\psi(0,t,k) - \mathrm{I}$ of the jump matrix (2.1.6) belong to $H_1(\mathbb{R})$.

We next consider the t-problem. Let $\hat{\Phi}(t,k)$ be defined by the integral equation (2.2.4). Let $\hat{\Psi}(t,k)$ be defined by a similar integral equation with $\int_0^t$ replaced by $\int_\infty^t$. If $q(0,t)$, $q_x(0,t) \in L_1(\mathbb{R}^+)$, these integral equations have continuous and bounded solutions for fixed k. Also, $\hat{\Phi}$ and $\hat{\Psi}$ have the analytic dependence in k indicated in equation (2.2.4) and $\hat{\Phi}, \hat{\Psi} \to I$ as $k \to \infty$. Furthermore, if in addition, $q(0,t) \in L_2(\mathbb{R}^+)$ and the first derivatives of $q(0,t)$ and $q_x(0,t) \in L_1(\mathbb{R}^+)$, then $\hat{\Psi}(0,k) - \mathrm{I} \in L_2$ for $k^2 \in \mathbb{R}$. Finally, if in addition, $tq(0,t)$, $tq_t(0,t)$, $tq_{tt}(0,t) \in L_1(\mathbb{R}^+)$, then $\hat{\Psi}(0,k) - \mathrm{I} \in H_1$ for $k^2 \in \mathbb{R}$.

In summary, let

$$(3.2) \qquad v(t) \div q(0,t), \quad w(t) \div q_x(0,t).$$

If

$$(3.3) \; v(t) \in L_1 \cap L_2(\mathbb{R}^+), \qquad v'(t), \;\; w(t), \;\; w'(t), \;\; tv(t), \;\; tv'(t), \;\; tv''(t) \in L_1(\mathbb{R}^+),$$

then $\hat{\Psi}(t,k)$ and $\hat{\Phi}(t,k)$ exist and are related through a matrix $\hat{\Psi}(0,k)$ such that $\hat{\Psi}(0,k) - \mathrm{I} \in H_1$ for $k^2 \in \mathbb{R}$.

In §2.2, we formulated an RH problem which involves $\psi(0,t,k)$ in addition to $\hat{\Phi}(t,k)$ and $\hat{\Psi}(t,k)$. The function $\psi(0,t,k)$ satisfies equation (2.2.1), which is uniquely determined in terms of $v(t)$ and $w(t)$. On the other hand, $\psi(x,0,k)$ satisfies equation (1.3a), which is uniquely defined in terms of $u(x) = q(x,0)$. The equality of $\psi(0,t,k)$ and $\psi(x,0,k)$ at $x = t = 0$ is guaranteed iff

$$(3.4) \qquad u(0) = v(0).$$

The relationship between $\psi(0,t,k)$, $\hat{\Phi}(t,k)$, and $\hat{\Psi}(t,k)$ involves the matrices $\psi(0,0,k)$ and $\hat{\Psi}(0,k)$, which under the assumptions (3.1)–(3.4) belong to H_1 and have the analytic dependence indicated by the appropriate superscripts.

THEOREM 3.1. *Assume the following:*

(i) *Equations* (3.1), (3.3), *and* (3.4) *are valid.*

(ii) *All the zeros of* $\psi_2^+(0,t,k)$, *of* $s_2^+(k)$ (*defined by equation* (1.15a)), *and of* $\rho(k)$ (*defined by equation* (1.15b)) *are simple, they do not coincide with each other, they do not lie on* $k^2 \in \mathbb{R}$, *and there is at most a finite number of them. The function* $\rho(k)$ *has no zeros if* $\lambda = 1$.

Then, the 2×2 *matrix* $\hat{Z}_p(x,t,k)$ *defined by equation* (1.18) *has unit determinant and satisfies the jump conditions* (1.19). *The jump matrices are defined in terms of* $\psi(0,0,k)$ *and* $\hat{\Psi}(0,k)$, *which satisfy* $\psi(0,0,k) - \mathrm{I}$, $\hat{\Psi}(0,k) - \mathrm{I} \in H_1$. *The matrix* $\hat{Z}_p(x,t,k)$ *is a meromorphic function in the complex* k*-plane cut along* $Im(k^2) = 0$. *Its possible poles can occur only at the zeros of* $\rho(k)$ *for* $k \in \mathrm{II}$ *and at the complex conjugate of these zeros. The matrix* $\hat{Z}_p(x,t,k)$ *can be obtained by solving the RH problem of Figure* 1.1. *This RH is always solvable. The solution* $q(x,t)$ *of the NLS can be obtained from* $q(x,t) = 2i \lim_{k \to \infty}(k\hat{Z}_p(x,t,k))_{12}$, $k \in \mathrm{I}$.

Proof. It follows from Propositions 2.1 and 2.2 and the following properties of the jump matrices: (a) they are H_1 functions; (b) their product equals unity, which guarantees continuity at $k = 0$; (c) they satisfy certain symmetry conditions involving complex conjugation and transposition. These symmetry conditions imply that there exists a vanishing lemma [7], i.e., the homogeneous RH problem has only the zero solution. □

The main technical difficulty associated with the scheme presented in this paper is to find conditions of $u(x)$ and $v(t)$ which guarantee the assumption (3.1) as well as the assumption that $w(t)$, $w'(t) \in L_1(\mathbb{R}^+)$.

It was shown in [13] that if

$$u(x) \in H_2(\mathbb{R}^+), \quad v \in C_2(\mathbb{R}^+), \quad \text{and} \quad u(0) = v(0), \tag{3.5}$$

then

$$t \to q(,t) \text{ is continuous from } \mathbb{R}^+ \text{ into } H_2(\mathbb{R}^+) \tag{3.6}$$

and

$$t \to q_t(,t) \text{ is continuous from } \mathbb{R}^+ \text{ into } L_2(\mathbb{R}^+). \tag{3.7}$$

Following Sung [14], we shall show that under some additional conditions on $u(x)$, assumption (3.1) is valid.

LEMMA 3.1. *Assume that in addition to assumptions* (3.5),

$$xu(x) \text{ and } x^2u(x) \in L_2(\mathbb{R}^+). \tag{3.8}$$

Then equation (3.1) *is valid.*

Proof. We shall first show that the assumption $xu(x) \in L_2(\mathbb{R}^+)$ implies that $q(x,t) \in L_1(\mathbb{R}^+)$ for fixed t.

The NLS equation and its complex conjugate imply

$$|q|_t^2 = i(q_x\bar{q} - \bar{q}_x q)_x.$$

Thus

$$\begin{aligned}\partial_t \int_0^\infty x^2|q|^2 e^{-\varepsilon x}dx &= i\textstyle\int_0^\infty x^2 e^{-\varepsilon x}(q_x\bar{q} - \bar{q}_x q)_x dx\\ &= -i\int_0^\infty (2x - \varepsilon x^2)e^{-\varepsilon x}(q_x\bar{q} - \bar{q}_x q)dx\\ &\le \int_0^\infty [4x|q||q_x|e^{-\varepsilon x} + 2\varepsilon x^2|q||q_x|e^{-\varepsilon x}]dx\\ &= 4\int_0^\infty \left|e^{-\frac{\varepsilon x}{2}}q_x\right| \left|xqe^{-\frac{\varepsilon x}{2}}\right| dx + 4\int_0^\infty \left|\frac{\varepsilon x}{2}e^{-\frac{\varepsilon x}{2}}q_x\right| \left|xqe^{-\frac{\varepsilon x}{2}}\right| dx.\end{aligned}$$

The maxima of $\exp(-\varepsilon x/2)$ and $\varepsilon x/2\exp(-\varepsilon x/2)$ are 1 and $1/e$, respectively; thus the lhs of the above equation is not greater than

$$4\left(1 + \frac{1}{e}\right)\int_0^\infty |q_x| \left|xqe^{-\frac{\varepsilon x}{2}}\right| dx.$$

Let

$$\varphi(t) \doteqdot \left\|xq(x,t)e^{-\frac{\varepsilon x}{2}}\right\|_{L_2^x(\mathbb{R}^+)},$$

where $L_2^x(\mathbb{R}^+)$ indicates L_2 in the variable x. Then

$$\partial_t(\varphi^2) \leq 4\left(1+\frac{1}{e}\right)\max_{t\in[0,\infty)}\|q_x\|_{L_2^x(\mathbb{R}^+)}\varphi. \tag{3.9}$$

Assuming that $xq(x,0) \in L_2(\mathbb{R}^+)$ and letting $\varepsilon \to 0$, equation (3.9) yields that $xq(x,t) \in L_2^x(\mathbb{R}^+)$.

Since $q(x,t)$ and $xq(x,t) \in L_2^x(\mathbb{R}^+)$, the identity

$$\int_0^\infty q(x,t)dx = \int_0^\infty [(1+x)q]\frac{1}{(1+x)}dx$$

implies that $q(x,t) \in L_1^x(\mathbb{R}^+)$.

We shall now show that the assumption $x^2u(x) \in L_2(\mathbb{R}^+)$ implies that $x^2q(x,t) \in L_2^x(\mathbb{R}^+)$. Let

$$\psi(t) \doteq \left\|x^2qe^{-\frac{\varepsilon x}{2}}\right\|_{L_2^x(\mathbb{R}^+)}.$$

Similar considerations as above yield

$$\partial_t\psi^2 \leq \left(8+\frac{4}{e}\right)\int_0^\infty |xq_x|\left|x^2qe^{-\frac{\varepsilon x}{2}}\right|dx \leq \left(8+\frac{4}{e}\right)\|xq_x\|_{L_2^x(\mathbb{R}^+)}\psi.$$

Thus if $x^2q(x,0) \in L_2(\mathbb{R}^+)$, ψ exists, and since $x^2q(x,t) \in L_2^x(\mathbb{R}^+)$, it follows that $xq(x,t) \in L_1^x(\mathbb{R}^+)$. □

4. The asymptotic analysis. In order to determine the large-t behavior of the solution $q(x,t)$, one needs to study the large-t asymptotic behavior of the oscillatory RH problem (1.19). The corresponding problem for integrable equations on the full line was first studied in [8] (see also [9], [12], and the review [10]). A rigorous and elegant approach to studying the asymptotic behavior of RH problems has recently been developed in [11]. In what follows we shall use this new approach.

We first study the solution $\hat{Z}(x,t,k)$ of the regular RH problem corresponding to the RH problem (1.19) (see Proposition 2.4 (iii)).

THEOREM 4.1. *Under the assumptions of Proposition* 2.4, *the solution* $\hat{Z}(x,t,k)$ *of the regular RH problem corresponding to* (1.19) *satisfies the asymptotic equation*

$$\hat{Z}(x,t,k) = \left(\mathrm{I}+O\left(t^{-\frac{1}{2}}\right)\right)(\delta(k))^{\sigma_3}, \quad t\to\infty, \quad 0<A\leq\frac{x}{t}\leq B<\infty, \tag{4.1}$$

uniformly for $|Imk| \geq \varepsilon > 0$. *The scalar function* $\delta(k)$ *is given by*

$$\delta(k) = \exp\left[\frac{1}{2\pi i}\int_{-\infty}^{k_0}\frac{\ln(1-\lambda|b(k')-\lambda\overline{c(k')}|^2)}{k'-k}dk'\right], \quad k_0 = -\frac{x}{4t}. \tag{4.2}$$

Proof. The method of [11] can be thought of as a nonlinear steepest-descent method. The stationary point and the directions of the steepest descent associated with $\exp 2i(kx+2k^2t)$ are given by $k_0 = -x/4t$ and $Im(i(k-k_0)^2) = 0$, respectively. This implies that we must deform the original RH problem to one defined on the above steepest-descent contours (see the solid lines of Figure 4.1). We now discuss how this deformation can be achieved.

The jump matrix along the positive real axis can be factorized into two triangular matrices. Using this factorization, we find

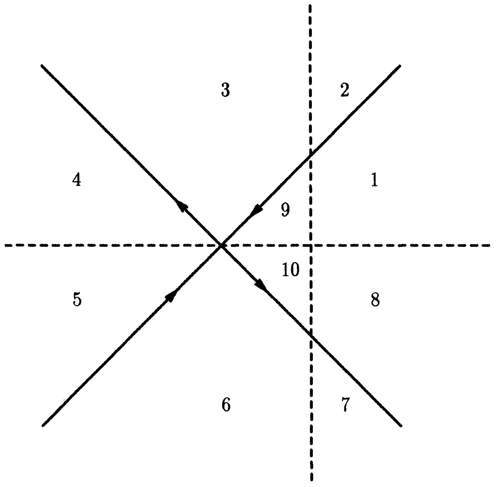


FIG. 4.1.

$$\hat{Z}^- \begin{pmatrix} 1 & b_0(k)e^{-\theta} \\ 0 & 1 \end{pmatrix} = \hat{Z}^+ \begin{pmatrix} 1 & 0 \\ \lambda\overline{b_0(k)}e^{\theta} & 1 \end{pmatrix}, \quad k \in \mathbb{R}^+. \tag{4.3}$$

Suppose that $b_0(k)$ is a rational function with appropriately chosen poles such that $b_0(k)$ is analytic in region 8. Since $e^{-\theta}$ and e^{θ} are analytic and decreasing in regions 8 and 1, respectively, it follows that the relevant jump matrices can be absorbed into $\hat{Z}^-$ and $\hat{Z}^+$. In this way, one can eliminate the jump along $\mathbb{R}^+$. Let c_0 and

$$r_0(k) \div b_0(k) - \lambda\overline{c_0(k)}, \tag{4.4}$$

be appropriate rational functions. Then regions 9 and 10 can be handled without difficulty since the factorization of the jump matrix for $k_0 < k < 0$ still has the "correct" triangularity. Also, the jumps along the broken lines separating regions 1 and 9 and regions 8 and 10 disappear. However, the factorization of the jump matrix for $k < k_0$ has the "wrong" triangularity,

$$\hat{Z}^- = \hat{Z}^+ \begin{pmatrix} 1 & r_0 e^{-\theta} \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\lambda\bar{r}_0 e^{\theta} & 1 \end{pmatrix}, \tag{4.5}$$

i.e., the jump matrix involving $e^{-\theta}$ cannot be absorbed into $\hat{Z}^+$. To overcome this problem, one introduces the function $\delta(k)$. This function is analytic in the complex k-plane cut along $(-\infty, k_0]$; along this cut, it satisfies the jump condition

$$\delta_+(k) = \delta_-(k)(1 - \lambda|b(k) - \lambda\bar{c}(k)|^2), \quad k \in (-\infty, k_0]. \tag{4.6}$$

This jump is precisely chosen by the requirement of reversing the triangularity of the jump along $(-\infty, k_0)$. Indeed, if

$$\hat{W}(x,t,k) = \hat{Z}(x,t,k)(\delta(k))^{-\sigma_3} \tag{4.7}$$

and if G denotes the jump matrices associated with $\hat{Z}$, then the jump matrices associated with $\hat{W}$ are given by $G_0 = \delta^{\sigma_3} G \delta^{-\sigma_3}$. The jump matrices of the RH problem

$$\hat{W}^-(x,t,k) = \hat{W}^+(x,t,k)G_0(x,t,k), \quad k^2 \in \mathbb{R}, \quad \hat{W} \to \mathrm{I}, \quad k \to \infty, \tag{4.8}$$

possess the correct triangular factorizations:

$$G_0(x,t,k) = \begin{pmatrix} 1 & 0 \\ \lambda \bar{b}_0(k)\delta^{-2}(k)e^{\theta} & 1 \end{pmatrix} \begin{pmatrix} 1 & -b_0(k)\delta^2(k)e^{-\theta} \\ 0 & 1 \end{pmatrix}, \quad k \in \mathbb{R}^+,$$

$$G_0(x,t,k) = \begin{pmatrix} 1 & r_0(k)\delta^2(k)e^{-\theta} \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\lambda \bar{r}_0(k)\delta^{-2}e^{\theta} & 1 \end{pmatrix}, \quad k \in [k_0, 0],$$

$$G_0(x,t,k) = \begin{pmatrix} 1 & 0 \\ \frac{-\lambda \overline{r_0(k)}\delta_-^{-2}(k)}{1-\lambda|r_0(k)|^2}e^{\theta} & 1 \end{pmatrix} \begin{pmatrix} 1 & \frac{r_0(k)}{1-\lambda|r_0(k)|^2}\delta_+^2(k)e^{-\theta} \\ 0 & 1 \end{pmatrix}, \quad k < k_0,$$

where $\delta_\pm(k) = \delta(k \pm i0)$, $k \in \mathbb{R}$. The first two equations above follow from equations (4.3) and (4.5). For the derivation of the third equation above, we use equation (4.6) and the fact that $|b(k) - \lambda\bar{c}(k)| = |r_0|$ (see the definitions of b_0 and c_0 in Proposition 2.4 (iii)).

The triangular factorizations of G_0 imply that the jumps along the real axis can be eliminated. The jump condition along the broken line separating regions 2 and 3 is given by

$$\hat{W}^- = \hat{W}^+ \begin{pmatrix} 1 & 0 \\ c_0\delta^{-2}e^{\theta} & 1 \end{pmatrix};$$

this shows that the jump matrix can be absorbed into $\hat{W}^+$. The proof continues similarly for the jump along the broken line separating regions 6 and 7. Hence, the function

$$X(x,t,k) = \hat{W}(x,t,k)K(x,t,k), \tag{4.9}$$

where $K(x,t,k)$ is given by

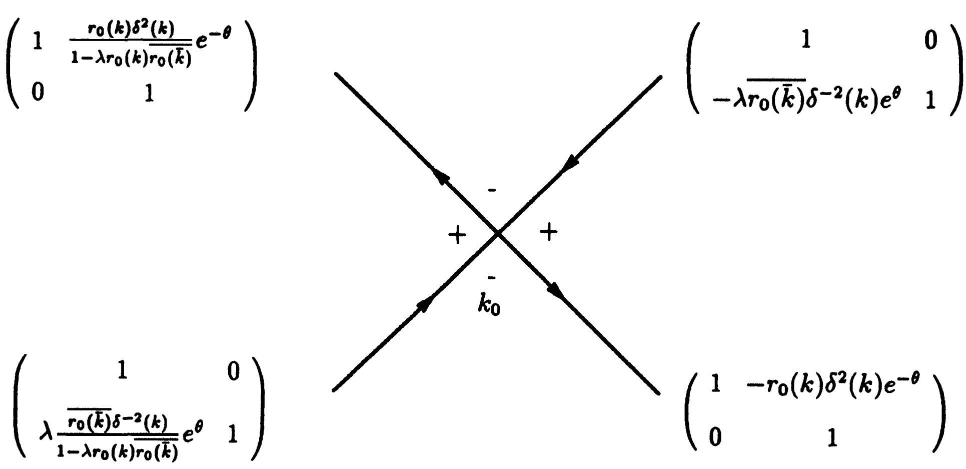
$$\begin{pmatrix} 1 & 0 \\ \lambda\overline{b_0(\bar{k})}\delta^{-2}(k)e^{\theta} & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ c_0(k)\delta^{-2}(k)e^{\theta} & 1 \end{pmatrix}, \ \mathrm{I}, \begin{pmatrix} 1 & -\frac{r_0(k)}{1-\lambda r_0(k)\overline{r_0(\bar{k})}}\delta^2(k)e^{-\theta} \\ 0 & 1 \end{pmatrix},$$

$$\begin{pmatrix} 1 & 0 \\ -\lambda\frac{\overline{r_0(\bar{k})}}{1-\lambda r_0(k)\overline{r_0(\bar{k})}}\delta^{-2}(k)e^{\theta} & 1 \end{pmatrix}, \ \mathrm{I}, \ \begin{pmatrix} 1 & \lambda\overline{c_0(\bar{k})}\delta^2(k)e^{-\theta} \\ 0 & 1 \end{pmatrix},$$

$$\begin{pmatrix} 1 & b_0(k)\delta^2(k)e^{-\theta} \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ \lambda\overline{r_0(\bar{k})}\delta^{-2}(k)e^{\theta} & 1 \end{pmatrix}, \begin{pmatrix} 1 & r_0(k)\delta^2(k)e^{-\theta} \\ 0 & 1 \end{pmatrix}$$

for $k \in 1, 2, \ldots, 9, 10$ respectively is a sectionally holomorphic function satisfying the RH problem depicted in Figure 4.2 (also $X \to \mathrm{I}$ as $k \to \infty$). The RH problem for $X(x,t,k)$ has the crucial property that its jump matrices decay exponentially to the identity away from the stationary point k_0. This, just like the classical steepest-descent method, implies

$$X(x,t,k) = \mathrm{I} + O(t^{-\frac{1}{2}}) \tag{4.10}$$



$\begin{pmatrix} 1 & \frac{r_0(k)\delta^2(k)}{1-\lambda r_0(k)\overline{r_0(\bar{k})}}e^{-\theta} \\ 0 & 1 \end{pmatrix}$
$\begin{pmatrix} 1 & 0 \\ -\lambda\overline{r_0(\bar{k})}\delta^{-2}(k)e^{\theta} & 1 \end{pmatrix}$
-
+
+
-
k_0
$\begin{pmatrix} 1 & 0 \\ \lambda\frac{\overline{r_0(\bar{k})}\delta^{-2}(k)}{1-\lambda r_0(k)\overline{r_0(\bar{k})}}e^{\theta} & 1 \end{pmatrix}$
$\begin{pmatrix} 1 & -r_0(k)\delta^2(k)e^{-\theta} \\ 0 & 1 \end{pmatrix}$

FIG. 4.2. *The deformed RH problem arising in the asymptotic analysis of the initial-boundary value problem of NLS. The x,t dependence enters only through $\theta(x,t) = 2i(kx + 2k^2t)$ and $\delta = \delta(k;k_0)$, $k_0 = -x/4t$.*

for k away from k_0. Indeed, if Γ and $\tilde{G}_0$ denote the contours and the jump matrices of Figure 4.2, then

$$X(x,t,k) = \mathrm{I} + \frac{1}{2\pi i}\int_\Gamma \frac{X^+(x,t,k')(\mathrm{I}-\tilde{G}_0(x,t,k'))}{k'-k}dk' \tag{4.11}$$

for k not on Γ. Taking into account the a priori estimate $|X^+(x,t,k)| \leq$ const and using the classical Laplace's method to the integral of the rhs of equation (4.11), one finds equation (4.10).

This concludes the proof of Theorem 4.1 in the case that b_0 and c_0 are rational. The general case can be reduced to this case following the construction of [11].

Remark 4.1. In the solitonless case, $\hat{Z}_p = \hat{Z}$, and Theorem 4.1 gives the asymptotic solution of the RH problem (1.19). Using equation (2.3.1b), which relates $q(x,t)$ to $\hat{Z}$, and the asymptotic relation (4.1), it follows that in the solitonless case,

$$q(x,t) = O(t^{-\frac{1}{2}}), \quad t \to \infty, \quad 0 \leq A \leq \frac{x}{t} \leq B. \tag{4.12}$$

We now consider the case that poles $\{k_j\}_1^N$ do exist. We assume $\lambda = -1$.

THEOREM 4.2. *Under the assumptions of Proposition* 2.4, *the solution $\hat{Z}_p(x,t,k)$ of the RH problem* (1.19) *satisfies the asymptotic equation*

$$\hat{Z}_p(x,t,k) = (\mathrm{I}+O(t^{-\frac{1}{2}}))\hat{Z}_S(x,t,k)(\delta(k))^{\sigma_3}, \quad t \to \infty, \quad 0 < A \leq \frac{x}{t} \leq B < \infty, \tag{4.13}$$

uniformly for $|Imk| \geq \varepsilon > 0$. The scalar function $\delta(k)$ is defined in equation (4.2). *The matrix function $\hat{Z}_S(x,t,k)$ is given by the algebraic equations* (2.4.2)–(2.4.4) *with $\lambda = -1$, $\hat{Z}$ replaced by* I, *and c_j replaced by $c_j(\delta(k_j))^{-2}$.*

Proof. Equation (4.13) is a direct consequence of Proposition 2.4, Theorem 4.1, and the equation $\overline{\delta(k_j)} = (\delta(\bar{k}_j))^{-1}$.

Remark 4.2. The function $\hat{Z}_S$ is nothing but the matrix eigenfunction corresponding to the pure N-soliton solution $q_s(x,t)$ of the NLS equation with parameters $\{k_j\}_1^N$ and $\{c_j(\delta(k_j))^{-2}\}_1^N$. This implies that

$$q(x,t) = q_s(x,t) + O(t^{-\frac{1}{2}}). \tag{4.14}$$

Using the well-known formula for the N-soliton solution of the NLS (or the algebraic system (2.4.3) directly), one can easily extract from (4.14) the asymptotics of $q(x,t)$ along the soliton rays, given in (1.4) and (1.5).

Remark 4.3. Just as in the classical steepest-descent method, one can improve estimate (4.10) by calculuating the contribution from the stationary point k_0 in closed form. It turns out [12] that the corresponding model RH problem can be solved explicitly in terms of parabolic cylindrical functions. The analysis is similar to that for the full-line problem presented in [10]. This leads to the following formula for the dispersive part of the asymptotics of $q(x,t)$:

(4.15)

$$q(x,t) = \alpha\left(-\frac{x}{4t}\right)t^{-1/2}\exp\left\{\frac{ix^2}{4t} + 2i\alpha^2\left(-\frac{x}{4t}\right)\log t + i\varphi_0\left(-\frac{x}{4t}\right)\right\} + 0(t^{-1/2}),$$

where the amplitude α and the phase φ_0 are given by

$$\alpha^2(k) = \frac{1}{4\pi}\log[1 + |b(k) + \overline{c(k)}|^2], \tag{4.16a}$$

$$\varphi_0(k) = 2\alpha^2(k)\log 2 + \frac{3\pi}{4} + \arg(b(k) + \overline{c(k)})$$

$$+\arg\Gamma(-2i\alpha^2(k)) + 4\int_{-\infty}^{k}\log|\mu - k|d\alpha^2(\mu) + 2\sum_{j=1}^{N}\arg(k_j - k)\mathrm{sign}(\xi_j - k). \tag{4.16b}$$

Remark 4.4. One can use equation (4.16a) to replace $\log[1 + |b(k) + \overline{c(k)}|^2]$ in the integral terms of equations (1.5) by $4\pi\alpha^2$. This shows that these terms indeed represent the interaction of solitons with the dispersive part.

Remark 4.5. In the case of the NLS on the full line, one can use equations (4.16) to solve b and c in terms of α and φ_0. However, in our case, this cannot be done since to define b and c, one needs two real functions defined on the whole linear (see Remark 2 in §2), while α and φ_0 are real functions defined in the half-line. This is a reflection of the fact that the information traveling towards the boundary is lost as $t \to \infty$. In the case of zero initial data, waves travel away from the boundary, no information is lost asymptotically, and the asymptotics of $q(x,t)$ can be used to recover c and hence $q(0,t)$.

Acknowledgments. The authors are grateful to L. Sung for many useful suggestions and to I. M. Gel'fand for his encouragement. The idea of using a combination of exact methods and of PDE techniques to solve initial-boundary value problems emerged after many discussions with J. Bona.

STABILITY OF THE BUNSEN FLAME PROFILES IN THE KURAMOTO–SIVASHINSKY EQUATION*

DANIEL MICHELSON†

Abstract. The stability of the conical stationary solutions of the Kuramoto–Sivashinsky equation $u_t + \Delta^2 u + \Delta u + |\nabla u|^2 = c^2$ in one and two space dimensions is studied. It is shown that these solutions are unstable in the whole space. Next the problem is studied in the one-dimensional (1D) case in a bounded interval $|x| \leq l$ and in the 2D case in a disc $0 \leq r < l$ with natural boundary conditions. It is proved that for a large slope c the above stationary solutions are stable. In the 1D case part of the proof is computer assisted.

Key words. Bunsen flames, Kuramoto–Sivashinsky equation, computer-assisted proofs

1. Introduction.

It was shown in [2] and [3] that the Kuramoto–Sivashinsky equation

$$u_t + \Delta^2 u + \Delta u + |\nabla u|^2 = c^2, \quad u = u(x,t), \qquad x \in R^1 \quad \text{or} \quad x \in R^2 \tag{1.1}$$

possesses stationary conical solutions. In the context of combustion theory these solutions represent Bunsen flames on infinite linear or circular burners. From the mathematical point of view, in the one-dimensional case these are the solutions of the ordinary differential equation (ODE)

$$y''' + y' = c^2 - y^2, \quad y(x) = u'(x), \qquad -\infty < x < \infty, \tag{1.2}$$

which satisfy the boundary conditions

$$y(\pm\infty) = \mp c \tag{1.3}$$

and in the two-dimensional case these are the radial solutions $u(r)$ of the ODE

$$\left(\frac{d^2}{dr^2} + \frac{1}{r}\frac{d}{dr}\right)\left(\frac{d}{dr} + \frac{1}{r}\right) y + \left(\frac{d}{dr} + \frac{1}{r}\right) y = c^2 - y^2, \qquad y(r) = u'(r), \tag{1.4}$$

with the boundary conditions

$$y(0) = y''(0) = 0, \qquad y(\infty) = -c. \tag{1.5}$$

In [2] it was proved analytically that for large c the problem (1.2), (1.3) has an odd solution. The result of [7] implies the uniqueness of a bounded solution of (1.2) for large c. Problem (1.4), (1.5) is apparently not amenable to analytical treatment. Nevertheless, the existence of solutions for (1.4), (1.5) was established in [3] for $0.27 \approx c_0 < c \leq \infty$ by a rigorous computer-assisted proof. The uniqueness for large c (for small c uniqueness is not expected) was not proved; however the computer program verified the following transversality condition.

Transversality condition. Let y_0 be a solution of (1.4), (1.5) such that

$$y_0(0) = y_0''(0) = 0 \tag{1.6}$$

*Received by the editors August 27, 1993; accepted for publication (in revised form) August 24, 1994.

and let y be the solution of the linear problem

$$L[y_0]y = \left[\left(\frac{d^2}{dr} + \frac{1}{r}\frac{d}{dr}\right)\left(\frac{d}{dr} + \frac{1}{r}\right) + \left(\frac{d}{dr} + \frac{1}{r}\right) + 2y_0\right] y = 0, \tag{1.7}$$

$$y(0) = y''(0) = 0, \qquad y'(0) = 1. \tag{1.8}$$

Then, for large r the vector $\overline{y}(r) = (y(r), y'(r), y''(r))$ is transversal to the stable two-dimensional manifold $\mathcal{M}_2(r)$ of the flow defined by (1.7).

Note that the condition $y(0) = y''(0) = 0$ is imposed because we wish the corresponding u to be a solution of the partial differential equation in the plane. The above transversality condition was shown to hold for the computed radial solution $y_0(r)$ in the range $c_0 < c \leq \infty$. Our $y_0(r)$ is negative for $r > 0$. In [4] the computer also checked that for large c

$$y_0(r)/r + y_0'(r) < 0 \text{ for } r > 0. \tag{1.9}$$

We conjecture that the above condition defines y_0 uniquely. In the 1D case the transversality and the negativeness of y_0 for large c is proved analytically (e.g., see [6]).

Thus we take the existence of y_0 and the transversality condition for granted and pose the following question: *is the corresponding solution $u_0(x)$ stable in the sense of the evolutionary problem* (1.1) *with a fixed c*? Since in [4] it was shown that rotating solutions bifurcate from u_0, the answer should be negative. Actually, u_0 turns out to be linearly unstable also in the space of radial functions. The precise statement is as follows.

THEOREM 1. *For each s in the domain $\mathcal{D}$*

$$\mathcal{D} = \left\{ s \in \mathbb{C} | 0 < |\text{Ims}| < 2c, 0 < \text{Res} < \left(\frac{\text{Ims}}{2c}\right)^2 - \left(\frac{\text{Ims}}{2c}\right)^4 \right\} \tag{1.10}$$

the eigenvalue problem

$$\left(s + \Delta^2 + \Delta + 2u_0' \frac{\partial}{\partial r}\right) v = 0, \qquad v = v(x), \quad x \in R^2 \tag{1.11}$$

has radial exponentially decreasing solutions. In the 1D *case the corresponding function $v(x)$ depends on $x \in R^1$ and is even.*

As follows from the general theory of linear parabolic equations, the Cauchy problem for (1.1) when linearized at u_0 is well posed in a proper sense. Let the initial condition in (1.1) be $u = u_0 + \epsilon \text{Re } v$, where v is the eigenfunction in (1.11). Since the nonlinearity in (1.1) is weak, one can easily prove that the difference $u - u_0$ will grow exponentially in time for $t \leq \text{const} \cdot \log \epsilon^{-1}$.

Yet, numerical experiments show that the Bunsen flame profiles are stable for large c. The reason for it is the boundedness of the domain of x. Hence we consider (1.1) in a bounded domain

$$\Omega : 0 \leq r \leq l_0 \text{ in 2D} \quad \text{or} \quad |x| \leq l_0 \quad \text{in 1D}. \tag{1.12}$$

Let u_0 be the conical stationary solution of (1.1) in R^2 or R^1. We will impose the following boundary conditions:

$$u = u_0, \qquad \Delta u = \Delta u_0 \quad \text{at } \partial\Omega \tag{1.13}$$

or another pair

$$u = u_0, \qquad u_r = u_{0r} \quad \text{at } \partial\Omega. \tag{1.14}$$

In the 1D case Δu is replaced by u_{xx} and u_r by u_x. It is also possible to set similar boundary conditions that are independent of u_0

$$u = 0 \quad \text{and} \quad \Delta u = 0 \quad \text{at } \partial\Omega \tag{1.15}$$

or

$$u = 0 \quad \text{and} \quad u_r = -c \quad \text{at } \partial\Omega. \tag{1.16}$$

In the latter case one should first find a stationary radial solution $\tilde{u}_0$ that satisfies (1.15) or (1.16) and then study its stability. In the 1D case for large c we will consider more general nonlinear boundary conditions

$$S_\pm(\overline{u}_c(\pm l_0)) = 0, \tag{1.17}$$

where

$$\overline{u}_c(x) = c^{-2/3}(u(x), c^{-1/3}u'(x), c^{-2/3}u''(x), c^{-1}u'''(x)) \tag{1.18}$$

and $S_\pm : C^4 \to C^2$ are smooth mappings that satisfy

$$S_+(u, u', u'', u''') = S_-(u, -u', u'', -u''') \quad \text{and} \quad S_+(0, -1, 0, 0) = 0 \tag{1.19}$$

so that (1.17) is invariant under the transformation $x \to -x$. We will assume that the differential $dS_+[0, -1, 0, 0]$ of S_+ at $(0, -1, 0, 0)$ satisfies the Lopatinsky condition for the equation

$$\frac{d^4u}{dx^4} - \frac{2du}{dx} + su = 0, \qquad \text{Re}s \geq 0. \tag{1.20}$$

Namely, let λ_3, λ_4 be the two roots of the equation

$$\lambda^4 - 2\lambda + s = 0, \qquad \text{Re}s \geq 0 \tag{1.21}$$

in the half-plane Re $\lambda \geq 0$. Then we request that the vectors

$$dS_+[0, -1, 0, 0] \cdot (1, \lambda_i, \lambda_i^2, \lambda_i^3)^T, \qquad i = 3, 4 \tag{1.22}$$

are independent for all Re$s \geq 0$.

Concerning the existence of a stationary solution we will prove the following result in §3.

THEOREM 2. *Under the transversality condition,* (1.1) *with boundary conditions* (1.15) *or* (1.16) *and large* $l = l_0c^{1/3}$ *has a stationary solution* $\tilde{u}_0$ *close to* u_0. *The same result applies to the* 1D *problem with boundary condition* (1.17) *and large* c *and* l.

Concerning the stability of the stationary solution we will prove the following main result.

THEOREM 3. *For each* $l_0 > 0$ *there exists* $c^*(l_0)$ *such that for* $c > c^*(l_0)$ *the stationary radial solutions* $u_0(r)$ *and* $\tilde{u}_0(r)$ *are asymptotically stable in the sense of the corresponding evolutionary problem for* (1.1), *with boundary conditions* (1.13), (1.14) *and* (1.15), (1.16), *respectively. In the* 1D *case the same result holds for the* *boundary condition* (1.17) *and* $c > c^*, l_0 c^{1/3} > l^*$, *where* c^*, l^* *are some constants independent of* l_0.

The stability of the stationary solution for large c is linked to the eigenvalue problem

$$\left(s + \Delta^2 + 2y_0 \frac{\partial}{\partial r}\right) v = 0, \quad v = v(x), \quad x \in R^2 \text{ or } x \in R^1, \tag{1.23}$$

where y_0 is the solution of the equation

$$\left(\frac{d^2}{dr} + \frac{1}{r}\frac{d}{dr}\right)\left(\frac{d}{dr} + \frac{1}{r}\right) y = 1 - y^2, \qquad y(0) = y''(0) = 0, \quad y(\infty) = -1 \tag{1.24}$$

and in the 1D case, the solution of

$$y''' = 1 - y^2, \quad y(0) = y''(0) = 0, \quad y(\infty) = -1. \tag{1.25}$$

In the 2D case, (1.23) has no exponentially decreasing solutions as $|x| \to \infty$ with $\mathrm{Re}s \geq 0$. This follows from the property (1.9) of y_0. In the 1D case we would need $y_0'(x) < 0$ for $x > 0$ but this is not the case. Therefore we need the assistance of a computer. The proof is carried out in interval arithmetic and is completely rigorous module human or hardware errors. In §5 we show how to restrict problem (1.23) to a finite domain of $s : 0 \leq \mathrm{Re}s \leq .164, 0 \leq \mathrm{Im}s \leq 1.6$. Due to its length (about 800 lines, not counting the interval arithmetic library) the computer program is not included, but it can be obtained from the author upon request.

2. Instability in the unbounded domain.

Since we are mainly concerned with the case of large c, it is convenient to rescale problem (1.1) as follows:

$$u_{\text{new}} = c^{2/3} u_{\text{old}}, \quad x_{\text{new}} = c^{1/3} x_{\text{old}}, \quad t_{\text{new}} = c^{4/3} t_{\text{old}}. \tag{2.1}$$

Then (1.1) becomes

$$u_t + \Delta^2 u + \alpha \Delta u + |\nabla u|^2 = 1, \qquad 0 \leq \alpha = c^{-2/3} \leq \alpha_0. \tag{2.2}$$

The corresponding eigenvalue problem is

$$sv + \Delta^2 v + \alpha \Delta v + 2u_0' v_r = 0, \tag{2.3}$$

where $y_0 = u_0'$ is the solution of

$$\begin{gathered}\left(\frac{d^2}{dr^2} + \frac{1}{r}\frac{d}{dr}\right)\left(\frac{d}{dr} + \frac{1}{r}\right) y + \alpha \left(\frac{d}{dr} + \frac{1}{r}\right) y = 1 - y^2, \\ y(0) = y''(0), \quad y(\infty) = -1.\end{gathered} \tag{2.4}$$

In the 1D case the equation for y_0 is

$$y''' + \alpha y' = 1 - y^2, \quad y(0) = y''(0) = 0, \quad y(\infty) = -1. \tag{2.5}$$

As $x \to \infty$ the limiting characteristic equation is

$$s + \lambda^4 + \alpha\lambda^2 - 2\lambda = 0. \tag{2.6}$$

For large $|s|$ with Re$s > 0$, two of the roots of (2.6), say λ_1, λ_2, have negative real parts and two, λ_3, λ_4, have Re $\lambda > 0$. If $\lambda = i\omega$ is imaginary, then s lies on the line

$$s = -\omega^4 + \alpha\omega^2 + 2i\omega \tag{2.7}$$

and for $0 < |\omega| < \alpha^{1/2}$ the corresponding s has Re$s > 0$. Denote by $\mathcal{D}$ the domain of s bounded by the above line and Re$s = 0$,

$$\mathcal{D} = \left\{ s \in \mathbb{C} | 0 < |\text{Im} s| < 2\alpha^{1/2}, 0 < \text{Re} s < \alpha \left(\frac{\text{Im} s}{2}\right)^2 - \left(\frac{\text{Im} s}{2}\right)^4 \right\}. \tag{2.8}$$

This is nothing but the domain $\mathcal{D}$ defined at (1.10) in the transformed variables. It is easy to see that for small $s \in \mathcal{D}$, (2.6) has three roots, $\lambda_1, \lambda_2, \lambda_3$ with Re $\lambda < 0$ and one λ_4 with Re $\lambda > 0$. By continuity this result holds for all $s \in \mathcal{D}$ while for s outside $\mathcal{D}$ and with Re$s > 0$, (2.6) has two roots λ_1, λ_2 with negative and two roots λ_3, λ_4 with positive real parts. Now, fix $s \in \mathcal{D}$. First consider the 2D case. Equation (2.3) for a radial function $v(r)$ becomes

$$sv + \left(\frac{d^2}{dr^2} + \frac{1}{r}\frac{d}{dr}\right)^2 v + \alpha \left(\frac{d^2}{dr^2} + \frac{1}{r}\frac{d}{dr}\right) v + 2y_0 \frac{dv}{dr} = 0 \tag{2.9}$$

with initial conditions

$$v'(0) = v'''(0) = 0. \tag{2.10}$$

The function y_0 has an asymptotic expansion

$$y_0 \sim -1 + \sum_{i=1}^{\infty} b_i r^{-i}, \qquad b_1 = -\alpha/2, b_2 = \alpha^2/8 \tag{2.11}$$

(see [3, (3.21)]). In the case when all roots λ_i of (2.7) are distinct and have different real parts, (2.10) has four independent solutions v_i with asymptotics

$$v_i(r) \sim e^{\lambda_i r} \sum_{n=0}^{\infty} a_{in} r^{-n}. \tag{2.12}$$

In our case λ_4 is always distinct and has a distinct real part, but $\lambda_1, \lambda_2, \lambda_3$ may have multiple real parts, e.g., Re λ_1 = Re λ_2 for Re$s = 0$. Still, one can choose four independent solutions such that v_1, v_2, v_3 are exponentially decreasing while v_4 is exponentially increasing (actually, v_4 is as in (2.12)). In the neighborhood of $r = 0$, $y_0(r)$ could be expanded into converging power series with odd powers of r (see [3]). This implies (see [4]) that the solution v of (2.9), (2.10) in a neighborhood of $r = 0$ could be expanded into a series

$$v(r) = \sum_{n=0}^{\infty} a_n r^{2n}, \tag{2.13}$$

where a_0 and a_1 are free parameters. We can choose two independent solutions φ_1 and φ_2 by selecting pairs $a_0 = 1, a_1 = 0$, or $a_0 = 0, a_1 = 1$. Since $\varphi_i = \sum_{j=1}^{4} c_{ij} v_j, i = 1, 2$ we can select a linear combination $\varphi = k_1\varphi_1 + k_2\varphi_2$ such that φ is a linear combination of v_1, v_2, v_3 only. Thus, for any $s \in \mathcal{D}$ we obtain a solution $v = \varphi$ of (2.9), (2.10) that decays exponentially at infinity.

In the 1D case y_0 approaches -1 along the stable 2D manifold defined by (2.5) (see [2]) and has the asymptotics

$$y_0(x) = -1 + O(e^{x\mathrm{Re}\lambda_{10}}), \tag{2.14}$$

where λ_{10} is the root of the equation

$$\lambda^3 + \alpha\lambda - 2 - 0 \tag{2.15}$$

with Re $\lambda < 0$. Again we have four independent solutions $v_i(x)$ of the equation

$$sv + \frac{d^4v}{dx^4} + \alpha\frac{d^2v}{dx^2} + 2y_0\frac{dv}{dx} = 0 \tag{2.16}$$

with v_4 exponentially increasing and v_1, v_2, v_3 exponentially decreasing. The solutions φ_1, φ_2 that satisfy (2.10) will be defined by initial conditions $\varphi_1(0) = 1, \varphi_1''(0) = 0$ and $\varphi_2(0) = 0, \varphi_2''(0) = 1$. Again we obtain a linear combination $\varphi = k_1\varphi_1 + k_2\varphi_2$ that decays exponentially as $x \to \infty$. This completes the proof of Theorem 1.

3. The existence of a stationary solution in a bounded domain. Let us consider a more general situation. Given a system of ODEs in R^n

$$\frac{dx}{dt} = f(x, t^{-1}), \qquad t_0 \le t < \infty, \tag{3.1}$$

where f depends smoothly on x and t^{-1}, and

$$f(0,0) = 0, \quad d_x f(0,0) = \begin{pmatrix} \lambda_1 & 0 \\ 0 & M_2 \end{pmatrix}, \qquad \lambda_1 > 0, \text{ Re } M_2 < 0. \tag{3.2}$$

Let $x_0(t)$ be a solution of (3.1) that tends to 0 as $t \to \infty$. We are looking for a solution of the problem

$$x' = f(x, t^{-1}), \quad t_0 \le t \le t_1, \quad x(t_0) \in \gamma, \quad S(x(t_1), t_1^{-1}) = 0, \tag{3.3}$$

where $\gamma = \gamma(p)$ is a smooth curve in R^n with $\gamma(0) = x_0(t_0)$ and $S : R^n \times R^1 \to R^1$ is a smooth map in a neighborhood of zero with $S(0) = 0$. It is assumed that $\gamma'(0)$ is transversal to the stable manifold $\mathcal{M}_{n-1}(t)$ of the system (3.1) at $t = t_0$ and that $d_x S(0,0)$ does not vanish on the eigenvector $e_1 = (1, 0, \dots, 0)^T$ of the matrix $d_x f(0,0)$.

LEMMA 3.1. *Under the above conditions, problem* (3.3) *for a sufficiently large* t_1 *has a solution* $x(t)$ *such that*

$$|x(t) - x_0(t)| < K\left(\frac{t}{t_1}\right)^m e^{\lambda_1(t-t_1)}|S(x_0(t_1), t_1^{-1})|, \tag{3.4}$$

where K *does not depend on* t_1 *and* m *is a constant (to be defined later).*

The proof is based on a standard normalization procedure for the solution map $\varphi[t_0, t_1] : x(t_0) \to x(t_1)$ in a neighborhood of $x_0(t_0)$. Let us partition vector x as $x = (x_1, x_2), x_1 \in R^1, x_2 \in R^{n-1}$. Without loss of generality we may assume that the stable manifold $\mathcal{M}_{n-1}(t)$ is given by the equation $x_1 = 0$. Then the differential $A(t^{-1}) = d_x f(x_0(t), t^{-1})$ has the block triangular form

$$A(t^{-1}) = \begin{pmatrix} a_1 & 0 \\ A_{21} & A_{22} \end{pmatrix}. \tag{3.5}$$

Since the function $x_0(t)$ has an asymptotic expansion

$$x_0(t) = c_1 t^{-1} + c_2 t^{-2} + \cdots = c_1 t^{-1} + O(t^{-2}), \tag{3.6}$$

the entries of $A(t^{-1})$ are

$$a_1 = \lambda_1 + m t^{-1} + O(t^{-2}), \quad A_{21} = O(t^{-1}), \quad A_{22} = M_2 + O(t^{-1}). \tag{3.7}$$

Now normalize the variables

$$x(t) = x_0(t) + \tilde{x}(t)\rho(t, t_1), \qquad \rho(t, t_1) = e^{\lambda_1(t-t_1)} \left(\frac{t}{t_1}\right)^m. \tag{3.8}$$

System (3.1) becomes

$$\tilde{x}'(t) = \tilde{A}(t^{-1})\tilde{x} + \rho(t, t_1)O(|\tilde{x}|^2), \tag{3.9}$$

where $\tilde{A}$ has the same form as in (3.5) but with

$$\tilde{a}_1 = O(t^{-2}) \quad \text{and} \quad \tilde{A}_{22} = \tilde{M}_2 + O(t^{-1}) = M_2 - \lambda_1 I + O(t^{-1}). \tag{3.10}$$

Solve (3.9) on an interval $t \in [t^*, t_1]$ with given $\tilde{x}(t^*)$. Let us represent the solution as

$$\tilde{x}(t) = e^{\tilde{A}(0)(t-t^*)}\tilde{x}(t^*) + \Delta\tilde{x}(t), \qquad \Delta\tilde{x}(t^*) = 0. \tag{3.11}$$

Then $\Delta\tilde{x}$ satisfies

$$\begin{aligned} \Delta\tilde{x}' = {} & \tilde{A}(t^{-1})\Delta\tilde{x} + (0, O(t^{-1}))^T \tilde{x}(t^*) + O(t^{-2})\tilde{x}(t^*) \\ & + \rho(t, t_1)O(|\tilde{x}|^2) = \tilde{A}(t^{-1})\Delta\tilde{x} + g. \end{aligned} \tag{3.12}$$

Note that

$$\operatorname{Re} \tilde{A}(t^{-1}) < \begin{pmatrix} O(t^{-2}) & 0 \\ 0 & -cI \end{pmatrix}. \tag{3.13}$$

Multiplication of (3.12) by $\Delta\tilde{x}$ and integration over the interval $I = [t^*, t]$ yields

$$\begin{aligned} \tfrac{1}{2}|\Delta\tilde{x}(t)|^2 \le {} & -c\|\Delta\tilde{x}_2\|_2^2 + K\|t^{-2}\|_1 \|\Delta\tilde{x}_1\|_\infty^2 + \|g_1\|_1 \|\Delta\tilde{x}_1\|_\infty \\ & + \|g_2\|_2 \|\Delta\tilde{x}_2\|_2, \end{aligned} \tag{3.14}$$

where $\|\cdot\|_p$ are the L_p norms on I and $g = (g_1, g_2)$ is partitioned according to x. Hence, for $t^* > (4K)^{-1}$,

$$\begin{aligned} \|\Delta\tilde{x}\|_\infty \le {} & K(\|g_1\|_1 + \|g_2\|_2) \le K((\|t^{-2}\|_1 + \|t^{-1}\|_2)|\tilde{x}(t^*)| \\ & + \|\rho(t, t_1)\|_1 (\|\Delta\tilde{x}\|_\infty + |\tilde{x}(t^*)|)^2). \end{aligned} \tag{3.15}$$

It is easy to see that the norm $\|\rho(t, t_1)\|_1$ is uniformly bounded for all $t_0 \le t^* < t_1 < \infty$ while $\|t^{-2}\|_1, \|t^{-1}\|_2 \to 0$ as $t^*, t_1 \to \infty$. Thus, for small $|\tilde{x}(t^*)| < \delta$, and large $t^* \ge t_0^*$

$$\|\Delta\tilde{x}\|_\infty \le K((t^*)^{-1/2}|\tilde{x}(t^*)| + |\tilde{x}(t^*)|^2) \tag{3.16}$$

uniformly in t_1. Now, if we differentiate (3.11), (3.12) with respect to the initial vector $\tilde{x}(t^*)$ and proceed as above, we obtain

$$\|\partial\Delta\tilde{x}/\partial\tilde{x}(t^*)\|_\infty \le K((t^*)^{-1/2} + |\tilde{x}(t^*)|). \tag{3.17}$$

Thus, for large t^* the map

$$\tilde{\varphi}[t^*,t] : \tilde{x}(t^*) \to \tilde{x}(t) \tag{3.18}$$

in the neighborhood of 0 approximates in the C^1 norm the linear map $\exp(\tilde{A}(0)(t-t^*))$ uniformly in the parameters $t^* \le t \le t_1 < \infty$.

Now return to the problem in (3.3). Rescale the curve $\gamma(p)$ as

$$\tilde{p} = \rho(t_0,t_1)^{-1}p, \qquad \tilde{\gamma}(\tilde{p}) = (\rho(t_0,t_1))^{-1}(\gamma(p)-\gamma(0)). \tag{3.19}$$

By the transversality assumption $\tilde{\gamma}'(0) = \gamma'(0)$ has a nonzero component $\tilde{\gamma}_1'(0)$. Without loss of generality we may assume that t_0 coincides with t_0^*. Denote by $\tilde{\gamma}(\tilde{p},t)$ the curve

$$\tilde{\gamma}(\tilde{p},t) = \tilde{\varphi}[t_0,t]\tilde{\gamma}(\tilde{p}), \qquad \tilde{\gamma} = (\tilde{\gamma}_1,\tilde{\gamma}_2). \tag{3.20}$$

It follows from (3.11) and (3.17) that

$$|\tilde{\gamma}_2'(\tilde{p},t)| \le c_1|\tilde{\gamma}_1'(\tilde{p},t)|, \qquad \tilde{\gamma}' = \partial\tilde{\gamma}/\partial\tilde{p} \tag{3.21}$$

for all $|\tilde{p}| < \delta_1$, where c_1 and δ_1 are independent of t and t_1. It follows then again from (3.11), (3.16), and (3.17) that for any $\epsilon > 0$ there exist δ_2 and t_2 such that for $t_2 \le t \le t_1$ and $|\tilde{p}| < \delta_2$

$$|\tilde{\gamma}_2'(\tilde{p},t)| < \epsilon|\tilde{\gamma}_1'(\tilde{p},t)|. \tag{3.22}$$

Since for large $t^*, d\tilde{\varphi}[t^*,t]$, when restricted to the first component, is close to identity, therefore

$$|\tilde{\gamma}_1'(\tilde{p},t)| > \delta_3 \quad \text{for all } |\tilde{p}| < \delta_2 \quad \text{and} \quad t_2 \le t \le t_1. \tag{3.23}$$

The problem in (3.3) could be rewritten as a single equation

$$S(x_0(t_1) + \tilde{\gamma}(\tilde{p},t_1), t_1^{-1}) = 0. \tag{3.24}$$

Recall that $x_0(t_1) = O(t_1^{-1})$. We can apply to (3.24) the implicit function theorem where $t_1^{-1} \approx 0$ serves as a parameter. Indeed,

$$\begin{aligned} &d_xS(x_0(t_1) + \tilde{\gamma}(\tilde{p},t_1), t_1^{-1})\tilde{\gamma}'(\tilde{p},t_1) \\ &\quad = (d_xS(0,0) + O(|\tilde{p}|,t_1^{-1}))\tilde{\gamma}_1'(\tilde{p},t_1)(e_1 + O(\epsilon)) \end{aligned} \tag{3.25}$$

is for small $|\tilde{p}|$ and t_1^{-1} of a constant sign and bounded away from zero. Hence, (3.24) has a locally unique solution

$$\tilde{p} = O^*(S(x_0(t_1), t_1^{-1})). \tag{3.26}$$

The corresponding trajectory $x(t) = x_0(t) + \rho(t,t_1)\tilde{\gamma}(\tilde{p},t)$ then satisfies estimate (3.4). □

The above lemma obviously applies to the equations in (2.4) and (2.5). The vector $x = (y,y',y'')^T, t = x$, or $t = r$. The curve $\gamma(p)$ is given by the vector $x(t_0)$ corresponding to the initial condition $y(0) = y''(0) = 0, y'(0) = p_0 + p$. In cases (1.15) and (1.16) the value of S is $(d/dr + r^{-1})y(r)$ and $y(r)+1$ correspondingly. The eigenvector e_1 corresponds to $x = (1,\lambda_3,\lambda_3^2)^T$ where $\lambda_3 = 2^{1/3}$ is the positive root of (1.21) for $s = 0$. Clearly the condition $d_x S(0,0)e_1 \neq 0$ is satisfied. In the case of the general boundary condition as in (1.17) one should eliminate the first component u, since $u = \int y\,dx$ is defined up to a constant. Since the Lopatinsky condition is assumed to hold also for $s = 0$, we obtain that the vectors $d_x S_+ \cdot (1,0,0,0)^T$ and $d_x S_+ \cdot (1, \lambda_3, \lambda_3^2, \lambda_3^3)^T$ are independent. Let ξ be a row vector orthogonal to $d_x S_+(1,0,0,0)^T$. Then the boundary operator $S = \xi \cdot S_+$ will satisfy the conditions of the lemma. Finally, note that all estimates of Lemma 3.1 apply uniformly to (2.4) and (2.5) for all $0 \le \alpha \le \alpha_0$. In particular the lower limit for $t_1 = l = l_0 c^{1/3}$ could be fixed for all α as above.

In the radial case the value of $S(x_0(t_1), t_1^{-1})$ corresponding to y_0 as in (2.11) is

$$y_0'(l) + y_0(l)/l = -l^{-1} + O(l^{-2}) \tag{3.27}$$

in the case of (1.15) and

$$y_0(l) + 1 = -\frac{\alpha}{2} l^{-1} + O(l^{-2}) \tag{3.28}$$

in the case of (1.16). In the one-dimensional case, as follows from (2.14),

$$\xi \cdot S(0, y_0'(l), y_0''(l), y_0'''(l)) = O(e^{l \mathrm{Re} \lambda_{10}}). \tag{3.29}$$

By (3.4) the derivative $\tilde{y}_0 = \tilde{u}_0'$ of the stationary solution $\tilde{u}_0$ will satisfy in the radial case

$$|\overline{\tilde{y}}_0(r) - \overline{y}_0(r)| < K l^{-1} e^{-(\lambda_{30} - \delta)(l-r)}, \qquad 0 \le r \le l, \tag{3.30}$$

where λ_{30} is the positive root of (2.15) and $\delta > 0$ is arbitrarily small while K depends on δ but not on l and α. Here and elsewhere we denote by $\overline{y}$ the vector

$$\overline{y} = (y, y', y''). \tag{3.31}$$

In the 1D case

$$|\overline{\tilde{y}}_0(x) - \overline{y}_0(x)| < K e^{l Re \lambda_{10}} \cdot e^{-(\lambda_{30} - \delta)(l-r)}, \qquad 0 \le x \le l. \tag{3.32}$$

If we make $\tilde{u}_0(r)$ and $u_0(r)$ coincide at $r = l$, then the difference $\tilde{u}_0(r) - u_0(r) = \int_l^r (\overline{y}_0(r) - y_0(r))dr$ will satisfy the same estimates as in (3.30) and (3.32). This completes the proof of Theorem 2.

Recall that the function y_0 satisfies (1.9). In the next section we will need the same inequality for $\tilde{y}_0$.

LEMMA 3.2. *In the radial case the function $\tilde{y}_0$ for small α and large l satisfies*

$$\tilde{y}_0(r)/r + \tilde{y}_0'(r) \le 0 \quad \text{for } 0 \le r \le l. \tag{3.33}$$

Proof. First consider the case of the boundary condition (1.16). In view of (3.28) we can replace the constant K in (3.30) by $K(\alpha + l^{-1})$. Since $y_0'(r) + y_0(r)r^{-1}$ has the asymptotics $-r^{-1} + O(r^{-2})$ it follows that for r sufficiently large, say $r \ge r_0$ and small $\alpha + l^{-1}$, inequality (3.33) holds. Now, for $0 \le r \le r_0$,

$$|(\tilde{y}_0(r) - y_0(r))r^{-1} + (\tilde{y}_0(r) - y_0(r))'| \le 2 \sup_{0 \le \xi \le r} |\tilde{y}_0'(\xi) - y_0'(\xi)| \tag{3.34}$$

and is estimated by the right-hand side of (3.30). Since at the same time $y_0(r)r^{-1} + y_0'(r) < -\delta < 0$, for large l we obtain (3.33).

In the case of boundary condition (1.15), the operator $S = d/dr + r^{-1}$ when applied to $\tilde{y}_0$ vanishes at $r = l$. In the notation of Lemma 3.1 the vector $\bar{\tilde{y}}_0$ is represented by $x(t)$

$$x(t) = x_0(t) + \rho(t, t_1)(e^{\tilde{A}(0)(t-t_0)}\tilde{x}(t_0) + \Delta\tilde{x}(t)). \tag{3.35}$$

By (3.16) and the block form of $\tilde{A}$ in (3.10), it follows that for large $t_0, \Delta\tilde{x}(t)$ and $\Delta\tilde{x}'(t)$ are $o(\tilde{x}(t_0))$. Recall that by (3.21), $\tilde{x}(t_0) = O(\tilde{x}_1(t_0))$. Now apply to (3.35) the operator $S(\cdot, t^{-1})$. For $t_1 \gg t_0$ we obtain

$$S(x(t_1), t_1^{-1}) = S(x_0(t_1), t_1^{-1}) + d_xS(0,0)e_1\tilde{x}_1(t_0) + o(\tilde{x}_1(t_0)) = 0. \tag{3.36}$$

Here $S(x_0(t_1), t_1^{-1})$ equals $y_0(t_1)t_1^{-1} + y_0'(t_1) = -t_1^{-1} + O(t_1^{-2}) < 0$ and hence $d_xS(0,0)e_1\tilde{x}_1(t_0) = t_1^{-1}(1 + o(1)) > 0$. The derivative with respect to t

$$\begin{aligned} S(x(t), t^{-1})' = S(x_0(t), t^{-1})' &+ \rho'(t, t_1)(d_xS(0,0)e_1\tilde{x}_1(t_0) \\ &+ o(\tilde{x}(t_0))) + \rho(t, t_1)o(\tilde{x}(t_0)). \end{aligned} \tag{3.37}$$

Now, $S(x_0(t), t^{-1})' = t^{-2} + O(t^{-3}) > 0$, and

$$\rho'(t, t_1) = \rho(t, t_1)(\lambda_1 + mt^{-1}) > 0 \quad \text{for large } t. \tag{3.38}$$

Since $\rho(t, t_1) \sim \rho'(t, t_1)$ and $|\tilde{x}(t_0)| \sim |\tilde{x}_1(t_0)| \sim |d_xS(0,0)e_1\tilde{x}_1(t_0)|$, the above derivative is positive and hence $S(x(t), t^{-1}) < 0$. Thus (3.33) holds for $r_0 \le r \le l$ where r_0 is large but independent of l. The range of $0 \le r \le r_0$ is treated as before.

4. The stability of the radial stationary solution.

Let $\tilde{u}_0(r)$ be the radial solution found in the previous section. Namely, $\tilde{y}_0 = \tilde{u}_0'(r)$ is a solution of the equation in (2.4) with initial condition $\tilde{y}_0(0) = \tilde{y}_0''(0) = 0$ and boundary conditions $\tilde{y}_0'(l) + r^{-1}\tilde{y}_0(l) = 0$ in the case of (1.15) and $\tilde{y}_0(l) = -1$ in the case of (1.16). We assume that $\tilde{y}_0(r)$ satisfies estimate (3.33). We will study the eigenvalue problem

$$(sI + L)v = \left(s + \Delta^2 + \alpha\Delta + 2\tilde{y}_0\frac{\partial}{\partial r}\right)v = 0, \qquad v = v(x), \quad x \in \Omega, \tag{4.1}$$

where Ω is a disk $r \le l$, with boundary conditions

$$\Delta v = v = 0 \text{ at } \partial\Omega \tag{4.2}$$

or

$$v_r = v = 0 \text{ at } \partial\Omega. \tag{4.3}$$

Denote by $\mathcal{L}$ the unbounded operator L that acts in the space of functions that satisfy the boundary conditions (4.2) or (4.3). Our main result is the following theorem.

THEOREM 4.1. *For $\alpha = c^{-2/3}$ and $l = l_0c^{1/3}$ with l_0 and c as in Theorem* 3 *the spectrum $\sigma(-\mathcal{L})$ lies in the half plane* Res $< -\delta_0$, *where $\delta_0 > 0$ depends on l_0 but not on $c > c^*$.*

Note that (4.1), (4.2) and (4.1), (4.3) are well-posed elliptic problems that satisfy the Lopatinsky condition. The adjoint problem is

$$(\bar{s}I + \bar{L})v = \left(\bar{s} + \Delta^2 + \alpha\Delta - r^{-1}\frac{\partial}{\partial r}(\tilde{y}_0r)\cdot\right)v = 0 \tag{4.4}$$

with the same boundary conditions as for the direct problem. Hence we should only check that both the direct and adjoint problems have no eigenvalues with $\mathrm{Re}s \geq 0$. Moreover, since for large positive s both operators $sI + \mathcal{L}$ and $(sI + \mathcal{L})^*$ have zero kernel, the index of $sI + \mathcal{L}$ is zero and, by continuity, it remains zero for all s. Hence it is enough to show that problems (4.1), (4.2) and (4.1), (4.3) have no nontrivial smooth solutions with $\mathrm{Re}s \geq 0$.

For that sake multiply (4.1) by v in $L_2(\Omega)$ and take real part. We obtain

$$\mathrm{Re}s\ \|v\|^2 + \|\Delta v\|^2 - \alpha\|\nabla v\|^2 + \int_\Omega (-\tilde{y}_0 r^{-1} - \tilde{y}_0')|v|^2 = 0, \tag{4.5}$$

where $\|\cdot\|$ is the usual $L_2(\Omega)$ norm. The imaginary part of the product yields

$$|\mathrm{Im}s|\|v\|^2 \leq 2\|\tilde{y}_0\|_\infty \|v\| \cdot \|\nabla v\| \leq \|\tilde{y}_0\|_\infty (b_1\|v\|^2 + b_1^{-1}\|\nabla v\|^2). \tag{4.6}$$

Multiply both sides of (4.6) by b_2 and add to (4.5). We obtain

$$\begin{aligned}(\mathrm{Re}s + b_2|\mathrm{Im}s| - b_2 b_1\|\tilde{y}_0\|_\infty)\|v\|^2 - (\alpha + b_2 b_1^{-1}\|\tilde{y}_0\|_\infty)\|\nabla v\|^2 \\ + \int_\Omega (-\tilde{y}_0 r^{-1} - \tilde{y}_0')|v|^2 + \|\Delta v\|^2 \leq 0.\end{aligned} \tag{4.7}$$

Recall that by Lemma 3.2 the last integral is positive. Since our problem does not depend on the polar angle φ we may assume that

$$v(x) = e^{in\varphi} v_n(r). \tag{4.8}$$

Recall that v vanishes on $\partial\Omega$. Hence

$$\|v\|^2 \leq (l/\lambda_{n,1})^2 \|\nabla v_n\|^2 \leq (l/\lambda_{n,1})^4 \|\Delta v_n\|^2, \tag{4.9}$$

where $\lambda_{n,1}$ is the first zero of the nth Bessel function $J_n(r)$. Therefore

$$\alpha\|\nabla v\|^2 \leq \alpha l^2 \lambda_{n,1}^{-2} \|\Delta v\|^2 = l_0^2 \lambda_{n,1}^{-2} \|\Delta v\|^2 < \tfrac{1}{2}\|\Delta v\|^2 \tag{4.10}$$

provided

$$n \approx \lambda_{n,1} > l_0\sqrt{2}. \tag{4.11}$$

Thus (4.5) implies that $v = 0$ for n as above and any s with $\mathrm{Re}s \geq 0$.

Now let b_1 and b_2 in (4.7) be $b_1 = \alpha^{1/2}, b_2 = \alpha^{3/2}/\|\tilde{y}_0\|_\infty$. Then we obtain

$$(\mathrm{Re}s + \alpha^{3/2}|\mathrm{Im}s|/\|\tilde{y}_0\|_\infty - \alpha^2)\|v\|^2 - 2\alpha\|\nabla v\|^2 + \|\Delta v\|^2 \leq 0. \tag{4.12}$$

But if

$$\mathrm{Re}s + \alpha^{3/2}|\mathrm{Im}s|/\|\tilde{y}_0\|_\infty > 2\alpha^2 \tag{4.13}$$

the left-hand side of (4.12) is positive. Thus it remains to study the eigenvalue problem (4.1) for v as in (4.8) with bounded

$$n \leq n_0 \approx l_0\sqrt{2} \tag{4.14}$$

and s in a neighborhood of zero. For this sake we will need the following elementary result.

LEMMA 4.1. *Given a system of linear ODEs*

$$x'(t) = A(t,p)x(t), \quad x(t) \in \mathbb{C}^n, \quad t_0 \leq t < \infty \tag{4.15}$$

$A(t,p)$ has a form

$$A(t,p) = A^{(0)}(p) + \Delta A(t,p), \tag{4.16}$$

where $A^{(0)}(p), \Delta A(t,p)$ depends continuously on a vector parameter p at $p = 0$ and $\|\Delta A(t,p)\| \to 0$ as $t \to \infty$ uniformly in p. Let $A^{(0)}(p)$ have the block form

$$A^{(0)}(p) = A_I^{(0)}(p) \oplus A_{II}^{(0)}(p), \tag{4.17}$$

where

$$\operatorname{Re} A_I^{(0)}(p) \leq \mu_1 < \mu_2 \leq \operatorname{Re} A_{II}^{(0)}(p) \tag{4.18}$$

and partition the vector $x = \binom{x_I}{x_{II}}$ according to the above blocks. Then, for any ϵ_1, ϵ_2 there exists t_1 such that the space X of solutions of (4.15) *for $t \geq t_1$ splits into a direct sum $X = X_I \oplus X_{II}$ with the following properties:*

(i) *if $x \in X_I$ then*

$$|x_{II}(t)| < \epsilon_1 |x_I(t)|, \qquad |x_I(t)| < e^{(\mu_1+\epsilon_2)(t-t_1)}|x_I(t_1)|; \tag{4.19}$$

(ii) *if $x \in X_{II}$ then*

$$|x_I(t)| < \epsilon_1 |x_{II}(t)|, \qquad |x_{II}(t)| > e^{(\mu_2-\epsilon_2)(t-t_1)}|x_{II}(t_1)|; \tag{4.20}$$

(iii) *the restrictions $X_I(t), X_{II}(t)$ of X_I, X_{II} to any $t \in [t_1, \infty)$ depend continuously on p at $p = 0$.*

Proof. By substitution $x(t) \to x(t)e^{\mu t}$ we may assume that $\mu_1 < 0 < \mu_2$. Let $x(t)$ be a solution of (4.15) that tends to 0 as $t \to \infty$. Multiply both sides of (4.15) by Rx in $L_2[t_1, \infty)$ where $R = cI \oplus (-I)$ and take real part. We obtain

$$\frac{1}{2}|x_{II}(t_1)|^2 + \min(-c\mu_1, \mu_2)\|x\|_2^2 \leq \frac{c}{2}|x_I(t_1)|^2 + \|\Delta A\|_\infty \|x\|_2^2, \tag{4.21}$$

where $\|\cdot\|_p$ is the $L_p[t_1, \infty)$ norm. Take $c < \epsilon_1^2$ and t_1 large enough so that $\|\Delta A\|_\infty < \frac{1}{2}\min(-c\mu_1, \mu_2)$. Then $|x_{II}(t)| < \epsilon_1 |x_I(t)|$ for all $t \geq t_1$ and the solution $x(t)$ is uniquely determined by $x_I(t_1)$. The existence of a solution in $L_2[t_1, \infty)$ for any $x_I(t_1)$ could be proved by iteration scheme $(d/dt - A^{(0)}(p))x^{(n)} = \Delta A x^{(n-1)}$. The second inequality in (4.19) follows from the estimate

$$\begin{aligned} \frac{1}{2}\frac{d|x_I(t)|^2}{dt} &\leq \mu_1 |x_I(t)|^2 + |\Delta A||x_I(t)| \cdot |x(t)| \\ &\leq (\mu_1 + \|\Delta A\|_\infty (1 + \epsilon_1))|x_I(t)|^2 \end{aligned} \tag{4.22}$$

provided $\|\Delta A\|_\infty (1 + \epsilon_1) < \epsilon_2$. Thus X_I is identified with the space of the above solutions $x(t)$. Denote by $x(\cdot, p) \in X_I$ the solution of (4.15) with given $x_I(t_1) = a_I$ and consider the difference $\Delta x = x(\cdot, p) - x(\cdot, 0)$. Then Δx satisfies

$$(\Delta x)' - A(t,0)\Delta x = f = (A(t,p) - A(t,0))x(t,p). \tag{4.23}$$

By applying to (4.23) the same procedure as in (4.21) we prove that $|\Delta x_{II}(t_1)| \to 0$ as $\|A(\cdot, p) - A(\cdot, 0)\|_\infty \to 0$. Hence $X_I(t)$ depends continuously on $p \to 0$. The space X_{II}

could be taken as the space of solutions x of (4.15) with initial condition $x_I(t_1) = 0$ and arbitrary $x_{II}(t_1)$. Then

$$\frac{1}{2}(\epsilon_1^2|x_{II}(t)|^2 - |x_I(t)|^2)' \geq (-\mu_1)|x_I(t)|^2 + \epsilon_1^2\mu_2|x_{II}(t)|^2 - |\Delta A| \cdot |x(t)|^2 \geq 0 \tag{4.24}$$

provided $\|\Delta A\|_\infty < \min(-\mu_1, \epsilon_1^2\mu_2)$. Hence the estimate $|x_I(t)| < \epsilon_1|x_{II}(t)|$ is valid for all $t \geq t_1$. The second estimate in (4.20) follows as in (4.22). The continuous dependence of $X_{II}(t)$ on p follows from the definition of $X_{II}(t_1)$.

Now let us apply the lemma to our situation. Extend the function $\tilde{y}_0(r)$ to be equal $y_0(r)$ for $r > l$ and consider (4.1) for v as in (4.8) with n bounded as in (4.14). We obtain the equation

$$\left(s + \Delta_n^2 + \alpha\Delta_n + 2\tilde{y}_0\frac{d}{dr}\right)v_n = 0, \quad \Delta_n = \left(\frac{d}{dr}\right)^2 + r^{-1}\frac{d}{dr} + n^2r^{-2}. \tag{4.25}$$

Then the vector $\bar{v}_n = (v_n, v_n', v_n'', v_n''')^T$ corresponds to x and r to t. The small parameter $p = (s, \alpha, l^{-1})$. At $p = 0$ we obtain the equation

$$\left(\Delta_n^2 + 2y_0\frac{d}{dr}\right)v_n = 0. \tag{4.26}$$

The leading part $A^{(0)}(p)$ corresponds to the operator

$$s + \left(\frac{d}{dr}\right)^4 + \alpha\left(\frac{d}{dr}\right)^2 - 2\frac{d}{dr}. \tag{4.27}$$

At $p = 0$ the eigenvalues of $A^{(0)}$ are

$$\lambda_{1,2} = 2^{1/3}(-\tfrac{1}{2} \pm i\tfrac{\sqrt{3}}{2}), \quad \lambda_3 = 2^{1/3}, \quad \lambda_4 = 0.$$

We define

$$\mu_1 = -\tfrac{1}{2} \cdot 2^{1/3} + \delta, \qquad \mu_2 = -\delta. \tag{4.28}$$

Then, for small p, the condition in (4.18) is satisfied. By (3.30), ΔA also satisfies the conditions of Lemma 4.1. In the sequel we will follow the notation of Lemma 4.1.

Let X_I and X_{II} be defined as in Lemma 4.1 and $P_I(t,p), P_{II}(t,p)$ the projectors corresponding to the direct sum $\mathbb{C}^4 = X_I(t,p) \oplus X_{II}(t,p)$. Denote by $X_0(t,p)$ the 2D space of vectors $x(r)$ that correspond to the solutions of (4.25) with initial conditions (2.10). Clearly $X_0(t,p)$ depends continuously on $p \to 0$. Note that $X_0(t,0) \cap X_I(t,0) = 0$. Indeed, otherwise (4.26) would have a nontrivial solution that decreases exponentially as $t \to \infty$. This would violate estimate (4.5) with $s = \alpha = 0$ and $\tilde{y}_0 = y_0$. By continuity, for a fixed t_1 and small $|p|$,

$$|P_{II}(t_1,p)x(t_1)| > \delta_1|x(0)|, \qquad |P_I(t_1,p)x(t_1)| < K_1|x(0)| \tag{4.29}$$

for all the above solutions $x \in X_0$. The vector functions P_Ix and $P_{II}x$ are also solutions of (4.15) and hence their components x_I and x_{II} satisfy estimates (4.19), (4.20), respectively. Now assume that $x(t)$ satisfies the boundary condition

$$Sx(l) = 0, \tag{4.30}$$

where S corresponds to (4.2) or (4.3). It is easy to see that S satisfies the Lopatinsky condition at infinity. Namely, S does not vanish on the vectors x with the zero component $x_I = 0$. (Recall that the decomposition of $x = (x_I, x_{II})$ corresponds to the eigenvalue decomposition λ_1, λ_2 and λ_3, λ_4.) Hence, for small $|p|$ and ϵ_1

$$|Sx| > \delta_2|x| \quad \text{for all } x \in X_{II}(l). \tag{4.31}$$

Now,

$$0 = Sx(l) = SP_I(l,p)x(l) + SP_{II}(l,p)x(l) \tag{4.32}$$

where by (4.19), (4.20), and (4.29)

$$\begin{aligned} |P_I(l,p)x(l)| &< |P_I(t_1,p)x(t_1)|e^{(\mu_1+\epsilon_2)(l-t_1)} \\ &\leq K|x(0)|e^{(\mu_1+\epsilon_2)(l-t_1)} \end{aligned} \tag{4.33}$$

and

$$\begin{aligned} |P_{II}(l,p)x(l)| &> |P_{II}(t_1,p)x(t_1)|e^{(\mu_2-\epsilon_2)(l-t_1)} \\ &> \delta_1|x(0)|e^{(\mu_2-\epsilon_2)(l-t_1)} \end{aligned} \tag{4.34}$$

and therefore

$$|SP_{II}(l,p)x(l)| > \delta_1\delta_2|x(0)|e^{(\mu_2-\epsilon_2)(l-t_1)}. \tag{4.35}$$

Since $\mu_2 - \epsilon_2 > \mu_1 + \epsilon_2$, for large l independent of x and p the second term in the right hand side of (4.32) will overweigh the first one. This completes the proof of Theorem 4.1. Clearly, our proof also applies to the case of the boundary conditions (1.13) and (1.14). One should merely replace $\tilde{y}_0$ everywhere by y_0.

Finally, let us remark that it was essential in our proof that the boundary condition is such that the energy estimate (4.5) holds. Thus we could restrict the problem to a finite number n_0 of ODEs. This is essential, since the above value r_1 where the connection between the inner and outer solutions is made grows very fast with n. The alternative is to restrict l and use (4.9) for $n > Kl$. But then the asymptotic expansion of Lemma 4.1 would not be applicable to $v_n(l)$.

5. The stability of the one-dimensional stationary solution. In the 1D case the integral in (4.5) is replaced by $\int(-y_0')|v|^2\,dx$. The graph of the function $-y_0'$ is displayed below in Fig. 1. Thus the integral is not positive. Actually our computation shows that it is negative for $v = x$. Since $y_0' \to 0$ exponentially as $|x| \to \infty$, the function $v = x$ could be modified so that $v \to 0$ exponentially as $x \to \infty$ and still

$$\|v''\|_2^2 + \int_{-\infty}^{\infty}(-y_0')|v|^2\,dx < 0. \tag{5.1}$$

Moreover, one can also construct an even function v that decreases exponentially as $|x| > \infty$ and for which the above quadratic form is negative. Our (noninterval) computations also show that if the norm $\|v''\|_2^2$ in (5.1) is increased by a factor $K \geq 1.3$ then the resulting quadratic form is positive in the space of even function in $H^2(R)$. We mention these results here without proof only to explain why the energy method does not work in the 1D case.

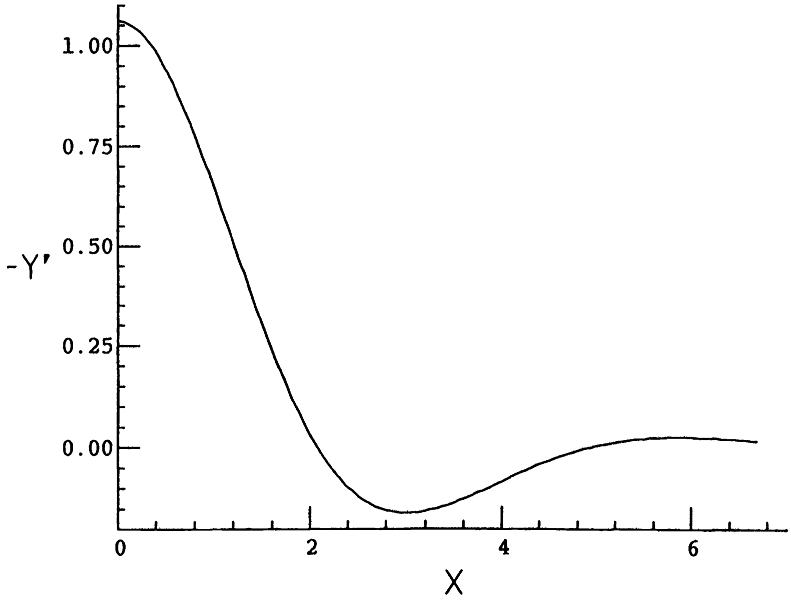

FIG. 1.

Recall that our rescaled eigenvalue problem is

$$L(s,\alpha)v = sv + v^{(4)} + \alpha v'' + 2\tilde{y}_0(x)v' = 0, \qquad |x| \le l \tag{5.2}$$

with boundary condition

$$dS_\pm[\bar{\tilde{u}}_0(l)]\bar{v}(l) = 0, \tag{5.3}$$

where $dS_\pm[\bar{\tilde{u}}_0(l)]$ are the differentials of $S_\pm$ at the points $\bar{\tilde{u}}_0(\pm l)$. Recall that $\tilde{y}_0(x)$ is an odd function of x. Since $S_\pm$ are related as in (1.19) it follows that $v(-x)$ is also a solution of (5.2), (5.3). Hence $v_1 = v(x) + v(-x)$ and $v_2 = v(x) - v(-x)$ are correspondingly even and odd solutions of (5.2), (5.3). Thus, without loss of generality we can consider the equivalent problems

$$L(s,\alpha)v = 0, \qquad 0 \le x \le l \tag{5.4}$$

with boundary condition at $x = l$

$$dS_+[\bar{\tilde{u}}_0(l)]\bar{v}(l) = 0 \tag{5.5}$$

and the boundary condition at $x = 0$

(5.6) (a) $v'(0) = v'''(0) = 0$

or

(b) $v(0) = v''(0) = 0.$

Since the problems (5.4)–(5.6) are uniformly Lopatinsky well posed for all large l and small α, it follows that for $|s| > K_0$ with K_0 independent of α and l the above problems have only trivial solutions. Now, for $|s| \leq K_0$ and small $\alpha + l^{-1}$ we wish to reduce these problems to the equation

$$sv + v^{(4)} + 2y_0 v' = 0, \qquad 0 \leq x < \infty, \tag{5.7}$$

with boundary conditions (5.6). Regarding the latter problem we make the following claim.

THEOREM 5.1. *Problem* (5.7), (5.6) *has no exponentially decreasing solutions for all* $s \in \mathbb{C}$ *with* $\operatorname{Re} s \geq 0$.

The reduction is carried out in the same way as in §4. The parameter $p = (s, \alpha, l^{-1})$, but the central point $p = 0$ is replaced by $p_0 = (s_0, 0, 0)$. The roots $\lambda_i(s)$ of (1.21) for $|s| < K_0$ and $\operatorname{Re} s \geq 0$ are separated: $\operatorname{Re}\lambda_{1,2}(s) < 0$ and $\operatorname{Re}\lambda_{3,4}(s) \geq 0$. Hence in a neighborhood of p_0 we may choose μ_1, μ_2 so that (4.18) holds. The constant matrix S in (4.30) is replaced by $dS_+[\overline{u}_0(l)]$. Still, since $dS_+[\overline{u}_0(\infty)]$ by assumption satisfies the Lopatinsky condition (see (1.22)), estimate (4.31) holds for large l. The reduction to problem (5.6), (5.7) then follows from (4.32)–(4.35).

Thus it remains to prove Theorem 5.1. Since $y_0(0) = 0$ and v satisfies the conditions in (5.6), we obtain the one-dimensional analog of (4.7). Namely

$$\begin{aligned}&(\operatorname{Re} s + b_2|\operatorname{Im} s| - b_2 b_1 \|y_0\|_\infty)\|v\|^2 - b_2 b_1^{-1}\|y_0\|_\infty \|v'\|^2 \\ &\quad + \int_0^\infty (-y_0')|v|^2\,dx + \|v''\|^2 \leq 0.\end{aligned} \tag{5.8}$$

Our computer program verified that

$$-y_0' > -\delta_0 = -0.164 \quad \text{and} \quad \|y_0\|_\infty < 1.23. \tag{5.9}$$

For the left-hand side of (5.8) to be positive definite it is sufficient that

$$\frac{1}{4}(b_2 b_1^{-1}\|y_0\|_\infty)^2 < \operatorname{Re} s - \delta_0 + b_2|\operatorname{Im} s| - b_2 b_1 \|y_0\|_\infty. \tag{5.10}$$

It is easy to check that the lowest bound on $\operatorname{Re} s$ is

$$\operatorname{Re} s > \delta_0 - \left(\frac{|\operatorname{Im} s|}{2\|y_0\|_\infty}\right)^4 \tag{5.11}$$

and is achieved when

$$b_1 = \frac{|\operatorname{Im} s|}{2\|y_0\|_\infty}, \qquad b_2 = \frac{|\operatorname{Im} s|^3}{4\|y_0\|_\infty^4}. \tag{5.12}$$

Since problem (5.7)–(5.6) is invariant under complex conjugation we may assume that $\operatorname{Im} s \geq 0$.

Thus, it remains to prove Theorem 5.1 in the domain

$$s \in \mathcal{D} : 0 \leq \operatorname{Re} s \leq \delta_0 = 0.164, \qquad 0 \leq \operatorname{Im} s \leq 2\|y_0\|_\infty \delta_0^{1/4} < 1.6. \tag{5.13}$$

We believe that this could be done by tedious hand computations in a way similar to [1]. Namely, one can expand y_0 and v into a power series near $x = 0$ that is valid up to $x \sim 4$ and to match it with exponential asymptotics of y_0 and v for large x. Instead we preferred a computer-based proof that involves millions of operations but requires that the reader only check a conceptually simple program.

The procedure of the proof is similar to the one in [3] and [4]. Unlike the real parameter α in [3] we have now a complex s. This forced us to modify all elementary interval arithmetic subroutines to include also the complex intervals. The domain $\mathcal{D}$ was subdivided into 40 small rectangles and for each of them the program ran separately. To manage rectangles in $\mathcal{D}$ of size $\delta \sim 0.08$ the dependence on s was expressed by Taylor formula of order 2. Also the estimates of the asymptotics of v for large x were carried out uniformly in s. Interested readers can obtain the program and the relevant analytical formulas and estimates from the author upon request.

ASYMPTOTIC EXPANSIONS WITH ERROR BOUNDS FOR THE COEFFICIENTS OF CAPACITY AND INDUCTION OF TWO SPHERES*

ANDREW H. VAN TUYL†

Abstract. Asymptotic expansions are obtained for the coefficients of capacity and induction of two spheres which hold as the distance ε between the spheres tends to zero, starting from expressions in terms of definite integrals obtained earlier [A. H. Van Tuyl, Electrostatic problems for two conducting spheres, *SIAM J. Math. Anal.*, 20 (1989), pp. 1293–1320]. Bounds for the remainders are given which hold uniformly for all ratios of the radii of the spheres. These asymptotic expansions are used to obtain an asymptotic expansion for the capacity of the spheres with respect to the infinite sphere with a uniform bound for the remainder and to find the asymptotic behavior of the capacity of two spheres. The asymptotic expansion for the capacity of two spheres with respect to the infinite sphere is also found directly from a definite-integral representation involving elliptic functions, leading to a smaller uniform bound for the remainder. Finally, the asymptotic behavior of the coefficients of potential is obtained, and the behavior of the potential difference and charge density as two spheres approach contact with given total charges is found.

Key words. coefficients of capacity, coefficients of capacity and induction, capacity, coefficients of potential, two spheres, charge density, asymptotic expansions

AMS subject classification. 31B20

1. Introduction.

The potential outside two charged conducting spheres and the charge density and total charge on each sphere were first given by Poisson [18] for both separated and tangent spheres. Further work was carried out by Plana [17] using Poisson's methods. Kirchhoff [11] corrected errors in [17] and [18] concerning the charge densities at the inner axial points as two spheres approach contact with equal radii and potentials and transformed some of Poisson's series to more rapidly convergent forms. Maxwell [14] discussed both separated and tangent spheres, obtaining new forms for the series expansions of the coefficients of capacity and induction in terms of dipolar coordinates. Barnes [2] expressed the coefficients of capacity and induction of two spheres in terms of the logarithmic derivative of his double gamma function [3]. Russell [20]–[25] carried out extensive investigations in order to facilitate the calculation of the coefficients of capacity and induction and related quantities. The latter quantities include the capacity of two spheres with respect to the infinite sphere and the capacity of two spheres. A summary of some of Russell's results is included in [12].

The capacity of two spheres has been of interest in connection with the conductivity of granular materials (Keller [10] and Batchelor and O'Brien [4]). The leading term of the asymptotic expansion of the capacity as the distance ε between the spheres tends to zero was obtained in [10], and an approximate constant term was added in [4]. Additional terms were obtained by Jeffrey in [9] by the use of the method of matched asymptotic expansions. Love [13] and Rawlins [19] have obtained the complete asymptotic expansion by different methods when the radii of the spheres are equal. However, both results are in error by the same factor due to misprints in [28].

Russell [20] obtained several terms of the asymptotic expansions of the coefficients of capacity and induction of two spheres by use of a generalization of a result due to Schlömilch [26]. However, results of the present paper show that some of his

†1000 West Nolcrest Drive, Silver Spring, MD 20903-1040 (avt@clark.net).

coefficients are in error. Buchholz [5] obtained the complete asymptotic expansions when the radii of the spheres are equal by use of the Mellin transform, but without an estimate for the remainder. The method of [5] was generalized in [8] to the case of unequal spheres, and numerical calculations were carried out in [8] to determine the optimum number of terms of the asymptotic expansion for a given separation of the spheres.

In §4 of the present paper, asymptotic expansions are obtained for the coefficients of capacity and induction starting from integral representations involving elliptic functions [27]. Bounds for the remainders are found which hold uniformly for $0 \leq r_1/r_2 \leq \infty$ in specified ranges of ε of the form $0 < \varepsilon \leq \varepsilon_0$, where r_1 and r_2 are the radii of the spheres. In the first part of §5, the results of §4 are used to obtain an asymptotic expansion of the capacity of the spheres with respect to the infinite sphere with a uniform bound for the remainder. A separate derivation of this asymptotic expansion is then carried out starting from an integral representation involving elliptic functions, and an improved bound for the remainder is obtained. The results of §5 also give the known expression for the capacity of two tangent spheres with respect to the infinite sphere and an integral representation involving hyperbolic functions.

In §6, the asymptotic behavior of the capacity of two spheres as the spheres approach tangency is found. When the radii are equal, the results of §4 are used to obtain the asymptotic expansion considered in [13] and [19] with a uniform bound for the remainder. In §7, the asymptotic behavior of the coefficients of potential as the spheres approach tangency is obtained. Also, the asymptotic behavior of the potential difference as the spheres approach contact with given total charges is found. Finally, in §8, the results of §7 are used to find the behavior of the charge density at the inner axial points as the spheres approach tangency with given total charges. A special case of interest is that in which the total charges are in the same ratio as the corresponding charges on two tangent spheres. These results are given in equivalent forms in [17] and [18], and agreement with the present results is found after correction of some misprints in each reference. Several misprints in [18] have been pointed out in [17].

2. Dipolar coordinates. As in [27], dipolar coordinates η, θ, and ϕ are defined by

$$x + i\rho = ia \cot \frac{1}{2}(\theta + i\eta), \tag{2.1}$$

$$y = \rho \cos \phi, \quad z = \rho \sin \phi, \tag{2.2}$$

with $a > 0$, $\rho > 0$. The coordinate surface η = constant is a sphere with $(a, 0, 0)$ and $(-a, 0, 0)$ as inverse points. The sphere $\eta = \eta_1$ has radius $a \operatorname{csch}|\eta_1|$ and center at $x = a \coth \eta_1$, $y = z = 0$. Hence, when $\eta_1 > 0 > \eta_2$, the sphere $\eta = \eta_1$ contains the point $(a, 0, 0)$ in its interior, and $\eta = \eta_2$ contains $(-a, 0, 0)$.

Let the spheres $\eta = \eta_1$ and $\eta = \eta_2$ have radii r_1 and r_2, respectively, and let the distance between the spheres be ε. Then as shown in [27], we have

$$a = \frac{\sqrt{\varepsilon(\varepsilon + 2r_1)(\varepsilon + 2r_2)(\varepsilon + 2r_1 + 2r_2)}}{2(\varepsilon + r_1 + r_2)} \tag{2.3}$$

and

$$\eta_1 = \sinh^{-1} \frac{a}{r_1}, \quad \eta_2 = -\sinh^{-1} \frac{a}{r_2}. \tag{2.4}$$

When $r_1 = r_2 = r$, (2.3) simplifies to

$$a = \frac{1}{2}\sqrt{\varepsilon(\varepsilon + 4r)}. \tag{2.5}$$

As $\varepsilon \to 0$, we have

$$a = \sqrt{\sigma\varepsilon}[1 + \mathrm{O}(\varepsilon)], \tag{2.6}$$

$$\eta_1 = \frac{\sqrt{\sigma\varepsilon}}{r_1}[1 + \mathrm{O}(\varepsilon)], \tag{2.7}$$

$$\eta_2 = -\frac{\sqrt{\sigma\varepsilon}}{r_2}[1 + \mathrm{O}(\varepsilon)], \tag{2.8}$$

and

$$\eta_1 - \eta_2 = 2\sqrt{\frac{\varepsilon}{\sigma}}[1 + \mathrm{O}(\varepsilon)], \tag{2.9}$$

where

$$\sigma = \frac{2r_1 r_2}{r_1 + r_2}. \tag{2.10}$$

3. Integral representations for the total charge. The total charges on the spheres in the first problem are given by

$$\begin{aligned} Q_1 &= C_{11}V_1 + C_{12}V_2, \\ Q_2 &= C_{12}V_1 + C_{22}V_2, \end{aligned} \tag{3.1}$$

where C_{11} and C_{22} are the coefficients of capacity and C_{12} is the coefficient of induction. From [15, p. 89], we obtain

$$C_{11} = a\sum_{n=0}^{\infty} \frac{e^{-N(\eta_1+\eta_2)}}{\sinh N\delta}, \tag{3.2}$$

$$C_{12} = -a\sum_{n=0}^{\infty} \frac{e^{-N\delta}}{\sinh N\delta}, \tag{3.3}$$

and

$$C_{22} = a\sum_{n=0}^{\infty} \frac{e^{N(\eta_1+\eta_2)}}{\sinh N\delta}, \tag{3.4}$$

where $\delta = \eta_1 - \eta_2$ and $N = n + 1/2$.

In [27], these series have been expresed in terms of definite integrals involving elliptic functions. Let $q = \exp(-\delta)$, and let the modulus k be defined implicitly by

$$-\log q = \eta_1 - \eta_2 = \pi K'/K, \tag{3.5}$$

where K is the complete elliptic integral of the first kind and $K' = K(k')$, $k'^2 = 1-k^2$. Also, let

$$q' = e^{-\pi K/K'} = e^{\pi^2/\log q}. \tag{3.6}$$

It follows from (2.9) and (3.5) that $q \sim \exp(-2\sqrt{\varepsilon/\sigma})$ and $q' \sim \exp(-2^{-1}\pi^2\sqrt{\sigma/\varepsilon})$ as $\varepsilon \to 0$. As in [27, Eq. (6.5)–(6.7)], we have

$$C_{11} = \frac{aKk}{\pi^2}\int_0^\pi \operatorname{Re}\,\operatorname{sn}\frac{K}{\pi}[t+i(\eta_1+\eta_2)]\csc\frac{t}{2}\,dt + \frac{iaKk}{\pi}\operatorname{sn}\frac{iK}{\pi}(\eta_1+\eta_2), \tag{3.7}$$

$$C_{12} = -\frac{aK}{\pi^2}\int_0^\pi\left(\operatorname{ns}\frac{Kt}{\pi} - \frac{\pi}{2K}\csc\frac{t}{2}\right)\csc\frac{t}{2}\,dt, \tag{3.8}$$

and

$$C_{22} = C_{11} - \frac{2iaKk}{\pi}\operatorname{sn}\frac{iK}{\pi}(\eta_1+\eta_2). \tag{3.9}$$

4. Asymptotic expansions for the coefficients of capacity and induction. Writing (3.5) in the form $\eta_2 = \eta_1 - \pi K'/K$ and substituting in (3.7), using the addition theorem for sn$u$ and Jacobi's imaginary transformation, we obtain

$$C_{11} = -\frac{aK}{\pi^2}\int_0^\pi \operatorname{Im}\,\operatorname{cs}\left[\frac{K}{\pi}(2\eta_1+it),\ k'\right]\csc\frac{t}{2}\,dt + \frac{aK}{\pi}\operatorname{cs}\left(\frac{2K\eta_1}{\pi},\ k'\right). \tag{4.1}$$

Referring to [29, p. 512], with q' defined by (3.6), we have

$$\begin{aligned} C_{11} = \frac{aK}{2\pi K'}\Bigg\{&\int_0^\pi \frac{\sinh\frac{Kt}{K'}\csc\frac{t}{2}\,dt}{\cosh\frac{Kt}{K'} - \cos\frac{2K\eta_1}{K'}} \\ &+4\sum_{n=1}^\infty \frac{q'^{2n}}{1+q'^{2n}}\cos\frac{2nK\eta_1}{K'}\int_0^\pi \sinh\frac{nKt}{K'}\csc\frac{t}{2}\,dt\Bigg\} \\ &+\frac{aK}{2K'}\left\{\cot\frac{K\eta_1}{K'} - 4\sum_{n=1}^\infty \frac{q'^{2n}}{1+q'^{2n}}\sin\frac{2nK\eta_1}{K'}\right\}, \end{aligned} \tag{4.2}$$

which converges for $\varepsilon > 0$. We find that

$$\begin{aligned} \left|\int_0^\pi \sinh\frac{nKt}{K'}\csc\frac{t}{2}\,dt\right| &< \pi\int_0^\pi \frac{\sinh\frac{nKt}{K'}\,dt}{t} \\ &< \pi\int_0^{nK\pi/K'}\cosh t\,dt = \pi\sinh\frac{nK\pi}{K'} \\ &< \frac{\pi}{2}q'^{-n}. \end{aligned} \tag{4.3}$$

Hence, denoting the first sum on the right of (4.2) by S_1, we have

$$|S_1| < \frac{\pi}{2}\sum_{n=1}^\infty q'^n = \frac{\pi}{2}\frac{q'}{1-q'}. \tag{4.4}$$

Similarly, denoting the second sum by S_2, we see that

$$|S_2| < \sum_{n=1}^{\infty} q'^{2n} = \frac{q'^2}{1-q'^2}. \tag{4.5}$$

We therefore have

$$C_{11} = \frac{aK}{2\pi K'}\left\{ \int_0^\pi \frac{\sinh\frac{Kt}{K'}\csc\frac{t}{2}\,dt}{\cosh\frac{Kt}{K'} - \cos 2\mu} + \pi\cot\mu + R^{(1)} \right\}, \tag{4.6}$$

where

$$\mu = K\eta_1/K' = \frac{\pi\eta_1}{\eta_1 - \eta_2} \tag{4.7}$$

by (3.5) and

$$|R^{(1)}| < 4|S_1| + 4\pi|S_2|. \tag{4.8}$$

It follows from (2.4) that $0 \le \mu \le \pi$, with $\mu = 0$ when $r_2/r_1 = 0$, and $\mu = \pi$ when $r_1/r_2 = 0$. We see that this range of μ is sufficient, since (4.6) is periodic in μ with period π. We see that $|R^{(1)}| = O(q')$ as $\varepsilon \to 0$.

We can verify that

$$\begin{aligned} &\int_0^\pi \frac{\sinh\frac{Kt}{K'}\csc\frac{t}{2}\,dt}{\cosh\frac{Kt}{K'} - \cos 2\mu} \\ &= 2\int_0^{\pi K/K'} \left(\frac{\sinh u}{\cosh u - \cos 2\mu} - 1\right)\left(\frac{K'u}{2K}\csc\frac{K'u}{2K} - 1\right)\frac{du}{u} \\ &+2\int_0^{\pi K/K'} \left[\frac{\sinh u}{(\cosh u - \cos 2\mu)u} - \frac{1-e^{-2u}}{u}\right] du \\ &+2\int_0^{\pi K/K'} \frac{1-e^{-2u}}{u}\,du \\ &+2\int_0^{\pi K/K'} \left(\frac{K'u}{2K}\csc\frac{K'u}{2K} - 1\right)\frac{du}{u}. \end{aligned} \tag{4.9}$$

We obtain

$$\int_0^{\pi K/K'} \left(\frac{K'u}{2K}\csc\frac{K'u}{2K} - 1\right)\frac{du}{u} = \log\frac{4}{\pi} \tag{4.10}$$

by direct integration, and we find from [1, Eq. 5.1.39] that

$$\begin{aligned} \int_0^{\pi K/K'} \frac{1-e^{-2u}}{u}\,du &= \log\frac{2\pi K}{K'} + \gamma + E_1\left(\frac{2\pi K}{K'}\right) \\ &= \log\left(-\frac{2}{\log q}\right) + 2\log\pi + \gamma + R^{(2)}/2. \end{aligned} \tag{4.11}$$

By use of the inequality

$$\int_a^\infty \frac{e^{-u}}{u}\,du < \frac{e^{-a}}{a}, \quad a > 0 \tag{4.12}$$

[1, Eq. 5.1.19], we obtain

$$\begin{aligned} |R^{(2)}| &= 2\int_{2\pi K/K'}^{\infty} \frac{e^{-u}}{u}\,du \\ &< \frac{K'}{\pi K} e^{-2\pi K/K'} = -\frac{q'^2}{\pi^2}\log q. \end{aligned} \tag{4.13}$$

We have

$$\begin{aligned} \left|\frac{\sinh u}{(\cosh u - \cos 2\mu)\,u} - \frac{1-e^{-2u}}{u}\right| &= \left(\frac{1-e^{-2u}}{u}\right)\left|\frac{2\cos 2\mu - e^{-u}}{1-2e^{-u}\cos 2\mu + e^{-2u}}\right| e^{-u} \\ &< \frac{(1+e^{-u})(2+e^{-u})}{1-e^{-u}}\cdot\frac{e^{-u}}{u} \\ &< 2.000031\frac{e^{-u}}{u} \end{aligned} \tag{4.14}$$

when $0 \le \mu \le \pi$ and $u \ge 12$. Hence,

$$\int_0^{\pi K/K'} \left[\frac{\sinh u}{(\cosh u - \cos 2\mu)\,u} - \frac{1-e^{-2u}}{u}\right] du = I + R^{(3)}, \tag{4.15}$$

where

$$I = \int_0^{\infty} \left[\frac{\sinh u}{(\cosh u - \cos 2\mu)\,u} - \frac{1-e^{-2u}}{u}\right] du \tag{4.16}$$

and by (4.12) and (4.14),

$$\begin{aligned} |R^{(3)}| &< 2.000031\int_{\pi K/K'}^{\infty} \frac{e^{-u}}{u}\,du \\ &< -4.00007q'\left(\frac{\log q}{2\pi^2}\right) \end{aligned} \tag{4.17}$$

for $0 \le \mu \le \pi$ and $-\log q \le \pi^2/12$. As in [27, Eq. (13.2)], we have

$$\begin{aligned} \frac{\sinh u}{(\cosh u - \cos 2\mu)^2} = \frac{4u}{\sin 2\mu}\Bigg\{ &\sum_{n=0}^{\infty} \frac{2\pi n + 2\mu}{[u^2 + (2\pi n + 2\mu)^2]^2} \\ &- \sum_{n=1}^{\infty} \frac{2\pi n - 2\mu}{[u^2 + (2\pi n - 2\mu)^2]^2}\Bigg\}. \end{aligned} \tag{4.18}$$

Substituting (4.18) into

$$\frac{dI}{d\mu} = -2\sin 2\mu \int_0^{\infty} \frac{\sinh u\,du}{(\cosh u - \cos 2\mu)^2\,u} \tag{4.19}$$

and interchanging summation and integration, we obtain

$$\begin{aligned} \frac{dI}{d\mu} &= -\frac{\pi}{2}\left[\sum_{n=0}^{\infty} \frac{1}{(\pi n + \mu)^2} - \sum_{n=1}^{\infty} \frac{1}{(\pi n - \mu)^2}\right] \\ &= -\frac{1}{2}\frac{d}{d\mu}\left[\psi\left(\frac{\mu}{\pi}\right) + \psi\left(1 - \frac{\mu}{\pi}\right)\right], \end{aligned} \tag{4.20}$$

where $\psi(z) = d \log \Gamma(z)/dz$. Hence,

$$I = -\psi\left(\frac{\mu}{\pi}\right) - \frac{\pi}{2}\cot\mu + c, \tag{4.21}$$

where c is a constant to be determined. The substitution $\mu = \pi/4$ yields

$$c = -\int_0^\infty \frac{\tanh u}{u} e^{-2u}\, du + \psi\left(\frac{1}{4}\right) + \frac{\pi}{2}. \tag{4.22}$$

We obtain

$$\int_0^\infty \frac{\tanh u}{u} e^{-2u}\, du = \log \frac{\pi}{2} \tag{4.23}$$

from [7, Eq. 3.551.9], and as in [7, Eq. 8.366.4], we have

$$\psi\left(\frac{1}{4}\right) = -\gamma - 3\log 2 - \frac{\pi}{2}. \tag{4.24}$$

Substitution of the preceding in (4.21) gives

$$I = -\psi\left(\frac{\mu}{\pi}\right) - \frac{\pi}{2}\cot\mu - \gamma - \log(4\pi). \tag{4.25}$$

Finally, we can obtain an asymptotic expansion for the first integral on the right-hand side of (4.9) by use of the identity

$$\begin{aligned} x\csc x = {} & 2\sum_{m=0}^{n} (-1)^m \frac{x^{2m}}{(2m)!}(1-2^{2m-1})B_{2m} \\ & + \frac{(-1)^{n+1}(2x)^{2n+2}}{(2n+1)!\sin x}\int_0^{1/2} B_{2n+1}(t)\sin 2xt\, dt \end{aligned} \tag{4.26}$$

[16, p. 32], which holds for real $x \neq \pm n\pi$, $n \geq 1$. Noting that $(-1)^{n+1}B_{2n+1}(t) > 0$ for $0 < t < 1/2$ and referring to [16, pp. 19 and 22], we find the inequalities

$$\begin{aligned} 0 < (-1)^{n+1}\int_0^{1/2} B_{2n+1}(t)\sin 2xt\, dt & < (-1)^{n+1}x\int_0^{1/2} B_{2n+1}(t)\, dt \\ & = (-1)^{n+1}\frac{x}{2n+2}B_{2n+2}\left(\frac{1}{2}\right) \\ & = (-1)^{n+1}x(2^{-2n-1}-1)\frac{B_{2n+2}}{2n+2}. \end{aligned} \tag{4.27}$$

Hence,

$$\begin{aligned} & \int_0^{\pi K/K'} \left(\frac{\sinh u}{\cosh u - \cos 2\mu} - 1\right)\left(\frac{K'u}{2K}\csc\frac{K'u}{2K} - 1\right)\frac{du}{u} \\ & = 2\sum_{m=1}^{n} \frac{(-1)^{m+1}(2^{2m-1}-1)B_{2m}}{(2m)!}\left(\frac{K'}{2K}\right)^{2m} \\ & \cdot \int_0^{\pi K/K'} \left(\frac{\cos 2\mu - e^{-u}}{\cosh u - \cos 2\mu}\right) u^{2m-1}\, du + R_n^{(4)}, \end{aligned} \tag{4.28}$$

where

$$
\begin{aligned}
|R_n^{(4)}| &< \frac{2(2^{2n+1}-1)|B_{2n+2}|}{(2n+2)!}\left(\frac{K'}{2K}\right)^{2n+3} \\
&\quad\cdot \int_0^{\pi K/K'} \left|\frac{\cos 2\mu - e^{-u}}{\cosh u - \cos 2\mu}\right| \frac{u^{2n+2}\,du}{\sin\frac{K'u}{2K}} \\
&< \frac{\pi(2^{2n+1}-1)|B_{2n+2}|}{(2n+2)!}\left(\frac{K'}{2K}\right)^{2n+2} \\
&\quad\cdot \int_0^{\pi K/K'} \left|\frac{\cos 2\mu - e^{-u}}{\cosh u - \cos 2\mu}\right| u^{2n+1}\,du.
\end{aligned}
\tag{4.29}
$$

Noting that

$$(\cos 2\mu - e^{-u})^2 \le 1 - 2e^{-u}\cos 2\mu + e^{-2u},$$

we have

$$
\begin{aligned}
\left|\frac{\cos 2\mu - e^{-u}}{\cosh u - \cos 2\mu}\right| &= \frac{2|\cos 2\mu - e^{-u}|e^{-u}}{1-2e^{-u}\cos 2\mu + e^{-2u}} \\
&\le \frac{2e^{-u}}{\sqrt{1-2e^{-u}\cos 2\mu + e^{-2u}}} \\
&< \frac{2e^{-u}}{1-e^{-u}}
\end{aligned}
\tag{4.30}
$$

for $0 \le \mu \le \pi$, $u > 0$. Hence, referring to [1, Eq. 23.2.7], we obtain

$$
\begin{aligned}
&\int_0^{\pi K/K'} \left|\frac{\cos 2\mu - e^{-u}}{\cosh u - \cos 2\mu}\right| u^{2n+1}\,du \\
&\quad < 2\int_0^{\infty} \frac{u^{2n+1}e^{-u}}{1-e^{-u}}\,du = 2\,\zeta(2n+2)\,(2n+1)!
\end{aligned}
\tag{4.31}
$$

for $0 \le \mu \le \pi$, $n \ge 1$, where $\zeta(s)$ is the Riemann zeta function. It follows from (4.29) and (4.31) that

$$|R_n^{(4)}| < 2\pi\zeta(2n+2)\frac{(2^{2n+1}-1)|B_{2n+2}|}{2n+2}\left(\frac{K'}{2K}\right)^{2n+2} \tag{4.32}$$

for $0 \le \mu \le \pi$, $n \ge 1$. Finally, by use of the inequality

$$\frac{(-1)^{n+1}(2^{2n-1}-1)B_{2n}}{(2n)!} < \pi^{-2n} \tag{4.33}$$

[1, Eq. 23.1.15], we obtain the simpler bound

$$
\begin{aligned}
|R_n^{(4)}| &< \frac{2\pi\zeta(2n+2)(-1)^n(2^{2n+1}-1)B_{2n+2}}{(2n+2)!}(2n+1)!\left(\frac{K'}{2K}\right)^{2n+2} \\
&< 2\zeta(2n+2)\pi^{-2n-1}(2n+1)!\left(\frac{K'}{2K}\right)^{2n+2} \\
&< 2.165\pi^{-2n-1}(2n+1)!\left(\frac{K'}{2K}\right)^{2n+2},
\end{aligned}
\tag{4.34}
$$

$0 \le \mu \le \pi$, $n \ge 1$, since $\zeta(2n+2)$ decreases monotonically toward 1 as $n \ge 1$ increases. In (4.34), the inequality $\zeta(4) < 1.0825$ is used. In terms of the variable $\log q = -\pi K'/K$, we have

$$|R_n^{(4)}| < 2.165\pi(2n+1)!\left(\frac{\log q}{2\pi^2}\right)^{2n+2} \tag{4.35}$$

for $0 \le \mu \le \pi$, $n \ge 1$. It follows that (4.28) is an asymptotic expansion which holds uniformly with respect to μ in the interval $0 \le \mu \le \pi$. We see that it is also a convergent expansion, since integration and summation can be interchanged in (4.28).

As in [27], we obtain a more convenient, but divergent, asymptotic expansion by writing

$$\begin{aligned}
&\sum_{m=1}^{n} \frac{(-1)^{m+1}(2^{2m-1}-1)B_{2m}}{(2m)!}\left(\frac{K'}{2K}\right)^{2m} \\
&\quad\cdot \int_0^{\pi K/K'} \left(\frac{\cos 2\mu - e^{-u}}{\cosh u - \cos 2\mu}\right) u^{2m-1}\,du \\
&= \sum_{m=1}^{n} \frac{(-1)^{m+1}(2^{2m-1}-1)B_{2m}}{(2m)!}\left(\frac{K'}{2K}\right)^{2m} \\
&\quad\cdot \int_0^{\infty} \left(\frac{\cos 2\mu - e^{-u}}{\cosh u - \cos 2\mu}\right) u^{2m-1}\,du + R_n^{(5)},
\end{aligned} \tag{4.36}$$

where

$$\begin{aligned}
R_n^{(5)} = &-\sum_{m=1}^{n} \frac{(-1)^{m+1}(2^{2m-1}-1)B_{2m}}{(2m)!}\left(\frac{K'}{2K}\right)^{2m} \\
&\cdot \int_{\pi K/K'}^{\infty} \left(\frac{\cos 2\mu - e^{-u}}{\cosh u - \cos 2\mu}\right) u^{2m-1}\,du.
\end{aligned} \tag{4.37}$$

The inequality

$$\int_x^{\infty} t^n e^{-t}\,dt < 2x^n e^{-x}, \tag{4.38}$$

$x \ge 2n$, $n \ge 0$, follows either from the asymptotic expansion with remainder of the incomplete gamma function, or by integration by parts and induction. From (4.30) and (4.38), we obtain

$$\begin{aligned}
\left|\int_{\pi K/K'}^{\infty} \left(\frac{\cos 2\mu - e^{-u}}{\cosh u - \cos 2\mu}\right) u^{2m-1}\,du\right| &< 2.00002 \int_{\pi K/K'}^{\infty} u^{2m-1} e^{-u} du \\
&< 4.00004\left(\frac{\pi K}{K'}\right)^{2m-1} e^{-\pi K/K'}
\end{aligned} \tag{4.39}$$

when $\pi K/K' \ge \max(12, 4m-2)$, $m \ge 1$. Hence, replacing $\pi K'/K$ by $-\log q$ and using (4.39), we have

$$|R_n^{(5)}| < -4.00004 \sum_{m=1}^{n} \frac{(-1)^{m+1}(2^{2m-1}-1)B_{2m}}{(2m)!}\left(\frac{\pi}{2}\right)^{2m-1} q' \frac{\log q}{\pi}$$

$$\begin{aligned} &< -4.00004 \sum_{m=1}^{n} 2^{1-2m} q' \frac{\log q}{\pi^2} \\ &< -4.00004 \left(\frac{2}{3}\right) q' \frac{\log q}{\pi^2} \\ &< -5.34q' \left(\frac{\log q}{2\pi^2}\right) \end{aligned} \tag{4.40}$$

when $\pi K/K' \geq \max(12, 4n-2)$, $n \geq 1$. From [6, p. 38], we have

$$\int_0^{\infty} \frac{\cos 2\mu - e^{-u}}{\cosh u - \cos 2\mu} u^{2m-1}\, du = \frac{(-1)^{m+1}(2\pi)^{2m}}{2m} B_{2m}\left(\frac{\mu}{\pi}\right). \tag{4.41}$$

Finally, from (4.6) through (4.41), we obtain

$$\begin{aligned} C_{11} = -\frac{a}{\log q} \Bigg\{ &\log\left(\frac{-2}{\log q}\right) - \psi\left(\frac{\mu}{\pi}\right) \\ &+ \sum_{m=1}^{n} \frac{(2^{2m-1}-1) B_{2m} B_{2m}(\frac{\mu}{\pi})}{(2m)!\, m} (\log q)^{2m} + R_n \Bigg\}, \end{aligned} \tag{4.42}$$

where

$$R_n = R^{(1)} + R^{(2)} + R^{(3)} + R_n^{(4)} + R_n^{(5)}. \tag{4.43}$$

Similarly, starting from (3.9) and using the same transformations as in (4.1), we obtain

$$\begin{aligned} C_{22} &= C_{11} - \frac{aK}{K'} \cot \mu \\ &= -\frac{a}{\log q} \Bigg\{ \log\left(\frac{-2}{\log q}\right) - \psi\left(1 - \frac{\mu}{\pi}\right) \\ &\qquad + \sum_{m=1}^{n} \frac{(2^{2m-1}-1) B_{2m} B_{2m}(\frac{\mu}{\pi})}{(2m)!\, m} (\log q)^{2m} + R_n \Bigg\} \end{aligned} \tag{4.44}$$

We see that when $\eta_2 = 0$ is substituted into (3.2), we obtain the expression for $-C_{12}$ with $q = e^{-\eta_1}$. We then have $\pi K/K' = \eta_1$, and hence $\mu = K\eta_1/K' = \pi$. It follows that we can obtain the asymptotic expansion for C_{12} from that for $-C_{11}$ by substituting $\mu = \pi$. Proceeding in this way, we find that

$$\begin{aligned} C_{12} = \frac{a}{\log q} \Bigg\{ &\log\left(\frac{-2}{\log q}\right) + \gamma \\ &+ \sum_{m=1}^{n} \frac{(2^{2m-1}-1)(B_{2m})^2}{(2m)!\, m} (\log q)^{2m} + R_n\big|_{\mu=\pi} \Bigg\}. \end{aligned} \tag{4.45}$$

When the radii of the spheres are equal, we have

$$\begin{aligned} C_{11} = C_{22} = -\frac{a}{\log q} \Bigg\{ &\log\left(\frac{-2}{\log q}\right) + \gamma + 2\log 2 \\ &- 2\sum_{m=1}^{n} \frac{(2^{2m-1}-1)^2 (B_{2m})^2}{(2m)! m} \left(\frac{\log q}{2}\right)^{2m} + R_n\big|_{\mu=\pi/2} \Bigg\}, \end{aligned} \tag{4.46}$$

since $\psi(1/2) = -\gamma - 2\log 2$ [1, Eq. 6.3.3] and $B_{2m}(1/2) = -(1-2^{1-2m})B_{2m}$ [1, Eq. 23.1.21].

When ε is sufficiently small, we can obtain more convenient bounds for the exponentially small remainder terms $R^{(1)}$, $R^{(2)}$, $R^{(3)}$, and $R_n^{(5)}$ as in [27, §9]. From the inequality

$$n! > n^n e^{-n}\sqrt{2\pi n} \tag{4.47}$$

for $n \geq 1$, we obtain

$$\begin{aligned} \frac{x^{2n+1}e^{-x/2}}{(2n+1)!} &< \left(\frac{x}{2n+1}\right)^{2n+1} e^{2n+1-x/2}\frac{1}{\sqrt{2\pi(2n+1)}} \\ &< \left(\frac{8}{e^3}\right)^3 \frac{1}{\sqrt{6\pi}} < 0.0145536, \qquad x > 8(2n+1), \\ &< \left(\frac{16}{e^7}\right)^3 \frac{1}{\sqrt{6\pi}} < 7.7.2\times 10^{-7}, \qquad x > 16(2n+1), \end{aligned} \tag{4.48}$$

$n \geq 1$, since $x^{2n+1}e^{-x/2}$ is decreasing in each case. Similarly, we find that

$$\begin{aligned} \frac{x^{2n+1}e^{-x}}{(2n+1)!} &< \left(\frac{x}{2n+1}\right)^{2n+1} e^{2n+1-x}\frac{1}{\sqrt{2\pi(2n+1)}} \\ &< \left(\frac{8}{e^7}\right)^3 \frac{1}{\sqrt{6\pi}} < 9\times 10^{-8} \end{aligned} \tag{4.49}$$

when $x \geq 8(2n+1)$ and $n \geq 1$. Multiplying both sides of the first line of (4.48) by x, we obtain

$$\frac{x^{2n+2}e^{-x/2}}{(2n+1)!} < \left(\frac{x}{2n+1}\right)^{2n+2} e^{2n+1-x/2}\sqrt{\frac{2n+1}{2\pi}} \tag{4.50}$$

under the same conditions as (4.48). For $u > 7$ and $n \geq 1$, the inequality

$$u^{2n+2}e^{-(u/2-1)(2n+1)} < u^4 e^{-3(u/2-1)}\sqrt{\frac{3}{2\pi}} \tag{4.51}$$

follows from the fact that the left-hand side is then a decreasing function of n. From (4.50) and (4.51), we find that

$$\begin{aligned} \frac{x^{2n+2}e^{-x/2}}{(2n+1)!} &< 8^4 e^{-9}\sqrt{\frac{3}{2\pi}} < 0.34929, \qquad x > 8(2n+1), \\ &< 16^4 e^{-21}\sqrt{\frac{3}{2\pi}} < 3.43374\times 10^{-5}, \qquad x > 16(2n+1), \end{aligned} \tag{4.52}$$

$n \geq 1$.

With $x = -2\pi^2/\log q$, we have $q' = e^{-x/2}$. When $x \geq 8(2n+1)$ and $n \geq 1$, we see that $q' \leq e^{-12}$. From (4.4), (4.5), (4.8), and (4.52), it follows that

$$\begin{aligned} |R^{(1)}| &< \frac{2\pi q'}{1-q'}(1+2q') \\ &< 6.283302(x^{2n+2}e^{-x/2})x^{-2n-2} \\ &< 2.1947(2n+1)!x^{-2n-2} \end{aligned} \tag{4.53}$$

when $x \geq 8(2n+1)$ and $n \geq 1$. Similarly, from (4.13), (4.17), (4.40), (4.48), and (4.49), we obtain

$$|R^{(2)}| < 0.0000002(2n+1)!x^{-2n-2}, \tag{4.54}$$

$$|R^{(3)}| < 0.05822(2n+1)!x^{-2n-2}, \tag{4.55}$$

and

$$|R_n^{(5)}| < 0.0778(2n+1)!x^{-2n-2} \tag{4.56}$$

when $x \geq 8(2n+1)$ and $n \geq 1$. Finally, from (4.34), (4.43), and (4.53)–(4.56), we have

$$|R_n| < 9.14\,(2n+1)!\left(\frac{\log q}{2\pi^2}\right)^{2n+2} \tag{4.57}$$

for $0 \leq \mu \leq \pi$ when $-\log q \leq \pi^2/4(2n+1)$ and $n \geq 1$. As we further restrict the interval in which ε lies, the exponentially small remainder terms eventually become negligible with respect to $R_n^{(4)}$. In particular, we obtain

$$|R_n| < 6.80159\,(2n+1)!\left(\frac{\log q}{2\pi^2}\right)^{2n+2}. \tag{4.58}$$

when $0 \leq \mu \leq \pi$ and $-\log q \leq \pi^2/8(2n+1)$, $n \geq 1$. We see that the coefficient in this bound differs from that in the bound for $R_n^{(4)}$ by 4 in the fifth decimal place. We find that $|R_1| < 54.9(1/24)^4 = 0.00017$ when $-\log q < \pi^2/12$. When $\log q = -\pi^2/12$ and $r_1 = r_2 = 1$, we have $\varepsilon = 0.172$.

To obtain the explicit dependence of C_{11}, C_{22}, and C_{12} on ε, we find from (3.5), (4.7), (2.7), and (2.9) that

$$-\log q = 2\sqrt{\varepsilon/\sigma}[1 + O(\varepsilon)] \tag{4.59}$$

and

$$\mu = \beta[1 + O(\varepsilon)], \tag{4.60}$$

where

$$\beta = \frac{\pi r_2}{r_1 + r_2}, \tag{4.61}$$

and σ is given by (2.10). We therefore have

$$C_{11} = \frac{\sigma}{4}\left\{\log\left(\frac{\sigma}{\varepsilon}\right) - 2\psi\left(\frac{\beta}{\pi}\right) + O(\varepsilon\log\varepsilon)\right\}, \tag{4.62}$$

$$C_{22} = \frac{\sigma}{4}\left\{\log\left(\frac{\sigma}{\varepsilon}\right) - 2\psi\left(1 - \frac{\beta}{\pi}\right) + O(\varepsilon\log\varepsilon)\right\}, \tag{4.63}$$

and

$$C_{12} = -\frac{\sigma}{4}\left\{\log\left(\frac{\sigma}{\varepsilon}\right) - 2\gamma + O(\varepsilon\log\varepsilon)\right\} \tag{4.64}$$

as $\varepsilon \to 0$.

Terms of the asymptotic expansions for C_{11}, C_{12}, and C_{22} corresponding to the preceding have been obtained by Russell [20], but without an investigation of the remainders. It can be shown that the terms of the asymptotic expansions for C_{11} and C_{22} in [20] agree with (4.42) and (4.44), respectively. However, the asymptotic expansion for C_{12} in [20] is given only through the first five terms, with the coefficients given as rational fractions. Comparison with (4.45) shows that the second, third, and fourth coefficients in [20] are too small by a factor of 1/2.

5. The capacity of two spheres with respect to the infinite sphere. Let $V_1 = V_2 = V$, and let Q_1 and Q_2 be the charges on spheres 1 and 2, respectively. Then the capacity of the spheres with respect to the infinite sphere is given by

$$C = \frac{Q_1 + Q_2}{V}. \tag{5.1}$$

It follows from (3.1) that

$$C = C_{11} + 2C_{12} + C_{22}. \tag{5.2}$$

We find from (5.2) and (3.9) that

$$Q_1/V = C_{11} + C_{12} = \frac{1}{2}C + \frac{iaKk}{\pi}\mathrm{sn}\frac{i(\eta_1 + \eta_2)}{\pi}, \tag{5.3}$$

$$Q_2/V = C_{22} + C_{12} = \frac{1}{2}C - \frac{iaKk}{\pi}\mathrm{sn}\frac{i(\eta_1 + \eta_2)}{\pi}, \tag{5.4}$$

and

$$(Q_1 - Q_2)/V = \frac{2iaKk}{\pi}\mathrm{sn}\frac{iK(\eta_1 + \eta_2)}{\pi} = \frac{2aK}{\pi}\mathrm{cs}\left(\frac{2K\eta_1}{\pi}, k'\right). \tag{5.5}$$

5.1. An asymptotic expansion for *C*. It follows immediately from (4.42)–(4.45) and (4.57) that

$$\begin{aligned} C = -\frac{a}{\log q}\bigg\{ & -\psi\left(\frac{\mu}{\pi}\right) - \psi\left(1 - \frac{\mu}{\pi}\right) - 2\gamma \\ & + 2\sum_{1}^{n} \frac{(2^{2m-1} - 1)}{(2m)!m}\left[B_{2m}B_{2m}\left(\frac{\mu}{\pi}\right) - B_{2m}^2\right](\log q)^{2m} + R_n\bigg\}, \end{aligned} \tag{5.6}$$

where

$$|R_n| < 36.6(2n+1)!\left(\frac{\log q}{2\pi^2}\right)^{2n+2} \tag{5.7}$$

for $0 \leq \mu \leq \pi$ when $-\log q \leq \pi^2/4(2n+1)$ and $n \geq 1$.

5.2. A smaller bound for $|R_n|$. We can obtain a smaller bound for $|R_n|$ by starting from the integral representation

$$C = \frac{2aK}{\pi^2}\int_0^{\pi}\left[\mathrm{Re}\,\mathrm{ns}\frac{K}{\pi}(t + 2i\eta_2) - \mathrm{ns}\frac{Kt}{\pi} + \frac{\pi}{2K}\csc\frac{t}{2}\right]\csc\frac{t}{2}\,dt, \tag{5.8}$$

which follows from (3.7) through (3.9). Proceeding as in §4, we find that

$$C = \frac{2aK}{\pi^2}\int_0^\pi \left\{ -\operatorname{Im}\operatorname{cs}\left[\frac{K}{\pi}(2\eta_1 + it), k'\right] + \operatorname{Im}\operatorname{cs}\left(\frac{iKt}{\pi}, k'\right) + \frac{\pi}{2K}\csc\frac{t}{2}\right\} dt$$

$$(5.9)\quad = \frac{aK}{\pi K'}\left\{ \int_0^\pi \left(\frac{\sinh\frac{Kt}{K'}}{\cosh\frac{Kt}{K'} - \cos 2\mu} - \coth\frac{Kt}{K'} + \frac{K'}{K}\csc\frac{t}{2}\right)\csc\frac{t}{2}\,dt \right.$$
$$\left. + 4\sum_{n=1}^{\infty}\frac{q'^{2n}}{1+q'^{2n}}\left(\cos\frac{2nK\eta_1}{K'} - 1\right)\int_0^\pi \sinh\frac{nKt}{K'}\cos\frac{t}{2}\,dt\right\},$$

where the series converges for all $\varepsilon > 0$.

Denoting the sum in (5.9) by S and using (4.3), noting that the integrand is ≥ 0, we have

$$(5.10)\qquad |S| < 2\sum_{n=1}^{\infty} q'^{2n}\int_0^\pi \sinh\frac{nKt}{K'}\cos\frac{t}{2}\,dt$$
$$< \pi\sum_{n=1}^{\infty} q'^{n} = \frac{\pi q'}{1-q'}.$$

Hence,

$$(5.11)\quad C = \frac{aK}{\pi K'}\left\{\int_0^\pi \left(\frac{\sinh\frac{Kt}{K'}}{\cosh\frac{Kt}{K'} - \cos 2\mu} - \coth\frac{Kt}{2K'} + \frac{K'}{K}\csc\frac{t}{2}\right)\csc\frac{t}{2}\,dt + R^{(1)}\right\},$$

where

$$(5.12)\qquad |R^{(1)}| < \frac{4\pi q'}{1-q'}.$$

We find that

$$\int_0^\pi \left(\frac{\sinh\frac{Kt}{K'}}{\cosh\frac{Kt}{K'} - \cos 2\mu} - \coth\frac{Kt}{2K'} + \frac{K'}{K}\csc\frac{t}{2}\right)\csc\frac{t}{2}\,dt$$
$$= 2\int_0^{\pi K/K'}\left(\frac{\sinh u}{\cosh u - \cos 2\mu} - \coth\frac{u}{2}\right)\left(\frac{K'u}{2K}\csc\frac{K'u}{2K} - 1\right)\frac{du}{u}$$
$$(5.13)\qquad +2\int_0^\infty \left(\frac{\sinh u}{\cosh u - \cos 2\mu} - \coth\frac{u}{2} + \frac{2}{u}\right)\frac{du}{u}$$
$$-2\int_{\pi K/K'}^\infty \left(\frac{\sinh u}{\cosh u - \cos 2\mu} - \coth\frac{u}{2}\right)\frac{du}{u}$$
$$-4\int_{\pi K/K'}^\infty \frac{du}{u^2} + \int_0^{\pi K/K'}\left[\left(\frac{K'}{K}\right)^2\csc^2\frac{K'u}{2K} - \frac{4}{u^2}\right]du.$$

We first have

$$(5.14)\quad -4\int_{\pi K/K'}^\infty \frac{du}{u^2} + \int_0^{\pi K/K'}\left[\left(\frac{K'}{K}\right)^2\csc^2\frac{K'u}{2K} - \frac{4}{u^2}\right]du = -\frac{4K}{\pi K'} + \frac{4K}{\pi K'} = 0.$$

Next, writing

$$(5.15)\qquad R^{(2)} = 2\int_{\pi K/K'}^\infty \left(\coth\frac{u}{2} - \frac{\sinh u}{\cosh u - \cos 2\mu}\right)\frac{du}{u},$$

we find that

$$\begin{aligned}
0 \le \coth\frac{u}{2} - \frac{\sinh u}{\cosh u - \cos 2\mu} &= \frac{(1-\cos 2\mu)(1+e^{-u})e^{-u}}{(1-e^{-u})(1-2e^{-u}\cos 2\mu + e^{-2u})} \\
&\le \frac{2(1+e^{-u})e^{-u}}{(1-e^{-u})^3}, \quad u \ge 0 \\
&\le 2.0001\, e^{-u}, \qquad u \ge 12.
\end{aligned} \tag{5.16}$$

Hence, by using (4.12), we obtain

$$\begin{aligned}
|R^{(2)}| &< 4.0002 \int_{\pi K/K'}^{\infty} \frac{e^{-u}\,du}{u} \\
&< -8.0004 q'\left(\frac{\log q}{2\pi^2}\right),
\end{aligned} \tag{5.17}$$

when $\pi K/K' \ge 12$.

While the integral

$$I = \int_0^\infty \left(\coth\frac{u}{2} - \frac{\sinh u}{\cosh u - \cos 2\mu} + \frac{2}{u}\right)\frac{du}{u} \tag{5.18}$$

can be evaluated by comparison with (5.6), it can also be evaluated directly by use of (4.21). We have

$$I = -\frac{1}{2}\left[\psi\left(\frac{\mu}{\pi}\right) + \psi\left(1 - \frac{\mu}{\pi}\right)\right] + c, \tag{5.19}$$

where c is a constant. Substituting $\mu = \pi/2$, we obtain

$$c = 2\int_0^\infty \left(\frac{1}{u} - \operatorname{csch} u\right)\frac{du}{u} + \psi\left(\frac{1}{2}\right). \tag{5.20}$$

From [7, Eq. 3.529.1], we have

$$\int_0^\infty \left(\frac{1}{u} - \operatorname{csch} u\right)\frac{du}{u} = \log 2. \tag{5.21}$$

Finally, substituting $\psi(1/2) = -\gamma - 2\log 2$, we obtain

$$I = -\frac{1}{2}\left[\psi\left(\frac{\mu}{\pi}\right) + \psi\left(1 - \frac{\mu}{\pi}\right) + 2\gamma\right]. \tag{5.22}$$

Proceeding as in §4, using (4.26) and (4.27), we have

$$\begin{aligned}
&\int_0^{\pi K/K'} \left(\frac{\sinh u}{\cosh u - \cos 2\mu} - \coth\frac{u}{2}\right)\left(\frac{K'u}{2K}\csc\frac{K'u}{2K} - 1\right)\frac{du}{u} \\
&= 2\sum_{m=1}^{n} \frac{(-1)^{m+1}(2^{2m-1}-1)B_{2m}}{(2m)!}\left(\frac{K'}{2K}\right)^{2m} \\
&\cdot \int_0^{\pi K/K'} \left(\frac{\sinh u}{\cosh u - \cos 2\mu} - \coth\frac{u}{2}\right)u^{2m-1}\,du + R_n^{(3)},
\end{aligned} \tag{5.23}$$

where

$$(5.24)\qquad |R_n^{(3)}| < \frac{\pi(2^{2n+1}-1)|B_{2n+2}|}{(2n+2)!}\left(\frac{K'}{2K}\right)^{2n+2} \cdot \int_0^{\pi K/K'} \left(\coth\frac{u}{2} - \frac{\sinh u}{\cosh u - \cos 2\mu}\right) u^{2n+1}\,du.$$

We note that the integrand in the last integral is positive when $u > 0$.

Denoting the integral in (5.24) by I and using (4.41), we obtain

$$(5.25)\qquad \begin{aligned} |I| &< \int_0^{\infty} \left(\coth\frac{u}{2} - \frac{\sinh u}{\cosh u - \cos 2\mu}\right) u^{2n+1}\,du \\ &= \int_0^{\infty} \left(\frac{1-e^{-u}}{\cosh u - 1} - \frac{\cos 2\mu - e^{-u}}{\cosh u - \cos 2\mu}\right) u^{2n+1}\,du \\ &= \frac{(-1)^n(2\pi)^{2n+2}}{2n+2}\left[B_{2n+2} - B_{2n+2}\left(\frac{\mu}{\pi}\right)\right]. \end{aligned}$$

From [16, p. 22] and (4.33), we have

$$(5.26)\qquad \begin{aligned} \left|B_{2n+2} - B_{2n+2}\left(\frac{\mu}{\pi}\right)\right| &\le \left|B_{2n+2} - B_{2n+2}\left(\frac{1}{2}\right)\right| = (2-2^{-2n-1})|B_{2n+2}| \\ &< \frac{2(2\pi)^{-2n-2}(2-2^{-2n-1})(2n+2)!}{1-2^{-2n-1}}. \end{aligned}$$

Finally, from (5.24)–(5.26) and (3.5), we obtain

$$(5.27)\qquad \begin{aligned} |R_n^{(3)}| &< 4\pi\frac{1-2^{-2n-2}}{1-2^{-2n-1}}(2n+1)!\left(\frac{\log q}{2\pi^2}\right)^{2n+2} \\ &< \frac{30}{7}\pi(2n+1)!\left(\frac{\log q}{2\pi^2}\right)^{2n+2}, \end{aligned}$$

$0 \le \mu \le \pi, n \ge 1$.

As in the case of (4.28), (5.23) is both an asymptotic and a convergent expansion. Proceeding as in (4.36) and (4.37), we write

$$(5.28)\qquad \begin{aligned} &\sum_{m=1}^{n} \frac{(-1)^{m+1}(2^{2m-1}-1)B_{2m}}{(2m)!}\left(\frac{K'}{2K}\right)^{2m} \cdot \int_0^{\pi K/K'} \left(\frac{\sinh u}{\cosh u - \cos 2\mu} - \coth\frac{u}{2}\right) u^{2m-1}\,du \\ &= \sum_{m=1}^{n} \frac{(-1)^{m+1}(2^{2m-1}-1)B_{2m}}{(2m)!}\left(\frac{K'}{2K}\right)^{2m} \cdot \int_0^{\infty} \left(\frac{\sinh u}{\cosh u - \cos 2\mu} - \coth\frac{u}{2}\right) u^{2m-1}\,du + R_n^{(4)}, \end{aligned}$$

where

$$(5.29)\qquad R_n^{(4)} = -\sum_{m=1}^{n} \frac{(-1)^{m+1}(2^{2m-1}-1)B_{2m}}{(2m)!}\left(\frac{K'}{2K}\right)^{2m} \cdot \int_{\pi K/K'}^{\infty} \left(\frac{\sinh u}{\cosh u - \cos 2\mu} - \coth\frac{u}{2}\right) u^{2m-1}\,du.$$

By use of (5.16) and (4.38), we find

$$
\begin{aligned}
0 &< \int_{\pi K/K'}^{\infty} \left(\coth\frac{u}{2} - \frac{\sinh u}{\cosh u - \cos 2\mu}\right) u^{2m-1}\,du \\
&< 2.0001 \int_{\pi K/K'}^{\infty} u^{2m-1} e^{-u}\,du \\
&< 4.0002 \left(\frac{\pi K}{K'}\right)^{2m-1} e^{-\pi K/K'}
\end{aligned}
\tag{5.30}
$$

when $\pi K/K' \geq 12$. Proceeding as in (4.40), we then obtain

$$
\begin{aligned}
|R_n^{(4)}| &< \frac{-2.0001 q' \log q}{\pi} \sum_{m=1}^{n} \frac{(-1)^{m+1}(2^{2m-1}-1)B_{2m}}{(2m)!} \left(\frac{\pi}{2}\right)^{2m-1} \\
&< \frac{-2.0001}{\pi^2} q' \log q \sum_{m=1}^{\infty} 2^{1-2m} \\
&< -1.3334 q' \left(\frac{\log q}{2\pi^2}\right)
\end{aligned}
\tag{5.31}
$$

when $-\log q \leq \pi^2/4(2n+1)$, $n \geq 1$. Next, Proceeding as in (4.53)–(4.56), we find that

$$
\begin{aligned}
|R^{(1)}| &< 4.38934\,(2n+1)!\,x^{-2n-2}, \\
|R^{(2)}| &< 0.11644\,(2n+1)!\,x^{-2n-2}, \\
|R_n^{(3)}| &< 13.4640\,(2n+1)!\,x^{-2n-2}, \\
|R^{(4)}| &< 0.01941\,(2n+1)!\,x^{-2n-2}
\end{aligned}
\tag{5.32}
$$

when $x \geq 8(2n+1)$, $n \geq 1$, where $x = 2\pi K/K'$. Finally, with $R_n = R^{(1)} + R^{(2)} + R_n^{(3)} + R^{(4)}$, we have

$$
|R_n| < 18.0\,(2n+1)! \left(\frac{\log q}{2\pi^2}\right)^{2n+2}
\tag{5.33}
$$

when $-\log q \leq \pi^2/4(2n+1)$, $n \geq 1$. The exponentially small remainder terms $R^{(1)}$, $R^{(2)}$, and $R^{(4)}$ become neglibible with respect to $R_n^{(3)}$ as we further restrict the interval in which ε lies. When $0 \leq \mu \leq \pi$ and $-\log q < \pi^2/8(2n+1)$, $n \geq 1$, we obtain

$$
|R_n| < 13.4644\,(2n+1)! \left(\frac{\pi^2}{2\pi}\right)^{(2n+2)}.
\tag{5.34}
$$

We see that the coefficient in this bound differs from that in the bound for $R_n^{(3)}$ by 4 in the fourth decimal place.

5.3. The capacity of two tangent spheres with respect to the infinite sphere. From (2.6), (2.9), (2.10), and (3.5), we have

$$
\lim_{\varepsilon \to 0} \frac{aK}{\pi K'} = \frac{r_1 r_2}{r_1 + r_2} = \sigma/2,
\tag{5.35}
$$

and from (4.60) and (4.61),

$$\lim_{\varepsilon\to 0}\mu = \beta. \tag{5.36}$$

Noting that μ and $\log q$ are continuous functions of ε for $\varepsilon \geq 0$, we find from (5.6) and (5.7) that C is a continuous function of ε at $\varepsilon = 0$. Hence, the capacity of two tangent spheres with respect to the infinite sphere is given by $C^{(0)} = \lim_{\varepsilon\to 0} C$, and we find from (5.11), (5.18), (5.22), (5.35), and (5.36) that

$$C^{(0)} = \sigma\int_0^\infty \left(\frac{\sinh u}{\cosh u - \cos 2\beta} - \coth\frac{u}{2} + \frac{2}{u}\right)\frac{du}{u} \tag{5.37}$$

$$= \frac{\sigma}{2}\left[-\psi\left(\frac{\beta}{\pi}\right) - \psi\left(1-\frac{\beta}{\pi}\right) - 2\gamma\right] \tag{5.38}$$

when $0 < \beta < \pi$. When $r_1 = r_2 = r$, (5.38) simplifies to

$$C^{(0)} = 2r\log 2. \tag{5.39}$$

Finally, the well-known results

$$Q_1^{(0)}/V = \lim_{\varepsilon\to 0} Q_1/V = \frac{\sigma}{2}\left[-\gamma - \psi\left(\frac{\beta}{\pi}\right)\right], \tag{5.40}$$

$$Q_2^{(0)}/V = \lim_{\varepsilon\to 0} Q_2/V = \frac{\sigma}{2}\left[-\gamma - \psi\left(1-\frac{\beta}{\pi}\right)\right], \tag{5.41}$$

and

$$(Q_1^{(0)} - Q_2^{(0)})/V = \lim_{\varepsilon\to 0}(Q_1 - Q_2)/V = \frac{\pi\sigma}{2}\cot\beta \tag{5.42}$$

follow from (5.3)–(5.5).

Poisson [18, pp. 56–59] has given expressions for $Q_1^{(0)}/V$, $Q_2^{(0)}/V$, and $C^{(0)}$ involving integrals between 0 and 1. When these integrals are evaluated, his expressions reduce to (5.40), (5.41), and (5.38), respectively. Also, the result (5.42) is given on page 59 of [18]. Expressions for $Q_1^{(0)}$ and $Q_2^{(0)}$ in terms of $\psi(z)$ are given in the second and third editions of Maxwell's treatise [14] but not in the first edition (1873).

6. The capacity of two spheres. With $Q_1 = -Q_2 = Q$, the capacity of two spheres is defined by

$$C_0 = \frac{Q}{V_1 - V_2}. \tag{6.1}$$

From (3.1) and (6.1), we have

$$C_0 = D/C, \tag{6.2}$$

where

$$D = C_{11}C_{22} - C_{12}^2 \tag{6.3}$$

and C is the capacity of the spheres with respect to the infinite sphere. When the radii of the spheres are equal, and hence $C_{11} = C_{22}$, we have

$$C_0 = \frac{1}{2}(C_{11} - C_{12}). \tag{6.4}$$

Let

$$C_{11} = -\frac{a}{\log q}\left[\log\left(\frac{-2}{\log q}\right) + \bar{C}_{11}\right], \tag{6.5}$$

$$C_{22} = -\frac{a}{\log q}\left[\log\left(\frac{-2}{\log q}\right) + \bar{C}_{22}\right], \tag{6.6}$$

and

$$C_{12} = \frac{a}{\log q}\left[\log\left(\frac{-2}{\log q}\right) + \bar{C}_{12}\right], \tag{6.7}$$

where $\bar{C}_{11}, \bar{C}_{22}$, and $\bar{C}_{12}$ are defined by (4.42), (4.44), and (4.45), respectively. It follows from (5.2) and the preceding that

$$C = -\frac{a}{\log q}(\bar{C}_{11} - 2\bar{C}_{12} + \bar{C}_{22}). \tag{6.8}$$

From (6.3) and (6.5)–(6.7), we obtain

$$D = \left(\frac{a}{\log q}\right)^2\left[(\bar{C}_{11} - 2\bar{C}_{12} + \bar{C}_{22})\log\left(\frac{-2}{\log q}\right) + \bar{C}_{11}\bar{C}_{22} - \bar{C}_{12}^2\right]. \tag{6.9}$$

Finally, from (6.2), (6.8), and (6.9), we have

$$C_0 = -\frac{a}{\log q}\left[\log\left(\frac{-2}{\log q}\right) + \frac{\bar{C}_{11}\bar{C}_{22} - \bar{C}_{12}^2}{\bar{C}_{11} - 2\bar{C}_{12} + \bar{C}_{22}}\right]. \tag{6.10}$$

For sufficiently small ε, we can obtain close upper and lower bounds for $\bar{C}_{11}, \bar{C}_{22}$, and $\bar{C}_{12}$ from (4.42) through (4.45) and (4.57). Similarly, bounds for C can be obtained from (5.6) and (5.33).

When the radii of the spheres are not equal, it follows from (4.42)–(4.45) and (6.10) that

$$C_0 = -\frac{a}{\log q}\left\{\log\left(\frac{-2}{\log q}\right) - \frac{\psi(\mu/\pi)\psi(1-\mu/\pi) - \gamma^2}{\psi(\mu/\pi) + \psi(1-\mu/\pi) + 2\gamma} + \mathrm{O}[(\log q)^2]\right\} \tag{6.11}$$

as $\varepsilon \to 0$. When the radii of the spheres are equal, we find from (4.42), (4.45), and (6.4) that

$$\begin{aligned} C_0 = \frac{-a}{\log q}\Bigg\{ &\log\left(\frac{-2}{\log q}\right) + \gamma \\ &+ \sum_{m=1}^{n} \frac{(2^{2m-1}-1)(B_{2m})^2}{(2m)!m}\left(\frac{\log q}{2}\right)^{2m} + R_n\Bigg\}, \end{aligned} \tag{6.12}$$

where, by (4.57),

$$|R_n| < 18.3(2n+1)!\left(\frac{\log q}{2\pi^2}\right)^{2n+2} \tag{6.13}$$

when $-\log q \le \pi^2/4(2n+1)$ and $n \ge 1$.

The asymptotic expansion (6.12) has been derived by different methods in [13] and [19], but the result obtained in each case differs from (6.12) by the factor 4. Agreement is obtained after correcting some misprints in [28, p. 232][1] and expressing the capacity in the same units as in (6.12).

[1] The factor 2 in (31) should be replaced by 1/2, and both right-hand sides of (32) should be multiplied by 4π.

7. Asymptotic behavior of the coefficients of potential as $\varepsilon \to 0$. The potentials V_1 and V_2 are given in terms of the total charges on the spheres by

$$\begin{aligned} V_1 &= p_{11}Q_1 + p_{12}Q_2, \\ V_2 &= p_{12}Q_1 + p_{22}Q_2, \end{aligned} \tag{7.1}$$

where p_{11}, p_{12}, and p_{22} are the coefficients of potential of the spheres. It follows from (3.1) that

$$p_{11} = \frac{C_{22}}{D}, \qquad p_{12} = -\frac{C_{12}}{D}, \qquad p_{22} = \frac{C_{11}}{D}, \tag{7.2}$$

where D is given by (6.3). As in the case of C_0, we can obtain upper and lower bounds for p_{11}, p_{12}, and p_{22} for sufficiently small ε by use of the results in §4.

From (4.62)–(4.64) and (5.38), we find that

$$p_{11} = \frac{1}{C^{(0)}}\left\{1 + \frac{\sigma}{C^{(0)}}\left[\psi\left(1 - \frac{\beta}{\pi}\right) + \gamma\right]^2 \left[\log\left(\frac{\sigma}{\varepsilon}\right)\right]^{-1} + O[(\log\varepsilon)^{-2}]\right\}, \tag{7.3}$$

$$p_{12} = \frac{1}{C^{(0)}}\left\{1 + \frac{\sigma}{C^{(0)}}\left[\psi\left(\frac{\beta}{\pi}\right) + \gamma\right]\left[\psi\left(1 - \frac{\beta}{\pi}\right) + \gamma\right]\left[\log\left(\frac{\sigma}{\varepsilon}\right)\right]^{-1} + O[(\log\varepsilon)^{-2}]\right\}, \tag{7.4}$$

and

$$p_{22} = \frac{1}{C^{(0)}}\left\{1 + \frac{\sigma}{C^{(0)}}\left[\psi\left(\frac{\beta}{\pi}\right) + \gamma\right]^2 \left[\log\left(\frac{\sigma}{\varepsilon}\right)\right]^{-1} + O[(\log\varepsilon)^{-2}]\right\}. \tag{7.5}$$

It follows from (7.1) and the preceding that both V_1 and V_2 are asymptotically equal to $(Q_1 + Q_2)/C^{(0)}$ as $\varepsilon \to 0$ and, hence, that $V_1 - V_2 \to 0$ as $\varepsilon \to 0$. When $r_1 = r_2$ and $Q_1 = Q_2$, we see that $V_1 = V_2$ for all ε.

From (7.2) and (7.1) together with (4.42), (4.44), and (4.45), we obtain

$$\begin{aligned} (V_1 - V_2)D = -\frac{a}{\log q}\Big\{ &-\left[\psi\left(1 - \frac{\mu}{\pi}\right) + \gamma\right] Q_1 + \left[\psi\left(\frac{\mu}{\pi}\right) + \gamma\right] Q_2 \\ &+ \frac{B_2}{2}\left[B_2\left(\frac{\mu}{\pi}\right) - B_2\right](Q_1 - Q_2)(\log q)^2 + \mathrm{O}[(\log q)^4]\Big\}. \end{aligned} \tag{7.6}$$

Using (4.59)–(4.61), we find that

$$V_1 - V_2 = \left\{-\left[\psi\left(1 - \frac{\beta}{\pi}\right) + \gamma\right] Q_1 + \left[\psi\left(\frac{\beta}{\pi}\right) + \gamma\right] Q_2 + \mathrm{O}(\varepsilon)\right\} \Big/ [D^{(0)} + \mathrm{O}(\varepsilon)], \tag{7.7}$$

where

$$D^{(0)} = C^{(0)}\left\{\frac{1}{2}\log(\sigma/\varepsilon) - \frac{\psi(\frac{\beta}{\pi})\psi(1 - \frac{\beta}{\pi}) - \gamma^2}{\psi(\frac{\beta}{\pi}) + \psi(1 - \frac{\beta}{\pi}) + 2\gamma}\right\}. \tag{7.8}$$

When $r_1 = r_2 = r$ while $Q_1 \neq Q_2$, noting that all higher-order terms in (7.6) are multiplied by $Q_1 - Q_2$, we find that (7.6) simplifies to

$$V_1 - V_2 = \frac{(Q_1 - Q_2)[1 + \mathrm{O}(\varepsilon)]}{r[\frac{1}{2}\log(r/\varepsilon) - \gamma - \log 2]}. \tag{7.9}$$

We see that the sum of the first two terms of the numerator of (7.7) vanishes when

$$Q_2/Q_1 = Q_2{}^{(0)}/Q_1{}^{(0)} = \frac{\psi(1-\beta/\pi)+\gamma}{\psi(\beta/\pi)+\gamma}, \tag{7.10}$$

where $Q_1{}^{(0)}$ and $Q_2{}^{(0)}$ are defined in (5.40) and (5.41), respectively. Noting that

$$\frac{\mu-\beta}{\pi} = \frac{r_1-r_2}{3(r_1+r_2)^2}\varepsilon + \mathrm{O}(\varepsilon^2), \tag{7.11}$$

$$(\log q)^2 = \frac{2(r_1+r_2)}{r_1r_2}\varepsilon + \mathrm{O}(\varepsilon^2), \tag{7.12}$$

and

$$\begin{aligned} \frac{1}{2}B_2[B_2(\mu/\pi)-B_2] &= \frac{1}{12}\frac{\beta}{\pi}\left(\frac{\beta}{\pi}-1\right)+\mathrm{O}(\varepsilon) \\ &= -\frac{1}{12}\frac{r_1r_2}{(r_1+r_2)^2}+\mathrm{O}(\varepsilon), \end{aligned} \tag{7.13}$$

we then find that

$$\begin{aligned} V_1 - V_2 = \frac{Q_1}{3(r_1+r_2)}\left\{\left[\left(\frac{r_1-r_2}{r_1+r_2}\right)\left\{\psi'\left(1-\frac{\beta}{\pi}\right)+\frac{Q_2{}^{(0)}}{Q_1{}^{(0)}}\psi'\left(\frac{\beta}{\pi}\right)\right\}\right.\right. \\ \left.\left. -\frac{1}{2}\left\{1-\frac{Q_2{}^{(0)}}{Q_1{}^{(0)}}\right\}\right]\varepsilon+\mathrm{O}(\varepsilon^2)\right\}\Big/[D^{(0)}+\mathrm{O}(\varepsilon)], \end{aligned} \tag{7.14}$$

where $D^{(0)}$ is given by (7.8). We see that this is the potential difference which results when two charged tangent spheres are separated slightly. When $r_1 = r_2$, the potentials remain equal for all values of ε.

8. Asymptotic behavior of the charge density at the inner axial points with Q_1 and Q_2 held constant. As in [27], the charge density at the inner axial point of sphere 1 is given by

$$D_1|_{\theta_1=\pi} = \left(\frac{V_1+V_2}{2}\right)D_{11}|_{\theta_1=\pi} + \left(\frac{V_1-V_2}{2}\right)D_{12}|_{\theta=\pi}, \tag{8.1}$$

where

$$D_{11}|_{\theta_1=\pi} = (\pi/\sigma)\sin\beta\,(\sigma/\varepsilon)^{3/2}\exp\left[-2^{-1}\pi^2(\sigma/\varepsilon)^{1/2}\right][1+\mathrm{O}(\varepsilon)] \tag{8.2}$$

and

$$D_{12}|_{\theta_1=\pi} = (2\pi\varepsilon)^{-1}[1+\mathrm{O}(\varepsilon)] \tag{8.3}$$

as $\varepsilon \to 0$. When (7.10) does not hold, it follows from (7.7)–(7.9) and (8.1)–(8.3) that

$$D_1|_{\theta=\pi} = \frac{1}{2\pi\varepsilon}\left\{-\left[\psi\left(1-\frac{\beta}{\pi}\right)+\gamma\right]Q_1+\left[\psi\left(\frac{\beta}{\pi}\right)+\gamma\right]Q_2+\mathrm{O}(\varepsilon)\right\}\Big/[D^{(0)}+\mathrm{O}(\varepsilon)] \tag{8.4}$$

when $r_1 \neq r_2$ and

$$D_1|_{\theta=\pi} = \frac{(Q_1 - Q_2)[1 + \mathrm{O}(\varepsilon)]}{2\pi\varepsilon r[\frac{1}{2}\log(r/\varepsilon) - \gamma - \log 2]} \tag{8.5}$$

when $r_1 = r_2 = r$ and $Q_1 \neq Q_2$.

When (7.10) is satisfied and $r_1 \neq r_2$, we find from (7.14) and (8.1)–(8.3) that

$$\begin{aligned} D_1|_{\theta=\pi} = \frac{Q_1}{6\pi(r_1+r_2)}\Bigg\{ \left(\frac{r_1 - r_2}{r_1 + r_2}\right) \left[\psi'\left(1 - \frac{\beta}{\pi}\right) + \frac{Q_2{}^{(0)}}{Q_1{}^{(0)}}\psi'\left(\frac{\beta}{\pi}\right)\right] \\ - \frac{1}{2}\left[1 - \frac{Q_2{}^{(0)}}{Q_1{}^{(0)}}\right] + \mathrm{O}(\varepsilon)\Bigg\} \Big/ [D^{(0)} + \mathrm{O}(\varepsilon)]. \end{aligned} \tag{8.6}$$

We see that

$$D_1|_{\theta=\pi} = \mathrm{O}[(\varepsilon\log\varepsilon)^{-1}] \tag{8.7}$$

when (7.10) does not hold and that

$$D_1|_{\theta=\pi} = \mathrm{O}[(\log\varepsilon)^{-1}] \tag{8.8}$$

when (7.10) holds and $r_1 \neq r_2$. When (7.10) holds and $r_1 = r_2 = r$, we have

$$D_1|_{\theta=\pi} = \mathrm{O}\left\{(r/\varepsilon)^{3/2}\exp\left[-2^{-1}\pi^2(r/\varepsilon)^{1/2}\right]\right\} \tag{8.9}$$

To the order of approximation shown in (8.4)–(8.6), we have

$$D_1|_{\theta=\pi} = -D_2|_{\theta=\pi} \tag{8.10}$$

However, when (7.10) is satisfied and $r_1 = r_2$, we see that

$$D_1|_{\theta=\pi} = D_2|_{\theta=\pi} \tag{8.11}$$

for all values of ε.

Results corresponding to (8.4) and (8.6) are given in [17] and [18]. However, both [17] and [18] contain misprints. After correction of these misprints and evaluation of some definite integrals, it can be shown that the results in [17] and [18] are identical to (8.4) and (8.6). While the first few terms of the asymptotic expansions of the coefficients of capacity and induction enter into these results, it was not known in [17] and [18] that these expansions are divergent. Also, the existence of the exponentially small contribution to $D_1|_{\theta=\pi}$ was not known. As noted in the introduction, the asymptotic behavior of $D_{11}|_{\theta=\pi}$ was first found by Kirchhoff in [11].

INFINITE TOEPLITZ AND HANKEL MATRICES WITH OPERATOR-VALUED ENTRIES*

ALBRECHT BÖTTCHER† AND BERND SILBERMANN‡

Abstract. Infinite Toeplitz matrices with operator-valued entries arise, for example, when interpreting Wiener–Hopf integral operators on $L^2(0,\infty)$ as matrices acting on the direct sum of countably many copies of $L^2(0,1)$. This paper concerns the question of asymptotically inverting such infinite Toeplitz matrices by having recourse to their finite principal sections. As expected from the corresponding theories for the scalar and matrix-valued cases, this problem leads to the investigation of compactness properties of infinite Hankel matrices. By introducing the concept of Q_n-compact operators on spaces of square-summable sequences with values in a separable Hilbert space, criteria for the applicability of the finite section method to Toeplitz operators with symbols in $C + H^\infty$, in PC, or with locally sectorial symbols are established.

Key words. infinite matrices, Toeplitz operators, Hankel operators, projection methods

1. Introduction.

Let $\mathcal{H}$ be a separable Hilbert space and let $l^2(\mathcal{H})$ stand for the Hilbert space of all sequences $f = (f_n)_{n=0}^{\infty}$ with values $f_n \in \mathcal{H}$ for which

$$\|f\|^2 := \sum_{n=0}^{\infty} \|f_n\|_{\mathcal{H}}^2 < \infty.$$

A function a defined on the complex unit circle $\mathbf{T}$ and taking on values in $\mathcal{L}(\mathcal{H})$, the C^*-algebra of all bounded linear operators on $\mathcal{H}$, is said to belong to $L^\infty(\mathcal{L}(\mathcal{H}))$ if it is weakly measurable and

$$\|a\|_\infty := \operatorname*{ess\,sup}_{t\in\mathbf{T}} \|a(t)\|_{\mathcal{L}(\mathcal{H})} < \infty.$$

Each function $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ induces both a Toeplitz operator $T(a)$ and a Hankel operator $H(a)$ on $l^2(\mathcal{H})$. If we denote the Fourier coefficients of a by $\{a_n\}_{n=-\infty}^{\infty}$,

$$a_n := \frac{1}{2\pi} \int_{-\pi}^{\pi} a(e^{i\theta}) e^{-in\theta}\, d\theta,$$

then $T(a)$ and $H(a)$ are the bounded operators on $l^2(\mathcal{H})$ given by the infinite matrices $(a_{j-k})_{j,k=0}^{\infty}$ and $(a_{j+k+1})_{j,k=0}^{\infty}$, respectively. The function a is in this context usually referred to as the *symbol* of the operators $T(a)$ and $H(a)$.

Toeplitz and Hankel operators have been studied for a long time in the scalar ($\dim \mathcal{H} = 1$) and matrix ($\dim \mathcal{H} < \infty$) cases; see [12], [5], [6] for "centennial" interim reports on the development. Much less is known in the operator case ($\dim \mathcal{H} = \infty$). The pioneering works in this direction are certainly the papers by Rabindranathan

[17] and Page [16]. Recent interest in this topic has come up with works by Treil [22], Gohberg and Kaashoek [13], [14] and the authors [7].

An important question in Toeplitz theory concerns the replacement of the equation $T(a)f = g$, i.e., the discrete Wiener–Hopf equation

$$\sum_{k=0}^{\infty} a_{j-k} f_k = g_j \qquad (j = 0, 1, 2, \ldots), \tag{1}$$

by its truncations (= finite sections) $T_n(a)f^{(n)} = P_n g$,

$$\sum_{k=0}^{n} a_{j-k} f_k^{(n)} = g_j \qquad (j = 0, 1, \ldots, n). \tag{2}$$

Here, by $P_n : l^2(\mathcal{H}) \to l^2(\mathcal{H})$ we denote the projections defined by

$$P_n : (g_0, g_1, g_2, \ldots) \mapsto (g_0, g_1, \ldots, g_n, 0, 0, \ldots), \tag{3}$$

and we let $T_n(a)$ stand for the compression $P_n T(a) P_n | \mathrm{Im} P_n$. If there is an $n_0 \geq 0$ such that equations (2) have a unique solution $f^{(n)} \in \mathrm{Im} P_n$ for every $g \in l^2(\mathcal{H})$ and every $n \geq n_0$ and if $f^{(n)}$ converges in $l^2(\mathcal{H})$ to a solution $f \in l^2(\mathcal{H})$ of (1), then the *finite-section method* is said to be applicable to $T(a)$. We write $T(a) \in \Pi\{P_n\}$ in this case. Some authors speak of the "projection method" instead of the "finite-section method"; we prefer the latter name, since there are many other projections methods (including various Galerkin–Petrov methods) one might apply to solve (1) approximately.

Here now is also the place to remark that Toeplitz matrices with operator-valued entries are not considered for academic purposes only. First, quarter-plane Toeplitz operators (with scalar-valued symbols) are nothing but Toeplitz matrices on $l^2(l^2)$ whose entries are themselves Toeplitz matrices. Secondly, in [13] it was pointed out that Wiener–Hopf integral operators may be "discretized" to become Toeplitz operators with operator-valued entries. This observation enabled Gohberg and Kaashoek to establish a first Szegö limit theorem for the Fredholm determinants of truncated Wiener–Hopf integral operators. Moreover, by having recourse to Toeplitz operators with operator-valued entries, the authors and Harold Widom [8] were able to prove a certain continuous analogue of the Fisher–Hartwig formula for Toeplitz determinants—up to now no other way of obtaining this analogue is known.

In the matrix case ($\dim \mathcal{H} < \infty$), there is a well-known strong interplay between Fredholm criteria and the finite-section method for Toeplitz operators on the one hand and compactness properties of Hankel operators on the other (see, e.g., [12] and [6]). Page [16] showed that studying compact Hankel operators on $l^2(\mathcal{H})$ with $\dim \mathcal{H} = \infty$ is also of interest; he proved the following operator-valued version of the celebrated Hartman theorem:

$$H(a) \in \mathcal{K}(l^2(\mathcal{H})) \qquad \Longleftrightarrow \qquad a \in C(\mathcal{K}(\mathcal{H})) + \overline{H^\infty(\mathcal{L}(\mathcal{H}))}. \tag{4}$$

Here $\mathcal{K}$ stands for the ideal of all compact operators, $C(\mathcal{K}(\mathcal{H}))$ denotes the continuous functions of $\mathbf{T}$ into $\mathcal{K}(\mathcal{H})$, and $\overline{H^\infty(\mathcal{L}(\mathcal{H}))}$ is the algebra of all $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ for which $a_n = 0$ for all $n \geq 1$. In what follows, we abbreviate the set on the right of (4) to $C_\mathcal{K} + \overline{H^\infty}$. Using (4) it is easy to realize that $C_\mathcal{K} + \overline{H^\infty}$ is, in fact, a Banach subalgebra of $L^\infty(\mathcal{L}(\mathcal{H}))$ (remember R. Douglas and D. Sarason for the scalar case!), and this almost immediately yields a Fredholm theory for Toeplitz operators $T(a)$ with $a \in C_{\mathcal{K}} + \overline{H^\infty}$ on $l^2(\mathcal{H})$ (see, e.g., [5, p. 90]). The finite-section method for Toeplitz operators generated by $C_{\mathcal{K}} + \overline{H^\infty}$ functions was disposed of in [7]; note that if a is of the form identity ($\in \overline{H^\infty(\mathcal{L}(\mathcal{H}))}$) plus trace-class operator ($\in C(\mathcal{K}(\mathcal{H}))$), which is the situation we are usually confronted with when studying determinants, then $C_{\mathcal{K}} + \overline{H^\infty}$ is just the algebra that satisfies us.

Nevertheless, when dealing with operators on $l^2(\mathcal{H})$ in the $\dim \mathcal{H} = \infty$ case, the concept of compactness should be replaced by what we will call Q_n-compactness. With P_n given by (3), put $Q_n = I - P_n$, that is,

$$Q_n : (g_0, g_1, g_2, \ldots) \mapsto (0, \ldots, 0, g_{n+1}, g_{n+2}, \ldots).$$

We say that an operator $K \in \mathcal{L}(l^2(\mathcal{H}))$ is *Q_n-compact* (and write $K \in \mathcal{Q}$) if $Q_n K \rightrightarrows 0$ and $KQ_n \rightrightarrows 0$ as $n \to \infty$, where here and in what follows, $\rightrightarrows$ denotes uniform convergence (= convergence in the norm of $\mathcal{L}(l^2(\mathcal{H}))$). Since $Q_n = Q_n^*$ and $Q_n \to 0$ strongly as $n \to \infty$, every compact operator is necessarily Q_n-compact. The archetypal example of a Q_n-compact but not compact operator on $l^2(\mathcal{H})$ is the Hankel operator $H(\varphi)$ generated by the function $\varphi(e^{i\theta}) = e^{i\theta} I$. We have

$$H(\varphi) = \begin{pmatrix} I & 0 & 0 & \ldots \\ 0 & 0 & 0 & \ldots \\ 0 & 0 & 0 & \ldots \\ \ldots & \ldots & \ldots & \ldots \end{pmatrix},$$

and if $\dim \mathcal{H} = \infty$, then $H(\varphi)$ is clearly not compact, while $Q_n H(\varphi) = H(\varphi) Q_n = 0$ for all n, implying that $H(\varphi)$ is Q_n-compact.

It is easy to see that even $H(a) \in \mathcal{Q}$ for every $a \in C(\mathcal{L}(\mathcal{H}))$. Indeed, if we denote by $\sigma_n a$ the nth Fejer–Cesaro mean of a, then

$$\|(a - \sigma_n a)(e^{ix})\| \le \frac{1}{2\pi} \int_{-\pi}^{\pi} \|a(e^{i(x+\theta)}) - a(e^{ix})\| \left(\frac{\sin \frac{n+1}{2}\theta}{\sin \frac{\theta}{2}} \right)^2 \frac{d\theta}{n+1},$$

from which we infer that $\|a - \sigma_n a\|_\infty \to 0$ as $n \to \infty$, implying that

$$\|Q_n H(a)\| = \|Q_n H(a - \sigma_n a)\| \le \|a - \sigma_n a\|_\infty = o(1) \ (n \to \infty).$$

(A different argument of verifying that $H(a)$ is Q_n-compact for every $a \in C(\mathcal{L}(\mathcal{H}))$ was given in [14].) We will show that, in fact,

$$(5) \qquad H(a) \in \mathcal{Q} \quad \Longleftrightarrow \quad a \in C(\mathcal{L}(\mathcal{H})) + \overline{H^\infty(\mathcal{L}(\mathcal{H}))}.$$

A consequence of (5) is that $C + \overline{H^\infty}$ (= abbreviation for the set on the right-hand side of (5)) is a closed subalgebra of $L^\infty(\mathcal{L}(\mathcal{H}))$. We will use (5) in order to establish the following result on the applicability of the finite-section method.

If $a \in C + \overline{H^\infty}$, then $T(a) \in \Pi\{P_n\}$ if and only if both $T(a)$ and $T(\tilde{a})$ are invertible.

Here and throughout what follows, $\tilde{a}$ denotes the function obtained from a by $\tilde{a}(e^{i\theta}) := a(e^{-i\theta})$. It is well known that in the case $\dim \mathcal{H} \ge 2$, the invertibility of $T(\tilde{a})$ is in no way related to the invertibility of $T(a)$.

Functions in $C + \overline{H^\infty}$ cannot have jumps. To provide results for Toeplitz operators induced by functions with jumps and other discontinuities, we use the localization technique introduced in [19] and developed further in [5] and [6] to establish the following criterion.

If $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ is locally sectorial (in a sense that will be specified below), then $T(a) \in \Pi\{P_n\}$ if and only if both $T(a)$ and $T(\tilde{a})$ are invertible.

The preceding theorem is in particular applicable to certain piecewise continuous functions, i.e., to functions $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ with the property that the one-sided limits $a(\tau \pm 0) \in \mathcal{L}(\mathcal{H})$ exist for every $\tau \in \mathbf{T}$; this class of functions will henceforth be denoted by $PC(\mathcal{L}(\mathcal{H}))$. In the $\dim \mathcal{H} < \infty$ case, the local sectoriality of a function $a \in PC(\mathcal{L}(\mathcal{H}))$ can be deduced from the Fredholmness (and thus all the more from the invertibility) of $T(a)$. We have not been able to prove such a result for $a \in PC(\mathcal{L}(\mathcal{H}))$. However, using results on the finite section method for quarter-plane Toeplitz operators with piecewise continuous symbols established in [3] and [6] or employing the "numerical symbol" constructed in [20], we can prove the following theorem.

If $a \in PC(\mathbf{C} + \mathcal{K}(\mathcal{H}))$, i.e., if $a \in PC(\mathcal{L}(\mathcal{H}))$ is a function with values in

$$\mathbf{C} + \mathcal{K}(\mathcal{H}) := \{\alpha I + K : \alpha \in \mathbf{C},\, K \in \mathcal{K}(\mathcal{H})\},$$

then $T(a) \in \Pi\{P_n\}$ if and only if both $T(a)$ and $T(\tilde{a})$ are invertible.

2. Continuous symbols. The purpose of this section is to prove that if $a \in C(\mathcal{L}(\mathcal{H}))$, then $T(a) \in \Pi\{P_n\}$ if and only if $T(a)$ and $T(\tilde{a})$ are invertible. The proofs we will give are straightforward and are not based on any sort of heavy machinery. A few general remarks are nevertheless in order.

It is well known (see, e.g., [12]) that if $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ and $T(a) \in \Pi\{P_n\}$, then $T(a)$ and $T(\tilde{a})$ are necessarily invertible. If, on the other hand, $T(a)$ is known to be invertible, then the applicability of the finite-section method is equivalent to the existence of an $n_0 \geq 0$ such that $T_n(a) : \mathrm{Im} P_n \to \mathrm{Im} P_n$ is invertible for all $n \geq n_0$ and such that

$$\sup_{n \geq n_0} \|T_n^{-1}(a) P_n\| < \infty.$$

We may express this also in the following form: if $T(a)$ is invertible, then $T(a) \in \Pi\{P_n\}$ if and only if there are sequences $\{R_n\}$, $\{R_n'\}$ and $\{C_n\}$, $\{C_n'\}$ of operators in $\mathcal{L}(\mathrm{Im} P_n)$ such that

$$R_n T_n(a) = P_n + C_n, \quad T_n(a) R_n' = P_n + C_n',$$

$$\sup_n \|R_n\| < \infty, \quad \sup_n \|R_n'\| < \infty, \quad \|C_n\| \to 0 \text{ and } \|C_n'\| \to 0 \text{ as } n \to \infty.$$

A key role in the investigation of the finite-section method is played by the operators W_n $(n = 0, 1, 2, \ldots)$ which are defined $l^2(\mathcal{H})$ by

$$W_n : (g_0, g_1, g_2, \ldots) \mapsto (g_n, g_{n-1}, \ldots, g_0, 0, 0, \ldots).$$

For example, with these operators at hand, one may easily understand why $T(\tilde{a})$ must be invertible if $T(a) \in \Pi\{P_n\}$. We have $W_n^2 = P_n$ and $W_n T_n(a) W_n = T_n(\tilde{a})$, whence

$$\sup_{n \geq n_0} \|T_n^{-1}(\tilde{a})\| = \sup_{n \geq n_0} \|W_n T_n^{-1}(a) W_n\| \leq \sup_{n \geq n_0} \|T_n^{-1}(a)\|.$$

We finally remark that the Hartman–Wintner theorem also holds in the operator-valued case (see, e.g., [7]): if $T(a)$ is invertible in $\mathcal{L}(l^2(\mathcal{H}))$, then a is invertible in $L^\infty(\mathcal{L}(\mathcal{H}))$.

Let us now turn to continuous symbols. Recall that the set $\mathcal{Q}$ of Q_n-*compact operators* is defined by

$$\mathcal{Q} = \{K \in \mathcal{L}(l^2(\mathcal{H})) : \quad Q_nK \rightrightarrows 0 \quad \text{and} \quad KQ_n \rightrightarrows 0 \quad \text{as} \quad n \to \infty\}.$$

As pointed out in the introduction, we have $H(a) \in \mathcal{Q}$ whenever $a \in C(\mathcal{L}(\mathcal{H}))$.

The following theorem is a special version of Corollary 8 of Devinatz and Shinbrot's paper [10]. It was independently established in [7] for symbols in $C(\mathcal{K}(\mathcal{H})) + H^\infty(\mathcal{L}(\mathcal{H}))$ and in [14] in the form presented here. The two proofs given below are proofs in the spirit of [5].

THEOREM 2.1. *Let $a \in C(\mathcal{L}(\mathcal{H}))$. Then $T(a) \in \Pi\{P_n\}$ if and only if $T(a)$ and $T(\tilde{a})$ are both invertible operators on $l^2(\mathcal{H})$.*

Proof. Suppose $T(a)$ and $T(\tilde{a})$ (and thus a and $\tilde{a}$) are invertible. One then may write down the identity $R_nT_n(a) = P_n + C_n$ with

$$\begin{aligned} R_n &= P_nT^{-1}(a)P_n + W_n(T^{-1}(\tilde{a}) - T(\tilde{a}^{-1}))W_n, \\ C_n &= -P_nT^{-1}(a)H(a)H(\tilde{a}^{-1})Q_nT(a)P_n - W_nT^{-1}(\tilde{a})H(\tilde{a})H(a^{-1})Q_nT(\tilde{a})W_n \end{aligned}$$

(see [5, p. 61]). Clearly, $\sup \|R_n\| < \infty$, and since $H(\tilde{a}^{-1})$ and $H(a^{-1})$ are in $\mathcal{Q}$, it follows that $H(\tilde{a}^{-1})Q_n \rightrightarrows 0$, $H(a^{-1})Q_n \rightrightarrows 0$, implying that $\|C_n\| \to 0$ as $n \to \infty$. In a similar way, one can show that $T_n(a)R_n = P_n + C'_n$ with $\|C'_n\| \to 0$ as $n \to \infty$. □

The preceding proof makes use of a curious identity. A perhaps more natural approach is based on the following fact, which has been known for a long time and has been employed by various authors in several contexts (see, e.g., [10], [4], [2], [21]).

LEMMA 2.2. *Let X be a linear space, P and Q be complementary projections on X (i.e., $P^2 = P$, $Q^2 = Q$, $P + Q = I$), and A be an invertible operator on X. Then the compression $PAP|\mathrm{Im}P$ is invertible on* ImP *if and only if the compression $QA^{-1}Q|\mathrm{Im}Q$ is invertible on* ImQ. *In that case,*

$$(PAP)^{-1}P = PA^{-1}P - PA^{-1}Q(QA^{-1}Q)^{-1}QA^{-1}P. \tag{6}$$

The simple proof, which merely amounts to verifying (6), is omitted (see, e.g., [5, p. 61]).

Now denote by $l^2_\#(\mathcal{H})$ the Hilbert space of all square-summable $\mathcal{H}$-valued doubly infinite sequences $(f_n)_{n=-\infty}^{\infty}$ and identify $l^2(\mathcal{H})$ as a subspace of $l^2_\#(\mathcal{H})$ in the natural way. Let P stand for the orthogonal projection of $l^2_\#(\mathcal{H})$ onto $l^2(\mathcal{H})$, put $Q = I - P$, and define the "flip operator" J on $l^2_\#(\mathcal{H})$ by $(Jf)_n = f_{-n}$ $(n = 0, \pm 1, \pm 2, \ldots)$. The Laurent operator $L(a)$ induced by a function $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ is given by the matrix $(a_{j-k})_{j,k=-\infty}^{\infty}$. Traditionally, one simply writes a instead of $L(a)$. With these notations, we may write Toeplitz and Hankel operators in the following form:

$$\begin{aligned} T(a) &= PaP|\mathrm{Im}P, \quad T(\tilde{a}) = JQaQJ|\mathrm{Im}P, \\ H(a) &= PaQJ|\mathrm{Im}P, \quad H(\tilde{a}) = JQaP|\mathrm{Im}P. \end{aligned}$$

Second proof of Theorem 2.1. Suppose the operators $T(a) = PaP|\mathrm{Im}P$ and $T(\tilde{a}) = JQaQJ|\mathrm{Im}P$ are invertible. Lemma 2.2 then tells us that $T(\tilde{a}^{-1}) = JQa^{-1}QJ|\mathrm{Im}P$ and $T(a^{-1}) = Pa^{-1}P|\mathrm{Im}P$ are also invertible. Using formula (6), we get

$$\begin{aligned} Q_nT^{-1}(a)Q_n &= Q_n(PaP)^{-1}PQ_n \\ &= Q_nPa^{-1}PQ_n - Q_nPa^{-1}Q(Qa^{-1}Q)^{-1}Qa^{-1}PQ_n \\ &= Q_nPa^{-1}PQ_n - Q_nPa^{-1}QJ(JQa^{-1}QJ)^{-1}JQa^{-1}PQ_n \\ &= Q_nT(a^{-1})Q_n - Q_nH(a^{-1})T^{-1}(\tilde{a}^{-1})H(\tilde{a}^{-1})Q_n. \end{aligned} \tag{7}$$

The second term of (7) goes uniformly to zero because $H(a^{-1})$ is Q_n-compact. The first term of (7), the operator $Q_nT(a^{-1})Q_n|\mathrm{Im}Q_n$, has the same matrix as $T(a^{-1})$. It follows that the left-hand side of (7), the operator $Q_nT^{-1}(a)Q_n|\mathrm{Im}Q_n$, is invertible for all sufficiently large n and that $\|(Q_nT^{-1}(a)Q_n)^{-1}Q_n\| < 2\|T^{-1}(a^{-1})\|$ for all n large enough. For these n, we deduce from Lemma 2.2 and formula (6) that

$$(8)\quad (P_nT(a)P_n)^{-1}P_n = P_nT^{-1}(a)P_n - P_nT^{-1}(a)Q_n(Q_nT^{-1}(a)Q_n)^{-1}Q_nT^{-1}(a)P_n,$$

and since the norm of the right-hand side of (8) does not exceed

$$\|T^{-1}(a)\| + 2\|T^{-1}(a)\|\,\|T^{-1}(a^{-1})\|\,\|T^{-1}(a)\|,$$

we obtain that $T(a) \in \Pi\{P_n\}$. □

3. Q_n-compact Hankel operators and $C + \overline{H^\infty}$ symbols. It is easy to see that the collection $\mathcal{Q}$ of all Q_n-compact operators is a closed subset of $\mathcal{L}(\mathcal{H})$. If $\dim\mathcal{H} = \infty$, then $\mathcal{Q} \neq \mathcal{K}$ and hence $\mathcal{Q}$ cannot be a two-sided ideal of $\mathcal{L}(l^2(\mathcal{H}))$. However, $\mathcal{Q}$ is a two-sided ideal of certain C^*-subalgebras of $\mathcal{L}(l^2(\mathcal{H}))$. Let $\mathcal{A}$ denote the smallest closed subalgebra of $\mathcal{L}(l^2(\mathcal{H}))$ containing the set

$$\{T(a):\ a \in L^\infty(\mathcal{L}(\mathcal{H}))\} \cup \{H(a):\ a \in L^\infty(\mathcal{L}(\mathcal{H}))\} \cup \mathcal{Q}.$$

PROPOSITION 3.1. *$\mathcal{Q}$ is a closed two-sided ideal of $\mathcal{A}$.*

Proof. It suffices to show that $Q_nT(a)K \rightrightarrows 0$ and $Q_nH(a)K \rightrightarrows 0$ whenever a is in $L^\infty(\mathcal{L}(\mathcal{H}))$ and $K \in \mathcal{Q}$. Given any $\varepsilon > 0$, choose n_0 so that $\|K - P_{n_0}K\| = \|Q_{n_0}K\| < \varepsilon$. We have

$$\begin{aligned}\|Q_nT(a)K\| &\leq \|Q_nT(a)(K - P_{n_0}K)\| + \|Q_nT(a)P_{n_0}K\|\\ &\leq \varepsilon\|T(a)\| + \|Q_nT(a)P_{n_0}\|\|K\|,\end{aligned}$$

and because

$$Q_nT(a)P_{n_0} = \begin{pmatrix} a_{n+1} & \cdots & a_{n-n_0+1}\\ a_{n+2} & \cdots & a_{n-n_0+2}\\ \cdots & \cdots & \cdots \end{pmatrix},$$

it follows that

$$\|Q_nT(a)P_{n_0}\|^2 \leq (n_0+1)\sum_{k>n}\|a_k\|^2 < \varepsilon$$

if only n is large enough (note that $L^\infty(\mathcal{L}(\mathcal{H})) \subset L^2(\mathcal{L}(\mathcal{H}))$ and hence $\sum\|a_k\|^2 < \infty$). This proves that $Q_nT(a)K \rightrightarrows 0$. It can be shown similary that $Q_nH(a)K \rightrightarrows 0$. □

The classical Nehari and Hartman theorems were extended by Page [16] to the operator-valued case: if $a \in L^\infty(\mathcal{L}(\mathcal{H}))$, then

$$(9)\qquad \|H(a)\| = \mathrm{dist}\left(a,\ \overline{H^\infty(\mathcal{L}(\mathcal{H}))}\right),$$

where dist refers to the distance in $L^\infty(\mathcal{L}(\mathcal{H}))$, and we have

$$(10)\qquad H(a) \in \mathcal{K}(\mathcal{H}) \iff a \in C(\mathcal{K}(\mathcal{H})) + \overline{H^\infty(\mathcal{L}(\mathcal{H}))}.$$

PROPOSITION 3.2. *Let $a \in L^\infty(\mathcal{L}(\mathcal{H}))$. Then*

$$(11)\qquad H(a) \in \mathcal{Q} \iff a \in C(\mathcal{L}(\mathcal{H})) + \overline{H^\infty(\mathcal{L}(\mathcal{H}))}.$$

In what follows, we abbreviate the set on the right-hand side of (11) to $C+\overline{H^\infty}$.

Proof. Since $H(g)=0$ for $g\in\overline{H^\infty}$ and $H(f)\in\mathcal{Q}$ for $f\in C$, we see that $H(a)\in\mathcal{Q}$ for every $a=f+g\in C+\overline{H^\infty}$. To show the reverse implication, note first that $\|Q_nH(a)\|=\|H(\chi_{-n-1}a)\|$, where $\chi_k(t)=t^k$ $(t\in\mathbf{T})$, and then use (9) to obtain

$$\|H(\chi_{-n-1}a)\|=\operatorname{dist}(\chi_{-n-1}a,\,\overline{H^\infty})=\operatorname{dist}(a,\chi_{n+1}\overline{H^\infty})\geq\operatorname{dist}(a,\,C+\overline{H^\infty}).$$

Thus, if $\|Q_nH(a)\|\to 0$ then $\operatorname{dist}(a,\,C+\overline{H^\infty})=0$, and we are left with showing that $C+\overline{H^\infty}$ is closed.

This can be done most easily with the help of the Zalcman–Rudin lemma (see, e.g, [6, p. 75]), which says the following: if E and F are closed subspaces of a Banach space X and if there exists a sequence $\{S_n\}_{n=0}^\infty$ of operators $S_n\in\mathcal{L}(X)$ such that $\sup_n\|S_n\|<\infty$, $S_n(X)\subset E$ for all n, $S_n(F)\subset F$ for all n, and $\|S_nu-u\|\to 0$ as $n\to\infty$ for all $u\in E$, then $E+F$ is a closed subspace of X. The closedness of $C+\overline{H^\infty}$ follows from this lemma with $X=L^\infty(\mathcal{L}(\mathcal{H}))$, $E=C(\mathcal{L}(\mathcal{H}))$, $F=\overline{H^\infty(\mathcal{L}(\mathcal{H}))}$ and $S_na=\sigma_na$, where σ_na is the nth Fejer–Cesaro mean of a. □

PROPOSITION 3.3. *$C+\overline{H^\infty}$ is a closed subalgebra of $L^\infty(\mathcal{L}(\mathcal{H}))$.*

Proof (in the spirit of L. Coburn (see [18, p. 102]) and M. G. Krein [15]). We already know that $C+\overline{H^\infty}$ is closed. To prove that $C+\overline{H^\infty}$ is an algebra, take $a,b\in C+\overline{H^\infty}$ and note that

$$\begin{aligned}Q_nH(ab)&=Q_nPabQJ=Q_nPaPbQJ+Q_nPaQJJQbJ\\&=Q_nT(a)H(b)+Q_nH(a)T(\tilde{b}).\end{aligned}$$

Clearly, $Q_nH(a)T(\tilde{b})\rightrightarrows 0$, while Proposition 3.1 gives that $Q_nT(a)H(b)\rightrightarrows 0$. Consequently, $Q_nH(ab)\rightrightarrows 0$ and Proposition 3.2 finally implies that $ab\in C+\overline{H^\infty}$. □

An operator $A\in\mathcal{A}$ will be called *$\mathcal{Q}$-Fredholm* if it is invertible modulo Q_n-compact operators, i.e., if $A+\mathcal{Q}$ is invertible in $\mathcal{A}/\mathcal{Q}$. The group of invertible elements of a unital Banach algebra $\mathfrak{A}$ will henceforth be denoted by $G\mathfrak{A}$.

PROPOSITION 3.4. *Let $a\in C+\overline{H^\infty}$. Then*

$$T(a)\text{ is }\mathcal{Q}\text{-Fredholm}\iff a\in G(C+\overline{H^\infty}).$$

Proof. Let $RT(a)=I+K$ with $R\in\mathcal{L}(l^2(\mathcal{H}))$ and $K\in\mathcal{Q}$. Then

$$\|R\|\,\|T(a)f\|+\|Kf\|\geq\|f\|\qquad\forall f\in l^2(\mathcal{H}),$$

and hence

$$\|R\|\,\|PaPg\|+\|KPg\|+\|Qg\|\geq\|g\|\qquad\forall g\in l^2_\#(\mathcal{H}).$$

Denote the bilateral shift on $l^2_\#(\mathcal{H})$ by $U=L(\chi_1)$. By replacing g with U^ng in the last inequality and taking into account that U^n is an isometry, we get

$$\|R\|\,\|U^{-n}PaPU^ng\|+\|KPU^ng\|+\|U^{-n}QU^ng\|\geq\|g\|\quad\forall g\in l^2_\#(\mathcal{H}).$$

Obviously, $U^{-n}PU^n\to I$, $U^{-n}QU^n\to 0$, and $U^{-n}PaPU^n\to L(a)$ strongly as $n\to\infty$. Since

$$\begin{aligned}\|KPU^ng\|&\leq\|(K-KP_{n_0})PU^ng\|+\|KP_{n_0}PU^ng\|\\&\leq\|KQ_{n_0}\|\,\|g\|+\|K\|\,\|P_{n_0}PU^ng\|\end{aligned}$$

and $\|P_{n_0}PU^n g\|^2 \le \|g_{-n}\|^2 + \cdots + \|g_{-n+n_0}\|^2 = o(1)$, it follows that $KPU^n \to 0$ strongly. Consequently, $\|R\|\,\|L(a)g\| \ge \|g\|$ for all $g \in l^2_{\#}(\mathcal{H})$, which implies that $a \in GL^\infty(\mathcal{H})$.

To show that even $a \in G(C + \overline{H^\infty})$, consider the identity

$$(12)\quad 0 = Paa^{-1}QJ = PaQJJQa^{-1}QJ + PaPa^{-1}QJ = H(a)T(\tilde{a}^{-1}) + T(a)H(a^{-1}).$$

Multiplication of (12) by R from the left and by Q_n from the right gives

$$0 = RH(a)T(\tilde{a}^{-1})Q_n + H(a^{-1})Q_n + KH(a^{-1})Q_n.$$

From Propositions 3.1 and 3.2, we infer that $H(a)T(\tilde{a}^{-1})Q_n \rightrightarrows 0$ and $KH(a^{-1})Q_n \rightrightarrows 0$, implying that $H(a^{-1})Q_n \rightrightarrows 0$. Starting with $T(a)S = I + K$ and $0 = JQa^{-1}aP$ gives $Q_nH(a^{-1}) \rightrightarrows 0$. Thus $H(a^{-1}) \in \mathcal{Q}$ and therefore $a^{-1} \in C + \overline{H^\infty}$ by Proposition 3.3.

The implication " $\Longleftarrow$ " of the present proposition follows immediately from the identities

$$T(a)T(a^{-1}) = I - H(a)H(\tilde{a}^{-1}), \quad T(a^{-1})T(a) = I - H(a^{-1})H(\tilde{a})$$

in conjunction with Proposition 3.1 and 3.2. □

The following result was established by Devinatz and Shinbrot [10] with the help of other methods.

THEOREM 3.5. *Let $a \in C + \overline{H^\infty}$. Then*

$$T(a) \in \Pi\{P_n\} \iff T(a),\ T(\tilde{a}) \in G\mathcal{L}(l^2(\mathcal{H})).$$

Proof. Since $a^{-1} \in C + \overline{H^\infty}$ whenever $T(a)$ is invertible (Proposition 3.4), the second proof of the Theorem 2.1 can be literally used in the situation considered here. □

We remark that the first proof of Theorem 2.1 also works in the present setting: the only modification is that we now may not conclude that $H(a)H(\tilde{a}^{-1})Q_n \rightrightarrows 0$ because $H(\tilde{a}^{-1}) \in \mathcal{Q}$; we have rather to say that $H(a) \in \mathcal{Q}$ and thus $H(a)H(\tilde{a}^{-1}) \in \mathcal{Q}$ due to Proposition 3.1.

4. Localization. We now consider operators of the form $T(a) + K$, where $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ is a possibly discontinuous function and K is a Q_n-compact operator. Notice that adding a perturbation K is not an academic subject. Many of the operators currently emerging are not pure Toeplitz operators but turn out to be perturbed Toeplitz operators. Our main result in this section implies the following. Suppose $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ and $T(a) + K$ and $T(\tilde{a})$ are invertible. If in a neighborhood of each point $\tau \in \mathbf{T}$ the function a coincides with a function a_τ for which $T(a_\tau) \in \Pi\{P_n\}$, then $T(a) \in \Pi\{P_n\}$. The proof of this result is based on the approach developed in [19].

Denote by $\mathbf{F}$ the linear space of all sequences $\{A_n\}_{n=0}^\infty$ of operators $A_n \in \mathcal{L}(\mathrm{Im}P_n)$ such that

$$(13)\qquad \|\{A_n\}\| := \sup_{n \ge 0} \|A_n\| < \infty.$$

With the operations $\{A_n\}\{B_n\} := \{A_nB_n\}$, $\{A_n\}^* := \{A_n^*\}$ and the norm (13), the space $\mathbf{F}$ is a C^*-algebra. Let $\mathbf{J}$ stand for the collection of all sequences in $\mathbf{F}$ of the form $\{P_nKP_n + W_nLW_n + C_n\}$ with $K, L \in \mathcal{Q}$ and $\|C_n\| \to 0$ as $n \to \infty$. Finally, define $\mathbf{S}$ as the smallest closed subalgebra of $\mathbf{F}$ containing $\mathbf{J}$ and all sequences $\{T_n(a)\}$ with $a \in L^\infty(\mathcal{L}(\mathcal{H}))$. Clearly, $\mathbf{S}$ is a C^*-algebra.

PROPOSITION 4.1. *$\mathbf{J}$ is a closed two-sided ideal of $\mathbf{S}$.*

Proof. That $\mathbf{J}$ is closed can be seen as in the $\dim \mathcal{H} = 1$ case, for which we refer to [5, p. 67].

To prove that $\mathbf{J}$ is an ideal, we first show the following implications:

$$L \in \mathcal{Q} \Longrightarrow W_n L W_n \to 0 \text{ strongly,} \tag{14}$$

$$L, K \in \mathcal{Q} \Longrightarrow W_n L W_n K \rightrightarrows 0. \tag{15}$$

Given any $\varepsilon > 0$, we can find an n_0 such that

$$\|W_n L W_n - W_n P_{n_0} L W_n\| < \varepsilon/3 \quad \forall n \geq n_0.$$

For $n \geq n_0$, the matrix of $W_n P_{n_0} L W_n$ is $\left(\begin{smallmatrix} 0 & 0 \\ A_n & B_n \end{smallmatrix}\right)$ with

$$A_n = W_{n_0} P_{n_0} L Q_{n-n_0} W_{n_0}, \quad B_n = W_{n_0} P_{n_0} L P_{n-n_0} W_{n-n_0}.$$

Clearly, $\|A_n\| < \varepsilon/3$ if n is large enough. For every $f \in l^2(\mathcal{H})$, we have

$$B_n f = W_{n_0} P_{n_0} L P_{m_0} W_{n-n_0} f + W_{n_0} P_{n_0} L Q_{m_0} W_{n-n_0} f$$

and $\|L Q_{m_0}\| < \varepsilon/6$ if m_0 is sufficiently large. Since

$$P_{m_0} W_{n-n_0} f = (f_{n-n_0}, \ldots, f_{n-n_0+m_0}, 0, 0, \ldots),$$

it follows that $\|P_{m_0} W_{n-n_0} f\| < \varepsilon/6$ for all sufficiently large n. Thus, we have shown that $\|W_n L W_n f\| < \varepsilon \|f\|$ for all $f \in l^2(\mathcal{H})$ and all sufficiently large n. This proves (14). To establish (15), choose n_0 so that $\|K - P_{n_0} K\| < \varepsilon$ and $\|L - P_{n_0} L\| < \varepsilon$ and note that $\|W_n L W_n K\|$ does not exceed

$$\begin{aligned} &\|W_n L W_n (K - P_{n_0} K)\| + \|W_n (L - P_{n_0} L) W_n P_{n_0} K\| + \|W_n P_{n_0} L W_n P_{n_0} K\| \\ &\quad \leq \|L\| \varepsilon + \|K\| \varepsilon + \|W_n P_{n_0} L W_n P_{n_0} K\|. \end{aligned}$$

The assertion now follows from the observation that $W_n P_{n_0} L W_n P_{n_0}$ has the matrix $\left(\begin{smallmatrix} 0 & 0 \\ A_n & 0 \end{smallmatrix}\right)$ with $A_n = W_{n_0} P_{n_0} L Q_{n-n_0} W_{n_0}$ as above.

Now we can easily check that $\mathbf{J}$ is an ideal of $\mathbf{S}$. What we must show is the following: if $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ and $K, L \in \mathcal{Q}$, then each of the six sequences

$$\begin{gathered} \{P_n T(a) P_n L P_n\}, \ \{P_n T(a) W_n L W_n\}, \ \{P_n K P_n L P_n\}, \\ \{P_n K W_n L W_n\}, \ \{W_n K W_n L P_n\}, \ \{W_n K W_n L W_n\} \end{gathered}$$

belongs to $\mathbf{J}$. For the last three sequences, this is immediate from (15). We have

$$P_n T(a) P_n L P_n = P_n T(a) P_{n_0} L P_n + P_n T(a) P_n (L - P_{n_0} L) P_n,$$

and since $T(a) P_{n_0} \in \mathcal{Q}$ by Proposition 3.1 and $\|L - P_{n_0} L\|$ is as small as desired if only n_0 is large enough, we deduce that $\{P_n T(a) P_n L P_n\} \in \mathbf{J}$ from the closedness of $\mathbf{J}$. That the second and third sequences are in $\mathbf{J}$ follows similarly from the representations

$$\begin{aligned} P_n T(a) W_n L W_n &= W_n T(\tilde{a}) P_{n_0} L W_n + W_n T(\tilde{a}) P_n (L - P_{n_0} L) W_n, \\ P_n K P_n L P_n &= P_n K P_{n_0} L P_n + P_n K P_n (L - P_{n_0} L) P_n. \qquad \square \end{aligned}$$

Now let A be any operator on $l^2(\mathcal{H})$ and suppose we have a sequence $\{A_n\} \in \mathbf{S}$ which converges strongly to A. We write $A \in \Pi\{A_n\}$ if the operators $A_n : \mathrm{Im}P_n \to \mathrm{Im}P_n$ are invertible for all sufficiently large n and $f^{(n)} = A_n^{-1}P_n g$ converges in $l^2(\mathcal{H})$ to a solution f of the equation $Af = g$ for every $g \in l^2(\mathcal{H})$. In the case where $A_n = P_nAP_n|\mathrm{Im}P_n$, we write $A \in \Pi\{P_n\}$ in place of $A \in \Pi\{A_n\}$, which is in accordance with our previous notation.

Again let $A \in \mathcal{L}(l^2(\mathcal{H}))$, $\{A_n\} \in \mathbf{S}$ and suppose $A_n \to A$ strongly. Then $\{W_nA_nW_n\}$ is also a sequence in $\mathbf{S}$. We claim that every sequence in $\mathbf{S}$ has a strong limit. To see this, it suffices to verify that $T_n(a)\,(a \in L^\infty(\mathcal{L}(\mathcal{H}))$, $P_nKP_n\,(K \in \mathcal{Q})$, and $W_nLW_n\,(L \in \mathcal{Q})$ converge strongly. But the strong convergence of $T_n(a)$ and P_nKP_n to $T(a)$ and K, respectively, is obvious, while (14) tells us that W_nLW_n converges strongly to zero. It follows that, in particular, $W_nA_nW_n$ has a strong limit; this limit will be denoted by $\tilde{A}$ (although it depends not only on A but also on the sequence $\{A_n\}$).

Finally, for $\{A_n\} \in \mathbf{S}$, we denote by $\{A_n\}^\pi$ the coset $\{A_n\} + \mathbf{J}$ in the quotient algebra $\mathbf{S}/\mathbf{J}$.

THEOREM 4.2. *Let $A \in \mathcal{L}(l^2(\mathcal{H}))$, $\{A_n\} \in \mathbf{S}$, and suppose that $A_n \to A$ strongly. Then $A \in \Pi\{A_n\}$ if and only if A and $\tilde{A}$ are invertible in $\mathcal{L}(l^2(\mathcal{H}))$ and $\{A_n\}^\pi$ is invertible in $\mathbf{S}/\mathbf{J}$.*

Proof. The "only if " part can shown by standard arguments (see [5, p. 68]). So assume $A, \tilde{A}$, and $\{A_n\}^\pi$ are invertible. From the invertibility of $\{A_n\}^\pi$, we deduce the existence of a sequence $\{R_n\} \in \mathbf{S}$ such that

$$A_nR_n = P_n + P_nKP_n + W_nLW_n + C_n$$

with $K, L \in \mathcal{Q}$ and $\|C_n\| \to 0$. Put

$$R_n' = R_n - P_nA^{-1}KP_n - W_n\tilde{A}^{-1}LW_n.$$

Since $\{P_nA^{-1}KP_n + W_n\tilde{A}^{-1}LW_n\} \in \mathbf{J}$, it follows that $\{R_n'\} \in \mathbf{S}$. Clearly,

$$(16)\quad A_nR_n' = P_n + P_n(K - A_nP_nA^{-1}K)P_n + W_n(L - W_nA_nW_n\tilde{A}^{-1}L)W_n + C_n.$$

We claim that if $\{B_n\}$ is any sequence in $\mathbf{S}$ and K any Q_n-compact operator, then $B_nK \rightrightarrows BK$ as $n \to \infty$. To show this, we may restrict ourselves to the cases where B_n is $T_n(a)$, P_nLP_n or W_nLW_n with $L \in \mathcal{Q}$. We have

$$T_n(a)P_nK - T(a)K = -Q_nT(a)K - P_nT(a)Q_nK \rightrightarrows 0$$

since $T(a)K \in \mathcal{Q}$ by Proposition 3.1 and $K \in \mathcal{Q}$ by assumption. Since $P_nL \rightrightarrows L$ and $P_nK \rightrightarrows K$, we obtain that $P_nLP_nK \rightrightarrows LK$. Finally, from (14) and (15), we infer that $W_nLW_nK \rightrightarrows 0 = 0 \cdot K$. This proves our claim.

From what has just been shown, we obtain in particular that

$$\begin{aligned} K - A_nP_nA^{-1}K &\rightrightarrows K - AA^{-1}K = 0, \\ L - W_nA_nW_n\tilde{A}^{-1}L &\rightrightarrows L - \tilde{A}\tilde{A}^{-1}L \;= 0, \end{aligned}$$

and hence (16) may be written in the form $A_nR_n' = P_n + C_n'$ with $\|C_n'\| \to 0$. In a similar fashion, one can find a sequence $\{R_n''\} \in \mathbf{S}$ such that $R_n''A_n = P_n + C_n''$ with $\|C_n''\| \to 0$. This implies that $A \in \Pi\{A_n\}$. □

The following extension of Theorem 3.5 is an immediate consequence of the preceding theorem.

THEOREM 4.3. *Let $a \in C + \overline{H^\infty}$ and $K \in \mathcal{Q}$. Then*

$$T(a) + K \in \Pi\{P_n\} \iff T(a) + K,\ T(\tilde{a}) \in G\mathcal{L}(l^2(\mathcal{H})).$$

Proof. Because $W_n(T(a)+K)W_n = T_n(\tilde{a}) + W_nKW_n$ converges strongly to $T(\tilde{a})$ (recall (14)), we get the implication "$\Longrightarrow$." Conversely, suppose $T(a)+K$ and $T(\tilde{a})$ are invertible. We must show that $\{T_n(a)+K\}^\pi = \{T_n(a)\}^\pi$ is also invertible.

Since $T(\tilde{a})$ is invertible, we have $\tilde{a}^{-1} \in C + H^\infty$ and thus $a^{-1} \in C + \overline{H^\infty}$ by virtue of Proposition 3.4. Consequently, $H(a)H(\tilde{a}^{-1})$ and $H(\tilde{a})H(a^{-1})$ are in $\mathcal{Q}$ due to Propositions 3.1 and 3.2. It remains to write down Widom's identity

$$T_n(a)T_n(a^{-1}) = P_n - P_nH(a)H(\tilde{a}^{-1})P_n - W_nH(\tilde{a})H(a^{-1})W_n$$

and to observe that $\{P_nH(a)H(\tilde{a}^{-1})P_n + W_nH(\tilde{a})H(a^{-1})W_n\} \in \mathbf{J}$. □

Let $\mathcal{C}$ be the smallest closed subalgebra of $\mathcal{L}(l^2(\mathcal{H}))$ containing all Toeplitz operators $T(\varphi)$ with $\varphi \in C(\mathcal{L}(\mathcal{H}))$. Using Proposition 3.2, one can easily show that every operator $A \in \mathcal{C}$ is of the form $A = T(\varphi) + K$ with $A \in C(\mathcal{L}(\mathcal{H}))$ and $K \in \mathcal{Q}$ (note that $\mathcal{Q}$ is in fact the quasi-commutator ideal of $\mathcal{C}$, i.e., the smallest closed two-sided ideal of $\mathcal{C}$ containing all quasi-commutators $T(\varphi\psi) - T(\varphi)T(\psi)$ $(\varphi, \psi \in C(\mathcal{L}(\mathcal{H})))$. Thus, Theorem 4.3 implies that if $A \in \mathcal{C}$, then

$$A \in \Pi\{P_n\} \iff A \text{ and } \tilde{A} := \lim_{n\to\infty} W_nAW_n \text{ are invertible.}$$

This is also the right place to give an interlude on so-called *paired operators*, which may be viewed as singular integral operators in matrix disguise and are, in the case of continuous coefficients, a nice example of Q_n-compactly perturbed Toeplitz operators. Given $a, b \in L^\infty(\mathcal{L}(\mathcal{H}))$, the paired operator induced by a and b is the operator $aP + bQ$ $(= L(a)P + L(b)Q)$ on $l^2_\#(\mathcal{H})$. Define $\mathcal{P}_n$ on $l^2_\#(\mathcal{H})$ by

$$\mathcal{P}_n\left((x_j)_{j=-\infty}^{\infty}\right) = (\ldots, 0, 0, x_{-n-1}, \ldots, x_{-1}, x_0, \ldots, x_n, 0, 0, \ldots).$$

We write $aP+bQ \in \Pi\{\mathcal{P}_n\}$ if the operators $A_n = \mathcal{P}_n(aP+bQ)\mathcal{P}_n|\mathrm{Im}\mathcal{P}_n$ are invertible for all sufficiently large n and $f^{(n)} = A_n^{-1}\mathcal{P}_ng$ converges in $l^2_\#(\mathcal{H})$ to a solution f of $(aP+bQ)f = g$ for every $g \in l^2_\#(\mathcal{H})$. The mapping

$$C\ :\ l^2_\#(\mathcal{H}) \to l^2(\mathcal{H}) \oplus l^2(\mathcal{H}),\ f \mapsto JQf \oplus Pf$$

is a Hilbert-space isomorphism, and $C(aP+bQ)C^{-1}$ and $C\mathcal{P}_nC^{-1}$ are given on $l^2(\mathcal{H}) \oplus l^2(\mathcal{H})$ by

$$\begin{pmatrix} JQbQJ & JQaP \\ PbQJ & PaP \end{pmatrix} = \begin{pmatrix} T(\tilde{b}) & H(\tilde{a}) \\ H(b) & T(a) \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} P_n & 0 \\ 0 & P_n \end{pmatrix},$$

respectively. Hence,

$$aP + bQ \in \Pi\{\mathcal{P}_n\} \iff \begin{pmatrix} T(\tilde{b}) & H(\tilde{a}) \\ H(b) & T(a) \end{pmatrix} \in \Pi\left\{\begin{pmatrix} P_n & 0 \\ 0 & P_n \end{pmatrix}\right\}.$$

Further, the mapping $D\ :\ l^2(\mathcal{H}) \oplus l^2(\mathcal{H}) \to l^2(\mathcal{H} \oplus \mathcal{H})$ defined by

$$D\ :\ (f_0, f_1, \ldots) \oplus (g_0, g_1, \ldots) \mapsto (f_0, g_0, f_1, g_1, \ldots)$$

is also a Hilbert-space isomorphism, and we have

$$D\begin{pmatrix} T(\tilde{b}) & H(\tilde{a}) \\ H(b) & T(a) \end{pmatrix} D^{-1} = T\begin{pmatrix} \tilde{b} & 0 \\ 0 & a \end{pmatrix} + H\begin{pmatrix} 0 & \tilde{a} \\ b & 0 \end{pmatrix},$$

$$D\begin{pmatrix} T_n(\tilde{b}) & P_nH(\tilde{a})P_n \\ P_nH(b)P_n & T_n(a) \end{pmatrix} D^{-1} = T_n\begin{pmatrix} \tilde{b} & 0 \\ 0 & a \end{pmatrix} + P_nH\begin{pmatrix} 0 & \tilde{a} \\ b & 0 \end{pmatrix} P_n.$$

Consequently,

$$aP + bQ \in \Pi\{\mathcal{P}_n\} \iff T(c) + K \in \Pi\{P_n\},$$

where $c = \left(\begin{smallmatrix} \tilde{b} & 0 \\ 0 & a \end{smallmatrix}\right)$ and $K = H\left(\begin{smallmatrix} 0 & \tilde{a} \\ b & 0 \end{smallmatrix}\right)$. If $a, b \in C(\mathcal{L}(\mathcal{H}))$, we are in the situation covered by Theorem 4.3 (only with $\mathcal{H} \oplus \mathcal{H}$ in place of $\mathcal{H}$). Since $T(\tilde{c}) = T\left(\begin{smallmatrix} b & 0 \\ 0 & \tilde{a} \end{smallmatrix}\right)$ is invertible if and only if $T(b)$ and $T(\tilde{a})$ are as well, we arrive at the following result, which was stated in a different form and proved by other methods (and under the a priori assumption that a and b be invertible) in [14].

THEOREM 4.4. *Let $a, b \in C(\mathcal{L}(\mathcal{H}))$. Then*

$$aP + bQ \in \Pi\{\mathcal{P}_n\} \iff aP + bQ \text{ and } PbP + QaQ \text{ are invertible.} \qquad \square$$

A moment's thought reveals that the above argument is also applicable to operators of the form $aP + bQ + L$, where $a, b \in C(\mathcal{L}(\mathcal{H}))$ and L is a Q_n-compact operator, that is, an operator for which $\mathcal{P}_nL \rightrightarrows L$ and $L\mathcal{P}_n \rightrightarrows L$. In that case, we have

$$aP + bQ + L \in \Pi\{\mathcal{P}_n\} \iff aP + bQ + L \text{ and } PbP + QaQ \text{ are invertible.}$$

We now turn to Toeplitz operators with discontinuous symbols. Let $C(\mathbf{C})$ denote the C^*-algebra of all complex-valued continuous functions on $\mathbf{T}$. If $\varphi \in C(\mathbf{C})$ and I is the identity operator on $\mathcal{H}$, we define $\varphi I \in \mathcal{L}(\mathcal{H})$ in the natural way (as $\varphi \otimes I$). In case φI is followed by another operator $a \in \mathcal{L}(\mathcal{H})$, we abbreviate $\varphi I A$ to φA.

Two functions $a, b \in L^\infty(\mathcal{L}(\mathcal{H}))$ are said to be *locally equivalent* at a point $\tau \in \mathbf{T}$ if

$$\inf\{\|\varphi(a - b)\| : \varphi \in C(\mathbf{C}),\ \varphi(\tau) = 1\} = 0.$$

THEOREM 4.5. *Let $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ and $K \in \mathcal{Q}$. Suppose $T(a) + K$ and $T(\tilde{a})$ are invertible and a is at every point $\tau \in \mathbf{T}$ locally equivalent to a function $a_\tau \in L^\infty(\mathcal{L}(\mathcal{H}))$ for which $\{T_n(a_\tau)\}^\pi$ is invertible. Then $T(a) + K \in \Pi\{P_n\}$.*

Proof. By virtue of Theorem 4.3, we are left with showing that $\{T_n(a)\}^\pi$ is invertible. This will be done by making use of the local principle of Allan and Douglas (see, e.g., [6, Thm. 1.34]) in the algebra $\mathbf{S}^\pi := \mathbf{S}/\mathbf{J}$.

The mapping $\gamma : C(\mathbf{C}) \to \mathbf{S}^\pi$, $\varphi \mapsto \{T_n(\varphi I)\}^\pi$ is readily seen to be a C^*-algebra homomorphism. Moreover, γ is injective: if $\{T_n(\varphi I)\} = \{P_nKP_n + W_nLW_n + C_n\}$ is in $\mathbf{J}$, then $T(\varphi I) = K$ is Q_n-compact, whence $\|T(\varphi I)\| = \|Q_nT(\varphi I)Q_n\| \to 0$, implying that $\varphi = 0$. It follows that $\gamma(C(\mathbf{C}))$ is a commutative C^*-algebra isomorphic to $C(\mathbf{C})$ and thus that the maximal ideal space of $\gamma(C(\mathbf{C}))$ may be naturally identified with $\mathbf{T}$.

For $\varphi \in C(\mathbf{C})$ and $b \in L^\infty(\mathcal{L}(\mathcal{H}))$, we have

$$\{T_n(\varphi I)\}^\pi\{T_n(b)\}^\pi = \{T_n(\varphi b)\}^\pi = \{T_n(b\varphi I)\}^\pi = \{T_n(b)\}^\pi\{T_n(\varphi I)\}^\pi,$$

and hence $\gamma(C(\mathbf{C}))$ is contained in the center of $\mathbf{S}^\pi$. For $\tau \in \mathbf{T}$, denote by $\mathbf{J}_\tau^\pi$ the smallest closed two-sided ideal of $\mathbf{S}^\pi$ containing the set $\{\{T_n(\varphi I)\}^\pi : \varphi \in C(\mathbf{C}), \varphi(\tau) = 0\}$.

The local principle of Allan and Douglas says that $\{T_n(a)\}^\pi$ is invertible in $\mathbf{S}^\pi$ if and only if for every $\tau \in \mathbf{T}$, the coset $\{T_n(a)\}^\pi + \mathbf{J}_\tau^\pi$ is invertible in $\mathbf{S}^\pi/\mathbf{J}_\tau^\pi$. But it is easy to see that $\{T_n(a)\}^\pi + \mathbf{J}_\tau^\pi = \{T_n(a_\tau)\}^\pi + \mathbf{J}_\tau^\pi$, and because $\{T_n(a_\tau)\}^\pi$ was assumed to be invertible, so all the more is $\{T_n(a_\tau)\}^\pi + \mathbf{J}_\tau^\pi$. □

Since, by Theorem 4.3, the element $\{T_n(a_\tau)\}^\pi$ is invertible whenever $T(a_\tau) \in \Pi\{P_n\}$, the preceding theorem is also true with the phrase "for which $\{T_n(a_\tau)\}^\pi$ is invertible" replaced by "for which $T(a_\tau) \in \Pi\{P_n\}$."

We also remark that Theorem 4.5 extends to localization over the algebra $QC(\mathbf{C})$ of all quasicontinuous functions, i.e., the operator-valued version of Theorem 7.32(i) in [6] is valid.

5. Locally sectorial symbols. The *essential range* $\mathfrak{R}(a)$ of a function $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ may be defined as the spectrum of the Laurent operator $L(a) \in \mathcal{L}(l^2_\#(\mathcal{H}))$. A scalar-valued function $a \in L^\infty(\mathcal{L}(\mathbf{C})) = L^\infty(\mathbf{C})$ is called globally sectorial if $\mathfrak{R}(a)$ is contained in some open half-plane whose boundary passes through the origin. There are at least two possibilities of extending the concept of sectoriality to operator-valued functions.

A function $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ is said to be *globally analytically sectorial* ($a \in GAS$) if there are $b, c \in G\mathcal{L}(\mathcal{H})$ and an $\varepsilon > 0$ such that

$$\operatorname{Re}(ba(t)ch, h) \geq \varepsilon \|h\|^2$$

for almost all $t \in \mathbf{T}$ and all $h \in \mathcal{H}$. Thus, if we denote by $\mathfrak{H}(a)$ the *Hausdorff range* of the function a,

$$\mathfrak{H}(a) := \{(\alpha h, h) : \alpha \in \mathfrak{R}(a), \|h\| = 1\},$$

then $a \in GAS$ if and only if there are $b, c \in G\mathcal{L}(\mathcal{H})$ such that $\mathfrak{H}(bac)$ is contained in the right open half-plane.

We call a function $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ *globally geometrically sectorial* ($a \in GGS$) if the convex hull of its essential range, conv $\mathfrak{R}(a)$, consists entirely of invertible operators: conv $\mathfrak{R}$ $(a) \subset G\mathcal{L}(\mathcal{H})$.

In the scalar case ($\dim\mathcal{H} = 1$), we have $GAS = GGS$, whereas in the $\dim \mathcal{H} > 1$ case $GAS \subset GGS$ but $GAS \neq GGS$ (see [1]).

A function $a \in L^\infty(\mathcal{L}(\mathcal{H}))$ is said to be *locally analytically* or *geometrically sectorial* ($a \in LAS$ or $a \in LGS$) if a is at every point $\tau \in \mathbf{T}$ locally equivalent to some function a_τ in GAS or LGS, respectively.

Functions in GAS are fairly well understood. One can show (see, e.g., [6, p. 104]) that the following are equivalent:

(i) $a \in GAS$;

(ii) there is a $d \in G\mathcal{L}(\mathcal{H})$ such that $\mathfrak{H}(ad)$ is contained in the right open half-plane;

(iii) there exist both an operator $e \in G\mathcal{L}(\mathcal{H})$ and a number $q \in (0,1)$ such that $\|I - a(t)e\| \leq q < 1$ for almost all $t \in \mathbf{T}$.

PROPOSITION 5.1. *If* $a \in GAS$, *then* $T(a) \in \Pi\{P_n\}$.

Proof. Let e and q be as in condition (iii) above. Then

$$\|I - T(a)T(e)\| \leq \|I - ae\| \leq q < 1,$$

which gives the invertibility of $T(a)$, and

$$\|P_n - T_n(a)T_n(e)\| \leq \|I - ae\| \leq q < 1.$$

The latter inequality implies that $T_n(a)$ is invertible for all n large enough and that $\|T_n^{-1}(a)\| \leq \|e\|/(1-q)$. □

THEOREM 5.2. *Let $a \in LAS$ and $K \in \mathcal{Q}$. Then*

$$T(a) + K \in \Pi\{P_n\} \iff T(a) + K,\ T(\tilde{a}) \in G\mathcal{L}(l^2(\mathcal{H})).$$

Proof. This is immediate from Theorem 4.5 and Proposition 5.1. □

We remark that Theorem 5.2 also holds for functions a which are locally analytically sectorial over $QC(\mathbf{C})$ (see Theorem 7.32(i) of [6]).

6. Piecewise continuous symbols. Let $PC(\mathcal{L}(\mathcal{H}))$ denote the C^*-algebra of all functions a in $L^\infty(\mathcal{L}(\mathcal{H}))$ having one-sided limits $a(\tau \pm 0)$ at every point $\tau \in \mathbf{T}$. At $\tau \in \mathbf{T}$, a function $a \in PC(\mathcal{L}(\mathcal{H}))$ is locally equivalent to the function $\chi_- a(\tau - 0) + \chi_+ a(\tau + 0)$, where $\chi_\pm$ stand for the characteristic functions of the half-circles $\{\tau e^{\pm i\theta} : 0 < \theta < \pi\}$. Thus, $a \in LAS$ if and only if for every $\tau \in \mathbf{T}$ there are $b_\tau, c_\tau \in G\mathcal{L}(\mathcal{H})$ such that $\mathfrak{H}(b_\tau a(\tau \pm 0) c_\tau)$ is contained in the right open half-plane, and $a \in LGS$ if and only if for every $\tau \in \mathbf{T}$ the line segment

$$[a(\tau-0), a(\tau+0)] = \{(1-\mu)a(\tau-0) + \mu a(\tau+0) \ : \ \mu \in [0,1]\}$$

is contained in $G\mathcal{L}(\mathcal{H})$.

Theorem 5.2 tells us that if $a \in PC(\mathcal{L}(\mathcal{H}))$ is in LAS, then $T(a) \in \Pi\{P_n\}$ if and only if $T(a)$ and $T(\tilde{a})$ are invertible. For matrix-valued functions $a \in PC(\mathcal{L}(\mathcal{H}))$ ($\dim \mathcal{H} < \infty$) it was shown by Clancey [9] that

$$T(a) \text{ is Fredholm} \iff a \in LAS \iff a \in LGS \tag{17}$$

(also see [6, Thm. 4.70]). Consequently, in the $\dim \mathcal{H} < \infty$ case we have the equivalence

$$T(a) \in \Pi\{P_n\} \iff T(a), T(\tilde{a}) \in G\mathcal{L}(l^2(\mathcal{H})) \tag{18}$$

for every $a \in PC(\mathcal{L}(\mathcal{H}))$. We have not been able to carry over (17) and (18) to the $\dim \mathcal{H} = \infty$ case for general $a \in PC(\mathcal{L}(\mathcal{H}))$. However, we will extend (18) and part of (17) to symbols a in $PC(\mathbf{C} + \mathcal{K}(\mathcal{H}))$ (recall the last paragraph of the introduction for the definition of $PC(\mathbf{C}+\mathcal{K}(\mathcal{H}))$). To do this, we present two independent approaches. The first is based on the theory of quarter-plane Toeplitz operators, while the second makes use of an approximation argument.

Here is the first approach. We now identify $l^2(\mathcal{H})$ with the Hilbert-space tensor product $l^2 \otimes \mathcal{H}$, where $l^2 := l^2(\mathbf{C})$. Then if $\chi_\pm$ are as above and $a, b \in \mathcal{L}(\mathcal{H})$ are any operators, we have

$$T(\chi_- a + \chi_+ b) = T(\chi_-) \otimes a + T(\chi_+) \otimes b \tag{19}$$

with $T(\chi_\pm) \in \mathcal{L}(l^2)$. Furthermore, if $\dim \mathcal{H} = \infty$ (and only this case will be considered in the following), we may without loss of generality assume that $\mathcal{H} = l^2$. Thus, we may think of (19) as an operator on $l^2 \otimes l^2$ (the l^2 space of a quarter-plane).

Let B denote the smallest closed subalgebra of $\mathcal{L}(l^2)$ containing the set $\{T(\varphi) : \varphi \in PC(\mathbf{C})\}$ and let $\mathsf{B} \otimes \mathsf{B}$ be the closure in $\mathcal{L}(l^2 \otimes l^2)$ of the set of all operators that are representable as finite sums of the form $\sum_j U_j \otimes V_j$ ($U_j, V_j \in \mathsf{B}$). In other words, $\mathsf{B} \otimes \mathsf{B}$ is the C^*-algebra tensor product of two copies of B. Hence, if in (19) the operators a and b lie in B , then $T(\chi_-) \otimes a + T(\chi_+) \otimes b$ belongs to $\mathsf{B} \otimes \mathsf{B}$, and operators in $\mathsf{B} \otimes \mathsf{B}$ are fairly well understood (see [11] or [6, pp. 363–369]).

THEOREM 6.1. *Let $a \in PC(\mathsf{B})$. Then*

$$T(a) \textit{ is } \mathcal{Q}\textit{-Fredholm} \iff a \in LGS.$$

Proof. For $\tau \in \mathbf{T}$, put $A_\tau = T(\chi_-) \otimes a(\tau-0) + T(\chi_+) \otimes a(\tau+0)$. Standard application of localization techniques gives that $T(a) + \mathcal{Q}$ is in $G(\mathcal{A}/\mathcal{Q})$ if and only if $A_\tau + \mathcal{Q}$ is in $G(\mathcal{A}/\mathcal{Q})$ for every $\tau \in \mathbf{T}$. Since $A_\tau \in \mathsf{B}\otimes\mathsf{B}$ and $\mathsf{B}\otimes\mathsf{B}$ is a C^*-subalgebra of $\mathcal{A}$, we obtain

$$\begin{aligned}&A_\tau + \mathcal{Q} \in G(\mathcal{A}/\mathcal{Q})\\ &\iff A_\tau + \mathcal{Q} \in G((\mathsf{B}\otimes\mathsf{B} + \mathcal{Q})/\mathcal{Q})\\ &\iff A_\tau + (\mathsf{B}\otimes\mathsf{B}\cap\mathcal{Q}) \in G(\mathsf{B}\otimes\mathsf{B}/(\mathsf{B}\otimes\mathsf{B}\cap\mathcal{Q})).\end{aligned}$$

Denote the compact operators on l^2 by $\mathcal{K} := \mathcal{K}(l^2)$. It is well known that $\mathcal{K}$ is a subset of B . When interpreting $l^2(\mathcal{H})$ as $l^2 \otimes \mathcal{H}$, the operators Q_n we have been working with so far may be identified as $Q_n \otimes I$. Using this, it is easy to show that $\mathsf{B}\otimes\mathsf{B}\cap\mathcal{Q}$ is nothing else than $\mathcal{K}\otimes\mathsf{B}$. Hence,

$$A_\tau + \mathcal{Q} \in G(\mathcal{A}/\mathcal{Q}) \iff A_\tau + \mathcal{K}\otimes\mathsf{B} \in G(\mathsf{B}\otimes\mathsf{B}/\mathcal{K}\otimes\mathsf{B}).$$

Invertibility criteria in $\mathsf{B}\otimes\mathsf{B}/\mathcal{K}\otimes\mathsf{B}$ were established in [11] (see also [6, pp. 363–369] for an alternative approach). All we need is the following. Suppose we are given a finite sum $\sum B_j \otimes C_j \in \mathsf{B}\otimes\mathsf{B}$ in which each B_j is a Toeplitz operator, say $T(b_j)$. Then

$$\begin{aligned}&\sum T(b_j)\otimes C_j + \mathcal{K}\otimes\mathsf{B} \in G(\mathsf{B}\otimes\mathsf{B}/\mathcal{K}\otimes\mathsf{B})\\ &\iff \sum((1-\mu)b_j(t-0) + \mu b_j(t+0))C_j \in G\mathsf{B} \quad \forall(t,\mu) \in \mathbf{T}\times[0,1].\end{aligned}$$

Application of this criterion to A_τ produces

$$\begin{aligned}&A_\tau + \mathcal{K}\otimes\mathsf{B} \in G(\mathsf{B}\otimes\mathsf{B}/\mathcal{K}\otimes\mathsf{B})\\ &\iff (1-\mu)a(\tau-0) + \mu a(\tau+0) \in G\mathsf{B} \quad \forall\mu \in [0,1]\\ &\iff [a(\tau-0), a(\tau+0)] \subset G\mathcal{L}(\mathcal{H})\end{aligned}$$

(for the last equivalence, note that B is a C^*-subalgebra of $\mathcal{L}(\mathcal{H})$). □

THEOREM 6.2. *Let $a \in PC(\mathsf{B})$ and $K \in \mathcal{Q}$. Then*

$$T(a) + K \in \Pi\{P_n\} \iff T(a) + K,\ T(\tilde{a}) \in G\mathcal{L}(l^2(\mathcal{H})).$$

Proof. Suppose $T(a) + K$ and $T(\tilde{a})$ are invertible. By Theorem 4.5, we are left with showing that

$$\{T_n(a_\tau)\} + \mathbf{J} \in G(\mathbf{S}/\mathbf{J}) \quad \forall\tau \in \mathbf{T},$$

where $a_\tau = \chi_- a(\tau-0) + \chi_+ a(\tau+0)$. We have

$$T_n(a_\tau) = T_n(\chi_-)\otimes a(\tau-0) + T_n(\chi_+)\otimes a(\tau+0). \tag{20}$$

The algebra $\mathbf{F}$ defined in §4 for $l^2(\mathcal{H})$ will be denoted by F in case $\mathcal{H} = \mathbf{C}$. Let S stand for the smallest closed subalgebra of F containing all sequences $\{T_n(\varphi)\}$ with $\varphi \in PC(\mathbf{C})$ and let J be the collection of all sequences of the form $\{P_nKP_n + W_nLW_n + C_n\}$ with $K, L \in \mathcal{K} := \mathcal{K}(l^2)$ and $\|C_n\| \to 0$. One can show (see [6, Prop. 7.27]) that J is a closed two-sided ideal of S.

Now recall that $l^2 \otimes l^2$ may be identified with $l^2(\mathbf{Z}_+ \times \mathbf{Z}_+)$, where $\mathbf{Z}_+ \times \mathbf{Z}_+$ is the discrete quarter-plane. Interpreting $l^2 \otimes l^2$ in this way allows us to think of the projections $P_n : l^2(l^2) \to l^2(l^2)$ defined by (3) as acting by the rule

$$\{g_{jk}\}_{j,k\geq 0} \mapsto \{h_{jk}\}_{j,k\geq 0}, \quad h_{j,k} = \begin{cases} g_{jk} & \text{if } j \leq n, \\ 0 & \text{if } j > n. \end{cases}$$

It is therefore convenient and also fits in with the notation of the preceding paragraph to replace P_n by $P_n \otimes I$ in this context.

Denote by $\mathbf{Y}$ the C^*-algebra of all sequences $\{A_n\}_{n=0}^\infty$ of operators $A_n \in \mathcal{L}(\mathrm{Im}(P_n \otimes I))$ such that $\|\{A_n\}\| := \sup_{n\geq 0} \|A_n\| < \infty$. For example, if $T_n(a_\tau)$ is given by (20), then $\{T_n(a_\tau)\}_{n=0}^\infty \in \mathbf{Y}$. Moreover, given a finite collection of sequences $\{U_n^{(j)}\} \in \mathsf{S}$ and a finite collection of operators $V^{(j)} \in \mathsf{B}$, it is clear that the sequence

$$\left\{\sum_j U_n^{(j)} \otimes V^{(j)}\right\}_{n=0}^\infty \tag{21}$$

belongs to $\mathbf{Y}$. The closure in $\mathbf{Y}$ of all sequences of the form (21) with $\{U_n^{(j)}\} \in \mathsf{S}$ and $V^{(j)} \in \mathsf{B}$ is denoted by $\mathsf{S}\otimes\mathsf{B}$, while $\mathsf{J}\otimes\mathsf{B}$ will stand for the closure in $\mathbf{Y}$ of the set of all sequences of the form (21) with $\{U_n^{(j)}\} \in \mathsf{J}$ and $V^{(j)} \in \mathsf{B}$. The sequence $\{T_n(a_\tau)\}_{n=0}^\infty$ defined by (20) obviously belongs not only to $\mathbf{Y}$ but even to $\mathsf{S} \otimes \mathsf{B}$. An invertibility criterion in $\mathsf{S}\otimes\mathsf{B}/\mathsf{J}\otimes\mathsf{B}$ can be obtained by the method of [6, pp. 381–389]. We merely quote the result for sequences of the form $\{\sum T_n(b_j) \otimes C_j\}_{n=0}^\infty$. One has

$$\begin{aligned} &\left\{\sum T_n(b_j) \otimes C_j\right\} + \mathsf{J} \otimes \mathsf{B} \in G(\mathsf{S} \otimes \mathsf{B}/\mathsf{J} \otimes \mathsf{B}) \\ &\iff \sum((1-\mu)b_j(t-0) + \mu b_j(t+0))C_j \in G\mathsf{B} \quad \forall(t,\mu) \in \mathbf{T} \times [0,1]. \end{aligned}$$

In the special case (19), we get, as in the proof of Theorem 6.1,

$$\{T_n(a_\tau)\} + \mathsf{J} \otimes \mathsf{B} \in G(\mathsf{S} \otimes \mathsf{B}/\mathsf{J} \otimes \mathsf{B}) \iff [a(\tau-0), a(\tau+0)] \subset G\mathcal{L}(\mathcal{H}).$$

Since $T(a) + K$ is invertible, we deduce from Theorem 6.1 that $[a(\tau-0), a(\tau+0)]$ is contained in $G\mathcal{L}(\mathcal{H})$ for every $\tau \in \mathbf{T}$. Hence, $\{T_n(a_\tau)\} + \mathsf{J} \otimes \mathsf{B}$ is invertible in $\mathsf{S}\otimes\mathsf{B}/\mathsf{J}\otimes\mathsf{B}$, and because clearly $\mathsf{J}\otimes\mathsf{B} \subset \mathbf{J}$ and $\mathsf{S}\otimes\mathsf{B} \subset \mathbf{S}$, it follows that all the more $\{T_n(a_\tau)\} + \mathbf{J}$ is invertible in $\mathbf{S}/\mathbf{J}$. □

We emphasize once again that $\mathbf{C} + \mathcal{K}(\mathcal{H}) \subset \mathsf{B}$ and therefore Theorems 6.1 and 6.2 hold in particular for $a \in PC(\mathbf{C} + \mathcal{K}(\mathcal{H}))$.

Let us finally present another approach to prove (18) for a in $PC(\mathbf{C}+\mathcal{K}(\mathcal{H}))$. We denote by $\mathbf{B}$ the smallest C^*-subalgebra of $\mathbf{S}$ containing all sequences $\{T_n(a)\}$ with $a \in PC(\mathbf{C} + \mathcal{K}(\mathcal{H}))$ and we let $\mathbf{G}$ stand for the collection of all sequences $\{C_n\} \in \mathbf{B}$ such that $C_n \rightrightarrows 0$ as $n \to \infty$. Clearly, $\mathbf{G}$ is a closed two-sided ideal of $\mathbf{B}$. Furthermore, let $\mathcal{B}$ denote the smallest C^*-subalgebra of $\mathcal{L}(l^2(\mathcal{H}))$ containing all operators $T(a)$ with $a \in PC(\mathbf{C} + \mathcal{K}(\mathcal{H}))$ and make $\mathcal{B} \times \mathcal{B}$ become a C^*-algebra by defining the algebraic operations on the ordered pairs $(T_1, T_2) \in \mathcal{B} \times \mathcal{B}$ componentwise and the norm as $\|(T_1, T_2)\| = \max\{\|T_1\|, \|T_2\|\}$. The mapping $\sigma : \mathbf{B} \to \mathcal{B} \times \mathcal{B}$ which associates with every sequence $\{A_n\}$ the pair of the strong limits $(\lim_{n\to\infty} A_n, \lim_{n\to\infty} W_n A_n W_n)$ is a C^*-algebra homomorphism. Since $\mathbf{G}$ is contained in the kernel of σ, we have a well-defined C^*-algebra homomorphism

$$\sigma^\pi : \mathbf{B}/\mathbf{G} \to \mathcal{B} \times \mathcal{B}, \quad \{A_n\} + \mathbf{G} \mapsto \sigma(\{A_n\}).$$

A dense subset of $\mathbf{B}$ is the set $\mathbf{B}_0$ of all sequences $\{A_n\}$ which are finite sums of finite products of the form

$$A_n = \sum_i \prod_j T_n(a_{ij}), \tag{22}$$

where $a_{ij} \in PC(\mathbf{C} + \mathcal{K}(\mathcal{H}))$ have at most finitely many jumps. Notice that

$$\sigma^\pi(\{A_n\} + \mathbf{G}) = \left(\sum_i \prod_j T(a_{ij}), \sum_i \prod_j T(\tilde{a}_{ij})\right) \tag{23}$$

in case A_n is given by (22).

THEOREM 6.3. *The mapping $\sigma^\pi : \mathbf{B}/\mathbf{G} \to \mathcal{B} \times \mathcal{B}$ is an isometrical C^*-algebra isomorphism of $\mathbf{B}/\mathbf{G}$ onto $\sigma^\pi(\mathbf{B}/\mathbf{G})$.*

Proof. Let $\{e_1, e_2, \ldots\}$ be any orthonormal basis of $\mathcal{H}$ and denote by S_k the orthonormal projection of $\mathcal{H}$ onto the linear hull of $\{e_1, \ldots, e_k\}$. Further, let $\mathbf{B}_k$ denote the smallest C^*-subalgebra of $\mathbf{B}$ containing all sequences of the form $\{T_n(fI + S_k h S_k)\}_{n=0}^{\infty}$, where $f \in PC(\mathbf{C})$ and $h \in PC(\mathcal{K}(\mathcal{H}))$. From [20, remark on p. 39], one can easily derive that

$$\|\sigma^\pi(\{A_n\} + \mathbf{G})\| = \|\{A_n\} + \mathbf{G}\| \tag{24}$$

for every sequence $\{A_n\} \in \mathbf{B}_k$. Now consider A_n of the form (22) and write $a_{ij} = f_{ij} I + h_{ij}$ with $f_{ij} \in PC(\mathbf{C})$ and $h_{ij} \in PC(\mathcal{K}(\mathcal{H}))$. Since h_{ij} has at most finitely many jumps, the essential range of h_{ij} is a compact subset of $\mathcal{K}(\mathcal{H})$. So Lemma 4.1 of [7] implies that $a_{ij}^k := f_{ij} I + S_k h_{ij} S_k$ converges in $PC(\mathcal{K}(\mathcal{H}))$ to a_{ij} as $k \to \infty$. Using (24) for $\{A_n\} \in \mathbf{B}_k$, we obtain

$$\left\|\sigma^\pi\left(\left\{\sum_i \prod_j T_n(a_{ij}^k)\right\} + \mathbf{G}\right)\right\| = \left\|\left\{\sum_i \prod_j T_n(a_{ij}^k)\right\} + \mathbf{G}\right\|,$$

and passage to the limit $k \to \infty$ yields

$$\left\|\sigma^\pi\left(\left\{\sum_i \prod_j T_n(a_{ij})\right\} + \mathbf{G}\right)\right\| = \left\|\left\{\sum_i \prod_j T_n(a_{ij})\right\} + \mathbf{G}\right\|$$

and thus (24) for every sequence $\{A_n\} \in \mathbf{B}_0$. Since $\mathbf{B}_0$ is dense in $\mathbf{B}$, we arrive at the assertion. □

THEOREM 6.4. *Suppose $a_{ij} \in PC(\mathbf{C} + \mathcal{K}(\mathcal{H}))$. Then*

$$\sum_i \prod_j T(a_{ij}) \in \Pi\left\{\sum_i \prod_j T_n(a_{ij})\right\} \tag{25}$$

if and only if both $\sum_i \prod_j T(a_{ij})$ and $\sum_i \prod_j T(\tilde{a}_{ij})$ are invertible. In particular, if $a \in PC(\mathbf{C} + \mathcal{K}(\mathcal{H}))$ and $K \in \mathcal{Q}$, then

$$T(a) + K \in \Pi\{P_n\} \iff T(a) + K,\ T(\tilde{a}) \in G\mathcal{L}(l^2(\mathcal{H})).$$

Proof. Define A_n by (22). The inclusion (25) holds if and only if $\{A_n\} + \mathbf{G}$ is invertible in $\mathbf{B}/\mathbf{G}$, and from Theorem 6.3 we infer that $\{A_n\} + \mathbf{G}$ is invertible if and only if the two operators on the right of (23) are invertible. □

Acknowledgment. This paper was strongly inspired by the article [14]. We wish to thank I. Gohberg and M. A. Kaashoek for a fruitful discussion on the topic and for useful comments on a preliminary version of the present paper.

SHARP ESTIMATES FOR COMPLETE ELLIPTIC INTEGRALS*

S.-L. QIU† AND M. K. VAMANAMURTHY‡

Abstract. Monotonicity and convexity properties of certain functions defined in terms of complete elliptic integrals are studied and sharp functional inequalities for these functions are obtained, thus answering some open questions.

Key words. concave, convex, elliptic integral

AMS subject classifications. 33A25

1. Introduction.

For $r \in (0,1)$, let $r' = (1-r^2)^{1/2}$. The functions

$$K(r) = \int_0^{\pi/2} (1 - r^2 \sin^2 t)^{-1/2} dt, \; K'(r) = K(r') \tag{1.1}$$

and

$$E(r) = \int_0^{\pi/2} (1 - r^2 \sin^2 t)^{1/2} dt, \; E'(r) = E(r') \tag{1.2}$$

are called the complete elliptic integrals of the first kind and second kind, respectively [BF], [BO], [BB]. Basic properties of these functions can be found in [WW].

It is well known that these elliptic integrals are indispensable tools for many applications in mathematics, physics, and engineering [C]. They play an important role in quasiconformal theory (see [LV], [AVV1]–[AVV4], [Vu], and [Q1]). Recently, many new properties were obtained for these functions and several conjectures and open problems were put forward [VV1], [VV2], [AVV5]–[AVV7]. Among them are the following three conjectures:

(i) The function $\sqrt[4]{1+r}K(r)/K(\sqrt{r})$ is increasing from [0,1) onto $[1, \sqrt[4]{2})$.

(ii) The function $r'e^{K(r)}$ is strictly concave on $(0,1)$.

(iii) For each $r \in (0,1)$,

$$1 + \frac{r'^2}{8} < \frac{K(r)}{\log(4/r')} < 1 + \frac{r'^2}{4}. \tag{1.3}$$

Conjecture (i) appears in [AVV6] and [AVV7], while (ii) and (iii) appear in [AVV7].

In this paper, we derive some monotonicity, concavity, and convexity properties of certain functions defined in terms of elliptic integrals, from which some sharp functional inequalities follow. In particular, we shall prove that conjectures (i)–(iii) are true. By presenting a double inequality stronger than (1.3), we shall derive lower and upper bounds for the function $(8+r^2)K(r)/\log(4/r')$ which improve the inequalities

$$9 < \frac{(8+r^2)K(r)}{\log(4/r')} < 9.1 \tag{1.4}$$

for $r \in (0,1)$. We observe that (1.4) is Conjecture (5) in [AVV6].

*Received by the editors December 29, 1993; accepted for publication (in revised form) September 23, 1994. This research was performed during the first author's visit to the Mathematics Department of the University of Helsinki with support from CIMO and the Finnish Ministry of Education.

‡Department of Mathematics, School of Mathematical and Information Sciences, University of Auckland, P.O. Box 92019, Auckland, New Zealand.

We often write K, K' and E, E' instead of $K(r), K'(r)$ and $E(r), E'(r)$, respectively, when the argument of the function is clear from the context.

Some of the main results of this paper are as follows.

THEOREM 1.1. *The function* $f(r) = \sqrt[4]{1+r}\; K(r)/K(\sqrt{r})$ *is strictly increasing from* $[0,1)$ *onto* $[1, \sqrt[4]{2})$.

THEOREM 1.2. *The function* $g(r) = r'e^{K(r)}$ *is strictly decreasing and concave from* $(0,1)$ *onto* $(4, e^{\pi/2})$.

THEOREM 1.3. *For each* $r \in (0,1)$,

$$1 + \frac{1}{8}r'^2 < \frac{K(r)}{\log(4/r')} \tag{1.5}$$

$$< \min\left\{1.013872\left(1+\frac{1}{8}r'^2\right), 1+\frac{1}{4}r'^2\right\}.$$

These two inequalities are asymptotically sharp as r tends to 1.

THEOREM 1.4. *For each* $r \in (0,1)$,

$$9 < \frac{(8+r^2)(8+r'^2)}{8} < \frac{(8+r^2)K(r)}{\log(4/r')} < 9.096. \tag{1.6}$$

The lower bound is sharp, and the upper bound 9.096 *cannot be replaced by a constant less than* 9.09437.

Remark 1. The first inequality in (1.4) has been proven separately by R. Kühnau and S.-L. Qiu (see [K] and [Q2]). Our present proof, however, is very simple as it is an immediate consequence of the first inequality in (1.5).

2. Preliminary results. In this section, we obtain some elementary properties of K and E which are needed for proofs of the main theorems stated in §1.

THEOREM 2.1. (1) *The function* $f_1(r) = \frac{r^2}{E(r)-r'^2K(r)}$ *is strictly decreasing and concave from* $(0,1)$ *onto* $(1, \frac{4}{\pi})$. *In particular, for* $r \in (0,1)$,

$$1 + \left(\frac{4}{\pi} - 1\right)(1-r) < \frac{r^2}{E(r)-r'^2K(r)} < \frac{4}{\pi}.$$

(2) *The function* $f_2(r) = [E(r) - r'^2K(r)]/(1-r')$ *is strictly decreasing and concave from* $(0,1)$ *onto* $(1, \frac{\pi}{2})$. *In particular, for* $r \in (0,1)$,

$$1 + \left(\frac{\pi}{2} - 1\right)(1-r) < \frac{E(r)-r'^2K(r)}{1-r'} < \min\left\{\frac{\pi}{2}, 1+r'\right\}. \tag{2.1}$$

(3) *The function* $f_3(r) = \frac{1-(E(r)-r'^2K(r))}{r'^2\log(\frac{4}{r'})}$ *is strictly decreasing from* $(0,1)$ *onto* $(\frac{1}{2}, \frac{1}{\log 4})$.

(4) *The function* $f_4(r) = (a+r^2)E(r) - (a-r^2)K(r)$ *is strictly increasing (decreasing) on* $(0,1)$ *if and only if* $a \le 1$ $(a \ge 4)$. *Moreover,*

$$f_4((0,1)) = \begin{cases} (0,\infty) & \textit{if } a < 1, \\ (0,2) & \textit{if } a = 1, \\ (-\infty, 0) & \textit{if } a \ge 4. \end{cases}$$

(5) *For each* $a \in [4,\infty), f_5(r) = E(r)/(a-r^2)$ *is strictly decreasing from* $[0,1]$ *onto* $[\frac{1}{a-1}, \frac{\pi}{2a}]$.

(6) *The function* $f_6(r) = r'^2(K(r)-E(r))/r^2$ *is strictly decreasing and concave from* $(0,1)$ *onto* $(0, \frac{\pi}{4})$.

(7) *The function* $f_7(r) = (E(r)E'(r) - K(r)E'(r) + r^2K(r)K'(r))/r^2$ *is strictly decreasing from* $(0,1)$ *onto* $(\frac{\pi}{2}, \infty)$.

(8) *The function* $f_8(r) = (K(r)-E(r)+\log r')/r^2$ *is strictly increasing from* $(0,1)$ *onto* $(\frac{\pi-2}{4}, \log 4 - 1)$.

Proof. (1) By differentiation,

$$\frac{-f_1'(r)}{r} = \frac{(K-E)-(E-r'^2K)}{(E-r'^2K)^2},$$

which is positive and has the form $0/0$ at $r = 0$. The ratio of the derivatives of the numerator and the denominator is $1/(2r'^2K)$ so that the result (1) follows from [AVV5, Thm. 2.2(3)] and the l'Hôpital monotone rule [AVV7, Thm. 1.24].

The limiting values are clear.

(2) By differentiation,

$$f_2'(r) = -\frac{r}{r'} \cdot \frac{E-r'K}{(1-r')^2}.$$

Since $(E-r'K)/(1-r')^2$ is strictly increasing from $(0,1)$ onto $(\frac{\pi}{8}, 1)$ [AVV6, Thm. 3.7], $f_2'(r)$ is negative and strictly decreasing on $(0,1)$, yielding the monotonicity and concavity of f_2.

Next, from the equality

$$f_2(r) = (1+r') \int_0^{\pi/2} \frac{\cos^2 t}{\sqrt{1-r^2\sin^2 t}} dt,$$

we see that $f_2(0) = \frac{\pi}{2}$ and $f_2(1) = 1$.

(3) The function f_3 has the form $0/0$ at $r = 1$. The ratio of the derivatives of the numerator and the denominator $= \frac{K}{2\log(4/r')-1}$, which is strictly decreasing, by [AVV5, Thm. 2.2(5)], so that f_3 has the same property by the l'Hôpital monotone rule [AVV7, Thm. 1.24]. The value $f_3(0) = 1/\log 4$ is clear, while $f_3(1) = \frac{1}{2}$ by l'Hôpital's rule.

(4) By differentiation and simplification,

$$f_4'(r) = \frac{r}{r'^2}(4-a-3r^2)E,$$

so that the assertions follow.

(5) Since $f_4(0) = 0$ and

$$r(a-r^2)^2 f_5'(r) = f_4(r),$$

the monotonicity of f_5 follows by (4). The limiting values are clear.

(6) By differentiation and simplification,

$$-f_6'(r) = \frac{2(K-E)-r^2E}{r^3},$$

which has the form $0/0$ at $r = 0$. The ratio of derivatives of the numerator and the denominator is

$$\frac{2rE}{3r'^2} + \frac{K-E}{3r},$$

which is positive and increasing by [AVV6, Thms. 1.3 and 2.1(6)]. Hence the result follows by the l'Hôpital monotone rule [AVV7, Thm. 1.24].

(7) By differentiation and simplification,

$$f_7'(r) = -\frac{2}{r^3 r'^2}(E-r'^2K)(E'-r^2K') < 0,$$

from which the monotonicity of f_7 follows. Since

$$f_7(r) = E'\frac{E - r'^2K}{r^2} + K(K' - E'),$$

we see that $f_7(0) = \infty$ and $f_7(1) = \frac{\pi}{2}$.

(8) The function f_8 has the form $0/0$ at $r = 0$. The ratio of the derivatives of the numerator and the denominator is $(E - 1)/(2r'^2)$, which again has the form $0/0$ at $r = 1$. The ratio of the derivatives of the numerator and the denominator is $(K - E)/(4r^2)$, which is strictly increasing by definitions (1.1) and (1.2). Hence f_8 also has the same property by the l'Hôpital monotone rule [AVV7, Thm. 1.24]. The end values are clear. □

LEMMA 2.2. (1) *The function* $f_9(r) = (9 - r^2)E(r) - 3(3 - r^2)r'^2K(r)$ *is strictly increasing from* $[0, 1)$ *onto* $[0, 8)$.

(2) *On* $(0, 1)$, *the function*

$$f_{10}(r) = 3(-75 + 34r^2 - 15r^4)r'^2K(r) + (225 - 214r^2 + 21r^4)E(r)$$

has exactly two zeros r_1 *and* r_2, $r_1 < r_2$. *Moreover,* $f_{10}(r) > 0$ *for* $r \in (0, r_1) \cup (r_2, 1)$, *and* $f_{10}(r) < 0$ *for* $r \in (r_1, r_2)$.

(3) *On* $(0, 1)$, *the function*

$$f_{11}(r) = (162 - 153r^2 + 32r^4 - 9r^6)K(r) - 6(9 - r^2)(3 - r^2)E(r)$$

has exactly two zeros r_3, r_4, $r_3 < r_4$. *Moreover,* $f_{11}(r) > 0$ *for* $r \in (0, r_3) \cup (r_4, 1)$, *and* $f_{11}(r) < 0$ *for* $r \in (r_3, r_4)$.

(4) *The function* $f_{12}(r) = \log(4/r') - \{r^2(9 - r^2)K(r)/f_9(r)\}$ *is strictly increasing on* $(0, r_3]$ *and on* $(r_4, 1)$, *and strictly decreasing on* (r_3, r_4).

(5) *On* $(0, 1)$, *the function* $f_{12}(r)$ *has a unique zero* $r_0 \in (\sin 29°, 1/2)$ *such that* $f_{12}(r) > 0$ *for* $r \in (0, r_0)$ *and* $f_{12}(r) < 0$ *for* $r \in (r_0, 1)$.

Proof. (1) Since

$$f_9'(r) = r(13 - 9r^2)K(r) > 0, \tag{2.2}$$

the monotonicity of f_9 follows. Clearly, $f_9(0) = f_9(1) - 8 = 0$.

(2) By differentiation and simplification,

$$\frac{1}{r}f_{10}'(r) = g_1(r), \tag{2.3}$$

where $g_1(r) = (-540 + 60r^2)E + (541 - 462r^2 + 225r^4)K$, and

$$\frac{r'^2}{r}g_1'(r) = g_2(r), \tag{2.4}$$

where $g_2(r) = [(1 + 258r^2 + 45r^4)(E - r'^2K)/r^2] - (264 - 720r^2)r'^2K$. Clearly, $g_1(0) = \pi/2$, $g_1(1) = \infty$, $g_2(0) = -527\pi/4$, and $g_2(1) = 304$.

By [AVV5, Thm. 2.2(3)(7)] or Theorem 2.1(1), g_2 is strictly increasing on $[0, b]$, where $b = \sqrt{264/720} = \sqrt{11/30} > \sin 37°$. Since

$$g_2(\sin 37°) = 79.37\ldots > 0,$$

g_2 has a zero $r_5 \in (0, b)$ such that $g_2(r) < 0$ for $r \in [0, r_5)$ and $g_2(r) > 0$ for $r \in (r_5, b)$.

On the other hand, for $r \in (b,1)$, it is clear that

$$g_2(r) > (1 + 258r^2 + 45r^4)(E - r'^2 K)/r^2 > 0.$$

Hence, r_5 is the unique zero of g_2 in $[0,1]$, $g_2(r) < 0$ for $r \in [0,r_5)$, and $g_2(r) > 0$ for $r \in (r_5,1]$.

It now follows from (2.4) that g_1 is strictly decreasing on $(0,r_5]$ and strictly increasing on $[r_5,1)$. Since

$$g_1(\sin 32^\circ) = -30.09\ldots < 0,$$

g_1 has exactly two zeros $r_6, r_7 \in (0,1)$, $r_6 < r_7$, so that $g_1(r) > 0$ for $r \in [0,r_6) \bigcup (r_7,1]$ and $g_1(r) < 0$ for $r \in (r_6,r_7)$.

Consequently, it follows from (2.3) that f_{10} is strictly increasing on $(0,r_6]$ and on $[r_7,1)$ and strictly decreasing on $[r_6,r_7]$. By computation, we have

$$f_{10}(0) = 0,\ f_{10}\left(\frac{1}{2}\right) = -2.19\ldots \quad \text{and} \quad f_{10}(1) = 32.$$

Hence, the result (2) follows by the piecewise monotonicity of f_{10}.

(3) Clearly, $f_{11}(0) = 0$ and $f_{11}(1) = \infty$. Since

$$f_{11}\left(\frac{1}{2}\right) = -0.118\ldots < 0,$$

the result for f_{11} follows from the derivative

$$\frac{r'^2}{r} f_{11}'(r) = f_{10}(r)$$

by (2).

(4) Assertion (4) follows from the derivative

$$[f_9(r)]^2 f_{12}'(r) = rKf_{11}(r)$$

by (3).

(5) First, we have

$$\begin{aligned} f_{12}(0) &= 2\log 2 - \frac{9\pi}{2}\lim_{r\to 0} r^2 \left\{ \int_0^{\frac{\pi}{2}} \frac{11r^2 - 3r^4 - r^2(9-r^2)\sin^2 t}{\sqrt{1 - r^2\sin^2 t}}dt \right\}^{-1} \\ &= 2\log 2 - \frac{18}{13} > 0 \end{aligned}$$

and

$$f_{12}(1) = \lim_{r\to 1}\left\{ \left(\log\frac{4}{r'} - K\right) + r'K \cdot \frac{f_9(r) - (9r^2 - r^4)}{r' f_9(r)} \right\} = 0,$$

since

$$\lim_{r\to 1}\left(\log\frac{4}{r'} - K\right) = \lim_{r\to 1} r'K = 0 \tag{2.5}$$

and

$$\lim_{r\to 1}\frac{f_9(r)-r^2(9-r^2)}{r'f_9(r)}=0$$

by l'Hôpital's rule. Hence, by (4), f_{12} has a unique zero r_0 in $(0,1)$.

Next, by computation, we have

$$f_{12}\left(\frac{1}{2}\right)=-0.0002\ldots\quad\text{and}\quad f_{12}(\sin 29°)=0.0007\ldots.$$

Hence, $r_0\in(\sin 29°,\frac{1}{2})$. □

LEMMA 2.3. (1) *The function* $f_{13}(r)=(5-r^2)E(r)-(5-3r^2)r'^2K(r)$ *is strictly increasing from* $[0,1)$ *onto* $[0,4)$.

(2) *The function* $f_{14}(r)=(50-15r^2+9r^4)r'^2K(r)-(50-40r^2+6r^4)E(r)$ *is strictly decreasing from* $[\sqrt{3/23},1)$ *onto* $(-16,f_{14}(\sqrt{3/23})]$.

(3) *The function* $f_{15}(r)=\log(4/r')-[r^2(5-r^2)K(r)/f_{13}(r)]$ *is positive and strictly decreasing on* $[1/\sqrt{2},1)$.

Proof. (1) By differentiation,

$$f_{13}'(r)=9rr'^2K>0,$$

$0<r<1$. Clearly, $f_{13}(0)=0$ and $f_{13}(1)=4$.

(2) We have

$$\begin{aligned}f_{14}'(r)&=3r\{(35-7r^2)E+(-35+26r^2-15r^4)K\}\\&=3r^3\int_0^{\pi/2}\frac{19-15r^2-(35-7r^2)\sin^2 t}{\sqrt{1-r^2\sin^2 t}}dt\\&=21r^3(5-r^2)\int_0^{\pi/2}\frac{[(19-15r^2)/(35-7r^2)]-\sin^2 t}{\sqrt{1-r^2\sin^2 t}}dt.\end{aligned}$$

It is easy to verify that $(19-15r^2)/(35-7r^2)\le\frac{1}{2}$ for $r\in[\sqrt{3/23},1)$. Hence it follows from the above equalities that

$$\begin{aligned}f_{14}'(r)&\le\frac{21}{2}r^3(5-r^2)\int_0^{\pi/2}\frac{\cos 2t}{\sqrt{1-r^2\sin^2 t}}dt\\&=\frac{21}{2}r(5-r^2)[2E-(2-r^2)K]\end{aligned}$$

for $r\in[\sqrt{3/23},1)$, which is negative by Theorem 2.1(1).

Clearly, $f_{14}(1)=-16$.

(3) By differentiation,

$$[f_{13}(r)]^2f_{15}'(r)=rKf_{14}(r). \tag{2.6}$$

Since

$$\begin{aligned}f_{14}\left(\frac{\sqrt{2}}{2}\right)&=\left(50-\frac{21}{4}\right)\frac{1}{2}K\left(\frac{\sqrt{2}}{2}\right)-\left(30+\frac{3}{2}\right)E\left(\frac{\sqrt{2}}{2}\right)\\&=-1.05841\ldots,\end{aligned}$$

$f_{14}(r)<0$ for all $r\in[\frac{\sqrt{2}}{2},1)$ by (2). The result now follows from (2.6). □

3. Proofs of main theorems. In this section, we prove the theorems stated in §1.

Proof of Theorem 1.1. First, it is clear that $f(0) = 1$. By l'Hôpital's rule, we get $f(1) = \sqrt[4]{2}$.

Next, by differentiation,

$$\begin{aligned}(3.1)\qquad & 4r(1-r)(1+r)^{3/4}K^2(\sqrt{r})f'(r)\\ &= 4K(\sqrt{r})[E(r) - r'^2K(r)]\\ &+ K(r)\left\{r(1-r)K(\sqrt{r}) - 2(1+r)[E(\sqrt{r}) - (1-r)K(\sqrt{r})]\right\}.\end{aligned}$$

By Theorem 2.1(2) and [VV2, Lem. 2.2(5)], we have

$$rK(\sqrt{r}) > 2[E(\sqrt{r}) - (1-r)K(\sqrt{r})]$$

for $r \in (0,1)$. Hence, it follows from (3.1) that

$$\begin{aligned}&4r(1-r)(1+r)^{3/4}K^2(\sqrt{r})f'(r)\\ &> 4K(\sqrt{r})[E(r) - r'^2K(r)] - 4rK(r)[E(\sqrt{r}) - (1-r)K(\sqrt{r})]\\ &= 4r^2K(r)K(\sqrt{r})\left\{\frac{E(r) - r'^2K(r)}{r^2K(r)} - \frac{E(\sqrt{r}) - (1-r)K(\sqrt{r})}{rK(\sqrt{r})}\right\}.\end{aligned}$$

Hence $f'(r) > 0$ for each $r \in (0,1)$ by Theorem 2.1(2). □

By Theorem 1.1, one can derive lower and upper bounds for $\mu(r^2)/\mu(r)$, where

$$(3.2)\qquad \mu(r) = \frac{\pi}{2}\frac{K'(r)}{K(r)},$$

$0 < r < 1$, which is a very important special function in the theory of quasiconformal mappings [LV].

COROLLARY 3.1. *For each* $r \in (0,1)$,

$$(3.3)\qquad 1 < \sqrt[4]{\frac{2}{1+r^2}} < \frac{\mu(r^2)}{\mu(r)} < \frac{2}{(1+r^2)^{3/4}} < 2.$$

Proof. By [AVV7, Thm. 3.31], for each $r \in (0,1)$,

$$\sqrt{\frac{2}{1+r^2}} < \frac{K'(r^2)}{K'(r)} < \frac{2}{1+r^2}.$$

Hence, by Theorem 1.1, for each $r \in (0,1)$,

$$\begin{aligned}\frac{\mu(r^2)}{\mu(r)} &= (1+r^2)^{1/4}\frac{K'(r^2)}{f(r^2)K'(r)}\\ &< (1+r^2)^{1/4}\frac{K'(r^2)}{K'(r)} < \frac{2}{(1+r^2)^{3/4}} < 2\end{aligned}$$

and

$$\frac{\mu(r^2)}{\mu(r)} > \left(\frac{1+r^2}{2}\right)^{1/4}\frac{K'(r^2)}{K'(r)} > \left(\frac{2}{1+r^2}\right)^{1/4} > 1.$$

Here $f(r)$ is as in Theorem 1.1. □

Remark 2. In [QV], it was proved that the function $\mu(r^2)/\mu(r)$ is strictly decreasing from $(0,1)$ onto $(1,2)$. Hence

$$1 < \mu(r^2)/\mu(r) < 2,$$

so that (3.3) improves this result.

Proof of Theorem 1.2. First, by differentiation,

$$g'(r) = e^K \frac{E - r'^2 K - r^2}{rr'},$$

which is negative by (2.1), so that $g(r)$ is strictly decreasing on (0,1).

Clearly, $g(0) = e^{\pi/2}$. By (2.5), we have

$$g(1) = \exp\{\lim_{r \to 1}(\log r' + K)\} = 4.$$

Next, we have

$$r'^3 e^{-K} g''(r) = \frac{1}{r^2}\{(E - r'^2 K)^2 + r'^2(K - E)\} - 1. \tag{3.4}$$

Define $G(r) = \{(E - r'^2 K)^2 + r'^2(K - E)\}/r^2$. Now we want to estimate $G(r)$ by investigating two cases.

Case 1: $0 < r \le \sin 68°$. In this case, by Theorem 2.1 (1) and (6), we have

$$G(r) < \left(\frac{E(b) - b'^2 K(b)}{b}\right)^2 + \left(\frac{a'}{a}\right)^2 [K(a) - E(a)] = G_1(a, b)$$

for $r \in (a, b] \subset (0, 1)$. Making use of this inequality, we get the following estimates by computation:

$$\begin{aligned}
G(r) &< G_1(0, \sin 30°) = 0.950\ldots, & r &\in (0, \sin 30°],\\
G(r) &< G_1(\sin 30°, \sin 43°) = 0.984\ldots, & r &\in (\sin 30°, \sin 43°],\\
G(r) &< G_1(\sin 43°, \sin 52°) = 0.994\ldots, & r &\in (\sin 43°, \sin 52°],\\
G(r) &< G_1(\sin 52°, \sin 58°) = 0.986\ldots, & r &\in (\sin 52°, \sin 58°],\\
G(r) &< G_1(\sin 58°, \sin 62°) = 0.977\ldots, & r &\in (\sin 58°, \sin 62°],\\
G(r) &< G_1(\sin 62°, \sin 65°) = 0.976\ldots, & r &\in (\sin 62°, \sin 65°],\\
G(r) &< G_1(\sin 65°, \sin 68°) = 0.987\ldots, & r &\in (\sin 65°, \sin 68°].
\end{aligned}$$

From these inequalities, it follows that

$$G(r) < 1 \text{ for } r \in (0, \sin 68°]. \tag{3.5}$$

Case 2: $\sin 68° < r < 1$. In this case, we consider the function $G_2(r) = r^2 G(r) - r^2$. Since $E \ge 1$, we have

$$\begin{aligned}
\frac{1}{r} G_2'(r) &= 2K(E - r'^2 K - 1) + 3E - 2\\
&> 1 - 2r'K \cdot \frac{1 - (E - r'^2 K)}{r'} = G_3(r), \text{ say.}
\end{aligned} \tag{3.6}$$

Since $r'K$ is strictly decreasing on $(0,1), G_3(r)$ is strictly increasing on (0,1) by Theorem 2.1(3).

Hence, for $r \in (\sin 68^\circ, 1)$,

$$\begin{aligned} G_3(r) &> 1 + 2K(\sin 68^\circ)[E(\sin 68^\circ) - \cos^2 68^\circ K(\sin 68^\circ) - 1] \\ &= 0.015\ldots > 0, \end{aligned}$$

showing that $G_2(r)$ is strictly increasing on $(\sin 68^\circ, 1)$ by (3.6).

Since $G_2(1) = 0$, we get

$$G_2(r) < 0 \text{ for } r \in (\sin 68^\circ, 1),$$

or equivalently,

$$G(r) < 1 \text{ for } r \in (\sin 68^\circ, 1). \tag{3.7}$$

Now it follows from (3.4) that $g''(r) < 0$, for each $r \in [0,1)$, by (3.5) and (3.7). This yields the concavity of g and completes the proof. □

COROLLARY 3.2. *For each* $r \in (0,1)$,

$$1 - r < \frac{r' e^{K(r)} - 4}{e^{\pi/2} - 4} < 1.$$

The lower and upper bounds are asymptotically sharp as r *tends to* 1 *and* 0, *respectively.*

Proof of Theorem 1.3. First, we prove the following inequalities:

$$1 + \frac{1}{8} r'^2 < \frac{K(r)}{\log(4/r')} < 1.013872 \left(1 + \frac{1}{8} r'^2\right) \tag{3.8}$$

for $r \in (0,1)$. For this, consider the function

$$h(r) = \frac{1}{9 - r^2} \frac{K(r)}{\log(4/r')}, \quad 0 < r < 1,$$

with $h(0) = \pi/(36 \log 2)$ and $h(1) = \frac{1}{8} < h(0)$.

By differentiation,

$$h'(r) = f_9(r) f_{12}(r) / \left\{ r \left[r'(9 - r^2) \log \frac{4}{r'} \right]^2 \right\}, \tag{3.9}$$

where f_9 and f_{12} are as in Lemma 2.2. Hence, by Lemma 2.2(1),(4), and (5), h is increasing on $(0, r_0]$ and decreasing on $(r_0, 1)$, and consequently,

$$h(1) < h(r) \le h(r_0) \tag{3.10}$$

for each $r \in [0,1)$, with $r_0 \in (\sin 29^\circ, \frac{1}{2})$.

Next, we have

$$\begin{aligned} h(r_0) &= \frac{1}{9 - r_0^2} \frac{K(r_0)}{\log(4/r_0')} < \frac{K(\frac{1}{2})}{(9 - \frac{1}{4}) \log(4/\cos 29^\circ)} \\ &= 0.126733\ldots < 0.126734. \end{aligned} \tag{3.11}$$

Now, (3.8) follows from (3.10) and (3.11). Moreover, the lower bound in (3.8) is asymptotically sharp as r tends to 1.

Next, we prove that

$$\frac{K(r)}{\log(4/r')} < 1 + \frac{1}{4}r'^2, \quad 0 < r < 1. \tag{3.12}$$

It is easy to show that $1.013872(1+\frac{1}{8}r'^2) \le 1+\frac{1}{4}r'^2$ for $r \in [0, a]$, where $a = \sqrt{\frac{54697}{61633}} = 0.94205\ldots$. Hence,

$$\frac{K(r)}{\log(4/r')} < 1 + \frac{1}{4}r'^2 \quad \text{for } r \in (0, a]. \tag{3.13}$$

Next, define

$$H(r) = \frac{1}{5-r^2}\frac{K(r)}{\log(4/r')}, \quad 0 < r < 1.$$

Clearly, $H(0) = \dfrac{\pi}{20\log 2}$ and $H(1) = \frac{1}{4} > H(0)$. By differentiation,

$$rr'^2\left[(5-r^2)\log\frac{4}{r'^2}\right]^2 H'(r) = f_{13}(r)f_{15}(r), \tag{3.14}$$

where f_{13} and f_{15} are as in Lemma 2.3.

By Lemma 2.3(3) for $r \in [\sqrt{2}/2, 1)$,

$$\begin{aligned} f_{15}(r) &> f_{15}(1) \\ &= \lim_{r\to 1}\left\{\left(\log\frac{4}{r'} - K\right) + r'K\frac{f_{13}(r) - r^2(5-r^2)}{r'f_{13}(r)}\right\} = 0 \end{aligned}$$

because of (2.5) and the fact that

$$\lim_{r\to 1}\frac{f_{13}(r) - r^2(5-r^2)}{r'f_{13}(r)} = 0$$

by l'Hôpital's rule. Therefore, by Lemma 2.3(1), it follows from (3.14) that $H(r)$ is strictly increasing on $[\sqrt{2}/2, 1)$, and hence,

$$H(r) < H(1) = \frac{1}{4} \tag{3.15}$$

for $r \in [\sqrt{2}/2, 1)$. In particular, (3.15) holds for $r \in (a, 1)$. Hence,

$$\frac{K(r)}{\log(4/r')} < 1 + \frac{1}{4}r'^2 \text{ for } r \in (a, 1). \tag{3.16}$$

Now, (3.12) follows from (3.13) and (3.16). Finally, (1.5) follows from (3.8) and (3.12). □

Proof of Theorem 1.4. First, by (1.5), we have

$$\frac{(8+r^2)K(r)}{\log(4/r')} > \frac{(8+r^2)(9-r^2)}{8} > 9 \tag{3.17}$$

for $r \in (0,1)$. The two inequalities are sharp at $r = 1$. Thus, the first and second inequalities in (1.6) hold and the lower bound 9 is sharp.

Next, by [Q2, Proof of Thm.], we have

$$\frac{(8+r^2)K(r)}{\log(4/r')} \le \max_{\sin 41^\circ < r < \sin 42^\circ} \frac{(8+r^2)K(r)}{\log(4/r')} \tag{3.18}$$

for each $r \in [0, \sin 41^\circ] \cup [\sin 42^\circ, 1]$.

For $r \in (\sin 41^\circ, \sin 42^\circ), h(r)$ is strictly decreasing by Lemma 2.2(5). Here $h(r)$ is as defined in the proof of Theorem 1.3. On the other hand, it is easy to verify that $(8+r^2)(9-r^2)$ is strictly increasing on $(0, \frac{1}{\sqrt{2}})$ and strictly decreasing on $(\frac{1}{\sqrt{2}}, 1)$. Therefore, for $\sin 41^\circ < r < \sin 42^\circ$,

$$\begin{aligned}
&\frac{(8+r^2)K}{\log(4/r')} = h(r)(8+r^2)(9-r^2) \\
&< \ h(\sin 41^\circ)(8+\sin^2 42^\circ)[9-\sin^2 42^\circ) \\
&\le \frac{(9-0.66905^2)(8+0.66915^2)}{9-0.65615^2}\,\frac{1.79925}{1.6677} \\
&= 9.0959\ldots < 9.096.
\end{aligned}$$

Combining the above estimate with (3.18) yields the third inequality in (1.6).

Finally, the upper bound in (1.6) cannot be replaced with a constant less than 9.09437, since

$$\begin{aligned}
\left.\frac{(8+r^2)K}{\log\frac{4}{r'}}\right|_{r=\sin 41^\circ} &\ge \frac{(8+0.65605^2)\times 1.79915}{\log\frac{4}{0.75465}} \\
&= 9.09437\ldots \qquad \square
\end{aligned}$$

Acknowledgment. The authors wish to thank Dr. M. Vuorinen for hospitality and many helpful discussions.

ON SOME SHARP REGULARITY ESTIMATIONS OF L^2-SCALING FUNCTIONS*

KA-SING LAU[†], MANG-FAI MA[†], AND JIANRONG WANG[‡]

Abstract. Let f be a compactly supported L^2-solution of the two-scale dilation equation and α be the L^2-Lipschitz exponent of f. We prove, in addition to other results, that there exists an integer $k \geq 0$ such that (i) $\frac{1}{h^{2\alpha}|\ln h|^k} \int_{-\infty}^{\infty} |f(x+h) - f(x)|^2 dx \approx p(h)$ as $h \to 0^+$, where p is a nonzero bounded continuous function with $p(2h) = p(h)$, and (ii) for $s > \alpha$, there exists a nonzero bounded continuous q (depends on s) with $q(2T) = q(T)$ and $\frac{1}{T^{2(s-\alpha)}(\ln T)^k} \int_{-T}^{T} |\omega^s \hat{f}(\omega)|^2 d\omega \approx q(T)$ as $T \to \infty$. The above α and k can be calculated through a transition matrix. These improve the previous result of Cohen and Daubechies concerning the Besov space containing f and Villemoes's result on the Sobolev exponent of $\hat{f}$.

1. Introduction.

The existence, regularity, and orthogonality of the compactly supported L^2-solution (notation: L^2_c-solution) of the two-scale dilation equation

$$f(x) = \sum_{n=0}^{N} c_n f(2x - n) \tag{1.1}$$

have been studied in great detail (e.g., [CD], [CH], [D], [DL1], [DL2], [E], [H], [LW1], [V], [W]). In much of the literature, the techniques and emphases are on the frequency domain, i.e., the consideration of the Fourier transformation of (1.1),

$$\hat{f}(\omega) = m_0\left(\frac{\omega}{2}\right) \hat{f}\left(\frac{\omega}{2}\right),$$

where $m_0(\omega) = \frac{1}{2}\sum c_n e^{in\omega}$ and $\hat{f}(\omega) = \int_{-\infty}^{\infty} f(x)e^{-i\omega x}dx$. On the other hand, there are linear algebraic methods on the time domain which also yield many important results concerning continuous solutions ([DL1], [DL2], [CH], [W]) and L^p-solutions [LW1].

In this paper, we continue our study through the second method. For the L^2-case, the existence and regularity results in [CD] and [V] are largely derived from the $(2N-1) \times (2N-1)$ matrix $\mathbf{W}_N$ associated with the operator $\mathbf{A}$ on functions in the frequency domain defined by

$$\mathbf{A}g(\omega) = \left|m_0\left(\frac{\omega}{2}\right)\right|^2 g\left(\frac{\omega}{2}\right) + \left|m_0\left(\frac{\omega}{2} + \pi\right)\right|^2 g\left(\frac{\omega}{2} + \pi\right)$$

(which was introduced in [CR]). The matrix $\mathbf{W}_N$ actually comes out more naturally in the time-domain consideration. For $g \in L^2(\mathbb{R})$ supported in $[0, N]$, if we let $\mathbf{a}(g)$ denote the autocorrelation vector of $a_n(g) = \int g(x+n)\overline{g(x)}dx$, $|n| < N$, and $Sg(x) = \sum_{n=0}^{N} c_n g(2x-n)$, then

$$\mathbf{a}(Sg) = \frac{1}{2}\mathbf{W}_N \mathbf{a}(g) \tag{1.2}$$

(Proposition 3.1). This is the most basic and important relationship in the L^2-consideration. Note that if g is an L^2_c-solution of (1.1), then $Sg = g$, and it follows that $\mathbf{a}(g)$ is a 2-eigenvector of $\mathbf{W}_N$. Villemoes [V] essentially proved that (1.1) has an L^2_c-solution if and only if $\mathbf{W}_N$ has a 2-eigenvector which is positive definite. Here we will give another characterization of the existence of the L^2_c-solution based on $\mathbf{W}_N$ and two other associated matrices $\mathbf{T}_0$ and $\mathbf{T}_1$ used in [DL1], [DL2], [CH], [W], and [LW1]. We also simplify a theorem of Cohen and Daubechies [CD, Thm. 4.3] concerning the eigenvalues of $\mathbf{W}_N$ and the Riesz basis property.

Our main objective is to consider the regularity of the L^2_c-solutions. Assuming $\sum c_n = 2$, let

$$\Lambda_{\max} = \max\{|\lambda| : \lambda \text{ is an eigenvalue of } \mathbf{W}_N^+ \text{ and } |\lambda| \neq 2\}$$

($\mathbf{W}_N^+$ is certain truncation of $\mathbf{W}_N$ to the positive coordinates) and let

$$\alpha = -\ln(\Lambda_{\max}/2)/(2\ln 2);$$

then $0 < \alpha \leq 1$. In [V], Villemoes proved that if f is an L^2_c-solution of (1.1) and if $r < \alpha$, then $\int_{-\infty}^{\infty} |\omega^r \hat{f}(\omega)|^2 d\omega < \infty$ so that f is in the Sobolev space $H^r(\mathbb{R})$ for $r < \alpha$, and the Sobolev exponent of f is α. By using the Littlewood–Paley method, Cohen and Daubechies [CD] showed that f is in the Besov space $B_2^{r,\infty}$ for all $r < \alpha$ (an equivalent definition of Besov space $B_2^{r,\infty}$ is $\sup_{h>0} \frac{1}{h^r}\|\Delta_h f\|_2 < \infty$, where $\Delta_h f = f(\cdot + h) - f(\cdot)$ [P]). They left out the critical case when the exponent $r = \alpha$. Here we obtain some sharp estimations of the regularity of f and the decaying rate of $\hat{f}$, which improve the previous results.

THEOREM 1.1. *Let f be an L^2_c-solution of* (1.1). *Let m be the highest order among those eigenvalues λ of $\mathbf{W}_N^+$ such that $|\lambda| = \Lambda_{\max}$; then*

$$\frac{1}{h^{2\alpha}|\ln h|^{m-1}} \int_{-\infty}^{\infty} |\Delta_h f|^2 = p(h) + o(h)$$

as $h \to 0^+$, where p is a nonzero bounded continuous multiplicative periodic function of period 2 (*i.e.*, $p(2h) = p(h), h > 0$). *(The order of an eigenvalue λ is the power of the factor $(x - \lambda)$ in the minimal polynomial.)*

If we define the L^2-Lipschitz exponent of $g \in L^2(\mathbb{R})$ by

$$L^2\text{-Lip}(g) = \inf\{s : 0 < \limsup_{h\to 0^+} \frac{1}{h^s}\|\Delta_h g\|_2\},$$

then it follows from Theorem 1.1 that the L^2-Lipschitz exponent of the L^2_c-solution f is α, which is also the Sobolev exponent of f for $0 < \alpha < 1$. To study higher-order regularity, the usual assumption is the l-sum rule, $l > 1$. Here we do not need such a hypothesis, we use the lth-order difference $\Delta_h^{(l)} f$ to define the L^2-Lipschitz order for $0 \leq \alpha \leq l$ ($\Lambda_{\max}$ has to be redefined). Theorem 1.1 can be extended accordingly with the exception that when α is an integer, then the logarithmic factor can be of order $m - 1$ or $m - 2$.

For the frequency domain, we have the following asymptotic result (including higher-order α).

THEOREM 1.2. *Under the above assumptions, for any $s > \alpha$*

$$\frac{1}{T^{2(s-\alpha)}(\ln T)^k} \int_{-T}^{T} |\omega^s \hat{f}(\omega)|^2 d\omega \approx q(T)$$

as $T \to \infty$, where q is a nonzero bounded continuous function with $q(2T) = q(T)$; if α is not *an integer, then $k = m - 1$; if α is an integer, then $k = m - 1$ or $m - 2$.*

Theorem 1.1 corresponds to Theorem 5.4 later in the text. The main idea of the proof is to extend the identity (1.2) to another autocorrelation vector $\mathbf{\Phi}(h) = [\Phi_0(h), \Phi_1(h), \cdots, \Phi_N(h)]$, where Φ_n is defined by

$$\Phi_n(h) = \int_{-\infty}^{\infty} \Delta_h f(x+n)\Delta_h f(x)dx,$$

and show that for any λ-eigenvector $\mathbf{u}$ of $\mathbf{W}_N^+, \lambda \neq 0, 2$, $\langle \mathbf{\Phi}(h), \mathbf{u}\rangle = h^{2\beta}p(h)$, where $\beta = -\ln(\lambda/2)/(2\ln 2)$ and p is a nonzero bounded continuous multiplicative periodic function (Lemma 5.1, Theorem 5.2). The most involved step is to show that $\langle \mathbf{\Phi}(h), \mathbf{u}\rangle \neq 0$ (Lemma 4.3), which makes use of a classical result of L. Schwartz on the *mean periodic functions* [Sch], [K], [RL]. Theorem 1.2 is contained in Theorem 5.7 and in §6, it is derived from Theorem 1.1 by using a new form of Tauberian theorem proved in [L3].

We remark that equation (1.1) actually describes a certain self-similarity of f. The self-similar measures in fractal theory are also defined by the same class of functional equation [Hu]. The genuine ideas of calculating the asymptotic properties in Theorems 1.1 and 1.2 are already contained in [L1], [LW2], [S1], [S2], and in particular in [L2].

The Daubechies four-coefficient scaling function $D_4 = f$ provides an interesting example for the above theorems (see §6 and the appendix). It follows from a direct calculation and Theorem 1.1 that $\Lambda_{\max} = \frac{1}{2}$, $\alpha = 1$, and the regularity is given by $\frac{1}{h^2|\ln h|}\int_{-\infty}^{\infty} |\Delta_h f|^2 \approx p(h)$ as $h \to 0^+$. It is also differentiable a.e. [D], [DL2], but the derivative is not in $L^2(\mathbb{R})$ in view of the asymptotic regularity behavior as $h \to 0^+$.

We organize the paper as follows. In §2, we introduce the transition matrix $\mathbf{W}_N$ as well as the two associated matrices $\mathbf{W}$ and $\mathbf{W}_N^+$. In §3, we consider some basic properties of the transition matrices in connection with the autocorrelation functions. For completeness, we simplify the existence characterization of the L_c^2-solutions proved in [LW1]. We also give a short proof of a theorem in [CD] concerning the eigenvalues of $\mathbf{W}_N$ when the solution has the Riesz basis property (Theorem 3.7). In §4 we set up the basic lemmas for the proof of Theorem 1.1, Lemma 4.3 being the most important one. Section 5 contains the proof of Theorems 1.1 and 1.2. Section 6 is concerned with the higher-order difference and the L^2-Lipschitz exponent $\alpha > 1$. At the end, we also include an appendix which contains some graphic implementations of the theorems where the functional equation (1.1) takes only four coefficients.

2. The transition matrices.

For any sequence $\{c_n\} \in \ell^1(\mathbb{Z})$, we let

$$\omega_n = \sum_{k\in\mathbb{Z}} c_k c_{k-n}, \quad n \in \mathbb{Z}.$$

Then ω_n is the convolution of the two sequences $\{c_n\}$ and $\{c_{-n}\}$; $\{\omega_n\} \in \ell^1(\mathbb{Z})$ and $\omega_{-n} = \omega_n$. We define the infinite matrix $\mathbf{W}$ by

$$\mathbf{W} = [\omega_{i-2j}] = \begin{pmatrix} \ddots & \vdots & \vdots & \vdots & \\ \cdots & \omega_1 & \omega_{-1} & \omega_{-3} & \cdots \\ \cdots & \omega_2 & \omega_0 & \omega_{-2} & \cdots \\ \cdots & \omega_3 & \omega_1 & \omega_{-1} & \cdots \\ & \vdots & \vdots & \vdots & \ddots \end{pmatrix},$$

and $\mathbf{W}_N$ is the restriction of $\mathbf{W}$ on the entries $-N \le i, j \le N$. We also define

$$\mathbf{W}^+ = \begin{pmatrix} \omega_0 & \omega_{-2} & \omega_{-4} & \cdots \\ \omega_1 + \omega_{-1} & \omega_{-1} + \omega_{-3} & \omega_{-3} + \omega_{-5} & \cdots \\ \omega_2 + \omega_{-2} & \omega_0 + \omega_{-4} & \omega_{-2} + \omega_{-6} & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix},$$

that is, each entry of $\mathbf{W}^+$ is given by

$$w_{ij}^+ = \begin{cases} \omega_{-2j} & \text{if } i = 0, \\ \omega_{i-2j} + \omega_{-i-2j} & \text{if } i > 0. \end{cases}$$

Geometrically, $\mathbf{W}^+$ is obtained by first deleting the left-half part of the columns of $\mathbf{W}$, then reflecting the upper half of this truncated matrix with respect to the zeroth row and adding it to the lower half. Similarly, we can truncate the matrix $\mathbf{W}_N$ to obtain $\mathbf{W}_N^+$.

When there is no confusion, we use $\mathbf{u}$ to denote the column vectors $[u_0, \dots, u_n]^t$, $[u_{-n}, \dots, u_0, \dots, u_n]^t$, and $[\dots, u_{-1}, u_0, u_1, \dots]^t$ ($[\cdot]^t$ denotes the transpose). We define $\mathbf{F} : \mathbb{C}^{N+1} \to \mathbb{C}^{2N+1}$ by

$$\mathbf{F}(\mathbf{u}) = \left[\frac{u_N}{2}, \dots, \frac{u_1}{2}, u_0, \frac{u_1}{2}, \dots, \frac{u_N}{2}\right]^t, \quad \mathbf{u} \in \mathbb{C}^{N+1},$$

and $\mathbf{G} : \mathbb{C}^{2N+1} \to \mathbb{C}^{N+1}$ by

$$\mathbf{G}(\mathbf{u}) = [u_0, u_1 + u_{-1}, \dots, u_N + u_{-N}]^t, \quad \mathbf{u} \in \mathbb{C}^{2N+1}.$$

It is clear that the adjoints of $\mathbf{F}$ and $\mathbf{G}$ are given by

$$\mathbf{F}^*(\mathbf{u}) = \left[u_0, \frac{1}{2}(u_1 + u_{-1}), \dots, \frac{1}{2}(u_N + u_{-N})\right]^t, \quad \mathbf{u} \in \mathbb{C}^{2N+1},$$

and

$$\mathbf{G}^*(\mathbf{u}) = [u_N, \dots, u_1, u_0, u_1, \dots, u_N]^t, \quad \mathbf{u} \in \mathbb{C}^{N+1}.$$

By a λ-eigenvector of a matrix $\mathbf{M}$, we mean a right eigenvector corresponding to the eigenvalue λ. The basic eigen properties of $\mathbf{W}_N$ and $\mathbf{W}_N^+$ are related as follows.

PROPOSITION 2.1. *If* $\mathbf{u} \in \mathbb{C}^{N+1}$ *is a* λ*-eigenvector of* $\mathbf{W}_N^+$ $((\mathbf{W}_N^+)^*$*, resp.), then* $\mathbf{F}(\mathbf{u})$ $(\mathbf{G}^*(\mathbf{u})$*, resp.)* $\in \mathbb{C}^{2N+1}$ *is a* λ*-eigenvector of* $\mathbf{W}_N$ $((\mathbf{W}_N)^*$*, resp.).*

Conversely, if $\mathbf{u} \in \mathbb{C}^{2N+1}$ *is a* λ*-eigenvector of* $\mathbf{W}_N$ $((\mathbf{W}_N)^*$*, resp.), then* $\mathbf{G}(\mathbf{u})$ $((\mathbf{F}^*)(\mathbf{u})$*, resp.) is either* 0 *or a* λ*-eigenvector of* $\mathbf{W}_N^+$ $((\mathbf{W}_N^+)^*$*, resp.).*

Proof. Using elementary linear algebra and the fact that $\omega_n = \omega_{-n}$ for all $n \in \mathbb{Z}$, we have

$$\mathbf{W}_N \circ \mathbf{F} = \mathbf{F} \circ \mathbf{W}_N^+ \quad \text{and} \quad \mathbf{G} \circ \mathbf{W}_N = \mathbf{W}_N^+ \circ \mathbf{G}. \tag{2.1}$$

Suppose $\mathbf{u} \in \mathbb{C}^{N+1}$ is a λ-eigenvector of $\mathbf{W}_N^+$; then $\mathbf{F}(\mathbf{u}) \ne 0$ and by (2.1),

$$\mathbf{W}_N(\mathbf{F}(\mathbf{u})) = \mathbf{F}(\mathbf{W}_N^+\mathbf{u}) = \mathbf{F}(\lambda\mathbf{u}) = \lambda\mathbf{F}(\mathbf{u}).$$

On the other hand, suppose $\mathbf{u} \in \mathbb{C}^{2N+1}$ is a nonzero λ-eigenvector of $\mathbf{W}_N$; then

$$\mathbf{W}_N^+(\mathbf{G}(\mathbf{u})) = \mathbf{G}(\mathbf{W}_N\mathbf{u}) = \mathbf{G}(\lambda\mathbf{u}) = \lambda\mathbf{G}(\mathbf{u}).$$

The statements for the adjoints follow from the dual relationship of (2.1):

$$\mathbf{F}^* \circ (\mathbf{W}_N)^* = (\mathbf{W}_N^+)^* \circ \mathbf{F}^* \quad \text{and} \quad (\mathbf{W}_N)^* \circ \mathbf{G}^* = \mathbf{G}^* \circ (\mathbf{W}_N^+)^*. \tag{2.2}$$

Remark. If $\mathbf{u}$ is a λ-eigenvector of $\mathbf{W}_N$, then the proposition implies that $\mathbf{v} = \mathbf{F}(\mathbf{G}(\mathbf{u}))$ and $\mathbf{w} = \mathbf{u} - \mathbf{v}$ are also eigenvectors of $\mathbf{W}_N$ provided that they are not zero. Note that $\mathbf{v}$ is a symmetric and $\mathbf{w}$ is antisymmetric. If all the λ-eigenvectors of $\mathbf{W}_N$ are antisymmetric, then λ is not an eigenvalue of $\mathbf{W}_N^+$.

If $c_n = 0$ for all $n \in \mathbb{Z} \setminus \{0, 1, \ldots, N\}$, then $\omega_n = 0$ for all $|n| > N$, and

$$\mathbf{W}_N = \begin{pmatrix} \omega_N & \omega_{N-2} & \cdots & \omega_{-N+2} & \omega_{-N} & 0 & \cdots & 0 & 0 \\ 0 & \omega_{N-1} & \cdots & \omega_{-N+3} & \omega_{-N+1} & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & \cdots & \omega_1 & \omega_{-1} & \omega_{-3} & \cdots & 0 & 0 \\ 0 & 0 & \cdots & \omega_2 & \omega_0 & \omega_{-2} & \cdots & 0 & 0 \\ 0 & 0 & \cdots & \omega_3 & \omega_1 & \omega_{-1} & \cdots & 0 & 0 \\ \vdots & \vdots & & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & \omega_{N-1} & \omega_{N-3} & \cdots & \omega_{-N+1} & 0 \\ 0 & 0 & \cdots & 0 & \omega_N & \omega_{N-2} & \cdots & \omega_{-N+2} & \omega_{-N} \end{pmatrix}.$$

PROPOSITION 2.2. *Suppose $\sum_n c_{2n} = \sum_n c_{2n+1} = 1$ and $c_n = 0$ for all $n \in \mathbb{Z} \setminus \{0, 1, \ldots, N\}$. Then 2 is an eigenvalue of the matrices $\mathbf{W}_N$, $\mathbf{W}_{N-1}$, and $\mathbf{W}_N^+$, the vector $[1, \ldots, 1]^t \in \mathbb{C}^{2N+1}$ (or $\mathbb{C}^{2N-1}$) is a 2-eigenvector of $\mathbf{W}_N$ ($\mathbf{W}_{N-1}$, respectively), and $[1, 2, \ldots, 2]^t \in \mathbb{C}^{N+1}$ is a 2-eigenvector for $\mathbf{W}_N^+$.*

Proof. Note that the sum of each row of $\mathbf{W}_N$ is 2. Hence 2 is an eigenvalue; the corresponding eigenvector is $[1, 1, \ldots, 1]^t$ and Proposition 2.1 implies that 2 is also an eigenvalue of $\mathbf{W}_N^+$ with eigenvector $[1, 2, \ldots, 2]^t$.

3. The autocorrelation function. Let L_c^2 denote the set of all L^2-functions with compact supports. We call the solution of (1.1) a *scaling function*. It is well known that if $f \in L^1(\mathbb{R})$, then $\operatorname{supp} f \subseteq [0, N]$. For convenience, we assume that the c_n's are real, where $c_n = 0$ for all $n \in \mathbb{Z} \setminus \{0, 1, \ldots, N\}$, so that the solution is also real. Note that $\sum c_n = 2^m$, where $m \geq 1$ is a necessity condition for the existence of an L^1-solution f; if $m > 1$, then f is the $(m-1)$th derivative of another L^1-scaling function corresponding to the coefficients $\{2^{-(m-1)} c_n\}$ [DL1]. We will assume, without loss of generality, that $\sum c_n = 2$ throughout the paper.

For $g : \mathbb{R} \to \mathbb{R}$, we define

$$(Sg)(x) = \sum_{n=0}^{N} c_n g(2x - n).$$

It is easy to show that if $\operatorname{supp} g \subseteq [0, N]$, then $\operatorname{supp}(Sg) \subseteq [0, N]$ also. For each such g, we let

$$a_n(g) = \int_{-\infty}^{\infty} g(t + n) g(t) dt, \quad n \in \mathbb{Z},$$

be the nth autocorrelation of g defined on $\mathbb{Z}$. It is clear that $a_n(g) = a_{-n}(g)$ and $a_n(g) = 0$ for all $|n| \geq N$. By slightly abusing notations, we use $\mathbf{a}(g)$ to denote the autocorrelation vectors of g:

$$\mathbf{a}(g) = [\ldots, a_{-1}(g), a_0(g), a_1(g), \ldots]^t \quad \text{or} \quad [a_{-k}(g), \ldots, a_0(g), \ldots, a_k(g)]^t,$$

depending on the situation. Let $\mathbf{e}_n$ be the vector (finitely or infinitely many entries) with 1 on the nth entry and 0 otherwise. The major property of the transition matrix $\mathbf{W}$ defined in §2 is given in the following proposition.

PROPOSITION 3.1. *Let $g \in L^2(\mathbb{R})$ be supported in $[0, N]$. Then*

$$\mathbf{a}(Sg) = \frac{1}{2}\mathbf{W}^*\mathbf{a}(g), \tag{3.1}$$

where $\mathbf{W}^*$ is the adjoint of $\mathbf{W}$. In particular,

$$\int_{-\infty}^{\infty} |(Sg)(t)|^2 dt = \frac{1}{2}\langle \mathbf{a}(g), \mathbf{W}\mathbf{e}_0\rangle = \frac{1}{2}\langle \mathbf{a}(g), \mathbf{W}_{N-1}\,\mathbf{e}_0\rangle.$$

Proof. The proof is based on the following observation: for $n \in \mathbb{Z}$,

$$\begin{aligned}
a_n(Sg) &= \int_{-\infty}^{\infty} (Sg)(t+n)(Sg)(t)\,dt \\
&= \sum_{i,j\in\mathbb{Z}} c_j c_i \int_{-\infty}^{\infty} g(2t+2n-j)g(2t-i)\,dt \\
&= \frac{1}{2}\sum_{i,j\in\mathbb{Z}} c_j c_i \int_{-\infty}^{\infty} g(t+2n+i-j)g(t)\,dt \\
&= \frac{1}{2}\sum_{k\in\mathbb{Z}}\left(\sum_{i\in\mathbb{Z}} c_i c_{i-(k-2n)}\right) a_k(g) \\
&= \frac{1}{2}\sum_{k\in\mathbb{Z}} \omega_{k-2n} a_k(g) \\
&= \frac{1}{2}[\mathbf{W}^*\,\mathbf{a}(g)]_n
\end{aligned}$$

(the second equality holds since we assume that $c_n = 0$ for all $n \in \mathbb{Z}\setminus\{0, 1, \ldots, N\}$). The last identity in the proposition holds due to the fact that $a_n(g) = 0$ for all $|n| \geq N$.

Remark. For $y \in \mathbb{R}$, if we let $a_n^{(y)}(g) = \int_{-\infty}^{\infty} g(t+n-y)g(t)dt$, then the same calculation yields

$$\mathbf{a}^{(y)}(Sg) = \frac{1}{2}\mathbf{W}^*\mathbf{a}^{(2y)}(g). \tag{3.1$'$}$$

We will use this fact in Theorem 3.7.

Recall that a sequence $\{u_n\}_{n=-\infty}^{\infty}$ is called *positive definite* if for any finite sequence $\{\xi_n\}$, $\sum u_{m-n}\xi_m\bar{\xi}_n \geq 0$. It is well known that the autocorrelation sequence $\{a_n(g)\}$ (letting $a_n(g) = 0$ for all $|n| \geq N$) is positive definite.

PROPOSITION 3.2. *Suppose f is a nonzero L_c^2-solution of* (1.1); *then* $\mathbf{a}(f)$ *is a 2-eigenvector of* $(\mathbf{W}_{N-1})^*$, $\sum a_n(f) \neq 0$, *and* $\{a_n(f)\}_{n=-\infty}^{\infty}$ *is a positive-definite sequence.*

Proof. In view of Proposition 3.1 and the remark above, we need only show that $\sum a_n(f) \neq 0$. This follows from the well-known Poisson formula $\sum a_n(f)e^{in\omega} = \sum |\hat{f}(\omega + 2\pi n)|^2$ and the sum is strictly positive for $\omega = 0$.

The existence of a vector satisfying the above conditions also implies the existence of an L^2_c-solution of (1.1), which has been observed by Villemoes in [V] (where he uses $\sum a_n(f)e^{inx} \geq 0$ instead of using the fact that $\{a_n(f)\}_{n=-\infty}^{\infty}$ is positive definite).

In order to construct the L^2_c-solution f of the dilation equation (1.1), we can formally proceed as follows: take a function g with supp$g \subseteq [0, N]$ and consider $\{S^k(g)\}_{k=1}^{\infty}$. If this sequence converges in L^2 to a function f, then f will be a solution to (1.1). Equivalently, we can write

$$S^k(g) = g + \sum_{l=0}^{k-1} S^l(Sg - g) \tag{3.2}$$

and consider the convergence of the series $\sum_{l=0}^{k-1} S^l(Sg - g)$. Let

$$\mathbf{T}_0 = [c_{2i-j-1}]_{1\leq i,j\leq N} = \begin{pmatrix} c_0 & 0 & 0 & \dots & 0 \\ c_2 & c_1 & c_0 & \dots & 0 \\ c_4 & c_3 & c_2 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \\ 0 & 0 & 0 & \dots & c_{N-1} \end{pmatrix},$$

$$\mathbf{T}_1 = [c_{2i-j}]_{1\leq i,j\leq N} = \begin{pmatrix} c_1 & c_0 & 0 & \dots & 0 \\ c_3 & c_2 & c_1 & \dots & 0 \\ c_5 & c_4 & c_3 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \\ 0 & 0 & 0 & \dots & c_N \end{pmatrix}.$$

These matrices were used in [DL1], [DL2], [CH], and [W] to study the continuous scaling solutions. In [LW1, Thm. 4.3], the authors also use such matrices to give a necessary and sufficient condition for the existence of the L^p_c-solutions; for the L^2-case, the criterion is reduced to consider the eigenvalues of $\mathbf{W}$. The proof is simplified later in Theorem 3.4. First, we state a very useful lemma concerning $\mathbf{T}_0 + \mathbf{T}_1$ which is proven in [LW1].

LEMMA 3.3. *Suppose* $\sum_{n=0}^{N} c_n = 2$. *Then the following hold:*

(i) 2 *is an eigenvalue of* $\mathbf{T}_0 + \mathbf{T}_1$.

(ii) *If* $\mathbf{v}$ *is a* 2*-eigenvector of* $\mathbf{T}_0 + \mathbf{T}_1$, *let* $g = \sum_{n=0}^{N-1} v_n \chi_{[n-1,n)}$; *then*

$$\left[\int_0^1 S^k g, \dots, \int_{N-1}^{N} S^k g\right]^t = \mathbf{v}.$$

(iii) *For* $1 \leq p < \infty$, *let* $f \in L^p_c(\mathbb{R})$ *be the* L^p_c*-solution of* (1.1) *and let* $\mathbf{v} = [\int_0^1 f, \dots, \int_{N-1}^{N} f]^t$; *then* $\mathbf{v}$ *is a* 2*-eigenvector of* $\mathbf{T}_0 + \mathbf{T}_1$. *For such* $\mathbf{v}$, *if we let* g *be defined as in* (ii), *then* $\{S^k(g)\}$ *converges back to* f *in the* L^p*-norm.*

THEOREM 3.4. *Suppose* $\sum_{n=0}^{N} c_n = 2$. *Let* $\mathbf{v}$ *be a* 2*-eigenvector of* $\mathbf{T}_0 + \mathbf{T}_1$ *and let* $g = \sum_{n=0}^{N-1} v_n \chi_{[n,n+1)}$. *Let* $H_{\mathbf{v}}$ *be the smallest invariant subspace of* $\mathbf{W}_{N-1}$ *containing* *the autocorrelation vector* $\mathbf{a}(Sg-g)$. *Then* (1.1) *has a nonzero* L_c^2*-solution if and only if all the eigenvalues of* $\mathbf{W}_{N-1}$ *restriced to* $H_{\mathbf{v}}$ *have modulus less than* 2.

Proof. Let $\tilde{g} = Sg - g$. Note that by Proposition 3.1, we have

$$\begin{aligned}\|S^l\tilde{g}\|^2 &= \int_0^N |S^l\tilde{g}(t)|^2\,dt \\ &= \frac{1}{2^l}\langle \mathbf{a}(\tilde{g}),\ \mathbf{W}_{N-1}^l\mathbf{e}_0\rangle \\ &= \langle \frac{1}{2^l}(\mathbf{W}_{N-1}^l)^*\,\mathbf{a}(\tilde{g}),\ \mathbf{e}_0\rangle.\end{aligned}$$

The assumption that $\frac{1}{2}(\mathbf{W}_{N-1})^*$ restricted on $H_{\mathbf{v}}$ has spectral radius less than 1 implies that $\{\frac{1}{2^l}(\mathbf{W}_{N-1}^l)^*\mathbf{a}(\tilde{g})\}$ converges to zero geometrically as $l \to \infty$; so does $\{\|S^l\tilde{g}\|^2\}$. Consequently, $S^k(g) = g + \sum_{l=0}^{k-1} S^l\tilde{g}$ converges in L^2. Let f be the limit. Then $f \in L_c^2(\mathbb{R})$; $f \neq 0$ because by Lemma 3.3(ii),

$$\left[\int_0^1 S^l\tilde{g}, \ldots, \int_{N-1}^N S^l\tilde{g}\right] = 0$$

so that

$$\left[\int_0^1 f, \ldots, \int_{N-1}^N f\right] = \left[\int_0^1 g, \ldots, \int_{N-1}^N g\right] = \mathbf{v} \neq \mathbf{0}.$$

To prove the converse, we observe that (3.2) and Proposition 3.1 imply that

$$\frac{1}{2^l}(\mathbf{W}^l)^*\mathbf{a}(Sg-g) = \mathbf{a}(S^l(Sg-g)) \longrightarrow 0 \quad \text{as} \quad l \longrightarrow \infty.$$

It follows that all the eigenvalues of $\mathbf{W}_{N-1}$ restricted to $H_{\mathbf{v}}$ have modulus less than 2.

For the special case where $\sum_n c_{2n} = \sum_n c_{2n+1} = 1$, Theorem 3.4 yields a simple criterion for the existence of the L_c^2-solution (see also [CD, Thm. 3.3]). We need to make use of the following simple facts.

LEMMA 3.5. *Suppose* $\sum_n c_{2n} = \sum_n c_{2n+1} = 1$.

(i) *Let* $\mathbf{v} = [v_0, v_1, \ldots, v_{N-1}]^t$ *and let* $g = \sum_{n=0}^{N-1} v_n\chi_{[n,n+1)}$. *Then for any* $k \in \mathbb{N}$ *and for almost all* $x \in [0,1)$,

$$\sum_{n=0}^{N-1} S^k g(x+n) = \sum_{n=0}^{N-1} v_n.$$

(ii) *Let* $H = \{\mathbf{u} \in \mathbb{C}^{2N-1} : \sum_{n=-(N-1)}^{N-1} u_n = 0\}$. *Then* $(\mathbf{W}_{N-1})^*$ *is invariant on* H.

Proof. The proofs of (i) and (ii) are quite similar. For (i), we make use of the fact that $[1, \ldots, 1]$ is a left 1-eigenvector of $\mathbf{T}_0$ and $\mathbf{T}_1$ (see,e.g., [H]). To prove (ii), note that $[1, 1, \ldots, 1]^t$ is a 2-eigenvector of $\mathbf{W}_{N-1}$ (Proposition 2.2); hence for $\mathbf{u} \in H$,

$$[1,1,\ldots,1]\,(\mathbf{W}_{N-1})^*\,\mathbf{u} = 2\,[1,1,\ldots,1]\,\mathbf{u} = 2\sum_{n=-(N-1)}^{N-1} u_n = 0.$$

This implies that the sum of the coordinates of $(\mathbf{W}_{N-1})^* \mathbf{u}$ is zero so that $(\mathbf{W}_{N-1})^*$ is invariant on H.

COROLLARY 3.6. *Suppose $\sum c_{2n} = \sum c_{2n+1} = 1$. If the eigenvalues of $(\mathbf{W}_{N-1})^*$ restricted on H have moduli less than 2, then* (1.1) *has an L^2_c-solution.*

Proof. Let $\mathbf{v} = [v_0, v_1, \ldots, v_{n-1}]^t$ be a 2-eigenvector of $\mathbf{T}_0 + \mathbf{T}_1$ as in Theorem 3.4. Then Lemma 3.5 implies that $\sum_{n=0}^{N-1} \tilde{g}(x+n) = 0$ for almost all $x \in [0,1)$. Since supp$g \subseteq [0,N]$, we actually have $\sum_{n=-\infty}^{\infty} \tilde{g}(x+n) = 0$ for almost all $x \in [0,1)$ and hence for almost all $x \in \mathbb{R}$. Therefore,

$$\begin{aligned}\sum_{|n|\le N-1} \mathbf{a}_n(\tilde{g}) &= \sum_{n=-\infty}^{\infty} \mathbf{a}_n(\tilde{g}) \\ &= \sum_{n=-\infty}^{\infty} \int_0^N \tilde{g}(t+n)\tilde{g}(t)\,dt \\ &= \int_0^N \left(\sum_{n=-\infty}^{\infty} \tilde{g}(t+n) \right) \tilde{g}(t)\,dt \\ &= 0,\end{aligned}$$

and $\mathbf{a}(\tilde{g}) \in H$. This implies that the subspace $H_{\mathbf{v}}$ in Theorem 3.4 is contained in H. By assumption, $\frac{1}{2}(\mathbf{W}_{N-1})^*$ restricted on H has spectral radius less than 1, and Theorem 3.4 applies.

In [LW1, Prop. 4.6], it is proven that the converse of the above corollary is also true if we assume that 2 is a simple eigenvalue of $\mathbf{W}_{N-1}$ and $\{\mathbf{W}^l_{N-1}\mathbf{e}_1\}$ generates $\mathbb{C}^{2N-1}$; for the four-coefficient case (N=3), the above additional assumptions are always true except for the case $c_0 = c_3 = 1$. By using a long and rather complicated argument Cohen and Daubechies [CD, Thm. 4.3] also showed that the converse is true if f has the Riesz-basis property. In the following, we will give a short proof of their theorem.

Recall that a function $f \in L^2(\mathbb{R})$ is said to satisfy the *Riesz-basis property* if the sequence of functions $f_n = f(\cdot - n), n \in \mathbb{Z}$ forms a Riesz-basis for the closure of its linear span in $L^2(\mathbb{R})$, i.e., there exist $C_1, C_2 > 0$ such that

$$C_1 \sum |\alpha_n|^2 \le \|\sum \alpha_n f_n\|^2 \le C_2 \sum |\alpha_n|^2.$$

Cohen [C], Lawton [La], and Villemoes [V] have given different criteria for such a property in terms of the Fourier transformation. In particular, Villemoes showed that if an L^2_c-solution f has the Riesz-basis property, then $\sum c_{2n} = \sum c_{2n+1} = 1$. Also, assuming such a summing condition, f has the Riesz-basis property if and only if $\sum a_n(f)e^{in\omega}$ is strictly positive.

THEOREM 3.7. *Suppose f is a solution of* (1.1) *and has the Riesz-basis property. Then $(\mathbf{W}_{N-1})^*$ restricted on H has spectral radius less than* 2.

Proof. Since f has the Riesz-basis property, then $\sum c_{2n} = \sum c_{2n+1} = 1$ [V] so that $(\mathbf{W}_{N-1})^*$ is invariant on H. All eigenvalues of $(\mathbf{W}_{N-1})^*$ have moduli less than or equal to 2 (see Propositon 5.3 in §5). The proof will be complete if we show that $(\mathbf{W}_{N-1})^*$ does not have another 2-eigenvector other than $\mathbf{a}(f)$, which is not in H.

Note that $\sum a_n(f)e^{in\omega} = \sum |\hat{f}(\omega + 2\pi k)|^2 > 0$ by the Riesz-basis property. Suppose $\mathbf{u}$ is another 2-eigenvector of $(\mathbf{W}_{N-1})^*$. By letting $u_n = 0$ for all $|n| \ge N$, $\mathbf{u}$ is a 2-eigenvector of $\mathbf{W}^*$. By Wiener's theorem, there exists $\{r_n\}_{n=-\infty}^{\infty} \in \ell^1$ such that

$$\sum r_n e^{in\omega} = \frac{\sum u_n e^{in\omega}}{\sum a_n(f)e^{in\omega}}.$$

It follows that $\mathbf{u} = \mathbf{r} * (\mathbf{a}(f))$ and

$$\begin{aligned} u_n &= \lim_{l\to\infty} \frac{1}{2^l}\langle(\mathbf{W}^*)^l\mathbf{u},\, \mathbf{e}_n\rangle \\ &= \lim_{l\to\infty} \frac{1}{2^l}\sum_k \langle r_k(\mathbf{W}^*)^l\mathbf{a}^{(k)}(f),\, \mathbf{e}_n\rangle \\ &= \lim_{l\to\infty} \sum_k \langle r_k\mathbf{a}^{(2^{-l}k)}(f),\, \mathbf{e}_n\rangle & \text{(use (3.1)')} \\ &= \sum_k r_k \,\langle \lim_{l\to\infty} \mathbf{a}^{(2^{-l}k)}(f),\, \mathbf{e}_n\rangle \\ &= C\,\langle\mathbf{a}(f),\, \mathbf{e}_n\rangle, \end{aligned}$$

where $C = \sum_k r_k$. This implies that $\mathbf{u}$ is a scalar multiple of $\mathbf{a}(f)$ and the proof is complete.

Remark. The above discussion gives a simple criterion for computer to check for the Riesz-basis property of the solution f given $\{c_n\}_{n=0}^{N}$ with $\sum c_{2n} = \sum c_{2n+1} = 1$: first show that the 2-eigenvalue of $(\mathbf{W}_{N-1})^*$ is simple and all other eigenvalues are less than 2 in modulus (this implies the existence of the solution by Corollary 3.6 and $\sum a_n(f)e^{in\omega} \geq 0$ by Proposition 3.2), and then show that the polynomial $\frac{1}{2}\sum a_n(f)z^n$ has no root on the unit circle.

4. Some lemmas. In the rest of the paper, we will use the difference quotient $\frac{1}{h^{2\beta}}\int_{-\infty}^{\infty}|\Delta_h f(t)|^2dt$ to study the regularity properties of the scaling function f. We prefer to use the matrix $\mathbf{W}_N^+$ rather than $\mathbf{W}_N$ because using the latter, we have to discard those eigenvalues which only give antisymmetric eigenvectors (see the remark for Proposition 2.1 and Lemma 4.3). As before, we assume that $\sum c_n = 2$. For $h \in \mathbb{R}$ and $n \in \mathbb{Z}$, we also define

$$\Phi_n(h) = \int_{-\infty}^{\infty} \Delta_h f(t+n)\Delta_h f(t)dt.$$

Since f is supported by $[0, N]$,

$$\Phi_n(h) = 0 \quad \forall\, 0 < h < 1,\ |n| \geq N+1. \tag{4.1}$$

We use $\mathbf{\Phi}(h)$ to denote

$$[\Phi_0(h), \Phi_1(h), \ldots, \Phi_N(h)]^t \quad\text{and}\quad [\Phi_0(h), \Phi_1(h), \ldots]^t.$$

If necessary, we will add the superscript N or ∞ to $\mathbf{\Phi}(h)$ to make the distinction. It is clear that $\Delta_h f$ satisfies

$$\Delta_h f(x) = \sum_{n=0}^{N} c_n \Delta_{2h} f(2x-n). \tag{4.2}$$

PROPOSITION 4.1. *Let* $\mathbf{W}$ *be the transition matrix corresponding to the scaling function* f *satisfying* (1.1). *Then for* $\mathbf{u} = [u_0, u_1, \ldots, u_N]^t \in \mathbb{C}^{N+1}$,

$$\langle \mathbf{\Phi}(h), \mathbf{u}\rangle = \frac{1}{2}\langle \mathbf{\Phi}(2h), \mathbf{W}_N^+ \mathbf{u}\rangle, \quad 0 < h < \frac{1}{2}. \tag{4.3}$$

Proof. The proof is basically the same as that of Proposition 3.1, using (4.2) instead of (1.1). For $0 \le n \le N$,

$$\begin{aligned}\Phi_n(h) &= \int_{-\infty}^{\infty} \Delta_h f(t+n)\Delta_h f(t)\, dt \\ &= \sum_{i,j\in\mathbb{Z}} c_j c_i \int_{-\infty}^{\infty} \Delta_{2h} f(2t+2n-j)\Delta_{2h} f(2t-i)\, dt \\ &\ \vdots \\ &= \frac{1}{2}[\mathbf{W}^* \mathbf{G}^*(\mathbf{\Phi}(2h))]_n \\ &= \frac{1}{2}[(\mathbf{W}_N^+)^*(\mathbf{\Phi}(2h))]_n.\end{aligned}$$

LEMMA 4.2. *If* $\mathbf{u}$ *is a* 2*-eigenvector or a* 0*-eigenvector of* $\mathbf{W}_N^+$, *then*

$$\langle \mathbf{\Phi}(h), \mathbf{u}\rangle = 0 \qquad \forall\ 0 < h < 1.$$

Proof. Let $\mathbf{u}$ be a 2-eigenvector of $\mathbf{W}_N^+$. We have, by (4.3), $\langle \mathbf{\Phi}(\frac{h}{2}), \mathbf{u}\rangle = \langle \mathbf{\Phi}(h), \mathbf{u}\rangle$. for all $0 < h < 1$. Hence, inductively,

$$\langle \mathbf{\Phi}(h), \mathbf{u}\rangle = \left\langle \mathbf{\Phi}\left(\frac{h}{2^2}\right), \mathbf{u}\right\rangle = \cdots = \left\langle \mathbf{\Phi}\left(\frac{h}{2^m}\right), \mathbf{u}\right\rangle$$

for all $0 < h < 1$, $m \ge 0$. But $\langle \mathbf{\Phi}(\frac{h}{2^m}), \mathbf{u}\rangle \to 0$ as $m \to \infty$, so it follows that $\langle \mathbf{\Phi}(h), \mathbf{u}\rangle = 0$ for all $0 < h < 1$. The same conclusion also holds if $\mathbf{u}$ is a 0-eigenvector since in such a case $\mathbf{W}_N^+ \mathbf{u} = 0$.

Our main lemma is the following.

LEMMA 4.3. *If* $\mathbf{u}$ *is a* λ*-eigenvector of* $\mathbf{W}_N^+$ *with* $\lambda \ne 0$ *or* 2, *then*

$$\langle \mathbf{\Phi}(h), \mathbf{u}\rangle \ne 0 \qquad \textit{for some } 0 < h < \frac{1}{2}.$$

The proof of this lemma is rather long. The basic idea is to prove by contradiction. Suppose otherwise, i.e., $\psi(h) = \langle \mathbf{\Phi}(h), \mathbf{u}\rangle = 0$ for all $0 < h < \frac{1}{2}$. We show that when $\mathbf{u}$ is replaced by the corresponding λ-eigenvector $\tilde{\mathbf{u}}$ for $\mathbf{W}^+$ (Lemma 4.4) and the inner product in $\psi(h)$ is acting on all positive coordinates, then the identity holds for all $h \in \mathbb{R}$. From this we deduce that the corresponding sequence $\{u_n\}$ is a linear combination of certain exponential sequences of the form $\{e^{ian}\}$. However, the eigenproperty of $\{u_n\}$ implies that this is impossible.

For this purpose, we first observe that for $h \in \mathbb{R}$,

$$\begin{aligned}\Phi_n(h) &= \int_{-\infty}^{\infty} \Delta_h f(t+n)\Delta_h f(t)\, dt \\ &= \int_{-\infty}^{\infty} (f(t+n+h) - f(t+n))(f(t+h) - f(t))\, dt.\end{aligned}$$

Multiplying out the integrand and changing the variables, we obtain

$$\Phi_n(h) = 2a_n(f) - \Psi_n(h), \tag{4.4}$$

where

$$\Psi_n(h) = \int_{-\infty}^{\infty} [f(t+h-n) + f(t+h+n)]f(t)\,dt$$

and $a_n(f)$ is the nth autocorrelation. We let

$$\mathbf{\Psi}^N(h) = [\Psi_0(h), \Psi_1(h), \ldots, \Psi_N(h)]^t \quad \text{and} \quad \mathbf{\Psi}^\infty(h) = [\Psi_0(h), \Psi_1(h), \ldots]^t.$$

Note that $[a_0(f), a_1(f), \ldots, a_N(f)]^t$ is a 2-eigenvector of $(\mathbf{W}_N^+)^*$ (use Proposition 3.2 and (2.2)). It is orthogonal to any λ-eigenvector $\mathbf{u}$ of $\mathbf{W}_N^+$ with $\lambda \neq 2$. For such $\mathbf{u}$, (4.4) implies that

$$\langle \mathbf{\Phi}^N(h), \mathbf{u}\rangle = -\langle \mathbf{\Psi}^N(h), \mathbf{u}\rangle, \quad h \in \mathbb{R}. \tag{4.5}$$

Let $\mathcal{S}$ be the class of all one-sided infinite sequences.

LEMMA 4.4. *If* $\mathbf{u}$ *is a* λ*-eigenvector of* $\mathbf{W}_N^+$ *with* $\lambda \neq 0$, *then there exists* $\tilde{\mathbf{u}} \in \mathcal{S}$, *a* λ*-eigenvector of* $\mathbf{W}^+$ *such that* $\tilde{u}_n = u_n$ *for all* $0 \le n \le N$. *Furthermore, for such a* $\tilde{\mathbf{u}}$,

$$\langle \mathbf{\Psi}^\infty(h), \tilde{\mathbf{u}}\rangle = \langle \mathbf{\Psi}^N(h), \mathbf{u}\rangle, \quad 0 < h < \frac{1}{2}.$$

Proof. Let $\mathbf{u} = [u_0, u_1, \ldots, u_N]^t$ be a λ-eigenvector of $\mathbf{W}_N^+$ with $\lambda \neq 0$. Note that for $i > 0$,

$$w_{ij}^+ = \omega_{i-2j} + \omega_{-i-2j}.$$

Since $\omega_n = 0$ for all $|n| > N$ and $N < i \le j$, $-i-2j < i-2j < -N$, we hence have $w_{ij}^+ = 0$ for all $N < i \le j$. We now construct $\tilde{\mathbf{u}}$ as follows: let $\tilde{u}_n = u_n$ for all $0 \le n \le N$ and define $\tilde{u}_{n+1}$ inductively as

$$\tilde{u}_{n+1} = \frac{1}{\lambda}\sum_{k=0}^{n} w_{n+1,k}^+ \tilde{u}_k, \quad n \ge N. \tag{4.6}$$

Then $\tilde{\mathbf{u}}$ is the required vector. The last assertion follows from the fact that for $0 < h < \frac{1}{2}$, $\Psi_n(h) = 0$ for all $n > N$.

In [Sch] (see also [K], [RL]), L. Schwartz proved the following classical result on *mean periodic functions*: Let μ be a bounded regular Borel measure on $\mathbb{R}$ with compact support. Let $\mathcal{C}$ be the class of continuous functions on $\mathbb{R}$ equipped with the compact open topology. Suppose there exists a nonzero $g \in \mathcal{C}$ that satisfies the convolution equation

$$\int_{-\infty}^{\infty} g(x-y)d\mu(y) = 0 \qquad \forall\, x \in \mathbb{R}.$$

Then g belongs to the closed linear subspace spanned by

$$\{e^{ia(\cdot)} : a \in \mathbb{C}, \int_{-\infty}^{\infty} e^{-iay}d\mu(y) = 0\}.$$

Heuristically, the convolution equation implies that $\hat{g}(z)\hat{\mu}(z) = 0$ (in the distribution sense). Since μ has compact support, $\hat{\mu}$ is an entire function and has only countably many discrete zeros. It follows that the support of $\hat{g}$ must be contained in the zeros of $\hat{\mu}$, and g is of the form asserted. We need the discrete version, which is an easy corollary of the above theorem: if $\{w_n\}_{n=-\infty}^{\infty}$ is a given sequence with only finitely many nonzero terms and if $\{x_n\}_{n=-\infty}^{\infty}$ is any sequence satisfying

$$\sum_{k=-\infty}^{\infty} x_{n-k}w_k = 0 \quad \forall\, n \in \mathbb{Z},$$

then $\{x_n\}_{n=-\infty}^{\infty}$ belongs to the closed (with respect to the product topology) linear subspace spanned by

$$\{\{e^{ian}\} : a \in \mathbb{C},\ \sum_{n=-\infty}^{\infty} e^{-ian}w_n = 0\}.$$

LEMMA 4.5. *Let* $\tilde{\mathbf{u}}$ *be a* λ*-eigenvector of* $\mathbf{W}^+$ *with* $\lambda \neq 0$ *or* 2. *Then*

$$\langle \mathbf{\Psi}^\infty(h), \tilde{\mathbf{u}}\rangle \neq 0 \qquad \textit{for some } 0 < h < \frac{1}{2}.$$

Proof. By Proposition 4.1, Lemma 4.4, and (4.5), we have for any $\mathbf{v} \in \mathcal{S}$,

$$\langle \mathbf{\Psi}^\infty(h), \mathbf{v}\rangle = \frac{1}{2}\langle \mathbf{\Psi}^\infty(2h), \mathbf{W}^+\mathbf{v}\rangle \quad \forall\, h \in \mathbb{R}. \tag{4.7}$$

For any fixed h, $\Psi_n(h) = 0$ for all large n; hence $\langle \mathbf{\Psi}^\infty(h), \tilde{\mathbf{u}}\rangle$ is well defined and is continuous on h. Suppose the lemma is false, i.e.,

$$\langle \mathbf{\Psi}^\infty(h), \tilde{\mathbf{u}}\rangle = 0 \qquad \forall\, 0 < h < \frac{1}{2}. \tag{4.8}$$

By (4.7), we have

$$0 = \langle \mathbf{\Psi}^\infty(h), \tilde{\mathbf{u}}\rangle = \frac{1}{2}\langle \mathbf{\Psi}^\infty(2h), \mathbf{W}^+\tilde{\mathbf{u}}\rangle = \frac{\lambda}{2}\langle \mathbf{\Psi}^\infty(2h), \tilde{\mathbf{u}}\rangle.$$

The assumption that $\lambda \neq 0$ implies that $\langle \mathbf{\Psi}^\infty(2h), \tilde{\mathbf{u}}\rangle = 0$ for all $0 < h < \frac{1}{2}$, i.e., (4.8) holds for all $0 < h < 1$. Repeating the same argument, we have that (4.8) holds for all $h > 0$ and hence for all $h \in \mathbb{R} \setminus \{0\}$ since $\mathbf{\Psi}^\infty(-h) = \mathbf{\Psi}^\infty(h)$. By continuity, we also have $\langle \mathbf{\Psi}^\infty(0), \tilde{\mathbf{u}}\rangle = 0$. We hence conclude that

$$\sum_{k=0}^{\infty} \tilde{u}_k \left(f * \tilde{f}(h-k) + f * \tilde{f}(h+k)\right) = 0 \qquad \forall\, h \in \mathbb{R},$$

where $\tilde{f}(x) = f(-x)$. By letting $x_0 = 2u_0$, $x_n = x_{-n} = \tilde{u}_n$ for $n > 0$, and by replacing h with $h + n$, $0 \leq h < 1$, we can rewrite the above as

$$\sum_{k=-\infty}^{\infty} x_{n-k} f * \tilde{f}(h+k) = 0 \qquad \forall\, n \in \mathbb{Z},\ h \in [0, 1).$$

Note that the autocorrelation function $f * \tilde{f}$ is continuous and has compact support. For each fixed $h \in [0,1)$, if we regard the sequence $\{f * \tilde{f}(h+n)\}$ as the $\{w_n\}$ in the above digression, then $\{x_n\}_{n=-\infty}^{\infty}$ must be in the closed linear subspace spanned by

$$A_h = \{\{e^{ian}\} : a \in \mathbb{C}, \sum_{n=-\infty}^{\infty} f * \tilde{f}(h+n)e^{-ian} = 0\}.$$

Since this is true for all $h \in [0,1)$, $\{x_n\}_{n=-\infty}^{\infty}$ must be in the closed linear subspace spanned by $\bigcap_{h\in[0,1)} A_h$. By using the Poisson summation formula ([Ch, p. 47]), we have

$$\begin{aligned} 0 &= \sum_{n=-\infty}^{\infty} f * \tilde{f}(h+n)e^{-ina} \\ &= \sum_{n=-\infty}^{\infty} \hat{f}(a+2\pi n)\hat{f}(-(a+2\pi n))e^{ih(a+2\pi n)} \\ &= e^{iha} \sum_{n=-\infty}^{\infty} \hat{f}(a+2\pi n)\hat{f}(-(a+2\pi n))e^{i2\pi nh} \end{aligned}$$

for all $h \in [0,1)$. This implies that

$$\hat{f}(a+2\pi n)\hat{f}(-(a+2\pi n)) = 0 \quad \forall n \in \mathbb{Z}.$$

Observe that the Fourier transformation of (1.1) is $\hat{f}(z) = \hat{f}(\frac{z}{2})m_0(\frac{z}{2})$, where $m_0(z) = \frac{1}{2}\sum c_n e^{inz}$ is a trigonometric polynomial of degree N. Let $F(z) = \hat{f}(z)\hat{f}(-z)$, $Q(e^{iz}) = m_0(z)m_0(-z)$. Since $F \neq 0$ in a neighborhood of 0, we conclude from $0 = F(a) = F(\frac{a}{2})Q(e^{ia/2})$ that for some l, $e^{ia/2^l}$ must be a root of Q. Hence the sequence $\{x_n\}_{n=-\infty}^{\infty}$ is in the close linear span of all the sequences of the form

$$\{\{e^{ian}\} : e^{ia/2^l} \text{ is a root of } Q(z) \text{ for some } l\}. \tag{4.9}$$

Now, by a direct calculation,

$$[\mathbf{W}(e^{ia(\cdot)})]_n = \sum_{k=-\infty}^{\infty} w_{n-2k}e^{iak} = 2^2 e^{ian/2}Q(e^{ia/2}).$$

This implies that for some l,

$$\mathbf{W}^l(e^{ia(\cdot)}) = 2^{2l}e^{ia(\cdot)/2^l}Q(e^{ia/2^l}) = 0. \tag{4.10}$$

On the other hand, in view of Lemma 4.4, the vector $\mathbf{x} = [\ldots, x_{-1}, x_0, x_1, \ldots]$ satisfies $\mathbf{W}\mathbf{x} = \lambda\mathbf{x}$. This is a contradiction since $\{x_n\}_{n=-\infty}^{\infty}$ is a combination of the sequences $\{e^{ian}\}_{n=-\infty}^{\infty}$ in (4.9), and (4.10) implies that $\mathbf{x}$ can not be an eigenvector.

Proof of Lemma 4.3. Suppose that $\mathbf{u}$ is an λ-eigenvector of $\mathbf{W}_N^+$ with $\lambda \neq 0$ or 2. By Lemma 4.4, there exists $\tilde{\mathbf{u}} \in \mathcal{S}$ such that $\mathbf{W}^+\tilde{\mathbf{u}} = \lambda\tilde{\mathbf{u}}$ and $\tilde{u}_n = u_n$ for all $0 \le n \le N$. By Lemma 4.5, we have $\langle \mathbf{\Psi}^\infty(h), \tilde{\mathbf{u}}\rangle \neq 0$ for some $0 < h < \frac{1}{2}$. For such h,

$$\begin{aligned} \langle \mathbf{\Phi}^N(h), \mathbf{u}\rangle &= -\langle \mathbf{\Psi}^N(h), \mathbf{u}\rangle && \text{(by (4.5))} \\ &= -\langle \mathbf{\Psi}^\infty(h), \tilde{\mathbf{u}}\rangle \\ &\neq 0. \end{aligned}$$

5. The L^2-Lipschitz exponent and asymptotics. For any $\beta \in \mathbb{C}$, we let

$$\mathbf{\Phi}^{(\beta)}(h) = \frac{1}{h^{2\beta}}\mathbf{\Phi}(h).$$

LEMMA 5.1. *Let $\lambda \neq 0, 2$ be an eigenvalue of $\mathbf{W}_N^+$, let $\beta = -\ln(\lambda/2)/(2\ln 2)$ (i.e., $\lambda/2^{1-2\beta} = 1$ and β takes the principal branch when λ is complex), and let $\hat{\mathbf{u}}$ be the corresponding eigenvector. Then*

$$\langle \mathbf{\Phi}^{(\beta)}(2h), \hat{\mathbf{u}}\rangle = \langle \mathbf{\Phi}^{(\beta)}(h), \hat{\mathbf{u}}\rangle \quad \forall\, 0 < h < \frac{1}{2}.$$

Proof. Let $\phi(h) = \langle \mathbf{\Phi}^{(\beta)}(h), \hat{\mathbf{u}}\rangle$. By Proposition 4.1, we have for $0 < h < \frac{1}{2}$,

$$\begin{aligned}\langle \mathbf{\Phi}^{(\beta)}(h), \hat{\mathbf{u}}\rangle &= \frac{1}{h^{2\beta}}\langle \mathbf{\Phi}(h), \hat{\mathbf{u}}\rangle \\ &= \frac{1}{2^{1-2\beta}} \cdot \frac{1}{(2h)^{2\beta}}\langle \mathbf{\Phi}(2h), \mathbf{W}_N^+\hat{\mathbf{u}}\rangle \\ &= \frac{\lambda}{2^{1-2\beta}}\langle \mathbf{\Phi}^{(\beta)}(2h), \hat{\mathbf{u}}\rangle.\end{aligned}$$

By the choice of β, we have $\phi(h) = \phi(2h)$ for all $0 < h < \frac{1}{2}$.

Recall that if $\mathbf{M}$ is a matrix on a vector space V with characteristic polynomial $p(x) = (x - \lambda_1)^{\ell_1} \cdots (x - \lambda_k)^{\ell_k}$ and minimal polynomial $q(x) = (x - \lambda_1)^{m_1} \cdots (x - \lambda_k)^{m_k}$, then $V = V_1 \oplus \cdots \oplus V_k$, each V_i has dimension ℓ_i, $\mathbf{M}$ is invariant on V_i, and $(\mathbf{M} - \lambda_i\mathbf{I})^{m_i}V_i = 0$ (m_i is called the *order* of λ_i). Moreover, according to the Jordan decomposition theorem,

$$V_i = U_{i1} \oplus \cdots \oplus U_{ir_i},$$

where each $s_{ij} := \dim U_{ij} \leq m_i$, with at least one of the $s_{ij} = m_i$; each U_{ij} is generated by

$$\mathbf{u}_1 = \mathbf{u},\ \mathbf{u}_2 = (\mathbf{M} - \lambda_i\mathbf{I})\mathbf{u}, \ldots,\ \mathbf{u}_{s_{ij}} = (\mathbf{M} - \lambda_i\mathbf{I})^{s_{ij}-1}\mathbf{u} \tag{5.1}$$

and $(\mathbf{M}-\lambda_i\mathbf{I})^{s_{ij}}\mathbf{u} = 0$ for some $\mathbf{u}$. Note that the last vector in (5.1) is a λ_i-eigenvector of $\mathbf{M}$.

Lemma 5.1 can be strengthened as follows.

THEOREM 5.2. *Let $\lambda \neq 0, 2$ be an eigenvalue of $\mathbf{W}_N^+$ and let $\beta = -\ln(\lambda/2)/(2\ln 2)$. Suppose there exists an m such that $(\mathbf{W}_N^+ - \lambda\mathbf{I})^{m-1}\mathbf{u} \neq \mathbf{0}, (\mathbf{W}_N^+ - \lambda\mathbf{I})^m\mathbf{u} = \mathbf{0}$. Then*

$$\langle \mathbf{\Phi}^{(\beta)}(h), \mathbf{u}\rangle = \sum_{k=1}^{m}(\ln h)^{k-1}p_k(h), \quad 0 < h < \frac{1}{2}, \tag{5.2}$$

where $p_k(h) = p_k(2h)$ for all $h > 0$ and $p_m \neq 0$. In particular, if $m = 1$, then $\langle \mathbf{\Phi}^{(\beta)}(h), \mathbf{u}\rangle = p_1(h)$.

Proof. Let

$$\mathbf{u}_m = \mathbf{u}, \ldots,\ \mathbf{u}_1 = (\mathbf{W}_N^+ - \lambda\mathbf{I})^{m-1}\mathbf{u}$$

and let $\phi_k(h) = \langle \mathbf{\Phi}^{(\beta)}(h), \mathbf{u}_k\rangle$. Note that $\mathbf{u}_1$ is a λ-eigenvector of $\mathbf{W}_N^+$. Hence by Lemma 4.3, $\phi_1 \neq 0$, and Lemma 5.1,

$$\phi_1(h) = \phi_1(2h) \qquad \forall\, 0 < h < \frac{1}{2}.$$

Let $g_1(h) = \phi_1(h)$. For $\mathbf{W}_N^+\mathbf{u}_2 = \lambda\mathbf{u}_2 + \mathbf{u}_1$, by the same argument as in Lemma 5.1, we have

$$\phi_2(h) = \phi_2(2h) + \frac{1}{\lambda}\phi_1(2h).$$

Let $g_2(h) = \phi_2(h) + \frac{\ln h}{\lambda \ln 2} g_1(h)$. Then

$$\phi_2(h) = g_2(h) - \frac{\ln h}{\lambda \ln 2} g_1(h),$$

and for $0 < h < \frac{1}{2}$,

$$\begin{aligned} g_2(h) &= \phi_2(2h) + \frac{1}{\lambda}\phi_1(h) + \frac{\ln h}{\lambda \ln 2}\, g_1(h) \\ &= \phi_2(2h) + \frac{\ln(2h)}{\lambda \ln 2} g_1(2h) \\ &= g_2(2h). \end{aligned}$$

Let $g_3(h) = \phi_3(h) + \frac{\ln h}{\lambda \ln 2} g_2(h) - \frac{(\ln h)(\ln(2h))}{2(\lambda \ln 2)^2} g_1(h)$. Then by a similar argument as above, we have

$$g_3(h) = g_3(2h) \qquad \forall\, 0 < h < \frac{1}{2}.$$

Inductively, we can find g_j, $1 \le j \le m$, such that $g_j(h) = g_j(2h)$ for $0 < h < \frac{1}{2}$ and

$$\phi_j(h) = g_j(h) + \sum_{k=1}^{j-1} \frac{(-1)^{j-k}}{(j-k)!\,(\lambda \ln 2)^{j-k}} \left(\prod_{l=1}^{j-k} \ln(2^{l-1}h) \right) g_k(h).$$

For $j = m$, we group those terms with $(\ln h)^k$ together and denote the corresponding coefficient by $p_k(h)$. Then p_k satisfies the periodic condition, and $p_m(h) = c\phi_1(h) \neq 0$. If we extend p_k by $p_k(h) = p_k(2h)$ to all h, the theorem follows.

Now, we define

$$\Lambda_{\max} = \max\{|\lambda| : \lambda \text{ is an eigenvalue of } \mathbf{W}_N^+ \text{ and } |\lambda| \neq 2\}.$$

PROPOSITION 5.3. *Suppose f is an L_c^2-solution of* (1.1). *Then* $\frac{1}{2} \le \Lambda_{\max} < 2$.

Proof. We first claim that $\Lambda_{\max} < 2$. Otherwise, let λ be an eigenvalue with $|\lambda| > 2$ and let $\mathbf{u}$ be a corresponding eigenvector. By using Proposition 4.1, we have

$$\left\langle \mathbf{\Phi}\left(\frac{h}{2^m}\right), \mathbf{u} \right\rangle = \left(\frac{\lambda}{2}\right)^m \langle \mathbf{\Phi}(h), \mathbf{u} \rangle \quad \forall\, 0 < h < \frac{1}{2}.$$

By Lemma 4.3, there exists $0 < h < \frac{1}{2}$ such that $|\langle \mathbf{\Phi}(h), \mathbf{u} \rangle| \neq 0$. Hence $|\langle \mathbf{\Phi}(\frac{h}{2^m}), \mathbf{u} \rangle|$ does not tend to zero as $m \to \infty$. This is a contradiction, and the claim follows.

If $\Lambda_{\max} < \frac{1}{2}$, then for any $\mathbf{u}$ in Theorem 5.2, the corresponding β satisfies $\operatorname{Re}\beta = -\ln(|\lambda|/2)/(2\ln 2) > 1$ and hence $\limsup_{h\to 0^+} \frac{1}{h^2}|\langle \mathbf{\Phi}(h), \mathbf{u} \rangle| = 0$. Since all such $\mathbf{u}$ form a Jordan basis, it follows that

$$\limsup_{h\to 0^+} \frac{1}{h^2} \int_{-\infty}^{\infty} |\Delta_h f(t)|^2\, dt = \limsup_{h\to 0^+} \frac{1}{h^2} \langle \mathbf{\Phi}(h), \mathbf{e}_0 \rangle = 0.$$

This implies that $\sup_{h>0} \frac{1}{h^2} \int_{-\infty}^{\infty} |\Delta_h f|^2 < \infty$ so that $f' \in L^2(\mathbb{R})$ and $\int |f'|^2 = \lim_{h\to 0} \frac{1}{h^2} \int_{-\infty}^{\infty} |\Delta_h f|^2 = 0$. This implies that $f = 0$ a.e., a contradiction.

THEOREM 5.4. *Suppose f is an L^2_c-solution of the dilation equation (1.1). Let $\alpha = -\ln(\Lambda_{\max}/2)/(2\ln 2)$ and let m be the highest order of the eigenvalues λ of $\mathbf{W}_N^+$ such that $|\lambda| = \Lambda_{\max}$. Then*

$$\lim_{h\to 0^+}\left(\frac{1}{h^{2\alpha}|\ln h|^{m-1}}\int_{-\infty}^{\infty}|\Delta_h f(x)|^2dx - p(h)\right) = 0, \tag{5.3}$$

where $p(h)$ is a nonzero bounded continuous multiplicative periodic function of period 2, i.e., $p(h) = p(2h), h > 0$.

Proof. Write $\mathbf{e}_0 = \sum_i b_i\mathbf{u}_i$, where $\{\mathbf{u}_i\}$ is a Jordan basis corresponding to the matrix $\mathbf{W}_N^+$. Let λ be the eigenvalues (there may be more than one) such that $|\lambda| = \Lambda_{\max}$ and has highest order m. By Theorem 5.2 and the choice of α, the terms $|\langle\mathbf{\Phi}(h), \mathbf{u}_i\rangle|$ of the form $h^{2\alpha}|\ln h|^{m-1}p(h)$ dominate $\langle\mathbf{\Phi}(h), \mathbf{e}_0\rangle$ as $h \to 0^+$; the corresponding coefficient b_i's are not all zero since $|\langle\mathbf{\Phi}(h), \mathbf{e}_0\rangle| \geq c|\langle\mathbf{\Phi}(h), \mathbf{u}_i\rangle|$ for some $c > 0$. We hence have

$$\int_{-\infty}^{\infty}|\Delta_h f(x)|^2dx = \langle\mathbf{\Phi}(h), \mathbf{e}_0\rangle = h^{2\alpha}|\ln h|^{m-1}p(h) + \delta(h),$$

where $p(h) = p(2h)$ and $\lim_{h\to 0^+}\delta(h)/(h^{2\alpha}|\ln h|^{m-1}) = 0$, and the theorem follows.

COROLLARY 5.5. *Suppose λ is an eigenvalue of $\mathbf{W}_N^+$ such that $|\lambda| = \Lambda_{\max} = \frac{1}{2}$ and λ has order 1. Then $\lambda = \frac{1}{2}$, f is differentiable a.e., and $f \in L^2(\mathbb{R})$.*

Proof. Let $\beta = -\ln(\lambda/2)/(2\ln 2) = 1 + i\theta$ and let $\mathbf{u}$ be the λ-eigenvector. Then

$$\begin{aligned}\frac{1}{h^2}\int_{-\infty}^{\infty}|\Delta_h f(x)|^2dx &= h^{i2\theta}\langle\mathbf{\Phi}^{\beta}(h), \mathbf{u}\rangle + o(h)\\ &= h^{i2\theta}p(h) + o(h),\end{aligned}$$

where $o(h) \to 0$ as $h \to 0$ and p is bounded and $p(h) = p(2h)$. It is well known that if $\sup_{h>0}\frac{1}{h^2}\int_{-\infty}^{\infty}|\Delta_h f(x)|^2dx$ is bounded, then f' exists a.e., $f' \in L^2(\mathbb{R})$, and

$$\lim_{h\to 0^+}\frac{1}{h^2}\int_{-\infty}^{\infty}|\Delta_h f(x)|^2dx = \int_{-\infty}^{\infty}|f'(x)|^2dx.$$

This implies that $\lim_{h\to 0^+}h^{i2\theta}p(h)$ exists. In view of periodicity, we have $\theta = 0$ and $p(h) = C$, and the corollary follows.

COROLLARY 5.6. *Let f, α, and m be as in Theorem 5.4. Then*

$$\sup_{n>0}\frac{1}{n^{m-1}2^{-2n\alpha}}\int_{2^{n-1}\pi\leq|\omega|<2^n\pi}|\hat{f}(\omega)|^2d\omega < \infty.$$

Proof. By using the Plancherel Theorem, we have

$$\begin{aligned}\varphi(h) &:= \frac{1}{h^{2\alpha}|\ln h|^{m-1}}\int_{-\infty}^{\infty}|\Delta_h f(x)|^2dx\\ &= \frac{C_1}{h^{2\alpha}|\ln h|^{m-1}}\int_{-\infty}^{\infty}|\hat{f}(\omega)|^2\sin^2(h\omega/2)d\omega\\ &\geq \frac{C_2}{h^{2\alpha}|\ln h|^{m-1}}\int_{\frac{\pi}{2h}\leq|\omega|<\frac{\pi}{h}}|\hat{f}(\omega)|^2d\omega.\end{aligned}$$

Since $\varphi(h)$ is bounded by Theorem 5.4, the result follows by taking $h = 2^{-n}$.

We remark that the above corollary implies that for any $r < \alpha$, f is in the Bosov space $B_2^{r,\infty}$ in the sense used in [CD, Thm. 3.3]. It also implies that $\int_{-\infty}^{\infty} |\omega^r \hat{f}(\omega)|^2 d\omega < \infty$ for $r < \alpha$, which is proven in [V]. By using the same technique as in [CD, Thm. 5.1], we can improve a pointwise estimate of $\hat{f}(\omega)$ presented there.

COROLLARY 5.7. *Let f, α, and m be as in Theorem* 5.4 *and assume that* $\sum c_{2n} = \sum c_{2n+1} = 1$. *Then*

$$|\hat{f}(\omega)| \le \frac{C(\ln(1+|\omega|))^{(m-1)/2}}{(1+|\omega|)^\alpha}.$$

Proof. For $\omega \in [2^{n-1}\pi, 2^n\pi], n \ge 1$, the assumption on the coefficients implies that $\hat{f}(2k\pi) = 0$ [Ch]. Hence

$$\begin{aligned}|\hat{f}(\omega)|^2 &\le \int_{2^{n-1}\pi \le |\xi| \le 2^n\pi} \frac{d|\hat{f}(\xi)|^2}{d\xi} d\xi \\ &\le C_1 \left(\int |\frac{d\hat{f}(\xi)}{d\xi}|^2 d\xi\right)^{1/2} \left(\int_{2^{n-1}\pi \le |\xi| \le 2^n\pi} |\hat{f}(\xi)|^2 d\xi\right)^{1/2} \\ &\le C_2 n^{(m-1)/2} 2^{-n\alpha} \\ &\le \frac{C_3(\ln(1+|\omega|))^{(m-1)/2}}{(1+|\omega|)^\alpha}.\end{aligned}$$

We define the *L^2-Lipschitz exponent* of a function $g \in L^2(\mathbb{R})$ as

$$\alpha := L^2\text{-Lip}(g) = \inf\{\beta > 0 : 0 < \limsup_{h\to 0^+} \frac{1}{h^{2\beta}} \int_{-\infty}^{\infty} |\Delta_h g(t)|^2 \, dt\}. \tag{5.4}$$

Note that $0 < \limsup_{h\to 0^+} \frac{1}{h^2} \int_{-\infty}^{\infty} |\Delta_h g(t)|^2 \, dt$ (otherwise, we can derive a contradiction by using the argument in the last paragraph of Proposition 5.3 to show that $g = 0$ a.e.). Hence $0 \le \alpha \le 1$. Also,

$$\limsup_{h\to 0^+} \frac{1}{h^{2\beta}} \int_{-\infty}^{\infty} |\Delta_h g(t)|^2 \, dt = \begin{cases} 0 & \text{if } \beta < \alpha, \\ \infty & \text{if } \beta > \alpha. \end{cases}$$

The next corollary follows directly from Theorem 5.4.

COROLLARY 5.8. *Suppose f is an L_c^2-solution of the dilation equation* (1.1). *Let* $\alpha = -\ln(\Lambda_{\max}/2)/(2\ln 2)$. *Then* $0 < \alpha \le 1$ *is the $L^2(\mathbb{R})$-Lipschitz exponent of f.*

Corollaries 5.6 and 5.7 give certain estimates of the Fourier transform of f. In the following we consider yet another sharper estimate on the average of the Fourier transformation of the L^2-scaling function. We make use of a special form of Tauberian theorem to convert the asymptotic result in Theorem 5.4 into the frequency domain. For $\beta, \gamma \in \mathbb{R}$, let

$$\mathcal{W}_{\beta,\gamma} = \left\{ g : g \text{ loc. Riem. integ. on } \mathbb{R}^+, \sum_{k=-\infty}^{\infty} \sup_{2^k \le t < 2^{k+1}} t^\beta |\ln t|^\gamma |g(t)| < \infty \right\}.$$

The following theorem is proven in [L3, Cor. 4.5].

THEOREM 5.9. *Suppose $F \geq 0$ is measurable on $\mathbb{R}^+$ and is bounded on $[0, a)$ for some $a > 0$. Let $g \in \mathcal{W}_{\beta,\gamma}(\mathbb{R}^+), \beta > 0, \gamma \geq 0$ be such that $G(\xi) = \int_0^\infty g(t)t^{\beta-1+i\xi}dt \neq 0$ for all ξ. Then*

$$\lim_{T\to\infty}\left(\frac{1}{T^\beta(\ln T)^\gamma}\int_0^\infty F(t)g\left(\frac{t}{T}\right)dt - P(T)\right) = 0$$

if and only if

$$\lim_{T\to\infty}\left(\frac{1}{T^\beta(\ln T)^\gamma}\int_0^T F(t)dt - Q(T)\right) = 0,$$

where P and Q are bounded multiplicative periodic functions of the same period and $P \not\equiv 0$ if and only if $Q \not\equiv 0$.

THEOREM 5.10. *Suppose f is the L^2_c-solution of* (1.1) *with L^2-Lipschitz exponent $\alpha \neq 1$. Let m be the highest order of the eigenvalues λ such that $|\lambda| = \Lambda_{\max}$. Then for any s such that $\alpha < s$, there exists a bounded continuous multiplicative periodic function q such that $q(T) = q(2T)$ and*

$$\lim_{T\to\infty}\left(\frac{1}{T^{2(s-\alpha)}(\ln T)^{m-1}}\int_{-T}^T |\xi^s\hat{f}(\xi)|^2 d\xi - q(T)\right) = 0.$$

Proof. By using the Phancherel Theorem as in Corollary 5.6,

$$\begin{aligned}\varphi(h) &= \frac{1}{h^{2\alpha}|\ln h|^{m-1}}\int_{-\infty}^\infty |\hat{f}(\omega)|^2\sin^2(h\omega/2)d\omega \\ &= \frac{1}{h^{2(\alpha-s)}|\ln h|^{m-1}}\int_{-\infty}^\infty |\omega^s\hat{f}(\omega)|^2\frac{\sin^2(h\omega/2)}{|h\omega|^{2s}}d\omega.\end{aligned}$$

By letting

$$F(\omega) = |\omega^s\hat{f}(\omega)|^2 + |\omega^s\hat{f}(-\omega)|^2, \quad g(\omega) = \frac{\sin^2(\omega/2)}{|\omega|^{2s}}, \quad h = \frac{1}{T},$$

the above reduces to

$$\varphi\left(\frac{1}{T}\right) = \frac{1}{T^{2(s-\alpha)}|\ln T|^{m-1}}\int_0^\infty F(\omega)g(\frac{\omega}{T})d\omega.$$

Let $\beta = 2(s-\alpha)$. Then $g \in \mathcal{W}_{\beta,m-1}$. Indeed, for $0 < \alpha < 1$,

$$\begin{aligned}&\sum_{k=-\infty}^\infty \sup_{2^k\leq\omega<2^{k+1}} \omega^\beta|\ln\omega|^{m-1}g(\omega) \\ &= \sum_{k=-\infty}^\infty \sup_{2^k\leq\omega<2^{k+1}} |\ln\omega|^{m-1}\frac{\sin^2(\omega/2)}{\omega^{2\alpha}} \\ &\leq C\left(\sum_{k=0}^\infty |k|^{m-1}2^{-2k(1-\alpha)} + \sum_{k=0}^\infty |k|^{m-1}2^{-2\alpha k}\right) < \infty.\end{aligned}$$

Also note that for $\alpha < s$, g is integrable and

$$\begin{aligned}G(\xi) &= \int_0^\infty g(\omega)\omega^{2(s-\alpha)-1+i\xi}d\omega = \int_0^\infty \sin^2(\omega/2)\omega^{i\xi-2\alpha-1}d\omega \\ &= -\frac{\sqrt{\pi}\Gamma(-\alpha+\frac{i\xi}{2})}{4^{(\alpha+1-\frac{i\xi}{2})}\Gamma(\alpha+\frac{1}{2}-\frac{i\xi}{2})} \neq 0\end{aligned} \tag{5.5}$$

for all ξ (where $\Gamma(\xi)$ is the gamma function which has no zero and has simple poles at $\xi = 0, -1, -2, \ldots$; the calculation is by Mathematica). Hence the conditions of g in Theorem 5.9 are fulfilled. Together with Theorem 5.4, there exists a nonzero q such that $q(2T) = q(T)$ for all T, and

$$\lim_{T\to\infty}\left(\frac{1}{T^{2(s-\alpha)}(\ln T)^{m-1}}\int_{-T}^{T}|\omega^s\hat{f}(\omega)|^2 d\omega - q(T)\right) = 0.$$

6. Higher-order L^2-Lipschitz exponent. In this section, we consider the higher-order difference so that the Lipschitz exponent is allowed to be greater than 1. For any interger $l > 0$, we define the lth-order difference of a function $g \in L^2(\mathbb{R})$ by

$$\Delta_h^{(l)}f(x) = \sum_{k=0}^{l}(-1)^k\binom{l}{k}f(x-kh)$$

and the L^2-Lipschitz exponent of g by

$$\alpha := L^2\text{-Lip}(g) = \inf\left\{\beta > 0 : 0 < \limsup_{h\to 0^+}\frac{1}{h^{2\beta}}\int_{-\infty}^{\infty}|\Delta_h^{(l)}g(t)|^2\,dt\right\}. \tag{6.1}$$

It is well known that $0 \le \alpha \le l$. For $0 < \alpha < 1$, the definition used in (5.4) coincides with new definition here, but for $\alpha = 1$, the two definitions may or may not be the same. We will clarify this situation in the following. Furthermore, we show that the asymptotic properties in the last section are also preserved for higher-order cases.

For simplicity, we only consider the case $l = 2$. Let f be the L_c^2-solution of (1.1), let

$$\tilde{\Phi}_n(h) = \int_{-\infty}^{\infty}\Delta_h^{(2)}f(x+n)\Delta_h^{(2)}f(x)dx$$

and let $\tilde{\mathbf{\Phi}}(h) = [\tilde{\Phi}_0(h), \tilde{\Phi}_1(h), \ldots, \tilde{\Phi}_N(h)]$.

LEMMA 6.1. *Suppose f is the L_c^2-solution of* (1.1). *Then for any* $\mathbf{u} \in \mathbb{C}^{N+1}$,

$$\langle\tilde{\mathbf{\Phi}}(h), \mathbf{u}\rangle = C\left\langle \mathbf{\Phi}(h) - \frac{1}{4}\mathbf{\Phi}(2h), \mathbf{u}\right\rangle. \tag{6.2}$$

Proof. Let $\mathbf{u} \in \mathbb{C}^{N+1}$. Then

$$\begin{aligned}\langle\tilde{\mathbf{\Phi}}(h), \mathbf{u}\rangle &= \sum_{n=0}^{N}u_n\int_{-\infty}^{\infty}\Delta_h^{(2)}f(x+n)\Delta_h^{(2)}f(x)dx \\ &= C\sum_{n=0}^{N}u_n\int_{-\infty}^{\infty}|\hat{f}(\omega)|^2e^{in\omega}\sin^4(h\omega)d\omega\end{aligned}$$

$$= C\sum_{n=0}^{N} u_n \int_{-\infty}^{\infty} |\hat{f}(\omega)|^2 e^{in\omega} \left(\sin^2(h\omega) - \frac{1}{4}\sin^2(2h\omega)\right) d\omega$$

$$= C\langle \mathbf{\Phi}(h) - \frac{1}{4}\mathbf{\Phi}(2h), \mathbf{u}\rangle.$$

LEMMA 6.2. *Let λ be an eigenvalue of $\mathbf{W}_N^+$, $\lambda \neq 0$ or 2.*
(i) *Let* $\mathbf{u}$ *be a λ-eigenvector. Then*

$$\langle \tilde{\mathbf{\Phi}}(h), \mathbf{u}\rangle \begin{cases} \not\equiv 0 & \text{if } \lambda \neq \frac{1}{2} \\ \equiv 0 & \text{if } \lambda = \frac{1}{2}. \end{cases}$$

(ii) *Suppose $\lambda = \frac{1}{2}$ has order $m > 1$, and let* $\mathbf{u}$ *be such that $(\mathbf{W}_N^+ - \frac{1}{2}\mathbf{I})^{m-1}\mathbf{u} \neq 0$. Then*

$$\langle \tilde{\mathbf{\Phi}}(h), \mathbf{u}\rangle = \tilde{p}(h)(\ln h)^{m-2}h^2 + \delta(h), \tag{6.3}$$

where $\tilde{p}$ is a nonzero bounded continuous function with $\tilde{p}(h) = \tilde{p}(2h)$ and $\delta(h)$ has order smaller than $(\ln h)^{m-2}h^2$.

Proof. (i) Note that for $\beta = -\ln(\lambda/2)/(2\ln 2)$, Lemma 5.1 implies that

$$\langle \mathbf{\Phi}(h), \mathbf{u}\rangle = p(h)h^{2\beta}$$

for some nonzero bounded continuous p such that $p(h) = p(2h)$. Hence by (6.2),

$$\langle \tilde{\mathbf{\Phi}}(h), \mathbf{u}\rangle = C\left(1 - \frac{2^{2\beta}}{4}\right)p(h)h^{2\beta}, \tag{6.4}$$

and the result follows.

(ii) Theorem 5.2 implies that $\langle \mathbf{\Phi}(h), \mathbf{u}\rangle$ has order $(\ln h)^{m-1}p(h)h^2$ as $h \to 0$, and $\frac{1}{4}\langle \mathbf{\Phi}(2h), \mathbf{u}\rangle$ has order $\frac{1}{4}(\ln 2h)^{m-1}p(2h)(2h)^2 = (\ln 2h)^{m-1}p(h)h^2$. Note that $(\ln h)^{m-1} - (\ln 2h)^{m-1}$ is of order $(\ln h)^{m-2}$. Consequently,

$$\langle \tilde{\mathbf{\Phi}}(h), \mathbf{u}\rangle = \left\langle \mathbf{\Phi}(h) - \frac{1}{4}\mathbf{\Phi}(2h), \mathbf{u}\right\rangle = \tilde{p}(h)(\ln h)^{m-2}h^2 + \delta(h),$$

where $\tilde{p}$ and $\delta(h)$ is as asserted (the order of $\delta(h)$ follows from the same argument and Theorem 5.2).

By using Lemma 6.2(i), we can extend Corollary 5.8 as follows.

PROPOSITION 6.3. *Suppose f is an L^2_c-solution of* (1.1). *Then the L^2-Lipschitz exponent of f is given by*

$$0 < \alpha = -\ln(\tilde{\Lambda}_{\max}/2)/(2\ln 2) \leq 2, \tag{6.5}$$

where

$$\tilde{\Lambda}_{\max} := \max\left\{|\lambda'| : \lambda' \textit{ eigenvalue of } \mathbf{W}_N^+ \textit{ and } |\lambda'| < \frac{1}{2}\right\}$$

if $\frac{1}{2}$ is an eigenvalue of order 1 *and is the only eigenvalue of modulus $\frac{1}{2}$*;

$$\tilde{\Lambda}_{\max} := \Lambda_{\max}$$

otherwise.

In the first case, f is differentiable a.e. and $f' \in L^2(\mathbb{R})$ (see the proof of Corollary 5.5), and f has Lipschitz exponent > 1. In the other case, the new and old definitions coincide.

The corresponding extension for Theorem 5.4 is the following.

THEOREM 6.4. *For the above α, let m be the highest order among those λ such that $|\lambda| = \tilde{\Lambda}_{\max}$. Then*

$$\lim_{h\to 0^+}\left(\frac{1}{h^{2\alpha}|\ln h|^{m-1}}\int_{-\infty}^{\infty}|\Delta_h^{(2)}f(x)|^2dx - p(h)\right) = 0 \tag{6.6}$$

except for the special case where $\lambda = \frac{1}{2}$ and the order m is strictly greater then the other eigenvalues of moduli $\frac{1}{2}$; in such a case, $\alpha = 1$ and

$$\lim_{h\to 0^+}\left(\frac{1}{h^{2}|\ln h|^{m-2}}\int_{-\infty}^{\infty}|\Delta_h^{(2)}f(x)|^2dx - p(h)\right) = 0. \tag{6.6$'$}$$

For the Fourier asymptotic result corresponding to Theorem 5.10, we note that

$$\begin{aligned}\tilde{\varphi}(h) &= \frac{1}{h^{2\alpha}|\ln h|^{m-1}}\int_{-\infty}^{\infty}|\Delta_h^{(2)}f(x)|^2dx\\ &= \frac{1}{h^{2\alpha}|\ln h|^{m-1}}\int_{-\infty}^{\infty}|\hat{f}(\omega)|^2\sin^4(\frac{h\omega}{2})d\omega.\end{aligned}$$

By taking

$$g(\omega) = \frac{\sin^4(\omega/2)}{|\omega|^{2s}}$$

and observing that for $\alpha < s$, g is integrable and

$$\begin{aligned}G(\xi) &= \int_0^{\infty} g(\omega)\omega^{2(s-\alpha)-1+i\xi}d\omega = \int_0^{\infty}\sin^4(\omega/2)\omega^{i\xi-2\alpha-1}d\omega\\ &= \frac{\sqrt{\pi}(4^{(\alpha-1-\frac{i\xi}{2})}-1)\Gamma(-\alpha+\frac{i\xi}{2})}{4^{(\alpha+1-\frac{i\xi}{2})}\Gamma(\alpha+\frac{1}{2}-\frac{i\xi}{2})} \neq 0\end{aligned}$$

for all ξ (compare this with (5.5)), we have the following.

THEOREM 6.5. *Under the same hypotheses as in Theorem* 6.4, *for $\alpha < s$, except for the special case,*

$$\lim_{T\to\infty}\left(\frac{1}{T^{2(s-\alpha)}|\ln T|^{m-1}}\int_{-T}^{T}|\omega^s\hat{f}(\omega)|^2d\omega - q(T)\right) = 0 \tag{6.7}$$

for some nonzero bounded continuous q (depending on s) such that $q(2T) = q(T)$. For the special case, we have

$$\lim_{T\to\infty}\left(\frac{1}{T^{2(s-1)}|\ln T|^{m-2}}\int_{-T}^{T}|\omega^s\hat{f}(\omega)|^2d\omega - q(T)\right) = 0. \tag{6.7$'$}$$

For the third-order difference $\Delta_h^{(3)} f$, we can use

$$\sin^6 x = \frac{15}{16}\sin^2 x - \frac{3}{8}\sin^2 2x + \frac{1}{16}\sin^2 3x$$

to replace the relationship in (6.2). For eigenvalues $\lambda = \frac{1}{2}$ or $\frac{1}{8}$ and the order m is as in the special case in Theorem 6.4 (the corresponding α are 1 and 2, respectively), the logarithmic terms in the asymptotic formulas are of order $m-2$. For the other cases, they are $m-1$. The higher-order difference $\Delta_h^{(l)} f$ behaves the same way.

As an example, we consider Daubechies's well-known scaling function D_4. Let f be the solution of (1.1) with coefficients

$$c_0 = \frac{1+\sqrt{3}}{4}, \quad c_3 = \frac{1-\sqrt{3}}{4}, \quad c_1 = 1 - c_3, \quad c_2 = 1 - c_0.$$

It follows from a direct calculation that

$$\mathbf{W}_3^+ = \begin{pmatrix} 2 & 0 & 0 & 0 \\ \frac{9}{4} & 1 & -\frac{1}{8} & 0 \\ 0 & 2 & 0 & 0 \\ -\frac{1}{4} & \frac{9}{8} & \frac{9}{8} & -\frac{1}{8} \end{pmatrix}$$

and the eigenvalues are 2, $\frac{1}{2}$, and $-\frac{1}{8}$, where $\frac{1}{2}$ has order 2. It fits into the above special case. By Theorem 5.4, $\alpha = 1$ and

$$\frac{1}{h^2|\ln h|}\int_{-\infty}^{\infty} |\Delta_h f(x)|^2 dx \approx p(h)$$

as $h \to 0^+$. It is known that f is differentiable a.e. [D], [DL2], but the asymptotic property implies that $f' \notin L^2(\mathbb{R})$. If we consider the second-order difference, then by a direct calculation and making use of the expressions in Theorem 5.2 and (6.4), we have

$$\frac{1}{h^2}\int_{-\infty}^{\infty} |\Delta_h^{(2)} f(x)|^2 dx \approx 2p(h)$$

as $h \to 0$.

For the Fourier transformation, we cannot apply Theorem 5.10 since $\alpha = 1$, but we can use (6.7)$'$ derived from the higher-order difference. It implies that for $1 < s$, there exists a bounded continuous q (depends on s) satisfying $q(T) = q(2T)$ and

$$\psi(T) = \frac{1}{T^{2(s-1)}}\int_{-T}^{T} |\omega^s \hat{f}(\omega)|^2 d\omega \approx q(T) \tag{6.8}$$

as $T \to \infty$. We include some graphic illustrations of this in the appendix.

Appendix. For the four-coefficient dilation equation

$$f(x) = c_0 f(2x) + c_1 f(2x-1) + c_2 f(2x-2) + c_3 f(2x-3)$$

with $c_0 + c_2 = 1$, $c_1 + c_3 = 1$, we use c_0 and c_3 as independent parameters to plot the various regions and functions.

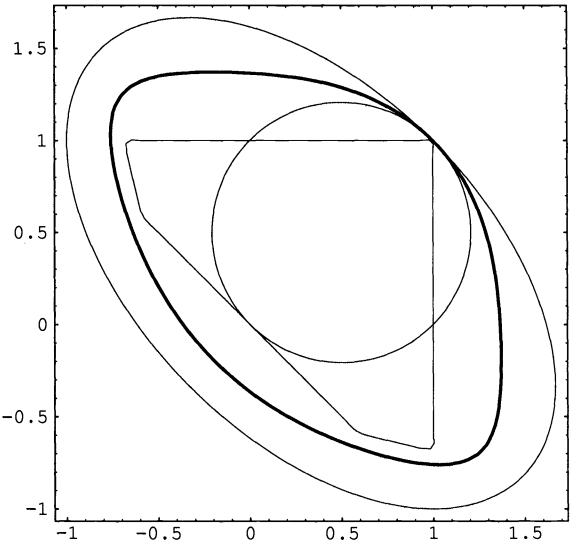

FIG. 1.

In Figure 1, the region bounded by the thicker curve corresponding to those (c_0, c_3) where all eigenvalues of $\mathbf{W}_3^+$ are less than or equal to 2 (2 is simple except at $(c_0, c_3) = (1, 1)$). This is the exact region where the L_c^2-solution exists [LW1].

The circular curve

$$\left(c_0 - \frac{1}{2}\right)^2 + \left(c_3 - \frac{1}{2}\right)^2 = \frac{1}{2}$$

is the circle of orthogonality [La]. The wavelet generated by the corresponding scaling function is orthonormal.

The triangular region is an approximation where the joint spectral radius of T_0 and T_1 restricted on H are less than 1 and the continuous solutions exist [DL1], [CH].

The ellipse is given by

$$c_0^2 + c_3^2 - c_0 - c_3 + c_0 c_3 = 0,$$

outside which no L^1-solution exists [H].

Figure 2(a) is the graph of the L^2-Lipschitz exponent $\alpha = -\ln(\Lambda_{\max}/2)/(2\ln 2)$.

Figure 2(b) is the graph of α on the circle of orthogonality, plotted in terms of the angles. Note that D_4 is the smoothest one on the circle.

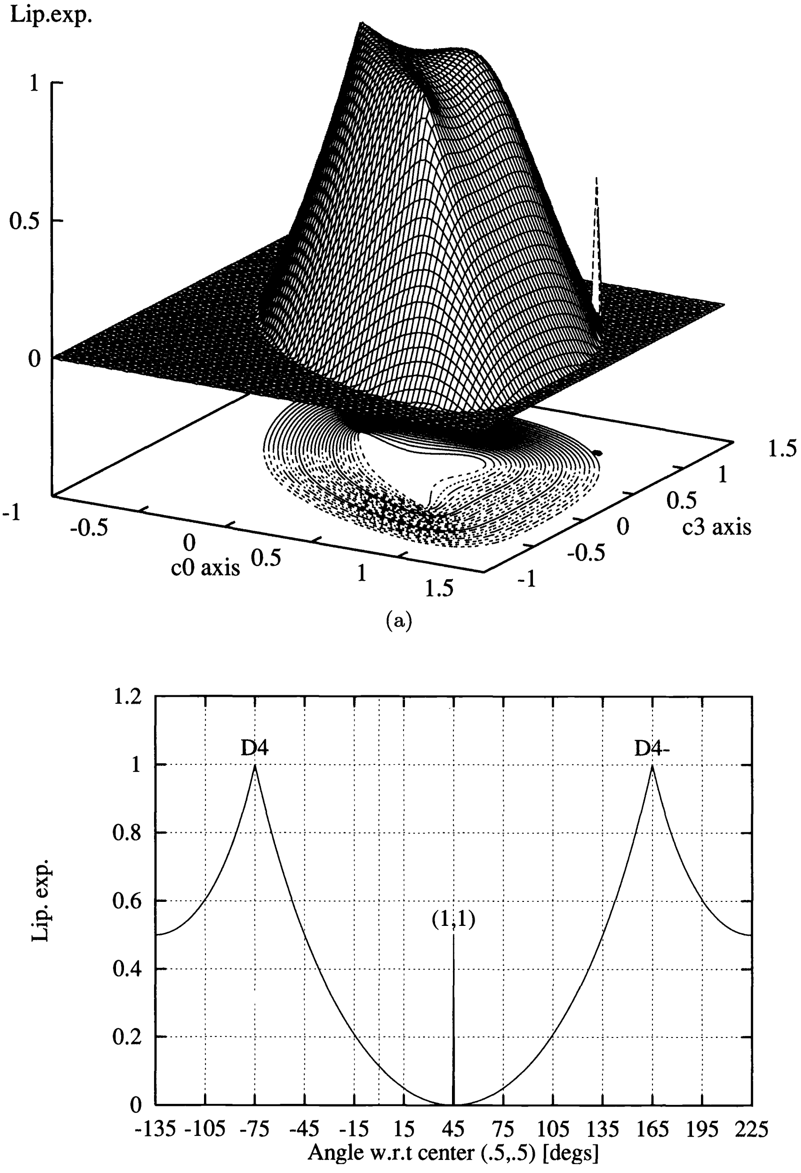
Figure 3(a) is the graph of the L^2-Lipschitz exponent $\alpha = -\ln(\tilde{\Lambda}_{\max}/2)/(2\ln 2)$, using the second-order difference.

Figure 3(b) is the cross-section of $c_0 + c_3 = 1$; Figure 3(c) is the cross-section of $c_0 = c_3$.

Figure 4(a) is the Daubechies scaling function $f = D_4$.

Figure 4(b) is its Fourier transformation $\hat{f}(\omega)$.

Figures 4(c), 4(e), and 4(g) are $\omega^s \hat{f}(\omega)$ with $s = 1.5, 1.25, 1.00$, respectively, and Figures 4(d) and 4(f) are the corresponding averages $\psi(T) = \frac{1}{T^{2(s-1)}} \int_{-T}^{T} |\omega^s \hat{f}(\omega)|^2 d\omega$.



(a)

(b)

FIG. 2.

Note that the $\psi(T)$ are approximately multiplicative periodic as $T \to \infty$. They follows from (6.5). We cannot draw such conclusions from the theorem for $s = \alpha = 1$ (see Figure 4(h)). However, if we take $\psi(T) = \frac{1}{\ln T} \int_{-T}^{T} |\omega \hat{f}(\omega)|^2 d\omega$, then it looks multiplicative periodic as in Figure 4(i); we have no proof for that yet.

Acknowledgments. The graphs in the appendix are due to Mr. Wonkoo Kim, to whom we express our deep gratitude.

DYADIC AFFINE DECOMPOSITIONS AND FUNCTIONAL WAVELET TRANSFORMS*

CHARLES K. CHUI† AND CHUN LI‡

Abstract. Decomposition of continuous functions can be accomplished by considering the difference of consecutive interpolation operators. When such a difference is expressed as an infinite series of some "wavelets" basis, the coefficient sequence becomes Donoho's "interpolating wavelet transform." Here, in contrast to the usual L^2-setting, no analyzing wavelet is used to describe the wavelet transform. The objective of this paper is to study the structure of such decomposition spaces, including the formulation of bases and their duals, which leads to the notion of functional wavelet transforms (FnWT) using the duals as analyzing wavelets. Such a transform retains some of the most important properties of the integral wavelet transform of Grossmann and Morlet, such as the property of vanishing moments, which has significant applications to engineering problems.

Key words. interpolating wavelets, wavelet decompositions, functional wavelet transform, vanishing moments, space of continuous functions, Dirac delta functions

AMS subject classifications. Primary 41A58; Secondary 42C30

1. Introduction.

In the study of orthogonal wavelets, a multiresolution analysis $\{V_j\}_{j\in\mathbb{Z}}$ of nested closed subspaces of $L^2 := L^2(\mathbb{R})$ along with their orthogonal complementary subspaces $\{W_j\}_{j\in\mathbb{Z}}$ are considered, namely,

$$\begin{cases} \operatorname{clos}_{L^2}\left(\bigcup_{j\in\mathbb{Z}} V_j\right) = L^2, \\ \bigcap_{j\in\mathbb{Z}} V_j = \{0\}, \\ V_{j+1} = V_j \oplus W_j, \quad j \in \mathbb{Z}, \end{cases}$$

so that the orthogonal decomposition

$$L^2 = \bigoplus_{j\in\mathbb{Z}} W_j$$

is achieved, where $V_{j+1} = V_j \oplus W_j$ means that $V_{j+1} = V_j + W_j$ and $V_j \perp W_j$. The spaces W_j can also be defined by

$$W_j = \{f - P_j^\perp f\colon\ f \in V_{j+1}\}, \quad j \in \mathbb{Z},$$

where $P_j^\perp$ is the orthogonal projection from L^2 to V_j. In this paper, we will study the decomposition of continuous functions induced by the cardinal interpolation projection.

To formulate a firm setting, the function space under consideration must be a subspace of $C := C(\mathbb{R})$, the space of continuous functions on $\mathbb{R}$. More precisely, we will consider the subspace

$$C_u = C_u(\mathbb{R}) := \{f \in C\colon\ f \text{ uniformly continuous and bounded on } \mathbb{R}\} \tag{1.1}$$

and will use the sup norm $\|\cdot\|_\infty$. Note that C_u is closed in the topology of this norm. Suppose that $\phi \in C_u$ has compact support and

$$V_j := \left\{ \sum_{k\in\mathbb{Z}} c_k\phi(2^j \cdot -k) \colon \{c_k\} \in \ell^\infty \right\}, \quad j \in \mathbb{Z}. \tag{1.2}$$

Then each V_j is a subspace of C_u. We will call ϕ a scaling function that generates an interpolating multiresolution analysis $\{V_j\}$ of C_u provided that the following conditions are satisfied:

(i) $V_j \subset V_{j+1}$, for all $j \in \mathbb{Z}$;

(ii) $\operatorname{clos}_{C_u}\left(\bigcup_{j\in\mathbb{Z}} V_j\right) = C_u$;

(iii) $\bigcap_{j\in\mathbb{Z}} V_j = \mathbb{C}$, the set of all complex numbers;

(iv) $f \in V_j \Leftrightarrow f(2\cdot) \in V_{j+1}, j \in \mathbb{Z}$;

(v) $f \in V_j \Rightarrow f(\cdot - 2^{-j}k) \in V_j, j \in \mathbb{Z}, k \in \mathbb{Z}$;

and

(vi) $\Phi(z) := \sum_k \phi(k)z^k \neq 0$ for all $|z| = 1$.

Condition (vi) is instrumental to solving the cardinal interpolation problem with "fundamental function"

$$\phi_L \in V_0 \text{ satisfying } \phi_L(k) = \delta_{k,0}, \qquad k \in \mathbb{Z}, \tag{1.3}$$

where $\delta_{k,0}$ denotes, as usual, the Kronecker delta symbol. Under assumption (vi), ϕ_L is unique and is given by

$$\phi_L(x) = \sum_k r_k\phi(x-k), \tag{1.4}$$

where $\{r_k\}$ is the coefficient sequence of the Laurent series expansion:

$$\frac{1}{\Phi(z)} = \sum_{k\in\mathbb{Z}} r_k z^k, \qquad |z| = 1. \tag{1.5}$$

We would like to point out that condition (vi) can be weakened to be

(vi′) $\Phi_c(z) := \sum_k \phi(k+c)z^k \neq 0$ for all $|z| = 1$

and for some $c \in [0,1)$, which may not be 0. In addition, the assumption that ϕ is compactly supported is not necessary for some of our results to be valid. Of course, ϕ still has to have sufficiently fast decay such as $\phi(x) = O\left(\frac{1}{(1+|x|)^{1+\varepsilon}}\right)$ for some $\varepsilon > 0$. In this paper, however, in order to significantly simplify our presentation, we will only consider compactly supported scaling functions $\phi \in C_u$ which satisfy conditions (i) and (vi). We will see later (in §3) that (ii)–(v) are only consequences of (i) and (vi). Hence, in the study of a multiresolution analysis of C_u, only conditions (i) and (vi) are required.

From the interpolating property of ϕ_L in (1.3), it follows that the cardinal interpolation projection operators P_j from C_u to V_j are given by

$$(P_jf)(x) := \sum_{k\in\mathbb{Z}} f\left(\frac{k}{2^j}\right)\phi_L(2^jx-k), \qquad f \in C_u. \tag{1.6}$$

Parallel to the study of orthogonal wavelets, we introduce the complementary subspaces $\{W_j\}$ of $\{V_j\}$ defined by

$$W_j := \{f - P_j f\colon\ f \in V_{j+1}\}, \qquad j \in \mathbb{Z}. \tag{1.7}$$

It is clear that

$$V_{j+1} = V_j + W_j \quad \text{and} \quad V_j \cap W_j = \{0\}, \quad j \in \mathbb{Z}, \tag{1.8}$$

and we will use the direct-sum notation

$$V_{j+1} = V_j \dot{+} W_j, \qquad j \in \mathbb{Z}, \tag{1.9}$$

to describe (1.8).

One of the objectives of this paper is to study the structure of the spaces W_j along with their duals. In particular, we will discuss the properties of the two bases $\{\psi(\cdot - k)\}$ and $\{\psi_L(\cdot - k)\}$ of W_0, where ψ and ψ_L are defined as follows:

$$\psi(x) := \sum_k (-1)^{k-1}\phi(k-1)\phi(2x-k) \tag{1.10}$$

and

$$\psi_L(x) := \phi_L(2x-1). \tag{1.11}$$

It should be mentioned that the function ψ in (1.10) has already appeared in Micchelli [8], while ψ_L has been investigated by Donoho [5] for the special case when ϕ_L is assumed to have compact support.

Since ϕ has compact support, the function ψ in (1.10) is only a finite linear combination of $\phi(2\cdot -k)$ and consequently also has compact support. As to the second function ψ_L, we point out that it does not have compact support in general. In fact, in view of (1.4) and (1.5), ϕ_L, and hence ψ_L, has compact support only if $\Phi(z)$ is a monomial, which is the trivial case. In this paper, we will call both ψ and ψ_L "interpolating wavelets." We also remark that

$$\phi \equiv \phi_L \Rightarrow \psi \equiv \psi_L. \tag{1.12}$$

From (ii), (iii), and the decomposition relation (1.9), it follows that

$$C_u = \mathbb{C} \dot{+} \sum_{j \in \mathbb{Z}} W_j. \tag{1.13}$$

Hence, by using the basis $\{\psi(2^j \cdot -k)\}$ of W_j, we have

$$f(x) = f(0) + \sum_{j,k \in \mathbb{Z}} d_k^j \psi(2^j x - k), \qquad x \in \mathbb{R}, \quad f \in C_u. \tag{1.14}$$

Another objective of this paper is to study the importance of the coefficient sequence $\{d_k^j\}$ in the (unique) representation of any $f \in C_u$. This sequence may be called Donoho's interpolating wavelet transform of f, studied in some detail in [5]. Our investigation leads to the construction of the "dual" $\tilde{\psi}$ of ψ, which naturally introduces the notion of "functional wavelet transform" relative to the "analyzing wavelet functional" $\tilde{\psi}$.

Let C_u^* be the dual space of C_u; that is, C_u^* is the space that consists of all the continuous linear functionals on C_u. By $\langle f, \tilde{f}\rangle$ we mean the value of $\tilde{f} \in C_u^*$ evaluated at $f \in C_u$. Thus, $\widetilde{\psi} \in C_u^*$ is called the dual of ψ if

$$\langle \psi(\cdot - k), \widetilde{\psi}\rangle = \delta_{k,0}, \qquad k \in \mathbb{Z}. \tag{1.15}$$

It will be clear in §3 that the coefficient sequence $\{d_k^j\}$ in (1.14) is given by

$$d_k^j = \langle f(2^{-j} \cdot + 2^{-j}k), \widetilde{\psi}\rangle = 2^j \langle f, \widetilde{\psi}(2^j \cdot - k)\rangle, \qquad j, k \in \mathbb{Z}, \tag{1.16}$$

where the dilation and translation (shift) $\widetilde{\psi}(a \cdot - b)$ of the linear functional $\widetilde{\psi}$ will be defined in §2. Thus, as in the L^2-setting, this formulation naturally leads to the notion of the "functional wavelet transform," defined by

$$(W_{\widetilde{\psi}} f)(b, a) := \frac{1}{a}\left\langle f, \widetilde{\psi}\left(\frac{\cdot - b}{a}\right)\right\rangle. \tag{1.17}$$

Let π_{m-1} denote the collection of all polynomials of degree $\leq m-1$ (or order m). It will be shown that if ϕ (locally) reproduces all polynomials in π_{m-1} for some positive integer m, in the sense that there exist constants $b_{j,k}$ with polynomial growth as $k \to \infty$, such that

$$x^j = \sum_k b_{j,k}\phi(x - k), \qquad x \in \mathbb{R}, \quad j = 0, 1, \ldots, m-1, \tag{1.18}$$

then

$$(W_{\widetilde{\psi}} p)\left(\frac{k}{2^j}, \frac{1}{2^j}\right) = 2^j \langle p, \widetilde{\psi}(2^j \cdot - k)\rangle = 0, \qquad p \in \pi_{m-1}, \quad j, k \in \mathbb{Z}. \tag{1.19}$$

This property of vanishing moment has significant applications to engineering problems that require detection, data compression, etc.

2. Bases and their duals. As in §1, let the scaling function ϕ generate the spaces V_j, $j \in \mathbb{Z}$, in the sense of (1.2). Since $V_0 \subset V_1$, there exists a sequence $\{p_k\} \in \ell^\infty$ such that

$$\phi(x) = \sum_k p_k \phi(2x - k), \qquad x \in \mathbb{R}. \tag{2.1}$$

Moreover, since ϕ is assumed to be a compactly supported continuous function, the sequence $\{p_k\}_{k\in\mathbb{Z}}$ has exponential decay (see [7]), so that the two-scale symbol

$$P(z) = P_\phi(z) := \frac{1}{2}\sum_k p_k z^k \tag{2.2}$$

is an analytic function in a neighborhood of the unit circle $|z| = 1$. Let $\Phi(z)$ be the symbol of $\{\phi(k)\}$ as defined before and assume that it does not vanish on the unit circle as in hypothesis (vi) in §1. We have the following.

LEMMA 2.1. *$P(z)$ and $\Phi(z)$ are governed by the identity*

$$\Phi(z^2) = P(z)\Phi(z) + P(-z)\Phi(-z), \qquad |z| = 1. \tag{2.3}$$

This result can be found in Rioul [9] and its proof is very similar to that of some similar results in our earlier work [2, 3]. For completeness, we include a short derivation here.

Proof.

$$\begin{aligned}\Phi(z^2) &= \sum_n \phi(n)z^{2n} = \sum_n\sum_k p_k\phi(2n-k)z^{2n}\\ &= \sum_k p_k z^k \sum_n \phi(2n-k)z^{2n-k}\\ &= \sum_k p_{2k}z^{2k}\sum_n \phi(2n)z^{2n} + \sum_k p_{2k+1}z^{2k+1}\sum_n \phi(2n-1)z^{2n-1}\\ &= [P(z)+P(-z)][\Phi(z)+\Phi(-z)]/2 + [P(z)-P(-z)][\Phi(z)-\Phi(-z)]/2\\ &= P(z)\Phi(z) + P(-z)\Phi(-z). \qquad \square\end{aligned}$$

Next, consider

$$Q(z) := \frac{1}{2}z\Phi(-z) = \frac{1}{2}\sum_k (-1)^{k-1}\phi(k-1)z^k \tag{2.4}$$

and let the interpolating wavelet ψ be defined as in (1.10). Then its Fourier transform is given by

$$\hat{\psi}(\omega) = Q(z)\hat{\phi}\left(\frac{\omega}{2}\right) = \frac{1}{2}z\Phi(-z)\hat{\phi}\left(\frac{\omega}{2}\right), \qquad z = e^{-i\frac{\omega}{2}}, \tag{2.5}$$

where, as usual, the Fourier transform $\hat{f}$ of a function f on $\mathbb{R}$ is defined by

$$\hat{f}(\omega) := \int_{\mathbb{R}} f(x)e^{-i\omega x}dx, \qquad \omega\in\mathbb{R}, \tag{2.6}$$

whenever it makes sense and/or distributionally otherwise. Of course from the two-scale equation (2.1), we have also

$$\hat{\phi}(\omega) = P(z)\hat{\phi}\left(\frac{\omega}{2}\right), \qquad z = e^{-i\frac{\omega}{2}}. \tag{2.7}$$

LEMMA 2.2. *Let $\Phi(z)$ satisfy* (vi) *in* §1; *that is,*

$$\Phi(z) := \sum_k \phi(k)z^k \neq 0, \quad |z| = 1. \tag{2.8}$$

Then there are positive constants $A \le B$ such that

$$A(\|\mathbf{c}\|_{\ell^\infty} + \|\mathbf{d}\|_{\ell^\infty}) \le \left\|\sum_k c_k\phi(\cdot-k) + \sum_k d_k\psi(\cdot-k)\right\|_\infty \le B(\|\mathbf{c}\|_{\ell^\infty} + \|\mathbf{d}\|_{\ell^\infty}) \tag{2.9}$$

for all $\mathbf{c} = \{c_k\}_{k\in\mathbb{Z}} \in \ell^\infty$ and $\mathbf{d} = \{d_k\}_{k\in\mathbb{Z}} \in \ell^\infty$.

Proof. Since the functions ϕ and ψ are compactly supported and continuous, the second inequality in (2.9) clearly holds for some constant B. To establish the first inequality in (2.9), we recall from a result of Jia and Micchelli [6] that it is sufficient to prove that $\{\hat{\phi}(\omega+2k\pi)\}$ and $\{\hat{\psi}(\omega+2k\pi)\}$ are linearly independent for all $\omega \in \mathbb{R}$. We first observe, by applying the Poisson summation formula

$$\sum_k \hat{\phi}(\omega+2k\pi) = \sum_n \phi(n)e^{-in\omega} \tag{2.10}$$

and condition (2.8), that

$$\sup_{k\in\mathbb{Z}} |\hat{\phi}(\omega+2k\pi)| > 0, \quad \omega \in \mathbb{R}. \tag{2.11}$$

Thus, combining this fact with the two-scale relations (2.5) and (2.7), we can easily conclude that the above statement is equivalent to

$$\Delta(z) := \begin{vmatrix} P(z) & Q(z) \\ P(-z) & Q(-z) \end{vmatrix} \neq 0 \quad \text{for all} \quad |z| = 1. \tag{2.12}$$

By (2.4), (2.3), Lemma 2.1, and condition (2.8), we have, for all $|z| = 1$,

$$\Delta(z) = \begin{vmatrix} P(z) & \frac{1}{2}z\Phi(-z) \\ P(-z) & -\frac{1}{2}z\Phi(z) \end{vmatrix} = -\frac{1}{2}z[P(z)\Phi(z) + P(-z)\Phi(-z)] = -\frac{1}{2}z\Phi(z^2) \neq 0.$$

This completes the proof of Lemma 2.2. □

In view of (2.9), the integer translates $\phi(\cdot - k)$ and $\psi(\cdot - k)$, $k \in \mathbb{Z}$, are said to be ℓ^∞-stable (see [6]). For simplicity, we will also say that ϕ and ψ are ℓ^∞-stable. An immediate consequence of (2.9) is that

$$A\|\mathbf{c}\|_{\ell^\infty} \leq \left\| \sum_k c_k\phi(\cdot - k) \right\|_\infty \leq B\|\mathbf{c}\|_{\ell^\infty}, \tag{2.13}$$

$$A\|\mathbf{c}\|_{\ell^\infty} \leq \left\| \sum_k c_k\psi(\cdot - k) \right\|_\infty \leq B\|\mathbf{c}\|_{\ell^\infty} \tag{2.14}$$

for all $\mathbf{c} = \{c_k\} \in \ell^\infty$, so that ϕ and ψ are ℓ^∞-stable themselves. It follows from (2.13) that the spaces V_j defined in (1.2) are closed subspaces of C_u, and hence, we can write

(2.15)

$$V_j = \text{clos}_{C_u} \text{ span}\{\phi(2^j \cdot -k)\colon\ k \in \mathbb{Z}\} := \text{clos}_{C_u} \left\{ \sum_k c_k\phi(2^j \cdot -k) \in C_u \right\}, \quad j \in \mathbb{Z},$$

where, somewhat differently from the usual definition, the span is not restricted to finite linear combinations. This leads to the following.

DEFINITION 2.3. *Let $X = X(\mathbb{R})$ be a normed linear space of functions over $\mathbb{R}$ and $\{S_j\}_{j\in\mathbb{Z}}$ a family of closed subspaces of X. If a function $f \in X$ exists such that*

$$S_j = \text{clos}_X \text{ span}\{f(2^j \cdot -k)\colon\ k \in \mathbb{Z}\}, \qquad j \in \mathbb{Z}, \tag{2.16}$$

then f is called a generator *that generates the subspaces S_j. Moreover, if there are constants $0 < A \leq B < \infty$ and $1 \leq p \leq \infty$ such that*

$$A\|\mathbf{c}\|_{\ell^p} \leq \left\| \sum_k c_k f(\cdot - k) \right\| \leq B\|\mathbf{c}\|_{\ell^p}, \quad \mathbf{c} = \{c_k\} \in \ell^p,$$

then we say that f is an ℓ^p-stable generator *of $S_j, j \in \mathbb{Z}$.*

Thus, in the sense of Definition 2.3, we see that, under condition (vi), or equivalently (2.8), ϕ is an ℓ^∞-stable generator of V_j. As to the fundamental function ϕ_L given in (1.4), it is clear from the interpolating property (1.3) and the property of exponential decay (because of the exponential decay property of $\{r_k\}$ in (1.5)), that ϕ_L is ℓ^∞-stable in the sense of (2.13) (with ϕ_L instead of ϕ there). Moreover, in view of (1.4) and the fact that

$$\phi(x) = \sum_k \phi(k)\phi_L(x-k), \tag{2.17}$$

we see that ϕ_L is also an ℓ^∞-stable generator that generates the closed subspaces V_j.

THEOREM 2.4. *Let* $\{V_j\}$ *be defined as in* (1.2) *and satisfy the conditions* (i) *and* (vi) *in* §1. *Also, let the subspaces* W_j *of* C_u *be defined as in* (1.7). *Then both* ψ *and* ψ_L, *defined in* (1.10) *and* (1.11), *respectively, are* ℓ^∞*-stable generators of* W_j, $j \in \mathbb{Z}$.

Proof. Since ϕ_L is ℓ^∞-stable, it follows that $\psi_L = \phi_L(2\cdot -1)$ is ℓ^∞-stable also. By (2.14), it is sufficient to prove that

$$W_j = \left\{\sum_k c_k\psi_L(2^j\cdot -k)\colon \{c_k\}\in\ell^\infty\right\} = \left\{\sum_k c_k\psi(2^j\cdot -k)\colon \{c_k\}\in\ell^\infty\right\} \tag{2.18}$$

holds for $j=0$. Let $g\in W_0$. Then there is an $f\in V_1$ such that $g(x) = f(x)-(P_0f)(x)$. Since P_1 is a projection from C_u to V_1, we can write

$$f(x) = (P_1f)(x) = \sum_k f\left(\frac{k}{2}\right)\phi_L(2x-k). \tag{2.19}$$

Also, since the fundamental function ϕ_L has the two-scale relation

$$\begin{aligned}\phi_L(x) &= \sum_k \phi_L\left(\frac{k}{2}\right)\phi_L(2x-k)\\ &= \phi_L(2x) + \sum_k \phi_L\left(k+\frac{1}{2}\right)\phi_L(2x-2k-1)\\ &= \phi_L(2x) + \sum_k \phi_L\left(k+\frac{1}{2}\right)\psi_L(x-k),\end{aligned} \tag{2.20}$$

we see from (2.19) and (2.20) that

$$\begin{aligned} g(x) &= \sum_k f\left(\frac{k}{2}\right)\phi_L(2x-k) - \sum_\ell f(\ell)\phi_L(x-\ell)\\ &= \sum_k f\left(\frac{k}{2}\right)\phi_L(2x-k)\\ &\quad -\sum_\ell f(\ell)\left[\phi_L(2x-2\ell)+\sum_k\phi_L\left(k+\frac{1}{2}\right)\psi_L(x-\ell-k)\right]\\ &= \sum_k f\left(k+\frac{1}{2}\right)\phi_L(2x-2k-1)\\ &\quad -\sum_\ell\sum_k f(\ell)\phi_L\left(k+\frac{1}{2}\right)\psi_L(x-\ell-k)\\ &= \sum_k f\left(k+\frac{1}{2}\right)\psi_L(x-k) - \sum_k\left[\sum_\ell f(\ell)\phi_L\left(k-\ell+\frac{1}{2}\right)\right]\psi_L(x-k)\\ &= \sum_k (f-P_0f)\left(k+\frac{1}{2}\right)\psi_L(x-k).\end{aligned} \tag{2.21}$$

The sequence $\{c_k\}$, defined by

$$c_k := (f - P_0 f)\left(k + \frac{1}{2}\right) = f\left(k + \frac{1}{2}\right) - \sum_{\ell} f(\ell)\phi_L\left(k - \ell + \frac{1}{2}\right), \tag{2.22}$$

is clearly in ℓ^∞. Hence, by (2.21), we have

$$W_0 \subset \left\{\sum_k c_k \psi_L(\cdot - k) \colon\ \{c_k\} \in \ell^\infty\right\}. \tag{2.23}$$

On the other hand, for any $g(x) = \sum_k c_k \psi_L(x - k)$ with $\{c_k\} \in \ell^\infty$, we have $g \in V_1$ and $g(\ell) = 0$ (since $\psi_L(\ell) = \phi_L(2\ell - 1) = 0$) for all $\ell \in \mathbb{Z}$, so that $g = g - P_0 g \in W_0$. This proves that

$$W_0 \supset \left\{\sum_k c_k \psi_L(\cdot - k) \colon\ \{c_k\} \in \ell^\infty\right\}. \tag{2.24}$$

Combining (2.23) and (2.24), we have the first equality in (2.18) for $j = 0$. To establish the second equality in (2.18) for $j = 0$, we only need to represent ψ and ψ_L as (possibly infinite) linear combinations of integer translates of each other with coefficient sequences in ℓ^1. For this purpose, we consider

$$\sum_j v_j z^{2j} := \Phi(z)\Phi(-z). \tag{2.25}$$

Then by (1.5) and (2.25), we have

$$\begin{aligned}\sum_n \left(\sum_j v_j r_{n-2j}\right) z^n &= \sum_j v_j z^{2j} \sum_n r_{n-2j} z^{n-2j} \\ &= \sum_j v_j z^{2j} \sum_k r_k z^k = \Phi(z)\Phi(-z)[\Phi(z)]^{-1} \\ &= \Phi(-z) = \sum_n (-1)^n \phi(n) z^n,\end{aligned}$$

so that

$$\sum_j v_j r_{n-2j-1} = (-1)^{n-1}\phi(n-1), \qquad n \in \mathbb{Z}. \tag{2.26}$$

Hence, it follows from (1.11), (1.4), (2.26), and (1.10) that

$$\begin{aligned}\sum_j v_j \psi_L(x - j) &= \sum_j v_j \phi_L(2x - 2j - 1) \\ &= \sum_j v_j \sum_k r_k \phi(2x - 2j - 1 - k) \\ &= \sum_n \left(\sum_j v_j r_{n-2j-1}\right) \phi(2x - n) \\ &= \sum_n (-1)^{n-1} \phi(n-1) \phi(2x - n) = \psi(x).\end{aligned} \tag{2.27}$$

On the other hand, it also follows from (2.27) that

$$\psi_L(x) = \sum_j w_j \psi(x-j), \tag{2.28}$$

with

$$\sum_j w_j z^{2j} := \left(\sum_j v_j z^{2j}\right)^{-1} = [\Phi(z)\Phi(-z)]^{-1}. \tag{2.29}$$

This proves our assertion and therefore completes the proof of Theorem 2.4. □

We turn to the discussion of duals. By using the classical Dirac delta function (distribution) δ, namely,

$$\langle f, \delta \rangle = f(0), \quad f \in C_u, \tag{2.30}$$

we can express the fundamental interpolating property of ϕ_L in (1.3) as

$$\langle \phi_L(\cdot + k), \delta \rangle = \phi_L(k) = \delta_{k,0}, \qquad k \in \mathbb{Z}. \tag{2.31}$$

In view of (2.31), we will say that ϕ_L and δ are duals to each other. In the following, we give a precise notion of dual functionals and describe what we mean by dilations, translations, and convergence of functionals.

DEFINITION 2.5. *Let $X = X(\mathbb{R})$ be a normed linear space of functions over $\mathbb{R}$, and $X^* = X^*(\mathbb{R})$ be its dual space, consisting of all the continuous linear functionals on X.*

(i) *For an element $f^* \in X^*$, its a-*dilation *and b-*translation (shift) $f^*(a \cdot -b)$, *where $a, b \in \mathbb{R}$, $a \neq 0$, is defined by*

$$\langle f, f^*(a \cdot -b) \rangle := \frac{1}{a}\left\langle f\left(\frac{\cdot + b}{a}\right), f^* \right\rangle, \quad f \in X. \tag{2.32}$$

(ii) *$f \in X$ and $f^* \in X^*$ are said to be* dual to each other *if*

$$\langle f(\cdot + k), f^* \rangle = \langle f, f^*(\cdot - k) \rangle = \delta_{k,0} \quad \text{for all} \quad k \in \mathbb{Z}. \tag{2.33}$$

Thus, f^* will also be called a dual of *f.*

(iii) *Let $\{\tilde{f}_k\}$ be a sequence in X^*. We say that the series $\sum_k \tilde{f}_k$ is* convergent *in X^* if $\sum_k \langle f, \tilde{f}_k \rangle$ is convergent for all $f \in X$ and its limit satisfies*

$$\left| \sum_k \langle f, \tilde{f}_k \rangle \right| \leq C\|f\|, \qquad f \in X,$$

for some positive constant C independent of f. Consequently, the series $\sum_k \tilde{f}_k$ can be considered as an element of X^* in the sense that

$$\left\langle f, \sum_k \tilde{f}_k \right\rangle := \sum_k \langle f, \tilde{f}_k \rangle, \quad f \in X. \tag{2.34}$$

Now, corresponding to the coefficient sequence $\{r_k\}$ of the Laurent expansion of $\Phi^{-1}(z)$ in (1.5), we consider the functional

$$\tilde{\phi} := \sum_k r_k \delta(\cdot + k). \tag{2.35}$$

Since $\{r_k\} \in \ell^1$, we see that $\tilde{\phi}$ is a continuous linear functional on C_u in the sense of Definition 2.5 (iii). It now follows from (1.4) that

$$\tag{2.36} \begin{aligned} \langle \phi, \tilde{\phi}(\cdot - j)\rangle &= \langle \phi(\cdot + j), \tilde{\phi}\rangle \\ &= \sum_k r_k \langle \phi(\cdot + j), \delta(\cdot + k)\rangle \\ &= \sum_k r_k \phi(j-k) = \phi_L(j) = \delta_{j,0}, \qquad j \in \mathbb{Z}, \end{aligned}$$

so that $\tilde{\phi}$ is a dual of ϕ.

Note that although a function $f \in X$ may have more than one dual in different subspaces of X^*, the dual f^* of f in the subspace generated by the integer translates of f^* is unique. Before we go into futher details, let us introduce the "dual subspaces"

$$\tag{2.37} \widetilde{V}_j := \left\{ \sum_j d_k \delta(2^j \cdot - k) \colon \ \{d_k\} \in \ell^1 \right\}, \qquad j \in \mathbb{Z}.$$

We will simply use the notation $\|\cdot\|$ for the functional norm for $\widetilde{V}_j$. We have the following result.

THEOREM 2.6. *The functional $\tilde{\phi}$ in* (2.35) *is in $\widetilde{V}_0$ and is the dual of the scaling function ϕ that generates $\{V_j\}$. Moreover, by setting*

$$\tag{2.38} \phi^0(x) := \sum_k |\phi(x-k)|, \quad \phi_L^0(x) := \sum_k |\phi_L(x-k)|,$$

then

$$\tag{2.39} \begin{cases} \|\phi^0\|_\infty^{-1}\|\mathbf{d}\|_{\ell^1} \le \left\| \sum_j d_j \tilde{\phi}(\cdot - j) \right\| \le \|\tilde{\phi}\| \|\mathbf{d}\|_{\ell^1}, \\ \|\phi_L^0\|_\infty^{-1}\|\mathbf{d}\|_{\ell^1} \le \left\| \sum_j d_j \delta(\cdot - j) \right\| \le \|\mathbf{d}\|_{\ell^1} \end{cases}$$

for all $\mathbf{d} = \{d_j\} \in \ell^1$. Furthermore,

$$\tag{2.40} \delta = \sum_j \phi(j) \tilde{\phi}(\cdot + j).$$

Consequently, both δ and $\tilde{\phi}$ are ℓ^1-stable generators of the dual spaces $\widetilde{V}_j$, $j \in \mathbb{Z}$.

Proof. The second inequalities in both sets of inequalities in (2.39) are obvious, since $\|\tilde{\phi}(\cdot - j)\| = \|\tilde{\phi}\|$ and $\|\delta(\cdot - j)\| = \|\delta\| = 1$. Now observe that

$$\left\langle \sum_k c_k \phi(\cdot - k), \sum_j d_j \tilde{\phi}(\cdot - j) \right\rangle = \sum_{j,k} d_j c_k \delta_{j,k} = \sum_j c_j d_j, \qquad \{c_k\} \in \ell^\infty, \ \{d_j\} \in \ell^1.$$

Thus, for all $\mathbf{c} = \{c_k\} \in \ell^\infty$ with $\|\mathbf{c}\|_{\ell^\infty} = 1$, we have, from (2.13),

$$\begin{aligned} \left| \sum_j d_j c_j \right| &\le \left\| \sum_j d_j \tilde{\phi}(\cdot - j) \right\| \left\| \sum_k c_k \phi(\cdot - k) \right\|_\infty \\ &\le \left\| \sum_j d_j \tilde{\phi}(\cdot - j) \right\| B \|\mathbf{c}\|_{\ell^\infty} = B \left\| \sum_j d_j \tilde{\phi}(\cdot - j) \right\|, \end{aligned}$$

where B is the absolute constant given in (2.13). Of course, it is clear that the constant B can be chosen as $B = \|\phi^0\|_\infty$. This yields

$$\begin{aligned}\left\|\sum_j d_j\tilde{\phi}(\cdot - j)\right\| &\geq B^{-1} \sup_{\|\mathbf{c}\|_{\ell^\infty}=1} \left|\sum_j d_j c_j\right| \\ &= B^{-1}\sum_j |d_j| = \|\phi^0\|_\infty^{-1}\|\mathbf{d}\|_{\ell^1}.\end{aligned}$$

This establishes the first inequality in the first of the two sets of inequalities in (2.39). The proof of the first inequality in the second set in (2.39) is similar. From (2.39) and (2.37), we see that δ is indeed an ℓ^1-stable generator of $\widetilde{V}_j$. Moreover, from (2.35) and (1.5), we also have (2.40), so that $\tilde{\phi}$ generates $\widetilde{V}_j$ as well. □

It is clear that δ satisfies the two-scale relation

$$\delta = 2\delta(2\cdot), \tag{2.41}$$

so that

$$\widetilde{V}_j \subset \widetilde{V}_{j+1}, \quad j \in \mathbb{Z}. \tag{2.42}$$

In addition, it follows from (2.18) and (2.37) that

$$W_j \perp \widetilde{V}_j, \qquad j \in \mathbb{Z}, \tag{2.43}$$

in the sense that

$$\langle g, \tilde{f}\rangle = 0 \quad \text{for all} \quad g \in W_j, \quad \tilde{f} \in V_j, \tag{2.44}$$

since

$$\langle \psi_L(\cdot + k), \delta\rangle = \psi_L(k) = \phi_L(2k-1) = 0, \quad k \in \mathbb{Z}. \tag{2.45}$$

The "orthogonality" property (2.43) is one of the main reasons that the dual spaces $\widetilde{V}_j$ are worth investigating. Next, following Cohen, Daubechies, and Feauveau [4], we will look for a subspace $\widetilde{W}_j$ of $\widetilde{V}_{j+1}$ that satisfies

$$\widetilde{V}_{j+1} = \widetilde{V}_j \dot{+} \widetilde{W}_j, \qquad j \in \mathbb{Z}, \tag{2.46}$$

$$V_j \perp \widetilde{W}_j, \qquad j \in \mathbb{Z}, \tag{2.47}$$

so that the generator of $\widetilde{W}_j$ is a dual of the generator of W_j. For this purpose, set

$$\tilde{\psi}_L := 2\sum_k (-1)^{k-1}\phi_L\left(\frac{1-k}{2}\right)\delta(2\cdot - k). \tag{2.48}$$

Then we have

$$\begin{aligned}\langle \psi_L, \tilde{\psi}_L(\cdot - j)\rangle &= \langle \psi_L(\cdot + j), \tilde{\psi}_L\rangle \\ &= \sum_k (-1)^{k-1}\phi_L\left(\frac{1-k}{2}\right) 2\langle \phi_L(2\cdot + 2j - 1), \delta(2\cdot - k)\rangle \\ &= \sum_k (-1)^{k-1}\phi_L\left(\frac{1-k}{2}\right)\phi_L(k + 2j - 1) \\ &= \sum_k (-1)^{k-1}\phi_L\left(\frac{1-k}{2}\right)\delta_{k+2j-1,0} \\ &= \phi_L(j) = \delta_{j,0}, \qquad j \in \mathbb{Z},\end{aligned} \tag{2.49}$$

so that $\tilde{\psi}_L$ is indeed a dual of ψ_L. Furthermore, observe that

$$\begin{aligned}\langle \phi_L, \tilde{\psi}_L(\cdot - j)\rangle &= \langle \phi_L(\cdot + j), \tilde{\psi}_L\rangle \\ &= \sum_k (-1)^{k-1} \phi_L\left(\frac{1-k}{2}\right) 2\langle \phi_L(\cdot + j), \delta(2\cdot -k)\rangle \\ &= \sum_k (-1)^{k-1} \phi_L\left(\frac{1-k}{2}\right) \phi_L\left(\frac{k}{2} + j\right) \\ &= \sum_\ell (-1)^{\ell} \phi_L\left(\frac{\ell}{2} + j\right) \phi_L\left(\frac{1-\ell}{2}\right) \\ &= -\langle \phi_L, \tilde{\psi}_L(\cdot - j)\rangle, \qquad j \in \mathbb{Z},\end{aligned}$$

so that

$$\langle \phi_L, \tilde{\psi}_L(\cdot - j)\rangle = 0, \qquad j \in \mathbb{Z}. \tag{2.50}$$

Hence, by setting

$$\widetilde{W}_j := \left\{ \sum_k d_k \tilde{\psi}_L(2^j \cdot -k) \colon \ \{d_k\} \in \ell^1 \right\}, \qquad j \in \mathbb{Z}, \tag{2.51}$$

we see that (2.47) holds. Later, in §3, we will see that (2.46) is also valid. Since $\tilde{\psi}_L$ is a dual of ψ_L and ψ_L is ℓ^∞-stable, it is clear from the proof of Theorem 2.6 that $\tilde{\psi}_L$ is an ℓ^1-stable generator of $\widetilde{W}_j$.

We now give another ℓ^1-stable generator of $\widetilde{W}_j$, which is a dual of ψ.

THEOREM 2.7. *Let*

$$S(z) = \sum_k s_k z^k := 2P(z)/\Phi(z^2), \qquad |z| = 1, \tag{2.52}$$

where $P(z)$ and $\Phi(z)$ are given in (2.2) *and* (2.8)*, respectively. Also, let ψ be defined as in* (1.10)*. Then the dual of ψ is given by*

$$\tilde{\psi} := 2\sum_k (-1)^{k-1} s_{1-k} \tilde{\phi}(2\cdot -k), \tag{2.53}$$

where $\tilde{\phi}$ is defined in (2.35)*. Furthermore, both $\tilde{\psi}_L$ and $\tilde{\psi}$ are ℓ^1-stable generators of $\widetilde{W}_j$, $j \in \mathbb{Z}$.*

Proof. Since ϕ and $\tilde{\phi}$ are dual to each other, we have from (1.10) and (2.53) that

$$\begin{aligned}&\langle \psi(\cdot + j), \tilde{\psi}\rangle \\ &= \left\langle \sum_\ell (-1)^{\ell-1} \phi(\ell - 1)\phi(2\cdot + 2j - \ell), 2\sum_k (-1)^{k-1} s_{1-k} \tilde{\phi}(2\cdot -k)\right\rangle \\ &= \sum_\ell \sum_k (-1)^{\ell+k} s_{1-k} \phi(\ell - 1)\langle \phi(\cdot - \ell + 2j), \tilde{\phi}(\cdot - k)\rangle \\ &= \sum_\ell \sum_k (-1)^{\ell+k} s_{1-k} \phi(\ell - 1)\delta_{\ell - 2j, k} \\ &= \sum_k s_{1-k}\phi(2j + k - 1) = \sum_k s_k \phi(2j - k), \qquad j \in \mathbb{Z}.\end{aligned} \tag{2.54}$$

On the other hand, by (2.52) and Lemma 2.1, we also have

$$\begin{aligned}(2.55)\qquad &\sum_j \left(\sum_k s_k \phi(2j-k)\right) z^{2j}\\ &= \sum_k s_k z^k \sum_j \phi(2j-k) z^{2j-k}\\ &= \sum_k s_{2k} z^{2k} \sum_j \phi(2j) z^{2j} + \sum_k s_{2k+1} z^{2k+1} \sum_j \phi(2j-1) z^{2j-1}\\ &= \frac{1}{4}[S(z)+S(-z)][\Phi(z)+\Phi(-z)] + \frac{1}{4}[S(z)-S(-z)][\Phi(z)-\Phi(-z)]\\ &= \frac{1}{2}S(z)\Phi(z) + \frac{1}{2}S(-z)\Phi(-z)\\ &= [P(z)\Phi(z)+P(-z)\Phi(-z)]/\Phi(z^2) = 1, \quad |z|=1.\end{aligned}$$

Hence, it follows from (2.54) and (2.55) that

$$(2.56)\qquad \langle \psi(\cdot + j), \widetilde{\psi}\rangle = \delta_{j,0}, \qquad j \in \mathbb{Z},$$

so that $\widetilde{\psi}$ is a dual of ψ.

We have already shown that $\widetilde{\psi}_L$ generates $\widetilde{W}_j$, $j \in \mathbb{Z}$ (see the discussion following (2.51)). To see that $\widetilde{\psi}$ also generates $\widetilde{W}_j$, it is sufficient to show that

$$(2.57)\qquad \widetilde{\psi}_L = \sum_\ell v_\ell \widetilde{\psi}(\cdot + \ell),$$

where $\{v_\ell\}$ is given by (2.25). Now, by (2.53) and (2.35), we have

$$\begin{aligned}(2.58)\qquad \sum_\ell v_\ell \widetilde{\psi}(\cdot+\ell) &= \sum_\ell v_\ell \left(2\sum_k (-1)^{k-1} s_{1-k} \widetilde{\phi}(2\cdot+2\ell-k)\right)\\ &= 2\sum_\ell \sum_k (-1)^{k-1} s_{1-k} v_\ell \sum_j r_j \delta(2\cdot+2\ell-k+j)\\ &= 2\sum_n (-1)^{n-1}\left(\sum_j \sum_\ell (-1)^j r_j v_\ell s_{1-j-n-2\ell}\right)\delta(2\cdot-n).\end{aligned}$$

Consequently, by (2.25) and (2.52), we obtain

$$\begin{aligned}(2.59)\qquad \sum_k \left(\sum_\ell v_\ell s_{k-2\ell}\right) z^k &= \sum_\ell v_\ell z^{2\ell} \sum_k s_{k-2\ell} z^{k-2\ell}\\ &= \sum_\ell v_\ell z^{2\ell} \sum_k s_k z^k = \Phi(z)\Phi(-z)2P(z)/\Phi(z^2)\\ &=: B(z) = \sum_k b_k z^k,\end{aligned}$$

and moreover, we have, by (1.5),

$$\begin{aligned}(2.60)\qquad \sum_m \left(\sum_j (-1)^j r_j b_{m-j}\right) z^m &= \sum_j (-1)^j r_j z^j \sum_m b_{m-j} z^{m-j}\\ &= [\Phi(-z)]^{-1} B(z) = 2\Phi(z)P(z)/\Phi(z^2).\end{aligned}$$

On the other hand, by (1.4) and (2.1), we also have

$$\phi_L\left(\frac{m}{2}\right) = \sum_k r_k \phi\left(\frac{m}{2} - k\right) = \sum_k r_k \sum_\ell p_\ell \phi(m - 2k - \ell),$$

so that

$$\begin{aligned}\sum_m \phi_L\left(\frac{m}{2}\right) z^m &= \sum_m \sum_k \sum_\ell r_k p_\ell \phi(m-2k-\ell) z^m \\ &= \sum_k r_k z^{2k} \sum_\ell p_\ell z^\ell \sum_m \phi(m-2k-\ell) z^{m-2k-\ell} \\ &= [\Phi(z^2)]^{-1} 2P(z)\Phi(z).\end{aligned} \tag{2.61}$$

Combining (2.61), (2.60), and (2.59), we arrive at

$$\begin{aligned}\phi_L\left(\frac{m}{2}\right) &= \sum_j (-1)^j r_j b_{m-j} \\ &= \sum_j \sum_\ell (-1)^j r_j v_\ell s_{m-j-2\ell}.\end{aligned} \tag{2.62}$$

Hence, substituting (2.62) into (2.58) (with $m = 1 - n$) and applying (2.48), we obtain (2.57). As in the proof of Theorem 2.6, the ℓ^1-stability of $\tilde\psi$ follows from the ℓ^∞-stability of its dual ψ (see Theorem 2.4). This completes the proof of Theorem 2.7. □

We end this section by pointing out that the functional

$$\tilde\eta := 2\sum_k (-1)^{k-1} \phi\left(\frac{1-k}{2}\right) \delta(2\cdot - k) \tag{2.63}$$

is also an ℓ^1-stable generator of $\widetilde{W}_j$. The advantage of $\tilde\eta$ over $\tilde\psi_L$ and $\tilde\psi$ is that it has compact support whenever ϕ is a compactly supported scaling function. The relation between $\tilde\eta$ and $\tilde\psi_L$ is given by

$$\tilde\eta = \sum_\ell \phi(\ell) \tilde\psi_L(\cdot + \ell). \tag{2.64}$$

Similarly, the dual of $\tilde\eta$ in W_0 is given by

$$\eta := \sum_k r_k \psi_L(\cdot - k), \tag{2.65}$$

and its ℓ^1-stability follows from the ℓ^∞-stability of η. The proof of these facts is similar to and even easier than the previous ones. Hence, it is safe to omit the details here.

3. Decompositions, multiresolution analyses, and the functional wavelet transform.

We will now complete our proof of the dual (orthogonal) decomposition (2.46)–(2.47) by establishing the decomposition relation (2.46). This and other related results are summarized in the following theorem.

THEOREM 3.1. *Let V_j, W_j be defined as in* (1.2), (1.7) *and $\widetilde{V}_j$, $\widetilde{W}_j$ as in* (2.37), (2.51). *Suppose that conditions* (i) *and* (vi) *stated in* §1 *hold. Then*

$$V_{j+1} = V_j \dot{+} W_j, \qquad j \in \mathbb{Z} \tag{3.1}$$

$$\widetilde{V}_{j+1} = \widetilde{V}_j \dot{+} \widetilde{W}_j, \qquad j \in \mathbb{Z}; \tag{3.2}$$

$$W_j \perp \widetilde{V}_j, \quad V_j \perp \widetilde{W}_j, \qquad j \in \mathbb{Z}; \quad \textit{and} \tag{3.3}$$

$$W_j \perp \widetilde{W}_k, \quad j \neq k, \quad j, k \in \mathbb{Z}. \tag{3.4}$$

Proof. Assertion (3.1) is the result (1.9) in §1, and (3.3) is the summary of (2.43) and (2.47)). Hence, it remains to establish (3.2) and (3.4). First, we see from (2.48) and (2.51) that $\widetilde{W}_j \subset \widetilde{V}_{j+1}$. So, by applying (2.42), we have

$$\widetilde{V}_{j+1} \supset \widetilde{V}_j + \widetilde{W}_j, \qquad j \in \mathbb{Z}. \tag{3.5}$$

On the other hand, it follows from (2.41) and (2.48) that

$$\begin{aligned}\tilde{\psi}_L &= 2\sum_k \phi_L(-k)\delta(2\cdot -2k-1) - 2\sum_k \phi_L\left(\frac{1}{2}-k\right)\delta(2\cdot -2k)\\ &= 2\delta(2\cdot -1) - \sum_k \phi_L\left(\frac{1}{2}-k\right)\delta(\cdot - k).\end{aligned} \tag{3.6}$$

This yields

$$\delta(2\cdot -1) = \frac{1}{2}\sum_k \phi_L\left(\frac{1}{2}-k\right)\delta(\cdot - k) + \frac{1}{2}\tilde{\psi}_L. \tag{3.7}$$

From (2.41) and (3.7), we see that $\widetilde{V}_{j+1} \subset \widetilde{V}_j + \widetilde{W}_j$. This, together with (3.5), gives

$$\widetilde{V}_{j+1} = \widetilde{V}_j + \widetilde{W}_j, \qquad j \in \mathbb{Z}. \tag{3.8}$$

To establish

$$\widetilde{V}_j \cap \widetilde{W}_j = \{0\}, \qquad j \in \mathbb{Z}, \tag{3.9}$$

we let $\tilde{f} \in \widetilde{V}_j \cap \widetilde{W}_j$ and write both

$$\tilde{f} = \sum_\ell c_\ell \delta(2^j \cdot -\ell), \quad \{c_\ell\} \in \ell^1, \tag{3.10}$$

and

$$\begin{aligned}\tilde{f} &= \sum_\ell d_\ell \tilde{\psi}_L(2^j \cdot -\ell)\\ &= 2\sum_\ell d_\ell \delta(2^{j+1} \cdot -2\ell - 1) - \sum_\ell d_\ell \sum_k \phi_L\left(\frac{1}{2}-k\right)\delta(2^j \cdot -\ell - k)\\ &= 2\sum_\ell d_\ell \delta(2^{j+1} \cdot -2\ell - 1) - \sum_\ell\left(\sum_k d_{\ell-k}\phi_L\left(\frac{1}{2}-k\right)\right)\delta(2^j \cdot -\ell)\end{aligned} \tag{3.11}$$

for some $\{d_\ell\} \in \ell^1$, where the second equality in (3.11) follows from (3.6). By (2.41), (3.10), and (3.11), we obtain

$$\sum_\ell b_\ell \delta(2^{j+1} \cdot -\ell) = 0, \tag{3.12}$$

where $b_{2\ell+1} = d_\ell$ and $b_{2\ell} = -(c_\ell + \sum_k \phi_L(\frac{1}{2}-k)d_{\ell-k})$, $\ell \in \mathbb{Z}$. Clearly $\{b_\ell\} \in \ell^1$, so that the ℓ^1-stability of δ (cf. (2.39)) and (3.12) together imply that $b_\ell = 0$, $\ell \in \mathbb{Z}$. This turns out to be $d_\ell = b_{2\ell+1} = 0$ and $c_\ell = -(b_{2\ell} + \sum_k \phi_L(\frac{1}{2}-k)d_{\ell-k}) = 0$, $\ell \in \mathbb{Z}$. Hence $\tilde{f} = 0$ and (3.9) is established. Combining (3.8) and (3.9) gives (3.2).

Finally, to prove (3.4), we may assume, without loss of generality, that $j < k$. Thus,

$$W_j \subset V_{j+1} \subset \cdots \subset V_k \perp \widetilde{W}_k, \tag{3.13}$$

where the last orthogonality relation comes from (3.3), so that (3.4) holds. This completes the proof of Theorem 3.1. □

In the notion of interpolating multiresolution analysis $\{V_j\}$ of C_u as described in §1, six conditions are imposed on $\{V_j\}$. In the following theorem, we will see that these conditions are not independent.

THEOREM 3.2. *Let the spaces* V_j *be defined as in* (1.2). *Suppose that conditions* (i) *and* (vi) *described in* §1 *hold. Then conditions* (ii)–(v) *there also hold.*

Proof. It is clear that (iv) and (v) are consequences of the definition (1.2). It only remains to prove (ii) and (iii).

Since we have assumed that the generator ϕ of V_j is a compactly supported continuous function, it is obvious that each element of V_j is a uniformly continuous bounded function, so that

$$V_j \subset C_u, \qquad j \in \mathbb{Z}. \tag{3.14}$$

For each $f \in C_u$, let $P_j f$ be given as in (1.6). Then $P_j f \in V_j$, and as proven in [5], we have

$$\begin{aligned} \|f - P_j f\|_\infty &\le \omega(f; 2^{-j}) + \omega(P_j f; 2^{-j}) \\ &\le (1 + C)\omega(f; 2^{-j}), \end{aligned} \tag{3.15}$$

where $C := \|\phi_L^0\|_\infty$ is a constant with ϕ_L^0 already introduced in (2.38). Here, the standard notation

$$\omega(f; t) := \sup_{|h| \le t} \|f(\cdot + h) - f(\cdot)\|_\infty \tag{3.16}$$

of the uniform modulus of continuity is used. Since f is uniformly continuous, it follows from (3.15) that

$$\|f - P_j f\|_\infty \to 0 \quad \text{as} \quad j \to \infty. \tag{3.17}$$

This together with (3.14) yields condition (ii). To establish (iii), let $f \in \bigcap_{j \in \mathbb{Z}} V_j$. Then we can write

$$f = \sum_k c_k^j \phi(2^j \cdot - k), \quad \{c_k^j\} \in \ell^\infty, \qquad j \in \mathbb{Z}.$$

Since ϕ is ℓ^∞-stable, we have $\|f\|_\infty \ge A\|\mathbf{c}^j\|_{\ell^\infty}$, where $A > 0$ is the absolute constant in (2.13). Thus, for any $x, y \in \mathbb{R}$, we obtain

$$\begin{aligned} |f(x) - f(y)| &\le \|\mathbf{c}^j\|_{\ell^\infty} \sum_k |\phi(2^j x - k) - \phi(2^j y - k)| \\ &\le A^{-1}\|f\|_\infty \sum_k |\phi(2^j x - k) - \phi(2^j y - k)| \to 0 \end{aligned}$$

as $j \to -\infty$. That is, $f(x) = f(y)$ for all $x, y \in \mathbb{R}$. This yields $\bigcap_{j \in \mathbb{Z}} V_j \subset \mathbb{C}$. On the other hand, since ϕ satisfies the two-scale relation (2.1) with ℓ^∞-stability, we have

$$\sum_k \phi(x - k) = \hat{\phi}(0) \neq 0, \qquad x \in \mathbb{R} \tag{3.18}$$

(cf. [6]), so that $\bigcap_{j\in\mathbb{Z}} V_j$ indeed consists only of the constant functions. This establishes (iii) and completes the proof of Theorem 3.2. □

It now follows from Theorems 3.1 and 3.2 that

$$C_u = V_j \dot{+} \dot{\sum_{\ell\geq j}} W_\ell = \mathbb{C} + \dot{\sum_{\ell\in\mathbb{Z}}} W_\ell, \tag{3.19}$$

where the $\dot{\sum}$ denotes direct summation. Of course, we must be careful in making sure that the statements in (3.19) actually make sense, since direct summation is usually an algebraic concept. We will return to this after Theorem 3.5 is established.

For the cardinal interpolation projection operators P_j in (1.6), we can write, on one hand,

$$(P_j f)(x) = \sum_k 2^j \langle f, \delta(2^j \cdot - k)\rangle \phi_L(2^j x - k), \tag{3.20}$$

and by applying (1.4), (1.6), and (2.35), we can also write, on the other hand,

$$\begin{aligned}(P_j f)(x) &= \sum_k f(2^{-j}k) \sum_\ell r_\ell \phi(2^j x - k - \ell) \\ &= \sum_k \left(\sum_\ell r_\ell f(2^{-j}(k-\ell))\right) \phi(2^j x - k) \\ &= \sum_k \langle f(2^{-j}(\cdot + k)), \tilde{\phi}\rangle \phi(2^j x - k) \\ &= \sum_k 2^j \langle f, \tilde{\phi}(2^j \cdot - k)\rangle \phi(2^j x - k).\end{aligned} \tag{3.21}$$

We define another family of projection operators Δ_j from C_u to W_j as follows:

$$(\Delta_j f)(x) := \sum_k 2^j \langle f, \tilde{\psi}(2^j \cdot - k)\rangle \psi(2^j x - k), \tag{3.22}$$

where the dual $\tilde{\psi}$ of ψ is given in (2.53). From (2.27) and (2.57), similar to the deduction of (3.21), we also have

$$(\Delta_j f) = \sum_k 2^j \langle f, \tilde{\psi}_L(2^j \cdot - k)\rangle \psi_L(2^j x - k). \tag{3.23}$$

Hence, for each of the projection operators P_j and Δ_j, we have two different representations. These two operators are related as follows.

LEMMA 3.3. *The projection operators P_j and Δ_j satsify the relation*

$$P_{j+1} = P_j + \Delta_j, \qquad j \in \mathbb{Z}. \tag{3.24}$$

Proof. It is sufficient to prove (3.24) for $j = 0$ and we will apply (3.23) and (3.20) (i.e., (1.6)) to establish this assertion. To this end, we need to use the two-scale equation (2.20) for the fundamental function ϕ_L, which has the equivalent form

$$\phi_L(2x) = \phi_L(x) - \sum_\ell \phi_L\left(\ell + \frac{1}{2}\right) \phi_L(2x - 2\ell - 1). \tag{3.25}$$

Thus, for all $f \in C_u(\mathbb{R})$, we have

$$
\begin{aligned}
(3.26)\qquad (P_1 f)(x) &= \sum_k f\left(\frac{k}{2}\right)\phi_L(2x-k)\\
&= \sum_k f(k)\phi_L(2x-2k) + \sum_k f\left(k+\frac{1}{2}\right)\phi_L(2x-2k-1)\\
&= \sum_k f(k)[\phi_L(x-k) - \sum_\ell \phi_L\left(\ell+\frac{1}{2}\right)\phi_L(2x-2k-2\ell-1)]\\
&\quad + \sum_k f\left(k+\frac{1}{2}\right)\phi_L(2x-2k-1)\\
&= \sum_k f(k)\phi_L(x-k) + \sum_k \left[f\left(k+\frac{1}{2}\right)\right.\\
&\quad \left. - \sum_\ell f(k-\ell)\phi_L\left(\ell+\frac{1}{2}\right)\right]\phi_L(2x-2k-1)\\
&= (P_0 f)(x)\\
&\quad + \sum_k \left[\sum_\ell (-1)^{\ell-1} f\left(k+\frac{\ell}{2}\right)\phi_L\left(\frac{1-\ell}{2}\right)\right]\phi_L(2x-2k-1).
\end{aligned}
$$

On the other hand, from (3.23), (2.48), and (1.11), we also have
(3.27)

$$
\begin{aligned}
(\Delta_0 f)(x) &= \sum_k \langle f, \tilde{\psi}_L(\cdot - k)\rangle \psi_L(x-k)\\
&= \sum_k 2\sum_\ell (-1)^{\ell-1}\phi_L\left(\frac{1-\ell}{2}\right)\langle f, \delta(2\cdot -2k-\ell)\rangle \phi_L(2x-2k-1)\\
&= \sum_k \left[\sum_\ell (-1)^{\ell-1}\phi_L\left(\frac{1-\ell}{2}\right) f\left(k+\frac{\ell}{2}\right)\right]\phi_L(2x-2k-1),
\end{aligned}
$$

so that combining this fact with (3.26) yields

$$
(P_1 f)(x) = (P_0 f)(x) + (\Delta_0 f)(x), \qquad x \in \mathbb{R}.
$$

This proves (3.24) for $j = 0$. □

LEMMA 3.4. *The dual pair* ψ, $\tilde{\psi}$ *in* (1.10) *and* (2.53) *satisfies*

$$
(3.28)\qquad \langle \psi(2^j \cdot -k), \tilde{\psi}(2^{j'} \cdot -k')\rangle = 2^{-j}\delta_{j,j'}\delta_{k,k'}, \qquad j, j', k, k' \in \mathbb{Z},
$$

and

$$
(3.29)\qquad \langle 1, \tilde{\psi}(2^j \cdot -k)\rangle = 0, \qquad j, k \in \mathbb{Z},
$$

where 1 *is viewed as a constant function. Similar results also hold for the dual pair* ψ_L, $\tilde{\psi}_L$ *in* (1.11) *and* (2.48).

Proof. By Theorem 2.7, we see that for $j' = j$,

$$
\langle \psi(2^j \cdot -k), \tilde{\psi}(2^j \cdot -k')\rangle = 2^{-j}\langle \psi(\cdot - k), \tilde{\psi}(\cdot - k')\rangle = 2^{-j}\delta_{k,k'}.
$$

For different j and j', since $\psi(2^j \cdot -k) \in W_j$, $\widetilde{\psi}(2^{j'} \cdot -k) \in \widetilde{W}_{j'}$, we see that (3.4) implies

$$\langle \psi(2^j \cdot -k), \widetilde{\psi}(2^{j'} \cdot -k') \rangle = 0.$$

This proves (3.28). To establish (3.29), we have, from (3.18),

$$1 = [\hat{\phi}(0)]^{-1} \sum_k \phi(2^j x - k) \in V_j,$$

so that (3.29) is a consequence of (3.3) and the fact that $\widetilde{\psi}(2^j \cdot -k) \in \widetilde{W}_j$. This establishes Lemma 3.4. □

One of the main results in this section is the following.

THEOREM 3.5. *Every $f \in C_u$ has a unique and pointwise convergent decomposition*

$$f(x) = f(0) + \sum_{j \in \mathbb{Z}} g_j(x), \qquad x \in \mathbb{R}, \tag{3.30}$$

where $g_j = \Delta_j f \in W_j$ with the projection operators Δ_j given as in (3.22) *or* (3.23). *Furthermore, for each $m \in \mathbb{Z}$ and $f \in C_u$, the series*

$$f = P_m f + \sum_{j \geq m} \Delta_j f \tag{3.31}$$

is unformly convergent in C_u (under the sup norm).

Proof. Given $\varepsilon > 0$, by (3.15) there exists an $N \in \mathbb{Z}$ such that

$$\|f - P_n f\|_\infty < \varepsilon \quad \text{for all} \quad n > N.$$

Now, for any $m \in \mathbb{Z}$ and integer $n \geq \max\{m, N\}$, since we have, by Lemma 3.3, $\sum_{j=m}^n \Delta_j = P_{n+1} - P_m$, it follows that

$$\left\| f - P_m f - \sum_{j=m}^{n} \Delta_j f \right\|_\infty = \|f - P_{n+1} f\|_\infty < \varepsilon.$$

This proves that the convergence in (3.31) is uniform. Also, according to (3.31), pointwise convergence in (3.30) is equivalent to pointwise convergence of

$$\lim_{m \to -\infty} (P_m f)(x) = f(0), \qquad x \in \mathbb{R}. \tag{3.32}$$

Hence, since we have, by (1.6),

$$(P_m f)(x) = f(0)\phi_L(2^m x) + \sum_{k \neq 0} f(2^{-m}k)\phi_L(2^m x - k)$$

and therefore

$$\begin{aligned} |(P_m f)(x) - f(0)| &\leq |f(0)||1 - \phi_L(2^m x)| + \sum_{k \neq 0} |f(2^{-m}k)||\phi_L(2^m x - k)| \\ &\leq \|f\|_\infty (|1 - \phi_L(2^m x)| + \sum_{k \neq 0} |\phi_L(2^m x - k)|), \end{aligned}$$

it follows that

$$\overline{\lim_{m \to -\infty}} |(P_m f)(x) - f(0)| \leq \|f\|_\infty (|1 - \phi_L(0)| + \sum_{k \neq 0} |\phi_L(k)|) = 0,$$

which yields (3.32) and hence (3.30). To establish the uniqueness of the decomposition, we see that if $c + \sum_{j\in\mathbb{Z}} g_j$ is another (pointwise convergent) representation for f with $c \in \mathbb{R}$, $g_j \in W_j$, then since every $g_j \in W_j$, $j \in \mathbb{Z}$, satisfies $g_j(0) = 0$ (see (2.45)), we immediately have $c = f(0)$. Moreover, according to Lemma 3.4 and (3.22) or (3.23), one can easily verify that $\Delta_j f = g_j$, $j \in \mathbb{Z}$. This completes the proof of Theorem 3.5. □

Remark. We need to point out that the convergence in (3.30) is not uniform in general. As a simple example, consider $f = \phi_L$. Then it is clear that $(P_j f)(x) = \phi_L(2^j x)$ for $j < 0$, and hence,

$$\|P_j f - f(0)\|_\infty = \|\phi_L(2^j\cdot) - \phi_L(0)\|_\infty = \|\phi_L - 1\|_\infty \geq 1.$$

This shows that the convergence in (3.32), and hence (3.30), is not uniform.

As a corollary of Theorem 3.5, we have from (3.3) that

$$f(x) = f(0) + \sum_{\ell<j}(\Delta_\ell f)(x), \qquad x \in \mathbb{R}, \tag{3.33}$$

for every $f \in V_j$. The reason is that for $\ell \geq j$, we have $f \in V_j \subset V_\ell \perp \widetilde{W}_\ell$, so that $\langle f, \widetilde{\psi}(2^\ell\cdot -k)\rangle = 0$, $k \in \mathbb{Z}$, and $(\Delta_\ell f)(x) = \sum_k 2^\ell\langle f, \widetilde{\psi}(2^\ell\cdot -k)\rangle\psi(2^\ell x - k) = 0$. As a consequence of (3.30) and (3.33), we see that the infinite direct sums in (3.19) as well as the direct sum

$$V_j = \mathbb{C}\dot{+}\dot{\sum_{\ell<j}} W_j \tag{3.34}$$

do make sense (with pointwise convergence).

From (3.22) and (3.30), we can write, for each $f \in C_u$,

$$f(x) = f(0) + \sum_{j\in\mathbb{Z}}\sum_{k\in\mathbb{Z}} d_k^j\psi(2^j x - k), \qquad x \in \mathbb{R}, \tag{3.35}$$

where

$$d_k^j = 2^j\langle f, \widetilde{\psi}(2^j\cdot -k)\rangle, \qquad j,k \in \mathbb{Z}. \tag{3.36}$$

We are now ready to introduce the notion of "functional wavelet transforms" (FnWT)

$$(W_{\widetilde{\psi}}f)(b,a) := \frac{1}{a}\left\langle f, \widetilde{\psi}\left(\frac{\cdot - b}{a}\right)\right\rangle, \qquad a \neq 0, \quad b \in \mathbb{R}, \tag{3.37}$$

as mentioned in (1.17). Recall that the usual integral wavelet transform (IWT) is an inner product in L^2, which is the dual space of itself. Hence, we may consider the FnWT as a generalization of the IWT. Recall also that the values of the IWT at the dyadic points $\left(\frac{k}{2^j}, \frac{1}{2^j}\right)$ can be computed via certain pyramid decomposition-reconstruction algorithms under the structure of a multiresolution analysis of L^2. The same is true for the situation of the FnWT, though the FnWT can be computed directly without integration (e.g., by the point-value functional and its linear combinations). This will be done in the next section. We end this section by deriving the property of vanishing moments of $\widetilde{\psi}$ as mentioned in §1.

THEOREM 3.6. *Let $\widetilde{\psi}$ be defined as in* (2.53). *If the scaling function ϕ (locally) reproduces all polynomials of degree up to $m-1$, where m is a positive integer, in the sense that*

$$x^j = \sum_k b_k^j \phi(x-k), \qquad x \in \mathbb{R}, \quad j = 0, 1, \ldots, m-1, \tag{3.38}$$

for some constants b_k^j with polynomial growth as $k \to \infty$, then

$$\langle p, \widetilde{\psi} \rangle = 0, \quad \textit{for all} \quad p \in \pi_{m-1}. \tag{3.39}$$

Similar results also hold for $\widetilde{\psi}_L$ in (2.48).

Remark. Since a nontrivial polynomial $p(x)$ does not belong to the space C_u, the meaning of $\langle p, \widetilde{\psi} \rangle$ must be clarified. However, this will be clear from the following proof of the theorem. In addition, since dilation and translation are invariant for polynomials, (1.19) follows from (3.39).

Proof. By (3.29), we have seen that (3.39) is valid for $p(x) \equiv 1$. For the general case, the proof of (3.39) is different from that of (3.29), and we first need to make sure that $\langle p, \widetilde{\psi} \rangle$ is well defined for any polynomial p.

From (2.53) and (2.35), we can write

$$\begin{aligned} \widetilde{\psi} &= 2\sum_k (-1)^{k-1} s_{1-k} \sum_\ell r_\ell \delta(2\cdot -k+\ell) \\ &= 2\sum_n (-1)^{n-1} \left(\sum_\ell (-1)^\ell r_\ell s_{1-n-\ell} \right) \delta(2\cdot -n) \\ &= 2\sum_n t_n \delta(2\cdot -n), \end{aligned} \tag{3.40}$$

where

$$t_n = (-1)^{n-1} \sum_\ell (-1)^\ell r_\ell s_{1-n-\ell}, \qquad n \in \mathbb{Z}. \tag{3.41}$$

Since $\{r_k\}$ and $\{s_k\}$ in (1.5) and (2.52), respectively, have exponential decay, so does $\{t_n\}$ in (3.41). Thus, the series

$$2\sum_n t_n \langle p, \delta(2\cdot -n) \rangle = \sum_n t_n p\left(\frac{n}{2}\right) \tag{3.42}$$

is absolutely convergent for any polynomial p, and according to (3.40) and (3.42), we may define

$$\langle p, \widetilde{\psi} \rangle := \sum_n t_n p\left(\frac{n}{2}\right), \qquad p \in \pi_{m-1}. \tag{3.43}$$

This is similar to but not completely the same as Definition 2.5 (iii).

Now, for $p(x) = x^j$, $0 \le j \le m-1$, from (3.38) and (3.43) we obtain

$$\langle p, \widetilde{\psi} \rangle = \sum_n \sum_k b_k^j t_n \phi\left(\frac{n}{2} - k\right). \tag{3.44}$$

Since b_k^j is of polynomial growth, t_n is of exponential decay, and ϕ is compactly supported, the double series in (3.44) is absolutely convergent, and consequently, we can interchange the order of summations in (3.44) to yield

$$\langle p,\widetilde{\psi}\rangle=\sum_k b_k^j\sum_n t_n\phi\left(\frac{n}{2}-k\right)=\sum_k b_k^j\langle\phi(\cdot-k),\widetilde{\psi}\rangle, \tag{3.45}$$

where the last equality in (3.45) follows from (3.40). From (3.45), it is clear that $\langle p,\widetilde{\psi}\rangle=0$ for all $p\in\pi_{m-1}$, since $\langle\phi(\cdot-k),\widetilde{\psi}\rangle=0$, for all $k\in\mathbb{Z}$ (see (2.47) and Theorem 2.7). This proves (3.39). From (2.57), we also have $\langle p,\widetilde{\psi_L}\rangle=0$ for all $p\in\pi_{m-1}$. This completes the proof of Theorem 3.6. □

4. Algorithms and examples. To derive the decomposition-reconstruction algorithms for the interpolating wavelets ψ_L and ψ, we need an explicit decomposition formula for $\phi_L(2x-\ell)$ and $\phi(2x-\ell)$, $\ell\in\mathbb{Z}$.

Taking $f(x)=\phi_L(2x-\ell)$ as in the proof of Theorem 2.4 and applying (2.21), (1.6), and (1.3), we immediately obtain

$$\begin{aligned}\phi_L(2x-\ell)&=f(x)=(P_0f)(x)+(f-P_0f)(x)\\&=\sum_k\delta_{2k,\ell}\phi_L(x-k)\\&\quad+\sum_k\left[\delta_{2k+1,\ell}-\sum_m\delta_{2m,\ell}\phi\left(k-m+\frac{1}{2}\right)\right]\psi_L(x-k).\end{aligned}\tag{4.1}$$

However, in practical applications, we may wish to use ϕ instead of ϕ_L. For this, we need the following result.

THEOREM 4.1. *Let the sequences $\{g_m\}\in\ell^1$ and $\{h_n\}\in\ell^1$ be determined by the following equations:*

$$\Phi(z)/\Phi(z^2)=\sum_n g_nz^n, \tag{4.2}$$

$$2z^{-1}P(-z)/\Phi(z^2)=\sum_n h_nz^n, \tag{4.3}$$

where $P(z)$ and $\Phi(z)$ are given in (2.2) and (2.8), respectively. Then

$$\phi(2x-\ell)=\sum_k[g_{2k-\ell}\phi(x-k)+h_{2k-\ell}\psi(x-k)],\qquad \ell\in\mathbb{Z}. \tag{4.4}$$

Proof. Since $\phi(2x-\ell)\in V_1=V_0\dot{+}W_0$ (cf. (3.1)), we can write

$$\phi(2x-\ell)=\sum_k g_k^\ell\phi(x-k)+\sum_k h_k^\ell\psi(x-k) \tag{4.5}$$

for some $\{g_k^\ell\}\in\ell^\infty$ and $\{h_k^\ell\}\in\ell^\infty$, $\ell\in\mathbb{Z}$. By applying the duals $\tilde{\phi}$ and $\widetilde{\psi}$ on (4.5) and observing that (3.3) holds, we have

$$\begin{cases}g_k^\ell=\langle\phi(2\cdot-\ell),\tilde{\phi}(\cdot-k)\rangle=\langle\phi(2\cdot+2k-\ell),\tilde{\phi}\rangle,\\ h_k^\ell=\langle\phi(2\cdot-\ell),\widetilde{\psi}(\cdot-k)\rangle=\langle\phi(2\cdot+2k-\ell),\widetilde{\psi}\rangle,\end{cases}\tag{4.6}$$

so that by setting

$$(4.7)\qquad \begin{cases} g_n := \langle \phi(2\cdot +n), \tilde{\phi}\rangle, \\ h_n := \langle \phi(2\cdot +n), \tilde{\psi}\rangle, \quad n \in \mathbb{Z}, \end{cases}$$

we see that (4.4) is a consequence of (4.5)–(4.7). It remains to prove that the sequences $\{g_n\}$ and $\{h_n\}$ defined in (4.7) satisfy equations (4.2) and (4.3).

By (2.35) and (4.7), we have

$$\begin{aligned} g_n &= \left\langle \phi(2\cdot +n), \sum_k r_k \delta(\cdot + k)\right\rangle \\ &= \sum_k r_k \langle \phi(2\cdot +n), \delta(\cdot + k)\rangle \\ &= \sum_k r_k \phi(n-2k), \end{aligned}$$

and consequently,

$$\begin{aligned} \sum_n g_n z^n &= \sum_n \sum_k r_k \phi(n-2k) z^n \\ &= \sum_k r_k z^{2k} \sum_n \phi(n-2k) z^{n-2k} \\ &= \sum_k r_k z^{2k} \sum_n \phi(n) z^n \\ &= \Phi(z)/\Phi(z^2), \end{aligned}$$

where the last equality follows from (2.8) and (1.5). This establishes (4.2). By (2.53), (4.7), and the duality between ϕ and $\tilde{\phi}$, we have

$$\begin{aligned} h_n &= \left\langle \phi(2\cdot +n), 2\sum_k (-1)^{k-1} s_{1-k} \tilde{\phi}(2\cdot -k)\right\rangle \\ &= \sum_k (-1)^{k-1} s_{1-k} \langle \phi(\cdot + n), \tilde{\phi}(\cdot - k)\rangle \\ &= \sum_k (-1)^{k-1} s_{1-k} \delta_{k,-n} = (-1)^{n+1} s_{n+1}, \end{aligned}$$

so that

$$\begin{aligned} \sum_n h_n z^n &= \sum_n (-1)^{n+1} s_{n+1} z^n \\ &= z^{-1} \sum_n s_n (-z)^n = 2z^{-1} P(-z)/\Phi(z^2), \end{aligned}$$

where the last equality follows from (2.52). This proves (2.43). From (4.2) and (4.3) it is clear that $\{g_n\} \in \ell^1$ and $\{h_n\} \in \ell^1$. This completes the proof of Theorem 4.1. □

With the decomposition formula (4.4) in hand, the algorithms for our interpolating wavelet ψ are almost the same as that in the L^2 setting. For any $f \in C_u$, let $f_N = P_N f$ be the projection of f to V_N for a fixed $N \in \mathbb{Z}$. More generally, we don't have to use the cardinal interpolant $P_N f$. We may consider V_N as the "sample space" and f_N the "data" (or measurement) of f on V_N. Since

$$V_N = W_{N-1} \dotplus V_{N-1} = \cdots \\ = W_{N-1} \dotplus \cdots \dotplus W_{N-M} \dotplus V_{N-M} \tag{4.8}$$

for any positive integer M, f_N has the unique decomposition

$$f_N(x) = g_{N-1}(x) + f_{N-1}(x) = \cdots \\ = g_{N-1}(x) + g_{N-2}(x) + \cdots + g_{N-M}(x) + f_{N-M}(x), \tag{4.9}$$

where

$$f_{j+1} = g_j + f_j, \quad f_j \in V_j, \quad g_j \in W_j, \quad j = N-M, \ldots, N-1. \tag{4.10}$$

Let us write

$$f_j(x) = \sum_k c_k^j \phi(2^j x - k) \in V_j, \quad \mathbf{c}^j = \{c_k^j\}, \tag{4.11}$$

and

$$g_j(x) = \sum_k d_k^j \psi(2^j x - k), \quad \mathbf{d}^j = \{d_k^j\}. \tag{4.12}$$

Then the decomposition in (4.9) is uniquely determined by the sequences $\mathbf{c}^j$ and $\mathbf{d}^j$ in (4.11) and (4.12), respectively. As shown in the last section, we have

$$d_k^j = 2^j \langle g_j, \tilde{\psi}(2^j \cdot - k) \rangle \\ = 2^j \langle f_N, \tilde{\psi}(2^j \cdot - k) \rangle = (W_{\tilde{\psi}} f_N) \left(\frac{k}{2^j}, \frac{1}{2^j} \right), \tag{4.13}$$

where $W_{\tilde{\psi}} f$ is the FnWT of f defined in (3.36). By using the dual property between ϕ and $\tilde{\phi}$ and noticing that $\tilde{\phi}(2^j \cdot - k) \in \tilde{V}_j \subset \tilde{V}_\ell \perp W_\ell$, $j \leq \ell \leq N$, we have

$$c_k^j = 2^j \langle f_j, \tilde{\phi}(2^j \cdot - k) \rangle \\ = 2^j \langle f_N, \tilde{\phi}(2^j \cdot - k) \rangle = (W_{\tilde{\phi}} f_N) \left(\frac{k}{2^j}, \frac{1}{2^j} \right). \tag{4.14}$$

4.1. Decomposition algorithm. Let the sequences $\{g_n\}$ and $\{h_n\}$ be as in Theorem 4.1. We have the following formula to produce $\mathbf{c}^j = \{c_k^j\}$ and $\mathbf{d}^j = \{d_k^j\}$, $j = N-M, \ldots, N-1$, from $\mathbf{c}^N = \{c_k^N\}$:

$$\begin{cases} c_k^{j-1} = \sum_\ell g_{2k-\ell} c_\ell^j, \\ d_k^{j-1} = \sum_\ell h_{2k-\ell} c_\ell^j, \quad k \in \mathbb{Z} \quad \text{and} \quad j = N, N-1, \ldots, N-M+1. \end{cases} \tag{4.15}$$

$$\begin{tikzcd} & \mathbf{d}^{N-1} & & \mathbf{d}^{N-2} & & & & \mathbf{d}^{N-M} \\ \mathbf{c}^N \arrow[r] \arrow[ur] & \mathbf{c}^{N-1} \arrow[rr] \arrow[urr] & & \mathbf{c}^{N-2} \arrow[r] \arrow[ur] & \cdots \arrow[rrr] \arrow[urrr] & & & \mathbf{c}^{N-M}. \end{tikzcd}$$

4.2. Reconstruction algorithm. Let $\{p_n\}$ be the two-scale sequence in (2.1). Then we have the following formula to produce $\mathbf{c}^j$, $N-M+1 \leq j \leq N$, from $\mathbf{c}^{N-M}$ and $\mathbf{d}^j$, $N-M \leq j \leq N-1$:

$$c_k^j = \sum_\ell [p_{k-2\ell} c_\ell^{j-1} + (-1)^{k-1}\phi(k-2\ell-1) d_\ell^{j-1}], \tag{4.16}$$

$k \in \mathbb{Z}$, $j = N-M+1, \ldots, N$.

$$\begin{tikzcd}
\mathbf{d}^{N-M} \arrow[dr] & \mathbf{d}^{N-M+1} \arrow[dr] & {} \arrow[dr] & \mathbf{d}^{N-1} \arrow[dr] & \\
\mathbf{c}^{N-M} \arrow[r] & \mathbf{c}^{N-M+1} \arrow[r] & \cdots \arrow[r] & \mathbf{c}^{N-1} \arrow[r] & \mathbf{c}^{N}.
\end{tikzcd}$$

The proof of the above decomposition-reconstruction algorithms is the same as the L^2 setting (see [1, pp. 158–159]).

Examples. (i) Let $\phi_1 \in L^2$ be a compactly supported scaling function which generates a (dyadic) multiresolution analysis of L^2. Then it is easy to see that the autocorrelation function

$$\phi(x) := (\phi_1(-\cdot) * \bar{\phi}_1)(x) = \int_{\mathbb{R}} \overline{\phi_1(x+y)}\phi_1(y)dy \tag{4.17}$$

of ϕ_1 generates the multiresolution analysis of C_u as introduced in this paper.

(ii) Consider the mth-order cardinal B-spline function N_m, defined by

$$\begin{cases} N_1(x) := \chi_{[0,1]}(x), \\ N_m(x) := (N_{m-1} * N_1)(x) = \displaystyle\int_0^1 N_{m-1}(x-t)dt, \quad m \geq 2. \end{cases} \tag{4.18}$$

Then N_m satisfies the two-scale relation

$$N_m(x) = \sum_{k=0}^{m} 2^{-m+1}\binom{m}{k} N_m(2x-k) \tag{4.19}$$

and has compact support $[0, m]$. It is well known that

$$\sum_k N_m\left(k + \frac{1+(-1)^{m-1}}{4}\right) z^k \neq 0, \quad \text{for all } |z| = 1 \tag{4.20}$$

(see [10]). In particular, we have

$$\sum_k N_{2m}(k) z^k \neq 0, \qquad |z| = 1, \quad m \geq 1. \tag{4.21}$$

Thus, for the scaling function $\phi = N_{2m}$, our interpolating wavelet ψ is given by

$$\psi_{2m}(x) := \sum_{k=2}^{2m} (-1)^{k-1} N_{2m}(k-1) N_{2m}(2x-k). \tag{4.22}$$

Note that the support of ψ is $[1, 2m]$, which is even smaller than the support of N_{2m}. The graphs of ψ_4 and ψ_6 are shown in Figures 1 and 2.

STABILITY OF REFINABLE FUNCTIONS, MULTIRESOLUTION ANALYSIS, AND HAAR BASES*

DING-XUAN ZHOU†

Abstract. The stability of the integer translates of a univariate refinable function is characterized in terms of the mask sequence in the corresponding k-scale ($k \geq 2$) refinement equation. We show that the stability and refinement of some kinds of basis functions lead to a multiresolution analysis in $L^p(\mathbb{R}^s)(1 \leq p \leq \infty, s \in \mathbb{N})$ based on general lattices. As an application we determine explicitly all those multiresolution analyses in $L^2(\mathbb{R})$ associated with $(\mathbb{Z}, k)$ whose scaling functions are characteristic functions.

Key words. stability, wavelets, refinement equations, multiresolution analysis, Haar bases

1. Introduction.

Wavelet decompositions are based on basis functions that satisfy refinement equations. The stability of the integer translates of the basis function plays an essential role in the study of wavelets. Since the basis function can be determined by the mask of the corresponding refinement equation, it is natural to characterize the stability in terms of the mask sequence.

Let $s \in \mathbb{N}$, $1 \leq p \leq \infty$, $\phi \in L^p := L^p(\mathbb{R}^s)$; we say that the integer translates of ϕ are l^p-stable if there exist positive constants A_p and B_p such that for any $a \in l^p(\mathbb{Z}^s)$

$$A_p\|a\|_p \leq \left\| \sum_{\alpha \in \mathbb{Z}^s} a_\alpha \phi(\cdot - \alpha) \right\|_p \leq B_p\|a\|_p. \tag{1.1}$$

A locally integrable function ϕ is said to be refinable if it satisfies the refinement equation

$$\phi = \sum_{\alpha \in \mathbb{Z}^s} b_\alpha \phi(M \cdot -\alpha), \tag{1.2}$$

where $b \in l^\infty(\mathbb{Z}^s)$ is a complex-valued sequence called the mask of (1.2) and M is an $s \times s$ matrix called a scaling matrix such that $M\mathbb{Z}^s := \{M\alpha : \alpha \in \mathbb{Z}^s\} \subset \mathbb{Z}^s$ and $k := |\det M| \in \mathbb{N}$ with all the eigenvalues satisfying $|\lambda_1| \geq |\lambda_2| \geq \cdots \geq |\lambda_s| > 1$.

Recently, Jia and Wang [7] gave a criterion for l^2-stability of the integer translates of a univariate compactly supported refinable distribution in terms of the compactly supported mask of the corresponding refinement equation. In this paper, in the cases of $s = 1$ and power of k with $k \geq 2$, we consider the stability of the integer translates of noncompactly supported refinable functions. For a function that decays exponentially fast in $L^2(\mathbb{R})$ we give a criterion for this l^2-stability in terms of the mask sequence of the refinement equation that it satisfies.

Once we have obtained the stability of the integer translates of a refinable function, we can construct a multiresolution analysis and then wavelet decompositions for different kinds of function spaces as well as applications. This procedure has been discussed by many authors; see [1, 3, 5–12]. Here we only mention a recent work of Jia and Micchelli [5].

For a measurable function ϕ on $\mathbb{R}^s$, set

$$\phi^0(x) = \sum_{\alpha\in\mathbb{Z}^s} |\phi(x-\alpha)|.$$

Then ϕ^0 is a 1-periodic function. Define

$$|\phi|_p = \|\phi^0\|_{L^p([0,1)^s)}.$$

For $1 \le p \le \infty$, let $\mathcal{L}^p(\mathbb{R}^s)$ be the Banach space of all measurable functions ϕ for which $\|\phi\|_{\mathcal{L}^p} = |\phi|_p < \infty$. These spaces have many interesting properties that can be found in [5]. By means of these properties, Jia and Micchelli proved that the stability and refinement of an $\mathcal{L}^p$ basis function are sufficient to generate a multiresolution analysis of power of two in $L^p(\mathbb{R}^s)$ for $1 \le p < \infty$.

In the second part of this paper we give similar results for $1 \le p \le \infty$ and general lattices.

Finally, we use the above results to determine explicitly all the multiresolution analyses in $L^2(\mathbb{R})$ associated with $(\mathbb{Z}, k)$ whose scaling functions are characteristic functions, which is the main purpose of this paper. Such a scaling function can be expressed as the characteristic function χ_Q of some set Q defined by

$$Q = \left\{ \sum_{j=1}^{\infty} k^{-j}\epsilon_j : \epsilon_j \in \{n_0, \dots, n_{k-1}\} \right\}, \tag{1.3}$$

where $\{n_0, \dots, n_{k-1}\}$ is a collection of representatives of distinct cosets of $\mathbb{Z}/(k\mathbb{Z})$, say, $n_j \equiv j \pmod{k}$ for $0 \le j \le k-1$. Gröchenig and Madych [4] gave some conditions on Q that are sufficient and necessary for χ_Q to generate a multiresolution analysis in $L^2(\mathbb{R})$. However, these conditions cannot be verified easily. Using our above results and Euler's theorem from number theory, we show in the last section that χ_Q can generate a multiresolution analysis in $L^2(\mathbb{R})$ if and only if the numbers $\{n_1 - n_0, n_2 - n_0, \dots, n_{k-1} - n_0\}$ are relatively prime. Moreover, for any collection of representatives $\{n_0, n_1, \dots, n_{k-1}\}$ the set Q defined by (1.3) has measure $(n_1 - n_0, n_2 - n_0, \dots, n_{k-1} - n_0) \in \mathbb{N}$. Here for a set $\{m_1, \dots, m_J\}$ of integer numbers we use $(m_1, \dots, m_J)$ to denote the greatest common divisor (g.c.d.).

For further convenience, we need some notation.

For $x = (x_1, \dots, x_s) \in \mathbb{R}^s$, we let $|x| = \sum_{j=1}^s |x_j|$ be its norm in $\mathbb{R}^s$. We denote $|E|$ as the measure of the set $E \subset \mathbb{R}^s$.

For a sequence $b \in \mathbb{Z}^s$, we denote $\tilde{b}$ as its symbol

$$\tilde{b}(z) = \sum_{\alpha\in\mathbb{Z}^s} b_\alpha z^\alpha, \qquad z \in \mathbb{C}^s. \tag{1.4}$$

Given a function $\phi \in \mathcal{L}^p(\mathbb{R}^s)$ and a sequence $a \in l^\infty(\mathbb{Z}^s)$, the semidiscrete convolution product $\phi *' a$ is, by definition, the sum $\sum_{\alpha\in\mathbb{Z}^s} \phi(\cdot - \alpha)a(\alpha)$.

The Fourier transform of a function $\phi \in L^1(\mathbb{R}^s)$ is given by

$$\hat{\phi}(\omega) = \int_{\mathbb{R}^s} \phi(x) e^{-ix\cdot\omega}\, dx,$$

where for $x = (x_1, \dots, x_s)$ and $\omega = (\omega_1, \dots, \omega_s) \in \mathbb{R}^s, x \cdot \omega = \sum_{j=1}^s x_j\omega_j$. This operation can be uniquely extended to $L^2(\mathbb{R}^s)$. For $\phi \in L^2(\mathbb{R}^s)$, set for $\omega \in \mathbb{R}^s$

$$\Pi_\phi(\omega) = \sum_{\alpha\in\mathbb{Z}^s} |\hat{\phi}(\omega + 2\pi\alpha)|^2. \tag{1.5}$$

With all the above notation we can now state our main results.

2. A criterion for stability. In the univariate case the refinement equation (1.2) becomes

$$\phi = \sum_{n\in\mathbb{Z}} b_n \phi(k\cdot -n) \tag{2.1}$$

with $2 \leq k \in \mathbb{N}$, $(b_n) \in l^\infty(\mathbb{Z})$.

We want to characterize the stability of the integer translates of an exponentially decaying solution to (2.1) in terms of the zero distribution of the symbol of the mask sequence.

For generality we denote E^2 as the space of all the functions f in $\mathcal{L}^2(\mathbb{R})$ that satisfy

$$\|f(\cdot+n)\|_{L^2[0,1)} \leq Cq^{|n|} \tag{2.2}$$

for some constants $C > 0$ and $0 < q < 1$ that depend only on f.

Then we can state our first main result as follows.

THEOREM 1. *Let $\phi \in E^2$ be a solution to (2.1) with $\hat{\phi}(0) \neq 0$. Then the integer translates of ϕ are l^2-stable if and only if the following conditions are satisfied.*

(1) $b \in l^1(\mathbb{Z})$.

(2) $\sum_{l=0}^{k-1} |\tilde{b}(e^{-i2l\pi/k}z)| > 0$ *for any z on the unit circle $T := \{z \in \mathbb{C} : |z| = 1\}$.*

(3) *For any $m \in \mathbb{N}$ and $z \in T$ satisfying $z^{k^m} = z \neq 1$, there exists an integer $d \geq 0$ such that*

$$\sum_{l=1}^{k-1} |\tilde{b}(e^{-i2l\pi/k} z^{k^d})| > 0. \tag{2.3}$$

Proof of Theorem 1. Necessity. Suppose that the integer translates of $\phi \in E^2 \subset \mathcal{L}^2(\mathbb{R})$ are l^2-stable. Then by [5, Thm. 3.3] there exists $g = \phi *' a$, $a \in l^1$, such that for $\alpha, \beta \in \mathbb{Z}$

$$\langle \phi(\cdot - \alpha), g(\cdot - \beta)\rangle = \delta_{\alpha,\beta}.$$

Note that $b \in l^\infty$ and $\phi, g \in \mathcal{L}^2(\mathbb{R})$. Using the dominated convergence theorem, we obtain from (2.1) that

$$b_n = \left\langle \phi\left(\frac{1}{k}\cdot\right), g(\cdot - n)\right\rangle.$$

Hence, condition (1) is necessary:

$$\|b\|_1 \leq \left|\phi\left(\frac{1}{k}\cdot\right)\right|_2 |g|_2 \leq k^2|\phi|_2|g|_2 < \infty.$$

Therefore, $\tilde{b}(z)$ is continuous for $z \in T$.

To see the necessity of condition (2), we take the Fourier transforms of both sides of (2.1) and obtain

$$\hat{\phi}(\omega) = \frac{1}{k}\tilde{b}(e^{-i\omega/k})\hat{\phi}\left(\frac{\omega}{k}\right). \tag{2.4}$$

Note that for $\phi \in \mathcal{L}^2(\mathbb{R})$, $\Pi_\phi(\omega)$ is continuous for $\omega \in \mathbb{R}$. We have

$$\Pi_\phi(\omega) = \frac{1}{k^2}\sum_{l=0}^{k-1}\left|\tilde{b}(e^{-i2l\pi/k}e^{-i\omega/k})\right|^2 \Pi_\phi\left(\frac{\omega+2l\pi}{k}\right).$$

It was proved in [5, Thm. 3.3] that for $\phi \in \mathcal{L}^2(\mathbb{R})$, the integer translates of ϕ are l^2-stable if and only if $\Pi_\phi(\omega) > 0$ for any $\omega \in \mathbb{R}$. Therefore, we must have

$$\sum_{l=0}^{k-1}\left|\tilde{b}(e^{-i2l\pi/k}e^{-i\omega/k})\right| > 0.$$

Hence condition (2) is also necessary.

Finally, we prove the necessity of condition (3). Suppose to the contrary that there exist $m \in \mathbb{N}$ and $z_0 \in T$ such that $z_0^{k^m} = z_0 \neq 1$ and for all integers $d \geq 0$,

$$\sum_{l=1}^{k-1}\left|\tilde{b}(e^{-i2l\pi/k}z_0^{k^d})\right| = 0. \tag{2.5}$$

Let $z_0 = e^{-i2n\pi/(k^m-1)} \neq 1$. Then $n/(k^m-1) \notin \mathbb{Z}$. We claim that for all $\alpha \in \mathbb{Z}$,

$$\hat{\phi}(2n\pi/(k^m-1)+2\alpha\pi) = 0, \tag{2.6}$$

which implies that the integer translates of ϕ are l^2-unstable.

To prove (2.6), we set $n+(k^m-1)\alpha = k^p q$, where $p \geq 0$ and q are integers and $k \not| |q|$ or $q = 0$. Since $n/(k^m-1) \notin \mathbb{Z}$, we must have $q \neq 0$.

By (2.4) we have

$$\begin{aligned}\hat{\phi}(2n\pi/(k^m-1)+2\alpha\pi) &= \hat{\phi}(2k^p q\pi/(k^m-1)) \\ &= \prod_{j=1}^{p+1}\left[\frac{1}{k}\tilde{b}(e^{-i2k^{p-j}q\pi/(k^m-1)})\right]\hat{\phi}(2q\pi/(k(k^m-1))).\end{aligned}$$

Under assumption (2.5) we now prove that

$$\tilde{b}(e^{-i2q\pi/(k(k^m-1))}) = 0, \tag{2.7}$$

which implies (2.6).

To this end, we choose $r = (k^{m(p+1)}-1)/(k^m-1) \in \mathbb{N}$ and set $-qr = uk+v$ with $u, v \in \mathbb{Z}$ and $0 \leq v < k$. Then we must have $v \neq 0$, since $(k,r) = 1$ and $k \not| |q|$.

Therefore, we have

$$\begin{aligned}\tilde{b}(e^{-i2q\pi/(k(k^m-1))}) &= \tilde{b}(e^{-i2q\pi[k^{m(p+1)}-r(k^m-1)]/[k(k^m-1)]}) \\ &= \tilde{b}(e^{i2qr\pi/k}e^{-i2\pi k^p q k^{(m-1)(p+1)}/(k^m-1)}) \\ &= \tilde{b}(e^{-i2v\pi/k}(e^{-i2\pi n/(k^m-1)})^{k^{(m-1)(p+1)}}) \\ &= \tilde{b}(e^{-i2v\pi/k}z_0^{k^{(m-1)(p+1)}}) \\ &= 0.\end{aligned}$$

Thus, the proof of the necessity is complete.

Sufficiency. We note that $\phi \in \mathcal{L}^2(\mathbb{R})$ satisfies

$$\sum_{n\in\mathbb{Z}} |\hat{\phi}(\omega + 2n\pi)|^2 = \sum_{n\in\mathbb{Z}} \langle \phi(\cdot + n), \phi \rangle e^{-in\omega}.$$

For this, see [5, Thm. 3.2].

Let

$$K(\phi) = \left\{ z = e^{-i\omega} \in T : \omega \in \mathbb{R}, \sum_{n\in\mathbb{Z}} |\hat{\phi}(\omega + 2n\pi)|^2 = 0 \right\}. \tag{2.8}$$

Since $\phi \in E^2$, the sequence $\{\langle \phi(\cdot + n), \phi\rangle\}_{n\in\mathbb{Z}}$ decays exponentially fast. Hence the function

$$\sum_{n\in\mathbb{Z}} \langle \phi(\cdot + n), \phi \rangle z^n$$

is analytic in a domain $\{z \subset \mathbb{C} : r_1 < |z| < r_2\}$ with $0 < r_1 < 1 < r_2$ and, therefore, has only finitely many zero points on T. That is, $K(\phi)$ is a finite set.

Suppose that the three conditions of Theorem 1 are satisfied. We show that $K(\phi)$ is empty, which implies that ϕ has l^2-stable integer translates.

We first prove the following statement.

If $z \in K(\phi)$, then there exists a positive integer m such that

$$z^{k^m} = z \neq 1. \tag{2.9}$$

Let $z_0 = e^{-i\zeta} \in K(\phi)$. Then $z_0 \neq 1$ since $\hat{\phi}(0) \neq 0$. From condition (1), we know that $\tilde{b}(z)$ is continuous on T. Thus, we can use (2.4) and obtain

$$\Pi_\phi(\zeta) = \frac{1}{k^2} \sum_{l=0}^{k-1} \left| \tilde{b}(e^{-i(\zeta+2l\pi)/k}) \right|^2 \Pi_\phi\left(\frac{\zeta}{k} + \frac{2l\pi}{k} \right) = 0.$$

From condition (2) we know that there exists $l \in \{0, 1, \ldots, k-1\}$ such that $\tilde{b}(e^{-i2l\pi/k} e^{-i\zeta/k}) \neq 0$. Hence,

$$\Pi_\phi\left(\frac{\zeta}{k} + \frac{2l\pi}{k} \right) = 0$$

and $e^{-i(\zeta+2l\pi)/k} \in K(\phi)$. This shows that there exists $z_1 \in K(\phi)$ such that $z_1^k = z_0$. Repeating this process, we can find a sequence $\{z_n\}_{n=0,1,\ldots}$ in $K(\phi)$ such that $z_n^k = z_{n-1}$ for $n \in \mathbb{N}$. But $K(\phi)$ is a finite set. We must have integers $0 \leq p < q$ such that $z_p = z_q$. Then we obtain

$$z_p = z_q^{k^{q-p}} = z_q$$

and

$$z_0 = z_q^{k^q} = z_q^{k^{2q-p}} = z_0^{k^{q-p}}.$$

Here $q - p \in \mathbb{N}$. Therefore, (2.9) holds and the statement is true.

We use this statement to prove the sufficiency. Suppose to the contrary that the integer translates of ϕ are l^2-unstable. Equivalently, $K(\phi)$ is not empty, say, $z \in K(\phi)$.

Then, by (2.9) there exists $m \in \mathbb{N}$ such that $z^{k^m} = z \neq 1$. Set $z = e^{-i2\pi k^p q/(k^m-1)}$, where $q, p \geq 0$ and $k \not| q$.

We show that for $z_0 = e^{-i2\pi q/(k^m-1)} \neq 1$ and any integers $d \geq 0, l = 1, 2, \ldots, k-1$,

$$\tilde{b}(e^{-i2l\pi/k} z_0^{k^d}) = 0, \tag{2.10}$$

which is a contradiction to condition (3). Hence the integer translates must be l^2-stable.

To prove (2.10) for d and l, we let $\omega_0 = 2\pi k^{p+m(d+1)} q/(k^m - 1)$. Then $e^{-i\omega_0} = z \in K(\phi)$, i.e., $\Pi_\phi(\omega_0) = 0$.

By (2.4), we have for $l = 0, 1, \ldots, k-1$,

$$\begin{aligned}\sum_{n\in\mathbb{Z}} &|\hat{\phi}(\omega_0 + 2\pi(kn + l))|^2 \\ &= \frac{1}{k^2}|\tilde{b}(e^{-i(\omega_0+2l\pi)/k})|^2 \Pi_\phi\left(\frac{\omega_0 + 2l\pi}{k}\right) = 0.\end{aligned}$$

Thus, either $\tilde{b}(e^{-i(\omega_0+2l\pi)/k})$ or $\Pi_\phi\left(\frac{\omega_0+2l\pi}{k}\right)$ must be zero.

On the other hand, we claim that for $l = 1, 2, \ldots, k-1$,

$$\Pi_\phi\left(\frac{\omega_0 + 2l\pi}{k}\right) \neq 0.$$

Since otherwise, $e^{-i(\omega_0+2l\pi)/k} \in K(\phi)$, by (2.9), there exists a positive integer α such that $(e^{-i(\omega_0+2l\pi)/k})^{k^\alpha - 1} = 1$. Hence,

$$\frac{1}{2\pi}(\omega_0 + 2l\pi)(k^\alpha - 1)/k = (k^{p+m(d+1)}q/(k^m - 1) + l)(k^\alpha - 1)/k \in \mathbb{Z}.$$

We observe that for any $n \in \mathbb{N}$, $(k^n - 1, k) = 1$. Therefore,

$$k^{p+m(d+1)-1}q(k^\alpha - 1) + l(k^\alpha - 1)(k^m - 1)/k \in \mathbb{Z}$$

and

$$l/k \in \mathbb{Z},$$

which is a contradiction.

We have proved our claim and obtain for $l = 1, 2, \ldots, k-1$,

$$\tilde{b}(e^{-i(\omega_0+2l\pi)/k}) = 0. \tag{2.11}$$

By condition (2) we also have from (2.11)

$$\tilde{b}(e^{-i\omega_0/k}) \neq 0.$$

Hence, $\Pi_\phi(\omega_0/k) = 0$.

Let $\omega_j = k^{-j}\omega_0 = 2\pi k^{p+m(d+1)-j}q/(k^m - 1)$. Our process for ω_0 can be repeated for ω_j with $j = 1, 2, \ldots, p + m(d+1) - 1$. In fact, for $1 \leq j \leq p + m(d+1) - 1$, we have

$$\tilde{b}(e^{-i(\omega_j+2\pi l)/k}) = 0, \qquad l = 1, 2, \ldots, k-1,$$

and

$$\Pi_\phi\left(\frac{\omega_j}{k}\right) = 0.$$

In particular, for $l = 1, 2, \ldots, k-1$,

$$\tilde{b}(e^{-i2\pi l/k} z_0^{k^d}) = \tilde{b}(e^{-i(\omega_{p+m(d+1)-d}+2l\pi)/k}) = 0.$$

Thus, we have proved (2.10) for any integer $d \geq 0$ and $l = 1, 2, \ldots, k-1$.

The proof of Theorem 1 is complete. □

Remark. If we replace the condition $\phi \in E^2$ by the assumption that $\phi \in \mathcal{L}^2(\mathbb{R})$ and $\Pi_\phi(\cdot)$ has only finitely many zeros on $[0, 2\pi)$, then Theorem 1 still holds. In fact, this observation is also true for multivariate cases, which we shall discuss elsewhere.

Remark. Even if a refinable function that has l^2-stable integer translates is of compact support, it may happen that the mask of the corresponding refinement equation does not have compact support. Let $k = 2$ and $\phi \in \mathcal{L}^2(\mathbb{R})$ be a compactly supported refinable function whose integer translates are l^2-stable. Suppose that ϕ satisfies the refinement equation

$$\phi\left(\frac{1}{2}\cdot\right) = \phi *' b$$

with the mask b of compact support. Then for a finitely supported sequence a, the function $\psi = \phi *' a$ has l^2-stable integer translates if and only if $\tilde{a}(z)$ has no zeros on T. In this case, ψ is also refinable. The mask of the corresponding refinement equation is of compact support if and only if $\tilde{a}(z^2)\tilde{b}(z)/\tilde{a}(z)$ is a Laurent polynomial. For example, we choose $\phi \in C(\mathbb{R})$ to be of compact support, to be refinable, and to have orthogonal integer translates. Then $\phi(\cdot) + c\phi(\cdot + 2n)$ with $n \in \mathbb{N}$ and $0 \neq c \notin T$ is a refinable compactly supported function and has l^2-stable integer translates. But the mask of the corresponding refinement equation is of no compact support.

By the method in the first part of the proof of Theorem 1 and some estimates in [5] we can easily obtain the following result.

THEOREM 2. *Suppose that $s \in \mathbb{N}$, $\{\phi_1, \ldots, \phi_n\} \subset \mathcal{L}^p(\mathbb{R}^s)$ have l^p-stable integer translates with $2 \leq p \leq \infty$ (for a definition, see* [5]*). Denote $S_p(\phi_1, \ldots, \phi_n) = \{\sum_{j=1}^n \phi_j *' a_j : a_1, \ldots, a_n \in l^p(\mathbb{Z}^s)\}$. Then the mapping*

$$L_{\phi_1,\ldots,\phi_n} : (l^p)^n \longrightarrow L^p(\mathbb{R}^s)$$

given by

$$L_{\phi_1,\ldots,\phi_n}(a_1, \ldots, a_n) = \sum_{j=1}^n \phi_j *' a_j$$

defines an isomorphism from $(l^1)^n$ onto the space $\mathcal{L}^p(\mathbb{R}^s) \cap S_p(\phi_1, \ldots, \phi_n)$ with the norm $|\ |_p$.

Combining Theorem 1 with [2], we can give a similar criterion for the orthogonality.

THEOREM 3. *Let $\phi \in E^2$ be a solution to* (2.1) *with $\hat{\phi}(0) = 1$. Then the integer translates of ϕ are orthogonal if and only if the mask b satisfies the conditions* (1) *and* (3) *in Theorem* 1 *and the following condition:*

$$\sum_{l=0}^{k-1} \left|\tilde{b}(e^{-i2l\pi/k} z)\right|^2 = k^2 \quad \textit{for all } z \in T.$$

By our method here and some ideas from [7] we can also give some criteria for the stability and linear independence of the integer translates of a refinable (associated with $(\mathbb{Z}, k)$) compactly supported distribution (for the definitions, see [7]).

Let $\{b_n\}_{n\in\mathbb{Z}}$ be a finitely supported sequence with $\sum_{n\in\mathbb{Z}} b_n = k, k \geq 2$; and let ϕ be the compactly supported distribution solution to the refinement equation (2.1) with $\hat{\phi}(0) = 1$. Then we have the following result.

THEOREM 4. *The integer translates of ϕ are stable if and only if conditions* (2) *and* (3) *in Theorem* 1 *are satisfied.*

THEOREM 5. *The integer translates of ϕ are linearly independent if and only if the symbol of the mask $\tilde{b}(z)$ satisfies condition* (3) *in Theorem* 1 *and the following condition:*

$$\sum_{l=0}^{k-1} \left|\tilde{b}(e^{-i2l\pi/k}z)\right| > 0 \quad \textit{for all } z \in \mathbb{C} \setminus \{0\}.$$

3. Multiresolution analysis in $L^p(\mathbb{R}^s)$. Most constructions of wavelet decompositions are based on multiresolution analyses.

We say that a sequence $\{V_j\}_{j\in\mathbb{Z}}$ of closed subspaces of $L^p(\mathbb{R}^s)$ $(1 \leq p \leq \infty, s \in \mathbb{N})$ forms a multiresolution analysis in $L^p(\mathbb{R}^s)$ with respect to a scaling matrix M as defined in §1 if it satisfies the following conditions.

(R1) $V_j \subset V_{j+1}$ for all $j \in \mathbb{Z}$.

(R2) $f \in V_0$ if and only if $f(\cdot - \alpha) \in V_0$ for all $\alpha \in \mathbb{Z}^s$.

(R3) $f \in V_j$ if and only if $f(M\cdot) \in V_{j+1}$ for all $j \in \mathbb{Z}$.

(R4) There exists an isomorphism from $l^p(\mathbb{Z}^s)$ onto V_0 that commutes with shift operators.

(R5) $\cap_{j\in\mathbb{Z}} V_j = \{0\}$ for $1 \leq p < \infty$;

$$\dim\left(\bigcap_{j\in\mathbb{Z}} V_j\right) < \infty \quad \text{for } p = \infty.$$

(R6) $\cup_{j\in\mathbb{Z}} V_j$ is dense in $(L^p(\mathbb{R}^s), \|\cdot\|_p)$ for $1 \leq p < \infty$ and in $(L^\infty(\mathbb{R}^s), \sigma(L^\infty, L^1))$ for $p = \infty$.

The concept of multiresolution analysis was first introduced by Mallat [10] and Meyer [11] for the case $p = 2$, which is of most interest. In this case, there is a function ϕ in V_0 whose integer translates form an unconditional basis of V_0. Such a function is called scaling function.

Jia and Micchelli [5] discussed the cases of $1 \leq p < \infty$ and power two in more detail. They proved that the refinement and stability of integer translates of certain basis function are sufficient to lead to a multiresolution analysis of $L^p(\mathbb{R}^s)$ for $1 \leq p < \infty$. For general scaling matrices and $p = 2$, see also [6, 9]. In this section we develop this theory to the case $p = \infty$. Our definition for this case is somewhat different from that of Jia and Micchelli.

In the next section we shall use the results for a general scaling matrix in the univariate case. Hence, we present our statements for the general lattices and for $1 \leq p \leq \infty$. We shall only give the detailed proof for the case $p = \infty$ and omit the proof for $1 \leq p < \infty$ because it can be obtained by the same methods as in [5, 6].

We first state our main result in this section and prove it later.

THEOREM 6. *Let $\phi \in \mathcal{L}^p(\mathbb{R}^s)$ for $1 \leq p < \infty$; $\phi, \phi^0 \in C(\mathbb{R}^s)$ for $p = \infty$; $s \in \mathbb{N}$; and M is a scaling matrix. Define $V_0 = S_p(\phi)$ and $V_j = \{f(M^j\cdot) : f \in V_0\}$. If ϕ is* *refinable with an l^1-mask and has l^p-stable integer translates, then $\{V_j\}_{j\in\mathbb{Z}}$ forms a multiresolution analysis in $L^p(\mathbb{R}^s)$.*

The proof of Theorem 6 is divided into a few parts. We first prove the property (R5).

THEOREM 7. *Let $\phi \in \mathcal{L}^p(\mathbb{R}^s)$ for $1 \le p < \infty$; $\phi, \phi^0 \in C(\mathbb{R}^s)$ for $p = \infty$; $V_0 = S_p(\phi)$; and $V_j = \{f(M^j\cdot) : f \in V_0\}$. If ϕ has l^p-stable integer translates, then $\cap_{j\in\mathbb{Z}} V_j = \{0\}$ for $1 \le p < \infty$ while $\cap_{j\in\mathbb{Z}} V_j$ is the set of constant functions in $\mathbb{R}^s$ for $p = \infty$.*

Proof of Theorem 7 for $p = \infty$. Let $f \in \cap_{j\in\mathbb{Z}} V_j$. Then $f(M^j\cdot) \in V_0$ for any $j \in \mathbb{Z}$. Hence there exists a sequence $a^{(j)} \in l^\infty$ such that

$$f(M^j x) = \phi *' a^{(j)}(x) = \sum_{\alpha\in\mathbb{Z}^s} a_\alpha^{(j)} \phi(x - \alpha)$$

and

$$\|a^{(j)}\|_\infty \le A_\infty^{-1} \|f(M^j\cdot)\|_\infty = A_\infty^{-1} \|f\|_\infty.$$

For any fixed $x \neq y \in \mathbb{R}^s$, we have

$$\begin{aligned} |f(x) - f(y)| &\le \|a^{(j)}\|_\infty \sum_{\alpha\in\mathbb{Z}^s} |\phi(M^{-j}x - \alpha) - \phi(M^{-j}y - \alpha)| \\ &\le A_\infty^{-1} \|f\|_\infty \sum_{\alpha\in\mathbb{Z}^s} |\phi(M^{-j}x - \alpha) - \phi(M^{-j}y - \alpha)|. \end{aligned}$$

We observe that $\phi, \phi^0 \in C(\mathbb{R}^s)$; hence the series

$$\sum_{\alpha\in\mathbb{Z}^s} |\phi(\omega - \alpha)|$$

is uniformly convergent for $\omega \in [-1, 1)^s$. We also note that $M^{-j}x, M^{-j}y \to 0$ as $j \to \infty$. Therefore,

$$|f(x) - f(y)| \to 0 \quad \text{as } j \to \infty.$$

Thus, we know that f is a constant function. The proof of Theorem 7 for $p = \infty$ is complete.

Remark. In the case $p = \infty$, the assumption $\phi, \phi^0 \in C(\mathbb{R}^s)$ in Theorem 7 cannot be replaced by $\phi \in \mathcal{L}^\infty(\mathbb{R}^s)$, which can be seen from the Haar basis.

Let ϕ be the characteristic function of the set $[0, 1)^s$. Then $\phi \in \mathcal{L}^\infty(\mathbb{R}^s)$ and has l^∞-stable integer translates while

$$\dim\left(\bigcap_{j\in\mathbb{Z}} V_j\right) = 2^s.$$

THEOREM 8. *If $\phi \in L^1(\mathbb{R}^s)$ satisfies the refinement equation* (1.2) *with the mask $b \in l^1(\mathbb{Z}^s)$, then $\hat{\phi}(2\beta\pi) = 0$ for $\beta \in \mathbb{Z}^s\backslash\{0\}$ and*

$$\sum_{\alpha\in\mathbb{Z}^s} \phi(\cdot - \alpha) = \hat{\phi}(0). \tag{3.1}$$

Now if for some $1 \leq p \leq \infty$, $\phi \in \mathcal{L}^p(\mathbb{R}^s) \subset L^1(\mathbb{R}^s)$ satisfies the refinement equation (1.2) with the mask $b \in l^1$ and has l^p-stable integer translates, we know from [5, Thm. 3.5] and Theorem 8 that $\hat{\phi}(0) \neq 0$. Therefore, after normalization we can assume that $\hat{\phi}(0) = 1$. In this case we can state property (R6) as follows.

THEOREM 9. *If $\phi \in \mathcal{L}^p(\mathbb{R}^s)$, $1 \leq p \leq \infty$, $\sum_{\alpha\in\mathbb{Z}^s} \phi(\cdot - \alpha) = 1$, then $\cup_{j\in\mathbb{Z}} V_j$ is dense in $(L^p(\mathbb{R}^s), \|\cdot\|_p)$ for $1 \leq p < \infty$ and in $(L^\infty(\mathbb{R}^s), \sigma(L^\infty, L^1))$ for $p = \infty$.*

Proof of Theorem 9 *for $p = \infty$.* Assume first that $f \in C_0(\mathbb{R}^s)$. We state that for any $g \in L^1(\mathbb{R}^s)$,

$$\epsilon_j := \left| \int_{\mathbb{R}^s} \left[f(x) - \sum_{\alpha\in\mathbb{Z}^s} \phi(M^j x - \alpha) f(M^{-j}\alpha) \right] g(x)\, dx \right| \to 0 \tag{3.2}$$

as $j \to \infty$.

Note that $C_0(\mathbb{R}^s)$ is dense in $L^1(\mathbb{R}^s)$ and

$$\left| f(x) - \sum_{\alpha\in\mathbb{Z}^s} \phi(M^j x - \alpha) f(M^{-j}\alpha) \right| \leq \|f\|_\infty + \|f\|_\infty \|\phi^0\|_\infty < \infty.$$

It is sufficient to prove (3.2) under the assumption that $g \in C_0(\mathbb{R}^s)$, which can, in turn, be derived from Theorem 8 by some similar arguments and methods from [6]. We omit the details here.

Once we have the statement (3.2), the proof is easier.

To see that $\cup_{j\in\mathbb{Z}} V_j$ is dense in $(L^\infty(\mathbb{R}^s), \sigma(L^\infty, L^1))$, we let $0 \neq f \in L^\infty(\mathbb{R}^s)$, $\{g_1, \ldots, g_n\} \subset L^1(\mathbb{R}^s)$, and $\epsilon > 0$. We need to find some $h \in \cup_{j\in\mathbb{Z}} V_j$ such that for $j = 1, 2, \ldots, n$,

$$\left| \int_{\mathbb{R}^s} (f(x) - h(x)) g_j(x)\, dx \right| < \epsilon. \tag{3.3}$$

By Lusin's Theorem, for any $\delta > 0$ there exist $f_\delta \in C(\mathbb{R}^s)$ and a measurable set $E_\delta \subset \mathbb{R}^s$ such that

$$|E_\delta| < \delta,$$
$$f_\delta(x) = f(x) \quad \text{if } x \in \mathbb{R}^s \backslash E_\delta,$$

and

$$\|f_\delta\|_\infty \leq \|f\|_\infty.$$

Furthermore, for any $r > 0$ we choose $f_{\delta,r} \in C_0(\mathbb{R}^s)$ such that supp $f_{\delta,r} \subset B_{r+1} := \{x \in \mathbb{R}^s : |x| \leq r + 1\}$, $f_{\delta,r}|_{B_r} = f_\delta|_{B_r}$, and

$$\|f_{\delta,r}\|_\infty \leq \|f_\delta\|_\infty \leq \|f\|_\infty.$$

Since $\{g_j\}_{j=1}^n \subset L^1(\mathbb{R}^s)$, for sufficiently large r and sufficiently small δ we have for $j = 1, 2, \ldots, n$,

$$\int_{E_\delta} |g_j(x)|\, dx < \frac{\epsilon}{8\|f\|_\infty}$$

and

$$\int_{\mathbb{R}^s - B_r} |g_j(x)|\, dx < \frac{\epsilon}{8\|f\|_\infty}.$$

Therefore,

$$\left|\int_{\mathbb{R}^s}(f(x)-f_{\delta,r}(x))g_j(x)\,dx\right| \leq \int_{E_\delta}|f(x)-f_\delta(x)||g_j(x)|\,dx$$
$$+\int_{\mathbb{R}^s-B_r}|f_{\delta,r}(x)-f_\delta(x)||g_j(x)|\,dx<\frac{\epsilon}{2}.$$

Now applying (3.2) to $f_{\delta,r}$ and $\{g_j\}_{j=1}^n$ we can find $m \in \mathbb{N}$ such that for $j = 1,2,\ldots,n$,

$$\left|\int_{\mathbb{R}^s}\left[f_{\delta,r}(x)-\sum_{\alpha\in\mathbb{Z}^s}\phi(M^m x-\alpha)f_{\delta,r}(M^{-m}\alpha)\right]g_j(x)\,dx\right|<\frac{\epsilon}{2}.$$

Hence, for $h(x)=\sum_{\alpha\in\mathbb{Z}^s}\phi(M^m x-\alpha)f_{\delta,r}(M^{-m}\alpha)\in\cup_{j\in\mathbb{Z}}V_j$, (3.3) is valid.

The proof of Theorem 9 is complete.

With all the above results, the proof of Theorem 6 is now easy.

Proof of Theorem 6. By the definition of $\{V_j\}_{j\in\mathbb{Z}}$, (R1), (R2), and (R3) follow immediately since the mask b of the refinement equation for ϕ is in $l^1(\mathbb{Z}^s)$. Note that the integer translates of ϕ are l^p-stable. We know that the mapping $L_\phi : l^p(\mathbb{Z}^s)\to V_0$ defined by

$$L_\phi(a)=\phi *' a$$

is an isomorphism from $l^p(\mathbb{Z}^s)$ onto V_0 that commutes with shift operators. Property (R5) follows from Theorem 7 while (R6) is obtained from Theorem 9 since the assumption $\sum_{\alpha\in\mathbb{Z}^s}\phi(\cdot-\alpha)=\hat{\phi}(0)\neq 0$ is satisfied by Theorem 8 and the stability.

The proof of Theorem 6 is complete.

4. Determination of scaling functions of Haar type. Combining the results in §§2 and 3, we can give some criteria for a refinable function to generate a multiresolution analysis in $L^2(\mathbb{R})$ associated with $(\mathbb{Z},k)$. This has an interesting application in determining all the scaling functions of Haar type.

Let $k\geq 2$ be a positive integer. We want to determine all those multiresolution analyses of $L^2(\mathbb{R})$ associated with $(\mathbb{Z},k)$ whose scaling functions are characteristic functions. It was shown by Gröchenig and Madych [4] that such a scaling function must be the characteristic function χ_Q of some set Q defined by

$$Q=\left\{x\in\mathbb{R}:x=\sum_{j=1}^{\infty}k^{-j}\epsilon_j,\epsilon_j\in\{n_0,n_1,\ldots,n_{k-1}\}\right\}, \tag{4.1}$$

where $\{n_0,n_1,\ldots,n_{k-1}\}$ is a collection of representatives of distinct cosets of $\mathbb{Z}/(k\mathbb{Z})$, say, $n_j\equiv j \pmod{k}$ for $j=0,1,\ldots,k-1$. However, χ_Q may fail to be a scaling function. In fact, for $k=2$, it is well known that $\chi_{[0,1)}$ is the unique scaling function up to an integer translate. For this, see Daubechies [3] and Gröchenig and Madych [4].

The main purpose of this section is to characterize for general $k\in\mathbb{N}$ such scaling functions in terms of the number theory property of the representatives of the cosets. To this end, we need Euler's theorem from number theory. Euler's theorem says that if p and q are relatively prime integers $q>1$, then

$$p^{\varphi(q)}\equiv 1 \pmod{q}, \tag{4.2}$$

where $\varphi(q) \in \mathbb{N}$ is the Euler number of q; i.e., $\varphi(q)$ is the number of positive integers $\leq q$ that are relatively prime to q.

Now we can state our main result in this section.

THEOREM 10. *Suppose that $\{n_0, n_1, \ldots, n_{k-1}\}$ is a collection of representatives of distinct cosets of $\mathbb{Z}/(k\mathbb{Z})$ and the set Q is defined by* (4.1). *If $k > 2$ and for $j = 0, 1, \ldots, k-1$, $n_j \equiv j \pmod k$. Then $\phi = \chi_Q$ is a scaling function of a multiresolution analysis in $L^2(\mathbb{R})$ associated with $(\mathbb{Z}, k)$ if and only if*

$$(n_1 - n_0, n_2 - n_0, \ldots, n_{k-1} - n_0) = 1. \tag{4.3}$$

Proof of Theorem 10. Since $\phi \in \mathcal{L}^2(\mathbb{R})$ and satisfies the refinement equation

$$\phi(x) = \sum_{j=0}^{k-1} \phi(kx - n_j), \tag{4.4}$$

by Theorem 1 in §2 and Theorem 6 in §3 it is sufficient to prove that (4.3) holds if and only if the symbol of the mask

$$\tilde{b}(z) = \sum_{j=0}^{k-1} z^{n_j} \tag{4.5}$$

satisfies conditions (2) and (3) in Theorem 1.

We first claim that condition (2) is always valid for any collection of representatives. To show this, we denote $\omega_0 = e^{-i2\pi/k}$. Then $\omega_0^k = 1$ and $e^{-i2l\pi/k} = \omega_0^l$.

For any $z \in T$, we must have

$$\begin{pmatrix} \tilde{b}(e^{-i2\pi 0/k}z) \\ \tilde{b}(e^{-i2\pi/k}z) \\ \vdots \\ \tilde{b}(e^{-i2\pi(k-1)/k}z) \end{pmatrix} = \begin{pmatrix} \tilde{b}(\omega_0^0 z) \\ \tilde{b}(\omega_0 z) \\ \vdots \\ \tilde{b}(\omega_0^{k-1}z) \end{pmatrix}$$
$$= \begin{pmatrix} 1 & 1 & \cdots & 1 \\ 1 & \omega_0 & \cdots & \omega_0^{k-1} \\ \vdots & & & \\ 1 & \omega_0^{k-1} & \cdots & (\omega_0^{k-1})^{k-1} \end{pmatrix} \begin{pmatrix} z^{n_0} \\ z^{n_1} \\ \vdots \\ z^{n_{k-1}} \end{pmatrix} \neq 0$$

since the determinant of the coefficient matrix is a Vandermonde determinant and is therefore not equal to zero, while the vector $(z^{n_0}, \ldots, z^{n_{k-1}}) \neq 0$. Thus we have proved our claim.

Now we need only to prove that $\tilde{b}(z)$ does not satisfy condition (3) in Theorem 1 if and only if (4.3) is not true. We observe that the first statement is equivalent to the fact that there exist $m \in \mathbb{N}$ and $n \in \mathbb{Z}$ such that $n/(k^m - 1) \notin \mathbb{Z}$ and for $z = e^{-i2n\pi/(k^m-1)}$ and any $d \geq 0$, $l = 1, 2, \ldots, k-1$,

$$\tilde{b}(\omega_0^l z^{k^d}) = \sum_{j=0}^{k-1} \omega_0^{jl} e^{-i2\pi n n_j k^d/(k^m-1)} = 0,$$

which is equivalent to

$$A \begin{pmatrix} 1 \\ e^{-i2\pi n(n_1-n_0)k^d/(k^m-1)} \\ \vdots \\ e^{-i2\pi n(n_{k-1}-n_0)k^d/(k^m-1)} \end{pmatrix} = 0. \tag{4.6}$$

Here A is the $(k-1)\times k$ matrix defined by

$$(A)_{l,j} = \omega_0^{l(j-1)}, \qquad l = 1,\ldots,k-1,\ j = 1,\ldots,k.$$

The rows of A are the rows of a $k \times k$ matrix whose determinant is a Vandermonde determinant; hence, A has rank of $k-1$. Therefore, (4.6) has the unique solution $(1,1,\ldots,1)$.

Thus, $\tilde{b}(z)$ does not satisfy condition (3) in Theorem 1 if and only if there exist $m \in \mathbb{N}$ and $n \in \mathbb{Z}$ such that $n/(k^m-1) \notin \mathbb{Z}$ and

$$n(n_j - n_0)k^d/(k^m-1) \in \mathbb{Z} \quad \text{for } j = 1,2,\ldots,k-1 \text{ and } d \geq 0. \tag{4.7}$$

We can now prove the necessity and sufficiency as follows.

Suppose that (4.3) holds. Then (4.7) is not true, which implies that $\tilde{b}(z)$ satisfies condition (3) in Theorem 1. Since otherwise there exist $m \in \mathbb{N}$ and $n \in \mathbb{Z}$ such that $n/(k^m-1) \notin \mathbb{Z}$ and for $j = 1,2,\ldots,k-1, d \geq 0$, it follows that

$$n(n_j - n_0)k^d/(k^m-1) \in \mathbb{Z}.$$

But $(n_1 - n_0, n_2 - n_0, \ldots, n_{k-1} - n_0) = 1$ and $(k^d, k^m - 1) = 1$, so we must have $n/(k^m-1) \in \mathbb{Z}$, which is a contradiction. Thus we have proved the sufficiency.

Conversely, suppose that (4.3) does not hold. We need to show that (4.7) is true. To this end, we use Euler's theorem.

Let $q = (n_1 - n_0, n_2 - n_0, \ldots, n_{k-1} - n_0) \in \mathbb{N}$. By the assumption, $q \geq 2$.

On the other hand, $n_1 - n_0 \equiv 1 \pmod{k}$. Hence $(n_1 - n_0, k) = 1$ and $(q,k) = 1$. By Euler's theorem we have

$$k^{\varphi(q)} \equiv 1 \pmod{q}.$$

Let $m = \varphi(q) \in \mathbb{N}$ and $n = (k^{\varphi(q)} - 1)/q \in \mathbb{Z}$. Then,

$$\frac{n}{k^m - 1} = \frac{1}{q} \notin \mathbb{Z},$$

while for $j = 1,2,\ldots,k-1$,

$$n(n_j - n_0)k^d/(k^m-1) = k^d(n_j - n_0)/q \in \mathbb{Z}.$$

Hence, (4.7) is true, which implies that $\tilde{b}(z)$ does not satisfy condition (3) in Theorem 1. Therefore, the necessity holds.

The proof of Theorem 10 is complete.

More generally, if $(n_1 - n_0, n_2 - n_0, \ldots, n_{k-1} - n_0) \neq 1$, then we know that $\varphi = \chi_Q$ fails to be a scaling function. Equivalently, $|Q| > 1$.

Using Theorem 10, we can give a more exact statement for these cases.

COROLLARY. *Let $2 < k \in \mathbb{N}$ and for $j = 0, 1, \ldots, k-1$, $n_j \in \mathbb{Z}$ satisfies $n_j \equiv j$ (mod k). Then we have*

$$\left| \left\{ x \in \mathbb{R} : x = \sum_{j=1}^{\infty} k^{-j} \epsilon_j,\ \epsilon_j \in \{n_0, n_1, \ldots, n_{k-1}\} \right\} \right|$$
$$= (n_1 - n_0, n_2 - n_0, \ldots, n_{k-1} - n_0).$$

Thus we have determined all the Haar-type scaling functions of multiresolution analyses in $L^2(\mathbb{R})$ associated with $(\mathbb{Z}, k)$ for general k.

The cases of multidimensions and of smooth scaling functions will be discussed elsewhere.

Note added in proof. After my paper was submitted and reviewed, I learned from I. Daubechies that results similar to those in §4 had been obtained independently by K. Gröchenig and A. Haas in [Self-similar lattice tilings, *J. Fourier Anal. Appl.*].

GLOBAL SOLVABILITY OF THE ANHARMONIC OSCILLATOR MODEL FROM NONLINEAR OPTICS*

J. L. JOLY[†], G. METIVIER[‡], AND J. RAUCH[§]

Abstract. The field equations describing the propagation of electromagnetic waves in a nonlinear dielectric medium whose polarization responds locally to the electric field as an anharmonic oscillator with potential $V(P)$ have smooth solutions global in space and time for arbitrary smooth initial data as soon as V has bounded derivatives of order less than or equal to three. This is true in spite of the fact that solutions of the nonlinear Shrödinger equation which approximate the fields in the slowly varying envelope approximation may blow up in finite time.

Key words. nonlinear optics, nonlinear Maxwell equations, nonlinear Schrödinger equation, saturated susceptibility equation

AMS subject classifications. 35L60, 35Q60, 78A60

1. Introduction. A standard model, due to Lorentz [L] (see also [F, Chaps. I-31 and II-33]), of the linear dispersive behavior of electromagnetic waves is given by the system of partial differential equations

$$\partial_t B + \operatorname{curl} E = 0, \tag{1.1}$$

$$\partial_t E - \operatorname{curl} B = -\partial_t P, \tag{1.2}$$

$$\partial_t^2 P + \partial_t P/T_1 + aP = bE \tag{1.3}$$

with positive constants a , b, and T_1. The physical origin of equation (1.3) is a model of the electron as bound to the nucleus by a Hooke's law spring force. Here E and B are the electric and magnetic fields and the vector field P is the polarization of the medium. A simple and natural model (see [Bl], [O]) to explain nonlinear dispersive phenomena is to replace the linear restoring force with a nonlinear law:

$$\partial_t^2 P + \partial_t P/T_1 + \nabla V(P) = bE. \tag{1.4}$$

If the Taylor expansion of V at the origin is

$$V(P) = \frac{a}{2}\,|P|^2 - \beta |P|^4 + \text{higher-order terms},$$

then asymptotic analysis of small-amplitude solutions reveals a focusing cubic term; that is, the nonlinear susceptibility, n_2, is strictly positive (see [B], [DR1], [NM]). In

addition, the slowly varying envelope approximation (see [NM], [DR2]) leads to amplitudes which are solutions to nonlinear Schrödinger equations. In the monochromatic case, the equation has a focusing cubic nonlinearity when β is positive. In this case, there are solutions of the Schrödinger equation which explode in finite time. Our main theorem shows that the solutions of the underlying field equations (1.1), (1.2), and (1.4) do not break down. These equations have global smooth solution for arbitrary smooth data under appropriate hypotheses on the potential energy function V. An analogous result for the Maxwell–Bloch equations which come from modelling the matter as a gas of finite-state quantum systems is proved in [DR1]. In both cases, the fundamental nonlinear field equations are globally solvable even when the reduced Schrödinger equation is not. These contradictory predictions are resolved by the observation that near the focal point, amplitudes grow and the assumptions underlying the slowly varying envelope approximation are no longer satisfied. Once it is known that the underlying equations have smooth solutions, it is natural to ask what the behavior is near a focal point. This appears to us to be a very difficult problem. A first step in considering large-amplitude solutions is to go beyond the regime of Taylor expansions about $P = 0$. It might seem reasonable to simply take the potential

$$V(P) = \frac{a}{2}\,|P|^2 - \beta|P|^4.$$

However, for large displacements this is strongly repulsive. In fact, it is so repulsive that solutions of the classical spring equation

$$\partial_t^2 P + \partial_t P/T_1 + \nabla V(P) = 0 \tag{1.5}$$

with large initial energy diverge to infinity in finite time.

MAIN HYPOTHESIS. *The potential-energy function $V : \mathbf{R}^3 \to \mathbf{R}$ satisfies $V(0) = 0$ and is infinitely differentiable with second- and third-order partial derivatives uniformly bounded.*

This implies that $|\nabla V(P)|$ [resp. $V(P)$] grows at most linearly [resp. quadratically] as $P \to +\infty$. That is, there is a C such that for all $\beta \in \mathbf{N}^3$ with $|\beta| \leq 3$ and $P \in \mathbf{R}^3$,

$$|\partial^\beta V(P)| \leq C\ (1\ +\ |P|)^{\max(2-|\beta|,0)}. \tag{1.6}$$

An example is the potential

$$V(P) := \frac{\frac{a}{2}\,|P|^2 - \beta'|P|^4}{1+\gamma|P|^2}, \quad \gamma > 0\,.$$

On one hand, this hypothesis is very strong since the nonlinear term $\nabla V(P)$ is then a globally Lipshitzean function of P. In particular, the ordinary differential equation (1.5) is globally solvable. On the other hand, the hypothesis is reasonable since, as observed above, what is needed to produce a Kerr nonlinearity is that $\partial^2 V/\partial P_i \partial P_j$ be smaller than Hooke's law when $P \approx 0$. The hypothesis roughly asserts that this comparison is valid for all P. A second plausibility argument is that models of nonlinear susceptibility often include saturation effects. For such models, one would have $|\partial^\beta V(P)| \to 0$ as $P \to \infty$ for $|\beta| \geq 2$ and so the hypothesis would be satisfied.

Assuming the Main Hypothesis, it is routine to prove the global solvability of a semilinear equation of the form $(\partial_{tt} - \triangle)P + \nabla V(P) = 0$. However, there is no

Laplacian in the anharmonic spring equation (1.4), and the existence proof is delicate relying on the detailed structure of the system.

Taking the divergence of (1.1) and (1.2) implies that

$$\partial_t \operatorname{div}(E+P) = \partial_t \operatorname{div}(B) = 0. \tag{1.7}$$

The physically relevant solutions are those which satisfy

$$\operatorname{div}(E+P) = \operatorname{div}(B) = 0. \tag{1.8}$$

Thanks to 1.7 this holds as soon as it holds at $t = 0$, so (1.8) is only a constraint on the initial data.

MAIN THEOREM. *If $s \geq 2$ and the initial data $B(0), E(0), P(0)$, and $\partial_t P(0)$ belong to $H^s(\mathbf{R}^3)$ and satisty $\operatorname{div}\big(E(0)+P(0)\big) = \operatorname{div}(B(0)) = 0$, then there is one and only one solution of equations (1.1), (1.2), (1.4), and (1.8) which achieves these initial data and is such that B, E, P, and $\partial_t P$ are continuous functions of $t \in [0, \infty[$ with values in $H^s(\mathbf{R}^3)$. The values of the solution at $\underline{t}, \underline{x}$ depend only on the values of the initial data on the ball of radius $\underline{t}$ with center $\underline{x}$.*

It follows that if the initial data belong to $C_0^\infty(\mathbf{R}^3)$, then the solution has compact support whose diameter grows linearly with t. Using the equation to express time derivatives in terms of spatial derivatives shows that the solution is an infinitely differentiable function of t, x [Ra]. Let

$$U(t,x) := \big(E(t,x)\,, B(t,x)\,, P(t,x)\,, \partial_t P(t,x)\big). \tag{1.9}$$

Equation (1.4) is written as a system for the pair (P, Q) with $Q := \partial_t P$:

$$\partial_t P = Q, \qquad \partial_t Q = bE - \frac{Q}{T_1} - \nabla V(P).$$

The equations for U then take the form of a semilinear symmetric hyperbolic system:

$$\begin{gathered} LU := \partial_t U - \sum_{1 \leq j \leq 3} A_j \partial_j U = F(U), \\ F(U) := \left(-Q\,, 0\,, Q\,, bE - \frac{Q}{T_1} - \nabla V(P)\right). \end{gathered} \tag{1.10}$$

The symmetry means that the matrices A_j are symmetric and real. In this case, the A_j are 12×12 real symmetric matrices whose last six rows vanish. The next result is classical, dating back to Schauder [S]. A short modern proof uses the first theorem in [Re] in the Hilbert space of $U \in H^s(\mathbf{R}^3)$ such that $\operatorname{div}(E+P) = \operatorname{div}(B) = 0$. The operator$\sum_{1 \leq j \leq 3} A_j \partial_j$ is anti-self-adjoint and for $s > 3/2$, the nonlinear term $F(U)$ is locally Lipshitzean.

LOCAL EXISTENCE THEOREM. *If $s > 3/2$ and $U(0,.) \in H^s(\mathbf{R}^3)$, then there are a $T_* \in]\,0, \infty]$ and a unique $U \in C([0, T_{/,*}[: H^s(\mathbf{R}^3))$ which satisfy (1.1), (1.2), and (1.4) and attain these initial values. The solution depends continuously on the initial data in the sense that if $\varphi \in H^s(\mathbf{R}^3)$ and $T < T_*(\varphi)$, then there is an $H^s(\mathbf{R}^3)$ neighborhood $\mathcal{O}$ of φ such that $T_*(\psi) > T$ for all $\psi \in \mathcal{O}$ and the map from initial data to solution is continuous from $\mathcal{O}$ to $C([0,T] : H^s(\mathbf{R}^3))$. There is a lower bound $T_* \geq c(s, {}_{,}\|U(0)\|_{H^s(\mathbf{R}^3)}) > 0$, where $c(s, \lambda)$ is a nonincreasing function of λ. The* *values of U at $(\underline{t}, \underline{x})$ depend only on the values of the initial data on the ball of radius $\underline{t}$ with center $\underline{x}$.*

Our main result asserts that the solutions do not blow up in finite time. The Main Theorem then takes the following form.

MAIN THEOREM 1. *If $s \geq 2$ and the initial data $U(0,.) \in H^s(\mathbf{R}^3)$ satisfy $\operatorname{div}(E(0)+P(0)) = \operatorname{div}(B(0)) = 0$, then $T_* = \infty$.*

This result is a special case of a general result which isolates the essential features of (1.10) which guarantee global existence. Write the nonlinear term as a sum of linear and nonlinear parts by Taylor expansion at $U = 0$:

$$\begin{aligned} &F(U) := -BU + f(U), \\ (1.11) \qquad &BU := \left(-Q\,,\ 0\,,\ Q\,,\ bE - \frac{Q}{T_1} - \left(\nabla^2 V(0)\right) P\right), \\ &f(U) := \left(0\,,0\,,0\,,\ -\nabla V(P) + \left(\nabla^2 V(0)\right) P\right). \end{aligned}$$

The basic system then has the form

$$(1.12) \qquad \partial_t U - \sum_{1 \leq j \leq 3} A_j \partial_j U - BU = f(U).$$

We next introduce a class of $N \times N$ systems of the form of (1.12), including (1.10) as a special case.

ASSUMPTION 1. *The $N \times N$ system (1.12) has hermitian symmetric constant matrix coefficients A_j and constant B. For $\xi \neq 0$, the kernel of $A(\xi) := \sum \xi_j A_j$ has dimension independent of ξ.*

For the anharmonic oscillator model, this dimension is equal to 8, the kernel consisting of vectors such that E and B are parallel to ξ.

ASSUMPTION 2. *The nonlinear function $f : \mathbf{C}^N \to \mathbf{C}^N$ has range contained in $\bigcap \{\operatorname{Ker} A(\xi) : \xi \neq 0\}$. In addition, $f(0) = 0$, $\nabla f(0) = 0$, and the first derivatives $\partial f / \partial U_j$ are uniformly bounded in $\mathbf{C}^N$.*

For the anharmonic oscillator model, the Main Hypothesis yields the derivative bound in Assumption 2. Moreover, the nonlinear term takes values in the vectors whose first nine components vanish, and the kernel of the A_j includes the vectors whose first six components vanish, so Assumption 2 is satisfied . Thus Main Theorem 1 is a special case of the following result.

MAIN THEOREM 2. *For semilinear symmetric hyperbolic systems satisfying Assumptions 1 and 2, $s \geq 2$, and $U(0) \in H^2(\mathbf{R}^3)$, the Cauchy problem is globally solvable, that is, $T_* = \infty$.*

To prove Main Theorem 2, it is sufficient to prove the following a priori estimate. For any $T \in]0, \infty[$ and any $M > 0$, there is a constant $C(T, M)$ such that if $\underline{t} \in]0, T]$ and U is a smooth compactly supported solution of (1.12) on $[0, \underline{t}] \times \mathbf{R}^3$ such that

$$(1.13) \qquad \|U(0)\|_{H^2(\mathbf{R}^3)} \leq M,$$

then

$$(1.14) \qquad \|U(t,.)\|_{H^2(\mathbf{R}^3)} \leq C(T, M) \quad \text{for } 0 \leq t \leq \underline{t}.$$

To prove that (1.14) is sufficient, one must show that if $U(0) \in H^s(\mathbf{R}^3)$, $s \geq 2$, and $T > 0$, then $T_* \geq T$. Gagliardo–Nirenberg estimates imply that for a smooth solution U and $s \geq 2$, one has

$$(1.15) \qquad \|U(t,.)\|_{H^s(\mathbf{R}^3)} \leq C\,\|U(0)\|_{H^s(\mathbf{R}^3)} \quad \text{for } 0 \leq t \leq \underline{t},$$

where C only depends on the L^∞ norm of U on $[0,\underline{t}] \times \mathbf{R}^3$. These estimates and the Local Existence Theorem imply the following corollary (see, e.g., [M], [GR]). If $T_* < +\infty$, then

$$\limsup_{t\to T_*} \|U(t,.)\|_{L^\infty(\mathbf{R}^3)} = +\infty. \tag{1.16}$$

Moreover, by continuity, the a priori estimates (1.14) extend to solutions $U \in C^0([0,\underline{t}] : H^s(\mathbf{R}^3))$. The Sobolev imbedding $H^2(\mathbf{R}^3) \subset L^\infty(\mathbf{R}^3)$ and (1.14) show that the L^∞ norm of an H^s solution U cannot blow up before time T and therefore $T_* \geq T$.

The proof of Main Theorem 2 proceeds by a sequence of estimates leading to (1.14). These estimates are presented in §§2–6.

Remark 1. The divergence conditions $\operatorname{div}\big(E(0)+P(0)\big) = \operatorname{div}\big(B(0)\big) = 0$ are not necessary for global existence. We included them in the statement of Main Theorem 1 since they are required for the physically relevant solutions.

Remark 2. Main Theorem 2 applies to the sytem (1.1)–(1.2) with (1.4) replaced by the more general law

$$\partial_t^2 P = F(E, B, P, \partial_t P), \tag{1.17}$$

where $F \in C^3(\mathbf{R}^{12} : \mathbf{R}^3)$, $F(0) = 0$, and F has bounded first and second derivatives. Another generalization is the case of a finite number of anharmonic oscillators. This corresponds more closely to what one would find from nonlinear terms in quantum perturabtion theory. The dynamics of the polarization is then given by

$$P = \sum_{j=1}^{n} P^j\,, \qquad \partial_t^2 P^j + \partial_t P^j / T_1^j + \nabla V^j(P^j) = b^j E\,.$$

Here each of the potentials V^j satisfies the Main Hypothesis.

2. $L^2(\mathbf{R}^3)$ estimates for U.

Let

$$K := \|(B+B^*)/2\| + \sup_{u\in\mathbf{C}^N} \{\|\nabla f(U)\|\}, \tag{2.1}$$

which is finite thanks to Assumption 2. Then since $f(0) = 0$, one has the Lipshitz bound

$$\|f(U)\|_{\mathbf{C}^N} \leq K\|U\|_{\mathbf{C}^N}. \tag{2.2}$$

For a smooth compactly supported solution U satisfying (1.13), we perform the standard energy estimate. Namely, take the $\mathbf{C}^N$ scalar product of the the partial differential equation (1.12) with U and integrate over $\mathbf{R}^3$. Then take the real part to find that

$$\partial_t \|U(t)\|^2_{L^2(\mathbf{R}^3)} \leq 2K \|U(t)\|^2_{L^2(\mathbf{R}^3)}.$$

It follows that

$$\|U(t)\|_{L^2(\mathbf{R}^3)} \leq e^{Kt} \|U(0)\|_{L^2(\mathbf{R}^3)}. \tag{2.3}$$

3. An $H^1(\mathbf{R}^3)$ estimate for U.

Let ∂ denote one of $\partial/\partial x_j$ for $1 \leq j \leq 3$. Then

$$(L-B)(\partial U) = -\partial\big(f(U)\big) = -(\nabla f(U))\,\partial U. \tag{3.1}$$

The main hypothesis implies that ∇f is bounded and thus

$$|\,\partial(f(U))\,(t,x)\,| \le K\,|\partial U(t,x)|\,. \tag{3.2}$$

The standard energy method, namely, taking the scalar product of (3.1) with ∂U and integration dx over $\mathbf{R}^3$, yields

$$\partial_t\,||\partial U(t)||^2_{L^2(\mathbf{R}^3)} \le 2K\,||\partial U(t)||^2_{L^2(\mathbf{R}^3)}. \tag{3.3}$$

Summing the resulting expressions over the three values of ∂ and applying Gronwall's inequality shows that for $0 \le t \le \underline{t} \le T$,

$$||\partial U(t)||_{L^2(\mathbf{R}^3)} \le C(T,M). \tag{3.4}$$

In particular, we control the $H^1(\mathbf{R}^3)$ norm of $U(t)$.

4. An $H^2(\mathbf{R}^3)$ estimate for the propagating part of U. Denote by $\Pi_0(\xi)$ the orthogonal projector on $\operatorname{Ker}A(\xi)$, defining a smooth matrix-valued function homogeneous of degree zero on $\xi \neq 0$. Let $\Pi_1(\xi) := I - \Pi_0(\xi)$. The next estimates depend on the decomposition

$$U = u_0 + u_1\,, \qquad u_\nu := \Pi_\nu(D)\,U := \mathcal{F}^{-1}\,\Pi_\nu(\xi)\,\mathcal{F}\,U. \tag{4.1}$$

The key intuition is that u_0 corresponds to zero speeds and u_1 to nonzero speeds. This will show that u_0 can only weakly influence u_1 since the corresponding waves cross transversely. Furthermore, the nonlinear term does not influence the u_1 part thanks to Assumption 2. These two facts suffice to pass from an H^1 estimate for U to an H^2 estimate for u_1. Let

$$B_{\mu\nu}(D) := \Pi_\mu(D)\,B\,\Pi_\nu(D). \tag{4.2}$$

Multiply (1.12) by $\Pi_1(D)$ using the facts that $\Pi_1 f = 0$ and $\Pi_1(\xi)A(\xi) = A(\xi)\Pi_1(\xi) = A(\xi)$ to find

$$\Big(\partial_t - \sum A_j\partial_j\Big)u_1 - B_{11}(D)u_1 - B_{10}(D)u_0 = 0. \tag{4.3}$$

Similarly, multiplying by $\Pi_0(D)$ yields

$$\partial_t u_0 - B_{00}u - B_{01}(D)\,u_1 = \Pi_0(D)\,f(U).$$

Differentiate with respect to x to find

$$\partial_t Du_0 - B_{00}u_0 - B_{01}(D)\,Du_1 = \Pi_0(D)\,\big(f'(U)DU\big). \tag{4.4}$$

Since f' is bounded and the $\Pi_\nu(D)$ are bounded in L^2, this yields the estimate

$$||\partial_t u_0(t)||_{H^1(\mathbf{R}^3)} \le C\,||U(t)||_{H^1(\mathbf{R}^3)}. \tag{4.5}$$

Let $\langle\xi\rangle := (1 + |\xi|^2)^{1/2}$ and notice that u_1 then satisfies the modified equation

$$\Big(\partial_t - \sum A_j\partial_j - i\langle D\rangle\Pi_0(D)\Big)u_1 - B_{11}u_1 - B_{10}u_0 = 0 \tag{4.6}$$

involving the anti-self-adjoint elliptic operator

$$G(D) := \sum A_j\partial_j + i\langle D\rangle \Pi_0(D), \quad G(\xi) := -i\langle\xi\rangle\Pi_0(\xi) + \sum i\, A_j\xi_j. \tag{4.7}$$

Then $u_1 = z + w$, where z and w are the solutions of the initial-value problems

$$\big(\partial_t - G(D)\big)z - B_{11}z = 0, \qquad z(0,\,.\,) = u_1(0,\,.\,), \tag{4.8}$$

$$\big(\partial_t - G(D)\,\big)w - B_{11}w - B_{10}u_0 = 0, \quad w(0,\,.\,) = 0. \tag{4.9}$$

For z, we have the elementary estimate

$$||z(t)||_{H^2(\mathbf{R}^3)} \le e^{Kt}\,||z(0)||_{H^2(\mathbf{R}^3)} \le e^{Kt}\,M. \tag{4.10}$$

Duhamel's formula yields the following formula for the Fourier transform of w:

$$\hat{w}(t,\xi)) = \int_0^t e^{(G(\xi)+B_{11}(\xi))(t-s)}\, B_{10}(\xi)\,\hat{u}_0(s,\xi)\; ds. \tag{4.11}$$

Introduce

$$\Phi(t,s,\xi) := -\int_s^t e^{(G(\xi)+B_{11}(\xi))\,(t-\sigma)}\; d\sigma$$

so that

$$\partial_s\,\Phi(t,s,\xi) = e^{(G(\xi)+B_{11}(\xi))\,(t-s)} \quad \text{and} \quad \Phi(t,t,\xi) = 0.$$

Integration by parts in (4.11) yields

$$\hat{w}(t,\xi)) = \Phi(t,0,\xi)B_{10}(\xi)\,\hat{u}_0(0,\xi) - \int_0^t \Phi(t,s,\xi)B_{10}(\xi)\,\partial_t\hat{u}_0(s,\xi)\; ds. \tag{4.12}$$

The symmetric hyperbolicity implies that

$$||\Phi(t,s,\xi)|| \le \int_0^{|t-s|} e^{K\sigma}\, d\sigma. \tag{4.13}$$

The ellipticity of G implies that for large $|\xi|$, $G+B$ is invertible and has norm $O(|\xi|^{-1})$. For such ξ,

$$\Phi(t,s,\xi) = -(G(\xi) + B_{11}(\xi))^{-1}\big(e^{(G(\xi)+B_{11}(\xi))(t-s)} - I\big).$$

Together with (4.13), this implies

$$|\Phi(t,s,\xi)| \le C(T)\langle\xi\rangle^{-1} \quad \text{for } s,t \in [0,T] \text{ and } \xi \in \mathbf{R}^3. \tag{4.14}$$

Then (4.12) yields

$$\begin{aligned} ||w(t)||_{H^2(\mathbf{R}^3)} &\le C(T)\bigg(||u_0(0)||_{H^1(\mathbf{R}^3)} + \int_0^t ||\partial_t u_0(s)||_{H^1(\mathbf{R}^3)}\; ds\bigg) \\ &\le C(T,M), \end{aligned} \tag{4.15}$$

where (3.4) and (4.5) are used in the last step. Estimates (4.10) and (4.15) show that

$$\|u_1(t)\|_{H^2(\mathbf{R}^3)} \leq C(T,M). \tag{4.16}$$

5. An $L^6(\mathbf{R}^3)$ estimate for Du_0. Consider the right-hand side of (4.4). Since f' is bounded, it follows that

$$\|f'(U(t))DU\|_{L^6(\mathbf{R}^3)} \leq C\|DU(t))\|_{L^6(\mathbf{R}^3)}. \tag{5.1}$$

Since the singular integral operator $\Pi_0(D)$ is bounded from $L^6(\mathbf{R}^3)$ to itself, (4.4) and (5.1) yield

$$\begin{aligned} \|\partial_t Du_0\|_{L^6(\mathbf{R}^3)} &\leq C(\|Du_1\|_{L^6(\mathbf{R}^3)} + \|DU(t))\|_{L^6(\mathbf{R}^3)}) \\ &\leq 2C\,\|Du_1\|_{L^6(\mathbf{R}^3)} + C\,\|\,Du_0\|_{L^6(\mathbf{R}^3)}. \end{aligned} \tag{5.2}$$

The Sobolev imbedding $H^1(\mathbf{R}^3) \subset L^6(\mathbf{R}^3)$ implies that

$$\|Du_1\|_{L^6(\mathbf{R}^3)} \leq C'\|Du_1(t)\|_{H^1(\mathbf{R}^3)} \leq C(T,M) \tag{5.3}$$

thanks to (4.16). Thus integrating inequality (5.2) yields

$$\|Du_0\|_{L^6(\mathbf{R}^3)} \leq C(T,M). \tag{5.4}$$

6. Endgame. The second derivatives $v := D_iD_jU$ satisfy

$$Lv = f'(U)\,v + \sum_{1\leq\alpha,\beta\leq 3} \frac{\partial^2 f(U)}{\partial U_\alpha \partial U_\beta}\,(D_iU_\alpha)\,(D_jU_\beta). \tag{6.1}$$

Thanks to the boundedness of f' and f'', the standard energy method applied to (6.1) yields

$$\begin{aligned} \partial_t\|D^2U(t)\|^2_{L^2(\mathbf{R}^3)} &\leq C\|D^2U(t)\|^2_{L^2(\mathbf{R}^3)} + C\int_0^t \|D_iU(s)\,D_jU(s)\|^2_{L^2(\mathbf{R}^3)}\,ds \\ &\leq C\|D^2U(t)\|^2_{L^2(\mathbf{R}^3)} + C\int_0^t \|DU(s)\|^2_{L^4(\mathbf{R}^3)}\,ds. \end{aligned} \tag{6.2}$$

Interpolating between the L^2 estimate (3.4) and the L^6 estimates (5.3)–(5.4) shows that the integrand is bounded by $C(T,M)$. Then Gronwall's method shows that

$$\|D^2U(t)\|_{L^2(\mathbf{R}^3)} \leq C(T,M) \quad \text{for} \quad 0 \leq t \leq T. \tag{6.3}$$

This together with (2.3) and (3.4) proves the desired estimate (1.14), and the proof of the Main Theorems is complete.

Acknowledgments. The authors gratefully acknowledge the support of the North Atlantic Treaty Organization, the U. S. Office of Naval Research, and the National Science Foundation. They also thank the Centre de Mathématiques and the Centre de Mathématiques Appliquées of the Ecole Polytechnique in Palaiseau for the welcome offered to J. Rauch during the academic year 1992–1993. All three thank Simone, Florence, Ludovic, Geraldine, and the citizens of St. Marsal for their hospitality in July 1993, when much of this research was performed.

INITIAL-VALUE PROBLEMS WITH INFLOW BOUNDARIES FOR MAXWELL FLUIDS*

MICHAEL RENARDY†

Abstract. We consider the two-dimensional flow of an upper convected Maxwell fluid transverse to a domain bounded by parallel planes. We characterize a set of inflow boundary conditions, which leads to a well-posed initial-boundary value problem.

Key words. polymer rheology, inflow boundaries, local existence

AMS subject classifications. 35L20, 35Q99, 76A10

1. Introduction.

Many problems in computational fluid dynamics involve "open" boundaries (i.e., boundaries through which the fluid enters or leaves the domain). Such open boundaries typically arise from the need to truncate the domain. Boundary conditions at open boundaries are therefore not dictated by physics but are a mathematical artifact. For Newtonian fluids, boundary conditions at open boundaries can be chosen of the same type as those at physical boundaries. For example, the prescription of either velocities or tractions leads to a well-posed problem. (Of course, it is a considerable problem to decide which boundary conditions are suitable for a specific application.) Non-Newtonian fluids, on the other hand, present a more fundamental problem. Such fluids have memory, and hence their equations of motion require information which depends on the flow of the fluid before it enters the domain. This manifests itself in the need for additional boundary conditions at inflow boundaries.

A simple model problem for studying this issue is the perturbation of uniform flow in a domain bounded by two parallel planes. In [2], I studied this problem for a fluid with a differential constitutive equation of Maxwell type. Velocities were prescribed on both planes and, in addition, partial information about the extra stresses was needed at the inflow boundary. An alternative way to prescribe such partial information was given in [4]. The solution was constructed by an iteration which alternately solves an elliptic problem of the same kind as the Stokes equation and then determines stresses by integration along stream lines. However, the procedure in [2] is limited to steady flows and does not extend in any straightforward way to time-dependent problems. An existence result for time-dependent problems without open boundaries was given in [3].

It appears natural to approach time-dependent problems with open boundaries by combining the approaches of [2] and [3]. In essence, this is what we shall do in this paper. However, there is a difficulty. Problems which are elliptic in the steady case [2] are replaced by hyperbolic problems in the time-dependent case. Associated with this is a loss of regularity of the solution, which becomes extremely difficult to control in an iteration. In order to overcome this difficulty, we shall have to rely on a special feature which is particular to one constitutive model (the upper convected

†Department of Mathematics and Interdisciplinary Center for Applied Mathematics, Virginia Polytechnic Institute and State University, Blacksburg, VA 24061-0123 (renardym@math.vt.edu).

Maxwell fluid), and we shall have to modify the boundary conditions. This is not a very satisfactory state of affairs, and further research on this problem is needed.

2. Governing equations.

The equations of motion for an incompressible fluid are

$$\rho\Big(\frac{\partial \mathbf{v}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{v}\Big) = \operatorname{div}\mathbf{T} - \nabla p + \mathbf{f}, \tag{1}$$

$$\operatorname{div}\mathbf{v} = 0. \tag{2}$$

Here $\mathbf{v}$ is the velocity, $\mathbf{T}$ the extra stress, p the pressure, ρ the density, and $\mathbf{f}$ a given body force. We assume the constitutive law of an upper convected Maxwell fluid:

$$\frac{\partial \mathbf{T}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{T} - (\nabla\mathbf{v})\mathbf{T} - \mathbf{T}(\nabla\mathbf{v})^T + \lambda\mathbf{T} = \mu(\nabla\mathbf{v} + (\nabla\mathbf{v})^T), \tag{3}$$

where λ and μ are positive constants, and the gradient of a vector is defined with the convention that the column index refers to the direction of differentiation and the row index to the component of the vector.

Our task will be to solve the equations for $t \geq 0$ and $\mathbf{x} = (x,y) \in \Omega := (0,L)\times\mathbb{R}$, subject to initial conditions

$$\mathbf{v}(\mathbf{x},0) = \mathbf{v}_0(\mathbf{x}), \qquad \mathbf{T}(\mathbf{x},0) = \mathbf{T}_0(\mathbf{x}), \qquad \mathbf{x}\in\Omega, \tag{4}$$

and boundary conditions. Throughout, we shall assume periodicity in y with a given period M. We shall make assumptions on the velocity which imply that the boundary $x = 0$ is an inflow boundary and the boundary $x = L$ is an outflow boundary. The boundary conditions for the velocity will be as follows:

$$\mathbf{v}(0,y,t) = \mathbf{v}_{\text{in}}(y,t), \ \Big(\frac{\partial^2\mathbf{v}}{\partial t^2} + (\mathbf{v}\cdot\nabla)\frac{\partial\mathbf{v}}{\partial t} - \Big(\frac{\partial\mathbf{v}}{\partial t}\cdot\nabla\Big)\mathbf{v}\Big)(L,y,t) = \mathbf{w}_{\text{out}}(y,t),$$

$$\frac{\partial\mathbf{v}}{\partial t}\cdot\mathbf{e}_1(L,y,0) = u_{\text{out}}(y). \tag{5}$$

Here $\mathbf{e}_1$ is a unit vector in the x-direction. Equation (5) means that we prescribe the velocity at the inflow boundary, while the quantity prescribed at the outflow boundary is the time derivative of the acceleration modified by a correction term which makes it into a divergence-free vector field. The condition on the normal component of $\partial\mathbf{v}/\partial t$ will be needed to determine an initial value of $\partial\mathbf{v}/\partial t$; note that (1) determines $\partial\mathbf{v}/\partial t$ up to a gradient, and the boundary values of the normal component are precisely the additional information that is required. The choice of boundary conditions might appear peculiar at this point; we shall see later in the proof why this particular choice makes the energy estimates "work." In addition, we need inflow boundary conditions for the stress. They are as follows:

$$p(0,y,t) = \pi(y,t), \qquad \frac{1}{2}(T_{11}(0,y,t) - T_{22}(0,y,t)) = \tau(y,t). \tag{6}$$

The inflow boundary conditions chosen here are slightly different from those in [2]. Moreover, the proof given in this paper works only for the upper convective Maxwell model and not for similar models of differential type. The reasons for this will be given below.

3. Construction of solutions. The equations (1)–(3) form a system of combined type, and there appear to be no methods available to deal with such systems directly. Hence all schemes to construct solutions have been based on some preprocessing of the equations, which leads to a decoupling into simpler problems at leading order. We shall also use this idea here. We begin by applying the operation $\partial/\partial t + (\mathbf{v}\cdot\nabla) + \lambda + (\nabla\mathbf{v})^T$ to equation (1). After using (3), this yields

$$\begin{aligned}&\rho\Big(\frac{\partial^2\mathbf{v}}{\partial t^2} + 2(\mathbf{v}\cdot\nabla)\frac{\partial\mathbf{v}}{\partial t} + \Big(\frac{\partial\mathbf{v}}{\partial t}\cdot\nabla\Big)\mathbf{v} + (\mathbf{v}\cdot\nabla)^2\mathbf{v} + ((\nabla\mathbf{v})^T + \lambda)\Big[\frac{\partial\mathbf{v}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{v}\Big]\Big)\\ &= \mu\Delta\mathbf{v} + (\mathbf{T}:\partial^2)\mathbf{v} + (\nabla\mathbf{v} + (\nabla\mathbf{v})^T)\text{div }\mathbf{T} - \nabla q + \frac{\partial\mathbf{f}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{f} + (\nabla\mathbf{v})^T\mathbf{f} + \lambda\mathbf{f}.\end{aligned}\tag{7}$$

Here the notation $\mathbf{T}:\partial^2$ stands for $\sum T_{ij}\partial^2/\partial x_i\partial x_j$ and

$$q = \frac{\partial p}{\partial t} + (\mathbf{v}\cdot\nabla)p + \lambda p.\tag{8}$$

In [3], an iteration scheme was used to solve the equations. The scheme alternately uses (7) to update the velocity field and then (3) to update the stress. In order to do this, one has to prescribe $\mathbf{T}$ at the inflow boundary. However, the outcome would then be a solution to (3) and (7), and in order to get back to (1), one has to restrict the inflow boundary data so that (1) is satisfied at the inflow boundary. In [2], this led to a system of ordinary differential equations (ODEs) for the inflow boundary data, which was used to determine some stress components in terms of others. This system has to be solved at each step of the iteration to generate the inflow conditions for (3). Roughly speaking, one solves (3) and (8) for x-derivatives of $\mathbf{T}$ and p and inserts the result in (1). The resulting system is then solved for the values of T_{12} and p on the inflow boundary. In the time-dependent case, following the same procedure leads to a hyperbolic partial differential equation (PDE) system in place of the ODEs. Associated with this is a loss of regularity, which I do not know how to cope with in general. For the upper convected Maxwell model, however, the special features of the equation allow some "slack" so that the loss of regularity does not matter. To take advantage of this, we need to modify the inflow boundary conditions that were used in [2]. Instead of prescribing T_{11} and T_{22} as we did there, we now prescribe p and $(T_{11} - T_{22})/2$.

We need to reformulate (7) a little further. We solve (1) for div $\mathbf{T}$ and substitute the result on the right-hand side of (7). As a result, we find

$$\begin{aligned}&\rho\Big(\frac{\partial^2\mathbf{v}}{\partial t^2} + 2(\mathbf{v}\cdot\nabla)\frac{\partial\mathbf{v}}{\partial t} + \Big(\frac{\partial\mathbf{v}}{\partial t}\cdot\nabla\Big)\mathbf{v} + (\mathbf{v}\cdot\nabla)^2\mathbf{v} + (\lambda - (\nabla\mathbf{v}))\Big[\frac{\partial\mathbf{v}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{v}\Big]\Big)\\ &= \mu\Delta\mathbf{v} + (\mathbf{T}:\partial^2)\mathbf{v} + (\nabla\mathbf{v} + (\nabla\mathbf{v})^T)\nabla p - \nabla q + \frac{\partial\mathbf{f}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{f} - (\nabla\mathbf{v})\mathbf{f} + \lambda\mathbf{f}.\end{aligned}\tag{9}$$

In contrast to (7), the right-hand side of (9) does not contain any derivatives of $\mathbf{T}$ but only of p. This trick works only for the upper convected Maxwell model, and it is this feature which allows us to cope with a loss of regularity as long as it occurs only in $\mathbf{T}$ and not in p.

The iteration will now proceed as follows. For given $\mathbf{v}^n$, q^n, p^n, and $\mathbf{T}^n$, we determine p^{n+1} by solving the equation

$$\frac{\partial p^{n+1}}{\partial t} + (\mathbf{v}^n\cdot\nabla)p^{n+1} + \lambda p^{n+1} = q^n\tag{10}$$

with initial condition $p^{n+1}(x,y,0) = p_0(x,y)$ and inflow condition $p^{n+1}(0,y,t) = \pi(y,t)$. Here p_0 is the initial pressure, which can be determined from (1) and the prescribed initial and boundary data. To avoid the usual ambiguity of undetermined constants in the pressure, we shall fix the spatial average of q and of the initial value of p to be zero.

Next, we need to provide complete inflow conditions for the stresses. Let us use the notations $T_+ = (T_{11} + T_{22})/2$ and $T_- = (T_{11} - T_{22})/2$. We rewrite (1) as follows:

$$\begin{aligned} &\frac{\partial T_+}{\partial x} + \frac{\partial T_{12}}{\partial y} = \frac{\partial p}{\partial x} - \frac{\partial T_-}{\partial x} + \rho\left(\frac{\partial v_1}{\partial t} + (\mathbf{v}\cdot\nabla)v_1\right) - f_1, \\ &\frac{\partial T_{12}}{\partial x} + \frac{\partial T_+}{\partial y} = \frac{\partial p}{\partial y} + \frac{\partial T_-}{\partial y} + \rho\left(\frac{\partial v_2}{\partial t} + (\mathbf{v}\cdot\nabla)v_2\right) - f_2. \end{aligned} \tag{11}$$

We now solve (3) and (8) for the x-derivatives of $\mathbf{T}$ and p and insert the result in (11). The resulting system is of the form

$$\begin{aligned} &-\frac{1}{v_1}\frac{\partial T_+}{\partial t} - \frac{v_2}{v_1}\frac{\partial T_+}{\partial y} + \frac{\partial T_{12}}{\partial y} = \phi_1\left(\mathbf{v}, \frac{\partial \mathbf{v}}{\partial t}, \nabla\mathbf{v}, q, \mathbf{T}, \frac{\partial T_-}{\partial t}, \frac{\partial T_-}{\partial y}, p, \frac{\partial p}{\partial t}, \frac{\partial p}{\partial y}, \mathbf{f}\right), \\ &-\frac{1}{v_1}\frac{\partial T_{12}}{\partial t} - \frac{v_2}{v_1}\frac{\partial T_{12}}{\partial y} + \frac{\partial T_+}{\partial y} = \phi_2\left(\mathbf{v}, \frac{\partial \mathbf{v}}{\partial t}, \nabla\mathbf{v}, q, \mathbf{T}, \frac{\partial T_-}{\partial t}, \frac{\partial T_-}{\partial y}, p, \frac{\partial p}{\partial t}, \frac{\partial p}{\partial y}, \mathbf{f}\right). \end{aligned} \tag{12}$$

Since (12) contains to x-derivatives of the stresses, we can impose it as a condition to be satisfied at the inflow boundary $x = 0$. We incorporate it in the iteration as follows:

$$\begin{aligned} &-\frac{1}{v_1^n}\frac{\partial T_+^{n+1}}{\partial t} - \frac{v_2^n}{v_1^n}\frac{\partial T_+^{n+1}}{\partial y} + \frac{\partial T_{12}^{n+1}}{\partial y} \\ &\qquad = \phi_1\left(\mathbf{v}^n, \frac{\partial \mathbf{v}^n}{\partial t}, \nabla\mathbf{v}^n, q^n, \mathbf{T}^{n+1}, \frac{\partial \tau}{\partial t}, \frac{\partial \tau}{\partial y}, \pi, \frac{\partial \pi}{\partial t}, \frac{\partial \pi}{\partial y}, \mathbf{f}\right), \\ &-\frac{1}{v_1^n}\frac{\partial T_{12}^{n+1}}{\partial t} - \frac{v_2^n}{v_1^n}\frac{\partial T_{12}^{n+1}}{\partial y} + \frac{\partial T_+^{n+1}}{\partial y} \\ &\qquad = \phi_2\left(\mathbf{v}^n, \frac{\partial \mathbf{v}^n}{\partial t}, \nabla\mathbf{v}^n, q^n, \mathbf{T}^{n+1}, \frac{\partial \tau}{\partial t}, \frac{\partial \tau}{\partial y}, \pi, \frac{\partial \pi}{\partial t}, \frac{\partial \pi}{\partial y}, \mathbf{f}\right). \end{aligned} \tag{13}$$

Here

$$\mathbf{T}^{n+1} = \begin{pmatrix} T_+^{n+1} + \tau & T_{12}^{n+1} \\ T_{12}^{n+1} & T_+^{n+1} - \tau \end{pmatrix}. \tag{14}$$

Having solved (13), we now have complete inflow data for the stresses, which we use to solve (3):

$$\frac{\partial \mathbf{T}^{n+1}}{\partial t} + (\mathbf{v}^n\cdot\nabla)\mathbf{T}^{n+1} = (\nabla\mathbf{v}^n)\mathbf{T}^n + \mathbf{T}^n(\nabla\mathbf{v}^n)^T - \lambda\mathbf{T}^n + \mu(\nabla\mathbf{v}^n + (\nabla\mathbf{v}^n)^T). \tag{15}$$

Finally, we obtain new values for $\mathbf{v}$ and q by solving the equation

$$\begin{aligned} &\rho\Big(\frac{\partial^2\mathbf{v}^{n+1}}{\partial t^2} + 2(\mathbf{v}^n\cdot\nabla)\frac{\partial \mathbf{v}^{n+1}}{\partial t} + \Big(\frac{\partial \mathbf{v}^n}{\partial t}\cdot\nabla\Big)\mathbf{v}^n + (\mathbf{v}^n\cdot\nabla)^2\mathbf{v}^{n+1} \\ &\quad + (\lambda - (\nabla\mathbf{v}^n))\Big[\frac{\partial \mathbf{v}^n}{\partial t} + (\mathbf{v}^n\cdot\nabla)\mathbf{v}^n\Big]\Big) = \mu\Delta\mathbf{v}^{n+1} + (\mathbf{T}^{n+1} : \partial^2)\mathbf{v}^{n+1} \\ &\quad + (\nabla\mathbf{v}^n + (\nabla\mathbf{v}^n)^T)\nabla p^{n+1} - \nabla q^{n+1} + \frac{\partial \mathbf{f}}{\partial t} + (\mathbf{v}^n\cdot\nabla)\mathbf{f} - (\nabla\mathbf{v}^n)\mathbf{f} + \lambda\mathbf{f} \end{aligned} \tag{16}$$

with the incompressibility condition (2) and initial and boundary conditions for $\mathbf{v}^{n+1}$. Here the outflow condition is implemented in the form

$$\left(\frac{\partial^2 \mathbf{v}^{n+1}}{\partial t^2} + (\mathbf{v}^n \cdot \nabla)\frac{\partial \mathbf{v}^{n+1}}{\partial t} - \left(\frac{\partial \mathbf{v}^{n+1}}{\partial t} \cdot \nabla\right)\mathbf{v}^n\right)(L, y, t) = \mathbf{w}_{\text{out}}(y, t). \tag{17}$$

4. Statement of result. In the following, we use the notation H_p^k for spaces of functions which have k locally square integrable derivatives and are periodic with period M in the unbounded direction. Moreover, we shall, in abuse of proper notation, say that a vector or tensor valued quantity is in a function space X if all components are in X. We shall make the following assumptions:

(S1) $\mathbf{v}_0 \in H_p^5((0,L) \times \mathbb{R})$, $\mathbf{T}_0 \in H_p^5((0,L) \times \mathbb{R})$.

(S2) $\mathbf{v}_{\text{in}} \in H_p^{11/2}((0,T) \times \mathbb{R})$, $\mathbf{w}_{\text{out}} \in H_p^{7/2}((0,T) \times \mathbb{R})$, $u_{\text{out}} \in H_p^{7/2}(\mathbb{R})$. In addition, the first component of $\mathbf{v}_{\text{in}}$ is in $H^6((0,T); H_p^{-1/2}(\mathbb{R}))$ and the first component of $\mathbf{w}_{\text{out}}$ is in $H^{9/2}((0,T); H_p^{-1}(\mathbb{R}))$.

(S3) $\pi, \tau \in H_p^4((0,T) \times \mathbb{R}))$.

(S4) $\mathbf{f} \in \bigcap_{k=0}^5 W^{k,1}((0,T); H_p^{5-k}((0,L) \times \mathbb{R}))$.

(E) $\mathbf{T}_0 + \mu - \mathbf{v}_0\mathbf{v}_0^T$ is uniformly positive definite.

(C1) The initial values of $\mathbf{v}$ and its derivatives up to fourth order, p and its derivatives up to third order, and $\mathbf{T}$ and its derivatives up to second order are compatible with the prescribed boundary conditions.

(C2) div $\mathbf{v}_0 = 0$.

(C3)
$$\frac{d^2}{dt^2}\int_0^M \mathbf{v}_{\text{in}}(y,t) \cdot \mathbf{e}_1 \, dy = \int_0^M \mathbf{w}_{\text{out}} \cdot \mathbf{e}_1 \, dy,$$
$$\int_0^M \frac{\partial \mathbf{v}_{\text{in}}}{\partial t}(y,0) \cdot \mathbf{e}_1 \, dy = \int_0^M u_{\text{out}}(y) \, dy.$$

(I) $\mathbf{v}_{\text{in}} \cdot \mathbf{e}_1 > 0$, $\mathbf{v}_0 \cdot \mathbf{e}_1 > 0$.

In assumption (C1), the initial values of derivatives are to be computed from the equations. For example, (1), together with initial values of $\mathbf{v}$ and $\mathbf{T}$, yields an initial value of $\rho\partial\mathbf{v}/\partial t + \nabla p$. Using the divergence condition and the boundary data for the normal component of $\partial\mathbf{v}/\partial t$, we can calculate initial data of $\partial\mathbf{v}/\partial t$ and ∇p from this. At the inflow boundary, the tangential component of ∇p has to be compatible with π, and from the knowledge of π and ∇p, we can evaluate p. This procedure can be repeated for higher time derivatives.

Our result will be as follows.

THEOREM. *Under the assumptions above, there exists $T' > 0$ such that the initial-boundary value problem* (1)–(6) *has a solution with the regularity*

$$\begin{aligned} &\mathbf{v} \in H_p^5((0,T') \times (0,L) \times \mathbb{R}), \\ &p \in \bigcap_{i=0}^{3} C^i([0,T']; H_p^{4-i}((0,L) \times \mathbb{R})), \\ &\mathbf{T} \in \bigcap_{i=0}^{3} C^i([0,T']; H^{3-i}((0,L) \times \mathbb{R})). \end{aligned} \tag{18}$$

The assumption that $\mathbf{T}_0 \in H^5_p((0,L) \times \mathbb{R}$ may appear excessive in view of the regularity obtained for the solution. However, as in [3], this assumption is needed to ensure regularity of initial values for time derivatives of $\mathbf{v}$.

The proof is based on a contraction argument. We define $Z(M,T')$ to be the set of all functions $(\mathbf{v},q,p,\mathbf{T})$, defined on $(0,T')\times(0,L)\times\mathbb{R}$ with the following properties:

$$
\begin{aligned}
&\mathbf{v} \in H^5_p((0,T') \times (0,L) \times \mathbb{R}),\\
&q \in \bigcap_{i=0}^{3} H^i((0,T'); H^{4-i}_p((0,L) \times \mathbb{R})),\\
&q(0,\cdot,\cdot) \in W^{3,\infty}(0,T'); L^2_p(\mathbb{R})),\\
&p \in \bigcap_{i=0}^{3} W^{i,\infty}((0,T'); H^{4-i}_p((0,L) \times \mathbb{R})) \cap H^4((0,T'); L^2_p((0,L) \times \mathbb{R})),\\
&\mathbf{T} \in \bigcap_{i=0}^{3} W^{i,\infty}((0,T'); H^{3-i}_p((0,L) \times \mathbb{R})),\\
&\sum_{i=0}^{5} \|\mathbf{v}\|_{i,5-i,2} + \sum_{i=0}^{3} \|q\|_{i,4-i,2} + \sum_{i=0}^{3} \|p\|_{i,4-i,\infty} + \sum_{i=0}^{3} \|\mathbf{T}\|_{i,3-i,\infty} \le M,\\
&\operatorname{div} \mathbf{v} = 0,\ \mathbf{v}(0,y,t) = \mathbf{v}_{\text{in}}(y,t),\\
&\int_0^1 \int_0^M q(x,y,t)\,dy\,dx = 0,\\
&\text{The initial values of time derivatives up to the indicated orders}\\
&\quad\text{agree with those determined from the equations:}\\
&\mathbf{v}:\ 4,\ q:\ 2,\ p:\ 3,\ \mathbf{T}:\ 2.
\end{aligned}
\tag{19}
$$

Here $\|\cdot\|_{i,k,q}$ denotes the norm in $W^{i,q}((0,T'); H^k_p((0,L) \times \mathbb{R}))$. We shall show that the mapping defined by the iteration in §3 maps $Z(M,T')$ into itself if M is sufficiently large and T' is sufficiently small relative to M. Moreover, it is a contraction if $Z(M,T')$ is equipped with the norm

$$
\begin{aligned}
d((\mathbf{v},q,p,\mathbf{T}),(\hat{\mathbf{v}},\hat{q},\hat{p},\hat{\mathbf{T}})) &= \sum_{i=0}^{4} \|\mathbf{v} - \hat{\mathbf{v}}\|_{i,4-i,2} + \sum_{i=0}^{2} \|q - \hat{q}\|_{i,3-i,2}\\
&+ \|q(0,\cdot,\cdot) - \hat{q}(0,\cdot,\cdot)\|_{2,0,\infty} + \sum_{i=0}^{2} \|p - \hat{p}\|_{i,3-i,\infty} + \sum_{i=0}^{2} \|\mathbf{T} - \hat{\mathbf{T}}\|_{i,2-i,\infty}.
\end{aligned}
\tag{20}
$$

It is easy to see that $Z(M,T')$ is complete; we need to check that it is nonempty if M is large enough. The existence of functions which, along with their derivatives, satisfy the given initial conditions, follows from the inverse trace theorem ([1, p. 21]), and as a result, we can find functions q, p, and $\mathbf{T}$ which satisfy all the requirements above.

It remains to construct a velocity field which satisfies the inflow conditions, the divergence condition, and the initial conditions. It is easy to find a divergence-free vector field which has the required regularity and satisfies the inflow conditions. Therefore, without loss of generality, we can henceforth require that $\mathbf{v} = \mathbf{0}$ on the boundary. This is the case studied in [3], and the only difference is that we require an additional order of regularity.

Our task is now to find a divergence-free $\mathbf{v}$ such that $\mathbf{v} = \mathbf{0}$ on the boundary and

$$\frac{\partial^i \mathbf{v}}{\partial t^i}(x, y, 0) = \mathbf{v}_i(x, y), \quad i = 0, 1, 2, 3, 4, \tag{21}$$

where $\mathbf{v}_i \in H_p^{5-i}((0, L) \times \mathrm{I\!R})$ is divergence-free and vanishes on the boundary. Following the ideas of [3], we take a_1 and a_2 to be functions such that

$$a_i = \frac{\partial a_i}{\partial x} = \frac{\partial^2 a_i}{\partial x^2} = 0, \quad -\frac{\partial^3 a_i}{\partial x^3} = (\mathcal{S}\mathbf{v}_i) \cdot \mathbf{e}_2, \quad \frac{\partial^4 a_1}{\partial x^4} = 0 \tag{22}$$

on the boundary, where $\mathcal{S}$ is the Stokes operator. The trace theorem shows that such functions a_i exist and $a_i \in H_p^{6-i}((0, L) \times \mathrm{I\!R})$. Next, we decompose $\mathbf{v}$ in the form $\mathbf{v} = \mathbf{v}_0 + \hat{\mathbf{v}} + \tilde{\mathbf{v}}$, where $\mathbf{v}_0$ is the initial value from (21) and $\hat{\mathbf{v}}$ is required to satisfy the initial conditions

$$\hat{\mathbf{v}}(x, y, 0) = \mathbf{0}, \quad \frac{\partial \hat{\mathbf{v}}}{\partial t}(x, y, 0) = \mathbf{v}_1(x, y) - \operatorname{curl} a_1, \quad \frac{\partial^2 \hat{\mathbf{v}}}{\partial t^2}(x, y, 0) = \mathbf{v}_2(x, y) - \operatorname{curl} a_2,$$

$$\frac{\partial^3 \hat{\mathbf{v}}}{\partial t^3}(x, y, 0) = \mathbf{v}_3(x, y), \quad \frac{\partial^4 \hat{\mathbf{v}}}{\partial t^4}(x, y, 0) = \mathbf{v}_4(x, y). \tag{23}$$

Here the curl operator is defined by

$$\operatorname{curl} a = \frac{\partial a}{\partial y}\mathbf{e}_1 - \frac{\partial a}{\partial x}\mathbf{e}_2. \tag{24}$$

It is easily verified that $\mathbf{v}_4 \in D((-\mathcal{S})^{1/2})$, $\mathbf{v}_3 \in D(\mathcal{S})$, $\mathbf{v}_2 - \operatorname{curl} a_2 \in D((-\mathcal{S})^{3/2})$, and $\mathbf{v}_1 \in D(\mathcal{S}^2)$. The inverse trace theorem ([1, p. 21]) shows that a divergence-free vector field $\hat{\mathbf{v}}$ with the required initial conditions and the regularity

$$\hat{\mathbf{v}} \in \bigcap_{i=0}^{5} C^i([0, T']; D((-\mathcal{S})^{(5-i)/2}) \tag{25}$$

exists. The final contribution $\tilde{\mathbf{v}}$ is constructed as $\operatorname{curl} \tilde{a}$, were $\tilde{a}$ has to satisfy

$$\tilde{a}(x, y, 0) = 0, \quad \frac{\partial \tilde{a}}{\partial t}(x, y, 0) = a_1(x, y), \quad \frac{\partial^2 \tilde{a}}{\partial t^2}(x, y, 0) = a_2(x, y),$$

$$\frac{\partial^3 \tilde{a}}{\partial t^3}(x, y, 0) = 0, \quad \frac{\partial^4 \tilde{a}}{\partial t^4} = 0. \tag{26}$$

From the conditions (22), it follows that $a_i \in D(\mathcal{B}^{(6-i)/4})$, where $\mathcal{B}$ is the biharmonic operator with Dirichlet boundary conditions. Invoking the inverse trace theorem again, we find that there exists $\tilde{a}$ satisfying (26) with the regularity

$$\tilde{a} \in \bigcap_{i=0}^{5} C^i([0, T']; D(\mathcal{B}^{(6-i)/4})). \tag{27}$$

This completes the argument.

5. Stress integration. We now need to provide the estimates which will establish that the iteration defined in §3 gives a contraction on $Z(M,T')$. We note that if T' is chosen small enough relative to M, then (I) implies that $\mathbf{v}\cdot\mathbf{e}_1 > 0$ for any element of $Z(M,T')$. We shall assume throughout that this is the case.

Let us assume that $\mathbf{v}^n$, q^n, p^n, and $\mathbf{T}^n$ are given. In this section, we shall obtain estimates for p^{n+1} and $\mathbf{T}^{n+1}$. The equations involved in determining these are easily solved, e.g., by the method of characteristics, and we shall obtain energy estimates for the solutions. For convencience, we make the following definition.

DEFINITION. *A function $\phi(M,T')$ is called* controllable *if there exists a positively valued function $T'(M)$ and a constant C such that $\phi(M,T'(M)) \le C$ for sufficiently large M.*

In general, of course, $T'(M)$ will tend to zero as $M \to \infty$.

We start with (10). We multiply both side by p^{n+1} and integrate over $(0,t)\times\Omega$. This yields

$$\begin{aligned}&\frac{1}{2}\int_\Omega (p^{n+1}(\mathbf{x},t))^2\,dx\,dy + \lambda\int_0^t\int_\Omega (p^{n+1}(\mathbf{x},\tau))^2\,dx\,dy\,d\tau\\ &= \int_0^t\int_\Omega p^{n+1}(\mathbf{x},\tau)q^n(\mathbf{x},\tau)\,dx\,dy\,d\tau + \frac{1}{2}\int_\Omega p_0(\mathbf{x})^2\,dx\,dy\\ &+\frac{1}{2}\int_0^t\int_0^M \mathbf{v}_{\text{in}}(y,\tau)\cdot\mathbf{e}_1\pi(y,\tau)^2\,dy\,d\tau\\ &-\frac{1}{2}\int_0^t\int_0^M \mathbf{v}(L,y,\tau)\cdot\mathbf{e}_1(p^{n+1}(L,y,\tau))^2\,dy\,d\tau.\end{aligned}\tag{28}$$

This yields the estimate

$$\|p^{n+1}\|_{0,0,\infty} \le C(\sqrt{T'}\|q^n\|_{0,0,2} + \|p_0\|_0 + \|\pi\|_0).\tag{29}$$

Here $\|\cdot\|_k$ with a single index k shall denote the norm in $H^k(\Omega)$ or $H^k_p((0,T')\times\mathbb{R})$, respectively.

We can now differentiate (10) and obtain estimates for derivatives of p^{n+1} in the same fashion; note that the value of the x-derivative of p^{n+1} at the inflow boundary is determined by the equation itself in terms of given data and the value of q^n at the inflow boundary. By proceeding in this fashion, we find an estimate of the form

$$\sum_{i=0}^{3}\|p^{n+1}\|_{i,4-i,\infty} \le \phi(M,T'),\tag{30}$$

where the function $\phi(M,T')$ is controllable. (Note that the right-hand side of (29), for instance, has a bound of the form $C_1M\sqrt{T'}+C_2$, which is obviously controllable by setting $T'=1/M^2$.)

In a similar fashion, the solution of (13) yields controllable bounds for $\|\mathbf{T}\|_3$ on the inflow boundary, and this can be used in (15) to get a controllable bound for $\sum_{i=0}^3\|\mathbf{T}\|_{i,3-i,\infty}$.

We have derived all the estimates for stress integration which are needed to show that the iteration maps $Z(M,T')$ into itself. The contraction estimates are derived in the same fashion, and we outline only one step. Consider two iteration sequences for equation (10) and take the difference. We get

$$\left(\frac{\partial}{\partial t} + (\mathbf{v}^n\cdot\nabla)\right)(p^{n+1}-\hat{p}^{n+1}) + \lambda(p^{n+1}-\hat{p}^{n+1}) = q^n - \hat{q}^n - ((\mathbf{v}^n-\hat{\mathbf{v}}^n)\cdot\nabla)\hat{p}^{n+1},\tag{31}$$

with initial and inflow values of $p^{n+1} - \hat{p}^{n+1}$ equal to zero. Proceeding as above, we obtain from (31) the estimate

$$\begin{aligned}(32)\quad &\sum_{i=0}^{2} \|p^{n+1} - \hat{p}^{n+1}\|_{i,3-i,\infty} + \|p - \hat{p}\|_{3,0,2} \le C\Big(\sum_{i=0}^{2}(\|q^n - \hat{q}^n\|_{i,3-i,1} \\ &\qquad + \|q^n(0,\cdot,\cdot) - \hat{q}^n(0,\cdot,\cdot)\|_{2,0,2}) + M\sum_{i=0}^{4} \|\mathbf{v}^n - \hat{\mathbf{v}}^n\|_{i,4-i,1}\Big) \\ &\le C\sqrt{T'}\Big(\sum_{i=0}^{3}(\|q^n - \hat{q}^n\|_{i,3-i,2} + \|q^n - \hat{q}^n\|_{2,0,\infty}) \\ &\qquad + M\sum_{i=0}^{4} \|\mathbf{v}^n - \hat{\mathbf{v}}^n\|_{i,4-i,2}\Big).\end{aligned}$$

Similar considerations apply to the integration of $\mathbf{T}$.

6. The velocity equation. We now consider the solution of the equation (16). To simplify notation, we shall write $\mathbf{v}$ and q for $\mathbf{v}^{n+1}$ and q^{n+1}, $\mathbf{w}$ for $\mathbf{v}^n$, and $\mathbf{T}$ for $\mathbf{T}^{n+1}$. The problem now assumes the form

$$(33)\qquad \rho\Big(\frac{\partial^2 \mathbf{v}}{\partial t^2} + 2(\mathbf{w}\cdot\nabla)\frac{\partial \mathbf{v}}{\partial t} + (\mathbf{w}\cdot\nabla)^2\mathbf{v}\Big) = \mu\Delta\mathbf{v} + \mathbf{T} : \nabla^2\mathbf{v} - \nabla q + \tilde{\mathbf{f}},$$

where $\tilde{\mathbf{f}}$ is a known forcing function. In addition, we have to satisfy the divergence condition

$$(34)\qquad \operatorname{div} \mathbf{v} = 0,$$

the boundary conditions

$$(35)\quad \mathbf{v}(0,y,t) = \mathbf{v}_{\text{in}}(y,t), \qquad \Big(\frac{\partial^2 \mathbf{v}}{\partial t^2} + (\mathbf{w}\cdot\nabla)\frac{\partial \mathbf{v}}{\partial t} - \Big(\frac{\partial \mathbf{v}}{\partial t}\cdot\nabla\Big)\mathbf{w}\Big)(L,y,t) = \mathbf{w}_{\text{out}}(y,t),$$

and the initial conditions

$$(36)\qquad \mathbf{v}(x,y,0) = \mathbf{v}_0(x,y), \qquad \frac{\partial \mathbf{v}}{\partial t}(x,y,0) = \mathbf{v}_1(x,y).$$

Our goal for this section is the following result.

LEMMA. *The problem* (33)–(36) *has a unique solution, which satisfies an estimate of the form*

$$\begin{aligned}(37)\quad &\sum_{i=0}^{5} \|\mathbf{v}\|_{i,5-i,2} + \sum_{i=0}^{3} \|q\|_{i,4-i,2} \le C\Big(\sum_{i=0}^{3} \|\tilde{\mathbf{f}}\|_{i,3-i,\infty} + \sum_{i=0}^{2}\Big\|\frac{\partial^2 \tilde{\mathbf{f}}}{\partial t^2} + (\mathbf{w}\cdot\nabla)\frac{\partial \tilde{\mathbf{f}}}{\partial t}\Big\|_{i,2-i,1} \\ &\qquad + \|\mathbf{v}_0\|_5 + \|\mathbf{v}_1\|_4 + \|\mathbf{v}_{\text{in}}\| + \|\mathbf{w}_{\text{out}}\|\Big).\end{aligned}$$

Here the norms of $\mathbf{v}_{\text{in}}$ *and* $\mathbf{w}_{\text{out}}$ *are in the function spaces specified in assumption* (S2), *and the constant* C *depends only the initial data and on*

$$(38)\qquad \sum_{i=0}^{5} \|\mathbf{w}\|_{i,5-i,1} + \sum_{i=0}^{3} \Big(\|\mathbf{T}\|_{i,3-i,\infty} + \Big\|\frac{\partial \mathbf{T}}{\partial t} + (\mathbf{w}\cdot\nabla)\mathbf{T}\Big\|_{i,3-i,1}\Big).$$

Moreover, in any subdomain away from the outflow boundary, we obtain a bound with the same right-hand side as (37) *for*

$$\sum_{i=0}^{5} \|\mathbf{v}\|_{i,5-i,\infty} + \sum_{i=0}^{3} \|q\|_{i,4-i,\infty}.$$

Since the right-hand side in (37) is easily shown to be controllable, the lemma allows us to complete the proof that the iteration maps $Z(M, T')$ into itself as long as T' is small relative to M. Moreover, to show the contraction estimate, we can, similarly as in the previous section, take the difference between two problems of the form (33)–(36) and use the analogue of the preceding lemma at one less order of differentiability to estimate the difference between the solutions. We omit the details of this rather routine argument and devote the rest of the paper to proving the lemma.

We first construct a divergence-free $\mathbf{v}$ which satisfies the boundary conditions. To satisfy the divergence condition, we express $\mathbf{v}$ in terms of a streamfunction: $\mathbf{v} = (-\psi_y, \psi_x)$. Moreover, let ϕ denote the corresponding streamfunction for $\mathbf{w}$. The function ψ is the sum of a part which is linear in y and independent of x and a part which is periodic in y. The coefficient of the linear part is simply given by the average the first component of $\mathbf{v}_{\text{in}}$ and is hence of class $H^6(0,T)$. We can therefore focus on the periodic part. At the inflow boundary, we have prescribed values for ψ_y and ψ_x, and we can integrate with respect to y to obtain prescribed values of $\psi \in H^6((0,T); H_p^{1/2}(\mathbb{R})) \cap L^2((0,T); H_p^{13/2}(\mathbb{R}))$ and $\psi_x \in H_p^{11/2}((0,T) \times \mathbb{R})$. Using the inverse trace theorem, we can construct a ψ satisfying these boundary conditions which lies in $H^6((0,T); H_p^1((0,L) \times \mathbb{R})) \cap L^2((0,T); H_p^7((0,L) \times (\mathbb{R}))$. On the outflow boundary the prescribed data are $-\psi_{ytt} + \frac{\partial}{\partial y}(\phi_y \psi_{xt} - \phi_x \psi_{yt})$ and $\psi_{xtt} - \phi_y \psi_{xxt} + \phi_x \psi_{xyt} + \psi_{yt} \phi_{xx} - \psi_{xt} \phi_{xy}$. To find a function ψ satisfying these boundary conditions we arbitrarily set $\psi = 0$ on the boundary and then integrate the first boundary condition with respect to y. This leaves us with having to satisfy a given condition for $\psi_{xt} \in H_p^{9/2}((0,T) \times \mathbb{R})$, and from the second boundary condition, we can find $\psi_{xxt} \in H_p^{7/2}((0,T) \times \mathbb{R})$. Using the inverse trace theorem, we can find $\psi_t \in H_p^6((0,T) \times (0,L) \times \mathbb{R})$ so that the given boundary conditions are satisfied. We can thus construct a velocity field $\mathbf{v}^*$, satisfying the given boundary conditions, which has a time derivative of class H^5. We can now replace $\mathbf{v}$ in (33) by $\tilde{\mathbf{v}} + \mathbf{v}^*$ and absorb the terms resulting from $\mathbf{v}^*$ into the forcing function $\tilde{\mathbf{f}}$. For the rest of the section, we shall therefore assume homogeneous boundary conditions.

In order to construct solutions of (33), we shall take derivatives of the equation and reformulate it as a problem for higher derivatives of $\mathbf{v}$. In the process, we shall successively express lower-order time derivatives of $\mathbf{v}$ in terms of higher-order time derivatives. As a first step, let us take a time derivative of (33). We get

(39)
$$\begin{aligned}\rho(\mathbf{v}_{ttt} + 2(\mathbf{w} \cdot \nabla)\mathbf{v}_{tt} + 2(\mathbf{w}_t \cdot \nabla)\mathbf{v}_t + (\mathbf{w} \cdot \nabla)^2 \mathbf{v}_t) &= \mu \Delta \mathbf{v}_t + \mathbf{T} : \partial^2 \mathbf{v}_t - \nabla q_t + \tilde{\mathbf{f}}_t \\ &+ \mathbf{T}_t : \partial^2 \mathbf{v} - \rho(\mathbf{w} \cdot \nabla)(\mathbf{w}_t \cdot \nabla)\mathbf{v} - \rho(\mathbf{w}_t \cdot \nabla)(\mathbf{w} \cdot \nabla)\mathbf{v}.\end{aligned}$$

Moreover, $\mathbf{v}_t$ must be divergence free, vanish on the inflow boundary, satisfy the outflow condition (35), and satisfy the appropriate initial conditions. We would like to convert (39) to a problem which involves only $\mathbf{v}_t$ but not $\mathbf{v}$ itself. Of course, we could think of $\mathbf{v}$ as the time-integral of $\mathbf{v}_t$, but if we do so, then the spatial regularity of $\mathbf{v}$ implied by that of $\mathbf{v}_t$ is not sufficient to deal with the terms in (39). The remedy is to replace $\mathbf{v}$ in (39) by a new quantity $\hat{\mathbf{v}}$, which would equal $\mathbf{v}$ for a solution of (33).

Note that we can think of (33)–(35) as an elliptic boundary value problem for $\mathbf{v}$ if $\mathbf{v}_t$ is given. To make the outflow condition into a boundary condition for $\mathbf{v}$, we integrate it with respect to time:

$$(40)\quad \mathbf{v}_t + (\mathbf{w}\cdot\nabla)\mathbf{v} = (\mathbf{v}_t + (\mathbf{w}\cdot\nabla)\mathbf{v})(y,0) + \int_0^t [(\mathbf{w}_t\cdot\nabla)\mathbf{v} + (\mathbf{v}_t\cdot\nabla)\mathbf{w}](y,\tau)\,d\tau.$$

The idea now is to set $\hat{\mathbf{v}}$ equal to the solution of this elliptic boundary value problem. A minor problem is that the elliptic boundary value problem might not be uniquely solvable; however, it can be made uniquely solvable by a finite-rank perturbation. Let P be a finite-rank operator achieving this. Then we define $\hat{\mathbf{v}}$ as the solution of the problem

$$(41)\quad \rho(\mathbf{v}_{tt} + 2(\mathbf{w}\cdot\nabla)\mathbf{v}_t + (\mathbf{w}\cdot\nabla)^2)\hat{\mathbf{v}}) = \mu\Delta\hat{\mathbf{v}} + \mathbf{T} : \nabla^2\hat{\mathbf{v}} + P(\hat{\mathbf{v}} - \mathbf{v}) - \nabla\hat{q} + \tilde{\mathbf{f}},$$

with the additional conditions that $\hat{\mathbf{v}}$ is divergence free, vanishes at the inflow boundary, and satisfies

$$(42)\quad \mathbf{v}_t + (\mathbf{w}\cdot\nabla)\hat{\mathbf{v}} = (\mathbf{v}_t + (\mathbf{w}\cdot\nabla)\mathbf{v})(y,0) + \int_0^t [(\mathbf{w}_t\cdot\nabla)\hat{\mathbf{v}} + (\mathbf{v}_t\cdot\nabla)\mathbf{w}](y,\tau)\,d\tau$$

at the outflow boundary. Equation (39) is now modified to

$$(43)\quad \begin{aligned}\rho(\mathbf{v}_{ttt} + 2(\mathbf{w}\cdot\nabla)\mathbf{v}_{tt} + 2(\mathbf{w}_t\cdot\nabla)\mathbf{v}_t + (\mathbf{w}\cdot\nabla)^2\mathbf{v}_t) &= \mu\Delta\mathbf{v}_t + \mathbf{T} : \partial^2\mathbf{v}_t - \nabla q_t + \tilde{\mathbf{f}}_t\\ &+ \mathbf{T}_t : \partial^2\hat{\mathbf{v}} - \rho(\mathbf{w}\cdot\nabla)(\mathbf{w}_t\cdot\nabla)\hat{\mathbf{v}} - \rho(\mathbf{w}_t\cdot\nabla)(\mathbf{w}\cdot\nabla)\hat{\mathbf{v}}.\end{aligned}$$

We can choose P such that $P\mathbf{v}$ is of class $H_p^5((0,L)\times\mathbb{R})$, regardless of whether $\mathbf{v}$ itself has this regularity. For the solution of (41), we then have the estimate

$$(44)\quad \sum_{i=0}^{3}\|\hat{\mathbf{v}}\|_{i,5-i,2} + \|\hat{q}\|_{i,4-i,2} \le C\left(\sum_{i=0}^{4}\|\mathbf{v}_t\|_{i,4-i,2} + \sum_{i=0}^{3}\|\tilde{\mathbf{f}}\|_{i,3-i,2} + K\right),$$

where K is a term depending only on the initial data. We must make sure that the new problem (43) is equivalent to the original one. To this end, we take the time derivative of (41) and subtract (43). This yields

$$(45)\quad \mu\Delta(\hat{\mathbf{v}}_t - \mathbf{v}_t) + \mathbf{T} : \partial^2(\hat{\mathbf{v}}_t - \mathbf{v}_t) + P(\hat{\mathbf{v}}_t - \mathbf{v}_t) - \rho(\mathbf{w}\cdot\nabla)^2(\hat{\mathbf{v}}_t - \mathbf{v}_t) - \nabla(\hat{q}_t - q_t) = \mathbf{0}.$$

Moreover, the difference $\hat{\mathbf{v}}_t - \mathbf{v}_t$ has zero divergence and vanishes at the inflow boundary, and at the outflow boundary we have

$$(46)\quad (\mathbf{w}\cdot\nabla)(\hat{\mathbf{v}}_t - \mathbf{v}_t) = \mathbf{0}.$$

It now follows from the unique solvability of the elliptic boundary value problem that $\hat{\mathbf{v}}_t - \mathbf{v}_t = \mathbf{0}$, and since the initial data for $\mathbf{v}$ and $\hat{\mathbf{v}}$ agree, we have $\mathbf{v} = \hat{\mathbf{v}}$.

We shall solve (43) iteratively as follows:

$$(47)\quad \begin{aligned}\rho(\mathbf{v}^n_{ttt} + 2(\mathbf{w}\cdot\nabla)\mathbf{v}^n_{tt} + 2(\mathbf{w}_t\cdot\nabla)\mathbf{v}^{n-1}_t + (\mathbf{w}\cdot\nabla)^2\mathbf{v}^n_t) &= \mu\Delta\mathbf{v}^n_t + \mathbf{T} : \partial^2\mathbf{v}^n_t - \nabla q^n_t\\ &+ \tilde{\mathbf{f}}_t + \mathbf{T}_t : \partial^2\hat{\mathbf{v}}^{n-1} - \rho(\mathbf{w}\cdot\nabla)(\mathbf{w}_t\cdot\nabla)\hat{\mathbf{v}}^{n-1} - \rho(\mathbf{w}_t\cdot\nabla)(\mathbf{w}\cdot\nabla)\hat{\mathbf{v}}^{n-1}.\end{aligned}$$

At each step, this problem is of a similar form as (33), namely, if we write $\mathbf{v}^*$ instead of $\mathbf{v}_t^n$, then (47) has the form

$$\rho(\mathbf{v}_{tt}^* + 2(\mathbf{w}\cdot\nabla)\mathbf{v}_t^* + (\mathbf{w}\cdot\nabla)^2\mathbf{v}^*) = \mu\Delta\mathbf{v}^* + \mathbf{T} : \nabla^2\mathbf{v}^* - \nabla q^* + \mathbf{f}^*, \tag{48}$$

with a new forcing function $\mathbf{f}^*$. The boundary conditions are $\mathbf{v}^* = \mathbf{0}$ at the inflow boundary and $\mathbf{v}_t^* + (\mathbf{w}\cdot\nabla)\mathbf{v}^* - (\mathbf{v}^*\cdot\nabla)\mathbf{w} = \mathbf{0}$ at the outflow boundary. We shall now consider (48) with these boundary conditions and prove the following estimate, which is analogous to (37):

$$\begin{aligned}&\sum_{i=0}^{4}\|\mathbf{v}^*\|_{i,4-i,2} + \sum_{i=0}^{2}\|q^*\|_{i,3-i,2}\\ &\quad\le C\Big(\sum_{i=0}^{2}\|\tilde{\mathbf{f}}^*\|_{i,2-i,\infty} + \sum_{i=0}^{2}\Big\|\frac{\partial\mathbf{f}^*}{\partial t} + (\mathbf{w}\cdot\nabla)\mathbf{f}^*\Big\|_{i,2-i,1} + \|\mathbf{v}_0^*\|_4 + \|\mathbf{v}_1^*\|_3\Big).\end{aligned} \tag{49}$$

In conjuction with (44), this estimate can be used to show convergence of the iteration (47), and the solution then satisfies (33). Moreover, we shall show that the bound (49) also holds for

$$\sum_{i=0}^{4}\|\mathbf{v}^*\|_{i,4-i,\infty} + \sum_{i=0}^{2}\|q^*\|_{i,3-i,\infty}$$

in any subregion away from the outflow boundary. We can then use local elliptic estimates for (41) to get bounds on L^∞-type (in time) norms of $\hat{\mathbf{v}}$ and $\hat{q}$. Henceforth, we shall therefore consider (48) and aim to prove (49).

For the following, we need to introduce two functions $\alpha(x)$ and $\beta(x)$, which will be assumed to have the following properties for some positive value of ϵ:

$$\begin{aligned}&\alpha,\beta\in C^\infty([0,L];[0,1]),\quad \alpha(x)=1,\quad \beta(x)=0\quad\text{for}\quad x\in[L-\epsilon,L],\\ &\beta(x)=1,\quad \alpha(x)=0\quad\text{for}\quad x\in[0,\epsilon],\quad (1-\alpha)(1-\beta)=0.\end{aligned} \tag{50}$$

We now apply the operation $\frac{\partial}{\partial t} + (\alpha\mathbf{w}\cdot\nabla) + (\nabla(\alpha\mathbf{w}))^T$ to (48), and we introduce the new variable $\mathbf{u} = \mathbf{v}_t^* + \alpha(\mathbf{w}\cdot\nabla)\mathbf{v}^* - (\mathbf{v}^*\cdot\nabla)(\alpha\mathbf{w}) + \mathbf{v}^*\text{div }(\alpha\mathbf{w})$. The resulting equations are complicated, and we shall not write them out in full. However, we shall indicate their structure and emphasize the essential points. First, the left-hand side of (48) can be written in the form

$$\rho\big(\mathbf{u}_t + (2-\alpha)(\mathbf{w}\cdot\nabla)\mathbf{u} + (1-\alpha(2-\alpha))(\mathbf{w}\cdot\nabla)^2\mathbf{v}^* + \mathbf{h}_1(\mathbf{v}^*,\nabla\mathbf{v}^*,\mathbf{u})\big), \tag{51}$$

where we do not write out the form of the term $\mathbf{h}_1$; the essential point is that it does not involve second derivatives of $\mathbf{v}^*$ or any derivatives of $\mathbf{u}$. We use (51) and apply the operation $\frac{\partial}{\partial t} + \alpha(\mathbf{w}\cdot\nabla) + (\nabla(\alpha\mathbf{w}))^T$ to (48). Wherever we encounter a time derivative of $\mathbf{v}^*$, we reexpress it in terms of $\mathbf{u}$ and spatial derivatives of $\mathbf{v}^*$. Doing so, we find an equation of the form

$$\begin{aligned}\rho(\mathbf{u}_{tt} + 2(\mathbf{w}\cdot\nabla)\mathbf{u}_t + (\mathbf{w}\cdot\nabla)^2\mathbf{u}) &= \mu\Delta\mathbf{u} + \mathbf{T} : \partial^2\mathbf{u} - \nabla s\\ &\quad + \mathbf{h}_2(\mathbf{u},\mathbf{u}_t,\nabla\mathbf{u},\mathbf{v}^*,\nabla\mathbf{v}^*,\nabla^2\mathbf{v}^*,\mathbf{f}^*,\mathbf{f}_t^* + \alpha(\mathbf{w}\cdot\nabla)\mathbf{f}^*).\end{aligned} \tag{52}$$

Here $s = q_t^* + \alpha(\mathbf{w}\cdot\nabla)q^*$. Note that $\mathbf{u}$ has been defined in such a way that it is divergence free and vanishes on the boundary. Following similar ideas as above, we shall reduce our problem to showing that (52) has a unique solution satisfying an estimate of the form

(53)
$$\sum_{i=0}^{3} \|\mathbf{u}\|_{i,3-i,\infty} + \sum_{i=0}^{1} \|s\|_{i,2-i,\infty} \\ \le C \left(\sum_{i=0}^{1} \|\mathbf{h}_2\|_{i,1-i,\infty} + \sum_{i=0}^{1} \left\| \frac{\partial \mathbf{h}_2}{\partial t} + \beta(\mathbf{w}\cdot\nabla)\mathbf{h}_2 \right\|_{i,1-i,1} + \|\mathbf{u}_0\|_3 + \|\mathbf{u}_1\|_2 \right).$$

Here, as usual, $\mathbf{u}_0$ and $\mathbf{u}_1$ are the initial conditions for $\mathbf{u}$ and $\mathbf{u}_t$. In order to use (53) to solve (52) in an iterative fashion, we must, in an analogous fashion as above, replace $\mathbf{v}^*$ by a different quantity $\hat{\mathbf{v}}^*$. However, this step is now more complicated because we cannot simply use (48) to solve for $\mathbf{v}^*$ in terms of $\mathbf{u}$. This is because we lack a condition for $\mathbf{v}^*$ at the outflow boundary.

To construct $\hat{\mathbf{v}}^*$, we shall, of course, start with (48), which we can rewrite in the form

$$(54)\qquad \rho\big(\mathbf{u}_t + (2-\alpha)(\mathbf{w}\cdot\nabla)\mathbf{u} + (1-\alpha(2-\alpha))(\mathbf{w}\cdot\nabla)^2\mathbf{v}^* + \mathbf{h}_1(\mathbf{v}^*,\nabla\mathbf{v}^*,\mathbf{u})\big) \\ = \mu\Delta\mathbf{v}^* + \mathbf{T}:\partial^2\mathbf{v}^* - \nabla q^* + \mathbf{f}^*.$$

We have the inflow boundary condition $\mathbf{v}^* = \mathbf{0}$ but no outflow condition. To create an outflow condition, we consider (54) for $t = T'$. In addition, we consider (54) for $y = L$, and make the substitution

$$(55)\qquad \mathbf{v}_x^* = \frac{1}{w_1}(\mathbf{u} - \mathbf{v}_t^* - w_2\mathbf{v}_y^* + (\mathbf{v}^*\cdot\nabla)\mathbf{w}).$$

That is, the x-derivative of $\mathbf{v}^*$ has been expressed in terms of $\mathbf{u}$ and derivatives of $\mathbf{v}^*$ which are tangential to the (y,t)-plane. By differentiating (55), we can also reexpress the second derivative with respect to x.

For the pressure, we need to proceed in a slightly more complicated fashion. The reason is that (53) only provides estimates for spatial derivatives of s and not for the second time derivative of s. To circumvent this problem, let A be a positive definite self-adjoint operator in $L_p^2((0,L)\times\mathbb{R})$ which generates the interpolation scale of Sobolev spaces, i.e., the domain of A^n is $H_p^n((0,L)\times\mathbb{R})$. Let now r be the solution of

$$(56)\qquad r_t + Ar = s,\ r(0) = 0$$

and set $q^* = r + \phi$. Then ϕ satisfies the equation

$$(57)\qquad \phi_t + \alpha(\mathbf{w}\cdot\nabla)\phi = -\alpha(\mathbf{w}\cdot\nabla)r + Ar.$$

Moreover, we have the estimate

$$(58)\qquad \sum_{i=0}^{2} \|r\|_{i,3-i,2} \le C\sum_{i=0}^{1} \|s\|_{i,2-i,2}.$$

We now consider r as given in terms of s and introduce ϕ as a new variable. On the outflow boundary, we use the relationship

$$(59)\qquad \phi_x = \frac{1}{w_1}(Ar - (\mathbf{w}\cdot\nabla)r - \phi_t - w_2\phi_y)$$

to eliminate the derivative normal to the boundary. On the outflow boundary, we can therefore rewrite (54) into an equation in the (y,t)-plane which has the following form

$$\begin{aligned}\mu\Big(\mathbf{v}^*_{yy} + \frac{1}{w_1^2}(\mathbf{v}^*_{tt} + 2w_2\mathbf{v}^*_{yt} + w_2^2\mathbf{v}^*_{yy})\Big) + T_{yy}\mathbf{v}^*_{yy}\\ -\frac{2}{w_1}T_{xy}(\mathbf{v}^*_{yt} + w_2\mathbf{v}^*_{yy}) + \frac{1}{w_1^2}T_{xx}(\mathbf{v}^*_{tt} + 2w_2\mathbf{v}^*_{yt} + w_2^2\mathbf{v}^*_{yy})\\ + \frac{1}{w_1}(\phi_t - w_2\phi_y)\mathbf{e}_1 - \phi_y\mathbf{e}_2 = \mathbf{h}_3(\mathbf{u}, \mathbf{u}_t, \nabla\mathbf{u}, \mathbf{v}^*, \mathbf{v}^*_t, \nabla\mathbf{v}^*, Ar, \nabla r, \mathbf{f}^*).\end{aligned}\tag{60}$$

The divergence condition can be rewritten as

$$-\frac{1}{w_1}\left(\frac{\partial v_1^*}{\partial t} + w_2\frac{\partial v_1^*}{\partial y}\right) + \frac{\partial v_2^*}{\partial y} = -\frac{1}{w_1}(u_1 + (\mathbf{v}^*\cdot\nabla)w_1).\tag{61}$$

We now consider an elliptic boundary value problem which consists of (54) and the condition div $\mathbf{v}^* = 0$ on the set $\{T'\}\times(0,L)\times\mathbb{R}$, (60) and (61) on the set $(0,T')\times\{L\}\times\mathbb{R}$, the boundary condition $\mathbf{v}^* = \mathbf{0}$ on the set $\{T'\}\times\{0\}\times\mathbb{R}$, the boundary condition $\mathbf{v}^* = \mathbf{v}^*(L,y,0)$ (given in terms of the initial data) on the set $\{0\}\times\{L\}\times\mathbb{R}$, and interface conditions on the set $\{T'\}\times\{L\}\times\mathbb{R}$. These interface conditions are the continuity of $\mathbf{v}^*$ and ϕ and the equation

$$\mathbf{u} = \mathbf{v}^*_t + (\mathbf{w}\cdot\nabla)\mathbf{v}^* - (\mathbf{v}^*\cdot\nabla)\mathbf{w}.\tag{62}$$

It can be checked that the equations are elliptic and the boundary and interface conditions satisfy the complementing condition. We change $\mathbf{v}^*$ to $\hat{\mathbf{v}}^*$, add a finite-rank perturbation to ensure unique solvability, and solve for $\hat{\mathbf{v}}^*$. This yields an estimate of the form

$$\begin{aligned}\|\hat{\mathbf{v}}^*\|_{7/2} + \|\phi\|_{5/2} \le C(\|\mathbf{u}\|_{5/2} + \|\nabla\mathbf{u}\|_{3/2} + \|\mathbf{u}_t\|_{3/2}\\ + \|Ar\|_{3/2} + \|\nabla r\|_{3/2} + \|\mathbf{f}^*\|_{3/2} + \|\mathbf{v}^*(L,\cdot,0)\|_3).\end{aligned}\tag{63}$$

Here the Sobolev norms refer to the sets $\{T'\}\times(0,L)\times\mathbb{R}$ and $(0,T')\times\{L\}\times\mathbb{R}$.

We now choose $\hat{\mathbf{v}}^*$ at the outflow boundary to be the value just obtained and then obtain $\hat{\mathbf{v}}^*$ elsewhere by solving (54) with inflow and outflow conditions. Again we modify by a finite-rank operator if necessary. The $\hat{\mathbf{v}}^*$ thus obtained now replaces $\mathbf{v}^*$ in (52). Over the whole domain $(0,T')\times(0,L)\times\mathbb{R}$, we now have an estimate of the form

$$\sum_{i=0}^{2}\|\hat{\mathbf{v}}^*\|_{i,4-i,2} \le C\left(\sum_{i=0}^{3}\|\mathbf{u}\|_{i,3-i,2} + \sum_{i=0}^{1}\|s\|_{i,2-i,2} + \sum_{i=0}^{2}\|\mathbf{f}^*\|_{i,2-i,2} + \|\mathbf{v}^*(\cdot,\cdot,0)\|_{7/2}\right),\tag{64}$$

and this suffices to solve (52) iteratively. (In any region away from the outflow boundary, we can use local elliptic estimates to get bounds on norms of $\mathbf{v}^*$ and q^* which are L^∞ with respect to time.) The proof that the new problem is equivalent to the old one proceeds similarly as above; one integrates (52) (in which $\mathbf{v}^*$ has been replaced by $\hat{\mathbf{v}}^*$) along lines $d\mathbf{x}/dt = \alpha\mathbf{w}$, and from the result one can derive an elliptic equation for $\mathbf{v}^*$. By comparing this equation with that for $\hat{\mathbf{v}}^*$, one can derive an elliptic problem satisfied by the difference $\mathbf{v}^* - \hat{\mathbf{v}}^*$, which is of an analogous form as the one from which we obtained $\hat{\mathbf{v}}^*$ above. Then one uses a uniqueness argument.

We can now concentrate on solving (52) and establishing the estimate (53). We first take two more time derivatives, and we continue with the practice of expressing lower-order time derivatives by higher-order time derivatives in terms of elliptic boundary value problems. Denoting $\mathbf{u}_{tt} = \mathbf{g}$, $s_{tt} = \pi$, we end up having to solve a problem of the form

$$\rho(\mathbf{g}_{tt} + 2(\mathbf{w}\cdot\nabla)\mathbf{g}_t + (\mathbf{w}\cdot\nabla)^2\mathbf{g}) = \mu\Delta\mathbf{g} + \mathbf{T} : \partial^2\mathbf{g} - \nabla\pi + \tilde{\mathbf{h}}_t + \hat{\mathbf{h}}, \tag{65}$$

subject to the conditions that $\mathbf{g}$ is divergence free, vanishes on the boundary, and satisfies given initial conditions $\mathbf{g} = \mathbf{g}_0 \in H^1_p((0,L)\times\mathrm{I\!R})$, $\mathbf{g}_t = \mathbf{g}_1 \in L^2_p(\mathrm{I\!R})$. Compatibility between initial and boundary conditions still holds. We need to prove an estimate of the form

(66)
$$\|\mathbf{g}\|_{0,1,\infty} + \|\mathbf{g}\|_{1,0,\infty} \leq C(\|\mathbf{g}_0\|_1 + \|\mathbf{g}_1\|_0 + \|\tilde{\mathbf{h}}\|_{0,0,\infty} + \|\tilde{\mathbf{h}}_t + \beta(\mathbf{w}\cdot\nabla)\tilde{\mathbf{h}}\|_{0,0,1} + \|\hat{\mathbf{h}}\|_{0,0,1}).$$

We shall first derive a formal energy estimate for (65) and then show how this energy estimate can be used to show existence when used in conjunction with a Galerkin argument. To obtain an energy estimate, we multiply (65) by $\mathbf{z} := \mathbf{g}_t + \beta(\mathbf{w}\cdot\nabla)\mathbf{g} - (\mathbf{g}\cdot\nabla)(\beta\mathbf{w}) + \mathbf{g}\,\mathrm{div}\,(\beta\mathbf{w})$ and integrate over $(0,t)\times(0,L)\times(0,M)$. We shall use the notation

$$[\mathbf{a},\mathbf{b}](t) := \int_0^t\int_0^L\int_0^M \mathbf{a}(x,y,\tau)\cdot\mathbf{b}(x,y,\tau)\,dy\,dx\,d\tau. \tag{67}$$

For the various terms in (63), we find the following, after a number of integrations by parts:

$$\begin{aligned}
[\mathbf{g}_{tt},\mathbf{z}] &= \frac{1}{2}\frac{d}{dt}\int_0^L\int_0^M |\mathbf{g}_t(x,y,t)|^2\,dy\,dx \\
&+ \frac{d}{dt}\int_0^L\int_0^M (\beta(\mathbf{w}\cdot\nabla)\mathbf{g})\cdot\mathbf{g}_t(x,y,t)\,dy\,dx \\
&+ \frac{1}{2}[\mathrm{div}\,(\beta\mathbf{w})\mathbf{g}_t,\mathbf{g}_t] - [\beta(\mathbf{w}_t\cdot\nabla)\mathbf{g},\mathbf{g}_t] \\
&- \frac{d}{dt}\int_0^L\int_0^M [(\mathbf{g}\cdot\nabla)(\beta\mathbf{w})]\cdot\mathbf{g}_t(x,y,t)\,dy\,dx \\
&+ [(\mathbf{g}_t\cdot\nabla)(\beta\mathbf{w}),\mathbf{g}_t] + [(\mathbf{g}\cdot\nabla)(\beta\mathbf{w}_t),\mathbf{g}_t] \\
&+ \frac{d}{dt}\int_0^L\int_0^M \mathrm{div}\,(\beta\mathbf{w})\mathbf{g}\cdot\mathbf{g}_t(x,y,t)\,dy\,dx \\
&- [\mathrm{div}\,(\beta\mathbf{w})\mathbf{g}_t,\mathbf{g}_t] - [\mathrm{div}\,(\beta\mathbf{w}_t)\mathbf{g},\mathbf{g}_t].
\end{aligned} \tag{68}$$

$$
\begin{aligned}
[(\mathbf{w}\cdot\nabla)\mathbf{g}_t,\mathbf{z}] = {} & \frac{1}{2}\frac{d}{dt}\int_0^L\int_0^M \beta|(\mathbf{w}\cdot\nabla)\mathbf{g}|^2(x,y,t)\,dy\,dx \\
& -[\beta(\mathbf{w}_t\cdot\nabla)\mathbf{g},(\mathbf{w}\cdot\nabla)\mathbf{g}] \\
& -\frac{d}{dt}\int_0^L\int_0^M((\mathbf{g}\cdot\nabla))(\beta\mathbf{w})\cdot((\mathbf{w}\cdot\nabla)\mathbf{g})\,dy\,dx \\
& +[(\mathbf{g}_t\cdot\nabla)(\beta\mathbf{w}),(\mathbf{w}\cdot\nabla)\mathbf{g}]+[(\mathbf{g}\cdot\nabla)(\beta\mathbf{w}_t),(\mathbf{w}\cdot\nabla)\mathbf{g}] \\
& +[(\mathbf{g}\cdot\nabla)\beta\mathbf{w},(\mathbf{w}_t\cdot\nabla)\mathbf{g}] \\
& +\frac{d}{dt}\int_0^L\int_0^M \operatorname{div}\,(\beta\mathbf{w})(\mathbf{g}\cdot(\mathbf{w}\cdot\nabla)\mathbf{g})(x,y,t)\,dy\,dx \\
& -[\operatorname{div}\,(\beta\mathbf{w}_t)\mathbf{g},(\mathbf{w}\cdot\nabla)\mathbf{g}]-[\operatorname{div}\,(\beta\mathbf{w})\mathbf{g}_t,(\mathbf{w}\cdot\nabla)\mathbf{g}] \\
& -[\operatorname{div}\,(\beta\mathbf{w})\mathbf{g},(\mathbf{w}_t\cdot\nabla)\mathbf{g}].
\end{aligned}
\tag{69}
$$

$$
[\nabla\pi,\mathbf{z}]=0. \tag{70}
$$

(71)

$$
\begin{aligned}
[\tilde{\mathbf{h}}_t,\mathbf{z}] = {} & [\tilde{\mathbf{h}}_t+\beta(\mathbf{w}\cdot\nabla)\tilde{\mathbf{h}},\mathbf{g}_t]-[\tilde{\mathbf{h}},\beta(\mathbf{w}_t\cdot\nabla)\mathbf{g}+\mathbf{g}\operatorname{div}\,(\beta\mathbf{w}_t)] \\
& +\frac{d}{dt}\int_0^L\int_0^M \tilde{\mathbf{h}}\cdot(\beta(\mathbf{w}\cdot\nabla)\mathbf{g}-(\mathbf{g}\cdot\nabla)(\beta\mathbf{w})+\mathbf{g}\operatorname{div}\,(\beta\mathbf{w}))(x,y,t)\,dy\,dx \\
& +[\tilde{\mathbf{h}},(\mathbf{g}_t\cdot\nabla)(\beta\mathbf{w})+(\mathbf{g}\cdot\nabla)(\beta\mathbf{w}_t)].
\end{aligned}
$$

To deal with the remaining terms, we use the notation

$$
\mathbf{A}=\mu+\mathbf{T}-\rho\mathbf{w}\mathbf{w}^T. \tag{72}
$$

Since the expression for $[\mathbf{A}:\partial^2\mathbf{g},\mathbf{z}]$ is somewhat lengthy, we list it in several parts. We find

(73)

$$
\begin{aligned}
[\mathbf{A}:\partial^2\mathbf{g},\mathbf{g}_t] = {} & -\frac{1}{2}\frac{d}{dt}\int_0^L\int_0^M \operatorname{tr}((\nabla\mathbf{g})\mathbf{A}(\nabla\mathbf{g})^T)\,dy\,dx \\
& +\frac{1}{2}\int_0^t\int_0^L\int_0^M \operatorname{tr}((\nabla\mathbf{g})\mathbf{A}_t(\nabla\mathbf{g})^T)\,dy\,dx\,d\tau-[((\operatorname{div}\,\mathbf{A})\cdot\nabla)\mathbf{g},\mathbf{g}_t],
\end{aligned}
$$

$$
\begin{aligned}
& [\mathbf{A}:\partial^2\mathbf{g},-(\mathbf{g}\cdot\nabla)(\beta\mathbf{w})+\mathbf{g}\operatorname{div}\,(\beta\mathbf{w})]= \\
& \qquad -[((\operatorname{div}\,\mathbf{A})\cdot\nabla)\mathbf{g},-(\mathbf{g}\cdot\nabla)(\beta\mathbf{w})+\mathbf{g}\operatorname{div}\,(\beta\mathbf{w})] \\
& \qquad -\int_0^t\int_0^L\int_0^M \operatorname{tr}[(\nabla\mathbf{g})\mathbf{A}\nabla(-(\mathbf{g}\cdot\nabla)(\beta\mathbf{w})+\mathbf{g}\operatorname{div}\,(\beta\mathbf{w}))^T]\,dy\,dx\,d\tau,
\end{aligned}
\tag{74}
$$

Finally, we consider the term

$$
[\mathbf{A}:\partial^2\mathbf{g},\beta(\mathbf{w}\cdot\nabla)\mathbf{g}]=-[\beta(\mathbf{w}\cdot\nabla)(\mathbf{A}:\partial^2\mathbf{g}),\mathbf{g}]-[\mathbf{A}:\partial^2\mathbf{g},\operatorname{div}\,(\beta\mathbf{w})\mathbf{g}]. \tag{75}
$$

In the second term, we integrate by parts again to find

$$
\begin{aligned}
[\mathbf{A}:\partial^2\mathbf{g},\operatorname{div}\,(\beta\mathbf{w})\mathbf{g}] = {} & -\sum_{i,j}\left[A_{ij}\frac{\partial\mathbf{g}}{\partial x_j},\frac{\partial}{\partial x_i}(\operatorname{div}\,(\beta\mathbf{w})\mathbf{g})\right] \\
& -\sum_{i,j}\left[\frac{\partial A_{ij}}{\partial x_i}\frac{\partial\mathbf{g}}{\partial x_j},\operatorname{div}\,(\beta\mathbf{w})\mathbf{g}\right].
\end{aligned}
\tag{76}
$$

For the first term, integration by parts yields

$$(77)\quad \begin{aligned}-[\beta(\mathbf{w}\cdot\nabla)(\mathbf{A}:\partial^2\mathbf{g}),\mathbf{g}] &= \sum_{i,j}\left[\beta(\mathbf{w}\cdot\nabla)(A_{ij}\frac{\partial\mathbf{g}}{\partial x_j}),\frac{\partial\mathbf{g}}{\partial x_i}\right]\\ &\quad+\sum_{i,j}\left[\left(\frac{\partial(\beta\mathbf{w})}{\partial x_i}\cdot\nabla\right)\left(A_{ij}\frac{\partial\mathbf{g}}{\partial x_j}\right),\mathbf{g}\right]+\left[\beta(\mathbf{w}\cdot\nabla)\left(\frac{\partial A_{ij}}{\partial x_i}\frac{\partial\mathbf{g}}{\partial x_j}\right),\mathbf{g}\right].\end{aligned}$$

In the last two terms, we can do further integrations by parts to obtain expressions which are quadratic in the first derivatives of $\mathbf{g}$. For the first term on the right of (77), we note that

$$(78)\quad \frac{1}{2}\sum_{i,j}\beta(\mathbf{w}\cdot\nabla)\left(A_{ij}\frac{\partial\mathbf{g}}{\partial x_i}\cdot\frac{\partial\mathbf{g}}{\partial x_j}\right)=\sum_{i,j}\beta(\mathbf{w}\cdot\nabla)\left(A_{ij}\frac{\partial\mathbf{g}}{\partial x_j}\right)\cdot\frac{\partial\mathbf{g}}{\partial x_i}-\frac{1}{2}\frac{\partial\mathbf{g}}{\partial x_i}\cdot\frac{\partial\mathbf{g}}{\partial x_j}\beta(\mathbf{w}\cdot\nabla)A_{ij}.$$

From integrating (78), we therefore obtain an integral of

$$(79)\qquad \frac{1}{2}\sum_{i,j}\beta(\mathbf{w}\cdot\mathbf{n})A_{ij}\frac{\partial\mathbf{g}}{\partial x_i}\frac{\partial\mathbf{g}}{\partial x_j}$$

over the boundary. Since $\beta = 0$ on the outflow boundary, only the inflow boundary makes a contribution, and this contribution is negative.

From the formal energy estimate, we can easily derive a bound of the form (66). However, in deriving the energy estimate, we have of course done manipulations which are not justified by the regularity we expect of the solution. To make the argument rigorous, we use a Galerkin approximation. For technical reasons, we split (65) into two problems, one where the forcing term in the equation is as given and the initial data are zero and another where the forcing term is zero and the initial data are given. Obviously, the solution of (65) is then obtained by adding the solutions of the two subproblems. Let us first deal with the problem for zero initial data. We define a space

$$(80)\qquad X=\{\mathbf{g}\in H^1_p((0,L)\times\mathbb{R})\mid \operatorname{div}\mathbf{g}=0,\ \mathbf{g}(0,\cdot)=\mathbf{g}(L,\cdot)=\mathbf{0}\}.$$

Let ϕ^n, $n\in\mathbb{N}$, be a basis for X, i.e., a linearly independent set with a dense linear span. We can take the ϕ_n such that they vanish in a neighborhood of the boundary and are of class C^∞. We now seek Galerkin approximations such that

$$(81)\qquad \mathbf{g}^N_t+\beta(\mathbf{w}\cdot\nabla)\mathbf{g}_N-(\mathbf{g}^N\cdot\nabla)\mathbf{w}+\mathbf{g}^N\operatorname{div}(\beta\mathbf{w})=\sum_{i=1}^N c_i(t)\phi^i(x,y),$$

and $\mathbf{g}^N$ is determined from integrating (81) subject to zero initial and inflow conditions. We require the equation

$$(82)\qquad (\rho(\mathbf{g}^N_{tt}+2(\mathbf{w}\cdot\nabla)\mathbf{g}^N_t+(\mathbf{w}\cdot\nabla)^2\mathbf{g}^N)-\mu\Delta\mathbf{g}^N-\mathbf{T}:\partial^2\mathbf{g}^N-\tilde{\mathbf{h}}_t-\hat{\mathbf{h}},\phi^i)=0$$

to hold for every $i=1,\dots,N$. Here $(\cdot,\cdot)$ is the inner product in $L^2_p((0,L)\times\mathbb{R})$. The initial conditions are zero. For any fixed N, equation (82) is a system of Volterra integrodifferential equations which can be solved. By choosing the test function

$$(83)\qquad \mathbf{z}^N=\sum_{i=1}^N c_i(t)\phi^i(x,y),$$

one can repeat the energy estimates above (now there is sufficient regularity to justify the manipulations) and obtain uniform bounds for the approximate solutions $\mathbf{g}^N$. As usual, one can then extract a weakly-$*$ convergent subsequence, the limit of which yields the solution we seek.

For zero forcing terms and nonzero initial data, we need to do much less fancy footwork. We can obtain a much simpler energy estimate than above by simply multiplying (65) by $\mathbf{g}_t$. A standard Galerkin argument (along the lines of §8.2 in Chapter 3 of [1]) can then be used for a rigorous justification.

A GEOMETRIC INTERPRETATION OF THE HEAT EQUATION WITH MULTIVALUED INITIAL DATA*

LAWRENCE C. EVANS†

Abstract. We utilize the level-set method to interpret geometrically what it means to solve the heat equation with multivalued initial data. We prove that in one space dimension, the limits of "geometrically natural" approximations instantly unfold multivalued initial data, according to an equal-area rule. In higher dimensions, the limits of certain "analytically natural" approximations display similar effects.

Key words. heat equation, level-set method, viscosity solutions

AMS subject classification. 35K05

1. Introduction.

A formal analysis of Burgers' equation,

$$u_t + uu_x = 0 \quad \text{in } \mathbb{R} \times (0, \infty), \tag{1.1}$$

obtained by tracking classical characteristics, suggests that a solution will in general become multivalued after a time. If, for instance, the initial data represent a mass of fluid centered at the origin, the solution u corresponds to a wave whose velocity at each point equals its height. As the higher parts of the wave consequently move faster than the lower, the wave will later "break" and "fold over." It is customary to reject such multivaluedness on physical grounds (cf. Whitham [25]) by accepting as true solutions u of (1.1) only those arising as limits when $\varepsilon \to 0^+$ of solutions u^ε to the "viscous" approximations

$$u_t^\varepsilon + u^\varepsilon u_x^\varepsilon = \varepsilon u_{xx}^\varepsilon \quad \text{in } \mathbb{R} \times (0, \infty). \tag{1.2}$$

The term $\varepsilon u_{xx}^\varepsilon$ forces the approximate solutions u^ε to remain smooth, and so any limit u is single valued, although in general discontinuous in regions of shock formation. If we imagine $\varepsilon > 0$ as fixed and think of the nonlinear term in (1.2) as a lower-order perturbation, the function u^ε is well behaved since the linear heat equation (a) smooths irregular initial data and, in particular, (b) keeps solutions from becoming multivalued.

This paper provides a further analysis and geometric interpretation of the effect (b) for the linear heat equation. We will show that a solution of the heat equation is single valued at times $t > 0$, even if the initial function is multivalued, with a graph that admits folds, complicated topology, etc. Otherwise stated, we assert that property (b) is so pronounced that not only will single-valued initial data remain so, but also multivalued data will instantly become single valued under the heat evolution.

Making sense of this claim requires that we first of all devise a way to solve the heat equation with multivalued starting data. This problem we will approach using the so-called "level-set method." The idea is to think of $\mathbb{R}^n \times (0, \infty)$ as being completely filled up with hypersurfaces, each of which represents a solution to the heat equation on $\mathbb{R}^{n-1} \times (0, \infty)$. We then regard these surfaces as being the level sets of a function $v : \mathbb{R}^n \times [0, \infty) \to \mathbb{R}$ and write down a nonlinear partial differential equation (PDE) that v verifies. We next attempt to analyze this nonlinear PDE rigorously and,

† Department of Mathematics, University of California at Berkeley, Berkeley, CA 94720.

in particular, to prove that various approximate solutions v^ε converge to a limit v. We can then regard the various level sets of v as determining solutions of the heat equation, even starting from possibly multivalued initial data.

The formal calculations are as follows. Think of $v : \mathbb{R}^n \times [0,\infty) \to \mathbb{R}$ as a smooth function each of whose level sets, thought of as graphs in the x_n-direction, solve the heat equation. Suppose a portion of some such level set is—locally, at least—represented by the smooth graph

$$x_n = u(x',t) \qquad (t \geq 0, \ \ x' \in \mathbb{R}^{n-1}). \tag{1.3}$$

Then

$$v(x', u(x',t), t)$$

is constant in the variables $x' \in \mathbb{R}^{n-1}$ and $t \geq 0$. Differentiating, we deduce

$$v_{x_n} u_t + v_t = 0, \tag{1.4}$$

$$v_{x_i} + v_{x_n} u_{x_i} = 0 \qquad (1 \leq i \leq n-1), \tag{1.5}$$

$$\Delta' v + 2\sum_{i=1}^{n-1} v_{x_i x_n} u_{x_i} + v_{x_n x_n}|D'u|^2 + v_{x_n}\Delta' u = 0, \tag{1.6}$$

where $D' = (\frac{\partial}{\partial x_1}, \ldots, \frac{\partial}{\partial x_{n-1}})$ and $\Delta' = \sum_{i=1}^{n-1} \frac{\partial^2}{\partial x_i^2}$ denote, respectively, the gradient and the Laplacian in the x'-variables, $x' = (x_1, \ldots, x_{n-1})$. Assuming that $v_{x_n} \neq 0$ and that u solves the heat equation

$$u_t = \Delta' u \qquad \text{in } \mathbb{R}^{n-1} \times (0,\infty),$$

we can simplify (1.6), using (1.4) and (1.5) to conclude

$$v_t = \Delta' v - \frac{2v_{x_i}}{v_{x_n}} v_{x_i x_n} + \frac{|D'v|^2}{v_{x_n}^2} v_{x_n x_n} \tag{1.7}$$

along the given level set of v, the implicit summation being for $i = 1$ to $n-1$. We now suppose that each level set of v represents the graph of a solution of the heat equation. The nonlinear PDE (1.7) then holds—formally, at least—everywhere in $\mathbb{R}^n \times (0,\infty)$.

Let us refer to (1.7) as the *level-surface heat equation.* Observe that (1.7) is degenerate parabolic and is undefined wherever $v_{x_n} = 0$.

Our plan hereafter is to study the initial value problem for the PDE (1.7) and to try to understand the behavior in time of the level sets of solutions; we informally regard these as defining the generalized heat flow. We will therefore be particularly interested in a "geometric" interpretation of the level surface heat equation, as this viewpoint will suggest natural approximation schemes.

This paper is structured so that §§2 and 3 recall the general theory of weak (that is, viscosity) solutions of "geometric" parabolic PDEs, following Chen, Giga, and Goto [8]. In §§4–6, we focus our attention on the case $n = 2$ and study the motion of the approximating level curves in the limit as $\varepsilon \to 0$. We prove in §5 that these curves rapidly unfold to become graphs. This assertion allows us to interpret the level-surface heat equation as "instantly unfolding" multivalued initial data, although the precise nature of this transformation remains unclear in general. We do, however, manage in §6 to show rigorously that in certain circumstances this process follows an equal-area construction.

The behavior of the level sets in the general case ($n \geq 3$) appears much more complicated. We are, in particular, unable to analyze carefully the asymptotic behavior of the level sets of the geometrically natural approximations (4.3_ε), and we propose instead in §7 to analyze certain analytically natural approximations (cf. (7.4_ε)). We prove that in the limit as $\varepsilon \to 0$, the level sets again become graphs. Further work is indicated here, as the limiting behavior of the level solution presumably entails some kind of interesting higher-dimensional analogue of the equal-area construction.

The key point of §§4–7 is the identification in the PDE (1.7) and in the approximations (2.5_ε) and (7.4_ε) of geometric and/or analytic mechanisms that force the instantaneous unfolding of level sets.

The general technique of studying nonlinear PDEs whose level sets evolve according to various geometric laws has in recent years proved extremely fruitful; see Osher and Sethian [23] for numerics and Chen, Giga, and Goto [8], Evans and Spruck [9]–[12], Soner [24], etc., for theory. The guiding insight for this paper, that the level-set method is also useful for other, nongeometric PDEs, is, in fact, very old: Caratheodory in his book [7, §49] describes a related method of Jacobi for investigating Hamilton–Jacobi PDEs. Recently, S. Osher has revived the technique in [22] within the context of image processing. His work is inspired by the paper by Bruckstein and Kimmel [5], and this paper is inspired by his. We hope also that the following study will be relevant in an investigation of a PDE/viscosity-solution approach to crystalline curvature motion, a la J. Taylor (cf. Cahn, Handwerker, and Taylor [6] and the references therein). The formal PDEs describing crystalline curvature motion involve various strong singularities, and the hope is that the level sets of solutions to smoother, approximating PDEs will in the limit instantly develop faces, evolving thereafter according to certain ordinary differential equations (ODE). This conjectured effect is presumably some kind of more complicated variant of the instant unfolding established here.

2. The level-surface heat equation: Geometrically natural approximations.

We commence our study of the initial value problem for the level-surface heat equation

$$(2.1)\qquad \begin{cases} v_t = \Delta' v - \frac{2v_{x_i}}{v_{x_n}} v_{x_i x_n} + \frac{|D'v|^2}{v_{x_n}^2} v_{x_n x_n} & \text{in } \mathbb{R}^n \times (0,\infty), \\ v = g & \text{in } \mathbb{R}^n \times \{t=0\} \end{cases}$$

by first noting that the PDE is of the general form

$$(2.2)\qquad v_t = F(D^2 v, Dv)$$

for F defined by

$$(2.3)\qquad F(R,p) = p_n^{-2}\left(p_n^2 \sum_{i=1}^{n-1} r_{ii} - 2\sum_{i=1}^{n-1} p_i p_n r_{in} + |p'|^2 r_{nn}\right),$$

where $R = ((r_{ij})) \in M^{n\times n}$, the space of $n \times n$ real matrices, and $p = (p', p_n) \in \mathbb{R}^n$, $p' = (p_1, \ldots, p_{n-1}) \in \mathbb{R}^{n-1}$, $p_n \neq 0$. The nonlinear term satisfies the structural identity

$$(2.4)\qquad F(\lambda R + \mu(p \otimes p), \lambda p) = \lambda F(R,p)$$

for all $\lambda, \mu \in \mathbb{R}$, $R \in M^{n\times n}$, $p \in \mathbb{R}^n$ with $p_n \neq 0$. The level surface heat equation is consequently "geometric" in the terminology of Chen, Giga, and Goto [8]. This means that the evolution in time of each level set of v depends only upon the geometry of that set and is unaffected by the behavior of neighboring level sets of v. (In studying parametric—that is, "geometric"—integrals in the calculus of variations, it is often useful to study associated nonparametric integrals, as, for instance, in Federer [13, §5.1.9]. Here we are in some sense reversing the customary procedure by transforming the (nongeometric) heat equation into the (geometric) level-surface heat equation.)

Although our PDE (2.1) verifies (2.4), it nevertheless does not fall within the scope of Chen, Giga, and Goto [8] since the nonlinear term is singular along the plane $\{p_n = 0\}$. Ishii [17] has recently extended the general theory to allow for singularities on such a set, but the level-set heat equation again fails to be covered because the coefficients $p_i p_n^{-1}$ and $|p'|^2 p_n^{-2}$ are unbounded near $\{p_n = 0\}$. See also Ohnuma and Sato [20]. We are, in fact, not able to devise a satisfactory notion of weak solution for (2.1). We will see, however, that this is not really the key issue: the point is that limits of solutions to approximating PDE evolve so that the level sets become graphs in the x_n-direction. The strong singularity, which precludes any invocation of [8], [17], or [20], forces this simplified behavior of the level sets.

It is therefore appropriate now to turn our attention to a well-behaved approximation scheme which is "geometrically natural."

Let us fix $\varepsilon > 0$ and consider instead of (2.1) the problem

$$(2.5_\varepsilon) \qquad \begin{cases} v_t^\varepsilon = \frac{(v_{x_n}^\varepsilon)^2 \Delta' v^\varepsilon - 2 v_{x_i}^\varepsilon v_{x_n}^\varepsilon v_{x_i x_n}^\varepsilon + |D' v^\varepsilon|^2 v_{x_n x_n}^\varepsilon}{(v_{x_n}^\varepsilon)^2 + \varepsilon^2 |D' v^\varepsilon|^2} & \text{in } \mathbb{R}^n \times (0,\infty), \\ v^\varepsilon = g & \text{on } \mathbb{R}^n \times \{t=0\}. \end{cases}$$

The PDE (2.5_ε) has the structure

$$v_t^\varepsilon = F^\varepsilon(D^2 v^\varepsilon, D v^\varepsilon)$$

for

$$F^\varepsilon(R,p) = (p_n^2 + \varepsilon^2 |p'|^2)^{-1} \left(p_n^2 \sum_{i=1}^{n-1} r_{ii} - 2 \sum_{i=1}^{n-1} p_i p_n r_{in} + |p'|^2 r_{nn} \right),$$

where $R = ((r_{ij})) \in M^{n \times n}$, $p = (p', p_n) \in \mathbb{R}^n$, $p \neq 0$. A computation verifies the identity

$$F^\varepsilon(\lambda R + \mu(p \otimes p), \lambda p) = \lambda F^\varepsilon(R,p) \qquad (\mu, \lambda \in \mathbb{R}, \ p \neq 0),$$

and so (2.5_ε) is geometric. And although the nonlinearity F^ε is not defined at $\{p = 0\}$, it, unlike F, is bounded on compact subsets of $M^{n \times n} \times (\mathbb{R}^n - \{0\})$. In particular, (2.5_ε) is included in the existence and uniqueness theory of Chen, Giga, and Goto [8]. We recall the relevant definitions.

DEFINITION 2.1. *A bounded, uniformly continuous function v^ε is a* weak subsolution (supersolution) *of (2.5_ε) provided that for each smooth $\phi \in C^\infty(\mathbb{R}^n \times (0,\infty))$ such that*

$$(2.6) \qquad \begin{aligned} &v^\varepsilon - \phi \textit{ attains a local maximum (minimum)} \\ &\textit{at a point } (x_0, t_0) \in \mathbb{R}^n \times (0,\infty), \end{aligned}$$

(a) *if*

$$(2.7) \qquad D\phi(x_0, t_0) \neq 0,$$

then

$$(2.8) \quad \phi_t - (\phi_{x_n}^2 + \varepsilon^2 |D'\phi|^2)^{-1} (\phi_{x_n}^2 \Delta' \phi - 2 \phi_{x_i} \phi_{x_n} \phi_{x_i x_n} + |D'\phi|^2 \phi_{x_n x_n}) \leq 0 \ \ (\geq 0)$$

at the point (x_0, t_0); and

(b) *if*

$$D\phi(x_0,t_0)=0, \qquad D^2\phi(x_0,t_0)=0, \tag{2.9}$$

then

$$\phi_t \le 0 \quad (\ge 0) \tag{2.10}$$

at the point (x_0,t_0).

DEFINITION 2.2. *We call* v^ε *a* weak solution *if* v^ε *is both a weak subsolution and supersolution.*

Observe that there is no requirement if

$$D\phi(x_0,t_0)=0, \qquad D^2\phi(x_0,t_0)\neq 0. \tag{2.11}$$

Let us now suppose $g:\mathbb{R}^n\to\mathbb{R}$ is smooth, $\sup_{\mathbb{R}^n}|g|$, $|Dg|<\infty$, and for some $R>0$,

$$\begin{cases} D'g=0 & \text{if } |x'|\ge R \text{ or } |x_n|\ge R, \\ g_{x_n}>0 & \text{if } |x_n|\le R,\ |x'|\ge R, \\ g_{x_n}=0 & \text{if } |x_n|\ge R. \end{cases} \tag{2.12}$$

In particular, the level sets of g are flat graphs in $\{|x_n|\ge R\}$ and $\{|x'|\ge R\}$.

THEOREM 2.3 (existence of approximate solutions).

(i) *For each* $\varepsilon>0$, *there exists a unique weak solution of* (2.5_ε).

(ii) *In addition,* v^ε *is Lipschitz continuous, with the bounds*

$$\sup_{\mathbb{R}^n\times(0,\infty)}|Dv^\varepsilon| \le \sup_{\mathbb{R}^n}|Dg|, \tag{2.13}$$

$$\sup_{\mathbb{R}^n\times(0,\infty)}|v^\varepsilon_t| \le \frac{C}{\varepsilon^2}\sup_{\mathbb{R}^n}|D^2g|. \tag{2.14}$$

(iii) *Furthermore, the mapping* $g\mapsto v^\varepsilon(\cdot\ ,t)$ *is a contraction in* $L^\infty(\mathbb{R}^n)$.

Proof. For $\delta>0$, we further approximate by the PDE

$$\begin{cases} v^{\varepsilon,\delta}_t = ((v^{\varepsilon,\delta}_{x_n})^2+\varepsilon^2|D'v^{\varepsilon,\delta}|^2+\delta)^{-1}((v^{\varepsilon,\delta}_{x_n})^2\Delta' v^{\varepsilon,\delta} - 2v^{\varepsilon,\delta}_{x_i}v^{\varepsilon,\delta}_{x_n}v^{\varepsilon,\delta}_{x_ix_n} \\ \qquad\qquad + |D'v^{\varepsilon,\delta}|^2 v^{\varepsilon,\delta}_{x_nx_n}) + \delta\Delta v^{\varepsilon,\delta} \quad \text{in } \mathbb{R}^n\times(0,\infty), \\ v^{\varepsilon,\delta}=g \qquad \text{on } \mathbb{R}^n\times\{t=0\}. \end{cases} \tag{$2.15_{\delta,\varepsilon}$}$$

This equation has the form

$$v^{\varepsilon,\delta}_t = a^{\varepsilon,\delta}_{ij}(Dv^{\delta,\varepsilon})v^{\varepsilon,\delta}_{x_ix_j} \qquad \text{in } \mathbb{R}^n\times(0,\infty), \tag{2.16}$$

the implicit summation in (2.16) being for $1\le i,j\le n$. The coefficients $a^{\varepsilon,\delta}_{ij}$ are smooth, bounded, and uniformly elliptic, and consequently the quasi-linear PDE (2.15) has a unique, smooth, bounded solution (cf. Ladyzhenskaya, Solonnikov, and Ural'ceva [18]).

Differentiating $(2.15_{\delta,\varepsilon})$ in the unit direction ξ, we find

$$v^{\varepsilon,\delta}_{\xi t} = a^{\varepsilon,\delta}_{ij}v^{\varepsilon,\delta}_{\xi x_ix_j} + a^{\varepsilon,\delta}_{ij,p_l}v^{\varepsilon,\delta}_{x_ix_j}v^{\varepsilon,\delta}_{\xi x_l}.$$

The maximum principle therefore implies that $v_\xi^{\varepsilon,\delta}$ attains its maximum at $t = 0$; whence

$$\sup_{\substack{0<\varepsilon,\delta\leq 1\\ \mathbb{R}^n\times(0,\infty)}} |Dv^{\varepsilon,\delta}| = \sup_{\substack{0<\varepsilon,\delta\leq 1\\ \mathbb{R}^n}} |Dv^{\varepsilon,\delta}|\,|_{t=0} = \sup_{\mathbb{R}^n} |Dg|, \tag{2.17}$$

$$\sup_{\substack{0<\delta\leq 1\\ \mathbb{R}^n\times(0,\infty)}} |v_t^{\varepsilon,\delta}| = \sup_{\substack{0<\delta\leq 1\\ \mathbb{R}^n}} |v_t^{\varepsilon,\delta}|\,|_{t=0} \leq \frac{C}{\varepsilon^2}\sup_{\mathbb{R}^n} |D^2 g|. \tag{2.18}$$

Owing to the bounds (2.17) and (2.18), there exists a sequence $\delta_j \to 0$ and a Lipschitz function v^ε such that

$$v^{\varepsilon,\delta_j} \longrightarrow v^\varepsilon \quad \text{locally uniformly in } \mathbb{R}^n \times [0,\infty). \tag{2.19}$$

Routine viscosity-solution arguments (cf. [8], [9]) prove v^ε to be a weak solution of (2.5_ε). Estimates (2.13) and (2.14) follow from (2.17) and (2.18). The uniqueness of the weak solution follows from Chen, Giga, and Goto [8], as does the contraction assertion (iii). □

We next derive a bound on v_t^ε which does not depend on $\varepsilon > 0$. This will later be useful in investigating the instantaneous unfolding of level sets.

LEMMA 2.4. *For each compact set $K \subset \mathbb{R}^n$, there exists a constant $C = C(K)$ such that*

$$\operatorname*{ess\,sup}_{\substack{0<\varepsilon\leq 1\\ x\in K}} |v_t^\varepsilon(x,t)| \leq C\left(1+\frac{1}{t}\right) \tag{2.20}$$

for a.e. $t > 0$.

Proof. 1. We will employ a scaling argument. For each $\lambda > 1$, set

$$w(x,t) = w^{\varepsilon,\lambda}(x,t) = v^\varepsilon(\lambda x, \lambda^2 t) \qquad (x \in \mathbb{R}^n, \quad t > 0). \tag{2.21}$$

2. We assert the following:

$$w_t = (w_{x_n}^2 + \varepsilon^2|D'w|^2)^{-1}(w_{x_n}^2\Delta' w - 2w_{x_i}w_{x_n}w_{x_ix_n} + |D'w|^2 w_{x_nx_n}) \tag{2.22}$$

in $R^n \times (0,\infty)$ in the weak sense. To verify this claim, let us suppose that $\phi \in C^\infty(\mathbb{R}^n \times (0,\infty))$ is given and $w - \phi$ has a local maximum at a point $(x_0,t_0) \in \mathbb{R}^n \times (0,\infty)$ with $D\phi(x_0,t_0) \neq 0$. Define

$$\psi(x,t) = \phi(\lambda^{-1}x, \lambda^{-2}t). \tag{2.23}$$

Then $v^\varepsilon - \psi$ has a local maximum at the point $(x_\lambda, t_\lambda) = (\lambda x_0, \lambda^2 t_0)$. Now

$$\begin{cases} \psi_t(x_\lambda,t_\lambda) = \lambda^{-2}\phi_t(x_0,t_0), \\ D\psi(x_\lambda,t_\lambda) = \lambda^{-1}D\phi(x_0,t_0), \\ D^2\psi(x_\lambda,t_\lambda) = \lambda^{-2}D^2\phi(x_0,t_0), \end{cases} \tag{2.24}$$

and consequently $D\psi(x_\lambda,t_\lambda) \neq 0$. Because v^ε is a weak solution of (2.5_ε), we have

$$\psi_t \leq (\psi_{x_n}^2 + \varepsilon^2|D'\psi|^2)^{-1}(\psi_{x_n}^2\Delta'\psi - 2\psi_{x_i}\psi_{x_n}\psi_{x_ix_n} + |D'\psi|^2\psi_{x_nx_n}) \leq 0$$

at (x_λ, t_λ). Employing (2.24), we therefore deduce

$$\phi_t \leq (\phi_{x_n}^2 + \varepsilon^2|D'\phi|^2)^{-1}(\phi_{x_n}^2\Delta'\phi - 2\phi_{x_i}\phi_{x_n}\phi_{x_ix_n} + |D'\phi|^2\phi_{x_nx_n}) \leq 0$$

at (x_0, t_0). We similarly deduce $\phi_t \le 0$ at (x_0, t_0) if $D\phi(x_0, t_0) = D^2\phi(x_0, t_0) = 0$. The opposite inequalities obtain should $w - \phi$ have a local minimum at (x_0, t_0). The claim (2.22) is proved.

3. In view of the contraction property for solutions of (2.5_ε) (Theorem 2.3(iii)), we have for each $x_0 \in \mathbb{R}^n$, $t_0 > 0$ that

$$|w^{\varepsilon,\lambda}(x_0, t_0) - v^\varepsilon(x, t_0)| \le \|g^\lambda - g\|_{L^\infty(\mathbb{R}^n)},$$

where $g^\lambda(x) = g(\lambda x)$, $x \in \mathbb{R}^n$. Consequently, taking $x_0 = 0$ above and recalling (2.21), we find

$$\frac{|v^\varepsilon(0, \lambda^2 t_0) - v^\varepsilon(0, t_0)|}{\lambda - 1} \le \frac{\|g^\lambda - g\|}{\lambda - 1} L^\infty(\mathbb{R}^n). \tag{2.25}$$

Now for a.e. $t_0 > 0$, $t \mapsto v^\varepsilon(0, t)$ is differentiable at $t = t_0$. For such a time t_0, we let $\lambda \to 1^+$:

$$2t_0 |v_t^\varepsilon(0, t_0)| \le \|Dg \cdot x\|_{L^\infty(\mathbb{R}^n)}.$$

Since $\sup_{\mathbb{R}^n} |Dg| < \infty$ and since g satisfies (2.12), the last term is finite. Consequently,

$$|v_t^\varepsilon(0, t_0)| \le \frac{C}{t_0},$$

assuming v^ε is differentiable at $(0, t_0)$. Shifting in space, we can replace 0 in the above calculation by any point $x_0 \in K$, K a given compact subset of $\mathbb{R}^n$. Thus

$$|v_t^\varepsilon(x_0, t_0)| \le \frac{C(K)}{t_0},$$

provided v^ε is differentiable in t at (x_0, t_0). But for a.e. x_0, $t \mapsto v^\varepsilon(x_0, t)$ is differentiable in t for a.e. t_0, according to Rademacher's theorem. □

3. Level sets solve the heat equation. It remains to interpret the level sets of any limit v of the approximate solutions v^ε as solving the heat equation. We modify a technique from [11].

THEOREM 3.1. *Assume $\varepsilon_j \to 0$ and*

$$v^{\varepsilon_j} \longrightarrow v \text{ locally uniformly in } \mathbb{R}^n \times (0, \infty). \tag{3.1}$$

Suppose that some level set of v can be represented in some region $N \subset \mathbb{R}^n \times (0, \infty)$ as a graph in the x_n-direction. That is, assume

$$N \cap \{(x, t) | v(x, t) = C\} = N \cap \{(x, t) | x_n = u(x', t)\} \tag{3.2}$$

for some constant C and some continuous function $u : \mathbb{R}^{n-1} \times (0, \infty) \to \mathbb{R}$. Then the height function u is smooth, and u solves the heat equation

$$u_t = \Delta' u \text{ within } N. \tag{3.3}$$

Proof. 1. We will show the heat equation (3.3) is satisfied in the weak (i.e., viscosity) sense. Let $\psi \in C^\infty(\mathbb{R}^{n-1} \times (0, \infty))$ and suppose

$$\begin{aligned} &u - \psi \text{ has a maximum (minimum) at a point} \\ &(x_0', t_0) \text{ such that } (x_0', u(x_0', t_0), t_0) = (x_0, t_0) \in N. \end{aligned} \tag{3.4}$$

We must show

$$\psi_t - \Delta'\psi \leq 0 \;\; (\geq 0) \quad \text{at} \quad (x_0', t_0). \tag{3.5}$$

Let us first assume

$$\begin{aligned} &u - \psi \;\text{ has a strict maximum at } (x_0', t_0) \\ &\text{with } \; u(x_0', t_0) = \psi(x_0', t_0). \end{aligned} \tag{3.6}$$

2. Without loss of generality, we may take $C = 0$. We may as well also suppose that

$$v^\varepsilon, v \leq 0 \quad \text{in} \quad \mathbb{R}^n \times (0, \infty);$$

otherwise, we note that $\tilde{v}^\varepsilon = -(v^\varepsilon)^2$ is also a weak solution of (2.5$_\varepsilon$) and $\tilde{v}^\varepsilon \to -v^2 \leq 0$. Also, we can assume $\lim_{|x'| \to \infty} \psi = +\infty$. Next, set

$$\phi(x,t) = \psi(x',t) - x_n. \tag{3.7}$$

Since $\psi(x',t) \geq u(x',t)$ for x' near x_0' and t near t_0,

$$\phi(x,t) \geq u(x',t) - x_n = 0$$

for all points on the level surface $\{v = 0\}$. Furthermore, $\phi(x_0, t_0) = v(x_0, t_0)$ when $(x_0, t_0) = (x_0', u(x_0', t_0), t_0)$. Define

$$\Phi(z) = \begin{cases} z & (z \geq 0), \\ \inf\{\phi(x,t) | v(x,t) \geq z\} & (z < 0); \end{cases}$$

then

$$\begin{cases} \Phi(0) = 0, & \Phi \text{ is lower semicontinuous,} \\ \Phi(z) \leq 0 & \text{if } \; z \leq 0, \\ \phi \geq \Phi(v). \end{cases}$$

Select a continuous function $\Psi : \mathbb{R} \to \mathbb{R}$ so that $\Psi \leq \Phi$, $\Psi(z) = \Phi(z)$ for $z \geq 0$. Consequently,

$$\phi \geq \Psi(v) = \overline{v}$$

with equality only at (x_0, t_0). Now

$$\overline{v}^\varepsilon = \Psi(v^\varepsilon)$$

is a weak solution of

$$\overline{v}^\varepsilon_t = ((\overline{v}^\varepsilon_{x_n})^2 + \varepsilon^2 |D\overline{v}^\varepsilon|^2)^{-1}((\overline{v}^\varepsilon_{x_n})^2 \Delta' \overline{v}^\varepsilon - 2\overline{v}^\varepsilon_{x_i} \overline{v}^\varepsilon_{x_n} \overline{v}^\varepsilon_{x_i x_n} + |D'\overline{v}^\varepsilon|^2 \overline{v}^\varepsilon_{x_n x_n}).$$

Since $\overline{v}^{\varepsilon_j} \to \overline{v}$ locally uniformly,

$$\overline{v}^{\varepsilon_j} - \phi \;\text{ has a maximum at a point } (x_{\varepsilon_j}, t_{\varepsilon_j})$$

with $(x_{\varepsilon_j}, t_{\varepsilon_j}) \to (x_0, t_0)$. As $\phi_{x_n} \neq 0$, we conclude

$$\phi_t \leq (\phi^2_{x_n} + \varepsilon_j^2 |D'\phi|^2)^{-1}(\phi^2_{x_n} \Delta'\phi - 2\phi_{x_i}\phi_{x_n}\phi_{x_i x_n} + |D'\phi|^2 \phi_{x_n x_n})$$

at $(x_{\varepsilon_j}, t_{\varepsilon_j})$. Recalling the definition (3.7) of ϕ, we obtain

$$\psi_t \leq (1 + \varepsilon_j^2 |D'\psi|^2)^{-1} \Delta'\psi$$

at $(x'_{\varepsilon_j}, t_{\varepsilon_j})$. Let $\varepsilon_j \to 0$ to discover

$$\psi_t \leq \Delta'\psi \quad \text{at} \quad (x_0', t_0).$$

The opposite inequality similarly holds if $u-\psi$ has a strict minimum at (x_0', t_0). Thus

$$u_t = \Delta' u \quad \text{in} \quad N$$

in the weak sense.

3. Finally, choose any cylinder $C' = B'(x_0', r) \times [t_0, t_0 + r^2] \subset N$ and consider the PDE

$$\begin{cases} \tilde{u}_t = \Delta' \tilde{u} & \text{in } C', \\ \tilde{u} = u & \text{on } B'(x_0', r) \times \{t = t_0\}, \\ \tilde{u} = u & \text{on } \partial B'(x_0', r) \times [t_0, t_0 + r^2]. \end{cases}$$

There exists a unique solution $\tilde{u}$, $\tilde{u}$ continuous on C' and C^∞ in the interior of C'. By uniqueness of viscosity solutions,

$$\tilde{u} = u,$$

and so u is C^∞ within N. □

4. Motion of level curves in the plane: Geometric interpretation. As noted in §2, the limit v of the solutions v^ε of (2.5_ε) is not in general a solution to the initial value problem (2.1), as v does not always continuously take on the initial value g. An informal interpretation of what happens is as follows. Assuming that the limit v continuously takes on the initial value $\tilde{g}$, we expect the approximations v^ε to develop an "initial layer," during which the level sets of v^ε move very rapidly, from those of g to approximately the level sets of $\tilde{g}$. Thereafter, the level sets of v^ε approximate the level sets of v and move slowly. Our intention is to substantiate this picture as rigorously as possible.

To simplify matters, for this and the next two sections, let us suppose $n = 2$, so that, as we shall see, a typical level set of v^ε is a curve evolving in the plane $\mathbb{R}^2$. We write $(x_1, x_2) = (x, y)$ to denote a typical point. We return now to our PDEs (2.1) and (2.5_ε) and explicitly display the geometric meaning. Let us temporarily suppose that v is a smooth solution of (2.1), with $v_y \neq 0$ in some region, to which we turn our attention. Then

$$\boldsymbol{\nu} = \frac{Dv}{|Dv|} = \frac{(v_x, v_y)}{|Dv|} = (\nu^1, \nu^2)$$

is a unit normal vector field to any given level curve. The normal velocity of this curve is $v_t/|Dv|$ and its curvature is

$$\begin{aligned} \kappa = \operatorname{div}(\boldsymbol{\nu}) &= \frac{1}{|Dv|} \frac{(\Delta v - v_{x_i} v_{x_i} v_{x_i x_j})}{|Dv|^2} \\ &= \frac{1}{|Dv|^3}(v_y^2 v_{xx} - 2 v_x v_y v_{xy} + v_x^2 v_{yy}). \end{aligned} \tag{4.1}$$

Since v solves (2.1) and thus

$$v_t = v_{xx} - \frac{2v_x}{v_y} v_{xy} + \frac{v_x^2}{v_y^2} v_{yy},$$

we can utilize (4.1) to compute that

$$\frac{v_t}{|Dv|} = \frac{|Dv|^2}{(v_y)^2} \kappa.$$

Thus the geometric law for the motion of the level curves of v is

$$\text{normal velocity} = \frac{\kappa}{(\nu^2)^2}. \tag{4.2}$$

In particular, (4.2) provides a geometric interpretation of the one-dimensional heat equation. Analogously, the PDE (2.5_ε) implies that the level curves of v^ε evolve according to the geometric law that

$$\text{normal velocity} = \frac{\kappa}{(\nu^2)^2 + \varepsilon^2(\nu^1)^2}. \tag{4.3_ε}$$

Thus the approximation $\varepsilon = 1$ corresponds to classical curvature motion and $\varepsilon = 0$ to the heat equation. It is clear that (4.3_ε) is in some sense a natural approximation to (4.2). The law of motion (4.2) ordains—at least formally—an infinite propagation velocity whenever the normal ν is horizontal and $\kappa \neq 0$. The approximate law of motion (4.3_ε), on the other hand, is a smooth nonisotropic modification of classical flow by curvature in the plane (cf. Oaks [19], Grayson [16], Gage and Hamilton [15], etc.).

We illustrate the effects of such a motion upon a given curve Γ_0 in Figure 1.

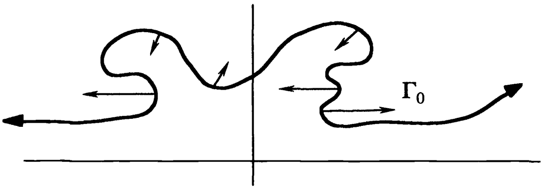

FIG. 1.

If we regard Γ_0 as an initial level set of v^ε, the law of motion (4.3_ε) forces a large horizontal velocity, as illustrated, along the folds and a small velocity in the regions where the curve is approximately flat and approximately horizontal.

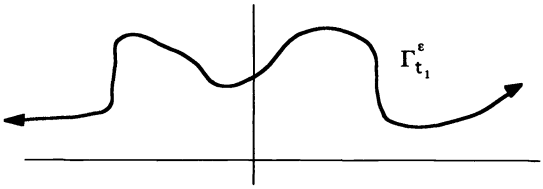

FIG. 2. $\Gamma^\varepsilon_{t_1}$ $(0 < t_1 << 1)$.

We consequently expect the level set to evolve quickly into a shape approximately like that in Figure 2: there is no longer a large horizontal velocity since the curvature is small where the curve is close to vertical. Thereafter, the motion should be approximated by the usual heat flow (see Figure 3).

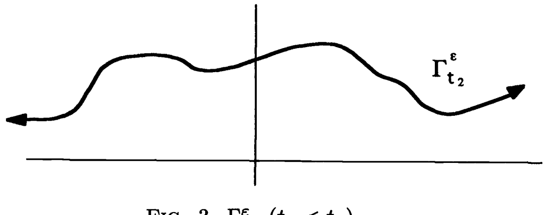

FIG. 3. $\Gamma^\varepsilon_{t_2}$ $(t_1 < t_2)$.

This example suggests that the level sets of v^ϵ, if not initially graphs, will rapidly unfold and become graphs.

The following formal calculation reinforces this belief. Suppose v is a smooth solution of (2.1) for $n = 2$,

$$v_t = v_{xx} - \frac{2v_x}{v_y}v_{xy} + \frac{v_x^2}{v_y^2}v_{yy} \quad \text{in } \mathbb{R}^2 \times (0, \infty) \tag{4.4}$$

with $|Dv| \neq 0$. Let Γ_t denote some level curve of v at a fixed time $t > 0$. Consider the ODE

$$\begin{cases} \dot{x}(s) = v_y(x(s), y(s), t), \\ \dot{y}(s) = -v_x(x(s), y(s), t) \qquad (\dot{} = \frac{d}{ds}). \end{cases} \tag{4.5}$$

Then

$$\frac{d}{ds}\, v(x(s), y(s), t) = 0, \tag{4.6}$$

and so if $(x(0), y(0)) \in \Gamma_t$, we have $(x(s), y(s)) \in \Gamma_t$ as well for all $s \in \mathbb{R}$. Differentiating (4.6) with respect to s, we compute

$$v_x\ddot{x} + v_y\ddot{y} + v_{xx}(\dot{x})^2 + 2v_{xy}\dot{x}\dot{y} + v_{yy}(\dot{y})^2 = 0.$$

Thus (4.5) implies

$$\begin{aligned} |\dot{x}\ddot{y} - \dot{y}\ddot{x}| &= |v_y^2 v_{xx} - 2v_x v_y v_{xy} + v_x^2 v_{yy}| \\ &= |\dot{x}|^2 |v_t| \qquad \text{by (4.4)}. \end{aligned}$$

According to (2.20), we have the estimate

$$|v_t| \leq \frac{C}{t},$$

and thus

$$|\dot{x}\ddot{y} - \dot{y}\ddot{x}| \leq \frac{C}{t}|\dot{x}|^2. \tag{4.7}$$

But

$$\frac{d}{ds}\left(\frac{\dot{x}}{((\dot{x})^2 + (\dot{y})^2)^{\frac{1}{2}}}\right) = \frac{\dot{y}(\dot{y}\ddot{x} - \dot{x}\ddot{y})}{((\dot{x})^2 + (\dot{y})^2)^{\frac{3}{2}}} = \dot{y}\kappa.$$

Consequently, (4.7) implies

$$\begin{aligned} \left|\frac{d}{ds}\left(\frac{\dot{x}}{((\dot{x})^2 + (\dot{y})^2)^{\frac{1}{2}}}\right)\right| &\leq \frac{C}{t}\,\frac{|\dot{y}||\dot{x}|^2}{((\dot{x})^2 + (\dot{y})^2)^{\frac{3}{2}}} \\ &\leq \frac{C}{t}\,\frac{|\dot{x}|}{((\dot{x})^2 + (\dot{y})^2)^{\frac{1}{2}}}. \end{aligned}$$

Applying Gronwall's inequality, we see that $\dot{x} = v_y$ either never vanishes along Γ_t or else is identically zero. The later possibility is excluded, as the level sets of v are horizontal lines for large $|x|$. Hence Γ_t is a graph, $y = u(x, t)$, for some function $u(\cdot\,, t) : \mathbb{R} \to \mathbb{R}$, which necessarily solves the heat equation.

The point of the foregoing calculation is that the curvature $\kappa = (\dot{y}\ddot{x} - \dot{x}\ddot{y})((\dot{x})^2 + (\dot{y})^2)^{-\frac{3}{2}}$ of the local curve Γ_t can be computed in terms of the right-hand side of the PDE (4.4), which in turn is bounded at each time $t > 0$. However, the proof is *not* geometrically intrinsic inasmuch as the bound on v_t implies an estimate only in $\frac{\kappa|Dv|}{|\nu^2|^2}$

and not $\frac{\kappa}{(\nu^2)^2}$. Note in particular that the parameter s is not arclength. It is consequently difficult to modify the foregoing computation to make a rigorous assertion: we lack in particular any good lower bounds on $\{|Dv^\varepsilon|\}_{0<\varepsilon\leq 1}$. Some different tools are called for, entailing a closer look at the level curves of the approximations.

5. Unfolding of the level curves of v^ε in the plane. We focus our attention on the approximations (2.5_ε), which for $n = 2$ read

$$(5.1_\varepsilon)\qquad \begin{cases} v_t^\varepsilon = \frac{(v_y^\varepsilon)^2 v_{xx}^\varepsilon - 2v_x^\varepsilon v_y^\varepsilon v_{xy}^\varepsilon + (v_x^\varepsilon)^2 v_{yy}^\varepsilon}{(v_y^\varepsilon)^2 + \varepsilon^2 (v_x^\varepsilon)^2} & \text{in } \mathbb{R}^2 \times (0,\infty), \\ v^\varepsilon = g & \text{on } \mathbb{R}^2 \times \{t = 0\}. \end{cases}$$

As observed in §4, this PDE says that the level curves of v^ε move with normal velocity $((\nu^2)^2 + \varepsilon^2(\nu^1)^2)^{-1}\kappa$.

Let us first note that each level set of v^ε is in fact a smooth, embedded curve for all times $t \geq 0$ provided it is so at $t = 0$. This fact is a variant of M. Grayson's important theorem that an embedded curve moving under curvature motion in the plane remains smooth and embedded until (and if) it collapses to a point. See Oaks [9] for proofs.

Let us hereafter look at a given level set $\Gamma_t^\varepsilon = \{(x,y) \in \mathbb{R}^n | v^\varepsilon(x,y,t) = C\}$ for some given constant C. We assume

$$(5.2)\qquad \begin{cases} \Gamma_0^\varepsilon \text{ is a smooth, embedded curve with} \\ p(\Gamma_0^\varepsilon) = \mathbb{R}, \end{cases}$$

$p(\,\cdot\,)$ denoting the projection on $\mathbb{R}^2$ onto the x-axis. In view of hypothesis (2.12), Γ_0^ε is a horizontal line within the region $\{|x| \geq R\}$ (see Figure 4).

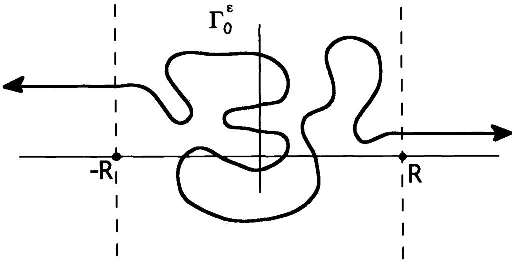

FIG. 4

First, we study the level sets $\{\Gamma_t^\varepsilon\}_{t\geq 0}$ in the region $\{|x| \geq R\}$.

LEMMA 5.1.

(i) *For each time $t \geq 0$, Γ_t^ε is a single-valued graph in the region $\{|x| \geq R\}$; that is,*

$$(5.3)\qquad \Gamma_t^\varepsilon \cap \{|x| \geq R\} = \{(x,y) \in \mathbb{R}^n \,||x| \geq R,\ u^\varepsilon(x,t) = y\}$$

for some smooth function $u^\varepsilon : \mathbb{R} \times [0,\infty) \to \mathbb{R}$.

(ii) *The height function u^ε solves the PDE*

$$(5.4)\qquad u_t^\varepsilon = \frac{u_{xx}^\varepsilon}{1 + \varepsilon^2 (u_x^\varepsilon)^2} \qquad \textit{in } \{|x| \geq R\} \times (0,\infty).$$

(iii) *There exists a constant C depending only on R such that*

$$\sup_{0<\varepsilon\leq 1} \sup_{\substack{|x|\geq R+1 \\ t\geq 0}} |u_x^\varepsilon| \leq C < \infty. \tag{5.5}$$

Proof. 1. At time $t = 0$, the curve Γ_0^ε and the vertical line $\{x = R\}$ meet transversely (in fact, perpendicularly) at a single point. According to results of Angenent [1], [2], the curves Γ_0^ε and $\{x = R\}$ intersect at most once for each time $t > 0$. (Indeed, near any point p_0 where the normal to Γ_t^ε is bounded away from $e_2 = (0, 1)$, we can locally represent Γ_t^ε as a graph in the y-direction.) Thus for some neighborhood N of p_0,

$$\Gamma_t^\varepsilon \cap N = \{(x, y, t) \in N | w^\varepsilon(y, t) = x\},$$

where $w^\varepsilon : \mathbb{R} \times (0, \infty) \to \mathbb{R}$ is smooth and solves the PDE

$$w_t^\varepsilon = \frac{w_{yy}^\varepsilon}{(w_y^\varepsilon)^2 + \varepsilon^2} \qquad \text{near } p_0$$

(cf. (6.2_ε) below). According to Angenent [1, Thm. C], the number of crossings of the line $\{x = \mathbb{R}\}$ is nonincreasing in time. (See also Angenent [2, §5] for a related assertion for isotropic curvature flow.)

As $\Gamma_t^\varepsilon \cap \{x > R\} \neq \emptyset$ and $\Gamma_t^\varepsilon \cap \{x < -R\} \neq \emptyset$, in fact, Γ_t^ε intersects the line $\{x = R\}$ precisely once. Let $y(t)$ denote the point of intersection; then $t \mapsto y(t)$ is smooth. Furthermore, $\{y(t)\}_{t\geq 0}$ is bounded since $\{\Gamma_t^\varepsilon\}_{t\geq 0}$ cannot intersect the lines $y = \pm R$.

2. Now consider the PDE

$$u_t^\varepsilon = \frac{u_{xx}^\varepsilon}{1 + \varepsilon^2 (u_x^\varepsilon)^2} \qquad \text{in } \{x > R\} \times (0, \infty) \tag{5.5_ε}$$

with the initial condition

$$u^\varepsilon(x, 0) \equiv y(0) \tag{5.6}$$

and boundary conditions

$$u^\varepsilon(0, t) = y(t), \qquad \lim_{x\to\infty} u^\varepsilon(x, t) = y(0). \tag{5.7}$$

This initial/boundary-value problem has a unique, smooth solution u^ε (cf. [18]) whose graph moves according to the geometric motion (4.3_ε). By uniqueness, $\Gamma_t^\varepsilon \cap \{x > R\}$ is the graph of u^ε.

3. We next employ routine Bernstein-type methods to derive uniform interior estimates for u_x^ε in $\{x > R + 1\} \times [0, \infty)$. For simplicity of notation, we suppress the superscript ε.

Let $\zeta \in C_c^\infty(\mathbb{R})$ be a cutoff function such that

$$0 \leq \zeta \leq 1, \qquad \operatorname{spt}(\zeta) \subset (R, \infty), \tag{5.8}$$

and set

$$z = \zeta^2 u_x^2 + \lambda u^2,$$

the constant $\lambda > 0$ to be selected later. Then

$$\text{(5.9)}\qquad \begin{cases} z_t &= 2\zeta^2 u_x u_{xt} + 2\lambda u u_t, \\ z_x &= 2\zeta^2 u_x u_{xx} + 2\zeta\zeta_x u_x^2 + 2\lambda u u_x, \\ z_{xx} &= 2\zeta^2 u_x u_{xxx} + 2\zeta^2 u_{xx}^2 + 8\zeta\zeta_x u_x u_{xx} \\ & \quad + 2(\zeta\zeta_{xx} + \zeta_x^2)u_x^2 + 2\lambda u u_{xx} + 2\lambda u_x^2. \end{cases}$$

Differentiate the PDE (5.5_ε) with respect to x:

$$\text{(5.10)}\qquad u_{xt} = \frac{u_{xxx}}{1+\varepsilon^2 u_x^2} - \frac{2\varepsilon^2 u_x u_{xx}^2}{(1+\varepsilon^2 u_x^2)^2}.$$

Fix $T > 0$. If z attains its maximum over $\{x \geq R\} \times [0, T]$ at some point $x_0 > R$, $0 < t_0 \leq T$, where $u_x(x_0, t_0) \neq 0$, then

$$0 \leq z_t - \frac{z_{xx}}{1+\varepsilon^2 u_x^2} \qquad \text{at } (x_0, t_0).$$

Utilizing (5.9), we compute

$$\begin{aligned} 0 \leq{}& 2\zeta^2 u_x \left(u_{xt} - \frac{u_{xxx}}{1+\varepsilon^2 u_x^2} \right) + 2\lambda u \left(u_t - \frac{u_{xx}}{1+\varepsilon^2 u_x^2} \right) \\ & - \frac{2\zeta^2 u_{xx}^2}{1+\varepsilon^2 u_x^2} - \frac{2\lambda u_x^2}{1+\varepsilon^2 u_x^2} - \frac{8\zeta\zeta_x u_x u_{xx}}{1+\varepsilon^2 u_x^2} - \frac{2(\zeta\zeta_{xx} + \zeta_x^2)u_x^2}{1+\varepsilon^2 u_x^2}. \end{aligned}$$

We simplify, making use of (5.5_ε) and (5.10):

$$\begin{aligned} 0 &\leq 2\zeta^2 u_x \left(\frac{-2\varepsilon^2 u_x u_{xx}^2}{(1+\varepsilon^2 u_x^2)^2} \right) - \frac{2\zeta^2 u_{xx}^2}{1+\varepsilon^2 u_x^2} - \frac{2\lambda u_x^2}{1+\varepsilon^2 u_x^2} \\ &\quad + \frac{C\zeta |u_x||u_{xx}|}{1+\varepsilon^2 u_x^2} + \frac{C u_x^2}{1+\varepsilon^2 u_x^2} \\ &\leq \frac{C u_x^2}{1+\varepsilon^2 u_x^2} - \frac{2\lambda u_x^2}{1+\varepsilon^2 u_x^2} \\ &< 0 \end{aligned}$$

if $\lambda > 0$ is fixed large enough. Thus z cannot in fact attain its maximum at a point $(x_0, t_0) \in \{x > R\} \times (0, T]$, with $u_x(x_0, t_0) \neq 0$.

Now restore the superscript ε. Since $z^\varepsilon = \zeta^2 (u_x^\varepsilon)^2 + \lambda (u^\varepsilon)^2$ cannot attain an interior maximum unless $u_x = 0$, and since u^ε is bounded, we deduce that

$$\sup_{\varepsilon > 0} \sup_{\substack{x \geq R \\ t \geq 0}} |z^\varepsilon| \leq C < \infty,$$

the constant C depending only on R and $\sup |\zeta_x|, |\zeta_{xx}|$. Given any point (x, t) with $x > R + 1$, we select ζ so that $\zeta(x) = 1$ and conclude

$$\sup_{\varepsilon > 0} |u_x^\varepsilon(x, t)| \leq C < \infty.$$

The constant C depends only on R.

Similar arguments apply for the region $\{x < -R\}$. □

Next we study the evolution of $\{\Gamma_t^\varepsilon\}_{t \geq 0}$ within the set $\{|x| \leq R\}$.

LEMMA 5.2. *There exists a constant* C *such that for each* $0 < \varepsilon \le 1$ *and* $T > 0$,

(5.11)
$$\sup_{0\le t\le T} H^1(\Gamma_t^\varepsilon \cap \{|x| \le R+1\}) + \int_0^T \int_{\Gamma_t^\varepsilon\cap\{|x|\le R+1\}} \frac{(\kappa^\varepsilon)^2}{(\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2}\, dH^1\, dt$$
$$\le C(H^1(\Gamma_0^\varepsilon \cap \{|x| \le R+1\}) + T).$$

Here H^1 denotes the one-dimensional Hausdorff measure and $\nu^\varepsilon = (\nu^{\varepsilon,1}, \nu^{\varepsilon,2})$ is the unit normal to Γ_t^ε (taken to be pointing upwards in $\{|x| \ge R\}$).

Proof. Select a cutoff function $\zeta \in C_c^\infty(\mathbb{R}^2)$ such that

$$\text{(5.12)}\qquad \begin{cases} 0 \le \zeta \le 1, & \zeta \equiv 1 \quad \text{if } |x| \le R+1,\ |y| \le R+1,\\ & \zeta \equiv 0 \quad \text{if } |x| \ge R+2 \ \text{ or } |y| \ge R+2,\\ |D\zeta| \le C. & \end{cases}$$

Then

$$\frac{d}{dt}\left(\int_{\Gamma_t^\varepsilon} \zeta^2 dH^1\right) = \int_{\Gamma_t^\varepsilon} \zeta^2 \kappa^\varepsilon \boldsymbol{\nu}^\varepsilon \cdot \mathbf{v}^\varepsilon dH^1 + \int_{\Gamma_t^\varepsilon} 2\zeta \mathbf{v}^\varepsilon \cdot D\zeta\, dH^1,$$

$\mathbf{v}^\varepsilon$ denoting the normal velocity vector. Now, according to (4.3_ε),

$$\mathbf{v}^\varepsilon = \frac{-\kappa^\varepsilon}{(\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2}\, \nu^\varepsilon.$$

Thus

$$\text{(5.13)}\qquad \begin{aligned} \frac{d}{dt}\left(\int_{\Gamma_t^\varepsilon} \zeta^2 dH^1\right) &\le -\int_{\Gamma_t^\varepsilon} \frac{\zeta^2(\kappa^\varepsilon)^2}{(\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2}\, dH^1 \\ &\quad + 2\int_{\Gamma_t^\varepsilon} \frac{\zeta|D\zeta||\kappa^\varepsilon|}{(\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2}\, dH^1 \\ &\le -\tfrac{1}{2}\int_{\Gamma_t^\varepsilon} \frac{\zeta^2(\kappa^\varepsilon)^2}{(\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2}\, dH^1 \\ &\quad + C\int_{\Gamma_t^\varepsilon} \frac{|D\zeta|^2}{(\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2}\, dH^1. \end{aligned}$$

Since $\Gamma_t^\varepsilon \cap \{|y| > R\} = \emptyset$ and $|D\zeta| \ne 0$ only if $R+1 \le |x| \le R+2$ or $R+1 \le |y| \le R+2$, we can compute

$$\text{(5.14)}\qquad \begin{aligned} \int_{\Gamma_t^\varepsilon} \frac{|D\zeta|^2}{(\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2}\, dH^1 &\le C\int_{\Gamma_t^\varepsilon\cap\{R+1\le|x|\le R+2\}} \frac{1}{(\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2}\, dH^1 \\ &= \int_{\{R+1\le|x|\le R+2\}} \frac{(1+(u_x^\varepsilon)^2)^{\frac{3}{2}}}{1+\varepsilon^2(u_x^\varepsilon)^2}\, dx \\ &\le C \qquad \text{by Lemma 5.1(iii).} \end{aligned}$$

Integrating (5.13), we obtain inequality (5.11). □

Finally, we estimate a time T_ε by which the level sets Γ_t^ε have become graphs. The method is to devise a kind of Harnack inequality for $\nu^{2,\varepsilon}$.

THEOREM 5.3 (unfolding of level curves). *There exists a time $T_\varepsilon > 0$ such that Γ_t^ε is a smooth graph in the y-direction for all times $t \geq T_\varepsilon$. Furthermore, we have the estimate*

$$0 < T_\varepsilon \leq \frac{C(H^1(\Gamma_0^\varepsilon \cap \{|x| \leq R+1\})+1)^2}{(\log\varepsilon)^2}. \tag{5.15}$$

Proof. In the following calculations, s denotes arclength and $\dot{} = \frac{d}{ds}$. Then for each fixed time $t \geq 0$,

$$\frac{d}{ds}\log((\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2) = \frac{2\nu^{2,\varepsilon}\dot{\nu}^{2,\varepsilon} + 2\varepsilon^2\nu^{1,\varepsilon}\dot{\nu}^{1,\varepsilon}}{(\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2},$$

and so

$$\left|\frac{d}{ds}\log((\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2)\right| \leq \frac{C|\kappa^\varepsilon|}{((\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2)^{\frac{1}{2}}}.$$

Let p_0 denote the point where Γ_t^ε intersects the line $x = R+1$ and take p_1 to be any point on $\Gamma_t^\varepsilon \cap \{|x| \leq R\}$. Choose arclength parametrization so that p_0 corresponds to s_0 and p_1 to $s_1 > s_0$. Then

$$\begin{aligned}\log((\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2)|_{p_1} &\geq \log((\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2)|_{p_0} \\ &\quad - C\int_{s_0}^{s_1}\frac{|\kappa^\varepsilon|}{((\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2)^{\frac{1}{2}}}\,ds \\ &\geq \log((\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2)|_{p_0} \\ &\quad - C\int_{\Gamma_t^\varepsilon\cap\{|x|\leq R+1\}}\frac{|\kappa^\varepsilon|}{((\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2)^{\frac{1}{2}}}\,dH^1.\end{aligned}$$

Now $\nu^{2,\varepsilon}|_{p_0}$ is bounded away from 0—say $(\nu^{2,\varepsilon})^2 \geq \theta > 0$—uniformly in ε and t according to Lemma 3.1(iii). Consequently,

(5.16)

$$\begin{aligned}\inf_{\Gamma_t^\varepsilon}\log((\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2) \geq \log(\theta) - C&\left(\int_{\Gamma_t^\varepsilon\cap\{|x|\leq R+1\}}\frac{|\kappa^\varepsilon|^2}{(\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2}\,dH^1\right)^{\frac{1}{2}} \\ &\times H^1(\Gamma_t^\varepsilon \cap \{|x| \leq R+1\})^{\frac{1}{2}}.\end{aligned}$$

Now return to estimate (5.11) with $T = T_\varepsilon \leq 1$ as selected below. There exists a time $0 < t_\varepsilon \leq T^\varepsilon$ such that

$$\int_{\Gamma_{t_\varepsilon}^\varepsilon\cap\{|x|\leq r+1\}}\frac{(\kappa^\varepsilon)^2}{(\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2}\,dH^1 \leq \frac{C}{T_\varepsilon}(H^1(\Gamma_0^\varepsilon \cap \{|x| \leq R+1\})+1).$$

Set $t = t_\varepsilon$ in (5.16):

$$\inf_{\Gamma_{t_\varepsilon}^\varepsilon}\log((\nu^{2,\varepsilon})^2 + \varepsilon^2(\nu^{1,\varepsilon})^2) \geq \log\theta - \frac{C}{T_\varepsilon^{\frac{1}{2}}}(H^1(\Gamma_0^\varepsilon \cap \{|x| \leq R+1\})+1).$$

Consequently,

$$\inf_{\Gamma_{t_\varepsilon}^\varepsilon}(\nu^{2,\varepsilon})^2 \geq \theta e^{-\frac{C}{T_\varepsilon^{\frac{1}{2}}}(H^1(\Gamma_0^\varepsilon\cap\{|x|\leq R+1\})+1)} - \varepsilon > 0 \tag{5.17}$$

provided

$$-\frac{C}{T_\varepsilon^{\frac{1}{2}}}(H^1(\Gamma_0^\varepsilon \cap \{|x| \leq R+1\})+1) > \log\left(\frac{\varepsilon}{\theta}\right). \tag{5.18}$$

But if

$$T_\varepsilon \geq C\frac{H^1((\Gamma_0^\varepsilon \cap \{|x| \leq R+1\})+1)^2}{(\log \varepsilon)^2}$$

for some constant C, estimates (5.18) and thus (5.17) obtain. Consequently, there exists a time $0 \leq t_\varepsilon \leq T_\varepsilon$ for which estimate (5.17) holds. The curve $\Gamma_{t_\varepsilon}^\varepsilon$ is therefore a graph in the e_2-direction. The evolution maintains the property of being a graph, and thus Γ_t^ε is a graph for all times $t \geq T_\varepsilon$. □

6. Equal-area construction. The calculations in §5 demonstrate that the level curves of v^ε become graphs in the y-direction after a time of order $(\log \varepsilon)^{-2}$; thus, given a curve Γ_0 in the plane which is a horizontal line in the region $\{|x| > R\}$ for some $R > 0$, we can envision defining the operator

$$\mathcal{G}(\Gamma_0) = \lim_{t \to 0^+} \lim_{\varepsilon \to 0} \Gamma_t^\varepsilon. \tag{6.1}$$

The effect of $\mathcal{G}$ would be to replace the curve Γ_0 with a graph $\mathcal{G}(\Gamma_0)$, presumably in some natural, canonical way. This is mostly speculation since it is not known in general that the limits in (6.1) exist.

It is possible in one simple case to give a rigorous analysis. Let us assume Γ_0 is the backward-S-shaped curve in Figure 5.

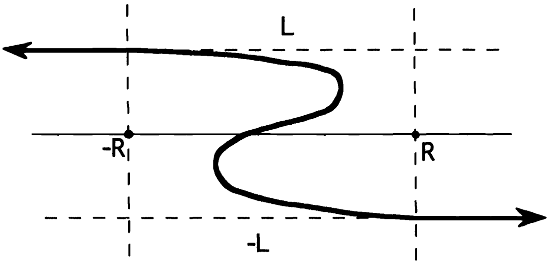

FIG. 5.

We will prove that in this case $\mathcal{G}(\Gamma_0)$ exists and is the graph (with a jump) obtained by the Maxwell equal-area construction (see Figure 6).

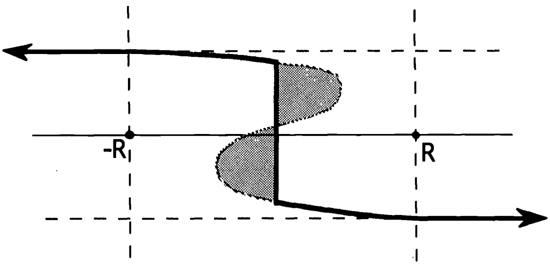

FIG. 6.

Consequently, the heat equation "instantly converts Γ_0 into $\mathcal{G}(\Gamma_0)$."

To make this assertion rigorous, let us suppose that Γ_0 is flat outside $\{|x| \leq R\}$ for some $R > 0$, say $\Gamma_0 = \{y = -L\}$ on $\{x > R\}$ and $\Gamma_0 = \{y = L\}$ on $\{x < -R\}$, where $L > 0$. We propose to interpret Γ_0 and its subsequent evolution $\{\Gamma_t^\varepsilon\}_{t\geq 0}$ under the geometric motion (4.3_ε) as the graph in the x-direction of a function $w^\varepsilon(y,t)$. We easily deduce that the PDE w^ε verifies by noting the graph of w^ε is a level curve of v^ε, v^ε solving (5.1_ε). For the following computation, suppose v^ε is smooth, with $v_x^\varepsilon \neq 0$. Then

$$v^\varepsilon(w^\varepsilon(y,t),y,t) = C \qquad (y \in \mathbb{R},\ \ t \geq 0)$$

for some constant C. Consequently,

$$\begin{gathered} v_x^\varepsilon w_t^\varepsilon + v_t^\varepsilon = 0, \qquad v_x^\varepsilon w_y^\varepsilon + v_y^\varepsilon = 0, \\ v_{xx}^\varepsilon (w_y^\varepsilon)^2 + 2v_{xy}^\varepsilon w_y^\varepsilon + v_x^\varepsilon w_{yy}^\varepsilon + v_{yy}^\varepsilon = 0. \end{gathered}$$

Substituting into (5.1_ε), we deduce after some easy computations that

$$w_t^\varepsilon = \frac{w_{yy}^\varepsilon}{(w_y^\varepsilon)^2 + \varepsilon^2} \qquad \text{in } (-L,L)\times(0,\infty). \tag{6.2}$$

Remark. Note in particular the case $\varepsilon = 0$. If a function $y = u(x,t)$ solves the heat equation and its graph can be written as function $x = w(y,t)$, then w solves

$$w_t = \frac{w_{yy}}{(w_y)^2}. \tag{6.3}$$

This PDE and the corresponding divergence-structure PDE

$$z_t = \left(\frac{z_y}{z^2}\right)_y \tag{6.4}$$

satisfied by $z = w_y$ have been identified in several papers as being exactly solvable; see Bluman and Kumai [3], [4], Fokas and Yortos [14], and Olver [21]. The point is that (6.3) is tranformed into the linear heat equation by a simple rotation through $\pi/2$. □

We propose to study the limits of the function w^ε as $\varepsilon \to 0$ provided the initial data is

$$w^\varepsilon = h \qquad \text{on } (-L,L)\times\{t=0\}, \tag{6.5}$$

where $h : (-L,L) \to \mathbb{R}$ has the graph obtained by rotating Γ_0 clockwise through $\pi/2$.

We transform (6.2) and (6.5) to read

$$\begin{cases} w_t^\varepsilon = (\Phi^\varepsilon(w_y^\varepsilon))_y & \text{in } (-L,L)\times(0,\infty), \\ w^\varepsilon = -\infty & \text{on } \{-L\}\times(0,\infty), \\ w^\varepsilon = +\infty & \text{on } \{L\}\times(0,\infty), \\ w^\varepsilon = h & \text{on } \mathbb{R}\times\{t=0\} \end{cases} \tag{6.6_ε}$$

for

$$\Phi^\varepsilon(r) = \frac{1}{\varepsilon}\left(\arctan\left(\frac{r}{\varepsilon}\right) - \frac{\pi}{2}\right) \qquad (r \in \mathbb{R}). \tag{6.7}$$

Consider next the initial-value boundary problem

$$\begin{cases} W_t^\varepsilon = \Phi^\varepsilon(W_{yy}^\varepsilon) & \text{in } (-L,L)\times(0,\infty), \\ W^\varepsilon = A & \text{on } \{-L\}\times[0,\infty), \\ W^\varepsilon = B & \text{on } \{L\}\times[0,\infty), \\ W^\varepsilon = H & \text{on } \mathbb{R}\times\{t=0\}, \end{cases} \tag{6.8_ε}$$

where

$$H' = h \quad \text{in } |y| < L, \quad \min H = 0, \qquad H(-L) = A, \quad H(L) = B. \tag{6.9}$$

Thus H has two wells and $H(y) = +\infty$ for $|y| > L$ (see Figure 7).

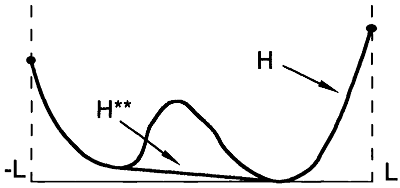

FIG. 7.

LEMMA 6.1. *There exists for each $\varepsilon > 0$ a unique smooth solution W^ε of* (6.8_ε).

Proof. 1. The curve Γ_0 intersects each horizontal line $\{y = C\}$ precisely once for each $-L < C < L$. Furthermore, this intersection is transverse. Consequently, Angenent's theorem [1] implies Γ_t^ε intersects each line $\{y = C\}$ precisely once for each time $t > 0$, and so Γ_t^ε is a graph in the x-direction—say $x = w^\varepsilon(y,t)$, where $|y| < L$, $t \geq 0$. The function w^ε is a smooth solution of $w_t^\varepsilon = (\Phi^\varepsilon(w_y^\varepsilon))_y$. Define

$$W^\varepsilon(y,t) = A + \int_{-L}^{y} w^\varepsilon(z,t)dz \qquad \text{for } |y| < L.$$

Then W^ε is a smooth solution of the PDE $W_t^\varepsilon = \Phi^\varepsilon(W_{yy}^\varepsilon)$, with $W^\varepsilon = H$ at $t = 0$. Now, near the lines $y = \pm L$, the graph of w^ε is approximately the graph of a solution to the heat equation rotated through $\pi/2$. Consequently,

$$\lim_{y \to \pm L} w_y^\varepsilon = \lim_{y \to \pm L} W_{yy}^\varepsilon = +\infty,$$

and so

$$\lim_{y \to \pm L} w_t^\varepsilon = \lim_{y \to \pm L} \Phi^\varepsilon(W_{yy}^\varepsilon) = 0 \tag{6.10}$$

uniformly in $[0,T]$ for each $T > 0$. Thus $w^\varepsilon(-L,t) = A$, $w^\varepsilon(L,t) = B$ for $t \geq 0$.

2. If W^ε and $\tilde{W}^\varepsilon$ are two solutions, the graphs of $w^\varepsilon = W_y^\varepsilon$ and $\tilde{w}^\varepsilon = \tilde{W}_y^\varepsilon$ both evolve according to the geometric motion (4.3_ε) starting from Γ_0. By uniqueness, $w^\varepsilon \equiv \tilde{w}^\varepsilon$. Since $W^\varepsilon(L,t) = \tilde{W}^\varepsilon(L,t)$ for all $t \geq 0$, $W^\varepsilon \equiv \tilde{W}^\varepsilon$. □

Next we study the asymptotic behavior of W^ε as $\varepsilon \to 0$. Let us write H^{**} to denote the convex regularization of H; that is, H^{**} is the largest convex function less than or equal to H.

THEOREM 6.2 (equal-area construction). *We have*

$$\lim_{t \to 0^+} \lim_{\varepsilon \to 0} W^\varepsilon(\cdot,t) = H^{**} \tag{6.11}$$

locally uniformly in $(-L,L)$, *and*

$$\lim_{t \to 0^+} \lim_{\varepsilon \to 0} w^\varepsilon(\cdot,t) = (H^{**})' \tag{6.12}$$

in $L^p_{\text{loc}}(-L,L)$ $(1 \leq p < \infty)$. *In particular, the limits in* (6.11) *and* (6.12) *exist.*

Proof. 1. Fix $t > 0$. Inasmuch as $\Phi^\varepsilon \leq 0$, we deduce from (6.8_ε) that

$$W^\varepsilon(y,t) \leq H(y) \qquad (|y| < L, \quad t \geq 0). \tag{6.13}$$

Recall also that the graph Γ_t^ε of $w^\varepsilon = W_y^\varepsilon$ moves following (4.3_ε). According to Theorem 5.3, Γ_t^ε is a graph in the y-direction for times $t \geq T_\varepsilon = O((\log \varepsilon)^{-2})$. The mapping $y \mapsto w^\varepsilon(y,t)$ is therefore strictly increasing for times $t \geq T_\varepsilon$. Consequently, $y \mapsto W^\varepsilon(y,t)$ is uniformly convex.

Fix a small time $\tau > 0$. Then, replacing τ_ε by τ in (5.17), we deduce for some time $0 \leq t_\varepsilon \leq \tau$ that

$$\begin{aligned}\inf_{\Gamma_{t_\varepsilon}^\varepsilon}(\nu^{2,\varepsilon})^2 &\geq \theta\, e^{-C/\tau^{\frac{1}{2}}} - \varepsilon \\ &\geq \gamma\end{aligned}$$

for $\gamma = \gamma(\tau) > 0$ and all ε sufficiently small. In particular, therefore,

$$\sup_{\substack{t \geq \tau \\ x \in \mathbb{R}}} |u_x^\varepsilon(x,t)| < M$$

for ε sufficiently small, $M = M(\tau)$. Consequently,

$$W_{yy}^\varepsilon(y,t) \geq \mu > 0 \tag{6.14}$$

for some constant $\mu > 0$ and all $t \geq \tau$, $|y| < L$. Since

$$\lim_{\varepsilon \to 0} \Phi^\varepsilon(r) = -\frac{1}{r} \qquad \text{if } r > 0 \tag{6.15}$$

uniformly on compact subsets of $[\mu, \infty)$, we deduce from the PDE (6.8_ε) that

$$\sup_{\varepsilon > 0} \sup_{\substack{t \geq \tau > 0 \\ |y| < L}} |W_t^\varepsilon(y,t)| < \infty.$$

But also

$$\sup_{\varepsilon > 0} \sup_{\substack{t \geq 0 \\ |y| \leq L - \sigma}} |W_y^\varepsilon(y,t)| < \infty$$

for each $\sigma > 0$. Hence we can extract a subsequence $\varepsilon_j \to 0$ and find a function $W : \mathbb{R} \times (0,\infty) \to \mathbb{R}$ such that

$$W^{\varepsilon_j} \longrightarrow W \qquad \text{locally uniformly in } (-L,L) \times (0,\infty). \tag{6.16}$$

In view of (6.13) and (6.14), for each $t > 0$,

$$y \mapsto W(y,t) \quad \text{is convex and} \quad W(y,t) \leq H^{**}(y) \quad (|y| < L). \tag{6.17}$$

2. Next, assume

$$\hat{H} \text{ is uniformly convex}, \quad \hat{H} \leq H. \tag{6.18}$$

Let $\hat{W}^\varepsilon$ denote the solution of (6.8_ε) with $\hat{H}$ replacing H. Then

$$\hat{W}^\varepsilon \leq W^\varepsilon \quad \text{on } [-L,L] \times (0,\infty) \tag{6.19}$$

by the maximum principle. Passing to a further subsequence if necessary, we may assume

$$\hat{W}^{\varepsilon_j} \longrightarrow \hat{W} \quad \text{locally uniformly in } (-L,L) \times (0,\infty). \tag{6.20}$$

Since $\hat{H}'' \geq \theta > 0$ for some $\theta > 0$, we see from (6.15) that $\hat{W}$ is a smooth solution of

$$\hat{W}_t = -(\hat{W}_{yy})^{-1} \quad \text{in } (-L,L) \times (0,\infty).$$

Therefore,

$$\sup_{\substack{t\geq 0\\ |y|\leq L}} |\hat{W}_t| < \infty,$$

and so

$$\sup_{|y|\leq L} |\hat{W}(y,t) - \hat{H}(y)| = O(t) \quad \text{as } t \to 0. \tag{6.21}$$

From (6.17)–(6.21), we deduce

$$H^{**}(y) \geq W(y,t) \geq \hat{H}(y) + O(t) \quad (|y| \leq L). \tag{6.22}$$

Since the mappings $y \mapsto W(y,t)$ are convex and bounded for $0 < t \leq 1$, the derivatives $\{W_y(\,\cdot, t))\}_{0<t\leq 1}$ are uniformly locally bounded. Hence there exists a sequence $t_k \to 0$ and a convex function G such that

$$W(\cdot, t_k) \longrightarrow G$$

locally uniformly. Owing to (6.21),

$$H^{**}(y) \geq G(y) \geq \hat{H}(y) \qquad (|y| \leq L)$$

for each uniformly convex $\hat{H} \leq H$, as above. We conclude that $G = H^{**}$. This deduction holds for any such sequence $t_k \to 0$, and so

$$\lim_{t\to 0^+} W(\cdot, t) = H^{**} \tag{6.23}$$

locally uniformly.

As $y \mapsto W(y,t)$ is convex for each $t > 0$, the limit

$$\lim_{t\to 0^+} W_y(\cdot, t) = (H^{**})' \tag{6.24}$$

exists in L^p_{loc}, $1 \leq p < \infty$. Furthermore, for each fixed $t > 0$,

$$w^{\varepsilon_j}(\cdot, t) = W^{\varepsilon_j}_y(\cdot, t) \longrightarrow W_y(\cdot, t) \quad \text{in } L^p_{\text{loc}}.$$

Consequently, we may rewrite (6.23) and (6.24) to read

$$\begin{cases} \lim_{t\to 0^+} \lim_{\varepsilon_j \to 0} W^{\varepsilon_j}(\cdot, t) = H^{**}, \\ \lim_{t\to 0^+} \lim_{\varepsilon_j \to 0} w^{\varepsilon_j}(\cdot, t) = (H^{**})'. \end{cases} \tag{6.25}$$

3. It remains to replace the subsequence $\varepsilon_j \to 0$ in (6.25) with the full limit $\varepsilon \to 0^+$. Suppose therefore that we have another sequence $\varepsilon_i \to 0$, and

$$W^{\varepsilon_i} \longrightarrow \tilde{W}$$

locally uniformly in $(-L, L) \times (0, \infty)$. Then, as above,

$$H^{**} \geq \tilde{W} \geq \hat{H} + O(t)$$

for any uniformly convex $\hat{H} \leq H$. Thus given any $\delta > 0$, there exists a time $t_\delta > 0$ such that $t_\delta \to 0$ as $\delta \to 0$ and

$$\|\tilde{W}(\cdot, t_\delta) - W(\cdot, t_\delta)\|_{L^\infty(-L,L)} \leq \delta.$$

Now W and $\tilde{W}$ are uniformly convex and smooth in $\mathbb{R} \times [t_\delta, \infty)$, and

$$W_t = -(W_{yy})^{-1}, \quad \tilde{W}_t = -(\tilde{W}_{yy})^{-1} \quad \text{in } (-L, L) \times [t_\delta, \infty).$$

Furthermore,

$$W = \tilde{W} \quad \text{on} \quad \{-L\} \times (0,\infty) \quad \text{and} \quad \{L\} \times (0,\infty).$$

Thus the maximum principle implies

$$\sup_{\substack{|y|\leq L \\ t\geq t_\delta}} |\tilde{W}(y,t) - W(y,t)| < \delta.$$

This estimate obtains for each $\delta > 0$, and consequently $W = \tilde{W}$ on $[-L, L]\times [0,\infty)$. □

7. Analytically natural approximations: Motion of level sets in $\mathbb{R}^n$. It seems difficult to extend to $\mathbb{R}^n$ most of the analysis in §§4–6 concerning the unfolding of the level curves in the plane. Indeed, even the laws of evolution (4.2) and (4.3_ε) become considerably more complicated in higher dimensions.

To deduce the geometric law of motion in general, let us for the purposes of the following calculation suppose v is a smooth solution of the level-surface heat equation

$$v_t = \Delta' v - \frac{2v_{x_i}}{v_{x_n}} v_{x_i x_n} + \frac{|D'v|^2}{v_{x_n}^2} v_{x_n x_n} \quad \text{in } \mathbb{R}^n \times (0,\infty), \tag{7.1}$$

where, recall, the implicit summation is for $i = 1$ to $n-1$. We also assume $v_{x_n} \neq 0$ in some region, in which we analyze as follows the motion of the level surfaces of v. Let $\{\Gamma_t\}_{t\geq 0}$ denote some such level surface. Recall that

$$\boldsymbol{\nu} = \frac{Dv}{|Dv|} = (\nu^1, \ldots, \nu^n)$$

is a unit normal vector field to Γ_t and $v_t/|Dv|$ is the normal velocity. We also write $\boldsymbol{\nu} = (\nu', \nu^n)$ and denote by Γ_t' the surfaces obtained by intersecting Γ_t with the planes $\{x_n = \text{constant}\}$. Then $(n-1)$ times the mean curvature of Γ_t is

$$H = \operatorname{div}(\boldsymbol{\nu}) = \operatorname{div}\left(\frac{Dv}{|Dv|}\right)$$

and $(n-2)$ times the mean curvature of Γ_t' is

$$H' = \operatorname{div}\left(\frac{D'v}{|D'v|}\right),$$

the latter divergence computed in the variables $x' = (x_1, \ldots x_{n-1})$ with x_n held fixed.

Now

$$|Dv|H = \Delta v - \frac{v_{x_k} v_{x_l}}{|Dv|^2} v_{x_k x_l},$$

the summation for $1 \leq k, l \leq n$. Consequently,

$$\begin{aligned} |Dv|^3 H &= |Dv|^2 \Delta v - v_{x_k} v_{x_l} v_{x_k x_l} \\ &= |D'v|^2 \Delta' v + |D'v|^2 v_{x_n x_n} + v_{x_n}^2 \Delta' v - 2 v_{x_i} v_{x_n} v_{x_i x_n} - v_{x_i} v_{x_j} v_{x_i x_j}, \end{aligned}$$

summing $1 \leq i, j \leq n-1$. Thus (7.1) implies

$$\begin{aligned} |Dv|^3 H &= v_{x_n}^2 v_t + |D'v|^2 \Delta' v - v_{x_i} v_{x_j} v_{x_i x_j} \\ &= v_{x_n}^2 v_t + |D'v|^3 H'. \end{aligned}$$

Hence

$$\frac{v_t}{|Dv|} = \frac{|Dv|^2}{v_{x_n}^2} H - \frac{|D'v|^3}{|Dv|v_{x_n}^2} H'.$$

Consequently the level sets of v evolve so that

$$\text{normal velocity} = \frac{1}{(\nu^n)^2} H - \frac{|\nu'|^3}{(\nu^n)^2} H'. \tag{7.2}$$

For the approximations v^ε, which solve (3.2_ε), the law of motion of the level sets is

$$\text{normal velocity} = \frac{1}{(\nu^n)^2 + \varepsilon^2|\nu'|^2} H - \frac{|\nu'|^3}{(\nu^n)^2 + \varepsilon^2|\nu'|^2} H'. \tag{7.3_ε}$$

The evolution given by the PDE (2.5_ε), or equivalently (7.3_ε), is "geometrically natural" but nonetheless hard to visualize and difficult to study rigorously. We therefore propose to study instead the solutions w^ε of the "analytically natural" approximations

(7.4_ε)
$$\begin{cases} w_t^\varepsilon = ((w_{x_n}^\varepsilon)^2 + \varepsilon^2)^{-1}(((w_{x_n}^\varepsilon)^2 + \varepsilon^2)\Delta' w^\varepsilon - 2w_{x_i}^\varepsilon w_{x_n}^\varepsilon w_{x_i x_n}^\varepsilon + |D'w^\varepsilon|^2 w_{x_n x_n}^\varepsilon) \\ \qquad \text{in } \mathbb{R}^n \times (0,\infty), \\ w^\varepsilon = g \qquad \text{on } \mathbb{R}^n \times \{t=0\}, \end{cases}$$

the summation for $i = 1, \dots, n-1$. This PDE does not verify the geometric scaling identity (3.3), (3.5) but on the other hand is defined pointwise even if $|Dw^\varepsilon| = 0$. In the rest of the paper, we provide some preliminary analysis of the behavior of w^ε as $\varepsilon \to 0$. Many questions remain open, however.

LEMMA 7.1. *There exists a unique weak solution to* (7.4_ε). *In addition, we have the estimates*

$$\sup_{0<\varepsilon\le 1} \operatorname*{ess\,sup}_{\mathbb{R}\times[0,\infty)} |w^\varepsilon|, |Dw^\varepsilon| < \infty, \tag{7.5}$$

$$\operatorname*{ess\,sup}_{\substack{0<\varepsilon\le 1\\ x\in K}} |w_t^\varepsilon(x,t)| \le C\left(1 + \frac{1}{t}\right). \tag{7.6}$$

Proof. Since (7.4_ε) is not uniformly parabolic, we approximate further by considering the PDE

$$\begin{cases} w_t^{\varepsilon,\delta} = ((w_{x_n}^{\varepsilon,\delta})^2 + \varepsilon^2)^{-1}((w_{x_n}^{\varepsilon,\delta})^2 + \varepsilon^2)\Delta' w^{\varepsilon,\delta} \\ \qquad -2w_{x_i}^{\varepsilon,\delta} w_{x_n}^{\varepsilon,\delta} w_{x_i x_n}^{\varepsilon,\delta} + (|D'w|^2 + \delta) w_{x_n x_n}^{\varepsilon,\delta}) & \text{in } \mathbb{R}^n \times (0,\infty), \\ w^{\varepsilon,\delta} = g & \text{on } \mathbb{R}^n \times \{t=0\}. \end{cases} \tag{$7.7_{\varepsilon,\delta}$}$$

This PDE is uniformly parabolic for any solution with bounded gradient and so possesses a unique, bounded, smooth solution $w^{\varepsilon,\delta}$. We have the estimates

$$\sup_{\delta>0} \sup_{\mathbb{R}^n\times[0,\infty)} |w^{\varepsilon,\delta}|, |Dw^{\varepsilon,\delta}|, |w_t^{\varepsilon,\delta}| < \infty,$$

and thus there exists a subsequence $\delta_j \to 0$ and a Lipschitz function w^ε such that

$$w^{\varepsilon,\delta_j} \longrightarrow w^\varepsilon \quad \text{locally uniformly on } \mathbb{R}^n \times [0,\infty).$$

Then w^ε is the unique weak (i.e., viscosity) solution of (7.4_ε).

Estimate (7.5) is clear from the contraction property of the mapping $t \mapsto w^\varepsilon(\cdot, t)$. To prove estimate (7.6), we modify the method of Lemma 2.4 by noting that

$$z(x,t) = z^{\varepsilon,\lambda}(x,t) = w^\varepsilon(\lambda x', x_n, \lambda^2 t)$$

is also a weak solution of

$$z_t = (z_{x_n}^2 + \varepsilon^2)^{-1}((z_{x_n}^2 + \varepsilon^2)\Delta' z - 2z_{x_i} z_{x_n} z_{x_i x_n} + |D'z|^2 z_{x_n x_n}) \quad \text{in } \mathbb{R}^n \times (0,\infty). \ \square$$

In view of the bounds (7.5), (7.6), there exists a sequence $\varepsilon_j \to 0$ and a locally Lipschitz function v on $\mathbb{R}^n \times (0,\infty)$ such that

$$w^{\varepsilon_j} \longrightarrow v \quad \text{locally uniformly on } \mathbb{R} \times (0,\infty).$$

It is straightforward to verify that v is a weak solution of the level-surface heat equation, although in general v will not continuously attain the initial values presented by g. We expect instead that the level sets of v will be graphs in the x_n-direction, the point being that the PDE (7.4$_\varepsilon$) contains some kind of mechanism forcing the derivatives $w_{x_n}^\varepsilon$ to become nonnegative as $\varepsilon \to 0$, even though this is not necessarily true at time $t = 0$.

THEOREM 7.2. *We have*

$$v_{x_n} \geq 0 \quad a.e.\ in\ \mathbb{R}^n \times (0,\infty).$$

Proof. 1. We consider the PDE (7.7$_{\varepsilon,\delta}$) and for notational simplicity suppress the superscripts ε, δ. Thus $w = w^{\varepsilon,\delta}$ satisfies

(7.8)
$$w_t = (w_{x_n}^2 + \varepsilon^2)^{-1}((w_{x_n}^2 + \varepsilon^2)\Delta' w - 2w_{x_i} w_{x_n} w_{x_i x_n} + (|D'w|^2 + \delta) w_{x_n x_n}) \quad \text{in } \mathbb{R}^n \times (0,\infty).$$

Differentiate (7.8) with respect to x_n and (selectively) set $z = z^{\varepsilon,\delta} = w_{x_n}$:

$$\begin{aligned} &z_t - (w_{x_n}^2 + \varepsilon)^{-1}((w_{x_n}^2 + \varepsilon)\Delta' z - 2w_{x_i} w_{x_n} z_{x_i x_n} + (|D'w|^2 + \delta) z_{x_n x_n}) \\ &= -\frac{2z|D'z|^2}{z^2 + \varepsilon^2} + \left(-2\, \frac{w_{x_i} w_{x_i x_n}}{w_{x_n}^2 + \varepsilon^2} + 4\, \frac{w_{x_i} w_{x_n}^2 w_{x_i x_n}}{(w_{x_n}^2 + \varepsilon^2)^2} \right. \\ &\quad \left. + 2\, \frac{w_{x_i} w_{x_i x_n}}{w_{x_n}^2 + \varepsilon^2} - 2\, \frac{(|D'w|^2 + \delta) w_{x_n x_n} w_{x_n}}{(w_{x_n}^2 + \varepsilon^2)^2} \right) z_{x_n}. \end{aligned} \tag{7.9}$$

This PDE has the form

$$z_t - a_{kl} z_{x_k x_l} = -\frac{2z|D'z|^2}{z^2 + \varepsilon^2} + b z_{x_n} \quad \text{in } \mathbb{R}^n \times (0,\infty), \tag{7.10}$$

where the coefficients $((a_{kl}))_{1 \leq k,l \leq n}$ are uniformly positive definite.

2. We propose to compare $z = z(x,t)$ with $\tilde{z} = \tilde{z}^\varepsilon = \tilde{z}(x',t)$, a solution of

$$\begin{cases} \tilde{z}_t - \Delta' \tilde{z} = -\frac{2\tilde{z}|D'\tilde{z}|^2}{\tilde{z}^2 + \varepsilon^2} & \text{in } \mathbb{R}^{n-1} \times (0,\infty), \\ \tilde{z} = \tilde{g} & \text{on } \mathbb{R}^{n-1} \times \{t = 0\}. \end{cases} \tag{7.11$_\varepsilon$}$$

Here

$$\tilde{g}(x') \equiv \inf_{x_n} g_{x_n}(x', x_n) \qquad (x' \in \mathbb{R}^{n-1}). \tag{7.12}$$

In view of hypothesis (2.12),

$$\tilde{g} = 0 \quad \text{if} \quad |x'| \geq R. \tag{7.13}$$

Set

$$\min_{\mathbb{R}^{n-1}} \tilde{g} \equiv m. \tag{7.14}$$

We may assume $m < 0$, as otherwise we at once deduce that $\tilde{z} \geq 0$ in $\mathbb{R}^{n-1} \times [0, \infty)$.

Let us transform the PDE (7.11_ε) into the heat equation by writing

$$\phi(\tilde{z}) = \tilde{u}, \tag{7.15}$$

where

$$\phi(x) = \phi^\varepsilon(x) = \frac{1}{\varepsilon}\left[\arctan\left(\frac{x}{\varepsilon}\right) - \arctan\left(\frac{m}{\varepsilon}\right)\right] \qquad (x \in \mathbb{R}). \tag{7.16}$$

A calculation verifies

$$\tilde{u}_t = \Delta' \tilde{u} \quad \text{ in } \quad \mathbb{R}^{n-1} \times (0, \infty). \tag{7.17}$$

Now in view of (7.14), we have the normalization

$$\min_{\mathbb{R}^{n-1}} \tilde{u}(\,\cdot, 0) = 0, \tag{7.18}$$

and furthermore

$$\tilde{u}(\cdot, 0)|_{\mathbb{R}^{n-1} - B(0,R)} = -\varepsilon^{-1} \arctan\left(\frac{m}{\varepsilon}\right) \geq C\varepsilon^{-1} \tag{7.19}$$

since $m < 0$. Now,

$$\begin{aligned}
\tilde{u}(x', t) &= \frac{1}{(4\pi t)^{\frac{n-1}{2}}} \int_{\mathbb{R}^{n-1}} e^{-\frac{|x'-y'|^2}{4t}} \tilde{u}(y', 0) dy' \\
&\geq \frac{C}{\varepsilon (4\pi t)^{\frac{n-1}{2}}} \int_{\mathbb{R}^{n-1} - B(0,R)} e^{-\frac{|x'-y'|^2}{4t}} \, dy' \\
&\geq \frac{C}{\varepsilon t^{\frac{n-1}{2}}} \int_{\mathbb{R}^{n-1} - B(0,R)} e^{-\frac{|y'|^2}{4t}} \, dy' \\
&= \frac{C}{\varepsilon} \int_{\mathbb{R}^{n-1} - B(0, \frac{R}{t^{\frac{1}{2}}})} e^{-|z'|^2/4} \, dz'.
\end{aligned}$$

Fix any time $t_0 > 0$. Then if $x' \in \mathbb{R}^{n-1}$, $t \geq t_0$, there exists $\gamma = \gamma(t_0) > 0$ such that

$$\tilde{u}(x', t) \geq \gamma \varepsilon^{-1}.$$

Owing then to (7.15) and (7.16),

$$\arctan\left(\frac{\tilde{z}^\varepsilon(x', t)}{\varepsilon}\right) - \arctan\left(\frac{m}{\varepsilon}\right) \geq \gamma > 0, \tag{7.20}$$

and we have now restored the superscript ε on $\tilde{z}^\varepsilon$, the solution of (7.11_ε). Since $m < 0$,

$$\arctan\left(\frac{m}{\varepsilon}\right) = -\frac{\pi}{2} + o(1) \quad \text{ as } \varepsilon \to 0.$$

Consequently, (7.20) implies

$$\tilde{z}^\varepsilon(x, t) \geq \varepsilon \tan\left(\gamma - \frac{\pi}{2} + o(1)\right) \geq -C\varepsilon \qquad (x' \in \mathbb{R}^{n-1},\ t \geq t_0). \tag{7.21}$$

3. Now return to the PDE (7.10) and note that $\tilde{z} = \tilde{z}^\varepsilon$, regarded now as a function of $x \in \mathbb{R}^n$, $t \geq 0$, solves the PDE

$$\tilde{z}_t - a_{kl}\tilde{z}_{x_k x_l} = -\frac{2\tilde{z}}{\tilde{z}^2 + \varepsilon^2}|D'z|^2 + b\tilde{z}_{x_n} \quad \text{in } \mathbb{R}^n \times (0,\infty) \tag{7.22}$$

with

$$\tilde{z} \leq z \quad \text{on } \mathbb{R}^n \times \{t = 0\}. \tag{7.23}$$

We claim that, in fact,

$$\tilde{z} \leq z \text{ in } \mathbb{R}^n \times [0,\infty). \tag{7.24}$$

To see this, write $\tilde{u} = \phi(\tilde{z})$ (as in (7.15)) and $u = \phi(z)$. We invoke (7.10) and (7.16) to calculate

$$\begin{aligned} u_t - a_{kl}u_{x_k x_l} &= bu_{x_n} + 2a_{in}\frac{\phi''}{(\phi')^2}u_{x_i}u_{x_n} - \frac{a_{nn}\phi''}{(\phi')^2}\,u_{x_n}^2 \quad \text{in } \mathbb{R}^n \times (0,\infty) \\ &= cu_{x_n}, \end{aligned}$$

for

$$c = c(x,t) = b(x,t) + 2a_{in}\frac{\phi''(z)}{\phi'(z)^2}u_{x_i} - a_{nn}\frac{\phi''(z)}{\phi'(z)^2}u_{x_n}.$$

Now since $\tilde{u}$ solves the heat equation (7.17) and does not depend on the variable x_n, we have

$$\tilde{u}_t - a_{kl}\tilde{u}_{x_k x_l} = c\tilde{u}_{x_n} \qquad \text{in } \mathbb{R}^n \times (0,\infty)$$

as well. Because ϕ is strictly monotone,

$$\tilde{u} \leq u \quad \text{on} \quad \mathbb{R}^n \times \{t = 0\}.$$

Consequently, the maximum principle implies

$$\tilde{u} \leq u \quad \text{in} \quad \mathbb{R}^n \times [0,\infty);$$

whence (7.24) follows.

4. We finally restore the superscripts to the notation and rewrite (7.24) as

$$z^\varepsilon \leq z^{\varepsilon,\delta} = w_{x_n}^{\varepsilon,\delta} \qquad \text{in } \mathbb{R}^n \times [0,\infty).$$

Letting $\delta \to 0$, we deduce

$$z^\varepsilon \leq w_{x_n}^\varepsilon \qquad \text{a.e. in } \mathbb{R}^n \times [0,\infty), \tag{7.25}$$

w^ε the weak solution of the approximation (7.4$_\varepsilon$). Observe also that we have

$$w_{x_n}^\varepsilon \overset{*}{\rightharpoonup} v_{x_n} \tag{7.26}$$

weakly star in $L^\infty(\mathbb{R}^n \times (0,\infty))$. Finally, fix $t_0 > 0$. Then from (7.21) and (7.25), we deduce that

$$v_{x_n} \geq 0 \qquad \text{a.e. in } \mathbb{R}^n \times [t_0,\infty).$$

This conclusion is valid for each time $t_0 > 0$. □

INVERTIBILITY AND A TOPOLOGICAL PROPERTY OF SOBOLEV MAPS*

STEFAN MÜLLER†, SCOTT J. SPECTOR‡, AND QI TANG§

Abstract. Let Ω be a bounded domain in $\mathbb{R}^n$, let $\mathbf{d} : \overline{\Omega} \to \overline{\Omega}$ be a homeomorphism, and consider a function $\mathbf{u} : \overline{\Omega} \to \mathbb{R}^n$ that agrees with $\mathbf{d}$ on $\partial\Omega$. If $\mathbf{u}$ is continuous and injective then $\mathbf{u}(\Omega) = \mathbf{d}(\Omega)$. Motivated by problems in nonlinear elasticity the relationship between $\mathbf{u}(\Omega)$ and $\mathbf{d}(\Omega)$ is analyzed when the continuity and invertibility assumptions are weakened. Specifically maps that are continuous on almost every line and maps that lie in the Sobolev space $W^{1,p}$ with $n-1<p<n$ are considered.

Key words. Sobolev spaces, elasticity, cavitation, singular minimizers, injectivity almost everywhere

AMS subject classifications. 73G05, 73C50, 46E35, 26B99

1. Introduction.

In this paper, we investigate a topological property of maps $\mathbf{u} : \Omega \subset \mathbb{R}^n \to \mathbb{R}^n$ that lie in certain Sobolev classes. In view of applications to nonlinear elasticity, we are specifically interested in the extent to which the boundary data $\mathbf{u}|_{\partial\Omega}$ determines the image of Ω under $\mathbf{u}$, provided that $\mathbf{u}$ satisfies certain hypotheses of invertibility.

In the context of continuous maps, one has the following classical result. Let $\Omega \subset \mathbb{R}^n$ be a bounded domain (a nonempty, connected, open set). Suppose that $\mathbf{u}$ and $\mathbf{d}$ are continuous maps from $\overline{\Omega}$ into $\mathbb{R}^n$ and that the restriction of each map to Ω is injective. If $\mathbf{u}$ and $\mathbf{d}$ agree on the boundary, $\partial\Omega$, then $\mathbf{u}(\Omega) = \mathbf{d}(\Omega)$. For a continuously differentiable map $\mathbf{u}$, the global invertibility condition can be replaced by the pointwise condition $\det D\mathbf{u} \neq 0$. Ball has generalized this result to Sobolev maps.

THEOREM (see [BA 81]). *Let* $\mathbf{d}$ *and* Ω *be as above. Assume that* Ω *has Lipschitz boundary and that* $\mathbf{d}(\Omega)$ *satisfies the cone condition. Suppose that, for some* $p > n$ *and* $q > n$, $\mathbf{u} \in W^{1,p}(\Omega;\mathbb{R}^n) \cap C^0(\overline{\Omega};\mathbb{R}^n)$, $\det D\mathbf{u} > 0$ *a.e. and*

$$\int_\Omega |D\mathbf{u}(\mathbf{x})|^p + \frac{|\operatorname{adj} D\mathbf{u}(\mathbf{x})|^q}{(\det D\mathbf{u}(\mathbf{x}))^{q-1}} d\mathbf{x} < \infty. \tag{1.1}$$

If $\mathbf{u} = \mathbf{d}$ *on* $\partial\Omega$ *then* $\mathbf{u}|_\Omega$ *is a homeomorphism and* $\mathbf{u}(\Omega) = \mathbf{d}(\Omega)$.

Here adj $\mathbf{F}$ denotes the transpose of the matrix of cofactors of the matrix $\mathbf{F}$ and (1.1) is chosen so that the inverse of $\mathbf{u}$ (if it exists) lies in the space $W^{1,q}$. Ball's proof relies on subtle arguments that involve the Brouwer degree and approximation of a tentative inverse.

We note that the motivation for studying such properties of Sobolev maps arises in nonlinear elasticity. In order that such a map correspond to a reasonable physical notion of a deformation, it must satisfy some invertibility hypotheses. (For example, one might require that $\det D\mathbf{u} > 0$ a.e. and that $\mathbf{u}|_{\Omega\backslash N}$ be one-to-one, where N has measure zero.) Questions then arise as to the proper formulation of, the relationships among, and the topological implications of such hypotheses. For many materials, the expression on the left-hand side of (1.1) gives a lower bound (up to a constant) for the energy of an elastic body undergoing a deformation $\mathbf{u}$. However, for some materials, one only has the lower bound $\int_\Omega |D\mathbf{u}(\mathbf{x})|^p d\mathbf{x}$ for some $p < n$. Such materials allow discontinuous deformations that correspond to the formation of a hole or cavity in the material (see, e.g., [Ba 82]). Moreover, the formation of such cavities has been observed in experiments on such materials (see, e.g., [GL 58]). In this case, the above theorem of Ball does not apply and we propose to study the situation in more detail.

Our first result concerns maps that are continuous on almost every line segment. This is the case, for example, for (the precise representative of) maps in $W^{1,1}(\Omega;\mathbb{R}^n)$ (see [Mo 66]). In the following, we denote the k-dimensional Hausdorff measure by $\mathcal{H}^k$.

THEOREM TL (topological location theorem). *Let $\Omega \subset \mathbb{R}^n$ be a bounded domain and let $\mathbf{d} : \overline{\Omega} \to \mathbb{R}^n$ be a homeomorphism. Suppose that $\mathbf{u} : \overline{\Omega} \to \mathbb{R}^n$ satisfies the following:*

(i) *$\mathbf{u}(\mathbf{x}) = \mathbf{d}(\mathbf{x})$ for every $\mathbf{x} \in \partial\Omega$;*

(ii) *there is a set $N \subset \Omega$ with $\mathcal{H}^{n-1}(N) = 0$ such that $\mathbf{u}|_{\overline{\Omega}\backslash N}$ is injective; and*

(iii) *each of the n functions $t \mapsto \mathbf{u}(t, x_2, \ldots, x_n), \ldots, t \mapsto \mathbf{u}(x_1, \ldots, x_{n-1}, t)$ is continuous on each line segment in Ω for $\mathcal{L}^{n-1}$ almost every value of the other independent variables. Then either*

$$\mathbf{u}(\mathbf{x}) \in \mathbf{d}(\Omega) \quad \textit{for a.e. } \mathbf{x} \in \Omega$$

or

$$\mathbf{u}(\mathbf{x}) \in \mathbb{R}^n\backslash\mathbf{d}(\overline{\Omega}) \quad \textit{for a.e. } \mathbf{x} \in \Omega.$$

Remarks. 1. If $\mathbf{u}$ is the precise representative (see (2.12) and Proposition 2.7) of a map in $W^{1,1}(\Omega;\mathbb{R}^n)$, then the conclusion of this theorem actually holds for $\mathcal{H}^{n-1}$ a.e. $\mathbf{x} \in \Omega$ (see the proof of Theorem AL in §4).

2. We have not been able to determine if the conclusion of the theorem is also valid if one replaces hypothesis (i) with the more natural hypothesis that $\mathbf{u} = \mathbf{d}$ $\mathcal{H}^{n-1}$ a.e. on $\partial\Omega$.

3. In §5, we give an example that shows that the conclusion of the theorem may not be valid if the set N satisfies $\mathcal{H}^{n-1}(N) > 0$.

4. The proof of this theorem, which is given in §3, exploits the fact that the image of "most" line segments cannot intersect $\mathbf{d}(\partial\Omega)$ and hence must remain in $\mathbf{d}(\Omega)$ or $\mathbb{R}^n\backslash\mathbf{d}(\overline{\Omega})$. The use of line segments in different directions yields the same conclusion for little cubes (minus a null set) and the fact that Ω is connected finishes the argument.

In contrast to the case of continuous $\mathbf{u}$, one cannot, in general, conclude that $\mathbf{u}(\Omega) = \mathbf{d}(\Omega)$ or even that $\mathbf{u}(\Omega) \subset \mathbf{d}(\Omega)$. For example, take Ω to be the unit ball and consider the maps

$$\mathbf{f}(\mathbf{x}) = \frac{1 + |\mathbf{x}|}{2|\mathbf{x}|}\,\mathbf{x} \tag{1.2}$$

and

$$\mathbf{g}(\mathbf{x}) = \frac{2 - |\mathbf{x}|}{|\mathbf{x}|}\,\mathbf{x}, \tag{1.3}$$

each of which is equal to the identity on the boundary of the unit ball, $B(\mathbf{0},1)$. However,

$$\mathbf{f}(B(\mathbf{0},1)) \subset B(\mathbf{0},1),$$
$$\mathbf{g}(B(\mathbf{0},1)) \subset \mathbb{R}^n \backslash \overline{B(\mathbf{0},1)}.$$

We next aim for conditions that distinguish between the two alternatives given in Theorem TL. To this end, we note that the map $\mathbf{f}$ given by (1.2) satisfies $\det D\mathbf{f} > 0$ a.e. and $\mathbf{f}(\Omega) \subset \mathbf{d}(\Omega)$, while the map $\mathbf{g}$ given by (1.3) satisfies $\det D\mathbf{g} < 0$ a.e. and $\mathbf{g}(\Omega) \subset \mathbb{R}^n \backslash \mathbf{d}(\overline{\Omega})$. The following result shows that the sign of the Jacobian does indeed distinguish between the two alternatives. For simplicity, we focus on the case when $\mathbf{d}$ is the identity and Ω is the unit ball. We refer to §2 for the definition of the precise representative.

THEOREM AL (analytic location theorem). *Let Ω be the unit ball in $\mathbb{R}^n$. Suppose that $\mathbf{u} \in W^{1,p}(\Omega; \mathbb{R}^n)$, with $p > n-1$. Let $\mathbf{u}^*$ denote the precise representative. Suppose that*

(i) $\mathbf{u}^*(\mathbf{x}) = \mathbf{x}$ *for $\mathcal{H}^1$ a.e. $\mathbf{x} \in \partial\Omega$;*

(ii) *there is a set $N \subset \Omega$ with $\mathcal{H}^1(N) = 0$ such that $\mathbf{u}|_{\overline{\Omega}\backslash N}$ is injective; and*

(iii) $\det D\mathbf{u} \neq 0$ *a.e. and* $\det D\mathbf{u} > 0$ *on a set of positive measure.*

Then

$$\mathbf{u}(\mathbf{x}) \in \Omega \text{ for } \mathcal{H}^1 \text{ a.e. } \mathbf{x} \in \Omega$$

and

$$\det D\mathbf{u} > 0 \text{ a.e.}$$

Remarks. 1. Various generalizations are possible. The unit ball can be replaced by a more general smooth (or even Lipschitz) domain. It suffices that the restriction to the boundary of the precise representative agree $\mathcal{H}^1$ a.e. with the restriction of a continuously differentiable diffeomorphism $\mathbf{d}$. (Weaker smoothness assumptions on $\mathbf{d}$ will also suffice.) These and other generalizations are left to the (technically) courageous reader.

2. In regard to hypothesis (ii), Theorem TL suggests that the condition $\mathcal{H}^{n-1}(N) = 0$ might be sufficient. However, we have been unable to prove or disprove such a statement. The heart of the matter seems to be whether a map $\mathbf{w} \in W^{1,p}(S^{n-1}; \mathbb{R}^n)$ that is injective $\mathcal{H}^{n-2}$ a.e. has a degree that is nonzero on exactly one component. This seems plausible since $\mathcal{H}^{n-2}$ null sets do not disconnect S^{n-1}.

3. In view of applications to nonlinear elasticity, it would be useful to determine conditions that imply hypothesis (ii) (as well as hypothesis (ii) of Theorem TL). In this regard, Ciarlet and Nečas [CN 87] give a criterion based upon the change of variables formula that ensures injectivity $\mathcal{L}^n$ a.e. (see Šverák [Šv 88] and Tang [Ta 88] for further extensions). No such criterion seems to be known for invertibility $\mathcal{H}^1$ a.e. or $\mathcal{H}^{n-1}$ a.e.

The proof of Theorem AL is simple in spirit but requires some technical preparation, which we have summarized in §2. The main idea is as follows. The first step is to show that

$$\det D\mathbf{u} > 0 \text{ a.e.} \quad \text{or} \quad \det D\mathbf{u} < 0 \text{ a.e.} \tag{1.4}$$

To this end, let $B(\mathbf{a}, r) \subset \Omega$ be the ball of radius r centered at $\mathbf{a}$. For $\mathcal{L}^1$ a.e. r, $\mathbf{u}^*|_{\partial B(\mathbf{a},r)}$ is injective and in $W^{1,p}(\partial B(\mathbf{a}, r); \mathbb{R}^n)$ (and hence continuous). By the Jordan separation theorem, $\mathbb{R}^n \backslash \mathbf{u}^*(\partial B(\mathbf{a}, r))$ consists of two components, one of which is bounded. Let U be the bounded component. Moreover, the Brouwer degree of $\mathbf{u}^*|_{\partial B(\mathbf{a},r)}$ in U is either $+1$ or -1. Assume the former for definiteness. In this case, the outward unit normal $\mathbf{n}$ to U can be expressed in terms of the cofactors of the tangential derivatives as

$$\mathbf{n} = \frac{(\Lambda_{n-1}D\mathbf{u})\boldsymbol{\nu}}{|(\Lambda_{n-1}D\mathbf{u})\boldsymbol{\nu}|} \tag{1.5}$$

(see Lemma 2.4), where $\boldsymbol{\nu}$ is the outward unit normal to $B(\mathbf{a}, r)$.

Next, by Theorem TL, either $\mathbf{u}(\mathbf{x}) \in U$ for a.e. $\mathbf{x} \in B(\mathbf{a}, r)$ or $\mathbf{u}(\mathbf{x}) \in \mathbb{R}^n \backslash \overline{U}$ for a.e. $\mathbf{x} \in B(\mathbf{a}, r)$. Suppose the latter. Now if $\mathbf{u}^*$ was C^1 at $\mathbf{z} \in \partial B(\mathbf{a}, r)$, it would follow from (1.5) that $\det D\mathbf{u}^*(\mathbf{z}) < 0$. This result can also be obtained in the current situation from an approximation argument (see Proposition 2.6 and [MS 95, Lem. 2.5]). In particular, $\det D\mathbf{u}$ is of constant sign on a.e. sphere and one easily deduces (1.4) (see Lemma 4.1).

For the second step, we argue by contradiction and assume that the second alternative in Theorem TL is satisfied. Extend $\mathbf{u}$ to an $\mathcal{H}^1$ a.e. injective map of $B(\mathbf{0}, 2)$ by letting $\mathbf{u}(\mathbf{x}) = \mathbf{x}/|\mathbf{x}|^2$ on $B(\mathbf{0}, 2) \backslash B(\mathbf{0}, 1)$. The first step applied to the extended map implies that $\det D\mathbf{u} < 0$ a.e. in $B(\mathbf{0}, 2)$, which is the desired contradiction.

Finally, we mention some related work. The idea of using degree-theoretic arguments on almost every sphere is due to Šverák [Šv 88] (see [MTY 94] for some extensions). This approach necessitates the assumption $p > n - 1$ in order that the maps be continuous on such spheres. Malý [Ma 93] recently used rather delicate estimates to show that in certain situations some information can be obtained about the borderline case $p = n - 1$. It is well known that for $p \leq n$ maps in $W^{1,p}$ may have very pathological behavior. Besicovitch [Be 50] constructed continuous maps from $\mathbb{R}^2$ into $\mathbb{R}^3$ that are in $W^{1,2}$ but that map a Lebesgue null set onto a set of positive $\mathcal{L}^3$-measure. Ponomarev [Po 87] obtained homeomorphisms in $W^{1,p}(p < n)$ that map null sets onto sets of positive measure and Malý and Martio [MM 92] solved a long-standing conjecture by exhibiting a continuous map in $W^{1,n}$ that satisfies $\det D\mathbf{u} = 0$ a.e. and maps a null set onto a set of positive measure. For $p > n$, such behavior is, of course, ruled out by the area formula of Marcus and Mizel [MM 73]. If $p = n$ and $\det D\mathbf{u} > 0$ a.e., then $\mathbf{u}$ has a continuous representative that maps null sets onto null sets (see [GV 76], [Šv 88], and [MZ 92]).

2. Preliminaries. In this section, we review the main analytical tools used in the paper. We first introduce some notation from multilinear algebra which will be useful in describing the behavior of surfaces under differentiable maps. One of our basic tools is the Brouwer degree, and we will make use of its representation as a boundary integral (Proposition 2.1) as well as the Jordan separation theorem (Proposition 2.2). We then review some facts about sets of finite perimeter. Together with the boundary representation for the Brouwer degree, these lead to a description of the generalized normal of the connected components of $\mathbb{R}^n/\mathbf{u}(\partial\Omega)$ (see Lemma 2.4). A second characterization of that normal is obtained in Proposition 2.6. Here the notion of approximate differentiability turns out to be very useful. The comparison of the characterizations in Lemma 2.4 and Proposition 2.6 is at the basis of our proof of Theorem AL. Finally, we recall the notion of the precise representative $\mathbf{u}^*$ of a Sobolev function $\mathbf{u} \in W^{1,p}$, which allows one to assign to $\mathbf{u}$ pointwise values off a set of Hausdorff dimension $n - p$.

We now introduce some notation from multilinear algebra (see, e.g., [Fe 69, Chap. 1] or [Sp 65, Chap. 4]). We denote by $\cdot$ the scalar product of vectors in $\mathbb{R}^n$ and by $\wedge$ their exterior product. For $n \geq 2$, we identify the space $\Lambda_{n-1}\mathbb{R}^n$ of alternating $n - 1$ tensors on $\mathbb{R}^n$ with $\mathbb{R}^n$ by means of the map

$$(\mathbf{a}_1, \mathbf{a}_2, \ldots, \mathbf{a}_{n-1}) \mapsto \mathbf{a}_1 \wedge \mathbf{a}_2 \wedge \cdots \wedge \mathbf{a}_{n-1},$$

which is characterized by the following conditions:

(i) it is multilinear and alternating; and

(ii) if $\mathbf{e}_1, \mathbf{e}_2, \ldots, \mathbf{e}_n$ is the canonical basis for $\mathbb{R}^n$, then $\mathbf{e}_1 \wedge \cdots \wedge \mathbf{e}_{i-1} \wedge \mathbf{e}_{i+1} \wedge \cdots \wedge \mathbf{e}_n = (-1)^{n-i}\mathbf{e}_i$.

If $\mathbf{a}, \mathbf{b} \in \mathbb{R}^3$, then $\mathbf{a} \wedge \mathbf{b}$ is the usual vector (cross) product.

We write $\mathrm{Lin}^{n\times m}$ for the set of all linear maps from $\mathbb{R}^m$ into $\mathbb{R}^n$ and $\mathrm{adj} : \mathrm{Lin}^{n\times n} \to \mathrm{Lin}^{n\times n}$ for the unique continuous function that satisfies

$$\mathbf{F}(\mathrm{adj}\,\mathbf{F}) = (\det \mathbf{F})\mathbf{Id} \tag{2.1}$$

for all $\mathbf{F} \in \mathrm{Lin}^{n\times n}$, where $\det \mathbf{F}$ is the determinant of $\mathbf{F}$ and $\mathbf{Id} \in \mathrm{Lin}^{n\times n}$ is the identity mapping. Thus, with respect to any orthonormal basis, the matrix corresponding to $\mathrm{adj}\,\mathbf{F}$ is the transpose of the cofactor matrix corresponding to $\mathbf{F}$. We note that $\mathrm{adj}\,\mathbf{F}$ satisfies

$$(\mathrm{adj}\,\mathbf{F})^T(\mathbf{a}_1 \wedge \mathbf{a}_2 \wedge \cdots \wedge \mathbf{a}_{n-1}) = \mathbf{F}\mathbf{a}_1 \wedge \mathbf{F}\mathbf{a}_2 \wedge \cdots \wedge \mathbf{F}\mathbf{a}_{n-1} \tag{2.2}$$

for all vectors $\mathbf{a}_1, \mathbf{a}_2, \ldots, \mathbf{a}_{n-1} \in \mathbb{R}^n$.

If V is an $(n-1)$-dimensional subspace of $\mathbb{R}^n$ and $\mathbf{L} : V \to \mathbb{R}^n$ is linear, then we define $\Lambda_{n-1}\mathbf{L} : \Lambda_{n-1}V \to \mathbb{R}^n$ by

$$(\Lambda_{n-1}\mathbf{L})(\mathbf{a}_1 \wedge \mathbf{a}_2 \wedge \cdots \wedge \mathbf{a}_{n-1}) = \mathbf{L}\mathbf{a}_1 \wedge \mathbf{L}\mathbf{a}_2 \wedge \cdots \wedge \mathbf{L}\mathbf{a}_{n-1}. \tag{2.3}$$

Let $\mathbf{v}$ be a unit vector normal to V. Then the one-dimensional subspace $\Lambda_{n-1}V$ can be identified with $\{\lambda\mathbf{v} : \lambda \in \mathbb{R}\}$. If $\tilde{\mathbf{L}} \in \mathrm{Lin}^{n\times n}$ is a linear extention of $\mathbf{L}$, then, by (2.2) and (2.3),

$$(\Lambda_{n-1}\mathbf{L})\mathbf{v} = (\mathrm{adj}\,\tilde{\mathbf{L}})^T\mathbf{v}. \tag{2.4}$$

In the following, Ω will denote a nonempty, bounded, open subset of $\mathbb{R}^n$, $n \geq 2$, whose boundary $\partial\Omega$ is smooth. We denote by $L^p(\Omega)$ and $W^{1,p}(\Omega)$ the spaces of p-summable and Sobolev functions, respectively. A vector-valued or matrix-valued function is in $L^p(W^{1,p})$ if all its components are, and we write, e.g., $L^p(\Omega; \mathbb{R}^n)$. The spaces $W^{1,p}(\partial\Omega)$ are defined by local charts (see, e.g., [Mo 66]).

We denote the n-dimensional Lebesgue measure by $\mathcal{L}^n$ and write $\mathcal{H}^k$ for the k-dimensional Hausdorff measure. We use the notation

$$B(\mathbf{a}, r) = \{\mathbf{x} \in \mathbb{R}^n : |\mathbf{x} - \mathbf{a}| < r\}, \quad S(\mathbf{a}, r) := \partial B(\mathbf{a}, r).$$

We briefly recall some facts about the Brouwer degree (see, e.g., Schwartz [Sc 69] for more details). Let $\mathbf{u} : \overline{\Omega} \to \mathbb{R}^n$ be a C^∞ map. If $\mathbf{y}_0 \in R^n \backslash \mathbf{u}(\partial\Omega)$ is such that $\det D\mathbf{u}(\mathbf{x}) \neq 0$ for all $\mathbf{x} \in \mathbf{u}^{-1}(\mathbf{y}_0)$, one defines

$$\deg(\mathbf{u}, \Omega, \mathbf{y}_0) = \sum_{\mathbf{x} \in \mathbf{u}^{-1}(\mathbf{y})} \mathrm{sgn}\det D\mathbf{u}(\mathbf{x}).$$

If φ is a C^∞ function supported in the connected component of $R^n \backslash \mathbf{u}(\partial\Omega)$ that contains $\mathbf{y}_0$, one can show that

$$\int_\Omega (\varphi \circ \mathbf{u}) \det D\mathbf{u}\, d\mathbf{x} = \deg(\mathbf{u}, \Omega, \mathbf{y}_0) \int_{\mathbb{R}^n} \varphi\, d\mathbf{y}. \tag{2.5}$$

Using this formula and approximating by C^∞ functions, one can define $\deg(\mathbf{u}, \Omega, \mathbf{y})$ for any continuous function $\mathbf{u} : \overline{\Omega} \to \mathbb{R}^n$ and any $\mathbf{y} \in \mathbb{R}^n \backslash \mathbf{u}(\partial\Omega)$. Moreover, the degree only depends on $\mathbf{u}|_{\partial\Omega}$.

Indeed, if $\mathbf{u} \in C^\infty(\overline{\Omega}; R^n)$, then since Ω has smooth boundary, the degree can be expressed as a boundary integral as follows. First, recall the identity (see, e.g., [Mo

66, Lem. 4.4.6])

$$\operatorname{div}(\operatorname{adj} D\mathbf{u})^T = \mathbf{0}$$

or, in components,

$$\frac{\partial}{\partial x^j}(\operatorname{adj} D\mathbf{u})_i^j = 0 \quad \text{for } i = 1, \ldots, n.$$

Let φ be as above and let $\mathbf{g} : \mathbb{R}^n \to \mathbb{R}^n$ be C^∞ with $\operatorname{div}\mathbf{g} = \varphi$. Then the above identity in connection with (2.1) implies that

$$\operatorname{div}[(\operatorname{adj} D\mathbf{u})(\mathbf{g} \circ \mathbf{u})] = (\varphi \circ \mathbf{u}) \det D\mathbf{u}.$$

Thus by the divergence theorem and (2.4),

$$\int_\Omega (\varphi \circ \mathbf{u}) \det D\mathbf{u}\, d\mathbf{x} = \int_{\partial\Omega} (\mathbf{g} \circ \mathbf{u}) \cdot (\Lambda_{n-1} D\mathbf{u})\boldsymbol{\nu}\, d\mathcal{H}^{n-1},$$

and hence by (2.5),

$$\deg(\mathbf{u}, \partial\Omega, \mathbf{y}_0) \int_{\mathbb{R}^n} \varphi\, d\mathbf{y} = \int_{\partial\Omega} (\mathbf{g} \circ \mathbf{u}) \cdot (\Lambda_{n-1} D\mathbf{u})\boldsymbol{\nu}\, d\mathcal{H}^{n-1}. \tag{2.6}$$

Here $\boldsymbol{\nu}$ denotes the outward normal to $\partial\Omega$ and $D\mathbf{u}$ is viewed as a map from the tangent space of $\partial\Omega$ to $\mathbb{R}^n$.

PROPOSITION 2.1. *Let $p > n-1$. Suppose that $\overline{\mathbf{u}}$ is the continuous representative of a function in $W^{1,p}(\partial\Omega; \mathbb{R}^n)$. Then $\overline{\mathbf{u}}$ satisfies equation* (2.6). *Moreover, if $\mathbf{h} \in C^1(\mathbb{R}^n; \mathbb{R}^n)$ then*

$$\int_{\mathbb{R}^n} \deg(\overline{\mathbf{u}}, \partial\Omega, \mathbf{y})(\operatorname{div}\mathbf{h})(\mathbf{y})\, d\mathbf{y} = \int_{\partial\Omega} (\mathbf{h} \circ \overline{\mathbf{u}}) \cdot (\Lambda_{n-1} D\overline{\mathbf{u}})\boldsymbol{\nu}\, d\mathcal{H}^{n-1} \tag{2.7}$$

Remark. Note that $\overline{\mathbf{u}}$ is differentiable $\mathcal{H}^{n-1}$ a.e. on $\partial\Omega$ (see, e.g., [EG 92]) and $D\overline{\mathbf{u}}(\mathbf{x})$ is viewed as a linear map from the tangent space $T_\mathbf{x}(\partial\Omega)$ into $\mathbb{R}^n$.

Proof. For (2.6), see [Šv 88, Lem. 1]. In order to prove (2.7), we will use a slightly sharpened version of (2.6). Let U_i be a connected component of $\mathbb{R}^n \backslash \overline{\mathbf{u}}(\partial\Omega)$ and suppose that $\psi_i \in \mathcal{L}^q(\mathbb{R}^n)$, $q > n$, with support in U_i. Write $\mathbf{k}(\mathbf{z}) = c_n \mathbf{z}/|\mathbf{z}|^n$ and let $\mathbf{b}_i = \mathbf{k} * \psi_i$ so that $\operatorname{div}\mathbf{b}_i = \psi_i$. We claim that

$$\begin{aligned}\int_{\mathbb{R}^n} \deg(\overline{\mathbf{u}}, \partial\Omega, \mathbf{y})\psi_i\, d\mathbf{y} &= \deg(\overline{\mathbf{u}}, \partial\Omega, U_i) \int_{\mathbb{R}^n} \psi_i\, d\mathbf{y} \\ &= \int_{\partial\Omega} (\mathbf{b}_i \circ \overline{\mathbf{u}}) \cdot (\Lambda_{n-1} D\overline{\mathbf{u}})\boldsymbol{\nu}\, d\mathcal{H}^{n-1}.\end{aligned} \tag{2.8}$$

Indeed, this follows easily from (2.6) if we approximate ψ_i in $\mathcal{L}^q$ by $C_0^\infty(U_i)$ functions $\psi_i^{(j)}$ and use the fact that $\mathbf{b}_i^{(j)}$ converges in $W^{1,q}_{loc}(\mathbb{R}^n; \mathbb{R}^n)$ (and hence locally uniformly) and that $\overline{\mathbf{u}}(\partial\Omega)$ is compact.

We next observe that $\deg(\overline{\mathbf{u}}, \partial\Omega, \cdot)$ is integrable. To see this, it suffices to let $\psi_i = \chi_{U_i} \operatorname{sgn}(\deg(\overline{\mathbf{u}}, \partial\Omega, U_i))$ (with the convention $\operatorname{sgn}(0) = 0$) and to observe that $\mathbf{b} := \sum_i \mathbf{b}_i$ converges in $W^{1,q}_{loc}$ (and hence locally uniformly) since the degree vanishes on the unbounded component of $\mathbb{R}^n \backslash \overline{\mathbf{u}}(\partial\Omega)$.

Finally, let $\psi_i = \chi_{U_i} \operatorname{div}\mathbf{h}$ and note that $\mathcal{L}^n(\overline{\mathbf{u}}(\partial\Omega)) = 0$ by the area formula. Thus it follows from (2.8) and the dominated convergence theorem that

$$\int_{\mathbb{R}^n} \deg(\overline{\mathbf{u}}, \partial\Omega, \mathbf{y}) \operatorname{div}\mathbf{h}\, d\mathbf{y} = \int_{\partial\Omega} (\mathbf{b} \circ \overline{\mathbf{u}}) \cdot (\Lambda_{n-1} D\overline{\mathbf{u}})\boldsymbol{\nu}\, d\mathcal{H}^{n-1}.$$

Moreover, $\operatorname{div}\mathbf{b} = \operatorname{div}\mathbf{h}$ and hence (2.6) applied to $\mathbf{b}-\mathbf{h}$ implies that

$$\int_{\partial\Omega} (\mathbf{b}\circ\overline{\mathbf{u}})\cdot(\Lambda_{n-1}D\overline{\mathbf{u}})\boldsymbol{\nu}\,d\mathcal{H}^{n-1} = \int_{\partial\Omega} (\mathbf{h}\circ\overline{\mathbf{u}})\cdot(\Lambda_{n-1}D\overline{\mathbf{u}})\boldsymbol{\nu}\,d\mathcal{H}^{n-1},$$

which finishes the proof. □

We will use the following generalization of the Jordan curve theorem (see, e.g., [Sc 69, Thm. 3.21]).

PROPOSITION 2.2. *Assume that $\mathbb{R}^n\backslash\partial\Omega$ consists of exactly two connected components. Suppose that $\overline{\mathbf{u}} : \partial\Omega \to \mathbb{R}^n$ is continuous and injective. Then $\mathbb{R}^n\backslash\overline{\mathbf{u}}(\partial\Omega)$ consists of exactly two connected components U and V and $\partial U = \partial V = \overline{\mathbf{u}}(\partial\Omega)$. If we denote by U the bounded component, we have*

$$\deg(\overline{\mathbf{u}},\partial\Omega,\mathbf{y}) = \begin{cases} m & \text{if } \mathbf{y}\in U, \\ 0 & \text{if } \mathbf{y}\notin \mathbb{R}^n\backslash\overline{U}, \end{cases}$$

where $m\in\{-1,1\}$.

Next, we briefly recall some properties of functions of bounded variation and sets of finite perimeter. More details can be found in [EG 92], [Gi 84], or [Zi 89]. A function $\varphi \in L^1(\mathbb{R}^n)$ is said to be of bounded variation ($\varphi\in BV(\mathbb{R}^n)$) if its distributional derivatives are signed measures, i.e., if

$$\|D\varphi\|_{\mathcal{M}} := \sup\left\{\int_{\mathbb{R}^n} \varphi \operatorname{div}\mathbf{w}\,d\mathbf{y} : \mathbf{w}\in C_0^1(\mathbb{R}^n;\mathbb{R}^n), |\mathbf{w}|\le 1\right\} < \infty.$$

A measurable set A is said to have finite perimeter if its characteristic function χ_A is in $BV(\mathbb{R}^n)$. Sets of finite perimeter enjoy a surprising degree of regularity. Specifically, there exists a set $\partial^* A$ (the reduced boundary) and a function $\boldsymbol{\nu} : \partial^*A \to \mathbb{R}^n$ (the generalized outward unit normal, denoted $\boldsymbol{\nu}(\mathbf{a},A)$) such that the distributional derivative $D\chi_A$ satisfies

$$D\chi_A = -\boldsymbol{\nu}\mathcal{H}^{n-1}\lfloor\,\partial^*A$$

(where $\lfloor$ denotes the restriction) and

$$\mathcal{H}^{n-1}(\partial^*A) = \|D\chi_A\|_{\mathcal{M}}, \quad |\boldsymbol{\nu}| = 1 \quad \mathcal{H}^{n-1} \text{ a.e. on } \partial^*A.$$

Moreover, $\boldsymbol{\nu}$ agrees with the measure-theoretic normal $\mathcal{H}^{n-1}$ a.e. on ∂^*A, i.e., for $\mathcal{H}^{n-1}$ a.e. $\mathbf{a}\in\partial^*A$, one has

$$\lim_{r\to 0+} \frac{\mathcal{L}^n\{\mathbf{x}\in B(\mathbf{a},r)\cap A : (\mathbf{x}-\mathbf{a})\cdot\boldsymbol{\nu}(\mathbf{a},A)\ge 0\}}{r^n} = 0, \tag{2.9}$$

$$\lim_{r\to 0+} \frac{\mathcal{L}^n\{\mathbf{x}\in B(\mathbf{a},r)\backslash A : (\mathbf{x}-\mathbf{a})\cdot\boldsymbol{\nu}(\mathbf{a},A)\le 0\}}{r^n} = 0. \tag{2.10}$$

In order to compare the outward unit normals of Ω and $\mathbf{u}(\Omega)$, we will use the following version of the area formula.

PROPOSITION 2.3 (see [MM 73], [Fe 69, Cor. 3.2.20]). *Let Γ be an oriented, smooth, $(n-1)$-dimensional manifold with continuous unit normal field $\boldsymbol{\nu}$. Suppose that $\mathbf{u}\in W^{1,p}(\Gamma;\mathbb{R}^n)\cap C^0(\Gamma;\mathbb{R}^n)$ with $p > n-1$. Then for any $\mathcal{H}^{n-1}$-measurable $A\subset\Gamma$,*

$$\mathcal{H}^{n-1}(\mathbf{u}(A)) \le \int_A |(\Lambda_{n-1}D\mathbf{u})\boldsymbol{\nu}|\,d\mathcal{H}^{n-1} \le \int_A |D\mathbf{u}|^{n-1}\,d\mathcal{H}^{n-1}.$$

Moreover, if $\varphi : \mathbb{R}^n \to \mathbb{R}$ is $\mathcal{H}^{n-1}$-measurable and $\mathbf{u}$ *is injective then*

$$\int_A (\varphi \circ \mathbf{u}) |(\Lambda_{n-1} D\mathbf{u})\boldsymbol{\nu}|\, d\mathcal{H}^{n-1} = \int_{\mathbf{u}(A)} \varphi \, d\mathcal{H}^{n-1}$$

whenever either integrand is in L^1.

Remark. One consequence of the above result that we will need is that the image under $\mathbf{u}$ of the set $\{\mathbf{x} \in \Gamma : (\Lambda_{n-1} D\mathbf{u}(\mathbf{x}))\boldsymbol{\nu}(\mathbf{x}) = \mathbf{0}\}$ is an $\mathcal{H}^{n-1}$ null set.

LEMMA 2.4. *Let Ω have smooth boundary with outward unit normal $\boldsymbol{\nu}$. Suppose that $\mathbb{R}^n \backslash \partial\Omega$ has exactly two connected components. Let $\mathbf{u} \in W^{1,p}(\partial\Omega; \mathbb{R}^n) \cap C^0(\partial\Omega; \mathbb{R}^n)$, with $p > n-1$, and assume that* $\mathbf{u}$ *is injective. Denote by U the bounded component of $\mathbb{R}^n \backslash \mathbf{u}(\partial\Omega)$ (cf. Proposition 2.2). Then U has finite perimeter, the reduced boundary $\partial^* U$ agrees with $\partial U = \mathbf{u}(\partial\Omega)$ up to an $\mathcal{H}^{n-1}$ null set, and the generalized normal $\tilde{\boldsymbol{\nu}}$ satisfies*

$$\tilde{\boldsymbol{\nu}}(\mathbf{y}, U) = m \frac{(\Lambda_{n-1} D\mathbf{u})\boldsymbol{\nu}}{|(\Lambda_{n-1} D\mathbf{u})\boldsymbol{\nu}|} (\mathbf{u}^{-1}(\mathbf{y})) \quad \textit{for } \mathcal{H}^{n-1} \textit{ a.e. } \mathbf{y} \in \mathbf{u}(\partial\Omega),$$

where $m = \deg(\mathbf{u}, \partial\Omega, U)$. If, moreover, $|(\Lambda_{n-1} D\mathbf{u})\boldsymbol{\nu}| > 0$ $\mathcal{H}^{n-1}$ a.e., then

$$\tilde{\boldsymbol{\nu}}(\mathbf{u}(\mathbf{x}), U) = m \frac{(\Lambda_{n-1} D\mathbf{u}(\mathbf{x}))\boldsymbol{\nu}(\mathbf{x})}{|(\Lambda_{n-1} D\mathbf{u}(\mathbf{x}))\boldsymbol{\nu}(\mathbf{x})|} \quad \textit{for } \mathcal{H}^{n-1} \textit{ a.e. } \mathbf{x} \in \partial\Omega.$$

Proof. Define

$$\tilde{\boldsymbol{\nu}}(\mathbf{y}) = \begin{cases} \mathbf{0} & \text{if } \Lambda_{n-1} D\mathbf{u}(\mathbf{u}^{-1}(\mathbf{y}))\boldsymbol{\nu}(\mathbf{u}^{-1}(\mathbf{y})) = \mathbf{0}, \\ \frac{(\Lambda_{n-1} D\mathbf{u})\boldsymbol{\nu}}{|(\Lambda_{n-1} D\mathbf{u})\boldsymbol{\nu}|} (\mathbf{u}^{-1}(\mathbf{y})) & \text{otherwise,} \end{cases}$$

and note that, by Proposition 2.3, $|\tilde{\boldsymbol{\nu}}(\mathbf{y})| = 1$ for $\mathcal{H}^{n-1}$ a.e. $\mathbf{y}$. Let $\mathbf{g} \in C^1(\mathbb{R}^n; \mathbb{R}^n)$. Then, by the area formula with $\varphi = \mathbf{g} \cdot \tilde{\boldsymbol{\nu}}$,

$$\int_{\partial\Omega} (\mathbf{g} \circ \mathbf{u}) \cdot (\Lambda_{n-1} D\mathbf{u})\boldsymbol{\nu} \, d\mathcal{H}^{n-1} = \int_{\mathbf{u}(\partial\Omega)} \mathbf{g} \cdot \tilde{\boldsymbol{\nu}} \, d\mathcal{H}^{n-1},$$

and hence, by Propositions 2.1 and 2.2,

$$\begin{aligned} \int_{\mathbf{u}(\partial\Omega)} \mathbf{g} \cdot \tilde{\boldsymbol{\nu}} \, d\mathcal{H}^{n-1} &= \int_{\mathbb{R}^n} \deg(\mathbf{u}, \partial\Omega, \mathbf{y})(\operatorname{div} \mathbf{g})(\mathbf{y}) \, d\mathbf{y} \\ &= m \int_{\mathbb{R}^n} \chi_U (\operatorname{div} \mathbf{g}) \, d\mathbf{y}, \end{aligned} \tag{2.11}$$

where $m \in \{-1, 1\}$.

Finally, it is clear from (2.11) that U has finite perimeter and

$$D\chi_U = -m\boldsymbol{\nu} \mathcal{H}^{n-1} \lfloor \mathbf{u}(\partial\Omega). \qquad \square$$

We next give a characterization of the (measure-theoretic) normal of the image $\mathbf{u}(D)$ of subsets $D \subset \Omega$. To this end, it is useful to consider the approximate derivative of $\mathbf{u}$.

DEFINITION 2.5. *Let $E \subset \mathbb{R}^n$ be a measurable set. For $\mathbf{x} \in \mathbb{R}^n$, we define the upper and lower density of E at $\mathbf{x}$ by*

$$D^+(\mathbf{x}, E) = \limsup_{r \to 0+} \frac{\mathcal{L}^n(B(\mathbf{x}, r) \cap E)}{\omega_n r^n},$$

$$D^-(\mathbf{x}, E) = \liminf_{r \to 0+} \frac{\mathcal{L}^n(B(\mathbf{x}, r) \cap E)}{\omega_n r^n},$$

where ω_n *denotes the volume of the unit ball in* $\mathbb{R}^n$. *If the two values agree, their common value is the* density, $D(\mathbf{x}, E)$, *of* E *at* $\mathbf{x}$. *We will sometimes say that* $\mathbf{x}$ *is a point of density* $D(\mathbf{x}, E)$ *of* E.

Let $\mathbf{u} : E \to \mathbb{R}^m$ be measurable. We say that $\mathbf{u}$ is *approximately differentiable* at $\mathbf{x}$ if there is an $\mathbf{F} \in \mathrm{Lin}^{m\times n}$ such that for every $\varepsilon > 0$,

$$\lim_{r\to 0+} \frac{\mathcal{L}^n\{\mathbf{z} \in B(\mathbf{x},r) \cap E : |\mathbf{u}(\mathbf{z}) - \mathbf{u}(\mathbf{x}) - \mathbf{F}(\mathbf{x}-\mathbf{z})| < \varepsilon r\}}{\omega_n r^n} = 1,$$

and we write

$$(\mathrm{ap}\, D\mathbf{u})(\mathbf{x}) := \mathbf{F}.$$

Remark. By the Lebesgue point theorem, $D(\mathbf{x}, E) = 1$ for $\mathcal{L}^n$ a.e. $\mathbf{x} \in E$. If E is open and $\mathbf{u}$ is (a representative of an equivalence class) in $W^{1,1}(E)$ then $\mathrm{ap}\, D\mathbf{u}$ exists $\mathcal{L}^n$ a.e. and agrees with the distributional derivative (see, e.g., [Fe 69, Thms. 3.1.4 and 4.5.9] or [EG 92]).

If $\mathbf{u} : \overline{\Omega} \to \mathbf{u}(\overline{\Omega})$ is a diffeomorphism then for any $\mathbf{x} \in \partial\Omega$ the outward unit normal $\mathbf{n}$ to $\mathbf{u}(\overline{\Omega})$ at $\mathbf{u}(\mathbf{x})$ is given by

$$\mathbf{n}(\mathbf{u}(\mathbf{x})) = \mathrm{sgn}(\det D\mathbf{u}(\mathbf{x})) \frac{(\Lambda_{n-1} D\mathbf{u}(\mathbf{x}))\boldsymbol{\nu}(\mathbf{x})}{|(\Lambda_{n-1} D\mathbf{u}(\mathbf{x}))\boldsymbol{\nu}(\mathbf{x})|}.$$

The following proposition shows that a suitable version of this formula is also valid for Sobolev functions. See, e.g., [MS 95, Lem. 2.5] for a proof.

PROPOSITION 2.6. *Let* $\mathbf{u} : \Omega \to \mathbb{R}^n$ *be (a representative of an equivalence class) in* $W^{1,1}(\Omega; \mathbb{R}^n)$ *and assume that* $\det D\mathbf{u} \neq 0$ $\mathcal{L}^n$ *a.e. Then there is an* $\Omega_1 \subset \Omega$ *of full measure such that*

(i) $\mathbf{u}$ *is approximately differentiable on* Ω_1*;*

(ii) $\det(\mathrm{ap}\, D\mathbf{u}) \neq 0$ *on* Ω_1*;*

(iii) *if* $E \subset\subset \Omega$ *has smooth boundary,* $\mathbf{x}_0 \in \partial E \cap \Omega_1$, $\boldsymbol{\nu}$ *is the outward unit normal to* E *at* $\mathbf{x}_0$*, and*

$$\mathbf{n} = \mathrm{sgn} \det((\mathrm{ap}\, D\mathbf{u})(\mathbf{x}_0)) \frac{(\Lambda_{n-1}(\mathrm{ap}\, D\mathbf{u})(\mathbf{x}_0))\boldsymbol{\nu}}{|(\Lambda_{n-1}(\mathrm{ap}\, D\mathbf{u})(\mathbf{x}_0))\boldsymbol{\nu}|}.$$

Then for any $r > 0$ *and any* $\mathcal{L}^n$ *null set* N*, the set*

$$\mathbf{u}((E\backslash N) \cap B(\mathbf{x}_0, r)) \cap \{\mathbf{y} : (\mathbf{y} - \mathbf{u}(\mathbf{x}_0)) \cdot \mathbf{n} \leq 0\}$$

has density $1/2$ *at* $\mathbf{u}(\mathbf{x}_0)$.

Remarks. 1. Note that $\det((\mathrm{ap}\, D\mathbf{u})(\mathbf{x}_0)) \neq 0$ implies $(\Lambda_{n-1}(\mathrm{ap}\, D\mathbf{u})(\mathbf{x}_0))\boldsymbol{\nu} \neq \mathbf{0}$. Also, E need not be smooth. It suffices that E have a measure-theoretic normal $\boldsymbol{\nu}$ at $\mathbf{x}_0$.

2. If $\mathbf{u}(E\backslash N)$ has a measure-theoretic normal $\boldsymbol{\nu}$ at $\mathbf{u}(\mathbf{x}_0)$ (cf. (2.9) and (2.10)), then the above proposition yields $\tilde{\boldsymbol{\nu}} = \mathbf{n}$.

Since we are interested in the behavior of Sobolev functions on lower-dimensional sets, it is useful to consider a specific representative. The *precise representative* $\mathbf{u}^*$: $\Omega \to \mathbb{R}^n$ of an equivalence class $\{\mathbf{u}\} \in W^{1,p}(\Omega; \mathbb{R}^n)$ is defined by

$$\mathbf{u}^*(\mathbf{x}) = \begin{cases} \lim\limits_{r\to 0+} ⨍_{B(\mathbf{x},r)} \mathbf{u}(\mathbf{z})d\mathbf{z} & \text{if the limit exists,} \\ \mathbf{0} & \text{otherwise,} \end{cases} \tag{2.12}$$

where $⨍_A$ denotes the average value of the integrand over A, i.e., the integral of the function over A divided by the n-dimensional Lebesgue measure of A.

The definition of $\mathbf{u}^*$ at points where the above limit does not exist is somewhat arbitrary. For a thorough discussion of precise representatives, we refer to [EG 92] or [Zi 89]. The main properties of $\mathbf{u}^*$ are summarized below.

PROPOSITION 2.7. *Let* $\mathbf{u} \in W^{1,p}(\Omega;\mathbb{R}^n)$ *with* $1 \leq p < n$. *Let* $p^* := np/(n-p)$ *be the Sobolev conjugate exponent. Then there are sets* P *and* P' *with* $\operatorname{cap}_p(P) = \operatorname{cap}_p(P') = 0$ *such that the following properties are satisfied:*

(i) (*existence of the limit*). *The limit in the definition of* $\mathbf{u}^*$ *exists for all* $\mathbf{x} \in \Omega\backslash P$ *and, if* $\rho_r(\cdot) = r^{-n}\rho(\frac{\cdot}{r})$ *is the standard family of molifiers,*

$$(\rho_r * \mathbf{u})(\mathbf{x}) \to \mathbf{u}^*(\mathbf{x})$$

for each $\mathbf{x} \in \Omega\backslash P$.

(ii) (*Lebesgue points*). *For any* $\mathbf{x} \in \Omega\backslash P$,

$$\lim_{r\to 0+} \fint_{B(\mathbf{x},r)} |\mathbf{u}(\mathbf{z}) - \mathbf{u}^*(\mathbf{x})|^{p^*} d\mathbf{z} = 0.$$

(iii) (*invariance upon change of variables*). *If* $\mathbf{g}$ *is a bi-Lipschitz map, then*

$$(\mathbf{u}\circ\mathbf{g})^* = \mathbf{u}^*\circ\mathbf{g} \text{ on } \mathbf{g}^{-1}(\Omega)\backslash P'.$$

(iv) (*continuity on lines*). $\mathbf{u}^*$ *is absolutely continuous on* $\mathcal{L}^{n-1}$ *a.e. line segment parallel to the coordinate axes.*

(v) (*restriction to hyperplanes*). *For* $\mathcal{L}^1$ *a.e. coordinate hyperplane* H *the restriction* $\mathbf{v} := \mathbf{u}^*|_{H\cap\Omega}$ *is in* $W^{1,p}(H\cap\Omega;\mathbb{R}^n)$ *and* $\operatorname{ap} D\mathbf{v} = (\operatorname{ap} D\mathbf{u})|_{H\cap\Omega}\,\mathcal{H}^{n-1}$ *a.e. on* H. *If, moreover,* $p > n-1$, *then* $\mathbf{v}$ *is continuous.*

Remarks. 1. The property $\operatorname{cap}_p(P) = 0$ implies that $\mathcal{H}^\delta(P) = 0$ for every $\delta > n-p$. For $p > n-1$ one has in particular $\mathcal{H}^1(P) = 0$.

2. Consider $p > n-1$. If we use polar coordinates, it follows from (iii) and (v) that $\mathbf{u}^*$ is continuous on the spheres $S(\mathbf{a}, r)$ for $\mathcal{L}^1$ a.e. r.

3. The equality of the approximate derivatives in (v) is a consequence of the same equality for the corresponding distributional derivatives and the fact that each of the approximate derivatives is a representative of (the equivalence class that contains) the corresponding distributional derivative.

In the following, we will be concerned with maps $\mathbf{u} \in W^{1,p}(\Omega;\mathbb{R}^n)$ and we wish to define $\mathbf{u}^*$ on $\partial\Omega$. Let $E : W^{1,p}(\Omega;\mathbb{R}^n) \to W^{1,p}(\mathbb{R}^n;\mathbb{R}^n)$ be an extension operator (which exists if $\partial\Omega$ is Lipschitz, see, e.g., [GT 83, Thm. 7.25]) and define

$$\mathbf{u}^*(\mathbf{x}) := (E\mathbf{u})^*(\mathbf{x}) \quad \text{for } \mathbf{x} \in \partial\Omega. \tag{2.13}$$

A slightly different approach is to first consider the trace $\mathbf{v} = \mathbf{u}|_{\partial\Omega}$ (which is well defined as an equivalence class in $L^p(\partial\Omega)$). If $\mathbf{c} : U \subset \mathbb{R}^{n-1} \to \Gamma$ is a chart of Γ, one could then define

$$\mathbf{u}^{**}(\mathbf{c}(\mathbf{x})) := (\mathbf{v}\circ\mathbf{c})^*(\mathbf{x}). \tag{2.14}$$

It turns out that the two definitions agree up to a set of Hausdorff dimension $n-p$.

LEMMA 2.8. *Let* $A = \{\mathbf{x} : \mathbf{u}^*(\mathbf{x}) \neq \mathbf{u}^{**}(\mathbf{x})\}$. *Then* $H^\delta(A) = 0$ *for every* $\delta > n-p$.

Remark. This result shows that (2.13) and (2.14) are essentially independent of the choice of E and $\mathbf{c}$. The result is probably well known to experts, but we have included a proof for the convenience of the reader.

Proof. As is usual in such situations, we locally flatten $\partial\Omega$ to reduce the problem to the following case. Let $\mathbf{u} \in W^{1,p}(\mathbb{R}^n;\mathbb{R}^n)$, $H = \mathbb{R}^{n-1}\times\{0\}$, and let $\mathbf{v}$ be the trace of $\mathbf{u}$ on H. Define $A = \{\mathbf{x} \in H : \mathbf{u}^*(\mathbf{x}) \neq \mathbf{v}^*(\mathbf{x})\}$. Then we must show that $\mathcal{H}^\delta(A) = 0$.

We note that the definition of trace gives us

$$\int_V |\mathbf{u}(\mathbf{x}',x_n)-\mathbf{v}(\mathbf{x}')|\,d\mathbf{x}' \le \int_V \int_0^{x_n} \left|\frac{\partial \mathbf{u}}{\partial x_n}\right|(\mathbf{x}',t)\,dt\,d\mathbf{x}'$$

for any (measurable) $V \subset \mathbb{R}^{n-1}$. Thus, if we write $\mathbf{a} = (\mathbf{a}',0)$ and let $Q(\mathbf{a},r)$ be the cube $\mathbf{a}+r(-\frac{1}{2},\frac{1}{2})^n$ and $Q'(\mathbf{a}',r) = \mathbf{a}'+r(-\frac{1}{2},\frac{1}{2})^{n-1}$, we find that

$$\left| \fint_{Q'(\mathbf{a}',r)} \mathbf{v}(\mathbf{x}')\,d\mathbf{x}' - \mathbf{u}^*(\mathbf{a})\right|$$

$$\le \fint_{Q(\mathbf{a},r)} \left|\mathbf{v}(\mathbf{x}')-\mathbf{u}(\mathbf{x}',x_n)\right| d\mathbf{x}'\,dx_n + \fint_{Q(\mathbf{a},r)} \left|\mathbf{u}(\mathbf{x})-\mathbf{u}^*(\mathbf{a})\right| d\mathbf{x}$$

$$\le r \fint_{Q(\mathbf{a},r)} \left|\frac{\partial \mathbf{u}}{\partial x_n}\right| d\mathbf{x} + \fint_{Q(\mathbf{a},r)} \left|\mathbf{u}(\mathbf{x})-\mathbf{u}^*(\mathbf{a})\right| d\mathbf{x}.$$

Therefore, $A \subset A_1 \cup A_2$, where

$$A_1 = \left\{\mathbf{a}\in\mathbb{R}^n : \limsup_{r\to 0^+} \; r \fint_{Q(\mathbf{a},r)} |D\mathbf{u}|\,d\mathbf{x} > 0\right\}$$

$$\subset \left\{\mathbf{a}\in\mathbb{R}^n : \limsup_{r\to 0^+} \; r^{p-n} \int_{Q(\mathbf{a},r)} |D\mathbf{u}|^p d\mathbf{x} > 0\right\} =: \hat{A}_1,$$

$$A_2 = \left\{\mathbf{a}\in\mathbb{R}^n : \limsup_{r\to 0^+} \fint_{Q(\mathbf{a},r)} \left|\mathbf{u}(\mathbf{x})-\mathbf{u}^*(\mathbf{a})\right| d\mathbf{x} > 0\right\}.$$

Thus, by [EG 92, §2.4.3, Thm. 3], $\mathcal{H}^{n-p}(\hat{A}_1) = 0$, while Proposition 2.7(ii) implies that $\mathcal{H}^\delta(A_2) = 0$ for all $\delta > n-p$. □

3. Proof of Theorem TL. To simplify the notation, we let $n = 3$. First, note that since $\mathbf{d}$ is continuous and one-to-one, it is an open mapping (see, e.g., [Sc 69, Cor. 3.2]). In particular, $\mathbf{d}(\Omega)$ is open and hence (see, e.g., [Ci 88, Thm. 1.2–7]) $\partial\mathbf{d}(\Omega) \subset \mathbf{d}(\partial\Omega)$. Thus, if $\mathbf{u}$ is continuous on any line segment $L \subset \Omega$, then either

(I) $\mathbf{u}(L) \subset \mathbf{d}(\Omega)$;
(E) $\mathbf{u}(L) \subset \mathbb{R}^n \backslash \mathbf{d}(\overline{\Omega})$; or
(B) $\mathbf{u}(L)$ contains a point $\mathbf{y} = \mathbf{d}(\mathbf{x})$ with $\mathbf{x} \in \partial\Omega$.

Moreover, in the last case, the point $\mathbf{m} \in L$ for which $\mathbf{y} = \mathbf{u}(\mathbf{m})$ must be contained in the set N of hypothesis (ii) with $\mathcal{H}^2(N) = 0$.

Next, let $\mathbf{a} \in \Omega$, $\delta > 0$ be such that the open cube

$$C := (a_1, a_1+\delta) \times (a_2, a_2+\delta) \times (a_3, a_3, +\delta) \subset \Omega$$

and define

$$C_{ij} = (a_i, a_i+\delta) \times (a_j, a_j+\delta)$$

for $i,j = 1,2,3$, $i<j$, the projection of C onto the i,j-plane. Then, in particular, by hypothesis (iii), there is an $\mathcal{L}^2$-measurable set $S_{23} \subset C_{23}$ with $\mathcal{L}^2(S_{23}) = \mathcal{L}^2(C_{23}) = \delta^2$

such that the function

$$t \mapsto \mathbf{u}(t, z_2, z_3), \quad t \in (a_1, a_1, +\delta)$$

is continuous for each $z = (z_2, z_3) \in S_{23}$.

Let S_I (S_E) be the subset of S_{23} such that the image under $\mathbf{u}$ of $(a_1, a_1 + \delta) \times S_I$ ($(a_1, a_1 + \delta) \times S_E$) is contained in $\mathbf{d}(\Omega)$ ($\mathbb{R}^n \backslash \mathbf{d}(\overline{\Omega})$). Note that by the first paragraph of this proof, $S_I \cap S_E = \emptyset$ and the set $S_{23} \backslash (S_I \cup S_E)$ must be contained in the projection of the $\mathcal{H}^2$ null set N onto the 2, 3-plane. Thus the $\mathcal{L}^2$-measure of $S_{23} \backslash (S_I \cup S_E)$ is zero and hence

$$\mathcal{L}^2(S_I \cup S_E) = \delta^2.$$

We will now show that S_I and S_E are each $\mathcal{L}^2$-measurable and one of these sets has $\mathcal{L}^2$-measure zero while the other has $\mathcal{L}^2$-measure δ^2. It will then follow that

$$\mathbf{u}(\mathbf{x}) \in \mathbf{d}(\Omega) \quad \text{for a.e. } \mathbf{x} \in C, \tag{3.1}$$

or

$$\mathbf{u}(\mathbf{x}) \in \mathbb{R}^n \backslash \mathbf{d}(\overline{\Omega}) \quad \text{for a.e. } \mathbf{x} \in C. \tag{3.2}$$

Let L_I (L_E) be the projection of S_I (S_E) on the x_2-axis and define (see Figure 1)

$$A_{12} := (a_1, a_1 + \delta) \times (L_I \cap L_E) \subset C_{12}.$$

Let $\mathbf{z} = (z_1, z_2) \in A_{12}$. Then by construction there are $z_3^I, z_3^E \in (a_3, a_3 + \delta)$ such that $(z_2, z_3^I) \in S_I$ and $(z_2, z_3^E) \in S_E$. Thus the image under $\mathbf{u}$ of the line segment $\{(t, z_2, z_3^I) : a_1 < t < a_1 + \delta\}$ is contained in $\mathbf{d}(\Omega)$ while the image under $\mathbf{u}$ of the line segment $\{(t, z_2, z_3^E) : a_1 < t < a_1 + \delta\}$ is contained in $\mathbb{R}^n \backslash \mathbf{d}(\overline{\Omega})$. We note that the line segment $\{(z_1, z_2, t) : a_3 < t < a_3 + \delta\}$ intersects both of these line segments and hence that $\mathbf{u}$ cannot be continuous on this line. Therefore, by hypothesis (iii), $\mathcal{L}^2(A_{12}) = 0$ and hence $\mathcal{L}^1(L_I \cap L_E) = 0$.

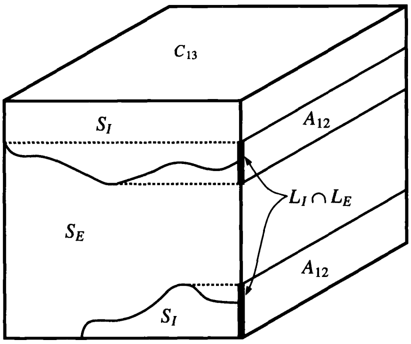

FIG. 1. *The cube C.*

Let L_I^* (L_E^*) be the projection of S_I (S_E) on the x_3-axis. Then by the argument used in the previous paragraph, $\mathcal{L}^1(L_I^* \cap L_E^*) = 0$. Now,

$$S_I \subset L_I \times L_I^* \subset C_{23}, \quad S_E \subset L_E \times L_E^* \subset C_{23},$$

and hence

$$S_I \cup S_E \subset (L_I \times L_I^*) \cup (L_E \times L_E^*) \subset C_{23}.$$

Since $\mathcal{L}^2(S_I \cup S_E) = \mathcal{L}^2(C_{23}) = \delta^2$, we conclude that the set $(L_I \times L_I^*) \cup (L_E \times L_E^*)$ is $\mathcal{L}^2$-measurable with measure δ^2 and hence, in particular, that

$$\mathcal{L}^2(L_I \times L_E^*) = 0.$$

A standard result from real analysis (e.g., Fubini's theorem) then implies that at least one of the sets L_I or L_E^* is $\mathcal{L}^1$-measurable with measure zero. Consequently, either S_I or S_E has $\mathcal{L}^2$-measure zero which gives us (3.1) or (3.2).

Next, let Ω_I (Ω_E) be the union of all open cubes $C \subset \Omega$, whose edges are parallel to the coordinate axes, such that (3.1) ((3.2)) is satisfied. Then Ω_I and Ω_E are open subsets of Ω and, by the above argument, $\Omega = \Omega_I \cup \Omega_E$. We note that $\Omega_I \cap \Omega_E$ is open. If it were nonempty, then it would contain an open cube C that would satisfy (3.1) and (3.2), which is not possible. Thus $\Omega_I \cap \Omega_E = \emptyset$. However, Ω is connected and hence either Ω_I or Ω_E must be empty.

Finally, let C_i, $i = 1, 2, 3, \ldots$ be an ordering of those open cubes in Ω_I or Ω_E that have edges of rational length and whose centers have rational coordinates. Then by the density of the rationals $\Omega = \bigcup_{i=1}^{\infty} C_i$. Now, by the conclusion of the previous paragraph, there are $M_i \subset C_i$ such that $\mathcal{L}^3(M_i) = 0$ and either $\mathbf{u}(C_i \backslash M_i) \subset \mathbf{d}(\Omega)$ for every i or $\mathbf{u}(C_i \backslash M_i) \subset \mathbb{R}^n \backslash \mathbf{d}(\overline{\Omega})$ for every i. Thus if we define $M := \bigcup_{i=1}^{\infty} M_i$, we conclude that $\mathcal{L}^3(M) = 0$ and either $\mathbf{u}(\Omega \backslash M) \subset \mathbf{d}(\Omega)$ or $\mathbf{u}(\Omega \backslash M) \subset \mathbb{R}^n \backslash \mathbf{d}(\overline{\Omega})$, which is the desired result. □

We note that Proposition 2.2 (the Jordan separation theorem) together with the proof of Theorem TL yield the following result, which we will use in the next section.

COROLLARY 3.1. *Let Ω be a domain in $\mathbb{R}^n$. Suppose that $\mathbf{u} : \overline{\Omega} \mapsto \mathbb{R}^n$ satisfies hypotheses* (ii) *and* (iii) *of Theorem TL. Assume further that the restriction $\mathbf{u}|_{\partial\Omega}$ is continuous and injective, that $\mathbb{R}^n \backslash \Omega$ consists of exactly two connected components, and hence* (*see Proposition* 2.2) *that $\mathbb{R}^n \backslash \mathbf{u}(\partial\Omega)$ consists of exactly two connected components U and V. Then*

$$\mathbf{u}(\mathbf{x}) \in U \quad \textit{for a.e. } \mathbf{x} \in \Omega \qquad \textit{or} \qquad \mathbf{u}(\mathbf{x}) \in V \quad \textit{for a.e. } \mathbf{x} \in \Omega.$$

4. Proof of Theorem AL.

We show first that for a function that satisfies the regularity and invertibility properties of Theorem AL, the Jacobian is of one sign.

LEMMA 4.1. *Let Ω be a domain in $\mathbb{R}^n$ and let $\mathbf{v} \in W^{1,p}(\Omega; \mathbb{R}^n)$ with $p > n - 1$. Suppose that $\det D\mathbf{v} \neq 0$ $\mathcal{L}^n$ a.e. and that there is an $\mathcal{H}^1$ null set $M \subset \Omega$ such that the precise representative $\mathbf{v}^*$ is injective on $\Omega \backslash M$. Then*

$$\det D\mathbf{v} > 0 \quad \mathcal{L}^n \textit{ a.e.} \qquad \textit{or} \qquad \det D\mathbf{v} < 0 \quad \mathcal{L}^n \textit{ a.e.}$$

Proof. We first show that $\operatorname{sgn}\det(\operatorname{ap} D\mathbf{v})$ is constant ($\mathcal{H}^{n-1}$ a.e.) on "most" spheres. Let $\mathbf{a} \in \Omega$ and $r_{\mathbf{a}} := \operatorname{dist}(\mathbf{a}, \partial\Omega)$. In view of Proposition 2.7, there exists an $\mathcal{L}^1$ null set $N_{\mathbf{a}}$ such that for $r \in (0, r_{\mathbf{a}}) \backslash N_{\mathbf{a}}$ one has

$$\begin{gathered}
\mathbf{v}^*|_S \in W^{1,p}(S; \mathbb{R}^n) \cap C^0(S; \mathbb{R}^n), \\
(\operatorname{ap} D)(\mathbf{v}^*|_S)(\mathbf{x}) = (\operatorname{ap} D\mathbf{v}^*)|_{T_{\mathbf{x}}S}(\mathbf{x}) \quad \text{for } \mathcal{H}^{n-1} \text{ a.e. } \mathbf{x} \in S, \\
|(\Lambda_{n-1}(\operatorname{ap} D\mathbf{v}^*))\boldsymbol{\nu}| > 0 \quad \text{for } \mathcal{H}^{n-1} \text{ a.e. on } S, \\
\mathcal{H}^{n-1}(S \backslash \Omega_1) = 0, \\
S \cap M = \emptyset,
\end{gathered}$$

where Ω_1 is the set that occurs in Proposition 2.6 and $\boldsymbol{\nu} = \frac{\mathbf{x}-\mathbf{a}}{|\mathbf{x}-\mathbf{a}|}$ is the outward unit to $S := S(\mathbf{a}, r)$. (To verify the third assertion, note that if $(\Lambda_{n-1}(\operatorname{ap} D\mathbf{v}^*)(\mathbf{x}))\mathbf{e} = \mathbf{0}$ for some $\mathbf{e} \neq \mathbf{0}$, then $\det((\operatorname{ap} D\mathbf{v}^*)(\mathbf{x})) = 0$.)

Let U be the bounded component of $\mathbb{R}^n\backslash\mathbf{v}^*(S(\mathbf{a},r))$ (see Proposition 2.2). Then by Corollary 3.1, there is an $\mathcal{L}^n$ null set N_{TL} such that

$$\mathbf{v}^*(B(\mathbf{a},r)\backslash N_{TL}) \subset U \tag{4.1}$$

or

$$\mathbf{v}^*(B(\mathbf{a},r)\backslash N_{TL}) \subset \mathbb{R}^n\backslash\overline{U}. \tag{4.2}$$

Also, by Lemma 2.4, U has finite perimeter and the generalized outer normal satisfies

$$\boldsymbol{\nu}(\mathbf{v}^*(\mathbf{x}),U) = m\frac{(\Lambda_{n-1}D\mathbf{v}^*(\mathbf{x}))\boldsymbol{\nu}(\mathbf{x})}{|(\Lambda_{n-1}D\mathbf{v}^*(\mathbf{x}))\boldsymbol{\nu}(\mathbf{x})|} \quad \text{for } \mathcal{H}^{n-1} \text{ a.e.} \quad \mathbf{x}\in S(\mathbf{a},r),$$

where m is a constant, which is either $+1$ or -1.

We now apply Proposition 2.6 and recall the definition (2.9) and (2.10) of the measure-theoretic normal. If (4.1) holds, one deduces

$$\operatorname{sgn}\det((\operatorname{ap}D\mathbf{v})(\mathbf{x})) = m \quad \text{for } \mathcal{H}^{n-1} \text{ a.e.} \quad \mathbf{x}\in S(\mathbf{a},r),$$

while (4.2) gives

$$\operatorname{sgn}\det((\operatorname{ap}D\mathbf{v})(\mathbf{x})) = -m \quad \text{for } \mathcal{H}^{n-1} \text{ a.e.} \quad \mathbf{x}\in S(\mathbf{a},r).$$

It follows that $\operatorname{sgn}\det((\operatorname{ap}D\mathbf{v})(\mathbf{x}))$ is constant on $S(\mathbf{a},r)$ ($\mathcal{H}^{n-1}$ a.e.) for $r\in(0,r_{\mathbf{a}})\backslash N_{\mathbf{a}}$.

Define

$$\psi := \operatorname{sgn}\det(\operatorname{ap}D\mathbf{v}), \quad \Omega^{\pm} := \{\mathbf{x}\in\Omega : \psi(\mathbf{x}) = \pm1\}.$$

We will show that the precise representative, ψ^*, of ψ is locally constant and the desired result will follow from the fact that Ω is connected.

Let $\mathbf{x}\in\Omega$ and assume for definiteness that $\psi^*(\mathbf{x}) = +1$. Suppose for the sake of contradiction that $\mathbf{y}\in B(\mathbf{x},r_{\mathbf{x}})$ satisfies $\psi^*(\mathbf{y}) = -1$. Define $\mathbf{a} = (\mathbf{x}+\mathbf{y})/2$, $\rho := |\mathbf{x}-\mathbf{y}|/2$, and note that $B(\mathbf{a},\rho)\subset\subset\Omega$. Also, define

$$A^{\pm} := \{r\in(0,r_{\mathbf{a}})\backslash N_{\mathbf{a}} : \mathcal{H}^{n-1}(\Omega^{\pm}\cap S(\mathbf{a},r)) > 0\}$$

and note that the sets $A^{\pm}$ are $\mathcal{L}^1$-measurable since the functions $t\mapsto\mathcal{H}^{n-1}(S(\mathbf{a},t)\cap\Omega^{\pm})$ are measurable (by Fubini's theorem or the coarea formula).

Now, since $\psi^*(\mathbf{x}) = +1$ and $|\mathbf{x}-\mathbf{a}| = \rho$, it follows that A^+ has density 1 at ρ. Similarly, since $\varphi^*(\mathbf{y}) = -1$, A^- must have density 1 at ρ. However, this is not possible since $A^+\cap A^- = \emptyset$. Therefore, $\varphi^*(\mathbf{y}) = +1$ for a.e. $\mathbf{y}\in B(\mathbf{x},r_{\mathbf{x}})$ which implies that $\varphi^*(\mathbf{y}) = +1$ for *every* $\mathbf{y}\in B(\mathbf{x},r_{\mathbf{x}})$. Since Ω is connected this gives the desired result. □

Proof of Theorem AL. We note that hypothesis (iii) and Lemma 4.1 yield $\det D\mathbf{u} > 0$ a.e. In order to prove that $\mathbf{u}(\mathbf{x})\in B = B(\mathbf{0},1)$, we will first show that there is an $\mathcal{H}^1$ null set N such that either

$$\mathbf{u}^*(B\backslash N)\subset B, \tag{4.3}$$

or

$$\mathbf{u}^*(B\backslash N)\subset\mathbb{R}^n\backslash\overline{B}. \tag{4.4}$$

Indeed, *define* a function $\tilde{\mathbf{u}} : \overline{B}\to\mathbb{R}^n$

$$\tilde{\mathbf{u}}(\mathbf{x}) := \begin{cases} \mathbf{u}^*(\mathbf{x}), & \mathbf{x}\in B, \\ \mathbf{x}, & \mathbf{x}\in\partial B. \end{cases}$$

Then $\tilde{\mathbf{u}}$ satisfies the hypotheses of Theorem TL since $\mathbf{u}^*(\mathbf{x}) = \mathbf{x}$ for $\mathcal{H}^1$ a.e. $\mathbf{x}\in\partial B$. (see Proposition 2.7 and Lemma 2.8). Thus we obtain (4.3) or (4.4) with $\mathcal{L}^n(N) = 0$.

Next, let P be the cap_p null set of Proposition 2.7. Then, since B is open, (4.3) and Proposition 2.7(ii) yield $\mathbf{u}^*(B\backslash P) \subset B$, while (4.4) and Proposition 2.7(ii) give us $\mathbf{u}^*(B\backslash P) \subset \mathbb{R}^n\backslash\overline{B}$.

If (4.3) is satisfied, then we are done. If instead (4.4) is satisfied, define an extension of $\mathbf{u}$ to $B(\mathbf{0},2)$ by

$$\mathbf{w}(\mathbf{x}) := \begin{cases} \mathbf{u}^*(\mathbf{x}), & \mathbf{x} \in B, \\ \mathbf{x}/|\mathbf{x}|^2, & \mathbf{x} \in B(\mathbf{0},2)\backslash B. \end{cases}$$

Then $\mathbf{w} \in W^{1,p}(B(\mathbf{0},2),\mathbb{R}^n)$ and by Lemma 2.8 $\mathbf{w}^*(\underset{\sim}{\mathrm{x}}) = \mathbf{w}(\mathbf{x})$ for $\mathcal{H}^1$ a.e. $\mathbf{x} \in B(\mathbf{0},2)$. Thus, by hypothesis (ii) and (4.4), $\mathbf{w}$ is injective off an $\mathcal{H}^1$ null set and hence $\mathbf{w}$ satisfies the hypotheses of Lemma 4.1. However, $\det D\mathbf{w} > 0$ a.e. on B and $\det D\mathbf{w} < 0$ a.e. on $B(\mathbf{0},2)\backslash\overline{B}$, which contradicts the conclusion of Lemma 4.1. Therefore, (4.3) must instead be satisfied. □

5. Counterexamples. We present two examples which show that hypothesis (ii) of Theorem TL cannot be relaxed to allow $\mathcal{H}^{n-1}(N) > 0$. For the first example, take $\Omega = B = B(\mathbf{0},1) \subset \mathbb{R}^2$, the unit disk. We construct a map $\mathbf{u} \in W^{1,p}(B;\mathbb{R}^2)$ (for all $p < 2$) that satisfies $\mathbf{u}|_{\partial B} = \mathbf{id}$ and whose image is $(B\backslash B(\mathbf{b},1/2)) \cup B(\mathbf{a},1/2)$, where $\mathbf{a} = (3/2,0)$ and $\mathbf{b} = (1/2,0)$ (see Figure 2). This will be achieved as follows. Each circle $S(\mathbf{0},r)$ is mapped to a union of two (reversely oriented) circles that touch only at the point $(1,0)$. These circles are nested (for different values or r) in such a way that as $r \longrightarrow 1$ the circles on the left increase to the unit circle while those on the right shrink to the point $(1,0)$. As $r \longrightarrow 0$, the circles approach the circles $S(\mathbf{a},1/2)$ and $S(\mathbf{b},1/2)$, respectively (see Figure 2). At the same time as the circles on the left increase, their preimage also occupies a larger position of $S(\mathbf{0},r)$. In such a way, it is possible to make $\mathbf{u}$ (Lipschitz) continuous away from the origin with $\mathbf{u} = \mathbf{id}$ on ∂B.

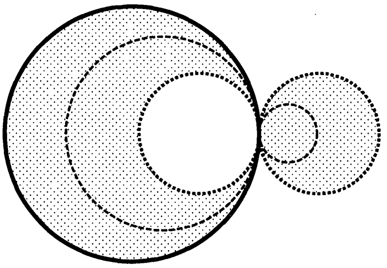

FIG. 2. *The image of a circle $S(\mathbf{0},R)$ for different values of R : $R = 1$ (solid line), $R = 1/2$ (dashed line), and asymptotically as $r \longrightarrow 0$ (dotted line). The filled region is the image under $\mathbf{u}$ of the unit disk.*

We now proceed with a detailed description of $\mathbf{u}$ and a verification of its properties. The circles on the left and the right are parametrized, respectively, by

$$\gamma_1(s,t) = (1-s,0) + s(\cos t, \sin t) \tag{5.1}$$

and

$$\gamma_2(s,t) = (1+s,0) + s(\cos t, -\sin t). \tag{5.2}$$

Let (R,θ) be polar coordinates in $\mathbb{R}^2$, and let

$$r = \frac{1+R}{2}$$

and

$$\mathbf{u}(R,\theta) = \begin{cases} \gamma_1\big(r, r^{-1}(\theta - (1-r)\pi)\big) & \text{if} \quad \pi(1-r) \le \theta \le 2\pi - \pi(1-r), \\ \gamma_2\big(1-r, (1-r)^{-1}\theta - \pi\big) & \text{if} \quad |\theta| < \pi(1-r). \end{cases}$$

One easily checks that $\mathbf{u}|_{\partial B} = \mathbf{id}$ and that $\mathbf{u}$ is Lipschitz away from the origin where $|\nabla \mathbf{u}|$ has a $1/R$ singularity. Hence $\mathbf{u} \in W^{1,p}(B; \mathbb{R}^2)$ for all $p < 2$ and, in particular, $\mathbf{u}$ is continuous on every straight line segment that does not pass through the origin. Now circles defined by (5.1) and (5.2) only have the point $(1,0)$ in common and this point corresponds to $t = 0$. Hence $\mathbf{u}|_{B\setminus N}$ is injective where

$$N = \left\{ (R\cos\theta, R\sin\theta) : \theta = \pm\pi\left(1 - \frac{R+2}{2}\right) \right\}$$

and $\mathcal{H}^1(N) > 0$. Note that one also has $\det D\mathbf{u} > 0$ a.e.

The function $\mathbf{u}$ is Lipschitz on $B\setminus\{\mathbf{0}\}$, but not C^1, since $\frac{\partial \mathbf{u}}{\partial\theta}$ is discontinuous at $\theta = \pm\pi(1-r)$. This could be fixed by reversing the orientation of the circles on the right, i.e., replacing $\gamma_2(s,t)$ by $\gamma_2(s,-t)$. Then, however, one loses the property $\det D\mathbf{u} > 0$ a.e.

For our second example, we take $\Omega = (-1,1) \times (-1,1) \subset \mathbb{R}^2$ and consider the composition of a number of maps, each of which has a simple physical interpretation. First, let

$$\mathbf{h}_0(x,y) = \frac{R+3}{4R}(x,y), \quad R = \max\{|x|, |y|\},$$

which opens a square hole at the center of the body (see Figure 3). We then compose with the map

$$\mathbf{h}_1(x,y) = \begin{cases} \big(x, 1 - (1-y)(7 - 8|x|)\big) & \text{if} \quad |x| < \frac{3}{4}, \quad \frac{3}{4} < y < 1, \\ \big(x, -1 + \frac{4}{3}|x|(y+1)\big) & \text{if} \quad |x| < \frac{3}{4}, \ -1 < y < -\frac{3}{4}, \\ (x,y) & \text{at all other points in the range of } \mathbf{h}_0, \end{cases}$$

which "pinches" part of the hole to the boundary and stretches another portion of the hole.

Next, we compose with the map

$$\mathbf{h}_2(x,y) = \begin{cases} \big(\frac{8xy}{4y+3}, y\big) & \text{if} \quad |x| < \frac{4y+3}{8}, \quad 0 \le y < \frac{3}{4}, \\ \big(\frac{-8xy}{4y+3}, y\big) & \text{if} \quad |x| < \frac{4y+3}{8}, \ -\frac{1}{4} < y \le 0, \\ (x,y) & \text{at all other points in the range of } \mathbf{h}_1 \circ \mathbf{h}_0, \end{cases}$$

which "pinches" the previously stretched portion of the hole. Finally, we compose with the map

$$\mathbf{h}_3(x,y) = \begin{cases} \big(x, 1 - \frac{(1-y)(6-7x)}{3(1-x)}\big) & \text{if} \quad |x| < \frac{3}{4}, \quad 0 \le y < 1, \\ (x, y-1) & \text{if} \quad |x| < \frac{3}{4}, \ -\frac{1}{4} < y \le 0, \\ (x,y) & \text{at all other points in the range of } \mathbf{h}_2 \circ \mathbf{h}_1 \circ \mathbf{h}_0, \end{cases}$$

which stretches the portion of the hole that was just pinched and moves a portion of it "outside" the body.

We note that each of the maps $\mathbf{h}_1, \mathbf{h}_2$, and $\mathbf{h}_3$ is Lipschitz on the range of the previous map and hence has a Lipschitz extention (see, e.g., [Fe 69, Thm. 2.10.43] or [EG 92]) to all of $\mathbb{R}^2$. In addition, Ball and Murat [BM 84] have shown that

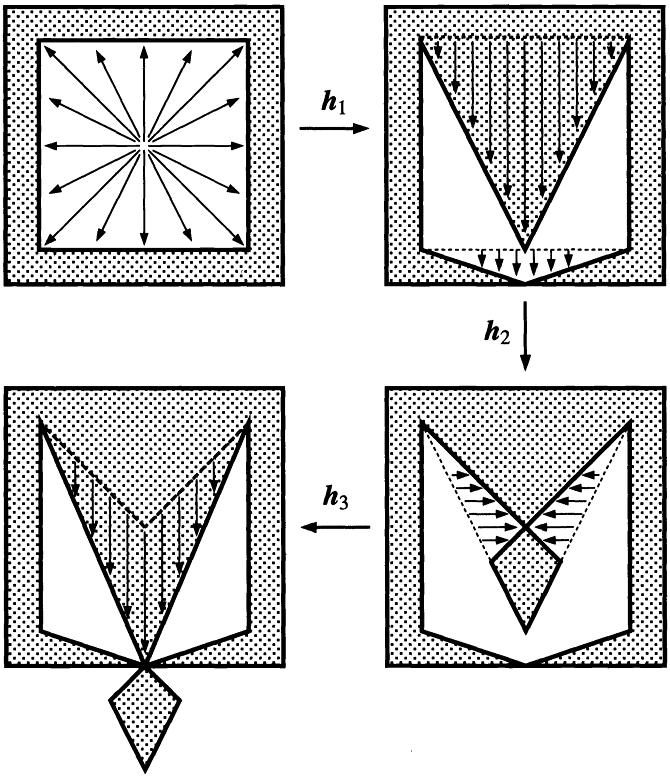

FIG. 3. *After cavitation, successive stretches and pinches cause a portion of the material to penetrate the boundary.*

$\mathbf{h}_0 \in W^{1,p}(\Omega;\mathbb{R}^2)$ for all $1 \leq p < 2$. Thus, by the chain rule (see, e.g., [Zi 89]), $\mathbf{u} = \mathbf{h}_3 \circ \mathbf{h}_2 \circ \mathbf{h}_1 \circ \mathbf{h}_0 \in W^{1,p}(\Omega;\mathbb{R}^2)$.

It is clear that one could also construct such an example that is C^1 away from the cavitation and pinching points.

QUASI-LINEAR RELAXED DIRICHLET PROBLEMS*

STEFANO FINZI VITA[†], FRANÇOIS MURAT[‡], AND NICOLETTA A. TCHOU[§]

Abstract. We study the existence and the asymptotic behavior of solutions of quasi-linear elliptic problems with homogeneous Dirichlet boundary conditions for the so-called *relaxed Dirichlet problems*. These problems, introduced in the linear case by Dal Maso and Mosco [*Arch. Rational Mech. Anal.*, 95 (1986), pp. 345–387; *Appl. Math. Optim.*, 15 (1987), pp. 15–63], involve zero-order terms with Borel measures, which can take infinite values but vanish on sets with zero capacity.

We prove two existence results when the nonlinear term has quadratic growth with respect to the gradient by extending the techniques of Boccardo, Murat, and Puel [*Res. Notes in Math.* 84, Pitman, London, 1983, pp. 19–73] to the relaxed case. We also prove in the subquadratic case a stability property for bounded solutions with respect to the γ-convergence of measures when the limit measure is sufficiently regular, making essential use of the correctors result of Finzi Vita and Tchou [*Asymptotic Anal.*, 5 (1992), pp. 269–281].

1. Introduction.

We are interested in the study of quasi-linear relaxed Dirichlet problems that can *formally* be written as

$$(1.1)\qquad \begin{cases} -\Delta u + \lambda_0 u + \mu u = f(x, u, Du) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where Ω is a bounded domain in $\mathbb{R}^N$, λ_0 is a nonnegative constant, f is a given function that satisfies a quadratic growth hypothesis with respect to Du, and μ is a measure in the class $M_0(\Omega)$ of all nonnegative Borel measures on Ω that vanish on subsets of Ω with zero harmonic capacity. We remark that this definition allows $\mu(B) = +\infty$ on some Borel subset B of Ω with positive capacity, as shown by the example of the measure ∞_S that is defined, for a given subset S of Ω with $\text{cap}(S) > 0$, by

$$\infty_S(A) := \begin{cases} 0 & \text{if } \text{cap}(S \cap A) = 0, \\ +\infty & \text{if } \text{cap}(S \cap A) > 0, \end{cases}$$

for any Borel subset A of Ω.

To give a precise and correct meaning to solutions of problems such as (1.1), we first recall the meaning of the solution in the linear case, i.e., for problems that can be formally written as

$$(1.2)\qquad \begin{cases} -\Delta u + \mu u = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

for a given $f \in H^{-1}(\Omega)$. Problems of type (1.2) have been introduced by G. Dal Maso and U. Mosco in [DM2] to study limits of Dirichlet problems in highly perturbed domains (see also [CM]).

For every $\mu \in M_0(\Omega)$, we denote by $L^2_\mu(\Omega)$ the space of square integrable functions with respect to the measure μ and by $V_\mu(\Omega)$ the Hilbert space $H^1_0(\Omega) \cap L^2_\mu(\Omega)$, equipped with the scalar product

$$((v,w))_\mu := \int_\Omega DvDw\,dx + \int_\Omega vw\,d\mu.$$

The solution u of problem (1.2) is then defined as the unique function of $V_\mu(\Omega)$, which solves

$$((u,v))_\mu = \langle f,v\rangle_{H^{-1},H^1_0} \quad \text{for all } v \in V_\mu(\Omega), \tag{1.3}$$

or, equivalently, as the unique minimizing point in $V_\mu(\Omega)$ of the functional $((v,v))_\mu - 2\langle f,v\rangle_{H^{-1},H^1_0}$.

We refer to [DM1] and [DM2] for detailed studies of the properties of these solutions. Let us only mention that (1.2) is only a formal writing of (1.3) and that in general one does not have $-\Delta u + \mu u = f$ in the distributional sense in Ω, since in general the $C^\infty_0(\Omega)$ functions do not belong to $L^2_\mu(\Omega)$ (consider, for example, the case $\mu = \infty_S$ described above).

We now recall the notion of γ-convergence of measures, which is defined by means of the Γ-convergence of the corresponding functionals defined in $L^2(\Omega)$: for every $\mu \in M_0(\Omega)$, let J_μ be the functional defined by

$$J_\mu(v) = \begin{cases} ((v,v))_\mu = \displaystyle\int_\Omega |Dv|^2\,dx + \int_\Omega v^2\,d\mu & \text{if } v \in V_\mu(\Omega), \\ +\infty & \text{if } v \in L^2(\Omega) \setminus V_\mu(\Omega). \end{cases}$$

DEFINITION 1.1. *The sequence μ_ϵ in $M_0(\Omega)$ is said to* γ-converge *to a measure $\mu_0 \in M_0(\Omega)$ ($\mu_\epsilon \xrightarrow{\gamma} \mu_0$) if the corresponding functionals J_{μ_ϵ} Γ-converge to the functional J_{μ_0} in the space $L^2(\Omega)$; that is, if*

(i) *for every $v \in L^2(\Omega)$ and for every sequence v_ϵ converging to v in $L^2(\Omega)$ one has*

$$J_{\mu_0}(v) \le \liminf_\epsilon J_{\mu_\epsilon}(v_\epsilon),$$

(ii) *for every $v \in L^2(\Omega)$ there exists a sequence v_ϵ converging to v in $L^2(\Omega)$ such that*

$$J_{\mu_0}(v) = \lim_\epsilon J_{\mu_\epsilon}(v_\epsilon).$$

The previous convergence can be proved to be equivalent to the strong convergence in $L^2(\Omega)$ of the resolvent operators of problem (1.3) (see [DM2]): in other words, μ_ϵ γ-converges to μ_0 if and only if for every $f \in L^2(\Omega)$ the solutions u_ϵ of (1.3) for μ_ϵ converge strongly in $L^2(\Omega)$ (and weakly in $H^1_0(\Omega)$) to the solution u_0 of (1.3) for μ_0. In [DM2] it is shown that the set $M_0(\Omega)$ is closed and sequentially compact with respect to the γ-convergence and that the measures ∞_S defined above as well as the regular measures with bounded density with respect to the Lebesgue measure are dense in $M_0(\Omega)$. These results give motivation to the use of the class $M_0(\Omega)$. Relaxed Dirichlet problems such as (1.2) form in fact the smallest family of equations, stable under the $L^2(\Omega)$ convergence of the solutions, which contains Dirichlet problems for the Laplace operator on any subdomain A of Ω (which are formally equivalent, by definition, to relaxed problems of type (1.2) with measures $\mu = \infty_S$, $S = \Omega - A$). Moreover, as already remarked, this class of measures gives the structure of a Hilbert space to the space $V_\mu(\Omega)$.

Let us consider the space

$$V^1_\mu(\Omega) := \{v \in H^1(\Omega) \cap L^2_\mu(\Omega) : v - 1 \in H^1_0(\Omega)\}.$$

We are now in position to state the definition of correctors (see [T], [CM]).

DEFINITION 1.2. *If the sequence μ_ϵ in $M_0(\Omega)$ γ-converges to μ_0, a sequence w_ϵ in $V^1_{\mu_\epsilon}(\Omega)$ is said to be a sequence of* correctors *for problem* (1.2) *if, for any $f \in L^2(\Omega)$, defining u_ϵ and u_0 as the solutions of* (1.3) *for μ_ϵ and μ_0, one has, as ϵ tends to zero,*

$$u_\epsilon - w_\epsilon u_0 \to 0 \textit{ strongly in } W^{1,1}_0(\Omega). \tag{1.4}$$

In other words,

$$Du_\epsilon = D(w_\epsilon u_0) + r_\epsilon, \textit{ with } r_\epsilon \to 0 \textit{ strongly in } (L^1(\Omega))^N.$$

We recall the following definition (see [DM2]).

DEFINITION 1.3. *Assume that $V^1_\mu(\Omega)$ is not empty. The* μ-capacitary potential *z associated with a measure $\mu \in M_0(\Omega)$ is defined as the unique minimum point in $V^1_\mu(\Omega)$ of the functional $J_\mu(.)$.*

Note that Definition 1.3 has a meaning only if the space $V^1_\mu(\Omega)$ is not empty—a hypothesis that we will always suppose to be satisfied. This is, for example, the case if μ is assumed to be zero in a neighborhood of $\partial\Omega$.

By definition, then z solves the variational problem

$$z \in V^1_\mu(\Omega), \quad ((z, v))_\mu = 0 \text{ for all } v \in V_\mu(\Omega); \tag{1.5}$$

i.e., z is a solution of the relaxed problem that can formally be written as

$$\begin{cases} -\Delta z + \mu z = 0 & \text{in } \Omega, \\ z = 1 & \text{on } \partial\Omega. \end{cases}$$

Moreover, $z \in L^\infty(\Omega)$ since it can be easily proved that $0 \le z \le 1$ (in the sense of $H^1(\Omega)$).

Making use of Definition 1.3, [FT] suggests a method for constructing a sequence of correctors. Let us denote by $z_\epsilon \in V^1_{\mu_\epsilon}(\Omega)$ and $z_0 \in V^1_{\mu_0}(\Omega)$ the capacitary potentials associated with μ_ϵ and μ_0, respectively. Under the assumption (1.8) on the limit measure μ_0, the functions

$$w_\epsilon = \frac{z_\epsilon}{z_0} \tag{1.6}$$

define a sequence of correctors for problem (1.3), in accordance with Definition 1.2. More precisely one has (see [FT, Thm. 3.6]) the following theorem.

THEOREM 1.4. *Let Ω be sufficiently smooth, and assume that a sequence μ_ϵ is given in $M_0(\Omega)$ such that for every ϵ the spaces $V^1_{\mu_\epsilon}(\Omega)$ are not empty and*

$$\mu_\epsilon \xrightarrow{\gamma} \mu_0. \tag{1.7}$$

Assume also that

$$\mu_0 = m(x)dx, \qquad m \in L^\infty(\Omega),\ m \geq 0, \tag{1.8}$$

and that

$$f \in L^\infty(\Omega). \tag{1.9}$$

Then the functions w_ϵ *defined by* (1.6) *are in* $V^1_{\mu_\epsilon}(\Omega) \cap L^\infty(\Omega)$, *and for the solutions* u_ϵ *and* u_0 *of* (1.3) *corresponding to* μ_ϵ *and* μ_0 *one has the corrector result*

$$\|u_\epsilon - w_\epsilon u_0\|_{H^1_0(\Omega)} \to 0. \tag{1.10}$$

Remark 1.1. It is easily shown that $0 \leq z_\epsilon \leq 1$, while hypothesis (1.8) implies that $\alpha \leq z_0 \leq 1$ for some $\alpha > 0$ (see [FT, Prop. 3.2]). Thus w_ϵ is bounded in $L^\infty(\Omega)$. The sequence w_ϵ is also bounded in $H^1_0(\Omega)$ because $1/z_0$ can be proved to belong to $W^{1,\infty}(\Omega)$ under the hypothesis (1.8). Thus

$$w_\epsilon \rightharpoonup 1 \text{ weakly in } H^1(\Omega).$$

This property actually holds (see [DM2] or [FT, Rem. 3.1]) under the assumption that Ω belongs, with respect to μ_0, to a *rich* class of sets. This is the case here, since for a Radon measure it has been proved in [DM2] that this class contains all bounded Borel sets E with $\mu_0(\partial E) = 0$.

Theorem 1.1 extends, with a different definition of correctors, the results obtained by D. Cioranescu and F. Murat [CM] in an "abstract" setting that applies to the case of periodically perforated domains with holes of critical size.

Hypotheses (1.8) and (1.9) of Theorem 1.1 can be weakened (see [FT]). Moreover, we mention that another sequence of correctors has been recently proposed by A. Garroni and G. Dal Maso [GDM] (see also [Ca2], [CG], [DMM1], and [DMM2] for the nonlinear case) whose main advantage is that no hypothesis (on, for example, $V^1_{\mu_\epsilon}(\Omega)$, $\partial\Omega$) is required for it to work.

Let us come back to the quasi-linear problem (1.1). We shall consider in §2 nonlinear terms f with quadratic growth with respect to the gradient under two different sets of hypotheses.

(a) *Bounded case.* We assume $\lambda_0 > 0$ and that $|f(x,s,p)| \leq c_0 + b(|s|)|p|^2$ for some constant c_0 and function b; we are interested in bounded weak solutions and offer the following more precise definition.

DEFINITION 1.5. *A bounded weak solution of* (1.1) *is a function* u *such that*

$$\begin{cases} u \in V_\mu(\Omega) \cap L^\infty(\Omega), \\ ((u,v))_\mu + \lambda_0 \displaystyle\int_\Omega uv\,dx = \int_\Omega f(x,u,Du)v\,dx \quad \textit{for all } v \in V_\mu(\Omega) \cap L^\infty(\Omega). \end{cases} \tag{1.11}$$

(b) *Unbounded case.* We discuss the interesting case where $f(x,s,p) = h(x) - g(x,s,p)$, h is in $H^{-1}(\Omega)$, and g satisfies $|g(x,s,p)| \leq b(|s|)(1+|p|^2)$ as well as the sign condition $g(x,s,p)s \geq 0$. The term $\lambda_0 u$ can be included in g in this case, so we will only consider $\lambda_0 = 0$. Then (1.1) becomes

$$\begin{cases} -\Delta u + \mu u + g(x,u,Du) = h & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.12}$$

and we cannot expect a possible solution to be in $L^\infty(\Omega)$ (consider the case where $\mu = 0$ and $g = 0$; the solution is only in $H_0^1(\Omega)$ since h belongs to $H^{-1}(\Omega)$).

DEFINITION 1.6. *A weak solution of* (1.12) *is a function u such that*

$$(1.13)\quad \begin{cases} u \in V_\mu(\Omega), \quad g(x,u,Du) \in L^1(\Omega), \quad g(x,u,Du)u \in L^1(\Omega), \\ ((u,v))_\mu + \displaystyle\int_\Omega g(x,u,Du)v\,dx = \langle h,v\rangle_{H^{-1},H_0^1} \quad \textit{for all } v \in V_\mu(\Omega) \cap L^\infty(\Omega). \end{cases}$$

In the bounded case (a), by extending the techniques of [BMP1] to the relaxed case, we will prove in Theorem 2.1 the existence of a bounded weak solution of problem (1.11).

The proof will also imply that the bounded weak solutions of (1.11), in the sense of Definition 1.4, are uniformly bounded in $L^\infty(\Omega) \cap H_0^1(\Omega)$, independently of the measure μ. This property of solutions will be essential for us to prove, in §3, the homogenization result of Theorem 3.1. In this theorem we prove a stability property of solutions of (1.11) with respect to the γ-convergence of measures when the growth of f with respect to Du is assumed to be strictly subquadratic. An important role is played in the proof of this result by the use of the correctors (1.6) of the linear equation.

Note that this homogenization result is no more true in the case of an "exactly quadratic" (not strictly subquadratic) growth for f. Indeed, it has recently been shown by J. Casado-Diaz [Ca1] that in the exactly quadratic case the linear corrector result is no more valid. A new corrector has been constructed, and an extra nonlinear term appears in front of the measure μ_0 (see Remark 3.2 at the end of §3).

In the unbounded case (b), we shall prove in Theorem 2.2 of §2 the existence of weak solutions (without any L^∞ bound) for the relaxed quasi-linear problem (1.13). This result extends the results of [BMP2] and [BBM] to relaxed problems.

2. Existence results.

In this section we prove two existence results for the solutions of the relaxed quasi-linear elliptic problems (1.11) and (1.13).

2.1. The bounded case.

Let us assume that

$$(E_a1)\qquad \lambda_0 > 0, \qquad \mu \in M_0(\Omega),$$

$$(E_a2)\qquad \begin{cases} f : \Omega \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}^N \text{ is a Carathéodory function satisfying} \\ |f(x,s,p)| \le c_0 + b(|s|)|p|^2, \end{cases}$$

where $b(.)$ is an increasing function from $\mathbb{R}^+$ to $\mathbb{R}^+$ and $c_0 \in \mathbb{R}^+$.

THEOREM 2.1. *Under assumptions* (E_a1) *and* (E_a2), *there exists at least a bounded weak solution u of problem* (1.11).

Remark 2.1. Theorem 2.1 extends the result of [BMP1, Thm. 2.1] to the case of relaxed Dirichlet problems. The proof is henceforth very similar; nevertheless, for the sake of completeness we prefer to repeat its main steps, underlying the changes we have to make in the present case (particularly in Step 3).

Proof. We divide the proof into four steps:

Step 1: *Existence of approximate solutions.* We construct a sequence of problems that approximate (1.11) by introducing for $\epsilon > 0$ the bounded Carathéodory function

$$f_\epsilon(x,s,p) = \frac{f(x,s,p)}{1 + \epsilon|f(x,s,p)|};$$

note that $|f_\epsilon(x,s,p)| \leq \frac{1}{\epsilon}$ and $|f_\epsilon(x,s,p)| \leq |f(x,s,p)|$.

We shall first prove, for $\epsilon > 0$ fixed, the existence of a solution u_ϵ of the quasilinear problem

$$(1.11_\epsilon)\quad \begin{cases} \displaystyle\int_\Omega Du_\epsilon Dv\,dx + \lambda_0 \int_\Omega u_\epsilon v\,dx + \int_\Omega u_\epsilon v\,d\mu = \int_\Omega f_\epsilon(x,u_\epsilon,Du_\epsilon)v\,dx \quad \text{for all } v \in V_\mu(\Omega), \\ u_\epsilon \in V_\mu(\Omega) \cap L^\infty(\Omega), \end{cases}$$

which can be formally written as

$$\begin{cases} -\Delta u_\epsilon + \lambda_0 u_\epsilon + \mu u_\epsilon = f_\epsilon(x,u_\epsilon,Du_\epsilon) & \text{in } \Omega, \\ u_\epsilon = 0 & \text{on } \partial\Omega. \end{cases}$$

Since for ϵ fixed the application $w \to f_\epsilon(x,w,Dw)$ is bounded from $H_0^1(\Omega)$ into $L^\infty(\Omega)$, the mapping $S : V_\mu(\Omega) \to V_\mu(\Omega)$ that associates with each function $w \in V_\mu(\Omega)$ the unique solution $\overline{w} = Sw$ of the linear problem

$$\begin{cases} \displaystyle\int_\Omega D\overline{w}Dv\,dx + \lambda_0 \int_\Omega \overline{w}v\,dx + \int_\Omega \overline{w}v\,d\mu = \int_\Omega f_\epsilon(x,w,Dw)v\,dx \quad \text{for all } v \in V_\mu(\Omega), \\ \overline{w} \in V_\mu(\Omega), \end{cases}$$

which formally reads as

$$\begin{cases} -\Delta\overline{w} + \lambda_0\overline{w} + \mu\overline{w} = f_\epsilon(x,w,Dw) & \text{in } \Omega, \\ \overline{w} = 0 & \text{on } \partial\Omega, \end{cases}$$

satisfies the hypotheses of the Schauder fixed-point theorem. Thus (1.11_ϵ) has at least a solution that belongs to $V_\mu(\Omega)$. Moreover, this solution is in $L^\infty(\Omega)$, with

$$(2.1)\qquad -\frac{1}{\lambda_0\epsilon} \leq u_\epsilon \leq \frac{1}{\lambda_0\epsilon}.$$

To prove this, we use the function $z_\epsilon = (u_\epsilon - 1/(\lambda_0\epsilon))^+$ as the test function in problem (1.11_ϵ). This is possible since $z_\epsilon \in H_0^1(\Omega)$; moreover, $0 \leq z_\epsilon \leq u_\epsilon^+$, so z_ϵ belongs to $L^2_\mu(\Omega)$ and thus to $V_\mu(\Omega)$. Then, since $\mu \geq 0$ and $|f_\epsilon| \leq \frac{1}{\epsilon}$,

$$\begin{aligned} \int_\Omega |Dz_\epsilon|^2\,dx &\leq \int_\Omega (-\lambda_0 u_\epsilon + f_\epsilon(x,u_\epsilon,Du_\epsilon))z_\epsilon\,dx \\ &\leq \int_\Omega \left(-\lambda_0 u_\epsilon + \frac{1}{\epsilon}\right) z_\epsilon\,dx = \int_\Omega \left(-\lambda_0 u_\epsilon + \frac{1}{\epsilon}\right)\left(u_\epsilon - \frac{1}{\lambda_0\epsilon}\right)^+ dx \leq 0, \end{aligned}$$

so that $z_\epsilon = 0$. This proves one of the inequalities of (2.1). The other inequality is proved in the same way by considering the test function $z_\epsilon = -(u_\epsilon + 1/(\lambda_0\epsilon))^-$. Thus $u_\epsilon \in L^\infty(\Omega)$.

By this method we have also proved that $u_\epsilon \in L^\infty_\mu(\Omega)$. Indeed, from $z_\epsilon = 0$ in the sense of $H_0^1(\Omega)$, we deduce that $z_\epsilon = 0$ except on a set E of zero capacity; thanks to the definition of the space $M_0(\Omega)$, we have $\mu(E) = 0$ and we deduce $z_\epsilon = 0$ in $L^\infty_\mu(\Omega)$ too. In fact, this proof asserts that $H_0^1(\Omega) \cap L^\infty(\Omega) \subseteq H_0^1(\Omega) \cap L^\infty_\mu(\Omega)$.

Step 2: The solutions u_ϵ of problem (1.11_ϵ) are uniformly bounded in $V_\mu(\Omega) \cap L^\infty(\Omega)$. It is enough here to repeat the proofs of Steps 2 and 3 of Theorem 2.1 of

[BMP1], which is concerned with the case where $\mu = 0$. To prove the uniform bound in $L^\infty(\Omega)$, we remark that the functions $T_\epsilon(z_\epsilon^+)$, where

$$T_\epsilon(v) = v\ \exp(t_\epsilon v^2), \quad z_\epsilon = u_\epsilon - \frac{c_0}{\lambda_0}, \quad t_\epsilon = \frac{b(\|u_\epsilon\|_{L^\infty})^2}{2},$$

can be used as test functions in (1.11_ϵ) since $z_\epsilon^+ \in V_\mu(\Omega) \cap L^\infty(\Omega) \cap L^\infty_\mu(\Omega)$. Then the same computations as in [BMP1] yield, using the hypothesis (E_a1),

$$\|u_\epsilon\|_{L^\infty} \le \frac{c_0}{\lambda_0},$$

and the same estimate holds in $L^\infty_\mu(\Omega)$. Let

$$c_1 = b\left(\frac{c_0}{\lambda_0}\right).$$

To show the uniform estimate in $H_0^1(\Omega)$, we use as test function in (1.11_ϵ) the function $T(u_\epsilon) \in V_\mu(\Omega)$, where $T(v) = v\ \exp(tv^2)$ and $t = c_1^2/2$. This leads us to the inequality

$$\int_\Omega |Du_\epsilon|^2\,dx + \int_\Omega u_\epsilon^2\,d\mu \le K, \tag{2.2}$$

which means that u_ϵ is uniformly bounded in $V_\mu(\Omega)$.

Extracting a subsequence (still denoted by u_ϵ), we have proved the existence of a function $u \in V_\mu(\Omega) \cap L^\infty(\Omega)$ such that

$$u_\epsilon \rightharpoonup u \text{ weakly in } H_0^1(\Omega);$$

$$u_\epsilon \rightharpoonup u \text{ weakly in } L^2_\mu(\Omega);$$

$$u_\epsilon \to u \text{ strongly in } L^p(\Omega) \text{ for any } p < +\infty \text{ and weakly * in } L^\infty(\Omega);$$

$$u_\epsilon \to u \text{ a.e. in } \Omega.$$

Hence, we conclude in particular that

$$\|u\|_{L^\infty} \le \frac{c_0}{\lambda_0}.$$

Note that this $L^\infty(\Omega)$ bound as well as the $H_0^1(\Omega)$ bound

$$\|u\|_{H_0^1(\Omega)} \le K,$$

which is easily derived from (2.2), do not depend on the measure μ but only on c_0, λ_0, c_1, and Ω.

Step 3: *The sequence u_ϵ converges strongly in $H_0^1(\Omega)$ and $L^2_\mu(\Omega)$ to the function u.* This step is the more original one with respect to the proof of [BMP1] and uses an argument that was used in [Mo] in the context of nonlinear parabolic equations. Let ϵ and η be two positive parameters and u_ϵ and u_η be the corresponding solutions of (1.11_ϵ) and (1.11_η). Let $T(v) = v \exp(tv^2)$ and $t = 16c_1^2$. Subtracting (1.11_η) from (1.11_ϵ) and using the test function $T(u_\epsilon - u_\eta)$, which belongs to $V_\mu(\Omega)$, we obtain

$$\begin{aligned} \int_\Omega |Du_\epsilon - Du_\eta|^2 T'(u_\epsilon - u_\eta)\,dx &+ \lambda_0 \int_\Omega (u_\epsilon - u_\eta)T(u_\epsilon - u_\eta)\,dx \\ &+ \int_\Omega (u_\epsilon - u_\eta)T(u_\epsilon - u_\eta)\,d\mu \\ &= \int_\Omega [f_\epsilon(x, u_\epsilon, Du_\epsilon) - f_\eta(x, u_\eta, Du_\eta)]T(u_\epsilon - u_\eta)\,dx \\ &\le \int_\Omega [2c_0 + c_1|Du_\epsilon|^2 + c_1|Du_\eta|^2]|T(u_\epsilon - u_\eta)|\,dx \\ &\le \int_\Omega [2c_0 + 3c_1|Du_\epsilon|^2]|T(u_\epsilon - u_\eta)|\,dx \\ &+ \int_\Omega 2c_1|Du_\epsilon - Du_\eta|^2|T(u_\epsilon - u_\eta)|\,dx, \end{aligned} \tag{2.3}$$

where we have used the hypothesis (E_a2) on f and $|f_\epsilon| \le |f|$. Since the second and third integrals of the left-hand side are nonnegative, we get

$$\begin{aligned} \int_\Omega |Du_\epsilon - Du_\eta|^2 [T'(u_\epsilon - u_\eta) - 2c_1|T(u_\epsilon - u_\eta)|]\,dx \\ \le \int_\Omega [2c_0 + 3c_1|Du_\epsilon|^2]|T(u_\epsilon - u_\eta)|\,dx. \end{aligned}$$

The choice of t implies $T'(v) - 8c_1|T(v)| \ge \frac{1}{2}$. Now let η go to zero; by the results of Step 2 on the sequence u_η, the continuity of the functions T and T', and the weak lower semicontinuity of the left-hand side, we easily pass to the limit (as η tends to zero and ϵ is fixed) in the previous inequality, so that

$$\begin{aligned} \int_\Omega |Du_\epsilon - Du|^2 [T'(u_\epsilon - u) - 2c_1|T(u_\epsilon - u)|]\,dx \\ \le \int_\Omega [2c_0 + 3c_1|Du_\epsilon|^2]|T(u_\epsilon - u)|\,dx \\ \le \int_\Omega [2c_0 + 6c_1|Du|^2 + 6c_1|Du_\epsilon - Du|^2]|T(u_\epsilon - u)|\,dx. \end{aligned}$$

Then for t fixed as before,

$$\begin{aligned} \frac{1}{2}\int_\Omega |Du_\epsilon - Du|^2\,dx &\le \int_\Omega |Du_\epsilon - Du|^2[T'(u_\epsilon - u) - 8c_1|T(u_\epsilon - u)|]\,dx \\ &\le \int_\Omega [2c_0 + 6c_1|Du|^2]|T(u_\epsilon - u)|\,dx. \end{aligned}$$

Since the last integral tends to zero as ϵ tends to zero, we have proved that u_ϵ tends to u strongly in $H_0^1(\Omega)$. This convergence is strong in $L^2_\mu(\Omega)$ too, since, coming back to the first inequality in (2.3), we get

$$\begin{aligned} \int_\Omega |u_\epsilon - u_\eta|^2\,d\mu &\le \int_\Omega (u_\epsilon - u_\eta)T(u_\epsilon - u_\eta)\,d\mu \\ &\le \int_\Omega [2c_0 + c_1|Du_\epsilon|^2 + c_1|Du_\eta|^2]|T(u_\epsilon - u_\eta)\,dx, \end{aligned}$$

which is easily shown to converge to zero.

Step 4: *Passing to the limit in* (1.11_ϵ) *and proving that u is a solution of problem* (1.11). By Step 3 we know that (up to the extraction of a subsequence) $Du_\epsilon \to Du$ a.e. in Ω. Then $f_\epsilon(u_\epsilon, Du_\epsilon) \to f(u, Du)$ a.e. in Ω. Since $|f_\epsilon(u_\epsilon, Du_\epsilon)| \le c_0 + c_1|Du_\epsilon|^2$, which converges strongly in $L^1(\Omega)$, Vitali's theorem ensures that $f_\epsilon(u_\epsilon, Du_\epsilon) \to f(u, Du)$ strongly in $L^1(\Omega)$. This shows that u solves problem (1.11), as we wanted to prove. □

Remark 2.2. As already observed in [BMP1, Rem. 3.3], the strict positivity of λ_0 (first part of assumption (E_a1)) is essential in the proof of Theorem 1.1 because it allows us to obtain the $L^\infty(\Omega)$ bound on u_ϵ. Since the term containing the measure could degenerate somewhere in Ω (either with $\mu = 0$ or with $\mu = +\infty$), the existence of a solution is no more guaranteed in the absence of the zero-order term in the operator. As a counterexample, one could consider the counterexample introduced by J. L. Kazdan and R. J. Kramer in [KK] (see also [BMP1, Contre-ex. 3.1]) with an extra term μu, with either $\mu \equiv 0$ or $\mu = \infty_E$, E being a closed subset of Ω.

Of course, hypothesis (E_a1) can be replaced by

$$\lambda_0 \ge 0, \quad \mu \in M_0(\Omega), \quad \mu + \lambda_0\, dx \ge a_0 dx$$

for a strictly positive constant a_0.

2.2. The unbounded case. Let us now consider the problem (1.13) and assume that

$$(E_b1) \qquad \mu \in M_0(\Omega), \quad h = -\operatorname{div} r \in H^{-1}(\Omega), \quad r \in (L^2(\Omega))^N,$$

$$(E_b2) \qquad \begin{cases} g : \Omega \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}^N \text{ is a Carathéodory function satisfying} \\ |g(x,s,p)| \le b(|s|)(1+|p|^2) \\ \text{and} \\ g(x,s,p)s \ge 0, \end{cases}$$

where $b(.)$ is a continuous and increasing function from $\mathbb{R}^+$ to $\mathbb{R}^+$.

As already remarked, the main feature of this case is that, due to the lack of regularity of h, a solution of (1.13) is no more in $L^\infty(\Omega)$. This property, which was crucial in the proof of Theorem 2.1, now must be replaced by the use of truncations (see also [BBM], [BGM], [LM], and [M], where the same idea is used).

THEOREM 2.2. *Under assumptions* (E_b1) *and* (E_b2), *there exists at least a weak solution u of problem* (1.13).

Proof. We divided the proof into four steps.

Step 1: *Existence of approximate solutions.* We construct a sequence of problems that approximates (1.13) by introducing for $\epsilon > 0$ the Carathéodory function:

$$g_\epsilon(x,s,p) = \frac{g(x,s,p)}{1+\epsilon|g(x,s,p)|}.$$

By this definition g_ϵ has the same properties as g (growth and sign condition) but is bounded by $\frac{1}{\epsilon}$. We can then repeat the argument of Step 1 of the proof of Theorem 2.1, which shows the existence of a weak solution u_ϵ (which here does not belong to

$L^\infty(\Omega)$ since h only belongs to $H^{-1}(\Omega)$) of the quasi-linear problem

$$(1.13_\epsilon) \qquad \begin{cases} \displaystyle\int_\Omega Du_\epsilon Dv\,dx + \int_\Omega u_\epsilon v\,d\mu + \int_\Omega g_\epsilon(x,u_\epsilon,Du_\epsilon)v\,dx = \langle h,v\rangle_{H^{-1},H_0^1}, \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{for all } v \in V_\mu(\Omega), \\ u_\epsilon \in V_\mu(\Omega). \end{cases}$$

Step 2: *The solutions u_ϵ of problem* (1.13_ϵ) *are uniformly bounded in* $V_\mu(\Omega)$. It is enough to use u_ϵ as the test function in problem (1.13_ϵ) and to use the sign condition on g to get a uniform bound in $V_\mu(\Omega)$:

$$\int_\Omega |Du_\epsilon|^2\,dx + \int_\Omega u_\epsilon^2\,d\mu \le K.$$

Extracting a subsequence (still denoted by u_ϵ), we have

$$\begin{aligned} u_\epsilon &\rightharpoonup u \quad \text{weakly in } H_0^1(\Omega), \\ u_\epsilon &\rightharpoonup u \quad \text{weakly in } L^2_\mu(\Omega), \\ u_\epsilon &\to u \quad \text{a.e. in } \Omega. \end{aligned}$$

The above estimate also proves that

$$(2.4) \qquad \int_\Omega g_\epsilon(x,u_\epsilon,Du_\epsilon)u_\epsilon\,dx \le K.$$

Step 3: *Strong convergence of* $T_k(u_\epsilon)$. For a positive constant k, let $T_k(w)$ denote the truncation of the function w at level k, that is,

$$T_k(w) = \begin{cases} k & \text{if } w > k, \\ w & \text{if } |w| \le k, \\ -k & \text{if } w < -k, \end{cases}$$

and let

$$G_k(w) = w - T_k(w).$$

We remark that if $w \in V_\mu(\Omega)$, then both $T_k(w)$ and $G_k(w)$ are in $V_\mu(\Omega)$. We will prove the following convergence results:

$$(2.5) \qquad \lim_{k\to+\infty} \limsup_{\epsilon\to 0} \|G_k(u_\epsilon)\|_{H_0^1(\Omega)} = 0,$$

$$(2.6) \qquad T_k^\pm(u_\epsilon) \to T_k^\pm(u) \text{ strongly in } H_0^1(\Omega) \text{ and in } L^2_\mu(\Omega),$$

where w^+ (w^-) denotes the positive (negative) part of a function w.

Take $v = G_k(u_\epsilon)$ as a test function in (1.13_ϵ); then

$$\int_\Omega Du_\epsilon DG_k(u_\epsilon)\,dx + \int_\Omega g_\epsilon(x,u_\epsilon,Du_\epsilon)G_k(u_\epsilon)\,dx \\ + \int_\Omega u_\epsilon G_k(u_\epsilon)\,d\mu = \langle h, G_k(u_\epsilon)\rangle_{H^{-1},H_0^1}.$$

Since $G_k(u_\epsilon)$ has the sign of u_ϵ, the second and third terms of the left-hand side are nonnegative, so we obtain

$$\begin{aligned}\int_\Omega |DG_k(u_\epsilon)|^2\,dx \le \langle h, G_k(u_\epsilon)\rangle_{H^{-1},H_0^1} &= \int_{|u_\epsilon|\ge k} rDG_k(u_\epsilon)\,dx \\ &\le \frac{1}{2}\int_{|u_\epsilon|\ge k} |r|^2\,dx + \frac{1}{2}\int_\Omega |DG_k(u_\epsilon)|^2\,dx.\end{aligned}$$

Thus

$$\limsup_{\epsilon\to 0} \|DG_k(u_\epsilon)\|^2_{L^2(\Omega)} \le \int_{|u|\ge k} |r|^2\,dx,$$

and (2.5) follows when $k \to +\infty$.

The proof of (2.6) is more delicate. We will write it only for the positive parts (the other part of the proof is analogous). We adopt the approach already used in Step 3 of the proof of Theorem 2.1. For two positive parameters ϵ and η, let u_ϵ and u_η be the corresponding solutions of (1.13_ϵ) and (1.13_η). By subtracting these two equations we get, for any $v \in V_\mu(\Omega)$,

$$\int_\Omega D(u_\epsilon - u_\eta)Dv\,dx + \int_\Omega (u_\epsilon - u_\eta)v\,d\mu + \int_\Omega (g_\epsilon(x,u_\epsilon,Du_\epsilon) - g_\eta(x,u_\eta,Du_\eta))v\,dx = 0.$$

Let us take in this weak formulation the test function $T(T_k^+(u_\epsilon) - T_k^+(u_\eta)) \in V_\mu(\Omega)$, where as usual $T(v) = v\exp(tv^2)$, with a positive constant t to be chosen later. Since

$$Dv = DT_k^+(v) + DG_k^+(v) - Dv^-,$$

we obtain

$$\begin{aligned}&\int_\Omega |D(T_k^+(u_\epsilon) - T_k^+(u_\eta))|^2 T'(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx \\ &\quad + \int_\Omega (u_\epsilon - u_\eta)T(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,d\mu \\ &\quad = -\int_\Omega [g_\epsilon(x,u_\epsilon,Du_\epsilon) - g_\eta(x,u_\eta,Du_\eta)]T(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx \\ &\qquad - \int_\Omega D(G_k^+(u_\epsilon) - G_k^+(u_\eta))D(T_k^+(u_\epsilon) - T_k^+(u_\eta))T'(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx \\ &\qquad + \int_\Omega D(u_\epsilon^- - u_\eta^-)D(T_k^+(u_\epsilon) - T_k^+(u_\eta))T'(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx.\end{aligned}\tag{2.7}$$

Let us consider separately each term of (2.7). First, it is easy to check that the second term of the left-hand side of (2.7) is nonnegative; more precisely, an analysis of all possible cases (namely $u_\epsilon \le 0$, $u_\epsilon > 0$, $u_\eta \le 0$, $u_\eta > 0$) shows that

$$\int_\Omega (u_\epsilon - u_\eta)T(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,d\mu \ge \int_\Omega [T_k^+(u_\epsilon) - T_k^+(u_\eta)]^2\,d\mu.\tag{2.8}$$

Let us now define

$$\begin{aligned}L_{k,\epsilon} &= \{x \in \Omega : 0 < u_\epsilon(x) < k\}, \\ U_{k,\epsilon} &= \{x \in \Omega : u_\epsilon(x) \ge k\}.\end{aligned}$$

Concerning the first term in the right-hand side of (2.7), using a detailed analysis of all possible cases (namely $u_\epsilon \leq 0$, $0 < u_\epsilon \leq k$, $u_\epsilon \geq k$, $u_\eta \leq 0$, $0 < u_\eta \leq k$, $u_\eta \geq k$), then the sign condition on g_ϵ and g_η, and finally the growth condition, one shows that

$$\begin{aligned}
&-\int_\Omega [g_\epsilon(x,u_\epsilon,Du_\epsilon) - g_\eta(x,u_\eta,Du_\eta)]T(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx\\
&\quad\leq -\int_{L_{k,\epsilon}\cap L_{k,\eta}} [g_\epsilon(x,u_\epsilon,Du_\epsilon) - g_\eta(x,u_\eta,Du_\eta)]T(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx\\
&\qquad -\int_{L_{k,\epsilon}\cap U_{k,\eta}} g_\epsilon(x,u_\epsilon,Du_\epsilon)T(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx\\
&\qquad +\int_{U_{k,\epsilon}\cap L_{k,\eta}} g_\eta(x,u_\eta,Du_\eta)T(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx \qquad (2.9)\\
&\quad\leq b(k)\int_\Omega [4 + 2|DT_k^+(u_\epsilon)|^2 + 2|DT_k^+(u_\eta)|^2]|T(T_k^+(u_\epsilon) - T_k^+(u_\eta))|\,dx\\
&\quad\leq b(k)\int_\Omega [4 + 6|DT_k^+(u_\epsilon)|^2]|T(T_k^+(u_\epsilon) - T_k^+(u_\eta))|\,dx\\
&\qquad + b(k)\int_\Omega 4|D(T_k^+(u_\epsilon) - T_k^+(u_\eta))|^2|T(T_k^+(u_\epsilon) - T_k^+(u_\eta))|\,dx.
\end{aligned}$$

Finally, the last two terms of (2.7) can be written as

$$\begin{aligned}
&-\int_\Omega D(G_k^+(u_\epsilon) - G_k^+(u_\eta))D(T_k^+(u_\epsilon) - T_k^+(u_\eta))T'(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx\\
&\quad = \int_\Omega [DG_k^+(u_\epsilon)DT_k^+(u_\eta) + DG_k^+(u_\eta)DT_k^+(u_\epsilon)]T'(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx, \qquad (2.10)
\end{aligned}$$

$$\begin{aligned}
&\int_\Omega D(u_\epsilon^- - u_\eta^-)D(T_k^+(u_\epsilon) - T_k^+(u_\eta))T'(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx\\
&\quad = -\int_\Omega [Du_\epsilon^- DT_k^+(u_\eta) + Du_\eta^- DT_k^+(u_\eta)]T'(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx. \qquad (2.11)
\end{aligned}$$

Substituting the results (2.8)–(2.11) into (2.7), we have

$$\begin{aligned}
&\int_\Omega |D(T_k^+(u_\epsilon) - T_k^+(u_\eta))|^2[T'(T_k^+(u_\epsilon) - T_k^+(u_\eta)) - 4b(k)|T(T_k^+(u_\epsilon) - T_k^+(u_\eta))|]\,dx\\
&\quad + \int_\Omega [T_k^+(u_\epsilon) - T_k^+(u_\eta)]^2 d\mu\\
&\qquad \leq b(k)\int_\Omega [4 + 6|DT_k^+(u_\epsilon)|^2]|T(T_k^+(u_\epsilon) - T_k^+(u_\eta))|\,dx\\
&\qquad\quad + \int_\Omega [DG_k^+(u_\epsilon)DT_k^+(u_\eta) + DG_k^+(u_\eta)DT_k^+(u_\epsilon)]\,T'(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx\\
&\qquad\quad - \int_\Omega [Du_\epsilon^- DT_k^+(u_\eta) + Du_\eta^- DT_k^+(u_\epsilon)]T'(T_k^+(u_\epsilon) - T_k^+(u_\eta))\,dx.
\end{aligned}$$

Now fix $t = 64(b(k))^2$, which implies $T'(v) - 16b(k)|T(v)| \geq \frac{1}{2}$. For a fixed ϵ, the fact that the sequence u_η weakly converges in $H_0^1(\Omega)$ to u allows us to pass to the limit in the previous inequality as η goes to zero (we use in particular the weak lower semicontinuity in $H_0^1(\Omega)$ of the left-hand side), so

$$\begin{aligned}\int_\Omega &|D(T_k^+(u_\epsilon) - T_k^+(u))|^2[T'(T_k^+(u_\epsilon) - T_k^+(u)) - 16b(k)|T(T_k^+(u_\epsilon) - T_k^+(u))|]\,dx\\ &+ \int_\Omega [T_k^+(u_\epsilon) - T_k^+(u)]^2 d\mu\\ &\quad\le b(k)\int_\Omega [4 + 12|DT_k^+(u)|^2]|T(T_k^+(u_\epsilon) - T_k^+(u))|\,dx\\ &\qquad + \int_\Omega [DG_k^+(u_\epsilon)DT_k^+(u) + DG_k^+(u)DT_k^+(u_\epsilon)]T'(T_k^+(u_\epsilon) - T_k^+(u))\,dx\\ &\qquad - \int_\Omega [Du_\epsilon^- DT_k^+(u) + Du^- DT_k^+(u_\epsilon)]T'(T_k^+(u_\epsilon) - T_k^+(u))\,dx.\end{aligned}$$

Now let ϵ tend to zero. The strong convergence of $T_k^+(u_\epsilon)$ to $T_k^+(u)$ in $H_0^1(\Omega) \cap L_\mu^2(\Omega)$ (i.e., (2.6)) then follows since the three integrals in the right-hand side converge to zero.

Step 4: *The sequence u_ϵ converges strongly in $H_0^1(\Omega)$ and in $L_\mu^2(\Omega)$ and the end of the proof.* Since, by definition, $u_\epsilon^+ - u^+ = (T_k^+(u_\epsilon) - T_k^+(u)) + (G_k^+(u_\epsilon) - G_k^+(u))$, we have for the $H_0^1(\Omega)$ or $L_\mu^2(\Omega)$ norm

$$\|u_\epsilon^+ - u^+\| \le \|T_k^+(u_\epsilon) - T_k^+(u)\| + \|G_k^+(u_\epsilon)\| + \|G_k^+(u)\|.$$

Using (2.5) and (2.6), this proves the strong convergence of u_ϵ^+ to u^+. The analogous result for u_ϵ^- proves that

$$u_\epsilon \to u \text{ strongly in } H_0^1(\Omega) \text{ and in } L_\mu^2(\Omega). \tag{2.12}$$

Extracting a subsequence such that $Du_\epsilon \to Du$ a.e. in Ω, we deduce from (2.4) and Fatou's lemma that

$$g(x, u, Du)u \in L^1(\Omega).$$

Writing

$$\int_\Omega |g(x, u, Du)|\,dx \le \int_{|u|\le 1} b(1)(1 + |Du|^2)\,dx + \int_{|u|\ge 1} g(x, u, Du)u\,dx$$

implies that $g(x, u, Du) \in L^1(\Omega)$.

Finally, in view of (2.4) we have

$$\int_{|u_\epsilon|>m} |g_\epsilon(x, u_\epsilon, Du_\epsilon)|\,dx \le \frac{1}{m}\int_{|u_\epsilon|>m} g_\epsilon(x, u_\epsilon, Du_\epsilon)u_\epsilon\,dx \le \frac{K}{m}. \tag{2.13}$$

On the other hand, for m fixed, Vitali's theorem, the estimate

$$|\chi_{|u_\epsilon|\le m} g_\epsilon(x, u_\epsilon, Du_\epsilon)| \le b(m)(1 + |Du_\epsilon|^2),$$

and (2.12) imply that

$$\chi_{|u_\epsilon|\le m} g_\epsilon(x, u_\epsilon, Du_\epsilon) \to \chi_{|u|\le m} g(x, u, Du) \text{ strongly in } L^1(\Omega). \tag{2.14}$$

Combining (2.13), (2.14), and

$$\int_{|u|\geq m} |g(x,u,Du)|\,dx \leq \frac{1}{m}\int_\Omega g(x,u,Du)u\,dx,$$

we obtain

$$g_\epsilon(x,u_\epsilon,Du_\epsilon) \to g(x,u,Du) \text{ strongly in } L^1(\Omega),$$

which allows us to pass to the limit in (1.13_ϵ) and to obtain (1.13).

The proof of the Theorem 2.2 is complete. □

3. Homogenization. In this section we study the convergence of the solution of (1.1) when the measure μ varies. We shall consider only nonlinear terms with subquadratic growth with respect to the gradient and prove the stability (Theorem 3.1). The general quadratic case is, however, very different, as it has recently been shown in Casado-Diaz [Ca1] (see Remark 3.2).

Let us consider the sequence of problems

$$(3.1_\epsilon)\qquad \begin{cases} \displaystyle\int_\Omega Du_\epsilon Dv\,dx + \lambda_0\int_\Omega u_\epsilon v\,dx + \int_\Omega u_\epsilon v\,d\mu_\epsilon = \int_\Omega f(x,Du_\epsilon)v\,dx \\ \qquad\qquad\qquad\qquad\qquad\qquad \text{for all } v \in V_{\mu_\epsilon}(\Omega)\cap L^\infty(\Omega), \\ u_\epsilon \in V_{\mu_\epsilon}(\Omega)\cap L^\infty(\Omega), \end{cases}$$

where Ω is a bounded domain in $\mathbb{R}^N$ with smooth boundary, $\mu_\epsilon \in M_0(\Omega)$, and for the sake of simplicity, we consider only nonlinear terms that do not depend explicitly on u_ϵ. The general case is evoked in Remark 3.3. We assume the following hypotheses:

(H1)

$$\begin{cases} |f(x,p_1) - f(x,p_2)| \leq K(1+|p_1|^{s-\gamma}+|p_2|^{s-\gamma})|p_1-p_2|^\gamma, \\ \qquad\qquad \text{for any } p_1,p_2 \in \mathbb{R}^N, \text{ with } 0<\gamma\leq 1,\ \gamma\leq s<2; \\ |f(x,0)| \leq c_0, \end{cases}$$

$$(\text{H2})\qquad \begin{cases} \lambda_0 > 0, \qquad \mu_\epsilon \xrightarrow{\gamma} \mu_0, \qquad V^1_{\mu_\epsilon}(\Omega) \neq \emptyset; \\ \mu_0 = m(x)dx, \quad \text{where } m \in L^\infty(\Omega),\ m \geq 0. \end{cases}$$

Note that (H1) implies in particular that f has a strictly subquadratic growth in the gradient since

$$(3.2)\qquad |f(x,p)| \leq c_1(1+|p|^s), \quad \text{for any } p \in \mathbb{R}^N\ (s<2),$$

so hypothesis (E_a2) is satisfied. Therefore, the existence result of Theorem 2.1 holds in this case.

On the other hand, hypothesis (H2) allows us to use the corrector result of Theorem 1.1.

We also make an additional hypothesis on the correctors w_ϵ defined by (1.6). We assume that

$$(\text{H3})\qquad Dw_\epsilon \to 0 \text{ a.e. in } \Omega.$$

Hypothesis (H3) was recently proved to hold true by Casado-Diaz [Ca1] and Dal Maso and Murat [DMM] for the correctors considered by these authors. We will prove in Remark 3.1 that (H3) holds in this case of periodically perforated domains with holes of critical size. This property was also observed by Boccardo and Donato [BD] and Labani and Picard [LP].

We shall prove the following theorem.

THEOREM 3.1. *Assume* (H1), (H2), *and* (H3), *and let* $u_\epsilon \in V_{\mu_\epsilon}(\Omega) \cap L^\infty(\Omega)$ *be any sequence of solutions of* (3.1_ϵ). *Up to the extraction of a subsequence we have*

$$u_\epsilon \rightharpoonup u_0 \textit{ weakly in } H^1(\Omega),$$

where u_0 *is a solution of*

$$(3.1_0) \qquad \begin{cases} \displaystyle\int_\Omega Du_0 Dv\,dx + \lambda_0 \int_\Omega u_0 v\,dx + \int_\Omega u_0 v\,d\mu_0 = \int_\Omega f(x, Du_0) v\,dx \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad \textit{for all } v \in V_{\mu_0}(\Omega) \cap L^\infty(\Omega), \\ u_0 \in V_{\mu_0}(\Omega) \cap L^\infty(\Omega), \end{cases}$$

which reads formally as

$$\begin{cases} -\Delta u_0 + \lambda_0 u_0 + \mu_0 u_0 = f(x, Du_0) & \textit{in } \Omega, \\ u_0 = 0 & \textit{on } \partial\Omega. \end{cases}$$

In other words, Theorem 3.1 asserts that by passing to the limit on μ_ϵ both the operator and the right-hand side remain unchanged. This is a stability result.

Proof. We distinguish four steps in the proof.

Step 1: *Bounds for the solutions* u_ϵ *and* $f(x, Du_\epsilon) = g_\epsilon$. In view of (3.2), we know from Theorem 2.1 the existence of at least one solution of (3.1_ϵ). It also follows from the proof of Theorem 2.1 (see the end of Step 2 of that proof) that any solution of this problem is bounded in $H_0^1(\Omega)$ and $L^\infty(\Omega)$ by a constant that depends only on c_0, λ_0, and Ω, i.e.,

$$(3.3) \qquad \|u_\epsilon\|_{H_0^1} + \|u_\epsilon\|_{L^2_{\mu_\epsilon}} + \|u_\epsilon\|_{L^\infty} \le K.$$

We can thus extract a subsequence (still denoted by u_ϵ) such that

$$u_\epsilon \rightharpoonup u \text{ weakly in } H_0^1(\Omega),$$
$$u_\epsilon \to u \text{ strongly in } L^p(\Omega), \text{ for any } p < \infty, \text{ weakly * in } L^\infty(\Omega) \text{ and a.e. in } \Omega.$$

Let $g_\epsilon = f(x, Du_\epsilon)$. Take $q = \frac{2}{s} > 1$. Using Hölder's inequality, we get

$$\int_\Omega |g_\epsilon|^q\,dx = \int_\Omega |f(x, Du_\epsilon)|^q\,dx \le c_1^q \int_\Omega (1 + |Du_\epsilon|^s)^q\,dx \le \text{Cst}.$$

Extracting a new subsequence, there exists a function g_0 such that

$$f(x, Du_\epsilon) = g_\epsilon \rightharpoonup g_0 \text{ weakly in } L^q(\Omega).$$

Step 2: *A first passage to the limit in* (3.1_ϵ). In this step and in Step 3, we use the corrector result. Note that hypothesis (H2) is used only here and in Step 3. Note also that we could have $\lambda_0 = 0$ now and in what follows. The hypothesis $\lambda_0 > 0$ is indeed essential only in the proofs of the existence of u_ϵ and of the uniform estimates on u_ϵ (Step 1).

Now consider the sequence of functions w_ϵ defined by (1.6) in §1. Since, as observed in Remark 1.1, w_ϵ is bounded in L^∞, we have

$$w_\epsilon \to 1 \text{ strongly in } L^p(\Omega) \text{ for any } p < +\infty, \text{ and weakly * in } L^\infty(\Omega).$$

We claim

$$\text{(3.4)} \qquad \begin{cases} v_\epsilon \in V_{\mu_\epsilon}(\Omega), \qquad v_0 \in V_{\mu_0}(\Omega), \qquad v_\epsilon \rightharpoonup v_0 \text{ weakly in } H_0^1(\Omega) \\ \Rightarrow \displaystyle\int_\Omega Dw_\epsilon Dv_\epsilon\, dx + \int_\Omega w_\epsilon v_\epsilon\, d\mu_\epsilon \to \int_\Omega v_0\, d\mu_0. \end{cases}$$

Indeed, recalling the definitions of $w_\epsilon = z_\epsilon/z_0$ and z_ϵ, which solves (1.5) for the measure μ_ϵ, and the fact that z_0 and $1/z_0$ belong to $W^{1,\infty}(\Omega)$ (this is a consequence of hypothesis (H2), see [FT, Prop. 3.2]), and finally the fact that z_0 solves (1.5) for the measure μ_0, we have

$$\begin{aligned} &\int_\Omega Dw_\epsilon Dv_\epsilon\, dx + \int_\Omega w_\epsilon v_\epsilon\, d\mu_\epsilon \\ &= \left(\left(z_\epsilon, \frac{v_\epsilon}{z_0}\right)\right)_{\mu_\epsilon} + \int_\Omega D\left(\frac{1}{z_0}\right) Dv_\epsilon z_\epsilon\, dx - \int_\Omega Dz_\epsilon D\left(\frac{1}{z_0}\right) v_\epsilon\, dx \\ &\to \int_\Omega D\left(\frac{1}{z_0}\right) Dv_0 z_0\, dx - \int_\Omega Dz_0 D\left(\frac{1}{z_0}\right) v_0\, dx \\ &= -\int_\Omega Dz_0 D\left(\frac{v_0}{z_0}\right) dx = \int_\Omega v_0\, d\mu_0. \end{aligned}$$

For $\phi \in V_{\mu_0}(\Omega) \cap L^\infty(\Omega)$, take ϕw_ϵ, which belongs to $V_{\mu_\epsilon}(\Omega)$, as a test function in (3.1_ϵ). This yields

$$\text{(3.5)} \qquad \begin{aligned} &\int_\Omega Du_\epsilon D(\phi w_\epsilon)\, dx + \lambda_0 \int_\Omega u_\epsilon \phi w_\epsilon\, dx + \int_\Omega u_\epsilon \phi w_\epsilon\, d\mu_\epsilon \\ &\quad = \int_\Omega f(x, Du_\epsilon)\phi w_\epsilon\, dx = \int_\Omega g_\epsilon \phi w_\epsilon\, dx. \end{aligned}$$

Now w_ϵ tends to 1 strongly in $L^p(\Omega)$ for any $p < \infty$, while g_ϵ tends to g_0 weakly in $L^q(\Omega)$ with $q = \frac{2}{s} > 1$; the right-hand side of (3.5) then converges to $\int_\Omega g_0 \phi\, dx$.

We rewrite the left-hand side of (3.5) and pass to the limit using in particular (3.4) with $v_\epsilon = \phi u_\epsilon$. This yields

$$\begin{aligned} &\int_\Omega Du_\epsilon D(\phi w_\epsilon)\, dx + \lambda_0 \int_\Omega u_\epsilon \phi w_\epsilon\, dx + \int_\Omega u_\epsilon \phi w_\epsilon\, d\mu_\epsilon \\ &= \int_\Omega Dw_\epsilon D(\phi u_\epsilon)\, dx + \int_\Omega u_\epsilon \phi w_\epsilon\, d\mu_\epsilon + \lambda_0 \int_\Omega u_\epsilon \phi w_\epsilon\, dx \\ &\quad - \int_\Omega Dw_\epsilon D\phi u_\epsilon\, dx + \int_\Omega Du_\epsilon D\phi w_\epsilon\, dx \\ &\to \int_\Omega u_0 \phi\, d\mu_0 + \lambda_0 \int_\Omega u_0 \phi\, dx + \int_\Omega Du_0 D\phi\, dx. \end{aligned}$$

From Definition 1.1 of the γ-convergence and the bound (3.3), we finally deduce that u_0 belongs to V_{μ_0}. Hence u_0 satisfies

$$\begin{cases} u_0 \in V_{\mu_0}(\Omega) \cap L^\infty(\Omega), \\ \displaystyle\int_\Omega Du_0 D\phi\, dx + \lambda_0 \int_\Omega u_0 \phi\, dx + \int_\Omega u_0 \phi\, d\mu_0 = \int_\Omega g_0 \phi\, dx \\ \qquad\qquad\qquad\qquad \text{for all } \phi \in V_{\mu_0}(\Omega) \cap L^\infty(\Omega). \end{cases}$$

Step 3: *Corrector result for the nonlinear problem.* Let us first prove the convergence of the energies. Taking $v = u_\epsilon$ as a test function in (3.1_ϵ), we pass easily to the limit since u_ϵ converges strongly to u in $L^p(\Omega)$ for any $p < \infty$. We obtain

$$(3.6)\qquad \begin{aligned} &\int_\Omega |Du_\epsilon|^2\, dx + \int_\Omega u_\epsilon^2\, d\mu_\epsilon = \int_\Omega u_\epsilon g_\epsilon\, dx - \lambda_0 \int_\Omega u_\epsilon^2\, dx \\ &\qquad \to \int_\Omega u_0 g_0\, dx - \lambda_0 \int_\Omega u_0^2\, dx = \int_\Omega |Du_0|^2\, dx + \int_\Omega u_0^2\, d\mu_0. \end{aligned}$$

We now claim that for any $\phi \in V_{\mu_0}(\Omega) \cap L^\infty(\Omega)$

$$(3.7)\qquad \begin{aligned} &\int_\Omega |D(u_\epsilon - w_\epsilon \phi)|^2\, dx + \int_\Omega (u_\epsilon - w_\epsilon \phi)^2\, d\mu_\epsilon \\ &\qquad \to \int_\Omega |D(u_0 - \phi)|^2\, dx + \int_\Omega (u_0 - \phi)^2\, d\mu_0. \end{aligned}$$

To prove this claim, we write the left-hand side of (3.7) as

$$\begin{aligned} &\left[\int_\Omega |Du_\epsilon|^2\, dx + \int_\Omega u_\epsilon^2 d\mu_\epsilon\right] + \left[\int_\Omega Dw_\epsilon D(\phi^2 w_\epsilon)\, dx + \int_\Omega (\phi^2 w_\epsilon) w_\epsilon\, d\mu_\epsilon\right] \\ &\quad - 2\left[\int_\Omega Dw_\epsilon D(\phi u_\epsilon)\, dx + \int_\Omega (\phi u_\epsilon) w_\epsilon\, d\mu_\epsilon\right] \\ &\quad + \int_\Omega w_\epsilon^2 |D\phi|^2\, dx - 2\int_\Omega w_\epsilon Du_\epsilon D\phi\, dx + 2\int_\Omega u_\epsilon Dw_\epsilon D\phi\, dx, \end{aligned}$$

where it is easy to pass to the limit by using (3.4) with $v_\epsilon = \phi^2 w_\epsilon$ and (3.6) with $v_\epsilon = \phi u_\epsilon$. This proves (3.7).

Taking now $\phi = u_0$ in (3.7) we obtain

$$(3.8)\qquad u_\epsilon - w_\epsilon u_0 \to 0 \text{ strongly in } H_0^1(\Omega).$$

The previous proof is similar to the proof of Theorem 3.4 of [CM] and Theorem 3.6 of [FT]. Note, however, that we assumed here ϕ (and u_0) belongs to $V_{\mu_0}(\Omega) \cap L^\infty(\Omega)$, which allows us to obtain (3.8), a result that is stronger than the result of [CM].

Step 4: *Identifying* g_0 *as* $f(x, Du_0)$. In the proof of this step, we use hypothesis (H1), which implies, with $p_1 = D(u_\epsilon)$, $p_2 = D(w_\epsilon u_0)$, that

$$|f(x, Du_\epsilon) - f(x, D(w_\epsilon u_0))| \le K(1 + |Du_\epsilon|^{s-\gamma} + |D(w_\epsilon u_0)|^{s-\gamma})|D(u_\epsilon - w_\epsilon u_0)|^\gamma.$$

It can easily be proved that any term in the right-hand side converges to zero strongly in $L^1(\Omega)$. Let us consider, for example, the last term in the case $s > \gamma$. It is enough to apply Hölder's inequality with $p = \frac{2}{s-\gamma}$ and $p' = \frac{2}{2-s+\gamma}$ to get

$$\int_\Omega |D(w_\epsilon u_0)|^{s-\gamma} |D(u_\epsilon - w_\epsilon u_0)|^\gamma \, dx$$
$$\leq \left(\int_\Omega |D(w_\epsilon u_0)|^2 \, dx \right)^{\frac{s-\gamma}{2}} \left(\int_\Omega |D(u_\epsilon - w_\epsilon u_0)|^{\frac{2\gamma}{2-s+\gamma}} \, dx \right)^{\frac{2-s+\gamma}{2}}$$

The condition $s < 2$ implies that $\frac{2\gamma}{2-s+\gamma} < 2$, and the result follows from the corrector result (3.8). We have proved that

$$f(x, Du_\epsilon) - f(x, D(w_\epsilon u_0)) \to 0 \text{ strongly in } L^1(\Omega). \tag{3.9}$$

Let us now prove that

$$f(x, D(w_\epsilon u_0)) \to f(x, Du_0) \text{ strongly in } L^1(\Omega). \tag{3.10}$$

By hypothesis (H3), $Dw_\epsilon \to 0$ a.e. Because of the continuity of f with respect to p (see hypothesis (H1)), we have

$$f(x, D(w_\epsilon u_0)) = f(x, u_0 Dw_\epsilon + w_\epsilon Du_0) \to f(x, Du_0) \text{ a.e.}$$

On the other hand, (3.2) implies

$$f(x, D(w_\epsilon u_0))| \leq C_1(1 + |Dw_\epsilon u_0 + w_\epsilon Du_0|^s) \leq 2C_1(1 + |Dw_\epsilon|^s |u_0|^s + |Du_0|^s).$$

The proof of (3.10) is then achieved using Vitali's convergence theorem since $Dw_\epsilon \to 0$ a.e. and Dw_ϵ is bounded in $(L^2(\Omega))^N$.

From (3.9) and (3.10) we obtain that

$$g_\epsilon = f(x, Du_\epsilon) \to f(x, Du_0) \text{ strongly in } L^1(\Omega),$$

which proves that $g_0 = f(x, Du_0)$. Using this result in the limit problem for u_0 at the end of Step 2, we complete the proof of the theorem. □

Remark 3.1. Hypothesis (H3) is satisfied, for instance, in the case of domains periodically perforated by holes that are balls of critical size. More precisely, we consider in this remark the case where the measure μ_ϵ is given by $\mu_\epsilon = \infty_{T_\epsilon}$ (see the definition in the introduction), where T_ϵ is the union of the balls of radius $a_\epsilon = C_0 \epsilon^{N/(N-2)}$ (when $N \geq 3$) or $a_\epsilon = C_0 \exp(-c_0/\epsilon^2)$ (when $N = 2$), whose centers are distributed at the vertices of a lattice in $\mathbb{R}^N$, with cell size 2ϵ (see [CM, Ex. 2.1]).

An explicit computation, based on the proof of Theorem 2.2 of [CM] (see in particular formula (2.2)), in the case $N \geq 3$ (the case $N = 2$ is similar) gives

$$\int_\Omega |Dw_\epsilon|^\theta \, dx \sim \frac{\text{meas}\, \Omega}{(2\epsilon)^N} S_N \int_{a_\epsilon}^{\epsilon} \left| \frac{dw_\epsilon}{dr} \right|^\theta r^{N-1} \, dr$$
$$\sim \frac{\text{meas}\, \Omega}{(2\epsilon)^N} S_N \int_{a_\epsilon}^{\epsilon} |(N-2)(a_\epsilon)^{N-2} r^{-(N-1)}|^\theta r^{N-1} \, dr$$
$$\sim \text{ Cst } \frac{1}{\epsilon^N} (a_\epsilon)^{(N-2)\theta} (a_\epsilon)^{-(N-1)(\theta-1)+1}$$
$$= \text{Cst} \frac{(a_\epsilon)^{N-\theta}}{\epsilon^N} = \text{ Cst } C_0^{N-\theta} \epsilon^{N \frac{2-\theta}{N-2}},$$

which gives, if $\theta < 2$,

$$\int_\Omega |Dw_\epsilon|^\theta \, dx \to 0.$$

This result proves that, at least for a subsequence, hypothesis (H3) is satisfied for this example.

Remark 3.2. The restriction $s < 2$ is crucial in the above proof but also in the statement of Theorem 3.1, as proved by Casado-Diaz [Ca1].

Indeed the result is drastically different in the "exactly quadratic" case ($s = 2$) since when, for example,

$$f(x, Du) = h(x) + \gamma |Du|^2, \qquad \text{with } h \in L^\infty(\Omega), \tag{3.11}$$

the result of the passage to the limit reads as

$$\begin{cases} -\Delta u_0 + \lambda_0 u_0 + \dfrac{1}{\gamma}(1 - e^{-\gamma u_0})\mu_0 = f(x, Du_0) & \text{in } \Omega, \\ u_0 = 0 & \text{on } \partial\Omega. \end{cases} \tag{3.12}$$

If one compares this result with (3.1_0), one sees that the nonlinearity with respect to the gradient is the same (namely $f(x, Du_0)$), in both (3.1_0) and (3.12), but that the term $u_0\mu_0$ in (3.1_0) has been replaced by $\frac{1}{\gamma}(1 - e^{-\gamma u_0})\mu_0$ in (3.12).

Also, an important fact is that the corrector result (3.8) does not hold true when $s = 2$. In the previous example (3.11) we have in place of (3.8) the result

$$\left\| u_\epsilon - \frac{1}{\gamma} \log(1 + (e^{\gamma u_0} - 1)w_\epsilon) \right\|_{H_0^1(\Omega)} \to 0,$$

while the expression of the corrector in the general case is more complicated.

For more details on the quadratic case, we then refer the reader to the work of Casado-Diaz [Ca1].

Remark 3.3. It is possible to obtain a result analogous to Theorem 3.1 if the nonlinear term also depends on the function u_ϵ. We only need to replace hypothesis (H2) by

$$\text{(H2)}' \quad \begin{cases} |f(x,t,p)| \le C_1(1 + |p|^s), \\ |f(x,t_1,p_1) - f(x,t_2,p_2)| \\ \le n(t_1,t_2)\{(1 + |p_1|^{s-\gamma} + |p_2|^{s-\gamma})|p_1 - p_2|^\gamma + |t_1 - t_2|^r(|p_1|^s + |p_2|^s)\}, \\ \hfill \text{for any } t_1, t_2 \in \mathbb{R}, \text{for any } p_1, p_2 \in \mathbb{R}^N, \end{cases}$$

where $0 < \gamma \le 1$, $\gamma \le s < 2$, $r > 0$, and $n : \mathbb{R}^2 \to \mathbb{R}$ is a function that is bounded on the bounded subsets of $\mathbb{R}^2$. Indeed the first part of (H2)$'$ allows us to obtain the existence of a solution u_ϵ and its boundedness in $H_0^1(\Omega) \cap L^\infty(\Omega)$ (as in Step 1 above) while the second part of (H2)$'$ allows to perform the proof we made in Step 4.

STRUCTURE OF RADIAL SOLUTIONS TO $\Delta u + K(|x|)|u|^{p-1}u = 0$ IN $\mathbf{R}^n$*

EIJI YANAGIDA[†]

Abstract. The elliptic equation equation $\Delta u + K(r)|u|^{p-1}u = 0$ in $\mathbf{R}^n$ is studied, where $r = |x|, p > 1, n > 2$, and $K(r) > 0$ for $r \in (0, \infty)$. If $rK_r(r)/K(r)$ is nonincreasing in r, then the structure of radial solutions is determined completely by analyzing linearized equations around the solutions.

Key words. semilinear elliptic equation, radial solutions, structure

AMS subject classifications. 34C10, 35J25

1. Introduction. The purpose of this paper is to investigate the structure of radial solutions to the semilinear elliptic equation

$$\Delta u + K(|x|)|u|^{p-1}u = 0, \qquad x \in \mathbf{R}^n,$$

where $p > 1, n > 2, \Delta = \sum_{i=1}^n \partial^2/\partial x_i^2$, and $|x| = \{\sum_{i=1}^n x_i^2\}^{1/2}$. This equation appears in various fields such as astrophysics, combustion, and differential geometry.

Since radial solutions (i.e., solutions with $u = u(|x|)$ for all $x \in \mathbf{R}^n$) are of particular interest, we will study the initial value problem

$$\text{(1.1)} \qquad \begin{cases} \{r^{n-1}u_r(r)\}_r + r^{n-1}K(r)|u(r)|^{p-1}u(r) = 0, & r > 0, \\ u(0) = \alpha > 0, \end{cases}$$

where $r = |x|$. Throughout this paper, we assume that

$$\text{(K.0)} \qquad \begin{cases} K(r) & \in C^1((0,\infty)), \\ K(r) & > 0 \quad \text{on } (0,\infty), \\ rK(r) & \in L^1(0,1). \end{cases}$$

Then, for any $\alpha > 0$, problem (1.1) has the unique global solution $u(r) \in C([0,\infty)) \cap C^2((0,\infty))$ (see Ni and Yotsutani [12] for the local existence and regularity and Coffman and Ullrich [3] for the global existence). We denote the solution by $u(r;\alpha)$.

We classify the solutions as follows.

Type $R(i)$. $u(r;\alpha)$ has exactly i zeros on $(0,\infty)$, and $r^{n-2}|u(r;\alpha)| \to \beta$ as $r \to \infty$ for some constant $\beta > 0$.

Type $S(i)$. $u(r;\alpha)$ has exactly i zeros on $(0,\infty)$, and $r^{n-2}|u(r;\alpha)| \to \infty$ as $r \to \infty$.

Type O. $u(r;\alpha)$ has infinitely many zeros on $(0,\infty)$.

By virtue of (d) of Lemma 2.1, any solution of (1.1) is classified into one of the above types.

Let λ be a number given by

$$\lambda := \frac{(n-2)p-(n+2)}{2},$$

which is related to the Pohozaev identity (see Lemma 2.2) and plays an important role for the existence of solutions of each type. The existence of a solution of Type $R(i)$ was studied by Yanagida and Yotsutani [17] and later generalized by Naito [11] and Kabeya, Yanagida, and Yotsutani [5]. According to their results, the following theorem holds.

THEOREM A. *Suppose that* $\lim_{r\to 0}\inf rK_r(r)/K(r) > \lambda$ *and* $\lim_{r\to\infty}\sup rK_r(r)/K(r) < \lambda$. *Then there exist* $0 < \alpha_1 < \alpha_2 < \cdots < \infty$ *such that* $u(r;\alpha_{i+1})$ *is of Type* $R(i)$.

Once this theorem is established, it is natural to ask whether the solution of Type $R(i)$ is unique or not, or, more generally, what the entire structure of solutions is. Under various assumptions on $K(r)$ and p, uniqueness of a solution of Type $R(0)$ was proved by Kwong and Li [10] and Yanagida [14], and the entire structure of positive solutions was studied by Kawano, Yanagida, and Yotsutani independently and in conjunction with one another [6, 13, 18]. However, little is known concerning the uniqueness or structure of radial solutions that may change sign. In this paper, we study the structure of radial solutions of (1.1) under the following quite simple condition on $K(r)$:

$$\text{(K.1)} \qquad rK_r(r)/K(r) \text{ is nonincreasing in } r \in (0,\infty).$$

We note that, under this condition, we can define σ and ℓ by

$$\sigma := \lim_{r\to 0} rK_r(r)/K(r) \in (-\infty, +\infty],$$
$$\ell := \lim_{r\to\infty} rK_r(r)/K(r) \in [-\infty, +\infty).$$

The following theorem is a main result of this paper.

THEOREM 1. *Suppose that* (K.1) *and the inequalities* $-\infty \le \ell < \lambda < \sigma \le +\infty$ *are satisfied. Then the following hold.*

(a) *There exist* $0 = \alpha_0 < \alpha_1 < \alpha_2 < \cdots < \infty$ *with* $\lim_{i\to\infty}\alpha_i = \infty$ *such that* $u(r;\alpha)$ *is of Type* $R(i)$ *if and only if* $\alpha = \alpha_{i+1}$, *and* $u(r;\alpha)$ *is of Type* $S(i)$ *for every* $\alpha \in (\alpha_i, \alpha_{i+1})$.

(b) *The ith zero of* $u(r;\alpha)$ *is a strictly decreasing function of* $\alpha \in (\alpha_i,\infty)$ *for every* i.

(c) *Let* $\beta_i := \lim_{r\to\infty} r^{n-2}|u(r;\alpha_i)|$. *Then* $\{\beta_i\}$ *is a monotone increasing positive sequence with* $\lim_{i\to\infty}\beta_i = \infty$.

(d) *The zeros of* $u(r;\alpha_i)$ *separate and are separated by those of* $u(r;\alpha_{i+1})$.

When the inequalities $\ell < \lambda < \sigma$ are not satisfied, we have the next theorem.

THEOREM 2. (a) *If* $rK_r(r)/K(r) \equiv \lambda$ *on* $(0,\infty)$, *then* $u(r;\alpha)$ *is of Type* $R(0)$ *for every* $\alpha \in (0,\infty)$.

(b) *If* $rK_r(r)/K(r) \le \lambda$ *and* $rK_r(r)/K(r) \not\equiv \lambda$ *on* $(0,\infty)$, *then* $u(r;\alpha)$ *is of Type* $S(0)$ *for every* $\alpha \in (0,\infty)$.

(c) *If* $rK_r(r)/K(r) \ge \lambda$ *and* $rK_r(r)/K(r) \not\equiv \lambda$ *on* $(0,\infty)$, *then* $u(r;\alpha)$ *is of Type* O *for every* $\alpha \in (0,\infty)$. *In addition, if* (K.1) *holds, then the ith zero of* $u(r;\alpha)$ *is a strictly decreasing function of* $\alpha \in (0,\infty)$ *for every* i.

This theorem, except the latter part of (c), was proved in [1, 4, 8]. We will give a simplified proof for self-containedness. We note that, by virtue of Theorems 1 and 2, the structure of solutions to (1.1) under the condition (K.1) can be completely determined.

The outline of this paper is as follows. In §2, we give several fundamental properties of solutions to (1.1). In §3, we give two important propositions concerning the properties of zeros of $u(r;\alpha)$. Then we give a proof of Theorem 1 by using these propositions. A proof of Theorem 2 is given in §4. Sections 5 and 6 are devoted to proofs of the propositions.

2. Fundamental properties of solutions.

In this section, we collect fundamental facts that will be used in subsequent sections.

LEMMA 2.1. *Any solution of* (1.1) *has the following properties:*

(a) $u_r(r;\alpha) = -\int_0^r (s/r)^{n-1}K(s)|u(s;\alpha)|^{p-1}u(s;\alpha)\,ds$.

(b) $u(r;\alpha) = \alpha - \frac{1}{n-2}\int_0^r \{1-(s/r)^{n-2}\}sK(s)|u(s;\alpha)|^{p-1}u(s;\alpha)\,ds$.

(c) $\lim_{r\to 0} ru_r(r;\alpha) = 0$.

(d) *If* $u(r;\alpha)>0$ (*resp.*, $u(r;\alpha)<0$) *on* (R,∞) *for some* $R\geq 0$, *then* $\{r^{n-2}u(r;\alpha)\}_r > 0$ (*resp.*, $\{r^{n-2}u(r;\alpha)\}_r < 0$) *on* (R,∞).

(e) *If* $r^{n-2}u(r;\alpha)\to\gamma$ *as* $r\to\infty$ *for some constant* $\gamma\neq 0$, *then* $r^{n-1}u_r(r;\alpha)\to -(n-2)\gamma$ *as* $r\to\infty$.

(f) *If* $u(r;\alpha)$ *is not of Type O and satisfies* $u(r;\alpha)\to 0$ *as* $r\to\infty$, *then* $ru_r(r;\alpha)\to 0$ *as* $r\to\infty$.

Proof. For (a) and (b), see Propositions 4.1 and 4.2 of [12]. For (c), see (4.5) of [12]. Assertions (d) and (e) were proved in Lemmas 7.1 and 7.2 of [12] for positive solutions. The proof applies to solutions of (1.1) with an obvious change. By (a) and (d), if $u(r;\alpha)>0$ (resp., $u(r;\alpha)<0$) in a neighborhood of $r=\infty$ and $u(r;\alpha)\to 0$ as $r\to\infty$, then there exists $R\geq 0$ such that

$$0 < -ru_r < (n-2)u \quad (\text{resp.}, 0 < ru_r < -(n-2)u) \tag{2.1}$$

on (R,∞). Since $u\to 0$ as $r\to\infty$, (f) holds. □

The following identity is a variant of the well-known Pohozaev identity.

LEMMA 2.2. *Any solution* $u = u(r;\alpha)$ *of* (1.1) *satisfies the identity*

$$\frac{d}{dr}P(r;u) \equiv \frac{1}{p+1}r^{n-1}K(r)\{rK_r(r)/K(r)-\lambda\}|u|^{p+1},$$

where

$$P(r;u) := \frac{1}{2}r^{n-1}u_r\{ru_r+(n-2)u\} + \frac{1}{p+1}r^nK(r)|u|^{p+1}.$$

Proof. The equation in (1.1) can be written as

$$\{ru_r+(n-2)u\}_r = -rK(r)|u|^{p-1}u. \tag{2.2}$$

Carrying out the differentiation and using (1.1) and (2.2), we obtain

$$\begin{aligned}\frac{d}{dr}P(r;u) &= \frac{1}{2}(r^{n-1}u_r)_r\{ru_r+(n-2)u\} + \frac{1}{2}r^{n-1}u_r\{ru_r+(n-2)u\}_r \\ &\quad + \frac{1}{p+1}\{r^nK(r)|u|^{p+1}\}_r \\ &= -\frac{1}{2}\{r^{n-1}K(r)|u|^{p-1}u\}\{ru_r+(n-2)u\} - \frac{1}{2}r^{n-1}u_r\{rK(r)|u|^{p-1}u\} \\ &\quad + \frac{1}{p+1}\{r^nK(r)|u|^{p+1}\}_r \\ &= \frac{1}{p+1}r^{n-1}K(r)\{rK_r(r)/K(r)-\lambda\}|u|^{p+1}.\end{aligned}$$

Thus we get the desired identity. □

The following characterizations of solutions to (1.1) in terms of $P(r;u)$ are useful.

LEMMA 2.3. (a) *For any solution* $u = u(r;\alpha)$ *of* (1.1), *there exists a sequence* $\{\varepsilon_j\}$ *such that* $\varepsilon_j \to 0, \varepsilon_j^n K(\varepsilon_j) \to 0$, *and* $P(\varepsilon_j;u) \to 0$ *as* $j \to \infty$.

(b) *If* $u = u(r;\alpha)$ *is of Type* $R(i)$, *then there exists a sequence* $\{\bar{r}_j\}$ *such that* $\bar{r}_j \to \infty$ *and* $P(\bar{r}_j;u) \to 0$ *as* $j \to \infty$.

(c) *If* $u = u(r;\alpha)$ *is of Type* $S(i)$ *and satisfies* $uu_{\mathrm{r}} < 0$ *in a neighborhood of* $r = \infty$, *then there exists a sequence* $\{\hat{r}_j\}$ *such that* $\hat{r}_j \to \infty$ *as* $j \to \infty$ *and* $P(\hat{r}_j;u) < 0$ *for every* j.

(d) *If* $u = u(r;\alpha)$ *is of Type* O, *then there exists a sequence* $\{\tilde{r}_j\}$ *such that* $\tilde{r}_j \to \infty$ *as* $j \to \infty$ *and* $P(\tilde{r}_j;u) > 0$ *for every* j.

Proof. Since $rK(r) \in L^1(0,1)$, there exists a sequence $\{\varepsilon_j\}$ such that $\varepsilon_j \to 0$ and $\varepsilon_j^2 K(\varepsilon_j) \to 0$ as $j \to \infty$. On the other hand, by Lemma 2.1(c), we have

$$\lim_{r\to 0} r^{n-1}u_r\{ru_r + (n-2)u\} = 0.$$

Hence it follows that $\varepsilon_j^n K(\varepsilon_j) \to 0$ and $P(\varepsilon_j;u) \to 0$ as $j \to \infty$ in view of $n > 2$. Thus (a) holds.

If $u = u(r;\alpha)$ is of Type $R(i)$ and $r^{n-2}u(r;\alpha) \to \gamma$ as $r \to \infty$, it follows from Lemma 2.1(a),(e) that

$$r^{n-1}u_r(r;\alpha) = -\int_0^r s^{n-1}K(s)|u(s;\alpha)|^{p-1}u(s;\alpha)\,ds \to -(n-2)\gamma$$

as $r \to \infty$. Since the above integral is convergent as $r \to \infty$, there exists a sequence $\{\bar{r}_j\}$ such that $\bar{r}_j \to \infty$ and $\bar{r}_j^n K(\bar{r}_j)|u(\bar{r}_j;\alpha)|^p \to 0$ as $j \to \infty$. On the other hand, we have

$$\lim_{r\to\infty} r^{n-1}u_r\{ru_r + (n-2)u\} = 0$$

in view of Lemma 2.1(e),(f). These imply that $P(\bar{r}_j;u) \to 0$ as $j \to \infty$. Thus (b) holds.

Next, we prove (c) by assuming that $u > 0$ and $u_r < 0$ in a neighborhood of $r = \infty$. If r is sufficiently large, we have

$$\begin{aligned} P(r;u) &= \frac{1}{2}r^2u_r\{r^{n-2}u_r + (n-2)r^{n-3}u\} + \frac{1}{p+1}ru\{r^{n-1}K(r)|u|^{p-1}u\} \\ &= \frac{1}{2}r^2u_r(r^{n-2}u)_r - \frac{1}{p+1}ru(r^{n-1}u_r)_r \\ &= -r^nuu_r\left\{-\frac{1}{2}\frac{(r^{n-2}u)_r}{r^{n-2}u} + \frac{1}{p+1}\frac{(r^{n-1}u_r)_r}{r^{n-1}u_r}\right\} \\ &= -r^nuu_r\frac{d}{dr}\left\{-\frac{1}{2}\log(r^{n-2}u) + \frac{1}{p+1}\log(-r^{n-1}u_r)\right\} \\ &= -r^nuu_r\frac{d}{dr}\left\{\left(\frac{1}{p+1} - \frac{1}{2}\right)\log(r^{n-2}u) + \frac{1}{p+1}\log\left(\frac{-r^{n-1}u_r}{r^{n-2}u}\right)\right\}. \end{aligned}$$

Here $r^{n-2}u \to \infty$ as $r \to \infty$ if $u = u(r;\alpha)$ is of Type $S(i)$. Moreover, it follows from (2.1) that $-ru_r(r)/u(r) < n-2$ if r is sufficiently large. Hence we have

$$\left(\frac{1}{p+1} - \frac{1}{2}\right)\log(r^{n-2}u) + \frac{1}{p+1}\log\left(\frac{-r^{n-1}u_r}{r^{n-2}u}\right) \to -\infty$$

as $r \to \infty$. This implies (c). The proof in the case $u < 0$ and $u_r > 0$ in a neighborhood of $r = \infty$ can be obtained in the same manner.

Finally let $u = u(r;\alpha)$ be of Type O and let $z_j(\alpha)$ denote the jth zero of $u = u(r;\alpha)$. If $u_r(z_j(\alpha);\alpha) = 0$, then $u(r;\alpha) \equiv 0$ for all r, contradicting $u(0;\alpha) = \alpha > 0$. Hence we obtain $u_r(z_j(\alpha);\alpha) \neq 0$ for every j. Then

$$P(z_j(\alpha);u) = \frac{1}{2} z_j(\alpha)^n u_r(z_j(\alpha);\alpha)^2 > 0. \tag{2.3}$$

Thus (d) holds by taking $\tilde{r}_j = z_j(\alpha)$. □

LEMMA 2.4. *Suppose that $rK(r) \notin L^1(1,\infty)$. If $u = u(r;\alpha)$ is not of Type O, then $uu_r < 0$ in a neighborhood of $r = \infty$.*

Proof. We consider the case where $u(r;\alpha) > 0$ in a neighborhood of $r = \infty$. The proof in the case where $u(r;\alpha) < 0$ in a neighborhood of $r = \infty$ is obtained in the same manner.

Since $(r^{n-1}u_r)_r = -r^{n-1}K(r)|u|^{p-1}u < 0$ if $u > 0, r^{n-1}u_r$ is a strictly decreasing function of r in a neighborhood of $r = \infty$. This means that $u_r(r;\alpha) > 0$ near $r = \infty$ or $u_r(r;\alpha) < 0$ near $r = \infty$. Suppose that the former holds. Then there exist $\delta > 0$ and $R > 0$ such that $u(r;\alpha) > \delta$ on $[R,\infty)$. Integrating (2.2) over $[R,r]$, we get

$$\begin{aligned} &ru_r(r;\alpha) + (n-2)u(r;\alpha) \\ &\quad = Ru_r(R;\alpha) + (n-2)u(R;\alpha) \\ &\qquad - \int_R^r sK(s)|u(s;\alpha)|^{p-1}u(s;\alpha)\,ds \\ &\quad \le Ru_r(R;\alpha) + (n-2)u(R;\alpha) \\ &\qquad - \delta^p \int_R^r sK(s)\,ds. \end{aligned}$$

Here, by assumption, the right-hand side diverges to $-\infty$ as $r \to \infty$, while the left-hand side is positive in view of Lemma 2.1(d). This is a contradiction. Thus it is shown that $u_r(r;\alpha) < 0$ in a neighborhood of $r = \infty$. □

LEMMA 2.5. *If $\lim_{r\to\infty} \sup rK_r(r)/K(r) < \lambda$, then $u(r;\alpha)$ is not of Type O for any $\alpha > 0$.*

Proof. Set

$$w(t;\alpha) := r^{n-2}u(r;\alpha), \qquad t := r^{n-2}.$$

Then the equation in (1.1) is rewritten as

$$w_{tt} + M(t)|w|^{p-1}w = 0, \tag{2.4}$$

where

$$M(t) := (n-2)^{-2}t^{-p-(n-4)/(n-2)}K(t^{1/(n-2)}).$$

It was shown in Theorem 2 of Kiguradze [7] that if $M(t)$ satisfies

$$\frac{d}{dt}\{t^{(p+3)/2+\varepsilon}M(t)\} \le 0 \quad \text{on } (T,\infty) \tag{2.5}$$

for some $\varepsilon > 0$ and $T > 0$, then any solution of (2.4) has at most a finite number of zeros on (T,∞).

Changing the variable from t to r, we get

$$\begin{aligned}\frac{d}{dt}\{t^{(p+3)/2+\varepsilon}M(t)\} &= (n-2)^2\frac{d}{dt}\{t^{(3-p)/2+\varepsilon-(n-4)/(n-2)}K(t^{1/(n-2)})\}\\ &= (n-2)^2\frac{dr}{dt}\frac{d}{dr}\{r^{(n-2)((3-p)/2+\varepsilon)-(n-4)}K(r)\}\\ &= (n-2)r^{n-3}\frac{d}{dr}\{r^{-\lambda+(n-2)\varepsilon}K(r)\}\\ &= (n-2)r^{n-3}K(r)\{rK_r/K(r)-\lambda+(n-2)\varepsilon\}.\end{aligned}$$

By assumption on $K(r)$, if we take $\varepsilon > 0$ sufficiently small and $T > 0$ sufficiently large, then the condition (2.5) is satisfied. This completes the proof. □

LEMMA 2.6. *If* (K.1) *holds, then* $\sigma = \lim_{r\to 0} rK_r(r)/K(r) \in (-2, +\infty]$.

Proof. Suppose that $\sigma \le -2$. Then, by (K.1), we have $rK_r(r)/K(r) \le -2$ on $(0,\infty)$, which is equivalent to $\{r^2K(r)\}_r \le 0$ on $(0,\infty)$. Hence there exists a constant $C > 0$ such that $r^2K(r) \ge C$ on (0, 1). However this contradicts the assumption $rK(r) \in L^1(0,1)$. □

LEMMA 2.7. *If* $\ell = \lim_{r\to\infty} rK_r(r)/K(r) \in (-\infty, \lambda)$, *then* $r^{n-1-(n-2)p}K(r) \in L^1(1,\infty)$.

Proof. We have

$$\lambda + n - (n-2)p = -\frac{(n-2)(p-1)}{2} < 0.$$

Hence, if we take $\varepsilon > 0$ small enough, then

$$\begin{aligned}&\{r^{n-(n-2)p+\varepsilon}K(r)\}_r\\ &\quad = r^{n-1-(n-2)p+\varepsilon}K(r)\{rK_r/K(r)+n-(n-2)p+\varepsilon\}\\ &\quad < r^{n-1-(n-2)p}K(r)\{rK_r/K(r)-\lambda\} < 0\end{aligned}$$

for every sufficiently large $r > 0$. Therefore there exists a constant $C > 0$ such that

$$r^{n-1-(n-2)p}K(r) < Cr^{-1-\varepsilon} \quad \text{for } r > 1.$$

This implies that $r^{n-1-(n-2)p}K(r) \in L^1(1,\infty)$. □

3. Proof of Theorem 1.

In this section, we give a proof of Theorem 1.

Let $U = U(r)$ be the unique solution of the following linearized equation of (1.1) at $u(r;\alpha)$:

$$(3.1) \qquad \begin{cases} (r^{n-1}U_r)_r + pr^{n-1}K(r)|u(r;\alpha)|^{p-1}U = 0, & r > 0,\\ U(0) = 1. \end{cases}$$

Differentiating (1.1) with respect to α, we see that the unique solution of this equation is given by

$$U(r) = \frac{\partial}{\partial\alpha}u(r;\alpha).$$

Let $z_j(\alpha)$ denote the jth zero of $u(r;\alpha)$, and let τ_j denote the jth zero of $U(r)$.

The following two propositions are the most technical part in this paper. We will give their proofs in §§5 and 6, respectively.

PROPOSITION 3.1. *Suppose that* (K.1) *holds. If $u(r;\alpha)$ has at least $i\,(>0)$ zeros on $(0,\infty)$, then $U(r)$ has exactly i zeros on $(0,z_i(\alpha))$ satisfying $\tau_1\in(0,z_1(\alpha))$ and $\tau_j\in(z_{j-1}(\alpha),z_j(\alpha)), j=2,3,\dots,i$.*

PROPOSITION 3.2. *Suppose that* (K.1) *holds and $rK_r(r)/K(r)\not\equiv\lambda$. If $u(r;\alpha)$ is of Type $R(i)$, then there exists $\delta>0$ such that $u(r;\alpha')$ has at least $i+1$ zeros for every $\alpha'\in(\alpha,\alpha+\delta)$.*

Now let us complete the proof of Theorem 1 by using these propositions.

Proof of Theorem 1(b). Differentiating $u(z_j(\alpha);\alpha)=0$ with respect to α, we obtain

$$u_r(z_j(\alpha);\alpha)\frac{d}{d\alpha}z_j(\alpha)+U(z_j(\alpha))=0. \tag{3.2}$$

Here, by Proposition 3.1, U satisfies

$$\begin{cases} U(z_j(\alpha))<0 & \text{if } u_r(z_j(\alpha);\alpha)<0,\\ U(z_j(\alpha))>0 & \text{if } u_r(z_j(\alpha);\alpha)>0.\end{cases}$$

Hence we obtain $\frac{d}{d\alpha}z_j(\alpha)<0$. □

Proof of Theorem 1(a). Since any zero of $u(r;\alpha)$ is a strictly decreasing continuous function of α, the zero does not disappear as α increases.

Let $\{\alpha_i\}$ be a nondecreasing sequence defined by $\alpha_0=0$ and

$$\alpha_i:=\sup\{\alpha|u(r;\alpha)\text{ has at most } i-1 \text{ zeros }\},\qquad i=1,2,3,\dots. \tag{3.3}$$

Since the number of zeros of $u(r;\alpha)$ never decreases as α increases, we see from Lemma 2.5 that $\alpha_i<\infty$ for every i and that $\alpha_i\to\infty$ as $i\to\infty$. Moreover, in view of Proposition 3.2, $u(r;\alpha)$ must be of Type $S(i)$ for every $\alpha\in(\alpha_i,\alpha_{i+1})$. This implies that the sequence $\{\alpha_i\}$ given in Theorem A coincides with the sequence $\{\alpha_i\}$ given by (3.3). Thus the proof is complete. □

Proof of Theorem 1(c). We introduce the Kelvin transformation

$$v(s):=r^{n-2}u(r),\qquad s:=r^{-1}. \tag{3.4}$$

By this transformation, the equation in (1.1) is rewritten as

$$(s^{n-1}v_s)_s+s^{n-1}L(s)|v|^{p-1}v=0,$$

where

$$L(s):=s^{2\lambda}K(s^{-1}).$$

It is clear that $L(s)\in C^1((0,\infty))$ and $L(r)>0$ on $(0,\infty)$. Also, if $\ell<\lambda$, then it follows from Lemma 2.7 that

$$\lim_{\varepsilon\to0}\int_\varepsilon^1 sL(s)\,ds=\int_1^\infty r^{n-1-(n-2)p}K(r)\,dr<\infty.$$

Thus $L(s)$ satisfies the condition (K.0). Moreover, we have

$$\begin{aligned} sL_s(s)/L(s)&=s\{2\lambda s^{2\lambda-1}K(s^{-1})-s^{2\lambda-2}K_r(s^{-1})\}/s^{2\lambda}K(s^{-1})\\ &=2\lambda-rK_r(s^{-1})/K(s^{-1}).\end{aligned}$$

Hence $sL_s(s)/L(s)$ is a nonincreasing function of s and satisfies

$$\lim_{s\to 0} sL_s(s)/L(s) = 2\lambda - \ell > \lambda,$$
$$\lim_{s\to 0} sL_s(s)/L(s) = 2\lambda - \sigma < \lambda.$$

Thus $L(s)$ satisfies the same condition as $K(r)$.

Now let us consider the initial value problem

$$(3.5) \qquad \begin{cases} (s^{n-1}v_s)_s + s^{n-1}L(s)|v|^{p-1}v = 0, \\ v(0) = \beta > 0. \end{cases}$$

We denote by $v(s;\beta)$ the unique solution of this problem. By applying Theorem 1(a) to (3.5), there exist $0 = \beta_0 < \beta_1 < \beta_2 < \cdots < \infty$ with $\lim_{i\to\infty}\beta_i = \infty$ such that $v(s;\beta)$ is of Type $R(i)$ if and only if $\beta = \beta_i$. In view of (3.4), we see that $u(r;\alpha_i)$ and $v(s;\beta_i)$ are related by

$$(3.6) \qquad u(r;\alpha_i) \equiv (-1)^{i+1}r^{-(n-2)}v(r^{-1};\beta_i) \quad \text{on } (0,\infty)$$

and that $u(r;\alpha_i)$ satisfies

$$\lim_{r\to\infty} r^{n-2}|u(r;\alpha_i)| = \beta_i.$$

This proves (c). □

Proof of Theorem 1(d). Let $z_j(\alpha)$ and $y_j(\beta)$ be the jth zero of $u(r;\alpha)$ and $v(s;\beta)$, respectively. By (b) and $\alpha_i < \alpha_{i+1}$, we have

$$(3.7) \qquad z_j(\alpha_i) > z_j(\alpha_{i+1}).$$

Similarly, by applying (a) and (b) to (3.5), we have

$$y_{i-j}(\beta_i) > y_{i-j}(\beta_{i+1}).$$

Here, in view of (3.4) and (3.6), we see that $y_{i-j}(\beta_i) = 1/z_j(\alpha_i)$ and $y_{i-j}(\beta_{i+1}) = 1/z_{j+1}(\alpha_{i+1})$. Hence we get

$$(3.8) \qquad z_j(\alpha_i) < z_{j+1}(\alpha_{i+1}).$$

Thus, by (3.7) and (3.8), we obtain

$$z_j(\alpha_{i+1}) < z_j(\alpha_i) < z_{j+1}(\alpha_{i+1})$$

for every i and j. This completes the proof of (d). □

4. Proof of Theorem 2. In this section we give a proof of Theorem 2.

Proof of Theorem 2(a). Assume that $rK_r(r)/K(r) \equiv \lambda$ on $(0,\infty)$. Then, by Lemma 2.2 and Lemma 2.3(a), we have $P(r;u) \equiv P(\varepsilon_j;u)$ on $[\varepsilon_j,\infty)$. Letting $j\to\infty$, we obtain $P(r;u) \equiv 0$ on $(0,\infty)$. Hence, in view of (2.3), $u(r;\alpha)$ has no zero on $(0,\infty)$. Then it follows from Lemma 2.1 that $u > 0$ and $u_r < 0$ on $(0,\infty)$. Thus, by Lemma 2.3, $u(r;\alpha)$ must be of Type $R(0)$ for every $\alpha \in (0,\infty)$. □

Proof of Theorem 2(b). Assume that $rK_r(r)/K(r) \le \lambda$ and $rK_r(r)/K(r) \not\equiv \lambda$ on $(0,\infty)$. Then, by Lemma 2.2 and Lemma 2.3(a), we have $P(r;u) \le 0$ on $(0,\infty)$ and there exist $R > 0$ and $\delta > 0$ such that $P(r;u) < -\delta$ on (R,∞). Hence, in view of (2.3), $u(r;\alpha)$ has no zero on $(0,\infty)$. Then it follows from Lemma 2.1 that $u > 0$ and $u_r < 0$ on $(0,\infty)$. Thus, by Lemma 2.3, $u(r;\alpha)$ must be of Type $S(0)$ for every $\alpha \in (0,\infty)$. Thus (b) is proved. □

Proof of Theorem 2(c). Assume that $rK_r(r)/K(r) \geq \lambda$ and $rK_r(r)/K(r) \not\equiv \lambda$ on $(0,\infty)$. The inequality $rK_r(r)/K(r) \geq \lambda$ is equivalent to $\{r^{-\lambda}K(r)\}_r \geq 0$. Hence there exists a constant $C > 0$ such that $K(r) \geq Cr^{\lambda}$ on $(1,\infty)$. Here

$$\lambda = \frac{(n-2)p-(n+2)}{2} = \frac{(n-2)(p-1)}{2} - 2 > -2.$$

This implies that $rK(r) \notin L^1(1,\infty)$. On the other hand, by Lemma 2.2, there exist $R > 0$ and $\delta > 0$ such that $P(r;u) > \delta$ on (R,∞). Hence, by Lemmas 2.3 and 2.4, $u(r;\alpha)$ must be of Type O for every $\alpha \in (0,\infty)$. Moreover, by Proposition 3.1 and (3.2), we obtain $\frac{d}{d\alpha}z_j(\alpha) < 0$ for every j. Thus the proof is complete. □

5. Proof of Proposition 3.1. In this section, we give a proof of Proposition 3.1. Throughout this section, we assume that $u(r;\alpha)$ has at least $i\,(> 0)$ zeros on $(0,\infty)$. By developing the ideas in [9, 15, 16], we will construct a comparison function that oscillates faster than $U(r)$.

We prepare a few lemmas. For convenience, we set $z_0(\alpha) = 0$ in the following.

LEMMA 5.1. *Suppose that* (K.1) *holds. Then the inequality* $(ru_r/u)_r < 0$ *holds for* $r \in (z_{j-1}(\alpha), z_j(\alpha)), j = 1,2,3,\dots,i$.

Proof. By (2.2), we have

$$\begin{aligned}(ru_r/u)_r &= \frac{(ru_r)_r u - ru_r^2}{u^2}\\ &= -\frac{u_r\{ru_r + (n-2)u\} + rK(r)|u|^{p+1}}{u^2}.\end{aligned}$$

Since $p > 1$ and $K(r) > 0$, we obtain

$$(ru_r/u)_r < -\frac{2P(r;u)}{r^{n-1}u^2}.$$

Thus it is sufficient to show that $P(r;u) \geq 0$ on $(0, z_i(\alpha))$.

By (K.1) and Lemma 2.2, there exists $R \in [0,\infty]$ such that

$$\begin{aligned}&\frac{d}{dr}P(r;u) \geq 0 \quad \text{for } r \in (0,R),\\ &\frac{d}{dr}P(r;u) \leq 0 \quad \text{for } r \in (R,\infty).\end{aligned}$$

Hence we have $P(r;u) \geq P(\varepsilon_j;u)$ for $r \in [\varepsilon_j, R)$, where $\{\varepsilon_j\}$ is the sequence as in Lemma 2.3(a). Letting $j \to \infty$, we obtain $P(r;u) \geq 0$ for $r \in (0,R)$. Thus, if $z_i(\alpha) \leq R$, then $P(r;u) \geq 0$ for $r \in (0, z_i(\alpha))$. Conversely, if $z_i(\alpha) > R$, then it follows from (2.3) that $P(r;u) \geq P(z_i(\alpha);u) > 0$ for $r \in (R, z_i(\alpha)]$. Thus the proof is complete. □

Let L be a linear operator defined by

$$L[U] = (r^{n-1}U_r)_r + pr^{n-1}K(r)|u(r;\alpha)|^{p-1}U.$$

Then (3.1) is equivalent to $L[U(r)] = 0$ and $U(0) = 1$.

LEMMA 5.2. *Suppose that* (K.1) *holds. Then there exist sequences* $\{\mu_j\}$ *and* $\{\rho_j\}, j = 1, 2, \ldots, i$, *such that*

(a) $0 < \mu_1 < +\infty$;

(b) $-\infty < \mu_i \leq \mu_{i-1} \leq \cdots \leq \mu_1 < \infty$;

(c) $\rho_j \in (z_{j-1}(\alpha), z_j(\alpha))$;

(d) *if* j *is odd, then*

$$\begin{cases} \mu_j u + r u_r > 0 \textit{ and } L[\mu_j u + r u_r] \leq 0 & \textit{for } r \in (z_{j-1}(\alpha), \rho_j), \\ \mu_j u + r u_r < 0 \textit{ and } L[\mu_j u + r u_r] \geq 0 & \textit{for } r \in (\rho_j, z_j(\alpha)), \end{cases}$$

and if j *is even, then*

$$\begin{cases} \mu_j u + r u_r < 0 \textit{ and } L[\mu_j u + r u_r] \geq 0 & \textit{for } r \in (z_{j-1}(\alpha), \rho_j), \\ \mu_j u + r u_r > 0 \textit{ and } L[\mu_j u + r u_r] \leq 0 & \textit{for } r \in (\rho_j, z_j(\alpha)). \end{cases}$$

Proof. We have

$$\begin{aligned} L[u] &= (r^{n-1}u_r)_r + pr^{n-1}K(r)|u|^{p-1}u, \\ L[ru_r] &= \{r^{n-1}(ru_r)_r\}_r + pr^{n-1}K(r)|u|^{p-1}(ru_r). \end{aligned}$$

Using

$$(r^{n-1}u_r)_r = -r^{n-1}K(r)|u|^{p-1}u, \tag{5.1}$$

we get

$$L[u] = (p-1)r^{n-1}K(r)|u|^{p-1}u. \tag{5.2}$$

Using (5.1) and

$$\begin{aligned} (r^{n-1}u_r)_{rr} &= -\{r^{n-1}K(r)|u|^{p-1}u\}_r \\ &= -(n-1)r^{n-2}K(r)|u|^{p-1}u - r^{n-1}K_r(r)|u|^{p-1}u - pr^{n-1}K(r)|u|^{p-1}u_r, \end{aligned}$$

we get

$$L[ru_r] = -r^{n-1}K(r)\{rK_r(r)/K(r) + 2\}|u|^{p-1}u. \tag{5.3}$$

Thus, by (5.2) and (5.3), we obtain

$$L[\mu u + ru_r] = r^{n-1}K(r)|u|^{p-1}u\{(p-1)\mu - rK_r(r)/K(r) - 2\}, \tag{5.4}$$

where μ is a parameter.

Let Γ be a curve on the two-dimensional plane defined by

$$\Gamma := \{(r, rK_r(r)/K(r) + 2); r \in (0, \infty)\}.$$

According to Lemma 5.1, for any $\rho \in (0, z_1(\alpha))$, there exists a unique $\mu = \bar{\mu}_1(\rho) \in (0, +\infty)$ such that

$$\begin{cases} \bar{\mu}_1(\rho)u + ru_r > 0 & \text{for } r \in (0, \rho), \\ \bar{\mu}_1(\rho)u + ru_r < 0 & \text{for } r \in (\rho, z_1(\alpha)), \end{cases}$$

and $\bar{\mu}_1(\rho)$ is a strictly increasing continuous function of ρ satisfying

$$\begin{cases} \bar{\mu}_1(\rho) \downarrow 0 & \text{as } \rho \downarrow 0, \\ \bar{\mu}_1(\rho) \uparrow +\infty & \text{as } \rho \uparrow z_1(\alpha). \end{cases}$$

By Lemma 2.6, this implies that the point $(\rho, (p-1)\bar{\mu}_1(\rho))$ is below Γ if $\rho = +0$ and above Γ if $\rho = z_1(\alpha) - 0$. Hence, by the continuity of Γ, there exist $\rho_1 \in (0, z_1(\alpha))$ and $\mu_1 := \bar{\mu}_1(\rho_1) > 0$ such that $(\rho_1, (p-1)\mu_1)$ is just on the curve Γ, i.e.,

$$(p-1)\mu_1 - \rho_1 K_r(\rho_1)/K(\rho_1) - 2 = 0.$$

Then, since $rK_r(r)/K(r)$ is nonincreasing, we have

$$\begin{cases} (p-1)\mu_1 - rK_r(r)/K(r) - 2 \le 0 & \text{for } r \in (0, \rho_1), \\ (p-1)\mu_1 - rK_r(r)/K(r) - 2 \ge 0 & \text{for } r \in (\rho_1, z_1(\alpha)). \end{cases}$$

By (5.4), this implies

$$\begin{cases} L[\mu_1 u + r u_r] \le 0 & \text{for } r \in (0, \rho_1), \\ L[\mu_1 u + r u_r] \ge 0 & \text{for } r \in (\rho_1, z_1(\alpha)). \end{cases}$$

Similarly, for any $\rho \in (z_1(\alpha), z_2(\alpha))$, there exists $\mu = \bar{\mu}_2(\rho) \in (-\infty, +\infty)$ such that

$$\begin{cases} \bar{\mu}_2(\rho) u + r u_r < 0 & \text{for } r \in (z_1(\alpha), \rho), \\ \bar{\mu}_2(\rho) u + r u_r > 0 & \text{for } r \in (\rho, z_2(\alpha)), \end{cases}$$

and $\bar{\mu}_2(\rho)$ is a strictly increasing continuous function of ρ satisfying

$$\begin{cases} \bar{\mu}_2(\rho) \downarrow -\infty & \text{as } \rho \downarrow z_1(\alpha), \\ \bar{\mu}_2(\rho) \uparrow +\infty & \text{as } \rho \uparrow z_2(\alpha). \end{cases}$$

This implies that the point $(\rho, (p-1)\bar{\mu}_2(\rho))$ is below Γ if $\rho = z_1(\alpha) + 0$ and above Γ if $\rho = z_2(\alpha) - 0$. Hence, by the continuity of Γ, there exists $\rho_2 \in (z_1(\alpha), z_2(\alpha))$ and $\mu_2 := \bar{\mu}_2(\rho_2)$ such that $(\rho_2, (p-1)\mu_2)$ is just on the curve Γ, i.e.,

$$(p-1)\mu_2 - \rho_2 K_r(\rho_2)/K(\rho_2) - 2 = 0.$$

Then, by (K.1), we have

$$\begin{cases} (p-1)\mu_2 - rK_r(r)/K(r) - 2 \le 0 & \text{for } r \in (z_1(\alpha), \rho_2), \\ (p-1)\mu_2 - rK_r(r)/K(r) - 2 \ge 0 & \text{for } r \in (\rho_2, z_2(\alpha)). \end{cases}$$

By (5.4), this implies

$$\begin{cases} L[\mu_2 u + r u_r] \ge 0 & \text{for } r \in (z_1(\alpha), \rho_2), \\ L[\mu_2 u + r u_r] \le 0 & \text{for } r \in (\rho_2, z_2(\alpha)). \end{cases}$$

Repeating this process, we obtain (a), (c), and (d).

Finally, since $\{\rho_j\}$ is a strictly increasing sequence and

$$(p-1)\mu_j - \rho_j K_r(\rho_j)/K(\rho_j) - 2 = 0,$$

it follows from (K.1) that $\{\mu_j\}$ is a nonincreasing sequence. Thus (b) holds. □

Let $V(r)$ be a function on $(0, z_i(\alpha)]$ defined by

$$V(r) = \mu_j u(r;\alpha) + r u_r(r;\alpha)) \quad \text{for } r \in (z_{j-1}(\alpha), z_j(\alpha)],\ j = 1,2,3,\dots,i, \tag{5.5}$$

where $\{\mu_j\}$ is the sequence given in Lemma 5.2. Since $u(r;\alpha) = 0$ at $r = z_j(\alpha), V(r)$ is a continuous function. However $V(r)$ is not smooth at $r = z_j(\alpha)$ if $\mu_j \neq \mu_{j+1}$. Note that, by Lemma 5.2(d), $V(r) = 0$ if and only if $r = \rho_j$.

Let us introduce the Prüfer transformation

$$\begin{cases} u(r;\alpha) = Q(r;u)\cos(\theta(r;u)), \\ -r^{n-1}u_r(r;\alpha) = Q(r;u)\sin(\theta(r;u)), \end{cases}$$

where $Q(r;u) := \{u(r;\alpha)^2 + (r^{n-1}u_r(r;\alpha))^2\}^{1/2} > 0$ and $\theta(r;u)$ is a smooth function of r satisfying $\theta(0;u) = 0$. Since $u_r = r^{1-n}(r^{n-1}u_r)$ and $-(r^{n-1}u_r)_r = r^{n-1}K(r)|u|^{p-1}u$, we have

$$Q_r\cos(\theta) - Q\sin(\theta)\theta_r = -r^{1-n}Q\sin(\theta), \tag{5.6}$$

$$Q_r\sin(\theta) + Q\cos(\theta)\theta_r = r^{n-1}K(r)|u|^{p-1}Q\cos(\theta), \tag{5.7}$$

where $Q = Q(r;u)$ and $\theta = \theta(r;u)$. Multiplying (5.6) and (5.7) by $-\sin(\theta)$ and $\cos(\theta)$, respectively, and adding them, we obtain

$$\theta_{\mathrm{r}}(r;u) = r^{1-n}\sin^2(\theta(r;u)) + r^{n-1}K(r)|u|^{p-1}\cos^2(\theta(r;u)). \tag{5.8}$$

Similarly, put

$$\begin{cases} U(r) = Q(r;U)\cos(\theta(r;U)), \\ -r^{n-1}U_r(r) = Q(r;U)\sin(\theta(r;U)). \end{cases}$$

Then we may assume that $\theta(0;U) = 0$ and

$$\theta_r(r;U) = r^{1-n}\sin^2(\theta(r;U)) + pr^{n-1}K(r)|u|^{p-1}\cos^2(\theta(r;U)). \tag{5.9}$$

As for the function $V(r)$, the situation is a little delicate. Put

$$\begin{cases} V(r) = Q(r;V)\cos(\theta(r;V)), \\ -r^{n-1}V_r(r) = Q(r;V)\sin(\theta(r;V)). \end{cases}$$

Since $0 < \mu_1 < +\infty$, we have $V(0) > 0$. Hence we may assume that $\theta(r;V) \in (-\pi/2, \pi/2)$ if $r > 0$ is sufficiently small. We may assume that $\theta(r;V)$ is continuous on $(z_{j-1}(\alpha), z_j(\alpha))$. However, since $V(r)$ may not be smooth at $r = z_j(\alpha), \theta(r;V)$ may be discontinuous at $r = z_j(\alpha)$. In fact, we have

$$V_r(z_j(\alpha)+0) - V_r(z_j(\alpha)-0) = (\mu_{j+1} - \mu_j)u_r(z_j(\alpha);\alpha).$$

Since $\mu_j \geq \mu_{j+1}$ and

$$\begin{cases} u_r(z_j(\alpha);\alpha) < 0 & \text{if } j > 0 \text{ is odd}, \\ u_r(z_j(\alpha);\alpha) > 0 & \text{if } j > 0 \text{ is even}, \end{cases}$$

we obtain

$$\begin{cases} V_r(z_j(\alpha)-0) \le V_r(z_j(\alpha)+0) & \text{if } j \text{ is odd,} \\ V_r(z_j(\alpha)-0) \ge V_r(z_j(\alpha)+0) & \text{if } j \text{ is even.} \end{cases}$$

Since

$$\begin{cases} V(z_j(\alpha)) < 0 & \text{if } j \text{ is odd,} \\ V(z_j(\alpha)) > 0 & \text{if } j \text{ is even,} \end{cases}$$

we may assume that $\theta(r;V)$ satisfies

$$\theta(z_j(\alpha)+0;V) - \theta(z_j(\alpha)-0;V) \in [0,\pi) \tag{5.10}$$

for $j = 1, 2, \ldots, i-1$.

Now, by Lemma 5.2(d), $V(r)$ satisfies $-V(r)L[V(r)] \ge 0$. This is equivalent to

$$-Q\cos(\theta)\{-Q_r\sin(\theta) - Q\cos(\theta)\theta_r + pr^{n-1}K(r)|u|^{p-1}Q\cos(\theta)\} \ge 0,$$

where $Q = Q(r;V)$ and $\theta = \theta(r;V)$. On the other hand, $r^{n-1}V_r\{V_r - r^{1-n}(r^{n-1}V_r)\} = 0$ is equivalent to

$$-Q\sin(\theta)\{Q_r\cos(\theta) - Q\sin(\theta)\theta_r + r^{1-n}Q\sin(\theta)\} = 0.$$

Adding these two equalities, we obtain the differential inequality

$$\theta_r(r;V) \ge r^{1-n}\sin^2(\theta(r;V)) + pr^{n-1}K(r)|u|^{p-1}\cos^2(\theta(r;V)) \tag{5.11}$$

for $r \ne z_j(\alpha)$.

Now we have the next lemma.

LEMMA 5.3. *Suppose that* (K.1) *holds. Then* $\theta(r;u) < \theta(r;U) \le \theta(r;V)$ *for* $r \in (0, z_i(\alpha)]$.

Proof. We want to apply the comparison theorem (see [2, Chap. 8, Thm. 1.2]). However, since the right-hand sides of (5.8), (5.9), and (5.11) have singularities at $r = 0$, we need careful consideration in a neighborhood of $r = 0$.

First we prove the inequality $\theta(r;u) < \theta(r;U)$. Integrating $uL[U] = 0$ by parts on $[\varepsilon_j, r]$, we get

$$[r^{n-1}(U_r u - U u_r)]_{\varepsilon_j}^r = -(p-1)\int_{\varepsilon_j}^r s^{n-1}K(s)|u|^{p-1}uU\,ds, \tag{5.12}$$

where $\{\varepsilon_j\}$ is the sequence as in Lemma 2.3(a). Here, as $j \to \infty$, we have

$$\begin{aligned} u(\varepsilon_j;\alpha) &\to \alpha, \\ \varepsilon_j^{n-1}u_r(\varepsilon_j;\alpha) &\to 0, \\ U(\varepsilon_j) &\to 1, \\ \varepsilon_j^{n-1}U_r(\varepsilon_j) &= -\textstyle\int_0^{\varepsilon_j} pr^{n-1}K(r)|u|^{p-1}U\,dr \to 0. \end{aligned}$$

Thus we obtain

$$r^{n-1}(U_r u - U u_r) = -(p-1)\lim_{j\to\infty}\int_{\varepsilon_j}^r s^{n-1}K(s)|u|^{p-1}uU\,ds.$$

If $0 < r < \min\{z_1(\alpha), \tau_1\}$, then the right-hand side of this equality is negative. Hence we obtain $-r^{n-1}u_r/u < -r^{n-1}U_r/U$, i.e., $\theta(r; u) < \theta(r; U)$ if $r > 0$ is small. For $r > 0$, the right-hand sides of (5.8) and (5.9) have no singularity. Hence we can apply the comparison theorem to show that $\theta(r; u) < \theta(r; U)$ for all $r > 0$.

Next we prove $\theta(r; U) \leq \theta(r; V)$. Let $r > 0$ be sufficiently small. Integrating $VL[U] = 0$ by parts on $[\varepsilon_j, r]$, we get

$$[r^{n-1}(U_rV - UV_r)]_{\varepsilon_j}^r = -\int_{\varepsilon_j}^r L[V]U\,ds.$$

Here, as $j \to \infty$, we have

$$\begin{aligned} U(\varepsilon_j) &\to 1, \\ \varepsilon_j^{n-1}U_r(\varepsilon_j) &\to 0, \\ V(\varepsilon_j) &\to \mu_1\alpha, \\ \varepsilon_j^{n-1}V_r(\varepsilon_j) &= \varepsilon_j^{n-1}\{(\mu_1+1)u_r(\varepsilon_j;\alpha) + \varepsilon_j u_{rr}(\varepsilon_j;\alpha)\} \\ &= \varepsilon_j^{n-1}\{(\mu_1 - n + 2)u_r(\varepsilon_j;\alpha) - \varepsilon_j K(\varepsilon_j)|u(\varepsilon_j;\alpha)|^{p-1}u(\varepsilon_j;\alpha)\} \to 0. \end{aligned}$$

Thus we obtain

$$r^{n-1}(U_rV - UV_r) = -\lim_{j\to\infty}\int_{\varepsilon_j}^r L[V]U\,ds.$$

Here the right-hand side of this equality is nonnegative in view of Lemma 5.2(d). Thus we obtain $-r^{n-1}U_r/U \leq -r^{n-1}V_r/V$, i.e., $\theta(r; U) \leq \theta(r; V)$ if $r > 0$ is small. For $r > 0$, the right-hand sides of (5.9) and (5.11) have no singularity. Hence we can apply the comparison theorem to show that $\theta(r; U) \leq \theta(r; V)$ for $r \in (0, z_1(\alpha))$. Then, by (5.10), we obtain $\theta(z_1(\alpha) - 0; U) \leq \theta(z_1(\alpha) + 0; V)$. Again we can apply the comparison theorem to show that $\theta(r; U) \leq \theta(r; V)$ for $r \in (z_1(\alpha), z_2(\alpha))$. Repeating this process, we obtain $\theta(r; U) \leq \theta(r; V)$ for $r \in (0, z_i(\alpha))$. □

Let us complete the proof of Proposition 3.1.

Proof of Proposition 3.1. By Lemma 5.3, the inequalities $\theta(r; u) < \theta(r; U) \leq \theta(r; V)$ hold. These imply that $U(r)$ oscillates faster than $u(r; \alpha)$ and more slowly than $V(r)$. Since ρ_j is the unique zero of $V(r)$ in $[z_{j-1}(\alpha), z_j(\alpha)]$, we obtain $z_{j-1}(\alpha) < \rho_j \leq \tau_j < z_j(\alpha)$ for $j = 1, 2, \ldots, i$. This completes the proof. □

6. Proof of Proposition 3.2. In this section we give a proof of Proposition 3.2. For convenience, we put $z_0(\alpha) = 0$ and $z_{i+1}(\alpha) = \infty$ if $u(r; \alpha)$ is of Type $R(i)$.

The following lemma can be proved in the same way as Lemma 5.2 by noting Lemma 2.1(d) and Lemma 2.3(b). We omit the proof.

LEMMA 6.1. *Suppose that* (K.1) *holds. If* $u = u(r; \alpha)$ *is of Type* $R(i)$, *then there exist sequences* $\{\mu_j\}$ *and* $\{\rho_j\}$, $j = 1, 2, \ldots, i+1$, *such that*

(a) $0 < \mu_1 < +\infty$ *and* $-\infty < \mu_{i+1} < n - 2$,

(b) $-\infty < \mu_{i+1} \leq \mu_i \leq \cdots \leq \mu_1 < +\infty$,

(c) $\rho_j \in (z_{j-1}(\alpha), z_j(\alpha))$,

(d) *if* j *is odd, then*

$$\begin{cases} \mu_j u + r u_r > 0 \text{ and } L[\mu_j u + r u_r] \leq 0 & \text{for } r \in (z_{j-1}(\alpha), \rho_j), \\ \mu_j u + r u_r < 0 \text{ and } L[\mu_j u + r u_r] \geq 0 & \text{for } r \in (\rho_j, z_j(\alpha)), \end{cases}$$

and if j is even, then

$$\begin{cases} \mu_j u + r u_r < 0 \text{ and } L[\mu_j u + r u_r] \geq 0 & \text{for } r \in (z_{j-1}(\alpha), \rho_j), \\ \mu_j u + r u_r > 0 \text{ and } L[\mu_j u + r u_r] \leq 0 & \text{for } r \in (\rho_j, z_j(\alpha)). \end{cases}$$

Let $u(r;\alpha)$ be of Type $R(i)$, and let $V(r)$ be defined by

$$V(r) = \mu_j u(r;\alpha) + r u_r(r;\alpha) \quad \text{for } r \in [z_{j-1}(\alpha), z_j(\alpha)), j = 1, 2, \ldots, i+1.$$

Further let $\theta(r;u), \theta(r;U)$, and $\theta(r;V)$ be as in the previous section. Then, similar to Lemma 5.3, we have

$$\theta(r;u) < \theta(r;U) \leq \theta(r;V) \quad \text{on } (0,\infty). \tag{6.1}$$

Moreover, if $rK_r(r)/K(r) \not\equiv \text{Constant}$, then $L[V] \not\equiv 0$ in view of the proof of Lemma 5.2. By [2, Chap. 8, Thm. 1.2], this implies that there exists $R > 0$ such that

$$\theta(r;u) < \theta(r;U) < \theta(r;V) \quad \text{on } [R,\infty). \tag{6.2}$$

LEMMA 6.2. *Suppose that* (K.1) *holds. If $u(r;\alpha)$ is of Type $R(i)$, then $U(r)$ has exactly $i+1$ zeros on $(0,\infty)$ satisfying $\tau_j \in (z_{j-1}(\alpha), z_j(\alpha)), j = 1, 2, \ldots, i+1$.*

Proof. By Proposition 3.1, $U(r)$ has one and only one zero in $(z_{j-1}(\alpha), z_j(\alpha))$ for $j = 1, 2, \ldots, i$. By (6.1), $U(r)$ has at most one zero in $(z_i(\alpha), \infty)$. Thus it is sufficient to show that $U(r)$ has a zero in $(z_i(\alpha), \infty)$.

First we consider the case where $i\,(> 0)$ is even. Then $u(r;\alpha) > 0$ in a neighborhood of $r = \infty$. We will derive a contradiction by assuming that $U(r) > 0$ on $[z_i(\alpha), \infty)$. Similar to (5.12), we have

$$[r^{n-1}(U_r u - U u_r)]^r_{z_j(\alpha)} = -(p-1) \int_{z_i(\alpha)}^r s^{n-1} K(s) u^p U \, ds < 0. \tag{6.3}$$

Since $u(z_i(\alpha);\alpha) = 0, u_r(z_i(\alpha);\alpha) > 0$, and $U(z_i(\alpha)) > 0$, we obtain $r^{n-1}(U_r u - U u_r) < 0$ or $(U/u)_r < 0$ on $[z_i(\alpha), \infty)$. Hence there exists a constant $C > 0$ such that $0 < U < Cu$ on $[z_i(\alpha), \infty)$. Then we have

$$|r^{n-1} u_r U| < C |r^{n-1} u_r u| \to 0 \quad \text{as } r \to \infty.$$

Moreover, integrating (3.1) over $[z_i(\alpha), r]$, we obtain

$$\begin{aligned} |r^{n-1} U_r(r)| &\leq z_i(\alpha)^{n-1} |U_r(z_i(\alpha))| + p \int_{z_i(\alpha)}^r s^{n-1} K(s) u^{p-1} U \, ds \\ &\leq z_i(\alpha)^{n-1} |U_r(z_i(\alpha))| + Cp \int_{z_i(\alpha)}^r s^{n-1} K(s) u^p \, ds. \end{aligned}$$

Since $u(r;\alpha)$ is of Type $R(i)$, the integral in the right-hand side is convergent as $r \to \infty$. Hence $r^{n-1} U_r u \to 0$ as $r \to \infty$. Thus it is shown that the left-hand side of (6.3) is positive if r is sufficiently large. This contradicts (6.3). Hence $U(r)$ must have a zero in $(z_i(\alpha), \infty)$.

The proof in the case i is odd is obtained in the same manner. Finally the proof in the case $i = 0$ can be obtained by replacing $z_i(\alpha)$ by ε_j and letting $j \to \infty$, where $\{\varepsilon_j\}$ is the sequence as in Lemma 2.3(a). □

Now let us complete the proof of Proposition 3.2.

Proof of Proposition 3.2. We consider the case where i is even. The proof in the case i is odd can be obtained similarly. Note that if i is even, then $u(r;\alpha) > 0, U(r) < 0$, and $V(r) < 0$ in a neighborhood of $r = \infty$.

Assume that $u(r;\alpha)$ is of Type $R(i)$. Then, by the continuity of solutions with respect to initial data, there exists $\delta > 0$ such that $u(r;\alpha')$ has at least i zeros for $a' \in (\alpha, \alpha + \delta)$. Put

$$W(r) := \frac{u(r;\alpha') - u(r;\alpha)}{\alpha' - \alpha}.$$

Then $W(r)$ satisfies

$$\begin{cases} (r^{n-1}W_r)_r + r^{n-1}K(r)h(r)W = 0, & r > 0, \\ W(0) = 1, \end{cases}$$

where $h(r)$ is a continuous function given by

$$h(r) := \begin{cases} \dfrac{|u(r;\alpha')|^{p-1}u(r;\alpha') - |u(r;\alpha)|^{p-1}u(r;\alpha)}{u(r;\alpha') - u(r;\alpha)} \\ \qquad\qquad\qquad \text{if } u(r;\alpha') \neq u(r;\alpha), \\ p|u(r;\alpha)|^{p-1} \quad \text{if } u(r;\alpha') = u(r;\alpha). \end{cases}$$

We fix R so large that (6.2) and $R > \tau_{i+1}$ hold, where τ_{i+1} is the $(i+1)$th zero of $U(r)$. By definition, $W(r) \to U(r)$ and $W_r(r) \to U_r(r)$ as $\alpha' \to \alpha$ uniformly in $[0, R]$. Hence, if $\alpha' - \alpha > 0$ is sufficiently small, $W(r)$ has exactly $i + 1$ zeros on $[0, R]$ and satisfies $W(R) < 0$. Moreover, since the inequality $\theta(R; U) < \theta(R; V)$ is equivalent to

$$U_r(R)V(R) - U(R)V_r(R) > 0,$$

we have

$$W_r(R)V(R) - W(R)V_r(R) > 0 \tag{6.4}$$

if $\alpha' - \alpha > 0$ is sufficiently small.

For the behavior of $u(r;\alpha)$ in (R, ∞), one of the following three cases occurs.

Case 1. There exists $R_0 \in (R, \infty)$ such that $0 < u(r;\alpha') < u(r;\alpha)$ for $r \in (R, R_0)$ and $u(R_0;\alpha') - u(R_0;\alpha) = 0$.

Case 2. $0 < u(r;\alpha') < u(r;\alpha)$ for all $r \in (R, \infty)$.

Case 3. There exists $z_{i+1}(\alpha')$ such that $0 < u(r;\alpha') < u(r;\alpha)$ for $r \in (R, z_{i+1}(\alpha'))$ and $u(z_{i+1}(\alpha');\alpha') = 0$.

First suppose that Case 1 holds. Then $W(r)L[V(r)] \leq 0$ on $[R, R_0]$. Integrating this inequality by parts on $[R, R_0]$, we get

$$[r^{n-1}(W_rV - WV_r)]_R^{R_0} \geq \int_R^{R_0} r^{n-1}K(r)\{p|u(r;\alpha)|^{p-1} - h(r)\}V(r)W(r)\,dr. \tag{6.5}$$

Here, by $W(R_0) = 0, W_r(R_0) > 0, V(R_0) < 0$, and (6.4), the left-hand side of (6.5) is negative. On the other hand, since $p|u(r;\alpha)|^{p-1} > h(r)$ in view of $0 < u(r;\alpha') < u(r;\alpha)$ for $r \in (R, R_0)$, the right-hand side of (6.5) is positive. This is a contradiction.

Next suppose that Case 2 holds. Then $u(r;\alpha')$ also must be of Type $R(i)$. Similar to (6.5), integrating $W(r)L[V(r)] \leq 0$ by parts on $[R,r]$ and using (6.4), we obtain

$$r^{n-1}(W_rV - WV_r) > \int_R^r s^{n-1}K(s)\{p|u(s;\alpha)|^{p-1} - h(s)\}V(s)W(s)\,ds.$$

Here the integrand is positive. Hence we can take a constant $C_1 > 0$ such that

$$r^{n-1}(W_rV - WV_r) > C_1 \quad \text{for } r \in (R,\infty),$$

which is equivalent to

$$(W/V)_r > C_1 r^{1-n}V^{-2} \quad \text{for } r \in (R,\infty). \tag{6.6}$$

On the other hand, by the definition of V, we have

$$V(r)/u(r;\alpha) = \mu_{i+1} + ru_r(r;\alpha)/u(r;\alpha) \quad \text{for } r \in (z_i(\alpha),\infty).$$

Hence we see from Lemma 2.1(e) and Lemma 6.1(a) that

$$\lim_{r\to\infty} V(r)/u(r;\alpha) = \mu_{i+1} - (n-2) < 0.$$

Therefore there exist constants $C_2 > C_3 > 0$ such that

$$-C_2r^{2-n} < V(r) < -C_3r^{2-n} \quad \text{for } r \in (R,\infty). \tag{6.7}$$

Hence, by (6.6), we obtain

$$\begin{aligned}(W/V)_r &> C_1r^{1-n}V^{-2}\\ &\geq (C_1/C_2^2)r^{n-3} \quad \text{for } r \in (R,\infty).\end{aligned}$$

This implies that $W/V \to \infty$ as $r \to \infty$. Then it follows from (6.7) that $r^{n-2}W \to -\infty$ as $r \to \infty$. However, this contradicts the fact that both $u(r;\alpha')$ and $u(r;\alpha)$ are of Type $R(i)$.

Consequently, we conclude that Case 3 must hold. □

INITIAL AND INITIAL-BOUNDARY VALUE PROBLEMS FOR A VORTEX FILAMENT WITH OR WITHOUT AXIAL FLOW*

TAKAHIRO NISHIYAMA† AND ATUSI TANI†

Abstract. The equations which describe the motion of a vortex filament with or without an axial flow inside its core are considered. The initial and the initial-boundary value problems are proved to have unique and smooth solutions globally in time. These results are obtained by adding vanishing parabolic terms which conserve the length of the filament.

Key words. vortex filament, perfect fluid, localized induction equation, initial and initial-boundary value problems, unique and smooth solvability

AMS subject classifications. 35Q, 76C

1. Introduction.

The system of equations

$$x_t = x_s \times x_{ss} + a\left\{x_{sss} + \frac{3}{2}x_{ss} \times (x_s \times x_{ss})\right\} \tag{1.1}$$

approximately describes the deformation of a vortex filament with or without axial velocity in its thin core, in a perfect fluid. Here $x = x(s,t)$ denotes the position of a point on the filament in $\boldsymbol{R}^3$ as a vector-valued function of arclength s ($\in \boldsymbol{R}$) and time t (> 0), and a real constant a represents the magnitude of the effect of the axial flow. In particular, (1.1) with $a = 0$, from which the axial-flow effect is absent, is called the localized induction equation (LIE).

Since Da Rios [1] formulated the LIE in 1906, many authors have studied it from various points of view (see [9], [10], and the references therein). In [8], we proved the weak solvability of some initial and initial-boundary value problems for the LIE, although the expected uniqueness and smoothness of the solution were not found. On the other hand, (1.1) with $a \neq 0$ was originally derived by Fukumoto and Miyazaki [2] as a generalization of the LIE from the Moore–Saffman equation in [7].

Differentiating (1.1) with respect to s and setting $v = x_s$, we have

$$v_t = v \times v_{ss} + a\left\{v_{sss} + \frac{3}{2}v_{ss} \times (v \times v_s) + \frac{3}{2}v_s \times (v \times v_{ss})\right\}. \tag{1.2}$$

Impose the initial condition

$$v(s,0) = v_0(s), \quad |v_0| = 1, \tag{1.3}$$

on (1.2) for $s \in \boldsymbol{R}$. One of our aims in this paper is to establish the unique and smooth solvability of the initial value problem (1.2) with (1.3) in the space where the curvature of the vortex filament $|v_s|$ tends to zero as $s \to \pm\infty$, on the time interval $[0,T]$ with any $T > 0$. In order to achieve it, we first investigate the parabolic regularization

$$\begin{aligned} v_t = v \times v_{ss} + a\left\{v_{sss} + \frac{3}{2}v_{ss} \times (v \times v_s) + \frac{3}{2}v_s \times (v \times v_{ss})\right\} \\ -\epsilon\left\{v_{ssss} + 4(v_s \cdot v_{sss})v + 3|v_{ss}|^2 v\right\} \end{aligned} \tag{1.4}$$

for $\epsilon > 0$. After that, we let $\epsilon \to 0$.

The other aim is to obtain the unique and smooth solvability of an initial-boundary value problem for (1.2) by the above method. At this time, we treat the case $a = 0$ only.

By the way, (1.1) or (1.2) can be transformed into the Hirota equation (or the nonlinear Schrödinger equation if $a = 0$),

$$i\Psi_t + \Psi_{ss} + \frac{1}{2}|\Psi|^2\Psi - ia\left(\Psi_{sss} + \frac{3}{2}|\Psi|^2\Psi_s\right) = 0 \tag{1.5}$$

for $\Psi = \kappa(s,t)\exp\left(i\int_0^s \tau(s,t)ds + i\eta(t)\right)$, where $\kappa(s,t)$ and $\tau(s,t)$ are the curvature and the torsion of the filament, respectively, and $\eta(t)$ is a real function of t (see [2], [3], [5]). But, as in [8], we should remark that (1.5) is always equivalent to neither (1.1) nor (1.2). In fact, if the filament has a segment where $|x_{ss}|$ vanishes and τ is indefinite, then $\operatorname{Arg}\Psi$ is not well defined even outside there.

We introduce the notation and a result for a linear parabolic system in §2. Then a solution of (1.4) with (1.3) is obtained uniquely on $[0,T]$ with ϵ small enough in §3. In §4, we establish the theorem for (1.2) and (1.3) and obtain a corollary on the vanishing axial flow. In §5, an initial-boundary value problem is discussed.

2. Preliminaries. Let us introduce our notation. m denotes an arbitrary non-negative integer unless we particularly note otherwise. The norms of vector-valued functions in $L^2(\Omega)$ and in the Sobolev space $W_2^m(\Omega)$ are denoted by $\|\cdot\|_\Omega$ and $\|\cdot\|_\Omega^{(m)}$, respectively. Then $\|\cdot\|_\Omega^{(0)} = \|\cdot\|_\Omega$. When $\Omega = \boldsymbol{R}$, we write the norms as simply $\|\cdot\|$ and $\|\cdot\|^{(m)}$. The set of all continuous (resp. once continuously differentiable) functions in a Hilbert space X on a finite time interval $[0,T]$ is denoted by $C(0,T;X)$ (resp. $C^1(0,T;X)$). The class of Hölder-continuous X-valued functions on $[0,T]$ is written as $C^\beta(0,T;X)$, $0 < \beta < 1$. The norm $\langle\cdot\rangle_T$ (resp. $\langle\cdot\rangle_T^{(\beta)}$) represents the supremum (resp. the Hölder norm) over $[0,T]$. Positive constants, denoted by c, c_*, and c_a, change from line to line, but the second is independent of both ϵ and a and the third is monotonically increasing in $|a|$ and independent of ϵ. The operator D is equal to $\partial/\partial s$.

Next, consider a linear equation

$$u_t = -\epsilon u_{ssss} + f(s,t) \tag{2.1}$$

with

$$u(s,0) = u_0(s) \tag{2.2}$$

for $s \in \boldsymbol{R}$. Then we get the following result.

LEMMA 2.1. *If $\epsilon > 0$, $u_0 \in W_2^{4+m}(\boldsymbol{R})$, and $f \in C^\beta(0,T;W_2^m(\boldsymbol{R}))$ for $T > 0$, $0 < \beta < 1$, then there exists a unique solution of (2.1), (2.2) in $C(0,T;W_2^{4+m}(\boldsymbol{R}))\cap C^1(0,T;W_2^m(\boldsymbol{R}))$. Moreover, the following estimate is valid:*

$$\langle\|u\|^{(4+m)}\rangle_T + \langle\|u_t\|^{(m)}\rangle_T \le c\left(\|u_0\|^{(4+m)} + \langle\|f\|^{(m)}\rangle_T^{(\beta)}\right), \tag{2.3}$$

where c is independent of u_0 and f.

This lemma was proved in more general form by the theory of analytic semigroups in [6, Thm. 5.8], [11, Thm. IV.6.E].

3. Solvability of (1.4) with (1.3). Noting that v is a tangential vector and is not square integrable over $\boldsymbol{R}$, we obtain the following.

PROPOSITION 3.1. *Let $\epsilon > 0$, $a \in \boldsymbol{R}$, and $v_{0s} \in W_2^{3+m}(\boldsymbol{R})$. Then on some time interval $[0, T_0]$, $T_0 > 0$, there exists a unique solution v of* (1.4) *with* (1.3) *such that* $(v - v_0) \in C(0, T_0; W_2^{4+m}(\boldsymbol{R})) \cap C^1(0, T_0; W_2^m(\boldsymbol{R}))$.

Proof. Let $u^{(0)} = 0$ and $u^{(n)}$ $(n = 1, 2, \ldots)$ be a solution in Lemma 2.1 on a time interval $[0, t]$ with $0 < \beta < 1/4$, $u_0 = 0$, and

$$\begin{aligned} f = f^{(n-1)} \equiv v^{(n-1)} \times v_{ss}^{(n-1)} &+ a\Big\{ v_{sss}^{(n-1)} + \frac{3}{2} v_{ss}^{(n-1)} \times \left(v^{(n-1)} \times v_s^{(n-1)} \right) \\ &+ \frac{3}{2} v_s^{(n-1)} \times \left(v^{(n-1)} \times v_{ss}^{(n-1)} \right) \Big\} \\ &- \epsilon \Big\{ v_{0ssss} + 4 \left(v_s^{(n-1)} \cdot v_{sss}^{(n-1)} \right) v^{(n-1)} + 3 \left| v_{ss}^{(n-1)} \right|^2 v^{(n-1)} \Big\}, \end{aligned}$$

where $v^{(n-1)} = u^{(n-1)} + v_0$ and $u^{(n-1)} \in C(0, t; W_2^{4+m}(\boldsymbol{R})) \cap C^1(0, t; W_2^m(\boldsymbol{R}))$. Since the multiplicative inequality yields

$$\begin{aligned} &\left\| u^{(n-1)}(\cdot, t') - u^{(n-1)}(\cdot, t'') \right\|^{(3+m)} \\ &\leq c \left(\left\| u^{(n-1)}(\cdot, t') - u^{(n-1)}(\cdot, t'') \right\|^{(4+m)} \right)^{1-\theta} \left(\left\| u^{(n-1)}(\cdot, t') - u^{(n-1)}(\cdot, t'') \right\|^{(m)} \right)^{\theta} \\ &\leq c \left(\langle \| u^{(n-1)} \|^{(4+m)} \rangle_t + \langle \| u_t^{(n-1)} \|^{(m)} \rangle_t \right) |t' - t''|^{\theta} \end{aligned}$$

for $t', t'' \in [0, t]$, and $0 \leq \theta \leq 1/4$, $u^{(n)}$ is well defined for each n. Indeed, it follows from (2.3) and the imbedding theorem that

$$\begin{aligned} A_n &\equiv \langle \| u^{(n)} \|^{(4+m)} \rangle_t + \langle \| u_t^{(n)} \|^{(m)} \rangle_t \\ &\leq c \langle \| f^{(n-1)} \|^{(m)} \rangle_t^{(\beta)} \\ &\leq c \left(1 + \langle \| u^{(n-1)} \|^{(3+m)} \rangle_t^{(\beta)} \right)^2 \langle \| u^{(n-1)} \|^{(3+m)} \rangle_t^{(\beta)} + c \\ &\leq c t^{1/4-\beta} (1 + A_{n-1})^2 A_{n-1} + c. \end{aligned}$$

Here c depends on v_0. Choose $t = T_1$ so small that there exists a constant M independent of n and satisfying $c T_1^{1/4-\beta}(1 + M)^2 M + c \leq M$. Then we obtain $A_n \leq M$ if $A_{n-1} \leq M$. Hence $A_n \leq M$ with n arbitrary.

Setting $w^{(n)} = u^{(n)} - u^{(n-1)}$, we have

$$w_t^{(n+1)} = -\epsilon w_{ssss}^{(n+1)} + f^{(n)} - f^{(n-1)},$$

$$w^{(n+1)}(s, 0) = 0.$$

Again by (2.3) and the fact that A_{n-1} and A_n are bounded by M, we estimate $w^{(n+1)}$ on $[0, t]$, $0 < t \leq T_1$, as

$$\begin{aligned} &\langle \| w^{(n+1)} \|^{(4+m)} \rangle_t + \langle \| w_t^{(n+1)} \|^{(m)} \rangle_t \\ &\leq c t^{1/4-\beta} (1 + M)^2 \left(\langle \| w^{(n)} \|^{(4+m)} \rangle_t + \langle \| w_t^{(n)} \|^{(m)} \rangle_t \right). \end{aligned}$$

If we choose $T_0 \in (0, T_1]$ so small that $cT_0^{1/4-\beta}(1+M)^2 < 1$, then the sequence $\{u^{(n)}\}$ converges to the function $v - v_0$ in the space $C(0, T_0; W_2^{4+m}(\boldsymbol{R})) \cap C^1(0, T_0; W_2^m(\boldsymbol{R}))$, where v is a solution of (1.3) and (1.4).

The uniqueness of v can be easily proved. □

Next, we prove the following lemma, which implies that the length of the vortex filament is conserved.

LEMMA 3.1. *Let v be a solution of* (1.3) *and* (1.4) *such that* $(v - v_0) \in C(0, T; W_2^{4+m}(\boldsymbol{R})) \cap C^1(0, T; W_2^m(\boldsymbol{R}))$, $T > 0$. *Then*

$$|v| = 1 \tag{3.1}$$

holds for any $(s, t) \in \boldsymbol{R} \times [0, T]$.

Proof. Define the function $h(s, t)$ by

$$h(s,t) = |v|^2 - 1$$

for $s \in \boldsymbol{R}$, $0 \le t \le T$. Then we obtain

$$h_s = 2v \cdot v_s,$$

$$h_{ss} = 2(v \cdot v_{ss} + |v_s|^2),$$

$$h_{sss} = 2(v \cdot v_{sss} + 3v_s \cdot v_{ss}),$$

$$h_{ssss} = 2(v \cdot v_{ssss} + 4v_s \cdot v_{sss} + 3|v_{ss}|^2).$$

Using these relations, (1.4) multiplied by v, and (1.3), we have

$$h_t = a\{h_{sss} - 3(v \cdot v_{ss})h_s + 6(v_s \cdot v_{ss})h\} - \epsilon\{h_{ssss} + 8(v_s \cdot v_{sss})h + 6|v_{ss}|^2 h\},$$

$$h(s, 0) = 0.$$

For this linear system, we conclude that $h = 0$ is the only solution because of $\|h\| = 0$ yielded by the estimate $(d/dt)\|h\|^2 \le c\|h\|^2$, where c depends on $\langle \|v - v_0\|^{(4)} \rangle_T$ and $\|v_{0s}\|^{(3)}$. Hence (3.1) follows. □

Utilizing Lemma 3.1, we derive an a priori estimate for (1.4).

LEMMA 3.2. *Let v be as in Lemma* 3.1. *Then there exists a positive constant ϵ_0 depending only on T and $\|v_{0s}\|$ such that v for any $\epsilon \in (0, \epsilon_0]$ satisfies the estimate*

$$\langle \|v - v_0\|^{(4+m)} \rangle_T + \langle \|v_t\|^{(m)} \rangle_T \le c_a, \tag{3.2}$$

where c_a depends only on $\|v_{0s}\|^{(3+m)}$, ϵ_0, T, and $|a|$.

Proof. By the density theorem it is sufficient to prove (3.2) for an infinitely s-differentiable v with a compact support.

From (3.1), we have

$$v \cdot v_s = 0, \quad v \cdot D^n v = -\frac{1}{2} \sum_{k=1}^{n-1} {}_nC_k \, D^k v \cdot D^{n-k} v \quad (n \ge 2). \tag{3.3}$$

It also follows from (3.1) that on the point where $|v_s|$ is nonzero, the vectors v, $v_s/|v_s|$, $v \times v_s/|v_s|$ are the orthonormal ones in $\boldsymbol{R}^3$. Then

$$v_s \times D^n v = v_s \times \left[(v \cdot D^n v)v + \frac{\big\{(v \times v_s) \cdot D^n v\big\} v \times v_s}{|v_s|^2} \right]$$

holds for $n \geq 2$ and leads to

$$v_s \times D^n v = -(v \cdot D^n v) v \times v_s + \big\{(v \times v_s) \cdot D^n v\big\} v. \tag{3.4}$$

Clearly, (3.4) is also valid where $v_s = 0$.

Multiplying (1.4) by v_{ss}, integrating over $\boldsymbol{R}$, and using (3.3), we obtain

$$\begin{aligned} \frac{d}{dt}\|v_s(\cdot,t)\|^2 &= -2\epsilon\left(\|v_{sss}\|^2 + 4\int_{\mathbf{R}} |v_s|^2 v_s \cdot v_{sss} ds + 3\big\||v_s||v_{ss}|\big\|^2\right) \\ &\leq -\epsilon\|v_{sss}\|^2 + \epsilon c_0 \|v_s\|^{10}, \end{aligned}$$

where c_0 is a positive constant yielded by use of the multiplicative inequality and Young's. Let $r(t)$ be a solution of the scalar equation $dr/dt = \epsilon c_0 r^5$ with $r(0) = \|v_{0s}\|^2$. Then we solve it as $r(t) = (\|v_{0s}\|^{-8} - 4\epsilon c_0 t)^{-1/4}$ when $4\epsilon c_0 t < \|v_{0s}\|^{-8}$. Choosing ϵ_0 so small that

$$0 < \epsilon_0 < \left(4c_0 T\|v_{0s}\|^8\right)^{-1}, \tag{3.5}$$

we have

$$\|v_s(\cdot,t)\| \leq r(t)^{1/2} \leq c_* \tag{3.6}$$

on $[0,T]$ for all $\epsilon \in (0,\epsilon_0]$.

Next, by (3.3), (3.4), (3.6), and the multiplicative and Young's inequalities, we obtain

$$\begin{aligned} &\frac{d}{dt}\left(\|v_{ss}(\cdot,t)\|^2 - \frac{5}{4}\big\||v_s(\cdot,t)|^2\big\|^2\right) \\ &= -\int_{\mathbf{R}} (2v_{sss} \cdot v_{st} + 5|v_s|^2 v_s \cdot v_{st}) ds \\ &\leq \int_{\mathbf{R}} 3\left\{|v_s|^2 v_{ss} \cdot (v \times v_s)\right\}_s ds \\ &\quad + a\int_{\mathbf{R}} \left\{|v_s|^2|v_{ss}|^2 + 8(v_s \cdot v_{ss})^2 - 5|v_s|^2 v_s \cdot v_{sss}\right\}_s ds \\ &\quad - 2\epsilon\|v_{ssss}\|^2 + \epsilon c_*\left(\|v_{ssss}\|^{5/3} + \|v_{ssss}\|^{4/3}\right) \\ &\leq c_*. \end{aligned}$$

It yields

$$\begin{aligned} \|v_{ss}(\cdot,t)\|^2 &\leq \|v_{0ss}\|^2 - \frac{5}{4}\big\||v_{0s}|^2\big\|^2 + \frac{5}{4}\big\||v_s(\cdot,t)|^2\big\|^2 + c_* t \\ &\leq c_* + \frac{1}{2}\|v_{ss}(\cdot,t)\|^2 + c_*\|v_s(\cdot,t)\|^6 + c_* t, \end{aligned}$$

from which

$$\langle\|v_{ss}\|\rangle_T \leq c_* \tag{3.7}$$

follows.

In the same way, by boring calculation we can verify

$$\frac{d}{dt}\left(\|v_{sss}\|^2 - \frac{7}{2}\||v_s||v_{ss}|\|^2 - 14\|v_s \cdot v_{ss}\|^2 + \frac{21}{8}\||v_s|^3\|^2\right) \le c_*,$$

which yields

$$\langle\|v_{sss}\|\rangle_T \le c_*. \tag{3.8}$$

Here we made use of the formula

$$|v_s|^2(v \times v_{ss}) \cdot v_{ssss} = (v_s \cdot v_{ss})(v \times v_s) \cdot v_{ssss} - (v_s \cdot v_{ssss})(v \times v_s) \cdot v_{ss},$$

which is proved as (3.4).

Let $j = 4, 5, \ldots, 4+m$. Then, using (3.3), (3.4), and integration by parts, we can derive $(d/dt)\|D^j v\|^2 \le c_a\|D^j v\|^2 + c_a$ if $\langle\|v_s\|^{(j-2)}\rangle_T \le c_a$ is given. This fact, together with (3.6), (3.7), (3.8), and Gronwall's inequality, yields $\langle\|v_s\|^{(3+m)}\rangle_T \le c_a$. Hence we have $\langle\|(v - v_0)_s\|^{(3+m)}\rangle_T \le c_a$. The estimates $\langle\|v_t\|^{(m)}\rangle_T \le c_a$ and $\langle\|v - v_0\|\rangle_T \le c_a$ are easily obtained. □

From Proposition 3.1 and Lemmas 3.1 and 3.2, by the standard continuation argument, we have the following theorem.

THEOREM 3.1. *Let* $T > 0$, $v_{0s} \in W_2^{3+m}(\boldsymbol{R})$, *and* $a \in \boldsymbol{R}$. *Then for each* $\epsilon \in (0, \epsilon_0]$ *with* ϵ_0 *satisfying* (3.5), *there exists a unique solution* v *of* (1.3), (1.4) *such that* $(v - v_0) \in C(0, T; W_2^{4+m}(\boldsymbol{R})) \cap C^1(0, T; W_2^m(\boldsymbol{R}))$, (3.1), *and* (3.2) *hold.*

4. Solvability of (1.2) with (1.3).

Considering the limit $\epsilon \to 0$, we establish the following theorem. Its proof is based mainly on the method in [4, §3].

THEOREM 4.1. *Let* $v_{0s} \in W_2^{3+m}(\boldsymbol{R})$ *and* $a \in \boldsymbol{R}$. *Then there exists a unique solution* v *of* (1.2), (1.3) *such that* (3.1) *is satisfied,* $(v - v_0) \in C(0, T; W_2^{4+m}(\boldsymbol{R})) \cap C^1(0, T; W_2^{1+m}(\boldsymbol{R}))$ *if* $a \neq 0$, *and* $(v - v_0) \in C(0, T; W_2^{4+m}(\boldsymbol{R})) \cap C^1(0, T; W_2^{2+m}(\boldsymbol{R}))$ *if* $a = 0$ *with any* $T > 0$.

Proof. Let $v^\epsilon(s, t)$ be the solution of (1.3), (1.4) in Theorem 3.1. Subtracting (1.4) for $\epsilon = \epsilon''$ from that for $\epsilon = \epsilon'$ $(0 < \epsilon'' < \epsilon' \le \epsilon_0)$ and setting $z = v^{\epsilon'} - v^{\epsilon''}$, we estimate z as

$$\frac{d}{dt}\left(\|z\|^2 + \|z_s\|^2\right) \le c_a\left(\|z\|^2 + \|z_s\|^2\right) + \epsilon' c_a. \tag{4.1}$$

Here we used (3.2) and $v^{\epsilon''} \cdot z_s = v_s^{\epsilon'} \cdot v^{\epsilon''} = -v_s^{\epsilon'} \cdot z$. Since $z(s, 0) = 0$, it follows that $\langle\|z\|^{(1)}\rangle_T \le c_a(\epsilon')^{1/2}$. Thus $v^\epsilon - v_0$ converges strongly to some function $(w - v_0) \in C(0, T; W_2^1(\boldsymbol{R}))$ for $W_2^1(\boldsymbol{R})$-norm and uniformly in $t \in [0, T]$ as $\epsilon \to 0$. From this, we know $|w| = 1$.

On the other hand, (3.2) implies that $(w - v_0) \in L^\infty(0, T; W_2^{4+m}(\boldsymbol{R}))$ and that the weak convergence $(v^\epsilon - v_0) \to (w - v_0)$ holds in $W_2^{4+m}(\boldsymbol{R})$, uniformly for t. Clearly, $w(s, 0) = v_0$ and $\|w(\cdot, t) - v_0\|^{(4+m)} \le c_a$.

Since $G(v^\epsilon) \equiv v^\epsilon \times v_{ss}^\epsilon + (3/2)a\{v_{ss}^\epsilon \times (v^\epsilon \times v_s^\epsilon) + v_s^\epsilon \times (v^\epsilon \times v_{ss}^\epsilon)\}$ is bounded by c_a in $W_2^{2+m}(\boldsymbol{R})$ for every t, its subsequence (if necessary) weakly converges in $W_2^{2+m}(\boldsymbol{R})$ and uniformly for t. Let $\Phi = \Phi(s)$ be an infinitely differentiable vector function with a compact support. Then

$$\left|\left(G(v^\epsilon) - G(w), \Phi\right)^{(2+m)}\right|$$

$$= \left| \int_{\mathbf{R}} \left[v^\epsilon \times v_s^\epsilon - w \times w_s + \frac{3}{2} a \{ v_s^\epsilon \times (v^\epsilon \times v_s^\epsilon) \right.\right.$$
$$\left.\left. - w_s \times (w \times w_s) \} \right] \cdot \left\{ \sum_{j=0}^{2+m} (-1)^{j+1} D^{2j+1} \Phi \right\} ds \right|$$
$$\leq c_a \| v^\epsilon - w \|^{(1)},$$

where $(\cdot, \cdot)^{(m)}$ means the scalar product in $W_2^m(\boldsymbol{R})$, tends to zero uniformly in $t \in [0, T]$ as $\epsilon \to 0$. Hence the weak limit of $G(v^\epsilon)$ is equal to $G(w) \in L^\infty(0, T; W_2^{2+m}(\boldsymbol{R}))$.

Next, integrate (1.4) over $[t', t''] \subset [0, T]$. Then we get

$$v^\epsilon(s, t'') - v^\epsilon(s, t')$$
$$= \int_{t'}^{t''} \left[a v_{sss}^\epsilon + G(v^\epsilon) - \epsilon \{ v_{ssss}^\epsilon + 4(v_s^\epsilon \cdot v_{sss}^\epsilon) v^\epsilon + 3 |v_{ss}^\epsilon|^2 v^\epsilon \} \right] dt.$$

Taking its scalar product in $W_2^{1+m}(\boldsymbol{R})$ (resp. $W_2^{2+m}(\boldsymbol{R})$) with the above Φ if $a \neq 0$ (resp. $a = 0$) and letting $\epsilon \to 0$, we have

$$w(s, t'') - w(s, t') = \int_{t'}^{t''} \big(a w_{sss} + G(w) \big) dt.$$

Hence w is a solution of (1.2) and (1.3).

Let us verify the uniqueness of the solution w. Assume that there exist two solutions w' and w'' for (1.2) with the same data. Then for $z = w' - w''$, we obtain the same estimate with (4.1) but $\epsilon' = 0$. Hence $z = 0$ follows.

Utilizing (3.2), we derive $(d/dt) \big(\| v_{ss}^\epsilon \|^{(2+m)} \big)^2 \leq c_a$ from (1.4) for $\epsilon \in (0, \epsilon_0]$. Therefore, $\| v_{ss}^\epsilon(\cdot, t) \|^{(2+m)} \leq \| v_{0ss} \|^{(2+m)} + c_a t^{1/2}$ follows. By the limit $\epsilon \to 0$ we have $\| w_{ss}(\cdot, t) \|^{(2+m)} \leq \| v_{0ss} \|^{(2+m)} + c_a t^{1/2}$, which leads to $\limsup_{t \to 0} \| w_{ss}(\cdot, t) \|^{(2+m)} \leq \| v_{0ss} \|^{(2+m)} = \| w_{ss}(\cdot, 0) \|^{(2+m)}$. Since w_{ss} is weakly continuous in $W_2^{2+m}(\boldsymbol{R})$, it is strongly continuous in $W_2^{2+m}(\boldsymbol{R})$ at $t = 0$. As in [4], making use of the uniqueness of w and the reversibility of (1.2) in t, we can show $w_{ss} \in C(0, T; W_2^{2+m}(\boldsymbol{R}))$. Then it yields $(w - v_0) \in C(0, T; W_2^{4+m}(\boldsymbol{R})) \cap C^1(0, T; W_2^{1+m}(\boldsymbol{R}))$ if $a \neq 0$, $(w - v_0) \in C(0, T; W_2^{4+m}(\boldsymbol{R})) \cap C^1(0, T; W_2^{2+m}(\boldsymbol{R}))$ if $a = 0$. □

Since we have $c_a \leq c_*$ if $|a| \leq 1$ is assumed, the limit $a \to 0$ can be discussed in the same way as $\epsilon \to 0$.

COROLLARY. *In Theorem* 4.1, *the difference between the solution* v *for* $a \neq 0$ *and that for* $a = 0$ *converges to zero strongly in* $W_2^1(\boldsymbol{R})$ *and weakly in* $W_2^{4+m}(\boldsymbol{R})$, *uniformly in* t *as* $a \to 0$.

It should be noted that our method is also applicable when $a \in \boldsymbol{R}$ and the spatially periodic condition $v(s, t) = v(s + 1, t)$ is imposed.

5. Initial-boundary value problem. In this section, the domain of s is restricted to $J \equiv (-1, 1)$ and a is assumed to be equal to zero. As a boundary condition imposed on (1.2), we take

$$v_s(\pm 1, t) = 0. \tag{5.1}$$

Let V^m be the completion with respect to $\| \cdot \|_J^{(m)}$ of the space where every element g belongs to $C^\infty([-1, 1])$ and satisfies $D^{2j-1} g(\pm 1) = 0$ for $j = 1, 2, \ldots$. Then by the Fourier expansion and Parseval's equality, we obtain the following result.

LEMMA 5.1. *If $\epsilon > 0$, $u_0 \in V^{4+m}$, and $f \in C^{\beta}(0,T;V^m)$ for $T > 0$, $0 < \beta < 1$, then there exists a unique solution of* (2.1), (2.2), *and* $u_s(\pm 1,t) = u_{sss}(\pm 1,t) = 0$ *in* $C(0,T;V^{4+m}) \cap C^1(0,T;V^m)$. *Moreover, the following estimate is valid:*

$$\langle \|u\|_J^{(4+m)} \rangle_T + \langle \|u_t\|_J^{(m)} \rangle_T \le c\left(\|u_0\|_J^{(4+m)} + \langle \|f\|_J^{(m)} \rangle_T^{(\beta)}\right),$$

where c is independent of u_0 and f.

Let $g = (g_1, g_2, g_3) \in V^n$, $n \ge 2$. Then for $k = 1, 2, \dots, n-1$, we verify

$$\|D^k g\|_J^2 = -\int_J D^{k-1}g \cdot D^{k+1}g \, ds \le \|D^{k-1}g\|_J \, \|D^{k+1}g\|_J,$$

$$|D^k g(s)|^2 = \sum_{i=1}^{3} 2 \int_{s_i}^{s} D^k g_i \, D^{k+1} g_i \, ds \le 2\|D^k g\|_J \, \|D^{k+1} g\|_J.$$

Here s_i ($i = 1, 2, 3$) is a point on $[-1, 1]$ satisfying $D^k g_i(s_i) = 0$, whose existence is trivial for an odd k and is obtained from $\int_J D^k g \, ds = 0$ for an even k. From this, we know the validity of the multiplicative inequality for an element in V^n.

Therefore, using Lemma 5.1, we prove the following theorem for (1.4) with (1.3), (5.1), and

$$v_{sss}(\pm 1, t) = 0. \tag{5.2}$$

THEOREM 5.1. *Let $T > 0$, $v_0 \in V^{4+m}$, and $a = 0$. Then for each $\epsilon \in (0, \epsilon_0]$ with $0 < \epsilon_0 < (4c_0 T \|v_{0s}\|_J^8)^{-1}$, there exists a unique solution of* (1.3), (1.4), (5.1), (5.2) *such that $v \in C(0,T;V^{4+m}) \cap C^1(0,T;V^m)$ and* (3.1) *holds. Moreover, $\langle \|v\|_J^{(4+m)} \rangle_T + \langle \|v_t\|_J^{(m)} \rangle_T \le c_*$ is valid, where c_* depends only on v_0, T, and ϵ_0.*

Proof. The proof is divided into two parts. One is to establish the existence of a temporally local solution. It is done as in the proof of Proposition 3.1 because the s-derivatives of any odd order for $v \times v_{ss}$, $(v_s \cdot v_{sss})v$, $|v_{ss}|^2 v$ are equal to zero at $s = \pm 1$ if $D^{2j-1}v(\pm 1, t) = 0$ for $j = 1, 2, \dots$. The other is to derive (3.1) and the a priori estimate in the theorem, and we do so by the method in the proofs of Lemmas 3.1 and 3.2. □

In the same manner as in the proof of Theorem 4.1, we establish the following theorem.

THEOREM 5.2. *Let $v_0 \in V^{4+m}$ and $a = 0$. Then there exists a unique solution of* (1.2), (1.3), (5.1) *such that $v \in C(0,T;V^{4+m}) \cap C^1(0,T;V^{2+m})$ with any $T > 0$ and* (3.1) *is satisfied.*

Here we noted that (5.2) is formally derived from (1.2) with $a = 0$, (1.3), and (5.1), irrespective of the class of v. In fact, (3.1) is formally obtained because of $v \cdot v_t = 0$, and $v_{sss} = (v_{st} - v_s \times v_{ss}) \times v - 3(v_s \cdot v_{ss})v$ follows.

Remark. Our method is also useful to another initial-boundary value problem given by (1.2) with $a = 0$ for $s > 0$, (1.3), and the condition $v_s(0, t) = 0$.

SOLUTIONS FOR A TWO-DIMENSIONAL HYPERBOLIC-ELLIPTIC COUPLED SYSTEM*

GARY GANSER†, XIAOPING HU†, AND DENING LI†

Abstract. We study a two-dimensional hyperbolic-elliptic coupled system arising from the study of a gas fluidized bed model. The well-posedness of an initial-boundary value problem is discussed and the short-time existence of classical solutions is obtained.

Key words. two-dimensional hyperbolic-elliptic coupled system, fluidized bed

AMS subject classifications. Primary 35L50, 35L65, 35M05; Secondary 35J25

1. Introduction. The mathematical model describing a gas fluidized bed can be derived from the conservation of mass of each phase and the conservation of momentum. Let α denote the concentration by volume of particles and $\mathbf{v}_p$, $\mathbf{v}_g$ denote the velocities in the particle and gas phases. If the relatively small density of gas is neglected and the intrinsic density ρ of particles is assumed to be constant, then the governing equations are the following system [2, 3]:

$$(1.1)\quad \begin{cases} \partial_t\alpha + \nabla\cdot(\alpha\mathbf{v}_p) = 0, \\ \partial_t(1-\alpha) + \nabla\cdot(1-\alpha)\mathbf{v}_g = 0, \\ \rho\partial_t(\alpha\mathbf{v}_p) + \rho\nabla\cdot(\alpha\mathbf{v}_p\mathbf{v}_p) = -\alpha\nabla p_g - \rho\nu^2\nabla F(\alpha) - \rho\alpha\mathbf{g} + B(\alpha)(\mathbf{v}_g - \mathbf{v}_p), \\ (1-\alpha)\nabla p_g + B(\alpha)(\mathbf{v}_g - \mathbf{v}_p) = 0. \end{cases}$$

Here $\nu > 0$ is the terminal velocity of an isolated falling particle, $\mathbf{g}$ is the constant gravity vector with $g = |\mathbf{g}|$, $B(\alpha)$ is the drag coefficient, and $\rho\nu^2F(\alpha)$ models the pressure difference in the two phases. For simplicity, we will assume in this paper that (see [2, 3])

$$(1.2)\quad \begin{cases} B(\alpha) = \dfrac{g\rho}{\nu}\dfrac{\alpha}{(1-\alpha)^2}, \\ F'(\alpha) > 0,\ \ F''(\alpha) > 0, \ \ \text{for } \alpha > 0. \end{cases}$$

There have been many discussions of system (1.1) for the case of one space variable [2, 3]. In particular, a traveling-wave solution containing admissible shocks was given in [4]. The general case of more space variables has potentially more interesting features, e.g., spherical regions devoid of particles called bubbles [3]. Only numerical studies of (1.1) have been done in the higher-dimensional case. Analytical work such as linear studies [3] has been restricted to approximations of (1.1) or similar systems.

In this paper, for the two-dimensional flow, we introduce the stream function $\phi(x, y)$ such that

$$(1.3)\quad \begin{cases} \alpha v_{p1} + (1-\alpha)v_{g1} = \partial_y\phi, \\ \alpha v_{p2} + (1-\alpha)v_{g2} = -\partial_x\phi; \end{cases}$$

therefore, we can express $\mathbf{v}_g$ in terms of $\mathbf{v}_p$ and ϕ:

$$v_{g1} = \frac{\partial_y \phi - v_{p1}}{1-\alpha},$$

$$v_{g2} = \frac{-\partial_x \phi - v_{p2}}{1-\alpha}.$$

The term ∇p_g can be eliminated by the last two equations in (1.1). From the last equation in (1.1) and $\partial_{xy} p_g = \partial_{yx} p_g$, we obtain

$$\left[\frac{B(\phi_y - u)}{(1-\alpha)^2}\right]_y = \left[\frac{B(-\phi_x - v)}{(1-\alpha)^2}\right]_x.$$

Therefore, system (1.1) can be rewritten as the following system for the variables of particle concentration α, particle velocity $\mathbf{v}_p = (u, v)$, and the stream function ϕ:

$$(1.4)\quad \begin{cases} \alpha_t + (\alpha u)_x + (\alpha v)_y = 0, \\ (\alpha u)_t + (\alpha u^2)_x + (\alpha u v)_y = -\nu^2 \partial_x F(\alpha) + \dfrac{g\alpha(\phi_y - u)}{\nu(1-\alpha)^4}, \\ (\alpha v)_t + (\alpha u v)_x + (\alpha v^2)_y = -\nu^2 \partial_y F(\alpha) + \dfrac{g\alpha(-\phi_x - v)}{\nu(1-\alpha)^4} - g\alpha, \\ \triangle \phi = u_y - v_x - \dfrac{G'(\alpha)}{G(\alpha)}\left[\alpha_x(\phi_x + v) + \alpha_y(\phi_y - u)\right], \end{cases}$$

where $G(\alpha) = B(\alpha)(1-\alpha)^{-2}$. The equations in (1.4) form a quasi-linear hyperbolic-elliptic coupled system of the variables (α, u, v, ϕ) in the two-dimensional space.

In this paper, we discuss an initial-boundary value problem of (1.4), derive the well-posedness of the linearized equations, and establish the existence of the solution for the nonlinear problem.

Consider the infinite vertical fluidized bed bounded in $-a \le x \le a$ $(a > 0)$. Assume that at the initial time $t = 0$, the distribution of (α, u, v) is known. Define $\Omega = (-a,\ a) \times R$. We have the initial conditions

$$(1.5)\qquad (\alpha, u, v)(0, x, y) = (\alpha_0, u_0, v_0)(x, y), \qquad (x, y) \in \Omega.$$

At the boundaries $x = \pm a$, we have the physical condition

$$(1.6)\qquad u = 0, \qquad \phi_y = 0.$$

At $y = \pm\infty$, we assume that the fluidized bed is in a homogeneous state; the velocities of gas entering and leaving the fluidized bed are the same constant J:

$$(1.7)\qquad \phi_x = -J.$$

From (1.7), we may assume

$$\phi(t, x, y) = \psi(t, x, y) - Jx;$$

hence (1.7) becomes the condition for the new variable ψ:

$$(1.8)\qquad \psi_x(t, x, \pm\infty) = 0.$$

Obviously, ϕ (and ψ) can be uniquely determined up to a constant; hence without loss of generality, we may assume $\psi(0,x,\pm\infty)=0$. The condition for ϕ on $x=\pm a$ now translates into $\psi(t,\pm a,y)=0$.

To sum up, the initial-boundary problem for (α,u,v,ψ) that we discuss in this paper is as follows:

$$\left\{\begin{aligned} &\alpha_t+(\alpha u)_x+(\alpha v)_y=0,\\ &\alpha u_t+\alpha u u_x+\alpha v u_y=-\nu^2\partial_x F(\alpha)+\frac{g\alpha(\psi_y-u)}{\nu(1-\alpha)^4},\\ &\alpha v_t+\alpha u v_x+\alpha v v_y=-\nu^2\partial_y F(\alpha)+\frac{g\alpha(J-\psi_x-v)}{\nu(1-\alpha)^4}-g\alpha,\\ &\Delta\psi=u_y-v_x-\frac{G'(\alpha)}{G(\alpha)}\left[\alpha_x(\psi_x-J+v)+\alpha_y(\psi_y-u)\right].\end{aligned}\right. \tag{1.9}$$

$$(\alpha,u,v)(0,x,y)=(\alpha_0,u_0,v_0)(x,y),\qquad (x,y)\in\Omega. \tag{1.10}$$

$$u(t,\pm a,y)=0,\qquad \psi(t,\pm a,y)=0. \tag{1.11}$$

$$\psi(t,x,\pm\infty)=0,\qquad 0<t<\infty,\qquad -a\le x\le a. \tag{1.12}$$

Denote $U=(\alpha,u,v)$, $DU=(U,U_x,U_y)$, and $D\psi=(\psi,\psi_x,\psi_y)$; then system (1.9) can be abbreviated as the following:

$$\left\{\begin{aligned} &A_0(U)\partial_t U+A_1(U)\partial_x U+A_2(U)\partial_y U=H_1(U,D\psi),\\ &\Delta\psi+B_1(DU)\partial_x\psi+B_2(DU)\partial_y\psi=H_2(DU),\end{aligned}\right. \tag{1.13}$$

where

$$A_0(U)=\begin{pmatrix}1&0&0\\0&\mu(\alpha)&0\\0,&0&\mu(\alpha)\end{pmatrix},\qquad A_1(U)=\begin{pmatrix}u&\alpha&0\\\alpha&u\mu(\alpha)&0\\0,&0&u\mu(\alpha)\end{pmatrix},$$

$$A_2(U)=\begin{pmatrix}v&0&\alpha\\0&v\mu(\alpha)&0\\\alpha,&0&v\mu(\alpha)\end{pmatrix},\qquad \mu(\alpha)=\frac{\alpha^2}{\nu^2F'(\alpha)},$$

and B_1,B_2,H_1, and H_2 are sufficient smooth functions of their arguments in the relevant domain; the explicit forms of these functions bear no importance in the following discussion.

The first part of system (1.13) is a quasi-linear symmetric hyperbolic system for U and the second is an elliptic equation in (x,y) for ψ with linear principal part. In particular, the variable t appears in the second equation only as a parameter for ψ. We consider the solutions of (1.9)–(1.12) which are constants at $y=\pm\infty$. From (1.9) and (1.11), these constants are not arbitrary. They must satisfy the following conditions:

$$u=0,\qquad v=J-\nu(1-\alpha)^4. \tag{1.14}$$

Because the boundaries $x = \pm a$ are characteristic with respect to the hyperbolic system in (1.13), we will use the partially tangential Sobolev spaces.

For any nonnegative integer m, let $E_m(\Omega)$ denote the spaces

$$E_m = \{w \in L^2(\Omega), (x^2 - a^2)^i \partial_x^j \partial_y^k w \in L^2 \text{ for } 0 \le i \le j, k + 2j - i \le m\}$$

with norm

$$\|w\|_m^2 = \sum_{0 \le i \le j, k+2j-i \le m} \int_\Omega |(x^2 - a^2)^i \partial_x^j \partial_y^k w|^2 \, dx \, dy. \tag{1.15}$$

Denote $E_{m,T}$ as the space

$$E_{m,T} = \{w(t,x,y) : \partial_t^k w \in L^\infty([0,T], E_{m-k}), \text{ for } 0 \le k \le m\} \tag{1.16}$$

with the norm defined as

$$|||w|||_{m,T} = \sup_{0 \le t \le T} \left(\sum_{k=0}^{m} \|\partial_t^k w(t)\|_{m-k}^2 \right)^{\frac{1}{2}}. \tag{1.17}$$

In particular, for positive even numbers $2m$, the spaces E_{2m} coincide with the spaces $\tilde{E}_{2m}$ in [1]. For these spaces, we have similar embedding results.

LEMMA 1.1. *For the spaces E_{2m} and $E_{2m,T}$ and for $j \le m - 1$, we have the following embedding properties:*

$$E_{2m}(\Omega) \subset C^j(\Omega),$$

$$E_{2m,T} \subset C^j([0,T] \times \Omega).$$

The first part of the lemma is a special case of Proposition 4.1.2 of [1]; see also [6, 8]. The second part of the lemma follows directly from the definition in (1.16) for $E_{2m,T}$.

In this paper, we prove the existence and uniqueness of smooth solutions for the coupled system in (1.9) with the boundary and initial conditions in (1.10)–(1.12). To simplify the discussion, we will assume the initial data $U_0 \in C^\infty(\bar{\Omega})$. Obviously, certain compatibility conditions at $(t,x) = (0, \pm a)$ are necessary in order to obtain the existence of classical solutions. The zero-order compatibility condition is simply $U_0(\pm a, y) = 0$. The first-order compatibility condition is obtained by comparing $\partial_t u(0, \pm a, y) = 0$ with the value of $\partial_t v$ determined from the initial condition (1.11) and the equations in (1.13). The higher-order compatibility condition can be derived similarly. Since the value of ψ at $t = 0$ is not given explicitly and has to be found by solving the Dirichlet problem, we will use the following equivalent concept of the compatibility.

The initial data U_0 are called kth-order compatible if there is an approximate solution $\tilde{U}$, $\tilde{\psi}$ such that

(1) $(\tilde{U}, \tilde{\psi})$ satisfies the initial and boundary conditions in (1.10)–(1.12);

(2) $(\tilde{U}, \tilde{\psi})$ satisfies

$$\begin{cases} A_0(\tilde{U})\partial_t \tilde{U} + A_1(\tilde{U})\partial_x \tilde{U} + A_2(\tilde{U})\partial_y \tilde{U} - H_1(\tilde{U}, D\tilde{\psi}) = \tilde{F}_1, \\ \Delta\tilde{\psi} + B_1(D\tilde{U})\partial_x \tilde{\psi} + B_2(D\tilde{U})\partial_y \tilde{\psi} - H_2(D\tilde{U}) = \tilde{F}_2 \end{cases} \tag{1.18}$$

with

$$\partial_t^j \tilde{F}_1(0,x,y) = \partial_t^j \tilde{F}_2(0,x,y) = 0, \quad 0 \le j \le k-1. \tag{1.19}$$

Interested readers are also referred to [1, 4].

Let $\mathbf{G} \subset (0,1) \times R^2$ be an open set such that $\mathbf{G} \subset\subset (0,1) \times R^2$, $U \in E_{2m,T}$, and $D\psi \in E_{2m,T}$ with $U(t,x,y) \in \mathbf{G}$ for all $(t,x,y) \in [0,T] \times \Omega$. Then the main result is the following.

THEOREM 1.1. *Assume the initial value U_0 in* (1.10)–(1.12) *satisfies*

(i) $U_0 \in C^\infty(\bar{\Omega})$, *and*

(ii) U_0 *are 2mth-order compatible,* $\tilde{U} \in E_{2m+1,T}$, *and* $D\tilde{\psi} \in E_{2m,T}$ *with* $\tilde{U}(t,x,y) \in \mathbf{G} \subset\subset (0,1) \times R^2$ *for all* $(t,x,y) \in [0,T] \times \Omega$.

Then there is a $T > 0$ such that the equations in (1.9) *with the initial-boundary conditions in* (1.10)–(1.12) *have a unique classical solution* (U,ψ) *with* $U(t,x,y) \in C^1([0,T] \times \Omega)$ *and* $\psi(t,x,y) \in C\left([0,T], C^2(\Omega)\right)$. *Furthermore,*

$$U, D\psi \in E_{2m,T}. \tag{1.20}$$

The outline of the paper is as follows. In §2, we derive the estimate for the linearized problem of (1.9)–(1.12). Section 3 is devoted to linear iteration to establish the existence of the local solution. Finally, the uniqueness of the solution is proved in §4.

2. Estimate for the linearized problem. It is easy to see that $A_0(U)$ is uniformly positive definite:

$$\sigma I \le A_0(U) \le \sigma^{-1} I.$$

Let (V,φ) denote the perturbations of (U,ψ). Consider the linearization problem of (1.9)–(1.12) for (V,φ):

$$A_0(U)\partial_t V + A_1(U)\partial_x V + A_2(U)\partial_y V = F_1, \tag{2.1a}$$

$$\Delta\varphi + B_1(DU)\partial_x\varphi + B_2(DU)\partial_y\varphi = F_2, \tag{2.1b}$$

$$V(0,x,y) = 0, \tag{2.2}$$

$$\varphi(t,\pm a,y) = 0, \qquad V_2(t,\pm a,y) = 0, \qquad \varphi(t,x,\pm\infty) = 0, \tag{2.3}$$

where $F_1 \in E_{2m,T}$, F_2, $\partial_t F_2 \in E_{2m-1,T}$, and $\partial_t^j F_1(0,x,y) = 0$ for $0 \le j \le 2m-1$. It follows from (2.3) and $\partial_t^j F_1(0,x,y) = 0$ $(0 \le j \le 2m-1)$ that the smooth solutions $V(t,x,y)$ satisfy

$$\partial_t^j V(0,x,y) = 0 \text{ for } 0 \le j \le 2m. \tag{2.4}$$

For the smooth solutions of this linear problem, we have the following estimate.

THEOREM 2.1. *There are constants C_1 and C_2, depending only on the upper bound of $|||U|||_{2m,T}$, such that the smooth solutions (V,φ) of* (2.1)–(2.3) *satisfy the following energy estimate:*

$$|||V|||_{2m,T} \le C_1 T |||F_1|||_{2m,T}, \tag{2.5}$$

$$|||D\varphi|||_{2m,T} \le C_2\left(|||F_2|||_{2m-1,T} + |||\partial_t F_2|||_{2m-1,T}\right), \tag{2.6}$$

where $D\phi = (\varphi, \partial_x\varphi, \partial_y\varphi)$.

Proof. In the following, C denotes a constant depending on $|||U|||_{2m,T}$, but independent of $T << 1$.

The proof of (2.5) consists of two steps. First, we derive the purely tangential estimate. In order to treat the nondegenerate terms, we need to use the first two equations of (2.1a). Since $U(t,x,y) \in \mathbf{G}$, $\mu(\alpha) > 0$, and U satisfies (1.11), there is a constant $\delta > 0$ such that for some $\epsilon > 0$, which depends only on min $\{\alpha^2/\mu(\alpha)\}$ and $\|\partial_x\left(u \pm \alpha^2/\mu(\alpha)\right)\|_\infty$, we have

$$|u \pm \alpha^2/\mu(\alpha)| \ge \delta \text{ for } x \in [-a,\ -a+\epsilon] \cup [a-\epsilon,\ a],\ y \in R,\ t \in [0,\ T]. \tag{2.7}$$

For $j+k+l \le 2m$, denote $V_{j,k,l} = (x^2-a^2)^j \partial_x^j \partial_y^k \partial_t^l V$. From (2.1), we have

$$A_0\partial_t V_{j,k,l} + A_1\partial_x V_{j,k,l} + A_2\partial_y V_{j,k,l} = F_{j,k,l} \tag{2.8}$$

with

$$\begin{aligned} F_{j,k,l} &= (x^2-a^2)^j A_0 \partial_x^j\partial_y^k\partial_t^l(A_0^{-1}F_1) \\ &+ A_0[A_0^{-1}A_1\partial_x V_{j,k,l} - (x^2-a^2)^j\partial_x^j\partial_y^k\partial_t^l(A_0^{-1}A_1\partial_x V)] \\ &+ A_0[A_0^{-1}A_2\partial_y V_{j,k,l} - (x^2-a^2)^j\partial_x^j\partial_y^k\partial_t^l(A_0^{-1}A_2\partial_y V)]. \end{aligned} \tag{2.9}$$

Let $A = (A_0, A_1, A_2)$ with $\nabla \cdot A = (A_0)_t + (A_1)_x + (A_2)_y$. Taking inner product of (2.8) with $V_{j,k,l}$ in $(x,y) \in \Omega$ and integrating by parts, we have

$$\partial_t\langle V_{j,k,l}, A_0 V_{j,k,l}\rangle + \langle A_1 V_{j,k,l}, V_{j,k,l}\rangle_{x=-a}^{x=a} = \langle V_{j,k,l}, (\nabla\cdot A)\, V_{j,k,l}\rangle + 2\langle F_{j,k,l}, V_{j,k,l}\rangle.$$

The boundary terms at $x = \pm a$ are

$$\langle V_{j,k,l}, A_1 V_{j,k,l}\rangle = 2(x^2-a^2)^{2j}\alpha\partial_x^j\partial_y^k\partial_t^l V_1 \partial_x^j\partial_y^k\partial_t^l V_2.$$

They are all zeroes because for $j = 0$, it is zero by the boundary condition in (2.3) for V, and for $j > 0$, it is zero since $(x^2 - a^2) = 0$. Applying Gronwall's inequality and (2.4), we derive for $t \in [0,\ T]$

$$\|V_{j,k,l}(t)\|_0 \le \sigma\langle V_{j,k,l}, A_0 V_{j,k,l}\rangle^{\frac{1}{2}} \le C\int_0^t \|F_{j,k,l}(\tau)\|_0\, d\tau. \tag{2.10}$$

The $F_{j,k,l}$ terms in (2.9) are estimated as follows. Obviously, for the first and the third terms of (2.9), we have

$$\|(x^2-a^2)^j A_0\partial_x^j\partial_y^k\partial_t^l(A_0^{-1}F_1)\|_0 \le C|||F_1|||_{2m,T}$$

and

$$\begin{aligned} &\|A_0[A_0^{-1}A_2\partial_y V_{j,k,l} - (x^2-a^2)^j\partial_x^j\partial_y^k\partial_t^l(A_0^{-1}A_2\partial_y V)]\|_0 \\ &\le C\sum_{j+k+l\le 2m}\|(x^2-a^2)^j\partial_x^j\partial_y^k\partial_t^l V(t)\|_0. \end{aligned}$$

It remains to estimate

$$A_0[A_0^{-1}A_1\partial_x V_{j,k,l} - (x^2-a^2)^j\partial_x^j\partial_y^k\partial_t^l(A_0^{-1}A_1\partial_x V)]. \tag{2.11}$$

In the interior domain away from the boundaries $x = \pm a$, the term in (2.11) is estimated in the same way as we estimate the third term of (2.9). We need only to consider the estimate of (2.11) near $x = \pm a$. (2.11) is the sum of two parts. The first part consists of the terms such that the order of x-derivatives applied on V is at most equal to the order of the factor $(x^2 - a^2)$. This part can be controlled by

$$\sum_{j+k+l\le 2m} \|(x^2 - a^2)^j \partial_x^j \partial_y^k \partial_t^l V\|_0. \tag{2.12}$$

The second part consists of the terms of the form

$$(x^2 - a^2)^j \partial_x^{j+1} \partial_y^{k_1} \partial_t^{l_1} V \quad \text{with} \quad k_1 + l_1 < 2m - j. \tag{2.13}$$

Since u is the only nonzero element in the third row of $A_0^{-1}A_1$, the third component in (2.13) is controlled by (2.12). For the first two components in (2.13), because of (2.7) we can express V_1 and V_2 in terms of a combination of $\partial_t V$, $\partial_y V$, and F_1. Consequently, the first two components of $(x^2 - a^2)^j \partial_x^{j+1} \partial_y^{k_1} \partial_t^{l_1} V$ can be expressed as a linear combination of

$$(x^2-a^2)^j \partial_x^j \partial_y^{k_1+1} \partial_t^{l_1} V, \qquad (x^2-a^2)^j \partial_x^j \partial_y^{k_1} \partial_t^{l_1+1} V, \qquad (x^2-a^2)^j \partial_x^j \partial_y^{k_1} \partial_t^{l_1} F_1, \tag{2.14}$$

and the later can be controlled by

$$\|(x^2 - a^2)^j \partial_x^j \partial_y^k \partial_t^l V\|_0 \quad \text{and} \quad \|(x^2 - a^2)^j \partial_x^j \partial_y^k \partial_t^l F_1\|_0 \tag{2.15}$$

To summarize, we obtain

$$\|F_{j,k,l}(t)\|_0 \le C \left[|||F_1|||_{2m,T} + \sum_{j+k+l\le 2m} \|(x^2 - a^2)^j \partial_x^j \partial_y^k \partial_t^l V\|_0 \right]. \tag{2.16}$$

Taking summation in (2.10) for all $j + k + l \le 2m$, we have

$$\sum_{j+k+l\le 2m} \|V_{j,k,l}(t)\|_0 \le C \int_0^t \left[\sum_{j+k+l\le 2m} \|V_{j,k,l}(\tau)\|_0 + |||F_1|||_{2m,T} \right] d\tau. \tag{2.17}$$

From (2.4) and applying Gronwall's inequality, we obtain for $t \in [0, T]$

$$\sum_{j+k+l\le 2m} \|V_{j,k,l}(t)\|_0 \le CT|||F_1|||_{2m,T}. \tag{2.18}$$

Next, we prove the nontangential part in (2.5). We prove the following by induction on $0 \le r \le m$:

$$\sum_{0\le j-i\le r, k+l+2j-i\le 2m} \|(x^2 - a^2)^i \partial_x^j \partial_y^k \partial_t^l V(t)\|_0 \le CT|||F_1|||_{2m,T}. \tag{2.19}$$

The case $r = 0$ is simply (2.18). Assume (2.19) is true for $0, 1, \ldots, r - 1$. The estimate in (2.19) is trivial in the interior domain; hence we need only to consider the proof of (2.19) near the boundary. At the boundaries $x = \pm a$, for $2r + i + k + l \le 2m$, consider the first two components of $(x^2 - a^2)^i \partial_x^{i+n} \partial_y^k \partial_t^l V$. By applying the operator

$(x^2-a^2)^i\partial_x^{i+r-1}\partial_y^k\partial_t^l$ to the first two equations in (2.1a), these first two components can be expressed as a linear combination of the following terms:

$$(x^2-a^2)^i\partial_x^{i+r-1}\partial_y^{k+1}\partial_t^l V, \qquad (x^2-a^2)^i\partial_x^{i+r-1}\partial_y^k\partial_t^{l+1} V, \qquad (x^2-a^2)^i\partial_x^{i+r-1}\partial_y^k\partial_t^l F_1.$$

By induction, the first two terms can be controlled by $T|||F_1|||_{2m,T}$ and the third term can be controlled by $T\|(x^2-a^2)^i\partial_x^{i+n-1}\partial_y^k\partial_t^{l+1}F_1\|_0$, which in turn is controlled by $T|||F_1|||_{2m,T}$.

Furthermore, because $2r+i+k+l \le 2m$, we can also apply the operators $(x^2-a^2)^i\partial_x^{i+r-1}\partial_y^{k+1}\partial_t^l$ or $(x^2-a^2)^i\partial_x^{i+r-1}\partial_y^k\partial_t^{l+1}$ to the first two equations in (2.1a) to obtain the estimate for

$$\|(x^2-a^2)^i\partial_x^{i+r}\partial_y^{k+1}\partial_t^l V_{1,2}\|_0 + \|(x^2-a^2)^i\partial_x^{i+r}\partial_y^k\partial_t^{l+1} V_{1,2}\|_0. \tag{2.20}$$

For the third component, $(x^2-a^2)^i\partial_x^{i+r}\partial_y^k\partial_t^l V_3$, we consider the third equation of (2.1a) as an equation for the variable V_3. Applying the operator $(x^2-a^2)^i\partial_x^{i+n}\partial_y^k\partial_t^l$ to this equation, we obtain an equation for the variable $(x^2-a^2)^i\partial_x^{i+r}\partial_y^k\partial_t^l V_3$:

$$(\partial_t + u\partial_x + v\partial_y)(x^2-a^2)^i\partial_x^{i+r}\partial_y^k\partial_t^l V_3 = G. \tag{2.21}$$

In addition to the standard right-side term, $(x^2-a^2)^i\partial_x^{i+r}\partial_y^k\partial_t^l F_1$, the term G in (2.21) contains other two parts. The first part comes from the commutator

$$[(x^2-a^2)^i\partial_x^{i+r}\partial_y^k\partial_t^l, u\mu^{-1}(\alpha)\partial_x]V_3,$$

which is the linear combination of the following terms:

$$(x^2-a^2)^i\partial_x^{i+r}\partial_y^k\partial_t^l V_3, \quad (x^2-a^2)^{i+1}\partial_x^{i+r+1}\partial_y^{k-1}\partial_t^l V_3, \quad (x^2-a^2)^{i+1}\partial_x^{i+r+1}\partial_y^k\partial_t^{l-1} V_3. \tag{2.22}$$

The first term in (2.22) is the standard lower-order term for (2.21). The other two terms in (2.22) can be treated by further induction on $k+l$ by noticing that these terms do not appear for $k+l=0$.

The second part in G comes from the commutators

$$[(x^2-a^2)^i\partial_x^{i+r}\partial_y^k\partial_t^l, v\mu^{-1}(\alpha)\partial_y]V_3 \tag{2.23}$$

and

$$(x^2-a^2)^i\partial_x^{i+r}\partial_y^k\partial_t^l[\alpha\mu^{-1}(\alpha)\partial_y V_1]. \tag{2.24}$$

The terms in (2.23) are either standard lower-order terms relative to (2.21) or terms where x-derivatives are one order lower than $i+r$. The latter can be controlled by induction assumption. The term in (2.24) is obviously controlled by (2.20).

Since $u=0$ at the boundaries $x=\pm a$, no boundary condition is required to obtain the energy estimate for equation (2.21) from integration by parts. Finally, applying Gronwall's inequality, we obtain

$$\begin{aligned} &\|(x^2-a^2)^i\partial_x^{i+r}\partial_y^k\partial_t^l V_3\|_0 \\ &\quad \le CT\left\{\sum_{k_1+l_1\le 2m-i-2r+1}\|(x^2-a^2)^i\partial_x^{i+r}\partial_y^{k_1}\partial_t^{l_1}V_1\|_0 + |||F_1|||_{2m,T}\right\}. \end{aligned} \tag{2.25}$$

This completes the proof of induction on r and consequently (2.5).

We now turn to the proof of (2.6). Applying the operator $(x^2-a^2)^i\partial_x^j\partial_y^k\partial_t^l$ to (2.1b) for $0 \le i \le j$, we have

$$\begin{aligned}\Delta(x^2-a^2)^i\partial_x^j\partial_y^k\partial_t^l\varphi + B_1(DU)\partial_x(x^2-a^2)^i\partial_x^j\partial_y^k\partial_t^l\varphi \\ + B_2(DU)\partial_y(x^2-a^2)^i\partial_x^j\partial_y^k\partial_t^l\varphi = \tilde{F}_2,\end{aligned} \tag{2.26}$$

where

$$\begin{aligned}\tilde{F}_2 = (x^2-a^2)^i\partial_x^j\partial_y^k\partial_t^l F_2 + \left[B_1(DU)\partial_x, (x^2-a^2)^i\partial_x^j\partial_y^k\partial_t^l\right]\varphi \\ + (x^2-a^2)^i\left[B_2(DU)\partial_y, \partial_x^j\partial_y^k\partial_t^l\right]\varphi + \left[\partial_x^2, (x^2-a^2)^i\partial_x^j\partial_y^k\partial_t^l\right]\varphi.\end{aligned} \tag{2.27}$$

For the special case $(j,k,l) = (0,0,l)$ with $l < 2m$, from (2.26) and the fact that $\partial_t^l\varphi = 0$ on the boundaries, we can use the classical result for second-order elliptic Dirichlet problems [5] to obtain

$$\|\partial_t^l D\varphi\|_{H^2} \le C\|\tilde{F}_2\|_0 \le C\left\{\sum_{l_1<l}\|\partial_t^{l_1}D\varphi\|_0 + \|\partial_t^l F_2\|_0\right\},$$

which implies that

$$\sum_{l<2m}\|\partial_t^l D\varphi\|_0 \le C|||F_2|||_{2m-1,T}. \tag{2.28}$$

For $(j,k,l) = (0,0,2m)$, we have from (2.26)–(2.28)

$$\|\partial_t^{2m}D\varphi\|_0 \le \|\partial_t^{2m}\varphi\|_{H^1} \le C\|\tilde{F}_2\|_{H^{-1}} \le C\left\{\|\partial_t^{2m}F_2\|_{H^{-1}} + |||F_2|||_{2m-1,T}\right\}. \tag{2.29}$$

From (2.29) and (2.30), it follows that

$$\sum_{l\le 2m}\|\partial_t^l D\varphi\|_0 \le C\left\{\|\partial_t^{2m}F_2\|_{H^{-1}} + |||F_2|||_{2m-1,T}\right\}. \tag{2.30}$$

Next, we estimate $(x^2-a^2)^i\partial_x^j\partial_y^k\partial_t^l D\varphi$. By directly differentiating equation (2.1b), it is easy to see that the estimate of $(x^2-a^2)^i\partial_x^j\partial_y^k\partial_t^l D\varphi$ can be reduced to the estimate of $(x^2-a^2)^i\partial_x^{j-1}\partial_y^{k+1}\partial_t^l D\varphi$. Therefore, we need only to consider the special case $j=0$. We will perform induction on $k+l$. By (2.30), we will always assume $k>0$.

Consider (2.26) with $i=j=0$ and $k+l=r$. Because of the boundary condition

$$\partial_y^k\partial_t^l\varphi|_{\partial\Omega} = 0, \tag{2.31}$$

similarly as in deriving (2.28), we obtain

$$\sum_{k+l=r+1,k>0}\|\partial_y^k\partial_t^l D\varphi\|_0 \le C\|\tilde{F}_2\|_0 \le C\sum_{k+l\le r}\left(\|\partial_y^k\partial_t^l D\varphi\|_0 + \|\partial_y^k\partial_t^l F_2\|_0\right).$$

By induction assumption, we have

$$\sum_{k+l\le r}\|\partial_y^k\partial_t^l D\varphi\|_0 \le C\left\{\|\partial_t^{2m}F_2\|_{H^{-1}} + |||F_2|||_{2m-1,T}\right\}. \tag{2.32}$$

Therefore,

$$\sum_{i\le j,k+l+2j-i\le 2m}\|(x^2-a^2)^i\partial_x^j\partial_y^k\partial_t^l D\varphi\|_0 \le C\left\{\|\partial_t^{2m}F_2\|_{H^{-1}} + |||F_2|||_{2m-1,T}\right\}. \tag{2.33}$$

This gives (2.6).

Finally, the dependency of the constants on $|||U|||_{2m,T}$ comes from the Nirenberg inequality and the Banach algebra property of the space $E_{2m,T}$ for $m \geq 1$; see [1, 6]. This completes the proof of Theorem 2.1.

Remark 1. In Theorem 2.1, the term $|||\partial_t F_2|||_{2m-1,T}$ is included in (2.6) to account for the derivative in the t direction because the solution of Laplace equation has no regularizing effect on the t-derivative. However, if F_2 has the special form $F_2 = DG_2$ in (2.1b), then (2.6) can be replaced simply by

$$|||D\varphi|||_{2m,T} \leq C_2|||G_2|||_{2m,T}. \tag{2.34}$$

This is because, in this case, the regularizing effect of inverse Laplacian cancels the one-order space derivative on G_2 and the two sides of (2.34) have the same regularity in the t direction. We will use this fact in the proof of Theorem 4.1.

3. Linear iteration. In this section, we will use linear iteration to prove the existence of classical solutions for the nonlinear problem in (1.10)–(1.12) in Theorem 1.1.

Assume the initial data $U_0 \in C^\infty(\bar{\Omega})$ are $2m$th-order compatible, and $(\tilde{U}, \tilde{\psi})$ are the approximate solutions such that $\tilde{U} \in E_{2m+1,T}$ and $D\tilde{\psi} \in E_{2m,T}$ with $\tilde{U}(t,x,y) \in \mathbf{G}_1 \subset\subset \mathbf{G}_2 \subset\subset \mathbf{G} = (0,1) \times R^2$ for all $(t,x,y) \in [0, T] \times \Omega$. From the embedding property of the space E_{2m}, there is an $\epsilon_0 > 0$ so small such that if

$$|||U - \tilde{U}|||_{2m,T} \leq \epsilon_0, \tag{3.1}$$

then we have $U(t,x,y) \in \bar{\mathbf{G}}_2$.

Our solution is constructed through the following iteration scheme:

$$\begin{cases} A_0(U^{(k)})\partial_t U^{(k+1)} + A_1(U^{(k)})\partial_x U^{(k+1)} + A_2(U^{(k)})\partial_y U^{(k+1)} = H_1(U^{(k)}, D\psi^{(k)}), \\ \Delta\psi^{(k+1)} + B_1(DU^{(k)})\partial_x\psi^{(k+1)} + B_2(DU^{(k)})\partial_y\psi^{(k+1)} = H_2(DU^{(k)}), \end{cases} \tag{3.2}$$

$$U^{(k+1)}(0,x,y) = U_0(x,y), \tag{3.3}$$

$$u^{(k+1)}(t, \pm a, y) = 0, \qquad \psi^{(k+1)}(t, \pm a, y) = 0, \qquad \psi^{(k+1)}(t, x, \pm\infty) = 0 \tag{3.4}$$

for $k = 0, 1, 2, \dots$ with

$$U^{(0)}(t,x,y) = \tilde{U}(t,x,y), \qquad \psi^{(0)}(t,x,y) = \tilde{\psi}(t,x,y).$$

Here, $U^{(k+1)}, \psi^{(k+1)}$ can be solved in any interval $[0, T_k]$ in which

$$U^{(k)}(t,x,y) \in \mathbf{G}_2 \quad \text{for } (t,x,y) \in [0, T_k] \times \Omega$$

and

$$U^{(k)}(t,x,y) \in C^1([0, T_k] \times \Omega), \qquad \psi^{(k)}(t,x,y) \in C\big([0, T_k], C^1(\Omega)\big).$$

For this sequence of $(U^{(k)}, \psi^{(k)})$, we also have the following result.

LEMMA 3.1. *The sequence of $(U^{(k)}, \psi^{(k)})$ has zero traces at $t = 0$ up to order $2m$:*

$$\begin{aligned} &\partial_t^j \left(U^{(k+1)} - \tilde{U}\right)(0,x,y) = 0, \quad 0 \leq j \leq 2m, \\ &\partial_t^j \left(\psi^{(k+1)} - \tilde{\psi}\right)(0,x,y) = 0, \quad 0 \leq j \leq 2m-1 \end{aligned} \tag{3.5}$$

for $k = 0, 1, 2, \ldots$.

Proof. It follows from (1.18) and (3.2) that for $k = 0, 1, 2, 3, \ldots$

$$\tag{3.6} \begin{cases} A_0(U^{(k)})\partial_t \left[U^{(k+1)} - U^{(0)}\right] + A_1(U^{(k)})\partial_x \left[U^{(k+1)} - U^{(0)}\right] \\ \quad + A_2(U^{(k)})\partial_y \left[U^{(k+1)} - U^{(0)}\right] \\ = H_1(U^{(k)}, D\psi^{(k)}) - H_1(U^{(0)}, D\psi^{(0)}) - \tilde{F}_1 + H_3(U^{(0)}, U^{(k)}), \\ \Delta\left[\psi^{(k+1)} - \psi^{(0)}\right] + B_1(DU^{(k)})\partial_x \left[\psi^{(k+1)} - \psi^{(0)}\right] \\ \quad + B_2(DU^{(k)})\partial_y \left[\psi^{(k+1)} - \psi^{(0)}\right] \\ = H_2(DU^{(k)}) - H_2(DU^{(0)}) - \tilde{F}_2 + H_4(U^{(0)}, U^{(k)}, \psi^{(0)}), \end{cases}$$

where

$$\tag{3.7} \begin{cases} H_3 = \left[A_0(U^{(0)}) - A_0(U^{(k)})\right]\partial_t U^{(0)} + \left[A_1(U^{(0)}) - A_1(U^{(k)})\right]\partial_x U^{(0)} \\ \qquad + \left[A_2(U^{(0)}) - A_2(U^{(k)})\right]\partial_y U^{(0)} - \tilde{F}_1, \\ H_4 = \left[B_1(DU^{(0)}) - B_1(DU^{(k)})\right]\partial_x \psi^{(0)} + \left[B_2(DU^{(0)}) - B_2(DU^{(k)})\right]\partial_y \psi^{(0)} - \tilde{F}_2. \end{cases}$$

For $k = 0$, (3.6) becomes simply

$$\tag{3.8} \begin{cases} A_0(U^{(0)})\partial_t \left[U^{(1)} - U^{(0)}\right] + A_1(U^{(0)})\partial_x \left[U^{(1)} - U^{(0)}\right] \\ \quad + A_2(U^{(0)})\partial_y \left[U^{(1)} - U^{(0)}\right] = -\tilde{F}_1, \\ \Delta\left[\psi^{(1)} - \psi^{(0)}\right] + B_1(DU^{(0)})\partial_x \left[\psi^{(1)} - \psi^{(0)}\right] \\ \quad + B_2(DU^{(0)})\partial_y \left[\psi^{(1)} - \psi^{(0)}\right] = -\tilde{F}_2. \end{cases}$$

Since $\partial_t^j \tilde{F}_2(0, x, y) = 0$ $(0 \le j \le 2m - 1)$, taking the derivative with respect to t in the second equation of (3.8), we have

$$\tag{3.9} \partial_t^j \left[\psi^{(1)} - \psi^{(0)}\right](0, x, y) = 0 \quad (0 \le j \le 2m - 1).$$

Since both $U^{(1)}$ and $U^{(0)}$ satisfy (1.10), we have $\left(U^{(1)} - U^{(0)}\right)(0, x, y) = 0$. Therefore, we derive inductively on j from (3.6), (3.9), and $\partial_t^j \tilde{F}_1 = 0\,(0 \le j \le 2m - 1)$ that

$$\partial_t^j (U^{(1)} - U^{(0)})(0, x, y) = 0 \quad \text{for } 0 \le j \le 2m.$$

This proves (3.5) for $k = 0$. The cases for $k > 0$ can be easily proved inductively by noticing that the terms H_3 and H_4 in (3.7) have zero traces up to order $2m - 1$ by induction assumption.

The following lemma establishes the existence of iteration sequence in a common time interval.

LEMMA 3.2. *There are constants $T_0 > 0$ and $\ell > 0$ such that the iteration sequence $\{U^{(k)}, \psi^{(k)}\}$ satisfies*

$$\tag{3.10} |||U^{(k)} - \tilde{U}|||_{2m,T_0} \le \epsilon_0, \qquad |||D(\psi^{(k)} - \tilde{\psi})|||_{2m,T_0} \le \ell$$

for all $k \in \mathbf{Z}^+$. The constants T_0 and ℓ depend only on the approximate solution $(\tilde{U}, \tilde{\psi})$ (which in turn can be determined from the initial data U_0) up to order $|||\tilde{U}|||_{2m+1,T}$, $|||D\tilde{\psi}|||_{2m,T}$.

Proof. This can be shown inductively on k. For simplicity, we denote $U^{(k)}$ by U, $\psi^{(k)}$ by ψ, $U^{(k+1)} - U^{(0)}$ by V, and $\psi^{(k+1)} - \psi^{(0)}$ by Ψ. We apply (2.5) and (2.6) to system (3.6). Noticing that the right sides of (3.6) have zero traces at $T = 0$ up to order $2m - 1$ and that the constants C_1 and C_2 in (2.5) and (2.6) depend only on $|||U|||_{2m,T}$, we obtain

$$|||V|||_{2m,T} \le CT, \qquad |||D\Psi|||_{2m,T} \le C', \tag{3.11}$$

where the constants C and C' depend only on

$$\begin{aligned} C &= C(|||\tilde{F}_1||||_{2m,T}, |||U - U^{(0)}|||_{2m,T}, |||D(\psi - \psi^{(0)})|||_{2m,T}), \\ C' &= C'(|||\tilde{F}_2||||_{2m-1,T}, |||U - U^{(0)}|||_{2m,T}, |||D(\psi - \psi^{(0)})|||_{2m,T}). \end{aligned} \tag{3.12}$$

$|||\tilde{F}_1||||_{2m,T}$ and $|||\tilde{F}_2||||_{2m-1,T}$ depend only on $|||\tilde{U}|||_{2m+1,T}$ and $|||D\tilde{\psi}|||_{2m,T}$. By induction assumption, $|||U|||_{2m,T}$ and $|||D\psi|||_{2m,T}$ are uniformly bounded by (3.10). Therefore, T_0 can be easily decided from (3.11) and depends only on $|||\tilde{U}|||_{2m+1,T}$ and $|||D\tilde{\psi}|||_{2m,T}$. This completes the proof of the lemma.

Next lemma establishes the convergence of the solution sequence above.

LEMMA 3.3. *There are positive constants* T_1, $0 < T_1 \le T_0$, ρ_1, ρ_2, $\rho_1 + \rho_2 < 1$, *and* $\tilde{C}$ *such that the functions* $\{U^{(k)}, \psi^{(k)}\}$ *obtained from* (3.1)–(3.4) *satisfy*

$$|||U^{(k+2)} - U^{(k+1)}|||_{2,T_1} \le \rho_1 |||U^{(k+1)} - U^{(k)}|||_{2,T_1} + \rho_2 |||U^{(k)} - U^{(k-1)}|||_{2,T_1} \tag{3.13}$$

and

$$|||D\psi^{(k+1)} - D\psi^{(k)}|||_{2,T_1} \le \tilde{C} |||U^{(k)} - U^{(k-1)}|||_{2,T_1}, \tag{3.14}$$

$k = 1, 2, 3, \ldots$.

Proof. Denote $V^{(k)} = U^{(k+1)} - U^{(k)}$ and $\Psi^{(k)} = \psi^{(k+1)} - \psi^{(k)}$, $k = 0, 1, 2, \ldots$. It follows from (3.2) that

$$\begin{aligned} &A_0(U^{(k)})\partial_t V^{(k)} + A_1(U^{(k)})\partial_x V^{(k)} + A_2(U^{(k)})\partial_y V^{(k)} \\ &\quad = H_1(U^{(k)}, D\psi^{(k)}) - H_1(U^{(k-1)}, D\psi^{(k-1)}) - \left(A_0(U^{(k)}) - A_0(U^{(k-1)})\right) \partial_t U^{(k)} \\ &\quad\quad - \left(A_1(U^{(k)}) - A_1(U^{(k-1)})\right) \partial_x U^{(k)} - \left(A_2(U^{(k)}) - A_2(U^{(k-1)})\right) \partial_y U^{(k)}, \end{aligned} \tag{3.15}$$

$$\begin{aligned} &\Delta\Psi^{(k)} + B_1(DU^{(k)})\partial_x \Psi^{(k)} + B_2(DU^{(k)})\partial_y \Psi^{(k)} \\ &\quad = H_2(DU^{(k)}) - H_2(DU^{(k-1)}) - \left(B_1(DU^{(k)}) - B_1(DU^{(k-1)})\right) \partial_x U^{(k)} \\ &\quad\quad - \left(B_2(DU^{(k)}) - B_2(DU^{(k-1)})\right) \partial_y U^{(k)}. \end{aligned} \tag{3.16}$$

By Lemma 3.2 and the Banach algebra property of the space $E_{m,T}$, there exists $C = C(\bar{\mathbf{G}}_2)$ such that, for any $0 < T \le T_0$,

$$\begin{aligned} &|||H_1(U^{(k)}, D\psi^{(k)}) - H_1(U^{(k-1)}, D\psi^{(k-1)})|||_{2,T} \\ &\quad \le C(\bar{\mathbf{G}}_2) \left(|||V^{(k-1)}|||_{2,T} + |||D\Psi^{(k-1)}|||_{2,T}\right), \end{aligned}$$

$$\begin{aligned} &|||\left(A_0(U^{(k)}) - A_0(U^{(k-1)})\right) \partial_t U^{(k)}|||_{2,T} + |||\left(A_1(U^{(k)}) - A_1(U^{(k-1)})\right) \partial_x U^{(k)}|||_{2,T} \\ &\quad + |||\left(A_2(U^{(k)}) - A_2(U^{(k-1)})\right) \partial_y U^{(k)}|||_{2,T} \le C(\bar{\mathbf{G}}_2) |||V^{(k-1)}|||_{2,T}, \end{aligned}$$

$$\begin{aligned} &|||D(H_2(DU^{(k)}) - H_2(DU^{(k-1)}))|||_{0,T} \\ &\quad + |||D\left((B_1(DU^{(k)}) - B_1(DU^{(k-1)}))\partial_x U^{(k)}\right)|||_{0,T} \\ &\quad + |||D\left((B_2(DU^{(k)}) - B_2(DU^{(k-1)}))\partial_y U^{(k)}\right)|||_{0,T} \le C(\bar{\mathbf{G}}_2) |||V^{(k-1)}|||_{2,T}. \end{aligned}$$

Thus, applying (2.5) and (2.6) to (3.15) and (3.16), we have

$$|||D\psi^{(k+1)}(t) - D\psi^{(k)}|||_{2,T} \leq C_2(\bar{\mathbf{G}}_2)|||V^{(k-1)}|||_{2,T}, \tag{3.17}$$

$$\begin{aligned} &|||U^{(k+1)}(t) - U^{(k)}(t)|||_{2,T} \\ &\leq C_1(\bar{\mathbf{G}}_2)T\left(|||V^{(k-1)}|||_{2,T} + |||D\Psi^{(k-1)}|||_{2,T}\right) \\ &\leq C_1(\bar{\mathbf{G}}_2)T|||V^{(k-1)}|||_{2,T} + C_1(\bar{\mathbf{G}}_2)C_2(\bar{\mathbf{G}}_2)T|||V^{(k-2)}|||_{2,T} \end{aligned} \tag{3.18}$$

Therefore, in order to prove Lemma 3.3, we need only to choose $\tilde{C} = C_2(\bar{\mathbf{G}}_2)$, $\rho_2 = C_1(\bar{\mathbf{G}}_2)C_2(\bar{\mathbf{G}}_2)T_1$, and $\rho_1 = C_1(\bar{\mathbf{G}}_2)T_1$ with $T_1 < \left(C_1(\bar{\mathbf{G}}_2) + C_1(\bar{\mathbf{G}}_2)C_2(\bar{\mathbf{G}}_2)\right)^{-1}$.

Now, we are ready to prove the existence part of Theorem 1.1.

Proof of Theorem 1.1. It follows from (3.13) and (3.14) that

$$\sum_{k=1}^{\infty} |||U^{(k+1)} - U^{(k)}|||_{2,T_1} < \infty$$

and

$$\sum_{k=1}^{\infty} |||D\psi^{(k+1)} - D\psi^{(k)}|||_{2,T_1} < \infty.$$

Therefore, there exist $U \in E_{2,T_1}$ and ψ with $D\psi \in E_{2,T_1}$ such that

$$\lim_{k\to\infty} \left(|||U^{(k)} - U|||_{2,T_1} + |||D\psi^{(k)} - D\psi|||_{2,T_1}\right) = 0. \tag{3.19}$$

The $E_{m,T}$ space interpolation inequalities [1] implies that there exists a constant $C = C(m)$ such that for any $s \in [2, 2m]$,

$$||V||_s \leq C||V||_2^{\frac{2m-s}{2m-2}} ||V||_{2m}^{\frac{s-2}{2m-2}}, \tag{3.20}$$

where $||\cdot||_s$ is the norm of the space E_s. Thus from Lemma 3.2 and Lemma 3.3, we have that, for any $s < 2m$

$$\lim_{k\to\infty} \left(|||U^{(k)} - U|||_{s,T_1} + |||D\psi^{(k)} - D\psi|||_{s,T_1}\right) = 0.$$

If we choose $s > 2$, the imbedding property in Lemma 1.1 for the space $E_{m,T}$ implies that $U^{(k)} \to U$ in $C\left([0,\ T_2], C^1(\Omega)\right)$ and $\psi^{(k)} \to \psi$ in $C\left([0,\ T_1], C^2(\Omega)\right)$. From (3.1), we have

$$\begin{aligned} \partial_t U^{(k+1)} =& A_0^{-1}(U^{(k)})H_1(U^{(k)}, D\psi^{(k)}) - A_0^{-1}(U^{(k)})A_1(U^{(k)})\partial_x U^{(k+1)} \\ &- A_0^{-1}(U^{(k)})A_2(U^{(k)})\partial_y U^{(k+1)}, \end{aligned}$$

thus $\partial_t U^{(k)} \to \partial_t U$ in $C([0, T_1], C(\Omega))$. Letting $k \to \infty$ in (3.2), we obtain that $U(t,x,y)$ and $\psi(t,x,y)$ satisfy (1.9)–(1.12) in the classical sense. This completes the proof of Theorem 1.1.

4. Uniqueness. The solution we obtained in §3 is unique in the following sense.

THEOREM 4.1. *Let* (U_i, ψ_i) $(i = 1, 2)$ *with* $U_i \in E_{2m,T}$, $D\psi_i \in E_{2m,T}$ *be the solutions of the coupled system in* (1.9)–(1.12) *with the same initial value* $U_0(x,y) \in E_{2m}(\Omega)$, *which are* 2*m*th*-order compatible. If* $U_i(t,x,y) \in \mathbf{G}_2$ *for* $(t,x,y) \in [0,\ T] \times \Omega$, *then* $U_1(t,x,y) \equiv U_2(t,x,y)$, $\psi_1(t,x,y) \equiv \psi_2(t,x,y)$.

Proof. Setting $U = U_1 - U_2$ and $\psi = \psi_1 - \psi_2$, we have

$$\left\{\begin{array}{l} A_0(U_1)\partial_t U + A_1(U_1)\partial_x U + A_2(U_1)\partial_y U = W_1, \\ \Delta\psi + B_1(DU_1)\partial_x\psi + B_2(DU_1)\partial_y\psi = W_2 \end{array}\right. \tag{4.1}$$

with

$$\left\{\begin{array}{l} \psi(t,-a,y) = \psi(t,a,y) = 0, \;\; \psi(t,x,-\infty) = \psi(t,x,\infty) = 0, \\ u_2(t,-a,y) = u_2(t,a,y) = 0, \\ U(0,x,y) = 0. \end{array}\right. \tag{4.2}$$

Here

$$\begin{aligned} W_1 = H_1(U_1, D\psi_1) - H_1(U_2, D\psi_2) - \big(A_0(U_1) - A_0(U_2)\big)\partial_t U_2 \\ - \big(A_1(U_1) - A_1(U_2)\big)\partial_x U_2 - \big(A_2(U_1) - A_2(U_2)\big)\partial_y U_2, \end{aligned} \tag{4.3}$$

$$\begin{aligned} W_2 = H_2(DU_1) - H_2(DU_2) - \big(B_1(DU_1) - B_1(DU_2)\big)\partial_x\psi_2 \\ - \big(B_2(DU_1) - B_2(DU_2)\big)\partial_y\psi_2. \end{aligned} \tag{4.4}$$

By the Nirenberg inequalities and Taylor's theorem, there are constants C_1 and C_2, such that, for $t \in [0, T]$,

$$|||W_1|||_{2m,t} \le C_1 \left(|||U|||_{2m,t} + |||D\psi|||_{2m,t}\right), \tag{4.5}$$

$$|||W_2|||_{2m-1,t} \le C_2|||U|||_{2m,t}. \tag{4.6}$$

From (2.34) in Remark 1 and (4.6), it follows that there exists C' such that

$$|||D\psi|||_{2m,t} \le C'|||U|||_{2m,t}. \tag{4.7}$$

Again it follows from (2.5), (4.5), and (4.7) that there exists C'' such that

$$||U||_{2m,t} \le C''t|||U|||_{2m,t}. \tag{4.8}$$

The inequality (4.8) implies that for $t \ll 1$, we have $|||U|||_{2m,t} = 0$ and consequently $|||D\psi|||_{2m,t} = 0$. Then by the standard continuation argument, we obtain $(U, \psi) \equiv (0,0)$ for all $t \in [0, T]$. This completes the proof.

EXISTENCE AND BLOW-UP OF SOLUTIONS TO TWO-PHASE NONEQUILIBRIUM PROBLEMS*

ZHICHENG GUAN[†] AND XU-JIA WANG[†]

Abstract. In this paper, we deal with the one-dimensional Stefan problem

$$u_t - u_{xx} = \Gamma'(t)\delta(x - \Gamma(t)) \text{ in } I\!R \times I\!R^+, u(x,0) = u_0(x)$$

with a kinetic condition $\Gamma'(t) = f(u)$ on the free boundary $F = \{(x,t), x = \Gamma(t)\}$, where $\delta(x)$ is the Dirac function. We show that if $|f(u)| \leq M\, e^{\gamma|u|}$ for some $M > 0$ and $\gamma \in (0, \frac{1}{4})$, then there exists a global solution to the above problem. We also give an example to show that the solution may blow up in finite time if $f(u) \geq Ce^{|u|}$ for some $C > 0$.

1. Introduction.

In this paper, we deal with the following one-dimensional Stefan problem with kinetic condition on the free boundary:

$$(1.1)\qquad \begin{cases} u_t - u_{xx} = 0 & \text{in } Q\backslash F, \\ u^-(\Gamma(t),t) = u^+(\Gamma(t),t) & \text{on } F, \\ u_x^-(\Gamma(t),t) - u_x^+(\Gamma(t),t) = \Gamma'(t) & \text{on } F, \\ \Gamma'(t) = f(u),\ \Gamma(0) = b & \text{on } F, \\ u(x,0) = u_0(x), & \end{cases}$$

where $Q = I\!R \times I\!R^+$ and $F = \{(x,t); x = \Gamma(t)\}$ is the free boundary.

Problem (1.1) with $Q = (0,1) \times (0,T]$ has been studied by many authors [3, 9, 10], and the case when $Q = I\!R \times I\!R^+$ has been studied by Yin [11]. In both cases, the local existence and uniqueness of solutions have been established. But to obtain the global existence of solutions, the condition that $f(u)u \leq C(1 + u^2)$ was imposed in [3, 9, 10].

Here we are interested in the existence of global solutions without the restriction above. Recently one of the authors [8] obtained the global existence of solutions to the problem (1.1) with $Q = (0,1) \times (0,\infty)$ under the following conditions:

(i) $f(u) = u^{2m}$,

(ii) $\Gamma(0) = \Gamma_0 \geq 1 - K_0^{1-2m}(1 - \frac{1}{2m})^{2m}/(2m-1)$,

where $m > \frac{1}{2}$ and $K_0 = \max\{\|u_0(x)\|_{L^\infty(0,1)}, \|u(0,t)\|_{L^\infty(0,\infty)}, \|u(1,t)\|_{L^\infty(0,\infty)}\}$.

In this paper, we will prove that if $|f(u)| \leq M\, e^{\gamma|u|}$ for some $M > 0$ and $\gamma \in (0, \frac{1}{4})$, then there exists a global solution to the problem (1.1). If $f(u) \geq \delta e^{|u|}$ for some $\delta > 0$, we will give an example to show that the solution may blow up in finite time.

This paper is arranged as follows. In §1, we give the finite-time blow-up example. In §2, we prove the global existence result for the problem (1.1).

2. A blow-up example.

For any given $T > 0$, we construct $f(u)$ and $\Gamma(t)$ so that the solution u of problem (1.1) blows up at $t = T$.

*Received by the editors June 25, 1993; accepted for publication (in revised form) November 11, 1994. This research was supported by the NNSF of China and the NSF of Zhejiang Province.

[†]Department of Mathematics, Zhejiang University, Hangzhou 310027, People's Republic of China.

Let $\Gamma(t) \in C^2[0,T)$ be given; we consider the problem

$$\text{(2.1)} \qquad \begin{cases} u_t - u_{xx} = 0 & \text{in } Q\backslash F, \\ u^-(\Gamma(t),t) = u^+(\Gamma(t),t) & \text{on } F, \\ u_x^-(\Gamma(t),t) - u_x^+(\Gamma(t),t) = \Gamma'(t) & \text{on } F, \\ u(x,0) = 0 \text{ and } u(x,t) \to 0 & \text{as } |x| \to \infty. \end{cases}$$

Problem (2.1) is uniquely solvable. In the sense of distributions, the solution of (2.1) is equivalent to the solution of

$$\text{(2.2)} \qquad \begin{cases} u_t - u_{xx} = \Gamma'(t)\delta(x - \Gamma(t)) & \text{in } I\!R \times (0,T), \\ u(x,0) = 0, \end{cases}$$

where $\delta(x)$ is the Dirac function. The solution of (2.2) is given by

$$\text{(2.3)} \qquad u(x,t) = \int_0^t \int_{-\infty}^{\infty} \Gamma'(s)\delta(\xi - \Gamma(s))K(x-\xi, t-s)d\xi ds,$$

where

$$K(x,t) = \begin{cases} \frac{1}{\sqrt{4\pi t}} e^{-\frac{x^2}{4t}}, & t > 0, \\ 0, & t \leq 0. \end{cases}$$

Hence

$$\text{(2.4)} \qquad \begin{aligned} u(x,t) &= \int_0^t \frac{\Gamma'(s)}{\sqrt{4\pi(t-s)}} e^{-\frac{|x-\Gamma(s)|^2}{4(t-s)}} ds \\ &= \int_0^t \frac{\Gamma'(t-s)}{\sqrt{4\pi s}} e^{-\frac{|x-\Gamma(t-s)|^2}{4s}} ds. \end{aligned}$$

For $u(x,t)$ given above, one can verify that (see [1, Chap. 14])

$$\text{(2.5)} \qquad \lim_{x\to\Gamma(t)^-} \frac{\partial u(x,t)}{\partial x} = \frac{1}{2}\Gamma'(t) + \int_0^t \frac{\partial K}{\partial x}(\Gamma(t) - \Gamma(s), t-s)\Gamma'(s)\, ds,$$

$$\text{(2.6)} \qquad \lim_{x\to\Gamma(t)^+} \frac{\partial u(x,t)}{\partial x} = -\frac{1}{2}\Gamma'(t) + \int_0^t \frac{\partial K}{\partial x}(\Gamma(t) - \Gamma(s), t-s)\Gamma'(s)\, ds.$$

Hence the function $u(x,t)$ in (2.4) is a solution of (1.1). Note that for any $t > 0$, the maximum of $|u(x,t)|$ in $I\!R \times \underline{(0,T)}$ is attained on F.

Now let $\Gamma(t) = -\delta\sqrt{T-t}$, where $0 < \delta \leq \frac{1}{2}$ is a constant. Denote $\varepsilon = T - t$. We have

$$\text{(2.7)} \qquad \Gamma'(t-s) = \frac{\delta}{2\sqrt{\varepsilon+s}}, \quad \Gamma''(t-s) = \frac{\delta}{4(\varepsilon+s)^{3/2}}.$$

Let $F(t,s) = \frac{1}{4s}|\Gamma(t) - \Gamma(t-s)|^2 = \frac{\delta^2}{4s}|\sqrt{\varepsilon+s} - \sqrt{\varepsilon}|^2$. Then

$$\text{(2.8)} \qquad F(t,s) = \frac{\delta^2}{4} \frac{\sqrt{\varepsilon+s} - \sqrt{\varepsilon}}{\sqrt{\varepsilon+s} + \sqrt{\varepsilon}} < \frac{\delta^2}{4},$$

$$\frac{\partial}{\partial t}F(t,s)=\frac{\delta^2}{4s}(\sqrt{\varepsilon+s}-\sqrt{\varepsilon})\left(\frac{1}{\sqrt{\varepsilon}}-\frac{1}{\sqrt{\varepsilon+s}}\right)\le\frac{\delta^2}{4}\frac{1}{\sqrt{\varepsilon}\sqrt{\varepsilon+s}}. \tag{2.9}$$

From (2.4), we therefore obtain

$$\begin{aligned} u(\Gamma(t),t)&=\int_0^t\frac{\Gamma'(t-s)}{\sqrt{4\pi s}}e^{-F(t,s)}\,ds\\ &\ge\frac{e^{-\delta^2/4}}{\sqrt{4\pi}}\int_0^t\frac{\Gamma'(t-s)}{\sqrt{s}}\,ds\\ &=\frac{e^{-\delta^2/4}}{\sqrt{4\pi}}\int_0^t\frac{\delta}{2\sqrt{s}\sqrt{\varepsilon+s}}\,ds\\ &=\frac{e^{-\delta^2/4}}{4\sqrt{\pi}}\int_0^{t/\varepsilon}\frac{\delta}{\sqrt{s}\sqrt{1+s}}\,ds\\ &=\frac{\delta e^{-\delta^2/4}}{2\sqrt{\pi}}\log\left(\sqrt{1+\frac{t}{\varepsilon}}+\sqrt{\frac{t}{\varepsilon}}\right)\\ &\ge\frac{\delta}{16}\log\left(1+\frac{t}{\varepsilon}\right)=\frac{\delta}{16}\log\frac{T}{T-t}; \end{aligned} \tag{2.10}$$

and

$$\begin{aligned} u(\Gamma(t),t)&\le\frac{1}{\sqrt{4\pi}}\int_0^t\frac{\Gamma'(t-s)}{\sqrt{s}}\,ds\\ &=\frac{1}{4\sqrt{\pi}}\int_0^{t/\varepsilon}\frac{\delta}{\sqrt{s}\sqrt{1+s}}\,ds\\ &=\frac{\delta}{2\sqrt{\pi}}\log\left(\sqrt{1+\frac{t}{\varepsilon}}+\sqrt{\frac{t}{\varepsilon}}\right)\\ &\le\begin{cases}\delta\cdot\sqrt{\frac{t}{T-t}} & \text{if } t\le T/2\\ \delta\cdot\log\frac{T}{T-t} & \text{if } t\ge T/2.\end{cases} \end{aligned} \tag{2.11}$$

From (2.10), it follows that $u(\Gamma(t),t)\to\infty$ as $t\to T$. Next, we show that $u(\Gamma(t),t)$ is strictly increasing in $t\in(0,T)$. We have

$$\begin{aligned} \frac{d}{dt}u(\Gamma(t),t)&=\int_0^t\frac{\Gamma''(t-s)}{\sqrt{4\pi s}}\,e^{-F(t,s)}\,ds-\int_0^t\frac{\Gamma'(t-s)}{\sqrt{4\pi s}}\,F_te^{-F(t,s)}\,ds\\ &\quad+\frac{\Gamma'(0)}{\sqrt{4\pi t}}\,e^{-|\Gamma(t)-\Gamma(0)|^2/4t}=:I_1+I_2+I_3, \end{aligned} \tag{2.12}$$

where $I_3>0$. By (2.7) and (2.8), we have

$$\begin{aligned} I_1&\ge\frac{e^{-1/4}}{\sqrt{4\pi}}\int_0^t\frac{\Gamma''(t-s)}{\sqrt{s}}\,ds\\ &=\frac{e^{-1/4}}{8\sqrt{\pi}}\int_0^t\frac{\delta}{\sqrt{s}(\varepsilon+s)^{3/2}}\,ds\\ &=\frac{\delta e^{-1/4}}{8\varepsilon\sqrt{\pi}}\int_0^{t/\varepsilon}\frac{1}{\sqrt{s}(1+s)^{3/2}}\,ds\\ &=\frac{\delta e^{-1/4}}{4\varepsilon\sqrt{\pi}}\sqrt{\frac{t}{t+\varepsilon}}=\frac{\delta e^{-1/4}}{4\varepsilon\sqrt{\pi}}\sqrt{\frac{t}{T}}. \end{aligned} \tag{2.13}$$

From (2.9), we have

$$
\begin{aligned}
|I_2| &\le \int_0^t \frac{|\Gamma'(t-s)F_t|}{\sqrt{4\pi s}}\,ds \\
&\le \int_0^t \frac{\delta^2|\Gamma'(t-s)|}{8\sqrt{\pi}\sqrt{s}\sqrt{\varepsilon}\sqrt{\varepsilon+s}}ds \\
&\le \frac{\delta^3}{16\sqrt{\pi}}\int_0^t \frac{1}{(\varepsilon+s)\sqrt{\varepsilon}\sqrt{s}}ds \\
&= \frac{\delta^3}{16\varepsilon\sqrt{\pi}}\int_0^{t/\varepsilon} \frac{1}{\sqrt{s}(1+s)}\,ds \\
&= \frac{\delta^3}{8\varepsilon\sqrt{\pi}}\operatorname{arctg}\sqrt{\frac{t}{T-t}},
\end{aligned}
\tag{2.14}
$$

where $\varepsilon = T - t$. Note that since $\sin\theta \ge \frac{2}{\pi}\theta$ for $\theta \in (0, \frac{\pi}{2})$, we have $\sqrt{\frac{t}{T}} \ge \frac{2}{\pi}\operatorname{arctg}\sqrt{\frac{t}{T-t}}$. Hence if $0 < \delta \le \frac{1}{2}$, by (2.13) and (2.14) we have $I_1 > I_2$, and so $\frac{d}{dt}u(\Gamma(t), t) > 0$ for $t \in (0, 1)$.

Since $u(\Gamma(t), t)$ is strictly increasing and tends to infinity as $t \to T$, we can define $f(u) : I\!R^+ \to I\!R^+$ by

$$
f(u(\Gamma(t),t)) = \Gamma'(t) = \frac{\delta}{2\sqrt{T-t}}.
\tag{2.15}
$$

For the function $f(u)$ defined above, we therefore conclude that the solution $u(x,t)$ blows up at time $t = T$.

Remark 2.1. Since $\Gamma'(t)$ and $u(\Gamma(t), t)$ are positive and strictly increasing, it follows that $f(u)$ is also positive and increasing in $(0, T)$. From (2.10) and (2.11), it is easy to see that $f(u)$ is of exponential growth as $u \to +\infty$. From (2.10) and (2.15), we have

$$
f(u) \le \frac{\delta}{2\sqrt{T}}e^{8u/\delta};
\tag{2.16}
$$

by (2.11) and (2.15), we have

$$
f(u) \ge \frac{\delta}{2\sqrt{T}}e^{u/2\delta} \text{ for } u \ge \delta,
\tag{2.17}
$$

where $\delta \in (0, \frac{1}{2}]$. Moreover, $\lim_{u\to 0} f(u) = \frac{\delta}{2\sqrt{T}}$.

3. Global existence. Let us begin with the local existence and regularity for solutions of (1.1). Suppose $u(x,t)$ is a solution of (1.1). Then $u(x,t)$ satisfies in the sense of distributions that

$$
\begin{cases}
u_t - u_{xx} = \Gamma'(t)\delta(x - \Gamma(t)) & \text{in } I\!R \times I\!R^+, \\
u(x,0) = u_0(x).
\end{cases}
$$

Hence

(3.1)

$$
\begin{aligned}
u(x,t) &= \int_{-\infty}^{\infty} K(x-\xi,t)u_0(\xi)d\xi + \int_0^t\int_{-\infty}^{\infty} \Gamma'(s)\delta(\xi-\Gamma(s))K(x-\xi,t-s)d\xi ds \\
&= \int_{-\infty}^{\infty} K(x-\xi,t)u_0(\xi)d\xi + \int_0^t \Gamma'(s)K(x-\Gamma(s),t-s)ds,
\end{aligned}
$$

where $K(x,t)$ was as defined in §2. We have the following lemma.

LEMMA 3.1. *Suppose* $u_0(x) \in C(I\!R) \cap L^\infty(I\!R)$ *and* $f(y)$ *is locally Lipschitz continuous. Then the problem* (1.1) *admits a local solution* $u(x,t) \in C^0(Q_T) \cap C^\infty(Q_T^\pm)$ *and* $\Gamma(t) \in C^1[0,T]$ *for some* $T > 0$, *where* $Q_T^+ = Q_T \cap \{x > \Gamma(t)\}$, $Q_T^- = Q_T \cap \{x < \Gamma(t)\}$, $Q_T = I\!R \times (0,T]$.

Proof. Let

$$A = \{\Gamma(t) \in C^1[0,T];\quad \Gamma(0) = b, \Gamma'(b) = f(u_0(b)),\ \text{and}\ \|\Gamma\|_{C^1[0,T]} \le M\},$$

where $M > 1$ and $T < 1$ are positive constants to be determined. For any $\Gamma(t) \in A$, let $u(x,t)$ be the function defined by (3.1). Then $u(\Gamma(t),t) \in C[0,T]$. Direct computation gives

$$|u_1(\Gamma_1(t),t) - u_2(\Gamma_2(t),t)| \le Ct^{1/2}\|\Gamma_1 - \Gamma_2\|_{C^1[0,T]},$$

where C is independent of t.

Let $G:\ \Gamma \in A \to \widetilde{\Gamma}(t) \in A$ be a mapping defined by

$$\widetilde{\Gamma}(t) = b + \int_0^t f(u(\Gamma(s),s))\,ds.$$

Then $\widetilde{\Gamma}(0) = b$, $\widetilde{\Gamma}'(0) = f(u_0(b))$, and $\widetilde{\Gamma} \in C^1[0,T]$. If M is large enough and T is small enough, by the Lipschitz continuity of f, it is easy to check that $G(A) \subset A$ and G is a contraction mapping. Hence G has a fixed point which gives a local solution to the problem (1.1). □

Remark 3.1. The fact that G is a contraction mapping implies the uniqueness of solutions to (1.1). Let

$$A = \{\Gamma \in C^1[0,T] \cap C^{1,1}(0,T];\quad \Gamma(0) = b, \Gamma'(0) = f(u_0(b)),\ \text{and}\ \|\Gamma\|_{\widetilde{C}^{1,1}(0,T]} < M\},$$

where

$$\|\Gamma\|_{\widetilde{C}^{1,1}(0,T]} = \|\Gamma\|_{C^1[0,T]} + \sup_{0<t<t+\delta\le T} t\delta^{-1}|\Gamma'(t+\delta) - \Gamma(t)|.$$

Then more careful computation (see Lemma 14.2.8 in [1]) shows that G is also a contraction mapping provided T is small enough. Hence the local solution satisfies $\Gamma \in C^{1,1}(0,T]$ and (by the intermediate Schauder estimates) $u \in C_{x,t}^{1+\alpha,(1+\alpha)/2}(\overline{Q_{T,\varepsilon}^\pm})$ for any $\varepsilon \in (0,T)$ and $\alpha \in (0,1)$, where $Q_{T,\varepsilon}^\pm = Q_T^\pm \cap \{t > \varepsilon\}$.

The main result of this section is the following theorem.

THEOREM 3.1. *Suppose* $u_0(x) \in C(I\!R)$ *is bounded and* $f(t)$ *is locally Lipschitz continuous. If there exist constants* $M > 0$ *and* $\gamma \in (0, \frac{1}{4})$ *so that*

$$|f(u)| \le M\,e^{\gamma|u|}, \tag{3.2}$$

then there exists a global solution to the problem (1.1).

Proof. For any $T > 0$, we will prove

$$u(x,T) \le M(T) =: M_0 + 1 + \frac{4}{\varepsilon}M(1+T)^2 e^{k^*+2}, \tag{3.3}$$

where $M_0 = \|u_0\|_{L^\infty(I\!R)}$,

$$\varepsilon = (1-4\gamma)/8, \tag{3.4}$$

and

$$k^* = \max(k_1^*,\ k_2^*,\ k_3^*)$$

with

$$k_1^* = \frac{48}{\varepsilon^3}(M_0 + T + 4),\quad k_2^* = \frac{1}{\varepsilon\gamma}\left|\log\frac{\varepsilon\gamma}{2}\right|,\quad k_3^* = \frac{4}{1-4\gamma}(M_0 + T + 4 + M(1+T)).$$

Note that (3.3) implies $u(x,t) \le C_1(1 + t^2 e^{C_2 t})$ for some C_1 and C_2 depending only on M_0, ε, γ, and M.

To prove (3.3), we argue by contradiction. Suppose (3.3) is false at $T > 0$. By the maximum principle, we have

$$|u(\Gamma(T), T)| \ge M(T). \tag{3.5}$$

The first integral on the right-hand side of (3.1) is the solution of the Cauchy problem

$$\begin{cases} u_t - u_{xx} = 0 \text{ in } I\!R \times I\!R^+, \\ u(x,0) = u_0(x). \end{cases}$$

Hence it is bounded with bound M_0. For the second integral, we have

$$\begin{aligned} \int_0^t \Gamma'(s) K(\Gamma(t) - \Gamma(s), t-s) ds &= \frac{1}{\sqrt{4\pi}} \int_0^t \frac{\Gamma'(s)}{\sqrt{t-s}} e^{-(\Gamma(t)-\Gamma(s))^2/4(t-s)} ds \\ &= \frac{-1}{\sqrt{\pi}} \int_0^t e^{-(\Gamma(t)-\Gamma(s))^2/4(t-s)} d\frac{\Gamma(t)-\Gamma(s)}{2\sqrt{t-s}} \\ &+ \frac{1}{4\sqrt{\pi}} \int_0^t \frac{\Gamma(t)-\Gamma(s)}{(t-s)^{3/2}} e^{-(\Gamma(t)-\Gamma(s))^2/4(t-s)} ds. \end{aligned} \tag{3.6}$$

Since

$$\int_{-\infty}^{\infty} e^{-t^2} dt = \sqrt{\pi}, \tag{3.7}$$

the first integral on the right-hand side of (3.6) is bounded. We therefore conclude that

$$|w(T)| \ge 4\sqrt{\pi}(M(T) - M_0 - 1),$$

where

$$w(t) = \int_0^t \frac{\Gamma(t)-\Gamma(s)}{(t-s)^{3/2}} e^{-(\Gamma(t)-\Gamma(s))^2/4(t-s)} ds. \tag{3.8}$$

Note that the integrand in (3.8) satisfies

$$\frac{|\Gamma(t)-\Gamma(s)|}{(t-s)^{3/2}} e^{-(\Gamma(t)-\Gamma(s))^2/4(t-s)} < \frac{1}{t-s}. \tag{3.9}$$

Let

$$E = \{t \in [0,T];\ \ \forall\ \ s < t, |\Gamma(t) - \Gamma(s)| \le \sqrt{t-s}/(4 + \log^2(t-s))\}.$$

By the C^1 continuity of Γ, it follows that $[0,\delta_0] \subset E$ for some $\delta_0 > 0$ small. Let $D = [0,T]\backslash E$. For any $t \in D$, let

$$\delta(t) = \inf\{\varepsilon \in (0,t); |\Gamma(t) - \Gamma(t-\varepsilon)| > \sqrt{\varepsilon}/(4+\log^2 \varepsilon)\}.$$

Since $\Gamma(t) \in C^1[0,T]$, it follows that D is an open subset of $[0,T]$, $\delta(t)$ is positive and upper semicontinuous on D, and for any $\tau \in (0,T)$, there exists a constant $C_\tau > 0$ so that

$$\delta(t) \geq C_\tau \quad \text{for any } t \in (0,\tau). \tag{3.10}$$

Moreover,

$$|\Gamma(t) - \Gamma(t-\delta(t))| = \sqrt{\delta(t)}/(4+\log^2 \delta(t)) \quad \text{for } t \in D. \tag{3.11}$$

For any $t \in E$, we have

$$|w(t)| \leq \int_0^t \frac{|\Gamma(t)-\Gamma(s)|}{(t-s)^{3/2}} ds \leq \int_0^t \frac{1}{(t-s)(4+\log^2(t-s))} ds \leq 1.$$

Hence by (3.1), (3.6), and (3.7), we have

$$|u(\Gamma(t),t)| \leq M_0 + 2 \quad \text{for} \quad t \in E. \tag{3.12}$$

For any $t \in D$, by (3.9) we have

$$\begin{aligned} |w(t)| &= \left| \left(\int_0^{t-\delta(t)} + \int_{t-\delta(t)}^t \right) \left(\frac{|\Gamma(t)-\Gamma(s)|}{(t-s)^{3/2}} e^{-(\Gamma(t)-\Gamma(s))^2/4(t-s)} \right) ds \right| \\ &\leq \int_0^{t-\delta(t)} \frac{1}{t-s} ds + \int_{t-\delta(t)}^t \frac{1}{(t-s)(4+\log^2(t-s))} ds \\ &\leq 1 + \log T - \log \delta(t) \leq 1 + T - \log \delta(t). \end{aligned} \tag{3.13}$$

Since the first integral of the right-hand side of (3.1) is bounded with bound M_0, from (3.6) we have

$$\int_0^T \frac{|\Gamma'(s)|}{\sqrt{t-s}} ds \geq \sqrt{4\pi}(|u(\Gamma(T),T)| - M_0) \geq \sqrt{4\pi}(M(T) - M_0 - 1). \tag{3.14}$$

Let

$$\beta = \int_0^T e^{2\gamma(1+\varepsilon)|u(\Gamma(s),s)|} ds.$$

By (3.2), we have

(3.15)
$$\begin{aligned} &\int_0^T \frac{|\Gamma'(s)|}{\sqrt{T-s}} ds \leq M \int_0^T \frac{e^{\gamma|u(\Gamma(s),s)|}}{\sqrt{T-s}} ds \\ &\leq M \left(\int_0^T (T-s)^{-(1+\varepsilon)/(1+2\varepsilon)} ds \right)^{(1+2\varepsilon)/2(1+\varepsilon)} \left(\int_0^T e^{2\gamma(1+\varepsilon)|u(\Gamma(s),s)|} ds \right)^{1/2(1+\varepsilon)} \\ &\leq \frac{1+2\varepsilon}{\varepsilon} M T^{\varepsilon/2(1+\varepsilon)} \left(\int_0^T e^{2\gamma(1+\varepsilon)|u(\Gamma(s),s)|} ds \right)^{1/2(1+\varepsilon)} \\ &\leq \frac{1+2\varepsilon}{\varepsilon} M \, T^{\varepsilon/2(1+\varepsilon)} \beta^{1/2(1+\varepsilon)}. \end{aligned}$$

Combining (3.14) and (3.15) yields

$$\beta > 4(T+1)e^{k^*+2}. \tag{3.16}$$

For any integer $k \geq 0$, let

$$A_k = \{t \in [0,T];\ \ k \leq |u(\Gamma(t),t)| \leq k+1\}.$$

Then

$$\sum_{k=0}^{\infty} \text{mes}(A_k)e^{2\gamma(1+\varepsilon)(k+1)} \geq \beta.$$

Let

$$a_k = e^{2\gamma(1+\varepsilon)(k+1)}\text{mes}(A_k)/\beta.$$

Then

$$\sum_{k=0}^{\infty} a_k \geq 1,$$

and by (3.16),

$$\sum_{k=0}^{k^*} a_k \leq \sum_{k=0}^{k^*} \frac{\text{mes}(A_k)}{\beta} e^{2\gamma(1+\varepsilon)(k+1)} \leq \frac{\text{mes}(A_k)}{\beta} e^{2\gamma(1+\varepsilon)(k^*+2)} \leq \frac{1}{2}.$$

Hence

$$\sum_{k=k^*+1}^{\infty} a_k \geq \frac{1}{2}.$$

Since $k^* \geq k_2^* = \frac{1}{\varepsilon\gamma}|\log\frac{\varepsilon\gamma}{2}|$, we have

$$\sum_{k=k^*+1}^{\infty} e^{-\varepsilon\gamma k} \leq \frac{1}{2}.$$

Hence there exists a $k > k^*$ so that $a_k \geq e^{-\varepsilon\gamma k}$.

For the integer k determined above, by $a_k \geq e^{-\varepsilon\gamma k}$ we have

$$e^{2\gamma(1+\varepsilon)(k+1)}\text{mes}(A_k) > \beta\, e^{-\varepsilon\gamma k},$$

which implies

$$\text{mes}(A_k) > \beta\, e^{-2\gamma(1+2\varepsilon)(k+1)}. \tag{3.17}$$

From (3.12), we have $A_k \subset D$ for $k \geq k^*$. From (3.1), (3.6), (3.7), and (3.13), we have

$$|u(\Gamma(t),t)| \leq \|u_0\|_{L^\infty} + 2 + |w(t)| \leq M_0 + T + 3 - \log\delta(t).$$

Since $k \leq |u(\Gamma(t),t)| \leq k+1$ in A_k, by (3.13) it follows that

$$\delta(t) \leq e^{-k+M'} \quad \text{for} \ \ t \in A_k, \tag{3.18}$$

where $M' = M_0 + T + 3$.

Let $t^0 = \sup\{t \in A_k\}$, and $t_0 = t^0 - \delta(t^0)$. By the closedness of A_k, we have $t^0 \in A_k$. For any $j \geq 1$, we define t^j and t_j inductively by letting $t^j = \sup\{t \leq t_{j-1}, t \in A_k\}$ and $t_j = t^j - \delta(t^j)$. Since A_k is closed, it follows that $t^j \in A_k$. By (3.10), the above procedure finishes after finitely many steps, that is, there is a $j_0 > 0$ so that $(0, t_{j_0}) \cap A_k = \emptyset$.

We therefore obtain a sequence of intervals (t_j, t^j) which satisfies the following properties:

(i) $t_j \geq t^{j+1}$;

(ii) $A_k \subset \cup_{j=0}^{j_0}[t_j, t^j]$;

(iii) $t^j \in A_k$.

By (i) and (3.11), we conclude

$$\int_0^T |\Gamma'(s)|ds \geq \sum_{j=0}^{j_0} |\Gamma(t^j) - \Gamma(t_j)| = \sum \sqrt{\delta(t^j)}/(4 + \log^2 \delta(t^j)).$$

Noticing that $k > k_1^* = \frac{48}{\varepsilon^3}(M_0 + T + 4)$, we have $\sqrt{\delta(t^j)}/(4 + \log^2 \delta(t^j) \geq [\delta(t^j)]^{(1+\varepsilon)/2}$. By (ii), (3.18), and (3.17), it follows that

$$\begin{aligned}\int_0^T |\Gamma'(s)|ds &\geq \sum(\delta(t^j))^{(1+\varepsilon)/2} \\ &\geq \inf(|\delta(t^j)|^{-(1-\varepsilon)/2}) \sum \delta(t^j) \\ &\geq \inf(|\delta(t^j)|^{-(1-\varepsilon)/2}) \text{mes} A_k \\ &\geq e^{(k-M')(1-\varepsilon)/2} \text{mes} A_k \\ &\geq e^{(k-M')(1-\varepsilon)/2} \cdot e^{-2\gamma(1+2\varepsilon)(k+1)}\beta \\ &\geq e^{(\frac{1}{2}-2\gamma-2\varepsilon)k-M'-1}\beta.\end{aligned}$$

On the other hand,

$$\begin{aligned}\int_0^T |\Gamma'(s)|ds &\leq M \int_0^T e^{\gamma|u(\Gamma(s),s)|} ds \\ &\leq M \left(\int_0^T ds\right)^{(1+2\varepsilon)/2(1+\varepsilon)} \left(\int_0^T e^{2\gamma(1+\varepsilon)|u(\Gamma(s),s)|} ds\right)^{1/2(1+\varepsilon)} \\ &\leq M T^{(1+2\varepsilon)/2(1+\varepsilon)} \beta^{1/2(1+\varepsilon)} \leq M(1+T)\beta^{1/2(1+\varepsilon)}.\end{aligned}$$

We obtain

$$e^{(\frac{1}{2}-2\gamma-2\varepsilon)k-M'-1}\beta \leq M(1+T)\beta^{1/2(1+\varepsilon)}.$$

But $k \geq k^* \geq \frac{4}{1-4\gamma}(M_0 + T + 4 + M(1+T))$, so we reach a contradiction because of $\beta > 1$. Hence (3.3) holds, which completes the proof. □

Remark 3.2. It is interesting to compare Theorem 3.1 with the finite-time blow-up example in §2. Theorem 3.1 asserts that (1.1) possesses a global solution provided $f(u) \leq Me^{\gamma|u|}$ for some $M > 0$ and $\gamma \in (0, \frac{1}{4})$, while in the example of §2, if we choose $\delta = \frac{1}{2}$ and let T be large enough, then the solution of (2.1) blows up in finite time, though $f(u) \leq \frac{1}{\sqrt{T}}e^{16u}$ by (2.16).

Remark 3.3. The condition $\gamma \in (0, \frac{1}{4})$ in Theorem 3.1 may be improved, but we are unable to do so by the method employed above.

It is not hard to see that the result in Theorem 3.1 is also true if the domain $Q = I\!R \times I\!R^+$ in problem (1.1) is replaced by $Q = (0,1) \times (0,T]$. Let us consider the problem

$$(3.19) \qquad \begin{cases} u_t - u_{xx} = 0 & \text{in } Q\backslash F \\ u^-(\Gamma(t),t) = u^+(\Gamma(t),t) & \text{on } F, \\ u_x^-(\Gamma(t),t) - u_x^+(\Gamma(t),t) = \Gamma'(t) & \text{on } F, \\ \Gamma'(t) = f(u),\ \Gamma(0) = b \in (0,1) & \text{on } F, \\ u(x,0) = u_0(x) & \text{and } \ u(0,t) = u(1,t) = 0. \end{cases}$$

The problem (3.19) has been studied in [8], where the author proved the global existence of solutions under conditions (i) and (ii) stated in the introduction. Here we have the following theorem.

THEOREM 3.2. *Suppose* $u_0(x) \in C[0,1]$, $f(u)$ *is locally Lipschitz continuous, and* $|f(u)| \leq Me^{\gamma|u|}$ *for some* $M > 0$ *and* $\gamma \in (0, \frac{1}{4})$. *Then there is a global solution to the problem* (3.19).

By global solution, we mean either $0 < \Gamma(t) < 1$ for $t \in [0,T]$ and $\Gamma(t) \in C^{1,1}[0,T]$, or there exists a $t_0 \in (0,T]$ so that the solution exists up to the moment $t = t_0$, $\lim_{t\to t_0} \Gamma(t)$ is 0 or 1 and $\Gamma(t) \in C^{1,1}[0,t_0)$.

The proof is similar to that of Theorem 3.1 with (3.1) replaced by

$$(3.20) \quad \begin{aligned} u(x,t) &= \int_0^1 (\theta(x-\xi,t) - \theta(x+\xi,t))u_0(\xi)d\xi \\ &\quad + \int_0^t \int_0^1 \Gamma'(s)\delta(\xi - \Gamma(s))[\theta(x-\xi,t-s) - \theta(x+\xi,t-s)]d\xi ds \\ &= \int_0^1 (\theta(x-\xi,t) - \theta(x+\xi,t))u_0(\xi)d\xi \\ &\quad + \int_0^t \Gamma'(s)[\theta(x-\Gamma(s),t-s) - \theta(x+\Gamma(s),t-s)]ds, \end{aligned}$$

where

$$\theta(x,t) = \sum_{m=-\infty}^{\infty} K(x+2m,t)$$

and $K(x,t)$ is the fundamental solution of the heat equation $u_t - u_{xx} = 0$. We omit the proof here.

Acknowledgment. We would like to express our thanks to the referee for helpful comments.

GLOBAL UNIQUENESS IN THE IMPEDANCE-IMAGING PROBLEM FOR LESS REGULAR CONDUCTIVITIES[*]

RUSSELL M. BROWN[†]

Abstract. If $L_\gamma = \operatorname{div} \gamma \nabla$ is an elliptic operator with scalar coefficient γ, we show that we can recover the coefficient γ from the Dirichlet-to-Neumann map under the assumption that γ has only $3/2 + \epsilon$ derivatives. Previously, the best result required γ to have two derivatives.

Key words. inverse problem, Dirichlet-to-Neumann map, impedance imaging, Besov space

AMS subject classification. 35R30

Let $\Omega \subset \mathbf{R}^n$, $n \geq 3$, be a bounded open set and let $L_\gamma = \operatorname{div} \gamma \nabla$ be an elliptic operator on Ω with scalar coefficient γ. We let Λ_γ denote the Dirichlet-to-Neumann map $\Lambda_\gamma f = \gamma \partial u / \partial \nu$, where u is the solution to the Dirichlet problem $L_\gamma u = 0$ in Ω, $u = f$ on $\partial\Omega$. In 1987, Sylvester and Uhlmann [10] showed that if we restrict attention to γ which are sufficiently smooth, then the map $\gamma \to \Lambda_\gamma$ is injective. Nachman, Sylvester, and Uhlmann [8] showed that injectivity continues to hold if γ has two bounded derivatives. Extensions to slightly less smooth conductivities or the related Schrödinger equation are given in Chanillo [3] and Ramm [9]. Isakov [5] has established injectivity for conductivities with jump discontinuities.

Since the only smoothness assumption needed to define Λ_γ is that γ be measurable, it is reasonable to ask if the map $\gamma \to \Lambda_\gamma$ is injective under less restrictive hypotheses on γ. In this paper, we show that γ need have only $3/2 + \epsilon$ derivatives. There is no reason to believe that the result in this paper is optimal. We conjecture that the right smoothness assumption is that γ have one derivative. However, the methods presented here do not give this. To state our main result, we recall the standard space of Hölder-continuous functions $C^\alpha(\bar\Omega) = \{f : f : \Omega \to \mathbf{R}$ and $|f(x) - f(y)| \leq M|x-y|^\alpha$ for some $M > 0\}$.

THEOREM 1. *Let $\Omega \subset \mathbf{R}^n$, $n \geq 3$, be a bounded, Lipschitz domain. Then the map $\gamma \to \Lambda_\gamma$ is injective on the set $\{\gamma : \gamma > 0$ in $\bar\Omega$, $\nabla\gamma \in \cup_{\epsilon>0} C^{1/2+\epsilon}(\bar\Omega)\}$.*

The outline of our argument is the same as in [10]. We construct special solutions of $L_\gamma u = 0$ by studying a Schrödinger operator $\Delta - q$. The innovation here is that we consider potentials q which lie in a Besov space of negative order.

We begin by recalling the Besov spaces and some of their simple properties. We will use the monograph of Bergh and Löfstrom [2] as our reference for these spaces. For $s \in \mathbf{R}$ and $1 \leq p, q \leq \infty$, we let $B^s_{p,q}$ denote the Besov space of distributions. Roughly speaking, a distribution in $B^s_{p,q}$ has s derivatives in L^p. We recall that if $0 < s < 1$, $1 \leq p, q < \infty$, then $f \in B^s_{p,q}$ if and only if

$$(1) \qquad \|f\|_{L^p} + \left(\int_{\mathbf{R}^n} \left(\int_{\mathbf{R}^n} |f(x+h) - f(x)|^p \, dx \right)^{q/p} |h|^{-n-sq} \, dh \right)^{1/q}$$

is finite. Furthermore, the expression in (1) gives a norm on $B^s_{p,q}$. When $p = q = \infty$,

[†] Department of Mathematics, University of Kentucky, Lexington, KY 40506-0027 (rbrown@ms.uky.edu).

the limiting version of (1) is

$$\|f\|_{L^\infty} + \sup_{x\in\mathbf{R}^n,\ |h|\neq o} |h|^{-s}|f(x+h) - f(x)|.$$

This provides a norm for $B^s_{\infty,\infty}$ and thus, for $0 < s < 1$, $B^s_{\infty,\infty} = C^s(\mathbf{R}^n)$.

We also consider a scale of weighted Besov spaces $B^{s,\delta}_{p,q}$ defined for $\delta \in \mathbf{R}$ by

$$B^{s,\delta}_{p,q} = \{f :\ (1+|x|^2)^{\delta/2} f \in B^s_{p,q}\}$$

with the norm

$$\|f\|_{B^{s,\delta}_{p,q}} = \|(1+|x|^2)^{\delta/2} f\|_{B^s_{p,q}}.$$

We will use $B^{s,c}_{p,q}$ to denote the distributions in $B^s_{p,q}$ which are compactly supported and

$$B^{s,\mathrm{loc}}_{p,q} = \{f :\ \psi f \in B^s_{p,q}\ \text{ for each } \psi \in C^\infty_0(\mathbf{R}^n)\}.$$

We recall that $B^0_{2,2}$ is the usual Lebesgue space L^2 on $\mathbf{R}^n$. If follows that

$$B^{0,\delta}_{2,2} = \{f :\ (1+|x|^2)^{\delta/2} f \in L^2\}$$

is the weighted Lebesgue space L^2_δ used by Sylvester and Uhlmann. We also have that $B^1_{2,2}$ is the Sobolev space of functions having one derivative in L^2 and that

$$B^{1,\delta}_{2,2} = \{f :\ f,\ \ \nabla f \in L^2_\delta\}. \tag{2}$$

Next, we note that since $B^s_{2,2}$ and $B^{s,\delta}_{2,2}$ are isomorphic, we may identify the complex interpolation spaces

$$[B^{s_0,\delta}_{2,2} B^{s_1,\delta}_{2,2}]_\theta = B^{s_\theta,\delta}_{2,2}, \qquad 0 < \theta < 1,$$

where s_0, $s_1 \in \mathbf{R}$, $s_\theta = (1-\theta)s_0 + \theta s_1$ (see [2, Thm. 6.4.5]).

The reason for introducing the Besov spaces to be able to define products of (certain) distributions as bilinear maps between Besov spaces. This depends on the following elementary result regarding multiplication in Besov spaces.

PROPOSITION 2. (a) *If* $\|\phi\|_\infty + \|\nabla\phi\|_\infty \leq M$, *then for* $0 < s < 1$, $\delta \in \mathbf{R}$, $1 \leq p,\ q \leq \infty$,

$$\|\psi u\|_{B^{s,\delta}_{p,q}} \leq C\|u\|_{B^{s,\delta}_{p,q}} M,$$

where $C = C(n,p,q)$.

(b) *For* $0 < s < 1$,

$$\|uv\|_{B^s_{1,2}} \leq C\|u\|_{B^s_{2,2}}\|v\|_{B^s_{2,2}},$$

where $C = C(s,n)$.

We do not prove this proposition, but note that each result follows easily from the norm for $B^s_{p,q}$ given in (1). I thank Mike Frazier for telling me of part (b) of the above proposition.

Next, we give estimates for the operator G_ζ, which is the solution operator to the equation

$$\Delta u + 2\zeta \cdot \nabla u = f,$$

where $\zeta \in \mathbf{C}^n$.

We observe that G_ζ, defined by

$$G_\zeta f = \left(\frac{\hat{f}}{-|\xi|^2 + 2i\zeta \cdot \xi} \right)^{\vee}, \tag{3}$$

maps from $\mathcal{S}$ to $\mathcal{S}'$. Here we are using the Fourier transform defined by $\hat{f}(\xi) = \int_{\mathbf{R}^n} e^{-ix\cdot\xi}\, dx$. In [10], it is shown that if $\zeta \cdot \zeta = 0$, then $G_\zeta : L^2_{\delta+1} \to L^2_\delta$, $-1 < \delta < 0$, with the bound

$$\|G_\zeta f\|_{L^2_\delta} \leq \frac{C}{|\zeta|} \|f\|_{L^2_{\delta+1}}, \qquad |\zeta| > 1 \text{ and } -1 < \delta < 0. \tag{4}$$

We give a simple extension of this result to obtain mapping properties of G_ζ on $B^{s,\delta}_{2,2}$. Shortly before this paper was written, A. Nachman established related estimates for the operator G_ζ in two dimensions [7, Lem. 1.3].

THEOREM 3. *Let $\zeta \in \mathbf{C}^n$ satisfy $\zeta \cdot \zeta = 0$ and $|\zeta| > 1$. Then for $-1 < \delta < 0$ and $0 \leq s \leq 1/2$, the map G_ζ defined by* (3) *satisfies*

$$\|G_\zeta f\|_{B^{s,\delta}_{2,2}} \leq \frac{C}{|\zeta|^{1-2s}} \|f\|_{B^{-s,\delta+1}_{2,2}},$$

where $C = C(n, s, \delta)$.

Proof. We choose a function ϕ satisfying $\phi = 1$ on $\{\xi : |\xi| \leq 4|\zeta|\}$, $\operatorname{supp} \phi \subset \{\xi : |\xi| < 8|\zeta|\}$, and $|\nabla\phi| \leq C/|\zeta|$. For $u \in L^2_\delta$, we define

$$Tu = \nabla[(\phi\hat{u})^{\vee}].$$

We claim that

$$\|Tu\|_{L^2_\delta} \leq C|\zeta|\, \|u\|_{L^2_\delta}, \qquad -1 \leq \delta \leq 1. \tag{5}$$

When $\delta = 0$, this is elementary since T is a multiplier operator whose symbol is bounded by $C|\zeta|$. To obtain (5) when $\delta = 1$, note that

$$\|\hat{u}\|_{L^2} + \|\nabla\hat{u}\|_{L^2}$$

gives an equivalent norm on the weighted Lebesgue space L^2_1. Now

$$\nabla\widehat{Tu} = i\xi\phi\nabla\hat{u} + \hat{u}\nabla(i\xi\phi)$$

and hence

$$\|\nabla\widehat{Tu}\|_{L^2} \leq C(|\zeta| + 1)\, \|u\|_{L^2_1}.$$

If we recall that $|\zeta| \geq 1$, then (5) follows for $\delta = 1$. The estimate (5) follows by duality when $\delta = -1$ and by interpolation for the remaining values of δ. □

Next, define on operator S by

$$(Sf)^\wedge(\xi) = \frac{i\xi(1-\phi)\hat{f}}{(-|\xi|^2 + 2i\xi\cdot\zeta)}$$
$$= \frac{1}{|\xi|}\psi\hat{f},$$

where $\psi(\xi) = i\xi|\xi|(1-\phi)/(-|\xi|^2 + 2i\xi\cdot\zeta)$. The argument used to treat T shows that

$$f \to (\psi\hat{f})^\vee$$

is bounded on L^2_δ, $-1 \le \delta \le 1$, and the norm of this operator is bounded for $|\zeta| \ge 1$.

The fractional integral $f \to (|\xi|^{-1}\hat{f})^\vee$ maps $L^2_{\delta+1}$ to L^2_δ, $-1 < \delta < 0$, by the argument in [10, Lem. 3.1]. This gives

$$\|Sf\|_{L^2_\delta} \le C(n,\delta)\|f\|_{L^2_{\delta+1}}, \qquad -1 < \delta < 0.$$

Summarizing, we have $\nabla G_\zeta f = T(G_\zeta f) + Sf$ and hence

$$\|\nabla G_\zeta f\|_{L^2_\delta} \le C|\zeta|\,\|G_\zeta f\|_{L^2_\delta} + C\|f\|_{L^2_{\delta+1}}$$
$$\le C\|f\|_{L^2_{\delta+1}},$$

where the second inequality is (4).

Combining this with (5) and the characterization of $B^{1,\delta}_{2,2}$ in (2) gives

$$\|G_\zeta f\|_{B^{1,\delta}_{2,2}} \le C\|f\|_{B^{0,\delta+1}_{2,2}}, \qquad -1 < \delta < 0.$$

By duality, we have

$$\|G_\zeta f\|_{B^{0,\delta}_{2,2}} \le C\|f\|_{B^{-1,\delta+1}_{2,2}}, \qquad -1 < \delta < 0.$$

Interpolating between these estimates and (4) gives

$$\|G_\zeta f\|_{B^{s,\delta}_{2,2}} \le \frac{C}{|\zeta|^{1-s}}\|f\|_{B^{0,\delta+1}_{2,2}} \tag{6}$$

and

$$\|G_\zeta f\|_{B^{0,\delta}_{2,2}} \le \frac{C}{|\zeta|^{1-s}}\|f\|_{B^{-s,\delta+1}_{2,2}}, \tag{7}$$

where each inequality holds for $0 \le s \le 1$ and $-1 < \delta < 0$. Finally, interpolating between (6) and (7) gives the estimate of the theorem.

If g is a function on $\mathbf{R}^n$ satisfying

$$\lambda^{-1} < g < \lambda \tag{8}$$

for some $\lambda > 0$ and ∇g is bounded and compactly supported, then for $u \in C^\infty(\mathbf{R}^n)$, we may define a distribution $m_q(u)$ by

$$m_q(u)(v) = -\int_{\mathbf{R}^n} \nabla g \cdot \nabla\left(\frac{1}{g}uv\right)\, dx. \tag{9}$$

Formally, $q = g^{-1}\Delta g$ will be the potential in our Schrödinger operator and $m_q(u)$ is the product qu. Our main result on m_q is the following.

THEOREM 4. *Suppose that g is defined on $\mathbf{R}^n$, satisfies* (8), *and for some s, $0 < s < 1$, and $M > 0$, satisfies*

$$\|\nabla g\|_{B^{1-s}_{\infty,2}} \le M, \tag{10}$$

$$\operatorname{supp} \nabla g \subset \{x : \ |x| < M\}. \tag{11}$$

Then there exists $C = C(M, \lambda, s)$ so that the map m_q satisfies

$$\|m_q(u)\|_{B^{-s,\delta+1}_{2,2}} \le C\|u\|_{B^{s,\delta}_{2,2}}.$$

Before presenting the proof of this theorem, we note that if $\psi \in C_0^\infty(\mathbf{R}^n)$, then

$$\|\psi u\|_{B^s_{p,q}} \le C(\psi, \delta, s, p, q)\|u\|_{B^{s,\delta}_{p,q}}, \tag{12}$$

and if $u \in B^{s,c}_{2,2}$, with $\operatorname{supp} u \subset \{x : \ |x| < R\}$, then

$$\|u\|_{B^{s,\delta}_{2,2}} \le C(R, \delta)\|u\|_{B^s_{2,2}}. \tag{13}$$

In each case, the stated inequality follows by observing that if $\psi \in C_0^\infty(\mathbf{R}^n)$ and $r \in \mathbf{R}$, then $u \to (1 + |x|^2)^r \psi u$ is bounded on each Besov space.

Proof of Theorem 4. We prove the estimate of the theorem for u smooth, and then we may extend m_q to $B^{s,\delta}_{2,2}$ by density. Let $\psi = 1$ on $\operatorname{supp} \nabla g$ with $\psi \in C_0^\infty(\mathbf{R}^n)$. Then we write

$$\begin{aligned} |m_q(u)(\phi)| &= \left| \int \psi \nabla g \cdot \nabla \left(\psi^2 \frac{u\phi}{g} \right) dx \right| \\ &\le \|\psi \nabla g\|_{B^{1-s}_{\infty,2}} \|\nabla(\psi^2 g^{-1} u\phi)\|_{B^{s-1}_{1,2}}. \end{aligned} \tag{14}$$

We use the fact that $\partial/\partial x_i : B^s_{2,2} \to B^{s-1}_{2,2}$, Proposition 2(b), and then (13) to obtain

$$\begin{aligned} \|\nabla(\psi^2 g^{-1} u\phi)\|_{B^{s-1}_{1,2}} &\le C\|\psi^2 u\phi\|_{B^s_{1,2}} \\ &\le C\|\psi u\|_{B^s_{2,2}} \|\psi\phi\|_{B^s_{2,2}} \\ &\le C\|u\|_{B^{s,\delta}_{2,2}} \|\phi\|_{B^{s,-\delta-1}_{2,2}}. \end{aligned} \tag{15}$$

Using (12) and (15) in (14) gives that

$$|m_q(u)(\phi)| \le C\|\nabla g\|_{B^{1-s}_{\infty,2}} \|u\|_{B^{s,\delta}_{2,2}} \|\phi\|_{B^{s,-\delta-1}_{2,2}}$$

or that $m_q(u)$ is in the dual of $B^{s,-\delta-1}_{2,2}$, $(B^{s,-\delta-1}_{2,2})' = B^{-s,\delta+1}_{2,2}$ (see [2, Cor. 6.2.8] for the duals of unweighted Besov spaces). □

Remark. An examination of the above proof shows that in fact we have $m_q : B^{s,\mathrm{loc}}_{2,2} \to B^{s,c}_{2,2}$. We will use this in Corollary 6 to define $m_q(1)$.

Our next theorem considers solutions to the equation

$$\Delta\psi + 2\zeta\cdot\nabla\psi - m_q(\psi) = f.$$

THEOREM 5. *Let g satisfy* (8), (10), *and* (11) *and let $\zeta \in \mathbf{C}^n$ satisfy $\zeta\cdot\zeta = 0$. If $0 < s < 1/2$, $-1 < \delta < 0$, and $f \in B^{-s,\delta+1}_{2,2}$, then there exists $C_0 = C_0(\lambda, M, s, \delta, n)$ so that for $|\zeta| > C_0$, there exists a unique solution to*

$$\Delta\psi + 2\zeta\cdot\nabla\psi - m_q(\psi) = f, \qquad \psi \in B^{s,\delta}_{2,2}, \tag{16}$$

and this solution satisfies

$$\|\psi\|_{B^{s,\delta}_{2,2}} \le \frac{C}{|\zeta|^{1-2s}}\|f\|_{B^{-s,\delta+1}_{2,2}},$$

where $C = C(n, s, \delta, M, \lambda)$.

Proof. Consider the map $\psi \to G_\zeta(m_q(\psi))$. By Theorems 3 and 4, we have

$$\|G_\zeta(m_q(\psi))\|_{B^{s,\delta}_{2,2}} \le \frac{C}{|\zeta|^{1-s}}\|\psi\|_{B^{s,\delta}_{2,2}}.$$

Hence, if $|\zeta|$ is sufficiently large, then this map is a contraction on $B^{s,\delta}_{2,2}$.

From the uniqueness of solutions to $\Delta\psi + 2\zeta\cdot\nabla\psi = 0$, $\psi \in L^2_\delta$ (see [10, Cor. 3.4], [4, Thm. 7.1.27]), ψ satisfies (16) if and only if

$$\psi = G_\zeta(f) + G_\zeta(m_q(\psi)), \tag{17}$$

and by Theorem 3, $G_\zeta(f) \in B^{s,\delta}_{2,2}$. Thus the contraction-mapping principle implies solutions to (17) exist and are unique in $B^{s,\delta}_{2,2}$. □

Now we are ready to return to the study of $L_\gamma = \operatorname{div}\gamma\nabla$. It will be convenient to assume that γ is defined in all of $\mathbf{R}^n$ and satisfies for some $1/2 > \epsilon > 0$ and $R > 0$, $\lambda > 1$,

$$\lambda^{-1} < \gamma < \lambda, \tag{18}$$

$$\nabla\gamma \in B^{1/2+2\epsilon,c}_{\infty,\infty} \subset B^{1/2+\epsilon,c}_{\infty,2} \quad \text{for some } \epsilon > 0, \tag{19}$$

$$\gamma(x) = 1 \ \text{ if } \ |x| > R \tag{20}$$

The embedding in (19) follows easily from the definition of the $B^s_{p,q}$-norm [2, Def. 6.2.2]. Thus if $g = \sqrt{\gamma}$, g satisfies the hypotheses of Theorem 5 with $s = 1/2 - \epsilon$.

COROLLARY 6. *Suppose that γ satisfies* (18)–(20) *and $\zeta \in \mathbf{C}^n$ satisfies $\zeta\cdot\zeta = 0$ and $|\zeta| > C_0$. Then there exists a solution to $L_\gamma u = 0$ of the form*

$$u(x) = \gamma(x)^{-1/2}(1 + \psi(x))e^{x\cdot\zeta}, \qquad \psi \in B^{1/2-\epsilon,\delta}_{2,2}.$$

Furthermore, $D^2u \in L^2_{\mathrm{loc}}(\mathbf{R}^n)$.

Proof. Given γ, we construct m_q as in (9), with $g = \sqrt{\gamma}$. We let ψ be the solution of

$$\Delta\psi + 2\zeta\cdot\nabla\psi - m_q(\psi) = m_q(1)$$

from Theorem 5. Since $v = e^{x\cdot\zeta}(1+\psi)$ solves $\Delta v - m_q(v) = 0$ in $\mathcal{S}'$ and $m_q(v) \in B^{\epsilon-1/2,c}_{2,2}$, regularity theory for Δ implies $v \in B^{\epsilon+3/2,\text{loc}}_{2,2}$ and, in particular, $\nabla v \in L^2_{\text{loc}}$. Then a calculation shows that $u = \gamma^{-1/2}v$ solves $L_\gamma u = 0$, $\nabla u \in L^2_{\text{loc}}$. Finally, since γ is C^1, regularity theory for L_γ implies $\nabla^2 u \in L^2_{\text{loc}}$. □

THEOREM 7. *Suppose that $\partial\Omega$ is Lipschitz and $\Lambda_{\gamma_1} = \Lambda_{\gamma_2}$. If $\nabla\gamma_i \in C^{1/2+2\epsilon}(\bar\Omega)$ for some $\epsilon > 0$, then there exist extensions of γ_i to $\mathbf{R}^n$ so that, with $g_i = \sqrt{\gamma_i}$,*

$$\int_{\mathbf{R}^n} \nabla g_1 \cdot \nabla(g_1^{-1}\phi) = \int_{\mathbf{R}^n} \nabla g_2 \cdot \nabla(g_2^{-1}\phi), \quad \phi \in C_0^\infty(\mathbf{R}^n).$$

Proof. We begin by observing that since $\Lambda_{\gamma_1} = \Lambda_{\gamma_2}$ and $\partial\Omega$ is Lipschitz, we have $\gamma_1 = \gamma_2$ and $\nabla\gamma_1 = \nabla\gamma_2$ on $\partial\Omega$. This result was proven for smooth conductivities in [6] and for C^1 conductivities in Lipschitz domains by [1]. Thus we may extend γ_1 and γ_2 to $\mathbf{R}^n$ so that $\gamma_1 = \gamma_2$ in $\mathbf{R}^n \setminus \bar\Omega$ and satisfies (18)–(20).

We let u_1 and u_2, be solutions of $L_{\gamma_i}\, u_i = 0$, $\nabla u_i \in L^2(\Omega)$, $i = 1,2$. We let $v_i = \gamma_i^{1/2}u_i$ and obtain

$$\begin{aligned}\int_{\partial\Omega} u_2\Lambda_{\gamma_1}u_1 &= \int_\Omega \gamma_1\nabla(\gamma_1^{-1/2}v_1)\cdot\nabla(\gamma_1^{-1/2}v_2)\,dx \\ &= \int_\Omega -\nabla\gamma_1^{1/2}\cdot\nabla(\gamma_1^{-1/2}v_1v_2) + \nabla v_1\cdot\nabla v_2\,dx,\end{aligned}$$

where have used the facts that $\gamma_1 = \gamma_2$ on $\partial\Omega$ and the second equality depends on the product rule.

Reversing the roles of u_1 and u_2 gives

$$\int_{\partial\Omega} u_1\Lambda_{\gamma_2}u_2 = \int_\Omega -\nabla\gamma_2^{1/2}\cdot\nabla(\gamma_2^{-1/2}v_1v_2) + \nabla v_1\cdot\nabla v_2\,dx.$$

If we subtract these expressions and use the fact that Λ_{γ_2} is a symmetric operator, we have

$$\begin{aligned}\int_{\partial\Omega} u_1(\Lambda_{\gamma_1} - \Lambda_{\gamma_2})u_2 &= \int_\Omega -\nabla\gamma_1^{1/2}\cdot\nabla(\gamma_1^{-1/2}v_1v_2) \\ &\qquad + \nabla\gamma_2^{1/2}\cdot\nabla(\gamma_1^{-1/2}v_1v_2)\,dx.\end{aligned}\tag{21}$$

If we assume that u_1 and u_2 are defined in all of $\mathbf{R}^n$, then (21), our assumptions that $\Lambda_{\gamma_1} = \Lambda_{\gamma_2}$ and that $\gamma_1 = \gamma_2$ in $\mathbf{R}^n \setminus \bar\Omega$ give

$$0 = \int_{\mathbf{R}^n} -\nabla\gamma_1^{1/2}\cdot\nabla(\gamma_1^{-1/2}v_1v_2) + \nabla\gamma_2^{1/2}\cdot\nabla(\gamma_2^{-1/2}v_1v_2)\,dx.$$

To choose u_1 and u_2, we fix $k \in \mathbf{R}^n$ and then note that the argument in [10, p. 157] and the estimate of Theorem 5 allow us to construct sequences $u_1^{(n)}, u_2^{(n)}$ so that $L_{\gamma_i}u_i^{(n)} = 0$ and $v_1^{(n)}\cdot v_2^{(n)} \to e^{ix\cdot k}$ in $B^{1/2-\epsilon,\text{loc}}_{1,2}$ as $n \to \infty$. Hence we conclude that

$$\int \nabla\gamma_1^{1/2}\cdot\nabla(\gamma_1^{-1/2}e^{ix\cdot k}) = \int \nabla\gamma_2^{1/2}\cdot\nabla(\gamma_2^{-1/2}e^{ix\cdot k}), \qquad k \in \mathbf{R}^n.$$

This implies the conclusion of the theorem. □

PROPOSITION 8. *If the conclusion of Theorem* 7 *holds, then* $g_1 = g_2$.

Proof. We have

$$\int \nabla g_1 \cdot \nabla \left(\frac{1}{g_1}\phi\right) = \int \nabla g_2 \cdot \nabla \left(\frac{1}{g_2}\phi\right)$$

for all $\phi \in C_0^1(\mathbf{R}^n)$. Replace ϕ by $g_1 g_2 \psi$ and observe that this gives

$$\int g_1 g_2 \nabla(\log g_1 - \log g_2) \cdot \nabla\psi = 0.$$

In particular, if $\psi = \log \frac{g_1}{g_2}$, then $\log \frac{g_1}{g_2} = 0$ in $\mathbf{R}^n$. □

This proposition amounts to observing that the equality $g_1^{-1}\Delta g_1 = g_2^{-1}\Delta g_2$ implies that $\operatorname{div} g_1 g_2 \nabla \log(g_1/g_2) = 0$. I thank J. Tolle for showing me this argument, which is due to G. Alessandrini.

Proof of Theorem 1. Suppose that γ_1 and γ_2 are as in the Theorem and that $\Lambda_{\gamma_1} = \Lambda_{\gamma_2}$. Then we conclude that $\sqrt{\gamma}_1 = \sqrt{\gamma}_2$ from Theorem 7 and Proposition 8. □

LORENZ EQUATIONS PART I: EXISTENCE AND NONEXISTENCE OF HOMOCLINIC ORBITS*

XINFU CHEN†

Abstract. The Lorenz equations are a system of three ordinary differential equations

$$x' = s(y - x), \quad y' = Rx - y - xz, \quad z' = xy - qz,$$

where s, R, and q are positive parameters. We show that this system has homoclinic orbits associated with the origin (i.e., orbits that tend to the origin as $t \to \pm\infty$) if and only if $s > (2q + 1)/3$. The method is based on Liapunov functions and a shooting argument used previously by Hastings and Troy in studying homoclinic orbits of the Lorenz equations.

Key words. Lorenz equations, homoclinic orbits, shooting methods, Liapunov functions, asymptotic behavior

AMS subject classification. 34C37

1. Introduction.

The Lorenz equations we studied here are a system of ordinary differential equations

$$\begin{cases} x' = s(y - x), \\ y' = Rx - y - xz, \\ z' = xy - qz, \end{cases} \tag{1.1}$$

where $' = \frac{d}{dt}$ and s, R, and q are positive parameters. This system was first presented in 1963 by E. N. Lorenz [11] in studying fluid convection in a two-dimensional layer heated from below. In the last decades, there has been an immense amount of interest generated by these equations due to the fact that for some parameter values, numerical computed solutions oscillate in the pseudorandom way which people call "chaotic." For more detailed description of the observed "chaotic" behavior and mathematical theories built upon (1.1), such as the geometric models of the Lorenz equations, Sil'nikov-type or homoclinic bifurcations, and averaging methods, see [3], [5], [13]–[16], [18], a review book of Sparrow [17], a mathematical textbook of Guckenheimer and Holmes [4], and the references therein.

Generally speaking, to apply certain well-developed theories to the concrete example of (1.1), certain hypotheses have to be verified. One way to achieve this would be by a computer simulation, but there are few rigorous results. Recently, Hastings and Troy [8], [9], Hassard, Hastings, Troy, and Zhang [7], and Mischaikow and Mrozek [12] built up mathematical theories for certain characterizations of the chaotic behavior of (1.1) and implemented rigorous arithmetic numerical schemes to verify the validity of their hypotheses, and hence lead to affirmative conclusions on the chaotic behavior they studied for the solutions of (1.1) for certain parameter values (s, R, q).

Among all the solutions of (1.1), a very special one is a homoclinic orbit associated with the origin, which is a solution having the property that it approaches the origin as $t \to \pm\infty$. In developing geometric model theories or bifurcation theories, homoclinic orbits play an essential role. An example of its fascination and importance can be read from the phase "homoclinic explosion," which is used to refer to the appearance

of various kinds of chaotic behavior when parameters are perturbed from the values where there is a homoclinic orbit; see, for example, Sparrow [17] and Robinson [14]. Therefore, it is important to find these homoclinic orbits. The existence of homoclinic orbits associated with the origin for (1.1) can be seen from strong numerical evidence. The first pure mathematical proof is given by Hastings and Troy [10]. Using a shooting argument and a pioneering, though tedious, mathematical analysis on the nature of the solution when $(s, R, q) = (10, 1000, 1)$, they were able to show that for each (s, q) in some neighborhood of the point $(10, 1)$ there is an R in the interval $(1, 1000)$ such that the Lorenz equations have a homoclinic orbit associated with the origin. A rigorous numerical implementation of a similar method for the existence of a homoclinic orbit was used by Hassard and Zhang [6] to pin down the value of the parameter R. They showed that when $s = 10$ and $q = 8/3$, R is between 13.9265 and 13.927.

In this paper, we shall study the existence and nonexistence of homoclinic orbits of (1.1). In particular we prove the following theorem.

THEOREM 1.1. *Assume that s and q are given positive constants. Then the Lorenz equations* (1.1) *have at least one homoclinic orbit associated with the origin for some $R \in (0, \infty)$ if and only if $s > \frac{2q+1}{3}$.*

For the existence part, the proof is based on a shooting argument developed in [10], where the shooting parameter is R. In completing this shooting argument, one of the essential difficulties lies in the study of the behavior of the solution for large R. Impressed by the magnitude of the value $R = 1000$ taken in [10], here we replace their analysis for $R = 1000$ by studying the asymptotic behavior of the solution as $R \to \infty$. Though substantial information, compared to that obtained in [10] for $R = 1000$, was lost, the key properties needed to complete the shooting argument were not. The main advantage of our method is that we can establish the existence of homoclinic orbits for a large set of values of (s, q).

The proof of nonexistence is based solely on Liapunov functions. Fortunately, the result obtained compliments perfectly the existence result, as is seen from Theorem 1.1.

We shall prove the nonexistence part of Theorem 1.1 in §2 and the existence part in §§3 and 4.

Remark 1.2. As will be seen in the proof of Theorem 1.1, the homoclinic orbit established in this paper is the simplest one among all homoclinic orbits the Lorenz system could have; namely, its x coordinate does not change sign and has only one local extreme, so that in the x–x' phase plane, the orbit forms a single loop on the right or the left half plane.

In [1], we prove the existence of homoclinic orbits having the property that the x coordinate can change any prescribed number of times, and in each time interval where x does not change sign, x' can change an arbitrarily prescribed odd number of times (except in the first two intervals). Also we prove the existence of orbits having the property that the x coordinate changes sign infinitely many times and during each time interval where x does not change, x' changes a certain number of signs according to a prescribed double-bounded odd integer sequence.

In forthcoming paper [2], we shall prove the existence of homoclinic explosion for the Lorenz system for certain parameters; namely, we shall prove the existence of a horseshoelike Poincaré map.

2. Nonexistence of homoclinic orbits.

First, we recall a boundedness lemma originated by Lorenz [11].

LEMMA 2.1. *The region* $D := \{(x,y,z) \mid x^2 + \frac{1}{R}y^2 + \frac{1}{R}(z-(1+s)R)^2 \leq \frac{qR(1+s)^2+1}{\min\{2s,2,q\}}\}$ *is positively invariant; that is, if a trajectory enters* D *at some time, it will stay there forever. In addition, every trajectory will enter* D *in finite time.*

Proof. Set $V = x^2 + \frac{1}{R}y^2 + \frac{1}{R}(z-(1+s)R)^2 - \frac{qR(1+s)^2+1}{\min\{2s,2,q\}}$. Then along any trajectory of (1.1),

$$V' = -2sx^2 - \tfrac{2}{R}y^2 - \tfrac{q}{R}(z-(1+s)R)^2 - \tfrac{q}{R}z^2 + qR(1+s)^2 \leq -\min\{2s,2,q\}V - 1 - \tfrac{q}{R}z^2.$$

The assertion of the lemma thus follows. □

The following lemma shows that the case $R \in (0,1]$ is trivial.

LEMMA 2.2. *Assume that* $R \in (0,1]$. *Then for every positive* s *and* q, *every solution of* (1.1) *approaches, as* $t \to \infty$, $(0,0,0)$ *when* $R \in (0,1)$ *or* $(x^*, x^*, 0)$ *for some* $x^* \in (-\infty, \infty)$ *when* $R = 1$. *Consequently, there are no homoclinic orbits associated with any stationary points of* (1.1).

Proof. Define $V(x,y,z) = x^2 + sy^2 + sz^2$. Since $R \in (0,1]$, along any trajectory of (1.1),

$$V' = -2s\Big\{[x - \tfrac{1+R}{2}y]^2 + [1 - (\tfrac{1+R}{2})^2]y^2 + qz^2\Big\} \leq 0,$$

where the equal sign is taken only at the stationary points of the Lorenz system. The assertion of the lemma thus follows from a standard theory of Liapunov functions. □

In what follows, we shall always assume that

$$s > 0, \qquad q > 0, \qquad R > 1.$$

In this case, (1.1) has three stationary points located at

$$C^0 = (0,0,0), \qquad C_R^{\pm} = \left(\pm\sqrt{q(R-1)}, \sqrt{q(R-1)}, R-1\right).$$

When $R > 1$, the origin C^0 is nonstable and the linearized flow near the origin has three real eigenvalues,

$$(2.1) \quad \lambda_i^0 = \tfrac{1}{2}\Big\{-(s+1) - (-1)^i\sqrt{(s+1)^2 + 4s(R-1)}\Big\}\ (i = 1,2), \quad \lambda_3^0 = -q.$$

The eigenvectors corresponding to λ_1^0 and λ_2^0 lie on the x–y plane, whereas the eigenvalue λ_3 corresponds to the two trajectories being the positive and negative z-axis. Since λ_1^0 is positive and λ_2^0 and λ_3^0 are negative, at C^0, there is a two-dimensional stable manifold which contains the z-axis, and a one-dimensional unstable manifold $\gamma = \gamma^+ \cup \gamma^- \cup C^0$, where γ^- is the reflection of γ^+ across the z-axis and γ^+ initially points into the positive octant. In fact, the trace of γ^+ is a smooth curve starting from the origin having the asymptotic behavior $\gamma = (x, (1+\frac{\lambda_1^0}{s})x + O(x^2), \frac{\lambda_1^0+s}{s(2\lambda_1^0+q)}x^2 + O(x^3))$ for small positive x.

When $R > 1$, the characteristic function for the eigenvalues of the linearized flow near the stationary point C^+ and C^- is

$$\lambda^3 + (1+s+q)\lambda^2 + (s+R)q\lambda + 2sq(R-1) = 0.$$

This equation has a negative root, and, when the real part of the other two roots (which are complex conjugate to each other) are nonnegative, its imaginary part is nonzero. That is, either $C^{\pm}$ is stable or $C^{\pm}$ has a one-dimensional stable manifold and a two-dimensional unstable manifold on which the flow is of spiral type.

It is convenient to introduce

$$Q := z - \tfrac{1}{2s}x^2, \qquad \mu = 1 - \tfrac{q}{2s}.$$

Then, one can directly verify that the Lorenz equations (1.1) are equivalent to the following system:

$$(2.2) \qquad \begin{cases} x'' + (1+s)x' = s\Big\{(R-1) - Q - \tfrac{1}{2s}x^2\Big\}x \quad (= s(R-1-z)x), \\ Q' + qQ = \mu x^2. \end{cases}$$

To show that (2.2) has no homoclinic orbits associated with the origin when $s \le \frac{2q+1}{3}$, we considered three cases:

$$(1)\ 0 < s < \tfrac{q}{2}, \qquad (2)\ s = \tfrac{q}{2}, \qquad (3)\ \tfrac{q}{2} < s \le \tfrac{2q+1}{3}.$$

First we consider the case $0 < s < \frac{q}{2}$.

LEMMA 2.3. *Assume that* $0 < s < \frac{q}{2}$. *Then for any* $R > 1$, (1.1) *has no homoclinic orbits associated with any stationary points. In addition, as* $t \to \infty$, *every trajectory has a limit that is one of the stationary points of* (1.1).

Proof. Define $V = x'^2 + \frac{s}{2|\mu|q}Q'^2 + \frac{s}{2q}(x^2 - (R-1)q)^2$. Since $\mu = 1 - \frac{q}{2s} \le 0$, substituting Q' by $-qQ + \mu x^2$ yields

$$V = x'^2 + sx^2\Big[\tfrac{1}{4s}x^2 + Q - (R-1)\Big] - \tfrac{sq}{2\mu}Q^2 + \tfrac{s(R-1)^2 q}{2}.$$

It then follows by using the differential equations in (2.2) that along any trajectory,

$$\begin{aligned} V' &= 2x'\Big\{x'' + sx\Big[\tfrac{1}{2s}x^2 + Q - (R-1)\Big]\Big\} + \frac{s}{\mu}Q'\Big\{\mu x^2 - qQ\Big\} \\ &= -2(1+s)x'^2 + \frac{s}{\mu}Q'^2. \end{aligned}$$

Since $\mu < 0$, $V' \le 0$ for all $t \in (-\infty, \infty)$ and in addition, $V' = 0$ if and only if $x' = 0$ and $Q' = 0$. The assertions of the Lemma thus follow by the properties of the Liapunov function V. □

Next we consider the case $s = \frac{q}{2} > 0$.

LEMMA 2.4. *Assume that* $s = \frac{q}{2} > 0$. *Then the assertion of Lemma* 2.2 *holds.*

Proof. Note that when $s = \frac{q}{2}$, $\mu = 0$, so that $Q' = -qQ$. Consequently, $Q(t) = Q(0)e^{-qt}$. In particular, on γ^+, $Q(t) \equiv 0$ so that $x'' + (1+s)x' = sx[(R-1) - \frac{1}{2s}x^2]$. Set $V = x'^2 + \frac{1}{4}[x^2 - 2s(R-1)]^2$. Then $V' = -2(1+s)x'^2 \le 0$ and therefore γ^+ approaches C^+ as $t \to \infty$. (Note that the set $\{(x,y,z) | V < 0\}$ consists of two disjoint domains with C^+ and C^- in each of them.)

For any other trajectories, $Q(t) \to 0$ as $t \to \infty$, and one can show that every trajectory has to tend to one of the stationary points. Details are omitted. □

Finally, we consider the case $\frac{q}{2} < s \le \frac{2q+1}{3}$.

LEMMA 2.5. *Assume that* $0 < \frac{q}{2} < s \le \frac{2q+1}{3}$. *Then for any* $R > 1$, *the Lorenz equations* (1.1) *have no homoclinic orbits associated with the origin.*

Proof. We need only show that $\gamma^{\pm}$ does not approach the origin as $t \to \infty$. By symmetry, we need only consider γ^+.

First, notice that $\mu = 1 - \frac{q}{2s} > 0$, so that $Q' + qQ = \mu x^2 \geq 0$. It then follows that on γ^+, $Q(t) > 0$ for all t.

Define

$$V = x'^2 + sx^2\Big\{\tfrac{1}{4s}x^2 + Q - (R-1)\Big\} + (1+s)xx'.$$

Then, along γ^+,

$$\begin{aligned} V' &= 2x'\Big\{x'' + sx[\tfrac{1}{2s}x^2 + Q - (R-1)]\Big\} + sx^2Q' + (1+s)x'^2 + (1+s)xx'' \\ &= 2x'\Big\{-(1+s)x'\Big\} + sx^2[-qQ + \mu x^2] + (1+s)x'^2 \\ &\qquad + (1+s)x\Big\{-(1+s)x' + s[(R-1) - Q - \tfrac{1}{4s}x^2 - \tfrac{1}{4s}x^2]\Big\} \\ &= -(1+s)\Big\{x'^2 + (1+s)xx' + sx^2[\tfrac{1}{4s}x^2 + Q - (R-1)]\Big\} + \Big(\mu s - \tfrac{1+s}{4}\Big)x^4 - sqQx^2 \\ &= -(1+s)V + \tfrac{3}{4}\Big(s - \tfrac{2q+1}{3}\Big)x^4 - sqQx^2, \end{aligned}$$

where we have used the equations in (2.2) in the second equality, and the definition of V and the relation $\mu s - \frac{1+s}{4} = (1 - \frac{q}{2s})s - \frac{1+s}{4} = \frac{3}{4}(s - \frac{2q+1}{3})$ in the last equality.

Since $s \leq \frac{2q+1}{3}$ and $Q > 0$ on $\gamma^{\pm}$, the last equation yields

$$V'(t) + (1+s)V(t) \leq 0 \qquad \text{on } \gamma^+ \text{ for all } t \in (-\infty, \infty).$$

In particular, since $V(-\infty) = 0$, we have that $V(t) \leq 0$ for all t. Since Gronwall's inequality implies that $V(t) \leq V(0)e^{-(1+s)t}$ for all $t > 0$, we have that $|V(t)| \geq |V(0)|e^{-(1+s)t}$ for all $t > 0$.

We now claim that γ^+ cannot approach $C^0 = (0,0,0)$ as $t \to \infty$. In fact, if a trajectory is on the stable manifold of the origin and is not the z-axis, then for t sufficiently large, $x'' = -(1+s)x' + (R - 1 + o(1))x$, so that $x, x', x'' = O(e^{[\lambda_2^0 + o(1)]t})$ as $t \to \infty$. That is, if γ^+ approaches the origin as $t \to \infty$, then $V(t) = O(e^{2[\lambda_2 + o(1)]t})$. But this is impossible since $|V(t)| \geq |V(0)|e^{-(1+s)t}$ for all $t > 0$ and, from the expression of λ_2^0 in (2.1), $\lambda_2^0 < -(1+s)$. Therefore, γ^+ cannot approach the origin; namely, there is no homoclinic orbit associated with the origin. □

Summarizing Lemmas 2.2–2.5, we now can conclude the following theorem.

THEOREM 2.6. *Assume that* $0 < s \leq \frac{2q+1}{3}$. *Then for any* $R \in (0, \infty)$, *the Lorenz equations* (1.1) *have no homoclinic orbits associated with the origin.*

Remark. Lemmas 2.3 and 2.4 show that when $R > 1$ and $s \leq \frac{q}{2}$, $\gamma^{\pm}$ approaches $C^{\pm}$ as $t \to \infty$ and every other trajectory of (1.1) approaches one of the stationary points. However, we are unable to show the same conclusion for the case $\frac{q}{2} < s \leq \frac{2q+1}{3}$.

3. Existence of homoclinic orbits associated with the origin.

We now begin to show the existence part of Theorem 1.1; namely, we prove the following theorem.

THEOREM 3.1. *Assume that* $q > 0$ *and* $s > \frac{2q+1}{3}$. *Then there exists* $R \in (1 + \frac{q}{2s}, \infty)$ *such that the Lorenz equations* (1.1) *have a homoclinic orbit associated with the origin and lying on the half space* $\{(x,y,z) | x > 0\}$.

Clearly, Theorem 1.1 follows from Theorems 2.6 and 3.1.

In the sequel, we shall always assume that s, R, and q satisfy

$$q > 0, \qquad s > \frac{2q+1}{3}, \qquad R > 1.$$

Notice that the first two conditions imply that $\mu = 1 - \frac{q}{2s} > 0$.

The proof is based on a shooting argument first used by Hastings and Troy [10] and later used by Hassard and Zhang [6]; here R is the shooting parameter. In what follows, we shall use γ_R^+ to denote the trajectory of the stable manifold associated with the origin which initially enters the positive octant. Also we use x_R, y_R, z_R, Q_R to denote the solution with the trajectory γ_R^+. To set up the shooting argument, we define a set $\mathfrak{R}$ as follows:

$$\mathfrak{R} = \left\{ R > 1 \;\middle|\; \begin{array}{l} \text{(i) } \exists\, T_R^1 \text{ such that } x_R'(T_R^1) = 0,\ x_R''(T_R^1) < 0, \text{ and } x_R' > 0 \text{ in } (-\infty, T_R^1); \\ \text{(ii) } \exists\, T_R^2 > T_R^1 \text{ such that } x_R'(T_R^2) = -sx(T_R^2) \text{ and } x_R'' < -sx_R' \text{ in } [T_R^1, T_R^2]; \\ \text{(iii) } \exists\, T_R^3 > T_R^2 \text{ such that } x_R(T_R^3) = 0 \text{ and } x_R' < -sx_R \text{ in } (T_R^2, T_R^3]. \end{array} \right\}$$

Observe that $x_R' + sx_R = sy_R$, so that the second condition in the definition means that $y_R(T_R^2) = 0$ and $y_R' < 0$ in $[T_R^1, T_R^2]$, and the third condition means that $y_R < 0$ in $(T_R^2, T_R^3]$.

LEMMA 3.2. *The set $\mathfrak{R}$ is open.*

Proof. Assume that $\bar{R} \in \mathfrak{R}$. Since $x_{\bar{R}}''(T_{\bar{R}}^1) \neq 0$, $(x_{\bar{R}}' + sx_{\bar{R}})'(T_{\bar{R}}^2) \neq 0$, and $x_{\bar{R}}'(T_{\bar{R}}^3) \neq 0$, by the continuity of the trajectory γ_R^+ with respect to R and the implicit-function theorem, for all R sufficiently close to $\bar{R}$, there exist T_R^1, T_R^2, and T_R^3 satisfying the three conditions in the definition of $\mathfrak{R}$; that is, $R \in \mathfrak{R}$. Hence, $\mathfrak{R}$ is open. □

LEMMA 3.3. *Assume that $R \in (1, 1 + \frac{q}{2s}]$. Then the "box" $B := \{(x,y,z) \mid 0 < x < \sqrt{q}, 0 < y < \sqrt{q}, \frac{1}{2s}x^2 < z < 1\}$ is positively invariant. Since initially γ_R^+ stays in B, γ_R^+ stays in B for all $t \in (-\infty, \infty)$. Consequently, $R \notin \mathfrak{R}$ and there are no homoclinic orbits associated with the origin.*

Proof. The argument given below is adapted from [10].

To show that B is positive invariant, we need only check the direction of the vector field of (1.1) on the boundary of B.

On the bottom face of B, $Q = 0$. Since $Q' + qQ = \mu x^2 \geq 0$, we know that once Q is positive, it will remain positive. It then follows that no trajectory can exit B from the face $\{z = \frac{1}{2s}x^2\}$.

On the top face of B, $z = 1$. It follows that $z' = xy - qz = xy - q < 0$ except at $(x,y) = (\sqrt{q}, \sqrt{q})$. When $(x,y,z) = (\sqrt{q}, \sqrt{q}, 1)$, $y' = (R-2)\sqrt{q} < 0, z' = 0, z'' = \sqrt{q}y' < 0, x' = 0, x'' = (R-2)\sqrt{q} < 0$. Hence, no trajectory can exit from the top face of B. Similarly, one can show that no trajectory can exit B from the left face $\{x = 0\}$, the right face $\{x = \sqrt{q}\}$, and the front face $\{y = 0\}$ of B. It remains to consider the back face (without edges) of B.

On the back face $\{y = \sqrt{q}, 0 < x < \sqrt{q}, \frac{1}{2s}x^2 < z < 1\}$ of B, $y' = (R-z)x - \sqrt{q}$. Since $R \leq 1 + \frac{q}{2s}$ and $z > \frac{1}{2s}x^2$, $y' < x(1 + \frac{q}{2s} - \frac{1}{2s}x^2) - \sqrt{q} = (\sqrt{q} - x)(\frac{x(x+\sqrt{q})}{2s} - 1) \leq (\sqrt{q} - x)(\frac{q}{s} - 1) \leq 0$. We then also conclude that no trajectory can exit from B on the face $\{y = \sqrt{q}\}$.

In conclusion, B is positive invariant and $R \notin \mathfrak{R}$. Since an orbit cannot enter the origin from the inside of B, there are no homoclinic orbits associated with the origin. This completes the proof of the lemma. □

LEMMA 3.4. *There exists $R_0 \gg 1$ such that $[R_0, \infty) \in \mathfrak{R}$.*

This is a technical lemma, and we shall leave the proof to the next section. In fact, this is the major difference of our proof from that of Hastings and Troy [10] and Hassard and Zhang [6].

Assume for the moment that Lemma 3.4 has been proven. We can now complete the proof of Theorem 3.1. The argument below is essentially the same as that in [10] and [6]. Here we provide it for completeness, as well as for the reader's convenience.

Proof of Theorem 3.1. Define $R^* \equiv \inf\{R \mid R \in \mathfrak{R}\}$. From Lemmas 3.3 and 3.4, $R^* \in [1+\frac{q}{2s},\infty)$, so that $\gamma^+_{R^*}$ is well defined. Since $\mathfrak{R}$ is open, $R^* \notin \mathfrak{R}$. We now show that $\gamma^+_{R^*}$ is a homoclinic orbit, via the following steps:

1. there exists $T^1_{R^*}$ satisfying the first condition in the definition of $\mathfrak{R}$; namely, $x_{R^*} > 0$ in $(-\infty, T^1_{R^*})$, $x'_{R^*}(T^1_{R^*}) = 0$, and $x''_{R^*}(T^1_{R^*}) < 0$;
2. there exists $T^2_{R^*}$ satisfying the second condition in the definition of $\mathfrak{R}$; namely, $(x'_{R^*} + sx_{R^*})' < 0$ on $[T^1_{R^*}, T^2_{R^*}]$ and $(x_{R^*} + sx_{R^*})(T^2_{R^*}) = 0$;
3. $x_{R^*} > 0$ for all $t \in (-\infty,\infty)$, $x'_{R^*} < -sx_{R^*}$ for all $t \in (T^2_{R^*},\infty)$, and $\gamma^+_{R^*}$ approaches the origin as $t \to \infty$.

The first step. Since γ_{R^*} is on the unstable manifold of the origin, $x_{R^*} > 0$ and $x'_{R^*} > 0$ for all t sufficiently negative large. We claim that there is a first time such that $x'_{R^*} = 0$. In fact, if it is not true, then $x'_{R^*} > 0$ for all t, which implies that as $t \to \infty$, γ_{R^*} approaches the stationary point $C^+_{R^*} \equiv (\sqrt{q(R^*-1)}, \sqrt{q(R^*-1)}, R^*-1)$. (Recall that all the trajectories are bounded for positive t.) There are only two possibilities: (i) C_{R^*} is stable; (ii) C_{R^*} is nonstable with a two-dimensional unstable manifold on which the flow is of spiral type. In the first case, there is a small ball centered at C_{R^*} such that the vector fields of (1.1) intersect the boundary of the ball nontangentially and inwards. Consequently, when R is sufficiently close to R^*, the vector fields with the parameter R also intersect the boundary of the ball nontangentially and inwards, so that the ball is positively invariant. Since for all R sufficiently close to R^*, γ^+_R is close to $\gamma^+_{R^*}$ up to the time when γ^+_R enters the ball, which means that γ^+_R will be trapped into the ball before x_R reaches its first zero. Clearly, this violates the definition of R^*. In the second case, there are two small balls B_1 and B_2, both centered at C_{R^*} and $B_1 \subset B_2$, such that any trajectory starting from any point on the boundary of B_1 has to wind around $\gamma^+_{R^*}$ at least two times before it could possibly exit from the boundary of B_2. This implies that for R sufficiently close to R^*, any trajectory that hits B_1 has to wind around the stable manifold of the stationary point C^+_R at least one time before it could possibly hit the boundary of B_2, which means that x'_R has to change sign at least two times before x_R could possibly reach its first zero. Clearly, this is impossible for R in $\mathfrak{R}$. Therefore, there is a first time $T^1_{R^*}$ such that x'_{R^*} takes its first zero.

Since $T^1_{R^*}$ is the first zero of x'_{R^*}, $x'_{R^*} > 0$ in $(-\infty, T^1_{R^*})$ and $x''_{R^*}(T^1_{R^*}) \leq 0$. Therefore $Q''_{R^*} + qQ'_{R^*} = 2\mu x_{R^*}x'_{R^*} > 0$ in $(-\infty, T^1_{R^*})$, so that $Q'_{R^*} > 0$ on $(-\infty, T^1_{R^*}]$, and $z'_{R^*} = Q'_{R^*} + \frac{1}{s}x_{R^*}x'_{R^*} > 0$ in $(-\infty, T^1_{R^*}]$ as well. This excludes the possibility of $x''_{R^*}(T^1_{R^*})$ being zero, since otherwise $x'''_{R^*}(T^1_{R^*}) \geq 0$, and from the equation for x_{R^*}, one can derive that $z_{R^*} = R^* - 1$ and $z'_{R^*} \leq 0$, which is impossible. Hence $x''_{R^*}(T^1_{R^*}) < 0$. Consequently, $x'_{R^*} + sx_{R^*} > 0$ and $(x'_* + sx_{R^*})' < 0$ at T^1_*.

The second step. Since the solution of (1.1) is autonomous, we can shift t such that $T^1_R = 0$ for all $R \in \mathfrak{R} \cup R^*$. Under this normalization, since $x''_R(0) \neq 0$, by the Implicit Function Theorem, the solution of (1.1) is both smooth in time t and in the parameter R. We claim that $T^2_{R^*} = \liminf_{R\in\mathfrak{R}, R\searrow R^*} T^2_R$ is finite. In fact if $T^2_{R^*} = \infty$, then by the continuity of the trajectory in R and the definition of T^2_R, $(x'_{R^*} + sx_{R^*})' \leq 0$ and $(x'_{R^*} + sx_{R^*}) \geq 0$ for all $t > 0$. It then follows that $x'_{R^*} + sx_{R^*}$ is positive and monotonically decreasing in $[0,\infty)$, so that either x'_{R^*} reaches zero and then becomes positive at some time in $(0,\infty)$ before x_{R^*} reaches its first zero in $(-\infty,\infty)$ or $sx_{R^*} > -x'_{R^*} \geq 0$ for all $t > T^1_{R^*}$. The first case cannot happen since R^* is a limit point of $\mathfrak{R}$ in which x_R obtains its first zero before x'_R obtains its first zero in $(0,\infty)$. The second case implies that on the phase plane of x vis

x', (x_{R^*}, x'_{R^*}) approaches $(0,0)$ from the sector bounded by the positive x-axis and the line $x' + sx = 0$ (the possibility that x_{R^*} monotonically decreases to $\sqrt{q(R^* - 1)}$ can be excluded in a similar way as in the first step). This is impossible since the direction that a trajectory can approach the origin on the x–x' phase plane is $(1, \lambda_2^0)$ but $\lambda_2^0 < -(1+s)$. Hence, $T^2_{R^*} < \infty$.

By the definition of $T^2_{R^*}$, the continuity of solutions in R, and the second condition in the definition of $\Re$, $x'_{R^*} + sx_{R^*} = 0$ at $T^2_{R^*}$ and $(x'_{R^*} + sx_{R^*})' \le 0$ in $[0, T^2_{R^*}]$. If $(x'_{R^*} + sx_{R^*})' = 0$ at some point $T \in (0, T^2_{R^*})$, then $(x'_{R^*} + sx_{R^*})(T) > 0$ and $(x'_{R^*} + sx_{R^*})''(T) = 0$. From the differential equation $(x'+sx)'+(x'+sx) = s(R-z)x$, we then have that $z_{R^*}(T) < R^*$ and $z'_{R^*}(T) \ge 0$. In addition, from $z''+qz' = \frac{1}{s}[x(x'+sx)]' = x'(x'+sx)+x(x'+sx)' \le 0$ in $[T, T^2_{R^*}]$, we have that $z'_{R^*} < 0$ in $(T, T^2_{R^*}]$. Thus $z_{R^*}(T^2_{R^*}) < R^*$. However, at $T^2_{R^*}$, $sx_{R^*}(R^* - z_{R^*}) = (x'_{R^*}+sx_{R^*})'+(x'_{R^*}+sx_{R^*}) \le 0$, which implies that $z_{R^*}(T^2_{R^*}) \ge R^*$; we get a contradiction. This contradiction shows that $(x'_{R^*} + sx_{R^*}) < 0$ in $(0, T^2_{R^*})$. Now if $(x'_{R^*} + sx_{R^*})' = 0$ at $T^2_{R^*}$, then since by continuity and the definition of R^*, $x'_{R^*} + sx_{R^*}$ is positive in $[0, T^2_{R^*})$ and nonpositive in $[T^2_{R^*}, T^2_{R^*} + \delta)$ for some $\delta > 0$, we must have $(x_{R^*} + sx_{R^*})'' = 0$. Recall that this is equivalent to $y_{R^*} = y'_{R^*} = y''_{R^*} = 0$ at $T^2_{R^*}$, which, in turn, implies that $x_{R^*} = y_{R^*} = z_{R^*} = 0$; clearly this is impossible. Therefore, $T^2_{R^*}$ satisfies the second condition in the definition of $\Re$.

The final step. Now let $T^3_{R^*} = \liminf_{R \in \Re, R \searrow R^*} T^3_R$. We first claim that $T^3_{R^*} = \infty$. Assume that this is not true. Then $x(T^3_{R^*}) = 0$ and $x_{R^*} \ge 0$ for all $t \in (-\infty, T^3_{R^*}]$. From the continuity and the definition of R^*, $x'_{R^*} + sx_{R^*} \le 0$ for all $t \in [T^2_{R^*}, T^3_{R^*}]$. If $(x'_{R^*} + sx_{R^*})(T) = 0$ for some T in $(T^2_{R^*}, T^3_{R^*})$, then $(x'_{R^*} + sx_{R^*})'(T) = 0$, $(x'_{R^*} + sx_{R^*})''(T) \le 0$, and $x_{R^*}(T) > 0$. But from the equations $(x'_{R^*} + sx_{R^*})' + (x'_{R^*}+sx_{R^*})' = s(R^* - z_{R^*})x_{R^*}$ and $z'_{R^*} = \frac{1}{s}x_{R^*}(x'_{R^*}+sx_{R^*}) - qz_{R^*}$, this implies that $z_{R^*}(T) = R^*$ and $z'_{R^*}(T) < 0$. Consequently, $(x'_{R^*} + sx_{R^*})''(T) = -z'_{R^*}(T)x_{R^*}(T) > 0$, which is a contradiction. This contradiction shows that $x'_{R^*} + sx_{R^*} < 0$ in $(T^2_{R^*}, T^3_{R^*})$. Also, since $x'_{R^*}(T^3_{R^*}) = 0$ implies that the trajectory is the z-axis, we must have $x'(T^3_{R^*}) < 0$. Therefore, $T^3_{R^*}$ satisfies the third condition in the definition of $\Re$. Hence, from the first two steps, we have that $R^* \in \Re$, again a contradiction. This contradiction shows that $T^3_{R^*} = \infty$. Hence, we have that $x_{R^*} > 0$ for all t and, by a similar argument as above, $x'_{R^*} < -sx_{R^*} < 0$ for all $t > T^2_{R^*}$. Therefore, as $t \to \infty$, x_{R^*} and x'_{R^*} approach zero. That is, $\gamma^+_{R^*}$ approaches the origin.

This completes the proof of Theorem 3.1. □

4. Solutions for large *R*. To prove Lemma 3.3, we now study the behavior of the solutions of (1.1) for large R. To this end, we introduce a variation of a transformation which was first used by Robbins [13] and then by Swinnerton-Dyer [18] to establish, among other things, the existence of periodic solutions of (1.1) for large R. The transformation is as follows (assume that $q \ne 2s$):

$$\begin{aligned} &\tau = \sqrt{s(R-1)}\,t, && \varepsilon = (1+s)/\sqrt{s(R-1)}, \\ &\alpha = 4\mu s/(1+s), && \beta = q/(1+s), \\ &x_R(t) = 2\sqrt{s(R-1)}x_\varepsilon(\tau), && Q_R(t) = 4\mu\sqrt{s(R-1)}Q_\varepsilon(\tau). \end{aligned} \tag{4.1}$$

Under this transformation, the system (1.1) or (2.2) becomes

$$\begin{cases} \ddot{x}_\varepsilon = x_\varepsilon(1 - 2x_\varepsilon^2) - \varepsilon(\dot{x}_\varepsilon + \alpha x_\varepsilon Q_\varepsilon), \\ \dot{Q}_\varepsilon = x_\varepsilon^2 - \varepsilon\beta Q_\varepsilon, \end{cases} \tag{4.2}$$

where $\dot{} = \frac{d}{d\tau}$.

In what follows, we shall use the phase space $(x, \dot{x}, Q)$, so that a trajectory of (4.2) refers to its trace of points $(x_\varepsilon(\tau), \dot{x}_\varepsilon(\tau), Q_\varepsilon(\tau))$ for all $\tau \in (-\infty, \infty)$.

When $\varepsilon = 0$, the system (4.2) can be solved by quadrature. A solution of interest is given in the following lemma.

LEMMA 4.1. *When $\varepsilon = 0$, the system* (4.2) *has a unique trajectory γ_0^+ which approaches the origin as $\tau \to -\infty$ and lies in the first octant for sufficient negative large τ. Its corresponding solution is given by*

$$(4.3) \qquad X^0(\tau) = (\cosh\tau)^{-1}, \qquad Q^0(\tau) = 1 + \tanh\tau, \qquad t \in (-\infty, \infty).$$

The assertion of the Lemma follows by a direct calculation and details are omitted.

Note that in (4.3), we have normalized the solution such that X^0 obtains its maximum at $\tau = 0$.

One may notice that the stationary point $(0, 0, 0)$ of (4.2) changes from saddle type to degenerate type when ε is changed from positive to zero, so that the continuous dependence of the unstable manifold of the origin with respect to ε has to be rigorously verified. Hence, we provide the following lemma for completeness.

LEMMA 4.2. (1) *For every $\varepsilon \geq 0$,* (4.2) *has a unique trajectory γ_ε^+ which approaches the origin as $\tau \to -\infty$ and initially x_ε is positive.*

(2) *There exists a positive constant δ_1 such that for every $\varepsilon \in [0, 1]$, γ_ε^+ has the expansion*

$$x_\varepsilon = \xi, \qquad \dot{x}_\varepsilon = P(\varepsilon, \xi), \qquad Q_\varepsilon = Q(\varepsilon, \xi) \quad \textit{for all } \xi \in (0, \delta_1],$$

where $P(\varepsilon, \xi)$ and $Q(\varepsilon, \xi)$ are analytic functions of ξ and ε in an open neighborhood containing $[0, \delta_1] \times [0, 1]$. In addition, there exists a positive constant C_1 such that for all $\varepsilon \in [0, 1]$ and all $\xi \in [0, \delta_1]$, $P(\varepsilon, \xi)$ and $Q(\varepsilon, \xi)$ satisfy the following estimates:

$$(4.4) \qquad \begin{array}{ll} |P(\varepsilon, \xi) - \lambda_\varepsilon^P \xi| \leq C_1 \xi^2, & \textit{where } \lambda_\varepsilon^P := \sqrt{1 + (\varepsilon/2)^2} - \varepsilon/2, \\ |Q(\varepsilon, \xi) - \lambda_\varepsilon^Q \xi| \leq C_1 \xi^2, & \textit{where } \lambda_\varepsilon^Q := 1/(2\lambda_\varepsilon^P + \beta\varepsilon). \end{array}$$

(3) *There exists a small positive constant $\varepsilon_1 \in (0, 1]$ such that for all $\varepsilon \in [0, \varepsilon_1]$, the x_ε component of γ_ε^+ can obtain its first maximum. In addition, if one normalizes the solution $(X^\varepsilon, \dot{X}^\varepsilon, Q^\varepsilon)$ of* (4.2) *corresponding to γ_ε^+ such that X^ε obtains its first maximum at $\tau = 0$, then as a function of variables ε and τ, $(X^\varepsilon(\tau), \dot{X}^\varepsilon(\tau), Q^\varepsilon(\tau))$ is analytic in $[0, \varepsilon_1] \times (-\infty, \infty)$. Consequently, for all $T > 0$, there exists a constant $C_2(T)$ such that*

$$\|X^\varepsilon - X^0\|_{C^2([-T,T])} + \|Q^\varepsilon - Q^0\|_{C^1([-T,T])} \leq C_2(T)\varepsilon.$$

Proof. (1) When $\varepsilon > 0$, (4.2) is equivalent to (1.1) so that γ_ε^+ is well defined, whereas when $\varepsilon = 0$, γ_0^+ is given by Lemma 4.1.

(2) In a small neighborhood of the origin, γ_ε^+ can be obtained by solving the system of two ordinary differential equations:

$$\tfrac{d}{dx}P = x(1 - 2x^2)/P - \varepsilon(1 + \alpha Q/P), \qquad \tfrac{d}{dx}Q = x^2/P - \varepsilon\beta Q/P,$$

where x is an independent variable. One can verify that this new system has a convergent power series solution $P = P(\varepsilon, x) := \sum_{i=0}^\infty p_i(\varepsilon)x^i$, $Q = Q(\varepsilon, x) := \sum_{i=0}^\infty q_i(\varepsilon)x^i$ in some interval $[0, \delta_1]$ which is independent of $\varepsilon \in [0, 1]$, provided that one takes $p_0 = 0$, $p_1 = \lambda_\varepsilon^P$, $q_0 = q_1 = 0$, and $q_2 = \lambda_2^Q$, where λ_ε^P and λ_ε^Q are defined in (4.4), whereas all the other coefficients are uniquely determined by the differential equations. Clearly, this solution corresponds to γ_ε^+. In addition, by adding a dummy equation $\frac{d}{dx}\varepsilon = 0$, if necessary, one can show by the implicit-function theorem that $P(\varepsilon,\xi)$ and $Q(\varepsilon,x)$ are analytic in ε and x. This proves the second assertion of the lemma.

(3) From (2), the curve $(\delta_1, P(\varepsilon,\delta_1), Q(\varepsilon,\delta_1))$ is analytic in $\varepsilon \in [0,1]$. Taking this as initial conditions for (4.2) at $\tau = 0$, we have a solution $(\hat{x}_\varepsilon(\tau), \dot{\hat{x}}_\varepsilon(\tau), \hat{Q}_\varepsilon(\tau))$ which is analytic in both ε and τ. In addition, since at the point where $\hat{x}_0$ obtains its maximum, $\hat{x}_0'' = -1 \neq 0$, for all small ε, we can use the implicit-function theorem to solve, for T_ε, the equation $\hat{x}_\varepsilon'(T_\varepsilon) = 0$ near the place where $\hat{x}_0$ obtains its maximum. The function T_ε thus obtained is analytic in ε in $[0,\varepsilon_1]$ for some small positive ε_1. Shifting the time phase of the solution $(\hat{x}_\varepsilon, \dot{\hat{x}}_\varepsilon, \hat{Q}_\varepsilon)$ by T_ε, we then obtain the third assertion of the lemma. □

In what follows, we shall always use the representation $(X^\varepsilon, \dot{X}^\varepsilon, Q^\varepsilon)$ stated in Lemma 4.2 (3) for γ_ε^+, where $\varepsilon \in [0,\varepsilon_1]$.

LEMMA 4.3. *There exists a constant $\varepsilon_2 \in (0,\varepsilon_1]$ such that the following holds:*

(i) *For every $\varepsilon \in [0,\varepsilon_2]$, $\dot{X}^\varepsilon > 0$ in $(-\infty,0)$, $\dot{X}^\varepsilon(0) = 0$, and $\ddot{X}^\varepsilon(0) < -1/2$.*

(ii) *For every $\varepsilon \in (0,\varepsilon_2]$, there exists $T_\varepsilon^2 \in (0,\sqrt{\varepsilon}]$ such that*

$$(\dot{X}^\varepsilon + \tfrac{s\varepsilon}{1+s}X^\varepsilon)(T_\varepsilon^2) = 0, \qquad \tfrac{d}{d\tau}(\dot{X}^\varepsilon + \tfrac{s\varepsilon}{1+s}X^\varepsilon) < -1/4 \text{ in } [0,T_\varepsilon^2].$$

Proof. Since $\ddot{X}^0(0) = -1$, the first assertion follows from Lemma 4.2, whereas the second assertion follows by the continuity of the solution with respect to ε and τ and the implicit-function theorem. □

Observe that under the transformation (4.1), the quantity $x_R'+sx_R$ in the original variables becomes $\frac{2(1+s)^2}{\varepsilon^2}(\dot{x}_\varepsilon + \frac{s\varepsilon}{1+s}x_\varepsilon)$, so that when $R \in [\frac{1}{s}(\frac{1+s}{\varepsilon_2})^2, \infty)$, γ_R^+ defined in §3 satisfies the first two conditions in the definition of $\mathfrak{R}$. We now proceed to show that the third condition in the definition of $\mathfrak{R}$ is also satisfied by γ_R^+ for large R, or equivalently, by γ_ε^+ for small ε.

LEMMA 4.4. (1) *Define $H_\varepsilon = \dot{x}_\varepsilon^2 + x_\varepsilon^4 - x_\varepsilon^2$. Then, along any trajectory of* (4.2),

$$\tfrac{1}{2\varepsilon}\dot{H}_\varepsilon = -\dot{x}_\varepsilon^2 - \alpha Q_\varepsilon x_\varepsilon \dot{x}_\varepsilon, \qquad \textit{for all } \varepsilon \geq 0, \tau \in (-\infty,\infty). \tag{4.5}$$

(2) *Define $m := -\int_{-\infty}^{\infty} \left[(\dot{X}^0)^2 + \alpha Q^0 X^0 \dot{X}^0\right] d\tau$. Then $m = \frac{2}{1+s}\left[s - \frac{2q+1}{3}\right]$.*

(3) *For any $T > 0$, there exists $C_3(T) > 0$ such that for all $\varepsilon \in [0,\varepsilon_2]$,*

$$\left| \int_{-\infty}^{T} \left[(\dot{X}^\varepsilon)^2 + \alpha Q^\varepsilon X^\varepsilon \dot{X}^\varepsilon - (\dot{X}^0)^2 - \alpha Q^0 X^0 \dot{X}^0\right] d\tau \right| \leq C_3(T)\varepsilon.$$

Proof. The first two assertions follow from the differential equations in (4.2), the explicit expressions of X^0 and Q^0 in Lemma 4.1, the definition of α in (4.1), and direct computation; details are omitted. We now prove (3).

Let $T_\varepsilon(\delta_1) < 0$ be the time such that $X^\varepsilon(T_\varepsilon(\delta_1)) = \delta_1$. Since at $T_\varepsilon(\delta_1)$, $\dot{X}^\varepsilon > 0$, $T_\varepsilon(\delta_1)$ is analytic in ε. Hence the integral of $(\dot{X}^\varepsilon)^2 + \alpha Q^\varepsilon X^\varepsilon \dot{X}^\varepsilon$ from $[T_\varepsilon(\delta_1), T]$ differs from the integral of $(\dot{X}^0)^2 + \alpha Q^0 X^0 \dot{X}^0$ from $[T_0(\delta_1), T]$ by a quantity of order ε. Using the change of variables $\xi = X^\varepsilon(\tau)$, we have that

$$\int_{-\infty}^{T_\varepsilon(\delta_1)} \left[(\dot{X}^\varepsilon)^2 + \alpha Q^\varepsilon X^\varepsilon \dot{X}^\varepsilon\right] d\tau = \int_0^{\delta_1} \left[P(\varepsilon,\xi) + \alpha Q(\varepsilon,\xi)\xi\right] d\xi$$
$$= \int_0^{\delta_1} \left[P(0,\xi) + \alpha Q(0,\xi)\xi\right] d\xi + O(\varepsilon) = \int_{-\infty}^{T_0(\delta_1)} \left[(\dot{X}^0)^2 + \alpha Q^0 X^0 \dot{X}^0\right] d\tau + O(\varepsilon).$$

The third assertion of the lemma thus follows. □

We now are ready to prove the following lemma.

LEMMA 4.5. *Assume that* $s > \frac{2q+1}{3}$. *Then there exists* $\varepsilon_0 \in (0, \varepsilon_2]$ *such that for every* $\varepsilon \in (0, \varepsilon_0]$, *there exists* $T_\varepsilon^3 > T_\varepsilon^2$ *such that the following hold:*

$$X^\varepsilon(T_\varepsilon^3) = 0, \qquad \dot{X}^\varepsilon < 0\, in\, (0, T_\varepsilon^3], \qquad and\, (\dot{X}^\varepsilon + \tfrac{s\varepsilon}{1+s} X^\varepsilon) < 0\, in\, (T_\varepsilon^2, T_\varepsilon^3].$$

Proof. Since $s > \frac{2q+1}{3}$, m defined in Lemma 4.4 is positive. Let T_m be a large positive constant such that

$$\int_{T_m}^{\infty} \Big[(\dot{X}^0)^2 + \alpha |Q^0 X^0 \dot{X}^0| \Big]\, d\tau < \tfrac{1}{8} m, \tag{4.6}$$

$$\delta_m := X^0(T_m) < \min\{\tfrac{1}{8}, \tfrac{1}{12} m\}. \tag{4.7}$$

By the continuous dependence of the solution on ε, we can find a positive constant $\varepsilon_0 \in (0, \min\{1/\sqrt{2}, \varepsilon_2, m(8C_3(T_m))^{-1}\}]$ such that for all $\varepsilon \in [0, \varepsilon_0]$,

$$\dot{X}^\varepsilon < -\tfrac{s\varepsilon}{1+s} X^\varepsilon < 0 \qquad \text{in } (T_\varepsilon^2, T_m + 1], \tag{4.8}$$

$$|X^\varepsilon(T_m) - X^0(T_m)| + |Q^\varepsilon(T_m) - Q^0(T_m)| \le \tfrac{1}{2} \delta_m. \tag{4.9}$$

Denote the value of H_ε on γ_ε^+ by H^ε. Since $H^\varepsilon(-\infty) = 0$, integrating (4.5) along γ_ε^+ from $-\infty$ to T_m and using Lemma 4.4, we have that

$$\begin{aligned}
\tfrac{1}{2\varepsilon} H^\varepsilon(T_m) &= \int_{-\infty}^{T_m} \Big[-(\dot{X}^\varepsilon)^2 - \alpha Q^\varepsilon X^\varepsilon \dot{X}^\varepsilon \Big]\, d\tau \\
&= \int_{-\infty}^{\infty} \Big[-(\dot{X}^0)^2 - \alpha Q^\varepsilon X^0 \dot{X}^0 \Big]\, d\tau + \int_{T_m}^{\infty} \Big[(\dot{X}^0)^2 + \alpha Q^\varepsilon X^0 \dot{X}^0 \Big]\, d\tau \\
&\quad + \int_{-\infty}^{T_m} \Big[(\dot{X}^\varepsilon)^2 + \alpha Q^\varepsilon X^\varepsilon \dot{X}^\varepsilon - (\dot{X}^0)^2 - \alpha Q^0 X^0 \dot{X}^0 \Big]\, d\tau \\
&\ge m - \tfrac{1}{8} m - C_3(T_m)\varepsilon \ge \tfrac{6}{8} m \qquad \forall \varepsilon \in [0, \varepsilon_0].
\end{aligned}$$

Hence, $H^\varepsilon(T_m) \ge \frac{3}{2} m\varepsilon$ for all $\varepsilon \in [0, \varepsilon_0]$.

Now for all $\varepsilon \in (0, \varepsilon_0]$, define

$$T_\varepsilon^3 := \inf \Big\{ \tau > T_m \;\Big|\; X^\varepsilon > 0, \dot{X}^\varepsilon < 0 \text{ and } H^\varepsilon > m\varepsilon \text{ in } [T_m, \tau] \Big\}.$$

In view of (4.8), T_ε^3 is well defined and $T_\varepsilon^3 > T_m + 1$.

Since $\dot{X}^\varepsilon < 0$ in $[T_m, T_\varepsilon^3)$, we have that $0 \le X^\varepsilon(\tau) \le X^\varepsilon(T_m) \le \frac{3}{2}\delta_m \le \frac{3}{16}$ for all $\tau \in [T_m, T_\varepsilon^3]$. In addition, from the definition of H^ε, in $[T_m, T_\varepsilon^3]$,

$$-\dot{X}^\varepsilon = \sqrt{H^\varepsilon + (X^\varepsilon)^2[1 - (X^\varepsilon)^2]} \ge \sqrt{m\varepsilon + \tfrac{1}{2}(X^\varepsilon)^2}.$$

Therefore, we have that $-\dot{X} \ge \sqrt{m\varepsilon}$ in $[T_m, T_\varepsilon^3]$, which implies that $T_\varepsilon^3 \le X^\varepsilon(T_m)/\sqrt{m\varepsilon} < \infty$. Also we have that $-\dot{X}^\varepsilon > X^\varepsilon/\sqrt{2}$ in $[T_m, T_\varepsilon^3]$, which, together with (4.8) and the fact that $\varepsilon_0 \le 1/\sqrt{2}$, yields

$$\dot{X}^\varepsilon + \tfrac{s\varepsilon}{1+s} X^\varepsilon < 0 \text{ in } (T_\varepsilon^2, T_\varepsilon^3], \qquad \text{for all } \varepsilon \in [0, \varepsilon_0].$$

Hence, to finish the proof, we need only show that $X^\varepsilon(T_\varepsilon^3) = 0$.

At T_ε^3, there are only two possibilities: either $X^\varepsilon(T_\varepsilon^3) = 0$ or $H^\varepsilon(T_\varepsilon^3) = m\varepsilon$. We shall show that the second alternative will not happen by integrating the identity (4.5) from T_m to T_ε^3. To do this, we need an estimate for the maximum of $\dot{X}^\varepsilon$ in $[T_m, T_\varepsilon^3]$. (Though this can be directly verified by using Lemma 2.1, we provide another proof here for possible other applications.)

Since $Q^\varepsilon > 0$ for all $\tau \in (-\infty, \infty)$ and all $\varepsilon \geq 0$, $\dot{Q}^\varepsilon = -\varepsilon\beta Q^\varepsilon + (X^\varepsilon)^2 < (X^\varepsilon)^2$. Consequently, for all $\tau \in (T_m, T_\varepsilon^3]$,

$$\begin{aligned} Q^\varepsilon(\tau) &< Q^\varepsilon(T_m) + \int_{T_m}^{\tau} (X^\varepsilon)^2 = Q^\varepsilon(T_m) + \int_{X^\varepsilon(T_m)}^{X^\varepsilon(\tau)} \frac{X^\varepsilon}{\dot{X}^\varepsilon}\, dX^\varepsilon \\ &\leq Q^\varepsilon(T_m) + \int_0^{X^\varepsilon(T_m)} \frac{x}{\sqrt{m\varepsilon + x^2/2}} dx \leq Q(T_m) + \sqrt{2} X^\varepsilon(T_m) \leq 4, \end{aligned}$$

since $Q^\varepsilon(T_m) = Q^0(T_m) + \frac{1}{2}\delta_m \leq \frac{5}{2}$ and $X^\varepsilon(T_m) \leq \frac{3}{2}\delta_m < \frac{1}{2}$. Integrating (4.5) from T_m to $\tau \in [T_m, T_\varepsilon^3]$ then yields

$$\tfrac{1}{2\varepsilon}[H^\varepsilon(\tau) - H^\varepsilon(T_m)] \leq -\alpha \int_{T_m}^{\tau} Q^\varepsilon X^\varepsilon \dot{X}^\varepsilon \leq -4\alpha \int_{T_m}^{T_\varepsilon^3} X^\varepsilon \dot{X}^\varepsilon\, d\tau \leq 2\alpha (X^\varepsilon(T_m))^2 \leq \tfrac{1}{2}$$

for all $\varepsilon \in [0, \varepsilon_0]$, since $\alpha = \frac{4\mu s}{1+s} < 4$ and $X^\varepsilon(T_m) \leq \frac{3}{2}\delta_m \leq \frac{1}{4}$. It then follows from the definition of H^ε that $|\dot{X}^\varepsilon| \leq \sqrt{H^\varepsilon + X^2} \leq 1$ for all $\tau \in [T_m, T_\varepsilon^3]$.

Having the estimate for $|\dot{X}^\varepsilon|$ in $[T_m, T_\varepsilon^3]$, we can now integrate the identity (4.5) from T_m to T_ε^3 and using the fact that $-\alpha Q^\varepsilon X^\varepsilon \dot{X}^\varepsilon \geq 0$ in $(0, T_\varepsilon^3)$, obtain that

$$\begin{aligned} \tfrac{1}{2\varepsilon}\Big[H^\varepsilon(T_\varepsilon^3) - H^\varepsilon(T_m)\Big] &\geq -\int_{T_m}^{T_\varepsilon^3} (\dot{X}^\varepsilon)^2\, d\tau = -\int_{X^\varepsilon(T_m)}^{X^\varepsilon(T_\varepsilon^3)} \dot{X}^\varepsilon\, dX^\varepsilon \\ &\geq -X^\varepsilon(T_m) \geq -\tfrac{3}{2}\delta_m \qquad \forall \varepsilon \in [0, \varepsilon_0]. \end{aligned}$$

Therefore, $H^\varepsilon(T_\varepsilon^3) \geq H^\varepsilon(T_m) - 3\varepsilon\delta_m \geq \frac{3}{2}m\varepsilon - 3\varepsilon\delta_m \geq \frac{5}{4}m\varepsilon$ by the smallness of δ_m. Hence, we must have $X^\varepsilon(T_\varepsilon^3) = 0$. This completes the proof of the lemma. □

As mentioned earlier, since $X_R' + sX_R = \frac{2(1+s)^2}{\varepsilon^2}[\dot{x}_\varepsilon + \frac{s\varepsilon}{1+s}x_\varepsilon]$, Lemmas 4.3 and 4.5 imply that for R large enough, γ_R^+ satisfies the three conditions in the definition $\mathfrak{R}$; that is, $R \in \mathfrak{R}$. The assertion of Lemma 3.3 thus follows, thereby completing the proof of Theorem 3.1.

Acknowledgments. The author is grateful to Professor Stuart P. Hastings for bringing the author's attention to the fascinating Lorenz equations, demonstrating invaluable numerical calculations, and providing much appreciated direction through numerous communications.

Note added in proof. During this paper's production, the author learned of a previous result by G. A. Leonov [*Differential Equations*, 24 (1988), pp. 634–638; *Russian Math. Surveys*, 43 (1988), pp. 216–217]. He proved that when $s > \frac{2q+1}{3}$, the Lorenz system has a homoclinic orbit for some large R.

A GEOMETRIC APPROACH TO GLOBAL-STABILITY PROBLEMS*

MICHAEL Y. LI† AND JAMES S. MULDOWNEY‡

Abstract. A new criterion for the global stability of equilibria is derived for nonlinear autonomous ordinary differential equations in any finite dimension based on recent developments in higher-dimensional generalizations of the criteria of Bendixson and Dulac for planar systems and on a local version of the C^1 closing lemma of Pugh. The classical result of Lyapunov is obtained as a special case.

Key words. global stability, Bendixson criterion, compound equations

AMS subject classifications. 34D20, 34C35

1. Introduction.

Let the map $x \mapsto f(x)$ from an open subset $D \subset \mathbf{R}^n$ to $\mathbf{R}^n$ be such that each solution $x(t)$ to the differential equation

$$x' = f(x) \tag{1.1}$$

is uniquely determined by its initial value $x(0) = x_0$, and denote this solution by $x(t, x_0)$.

An equilibrium point $\bar{x} \in D$ of (1.1) is said to be *locally stable*—or simply *stable*—if, for each neighbourhood U of $\bar{x}$, there exists a neighbourhood V of $\bar{x}$ such that $x(t, V) \subset U$ for all $t > 0$; it is said to *attract points* in a neighbourhood W if $x(t, x_0) \to \bar{x}$ as $t \to \infty$ for each $x_0 \in W$. It is important to note that this convergence may not be uniform for $x_0 \in W$, and $\bar{x}$ may fail to be stable when it attracts points in a neighbourhood. This can be demonstrated by an example of $\bar{x}$ with a homoclinic orbit. However, if a stable $\bar{x}$ attracts points in a bounded set W, then the attraction is uniform with respect to $x_0 \in W$. In this case, $\bar{x}$ is said to attract W. We say $\bar{x}$ is *asymptotically stable* if it is stable and attracts a neighbourhood. The *basin of attraction* of $\bar{x}$ is the union of all points which it attracts. If $\bar{x}$ is asymptotically stable, its basin of attraction is an open subset of D and contains a neighbourhood of $\bar{x}$. An equilibrium $\bar{x}$ is said to be *globally asymptotically stable*—or simply *globally stable*—with respect to an open set D_1 if it is asymptotically stable and its basin of attraction contains D_1.

The local stability of an equilibrium $\bar{x}$ can be routinely verified by construction of a Lyapunov function in a small neighbourhood of $\bar{x}$ or by linearizing (1.1) at $\bar{x}$ if f is C^1. The primary interest of this paper is in the problem of global stability. Note that if $\bar{x}$ is globally stable with respect to D_1, then $\bar{x}$ is necessarily the only equilibrium in D_1 and there exists compact neighbourhood K of $\bar{x}$ such that each compact subset $F \subset D_1$ satisfies $x(t, F) \subset K$ for sufficiently large t. Such a K is called *absorbing* in D_1 for (1.1). An open set $D \subset \mathbf{R}^n$ is *simply connected* if each closed curve in D can be

continuously deformed to a point within D. Without loss of generality, we formulate the problem as follows:

THE GLOBAL-STABILITY PROBLEM. *Assume that*

(H_1) *D is simply connected;*

(H_2) *there is a compact absorbing set $K \subset D$;*

(H_3) *$\bar{x}$ is the only equilibrium of* (1.1) *in D.*

Find conditions under which the global stability of $\bar{x}$ with respect to D is implied by its local stability.

The difficulty associated with this problem is largely due to the lack of practical tools. The method of Lyapunov functions is most commonly used (see [5], [6]); its application is often hindered by the fact that in many cases global Lyapunov functions are difficult to construct and there is practically no general approach to the construction of such functions. The application of the theory of monotone flows [8], [21] is an alternative which has been successfully implemented in recent years.

A new approach to the global-stability problem has emerged from a series of papers on higher-dimensional generalizations of the criteria of Bendixson and Dulac for planar systems and on so-called autonomous convergence theorems. Assume that (1.1) satisfies a condition in D which precludes the existence of periodic solutions and suppose that this condition is robust in the sense that it is also satisfied by ordinary differential equations that are C^1-close to (1.1); then every nonwandering point of (1.1) is an equilibrium, since otherwise, by the C^1 closing lemma of Pugh [19], [20], we can perturb (1.1) near such a nonequilibrium nonwandering point to get a periodic solution. As a special case, every omega limit point of (1.1) is an equilibrium. In the context of our global-stability problem, this implies that $\bar{x}$ attracts points in D. As a consequence its global stability is implied by the local stability.

Higher-dimensional generalizations of Bendixson's criterion have been obtained in papers of R. A. Smith [22] and J. S. Muldowney [17]. This was further developed and the generalized Dulac criteria derived in [11] based on the study of evolution of general surface functionals under (1.1). Smith used the fact that his condition has the required robustness to imply that all bounded trajectories converge to equilibria. Such results are called, after Smith [22], autonomous convergence theorems, and they are further explored in [12] and proved under the generalized Dulac conditions developed in [11]. In the special case that (1.1) has a unique equilibrium $\bar{x}$ in D, it is proved in [12] that each of these generalized Dulac conditions also implies the local stability of $\bar{x}$ and hence its global stability with respect to D. As shown in [12], the traditional method of Lyapunov functions can also be interpreted in this context.

Each of these conditions will be called a *Bendixson criterion* in this paper. Our main purpose is to introduce a new Bendixson criterion for (1.1) which is an extension of the generalized Dulac conditions in [11] and [12]. Roughly speaking, instead of requiring these generalized Dulac conditions to hold pointwise in D as in [11] and [12], we require that they hold after being averaged over time along all the trajectories. Because of this time average along trajectories, it is not always true that our Bendixson criterion is robust under small C^1 perturbations of f. We introduce the notion of robustness of a Bendixson criterion under *local* C^1 perturbations of f in the sense that it is also satisfied by g which is C^1-close to f and differs from f only near a point. We prove that our Bendixson criterion is robust in this weaker sense. Using a local version of Pugh's closing lemma [7], we develop the theory of [12] under weaker conditions.

For autonomous systems which possess the Poincaré–Bendixson property, a different method for proving global stability was recently used in [1] for a planar system associated with a chemostat model and in [13] for a three-dimensional competitive system arising from an epidemiological model. In this case, the key step is to rule out periodic trajectories. This was accomplished by proving that periodic trajectories are orbitally asymptotically stable whenever they exist using the stability criterion of Poincaré for planar systems (as in [1]) and its higher-dimensional generalizations (as in [13]) developed in [17].

The present paper is arranged as follows: in the next section, we establish the general framework; in §3, we introduce our Bendixson criterion in Theorem 3.1 and prove a new global-stability result in Theorem 3.5; in §4, as an example, we consider a global-stability problem arising in an epidemiological model.

2. A general principle for global stability. We begin by formulating the local version of the C^1 closing lemma of Pugh as in [7]. Let $|\cdot|$ denote a vector norm on $\mathbf{R}^n$ and the operator norm which it induces for linear mappings from $\mathbf{R}^n$ to $\mathbf{R}^n$. The distance between two functions f, $g \in C^1(D \to \mathbf{R}^n)$ such that $f - g$ has compact support is

$$|f-g|_{C^1} = \sup\left\{|f(x)-g(x)| + \left|\frac{\partial f}{\partial x}(x) - \frac{\partial g}{\partial x}(x)\right| \; : \; x \in D\right\}.$$

Here and throughout the paper, $\frac{\partial f}{\partial x}$ denotes the Jacobian matrix of a mapping f. A function $g \in C^1(D \to \mathbf{R}^n)$ is called a C^1 *local ϵ-perturbation* of f at $x_0 \in D$ if there exists an open neighbourhood U of x_0 in D such that the support $\text{supp}(f-g) \subset U$ and $|f-g|_{C^1} < \epsilon$. For such g, we consider the corresponding differential equation

$$x' = g(x). \tag{2.1}$$

A point $x_0 \in D$ is *wandering* for (1.1) if there exists a neighbourhood U of x_0 and $T > 0$ such that $U \cap x(t, U)$ is empty for all $t > T$. Thus, for example, any equilibrium, alpha limit point, or omega limit point is nonwandering.

LEMMA 2.1. *Let $f \in C^1(D \to \mathbf{R}^n)$. Suppose that x_0 is a nonwandering point for* (1.1) *and that $f(x_0) \neq 0$. Then, for each neighbourhood U of x_0 and $\epsilon > 0$, there exists a C^1 local ϵ-perturbation g of f at x_0 such that*

(1) $\text{supp}\,(f-g) \subset U$ *and*

(2) *the system* (2.1) *has a nonconstant periodic solution whose trajectory passes through x_0.*

A *Bendixson criterion* for (1.1) is a condition satisfied by f which precludes the existence of nonconstant periodic solutions to (1.1). A Bendixson criterion is said to be *robust under C^1 local perturbations of f at x_0* if, for each sufficiently small $\epsilon > 0$ and neighbourhood U of x_0, it is also satisfied by each C^1 local ϵ-perturbations g such that $\text{supp}(f-g) \subset U$.

Given in the following are some examples of Bendixson criteria.

(1) When $n = 2$, $D = \mathbf{R}^2$, the classical result of Bendixson states that if

$$\text{div}(f) < 0 \quad \text{in} \quad \mathbf{R}^2, \tag{2.2}$$

then (1.1) has no nonconstant periodic solutions. Bendixson's criterion (2.2) was later generalized to the Dulac criterion

$$\text{div}(\alpha f) < 0, \tag{2.3}$$

where $x \mapsto \alpha(x)$ is some scalar-valued function. Conditions (2.2) and (2.3) can be replaced by $\operatorname{div}(f) > 0$ and $\operatorname{div}(\alpha f) > 0$, respectively, so that it is not the sign but having constant sign throughout D that is important.

(2) Let W be the Euclidean unit ball in $\mathbf{R}^2$ and let $\overline{W}$ and ∂W be its closure and boundary, respectively. If $D \subset \mathbf{R}^n$, a function $\varphi \in \operatorname{Lip}(\overline{W} \to D)$ will be described as a *simply connected rectifiable* 2*-surface in* D; a function $\psi \in \operatorname{Lip}(\partial W \to D)$ is a *closed rectifiable curve in* D and will be called *simple* if it is one to one. Let $|\cdot|$ denote a vector norm in $\mathbf{R}^N$ as well as the matrix norm which it induces for $N \times N$ matrices. The *Lozinskiĭ measure* $\mu(E)$ of a $N \times N$ matrix E with respect to the norm $|\cdot|$ is defined as

$$\mu(E) = \lim_{h \to 0+} \frac{|I + hE| - 1}{h}$$

(see [3, p. 41]). Lozinskiĭ measures have been used for estimation of eigenvalues of matrices. They also arise in the stability analysis of linear differential systems when certain vector norm of solutions are used as Lyapunov functions. Readers are refered to [3] for their properties and applications. Consider a nonsingular $\binom{n}{2} \times \binom{n}{2}$ matrix-valued function $x \mapsto A(x)$ which is C^1 in D and a vector norm $|\cdot|$ on $\mathbf{R}^{\binom{n}{2}}$. Let μ be the Lozinskiĭ measure with respect to $|\cdot|$. Under assumptions (H_1) and (H_2), it is proved in [11] that if

$$\mu\left(A_f A^{-1} + A\frac{\partial f}{\partial x}^{[2]} A^{-1}\right) \leq -\delta < 0 \quad \text{on} \quad K, \tag{2.4}$$

then no simple closed rectifiable curve in D can be invariant with respect to (1.1). Here $A_f = (DA)(f)$ or, equivalently, A_f is the matrix obtained by replacing each entry a_{ij} in A by its directional derivative in the direction of f, $\frac{\partial a_{ij}}{\partial x}^* f$, and $\frac{\partial f}{\partial x}^{[2]}$ is the second additive compound matrix of $\frac{\partial f}{\partial x}$ (see [15], [17]). For readers unfamiliar with the Lozinskiĭ measure, the condition (2.4) is equivalent to assuming that $V(x, y) = |A(x)y|$ is a Lyapunov function whose derivative with respect to the $n + \binom{n}{2}$-dimensional system

$$\frac{dx}{dt} = f(x), \qquad \frac{dy}{dt} = \frac{\partial f}{\partial x}^{[2]}(x)\, y$$

is negative definite. It rules out not only periodic trajectories but also homoclinic trajectories and heteroclinic loops since each case gives rise to a simple closed rectifiable invariant curve.

Setting $A = I$ in (2.4) leads to the following condition:

$$\mu\left(\frac{\partial f}{\partial x}^{[2]}\right) < 0, \tag{2.5}$$

which was first obtained in [17]. If the norm $|\cdot|$ is such that $|y| = |y^* y|^{\frac{1}{2}}$, then calculation of the Lozinskiĭ measure μ in (2.5) according to [2] or [17] yields

$$\lambda_1 + \lambda_2 < 0, \tag{2.6}$$

where $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n$ are eigenvalues of $\frac{1}{2}(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial x}^*)$, a condition which was first established in [22]. Note that when $n = 2$, condition (2.5) is the classical Bendixson criterion. The criterion (2.4) provides the flexibility of a choice of $\binom{n}{2} \times \binom{n}{2}$ arbitrary functions in addition to the choice of vector norms $|\cdot|$ in deriving suitable conditions.

(3) Let $x \mapsto V(x)$ be a scalar-valued function which is C^1 in D. Then the condition

$$\frac{\partial V}{\partial x} f(x) < 0 \quad \text{if} \quad f(x) \neq 0 \tag{2.7}$$

is a Bendixson criterion since $V(x)$ is strictly decreasing along each solution of (1.1). Such a function is usually called a *global Lyapunov function* for (1.1).

Suppose that f satisfies a Bendixson criterion which is robust under C^1 local perturbations of f at all nonwandering points of (1.1) which are not equilibria. Then, for each C^1 local ϵ-perturbation g of f at such a nonwandering point, when ϵ is sufficiently small, (2.1) can not have any nonconstant periodic solutions. Therefore, Lemma 2.1 implies that every nonequilibrium point of (1.1) must be wandering. We thus have the following result.

PROPOSITION 2.2. *Suppose a Bendixson criterion for* (1.1) *is robust under* C^1 *local perturbations of* f *at all nonequilibrium nonwandering points to* (1.1). *Then every nonequilibrium point of* (1.1) *is wandering.*

Suppose $D = \mathbf{R}^n$ and all solutions to (1.1) are forwardly bounded. Then for each $x_0 \in \mathbf{R}^n$, $\omega(x_0)$ is nonempty and compact. If we assume that (1.1) has a unique equilibrium $\bar{x}$ in $\mathbf{R}^n$, then the conditions of Proposition 2.2 imply that $\omega(x_0) = \bar{x}$ for all $x_0 \in \mathbf{R}^n$. If $\bar{x}$ is also stable, then it is globally stable with respect to D. This provides a solution to the global-stability problem.

THEOREM 2.3 (global-stability principle). *Assume that*

(1) $D = \mathbf{R}^n$ *and all solutions to* (1.1) *are forwardly bounded;*

(2) $\bar{x} \in \mathbf{R}^n$ *is the unique equilibrium of* (1.1) *in* $\mathbf{R}^n$; *and*

(3) (1.1) *satisfies a Bendixson criterion that is robust under* C^1 *local perturbations of* f *at each nonwandering point* x_1 *for* (1.1) *such that* $f(x_1) \neq 0$.

Then $\bar{x}$ *is globally stable in* $\mathbf{R}^n$ *provided it is stable.*

If $D \subset \mathbf{R}^n$ is an open subset, results like Theorem 2.3 also hold under the assumption (H_2) that D contains a compact absorbing set K. In this case, the trajectory of each solution to (1.1) eventually enters and remains in K; it does not approach the boundary of D. Condition (3) of Theorem 2.3 implies that its omega limit set is the singleton $\{\bar{x}\}$. Therefore, we have the following local version of Theorem 2.3.

THEOREM 2.4. *Suppose that assumptions* (H_2) *and* (H_3) *hold and that* (1.1) *satisfies a Bendixson criterion that is robust under* C^1 *local perturbations of* f *at all nonequilibrium nonwandering points for* (1.1). *Then* $\bar{x}$ *is globally asymptotically stable with respect to* D *provided it is stable.*

In many cases, a Bendixson criterion would imply that the unique equilibrium $\bar{x}$ is locally stable. This is the case for conditions (2.4) and (2.7). The following result, which contains the classical global-stability result of Lyapunov (see [5]), was proved in [12].

THEOREM 2.5. *Under assumptions* (H_1), (H_2), *and* (H_3), $\bar{x}$ *is globally asymptotically stable in* D *provided that either* (2.4) *or* (2.7) *holds.*

Remark. Another generalization of the global stability result of Lyapunov is LaSalle's invariance principle, [10, Chap. 2, Thm. 6.4], in which properties of limit sets are obtained when (2.7) is replaced by the weak inequality $\frac{\partial V}{\partial x} f(x) \leq 0$ in D. For discussions on the relation of LaSalle's result with autonomous convergence theorems, we refer the reader to [12].

3. The quantity $\bar{q}_2$.

In this section, we develop some new Bendixson criteria which are robust under local C^1 perturbations. Assume that (1.1) has a compact absorbing set $K \subset D$. Then every solution $x(t, x_0)$ of (1.1) exists for all $t > 0$. The following quantities are well defined:

$$\bar{q}_2 = \limsup_{t\to\infty} \sup_{x_0\in K} \frac{1}{t}\int_0^t \mu(B(x(s,x_0)))\,ds, \tag{3.1}$$

where

$$B = A_f A^{-1} + A\frac{\partial f}{\partial x}^{[2]} A^{-1} \tag{3.2}$$

and $x \mapsto A(x)$ is a $\binom{n}{2} \times \binom{n}{2}$ matrix-valued function as in (2.4).

Let $\psi \in \mathrm{Lip}(\partial W \to D)$ be a simple closed rectifiable curve in D. Then

$$\Sigma(\psi, D) = \{\varphi \in \mathrm{Lip}(\overline{W} \to D) \ : \ \varphi(\partial W) = \psi(\partial W)\}$$

is nonempty since D is simply connected. Define a functional $\mathcal{S}$ on $\Sigma(\psi, D)$ by

$$\mathcal{S}\varphi = \int_{\overline{W}} \left| A(\varphi)\,\frac{\partial\varphi}{\partial u_1} \wedge \frac{\partial\varphi}{\partial u_2} \right|. \tag{3.3}$$

From Proposition 2.2 of [11] and the fact that $|A^{-1}(x)|$ is uniformly bounded for x in any compact subset of D, for each compact $F \subset D$, there exists $\delta > 0$ such that

$$\mathcal{S}\varphi \geq \delta \tag{3.4}$$

for all $\varphi \in \Sigma(\psi, D)$ such that $\varphi(\overline{W}) \subset F$. Let $\varphi_t = x(t,\varphi)$. Then $y_i(t) = \frac{\partial\varphi_t}{\partial u_i}$, $i = 1, 2$, are solutions of the linear variational equation of (1.1)

$$y'(t) = \frac{\partial f}{\partial x}(\varphi_t(u))\,y(t) \tag{3.5}$$

and $z(t) = \frac{\partial\varphi_t}{\partial u_1} \wedge \frac{\partial\varphi_t}{\partial u_2}$ a solution of the second compound equation of (3.5) (see [15], [17]),

$$z'(t) = \frac{\partial f}{\partial x}^{[2]}(\varphi_t(u))\,z(t). \tag{3.6}$$

Straightforward differentiation shows that $w(t) = A(\varphi_t)\,\frac{\partial\varphi_t}{\partial u_1} \wedge \frac{\partial\varphi_t}{\partial u_2}$ satisfies the differential equation $w'(t) = B(\varphi_t(u))\,w(t)$ with B given in (3.2). Suppose $\bar{q}_2 < 0$. Let $2\epsilon_0 = -\bar{q}_2 > 0$. Then there exists $T > 0$ such that, for $t > T$ and $x_0 \in K$,

$$\int_0^t \mu(B(x(s,x_0)))ds \leq -\epsilon_0\, t.$$

From a property of Lozinskiĭ measure,

$$\begin{aligned}
\mathcal{S}\varphi_t &= \int_{\overline{W}} \left| A(\varphi_t)\,\frac{\partial\varphi_t}{\partial u_1} \wedge \frac{\partial\varphi_t}{\partial u_2} \right| \\
&\leq \int_{\overline{W}} \left| A(\varphi)\frac{\partial\varphi}{\partial u_1} \wedge \frac{\partial\varphi}{\partial u_2} \right| \exp\left(\int_0^t \mu(B(\varphi_s(u))\,ds\right) \\
&\leq \mathcal{S}\varphi\, \exp(-\epsilon_0\, t).
\end{aligned}$$

(see [3, p. 41]). Therefore, $\mathcal{S}\varphi_t \to 0$ as $t \to \infty$. This contradicts (3.4) if ψ is invariant with respect to (1.1) since in this case, $\varphi_t \in \Sigma(\psi, D)$ and $\varphi_t(\overline{W}) \subset K$ for all sufficiently large t. We thus have established the following result.

THEOREM 3.1. *Under assumptions* (H_1) *and* (H_2), *if*

$$\bar{q}_2 < 0, \tag{3.7}$$

then no simple closed rectifiable curve in D can be invariant with respect to (1.1). *In particular,* (3.7) *is a Bendixson criterion for* (1.1).

Remarks. (1) When $A = I$ and $|\cdot|$ is chosen as the euclidean norm, the corresponding $\bar{q}_2$ is related to a quantity q_2 defined by Temam ([23, p. 277]) in the context of evolution equations in an infinite-dimensional Hilbert space. Temam defines q_2 over a compact invariant set, whereas $\bar{q}_2$ is defined over a compact absorbing set. Suppose K is a compact absorbing set in D. Then its omega limit set $F = \omega(K)$ is the maximal compact invariant set in D, which is usually called the *global attractor* of (1.1) in D. Suppose q_2 is defined over F. Then it is proved in [23, Chap. V, Prop. 2.1 and Thm. 3.3] that $q_2 < 0$ implies that the Hausdorff dimension of F is less than two. By a result of Smith [22, Thm. 5], E contains no simple closed piecewise smooth invariant curves. In particular, (1.1) has no nonconstant periodic solutions. This shows that $q_2 < 0$ is a Bendixson criterion. Since the global attractor E is not necessarily preserved under a local C^1 perturbation of (1.1) at a nonwandering point, the criterion $q_2 < 0$ may not be robust under such perturbations.

(2) Condition (3.7) is clearly implied by (2.4).

Let $x_0 \in D$ be a nonwandering point such that $f(x_0) \neq 0$. Then, for each sufficiently small neighbourhood U of x_0, there exists $t_1 > 0$ such that $x(t_1, U) \cap U = \emptyset$, and $x(t, U) \cap U \neq \emptyset$ for some $t > t_1$. The following quantities are then well defined.

$$\begin{aligned}\tau(U;\ x_0) = \inf\{\, t > 0\ :\ & x(t,U) \cap U \neq \emptyset, \\ & \text{and } \exists\ t_1 < t \text{ such that } x(t_1, U) \cap U = \emptyset\,\}\end{aligned}$$

and

$$\tau(x_0) = \sup\{\,\tau(U;\ x_0)\ :\ U \text{ is a sufficiently small neighbourhood of } x_0\}; \tag{3.8}$$

when x_0 is an equilibrium, $\tau(x_0)$ is defined to be zero. We call $\tau(x_0)$ the *minimum return time* at the nonwandering point x_0. It follows from the continuous dependence on initial conditions that x_0 is an equilibrium if and only if $\tau(x_0) = 0$. In fact, the following is true.

LEMMA 3.2. *Let x_0 be nonwandering. A solution $x(t, x_0)$ to* (1.1) *is periodic if and only if $\tau(x_0)$ is finite, in which case $\tau(x_0)$ is the minimum period.*

Proof. From the definition, if $\tau(x_0) < \infty$, there exist sequences $x_k \to x_0$, $t_k \to \tau(x_0)$ ($k \to \infty$) such that $x(t_k, x_{2k}) = x_{2k+1}$, which implies that $x(t, x_0)$ is a periodic solution of period $\tau(x_0)$. Thus the least period T satisfies $0 \leq T \leq \tau(x_0)$. Conversely, if $x(t, x_0)$ is a periodic solution of period T, then $\tau(U, x_0) \leq T$ for all sufficiently small neighbourhoods U of x_0 since $x(T, x_0) = x_0 \in U$. Thus $\tau(x_0) \leq T$. The lemma follows from these two observations. □

PROPOSITION 3.3. *Suppose $\tau(x_0) = +\infty$. Then the condition $\bar{q}_2 < 0$ is robust under C^1 local perturbations of f at x_0.*

Proof. Let $\delta = -\bar{q}_2 > 0$. Since K is absorbing, there exists $T > 1$ such that $x(t, K) \subset K$ if $t > T$ and

$$\int_{t_2}^{t_1} \mu\left(B(x(s, x_1))\right) ds \leq -\frac{\delta(t_1 - t_2)}{2} \tag{3.9}$$

for all $t_1, t_2 \geq 0$ such that $t_1 - t_2 > T$ and all $x_1 \in K$. The assumption $\tau(x_0) = +\infty$ implies that $f(x_0) \neq 0$ and $\tau(U; x_0) > T$ for all sufficiently small neighbourhoods U

of x_0. Let Π be a $n-1$-dimensional transversal to the vector $f(x_0)$ at x_0 and U_1 be a sufficiently small ball in Π centered at x_0. Consider the flow box

$$\Sigma = \{x(t, U_1) \ : \ -\alpha \leq t \leq \alpha\}$$

generated by the evolution of the ball $U_1 \subset \Pi$ along the solutions of (1.1) for a small time interval $[-\alpha, \alpha]$ (see Figure 1). Let $\Gamma_+ = x(\alpha, U_1)$ and $\Gamma_- = x(-\alpha, U_1)$. By taking the ball $U_1 \subset \Pi$ and $\alpha > 0$ sufficiently small, we can ensure that all solutions of (1.1) starting in Σ leave Σ and that $\tau(\Sigma; x_0) > T$. As a consequence, each trajectory starting at Γ_+ leaves $\overline{\Sigma}$ and returns to Γ_-, if it ever returns, at a time greater than T.

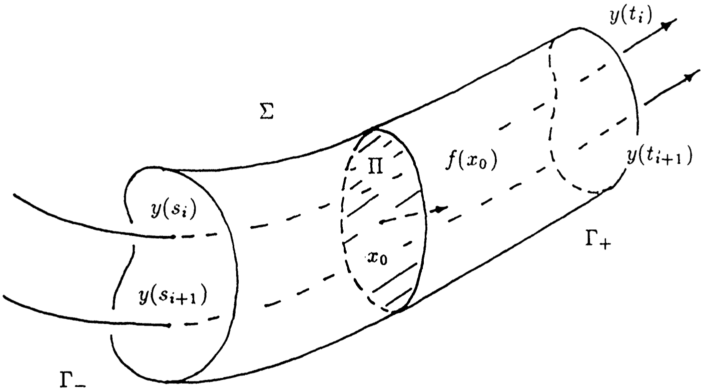

FIG. 1.

Let g be a C^1 local ϵ-perturbation of f at x_0 such that $\text{supp}(f-g) \subset \Sigma$. Consider the differential equation (2.1). K is also absorbing for (2.1) if Σ is sufficiently small since f and g agree on $D \backslash \Sigma$. Let B^f and B^g denote the matrix B defined in (3.2) and $\overline{q}_2(f)$ and $\overline{q}_2(g)$ the quantity $\overline{q}_2$ in (3.1) for f and g, respectively. If the trajectory of a solution $y(t, y_0)$ to (2.1) does not intersect Σ after a certain time, then it coincides with the trajectory of a solution to (1.1) for sufficiently large t. There exists $\bar{t} > 0$ such that no solution of (1.1) and (2.1) remains in $\overline{\Sigma}$ for a time interval greater than $\bar{t}$. For such a solution, it follows from (3.9) that

$$\frac{1}{t}\int_0^t \mu\left(B^g(y(s, y_0))\right) ds \leq -\frac{\delta}{4}.$$

Suppose the trajectory of $y(t, y_0)$ intersects Σ infinitely often. We may assume that $y_0 \in \Gamma_+ \cap K$. Let $t_0 = 0$ and

$$T < s_1 < t_1 < s_2 < t_2 < \cdots < s_n < t_n < s_{n+1} < \cdots$$

be a sequence such that

(i) s_i and t_i are the successive time $y(t, y_0)$ intersects Γ_- and Γ_+, respectively, when it returns to Σ,

(ii) $y(t, y_0) \in \Sigma$, $s_i \leq t \leq t_i$, for each $i \geq 1$,

(iii) $y(t, y_0) \notin \Sigma$, $t_i < t < s_{i+1}$ for each $i \geq 0$.

Then we have

(iv) $t_i - s_i \leq \bar{t}$ for each $i \geq 1$,

(v) $s_{i+1} - t_i > T$ for each $i \geq 0$,

(vi) $y(t, y_0)$ coincides with the solution $x(t, y_i)$ of (1.1) for $t_i < t < s_{i+1}$, where $y_i = y(t_i, y_0)$ for each $i \geq 0$ (see Figure 1).

Since $|f-g|_{C^1} < \epsilon$, we may choose ϵ sufficiently small that

$$|\mu\left(B^f(x)\right) - \mu\left(B^g(y)\right)| < \frac{\delta}{4\bar{t}}$$

for x, y in Σ. Therefore, for each $i \geq 0$,

(3.10)

$$\int_{t_i}^{t_{i+1}} \mu\left(B^g(y(s,y_0))\right) ds = \int_{t_i}^{t_{i+1}} \mu\left(B^f(x(s,y_i))\right) ds + $$

$$\int_{t_i}^{t_{i+1}} \left[\mu\left(B^f(x(s,y_i))\right) - \mu\left(B^g(y(s,y_0))\right)\right] ds$$

$$\leq -\frac{\delta}{2}\,(t_{i+1}-t_i) + (t_{i+1}-s_{i+1})\,\frac{\delta}{4\bar{t}}$$

$$\leq -\frac{\delta}{2}\,(t_{i+1}-t_i) + \frac{\delta}{4} \leq -\frac{\delta}{4}\,(t_{i+1}-t_i)$$

since $t_{i+1}-t_i \geq T > 1$. Thus for all sufficiently large t, $t_n < t \leq t_{n+1}$ for some n, and

$$\frac{1}{t}\int_0^t \mu\left(B^g(y(s,y_0))\right) ds = \frac{1}{t}\int_0^{t_n} \mu(B^g) + \frac{1}{t}\int_{t_n}^{t} \mu(B^g)$$

$$= \frac{1}{t}\sum_{i=0}^{n-1}\int_{t_i}^{t_{i+1}} \mu(B^g) + \frac{1}{t}\int_{t_n}^{t} \mu(B^g)$$

$$\leq -\frac{\delta}{4}\frac{1}{t}\sum_{i=0}^{n-1}(t_{i+1}-t_i) + \frac{1}{t}\int_{t_n}^{t} \mu(B^g)$$

$$\leq -\frac{\delta}{4}\frac{t_n}{t} + \frac{1}{t}\int_{t_n}^{t} \mu\left(B^g\right).$$

If $t-t_n > T$, then, as in (3.10), $\frac{1}{t}\int_{t_n}^{t} \mu(B^g) < -\frac{\delta}{4}\frac{t-t_n}{t}$. Therefore, in this case,

$$\frac{1}{t}\int_0^t \mu(B^g) \leq -\frac{\delta}{4}.$$

If $t-t_n \leq T$, then $\frac{t-t_n}{t} \leq \frac{T}{t}$ and thus $\frac{t_n}{t} \geq 1-\frac{T}{t} > \frac{1}{2}$ when t is sufficiently large. Hence, in this case,

$$\frac{1}{t}\int_0^t \mu(B^g) < -\frac{\delta}{4}\frac{t_n}{t} + \frac{t-t_n}{t}\max_{x\in K}\mu(B^g(x)) < -\frac{\delta}{16}.$$

Therefore, for sufficiently large t and for $y_0 \in K$,

$$\frac{1}{t}\int_0^t \mu\left(B^g(y(s,y_0))\right) ds < -\frac{\delta}{16},$$

which leads to $\bar{q}_2(g) < 0$, completing the proof of the lemma. □

By Theorem 2.4, the results established in Theorem 3.1 and Proposition 3.3 imply that the global stability of the unique equilibrium $\bar{x}$ is equivalent to its local stability under condition (3.7). The following result is in the spirit of Proposition 2.4 in [12]; it deals with the asymptotic behaviour of solutions to (1.1) near an equilibrium under condition (3.7) when multiple equilibria are allowed.

PROPOSITION 3.4. *Under assumptions* (H_1) *and* (H_2), *if* $\bar{q}_2 < 0$, *then the dimension of the stable manifold of any equilibrium is at least* $(n-1)$; *if an equilibrium is not isolated, then its stable manifold has dimension* $(n-1)$ *and it has a centre manifold of dimension one which contains all nearby equilibria.*

Proof. Observe that at an equilibrium x_1, $\bar{q}_2 < 0$ implies

$$\mu\left(A\frac{\partial f^{[2]}}{\partial x}A^{-1}\right) < 0$$

since $f(x_1) = 0$ implies $A_{f(x_1)}(x_1) = 0$. This is inequality (8) in [12], and the rest of the proof is the same as the corresponding part in the proof of Proposition 2.4 in [12]. □

THEOREM 3.5. *Under assumptions* (H_1), (H_2), *and* (H_3), *the unique equilibrium* $\bar{x}$ *is globally stable in* D *if* $\bar{q}_2 < 0$.

Proof. From Theorems 2.4 and 3.1 and Proposition 3.3, it remains to prove the local stability of $\bar{x}$. Assume the contrary. Then $\bar{x}$ is both the omega limit point and alpha limit point of a homoclinic trajectory, which gives rise to a simple closed rectifiable curve γ whose existence is precluded by $\bar{q}_2 < 0$ from Theorem 3.1. The proof for the rectifiability of γ is the same as that given in the proof of Corollary 2.6 in [12]. The key to that proof was the local structure of solutions to (1.1) near equilibria established in Proposition 3.4. □

Remark. In the presence of multiple equilibria, it was proved in [12] and [22] that every nonempty alpha and and omega limit set is a single equilibrium under any of the Bendixson criteria (2.4), (2.6), and (2.7). Results of this type are called *autonomous convergence theorems.* The main ingredients in the proof given in [12] are the C^1 robustness of the Bendixson criterion, a result like Proposition 3.4, and the center manifold theorem (see [4]). Therefore, the same result holds under assumptions (H_1) and (H_2) and our weaker condition $\bar{q}_2 < 0$.

4. Example: An epidemiological model.

Let S, E, I, and R denote the susceptible, exposed, infectious, and recovered fractions in a population. A one-population *SEIRS* model for the spread of an infectious disease in the population is described by the following system of differential equations:

$$\begin{aligned} S' &= -\lambda SI + \nu - \nu S + \delta R, \\ E' &= \lambda IS - (\epsilon + \nu)E, \\ I' &= \epsilon E - (\gamma + \nu)I, \\ R' &= \gamma I - (\delta + \nu)R. \end{aligned} \tag{4.1}$$

Individuals are susceptible, then exposed (in the latent period), then infectious, then recovered with temporary immunity, and then susceptible again when the immunity is lost. The parameter δ describes the rate that the recovered population loses immunity, ϵ is the rate that the exposed population becomes infectious, and γ denotes the rate that the infectious population becomes recovered. There is no disease-related death. The natural death rate and birth rate are assumed to be equal (denoted by ν), and thus $S + E + I + R = 1$ for all time. All parameters are nonnegative. The case $\nu = 0$ corresponds to no death and no birth. If $\delta = 0$, infected individuals recover with permanent immunity; that is, once recovered, they will not become susceptible again. Note that ϵ is assumed to be positive since we consider an infectious disease. We also assume that $\nu + \delta > 0$; otherwise, the model (4.1) is not interesting in that all the population will eventually be recovered and there will be no susceptibles.

The model (4.1) has been extensively studied in the literature; see [14] and its references. It is known that the qualitative behaviour of (4.1) is determined by the contact number $\sigma = \lambda\epsilon/(\epsilon+\nu)(\gamma+\nu)$, which satisfies a threshold condition. If $\sigma \leq 1$, the disease-free equilibrium $P_0 = (1,0,0,0)$ is the only equilibrium and is globally asymptotically stable in the feasible region $\Gamma = \{(S,E,I,R) \in \mathbf{R}^4_+ \ : \ S+E+I+R = 1\}$; namely, the disease dies out. If $\sigma > 1$, then P_0 loses its stability and a unique endemic equilibrium P^* emerges in the interior of Γ and is locally asymptotically stable. It has been conjectured (see [14]) that P^* is globally asymptotically stable in the interior of Γ when $\sigma > 1$ such that the disease remains endemic and approaches a unique endemic equilibrium for all initial configurations.

This conjecture was proved to be true for the case $\delta = 0$ in [13]. A crucial part of the proof is that, when $\delta = 0$, (4.1) can be reduced to a three-dimensional competitive system. Since this property of (4.1) may not be preserved for $\delta > 0$, the method in [13] does not apply to the case $\delta > 0$. In this section, we apply the theory developed in previous sections to show that this conjecture is also true for small δ.

Using $R = 1 - S - E - I$, we can reduce (4.1) to the following three-dimensional system:

$$\begin{aligned} S' &= -\lambda SI + \nu - \nu S + \delta(1 - S - E - I), \\ E' &= \lambda SI - (\epsilon+\nu)E, \\ I' &= \epsilon E - (\gamma+\nu)I, \end{aligned} \tag{4.2}$$

and transform the simplex $\Gamma \subset \mathbf{R}^4_+$ to the following convex region in $\mathbf{R}^3_+$:

$$T = \{(S,E,I) \in \mathbf{R}^3_+ \ : \ 0 \leq S+E+I \leq 1\}.$$

The disease-free equilibrium P_0 becomes $(1,0,0)$ and the endemic equilibrium P^* becomes an interior equilibrium in T. For simplicity of notation, we will denote these two equilibria of (4.2) by P_0 and P^*. The following result can be proved in the same way as in §3 of [14].

PROPOSITION 4.1. *If $\sigma \leq 1$, P_0 is globally asymptotically stable in T. If $\sigma > 1$, P_0 is unstable and the trajectories sufficiently close to P_0 leave P_0 except those on the S-axis which approach P_0 along this axis.*

In the following, we apply Theorem 3.5 to (4.2) to show that P^* is globally stable in the interior of T when $\sigma > 1$.

To show the existence of a compact set which is absorbing in the interior of T is equivalent to proving that (4.2) is uniformly persistent, which means that there exists $c > 0$ such that every solution $(S(t), E(t), I(t))$ of (4.2) with $(S(0), E(0), I(0))$ in the interior of T satisfies

$$\liminf_{t\to\infty} |(S(t), E(t), I(t))| \geq c$$

(cf. [2]). Uniform persistence may also be defined for discrete dynamical systems or iterated maps (see [9]). It can be proved that (4.2) is uniformly persistent if and only if the time-one map associated with (4.2) is uniformly persisitent in the sense of [9].

A compact invariant set $F \subset T$ of (4.2) is said to be *isolated* if there is a neighbourhood $N \subset T$ of F such that F is the maximal invariant subset of N. The *stable set*

F^s of F is the set of $P \in T$ such that the omega limit set $\omega(P) \subset F$. These concepts can be similarly defined for the time-one map associated with (4.2) (see [9]). Using Theorem 4.1 of [9], we can prove the following result.

PROPOSITION 4.2. *System* (4.2) *is uniformly persistent in* T *when* $\sigma > 1$.

Proof. We show that, when $\sigma > 1$, the time-one map associated with (4.2) satisfies the conditions of Theorem 4.1 of [9], namely, (i) the maximal compact invariant set M in the boundary of T is isolated and (ii) the stable set M^s of M is contained in the boundary of T. It can be shown that the time-one map of (4.2) satisfies (i) and (ii) if (4.2) does. Since $M = \{P_0\}$, Proposition 4.1 implies that, when $\sigma > 1$, M^s is contained in the S-axis and thus in the boundary of T. It also implies that M^s is isolated in T. Therefore, the proposition follows from Theorem 4.1 of [9]. □

THEOREM 4.3. *Assume that* $\sigma > 1$. *Then there exists* $\bar{\delta} > 0$ *such that the unique interior equilibrium* P^* *is globally stable in the interior of* T *when* $\delta \leq \bar{\delta}$.

Proof. By Proposition 4.2, when $\sigma > 1$, there exists a compact set K in the interior of T which is absorbing for (4.2). The proof of the theorem consists of choosing a suitable vector norm $|\cdot|$ in $\mathbf{R}^3$ and a 3×3 matrix-valued function $A(x)$ so that the quantity $\bar{q}_2$ defined in (3.1) is negative. We set A as the following diagonal matrix:

$$A(S,E,I) = \operatorname{diag}\left(1,\ \frac{E}{I},\ \frac{E}{I}\right). \tag{4.3}$$

Then A is C^1 and nonsigular in the interior of T. Let f denote the vector field of (4.2). Then

$$A_f A^{-1} = \operatorname{diag}\left(0,\ \frac{I}{E}\left(\frac{E}{I}\right)_f,\ \frac{I}{E}\left(\frac{E}{I}\right)_f\right).$$

The second compound matrix $J^{[2]}$ of the Jacobian matrix $J = \frac{\partial f}{\partial x}$ can be calculated as follows:

$$J^{[2]} = \begin{bmatrix} -\lambda I - \delta - \epsilon - 2\nu & \lambda S & \lambda S + \delta \\ \epsilon & -\lambda I - \delta - \gamma - 2\nu & -\delta \\ 0 & \lambda I & -\epsilon - \gamma - 2\nu \end{bmatrix}$$

(see the appendix of [12]). Therefore, the matrix $B = A_f A^{-1} + A J^{[2]} A^{-1}$ can be written in the following block form:

$$B = \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \tag{4.4}$$

with

$$B_{11} = -\lambda I - \delta - \epsilon - 2\nu, \quad B_{12} = \left(\frac{\lambda S I}{E},\ \frac{(\lambda S + \delta) I}{E}\right), \quad B_{21} = \left(\frac{\epsilon E}{I},\ 0\right)^*,$$

$$B_{22} = \begin{bmatrix} \frac{I}{E}\left(\frac{E}{I}\right)_f - \lambda I - \delta - \gamma - 2\nu & -\delta \\ \lambda I & \frac{I}{E}\left(\frac{E}{I}\right)_f - \epsilon - \gamma - 2\nu \end{bmatrix}.$$

The vector norm $|\cdot|$ in $\mathbf{R}^3 \cong \mathbf{R}^{\binom{3}{2}}$ is chosen as

$$|(u,v,w)| = \sup\{|u|,\ |v| + |w|\}. \tag{4.5}$$

The Lozinskiĭ measure $\mu(B)$ with respect to $|\cdot|$ can be estimated as follows (see [16] or [18]):

$$\mu(B) \le \sup\{g_1, g_2\}, \tag{4.6}$$

where

$$g_1 = B_{11} + |B_{12}| = -\lambda I - \delta - \epsilon - 2\nu + \frac{(\lambda S + \delta)I}{E}, \tag{4.7}$$

$$g_2 = \mu_1(B_{22}) + |B_{21}| \le \frac{I}{E}\left(\frac{E}{I}\right)_f - \delta - \gamma - 2\nu + \frac{\epsilon E}{I} \tag{4.8}$$

if $\delta \le \epsilon/2$. Note that $\mu_1(B_{22})$ is the Lozinskiĭ measure of the 2×2 matrix B_{22} with respect to the l_1 norm in $\mathbf{R}^2$, $|B_{12}|$ and $|B_{21}|$ are the operator norms of B_{12} and B_{21} when they are regarded as mappings from $\mathbf{R}^2$ to $\mathbf{R}$ and from $\mathbf{R}$ to $\mathbf{R}^2$, respectively, and $\mathbf{R}^2$ is endowed with the l_1 norm. Also note that since B_{11} is a scalar, its Lozinskiĭ measure with respect to any vector norm in $\mathbf{R}^1$ is equal to B_{11}. A solution $(S(t), E(t), I(t))$ to (4.2) with $(S(0), E(0), I(0))$ in the absorbing set K exists for all $t > 0$. From the equations in (4.2), we find

$$\frac{I}{E}\left(\frac{E}{I}\right)_f = \frac{E'}{E} - \frac{I'}{I} \tag{4.9}$$

and

$$\frac{\lambda S I}{E} = \frac{E'}{E} + \epsilon + \nu, \tag{4.10}$$

$$\frac{\epsilon E}{I} = \frac{I'}{I} + \gamma + \nu. \tag{4.11}$$

Relations (4.6)–(4.11) imply

$$\mu(B) \le \frac{E'}{E} - \delta - \nu + \sup\left\{\frac{\delta}{E} - \lambda I,\ 0\right\}.$$

Since (4.2) is uniformly persistent when $\sigma > 1$, there exist $c > 0$ and $T > 0$ such that $t > T$ implies

$$E(t) \ge c, \qquad I(t) \ge c, \qquad \text{and} \qquad \frac{1}{t}\log E(t) < \frac{\delta + \nu}{2}$$

for all $(S(0), E(0), I(0)) \in K$. Set $\bar{\delta} = \min\{\epsilon/2,\ \lambda c^2\}$. Then $t > T$ and $\delta < \bar{\delta}$ imply $\delta/E - \lambda I \le 0$, and thus

$$\frac{1}{t}\int_0^t \mu(B)\,dt < \log E(t) - (\delta + \nu) < -\frac{1}{2}(\delta + \nu)$$

for all $(S(0), E(0), I(0)) \in K$, which in turn implies that $\bar{q}_2 < 0$, completing the proof of Theorem 4.3. □

Acknowledgments. The final draft of this paper was completed when one of the authors (M. Y. Li) was visiting the Centre de Recherches Mathématiques (CRM) at the Université de Montréal as a NSERC postdoctoral fellow. He is grateful for the hospitality of the CRM and the support of the NSERC Postdoctoral Fellowship. The authors would like to thank the referees for their valuable suggestions that helped to improve the original manuscript.

BIFURCATION OF FIXED POINTS IN COUPLED JOSEPHSON JUNCTIONS*

M. ST. VINCENT[†]

Abstract. The fixed points of the equations describing a pair of coupled Josephson junctions are investigated and are shown to undergo an infinite number of bifurcations as parameters are varied. The bifurcation curves are then analyzed in a region of parameter space where interesting dynamical behavior is also known to occur. It is shown that the bifurcation curves fall into four one-parameter families, and the curves in each family are described. The paper concludes with a discussion of a conjectured mechanism by which simultaneous bifurcations could give rise to interesting dynamical solutions.

Key words. bifurcation, fixed point, Josephson junctions, coupled oscillators, coupled pendulums

AMS subject classification. 34C23

1. Introduction.

In this paper, we investigate the fixed points of the system

$$\ddot{\varphi}_1 + \gamma\dot{\varphi}_1 + \sin\varphi_1 + k(\varphi_1 - \varphi_2 + H) = I, \tag{1.1a}$$

$$\ddot{\varphi}_2 + \gamma\dot{\varphi}_2 + \sin\varphi_2 - k(\varphi_1 - \varphi_2 + H) = 0, \tag{1.1b}$$

which has been used to describe the behavior of a pair of coupled Josephson junctions in the current-driven case [1–3] ((1.1) also describes the behavior of a pair of damped nonlinear pendulums connected along a common axis of rotation by a linear spring, with one of them driven by a constant torque I, as stated in [2, 4]). Here γ, H, I, and k are constants, with the damping γ and coupling parameter k both positive. Following Imry and Schulman [1], we observe that the case of $I < 0$ can be transformed to $I > 0$ by replacing solutions φ_1, φ_2 by $-\varphi_1$, $-\varphi_2$, and so will also require I to be positive.

Previous work on (1.1) has focused on its dynamic behavior. Some discussion of fixed points was presented by Imry and Schulman [1], and a more comprehensive discussion of equilibria in a related system that contains the case $H = 0$ was done by Henderson, Levi, and Odeh in [6]. The results of this paper provide a thorough analysis of the fixed points of (1.1) and their bifurcations, especially in the region of weak coupling (small k), and provide support for a conjectured mechanism by which bifurcating fixed points may give rise to dynamical behavior. The interesting dynamical behavior investigated by Levi [2, 4] and Imry and Schulman [1] occurs in that region also.

In the work done here, γ and H are fixed, and we investigate the behavior of the fixed points as the parameters I and k vary. As will be seen, fixed points can occur only for $|I| < 2$, and occur for any such I whenever k is small enough. Furthermore, since the flow $(\varphi_1, \dot{\varphi}_1, \varphi_2, \dot{\varphi}_2)$ induced on $\mathbb{R}^4$ by (1.1) commutes with translation by $(2\pi, 0, 2\pi, 0)$, each fixed point has an infinite number of equivalent copies. When points of $\mathbb{R}^4$ that differ by such a translation are identified, the flow on the resulting phase space $S^1 \times \mathbb{R}^3$ has only a finite number of fixed points, and it will be shown that the number of fixed points is $O(1/k)$ as $k \to \infty$.

From the dependence of the number of fixed points on I and k, it is clear that the fixed points of (1.1) undergo a large number of bifurcations as these parameters are

* Received by the editors October 8, 1992; accepted for publication (in revised form) December 6, 1994.

[†] Department of Mathematics and Computer Science, Merrimack College, North Andover, MA 01845.

varied. As was shown by Imry and Schulman [1], these must all be static bifurcations in which a pair of fixed points merge and disappear. It will be shown here that these bifurcations are of two types: (1) those in which a sink merges with a saddle having one eigenvalue with positive real part, and (2) those in which a saddle having one eigenvalue with positive real part merges with one having two. Conditions for the occurrence of these bifurcations will be analyzed for (I,k) in the set

$$S=\left\{(I,k):0<I<2, 0<k<\min\left(\frac{1}{2}\sqrt{1-(I-1)^2},\ \frac{1}{2}\sqrt{1-I^2/4}\right)\right\},$$

allowing us to obtain bifurcation diagrams there (Figs. 2a, 2b).

The bifurcation diagrams in S make clear the existence of a countable number of points at which simultaneous bifurcations occur. This has suggested a possible connection with some of the *running periodic* solutions of (1.1). These are solutions for which $\varphi_i(t+T)=\varphi_i(t)+2m\pi$, $i=1,2$, where T is positive and m is an integer. It turns out that m must also be positive (this follows from a slight modification of an argument in [2]). These solutions are periodic in the cylindrical phase space $S^1\times\mathbb{R}^3$ but not in $\mathbb{R}^4$. Among the most interesting of these are the so-called *beating* solutions (Imry and Schulman [1] and Levi [2, 4]). These are running periodic solutions in which first one oscillator is nearly constant while the other runs through a number of oscillations, and then they exchange roles for the remainder of the period. In the two transitions the solution is for a short while nearly static. This led Kopell [5] to speculate that such solutions might arise from a pair of simultaneous sink-saddle bifurcations in which the closure of the unstable manifolds of the saddles forms a closed curve in the $S^1\times\mathbb{R}^3$ phase space, with each unstable manifold connecting the sinks. This closed curve would become the orbit of the beating solution when the fixed points merge and disappear (see Fig. 3). Support for this conjecture will be provided by demonstrating that there are a countable number of points in S at which simultaneous sink-saddle bifurcations occur, although no attempt will be made to show that the unstable manifolds ever connect the sinks. Furthermore, it will be seen that some of these bifurcations occur in the small region of S where Imry and Schulman found beating solutions and involve fixed points near the nearly static transitions in those beating solutions. It should be noted that beating solutions also occur for the systems in [6–8].

The remainder of the paper is organized as follows. Section 2 contains general results on the existence and stability of fixed points that are valid for all parameter values. In particular, it is shown that fixed points correspond to the intersection of certain horizontal lines with a closed curve C that depends on I and k. Further progress is made in §3 by restricting attention to values of (I,k) in S. This allows estimates to be obtained that make it possible to determine the shape of C (see Fig. 1), and that will be needed later. It is then shown how the character of a fixed point is determined by the location of the corresponding point on C. Section 4 contains an analysis of the bifurcation curves in S. It is shown that these bifurcation curves fall into four one-parameter families, and descriptions of the curves in each family are obtained. This is the main result of the paper and is contained in Theorem 4.2. The paper ends with a demonstration that the results obtained are consistent with the conjectures on beating solutions.

2. Existence and stability of fixed points. As previously mentioned, the analysis of (1.1) can be simplified by restricting our attention to the $S^1\times\mathbb{R}^3$ phase space. This will be done here by representing each equivalence class of fixed points by its representative $(\varphi_1,0,\varphi_2,0)$ with $\varphi_1\in[-\pi/2,3\pi/2)$. From (1.1) we see immediately

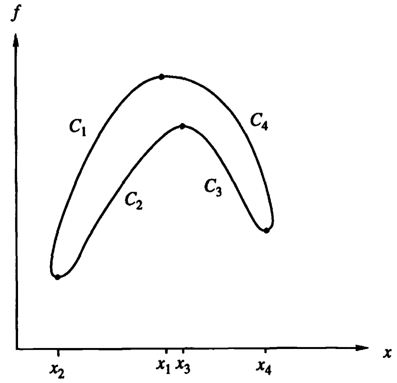

FIG. 1. *A sketch of the curve $C = C_1 \cup C_2 \cup C_3 \cup C_4$ for values of (I, k) in S with the locations of the critical points $x_1, \ldots, x_4$ indicated. Each intersection of C by a horizontal line of height $I - k(2L\pi + h)$ corresponds to an equivalence class of fixed points, each having φ_1 equal to the x-coordinate of the point on C* (mod 2π)*. Bifurcations occur when these correspond to one of the critical points.* (*Note: certain features of C have been exaggerated for purposes of illustration.*)

that $(\varphi_1, 0, \varphi_2, 0)$ will be a fixed point if and only if the constants φ_1, φ_2 satisfy

$$\sin\varphi_1 + k(\varphi_1 - \varphi_2 + H) = I,$$

$$\sin\varphi_2 - k(\varphi_1 - \varphi_2 + H) = 0,$$

which is equivalent to

$$\sin\varphi_1 + k(\varphi_1 - \varphi_2 + H) = I, \tag{2.1a}$$

$$\sin\varphi_1 + \sin\varphi_2 = I. \tag{2.1b}$$

From (2.1b), it follows that $|I| \le 2$ is necessary for the existence of fixed points, and that φ_2 must be given by either

$$\varphi_2 = \sin^{-1}(I - \sin\varphi_1) - 2L\pi \tag{2.2.1}$$

or

$$\varphi_2 = \pi - \sin^{-1}(I - \sin\varphi_1) - 2L\pi \tag{2.2.2}$$

for some integer L. Together with (2.1a), this shows that if $0 < I < 2$ and $\varphi_1 \in [-\pi/2, 3\pi/2)$, then $(\varphi_1, 0, \varphi_2, 0)$ will be a fixed point if and only if there is an integer L such that φ_1 satisfies

$$f_i(\varphi_1) = I - k(2L\pi + H) \tag{2.3.i}$$

for either $i = 1$ or $i = 2$, and φ_2 is given by the corresponding equation (2.2.i). The functions $f_i : J_I \to \mathbb{R}$ $(i = 1, 2)$ are given by

$$f_1(x) = \sin x + k[x - \sin^{-1}(I - \sin x)],$$

$$f_2(x) = \sin x + k[x + \sin^{-1}(I - \sin x) - \pi],$$

with domain $J_I = [\sin^{-1}(I-1),\ \pi - \sin^{-1}(I-1)]$. To emphasize their dependence on parameters, $f_i(x; I, k)$ will sometimes be written for $f_i(x)$.

As is readily verified, the functions $f_i(x)$ are continuous on J_I and smooth on its interior (with respect to I and k as well as x) and agree at its endpoints. Furthermore, $f_1(x) > f_2(x)$ on the interior of J_I, with $f_1'(x) \to +\infty$, $f_2' \to -\infty$ as x approaches the left endpoint and $f_1'(x) \to -\infty$, $f_2'(x) \to +\infty$ as x approaches the right endpoint. Consequently, the graphs of $f_i(x)$ together form a smooth closed curve C. As shown by (2.3), we now have the following proposition.

PROPOSITION 2.1. *Each equivalence class of fixed points corresponds to an intersection of C by a horizontal line of height $I - k(2L\pi + H)$.*

Since the horizontal lines are separated by a distance $2\pi k$ and the functions f_i have O(1) variation across J_I, (1.1) must have O($1/k$) nonequivalent fixed points as $k \to 0$, whenever $0 < I < 2$. Further results will be obtained from the shape of C, which the restriction to $(I, k) \in S$, made in the next section, will make it possible to determine (see Fig. 1).

To consider the stability of fixed points, let $\nu_i = \dot{\varphi}_i$ and rewrite (1.1) as the first-order system

$$\frac{d}{dt}\begin{pmatrix} \varphi_1 \\ \nu_1 \\ \varphi_2 \\ \nu_2 \end{pmatrix} = \begin{pmatrix} \nu_1 \\ I - k(\varphi_1 - \varphi_2 + H) - \sin\varphi_1 - \gamma\nu_1 \\ \nu_2 \\ k(\varphi_1 - \varphi_2 + H) - \sin\varphi_2 - \gamma\nu_2 \end{pmatrix}.$$

The linearization of this system about a fixed point $(\varphi_1, 0, \varphi_2, 0)$ has coefficient matrix

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ -(k+\cos\varphi_1) & -\gamma & k & 0 \\ 0 & 0 & 0 & 1 \\ k & 0 & -(k+\cos\varphi_2) & -\gamma \end{pmatrix},$$

which has eigenvalues

$$\frac{1}{2}\left(-\gamma \pm \sqrt{\gamma^2 - 4a_+}\right) \text{ and } \frac{1}{2}\left(-\gamma \pm \sqrt{\gamma^2 - 4a_-}\right),$$

where

$$a_{\pm} = k + \frac{\cos\varphi_1 + \cos\varphi_2}{2} \pm \left[\left(\frac{\cos\varphi_1 - \cos\varphi_2}{2}\right)^2 + k^2\right]^{1/2}.$$

Thus each fixed point has at least two eigenvalues with a negative real part, with the remaining eigenvalues having real parts whose signs are determined by the relative magnitudes of

$$\left|k + \frac{\cos\varphi_1 + \cos\varphi_2}{2}\right| \text{ and } \left[\left(\frac{\cos\varphi_1 - \cos\varphi_2}{2}\right)^2 + k^2\right]^{1/2}$$

and the sign of $k + (\cos\varphi_1 + \cos\varphi_2)/2$.

Now define

$$g(\varphi_1, \varphi_2) = \cos\varphi_1\cos\varphi_2 + k(\cos\varphi_1 + \cos\varphi_2)$$

as in [1], and let

$$h(\varphi_1, \varphi_2) = k + (\cos\varphi_1 + \cos\varphi_2)/2.$$

It is easily verified that $|h(\varphi_1, \varphi_2)|$ has the same relation $(>, =, <)$ to $[((\cos\varphi_1 - \cos\varphi_2)/2)^2 + k^2]^{1/2}$ as $g(\varphi_1, \varphi_2)$ has to zero, so we now have the following proposition.

PROPOSITION 2.2. *An equilibrium solution* $(\varphi_1, 0, \varphi_2, 0)$ *will be*

(i) *a sink if* $g(\varphi_1, \varphi_2) > 0$ *and* $h(\varphi_1, \varphi_2) > 0$,

(ii) *a saddle having a one-dimensional unstable manifold if* $g(\varphi_1, \varphi_2) < 0$,

(iii) *a saddle having a two-dimensional unstable manifold if* $g(\varphi_1, \varphi_2) > 0$ *and* $h(\varphi_1, \varphi_2) < 0$.

Since the equilibrium solution is structurally stable in each of the above cases, and since h cannot be zero if g is positive, bifurcations can occur only when $g(\varphi_1, \varphi_2) = 0$. In that case there will be exactly one eigenvalue with real part zero. This rules out the possibility of Hopf bifurcations, which require the existence of a fixed point having two eigenvalues on the imaginary axis. We note also that the types of equilibria described above are the only types that occur for the related systems in [6–8].

We now show that the sign of g at a fixed point can be determined by the location of the corresponding point where the curve C is intersected by a horizontal line of height $I - k(2L\pi + H)$. Since φ_2 is given by (2.2.i) when this point lies on the part of C given by the graph of f_i, we define functions $g_i : J_I \to \mathbb{R}$ $(i = 1, 2)$ by $g_1(x) = g(x, \sin^{-1}(I - \sin x))$ and $g_2(x) = g(x, \pi - \sin^{-1}(I - \sin x))$. Thus

$$g_1(x) = (\cos x)\sqrt{1 - (I - \sin x)^2} + k(\cos x + \sqrt{1 - (I - \sin x)^2}),$$

$$g_2(x) = -(\cos x)\sqrt{1 - (I - \sin x)^2} + k(\cos x - \sqrt{1 - (I - \sin x)^2}).$$

Comparison of $g_i(x)$ with $f_i'(x)$ shows that

$$(2.4) \qquad g_1(x) = f_1'(x)\sqrt{1 - (I - \sin x)^2} \text{ and } g_2(x) = -f_2'(x)\sqrt{1 - (I - \sin x)^2}$$

on the interior of J_I. Since the term under the radical is zero only at the endpoints of J_I, the sign of g at an equilibrium solution is determined by the slope at the corresponding point of C and the segment (graph of f_1 or f_2) it lies on. It is also easily verified that $g_i \neq 0$ at the endpoints of J_I for $0 < I < 2$, so we now have the next proposition.

PROPOSITION 2.3. *Bifurcations can only occur at fixed points that correspond to a point at which the curve C has a horizontal tangent.*

3. Restriction to parameter region S.

From now on we will only consider $(I, k) \in S$. This will allow us to determine the shape of C (Fig. 1). In particular, we will see that C has a horizontal tangent at four points. Bifurcations will occur only when a horizontal line of height $I - k(2L\pi + H)$ passes through one of these critical points, and the stability of nonbifurcating equilibria will be determined by which of the four segments bounded by the critical points the corresponding point of C lies on.

To begin, observe that the shape of C is determined by the way in which g_1 and g_2 change sign across J_I, as shown by (2.4). In order to understand the behavior of g_1 and g_2, we need some observations about $\cos x$ and $[1 - (I - \sin x)^2]^{1/2}$ on J_I. As a notational convenience, define $\sigma : J_I \to \mathbb{R}$ by $\sigma(x) = [1 - (I - \sin x)^2]^{1/2}$. We then have Lemma 3.1.

LEMMA 3.1. *If $(I, k) \in S$, then there are points a_i, b_i in $(\sin^{-1}(I - 1), \pi/2) \subset J_I$ and their reflections $a_i' = \pi - a_i$, $b_i' = \pi - b_i$ in $(\pi/2, \pi - \sin^{-1}(I - 1)) \subset J_I (i = 1, 2, 3)$ with $a_1 < a_2 < a_3 < b_1 < b_2 < b_3$ and $b_1 > 0$ such that*

(i) $\sigma(a_1) = k/2$, $\sigma(a_2) = k$, $\sigma(a_3) = 2k$, *and* $\sigma(a_i') = \sigma(a_i)(i = 1, 2, 3)$;

(ii) $\cos b_1 = 2k$, $\cos b_2 = k$, $\cos b_3 = k/2$, *and* $\cos b_i' = -\cos b_i (i = 1, 2, 3)$;

(iii) σ *is increasing on* $[\sin^{-1}(I-1), a_3]$ *and decreasing on* $[a_3', \pi - \sin^{-1}(I-1)]$ *with* $\sigma > 2k$ *on* (a_3, a_3');

(iv) $\cos x$ *is decreasing on* $[b_1, b_1']$ *with* $\cos x > 2k$ *on* $[\sin^{-1}(I-1), b_1)$ *and* $\cos x < -2k$ *on* $(b_1', \pi - \sin^{-1}(I-1)]$.

Proof. First, observe that σ has a critical point at $\pi/2$ and that $\sigma(\pi/2) = [1 - (I-1)^2]^{1/2}$ is greater than $2k$ since $(I, k) \in S$. Furthermore, σ is zero only at the endpoints of J_I and is symmetrical about $\pi/2$. If $1 \leq I < 2$, then σ is increasing on $[\sin^{-1}(I-1), \pi/2]$, while if $0 < I < 1$, then σ increases until it reaches its maximum value at a point of $(\sin^{-1}(I-1), \pi/2)$ and then decreases to its value at $\pi/2$. In either case, (i) and (ii) follow immediately, with $a_1 < a_2 < a_3$ all in $(\sin^{-1}(I-1), \pi/2)$.

Now observe that $2k < 1$ since $k < \sqrt{2}/3$ in S, so we can define $b_1 = \cos^{-1}(2k)$, etc. Also, $\cos x$ is decreasing on $[b_1, b_1']$ since $[b_1, b_1'] \subset (0, \pi)$, and $b_1 < b_2 < b_3$ are in $(\sin^{-1}(I-1), \pi/2)$ since $\cos(\sin^{-1}(I-1)) = [1-(I-1)^2]^{1/2}$ is greater than $2k$ in S. The inequalities in (iv) now follow easily, so (ii) and (iv) are proved.

All that remains is to show that $a_3 < b_1$. But we must have $a_3 < \sin^{-1}(I/2) < b_1$, since $\sigma(\sin^{-1}(I/2)) = \cos(\sin^{-1}(I/2)) = (1 - I^2/4)^{1/2}$ is greater than $2k$ for $(I, k) \in S$. □

We can now obtain enough information about g_1 and g_2 to determine the shape of C when $(I, k) \in S$. The results are stated in Proposition 3.2.

PROPOSITION 3.2. *If* $(I, k) \in S$, *then*

(i) f_1 *has a local maximum at a point* x_1 *in* (b_3', b_2') *and*

(ii) f_2 *has a local maximum at a point* x_3 *in* (b_2', b_1') *and a pair of local minima at* x_2 *in* (a_1, a_2) *and* x_4 *in* (a_3', a_2').

Furthermore, f_1 *and* f_2 *do not have any other critical points.*

Proof. In view of (2.4), it is sufficient to show that g_1 is positive on $[\sin^{-1}(I-1), b_3']$ and negative on $[b_2', \pi - \sin^{-1}(I-1)]$, with $g_1' < 0$ on $[b_3', b_2']$, and, similarly, that g_2 is positive on $[\sin^{-1}(I-1), a_1] \cup [b_1', a_3']$ and negative on $[a_2, b_2'] \cup [a_2', \pi - \sin^{-1}(I-1)]$, with $g_2' < 0$ on $[a_1, a_2] \cup [a_3', a_2']$ and $g_2' > 0$ on $[b_2', b_1']$.

To show that g_2 is positive on $[b_1', a_3']$, observe that $\cos x < -2k$ on $(b_1', a_3']$ and $\sigma(x) > 2k$ on $[b_1, a_3')$ from Lemma 3.1, so that $g_2(x) = (k - \frac{1}{2}\sigma(x))\cos x - (k + \frac{1}{2}\cos x)\sigma(x)$ is clearly positive on $[b_1', a_3']$. Similarly, to show that $g_2' < 0$ on $[a_1, a_2]$, observe that $g_2' = -[(k + \cos x)(I - \sin x)\cos x]/\sigma - (k - \sigma)\sin x$. Also, on $[a_1, a_2]$ we have $I - \sin x > 0$ (since σ is increasing), $k/2 \leq \sigma \leq k$, and $\cos x > 2k$. Then $I - \sin x \geq (1 - k^2)^{1/2}$ since $\sigma \leq k$, and $|\sin x| < (1 - 4k^2)^{1/2}$ since $\cos x > 2k$, so $g_2' < -[3k(1-k^2)^{1/2} 2k]/k + (k/2)(1-4k^2)^{1/2} = (k/2)(1-4k^2)^{1/2} - 6k(1-k^2)^{1/2} < 0$.

The other proofs are similar and are thus omitted. □

It can also be shown that $f_2(x_2) < f_2(x_4)$, so that f_2 takes its global minimum only at x_2. Thus the shape of C must be as indicated in Fig. 1.

The critical points divide C into four segments, which we label $C_1, \ldots, C_4$ as in Fig. 1. We now show that the stability of an equilibrium solution is completely determined by which of these segments the corresponding point of C lies on. To begin, observe that (2.4) shows that g will be positive at a fixed point if the corresponding point lies on C_1 or C_3 and will be negative if it lies on C_2 or C_4. By Proposition 2.2, this determines the nature of equilibria whose corresponding points lie on C_2 or C_4, but for the rest we also need to know the sign of h. To this end, we make use of (2.2) to define

$$h_1(x) = h(x, \sin^{-1}(I - \sin x)) = (2k + \sigma(x) + \cos x)/2$$

and

$$h_2(x) = h(x, \pi - \sin^{-1}(I - \sin x)) = (2k - \sigma(x) + \cos x)/2.$$

From Lemma 3.1 we see that h_1 is positive on $[\sin^{-1}(I-1), b_1']$ and that h_2 is positive on $[\sin^{-1}(I-1), a_3]$ and negative on $[\pi/2, \pi - \sin^{-1}(I-1)]$. Together with Proposition 2.2, this now yields Theorem 3.3.

THEOREM 3.3. *If (I,k) is in S, then an equilibrium solution $(\varphi_1, 0, \varphi_2, 0)$ will be*

(i) *a sink if the corresponding point lies on C_1,*

(ii) *a saddle having a one-dimensional unstable manifold if the corresponding point lies on C_2 or C_4,*

(iii) *a saddle having a two-dimensional unstable manifold if the corresponding point lies on C_3.*

Recalling Proposition 2.3, it is now clear that when $(I,k) \in S$, a bifurcation will occur at an equilibrium solution if and only if it corresponds to one of the critical points $x_1, \ldots, x_4$ of C.

4. Existence of bifurcation points in S. Now define functions F_i $(i = 1, 2, 3, 4)$ by

$$F_1 = f_1(x_1(I,k), I, k) - I + k(2L\pi + H),$$

$$F_i = f_2(x_i(I,k), I, k) - I + k(2L\pi + H) \quad (i = 2, 3, 4).$$

If (I,k) is in S, then a horizontal line of height $I - k(2L\pi + H)$ will pass through the critical point $x_i(I,k)$ of C if and only if $F_i = 0$ for those values of I, k, L, and H. Thus bifurcation points in S correspond to zeros of the functions F_i and, as will be seen, for any given $H \in \mathbb{R}$ each function F_i will determine a one-parameter family of bifurcation curves in S parameterized by the integer L. To analyze these curves, we need estimates for the functions F_i and their derivatives

$$\frac{\partial F_1}{\partial k} = x_1 - \sin^{-1}(I - \sin x_1) + 2L\pi + H,$$

$$\frac{\partial F_1}{\partial I} = -[k/\sigma(x_1)] - 1,$$

$$\frac{\partial F_i}{\partial k} = x_i + \sin^{-1}(I - \sin x_i) + (2L-1)\pi + H,$$

$$\frac{\partial F_i}{\partial I} = [k/\sigma(x_i)] - 1 \quad (i = 2, 3, 4).$$

The required estimates are easily obtained from Lemma 3.1 and are contained in the following lemma. The proof is elementary and so is omitted.

LEMMA 4.1. *Given any $H \in \mathbb{R}$ and integer L, the functions F_i satisfy the following for all (I,k) in S.*

$$\text{(i)} \quad \sqrt{1-k^2} - I + k(2L\pi + H) < F_1 < \sqrt{1 - k^2/4} - I + k[(2L+1)\pi + H],$$

$$-\sqrt{1-k^2/4} + k[(2L-1)\pi + H) < F_2 < -\sqrt{1-k^2} + k(2L\pi + H),$$

$$\sqrt{1-4k^2} - I + k[(2L-1)\pi + H] < F_3 < \sqrt{1-k^2} - I + k[(2L+1/2)\pi + H],$$

$$-\sqrt{1-k^2} + k[(2L-1/2)\pi + H] < F_4 < -\sqrt{1-4k^2} + k[(2L+1)\pi + H].$$

(ii)
$$2L\pi + H < \frac{\partial F_1}{\partial k} < (2L+1)\pi + H,$$

$$(2L-1)\pi + H < \frac{\partial F_2}{\partial k} < 2L\pi + H,$$

$$(2L-1)\pi + H < \frac{\partial F_i}{\partial k} < (2L+1/2)\pi + H, \quad (i = 3,4).$$

(iii)
$$-\frac{3}{2} < \frac{\partial F_1}{\partial I} < -1, 0 < \frac{\partial F_2}{\partial I} < 1,$$

$$-1 < \frac{\partial F_3}{\partial I} < -\frac{1}{2}, \quad -\frac{1}{2} < \frac{\partial F_4}{\partial I} < 0.$$

Lemma 4.1 contains most of what we will need to analyze the bifurcation curves in S. The results are contained in Theorem 4.2.

THEOREM 4.2. *Let H be given. For each of the functions F_i, the zeros in S form a family of smooth curves, each associated with a value of the integer L. Furthermore, we have the following.*

(i) *For each L for which $2L\pi + H \notin [-\pi, 0]$, the zeros of F_1 in S form a smooth curve having one endpoint at $(I,k) = (1,0)$ and the other on the upper boundary of S. Curves in the subfamily for which $2L\pi + H > 0$ have positive slope $k'(I)$, while those for which $2L\pi + H < -\pi$ have negative slope. Each curve lies above those of its subfamily that corresponds to larger values of $|L|$.*

(ii) *For each L for which $2L\pi + H \geq \pi + 4\sqrt{7}/3$, the zeros of F_2 in S form a smooth curve with endpoints that are on the upper boundary of S and opposite sides of the line $I = 2/3$. Each of these curves has negative slope and lies entirely above those that correspond to larger values of L. F_2 does not have any zeros in S for those values of L for which $2L\pi + H \leq 3/\sqrt{2}$.*

(iii) *For each L for which $2L\pi + H \notin [-\pi/2, \pi]$, the zeros of F_3 in S form a smooth curve having one endpoint at $(I,k) = (1,0)$, and the other on the upper boundary of S. Curves in the subfamily for which $2L\pi + H > \pi$ have positive slope, while those for which $2L\pi + H < -\pi/2$ have negative slope. Each curve lies above those of its subfamily that correspond to larger values of $|L|$.*

(iv) *For each L for which $2L\pi + H \geq \pi + \sqrt{3}$, the zeros of F_4 in S form a smooth curve with endpoints that are on the upper boundary of S and opposite sides of the line $I = 2/3$. Each of these curves has positive slope and lies entirely above those that correspond to larger values of L. F_4 does not have any zeros in S for those values of L for which $2L\pi + H \leq 3/\sqrt{2} - \pi/2$.*

In each case, the curves accumulate on the I-axis as $L \longrightarrow +\infty$, and as $L \longrightarrow -\infty$ in cases (i) *and* (iii).

Proof. That the zeros of F_i in S form smooth curves follows from the fact that $\partial F_i/\partial I$ is never zero in S by (iii) of Lemma 4.1. Proofs of (i) and (ii) of Theorem 4.2 follow. The proofs of (iii) and (iv) are done in the same way.

(i) First, observe that $F_1 = 1 - I$ on the lower boundary ($k = 0$) of S, by (i) of Lemma 4.1. Now consider the case when $2L\pi + H > 0$. Then $\partial F_1/\partial k$ is bounded above zero in S from Lemma 4.1, so F_1 will have a unique zero in S for each value of I in (1, 2) that is close enough to 1 but will not have any for $I \leq 1$. The curve formed by these zeros must have positive slope since $\partial F_1/\partial I < 0$ from Lemma 4.1. Consequently, the other endpoint must lie on the upper boundary of S. Furthermore, it is clear from $\partial F_1/\partial I < 0$ that F_1 cannot have any other zeros in S for this value of

L. That each curve in this subfamily lies above those corresponding to larger values of L follows easily from (ii) of Lemma 4.1, since the lower bound for $\partial F_1/\partial k$ when $L = j+1$ is larger than the upper bound when $L = j$ for each integer j.

The case when $2L\pi + H < -\pi$ is similar but with $\partial F_1/\partial k$ bounded below zero.

(ii) Observe that $F_2 = -1$ on the lower boundary ($k = 0$) of S, and that the largest value of k to occur in the closure of S is $\sqrt{2}/3$ and occurs only at the point $(I,k) = (2/3, \sqrt{2}/3)$ on the upper boundary of S. To see that F_2 cannot have zeros in S when $2L\pi + H < 3/\sqrt{2}$, notice that then $\partial F_2/\partial k < 3/\sqrt{2}$ from Lemma 4.1. But then the maximum value of F_2 in the closure of S must be less than $-1+(\sqrt{2}/3)(3/\sqrt{2}) = 0$.

Now let L be such that $2L\pi + H \geq \pi + 4\sqrt{7}/3$. Then $\partial F_2/\partial k \geq 4\sqrt{7}/3$ in S from Lemma 4.1. At any point of S for which $k \geq \sqrt{7}/8$, we have $F_2 > -1 + (\sqrt{7}/8)(4\sqrt{7}/3) = 1/6$. Since such points occur for all $I \in (1/4, 3/2)$, it follows that F_2 has zeros in S for all such I. The curve formed by these zeros has negative slope since $\partial F_2/\partial I$ and $\partial F_2/\partial k$ are both positive and clearly must have endpoints on the upper boundary of S. That F_2 cannot have any other zeros in S for this value of L follows from the fact that they would form curves that have endpoints on the upper boundary of S and must either lie to the left of $I = 1/4$ or to the right of $I = 3/2$. But F_2 cannot have more than one zero on the upper boundary of S to the left of $I = 1/4$ since $dF_2/dI > 0$ there. Similarly, F_2 cannot have more than one zero to the right of $I = 3/2$ on the upper boundary of S since $dF_2/dI < 0$ there.

All that remains is to show that each curve of this family lies entirely above those that correspond to larger values of L. But this follows from (ii) of Lemma 4.1 in the same way as the corresponding claim in (i). □

Theorem 4.2 is the main result of this paper. Although it does not describe the bifurcation curves outside of S, it provides a nearly complete description of them in S. As is clear from the theorem, the bifurcation curves in case (iii) appear similar to those in case (i). Similarly, those in case (iv) appear like those in case (ii), though with slopes of opposite signs. The curves in cases (i) and (ii) are sketched in Figs. 2a and b.

Remark. We now have enough information about the bifurcations in S to determine whether or not the conjecture by Kopell [5] that beating solutions could arise from simultaneous sink-saddle bifurcations is consistent with what is known about the beating solutions from numerical experiments (see Fig. 3). Let L_1 and L_2 be integers such that the line of height $I - k(2L_i\pi + H)$ passes through the critical point of C at x_i ($i = 1, 2$). If the conjecture is correct, then we would expect the beating solutions to be such that transitions when φ_2 becomes nearly stationary occur for (φ_1, φ_2) near points equivalent to $(x_1, \sin^{-1}(I - \sin x_1) - 2L_1\pi)$ (mod 2π in each component), and that the other transitions occur near points equivalent to $(x_2, \pi - \sin^{-1}(I - \sin x_2) - 2L_2\pi)$. Furthermore, when φ_1 is nearly constant we would expect it to slowly move from near a value equivalent to x_2 (mod 2π) to near one equivalent to x_1. Similarly, φ_2 would be expected to slowly vary from near a value equivalent to $\sin^{-1}(I - \sin x_1)$ to near one equivalent to $\pi - \sin^{-1}(I - \sin x_2)$ when it is nearly constant. Appropriate values of L_1 and L_2 can be found by observing that $2L_1\pi$ would approximate the minimum and $2L_2\pi$ the maximum value of $\varphi_1 - \varphi_2$ in the beating solution.

For $\gamma = 0.5$, $H = 0$, and $k = 0.001$, Imry and Schulman [1] report finding beating solutions only for $|I - 1.6| < 0.05$, and that the extreme values of $\varphi_1 - \varphi_2$ for these are close to 188π and 320π. Since L_1 corresponds to a curve in family (i), and L_2 to a curve in family (ii), a first test of the conjecture is to determine if the bifurcation curve with $L = 94$ in the family from F_1 intersects the one with $L = 160$ in the family from F_2 at a point of S near $(I,k) = (1.6, 0.001)$.

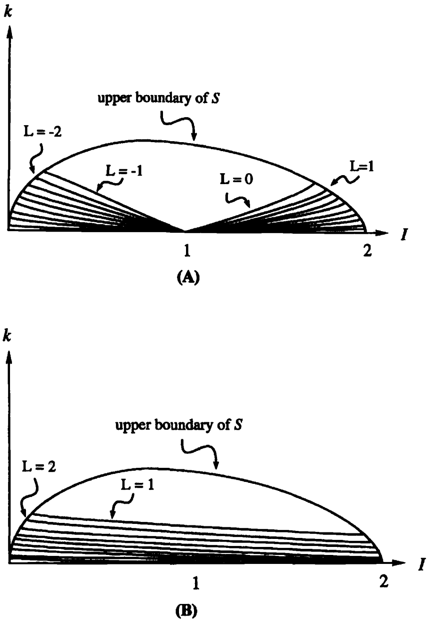

FIG. 2. (a) *A sketch of the bifurcation curves in family* (i) *for* $H = \frac{1}{2}$. *Bifurcation curves in the subfamily having positive slope correspond successively to* $L = 0, 1, 2, \ldots$, *while those in the subfamily having negative slope correspond successively to* $L = -1, -2, -3, \ldots$. *In each case, the curves accumulate on the* I*-axis as* $|L| \to \infty$. (b) *A sketch of the bifurcation curves in family* (ii) *for* $H = \frac{1}{2}$. *These curves have negative slope, correspond successively to* $L = 1, 2, 3, \ldots$, *and accumulate on the* I*-axis as* $L \to \infty$.

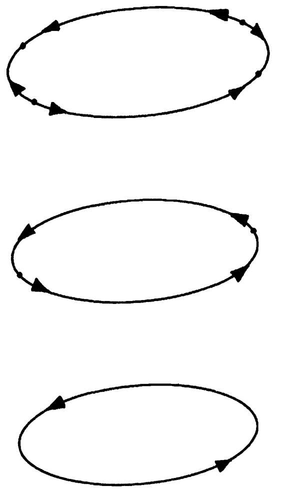

FIG. 3. *A highly schematic illustration of the idea of the conjecture. The fixed points disappear in a pair of simultaneous sink-saddle bifurcations, leaving a beating solution in their wake.*

From Theorem 4.2, we see that these two curves intersect in at most one point, since they have slopes of opposite sign. Using $L = 160$ in the estimate for F_2 in Lemma 4.1 shows that $0.000994 < k < 0.000998$ along the corresponding bifurcation curve. Similarly, the estimate for F_1 with $L = 94$ shows that $k < 0.000994$ at $I = 1.587$, and $k > 0.000998$ at $I = 1.593$ on the $L_1 = 94$ bifurcation curve. Consequently, these curves must intersect at a point very close to $(I,k) = (1.59, 0.000996)$, which is in good agreement with the conjectured intersection near $(I,k) = (1.6, 0.001)$.

To further test the conjecture, it should be mentioned that numerical approximation of the beating solutions shows that during the time when they are nearly stationary φ_1 and φ_2 slowly vary from being near values equivalent to $\pi/5 \pmod{2\pi}$ to being near values equivalent to $\pi/2$. On the other hand, the estimates in Lemma 3.1 show that when k is small (e.g., near 0.001), x_1 and x_2 are very close to $\pi/2$ and $\sin^{-1}(I-1)$, respectively. Since I is near 1.6, we see that x_2 is near $\pi/5$. It now follows that $\sin^{-1}(I - \sin x_1)$ is near $\pi/5$, and that $\pi - \sin^{-1}(I - \sin x_2)$ is near $\pi/2$. Thus, the conjectured behavior of φ_1 and φ_2 when they are nearly constant is also in good agreement with the numerical results.

In light of the conjecture, the similarity of the bifurcation curves in families (iii) and (iv) to those in families (i) and (ii) suggests the possibility that there might be another class of beating solutions. In this regard, we mention that the existence of *unstable* beating solutions has been proved by Levi [2, 4]. Such solutions could perhaps arise by a mechanism similar to that of the conjecture but involving simultaneous bifurcations corresponding to an intersection of curves from families (iii) and (iv). In that case, the role of the sinks in the conjecture would be played by saddles having a one-dimensional unstable manifold, and the role of the saddles would be played by saddles having a two-dimensional unstable manifold. The work done by Levi in [2] and [4] does not appear to have an impact on these conjectures, since it excludes the region of parameter space where bifurcations of the beating solutions occur.

Acknowledgments. It is with pleasure that I thank Nancy Kopell and Mark Levi for many interesting discussions of Josephson junctions.

MINIMAL PERIODS FOR SOLUTIONS OF SOME CLASSICAL FIELD EQUATIONS*

D. STUART[†]

Abstract. Time-periodic solutions of a class of coupled semilinear wave equations in any space dimension are considered. It is shown that there is a lower bound on the period of solutions which have finite energy and decay at a certain rate at spatial infinity. This generalises results of Coron and Levine which obtained the same bound for, respectively, scalar equations in one space dimension and solutions with spherical symmetry on exterior domains in higher space dimensions. The methods used are adapted from work of Kato on the absence of positive eigenvalues for Schrödinger operators.

Key words. breathers, minimal period, nonlinear wave equations, period solutions

AMS subject classification. 35B

1. Introduction.

In this note we shall extend results of Coron [2] and Levine [7] on the minimal period of (time-) periodic solutions of nonlinear wave equations to certain systems of semilinear wave equations in several space dimensions. The proof is an adaptation of Kato's method in Schrödinger operators [6]. We shall start by recalling some known time-periodic solutions, and then we will explain the lower bound on the period of such solutions. In one dimension, the sine-Gordon equation

$$u_{tt} - u_{xx} + \sin u = 0,$$

where u is real valued, has periodic solutions called breathers with period larger than 2π (see, for example, [8]). For single equations in one space dimension, this example is expected to be essentially unique; see [1, 3]. Spherically symmetric solutions on $\mathbf{R}^3$ which are not bounded at the origin are discussed in [9]. However, for systems, there are plenty of periodic solutions given by the following method. Consider the *complex* field equation for $\phi : \mathbf{R}^{1+n} \to \mathbf{C}$ of the form

$$\phi_{tt} - \Delta\phi + a^2\phi = f(|\phi|)\phi,$$

where f is real and $f(0) = 0, f'(0) = 0$. This has periodic solutions for a large class of functions f (see, for example, [4]). These solutions are of the form $\phi(t,x) = e^{i\omega t}u(x)$, where u satisfies an elliptic equation and $\omega^2 \le a^2$. Therefore, the period of these solutions is always bigger than or equal to $\frac{2\pi}{a}$.

In [2], the equation

$$u_{tt} - u_{xx} + g(u) = 0$$

with $g \in C^2(\mathbf{R})$, $g(0) = 0$, was considered. It was proved that if $u(t,x)$ is a twice differentiable real-valued function such that $u(t+T,x) = u(t,x)$ and

$$\int_{-\infty}^{+\infty}\int_0^T |u(t,x)|dtdx < \infty,$$

$$\lim_{|x|\to+\infty}\int_0^T (u_t^2 + u_x^2)dt = 0,$$

* Received by the editors September 12, 1994; accepted for publication (in revised form) December 6, 1994. This research was supported by National Science Foundation grant DMS-9214067.

[†] Department of Mathematics, University of California at Davis, Davis, CA 95616 (dmstuart@aztec.ucdavis.edu).

$$\lim_{|x|\to+\infty}\max_{0\le t\le T}|u(t,x)|=0,$$

then either u is independent of time or $(\frac{2\pi}{T})^2 \le g'(0)$. This gives a lower bound for the period. In [7], this was generalised to real scalar equations in several space dimensions under the assumption of spherical symmetry. (In this paper, it was only assumed that the solution existed in an exterior domain; thus regularity at the origin was not required). In the present paper, we will generalise this lower bound on the period to classes of systems in several space dimensions *without assuming the solution to be spherically symmetric.* We will do this by by obtaining lower bounds at infinity on a solution which violates this condition. We then show that these bounds imply it has infinite energy. To do this, it is necessary to make some assumptions about the decay of the solution at spatial infinity which are somewhat stronger than those required for Coron's result. We will state some consequences of the main theorem before stating the result in generality. In what follows, a T-periodic function u is a function of $(t,x)\in\mathbf{R}^{1+n}$ such that $u(t+T,x)=u(t,x)$.

THEOREM 1. *Consider a T-periodic solution u of the following system of coupled wave equations in* $\mathbf{R}^{1+3}$,

$$u^\alpha_{tt}-\Delta u^\alpha+u^\alpha+f^\alpha(u)=0,\qquad \alpha=1,\dots,m,$$

which is not independent of time, which satisfies the condition in equation (3) *below, and which is such that* $u=O(\frac{1}{|x|})$ *as* $|x|\to\infty$. *Then if for all* α, $f^\alpha(u)$ *is a homogeneous polynomial of third degree, then the period* $T\ge 2\pi$.

THEOREM 2. *Consider a time-periodic solution u of the system of nonlinear wave equations in* $\mathbf{R}^{1+n}n\ge 3$

$$u^\alpha_{tt}-\Delta u^\alpha+f^\alpha(u)=0,\qquad \alpha=1,\dots,m,$$

which satisfies the condition in equation (3) *below and which is such that* $u=O(|x|^{-\frac{(n-1)}{2}})$ *as* $|x|\to\infty$. *Then if* $n\ge 4$ *and if for every* α, $f^\alpha(u)$ *is a homogeneous polynomial of second degree, then u is independent of time. If* $n=3$ *and if for every* α, $f^\alpha(u)$ *is a homogeneous polynomial of third degree, then u is independent of time. In the case* $n=3$, *if* $u=o(\frac{1}{|x|})$ *as* $|x|\to\infty$ *and if for every* α, $f^\alpha(u)$ *is a homogeneous polynomial of second degree, then u is independent of time.*

These theorems are consequences of the main theorem, which we give in the next section. Another type of restriction on the possible existence of time-periodic solutions can be obtained by arguments based on Pohazaev-type identities [5].

2. The main theorem.

Consider the system of equations

$$u^\alpha_{tt}-\Delta u^\alpha+k_\alpha^2u^\alpha+f^\alpha(u)=0 \tag{1}$$

for a vector-valued function $u=\{u^\alpha\}_{\alpha=1}^m$ of $(t,x)\in\mathbf{R}^{1+n}$. We do *not* use the summation convention. We will assume that $f:\mathbf{R}^m\to\mathbf{R}^m$ is a twice continuously differentiable function with $f(0)=f'(0)=0$ and that u is a twice continuously differentiable solution which is T-periodic in time and *not independent of time.* We can then write

$$u(t,x)=\overline{u}(x)+\hat{u}(t,x),$$

where $\overline{u} = \frac{1}{T}\int_0^T u(t,x)dt$ and $\hat{u} \neq 0$ and satisfies

$$\int_0^T |\hat{u}_t|^2 dt \geq \left(\frac{2\pi}{T}\right)^2 \int_0^T |\hat{u}|^2 dt.$$

It turns out to be useful to think of the equation as an ordinary differential equation in r with values in the Hilbert space H which consists of T-periodic functions on the unit sphere with norm

$$\|u(r)\|^2 \equiv \int_0^T \int_{S^{n-1}} \sum_\alpha |u^\alpha|^2 dSdt, \tag{2}$$

where dS is the usual measure on the unit sphere. The corresponding inner product will be written $(\cdot,\cdot)$. Since f is C^2, it follows from the fundamental theorem of calculus that there exist continuous functions $h^\alpha_{\beta\gamma}(\overline{u},\hat{u})$ such that

$$f^\alpha(u) = f^\alpha(\overline{u}) + f^\alpha(\hat{u}) + \sum_{\beta,\gamma} \overline{u}^\beta \hat{u}^\gamma h^\alpha_{\beta\gamma}(\overline{u},\hat{u}).$$

Introduce the following function:

$$q[u](R) \equiv \max_{|x|=R} \max_{0\leq t\leq T} \left\{ \frac{|f(\hat{u}(t,x))|}{\|\hat{u}(R)\|} + \left| \sum_\beta \overline{u}_\beta(t,x) h^\alpha_{\beta\gamma}(\overline{u}(t,x),\hat{u}(t,x)) \right| \right\}.$$

Notation. Here the norm on the linear transformation $\sum_\beta \overline{u}_\beta h^\alpha_{\beta\gamma}(\overline{u},\hat{u}) : \mathbf{R}^m \to \mathbf{R}^m$ is that induced from the Euclidean norm on $\mathbf{R}^m$. We will often omit the argument $[u]$ from q. Define $k = \max_\alpha |k_\alpha|$.

We will prove the following theorem.

MAIN THEOREM. *Assume that $u \in C^2(\mathbf{R}^{1+n};\mathbf{R}^m)$ is a T-periodic solution of equation* (1) *which is not independent of time and such that the following conditions are satisfied:*

$$\sum_{\alpha=1}^m \int_0^T \int_{\mathbf{R}^n} (|u^\alpha_t|^2 + |\nabla u^\alpha|^2) dxdt < \infty, \tag{3}$$

$$\lim_{R\to\infty} Rq[u](R) = 0. \tag{4}$$

Then $T \geq \frac{2\pi}{k}$.

Remark. To prove this theorem, we will assume we have a solution for which

$$\left(\frac{2\pi}{T}\right)^2 > k^2 \tag{5}$$

and use a sucession of lemmas which place lower bounds on the behaviour of certain spherical averages as $|x| = r \to \infty$ which contradict the first assumption.

The technical difficulties which arise from the lack of spherical symmetry are due to the fact that the operator $-\Delta$ contains a component $-r^{-2}\Delta_S$, where Δ_S is the spherical Laplacian. This term has the opposite sign to the term $\partial_t^2 + k_\alpha^2$. It seems not to be possible to eliminate this difficulty by averaging over the sphere due to the presence of nonlinear terms.

Let K be a diagonal $m \times m$ matrix such that $(Ku)^\alpha = k_\alpha u^\alpha$ and $(K^2 u)^\alpha = k_\alpha^2 u^\alpha$. It will be clear from the proof that we could generalise this to consider a system of equations in which the matrix K is positive definite but not diagonal. We will work with $\hat{u}$, which satisfies

$$\hat{u}_{tt}^\alpha - \Delta \hat{u}^\alpha + k_\alpha^2 \hat{u}^\alpha + f^\alpha(\overline{u}) + f^\alpha(\hat{u}) + \sum_{\beta,\gamma} \overline{u}^\beta \hat{u}^\gamma h_{\beta\gamma}^\alpha(\overline{u}, \hat{u}) - \Delta \overline{u}^\alpha + k_\alpha^2 \overline{u}^\alpha = 0.$$

It is convenient to rescale as follows: define

$$w \equiv r^{\frac{n-1}{2}} \hat{u} \quad \text{and} \quad w_m \equiv r^m w. \tag{6}$$

We then calculate that these satisfy the following equations:

$$\begin{aligned}
&-(w^\alpha)'' + \left(k_\alpha^2 + \frac{\mu}{r^2}\right) w^\alpha + \partial_t^2 w^\alpha - \frac{1}{r^2} \Delta_s w^\alpha \\
&\qquad + r^{\frac{n-1}{2}} \left(f^\alpha(\overline{u}) + f^\alpha(\hat{u}) + \sum_{\beta,\gamma} \overline{u}^\beta \hat{u}^\gamma h_{\beta\gamma}^\alpha(\overline{u}, \hat{u}) - \Delta \overline{u}^\alpha + k_\alpha^2 \overline{u}^\alpha \right) = 0, \\
&-(w_m^\alpha)'' + \frac{2m}{r} (w_m^\alpha)' + \left(k_\alpha^2 + \frac{\mu - m(m+1)}{r^2}\right) w_m^\alpha + \partial_t^2 w_m^\alpha - \frac{1}{r^2} \Delta_s w_m^\alpha \\
&\qquad + r^{m + \frac{n-1}{2}} \left(f^\alpha(\overline{u}) + f^\alpha(\hat{u}) + \sum_{\beta,\gamma} \overline{u}^\beta \hat{u}^\gamma h_{\beta\gamma}^\alpha(\overline{u}, \hat{u}) - \Delta \overline{u}^\alpha + k_\alpha^2 \overline{u}^\alpha \right) = 0,
\end{aligned}$$

where $\mu = \frac{1}{4}(n-1)(n-3)$, Δ_s is the spherical Laplacian, and $'$ means $\frac{d}{dr}$. To understand the solutions, we introduce the following quantity:

$$Q(r) \equiv \|w'\|^2 + \|\dot{w}\|^2 - \|Kw\|^2 - \frac{\mu}{r^2} \|w\|^2 + \frac{1}{r^2} (w, \Delta_s w).$$

This is useful because of the following result.

LEMMA. *There exists a number R_1 such that for $r \geq R_1$,*

$$\frac{\partial}{\partial r} \Big(rQ(r) \Big) \geq 0.$$

Proof. First of all, using $\int_0^T w dt = 0$, we calculate that

$$\begin{aligned}
(rQ)' &\geq \|w'\|^2 + \left(\left(\frac{2\pi}{T} \right)^2 - k^2 + \frac{\mu}{r^2} \right) \|w\|^2 - \frac{1}{r^2} (w, \Delta_s w) \\
&\qquad + 2 \left(r(w^\alpha)', r^{\frac{n-1}{2}} f^\alpha(\hat{u}) + \sum_{\beta,\gamma} \overline{u}^\beta w^\gamma h_{\beta\gamma}^\alpha(\overline{u}, \hat{u}) \right) \\
&\geq \|w'\|^2 + \left(\left(\frac{2\pi}{T} \right)^2 - k^2 + \frac{\mu}{r^2} \right) \|w\|^2 - 2|rq(r)| \|w'\| \|w\|,
\end{aligned}$$

where $k = \max_\alpha |k_\alpha|$. It is clear that this is a nonnegative quadratic form for large r, on account of equations (4) and (5).

The next stage is to show that there are arbitrarily large values of r for which

$Q > 0$. To do this, we introduce, following Kato, a subsidiary function:

$$\begin{aligned} &Q(r; m, s) \\ &\equiv \|w'_m\|^2 + \|\dot{w}_m\|^2 - \|Kw_m\|^2 - \left(\frac{\mu}{r^2} + \frac{2s}{r} - \frac{m(m+1)}{r^2}\right)\|w_m\|^2 + \frac{1}{r^2}(w_m, \Delta_s w_m). \end{aligned}$$

LEMMA. *For every $R_2 > 0$, there exists a number $s_1 > 0$ such that for $s < s_1$, there exists a number M_1 such that for $m \geq M_1$ and $r \geq R_2$, we have*

$$(r^2 Q(r; m, s))' \geq 0.$$

Proof. Using $\int_0^T w_m dt = 0$, we calculate that

$$\begin{aligned} (r^2 Q(r; m, s))' = 2r \Bigg[&(2m+1)\|w'_m\|^2 + \|\dot{w}_m\|^2 - \frac{s}{r}\|w_m\|^2 - \|Kw_m\|^2 \\ &+ \left(r(w^\alpha_m)', r^{m+\frac{n-1}{2}} f^\alpha(\hat{u}) + \sum_{\beta,\gamma} \overline{u}^\beta w^\gamma_m h^\alpha_{\beta\gamma}(\overline{u}, \hat{u}) - \frac{2s}{r} w^\alpha_m \right) \Bigg] \\ \geq 2r \Bigg[&(2m+1)\|w'_m\|^2 + \left(\left(\frac{2\pi}{T}\right)^2 - k^2 - \frac{s}{r} \right) \|w_m\|^2 \\ &-2|(rq(r) + 2s)| \|w'_m\| \|w_m\| \Bigg]. \end{aligned}$$

The condition for this form to be definite is therefore satisfied for sufficiently large m as long as we choose s such that

$$\left(\left(\frac{2\pi}{T}\right)^2 - k^2 - \frac{s}{r} \right) \geq 0.$$

So we let s_1 be given by

$$s_1 = R_2 \left(\left(\frac{2\pi}{T}\right)^2 - k^2 \right).$$

Next, for $s < s_1$, the condition for positivity of the quadratic form is

$$(rq + 2s)^2 \leq (2m+1)\left(\left(\frac{2\pi}{T}\right)^2 - k^2 - \frac{s}{r} \right),$$

and since $rq(r)$ is bounded, this is satisfied for $r \geq R_2, s < s_1$ if m larger than some number $M_1(s)$.

Before going on, we will record the following formula for $Q(r; m, s)$:

$$\begin{aligned} Q(r; m, s) = r^{2m} \Bigg(&\|w'\|^2 + \frac{2m}{r}(w, w') + \|\dot{w}\|^2 - \|Kw\|^2 \\ &- \left(\frac{\mu}{r^2} + \frac{2s}{r} - \frac{m(2m+1)}{r^2} \right) \|w\|^2 + \frac{1}{r^2}(w, \Delta_s w) \Bigg) \end{aligned}$$

$$= r^{2m} \left(Q(r) + \frac{2m}{r}(w, w') - \left(\frac{2s}{r} - \frac{m(2m+1)}{r^2} \right) \|w\|^2 \right). \tag{7}$$

COROLLARY. *There exist arbitrarily large values of r for which $Q(r) > 0$.*

Proof. Since we are assuming that $\int u_t^2 dx = \int_0^\infty \|w\|^2 dr < \infty$, we may assume that there is an unbounded subset S of the positive real axis such that for $r \in S$, $(w, w')(r) \leq 0$. At such a point, we know from equation (7) that

$$Q(r; m, s) \leq r^{2m} \left(Q(r) - \left(\frac{2s}{r} - \frac{m(2m+1)}{r^2} \right) \|w\|^2 \right) \quad \text{for } r \in S.$$

Now let R_3 be a value of r for which $\|w\| \neq 0$. Such a number exists because we assumed that u is not independent of time. Then, first of all, we can find a number M_2 such that for $m \geq M_2$, $Q(R_3; m, s) > 0$ because $Q(R_3; m, s)$ is quadratic in m from equation (7). Then we apply the previous lemma to deduce that for sufficiently small s and large m, $Q(r; m, s) > 0$ for all $r \geq R_3$. Choosing $r \in S$ sufficently large that $\frac{2s}{r} - \frac{m(2m+1)}{r^2} > 0$, it then follows from the preceeding formula that $Q(r) > 0$ as required on an unbounded set.

Proof of Main Theorem. Finally, to prove the theorem, we choose a number $R_4 > R_1$ for which $Q(R_4) > 0$. Then by the first lemma, we know that for $r > R_4$,

$$Q(r) \geq \frac{R_4 Q(R_4)}{r},$$

from which it follows that $Q(r)$ is not integrable. Now to complete the proof, notice that

$$\begin{aligned}
r^{n-1}(\|\nabla u\|^2 + \|u_t\|^2) &\geq r^{n-1}(\|\nabla \hat{u}\|^2 + \|\hat{u}_t\|^2) \\
&\geq r^{n-1}\left(\|\hat{u}'\|^2 + \frac{2\pi^2}{T^2}\|\hat{u}\|^2 \right) + \frac{1}{2}\|w_t\|^2 \quad \text{from equation (2)} \\
&\geq \|w'\|^2 - \frac{(n-1)}{r}(w, w') + \frac{(n-1)^2}{4r^2}\|w\|^2 \\
&\qquad + \frac{2\pi^2}{T^2}\|w\|^2 + \frac{1}{2}\|w_t\|^2 \quad \text{from equation (6)} \\
&\geq \frac{1}{2}(\|w'\|^2 + \|w_t\|^2) + \left(\frac{2\pi^2}{T^2} - \frac{(n-1)^2}{4r^2} \right)\|w\|^2 \\
&\geq \frac{1}{2}Q(r) \quad \text{for sufficently large r} \geq R_5.
\end{aligned}$$

It follows that $r^{n-1}(\|\nabla u\|^2 + \|u_t\|^2)$ is not integrable on $[R_5, \infty)$ and hence that the finite-energy assumption

$$\int_0^T \int_{\mathbf{R}^n} (u_t^2 + |\nabla u|^2) dx dt = \int_0^\infty r^{n-1}(\|\nabla u\|^2 + \|u_t\|^2) dr < \infty$$

is violated. This completes the proof.

Acknowledgments. I would like to thank Richard Montgomery for discussions related to this work and the referee for helpful comments.

ASYMPTOTIC AND NUMERICAL APPROXIMATIONS OF THE ZEROS OF FOURIER INTEGRALS*

DAVID SENOUF[†]

To the memory of Midge Bennahum.

Abstract. The asymptotic behavior as $y \to +\infty$ of Fourier integrals of the form

$$f_n(y) = \int_{-\infty}^{\infty} e^{-t^{2n}+iyt}dt, \quad n \in \mathbb{N}, \quad n \geq 2,$$

is derived via the method of steepest descents. A general formula is found for the coefficients of the expansion of $f_n(y)$ in the sector $|\arg y| < \frac{2n-1}{2n}\frac{\pi}{2}$ centered about the anti-Stokes line $y \in \mathbb{R}$. A high-order asymptotic approximation of the real zeros of $f_n(y)$ is also obtained. A simple numerical method designed to compute the zeros of $f_n(y)$ is described. For $n = 2$ and $n = 3$, the asymptotic estimates of the zeros are compared to numerically computed values.

Key words. asymptotic expansions, steepest descents, Fourier integrals, Pearcey integral, zeros

AMS subject classifications. 30E15, 33B10, 41A60

1. Introduction.

In [20], Pólya showed that functions of the form

$$\int_{-\infty}^{\infty} e^{-at^{4n}+bt^{2n}+ct^2+iyt}dt, \qquad n \in \mathbb{N}, \quad n \geq 1, \quad a > 0, \quad b \in \mathbb{R}, \quad c \geq 0, \tag{1}$$

have only real zeros. Similar results are found in [19] concerning functions of the form

$$f_n(y) = \int_{-\infty}^{\infty} e^{-t^{2n}+iyt}dt, \qquad n \in \mathbb{N}, \quad n \geq 2. \tag{2}$$

In [7], de Bruijn generalized Pólya's results to a larger class of functions whose zeros are real. Recently, Paris analyzed in [16] a generalized form of the Pearcey integral of which the "Pólya" functions given by (1) are particular cases. He studied the asymptotic behavior of

$$P_n'(X,Y) = \int_{-\infty}^{\infty} e^{i(u^{2n}+Xu^n+Yu)}du, \qquad n \in \mathbb{N}, \quad n \geq 2, \tag{3}$$

as $|X| \to \infty$ or $|Y| \to \infty$. By rotation of the path of integration ($u = te^{\frac{\pi i}{4n}}$) and use of Jordan's lemma, it can be expressed as

$$P_n'(X,Y) = P_n(x,y) = e^{\frac{\pi i}{4n}} \int_{-\infty}^{\infty} e^{-t^{2n}-xt^n+iyt}dt \tag{4}$$

with $x = Xe^{-\frac{\pi i}{4}}$ and $y = Ye^{\frac{\pi i}{4n}}$. For n even, $x > 0$, $P_n(x,y)$ falls into the category of functions (1) considered by Pólya. For $x = 0$, f_n and P_n are related by $f_n(y) = e^{-\frac{\pi i}{4n}}P_n(0,y)$. The Pearcey integral $P_2(x,y)$ has been studied by Kaminski [14], Paris [17], and references therein. The advantage of the method described by Paris is that it

avoids the complicated, sometimes impossible task of finding a closed-form expression for the saddle points.

Although a large portion of this work is devoted to the derivation of the asymptotic expansion of $f_n(y)$ as $y \to +\infty$, our main objective is the derivation of asymptotic approximations for the zeros of $f_n(y)$. The order of this real analytic even function, which is defined as the positive number λ_n for which $\max_{|y|=r} |f_n(y)| \leq \exp(r^{\lambda_n+\epsilon})$ $\forall \epsilon > 0$ as soon as r is sufficiently large, is the rational number $1 < \lambda_n = \frac{2n}{2n-1} < 2$. The order being fractional, it is known that $f_n(y)$ has infinitely many zeros [2, 4], which, from the results of Pólya, must be real; thus we are mainly interested in the behavior of $P_n(0, y)$ for large real values of y. The expansion we find is an expression on the anti-Stokes line $\arg y = 0$ where two saddle points have equal contributions. Hence we first consider the real-valued function $f_n(y) : \mathbb{R} \to \mathbb{R}$, which, by the change of variable $t \to z\left(\frac{y}{2n}\right)^{1/(2n-1)}$ for $|\arg y| < \frac{2n-1}{2n}\pi/2$, can be expressed in terms of another function $\mathcal{F}_n(\mu)$ defined as follows:

$$f_n(y) = \left(\frac{y}{2n}\right)^{\frac{1}{2n-1}} \mathcal{F}_n\left(\left(\frac{y}{2n}\right)^{\frac{2n}{2n-1}}\right), \tag{5}$$

where for $|\arg \mu| < \pi/2$,

$$\mathcal{F}_n(\mu) = \int_{-\infty}^{\infty} e^{\mu\,(2niz - z^{2n})} dz = 2\int_0^{+\infty} \cos(2n\mu z) e^{-\mu z^{2n}} dz. \tag{6}$$

The advantage of introducing the function $\mathcal{F}_n(\mu)$ is that its saddle points are fixed to the unit disk, contrary to those of $f_n(y)$, which depend on the large variable y.

The expansion of functions of the type of $f_n(y)$ can be found as early as 1916 in the work of Brillouin in [5] and then in 1924 in the work of Burwell [8], who obtained first-order asymptotics for the location of the zeros of such functions (see also [3]). Recently, Christ also characterized the zeros of similar functions in [9, Lem. 2.1]. In [18, Chap. 3], Paris and Wood investigate the asymptotic properties of high-order differential equations whose solutions have integral representations closely related to (2). In their work, they derive recurrence relations to determine the coefficients of the asymptotic expansions (see, for example, [18, Eq. 3.4.16]). We provide a different approach than Paris and Wood's using the classical method of steepest descents, and we derive the full (generalized) asymptotic expansion of $\mathcal{F}_n(\mu)$ as $\mu \to +\infty$ valid in the sector $|\arg \mu| < \pi/2$ together with high-order asymptotic approximations of its zeros. We provide a systematic way of calculating every coefficient of the expansion of $\mathcal{F}_n(\mu)$ via series reversion in terms of multinomial coefficients. This formulation can be compared to the results of Paris and Wood in [18] in which the coefficients are described by a $2n$-term recursion relation which is derived from ordinary differential equation (ODE) methods.

In the last section, we describe a simple numerical algorithm which computes the zeros of the function $\mathcal{F}_n(\mu)$. This algorithm is efficient for small values of the zeros, and for $n = 2$ and $n = 3$, it is implemented to gauge the accuracy of the asymptotic estimates. An application of the high-order asymptotic approximations of the zeros of $\mathcal{F}_2(\mu)$ derived in this article can be found in [22]–[24].

We introduce the following definitions and notations.

Definition 1.1. Compound asymptotic expansion (c.a.e.) *of $f(z)$ with respect* *to the asymptotic sequences* $\{\phi_n^1(z)\}$ *and* $\{\phi_n^2(z)\}$: *we write*

$$f(z) \overset{z\to z_0}{\sim} g_1(z)\left[\sum_{n=0}^{\infty} f_n^1(z);\ \{\phi_n^1(z)\}\right] + g_2(z)\left[\sum_{n=0}^{\infty} f_n^2(z);\ \{\phi_n^2(z)\}\right],$$

where it is understood that

$$f(z) \sim g_1(z)\left[\sum_{n=0}^{\infty} f_n^1(z) + o(\phi_n^1(z))\right] + g_2(z)\left[\sum_{n=0}^{\infty} f_n^2(z) + o(\phi_n^2(z))\right] \quad \text{as } z \to z_0.$$

As an alternative to a c.a.e., it may be possible to express the asymptotic expansion of $f(z)$ as a generalized asymptotic expansion.

DEFINITION 1.2. Generalized asymptotic expansion (g.a.e.) *of* $f(z)$ *with respect to the asymptotic sequence* $\{\phi_n(z)\}$: *let* $\{\phi_n(z)\}$ *be an asymptotic sequence as* $z \to z_0 \in R$, *where* R *is a region in the complex plane and* $f(z)$ *and* $f_n(z)$, $n = 0, 1, \ldots$, *are functions such that for each positive integer* m,

$$f(z) = \sum_{n=0}^{m-1} f_n(z) + \mathcal{O}\left(\phi_m(z)\right) \quad (z \to z_0 \in R).$$

Then we say that $\sum_n f_n(z)$ *is a g.a.e. with respect to the asymptotic sequence* $\{\phi_n(z)\}$ *and write*

$$f(z) \sim \sum_{n=0}^{\infty} f_n(z); \quad \{\phi_n(z)\} \text{ as } z \to z_0 \in R.$$

For convenience, we also write it as

$$f(z) \underset{\{\phi_n(z)\}}{\overset{z\to z_0}{\sim}} \sum_{n=0}^{\infty} f_n(z).$$

We prove the following.

THEOREM 1.1. *Let* $n \in \mathbb{N}, n \geq 2$, *and for* $|\arg \mu| < \pi/2$, *let*

$$\mathcal{F}_n(\mu) = \int_{-\infty}^{\infty} e^{\mu\,(2niz - z^{2n})} dz.$$

The g.a.e. of $\mathcal{F}_n(\mu)$ *as* $\mu \to +\infty$ *with respect to the asymptotic sequence* $\{\phi_j(\mu) = \mu^{-j}\}$, *valid in the sector* $|\arg \mu| < \pi/2$, *is*

$$\mathcal{F}_n(\mu) \underset{\{\mu^{-j}\}}{\overset{\mu\to+\infty}{\sim}} \sqrt{\frac{4\pi}{n(2n-1)\mu}} \exp\left\{-\mu\,(2n-1)\sin\left(\frac{\pi}{4n-2}\right)\right\} \mathcal{H}_n(\mu),$$

where

$$\mathcal{H}_n(\mu) = \sum_{j=0}^{\infty} \frac{\alpha_{n,j}}{\mu^j} \cos\left(\mu\,(2n-1)\cos\left(\frac{\pi}{4n-2}\right) + \frac{\pi}{4n-2}(1 - n(1+2j))\right)$$

and the coefficients $\alpha_{n,j}$ *are normalized rational numbers* $(\alpha_{n,0} = 1)$ *given by*

$$\alpha_{n,j} = \frac{\Gamma(j+1/2)}{\sqrt{\pi}\big(n(2n-1)\big)^j} \cdot \sum_{m=0}^{2j} \left\{ \frac{(1/2-j-m)_m}{\big(n(2n-1)\big)^m} \cdot {\sum_{\sigma}}' \prod_{k=1}^{2n-2} \frac{1}{\sigma_k!} \binom{2n}{k+2}^{\sigma_k} \right\}.$$

The summation ${\sum'}_{\sigma}$ *is to take place over all possible* $\boldsymbol{\sigma} = (\sigma_1, \ldots, \sigma_{2n-2}) \in \mathbb{N}^{2n-2}$ *such that* $\sigma_1 + \sigma_2 + \cdots + \sigma_{2n-2} = m$ *and* $\sigma_1 + 2\sigma_2 + \cdots + (2n-2)\sigma_{2n-2} = 2j$. *Moreover, the first-order approximation of the kth ordered positive zero of* $\mathcal{F}_n(\mu)$ *is given by* (*for* $k \geq 1$)

$$\mu_{k,n}^{(0)} = \frac{\pi}{4n-2} \sec\left(\frac{\pi}{4n-2}\right) \left(\frac{n-1}{2n-1} - 1 + 2k\right) + \mathcal{O}\left(\frac{1}{k}\right) \quad \text{as } k \to +\infty.$$

Let

$$\mathcal{G}_n(\mu) = \mu + \frac{\sec(\frac{\pi}{4n-2})}{(2n-1)\,\mu} \left\{ \alpha_{n,1} \sin\left(\frac{n\pi}{2n-1}\right) - \frac{\alpha_{n,1}^2 - 2\alpha_{n,2}}{2\mu} \sin\left(\frac{2n\pi}{2n-1}\right) \right.$$
$$\left. + \frac{\alpha_{n,1}^3 - 3\alpha_{n,1}\alpha_{n,2} + 3\alpha_{n,3}}{3\mu^2} \sin\left(\frac{3n\pi}{2n-1}\right) - \frac{\sec(\frac{\pi}{4n-2})}{(2n-1)} \frac{\alpha_{n,1}^2}{\mu^2} \sin^2\left(\frac{n\pi}{2n-1}\right) \right\}.$$

Then the fourth-order approximation is given by

$$\mu_{k,n} = \mathcal{G}_n\left(\mu_{k,n}^{(0)}\right) + \mathcal{O}\left(\frac{1}{k^4}\right) \quad as\, k \to +\infty.$$

The corresponding kth ordered zero $y_{k,n}$ of $f_n(y)$ is given by

$$y_{k,n} = \pm 2n \left(\mu_{k,n}\right)^{\frac{2n-1}{2n}}. \tag{7}$$

Similarly, the corresponding expansion for the function $f_n(y)$ is obtained from that of $\mathcal{F}_n(\mu)$ by relation (5). Note finally that the behavior of $f_n(y)$ is exponentially small for large y in the sector $|\arg y| < \pi/(4n)$, and the behavior of $\mathcal{F}_n(\mu)$ is exponentially small for large μ in the sector $|\arg \mu| < \pi/(4n-2)$. In the respective complements of these sectors within $|\arg y| < \frac{2n-1}{2n}\frac{\pi}{2}$ (resp. $|\arg \mu| < \pi/2$), the behavior of $f_n(y)$ (resp. $\mathcal{F}_n(\mu)$) is exponentially large for large y (resp. large μ) (cf. [17, §5]).

2. Asymptotic expansion of $F(\mu) = \int_{-\infty}^{\infty} e^{\mu(4iz - z^4)} dz$ as $\mu \to +\infty$. We first describe the procedure for $n = 2$ corresponding to a special case of the Pearcey integral, which we generalize in the following section to arbitrary $n \in \mathbb{N}$. The result in this section has been derived by Paris and Wood in [18, pp. 64–72] using differential equation methods and will serve as comparison. The coefficients they derive, corresponding to the coefficients $\alpha_{2,j}$ in Corollary 2.1, are given in terms of a recurrence relation, whereas we offer a different approach and a different formulation in terms of elementary functions and combinatorial coefficients. This section serves as exposition for the general case $n \in \mathbb{N}$ and as such contains more details.

We are interested in deriving an asymptotic expansion of $F(\mu)$ as $\mu \to +\infty$, where

$$F(\mu) = \int_{-\infty}^{\infty} e^{\mu w(z)} dz, \quad w(z) = 4iz - z^4.$$

The method we use to do so is a standard method for asymptotic expansions of integrals depending on a parameter (cf. [6, 11, 25]). This method, known as Debye's method of steepest descents, is based on deforming the original path of integration through the local extrema of the integrand. The new path is chosen in such a way that along it, the integrand does not oscillate; i.e., the imaginary part of $w(z)$ remains constant. If there are several extrema z_s, only those for which $\Re w(z_s)$ is greatest are taken into consideration. Those that qualify are called the contributing saddle points. In our analysis, we expect two such extrema which must satisfy the condition $\Re w(z_0) = \Re w(z_1)$. These two equally relevant saddle points allow for the cancellation which generates the zeros of $F(\mu)$.

2.1. Saddle points, steepest paths, and contour deformation. We first locate the zeros of $w'(z)$, which we denote $z_s = \xi_s + i\,\eta_s$ and refer to as the saddle points of the integrand. For the quartic polynomial $w(z) = 4iz - z^4$, there are three saddle points:

$$0 = w'(z_s) = 4i - 4z_s^3 \Longrightarrow \{z_0, z_1, z_2\} = \left\{e^{\frac{\pi i}{6}}, e^{\frac{5\pi i}{6}}, e^{-\frac{\pi i}{2}}\right\}. \tag{8}$$

To determine which saddle points have a dominant contribution, we find $\Re w(z_s)$ for $s = 0, 1, 2$. Since $0 = \frac{z_s}{4}\, w'(z_s) = iz_s - z_s^4$, we find $w(z_s) = 4iz_s - z_s^4 = 3iz_s$ and therefore

$$\begin{aligned}\{w(z_0), w(z_1), w(z_2)\} &= \left\{3e^{\frac{2\pi i}{3}}, 3e^{\frac{4\pi i}{3}}, 3\right\}\\ &= \left\{-3/2 + i\,3\sqrt{3}/2, -3/2 - i\,3\sqrt{3}/2, 3\right\}.\end{aligned}$$

It would therefore seem that the dominant contribution comes from $z_2 = -i$. However, we will see that it is not possible to deform the original integration path through z_2. It is also apparent that z_0 and z_1 are equally valid candidates, for they have the same contribution:

$$\Re w(z_0) = \Re w(z_1) = -3/2.$$

It is, in fact, this symmetry which allows for the cancellation of the two asymptotic expansions generated by z_0 and z_1, which in turn will permit the determination of the asymptotic zeros of $F(\mu)$ with as much precision as necessary. Note that subsequently we often use the subscript s to state a property that is valid for both relevant saddle-points indexed by $s = 0, 1$. The deformed path of integration must satisfy the following conditions:

(i) The new path must go through a zero z_s of $w'(z)$.
(ii) $\Im w(z) = \Im w(z_s)$ on the new path.
(iii) $\Re w(z) \le \Re w(z_s)$ on the new path.

The next step consists of analyzing the hills, valleys, and paths of steepest descent and ascent of these saddle points. The level curves separating the hills and valleys of the saddle points z_s and the steepest paths emerging from them are given by

(i) steepest paths: $\Im\{\, w(z) - w(z_s)\,\} = 0$,
(ii) level curves: $\Re\{\, w(z) - w(z_s)\,\} = 0$,

where

$$\begin{aligned}w(z) = w(\xi + i\eta) &= 4i(\xi + i\eta) - (\xi + i\eta)^4\\ &= -4\eta - \xi^4 + 6\eta^2\xi^2 - \eta^4 + 4i(\xi - \xi^3\eta + \eta^3\xi).\end{aligned}$$

The level curves that separate the hills and valleys above and below the saddle points are determined by the real branches of the following equations:

$$-4\eta - \xi^4 + 6\eta^2\xi^2 - \eta^4 = \Re w(z_s),$$
$$\{\Re w(z_0), \Re w(z_1), \Re w(z_2)\} = \{-3/2, -3/2, 1\}.$$

Solving the biquadratic equation in ξ for ξ as a function of η wherever it is permitted (both ξ and η are real variables), the asymptotic behavior of these curves as $\eta \to \pm\infty$ is given by $\xi(\eta) \sim \pm\sqrt{3 \pm 2\sqrt{2}}\,\eta$; that is, they all end at $\infty \exp(\frac{2k+1}{8}\pi i)$ for some $k \in \mathbb{N}$.

The steepest paths out of each of the saddle points are determined by the real branches of the following cubic equations:

$$\xi - \xi^3\eta + \xi\eta^3 = \Im w(z_s)/4,$$
$$\{\Im w(z_0), \Im w(z_1), \Im w(z_2)\} = \left\{3\sqrt{3}/2, -3\sqrt{3}/2, 0\right\}.$$

It can be shown that the (steepest) descent paths emerging from the saddle points go from $\infty e^{i\pi/2} \leftarrow z_0 \to +\infty$ and from $-\infty \leftarrow z_1 \to \infty e^{i\pi/2}$; the (steepest) ascent paths go from $\infty e^{-i\pi/4} \leftarrow z_0 \to \infty e^{i\pi/4}$ and from $\infty e^{i3\pi/4} \leftarrow z_1 \to \infty e^{i5\pi/4}$. The steepest descent path through $z_2 = -i$ is the imaginary axis ($\xi = 0$), and as such, we may not deform the original path through it. Therefore, this saddle point does not contribute to the asymptotic expansion of $F(\mu)$. The convergence of the integral is preserved because the new paths always remain in the valleys of z_0 and z_1, and $w(e^{i\frac{\pi}{2}}z) = \mathcal{O}(-(iz)^4) = \mathcal{O}(-z^4)$ as $z \to +\infty$. The path deformation through z_0 and z_1 displayed in Fig. 1 is justified by a simple application of Cauchy's theorem. The solid lines represent the steepest paths and the dotted ones represent the level curves separating the hills and valleys above and below the saddle points z_0, z_1, z_2. The complete topography of the surface $u(\xi, \eta)$ is shown on Fig. 1.

Although we have just seen that it is possible to carry out the full (global) analysis of the steepest descent paths, it is not necessary do so. From a local analysis of the steepest directions at the saddle points, one can choose a simple path that will have the desired properties. Let α_s be the steepest descent direction at the saddle point z_s (also known as the axis of the saddle point z_s). It is determined by the inequality

$$(z - z_s)^2 \frac{w''(z_s)}{2!} \leq 0 \Longrightarrow \arg\{z - z_s\} = \pm\pi/2 - \arg\{w''(z_s)\}$$

(cf. [6, Chap. 5]). Since $\alpha_s = \lim_{z\to z_s} \arg\{z - z_s\}$ along the steepest paths, where the correct choice of α_s is determined by the direction in which the saddle point is crossed, we find that $\alpha_s = -(-1)^s\pi/6$. The path we consider is a combination of half-lines and line segments in the complex plane: $\gamma = \left(-\infty, -\sqrt{3}\right] \cup \mathcal{L}_1 \cup \mathcal{L}_0 \cup \left[\sqrt{3}, +\infty\right)$, where $\mathcal{L}_0$ and $\mathcal{L}_1$ are given by

$$\begin{cases} \mathcal{L}_0: & z(t) = e^{i\pi/6} + e^{-i\pi/6}t \quad -1 \leq t \leq 1, \\ \mathcal{L}_1: & z(t) = e^{i5\pi/6} + e^{i\pi/6}t \quad -1 \leq t \leq 1 \end{cases}$$

(see Fig. 2). Note that $\mathcal{L}_s$ is the parametrized line interval $z(t) = z_s + e^{i\alpha_s}t$ for $-1 \leq t \leq 1$, on which $z(0) = z_s$, $z(-1) = -\sqrt{3}$, $z(1) = i$ on $\mathcal{L}_1$ and $z(-1) = i$, $z(1) = \sqrt{3}$ on $\mathcal{L}_0$. Let $h_s(t) = \Re\{w(z(t)) - w(z_s)\} : [-1,1] \to \mathbb{R}$. Since $h_s(t) = -6t^2 - (-1)^s 2t^3 + t^4/2$, its only maximum for $t \in [-1,1]$ is located at $t = 0$, which

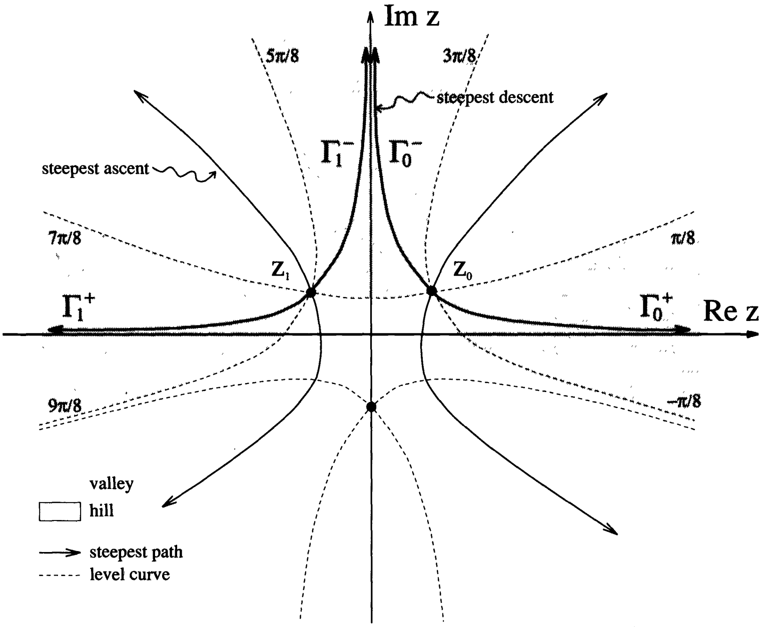

FIG. 1. *Hills, valleys, level curves, and steepest paths of the saddle points* $z_0 = e^{i\pi/6}$, $z_1 = e^{i5\pi/6}$ *relevant to the expansion of* $F(\mu) = \int_{-\infty}^{\infty} e^{\mu(4iz-z^4)}dz$ *as* $\mu \to +\infty$.

corresponds to $z = z_s$. Hence the maximal contribution on the paths $\mathcal{L}_0$, $\mathcal{L}_1$ occurs at z_0, z_1. Moreover, the contributions on the real intervals $(-\infty, -\sqrt{3}]$ and $[\sqrt{3}, +\infty)$ are negligible since $\Re w(z) = -z^4$. Thus the new path γ is admissible and we can still apply the series-reversion process that follows. Indeed, we would only need to verify that the steepest descent path runs from $\pm\infty$ to $i\infty$, and we would infer that the descent path γ is asymptotically equivalent to the steepest descent path Γ.

Now that the path deformation is justified, we can proceed with the expansion regardless of whether we use the exact steepest descent path Γ or just an approximate descent path γ. Since on the steepest descent paths $\Im\{w(z) - w(z_s)\} = 0$ for $s = 0, 1$, we have $w(z) - w(z_s) = -\tau$, $\tau \in \mathbb{R}^+$. Therefore,

(i) as $z \to e^{i\frac{k\pi}{2}}\infty$ for $k \in \mathbb{N}$, $\tau = w(z_s) - w(z) \to +\infty$,

(ii) as $z \to z_s$, $\tau = w(z_s) - w(z) \to 0$.

Deforming the path of integration from the real axis to

$$\Gamma = \Gamma_0 \cup \Gamma_1 = \Gamma_1^- - \Gamma_1^+ + \Gamma_0^+ - \Gamma_0^-,$$

$F(\mu)$ can be written as

$$F(\mu) = \int_\Gamma e^{\mu w(z)}\,dz = \int_{\Gamma_1^- - \Gamma_1^+} e^{\mu w(z)}\,dz + \int_{\Gamma_0^+ - \Gamma_0^-} e^{\mu w(z)}\,dz.$$

Here $\Gamma_s^\pm$ are the respective steepest descent paths emerging from the saddle points z_s, where the ± signs refer to the corresponding branches $z_s^\pm(\tau)$ of the solution to the equation $\tau = w(z_s) - w(z)$ on Γ_s. The assignment of the correct branches $z_s^\pm(\tau)$ to the two steepest descent paths emerging from the saddle points z_s will follow once we have the series expansion for $z_s^\pm(\tau)$ about $\tau = 0$. Proceeding with the path deformation,

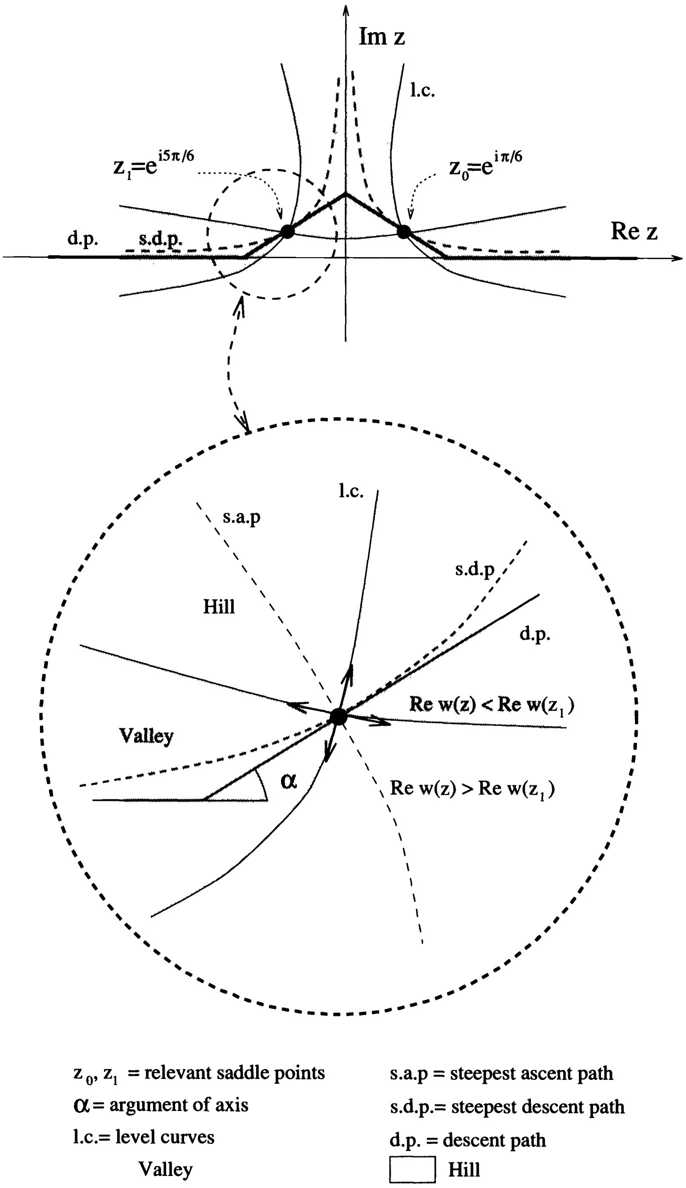

FIG. 2. *Comparison of the local/global analysis of the hills, valleys, level curves, and steepest paths of the saddle points* $z_0 = e^{i\pi/6}$, $z_1 = e^{i5\pi/6}$ *relevant to the expansion of* $F(\mu) = \int_{-\infty}^{\infty} e^{\mu(4iz-z^4)}dz$ *as* $\mu \to +\infty$.

we have

$$
\begin{aligned}
F(\mu) &= \int_{\Gamma_1^- - \Gamma_1^+} e^{\mu(w(z_1)-\tau)}\,dz + \int_{\Gamma_0^+ - \Gamma_0^-} e^{\mu(w(z_0)-\tau)}\,dz \\
&= \int_0^{+\infty} e^{\mu(w(z_1)-\tau)} \left(\frac{dz_1^-}{d\tau} - \frac{dz_1^+}{d\tau}\right)(\tau)\,d\tau \\
&\quad + \int_0^{+\infty} e^{\mu(w(z_0)-\tau)} \left(\frac{dz_0^+}{d\tau} - \frac{dz_0^-}{d\tau}\right)(\tau)\,d\tau \\
&= \sum_{s=0,1} (-1)^s e^{\mu w(z_s)} \int_0^{+\infty} \Phi_s(\tau)\, e^{-\mu\tau}\,d\tau,
\end{aligned}
$$

where $\Phi_s(\tau) = \left(\frac{dz_s^+}{d\tau} - \frac{dz_s^-}{d\tau}\right)(\tau)$.

2.2. Series reversion. We have transformed the original integral into a sum of Laplace integrals. It is now necessary to find a series expansion in the sense of Watson (cf. [11, §22]) for $\Phi_s(\tau)$ and justify the use of Watson's lemma in order to obtain the asymptotic expansion of $F(\mu)$ by term-by-term integration. From the Lagrange formula for the reversion of series (see [12]), we can invert the equation $\tau = w(z_s) - w(z)$ for z as a function of τ for τ near 0. We find that the two branches $z_s^\pm(\tau)$ corresponding to the steepest descent paths starting at $z = z_s^\pm(0) = z_s$ are given by convergent series in powers of $\sqrt{\tau}$ in a neighborhood of $\tau = 0$:

$$z_s^\pm(\tau) = z_s + \sum_{n=1}^{\infty} c_n(z_s)\,(\pm\sqrt{\tau})^n, \tag{9}$$

where

$$c_n(z_s) = \frac{1}{n!}\lim_{z\to z_s}\frac{d^{n-1}}{dz^{n-1}}\left\{f(z)^{-n/2}\right\}, \tag{10}$$

and $f(z) = (w(z_s) - w(z))/(z - z_s)^2$ is defined by

$$\tau = w(z_s) - w(z) = (z - z_s)^2 f(z) = (z - z_s)^2\left(6z_s^2 + 4z_s(z - z_s) + (z - z_s)^2\right).$$

In the definition of the coefficients $c_n(z_s)$, we are taking the principal value of the square root of $f(z)$ for which $\sqrt{f(z_s)} = \sqrt{6}z_s$. We thus have

$$\frac{dz_s^\pm}{d\tau}(\tau) = \sum_{n=1}^{\infty}\frac{n}{2}c_n(z_s)\,(\pm1)^n\tau^{n/2-1} \tag{11}$$

so that

$$\Phi_s(\tau) = \frac{dz_s^+}{d\tau} - \frac{dz_s^-}{d\tau} = \sum_{n=1}^{\infty} nc_n(z_s)\left(\frac{1-(-1)^n}{2}\right)\tau^{n/2-1}.$$

We may now look into assigning different branches of $z_s^\pm(\tau)$ to the different paths $\Gamma_s^\pm$. The motion of $z_s^\pm(\tau)$ along the paths $\Gamma_s^\pm$ as τ increases from $\tau = 0$ to some $0 < \tau \ll 1$ is determined by

$$z_s^\pm(\tau) = z_s \pm c_1(z_s)\sqrt{\tau} + \mathcal{O}(\tau) \qquad \text{as } \tau \to 0^+. \tag{12}$$

Since $c_1(z_s) = \lim_{z\to z_s} f(z)^{-1/2} = (\sqrt{6}z_s)^{-1}$, we have $\arg(c_1(z_s)) = -\arg(z_s)$. Since $\arg(z_0) = \pi/6$ and $\arg(z_1) = 5\pi/6$, we have $\cos(\arg(z_1)) = \cos(5\pi/6) < 0$ and $\cos(\arg(z_0)) = \cos(\pi/6) > 0$. Hence $z_0^+(\tau)$ has increasing real part for τ increasing, and therefore $z_0^+(\tau)$ is the branch that goes from z_0 to $+\infty$ and conversely $z_0^-(\tau)$ is the branch that goes from z_0 to $e^{i\frac{\pi}{2}}\infty$. We name the branches, respectively, Γ_0^+ and Γ_0^-. Similarly, we find that $z_1^-(\tau)$ is the branch that goes from z_1 to $e^{i\frac{\pi}{2}}\infty$ and $z_1^+(\tau)$ is the branch that goes from z_1 to $-\infty$. We name the branches, respectively, Γ_1^- and Γ_1^+.

2.3. Watson's lemma and asymptotic development. In order to apply Watson's lemma, we need to verify that

$$|\Phi_s(\tau)| = \left| \frac{dz_s^+}{d\tau} - \frac{dz_s^-}{d\tau} \right| < Ke^{b\tau}$$

for some positive K and b independent of τ when $\tau \geq \tau_0 > 0$ (see [11]):

$$\begin{aligned} &\tau = w(z_s) - w(z), \qquad \text{for } z \in \Gamma_s \\ \Longrightarrow &\frac{d\tau}{dz} = -w'(z) = 4(z^3 - i) = 4(z^3 - z_s^3) \\ \Longrightarrow &\Phi_s(\tau) = \frac{dz_s^+}{d\tau}(\tau) - \frac{dz_s^-}{d\tau}(\tau) = \frac{1}{4}\left(\frac{1}{z_s^+(\tau)^3 - z_s^3} - \frac{1}{z_s^-(\tau)^3 - z_s^3} \right). \end{aligned}$$

Since $|\Phi_s(\tau)| = \mathcal{O}(1)$ as $\tau \to +\infty$, using Watson's lemma, we may substitute the series expansion of $\Phi_s(\tau)$ (in the sense of Watson) and integrate term by term to obtain a compound asymptotic expansion with respect to the asymptotic sequence $\{\phi_n(\mu) = \mu^{-n}\}$ (see Definition 1.1):

$$\begin{aligned} F(\mu) &\overset{\mu\to+\infty}{\sim} \sum_{s=0,1} (-1)^s e^{\mu w(z_s)} \sum_{n=1}^{\infty} n c_n(z_s) \left(\frac{1-(-1)^n}{2} \right) \Gamma\left(\frac{n}{2}\right) \mu^{-n/2} \\ &= \sum_{s=0,1} (-1)^s e^{\mu w(z_s)} \sum_{n=0}^{\infty} (2n+1) c_{2n+1}(z_s) \Gamma\left(n + \frac{1}{2}\right) \mu^{-(n+1/2)}. \end{aligned}$$

We let

$$a_n(z_s) = (2n+1)c_{2n+1}(z_s) = \frac{1}{(2n)!} \lim_{z\to z_s} \frac{d^{2n}}{dz^{2n}} \left\{ f(z)^{-(n+1/2)} \right\} \tag{13}$$

so that

$$F(\mu) \overset{\mu\to+\infty}{\sim} \frac{1}{\sqrt{\mu}} \sum_{s=0,1} (-1)^s e^{\mu w(z_s)} \sum_{n=0}^{\infty} a_n(z_s) \Gamma\left(n + \frac{1}{2}\right) \mu^{-n}. \tag{14}$$

We proceed with the explicit determination of the coefficients $a_n(z_s)$ in the expansion of F, where $a_n(z_s)$ is the $2n$th coefficient in the Taylor expansion of $f(z)^{-(n+\frac{1}{2})}$ about $z = z_s$. Using the binomial theorem twice, we find

$$\begin{aligned} \left(\frac{f(z)}{6z_s^2} \right)^{-(n+1/2)} &= \left\{ 1 + \frac{2}{3z_s}(z - z_s) \left(1 + \frac{1}{4z_s}(z - z_s) \right) \right\}^{-(n+1/2)} \\ &= \sum_{k=0}^{\infty} \sum_{j=0}^{k} \binom{-n-\frac{1}{2}}{k} \binom{k}{j} \left(\frac{8}{3}\right)^k (4z_s)^{j-2k} (z - z_s)^{2k-j}. \end{aligned}$$

In order to take into account every term that contributes to $a_n(z_s)$, we find the range of k over which we sum by setting $2k - j = 2n$, that is $j = 2(k - n)$. Since j ranges from 0 to k, k ranges from n to $2n$. Thus summing over k from n to $2n$, we find

$$\begin{aligned} a_n(z_s) &= \frac{6^{-(n+1/2)}}{4^{2n}} z_s^{-(4n+1)} \sum_{k=n}^{2n} \binom{-n-\frac{1}{2}}{k} \binom{k}{2(k-n)} \left(\frac{8}{3}\right)^k \\ &= 6^{-(2n+1/2)} z_s^{-(4n+1)} \sum_{k=0}^{n} \binom{-n-\frac{1}{2}}{k+n} \binom{k+n}{2k} \left(\frac{8}{3}\right)^k. \end{aligned}$$

We introduce normalized coefficients ($\alpha_0 = 1$) which do not depend on z_s: let

$$\alpha_n = \Gamma(n+1/2)\sqrt{\frac{6}{\pi}}\, a_n(z_s)\, z_s^{4n+1};$$

then the compound asymptotic expansion of $F(\mu)$ with respect to the asymptotic sequence $\{\mu^{-n}\}$ as $\mu \to +\infty$ is

$$F(\mu) \overset{\mu\to+\infty}{\sim} \sqrt{\frac{\pi}{6\mu}} \sum_{s=0,1} (-1)^s e^{\mu w(z_s)} \sum_{n=0}^{\infty} \alpha_n z_s^{-(4n+1)} \mu^{-n},$$

where the rational coefficients α_n are given by

$$\alpha_n = \frac{\Gamma(\frac{1}{2}+n)}{6^{2n}\sqrt{\pi}} \sum_{k=0}^{n} \binom{-n-\frac{1}{2}}{k+n} \binom{k+n}{2k} \left(\frac{8}{3}\right)^k. \tag{15}$$

The first five values of α_n can easily be computed using a computer algebra system such as Mathematica [21] either directly from (15) or using the Mathematica code provided in Appendix C (see also Table 3):

$$\alpha_0 = 1,\ \alpha_1 = \frac{7}{144},\ \alpha_2 = \frac{385}{41472},\ \alpha_3 = \frac{39655}{17915904},\ \alpha_4 = \frac{665665}{10319560704}. \tag{16}$$

One can compare the coefficients α_n to the coefficients c_n introduced by Paris and Wood in [17, p. 397] and [18, p. 72, Eq. 3.4.16], which are found via a 4-term recurrence relation. It is easy to see that they are related by $\alpha_n = c_n/3^n$. Since

$$z_0 = e^{i\frac{\pi}{6}},\quad z_0^{4n} = e^{\frac{2n\pi}{3}i},\quad w(z_0) = w(e^{i\frac{\pi}{6}}) = -\frac{3}{2} + i\frac{3\sqrt{3}}{2},$$

$$z_1 = e^{i\frac{5\pi}{6}},\quad z_1^{4n} = e^{-\frac{2n\pi}{3}i},\quad w(z_1) = w(e^{i\frac{5\pi}{6}}) = -\frac{3}{2} - i\frac{3\sqrt{3}}{2},$$

we have

$$F(\mu) \overset{\mu\to+\infty}{\sim} \sqrt{\frac{\pi}{6\mu}} e^{-\frac{3}{2}\mu} \left\{ e^{i(3\frac{\sqrt{3}}{2}\mu-\frac{\pi}{6})} \sum_{n=0}^{\infty} \alpha_n e^{-i\frac{2n\pi}{3}} \mu^{-n} \right.$$
$$\left. + e^{-i(3\frac{\sqrt{3}}{2}\mu-\frac{\pi}{6})} \sum_{n=0}^{\infty} \alpha_n e^{i\frac{2n\pi}{3}} \mu^{-n} \right\}.$$

We can formulate this as a generalized asymptotic expansion with respect to the asymptotic sequence $\{\mu^{-n}\}$ (see Definition 1.2):

$$F(\mu) \underset{\{\mu^{-n}\}}{\overset{\mu\to+\infty}{\sim}} \sqrt{\frac{2\pi}{3\mu}} e^{-\frac{3}{2}\mu} \sum_{n=0}^{\infty} \alpha_n \cos\left(3\frac{\sqrt{3}}{2}\mu - \frac{\pi}{6} - \frac{2n\pi}{3}\right) \mu^{-n}. \tag{17}$$

2.4. Asymptotic zeros of $F(\mu)$. To determine the asymptotic zeros of $F(\mu)$, we make use of the compound asymptotic relation

$$h(\mu) = \sqrt{\frac{3\mu}{2\pi}} e^{\frac{3}{2}\mu} F(\mu) \overset{\mu\to+\infty}{\sim} \cos\left(3\frac{\sqrt{3}}{2}\mu - \frac{\pi}{6}\right) \sum_{n=0}^{\infty} \alpha_n \cos\left(\frac{2n\pi}{3}\right) \mu^{-n}$$
$$+ \sin\left(3\frac{\sqrt{3}}{2}\mu - \frac{\pi}{6}\right) \sum_{n=1}^{\infty} \alpha_n \sin\left(\frac{2n\pi}{3}\right) \mu^{-n}. \tag{18}$$

Let $h_m(\mu)$ be the partial sum

$$h_m(\mu) = \cos\left(3\frac{\sqrt{3}}{2}\mu - \frac{\pi}{6}\right)\sum_{n=0}^{m} \alpha_n \cos\left(\frac{2n\pi}{3}\right)\mu^{-n} + \sin\left(3\frac{\sqrt{3}}{2}\mu - \frac{\pi}{6}\right)\sum_{n=1}^{m} \alpha_n \sin\left(\frac{2n\pi}{3}\right)\mu^{-n}. \tag{19}$$

Then solving the equation $h_m(\mu) = 0$ is equivalent to solving

$$\tan\left(3\frac{\sqrt{3}}{2}\mu - \frac{\pi}{6}\right) = -\frac{\sum_{n=0}^{m} \alpha_n \cos\left(\frac{2n\pi}{3}\right)\mu^{-n}}{\sum_{n=1}^{m} \alpha_n \sin\left(\frac{2n\pi}{3}\right)\mu^{-n}}; \tag{20}$$

that is,

$$3\frac{\sqrt{3}}{2}\mu - \frac{\pi}{6} = k\pi - \tan^{-1}\left(\frac{\sum_{n=0}^{m} \alpha_n \cos\left(\frac{2n\pi}{3}\right)\mu^{-n}}{\sum_{n=1}^{m} \alpha_n \sin\left(\frac{2n\pi}{3}\right)\mu^{-n}}\right), \tag{21}$$

where $|\tan^{-1} x| < \pi/2$. For m sufficiently large, we have, as $\mu \to +\infty$,

$$\tan^{-1}\left(\frac{\sum_{n=0}^{m} \alpha_n \cos\left(\frac{2n\pi}{3}\right)\mu^{-n}}{\sum_{n=1}^{m} \alpha_n \sin\left(\frac{2n\pi}{3}\right)\mu^{-n}}\right) = \frac{\pi}{2} - \frac{7}{96\sqrt{3}\,\mu} + \frac{7}{576\sqrt{3}\,\mu^2} + \frac{49}{497664\sqrt{3}\,\mu^4} - \frac{379351}{268738560\sqrt{3}\,\mu^5} + \mathcal{O}\left(\frac{1}{\mu^6}\right). \tag{22}$$

Thus we have, as $\mu \to +\infty$,

$$3\frac{\sqrt{3}}{2}\mu - \frac{\pi}{6} = k\pi - \left\{\frac{\pi}{2} - \frac{7}{96\sqrt{3}\,\mu} + \frac{7}{576\sqrt{3}\,\mu^2} + \frac{49}{497664\sqrt{3}\,\mu^4} - \frac{379351}{268738560\sqrt{3}\,\mu^5}\right\} + \mathcal{O}\left(\frac{1}{\mu^6}\right). \tag{23}$$

Letting

$$\mu_k^{(0)} = \frac{2\pi}{3\sqrt{3}}(k - 1/3), \qquad k \geq 1, \tag{24}$$

we have

$$\mu = \mu_k^{(0)} + \frac{7}{432\,\mu}\left\{1 - \frac{1}{6\,\mu} - \frac{7}{5184\,\mu^3} + \frac{54193}{2799360\,\mu^4}\right\} + \mathcal{O}\left(\frac{1}{\mu^6}\right). \tag{25}$$

We now state a lemma which enables us to improve the first-order asymptotic estimate to a higher-order one. Its proof is based on the reversion of (asymptotic) series by either Lagrange's formula (see [15, p. 21, §8.4]) or using the method of successive resubstitution (see Appendix A).

Lemma 2.1. *If* $\mu^{(0)} = \mathcal{O}(k)$ *as* $k \to +\infty$ *and*

$$\mu = \mu^{(0)} + \frac{a_1}{\mu}\left(a_2 + \frac{a_3}{\mu} + \frac{a_4}{\mu^2} + \frac{a_5}{\mu^3} + \frac{a_6}{\mu^4}\right) + \mathcal{O}\left(\frac{1}{\mu^6}\right)$$

is an asymptotic relation which holds as $\mu \to +\infty$, *then*

$$\mu = \mu^{(0)} + \frac{a_1}{\mu^{(0)}} \left(a_2 + \frac{a_3}{\mu^{(0)}} + \frac{a_4 - a_1 a_2^2}{{\mu^{(0)}}^2} + \frac{a_5 - 3a_1a_2a_3}{{\mu^{(0)}}^3} \right.$$
$$\left. + \frac{a_6 - 2a_1a_3^2 + 2a_1^2a_2^3 - 4a_1a_2a_4}{{\mu^{(0)}}^4} \right) + \mathcal{O}\left(\frac{1}{k^6}\right) \qquad \textit{as } k \to +\infty.$$

Combining (15), (24), (25), and Lemma 2.1, we have proven the following.

COROLLARY 2.1. *For* $n = 2$, *the rational coefficients* $\alpha_{2,j}$ *in the expansion of* $\mathcal{F}_2(\mu) = \int_{-\infty}^{\infty} e^{\mu(4ix - x^4)}dx$ *are*

$$\alpha_{2,j} = \frac{\Gamma(\frac{1}{2} + j)}{6^{2j}\sqrt{\pi}} \sum_{k=0}^{j} \binom{-j - \frac{1}{2}}{k + j} \binom{k + j}{2k} \left(\frac{8}{3}\right)^k .$$

For $k \geq 1$, *the approximation of the* k*th ordered positive zero* $\mu_{k,2}$ *of* $\mathcal{F}_2(\mu)$ *is given by*

$$\mu_{k,2}^{(0)} = \frac{2\pi}{3\sqrt{3}} \left(k - \frac{1}{3}\right) + \mathcal{O}\left(\frac{1}{k}\right) \qquad \textit{as } k \to +\infty.$$

The sixth-order approximation is

$$\mu_{k,2} = \mathcal{G}_2\left(\mu_{k,2}^{(0)}\right) + \mathcal{O}\left(\frac{1}{k^6}\right) \qquad \textit{as } k \to +\infty,$$

$$\mathcal{G}_2(\mu) = \mu + \frac{7}{432\mu}\left(1 - \frac{1}{6\mu}\left(1 + \frac{7}{72\mu}\left(1 - \frac{5}{12\mu}\left(1 + \frac{53143}{18900\mu}\right)\right)\right)\right).$$

The fact that this is actually the expansion of the kth ordered zero of $F(\mu)$ can be proved by the argument principle (see [12, 15]).

3. Asymptotic expansion of $\mathcal{F}_n(\mu)$ as $\mu \to +\infty$. For $n \geq 2$ and $|\arg \mu| < \pi/2$, we consider the function introduced in (6):

$$\mathcal{F}_n(\mu) = \int_{-\infty}^{\infty} e^{\mu\,(2niz - z^{2n})} dz.$$

The saddle points z_s of the integrand and their contributions are given by

$$\left\{ \begin{array}{l} w_n(z) = 2niz - z^{2n}, \\ w_n'(z_s) = 2niz_s - 2nz_s^{2n-1} = 0, \\ 0 = \frac{z_s}{2n} w_n'(z_s) = iz_s - z_s^{2n}, \end{array} \right. \implies \left\{ \begin{array}{l} z_s = \exp(\frac{i\pi}{4n-2}(1 + 4k)), \\ w_n(z_s) = (2n - 1)iz_s, \\ \Re w_n(z_s) = -(2n - 1)\Im z_s. \end{array} \right.$$

Thus

$$\Re w_n(z_s) = -(2n - 1)\sin\left(\frac{\pi}{4n - 2}(1 + 4k)\right), \qquad k = 0, 1, \ldots, 2n - 2.$$

On the two steepest descent paths emerging from relevant saddle points, we have

$$w_n(z) - w_n(z_s) = -(z - z_s)^2 f_n(z) = -\tau \leq 0,$$
$$f_n(z) = -\sum_{k=0}^{2n-2} \frac{w_n^{(k+2)}(z_s)}{(k + 2)!}(z - z_s)^k.$$

As before, we expect to have contributions from two equally relevant saddle points which come in symmetric pairs satisfying the relation $z_0 = -\overline{z_1}$ (see §3.2). The assignment of the branches $z_s^{\pm}(\tau)$ to the steepest descent paths must be dealt with carefully. From Lagrange's formula, we express $z_s^{\pm}(\tau)$ as convergent series in powers of $\sqrt{\tau}$ in a neighborhood of $\tau = 0$:

$$z_s^{\pm}(\tau) = z_s + \sum_{j=1}^{\infty} \mathfrak{c}_{n,j}(z_s)(\pm\sqrt{\tau})^j$$

with

$$\mathfrak{c}_{n,j}(z_s) = \frac{1}{j!} \lim_{z \to z_s} \frac{d^{j-1}}{dz^{j-1}} \left\{ f_n(z)^{-j/2} \right\}.$$

Since $\mathfrak{c}_{n,1}(z_s) = f_n(z_s)^{-1/2} = \binom{2n}{2}^{-1/2} z_s^{1-n}$, the behavior of $z_s^{\pm}(\tau)$ in a neighborhood of $\tau = 0$ is determined by

$$z_s^{\pm}(\tau) = z_s \pm \frac{z_s^{1-n}}{\sqrt{\binom{2n}{2}}} \sqrt{\tau} + \mathcal{O}(\tau) \qquad \text{as } \tau \to 0^+.$$

In the definition of $\mathfrak{c}_{n,j}(z_s)$, we have taken the principal value of $\sqrt{f_n(z)}$ for which $\sqrt{f_n(z_s)} = \sqrt{\binom{2n}{2}} z_s^{n-1}$. In what follows, we assume that the pair of relevant saddle points $\{z_0, z_1 = -\overline{z_0}\}$ is the first pair with smallest positive imaginary part, that is, $z_0 = \exp(\frac{i\pi}{4n-2})$ and $z_1 = -\exp(-\frac{i\pi}{4n-2})$. This is so because it is the only pair whose steepest descent paths are admissible in the sense that the original path of integration cannot be deformed through any of the steepest descent paths emerging from the other saddle points with negative imaginary part. Indeed, such saddle points would yield an incorrect increasing exponential behavior since we would then have $\Re w_n(z_s) = -(2n-1)\,\Im z_s > 0$. None of the other saddle points with positive imaginary part (all saddle points come in symmetric pair $\{z_s, -\overline{z_s}\}$ except those for which $\Re z_s = 0$) have admissible steepest descent paths. Even if it were possible to deform the path of integration through another pair, their contribution would be exponentially smaller than that of the pair $\{z_0, -\overline{z_0}\}$. On the steepest descent paths $\Gamma_1^{\pm}$ corresponding to the equation $\tau = w(z_1) - w(z)$, we have

$$z_1^{\pm}(\tau) = z_1 \mp (-1)^n \frac{e^{i\frac{n-1}{4n-2}\pi}}{\sqrt{\binom{2n}{2}}} \sqrt{\tau} + \mathcal{O}(\tau) \qquad \text{as } \tau \to 0^+.$$

Following the motion of $z_1^{\pm}(\tau)$ along $\Gamma_1^{\pm}$ for increasing $\tau > 0$ as in (12), one can correctly choose the branches $z_1^{\pm}(\tau)$. Hence we see that the assignment of the branches $z_1^{\pm}(\tau)$ changes from the upper branch to the lower one (as shown in Fig. 3) depending on the parity of the index n. Note that this feature is not present in the case of $z_0^{\pm}(\tau)$. In the case $n = 3$, the paths of steepest descent labeled $\Gamma_0^{\pm}$ go from $e^{\frac{\pi i}{3}}\infty \leftarrow z_0 = e^{\frac{\pi i}{10}} \to +\infty$; the ones labeled $\Gamma_1^{\pm}$ go from $-\infty \leftarrow z_1 = -\overline{z_0} = e^{\frac{9\pi i}{10}} \to e^{\frac{2\pi i}{3}}\infty$. There is a third path labeled Γ_2 which connects Γ_1^{+} and Γ_0^{-}. This third path remains in the common valley of the saddle points z_0 and $-\overline{z_0}$ and is subdominant with respect to the other paths. In other words, its contribution is exponentially small compared to the contributions of Γ_0 and Γ_1. In the general case, the topography remains similar. We

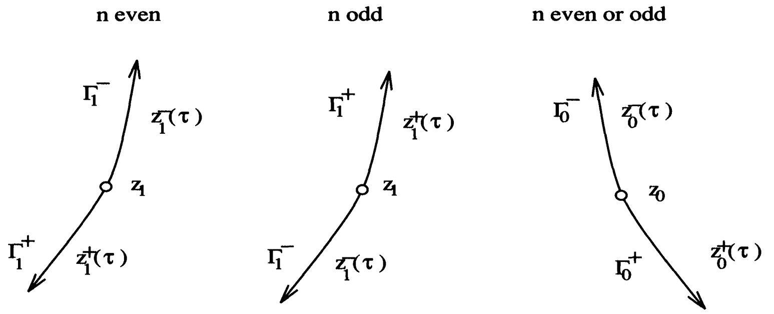

FIG. 3. *Interchange of the branch assignment $z_1^{\pm}(\tau)$ according to the parity of the index n.*

expect the paths of steepest descent emerging from the saddle points at $z_0 = e^{\frac{\pi i}{4n-2}}$ and $z_1 = -\overline{z_0}$ to end in respective valleys. Let

$$\Gamma_n = \Gamma_0^+ - \Gamma_0^- + \Gamma_1^{(-)^{n+1}} - \Gamma_1^{(-)^n} + \Gamma_2$$

denote the new path of integration, where

$$\Gamma_1^{(-)^n} = \begin{cases} \Gamma_1^+ & \text{if } n \text{ even,} \\ \Gamma_1^- & \text{if } n \text{ odd} \end{cases}$$

and reciprocally for $\Gamma_1^{(-)^{n+1}}$. The asymptotic behavior of these paths is as follows:

$$\begin{aligned} &\Gamma_0^+ : z_0 \to +\infty, \qquad \Gamma_0^- : z_0 \to \infty\, e^{i\pi/n} \\ &\Gamma_1^{(-)^{n+1}} : z_1 \to \infty\, e^{i(\pi-\pi/n)}, \qquad \Gamma_1^{(-)^n} : z_1 \to -\infty, \\ &\Gamma_2 : \infty\, e^{i(\pi-\pi/n)} \to \infty\, e^{i\pi/n}. \end{aligned}$$

One can also choose a simple descent path which is the straight line $\gamma_n : \Im z = \Im z_0 = \sin(\frac{\pi}{4n-2})$ in the complex plane going through both saddle points z_0 and $-\overline{z_0}$ parallel to the real axis depicted in Fig. 4 as a dashed path (see the argument in [9, Lem. 2.1]). We now deform the original contour of integration along the path Γ_n or γ_n as in Fig. 4, and we take into account the interchange of the branches $z_1^{\pm}(\tau)$ based on the parity of the index n by including a factor $(-1)^{s\cdot n}$, $s = 0, 1$, in (14). We notice that $|\Phi_s(\tau)| = |dz_s^+/d\tau - dz_s^-/d\tau| = \mathcal{O}(1)$ as $\tau \to +\infty$, so we can appeal to Watson's lemma to find a compound asymptotic expansion for $\mathcal{F}_n(\mu)$ with respect to the asymptotic sequence $\{\phi_j(\mu) = \mu^{-j}\}$:

$$\mathcal{F}_n(\mu) \overset{\mu\to+\infty}{\sim} \frac{1}{\sqrt{\mu}} \sum_{s=0,1} (-1)^{s(1+n)} e^{\mu w_n(z_s)} \sum_{j=0}^{\infty} \mathfrak{a}_{n,j}(z_s)\, \Gamma\Big(j + \frac{1}{2}\Big) \mu^{-j}, \tag{26}$$

$$\mathfrak{a}_{n,j}(z_s) = (2j+1)\, \mathfrak{c}_{n,2j+1}(z_s) = \frac{1}{(2j)!} \lim_{z\to z_s} \frac{d^{2j}}{dz^{2j}} \left\{ f_n(z)^{-(j+1/2)} \right\}. \tag{27}$$

3.1. Coefficients of the expansion.

Let

$$\mathfrak{a}_{n,j}(z_s) = \frac{1}{(2j)!} \lim_{z\to z_s} \frac{d^{2j}}{dz^{2j}} \left\{ g_j(f_n(z)) \right\},$$

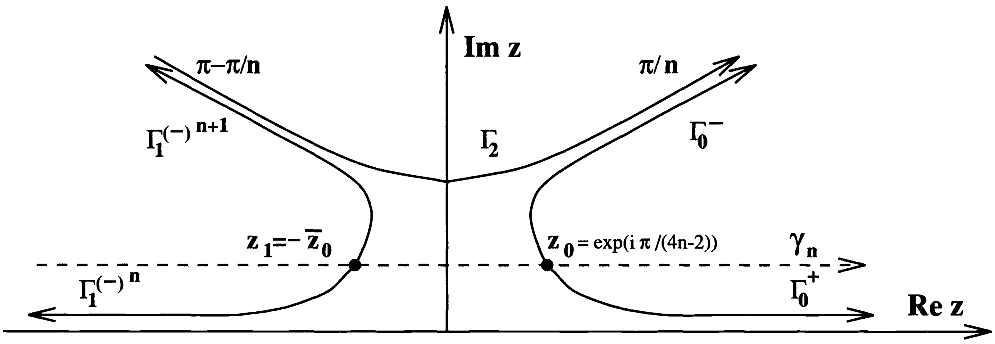

FIG. 4. *Steepest descent path (solid)* $\Gamma_n = \Gamma_0^+ - \Gamma_0^- + \Gamma_1^{(-)^{n+1}} - \Gamma_1^{(-)^n} + \Gamma_2$ *and alternate path (dashed)* $\gamma_n : \Im z = \Im z_0 = \sin(\frac{\pi}{4n-2})$ *in the expansion of* $\mathcal{F}_n(\mu) = \int_{-\infty}^{\infty} e^{\mu(2niz-z^{2n})}\,dz$ *as* $\mu \to +\infty$ *for* $n \geq 3$.

where

$$g_j(z) = z^{-j-1/2}, \quad f_n(z) = \sum_{k=0}^{2n-2} \binom{2n}{k+2} z_s^{2n-2-k}(z-z_s)^k.$$

According to the definition of Pochhammer's symbol $(z)_n$, we let $(1/2-j-m)_m = \Gamma(1/2-j)/\Gamma(1/2-j-m) = (-j-1/2)\cdot(-j-3/2)\cdots(1/2-j-m)$ for $m \geq 1$ and let $(1/2-j)_0 = 1$ so that we may write

$$g_j^{(m)}(f_n(z_s)) = \left(n(2n-1)\,z_s^{2n-2}\right)^{-j-1/2-m}(1/2-j-m)_m, \tag{28}$$

$$\frac{f_n^{(k)}(z_s)}{k!} = \begin{cases} \binom{2n}{k+2} z_s^{2n-2-k}, & 0 \leq k \leq 2n-2, \\ 0, & k \geq 2n-1. \end{cases} \tag{29}$$

Using (28) and (29) in Faà di Bruno's formula (see (50)), we find

$$\begin{aligned} \mathfrak{a}_{n,j}(z_s) = \sum_{m=0}^{2j} \Bigg\{ & \left(n(2n-1)\,z_s^{2n-2}\right)^{-j-\frac{1}{2}-m}(1/2-j-m)_m \\ & \times \sum_{\boldsymbol{\sigma}}{}' \prod_{k=1}^{2j} \frac{1}{\sigma_k!}\left(\binom{2n}{k+2} z_s^{2n-2-k}\right)^{\sigma_k} \Bigg\}. \end{aligned} \tag{30}$$

The summation $\sum'_{\boldsymbol{\sigma}}$ is taken over all $2j$-vectors $\boldsymbol{\sigma} = (\sigma_1, \ldots, \sigma_{2j}) \in \mathbb{N}^{2j}$ such that the following conditions are simultaneously satisfied:

$$\left\{ \begin{array}{c} \sigma_1 + \sigma_2 + \cdots + \sigma_{2j} = m, \\ \sigma_1 + 2\sigma_2 + \cdots + 2j\sigma_{2j} = 2j, \\ \sigma_k = 0 \quad \forall k \geq 2n-1 \end{array} \right\}. \tag{31}$$

The last condition $\sigma_k = 0 \forall k \geq 2n-1$ arises from the fact that $f_n(z)$ is a polynomial of order $2n-2$ and therefore any derivative of order $k \geq 2n-1$ of $f_n(z)$ is zero. In order for the product to be nontrivial, we must set the corresponding powers σ_k to zero when $k \geq 2n-1$ (see (50)). This amounts to using the truncated $(2n-2)$-vector $\boldsymbol{\sigma} = (\sigma_1, \ldots, \sigma_{2n-2}) \in \mathbb{N}^{2n-2}$ in the last product, whereby we can reduce conditions (31) to a new set of conditions

$$\left\{ \begin{array}{c} \sigma_1 + \sigma_2 + \cdots + \sigma_{2n-2} = m, \\ \sigma_1 + 2\sigma_2 + \cdots + (2n-2)\sigma_{2n-2} = 2j, \\ \sigma_k = 0 \quad \forall k \geq 2n-1 \end{array} \right\}. \tag{32}$$

We express (30) as

$$\begin{aligned} \mathfrak{a}_{n,j}(z_s) = \sum_{m=0}^{2j} \Bigg\{ & \left(n(2n-1)\, z_s^{2n-2}\right)^{-j-\frac{1}{2}-m} (1/2-j-m)_m \\ & \times \sum_{\sigma}{}' \prod_{k=1}^{2n-2} \frac{1}{\sigma_k!} \left(\binom{2n}{k+2} z_s^{2n-2-k} \right)^{\sigma_k} \Bigg\}. \end{aligned} \tag{33}$$

Using the first and second condition in (32), we notice that

$$\prod_{k=1}^{2n-2} z_s^{(2n-2-k)\cdot\sigma_k} = z_s^{(2n-2)\sum_{k=1}^{2n-2}\sigma_k - \sum_{k=1}^{2n-2} k\sigma_k} = z_s^{(2n-2)m-2j}.$$

We can therefore extract the z_s dependency from the summation signs in (33):

$$\begin{aligned} \mathfrak{a}_{n,j}(z_s) = \frac{z_s^{1-n(1+2j)}}{\left(n(2n-1)\right)^{j+1/2}} \sum_{m=0}^{2j} \Bigg\{ & \frac{(1/2-j-m)_m}{\left(n(2n-1)\right)^m} \\ & \times \sum_{\sigma}{}' \prod_{k=1}^{2n-2} \frac{1}{\sigma_k!} \binom{2n}{k+2}^{\sigma_k} \Bigg\}. \end{aligned} \tag{34}$$

We introduce normalized coefficients ($\alpha_{n,0} = 1$) which do not depend on the saddle points z_s:

$$\alpha_{n,j} = \Gamma(j+1/2) \sqrt{\frac{n(2n-1)}{\pi}} z_s^{n(1+2j)-1} \, \mathfrak{a}_{n,j}(z_s). \tag{35}$$

The jth coefficient for $j \geq 0$ is then a rational number given by

$$\begin{aligned} \alpha_{n,j} = \frac{\Gamma(j+1/2)}{\sqrt{\pi}\left(n(2n-1)\right)^j} \sum_{m=0}^{2j} \Bigg\{ & \frac{(1/2-j-m)_m}{\left(n(2n-1)\right)^m} \\ & \times \sum_{\sigma}{}' \prod_{k=1}^{2n-2} \frac{1}{\sigma_k!} \binom{2n}{k+2}^{\sigma_k} \Bigg\}, \end{aligned} \tag{36}$$

where the summation $\sum'_{\boldsymbol{\sigma}}$ is taken over all possible $\boldsymbol{\sigma} \in \mathbb{N}^{2n-2}$ such that

$$\left\{ \begin{array}{c} \sigma_1 + \sigma_2 + \cdots + \sigma_{2n-2} = m, \\ \sigma_1 + 2\sigma_2 + \cdots + (2n-2)\sigma_{2n-2} = 2j \end{array} \right\}. \tag{37}$$

A Mathematica code is provided for the reader's convenience in Appendix C to compute the coefficients $\alpha_{n,j}$ from (36) and (37) (see also Table 3).

3.2. Asymptotic expansion of $\mathcal{F}_n(\mu)$ as $\mu \to +\infty$. From equation (26), we find

$$\mathcal{F}_n(\mu) \overset{\mu\to+\infty}{\sim} \sqrt{\frac{\pi}{n(2n-1)\mu}} \sum_{s=0,1} (-1)^{s(1+n)} e^{\mu w_n(z_s)} \sum_{j=0}^{\infty} \alpha_{n,j}\, z_s^{1-n(1+2j)} \mu^{-j}.$$

Since $z_0 = -\overline{z_1} \in \Delta = \{z \in \mathbb{C} : |z| = 1\}$ and $w_n(z_0) = \overline{w_n(z_1)}$, we find

$$\mathcal{F}_n(\mu) \underset{\{\mu^{-j}\}}{\overset{\mu\to+\infty}{\sim}} \sqrt{\frac{4\pi}{n(2n-1)\mu}}\, e^{\mu \Re w_n(z_0)}\, \mathcal{H}_n(\mu), \tag{38}$$

where $\mathcal{H}_n(\mu)$ should be interpreted as a generalized asymptotic expansion with respect to the asymptotic sequence $\{\mu^{-j}\}$:

$$\mathcal{H}_n(\mu) = \sum_{j=0}^{\infty} \frac{\alpha_{n,j}}{\mu^j} \cos\left(\mu\, \Im w_n(z_0) + (1 - n(1+2j)) \arg(z_0)\right). \tag{39}$$

Since $w_n(z_0) = (2n-1) i z_0$ and $z_0 = e^{\frac{\pi i}{4n-2}}$,

$$\Re w_n(z_0) = -(2n-1)\Im z_0 = -(2n-1)\sin\left(\frac{\pi}{4n-2}\right),$$

$$\Im w_n(z_0) = (2n-1)\Re z_0 = (2n-1)\cos\left(\frac{\pi}{4n-2}\right).$$

Thus (38) is

$$\mathcal{F}_n(\mu) \underset{\{\mu^{-j}\}}{\overset{\mu\to+\infty}{\sim}} \sqrt{\frac{4\pi}{n(2n-1)\mu}} \exp\left\{-\mu\,(2n-1)\sin\left(\frac{\pi}{4n-2}\right)\right\} \mathcal{H}_n(\mu) \tag{40}$$

and (39) becomes

$$\mathcal{H}_n(\mu) = \sum_{j=0}^{\infty} \frac{\alpha_{n,j}}{\mu^j} \cos\left(\mu\,(2n-1)\cos\left(\frac{\pi}{4n-2}\right) + \pi\,\frac{1-n(1+2j)}{4n-2}\right). \tag{41}$$

3.3. Asymptotic zeros of $\mathcal{F}_n(\mu)$. $\mathcal{H}_n(\mu)$ is the component of the expansion of $\mathcal{F}_n(\mu)$ that determines its zeros, and its mth partial sum $\mathcal{H}_{n,m}(\mu)$ can also be expressed as a compound asymptotic expansion (see Definition 1.1):

$$\begin{aligned}\mathcal{H}_{n,m}(\mu) &= \cos\left(\mu\,(2n-1)\cos\left(\frac{\pi}{4n-2}\right) - \pi\,\frac{n-1}{4n-2}\right)\sum_{j=0}^{m} \frac{\alpha_{n,j}}{\mu^j}\cos\left(\frac{nj\pi}{2n-1}\right)\\ &+ \sin\left(\mu\,(2n-1)\cos\left(\frac{\pi}{4n-2}\right) - \pi\,\frac{n-1}{4n-2}\right)\sum_{j=1}^{m} \frac{\alpha_{n,j}}{\mu^j}\sin\left(\frac{nj\pi}{2n-1}\right).\end{aligned} \tag{42}$$

The first-order approximation for the zeros of $\mathcal{H}_{n,m}(\mu)$ is found immediately by setting $\cos(\mu\,(2n-1)\cos(\frac{\pi}{4n-2}) - \pi\,\frac{n-1}{4n-2}) = 0$. Thus we find that the kth ordered positive zero $\mu_{k,n}^{(0)}$ of $\mathcal{F}_n(\mu)$ is given (for $k \geq 1$ so that $\mu_{k,n}^{(0)} > 0$) by

$$\mu_{k,n}^{(0)} = \frac{\pi}{4n-2}\sec\left(\frac{\pi}{4n-2}\right)\left(\frac{n-1}{2n-1} - 1 + 2k\right) + \mathcal{O}\left(\frac{1}{k}\right) \tag{43}$$

as $k \to +\infty$. Solving the equation $\mathcal{H}_{n,m}(\mu) = 0$ yields

$$\begin{aligned}(44)\qquad &\mu(2n-1)\cos\left(\frac{\pi}{4n-2}\right) - \pi\frac{n-1}{4n-2}\\ &\qquad = k\pi - \tan^{-1}\left(\frac{\sum_{j=0}^{m}\frac{\alpha_{n,j}}{\mu^j}\cos\left(\frac{nj\pi}{2n-1}\right)}{\sum_{j=1}^{m}\frac{\alpha_{n,j}}{\mu^j}\sin\left(\frac{nj\pi}{2n-1}\right)}\right).\end{aligned}$$

We expand the $\tan^{-1}$ for large μ and sufficiently large m and combine it with (43) and (44) to find

$$\begin{aligned}\mu = \mu_{k,n}^{(0)} + \frac{\sec(\frac{\pi}{4n-2})}{(2n-1)\mu}\Bigg\{&\alpha_{n,1}\sin\left(\frac{n\pi}{2n-1}\right) - \left(\alpha_{n,1}^2 - 2\alpha_{n,2}\right)\sin\left(\frac{2n\pi}{2n-1}\right)\frac{1}{2\mu}\\ &+ \left(\alpha_{n,1}^3 - 3\alpha_{n,1}\alpha_{n,2} + 3\alpha_{n,3}\right)\sin\left(\frac{3n\pi}{2n-1}\right)\frac{1}{3\mu^2}\\ &- \left(\alpha_{n,1}^4 - 4\alpha_{n,1}^2\alpha_{n,2} + 2\alpha_{n,2}^2 + 4\alpha_{n,1}\alpha_{n,3} - 4\alpha_{n,4}\right)\sin\left(\frac{4n\pi}{2n-1}\right)\frac{1}{4\mu^3}\\ &+ \big(\alpha_{n,1}^5 - 5\alpha_{n,1}^3\alpha_{n,2} + 5\alpha_{n,1}\alpha_{n,2}^2 + 5\alpha_{n,1}^2\alpha_{n,3} - 5\alpha_{n,2}\alpha_{n,3}\\ &- 5\alpha_{n,1}\alpha_{n,4} + 5\alpha_{n,5}\big)\sin\left(\frac{5n\pi}{2n-1}\right)\frac{1}{5\mu^4}\Bigg\} + \mathcal{O}\left(\frac{1}{\mu^6}\right).\end{aligned}$$

Appealing to Lemma 2.1, we define

$$\begin{aligned}(45)\quad \mathcal{G}_n(\mu) = \mu + \frac{\sec(\frac{\pi}{4n-2})}{(2n-1)\mu}\Bigg\{&\alpha_{n,1}\sin\left(\frac{n\pi}{2n-1}\right) - \frac{\alpha_{n,1}^2 - 2\alpha_{n,2}}{2\mu}\sin\left(\frac{2n\pi}{2n-1}\right)\\ &+ \frac{\alpha_{n,1}^3 - 3\alpha_{n,1}\alpha_{n,2} + 3\alpha_{n,3}}{3\mu^2}\sin\left(\frac{3n\pi}{2n-1}\right) - \frac{\sec(\frac{\pi}{4n-2})}{(2n-1)}\frac{\alpha_{n,1}^2}{\mu^2}\sin^2\left(\frac{n\pi}{2n-1}\right)\Bigg\}.\end{aligned}$$

Let $\mu_{k,n}$ denote the kth ordered positive zero of $\mathcal{F}_n(\mu)$ so that the fourth-order approximation of $\mu_{k,n}$ is given by

$$\mu_{k,n} = \mathcal{G}_n\left(\mu_{k,n}^{(0)}\right) + \mathcal{O}\left(\frac{1}{k^4}\right) \quad \text{as } k \to +\infty.$$

Combining (36), (37), (40), (41), (43), and (45), Theorem 1.1 is proved. □

3.4. Coefficients $\alpha_{2,j}$. For $n = 2$, we verify the validity of formula (36) by finding the corresponding coefficients $\alpha_{2,j}$, which should match the coefficients α_j of §2. The conditions (32) on $\boldsymbol{\sigma} = (\sigma_1, \ldots, \sigma_{2j})$ come out to be

$$\begin{cases}\displaystyle\sum_{k=1}^{2j}\sigma_k = m,\\ \displaystyle\sum_{k=1}^{2j}k\sigma_k = 2j,\\ \sigma_k = 0 \quad \forall k \geq 3\end{cases}$$

From the third condition, we have that the only nonzero coefficients are σ_1 and σ_2. From the first and second condition, they satisfy the 2×2 system

$$\begin{cases}\sigma_1 + \sigma_2 = m,\\ \sigma_1 + 2\sigma_2 = 2j,\end{cases}$$

whose unique solution is $\boldsymbol{\sigma} = \big(\sigma_1 = 2(m-j), \sigma_2 = 2j - m\big)$. Using $n = 2$, we have

$$\sum_{\boldsymbol{\sigma}}{}' \prod_{k=1}^{2n-2} \frac{1}{\sigma_k!}\binom{2n}{k+2}^{\sigma_k} = \frac{4^{2(m-j)}}{(2(m-j))!}\cdot\frac{1}{(2j-m)!}.$$

Equation (36) becomes

$$\alpha_{2,j} = \frac{\Gamma(j+1/2)}{\sqrt{\pi}\,6^j}\sum_{m=0}^{2j}\frac{(1/2-j-m)_m}{6^m}\cdot\frac{4^{2(m-j)}}{(2(m-j))!}\cdot\frac{1}{(2j-m)!}.$$

We discard all terms $m < j$; thus we let $m = k + j$ so that k ranges from 0 to j:

$$\begin{aligned}\alpha_{2,j} &= \frac{\Gamma(j+1/2)}{\sqrt{\pi}\,6^{2j}}\sum_{k=0}^{j}\frac{(k+j)!\binom{-j-1/2}{k+j}}{6^k}\cdot\frac{16^k}{(2k)!}\cdot\frac{1}{(j-k)!}\\ &= \frac{\Gamma(j+1/2)}{\sqrt{\pi}\,6^{2j}}\sum_{k=0}^{j}\binom{-j-1/2}{k+j}\binom{k+j}{2k}\left(\frac{8}{3}\right)^k\\ &= \alpha_j \qquad \text{(see (15))}.\end{aligned}$$

3.5. Asymptotic zeros of $\mathcal{F}_3(\mu)$. For $n = 3$, the first four coefficients $\alpha_{3,j}, j = 1, \dots, 4$ are given by

$$\alpha_{3,0} = 1, \quad \alpha_{3,1} = \frac{11}{180}, \quad \alpha_{3,2} = \frac{517}{64800}, \quad \alpha_{3,3} = \frac{-22253}{174960000} \tag{46}$$

(see Appendix C and Table 3). In order to describe the asymptotic approximations of the zeros of $\mathcal{F}_3(\mu)$, we need the following trigonometric expressions:

$$\begin{aligned}&\sin\left(\frac{\pi}{10}\right) = -\cos\left(\frac{3\pi}{5}\right) = \frac{\sqrt{5}-1}{4}, \quad \cos\left(\frac{6\pi}{5}\right) = -\frac{1+\sqrt{5}}{4},\\ &\sin\left(\frac{6\pi}{5}\right) = -\frac{1}{2}\sqrt{\frac{5-\sqrt{5}}{2}}, \quad \cos\left(\frac{\pi}{10}\right) = \sin\left(\frac{3\pi}{5}\right) = \frac{1}{2}\sqrt{\frac{5+\sqrt{5}}{2}},\\ &\sin\left(\frac{9\pi}{5}\right) = -\sin\left(\frac{\pi}{5}\right) = -2\sin\left(\frac{\pi}{10}\right)\cos\left(\frac{\pi}{10}\right).\end{aligned}$$

Using (36), the first-order approximation is

$$\mu_{k,3}^{(0)} = \frac{2\pi}{5}\sqrt{\frac{2}{5+\sqrt{5}}}\left(k - \frac{3}{10}\right), \qquad k \geq 1 \qquad (\mu > 0), \tag{47}$$

and combining (45) and (46), the fourth-order approximation is given in the following corollary.

COROLLARY 3.1. *For $n = 3$ and $k \geq 1$, the approximation of the kth ordered positive zero $\mu_{k,3}$ of $\mathcal{F}_3(\mu) = \int_{-\infty}^{\infty} e^{\mu(6iz - z^6)}dz$ is given by*

$$\mu_{k,3}^{(0)} = \frac{2\pi}{5}\sqrt{\frac{2}{5+\sqrt{5}}}\left(k - \frac{3}{10}\right) + \mathcal{O}\left(\frac{1}{k}\right) \quad \textit{as } k \to +\infty.$$

The fourth-order approximation is

$$\mu_{k,3} = \mathcal{G}_3\left(\mu_{k,3}^{(0)}\right) + \mathcal{O}\left(\frac{1}{k^4}\right) \quad \textit{as } k \to +\infty,$$

$$\mathcal{G}_3(\mu) = \mu + \frac{11}{900\,\mu}\left(1 - \frac{\sqrt{5}-1}{20\mu} - \frac{11}{900}\left(1 - \frac{119}{165}\frac{\sqrt{5}-1}{2}\right)\frac{1}{\mu^2}\right).$$

4. Numerical evaluation of the zeros of $\mathcal{F}_n(\mu)$.

In this section, a numerical method is designed to compute the zeros of the function $\mathcal{F}_n(\mu)$. The purpose of including such an analysis is to judge the accuracy of the asymptotic approximations. This numerical algorithm shows that the high accuracy of the asymptotic predictions is attained for moderatly large zeros, thereby confirming the strength of the asymptotics.

The function $\mathcal{F}_n(\mu)$ is approximated using Simpson's rule and extrapolation, to which we apply the secant method to locate the zeros. The asymptotic approximations of the zeros $\mu_{k,2}$ and $\mu_{k,3}$ of $\mathcal{F}_2(\mu)$ and $\mathcal{F}_3(\mu)$ derived in the previous sections are compared to their numerically calculated values. We also compare these estimates to the zeros of $h_{10}(\mu) = \mathcal{H}_{2,10}(\mu)$ and $\mathcal{H}_{3,10}(\mu)$ (see (19) and (42)), which are computed with the secant method.

4.1. Numerical approximation $\mathcal{F}_n^{m,l}(\mu)$ of $\mathcal{F}_n(\mu)$ by Simpson's rule.

The numerical evaluation of Pearcey-type integrals has been studied by Connor and Curtis in [10]. However, since we consider a special case of Pearcey integrals, we devise a simple algorithm to numerically evaluate $\mathcal{F}_n(\mu)$. Using the alternate expression for $\mathcal{F}_n(\mu)$ (see (6)) given by

$$\mathcal{F}_n(\mu) = 2\int_0^{+\infty} \cos(2n\mu y)\, e^{-\mu y^{2n}}\, dy,$$

we construct the approximation by dividing the range of integration into subintervals over which the integrand does not oscillate. Let

$$x_{-1} = 0, \quad x_k = x_k(\mu) = \frac{(k+1/2)\pi}{2n\mu} \quad \text{for } k \in \mathbb{N},$$

$$g_n(\mu, y) = 2\cos(2n\mu y)\exp(-\mu y^{2n}), \qquad \mathcal{I}_n^k(\mu) = (-1)^k \int_{x_{k-1}}^{x_k} |g_n(\mu, y)|\, dy$$

so that

$$\mathcal{F}_n(\mu) = \sum_{k=0}^{\infty} \mathcal{I}_n^k(\mu) = \overbrace{\sum_{k=0}^{m} \mathcal{I}_n^k(\mu)}^{\mathcal{Q}_n^m(\mu)} + \overbrace{\sum_{k=m+1}^{\infty} \mathcal{I}_n^k(\mu)}^{\mathcal{R}_n^m(\mu)},$$

where

$$\mathcal{Q}_n^m(\mu) = \int_0^{x_m} g_n(\mu, y)\, dy, \qquad \mathcal{R}_n^m(\mu) = \int_{x_m}^{+\infty} g_n(\mu, y)\, dy.$$

We first estimate the remainder $\mathcal{R}_n^m(\mu)$:

$$|\mathcal{R}_n^m(\mu)| \le 2\int_{x_m}^{+\infty} e^{-\mu y^{2n}}\, dy = \frac{\Gamma\left(\frac{1}{2n}, \mu x_m^{2n}\right)}{n\mu^{\frac{1}{2n}}},$$

where $\Gamma(a, x)$ is the incomplete gamma function defined for $\Re a > 0$. Since $\Gamma(a, x) \sim e^{-x} x^{a-1}$ as $x \to +\infty$ (see [1]), we find that

$$|\mathcal{R}_n^m(\mu)| \leq \frac{e^{-\mu x_m^{2n}}}{n\mu x_m^{2n-1}} \qquad \text{for sufficiently large } \mu x_m^{2n}.$$

The endpoint $x_m(\mu) = (m + 1/2)\pi/(2n\mu)$ is chosen in such a way that the contribution from the remainder $\mathcal{R}_n^m(\mu)$ is negligible for a fixed (bounded) μ. If we require that

$$\exp\left(-\mu x_m^{2n}\right) < \varepsilon = 10^{-\kappa}, \quad \kappa \in \mathbb{N}, \tag{48}$$

then it yields a good initial choice for m given by

$$m = m[\kappa; n, \mu_{\max}] = \operatorname{Int}\left[\frac{2n}{\pi}\mu_{\max}^{\frac{2n-1}{2n}}(\kappa \log 10)^{\frac{1}{2n}} - \frac{1}{2}\right] + 1, \tag{49}$$

where Int $[x]$ denotes the integer part of x and $\mu_{\max}$ is a bound on the largest zero we wish compute. It is clear from this analysis that the larger $\mu_{\max}$ is, the larger m will need to be, which is why this algorithm is practical only for small roots $\mu_{k,n}$.

We now approximate $\mathcal{Q}_n^m(\mu)$ by $\mathcal{Q}_n^{m,l}(\mu)$ for large l and moderate m (due to the rapid decay of the integrand),

$$\mathcal{Q}_n^m(\mu) = \sum_{k=0}^{m} \mathcal{I}_n^k(\mu) \approx \mathcal{Q}_n^{m,l}(\mu) = \sum_{k=0}^{m} \mathcal{I}_n^{k,l}(\mu),$$

where each integral $\mathcal{I}_n^k(\mu)$ is approximated by $\mathcal{I}_n^{k,l}(\mu)$ using Simpson's rule: l is the number of gridpoints and the spacing h is defined by

$$h = \frac{\Delta x_k}{l} = \frac{x_{k+1} - x_k}{l} = \frac{\pi}{2n\mu l}.$$

Since the discretization errors for $\mathcal{I}_n^{k,l}$ and $\mathcal{Q}_n^{m,l}$ are given by

$$\mathcal{I}_n^k(\mu) = \mathcal{I}_n^{k,l}(\mu) + \mathcal{O}\left(\frac{1}{l^4}\right), \quad \mathcal{Q}_n^m(\mu) = \mathcal{Q}_n^{m,l}(\mu) + \mathcal{O}\left(\frac{m}{l^4}\right),$$

we can use extrapolation with $\mathcal{Q}_n^{m,l}$ to improve the approximation of $\mathcal{F}_n^{m,l}$ as follows:

$$\mathcal{F}_n^{m,l}(\mu) = \mathcal{Q}_n^{m,2l}(\mu) + \frac{\mathcal{Q}_n^{m,2l}(\mu) - \mathcal{Q}_n^{m,l}(\mu)}{2^4 - 1} \Longrightarrow \mathcal{Q}_n^m(\mu) = \mathcal{F}_n^{m,l}(\mu) + \mathcal{O}\left(\frac{m}{l^5}\right).$$

Thus the final approximation is

$$\mathcal{F}_n(\mu) = \mathcal{F}_n^{m,l}(\mu) + \mathcal{O}\left(\frac{m}{l^5}\right) + \mathcal{O}\left(\frac{e^{-\mu x_m^{2n}}}{\mu x_m^{2n-1}}\right)$$

as $\mu x_m^{2n} \to +\infty$ and $l \to +\infty$. Clearly, the constraint on this algorithm arises from the choice of l since a moderately large value of $m \ll l$ is sufficient to make the remainder $\mathcal{R}_n^m(\mu)$ as small as desired. Moreover, it is difficult to estimate the asymptotic constant in the term $\mathcal{O}(m/l^5)$, which may be large since it involves $\frac{\partial^4}{\partial y^4} g_n(\mu, y)$. Hence the choice for l is made by doubling its value until two successive values of all the zeros $\mu_{k,n} < \mu_{\max}$ agree to 10 significant digits.

4.2. Numerical approximation of the zeros of $\mathcal{F}_n^{m,l}(\mu)$ and $\mathcal{H}_{n,m}(\mu)$ by the secant method. We use the secant method to approximate the zeros of $\mathcal{F}_n^{m,l}(\mu)$ and $\mathcal{H}_{n,m}(\mu)$, which appear in the "Numerical values" column and the "$\mathcal{H}_{n,m}^{-1}(0)$" column of Tables 1 and 2, respectively. From (42), we express $\mathcal{H}_{n,m}(\mu)$ as

$$\mathcal{H}_{n,m}(\mu) = \sum_{j=0}^{m} \alpha_{n,j} \cos\left(\mu\,(2n-1)\cos\left(\frac{\pi}{4n-2}\right) + \pi\,\frac{1-n(1+2j)}{4n-2}\right)\mu^{-j}$$

and let $\mathcal{K}(\mu)$ stand for either $\mathcal{F}_n^{m,l}(\mu)$ or $\mathcal{H}_{n,m}(\mu)$. Then the procedure consists in successively evaluating, for any $k \geq 1$ ($\mu > 0$),

$$\mu_{k,n}^0 = \frac{\pi}{4n-2}\sec\left(\frac{\pi}{4n-2}\right)\left(\frac{n-1}{2n-1} - 1 + 2k\right),$$

$$\mu_{k,n}^1 = \mu_{k,n}^0 - \frac{2\,\delta\mu}{\mathcal{K}(\mu_{k,n}^0+\delta\mu) - \mathcal{K}(\mu_{k,n}^0-\delta\mu)}\cdot\mathcal{K}(\mu_{k,n}^0) \qquad (\delta\mu = 10^{-2}),$$

$$\mu_{k,n}^{j+1} = \mu_{k,n}^j - \frac{\mu_{k,n}^j - \mu_{k,n}^{j-1}}{\mathcal{K}(\mu_{k,n}^j) - \mathcal{K}(\mu_{k,n}^{j-1})}\cdot\mathcal{K}(\mu_{k,n}^j), \qquad j \geq 1,$$

until the convergence of $\mu_{k,n}^j \to \mu_{k,n}$, which is based upon a relative-error test of the form

$$\left|\frac{\mu_{k,n}^{j+1} - \mu_{k,n}^j}{\mu_{k,n}^{j+1}}\right| < \text{tol} \; = 10^{-10}.$$

4.3. $n = 2$. If m is chosen so as to satisfy (48), then a crude initial choice for l is $l = 10^{\kappa/5}$ (typically $\kappa = 12 \Rightarrow l \approx 250$). We take $\mu_{\max} = 11$ to be a bound for the largest zero we wish to compute and take $\kappa = 12$ so that from (49), we find that $m = m[12; 2, 11] = 18$. Starting from $l = 10^{\kappa/5} \approx 250$, we double the value of l until all 10 significant figures in the column "Numerical zeros" of Table 1 do not change. The first such value is $l = 1000$. Note that for $k \leq 5$ ($\mu_{\max} \leq 6$), $m = 12$ is sufficient. One can see in Table 1 that the values computed from the asymptotic approximations are very good. Notice that the first zero $\mu_{1,2}$ is not well approximated by any of the asymptotic predictions since it is less than 1. Beyond the first zero, the asymptotic approximations improve with increasing index k. For $5 \leq k \leq 8$, $\mathcal{H}_{2,10}^{-1}(0)$ agrees with the numerical values up to 10 digits. For $k \geq 5$, $\mu_{k,2}^{(5)}$ and the numerical values agree up to 8 digits. For $k \geq 8$, the numerical and asymptotic values grow apart due to the lack of accuracy of the numerical procedure (see the comment following equation (49)). Note also that for $k \geq 8$, $\mu_{k,2}^{(5)}$ and $\mathcal{H}_{2,10}^{-1}(0)$ agree up to 10 digits ($\mathcal{H}_{2,10}^{-1}(0)$ is computed for the sake of comparison of the asymptotic and numerical estimates). In computing $\mathcal{H}_{2,10}(\mu)$, the 10 coefficients $\alpha_{2,j}, j = 1, \ldots, 10$ are determined using Appendix C. The same is done for $\mathcal{H}_{3,10}(\mu)$ below.

4.4. $n = 3$. Once again, we take $\mu_{\max} = 11$ to be a bound for the largest zero we wish to compute and take $\kappa = 12$ so that from (49), we find that $m = m[12; 3, 11] = 25$. As in the case $n = 2$, starting from $l = 250$, we double l until all 10 significant figures in the column "Numerical zeros" of Table 2 do not change. The first such value is $l = 1000$. For $k \geq 10$, there is 6-digit accuracy when we compare $\mu_{k,3}^{(3)}$ (see (3.1)) and the numerical values; for $10 \leq k \leq 14$, there is also 10-digit accuracy when comparing the numerical values with $\mathcal{H}_{3,10}^{-1}(0)$ and 7-digit accuracy between $\mu_{k,3}^{(3)}$ and $\mathcal{H}_{3,10}^{-1}(0)$ for $k \geq 16$. These results are reported in Table 2.

TABLE 1
Numerical approximation of the zeros $\mu_{k,2}$ *of* $\mathcal{F}_2(\mu) = \int_{-\infty}^{\infty} e^{\mu(4iz-z^4)}dz$.

Appendix A. Proof of Lemma 2.1. To prove this lemma, we succesively substitute higher estimates in the equation: Let $\zeta = \mu^{(0)}$; then the asymptotic relation reads

$$\mu = \zeta + \frac{a_1}{\mu}\left(a_2 + \frac{a_3}{\mu} + \frac{a_4}{\mu^2} + \frac{a_5}{\mu^3} + \frac{a_6}{\mu^4}\right) + \mathcal{O}\left(\frac{1}{\mu^6}\right).$$

We have

$$\mu = \zeta + \frac{a_1 a_2}{\zeta} + \mathcal{O}\left(\frac{1}{\zeta^2}\right)$$

followed by

$$\mu = \zeta + \frac{a_1 a_2}{\zeta} + \frac{a_1 a_3}{\zeta^2} + \mathcal{O}\left(\frac{1}{\zeta^3}\right).$$

We now have

$$\begin{aligned}
\frac{a_1 a_2}{\mu} &= \frac{a_1 a_2}{\zeta}\left(1 - \frac{a_1 a_2}{\zeta^2} - \frac{a_1 a_3}{\zeta^3}\right) + \mathcal{O}\left(\frac{1}{\zeta^5}\right),\\
\frac{a_1 a_3}{\mu^2} &= \frac{a_1 a_3}{\zeta^2}\left(1 - 2\frac{a_1 a_2}{\zeta^2}\right) + \mathcal{O}\left(\frac{1}{\zeta^5}\right)
\end{aligned}$$

so that there is a $-(a_1a_2)^2/\zeta^3$ and a $-3a_1^2a_2a_3/\zeta^4$ correction term:

$$\mu = \zeta + \frac{a_1 a_2}{\zeta} + \frac{a_1 a_3}{\zeta^2} + \frac{a_1 a_4 - (a_1 a_2)^2}{\zeta^3} + \frac{a_1 a_5 - 3a_1^2 a_2 a_3}{\zeta^4} + \mathcal{O}\left(\frac{1}{\zeta^5}\right).$$

Finally, we use

$$\begin{aligned}
\frac{a_1 a_2}{\mu} &= \frac{a_1 a_2}{\zeta}\left(1 - \frac{a_1 a_2}{\zeta^2} - \frac{a_1 a_3}{\zeta^3} - \frac{a_1 a_4 - (a_1 a_2)^2}{\zeta^4} + \frac{(a_1 a_2)^2}{\zeta^4}\right) + \mathcal{O}\left(\frac{1}{\zeta^6}\right),\\
\frac{a_1 a_3}{\mu^2} &= \frac{a_1 a_3}{\zeta^2}\left(1 - 2\left(\frac{a_1 a_2}{\zeta^2} + \frac{a_1 a_3}{\zeta^3}\right)\right) + \mathcal{O}\left(\frac{1}{\zeta^6}\right),\\
\frac{a_1 a_4}{\mu^3} &= \frac{a_1 a_4}{\zeta^3}\left(1 - 3\frac{a_1 a_2}{\zeta^2}\right) + \mathcal{O}\left(\frac{1}{\zeta^6}\right)
\end{aligned}$$

so that we must add a $\left(-4a_1^2a_2a_4 + 2a_1^3a_2^3 - 2a_1^2a_3^2\right)/\zeta^5$ correction term. Thus we find

$$\begin{aligned}
\mu = \zeta + \frac{a_1}{\zeta}\Bigg(a_2 &+ \frac{a_3}{\zeta} + \frac{a_4 - a_1 a_2^2}{\zeta^2} + \frac{a_5 - 3a_1 a_2 a_3}{\zeta^3}\\
&+ \frac{a_6 - 2a_1 a_3^2 + 2a_1^2 a_2^3 - 4a_1 a_2 a_4}{\zeta^4}\Bigg) + \mathcal{O}\left(\frac{1}{\zeta^6}\right) \quad \text{as } \zeta = \mu^{(0)} \to +\infty.
\end{aligned}$$

Appendix B. Faà di Bruno's formula. For $\boldsymbol{a} = (a_1, a_2, \dots, a_n) \in \mathbb{N}^n$, following the notation in [1], we define the multinomial coefficients

$$\begin{aligned}
(n; a_1, a_2, \dots, a_n) &= \frac{n!}{a_1! a_2! \cdots a_n!},\\
(n; a_1, a_2, \dots, a_n)' &= \frac{n!}{(1!)^{a_1} a_1! (2!)^{a_2} a_2! \cdots (n!)^{a_n} a_n!}.
\end{aligned}$$

The nth derivative of the composition of two functions is given by Faà di Bruno's formula in [1, §24.1.2] and [13]:

$$\begin{aligned}
\frac{d^n}{dx^n} g(f(x)) &= \sum_{m=0}^{n} g^{(m)}(f(x)) \cdot \sideset{}{'}\sum_{\boldsymbol{a} \in \mathbb{N}^n} (n; a_1, a_2, \dots, a_n)' \cdot \prod_{k=1}^{n} \left\{f^{(k)}(x)\right\}^{a_k}\\
&= \sum_{m=0}^{n} g^{(m)}(f(x)) \cdot \sideset{}{'}\sum_{\boldsymbol{a} \in \mathbb{N}^n} \frac{n!}{a_1! a_2! \cdots a_n!} \cdot \prod_{k=1}^{n} \left\{\frac{f^{(k)}(x)}{k!}\right\}^{a_k}, \qquad (50)
\end{aligned}$$

where the second summation sign $\sum'_{\boldsymbol{a} \in \mathbb{N}^n}$ is taken over all integer n-vectors $\boldsymbol{a} = (a_1, a_2, \dots, a_n) \in \mathbb{N}^n$ such that $\sum_k k a_k = a_1 + 2a_2 + \cdots + na_n = n$ and $|\boldsymbol{a}| = \sum_k a_k = a_1 + a_2 + \cdots + a_n = m$.

SETS OF SUPERRESOLUTION AND THE MAXIMUM ENTROPY METHOD ON THE MEAN*

F. GAMBOA[†] AND E. GASSIAT[‡]

Abstract. Consider the problem of recovering a probability measure supported on a compact polish space U, endowed with a probability P, when the available measurements only concern some of its Φ-moments; Φ is here a given k-dimensional continuous real function on U. Provided the *true* moment c lies on the boundary of the convex hull of $\Phi(U)$, we exhibit a support of uniform concentration, that is, a measurable set $R_{c,\delta}(\epsilon)$ (depending on a small positive number δ) such that for any solution μ which satisfies $\| \int \Phi \, d\mu - c\|_2 \leq \epsilon$, we have $\mu(R_{c,\delta}(\epsilon)) \geq 1 - K(\epsilon)$ and $P(R_{c,\delta}(\epsilon)) \leq$ C.$K(\epsilon)$, where $K(\epsilon)$ decreases to 0 with ϵ and C is a constant number. The construction of $R_{c,\delta}(\epsilon)$ and the results are intimately connected with the maximum entropy method on the mean (MEM) developed by Gamboa and Gassiat. This method gives a general framework for superresolution theory via Pythagoras inequalities on families of dissimilarities linked with MEM. In particular cases, we prove that $K(\epsilon)$ is the exact rate of uniform concentration over $R_{c,\delta}(\epsilon)$.

Key words. superresolution, moment problem, dissimilarity, positivity constraint, maximum entropy

1. Introduction.

Consider the equation

$$y_j = \int_U \Phi_j(x) \, d\mu(x) + \epsilon_j, j = 1, \ldots, k, \tag{1}$$

where U is a compact measurable space, (Φ_j) are known continuous functions, $(\epsilon_j)_{j=1,\ldots,k}$ represents noise, and we want to recover the positive measure μ. A typical example of such a situation is band-limited discrete Fourier measurements, problems in tomography, spectroscopy, astronomy, etc. To recover μ, we first suppose that all we know about the noise $(\epsilon_j)_{j=1,\ldots,k}$ is that it is bounded in *l2-norm* by a known constant ϵ. We now call *reconstruction* any method of recovery $\hat{\mu}(y)$ based on the observations $y = (y_j)_{j=1,\ldots,k}$.

The particularity of such problems is that they are ill posed. In general, the moments $\int_U \Phi_j(x) \, d\mu(x), j = 1, \ldots, k$, are not sufficient to characterize the measure μ. For example, if the Φ_j consist in the first trigonometric functions, the first k Fourier coefficients do not determine μ in general. Years ago, techniques called generically *maximum entropy techniques* (ME) were developed and seemed, in particular situations, to significantly improve the restored solutions, compared with the usual linear methods. Such techniques consist of choosing a reconstruction by minimizing a functional $J(\mu)$, subject to the constraint $\| \int \Phi \, d\mu - y\|_2 < \epsilon$, or to minimize $J(\mu) + \lambda \| \int \Phi \, d\mu - y\|_2$, which is the same by an appropriate choice of λ. Typically,

$$J(\mu) = \int_U \frac{d\mu}{dP} \log \frac{d\mu}{dP} \, dP,$$

where P is a given prior measure. These reconstructions are highly nonlinear in the observations. It has also been well established that the improvement is due to

two major facts: ME takes into account a priori information by imposing implicitly important restrictions on the solution (e.g., positivity), and the *true* measure μ is sparse enough. This improvement was described in terms of *superresolution* by Frieden (see [11]). Let us explain what we mean by *resolution* and *superresolution.* When the observed moments are the Fourier coefficients, all linear translation invariant reconstructions obey the so-called *Rayleigh limit* R at fixed noise level. If μ consists of two spikes spaced by more than R, linear reconstructions may show clearly two spikes; in the opposite, if μ consists of two spikes spaced by less than R, linear reconstructions are unable to resolve clearly the two spikes. This is why R is a *resolution* limit. Now, as is shown in [11] on some examples, ME is able to resolve clearly two spikes spaced by about $R/3$: this is the so-called *superresolution phenomenon.* Though for moments other than Fourier there does not exist such a quantified resolution limit, we extend the notion to any moment problem.

Theoretical results on the subject are very few and recent; see §5 for a survey. The key idea is that, provided the *true* measure μ exhibits some *extremal* conditions (e.g., sparsity), and provided we incorporate in the reconstruction method adequate a priori information (typically the positivity of μ), the resolution of μ (when μ is interpreted as a signal) can be surprisingly high (see, for example, [18], [11], and, for a large bibliography on the subject, [7–9]). Our aim in this work is to understand clearly and quantify precisely what happens in such problems, as well as to give computational solutions for the applications. Let us first give a very simple explanation of the *superresolution phenomenon.* For this, we need to make our notations precise.

- U is a given compact Polish space.
- $\Phi := (\Phi_1, \dots, \Phi_k)$ is a given k-dimensional real function on U. We assume that Φ is continuous and that $\Phi_1 := 1$.

Define $\mathcal{M}_+(U)$ the set of all positive measures on U and $\mathcal{P}(U)$ the set of all probability distributions on U. Let

$$\mathcal{K} := \left\{ c \in \mathbb{R}^k : \exists \mu \in \mathcal{M}_+(U), \int_U \Phi \, d\mu = c \right\},$$

$$\mathcal{K}_1 := \mathcal{K} \cap \{c_1 = 1\}.$$

$\mathrm{ri}(\mathcal{K}_1)$ will denote the relative interior of $\mathcal{K}_1$ (see [24]). Obviously, $\mathcal{K}_1$ is the convex hull of $\Phi(U)$. We shall now consider only probability measures as searched measures. Define

$$\mathcal{S}(c) := \left\{ \mu \in \mathcal{P}(U) : \int_U \Phi(x) \, d\mu(x) = c \right\}$$

and

$$\mathcal{S}(c, \epsilon) := \left\{ \mu \in \mathcal{P}(U) : \left\| c - \int_U \Phi \, d\mu \right\| \leq \epsilon \right\}.$$

In some sense, as ϵ decreases to 0, $\mathcal{S}(c, \epsilon)$ *tends* to $\mathcal{S}(c)$ so that, if $\mathcal{S}(c)$ is reduced to a singleton, the diameter of $\mathcal{S}(c, \epsilon)$ for a weak convergence distance decreases to 0 with ϵ. This is formalized in Theorem 1.

Now, if $\mathcal{S}(c)$ is reduced to a singleton, then $\bar{c} = \int_U \Phi(x) \, d\mu(x)$, where μ is an atomic measure. If ϵ is small enough, any member ν of the set $\mathcal{S}(c, \epsilon)$ will be very close to μ: this is exactly a superresolution phenomenon. Let us now state the precise theorem (which extends the main Theorem of [16]), which is proved in §6. Let d be any distance on $\mathcal{P}(U)$ which is continuous for the weak convergence topology (the Prokhorov distance is an example of such distances).

THEOREM 1. *The following propositions are equivalent:*

$$\lim_{\epsilon\to 0} \sup_{\mu_1,\mu_2\in\mathcal{S}(c,\epsilon)} d(\mu_1,\mu_2) = 0, \tag{2}$$

$$\mathcal{S}(c) \textit{ is reduced to the singleton } \{\sigma_c\}, \tag{3}$$

$$\exists\sigma_c : \lim_{\epsilon\to 0} \sup_{\mu\in\mathcal{S}(c,\epsilon)} d(\mu,\sigma_c) = 0. \tag{4}$$

We will say that c is a determined point if the set $\mathcal{S}(c)$ is reduced to a singleton. Conditions on c to be determined are given in [14]. The result of Theorem 1 is qualitative. It says that superresolution phenomena appear only around determined points and for reconstructions that preserve positivity. We will call it *the strong superresolution phenomenon*, as it describes the whole signal (location and intensity). We see that the a priori information is the positivity of the measure (see the definition of $\mathcal{S}(c)$), and that the extremal condition on μ is that the point $\int_U \Phi(x)\,d\mu(x)$ is determined, which implies a special atomicity of μ. (This explains the necessity that the true measure be sparse enough for superresolution phenomena to appear.) Notice that Theorem 1 shows that *entropy* does not play any particular role in the superresolution phenomenon. Indeed, any reconstruction that satisfies the positivity constraint will exhibit the same superresolution property as soon as the moment constraint is near to be determined. It is surprising that the first formulation of superresolution as a boundary problem in the moment problem appears in [16].

Our precise interest in this paper is to make clear how the resolution of a signal may be improved by imposing positivity. To be more precise, we are not interested in the whole signal but in the location of the signal. Indeed, in many applications, the location of the signal is the significant information which is looked for. In our formulation, we want to see how good approximations of the support of μ may be found and to understand the role of the moment functions $\Phi_1,\dots,\Phi_k$ in this process. In earlier quantitative results (see §5 for references), the space U is discretized, so that some a priori resolution is imposed, and the quantification is essentially made for the intensities. Surprisingly, except for the qualitative paper of Gassiat [16], no earlier works posed the problem in terms of location, that is in terms of support of the measure.

Let us return to our problem. The set of determined points is included in the boundary of $\mathcal{K}_1$. In general the inclusion is strict. If c lies in the boundary of $\mathcal{K}_1$ (and is not necessarily determined), a *weak superresolution phenomenon* holds. Indeed, all the measures of $\mathcal{S}(c)$ are concentrated on a level set

$$\mathcal{C}(c) := \{x \in U : \langle v, \Phi(x)\rangle = 0\}$$

for a particular choice of v (see [19, Th. 1.1, p. 58]). The aim of this work is to develop similar ideas as in Theorem 1 for the subset of $\mathcal{C}(c)$,

$$\cup_{\sigma\in\mathcal{S}(c)}\mathrm{Supp}\sigma := R_c,$$

and to quantify the results. Namely, we propose a construction of *uniform concentration supports*: $R_{c,\delta}(\epsilon)$ such that any probability measure of $\mathcal{S}(c,\epsilon)$ is nearly concentrated on $R_{c,\delta}(\epsilon)$. $R_{c,\delta}(\epsilon)$ will be the approximating set of R_c; it is built as a particular level set of a Φ-polynomial $\langle v^*, \Phi\rangle$. We quantify this concentration property and, in particular cases, we get the exact rate of *superconcentration.* This enables one to locate a signal at a known precision, depending on the error ϵ, even when no *strong* superresolution phenomenon holds. All the results are based on the general reconstruction method called MEM for moment problems developed in [13]. It is interesting to notice that, as soon as one knows this reconstruction, all theorems proved here involve only elementary computations. In other words, as soon as the structure of the problem is clearly seen, the superconcentration properties do not involve sophisticated techniques; they are all "hidden" in the MEM method. In particular cases, direct calculations on appropriate level sets lead to the exact superconcentration rate without the use of the MEM dissimilarities. However, we would like to emphasize several points to show the interest of the technique developed therein. First, MEM leads to a general framework for superresolution theory in a different context: see [14] for L_1-superresolution results; see also [15] for a continuous superresolution result. This general framework also has a computational advantage: the computation of the parameter v^* of the level set, via MEM, involves strictly convex optimization, and the superresolution rate $K(\epsilon)$ is a by-product of the computation. Moreover, the idea of using level sets as approximations of the support arose directly from MEM. This lead several authors, inspired by the first version of this work, to develop the pure level set point of view [10], [20]. In general, the MEM framework exploits general probabilistic ideas: Laplace methods and developments of Cramer transforms on the boundary of their domain, which have interest by themselves.

To our knowledge, all these results are new and give new ideas to understand superresolution. Notice also that, though numerical applications of the results are easy to obtain using convex programming, explicit formulations are untractable, even on very simple examples. We will develop numerical examples and other ideas in a forthcoming paper.

The paper is organized as follows. In the next section, we give our notations and recall the basic results concerning MEM. In §3, we state and illustrate our superresolution results. In §4, we study a family of dissimilarities which gave the key idea to prove the superconcentration theorems. In §5, we give a survey on earlier results and study connections with ours. All technical proofs are collected in §6.

2. The MEM basic results.

Our work is based on results about the MEM. Let us recall what will be useful for this paper. Let P be a given reference probability distribution on U such that for any vector v in $\mathbb{R}^k, P(\langle v, \Phi\rangle = 0) = 0$. Let F be a given probability measure on $[0, +\infty[$ whose convex hull of the support equals $[0, +\infty[$. Define ψ by

$$\psi(t) := \log \int_{[0,+\infty[} \exp(tx)\, dF(x), t \in \mathbb{R},$$

and suppose that $\psi(t)$ is finite if and only if $t \in]-\infty, \alpha[, \alpha < +\infty$.

Define

$$\gamma(s) := \sup_{t\in\mathbb{R}}(st - \psi(t)).$$

For any measurable function f on $\mathbb{R}_+$, let

$$\Gamma(f) := \int_U \gamma[f(x)]\, dP(x).$$

For any μ in $\mathcal{M}_+(U)$, let

$$I(\mu) := \Gamma\left(\frac{d\mu}{dP}\right) + \alpha\left(\mu - \frac{d\mu}{dP}P\right)(U).$$

For any c and v in $\mathbb{R}^k$ and any nonnegative ϵ, let

$$H^\epsilon(v,c) := \int_U \psi(\langle v, \Phi(x)\rangle)\, dP(x) - \langle v, c\rangle + \epsilon\|v\|_{k-1},$$

where $\|v\|_{k-1}$ is the Euclidian norm of the vector $(v_2, \dots, v_k)$. Define also

$$h^*(c,\epsilon) := -\inf_{v\in\mathbb{R}^k} H^\epsilon(v,c).$$

In [13], we proved the following results. (For related works in optimization, see [1], [2].)

THEOREM 2. *Let $c \in \mathbb{R}^k$ be such that the Euclidian ball centered at c with diameter ϵ intersects* $\mathrm{ri}(\mathcal{K}_1)$. *Let v^ϵ be the unique minimizer of $H^\epsilon(v,c)$. There exists a positive measure σ^ϵ such that*

$$G^{\mathrm{MEM},\epsilon} := \psi'(\langle v^\epsilon, \Phi\rangle)P + \sigma^\epsilon \in \mathcal{S}(c,\epsilon), \tag{5}$$

Supp $\sigma^\epsilon \subset \{x; \langle v^\epsilon, \Phi(x)\rangle = \alpha\}$. *Moreover,*

$$h^*(c,\epsilon) = -H^\epsilon(v^\epsilon, c) = \inf_{f: fP\in\mathcal{S}(c,\epsilon)} \Gamma(f) = \min_{\mu\in\mathcal{S}(c,\epsilon)} I(\mu) = I(G^{MEM,\epsilon}).$$

THEOREM 3. *Assume that F weighs $\{0\}$; then*

$$\begin{aligned} h^*(c,0) &< -\log F(\{0\}) + \alpha \Leftrightarrow c \in \mathrm{ri}(\mathcal{K}_1),\\ h^*(c,0) &= -\log F(\{0\}) + \alpha \Leftrightarrow c \in \mathrm{bd}(\mathcal{K}_1),\\ h^*(c,0) &= +\infty \Leftrightarrow c \notin \mathcal{K}_1. \end{aligned}$$

The idea of such characterization of $\mathrm{bd}(\mathcal{K}_1)$ arose from the probabilistic interpretation of $G^{\mathrm{MEM},\epsilon}$ and its relation with the large deviations theory. Lewis has shown later in [21] that these theorems hold for a wider class of convex functions ψ.

3. Superresolution results.

3.1. Main theorem. Let $\overline{c}$ be a point in the boundary of $\mathcal{K}_1$. The MEM solution in $\mathcal{S}(\overline{c},\epsilon)$ is $G^{\mathrm{MEM},\epsilon}$ as defined in (5). Observe the following.

- First, $\forall x \in U, \langle v^\epsilon, \Phi(x)\rangle \le \alpha$ as follows from the definition of v^ϵ. Indeed, if not, as Φ is continuous, $H^\epsilon(v^\epsilon, \overline{c})$ is infinite, which contradicts Theorem 2.
- Second, any accumulation point of the sequence $G^{\mathrm{MEM},\epsilon}$ as ϵ decreases to 0 is a singular measure (with respect to P) $\sigma_{\overline{c}}$ such that

$$\begin{aligned} &\forall x \in \mathrm{Supp}\ \sigma_{\overline{c}}, \quad \lim_{\epsilon\to 0}\langle v^\epsilon, \Phi(x)\rangle = \alpha,\\ &\forall x \notin \mathrm{Supp}\ \sigma_{\overline{c}}, \quad \lim_{\epsilon\to 0}\langle v^\epsilon, \Phi(x)\rangle = -\infty. \end{aligned}$$

Intuitively, we may now approximate $R_{\overline{c}}$ by a set of points x such that $\langle v^\epsilon, \Phi(x)\rangle$ is near α. Precisely, define

$$g_\epsilon(x) := \alpha - \langle v^\epsilon, \Phi(x)\rangle.$$

For any positive real δ, define

$$R_{\overline{c},\delta}(\epsilon) := \{x \in U : g_\epsilon(x) \leq \delta\}.$$

$R_{\overline{c},\delta}(\epsilon)$ will be the approximating set of $R_{\overline{c}}$. We have the following theorem.

THEOREM 4. *Assume that F weighs* 0 *and set*

$$F := F(\{0\})\,\delta_0 + (1 - F(\{0\}))F_1,$$

$$\forall t \in]-\infty, \alpha[, \quad \psi_1(t) := \log \int_{]0,+\infty[} \exp(tx)\,dF_1(x).$$

Let $a := \frac{1-F(\{0\})}{F(\{0\})}$. *We have*

$$P(R_{\overline{c},\delta}(\epsilon)) \log(1 + a e^{\psi_1(\alpha-\delta)}) + \delta \sup_{\mu \in \mathcal{S}(\overline{c},\epsilon)} \mu(R^c_{\overline{c},\delta}(\epsilon)) \leq K(\epsilon),$$

where $K(\epsilon) := -\log F(\{0\}) + \alpha - h^*(\overline{c},\epsilon)$ *decreases to* 0 *with* ϵ, *and* $R^c_{\overline{c},\delta}(\epsilon)$ *denotes the complementary set of* $R_{\overline{c},\delta}(\epsilon)$ *in* U.

Observe that $R_{\overline{c},\delta}(\epsilon)$ depends on ϵ, and that δ is a parameter which has to be chosen: it might be chosen as a function of ϵ. $R_{\overline{c},\delta}(\epsilon)$ also depends on the choice of F. We will discuss this problem in a forthcoming paper.

This theorem quantifies the concentration of the supports of any solution of the moment problem near the boundary. Indeed, it says that, keeping δ fixed, you can define a measurable set $R_{\overline{c},\delta}(\epsilon)$ (which is a level set associated with an MEM solution, reachable using convex programming) such that, simultaneously, its P-measure is small, and any solution of the moment problem with perturbation ϵ is concentrated on this set except for a small part, *small* being quantified by the speed $K(\epsilon)$ in both assertions.

Example. Choose for F_1, the exponential distribution with parameter 1,

$$\psi_1(t) = \log \frac{1}{1-t}$$

so that $\alpha = 1$. Choose also $\delta := 1, F(\{0\}) = e^{-1}$, and the theorem says

$$P(R_{\overline{c},1}(\epsilon)) + \sup_{\mu \in \mathcal{S}(\overline{c},\epsilon)} \mu(R^c_{\overline{c},1}(\epsilon)) \leq K(\epsilon)$$

so that simultaneously

$$P(R_{\overline{c},1}(\epsilon)) \leq K(\epsilon)$$

and for any ϵ-*solution* μ (that is, $\mu \in \mathcal{S}(\overline{c},\epsilon)$) of the boundary point

$$\mu(R_{\overline{c},1}(\epsilon)) \geq 1 - K(\epsilon)$$

(μ is $K(\epsilon)$-*concentrated* on $R_{\overline{c},1}(\epsilon)$).

Remarks. For particular moment problems (especially T-systems), the approximating set may be chosen as the level set $\mathcal{C}(c)$ defined in §1, and it can be proved to lead to the optimal rate. This was developed later in [10] and [20]. However, the advantages of our method are that, on the basis of the observations, the level set is computed through strictly convex minimization programming together with the rate $K(\epsilon)$ (see §3.4), and our method gives a general framework for other superresolution problems using the dissimilarities defined in §4 as explained in §3.4.5; see also [14] and [15].

Proof of Theorem 4. We first prove the decreasing property of $K(\epsilon)$. To see this, observe that $h^*(c,0)$ is a convex function with domain $\mathcal{K}$, so that it is continuous on $\mathrm{ri}(\mathcal{K}_1)$. Moreover, $h^*(c,0)$ converges to $h^*(\bar{c},0)$ when c tends to $\bar{c}$ and when c stays in the relative interior of $\mathcal{K}_1$. We easily have (using, for instance, subgradient arguments)

$$h^*(\bar{c},\epsilon) = \inf_{c\in\mathcal{K}_1, \|c-\bar{c}\|\le\epsilon} h^*(c,0) = \min_{c\in\mathcal{K}_1, \|c-\bar{c}\|\le\epsilon} h(c,0) = h^*(c_\epsilon,0), \tag{6}$$

where $\|c_\epsilon - \bar{c}\| \le \epsilon$. Since h^* is strictly convex and constant on $\mathrm{bd}\mathcal{K}_1, c_\epsilon$ is in the relative interior of $\mathcal{K}_1$ for all positive ϵ, and c_ϵ tends to $\bar{c}$ when ϵ tends to 0; therefore,

$$\lim_{\epsilon\to 0} h^*(\bar{c},\epsilon) = h^*(\bar{c},0) = -\log F(\{0\}) + \alpha$$

and it follows that

$$\lim_{\epsilon\to 0} K(\epsilon) = 0.$$

Now let σ be any element of $\mathcal{S}(\bar{c},\epsilon)$. Let

$$I := \int_U \psi(\langle v^\epsilon, \Phi(x)\rangle)\, dP(x) - \log F(\{0\}) + \int_U (\alpha - \langle v^\epsilon, \Phi(x)\rangle)\, d\sigma(x).$$

First, we have

$$I = \int_U \psi(\langle v^\epsilon, \Phi(x)\rangle)\, dP(x) - \left\langle v^\epsilon, \int_U \Phi(x)\, d\sigma(x) \right\rangle + \alpha - \log F(\{0\}).$$

Using equation (6), we have

$$\begin{aligned} h(\bar{c},\epsilon) &= -\int_U \psi(\langle v^\epsilon, \Phi(x)\rangle)\, dP(x) + \langle v^\epsilon, c_\epsilon\rangle \\ &= -\int_U \psi(\langle v^\epsilon, \Phi(x)\rangle)\, dP(x) + \langle v^\epsilon, \bar{c}\rangle - \epsilon\|v^\epsilon\| \end{aligned}$$

and $\| \int_U \langle v^\epsilon, \Phi(x)\rangle\, d\sigma(x) - \bar{c}\| \le \epsilon$, so that using the Schwarz inequality, we have

$$-\int_U \psi(\langle v^\epsilon, \Phi(x)\rangle)\, dP(x) + \int_U \langle v^\epsilon, \Phi(x)\rangle\, d\sigma(x) \ge h^*(\bar{c},\epsilon)$$

and

$$I \le \alpha - \log F(\{0\}) - h^*(\bar{c},\epsilon). \tag{7}$$

Now, obviously,

$$\int_U g_\epsilon\, d\sigma \ge \delta\sigma(R^c_{\bar{c},\delta}(\epsilon)). \tag{8}$$

Also,

$$\int_U \psi(\langle v^\epsilon, \Phi\rangle)\, dP - \log F(\{0\}) = \int_U \log(1 + ae^{\psi_1(\alpha - g_\epsilon)})\, dP.$$

Using the fact that ψ_1 is increasing,

$$\int_U \psi(\langle v^\epsilon, \Phi\rangle)\,dP - \log F(\{0\}) \geq \int_{R_{\overline{c},\delta(\epsilon)}} \log(1 + ae^{\psi_1(\alpha-\delta)})\,dP,$$

so that

$$\int_U \psi(\langle v^\epsilon, \Phi\rangle)\,dP - \log F(\{0\}) \geq P(R_{\overline{c},\delta}(\epsilon))\log(1 + ae^{\psi_1(\alpha-\delta)}). \tag{9}$$

Adding (8) and (9), we have

$$P(R_{\overline{c},\delta}(\epsilon))\log(1 + ae^{\psi_1(\alpha-\delta)}) + \delta\sigma(R^c_{\overline{c},\delta}(\epsilon)) \leq K(\epsilon).$$

Taking the supremum over $\mathcal{S}(\overline{c},\epsilon)$, we get the inequality of the theorem.

Remark. The idea of considering the functional I to get inequality (7) has in itself no intuitive evidence. The idea from which it comes, which is hidden in (7), is analogous to a *Pythagoras inequality* which holds for a dissimilarity linked with the MEM construction. This will be explained in §4.

3.2. Lower bound for the superconcentration. In §§3.2 and 3.3, we will assume that U is a compact set of $\mathbb{R}^d$. Theorem 4 gives an upper bound for the superconcentration property over $R_{\overline{c},\delta}(\epsilon)$. Here we will give a lower bound for it which holds for any choice of F.

THEOREM 5. *Suppose that P is the normalized Lebesgue measure on $U, \Phi \in [C^1(U_0)]^k$, where $U \subset \operatorname{int}(U_0)$. Then there exists a positive constant C (depending only on d) such that for small enough ϵ,*

$$\sup_{\mu\in\mathcal{S}(\overline{c},\epsilon)} \mu(R^c_{\overline{c},\delta}(\epsilon)) \geq C\epsilon K(\epsilon)^{-1/d}[\log(1 + ae^{\psi_1(\alpha-\delta)})]^{1/d}.$$

3.3. Exact rate of superconcentration. Under additional assumptions, we are able to give the exact rate of superconcentration over $R_{\overline{c},\delta}(\epsilon)$. We restrict F to be member of the following family of distributions. For all $\beta > 0, F_\beta$ denotes the Poissonized distribution of the $\gamma(\beta,1)$ distribution. That is, F_β is the distribution of the random variable Z defined by

$$Z := \sum_{i=0}^{N} Y_i,$$

where $Y_0 := 0, (Y_i)$ is a sequence of independent random variables with common distribution $\gamma(\beta,1)$ and N is an independent random variable with Poisson distribution of parameter 1. Then, the log-Laplace transform of F_β is

$$\begin{aligned}\psi_\beta(\tau) &= \frac{1}{(1-\tau)^\beta} - 1 \quad \text{if } \tau < 1\\ &= +\infty \quad \text{if } \tau \geq 1.\end{aligned}$$

It is obvious that $\alpha = 1, F_\beta(\{0\}) = e^{-1}$, and ψ_β satisfies the assumptions required for the MEM construction. K_β will denote the associated K function.

We will now make an *integrability* assumption. For this purpose, let us introduce the following definition.

DEFINITION 1. *Let $\overline{c} \in \mathrm{bd}(\mathcal{K}_1)$. The critical exponent $\beta_0(\overline{c})$ is the upper bound of the set*

$$\left\{\beta \geq 0, \exists v \in \mathbb{R}^k : \forall x \in U, \langle v, \Phi(x)\rangle \geq 0; \langle v, \overline{c}\rangle = 0, \int_U \frac{dP(x)}{\langle v, \Phi(x)\rangle^\beta} < \infty\right\}.$$

Under the assumption that $\beta_0(\overline{c})$ is positive, for small ϵ and for $\beta < \beta_0(\overline{c})$, we give a precise description of $K_\beta(\epsilon)$ and the associated vector v^ϵ. Precisely, define

$$\begin{aligned}
u^\epsilon &:= (1 - v_1^\epsilon, -v_2^\epsilon, \dots, -v_k^\epsilon),\\
w^\epsilon &:= (\langle u^\epsilon, \overline{c}\rangle, u_2^\epsilon, \dots, u_k^\epsilon),\\
d(\epsilon) &:= \frac{w^\epsilon}{\|w^\epsilon\|} = (d_1(\epsilon), \tilde{d}(\epsilon)),\\
\tilde{\Phi}(x) &:= (\Phi_j(x) - \overline{c}_j)_{j=2,\dots,k},\\
\xi_{\beta,0}(d) &:= \int_U \frac{dP(x)}{(\max(0, \langle \tilde{d}, \tilde{\phi}(x)\rangle))^\beta}, \quad d = (d_1, \tilde{d}) \in \mathbb{R}^k.
\end{aligned}$$

PROPOSITION 1. *Suppose $\beta_0(\overline{c}) > 0$. Let $\beta < \beta_0(\overline{c})$. Then the following hold.*

- *$d(\epsilon)$ converges to $(0, \tilde{d}(0))$, where $\tilde{d}(0)$ is the unique minimizer of $\xi_{\beta,0}(d)$ on the intersection between the unit sphere and the hyperplane $d_1 = 0$.*
- *$K_\beta(\epsilon) \sim C_\beta \epsilon^{\beta/\beta+1}, \epsilon \to 0$ for a positive constant C_β.*

We will now assume that $\Phi \in [C^2(U)]^k$ and

- (I2) $\exists x_m \in \mathrm{int}(U), \exists \sigma \in \mathcal{S}(\overline{c})$ such that

$$\sigma(\{x_m\}) > 0,$$
$$\langle \tilde{d}(0), D^2\tilde{\Phi}(x_m)\rangle \neq 0.$$

We are now able to give the following theorem.

THEOREM 6. *Suppose that $\Phi \in [C^2(U)]^k, \beta_0(\overline{c}) > 0, \beta < \beta_0(\overline{c})$, and (I2) holds. Then, for ϵ sufficiently small, there exist two constants C_1, C_2, which depend only on β, δ, and $\overline{c}$, such that*

$$C_1 \epsilon^{\frac{\beta}{\beta+1}} \leq \sup_{\mu \in \mathcal{S}(\overline{c},\epsilon)} \mu(R^c_{\overline{c},\delta}(\epsilon)) \leq C_2 \epsilon^{\frac{\beta}{\beta+1}}.$$

In the specified situation, Theorem 6 says that the rate of uniform concentration over $R_{\overline{c},\delta}(\epsilon)$ is exactly $\epsilon^{\beta/\beta+1}$.

In specific situations, when Φ is a T-system (see also §3.4.4), it is possible to choose a different approximating support set: a level set of the supporting hyperplane at the boundary point $\overline{c}$, and simpler calculation leads to the optimal rate $\epsilon^{1/3}$. However, this particular level set is difficult to compute, even for known $\overline{c}$. However, this other point of view was developed afterwards in [10].

We show in §6 (Lemma 5) that assumption (I2) holds whenever the following geometrical assumption holds.

- (I3) $\exists x_m \in \mathrm{int}(U), \exists \sigma \in \mathcal{S}(\overline{c})$, and there exists an orthogonal basis $(b_2, \dots, b_k)$ of $\mathbb{R}^{k-1}$ such that

$$\sigma(\{x_m\}) > 0,$$
$$\langle b_j, \tilde{\Phi}\rangle \geq 0,$$
$$\langle b_j, D^2\tilde{\Phi}(x_m)\rangle \neq 0.$$

3.4. Remarks and applications.

3.4.1. Superconcentration for positive reconstructions. Consider the problem of estimating the support of μ using observation (1). With the same arguments as for Theorem 4, it is easy to get

$$P(R_{y,\delta}(\epsilon))\log(1+ae^{\psi_1(\alpha-\delta)})+\delta\sup_{\sigma\in\mathcal{S}(y,\epsilon)}\sigma(R^c_{y,\delta}(\epsilon))\leq-\log F(\{0\})+\alpha-h^*(y,\epsilon).$$

Here, as ϵ tends to 0, y tends to $\bar{c}=\int_U\Phi\,d\mu$, so that as soon as $\bar{c}$ lies on $\mathrm{bd}(\mathcal{K}_1)$, $-\log F(\{0\})+\alpha-h^*(y,\epsilon)$ tends to 0, and the inequality is again a superconcentration inequality, in which only the knowledge of the observations y and of the noise level ϵ are involved.

As $\mu\in\mathcal{S}(y,\epsilon)$, we get

$$P(R_{y,\delta}(\epsilon))\log(1+ae^{\psi_1(\alpha-\delta)})+\delta.\mu(R^c_{y,\delta}(\epsilon))\leq-\log F(\{0\})+\alpha-h^*(y,\epsilon),$$

and $R_{y,\delta}$ is a good estimator for the support of μ on the basis of y.

3.4.2. Superconcentration for a point near the boundary. All the results we have given have been written for measures of $\mathcal{S}(\bar{c},\epsilon)$, where $\bar{c}$ is a boundary point of $\mathcal{K}_1$. Let $c^*:=\bar{c}+\epsilon\,\Delta c$ with $\Delta c:=(0,\tilde{\Delta}c)$, $\|\tilde{\Delta}c\|_{k-1}=1$. We assume that c^* is an inner point of $\mathcal{K}_1$. When ϵ is small, we can ask, "What are the superconcentration properties of $\mathcal{S}(c^*)$?"

Since $\mathcal{S}(c^*)\subset\mathcal{S}(\bar{c},\epsilon)$, all the results given before stay true, changing $\mathcal{S}(\bar{c},\epsilon)$ by $\mathcal{S}(c^*)$ everywhere. However, using the MEM technique, we can give more local results. (Indeed, the previous ones do not depend on the given direction $\tilde{\Delta}c$.) Let

$$G_\beta^{\mathrm{MEM}}=\psi'_\beta(\langle v^*,\Phi(x)\rangle)P+\sigma$$

be the element of $\mathcal{S}(c^*)$ selected using MEM procedure with prior F_β (see §2). Let

$$\tilde{R}_{c^*,\delta,\beta}:=\{x\in U,1-\langle v^*,\Phi(x)\rangle\leq\delta\}.$$

Then, under some regularity assumptions (as in Theorem 6), using the Pythagoras identity (10) (see §4) and following the same ideas as before, we have

$$C_1\epsilon^{\frac{\beta}{\beta+1}}\leq\sup_{\mu\in\mathcal{S}(c^*)}\mu(\tilde{R}_{c^*,\delta,\beta})\leq C_2\epsilon^{\frac{\beta}{\beta+1}},$$

where the constants C_1 and C_2 depend only on β,δ, and c^*. For a given boundary point $\bar{c}$ and for almost all directions Δc, the constant of the superconcentration inequalities are significantly better when we use this local formulation.

3.4.3. Asymptotic behavior of $R_{\bar{c},\delta,\beta}(\epsilon)$.

LEMMA 1. *Let*

$$\mathcal{V}(\bar{c},\beta):=\left\{x\in U,-\sum_{j=2}^{k}d_j(0)\bar{c}_j+\langle\tilde{d}(0),\Phi(x)\rangle=0\right\}.$$

Suppose that $\beta_0(\bar{c})>0$. Then, for all $\beta<\beta_0(\bar{c})$,

$$\cup_{\sigma\in\mathcal{S}(\bar{c})}\mathrm{supp}\sigma\subset\varliminf_{\epsilon\longrightarrow0^+}R_{\bar{c},\delta,\beta}(\epsilon)\subset\varlimsup_{\epsilon\longrightarrow0^+}R_{\bar{c},\delta,\beta}(\epsilon)\subset\mathcal{V}(\bar{c},\beta).$$

Proof. If $x \in \overline{\lim}_{\epsilon \to 0^+} R_{\overline{c},\delta,\beta}(\epsilon)$, then there exits a decreasing sequence (ϵ_n) converging to 0 such that

$$\forall n \in N, \quad \langle v^{\epsilon_n}, \Phi(x) \rangle \leq \delta,$$

which is equivalent to

$$\forall n \in N, \quad d_1(\epsilon_n) + \langle \tilde{d}(\epsilon_n), \tilde{\Phi}(x) \rangle \leq \frac{\delta}{\|v^{\epsilon_n}\|}.$$

Taking the limit as n goes to infinity, we get $\langle \tilde{d}(0), \tilde{\Phi}(x) \rangle = 0$.

Let $x \in \cup_{\sigma \in \mathcal{S}(\overline{c})} \mathrm{supp} \sigma$. Then there exists $\sigma \in \mathcal{S}(\overline{c})$ with $\sigma(\{x\}) = p > 0$ (see [19, Thm. 3.1, p. 71). Therefore, by Theorem 4, $\sigma(R^c_{\overline{c},\delta,\beta}(\epsilon)) \leq \frac{K(\epsilon)}{\delta}$. Now, as soon as $\frac{K(\epsilon)}{\delta} < p$ we have $\sigma(R^c_{\overline{c},\delta,\beta}(\epsilon)) < p$ and $x \in R_{\overline{c},\delta,\beta(\epsilon)}$. □

3.4.4. Examples. Explicit calculations are untractable even for simple examples, but numerical applications may be directly developed. For this we refer to a forthcoming paper. However, let us give ideas about typical situations.

Analytic functions. Suppose that $U = [0,1], P$ is the uniform probability, and Φ is analytic. Then for all v in $\mathbb{R}^k$, the set

$$\mathcal{O}(v) = \{x \in [0,1], \langle v, \Phi(x) \rangle = 0\}$$

has a finite number of elements. Therefore, since we can develop the function $\langle v, \Phi(x) \rangle$ near each point x^* of $\mathcal{O}(v)$ in a convergent entire series, for all boundary point $\overline{c}$ of $\mathcal{K}_1$ we have $\beta_0(\overline{c}) > 0$. Then Proposition 4 always holds (see §6). We do not know if the assertion $\beta_0(\overline{c}) > 0$ is still true for an analytic system Φ on $U \subset \mathbb{R}^d$. In the multidimensional framework, even when the components of Φ are polynomials, the description of $\mathcal{O}(v)$ and its connected components is not easier [22], [17].

T-systems. Let $U = [0,1], \Phi(x)$ be a T-system $(\forall v \in \mathbb{R}^k, \sharp\mathcal{O}(v) \leq k-1)$, and P the uniform probability. In this case, any boundary point is determinate (see for example [19, Thm. 4.1, p. 78]). More precisely, a point $\overline{c}$ is determined if and only if (see [19, Thm. 4.1, p.78])

$$\overline{c} = \sum_{j=1}^{q} p_j \Phi(x_j), \qquad \sum_{j=1}^{q} p_j = 1, x_j \neq x_{j'}, j \neq j',$$

with $i(\overline{c}) = \sum_{j=1}^{q} \eta(x_j) \leq k-1$, where, when Φ is not periodic,

$$\begin{aligned} \eta(x) &:= 1 \quad \text{if } x \in]0,1[\\ &:= 2, \quad x = 0 \text{ or } x = 1 \end{aligned}$$

and $\eta(x) := 1$ for all x when Φ is periodic. It is possible to prove that, for any determined point $\overline{c}, \beta_0(\overline{c}) = \frac{1}{2}$, and that assumption (I3) and Theorem 6 hold as soon as one of the $x_j \neq 0, 1$ (see Lemma 5).

As an example, suppose now that $\Phi(x) = (1, \ldots, x^{k-1})$, that $i(\overline{c}) = k-1$, and $\forall j = 1 \ldots q, x_j \neq 0, 1$. Then there exists a unique nonnegative polynomial which vanishes at points $x_1, \ldots, x_q$. Therefore, we have

$$\xi_{\beta,0}[(0, \tilde{d}(0))] = \int_0^1 \frac{dx}{\prod_{j=1}^{q} (x - x_j)^{2\beta}} \left(\sum_{j=0}^{q} b_j^2 \right)^{-\frac{\beta}{2}},$$

where

$$b_j = \sum_{l+l'=j} (-1)^j \sum_{1 \le j_1 < j_2 < \cdots < j_{q-l} \le q} x_{j_1}, \dots, x_{j_{q-l}} \sum_{1 \le j_1 < j_2 < \cdots < j_{q-l'} \le q} x_{j_1}, \dots, x_{j_{q-l'}}.$$

Through this evaluation of $\xi_{\beta,0}[(0, \tilde{d}(0))]$, we see that the constant that appears in the superconcentration inequality is smaller whenever $i(\overline{c}) < k - 1$. Indeed, in this case the set of nonnegative polynomials which vanish at points $x_1, \dots, x_q$ is not reduced to a singleton.

3.4.5. Further applications. The methodology introduced in this paper to investigate superresolution phenomena can be used in other situations as soon as we dispose of the MEM reconstruction technique. This is the case in the following examples.

Markov moment problem. In this inverse problem, we replace the set of all positive measures by the set of all nonnegative measurable functions bounded by $L > 1$ (when the searched functions are probability densities (see [19, Chap. VII] for more details on Markov moment problems). The MEM method could be applied exactly as we did previously. A determined point $\overline{c}$ admits for some $d \in \mathbb{R}^k$ the representation

$$\overline{c} = L \int_U \Phi(x) 1_{\{x \in U, \langle d, \Phi(x) \rangle \ge 0\}} \, dP(x).$$

The Dirac measures are replaced here by indicator functions, so that stronger distances may be used to describe superresolution. Using the ψ-dissimilarity (see §4) for an appropriate prior we can evaluate for small ϵ

$$\sup_{f \in \mathcal{C}_{0,L}, \int \Phi f \, dP \in B(\overline{c}, \epsilon)} \| f - 1_{\{x \in U, \langle d, \Phi(x) \rangle \ge 0\}} \|_1$$

or

$$\sup_{f, g \in \mathcal{C}_{0,L}, \int \Phi f \, dP \in B(\overline{c}, \epsilon), \int \Phi f \, dP \in B(\overline{c}, \epsilon)} \| f - g \|_1,$$

where $\|f\|_1 := \int |f| \, dP$ and

$$\mathcal{C}_{0,L} := \{ f \text{ measurable}, 0 \le f \le L, P \text{ almost surely} \}.$$

We remark that the compactness assumption $\Phi_1(x) = 1$ can be removed here. Indeed, the condition $f \in \mathcal{C}_{0,L}$ is a very strong compactness assumption. We also remark that, for the Markov moment problem, the evaluation of the superresolution rate function $K(\epsilon)$ is easier. Indeed, the Lagrangian function $H^\epsilon(v, c)$ (see §2) is defined here on all of $\mathbb{R}^k$ [5].

These ideas are developed in [14] and later in [20].

Multidimensional moment problems. We will discuss here the case of superresolution rate for multidimensional moment problems. That is, keeping the same notations as in the previous sections, Φ is now a matrix-valued function from U to $\mathbb{R}^k \times \mathbb{R}^m$ with

$$\phi_{1,j}(x) := 1, \quad j = 1, \dots, m.$$

The inverse problem consists of recovering a vector-valued positive measure $\mu = (\mu_j)_{j=1,\dots,m}$ (we can also require more than the simple positivity of the components, typically $(d\mu)/(dP) \in \mathcal{C}$, where $\mathcal{C}$ is a given convex set) satisfying the linear constraint

$$\int_U \Phi(x)\, d\mu(x) = c.$$

The MEM method for this reconstruction problem has been developed in [12]. Therefore, with extra work, we can hope to find the same kind of superconcentration results.

4. A dissimilarity linked with MEM construction. In this section, we introduce and study a dissimilarity between a nonnegative function and a positive measure. This dissimilarity is linked with the MEM construction. We first begin with its definition.

DEFINITION 2. *Let G be in $\mathcal{M}_+(U)$; g will denote the Radon–Nikodým derivative of G with respect to P. Let*

$$\mathcal{M}_+^{\psi,G} := \{\textit{nonnegative measurable function } h \textit{ on } U, \psi'^{-1}(h) \in L^1(G - gP)\}.$$

Let h be in $\mathcal{M}_+^{\psi,G}$. The generalized ψ-dissimilarity $\mathcal{D}_\psi(G,h)$ between G and h is defined by

$$\mathcal{D}_\psi(G,h) := D_\psi(g,h) + \alpha(G - gP)(U) - \int_U \psi'^{-1}[h(x)]\, d(G - gP),$$

where the ψ-dissimilarity $D_\psi(g,h)$ between g and h is defined by

$$\begin{aligned} D_\psi(g,h) := & \int_U g(x)(\psi'^{-1}[g(x)] - \psi'^{-1}[h(x)])\, dP(x) \\ & - \int_U \psi[\psi'^{-1}\{g(x)\}]\, dP(x) + \int_U \psi[\psi'^{-1}\{h(x)\}]\, dP(x) \end{aligned}$$

when all the functions involved are integrable, and $+\infty$ otherwise.

The terminology of dissimilarity is justified by the following proposition (proved in §6).

PROPOSITION 2. *We have that*

$$\forall G \in \mathcal{M}_+(U), h \in \mathcal{M}_+^{\psi,G}, \mathcal{D}_\psi(G,h) \geq 0$$

$\mathcal{D}_\psi(G,h)$ vanishes if and only if

$$\frac{dG}{dP} = h \ (\textit{P almost surely}) \textit{ and } \operatorname{Supp}\left(G - \frac{dG}{dP}P\right) \subset \{x \in U, h = \infty\}.$$

We can also give a dual definition of the dissimilarities in the case of densities.

PROPOSITION 3. *For any measurable nonnegative functions g and h,*

$$\begin{aligned} D_\psi(g,h) = & \sup_{l \in C(U)} \left\{ \int_U l(x) g(x)\, dP(x) - \int_U \psi[l(x) - \psi'^{-1}\{h(x)\}]\, dP(x) \right\} \\ & + \int_U \psi[\psi'^{-1}(h(x))]\, dP(x). \end{aligned}$$

The following Pythagoras theorem gives a relation between the ψ-dissimilarity and the MEM method. It has been the key tool for finding our superconcentration result (7). Indeed, using Lemma 2, (11) leads to (7). It is a consequence of the same relation proved by Csiszar for the Kullbak divergence in [3]. (See the proof of Theorem 7.)

THEOREM 7. *Let c be an inner point of $\mathcal{K}_1$; then*

$$\begin{aligned}\forall G \in \mathcal{S}(c), \quad \mathcal{D}_\psi(G, \psi'(0)) &= I(G) \\ &= \mathcal{D}_\psi(G, \psi'(\langle v^*, \Phi\rangle)) + \mathcal{D}_\psi(G^{\mathrm{MEM}}, \psi'(0)) \\ &= \mathcal{D}_\psi(G, \psi'(\langle v^*, \Phi\rangle)) + I(G^{\mathrm{MEM}}).\end{aligned} \tag{10}$$

Let c be a point of $\mathbb{R}^k$ such that $\mathcal{S}(c, \epsilon)$ is nonvoid; then

$$\begin{aligned}&\forall G \in \mathcal{S}(c, \epsilon), \\ &\mathcal{D}_\psi(G, \psi'(0)) = I(G) \\ &\qquad \geq \mathcal{D}_\psi(G, \psi'(\langle v^\epsilon, \Phi\rangle)) + \mathcal{D}_\psi(G^{\mathrm{MEM},\epsilon}, \psi'(0)) \\ &\qquad = \mathcal{D}_\psi(G, \psi'(\langle v^\epsilon, \Phi\rangle)) + I(G^{\mathrm{MEM},\epsilon}).\end{aligned} \tag{11}$$

LEMMA 2. *Let $G \in \mathcal{M}_+(U)$; then*

$$I(G) \leq -\log F(\{0\}) + \alpha.$$

Lemma 2 is proved in [13, Eqs. (19) and (20)].

5. Earlier results on superresolution.

- The first qualitative result on superresolution appears in Gassiat [16]. It gives the qualitative results of Theorems 1 and 4 in the restrictive situation where $\Phi_1, \ldots, \Phi_k$ form a T-system. The proof relies on properties of such a system, which is clearly not necessary.
- The first quantitative superresolution result appears in Donoho et al. [9]. In this work, U is the *discretized* torus and the functions Φ_j are the sine and cosine first functions (so that the c_j are the first Fourier coefficients). The authors give an evaluation of

$$\sup_{\mu_1, \mu_2 \in \mathcal{S}(c, \epsilon)} \sum_{x \in U} |\mu_1(x) - \mu_2(x)|.$$

The techniques rely heavily on Fourier analysis.

- In Donoho [7], the author gives a superresolution inequality in a very different context. The space U is again discretized: U is the lattice ΔZ. The moment constraints are no longer of finite number: the observation is the Fourier transform of the measure, $\hat{\mu}(\omega), |\omega| \leq \Omega$, where Ω is less than the Rayleigh constant $\frac{2\pi}{\Delta}$. In this work, the measure μ is supposed to be *sparse* enough, not necessarily positive, and the set of reconstructions is supposed to be the set of measures ν (possibly signed), which possess the same *sparsity property*, and satisfy

$$||\hat{\nu} - \hat{\mu}||_{2,[-\Omega,\Omega]} \leq \epsilon.$$

As U is not compact, uniqueness is necessary here, but it is not known if uniqueness is sufficient for superresolution to hold (compare with Theorem 1 in the compact situation). The superresolution inequality given shows also how sparsity quantifies the capacity to superresolve (see [7] for exact result). The techniques rely on hard Fourier analysis and connections with interpolation problems.

- Following similar ideas, in [8] Donoho and Gassiat give superresolution inequalities when μ is supposed to be positive and sparse enough, but the set of reconstructions is now the set of all positive measures ν such that

$$\|\hat{\nu} - \hat{\mu}\|_{2,[-\Omega,\Omega]} \leq \epsilon.$$

An application is given for the case of the torus.

In our work, the ϕ_j do not need to be trigonometric functions for the result to hold. The dependence on the ϕ_j appears in the computation of the function $K(\epsilon)$, through $H^{\epsilon}(v, c)$. In our opinion, these results are very complementary to ours.

6. Proofs.

6.1. Proof of Theorem 1.

- (2) $\Rightarrow$ (3). Indeed,

$$\forall \epsilon > 0, \qquad \sup_{\mu_1,\mu_2 \in \mathcal{S}(c,\epsilon)} d(\mu_1, \mu_2) \geq \sup_{\mu_1,\mu_2 \in \mathcal{S}(c)} d(\mu_1, \mu_2).$$

- (3) $\Rightarrow$ (4). As U is compact, $\mathcal{S}(c, \epsilon)$ is a compact set of positive measures. Now, $d(., \sigma_c)$ is continuous (for the weak topology on $\mathcal{M}_+(U)$) so that

$$\forall \epsilon > 0, \quad \exists \mu_\epsilon \in \mathcal{S}(c, \epsilon) : \sup_{\mu \in \mathcal{S}(c,\epsilon)} d(\mu, \sigma_c) = d(\mu_\epsilon, \sigma_c).$$

Again using the compactness of $\mathcal{S}(c, \epsilon)$, the sequence (μ_ϵ) has at least one accumulation point μ^* when ϵ decreases to 0. Using the continuity of the application $\mu \longrightarrow \int \Phi \, d\mu, \mu^*$ lies in $\mathcal{S}(c)$. Therefore, $\mu^* = \sigma_c$ and $\lim_{\epsilon \to 0^+} d(\mu_\epsilon, \sigma_c) = 0$.

- (4) $\Rightarrow$ (2) is obvious using triangular inequality.

6.2. Proof of Theorem 5.

Using assumption (I1), we can write

$$\bar{c} = \sum_{i=1}^{q} p_i \Phi(x_i),$$

where $p_i > 0, \sum_{i=1}^{q} p_i = 1$.

Define

$$c(\epsilon) := \sum_{i=2}^{q} p_i \Phi(x_i) + [p_1 - h(\epsilon)]\Phi(x_1) + h(\epsilon)\Phi(x_1 + l(\epsilon)u),$$

where u is a point in $\mathbb{R}^d$ of modulus 1, h and l are positive and *small* functions of ϵ such that $h(\epsilon) < p_1$, and $x_1 + l(\epsilon)u$ lies in U. (This is possible with an appropriate choice of u even if $x_1 \in \mathrm{bd}(U)$.) Using the Taylor expansion until order 1, we get

$$\|c(\epsilon) - \bar{c}\| \leq h(\epsilon)l(\epsilon)\|\Phi'\|_{\infty,U_0}.$$

Therefore, set

$$h(\epsilon)l(\epsilon)\|\Phi'\|_{\infty,U_0} := \epsilon, \tag{12}$$

so that

$$\sigma_\epsilon = \sum_{i=2}^{q} p_i\, \delta_{x_i} + (p_1 - h(\epsilon))\, \delta_{x_1} + h(\epsilon)\, \delta_{x_1 + l(\epsilon)u}$$

is in $\mathcal{S}(\overline{c}, \epsilon)$.

As soon as $x_1 + l(\epsilon)u$ is in $R^{c}_{\overline{c},\delta}(\epsilon)$, we will have

$$\sup_{\mu \in \mathcal{S}(\overline{c},\epsilon)} \mu(R^{c}_{\overline{c},\delta}(\epsilon)) \geq h(\epsilon).$$

Using Theorem 4 we get

$$P(R_{\overline{c},\delta}(\epsilon)) < C_1 K(\epsilon)$$

with $C_1 := 1/\log(1 + ae^{\psi_1(\alpha - \delta)})$. For small enough $\epsilon, x_1 \in R_{\overline{c},\delta}(\epsilon)$; see Lemma 1. Now

$$P(B(x_1, r)) = r^d \mathrm{Ct}(d, P),$$

so that for $r = \left(\frac{C_1 K(\epsilon)}{\mathrm{Ct}(d,P)}\right)^{1/d}$ there exists u of modulus one and $l(\epsilon) \leq r$ such that $x_1 + l(\epsilon)u$ is in $R^{c}_{\overline{c},\delta}(\epsilon)$ and we may take

$$l(\epsilon) := [C_1 K(\epsilon)/\mathrm{Ct}(d, P)]^{1/d}.$$

Evaluate $h(\epsilon)$ using (12), and the theorem is straightforward. □

6.3. Proof of Theorem 6. When $\beta_0(\overline{c}) > 0$, we will study the behavior near 0^+ of $K_\beta(.)$ for all $\beta < \beta_0(\overline{c})$.

LEMMA 3.

$$\forall \epsilon \geq 0, \quad \forall \beta > 0, \quad K_\beta(\epsilon) = \beta^{\frac{1}{\beta+1}} \left(1 + \frac{1}{\beta}\right) \cdot \left[\inf_{d \in \mathbb{R}^k, \|d\|=1} \int_U \left(\frac{d_1 + \epsilon\|\tilde{d}\|}{\max(0, d_1 + \langle \tilde{d}\tilde{\Phi}(x)\rangle)}\right)^{\beta} dP(x)\right]^{\frac{1}{\beta+1}}$$

where $\tilde{\Phi}(x) := (\Phi_j(x) - \overline{c}_j)_{j=2,\dots,k}, d := (d_1, \tilde{d})$.

Proof. By definition,

$$\begin{aligned} K_\beta(\epsilon) &= -\log F_\beta(\{0\}) + 1 - h^*(\overline{c}, \epsilon) \\ &= 1 + 1 + \inf_{v \in \mathbb{R}^k} \left[\int_U \frac{dP(x)}{(1 - \min(1, \langle v, \Phi(x)\rangle))^\beta} - 1 - \langle v, \overline{c}\rangle + \epsilon\|v\|_{k-1}\right]. \end{aligned}$$

Making the variable changes $u := (1 - v_1, -v_2, \dots, -v_k)$ and $w := (\langle u, \overline{c}\rangle, u_2, \dots, u_k)$, we find

$$\begin{aligned} K_\beta(\epsilon) &= \inf_{w \in \mathbb{R}^k} \left[\int_U \frac{dP(x)}{(\max(0, w_1 + \langle \tilde{w}, \tilde{\Phi}(x)\rangle))^\beta} + w_1 + \epsilon\|\tilde{w}\|\right] \\ &= \inf_{d \in \mathbb{R}^k, \|d\|=1} \inf_{r > 0} \left[\frac{1}{r^\beta} \int_U \frac{dP(x)}{(\max(0, d_1 + \langle \tilde{d}, \tilde{\Phi}(x)\rangle))^\beta} + r(d_1 + \epsilon\|\tilde{d}\|)\right], \end{aligned}$$

where $d := (d_1, \tilde{d}), w := (w_1, \tilde{w})$.

Now, by an obvious optimization calculus on r, we get

$$K_\beta(\epsilon) = \inf_{d\in\mathbb{R}^k,\|d\|=1}\left[\beta^{\frac{1}{\beta+1}}\left(1+\frac{1}{\beta}\right)\left(\int_U\left[\frac{d_1+\epsilon\|\tilde{d}\|}{\max(0,d_1+\langle\tilde{d},\tilde{\Phi}(x)\rangle)}\right]^\beta dP(x)\right)^{\frac{1}{\beta+1}}\right]$$

$$=\beta^{\frac{1}{\beta+1}}\left(1+\frac{1}{\beta}\right)\left[\inf_{d\in\mathbb{R}^k,\|d\|=1}\int_U\left(\frac{d_1+\epsilon\|\tilde{d}\|}{\max(0,d_1+\langle\tilde{d},\tilde{\Phi}(x)\rangle)}\right)^\beta dP(x)\right]^{\frac{1}{\beta+1}}. \qquad \square$$

LEMMA 4. *Suppose that the critical exponent $\beta_0(\bar{c})$ is positive. Let*

$$\xi_{\beta,\epsilon}(d) := \int_U\left(\frac{\frac{d_1}{\epsilon}+\|\tilde{d}\|}{\max(0,d_1+\langle\tilde{d},\tilde{\Phi}(x)\rangle)}\right)^\beta dP(x), \epsilon>0, 0<\beta<\beta_0(\bar{c}), d\in\mathbb{R}^k,$$

$$\xi_{\beta,0}(d) = \int_U\frac{dP(x)}{\max(0,\langle\tilde{d},\tilde{\Phi}(x)\rangle)^\beta}, 0<\beta<\beta_0(\bar{c}), d\in\mathbb{R}^k.$$

Then we have the following.

- *For all $\epsilon>0$, $\xi_{\beta,\epsilon}(.)$ has a unique minimizer $d(\epsilon)$ on the unit sphere.*
- *$\xi_{\beta,0}(.)$ has a unique minimizer $(0,\tilde{d}(0))$ on the intersection between the unit sphere and the hyperplane $d_1=0$.*

Moreover, $d_1(\epsilon)$ is a positive function of ϵ and

$$\lim_{\epsilon\to0^+} d(\epsilon) = (0,\tilde{d}(0)),$$

$$\lim_{\epsilon\to0^+}\xi_{\beta,\epsilon}[d(\epsilon)] = \xi_{\beta,0}[(0,\tilde{d}(0))].$$

An application of the previous lemma leads to the following proposition.

PROPOSITION 4. *Suppose that the critical exponent $\beta_0(\bar{c})$ is positive. Then, for ϵ sufficiently small and $0<\beta<\beta_0(\bar{c})$,*

$$K_\beta(\epsilon)\sim C_\beta\epsilon^{\frac{\beta}{\beta+1}},$$

where

$$C_\beta := (\xi_{\beta,0}[(0,\tilde{d}(0))])^{\frac{1}{\beta+1}}\beta^{\frac{1}{\beta+1}}\left(1+\frac{1}{\beta}\right).$$

Lemma 4 and Proposition 4 prove Proposition 1.

Proof of Lemma 4.

- For $\epsilon>0$, uniqueness of $d(\epsilon)$ follows from uniqueness of the Lagrange multiplier v^ϵ (see §2).
- For $\epsilon=0$, let $v\in\mathbb{R}^k$ such that

$$\forall x\in U,\quad \langle v,\Phi(x)\rangle\geq0; \langle v,\bar{c}\rangle=0, \int_U\frac{dP(x)}{\langle v,\Phi(x)\rangle^\beta}<\infty.$$

Therefore,

$$v_1=-\sum_{j=2}^k v_j\bar{c}_j,$$

so that

$$\|\tilde{v}\|^{-\beta}\int_U \frac{dP(x)}{\max(0,\langle\tilde{v},\tilde{\Phi}(x)\rangle)^{\beta}}<\infty,$$

and $\inf_{d\in\mathbb{R}^k,\|d\|=1}\xi_{\beta,0}(d)<\infty$.

Now, on the convex set $\{(0,\tilde{d})\in\mathbb{R}^k,\|\tilde{d}\|\le 1\}$, the function $\xi_{\beta,0}(.)$ is strictly convex, so its minimum value is reached at a unique point $(0,\tilde{d}(0))$. Since

$$\xi_{\beta,0}(0,\tilde{d}(0))=\xi_{\beta,0}\left(\left(0,\frac{\tilde{d}(0)}{\|\tilde{d}(0)\|}\right)\right)\|\tilde{d}(0)\|^{-\beta},$$

we necessarily have $\|\tilde{d}(0)\|=1$.

We shall now prove the last points of the lemma. Let $\sigma\in\mathcal{S}(\overline{c})$; we have

$$\forall\epsilon>0,\quad\int_U(d_1(\epsilon)+\langle\tilde{d}(\epsilon),\tilde{\Phi}(x)\rangle)\,d\sigma(x)=d_1(\epsilon).$$

Therefore, since $d_1(\epsilon)+\langle\tilde{d}(\epsilon),\tilde{\Phi}(x)\rangle$ is nonnegative on $U, d_1(\epsilon)\ge 0$.

Now, since $K(\epsilon)=[\epsilon^{\beta}\xi_{\beta,\epsilon}\{d(\epsilon)\}]^{1/(\beta+1)}(1+\frac{1}{\beta})\beta^{1/(\beta+1)}$ we have that

$$\lim_{\epsilon\to0^+}d_1(\epsilon)=0,$$
$$\lim_{\epsilon\to0^+}\|\tilde{d}(\epsilon)\|=1.$$

Therefore,

$$\int_U\left(\frac{\|\tilde{d}\|}{\max(0,d_1+\langle\tilde{d},\tilde{\Phi}(x)\rangle)}\right)^{\beta}dP(x)\le\xi_{\beta,\epsilon}[d(\epsilon)].$$

Let d^* be any accumulation point of the function $d(\epsilon)$ as ϵ decreases to 0. We have, using Fatou's lemma,

$$\underline{\lim}_{\epsilon\to0^+}\xi_{\beta,\epsilon}[d(\epsilon)]\ge\int_U\frac{1}{(\max(0,\langle\tilde{d}^*,\tilde{\Phi}(x)\rangle))^{\beta}}dP(x).$$

On the other hand, $\forall\,d\in\mathbb{R}^k,\|d\|=1,\xi_{\beta,\epsilon}(d(\epsilon))\le\xi_{\beta,\epsilon}(d)$.

Taking $d_1:=0$ and minimizing the right term of the previous inequality, we find

$$\xi_{\beta,\epsilon}[d(\epsilon)]\le\xi_{\beta,0}[(0,\tilde{d}(0))].$$

Since $\xi_{\beta,0}(0,.)$ is strictly convex we have $\tilde{d}^*=\tilde{d}(0)$ and

$$\lim_{\epsilon\to0^+}\xi_{\beta,\epsilon}(d(\epsilon))=\xi_{\beta,0}(0,\tilde{d}(0)).$$

We remark that we also have $\lim_{\epsilon\to0^+}\frac{d_1(\epsilon)}{\epsilon}=0$.

Indeed, let $d_1^*=\overline{\lim}_{\epsilon\to0^+}\frac{d_1(\epsilon)}{\epsilon}$; then, by Fatou's lemma,

$$(d_1^*+1)^{\beta}\xi_{\beta,0}(0,\tilde{d}(0))\le\xi_{\beta,0}(0,\tilde{d}(0)).$$

And $d_1^*=0$. □

LEMMA 5. *Let $\bar{c} \in \mathrm{bd}(\mathcal{K}_1)$. Suppose that $U \subset \mathbb{R}^d$ and that $\Phi \in C^2(U)$. Suppose that the critical exponent $\beta_0(\bar{c})$ is positive. Let*

$$\bar{c} := \sum_{i=1}^{q} p_i \Phi(x_i),$$

where $p_i > 0$ and $\sum_{i=1}^{q} p_i = 1$.

Suppose there exists at least one x_m of the $x_j, j = 1, \ldots, r$, such that there exists an orthogonal basis $(b_2, \ldots, b_k)$ of $\mathbb{R}^{k-1}$ satisfying

- $\langle b_j, \tilde{\Phi}(x) \rangle \geq 0, \forall x \in U, j = 2, \ldots, k$;
- $x_m \in \mathrm{int}(U)$;
- $\langle b_j, D^2\tilde{\Phi}(x_m) \rangle \neq 0, j = 2, \ldots, k$. *Then,* $\langle \tilde{d}(0), D^2\tilde{\Phi}(x_m) \rangle \neq 0$.

Proof. Obviously, for $(0, \tilde{d}), (0, \tilde{e}) \in \mathbb{R}^k$,

$$\xi_{\beta,0}[(0,\tilde{d}) + (0,\tilde{e})] \leq \mathrm{Min}(\xi_{\beta,0}[(0,\tilde{d})], \xi_{\beta,0}[(0,\tilde{e})]),$$

so that

$$\xi_{\beta,0}\left(\frac{(0,\tilde{d}) + (0,\tilde{e})}{\|(0,\tilde{d}) + (0,\tilde{e})\|}\right) \leq \|(0,\tilde{d}) + (0,\tilde{e})\|^{\beta}\mathrm{Min}(\xi_{\beta,0}[(0,\tilde{d})], \xi_{\beta,0}[(0,\tilde{e})]).$$

Suppose that

$$\langle \tilde{d}(0), D^2\tilde{\Phi}(x_m) \rangle = 0$$

and let

$$\tilde{d}(0) = \sum_{j=2}^{k} \tilde{d}_j^b(0) b_j$$

be the decomposition of $\tilde{d}(0)$ on the basis $(b_2, \ldots, b_k)$.

Now, because $\langle b_j, \tilde{\Phi}(x) \rangle, j = 2, \ldots, k$, is nonnegative on U and vanishes at the point x_m, we have $\langle b_j, D^2\tilde{\Phi}(x_m) \rangle > 0, j = 2, \ldots, k$. Therefore, one of the components $(\tilde{d}_j^b(0))$ is negative. So we can assume that $\tilde{d}_2^b(0) < 0$. Thus, for $0 < \lambda < -2\tilde{d}_2^b(0)$, we have

$$\|\tilde{d}(0) + \lambda \tilde{d}_2^b(0) b_2\| < 1$$

so that

$$\xi_{\beta,0}\left(\frac{(0, \tilde{d}(0) + \lambda \tilde{d}_2^b(0) b_2)}{\|(0, \tilde{d}(0) + \lambda \tilde{d}_2^b(0) b_2)\|}\right) < \xi_{\beta,0}[(0, \tilde{d}(0))],$$

which contradicts the fact that $(0, \tilde{d}(0))$ achieves the minimum of $\xi_{\beta,0}[(0,.)]$ over $\{\|\tilde{d}\| = 1\}$. We may conclude that $\langle \tilde{d}(0), D^2\tilde{\Phi}(x_m) \rangle \neq 0$. □

Proof of Theorem 6. Without loss of generality, we may assume that $\langle \tilde{d}(0), D^2\tilde{\Phi}(x_1) \rangle \neq 0$. Define

$$c(\epsilon) := \sum_{i=2}^{r} p_i \Phi(x_i) + (1 - h(\epsilon)) p_1 \Phi(x_1) + \frac{h(\epsilon)}{2} p_1 \Phi(x_1 + l(\epsilon)u) + \Phi(x_1 - l(\epsilon)u),$$

with $u \in \mathbb{R}^d$, $\|u\| = 1$, and we choose $h(\epsilon) < 1$. We can write

$$c(\epsilon) = \int_U \Phi(x)\, d\sigma_\epsilon(x),$$

where

$$\sigma_\epsilon := \sum_{i=2}^{r} p_i\, \delta_{x_i} + p_1(1 - h(\epsilon))\delta_{x_1} + p_1 \frac{h(\epsilon)}{2}[\delta_{x_1 + l(\epsilon)u} + \delta_{x_1 - l(\epsilon)u}]$$

is a probability distribution, with support in U as soon as $l(\epsilon)$ is small enough. We have

$$c(\epsilon) = \bar{c} + \frac{h(\epsilon)}{2} p_1\{\Phi(x_1 + l(\epsilon)u) - \Phi(x_1) + \Phi(x_1 - l(\epsilon)u) - \Phi(x_1)\}.$$

Using a Taylor extension of order 2, we get

$$\|c(\epsilon) - \bar{c}\|_2 \le \frac{h(\epsilon) l^2(\epsilon)}{2} \|D^2\Phi\|_\infty. \tag{13}$$

We are now going to prove that either $x_1 + l(\epsilon)u$ or $x_1 - l(\epsilon)u$ is in $R^c_{\bar{c},\delta}(\epsilon)$ for a special value of $l(\epsilon)$ and a special choice of u. Using an exact Taylor extension of order 2, we have

$$\begin{aligned} &\alpha - \langle v_\epsilon, \Phi(x_1 + l(\epsilon)u)\rangle + \alpha - \langle v_\epsilon, \Phi(x_1 - l(\epsilon)u)\rangle \\ &\quad = 2(\alpha - \langle v_\epsilon, \Phi(x_1)\rangle) - \frac{l^2(\epsilon)}{2}\langle v_\epsilon, D^2\Phi(x_1 + \theta^* l(\epsilon)u)(u,u)\rangle \\ &\qquad - \frac{l^2(\epsilon)}{2}\langle v_\epsilon, D^2\Phi(x_1 - \theta^{**} l(\epsilon)u)(u,u)\rangle \end{aligned}$$

with

$$0 \le |\theta^*| \le 1, \qquad 0 \le |\theta^{**}| \le 1.$$

Now, using the convergence of $d(\epsilon)$ and the continuity of $D^2\tilde{\Phi}$, we have

$$\lim_{\epsilon \to 0^+} \alpha - \langle v_\epsilon, \Phi(x_1)\rangle = 0$$

and

$$-\frac{l^2(\epsilon)}{2}\langle v_\epsilon, D^2\Phi(x_1 + \theta^* l(\epsilon)u)(u,u)\rangle \sim \frac{l^2(\epsilon)}{2}\|v_\epsilon\|_{k-1}\langle \tilde{d}(0), D^2\tilde{\Phi}(x_1)(u,u)\rangle.$$

We can also write a similar formula for the other term.

Now choose u such that

$$\langle \tilde{d}(0), D^2\tilde{\Phi}(x_1)(u,u)\rangle = \eta > 0$$

and

$$l^2(\epsilon) = \frac{5\delta}{\eta}\frac{1}{\|v_\epsilon\|_{k-1}}.$$

Observe that we have $\lim_{\epsilon \to 0^+} l(\epsilon) = 0$.

For small ϵ,

$$\alpha - \langle v_\epsilon, \Phi(x_1)\rangle > -\delta$$

and

$$\frac{l^2(\epsilon)}{2}\langle v_\epsilon, D^2\Phi(x_1+\theta^* l(\epsilon)u)(u,u)\rangle = \frac{5\delta}{2\eta}\langle d(\epsilon), D^2\tilde{\Phi}(x_1+\theta^* l(\epsilon)u)(u,u)\rangle > 2\delta.$$

We can also write a similar formula for the other term.

Therefore, for small ϵ,

$$\alpha - \langle v_\epsilon, \Phi(x_1 + l(\epsilon)u)\rangle + \alpha - \langle v_\epsilon, \Phi(x_1 - l(\epsilon)u)\rangle > 2\delta,$$

so that either

$$\alpha - \langle v_\epsilon, \Phi(x_1 + l(\epsilon)u)\rangle > \delta$$

or

$$\alpha - \langle v_\epsilon, \Phi(x_1 - l(\epsilon)u)\rangle > \delta. \tag{14}$$

Now define

$$h(\epsilon) := \frac{2\epsilon}{\|D^2\Phi\|_\infty l^2(\epsilon)}.$$

Notice that $h(\epsilon) \to 0$, as $l^2(\epsilon) \sim \mathrm{Ct}\frac{\epsilon}{K(\epsilon)}$.

In view of (13), $\sigma_\epsilon \in \mathcal{S}(\bar{c}, \epsilon)$, and in view of (14),

$$\sigma_\epsilon(R^c_{\bar{c},\delta}(\epsilon)) \geq p_1\frac{h(\epsilon)}{2}.$$

Now,

$$p_1\frac{h(\epsilon)}{2} = \frac{p_1}{\|D^2\Phi\|_\infty}\frac{\eta}{5\delta}\epsilon\|v_\epsilon\|_{k-1} = C_1K(\epsilon).$$

And the theorem is proved. □

6.4. Proofs of Propositions 2 and 3. Proposition 2 follows from the study of the function

$$\theta(\tau) := \tau\{\psi'^{-1}[\tau] - \psi'^{-1}[\tau']\} - \psi[\psi'^{-1}\{\tau\}] + \psi[\psi'^{-1}\{\tau'\}].$$

For a fixed $\tau', \theta(\tau)$ is nonnegative and vanishes if and only if $\tau = \tau'$. Proposition 3 follows from the function change $k := l - \psi'^{-1}(h)$ and variational calculus (see [12] or [25]). □

6.5. Proof of Theorem 7. Let $G \in \mathcal{S}(c)$ with $I(G) < \infty$; we have

$$\begin{aligned}
\mathcal{D}_\psi(G, \psi'(\langle v^*, \Phi\rangle)) &= D_\psi\left(\frac{dG}{dP}, \psi'(\langle v^*, \Phi\rangle)\right) + \alpha\left[\left(G - \frac{dG}{dP}P\right)(U)\right] \\
&\quad - \int_U \langle v^*, \Phi(x)\rangle \left(G - \frac{dG}{dP}P\right)(dx) \\
&= \Gamma\left(\frac{dG}{dP}\right) - \int_U \langle v^*, \Phi(x)\rangle \frac{dG}{dP}\, dP(x) \\
&\quad + \int_U \psi(\langle v^*, \Phi(x)\rangle)\, dP(x) + \alpha\left[\left(G - \frac{dG}{dP}P\right)(U)\right] \\
&\quad - \int_U \langle v^*, \Phi(x)\rangle \left(G - \frac{dG}{dP}P\right)(dx) \\
&= \Gamma\left(\frac{dG}{dP}\right) - \langle v^*, c\rangle \\
&\quad + \int_U \psi(\langle v^*, \Phi(x)\rangle)\, dP(x) + \alpha\left[\left(G - \frac{dG}{dP}P\right)(U)\right] \\
&= \mathcal{D}_\psi(G, \psi'(0)) - \mathcal{D}_\psi(G^{\mathrm{MEM}}, \psi'(0)),
\end{aligned}$$

so (10) is proved.

Let $gP \in \mathcal{S}(c, \epsilon)$ with $g > 0$ and $g \in C(U)$. Let (x_i) be a sequence of points of U such that the empirical measure $\frac{1}{n}\sum_{i=1}^n \delta_{x_i}$ converges weakly to P. Let χ_n^g be the probability distribution on $(\mathbb{R}_+^n, \mathcal{B}(\mathbb{R}_+^n))$ with density with respect to $F^{\otimes n}$:

$$\prod_{i=1}^n \exp\{Y_i \psi'^{-1}[g(x_i)] - \psi(\psi'^{-1}[g(x_i)])\},$$

where $Y_1, \dots, Y_n$ are the coordinate variables on $(\mathbb{R}_+^n, \mathcal{B}(\mathbb{R}_+^n))$. Then we have that for large enough n (see [5]),

$$E_{\chi_n^g}\left\{\frac{1}{n}\sum_{i=1}^n Y_i \Phi(x_i)\right\} \in B(c, \epsilon). \tag{15}$$

Let P_n^{ME} be the probability given by the MEM construction at stage n for the relaxed constraint problem (see [13]). Now, a nice property of P_n^{ME} is that it satisfies a Pythagoras theorem (see [4], [26]). In particular, since χ_n^g satisfies (15), we have

$$\frac{1}{n}K(\chi_n^g, F^{\otimes n}) \geq \frac{1}{n}K(P_n^{\mathrm{ME}}, F^{\otimes n}) + \frac{1}{n}K(\chi_n^g, P_n^{\mathrm{ME}}).$$

Simple calculations lead to

$$\begin{aligned}
\frac{1}{n}K(\chi_n^g, F^{\otimes n}) &= \frac{1}{n}\sum_{j=1}^n \gamma(g(x_j)), \\
\frac{1}{n}K(P_n^{\mathrm{ME}}, F^{\otimes n}) &= \frac{1}{n}\sum_{j=1}^n \gamma(\psi'[\langle v_n, \Phi(x_j)\rangle]), \\
\frac{1}{n}K(\chi_n^g, P_n^{\mathrm{ME}}) &= \frac{1}{n}\sum_{j=1}^n \{g(x_j)\{\psi'^{-1}[g(x_j)] - \langle v_n, \Phi(x_j)\rangle\} \\
&\qquad - \psi[\psi'^{-1}\{g(x_j)\}] + \psi[\langle v_n, \Phi(x_j)\rangle]\},
\end{aligned}$$

where (v_n) is a sequence of $\mathbb{R}^k$ converging to v^ϵ. Taking the limit as n goes to infinity we find (see [13]),

$$\Gamma(g) \geq I(G^{MEM,\epsilon}) + D_\psi(g, \psi'(\langle v^\epsilon, \Phi(x)\rangle)). \tag{16}$$

Now, for any $G \in \mathcal{S}(c,\epsilon)$ by Lemma 6 (see below) there exists a sequence of positive continuous function (g_n) such that (g_nP) converges weakly to G and (17) and (18) hold. Therefore, using inequality (16) for g_n, as n goes to infinity we find (11). □

LEMMA 6. *Let $G \in \mathcal{M}_+$ and h be a nonnegative measurable function on U such that $\psi'^{-1}(h)$ is continuous and $\mathcal{D}_\psi(G,h) < \infty$. Then, there exists a sequence of continuous positive functions (g_n) such that g_nP converges weakly to G and*

$$\begin{aligned}\lim_{n\to\infty} D_\psi(g_n,h) &= \lim_{n\to\infty} \mathcal{D}_\psi(g_nP,h)\\ &= \mathcal{D}_\psi(G,h),\end{aligned} \tag{17}$$

$$\begin{aligned}\lim_{n\to\infty} \mathcal{D}_\psi(g_n,\psi'(0)) &= \lim_{n\to\infty} \mathcal{D}_\psi(g_nP,\psi'(0))\\ &= \mathcal{D}_\psi(G,\psi'(0)).\end{aligned} \tag{18}$$

Proof. The existence of a sequence (g_n) such that $g_n.P$ converges weakly to G and (18) holds is proved in [13, Lem. 3]. Therefore, we will only verify that (17) holds for this sequence. This is obvious using the formula

$$D_\psi(g_n,h) = \Gamma(g_n) - \Gamma(h) + \int_U (h(x) - g_n(x))\psi'^{-1}[h(x)]\,dP(x). \qquad \square$$

A DISTRIBUTIONAL SAMPLING THEOREM*

YOUMING LIU†

Abstract. The classical Shannon sampling theorem has many extentions [*A Tutorial in Theory and Applications*, C. K. Chui, ed., Academic Press, 1992, pp. 51–70], one of which is to functions of polynomial growth. In this paper, we shall prove the following theorem:

Let $F(\omega)$ be a distribution with compact support on $[-\pi, \pi]$ and $f(t)$ be the Fourier transform. Then

$$f(t) = \sum_n f(n) \frac{\sin \pi(t-n)}{\pi(t-n)}$$

holds in the sense of (C, α) summation under a very mild condition.

The above result improves the theorems in both [*SIAM J. Math. Anal.*, 19 (1988), pp. 1198–1203] and [*Generalized Functions, Convergence Structures, and Their Applications*, B. Stankovic et al., eds., Plenum Press, 1988, pp. 349–357] given by G. G. Walter.

Key words. sampling theorem, distribution, (C, α) summation

AMS subject classifications. 40G05, 41A05, 42C15, 94A11

1. Introduction.

The classical sampling theorem says that

$$f(t) = \sum_n f(n) \frac{\sin \pi(t-n)}{\pi(t-n)} \tag{1.1}$$

for any finite and π-bandlimited signal f (i.e., $f \in L^2(R)$ and the Fourier transform F of f has compact support on $[-\pi, \pi]$). The importance of this theorem was first recognized by Shannon in communication theory. However, many signals in communication do not have finite energy, i.e., $f \notin L^2(R)$. A general class of such signals is given by the Fourier transform of distributions with compact support. Without loss of generality, we consider $A_\pi = \{\hat{F} : F \in S' \text{ and } \operatorname{supp} F \subset [-\pi, \pi]\}$, where S' denotes all linear continuous functionals on Schwartz class S and $\hat{F}$ is the Fourier transform of a distribution F.

Several versions of the sampling theorem that are appropriate for such signals have been studied by Campbell [2], Pfaffelhuber [3], Lee [4], Hoskins [5], and Walter [6]. All suffered from the same shortcoming—that (1.1) had to be modified to obtain a convergence theorem. G. G. Walter retained the elegant formula (1.1) by requiring that the convergence of the series in (1.1) be interpreted in the sense of Abel summability [7].

In this paper, we establish (1.1) for some $F \in A_\pi$ in the sense of (C, α) summability, where α depends on F.

2. Preliminaries and lemmas.

Let g be a 2π-periodic function and $g \in L^2[-\pi, \pi]$, its Fourier series $\sum_n c_n e^{inx}$. The so-called (C, α) summability of the above series means that

$$\lim_{n \to \infty} \sigma_n^\alpha(x) = \lim_n \sum_{v=-n}^{n} \frac{(\alpha)_{n-|v|}}{(\alpha)_n} c_v e^{ivx} = f(x),$$

where $\sigma_n^\alpha(x)$ is called the (C,α) partial sum of nth order and $(\alpha)_n = C_{n+\alpha}^\alpha$ or $\binom{n+\alpha}{\alpha}$. In particular, $\sigma_n^0(x) = S_n(x)$ is the usual sum and $S_n(x) = \frac{1}{\pi}\int_{-\pi}^{\pi} g(y)D_n(x-y)dy$ with $D_n(x) = \sin(n+\frac{1}{2})x/2\sin\frac{x}{2}$, the Dirichet kernel. $\sigma_n^1(x) = \sigma_n(x)$ is the $(C,1)$ mean and $\sigma_n(x) = \frac{1}{\pi}\int_{-\pi}^{\pi} g(y)F_n(x-y)dy$ with $F_n(x) = \sin^2\frac{n+1}{2}x/2(n+1)\sin^2\frac{x}{2}$ is known as the Fejer kernel. In general ([8, p. 88]), $\sigma_n^\alpha(x) = \frac{1}{2\pi}\int_{-\pi}^{\pi} g(y)K_n^\alpha(x-y)dy$, where the (C,α) kernel $K_n^\alpha(x) = (1/(\alpha)_n)\sum_{v=0}^n(\alpha-1)_{n-v}D_v(x)$.

To introduce our main result, we need the following lemmas.

LEMMA 1 ([8, p. 115]). *For any real number $\alpha > -1$ and complex number z,*

$$\sum_{v=0}^{n}(\alpha)_v z^v = \left[\sum_{v=0}^{n}(\alpha-1)_v z^v - (\alpha)_n z^{n+1}\right]\frac{1}{1-z}, \tag{2.1}$$

where $(\alpha)_n = \Gamma(\alpha+n+1)/\Gamma(\alpha+1)\Gamma(n+1)$ and $\Gamma(t)$ is the Gamma function.

The proof can be given by the Abel transform [8]. However, when we restrict α to the integer case as in this paper, a fundamental argument follows. In fact, by multiplying both sides of (2.1) by $1-z$ and using $(\alpha)_v = \frac{v+\alpha}{\alpha}(\alpha-1)_v$, we can find a proof after some simple calculations.

Based on Lemma 1, we can show the following.

LEMMA 2. *For any positive integer α, the (C,α) kernel $K_n^\alpha(t)$ can be given by*

$$K_n^\alpha(t) = \frac{\sin[(n+\frac{\alpha+1}{2})t - \frac{\pi\alpha}{2}]}{(\alpha)_n(2\sin\frac{t}{2})^{\alpha+1}} - \sum_{k=1}^{\alpha}\frac{(k-1)_n}{(\alpha)_n}\sin\left[\frac{\alpha-k}{2}t - \frac{\pi(\alpha-k+1)}{2}\right]\left(2\sin\frac{t}{2}\right)^{-\alpha+k-2}.$$

Proof. We have pointed out that $K_n^\alpha(x) = (1/(\alpha)_n)\sum_{v=0}^n(\alpha-1)_{n-v}D_v(x)$. For simplicity, denoting $2\sin\frac{t}{2}(\alpha)_n K_n^\alpha(t)$ by I_n, we have $I_n = \sum_{v=0}^n(\alpha-1)_{n-v}\sin(v+\frac{1}{2})t = \mathrm{Im}[z^{n+\frac{1}{2}}\sum_{v=0}^n(\alpha-1)_v z^{-v}]$, where $z = e^{it}$ and Im denotes the imaginary part of z. By Lemma 1, we can also express I_n as $I_n = \mathrm{Im}[z^{n+\frac{1}{2}}/(1-z)\sum_{v=0}^n(\alpha-2)_v z^{-v}] - (\alpha-1)_n\mathrm{Im}z^{-\frac{1}{2}}/(1-z^{-1})$. Furthermore, it also follows from Lemma 1 that

$$I_n = \mathrm{Im}\frac{z^{n+\frac{1}{2}}}{(1-z^{-1})^{\alpha-1}}\sum_{v=0}^{n} z^{-v} - \sum_{k=2}^{\alpha}(k-1)_n\mathrm{Im}\frac{z^{-\frac{1}{2}}}{(1-z^{-1})^{\alpha-k+1}}.$$

That is,

$$I_n = \mathrm{Im}\frac{z^{n+\frac{1}{2}} - z^{-\frac{1}{2}}}{(1-z^{-1})^{\alpha}} - \sum_{k=2}^{\alpha}(k-1)_n\mathrm{Im}\frac{z^{-\frac{1}{2}}}{(1-z^{-1})^{\alpha-k+1}} = I_n^1 + I_n^2,$$

where

$$I_n^1 = \mathrm{Im}\frac{z^{n+\frac{1}{2}} - z^{-\frac{1}{2}}}{(1-z^{-1})^{\alpha}} \quad \text{and} \quad I_n^2 = -\sum_{k=2}^{\alpha}(k-1)_n\mathrm{Im}\frac{z^{-\frac{1}{2}}}{(1-z^{-1})^{\alpha-k+1}}.$$

On the other hand, it is easy to see that

$$I_n^1 = \frac{1}{(2\sin\frac{t}{2})^\alpha}\left\{\sin\left[\left(n+\frac{\alpha+1}{2}\right)t - \frac{\pi\alpha}{2}\right] - \sin\left(\frac{\alpha-1}{2}t - \frac{\pi\alpha}{2}\right)\right\}$$

and

$$I_n^2 = -\sum_{k=2}^{\alpha}(k-1)_n \frac{\sin[\frac{\alpha-k}{2}t - \frac{\pi}{2}(\alpha-k+1)]}{(2\sin\frac{t}{2})^{\alpha-k+1}}$$

since $z = e^{it}$. Therefore $I_n = I_n^1 + I_n^2 = \sin[(n+\frac{\alpha+1}{2})t - \frac{\pi\alpha}{2}]/(2\sin\frac{t}{2})^{\alpha} - \sum_{k=1}^{\alpha}(k-1)_n \sin[\frac{\alpha-k}{2}t - \frac{\pi}{2}(\alpha-k+1)](2\sin\frac{t}{2})^{\alpha-k+1}$. Finally, it follows that

$$K_n^{\alpha}(t)$$
$$= \frac{\sin[(n+\frac{\alpha+1}{2})t - \frac{\pi\alpha}{2}]}{(\alpha)_n(2\sin\frac{t}{2})^{\alpha+1}} - \sum_{k=1}^{\alpha}\frac{(k-1)_n}{(\alpha)_n}\sin\left[\frac{\alpha-k}{2}t - \frac{\pi}{2}(\alpha-k+1)\right]\left(2\sin\frac{t}{2}\right)^{-\alpha+k-2}$$

from the notation $I_n = 2\sin\frac{t}{2}(\alpha)_n K_n^{\alpha}(t)$. This completes the proof of Lemma 2.

LEMMA 3. *If $\alpha \geq 1$ and $\alpha \in Z$, then (C,α) kernel $K_n^{\alpha}(t) \geq 0$ for each $t \in R$.*

In fact, for $\alpha = 1$, $K_n^{\alpha}(t) = \frac{1}{n+1}\sum_{v=0}^{n} D_v(t) = F_n(t)$, which is the Fejer kernel, and $F_n(t) \geq 0$ since $F_n(t) = \sin^2\frac{n+1}{2}t/2(n+1)\sin^2\frac{t}{2}$. In general, since $F_v = \frac{1}{v+1}[D_0 + D_1 + \cdots + D_v]$, we have that $D_v = (v+1)F_v - vF_{v-1}$ and, furthermore, $K_n^{\alpha}(t) = (1/(\alpha)_n)\sum_{v=0}^{n}(\alpha-1)_{n-v}D_v(t) = (1/(\alpha)_n)\sum_{v=0}^{n}(\alpha-1)_{n-v}[(v+1)F_v - vF_{v-1}] = (1/(\alpha)_n)[\sum_{v=0}^{n}(\alpha-1)_{n-v}(v+1)F_v - \sum_{v=0}^{n-1}(\alpha-1)_{n-v-1}(v+1)F_v] = (1/(\alpha)_n)\{(n+1)F_n + \sum_{v=0}^{n-1}[(\alpha-1)_{n-v} - (\alpha-1)_{n-v-1}](v+1)F_v\} \geq 0$. To prove Theorem 5 below, we also need the following Lemma.

LEMMA 4 (see [6]). *For any distribution F with compact support on $[-\pi,\pi]$, there is a piecewise continuous function G with the same support on $[-\pi,\pi]$ and an integer p such that*

$$F = D^p G + \sum_{j=0}^{p-1} c_j \delta^{(j)},$$

where D^p is the pth differential operator and $\delta^{(j)}$ is the jth derivative of the well-known Dirac functional δ in the distribution sense.

3. Main theorem. With the four lemmas introduced in §2, we are now ready to derive our main theorem.

THEOREM 5. *Let $f \in A_\pi = \{f = \hat{F}, F \in S'$ and $\operatorname{supp} F \subseteq [-\pi,\pi]\}$ and the corresponding G in Lemma 4 satisfy that $G(\omega)/(\omega^2-\pi^2)^{p+2} \in L^1(R)$. Then*

$$f(t) = \sum_n f(n)\frac{\sin\pi(t-n)}{\pi(t-n)}$$

holds in the sense of (C,α) summability with $\alpha > p$ and $\alpha \in Z^+$.

Proof. We can assume that $\alpha = p+1$ since $(C,p+1)$ convergence is stronger than (C,α) convergence for $\alpha > p+1$. Let $\sigma_{nt}^{\alpha}(\omega)$ be the (C,α) mean of the nth partial sum of the Fourier series of the 2π-periodic extention of $e^{it\omega}K_{[-\pi,\pi]}(\omega)$. The proof will be divided into two steps. First, we show

$$\langle D^p G, \sigma_{nt}^{\alpha}\rangle \longrightarrow_{n\to\infty} \langle D^p G, e^{it\omega}\rangle, \tag{3.1}$$

i.e.,

$$\int_{-\pi}^{\pi} G(\omega)D^p\sigma_{nt}^{\alpha}(\omega)d\omega \longrightarrow_{n\to\infty} \int_{-\pi}^{\pi} G(\omega)D^p e^{it\omega}d\omega.$$

Note that the set of all distributions with compact support is identical with the dual E' of $E = C^\infty(R)$, where E is equipped with the topology of locally uniform convergence of functions and all its derivatives ([9, Chap. I.13, Thm. 2]). Here, because $\sigma^\alpha_{nt}(\omega)$ and $e^{it\omega}$ are test functions in E, (3.1) makes sense. Since $D^p\sigma^\alpha_{nt}(\omega) \longrightarrow_{n\to\infty} D^pe^{it\omega}$ a.e. for $\alpha > p$ ([10, p. 59]), we only need to prove L^1 boundedness of $G(\omega)D^p\sigma^\alpha_{nt}(\omega)$ to use the Lebesgue dominated-convergence theorem.

Consider $D^p\sigma^\alpha_{nt}(\omega) = \int_{-\pi}^{\pi} D^pK^\alpha_n(\omega - \xi)e^{it\xi}d\xi$. Noticing that both $K^\alpha_n(\omega)$ and $D^pK^\alpha_n(\omega)$ are 2π-periodic, we have

$$D^p\sigma^\alpha_{nt}(\omega) = 2i\sin\pi t D^{p-1}K^\alpha_n(\omega-\pi) - itD^{p-1}\sigma^\alpha_{nt}(\omega)$$

by the formula of integration by parts. Similarly it is easy to see that

$$D^p\sigma^\alpha_{nt}(\omega) = \sum_{k=1}^{p} P_k(t,\sin\pi t)D^{p-k}K^\alpha_n(\omega-\pi) + P_{\alpha+1}(t,\sin\pi t)\sigma^\alpha_{nt}(\omega), \tag{3.2}$$

where $P_k(t,\sin\pi t)$ are kth-degree polynomials of t and $\sin\pi t$.

On the other hand, it is easy to show that $|D^k\sin nt/\sin^{\alpha+1}t| \le c_kn^k|\sin t|^{-\alpha-1}$. In fact, it is true for $k=1$ due to the inequality $|\sin nt| \le n|\sin t|$ for $n \in Z^+$. Now suppose it is true for $j = 1, 2, \dots, k-1$. We prove that the same is true for $j = k$. Since $D^k\sin nt = D^k((\sin nt/\sin^{\alpha+1}t)\sin^{\alpha+1}t) = \sum_{j=0}^{k-1}\binom{k}{j}D^j(\sin nt/\sin^{\alpha+1}t)D^{k-j}\sin^{\alpha+1}t + D^k(\sin nt/\sin^{\alpha+1}t)\sin^{\alpha+1}t$, it follows that $|D^k\sin nt/\sin^{\alpha+1}t| \le c_kn^k|\sin t|^{-\alpha-1}$. Therefore,

$$|D^{p-k}K^\alpha_n(\omega-\pi)| \le C_k\left|\sin\frac{\omega-\pi}{2}\right|^{-\alpha-1} \tag{3.3}$$

for $1 \le k \le p$ due to Lemma 2. Obviously, $\sigma^\alpha_{nt}(\omega)$ is bounded since $K^\alpha_n(\omega) \ge 0$ (Lemma 3) and

$$|\sigma^\alpha_n(\omega)| \le \int_{-\pi}^{\pi}|K^\alpha_n(\omega-\xi)||e^{it\xi}|d\xi = 1. \tag{3.4}$$

Combining (3.2)–(3.4), we have

$$|D^p\sigma^\alpha_{nt}(\omega)| \le \sum_{k=1}^{p} A_kC_k\left|\sin\frac{\omega-\pi}{2}\right|^{-\alpha-1} + A_{\alpha+1}$$

for any t in bounded set, where $A_{\alpha+1}$ and $A_k(1 \le k \le p)$ are constants. Furthermore, it follows that $G(\omega)D^p\sigma^\alpha_{nt}(\omega)$ is L^1 bounded from the assumption on G and the assumption at the very beginning of the proof. Hence (3.1) is proved.

Next, it is easy to see that

$$\begin{aligned}\left\langle\sum_{j=0}^{p-1} c_j\delta^{(j)}, \sigma^\alpha_{nt}\right\rangle &= \sum_{j=0}^{p-1} c_j(-1)^jD^j\sigma^\alpha_{nt}(0)\\ &\longrightarrow_{n\to\infty}\sum_{j=0}^{p-1} c_j(-1)^j(it)^j = \left\langle\sum_{j=0}^{p-1} c_j\delta^{(j)}, e^{it\omega}\right\rangle.\end{aligned}$$

It follows that $\langle F, \sigma^\alpha_{nt}\rangle \to_{n\to\infty} \langle F, e^{it\omega}\rangle = f(t)$ from (3.1) and the above limit formula. But $\langle F, \sigma^\alpha_{nt}\rangle = \langle F, (C,\alpha)\sum_{k=-n}^{n} c_k(t)e^{ik\omega}\rangle$, $c_k(t) = \frac{1}{2\pi}\int_{-\pi}^{\pi} e^{it\omega}e^{-ik\omega}d\omega =$

$\sin\pi(t-k)/\pi(t-k)$, and $\langle F, e^{ik\omega}\rangle = f(k)$. Therefore, we have that

$$\lim_n (C,\alpha) \sum_{k=-n}^{n} f(k)\frac{\sin\pi(t-k)}{\pi(t-k)} = f(t),$$

i.e.,

$$f(t) = \sum_n f(n)\frac{\sin\pi(t-n)}{\pi(t-n)}$$

in the sense of (C,α) summability. This completes the proof of Theorem 5.

Remark 1. The condition $G(\omega)/(\omega^2-\pi^2)^{p+2} \in L^1(R)$ in Theorem 5 cannot be removed. For example, take $F(\omega) = \delta(\omega-\pi) - \delta(\omega+\pi) = DK_{[-\pi,\pi]}(\omega)$. Then F satisfies all conditions in Theorem 5 except for this L^1 condition. It is clear that the sampling theorem fails since $f(t) = \frac{1}{2\pi}\langle F(\omega), e^{i\omega t}\rangle = \frac{i}{\pi}\sin\pi t$ and $f(n) = 0$ for each integer n but $f(t)$ is not equal to 0 identically.

Remark 2. Theorem 5 improves the result in [6, Thm. 4.3]. In fact, the condition $\operatorname{supp} F \subset [-\pi+\sigma, \pi-\sigma]$ in [6] implies this L^1 condition. This theorem also improves the main result in [7] in some sense since (C,α) convergence is stronger than Abel convergence. In [7], G. G. Walter used a strange terminology on F, strongly integrable. Instead, in this paper, we used an easily understandable condition on G, i.e., L^1 condition, which is very weak. It should be pointed out that the strong integrability of F implies that $|G(\omega)/(\omega-\pi)^p|$ and $|G(\omega)/(\omega+\pi)^p|$ converge to 0 as $\omega \to \pm\pi$ [7]. Therefore, our conditions and Walter's are closely related.

CONSTRUCTION OF ORTHOGONAL WAVELETS USING FRACTAL INTERPOLATION FUNCTIONS*

GEORGE C. DONOVAN[†], JEFFREY S. GERONIMO[†], DOUGLAS P. HARDIN[‡], AND PETER R. MASSOPUST[§]

Abstract. Fractal interpolation functions are used to construct a compactly supported continuous, orthogonal wavelet basis spanning $L^2(\mathbb{R})$. The wavelets share many of the properties normally associated with spline wavelets, in particular, they have linear phase.

Key words. wavelets, fractal interpolation functions, linear phase

AMS subject classification. 41A15

1. Introduction. A wavelet basis of some function space, for example $L^2(\mathbb{R})$, is obtained by considering translates and dilates of one or several suitable functions [1, 5, 16, 17, 19]. Much of the recent interest in these bases has stemmed from the fact that they can be built having various useful properties such as continuity, orthogonality, compact support, vanishing moments, etc. Most of the wavelets that have been investigated to date can be constructed using the notion of multiresolution analysis [16, 17]. Let ϕ be a function in $L^2(\mathbb{R})$ and set $\phi_{k,j}(x) = \phi(2^k x - j)$. For each $k \in \mathbb{Z}$, denote by V_k the L^2-closure of the algebraic span of $\{\phi_{k,j} : j \in \mathbb{Z}\}$. The function ϕ is said to generate a multiresolution analysis if the following conditions are satisfied:

(i) $\cdots \subset V_{-1} \subset V_0 \subset V_1 \subset \cdots$;
(ii) $\operatorname{clos}_{L^2}\left(\bigcup_{k\in\mathbb{Z}} V_k\right) = L^2$;
(iii) $\bigcap_{k\in\mathbb{Z}} V_k = \{0\}$; and
(iv) $\{\phi_{0,j} : j \in \mathbb{Z}\}$ is a Riesz basis for V_0.

If ϕ generates a multiresolution analysis, then ϕ is called a *scaling function* and will satisfy the refinement equation

$$\phi(x) = \sum c_j \phi(2x - j). \tag{1.1}$$

There also exists a $\psi \in L^2(\mathbb{R})$ such that $\overline{\operatorname{span}\{\psi(\cdot - i), i \in \mathbb{Z}\}} = W_0$, where W_0 is the orthogonal complement of V_0 in V_1 [16, 17]. Furthermore, the function ψ satisfies the equation

$$\psi(x) = \sum d_j \phi(2x - j). \tag{1.2}$$

If $\{\phi_{0,k}\}$ is an orthonormal basis for V_0, the formula

$$d_j = (-1)^j c_{1-j} \tag{1.3}$$

gives a simple way of computing the coefficients of equation (1.2). The celebrated work of Daubechies [5] gives explicit construction of finite sequences of coefficients $\{c_j\}$ which give solutions of equation (1.1) that are orthogonal and compactly supported and have varying degrees of smoothness.

Recently, Hardin, Kessler, and Massopust [13] showed that certain classes of fractal interpolation functions (FIFs) also generate a multiresolution analysis of $L^2(\mathbb{R})$. This multiresolution analysis has certain geometric features that are similar to the multiresolution analysis generated by splines [4]. These results have been generalized to several dimensions in [8] and [9]. In [10], scaling functions were exhibited that form an orthonormal basis for the V_0 given in [10]. Here we continue the investigation of the multiresolution analysis arising from FIFs and construct orthogonal, compactly supported continuous wavelets. Wavelets with varying orders of differentiability will be considered in a later paper [7]. These wavelets fall outside the class constructed in [5] and the multiresolution analysis from which they arise yields several scaling functions instead of just one. In this case (1.1) takes the form

$$\Phi(x) = \sum C_j \Phi(2x - j), \tag{1.4}$$

where each C_j is a square matrix the size of which is determined by the number of scaling functions. Multiresolution analyses based upon several scaling functions have also appeared in the work of Micchelli [18], Goodman, Lee, and Wang [11], Goodman and Lee [12], Jia and Shen [14], and Hervé [15].

We proceed as follows. In §2, we review the relevant facts on FIFs and the multiresolution analysis arising from these function spaces. Then in §3, we exhibit and solve the equations that give scaling functions whose dilates form an orthonormal basis for a certain V_0. We also examine the smoothness of these scaling functions and exhibit their Fourier transforms. In §4, we use the scaling functions constructed above to find compactly supported, continuous, orthogonal wavelets. We investigate the support properties of these wavelets and discuss how to convert them into a wavelet basis for $L^2[0,1]$. Finally, in §5, we extend the methods developed in §§3 and 4 to integer scalings other than 2. For these cases there are a number of parameters that are free to be specified. We examine this in the case of scaling by three and exhibit a one parameter family of symmetric scaling functions.

2. Fractal interpolation functions.

Let $I = [0,1]$, $B(I)$ denote the Banach space of bounded real-valued functions on I with the ∞-norm, and let $C(I) \subset B(I)$ be the space of real-valued functions continuous on I. Let $u_i : [0,1) \to [0,1)$ and $v_i : [0,1) \times \mathbb{R} \to \mathbb{R}$, $i = 0, 1, \ldots, N-1$, be as follows:

$$u_i(x) = \frac{1}{N}(x + i), \tag{2.1}$$

$$v_i(x,y) = \lambda_i(x) + s_i y, \tag{2.2}$$

where $\lambda_i(x) \in \Pi_m$, the set of polynomials with degree at most m. It will always be assumed that $s = \max|s_i| < 1$. Let $I_i = u_i([0,1)) = [\frac{i}{N}, \frac{i+1}{N})$ for $i = 0, 1, 2, \ldots, N-1$, $\lambda = (\lambda_0, \lambda_1, \ldots, \lambda_{N-1})$, and define $\Phi_\lambda : B(I) \to B(I)$ by

$$(\Phi_\lambda f)(x) = v_i(u_i^{-1}(x), f(u_i^{-1}(x))) \tag{2.3}$$

for $x \in I_i$, $i = 0, 1, \ldots, N-1$. Note that $f_\lambda(0) = \lambda_0(0)/(1-s_0)$ and $f_\lambda(1^-) = \lambda_{N-1}(1^-)/(1-s_{N-1})$.

Equations (2.2) and (2.3) imply that Φ_λ is a contraction on $B(I)$ with contractivity s; thus,

$$\|\Phi_\lambda f - \Phi_\lambda g\|_\infty \le s\|f-g\|_\infty, \tag{2.4}$$

and so Φ_λ has a unique attractive fixed point $f_\lambda \in B(I)$. In the event that Φ_λ satisfies the join-up conditions

$$v_{i+1}(0, f_\lambda(0)) = v_i(1^-, f_\lambda(1^-)), \qquad i = 0, 1, \ldots, N-2, \tag{2.5}$$

then f_λ is continuous and is called a fractal interpolation function (Barnsley [2]). In general, $G = \text{graph } f_\lambda$ is typically a fractal set in $\mathbb{R}^2$ made up of images of itself. To see this, let $w_i : [0,1) \times R \to [0,1) \times R$ be given by

$$w_i(x,y) = (u_i(x), v_i(x,y))$$

for $i = 0, 1, \ldots, N-1$. Then (2.3) implies that

$$G = \bigcup_{j=0}^{N-1} w_j(G).$$

Let $\beta = \bigotimes_{j=0}^{N-1} \Pi_m$ and $\lambda \in \beta$. The following theorem gives the basic correspondence between elements in β and functions in $B(I)$.

THEOREM 2.1. (See [10, 12].) *The mapping* $\lambda \overset{\theta}{\mapsto} f_\lambda$ *is a linear isomorphism from* β *to* $\theta(\beta)$.

We will be interested in the case when $m = 1$. If f_λ satisfies equation (2.5), then $f_\lambda \in C(I)$ and the space $\theta(\bigotimes_{j=0}^{N-1} \Pi_1) \cap C(I) = S_0$ is $N+1$ dimensional. Thus each element $g \in S_0$ is completely determined by $g(i/N)$, $i = 0, 1, \ldots, N$. This allows us to view θ in a slightly different manner. Given $\bar{y} \in R^{N+1}$ let $f_{\bar{y}}$ be the unique element of S_0 passing through the points $(\frac{i}{N}, y_i)$, $i = 0, 1, \ldots, N$. We shall call functions $f_{\bar{y}} \in S_0$ affine fractal interpolation functions (AFIFs).

COROLLARY 2.2. *The map* $\theta : R^{N+1} \to S_0$ *is a linear isomorphism.*

The fact that S_0 is isomorphic to R^{N+1} adds a geometric component to the multiresolution analysis associated with FIFs and will play an important role in our construction of wavelets. Let $C_b(\mathbb{R})$ be the space of bounded continuous functions on $\mathbb{R}$ Fix $s_0, s_1, \ldots, s_{N-1}$, let $\tilde{V}_0 = \{f : f|_{[i,i+1)} \text{ is an AFIF}\} \cap C_b(\mathbb{R}) \cap L^2(\mathbb{R})$, and define $f \in \tilde{V}_k \Leftrightarrow f(N^{-k}\cdot) \in \tilde{V}_0$. Then it was shown in [10] and [13] that the sequence $\{\tilde{V}_i\}$ has the following properties:

(a) $\cdots \tilde{V}_{-1} \subset \tilde{V}_0 \subset \tilde{V}_1 \cdots$,

(b) $\bigcap_{k \in R} \tilde{V}_k = \{0\}$.

Note that in contrast with [16] and [17], the spaces $\{\tilde{V}_i\}$ given above are defined independently of any particular scaling functions, which is one of the several properties these spaces share with the spline spaces S_d^r with integer knots (see [10], [11]). In fact, $\tilde{V}_0$ is spanned by sets formed from the integer translates of several scaling functions.

We say a multiresolution analysis is *continuous* and/or *compactly supported* if it is generated by a finite set of scaling functions $\{\phi^i(x)\}_{i=1}^N$, $\phi^i(x) \in L^2(\mathbb{R})$, $i = 1, \ldots, N$ such that each ϕ^i is continuous and/or compactly supported on $\mathbb{R}$. If $\langle\phi^i(\cdot),$

$\phi^j(\cdot - k)\rangle = \delta_{i,j}\delta_{k,0}$, $i = 1,\ldots,N$, then the $\{\phi^i\}$'s generate an *orthogonal* multiresolution analysis.

In order to find *orthogonal scaling functions* $\{\phi^i\}_{i=1}^N$ that generate a continuous, compactly supported, orthogonal multiresolution analysis, we develop some quadrature formulas for AFIFs. Set $I^* = \int_0^1 f_{\bar{y}} g dx$, where $f_{\bar{y}} \in S_0$ and $g \in L^2(I)$. Then from (2.3), we find

$$\begin{aligned} I^* &= \sum_{i=0}^{N-1} \int_{[i/N,(i+1)/N]} f_{\bar{y}} g dx = \sum_{i=0}^{N-1} \int_{[i/N,(i+1)/N]} v_i(u_i^{-1}(x), f_{\bar{y}}(u_i^{-1}(x))g(x)dx \\ &= \frac{1}{N} \sum_{i=0}^{N-1} \int_0^1 v_i(x, f_{\bar{y}}(x))g(u_i(x))dx. \end{aligned}$$

If we use equation (2.2) along with the assumption that $\lambda_i(x) = a_i x + b_i$, $i = 0,1,\ldots,N-1$, in the above equation, we find that

$$\begin{aligned} I^* &= \frac{1}{N} \sum_{i=0}^{N-1} \int_0^1 (a_i x + b_i) g(u_i(x))dx \\ &\quad + \frac{1}{N} \sum_{i=0}^{N-1} s_i \int_0^1 g(u_i(x)) f_{\bar{y}}(x)dx. \end{aligned} \tag{2.6}$$

If $g = 1$, then (2.6) yields [13]

$$I^* = m_0 = \int_0^1 f_{\bar{y}}(x)dx = \frac{\frac{1}{N}\sum_{i=0}^{N-1}\left(\frac{a_i}{2} + b_i\right)}{1 - \frac{1}{N}\sum_{i=0}^{N-1} s_i}, \tag{2.7}$$

while for $g(x) = x$, we find [13]

$$I^* = m_1 = \int_0^1 x f_{\bar{y}}(x)dx = \frac{\frac{1}{N^2}\sum_{i=0}^{N-1}\left[a_i(\frac{i}{2} + \frac{1}{3}) + b_i(i + \frac{1}{2}) + i s_i m_0\right]}{1 - \frac{1}{N^2}\sum_{i=0}^{N-1} s_i}. \tag{2.8}$$

With (2.7) and (2.8), integrals of two fractal functions may be computed. To this end, let $\hat{v}_i(x,y) = \hat{\lambda}_i(x) + \hat{s}_i y$ with $\hat{\lambda}_i = \hat{a}_i x + \hat{b}_i$, $\hat{u}_i = u_i$, $i = 0,1,\ldots,N-1$, and set $g = \hat{f}_{\hat{y}}$. Then [13]

$$\begin{aligned} I^* &= \int_0^1 \hat{f}_{\hat{y}}(x) f_{\bar{y}}(x)dx \\ &= \frac{\frac{1}{N}\sum_{i=0}^{N-1}\left(s_i\hat{a}_i m_1 + \hat{s}_i a_i \hat{m}_1 + s_i\hat{b}_i m_0 + \hat{s}_i b_i \hat{m}_0 + \frac{a_i\hat{a}_i}{3} + \frac{(a_i\hat{b}_i + \hat{a}_i b_i)}{2} + b_i\hat{b}_i\right)}{1 - \frac{1}{N}\sum_{i=0}^{N-1} s_i\hat{s}_i}, \end{aligned} \tag{2.9}$$

where $\hat{m}_0$ and $\hat{m}_1$ are the zeroth and first moments, respectively, of $\hat{f}_{\hat{y}}$.

Consider the $N+1$-dimensional basis $\{f_{\bar{y}_i}\}_{i=0}^N$ spanning S_0, where $\bar{y}_i = e_i$, $0 < i < N$, $\{e_i\}_{i=0}^N$ being the standard basis in R^{N+1}, $\bar{y}_0 = (1, q_1, \ldots, q_{N-1}, 0)$, and $\bar{y}_N = (0, p_1, \ldots, p_{N-1}, 1)$. The sequences $\{p_i\}$ and $\{q_i\}$ are chosen so that $\langle f_{\bar{y}_0}, f_{\bar{y}_i}\rangle = 0 = \langle f_{\bar{y}_N}, f_{\bar{y}_i}\rangle$ for $i = 1,\ldots,N-1$. Extend $f_{\bar{y}_i}, i = 1,\ldots,N-1$, to be functions in

$\tilde{V}_0$ by defining each of them to be equal to 0 for $x \notin I$. Let $\{\phi^i\}_{i=0}^{N-2}$ be a sequence of orthogonal functions in $\tilde{V}_0$ obtained from $\{f_{\bar{y}_i}\}_{i=1}^{N-1}$ by the Gram–Schmidt procedure. The fact that these functions are nonzero follows from Corollary 2.2. Set

$$\phi^{N-1}(x) = \begin{cases} f_{\bar{y}_N}(x), & x \in [0,1), \\ f_{\bar{y}_0}(x-1), & x \in [1,2), \\ 0 & \text{elsewhere} \end{cases} \tag{2.10}$$

and $\hat{\phi}^i(x) = \phi^i(x)/\left\|\phi^i(x)\right\|_{L^2}$; then we find the following.

THEOREM 2.3. *Let $\tilde{V}_0$ and $\phi^i, i = 0,\ldots,N-1$, be as above. Then $\tilde{V}_0 = \operatorname{clos}_{L^2}\operatorname{span}$ $\{\phi^i(\cdot - l) : i = 0,\ldots,N-1, l \in \mathbb{Z}\}$. Furthermore, the set $\{\hat{\phi}^i\}_{i=0}^{N-1}$ generates a continuous, compactly supported multiresolution analysis.*

Proof. From Corollary 2.2 and (2.10), we see that each $\phi^i, i = 0,\ldots,N-1$, is compactly supported and is an element of $\tilde{V}_0$. Since every $f \in \tilde{V}_0$ is determined by its values at $\frac{i}{N}, i \in \mathbb{Z}, f$ has a unique expansion in terms of $f_{\bar{y}_i}, i = 1,\ldots,N-1$, and ϕ^{N-1} and their integer translates. Thus every $f \in \tilde{V}_0$ has a unique expansion in terms of $\{\hat{\phi}^i\}_{i=0}^{N-1}$ and their integer translates. In order to show that $\{\hat{\phi}^i\}_{i=0}^{N-1}$ generates a multiresolution analysis, we must show that (a) $\{\hat{\phi}^i\}_{i=0}^{N-1}$ and its integer translates form a Riesz basis for $\tilde{V}_0$ and (b) $\operatorname{clos}_{L^2}\bigcup_{k\in Z}\tilde{V}_k = L^2$. Since the set $\{\hat{\phi}^i\}_{i=0}^{N-2}$ and its integer translates are an orthogonal set, it follows that we need only show that there exits constants A and $B, 0 < A \leq B < \infty$, such that $\forall c = \{c_i\} \in l^2, A\|c\|_{l^2} \leq \|\sum c_i\hat{\phi}^{N-1}(\cdot - i)\|_{L^2} \leq B\|c\|_{l^2}$. It is easy to show that $B = \sqrt{3}$ provides an upper bound, while the lower bound is obtained by observing that $\|\sum c_i\hat{\phi}^{N-1}(\cdot - i)\|_{L^2}^2 = \sum_i\int_i^{i+1}(c_i\hat{\phi}^{N-1}(x-i) + c_{i-1}\hat{\phi}^{N-1}(x-(i-1)))^2dx$. Since $f_{\bar{y}_0}$ and $f_{\bar{y}_N}$ are linearly independent, the matrix

$$K = \begin{pmatrix} \langle f_{\bar{y}_0}, f_{\bar{y}_0}\rangle & \langle f_{\bar{y}_0}, f_{\bar{y}_N}\rangle \\ \langle f_{\bar{y}_0}, f_{\bar{y}_N}\rangle & \langle f_{\bar{y}_N}, f_{\bar{y}_N}\rangle \end{pmatrix}$$

is positive definite. Let λ be the smallest eigenvalue of $K/\|\phi^{N-1}\|^2$; then A can be taken to be equal to $\sqrt{\lambda}$.

To show that $\bigcup_{k\in Z}\tilde{V}_k$ is dense in L^2, we note that for all $x \in \mathbb{R}$,

$$1 = \sum_i \left(\sum_{j=1}^{N-1} c_i^j f_{\bar{y}_j}(x-i)\right) + \phi^{N-1}(x-i),$$

where $c_i^j = c^j = 1 - p_j - q_j$. Now (b) follows from Proposition 3.1 in [10]. □

3. Orthogonal scaling functions. We begin by considering AFIFs with scaling $N = 2$. By Theorem 2.3, $\{\phi^i\}_{i=0}^{1}$ (note that in this case $\phi^0 = f_{\bar{y}_1}$) and its integer translates span $\tilde{V}_0$, and we look for three mutually orthogonal functions $f_{\bar{y}_0}, f_{\bar{y}_1}$, and $f_{\bar{y}_2}$. From (2.1), (2.2), (2.3), and (2.5), we find that for $f_{\bar{y}_1}$, $\lambda_0 = x$, $\lambda_1 = 1 - x$ for $f_{\bar{y}_2}$, $\lambda_0 = (p_1 - s_0)x$, $\lambda_1 = (1 - s_1 - p_1)x + p_1$, while for $f_{\bar{y}_0}$, $\lambda_0 = (q_1 + s_0 - 1)x + 1 - s_0$, $\lambda_1 = (s_1 - q_1)x + q_1 - s_1$. Substituting these values into (2.9) gives

$$\begin{gathered}\int_0^1 f_{\bar{y}_1}f_{\bar{y}_2}dx = \\ \frac{(4 - 6s_0 + 16p_1 - 2s_1s_0 - 4s_0^2 - 4s_1^2 + 4p_1s_0s_1 + 3s_0^3 + 3s_0s_1^2 - 4p_1s_0^2 - 4p_1s_1^2)}{3(2 - s_0 - s_1)(4 - s_0 - s_1)(2 - s_0^2 - s_1^2)},\end{gathered} \tag{3.1}$$

$$(3.2)\quad \int_0^1 f_{\bar{y}_1} f_{\bar{y}_0} dx = \frac{(4 - 6s_1 + 16q_1 - 2s_1s_0 - 4s_0^2 - 4s_1^2 + 4q_1s_0s_1 + 3s_1^3 + 3s_1s_0^2 - 4q_1s_0^2 - 4q_1s_1^2)}{3(2 - s_0 - s_1)(4 - s_0 - s_1)(2 - s_0^2 - s_1^2)},$$

and

$$(3.3)\quad \begin{aligned} &\int_0^1 f_{\bar{y}_0} f_{\bar{y}_2} dx \\ &= [4(p_1 + q_1)(2s_0^2 + 2s_1^2 + s_0s_1 - 2) + 8p_1q_1(s_0^2 + s_1^2 - s_0s_1 - 4) \\ &\quad + (s_0^2 + s_1^2)^2 - (s_0^2 + s_1^2 + 1)^3 - 4(s_0 + s_1)^2 + s_0^3(-2 + 2s_1 - 6q_1) \\ &\quad + s_1^3(-2 - 6p_1 + 2s_0) + 6q_1s_0(2 - s_1^2) + 6p_1s_1(2 - s_0^2) \\ &\quad + 6s_0 + 6s_1 + 2s_1s_0]/6(-2 + s_0 + s_1)(-4 + s_0 + s_1)(-2 + s_0^2 + s_1^2). \end{aligned}$$

Solving (3.1) for p_1 and (3.2) for q_1 yields

$$(3.4)\quad p_1 = \frac{-(4 - 6s_0 - 2s_1s_0 - 4s_0^2 - 4s_1^2 + 3s_0^3 + 3s_0^2s_1)}{16 + 4s_0s_1 - 4s_0^2 - 4s_1^2}$$

and

$$(3.5)\quad q_1 = \frac{-(4 - 6s_1 - 2s_1s_0 - 4s_0^2 - 4s_1^2 + 3s_1^3 + 3s_0s_1^2)}{16 + 4s_0s_1 - 4s_0^2 - 4s_1^2}.$$

If we substitute (3.4) and (3.5) into (3.3), we find that

$$\int f_{\bar{y}_0} f_{\bar{y}_2} dx = \frac{p(s_0, s_1)}{12(-4 - s_0s_1 + s_0^2 + s_1^2)(-2 + s_0 + s_1)(-4 + s_0 + s_1)},$$

where

$$(3.6)\quad \begin{aligned} p(s_0, s_1) = {} & 2s_1^4 + 6s_1^3 - 7s_1^3s_0 + 18s_1^2s_0 - 28s_1^2 - 7s_1s_0^3 + 18s_1s_0^2 \\ & - 14s_1s_0 + 12s_1 + 2s_0^4 + 6s_0^3 - 28s_0^2 + 12s_0 + 8. \end{aligned}$$

Consequently, we have the following.

LEMMA 3.1. *The AFIFs $f_{\bar{y}_0}$, $f_{\bar{y}_1}$, and $f_{\bar{y}_2}$ with $\bar{y}_0 = (1, q_1, 0)$, $\bar{y}_1 = (0, 1, 0)$ and $\bar{y}_2 = (0, p_1, 1)$ constitute an orthogonal basis for S_0 only for pairs (s_0, s_1) such that $|s_0| < 1$, $|s_1| < 1$, and $p(s_0, s_1) = 0$.*

COROLLARY 3.2. *The only pairs (s_0, s_1) such that the basis $\{f_{\bar{x}_1}, f_{\bar{x}_2}, f_{\bar{x}_3}\}$ with $\bar{x}_1 = (0, 1, a)$, $\bar{x}_2 = (0, b, 1)$, and $\bar{x}_3 = (1, c, 0)$ can be made an orthogonal basis for S_0 are those pairs for which $p(s_0, s_1) = 0$. The same is true for bases of the form $\{f_{\bar{z}_1}, f_{\bar{z}_2}, f_{\bar{z}_3}\}$ with $\bar{z}_1 = (a, 1, 0)$, $\bar{z}_2 = (0, b, 1)$, and $\bar{z}_3 = (1, c, 0)$.*

Proof. Let (s_0, s_1) be such that $\{f_{\bar{x}_1}, f_{\bar{x}_2}, f_{\bar{x}_3}\}$ is an orthogonal basis. Suppose $a \neq 0$ (otherwise the result follows from Lemma 3.1) and let $\{\hat{f}_{\bar{x}_1}, \hat{f}_{\bar{x}_2}, \hat{f}_{\bar{x}_3}\}$ be the corresponding orthonormal basis. If $\hat{f}_{\bar{x}_1}(1) = a'$ and $\hat{f}_{\bar{x}_2}(1) = b'$, set $w_0 = b'\hat{f}_{\bar{x}_1} - a'\hat{f}_{\bar{x}_2}$ and $w = a'\hat{f}_{\bar{x}_1} + b'\hat{f}_{\bar{x}_2}$, where $a^{'2} + b^{'2} = 1$. Then $\{w_0, w_1, \hat{f}_{\bar{x}_3}\}$ is an orthonormal basis of S_0 with $w_0(0) = w_0(1) = 0$ and $w_1(0) = 0$. But by Lemma 3.1, this can only happen for values (s_0, s_1) such that $p(s_0, s_1) = 0$. An analogous argument can be applied to the basis $\{f_{\bar{z}_1}, f_{\bar{z}_2}, f_{\bar{z}_3}\}$. □

From Theorem 2.3 and Lemma 3.1, we have the following.

THEOREM 3.3. *Suppose that the pair* (s_0, s_1) *is such that* $p(s_0, s_1) = 0$ *with* $|s_0| < 1$ *and* $|s_1| < 1$. *Then* $\hat{\phi}^i$, $i = 0, 1$, *generate a continuous, compactly supported, orthogonal multiresolution analysis of* $L^2(\mathbb{R})$.

It follows from Theorem 2.3 that for general pairs (s_0, s_1) with $|s_0| < 1$ and $|s_1| < 1$,

$$\Phi(x) = \begin{pmatrix} \phi^0 \\ \phi^1 \end{pmatrix} = \sum_{i=0}^{3} C_i \Phi(2x - i). \tag{3.7}$$

The 2×2 matrices C_i, $i = 0, 1, 2, 3$, may be computed by evaluating (3.7) at $x = \frac{i}{4}$, $i = 1, 2, \ldots, 8$. From the values of λ_i, $i = 0, 1$, for $f_{\bar{y}_0}$, $f_{\bar{y}_1}$, and $f_{\bar{y}_2}$ computed earlier, we find

$$\begin{aligned} C_0 &= \begin{bmatrix} s_0 + 1/2 - p & 1 \\ \frac{p - s_0}{2} + p(s_0 - p) & p \end{bmatrix}, & C_1 &= \begin{bmatrix} s_1 + 1/2 - q & 0 \\ \frac{1 - s_1 - p}{2} + p(s_1 - q) & 1 \end{bmatrix}, \\ C_2 &= \begin{bmatrix} 0 & 0 \\ \frac{1 - s_0 - q}{2} + q(s_0 - p) & q \end{bmatrix}, & C_3 &= \begin{bmatrix} 0 & 0 \\ \frac{q - s_1}{2} + q(s_1 - q) & 0 \end{bmatrix}. \end{aligned} \tag{3.8}$$

For later use, we define the inner product

$$\langle \Phi, \Phi \rangle = \int_{\mathbb{R}} \Phi\Phi^* dx = \int_{\mathbb{R}} \begin{bmatrix} \phi^0(x)\phi^0(x) & \phi^0(x)\phi^1(x) \\ \phi^1(x)\phi^0(x) & \phi^1(x)\phi^1(x) \end{bmatrix} dx = E^2,$$

where

$$E^2 = \begin{bmatrix} \|\phi^0\|^2 & 0 \\ 0 & \|\phi^1\|^2 \end{bmatrix}.$$

We will now show that even if longer supports are considered, compactly supported, continuous orthogonal scaling functions whose integer translates span V_0 can only be constructed for those values (s_0, s_1) for which $p(s_0, s_1) = 0$ with $|s_0| < 1$ and $|s_1| < 1$.

LEMMA 3.4. *Suppose for a given three-dimensional subspace* V *of* $C(I)$ *there is no orthonormal basis with two functions vanishing at one endpoint and the remaining function vanishing at the other endpoint. Then any continuous, compactly supported pair of functions* ϕ^1 *and* ϕ^2, *composed of linear combinations of the basis elements of* V *and their integer translates constructed so that* $\langle \phi^i(x), \phi^j(x - k) \rangle = \delta_{i,j}\delta_{k,0}$, *must have the property that the leftmost nonzero components of* ϕ^1 *and* ϕ^2 *are linearly dependent, as are their rightmost nonzero components.*

Proof. Suppose the supports of ϕ^1 and ϕ^2 are $[0, N]$ and $[0, M]$, respectively, with $N + M \geq 3$. Because of continuity, $\phi^1(0), \phi^2(0), \phi^1(x + N - 1)|_{x=1}$, and $\phi^2(x + M - 1)|_{x=1}$ all vanish; furthermore, $\phi^1(x)|_{[0,1]}$ and $\phi^2(x)|_{[0,1]}$ are orthogonal to $\phi^1(x + N - 1)|_{[0,1]}$ and $\phi^2(x + M - 1)|_{[0,1]}$. Now $\phi^1(x)|_{[0,1]}$ cannot be independent of $\phi^2(x)|_{[0,1]}$ nor can $\phi^1(x + N - 1)|_{[0,1]}$ be independent of $\phi^2(x + M - 1)|_{[0,1]}$ without violating the hypothesis of the lemma. □

We note that by rotation it can always be arranged that $M \neq N$.

LEMMA 3.5. *If the hypotheses of Lemma* 3.4 *are satisfied, then no such pair of functions* ϕ^1 *and* ϕ^2 *exists.*

Proof. Suppose that ϕ^1 and ϕ^2 exist and that $M < N$, and set $y = \phi^1/\|\phi^1\|_2$ and $z = \phi^2/\|\phi^2\|_2$. Then y and z are orthonormal and for a suitable basis can be represented as

$$\begin{aligned} y &= (y_1, y_2, \ldots, y_M, 0, 0, \ldots, 0) \\ &= ((y_{1,1}, 0, 0), (y_{2,1}, y_{2,2}, y_{2,3}), \ldots, (0, 0, y_{M,3}), (0, 0, 0), \ldots, (0, 0, 0)) \end{aligned}$$

and

$$z = (z_1, z_2, \dots, z_N) = ((z_{1,1}, 0, 0), (z_{2,1}, z_{2,2}, z_{2,3}), \dots, (0, 0, z_{N,3})),$$

where $2 \le M < N$ and $z_{1,1} > 0$.

Consider the rotation r defined on pairs of vectors of the above form,

$$r(y,z) = \frac{1}{\sqrt{y_{1,1}^2 + z_{1,1}^2}}(z_{1,1}y - y_{1,1}z, y_{1,1}y + z_{1,1}z) = (\tilde{y}, \tilde{z}),$$

where

$$\tilde{y} = ((0,0,0), (\tilde{y}_{2,1}, \tilde{y}_{2,2}, \tilde{y}_{2,3}), \dots, (\tilde{y}_{N,1}, \tilde{y}_{N,2}, \tilde{y}_{N,3}))$$
$$\tilde{z} = \left(\left(\sqrt{z_{1,1}^2 + y_{1,1}^2}, 0, 0\right), (\tilde{z}_{2,1}, \tilde{z}_{2,2}, \tilde{z}_{2,3}), \dots, (\tilde{z}_{N,1}, \tilde{z}_{N,2}, \tilde{z}_{N,3})\right),$$

and the shift map s defined on the range of r by

$$s(\tilde{y}, \tilde{z}) = ((\tilde{y}_2, \tilde{y}_3, \dots, \tilde{y}_N, 0), (\tilde{z}_1, \dots, \tilde{z}_N)) = (\hat{y}, \hat{z}).$$

Both s and r are continuous, $\|\hat{z}\|_2 = \|\hat{y}\|_2 = 1$, and $\hat{y}$ and $\hat{z}$ satisfy the necessary orthogonality relations. The operations also preserve continuity of the components, so the functions corresponding to $\hat{y}$ and $\hat{z}$ are continuous. By Lemma 3.4, we know that $\hat{y}_1$ and $\hat{z}_1$ are linearly dependent, so $\hat{y}_{1,2} = 0 = \hat{y}_{1,3}$. It follows that $(\hat{y}, \hat{z})$ is back in the domain of r, so we can iterate the map $s \circ r$ on (y, z) to produce a sequence $(s \circ r)^j(y,z) = (y^{(j)}, z^{(j)})$ for $j = 0, 1, 2, \dots$. Since this sequence is contained in a compact set, we can extract a convergent subsequence with limit—say (Y, Z). By continuity of the inner product, we have that $\|Y\|_2 = \|Z\|_2 = 1$, Y and Z satisfy the orthogonality relations, and the functions corresponding to Y and Z are continuous.

Observe that $z_{1,1}^{(j)}$ is monotone increasing in j. Since it is a component of a unit vector, it is bounded above by 1 and hence converges to some number $Z_{1,1}$. We also have that $(z_{1,1}^{(j)})^2$ converges (to $Z_{1,1}^2$) so that the increments of this sequence, $(z_{1,1}^{(j+1)})^2 - (z_{1,1}^{(j)})^2 = (y_{1,1}^{(j)})^2$, must converge to 0. We claim that for each $i \in \{1, 2, \dots, N-1\}$, $\lim_{j\to\infty} y_{i,1}^{(j)} = 0$. We have just shown that this is true for $i = 1$, so suppose it is true for some i. Then for each j, we have

$$|y_{i,1}^{(j+1)}| = \left| \frac{z_{1,1}^{(j)} y_{i+1,1}^{(j)} - y_{1,1}^{(j)} z_{i+1,1}^{(j)}}{\sqrt{(y_{1,1}^{(j)})^2 + (z_{1,1}^{(j)})^2}} \right|.$$

Since $y_{1,1}^{(j)}$ and $z_{1,1}^{(j)}$ are both components of unit vectors, each is no larger than 1. Thus the denominator (above) is no larger than $\sqrt{2} < 2$, and we have

$$|y_{i,1}^{(j+1)}| \ge \tfrac{1}{2}|z_{1,1}^{(j)} y_{i+1,1}^{(j)}| - \tfrac{1}{2}|y_{1,1}^{(j)} z_{i+1,1}^{(j)}|,$$

or

$$\begin{aligned} |z_{1,1}^{(j)} y_{i+1,1}^{(j)}| &\le 2|y_{i,1}^{(j+1)}| + |y_{1,1}^{(j)} z_{i+1,1}^{(j)}| \\ &\le 2|y_{i,1}^{(j+1)}| + |y_{1,1}^{(j)}|. \end{aligned}$$

By our induction hypothesis, this last expression converges to 0. Furthermore, $z_{1,1}^{(j)} \ge z_{1,1} > 0$, so $\lim_{j\to\infty} y_{i+1,1}^{(j)} = 0$ and the claim is established by induction.

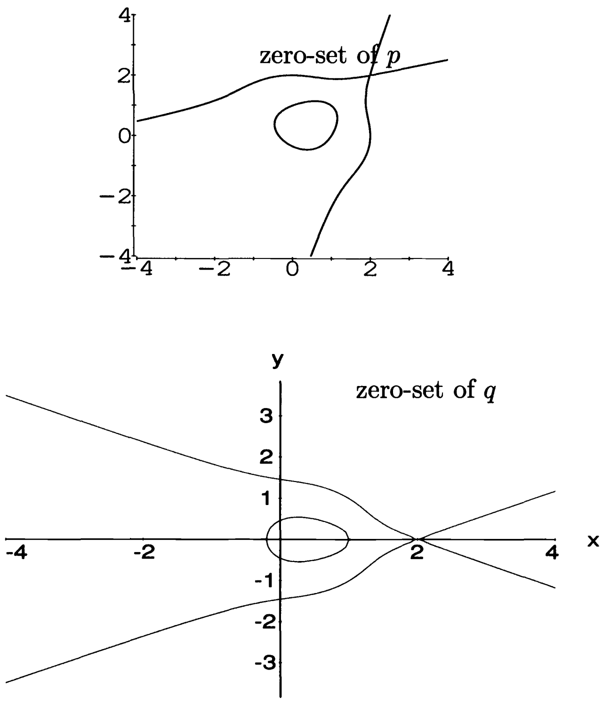

FIG. 1.

Now, our limit point (Y, Z) must have the property that $Y_{i,1} = 0$ for $i = 1, 2, \ldots, N$. But by the lemma, we also know that the leftmost nonzero 3-tuple in Y—say Y_p—is linearly dependent on $Z_1 = (Z_{1,1}, 0, 0)$. So Y_p has the form $(Y_{p,1}, 0, 0)$, and we have just shown that $Y_{p,1} = 0$. Therefore, Y must be 0, which contradicts the fact that $\|Y\| = 1$. □

With the above lemmas we are now able to prove the following.

THEOREM 3.6. *If s_0 and s_1 do not satisfy the relation $p(s_0, s_1) = 0$ (equation (3.6)), then there are no continuous, compactly supported, orthogonal scaling functions formed from the AFIFs generated by s_0 and s_1 such that the L^2-closure of the linear span these functions and their integer translates is $\tilde{V}_0$.*

Proof. It is easy to show that $\tilde{V}_0$ cannot be spanned by the integer translates of one continuous, compactly supported scaling function. This is because, if the scaling function is supported on $[0, M], M > 1$ and we consider an interval of length N, there will be at most $N + M - 1$ translates of ϕ supported on this interval. However, the same interval will contain $2N + 1$ interpolation points. Consequently, for large enough N, there will not be enough translates of ϕ to match all the necessary conditions. By Lemma 3.5 we need now only consider pairs s_0 and s_1 that allow an orthogonal basis for S_0 in which at least two basis vectors vanish at either 0 or 1. But Lemma 3.1 and Corollary 3.2 show that this can occur only in the case when $p(s_0, s_1) = 0$, which proves the result. □

Since compactly supported, continuous scaling functions constructed from AFIFs occur only for the pairs (s_0, s_1), $|s_0| < 1$, $|s_1| < 1$, such that $p(s_0, s_1) = 0$, we examine the zero-set of this polynomial. The next lemma shows that the particular set we are interested in is convex. This confirms the contour plot given in Figure 1.

LEMMA 3.7. *The zero-set of the polynomial*

$$\begin{aligned} p(s_0, s_1) = 2s_0^4 + 6s_0^3 - 7s_0^3 s_1 + 18s_0^2 s_1 - 28s_0^2 - 7s_0 s_1^3 + 18s_0 s_1^2 \\ - 14s_0 s_1 + 12s_0 + 2s_1^4 + 6s_1^3 - 28s_1^2 + 12s_1 + 8 \end{aligned}$$

has two connected components, one a convex closed curve and the other a pair of asymptotically linear curves that cross at a point.

Proof. First, we transform the polynomial using the change of variables

$$\begin{aligned} s_0 &= x - y, \\ s_1 &= x + y \end{aligned}$$

to get a new polynomial,

$$q(x, y) = 18y^4 + (-42 + 24x^2)y^2 - 10x^4 + 48x^3 - 70x^2 + 24x + 8.$$

Note that q is symmetric with respect to y for all values of x. The transformation is just a rotation by 45° and a dilation by $\sqrt{2}$, so it preserves all relevant properties of the zero-set.

Now, we want to find out where the transformed polynomial, q, takes the value 0. To do this we consider the equation $q(x, y) = 0$ and solve for y as a function of x. This gives

$$y = \pm\sqrt{\tfrac{7}{6} - \tfrac{2}{3}x^2 + \tfrac{1}{6}\sqrt{3}\sqrt{12x^4 - 32x^3 + 28x^2 - 16x + 11}},$$

or

$$y = \pm\sqrt{\tfrac{7}{6} - \tfrac{2}{3}x^2 - \tfrac{1}{6}\sqrt{3}\sqrt{12x^4 - 32x^3 + 28x^2 - 16x + 11}}.$$

The first solution gives a pair of asymptotically linear curves that cross at $x = 2$, $y = 0$. The second solution, which is real valued only for $x \in [-\frac{1}{5}, 1]$, gives two halves of a symmetric closed curve, γ, and is the one that we are primarily interested in.

Let f denote the positive branch of γ. If f is a concave down function, it follows by symmetry that γ is a convex curve. Furthermore, since the square-root function is monotone concave down, it suffices to show that f^2 $(= f \cdot f)$ is concave down. Thus, we wish to demonstrate that the second derivative of f^2 is nonpositive on $[-\frac{1}{5}, 1]$. That is,

$$0 \geq -\frac{4}{3} + \frac{\sqrt{3}(48x^3 - 96x^2 + 56x - 16)^2}{24p^{3/2}} - \frac{\sqrt{3}(144x^2 - 192x + 56)}{12p^{1/2}},$$

where $p = 12x^4 - 32x^3 + 28x^2 - 16x + 11$. Note that p is positive for all values of x, so the above expression is well defined. Also, since the denominators are powers of p, they are positive as well, and we can multiply them out to get an equivalent inequality,

$$0 \geq -4p^{3/2} - \sqrt{3}(-144x^6 + 576x^5 - 888x^4 + 832x^3 - 780x^2 + 528x - 122).$$

To show this, we approximate $\sqrt{p}$ with a linear polynomial, $q = \sqrt{3}(\frac{7}{4} - \frac{3}{4}x)$. Observe that $q \leq \sqrt{p}$ on $[-\frac{1}{5}, 1]$ since $p - q^2 = \frac{1}{16}(x-1)(192x^3 - 320x^2 + 101x - 29)$ is nonnegative

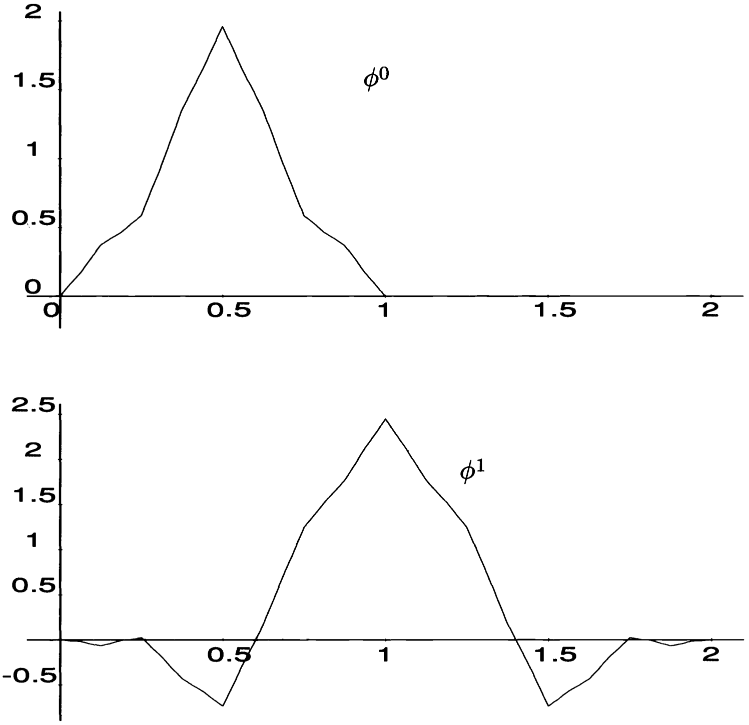

FIG. 2.

on that interval. Thus, by substituting pq for $p^{3/2}$ in the above and expanding, we have

$$\begin{aligned}
&-4p^{3/2} - \sqrt{3}(-144x^6 + 576x^5 - 888x^4 + 832x^3 - 780x^2 + 528x - 122)\\
&\le \sqrt{3}(-144x^6 + 612x^5 - 1068x^4 + 1140x^3 - 1024x^2 + 673x - 199)\\
&\le \sqrt{3}(-144x^6 + 612x^5 - 1068x^4 + 1140x^3 - 1024x^2 + 673x - 199)\\
&\quad + \tfrac{\sqrt{3}}{3125}(37683 - 19989x)\\
&= -\tfrac{4\sqrt{3}}{3125}(5x-4)^2(4500x^4 - 11925x^3 + 11415x^2 - 9729x + 9128)\\
&\le 0.
\end{aligned}$$

The last inequality is justified since both factors involving x are nonnegative for all values of x. □

Let (a, b) be the appropriate pair that solves the equations $\frac{dp}{ds_1} = 0$ and $p = 0$, which yields $a \approx -.4628$. Then by examining $p(s_0, s_1)$ and using Lemma 3.7, we see that for every $s_0 \in [a, 1)$, there is at least one and at most two values of s_1, $|s_1| < 1$ with $p(s_0, s_1) = 0$. If $s_0 = s_1$, then $x = 0$ in the polynomial $q(x, y)$ and we find $q(0, y) = -10y^4 + 48y^3 - 70y^2 + 24y + 8 = -2(5y+1)(y-1)(-2+y)^2$. Thus a solution of this equation is $y = -\frac{1}{5} = s_0 = s_1$, and equations (3.4) and (3.5) give $p_1 = q_1 = -\frac{3}{10}$. Consequently, for $s_0 = s_1 = -\frac{1}{5}$, the functions $f_{\bar{y}_0}, f_{\bar{y}_1}$, and $f_{\bar{y}_2}$, with $\bar{y}_0 = [1, -\frac{3}{10}, 0]$, $\bar{y}_1 = [0, 1, 0]$, and $\bar{y}_2 = [0, -\frac{3}{10}, 1]$, are mutually orthogonal. The scaling functions ϕ^0 and ϕ^1 given as in Theorem 3.3 are shown in Figure 2. Note that ϕ^0 is symmetric about $\frac{1}{2}$ while ϕ^1 is symmetric about 1. Consequently, individually both exhibit linear phase [4].

If we normalize $\hat{\Phi}$ so that $\langle \hat{\Phi}, \hat{\Phi} \rangle = I$, then the coefficients in (3.7) can be re-expressed as $\hat{\Phi}(x) = \sum_{i=0}^{3} \widehat{C}_i \sqrt{2} \hat{\Phi}(2x - i)$, where $\widehat{C}_i = E^{-1} C_i E / \sqrt{2}$. The $\{\widehat{C}_i\}$ for $s_0 = s_1 = -\frac{1}{5}$ are

$$\widehat{C}_0 = \begin{pmatrix} 3\sqrt{2}/10 & 4/5 \\ -1/20 & -3\sqrt{2}/20 \end{pmatrix}, \qquad \widehat{C}_1 = \begin{pmatrix} 3\sqrt{2}/10 & 0 \\ 9/20 & \sqrt{2}/2 \end{pmatrix},$$

$$\widehat{C}_2 = \begin{pmatrix} 0 & 0 \\ 9/20 & -3\sqrt{2}/20 \end{pmatrix}, \qquad \widehat{C}_3 = \begin{pmatrix} 0 & 0 \\ -1/20 & 0 \end{pmatrix}.$$

The values of p_1 and q_1 for other acceptable pairs s_0 and s_1 are given in Table 1.

We now consider the smoothness and approximation order of the function ϕ^i, $i = 0, 1$. Recall that the Hölder exponent of $f \in C(I)$ at x is

$$\alpha_x = \lim_{\epsilon \to 0} \inf\{\log|f(x) - f(y)| / \log|x - y| : y \in B(x, \epsilon)\}$$

and $\alpha = \inf\{\alpha_x, x \in I\}$ is called the Hölder exponent of f.

Let S be a closed subspace of $L^2(\mathbb{R})$, $E(f,S) = \min\{\|f - s\| : s \in S\}, \hat{f}$ be the Fourier transform of f, and $w_2^k(\mathbb{R}) = \{f \in L^2(\mathbb{R}) : \|f\|_{w_2^k} = \|(1 + |\cdot|^k)\hat{f}\| < \infty\}$. Following de Boor, DeVore, and Ron [6], we say that S provides approximation order k if for every $f \in w_2^k(\mathbb{R})$,

$$E(f, S^h) \leq C_S h^k \|f\|_{w_2^k}(\mathbb{R}),$$

where $S^h = \{s(\frac{\cdot}{h}) : s \in S\}$.

LEMMA 3.8. *Given any pair (s_0, s_1), $|s_0| < 1$, $|s_1| < 1$, let $f \in S_0$. If $|s_0| < \frac{1}{2}$ and $|s_1| < \frac{1}{2}$, then f is Lipschitz continuous, i.e., there exists an $M < \infty$ such that $\forall\, x, y \in [0,1], |f(x) - f(y)| \leq M|x - y|$. If $\max|s_i| > \frac{1}{2}$ and f is not a line, then f has Hölder exponent $\alpha = -\log\max|s_i|/\log 2$.*

We note that the second part of the lemma has already been proved by Bedford [3], and we include the proof for the convenience of the reader.

Proof. Let $s = \max_i |s_i|$, $\mathbf{i}_n = \{i_1, i_2, \ldots, i_n\}$, $i_j \in \{0,1\}$, $j = 1, \ldots, n$, and $a(\mathbf{i}_n) = i_1/2 + i_2/4 + \cdots + i_n/2^n$. Then for $x \in [a(\mathbf{i}_n), a(\mathbf{i}_n) + 1/2^n]$, we find from (2.3) that

$$\begin{aligned} f(x) &= \sum_{k=1}^{n} \left(2^{k-1}x + b_{i_k} - \sum_{m=1}^{k} \frac{i_m}{2^{m-1}}\right) \prod_{j=1}^{k-1} s_{i_j} \\ &\quad + \left(\prod_{j=1}^{n} s_{i_j}\right) f\left(2^n x - \sum_{m=1}^{n} 2^{n-m} i_m\right). \end{aligned} \tag{3.9}$$

Suppose $1/2^{n+1} \leq |x - y| \leq 1/2^n$ and $x, y \in [a(\mathbf{i}_n), a(\mathbf{i}_n) + 1/2^n]$; then the above formula shows us that

$$|f(x) - f(y)| \leq \sum_{k=1}^{n} (2s)^{k-1}|x - y| + s^n C, \tag{3.10}$$

where $C = 2\|f\|_\infty$. Suppose first that $s < \frac{1}{2}$ then

$$|f(x) - f(y)| \leq \sum_{k=1}^{n} (2s)^{k-1}|x - y| + (2s)^n 2C|x - y|,$$

where the fact that $1 \leq 2^{n+1}|x - y|$ has been used to obtain the last term in the above expression. Since $2s < 1$, we find that

$$|f(x) - f(y)| \leq \frac{1 + 2C}{1 - 2s}|x - y|. \tag{3.11}$$

If $1/2^{n+1} \leq |x - y| \leq 1/2^n$ but x and y are not in the same dyadic interval, let x_0 be the boundary point between the respective intervals that x and y are located in. Then $|f(x) - f(y)| \leq |f(x) - f(x_0)| + |f(x_0) - f(y)|$, and applying (3.11) gives

$$|f(x) - f(y)| \leq \frac{2(1 + 2C)}{1 - 2s}\,|x - y|$$

for all $x, y \in [0,1]$. This gives the Lipschitz continuity of f.

If $s = \max|s_i| > \frac{1}{2}$, assume without loss of generality that $f(0) = 0 = f(1)$. For if that is not the case, we can modify f by adding linear functions $L_1(x)$ and $L_2(x)$ so that $\hat{f} = f + L_1 + L_2$ is still in S_0, $\hat{f}(0) = \hat{f}(1) = 0$. If $1/2^{n+1} \leq |x-y| \leq 1/2^n$, $a(\mathbf{i}_n)$, $x, y \in [a(\mathbf{i}_n), a(\mathbf{i}_n) + 1/2^n]$, (3.10) implies

$$|f(x) - f(y)| \leq s^n \left(C + \sum_{k=1}^{n} (2s)^{k-n-1}\right) = s^n \left(C + \frac{2s}{1 - \frac{1}{2s}}\right).$$

Since $1/2^{n+1} \leq |x-y| \leq 1/2^n$, we find that $|x-y|^\alpha \geq 2^{-\alpha(n+1)} = 2^{-\alpha}2^{-\alpha n} = 2^{-\alpha}s^n$ with $\alpha = \frac{\ln s}{\ln 1/2}$. Hence

$$|f(x) - f(y)| \leq 2^\alpha \left(C + \frac{2s}{1 - \frac{1}{2s}}\right) |x-y|^\alpha \tag{3.12}$$

for x, y in the same dyadic interval of length $1/2^n$. If x and y are not in the same dyadic interval, then using the same argument as in the case when $2s < 1$, we find

$$|f(x) - f(y)| \leq 2^{\alpha+1} \left(C + \frac{2s}{1 - \frac{1}{2s}}\right) |x-y|^\alpha$$

for all $x, y \in [0,1]$. We need only show that α is the largest possible exponent. Suppose without loss of generality that $s = |s_0|$. Since f vanishes at 0 and 1 and $f(\frac{1}{2}) \neq 0$ (since f is not a line), there exist distinct points x_0 and $y_0 \in [0,1]$ such that $f(x_0) \neq f(y_0)$ and $(x_0 - y_0)/(f(x_0) - f(y_0)) > 0$. With $x_n = x_0/2^n$ and $y_n = y_0/2^n$, we find from (3.9) that

$$f(x_n) - f(y_n) = \sum_{k=1}^{n-1} (2s_0)^{k-1} \frac{x_0 - y_0}{2^n} + s_0^n (f(x_0) - f(y_0)).$$

Therefore,

$$\begin{aligned} |f(x_n) - f(y_n)| &= s^n |f(x_0) - f(y_0)| \left| 1 + \frac{x_0 - y_0}{f(x_0) - f(y_0)} \left(\frac{1}{2s}\right)^2 \frac{1 - (\frac{1}{2s_0})^{n-2}}{1 - \frac{1}{2s_0}} \right| \\ &\geq s^n C \geq k|x_n - y_n|^\alpha, \end{aligned}$$

which proves the result. □

We can now prove the following.

THEOREM 3.9. *Suppose the pair (s_0, s_1) is such that $|s_0| < 1$ and $|s_1| < 1$ with p_1 and q_1 satisfying (3.4) and (3.5), respectively. Then V_0 provides approximation order 2. If s_0 and s_1 are both in magnitude less than $\frac{1}{2}$, then ϕ^i, $i = 0, 1$, are both Lipschitz. If $s = \max|s_i| > \frac{1}{2}$, then ϕ^i, $i = 0, 1$, have Hölder exponent $\alpha = -\log s/\log 2$.*

Proof. In order to show that V_0 provides approximation order 2, we need only prove that the hat function

$$g(x) = \begin{cases} x, & 0 \leq x \leq 1, \\ 2 - x, & 1 \leq x \leq 2 \end{cases}$$

is in V_0 [20]. It is easy to see from (2.3) that for any pair s_0, s_1 with $0 \leq |s_0| < 1$ and $0 \leq |s_1| < 1$, $f_{[0,1/2,1]}(x) = x$. Consequently,

$$g(x) = (1/2 - p_1)\phi^0(x) + \phi^1(x) + (1/2 - q_1)\phi^0(x-1).$$

The fact that ϕ^0 and ϕ^1 are Lipschitz when $s < \frac{1}{2}$ follows from Lemma 3.7. Furthermore, Lemma 3.7 also shows that if $s > \frac{1}{2}$, then the Hölder exponent of ϕ^0 is $\log|s|/\log\frac{1}{2}$. This will also be true of ϕ^1 once it is shown that ϕ^1 is not piecewise linear. For $s > \frac{1}{2}$ this can happen only if $p_1 = q_1 = \frac{1}{2}$; however, from (3.1) we find that with $p_1 = \frac{1}{2}$,

$$\int f_{\bar y_1} f_{\bar y_2} dx = \frac{-2+s_0}{(-2+s_0+s_1)(-4+s_0+s_1)} \neq 0,$$

which is a contradiction. Therefore, $f_{\bar y_2}$ is not a line. A similar argument shows that $f_{\bar y_0}$ cannot be a line, and the result now follows. □

We complete this section by computing the Fourier transform of ϕ^0 and ϕ^1. To this end, set $g(x) = e^{ikx}$ with $N = 2$ in (2.6) to find

$$\begin{aligned}\hat f_{\bar y}(k) = \int_0^1 e^{ikx} f_{\bar y}(x)dx &= \frac{1}{2}\int_0^1 (a_0x + b_0)e^{ikx/2}dx \\ &+ \frac{1}{2}\int_0^1 e^{ik(x+1)/2}(a_1x+b_1)dx \\ &+ \frac{1}{2}(s_0 + e^{ik/2}s_1)\hat f_{\bar y}\left(\frac{k}{2}\right).\end{aligned}$$

For ϕ^0, $a_0 = 1$, $b_0 = 0$, $a_1 = -1$, and $b_1 = 1$. Consequently,

$$\hat\phi^0(k) = 8e^{ik/2}\frac{\sin^2 k/4}{k^2} + \frac{1}{2}(s_0 + e^{ik/2}s_1)\hat\phi^0\left(\frac{k}{2}\right).$$

With $C(k) = \frac{1}{2}(s_0 + e^{ik/2}s_1)$ and $h_1(k) = 8e^{ik/2}(\sin^2 k/4)/(k^2)$, we find that

$$\hat\phi^0(k) = \sum_{n=0}^{\infty}\left(\prod_{j=1}^{n} C\left(\frac{k}{2^{j-1}}\right)\right) h_1\left(\frac{k}{2^n}\right).$$

The above series converges uniformly for $k \in \mathbb{R}$ since $|C(k/2^j)| \leq (|s_0| + |s_1|)/2 = r < 1$, $j = 1, 2\ldots$, and since $|\sin x/x| \leq 1$ for all $x \in \mathbb{R}$.

To compute the Fourier transform of ϕ^1, we use the fact that ϕ^1 can be written in terms of the hat function g and ϕ^0 as shown above. Thus

$$\hat\phi^1(k) = \hat g(k) - \left(\frac{1}{2} - p_1 + \left(\frac{1}{2} - q_1\right)e^{ik}\right)\hat\phi^0(k).$$

In Figure 3, the magnitude of the Fourier transforms of ϕ^0 and ϕ^1 are plotted when $s_0 = s_1 = -\frac{1}{5}$.

4. Construction of compactly supported wavelets. Having constructed a multiresolution analysis based on the vector $\phi = \binom{\phi^0}{\phi^1}$ and its dilates and translates, we now construct compactly supported, continuous wavelets. If $\tilde W_0$ is the orthogonal complement of $\tilde V_0$ in $\tilde V_1$, then any $\Psi \in \tilde W_0$ can be written as $\Psi(x) = \binom{\psi^0(x)}{\psi^1(x)}$, where $\psi^i(x)|_{[j/2,(j+1)/2)}$, $i = 0, 1$, is an AFIF with interpolation points at the quarter integers.

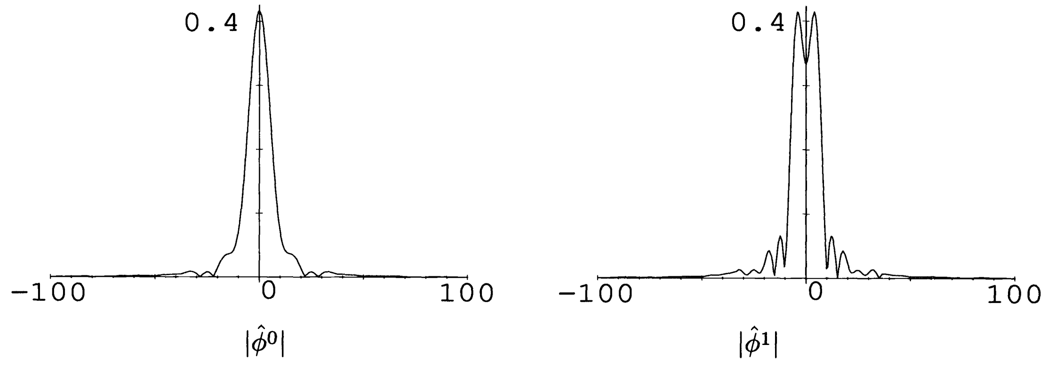

FIG. 3.

Since $\Phi(x) = \binom{\phi^0(x)}{\phi^1(x)}$ is supported on $[0,2]$, we shall look for $\Psi(x)$ to be supported on the same interval. Therefore, set

$$\psi^i(x) = \begin{cases} g_{\bar{y}_1^i}(x), & 0 \leq x \leq \dfrac{1}{2}, \\ g_{\bar{y}_2^i}(x), & \dfrac{1}{2} \leq x \leq 1, \\ g_{\bar{y}_3^i}(x), & 1 \leq x \leq \dfrac{3}{2}, \\ g_{\bar{y}_4^i}(x), & \dfrac{3}{2} \leq x \leq 1, \end{cases} \qquad i = 0, 1. \tag{4.1}$$

Here $\bar{y}_j^i$ are the values $\psi^i(x)$ taken at the quarter-integer points in the intervals indicated. In order to preserve continuity and keep the support of $\Phi(x)$ on $[0,2]$, $\bar{y}_1^i = [0, a_1^i, a_2^i]$, $\bar{y}_2^i = [a_2^i, a_3^i, a_4^i]$, $y_3^i = [a_4^i, a_5^i, a_6^i]$, and $\bar{y}_4^i = [a_6^i, a_7^i, 0]$, $i = 0, 1$. The coefficients a_j^i, $j = 1, 2, \ldots, 7$, $i = 0, 1$, are adjusted so that $\Psi(x)$ is orthogonal to $\Phi(x)$ and its translates and $\langle \psi_0^0(x), \psi^1(x) \rangle = 0$. In the case when $s_0 = -\frac{1}{5} = s_1$ and $p_1 = -\frac{3}{10} = q_1$, it follows from (2.7)–(2.9) that for $i = 0$ or 1,

$$\int_0^2 \psi^i(x)\phi^0(x)dx = \frac{5}{32}a_1^i + \frac{41}{96}a_2^i + \frac{5}{32}a_3^i + \frac{3}{64}a_4^i, \tag{4.2}$$

$$\int_0^1 \psi^i(x)\phi^0(x+1)dx = \frac{3}{64}a_4^i + \frac{5}{32}a_5^i + \frac{41}{96}a_6^i + \frac{5}{32}a_7^i, \tag{4.3}$$

$$\int_0^2 \psi^i(x)\phi^1(x)dx = -\frac{1}{48}a_1^i - \frac{1}{20}a_2^i + \frac{3}{16}a_3^i + \frac{107}{240}a_4^i + \frac{3}{16}a_5^i - \frac{1}{20}a_6^i - \frac{1}{48}a_7^i, \tag{4.4}$$

$$\int_0^2 \psi^i(x)\phi^1(x+1)dx = \frac{3}{16}a_1^i - \frac{1}{20}a_2^i - \frac{1}{48}a_3^i - \frac{1}{160}a_4^i, \tag{4.5}$$

$$\int_0^2 \psi^i(x)\phi^1(x-1)dx = -\frac{1}{160}a_4^i - \frac{1}{48}a_5^i - \frac{1}{20}a_6^i + \frac{3}{16}a_7^i, \tag{4.6}$$

and

$$\begin{aligned}\int_0^2 \psi^0(x)\psi^1(x)dx = {} & \frac{25}{96}(a_1^0a_1^1 + a_3^0a_3^1 + a_5^0a_5^1 + a_7^0a_7^1) \\ & + \frac{73}{192}(a_2^0a_2^1 + a_6^0a_6^1 + a_4^0a_4^1 + a_6^0a_6^1) \\ & + \frac{3}{128}(a_4^1a_2^0 + a_4^0a_2^1 + a_6^0a_4^1 + a_6^1a_4^0) \\ & + \frac{5}{64}(a_2^0a_1^1 + a_1^0a_2^1 + a_3^0a_2^1 + a_2^0a_3^1 \\ & \quad + a_4^0a_3^1 + a_3^0a_4^1 + a_5^0a_4^1 + a_4^0a_5^1 + a_6^0a_5^1 \\ & \quad + a_5^0a_6^1 + a_7^0a_6^1 + a_6^0a_7^1).\end{aligned} \tag{4.7}$$

The above equations once set equal to 0 will fix all but three of the unknowns. Two of these are used to normalize the integrals of ψ^0 and ψ^1. One unknown remains because of the one parameter family of rotations taking Ψ into other mother wavelets. A remarkable fact, to be shown below, is that once (4.3), (4.5), and (4.6) are satisfied, then $\langle \Psi, \Psi(\cdot + i)\rangle = 0 \ \forall\ i \in \mathbb{Z},\ i \neq 0$. A solution to the above equations that give $\langle \Psi, \Psi \rangle = I$ with Ψ having the smallest possible support is

$$\begin{aligned} y_1^0 &= \left[0, \frac{-3\sqrt{2}}{200}, \frac{9\sqrt{2}}{20}\right], & y_2^0 &= \left[\frac{9\sqrt{2}}{20}, \frac{-273\sqrt{2}}{200}, \frac{\sqrt{2}}{2}\right], \\ y_3^0 &= \left[\frac{\sqrt{2}}{2}, \frac{5\sqrt{2}}{200}, \frac{-3\sqrt{2}}{20}\right], & y_4^0 &= \left[\frac{-3\sqrt{2}}{20}, \frac{\sqrt{2}}{200}, 0\right], \end{aligned} \tag{4.8}$$

$$\begin{aligned} y_1^1 &= [0,0,0], & y_2^1 &= \left[0, \frac{3}{10}, -1\right], \\ y_3^1 &= \left[-1, \frac{48}{25}, \frac{-3}{5}\right], & y_4^1 &= \left[\frac{-3}{5}, \frac{1}{50}, 0\right] \end{aligned} \tag{4.9}$$

(see Figure 4). Since $\Psi \in \tilde{V}_1$, we have

$$\Psi(x) = \sum_{i=0}^{3} D_i \Phi(2x - i), \tag{4.10}$$

where for the particular Ψ given by (4.8) and (4.9),

$$\begin{aligned} D_0 &= \begin{pmatrix} \sqrt{3}/20 & 3\sqrt{6}/20 \\ 0 & 0 \end{pmatrix}, & D_1 &= \begin{pmatrix} -9\sqrt{3}/20 & 1/\sqrt{6} \\ 0 & -1/\sqrt{3} \end{pmatrix}, \\ D_2 &= \begin{pmatrix} 3\sqrt{3}/20 & -\sqrt{6}/20 \\ 3\sqrt{6}/10 & -\sqrt{3}/5 \end{pmatrix}, & D_3 &= \begin{pmatrix} -\sqrt{3}/60 & 0 \\ -\sqrt{6}/30 & 0 \end{pmatrix}. \end{aligned} \tag{4.11}$$

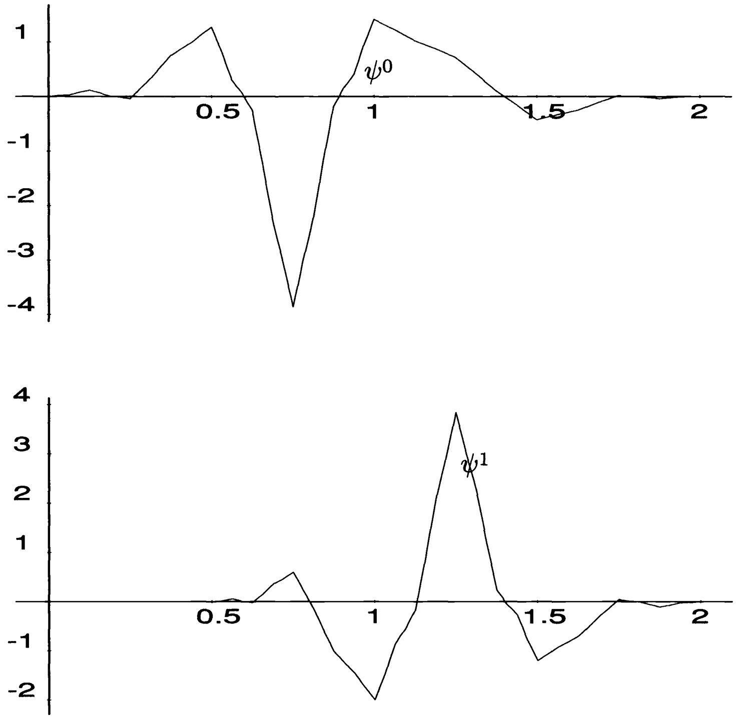

FIG. 4.

In order to see why the orthogonality of Ψ to the translates of Φ implies the orthogonality of Ψ to its nonzero integer translates, we examine the multiresolution analysis arising from Φ and consider the slightly more general case where $\Phi \in \mathbb{R}^N$, which we will use in §5. In this case, each C_i in (3.7) is an $N \times N$ matrix and Φ satisfies the N-scale dilation equation

$$\Phi(x) = \sum_{i=0}^{2N-1} C_i \Phi(Nx - i).$$

Likewise, the mother wavelet Ψ satisfies

$$\Psi(x) = \sum_{i=0}^{2N-1} D_i \Phi(Nx - i),$$

where the matrices D_i are $N(N-1) \times N$ matrices. The orthogonality of $\Phi(x)$ to its integer translates can be reexpressed as

$$(4.12) \qquad \int \Phi(x)\Phi^*(x-i)dx = \delta_{i,0} I_N = \sum_{k=0}^{2N-1} C_k C^*_{k-Ni} \qquad \forall\, i \in \mathbb{Z},$$

where I_N is the $N \times N$ identity matrix. Likewise, the orthogonality of Ψ against its translates gives

$$(4.13) \qquad \sum_{k=0}^{2N-1} D_k D^*_{k-Ni} = \delta_{i,0} I_{N(N-1)} \qquad \forall\, i \in \mathbb{Z}.$$

The fact that W_0 is orthogonal to V_0 in V_1 means

$$\sum_{k=0}^{2N-1} C_k D_{k-Ni}^* = 0 \qquad \forall\, i \in \mathbb{Z}, \tag{4.14}$$

while $V_1 = V_0 \oplus W_0$ can be expressed as

$$\sum_k C_{m-Nk}^* C_{n-Nk} + D_{m-Nk}^* D_{n-Nk} = \delta_{m,n} I_N \qquad \forall\, n, m \in \mathbb{Z} \tag{4.15}$$

(see [5]). If we set

$$H_1 = (C_0, C_1, \dots, C_{N-1}), \qquad H_2 = (C_N, C_{N+1}, \dots, C_{2N-1}),$$

$$G_1 = (D_0, D_1, \dots, D_{N-1}), \quad \text{and} \quad G_2 = (D_N, D_{N+1}, \dots, D_{2N-1}),$$

then (4.12) can be recast as

$$H_1 H_2^* = 0 \tag{4.16}$$

and

$$H_1 H_1^* + H_2 H_2^* = I_N. \tag{4.17}$$

Likewise, (4.13) and (4.14) become

$$G_1 G_2^* = 0, \tag{4.18}$$

$$G_1 G_1^* + G_2 G_2^* = I_{N(N-1)}, \tag{4.19}$$

$$H_2 G_1^* = 0, \tag{4.20}$$

$$H_1 G_2^* = 0, \tag{4.21}$$

and

$$H_1 G_1^* + H_2 G_2^* = 0. \tag{4.22}$$

Equation (4.15) can be recast as

$$H_1^* H_1 + H_2^* H_2 + G_1^* G_1 + G_2^* G_2 = I_{N^2} \tag{4.23}$$

and

$$H_1^* H_2 + G_1^* G_2 = 0. \tag{4.24}$$

The general solution to (4.16) is $H_2^* = P_1 Y$, where $P_1 : \mathbb{R}^{N^2} \to \mathbb{R}^{N^2}$ is an orthogonal projection onto the null space of H_1 and Y is any $N^2 \times N$ matrix. Likewise, from (4.21), it is easy to see that $G_2^* = P_1 X$, where X is any $N^2 \times N(N-1)$ matrix. If we set $H_1^* = (I_{N^2} - P_1)Y$, then (4.16) and (4.17) are satisfied and $Y = H_1^* + H_2^*$. Observe that $Y^*Y = I_N$. Equations (4.18)–(4.20) now suggest that $G_1^* = (I_{N^2} - P_1)X$ with $X^*X = I_{N(N-1)}$, and (4.22) says that $Y^*X = 0$. Since Y is an $N^2 \times N$ matrix, and X is an $N^2 \times N(N-1)$ matrix, it is an idea of Gil Strang that X can be obtained by letting its columns be the remaining orthonormal basis vectors for the $\mathbb{R}^{N^2}$, the first N basis vectors being the columns of Y. That is, we choose X so that the matrix $(Y\ X)$ is an orthogonal matrix. If this is done, (4.23) and (4.24) will also be satisfied since $YY^* + XX^* = I_{N^2}$. Thus equations (4.16)–(4.24) and the assumptions on G_1, G_2, H_1, and H_2 can be summarized as

$$\begin{pmatrix} Y^* \\ X^* \end{pmatrix}(Y\ X) = I_{N^2} = (Y\ X)\begin{pmatrix} Y^* \\ X^* \end{pmatrix}.$$

The filters arising from the above equations are closely related to those found in Vetterli [22] (also see Strang and Strela [21]). Thus we have shown the following.

THEOREM 4.1. *Let $\{C_i\}_{i=0}^{2N-1}$ be $N \times N$ matrices satisfying* (4.12). *Then there exist $N(N-1) \times N$ matrices $\{D_i\}_{i=0}^{2N-1}$ constructed as above so that equations* (4.13)–(4.15) *are satisfied.*

We now show that for any wavelet Ψ that is constructed using the above scaling function Φ, the minimum length of the support of any of its components is $\frac{3}{2}$ and at least one component must have a support greater than or equal to 2. Before proving the next lemma, we note that for $|s_0| < 1$, $|s_1| < 1$, and $f \in \tilde{V}_0$,

$$f(x) = \sum_i (c_i^0 \phi^0(x-i) + c_i^1 \phi^1(x-i)), \tag{4.25a}$$

where

$$c_i^1 = f(i+1) \tag{4.25b}$$

and

$$c_i^0 = f\left(i + \frac{1}{2}\right) - c_i^1 \phi^1\left(\frac{1}{2}\right) - c_{i-1}^1 \phi^1\left(\frac{3}{2}\right). \tag{4.25c}$$

LEMMA 4.2. *For any pair (s_0, s_1) such that $p(s_0, s_1) = 0$ with $|s_0| < 1$ and $|s_1| < 1$, there is no wavelet function supported on $[0,1]$ or on $[\frac{1}{2}, \frac{3}{2}]$.*

Proof. Denote by U_1 the restriction of $\tilde{V}_1$ to the interval $[0,1]$. That is, $U_1 = \{f|_{[0,1]} : f \in \tilde{V}_1\}$. We see that U_1 is a five-dimensional vector space. For notational simplicity, let

$$x_1 = \phi^1|_{[0,1]}, \qquad x_2 = \phi^1(\cdot + 1)|_{[0,1]},$$
$$x_3 = \phi^1(2\cdot +1)|_{[0,1]}, \qquad x_4 = \phi^1(2\cdot -1)|_{[0,1]}.$$

Note that $\operatorname{rank}\{\phi^0, x_1, x_2, x_3, x_4\} = 5$. Suppose that ψ^0 is a wavelet supported on $[0,1]$. Then ψ^0 is orthogonal to x_1, x_2, and ϕ^0 because of the orthogonality between wavelets and scaling functions. Also, from (4.25) applied to functions in $\tilde{V}_1$, we see that ψ^0 is orthogonal to $\phi^1(2\cdot +1)$ and $\phi^1(2\cdot -1)$ (and hence to x_3 and x_4) since ψ^0 vanishes at both 0 and 1. Thus $\psi^0 \in \{\phi^0, x_1, x_2, x_3, x_4\}^\perp = \{0\}$. This cannot be, so there is no such wavelet ψ^0.

Now suppose that ψ^0 is supported on $[\frac{1}{2}, \frac{3}{2}]$ and let

$$y_1 = \phi^0|_{[0,\frac{1}{2}]}, \qquad y_2 = \phi^1|_{[0,\frac{1}{2}]},$$
$$y_3 = \phi^0\left(\cdot + \frac{1}{2}\right)|_{[0,\frac{1}{2}]}, \qquad y_4 = \phi^1\left(\cdot + \frac{3}{2}\right)|_{[0,\frac{1}{2}]},$$
$$z_1 = \psi^0\left(\cdot + \frac{1}{2}\right)|_{[0,\frac{1}{2}]}, \qquad z_2 = \psi^0(\cdot + 1)|_{[0,\frac{1}{2}]}.$$

Note that the above are AFIFs on $[0, \frac{1}{2}]$. Since $f_{\bar{y}_2}(2\cdot)$ is orthogonal to $f_{\bar{y}_1}(2\cdot)$, it follows from (3.8) that if $s_0 \neq 0$ then y_1 and y_2 are linearly independent. A similar argument shows that if $s_1 \neq 0$ then y_3 and y_4 are linearly independent. Orthogonality between ψ^0 and $\phi^i(\cdot - j)$ dictates that z_1 must be orthogonal to y_3 and y_4. This implies that z_1 is orthogonal to all functions in $\tilde{V}_1|_{[0,\frac{1}{2}]}$ vanishing at $\frac{1}{2}$ since this space is three dimensional with basis $\{f_{\bar{y}_i}(2\cdot)\}_{i=0}^3$. Similarly, z_2 is orthogonal to all functions in $\tilde{V}_1|_{[0,\frac{1}{2}]}$ vanishing at 0. Thus it follows from (4.25) that ψ^0 is a multiple of $\phi^1(2\cdot -1)$. Now, ϕ^1 does not vanish at 1, but we require that $\langle \phi^1, \psi^0 \rangle = 0$. This cannot be, since among the functions $\phi^i(2 \cdot -j)$, of which ϕ^1 is a linear combination, the only one that does not vanish at 1 is $\phi^1(2 \cdot -1)$.

For the case of $s_0 = 0$ (or similarly for $s_1 = 0$), we can apply the quadrature formulas (2.9). Solving $p(0, s_1) = 0$ yields $s_1 = \sqrt{7} - 3$, which implies that y_3 and y_4 are linearly independent. Thus z_1 is still a multiple of the left half of $\phi^1(2\cdot)$. Rescale ψ^0 so that $z_1(\frac{1}{2}) = 1$; hence z_2 must have the form $f_{[1,r,0]}(2\cdot)$, where r is yet to be determined. Since $s_0 = 0, \phi^0(x)|_{[0,\frac{1}{2}]} = f_{[0,\frac{1}{2},1]}$, which is a line. From (2.9),

$$\langle \psi^0(\cdot + 1), \phi^0 \rangle = \langle z_2, y_1 \rangle = \frac{2 + 12r - 6s_1 + s_1^2}{6(s_1 - 2)(s_1 - 4)}.$$

In order for this to be equal to 0, $r = \frac{s_1}{2} - \frac{s_1^2}{12} - \frac{1}{6} = \sqrt{7} - 3$. We must also have $\langle \psi^0, \phi^1 \rangle = 0$. From the above remarks, we find that $\psi^0|_{[\frac{1}{2},1]} = f_{[0,p,1]}(2 \cdot -1)$, while $\phi^1|_{[\frac{1}{2},1]} = f_{[p,\frac{1-s_1+p+2s_1p}{2},1]}(2\cdot -1)$ and $\phi^1|_{[1,\frac{3}{2}]} = f_{[1,\frac{1+q}{2},q]}(2\cdot -2)$, where from (3.5) $q = (3s_1^2 + 2s_1 - 2)/(4s_1 + 8) = \sqrt{7}-3$ and from (3.4) $p = (1 - s_1^2)/(s_1^2 - 4) = (\sqrt{7} - 4)/6$. From (2.9), we find, after change of variables,

$$\begin{aligned}\langle \psi^0, \phi^1 \rangle &= \frac{1}{2}\int_0^1 f_{[0,p,1]}(x) f_{[p,\frac{1-s_1+p+2s_1p}{2},1]}(x)dx + \frac{1}{2}\int_0^1 f_{[1,r,0]}(x) f_{[1,\frac{1+q}{2},q]}(x)dx \\ &= \frac{(7 + 5\sqrt{7})(6r - 4\sqrt{7} + 25)}{756}.\end{aligned}$$

Thus in order for the above integral to be equal to 0, $r = (4\sqrt{7} - 25)/6$, which cannot be. □

This leads to the following.

THEOREM 4.3. *For any pair (s_0, s_1) with $p(s_0, s_1) = 0, |s_0| < 1$, and $|s_1| < 1$, let Ψ be a wavelet. Then the support of one component of Ψ must be of length $\geq \frac{3}{2}$, while the support of the other component must be of length ≥ 2.*

Proof. Lemma 4.2 shows that both components of Ψ must have support lengths of at least $\frac{3}{2}$. It is easy to see that not both may be supported on $[-1, \frac{1}{2}]$ since in that case either the pieces supported on $[-1, -\frac{1}{2}]$ or those on $[0, \frac{1}{2}]$ must be linearly dependent. A rotation of the components could then be used to find a wavelet whose support length is 1 which would contradict Lemma 4.2. A similar argument shows that not both components of Ψ may have support $[-\frac{1}{2}, 1]$.

Suppose $\Psi = \binom{\psi^1}{\psi^2}$, where $\operatorname{supp} \psi^1 = [-1, \frac{1}{2}]$ and $\operatorname{supp} \psi^2 = [-\frac{1}{2}, 1]$. In this case, the coefficients for the expansion of Ψ in terms of the normalized $\Phi(2\cdot)$ have the form

$$d_{-2} = \begin{bmatrix} 0 & \delta_1 \\ 0 & 0 \end{bmatrix}, \qquad d_{-1} = \begin{bmatrix} \delta_2 & \delta_3 \\ 0 & \delta_6 \end{bmatrix},$$

$$d_0 = \begin{bmatrix} \delta_4 & \delta_5 \\ \delta_7 & \delta_8 \end{bmatrix}, \qquad d_1 = \begin{bmatrix} 0 & 0 \\ \delta_9 & \delta_{10} \end{bmatrix},$$

with all others being 0. The relation $\langle \psi^0, \phi^1 \rangle = 0$, which must be satisfied, implies that $(2s_0 - 2q_1^1 + 1)\delta_5 = 0$. If δ_5 is not to be 0, then this is equivalent to $q_1^1 = \frac{1}{2} + s_0$. However, equation (3.5) also gives q_1^1 in terms of s_0 and s_1. Equating right-hand sides and simplifying gives

$$0 = \tilde{p}(s_0, s_1) = s_0^2 s_1 - 4s_0 s_1^2 + s_1^3 + 6s_0^2 + 6s_1^2 - 10s_1 - 12.$$

Of course, $p(s_0, s_1) = 0$ must still be satisfied, so

$$\begin{aligned} 0 &= -p(s_0, s_1) - \tilde{p}(s_0, s_1) \\ &= -2s_1^4 + 7s_1^3 s_0 + 7s_1 s_0^3 - 2s_0^4 - 6s_1^3 - 19s_1^2 s_0 - 14s_1 s_0^2 - 7s_0^3 \\ &\quad + 22s_1^2 + 14s_1 s_0 + 22s_0^2 - 12s_1 - 2s_0 + 4 \\ &= (\tilde{q}_2 \tilde{d}_2 + \tilde{r}_2)\tilde{d}_1 + \tilde{r}_1, \end{aligned}$$

where $\tilde{d}_1 = 3 - s_1$, $\tilde{d}_2 = 3 - 2s_0 - s_1$, $\tilde{r}_1 = -2s_0^4 + 14s_0^3 - 20s_0^2 + 58s_0 - 158$, $\tilde{r}_2 = -\frac{19}{8}s_1^3 - \frac{31}{8}s_1^2 - \frac{13}{8}s_1 + \frac{255}{8}$, and $\tilde{q}_2 = \frac{35}{8}s_1^2 + \frac{7}{4}s_1 s_0 + \frac{7}{2}s_0^2 + \frac{11}{4}s_1 - \frac{7}{4}s_0 + \frac{59}{8}$. It is easy to check that $\tilde{d}_1$, $\tilde{d}_2$, $\tilde{r}_1$, $\tilde{r}_2$, and $\tilde{q}_2$ are all positive for $(s_0, s_1) \in (-1,1)^2$, so the above equation has no valid solution, and it follows that $\delta_5 = 0$. A similar argument shows that $\delta_6 = 0$.

Now, $\langle \psi^0, \psi^1 \rangle = 0$ implies that $\delta_4 \delta_7 = 0$, which is satisfied only if $\delta_4 = 0$ or $\delta_7 = 0$. In the former case, ψ^0 is supported on $[-1, 0]$, and in the latter case, ψ^1 is supported on $[0, 1]$. By Lemma 4.2, neither case is possible. □

Although it has been shown by Daubechies [5] that with one scaling function, compactly supported, continuous wavelets cannot be symmetric, this is not the case with two scaling functions. In order to obtain wavelets supported on $[0, 2]$ that are symmetric or antisymmetric with respect to 1, it must be that $s_0 = s_1$. To see this, suppose that ψ is such a wavelet with support $[0, 2]$. Since $\psi \in \tilde{V}_1$, it follows using (2.2) and (2.3) that for $x \in [0, \frac{1}{2}], \psi(\frac{x}{2}) = a_0 x + s_0 \psi(x)$ and $\psi(2 - \frac{x}{2}) = -a_8 x + s_1 \psi(2 - x)$. The symmetry of ψ implies that $\psi(\frac{1}{2^n}) = \pm\psi(2 - \frac{1}{2^n})$, where the plus sign is used if ψ is symmetric with respect to 1 and the minus sign if it is antisymmetric with respect to 1. Comparing these equations we see that either $s_0 = s_1$, which implies that both s values are equal to $-\frac{1}{5}$, or ψ is linear on the intervals $[0, \frac{1}{2}]$ and $[\frac{3}{2}, 2]$. In the latter case, one can apply the same argument to $[\frac{1}{2}, 1]$ and $[1, \frac{3}{2}]$. These cannot both be lines, since in that case they might as well have been constructed for $s_0 = s_1 = 0$, contradicting Theorem 3.6. Suppose that one wavelet ψ^s is symmetric while the other ψ^a is antisymmetric with respect to 1 and set $\bar{y}_1^0 = [0, a_1^0, a_2^0]$, $\bar{y}_2^0 = [a_2^0, a_3^0, a_4^0]$, $\bar{y}_3^0 = [a_4^0, a_3^0, a_2^0]$, $\bar{y}_4^0 = [a_2^0, a_1^0, 0]$, $\bar{y}_1^1 = [0, a_1^1, a_2^1]$, $\bar{y}_2^1 = [a_2^1, a_3^1, 0]$, $\bar{y}_3^1 = [0, -a_3^1, -a_2^1]$, and $\bar{y}_4^1 = [-a_2^1, -a_1^1, 0]$; then equations similar to (4.2)–(4.5) ((4.6) is automatically satisfied) give $a_1^0 = 1$, $a_2^0 = -30$, $a_3^0 = 111$, $a_4^0 = -100$, $a_1^1 = 1$, $a_2^1 = -30$, and $a_3^1 = 81$. Here $\|\psi^s\|_{L^2} = \sqrt{2}\|\psi^a\|_{L^2}$. If ψ^s and ψ^a normalize to 1, then the corresponding matrices in (4.10) are

$$D_0 = \begin{bmatrix} -1/20 & -3\sqrt{2}/20 \\ -\sqrt{2}/20 & -3/10 \end{bmatrix}, \qquad D_1 = \begin{bmatrix} 9/20 & -1/\sqrt{2} \\ 9\sqrt{2}/20 & 0 \end{bmatrix},$$

$$D_2 = \begin{bmatrix} 9/20 & -3\sqrt{2}/20 \\ -9\sqrt{2}/20 & 3/10 \end{bmatrix}, \qquad D_3 = \begin{bmatrix} -1/20 & 0 \\ \sqrt{2}/20 & 0 \end{bmatrix}.$$

These wavelets are plotted in Figure 5. Consequently, ψ^s and ψ^a individually exhibit linear phase.

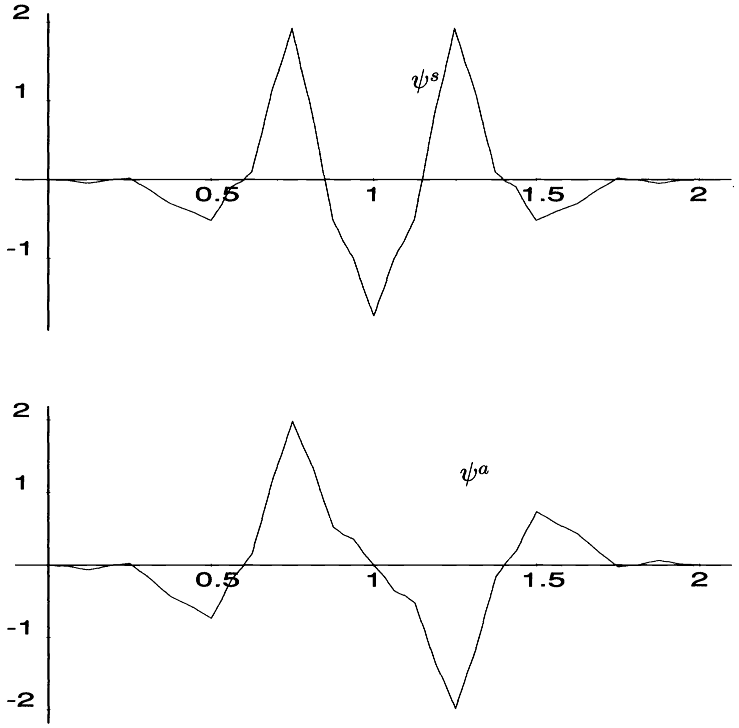

FIG. 5.

A similar computation where both wavelets are assumed to be symmetric with respect to 1 and supported on $[0,2]$ yields no solution.

Finally, we note that the multiresolution analysis arising from AFIFs is well suited for compact intervals. In fact, if we let $V_k' = \tilde{V}_k \cap L^2[0,1]$ and $\tilde{\phi}^i_{k,j} = \phi^i_{k,j}|_{[0,1]}$, then $\{V_k'\}$ provides a multiresolution analysis for $[0,1]$ and $\tilde{\phi}^i_{k,j}$, $j \in \mathbb{Z}$, $i = 0,1$, is an orthogonal basis for V_k'. To see what to do with the wavelets, write $\psi^i_j = \psi^i|_{[j-1,j]}$ and $\phi^i_j = \phi^i|_{[j-1,j]}$, $i = 0,1$, $j = 1,2$. We now rotate the wavelets, i.e.,

$$\psi^{+,0} = a\psi^0 + b\psi^1, \quad \psi^{+,1} = -b\psi^0 + a\psi^1 \tag{4.26}$$

with $|a|^2 + |b|^2 = 1$ so that

$$\langle \psi^{+,0}_j, \phi^1_j \rangle = 0, \qquad j = 1,2. \tag{4.27}$$

To see that this can be done, note that (4.27) is equivalent to

$$a\langle \psi^0_1, \phi^1_1 \rangle + b\langle \psi^1_1, \phi^1_1 \rangle = 0 \tag{4.28}$$

and

$$a\langle \psi^0_2, \phi^1_2 \rangle + b\langle \psi^1_2, \phi^1_2 \rangle = 0. \tag{4.29}$$

However, the fact that $\langle \psi^0, \phi^1 \rangle = \langle \psi^0_1, \phi^1_1 \rangle + \langle \psi^0_2, \phi^1_2 \rangle = 0$ and $\langle \psi^1, \phi^1 \rangle = \langle \psi^1_1, \phi^1_1 \rangle + \langle \psi^1_2, \phi^1_1 \rangle = 0$ shows us that (4.28) and (4.29) are not independent, which allows us to construct the desired rotation. With $\psi^{+,0}$ and $\psi^{+,1}$ constructed as in (4.26), set $\tilde{\psi}^0_{k,j} = \psi^{0,+}_{k,j}|_{[0,1]}$ and

$$\tilde{\psi}^1_{k,j} = \begin{cases} 0 & \text{if } \psi^{+,1}_{k,j} \cap [0,1]^c \neq \emptyset, \\ \psi^{+,1}_{k,j} & \text{otherwise.} \end{cases} \tag{4.30}$$

Then the nonzero components of $\{\tilde{\Psi}_{k,j}\}_{j\in\mathbb{Z}}$ form an orthogonal basis for $W'_k, k \geq 0$, where $V'_{k+1} = V'_k \oplus W'_k$. This leads to the following.

THEOREM 4.4. *$\{\tilde{\phi}^i_{k,j} = \phi^i_{k,j}|_{[0,1]} : k \geq 0,\ i = 0, 1, -i \leq j \leq 2^k - 1\}$ is an orthogonal basis for $V'_k = V_k \cap L^2[0,1]$, while $\{\tilde{\psi}^i_{k,j}, k \geq 0, i = 0, 1, i-1 \leq j \leq 2^k - (i+1)\}$ forms an orthogonal basis for W'_k. Furthermore, $V'_0 \bigoplus_{k\geq 0} W'_k = L^2[0,1]$.*

For the case where $s_0 = s_1 = -\frac{1}{5}$, it is easy to see that $\tilde{\psi}^0_{k,j}$ are just the symmetric wavelets restricted to $[0,1]$, i.e., $\tilde{\psi}^0_{k,j} = \psi^s_{k,j}|_{[0,1]}$, while $\tilde{\psi}^1_{k,j} = \psi^a_{k,j}$ if the support of $\psi^a_{k,j} \subset [0,1]$ and 0 otherwise.

5. Scaling by other integers. Many of the results of the previous sections can be used to produce scaling functions and wavelets satisfying dilation equations of the forms

$$\Phi(x) = \sum C_i \Phi(Nx - i)$$

and

$$\Psi(x) = \sum D_i \Phi(Nx - i)$$

with $N > 2$. Note that in this case the matrices D_i will in general not be square matrices. We begin by considering the $N+1$-dimensional basis $\{f_{\bar{y}_i}\}_{i=0}^N$ spanning S_0, where $\bar{y}_i = e_i$, $0 < i \leq N$, $\{e_i\}_{i=0}^N$ is the standard basis in R^{N+1}, and the last vector $\bar{y}_0$ is given by $\bar{y}_0 = [1, q_1, q_2, \ldots, q_{N-1}, 0]$. What is needed is to adjust q_i, $1 \leq i \leq N-1$, and s_j, $0 \leq j \leq N$, so that $f_{\bar{y}_0}$ is nonzero and orthogonal to $f_{\bar{y}_i}$, $1 \leq i \leq N$. Once this has been accomplished, orthogonal scaling functions ϕ^i, $0 \leq i \leq N-1$, can be obtained by applying the Gram–Schmidt procedure to the set $\{f_{\bar{y}_i}\}_{i=1}^N$. The functions ϕ^i, $0 \leq i \leq N-2$, obtained from the functions $\{f_{\bar{y}_i}\}_{i=1}^{N-1}$ will be continuous and supported on $[0,1]$ since each $f_{\bar{y}_i}$, $1 \leq i \leq N-1$, vanishes at 0 and 1. The last function ϕ^{N-1} can be obtained by subtracting from $f_{\bar{y}_N}$ its projection onto the subspace spanned by $\{\phi^i\}_{i=0}^{N-2}$ then piecing it together continuously with $f_{\bar{y}_0}$ as was done in the case $N = 2$ in §3. It follows from Theorem 5.3 below that it is sufficient to consider only a basis for S_0 of this type.

Since there are N orthogonality relations and $2N - 1$ unknowns (q_i, $1 \leq i \leq N-1$, and s_j, $0 \leq j \leq N-1$), it may be possible to impose other desirable conditions besides orthogonality and still obtain the required basis $\{\phi^i\}_{i=0}^{N-1}$. If $\Phi^*(x) = (\phi^1, \phi^2, \ldots, \phi^{N-1})$, then Φ will satisfy $\Phi(x) = \sum_{i=0}^{2N-1} C_i \Phi(Nx - i)$. $\Psi(x)$ may now be obtained from $\Phi(x)$ using Theorem 4.1 or the orthogonality equations (2.9) and solving as in §4.

In order to compute the orthogonality relations $\langle f_{\bar{y}_i}, f_{\bar{y}_0}\rangle = 0$, $1 \leq i \leq N$, $\lambda^i_j(x) = a^i_j x + b^i_j$, $0 \leq i \leq N$, $0 \leq j \leq N-1$, need to be computed. From (2.1)–(2.3) and (2.5), we find that $a^i_j = \delta_{i-1,j} - \delta_{i,j} - s_j \delta_{N,i}$ and $b^i_j = \delta_{i,j}$ for $1 \leq i \leq N$ and $0 \leq j \leq N-1$ with $q_0 = 1$ and $q_N = 0$. Also, $a^0_j = q_{j+1} - q_j + s_j$ and $b^0_j = q_j - s_j$ for $0 \leq j \leq N-1$. If $S_1 = \sum_{i=0}^{N-1} s_i$ and $S_2 = \sum_{i=0}^{N-1} i s_i$, it follows from (2.7) and (2.8) that $m^i_0 = 1/(N - S_1)$, $m^i_1 = ((N - S_1)i + S_2)/((N - S_1)(N^2 - S_1))$ for $1 \leq i \leq N-1$,

$m_0^N = (1-S_1)/(2(N-S_1))$,

$$m_1^N = \frac{N(3N-1)+(1-5N)S_1+3(1-N)S_2+2S_1^2}{6(N-S_1)(N^2-S_1)},$$

$$m_0^0 = \frac{1-S_1+2\sum_{i=1}^{N-1} q_i}{2(N-S_1)},$$

and

$$m_1^0 = \frac{S_1(S_1-(N+1))-3(N-1)S_2+N+6\sum_{i=1}^{N-1} q_i((N-S_1)i+S_2)}{6(N-S_1)(N^2-S_1)}.$$

With the above moments, (2.9) yields

$$\begin{aligned} I_{n,0} &= \langle f_{\bar{y}_n}, f_{\bar{y}_0}\rangle \\ &= \Bigg((s_{n-1}-s_n)m_1^0 + (m_0^n - m_1^n)\sum_{i=0}^{N-1} s_i(q_i - s_i) \\ &\quad + m_1^n \sum_{i=1}^{N-1} s_{i-1}q_i + s_n m_0^0 - \frac{s_{n-1}+2s_n}{6} \\ &\quad + \frac{1}{6}(q_{n-1}+4q_n+q_{n+1})\Bigg) \Bigg/ \left(N - \sum_{i=0}^{N-1} s_i^2\right), \qquad 1 \le n \le N-1, \end{aligned} \tag{5.1}$$

and

$$\begin{aligned} I_{N,0} = \Bigg(& m_1^0\left(s_{N-1} - \sum_{i=0}^{N-1} s_i^2\right) + \left(m_0^N - m_1^N - \frac{1}{6}\right)\sum_{i=0}^{N-1} s_i(q_i - s_i) \\ & + \sum_{i=1}^{N-1} s_{i-1}q_i(m_1^N - 1/3) + \frac{q_{N-1}-s_{N-1}}{6}\Bigg) \Bigg/ \left(N - \sum_{i=0}^{N-1} s_i^2\right). \end{aligned} \tag{5.2}$$

For $N=2$, (5.1) and (5.2) yield (3.2) and (3.3) with $p_1 = 0$. For $N=3$, (5.1) and (5.2) become more complicated and we shall restrict ourselves to considering s values that give symmetric or antisymmetric wavelets.

Just as when $N=2$, we require that the s values be arranged symmetrically, so s_0 must be the same as s_2. In this case, a one-parameter family of continuous, compactly supported, orthogonal scaling functions, each with linear phase, will be produced.

We proceed as before, examining what conditions s_0 must satisfy for compactly supported scaling functions to exist. Let Υ_0 be the space of vectors vanishing on both sides and Υ_1 be those vanishing on the left. Then Υ_0 is a two-dimensional space and has a basis of the form $\bar{x}_1 = [0,1,1,0]$ and $\bar{x}_2 = [0,1,-1,0]$. Let $\bar{x}_3 = [0,p_1,p_2,1]$ be a vector orthogonal to Υ_0 in Υ_1, so that $\{\bar{x}_1,\bar{x}_2,\bar{x}_3\}$ forms an orthogonal basis for Υ_1.

Now, if we can find $\bar{x}_4 = [1,q_1,q_2,0]$ orthogonal to Υ_1, then we easily generate the scaling functions

$$\phi^0 = \begin{cases} f_{\bar{x}_1} & \text{on } [0,1], \\ 0 & \text{elsewhere,} \end{cases} \quad \phi^1 = \begin{cases} f_{\bar{x}_2} & \text{on } [0,1], \\ 0 & \text{elsewhere,} \end{cases} \quad \text{and } \phi^2 = \begin{cases} f_{\bar{x}_3} & \text{on } [0,1], \\ f_{\bar{x}_4}(\cdot - 1) & \text{on } (1,2], \\ 0 & \text{elsewhere.} \end{cases}$$

If there exists no such $\bar{x}_4$, then there are no compactly supported scaling functions, as we can see from the following general result.

THEOREM 5.1. *Let V be an N-dimensional subspace of $C^0[0,1]$ such that there does not exist an orthonormal basis with $N-1$ of the basis functions vanishing at 0 and the remaining function vanishing at 1 or vice versa. Then there do not exist compactly supported $C^0(\mathbb{R})$ functions $\{\phi^j\}_{j=1}^{N-1}$ composed of linear combinations of basis elements of V and their integer translates constructed so that $\langle\phi^j(x),\phi^i(x-l)\rangle = \delta_{j,i}\delta_{0,l}$.*

Proof. The proof is by induction on N. The case $N = 3$ was established in Lemma 3.5. We only consider the step from $N = 3$ to $N = 4$, as the general argument is similar. For ease of notation set $x = \phi^1, y = \phi^2$, and $z = \phi^3$ and suppose that each is supported on a subset of $[0,M]$. Suppose V satisfies the hypotheses above. Then there are three cases we need to consider.

Case 1. One of the functions (say x) is supported on $[0,1]$, or x, y, and z can be transformed by a finite number of rotations and shifts so that this is the case. First, perform this transformation if necessary. We see that the components of y and z are restricted to a three-dimensional space, which has no orthonormal basis of vectors with two functions vanishing on the left and one vanishing on the right or vice versa. Thus by Lemmas 3.4 and 3.5, the scaling functions y and z cannot exist.

Case 2. All three functions have support $[0,2]$ or longer, and the leftmost components, $\{x_1,y_1,z_1\}$, have rank 1. In this case, we may begin to apply the rotate-and-shift strategy of Lemma 3.5 on y and z. If for some finite j, $y_1^{(j)}$ and $z_1^{(j)}$ are not linearly dependent, then we go to Case 3 below. Otherwise, the proof of Lemma 3.5 applies and we are done.

Case 3. All three functions have support $[0,2]$ or longer, and the leftmost components, $\{x_1,y_1,z_1\}$, have rank 2. Note that $\{x_1,y_1,z_1\}$ cannot have rank 3 because then the rightmost nonzero component of any of them would be orthogonal to all functions vanishing on the left, which we assumed was impossible. Here we apply an argument similar to the one found in Lemma 3.5 using two rotation maps instead of one. Many of the details in this proof are analogous to those in the proof of Lemma 3.5, so they are omitted here.

Since two among x_1, y_1, and z_1 must be linearly independent, we may assume that y_1 and z_1 are independent. We can rotate y and z so that y_1 and z_1 are orthogonal, and for an appropriate basis, we have

$$\begin{aligned} x &= ((x_{1,1},x_{1,2},0,0),x_2,x_3,\ldots,x_M),\\ y &= ((y_{1,1},0,0,0),y_2,y_3,\ldots,y_M),\\ z &= ((0,z_{1,2},0,0),z_2,z_3,\ldots,z_M), \end{aligned}$$

where $y_{1,1} > 0$ and $z_{1,2} > 0$. As before, we have a rotation r_1 which transforms x and y into

$$\begin{aligned} x' &= ((0,x'_{1,2},0,0),x'_2,\ldots,x'_M),\\ y' &= ((y'_{1,1},y'_{1,2},0,0),y'_2,\ldots,y'_M), \end{aligned}$$

leaving z unchanged, and a rotation r_2 which transforms x' and z into

$$\begin{aligned} x'' &= (0,x''_2,\ldots,x''_M),\\ z' &= ((0,z'_2,0,0),z'_2,\ldots,z'_M), \end{aligned}$$

leaving y' unchanged. We also have the shift map s, which takes x'' to

$$(x''_2,x''_3,\ldots,x''_M,0) = x''',$$

leaving y' and z' unchanged. The resulting vectors x''', y', and z' are themselves orthogonal scaling functions, and thus the leftmost components cannot have rank 3. Clearly, y'_1 and z'_1 are linearly independent, so their rank is 2. Now we iterate the map $s \circ r_2 \circ r_1$ to obtain the sequence $(x^{(j)}, y^{(j)}, z^{(j)}) = (s \circ r_2 \circ r_1)^j (x, y, z)$, which must have some limit point (X, Y, Z). Analogously to Lemma 3.5, both $\{y^{(j)}_{1,1}\}$ and $\{z^{(j)}_{1,2}\}$ are monotone increasing, from which it follows that $X_{k,1} = X_{k,2} = 0$ for $k = 1, 2, \ldots, M$ and hence that $X = 0$, which we know is not possible.

To proceed to higher N, we need only consider the analog of Case 3 above since the other cases are eliminated by the induction hypothesis. The analog of Case 3 is when all N functions have support $[0, 2]$ or longer and the dimension of the space spanned by the leftmost components of these functions is $N - 2$. In this case, $N - 2$ rotations are needed to reduce by iteration one of the functions to 0, thereby forcing a contradiction. □

Next, we investigate what conditions must be imposed on s_0 and s_1 in order that such a basis should exist. The vectors $[0, 1, 0, 0]$, $[0, 0, 1, 0]$, and $[0, 0, 0, 1]$ form a basis (not orthonormal) for Υ_1, so it suffices to check for orthogonality between $\bar{x}_3$ and each of these vectors. From (5.1) and (5.2), we find (where $\bar{y}_i, i = 0, 1, 2, 3$ are used), after some manipulation,

$$\begin{aligned} I_{1,0} = {} & 8s_0s_1q_2 - 108q_1 - 27q_2 + 12s_0 + 42s_1 + 60s_0q_1 - 48s_0q_2 - 8s_0s_1 \\ & - 24s_1q_1 - 24s_1q_2 + 76s_0^2 + 31s_1^2 + 8s_1s_0q_1 - 24s_0^3 - 6s_1^3 - 27 \\ & + 20s_0^2q_2 - 12s_0^2s_1 - 12s_0s_1^2 - s_1^2q_2 + 8s_1^2q_1 - 16q_1s_0^2 = 0, \end{aligned}$$

$$\begin{aligned} I_{2,0} = {} & 8s_0s_1q_2 - 27q_1 - 108q_2 + 12s_0 + 24s_1 - 48s_0q_1 + 60s_0q_2 - 8s_0s_1 \\ & - 24s_1q_1 - 24s_1q_2 + 28s_0^2 + 16s_1^2 + 8s_1s_0q_1 - 16s_0^2q_2 \\ & + 8s_1^2q_2 - s_1^2q_1 + 20q_1s_0^2 = 0, \end{aligned}$$

$$\begin{aligned} I_{3,0} = {} & -8s_0s_1q_2 - 27q_2 + 48s_0 + 12s_0q_1 + 12s_0q_2 - 4s_0s_1 + 24s_1q_1 \\ & + 42s_1q_2 - 50s_0^2 - 21s_1^2 - 8s_1s_0q_1 - 12s_0^2s_1q_2 - 32s_0^3 - 8s_1^3 \\ & + 76s_0^2q_2 - 16s_0^2s_1 - 16s_0s_1^2 + 31s_1^2q_2 + 16s_1^2q_1 + 28q_1s_0^2 \\ & - 24s_0^3q_2 + 8s_0^3s_1 + 6s_0^2s_1^2 + 4s_1^3s_0 - 6s_1^3q_2 - 12s_1^2s_0q_2 \\ & + 8s_0^4 + s_1^4 = 0. \end{aligned}$$

Solving the first two for q_1 and q_2 gives

$$q_1 = \frac{32s_0^3 - 76s_0^2 - 32s_0^2s_1 + 24s_0s_1 + 16s_0s_1^2 - 24s_1 + 36 - 56s_1^2 - 16s_1^3}{(6s_0 + 21s_1 + 45)(2s_0 - s_1 - 3)},$$

$$q_2 = \frac{40s_0^3 - 20s_0^2 - 4s_0^2s_1 + 12s_0s_1 + 20s_0s_1^2 - 36s_0 - 30s_1 - 19s_1^2 - 9 - 2s_1^3}{(6s_0 + 21s_1 + 45)(2s_0 - s_1 - 3)}.$$

If we substitute these expressions into the third equation and simplify, we get the desired relationship,

$$\begin{aligned} 0 = {} & 48s_0^4 - 256s_0^3 + 16s_0^2s_1^2 + 192s_0^2s_1 + 400s_0^2 + 16s_0s_1^3 - 96s_0s_1^2 \\ & - 272s_0s_1 - 192s_0 + s_1^4 + 16s_1^3 + 70s_1^2 + 48s_1 + 9. \end{aligned}$$

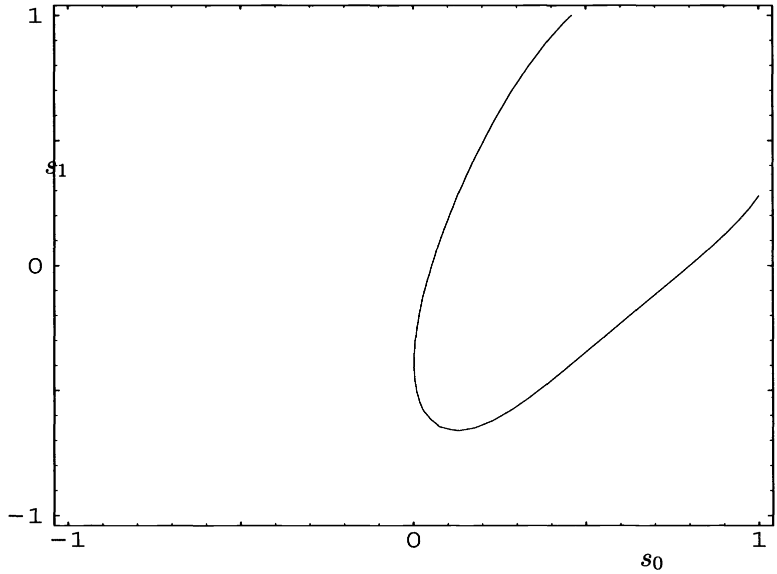

FIG. 6.

Let the polynomial on the right be denoted by $\hat{p}(s_0, s_1)$. The zero set of $\hat{p}$ is shown in Figure 6. From the above, the following is now clear.

THEOREM 5.2. *Continuous, compactly supported, orthogonal scaling functions* $\{\phi^j\}_{j=0}^2$ *can be constructed so that this set and its integer translates span* $\tilde{V}_0$ $(N = 3, s_2 = s_0)$ *if and only if* $|s_0| < 1$, $|s_1| < 1$, *and* $\hat{p}(s_0, s_1) = 0$.

As an example, we construct the scaling functions and wavelets generated from $s_0 = s_2 = \frac{3}{7}$, $s_1 = -\frac{3}{7}$. It is easy to check that these values do satisfy the conditions of Theorem 5.3, so the construction above gives the scaling functions shown in Figure 7. We then generate the wavelets, which are shown in Figure 8. The interpolation values for these functions are given in Tables 2 and 3. Table 4 gives the matrices in the dilation equation for the scaling functions obtained from $\bar{x}_1, \bar{x}_2, \bar{x}_3, \bar{x}_4$, $(s_0, s_1, s_2$ arbitrary) given above.

For general N, we consider two special cases: Case A, $s_i = 0$, $0 \le i \le N-2$, $s_{N-1} = s$; and Case B, $s_i = s$, $0 \le i \le N-1$.

For Case A, $S_1 = s$ and $S_2 = (N-1)s$. Therefore,

$$m_0^0 = \frac{(1 - s + 2\sum_{i=1}^{N-1} q_i)}{2(N-s)}$$

and

$$m_1^0 = \frac{(s^2 - s(3N^2 - 5N + 4)) + N + 6\sum_{i=1}^{N-1} q_i((N-s)i + (N-1)s)}{6(N^2 - s)(N-s)},$$

and (5.1) yields

$$(5.3)\quad I_{n,0} = \frac{(m_0^n - m_1^n)s(q_{N-1} - s)) + \frac{1}{6}(q_{n-1} + 4q_n + q_{n+1})}{N - s^2}, \qquad 1 \le n \le N-2.$$

With the benefit of hindsight, we set $q_{N-1} = s$ and solve

$$(5.4)\qquad I_{n,0} = q_{n-1} + 4q_n + q_{n+1}, \qquad 1 \le n \le N-2,$$

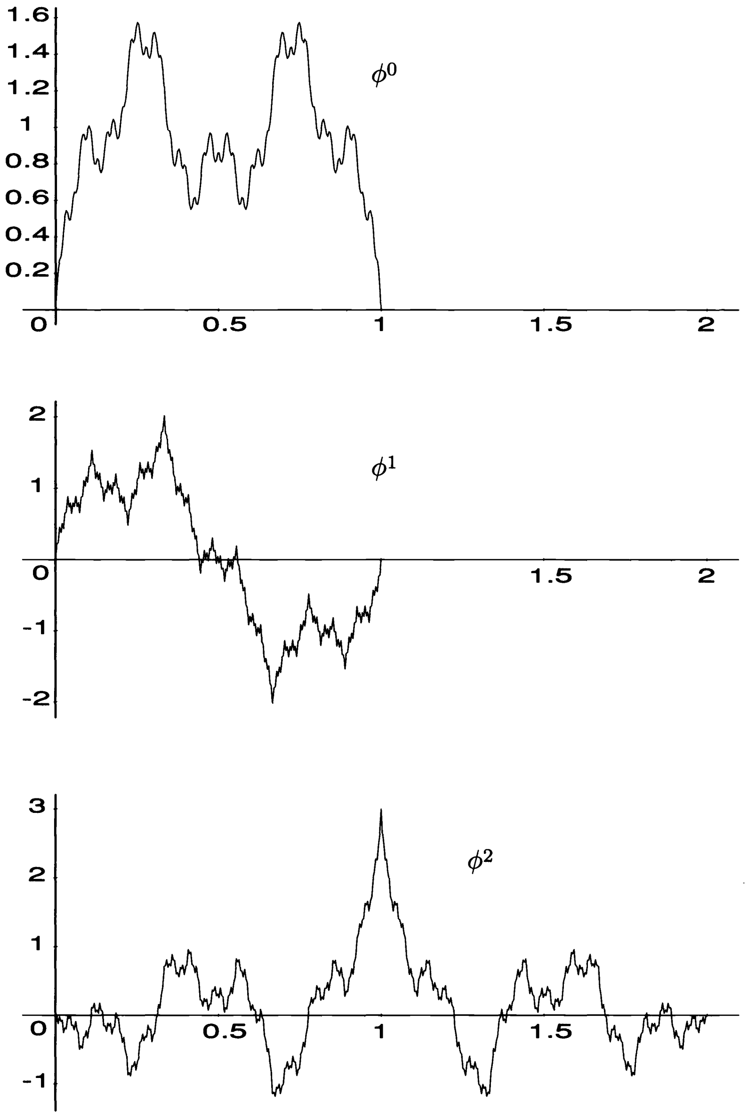

FIG. 7.

with boundary conditions $q_0 = 1$ and $q_{n-1} = s$. The solution is

$$q_n = \frac{U_{n-1}s}{U_{N-2}} + \frac{U_{N-n-2}}{U_{N-2}},$$

where U_i is the Chebyshev polynomial of the second kind evaluated at $x = -2$, i.e., $U_i = (\lambda^{i+1} - \lambda^{-(i+1)})/(\lambda - \lambda^{-1})$ with $\lambda = -2 + \sqrt{3}$. Using (5.4), we also find that

$$\sum_{n=1}^{N-1} q_n = \frac{1}{6}(5q_{N-1} + q_{N-2} + q_1 - 1) \tag{5.5}$$

TABLE 4

Dilation matrices for $n = 3$, s_0, s_1, s_2 arbitrary.

$$C_0 = \begin{pmatrix} \frac{2s_0+1-(p_1+p_2)}{2} & \frac{-(1+3(p_1-p_2)}{6} & 1 \\ \frac{1-(p_1+p_2)}{2} & \frac{6s_0-(1+3(p_1-p_2))}{6} & 1 \\ \frac{(p_1+p_2-1)(s_0-p_1)}{2} & \frac{(p_1-p_2+1/3)(s_0-p_1)}{2} & p_1 \end{pmatrix}$$

$$C_1 = \begin{pmatrix} \frac{2s_1+2-(p_1+p_2+q_1+q_2)}{2} & \frac{-(p_1-p_2+q_1-q_2)}{2} & 1 \\ \frac{p_1+p_2-(q_1+q_2)}{2} & s_1+1/3+\frac{p_1-p_2-(q_1-q_2)}{2} & -1 \\ \frac{(p_1+p_2)(s_1+1-p_2)-s_1-p_1(q_1+q_2)}{2} & \frac{(p_1-p_2)(1/3+s_1-p_2)+s_1/3-p_1(q_1-q_2)}{2} & p_2 \end{pmatrix}$$

$$C_2 = \begin{pmatrix} s_2+1/2-\frac{(q_1+q_2)}{2} & \frac{q_2-q_1+1/3}{2} & 0 \\ \frac{q_1+q_2-1}{2} & \frac{2s_2-1/3+q_1-q_2}{2} & 0 \\ \frac{1-p_1+s_2(p_1+p_2-1)-p_2(q_1+q_2)}{2} & \frac{4p_2-3p_1-1+3s_2(p_1-p_2+1/3)-3p_2(q_1-q_2)}{6} & 1 \end{pmatrix}$$

$$C_3 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ \frac{s_0(q_1+q_2-1)-q_1(p_1+p_2)-q_2+1}{2} & \frac{3s_0(q_1-q_2-1/3)-3q_1(p_1-p_2)+3q_2-4q_1+1}{6} & q_1 \end{pmatrix}$$

$$C_4 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ \frac{(s_1-q_1)(q_1+q_2-1)+q_2(1-p_1-p_2)}{2} & \frac{(s_1-q_1)(q_1-q_2-1/3)-q_2(p_1-p_2+1/3)}{2} & q_2 \end{pmatrix}$$

$$C_5 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ \frac{(s_2-q_2)(q_1+q_2-1)}{2} & \frac{(s_2-q_2)(q_1-q_2-1/3)}{2} & 0 \end{pmatrix}$$

and

$$\sum_{n=1}^{N-1} nq_n = \frac{((5N-4)q_{N-1} + (N-1)q_{N-2} - 1)}{6}. \tag{5.6}$$

To obtain $I_{N-1,0} = 0$ with $q_{N-1} = s$, we find from (5.1) that

$$s\left(m_1^0 + m_0^0 - \frac{1}{3}\right) + \frac{1}{6}(q_{N-2} + s) = 0. \tag{5.7}$$

Likewise, from (5.2), we find that $I_{N,0} = 0$ only if $s(s-1)m_1^0 = 0$. Since $s \neq 0$ or 1, we find

$$m_1^0 = 0. \tag{5.8}$$

Substitute (5.5) and (5.8) into (5.7), and (5.5) and (5.6) into (5.8) to find that (5.7) and (5.8) are both equal to 0 if and only if s satisfies the equation

$$s^2 + (N+1)(U_{N-3} + 2U_{N-2})s + N = 0, \qquad N \geq 2. \tag{5.9}$$

This leads to the following.

THEOREM 5.3. *Suppose $N \geq 2, s_i = 0, 0 \leq i \leq N-2$, and $s_{N-1} = s = (-b + \sqrt{b^2 - N})/2$ with $b = (N+1)(U_{N-3} + 2U_{N-2})$ with $U_i = (\lambda^{i+1} - \lambda^{-(i+1)})/(\lambda - \lambda^{-1})$ with $\lambda = -2 + \sqrt{3}$. Then there exist continuous, compactly supported, orthogonal scaling functions $\{\phi^i\}_{i=0}^{N-1}$ supported on $[0,2]$ such that this set and its integer translates span $\tilde{V}_0$.*

A set of mother wavelets $\{\psi^j\}_{j=1}^{N(N-1)}$ may be constructed using Theorem 4.1 or the orthogonality equations (2.9).

For Case B, $S_1 = Ns$ and $S_2 = N(N-1)s/2$. Therefore,

$$m_0^n = \frac{1}{N(1-s)}, \quad m_1^n = \frac{s(N-2n-1)+2n}{2N(1-s)(N-s)}, \quad 1 \leq n \leq N-1,$$

$$m^N = \frac{1-Ns}{2N(1-s)}, \quad m_1^N = \frac{4Ns^2 - s(3N+4N+1) + 6N - 2}{12N(1-s)(N-s)}, \quad m_0^0 = \frac{1-Ns+2a}{2N(1-s)},$$

and

$$m_1^0 = \frac{2Ns^2 - s(3N^2 - 4N + 5) + 2 + 12(1-s)a + 6(N-1)sb}{12N(1-s)(N-s)},$$

where $a = \sum_{i=1}^{N-1} q_i$ and $b = \sum_{i=1}^{N-1} iq_i$. The orthogonality conditions become

$$\begin{aligned} I_{n,0} = 0 = {} & s[s^2(N^2 - N(2n-1)) - 2s(N^2 - n(N+1) + 1) + 3N - N^2 - 2n] \\ & + 4(N-s)sa \\ & + \frac{N(1-s)(N-s)}{3}(q_{n-1} + 4q_n + q_{n+1}), \qquad 1 \leq n \leq N-1, \end{aligned} \tag{5.10}$$

and

$$\begin{aligned} I_{N,0} = 0 = {} & m_1^0 s(1-Ns) + \left(m_0^N - m_1^N - \frac{1}{6}\right)s(a - Ns + 1) \\ & + sa\left(m_1^N - \frac{1}{3}\right) + \frac{q_{N-1} - s}{6} \end{aligned} \tag{5.11}$$

with $n = N-1$ in (5.10), and we find

(5.12)
$$a = \frac{s^3(N^2-3N)+4s^2+s(N^2-N-2)-\frac{N}{3}(1-s)(N-s)(q_{N-2}+4q_{N-1})}{4s(N-s)}.$$

Therefore, for $1 \le n \le N-2$, (5.10) becomes

$$0 = q_{n-1} + 4q_n + q_{n+1} - d_n, \tag{5.13}$$

where $d_n = (q_{N-2}+4q_{N-1}) + (6/N(N-s))s(sN-1)(N-n-1)$. With $\bar{q}^* = (q_1, q_2, \dots, q_{N-2})$, H the $N-2 \times N-2$ tridiagonal matrix with 4 on the diagonal and 1 on the off diagonal, and $\bar{c}^* = (d_1 - 1, d_2, \dots, d_{N-3}, d_{N-2} - q_{N-1})$, we find that

$$\bar{q} = H^{-1}\bar{c}. \tag{5.14}$$

It follows from $HH^{-1} = I$ that

$$H^{-1}_{n,m} = \begin{cases} -\frac{U_{n-1}U_{N-2-m}}{U_{N-3}}, 0 \le n \le m \le N-1, \quad N \ge 3, \\ H^{-1}_{n,m} = H^{-1}_{m,n}, 0 \le m \le n \le N-1. \end{cases} \tag{5.15}$$

Here U_i is as in Case A above. The equation above gives $q_i, 1 \le i \le N-2$, in terms of q_{N-2} and q_{N-1}. Since $H^{-1}_{N-2,i} = -U_{i-1}/U_{N-3}$, we find that $\sum_{i=1}^{N-2} H^{-1}_{N-2,i} = \frac{1}{6}(U_{N-2} - U_{N-3} - 1)/U_{N-3}$. Solving (5.14) for q_{N-2} then substituting in the above calculations yields

$$q_{N-2} = \frac{(4 - 2U_{N-3} - 6U_{N-2})q_{N-1} + 6 - \frac{36s(sN-1)}{N(N-s)}\sum_{i=1}^{N-2} U_{i-1}(N-n-1)}{5U_{N-3} + U_{N-2} - 1}.$$

To solve for q_{N-1}, sum equation (5.10) from $n = 0$ to $N-2$ to find

$$a = \frac{s^2(3\,N^2 - 3\,N) + s(3\,N^2 - 8\,N) + 6}{N(6\,sN - 12\,s + 6\,N)} - \frac{(q_{N-1} + q_1)\,(s-1)\,N}{6\,sN - 12\,s + 6\,N}.$$

Eliminate q_1 from this equation using (5.12), and then comparing it with (5.12) gives a solution for q_{N-1}. Using a symbolic manipulation language such as Maple to solve these equations and using the recurrence formula for Chebyshev polynomials of the second kind, we find

$$\begin{aligned} q_{N-2} = &-\frac{s^3N((21\,N^2 - 93\,N + 104\,)U_{N-3} + (6\,N^2 - 24\,N + 28\,)U_{N-4} - 6\,N^2 + 12\,N + 4)}{d} \\ &+ \frac{2\,s^2((45\,N^2 - 45\,N + 52\,)U_{N-3} + (12\,N^2 12\,N + 14\,)U_{N-4} + 6\,N^3 + 2)}{d} \\ &+ \frac{3\,sN((7\,N^2 - N - 30\,)U_{N-3} + (2\,N^2 - 8\,)U_{N-4} - 2\,N^2 + 4\,N) - 12\,N^3}{d} \end{aligned}$$

and

$$\begin{aligned} q_{N-1} = &\frac{-s^3N(4 + 3\,N^2 - 9\,N) - 2\,s^2(3\,N^3 - 2) + 3\,sN^2(N-3) + 6\,N^3}{d} \\ &+ \frac{U_{N-4}(s^3N(213\,N^2 - 369\,N + 388) - s^2(336\,N^2 - 336\,N + 388) - sN(213\,N^2 - 33\,N - 336))}{d} \\ &- \frac{U_{N-5}(s^2(90\,N^2 - 90\,N + 104) - s^3N(57\,N^2 - 99\,N + 104) + sN(57\,N^2 - 9\,N - 90))}{d}, \end{aligned}$$

where

$$\begin{aligned} d = 2\,N(s-N)(s(2 + U_{N-4}(168\,N - 194) + U_{N-5}(45\,N - 52)) \\ + N(168\,U_{N-4} + 45\,U_{N-5})). \end{aligned}$$

Note that d is nonzero for $-1 \leq s \leq 1$. What remains is to solve (5.11). If we multiply (5.10) by $n-1$, sum for $n = 1$ to $N-1$, and then solve for $\sum_{n=0}^{N-1} nq_n = b$, we find, after using (5.12),

$$b = \frac{s^2(N^3 - 3N^2 + 2N) - s(N^2 - 3N + 1) - N}{6\,N - 6\,s} + \frac{(2\,N-1)\;Nq_{N-1}}{6}.$$

Substituting the above equations in (5.11) and simplifying using the recurrence formula for the Chebychev polynomials yields

$$\begin{aligned} 0 = N(s^3(U_{N-4}(35\,N^2 - 12\,N^3 + 35\,N^2 - 36\,N - 7) \\ + U_{N-3}(-45\,N^3 + 130\,N^2 - 135\,N - 26) - N^2 - 1) \\ + s^2(U_{N-4}(-12\,N^3 + 45\,N^2 + 2\,N + 21) \\ + U_{N-3}(7\,N - 45\,N^3 + 168\,N^2 + 7\,N + 78) - 3\,N^2 + 2\,N + 3) \\ + -6\,sN((3\,U_{N-4} + 11\,U_{N-3})(N+1) + 1) + 6\,N^2)(s-1)(s+1)/d_1, \end{aligned}$$

which is equal to 0 for $|s| < 1$ when

$$\begin{aligned} p_N(s) = s^3(U_{N-4}(35\,N^2 - 12\,N^3 - 36\,N - 7) + U_{N-3}(130\,N^2 - 45\,N^3 - 135\,N - 26) - N^2 - 1) \\ + s^2(U_{N-4}(21 - 12\,N^3 + 2\,N + 45\,N^2) + U_{N-3}(7\,N + 168\,N^2 - 45\,N^3 + 78) + 3 + 2\,N - 3\,N^2) \\ - 6\,sN(3\,U_{N-4}(N+1) + 11\,U_{N-3}(N+1) + 1) + 6\,N^2 = 0. \end{aligned}$$

Here

$$\begin{aligned} d_1 = s(24\, + (2016\,N - 2328\,)U_{N-4} + (540\,N - 624\,)U_{N-5}) \\ + 2016\,U_{N-4}N + 540\,U_{N-5}N(s-N)^2. \end{aligned}$$

Note that d_1 is nonzero for $-1 \leq s \leq 1$. To see that the above cubic has a zero for $|s| < 1$, we evaluate the polynomial p_N at $s = \pm 1$. Thus,

$$p_N(1) = -2\;(N-1)^2\,((45\,N - 26)\,U_{N-3} + (12\,N - 7)\,U_{N-4} - 1)$$

and

$$p_N(-1) = 4\;(N+1)^2\,(1 + 7\,U_{N-4} + 26\,U_{N-3})\,.$$

Since $|U_{N-3}| > |U_{N-4}| \geq 0$ and $|U_{N-3}| \geq 1$ for $N \geq 3$ and since sign $U_{N-3} = (-1)^{N+1}$, we see that sign $p_N(1) = (-1)^N$, while sign $p_N(-1) = (-1)^{N+1}$ for $N \geq 3$.

It now follows from $p_N(0) > 0$ that there is a real root s_N of p_N with $|s_N| < 1$ and sign $s_N = (-1)^{N+1}$, $N \geq 3$.

Thus we have shown the following.

THEOREM 5.4. *For $N \geq 3$ and $s_i = s, 0 \leq i \leq N-1$, with s a real root of $p_N, |s| < 1$, there exist continuous, compactly supported, orthogonal scaling functions $\{\phi^i\}_{i=0}^{N-1}$ supported on $[0,2]$ such that this set and its integer translates span $\tilde{V}_0$.*

We now give some examples from the above theorem (here we have factored a constant out of $p_N(s)$). For $N = 3$, $p_3(s) = 9s^3 - 7s^2 + 15s - 1$, $q_1 = -\frac{4}{3}(9s^2 + 2s - 3)/((3s+5)(s-3))$, and $q_2 = \frac{1}{3}(18s^3 - 9s^2 - 22s - 3)/((3s+5)(s-3))$. For $N =$

4, $p_4(s) = 53s^4+3s^2+51s+1$, $q_3 = \frac{1}{4}(48s^3 - 25s^2 - 61s + 2)/((5s + 7)(s - 4))$, $q_2 = \frac{1}{2}(2s + 1)(3s + 1)/(5s + 7)$, and $q_1 = -\frac{3}{4}(4s^3 + 33s^2 + 9s - 10)/((5s + 7)(s - 4))$. Finally, for $N = 5$, we have $p_5(s) = 7153s^3 + 3061s^2 + 4595s - 25$.

Acknowledgments. The second and third authors would like to thank Ingrid Daubechies and Gil Strang for their encouragement and insights.

CONTINUOUS DEPENDENCE ON INITIAL DATA FOR DISCONTINUOUS SOLUTIONS OF THE NAVIER–STOKES EQUATIONS FOR ONE-DIMENSIONAL, COMPRESSIBLE FLOW*

DAVID HOFF†

Abstract. We prove that discontinuous solutions of the Navier–Stokes equations for one-dimensional, compressible fluid flow depend continuously on their initial data. Perturbations in the different components are measured in various fractional Sobolev norms; L^2 bounds are then obtained by interpolation. This improves upon earlier results in which continuous dependence was known only in a much stronger topology, one inappropriately strong for the physical model. More generally, we derive a bound for the difference between exact and approximate weak solutions in terms of their initial differences and of the weak truncation error associated with the approximate solution.

Key words. continuous dependence, discontinuous solutions, Navier–Stokes equations

AMS subject classifications. 35Q30, 35R05, 65M15

1. Introduction.

We prove the continuous dependence on initial data of discontinuous solutions of the Navier–Stokes equations for one-dimensional, compressible fluid flow,

$$(1.1)\qquad \begin{cases} v_t - u_x = 0, \\ u_t + p(v,e)_x = \left(\frac{\varepsilon u_x}{v}\right)_x, \\ e_t + u_x p(v,e) = \frac{\varepsilon u_x^2}{v} + \lambda\left(\frac{T(e)_x}{v}\right)_x, \end{cases}$$

with Cauchy data

$$(1.2)\qquad (v,u,e)\big|_{t=0} = (v_0,u_0,e_0)$$

under assumptions consistent with the known existence theory. Here v, u, e, p, and T represent, respectively, the specific volume, velocity, specific internal energy, pressure, and temperature in the fluid, $t \geq 0$ is time, and $x \in \mathbb{R}$ is the Lagrangean coordinate (thus the lines $x =$ constant correspond to particle trajectories). ε and λ are positive viscosity and heat-conduction coefficients.

The key point of interest here is that the topology of continuous dependence is that of $L^2(\mathbb{R})$, which is particularly appropriate for the physical problem. By contrast, the only other known continuous dependence result, Theorem 4.1 of [2], is formulated in an exceptionally strong norm, one which dominates the *variation* in perturbations of the discontinuous quantity v. This norm appeared to be natural for certain technical reasons related to the fact that only incomplete smoothing occurs, owing to the degeneracy of the viscosity matrix and also to the particular rates of (partial) smoothing near the initial layer $t = 0$. On the other hand, this very strong norm is not at all appropriate from the physical point of view. For example, the mass measure is one

of the physically observable quantities, and the density $1/v$ is its derivative. The result of [2] therefore requires that the local variation in the derivative of an observable quantity be small; and this we must regard as unsatisfactory. There is also a very practical reason for clarifying the issue of continuous dependence; this is the fact that error bounds for approximate solutions can be derived only in norms in which the problem is known to be well posed. In particular, for the system under consideration here, error bounds for certain finite difference approximations are derived in Zhao and Hoff [4]; the rates of convergence obtained are unrealistically low, however, precisely because they are formulated in a norm which is inappropriately strong.

The goal of the present paper is therefore to show that, under assumptions consistent with the known existence theory of [1] and [2], discontinuous solutions depend continuously on their initial values in L^2, which is clearly a more suitable norm for the physical problem. This result is stated in the theorem below and is proved in §§2 and 3. (Actually, we prove a more general result, in which the difference between an exact weak solution and an approximate weak solution is bounded in terms of the truncation error associated with the latter and the difference in initial values.) The key idea is to substitute an adjoint-equation analysis for the more usual approach based on direct L^2-energy estimates. The adjoint functions are estimated in (positive) fractional Sobolev norms; error bounds are obtained by duality in (negative) fractional Sobolev norms, and L^2 information is then extracted by interpolation. As we shall see, this device has the effect of splitting nonintegrable singularities at $t = 0$ into the integrable products of singularities at the initial and forward times.

The present paper generalizes the result of Hoff and Zarnowski [3], in which L^2-continuous dependence was proved for the isentropic/isothermal version of (1.1), which consists of the first two equations only and with $p = p(v)$. The full Navier–Stokes system discussed here presents a number of technical complexities and difficulties not encountered in the simpler case, owing particularly to the coupling of the square of the velocity gradient into the energy equation in (1.1).

We now give a precise formulation of our results. First, concerning the functions p and T appearing in (1.1), we assume that there is a compact rectangle $R = [\underline{v}, \bar{v}] \times [\underline{e}, \bar{e}]$ contained in the open, positive quadrant of v-e space, such that

$$p \in C^1(R), \qquad T \in C^2([\underline{e},\bar{e}]), \tag{1.3}$$

and that there is a positive constant C such that

$$\begin{cases} C^{-1} \le T'(e), \\ C^{-1}e \le T(e) \le Ce \end{cases} \tag{1.4}$$

for $e \in [\underline{e}, \bar{e}]$.

Next, in order to describe weak solutions having different values at $x = \pm\infty$, we introduce states $U_\pm = [v_\pm, u_\pm, e_\pm]^t$ with $(v_\pm, e_\pm) \in R$, and we construct a smooth function $\tilde{U}(x) = [\tilde{v}(x), \tilde{u}(x), \tilde{e}(x)]^t$ such that

$$\tilde{U}(x) = U_\pm, \qquad \pm x \ge 1. \tag{1.5}$$

Weak solutions $U = [v, u, e]^t$ on $\mathbb{R} \times [0, \bar{t}]$ with initial value U_0 and end-states $U_\pm$ should then satisfy the following minimal regularity conditions:

$$U - \tilde{U} \in C([0, \bar{t}\,]; L^2(\mathbb{R})), \tag{1.6}$$

$$U(\cdot,0) = U_0, \tag{1.7}$$

$$(v,e) \in R \quad \text{a.e.}, \tag{1.8}$$

$$u - \tilde{u}, e - \tilde{e} \in L^2((0,\bar{t}\,); H^1(\mathbb{R})). \tag{1.9}$$

We let X denote the test-function space

$$X([t_1,t_2]) = (L^1 \cap L^\infty \cap H^1 \cap C^1)(\mathbb{R} \times [t_1,t_2]),$$

and we give the following weak formulation of the system (1.1)–(1.2).

DEFINITION. *Let $U = [v,u,e]^t$ satisfy* (1.6)–(1.9) *above. Then U is a weak solution of* (1.1) *on $\mathbb{R} \times [0,\bar{t}\,]$ with initial value U_0 and end-states $U_\pm$ provided that, for all intervals $[t_1,t_2] \subseteq [0,\bar{t}\,]$ and all test functions $\varphi, \psi, \chi \in X([t_1,t_2])$,*

$$\begin{aligned} \mathcal{L}_1(t_1,t_2,\varphi;U) \equiv \int (v - \tilde{v})\varphi\, dx\Big|_{t_1}^{t_2} + \int_{t_1}^{t_2} \int [(\tilde{v} - v)\varphi_t + u\varphi_x]\, dxdt \\ = 0; \end{aligned} \tag{1.10}$$

$$\begin{aligned} \mathcal{L}_2(t_1,t_2,\psi;U) &\equiv \int (u - \tilde{u})\psi\, dx\Big|_{t_1}^{t_2} \\ &\quad + \int_{t_1}^{t_2} \int \left[(\tilde{u} - u)\psi_t - p(v,e)\psi_x + \frac{\varepsilon u_x \psi_x}{v}\right] dxdt \\ &= 0; \end{aligned} \tag{1.11}$$

(1.12)

$$\begin{aligned} \mathcal{L}_3(t_1,t_2,\chi;U) &\equiv \int (e - \tilde{e})\chi\, dx\Big|_{t_1}^{t_2} \\ &\quad + \int_{t_1}^{t_2} \int \left[(\tilde{e} - e)\chi_t + \left(u_x p(v,e) - \frac{\varepsilon u_x^2}{v}\right)\chi + \frac{\lambda T(e)_x \chi_x}{v}\right] dxdt \\ &= 0. \end{aligned}$$

The existence of weak solutions and their additional regularity properties will be discussed below.

Solutions and approximate solutions will be compared in various fractional-norm Sobolev spaces. To describe these, we let $\beta \in \mathbb{R}$ and $\varphi \in \mathcal{S}$ ($\mathcal{S}$ is the Schwartz class of smooth, rapidly decreasing functions), and we define

$$|\varphi|_\beta = \left[\int_{\mathbb{R}} (1 + |\xi|)^{2\beta} |\hat{\varphi}(\xi)|^2 d\xi\right]^{1/2},$$

where $\hat{}$ denotes the Fourier transform. We then take H^β to be the completion of $\mathcal{S}$ with respect to the norm $|\cdot|_\beta$. Observe that if $\beta_1 \leq \beta_2$, then $|\varphi|_{\beta_1} \leq |\varphi|_{\beta_2}$, so that $H^{\beta_2} \subseteq H^{\beta_1}$. $|\cdot|_0$ is the usual L^2-norm, which we shall always denote by $\|\cdot\|$. Standard properties of the Fourier transform show that, given a nonnegative integer k, there is a positive constant $C = C(k)$ such that

$$C^{-1}|\varphi|_k \leq \sum_{0\leq j\leq k} \left\| \frac{d^j\varphi}{dx^j} \right\| \leq C|\varphi|_k.$$

We now choose indices α, β, and δ satisfying

$$\left\{ \begin{array}{l} \beta \in (0,1), \\ 0 < \alpha < \delta < \min\{\beta, 1/2\}. \end{array} \right. \tag{1.13}$$

The difference between an exact weak solution U and an approximate solution $U^h = [v^h, u^h, e^h]^t$ will be measured in the norm given by

$$\begin{aligned} E(t) = \|\Delta v(\cdot,t)\| &+ |\Delta u(\cdot,t)|_{-\alpha} + |\Delta e(\cdot,t)|_{-\beta} \\ &+ t^{\delta/2}\|\Delta u(\cdot,t)\| + t^{\beta/2}\|\Delta e(\cdot, t)\|, \end{aligned} \tag{1.14}$$

where $\Delta v = v^h - v$, etc. The constants α, β, and δ will be fixed throughout.

Clearly, an estimate for $E(t)$ must involve not only the initial difference $E(0)$, but also some measure of the extent to which the approximate solution U^h fails to be an exact weak solution. This measure, which we call the weak truncation error, is essentially the norm of the functional $\mathcal{L}_1 \oplus \mathcal{L}_2 \oplus \mathcal{L}_3$ over the space X^3, suitably topologized. Specifically, given $(\varphi, \psi, \chi) \in X([t_1, t_2])^3$, we first define the norm

(1.15)

$$\begin{aligned} |\!|\!|(\varphi, \psi, \chi)|\!|\!|_{[t_1,t_2]} = \sup_{t_1\leq t\leq t_2} \Big[&\|\varphi(\cdot, t)\| + |\psi(\cdot,t)|_\alpha + |\chi(\cdot,t)|_\beta \\ &(t_2 - t)^{(1-\alpha)/2}\|\psi_x(\cdot,t)\| + (t_2 - t)^{(1-\beta)/2}\|\chi_x(\cdot,t)\| \Big] \\ &+ \left(\int_{t_1}^{t_2} \int \left[\psi_x^2 + \chi_x^2 + (t_2 - t)^{1-\alpha}\psi_t^2 + (t_2 - t)^{1-\beta}\chi_t^2 \right] dxdt \right)^{1/2}. \end{aligned}$$

Then given an approximate solution $U^h = [v^h, u^h, e^h]^t$ satisfying (1.6)–(1.9), we define the weak truncation error

(1.16)

$$Q_1(t_1, t_2; U^h) = \sup \frac{|\mathcal{L}_1(s_1, s_2, \varphi; U^h)| + |\mathcal{L}_2(s_1, s_2, \psi; U^h)| + |\mathcal{L}_3(s_1, s_2, \chi; U^h)|}{|\!|\!|(\varphi, \psi, \chi)|\!|\!|_{[s_1,s_2]}}.$$

The sup here is taken over intervals $[s_1,s_2] \subseteq [t_1, t_2]$ and over test functions $(\varphi, \psi, \chi) \in X([s_1,s_2])^3$. It is clear that the first three terms in the definition (1.15) of $|\!|\!|(\varphi, \psi, \chi)|\!|\!|$ are dual to the first three terms in the definition (1.14) of $E(t)$. The other terms in (1.15) appear for technical reasons and reflect anticipated rates of smoothing for the adjoint system corresponding to (1.1). We shall also have need for the following auxiliary error functionals:

$$Q_2(t_1, t_2; U^h)^2 = \sup \left[\limsup_{\eta\to 0} |\mathcal{L}_2(s_1, s_2, j_\eta * t^\delta \Delta u; U^h)| \right], \tag{1.17}$$

where $j_\eta(x,t)$ is the standard space–time mollifier and the outer sup is over intervals $[s_1, s_2] \subseteq (t_1, t_2)$; and

$$Q_3(t_1, t_2; U^h) = \sup |\mathcal{L}_3(s_1, s_2, t^{\beta/2}\chi; U^h)|, \tag{1.18}$$

where the sup is again taken over intervals $[s_1, s_2] \subseteq [t_1, t_2]$ and over test functions $\chi \in X([s_1, s_2])$ for which

(1.19)
$$\sup_{s_1 \leq t \leq s_2} [\|\chi(\cdot,t)\| + (s_2 - t)^{1/2}\|\chi_x(\cdot,t)\|] + \left[\int_{s_1}^{s_2} \int [\chi_x^2 + (s_2 - t)\chi_t^2] \; dxdt\right]^{1/2} \leq 1.$$

Finally, we define the total truncation error,

$$Q = Q_1 + Q_2 + Q_3. \tag{1.20}$$

We expect that, in most contexts, Q_1 will be the dominant term in Q. Observe that, if U^h is an *exact* weak solution with end-states $U_\pm$, then $Q(t_1, t_2; U^h) = 0$.

Next, we describe the regularity properties of weak solutions which will be required for our analysis. Besides the minimal conditions (1.6)–(1.9), we shall assume that there are positive constants C_0 and r such that

$$\sup_{0 \leq t \leq \bar{t}} \|U(\cdot,t) - \tilde{U}\|^2 + \int_0^{\bar{t}} \int (u_x^2 + e_x^2) \; dxdt \leq C_0; \tag{1.21}$$

$$\begin{cases} v_t, u_x, e_x \in C((0, \bar{t}\,] \; ; L^2(\mathbb{R})) \text{ and} \\ \|v_t(\cdot,t)\|, \|u_x(\cdot,t)\|, \|e_x(\cdot,t)\| \leq C_0^{1/2} t^{-1/4}; \end{cases} \tag{1.22}$$

$$\begin{cases} v_t, u_x \in L^\infty_{\text{loc}} ((0,\bar{t}] \; ; L^\infty(\mathbb{R})) \text{ and} \\ \displaystyle\int_0^{\bar{t}} t^{\min\{\delta,\beta/2\}} \|u_x(\cdot,t)\|^2_{L^\infty(\mathbb{R})} dt \leq C_0, \\ \displaystyle\int_{t_1}^{t_2} \|v_t(\cdot,t)\|_{L^\infty(\mathbb{R})} dt \leq C_0^{1/2} |t_2 - t_1|^r; \end{cases} \tag{1.23}$$

$$u_t \in L^2((\tau, \bar{t}); L^2(\mathbb{R})) \text{ for all } \tau > 0. \tag{1.24}$$

Some discussion of these assumptions is in order. First, the local existence theory of [1] shows that (even when p and T are somewhat more general than in (1.3) and (1.4)) a local solution exists and satisfies all but two of the conditions (1.6)–(1.12) and (1.21)–(1.24), with C_0 a multiple of the initial norm $\|U_0 - \tilde{U}\|^2 + [\text{Var}(v_0)]^2 + [\text{Var}(u_0)]^2$, which is assumed to be finite. The two exceptions are the continuity (1.6) of $e(\cdot, t)$ into $L^2(\mathbb{R})$ at $t = 0$ and the smoothing rate in (1.22) for $\|e_x(\cdot,t)\|$. The second of these is proved in [2, Thm. 3.2], but under the additional assumptions that p and T satisfy the conditions (1.3) and (1.4), that $e_0 \in BV$, and that

$$\lambda^{1/2} C_0 \|T''\|^2_{L^\infty([\underline{e}, \bar{e}])} \ll 1, \tag{1.25}$$

where C_0 is now a multiple of $\|U_0 - \tilde{U}\|^2 + [\text{Var}(U_0)]^2$. Once the smoothing rate $\|e_x(\cdot,t)\| \sim t^{-1/4}$ has been established, an easy energy argument can be applied to the third equation in (1.1) to obtain that $\int_0^{\bar{t}} \int_{\mathbb{R}} t^{1/2+\theta} e_t^2 \, dxdt < \infty$ for any $\theta > 0$ (this is the analogue for e of the estimates (1.17) and (1.20) in [1] for u). The continuity (1.6) of $e(\cdot,t)$ into L^2 at $t = 0$ then follows easily. We observe that the condition (1.25) is vacuous in the polytropic case that T is a constant multiple of e and is in any event rather mild since λ is presumably small. We also point out that the rates of smoothing in (1.22) for u_x and e_x are optimal, even for solutions of the heat equation with initial data in $L^2 \cap BV$.

Concerning the assumptions (1.23), we appeal to the result (1.4) of Theorem 1.1 in [1], which shows that, for any $\theta > 0$,

$$\sup_{0<t\leq \bar{t}} t^{1/2+\theta}(\|u_x(\cdot,t)\|_{L^\infty} + \|v_t(\cdot,t)\|_{L^\infty}) < \infty.$$

This provides more than adequate justification for the assumptions (1.23).

In the present paper, we simply assume that a weak solution U exists and satisfies the conditions (1.6)–(1.12) and (1.21)–(1.24); it will be unnecessary to make explicit reference to particular properties of U_0 or to relate U_0 to the constant C_0. The smallness condition (1.25), on the other hand, will be made an explicit hypothesis in our main theorem, stated below. It appears to be necessary in order to achieve the required estimates for solutions of the adjoint of the first variation of the energy equation in (1.1) (see Lemma 2.2 below).

We can now state our main result.

THEOREM. *Assume that p and T satisfy the conditions* (1.3)–(1.4) *and let $\tilde{U}$ be as described above in* (1.5). *Then there are positive constants C and ζ such that, if U is a weak solution of* (1.1) *with end-states $U_\pm$, satisfying* (1.6)–(1.12) *and* (1.21)–(1.24), *if U^h satisfies* (1.6), (1.8), (1.9), *and* (1.21)–(1.24), *and if*

$$\lambda^{1/2} C_0 \|T''\|^2_{L^\infty([\underline{e},\bar{e}])} < \zeta, \tag{1.26}$$

then for intervals $[t_1, t_2] \subseteq [0, \bar{t}]$,

$$\sup_{t_1\leq t\leq t_2} E(t) + \left[\int_{t_1}^{t_2}\int t^\delta \Delta u_x^2\, dxdt\right]^{1/2} \leq C\left[E(t_1) + Q(t_1,t_2;U^h)\right]. \tag{1.27}$$

The error functional $E(t)$ here is as defined above in (1.14), *with $\Delta u = u^h - u$, etc., and Q is the total truncation error, defined in* (1.16)–(1.20). *The constant ζ depends only on $\underline{v}$, $\inf_{[\underline{e},\bar{e}]} T'(e)$ (see* (1.3)–(1.4)), *and on an upper bound for λ. The constant C depends on ϵ, λ, $p\big|_R$, $T\big|_{[\underline{e},\bar{e}]}$, α, β, δ, and r, and on upper bounds for C_0 and the reciprocal of the difference between the two sides of* (1.26).

(1.27) shows in particular that

$$\sup_{0\leq t\leq \bar{t}} \left[\|\Delta v(\cdot,t)\| + |\Delta u(\cdot,t)|_{-\alpha} + |\Delta e(\cdot,t)|_{-\beta}\right] \leq C[E(0) + Q(0,\bar{t};U^h)], \tag{1.28}$$

where

$$E(0) = \|\Delta v_0\| + |\Delta u_0|_{-\alpha} + |\Delta e_0|_{-\beta}.$$

Bounds for Δu and Δe in L^2 can be recovered in either of two ways, both of which entail the introduction of an initial layer. First, we may simply appeal to the definition (1.14) of E to obtain

$$\sup_{0\leq t\leq \bar{t}} \left[\|\Delta v(\cdot,t)\| + t^{\delta/2}\|\Delta u(\cdot,t)\| + t^{\beta/2}\|\Delta e(\cdot,t)\|\right] \leq C[E(0) + Q(0,\bar{t};U^h)]. \tag{1.29}$$

Alternatively, we may apply the bounds (1.22) for u_x and e_x and interpolate as follows:

$$\begin{aligned}\|\Delta u(\cdot,t)\| = |\Delta u|_0 &\leq |\Delta u|_1^{\alpha/(1+\alpha)} |\Delta u|_{-\alpha}^{1/(1+\alpha)} \\ &\leq Ct^{-\alpha/4(1+\alpha)} |\Delta u|_{-\alpha}^{1/(1+\alpha)},\end{aligned}$$

so that

$$|\Delta u|_{-\alpha} \geq C^{-1} t^{\alpha/4} \|\Delta u\|^{1+\alpha}.$$

Treating Δe in a similar way, we then find from (1.28) that

$$\begin{aligned}\sup_{0\leq t\leq \bar{t}} &\left[\|\Delta v(\cdot,t)\| + t^{\alpha/4}\|\Delta u(\cdot,t)\|^{1+\alpha} + t^{\beta/4}\|\Delta e(\cdot,t)\|^{1+\beta}\right] \\ &\leq C[E(0) + Q(0,\bar{t};U^h)].\end{aligned} \tag{1.30}$$

(1.30) may be an improvement over (1.29), depending upon the context.

The bounds (1.29) and (1.30) degenerate when t is close to zero. This difficulty may be dealt with as follows. The result (1.20) in Theorem 1.1 of [1] shows that, for every $\theta > 0$, there is a constant $C = C(\theta)$ such that

$$\int_0^{\bar{t}} \int t^{(1+\theta)/2} u_t^2 \, dx dt \leq C. \tag{1.31}$$

The same bound holds for e_t, at least under the hypotheses of the present theorem, as discussed above. It then follows easily that

$$\|u(\cdot,t) - u_0\|, \; \|e(\cdot,t) - e_0\| \leq Ct^{(1-\theta)/4}.$$

If the bound (1.31) holds as well for u_t^h and e_t^h (as when U^h itself is an exact weak solution), we can then simply triangulate to obtain that, for any $\theta > 0$, there is a constant $C = C(\theta)$ such that

$$\|\Delta u(\cdot,t)\| + \|\Delta e(\cdot,t)\| \leq C\left[\|\Delta u_0\| + \|\Delta e_0\| + t^{(1-\theta)/4}\right]. \tag{1.32}$$

(1.32) may be an improvement over (1.29) or (1.30) when t is close to zero.

In the case that U^h is itself an exact weak solution, $Q(0,\bar{t};U^h) = 0$, and (1.28)–(1.30) imply the uniqueness of weak solutions of the initial-value problem for (1.1) as well as the continuous dependence of the solution on the initial condition. Alternatively, when U^h is an approximation to U, the results (1.28)–(1.30) allow for the derivation of bounds for the error $U^h - U$ from bounds for the weak truncation error Q, which is a measure of the *consistency* of the numerical procedure used to generate U^h, and which presumably can be estimated in terms of mesh parameters or ranks of projection operators.

In §2, we prove the above theorem be estimating the various terms appearing in the definition (1.14) of E. The key estimates are obtained by subtracting the weak equations $\mathcal{L}_j(\cdot\,; U) = 0$ from the corresponding definitions (1.10)–(1.12) of the functionals $\mathcal{L}_j(\cdot\,; U^h)$ and choosing the test functions to satisfy an appropriate adjoint system. These adjoint equations are solved backwards in time, with "initial" data given in the appropriate dual classes. We state a number of important properties of these adjoint solutions, which we then apply to prove the main estimate (1.27). Bounds for the adjoint solutions follow from standard energy methods and interpolation theorems and are derived in §3.

2. Proof of the theorem. In this section, we prove the theorem described in §1 by estimating the various terms appearing in the definition (1.14) of $E(t)$. These estimates will be obtained in a sequence of lemmas directly from the weak forms (1.10)–(1.12), in which the test functions φ, ψ, and χ will be chosen to satisfy appropriate adjoint equations. The hypotheses of the theorem will be in force throughout this section, and C will always denote a generic positive constant as described in the theorem.

We begin with a bound for the term $t^{\beta/2}\|\Delta e(\cdot,t)\|$.

LEMMA 2.1. *There is a constant C such that, for $0 \le t_1 \le t_2 \le \bar{t}$,*

$$\begin{aligned} t_2^{\beta/2}\|\Delta e(\cdot,t_2)\| \le C\Bigg[& t_1^{\beta/2}\|\Delta e(\cdot,t_1)\| + \sup_{t_1\le t\le t_2}\left(\|\Delta v(\cdot,t)\| + |\Delta e(\cdot,t)|_{-\beta}\right) \\ & + \left(\int_{t_1}^{t_2}\int t^{\delta}\Delta u_x^2 dxdt\right)^{1/2} + Q_3(t_1,t_2;U^h)\Bigg] \end{aligned} \tag{2.1}$$

Proof. Without loss of generality, $[t_1,t_2] \subseteq (0,\bar{t})$. We subtract the equation $\mathcal{L}_3(t_1,t_2,t^{\beta/2}\chi;U) = 0$ from the definition (1.12) of $\mathcal{L}_3(t_1,t_2,t^{\beta/2}\chi;U^h)$ and rearrange to obtain

$$\begin{aligned} & t^{\beta/2}\int \Delta e(x,t)\chi(x,t)\,dx\Big|_{t_1}^{t_2} \\ &= \int_{t_1}^{t_2}\int t^{\beta/2}\Bigg[\Delta e\chi_t - \lambda\frac{\Delta T_x}{v^h}\chi_x - \lambda\left(\frac{1}{v^h}-\frac{1}{v}\right)T_x\chi_x \\ &\quad - \left(\Delta u_x p^h + \Delta p u_x - \varepsilon\frac{(u_x^h)^2 - u_x^2}{v^h} - \varepsilon\left(\frac{1}{v^h}-\frac{1}{v}\right)u_x^2\right)\chi\Bigg]\,dxdt \\ &\quad + \frac{\beta}{2}\int_{t_1}^{t_2}\int t^{(\beta/2)-1}\Delta e\chi\,dxdt + \mathcal{L}_3(t_1,t_2,t^{\beta/2}\chi;U^h). \end{aligned} \tag{2.2}$$

We shall choose the function χ so that the first two terms on the right here cancel, modulo lower order terms. Specifically, we let j_η be the standard space–time mollifier and we define $e_\eta = j_n * e$, $e_\eta^h = j_\eta * e^h$, and $v_\eta^h = j_\eta * v^h$. We let $A(x,t) = T[e^h(x,t), e(x,t)]$ be the usual divided difference, and $A_\eta = T[e_\eta^h, e_\eta]$. We then take χ to be the solution of the following adjoint system, solved backwards in time, with data specified at $t = t_2$:

$$\begin{cases} \chi_t + \lambda A_\eta\left(\dfrac{\chi_x}{v_\eta^h}\right)_x = 0, & t \le t_2, \\ \chi(x,t_2) = H(x). \end{cases} \tag{2.3}$$

For the present, we take H in the Schwartz class $\mathcal{S}(\mathbb{R})$. The first two terms on the right side of (2.2) then become

$$-\lambda\int_{t_1}^{t_2}\int t^{\beta/2}\left[\left(\frac{1}{v^h}-\frac{1}{v_\eta^h}\right)\Delta T_x\chi_x + \Big((A-A_\eta)\Delta e\Big)_x\frac{\chi_x}{v_\eta^h}\right]dxdt.$$

We thus obtain from (2.2) that

$$\begin{aligned} t_2^{\beta/2}\left|\int \Delta e(x,t_2)H(x)\,dx\right| &\leq t_1^{\beta/2}\left|\int (\Delta e\chi)(x,t_1)\,dx\right| \\ &+C\int_{t_1}^{t_2}\int t^{\beta/2}\Big[\left|\chi_x\Delta T_x(v^h-v^h_\eta)\right|+\left|\Big((A-A_\eta)\Delta e\Big)_x\chi_x\right| \\ &\qquad +|\Delta vT_x\chi_x|+|\Delta u_x\chi|+|\Delta pu_x\chi| \\ &\qquad +|(u^h_x+u_x)\Delta u_x\chi|+|\Delta vu^2_x\chi|\Big]\,dxdt \\ &+C\left|\int_{t_1}^{t_2}\int t^{(\beta/2)-1}\Delta e\chi\,dxdt\right|+|\mathcal{L}_3(t_1,t_2,t^{\beta/2}\chi;U^h)|. \end{aligned} \tag{2.4}$$

We shall bound each of the terms on the right side of (2.4) in terms of $\|H\|$ and then let $\eta\to 0$. First, however, we need to obtain various estimates for the adjoint function χ in terms of its data H.

LEMMA 2.2. *There are positive constants ζ and C, as described in the statement of the theorem, and independent of η, such that, if (1.26) holds, then the solution χ of the system (2.3) satisfies*

$$\begin{aligned} &\sup_{0\leq t\leq t_2}\left[\|\chi(\cdot,t)\|+(t_2-t)^{1/2}\|\chi_x(\cdot,t)\|\right] \\ &\qquad +\left(\int_0^{t_2}\left[\|\chi_x(\cdot,t)\|^2+(t_2-t)\|\chi_t(\cdot,t)\|^2\right]dt\right)^{1/2} \\ &\leq C\|H\| \end{aligned} \tag{2.5}$$

and

$$\sup_{0\leq t\leq t_2}\|\chi_x(\cdot,t)\|+\left(\int_0^{t_2}\|\chi_t(\cdot,t)\|^2\,dt\right)^{1/2}\leq C|H|_1. \tag{2.6}$$

(2.5) and (2.6) follow from standard energy estimates; details are deferred to §3.

We now apply Lemma 2.2 to bound each of the terms on the right side of (2.4) in terms of $\|H\|$; we then let $\eta\to 0$ and take the sup over $H\in\mathcal{S}$. We shall present the details for five representative terms. Similar arguments apply to the others.

Applying Lemma 2.2, we may bound the first term in the double integral in (2.4) by

$$C\left[\int_{t_1}^{t_2}\int \Delta T_x^2(v^h-v^h_\eta)^2dxdt\right]^{1/2}.$$

The integrand here approaches zero a.e. as $\eta\to 0$ and is bounded pointwise by $C\Delta T_x^2\in L^1(\mathbb{R}\times[t_1,t_2])$. This term therefore approaches zero as $\eta\to 0$. Next, we split the fifth term in the double integral in (2.4) by writing $|\Delta p|\leq C(|\Delta v|+|\Delta e|)$. Applying (1.22) and Lemma 2.2, we may then bound the second of the terms that result by

$$\begin{aligned} \int_{t_1}^{t_2}\int t^{\beta/2}|\Delta eu_x\chi|dxdt &\leq C\sup_{t_1\leq t\leq t_2}(t^{\beta/2}\|\Delta e(\cdot,t)\|)\int_{t_1}^{t_2}\|\chi(\cdot,t)\|^{1/2}\|\chi_x(\cdot,t)\|^{1/2}\|u_x(\cdot,t)\|\,dt \\ &\leq C\|H\|\sup_t(t^{\beta/2}\|\Delta e\|)\int_{t_1}^{t_2}(t_2-t)^{-1/4}t^{-1/4}dt \\ &\leq C|t_2-t_1|^{1/2}\|H\|\sup_t(t^{\beta/2}\|\Delta e\|). \end{aligned}$$

Applying (1.22) and Lemma 2.2 again, we may bound the next term in (2.4) by

$$\begin{aligned}\int_{t_1}^{t_2}\int t^{\beta/2}|u_x\Delta u_x\chi|dxdt &\le C\left(\int\int t^{\delta}\Delta u_x^2\right)^{1/2}\left(\int_{t_1}^{t_2} t^{\beta-\delta}\|\chi\|\|\chi_x\|\|u_x\|^2dt\right)^{1/2}\\ &\le C\|H\|\left(\int_{t_1}^{t_2}\int t^{\delta}\Delta u_x^2\right)^{1/2}\left(\int_{t_1}^{t_2} t^{\beta-\delta-1/2}(t_2-t)^{-1/2}dt\right)^{1/2}\\ &\le C\|H\|\left(\int_{t_1}^{t_2}\int t^{\delta}\Delta u_x^2\right)^{1/2}\end{aligned}$$

since $\beta > \delta$ by (1.13). Next, we bound the second last term in (2.4) by

$$\begin{aligned}&C\int_{t_1}^{t_2} t^{(\beta/2)-1}|\Delta e(\cdot,t)|_{-\beta}|\chi(\cdot,t)|_{\beta}\,dt\\ &\qquad\le C\sup_{t_1\le t\le t_2}|\Delta e(\cdot,t)|_{-\beta}\int_{t_1}^{t_2} t^{(\beta/2)-1}\|\chi(\cdot,t)\|^{1-\beta}\|\chi_x(\cdot,t)\|^{\beta}\,dt\\ &\qquad\le C\|H\|\sup|\Delta e|_{-\beta}\int_{t_1}^{t_2} t^{(\beta/2)-1}(t_2-t)^{-\beta/2}dt\\ &\qquad\le C\|H\|\sup|\Delta e|_{-\beta}\end{aligned}$$

since $\beta > 0$. Finally, since $\mathcal{L}_3$ is linear in the test function, we can apply the definition (1.18) of Q_3 to bound the last term in (2.4) by $\|H\|Q_3(t_1,t_2;U^h)$. Assembling all these estimates, then letting $\eta \to 0$ and taking the sup over $H \in \mathcal{S}$, we obtain from (2.4) that

$$\begin{aligned}t_2^{\beta/2}\|\Delta e(\cdot,t_2)\| \le C\Bigg[&t_1^{\beta/2}\|\Delta e(\cdot,t_1)\| + |t_2-t_1|^{1/2}\sup_{t_1\le t\le t_2}\left(t^{\beta/2}\|\Delta e(\cdot,t)\|\right)\\ &+\sup_{t_1\le t\le t_2}\left(\|\Delta v(\cdot,t)\| + |\Delta e(\cdot,t)|_{-\beta}\right)\\ &+\left(\int_{t_1}^{t_2}\int t^{\delta}\Delta u_x^2\right)^{1/2} + Q_3(t_1,t_2;U^h)\Bigg].\end{aligned}$$

A simple Gronwall-type estimate then enables us to eliminate the second term on the right here. This proves the lemma. □

In the following lemma, we extend the result (2.1) to include a bound for the term $t^{\delta/2}\|\Delta u(\cdot,t)\|$ appearing in the definition (1.14) of E.

Lemma 2.3. *There is a positive constant C, as described in the statement of the theorem, such that, for $0 \le t_1 \le t_2 \le \bar{t}$,*

$$\begin{aligned}&\sup_{t_1\le t\le t_2}\left(t^{\delta/2}\|\Delta u(\cdot,t)\| + t^{\beta/2}\|\Delta e(\cdot,t)\|\right) + \left(\int_{t_1}^{t_2}\int t^{\delta}\Delta u_x^2dxdt\right)^{1/2}\\ &\qquad\le C\Bigg[t_1^{\delta/2}\|\Delta u(\cdot,t_1)\| + t_1^{\beta/2}\|\Delta e(\cdot,t_1)\|\\ &\qquad\quad+\sup_{t_1\le t\le t_2}\left(\|\Delta v(\cdot,t)\| + |\Delta u(\cdot,t)|_{-\alpha} + |\Delta e(\cdot,t)|_{-\beta}\right)\\ &\qquad\quad+Q_2(t_1,t_2;U^h) + Q_3(t_1,t_2;U^h)\Bigg].\end{aligned}\tag{2.7}$$

Proof. Without loss of generality, $[t_1,t_2]\subseteq(0,\bar{t})$. A simple approximation argument shows first that we may take $\psi = t^\delta\Delta u$ in the definition (1.11) of $\mathcal{L}_2(t_1,t_2,\psi;U^h)$ and also that $\mathcal{L}_2(t_1,t_2,t^\delta\Delta u;U)=0$. We subtract the latter equation from the definition of $\mathcal{L}_2(t_1,t_2,t^\delta\Delta u;U^h)$ and rearrange, applying the fact that

$$\int_{t_1}^{t_2}\int \Delta u\Delta u_t\,dxdt = \frac{1}{2}\int \Delta u(x,\cdot)^2dx\Big|_{t_1}^{t_2},$$

which holds because $\Delta u\in C([t_1,t_2];L^2(\mathbb{R}))$ and $\Delta u_t\in L^2(\mathbb{R}\times[t_1,t_2])$ by (1.6) and (1.24). The result is that

(2.8)

$$\begin{aligned}\frac{1}{2}t_2^\delta\|\Delta u(\cdot,t_2)\|^2 &+ \varepsilon\int_{t_1}^{t_2}\int\frac{t^\delta\Delta u_x^2}{v^h}\\ &= \frac{1}{2}t_1^\delta\|\Delta u(\cdot,t_1)\|^2 + \int_{t_1}^{t_2}\int\left[\frac{1}{2}\delta t^{\delta-1}\Delta u^2 + t^\delta\Big(\Delta p\Delta u_x + O(\Delta v)u_x\Delta u_x\Big)\right]\\ &\qquad + \mathcal{L}_2(t_1,t_2,t^\delta\Delta u;U^h).\end{aligned}$$

A simple interpolation allows us to bound the first term in the double integral on the right by

$$\begin{aligned}C&\int_{t_1}^{t_2} t^{\delta-1}|\Delta u(\cdot,t)|_{-\alpha}^{2/(1+\alpha)}|\Delta u(\cdot,t)|_1^{2\alpha/(1+\alpha)}dt\\ &\le C\sup_{t_1\le t\le t_2}|\Delta u(\cdot,t)|_{-\alpha}^{2/(1+\alpha)}\int_{t_1}^{t_2} t^{\delta-1-\alpha\delta/(1+\alpha)}\left(t^\delta\int\Delta u_x^2dx\right)^{\alpha/(1+\alpha)}dt\\ &\le C\sup|\Delta u|_{-\alpha}^{2/(1+\alpha)}\left(\int_{t_1}^{t_2}\int t^\delta\Delta u_x^2\right)^{\alpha/(1+\alpha)}\end{aligned}$$

since $\delta>\alpha$ by (1.13). The second term in the double integral in (2.8) is bounded by

$$\begin{aligned}C&\int_{t_1}^{t_2}\int t^\delta(|\Delta v|+|\Delta e|)|\Delta u_x|dxdt\\ &\le C\left(\int_{t_1}^{t_2}\int t^\delta\Delta u_x^2\right)^{1/2}\left[\sup_{t_1\le t\le t_2}\|\Delta v(\cdot,t)\| + \left(\int_{t_1}^{t_2}t^{\delta-\beta}\left(t^\beta\int\Delta e^2dx\right)dt\right)^{1/2}\right]\\ &\le C\left(\int_{t_1}^{t_2}\int t^\delta\Delta u_x^2\right)^{1/2}\left[\sup\|\Delta v\| + |t_2-t_1|^{(\delta-\beta+1)/2}\sup(t^{\beta/2}\|\Delta e\|)\right].\end{aligned}$$

Next, we can bound the third term in the double integral in (2.8) by

$$\begin{aligned}C&\Big(\int\int t^\delta\Delta u_x^2\Big)^{1/2}\sup\|\Delta v\|\int_{t_1}^{t_2}t^\delta\|\Delta u(\cdot,t)\|_\infty^2\,dt\\ &\le C\left(\int_{t_1}^{t_2}\int t^\delta\Delta u_x^2\right)^{1/2}\sup\|\Delta v\|\end{aligned}$$

by (1.23). Finally, we apply the definition (1.17) of Q_2 to bound the last term in (2.8) by $Q_2(t_1,t_2;U^h)^2$. Assembling these estimates and applying Young's inequality, we thus obtain from (2.8) that

(2.9)

$$t_2^{\delta/2}\|\Delta u(\cdot,t_2)\| + \left(\int_{t_1}^{t_2}\int t^\delta \Delta u_x^2\right)^{1/2} \leq C\Bigg[t_1^{\delta/2}\|\Delta u(\cdot,t_1)\| + \sup_{t_1\leq t\leq t_2}\left(\|\Delta v(\cdot,t)\| + |\Delta u(\cdot,t)|_{-\alpha}\right) + |t_2-t_1|^{(\delta-\beta+1)/2}\sup_{t_1\leq t\leq t_2}\left(t^{\beta/2}\|\Delta e(\cdot,t)\|\right) + Q_2(t_1,t_2;U^h)\Bigg].$$

We now add a small multiple of (2.1) to (2.9), apply a simple Gronwall argument, and then take appropriate sups to obtain the result. □

In the following lemma, we obtain bounds for the terms $\|\Delta v\|$, $|\Delta u|_{-\alpha}$, and $|\Delta e|_{-\beta}$ appearing in the definition of E.

LEMMA 2.4. *There is a positive constant C, as described in the statement of the theorem, and a positive exponent θ, depending only on α, β, δ, and r, such that, for $0\leq t_1\leq t_2\leq \bar{t}$,*

$$\sup_{t_1\leq t\leq t_2}\left(\|\Delta v(\cdot,t)\| + |\Delta u(\cdot,t)|_{-\alpha} + |\Delta e(\cdot,t)|_{-\beta}\right) \leq C\Bigg[E(t_1) + |t_2-t_1|^\theta\left(\sup_{t_1\leq t\leq t_2}E(t) + \left(\int_{t_1}^{t_2}\int t^\delta\Delta u_x^2\right)^{1/2}\right) + Q(t_1,t_2;U^h)\Bigg]. \tag{2.10}$$

Proof. Without loss of generality, $[t_1,t_2]\subseteq(0,\bar{t})$. We subtract equations (1.10)–(1.12) $\mathcal{L}_j(t_1,t_2,\cdot\,;U) = 0$ from the corresponding definitions of the functionals $\mathcal{L}_j(t_1,t_2,\cdot\,;U^h)$ for test functions $\varphi,\psi,\chi\in X([t_1,t_2])$. Writing $\Delta p = a\Delta v + b\Delta e$ and rearranging, we obtain

(2.11)

$$\begin{aligned}\mathcal{L}_1+\mathcal{L}_2+\mathcal{L}_3 &= \int(\Delta v\varphi + \Delta u\psi + \Delta e\chi)\,dx\Big|_{t_1}^{t_2}\\ &+\int_{t_1}^{t_2}\int\Bigg[-\Delta v(\varphi_t + a\psi_x) - \Delta u(\psi_t+\varphi_x) + \Delta u_x\frac{\varepsilon\psi_x}{v^h}\\ &\qquad - \Delta e\chi_t + \Delta T_x\frac{\lambda\chi_x}{v^h}\Bigg]\,dxdt\\ &+\int_{t_1}^{t_2}\int\Bigg[-b\Delta e\psi_x + \varepsilon\left(\frac{1}{v^h}-\frac{1}{v}\right)u_x\psi_x + \lambda\left(\frac{1}{v^h}-\frac{1}{v}\right)T_x\chi_x + \Delta u_x p^h\chi\\ &\qquad + \Delta p u_x\chi + \frac{\varepsilon(u_x^h+u_x)\Delta u_x}{v^h}\chi + \varepsilon\left(\frac{1}{v^h}-\frac{1}{v}\right)u_x^2\chi\Bigg]\,dxdt.\end{aligned}$$

We shall choose the test functions φ, ψ, and χ so as to effectively eliminate the first double integral on the right-hand side in (2.11). First, we again denote the standard space–time mollifier by j_n, and we write $v_\eta = j_n * v$, $v_\eta^h = j_n * v^h$, etc. Then, just as in the proof of Lemma 2.1, we take A and A_η to be the divided differences $A = T[e^h, e]$ and $A_\eta = T[e_\eta^h, e_\eta]$. Next, we define the section p^e by $p^e(v) = p(v,e)$, so that $\Delta p = p^e[v^h,v]\Delta v + p(v^h,e^h) - p(v^h,e)$. We may then take $a = p^e[v^h,v]$ and $a_\eta = p^{e_\eta}[v^h_\eta, v_\eta]$. Now, given $F, G, H \in \mathcal{S}(\mathbb{R})$, we solve the adjoint system

$$\tag{2.12} \begin{cases} \varphi_t + a_\eta \psi_x = 0, \\ \psi_t + \varphi_x + \left(\dfrac{\varepsilon \psi_x}{v^h_\eta}\right)_x = 0, \\ \chi_t + \lambda A_\eta \left(\dfrac{\chi_x}{v^h_\eta}\right)_x = 0 \end{cases}$$

backwards in time, with initial data given at $t = t_2$:

$$\tag{2.13} (\varphi, \psi, \chi)\Big|_{t=t_2} = (F, G, H).$$

Observe that the third equation in (2.12) is identical to (2.3) so that, just as in the proof of Lemma 2.1,

$$\tag{2.14} \begin{aligned} &\int_{t_1}^{t_2} \int \left(-\Delta e \chi_t + \Delta T_x \frac{\lambda \chi_x}{v^h}\right) dxdt \\ &\quad = \lambda \int_{t_1}^{t_2} \int \left[\left(\frac{1}{v^h} - \frac{1}{v^h_\eta}\right) \Delta T_x \chi_x + \Big((A - A_\eta)\Delta e\Big)_x \frac{\chi_x}{v^h_\eta}\right] dxdt. \end{aligned}$$

Substituting (2.12) and (2.14) into (2.11) and rearranging, we thus obtain that

$$\tag{2.15} \begin{aligned} &\left| \int (\Delta v \varphi + \Delta u \psi + \Delta e)(x, t_2)\, dx \right| \\ &\quad \le \left| \int (\Delta v \varphi + \Delta u \psi + \Delta e \chi)(x, t_1)\, dx \right| \\ &\qquad + \left| \int_{t_1}^{t_2} \int \left[(a_\eta - a)\Delta v \psi_x + \varepsilon \Delta u_x \psi_x \left(\frac{1}{v^h} - \frac{1}{v^h_\eta}\right) \right.\right. \\ &\qquad\qquad \left.\left. + \lambda \Delta T_x \chi_x \left(\frac{1}{v^h} - \frac{1}{v^h_\eta}\right) + \lambda \Big((A - A_\eta)\Delta e\Big)_x \frac{\chi_x}{v^h_\eta} \right] dxdt \right| \\ &\qquad + \left| \int_{t_1}^{t_2} \int \left[-b \Delta e \psi_x + \varepsilon \left(\frac{1}{v^h} - \frac{1}{v}\right) u_x \psi_x + \lambda \left(\frac{1}{v^h} - \frac{1}{v}\right) T_x \chi_x + \Delta u_x p^h \chi \right.\right. \\ &\qquad\qquad \left.\left. + \Delta p u_x \chi + \varepsilon \frac{u^h_x + u_x}{v^h} \Delta u_x \chi + \varepsilon \left(\frac{1}{v^h} - \frac{1}{v}\right) u_x^2 \chi \right] dxdt \right| \\ &\qquad + |\mathcal{L}_1| + |\mathcal{L}_2| + |\mathcal{L}_3|. \end{aligned}$$

Before proceeding further, we need to obtain various bounds for the adjoint functions φ, ψ, and χ in terms of their data F, G, and H.

LEMMA 2.5. *There are positive constants C and ζ, as described in the statement of the theorem, and independent of η, such that, if* (1.26) *holds, then the solution (φ, ψ, χ) of the adjoint system* (2.12)–(2.13) *satisfies*

$$\tag{2.16} \begin{aligned} &|||(\varphi, \psi, \chi)|||_{[t_1, t_2]} \equiv \sup_{t_1 \le t \le t_2} \Big[\|\varphi(\cdot,t)\| + |\psi(\cdot,t)|_\alpha + |\chi(\cdot,t)|_\beta \\ &\qquad + (t_2 - t)^{(1-\alpha)/2} \|\psi_x(\cdot,t)\| + (t_2 - t)^{(1-\beta)/2} \|\chi_x(\cdot,t)\| \Big] \\ &\qquad + \left(\int_{t_1}^{t_2} \int [\psi_x^2 + \chi_x^2 + (t_2 - t)^{1-\alpha} \psi_t^2 + (t_2 - t)^{1-\beta} \chi_t^2]\, dxdt \right)^{1/2} \\ &\qquad \le CK, \end{aligned}$$

where $K = \|F\| + |G|_\alpha + |H|_\beta$.

(2.16) follows from standard energy estimates and interpolation results; the proof is deferred to §3.

Applying Lemma 2.5, we can thus bound the first integral on the right-hand side of (2.15) by $CKE(t_1)$, and straightforward arguments similar to those given in the proof of Lemma 2.1 show that the second integral vanishes in the limit as $\eta \to 0$. We shall apply Lemma 2.5 to bound the two most difficult terms in the third integral on the right-hand side of (2.15); similar, but simpler, arguments apply to the other terms. The second term in the integral in question is bounded by

$$C\left[\int_{t_1}^{t_2}\int |\Delta v u_x|\left|\frac{\varepsilon\psi_x}{v_\eta^h}+\varphi\right| dxdt + \int_{t_1}^{t_2}\int |\Delta v u_x \varphi|\,dxdt\right]. \tag{2.17}$$

We apply (1.23) and (2.16) to bound the second term in (2.17) by

$$\begin{aligned}C\sup_{t_1\le t\le t_2}\|\Delta v(\cdot,t)\| &\int_{t_1}^{t_2}\|u_x\|_\infty\|\varphi\|dt\\ &\le CK|t_2-t_1|^\theta \sup_{t_1\le t\le t_2} E(t).\end{aligned}$$

To bound the first term in (2.17), we note that, from the second equation in (2.12),

$$\begin{aligned}\left\|\frac{\varepsilon\psi_x}{v_\eta^h}+\varphi\right\|_\infty^2 &\le 2\left\|\frac{\varepsilon\psi_x}{v_\eta^h}+\varphi\right\|\,\left\|\left(\frac{\varepsilon\psi_x}{v_\eta^h}+\varphi\right)_x\right\|\\ &\le C(\|\psi_x\|+\|\varphi\|)\|\psi_t\|\\ &\le C(t_2-t)^{(\alpha-1)/2}K\|\psi_t\|.\end{aligned}$$

Thus by (1.22),

(2.18)

$$\begin{aligned}\int_{t_1}^{t_2}\int |\Delta v u_x|\left|\frac{\varepsilon\psi_x}{v_x^h}+\varphi\right| dxdt &\le CK^{1/2}\sup_{t_1\le t\le t_2}\|\Delta v(\cdot,t)\|\int_{t_1}^{t_2}(t_2-t)^{(\alpha-1)/4}\|\psi_t\|^{1/2}\|u_x\|dt\\ &\le CK^{1/2}\sup\|\Delta v\|\int_{t_1}^{t_2}(t_2-t)^{(\alpha-1)/2}t^{-1/4}\left[(t_2-t)^{1-\alpha}\int\psi_t^2dx\right]^{1/4}dt\\ &\le CK^{1/2}\sup\|\Delta v\|\left[\int_{t_1}^{t_2}(t_2-t)^{2(\alpha-1)/3}t^{-1/3}dt\right]^{3/4}\left[\int_{t_1}^{t_2}\int(t_2-t)^{1-\alpha}\psi_t^2\,dxdt\right]^{1/4}\\ &\le CK|t_2-t|^\theta\sup_{t_1\le t\le t_2}E(t).\end{aligned}$$

This completes the argument for the term in (2.17). Next, in order to estimate the second-to-last term in the third integral on the right side of (2.15), we shall derive a bound for $\|\chi\|_\infty$ in terms of $|\chi|_\beta$ and $|\chi|_1$. Thus let $m(\xi) = 1 + |\xi|$ and choose

$$q \in [0,1] \cap \left[0, \frac{1}{2(1-\beta)}\right). \tag{2.19}$$

Then

$$\begin{aligned}\|\chi\|_\infty \le \|\hat\chi\|_{L^1} &= \int (m^\beta|\hat\chi|)^q\left(m|\hat\chi|\right)^{1-q}m^{q(1-\beta)-1}dx\\ &\le \left[\int(m^\beta|\hat\chi|)^2\right]^{q/2}\left[\int(m|\hat\chi|)^2\right]^{(1-q)/2}\left[\int m^{2q(1-\beta)-2}\right]^{1/2}\\ &\le C|\chi|_\beta^q|\chi|_1^{1-q}\\ &\le CK(t_2-t)^{(\beta-1)(1-q)/2}.\end{aligned} \tag{2.20}$$

Applying (1.22) and (2.20), we may then bound the second-to-last term in the third integral in (2.15) by

$$
\begin{aligned}
C\left(\int_{t_1}^{t_2}\int t^\delta \Delta u_x^2\right)^{1/2} &\left[\int_{t_1}^{t_2} t^{-\delta}(\|u_x\|^2+\|u_x^h\|^2)\|\chi\|_\infty^2 dt\right]^{1/2} \\
&\leq CK\left(\int_{t_1}^{t_2}\int t^\delta \Delta u_x^2\right)^{1/2}\left[\int_{t_1}^{t_2} t^{-\delta-1/2}(t_2-t)^{(\beta-1)(1-q)}dt\right]^{1/2}.
\end{aligned}
$$

Treating the cases $\beta > 1/2$ and $\beta \leq 1/2$ separately, we find that q can be chosen, consistently with (2.19), so that the integral in this expression is bounded by $|t_2-t_1|^\theta$, and the term in question is bounded by

$$
CK|t_2-t_1|^\theta\left(\int_{t_1}^{t_2}\int t^\delta \Delta u_x^2\right)^{1/2}.
$$

(It is here that we use the hypothesis (1.13) that $\delta < \min\{1/2, \beta\}$). Last, we apply the definition (1.20) of Q and the estimate (2.16) to obtain

$$
\begin{aligned}
|\mathcal{L}_1| + |\mathcal{L}_2| + |\mathcal{L}_3| &\leq \||(\varphi,\psi,\chi)\||_{[t_1,t_2]} Q(t_1,t_2;U^h) \\
&\leq CKQ(t_1,t_2;U^h).
\end{aligned}
$$

Estimating the other terms in (2.15) in a similar way, letting $\eta \to 0$, then taking the sup over (F,G,H), we finally obtain the result (2.10). □

Proof of the theorem. Adding a small multiple of (2.10) to (2.7), we obtain that

$$
\begin{aligned}
\sup_{t_1\leq t\leq t_2} E(t) &+ \left(\int_{t_1}^{t_2}\int t^\delta \Delta u_x^2\right)^{1/2} \\
&\leq C\left[E(t_1) + |t_2-t_1|^\theta \sup_{t_1\leq t\leq t_2} E(t) + Q(t_1,t_2;U^h)\right].
\end{aligned}
$$

A simple Gronwall-type argument then enables us to eliminate the middle term on the right. This proves the main estimate (1.27). □

3. Adjoint equation estimates.

In this section, we prove the estimates (2.5) and (2.16) in Lemmas 2.2 and 2.5 for solutions of the adjoint system (2.12)–(2.13). We begin with a statement of two interpolation results; these will be used to derive the required fractional-Sobolev norm estimates from L^2 and H^1 estimates.

LEMMA 3.1. (a) *Let $T : \mathcal{S}(\mathbb{R}) \to L^2(\mathbb{R})$ be linear ($\mathcal{S}$ is the Schwartz class), and suppose that there are constants C_j such that, for $g \in \mathcal{S}(\mathbb{R})$,*

$$
|Tg|_{b_j} \leq C_j |g|_{a_j}, \qquad j = 1, 2,
$$

where $a_j, b_j \in \mathbb{R}$. Let $s \in [0,1]$ and set

$$
\left\{
\begin{aligned}
a &= sa_1 + (1-s)a_2, \\
b &= sb_1 + (1-s)b_2, \\
C &= C_1^s C_2^{1-s}.
\end{aligned}
\right. \tag{3.1}
$$

Then

$$|Tg|_b \le C|g|_a$$

for all $g \in \mathcal{S}(\mathbb{R})$.

(b) *Let* $S : \mathcal{S}(\mathbb{R}) \to L^2(\mathbb{R}\times[t_1,t_2])$ *be linear and* $w \in C([t_1,t_2])$ *be strictly positive. Suppose that there are constants* C_j *such that, for* $g \in \mathcal{S}(\mathbb{R})$,

$$\left(\int_{t_1}^{t_2}\int w^{b_j}|Sg|^2\,dxdt\right)^{1/2} \le C_j|g|_{a_j}, \qquad j=1,2,$$

where $a_j, b_j \in \mathbb{R}$. *Let* a, b, *and* C *be as in* (3.1); *then*

$$\left(\int_{t_1}^{t_2}\int w^{b}|Sg|^2\,dxdt\right)^{1/2} \le C|g|_a$$

for all $g \in \mathcal{S}(\mathbb{R})$.

These results follow from straightforward variations of the proof of the Riesz–Thorin theorem; we therefore omit their proofs. (However, see [3, Lem. 2.2] for related interpolation results in which $\mathbb{R}$ is replaced by a finite interval.)

Proof of Lemma 2.2. Let χ be the solution of the adjoint system (2.3), and define

$$\mathcal{A}(t) = \int \chi(x,t)^2 dx + \lambda(t_2 - t)\int \chi_x(x,t)^2\,dx.$$

Choosing times $t \le t_1 \le t_2$, we then obtain from the partial differential equation in (2.3) that

$$\frac{1}{2}\int \chi^2 dx\Big|_t^{t_1} + \lambda\int_t^{t_1}\int \frac{A_\eta \chi_x^2}{v_\eta^h}\,dxds = \lambda\int_t^{t_1}\int \frac{\chi\chi_x(A_\eta)_x}{v_\eta^h}\,dxds.$$

The term on the right here is bounded by

$$\begin{aligned}
&C\lambda\|T''\|_\infty\int_t^{t_1}\left(\int\chi^2\right)^{1/4}\left(\int\chi_x^2\right)^{3/4}\left[\left(\int e_x^2\right)^{1/2}+\left(\int e_x^{h2}\right)^{1/2}\right]dt\\
&\quad\le C\lambda^{1/4}\|T''\|_\infty C_0^{1/2}\sup_{t\le s\le t_1}\mathcal{A}(s)\int_t^{t_1}(t_2-s)^{-3/4}s^{-1/4}ds\\
&\quad\le C\lambda^{1/4}\|T''\|_\infty C_0^{1/2}\sup_{t\le s\le t_1}\mathcal{A}(s)
\end{aligned}$$

by (1.22), where C now denotes a generic positive constant depending only on the inf of v in R and the inf of T in $[\underline{e},\overline{e}]$ (see (1.3) and (1.4)) and on an upper bound for λ. Thus

$$\begin{aligned}
&\int\chi(x,t)^2dx + \lambda\int_t^{t_1}\int\chi_x^2\,dxds\\
&\quad\le C\left[\int\chi(x,t_1)^2dx + \lambda^{1/4}\|T''\|_\infty C_0^{1/2}\sup_{t\le s\le t_1}\mathcal{A}(s)\right].
\end{aligned}\tag{3.2}$$

Next, we multiply the partial differential equation in (2.3) by $(t_2 - s)A_\eta^{-1}\chi_t$ and integrate to obtain that

$$\int_t^{t_1}\int \frac{(t_2-s)}{A_\eta}\chi_t^2\,dxds - \lambda(t_2-s)\int \frac{\chi_x^2}{2v_\eta^h}\,dx\Big|_t^{t_1}$$
$$\leq C\lambda\int_t^{t_1}\int\left[\chi_x^2 + (t_2-s)\chi_x^2|(v_\eta^h)_t|\right]dxds.$$

The second term on the right here is bounded by

$$C\lambda\sup_{t\leq s\leq t_1}\left[(t_2-s)\int\chi_x^2 dx\right]\int_t^{t_1}\|(v_\eta^h)_t(\cdot,s)\|_\infty\,ds$$
$$\leq CC_0^{1/2}\sup_{t\leq s\leq t_1}\mathcal{A}(s)|t_1-t|^r$$

by (1.23). Thus

$$\int_t^{t_1}\int(t_2-s)\chi_t^2\,dxds + \lambda(t_2-t)\int\chi_x(x,t)^2\,dx$$
$$\leq C\lambda\left[(t_2-t_1)\int\chi_x(x,t_1)^2\,dx + \int_t^{t_1}\int\chi_x^2\,dxds\right] \tag{3.3}$$
$$+CC_0^{1/2}\sup_{t\leq s\leq t_1}\mathcal{A}(s)|t_1-t|^r.$$

Adding a small multiple of (3.3) to (3.2), we obtain

$$\mathcal{A}(t) + \int_t^{t_1}\int\left[\lambda\chi_x^2 + (t_2-s)\chi_t^2\right]dxds$$
$$\leq C\left[\mathcal{A}(t_1) + \left(\lambda^{1/4}\|T''\|_\infty C_0^{1/2} + |t_1-t|^r\right)\sup_{t\leq s\leq t_1}\mathcal{A}(s)\right].$$

We now choose $t_0 \in [0, t_1]$, take the sup over $t \in [t_0, t_1]$, and apply the hypothesis (1.26) that $C\lambda^{1/4}\|T''\|_\infty C_0^{1/2} < 1/2$; the result is that

$$\sup_{t_0\leq t\leq t_1}\mathcal{A}(t) + \int_{t_0}^{t_1}\int\left[\lambda\chi_x^2 + (t_2-t)\chi_t^2\right]dxdt$$
$$\leq C\left[\mathcal{A}(t_1) + C_0^{1/2}|t_1-t_0|^r\sup_{t_0\leq t\leq t_1}\mathcal{A}(t)\right].$$

A simple Gronwall-type argument then completes the proof of (2.5). The proof of (2.6) is similar. □

Proof of Lemma 2.5. We first observe that the initial-value problem in (2.12) and (2.13) for χ is identical to (2.3), so that the estimates (2.5) and (2.6) hold. We shall apply Lemma 3.1 to obtain bounds for the various fractional norms of χ in (2.16). Thus fix a time $t < t_2$ and define a linear operator $T : \mathcal{S}(\mathbb{R}) \to L^2(\mathbb{R})$ by $TH = \chi(\cdot, t)$, where χ is the solution of the problem (2.3). Then by (2.5) and (2.6), $|TH|_0 \leq C|H|_0$ and $|TH|_1 \leq C|H|_1$. Lemma 3.1(a) therefore applies to show that $|TH|_\beta \leq C|H|_\beta$, that is, that $\|\chi(\cdot,t)\|_\beta \leq C|H|_\beta$. In addition, $|TH|_1 \leq C(t_2-t)^{-1/2}|H|_0$ and $|TH|_1 \leq$

$C|H|_1$, again by (2.5) and (2.6), so that, by Lemma 3.1(a), $\|\chi_x(\cdot,t)\| \le |TH|_1 \le C(t_2-t)^{(\beta-1)/2}|H|_\beta$.

To obtain a bound for the last term on the left side of (2.16), we fix a time $t' < t_2$ and define a linear map $S : \mathcal{S} \to L^2(\mathbb{R} \times [0,t'])$ by $SH = \chi_t$, where again χ is the solution of (2.3). The estimates (2.5) and (2.6) then show that

$$\int_0^{t'}\int (t_2-t)|SH|^2\,dxdt \le C|H|_0^2$$

and

$$\int_0^{t'}\int |SH|^2\,dxdt \le C|H|_1^2.$$

Lemma 3.1(b) therefore applies to show that

$$\int_0^{t'}\int (t_2-t)^{1-\beta}|SH|^2\,dxdt \le C|H|_\beta^2,$$

so that

$$\int_0^{t_2}\int (t_2-t)^{1-\beta}\chi_t^2\,dxdt \le C|H|_\beta^2.$$

Summarizing, we have thus shown that

$$\begin{aligned}\sup_{0\le t\le t_2}&\left(|\chi(\cdot,t)|_\beta + (t_2-t)^{(1-\beta)/2}\|\chi_x(\cdot,t)\|\right)\\ &+\left(\int_0^{t_2}\int\left[\chi_x^2+(t_2-t)^{1-\beta}\chi_t^2\right]dxdt\right)^{1/2}\\ \le{}& C|H|_\beta.\end{aligned}\tag{3.4}$$

This completes the proof of those bounds in (2.16) which involve χ.

Next, we derive bounds for φ and ψ in L^2. We multiply the first two equations in (2.12) by φ and ψ, respectively, and add and integrate. Dropping the modifiers on the coefficients a and v, we obtain that, for $t \le t_2$,

$$\begin{aligned}\frac{1}{2}\int(\varphi^2+\psi^2)(x,t)\,dx &+ \varepsilon\int_t^{t_2}\int\frac{\psi_x^2}{v}\,dxds\\ &= \frac{1}{2}\int(F^2+G^2)dx + \int_t^{t_2}\int(a-1)\varphi\psi_x\,dxds.\end{aligned}$$

It follows easily that

$$\begin{aligned}\sup_{0\le t\le t_2}\left(\|\varphi(\cdot,t)\|+\|\psi(\cdot,t)\|\right) &+ \left(\int_0^{t_2}\int\psi_x^2\,dxdt\right)^{1/2}\\ &\le C(\|F\|+\|G\|).\end{aligned}\tag{3.5}$$

To derive an H^1 bound for ψ, we multiply the second equation in (2.12) by $(t_2-t)\psi_t$ and integrate to obtain

$$\begin{aligned}\int_t^{t_2}\int(t_2-s)\psi_t^2\,dxds &+ \varepsilon(t_2-t)\int\left(\frac{\psi_x^2}{2v}\right)(x,t)dx\\ &= (t_2-t)\int(\psi_x\varphi)(x,t)dx + \int_t^{t_2}\int\frac{\varepsilon\psi_x^2}{2}\left[\frac{1}{v}+\frac{(t_2-s)v_t}{v^2}\right]dxds\\ &\quad+\int_t^{t_2}\int\psi_x[\varphi+(t_2-s)a\psi_x]\,dxds.\end{aligned}$$

Applying (3.5), we then get

$$\begin{aligned}\int_t^{t_2}\int(t_2-s)\psi_t^2+(t_2-t)\int\psi_x(x,t)^2\,dx\\ \leq C\left[\|F\|^2+\|G\|^2+\int_t^{t_2}\int(t_2-s)\psi_x^2|v_t|\right].\end{aligned}$$

The last term here is bounded by

$$C\sup_{t\leq s\leq t_2}\left[(t_2-s)\int\psi_x(x,s)^2\,dx\right]|t_2-t|^r$$

by (1.23). Substituting, we conclude that

$$\begin{aligned}\sup_{0\leq t\leq t_2}\left[(t_2-t)^{1/2}\|\psi_x(\cdot,t)\|\right]\cdot+\left[\int_0^{t_2}\int(t_2-t)\psi_t^2\,dxdt\right]^{1/2}\\ \leq C(\|F\|+\|G\|)\leq C(\|F\|+|G|_\alpha).\end{aligned}\tag{3.6}$$

A simple variation of the above argument would show that

$$\begin{aligned}\sup_{0\leq t\leq t_2}\|\psi_x(\cdot,t)\|+\left[\int_0^{t_2}\int\psi_t^2\,dxdt\right]^{1/2}\\ \leq C(\|F\|+|G|_1).\end{aligned}\tag{3.7}$$

To obtain the fractional-norm estimates in (2.16) for ψ, we fix a time $t<t_2$ and linear maps $Z:\mathcal{S}\times\mathcal{S}\to L^2$ and $T:\mathcal{S}\to L^2$ by $Z(F,G)=\psi(\cdot,t)$ and $TG=Z(0,G)$. (3.5) and (3.7) then show that $|TG|_0\leq C|G|_0$ and $|TG|_1\leq C|G|_1$, so that, by Lemma 3.1(a),

$$|TG|_\alpha\leq C|G|_\alpha.\tag{3.8}$$

In addition, we have from (3.7) that

$$|Z(F,0)|_\alpha\leq|Z(F,0)|_1\leq C\|F\|.\tag{3.9}$$

Combining (3.8) and (3.9), we thus obtain that

$$\begin{aligned}|\psi(\cdot,t)|_\alpha&=|Z(F,G)|_\alpha\\ &\leq|Z(F,0)|_\alpha+|TG|_\alpha\\ &\leq C(\|F\|+|G|_\alpha).\end{aligned}\tag{3.10}$$

The bounds

$$\begin{aligned}\sup_{0\leq t\leq t_2}t^{(1-\alpha)/2}\|\psi_x(\cdot,t)\|+]\left[\int_0^{t_2}\int(t_2-t)^{1-\alpha}\psi_t^2\,dxdt\right]\\ \leq C(\|F\|+|G|_\alpha)\end{aligned}\tag{3.11}$$

follow in a similar way, just as in the derivation of (3.4) above. Combining (3.4), (3.5), (3.10), and (3.11), we thus obtain (2.16). □

A STEFAN PROBLEM FOR MULTIDIMENSIONAL REACTION-DIFFUSION SYSTEMS*

AVNER FRIEDMAN[†] AND BEI HU[‡]

Abstract. This paper deals with a Stefan problem for a system of three weakly coupled semilinear parabolic equations. This system describes the dissolution of a particle in a solution. The dissolved species A reacts chemically with species B already in the solution, thereby forming species C. Species C diffuses in the solution and some of it adsorbs to the particle's boundary and causes either (i) a decrease in the dissolution rate or (ii) an increase in the dissolution rate. It is proved that for the model in case (i) the solution is unstable in any small time interval, whereas for the model in case (ii), the problem has a unique solution in a small time interval.

Key words. Stefan problem, free boundary, nonstability

1. Introduction.

Consider a solid particle composed of chemical A with uniform concentration A^*. The particle is in a solution. In the solution there is also another chemical B. As the particle dissolves, the A that enters the solution reacts with B to form C. Then species C diffuses in the solution and some of it reaches the solid particle and adsorbs to its surface. We shall denote the concentrations of species A, B, and C in the solution simply by A, B, and C, respectively.

We consider here the two-dimensional model in polar coordinates (r, θ). Assuming that the solid particle is enclosed by a surface $r = g(\theta, t)$, the reaction-diffusion equations are

$$\frac{\partial A}{\partial t} = D_A \Delta A - KAB, \tag{1}$$

$$\frac{\partial B}{\partial t} = D_B \Delta B - KAB, \tag{2}$$

$$\frac{\partial C}{\partial t} = D_C \Delta C + KAB \tag{3}$$

in $\{r > g(\theta, t)\}$, where K is the reaction rate and D_A, D_B, and D_C are the diffusion coefficients.

Let $\vec{n}$ denote the inward normal to the surface

$$\Gamma_t = \{r = g(\theta,\, t)\}$$

and V_n the velocity of Γ_t in the normal direction. Then

$$\vec{n} = (n_r,\, n_\theta) = \left(\frac{-g}{\sqrt{g^2 + g_\theta^2}},\, \frac{g_\theta}{g\sqrt{g^2 + g_\theta^2}} \right), \tag{4}$$

$$V_n = \frac{-g}{\sqrt{g^2 + g_\theta^2}}\, g_t. \tag{5}$$

By conservation of mass, the rate at which the particle's boundary moves is proportional to the flux of species A away from the particle, that is,

$$V_n = \alpha D_A \frac{\partial A}{\partial n} \quad \text{on } \Gamma_t \qquad (\alpha > 0). \tag{6}$$

Since there is no flux of B through or adsorption of B to the particle's surface,

$$\frac{\partial B}{\partial n} = 0 \quad \text{on } \Gamma_t. \tag{7}$$

The adsorption of C to the surface is proportional to the local saturation and is given by the empirical law $D_C \frac{\partial C}{\partial n} = -\gamma C^n$ for some positive constants γ and n. As in [2, Chap. 18], we take $n = 4$, i.e.,

$$D_C \frac{\partial C}{\partial n} = -\gamma C^4; \tag{8}$$

all the results of this paper, however, remain valid for general n.

As in [2, Chap. 18] and [4], we take

$$A(\infty, t) = 0, \qquad B(\infty, t) = B^*, \qquad C(\infty, t) = 0, \tag{9}$$

where "∞" means the limit as r goes to ∞, uniformly in θ, and B^* is a positive constant.

We next define the boundary condition for A. Denote by $\zeta(\theta, t)$ the concentration of C which covers A in a unit area (length) of the free boundary at the point $r = g(\theta, t)$; $\zeta(\theta, t) = 1$ if the point $r = g(\theta, t)$ is fully covered. We take the boundary condition for A on the free boundary, as in [2, Chap. 18], to be

$$D_A \zeta(\theta, t) \frac{\partial A}{\partial n} + (1 - \zeta(\theta, t))^+ (A - A^*) = 0 \quad \text{on } \Gamma_t. \tag{10}$$

Finally, we impose the following initial conditions:

$$g(\theta, 0) = g_0(\theta), \qquad \zeta(\theta, 0) = \zeta_0(\theta), \tag{11}$$

$$A(r, \theta, 0) = A_0(r, \theta), \quad B(r, \theta, 0) = B_0(r, \theta), \quad C(r, \theta, 0) = C_0(r, \theta). \tag{12}$$

For simplicity, we shall henceforth take $\alpha = 1$ and $\gamma = 1$.

Before we can analyze problems (1)–(12), we need to derive an equation for the evolution of ζ. There are two factors affecting the change of $\zeta(\theta, t)$: the flux $-D_C \frac{\partial C}{\partial n}$ and the change in the surface element of Γ_t along the normal.

Denote by $\frac{D}{Dt}$ the total derivative along the normal direction. Then

$$\begin{aligned} \frac{D\zeta(\theta, t)}{Dt} &= \lim_{\Delta t \to 0} \frac{\zeta(\theta + V_n n_\theta \Delta t, t + \Delta t) - \zeta(\theta, t)}{\Delta t} \\ &= \frac{\partial \zeta}{\partial t} + n_\theta V_n \frac{\partial \zeta}{\partial \theta}. \end{aligned} \tag{13}$$

If we introduce the surface element along Γ_t,

$$S(\theta, t) = \Psi(\theta, t) d\theta, \quad \text{where } \Psi(\theta, t) = \sqrt{g^2(\theta, t) + g_\theta^2(\theta, t)},$$

then the evolution of ζ can be described in the form

$$\begin{aligned}\zeta(\theta + V_n n_\theta \Delta t,\, t+\Delta t)S(\theta + V_n n_\theta \Delta t,\, t+\Delta t) - \zeta(\theta,\, t)S(\theta,\, t)\\ = -D_C\frac{\partial C}{\partial n}\cdot S(\theta,\, t)\Delta t + O\left((\Delta t)^2\right).\end{aligned}$$

From this equation, we easily derive

$$\frac{D\zeta}{Dt} + Q\zeta = -D_C\frac{\partial C}{\partial n}, \tag{14}$$

where

$$\begin{aligned}Q &= \lim_{\Delta t\to 0}\frac{S(\theta + V_n n_\theta \Delta t,\, t+\Delta t) - S(\theta,\, t)}{\Delta t\cdot S(\theta,\, t)}\\
&= \lim_{\Delta t\to 0}\frac{\Psi(\theta + V_n n_\theta \Delta t,\, t+\Delta t)d(\theta + V_n n_\theta\Delta t) - \Psi(\theta,\, t)d\theta}{\Delta t\cdot \Psi(\theta,\, t)d\theta}\\
&= \lim_{\Delta t\to 0}\frac{\Psi(\theta + V_n n_\theta \Delta t,\, t+\Delta t)\left[1 + \Delta t\cdot(\partial(V_n n_\theta)/\partial\theta)\right] - \Psi(\theta,\, t)}{\Delta t\cdot \Psi(\theta,\, t)}\\
&= \frac{\Psi_t + V_n n_\theta \Psi_\theta + \Psi(V_n n_\theta)_\theta}{\Psi}\\
&= \frac{1}{\Psi}\left\{\frac{gg_t + g_\theta g_{\theta t}}{\sqrt{g^2+g_\theta^2}} + (\Psi V_n n_\theta)_\theta\right\} \qquad \text{(by (5))}\\
&= \frac{1}{\Psi}\left\{-V_n - \frac{g_\theta}{\Psi}\left(\frac{\Psi V_n}{g}\right)_\theta + \left(\frac{g_\theta}{g}V_n\right)_\theta\right\} \qquad \text{(by (4) and (5))}\\
&= \frac{1}{\Psi}\left\{-V_n + \frac{\Psi V_n}{g}\left(\frac{g_\theta}{\Psi}\right)_\theta\right\} = -\frac{V_n}{\Psi} + \frac{V_n}{g}\left(\frac{g_\theta}{\Psi}\right)_\theta.\end{aligned}$$

Substituting this into (14) and using (13), we get

$$\frac{\partial\zeta}{\partial t} + n_\theta V_n\frac{\partial\zeta}{\partial\theta} + V_n\left\{-\frac{1}{\sqrt{g^2+g_\theta^2}} + \frac{1}{g}\left(\frac{g_\theta}{\sqrt{g^2+g_\theta^2}}\right)_\theta\right\}\zeta = -D_C\frac{\partial C}{\partial n}. \tag{15}$$

It will be convenient to work with the variable

$$\xi(\theta,\, t) = \frac{1}{\zeta(\theta,\, t)}. \tag{16}$$

Then equations (6), (10), and (15) become

$$V_n = \frac{-gg_t}{\sqrt{g^2+g_\theta^2}} = D_A\frac{\partial A}{\partial n} = (\xi - 1)^+(A^* - A) \quad \text{on } \Gamma_t, \tag{17}$$

$$\begin{aligned}\frac{\partial\xi}{\partial t} + \frac{V_n}{g}\frac{g_\theta}{\sqrt{g^2+g_\theta^2}}\frac{\partial\xi}{\partial\theta} - \frac{V_n}{g}\left(\frac{g_\theta}{\sqrt{g^2+g_\theta^2}}\right)_\theta\xi + \frac{V_n}{\sqrt{g^2+g_\theta^2}}\xi\\ = -\xi^2C^4 \quad \text{on } \Gamma_t.\end{aligned} \tag{18}$$

When the initial data are independent of θ, it is shown [4] that the system has a unique classical solution. However, the situation becomes more complicated when we allow the initial data to depend on θ. In fact, it will be shown that the problem is thus not well posed for classical solutions. In §2, we linearize the problem about a radial solution. We then show that the solution to the linearized problem is unique (§4) but may blow up in arbitrarily small time no matter how smooth the initial data are (§3). Furthermore, the full nonlinear problem is not stable near the radial solution (§5).

There are some similarities between our problem and the Stefan problem with supercooled water. The Mullin–Sekerka instabilities for the latter problem are not as bad as in our case; the linearized problem (for the supercooled water model) is well posed for all time provided the data are smooth, and the instability is only in the sense that the absolute value of the solution goes to ∞ as $t \to \infty$. To explain the origin of the instabilities for our problem, consider a nonradial particle as in Figure 1.1.

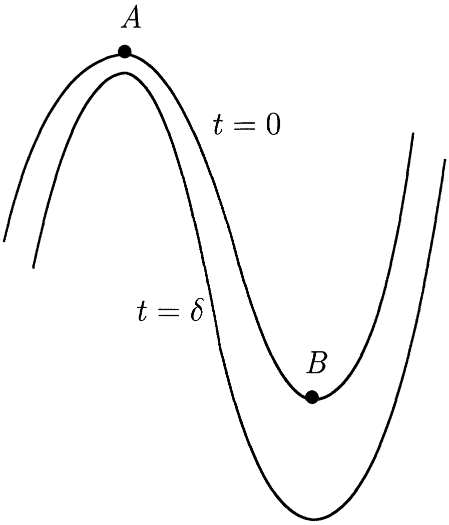

FIG. 1.1.

At a convex point A on the free boundary, as the particle dissolves, the local area shrinks. This increases the concentration ζ, which will then slow down the dissolution near A. The reverse situation occurs at a point B: the local area increases, ζ decreases, and the dissolution increases. This process tends to accentuate the ripples in the free boundary and will generally result in blow-up of the $C^{1+\beta}$ norm of Γ_t, at a very short time. This situation does not preclude the existence of a "weak solution," but the construction of an appropriate weak solution remains an open problem, even for much simpler Stefan problems such as in [3].

In the final section (§6), we shall consider the model where the adsorbed C increases the dissolution rather than inhibits it. (A situation like this arises, for instance, for an oil drop in water when soap is added to the water.) We shall establish in this case the existence and uniqueness of solutions for some small time.

Remark 1.1. It will be shown that $\zeta(r, \theta)$ satisfies a nonlinear second-order partial differential equation which is elliptic in case (i), where the adsorption of C slows the dissolution rate, and hyperbolic in case (ii), where the adsorption of C increases the dissolution rate; this equation is coupled, of course, to the equations for A, B, and C. In both cases, the data for ζ are the Cauchy data. Since the Cauchy problem is well posed for hyperbolic equations and ill posed for elliptic equations, this would explain mathematically why we get instability in case (i) and stability in case (ii).

Remark 1.2. The results of the paper extend to three-dimensional particles; the formulas are more complicated but the methods are the same.

2. The linearized problem. When the initial conditions in (11) and (12) are independent of θ and satisfy some regularity and compatibility assumptions, it is proved in [4] that the nonlinear system has a unique global radial solution (A^0, B^0, C^0, ζ^0, R^0) and that there is a finite shutdown time T^*, that is, $\zeta(T^*) = 1$ (and $\zeta(t) > 1$ if $t > T^*$). The radial solution satisfies

$$\left\{\begin{aligned} &R^0,\ \zeta^0 \in C^2[0, T^*), \\ &R^0(0) = R_0 > 0, \qquad \zeta^0(0) = \delta \in (0, 1), \\ &\frac{dR^0}{dt} < 0, \quad \frac{d\zeta^0}{dt} > 0 \quad \text{for } 0 \le t < T^* \end{aligned}\right. \tag{19}$$

and

$$\left\{\begin{aligned} &A^0, B^0, C^0 \in C^{2+\nu, 1+\frac{\nu}{2}}\{r \ge R^0(t), 0 \le t < T^*\}, \\ &\frac{\partial A^0}{\partial r} \le 0, \qquad \frac{\partial B^0}{\partial r} \ge 0, \\ &A^0 \ge 0, \quad B^0 \ge 0, \quad C^0 \ge 0, \end{aligned}\right. \tag{20}$$

where $0 < \nu < 1$; it is assumed that initially (20) holds, that

$$A^0(r, 0) = 0, \quad C^0(r, 0) = 0, \quad B^0(r, 0) = B^* \quad \text{if } r \ge R_0 + \delta_0 \tag{21}$$

for some $\delta_0 > 0$, and that the compatibility conditions

$$\frac{\partial^2 A^0(R_0, 0)}{\partial r^2} = \frac{\partial^2 B^0(R_0, 0)}{\partial r^2} = \frac{\partial^2 C^0(R_0, 0)}{\partial r^2} = 0, \quad A^0(R_0, 0) < A^*, \tag{22}$$

hold.

We linearize the system (1)–(3), (17), (18) with boundary conditions (7) and (8) about a radially symmetric solution by setting

$$\begin{gathered} A = A^0 + \varepsilon A^1, \qquad B = B^0 + \varepsilon B^1, \qquad C = C^0 + \varepsilon C^1, \\ g = R^0 + \varepsilon h, \qquad \xi = \xi^0 + \varepsilon \eta, \end{gathered} \tag{23}$$

where $\xi^0 = 1/\zeta^0$. Substituting (23) into (1)–(3) and dropping $O(\varepsilon^2)$ terms, we obtain

$$\begin{aligned} \left(\frac{\partial}{\partial t} - D_A \Delta\right) A^1 &= -K(A^1 B^0 + A^0 B^1), \qquad && r > R^0(t), \\ \left(\frac{\partial}{\partial t} - D_B \Delta\right) B^1 &= -K(A^1 B^0 + A^0 B^1), \qquad && r > R^0(t), \\ \left(\frac{\partial}{\partial t} - D_C \Delta\right) C^1 &= K(A^1 B^0 + A^0 B^1), \qquad && r > R^0(t). \end{aligned} \tag{24}$$

Clearly,

$$g_\theta^2 = \varepsilon^2 h_\theta^2.$$

Therefore, by (17),

$$D_A \frac{\partial A}{\partial n} = -g_t + O(\varepsilon^2).$$

Using (23), we get

$$D_A \left\{ \frac{\partial A^0}{\partial n}\bigg|_{r=g} - \frac{\partial A^0}{\partial n}\bigg|_{r=R^0} \right\} + \varepsilon D_A \frac{\partial A^1}{\partial n}\bigg|_{r=g} + D_A \frac{\partial A^0}{\partial n}\bigg|_{r=R^0}$$
$$= -\frac{dR^0}{dt} - \varepsilon \frac{\partial h}{\partial t} + O(\varepsilon^2)$$

so that, after dropping $O(\varepsilon^2)$ terms,

$$D_A \frac{\partial A^1}{\partial n} - D_A \frac{\partial^2 A^0}{\partial r^2} h = -\frac{\partial h}{\partial t} \quad \text{on} \quad r = R^0(t). \tag{25}$$

Similarly,

$$\frac{\partial B^1}{\partial n} - \frac{\partial^2 B^0}{\partial r^2} h = 0 \quad \text{on} \quad r = R^0(t), \tag{26}$$

$$\frac{\partial C^1}{\partial n} - \frac{\partial^2 C^0}{\partial r^2} h = 4(C^0)^3 C^1 + 4(C^0)^3 \frac{\partial C^0}{\partial r} h \quad \text{on} \quad r = R^0(t). \tag{27}$$

We next substitute g and ξ from (23) into (17) and (18) to obtain linearized equations for h and η. From (17),

$$V_n = -g_t + O(\varepsilon^2), \tag{28}$$

$$-g_t = (\xi - 1)(A^* - A) + O(\varepsilon^2). \tag{29}$$

Substituting g and ξ from (23) into (29), we get

$$\begin{aligned} -\frac{dR^0}{dt} - \varepsilon \frac{\partial h}{\partial t} &= \varepsilon \eta (A^* - A^0) - \varepsilon A^1 (\xi^0 - 1) \\ &\quad + (\xi^0 - 1) \left\{ (A^* - A^0)\Big|_{r=g} - (A^* - A^0)\Big|_{r=R^0} \right\} \\ &\quad + (\xi^0 - 1)(A^* - A^0)\Big|_{r=R^0} + O(\varepsilon^2). \end{aligned}$$

Dropping $O(\varepsilon^2)$ terms, we obtain

$$-\frac{\partial h}{\partial t} = \eta (A^* - A^0) - (\xi^0 - 1) A^1 + \frac{1}{D_A} (\xi^0 - 1)^2 (A^* - A^0) h. \tag{30}$$

Next, substituting (28) into (18) and recalling that $g_\theta = O(\varepsilon)$, we get

$$\xi_t - \frac{g_t g_\theta}{g^2} \xi_\theta + \frac{g_t}{g} \left(\frac{g_\theta}{g} \right)_\theta \xi - \frac{g_t}{g} \xi = -\xi^2 C^4 + O(\varepsilon^2).$$

Substituting g, ξ, and C from (23) and dropping $O(\varepsilon^2)$, we find that

$$\begin{aligned}&\eta_t + \frac{1}{(R^0)^2}\frac{dR^0}{dt}\xi^0 h_{\theta\theta} - \frac{1}{R^0}\frac{dR^0}{dt}\eta - \frac{1}{R^0}\xi^0 h_t + \frac{1}{(R^0)^2}\frac{dR^0}{dt}\xi^0 h\\ &= -2\xi^0(C^0)^4\eta - 4(C^0)^3(\xi^0)^2C^1 - 4(C^0)^3(\xi^0)^2\frac{\partial C^0}{\partial r}h \quad \text{on } r = R^0(t).\end{aligned}\tag{31}$$

We next express η in terms of h and h_t from (30) and substitute this into (31). This results in the elliptic equation

$$\begin{aligned}\mathcal{L}h \equiv\ &\frac{\partial}{\partial t}\left(a_1(t)\frac{\partial h}{\partial t}\right) + a_2(t)\frac{\partial^2 h}{\partial\theta^2} + b(t)\frac{\partial h}{\partial t} + c(t)h\\ &= f_1(t)C^1(R^0(t), \theta, t) + f_2(t)A^1(R^0(t), \theta, t)\\ &\quad + \frac{\partial}{\partial t}\left[f_3(t)A^1(R^0(t), \theta, t)\right],\end{aligned}\tag{32}$$

where

$$a_1(t) = -\frac{1}{A^* - A^0(R^0(t), t)}, \qquad (a_1(t) < 0),\tag{33}$$

$$a_2(t) = \frac{1}{(R^0(t))^2}\frac{dR^0(t)}{dt}\xi^0(t), \qquad (a_2(t) < 0),\tag{34}$$

$$\begin{aligned}b(t) = &-\frac{(\xi^0(t)-1)^2}{D_A} - \frac{\xi^0(t)}{R^0(t)}\\ &-\left\{2\xi^0(t)\Big(C^0\big(R^0(t), t\big)\Big)^4 - \frac{1}{R^0(t)}\frac{dR^0(t)}{dt}\right\}\frac{1}{A^* - A^0(R^0(t), t)},\end{aligned}\tag{35}$$

$$\begin{aligned}c(t) = &-\frac{2}{D_A}(\xi^0(t)-1)\frac{d\xi^0(t)}{dt} + \frac{1}{(R^0(t))^2}\frac{dR^0(t)}{dt}\xi^0(t)\\ &+4\Big(C^0\big(R^0(t), t\big)\Big)^3\big(\xi^0(t)\big)^2\frac{\partial C^0}{\partial r}\big(R^0(t), t\big)\\ &-\left\{2\xi^0(t)\Big(C^0\big(R^0(t), t\big)\Big)^4 - \frac{1}{R^0(t)}\frac{dR^0(t)}{dt}\right\}\frac{(\xi^0(t)-1)^2}{D_A},\end{aligned}\tag{36}$$

$$f_1(t) = -4\Big(C^0\big(R^0(t), t\big)\Big)^3\big(\xi^0(t)\big)^2,\tag{37}$$

$$f_2(t) = \left\{2\xi^0(t)\Big(C^0\big(R^0(t), t\big)\Big)^4 - \frac{1}{R^0(t)}\frac{dR^0(t)}{dt}\right\}\frac{\xi^0(t)-1}{A^* - A^0(R^0(t), t)},\tag{38}$$

$$f_3(t) = -\frac{\xi^0(t)-1}{A^* - A^0(R^0(t), t)}.\tag{39}$$

Notice that

$$\frac{\partial C^0}{\partial r} = \frac{1}{D_C}(C^0)^4 \quad \text{at } (R^0(t), t).$$

Therefore, all the coefficients a_1, a_2, b, c, f_1, f_2, and f_3 are Lipschitz continuous under the assumptions (20) and (21).

3. The linearized problem is unstable. In this section, we prove that the linearized problem is unstable. More specifically, we show that for any given small $T > 0$ and $\beta > 0$ and for any large positive integer m, there exist initial data for h and η whose first m derivatives are bounded by 1 such that a smooth solution exists for $0 < t < T$ but the $C^{1,\beta}$ norm of h becomes infinite at $t = T$.

THEOREM 3.1. *Consider the linearized problem* (24)–(27), (30), *and* (31) *under the assumptions* (19)–(22). *For any small* $T > 0$, $0 < \beta < \frac{1}{2}$, *and positive integer* m, *there exists a* C^m *solution* (A^1, B^1, C^1, h, η) *for* $0 < t < T$ *such that*

$$\left|D^j_\theta \eta(\theta, 0)\right| \leq 1, \quad \left|D^j_\theta h(\theta, 0)\right| \leq 1 \quad \textit{for} \quad 0 \leq j \leq m, \tag{40}$$

$$A^1(r, \theta, 0) = B^1(r, \theta, 0) = C^1(r, \theta, 0) \equiv 0 \quad \textit{for} \quad r \geq R^0(0), \tag{41}$$

but

$$\|h(\cdot, T - 0)\|_{C^{1+\beta}([0,2\pi])} = +\infty. \tag{42}$$

Proof. Let

$$\begin{aligned} G_T &= \{0 \leq \theta \leq 2\pi, \ 0 \leq t \leq T\}, \\ X &= \{h(\theta, t); \ h \ \text{and} \ h_t \ \text{belong to} \ C(G_T) \\ &\qquad \text{and are } 2\pi\text{-periodic in } \theta\}. \end{aligned}$$

Introduce the norm

$$\|h\|_X = \|h\|_{C(G_T)} + \|h_t\|_{C(G_T)}.$$

For each $h \in X$, we solve (24) with the boundary conditions (25)–(27), zero initial conditions, and zero boundary conditions at $r = \infty$. Clearly,

$$\begin{aligned} \|A^1\|_{L^\infty} &\leq C\|h\|_X + CT\|B^1\|_{L^\infty}, \\ \|B^1\|_{L^\infty} &\leq C\|h\|_X + CT\|A^1\|_{L^\infty}, \\ \|C^1\|_{L^\infty} &\leq C\|h\|_X + CT\left(\|A^1\|_{L^\infty} + \|B^1\|_{L^\infty}\right), \end{aligned}$$

so that

$$\|A^1\|_{L^\infty} + \|B^1\|_{L^\infty} + \|C^1\|_{L^\infty} \leq C\|h\|_X \tag{43}$$

if T is small enough.

Next, we use (43) and Hölder estimates for parabolic equations [7] to obtain

$$\begin{aligned} \|A^1\|_{C^{\alpha,\alpha/2}(\Omega_T)} + \|B^1\|_{C^{\alpha,\alpha/2}(\Omega_T)} + \|C^1\|_{C^{\alpha,\alpha/2}(\Omega_T)} \\ \leq C\|h\|_X \end{aligned} \tag{44}$$

for some $0 < \alpha < 1$, where

$$\Omega_T = \left\{(x_1, x_2, t); \ \sqrt{x_1^2 + x_2^2} \geq R^0(t), 0 \leq t \leq T\right\}.$$

The constant C is independent of T.

In what follows, we assume without loss of generality that $\frac{1}{2}\beta < \alpha < \beta$.

Since A^1, B^1, and C^1 have zero initial values, (44) implies that

$$\|A^1\|_{L^\infty} + \|B^1\|_{L^\infty} + \|C^1\|_{L^\infty} \le CT^{\alpha/2}\|h\|_X. \tag{45}$$

We now pick up any periodic function $k(\theta)$ such that

$$\|k\|_{C^{1+\beta}} = \infty, \qquad \|k\|_{C^{1+\beta/2}} < \infty \tag{46}$$

and denote by $\bar{h}$ the solution to the elliptic problem

$$\mathcal{L}\bar{h} = f_1(t)C^1(R^0(t),\, \theta,\, t) + f_2(t)A^1(R^0(t),\, \theta,\, t) + \frac{\partial}{\partial t}\left[f_3(t)A^1(R^0(t),\, \theta,\, t)\right], \tag{47}$$

$$\bar{h} \text{ is } 2\pi\text{-periodic in } \theta, \tag{48}$$

$$\bar{h}_t(\theta,\, 0) = 0, \qquad \bar{h}(\theta,\, T) = k(\theta). \tag{49}$$

We define the map W by

$$(Wh)(\theta,\, t) = \bar{h}(\theta,\, t).$$

We shall show that W has a fixed point, and this will give us the solution asserted in Theorem 3.1 (with η defined by (30)).

We first need to derive some estimates on h and its derivatives which will depend on the small parameter T in an appropriate way. It is convenient to scale variables by introducing

$$s = \frac{t}{T}, \qquad \varphi = \frac{\theta}{T}, \qquad \tilde{h}(s,\, \varphi) = \bar{h}(\theta,\, t).$$

Setting

$$\tilde{L}\tilde{h} \equiv \frac{\partial}{\partial s}\left(a_1(Ts)\frac{\partial \tilde{h}}{\partial s}\right) + a_2(Ts)\frac{\partial^2 \tilde{h}}{\partial \varphi^2} + Tb(Ts)\frac{\partial \tilde{h}}{\partial s} + T^2 c(Ts)\tilde{h},$$

we have

$$\begin{aligned} \tilde{L}\tilde{h} &= T^2 f_1(Ts)C^1\left(R^0(Ts),\, T\varphi,\, Ts\right) + T^2 f_2(Ts)A^1\left(R^0(Ts),\, T\varphi,\, Ts\right) \\ &\quad + T\frac{\partial}{\partial s}\left[f_3(Ts)A^1(R^0(Ts),\, T\varphi,\, Ts)\right] \end{aligned} \tag{50}$$

and

$$\begin{gathered} \left.\frac{\partial \tilde{h}}{\partial s}\right|_{s=0} = 0, \qquad \left.\tilde{h}\right|_{s=1} = k(T\varphi), \\ \tilde{h}(\varphi,\, s) \text{ is } \frac{2\pi}{T}\text{-periodic in } \varphi. \end{gathered} \tag{51}$$

To analyze the solution $\tilde{h}$, we introduce the auxiliary problem

$$
\begin{gathered}
a_1(Ts)\frac{\partial^2 v}{\partial s^2} + a_2(Ts)\frac{\partial^2 v}{\partial \varphi^2} = Tf_3(Ts)A^1(R^0(Ts), T\varphi, Ts), \\
v\Big|_{s=0} = 0, \qquad \frac{\partial v}{\partial s}\Big|_{s=1} = 0, \\
v \text{ is } \frac{2\pi}{T}\text{-periodic in } \varphi.
\end{gathered} \tag{52}
$$

Then

$$|||v|||_{L^\infty(\tilde{G})} \le CT|||A^1|||_{L^\infty},$$

where

$$\tilde{G} = \left[0, \frac{2\pi}{T}\right] \times [0, 1]$$

and $|||\cdot|||$ denotes norms in the variable (s, φ).

By Schauder's interior-boundary estimates [5],

$$
\begin{aligned}
|||v|||_{C^{2+\alpha/2}(\tilde{G})} &\le C\left(T|||A^1|||_{C^{\alpha/2}} + |||v|||_{L^\infty(\tilde{G})}\right) \\
&\le CT|||A^1|||_{C^{\alpha/2}},
\end{aligned} \tag{53}
$$

where $C^{\alpha/2}$ denotes Hölder space with exponent $\frac{\alpha}{2}$ in both space and time variables. Differentiating (52) in s and subtracting from equation (50), we find that

$$
\begin{aligned}
\tilde{L}_0(\tilde{h} - v_s) \;=\; & T^2 f_1(Ts)C^1\left(R^0(Ts), T\varphi, Ts\right) \\
& + T^2 f_2(Ts)A^1\left(R^0(Ts), T\varphi, Ts\right) \\
& - Tb(Ts)\frac{\partial^2 v}{\partial s^2} + T\frac{\partial a_2(Ts)}{\partial t}\frac{\partial^2 v}{\partial \varphi^2} \\
& - T^2 c(Ts)(\tilde{h} - v_s) - T^2 c(Ts)v_s, \\
\frac{\partial}{\partial s}(\tilde{h} - v_s)\Big|_{s=0} = 0, & \qquad (\tilde{h} - v_s)\Big|_{s=1} = k(Ts),
\end{aligned} \tag{54}
$$

where

$$\tilde{L}_0 = \tilde{L} - T^2 c(Ts).$$

By the maximum principle,

$$|||\tilde{h} - v_s|||_{L^\infty(\tilde{G})} \le C\Big(|||k|||_{L^\infty} + |||\text{the right-hand side of (54)}|||_{L^\infty}\Big).$$

Therefore, if we apply elliptic $C^{1+\alpha}$ estimates [9] to (54), we get

$$|||\tilde{h} - v_s|||_{C^{1+\alpha/2}(\tilde{G})} \le C\Big(|||k|||_{C^{1+\alpha/2}} + T^2|||A^1|||_{C^{\alpha/2}} + |||C^1|||_{C^{\alpha/2}} + T^2|||\tilde{h} - v_s|||_{L^\infty}\Big).$$

Recalling (53), we conclude that

$$|||\tilde{h}|||_{C^{1+\alpha/2}(\tilde{G})} \le C\left[|||k|||_{C^{1+\alpha/2}} + T\left(|||A^1|||_{C^{\alpha/2}} + |||C^1|||_{C^{\alpha/2}}\right)\right]$$

provided T is small enough. The above estimate written in terms of the variable $(t,\,\theta)$ reads

$$\begin{aligned}
&\|\bar h\|_{L^\infty} + T\Big(\|\bar h_t\|_{L^\infty} + \|\bar h_\theta\|_{L^\infty}\Big) + T^{1+\alpha/2}\Big([\bar h]_{C^{\alpha/2}} + [\bar h_\theta]_{C^{\alpha/2}}\Big)\\
&\qquad \le C\Big(\|k\|_{L^\infty} + T\|k_\theta\|_{L^\infty} + T^{1+\alpha/2}[k_\theta]_{C^{\alpha/2}}\Big)\\
&\qquad\quad + CT\Big(\|A^1\|_{L^\infty} + \|C^1\|_{L^\infty}\Big) + CT^{1+\alpha/2}\Big([A^1]_{C^{\alpha/2}} + [C^1]_{C^{\alpha/2}}\Big).
\end{aligned}\tag{55}$$

Using (44) and (45), we conclude that

$$\begin{aligned}
&\|\bar h\|_{L^\infty} + T\Big(\|\bar h_t\|_{L^\infty} + \|\bar h_\theta\|_{L^\infty}\Big) + T^{1+\alpha/2}\Big([\bar h_t]_{C^{\alpha/2}} + [\bar h_\theta]_{C^{\alpha/2}}\Big)\\
&\qquad \le C^*\Big(\|k\|_{L^\infty} + T\|k_\theta\|_{L^\infty} + T^{1+\alpha/2}[k_\theta]_{C^{\alpha/2}}\Big)\\
&\qquad\quad + CT^{1+\alpha/2}\Big(\|h\|_{L^\infty} + \|h_t\|_{L^\infty}\Big).
\end{aligned}\tag{56}$$

This estimate shows that if

$$X_0 = \Big\{h \in X;\ \|h\|_{L^\infty} + T\|h_t\|_{L^\infty} \le C^*\|k\|_{C^{1+\alpha/2}} + 1\Big\},$$

then W maps X_0 into itself provided T is small enough. It is also clear that WX_0 is a precompact subset of X_0 and that W is continuous. The Schauder fixed point theorem can then be applied to conclude that W has a fixed point h, and this gives a solution to the linearized problem with the same h.

Next, we show that h and η are C^m smooth.

The estimate (56) implies that

$$\|h\|_{C^{1+\alpha/2}(G_T)} \le C. \tag{57}$$

Recall by (49) that $h_t|_{t=0} = 0$. Since we have assumed (22), the compatibility condition (for parabolic equations) is satisfied for A^1, B^1, and C^1. We can therefore apply to equations (24) with boundary conditions (25)–(27), $C^{1+\alpha}$ parabolic estimates [8, Thm. 1.2], and Schauder estimates [7] to get

$$\begin{aligned}
&\|A^1\|_{C^{1+\alpha/2,\,1/2+\alpha/4}(\Omega_T)} \le C,\\
&\|B^1\|_{C^{2+\alpha/2,\,1+\alpha/4}(\Omega_T)} + \|C^1\|_{C^{2+\alpha/2,\,1+\alpha/4}(\Omega_T)} \le C.
\end{aligned}\tag{58}$$

We now differential (32) in θ and obtain the same equation for h_θ but with A^1 and C^1 replaced by A^1_θ and C^1_θ. If we use interior-boundary Schauder estimates (away from $t = T$), the procedure that led to (55)–(57) gives

$$\|h_\theta\|_{C^{1+\alpha/4}(G_{T-\varepsilon})} \le C_\varepsilon \tag{59}$$

for any $\varepsilon > 0$. By iterating this process m times, we arrive at the estimate

$$\left\|\frac{\partial^j h}{\partial\theta^j}\right\|_{C^{1+2^{-j-1}\alpha}(G_{T-\varepsilon j})} \le C_{\varepsilon,j} \quad (0 \le j \le m).$$

Since η is given by (31), we get similar estimates for η. Noting that ε is arbitrary, it follows that the solution has m derivatives (which are actually continuous) in θ.

Next, using (58) and interior-boundary Schauder estimates for h (away from $t = T$), we obtain

$$\|h\|_{C^{1+(1/2+\alpha/4)}(G_{T-\varepsilon})} \leq C. \tag{60}$$

The estimates (59) and (60) imply that

$$\|h_t\|_{C^{1+\alpha/2,1/2+\alpha/4}(G_{T-\varepsilon})} \leq C,$$

where $C^{1+\alpha/2,1/2+\alpha/4}$ means $C^{1+\alpha/2}$ in θ and $C^{1/2+\alpha/4}$ in t. Thus, by parabolic Schauder estimates,

$$\|A^1\|_{C^{2+\alpha/2,\,1+\alpha/4}(\Omega_{T-\varepsilon})} \leq C.$$

Notice that the coefficients in (33)–(39) are C^∞ for $t > 0$ (see [4]). Therefore, we can iterate the above process to conclude that h is C^m in (θ, t) away from $t = 0$ and $t = T$.

Finally, by multiplying the solution by a small enough constant δ, we find that δh and $\delta\eta$ have all their first m derivatives (in θ) bounded by 1 at $t = 0$ and that the solution of the linearized problem has (continuous) m derivatives for all $0 < t < T$ since (by (49)) $\delta h(\theta,\, T-0) = \delta k(\theta)$ and $\|\delta k\|_{C^{1+\beta}} = \infty$; this completes the proof of the theorem. □

4. Uniqueness for the linearized problem.

THEOREM 4.1. *Suppose that* $(A^1,\, B^1,\, C^1,\, h,\, \eta)$ *is a solution of the linearized problem for* $0 \leq t < T_0$ *such that*

$$A^1 = B^1 = C^1 = 0 \quad \text{at} \quad t = 0, \tag{61}$$

$$h = \eta = 0 \quad \text{at} \quad t = 0, \tag{62}$$

and

$$\begin{gathered} A^1,\, B^1, \text{ and } C^1 \quad \text{belong to} \quad C^{1+\alpha,(1+\alpha)/2}(\Omega_{T_0}), \\ h \in C^{1+\alpha,1+\alpha}(G_{T_0}), \qquad \eta \in C^{\alpha,\alpha}(G_{T_0}). \end{gathered} \tag{63}$$

Then

$$A^1 \equiv B^1 \equiv C^1 \equiv 0 \quad \text{in} \quad \Omega_{T_0}$$

and

$$h \equiv \eta \equiv 0 \quad \text{in} \quad G_{T_0}.$$

Proof. From (61), (62), and (30), it follows that

$$h_t(\theta,\, 0) \equiv 0. \tag{64}$$

Let $\varphi(\theta)$ be any 2π-periodic function such that

$$\varphi''(\theta) = -k^2\varphi(\theta),$$

where k is a nonnegative integer. Let

$$\tilde{A}(r, t) = \int_0^{2\pi} \varphi(\theta) A^1(r, \theta, t) d\theta$$

and define $\tilde{B}(r, t)$, $\tilde{C}(r, t)$, and $\tilde{h}(t)$ in a similar way. Then $\tilde{A}$, $\tilde{B}$, $\tilde{C}$, and $\tilde{h}$ satisfy the same boundary conditions (25)–(27) as A, B, C, and h. Multiplying the equations for A^1, B^1, and C^1 by $\varphi(\theta)$ and integrating with respect to θ, we find that

$$\begin{aligned} \tilde{A}_t &= D_A \left(\tilde{A}_{rr} + \frac{1}{r} \tilde{A}_r - \frac{k^2}{r^2} \tilde{A} \right) - K(\tilde{A}B^0 + A^0\tilde{B}), \\ \tilde{B}_t &= D_B \left(\tilde{B}_{rr} + \frac{1}{r} \tilde{B}_r - \frac{k^2}{r^2} \tilde{B} \right) - K(\tilde{A}B^0 + A^0\tilde{B}), \\ \tilde{C}_t &= D_C \left(\tilde{C}_{rr} + \frac{1}{r} \tilde{C}_r - \frac{k^2}{r^2} \tilde{C} \right) + K(\tilde{A}B^0 + A^0\tilde{B}) \end{aligned}$$

if $r > R^0(t)$. The same argument as in (43)–(45) shows that

(65) $$\|\tilde{A}\|_{L^\infty} + \|\tilde{B}\|_{L^\infty} + \|\tilde{C}\|_{L^\infty} \le CT^{\alpha/2} \left(\|\tilde{h}\|_{L^\infty} + \|\tilde{h}_t\|_{L^\infty} \right), \quad L^\infty = L^\infty(\Omega_T).$$

Next, multiplying (32) by $\varphi(\theta)$ and integrating with respect to θ, we obtain the differential equation

$$\begin{aligned} &\frac{d}{dt} \left(a_1 \frac{d\tilde{h}}{dt} \right) - k^2 a_2 \tilde{h} + b\tilde{h}_t + c\tilde{h} \\ &\quad = f_2(t)\tilde{C}\left(R^0(t), t\right) + f_2(t)\tilde{A}\left(R^0(t), t\right) + \frac{\partial}{\partial t}\left(f_3(t)\tilde{A}\left(R^0(t), t\right) \right). \end{aligned}$$

Since

$$\tilde{h} = \tilde{h}_t = 0 \quad \text{and} \quad \tilde{A} = 0 \quad \text{at} \quad t = 0,$$

we get by integration that

(66) $$\|\tilde{h}_t\|_{L^\infty} \le C\left(\|\tilde{A}\|_{L^\infty} + \|\tilde{C}\|_{L^\infty} \right) + CT\left((k^2+1)\|\tilde{h}\|_{L^\infty} + \|\tilde{h}_t\|_{L^\infty} \right).$$

Clearly,

(67) $$\|\tilde{h}\|_{L^\infty} \le T\|\tilde{h}_t\|_{L^\infty}.$$

Substituting (67) and (65) into (66) we find that if T is small enough (depending on k), then

$$\tilde{h} \equiv 0.$$

It then also follows that $\tilde{A} \equiv \tilde{B} \equiv \tilde{C} \equiv 0$ and $\eta \equiv 0$ if $t < T$. We can continue the process step by step to deduce that $\tilde{h} \equiv 0$ if $0 \le t < T_0$ (T_0 is independent of k).

Taking in particular $\varphi(\theta) = \sin kx$ or $\cos kx$ for any integers k, we see that the Fourier series of the continuously differentiable function $\theta \to h(\theta, t)$ vanishes identically. Therefore, $h \equiv 0$ and then also $A \equiv B \equiv C \equiv 0$ and $\eta \equiv 0$. □

5. The nonlinear problem is unstable. Theorem 3.1 can be extended to the full nonlinear problem. To be more precise, we say that a radial solution (A^0, B^0, C^0, ξ^0, R^0) satisfying (19)–(22) is *locally Lipschitz stable* if there exist $T > 0$ and a positive integer $m \geq 3$ such that for any solution (A, B, C, ξ, g) of the nonlinear problem, if

$$\begin{gathered}\|(A - A^0)_{t=0}\|_{C^m} + \|(B - B^0)_{t=0}\|_{C^m} + \|(C - C^0)_{t=0}\|_{C^m} \leq \varepsilon, \\ \|(\xi - \xi^0)_{t=0}\|_{C^m} + \|(g - R^0)_{t=0}\|_{C^m} \leq \varepsilon \quad \forall\varepsilon > 0\end{gathered} \tag{68}$$

and if the compatibility conditions hold (at $r = g(\theta,\, 0)$), then

$$\|A - A^0\|_{C^{2,1}} + \|B - B^0\|_{C^{2,1}} + \|C - C^0\|_{C^{2,1}} \leq C^* \varepsilon, \tag{69}$$

$$\|\xi - \xi^0\|_{C^{1,1}} \leq C^* \varepsilon, \qquad \|g - R^0\|_{C^{2,1}} \leq C^* \varepsilon \tag{70}$$

for some constant C^* independent of ε.

In (69), A^0, B^0, and C^0 have been extended as $C^{2+\nu,\, 1+\nu/2}$ functions in the domain

$$\Omega_{T,0} = \left\{\sqrt{x_1^2 + x_2^2} \geq R_0(t) - \delta_0, \quad 0 \leq t \leq T\right\}$$

for some $\delta_0 > 0$, and $C^{2,1}$ means $C^{2,1}(\Omega_T)$, where

$$\Omega_T = \{r \geq g(\theta,\, t), \quad 0 \leq t \leq T\}.$$

For T small enough, Ω_T is contained in $\Omega_{T,0}$. In (70), $C^{j,1}$ means $C^{j,1}(G_T)$.

THEOREM 5.1. *Each radial solution is not locally Lipschitz stable.*

Proof. Suppose the assertion is not true for a particular radial solution (A^0, B^0, C^0, ξ^0, R^0), that is, this solution is Lipschitz stable up to some fixed time $T > 0$.

Take any solution of the nonlinear problem with

$$\begin{gathered}A = A^0 + \varepsilon A^1_\varepsilon, \qquad B = B^0 + \varepsilon B^1_\varepsilon, \qquad C = C^0 + \varepsilon C^1_\varepsilon, \\ g = R^0 + \varepsilon h_\varepsilon, \qquad \xi = \xi^0 + \varepsilon \eta_\varepsilon,\end{gathered} \tag{71}$$

where

$$\begin{gathered}\|A^1_\varepsilon|_{t=0}\|_{C^m} + \|B^1_\varepsilon|_{t=0}\|_{C^m} + \|C^1|_{t=0}\|_{C^m} \leq 1, \\ \|h_\varepsilon|_{t=0}\|_{C^m} + \|\eta_\varepsilon|_{t=0}\|_{C^m} \leq 1\,.\end{gathered} \tag{72}$$

The Lipschitz stability implies that

$$\|A^1_\varepsilon\|_{C^{2,1}(\Omega_T)} + \|B^1_\varepsilon\|_{C^{2,1}(\Omega_T)} + \|C^1_\varepsilon\|_{C^{2,1}(\Omega_T)} \leq C, \tag{73}$$

$$\|\eta_\varepsilon\|_{C^{1,1}(G_T)} \leq C, \tag{74}$$

$$\|h_\varepsilon\|_{C^{2,1}(G_T)} \leq C, \tag{75}$$

where C is a constant independent of ε.

Differentiating the equation

$$g_t = -\frac{1}{g}\sqrt{g^2 + g_\theta^2}\,(\xi - 1)(A^* - A) \tag{76}$$

in θ and applying the estimates (73)–(75), we derive the bound

$$\|(h_\varepsilon)_{t\theta}\|_{L^\infty} \leq C. \tag{77}$$

Next, we differentiate (76) in t and use (73)–(75) and (77). We obtain

$$\|(h_\varepsilon)_{tt}\|_{L^\infty} \le C. \tag{78}$$

The estimates (75), (77), and (78) combined mean that

$$\|h_\varepsilon\|_{C^{2,2}(G_T)} \le C. \tag{79}$$

We now take a sequence of initial values as above with $\varepsilon \to 0$. For a subsequence $\varepsilon = \varepsilon_j \to 0$,

$$A^1_\varepsilon \to A^1, \quad B^1_\varepsilon \to B^1, \quad C^1_\varepsilon \to C^1 \quad \text{in } C^{1+\alpha,\,(1+\alpha)/2},$$
$$\eta_\varepsilon \to \eta \quad \text{in } C^{\alpha,\,\alpha},$$
$$h_\varepsilon \to h \quad \text{in } C^{1+\alpha,\,1+\alpha}$$

for any $0 < \alpha < 1$, and

$$\|\eta_t\|_{L^\infty} + \|\eta_\theta\|_{L^\infty} + \|h_{\theta\theta}\|_{L^\infty} + \|h_{\theta t}\|_{L^\infty} + \|h_{tt}\|_{L^\infty} < \infty. \tag{80}$$

We can then proceed as in §2 (but rigorously!) to prove that $(A^1_\varepsilon,\, B^1_\varepsilon,\, C^1_\varepsilon,\, \eta_\varepsilon,\, h_\varepsilon)$ satisfies the linearized equations and boundary conditions (on $r = R^0 + \varepsilon h_\varepsilon$) with an error term of order $O(\varepsilon)$. Letting $\varepsilon = \varepsilon_j \to 0$, we deduce that $(A^1\, B^1,\, C^1,\, \eta,\, h)$ is a solution to the linearized problem. Choose the initial values for the linearized problem to be as in Theorem 3.1. By uniqueness (Theorem 4.1), $(A^1,\, B^1,\, C^1,\, \eta,\, h)$ must coincide with the linearized solution established in Theorem 3.1 and, consequently,

$$\|h(\cdot,\, T)\|_{C^{1+\beta}} = \infty,$$

which is a contradiction to (80). □

6. A model with accelerated dissolution. In this section, we consider the case where the adsorbed C increases the dissolution of the grain:

$$D_A \frac{\partial A}{\partial n} + P(\zeta)(A - A^*) = 0 \quad \text{on } \Gamma_t, \tag{81}$$

where $P(s)$ is a smooth function and

$$P(s) > 0, \quad P'(s) > 0 \quad \text{for } s \ge 0. \tag{82}$$

Setting

$$k = g_\theta, \qquad F = A^* - A\,(g(\theta,\, t),\, \theta,\, t) \tag{83}$$

we then have, by (6),

$$V_n = P(\zeta)F$$

and, by (13)–(15),

$$\zeta_t = -\frac{k}{g\sqrt{g^2+k^2}} P(\zeta)F\zeta_\theta - \frac{P(\zeta)\zeta F}{g}\left(\frac{k}{\sqrt{g^2+k^2}}\right)_\theta + \frac{P(\zeta)\zeta F}{\sqrt{g^2+k^2}} + C^4$$

or

$$
\begin{aligned}
\zeta_t &= -\frac{k}{g\sqrt{g^2+k^2}}\,P(\zeta)F\zeta_\theta - \frac{P(\zeta)\zeta F g}{(g^2+k^2)^{3/2}}\,k_\theta \\
&\quad + P(\zeta)\zeta F\left[\frac{k^2}{(g^2+k^2)^{3/2}} + \frac{1}{\sqrt{g^2+k^2}}\right] + C^4.
\end{aligned}
\tag{84}
$$

Differentiating equation (5), written in the form

$$
g_t = -\frac{\sqrt{g^2+k^2}}{g}\,P(\zeta)F,
\tag{85}
$$

in θ, we obtain

$$
\begin{aligned}
k_t &= -\frac{k}{g\sqrt{g^2+k^2}}\,P(\zeta)Fk_\theta - \frac{\sqrt{g^2+k^2}}{g}\,P'(\zeta)F\zeta_\theta \\
&\quad - \frac{\sqrt{g^2+k^2}}{g}\,P(\zeta)F_\theta + P(\zeta)F\,\frac{k^3}{g^2\sqrt{g^2+k^2}}.
\end{aligned}
\tag{86}
$$

The system (84)–(86) is a nonlinear hyperbolic system. To transform it into a diagonalized form, introduce

$$
\begin{aligned}
\ell(\theta, t) &= \int_0^{k(\theta,t)} \frac{g(\theta,t)}{g^2(\theta,t)+s^2}\,ds + \int_{c_0}^{\zeta(\theta,t)} \left(\frac{P'(s)}{sP(s)}\right)^{1/2} ds, \\
m(\theta, t) &= \int_0^{k(\theta,t)} \frac{g(\theta,\, t)}{g^2(\theta,\, t)+s^2}\,ds - \int_{c_0}^{\zeta(\theta,t)} \left(\frac{P'(s)}{sP(s)}\right)^{1/2} ds, \qquad c_0 > 0.
\end{aligned}
\tag{87}
$$

Then

$$
\ell_t = \frac{g}{g^2+k^2}\,k_t + \left(\frac{P'(\zeta)}{\zeta P(\zeta)}\right)^{1/2} \zeta_t + g_t(\theta,\, t)\int_0^{k(\theta,t)} \frac{s^2 - g^2(\theta,\, t)}{(g^2(\theta,\, t)+s^2)^2}\,ds,
$$

$$
\ell_\theta = \frac{g}{g^2+k^2}\,k_\theta + \left(\frac{P'(\zeta)}{\zeta P(\zeta)}\right)^{1/2} \zeta_\theta + k(\theta,\, t)\int_0^{k(\theta,\, t)} \frac{s^2 - g^2(\theta,\, t)}{(g^2(\theta,\, t)+s^2)^2}\,ds,
$$

and similar formulas hold for m_t and m_θ.

A direct computation shows that

$$
\begin{aligned}
\ell_t &= -\left(\frac{k}{g\sqrt{g^2+k^2}}\,P(\zeta)F + \sqrt{\frac{P'(\zeta)\zeta P(\zeta)}{g^2+k^2}}\,F\right)\ell_\theta \\
&\quad + \left(\frac{k}{g\sqrt{g^2+k^2}}\,P(\zeta)F + \sqrt{\frac{P'(\zeta)\zeta P(\zeta)}{g^2+k^2}}\,F\right) k\int_0^k \frac{s^2-g^2}{(s^2+g^2)^2}\,ds \\
&\quad + g_t\int_0^k \frac{s^2-g^2}{(s^2+g^2)^2}\,ds - \frac{P(\zeta)}{\sqrt{g^2+k^2}}\,F_\theta + \frac{P(\zeta)Fk^3}{g(g^2+k^2)^{3/2}}
\end{aligned}
\tag{88}
$$

$$+ \sqrt{P'(\zeta)\zeta P(\zeta)}\, F \left[\frac{k^2}{(g^2+k^2)^{3/2}} + \frac{1}{\sqrt{g^2+k^2}} \right] + C^4 \sqrt{\frac{P'(\zeta)}{\zeta P(\zeta)}},$$

$$\begin{aligned} (89) \qquad m_t = &- \left(\frac{k}{g\sqrt{g^2+k^2}} P(\zeta) F - \sqrt{\frac{P'(\zeta)\zeta P(\zeta)}{g^2+k^2}}\, F \right) m_\theta \\ &+ \left(\frac{k}{g\sqrt{g^2+k^2}} P(\zeta) F - \sqrt{\frac{P'(\zeta)\zeta P(\zeta)}{g^2+k^2}}\, F \right) k \int_0^k \frac{s^2-g^2}{(s^2+g^2)^2}\, ds \\ &+ g_t \int_0^k \frac{s^2-g^2}{(s^2+g^2)^2}\, ds - \frac{P(\zeta)}{\sqrt{g^2+k^2}} F_\theta + \frac{P(\zeta) F k^3}{g(g^2+k^2)^{3/2}} \\ &- \sqrt{P'(\zeta)\zeta P(\zeta)}\, F \left[\frac{k^2}{(g^2+k^2)^{3/2}} + \frac{1}{\sqrt{g^2+k^2}} \right] - C^4 \sqrt{\frac{P'(\zeta)}{\zeta P(\zeta)}}. \end{aligned}$$

Substituting (85) into (88) and (89), we get

$$\ell_t + a\ell_\theta = \varphi(g,\, h,\, \zeta,\, F,\, F_\theta,\, E), \tag{90}$$

$$m_t + b m_\theta = \psi(g,\, h,\, \zeta,\, F,\, F_\theta,\, E), \tag{91}$$

where

$$E = C^4\,(g(\theta,\, t),\, \theta,\, t)\,,$$

φ and ψ are smooth functions as long as $g \ge c_0 > 0$, $\zeta \ge c_0$, and

$$a = \frac{k}{g\sqrt{g^2+k^2}} P(\zeta) F + \left(\frac{P'(\zeta)\zeta P(\zeta)}{g^2+k^2} \right)^{1/2} F, \tag{92}$$

$$b = \frac{k}{g\sqrt{g^2+k^2}} P(\zeta) F - \left(\frac{P'(\zeta)\zeta P(\zeta)}{g^2+k^2} \right)^{1/2} F. \tag{93}$$

We impose initial conditions

$$g|_{t=0} = g_0(\theta), \quad \zeta|_{t=0} = \zeta_0(\theta), \tag{94}$$

where $g_0(\theta)$ and $\zeta_0(\theta)$ are periodic functions such that

$$\begin{aligned} &g_0(\theta) \ge 2c_0, \quad \zeta_0(\theta) \ge 2c_0 \qquad (c_0 > 0), \\ &\|g_0\|_{C^{2+\alpha}} \le M, \quad \|\zeta_0\|_{C^{1+\alpha}} \le M, \end{aligned} \tag{95}$$

where $M < \infty$.

The system (85), (90), (91) is hyperbolic with given initial data

$$g = g_0(\theta), \qquad \ell|_{t=0} = \ell_0(\theta), \qquad m|_{t=0} = m_0(\theta) \tag{96}$$

and

$$g_0(\theta) \ge 2c_0 > 0,$$

$$\begin{aligned} &\ell_0(\theta) - m_0(\theta) \geq 2 \int_{c_0}^{2c_0} \left(\frac{P'(s)}{sP(s)} \right)^{1/2} ds \equiv 4c_1 > 0, \\ &\ell_0(\theta) + m_0(\theta) \leq \pi - 2c_2 \quad \text{for some } \ c_2 > 0, \\ &\|g_0\|_{C^{2+\alpha}} \leq M, \quad \|\ell_0\|_{C^{1+\alpha}} \leq C^*(M, c_0), \\ &\|m_0\|_{C^{1+\alpha}} \leq C^*(M, c_0). \end{aligned} \tag{97}$$

In what follows, we denote by

$$\| \quad \|_{C_\theta^{m+\alpha}(G_T)}$$

the $C^{m+\alpha}$ Hölder norm in θ, taken uniformly in t as (θ, t) varies in G_T, and by

$$\| \quad \|_{C_t^\alpha(G_T)}$$

the C^α norm in t, uniformly in θ as (θ, t) varies in G_T. Finally, by

$$\|u\|_{C^{k+\alpha,\, k+\alpha}(G_T)}$$

we denote the sum of the C^α Hölder norms (in $(\theta, t) \in G_T$) of all the derivatives $\partial_\theta^i \partial_t^j u$ with $0 \leq i + j \leq k$.

LEMMA 6.1. *Given F and E continuous in G_T and 2π-periodic in θ such that*

$$\|F\|_{C_\theta^{2+\alpha}(G_T)} \leq M_1, \quad \|E\|_{C_\theta^{1+\alpha}(G_T)} \leq M_1, \tag{98}$$

there exists a unique solution (ζ, g, k) of the system (84)–(86) *with initial conditions* (94) *and with $g_\theta = k$ for $0 \leq t \leq T$ provided T is small enough, and*

$$\|\zeta\|_{C_\theta^{1+\alpha}(G_T)} + \|g\|_{C_\theta^{2+\alpha}(G_T)} \leq \tilde{C}(M, c_0), \tag{99}$$

$$\|\zeta\|_{C^{1+\alpha,\, 1+\alpha}(G_T)} + \|g\|_{C^{2+\alpha,\, 2+\alpha}(G_T)} \leq C(M, M_1, c_0), \tag{100}$$

$$g(\theta, t) \geq c_0, \quad \zeta(\theta, t) \geq c_0 \quad in \ \Omega_T; \tag{101}$$

here T depends on M, M_1, and c_0.

LEMMA 6.2. *If $(\hat{F}, \hat{E})$ is another pair satisfying* (98), *then the corresponding solution $\hat{\zeta}$, $\hat{g}$ satisfies*

$$\begin{aligned} &\|\zeta - \hat{\zeta}\|_{C_\theta^\alpha(G_t)} + \|g - \hat{g}\|_{C_\theta^{1+\alpha}(G_t)} \\ &\qquad \leq C(M, M_1, c_0)t \left[\|F - \hat{F}\|_{C_\theta^{1+\alpha}(G_t)} + \|E - \hat{E}\|_{C_\theta^\alpha(G_t)} \right] \end{aligned} \tag{102}$$

for $0 \leq t \leq T$.

Proof of Lemma 6.1. From (87), we see that

$$k = g \tan\left(\frac{\ell + m}{2} \right) \quad \text{if } \ |\ell + m| < \pi \tag{103}$$

and

$$\int_{c_0}^{\zeta} \left(\frac{P'(s)}{sP(s)} \right)^{1/2} ds = \frac{\ell - m}{2} \quad \text{if } \ \ell - m > 0. \tag{104}$$

Since we are interested only in solutions for small time, without loss of generality, we may take $P(s) = s$ for s large. Then (104) uniquely defines ζ as a function of $(\ell - m)/2$,

$$\zeta = Y\left(\frac{\ell - m}{2}\right), \tag{105}$$

and $Y(s)$ is smooth for $s \geq c_1$, c_1 as in (97).

Substituting (103), (105) into the right-hand sides of (90)–(93) and (85), we find that (85) and (90), (91) form a quasilinear hyperbolic system for (g, ℓ, m). By standard results [1], [6], this system with the initial conditions (96) has a unique solution such that

$$\|g\|_{C^{1+\alpha,\,1+\alpha}(G_T)} + \|\ell\|_{C^{1+\alpha,\,1+\alpha}(G_T)} + \|m\|_{C^{1+\alpha,\,1+\alpha}(G_T)} \leq C(M, M_1, c_0) \tag{106}$$

provided T is small enough; the smallness of T is required also to ensure that

$$g(\theta, t) \geq c_0, \qquad |\ell + m| \leq \pi - c_2, \qquad \ell - m \geq c_1$$

in Ω_T (so that (103) and (105) determine k and ζ as smooth functions of ℓ and m); (101) is then also satisfied.

We next show that $k = g_\theta$. Differentiating (85) formally in θ and comparing with (86), we easily get

$$(g_\theta - k)_t = P(\zeta)F\frac{k^2}{g^2\sqrt{g^2 + k^2}}(g_\theta - k)$$

and, since $(g_\theta - k) = 0$ at $t = 0$, we conclude that $g_\theta \equiv k$. The differentiation in θ in (85) can be justified by first integrating in t and then differentiating in θ.

Since $g_\theta = k$, the estimates (106) imply (100). To prove (99), we consider the characteristics for ℓ given by

$$\frac{d\xi(\theta, t)}{dt} = a(\xi, t), \qquad \xi(\theta, t) = \theta. \tag{107}$$

It follows that

$$\frac{d\xi_\theta}{dt} = a_\xi(\xi, t)\xi_\theta, \qquad \xi_\theta(\theta, 0) = 1,$$

and therefore

$$\exp\left[-C(M, M_1, c_0)t\right] \leq \xi_\theta \leq \exp\left[C(M, M_1, c_0)t\right],$$

and so

$$\frac{1}{2} \leq \xi_\theta(\theta, t) \leq 2 \tag{108}$$

if T is small enough. This allows us to establish the C^α estimate of ℓ_θ:

$$\|\ell\|_{C_\theta^{1+\alpha}(G_T)} \leq C(M, c_0);$$

the constant $C(M, c_0)$ is independent of M_1. A similar estimate can be established for m, and together they yield the assertion (99). □

Remark 6.1. The fact that the constant $\tilde{C}(M, c_0)$ is independent of M_1 is crucial for establishing existence for the full nonlinear problem.

Proof of Lemma 6.2. The proof follows by standard arguments (cf. [1]), integrating along characteristics and applying the Gronwall inequality. □

Remark 6.2. From (100), we have

$$\begin{aligned}[g_t]_{C_t^{\alpha/2}(G_T)} + [D_\theta^2 g]_{C_t^{\alpha/2}(G_T)} + [\zeta_t]_{C_t^{\alpha/2}(G_T)} + [D_\theta \zeta]_{C_t^{\alpha/2}(G_T)} \\ \le C(M, M_1, c_0)T^{\alpha/2} \le 1\end{aligned} \tag{109}$$

if T is small enough.

Since $0 \le F \le A^*$, (84), (85), and (99) imply that

$$\|g_t\|_{C(G_T)} + \|\zeta_t\|_{C(G_T)} \le C(M, c_0, A^*), \tag{110}$$

$$\|g_t\|_{C_\theta^\alpha(G_T)} \le C(M, c_0)\left(1 + \|F\|_{C_\theta^\alpha(G_T)}\right). \tag{111}$$

Combining estimates (109)–(111), we then have

$$\|\zeta\|_{C^{1+\alpha, (1+\alpha)/2}(G_T)} \le \hat{C}(M, c_0, A^*), \tag{112}$$

$$\|g\|_{C^{2+\alpha, 1+\alpha/2}(G_T)} \le \hat{C}(M, c_0)\left[1 + \|F\|_{C_\theta^\alpha(G_T)}\right]. \tag{113}$$

We now consider the full nonlinear problem with initial conditions (94) satisfying (95) and with

$$A|_{t=0} = A_0(r, \theta), \qquad B|_{t=0} = B_0(r, \theta), \qquad C|_{t=0} = C_0(r, \theta) \tag{114}$$

for $r \ge g_0(\theta)$, where

$$A_0 \equiv 0, \quad B \equiv B^*, \quad C_0 \equiv 0 \quad \text{for} \quad r > R^* \tag{115}$$

for some large $R^* > R_0$. We further assume that

$$0 \le A_0 < A^*, \qquad 0 \le B_0 \le B^*, \qquad C_0 \ge 0, \tag{116}$$

$$\|A_0\|_{C^{2+\alpha}} + \|B_0\|_{C^{2+\alpha}} + \|C_0\|_{C^{2+\alpha}} \le M \tag{117}$$

in the region $\sqrt{x_1^2 + x_2^2} \ge g_0(\theta)$, and

$$\begin{aligned} D_A \frac{\partial A_0}{\partial n} + P(\zeta_0)(A_0 - A^*) = 0, \\ \frac{\partial B_0}{\partial n} = 0, \qquad D_C \frac{\partial C_0}{\partial n} = -C_0^4 \quad \text{on} \quad r = g_0(\theta). \end{aligned} \tag{118}$$

For simplicity, we have taken the M in (117) to be the same as (95).

THEOREM 6.3. *The full nonlinear problem with initial data satisfying* (95), (97), *and* (115)–(118) *has a unique classical solution for* $0 \le t \le T$ *for some small enough* $T > 0$; T *depends only on the constants appearing in conditions* (95) *and* (97).

The solution is such that g and ζ belong to $C_\theta^{1+\alpha}(G_T)$.

Proof. We shall prove existence by a fixed-point argument for a mapping W defined in the class

$$\begin{aligned} K = \Big\{(g, \zeta)\,;\ \|g\|_{C_\theta^{2+\alpha}(G_T)} \le \tilde{C}(M, c_0), \quad \|\zeta\|_{C^{1+\alpha, (1+\alpha)/2}(G_T)} \le \hat{C}(M, c_0, A^*), \\ \|g\|_{C^{2+\alpha, 1+\alpha/2}(G_T)} \le \hat{C}(M, c_0) 2\pi \left[1 + A^* + (1 + M)(1 + \tilde{C}(M, c_0))\right], \\ g|_{t=0} = g_0(\theta), \quad \zeta|_{t=0} = \zeta_0(\theta), \quad g(\theta, t) \ge c_0, \quad \zeta(\theta, t) \ge c_0\Big\}, \end{aligned}$$

where the constants $\hat{C}$ and $\tilde{C}$ are taken from (112), (113), and (99).

Given $(g, \zeta) \in K$, we substitute it into the boundary condition for A and then solve for A, B, and C. By the maximum principle,

$$0 \le A(r, \theta, t) \le A^*, \qquad 0 \le B(r, \theta, t) \le B^*$$

and hence

$$0 \le C(r, \theta, t) \le C(M, c_0),$$

where the constant is independent of T.

By the Schauder estimates [7]

$$\|A\|_{C^{2+\alpha,\,1+\alpha/2}(\Omega_T)} + \|B\|_{C^{2+\alpha,\,1+\alpha/2}(\Omega_T)} + \|C\|_{C^{2+\alpha,\,1+\alpha/2}(\Omega_T)} \le C(M, c_0) \tag{119}$$

with another constant $C(M, c_0)$ independent of T.

Consider the functions

$$F(\theta, t) = A^* - A(g(\theta, t), \theta, t), \qquad E(\theta, t) = C^4(g(\theta, t), \theta, t).$$

Then $0 \le F \le A^*$ and

$$\begin{aligned}[F]_{C^\alpha_\theta(G_T)} &\le 2\pi \|F_\theta\|_{C(G_T)} \\ &\le 2\pi \left[\|A_r\|_{C(\Omega_T)} \|g_\theta\|_{C(G_T)} + \|A_\theta\|_{C(G_T)}\right]\end{aligned}$$

and, by (119), (117), and the definition of K, we easily get

$$[F]_{C^\alpha_\theta(G_T)} \le 2\pi(M+1)(1+\tilde{C}(M, c_0)). \tag{120}$$

It is also clear that

$$\|F\|_{C^{2+\alpha}_\theta(G_T)} + \|E\|_{C^{1+\alpha}_\theta(G_T)} \le C_1(M, c_0) \equiv M_1. \tag{121}$$

We now solve (84) and (85) with (F, E) as above and denote the solution by $(\bar{g}, \bar{\zeta})$, and we then define a mapping W by

$$W(g, \zeta) = (\bar{g}, \bar{\zeta}).$$

By Lemma 6.1 and the estimates (112), (113), and (120), W maps K into itself.

Introduce a topology on K by the norm

$$\begin{aligned}\|(g, \zeta)\| = \|g\|_{C(G_T)} + \|g_\theta\|_{C(G_T)} + \|g_{\theta\theta}\|_{C(G_T)} \\ + \|\zeta\|_{C(G_T)} + \|\zeta_\theta\|_{C(G_T)}.\end{aligned}$$

Then K is a closed convex set and, by (100), $W : K \to K$ is compact. Since the mapping W is uniquely defined, it is then also continuous, and so, by Schauder's fixed-point theorem, W has a fixed point. This gives a solution to the full nonlinear problem.

To prove uniqueness suppose $(\hat{A}, \hat{B}, \hat{C}, \hat{g}, \hat{\zeta})$ is another solution. Then

$$\|\hat{\ell}_\theta\|_{C^\alpha_\theta(G_T)} \le C, \qquad \|\hat{m}_\theta\|_{C^\alpha_\theta(G_T)} \le C. \tag{122}$$

Using the differential equations for g, ℓ, and m, (122), and (108), we easily find that

$$\begin{aligned}&\|\zeta-\hat{\zeta}\|_{C_t^{\alpha}(G_T)}+\|g_\theta-\hat{g}_\theta\|_{C_t^{\alpha}(G_T)}+\|g_t-\hat{g}_t\|_{C(G_T)}\\ &\quad\le C\left[\|F-\hat{F}\|_{C_\theta^{1+\alpha}(G_T)}+\|E-\hat{E}\|_{C_\theta^{\alpha}(G_T)}\right]\equiv J.\end{aligned}\tag{123}$$

Hence

$$\|\zeta-\hat{\zeta}\|_{C_t^{\alpha/2}(G_T)}+\|g_\theta-\hat{g}_\theta\|_{C_t^{\alpha/2}(G_T)}\le CT^{\alpha/2}J.$$

Using also Lemma 6.2, we get

$$\|\zeta-\hat{\zeta}\|_{C^{\alpha,\,\alpha/2}(G_T)}+\|g-\hat{g}\|_{C^{1+\alpha,\,(1+\alpha)/2}(G_T)}\le CT^{\alpha/2}J.\tag{124}$$

We now proceed as in [3, §8]. Let

$$V(T)=\|g-\hat{g}\|_{L^\infty(G_T)}$$

and consider A and $\hat{A}$ in the common domain

$$\tilde{\Omega}_T=\{r>\hat{g}(r,\theta)+V(T)\}.$$

As in [3],

$$\begin{aligned}&\left\|\left[D_A\frac{\partial(A-\hat{A})}{\partial n}+P(\zeta)(A-\hat{A})\right]_{r=\hat{g}(\theta,t)+V(T)}\right\|_{C^{\alpha,\,\alpha/2}(G_T)}\\ &\quad\le C\left\{\|g-\hat{g}\|_{C^{1+\alpha,\,(1+\alpha)/2}(G_T)}+\|\zeta-\hat{\zeta}\|_{C^{\alpha,\,\alpha/2}(G_T)}\right\}.\end{aligned}$$

Similar estimates hold for B and C. By parabolic $C^{1+\alpha,\,(1+\alpha)/2}$ estimates [8], we then have

$$\begin{aligned}&\|A-\hat{A}\|_{C_\theta^{1+\alpha}(\tilde{\Omega}_T)}+\|B-\hat{B}\|_{C_\theta^{1+\alpha}(\tilde{\Omega}_T)}+\|C-\hat{C}\|_{C_\theta^{1+\alpha}(\tilde{\Omega}_T)}\\ &\quad\le C\left[\|g-\hat{g}\|_{C^{1+\alpha,\,(1+\alpha)/2}(G_T)}+\|\zeta-\hat{\zeta}\|_{C^{\alpha,\,\alpha/2}(G_T)}\right]\equiv L(T).\end{aligned}$$

Using this and the $C_\theta^{2+\alpha}$ regularity of A and $\hat{A}$, we find that

$$\|F-\hat{F}\|_{C_\theta^{1+\alpha}(\Omega_T)}\le CL(T).$$

A similar estimate holds for $E-\hat{E}$. Substituting these two estimates into (124) (recall the definition of J in (123)), we see that

$$L(T)\le CT^{\alpha/2}L(T)$$

and, therefore, $L(T)=0$ if T is small enough. Similarly, $L(t)\equiv 0$ if $0\le t\le T$ and then also $A=\hat{A}$, $B=\hat{B}$, and $C=\hat{C}$ if $0\le t\le T$.

The uniqueness proof can be extended to any time interval for which the solutions exist. □

Acknowledgment. The authors thank David Ross from Eastman Kodak for suggesting the problem studied in this paper and for stimulating discussions.

ON THE EXISTENCE OF SOLUTIONS OF THE CAUCHY PROBLEM FOR A DOUBLY NONLINEAR PARABOLIC EQUATION*

KAZUHIRO ISHIGE[†]

Abstract. For the existence of weak solutions of

$$\frac{\partial}{\partial t}(|u|^{\beta-1}u) = \operatorname{div}(|\nabla u|^{p-2}\nabla u) \qquad \text{with} \quad |u|^{\beta-1}u(\cdot,0) = \mu(\cdot),$$

we give a sufficient condition for the growth order of the initial data $\mu(x)$ as $|x| \to \infty$

Key words. Cauchy problem, doubly nonlinear parabolic equation

AMS subject classifications. 35K55, 35K57

1. Introduction.

We investigate the Cauchy problem for the following nonlinear diffusion equation:

$$(1.1) \qquad \frac{\partial}{\partial t}(|u|^{\beta-1}u) = \operatorname{div}(|\nabla u|^{p-2}\nabla u) \qquad \text{in} \quad \mathbf{S}_T, \quad \beta > 0, \ p > 1,$$

$$(1.2) \qquad |u|^{\beta-1}u(\cdot,0) = \mu(\cdot) \qquad \text{in} \quad \mathbf{R}^N.$$

Here $\mathbf{S}_T = \mathbf{R}^N \times (0,T)$, $0 < T < \infty$, and μ is an $L^1_{\text{loc}}(\mathbf{R}^N)$ function or a σ-finite Borel measure.

Equation (1.1) is called a doubly nonlinear parabolic equation, which contains the heat equation (i.e., $\beta = 1$, $p = 2$), the porous-medium equation (i.e., $\beta > 0$, $p = 2$), and the p-Laplacian equation (i.e., $\beta = 1$, $p > 1$). Equation (1.1) has been studied by several authors; for example, see [9], [11]–[13], [15], [16], [18], and [19]. We divide the Cauchy problem (1.1) with (1.2) into three cases,

$$\text{(I)} \quad (p-1)/\beta > 1, \qquad \text{(II)} \quad (p-1)/\beta = 1, \qquad \text{(III)} \quad 0 < (p-1)/\beta < 1,$$

and study the existence of the solution, respectively. For cases (I), (II), and (III), the behavior of solutions of (1.1) is completely different, and so we need this separation. Case (I) contains the so-called degenerate cases of the porous-medium and p-Laplacian equations, and case (III) contains the singular cases of these. In what follows, we call (I) the degenerate case and (III) the singular case, respectively.

A classical result of A. N. Tychonov [17] states that the Cauchy problem for the heat equation, $u_t = \Delta u$, has a unique classical solution in the strip $\mathbf{S}_T$ for continuous initial data $\mu(x)$ satisfying

$$(1.3) \qquad |\mu(x)| \le C \exp(|x|^2/4T) \qquad \text{as} \quad |x| \to \infty.$$

Moreover, D. G. Aronson [1] generalized the result of A. N. Tychonov for a parabolic operator with variable coefficients:

$$(1.4) \qquad \mathcal{L}u \equiv \frac{\partial}{\partial t}u - \frac{\partial}{\partial x_j}\left\{A_{ij}(x,t)\frac{\partial}{\partial x_i}u + A_j(x,t)u\right\}$$

*Received by the editors June 29, 1994; accepted for publication (in revised form) May 2, 1995..

with suitable conditions imposed on coefficients $A_{ij}(x,t)$ and $A_j(x,t)$. For the Cauchy problem for the equation $\mathcal{L}u = 0$ with initial data $\mu(x)$ satisfying

$$\int_{\mathbf{R}^N} \mu(x)\exp(-\Lambda|x|^2)dx < \infty, \qquad \Lambda > 0, \tag{1.5}$$

he proved that it has a unique classical solution in some strip $\mathbf{S}_{T'}$, where T' is a constant dependent on Λ. Furthermore, he proved that the solution u is written in the strip $\mathbf{S}_{T'}$ in the form

$$u(x,t) = \int_{\mathbf{R}^N} \Gamma(x,t;\xi,0)u_0(\xi)d\xi,$$

where Γ is the fundamental solution of $\mathcal{L}u = 0$. See also [2], [14], and [20].

For the degenerate case of the porous-medium equation,

$$u_t = \Delta(u^m), \quad m > 1, \tag{1.6}$$

P. Benilan, M. G. Crandall, and M. Pierre [4] proved that the Cauchy problem is uniquely solvable in the sense of weak solutions for initial data satisfying

$$\limsup_{\rho\to\infty} \rho^{-N-2/(m-1)} \int_{B_\rho} d|\mu| < \infty, \tag{1.7}$$

where B_ρ is a ball of radius $\rho > 0$ with center 0. On the other hand, for the degenerate case of the p-Laplacian equation,

$$u_t = \operatorname{div}(|\nabla u|^{p-2}\nabla u), \quad p > 2, \tag{1.8}$$

E. DiBenedetto and M. A. Herrero [6] proved similar results for initial data satisfying

$$\limsup_{\rho\to\infty} \rho^{-N-p/(p-2)} \int_{B_\rho} d|\mu| < \infty. \tag{1.9}$$

Furthermore, E. DiBenedetto and M. A. Herrero [7] and E. DiBenedetto and T. C. Kwong [8] studied the Cauchy problem for singular cases of the porous-medium equation ($(N-2)^+/2 < m < 1$) and the p-Laplacian equation ($2N/(N+1) < p < 2$), respectively, and obtained $L^\infty_{\mathrm{loc}}(\mathbf{R}^N)$ estimates of the solution for $L^1_{\mathrm{loc}}(\mathbf{R}^N)$ initial data.

Our purpose in this paper is to extend earlier results on the existence of solutions of the heat, porous-medium, and p-Laplacian equations to the doubly nonlinear parabolic equation (1.1). The main point of this paper is to treat case (II).

For case (II), if the initial data μ satisfies

$$\int_{\mathbf{R}^N} \exp(-\Lambda|x|^{p/(p-1)})d|\mu| < \infty \tag{1.10}$$

for some constant $\Lambda > 0$, then we prove that there exists a weak solution of (1.1) with (1.2) in the strip $\mathbf{S}_{T(\Lambda)}$, where $T(\Lambda) = (p-1)^{2(p-1)}\Lambda^{1-p}/p^p$. Here we remark that there exists a solution of (1.1) with initial data satisfying (1.10) which cannot be extended to a strip larger than $\mathbf{S}_{T(\Lambda)}$. Case (II) contains the heat equation, but our proof is completely different from that of [1] and [17]. In fact, in the proof of case (II), we do not use the fundamental solution of the heat equation, and the proof depends only on the structure conditions of the equation. Therefore our proof is applicable to more general equations than that of [1].

For the proof of case (II), we essentially use the techniques given in [5]–[8]. However, it seems difficult to apply them directly to case (II). To overcome this difficulty, we introduce a new function with weight ϕ_Λ (see equation (2.8) below) and obtain an $L^1(\mathbf{R}^N)$ estimate of ϕ_Λ (see (2.10)). By the estimate of $\|\phi_\Lambda(\cdot,t)\|_{L^1(\mathbf{R}^N)}$, we can estimate $\|u(\cdot,t)\|_{L^\infty(\bar{B}_\rho)}$ and $\|\nabla u(\cdot,t)\|_{L^{p-1}(B_\rho)}$ and prove that the optimal growth order of the initial data for this case is exponential.

For case (I), we will prove that there exists a weak solution of (1.1) under initial data satisfying

$$\limsup_{\rho\to\infty} \rho^{-N-p/d} \int_{B_\rho} d|\mu| < \infty, \tag{1.11}$$

with $d = (p-1)/\beta - 1$. Furthermore, for case (III) with $Nd+p>0$, we will give $L^\infty_{\text{loc}}(\mathbf{R}^N)$ estimates of the solution for $L^1_{\text{loc}}(\mathbf{R}^N)$ initial data. For cases (I) and (III), our proof depends heavily on an approach used in [5]–[8]. Recently, for case (III) of equation (1.1), V. Vespri [19] proved several inequalities through which the existence of solutions is proved.

Finally, we remark that—to our knowledge—there are no results for the uniqueness of weak solutions of (1.1), though the uniqueness of strong solutions of (1.1) is given in [9] and [16].

2. The main results.

In this section, we give the definition of a weak solution of (1.1) with (1.2) and state our results.

DEFINITION 1.1. *A measurable function $u(x,t)$ defined in $\mathbf{R}^N \times (0,T)$ is a weak solution of* (1.1) *and* (1.2) *if for any $\epsilon \in (0,T)$ and any bounded open set $\Omega \subset \mathbf{R}^N$, $|\nabla u|^{p-1} \in L^1(\Omega\times(0,T_\epsilon))$, $|u|^{\beta-1}u \in C(0,T_\epsilon;L^1(\Omega))$, and*

$$\int_\Omega |u|^{\beta-1}u\varphi(x,t)dx + \int_0^t\int_\Omega \{-|u|^{\beta-1}u\varphi_t + |\nabla u|^{p-2}\nabla u\cdot\nabla\varphi\}dxd\tau = \int_\Omega \varphi(x,0)d\mu \tag{2.1}$$

for all $0<t<T_\epsilon$ and all testing functions

$$\varphi \in W^{1,\infty}(0,T_\epsilon;L^\infty(\Omega)) \cap L^\infty(0,T_\epsilon;W_0^{1,\infty}(\Omega)). \tag{2.2}$$

Here $T_\epsilon = T-\epsilon$.

Throughout this paper, we set

$$m = 1/\beta, \qquad d = (p-1)/\beta - 1 = m(p-1)-1, \qquad \kappa_r = Nd+rp.$$

In particular, we set

$$\kappa = \kappa_1 = Nd+p, \qquad \kappa^* = \kappa_{mp} = Nd+mp^2$$

for simplicity. Furthermore, by $C = C(A_1,A_2,\dots)$ we denote a positive constant which depends only $\beta,p,A_1,A_2,\dots$.

Case (I): *The degenerate case* $(d > 0)$. In order to represent the growth order of the initial data $\mu(x)$, we define $|||f|||_r$ by

$$|||f|||_r = \sup_{\rho \geq r} \rho^{-\kappa/d} \int_{B_\rho} |f| dx \tag{2.3}$$

for $f \in L^1_{\mathrm{loc}}(\mathbf{R}^N)$. This norm is a modification of the one introduced in [6].

THEOREM 1.2. *Let $d > 0$ and μ be a σ-finite Borel measure in $\mathbf{R}^N$ satisfying*

$$|||\mu|||_r < \infty \qquad \textit{for some} \quad r > 0.$$

Then there exists a weak solution u of (1.1) *and* (1.2) *in the strip $\mathbf{S}_{T(\mu)}$, where*

$$T(\mu) = \begin{cases} C_1[\lim_{r\to\infty} |||\mu|||_r]^{-d} & \textit{if} \quad \lim_{r\to\infty} |||\mu|||_r > 0, \\ +\infty & \textit{if} \quad \lim_{r\to\infty} |||\mu|||_r = 0, \end{cases} \tag{2.4}$$

and $C_1 = C_1(N, \beta, p)$.

Let $T_r(\mu) = C_1 |||\mu|||_r^{-d}$. Then for any $t \in (0, T_r(\mu))$ and $\rho > 0$,

$$|||\, |u|^\beta(\cdot, t)\, |||_r \leq C_2 |||\mu|||_r, \tag{2.5}$$

$$\|u(\cdot, t)\|_{L^\infty(B_\rho)} \leq C_3 t^{-N/\beta\kappa} \rho^{p/\beta d} |||\mu|||_r^{p/\beta\kappa}, \tag{2.6}$$

and

$$\int_0^t \int_{B_\rho} |\nabla u|^{p-1} dx d\tau \leq C_4 t^{1/\kappa} \rho^{1+\kappa/d} |||\mu|||_r^{1+d/\kappa}, \tag{2.7}$$

where $C_i = C_i(N, \beta, p)$, $i = 2, 3, 4$.

Case (II): *The critical case* $(d = 0)$. For any $\lambda > 0$ and $\delta > 0$, let $\phi_\lambda(t)$ be a function defined by

$$\phi_\lambda(t) = \sup_{\tau \in (0,t)} \int_{\mathbf{R}^N} \eta(|x|) F(e^{g_\lambda} u^{p-1}) dx, \tag{2.8}$$

where

$$F(s) = \begin{cases} |s|^{1+\delta}/(1+\delta) & \text{if} \quad |s| \leq 1, \\ |s| - \delta/(1+\delta) & \text{if} \quad |s| \geq 1, \end{cases} \qquad \eta(s) = \begin{cases} 1 & \text{if} \quad s \leq 1, \\ s^{(N+p)/(p-1)} & \text{if} \quad s \geq 1, \end{cases}$$

and

$$g_\lambda(x, t) = -\lambda \left(\frac{|x|^p}{1-t} \right)^{1/(p-1)} (1 + t^l), \qquad 0 < l < 1/2. \tag{2.9}$$

Then our result for Case (II) is as follows.

THEOREM 1.3. *Let $d = 0$ and μ be a σ-finite Borel measure satisfying*

$$\int_{\mathbf{R}^N} \exp(-\Lambda |x|^{p/(p-1)}) d|\mu(x)| < \infty \tag{2.10}$$

for some $\Lambda > 0$. *Then there exists a weak solution* u *of* (1.1) *and* (1.2) *in the strip* $\mathbf{S}_{T(\Lambda)}$, *where* $T(\Lambda)$ *is a constant such that*

$$T(\Lambda) = \frac{(p-1)^{2(p-1)}}{p^p}\Lambda^{1-p}. \tag{2.11}$$

Furthermore, let $\delta > 0$ *be a sufficiently small constant. Then for any* $\lambda > \Lambda$, *there exists a constant* $T_0 > 0$ *such that* u *satisfies the following inequalities:*

$$\phi_\lambda(t) \le C_1\phi_\lambda(0) \le C\int_{\mathbf{R}^N} \exp(-\Lambda|x|^{p/(p-1)})d|\mu(x)|, \tag{2.12}$$

$$\|e^{g_\lambda(\cdot,t)}|u|^{p-1}\|_{L^\infty(\mathbf{R}^N)} \le C_2(1+t^{-N/p})\phi_\lambda(t) \tag{2.13}$$

for all $t \in (0,T_0)$, *where* $C = C(p,N,\Lambda,\lambda,\delta)$ *and* $C_i = C_i(p,N,\delta)$, $i = 1,2$.

The estimate of $T(\Lambda)$ in (2.11) is optimal in the sense that there exists a solution blowing up at $T(\Lambda)$. In fact, let $u(x,t)$ be a function such that

$$u(x,t) = (1-\sigma t)^{-N/p(p-1)}\exp\left[\gamma\left(\frac{|x|^p}{1-\sigma t}\right)^{1/(p-1)}\right], \qquad \gamma = \frac{p-1}{p}\left(\frac{\sigma}{p}\right)^{1/(p-1)},$$

where σ is any positive constant. Then $u(x,t)$ is a solution of (1.1) in the strip $\mathbf{S}_{1/\sigma}$, and

$$u^{p-1}(x,0) = \exp((p-1)\gamma|x|^{p/(p-1)}).$$

Then $T((p-1)\Lambda) = 1/\sigma$ and $u(x,t)$ blows up at $t = 1/\sigma$.

Case (III): *The singular case* ($d < 0$). We treat only the result for the case where $\kappa > 0$.

THEOREM 1.4. *Let* $d < 0$ *such that* $\kappa > 0$ *and let* μ *be a* σ*-finite Borel measure in* $\mathbf{R}^N$. *Then there exists a weak solution* u *of* (1.1) *and* (1.2) *in* $\mathbf{R}^N \times (0,\infty)$. *Furthermore, the solution* $u(x,t)$ *satisfies the following inequalities:*

$$\|\,|u|^\beta(\cdot,t)\,\|_{L^\infty(B_\rho)} \le C_1 t^{-N/\kappa}\left(\sup_{0<\tau<t}\int_{B_{2\rho}} |u|^\beta(x,\tau)dx\right)^{p/\kappa} + C_2\left(\frac{t}{\rho^p}\right)^{p/\kappa}$$

and

$$\sup_{0<\tau<t}\int_{B_\rho} |u|^\beta(x,\tau)dx \le C_3\int_{B_{2\rho}} d|\mu(x)| + C_4\left(\frac{t}{\rho^\kappa}\right)^{1/-d}$$

for any $t > 0$ *and* $\rho > 1$, *where* $C_i = C_i(N,m,p)$, $i = 1,2,3,4$.

The essential part of Theorem 1.4 was proved by V. Vespri. See Theorems 2–1 and 2–2 in [19].

We remark that the estimates of solutions given in Theorems 1.2–1.4 may be extended to nonnegative strong subsolutions of

$$\frac{\partial}{\partial t}(|u|^{\beta-1}u) - \mathrm{div}A(x,t,u,\nabla u) \le B(x,t,u,\nabla u). \tag{2.14}$$

Here the structure conditions below are satisfied:

$$\begin{cases} C_1|q|^p - g_1(x,t) \le A(x,t,u,q)\cdot q \le C_2|q|^p + g_2(x,t), \\ [A(x,t,u,q) - A(x,t,u,\tilde{q})]\cdot(q-\tilde{q}) \ge 0, \\ |B(x,t,u,q)| \le C_3|q|^{p-1} + g_3(x,t) \end{cases} \tag{2.15}$$

for any $(x,t,u) \in \mathbf{R}^N \times \mathbf{R}_+ \times \mathbf{R}$ and $q, \tilde{q} \in \mathbf{R}^N$, where C_i, $i = 1,2,3$, are given constants and g_i, $i = 1,2$, are given bounded functions in $\mathbf{R}^{N+1}$.

Furthermore, we remark that it is not restrictive to treat nonnegative continuous strong solutions of (1.1). In fact, by the results of [12] and [18] and the method of construction of the solutions in this paper, we can take a solution u as a continuous function. Moreover, the solution u is approximated by solutions u_n of suitable approximate equations (see (3.4)), which satisfy the structure conditions in (2.15). Then by Lemma 1–2 in [5], $u_{n+} = \max\{u_n, 0\}$ and $u_{n-} = -\min\{u_n, 0\}$ are continuous nonnegative strong subsolutions of the approximate equations, and the estimates of Theorems 1.2–1.4 hold for nonnegative strong subsolutions of (2.14). Therefore, throughout this paper, we treat only nonnegative continuous solutions of (1.1). See §3.

The organization of this paper is as follows. In §§3 and 4, we prove Theorem 1.3. In §3, we prove (2.11) for the $L^\infty_{\mathrm{loc}}(\mathbf{R}^N)$ initial data satisfying (2.10). In §4, we study the behavior of $\phi_\lambda(t)$ and complete the proof of Theorem 1.3. In §5, we prove Theorem 1.2 by arguments similar to those of [5]–[8]. In §6, via [7] and [19], we present some lemmas to prove Theorem 1.4.

3. Existence of solutions for Case (II). In this section, we consider the Cauchy problem of

$$\begin{cases} \dfrac{\partial}{\partial t}(|u|^{p-2}u) = \operatorname{div}(|\nabla u|^{p-2}\nabla u) & \text{in} \quad \mathbf{R}^N \times (0,T), \quad p > 1, \\ |u|^{p-2}u(x,0) = \mu(x) \in L^\infty_{\mathrm{loc}}(\mathbf{R}^N) & \text{in} \quad \mathbf{R}^N \end{cases} \tag{3.1}$$

under the condition in (2.10) and prove the following proposition. To prove Proposition 3.1, we need several lemmas.

PROPOSITION 3.1. *Let μ be a $L^\infty_{\mathrm{loc}}(\mathbf{R}^N)$ function such that*

$$\mu(x)\exp(-\Lambda|x|^{p/(p-1)}) \in L^\infty(\mathbf{R}^N).$$

Then there exists a weak solution $u(x,t)$ of (3.1) *in $\mathbf{S}_{T(\Lambda)}$, where $T(\Lambda)$ is a constant given in* (2.11). *Furthermore, for any $\epsilon \in (0, T(\Lambda))$, there exist constants C_1^ϵ and C_2^ϵ such that the solution $u(x,t)$ satisfies*

$$\begin{aligned} \sup_{0<\tau<T_\epsilon} \int_{\mathbf{R}^N} \exp(-C_1^\epsilon|x|^{p/(p-1)})u^p(x,\tau)dx + \iint_{\mathbf{S}_{T_\epsilon}} \exp(-C_1^\epsilon|x|^{p/(p-1)})|\nabla u|^p dx d\tau \\ \le C_2^\epsilon \, \|\mu\exp(-\Lambda|\cdot|^{p/(p-1)})\|_{L^\infty(\mathbf{R}^N)}, \end{aligned}$$

where $T_\epsilon = T(\Lambda) - \epsilon$.

To simplify notation, we introduce a functional space with weight $L^q_\lambda(\mathbf{R}^N)$. For $f \in L^q_{\mathrm{loc}}(\mathbf{R}^N)$ with $q \in [1,\infty]$, we define

$$\|f\|_{q,\lambda} \equiv \|\exp(-\lambda|\cdot|^{p/(p-1)})f(\cdot)\|_{L^q(\mathbf{R}^N)}, \qquad \lambda > 0,$$

and we say that $f \in L^q_\lambda(\mathbf{R}^N)$ if $\|f\|_{q,\lambda} < \infty$.

We begin by proving the existence of solutions of (3.1) for $\mu \in C_0^\infty(\mathbf{R}^N)$. The following lemma is an extension of Theorem 3 in [1].

LEMMA 3.2. *Let $\mu \in C_0^\infty(\mathbf{R}^N)$. Then there exists a solution $u(x,t)$ of* (3.1) *in the strip $\mathbf{S}_\infty$ which satisfies $0 \le \|u\|_{L^\infty(\mathbf{R}^N\times(0,\infty))} \le \|\mu\|_{L^\infty(\mathbf{R}^N)}$.*

Let

$$h_{\gamma,T}(x,t) = -\gamma\left(\frac{|x|^p}{T-t}\right)^{1/(p-1)}, \qquad \gamma > 0. \tag{3.2}$$

Then for any $\lambda > 0$, *there exist constants* γ_0 *and* C *dependent only on* p *such that*

$$\sup_{0<\tau<T_\lambda} \int_{\mathbf{R}^N} e^{ph_{\gamma_0,T_\lambda}(\cdot,t)/(p-1)} u^p dx + \iint_{\mathbf{S}_{T_\lambda}} |e^{h_{\gamma_0,T_\lambda}(x,\tau)/(p-1)} \nabla u|^p dx d\tau \le C\|\mu\|_{\frac{p}{p-1},\lambda}, \tag{3.3}$$

where $T_\lambda = \lambda^{1-p}\gamma_0^{p-1}$.

Proof. By $\theta_n(s)$ we denote a sequence of $C^1(\mathbf{R})$ functions such that $\theta(s) \to |s|^{\beta-1}s$ and $\theta'_n(s) \to \beta|s|^{\beta-1}$ uniformly on any compact set of $\mathbf{R}\setminus\{0\}$, where $\beta = p-1$. Then we consider the Cauchy–Dirichlet problem,

$$\begin{cases} \dfrac{\partial}{\partial t}\theta_n(u) = \operatorname{div}\{(|\nabla u|^2 + 1/n)^{(p-2)/2}\nabla u\} & \text{in} \quad B_n(0) \times (0,T), \\ u(x,t) = 0 & \text{on} \quad \partial B_n(0) \times (0,T), \\ \theta_n(u)(x,0) = \mu(x) & \text{in} \quad B_n(0), \end{cases} \tag{3.4}$$

where $p > 1$ and $\mu \in C_0^\infty(\mathbf{R}^N)$. Let n be a sufficiently large integer n such that $\operatorname{supp}(\mu) \subset B_n$. By [12], [16], and [18], there exists a classical solution u_n of (3.4) in $B_n \times (0,\infty)$ such that $0 \le |u_n(x,t)| \le \|\mu\|_{L^\infty(\mathbf{R}^N)}$ and $|u_n(x,t) - u_n(y,s)| \le M(|x-y|^\alpha + |t-s|^{\alpha/p})$ for all $(x,t),(y,s) \in B_n(0) \times (0,\infty)$. Here M and α are constants which are independent of n and depend only on $\|u_n\|_{L^\infty(\mathbf{R}^N\times(0,\infty))}$.

Let $h = h_{\gamma_0,T_\lambda}$ for simplicity, and set

$$\varphi_n(x,t) = \exp\left(\frac{p}{p-1}h(x,t)\right)u_n(x,t).$$

Then we have the following two inequalities:

$$\begin{aligned} &\int_0^{T_\lambda}\int_{B_n} \frac{\partial}{\partial t}\theta_n(u_n)\varphi_n dx d\tau \\ &\quad \ge \int_{B_n} e^{ph/(p-1)}\Theta_n(u_n)dx\Bigg|_{\tau=0}^{\tau=T_\lambda} - \frac{p-1}{p}\int_0^{T_\lambda}\int_{B_n} e^{ph/(p-1)}\Theta_n(u_n)\frac{\partial}{\partial t}h dx d\tau \end{aligned}$$

and

$$\begin{aligned} &\int_0^{T_\lambda}\int_{B_n} (|\nabla u|^2 + 1/n)^{(p-2)/2}\nabla u \cdot \nabla\varphi_n dx d\tau \\ &\quad \ge \int_0^{T_\lambda}\int_{B_n} e^{ph/(p-1)}(|\nabla u_n|^2 + 1/n)^{p-2}|\nabla u|^2 dx d\tau \\ &\qquad - \frac{p}{p-1}\int_0^{T_\lambda}\int_{B_n} e^{ph/(p-1)}u_n(|\nabla u_n|^2 + 1/n)^{(p-2)/2}|\nabla u||\nabla h| dx d\tau \\ &\quad \ge \frac{1}{2}\int_0^{T_\lambda}\int_{B_n} e^{ph/(p-1)}|\nabla u_n|^p dx d\tau - \frac{2^{p-1}}{p-1}\int_0^{T_\lambda}\int_{B_n} e^{ph/(p-1)}u_n^p|\nabla h|^p dx d\tau, \end{aligned}$$

where $\Theta_n(s) = \int_0^{\theta_n(s)} \theta_n^{-1}(t)dt$. We multiply φ_n by (3.4) and integrate over $B_n \times (0, T_\lambda)$. Since $\lim_{n\to\infty} \Theta_n(s) = (p-1)|s|^p/p$ and the function h_{γ_0,T_λ} has the relation

$$-\frac{\partial}{\partial t} h_{\gamma_0,T_\lambda} = \frac{(p-1)^{p-1}}{p^p}\gamma_0^{1-p}|\nabla h_{\gamma_0,T_\lambda}|^p, \tag{3.5}$$

we take a sufficiently small γ_0 such that

$$(p-1)^{p-1}\gamma_0^{1-p}/p^p > 2^{p-1}/(p-1)$$

and have

$$\begin{aligned}\sup_{0<\tau<T_\lambda} \int_{B_n} e^{ph/(p-1)}\Theta_n(u_n)dx + \int_0^{T_\lambda}\int_{B_n} e^{ph/(p-1)}|\nabla u_n|^p dx d\tau \\ \le C(p)\int_{B_n} e^{ph(x,0)/(p-1)}\Theta_n(\mu_n)dx\end{aligned} \tag{3.6}$$

for sufficiently large integers n.

Taking the limit as $n \to \infty$, by inequality (3.6) and the definition of Θ_n, there exists a function $u \in L^p_{\mathrm{loc}}(0, T_\lambda : W^{1,p}_{\mathrm{loc}}(\mathbf{R}^N))$ such that

$$u_n \rightharpoonup u \qquad \text{in} \quad L^p_{\mathrm{loc}}(0, T_\lambda : W^{1,p}_{\mathrm{loc}}(\mathbf{R}^N)) \quad \text{weakly},$$

and u satisfies inequality (3.3) and $0 \le \|u\|_{L^\infty(\mathbf{R}^N \times (0,T_\lambda))} \le \|\mu\|_{L^\infty(\mathbf{R}^N)}$. Furthermore, by the Minty lemma (see [3]), u is a weak solution of (3.1) in $\mathbf{S}_{T_\lambda}$. By $\lim_{\lambda\to 0} T_\lambda = \infty$, the solution $u(x,t)$ exists in $\mathbf{S}_\infty$. □

By Lemma 3.2, for any $\mu \in L^\infty_\lambda(\mathbf{R}^N)$, there exists a solution of (3.1) in the strip $\mathbf{S}_{T_{\gamma_0}}$. In order to expand the strip $\mathbf{S}_{T_{\gamma_0}}$ to a larger strip, we need two lemmas.

LEMMA 3.3. *Let μ be a function in $C_0^\infty(\mathbf{R}^N)$ and $u(x,t)$ be a solution of* (3.1) *constructed in Lemma* 3.2. *For any $\delta > 0$, let γ_δ be a constant such that*

$$\gamma_\delta = (p-1)\delta/(1+\delta)^{p/(p-1)}. \tag{3.7}$$

Then for any $T > 0$, there exists a constant $C = C(p, \delta)$ independent of T such that

$$\sup_{0<t<T} \| |u|^{p-1}(\cdot,t)e^{h_{\gamma_\delta,T}(\cdot,t)}\|_{L^{1+\delta}(\mathbf{R}^N)} \le C\|\mu(\cdot)e^{h_{\gamma_\delta,T}(\cdot,0)}\|_{L^{1+\delta}(\mathbf{R}^N)}. \tag{3.8}$$

Furthermore, we have $\max_{\delta>0}\gamma_\delta = \gamma_{p-1}$.

Proof. Let u_n be a solution of the Cauchy–Dirichlet problem (3.5). For any $\epsilon > 0$, set

$$\varphi_n(x,t) = (e^{h_{\gamma_\delta,T}}(u_n+\epsilon)^{p-1})^\delta e^{h_{\gamma_\delta,T}(x,t)} - \epsilon^{\delta(p-1)} \exp\left(-(1+\delta)\gamma\left(\frac{n^p}{T-t}\right)^{1/(p-1)}\right).$$

Then for any $0 < t < T$, we have

$$\begin{aligned}&\int_0^t\int_{B_n} (|\nabla u_n|^2 + 1/n)^{(p-2)/2}\nabla u_n \cdot \nabla\varphi_n dx d\tau \\ &\ge \delta(p-1)\int_0^t\int_{B_n} e^{(1+\delta)h_{\gamma_\delta,T}}(u_n+\epsilon)^{\delta(p-1)-1}(|\nabla u_n|^2+1/n)^{(p-2)/2}|\nabla u_n|^2 dx d\tau \\ &\quad - \int_0^t\int_{B_n} e^{(1+\delta)h_{\gamma_\delta,T}}(u_n+\epsilon)^{\delta(p-1)}(|\nabla u_n|^2+1/n)^{(p-2)/2}|\nabla u_n||\nabla h_{\gamma_0,T}|dx d\tau \\ &\ge -\frac{(1+\delta)^p}{\delta^{p-1}p^p}\int_0^t\int_{B_n}(e^{h_{\gamma_\delta,T}}(u_n+\epsilon)^{p-1})^{1+\delta}|\nabla h_{\gamma_0,T}|^p dx d\tau.\end{aligned}$$

Here we use the Young inequality $ab^{p-1} \leq (\tilde{\epsilon}^{1-p}/p)a^p + ((p-1)/p)\tilde{\epsilon}b^p$ with $\tilde{\epsilon} = \delta p/(1+\delta)$. Thus we obtain the following inequalities:

$$\begin{aligned}\liminf_{\epsilon\to 0} \int_0^t \int_{B_n} \frac{\partial}{\partial t}\theta_n(u_n)\varphi_n dx d\tau &\geq \int_{B_n} e^{(1+\delta)h_{\gamma_\delta,T}(x,\tau)}\tilde{\Theta}_n(u_n)dx\Big|_{\tau=0}^{\tau=t} \\ &- (1+\delta)\int_0^t \int_{B_n} e^{(1+\delta)h_{\gamma_\delta,T}}\tilde{\Theta}_n(u_n)\frac{\partial}{\partial t}h_{\gamma_\delta,T}dx d\tau\end{aligned}$$

and

$$\begin{aligned}&\liminf_{\epsilon\to 0} \int_0^t \int_{B_n} (|\nabla u_n|^2 + 1/n)^{(p-2)/2}\nabla u_n \cdot \nabla\varphi_n dx d\tau \\ &\quad\geq -\frac{(1+\delta)^p}{\delta^{p-1}p^p}\int_0^t \int_{B_n} (e^{h_{\gamma_\delta,T}}u_n^{p-1})^{1+\delta}|\nabla h_{\gamma_0,T}|^p dx d\tau,\end{aligned}$$

where $\tilde{\Theta}_n(s) = \int_0^{\theta_n(s)}[\theta^{-1}(t)]^{\delta(p-1)}dt$. Taking the limit as $n \to \infty$, by (3.5) and (3.7), we see that there exists a constant $C(\delta)$ such that

$$\int_{B_n} (e^{h_{\gamma_\delta,T}}|u|^{p-1})^{1+\delta}dx\Big|_{\tau=t} \leq C(\delta)\int_{B_n} (e^{h_{\gamma_\delta,T}}(x,0)\mu(x))^{1+\delta}dx,$$

and so the proof of Lemma 3.3 is complete. □

The following lemma is proved by the arguments similar to those of [5]–[8].

LEMMA 3.4. *Let u be a solution of* (3.1) *constructed in Lemma* 3.2. *For any $\lambda > 0$ and $r > 1$, there exist constants $C = C(r,\lambda)$ and $T_\lambda^* < 1$ such that*

$$\begin{aligned}&\|\eta(|x|)e^{g_\lambda}u^{p-1}\|_{L^\infty(B_{R_1}\times(t_1,t))} \\ &\quad\leq CM^{(N+p)/rp}\left(\int_{t_2}^t \int_{B_{R_2}} [\eta(|x|)e^{g_\lambda}u^{p-1}]^r dx d\tau\right)^{1/r}\end{aligned} \tag{3.9}$$

for any R_1 and R_2 with $0 < R_1 < R_2$ and any t, t_1, and t_2 with $0 < t_2 < t_1 < t \leq T_\lambda^*$, where

$$M = |\nabla g_\lambda|^p(R_2,t) + (R_2 - R_1)^{-p} + (t_1 - t_2)^{-1}. \tag{3.10}$$

Here η and g_λ are functions in (2.8).

Proof. We first assume that u is a nonnegative strong solution of (3.1). Let $t \in (0,1)$, $\sigma \in (0,1]$, and R_1 and R_2 with $0 < R_1 < R_2$ be fixed and consider the sequences

$$r_n = R_1 + \sigma(R_2 - R_1)2^{-n}, \qquad s_n = t_1 - \sigma(t_1 - t_2)2^{-n}.$$

Set $B_n = B_{r_n}$ and $Q_n = B_n \times (s_n, t)$, $n = 0, 1, 2, \ldots$, and denote by ζ_n a nonnegative piecewise-smooth function in Q_n such that $\zeta_n = 1$ on Q_{n+1}, $\mathrm{supp}\zeta_n \subset Q_n$,

$$|\nabla\zeta_n| \leq 2^{n+1}/\sigma(R_2 - R_1), \quad \text{and} \quad 0 \leq \frac{\partial}{\partial t}\zeta_n \leq 2^{n+1}/\sigma(t_1 - t_2).$$

Moreover, for any $k > 0$, set $k_n = k(1 - 2^{-(n+1)})$.

Set $\varphi_n = \eta(|x|)e^{g_\lambda}U_{k_n}^q\zeta_n^p$ and $U_k = [(\eta(|x|)e^{g_\lambda})^{1/(p-1)}u - k]_+$, where q is a constant to be chosen later. Then we have

$$\begin{aligned}(3.11)\quad \iint_{Q_n} |\nabla u|^{p-2}\nabla u \cdot \nabla\varphi_n dxd\tau &\geq \frac{q}{2}\iint_{Q_n} (\eta(|x|)e^{g_\lambda})^{p/(p-1)}U_{k_n}^{q-1}|\nabla u|^p\zeta_n^p dxd\tau \\ &- C\iint_{Q_n} \{\eta(|x|)e^{g_\lambda}u^{p-1}U_{k_n}^q\zeta_n^p|\nabla g_\lambda|^p + U_0^pU_{k_n}^{q-1}[|\nabla g_\lambda|^p + |\nabla\zeta_n|^p]\}dxd\tau\end{aligned}$$

and

$$\begin{aligned}(3.12)\quad \iint_{Q_n} \frac{\partial}{\partial t}(u^{p-1})\varphi_n dxd\tau &\geq \int_{B_n} \Lambda_n(x,t)\zeta_n^p dx\Big|_{t_n}^{t} - \iint_{Q_n} \Lambda_n(x,\tau)\frac{\partial}{\partial t}\zeta_n^p dxd\tau \\ &- \iint_{Q_n} \eta(|x|)e^{g_\lambda}u^{p-1}U_{k_n}^q\zeta^p\frac{\partial}{\partial t}g_\lambda dxd\tau,\end{aligned}$$

where

$$\Lambda_n(x,t) = \int_{k_n}^{\eta(|x|)e^{g_\lambda}u^{p-1}} (s^{1/(p-1)} - k_n)_+^q ds.$$

We divide the proof into two cases—(A) $p \geq 2$ and (B) $1 < p < 2$—and proceed the proof of (3.9), respectively.

Case (A): ($p \geq 2$). Since the function g_λ has the relation

$$(3.13)\qquad -\frac{\partial}{\partial t}g_\lambda(x,t) \geq C\lambda^{1-p}t^{l-1}|\nabla g_\lambda(x,t)|^p,$$

by (3.11) and (3.12), there exists a constant T_λ^* dependent only on λ such that for any $t \in (0, T_\lambda^*)$,

$$k_n^{p-2}\sup_{\tau\in(0,t_{n+1})}\int_{B_{n+1}} U_{k_n}^{q+1}dx + \iint_{Q_{n+1}} U_{k_n}^{q-1}|\nabla U_{k_n}|^p dxd\tau \leq K\iint_{Q_n} U_{k_n}^{q-1}dxd\tau,$$

where

$$K \equiv \frac{\|U_0\|_{L^\infty(Q_0)}^p}{\sigma^p}M = \frac{\|U_0\|_{L^\infty(Q_0)}^p}{\sigma^p}(|\nabla g_\lambda(R_2,t)|^p + (R_2 - R_1)^{-p} + (t_1 - t_2)^{-1}).$$

Now we set $\omega_n = U_{k_n}^{(p+q-1)/p}$, $s = p(q+1)/(p+q-1)$, and $s' = p(q-1)/(p+q-1)$ and obtain the following inequality:

$$(3.14)\qquad k_n^{p-2}\sup_{\tau\in(0,t_{n+1})}\int_{B_{n+1}} \omega_n^s dx + \iint_{Q_n} |\nabla\omega_n|^p dxd\tau \leq K\iint_{Q_n} \omega_n^{s'} dxd\tau.$$

By (3.14), the Gagliardo–Nirenberg inequality yields

$$(3.15)\qquad \iint_{Q_{n+1}} \omega_{n+1}^{q'}dxd\tau \leq Ck_n^{p(2-p)/N}K^{(N+p)/N}\left(\iint_{Q_n} \omega_n^{s'} dxd\tau\right)^{(N+p)/N},$$

where $q' = p(1 + s/N)$.

On the other hand by $s' < q'$ and the Hölder inequality, we have

$$\iint_{Q_{n+1}} \omega_{n+1}^{s'} dx d\tau \le \left(\iint_{Q_{n+1}} \omega_{n+1}^{q'} dx d\tau \right)^{s'/q'} (\text{meas } A_{n+1})^{1-s'/q'},$$

where $A_n = \{(x,t) \in Q_n \,|\, e^{g_\lambda/(p-1)} u > k_n\}$. Since

$$\iint_{Q_n} \omega_n^{s'} dx d\tau \ge |k_{n+1} - k_n|^{q-1} \text{meas } A_{n+1} = \frac{k^{q-1}}{2^{(n+1)(q-1)}} \text{meas } A_{n+1},$$

we set

$$y_n = \iint_{Q_n} U_{k_n}^{q-1} dx d\tau$$

and have

$$\left(\frac{2^{(n+1)(p-1)}}{k^{p-1}} y_n \right)^{(s'/q')-1} y_{n+1} \le \left(\iint_{Q_{n+1}} \omega_{n+1}^{q'} dx d\tau \right)^{s'/q'}. \tag{3.16}$$

By (3.15) and (3.16), we obtain

$$y_{n+1} \le C b^n k^c K^{\frac{N+p}{N} \frac{s'}{q'}} y_n^{1+\frac{s'p}{q'N}}, \tag{3.17}$$

where

$$c = \frac{p(2-p)}{N} \frac{s'}{q'} - (q-1) \frac{q'-s'}{q'}.$$

By Lemma 5–6 in [10, p. 95], it follows that $\|U_0\|_{L^\infty(Q_\infty)} \le k$ provided

$$\iint_{Q_0} U_0^{q-1} dx d\tau \le C k^{N+p+q-1} K^{-(N+p)/p}. \tag{3.18}$$

Therefore, we have

$$\begin{aligned} \|U_0\|_{L^\infty(Q_\infty)} \le{}& C \|U_0\|_{L^\infty(Q_0^\sigma)}^{(N+p)/(N+p+q-1)} \\ &\times \left[\frac{M^{(N+p)/p}}{\sigma^{N+p}} \iint_{Q_0^\sigma} U_0^{q-1} dx d\tau \right]^{1/(N+p+q-1)}. \end{aligned} \tag{3.19}$$

Here $Q_0^\sigma \equiv Q_0 = B_{R_1+\sigma(R_2-R_1)} \times (t_1 - \sigma(t_1 - t_2), t)$ and $Q_\infty = B_{R_1} \times (t_1, t)$.

Next, we use the method of iteration with respect to σ. Set $Q_s = Q_0^\sigma$ with $\sigma = \sum_{i=1}^s 2^{-i-1}$, and define $X_s = \|\eta e^{g_\lambda} u^{p-1}\|_{L^\infty(Q_s)}$. Applying (3.19) to the pair of cylinders $Q_s \subset Q_{s+1}$, we obtain

$$X_s \le C X_{s+1}^{(N+p)/(N+p+q-1)} \left[2^{s(N+p)} M^{(N+p)/p} \iint_{Q_0} U_0^{q-1} dx d\tau \right]^{1/(N+p+q-1)}.$$

By the Young inequality, for any $\nu > 0$, there exists a constant $C(\nu)$ such that

$$X_s \le \nu X_{s+1} + C(\nu) (2^{\frac{N+p}{q-1}})^s \left[M^{(N+p)/p} \iint_{Q_0} U_0^{q-1} dx d\tau \right]^{1/(q-1)}.$$

Iteration of these inequalities yields

$$X_0 \leq \nu^s X_\infty + C\left[M^{(N+p)/p} \iint_{Q_0} U_0^{q-1} dx d\tau\right]^{1/(q-1)} \left(\sum_{i=1}^{s} (\nu 2^{\frac{N+p}{q-1}})^i\right).$$

Choosing $\nu = 2^{-\frac{N+p}{q-1}-1}$ and taking the limit as $s \to \infty$, we obtain

$$\|U_0\|_{L^\infty(Q_{R_1})} \leq CM^{(N+p)/p(q-1)} \left(\int_{t_1}^{t} \int_{B_{R_2}} U_0^{q-1} dx d\tau\right)^{1/(q-1)}. \tag{3.20}$$

Therefore, we set $q-1 = r(p-1)$ and obtain inequality (3.9) for Case (A).

Case (B): $(1 < p < 2)$. By (3.11)–(3.13), instead of (3.14), we have

$$\|U_0\|_{L^\infty(Q_0)}^{p-2} \sup_{\tau \in (0,t)} \int_{B_{n+1}} \omega_n^s dx + \iint_{Q_n} |\nabla \omega_n|^p dx d\tau \leq k^{p-2} \tilde{K} \iint_{Q_n} \omega^{s'} dx d\tau$$

where

$$\tilde{K} = \|U_0\|_{L^\infty(Q_0)}^2 M.$$

By an argument similar to that of Case (A), instead of (3.17), we obtain

$$y_{n+1} \leq Cd^n \|U_0\|_{L^\infty(Q_0)}^{\frac{p(2-p)s'}{Nq'}} k^{-(q-1)\frac{q'-s'}{q'}+(p-2)\frac{(N+p)s'}{Nq'}} \tilde{K}^{\frac{(N+p)s'}{Nq'}} y_n^{1+\frac{s'p}{q'N}}.$$

Then by Lemma 5–6 in [8], it follows that $\|U_0\|_{L^\infty(Q_\infty)} \leq k$ provided

$$\iint_{Q_0} U_0^{q-1} dx d\tau \leq C\|U_0\|_{L^\infty(Q_0)}^{p-2} k^{q-p+1+\frac{2(N+p)}{p}} \tilde{K}^{-\frac{N+p}{p}}.$$

Thus we obtain

$$\|U_0\|_{L^\infty(Q_\infty)}^{q-p+1+\frac{2(N+p)}{p}} \leq C\|U_0\|_{L^\infty(Q_0)}^{2-p+\frac{2(N+p)}{p}} \frac{M^{(N+p)/p}}{\sigma^{N+p}} \iint_{Q_0} U_0^{q-1} dx d\tau.$$

We can obtain (3.20) for Case (B) by the calculations similar to those of (3.19), and therefore we complete the proof of Lemma 3.4 for nonnegative strong solutions.

Let u be a solution of (3.1) constructed in Lemma 3.2. Then we can approximate the solution u by u_n, where u_n is a solution of (3.4). By Lemma 1–2 in [5], the functions $\max\{u_n, 0\}$ and $-\min\{u, 0\}$ are strong subsolutions of (3.4). Since the argument above holds for not only nonnegative strong solution of (3.1) but also subsolution, $\max\{u_n, 0\}$ and $-\min\{u_n, 0\}$ satisfy the inequality (3.9). Consequently, by the Hölder inequality of u_n and the Ascoli–Arzelá theorem, the function u satisfies the inequality (3.4). □

Using Lemmas 3.2–3.4, we shall prove Proposition 3.1.

Proof of Proposition 3.1. Let $\mu \in C_0^\infty(\mathbf{R}^N)$. By Lemma 3.2, there exists a continuous solution $u(x,t)$ in $\mathbf{S}_\infty$, which satisfies (3.3). To simplify the following arguments, we assume $T_\Lambda = \gamma_0^{p-1}\Lambda^{p-1} > 1$. Then for any $\lambda > \Lambda$ with $T_\lambda > 1$, by Lemma 3.2, we have

$$\sup_{0<t<1} \|u(\cdot,t)\|_{p,\lambda_1}^p + \int_0^1 \|\nabla u(\cdot,t)\|_{p,\lambda_1}^p dt \leq C\|\mu\|_{\frac{p}{p-1},\lambda}, \tag{3.21}$$

where $\lambda_1 = (p-1)^{-1}\gamma_0(T_\lambda - 1)^{-1/(p-1)} = -h_{\gamma_0, T_\lambda}(\overline{x}, 1)$ with $|\overline{x}| = 1$.

Set $T(\lambda) = (p-1)^{2(p-1)}\lambda^{1-p}/p^p$. Then by Lemma 3.3, we obtain the following inequality:

$$\sup_{0<t<T(\lambda)} \|u^{p-1}(\cdot,t)e^{h_{\gamma_{p-1},T(\lambda)}(\cdot,t)}\|_{L^p(\mathbf{R}^N)} \le C\|\mu e^{h_{\gamma_{p-1},T(\lambda)}(\cdot,0)}\|_{L^p(\mathbf{R}^N)} = C\|\mu\|_{p,\lambda}$$

for any $\lambda > \Lambda$. In particular, for any $\epsilon > 0$, we have

$$\sup_{0<t<T_\epsilon(\lambda)} \|u^{p-1}(\cdot,t)\|_{p,\lambda_\epsilon} \le C\|\mu\|_{p,\lambda}, \tag{3.22}$$

where $T_\epsilon(\lambda) = T(\lambda) - \epsilon$ and $\lambda_\epsilon = \gamma_{p-1}\epsilon^{1/(p-1)} = -h_{\gamma_{p-1},T(\lambda)}(\overline{x}, T_\epsilon(\lambda))$ with $|\overline{x}| = 1$.

For any fixed $t_0 \in (0, T_\epsilon(\lambda))$, we apply Lemma 3.4 to the function $u(x, t+t_0)$. Then by (3.22), there exists a constant $T^*_{\lambda_\epsilon} (< 1)$ independent of t_0 such that

$$\begin{aligned}\|e^{g_{\lambda_\epsilon}(\cdot,t)}u^{p-1}\|_{\infty,B_\rho}(t+t_0) &\le C(\rho,t)\left(\int_{t_0+t/4}^{t_0+t}\int_{B_{2\rho}} [e^{g_{\lambda_\epsilon}}u^{p-1}]^p dx d\tau\right)^{1/p} \\ &\le C(\rho,t)\left(\int_{t_0+t/4}^{t_0+t} \|u^{p-1}(\cdot,\tau)\|^p_{p,\lambda_\epsilon} d\tau\right)^{1/p}\end{aligned}$$

for any $t \in (0, \min\{t_0 + T^*_{\lambda_\epsilon}, T_\epsilon(\lambda)\})$. Taking $t_\epsilon = T^*_{\lambda_\epsilon}/2$, we have

$$\sup_{1<\tau<T_\epsilon(\lambda)} \|e^{g_{\lambda_\epsilon}(\cdot,t_\epsilon)}u^{p-1}(\cdot,\tau)\|_{L^\infty(B_\rho)} \le C(\rho)\|\mu\|_{p,\lambda}.$$

Since $C(\rho)$ has at most polynomial growth order in ρ, we get

$$\sup_{1<\tau<T_\epsilon(\lambda)} \|u^{p-1}\|_{p/(p-1),\lambda_\epsilon{}'} \le C\|\mu\|_{p,\lambda}$$

for any $\lambda_\epsilon{}' > -g_{\lambda_\epsilon}(\overline{x}, t_\epsilon) > 0$ with $|\overline{x}| = 1$. Therefore, by Lemma 3.2, there exists a constant $\lambda_2 > \lambda_\epsilon{}'$ such that

$$\sup_{1<\tau<T_\epsilon(\lambda)} \|u(\cdot,\tau)\|^p_{p,\lambda_2} + \int_1^{T_\epsilon(\lambda)} \|\nabla u\|^p_{p,\lambda_2} d\tau \le C(\epsilon)\|\mu\|_{p,\lambda}. \tag{3.23}$$

By (3.21) and (3.23), for any $\epsilon > 0$ and any $\lambda > \Lambda$, there exist constants C_1^ϵ and C_2^ϵ such that

$$\begin{aligned}\sup_{0<\tau<T_\epsilon(\lambda)} \|u(\cdot,\tau)\|_{p,C_1^\epsilon} &+ \int_0^{T_\epsilon(\lambda)} \|\nabla u(\cdot,\tau)\|^p_{p,C_1^\epsilon} d\tau \\ &\le C_2^\epsilon\,[\|\mu\|_{p,\lambda} + \|\mu\|_{p/(p-1),\lambda}] \le C_2^\epsilon\,\|\mu\|_{\infty,\Lambda}.\end{aligned} \tag{3.24}$$

By the arbitrariness $\lambda > \Lambda$, we get the inequality in Proposition 3.1.

For any $\mu \in L^\infty_\Lambda(\mathbf{R}^N)$, there exists a sequence $\{\mu_n\}_{n=1}^\infty \subset C_0^\infty(\mathbf{R}^N)$ such that $\lim_{n\to\infty} \|\mu - \mu_n\|_{\infty,\Lambda} = 0$. Let $u_n(x,t)$ be a solution of (3.1) for initial condition μ_n. Then by (3.24) and an argument similar to that of Lemma 3.2, there exists a solution of (3.1) for the initial condition μ in the strip $\mathbf{S}_{T_\epsilon(\lambda)}$. By the arbitrariness of ϵ and

λ and the results of [12] and [18], there exists a solution u in the strip $\mathbf{S}_{T(\Lambda)}$, and therefore we complete the proof of Proposition 3.1. □

4. $L^\infty_{\rm loc}(\mathbf{R}^N)$ estimate for Case (II). In this section, we give $L^\infty_{\rm loc}(\mathbf{R}^N)$ estimates of the solution of (1.1) for Case (II) and complete the proof of Theorem 1.3. By the arguments in §3, we have only to treat continuous nonnegative strong solution of (1.1).

By Lemma 3.4, we have the following lemma.

LEMMA 4.1. *Let u be a solution of* (3.1) *constructed in* §3. *Then for* $0 < T_0 < T^*_\lambda$, *there exists a constant* $C = C(N, p, \delta, T_0)$ *such that*

$$\|e^{g_\lambda} u^{p-1}\|_{L^\infty(B_\rho)}(t) \le C + Ct^{-N/p}\phi_\lambda(t) \tag{4.1}$$

for $0 < t < T_0$.

Proof. For any $\rho > 0$ and $t > 0$, let $Q_s = B_{\rho_s} \times (t_s, t)$, where $\rho_s = \sum_{i=1}^s (2^{-i-1})\rho$ and $t_s = (1 - \sum_i^s (2^{-i-1}))t$. Applying Lemma 3.4 to the pair of cylinders $Q_s \subset Q_{s+1}$, we have

$$\|\eta e^{g_\lambda} u^{p-1}\|_{L^\infty(Q_s)} \le C\frac{M^{(N+p)/p(1+\delta)}}{b^{s/(1+\delta)}}\left(\iint_{Q_{s+1}} [\eta e^{g_\lambda} u^{p-1}]^{1+\delta} dx d\tau\right)^{1/(1+\delta)}, \tag{4.2}$$

where $M = |\nabla g_\lambda|^p(2\rho, t) + \rho^{-p} + t^{-1}$ and $b = 2^{-N-p}$.

For any measurable set E in $\mathbf{R}^N$, let χ_E be the characteristic function of E. Set

$$\chi_1(x) = \chi_{\{e^{g_\lambda} u^{p-1} \le 1\}}(x), \qquad \chi_2(x) = \chi_{\{e^{g_\lambda} u^{p-1} \ge 1\}}(x). \tag{4.3}$$

By (2.8),

$$\begin{aligned}
&\iint_{Q_{s+1}} [\eta(|x|) e^{g_\lambda} u^{p-1}]^{1+\delta} dx d\tau \\
&\quad \le \eta^\delta(2\rho) \iint_{Q_{s+1}} \eta(|x|)[e^{g_\lambda} u^{p-1}]^{1+\delta} \chi_1(x) dx d\tau \\
&\qquad\qquad + \|\eta e^{g_\lambda} u^{p-1}\|^\delta_{L^\infty(Q_{s+1})} \iint_{Q_{s+1}} \eta(|x|) e^{g_\lambda} u^{p-1} dx d\tau \\
&\quad \le C[\eta^\delta(2\rho) + \|\eta e^{g_\lambda} u^{p-1}\|^\delta_{L^\infty(Q_{s+1})}] \int_0^t \phi_\lambda(\tau) d\tau.
\end{aligned}$$

By (4.2), we have

$$\begin{aligned}
\|\eta e^{g_\lambda} u^{p-1}\|_{\infty, Q_s} \le & C\frac{M^{(N+p)/p(1+\delta)}}{b^{s/(1+\delta)}} \\
& \times \left([\eta^\delta(2\rho) + \|\eta e^{g_\lambda} u^{p-1}\|^\delta_{L^\infty(Q_{s+1})}] \int_0^t \phi_\lambda(\tau) d\tau\right)^{1/(1+\delta)}
\end{aligned}$$

Then by the Young inequality, for any $\nu > 0$, there exists a constant $C = C(\nu, \delta)$ such that

$$\begin{aligned}
\|\eta e^{g_\lambda} u^{p-1}\|_{L^\infty(Q_s)} \le & \nu \|\eta e^{g_\lambda} u^{p-1}\|_{L^\infty(Q_{s+1})} \\
& + C(\nu, \delta) 2^{(N+p)s} \left[\eta(2\rho) + M^{(N+p)/p} \int_0^t \phi_\lambda(\tau) d\tau\right].
\end{aligned}$$

Iteration of these inequalities yields

$$\|\eta e^{g_\lambda}u^{p-1}\|_{L^\infty(Q_0)} \le \nu^s\|\eta e^{g_\lambda}u^{p-1}\|_{L^\infty(Q_s)} + C(\nu,\delta)[\eta(2\rho)+M^{(N+p)/p}t\phi_\lambda(t)]\sum_{i=1}^{s}(\nu 2^{N+p})^i.$$

Setting $\nu = 2^{-(N+p+1)}$ and taking the limit as $s\to\infty$, we obtain

$$\|\eta e^{g_\lambda}u^{p-1}\|_{L^\infty(B_\rho)} \le C(\delta)\eta(2\rho)+C(\delta)[|\nabla g_\lambda|^p+t^{-1}]^{(N+p)/p}t\phi_\lambda(t). \tag{4.4}$$

Therefore, by (4.4), we have inequality (4.1) for the case where $\rho\le 1$.

For any $0<T_0<1$, there exists a constant $C=C(T_0)$ such that $|\nabla g_\lambda|^p(x,t) \le C|x|^{p/(p-1)}$. For the case where $\rho\ge 1$, by (4.4) and the definition of η, we obtain

$$\|e^{g_\lambda}u^{p-1}\|_{L^\infty(B_\rho\setminus B_{\rho/2})} \le C+Ct^{-N/p}\phi_\lambda(t),$$

where $C=C(p,N,\delta,T_0)$. Therefore, we obtain inequality (4.1) for the case where $\rho\ge 1$, and thus the proof of Lemma 4.1 is complete. □

LEMMA 4.2. *Let $\zeta(x)$ be a piecewise-smooth cutoff function such that $\zeta\equiv 1$ on B_ρ, $|\nabla\zeta|\le 1/\rho$, and* supp $\zeta\subset B_{2\rho}$. *For any $\beta>0$, there exists a constant $T_0\in(0,1)$ dependent only on p such that*

$$\limsup_{\epsilon\to 0}\int_0^t\int_{B_{2\rho}}\tau^\beta\eta(|x|)e^{g_\lambda}\frac{|\nabla u|^p}{u+\epsilon}[e^{g_\lambda}(u+\epsilon)^{p-1}]^\delta\zeta^p(x)dxd\tau \le C\left[\int_0^t\tau^{\beta-1}\phi_\lambda(\tau)d\tau+\int_0^t\tau^{\sigma-1}\phi_\lambda^{1+\delta}(\tau)d\tau\right] \tag{4.5}$$

for $0<t<T_0$ and $\rho\ge 1$, where $C=C(N,p,\delta)$ and $\sigma=\beta-\delta N/p$.

Proof. Let

$$\varphi_\epsilon(x,t)=t^\beta\eta(|x|)e^{g_\lambda}[e^{g_\lambda}(u+\epsilon)^{p-1}]^\delta\zeta^p(x).$$

Then we have

$$\liminf_{\epsilon\to 0}\int_0^t\int_{B_{2\rho}}\frac{\partial}{\partial t}(u^{p-1})\varphi_\epsilon dxd\tau \ge -\frac{\beta}{1+\delta}\int_0^t\int_{B_{2\rho}}\tau^{\beta-1}\eta[e^{g_\lambda}u^{p-1}]^{1+\delta}dxd\tau - \frac{1}{1+\delta}\int_0^t\int_{B_{2\rho}}\tau^\beta\eta[e^{g_\lambda}u^{p-1}]^{1+\delta}\frac{\partial}{\partial t}g_\lambda dxd\tau$$

and

$$\int_0^t\int_{B_{2\rho}}|\nabla u|^{p-2}\nabla u\cdot\nabla\varphi_\epsilon dxd\tau \ge \frac{(p-1)\delta}{2}\int_0^t\int_{B_{2\rho}}\tau^\beta e^{g_\lambda}\frac{|\nabla u|^p}{u+\epsilon}[e^{g_\lambda}(u+\epsilon)^{p-1}]^\delta dxd\tau - C(p,\delta)\int_0^t\int_{B_{2\rho}}\tau^\beta\eta[e^{g_\lambda}(u+\epsilon)^{p-1}]^{1+\delta}|\nabla g_\lambda|^p dxd\tau - \frac{C(p,\delta)}{\rho^p}\int_0^t\int_{B_{2\rho}}\tau^\beta\eta[e^{g_\lambda}(u+\epsilon)^{p-1}]^{1+\delta}dxd\tau.$$

Taking a sufficiently small T_0, by (3.13), we obtain

$$\limsup_{\epsilon\to 0}\int_0^t\int_{B_{2\rho}}\tau^\beta\eta(|x|)e^{g_\lambda}\frac{|\nabla u|^p}{u+\epsilon}[e^{g_\lambda}(u+\epsilon)^{p-1}]^\delta\zeta^p dxd\tau \leq C\int_0^t\int_{B_{2\rho}}\tau^{\beta-1}\eta(|x|)(e^{g_\lambda}u^{p-1})^{\delta+1}dxd\tau. \tag{4.6}$$

Here we used the relation $t^\beta/\rho^p \leq t^{\beta-1}$ for $0<t<T_0$. Thus we have

$$\int_0^t\int_{B_{2\rho}}\tau^{\beta-1}\eta(|x|)(e^{g_\lambda}u^{p-1})^{\delta+1}dxd\tau \leq \int_0^t\tau^{\beta-1}\phi_\lambda(\tau)d\tau + \int_0^t\int_{B_{2\rho}}\tau^{\beta-1}\eta(|x|)e^{g_\lambda}u^{p-1}\|e^{g_\lambda}u^{p-1}\|^\delta_{L^\infty(B_{2\rho})}(\tau)\chi_2 dxd\tau. \tag{4.7}$$

Furthermore, by Lemma 4.1, we have

$$\begin{aligned}\int_0^t\int_{B_{2\rho}}&\tau^{\beta-1}\eta(|x|)e^{g_\lambda}u^{p-1}\chi_2\|e^{g_\lambda}u^{p-1}\|^\delta_{L^\infty(B_{2\rho})}(\tau)dxd\tau\\ &\leq\int_0^t\int_{B_{2\rho}}\tau^{\beta-1}\eta(|x|)e^{g_\lambda}u^{p-1}\chi_2[1+\tau^{-\delta N/p}\phi_\lambda^\delta(\tau)]dxd\tau\\ &\leq C\int_0^t\tau^{\beta-1}\phi_\lambda(\tau)d\tau+C\int_0^t\tau^{\beta-1-\delta N/p}\phi_\lambda^{1+\delta}(\tau)d\tau\end{aligned} \tag{4.8}$$

for any $0<t<T_0$. Therefore, by (4.6)–(4.8), we obtain inequality (4.5). □

PROPOSITION 4.3. *For a sufficiently small constant $\delta>0$, there exists a constant $T_0=T_0(p,\delta,l,\|\mu\|_{1,\lambda})$ such that*

$$\phi_\lambda(t)\leq C\phi_\lambda(0) \tag{4.9}$$

for $0<t<T_0$, where $C=C(p,\delta)$. Furthermore,

$$\|e^{g_\lambda(\cdot,t)}u^{p-1}\|_{L^\infty(B_\rho)}\leq C(1+t^{-N/p})\phi_\lambda(0) \tag{4.10}$$

for any $\rho>0$ and $0<t<T_0$.

Proof. Set

$$\varphi_\epsilon(x,t)=\eta(|x|)e^{g_\lambda}F'(e^{g_\lambda}(u+\epsilon)^{p-1})\zeta^p(x),$$

where ζ is a function given in Lemma 4.2. Then we have

$$\lim_{\epsilon\to 0}\int_0^t\int_{B_{2\rho}}\frac{\partial}{\partial t}(u^{p-1})\varphi_\epsilon dxd\tau=\int_{B_{2\rho}}\eta(|x|)F(e^{g_\lambda}u^{p-1})\zeta^p dx\Big|_{\tau=0}^{\tau=t} - \int_0^t\int_{B_{2\rho}}\eta(|x|)[(e^{g_\lambda}u^{p-1})^{1+\delta}\chi_1+e^{g_\lambda}u^{p-1}\chi_2]\zeta^p\frac{\partial}{\partial t}g_\lambda dxd\tau$$

and

$$\begin{aligned}\int_0^t\int_{B_{2\rho}}&|\nabla u|^{p-2}\nabla u\cdot\nabla\varphi_\epsilon dxd\tau\\ &\geq\delta(p-1)\int_0^t\int_{B_{2\rho}}\eta e^{g_\lambda}\frac{|\nabla u|^p}{u+\epsilon}[e^{g_\lambda}(u+\epsilon)^{p-1}]^\delta\zeta^p\chi_1 dxd\tau\\ &-C(p,\delta)\int_0^t\int_{B_{2\rho}}\eta e^{g_\lambda}|\nabla u|^{p-1}(|\nabla g_\lambda|\zeta^p+\zeta^{p-1}|\nabla\zeta|)[e^{g_\lambda}(u+\epsilon)^{p-1}]^\delta\chi_1 dxd\tau\\ &-\int_0^t\int_{B_{2\rho}}\eta e^{g_\lambda}|\nabla u|^{p-1}(|\nabla g_\lambda|\zeta^p+\zeta^{p-1}|\nabla\zeta|)\chi_2 dxd\tau,\end{aligned}$$

where χ_i, $i=1,2$, is given in (4.3). The Young inequality yields

$$\begin{aligned}\int_0^t\int_{B_{2\rho}} &\eta e^{g_\lambda}|\nabla u|^{p-1}|\nabla g_\lambda|\zeta^p[e^{g_\lambda}(u+\epsilon)^{p-1}]^\delta\chi_1 dxd\tau\\ &\le \int_0^t\int_{B_{2\rho}}\tau^{1/2(p-1)}\eta e^{g_\lambda}\frac{|\nabla u|^p}{u+\epsilon}[e^{g_\lambda}(u+\epsilon)^{p-1}]^\delta\zeta^p\chi_1 dxd\tau\\ &\qquad+\int_0^t\int_{B_{2\rho}}\eta[e^{g_\lambda}(u+\epsilon)^{p-1}]^{1+\delta}\tau^{-1/2}|\nabla g_\lambda|^p\zeta^p\chi_1 dxd\tau\end{aligned}$$

and

$$\begin{aligned}\int_0^t\int_{B_{2\rho}}\eta e^{g_\lambda}|\nabla u|^{p-1}|\nabla g_\lambda|\zeta^p\chi_2 dxd\tau &\le \int_0^t\int_{B_{2\rho}}\tau^{1/2(p-1)}\eta e^{g_\lambda}\frac{|\nabla u|^p}{u+\epsilon}\zeta^p\chi_2 dxd\tau\\ &\qquad+\int_0^t\int_{B_{2\rho}}\eta e^{g_\lambda}(u+\epsilon)^{p-1}\tau^{-1/2}|\nabla g_\lambda|^p\zeta^p\chi_2 dxd\tau.\end{aligned}$$

Therefore, by (3.13) and the Young inequality, there exists a constant $C=C(N,p,\delta,l)$ such that

(4.11)
$$\begin{aligned}\int_{B_\rho}\eta(|x|)F(e^{g_\lambda}u^{p-1})dx\Big|_{\tau=t} &\le \int_{B_{2\rho}}\eta(|x|)F(e^{g_\lambda}u^{p-1})dx\Big|_{\tau=0}\\ &+\limsup_{\epsilon\to0}\int_0^t\int_{B_{2\rho}}\tau^{1/2(p-1)}\eta(|x|)e^{g_\lambda}\frac{|\nabla u|^p}{u+\epsilon}[e^{g_\lambda}(u+\epsilon)^{p-1}]^\delta\zeta^p dxd\tau\\ &+\frac{C}{\rho^p}\int_0^t\int_{B_{2\rho}}[\eta(|x|)(e^{g_\lambda}u^{p-1})^{\delta+1}\chi_1+\tau^{-1/2}\eta(|x|)e^{g_\lambda}u^{p-1}\chi_2]dxd\tau.\end{aligned}$$

Taking the limit as $\rho\to\infty$, by Lemma 4.2, we have

$$\begin{aligned}\phi_\lambda(t)&\le\phi_\lambda(0)+C\int_0^t[(\tau^{-1/2}+\tau^{\beta-1})\phi_\lambda(\tau)+\tau^{\sigma-1}\phi_\lambda^{1+\delta}(\tau)]d\tau\\ &\le\phi_\lambda(0)+C(t^{1/2}+t^\beta)\phi_\lambda(t)+C\int_0^t\tau^{\sigma-1}\phi_\lambda^{1+\delta}(\tau)d\tau,\end{aligned}$$

where σ is a constant given in Lemma 4.2. Here we take a sufficiently small $\delta>0$ such that $\sigma>0$ and fix δ. Taking a sufficiently small t such that $C(t^{1/2}+t^\beta)\le1/2$, we have

$$\phi_\lambda(t)\le2\phi_\lambda(0)+C\int_0^t\tau^{\sigma-1}\phi_\lambda^{1+\delta}(\tau)d\tau. \tag{4.12}$$

It follows by (4.12) that $\phi_\lambda(t)$ is maximized by the solution of

$$H'(t)=Ct^{\sigma-1}H^{1+\delta}(t),\qquad H(0)=2\phi_\lambda(0),$$

and so we have

$$\phi_\lambda(t)\le\frac{H(t)}{2}=\left[1-\frac{C\delta2^\delta}{\sigma}t^\sigma\phi_\lambda^\delta(0)\right]^{-1/\delta}\phi_\lambda(0)$$

provided the bracket is positive for any $0 < t < T_0$. In view of $\phi_\lambda(0) \le \|\mu\|_{1,\lambda}$, there exist constants $T_0 > 0$ and $C > 0$ such that $\phi_\lambda(t) \le C\phi_\lambda(0)$ for all $t \in (0, T_0)$, and so we obtain inequality (4.9). Furthermore, by (4.1) and (4.9), we have inequality (4.10), and the proof of Proposition 4.3 is complete. □

PROPOSITION 4.4. *By Proposition* 4.3, *it holds that*

$$\int_0^t \int_{B_\rho} \eta(|x|)e^{g_\lambda}|\nabla u|^{p-1}dxd\tau \le Ct^\sigma(\eta(\rho)\rho^N + \phi_\lambda(0) + \phi_\lambda^\delta(0)) \tag{4.13}$$

for any $\rho \ge 1$ *and* $0 < t < T_0 \le 1$.

Proof. By the Young inequality,

$$\int_0^t \int_{B_\rho} \eta(|x|)e^{g_\lambda}|\nabla u|^{p-1}dxd\tau \le \int_0^t \int_{B_\rho} \tau^\beta \eta e^{g_\lambda}\frac{|\nabla u|^p}{u+\epsilon}[e^{g_\lambda}(u+\epsilon)^{p-1}]^\delta dxd\tau$$
$$+ \int_0^t \int_{B_\rho} \tau^{-\beta(p-1)}\eta[e^{g_\lambda}(u+\epsilon)^{p-1}]^{1-\delta(p-1)}dxd\tau \equiv I_1(\epsilon) + I_2(\epsilon),$$

where $\beta = 1/2(p-1)$. By Lemma 4.2 and Proposition 4.3,

$$\limsup_{\epsilon\to 0} I_1(\epsilon) \le Ct^\sigma[\phi_\lambda(0) + \phi_\lambda^\delta(0)].$$

For the second term $I_2(\epsilon)$, we have

$$\lim_{\epsilon\to 0} I_2(\epsilon) \le \int_0^t \int_{B_\rho} \tau^{-\beta(p-1)}\eta(e^{g_\lambda}u^{p-1})^{1-\delta(p-1)}[\chi_1 + \chi_2]dxd\tau$$
$$\le Ct^{1/2}(\eta(\rho)\rho^N + \phi_\lambda(0)),$$

and so we have (4.13). □

We now can prove Theorem 1.3.

Proof of Theorem 1.3. By the definition of ϕ_λ,

$$\phi_\lambda(0) \le \int_{\mathbf{R}^N} \eta(|x|)\exp(-\lambda|x|^{p/(p-1)})\mu(x)dx.$$

Therefore, by Proposition 4.3 and $\lambda > \Lambda$, we obtain inequalities (2.12) and (2.13) for initial data $\mu \in C_0^\infty(\mathbf{R}^N)$.

Let μ_n be a function in $C_0^\infty(\mathbf{R}^N)$ such that

$$\lim_{n\to\infty} \int_{\mathbf{R}^N} \mu_n \exp(-\lambda|x|^{p/(p-1)})dx = \int_{\mathbf{R}^N} \exp(-\lambda|x|^{p/(p-1)})d\mu(x).$$

By Lemma 3.2, there exists a solution u_n of (3.1) for $u(x,0) = \mu_n(x)$ in $\mathbf{S}_\infty \equiv \mathbf{R}^N \times (0,\infty)$. By the argument of §3 and (4.10), we have

$$\int_\tau^{T_0} \int_{B_\rho} |\nabla u_n|^p dxdt \le C(\rho,\tau) \tag{4.14}$$

for any $0 < \tau < T_0$ and $\rho \ge 1$, where $C(\rho,\tau)$ is a constant independent of n. Consequently, by (4.14), the Minty lemma, and the result of [18], there exists a continuous function u satisfying $|\nabla u| \in L^p_{\text{loc}}(0, T_0 : L^p_{\text{loc}}(\mathbf{R}^N))$ such that

$$\int_\tau^{T_0} \int_{B_\rho} |\nabla u_n|^{p-2}\nabla u_n \cdot \nabla\varphi dxdt \to \int_\tau^{T_0} \int_{B_\rho} |\nabla u|^{p-2}\nabla u \cdot \nabla\varphi dxdt, \tag{4.15}$$

as $n \to \infty$, for all $0 < \tau < T_0$ and all $\varphi \in C^\infty(B_\rho \times (0, T_0)$ with $\operatorname{supp}(\varphi(\cdot, t)) \subset B_\rho$, $0 < t < T_0$. Furthermore, by Proposition 4.4, there exists a Radon measure $V = (V_1, V_2, \dots, V_N)$ such that

$$\lim_{n\to\infty} \int_0^{T_0} \int_{B_\rho} |\nabla u_n|^{p-2} \nabla u_n \cdot \nabla \varphi dx dt = \sum_{i=1}^N \int_0^{T_0} \int_{B_\rho} \frac{\partial}{\partial x_i} \varphi dV_i \tag{4.16}$$

and $\lim_{t\to 0} V_i(B_\rho \times (0,t)) = 0$, $i = 1, 2, \dots, N$. By (4.15) and (4.16), we see $U = |\nabla u|^{p-2}\nabla u$, and so we have $|\nabla u|^{p-1} \in L^1(0, T_0 : L^1_{\mathrm{loc}}\mathbf{R}^N)$. Consequently, the function u is a solution of (1.1) and (1.2) in $\mathbf{S}_{T_0}$.

On the other hand, by (4.10), we have

$$\| \exp(-\lambda(t)|x|^{p/(p-1)}) u(x,t) \|_{L^\infty(\mathbf{R}^N)} < \infty$$

for $0 < t < T_0$, where $\lambda(t) = \lambda(1 + t^{1/2}) = -g_\lambda(\overline{x}, t) =$ with $|\overline{x}| = 1$. Therefore, by Proposition 3.1, we can see that there exists a solution of (1.1) and (1.2) in $\mathbf{S}_{T(\Lambda)}$, and the proof of Theorem 1.3 is completed. □

5. $L^\infty_{\mathrm{loc}}(\mathbf{R}^N)$ estimate for Case (I). In this section, for Case (I), we give $L^\infty(\mathbf{R}^N)$ estimates of the solutions of (1.1). We set $v = |u|^{\beta-1}u$ and $d = m(p-1)-1 > 0$ and consider the following problem:

$$\begin{cases} \dfrac{\partial}{\partial t} v = \operatorname{div}(|\nabla v^m|^{p-2} \nabla v^m) & \text{in } \mathbf{R}^N \times (0, \infty), \\ v = \mu(x) \in C_0^\infty(\mathbf{R}^N) & \text{in } \mathbf{R}^N, \end{cases} \tag{5.1}$$

where $m = 1/\beta$. By arguments similar to those of §3, we have only to consider nonnegative solutions, and so we assume that $v \geq 0$ and $\mu \geq 0$.

LEMMA 5.1. *There exists a weak solution v of* (5.1) *in $\mathbf{S}_\infty$. The solution v satisfies the following inequalities:*

$$\|v\|_{L^\infty(\mathbf{R}^N)} \leq \|\mu\|_{L^\infty(\mathbf{R}^N)} \tag{5.2}$$

and

$$\int_\tau^t \int_{B_\rho} |\nabla v^m|^p dx d\tau \leq C[\rho^N \|v(\cdot, \tau)\|^{m+1}_{L^\infty(B_{2\rho})} + (t-\tau)\rho^{N-p} \|v\|^{mp}_{L^\infty(B_{2\rho} \times (\tau, t))}] \tag{5.3}$$

for any $0 < \tau < t$ and $\rho > 0$, where $C = C(p, m, N)$.

Proof. By the results of [16] and [18], for any sufficiently large n, there exists a weak solution v_n of the problem

$$\begin{cases} \dfrac{\partial}{\partial t} v = \operatorname{div}(|\nabla v^m|^{p-2} \nabla v^m) & \text{in } B_n \times (0, \infty), \\ v(x,t) = 0 & \text{on } \partial B_n \times (0, \infty), \\ v = \mu(x) & \text{in } B_n \end{cases} \tag{5.4}$$

such that $\|v_n\|_{L^\infty(B_n)} \leq \|\mu\|_{L^\infty(B_n)}$. For any $\rho > 0$ with $2\rho < n$, let ζ be a nonnegative piecewise-smooth cutoff function such that $\zeta \equiv 1$ on B_ρ, $\operatorname{supp}(\zeta) \subset B_{2\rho}$, and $|\nabla \zeta| \leq 1/\rho$. Then we multiply (5.4) by $\varphi(x,t) = v_n^m \zeta^p$, integrate it over $B_\rho \times (\tau, t)$, and obtain

$$\int_\tau^t \int_{B_\rho} |\nabla v_n^m|^p dx d\tau \leq C[\rho^N \|v(\cdot, \tau)\|^{m+1}_{L^\infty(B_{2\rho})} + (t-\tau)\rho^{N-p} \|v_n\|^{mp}_{L^\infty(B_{2\rho} \times (\tau, t))}].$$

Taking the limit as $n \to \infty$, we can prove Lemma 5.1 by the same argument as in Lemma 3.2. □

By an argument similar to that of Lemma 3.4, we obtain the following lemma, which is an extension of Lemma 3–1 in [6].

LEMMA 5–2. *Let $r > 0$ and v be a solution of* (5.1) *and*

$$\phi(t) = \sup_{\tau\in(0,t)} \tau^{N/\kappa} \sup_{\rho\geq r} \frac{\|v(\cdot,\tau)\|_{\infty,B_\rho}}{\rho^{p/d}}. \tag{5.5}$$

Then the solution v satisfies the following inequality:

$$\|v(\cdot,t)\|_{\infty,B_\rho} \leq C[K(t)]^{(N+p)/\kappa^*} \left(\int_{t/4}^{t} \int_{B_{2\rho}} v^{mp} dx d\tau\right)^{p/\kappa^*} \tag{5.6}$$

for all $\rho \geq r$, where

$$K(t) = t^{-Nd/\kappa} \phi^d(t) + t^{-1}. \tag{5.7}$$

Proof. We set $R_1 = \rho$ and $R_2 = 2\rho$ and define B_n, Q_n, and ζ_n as in Lemma 3.4. Furthermore we set

$$\varphi_n(x,t) = \begin{cases} (u-k_n)_+^{p-1}\zeta_n^p & \text{if } p \geq 2, \\ (u-k_n)_+\zeta_n^p & \text{if } 1 < p < 2 \end{cases}$$

and multiply φ_n by (5.1) to obtain that if $p \geq 2$,

$$\begin{aligned} &\int_{B_n} \Lambda_{n,1}(x,\tau)\zeta_n^p dx \Big|_{\tau=t_n} + \iint_{Q_n} (u-k_n)_+^{p-2} |\nabla u|^p \zeta^p dx d\tau \\ &\leq C \iint_{Q_n} (u-k_n)_+^{2(p-1)} |\nabla\zeta|^p dx d\tau + C \iint_{Q_n} \Lambda_{n,1}(x,\tau) \frac{\partial}{\partial t}\zeta_n^p dx d\tau \end{aligned} \tag{5.8}$$

and if $1 < p < 2$,

$$\begin{aligned} &\int_{B_n} \Lambda_{n,2}(x,\tau)\zeta_n^p dx \Big|_{\tau=t_n} + \iint_{Q_n} |\nabla(u-k_n)_+|^p \zeta^p dx d\tau \\ &\leq C \iint_{Q_n} (u-k_n)_+^{p} |\nabla\zeta|^p dx d\tau + C \iint_{Q_n} \Lambda_{n,2}(x,\tau) \frac{\partial}{\partial t}\zeta_n^p dx d\tau, \end{aligned} \tag{5.9}$$

where

$$\Lambda_{n,1}(x,t) = \int_{k_n^\beta}^{u^\beta(x,t)} (s^{1/\beta}-k_n)_+^{p-1} ds \quad \text{and} \quad \Lambda_{n,2}(x,t) = \int_{k_n^\beta}^{u^\beta(x,t)} (s^{1/\beta}-k_n)_+ ds.$$

Here we divide the proof of (5.6) into three cases,

(A) $m \geq 1$, $p \geq 2$, (B) $0 < m < 1$, $p \geq 2$, (C) $m \geq 1$, $1 < p < 2$,

and treat each case respectively.

Case (A): $m \ge 1$, $p \ge 2$. By (5.8) and $m \ge 1$,

$$\|u\|_{\infty,Q_n}^{-(m-1)/m} \sup_{t_n \le \tau \le t} \int_{B_n} (u-k_n)_+^p \zeta_n^p dx + \iint_{Q_n} |D[(u-k_n)_+^{2(p-1)/p} \zeta_n]|^p dxd\tau$$
$$\le C2^{np}\left[\|u\|_{\infty,Q_n}^{p-2}(\sigma\rho)^{-p} + k^{-(m-1)/m}(\sigma t)^{-1}\right] \iint_{Q_n} (u-k_n)_+^p dxd\tau.$$

Set $\omega_n = (u-k_n)_+^{2(p-1)/p}$ and $s = p^2/2(p-1)$, and we have

$$\|u\|_{\infty,Q_n}^{-(m-1)/m} \sup_{t_n \le \tau \le t} \int_{B_n} \omega_n^s \zeta_n^p dx + \iint_{Q_n} |D[\omega_n \zeta_n]|^p dxd\tau$$
$$\le C2^{np}\left[\|u\|_{\infty,Q_n}^{p-2}(\sigma\rho)^{-p} + k^{-(m-1)/m}(\sigma t)^{-1}\right] \iint_{Q_n} \omega_n^s dxd\tau.$$

Using the Gagliardo–Nirenberg inequality and the Hölder inequality as in Lemma 3.4, we have

$$\iint_{Q_{n+1}} (u-k_{n+1})_+^p dxd\tau \le Cb^n \left[\|u\|_{\infty,Q_n}^{p-2}(\sigma\rho)^{-p} + k^{-(m-1)/m}(\sigma t)^{-1}\right]^{(N+p)s/Nq}$$
$$\times \|u\|_{\infty,Q_0}^{(m-1)ps/mq} k^{-p(1-s/q)} \left(\iint_{Q_n} (u-k_n)_+^p dxd\tau\right)^{1+ps/Nq},$$

where $q = p(1+s/N)$ and b is a constant independent of n. By Lemma 5–6 in [8], we have the following inequality:

$$\|u\|_{\infty,Q_\infty}^{[N(p-2)+p^2]/p} \le C\|u\|_{\infty,Q_0}^{(m-1)/m}$$
$$\times \left[\|u\|_{\infty,Q_0}^{p-2}(\sigma\rho)^{-p} + \|u\|_{\infty,Q_\infty}^{-(m-1)/m}(\sigma t)^{-1}\right]^{1+N/p} \iint_{Q_0} u^p dxd\tau$$
$$\le C\|u\|_{\infty,Q_0}^{(m-1)/m} \|u\|_{\infty,Q_\infty}^{-(m-1)(1+N/p)/m}$$
$$\times \sigma^{-(p+N)} \left[\|u\|_{\infty,Q_0}^{p-2+(m-1)/m} \rho^{-p} + t^{-1}\right]^{1+N/p} \iint_{Q_0} u^p dxd\tau.$$

By $u = v^m$,

$$(5.10)\quad \|v\|_{\infty,Q_\infty}^{p(m-1)+\kappa_{mp}} \le C\|v\|_{\infty,Q_0}^{p(m-1)} \sigma^{-N-p} \left[\frac{\|v\|_{\infty,Q_0}^d}{\rho^p} + t^{-1}\right]^{N+p} \left(\iint_{Q_0} v^{mp} dxd\tau\right)^p,$$

where $Q_0 = B_{(1+\sigma)\rho} \times ((1-\sigma)t/2, t)$ and $Q_\infty = B_\rho \times (t/2, t)$.

Setting Q_s as in Lemma 3.4, and applying (5.10) to the pair of cylinders $Q_s \subset Q_{s+1}$, we have

$$X_s^{p(m-1)+\kappa_{mp}} \le CX_{s+1}^{p(m-1)} 2^{s(N+p)} \left[\frac{\|v\|_{\infty,Q_0}^d}{\rho^p} + t^{-1}\right]^{N+p} \left(\iint_{Q_0} v^{mp} dxd\tau\right)^p.$$

The Young inequality yields

$$X_s \le \nu X_{s+1} + C(\nu)(2^{N+p})^s \left[\frac{\|v\|_{\infty,Q_0}^d}{\rho^p} + t^{-1}\right]^{(N+p)/\kappa^*} \left(\iint_{Q_0} v^{mp} dxd\tau\right)^{p/\kappa^*},$$

where $\nu = 2^{-(N+p)-1}$. Iterating these inequalities and taking the limit as $s \to \infty$, we obtain

$$\|v\|_{\infty,Q_\rho} \le C\left[\frac{\|v\|^d_{\infty,Q_{2\rho}}}{\rho^p} + t^{-1}\right]^{(N+p)/\kappa_{mp}} \left(\int_{t/4}^{t}\int_{B_{2\rho}} v^{mp}\,dx\,d\tau\right)^{p/\kappa_{mp}}. \tag{5.11}$$

Therefore, by (5.5) and (5.11), we obtain inequality (5.6).

Case (B): $0 < m < 1$, $p \ge 2$. By (5.8) and $0 < m < 1$,

$$\begin{aligned} k^{-(m-1)/m} \sup_{t_n \le \tau \le t} \int_{B_n} (u-k_n)_+^p \zeta_n^p\,dx + \iint_{Q_n} |D[(u-k_n)_+^{2(p-1)/p}\zeta_n]|^p\,dx\,d\tau \\ \le C2^{np}\left[\|u\|^{p-2}_{\infty,Q_n}(\sigma\rho)^{-p} + \|v\|^{-(m-1)/m}_{\infty,Q_n}(\sigma t)^{-1}\right] \iint_{Q_n} (u-k_n)_+^p\,dx\,d\tau. \end{aligned}$$

Applying the Gagliardo–Nirenberg inequality, the Young inequality, and Lemma 5–6 in [10] as in Case (A), instead of (5.10), we have

$$\begin{aligned} \|v\|^{(1-m)(N+p)+\kappa_{mp}}_{\infty,Q_\infty} &\le C\|v\|^{(1-m)(N+p)}_{\infty,Q_0}\sigma^{-(N+p)p} \\ &\quad\times\left[\frac{\|v\|^d_{\infty,Q_0}}{\rho^p} + t^{-1}\right]^{N+p}\left(\iint_{Q_0} v^{mp}\,dx\,d\tau\right)^p. \end{aligned} \tag{5.12}$$

By the Young inequality and the argument of iteration, we can obtain (5.6) as in Case (A).

Case (C): $m \ge 1$, $1 < p < 2$. By (5.9) and $m \ge 1$,

$$\begin{aligned} \|u\|^{-(m-1)/m}_{\infty,Q_n} \sup_{t_n \le \tau \le t} \int_{B_n} (u-k_n)_+^2\,dx + \iint_{Q_n} |D(u-k_n)_+|^p\,dx\,d\tau \\ \le C2^{np}\left[\frac{1}{(\sigma\rho)^p} + \frac{k^{-(m-1)/m}}{\sigma t}\|u\|^{2-p}_{\infty,Q_0}\right]\iint_{Q_n}(u-k_n)_+^p\,dx\,d\tau, \end{aligned}$$

and by $1 < p < 2$,

$$\begin{aligned} \|u\|^{-(m-1)/m}_{\infty,Q_n}\left(\frac{k}{2^n}\right)^{2-p} \sup_{t_n \le \tau \le t} \int_{B_n} (u-k_{n+1})_+^p\,dx + \iint_{Q_n} |D(u-k_{n+1})_+|^p\,dx\,d\tau \\ \le C2^{np}\left[\frac{1}{(\sigma\rho)^p} + \frac{k^{-(m-1)/m}}{\sigma t}\|u\|^{2-p}_{\infty,Q_0}\right]\iint_{Q_n}(u-k_n)_+^p\,dx\,d\tau. \end{aligned}$$

By the Gagliardo–Nirenberg inequality and the Hölder inequality, we have

$$\begin{aligned} \iint_{Q_{n+1}} (u-k_{n+1})_+^p\,dx\,d\tau &\le Cb^n \|u\|^{(m-1)(1-p/q)/m}_{\infty,Q_0} k^{-p(1-p/q)+(p-2)(1-p/q)} \\ &\quad\times\left[(\sigma\rho)^{-p} + \frac{k^{-(m-1)/m}}{\sigma t}\|u\|^{2-p}_{\infty,Q_0}\right]\left(\iint_{Q_n}(u-k_n)_+^p\,dx\,d\tau\right)^{1+(q-p)/p}, \end{aligned}$$

where $q = p(1+p/N)$ and b is a constant independent of n.

By $m \geq 1$,

$$
\begin{aligned}
(\sigma\rho)^{-p} + \frac{k^{-(m-1)/m}}{\sigma t}\|u\|_{\infty,Q_0}^{2-p}
&\leq \|u\|_{\infty,Q_\infty}^{-(m-1)/m}\|u\|_{\infty,Q_0}^{2-p}\sigma^{-p}\left[\frac{\|u\|_{\infty,Q_0}^{(m-1)/m}\|u\|_{\infty,Q_0}^{2-p}\sigma^{-p}}{\rho^p} + t^{-1}\right] \\
&\leq \|v\|_{\infty,Q_\infty}^{-(m-1)}\|v\|_{\infty,Q_0}^{m(2-p)}\sigma^{-p}\left[\frac{\|v\|_{\infty,Q_0}^{d}}{\rho^p} + t^{-1}\right].
\end{aligned}
$$

Therefore, by Lemma 5–6 in [8], we obtain

$$
\begin{aligned}
\|v\|_{\infty,Q_\infty}^{2m+(m-1)(1+N/p)} \leq C\|v\|_{\infty,Q_0}^{m-1+m(2-p)(1+N/p)} \\
\times\left[\frac{\|v\|_{\infty,Q_0}^{d}}{\rho^p} + t^{-1}\right]^{1+N/p}\sigma^{-(p+N)}\iint_{Q_0} v^p dx d\tau.
\end{aligned}
$$

By the same argument as in Case (A), we obtain inequality (5.5) and complete the proof of Lemma 5.2. □

Let $\psi(t)$ be a function defined by

$$
\psi(t) = \sup_{\tau\in(0,t)} |||v(\cdot,\tau)|||_r. \tag{5.13}
$$

Then we can prove the following lemma.

LEMMA 5.3. *Let $\rho \geq r > 0$ and $\zeta(x)$ be a nonnegative piecewise-smooth cutoff function in $B_{2\rho}$ such that $\zeta \equiv 1$ on B_ρ, $\operatorname{supp}\zeta \subset B_{2\rho}$, and $|\nabla\zeta| < \rho^{-1}$. Then for any $t > 0$,*

$$
\begin{aligned}
&\int_0^t \int_{B_{2\rho}} |Dv^m|^{p-1}\zeta^{p-1} dx d\tau \\
&\quad\leq C\rho^{1+\kappa/d}\left(\int_0^t \tau^{(p+1)/\kappa-1}\phi^{d(p+1)/p}(\tau)\psi(\tau)d\tau\right. \\
&\qquad\left. + \int_0^t \tau^{1/\kappa-1}\phi^{d/p}(\tau)\psi(\tau)d\tau\right)^{(p-1)/p}\left(\int_0^t \tau^{1/\kappa-1}\phi^{d/p}(\tau)\psi(\tau)d\tau\right)^{1/p}.
\end{aligned}
$$

Proof. The Hölder inequality yields

$$
\begin{aligned}
&\int_0^t \int_{B_{2\rho}} |\nabla v^m|^{p-1}\zeta^{p-1} dx d\tau \\
&\leq\left(\int_0^t \int_{B_{2\rho}} \tau^{1/p}|\nabla v^m|^p (v^m+\epsilon)^{-(m+1)/mp}\zeta^p dx d\tau\right)^{1-1/p} \\
&\qquad\times\left(\int_0^t \int_{B_{2\rho}} \tau^{-(p-1)/p}(v^m+\epsilon)^{(m+1)(p-1)/mp} dx d\tau\right)^{1/p}
\end{aligned}
\tag{5.14}
$$

for any $\epsilon > 0$. Multiplying the equation by $g_\epsilon(v) = t^{1/p}(v^m+\epsilon)^{d/pm}\zeta^p$ and integrating it over $B_{2\rho}$, we have

$$
\begin{aligned}
&\int_0^t \int_{B_{2\rho}} \tau^{1/p}|\nabla v^m|^p (v^m+\epsilon)^{d/mp-1}\zeta^p dx d\tau \\
&\leq C\rho^{-p}\int_0^t \int_{B_{2\rho}} \tau^{1/p}(v^m+\epsilon)^{(mp^2-m-1)/mp} dx d\tau + C\int_0^t \int_{B_{2\rho}} \tau^{-(p-1)/p}\Lambda(\epsilon) dx d\tau,
\end{aligned}
\tag{5.15}
$$

where

$$\Lambda(\epsilon) = \int_0^v (s^m + \epsilon)^{d/mp} ds.$$

Taking the limit as $\epsilon \to 0$, by (5.14) and (5.15), we have

$$\int_0^t \int_{B_{2\rho}} |Dv^m|^{p-1} \zeta^{p-1} dx d\tau \le C(I_1 + I_2)^{(p-1)/p} I_2^{1/p},$$

where

$$I_1 \equiv \rho^{-p} \int_0^t \int_{B_{2\rho}} \tau^{1/p} v^{(mp^2-m-1)/p} dx d\tau, \quad I_2 \equiv \int_0^t \int_{B_{2\rho}} \tau^{-(p-1)/p} v^{(m+1)(p-1)/p} dx d\tau.$$

By (5.13),

$$I_1 \le C\rho^{1+\kappa/d} \int_0^t \tau^{(p+1)/\kappa - 1} \phi^{(p+1)d/p}(\tau) \psi(\tau) d\tau$$

and

$$I_2 \le C\rho^{1+\kappa/d} \int_0^t \tau^{1/\kappa - 1} \phi^{d/p}(\tau) \psi(\tau) d\tau.$$

Therefore, the proof of Lemma 5.3 is complete. □

By Lemmas 5.2 and 5.3, we can prove the following proposition by an argument similar to that of §3 in [6].

PROPOSITION 5.4. *Let u be a weak solution of* (5.1). *Then there exist constants C_i, $i = 0, 1, 2$, such that*

$$\phi(t) \le C_1 |||\mu|||_r^{p/\kappa}, \qquad \psi(t) \le C_2 |||\mu|||_r \tag{5.16}$$

for all $0 < t < C_0 |||\mu|||_r^{-d}$. Furthermore, there exist constants C_i, $i = 3, 4$, such that for any $\rho \ge r > 0$,

$$\|v(\cdot, t)\|_{\infty, B_\rho} \le C_4 t^{-N/\kappa} \rho^{p/d} |||\mu|||_r^{p/k}, \tag{5.17}$$

$$\int_0^t \int_{B_\rho} |\nabla v^m|^{p-1} dx d\tau \le C_5 t^{1/\kappa} \rho^{1+\kappa/d} |||\mu|||_r^{1+d/\kappa} \tag{5.18}$$

for all $0 < t < C_0 |||\mu|||_r^{-d}$.

By Proposition 5.4, we can prove Theorem 1.2. In fact, for any σ-finite nonnegative Borel measure μ satisfying $|||\mu|||_r$ for some $r > 0$, there exists a sequence $\{\mu_n\}_{i=1}^\infty \subset C_0^\infty(\mathbf{R}^N)$ such that

$$\lim_{n \to \infty} \int_{\mathbf{R}^N} \mu_n \varphi dx = \int_{\mathbf{R}^N} \varphi d\mu$$

for any $\varphi \in C_0(\mathbf{R}^N)$ and $|||\mu_n|||_r \to |||\mu|||_r$ as $n \to \infty$ for any $r > 0$. Let u_n be a solution of (5.1) for initial condition μ_n. Then by (5.3), (5.17), and (5.18), taking the limit as $n \to \infty$, we can see that there exists a solution of (1.1) for initial condition μ

by the same argument as in the proof of Theorem 1.3. Therefore, by Proposition 5.4, we can complete the proof of Theorem 1.2.

6. $L^\infty_{\rm loc}(\mathbf{R}^N)$ estimate for Case (III).

In order to prove Theorem 1.4, we need some $L^\infty_{\rm loc}(\mathbf{R}^N)$ estimates of the nonnegative solutions. By Theorems 2–1 and 2–2 in [19], we have the following proposition.

PROPOSITION 6.1. *Let v be a locally bounded nonnegative local weak solution of*

$$\frac{\partial}{\partial t}v = \operatorname{div}(|\nabla v^m|^{p-2}\nabla v^m) \quad in \quad \mathbf{S}_\infty, \quad d = m(p-1)-1<0. \tag{6.1}$$

If $\kappa_r > 0$, then there exist constants $C_i = C_i(N,m,p,r)$, $i = 1,2,3,4$, such that for any $t > 0$ and $\rho > 0$,

$$\sup_{x\in B_\rho} v(x,t) \le C_1 t^{-N/\kappa_r}\left(\sup_{0<\tau<t}\int_{B_{2\rho}} v^r(x,\tau)dx\right)^{p/\kappa_r} + C_2\left(\frac{t}{\rho^p}\right)^{p/\kappa_r} \tag{6.2}$$

and

$$\sup_{0<\tau<t}\int_{B_\rho} v^r(x,\tau)dx \le C_3\int_{B_{2\rho}} v^r(x,0)dx + C_4\left(\frac{t^r}{\rho^{\kappa_r}}\right)^{1/-d}. \tag{6.3}$$

We can also prove Proposition 6.1 in view of the arguments of the previous sections and [7]. We remark that Lemma 5.1 holds for equation (6.1).

The following lemma is presented via the same arguments as in Lemma I.4.1 and Corollary III.3.1 of [7] with minor changes.

LEMMA 6.2. *There exists a constant $C = C(N,m,p)$ such that for any $0 < s < t$, $\rho > 0$,*

$$\begin{aligned}\frac{1}{\rho}\int_s^t\int_{B_\rho} |\nabla v^m|^{p-1}dxd\tau \le C\left(\frac{t-s}{\rho^\kappa}\right)^{1/p} \\ \times\left\{\int_{B_{2\rho}} v(x,0)dx + \left(\frac{t}{\rho^\kappa}\right)^{-d}\right\}^{(m+1)(p-1)/p}\end{aligned} \tag{6.4}$$

Therefore, by (6.2)–(6.4), we can complete the proof of Theorem 1.4 in the same way as in that of Theorem 1.2.

GLOBAL STABILITY OF TRAVELING FRONTS AND CONVERGENCE TOWARDS STACKED FAMILIES OF WAVES IN MONOTONE PARABOLIC SYSTEMS*

JEAN-MICHEL ROQUEJOFFRE†, DAVID TERMAN‡, AND VITALY A. VOLPERT§

Abstract. A class of parabolic systems for which the maximum principle is valid is investigated. When two stable rest points can be connected by a traveling front, any solution of the Cauchy problem which initially has these two rest points as spatial limits will become monotone in finite time on every compact interval and converge to a traveling front. As an application, convergence to stacked waves is discussed.

Key words. global stability, traveling waves, wave stacks

AMS subject classifications. 35B40, 35K45

1. Introduction.

The problem under consideration is the long-time behaviour of the solutions of the Cauchy problem for a class of semilinear parabolic systems of the form

$$\begin{aligned} u_t - Du_{xx} &= F(u), \\ u(0,x) &= u_0(x). \end{aligned} \tag{1.1}$$

The unknown is the real-vector function $u(t,x) =. (u_1(t,x),\dots,u_n(t,x))$, the nonlinearity $F(u) = (F_1(u),\dots,F_n(u))$ is smooth, say of class C^1 in u, and D is a diagonal matrix with positive diagonal coefficients $(D_1,\dots,D_n)$. Such a system is called monotone if the following additional condition holds:

$$\forall i \in [1,n],\ \forall j \neq i,\quad \frac{\partial F_i}{\partial u_j} \geq 0. \tag{1.2}$$

It is well known [G], [VV1] that (1.2) implies a comparison principle: if $u_{10} \leq u_{20}$, then $u_1 \leq u_2$ as long as both solutions exist. The inequalities are meant to hold componentwise.

Traveling-front solutions of (1.1) are solutions of the form $u(t,x) = w(x+ct)$; if $F(w_-) = F(w_+) = 0$, then the front is said to connect the two rest points w_- and w_+ if it goes to w_- (resp. w_+) as $x \to -\infty$ (resp. as $x \to +\infty$). Denoting $w' = \frac{dw}{dx}$, we write the differential system satisfied by $w(x)$:

$$\begin{aligned} -w'' + cw' &= F(w), \\ \lim_{x\to\pm\infty} w(x) &= w_\pm. \end{aligned} \tag{1.3}$$

The existence of a solution (c,u) for (1.3) has been investigated in a number of frameworks. The scalar version is now understood. Systems of equations have also been

§Laboratoire d'Analyse Numérique, Université de Lyon I, 43 Boulevard du 11 Novembre 1918, 69622 Villeurbanne cedex, France.

extensively studied. For example, a model for competing species was considered in [G], while a model for chemical activity on isothermal catalyst surfaces was studied in [FT]. These are both systems with two equations; the more general case was considered in [VV1]. Nonmonotone systems also arise in many applications—in particular, combustion theory. Systems with two equations are considered in [BNS] and [T1], while models involving complex chemistry are studied in [B] and [T2]. This list is, of course, by no means exhaustive.

Henceforth, system (1.1) will always be assumed to be monotone, and this will not be mentioned again. Assume that F has two stable rest points $w_- < w_+$. Also assume that in the interval $[w^-, w^+]$, the only rest points w are such that the matrix $F'(w)$ has at least one eigenvalue in the right half-plane. This assumptions is meant to disallow waves that connect intermediate rest points, which could prevent the existence of a wave connecting w_- and w_+. Other stable rest points, not in the interval $[w_-, w_+]$, are allowed.

From [VV1], there indeed exists a unique $c \in I\!R$ and a unique—up to the translations—profile w such that (1.3) holds; furthermore, $w' > 0$. Henceforth, we will always denote by w the unique solution of (1.3) such that

$$w(0) = \frac{w^- + w^+}{2}. \tag{1.4}$$

It is proved in [VV2] that if the initial datum is monotone in x and satisfies decay conditions at $\pm\infty$, then $u(t)$ converges exponentially to a front. It is the purpose of this paper to remove the monotonicity assumption and to examine some consequences of this result when F has multiple stable rest points.

Let us recall that global stability for the bistable scalar case was treated by Fife and McLeod [FML]. The local stability of traveling fronts for monotone systems with two equations was considered in [G] and [FT]. In several space dimensions with nonhomogeneous convection, the problem has recently been solved by the first author in [R1] (monotone initial data) and [R2] (nonmonotone initial data).

The paper is organized as follows. In §2, we state our main results, and §§3 and 4 are devoted to their proofs.

2. Notations and main results. Let us denote by $\mathcal{S}(t)u_0$ the solution of (1.1)—which may, by the way, not exist globally. Let $UC(I\!R, I\!R^n)$ be the set of all bounded, uniformly continuous functions from $I\!R$ to $I\!R^n$; for $u \in UC(I\!R, I\!R^n)$ and $h \in I\!R$, define $\tau_h u(x) := u(x+h)$.

We will call $w_0 \in I\!R^n$ a *stable rest point* of F if $F(w_0) = 0$ and the eigenvalues of the matrix $F'(w_0)$ have negative real parts.

THEOREM 2.1. *Assume that $w^- \leq w^+$ are two stable rest points connected by a monotone front w with speed c. Let $u_0 \in UC(I\!R, I\!R^n)$ satisfy $w^- \leq u_0(x) \leq w^+$, and set*

$$\varepsilon(u_0) = \sup\left(\limsup_{x\to-\infty} |u_0(x) - w^-|, \ \limsup_{x\to+\infty} |u_0(x) - w^+| \right). \tag{2.1}$$

Then, if $\varepsilon(u_0)$ is small enough, $\mathcal{S}(t)u_0$ is defined for all time and there exist $x_0 \in I\!R$ and $\omega > 0$ such that

$$\|\mathcal{S}(t)u_0 - \tau_{x_0+ct}w\|_\infty = O(e^{-\omega t}).$$

When multiple ordered stable rest points exist, the long-time behaviour of $\mathcal{S}(t)u_0$ can be a difficult problem. However, the following natural case can be treated.

THEOREM 2.2 *Assume that* $w^- = w^1_\infty < \cdots < w^l_\infty < \cdots < w^k_\infty = w^+$, $1 \le l \le k$, *are* k *rest points such that the eigenvalues of the matrices* $F'(w^l)$ *have negative real parts. Assume that for all* $l \in [1,k]$, w^l_∞ *and* w^{l+1}_∞ *are connected by a monotone front* w^l *with speed* c^l *and that* $c^{l+1} < c^l$.

Let $u_0 \in UC(I\!R, I\!R^n)$ *satisfy* $w^- \le u_0(x) \le w^+$. *Then if* $\varepsilon(u_0)$ *is small enough—recall that* $\varepsilon(u_0)$ *is defined by* (2.1)—(1.1) *has a global solution* $\mathcal{S}(t)u_0$ *and there exist* $(x^1, \ldots, x^k) \in I\!R^k$ *and* $\omega > 0$ *such that*

$$\left\| \mathcal{S}(t)u_0 - w^1_\infty - \sum_{l=1}^{k} \left(\tau_{x^l + c^l t} w^l - w^l_\infty\right) \right\|_\infty = O(e^{-\omega t}).$$

Remarks. 1. Theorem 2.2 implies nonexistence results for certain solutions of (1.3); in particular, its assumptions preclude the existence of a single wave connecting w^- to w^+.

2. In contrast with the preceding remark, we may consider the union of the monotone fronts w^l as a stable wave train which connects w^- with w^+. The existence of stacked waves for systems with two equations was considered in [FT]. It was demonstrated there that if w^- and w^+ are any distinct, stable rest points and all of the rest points are nondegenerate, then there must exist a wave train which connects w^- with w^+. The stacked family may, of course, consist of a single traveling-wave solution. Theorem 2.2 demonstrates that this wave train is globally, asymptotically stable. A similar result concerning the existence of wave trains is proved in [T2], where a nonmonotone system is considered. The extension of this result to more general systems will be addressed elsewhere.

3. Convergence to traveling fronts.

Assume that the assumptions of Theorem 2.1 are satisfied. In particular, w is a monotone front with speed c. The first task in studying the stability of w is to rewrite (1.1) in the reference frame of the traveling front. This yields

$$\begin{aligned} u_t - Du_{xx} + cu_x &= F(u), \\ u(0,x) &= u_0(x). \end{aligned} \tag{3.1}$$

The solution will still be called $\mathcal{S}(t)u_0$. As is known, three ingredients are required in the proof of convergence: local stability, precompactness of the orbits, and quasiconvergence. One cannot hope to prove quasiconvergence without precompactness, and global stability is implied by local stability and quasiconvergence. Local stability is a consequence of Theorem 4.1 in [VV2], and we state it in a more general form which will be useful in §4.

THEOREM 3.1. *For* $v_0 \in UC(I\!R, I\!R^n)$ *and* $h \in UC(I\!R_+ \times I\!R, I\!R^n)$, *let* $u(t,x)$ *be the solution of*

$$\begin{aligned} u_t - Du_{xx} + cu_x &= F(u) + h(t), \\ u(0) &= w + v_0. \end{aligned} \tag{3.2}$$

Assume that $\|h(t)\|_\infty \le \delta e^{-2\omega t}$*—the same* ω *as in Theorem* 2.1. *There exist* $\gamma(v_0,h)$ *and* $C(v_0,h) > 0$ *defined and bounded for small* δ *and* $\|v_0\|_\infty$ *such that*

$$\|\mathcal{S}(t)u_0 - \tau_{\gamma(v_0,h)} w\|_\infty \le C(v_0,h)e^{-\omega t}.$$

We now turn to precompactness. The most common way to prove this is to trap $\mathcal{S}(t)u_0$ between two translates of the wave, as is stated below. Set $p_0 := (1, \ldots, 1)$.

LEMMA 3.2. *Let u_0 be as in Theorem 2.1. There exist $q > 0$, $\omega > 0$, and $\xi_1 < \xi_2$ such that for t_0 large enough, it holds that*

$$\forall t \geq t_0, \quad \tau_{\xi_1} w - qp_0 e^{-\omega t} \leq \mathcal{S}(t)u_0 \leq \tau_{\xi_2} w + qp_0 e^{-\omega t}. \tag{3.3}$$

Proof. Choose $\varepsilon_0 > 0$ so small that for all v_0 lying in the cube $[-\varepsilon_0, \varepsilon_0]^n$, the matrices $F'(w_- + v)$ and $F'(w_+ + v)$ have eigenvalues of negative real parts. As a consequence, the solutions $v_\pm(t)$ of the two differential systems

$$\frac{dv_-}{dt} = F(v_-), \quad v_-(0) = w^- + v_0,$$
$$\frac{dv_+}{dt} = F(v_+), \quad v_+(0) = w^+ + v_0$$

approach $w_\pm$ exponentially as $t \to +\infty$. Therefore, if $\varepsilon(u_0) \leq \varepsilon_0$, the function $\varepsilon(\mathcal{S}(t)u_0)$ goes exponentially to 0. In Theorem 3.1, we set $h \equiv 0$ and select $t_0 > 0$ large enough so that Theorem 3.1 works with $v_0 \equiv \varepsilon(\mathcal{S}(t_0)u_0)p_0$. Furthermore, there exists $M > 0$ such that

$$\tau_{-M}(w - v_0) \leq \mathcal{S}(t_0)u_0 \leq \tau_M(w + v_0).$$

From the comparison principle, we have, for all $t \geq t_0$,

$$\mathcal{S}(t - t_0)\big(\tau_{-M}(w - v_0)\big) \leq \mathcal{S}(t)u_0 \leq \mathcal{S}(t - t_0)\big(\tau_M(w + v_0)\big).$$

Since the semigroup commutes with the translations, we get (3.3). □

Lemma 3.2 implies global existence and precompactness. Therefore, it remains to prove quasiconvergence, and we will use the method of [R2]. We first need a lemma to replace the Harnack inequalities that were used in [R2], and in this scope we consider the linear parabolic system

$$u_t - Du_{xx} + cu_x = A(t,x)u, \quad x \in I\!R, \tag{3.4}$$

where $A(t,x) := \big(a_{ij}(t,x)\big)_{1 \leq i,j \leq n}$ is bounded and continuous and satisfies $a_{ij}(t,x) \geq 0$ if $i \neq j$. Henceforth, if $u(t,x)$ is a bounded solution of (3.4), we will set $\sup_{x \in I\!R} u(t,x) := \sup_{1 \leq i \leq n,\ x \in I\!R} u_i(t,x)$, and the same convention will be used for the infimum.

LEMMA 3.3. *Let $u(t,x) \geq 0$ be a globally bounded solution of* (3.4) *for which there exist $\mu, \alpha > 0$ such that*

$$\sup_{x \in I\!R} \left(\inf_{1 \leq i \leq n} u_i(t,x) \right) = \max_{x \in [-\alpha,\alpha]} \left(\min_{1 \leq i \leq n} u_i(t,x) \right) = \mu.$$

Choose $M > \alpha$ and $t \geq 1$. There exists $\eta(M) > 0$ such that $\inf_{x \in [-M,M]} u(t,x) \geq \eta(M)$.

Proof. For $t \geq 1$, let $x_t \in [-\alpha, \alpha]$ such that $u(t, x_t) \leq \mu p_0$. From the parabolic estimates, u_x is globally bounded; therefore, there exists $K > 0$ such that

$$u(t,y) \geq (\mu - K|x_t - y|)p_0$$

for all $y \in I\!R$; as a consequence, we get, for $|x_t - y|$, $u(t,y) \geq \frac{\mu}{2}p_0$.

Let us assume without loss of generality that $N := \frac{2K}{\mu}$ is a nonzero integer. For $j \in [-N, N]$, set $x_j := \frac{j}{N}$ and $I_j := [x_j, x_{j+1}]$. We choose $j \in [-N, N]$ such that $x_t \in I_j$; for $y \in I_j$, we may write—thanks once again to the parabolic estimates—

$$\forall \tau \in \left[-\frac{1}{2}, \frac{1}{2}\right], \quad u(t+\tau, y) \geq u(t, y) - K'\tau p_0,$$

where K' depends on neither t nor τ—recall that t was taken > 1. Thus for $0 \leq |\tau| \leq \delta := \frac{1}{4KK'}$, we have

$$u(t+\tau, y) \geq \frac{\mu}{4} p_0. \tag{3.5}$$

We now define by induction an increasing sequence $(t_p)_p$ such that $(t_{p+1} - t_p)_p$ is bounded away from 0. Set $t_0 := 0$ and for $p \geq 1$ assume that, for all $k \leq p$, we have managed to define t_k and an integer $j_k \in [-N, N]$ such that $x_{t_k} \in I_{j_k}$; also, assume that $t_{k+1} - t_k \geq \delta$ for $k \leq n-1$. The time t_{p+1} will be chosen to be the first instant when the inequality $u(t, y) \geq \frac{\mu}{4} p_0$ ceases to hold in I_{j_p}; obviously, from (3.5), we have $t_{p+1} - t_p \geq \delta$; however, t_{p+1} may be infinite, but this will not bother us too much.

Notice that for all n, the abscissa x_{t_p} can be chosen to remain in $[-\alpha, \alpha]$; this is allowed by the assumption.

Now choose $M > \alpha$; without loss of generality, we take $M \geq 1 + \alpha$. Set $\underline{a}_{ij} := \inf_{t \geq 0, x \in I\!R} a_{ij}(t, x)$ and $\underline{A} := (\underline{a}_{ij})_{1 \leq i,j \leq n}$. Setting $s_p := t_p - \frac{\delta}{2}$, we define the sequence $(u_p(t, x))_p$ by

$$\begin{aligned} \partial_t u_p - \partial_{xx} u_p + c\partial_x u_p &= \underline{A} u_p, \quad (t, x) \in]s_p, t_{p+1}] \times] - \infty, x_{j_p}], \\ u_p(t, x_{j_p}) &= \frac{\mu}{4}, \\ u_p(s_p, x) &= 0, \end{aligned} \tag{3.6}$$

and we also define the sequence $(v_p(t, x))_p$ by the same boundary problem as (3.6), but replacing $] - \infty, x_{j_p}]$ by $[x_{j_{p+1}}, +\infty[$. As is well known, the functions u_p and v_p are time-increasing for every p; moreover, we have $u_p(t, .) = \tau_{x_{j_p} - x_0} u_0(t - s_p)$ (resp. $v_p(t, .) = \tau_{x_{j_{p+1}} - x_0} v_0(t - s_p)$). Furthermore, the comparison principle implies that for every p and every $t \in [s_p, t_{p+1}]$ and $x \notin I_{j_p}$, $\sup(u_p(t), v_p(t)) \leq u(t)$. This together with (3.5) implies

$$\inf_{x \in [-M, M]} u(t, x) \geq \inf\left(\left(\mu, \inf_{x \in [-M, M]} (u_0(t_0, x), v_0(t_0, x))\right)\right) := \eta(M).$$

From (3.6) and the properties of u_p and v_p, we have $\eta(M) > 0$. □

We may now turn to the proof of Theorem 2.1. We will use the idea of [R2], with minor modifications. Notice that by precompactness, $\omega(u_0)$ is nonempty and compact in $UC(I\!R, I\!R^n)$.

LEMMA 3.4. *Let u_0 satisfy the assumptions of Theorem 1.1. Then there exists an x-increasing element in $\omega(u_0)$.*

Proof. From Lemma 3.2, there exist two real numbers $h_1 \leq h_2$ such that

$$\forall \psi \in \omega(u_0), \quad \tau_{h_1} w \leq \psi \leq \tau_{h_2} w. \tag{3.7}$$

Denote by h the following application, defined on $\omega(u_0)$:

$$\forall\psi \in \omega(u_0), \quad h(\psi) = \mathrm{Inf}\{h > 0 : \ \forall k \geq h, \tau_k\psi \geq \psi\};$$

from (3.7), we see that $h(\psi)$ is finite for $\psi \in \omega(u_0)$. Also, by compactness, h attains its minimum h_0 at some point $\psi_0 \in \omega(u_0)$. Assume that $h_0 > 0$. Notice that from the definition of h_0 and the maximum principle, we have $h\big(\mathcal{S}(t)\psi_0\big)= h_0$.

Let us first notice that, because of (3.7), there exists $\mu > 0$ such that

$$\forall t \geq 0, \quad \min_{1\leq i \leq n}\left\{\sup_{x\in\mathbb{R}}\Big(\mathcal{S}(t)\psi_{0,i}(x+h_0) - \mathcal{S}(t)\psi_{0,i}(x)\Big)\right\} \geq \mu. \tag{3.8}$$

For every $\delta \in \mathbb{R}$, let $v^\delta(t,x,y)$ be defined as $v^\delta = \tau_{h_0-\delta}\mathcal{S}(t)\psi_0 - \mathcal{S}(t)\psi_0$. The function v^0 solves

$$v^0_t + Dv^0_{xx} + cv^0_x = A(t,x)v^0 \quad \text{in } \mathbb{R}$$

with $A(t,x) = \int_0^1 F'(\sigma\tau_{h_0-\delta}\mathcal{S}(t)\psi_0 + (1-\sigma)\mathcal{S}(t)\psi_0 \, d\sigma$. The matrix $A(t,x)$ satisfies the assumptions of Lemma 3.3; therefore, for every large enough $M > 0$, there exist $\delta_0(M) \in]0,h_0[$ and $\mu(M) > 0$ such that

$$\forall\delta \in [0,\delta_0(M)[, \ \forall t \geq 1, \forall x \in [-M,M], \quad v^\delta(t,x) \geq \mu(M).$$

Let ε_0 be defined as in Lemma 3.2 and $M > 0$ be large enough so that for all $k \in [0,h]$ all $x \notin [-M,M]$ and all $t \geq 1$, we have $\tau_k\mathcal{S}(t)\psi_0(x) \in [-\varepsilon_0,\varepsilon_0]^n$. We are now going to study the evolution of $\mathcal{S}(t)\psi_0$. By compactness, there exist a sequence $(t_n)_n$ and $\psi_\infty \in \omega(u_0)$ such that

$$\lim_{n\to+\infty} \|\mathcal{S}(t_n)\psi_0 - \psi_\infty\|_\infty = 0.$$

From the definition of h_0, we know that for all $x \in [-M,M]$ and $k \geq h_0 - \delta_0$, $\psi_\infty(x+k) \geq \psi_\infty(x)$. Let us see what happens for $x \geq M$. From the definition of ε_0 and the maximum principle, we have

$$v^\delta(t,x) \geq -\varepsilon_0 e^{\int_0^t A(s,x)\,ds} p_0. \tag{3.9}$$

From the definition of ε_0, the right-hand side of (3.9) goes exponentially to 0. Furthermore, a similar phenomenon occurs for $x \leq -M$.

To sum up, we have just constructed $\psi_\infty \in \omega(u_0)$ such that for every $k \geq h_0 - \delta_0$, the inequality $\tau_k\psi_\infty \geq \psi_\infty$ holds, which implies that $h(\psi_\infty) \leq h_0 - \delta_0$. This contradicts the definition of h_0. □

Proof of Theorem 2.1. Let $\psi_0 \in \omega(u_0)$ be increasing in x. From Theorem 5.1 of [VV2]—convergence to traveling fronts for x-increasing initial data—$\mathcal{S}(t)\psi_0$ converges to some $\tau_{x_0}w$. From the closedness of $\omega(u_0)$, we infer that $\tau_{x_0}\psi_0 \in \omega(u_0)$, which is exactly quasiconvergence. □

4. Convergence to stacked waves. The first idea proceeds as in [FML]: first, construct sub- and supersolutions to make sure that everything happens in the right reference frames; we then use Theorem 3.1 to complete the proof. However, this method cannot be carried along the whole way: to make it work, one would need an additional assumption, namely, the existence of $p > 0$ such that every $F'(w^l_\infty)p > 0$ for all l.

This assumption is not irrelevant, but we prefer another method which works without it. Let us first remark that combining Theorem 2.1 with Theorem 3.1 yields the following result.

THEOREM 4.1. *Let u_0 satisfy the assumptions of Theorem* 2.1. *For $h \in UC(I\!R_+ \times I\!R, I\!R^n)$, let $u(t,x)$ be the solution of*

$$u_t - Du_{xx} + cu_x = F(u) + h(t), \qquad u(0) = w + u_0. \tag{4.1}$$

Assume that $h(t) = O(e^{-2\omega t})$. There exists $\varepsilon_0 > 0$ such that if $\varepsilon(u_0^l) \leq \varepsilon_0$ is small enough—see (2.1) *for the definition—$u(t)$ is defined for all time and there exists $x_0 \in I\!R$ such that*

$$\|u(t) - \tau_{x_0+ct}w\|_\infty = O(e^{-\omega t}).$$

The proof is standard and will not be given. The following consequence of Theorem 4.1 will be needed.

LEMMA 4.2. *Let α, k, and γ be positive. With the notations of Theorem* 2.1, *let $u(t,x)$ solve*

$$\begin{aligned} u_t - Du_{xx} + cu_x &= F(u), \quad x \geq -\alpha t, \\ u(t, -\alpha t) &= w_- - kp_0 e^{-\gamma t}, \\ u(t, +\infty) &= w_+. \end{aligned} \tag{4.2}$$

There exists $x_0 \in I\!R$ such that $\|u(t) - \tau_{x_0+ct}w\|_{L^\infty([-\alpha t, +\infty[)} = O(e^{-\omega t})$.

Proof. The proof requires two steps. Throughout the proof, the notation of §3 will be used.

Step 1: *Estimates at $x = -\alpha t$.* Let $\overline{u}_0$ be x-increasing and such that

$$\lim_{x \to -\infty} \overline{u}_0(x) = w_-, \quad \overline{u}_0 \geq u(0).$$

Clearly, $u \leq \overline{u}$; therefore, by Theorem 3.1, we have $u(t,x) \leq \tau_{x_1}w + O(e^{-\omega t})$.

Now recall that $F'(w_-)^{-1}$ sends the nonpositive cone of $I\!R^n$ onto its interior. To see this, we only have to write

$$F'(w_-)^{-1} = \lim_{t \to +\infty} \int_0^t e^{(t-s)F'(w_-)}\, ds,$$

which is obviously nonpositive by the comparison principle, and even negative. By continuity and Frobenius–Perron theorem, there exists $\varepsilon_0 > 0, \mu > 0$ and a vector $p > 0$ such that

$$\forall v \in [-\varepsilon_0, \varepsilon_0]^n, \quad F'(w_- + v)q \leq -\mu q. \tag{4.3}$$

Choosing $\gamma_1 < \inf(\gamma, \mu)$, we see that the function $\underline{u}(t) := w_- - \varepsilon q e^{-\gamma_1 t}$ is a subsolution to (4.2) as soon as ε is small enough. As a consequence, we get $\underline{u}(t) \leq u(t,x) \leq \overline{u}(t,x)$ once all the parameters are conveniently chosen. This yields an estimate of the form $\|u(t) - w_-\|_{L^\infty([-\alpha t, -\alpha t+2[)} = O(e^{-\omega t})$; from boundary estimates, we finally infer

$$|u_x(t, -\alpha t)| + |u_x(t, -\alpha t)| + |u_t(t, -\alpha t)| = O(e^{-\gamma_1 t}). \tag{4.4}$$

Step 2: *Convergence.* Let Γ be a C^∞ real-valued, nonnegative, nondecreasing function that is equal to 0 on $I\!R_-$ and to 1 on $[1,+\infty[$. Define componentwise the function $v(t,x)$ on the whole real line as

$$v_i(t,x) = (w_-)_i + \big(u_i(t,x) - (w_-)_i\big)\Gamma(x + \alpha t - 1). \tag{4.5}$$

From Step 1 above, the function v solves an equation of the type (4.1), and we may apply Theorem 4.1 to obtain Lemma 4.2. □

Let us now prove that, as we stated above, everything happens in the right reference frames.

LEMMA 4.3: *Let u_0 fulfill the assumptions of Theorem* 2.2. *There exist* $2k$ *real numbers* $\xi_\alpha^1 < \cdots < \xi_\alpha^l < \xi_\alpha^k$, $\alpha \in \{1,2\}$, *and* $q, \omega > 0$ *such that*

$$w_\infty^1 + \sum_{l=1}^{k}\big(\tau_{\xi_1^l + c^l t} w^l - w_\infty^l\big) - qp_0 e^{-\omega t} \le \mathcal{S}(t)u_0$$
$$\le w_\infty^1 + \sum_{l=1}^{k}\big(\tau_{\xi_2^l + c^l t} w^l - w_\infty^l\big) + qp_0 e^{-\omega t}.$$

Proof. Only the lower bound will be dealt with since the upper bound is similar. By an easy induction on $l \in [1,k]$, it is possible to find k functions $u^1(t,x), \dots, u^l(t,x), \dots, u^k(t,x)$ defined on some time interval of the form $[t_0, +\infty[$, $t_0 > 0$, large enough such that

- for all l, u^l is a solution of (4.2) with $\alpha = \frac{c^l + c^{l+1}}{2}$ and $c = c^l$,
- $\lim_{x \to +\infty} u^l(t,x) = w_\infty^{l+1}$,
- $u^l\big(t, \frac{c^l - c^{l+1}}{2}t\big) = u^{l+1}\big(t, -\frac{c^l - c^{l+1}}{2}t\big)$ for $l \le k$,
- $u^1(t,x) \le \mathcal{S}(t)u_0$,
- $u^l(t) \le \tau_{-c^l t}\mathcal{S}(t)u_0$, for $t \ge t_0$, $x \ge \frac{c^l - c^{l-1}}{2}$, and $l \ge 1$.

Now define $\underline{u}(t,x)$ as

$$\underline{u}(t,x) = \begin{cases} \tau_{c^1 t} u^1(t,x) & \text{if } \ x \le -\dfrac{c^1 + c^2}{2}t, \\ \tau_{c^l t} u^l(t,x) & \text{if } \ -\dfrac{c^l + c^{l-1}}{2}t \le x \le -\dfrac{c^l + c^{l+1}}{2}t, \\ \tau_{c^k t} u^k(t,x) & \text{if } \ x \ge -\dfrac{c^k + c^{k-1}}{2}t. \end{cases} \tag{4.5}$$

Obviously, $\underline{u}(t,x) \le \mathcal{S}(t)u_0$; application of Lemma 4.2 yields Lemma 4.3. □

Proof of Theorem 2.2. From Lemma 4.3, the vector function v^l, defined as in (4.5) with $\alpha^l = c^l$, satisfies an equation of the type (4.1). Therefore, Theorem 4.1 yields Theorem 2.2. □

TRAVELING-WAVE SOLUTIONS TO COMBUSTION MODELS FOR A REVERSIBLE REACTION*

ALEXIS BONNET†

Abstract. We prove the existence of traveling flames for a combustion model involving a reversible chemical reaction $\sum_{i=1}^{n} \nu_i A_i \rightleftharpoons \sum_{i=1}^{n} \mu_i A_i$. The proof of existence involves a degree theory argument and refined a priori estimates.

Key words. combustion, traveling waves, system of ordinary differential equations

AMS subject classifications. 34A34, 80A25, 80A30

1. Introduction. The study of planar flame is one of the fundamental problems in combustion (see, for example, [ZFK], [CFN], [JN], [W]). The rigorous mathematical treatment of this question was initiated by Berestycki, Nicolaenko, and Scheurer, who proved the existence of traveling waves for a simple combustion model [BNS]. They gave a complete analysis of the case of a one-step nonreversible reaction $A \longrightarrow B$ (see also [M] and [B3] for other qualitative properties and uniqueness results on this model). Later, Terman [T] and Heinze [H] addressed the question of complex chemistry. In their work, they considered only exothermic reactions. In [B1], we studied some complex chemical networks with the help of graph theory. We obtained the existence of traveling waves for complex chemical networks involving endothermic reactions. However, purely reversible reactions are not covered by these works.

In this paper, we consider the deflagration-wave problem for a compressible reacting gas with two or more species involved in a reversible chemical reaction.

$$A \rightleftharpoons B \tag{1.1}$$

or

$$\sum_{i=1}^{n} \nu_i A_i \rightleftharpoons \sum_{i=1}^{n} \mu_i A_i. \tag*{(1.1)$'$}$$

In the limit of small Mach number, the one-dimensional traveling-wave problem for the reversible chemical reaction (1.1) can be reduced to a system of two reaction-diffusion equations (see §2 for a review of the model)

$$\begin{cases} -T'' + cT' = -Y_1 f_1(T) + (1 - Y_1) f_2(T), \\ -d_1 Y_1'' + cY_1' = -Y_1 f_1(T) + (1 - Y_1) f_2(T) \end{cases} \tag{1.2}$$

with boundary conditions

$$\begin{cases} T(-\infty) = 0, \quad T(+\infty) = T^+, \\ Y_1(-\infty) = Y_1^-, \quad Y_1(+\infty) = Y_1^+. \end{cases} \tag{1.3}$$

*Received by the editors February 4, 1994; accepted for publication (in revised form) April 17, 1995. This work was partly done while the author was staying at the Courant Institute of Mathematical Sciences, New York University, and was supported by a Bourse Lavoisier of Ministère des Affaires Etrangères (France).

†Université de Cergy-Pointoise, 2 Avenue Adolphe Chauvin, 95302 Cergy-Pointoise cedex, France and Departement de Mathématiques et d'Informatique, École Normale Supérieure, 75230 Paris cedex 05, France.

The real c is the unknown mass flux of the wave.

In (1.2)–(1.3), T denotes the renormalized temperature of the mixture, Y_1 is the concentration of species A, and $1 - Y_1$ is the concentration of species B. Here we assume that A and B have the same diffusion coefficient d_1. For simplicity, d_1 is taken constant.

In system (1.2), $Y_1 f_1(T)$ is the rate of the semireaction $A \to B$ and $(1-Y_1)f_2(T)$ is the rate of the semireaction $B \to A$.

More precisely, we assume that the rates are of mass-action Arrhenius form

$$f_i = B_i(T)\exp\left(-\frac{E_i}{R(\alpha T + t_0)}\right), \quad i = 1, 2, \tag{1.4}$$

where E_i is the activation energy of the semireaction, $\alpha T + t_0$ is the absolute temperature of the mixture, and R a physical constant.

Notice that under conditions (1.3), the right-hand side of the equations in (1.2) vanishes for ($T = 0$, $Y_1 = Y_1^-$) and for ($T = T^+$, $Y_1 = Y_1^+$). Since we expect a flame to propagate, the mixture is not in equilibrium in the fresh gas ($T = 0$, $Y_1 = Y_1^-$). In other words, $-Y_1^- f_1(0) + (1 - Y_1^-)$ is not zero. However, this term is very small and the reaction is frozen because of the exponential dependance in temperature of the Arrhenius term. Thus the right-hand side of (1.2) is very small but not rigorously zero. This is what is refered as the cold-boundary difficulty (see [JN], [W], and [ZBLM]). Commonly, we introduce an ignition temperature $\theta > 0$ such that $B_i(T) = b_i\phi(T)\chi_{[\theta,+\infty)}$ for some $b_i > 0$. Under this hypothesis, one may expect system (1.2)–(1.3) to admit nontrivial solutions. A limit case is when $\theta = 0$ and ϕ is a smooth function such that $\phi(0) = 0$ and $\phi(T) > 0$ for $T > 0$. This hypothesis is used in some biological models and is known to yield to different qualitative results: the set of possible speed is no longer discrete (see [KPP]).

In (1.3), (T^+, Y_1^+) is the only pair (T, Y_1) with $T > \theta$ satisfying

$$\begin{cases} T = Y_1 - Y_1^-, \\ -Y_1 f_1(T) + (1 - Y_1)\, f_2(T) = 0. \end{cases} \tag{1.5}$$

We will prove the existence of traveling waves for the problem (1.2)–(1.3) in the cases $d_1 = 1$ (§3) and $d_1 \neq 1$ (§4). If $d_1 = 1$, the problem is reduced to a form to which the result of [BNS] in the scalar case applies.

The proof of existence given here for $d_1 \neq 1$ involves degree theory. The a priori estimates needed for the degree argument are obtained by mean of a backward-shooting method.

In §5, we discuss the limit $\theta \to 0$.

Finally, in §6, we extend our results to the more general chemical reaction (1.1)′. There, we have to solve a system of $n + 1$ reaction-diffusion equations

$$\begin{cases} -T'' + cT' = -\omega_1(T, Y) + \omega_2(T, Y), \\ -d_i Y_i'' + cY_i' = (\mu_i - \nu_i)\omega_1(T, Y) + (\nu_i - \mu_i)\omega_2(T, Y) \quad \text{for } i = 1, \dots, n, \end{cases} \tag{1.6}$$

where d_i is the diffusion coefficient of species A_i and ω_1 and ω_2 are the rates of the two semireactions. Our main theorem (Theorem 6.7 in §6) gives the existence of a flame for general kinetic rate ω_1 and ω_2 satisfying the monotonicity condition (6.7) in §6. This condition is satisfied in particular by the kinetic rates given by the law of mass action and the Arrhenius law. However, the result is not restricted to these laws.

2. The model for a reversible reaction $A \rightleftharpoons B$.

2.1. The model. When the hydrodynamic effects are neglected, the propagation of a deflagration flame is described by a thermodiffusive model. We are interested in the existence of traveling waves. These are flames propagating at a constant speed c. In a frame of reference moving at the same speed as the flame, the problem is written as a system of three reaction-diffusion equations of unknown (T, Y_1, Y_2, c),

$$\left\{\begin{aligned} -T'' + cT' &= Q_1 Y_1 f_1(T) + Q_2 Y_2 f_2(T), \\ -d_1 Y_1'' + cY_1' &= -Y_1 f_1(T) + Y_2 f_2(T), \\ -d_2 Y_2'' + cY_2' &= Y_1 f_1(T) - Y_2 f_2(T), \end{aligned}\right. \tag{2.1}$$

with boundary conditions in the fresh gas at $-\infty$,

$$T(-\infty) = 0, \quad Y_1(-\infty) = Y_1^-, \quad \text{and} \quad Y_2(-\infty) = Y_2^-, \tag{2.2}$$

where Y_1 (resp. Y_2) is the concentration of species A (resp. B). In (2.1), Q_1 and $Y_1 f_1(T)$ (resp. Q_2 and $Y_2 f_2(T)$) are the heat release and the rate of the semireaction $A \to B$ (resp. $B \to A$). As specified in the introduction, we assume that the rates are ruled by the mass-action law and the Arrhenius law:

$$f_i = B_i(T) \exp\left(-\frac{E_i}{R(\alpha T + t_0)}\right). \tag{2.3}$$

To resolve the cold-boundary problem, we assume that

$$B_i(T) = b_i\, \phi(T)\, \chi_{[\theta,+\infty)}, \tag{2.4}$$

where $b_i > 0$, $\theta > 0$ is the ignition temperature, and ϕ is some C^1 function with $\phi(0) = 0$ and $\phi(T) > 0$ on $(0, +\infty)$.

2.2. The diffusion coefficients. If we assume that A and B have the same diffusion coefficient, $d_1 = d_2$. Since Y_1 and Y_2 are bounded, an integration of the sum of the equations in Y_1 and Y_2 of system (2.1) gives the relation

$$Y_1 + Y_2 = Y_1^- + Y_2^-. \tag{2.5}$$

Assume $Y_1^- + Y_2^- = 1$; system (2.1) is then reduced to two reaction-diffusion equations as in (1.2):

$$\left\{\begin{aligned} -T'' + cT' &= -Y_1 f_1(T) + (1 - Y_1)\, f_2(T), \\ -d_1 Y_1'' + cY_1' &= -Y_1 f_1(T) + (1 - Y_1)\, f_2(T). \end{aligned}\right. \tag{2.6}$$

Remark 2.1. The coefficient d_1 is, in fact, the inverse of the Lewis number

$$Le = \frac{\lambda}{\rho C_p D}, \tag{2.7}$$

where λ is the thermal conductivity of the mixture, ρ is the density, C_p is the specific heat at constant pressure, and D is the diffusion coefficient of species A and B.

2.3. The heat release. We remark that by the first principle of thermodynamics, the heat release of the two semireactions are related:

$$Q_1 + Q_2 = 0.$$

The situation of an athermic reaction ($Q_1 = Q_2 = 0$) is not relevant in this model. If $Q_1 = Q_2 = 0$, the temperature will be a constant and system (1.2) reduces to $-d_1 Y_1'' + cY_1' = -Y_1 a_1 + (1 - Y_1)a_2$, where a_1 and a_2 are positive constants. This equation has no bounded solution except the constant $Y_1 \equiv a_2/(a_1 + a_2)$.

Without loss of generality, we may assume that Q_2 is positive and for a renormalized temperature, we may choose $Q_2 = 1$ and $Q_1 = -1$.

2.4. The boundary condition and the curve of chemical equilibrium. The boundary condition (2.2) prescribes only the concentrations and the temperature of the fresh gas. The composition and the temperature of the burnt gas are the unknowns of the problem. An integration of the difference of the two equations in (2.6) between $-\infty$ and $+\infty$ gives (if the limits exists at $+\infty$)

$$c(T(+\infty) - T(-\infty)) - c(Y_1(+\infty) - Y_1(-\infty)) = 0. \tag{2.8}$$

Since $T(-\infty) = 0$ and $Y_1(-\infty) = Y_1^-$, we get the necessary condition $T(+\infty) = Y_1(+\infty) - Y_1^-$. Moreover, if the limits T^+ and Y_1^+ of T and Y_1 exist at $+\infty$ for a solution of (1.2), then T^+ and Y^+ satisfy $-Y_1^+ f_1(T^+) + (1 - Y_1^+) f_2(T^+) = 0$. Therefore, Y_1^+ and T^+ are characterized by the set of equations

$$\begin{cases} T^+ = Y_1^+ - Y_1^-, \\ -Y_1^+ f_1(T^+) + (1 - Y_1^+) f_2(T^+) = 0. \end{cases} \tag{2.9}$$

We will now study the curve of chemical equilibrium defined by the second equation in (2.9). The approximation of activated states gives the relation between the activation energies and the heat release: $E_1 = E_2 + Q_2 = E_2 + 1$. Then, on the curve of chemical equilibrium, we define Y_1 as a function $Y_c(T)$ of T on $[\theta, +\infty)$:

$$Y_c(T) = \frac{1}{1 + \frac{b_1}{b_2} \exp\left(-\frac{1}{R(\alpha T + t_0)}\right)}. \tag{2.10}$$

By a straightforward calculation, $Y_c'(T)$ is negative and the equation $Y_c(T) = T + Y_1^-$ defines a unique T_0 and gives the existence and uniqueness of Y_1^+, $T^+ > 0$ satisfying (2.9) provided that $\theta < T_0$. In the following, the inequality $\theta < T_0$ will be a necessary and sufficient condition of existence of a traveling flame.

3. Lewis number equal to 1. When the Lewis number is equal to 1 (or equivalently $d_1 = 1$), system (1.2) reduces to a scalar equation. Indeed, the boundary conditions in (1.3) and the difference of the two equations of (1.2) give the relation $T = Y_1 - Y_1^-$. We are reduced to a scalar equation:

$$\begin{cases} -T'' + cT' = -(T + Y_1^-)f_1(T) + (1 - T - Y_1^-) f_2(T), \\ T(-\infty) = 0, \; T(0) = \theta. \end{cases} \tag{3.1}$$

The condition $T(0) = \theta$ removes the translational invariance. We may denote $k(T) = -(T+Y_1^-)f_1(T)+(1-T-Y_1^-)$. Then (3.1) is the scalar equation studied by Berestycki, Nicolaenko, and Scheurer, but here $k(T)$ is not positive everywhere:

$$\begin{cases} k(T) = 0 & \text{on} \quad [0, \theta], \\ k(T) > 0 & \text{on} \quad (\theta, T_0), \\ k(T) < 0 & \text{on} \quad (T_0, 1). \end{cases} \tag{3.2}$$

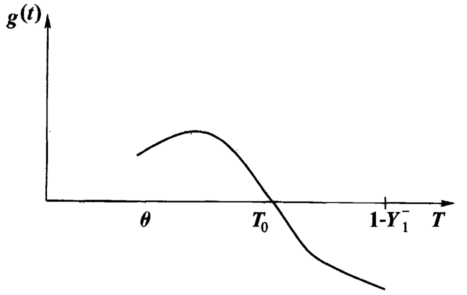

FIG. 1

The real T_0 is the unique solution of $Y_c(T) = T + Y_1^-$ (see identity (2.10)). (See Figure 1.)

Since $Y_2 = 1 - Y_1 = 1 - T - Y_1^-$ is the concentration of species B, it makes no physical sense to define g for $T > 1 - Y_1^-$. We have the following result.

THEOREM 3.1. *Under assumptions* (2.3) *and* (2.4), *if* $T_0 > \theta$, *then there exists a unique solution* $T : \mathbb{R} \to [0,1]$ *and* $c > 0$ *of problem* (3.1). *Moreover,* T *is of class* C^1, *it is of class* C^2 *on* $\mathbb{R} - \{0\}$, *and* $T(+\infty) = T_0$. *The condition* $T_0 > \theta$ *is necessary for the existence of a solution of* (3.1).

Proof. We will reduce the problem to the scalar case of [BNS]. For this purpose, let us prove the following lemma.

LEMMA 3.2. *For any bounded solution of* (3.1), *we have* $T(x) \leq T_0$ *on* $\mathbb{R}$.

COROLLARY 3.3. *If* $T_0 \leq \theta$, *problem* (3.1) *has no bounded solutions.*

Proof. For $T \geq T_0$, the inequality $-T'' + cT' < 0$ and the maximum principle imply that T cannot reach a local maximum at a point where $T > T_0$. Then if a solution (T, c) of (3.1) is such that T is larger than T_0 at some point x_0 in $\mathbb{R}$, T is increasing on $(x_0, +\infty)$. We have assumed that T was bounded, and we just saw that it was increasing on $(x_0, +\infty)$; therefore, T has a limit at $+\infty$: $T^+ > T_0$. Then, however, T^+ satisfies $k(T^+) = 0$, which implies $T^+ = T_0$—a contradiction. This completes the proof of Lemma 3.2.

A similar contradiction argument on a solution of (3.1) less than T_0 on $\mathbb{R}$ gives that for any bounded solution of (3.1), T has a limit at $+\infty$ and $T(+\infty) = T_0$.

To complete the proof of Theorem 3.1, we remark that since g is positive on (θ, T_0) and vanishes for $T = T_0$ and $T \in [0, \theta]$, the argument of Berestycki, Nicolaenko, and Scheurer gives the existence and uniqueness of a solution (T, c) of (3.1) with T increasing and $T(+\infty) = T_0$.

4. The reaction $A \rightleftharpoons B$ for Lewis number $\neq 1$.

4.1. Setting of the problem.

When the Lewis number $\neq 1$ (or equivalently $d_1 \neq 1$), the equations with unknown (T, Y, c) are

$$\left\{ \begin{array}{l} -T'' + cT' = -Y_1 f_1(T) + (1 - Y_1) f_2(T), \\ -d_1 Y_1'' + cY_1' = -Y_1 f_1(T) + (1 - Y_1) f_2(T), \\ T(-\infty) = 0, \ Y_1(-\infty) = Y_1^-. \end{array} \right. \tag{4.1}$$

We assume that the rate functions f_1 and f_2 satisfy assumptions (2.3) and (2.4).

To prove the existence of some solution (T, Y, c) of problem (4.1), we follow the same proof sketch as in [BNS]. On a truncated domain $[-a, +a]$, we prove the existence of solutions of the differential equations in (4.1) with adapted boundary condition (zero flux at $-a$). The existence is obtained by a degree argument for a fixed-point problem. The difficulty is to find some a priori bounds for T, Y_1, T', Y_1', and c. Then by passing to the limit $a = +\infty$, we prove the existence of a solution of (4.1).

4.2. Truncated problem on $\overline{I_a} = [-a, +a]$. Let T^+ and Y^+ be the temperature and concentration of the burnt gas as defined in (2.9). (We implicitly assume that $T_0 > \theta$.) We study the problem on $[-a, +a]$:

$$(4.2)\qquad \begin{cases} -T'' + cT' = -Y_1 f_1(T) + (1 - Y_1)\, f_2(T), \\ -d_1 Y_1'' + cY_1' = -Y_1 f_1(T) + (1 - Y_1)\, f_2(T), \\ -T'(-a) + cT(-a) = 0, \quad T(+a) = T^+, \quad T(0) = \theta, \\ -d_1 Y_1'(-a) + cY_1(-a) = cY_1^-, \quad Y_1(+a) = Y^+. \end{cases}$$

The condition $T(0) = \theta$ removes the translational invariance of the problem.

The proof of existence of a solution (T, Y_1, c) for problem (4.2) will involve degree theory. Let $X = C^1(\overline{I_a}) \times C^1(\overline{I_a}) \times I\!R$; X is a Banach space equipped with the norm

$$\|T, Y_1, c\|_X = \max\left(\|T\|_{C^1(\overline{I_a})}, \|Y_1\|_{C^1(\overline{I_a})}, |c|\right).$$

For $0 \le \tau \le 1$, we consider the mapping that sends (t, y, c) of X onto the unique solution (T, Y) of the linear system

$$(4.3)\qquad \begin{cases} -T'' + cT' = -\tau y f_1(t) + \tau(1 - y)\, f_2(t), \\ -d_1 Y'' + cY' = -\tau y f_1(t) + \tau(1 - y)\, f_2(t), \\ -T'(-a) + cT(-a) = 0, \quad T(+a) = T^+, \\ -d_1 Y'(-a) + cY(-a) = cY_1^-, \quad Y(+a) = Y^+ \end{cases}$$

and define $K_\tau : X \to X$, $(t, y, c) \mapsto (T, Y, c - T(0) + \theta)$. Then (t, y, c) is a solution of (4.2) if and only if (t, y, c) is a fixed point of K_1.

Remark 4.1. For the definition of f_1 and f_2, we take a smooth approximation χ_ϵ of $\chi_{[\theta,+\infty)}$ to ensure the existence and uniqueness of the solution of (4.3):

$$(4.4)\qquad \begin{cases} \chi_\epsilon = 0 \quad \text{on } [0, \theta], \quad \chi_\epsilon = 1 \quad \text{on } [\theta + \epsilon, +\infty), \\ f_i(T) = b_i \chi_\epsilon(T) \exp\left(-\dfrac{E_i}{R(\alpha T + t_0)}\right), \quad i = 1, 2. \end{cases}$$

To prove the existence of a solution of (4.2), we will compute the degree of $F_\tau = I - K_\tau$ at 0. For this purpose, let us consider an open subset Ω of X:

$$(4.5)\qquad \Omega = \left\{(t, y, c) \in X, \ \|t\|_{C^1(\overline{I_0})} < M, \ \|y\|_{C^1(\overline{I_0})} < M, \ \underline{c} < c < \overline{c}\right\}.$$

If for every τ, $F_\tau(\partial\Omega) \not\ni 0$, then $\deg(F_1, \Omega, 0) = \deg(F_0, \Omega, 0)$ by the homotopy property of the degree.

Step 1: *Construction of* Ω *such that* $F_\tau(\partial\Omega) \not\ni 0$. The main result here is as follows.

PROPOSITION 4.2. *There exist positive constants* M, $\underline{c}$, *and* $\overline{c}$ *such that* $F_\tau(\partial\Omega) \not\ni 0$ *for every* τ *in* $[0, 1]$.

The existence of M is a consequence of the following proposition.

PROPOSITION 4.3. *If* (T, Y, c) *is such that* $F_\tau(T, Y, c) = 0$, *then* Y *and* T *are strictly increasing:* $Y' > 0$ *and* $T' > 0$ *on* $[-a, a]$.

The proof will involve the following lemmas.

LEMMA 4.4. *Let* (T, Y, c) *satisfy* $F_\tau(T, Y, c) = 0$. *If* $T(x) = \theta$, *then* $x = 0$.

Proof. If the lemma is not true, there is at least one point x_0 where $T(x_0) = \theta$ and $T'(x_0) \leq 0$. Then, however, by the uniqueness of the solution of differential equations, we should have

$$\begin{cases} T(x) = \theta + \dfrac{T'(x_0)}{c}\left(e^{c(x-x_0)} - 1\right), \\ \text{and } Y(x) = Y(x_0) + \dfrac{Y'(x_0)}{c}\left(e^{c(x-x_0)} - 1\right) \quad \text{for } x \geq x_0, \end{cases} \tag{4.6}$$

which leads to a contradiction with the boundary condition at $+a$.

In conclusion, for $x > 0$, we must have $T > \theta$.

COROLLARY 4.5. *On* $[-a, 0]$, T *and* Y *are explicitly given by*

$$\begin{cases} T(x) = \theta\, e^{cx}, \\ Y(x) = Y_1^- + b\, e^{cx}; \end{cases} \tag{4.7}$$

moreover, $Y(0) > 0$.

Indeed, if $Y(0) \leq 0$, then $Y'(0) \leq 0$. We remark that $-Y f_1(T) + (1-Y) f_2(T) \leq 0$ for $Y \leq 0$. Therefore, the maximum principle implies that Y remains nonpositive on $[-a, a]$, which contradicts the boundary conditions at $+a$.

For simplicity of notation, we introduce the function

$$g(T, Y) = -Y f_1(T) + (1 - Y) f_2(T)$$

and the sets

$$\begin{cases} U^+ = \{(T,Y) \in I\!R^2,\ T > \theta,\ g(T,Y) \geq 0\}, \\ U^- = \{(T,Y) \in I\!R^2,\ T > \theta,\ g(T,Y) \leq 0\}, \\ \Gamma_e = U^+ \cap U^-. \end{cases} \tag{4.8}$$

The set Γ_e is the equilibrium curve for $T > \theta$ of the chemical reaction $A \rightleftharpoons B$. (See Figure 2.)

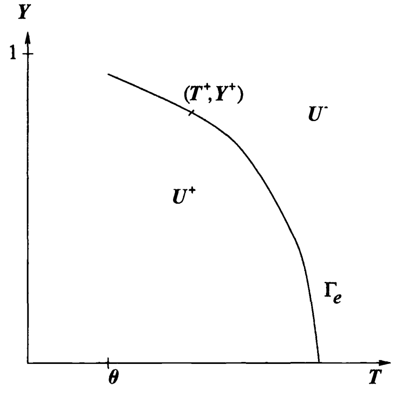

FIG. 2

LEMMA 4.6. *For* T, Y, *and* c *as in Proposition* 4.3, *we have*

$$T'(+a) > 0 \quad \text{and} \quad Y'(+a) > 0.$$

Proof. By integration of (4.3), we get $T'(+a) = Y'(+a)$. The discussion is then as follows:

(i) If $T'(+a) = Y'(+a) = 0$, then $T(x) = T^+$ and $Y(x) = Y^+$ is a solution of the two differential equations in (4.3). This is actually the only solution that satisfies $T(+a) = T^+$, $Y(+a) = Y^+$, and $T'(+a) = Y'(+a) = 0$. This leads to a contradiction with the boundary conditions at $-a$.

(ii) If $T'(+a) < 0$ and $Y'(+a) < 0$, the boundary conditions at $-a$ imply that T' and Y' cannot remain negative on $[-a, +a]$. Let x_0 be the largest x in $[-a, +a]$ where either T' or Y' is nonnegative (we have $x_0 < a$). Take, for instance, $T'(x_0) \geq 0$. Since T is C^1, we get $T'(x_0) = 0$. Now notice that if $(p, q) \in U^-$, then

$$\{(p', q') \in I\!R^2, p < p', q < q'\} \subset \overset{o}{U}{}^-,$$

where $\overset{o}{U}{}^-$ denotes the interior of U^-. By the definition of x_0, we have $T(x_0) > T(+a)$ and $Y(x_0) > Y(+a)$; therefore, $(T(x_0), Y(x_0)) \in \overset{o}{U}{}^-$, which leads to $g(T(x_0), Y(x_0)) < 0$. Then we remark that $-T''(x_0) + cT'(x_0) = g(T(x_0), Y(x_0)) < 0$. Since $T'(x_0) = 0$, we get $T''(x_0) > 0$ and consequently $T'(x) > 0$ on an interval $(x_0, x_0 + \epsilon)$ for some $\epsilon > 0$, which contradicts the maximality of x_0.

A similar contradiction is achieved if we assume that $Y'(x_0) \geq 0$. This completes the proof of Lemma 4.6.

We are now ready to prove Proposition 4.3 by contradiction. Indeed, if Proposition 4.3 is not true, there is a maximum x_0 where either $T'(x_0) \leq 0$ or $Y'(x_0) \leq 0$. Corollary 4.5 implies that $x_0 > 0$ and $T(x_0) > \theta$. Then the same argument as in Lemma 4.6 with the set U^+ in place of U^- gives a contradiction.

The proof of Proposition 4.3 is now complete.

Let us now go back to Proposition 4.2. Since T and Y are increasing and $Y_c(T)$ is decreasing, (T, Y) remains in U^+ on $[-a, a]$ and, by integration of (4.3), we get

$$-T' + cT \geq 0 \quad \text{and} \quad -d_1 Y' + cY \geq 0. \tag{4.9}$$

We have thus completed the proof of the following proposition.

PROPOSITION 4.7. *If* $F_\tau(T, Y, c) = 0$, *then* $0 < T \leq T^+$, $0 < Y \leq Y^+$, *and* $0 < T' \leq cT^+$, $0 < Y' \leq \frac{cY^+}{d_1}$.

The bound M in the definition (4.5) of Ω will be found as soon as c is bounded from above.

We get an upper bound for c independent of τ and $a > a_0$. As in [BNS], we have the following result.

PROPOSITION 4.8. *Let* $M = \sup_{\substack{\theta \leq t \leq T^+ \\ 0 \leq y \leq Y^+}} -yf_1(t) + (1-y)f_2(t)$ *and let* a_0 *be fixed. For every* $a \geq a_0$, *if* $F_\tau(T, Y, c) = 0$, *then* c *satisfies*

$$c \leq \max\left(-\frac{\log\theta}{a_0},\ \max\left(2M, \frac{\sqrt{2M}}{\theta}\right)\right). \tag{4.10}$$

Let us now find a lower bound for c that is independent of τ. The inequalities in (4.9) and the fact that $T(0) = \theta$ and $T'(0) = c\theta$ lead easily to $T(x) \leq \theta\, e^{cx}$ on $[0, +a]$ by Gronwall's lemma. As $T(+a) = T^+$, this gives

$$T^+ \leq \theta\, e^{ca} \tag{4.11}$$

and the following proposition.

PROPOSITION 4.9. *If* $F_\tau(T, Y, c) = 0$, *then* $c \geq \frac{1}{a}\log\frac{T^+}{\theta}$.

This lower bound of c is independent of τ but dependent on a. For the passage to the limit $a = +\infty$, we will need a lower bound on c independent of a, which will be developed in §4.3.

Propositions 4.7, 4.8, and 4.9 give the bounds M, $\underline{c}$, and $\overline{c}$ of Proposition 4.1. This completes the construction of the open-bounded set Ω with $F_\tau(\partial\Omega) \not\ni 0$ for $\tau \in [0,1]$. Moreover, $M = \max\left(Y^+, \overline{c}Y^+, \overline{c}\,\frac{Y^+}{d_1}\right)$ since $T^+ = Y^+ - Y_1^-$.

Step 2: *Justification of the degree.* As in [BNS], it is easy to verify that

$$\deg(F_0, \Omega, 0) = -1. \tag{4.12}$$

Indeed, for $\tau = 0$, we explicitly compute $K_0(t,y,c) = (T, Y, c - T(0) + \theta)$. We obtain $T(x) = T^+\ e^{c(x-a)}$, $Y(x) = T^+ e^{\frac{c}{d_1}(x-a)} + Y_1^-$, and $c - T(0) + \theta = c - T^+e^{-ca} + \theta$. Then $F_0(t,y,c) = 0$ if and only if $c = \frac{1}{a}\log\frac{T+}{\theta}$, $t(x) = T^+\ e^{c(x-a)}$, and $y(x) = T^+\ e^{\frac{c}{d_1}(x-a)} + Y_1^-$. The mapping K_0 is homotopic to $\Phi : X \to X$, $(t,y,c) \mapsto (T^+\ e^{c(x-a)}, T^+\ e^{\frac{c}{d_1}(x-a)} + Y_1^-, c - T^+e^{-ca} + \theta)$. The multiplicative property of the degree gives $\deg(Id - \Phi) = -1$ (notice that $c \mapsto T^+e^{-ca}$ is decreasing).

In conclusion, we have proved the following theorem.

THEOREM 4.10. *Under assumption* (4.4), *problem* (4.2) *on* $[-a, a]$ *has at least one solution* (T, Y, c) *in* X. *Moreover, there exist* $\underline{c}$, $\overline{c}$ $(0 < \underline{c} < \overline{c})$, *and* $M(\overline{c})$ *such that* $\|T\|_{\mathcal{C}^1(\overline{I_a})} < M(\overline{c})$ *and* $\|Y\|_{\mathcal{C}^1(\overline{I_a})} < M(\overline{c})$.

Let $\epsilon \to 0$ in (4.4). The existence theorem and the bounds above remain true for $f_i(T) = b_i\chi_{[\theta,+\infty)} \exp\left(-\frac{E_i}{R(\alpha T + t_0)}\right)$ and $f_i(T) = b_i\Phi(x)\,\chi_{[\theta,+\infty)} \exp\left(-\frac{E_i}{R(\alpha T + t_0)}\right)$.

4.3. The passage to the limit $a = +\infty$**.** For the passage to the limit, we need estimates independent of a. Proposition 4.8 gives an upper bound $\overline{c}$ of c that is independent of $a > a_0$. Let us now find a lower bound of c that is independent of a.

Step 1: *Lower bound of c independent of a.* An integration of the equation in T of system (4.2) gives

$$-T'(+a) + cT(+a) = \int_{-a}^{a} g(T,Y) = \int_{0}^{a} g(T,Y). \tag{4.13}$$

As $0 < T' \le \frac{T^+}{c}$, identity (4.13) gives

$$cT^+ > \int_0^a g(T,Y)\,dx.$$

We estimate the integral

$$\int_0^a g(T,Y)\,dx = \int_\theta^{T^+} \frac{g(t, Y(T^{-1}(t)))}{T'(T^{-1}(t))}\,dt$$
$$\ge \frac{1}{cT^+}\int_\theta^{T^+} g(t, Y(T^{-1}(t)))\,dt.$$

The two inequalities above give

$$(cT^+)^2 > \int_0^a g(t, Y(T^{-1}(t)))\,dt. \tag{4.14}$$

Since $g(t, Y(T^{-1}(t)\,)) > 0$, we only need to obtain a lower bound of this function on a finite interval of t. Let us remark that for $\epsilon < \frac{T^+ - \theta}{2}$, we have $g(Y,T) > 0$ on

$[\theta+\epsilon, T^+-\epsilon]\times[0\le Y\le Y^+]\subset \overset{o}{U}^-$. Then, by compactness, there exists $\delta_\epsilon>0$ such that

$$g(T,Y)>\delta_\epsilon \quad \text{on} \quad [\theta+\epsilon, T^+-\epsilon]\times[0\le Y\le Y^+].$$

For a solution (T,Y,c) of (4.2), we know that $0\le Y\le Y^+$. Then for $\epsilon_0=(T^+-\theta)/4$, we have

$$(cT^+)^2>\epsilon_0\delta_0 \quad \text{and} \quad c>c_0=\frac{\sqrt{\epsilon_0\delta_{\epsilon_0}}}{T^+}. \tag{4.15}$$

The real $c_0=\sqrt{\epsilon_0\delta_{\epsilon_0}}/T^+>0$ is a lower bound of c independent of a.

Step 2: *Passage to the limit* $a=+\infty$. Using the a priori estimate of §4.1 and the lower bound c_0 of c obtained above, we will prove the existence of a solution of problem (4.1).

THEOREM 4.11. *Assume that $\theta<T_0$. Assume that one of the conditions* (4.4) *or* (2.4) *on f_1 and f_2 is satisfied. Then there exists an increasing sequence $\{a_n\}_{n\in\mathbb{N}}$ with* $\lim a_n=+\infty$ *such that $(T_{a_n},Y_{a_n},c_{a_n})$ is a solution of* (4.2) *on $(-a_n,+a_n)$ and converges in $C^1_{\text{loc}}(\mathbb{R})\times C^1_{\text{loc}}(\mathbb{R})\times\mathbb{R}$ to a solution (T,Y,c) of* (4.1). *Moreover, (T,Y,c) satisfies*

$$\begin{gathered}T(+\infty)=T^+, \qquad Y(+\infty)=Y^+,\\ 0\le T\le T^+, \qquad 0\le Y\le Y^+,\\ 0\le T'\le cT^+, \qquad 0\le Y'\le\frac{cY^+}{d_1},\\ Y,T\in W^{2,\infty}(\mathbb{R}),\\ 0<c_0\le c\le\bar{c}<+\infty.\end{gathered}\tag{4.16}$$

The condition $T_0>\theta$ is necessary for the existence of a nontrivial bounded solution of (4.1).

Proof. The arguments are the same as in [BNS]. We use the bounds of T, Y, c, T', Y', and g to get a bound for T'' and Y'' and to prove the local convergence to a solution of the differential system in (4.1). The boundary conditions at $-\infty$ are obviously satisfied. For the limit at $+\infty$, we notice that T and Y are increasing and bounded. Their limits exist and we have $Y'(+\infty)=Y''(+\infty)=T'(+\infty)=T''(+\infty)=0$ and consequently $g(T(+\infty),Y(+\infty))=0$ with $T(+\infty)>\theta$. By integration of (4.1), $T(+\infty)=Y(+\infty)-Y_1^-$ and thus $T(+\infty)=T^+$ and $Y(+\infty)=Y^+$. The inequalities in (4.16) are straightforward.

Finally, we prove the following lemma.

LEMMA 4.12. *If $T_0\le\theta$ then* (4.1) *has no bounded nontrivial solutions.*

Proof. By contradiction, assume that $T_0\le\theta$ and let (T,Y_1,c) be a nontrivial bounded solution of (4.1). In other words, we assume that T and Y_1 are not constant. Then $c>0$ and there is a point x_0 where $T(x_0)=\theta$. We may assume that $x_0=0$ and that $T<\theta$ on $(-\infty,0)$. Therefore, on $(-\infty,0)$ we explicitly have $T=\theta\ e^{cx}$.

(i) If T is increasing on $\mathbb{R}$, then it has a limit $T^+>\theta$ at $+\infty$ since we assumed that T is bounded. Consequently, $-T'+cT$, which is also increasing, converges to cT^+ at $+\infty$. However, we know that $-T'+cT=-d_1Y_1'+c(Y_1-Y_1^-)$. Thus $-d_1Y_1'+c(Y_1-Y_1^-)$ converges to cT^+ at $+\infty$. This implies that $Y_1\to Y^+=T^++Y_1^-$ as $x\to+\infty$. Then $g(T^+,Y^+)=0$, and this gives $T^+=T_0$—a contradiction since $T_0\le\theta<T^+$

(ii) If T is not increasing on $\mathbb{R}$, it has a local maximum x_0, $T(x_0)>\theta$. At x_0, we have $-T''(x_0)+cT'(x_0)\ge0$, that is, $(T(x_0),Y_1(x_0))\in U^+$ (or, equivalently, $Y_1(x_0)\le Y_c(T(x_0))$). Since $T_0\le\theta$ and $Y_c(T)$ is decreasing, we have $T(x_0)>Y_c(T(x_0))-Y_1^-$ and we deduce that $d_1Y_1'(x_0)=c(Y_1(x_0)-Y_1^--T(x_0))<0$. Therefore, in a right neighborhood $(x_0, x_0+\epsilon)$ of x_0, we have $(T(x), Y_1(x)) \in U^+$. However, we know that in U^+, $-T''+cT' \geq 0$ and $-d_1 Y_1'' + cY_1' \geq 0$. Moreover, we know that if $(t,y) \in U^+$, then for all T and Y such that $T \leq t$ and $Y \leq y$, $g(T,Y) \geq 0$. The same contradiction argument as in Lemma 4.6 gives that if at a point x_1 we have $T'(x_1) < 0$, $Y_1'(x_1) < 0$ and $(T(x_1), Y_1(x_1)) \in U^+$, then $T'(x) < 0$, $Y_1'(x) < 0$, and $g(T(x), Y_1(x)) \geq 0$ for all $x \geq x_1$. Moreover, we have $T'' \leq cT' < 0$ and then $T \to -\infty$ as $x \to +\infty$, which contradicts the assumption: T and Y_1 are bounded. This completes the proof of the lemma and of Theorem 4.11.

5. The limit $\theta \to 0$. In §§3 and 4, we proved the existence of traveling waves for the problem with ignition temperature. Here we will study the limit $\theta \to 0$. This section uses the ideas of Marion [M], who studied the case of a direct reaction $A \to B$.

We assume here that f_1 and f_2 are given by $f_i(T) = b_i\,\phi(T)\exp\big(-\frac{E_i}{R(\alpha T+t_0)}\big)$, where $\phi(T)$ is chosen such that $\phi(0) = 0$, $\phi(T) > 0$ on $(0,+\infty)$ and ϕ is locally Lipschitz.

We consider the rate functions f_1^θ and f_2^θ defined as $f_i^\theta(T) = \chi_{[\theta,+\infty)}(T) f_1(T)$.

We will first prove that for $\theta \to 0$, translates of solutions of (4.1) for the rate functions f_i^θ converge to a solution (T, Y_1, c) of

$$\begin{cases} -T''+cT' = -Y_1 f_1(T) + (1-Y_1)\,f_2(T), \\ -d_1 Y_1'' + cY_1^1 = -Y_1 f_1(T) + (1-Y_1)\,f_2(T), \\ T(-\infty) = 0, \quad T(+\infty) = T^+, \\ Y_1(-\infty) = Y_1^-, \quad Y_1(+\infty) = Y^+. \end{cases} \tag{5.1}$$

In §4, we found a lower bound c_0 of c that is independent of θ for $\theta < \theta_0$ for some fixed $\theta_0 < T^+$. However, the upper bound of c and thus the bounds for Y' and T' found in §4 are not independent of θ (see (4.10)).

Let $(T_\theta, Y_\theta, c_\theta)$ be a solution of (4.1); since T_θ is increasing, we may define $h_\theta(s) = T'_\theta(T_\theta^{-1}(s))$ in the same way as in [M]. We have

$$\begin{aligned} h_\theta(T^+) &= h_\theta(0) = 0, \\ h'_\theta(s) &= c_\theta - \frac{g^\theta(s, Y_\theta(T_\theta^{-1}(s))}{h_\theta(s)}. \end{aligned} \tag{5.2}$$

For $x = 0$, notice that $T = \theta$ and $T' = c\theta$—that is to say, $h_\theta(\theta) = c_\theta\theta$. Then, since $h_\theta(T^+) = 0$, there exists $\theta_1 \in (\theta, T^+)$ such that

$$\forall s \in [\theta, \theta_1], \quad h_\theta(s) \geq \frac{c_\theta}{2}\, s \quad \text{and} \quad h_\theta(\theta_1) = \frac{c_\theta}{2}\,\theta_1. \tag{5.3}$$

Then $h'_\theta(\theta_1) \leq \frac{c_\theta}{2}$ and

$$\frac{c_\theta}{2} \geq h'_\theta(\theta_1) \geq c_\theta - \frac{g(\theta_1, Y(T_\theta^{-1}(\theta_1))}{\frac{c_\theta}{2}\,\theta_1}, \tag{5.4}$$

which gives

$$\left(\frac{c_\theta}{2}\right)^2 \leq \frac{g(\theta_1, Y(T_\theta^{-1}(\theta_1))}{\theta_1} \leq \frac{f_2(\theta_1)}{\theta_1}. \tag{5.5}$$

However, $\frac{f_2^\theta(\theta_1)}{\theta_1} = b_2 \frac{\phi(\theta_1)}{\theta_1} \exp\left(-\frac{E_2}{R(\alpha\theta_1+t_0)}\right)$ is bounded on $(0, T^+]$ since $\phi(0) = 0$ and since ϕ is locally Lipschitz. We have an upper bound of c independent of θ:

$$c_\theta \leq 2\sqrt{\sup_{s\in(0,T^+]} \frac{f_2(s)}{s}}. \tag{5.6}$$

By the same argument as in [M], it is easy to prove the following theorem.

THEOREM 5.1. *For each $\theta < \frac{T^+}{2}$, let z_θ be such that $T(z_\theta) = \frac{T^+}{2}$. There is a sequence $\{\theta_n\}_{n\in N}$, $0 < \theta_n < \frac{T^+}{2}$, $\lim \theta_n = 0$ such that $(T_{\theta_n}(x - z_{\theta_n}), Y_{\theta_n}(x - z_{\theta_n}), c_{\theta_n})$ converges to a solution (T, Y, c) of* (5.1).

Moreover, we can prove the following result easily as in [M].

THEOREM 5.2. *There exist $0 < \underline{c} < \bar{c}$ such that* (5.1) *has no solution (T, Y_1) for c in $[0, \underline{c}]$ and* (5.1) *has a solution for c in $[\bar{c}, +\infty)$. If $d_1 \leq 1$, then $\underline{c} = \bar{c}$.*

6. General case of reversible reaction.

6.1. Setting of the problem.

In §4, we made some special assumptions to reduce the problem to the study of a system of two reaction-diffusion equations. In this section, we address the general case of a reversible reaction involving n species A_i:

$$\sum_{i=1}^{n} \nu_i A_i \rightleftharpoons \sum_{i=1}^{n} \mu_i A_i. \tag{6.1}$$

The nonnegative constants ν_i and μ_i are the stoichiometric coefficients of the reaction. We may have $\nu_i > 0$ and $\mu_i > 0$ at the same time since that is the case in the branching step of chemical-reaction networks. For reasons explained in Remark 6.1 below, we will assume that $\nu_i \neq \mu_i$.

We will call the forward reaction $\sum_{i=1}^n \nu_i A_i \to \sum_{i=1}^n \mu_i A_i$ semireaction 1 and the backward reaction $\sum_{i=1}^n \mu_i A_i \to \sum_{i=1}^n \nu_i A_i$ semireaction 2. Without loss of generality, we assume that semireaction 2 is exothermic with $Q_2 = 1$ the heat released. The equations with unknown (T, Y, c) for the propagation of a planar traveling wave are

$$\begin{cases} -T'' + cT' = -\omega_1(T, Y) + \omega_2(T, Y), \\ -d_i Y_i'' + cY_i' = (\mu_i - \nu_i)\omega_1(T, Y) + (\nu_i - \mu_i)\omega_2(T, Y) \ \text{ for } i = 1, \ldots, n, \end{cases} \tag{6.2}$$

where Y denotes the vector $(Y_1, \ldots, Y_n)$. This system can be written as

$$\begin{cases} -T'' + cT' = -\omega_1(T, Y) + \omega_2(T, Y), \\ -d_i Y_i'' + cY_i' = (\nu_i - \mu_i)\big(-\omega_1(T, Y) + \omega_2(T, Y)\big) \ \text{ for } i = 1, \ldots, n. \end{cases} \tag{6.3}$$

We prescribe the concentrations of the species in the fresh gas at $-\infty$:

$$T(-\infty) = 0, \ Y_1(-\infty) = Y_1^-, \ldots, \ Y_n(-\infty) = Y_n^-. \tag{6.4}$$

In (6.3), the constants d_i are the diffusion coefficients of the chemical species A_i. Since they are not supposed to be equal to 1, we cannot reduce (6.3) to one equation as in §3. Moreover, we do not assume that the d_i's are equal to each other. This situation occurs, for example, in diluted reacting gases.

The usual expression of the rates of the semireactions, ω_1 and ω_2, is given by the mass-action and Arrhenius laws:

$$\omega_1(T,Y) = \prod_{\nu_i>0} Y_i^{\nu_i} B_1(T) \exp\left(-\frac{E_1}{R(\alpha T + t_0)}\right), \tag{6.5}$$
$$\omega_2(T,Y) = \prod_{\mu_i>0} Y_i^{\mu_i} B_2(T) \exp\left(-\frac{E_2}{R(\alpha T + t_0)}\right),$$

where E_j is the activation energy of each semireaction and $\alpha T + t_0$ is the absolute temperature of the mixture. As we explained in §2, the activation energies and the heats released, Q_1 and Q_2, are related to each other: $Q_1 + Q_2 = 0$ and $E_1 = E_2 + Q_2$. Above, we assume that semireaction 2 is exothermic ($Q_2 = 1$), and, consequently, we have $E_1 > E_2$. The cutoff function B_j is introduced to resolve the cold-boundary difficulty:

$$B_j(T) = b_j \chi_{[\theta,+\infty)}, \tag{6.6}$$

where b_j is a positive constant and $\theta > 0$ is the ignition temperature. In (6.6), the indicator function $\chi_{[\theta,+\infty)}$ can be replaced by a smooth approximation $\chi^{\epsilon}_{[\theta,+\infty)}$ as in (4.4).

In fact, the proof of existence applies to some more general functions ω_1 and ω_2. The only assumption we need is the Lipschitz continuity of ω_1 and ω_2 for $T > \theta$ and the following property:

$$\begin{cases} \text{for } T > \theta, \ \dfrac{\omega_1}{\omega_2} \text{ is increasing with respect to the } n+1 \text{ uplet} \\ (T, (\mu_1 - \nu_1)Y_1, (\nu_2 - \mu_2)Y_2, \ldots, (\nu_n - \mu_n)Y_n). \end{cases} \tag{6.7}$$

This means that when $T, (\nu_1 - \mu_1)Y_1, (\nu_2 - \mu_2)Y_2, \ldots, (\nu_n - \mu_n)Y_n$ are simultaneously increased, the value of $\frac{\omega_1}{\omega_2}(T,Y)$ is increased. Physically, this means that the rate functions $\omega_i \geq 0$ satisfy the following condition:

$$\text{for } T > \theta, \quad \begin{cases} \omega_1(T,Y) = 0 \Longleftrightarrow \exists i, & \nu_i > 0 \quad \text{and} \quad Y_i = 0, \\ \omega_2(T,Y) = 0 \Longleftrightarrow \exists i, & \mu_i > 0 \quad \text{and} \quad Y_i = 0. \end{cases} \tag{6.8}$$

This condition reads as follows: the rate of the reaction vanishes if the concentration of one of the reactants vanishes; the rate of the reaction is positive if the concentrations of all the reactants are positive.

Remark 6.1. Notice here that if for some i_0, $\mu_{i_0} = \nu_{i_0}$, then the chemical species A_{i_0} is globally neither consumed nor produced by the reversible reaction. Therefore, Y_{i_0} is a constant. Then if $Y_{i_0}^- = 0$, no reaction occurs ($\omega_1 = \omega_2 \equiv 0$). If $Y_{i_0}^- > 0$, the concentration Y_{i_0} appears as a constant in ω_1 and ω_2 and the equation in Y_{i_0} can be removed from system (6.3). Therefore, without loss of generality, we assume that $\mu_i \neq \nu_i$ for all i.

LEMMA 6.2. *The rate functions ω_1 and ω_2 defined by identities* (6.5) *and* (6.6) *satisfy properties* (6.7) *and* (6.8).

Proof. This is straightforward since $E_1 = E_2 + Q_2 = E_2 + 1$.

We are now interested in the composition of the burnt gas. Formally, the burnt gas should be in a state of chemical equilibrium. If the limits of Y_i and T at $+\infty$ exist, then an integration between $-\infty$ and $+\infty$ of linear combinations of equations in (6.3) gives the n relations

$$Y_i(+\infty) - Y_i(-\infty) = (\nu_i - \mu_i)(T(+\infty) - T(-\infty)) \quad \text{for } i = 1, \ldots, n.$$

Thus, with the boundary conditions (6.4), we get

$$Y_i(+\infty) = Y_i^- + (\nu_i - \mu_i)T(+\infty) \quad \text{for } i = 1, \dots, n. \tag{6.9}$$

Denote by Y_i^+ the right side of (6.9) and define $T^+ = T(+\infty)$. The reals Y_i^+ depend linearly on T^+. If the limit exists at $+\infty$, then the right-hand side of equation (6.3) is null, which gives a necessary condition on T^+, $Y^+ = (Y_1^+, \dots, Y_n^+)$:

$$\omega_1(T^+, Y^+) - \omega_2(T^+, Y^+) = 0. \tag{6.10}$$

Since Y^+ is a function of T^+, (6.10) gives a condition on T^+ that we can write for $T^+ > \theta$ as

$$\frac{\omega_1}{\omega_2}(T^+, Y^+(T^+)) = 1. \tag{6.11}$$

Also, we remark here that $(\nu_i - \mu_i)Y_i^+(T^+)$ is an increasing function of T^+. Therefore, Lemma 6.2 (or condition (6.7)) gives that $\frac{\omega_1}{\omega_2}(T^+, Y^+(T^+))$ is an increasing function of T^+. This gives the following proposition.

PROPOSITION 6.3. *There is a real $T^+ > \theta$ satisfying* (6.11) *if and only if*

$$\lim_{s \searrow \theta} \frac{\omega_1}{\omega_2}(s, Y^+(s)) < 1.$$

Moreover, T^+ is unique.

To prove the existence of a traveling-wave solution of (6.3) and (6.4), we will proceed as in §4.

6.2. Truncated problem on $\overline{I_a} = [-a, +a]$. We now study the problem on $[-a, +a]$.

$$\begin{cases} -T'' + cT' = -\omega_1(T, Y) + \omega_2(T, Y), \\ -d_iY_i'' + cY_i' = (\nu_i - \mu_i)\big(-\omega_1(T, Y) + \omega_2(T, Y)\big) \quad \text{for } i = 1, \dots, n \\ -T'(-a) + cT(-a) = 0, \quad T(+a) = T^+, \quad T(0) = \theta, \\ -d_iY_i'(-a) + cY_i(-a) = cY_i^-, \quad Y_i(+a) = Y_i^+ \quad \text{for } i = 1, \dots, n. \end{cases} \tag{6.12}$$

We now prove the following theorem.

THEOREM 6.4. *System* (6.2) *admits a solution (T^a, Y^a, c^a) on $[-a, +a]$, and there are positive constants $\underline{c}$, $\bar{c}$, and M independent of $a > a_0$ such that $||T^a||_{C^1(\overline{I_a})} < M$, $||Y_i^a||_{C^1(\overline{I_a})} < M$, and $\underline{c} < c < \bar{c}$.*

Proof. The proof of existence of a solution (T, Y, c) for problem (6.12) will involve degree theory as in §3. Since the proof follows the same sketch, we will detail only the specific results needed here.

6.2.1. A priori estimates and the monotonicity of T and Y_i. Some a priori estimates are needed for degree theory (see §4.1). These a priori estimates are easily derived as soon as T and Y_i are proved to be monotonic. The monotonicity of T and Y_i is obtained by the same kind of argument as in the proof of Proposition 4.3. Indeed, we first present the following lemma.

LEMMA 6.5. *For (T, Y, c), a solution of* (6.12), *we have*

$$T'(+a) > 0 \quad \textit{and} \quad (\nu_i - \mu_i)Y_i'(+a) > 0. \tag{6.13}$$

Proof. Indeed, by integration of (6.12), we get

$$Y_i'(+a) = (\nu_i - \mu_i)T'(+a). \tag{6.14}$$

Then the argument is the same as in Lemma 4.6. We introduce the sets U^+ and U^- associated with the function $g(T, Y) = -\omega_1(T, Y) + \omega_2(T, Y)$ as in (4.8). Identity (6.14) associated with Lemma 6.2 allows us to argue by contradiction on $T, Y_1, \ldots, Y_n$ exactly as we did in Lemma 4.6 with only T and Y.

With the same assumptions as in Proposition 4.3, we prove the following.

PROPOSITION 6.6. *T is increasing; Y_i is increasing if $\nu_i - \mu_i$ is positive and decreasing if $\nu_i - \mu_i$ is negative.*

With Proposition 6.6, we are able to derive the a priori estimates on T, Y, and c and get the existence of a traveling wave on a bounded domain.

6.3. Conclusion. The passage to the limit $a = +\infty$ is the same as in §4, and we can state the following theorem.

THEOREM 6.7. *Assume that $Q_2 > 0$ and that conditions* (6.7) *and* (6.8) *on ω_1 and ω_2 hold. If*

$$\lim_{s \searrow \theta} \frac{\omega_1}{\omega_2}(s, Y^+(s)) < 1, \tag{6.15}$$

then problem (6.3)–(6.4) *has at least a nontrivial solution (T, Y, c) in $\left(W^{2,\infty}(I\!R)\right)^{n+1} \times I\!R$. Moreover, T and Y_i are monotonic and satisfy*

$$\begin{cases} T(+\infty) = T^+, \\ Y_i(+\infty) = Y_i^+(T^+) = Y_i^- + (\nu_i - \mu_i)T^+. \end{cases} \tag{6.16}$$

TRAVELING-WAVE SOLUTIONS OF CONVECTION-DIFFUSION SYSTEMS IN NONCONSERVATION FORM*

LIONEL SAINSAULIEU†

Abstract. Hyperbolic systems in nonconservation form are found in several domains of mathematical physics, but the definitions of their shockwave solutions rely on the definition of the product of a Heavyside-type function with Dirac-type distribution. For systems in nonconservation form extracted from a convection-diffusion system, we prove a conjecture of Le Floch. This relies on the construction of traveling-wave solutions of a second-order system.

Key words. hyperbolic systems in nonconservation form, convection-diffusion systems, shockwaves, traveling waves, Lax entropy conditions

AMS subject classifications. 35A07, 35B45, 35J15

1. Introduction.

Many models used in fluid mechanics are written in the following form (in one-dimensional slab geometry):

$$\frac{\partial \mathbf{u}}{\partial t} + \mathbf{A}(\mathbf{u})\frac{\partial \mathbf{u}}{\partial x} - \frac{\partial}{\partial x}\left(\mathbf{D}(\mathbf{u})\frac{\partial \mathbf{u}}{\partial x}\right) = 0, \tag{1.1}$$

where $\mathbf{A}$ and $\mathbf{D}$ are two $p \times p$ C^2 matrix-valued functions defined on a subset Ω of $\mathbb{R}^p$. (See, for instance, [1].) When the matrix-valued function $\mathbf{A}$ is written in the form $\mathbf{A}(\mathbf{u}) = \mathbf{df}(\mathbf{u})$ for some flux function $\mathbf{f}$, we say that system (1.1) is in conservation form. However, it is now well established that some systems modeling two-phase fluid flows (see, for instance, [2]–[4]) or nonlinear elasticity (see [5]) are written in the form of a hyperbolic system in nonconservation form.

In order to avoid considering the small-scale effects connected with the diffusion phenomena or as the first step of a numerical method, consider the following first-order system extracted from (1.1):

$$\frac{\partial \mathbf{u}}{\partial t} + \mathbf{A}(\mathbf{u})\frac{\partial \mathbf{u}}{\partial x} = 0. \tag{1.2}$$

Usually, the matrix $\mathbf{A}(\mathbf{u})$ has real eigenvalues so that system (1.2) is hyperbolic. However, systems in nonconservation form present a number of unconventional mathematical features, and this leads to interesting new mathematical problems. Indeed, in the same manner as for hyperbolic systems in conservation form, we expect the formation of shockwaves in the solutions of (1.2), even with smooth initial data. But when $\mathbf{u} : \mathbb{R}_+ \times \mathbb{R} \to \Omega$ is a discontinuous function, the following product in nonconservation form,

$$\mathbf{A}(\mathbf{u})\frac{\partial \mathbf{u}}{\partial x}, \tag{1.3}$$

lacks meaning as a distribution and the usual theory of hyperbolic systems of conservation laws does not apply. In fact, many authors consider hyperbolic systems in

*Received by the editors March 4, 1994; accepted for publication (in revised form) May 5, 1995.

†CERMICS, École Nationale des Ponts et Chaussees, Central 2, La Courtine, 93167 Noisy-le-Grand cedex, France.

nonconservation form to be valuable models, which explains the great amount of work recently performed to give meaning to the product (1.3) when $\mathbf{u}$ is a discontinuous function.

The first author who gave meaning to (1.3) when $\mathbf{u}$ is the step function

$$\mathbf{u}(x,t) = \begin{cases} \mathbf{u}^L, & x < \sigma t, \\ \mathbf{u}^R, & x > \sigma t, \end{cases} \tag{1.4}$$

was probably Volpert (see [6]). His definition is, to some extent, the simplest one:

$$\mathbf{A}(\mathbf{u})\frac{\partial \mathbf{u}}{\partial x} = \frac{1}{2}\left(\mathbf{A}(\mathbf{u}^L) + \mathbf{A}(\mathbf{u}^R)\right)(\mathbf{u}^R - \mathbf{u}^L)\delta_{x=\sigma t}, \tag{1.5}$$

where δ denotes Dirac's delta function. The authors of [7] noticed that this definition is not satisfactory since it depends on the system of dependent variables $\mathbf{u}$. They generalized Volpert's definition by replacing the right-hand side of (1.5) with an average along some given path, namely,

$$\mathbf{A}(\mathbf{u})\frac{\partial \mathbf{u}}{\partial x} = \left(\int_0^1 \mathbf{A}(\phi(s;\mathbf{u}^L,\mathbf{u}^R))\frac{\partial \phi}{\partial s}(s;\mathbf{u}^L,\mathbf{u}^R)s\right)\delta_{x=\sigma t}, \tag{1.6}$$

where the function $\phi : [0,1] \times \Omega \times \Omega \to \Omega$ is Lipschitz continuous and satisfies

$$\phi(0;\mathbf{u}^L,\mathbf{u}^R) = \mathbf{u}^L, \quad \phi(1;\mathbf{u}^L,\mathbf{u}^R) = \mathbf{u}^R. \tag{1.7}$$

This definition is independent of the system of dependent variables, but it relies on the choice of the function ϕ. When the matrix $\mathbf{A}$ is the derivative of a flux function $\mathbf{f}$, the definition (1.6) is consistent with the theory of distributions. The right-hand side of (1.6) is independent of the choice of ϕ. On the contrary, when there is no flux function $\mathbf{f}$ such that $\mathbf{A} = \mathbf{df}$, the definition (1.6) indeed depends on ϕ. Given a family of paths ϕ, the authors give a solution of the Riemann problem

$$\frac{\partial \mathbf{u}}{\partial t} + \mathbf{A}(\mathbf{u})\frac{\partial \mathbf{u}}{\partial x} = 0, \quad \mathbf{u}(x,0) = \begin{cases} \mathbf{u}^L, & x < 0, \\ \mathbf{u}^R, & x > 0 \end{cases}$$

provided that $|\mathbf{u}^R - \mathbf{u}^L|$ is small enough.

In [8]–[9], the authors describe their own mathematical definition of the product in (1.3). This definition relies only on the matrix $\mathbf{A}$: some equations in (1.2) are considered in a strong sense and others in a weak sense (see [8] or [9] for more details).

In our opinion, the definition of a shockwave solution of a system in nonconservation form should depend on the dissipation mechanisms. Following [10], we define a shockwave solution of system (1.2) extracted from the second-order system (1.1) as the limit, when diffusion is neglected, of a traveling-wave solution of (1.1). It is important to notice that the points of view in [7] and [8] are very close to this definition. Indeed, compare the "microscopic structure" of a shockwave in the work of Colombeau with the path ϕ that connects the left and right states of a shockwave in the work of Dal Maso, Le Floch, and Murat, or a shockwave solution of (1.2) viewed as the limit, when diffusion is neglected, of a solution of (1.1). In each case, some extra information is added to the shockwave in the form of a continuous profile that connects the left and right states of the shock. When a second-order system in the form of (1.1) is a relevent model, our approach offers a simple definition of the shockwave solution of (1.2). However, a convenient choice of the function ϕ in the framework of Dal Maso, Le Floch, and Murat or a convenient treatment of system (1.2) using Colombeau's calculus gives the same shockwaves.

A continuous traveling wave $\mathbf{u}$ with speed σ that connects states $\mathbf{u}^L$ and $\mathbf{u}^R$ is a continuous bounded function in the form

$$\mathbf{u}(x,t) = \hat{\mathbf{u}}(x - \sigma t), \quad (x,t) \in \mathbb{R} \times \mathbb{R}_+, \tag{1.8}$$

with the following limits:

$$\lim_{x \to -\infty} \mathbf{u}(x,t) = \mathbf{u}^L, \qquad \lim_{x \to +\infty} \mathbf{u}(x,t) = \mathbf{u}^R. \tag{1.9}$$

The function $\mathbf{u}$ is a solution of (1.1) if $\hat{\mathbf{u}}$ is a solution of the following system of differential equations:

$$-\sigma \hat{\mathbf{u}}' + \mathbf{A}(\hat{\mathbf{u}})\hat{\mathbf{u}}' - (\mathbf{D}(\hat{\mathbf{u}})\hat{\mathbf{u}}')' = 0, \tag{1.10}$$

where $'$ denotes derivation with respect to x. Next, set

$$\hat{\mathbf{u}}_v(x) = \hat{\mathbf{u}}(x/v), \quad x \in \mathbb{R}.$$

Then the function $\hat{\mathbf{u}}_v$ is a solution of the differential system

$$-\sigma \hat{\mathbf{u}}_v' + \mathbf{A}(\hat{\mathbf{u}}_v)\hat{\mathbf{u}}_v' - v\,(\mathbf{D}(\hat{\mathbf{u}}_v)\hat{\mathbf{u}}_v') = 0 \tag{1.11$_v$}$$

and has the same limits as $\hat{\mathbf{u}}$ as ξ tends to $\pm\infty$. Furthermore, the family $(\hat{\mathbf{u}}_v')_{v>0}$ is bounded in $L^1(\mathbb{R})$ and, as ν tends to zero, tends almost everywhere to the following discontinuous function:

$$\hat{\mathbf{u}}_0(x) = \begin{cases} \mathbf{u}^R & \text{if } x > 0, \\ \mathbf{u}^L & \text{if } x < 0. \end{cases} \tag{1.12}$$

Following [10] and [11], we say that the function (1.12) is a shockwave solution of (1.2) compatible with the diffusion matrix $\mathbf{D}$. Unlike the case of hyperbolic systems of conservation laws, the function $\hat{\mathbf{u}}_0$ indeed depends on the shape of the diffusion matrix.

The mathematical justification of this definition relies on the existence of traveling-wave solutions of (1.1). A particular case is considered in [11]. A general existence result was conjectured in [10]. This paper is devoted to its rigorous proof for a general class of systems of the form of (1.1).

There are several papers dealing with traveling-wave solutions of second-order systems in conservation form. First, a general result may be found in [12]. The authors assume that the diffusion matrix is regular, but this assumption is usually not satisfied by fluid-flow models. To our knowledge, no general result concerning second-order systems with a singular diffusion matrix has yet been published. Several systems arising from fluid mechanics have been considered. In [13], the author proves the existence of traveling-wave solutions of the ZND detonation model. Setting the chemical reaction terms to zero then gives the existence of traveling-wave solutions of the system of Navier–Stokes equations. Two-dimensional viscous isentropic flow equations are considered in [14].

To study the traveling-wave solutions of a second-order system in conservation form, one integrates (1.10) (recall that, by assumption, $\mathbf{A}(\mathbf{u}) = \mathbf{df}(\mathbf{u})$). In [12] and [15], the authors write (1.10) in the form of a dynamical system. The traveling-wave solutions of (1.1) are then obtained using the powerful tools of dynamical-systems theory. Here system (1.1) is in nonconservation form and this method does not apply. In fact, we prove that a solution of (1.1) is in the form $\mathbf{u}(x) = \mathbf{u}^L + u(x)\mathbf{f}_0 + O(\epsilon^2)$, where $\mathbf{f}_0$ is a constant vector and the function u is solution of the following model equation:

$$-\frac{\epsilon}{2}u' + \left(\frac{u^2}{2}\right)' - u'' = 0, \quad u(-\infty) = 0, \quad u(+\infty) = \epsilon < 0.$$

The function u is written

$$u(x) = \frac{\epsilon}{1 + \exp\left(\epsilon\frac{x}{2}\right)}.$$

Section 2 gives our hypotheses and summarizes the results obtained in this paper. In §3, we prove the existence of traveling-wave solutions of (1.1) when the diffusion matrix $\mathbf{D}$ is the identity matrix. Using the results of §3, we deduce in §4 the existence of traveling-wave solutions of (1.1) for a wide class of diffusion matrices. Section 5 is devoted to the proof of a priori estimates of the solutions of (1.1), from which we deduce the uniqueness of the solutions constructed in §4. Finally some technical results concerning a nonlinear differential equation are given in the appendix.

2. Hypotheses and main results. We suppose that system (1.2) is strictly hyperbolic. For any $\mathbf{u} \in \Omega$, the matrix $\mathbf{A}(\mathbf{u})$ has p distinct real eigenvalues

$$\lambda_1(\mathbf{u}) < \cdots < \lambda_p(\mathbf{u}).$$

We denote by $\{\mathbf{r}_k(\mathbf{u})\}_{1\leq k\leq p}$ (resp., $\{\mathbf{l}_k(\mathbf{u})\}_{1\leq k\leq p}$) the right (resp., left) eigenvectors of the matrix $\mathbf{A}(\mathbf{u})$.

Recall that a characteristic field $\mathbf{r}_i$ is genuinely nonlinear (GNL) if

$$\forall\mathbf{u} \in \Omega, \quad \nabla\lambda_i(\mathbf{u}) \cdot \mathbf{r}_i(\mathbf{u}) \neq 0$$

and linearly degenerate (LD) if

$$\forall\mathbf{u} \in \Omega, \quad \nabla\lambda_i(\mathbf{u}) \cdot \mathbf{r}_i(\mathbf{u}) = 0.$$

(The theory of hyperbolic systems of conservation laws is examined in [15] and [16].) We suppose that each field $\mathbf{r}_k$, $1 \leq k \leq p$, is either LD or GNL. We normalize the GNL fields by

$$\forall\mathbf{u} \in \Omega, \quad \nabla\lambda_i(\mathbf{u}) \cdot \mathbf{r}_i(\mathbf{u}) = 1. \tag{2.1}$$

The vectors $\mathbf{l}_k$, $1 \leq k \leq p$, are normalized by

$$\mathbf{l}_k(\mathbf{u}) \cdot \mathbf{r}_l(\mathbf{u}) = \delta_{kl}.$$

We assume that the first r equations in (1.1) contain no diffusion terms and that only the last $q = p - r$ equations contain diffusion terms. This means that the matrix $\mathbf{D}(\mathbf{u})$ is of the form

$$\mathbf{D}(\mathbf{u}) = \begin{pmatrix} 0 & 0 \\ \mathbf{D}_1(\mathbf{u}) & \mathbf{D}_2(\mathbf{u}) \end{pmatrix}, \tag{2.2}$$

where $\mathbf{D}_1(\mathbf{u})$ is a $q \times r$ matrix and $\mathbf{D}_2(\mathbf{u})$ is a $q \times q$ matrix. Note that the diffusion matrix in a one-dimensional model of fluid flow is usually of the form of (2.2). For instance, the total-mass-conservation equation does not contain any diffusion term. Then we write the matrix $\mathbf{A}(\mathbf{u})$ in the following form:

$$\mathbf{A}(\mathbf{u}) = \begin{pmatrix} \mathbf{A}_1(\mathbf{u}) & \mathbf{A}_2(\mathbf{u}) \\ \mathbf{A}_3(\mathbf{u}) & \mathbf{A}_4(\mathbf{u}) \end{pmatrix}. \tag{2.3}$$

Here $\mathbf{A}_1(\mathbf{u})$ is a $r \times r$ matrix, $\mathbf{A}_2(\mathbf{u})$ is a $r \times q$ matrix, $\mathbf{A}_3(\mathbf{u})$ is a $q \times r$ matrix, and $\mathbf{A}_4(\mathbf{u})$ is a $q \times q$ matrix.

For $\mathbf{u}^L$ given in Ω and an index i such that $\mathbf{r}_i$ is GNL, we obtain below a half-curve of states that can be connected to $\mathbf{u}^L$ by a traveling-wave solution of (1.1). This half-curve is tangent in $\mathbf{u}^L$ to $\mathbf{r}_i(\mathbf{u}^L)$. However, we need the following two conditions to be satisfied:

$$\text{The matrix } \mathbf{A}_1(\mathbf{u}) - \sigma 1_r \text{ is regular.} \tag{2.4}$$

$$\ker \mathbf{D}(\mathbf{u}) \cap \left(\mathbf{A}(\mathbf{u}) - \sigma \mathbf{1}_p\right)^{-1} \text{range} \mathbf{D}(\mathbf{u}) = \{\mathbf{0}\}. \tag{2.5}$$

In fact, when one of these conditions is not satisfied, the only possible traveling-wave solutions of (1.1) have some discontinuous components (cf. [17]).

When $(\lambda_i(\mathbf{u}^L), \mathbf{u}^L)$ satisfies (2.4) and (2.5), we can find a positive number $\hat{\epsilon}$ such that for any $\mathbf{u} \in \Omega$ and $\sigma \in \mathbb{R}$ with

$$|\mathbf{u} - \mathbf{u}^L| \leq \hat{\epsilon}, \quad |\sigma - \lambda_i(\mathbf{u}^L)| \leq \hat{\epsilon}, \tag{2.6}$$

the matrix $\mathbf{A}_1(\mathbf{u}) - \sigma 1_r$ is regular and $\ker \mathbf{D}(\mathbf{u}) \cap \left(\mathbf{A}(\mathbf{u}) - \sigma \mathbf{1}_p\right)^{-1} \text{range} \mathbf{D}(\mathbf{u}) = \{\mathbf{0}\}$.

Next, we assume that for any GNL field $\mathbf{r}_i$,

$$\mathbf{l}_i(\mathbf{u}) \cdot \mathbf{D}(\mathbf{u}) \mathbf{r}_i(\mathbf{u}) \neq 0 \quad \forall \mathbf{u} \in \Omega. \tag{2.7}$$

This assumption may be found in [12] and is essential with regard to the stability of the wave.

A natural function space for studying (1.1) is the following:

$$W = \{\mathbf{u} \in L^\infty(\mathbb{R}), \ \mathbf{u}' \in L^1(\mathbb{R}), \ \mathbf{u}(-\infty) = \mathbf{0}\}.$$

With the norm

$$\|\mathbf{u}\|_W = \|\mathbf{u}'\|_{L^1(\mathbb{R})},$$

W is a Banach space.

The existence result is stated as follows.

THEOREM 2.1. *Consider a second-order system* (1.1) *whose diffusion matrix is of the form of* (2.2). *Let* $\mathbf{u}^L$ *belong to* Ω *and let* $i \in \{1, \ldots, p\}$ *such that* $\mathbf{r}_i$ *is GNL. Assume that the pair* $(\lambda_i(\mathbf{u}^L), \mathbf{u}^L)$ *satisfies* (2.4) *and* (2.5). *Then we can find a positive number* ϵ_0 *such that for any* $\sigma \in \left]\lambda_i(\mathbf{u}^L) - \epsilon_0/2, \lambda_i(\mathbf{u}^L)\right[$, *system* (1.1) *has a traveling-wave solution* $\mathbf{u}_\sigma : (x,t) \in \mathbb{R}_+ \times \mathbb{R} \to \mathbf{u}_\sigma(x - \sigma t)$ *with speed* σ *and* $\mathbf{u}_\sigma(-\infty) = \mathbf{u}^L$. *Furthermore,*

$$\mathbf{u}_\sigma(+\infty) = \mathbf{u}^L + 2(\sigma - \lambda_i(\mathbf{u}^L))\mathbf{r}_i(\mathbf{u}^L) + O\left(\left(\sigma - \lambda_i(\mathbf{u}^L)\right)^2\right). \tag{2.8}$$

These solutions are unique up to a translation. Indeed, we prove the following.

THEOREM 2.2. *Assume that all the characteristic fields $\mathbf{r}_i$, $1 \le i \le p$, are GNL. Let $\mathbf{u}^L \in \Omega$ and $\sigma \in \mathbb{R}$ such that the pair $(\sigma, \mathbf{u}^L)$ satisfies* (2.4) *and* (2.5). *We can find two positive numbers $\hat{c}$ and ϵ_1 such that if $\mathbf{v} : (x,t) \to \mathbf{v}(x - \sigma t)$ is a traveling-wave solution of* (1.1) *with speed σ and $\mathbf{v}(-\infty) = \mathbf{u}^L$ that satisfies*

$$\begin{gathered} \epsilon = |\mathbf{v}(+\infty) - \mathbf{u}^L| \le \epsilon_1, \\ \|\mathbf{v} - \mathbf{u}^L\|_W \le \hat{c}\epsilon, \end{gathered} \tag{2.9}$$

then $\lambda_i(\mathbf{u}^L) - \epsilon_0/2 < \sigma < \lambda_i(\mathbf{u}^L)$ and

$$\mathbf{v}(x) = \mathbf{u}_\sigma(x + a), \quad x \in \mathbb{R},$$

for some real number a.

3. Existence in the case of the identity-diffusion matrix. To begin, we prove Theorem 2.1 when the matrix $\mathbf{D}$ is the identity matrix. The proof is much simpler in this case, and the general case can be reduced to this simpler case, which is done in §4 below.

We are thus concerned with the construction of traveling-wave solutions of the following system:

$$\frac{\partial \mathbf{u}}{\partial t} + \mathbf{A}(\mathbf{u})\frac{\partial \mathbf{u}}{\partial x} - \frac{\partial^2 \mathbf{u}}{\partial x^2} = 0. \tag{3.1}$$

We assume that the first-order system extracted from (3.1),

$$\frac{\partial \mathbf{u}}{\partial t} + \mathbf{A}(\mathbf{u})\frac{\partial \mathbf{u}}{\partial x} = 0, \tag{3.2}$$

is strictly hyperbolic. Conditions (2.4) and (2.5) are obviously satisfied by any pair $(\sigma, \mathbf{u}) \in \mathbb{R} \times \Omega$ since $r = 0$ and $\ker \mathbf{D}(\mathbf{u}) = \{\mathbf{0}\}$. Then let $\mathbf{u}^L \in \Omega$ be fixed and choose an index i such that the field $\mathbf{r}_i$ is GNL.

As proved in §1, finding traveling-wave solutions of (3.1) amounts to finding bounded solutions of the following system of differential equations:

$$-\sigma \mathbf{u}' + \mathbf{A}(\mathbf{u})\mathbf{u}' - \mathbf{u}'' = 0, \tag{3.3}$$

where σ denotes the speed of the traveling wave. A function $\mathbf{u}$ with $\mathbf{u}(-\infty) = \mathbf{u}^L$ is a solution of (3.3) if

$$(\mathbf{A}(\mathbf{u}^L) - \sigma\mathbf{Id})(\mathbf{u}(x) - \mathbf{u}^L) - \mathbf{u}'(x) = \Phi(\mathbf{u})(x) = \int_{-\infty}^{x} \big(\mathbf{A}(\mathbf{u}^L) - \mathbf{A}(\mathbf{u}(s))\big)\mathbf{u}'(s)s. \tag{3.4}$$

We expect that the states that can be connected to a given left state $\mathbf{u}^L$ by a traveling-wave solution of (3.3) belong to some half-curves tangent in $\mathbf{u}^L$ to one of the right eigenvectors of $\mathbf{A}(\mathbf{u}^L)$. Next, we expect that the velocity of the traveling wave is close to the corresponding eigenvalue. For a given $\epsilon < 0$, we are thus led to look for solutions of (3.3) in the set $\Sigma_i^\epsilon \times \mathcal{K}_i^\epsilon$ defined by

$$\Sigma_i^\epsilon = \left\{\sigma \in \mathbb{R}, \ \left|\lambda_i(\mathbf{u}^L) - \sigma + \frac{\epsilon}{2}\right| \le c_0\epsilon^2\right\}, \tag{3.5}$$

(3.6)
$$\mathcal{K}_i^\epsilon = \left\{ \mathbf{u} \in \mathbf{u}^L + W;\ \|\mathbf{u}-\mathbf{u}^L\|_W \le 2|\epsilon||\mathbf{r}_i(\mathbf{u}^L)|,\ \left\|\mathbf{l}_k(\mathbf{u}^L)\cdot\left(\mathbf{u}-\mathbf{u}^L\right)\right\|_W \le c_0\epsilon^2,\ k \neq i \right\},$$

where c_0 is chosen a priori.

The function $\Phi(\mathbf{u})$ has the following behavior in $\mathcal{K}_i^\epsilon$.

LEMMA 3.1. *Let* $\mathbf{u}^1$ *and* $\mathbf{u}^2$ *belong to* $\mathcal{K}_i^\epsilon$. *Then* $\Phi(\mathbf{u}^j)$, $j = 1, 2$, *belongs to* W *and*

$$\|\Phi(\mathbf{u}^j)\|_W \le c_1\epsilon^2, \quad j = 1,\ 2, \qquad \|\Phi(\mathbf{u}^1)-\Phi(\mathbf{u}^2)\|_W \le c_1|\epsilon|\|\mathbf{u}^1-\mathbf{u}^2\|_W, \tag{3.7}$$

where c_1 *is independent of* c_0.

Here and below, C denotes a generic a priori constant which varies from relation to relation. We use C whenever the constants have no special significance in the proof.

LEMMA 3.2. *Let* $\mathbf{u}^1$ *and* $\mathbf{u}^2$ *belong to* $\mathcal{K}_i^\epsilon$. *Set* $u_i^j(x) = \mathbf{l}_i(\mathbf{u}^L)\cdot\left(\mathbf{u}^j(x)-\mathbf{u}^L\right)$, $j = 1, 2$. *Then*

$$\mathbf{l}_i(\mathbf{u}^L)\cdot\Phi(\mathbf{u}^j)(x) = \frac{(u_i^j(x))^2}{2} + \theta_i(\mathbf{u}^j)(x) \tag{3.8}$$

for some function θ_i *that satisfies*

$$\|\theta_i(\mathbf{u}^j)\|_W \le C|\epsilon|^3, \quad j = 1,\ 2, \tag{3.9a}$$

$$\|\theta_i(\mathbf{u}^1)-\theta_i(\mathbf{u}^2)\|_W \le C\left(\epsilon^2\|u_i^1-u_i^2\|_W + |\epsilon|\sum_{k\neq i}\left\|\mathbf{l}_k(\mathbf{u}^L)\cdot\left(\mathbf{u}^1-\mathbf{u}^2\right)\right\|_W\right). \tag{3.9b}$$

Proof. The proof of Lemma 3.1 is straightforward. Let us prove Lemma 3.2. Let be given $\mathbf{u}$ in $\mathcal{K}_i^\epsilon$. Set

$$u_i(x) = \mathbf{l}_i(\mathbf{u}^L)\cdot\left(\mathbf{u}(x)-\mathbf{u}^L\right).$$

Since $\mathbf{A}$ is a C^2 matrix-valued function, Taylor's formula gives

$$\mathbf{l}_i(\mathbf{u}^L)\cdot\left((\mathbf{A}(\mathbf{u}^L)-\mathbf{A}(\mathbf{u}))\mathbf{u}'(x)\right) = \mathbf{l}_i(\mathbf{u}^L)\cdot\left[\left(\mathbf{A}(\mathbf{u}^L)\cdot(\mathbf{u}^L-\mathbf{u}(x))\right)\mathbf{u}'(x)\right]+\beta_i(x), \tag{3.10a}$$

where the function β_i satisfies

$$|\beta_i(x)| \le C|\mathbf{u}(x)-\mathbf{u}^L|^2|\mathbf{u}'(x)|. \tag{3.10b}$$

However, the function $\mathbf{u}$ belongs to $\mathcal{K}_i^\epsilon$, and we write

$$\begin{aligned}\mathbf{l}_i(\mathbf{u}^L)&\cdot\left((\mathbf{A}(\mathbf{u}^L)-\mathbf{A}(\mathbf{u}))\mathbf{u}'(x)\right)\\ &= -\mathbf{l}_i(\mathbf{u}^L)\cdot\left(\mathbf{A}(\mathbf{u}^L)\cdot\left(\mathbf{r}_i(\mathbf{u}^L),\mathbf{r}_i(\mathbf{u}^L)\right)\right)u_i(x)u_i'(x)+\zeta_i(x),\end{aligned} \tag{3.11a}$$

where the function ζ_i is given by

$$\begin{aligned}\zeta_i(\mathbf{u}^j)(x) = {}&\beta_i(\mathbf{u}^j)(x)+\mathbf{l}_i(\mathbf{u}^L)\cdot\left\{\mathbf{A}(\mathbf{u}^L)\cdot\left[\mathbf{u}^L-\mathbf{u}+u_i(x)\mathbf{r}_i(\mathbf{u}^L)\right]\right)\mathbf{u}'(x)\right\}\\ &+u_i(x)\mathbf{l}_i(\mathbf{u}^L)\cdot\left\{\left[\mathbf{A}(\mathbf{u}^L)\cdot\mathbf{r}_i(\mathbf{u}^L)\right]\left[\mathbf{u}'(x)-u_i'(x)\mathbf{r}_i(\mathbf{u}^L)\right]\right\}.\end{aligned} \tag{3.11b}$$

Since the function $\mathbf{u}$ belongs to $\mathcal{K}_i^\epsilon$, we have the following estimate:

$$\|\zeta_i\|_{L^1(\mathbb{R})} \le C|\epsilon|^3. \tag{3.11c}$$

On the other hand, for $\mathbf{v} \in \Omega$, $(\lambda_i(\mathbf{v}), \mathbf{r}_i(\mathbf{v}))$ is an eigenpair of $\mathbf{A}(\mathbf{v})$:

$$\mathbf{A}(\mathbf{v})\mathbf{r}_i(\mathbf{v}) = \lambda_i(\mathbf{v})\mathbf{r}_i(\mathbf{v}).$$

Derive this identity with respect to $\mathbf{v}$ in the direction $\mathbf{r}_i(\mathbf{v})$ to obtain

$$\mathbf{A}(\mathbf{v})\cdot\big(\mathbf{r}_i(\mathbf{v}),\mathbf{r}_i(\mathbf{v})\big)+\mathbf{A}(\mathbf{v})\big(\mathbf{r}_i(\mathbf{v})\cdot\mathbf{r}_i(\mathbf{v})\big) = \big(\nabla\lambda_i(\mathbf{v})\cdot\mathbf{r}_i(\mathbf{v})\big)\mathbf{r}_i(\mathbf{v})+\lambda_i(\mathbf{v})\big(\mathbf{r}_i(\mathbf{v})\cdot\mathbf{r}_i(\mathbf{v})\big).$$

Next, apply the left eigenvector $\mathbf{l}_i(\mathbf{v})$ of $\mathbf{A}(\mathbf{v})$ on the left to this identity. Recalling that $\mathbf{l}_i(\mathbf{v}) \cdot \mathbf{r}_i(\mathbf{v}) = 1$, we get

$$\begin{aligned}\mathbf{l}_i(\mathbf{v}) \cdot \big(\mathbf{A}(\mathbf{v}) \cdot \big(\mathbf{r}_i(\mathbf{v}),\mathbf{r}_i(\mathbf{v})\big)\big) &+ \lambda_i(\mathbf{v})\big(\mathbf{r}_i(\mathbf{v}) \cdot \mathbf{r}_i(\mathbf{v})\big)\\ &= \big(\nabla\lambda_i(\mathbf{v}) \cdot \mathbf{r}_i(\mathbf{v})\big)\mathbf{r}_i(\mathbf{v}) + \lambda_i(\mathbf{v})\big(\mathbf{r}_i(\mathbf{v}) \cdot \mathbf{r}_i(\mathbf{v})\big).\end{aligned}$$

But the field $\mathbf{r}_i$ is GNL and normalized by (2.1). Hence

$$\mathbf{l}_i(\mathbf{v}) \cdot \big(\mathbf{A}(\mathbf{v}) \cdot \big(\mathbf{r}_i(\mathbf{v}),\mathbf{r}_i(\mathbf{v})\big)\big) = 1.$$

Finally, we have

$$\mathbf{l}_i(\mathbf{u}^L) \cdot \big((\mathbf{A}(\mathbf{u}^L) - \mathbf{A}(\mathbf{u}))\mathbf{u}'(x)\big) = -u_i(x)u_i'(x) + \zeta_i(x), \tag{3.12}$$

where the function ζ_i satisfies the estimate (3.11c). By integration of the formula (3.11c), we obtain that the function $\mathbf{l}_i(\mathbf{u}^L) \cdot \Phi(\mathbf{u})$ is written in the form of (3.8), where the function $\theta_i(\mathbf{u})$ is given by

$$\theta_i(\mathbf{u}^j)(x) = \int_{-\infty}^{x} \zeta_i(\mathbf{u}^j)(s)\, s.$$

The estimate (3.9a) follows from (3.11c).

Next, let be given $\mathbf{u}^1$ *and* $\mathbf{u}^2$ in $\mathcal{K}_i^\epsilon$. Set

$$\theta_i(\mathbf{u}^j)(x) = \mathbf{l}_i(\mathbf{u}^L) \cdot \Phi(\mathbf{u}^j)(x) + \frac{\big(u_i^j(x)\big)^2}{2}, \quad j = 1, 2.$$

The function ζ_i is of the third order in $\mathbf{u}^j$, and since $\mathbf{u}^j$ belongs to $\mathcal{K}_i^\epsilon$, the estimate in (3.9) follows from (3.10b) and (3.12). □

The system of differential equations (3.3) has been replaced by the fixed-point problem (3.4). More generally, we consider the following fixed-point problem:

$$\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)\big(\mathbf{u} - \mathbf{u}^L\big) - \mathbf{u}' = \hat{\Phi}(\sigma, \mathbf{u}), \tag{3.13}$$

where $\hat{\mathbf{A}}$ is a C^1 $p \times p$ matrix-valued function and $\hat{\Phi}$ is a continuous mapping from $\mathbb{R} \times \big(\mathbf{u}^L + W\big)$ to W. The main result of this section is the existence of fixed-point solutions of (3.13). Of course, as a consequence, this gives the existence of traveling-wave solutions of (3.1). The main reason we introduce this generality is that it allows us to handle the case of degenerate $\mathbf{D}$ without repeating the proof of Theorem 3.3 below.

We suppose that $\hat{\mathbf{A}}$ and $\hat{\Phi}$ satisfy the following:

[H1] Let $\mathbf{u}^L$ be fixed. There exist p distinct numbers $\hat{\lambda}_k(\mathbf{u}^L)$, $1 \le k \le p$, a subset $\mathcal{I}$ of $\{1, \dots, p\}$, and a positive number ϵ_2 such that if

$$|\sigma - \hat{\lambda}_k(\mathbf{u}^L)| \le \epsilon_2 \tag{3.14}$$

for some index $k \in \mathcal{I}$, the matrix $\hat{A}(\sigma, \mathbf{u}^L)$ has a simple eigenvalue $\tau_k(\sigma)$. Furthermore,

$$\left|\tau_k(\sigma) - \hat{\lambda}_k(\mathbf{u}^L) + \sigma\right| \le C|\hat{\lambda}_k(\mathbf{u}^L) - \sigma|^2. \tag{3.15}$$

Let $\mathbf{f}_k(\sigma)$ (resp., $\mathbf{g}_k(\sigma)$) denote the right (resp., left) eigenvector of $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)$ associated with $\tau_k(\sigma)$. The vector $\mathbf{g}_k(\sigma)$ is normalized by

$$\mathbf{g}_k(\sigma) \cdot \mathbf{f}_k(\sigma) = 1$$

and the functions $\sigma \to \tau_k(\sigma)$, $\mathbf{f}_k(\sigma)$, and $\mathbf{g}_k(\sigma)$ are C^1. Setting $\mathbf{F}_k(\sigma) = \big\{\mathbf{f} \in \mathbb{R}^p;\ \mathbf{g}_k(\sigma) \cdot \mathbf{f} = 0\big\}$, we have that

$$|\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)\mathbf{f}| \ge c_2|\mathbf{f}| \quad \forall \mathbf{f} \in \mathbf{F}_k(\sigma) \tag{3.16}$$

for some positive number c_2.

Assumption [H1] is obviously satisfied when $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L) = \mathbf{A}(\mathbf{u}^L) - \sigma\mathbf{Id}$. The numbers $\hat{\lambda}_k$, $1 \le k \le p$, are indeed the eigenvalues of $\mathbf{A}(\mathbf{u}^L)$; $\mathcal{I} = \{1, \dots, p\}$ and the eigenpair $(\hat{\tau}_k(\sigma), \hat{\mathbf{f}}_k(\sigma))$ is $\big(\lambda_k(\mathbf{u}^L) - \sigma, \mathbf{r}_k(\mathbf{u}^L)\big)$. Next, the vector space $\hat{\mathbf{F}}_k(\sigma)$ is given by

$$\hat{\mathbf{F}}_k(\sigma) = \bigoplus_{l \ne k} \mathbb{R}\mathbf{r}_l(\mathbf{u}^L).$$

Then, taking into account that the matrix $\mathbf{A}(\mathbf{u}^L)$ has p distinct eigenvalues and setting $c_2 = \inf_{l \ne k} |\lambda_l - \lambda_k| > 0$, condition (3.16) is met.

Note that when $\hat{\mathbf{A}}$ satisfies [H1], by virtue of (3.15), the pair $\big(\hat{\lambda}_k(\mathbf{u}^L), \mathbf{f}_k\big(\hat{\lambda}_k(\mathbf{u}^L)\big)\big)$ is an eigenpair of the matrix $\hat{\mathbf{A}}\big(\hat{\lambda}_k(\mathbf{u}^L), \mathbf{u}^L\big)$. For simplicity, we write

$$\hat{\lambda}_k(\mathbf{u}^L) = \hat{\lambda}_k^0, \quad \mathbf{f}_k(\hat{\lambda}_k(\mathbf{u}^L)) = \mathbf{f}_k^0, \quad \mathbf{g}_k(\hat{\lambda}_k(\mathbf{u}^L)) = \mathbf{g}_k^0.$$

Next, denote by $\mathbf{Q}_k(\sigma)$ the projector defined by the expression

$$\mathbf{Q}_k(\sigma)\mathbf{f} = \mathbf{f} - \big(\mathbf{g}_k(\sigma) \cdot \mathbf{f}\big)\mathbf{f}_k(\sigma), \quad \mathbf{f} \in \mathbb{R}^p, \tag{3.17}$$

and set $\mathbf{Q}_k^0 = \mathbf{Q}_k\big(\hat{\lambda}_k(\mathbf{u}^L)\big)$. The range of $\mathbf{Q}_k(\sigma)$ is the vector space $\mathbf{F}_k(\sigma)$. The two sets $\mathcal{K}_k^\epsilon$ and Σ_k^ϵ are naturally replaced by the following two sets:

$$\hat{\Sigma}_k^\epsilon = \Big\{\sigma \in \mathbb{R},\ \big|\hat{\lambda}_k(\mathbf{u}^L) - \sigma + \epsilon/2\big| \le c_3\epsilon^2\Big\}, \tag{3.18}$$

and

$$\hat{\mathcal{K}}_k^\epsilon = \big\{\mathbf{u} \in \mathbf{u}^L + W;\ \|\mathbf{u} - \mathbf{u}^L\|_W \le 2|\epsilon|\,|\mathbf{f}_k^0|,\ \big\|\mathbf{Q}_k^0(\mathbf{u} - \mathbf{u}^L)\big\|_W \le c_3\epsilon^2\big\}, \tag{3.19}$$

where c_3 is chosen a priori. Next, the function $\hat{\Phi}$ is assumed to satisfy the following two hypotheses:

[H2] For any pair $(\mathbf{u}^1, \mathbf{u}^2)$ that belongs to $\hat{\mathcal{K}}_i^\epsilon$, we have

$$\|\hat{\Phi}(\sigma, \mathbf{u}^j)\|_W \le c_4\epsilon^2, \ j = 1,\ 2, \quad \|\hat{\Phi}(\sigma, \mathbf{u}^1) - \hat{\Phi}(\sigma, \mathbf{u}^2)\|_W \le c_4|\epsilon|\|\mathbf{u}^1 - \mathbf{u}^2\|_W, \tag{3.20}$$

where c_4 is independent of c_3 in (3.18) and (3.19).

[H3] Let $\mathbf{u}^1$ *and* $\mathbf{u}^2$ belong to $\hat{\mathcal{K}}_i^\epsilon$. Set

$$u_i^j = \mathbf{g}_i(\sigma) \cdot \big(\mathbf{u}^j(x) - \mathbf{u}^L\big), \quad j = 1, 2. \tag{3.21}$$

Then

$$\mathbf{g}_i(\sigma) \cdot \hat{\Phi}(\sigma, \mathbf{u}^j) = \frac{\big(u_i^j(x)\big)^2}{2} + \hat{\theta}_i(\sigma, \mathbf{u}^j)(x), \tag{3.22}$$

where the function $\hat{\theta}_i$ satisfies

$$\begin{gathered} \|\hat{\theta}_i(\sigma, \mathbf{u}^j)\|_W \le C|\epsilon|^3, \quad j = 1, 2, \\ \|\hat{\theta}_i(\sigma, \mathbf{u}^1) - \hat{\theta}_i(\sigma, \mathbf{u}^2)| \le C \left(\epsilon^2 \|u_i^1 - u_i^2\|_W + |\epsilon| \|\mathbf{Q}_i(\sigma)\big(\mathbf{u}^1 - \mathbf{u}^2\big)\|_W\right). \end{gathered} \tag{3.23}$$

We can solve the fixed-point problem (3.13).

THEOREM 3.3. *Let $(\sigma, \mathbf{u}) \to \hat{\mathbf{A}}$ be a C^1 $p \times p$ matrix-valued function and let $\hat{\Phi}$ be a continuous mapping from $\mathbb{R} \times \big(\mathbf{u}^L + W\big)$ to W. Assume that* [H1], [H2], *and* [H3] *hold. Then we can find a positive number ϵ_0 such that for any index $i \in \mathcal{I}$, $\epsilon \in (-\epsilon_0, 0)$, and $\sigma \in \hat{\Sigma}_i^\epsilon$, the fixed-point problem* (3.13) *has a unique solution $\mathbf{u}$ in $\hat{\mathcal{K}}_i^\epsilon$.*

Proof. Let be given $\epsilon \in (-\epsilon_0, 0)$, where ϵ_0 is chosen below, $i \in \mathcal{I}$, and $\sigma \in \hat{\Sigma}_i^\epsilon$. We decompose a function $\mathbf{u}$ that belongs to $\hat{\mathcal{K}}_i^\epsilon$ into

$$\mathbf{u}(x) = \mathbf{u}^L + u_i(x)\mathbf{f}_i(\sigma) + \mathbf{Q}_i(\sigma)\big(\mathbf{u}(x) - \mathbf{u}^L\big). \tag{3.24}$$

The fixed-point problem (3.13) is then equivalent to the following problem:

$$\mathbf{Q}_i(\sigma)\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)\big(\mathbf{u} - \mathbf{u}^L\big) - \mathbf{Q}_i(\sigma)\mathbf{u}' = \mathbf{Q}_i(\sigma)\hat{\Phi}(\sigma, \mathbf{u}), \tag{3.25}$$

$$\tau_i(\sigma)u_i + \frac{u_i^2}{2} - u_i' = \hat{\theta}_i(\sigma, \mathbf{u}). \tag{3.26}$$

We solve (3.25)–(3.26) by using Banach's fixed-point theorem. For $\mathbf{v}$ that belongs to $\mathcal{K}_i^\epsilon$, we consider the following system of differential equations:

$$\mathbf{Q}_i(\sigma)\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)\big(\mathbf{u} - \mathbf{u}^L\big) - \mathbf{Q}_i(\sigma)\mathbf{u}' = \mathbf{Q}_i(\sigma)\hat{\Phi}(\sigma, \mathbf{v}), \tag{3.27}$$

$$\tau_i(\sigma)u_i + \frac{u_i^2}{2} - u_i' = \hat{\theta}_i(\mathbf{v}), \quad u_i(0) = -\tau_i(\sigma). \tag{3.28}$$

Note that the matrices $\mathbf{Q}_i(\sigma)$ and $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)$ commute so that system (3.27) is a system of $p - 1$ linear differential equations with constant coefficients in $\mathbf{F}_i(\sigma)$. Its solution relies on the following.

LEMMA 3.4. *Let $\mathbf{B}_0$ be a given $p \times p$ matrix and $\mathbf{F}_0$ be a subspace of $\mathbb{R}^p$ with $\mathbf{B}_0\mathbf{F}_0 \subset \mathbf{F}_0$. Assume that*

$$|\mathbf{B}_0\mathbf{f}| \ge \hat{c}|\mathbf{f}| \quad \forall \mathbf{f} \in \mathbf{F}_0. \tag{3.29}$$

Let $\mathbf{Q}_0$ *denote a projector onto* $\mathbf{F}_0$. *Then for* $\mathbf{z} \in W$, *the system of differential equations*

$$\mathbf{B}_0\mathbf{w} - \mathbf{w}' = \mathbf{Q}_0\mathbf{z}$$

has a unique bounded solution $\mathbf{w} : \mathbb{R} \to \mathbf{F}_0$ *with* $\mathbf{w}(-\infty) = \mathbf{0}$. *Furthermore,*

$$\|\mathbf{w}\|_W \leq C\,\|\mathbf{z}\|_W\,, \tag{3.30}$$

where C *only depends on* $\hat{c}$ *and* $\|\mathbf{Q}_0\|$.

Proof. Denote by $\mathbf{F}_0^+$ (resp., $\mathbf{F}_0^-$) the subspace of $\mathbf{F}_0$, invariant by $\mathbf{B}_0$, associated with the positive (resp., negative) eigenvalues of $\mathbf{B}_{0|\mathbf{F}_0}$. Denote by $\mathbf{Q}_0^+$ (resp., $\mathbf{Q}_0^-$) the restriction of $\mathbf{Q}_0$ to the subspace $\mathbf{F}_0^+$ (resp., $\mathbf{F}_0^-$). The unique bounded solution $\mathbf{w} : \mathbb{R} \to \mathbf{F}_0$ with $\mathbf{w}(-\infty) = \mathbf{0}$ of (3.29) is given by

$$\begin{aligned} \mathbf{Q}_0^+\mathbf{w}(x) &= -\int_x^{+\infty} \exp\left(\mathbf{Q}_0^+\mathbf{B}_0(x-s)\right)\mathbf{Q}_0\mathbf{z}(s)s \\ \mathbf{Q}_0^-\mathbf{w}(x) &= \int_{-\infty}^{x} \exp\left(\mathbf{Q}_0^-\mathbf{B}_0(x-s)\right)\mathbf{Q}_0\mathbf{z}(s)s. \end{aligned} \tag{3.31}$$

Finally, by (3.29), the mapping $\mathbf{Q}_0\mathbf{B}_0 : \mathbf{F}_0 \to \mathbf{F}_0$ is regular, and a straightforward computation allows us to conclude the proof of Lemma 3.4. □

Next, we solve the differential equation (3.28) thanks to the following

LEMMA 3.5. *Let* $\zeta \in W$ *and* c_5 *be a positive number. We can find* $\delta_0 > 0$ *such that for any* $\delta \in (-\delta_0, \delta_0)$, *if*

$$\|\zeta\|_W \leq c_5|\delta|^3, \tag{3.32}$$

the unique solution of the following Cauchy problem

$$\frac{\delta}{2}w(x) + \frac{(w(x))^2}{2} - w'(x) = \zeta(x), \quad w(0) = -\frac{\delta}{2} \tag{3.33}$$

is bounded: $w' \in L^1(\mathbb{R})$. *Furthermore,* w *satisfies the following estimate:*

$$w(x) = \frac{-\delta}{1+\exp(-\delta x/2)} + z \quad \text{with} \quad z \in W \quad \text{and} \quad \|z\|_W \leq C\delta^2. \tag{3.34}$$

The proof of Lemma 3.5 is technical and is given in the appendix.

Let us return to the solution of (3.27)–(3.28). Let $\mathbf{v}$ belong to $\mathcal{K}_i^\epsilon$. According to Lemma 3.4, there exists a unique bounded solution $\mathbf{w} : \mathbb{R} \to \mathbf{F}_i(\sigma)$ of the following system of $p-1$ differential equations:

$$\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)(\mathbf{w} - \mathbf{Q}_i(\sigma)\mathbf{u}^L) - \mathbf{w}' = \mathbf{Q}_i(\sigma)\hat{\Phi}(\mathbf{v}).$$

On the other hand, by virtue of (3.15) and (3.18), $\tau_i(\sigma)$ satisfies

$$\left|\tau_i(\sigma) + \frac{\epsilon}{2}\right| \leq C\epsilon^2. \tag{3.35}$$

But the function $\hat{\theta}_i(\mathbf{v})$ satisfies the estimate (3.23) and, provided that ϵ_0 is chosen small enough, we can apply Lemma 3.5. The differential equation (3.28) has a unique solution u_i that belongs to W. (Note that $u_i(-\infty) = 0$ since $\tau_i(\sigma) > 0$.)

Let $\mathbf{u}$ denote the unique function in $\mathbf{u}^L + W$ such that $\mathbf{Q}_i(\sigma)(\mathbf{u} - \mathbf{u}^L) = \mathbf{w}$ and $\mathbf{g}_i(\sigma) \cdot \big(\mathbf{u}(x) - \mathbf{u}^L\big) = u_i(x)$. The function $\mathbf{u}$ is by construction a solution of (3.27)–(3.28). Furthermore,

$$\mathbf{Q}_i^0(\mathbf{u} - \mathbf{u}^L) = \mathbf{Q}_i(\sigma)(\mathbf{u} - \mathbf{u}^L) + (\mathbf{Q}_i^0 - \mathbf{Q}_i(\sigma))(\mathbf{u} - \mathbf{u}^L)$$

and we deduce from (3.30) and (3.18) that

$$\|\mathbf{Q}_i^0(\mathbf{u} - \mathbf{u}^L)\| \le c_6\epsilon^2 + C|\epsilon|^3 m, \tag{3.36}$$

where c_6 is independent of c_3 and C depends continuously on c_3 and other constants. On the other hand, by virtue of (3.18), (3.34), and (3.35), we obviously have·

$$\|\mathbf{u} - \mathbf{u}^L\| \le \frac{3}{2}|\epsilon||\mathbf{f}_i(\sigma)| + C\epsilon^2.$$

Hence we can choose ϵ_0 small enough so that the function $\mathbf{u}$ belongs to $\mathcal{K}_i^\epsilon$. Setting $\mathbf{u} = \mathcal{F}(\sigma, \mathbf{v})$, we have thus constructed a mapping from $\mathcal{K}_i^\epsilon$ to itself. Next, we prove the following lemma.

LEMMA 3.6. *We can choose ϵ_0 such that for fixed $\epsilon \in (-\epsilon_0, 0)$ and $\sigma \in \hat{\Sigma}_i^\epsilon$, the mapping $\mathcal{F}^2$ defined by*

$$\mathcal{F}^2(\sigma, \mathbf{v}) = \mathcal{F}\big(\sigma, \mathcal{F}(\sigma, \mathbf{v})\big)$$

is a contraction.

Proof. We first obtain some estimates of $\mathcal{F}$.

LEMMA 3.7. *Let $\mathbf{v}^1$ and $\mathbf{v}^2$ belong to $\mathcal{K}_i^\epsilon$. Then*

$$\begin{aligned} \|\mathcal{F}(\sigma, \mathbf{v}^1) - \mathcal{F}(\sigma, \mathbf{v}^2)\|_W &\le C\left(|\epsilon|\, \|\mathbf{g}_i(\sigma)\cdot(\mathbf{v}^1 - \mathbf{v}^2)\|_W + \|\mathbf{Q}_i(\sigma)(\mathbf{v}^1 - \mathbf{v}^2)\|_W\right), \\ \big\|\mathbf{Q}_i(\sigma)\big(\mathcal{F}(\sigma, \mathbf{v}^1) - \mathcal{F}(\sigma, \mathbf{v}^2)\big)\big\|_W &\le C|\epsilon|\, \|\mathbf{v}^1 - \mathbf{v}^2\|_W. \end{aligned} \tag{3.37}$$

Assume that (3.37) holds. We obtain that the mapping $\mathbf{v} \in \mathcal{K}_i^\epsilon \to \mathcal{F}^2(\sigma, \mathbf{v})$ is a contraction by iterating (3.37). The proof of Lemma 3.6 is then complete. □

Proof of Lemma 3.7. Let $\mathbf{v}^1$ *and* $\mathbf{v}^2$ belong to $\hat{\mathcal{K}}_i^\epsilon$. Set $\mathbf{u}^j = \mathcal{F}(\sigma, \mathbf{v}^j)$, $j = 1, 2$. The function $\mathbf{w} = \mathbf{Q}_i(\sigma)(\mathbf{u}^1 - \mathbf{u}^2)$ is a solution of the following system of differential equations:

$$\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)\mathbf{w} - \mathbf{w}' = \mathbf{Q}_i(\sigma)\big(\hat{\Phi}(\sigma, \mathbf{v}^1) - \hat{\Phi}(\sigma, \mathbf{v}^2)\big).$$

Then, taking into account the estimate (3.20), Lemma 3.4 gives

$$\big\|\mathbf{Q}_i(\sigma)\big(\mathbf{u}^1 - \mathbf{u}^2\big)\big\|_W \le C|\epsilon|\, \|\mathbf{v}^1 - \mathbf{v}^2\|_W. \tag{3.38}$$

Next, we have the following lemma.

LEMMA 3.8. *Let $\delta \in (-\delta_0, \delta_0)$. and ζ^1, $\zeta^2 \in W$ satisfy* (3.32). *Denote by w^j, $j = 1, 2$, the solution of* (3.33) *when ζ is replaced by ζ^j. Then*

$$\|w^1 - w^2\|_W \le \frac{C}{|\delta|}\, \|\zeta^1 - \zeta^2\|_W.$$

The proof of Lemma 3.8 can be found in the appendix. Denoting by u_i^j, $j = 1, 2$, the solution of the differential equation

$$\tau_i(\sigma)u_i^j + \frac{(u_i^j)^2}{2} - (u_i^j)' = \hat{\theta}_i(\mathbf{v}^j), \qquad u_i^j(0) = -\tau_i(\sigma), \qquad j = 1, 2,$$

and taking into account the estimate (3.23), we deduce from Lemma 3.8 that

$$\|u_i^1 - u_i^2\|_W \leq C\,(|\epsilon|\,\|v_i^1 - v_i^2\| + \|\mathbf{Q}_i(\sigma)(\mathbf{v}^1 - \mathbf{v}^2)\|), \tag{3.39}$$

where $v_i^j(x) = \mathbf{g}_i(\sigma)\cdot(\mathbf{v}(x) - \mathbf{u}^L)$, $j = 1, 2$. By the definition of $\mathcal{F}$, (3.38) and (3.39) yield (3.37).

For $\epsilon \in (-\epsilon_0, 0)$ and $\sigma \in \hat{\Sigma}_i^\epsilon$, the mapping $\mathbf{v} \to \mathcal{F}^2(\sigma, \mathbf{v})$ is a contraction defined in $\hat{\mathcal{K}}_i^\epsilon$. There exists a unique $\mathbf{u}_\sigma \in \mathcal{K}_i^\epsilon$ such that $\mathbf{u}_\sigma = \mathcal{F}(\sigma, \mathbf{u}_\sigma)$. The function $\mathbf{u}_\sigma$ is a solution of (3.13) and the proof of Theorem 3.3 is complete. □

4. Existence for general diffusion matrices.

In §3, we proved the existence of traveling-wave solutions of (3.1). This system is simple to handle because here the diffusion matrix is the identity matrix. Here we consider more general diffusion matrices of the form of (2.3). We prove that a traveling-wave solution of (1.1) is a solution of a fixed-point problem of the form of (3.13). Indeed, let $\mathbf{u} = (\mathbf{u}_1, \mathbf{u}_2)$ be a traveling wave with speed σ solution of (1.1) such that $\mathbf{u}(-\infty) = \mathbf{u}^L$ and $\|\mathbf{u} - \mathbf{u}^L\|_W \leq \epsilon_2$ for some number ϵ_2 chosen below. Assume that the pair $(\sigma, \mathbf{u}^L)$ satisfies (2.4) and (2.5). Inserting the expressions (2.3) and (2.2) of the matrices $\mathbf{A}(\mathbf{u})$ and $\mathbf{D}(\mathbf{u})$ in (1.1), we obtain that $\mathbf{u}$ is a solution of the following system:

$$\big(\mathbf{A}_1(\mathbf{u}) - \sigma\mathbf{Id}_r\big)\mathbf{u}_1' + \mathbf{A}_2(\mathbf{u})\mathbf{u}_2' = \mathbf{0}, \tag{4.1}$$

$$\mathbf{A}_3(\mathbf{u})\mathbf{u}_1' + \big(\mathbf{A}_4(\mathbf{u}) - \sigma\mathbf{Id}_q\big)\mathbf{u}_2' - \big(\mathbf{D}_1(\mathbf{u})\mathbf{u}_1' + \mathbf{D}_2(\mathbf{u})\mathbf{u}_2'\big) = \mathbf{0}. \tag{4.2}$$

By virtue of (2.4), we obtain that for small enough ϵ_2, for any $x \in \mathbb{R}$, the matrix $\big(\mathbf{A}_1(\mathbf{u}(x)) - \sigma\mathbf{Id}_r\big)$ is regular. Hence

$$\mathbf{u}_1' = -\big(\mathbf{A}_1(\mathbf{u}) - \sigma\mathbf{Id}_r\big)^{-1}\mathbf{A}_2(\mathbf{u})\mathbf{u}_2'. \tag{4.3}$$

This differential equation defines a mapping $\mathbf{u}_2 \to \mathbf{u}_1$.

LEMMA 4.1. *Let $\mathbf{u}^L = (\mathbf{u}_1^L, \mathbf{u}_2^L) \in \Omega$ and $\sigma \in \mathbb{R}$ satisfy* (2.4) *and* (2.5); *we can find a positive ϵ_2 such that for any function $\mathbf{u}_2 \in \mathbf{u}_2^L + W$ with*

$$\|\mathbf{u}_2 - \mathbf{u}_2^L\|_W \leq \epsilon_2, \tag{4.4}$$

the system of differential equations (4.3) *has a unique solution $\mathbf{u}_1 = \mathcal{G}(\mathbf{u}_2) \in \mathbf{u}_1^L + W$. Furthermore, the mapping $\mathcal{G}$ is continuous:*

$$\|\mathcal{G}(\mathbf{u}_2^1) - \mathcal{G}(\mathbf{u}_2^2)\|_W \leq C\,\|\mathbf{u}_2^1 - \mathbf{u}_2^2\|_W\,. \tag{4.5}$$

Proof. A fixed-point method is convenient. Let $\mathbf{v} = (\mathbf{v}_1, \mathbf{v}_2) \in \mathbf{u}^L + W$ with $\|\mathbf{v} - \mathbf{u}^L\|_W \leq \epsilon_2$ and $\sigma \in \mathbb{R}$ such that $(\sigma, \mathbf{u}^L)$ satisfies (2.4) and (2.5). The unique bounded solution $\mathbf{u}_1$ of the system of differential equations

$$\mathbf{u}_1' = -\big(\mathbf{A}_1(\mathbf{v}) - \sigma\mathbf{Id}_r\big)^{-1}\mathbf{A}_2(\mathbf{v})\mathbf{v}_2', \quad \mathbf{u}_1(-\infty) = \mathbf{u}_1^L$$

is given by

$$\mathbf{u}_1(x) = \mathbf{u}_1^L - \int_{-\infty}^{x} \big(\mathbf{A}_1(\mathbf{v}) - \sigma\mathbf{Id}_r\big)^{-1}\mathbf{A}_2(\mathbf{v})\mathbf{v}_2'\, s. \tag{4.6}$$

For $\mathbf{v} = \mathbf{v}_1^m$, $m = 1, 2$, as above, let $\mathbf{u}_1^m$, $m = 1, 2$, denote the functions defined by (4.6). A straightforward computation allows us to estimate the norm $\|\mathbf{u}_1^1 - \mathbf{u}_1^2\|_W$:

$$\|\mathbf{u}_1^1 - \mathbf{u}_1^2\|_W \le C\epsilon_2 \, \|\mathbf{v}^1 - \mathbf{v}^2\|_W \, .$$

For $(\sigma, \mathbf{u}_2)$ satisfying (4.4), using Banach's fixed-point theorem, it is now a simple matter to obtain the existence and the uniqueness of the function $\mathbf{u}_1 \in \mathbf{u}_1^L + W$ such that the pair $\mathbf{u} = (\mathbf{u}_1, \mathbf{u}_2)$ is a solution of (4.3). The mapping $\mathcal{G}$ defined by $\mathbf{u}_1 = \mathcal{G}(\mathbf{u}_2)$ then obviously satisfies (4.5). □

Next, let us insert the expression (4.3) in (4.2). We obtain that $\mathbf{u}_2$ is a solution of the following system:

$$\mathbf{B}(\sigma, \mathbf{u})\mathbf{u}_2' - \left(\hat{\mathbf{D}}(\sigma, \mathbf{u})\mathbf{u}_2'\right)' = \mathbf{0}, \tag{4.7}$$

where

$$\mathbf{B}(\sigma, \mathbf{u}) = \mathbf{A}_4(\mathbf{u}) - \sigma\mathbf{Id}_q - \mathbf{A}_3(\mathbf{u})\big(\mathbf{A}_1(\mathbf{u}) - \sigma\mathbf{Id}_r\big)^{-1}\mathbf{A}_2(\mathbf{u}), \tag{4.8}$$

$$\hat{\mathbf{D}}(\sigma, \mathbf{u}) = \mathbf{D}_2(\mathbf{u}) - \mathbf{D}_1(\mathbf{u})\big(\mathbf{A}_1(\mathbf{u}) - \sigma\mathbf{Id}_r\big)^{-1}\mathbf{A}_2(\mathbf{u}). \tag{4.9}$$

LEMMA 4.2. *Assume that* $(\sigma, \mathbf{u}^L)$ *satisfies* (2.4) *and* (2.5). *We can choose* ϵ_2 *such that for any state* $\mathbf{u} \in \Omega$ *with* $|\mathbf{u} - \mathbf{u}^L| \le \epsilon_2$, *the matrix* $\hat{\mathbf{D}}(\sigma, \mathbf{u})$ *is regular.*

Proof. Let $\mathbf{h}_2$ belong to the kernel of $\hat{\mathbf{D}}(\sigma, \mathbf{u})$. Then the vector $\mathbf{h}$ defined by

$$\mathbf{h} = \begin{pmatrix} \big(\mathbf{A}_1(\mathbf{u}) - \sigma\mathbf{Id}_r\big)^{-1}\mathbf{A}_2(\mathbf{u})\mathbf{h}_2 \\ \mathbf{h}_2 \end{pmatrix}$$

belongs to the vector space $\ker\mathbf{D}(\mathbf{u}) \cap \big(\mathbf{A}(\mathbf{u}) - \sigma\mathbf{1}_p\big)^{-1}\mathrm{range}\mathbf{D}(\mathbf{u})$. By virtue of assumption (2.5), this is impossible when ϵ_2 is small enough. □

In fact, to write system (4.7) in the form of (3.13), we formally set

$$\mathbf{v}_2' = \hat{\mathbf{D}}(\sigma; (\mathcal{G}(\mathbf{u}_2), \mathbf{u}_2))\mathbf{u}_2', \quad \mathbf{v}_2(-\infty) = \mathbf{u}_2^L, \tag{4.10}$$

and we wish to write a system whose solution is $\mathbf{v}_2$. These considerations are made rigorous with the following lemma.

LEMMA 4.3. *Let* $(\sigma, \mathbf{u}^L)$ *satisfy* (2.4) *and* (2.5). *Let* $\mathbf{u}_2$ *belong to* $\mathbf{u}_2^L + W$ *that satisfies* (4.4). *The function* $\mathbf{v}_2 \in \mathbf{u}_2^L + W$, *whose derivative is given by* (4.10), *belongs to the set* $\mathbf{u}_2^L + W$ *and satisfies*

$$\left\|\mathbf{v}_2 - \mathbf{u}_2^L\right\|_W \le C\epsilon_2. \tag{4.11}$$

Conversely, we can choose ϵ_2 *such that for* $\mathbf{v}_2$ *that belongs to* $\mathbf{u}_2^L + W$ *and satisfies* (4.4), *there exists a unique solution* $\mathbf{u}_2 = \mathcal{H}_2(\mathbf{v}_2) \in \mathbf{u}_2^L + W$ *of* (4.10) *with*

$$\left\|\mathbf{u}_2 - \mathbf{u}_2^L\right\|_W \le C\epsilon_2. \tag{4.12}$$

The mapping $\mathcal{H}_2$ *is continuous:*

$$\|\mathcal{H}_2(\mathbf{v}_2^1) - \mathcal{H}_2(\mathbf{v}_2^2)\|_W \le C\,\|\mathbf{v}_2^1 - \mathbf{v}_2^2\|_W \quad \forall \mathbf{v}_2^1, \mathbf{v}_2^2 \in \mathbf{u}_2^L + W. \tag{4.13}$$

Proof. The derivation of the estimate (4.11) is straightforward. Conversely, let $\mathbf{v}_2$ in $\mathbf{u}_2^L + W$ satisfy (4.4). We solve (4.10) with a fixed-point method. The proof relies on Lemma 4.2 and is similar to the proof of Lemma 4.1. □

Next, we define the mapping $\mathcal{H}$ by

$$\mathcal{H}(\mathbf{v}_2) = (\mathcal{G}(\mathcal{H}_2(\mathbf{v}_2)), \mathcal{H}_2(\mathbf{v}_2)). \tag{4.14}$$

The mapping $\mathcal{H}$ is, of course, continuous. Furthermore, if $\mathbf{v}_2$ is a solution of the system of differential equations

$$\hat{\mathbf{A}}\big(\sigma, \mathcal{H}(\mathbf{v}_2)\big)\mathbf{v}_2' - \mathbf{v}_2'' = \mathbf{0}, \tag{4.15}$$

where the matrix-valued function $\hat{\mathbf{A}}$ is given by

$$\hat{\mathbf{A}}(\sigma, \mathbf{u}) = \mathbf{B}(\sigma, \mathbf{u})\big(\hat{\mathbf{D}}(\sigma, \mathbf{u})\big)^{-1}, \tag{4.16}$$

the function $\mathbf{u} = \mathcal{H}(\mathbf{v}_2)$ is a solution of (1.1).

Finally, system (1.1) has been replaced by system (4.15), where the matrix in front of the second-order derivative is the identity matrix. Next, if $\mathbf{v}_2$ is a solution of (4.15), then

$$\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)(\mathbf{v}_2 - \mathbf{v}_2^L) - \mathbf{v}_2' = \hat{\Phi}(\sigma, \mathbf{v}_2), \quad \mathbf{v}_2(-\infty) = \mathbf{u}_2^L, \tag{4.17}$$

where

$$\hat{\Phi}(\sigma, \mathbf{v}_2)(x) = \int_{-\infty}^{x} \Big(\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)\mathbf{v}_2' - \mathbf{B}(\sigma, \mathcal{H}(\mathbf{v}_2))\Big(\big(\hat{\mathbf{D}}(\sigma, \mathcal{H}(\mathbf{v}_2))\big)^{-1}\mathbf{v}_2'\Big)'\Big) ds. \tag{4.18}$$

To apply Theorem 3.3, we check that the matrix-valued function $\hat{\mathbf{A}}$ and the function $\hat{\Phi}$ satisfy hypotheses [H1], [H2], and [H3] from §3. We first prove the following proposition.

PROPOSITION 4.4. *The matrix-valued function $\hat{\mathbf{A}}$ satisfies assumption* [H1].

Proof. First, a straightforward computation gives the following lemma.

LEMMA 4.5. *For $\mathbf{u} \in \Omega$ and $\sigma \in \mathbb{R}$, the pair $(\tau, \mathbf{f}) \in \mathbb{R} \times \mathbb{R}^q$ is an eigenpair of the matrix $\hat{\mathbf{A}}(\sigma, \mathbf{u})$ if the vector $\mathbf{h}$, given by*

$$\mathbf{h} = \begin{pmatrix} -\big(\mathbf{A}_1(\mathbf{u}) - \sigma\mathbf{Id}_r\big)^{-1}\mathbf{A}_2(\mathbf{u})\big(\hat{\mathbf{D}}(\sigma, \mathbf{u})\big)^{-1}\mathbf{f} \\ \big(\hat{\mathbf{D}}(\sigma, \mathbf{u})\big)^{-1}\mathbf{f} \end{pmatrix}, \tag{4.19}$$

satisfies

$$\big(\mathbf{A}(\mathbf{u}) - \sigma\mathbf{Id}_p\big)\mathbf{h} = \tau\mathbf{D}(\mathbf{u})\mathbf{h}.$$

Next, we have the following lemma.

LEMMA 4.6. *Assume that the field $\mathbf{r}_i$ is GNL. Choose $\mathbf{u} \in \Omega$. There exists a C^1 curve $\sigma \in (\lambda_i(\mathbf{u}^L) - \hat{\epsilon}, \lambda_i(\mathbf{u}^L) + \hat{\epsilon}) \to (\tau_i(\sigma), \mathbf{h}_i(\sigma))$ such that*

$$\big(\mathbf{A}(\mathbf{u}) - \sigma\mathbf{Id}_p\big)\mathbf{h}_i(\sigma) = \tau_i(\sigma)\mathbf{D}(\mathbf{u})\mathbf{h}_i(\sigma) \tag{4.20}$$

and

$$\begin{gathered} (\mathbf{l}_i(\mathbf{u}), \mathbf{h}_i(\sigma)) = 1, \\ |\mathbf{h}_i(\sigma) - \mathbf{r}_i(\mathbf{u}^L)| \leq C|\lambda_i(\mathbf{u}) - \sigma|, \\ |\tau_i(\sigma) - \lambda_i(\mathbf{u}) + \sigma| \leq C|\lambda_i(\mathbf{u}^L) - \sigma|^2. \end{gathered} \tag{4.21}$$

Proof. First, when $\sigma = \lambda_i(\mathbf{u})$, system (4.20) has the solution $(\tau^0, \mathbf{h}^0) = (0, \mathbf{r}_i(\mathbf{u}))$. Next, we decompose a vector $\mathbf{h}$ on the eigenbasis $\{\mathbf{r}_k(\mathbf{u})\}_{1\leq k\leq p}$ of the matrix $\mathbf{A}(\mathbf{u})$: $\mathbf{h} = \sum_{k=1}^{p} h_k \mathbf{r}_k(\mathbf{u})$. We set $h_i = 1$ and define the mapping ϕ_σ from $\mathbb{R}^{p+1}$ to $\mathbb{R}^p$ by

$$\phi(\sigma, \tau, (h_k)_{k\neq i}) = (\mathbf{A}(\mathbf{u}) - \sigma \mathbf{1}) \sum_{k\neq i} h_k \mathbf{r}_k(\mathbf{u}) - \tau \mathbf{D}(\mathbf{u}) \Big(\mathbf{r}_i(\mathbf{u}) + \sum_{k\neq i} h_k \mathbf{r}_k(\mathbf{u}) \Big).$$

The mapping ϕ is C^∞, and a straightforward computation gives

$$\begin{aligned} &\frac{\partial \phi}{\partial \tau}(\lambda_i(\mathbf{u}), 0, \mathbf{0}) = -\mathbf{D}(\mathbf{u})\mathbf{r}_i(\mathbf{u}), \\ &\frac{\partial \phi}{\partial h_k}(\lambda_i(\mathbf{u}), 0, \mathbf{0}) = \big(\mathbf{A}(\mathbf{u}) - \lambda_i(\mathbf{u})\mathbf{Id}\big)\mathbf{r}_k(\mathbf{u}), \qquad k \neq i. \end{aligned}$$

The vector space spanned by the $p-1$ vectors $\big(\mathbf{A}(\mathbf{u}) - \lambda_i(\mathbf{u})\mathbf{Id}\big)\mathbf{r}_k(\mathbf{u})$, $k \neq i$, is $(\mathbf{l}_i(\mathbf{u}))^\perp$ because the matrix $\mathbf{A}(\mathbf{u})$ has distinct eigenvalues. On the other hand, since the field $\mathbf{r}_i$ is GNL, we have by virtue of (2.7) that $\mathbf{l}_i(\mathbf{u}) \cdot \mathbf{D}(\mathbf{u})\mathbf{r}_i(\mathbf{u}) \neq 0$, and we deduce that the p vectors $\big(\mathbf{A}(\mathbf{u}) - \lambda_i(\mathbf{u})\mathbf{Id}\big)\mathbf{r}_k(\mathbf{u})$, $k \neq i$, and $\mathbf{D}(\mathbf{u})\mathbf{r}_i(\mathbf{u})$ span $\mathbb{R}^p$. Thus we may apply the implicit-function theorem and obtain a C^1 curve $\sigma \to (\tau_i(\sigma), \mathbf{h}_i(\sigma))$ of solutions of (4.20). The derivation of (4.21) is then straightforward. □

We deduce from Lemmas 4.5 and 4.6 that given a GNL field $\mathbf{r}_i$, for ϵ_2 chosen small enough and σ such that $|\sigma - \lambda_i(\mathbf{u}^L)| \leq \epsilon_2$, the matrix $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)$ has a right eigenvector $\mathbf{f}_i(\sigma)$ associated with the eigenvalue $\tau_i(\sigma)$. By virtue of (4.21), the function $\sigma \to \tau_i(\sigma)$ satisfies (3.15). We denote by $\mathbf{g}_i(\sigma)$ the associated left eigenvector, normalized by $\mathbf{g}_i(\sigma) \cdot \mathbf{f}_i(\sigma) = 1$. The set $\mathcal{I}$ of hypothesis [H1] is thus the set of indices i for which the field $\mathbf{r}_i$ is genuinely nonlinear.

LEMMA 4.7. *Let $\sigma \in \mathbb{R}$ and $\mathbf{u}^L \in \Omega$ such that $(\sigma, \mathbf{u}^L)$ satisfies* (2.4) *and* (2.5). *Assume that the matrix $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)$ has an eigenpair $(\tau_0, \mathbf{f}_0)$. Denote by $\mathbf{g}_0$ the left eigenvector of $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)$ associated with τ_0 normalized by $\mathbf{g}_0 \cdot \mathbf{f}_0 = 1$. Denote by $\mathbf{F}_0$ the vector space $\mathbf{F}_0 = \{\mathbf{f},\ \mathbf{g}_0 \cdot \mathbf{f} = 0\}$. We can find a positive number $\hat{\alpha}$ that depends only on σ and $\mathbf{u}^L$ such that if $|\tau_0| \leq \hat{\alpha}$, then*

$$\big|\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)\mathbf{f}\big| \geq \hat{c}|\mathbf{f}| \quad \forall \mathbf{f} \in \mathbf{F}_0$$

for some number $\hat{c}$ independent of $\hat{\alpha}$.

Proof. Let $\mathbf{f} \in \mathbb{R}^q$ with $|\mathbf{f}| = 1$. Set

$$\alpha = \Big|\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)\mathbf{f}\Big|.$$

Next, define next the vector $\mathbf{h}$ by (4.19). By Lemma 4.5,

$$\big(\mathbf{A}(\mathbf{u}^L) - \sigma\mathbf{Id}\big)\mathbf{h} = \begin{pmatrix} \mathbf{0} \\ \hat{\mathbf{A}}(\sigma, \mathbf{u}^L)\mathbf{f} \end{pmatrix}$$

so that

$$|(\mathbf{A}(\mathbf{u}^L) - \sigma\mathbf{Id})\mathbf{h}| \leq \alpha.$$

But the matrix $\mathbf{A}(\mathbf{u}^L)$ has p distinct eigenvalues, and we deduce that

$$|\mathbf{h} - a\mathbf{r}_i(\mathbf{u}^L)| \leq C\alpha$$

for some real number a. On the other hand, the same computation applied to the vector $\mathbf{f}_0$ gives

$$|\mathbf{h}_0 - a_0\mathbf{r}_i(\mathbf{u}^L)| \leq C|\tau_0|,$$

where $\mathbf{h}_0$ is obtained from $\mathbf{f}_0$ according to (4.19). We deduce that

$$|\mathbf{h} - \mathbf{h}_0| \leq C(\alpha + |\tau_0|).$$

However, the matrix $\hat{\mathbf{D}}(\sigma, \mathbf{u}^L)$ is regular, and we obtain

$$|\mathbf{f} - \mathbf{f}_0| \leq C(\alpha + |\tau_0|).$$

Next, assume that the vector $\mathbf{f}$ belongs to the vector space $\mathbf{F}_0$. Then

$$1 = |\mathbf{g}_0 \cdot (\mathbf{f} - \mathbf{f}_0)| \leq C(\alpha + |\tau_0|)$$

so that

$$\alpha \geq \frac{1}{C} - |\tau_0|.$$

This concludes the proof of Lemma 4.7. □

Setting $\mathbf{F}_i(\sigma) = \{\mathbf{f} \in \mathbb{R}^p,\ \mathbf{g}_i(\sigma) \cdot \mathbf{f} = 0\}$, the estimate (3.16) follows from Lemma 4.7. The proof of Proposition 4.4 is complete. □

The function $\hat{\Phi}$ obviously satisfies assumption [H2] since it is quadratic in $\mathbf{v}_2$. Finally, we check [H3].

PROPOSITION 4.8. *Let i be an index such that the field $\mathbf{r}_i$ is genuinely nonlinear. Choose $\mathbf{u}^L \in \Omega$ such that $(\lambda_i(\mathbf{u}^L), \mathbf{u}^L)$ satisfies* (2.4) *and* (2.5). *Then the mapping $\hat{\Phi}$ satisfies the assumption* [H3].

Proof. Let $\mathbf{r}_i$ be a GNL field of $\mathbf{A}$ and assume that $(\lambda_i(\mathbf{u}^L), \mathbf{u}^L)$ satisfies (2.4) and (2.5). Let $\mathbf{v}_2 \in \mathbf{u}_2^L + W$. Set $\mathbf{u} = \mathcal{H}(\mathbf{v}_2)$. Then a straightforward computation gives

$$\begin{pmatrix} \mathbf{0} \\ \hat{\Phi}(\sigma, \mathbf{v}_2)(x) \end{pmatrix} = \Phi(\mathbf{u})(x) = \int_{-\infty}^{x} (\mathbf{A}(\mathbf{u}^L) - \mathbf{A}(\mathbf{u}(s)))\mathbf{u}'(s)ds. \tag{4.22}$$

Recalling that the properties of the mapping Φ are given by Lemmas 3.1 and 3.2, we must connect the functions $u_i = \mathbf{l}_i(\mathbf{u}^L) \cdot (\mathbf{u} - \mathbf{u}^L)$ and $v_i = \mathbf{g}_i^0 \cdot (\mathbf{v}_2 - \mathbf{u}_2^L)$, where $\mathbf{g}_i^0 = \mathbf{g}_i(\lambda_i(\mathbf{u}^L))$, to conclude the proof of Proposition 4.8.

LEMMA 4.9. *Assume that the field $\mathbf{r}_i$ is GNL and that $(\lambda_i(\mathbf{u}^L), \mathbf{u}^L)$ satisfies* (2.4) *and* (2.5). *Let $(\sigma, \mathbf{v}_2) \in \mathbb{R} \times (\mathbf{u}_2^L + W)$ such that*

$$|\sigma - \lambda_i(\mathbf{u}^L)| \leq \epsilon_2, \quad \|\mathbf{v}_2 - \mathbf{u}_2^L\|_W \leq \epsilon_2. \tag{4.23}$$

Let $\mathbf{u}_2 = \mathcal{H}_2(\mathbf{v}_2)$ denote the solution of (4.10), *set $\mathbf{u} = (\mathcal{G}(\mathbf{u}_2), \mathbf{u}_2)$, and let*

$$u_i(x) = \mathbf{l}_i(\mathbf{u}^L) \cdot (\mathbf{u}(x) - \mathbf{u}^L), \tag{4.24a}$$

$$v_i(x) = \mathbf{g}_i^0 \cdot (\mathbf{v}_2(x) - \mathbf{u}_2^L). \tag{4.24b}$$

Then, provided that ϵ_2 is small enough,

$$u_i = v_i + \varpi_i(\mathbf{v}_2), \tag{4.25a}$$

where the function ϖ *satisfies*

$$\|\varpi_i(\mathbf{v}_2)\|_W \le C(\epsilon^2 + \|\mathbf{Q}_i^0(\mathbf{v}_2 - \mathbf{u}_2^L\|_W) \quad \forall \mathbf{v}_2 \in \hat{\mathcal{K}}_i^\epsilon, \tag{4.25b}$$

$$\|\varpi(\mathbf{v}_2^1) - \varpi(\mathbf{v}_2^2)\|_W \le C\|\mathbf{v}_2^1 - \mathbf{v}_2^2\|_W \quad \forall \mathbf{v}_2^1,\, \mathbf{v}_2^2 \in \hat{\mathcal{K}}_i^\epsilon. \tag{4.25c}$$

Furthermore,

$$\|\mathbf{u} - \mathbf{u}^L - u_i \mathbf{r}_i(\mathbf{u}^L)\| \le C\left(\epsilon^2 + \|\mathbf{Q}_i^0(\mathbf{v}_2 - \mathbf{u}_2^L)\|\right). \tag{4.26}$$

Proof. Let $(\sigma, \mathbf{v}_2)$ satisfy (4.23) and $\mathbf{u}_2$ denote the solution of (4.10). Then

$$\mathbf{v}_2(x) - \mathbf{u}_2^L = \hat{\mathbf{D}}^0(\mathbf{u}_2(x) - \mathbf{u}_2^L) + \int_{-\infty}^{x} (\hat{\mathbf{D}}(\mathbf{u}(s)) - \hat{\mathbf{D}}^0)\mathbf{u}_2'(s)s,$$

where $\hat{\mathbf{D}}^0 = \hat{\mathbf{D}}(\lambda_i(\mathbf{u}^L), \mathbf{u}^L)$. Next, set $\mathbf{u}_1 = \mathcal{G}(\mathbf{u}_2)$. By the definition of $\mathbf{u}_1$, a straightforward computation gives

$$\left\|\mathbf{u}_1(x) - \mathbf{u}_1^L + \left(\mathbf{A}_1(\mathbf{u}^L) - \lambda_i(\mathbf{u}^L)\mathbf{Id}_r\right)\mathbf{A}_2(\mathbf{u}^L)(\mathbf{u}_2(x) - \mathbf{u}_2^L)\right\|_W \le C\epsilon^2,$$

and we deduce that

$$\left\|\mathbf{u} - \mathbf{u}^L - \mathbf{C}^0\left(\mathbf{v}_2 - \mathbf{u}_2^L\right)\right\| \le C\epsilon^2, \tag{4.27}$$

where the matrix $\mathbf{C}^0$ is given by

$$\mathbf{C}^0 = \begin{pmatrix} -\left(\mathbf{A}_1(\mathbf{u}^L) - \lambda_i(\mathbf{u}^L)\mathbf{Id}_r\right)^{-1}\mathbf{A}_2(\mathbf{u}^L)\left(\hat{\mathbf{D}}^0\right)^{-1} \\ \left(\hat{\mathbf{D}}^0\right)^{-1} \end{pmatrix}. \tag{4.28}$$

On the other hand, apply Lemma 4.5 with $\sigma = \lambda_i(\mathbf{u}^L)$. We obtain the following expression of the eigenvector $\mathbf{r}_i(\mathbf{u}^L)$ of $\mathbf{A}(\mathbf{u}^L)$ in function of $\mathbf{f}_i^0 = \mathbf{f}_i\left(\lambda_i(\mathbf{u}^L)\right)$:

$$\mathbf{r}_i(\mathbf{u}^L) = \mathbf{C}^0\mathbf{f}_i^0.$$

However, the function $\mathbf{v}_2$ is written

$$\mathbf{v}_2(x)\mathbf{u}_2^L = v_i(x)\mathbf{f}_i^0 + \mathbf{Q}_i^0(\mathbf{v}_2(x) - \mathbf{v}_2^L)$$

so that

$$\mathbf{C}^0\left(\mathbf{v}_2(x) - \mathbf{u}_2^L\right) = v_i(x)\mathbf{r}_i(\mathbf{u}^L) + \mathbf{C}^0\mathbf{Q}_i^0(\mathbf{v}_2(x) - \mathbf{u}_2^L). \tag{4.29}$$

Inserting (4.27) in this expression gives

$$\|\mathbf{u} - \mathbf{u}^L - v_i\mathbf{r}_i(\mathbf{u}^L)\|_W \le C(\epsilon^2 + \|\mathbf{Q}_i^0(\mathbf{v}_2 - \mathbf{u}_2^L)\|_W). \tag{4.30}$$

By the definition of the functions u_i and $\varpi(\mathbf{v}_2)$, we deduce (4.25b) from this estimate. On the other hand, the derivation of (4.24c) is straightforward and the estimate (4.26) follows from (4.30) and (4.25b). □

Lemma 4.9 shows that we can choose the constants in the definitions of the two sets $\mathcal{K}_i^\epsilon$ and $\hat{\mathcal{K}}_i^\epsilon$ such that if $\mathbf{v}_2$ belongs to $\hat{\mathcal{K}}_i^\epsilon$, the function $\mathbf{u} = \mathcal{H}(\mathbf{v}_2)$ belongs to $\mathcal{K}_i^\epsilon$. However, for $\mathbf{u}$ belonging to $\mathcal{K}_i^\epsilon$, Lemmas 3.1 and 3.2 apply and—thanks to the identity (4.22)—it is a simple matter to check that the function $\hat{\Phi}$ satisfies assumption [H3]. This completes the proof of Proposition 4.8. $\square$

We can now conclude the proof of Theorem 2.1. Assume that the field $\mathbf{r}_i$ is GNL and choose $\mathbf{u}^L \in \Omega$ such that $(\lambda_i(\mathbf{u}^L), \mathbf{u}^L)$ satisfies (2.4) and (2.5). Then we can find a positive ϵ_0 such that for $\sigma \in \mathbb{R}$ and $\mathbf{u} \in \mathbf{u}^L + W$ that satisfy $|\sigma - \lambda_i(\mathbf{u}^L)| \leq \epsilon_0$ and $\|\mathbf{u} - \mathbf{u}^L\|_W \leq \epsilon_0$, the pair $(\sigma, \mathbf{u})$ is a solution of (1.1) when the pair $(\sigma, \mathbf{v}_2)$ is a solution of (4.17). Next, since hypotheses [H1], [H2], and [H3] hold, we may apply Theorem 3.3. When σ belongs to Σ_i^ϵ, we obtain a solution of (4.17), from which we deduce the existence of a traveling wave $\mathbf{u}_\sigma$ with speed σ and $\mathbf{u}_\sigma(-\infty) = \mathbf{u}^L$, a solution of (1.1). We obtain next the estimate (2.8) from (4.25), and the proof of Theorem 2.1 is complete. $\square$

5. Uniqueness.

This section is devoted to the proof of Theorem 2.2. We assume in this section that every characteristic field $\mathbf{r}_i$ is GNL. Let $(\sigma, \mathbf{u}^L) \in \mathbb{R} \times \Omega$ satisfy (2.4) and (2.5). Let $\mathbf{u}$ be a traveling wave with speed σ and $\mathbf{u}(-\infty) = \mathbf{u}^L$, a solution of (1.1). Set $\delta = |\mathbf{u}(+\infty) - \mathbf{u}^L|$ and assume that

$$\|\mathbf{u} - \mathbf{u}^L\|_W \leq \hat{c}\delta. \tag{5.1}$$

The transformation of system (1.1) into the fixed-point problem (4.17) relies only on (2.4) and (2.5). Provided that δ is small enough, the function $\mathbf{u}$ is written $\mathbf{u} = (\mathbf{u}_1, \mathbf{u}_2)$ with $\mathbf{u}_1 = \mathcal{G}(\mathbf{u}_2)$. Next, the system of differential equations (4.10) has a unique bounded solution $\mathbf{v}_2$ that is a solution of (4.17). Note that only [H2] holds a priori, i.e.,

$$\left\|\hat{\Phi}(\sigma, \mathbf{v}_2)\right\|_W \leq C\delta^2. \tag{5.2}$$

The function $\hat{\Phi}$ is indeed quadratic in $\mathbf{v}_2$. On the contrary, the proofs of [H1] and [H3] rely on the fact that σ is close to one of the eigenvalues of $\mathbf{A}(\mathbf{u}^L)$, which we do not suppose.

To begin, we estimate σ.

LEMMA 5.1. *We can find two positive numbers c_7 and δ_1 such that if $\delta \leq \delta_1$, the matrix $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)$ has a small eigenvalue τ_0:*

$$|\tau_0| \leq c_7\delta. \tag{5.3}$$

Proof. Assume to the contrary that

$$\left|\left(\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)\right)^{-1}\right| \leq C \tag{5.4}$$

for some positive number C. Denote by $\mathbf{E}^+$ (resp., $\mathbf{E}^-$) the sum of the eigenspaces associated with the positive (resp., negative) eigenvalues of $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)$. Next, denote by $\mathbf{R}^+$ (resp., $\mathbf{R}^-$) the projector on $\mathbf{E}^+$ (resp., $\mathbf{E}^-$) with kernel $\mathbf{E}^-$ (resp. $\mathbf{E}^+$). The unique bounded solution of (4.17) is given by

$$\mathbf{R}^+\mathbf{v}_2(x) = \mathbf{R}^+\mathbf{u}_2^L - \int_x^{+\infty} \exp\bigl(\mathbf{R}^+\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)(x-s)\bigr)\hat{\Phi}(\sigma, \mathbf{v}_2)(s)s,$$

$$\mathbf{R}^-\mathbf{v}_2(x) = \mathbf{R}^-\mathbf{u}_2^L + \int_{-\infty}^{x} \exp\bigl(\mathbf{R}^-\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)(x-s)\bigr)\hat{\Phi}(\sigma, \mathbf{v}_2)(s)s.$$

By virtue of (5.4), we deduce that

$$\|\mathbf{v}_2 - \mathbf{u}_2^L\| \leq C\|\hat{\Phi}(\sigma, \mathbf{v}_2)\|_W$$

and, taking into account (5.2), we deduce that

$$\|\mathbf{v}_2 - \mathbf{u}_2^L\|_W \leq C\delta^2.$$

For δ small enough, this contradicts (5.1), and we deduce that the matrix $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)$ has a small eigenvalue τ_0 that satisfies (5.3) for some positive number c_7. □

Henceforth, we assume that $\delta \leq \delta_1$ so that the matrix $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)$ has an eigenvalue τ_0 that satisfies (5.3). Denote by $\mathbf{f}_0$ (resp., $\mathbf{g}_0$) the right (resp., left) eigenvector of $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)$ associated with τ_0. We normalize $\mathbf{g}_0$ by $\mathbf{g}_0 \cdot \mathbf{f}_0 = 1$.

LEMMA 5.2. *We can choose δ_1 such that if $\delta \leq \delta_1$,*

$$|\sigma - \lambda_i(\mathbf{u}^L)| \leq C\delta. \tag{5.5}$$

Proof. Let $\mathbf{h}_0$ denote the vector defined by (4.19) with $\mathbf{f} = \mathbf{f}_0$. According to Lemma 4.5, the pair $(\tau_0, \mathbf{h}_0)$ satisfies

$$\big(\mathbf{A}(\mathbf{u}^L) - \sigma\mathbf{Id}_p\big)\mathbf{h}_0 = \tau\mathbf{D}(\mathbf{u})\mathbf{h}_0,$$

and we deduce that

$$\big|(\mathbf{A}(\mathbf{u}^L) - \sigma\mathbf{Id}_p)\mathbf{h}_0\big| \leq C\delta.$$

However, the matrix $\mathbf{A}(\mathbf{u}^L)$ has p distinct eigenvalues, and if $\delta \leq \delta_1$ with δ_1 chosen small enough, we get (5.5) for some index $i \in \{1, \ldots, p\}$. □

Since $(\sigma, \mathbf{u}^L)$ satisfies (2.4) and (2.5), we obtain that provided that δ is small enough, the pair $(\lambda_i(\mathbf{u}^L), \mathbf{u}^L)$ also satisfies (2.4) and (2.5). The field $\mathbf{r}_i$ is by assumption GNL and we may apply Lemma 4.6. We obtain a C^1 curve $\sigma \rightarrow (\tau_i(\sigma), \mathbf{f}_i(\sigma))$ defined in a neighborhood of $\sigma = \lambda_i(\mathbf{u}^L)$ such that for any σ, the pair $(\tau_i(\sigma), \mathbf{f}_i(\sigma))$ is an eigenpair of $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)$. Then, obviously, the eigenvector $\mathbf{f}_0$ of $\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)$ is $\mathbf{f}_0 = \mathbf{f}_i(\sigma)$. In the same manner, $\mathbf{g}_0 = \mathbf{g}_i(\sigma)$ and $\tau_0 = \tau_i(\sigma)$.

Let $\mathbf{F}_i(\sigma)$ denote the vector space defined by $\mathbf{F}_i(\sigma) = \{\mathbf{f},\ \mathbf{g}_i(\sigma) \cdot \mathbf{f} = 0\}$. The assumptions of Lemma 4.7 are satisfied and provided that δ_1 is chosen small enough, we deduce that

$$\big|\hat{\mathbf{A}}(\sigma, \mathbf{u}^L)\mathbf{f}\big| \geq c_8|\mathbf{f}| \quad \forall \mathbf{f} \in \mathbf{F}_i(\sigma) \tag{5.6}$$

for some number c_8 independent of δ. The behavior of σ is precisely described with the following lemma.

LEMMA 5.3. *The number σ satisfies*

$$|\sigma - \lambda_i(\mathbf{u}^L) - \epsilon/2| \leq C\epsilon^2, \tag{5.7}$$

where

$$\epsilon = \mathbf{l}_i(\mathbf{u}^L) \cdot (\mathbf{u}(+\infty) - \mathbf{u}^L). \tag{5.8}$$

Proof. The function $\mathbf{u}$ is a solution of (1.1). We integrate this system over $\mathbb{R}$ to obtain

$$\big(\mathbf{A}(\mathbf{u}^L) - \sigma\mathbf{Id}\big)(\mathbf{u}(+\infty) - \mathbf{u}^L) = \Phi(\mathbf{u})(+\infty),$$

where $\Phi(\mathbf{u})$ is defined by (3.4). Next, we multiply this system on the left by the eigenvector $\mathbf{l}_i(\mathbf{u}^L)$:

$$\big(\lambda_i(\mathbf{u}^L) - \sigma\big)\mathbf{l}_i(\mathbf{u}^L) \cdot \big(\mathbf{u}(+\infty) - \mathbf{u}^L\big) = \mathbf{l}_i(\mathbf{u}^L) \cdot \hat{\Phi}(\mathbf{u})(+\infty).$$

We have assumed that every characteristic field of $\mathbf{A}$ is GNL, and we may apply Lemma 3.2. We obtain

$$\left|(\lambda_i(\mathbf{u}^L) - \sigma)u_i(+\infty) - \frac{(u_i(+\infty))^2}{2}\right| \leq C\delta^3, \tag{5.9}$$

where $u_i(x) = \mathbf{l}_i(\mathbf{u}^L) \cdot (\mathbf{u}(x) - \mathbf{u}^L)$.

On the other hand, define ϵ by (5.8). Then

$$\big||\epsilon| - \delta\big| \leq C\delta^2. \tag{5.10}$$

Indeed, since the function $\mathbf{Q}_i(\sigma)(\mathbf{v}_2 - \mathbf{u}_2^L)$ is a solution of (3.25), we obtain by virtue of Lemma 3.4 and the estimate (5.6) the following estimate:

$$\big\|\mathbf{Q}_i(\sigma)(\mathbf{v}_2 - \mathbf{u}_2^L)\big\|_W \leq C\delta^2.$$

Next, by the continuity of the mapping $\sigma \to \mathbf{Q}_i(\sigma)$, we deduce that

$$\big\|\mathbf{Q}_i^0(\mathbf{v}_2 - \mathbf{u}_2^L)\big\|_W \leq C\delta^2, \tag{5.11}$$

where $\mathbf{Q}_i^0 = \mathbf{Q}_i(\lambda_i(\mathbf{u}^L))$. Finally, we apply Lemma 4.9. The estimates (5.11) and (4.25) give

$$\|\mathbf{u} - \mathbf{u}^L - u_i\mathbf{r}_i(\mathbf{u}^L)\|_W \leq C\delta^2, \tag{5.12}$$

from which we deduce (5.10).

We insert (5.10) in (5.9) to obtain (5.7).

Thus far, we have proved that all the properties listed in assumptions [H1] and [H2] in §3 hold true. Furthermore, the properties of the function $\hat{\Phi}$ listed in assumption [H3] rely on the algebraic computation (4.22) and on Lemma 4.9 so that [H3] is valid. Next, by virtue of the estimates (5.7) and (5.12), σ belongs to Σ_i^ϵ defined by (3.5) and the function $\mathbf{u}$ belongs to $\mathcal{K}_i^\epsilon$ defined by (3.6) provided that c_0 is chosen large enough. In the same manner, since the function $\mathbf{v}_2$ satisfies (5.11), the pair $(\sigma, \mathbf{v}_2)$ belongs to $\hat{\Sigma}_i^\epsilon \times \hat{\mathcal{K}}_i^\epsilon$ defined by (3.18) and (3.19) provided that c_2 is chosen large enough.

Next, we prove that ϵ defined by (5.8) is negative. By virtue of [H3], the function $v_i = \mathbf{g}_i(\sigma) \cdot (\mathbf{v}_2 - \mathbf{u}_2^L)$ is a solution of the differential equation

$$\tau_i(\sigma)v_i + \frac{(v_i)^2}{2} - v_i' = \hat{\theta}_i(\sigma, \mathbf{v}_2),$$

where $\hat{\theta}$ satisfies (3.23) and

$$v_i(-\infty) = 0, \quad |v_i(+\infty) - \epsilon| \leq C\epsilon^2.$$

However, since σ satisfies (5.7), $\tau_i(\sigma)$ satisfies (3.35) so that $v_i(a) = -\tau_i(\sigma)/2$ for some real number a. The function $w_i = \mathbf{g}_i(\sigma) \cdot (\mathbf{w}_2 - \mathbf{u}_2^L)$, where $\mathbf{w}_2(x) = \mathbf{v}_2(x - a)$, $x \in \mathbb{R}$, is thus a solution of

$$\tau_i(\sigma)w_i + \frac{(w_i)^2}{2} - w_i' = \hat{\theta}_i(\sigma, \mathbf{w}_2), \quad w_i(0) = -\frac{\tau_i(\sigma)}{2}.$$

We can then apply Lemma 3.5:

$$\left\| w_i + \frac{2\tau_i(\sigma)}{1+\exp(-\tau_i(\sigma)x/2)} \right\|_W \le C\epsilon^2. \tag{5.13}$$

By virtue of (3.35), $\tau_i(\sigma)$ has the opposite sign of ϵ. If ϵ is positive, $\tau_i(\sigma)$ is negative, and we deduce from (5.13) that in this case

$$|w_i(-\infty) + \epsilon| \le C\epsilon^2,$$

which contradicts the fact that $w_i(-\infty) = 0$. Hence ϵ is negative.

We can now conclude the proof of Theorem 2.2. The functions $\mathbf{w}_2$ and $\mathbf{v}_2$ are solutions of (4.17). By construction of the mapping $\mathcal{F}$, we have

$$\mathbf{w}_2 = \mathcal{F}(\sigma, \mathbf{w}_2).$$

However, we proved that σ belongs to $\hat{\Sigma}_i^\epsilon$ and $\mathbf{w}_2$ belongs to $\hat{\mathcal{K}}_i^\epsilon$ for some index $i \in \{1, \ldots, p\}$ provided that c_3 in the definitions (3.18) and (3.19) is chosen large enough. On the other hand, we proved that ϵ is negative, and we proved in §3 that if $|\epsilon|$ is small enough, for $\sigma \in \hat{\Sigma}_i^\epsilon$, the mapping $\mathbf{v}_2 \to \mathcal{F}(\sigma, \mathbf{v}_2)$ has a unique fixed point in $\hat{\mathcal{K}}_i^\epsilon$. We deduce that if δ_0 is chosen small enough and if the function $\mathbf{u}$ satisfies (2.9), then $\mathbf{u}(x-a) = \mathbf{u}_\sigma(x)$, where $\mathbf{u}_\sigma$ is given by Theorem 2.1. This concludes the proof of Theorem 2.2. □

Appendix. A nonlinear differential equation. This appendix is devoted to the proof of Lemmas 3.5 and 3.8.

PROPOSITION A.1. *Let $\zeta \in W$ and d_0 be a positive number. We can find a positive δ_0 such that for any $\delta \in (-\delta_0, \delta_0)$, if*

$$\|\zeta\|_W \le d_0|\delta|^3, \tag{A.1}$$

the unique solution of the Cauchy problem

$$-\frac{\delta}{2}w(x) + \frac{(w(x))^2}{2} - w'(x) = \zeta(x), \quad w(0) = \frac{\delta}{2} \tag{A.2}$$

is bounded. $w' \in L^1(\mathbb{R})$ and satisfies the estimate

$$w(x) = \frac{\delta}{1+\exp(\delta x/2)} + z \quad \textit{with} \quad z \in W \quad \textit{and} \quad \|z\|_W \le d_1\delta^2. \tag{A.3}$$

Next, let ζ^m, $m = 1, 2$, satisfy (A.1). *Denote by w^m, $m = 1, 2$, the solution of the differential equation* (A.2), *where ζ is replaced by ζ^m, $m = 1, 2$. We have the estimate*

$$\|w^1 - w^2\|_W \le \frac{d_2}{|\delta|}\|\zeta^1 - \zeta^2\|_W. \tag{A.4}$$

Proof. When $\zeta = 0$, the unique solution of the Cauchy problem (A.2) is

$$w(x) = \frac{\delta}{1+\exp(\delta x/2)}.$$

Next, a function w in the form of (A.3) is a solution of (A.2) if the function z is a solution of the following differential equation:

$$\frac{\delta}{2}\text{th}\left(\frac{\delta x}{4}\right)z(x)+z'(x)=-\zeta(x)+\frac{(z(x))^2}{2},\quad z(0)=0. \tag{A.5}$$

We need the following lemma.

Lemma A.2. *Let $\zeta_1\in W$. Then the unique solution of the linear Cauchy problem,*

$$\frac{\delta}{2}\text{th}\left(\frac{\delta x}{4}\right)z(x)+z'(x)=\zeta(x),\quad z(0)=0, \tag{A.6}$$

lies in W. Furthermore,

$$\|z\|_W\le\frac{d_3}{|\delta|}\|\zeta\|_W. \tag{A.7}$$

Proof. Set $\hat{z}(x)=z(4x/\delta)$ and $\hat{\zeta}(x)=\zeta(4x/\delta)$. Then z is a solution of (A.6) if $\hat{z}$ satisfies

$$2\text{th}(x)\hat{z}(x)+\hat{z}'(x)=\frac{4}{\delta}\hat{\zeta}(x).$$

However, $\|\hat{\zeta}\|_W=\|\zeta\|_W$ and it suffices to prove Lemma A.2 when $\delta=4$. The solution of (A.6) is then

$$z(x)=\frac{-1}{\text{ch}^2(x)}\int_0^x\zeta(s)\text{ch}^2(s)ds,$$

and a straightforward integration by parts gives

$$z(x)=\frac{\zeta(x)}{\text{ch}^2(x)}\left(\frac{\text{sh}(2x)}{4}+\frac{x}{2}\right)-\frac{1}{\text{ch}^2(x)}\int_0^x\zeta'(s)\left(\frac{\text{sh}(2s)}{4}+\frac{s}{2}\right)ds.$$

We deduce that

$$\|z\|_W\le 7\|\zeta\|_W.$$

This concludes the proof of Lemma A.2. □

We solve equation (A.5) by using a fixed-point method. Choose $d_4=4d_3d_0$. Next, let K denote the following closed convex subset of W:

$$K=\left\{z\in W,\ z(0)=0,\ \|z\|_W\le d_4\delta^2\right\}.$$

Choose $\delta_0=1/2d_3d_4$. By Lemma A.2, for $\delta\in(-\delta_0,\delta_0)$ and $y\in K$, the unique solution of the Cauchy problem

$$\frac{\delta}{2}\text{th}\left(\frac{\delta x}{4}\right)z(x)+z'(x)=-\zeta(x)+\frac{(y(x))^2}{2},\quad z(0)=0 \tag{A.8}$$

lies in K. This defines a mapping $\mathcal{G}$ from K into itself. The mapping $\mathcal{G}$ is contracting. Indeed, let δ belong to $(-\delta_0,\delta_0)$, ζ^m, $m=1$, 2, satisfy (A.1), and y^m, $m=1$, 2, belong to K. For $m=1$, 2, denote by z^m the unique solution of the Cauchy problem (A.8), where the functions ζ and y are replaced by ζ^m and y^m, respectively. A straightforward computation gives

$$\frac{\delta}{2}\text{th}\left(\frac{\delta x}{4}\right)(z^1-z^2)(x)+(z^1-z^2)'(x)=(\zeta^2-\zeta^1)(x)+(y^1-y^2)(x)\frac{(y^1+y^2)(x)}{2}.$$

Applying Lemma A.2 again gives

$$\|z^1 - z^2\|_W \le d_3\left(\frac{1}{|\delta|}\|\zeta^1 - \zeta^2\|_W + d_4|\delta|\|y^1 - y^2\|_W\right). \tag{A.9}$$

However, $d_3 d_4|\delta| \le 1/2$ and the mapping $\mathcal{G}$ is thus a contraction. It has a unique fixed point in K, which means that the Cauchy problem (A.5) has a unique solution z. Then the function w defined by (A.3) is a solution of (A.2).

Finally, it remains to prove the estimate (A.4). Let ζ^m, $m = 1, 2$, satisfy (A.1) and denote by w^m, $m = 1, 2$, the solution of the Cauchy problem (A.3) when the function ζ is ζ^m. The estimate (A.9) is written

$$\|z^1 - z^2\|_W \le d_3\left(\frac{1}{|\delta|}\|\zeta^1 - \zeta^2\|_W + d_4|\delta|\,\|z^1 - z^2\|_W\right).$$

However, by construction, $d_3 d_4|\delta| \le 1/2$ and

$$\|z^1 - z^2\|_W \le \frac{2d_3}{|\delta|}\|\zeta^1 - \zeta^2\|_W.$$

This concludes the proof of Proposition A.1. □

Acknowledgments. I am indebted to P.-A. Raviart, who encouraged my interest in nonconservative hyperbolic systems and maintained a constant interest in my work. I also wish to thank D. Serre for many interesting discussions about systems in nonconservation form.

THE STABILITY OF ROLL SOLUTIONS OF THE TWO-DIMENSIONAL SWIFT–HOHENBERG EQUATION AND THE PHASE-DIFFUSION EQUATION*

MASATAKA KUWAMURA†

Abstract. A stability criterion of roll solutions of the two-dimensional Swift–Hohenberg equation is presented. It clarifies the effect of the system size on the primary instabilty of rolls. An interpretation of the phase-diffusion equation is also given from the viewpoint of spectral analysis. The key to carrying out the spectral analysis is that the infinite-dimensional system of linear equations naturally induced by the Fourier decomposition for the linearized eigenvalue problem of the roll solution can be reduced to the three-dimensional system.

Key words. phase-diffusion equation, Eckhauss instability, zigzag instability, Swift–Hohenberg equation

AMS subject classifications. 35B35, 35Q35, 76E15

1. Introduction. Let us consider a fluid contained in a rectangular cell whose aspect ratio of the depth of the fluid to the horizontal width is sufficiently small. For a critical temperature gradient between the upper and lower plates, buoyancy forces overcome the dissipative effects of viscous shear and thermal conduction, and the motionless fluid spontaneously breaks up into convective rolls of upward- and downward-moving regions of fluid as in Figure 1. In order to study this phenomena, the following simple model equation, which was first derived by Swift and Hohenberg [14], is proposed:

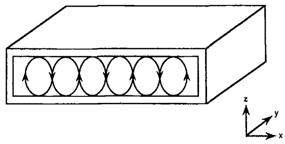

FIG. 1.

$$u_t = (\alpha - (1 + \partial_x^2 + \partial_y^2)^2)u - u^3, \tag{1}$$

where $u(x, y, t)$ represents the rescaled fluid field in a given horizontal plane, e.g., the vertical velocity component in the midplane of the convective rolls, and α is the reduced Rayleigh number, i.e.,

$$\alpha = \frac{R}{R_c} - 1,$$

where R_c is the critical Rayleigh number.

One can heuristically argue that the Swift–Hohenberg equation describes the onset of thermal convection, which forms roll patterns. Let $u \equiv 0$ be the trivial stationary solution of (1), which represents the rest state of the fluid. We immediately find that the eigenvalue of the linearized operator of the right-hand side of (1) at $u \equiv 0$ associated to the Fourier mode $\exp(i(kx + ly))$ is given by

* Received by the editors June 27, 1994; accepted for publication (in revised form) April 19, 1995.

$$\mu_{k,l} = \alpha - (1 - (k^2 + l^2))^2.$$

If $\alpha < 0$, then we see that $\mu_{k,l} < 0$ holds for all k and l, so $u \equiv 0$ is stable. This shows that convection does not occur provided $R < R_c$. If $\alpha > 0$, then we see that the largest eigenvalues are $\mu_{k,l} > 0$ $(k^2 + l^2 = 1)$, so $u \equiv 0$ is unstable. The instability in the direction of the Fourier mode $\exp(\pm ix)$ $(k = \pm 1,\, l = 0)$ grows up, and another equilibrium appears which has a spatially periodic structure in the x-direction and uniform in the y-direction. This shows that the convective rolls occur provided $R > R_c$.

The reader should consult Cross and Hohenberg [2], Greenside and Coughran, Jr. [3], Manneville [9], and Newell [10] for the physical background of the Swift–Hohenberg equation.

The above discussion suggests the possibility that there exist stationary solutions of (1) with $\alpha > 0$ which have a spatially periodic structure in the x-direction and are uniform in the y-direction. In fact, Collet and Eckmann [1] showed the following.

EXISTENCE OF ROLL SOLUTIONS. *Suppose that ω satisfies*

$$2/5 < \omega^2 < 2.$$

Then there exists a positive constant ε_0 independent of ω such that for $0 < \varepsilon < \varepsilon_0$, the equation

$$(\alpha - (1 + \partial_x^2 + \partial_y^2)^2)u - u^3 = 0$$

has a unique solution of the form

$$\alpha = 3\varepsilon^2 + (1 - \omega^2)^2, \tag{2}$$

and

$$u_0(x) = \overline{u}(\omega x), \tag{3}$$

where

$$\overline{u}(z) = \varepsilon 2\cos(z) + \sum_{n \geq 3,\, n:\text{odd}} \eta_n 2\cos(nz) \tag{4}$$

with

$$\mid \eta_n \mid \leq C\varepsilon^{1+2n/3}, \tag{5}$$

where η_n depends only on ω and ε.

Notice that that the roll solutions (3) are also stationary solutions of the one-dimensional Swift–Hohenberg equation

$$u_t = (\alpha - (1 + \partial_x^2)^2)u - u^3. \tag{6}$$

The linear stability criterion of the roll solutions (3) of the one-dimensional Swift–Hohenberg equation (6) was also given in [1] as follows.

LINEAR STABILITY CRITERION. *Let $A : L^2(\mathbf{R}) \longrightarrow L^2(\mathbf{R})$ be the linearized operator of the right-hand side of the above equation at u_0 defined by*

$$Av = (\alpha - (1 + \partial_x^2)^2)v - 3u_0^2 v, \quad v \in H^4(\mathbf{R}).$$

Let

$$W = \frac{\omega^2 - 1}{\sqrt{3}\varepsilon}. \tag{7}$$

If $|W| < 1/\sqrt{2}$, then for sufficiently small $\varepsilon > 0$, the spectrum of A lies in the closed left half-plane in $\mathbf{C}$. On the other hand, if $|W| > 1/\sqrt{2}$, then for sufficiently small $\varepsilon > 0$, the spectrum of A intersects the right half-plane.

On the other hand, Kuramoto [7] and Pomeau and Manneville [12] studied the slow dynamics of (1) near the stationary solutions u_0 from the viewpoint of physics. When one observes a roll pattern in large-aspect-ratio Rayleigh–Bénard convection, the pattern may look almost regular everywhere locally in space, whereas globally, the contours of equal phase may deviate largely from straight lines. Based upon the above observation, they proposed (A) to study the effect of perturbations to the stationary solutions u_0 as the phase modulation of $\overline{u}$ in terms of a longer space scale and a slower time scale than the original one, and (B) to regard as virtually negligible the deformations which are not absorbed in the phase modulation when the new scales are used. They studied the dynamics of the phase modulation of $\overline{u}$ by using the formal perturbation method. They succeeded to show at a formal level that the dynamics near u_0 is given by

$$\begin{cases} \overline{u}(\omega x + \phi(X, Y, T)), \\ \phi_T = D_{//}\phi_{XX} + D_{\perp}\phi_{YY}, \quad X = \nu x, \quad Y = \nu y, \quad T = \nu^2 t, \end{cases} \tag{8}$$

where

$$D_{//} = 4 - 8W^2 + O(\varepsilon), \tag{9}$$

$$D_{\perp} = 2\sqrt{3}\varepsilon W, \tag{10}$$

and W is given by (7). Here ν is an artificial parameter for performing a formal perturbation method. This parameter ν determines the new scales X, Y, and T. The diffusion equation in (8) is called the *phase-diffusion equation* which describes the dynamics near the roll solutions.

Thus u_0 is stable if $D_{//} > 0$ and $D_{\perp} > 0$. On the other hand, u_0 is unstable if either $D_{//} < 0$ (the Eckhauss instability) or $D_{\perp} < 0$ (the zigzag instability). See Figure 2.

According to the results of [7] and [12], we know that when the system size is sufficiently large, there are only two types of instabilities, Eckhauss and zigzag. Our question is now as follows: What happens when the system size is not large? For example, fluid mechanics tells us that the zigzag instability is not observed when the length of the axis of rolls is small. Hence the stability of rolls must decrease as the length of rolls increases. What is the critical length where the stability changes? How does the instability of rolls depend on the system size? The aim of this paper is to answer these questions and give a mathematical justification for the physicist's ideas. Before presenting our main results, we formulate our problem precisely.

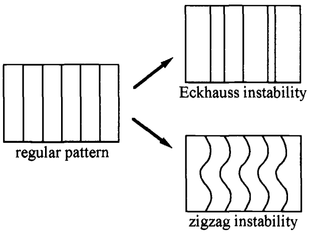

FIG. 2.

We restrict (1), which is originally defined on the infinite spatial domain $\mathbf{R^2}$, to the rectangle domain

$$\Omega = (-L/2, L/2) \times (-M/2, M/2), \quad 0 < L < \infty, \quad 0 < M < \infty$$

with periodic boundary conditions, i.e.,

$$u_t = (\alpha - (1 + \partial_x^2 + \partial_y^2)^2)u - u^3 \quad \text{for} \quad (x, y, t) \in \Omega \times (0, \infty) \tag{11}$$

with

$$\partial_x^j u(-L/2, y, t) = \partial_x^j u(L/2, y, t) \quad (j = 0, 1, 2, 3) \\ \text{for} \quad (y, t) \in (-M/2, M/2) \times (0, \infty)$$

and

$$\partial_y^j u(x, -M/2, t) = \partial_y^j u(x, M/2, t) \quad (j = 0, 1, 2, 3) \\ \text{for} \quad (x, t) \in (-L/2, L/2) \times (0, \infty).$$

This domain Ω serves as a window through which we can practically observe objects of infinite size. Here we assume

$$L = (2N)\lambda,$$

where $\lambda = 2\pi/\omega$ is the wavelength of $u_0(x)$ and N is a positive integer which corresponds to the number of rolls. In other words, the length of the side in the x-direction is an integer multiple of the basic wavelength of the roll pattern. Notice that M is the length of the axis of rolls.

We know that (11) generates a semiflow on $H_{per}^{4\beta}(\Omega)$ for $0 \le \beta < 1$, where

$$H_{per}^{4\beta}(\Omega) = \left\{ u(x, y) = \sum_{m,n=-\infty}^{\infty} u_{m,n} \exp(2\pi i n x/L) \exp(2\pi i m y/M); \right. \\ \left. \sum_{m,n=-\infty}^{\infty} (1 + |m|^2 + |n|^2)^{4\beta} |u_{m,n}|^2 < \infty \right\}.$$

For more details, see Henry [4] and Temam [15].

Notice that $u_0(x)$ is also a stationary solution of (11).

By (2) and (3), u_0 is determined by two parameters ε and ω, which represent the amplitude and wavenumber, respectively. Therefore, the stability of u_0 is determined by these parameters. However, we use a new parameter W instead of ω to investigate the stability of the equilibrium u_0, which is defined by (7). In what follows, we regard ε and W as independent parameters and consider that ω is determined by ε and W in terms of

$$\omega^2 = 1 + \sqrt{3}\varepsilon W. \tag{12}$$

The linear stability criterion of roll solutions is as follows.

THEOREM 1.1. *Let $A : L^2(\Omega) \longrightarrow L^2(\Omega)$ be the linearized operator of the right-hand side of* (1) *at u_0 defined by*

$$Av = (\alpha - (1 + \partial_x^2 + \partial_y^2)^2)v - 3u_0^2 v, \quad v \in H^4(\Omega) \tag{13}$$

with periodic boundary conditions

$$\begin{array}{ll} \partial_x^j v(-L/2, y) = \partial_x^j v(L/2, y) & \text{for} \quad y \in (-M/2, M/2), \\ \partial_y^j v(x, -M/2) = \partial_y^j v(x, M/2) & \text{for} \quad x \in (-L/2, L/2) \\ & (j = 0, 1, 2, 3). \end{array} \tag{14}$$

Then we have the following:

(A) *If $0 \leq W < 1/\sqrt{2}$, then for sufficiently small $\varepsilon > 0$, the spectrum of A lies in the closed left half-plane in* **C**. *This is independent of L and M.*

(B) *If $-1/\sqrt{2} < W < 0$, then for sufficiently small $\varepsilon > 0$,*

(i) *the spectrum of A lies in the closed left half-plane in* **C** *provided*

$$0 < \varepsilon < \frac{2\pi^2}{\sqrt{3}|W|M^2},$$

(ii) *the spectrum of A intersects the right half-plane in* **C** *provided*

$$\varepsilon > \frac{2\pi^2}{\sqrt{3}|W|M^2},$$

where $\varepsilon M^2 = O(1)$ as $\varepsilon \downarrow 0$ and $M \to \infty$.

(C) *If $|W| > 1/\sqrt{2}$, then for sufficiently small $\varepsilon > 0$ and large L, the spectrum of A intersects the right half-plane in* **C**.

When the rectangle domain Ω is sufficiently large and the roll pattern is stable, we can give an accurate characterization of the critical eigenvalues and the associated eigenfunctions.

THEOREM 1.2. *When L and M are sufficiently large, for $0 \leq W < 1/\sqrt{2}$ and sufficiently small $\varepsilon > 0$, there exist $\delta > 0$ which depend only on ε and W* (*independent of L and M*) *such that the following hold:*

(i) $\lim_{\varepsilon\downarrow 0} \delta(\varepsilon, W) = 0$.

(ii) *The eigenvalues of A which belong to the interval $[-\delta, 0]$ are given by*

$$\mu_{mn} = -D_\perp \nu_m - \nu_m^2 - D_{//}\kappa_n^2 + O((\kappa_n + \nu_m)^3)$$

$$\text{for} \quad 0 \leq \nu_m < \sqrt{3}\varepsilon\rho \quad \text{and} \quad |\kappa_n| \leq \sqrt{3}\varepsilon\rho/2,$$

where $D_{//}$ and $D_{\perp}$ are given by (9) *and* (10)*, respectively, and*

$$\nu_m = \left(\frac{2\pi m}{M}\right)^2,$$
$$\kappa_n = \frac{2\pi n}{L},$$

and $\rho > 0$ is a constant independent of ε, W, L, and M. The associated eigenfunctions are given by

$$\psi_{mn} = \partial_x u_0 \exp(2\pi i m y/M) \exp(2\pi i n x/L) + O(\kappa_n) + O(\nu_m).$$

(iii) *The other eigenvalues belong to the interval* $(-\infty, -\delta)$.

Theorem 1.2 says that there are many eigenvalues near zero when the system size is sufficiently large. However, these eigenvalues are discrete because L and M are finite. Therefore, we can take an eigenspace whose dimension is finite but sufficiently large as follows.

THEOREM 1.3. *When $0 < W < 1/\sqrt{2}$ and ε is sufficiently small, for sufficiently large L and M, we can choose $\beta > 0$ and $\gamma > 0$ which depend on ε, W, L, and M such that the following hold:*

(i) *β and γ satisfy*

$$0 < \beta < \gamma,$$
$$\lim_{L,M\to\infty} \beta(\varepsilon, W, L, M) = 0,$$
$$\lim_{L,M\to\infty} (\gamma(\varepsilon, W, L, M) - \beta(\varepsilon, W, L, M)) = 0.$$

(ii) *The eigenvalues of A which belong to the interval $[-\beta, 0]$ are given by*

$$\mu_{mn} = -D_{\perp}\left(\frac{2\pi m}{M}\right)^2 - D_{//}\left(\frac{2\pi n}{L}\right)^2 + o\left(\left(\frac{1}{M} + \frac{1}{L}\right)^2\right)$$

for $|m| \le \rho_1(M)$ and $|n| \le \rho_2(L)$, where $\rho_1(M)$ and $\rho_2(L)$ are integers such that

$$\lim_{M\to\infty} \rho_1(M) = \infty, \quad \lim_{M\to\infty} \frac{\rho_1(M)}{\sqrt[3]{M}} = 0,$$
$$\lim_{L\to\infty} \rho_2(L) = \infty, \quad \lim_{L\to\infty} \frac{\rho_2(L)}{\sqrt[3]{L}} = 0$$

and the associated eigenfunctions are given by

$$\psi_{mn} = \partial_x u_0 \exp(2\pi i m y/M) \exp(2\pi i n x/L) + O(1/M) + O(1/L).$$

(iii) *The eigenvalues μ which belong to the interval $(-\infty, -\beta)$ satisfy*

$$\mu < -\gamma.$$

The choice of the eigenspace in Theorem 1.3 is not unique because it depends on the choice of β and γ. Using an argument in the same spirit as that of inertial-manifold theory, the dynamics near the roll solutions can be well approximated by the dynamics projected on this space [8].

When the domain is square (i.e., $L = M$), we determine a scaling parameter ν by

$$\nu = \frac{\lambda}{L} \left(= \frac{\lambda}{M} \right), \tag{15}$$

where λ is the basic wavelength of roll patterns. Recalling the Fourier series expansion of the solutions of the phase-diffusion equation in (8), we find that under the scaling (15), the dynamics given by (8) are the same as the dynamics on the above eigenspace, i.e., the dynamics defined by the following system of the ordinary differential equations:

$$\frac{da_{mn}}{dT} = -(D_\perp (m\omega)^2 + D_{//}(n\omega)^2) a_{mn},$$

where a_{mn} is the coefficient of the eigenfunction

$$\psi_{mn} = \partial_x u_0 \exp(im\omega Y) \exp(in\omega X) + O(1/M) + O(1/L)$$

and $X = \nu x$, $Y = \nu y$, and $T = \nu^2 t$. Thus we know that the phase-diffusion equation describes the dynamics near the roll solutions and that Theorem 1.3 gives an interpretation of the phase-diffusion equation (8) from the viewpoint of spectral analysis.

The organization of this paper is as follows. Section 2 is devoted to the proof of Theorems 1.1 and 1.2. Our strategy for the proof is as follows. We apply the separation of the variables to the eigenvalue problem corresponding to (13). The y-component of the eigenvalue problem is easily solved. In order to solve the x-component, we apply the Bloch transformation introduced by Collet and Eckmann [1] to study the one-dimensional case. This technique converts the eigenvalue problem in $L^2(-L/2, L/2)$ into the one in $L^2(0, \lambda)$. Next, we deal with the system of linear equations naturally induced by the Fourier decomposition of the eigenvalue problem in the same line of arguments as in [1]. At first glance, it seems to be difficult to solve our problem since the dimension of the system is infinite. However, our system, can be reduced to the three-dimensional system which consists of the Fourier components with wavenumbers $\pm\omega$ and 0. This is the most outstanding property of our system; it enables us to carry out the spectral analysis precisely. Section 3 contains several concluding remarks.

2. Proof of Theorems 1.1 and 1.2. We consider the following eigenvalue problem:

$$Aw = \mu w \quad \text{in} \quad L^2(\Omega), \tag{16}$$

i.e.,

$$\alpha w - (1 + \partial_x^2)^2 w - 3u_0^2 w - 2(1 + \partial_x^2)\partial_y^2 w - \partial_y^4 w = \mu w \quad \text{in} \quad L^2(\Omega) \tag{17}$$

with the periodic boundary conditions in (14). We apply the separation of variables to (17). Let

$$w(x, y) = v(x)\varphi(y).$$

Then it follows from (17) that

$$(\alpha v - (1 + \partial_x^2)^2 v - 3u_0^2 v - \mu v)\varphi = 2(1 + \partial_x^2) v \partial_y^2 \varphi + v \partial_y^4 \varphi. \tag{18}$$

Now we consider the following eigenvalue problem:

$$-\partial_y^2\varphi = \nu\varphi \quad \text{in} \quad L^2(-M/2, M/2) \tag{19}$$

with periodic boundary conditions

$$\partial_y^j\varphi(-M/2) = \partial_y^j\varphi(M/2) \qquad (j = 0, 1). \tag{20}$$

Noting $-\partial_y^4\varphi = \nu\partial_y^2\varphi$ by (19), it follows from (18) that

$$\alpha v - (1 + \partial_x^2)^2 v - 3u_0^2 v + 2\nu(1 + \partial_x^2)v - \nu^2 v = \mu v.$$

For $\nu \geq 0$, let A_ν be the linear operator which maps $L^2(-L/2, L/2)$ into itself defined by

$$A_\nu v = \alpha v - (1 + \partial_x^2)^2 v - 3u_0^2 v + 2\nu(1 + \partial_x^2)v - \nu^2 v \tag{21}$$

with periodic boundary conditions

$$\partial_x^j v(-L/2) = \partial_x^j v(L/2) \qquad (j = 0, 1, 2, 3). \tag{22}$$

Then we obtain the following eigenvalue problem:

$$A_\nu v = \mu v \quad \text{in} \quad L^2(-L/2, L/2) \tag{23}$$

with the periodic boundary conditions in (22). Since (21) is a self-adjoint operator which has a compact resolvent, we denote the eigenvalues of (23) by

$$\mu_n(\nu) \quad \text{for} \quad n = 0, \pm 1, \pm 2, \ldots$$

and the associated eigenfunctions by

$$v_n(\nu) \quad \text{for} \quad n = 0, \pm 1, \pm 2, \ldots.$$

On the other hand, the eigenvalue problem (19) is easily solved. We denote the eigenvalues of (19) by

$$\nu_l = \left(\frac{2\pi l}{M}\right)^2 \quad \text{for} \quad l = 0, \pm 1, \pm 2, \ldots \tag{24}$$

and the associated eigenfunctions by

$$\varphi_l = \exp(2\pi i l y/M) \quad \text{for} \quad l = 0, \pm 1, \pm 2, \ldots. \tag{25}$$

Hence the eigenvalues of (16) are given by

$$\mu_n(\nu_l) \quad \text{for} \quad l, n = 0, \pm 1, \pm 2, \ldots$$

and the associated eigenfunctions by

$$v_n(\nu_l)\varphi_l \quad \text{for} \quad l, n = 0, \pm 1, \pm 2, \ldots.$$

Since $\{v_n(\nu)\}_{n\in\mathbf{Z}}$ and $\{\varphi_l\}_{l\in\mathbf{Z}}$ are complete in $L^2(-L/2, L/2)$ and $L^2(-M/2, M/2)$, respectively, we know that $\{v_n(\nu_l)\varphi_l\}_{l,n\in\mathbf{Z}}$ is complete in $L^2(\Omega)$, namely, all the eigenvalues of (16) are given by $\mu = \mu_n(\nu_l)$. Therefore, we consider the eigenvalue problem (23).

In order to study the eigenvalue problem (23), we use the Bloch technique, which is available for the analysis of Schrödinger operators with periodic potentials. For more details, see Reed and Simon [13].

First, we consider a direct decomposition of the space $L^2(-L/2, L/2)$. For each $n \in [-N, N-1]$, let $X_n = L^2(0, \lambda)$. We denote by X the direct sum $\bigoplus_{n=-N}^{N-1} X_n$ equipped with the inner product

$$\langle x, x'\rangle_X = \sum_{n=-N}^{N-1} \langle x_n, x'_n\rangle_{L^2(0,\lambda)}$$
$$\text{for} \quad x = (x_n) \in X, \quad x_n \in X_n, \quad \text{and} \quad x' = (x'_n) \in X, \quad x'_n \in X_n,$$

and the norm $\| \; x \; \|_X^2 = \langle x, x\rangle_X$. The follwing lemma shows that $X = \bigoplus X_n$ can be identified with $L^2(-L/2, L/2)$.

LEMMA 2.1 (Kuwamura [8, Lem. 1]). *Let U be the linear operator which maps $L^2(-L/2, L/2)$ into X defined by*

$$Uf = ((Uf)_n), \quad (Uf)_n \in X_n,$$
$$(Uf)_n(x) = \frac{1}{\sqrt{2N}} \sum_{m=-N}^{N-1} f(x + \lambda m)e^{-i\kappa_n(x+\lambda m)} \quad \text{for} \quad f \in L^2(-L/2, L/2)$$

and U^* be the linear operator which maps X into $L^2(-L/2, L/2)$ defined by

$$(U^*g)(x + \lambda m) = \frac{1}{\sqrt{2N}} \sum_{n=-N}^{N-1} g_n(x)e^{i\kappa_n(x+\lambda m)}, \quad -N \leq m \leq N-1,$$
$$\text{for} \quad g = (g_n) \in X, \quad g_n \in X_n = L^2(0, \lambda),$$

where $x \in [0, \lambda]$ and $\kappa_n = \omega n/2N = (2\pi n/L)(-N \leq n \leq N-1)$. Then we have

$$\|Uf\|_X^2 = \|f\|_{L^2(-L/2,L/2)}^2,$$

$$\|U^*g\|_{L^2(-L/2,L/2)}^2 = \|g\|_X^2,$$

$$\langle Uf, g\rangle_X = \langle f, U^*g\rangle_{L^2(-L/2,L/2)},$$

$$U^*U = id_{L^2(-L/2,L/2)},$$

$$UU^* = id_X.$$

The operator $A : X \longrightarrow X$ is called decomposable if and only if there exists a family of operators $A_n : X_n \longrightarrow X_n$ such that for each $x = (x_n) \in X$,

$$(Ax)_n = A_n x_n$$

holds. Then we write

$$A = \bigoplus_n A_n.$$

The following theorem shows that the linear operator (21) is decomposable.

THEOREM 2.2. *The operator $A_\nu : L^2(-L/2, L/2) \longrightarrow L^2(-L/2, L/2)$ defined by* (21) *with the periodic boundary conditions in* (22) *is decomposable. More precisely, let $A_{\nu,\kappa_n} : L^2(0,\lambda) \longrightarrow L^2(0,\lambda)$ be the family of operators defined by*

$$A_{\nu,\kappa_n}\psi = \alpha\psi - (1-(\kappa_n - i\partial_x)^2)^2\psi - 3u_0^2\psi + 2\nu(1-(\kappa_n - i\partial_x)^2)\psi - \nu^2\psi, \quad \psi \in H^4(0,\lambda), \tag{26}$$

with periodic boundary conditions

$$\partial_x^j\psi(0) = \partial_x^j\psi(\lambda) \qquad (j = 0,1,2,3), \tag{27}$$

where

$$\kappa_n = \frac{\omega n}{2N} = \frac{2\pi n}{L}, \qquad n \in [-N, N-1]. \tag{28}$$

Then

$$UA_\nu U^* = \bigoplus_n A_{\nu,\kappa_n} \tag{29}$$

holds, where $U^* : X \longrightarrow L^2(-L/2,L/2)$ and $U : L^2(-L/2,L/2) \longrightarrow X$ are given in Lemma 2.1.

Remark. We can obtain (26) as follows: for each $\psi \in L^2(0,\lambda)$, let

$$v(x) = e^{i\kappa_n x}\psi(x), \tag{30}$$

where κ_n is given by (28). Notice that v satisfies the periodic boundary conditions in (22) if and only if ψ satisfies the periodic boundary conditions in (27). Substituting (30) into (23), we have the following eigenvalue problem:

$$A_{\nu,\kappa_n}\psi = \mu\psi \quad \text{in} \quad L^2(0,\lambda) \tag{31}$$

with the periodic boundary conditions (27), where A_{ν,κ_n} is defined by (26). Notice that A_{ν,κ_n} is self-adjoint. The technique which transforms the eigenvalue problem (23) into (31) is called the Bloch technique. The relation (29) is essential for understanding the mathematical background of this technique.

We find that v is an eigenvector of A_ν associated to an eigenvalue μ if and only if there exists some κ_n such that $v(x) = e^{i\kappa_n x}\psi(x)$ holds, where ψ is an eigenvector of A_{ν,κ_n} associated to the eigenvalue μ. Therefore, we consider the eigenvalue problem (31) instead of (23).

Theorem 2.2 can be proved by similar argument to [8, Thm. 2]. Theorems 1.1 and 1.2 are the direct consequences of the following.

THEOREM 2.3. (A) *When $0 \le W < 1/\sqrt{2}$, for sufficiently small ε and each $n \in [-N, N-1]$ and $\nu = \nu_m \ge 0$, all the eigenvalues of A_{ν_m,κ_n} are negative except for the simple zero eigenvalue of A_{ν_0,κ_0}.*

(B) *When $-1/\sqrt{2} < W < 0$, for sufficiently small ε, we have the following:*

(i) *If* $0 < \varepsilon < 2\pi^2/\sqrt{3}|W|M^2$, *then for each* $n \in [-N, N-1]$ *and* $\nu = \nu_m \geq 0$, *all the eigenvalues of* A_{ν_m,κ_n} *are negative except for the simple zero eigenvalue of* A_{ν_0,κ_0}. *Here* $\varepsilon M^2 = O(1)$ *as* $\varepsilon \downarrow 0$ *and* $M \to \infty$.

(ii) *If* $\varepsilon > 2\pi^2/\sqrt{3}|W|M^2$, *then* $A_{\nu_{\pm 1},\kappa_0}$ *has a positive eigenvalue. Here,* $\varepsilon M^2 = O(1)$ *as* $\varepsilon \downarrow 0$ *and* $M \to \infty$.

(C) *When* $|W| > 1/\sqrt{2}$, *for sufficiently small* $\varepsilon > 0$ *and large* L, *there exists some* $n \in [-N, N-1]$ *such that* A_{ν_0,κ_n} *has a positive eigenvalue.*

THEOREM 2.4. *When* L *and* M *are sufficiently large, under the conditions of Theorem* 2.3(A), *there exists* $\rho > 0$ *independent of* ε, W, L, *and* M *such that the following hold:*

(i) *For each* $\kappa_n \in [-\sqrt{3}\rho\varepsilon/2, \sqrt{3}\rho\varepsilon/2]$ *and* $\nu_m \in [0, \sqrt{3}\rho\varepsilon]$, *the principal eigenvalue of* A_{ν_m,κ_n}*—say* μ_{mn}*—satisfies*

$$\mu_{mn} = -D_{\perp}\nu_m - \nu_m^2 - D_{//}\kappa_n^2 + O((\kappa_n + \nu_m)^3),$$

where

$$D_{//} = 4 - 8W^2 + O(\varepsilon),$$
$$D_{\perp} = 2\sqrt{3}\varepsilon W,$$

and

$$\nu_m = \left(\frac{2\pi m}{M}\right)^2,$$
$$\kappa_n = \frac{2\pi n}{L},$$

and the eigenfunction associated to the eigenvalue μ_{mn}*—say* ψ_{mn}*—satisfies*

$$\psi_{mn} = \partial_x u_0 + O(\kappa_n) + O(\nu_m).$$

The other eigenvalues of A_{ν_m,κ_n} *satisfy*

$$\mu < -\delta_1,$$

where $\delta_1 > 0$ *depends only on* ε *and* W.

(ii) *For each* $\kappa_n \notin [-\sqrt{3}\rho\varepsilon/2, \sqrt{3}\rho\varepsilon/2]$ *or* $\nu_m \notin [0, \sqrt{3}\rho\varepsilon]$, *all the eigenvalues of* A_{ν_m,κ_n} *satisfy*

$$\mu < -\delta_2,$$

where $\delta_2 > 0$ *depends only on* ε *and* W.

Proof of Theorems 2.3 *and* 2.4. We consider the eigenvalue problem (31), i.e.,

$$A_{\nu,\kappa_n}\psi = \mu\psi \quad \text{in} \quad L^2(0, \lambda)$$

with the periodic boundary conditions in (27), where

$$A_{\nu,\kappa_n}\psi = \alpha\psi - (1 - (\kappa_n - i\partial_x)^2)^2\psi - 3u_0^2\psi + 2\nu(1 - (\kappa_n - i\partial_x)^2)\psi - \nu^2\psi.$$

We decompose ψ and u_0 into their Fourier components

$$\psi(x) = \sum_m a_m e^{im\omega x}$$

and

$$u_0(x) = \sum_m b_m e^{im\omega x},$$

respectively. By (4) and (5), we know that

$$b_m = \begin{cases} \varepsilon & \text{for} \quad |m| = 1, \\ O(\varepsilon^{1+2|m|/3}) & \text{for} \quad |m| \geq 3, m : \text{odd}, \\ 0 & \text{for} \quad m : \text{even}. \end{cases} \tag{32}$$

Since $\psi \in L^2(0, \lambda)$ is naturally identfied with $(a_m)_{m \in \mathbf{Z}} \in l^2$, (31) is equivalent to the following system of equations:

$$\begin{aligned} &\alpha a_m - (1 - (\kappa_n + m\omega)^2)^2 a_m + 2\nu(1 - (\kappa_n + m\omega)^2) a_m \\ &\quad - \nu^2 a_m - \mu a_m - T_0 a_m = \sum_{r \neq m} T_{m-r} a_r \quad \text{for} \quad m \in \mathbf{Z}, \end{aligned} \tag{33}$$

where

$$T_r = 3 \sum_{p+q=r} b_p b_q.$$

By (32), we have

$$T_m = \begin{cases} 6\varepsilon^2 + O(\varepsilon^6) & \text{for} \quad m = 0, \\ 3\varepsilon^2 + O(\varepsilon^4) & \text{for} \quad |m| = 2, \\ O(|m|\varepsilon^{2(|m|+2)/3}) & \text{for} \quad |m| \geq 4, m : \text{even}, \\ 0 & \text{for} \quad m : \text{odd}. \end{cases} \tag{34}$$

Let

$$\begin{aligned} S_m &= \alpha - (1 - (\kappa_n + m\omega)^2)^2 + 2\nu(1 - (\kappa_n + m\omega)^2) - \nu^2 - T_0 - \mu \\ &= \alpha - \{1 - ((\kappa_n + m\omega)^2 + \nu)\}^2 - T_0 - \mu \end{aligned} \tag{35}$$

and

$$B_{m,j}(\psi) = \sum_{|r-m| \geq j} T_{m-r} a_r.$$

The system of equations (33) is rewritten as follows:

$$S_m a_m = B_{m,1}(\psi) \quad \text{for} \quad m \in \mathbf{Z}. \tag{36}$$

Notice that (36) has a trivial solution $\psi \equiv 0$. We will study (36) as follows. We solve the system of equations

$$S_m a_m = B_{m,1}(\psi) \quad \text{for} \quad |m| \geq 2. \tag{37}$$

for $(\ldots, a_{-3}, a_{-2}, a_2, a_3, \ldots) \in l^2$ as a function of a_{-1}, a_0 and a_1. (37) is solved by using the contraction-mapping theorem. We denote the solution of (37) by

$$a_m = a_m(a_{-1}, a_0, a_1), \quad \text{for} \quad |m| \geq 2. \tag{38}$$

Substituting (38) into

$$\left\{ \begin{aligned} S_{-1}a_{-1} &= B_{-1,1}(\psi), \\ S_0 a_0 &= B_{0,1}(\psi), \\ S_1 a_1 &= B_{1,1}(\psi), \end{aligned} \right. \tag{39}$$

we solve (39) for (a_{-1}, a_0, a_1). Now, we start to solve (37).

The following lemma is the key to reduce the infinite-dimensional system of linear equations (36) to the three-dimensional system (39).

LEMMA 2.5. *For $\mu \geq -1/4$ and sufficiently small $\varepsilon > 0$, the system of equations* (37) *has a unique solution of the following form:*

$$a_m = S_m^{-1} R_m a_0 \quad \text{for} \quad m: \text{ even} \tag{40}$$

and

$$a_m = S_m^{-1} R'_m a_{-1} + S_m^{-1} R''_m a_1 \quad \text{for} \quad m: \text{ odd}, \tag{41}$$

where

$$\begin{aligned} R_{\pm 2} &= T_{\pm 2} + O(\varepsilon^4), \\ R'_{-3} &= T_{-2} + O(\varepsilon^4), \\ R''_{-3} &= O(\varepsilon^4), \\ R'_3 &= O(\varepsilon^4), \\ R''_3 &= T_2 + O(\varepsilon^4), \\ R_m &= O(|m|\varepsilon^{2(|m|+2)/3}) \quad \text{for} \quad |m| \geq 4,\ m: \text{even}, \\ R'_m &= O(|m|\varepsilon^{2(|m|+1)/3}) \quad \text{for} \quad |m| \geq 4,\ m: \text{odd}, \\ R''_m &= O(|m|\varepsilon^{2(|m|+1)/3}) \quad \text{for} \quad |m| \geq 4,\ m: \text{odd}, \end{aligned}$$

Proof. Let $\phi = (\ldots, a_{-3}, a_{-2}, a_2, a_3, \ldots) \in l^2$. Then the system of equations (37) is rewritten as follows:

$$a_m = S_m^{-1} q_m + S_m^{-1} p_m(\phi) \quad \text{for} \quad |m| \geq 2, \tag{42}$$

where q_m is an inhomogeneous term, i.e.,

$$q_m = T_{m+1} a_{-1} + T_m a_0 + T_{m-1} a_1,$$

and $p_m(\phi)$ is a linear operator with respect to ϕ, i.e.,

$$p_m(\phi) = \sum_{|j| \geq 2, j \neq m} T_{m-j} a_j.$$

Noting (2), (12), and

$$\nu \geq 0, \quad |\kappa_n| = \left| \frac{\omega n}{2N} \right| \leq \omega/2,$$

we find

$$\begin{aligned} S_m &= \alpha - (1-(\kappa_n+m\omega)^2)^2 + 2\nu(1-(\kappa_n+m\omega)^2) - \nu^2 - T_0 - \mu \\ &\leq -Cm^4 \end{aligned} \tag{43}$$

for $\mu \geq -1/4$ and $|m| \geq 2$. Moreover, by (34), we have

$$|p_m(\phi)| \leq \left| \sum_{|j|\geq 2, j\neq m} T_{m-j}a_j \right| \leq C\varepsilon^2 \|\phi\|,$$

where

$$\|\phi\| = \left(\sum_{|j|\geq 2} |a_j|^2 \right)^{1/2} .$$

Therefore, (42) is solved by using the contraction-mapping theorem. In fact, the successive approximation starting from $\phi \equiv 0$ can be applied to (42). Then we have

$$a_m = S_m^{-1} R_m a_0 \quad \text{for} \quad m: \text{ even} \tag{44}$$

and

$$a_m = S_m^{-1} R_m' a_{-1} + S_m^{-1} R_m'' a_1 \quad \text{for} \quad m: \text{odd}, \tag{45}$$

where

$$\begin{aligned} R_m = T_m \quad &+ \sum_{|j|\geq 2, j\neq m} T_{m-j}T_jS_j^{-1} \\ &+ \sum_{|j|,|k|\geq 2, j\neq m, k\neq j} T_{m-j}T_{j-k}T_kS_j^{-1}S_k^{-1} \\ &+ \cdots, \end{aligned}$$

$$\begin{aligned} R_m' = T_{m+1} \quad &+ \sum_{|j|\geq 2, j\neq m} T_{m-j}T_{j+1}S_j^{-1} \\ &+ \sum_{|j|,|k|\geq 2, j\neq m, k\neq j} T_{m-j}T_{j-k}T_{k+1}S_j^{-1}S_k^{-1} \\ &+ \cdots, \end{aligned}$$

and

$$\begin{aligned} R_m'' = T_{m-1} \quad &+ \sum_{|j|\geq 2, j\neq m} T_{m-j}T_{j-1}S_j^{-1} \\ &+ \sum_{|j|,|k|\geq 2, j\neq m, k\neq j} T_{m-j}T_{j-k}T_{k-1}S_j^{-1}S_k^{-1} \\ &+ \cdots. \end{aligned}$$

Therefore, (40) and (41) follow from (34) and (43)–(45). □

Now we substitute (40) and (41) into (39). By (34) and (45), we have

$$\begin{aligned} B_{-1,1}(\psi) &= \textstyle\sum_{|r+1|\geq 1} T_{-1-r}a_r \\ &=: P_{-1}a_{-1} + P_1a_1, \end{aligned}$$

where

$$\begin{aligned} P_{-1} &= \textstyle\sum_{|r|\geq 2, r:\mathrm{odd}} T_{-1-r} S_r^{-1} R_r' \\ &= T_{-2} S_{-3}^{-1} T_2 + O(\varepsilon^6) \end{aligned} \tag{46}$$

and

$$\begin{aligned} P_1 &= T_{-2} + \textstyle\sum_{|r|\geq 2, r:\mathrm{odd}} T_{-1-r} S_r^{-1} R_r'' \\ &= T_{-2} + O(\varepsilon^6). \end{aligned} \tag{47}$$

Similarly, we have

$$B_{0,1}(\psi) = V_0 a_0$$

and

$$B_{-1,1}(\psi) = Q_{-1} a_{-1} + Q_1 a_1,$$

where

$$V_0 = T_{-2} S_{-2}^{-1} T_2 + T_{-2} S_2^{-1} T_2 + O(\varepsilon^6), \tag{48}$$

$$Q_{-1} = T_2 + O(\varepsilon^6), \tag{49}$$

and

$$Q_1 = T_{-2} S_3^{-1} T_2 + O(\varepsilon^6). \tag{50}$$

Thus we have the following equations:

$$(S_0 - V_0) a_0 = 0 \tag{51}$$

and

$$\begin{pmatrix} S_{-1} - P_{-1} & -P_1 \\ -Q_{-1} & S_1 - Q_1 \end{pmatrix} \begin{pmatrix} a_{-1} \\ a_1 \end{pmatrix} = 0. \tag{52}$$

First, we may ask whether equation (51) has a nontrivial solution. Suppose that (51) has a nontrivial solution. Then it follows from (35), (48), and (51) that

$$\alpha - \{1 - (\kappa_n^2 + \nu)\}^2 - T_0 - \mu - T_{-2} S_{-2}^{-1} T_2 - T_{-2} S_2^{-1} T_2 + O(\varepsilon^6) = 0.$$

Noting (2), (12), and (34), we have

$$\mu = -3\varepsilon^2 (1 - W^2) - \{1 - (\kappa_n^2 + \nu)\}^2 + O(\varepsilon^4).$$

Hence we see that when $|W| < 1/\sqrt{2}$, for sufficiently small ε,

$$\mu < -\varepsilon^2 (1 - W^2)$$

holds. Thus when $|W| < 1/\sqrt{2}$, there exists $\delta_0 > 0$ independent of ε such that for $\mu > -\delta_0 \varepsilon^2$, the equation (51) has no solution other than the trivial solution.

Next, we may ask whether equation (52) has a nontrivial solution. Noting (2), (12), (34), and (35), we have

$$\begin{pmatrix} S_{-1}-P_{-1} & -P_1 \\ -Q_{-1} & S_1-Q_1 \end{pmatrix} =$$

$$\begin{pmatrix} -3\varepsilon^2(1-W^2)-\{1-((\kappa_n-\omega)^2+\nu)\}^2 & -3\varepsilon^2 \\ -3\varepsilon^2 & -3\varepsilon^2(1-W^2)-\{1-((\kappa_n+\omega)^2+\nu)\}^2 \end{pmatrix}$$
$$-\mu I + O(\varepsilon^4).$$

Hence we consider the eigenvalues of

$$B = \begin{pmatrix} -3\varepsilon^2(1-W^2)-\{1-((\kappa_n-\omega)^2+\nu)\}^2 & -3\varepsilon^2 \\ -3\varepsilon^2 & -3\varepsilon^2(1-W^2)-\{1-((\kappa_n+\omega)^2+\nu)\}^2 \end{pmatrix}.$$

In order to investigate B, it is useful to parametrize ν and κ_n as follows:

$$\nu = \sqrt{3}\varepsilon\nu' \quad \text{for} \quad \nu' \geq 0 \tag{53}$$

and

$$\kappa_n = \sqrt{3}\varepsilon K_n/2. \tag{54}$$

Notice that

$$|K_n| \leq \frac{\omega}{\sqrt{3}\varepsilon}$$

by $|\kappa_n| \leq \omega/2$. Moreover, we set

$$x = \nu' + \sqrt{3}\varepsilon K_n^2/4 \geq 0 \tag{55}$$

and

$$y = \omega K_n. \tag{56}$$

Then, it follows from (53)–(56) and (12) that

$$\{1-((\omega-\kappa_n)^2+\nu)\}^2 = 3\varepsilon^2(W-y+x)^2$$

and

$$\{1-((\omega+\kappa_n)^2+\nu)\}^2 = 3\varepsilon^2(W+y+x)^2.$$

Hence we have

$$\begin{aligned} &-3\varepsilon^2(1-W^2)-\{1-((\kappa_n-\omega)^2+\nu)\}^2 \\ &\quad = -3\varepsilon^2(1+y^2+x^2+2Wx-2Wy-2yx) \end{aligned}$$

and

$$\begin{aligned} &-3\varepsilon^2(1-W^2)-\{1-((\kappa_n+\omega)^2+\nu)\}^2 \\ &\quad = -3\varepsilon^2(1+y^2+x^2+2Wx+2Wy+2yx). \end{aligned}$$

Therefore, the characteristic equation of the matrix $(1/3\varepsilon^2)B$ is given by

$$\begin{aligned}&\lambda^2 + 2(1 + y^2 + x^2 + 2Wx)\lambda \\ &\quad + (1 + y^2 + x^2 + 2Wx)^2 - (2Wy + 2yx)^2 - 1 = 0.\end{aligned}$$

We find that

$$\begin{aligned}&-(1 + y^2 + x^2 + 2Wx) \\ &\quad = -1 + W^2 - y^2 - (x + W)^2 < 0\end{aligned}$$

provided $|W| < 1/\sqrt{2}$. Moreover, we know that

$$\begin{aligned}&(1 + y^2 + x^2 + 2Wx)^2 - (2Wy + 2yx)^2 - 1 \\ &\quad = 2y^2 + 2x^2 - 4W^2(x + W)^2 + 4Wx + \{(x^2 - y^2) + 2W(x + W)\}^2 \\ &\quad \geq \omega^2 + 2x^2 - 4W^2(x + W)^2 + 4Wx\end{aligned}$$

holds provided $|K_n| \geq 1/\sqrt{2}$. Let

$$F(x) = \omega^2 + 2x^2 - 4W^2(x + W)^2 + 4Wx.$$

It is easy to check that when $|W| < 1/\sqrt{2}$,

$$\begin{aligned}F(x) &\geq \omega^2 - 2W^2 \\ &= 1 - 2W^2 + \sqrt{3}\varepsilon W > 0\end{aligned}$$

holds for sufficiently small $\varepsilon > 0$. Therefore, we find that when $|K_n| \geq 1/\sqrt{2}$ and $|W| < 1/\sqrt{2}$,

$$(1 + y^2 + x^2 + 2Wx)^2 - (2Wy + 2yx)^2 - 1 > 0$$

holds for sufficiently small $\varepsilon > 0$. Hence we know that the eigenvalues of $(1/3\varepsilon^2)B$ are negative. Thus there exists $\delta_1 > 0$ independent of ε such that when $|K_n| \geq 1/\sqrt{2}$ and $|W| < 1/\sqrt{2}$, the matrix $B - \mu I$ has no zero eigenvalue, i.e., $|B - \mu I| \neq 0$ for sufficiently small ε and $\mu > -\delta_1\varepsilon^2$. Thus we find that when $|K_n| \geq 1/\sqrt{2}$ and $|W| < 1/\sqrt{2}$,

$$\begin{vmatrix} S_{-1} - P_{-1} & -P_1 \\ -Q_{-1} & S_1 - Q_1 \end{vmatrix} \neq 0$$

holds for $\mu > -\delta_1\varepsilon^2$ and sufficiently small ε, so equation (52) has no solution other than the trivial solution.

Now we consider the case $|K_n| < 1/\sqrt{2}$. In this case, it follows from (53), (54), and (12) that

$$\{1 - ((\omega - \kappa_n)^2 + \nu)\}^2 = 3\varepsilon^2(W - K_n + \nu')^2 + O(\varepsilon^3)$$

and

$$\{1 - ((\omega + \kappa_n)^2 + \nu)\}^2 = 3\varepsilon^2(W + K_n + \nu')^2 + O(\varepsilon^3).$$

Hence we have

$$B = 3\varepsilon^2 \begin{pmatrix} W^2 - 1 - (W - K_n + \nu')^2 & -1 \\ -1 & W^2 - 1 - (W + K_n + \nu')^2 \end{pmatrix} + O(\varepsilon^3)$$

for sufficiently small ε. We consider the eigenvalues of

$$B' = \begin{pmatrix} W^2 - 1 - (W - K_n + \nu')^2 & -1 \\ -1 & W^2 - 1 - (W + K_n + \nu')^2 \end{pmatrix}.$$

We find that the characteristic equation of B' is

$$\begin{aligned}&\lambda^2 + 2(1 + K_n^2 + \nu'^2 + 2W\nu')\lambda \\ &\quad + (1 + K_n^2 + \nu'^2 + 2W\nu')^2 - 4K_n^2(W + \nu')^2 - 1 = 0,\end{aligned}$$

so the eigenvalues of B' are given by

$$\lambda_- = -1 - \nu'^2 - K_n^2 - 2W\nu' - \sqrt{1 + 4K_n^2(W + \nu')^2}$$

and

$$\lambda_+ = -1 - \nu'^2 - K_n^2 - 2W\nu' + \sqrt{1 + 4K_n^2(W + \nu')^2}.$$

We find that when $|W| < 1/\sqrt{2}$,

$$\lambda_- \;=\; -1 + W^2 - (\nu' + W)^2 - K_n^2 - \sqrt{1 + 4K_n^2(W + \nu')^2} \;<\; -1.$$

Using the inequality

$$\sqrt{1 + x} \leq 1 + x/2 \quad \text{for} \quad x \geq 0,$$

we obtain

$$\begin{aligned}\lambda_+ &\leq -1 - \nu'^2 - K_n^2 - 2W\nu' + 1 + 2K_n^2(W + \nu')^2 \\ &= -K_n^2(1 - 2W^2) - (\nu'^2 + 2W\nu')(1 - 2K_n^2).\end{aligned} \tag{57}$$

First, we consider the case $-1/\sqrt{2} < W < 0$. In this case, we know that

$$\nu'^2 + 2W\nu' < 0 \quad \text{for} \quad 0 < \nu' < -2W$$

and

$$\nu'^2 + 2W\nu' > 0 \quad \text{for} \quad \nu' > -2W.$$

By (53) and (24), we recall that

$$\nu'_m = \frac{\nu_m}{\sqrt{3}\varepsilon} = \frac{1}{\sqrt{3}\varepsilon}\left(\frac{2\pi m}{M}\right)^2.$$

Hence if

$$\frac{1}{\sqrt{3}\varepsilon}\left(\frac{2\pi}{M}\right)^2 > -2W,$$

i.e.,

$$0 < \varepsilon < \frac{2\pi^2}{\sqrt{3}|W|M^2},$$

then there exists $\delta_2 > 0$ independent of ε and M such that

$$\lambda_+ < -\delta_2$$

holds provided $\varepsilon M^2 = O(1)$ as $\varepsilon \downarrow 0$ and $M \to \infty$.

On the other hand, if

$$\frac{1}{\sqrt{3}\varepsilon}\left(\frac{2\pi}{M}\right)^2 < -2W,$$

i.e.,

$$\varepsilon > \frac{2\pi^2}{\sqrt{3}|W|M^2},$$

then there exists $\delta_3 > 0$ independent of ε and M such that for $K_n = 0$ and $\nu' = \nu'_{\pm 1}$,

$$\lambda_+ = -(\nu'^2 + 2W\nu') > \delta_3$$

holds provided $\varepsilon M^2 = O(1)$ as $\varepsilon \downarrow 0$ and $M \to \infty$.

Now we consider the case when $0 \le W < 1/\sqrt{2}$. Noting (57), we can choose $\rho > 0$ independent of ε, which will be spcified later such that

$$\lambda_+ \le -\min(\rho^2(1-2W^2), (\rho^2 + 2W\rho)/2)$$

holds for $|K_n| \ge \rho$ or $\nu' \ge \rho$. Hence there exists $\delta_4 > 0$ independent of ε such that when $|K_n| \ge \rho$ or $\nu' \ge \rho$, the matrix $B - \mu I$ has no zero eigenvalue, i.e., $|B - \mu I| \ne 0$ for $\mu > -\delta_4\varepsilon^2$ and sufficiently small ε. Thus we find that when $0 \le W < 1/\sqrt{2}$ and $\max(|K_n|, \nu') \ge \rho$,

$$\begin{vmatrix} S_{-1} - P_{-1} & -P_1 \\ -Q_{-1} & S_1 - Q_1 \end{vmatrix} \ne 0$$

holds for $\mu > -\delta_4\varepsilon^2$ and sufficiently small ε, so the equation (52) has no solution other than the trivial solution.

Finally, we consider the case where $0 \le W < 1/\sqrt{2}$, $|K_n| \le \rho$, and $0 \le \nu' \le \rho$. By (35), (46), (47), (49), and (50), we have

$$\begin{aligned}
&\begin{pmatrix} S_{-1} - P_{-1} & -P_1 \\ -Q_{-1} & S_1 - Q_1 \end{pmatrix} = \\
&\begin{pmatrix} \alpha - T_0 - \mu - \{1 - ((\kappa_n - \omega)^2 + \nu)\}^2 & -3\varepsilon^2 \\ -3\varepsilon^2 & \alpha - T_0 - \mu - \{1 - ((\kappa_n + \omega)^2 + \nu)\}^2 \end{pmatrix} \\
&\qquad +O(\varepsilon^4) \\
&\qquad =: B'' + O(\varepsilon^4)
\end{aligned}$$

for sufficiently small $\varepsilon > 0$. Noting

$$|\kappa_n| \le \sqrt{3}\rho\varepsilon/2 \tag{58}$$

and

$$0 \le \nu \le \sqrt{3}\rho\varepsilon, \tag{59}$$

it follows from (2) and (34) that the eigenvalue of B'' is given by

$$\lambda_\pm = -3\varepsilon^2 \pm 3\varepsilon^2 - \mu + O((\kappa_n + \nu)^2) + o(\varepsilon^2)$$

for sufficiently small ε. Hence we can choose an appropriate $\rho > 0$ independent of ε such that

$$|\lambda_+| > \varepsilon^2/4 \quad \text{for} \quad |\mu| > \varepsilon^2/2$$

and

$$|\lambda_-| > \varepsilon^2/4 \quad \text{for} \quad |\mu + 6\varepsilon^2| > \varepsilon^2/2.$$

Therefore, we find that for $|\mu| > \varepsilon^2/2$ and $|\mu + 6\varepsilon^2| > \varepsilon^2/2$,

$$\begin{vmatrix} S_{-1} - P_{-1} & -P_1 \\ -Q_{-1} & S_1 - Q_1 \end{vmatrix} \neq 0$$

holds, so equation (52) has no solution other than the trivial solution.

Finally, we consider the case $|\mu| < \varepsilon^2/2$ by using analytic-perturbation theory (Kato [5]). Noting (58) and (59), we expand the operator

$$A_{\nu_m,\kappa_n} = \alpha - (1 - (\kappa_n - i\partial_x)^2)^2 - 3u_0^2 + 2\nu_m(1 - (\kappa_n - i\partial_x)^2) - \nu_m^2 \quad \text{in} \quad L^2(0,\lambda)$$

with the periodic boundary conditions in (27) with respect to ν_m and κ_n near $\nu_m = \kappa_n = 0$. In what follows, for simplicity, we suppress the subscripts m and n of ν_m and κ_n, respectively. $A_{\nu,\kappa}$ is expanded in powers of ν and κ as follows:

$$A_{\nu,\kappa} = \sum_{m,n=0}^{4} A^{(m,n)} \nu^m \kappa^n,$$

where

$$\begin{aligned}
A^{(0,0)} &= \alpha - (1 + \partial_x^2)^2 - 3u_0^2, \\
A^{(0,1)} &= -4i(\partial_x + \partial_x^3), \quad A^{(1,0)} = 2(1 + \partial_x^2), \\
A^{(0,2)} &= 2 + 6\partial_x^2, \quad A^{(1,1)} = 4i\partial_x, \quad A^{(2,0)} = -1, \\
A^{(0,3)} &= 4i\partial_x, \quad A^{(1,2)} = -2, \quad A^{(2,1)} = A^{(3,0)} = 0, \\
A^{(0,4)} &= -1, \quad A^{(1,3)} = A^{(2,2)} = A^{(3,1)} = A^{(4,0)} = 0.
\end{aligned}$$

Since $A^{(m,n)}$ is relatively bounded with respect to $A^{(0,0)}$—that is, $\|A^{(m,n)}f\| \leq C(\|A^{(0,0)}f\| + \|f\|)$ holds for some $C > 0$—we can apply analytic-perturbation theory [5, Chap. 7, Thm. 2.6, and Remark 2.7].

We denote by $\mu_{\nu,\kappa}$ the pricipal eigenvalue of $A_{\nu,\kappa}$ and by $\psi_{\nu,\kappa}$ the associated eigenfunction of $\mu_{\nu,\kappa}$. Here we notice that $\mu_{0,0}$ is the simple zero eigenvalue of $A_{0,0}$, and its associated eigenfunction is $\psi_{0,0} = \partial_x u_0 = -2\varepsilon\omega \sin \omega x + O(\varepsilon^3)$. In fact, in a manner similar to the previous argument, we see that $A_{0,0}\psi = 0$ has no solution other than the trivial solution in $\langle \partial_x u_0 \rangle^\perp = \{v \in L^2(0,\lambda); \langle v, \partial_x u_0 \rangle = 0\}$. Hence the geometric multiplicity of $\mu_{0,0}$ is equal to one. Moreover, noting that $A_{0,0}$ is self-adjoint, we find that

$$R(A_{0,0}) = N(A_{0,0}^*)^\perp = N(A_{0,0})^\perp = \langle \partial_x u_0 \rangle^\perp$$

by the closed-range theorem, where R and N denote the range space and null space, respectively. Hence we see that $\partial_x u_0 \notin R(A_{0,0})$, so the algebraic multiplicity of $\mu_{0,0}$ is also equal to one.

Let $\mu_{\nu,\kappa}$ and $\psi_{\nu,\kappa}$ be expanded in powers of ν and κ as follows:

$$\mu_{\nu,\kappa} = \sum_{m,n=0}^{\infty} \mu^{(m,n)} \nu^m \kappa^n$$

and

$$\psi_{\nu,\kappa} = \sum_{m,n=0}^{\infty} \psi^{(m,n)} \nu^m \kappa^n.$$

Substituting this into $A_{\nu,\kappa}\psi_{\nu,\kappa} = \mu_{\nu,\kappa}\psi_{\nu,\kappa}$ and comparing the coefficient of each power of ν and κ, we obtain

$$A^{(0,0)}\psi^{(0,0)} = \mu^{(0,0)}\psi^{(0,0)}, \tag{60}$$

$$A^{(0,0)}\psi^{(0,1)} + A^{(0,1)}\psi^{(0,0)} = \mu^{(0,0)}\psi^{(0,1)} + \mu^{(0,1)}\psi^{(0,0)}, \tag{61}$$

$$A^{(0,0)}\psi^{(1,0)} + A^{(1,0)}\psi^{(0,0)} = \mu^{(0,0)}\psi^{(1,0)} + \mu^{(1,0)}\psi^{(0,0)}, \tag{62}$$

$$\begin{aligned} &A^{(0,0)}\psi^{(0,2)} + A^{(0,1)}\psi^{(0,1)} + A^{(0,2)}\psi^{(0,0)} \\ &= \mu^{(0,0)}\psi^{(0,2)} + \mu^{(0,1)}\psi^{(0,1)} + \mu^{(0,2)}\psi^{(0,0)}, \end{aligned} \tag{63}$$

$$\begin{aligned} &A^{(1,1)}\psi^{(0,0)} + A^{(1,0)}\psi^{(0,1)} + A^{(0,1)}\psi^{(1,0)} + A^{(0,0)}\psi^{(1,1)} \\ &= \mu^{(0,0)}\psi^{(1,1)} + \mu^{(0,1)}\psi^{(1,0)} + \mu^{(1,0)}\psi^{(0,1)} + \mu^{(1,1)}\psi^{(0,0)}, \end{aligned} \tag{64}$$

$$\begin{aligned} &A^{(0,0)}\psi^{(2,0)} + A^{(1,0)}\psi^{(1,0)} + A^{(2,0)}\psi^{(0,0)} \\ &= \mu^{(0,0)}\psi^{(2,0)} + \mu^{(1,0)}\psi^{(1,0)} + \mu^{(2,0)}\psi^{(0,0)}. \end{aligned} \tag{65}$$

Since $A^{(0,0)}$ is the linearized operator of the right-hand side of (6) at u_0, it follows from (60) that

$$\mu^{(0,0)} = 0 \tag{66}$$

and

$$\psi^{(0,0)} = \partial_x u_0 = -2\varepsilon\omega \sin \omega x + O(\varepsilon^3). \tag{67}$$

Hence, by (61) and (66), we have

$$A^{(0,0)}\psi^{(0,1)} = -A^{(0,1)}\psi^{(0,0)} + \mu^{(0,1)}\psi^{(0,0)}. \tag{68}$$

By the solvability condition for $\psi^{(0,1)}$, we have

$$\mu^{(0,1)} = \frac{\langle \psi^{(0,0)}, A^{(0,1)}\psi^{(0,0)} \rangle}{\langle \psi^{(0,0)}, \psi^{(0,0)} \rangle},$$

where $\langle \, , \rangle$ stands for the inner product in $L^2(0, \lambda)$. Noting (67) and the fact that $A^{(0,1)}$ is an odd-order differential operator, we see that

$$\langle \psi^{(0,0)}, A^{(0,1)}\psi^{(0,0)} \rangle = 0,$$

which leads to

$$\mu^{(0,1)} = 0. \tag{69}$$

Hence we can solve (68), i.e.,

$$A^{(0,0)}\psi^{(0,1)} = -A^{(0,1)}\psi^{(0,0)}. \tag{70}$$

Using (12) and (67), we decompose $\psi^{(0,1)}$ and $A^{(0,1)}\psi^{(0,0)}$ into their Fourier components as follows:

$$\psi^{(0,1)} = \sum_m c_m e^{im\omega x}, \quad \overline{c_m} = -c_{-m}$$

and

$$\begin{aligned} A^{(0,1)}\psi^{(0,0)} &= 4i\varepsilon(\omega^2 - \omega^4)(e^{i\omega x} + e^{-i\omega x}) + O(\varepsilon^3) \\ &= -4i\sqrt{3}W\varepsilon^2(e^{i\omega x} + e^{-i\omega x}) + O(\varepsilon^3). \end{aligned}$$

To solve equation (70), we must repeat the same line of arguments as applied to (33). Here we calculate the essential part of equation (70). Recalling (4), we have

$$\begin{aligned} A^{(0,0)}\psi^{(0,1)} &= (\alpha - (1 + \partial_x^2)^2 - 3u_0^2)\psi^{(0,1)} \\ &= \sum_m (\alpha - (1 - m^2\omega^2)^2 - 6\varepsilon^2) c_m e^{im\omega x} \\ &\quad -3\varepsilon^2 \sum_m c_m e^{i(m+2)\omega x} - 3\varepsilon^2 \sum_m c_m e^{i(m-2)\omega x} + O(\varepsilon^3). \end{aligned}$$

Comparing each coefficient of $e^{i\omega x}$ and $e^{-i\omega x}$ in (70), we obtain the following equations for c_1 and c_{-1}:

$$\left\{ \begin{array}{rcl} (\alpha - (1 - \omega^2)^2 - 6\varepsilon^2)c_1 - 3\varepsilon^2 c_{-1} &=& 4i\sqrt{3}W\varepsilon^2, \\ -3\varepsilon^2 c_1 + (\alpha - (1 - \omega^2)^2 - 6\varepsilon^2)c_{-1} &=& 4i\sqrt{3}W\varepsilon^2. \end{array} \right.$$

Noting (2), we have

$$-3\varepsilon^2 \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} c_1 \\ c_{-1} \end{pmatrix} = 4i\sqrt{3}W\varepsilon^2 \begin{pmatrix} 1 \\ 1 \end{pmatrix}.$$

Recalling the condition $\overline{c_1} = -c_{-1}$, we obtain

$$\mathrm{Im}c_1 = \mathrm{Im}c_{-1} = -\frac{2W}{\sqrt{3}}.$$

Therefore, we have

$$\psi^{(0,1)} = -\frac{4iW}{\sqrt{3}}\cos\omega x + C\sin\omega x + O(\varepsilon). \tag{71}$$

Similarly, it follows from (62) and (12) that

$$\begin{aligned} \mu^{(1,0)} &= \frac{\langle\psi^{(0,0)}, A^{(1,0)}\psi^{(0,0)}\rangle}{\langle\psi^{(0,0)}, \psi^{(0,0)}\rangle} \\ &= 2(1-\omega^2) \\ &= -2\sqrt{3}\varepsilon W \end{aligned}$$

and

$$\psi^{(1,0)} = \psi^{(0,0)} = \partial_x u_0.$$

Next, we consider (63). By (66) and (69), we have

$$A^{(0,0)}\psi^{(0,2)} = -A^{(0,1)}\psi^{(0,1)} - A^{(0,2)}\psi^{(0,0)} + \mu^{(0,2)}\psi^{(0,0)}.$$

By the solvability condition for $\psi^{(0,2)}$, we have

$$\mu^{(0,2)} = \frac{\langle\psi^{(0,0)}, A^{(0,1)}\psi^{(0,1)}\rangle + \langle\psi^{(0,0)}, A^{(0,2)}\psi^{(0,0)}\rangle}{\langle\psi^{(0,0)}, \psi^{(0,0)}\rangle}.$$

By (12), (67), and (71), we obtain

$$\begin{aligned} \langle\psi^{(0,0)}, \psi^{(0,0)}\rangle &= 4\varepsilon^2\pi + O(\varepsilon^3), \\ \langle\psi^{(0,0)}, A^{(0,1)}\psi^{(0,1)}\rangle &= 32\varepsilon^2 W^2\pi + O(\varepsilon^3), \\ \langle\psi^{(0,0)}, A^{(0,2)}\psi^{(0,0)}\rangle &= -16\varepsilon^2\pi + O(\varepsilon^3). \end{aligned}$$

Therefore, we find that

$$\mu^{(0,2)} = -4 + 8W^2 + O(\varepsilon).$$

Similarly, it follows from (64) and (65) that

$$\begin{aligned} \mu^{(1,1)} &= 0, \\ \mu^{(2,0)} &= -1. \end{aligned}$$

Thus the proof of Theorems 2.3 and 2.4 is complete. □

3. Concluding remarks. We studied the linear stability of roll solutions of the two-dimensional Swift–Hohenberg equation. We found that the system size affects the stability of the roll solutions. Moreover, we gave an interpretation of the phase-diffusion equation from the viewpoint of spectral analysis when the roll solutions are stable.

A natural question is as follows: What happens when the roll solution is unstable, namely, $D_\perp < 0$ or $D_{//} < 0$? From the viewpoint of spectral analysis, we expect that the primary instability of the roll solutions can be determined by the behavior of the principal eigenvalues. We proceed to perform a higher-order expansion for the eigenvalue problem

$$A_{\nu_m,\kappa_n}\psi_{\nu_m,\kappa_n} = \mu_{\nu_m,\kappa_n}\psi_{\nu_m,\kappa_n}$$

in the proof of Theorems 1.1 and 1.2. We have that for sufficiently small $2\pi m/M$ and $2\pi n/L$, the principal eigenvalues are given by

$$\begin{aligned}\mu_{mn} = &-D_\perp\left(\frac{2\pi m}{M}\right)^2 - D_{//}\left(\frac{2\pi n}{L}\right)^2\\ &-E\left(\frac{2\pi m}{M}\right)^4 - F\left(\frac{2\pi m}{M}\right)^2\left(\frac{2\pi n}{L}\right)^2 - G\left(\frac{2\pi n}{L}\right)^4 + o\left(\left(\frac{1}{M^2}+\frac{1}{L^2}\right)^3\right),\end{aligned}$$

where o is with respect to $1/M$ and $1/L$. E, F, and G are given by

$$E = 1, \quad F = -\frac{16W}{\sqrt{3}\varepsilon} + O(1), \quad G = \frac{32W^4}{3\varepsilon^2} + O\left(\frac{1}{\varepsilon}\right),$$

where O is with respect to ε. It follows that the wavenumbers of fastest growth are

$$m = \pm\frac{M}{2\pi}\sqrt{\frac{-D_\perp}{2E}} = \pm\frac{\sqrt[4]{3}M\sqrt{\varepsilon|W|}}{2\pi}$$

and

$$n = \pm\frac{L}{2\pi}\sqrt{\frac{-D_{//}}{2G}} = \pm\frac{\varepsilon L\sqrt{3(2W^2-1)}}{8\pi W^2}$$

provided $D_\perp < 0$ and $D_{//} < 0$, respectively. Unfortunately, we cannot rigorously prove that there are no other eigenvalues in the right half-plane in **C**. However, we suspect that the primary instability can be determined by the estimate above.

The phase-diffusion equation is ill posed when the roll solutions are unstable. The dynamics near the roll solutions cannot be described by only the dynamics of phase variables. In fact, various complex dynamics such as the wavenumber-changing process, the nucleation of dislocation are observed. Although many researchers have studied these phenomena, nothing has yet been proved by either mathematics or physics. (for instance, see [11] and the references therein).

Acknowledgments. The author expresses his sincere gratitude to the staff of Hiroshima National College of Maritime Technology, especially Professors Mamoru Sakamoto and Mitsuo Funaki, for their kind hospitality.

UNIQUE DETERMINATION OF A COLLECTION OF A FINITE NUMBER OF CRACKS FROM TWO BOUNDARY MEASUREMENTS*

HYUNSEOK KIM[†] AND JIN KEUN SEO[‡]

Abstract. We consider the problem of identification of a collection of a finite number of cracks in a planar domain. It is proved that the location and shape of any finite number of cracks can be determined from boundary-voltage measurements corresponding to two boundary-current fluxes.

Key words. cracks, boundary electric measurements, connected components, Jordan curve theorem

AMS subject classifications. 35R30, 35J25

1. Introduction. In [1], A. Friedman and M. Vogelius proved that the location and shape of a single crack (a curve) inside a planar domain can be uniquely determined from boundary-voltage measurements (Dirchlet data) corresponding to assigning two specific boundary-current fluxes (Neumann data). In [2], K. Bryan and M. Vogelius extended the above result by showing that if one knows a priori that the collection of cracks consists of at most n cracks, then it can be determined by voltage measurements corresponding to $n+1$ specific fluxes. In this paper, we prove that only two measurements are sufficient to determine a collection of cracks (see the Main Theorem below). Since it was proved in [1] that one flux is not sufficient to determine even a single crack, our result may be regarded as an optimal extension of [1] and [2]. We introduce some notations and definitions to precisely describe our result.

Let Ω be a simply connected bounded domain in R^2 with a smooth boundary $\partial\Omega$ and γ a positive real analytic function on $\overline{\Omega}$. By a crack, we mean a C^2 simple curve σ in Ω, i.e., a one-to-one twice continuously differentiable map $\sigma : [0,1] \to \Omega$ with nonvanishing derivative, and by a collection of cracks, we mean a collection of cracks consisting of a finite number of mutually disjoint cracks σ_k, $k = 1, \dots, n$ (possibly $n = 0$).

Given a function $\psi \in L^2(\partial\Omega)$ with average zero, i.e., $\int_{\partial\Omega} \psi\, ds = 0$ and a collection Σ of cracks in Ω, let us denote by $P(\psi, \Sigma)$ the following minimization problem:

$$P(\psi,\Sigma) : \left|\begin{array}{l} \text{Find a function u in } H^1(\Omega) \text{ that minimizes the functional} \\ \displaystyle J(v) = \frac{1}{2}\int\limits_{\Omega\Sigma} \gamma|\nabla v|^2 dx - \int\limits_{\partial\Omega} \psi v\, ds \\ \text{in the class } K = \{v \in H^1(\Omega)\text{: } v \text{ is constant on each } \sigma_k \text{ in } \Sigma\}. \end{array}\right.$$

This minimization problem physically corresponds to minimizing the total energy required to sustain the specified boundary-current flux ψ and the requirement that the potential u is constant on the cracks means that the cracks are perfectly conducting.

A solution u to the problem $P(\psi, \Sigma)$ is continuous on Ω (see Lemma 2.1 in [1]) and satisfies the following boundary value problem:

$$\begin{cases} \nabla \cdot (\gamma \nabla u) = 0 \text{ in } \Omega \backslash \Sigma, \\ u = \ \textit{constant} \ \text{ on each } \sigma_k \in \Sigma, \\ \gamma \dfrac{\partial u}{\partial \nu} = \psi \text{ on } \partial\Omega, \end{cases}$$

where $\frac{\partial}{\partial \nu}$ denotes the outward normal derivative on $\partial\Omega$.

Let us state our main result.

MAIN THEOREM. *Let ψ_1 and ψ_2 be two nonvanishing piecewise-continuous functions on $\partial\Omega$ with average zero such that for each real α, the set $\{z \in \partial\Omega : \psi_1(z) - \alpha\psi_2(z) \geq 0\}$ is connected and ψ_1 is not identical to $\alpha\psi_2$. Suppose that Σ and $\tilde{\Sigma}$ are collections of cracks in Ω and for each $i = 1, 2, u_i$ and $\tilde{u}_i$ are solutions to the problems $P(\psi_i, \Sigma)$ and $P(\psi_i, \tilde{\Sigma})$, respectively. Then $u_i = \tilde{u}_i$ for $i = 1, 2$ on $\partial\Omega$ implies that $\Sigma = \tilde{\Sigma}$.*

Remarks. (1) It is easy to construct functions ψ_i satisfying the hypotheses of the Main Theorem. For completeness, we give an example:

Imagine $\partial\Omega$ as the interval [0, 8] with endpoints 0 and 8 identified.

Define $\psi_i \in C^0([0, 8])$ as follows:

$$\psi_1(x) = \begin{cases} -1 & \text{for all } x \in [0,1] \cup [7,8], \\ 1 & \text{for all } x \in [3,5], \end{cases}$$

$$\psi_2(x) = \begin{cases} 0 & \text{for all } x \in [0,1] \cup [3,5] \cup [7,8], \\ 1 & \text{for } x = 2, \\ -1 & \text{for } x = 6, \end{cases}$$

and

ψ_i's are linear in the remaining domains.

Then the ψ_i's satisfy the hypotheses of the Main Theorem.

(2) Our results extend Theorem 1.1 of [1] for a special case. Indeed, we could remove the restriction $\epsilon \leq \epsilon_0$ of that theorem.

Our proof of the Main Theorem depends heavily on the maximum principle and topological properties of R^2.

In §2 we establish some preliminary lemmas, and in §3 we prove Main Theorem.

2. Preliminary lemmas. Throughout this section, we assume that u is a solution to the minimization problem $P(\psi, \Sigma)$, where ψ is a nonvanishing piecewise-continuous function on $\partial\Omega$ with $\int_{\partial\Omega} \psi \, ds = 0$ and Σ is a collection of cracks in Ω. Clearly, u is nonconstant.

LEMMA 2.1. *Let $\sigma \in \Sigma$, and let Ω' be a subdomain of Ω with $\sigma \subset \Omega'$. Then*

$$\inf_{\Omega'} u < u|_\sigma < \sup_{\Omega'} u.$$

Proof. Let $c = u|_\sigma$. To obtain a contradiction, assume that $c = \sup_{\Omega'} u$.

For $s > 0$, let V_s denote the open set

$$V_s = \{z \in \Omega' : \text{ dist } (z, \sigma) < s\}.$$

Choose $\epsilon > 0$ so small that $\overline{V_{2\epsilon}} \subset \Omega'$ and $(V_{2\epsilon} \backslash \sigma) \cap \Sigma = \emptyset$. If we set $a = \sup_{\partial V_\epsilon} u$; then it follows from the strong-maximum principle that $a < c$.

Let $b = (a + c)/2$, and define

$$\Omega'' = \{z \in V_\epsilon : u(z) > b\}.$$

Then

$$\sigma \subset \Omega'', \qquad \overline{\Omega''} \subset V_\epsilon, \quad \text{and} \quad \partial\Omega'' = \{z \in V_\epsilon : u(z) = b\}.$$

Define

$$\tilde{u} = \begin{cases} b & \text{for all } z \text{ in } \Omega'', \\ u(z) & \text{for all } z \text{ in } \Omega \backslash \Omega''. \end{cases}$$

Then $\tilde{u}$ belongs to the class K and $J(\tilde{u}) \leq J(u)$. Since u is a solution to the minimization problem $P(\psi, \Sigma)$, we obtain $J(\tilde{u}) = J(u)$ and, therefore, $\nabla u = 0$ in Ω''. Hence u is constant in Ω'', and by the analytic continuation, u is constant in Ω—a contradiction. The assumption that $c = \inf_{\Omega'} u$ also leads to the same contradiction. This completes the proof.

LEMMA 2.2. *If Ω' is a subdomain of Ω, then*

$$\inf_{\partial\Omega'} u \leq u(z) \leq \sup_{\partial\Omega'} u \quad \textit{for all } z \in \Omega'.$$

Proof. By the maximum principle, u cannot have a local maximum in $\Omega \backslash \Sigma$. The result now follows from Lemma 2.1.

We now state the key lemma for our proof of the Main Theorem.

LEMMA 2.3. *If the set $\{z \in \partial\Omega : \psi(z) \geq 0\}$ is connected, then we have $\nabla u(z) \neq 0$ for every z in $\Omega \backslash \Sigma$.*

Proof. To obtain a contradiction, assume that $\nabla u(z_0) = 0$ for some z_0 in $\Omega \backslash \Sigma$. Assume for simplicity that $z_0 = 0$ and $u(0) = 0$. Let (r, θ) denote polar coordinates near 0. Since $\nabla u(0) = 0$ and u is analytic near 0, we know that $\frac{\partial}{\partial r} u(0, \theta) = 0$, and by expanding in a Taylor series in r, we obtain

$$u(z) = r^n (a \sin(n\theta) + b \cos(n\theta) + rA(r, \theta))$$

for some a and b (not both zero) and some $n \geq 2$.

Here $A(r, \theta)$ is a smooth function near 0.

Since $a \sin(n\theta) + b \cos(n\theta) = \sqrt{a^2 + b^2} \sin(n\theta + \alpha)$ for some $\alpha \in [0, 2\pi]$, without loss of generality, we may assume by a rotation about 0 that $b = 0$. Since $a \neq 0$, we may also assume that $a > 0$.

Then we have

$$u(z) = u(r, \theta) = r^n (a \sin(n\theta) + rA(r, \theta))$$

and

$$\lim_{r \to 0} \left\{ \frac{u(r, \theta)}{r^n} - a \sin(n\theta) \right\} = 0 \quad \text{uniformly in } \theta.$$

Hence there exists an open disc $B = B(0,\delta)$ in $\Omega\backslash\Sigma$ with center 0 and radius δ such that u is positive in $S_1^+ \cup S_2^+$ and u is negative in $S_1^- \cup S_2^-$, where

$$S_i^+ = \left\{(r,\theta) \in B : \frac{(2i-2)\pi}{n} + \frac{\pi}{4n} < \theta < \frac{(2i-1)\pi}{n} - \frac{\pi}{4n}\right\},$$

and

$$S_i^- = \left\{(r,\theta) \in B : \frac{(2i-1)\pi}{n} + \frac{\pi}{4n} < \theta < \frac{2i\pi}{n} - \frac{\pi}{4n}\right\} \quad (i = 1,2).$$

Set

$$\Omega^+ = \{z \in \Omega : u(z) > 0\} \quad \text{and} \quad \Omega^- = \{z \in \Omega : u(z) < 0\}.$$

For each $i = 1,2$, let Ω_i^+ (respectively, Ω_i^-) denote the connected component of Ω^+ (respectively, Ω^-) containing S_i^+ (respectively, S_i^-). Then the sets Ω_i^+ and Ω_i^- are subdomains of Ω.

CLAIM 1. $\Omega_1^+ \cap \Omega_2^+ = \emptyset$ *and* $\Omega_1^- \cap \Omega_2^- = \emptyset$.

Proof. Suppose that $\Omega_1^+ \cap \Omega_2^+ \neq \emptyset$. Then by the definition of connected components, we see that $\Omega_1^+ = \Omega_2^+$. For each $i = 1,2$, choose a point z_i in S_i^+, and let ρ_i be a line segment in $S_i^+ \cup \{0\}$ whose endpoints are 0 and z_i. Since Ω_i^+ is an open connected subset of R^2, there exists a simple closed curve ρ in $\Omega_i^+ \cup \{0\}$ containing $\rho_1 \cup \rho_2$. Note that from the Jordan curve theorem, the interior of ρ contains either S_1^- or S_2^-. Hence by Lemma 2.2, u is nonnegative in either S_1^- or S_2^-—a contradiction. The assumption that $\Omega_1^- \cap \Omega_2^- \neq \emptyset$ also leads to a similar contradiction.

Set

$$\Gamma_i^+ = \partial\Omega_i^+ \cap \partial\Omega \quad \text{and} \quad \Gamma_i^- = \partial\Omega_i^- \cap \partial\Omega.$$

Then all sets Γ_i^+ and Γ_i^- are nonempty (if $\Gamma_i^+ = \emptyset$, then $\overline{\Omega_i^+} \subset \Omega$ and from the definition of connected components, $u = 0$ on $\partial\Omega_i^+$, which implies by Lemma 2.2 that $u = 0$ in Ω_i^+—a contradiction).

Let z_i^+ and z_i^- be points on $\partial\Omega$ such that

$$u(z_i^+) = \max_{\Gamma_i^+} u \quad \text{and} \quad u(z_i^-) = \min_{\Gamma_i^-} u \quad (i = 1,2).$$

Then by Lemma 2.2,

$$u(z_i^+) = \sup_{\Omega_i^+} u \quad \text{and} \quad u(z_i^-) = \inf_{\Omega_i^-} u \quad (i = 1,2).$$

CLAIM 2. $\psi(z_i^+) > 0$ *and* $\psi(z_i^-) < 0$.

Proof. Since $S_i^- \subset \Omega_i^-$, $u(z_i^-) < 0$ by Lemma 2.2 and since u is continuous on $\overline{\Omega}$, there is an open disc B_i^- centered at z_i^- such that $B_i^- \cap \Omega \subset \Omega_i^-$, and $B_i^- \cap \partial\Omega$ is a smooth portion of $\partial\Omega_i^-$. Hopf's lemma shows that $\psi(z_i^-) = \frac{\partial u}{\partial \nu}(z_i^-) < 0$. The same argument proves that $\psi(z_i^+) > 0$.

For each $i = 1,2$, choose z_i' in S_i^-, and let ρ_i' be a line segment in $S_i^- \cup \{0\}$ whose endpoints are 0 and z_i'. Then since each Ω_i^- is open and connected and since some open ball centered at each z_i^- intersects Ω_i^- as in the proof of Claim 2, there exists a simple curve ρ' in $\Omega_1^- \cup \Omega_2^- \cup \{0, z_1^-, z_2^-\}$ containing $\rho_1' \cup \rho_2'$ whose endpoints are z_1^- and z_2^-. By the Jordan curve theorem, we see that the curve ρ' divides Ω into two subdomains Ω_1 and Ω_2, where $\Omega_1^+ \subset \Omega_1$ and $\Omega_2^+ \subset \Omega_2$.

Note that $\partial\Omega \subset \partial\Omega_1 \cup \partial\Omega_2$, $\partial\Omega \cap \partial\Omega_1 \cap \partial\Omega_2 = \{z_1^-, z_2^-\}$, $z_1^+ \in \partial\Omega_1$, and $z_2^+ \in \partial\Omega_2$. Then it follows from Claim 2 that the set $\{z \in \partial\Omega : \psi(z) \geq 0\}$ consists of at least two disjoint curves, which is contrary to the hypothesis. This completes the proof.

3. Proof of the Main Theorem. It follows from the analytic continuation and continuity of u and $\tilde{u}$ that $u = \tilde{u}$ in Ω; for details, see Bryan and Vogelius [2, §2].

Suppose that $\Sigma \neq \tilde{\Sigma}$. Then we may assume that there is an simple curve ρ in $\Omega \backslash \Sigma$ such that each u_i is constant on ρ. Furthermore, we may assume that ρ is an analytic curve and $\frac{\partial u_2}{\partial \nu}(z_0) \neq 0$ for some z_0 in ρ. Otherwise, u_2 must be constant in Ω by the analytic continuation and $\psi_2 = 0$, which is a contradiction. Set $u = u_1 - \alpha u_2$ and $\psi = \psi_1 - \alpha \psi_2$, where $\alpha = \frac{\partial u_1}{\partial \nu}(z_0) / \frac{\partial u_2}{\partial \nu}(z_0)$. Then $\nabla u(z_0) = 0$, and using a standard argument, we can easily show that u is a solution to the minimization problem $P(\psi, \Sigma)$, which is contrary to Lemma 2.3. This completes the proof.

Remarks. (1) Our technique in this paper does not work in three-dimensional case because we do not have a three-dimensional version of the Jordan curve theorem. Indeed, we do not know how to solve the following interesting problem:

Let B be the unit ball in R^3, σ a curve in B, and ψ a smooth nonzero function on ∂B satisfying $\int_{\partial B} \psi \, ds = 0$. Suppose that the solution u to the Neumann problem

$$\begin{cases} \Delta u = 0 & \text{in } B, \\ \dfrac{\partial u}{\partial \nu} = \psi & \text{on } \partial B \end{cases}$$

satisfies $\nabla u = 0$ on σ. Is the set $\{x \in \partial B : \psi(x) > 0\}$ disconnected?

(2) A referee pointed out that the result in this paper works for the case $\gamma \in C^\infty(\Omega)$.

(3) After this paper was accepted for publication, we learned that a similar result was obtained independently by G. Alessandrini and A. Diaz Valenzuela [*SIAM J. Control. Optim.*, 34 (1996), pp. 913–921].

Acknowledgments. We would like to thank the referees for several valuable comments.

PHASE-FIELD THEORY FOR FITZHUGH–NAGUMO-TYPE SYSTEMS*

PIERPAOLO SORAVIA[†] AND PANAGIOTIS E. SOUGANIDIS[‡]

Abstract. In this paper, we study the asymptotics of Fitzhugh–Nagumo-type systems of reaction-diffusion equations with bistable nonlinearity. In the limit, we obtain an interface moving with normal velocity determined by the dynamics and the scaling.

Key words. Fitzhugh–Nagumo-type systems, phase-field theory, front propagation, phase transition, reaction-diffusion systems

AMS subject classifications. 35K47, 35K55, 35K65

Introduction. Several chemical and biological wave phenomena are modeled by systems of reaction-diffusion equations which, in a simplified form, look like

$$
\begin{cases} \text{(i)} \quad u_t^\epsilon - \alpha\beta\Delta u^\epsilon + \alpha f^\epsilon(u^\epsilon, v^\epsilon) = 0, \\ \\ \text{(ii)} \quad v_t^\epsilon - \epsilon\gamma(b\Delta v^\epsilon - g^\epsilon(u^\epsilon, v^\epsilon)) = 0 \end{cases} \quad \text{in } \mathbb{R}^N \times (0,\infty), \tag{0.1}
$$

where the positive constants α, β, γ, and b are related to the particular physical derivation, the positive parameter ϵ is a measure of the ratio of the rates of change of v^ϵ and u^ϵ, and, finally, the vector field $(u,v) \longrightarrow (f^\epsilon(u,v), g^\epsilon(u,v))$ is of *bistable type.* A typical bistable vector field is

$$
\begin{cases} f(u,v) = (u-\mu)(u^2-1)+v, \\ \\ g(u,v) = \sigma v - u \end{cases} \quad \text{for } \mu \in (-1,1) \text{ and } \sigma > 0. \tag{0.2}
$$

One of the best-known examples of (0.1) is the Fitzhugh–Nagumo model (see Fitzhugh [FH] and Nagumo, Arimoto, and Yoshizawa [NAY]), which describes waves in neural activity and the conduction of electric impulses in nerve axons. Other examples are the Belousov–Zhabatinskii chemical reactions (see Tyson and Fife [TF]). For an expanded list of references about physical problems modeled by (0.1) as well as a detailed discussion on the qualitative properties of the solutions of (0.1), we refer to the monographs of Fife [F1, F2], the papers of Hastings [H] and Chen [Chxy], and the references therein.

In this paper, we study the asymptotic behavior of the solutions of (0.1) in the limit $\epsilon \longrightarrow 0$ for either

$$
\alpha = \gamma = \epsilon^{-1} \quad \text{and} \quad \beta = \epsilon^2 \tag{0.3}
$$

or

$$
\alpha = \epsilon^{-2}, \quad \gamma = \epsilon^{-1}, \quad \text{and} \quad \beta = \epsilon^2. \tag{0.4}
$$

Below we describe our results in a somewhat informal way and only in a special case. The precise statements and assumptions in full generality are formulated in the main body of the paper.

The behavior in the limit $\epsilon \to 0$ of the solutions of (0.1) with (f, g) given by (0.2) when (0.3) holds is governed by the partial differential equation (PDE)

$$v_t - b\Delta v + g_\pm(v) = 0 \quad \text{in } \bigcup_{t>0}(\Omega^\pm(t) \times \{t\}), \tag{0.5}$$

where

$$g_\pm(v) = \sigma v - h_\pm(v),$$

$h_-(v)$ and $h_+(v)$ being the smallest and largest zeroes, respectively, of the map $u \mapsto f(u, v)$. The set

$$\Gamma(t) = \mathbb{R}^N \backslash (\Omega^+(t) \cup \Omega^-(t))$$

moves with normal velocity

$$V = -c(v(x,t)),$$

where $c(v(x,t))$ is the speed of the increasing traveling wave associated with $u \mapsto f(u, v(x,t))$ which connects $h_\pm(v(x,t))$.

To study the asymptotic limit (0.4) as $\epsilon \to 0$ of (0.1), we need to consider $f^\epsilon(u, v) = f(u, \epsilon v)$, where (f, g) is given by (0.2) and $\mu = 0$. In this case, the asymptotics are again governed by (0.5) but now the normal velocity V of the interface is

$$V = \kappa - \dot{c}(0)v(x,t),$$

where κ denotes the mean curvature of the interface. Finally, in either case, the u^ϵ's converge uniformly to $h_\pm(v)$ in $\bigcup_{t>0}\Omega^\pm(t) \times \{t\}$. Notice that all the above statements are global in time and not only up to the first time the geometric evolution develops singularities!

Local-in-time existence of smooth solutions for the limit problem when the speed of the interface is $c(v) - \epsilon\kappa$ was proved by Chen in [Chxy]. Giga, Goto, and Ishii in [GGI] gave a definition of global solutions to the above limit problem and proved their existence. Results equivalent to ours which, however, hold only as long as the evolution is smooth were obtained by Chen (see [Chx]).

We proceed with a brief review of what it means for a surface Γ_t to move with a prescribed normal velocity

$$V = V(Dn, n, x, t). \tag{0.6}$$

Surfaces in $\mathbb{R}^N$ evolving according to this rule can start out smooth and yet develop singularities at a later time. A great deal of work has been done recently in order to interpret the evolution of surfaces *past singularities.* Here we will be using a combination of the so-called *level-set* and *distance-function* approaches. For a detailed description of all approaches and their relationship as well as their consequences, we refer to the papers cited below and references therein.

The *level-set* approach was introduced for numerical calculations by Osher and Sethian (see [OsS]). (See also Ohta, Jasnow, and Kawasaki [OhJK] in the physics literature and Barles [Ba] for a first-order model for flame propagation.) This approach represents the evolving surface as the level set of an auxiliary function solving an appropriate nonlinear PDE. The level-set approach has been extensively developed by Evans and Spruck in [ESp] for motion by mean curvature and independently by Chen, Giga, and Goto (see [ChGG]) for more general geometric motions. Then Giga, Goto, Ishii, and Sato [GGIS] and later Goto [G] and Ishii and Souganidis [IS] used the level-set approach to study motions, where the velocity depends on space and time and V may depend on Dn in a superlinear way, respectively. All the above works are based on the theory of *viscosity solutions* to fully nonlinear second-order parabolic (possibly degenerate) equations, which were introduced by Crandall and Lions in [CrL] and Lions in [L]. (For a detailed overview of the theory of viscosity solutions as well as a complete list of references (until at least 1991), we refer the reader to Crandall, Ishii, and Lions [CrIL]).

The *distance-function* approach, which was initiated by Soner in [So1] and later extended to very general situations by Barles, Soner, and Souganidis (see [BaSS]), is more intrinsic. It describes the motion in terms of the properties of the distance function to the evolving surface. For the precise relation between the two approaches as well as their consequences, we refer to [BaSS].

The generalized evolution $\{\Gamma_t\}_{t\geq 0}$ governed by (0.6), which starts with a given closed surface $\Gamma_0 \subset \mathbb{R}^N$, exists and is uniquely defined for all $t \geq 0$. Moreover, it agrees with the classical differential-geometric flow as long as the latter exists. The geometric motion may, on the other hand, develop singularities, change topological type, and exhibit various other geometric pathologies.

In spite of these peculiarities, the generalized motion $\{\Gamma_t\}_{t\geq 0}$ has been proven in several occasions to be the *right* way to extend the classical motion past singularities. Some of the most definitive results in this direction were obtained by Evans, Soner, and Souganidis (see [ESoS]) and Barles, Soner, and Souganidis (see [BaSS]), who proved that the generalized evolution governs for all times the asymptotic behavior of the following semilinear reaction-diffusion equation, which was proposed by Allen and Cahn in [AC] to describe the time evolution of an "order parameter" u determining the phase of a polycrystalline material:

$$u_t - \alpha\beta\Delta u + \alpha F'(u) = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty)$$

in the limit $\epsilon \to 0^+$ for

$$\alpha = \epsilon^{-1} \quad \text{and} \quad \beta = \epsilon^2 \quad \text{or} \quad \alpha = \epsilon^{-2} \quad \text{and} \quad \beta = \epsilon^2.$$

Here F is a W-shaped potential and α and β are related to the physical model yielding the equation. The choice of the appropriate asymptotic limit is governed by the difference of the depths of the wells of F. The results of [BaSS] apply to more general situations where F also depends on (x, t) (see also [BaBS]). It is exactly this general dependence on the potential that will allow us to obtain in this paper the results mentioned above.

Formal asymptotic expansions suggesting the relation between generalized evolution and the asymptotics of reaction-diffusion equations have been carried out by Caginalp [Ca], Fife [F1, F2], Rubinstein, Sternberg, and Keller [RSK], and others. The radial case was studied by Bronsard and Kohn in [BrK]. In [DeMS], de Mottoni and Schatzmann gave a complete proof for the case of the classical geometric motion. Chen [Chxy] generalized much of this work and gave simpler proofs but still for smooth geometric evolutions, as has Korevaar in unpublished work. Ilmanen [I] and Soner [So2] refined [ESoS] to overcome the possibility of *interface fattening* and Katsoulakis, Kossioris, and Reitich [KKR] studied the asymptotics in bounded domains. Using the asymptotics of reaction-diffusion equations to build a generalized mean-curvature flow has been suggested by Bronsard and Kohn in [BrK], DeGiorgi in [DeG], and others. This is what is called the *phase-field* approach to mean curvature. An immediate consequence of [BaSS], [ESoS], etc. is the equivalance of the level-set/distance-function and phase-field approaches. Another recent result related to the above was obtained by Katsoulakis and Souganidis (see [KS1] and [KS2]), who proved that the hydrodynamic limit of certain interacting particle systems yields (again for all times) generalized front evolution. Finally, for a general theory about how moving fronts arise in the limit of appropriately scaled systems and/or equations, we refer to Barles and Souganidis [BaS]; see also Souganidis [Sou].

The paper is organized as follows. In §1, we formulate the asymptotic problem, state the assumptions, and recall some basic facts. In §2, we recall the precise definition of the generalized evolution and introduce the necessary tools from [BaSS]. Section 3 is devoted to the statement and the proof of our main result. Finally, in §4, we discuss the asymptotics of (0.1) in the limit (0.4).

1. The Fitzhugh–Nagumo model. As mentioned in the introduction, in this paper, we consider the behavior of system (0.1) with initial conditions

$$u^\epsilon = u_0^\epsilon \quad \text{and} \quad v^\epsilon = v_0^\epsilon \quad \text{on } \mathbb{R}^N \times \{0\} \tag{1.1}$$

in the asymptotic limits (0.3) or (0.4). For technical reasons which we will point out later, we will work in a periodic domain $\Pi \times [0,\infty)$, where Π is an N-dimensional torus.

Throughout the paper, we will assume that

$$f^\epsilon \text{ and } g^\epsilon \text{ are smooth} \quad \text{and} \quad f_v^\epsilon \geq 0, \quad g_u^\epsilon \leq 0 \quad \text{for small } \epsilon. \tag{1.2}$$

The sign conditions in (1.2), which are satisfied by (0.2), are not compatible with the standard maximum principle for systems. Our results also hold with similar proofs if instead of (1.2) we assume

$$f_v^\epsilon \geq 0, \quad g_u^\epsilon \geq 0 \quad \text{or} \quad f_v^\epsilon \leq 0, \quad g_u^\epsilon \leq 0 \quad \text{or} \quad f_v^\epsilon \leq 0, \quad g_u^\epsilon \geq 0. \tag{1.3}$$

The next set of assumptions are about the fact that, for each v fixed, $u \to f^\epsilon(u,v)$ is of *bistable* type, i.e., there exist $\overline{v}_- < \overline{v}_+$ such that for all $[v_-,v_+] \subseteq (\overline{v}_-,\overline{v}_+)$, $v \in [v_-,v_+]$, and ϵ and a sufficently small,

$$\begin{cases} u \mapsto f^\epsilon(u,v) - a \text{ vanishes at only three points} \\ \qquad\qquad h_-^\epsilon(v,a) < h_0^\epsilon(v,a) < h_+^\epsilon(v,a) \\ \text{and} \\ \text{(i)} \ f_u^\epsilon(h_\pm^\epsilon(v,a),v) \geq k > 0 \quad \text{and} \quad f_u^\epsilon(h_0^\epsilon(v,a),v) \leq -k \\ \text{(ii)} \ g^\epsilon, h_\pm^\epsilon, h_0^\epsilon \to g, h_\pm, h_0 \quad \text{as } \epsilon \to 0, \end{cases} \tag{1.4}$$

where $k = k(v_-,v_+)$ is independent of ϵ and all the limits are uniform in $v \in [v_-,v_+]$ and a. In view of (1.4), for each ϵ and a sufficiently small and $v \in (\overline{v}_-,\overline{v}_+)$, there exists a unique $c^\epsilon(v,a)$ and a unique-up-to-translations $q^\epsilon(\cdot,v,a)$ (cf. Aronson and Weinberger [AW], Fife and McLeod [FM], etc.) such that

$$q_{rr}^\epsilon(r,v,a) + c^\epsilon(v,a) q_r^\epsilon(r,v,a) = f^\epsilon(q^\epsilon(r,v,a)) - a \tag{1.5}$$

and

$$q^\epsilon(\pm\infty, v, a) = h^\epsilon_\pm(v, a). \tag{1.6}$$

We continue by listing some technical assumptions we make on (q^ϵ, c^ϵ). We then verify these assumptions for some special vector fields like the one given by (0.2). For more general f^ϵ's, we refer to [BaSS].

To this end, we assume that, as $\epsilon \to 0$,

$$q^\epsilon \text{ and } c^\epsilon \text{ depend smoothly on } (v, a) \tag{1.7}$$

and either

$$c^\epsilon(v, a) \to \alpha(v, a) \tag{1.8}$$

or

$$\epsilon^{-1} c^\epsilon(v, \epsilon a) \to \alpha(v, a) \quad \text{if } c^\epsilon(v, \epsilon a) \to 0 \tag{1.9}$$

with all the limits local uniform in (v, a). Moreover, we assume that there exists $K > 0$ (independent of v) such that

$$|\alpha(v, a) - \alpha(\hat{v}, a)| \leq K|v - \hat{v}| \tag{1.10}$$

for all sufficiently small a. In the case that (1.8) holds, we will also assume that there exists $K > 0$ such that

$$\begin{cases} \text{(i)} \ \lim\limits_{\epsilon \to 0} \sup\limits_{(r,v,a)} [\epsilon[|q^\epsilon_v| + |q^\epsilon_{rv}| + |q^\epsilon_a|] + \epsilon^2 |q^\epsilon_{vv}|] = 0, \\ \text{(ii)} \ |q^\epsilon_{rr}| + |q^\epsilon_r| \leq K e^{-K\delta} \quad \text{for all } |r| > \delta. \end{cases} \tag{1.11}$$

If (1.9) holds, then we assume that there exists $K > 0$ such that

$$\begin{cases} \text{(i)} \ \lim\limits_{\epsilon \to 0} \sup\limits_{(r,v,a)} [\epsilon(|q^\epsilon_v| + |q^\epsilon_{vv}| + |q^\epsilon_a|) + |q^\epsilon_{rv}|] = 0, \\ \text{(ii)} \ \frac{1}{\epsilon^2}|q^\epsilon_{rr}| + \frac{1}{\epsilon}|q^\epsilon_r| \leq K e^{-K\delta} \quad \text{for all } |r| > \delta. \end{cases} \tag{1.12}$$

Finally, for all v and ϵ, a sufficiently small, we assume that there exists $M > 0$ such that

$$q^\epsilon_r \geq 0 \quad \text{and} \quad \|q^\epsilon_v\|_\infty \leq M. \tag{1.13}$$

Next, we present a couple of examples where the above hypotheses hold true. Indeed, let $\mu^\epsilon \in (-1, 1)$ and consider either of the functions

$$f^\epsilon(u, v) = (u - \mu^\epsilon)(u^2 - 1) + v \tag{1.14}$$

or

$$f^\epsilon(u, v) = (u - \mu^\epsilon)(u^2 - 1) + \epsilon v. \tag{1.15}$$

It is immediate that in either case (1.4) holds. Moreover, the pair (q^ϵ, c^ϵ) is given by

$$(1.16)\qquad \begin{cases} q^\epsilon(r,v,a) = h_-^\epsilon(v,a) + m^\epsilon(v,a)(1+\exp(-m^\epsilon(v,a)(r+r_0^\epsilon(v,a))/\sqrt{2}))^{-1} \\ \text{and} \\ c^\epsilon(r,v,a) = (2h_0^\epsilon(v,a) - h_+^\epsilon(v,a) - h_-^\epsilon(v,a))/\sqrt{2}, \end{cases}$$

where

$$m^\epsilon(v,a) = h_+^\epsilon(v,a) - h_-^\epsilon(v,a)$$

and $r_0^\epsilon(v,a)$ is appropriately chosen. If f^ϵ is given by (1.15) and $\mu^\epsilon \to 0$, then (1.9) holds and $\alpha(v,a) = \frac{3}{\sqrt{2}}(v+a)$. The rest of the conditions above can be easily checked to hold.

The next set of assumptions are about the initial conditions (1.1). We assume that the periodic-in-Π functions $u_0^\epsilon, v_0^\epsilon \in L^\infty(\mathbb{R}^N)$ are such that, as $\epsilon \to 0$,

$$(1.17)\qquad v_0^\epsilon \to v_0 \quad \text{uniformly},$$

and that there exist an open set $\Omega_0 \subset \mathbb{R}^N$ and a closed, Π-periodic, $(N-1)$-hypersurface Γ_0 such that

$$(1.18)\qquad \mathbb{R}^N = \Omega_0 \cup \overline{\Omega}_0^c \cup \Gamma_0 \text{ (disjoint union)},$$

and the closed sets

$$(1.19)\qquad \Gamma_0^\epsilon = \{x \in \mathbb{R}^N : u_0^\epsilon(x) = h_0^\epsilon(v_0^\epsilon(x))\}$$

converge to Γ_0 in the Hausdorff metric, where

$$h_0^\epsilon(v) = h_0^\epsilon(v,0) \quad \text{and} \quad h_\pm^\epsilon(v) = h_\pm^\epsilon(v,0).$$

For each $\delta > 0$, there exists $\eta = \eta(\delta) > 0$ such that

$$(1.20)\qquad \begin{cases} \varliminf\limits_{\epsilon\to 0} u_0^\epsilon \ge h_0(v_0) + \eta & \qquad\qquad \Omega_0 \cap \{x : \operatorname{dist}(x,\Gamma_0) \ge \delta\}, \\ & \text{locally uniformly in} \\ \varlimsup\limits_{\epsilon\to 0} u_0^\epsilon \le h_0(v_0) - \eta & \qquad\qquad \overline{\Omega}_0^c \cap \{x : \operatorname{dist}(x,\Gamma_0) \ge \delta\}, \end{cases}$$

where $\operatorname{dist}(x,\Gamma_0)$ is the usual distance function from x to Γ_0. Notice that no smoothness is required on u_0^ϵ, Γ_0^ϵ, and Γ_0!

Our last assumption is about the existence of L^∞-bounds on the solution (u^ϵ, v^ϵ) of (0.1) and (1.2) which are independent of ϵ. We assume that

$$(1.21)\qquad \begin{cases} \text{there exist } M > 0,\ T > 0, \text{ and } \rho > 0 \text{ such that for all } \epsilon \text{ small,} \\ v^\epsilon \in (\overline{v}_- + \rho, \overline{v}_+ - \rho) \quad \text{and} \quad |u^\epsilon| \le M \quad \text{in } Q_T = \mathbb{R}^N \times (0,T). \end{cases}$$

This assumption, which is essential to defining $h_\pm^\epsilon$ and h_0^ϵ in (1.4), can be verified for the vector field (0.2) using the theory of invariant regions developed by Rauch and Smoller (see [RS]) and Chueh, Conley, and Smoller (see [ChCS]). The following lemma gives sufficient conditions so that (1.21) holds for any $T > 0$.

LEMMA 1.1. *Assume that $f^\epsilon(u,v)$ is given by* (1.14) *with $\mu = \mu^\epsilon$, $g(u,v) = \sigma v - u$, and that $\{v_0^\epsilon(x) : x \in \mathbb{R}^N\} \subset [v_-, v_+] \subset (\overline{v}_-, \overline{v}_+)$, where $\overline{v}_\pm$ are as in* (1.4). *Set $u_+ = \max_{[v_-,v_+]} h_+(v)$ and $u_- = \min_{[v_-,v_+]} h_-(v)$ and assume $\sigma v_+ > u_+$ and $\sigma v_- < u_-$. Then*

$$v^\epsilon \in [v_-, v_+] \quad \textit{and} \quad u^\epsilon \in [u_-, u_+] \quad \textit{on } \mathbb{R}^N \times (0, +\infty)$$

and $h^\epsilon_\pm(v^\epsilon, a)$ *and* $h^\epsilon_0(v^\epsilon, a)$ *are well defined for all* ϵ *and* a *sufficiently small. Finally, if* $v_c \in (\overline{v}_-, \overline{v}_+)$ *is the unique point such that*

$$\int_{h_-(v_c)}^{h_+(v_c)} f(u, v_c) du = 0$$

and $v_c \notin (v_-, v_+)$, *then* $\alpha(v, 0)$, *given by* (1.8), *has constant sign.* □

The proof of this lemma is based on the results of [ChCS] and the observation that for all suitably small $\rho > 0$, $[v_-, v_+] \times [\sigma v_- + \rho, \sigma v_+ - \rho]$ is, in the language of [RS], a contracting rectangle.

In the case that f^ϵ is given by (1.15) and $\mu^\epsilon = 0$, we need to make the additional assumption

$$0 \in (v_-, v_+). \tag{1.22}$$

We conclude this section with an easy consequence of the assumptions above.

LEMMA 1.2. *Assume* (1.21). *Then along sequences* $\epsilon_n \to 0$, $u^{\epsilon_n} \rightharpoonup u$ *in* $L^\infty(Q_T)$ *weak* $*$ *and* $v^{\epsilon_n} \to v$ *in* $C(Q_T)$.

Proof. The standard weak $*$ compactness of bounded sequences in $L^\infty(Q_T)$ yields that $u^{\epsilon_n} \rightharpoonup u$, $v^{\epsilon_n} \rightharpoonup v$, and $G^{\epsilon_n} = g(u^{\epsilon_n}, v^{\epsilon_n}) \rightharpoonup G$ in $L^\infty(Q_T)$ weak $*$. On the other hand, v^{ϵ_n} is a classical solution of

$$v^{\epsilon_n}_t - b\Delta v^{\epsilon_n} + G^{\epsilon_n} = 0 \quad \text{in } Q_T\,.$$

Classical parabolic theory (see [LUS]) implies that for any $p \in (1, \infty)$, there exists a subsequence (which we again denote by v^{ϵ_n}) $v^{\epsilon_n} \to v$ in $W^{2,1}_p(Q_T)$, where $W^{2,1}_p(Q_T)$ is the usual Sobolev space restricted to Π-periodic functions. (Incidentally, this is one of the places where the periodicity assumption plays a role.) Therefore, v solves (in the sense of distributions) the problem

$$\begin{cases} v_t - b\Delta v + G = 0 & \text{in } Q_T, \\ v = v_0 & \text{on } \mathbb{R}^N \times \{0\}. \end{cases} \tag{1.23}$$

If $p \in (1, \infty)$ is chosen sufficiently large, then $v^{\epsilon_n} \to v$ in $C(Q_T)$ by the standard Sobolev estimates. Finally, the uniqueness of weak solutions to (1.23) yields that the whole sequence $v^{\epsilon_n} \to v$ in $C(Q_T)$. □

Our goal in this paper is to prove a stronger convergence result for the sequence u^{ϵ_n} to find a relationship between u and v and to determine an expression for G.

2. Generalized front propagation.

We begin by recalling the level-set definition of generalized front propagation according to (0.6). Given a closed set $\Gamma_0 \subset \mathbb{R}^N$, $N \geq 2$, choose $\theta_0 \in UC(\mathbb{R}^N)$, where $UC(\Omega)$ denotes the space of uniformly continuous functions defined on Ω, satisfying

$$\Gamma_0 = \{x \in \mathbb{R}^N : \theta_0(x) = 0\} \tag{2.1}$$

and consider the PDEs

$$\begin{cases} \text{(i)} \;\; \theta_t = F(D^2\theta, D\theta, x, t) & \text{in } \mathbb{R}^N \times (0, \infty), \\ \text{(ii)} \;\; \theta = \theta_0 & \text{on } \mathbb{R}^N \times \{t = 0\}. \end{cases} \tag{2.2}$$

The function F is related to V in (0.6) by

$$F(A,p,x,t) = |p|V\left(-\frac{1}{|p|}\left(I - \frac{p\otimes p}{|p|^2}\right)A, -\frac{p}{|p|}, x, t\right) \tag{2.3}$$

for all $x \in \mathbb{R}^N$, $t \geq 0$, $p \in \mathbb{R}^N\backslash\{0\}$, and $A \in S^N$, the space of $N \times N$ symmetric matrices. For the derivation of F, we refer to [ChGG], [BaSS], [IS], etc. As is proved in [ChGG] (see also [BaSS] and [IS] for a relaxation of the assumptions of [ChGG]), the initial value problem (2.2) admits a unique solution $\theta \in UC(\mathbb{R}^N \times (0,\infty))$. (See [BaSS], [ChGG], [ESp], etc. for the relevant definitions, proofs, comments, etc.). Define the closed sets

$$\Gamma_t = \{x \in \mathbb{R}^N : \theta(x,t) = 0\}, \quad t \geq 0, \tag{2.4}$$

and call $\{\Gamma_t\}_{t\geq 0}$ the (level-set) *generalized evolution* according to (0.6) starting from Γ_0. It follows (consult [ChGG], [ESp] in the case Γ_0 is compact, and [BaSS] and [IS] if not) that the definition (2.3) does not depend on the choice of the particular function θ_0 satisfying (2.1). One of the most intriguing questions related to the generalized propagation described above is whether or not the sets Γ_t have interior. This is a rather complicated issue which we do not want to address here. Instead, we refer to [BaSS] for a detailed discussion.

A consequence of the level-set formulation is that the signed distance function to Γ_t satisfies certain equations which we state below. Of course, as mentioned in the introduction, this property of the distance function can also be taken to be the definition of the weak propagation (see [Sol], [BaSS]). To this end, we define the signed distance function $d(x,t)$ from x to Γ_t by

$$d(x,t) = \begin{cases} \operatorname{dist}(x,\Gamma_t) & \text{if } \theta(x,t) > 0, \\ -\operatorname{dist}(x,\Gamma_t) & \text{if } \theta(x,t) < 0, \end{cases} \tag{2.5}$$

where $\operatorname{dist}(x,\Gamma_t)$ is (again) the usual distance from x to Γ_t and $\theta \in UC(\mathbb{R}^N \times (0,\infty))$ is a solution of (2.2) which yields Γ_t.

THEOREM 2.1. *The signed distance function satisfies*

$$\begin{cases} d_t \geq F(D^2d, Dd, x - dDd, t), \\ -(D^2dDd, Dd) \geq 0 \end{cases} \qquad \textit{in } \{d > 0\} \tag{2.6}$$

and

$$\begin{cases} d_t \leq F(D^2d, Dd, x - dDd, t), \\ -(D^2dDd, Dd) \leq 0 \end{cases} \qquad \textit{in } \{d < 0\}. \tag{2.7}$$

For a discussion of the meaning of (2.6) and (2.7) as well as the proof, we refer to [BaSS].

As mentioned in the introduction, one of the most striking applications of the above is the rigorous asymptotics of

$$u_t - \alpha\beta\Delta u + \beta f(x,t,u) = 0 \quad \text{in } \mathbb{R}^N \times (0,\infty).$$

In the next section, we will use the main ideas involved in the proof of the above asymptotics to obtain our main results.

3. The asymptotics $\alpha = \gamma = \epsilon^{-1}$ and $\beta = \epsilon^2$ of the Fitzhugh–Nagumo system.

We consider the system

$$\begin{cases} u_t^\epsilon - \epsilon\Delta u^\epsilon + \frac{1}{\epsilon} f^\epsilon(u^\epsilon, v^\epsilon) = 0, \\ \\ v_t^\epsilon - b\Delta v^\epsilon + g^\epsilon(u^\epsilon, v^\epsilon) = 0, \end{cases} \quad \text{in } \mathbb{R}^N \times (0,\infty) \tag{3.1}$$

with initial condition $(u_0^\epsilon, v_0^\epsilon)$ and we assume (1.2), (1.4), (1.7), (1.8), (1.10), (1.11), (1.13), and (1.17)–(1.21). Lemma 1.2 yields the existence of sequences $\epsilon_n \to 0$ and functions $(u, v) \in L^\infty(Q_T) \times C(Q_T)$ such that $u^{\epsilon_n} \rightharpoonup u$ in $L^\infty(Q_T)$ weak $*$ and $v^{\epsilon_n} \to v$ in $C(Q_T)$. Let $\alpha(v) = \alpha(v, 0)$ be given by (1.8) and consider the front $\{\Gamma_t\}_{t \geq 0}$ defined by the geometric PDEs

$$\begin{cases} \theta_t + \alpha(v(x,t))|D\theta| = 0 & \text{in } \mathbb{R}^N \times (0,\infty), \\ \\ \theta = d_0 & \text{on } \mathbb{R}^N \times \{0\}, \end{cases} \tag{3.2}$$

where d_0 is the signed distance function from Γ_0, which is given by (1.18)–(1.20). Finally, let d be the signed distance function given by (2.5).

THEOREM 3.1. *Assume* (1.2), (1.4), (1.7), (1.8), (1.10), (1.11), (1.13), *and* (1.17)–(1.21) *and consider the functions* (u, v) *given by Lemma* 1.2 *for a given sequence* $\epsilon_n \to 0$, *and the front* Γ_t *which moves with normal velocity* $-\alpha(v)$. *Then*

$$\begin{cases} u = \begin{cases} h_+(v) & \{d > 0\} \\ & \text{in} \\ h_-(v) & \{d < 0\} \end{cases}, \quad u \in [h_-(v), h_+(v)] \quad \text{a.e. on } \Gamma_t, \\ \text{and} \\ u^{\epsilon_n} \to u \text{ locally uniformly in } \{d \neq 0\}. \end{cases} \tag{3.3}$$

Moreover, v satisfies (in the sense of distributions) the singular limit problem

$$v_t - b\Delta v + G(v) = 0 \quad \text{in } Q_T, \tag{3.4}$$

where

(3.5)

$$G(v) = \begin{cases} g(h_-(v), v) & \text{in } \{d < 0\} \\ \\ g(h_+(v), v) & \text{in } \{d > 0\} \end{cases} \quad \text{and} \quad G(v) \in [g(h_+(v), v), g(h_-(v), v)] \quad \text{a.e. on } \Gamma_t.$$

The existence of solutions of (3.4) and (3.5) was proved by Giga, Goto, and Ishii [GGI] by a method completely different from ours.

The assertion of Theorem 3.1 can be substantially strengthened as indicated in Theorem 3.2 below in the case where the front defined by (3.2) does not develop interior. For example, this can happen (cf. [BaSS]) when $\alpha(v(x,t))$ does not change sign. A sufficient condition for this to happen in the case of (0.2) is given by Lemma 1.1. Theorem 3.2 asserts that if interior does not develop, the conclusions of Theorem 3.1 hold for the whole family (u^ϵ, v^ϵ) and not only along sequences.

THEOREM 3.2. *In addition to the assumptions of Theorem* 3.1, *assume that*

$$\operatorname{meas}\{(x,t) : \theta(x,t) = 0\} = 0, \tag{3.6}$$

where θ *is the solution of* (3.2). *Then*

$$u^\epsilon \to \begin{cases} h_+(v) & \\ & \textit{locally uniformly in} \\ h_-(v) & \end{cases} \quad \begin{matrix} \{d > 0\} \\ \\ \{d < 0\} \end{matrix}$$

and

$$v^\epsilon \to v \quad \textit{in } C(Q_T).$$

In what follows, we will present the proofs of Theorems 3.1 and 3.2 under the additional hypothesis that

$$u_0^\epsilon(x) = q^\epsilon\left(\frac{d_0(x)}{\epsilon}, v_0^\epsilon(x), 0\right), \tag{3.7}$$

where d_0 is the signed distance function from Γ_0, $r \to q^\epsilon(r, v_0^\epsilon(x), 0)$ solves (1.5) and (1.6), and $q^\epsilon(0, v, 0) = h_0^\epsilon(v)$. This assumption is made only in order to simplify the presentation below. The general case follows by combining our arguments with those of Chen [Chx].

The basic step of the proof of Theorem 3.1 is based upon an adaptation of the proof presented in [BaSS] for the asymptotics of the scalar reaction-diffusion equation

$$u_t^\epsilon - \epsilon\Delta u^\epsilon + \frac{1}{\epsilon} f^\epsilon(u^\epsilon, x, t) = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty), \tag{3.8}$$

where f^ϵ is of bistable type. The proof is based upon building super- and subsolutions of (3.8) of the form

$$q^{a,\epsilon}\left(\frac{w^{a,\delta}}{\epsilon}, x, t\right),$$

where $q^{a,\epsilon}$ is a traveling wave corresponding to $u \mapsto f^\epsilon(u, x, t) \pm a$ and $w^{a,\delta}$ is some approximation to the signed distance of the limiting front.

In preparation for the proof of Theorem 3.1, we first regularize the function $v \in C(Q_T)$, which is obtained as the limit of v^{ϵ_n} by Lemma 1.2 by means of a sequence $(v^m)_{m\in\mathbf{N}} \subset C^{2,1}(Q_T)$ such that $v^m \to v$ in $C(Q_T)$. Then we approximate (3.2) by

$$\begin{cases} \theta_t^{a,\delta,m} + \alpha(v^m, a)|D\theta^{a,\delta,m}| = 0 & \text{in } \mathbb{R}^N \times (0, \infty), \\ \theta^{a,\delta,m} = d_0 + \delta & \text{on } \mathbb{R}^N \times \{0\}, \end{cases} \tag{3.9}$$

where $\alpha(v^m, a)$ is the limit of $c^\epsilon(v^m, a)$, which exists by (1.8) and $\delta > 0$. Observe that the assumptions on f^ϵ yield that $\alpha(v^m, a) \to \alpha(v)$ as $m \to \infty$ and $a \to 0$. Finally, the stability results of the geometric PDEs (cf. [BaSS]) yield

$$\theta^{a,\delta,m} \to \theta \quad \text{in } C(Q_T) \quad \text{as } m \to \infty, \quad \delta \to 0, \quad a \to 0. \tag{3.10}$$

As in [ESoS] and [BaSS], we introduce the auxiliary function $\eta_\delta : \mathbb{R} \to \mathbb{R}$ satisfying

$$\begin{cases} \eta_\delta \text{ is smooth}, \quad 0 \le \eta_\delta' \le C, \quad |\eta_\delta''| \le C\delta^{-1}, \quad \text{and} \\ \eta_\delta(z) = -\delta \quad \text{if } z \le \delta/4, \quad \eta_\delta(z) = z - \delta \quad \text{if } z \ge \delta/2, \end{cases} \tag{3.11}$$

and define

$$w^{a,\delta,m}(x,t) = \eta_\delta(d^{a,\delta,m}(x,t)),$$

where $x \mapsto d^{a,\delta,m}(x,t)$ is the signed distance function from the set

$$\{y \in \mathbb{R}^N : \theta^{a,\delta,m}(y,t) = 0\}.$$

A straightforward modification of the proof of Lemma 10.1 of [BaSS] yields the following.

LEMMA 3.1. *We have*

$$w_t^{a,\delta,m} + \alpha(v^m(x - w^{a,\delta,m}Dw^{a,\delta,m},t),a)|Dw^{a,\delta,m}| \geq -o(1) \ \ in\ \mathbb{R}^n \times (0,t^*),$$

where t^* is the extinction time of $\{\theta^{a,\delta,m} = 0\}$ and the $o(1)$, as $\delta \to 0$, only depends on the modulus of continuity of $v \in C(Q_T)$ and not on a, δ and m. Finally,

$$|Dw^{a,\delta,m}| = 1 \ \ in\ \left\{d^{a,\delta,m} > \frac{\delta}{2}\right\}.$$

We can now complete the construction of the supersolution which we need for the proof of Theorem 3.1. Since a subsolution can be built by a straightforward adaptation of the above, we omit the details. To this end, let q^ϵ be a traveling wave which corresponds to $u \mapsto f^\epsilon(u,v) - a$ and define

$$\Phi^{a,\delta,m,\epsilon}(x,t) = q^\epsilon\left(\frac{w^{a,\delta,m}(x,t)}{\epsilon}, v^m(x,t), a\right). \tag{3.12}$$

LEMMA 3.2. *Assume* (3.12) *and the assumptions of Theorem* 3.1. *Given $a > 0$, there exists $m_0 = m_0(a)$ such that for all $m \geq m_0$, there exists $\delta_0(a,m)$ such that for all $\delta \leq \delta_0$ there exists $\epsilon_0(a,m,\delta)$ with the property that for all $\epsilon \leq \epsilon_0(a,m,\delta)$, $\Phi^{a,m,\delta,\epsilon}$ is a supersolution of*

$$\phi_t - \epsilon\Delta\phi + \frac{1}{\epsilon}f^\epsilon(\phi,v^\epsilon) \geq 0 \quad in\ Q_T. \tag{3.13}$$

The proof of Lemma 3.2 follows along the lines of the proof of Theorem 9.1 of [BaSS] with few technical adjustments. For completeness we present it below, assuming for simplicity, however, that $w^{a,m,\delta}$ has derivatives, instead of interpreting all statements in the viscosity sense. This can be done easily following [ESoS] and [BaSS]. Finally, to simplify the notation we drop the superscripts whenever it does not create any confusion.

Proof. 1. The equation for the traveling wave yields

$$\begin{aligned} \Phi_t - \epsilon\Delta\Phi + \frac{1}{\epsilon}f^\epsilon(\Phi,v^\epsilon) &= \frac{1}{\epsilon}q_r^\epsilon(w_t - \epsilon\Delta w + c^\epsilon(v^m,a)) + \frac{a}{\epsilon} \\ &- \frac{1}{\epsilon}q_{rr}^\epsilon(|Dw|^2 - 1) + \frac{1}{\epsilon}[f^\epsilon(\Phi,v^\epsilon) - f^\epsilon(\Phi,v^m)] + J, \end{aligned} \tag{3.14}$$

where

$$J = q_v^\epsilon(v_t^m - \epsilon\Delta v^m) - 2q_{rv}^\epsilon Dw \cdot Dv^m - \epsilon q_{vv}^\epsilon|Dv^m|^2,$$

with the above quantities evaluated at $(w(x,t)/\epsilon, v^m(x,t), a)$.

In view of the assumptions on q^ϵ and the choice v^m, it follows that for each fixed m,

$$|\epsilon J| = o(1) \text{ as } \epsilon \to 0$$

uniformly in δ and a.

2. Choose m large and then ϵ small enough so that

$$\begin{gathered}\|v^\epsilon - v\|_\infty + \|v^m - v\|_\infty \le (4K)^{-1}a, \\ \|c^\epsilon(v^m, a) - \alpha(v^m, a)\|_\infty \le 4^{-1}a,\end{gathered}$$

and

$$|\epsilon J| \le 4^{-1}a,$$

where, by (1.4) and (1.21), $\|f_v^\epsilon\| \le K$ in $[-M, M] \times [\overline{v}_- + \rho_1 \overline{v}_+ - \rho]$. Using all of the above, (3.14) yields

$$\Phi_t - \epsilon\Delta\Phi + \frac{1}{\epsilon}f^\epsilon(\Phi, v^\epsilon) \ge \frac{q_r^\epsilon}{\epsilon}(w_t - \epsilon\Delta w + \alpha(v^m, a)) + \frac{a}{4\epsilon} - \frac{q_{rr}^\epsilon}{\epsilon}(|Dw|^2 - 1), \tag{3.15}$$

where again q_r^ϵ and q_{rr}^ϵ are evaluated at $(w/\epsilon, v^m, a)$.

3. We now use the inequalities for w given by Lemma 3.2. We have the following cases.

Case 1: $\delta/2 < d < 2\delta$. Lemma 3.1 yields

$$\Phi_t - \epsilon\Delta\Phi + \frac{1}{\epsilon}f^\epsilon(\Phi, v^\epsilon) \ge \frac{q_r^\epsilon}{\epsilon}\left(-\frac{\epsilon C}{\delta} - (K+1)Co(1)\right) + \frac{a}{4\epsilon} \ge 0$$

for $\delta \le \delta_0(a, m)$ and $\epsilon \le \epsilon_0(a, m, \delta)$, where K is as in (1.10) and since $\Delta d \le Cd^{-1}$ in $\{d > 0\}$.

Case 2: $d \le \delta/2$ *or* $d \ge 2\delta$. If $d \le \delta/2$, then $w \le -\delta/2$, and if $d \ge 2\delta$, then $w \ge \delta$. In either case, (3.15) and Lemma 3.1 yield

$$\Phi_t - \epsilon\Delta\Phi + \frac{1}{\epsilon}f^\epsilon(\Phi, v^\epsilon) \ge \frac{1}{\epsilon}\left[\frac{a}{4} - C|q_{rr}^\epsilon| + q_r^\epsilon\left(-\frac{C\epsilon}{\delta} - Co(1)\right)\right] > 0$$

for $\epsilon \le \epsilon_0(a, m, \delta)$ since by (1.11)(ii), $[|q_r^\epsilon| + |q_{rr}^\epsilon|] \to 0$ as $\epsilon \to 0$ uniformly in a, m, and δ. □

We are now ready to proceed with the proof of Theorem 3.1.

Proof of Theorem 3.1. 1. It follows from (1.14), (1.5), and (1.6), that for a and ϵ sufficiently small, there exist a constant c, independent of v^ϵ, a, and ϵ, and a traveling wave $r \mapsto q^\epsilon(r, v_0^\epsilon(x), a)$ such that

$$q^\epsilon(r, v_0^\epsilon, a) \ge q^\epsilon(r, v_0^\epsilon, 0) + ca\,,$$

where $q^\epsilon(\cdot, v_0^\epsilon, 0)$ is given in (3.7).

The above claim follows easily from our assumptions on the vector field by an appropriate choice of the initial condition $q^\epsilon(0, v, a)$. Indeed, recall that $q^\epsilon(0, v, 0) = h_0^\epsilon(v)$. In view of (1.4), there is a smooth function $\xi^\epsilon(v, a)$, defined for all $v \in [v, v_+]$ and all sufficiently small a and ϵ, such that

$$q^\epsilon(\xi^\epsilon(v, a), v, 0) = \frac{h_-^\epsilon(v, 0) + h_-^\epsilon(v, a)}{2}\,.$$

Now choose $q^\epsilon(\,\cdot\,, v, a)$ so that

$$q^\epsilon(\xi^\epsilon(v,a), v, a) = \frac{h_+^\epsilon(v,0) + h_+^\epsilon(v,a)}{2}\,.$$

The choices of $w^{a,m,\delta}$ and q^ϵ as well as (1.13) now yield

$$\Phi^{a,m,\delta,\epsilon}(x,0) = q^\epsilon\left(\frac{\eta_\delta(d_0^{a,m,\delta}(x))}{\epsilon}, v_0^m, a\right) \ge q^\epsilon\left(\frac{d_0(x)}{\epsilon}, v_0^\epsilon + \frac{a}{4K}, a\right) \ge u_0^\epsilon(x)$$

for small a and ϵ and large m.

2. Lemmas 3.2 and 3.3 and a comparison principle for viscosity solutions of reaction-diffusion equations (see [ESoS]) yield

$$\Phi^{a,m,\delta,\epsilon} \ge u^\epsilon.$$

Using (1.6) and (1.13) we get

$$\text{(3.16)} \qquad u^{\epsilon_n} \le h_+^{\epsilon_n}(v^m, a) \quad \text{for all } (x,t) \quad \text{and} \quad \overline{\lim}\, u^{\epsilon_n} \le h_-(v^m, a) \quad \text{in } \{d < 0\}.$$

The second inequality follows from the remark that if $d(x_0, t_0) < 0$, then $\theta(x_0, t_0) < 0$ and, therefore, $\theta^{a,m,\delta} \le -\xi < 0$ in a neighborhood of (x_0, t_0) for small a, m, δ, and ϵ. But then $d^{a,m,\delta} \le 0$ and, consequently, $w^{a,m,\delta} \le -\delta/2$ in this neighborhood; hence (3.16) follows.

3. Constructing appropriate subsolutions and arguing as before to obtain inequalities analogous to (3.16), we conclude that

$$\text{(3.17)} \qquad u^{\epsilon_n} \longrightarrow \begin{cases} h_+(v) & \text{in } \{d > 0\}, \\ h_-(v) & \text{in } \{d < 0\} \end{cases} \qquad \text{locally uniformly.}$$

Using that $u^{\epsilon_n} \rightharpoonup u$ in $L^\infty(Q_T)$ weak $*$, it is now easy to derive (3.3). Indeed, let $\phi \in C_c^\infty(B((x_0, t_0), \rho))$ be such that $0 \le \varphi$. Then (3.16) yields

$$\int_{Q_T} u^{\epsilon_n} \varphi\, dx dt \le \int_{Q_T} h_+^{\epsilon_n}(v^m, a) \varphi\, dx dt.$$

Letting $n \to +\infty$, $m \to +\infty$, and $a \to 0$ above, we get

$$\int_{Q_T} \varphi(h_+(v) - u)\, dx dt \ge 0,$$

and thus $h_+(v) \ge u$ a.e. in Q_T.

4. To prove (3.4) and (3.5), observe that, by Lemma 1.2, $g^\epsilon(u^\epsilon, v^\epsilon) \rightharpoonup G$ in $L^\infty(Q_T)$ weak $*$. In view of (3.17) and the fact that $v^{\epsilon_n} \to v$ in $C(Q_T)$, it follows immediately that $g^\epsilon \to G$ locally uniformly in $\{d \ne 0\}$, while to obtain (3.5) on Γ_t, we again use (3.16) and (1.2). □

We now proceed with the proof of Theorem 3.2. Here the construction of the super- and subsolutions will be a bit different. The reason is that we need to look at the whole system (3.1), which, in view of (1.2), does not satisfy the assumptions of the maximum principle. To overcome this difficulty, we introduce the function

$$\text{(3.18)} \qquad a(t) = a \exp(St),$$

where

$$S = (3 + L(K+2))L \quad \text{and} \quad a > 0.$$

Here $K > 0$ is such that

$$\|c_a^\epsilon\|_\infty + \|f_v^\epsilon\|_\infty \le K \text{ in } [-M, M] \times [\overline{v}_- + \rho, \overline{v}_+ - \rho],$$

with M given by (1.21), and L is the Lipschitz constant of g^ϵ in $[-M, M] \times [\overline{v}_- + \rho, \overline{v}_+ - \rho]$ and of $h_\pm^\epsilon$ and h_0^ϵ in $[-M, M] \times [\overline{v}_- + \rho, \overline{v}_+ - \rho] \times [0, A]$; recall that we are assuming (1.21).

As before, we introduce the functions

$$\bar{\Phi}^{a,m,\delta,\epsilon}(x,t) = q^\epsilon \left(\frac{w^{a,m,\delta}(x,t)}{\epsilon}, v^m(x,t), (K+1)a(t) \right) \tag{3.19}$$

and

$$\overline{v}(x,t) = v(x,t) + a(t) \quad \text{and} \quad \underline{v}(x,t) = v(x,t) - a(t), \tag{3.20}$$

where v comes from Lemma 1.2 along a fixed subsequence. Finally, let $\underline{\Phi}^{a,m,\delta,\epsilon}$ be defined as $\overline{\Phi}^{a,m,\delta,\epsilon}$ but using $\zeta_\delta(z) = -\eta_\delta(-z)$ in the definition of $w^{a,m,\delta}$.

LEMMA 3.3. *Let u and v be given by Lemma* 1.2 *and assume all the assumptions of Theorem* 3.2. *Then for any $a > 0$, $m \ge m_0(a)$, $\delta \le \delta_0(a,m)$, and $\epsilon \le \epsilon_0(a,m,\delta)$, the functions $\overline{\Phi}^{a,m,\delta,\epsilon}$ and $\underline{\Phi}^{a,m,\delta,\epsilon}$, $\overline{v}$, and $\underline{v}$ satisfy, in the viscosity sense,*

$$\left\{ \begin{array}{l} \text{(i) } \overline{\Phi}_t^{a,m,\delta,\epsilon} - \epsilon \Delta \overline{\Phi}^{a,m,\delta,\epsilon} + \frac{1}{\epsilon} f^\epsilon(\overline{\Phi}^{a,m,d,\epsilon}, \underline{v}) \ge 0, \\ \text{(ii) } \overline{v}_t - b\Delta \overline{v} + g^\epsilon(u,v) - a(t)S = 0 \end{array} \right. \quad \textit{in } Q_T \tag{3.21}$$

and

$$\left\{ \begin{array}{l} \text{(i) } \underline{\Phi}_t^{a,m,\delta,\epsilon} - \epsilon \Delta \underline{\Phi}^{a,m,\delta,\epsilon} + \frac{1}{\epsilon} f^\epsilon(\underline{\Phi}^{a,m,d,\epsilon}, \overline{v}) \le 0, \\ \text{(ii) } \underline{v}_t - b\Delta \underline{v} + g^\epsilon(u,v) + a(t)S = 0 \end{array} \right. \quad \textit{in } Q_T. \tag{3.22}$$

Proof. The proofs of (3.21)(i) and (3.22)(i) follow along the lines of the proof of Lemma 3.2. The main difference is that $\underline{v}$ does not depend on ϵ. Therefore, the proof is not restricted on the particular choice of the subsequence. On the other hand, (3.21)(ii) and (3.22)(ii) hold in the sense of distributions and follow trivially using (3.6). □

Next, we show that the pairs $(\overline{\Phi}^{a,m,\delta,\epsilon}, \overline{v})$ and $(\underline{\Phi}^{a,m,\delta,\epsilon}, \underline{v})$ are some kind of super- and subsolutions of (3.1). To simplify the notation, in what follows, we again drop the explicit dependence on (a, m, δ, ϵ) and write only $(\overline{\Phi}, \overline{v})$ and $(\underline{\Phi}, \underline{v})$.

LEMMA 3.4. *Assume* (1.2) *and* (3.6) *and let $a(t)$ be given by* (3.18). *Then*

$$-g(u,v) + a(t)S \ge_{.} -g(\overline{\Phi}, \overline{v}) \quad \textit{a.e. in } Q_T \tag{3.23}$$

for all $a > 0$, $m \ge m_0(a)$, and $\epsilon \le \epsilon_0(a)$. An analogous inequality holds for $(\underline{\Phi}, \underline{v})$.

Proof. 1. If $d(x,t) > 0$, then $u = h_+(v)$. Choose ϵ small and m large enough so that

$$\|v - v^m\|_\infty \le a \text{ and } |h_\pm^\epsilon - h_\pm| \le a \text{ in } [\overline{v}_- + \rho, \overline{v}_+ - \rho]$$

and compute

$$\begin{aligned}
&- g^\epsilon(u,v) + a(t)S \\
&\quad \geq -g^\epsilon(h_+^\epsilon(v^m,(K+1)a(t)),\overline{v}) - L(|h_+(v) - h_+^\epsilon(v^m,(K+1)a(t))| + a(t)) + a(t)S \\
&\quad \geq -g^\epsilon(h_+^\epsilon(v^m,(K+1)a(t)),\overline{v}) + La \geq -g^\epsilon(\overline{\Phi},\overline{v}).
\end{aligned}$$

2. If $d(x,t) < 0$, then $w^{a,m,\delta}(x,t) \leq -\delta$ for a, δ, and ϵ small and m large enough. Therefore,

$$\overline{\Phi}(x,t) \leq q^\epsilon\left(-\frac{\delta}{\epsilon}, v^m(x,t), (K+1)a(t)\right).$$

Then, by (1.12),

$$\begin{aligned}
&- g(u,v) + a(t)S \\
&= -g(h_-(v),v) + a(t)S \geq -g(h_-^\epsilon(v^m,(K+1)a(t)),\overline{v}) + aL \\
&\geq -g(\overline{\Phi},\overline{v}) + L\left[a - \left(q^\epsilon\left(-\frac{\delta}{\epsilon}, v^m, (K+1)a(t)\right) - h_-^\epsilon(v^m,(K+1)a(t))\right)\right] \\
&\geq -g(\overline{\Phi},\overline{v}) \quad \text{for } \epsilon \leq \epsilon_0(a,m,\delta). \qquad \square
\end{aligned}$$

We now introduce a change of variables in (3.1) in order to control the nonlinear term in the first equation. Indeed, let

$$\lambda^\epsilon = \frac{2}{\epsilon^2} \sup_{[-M,M]^2} |f_u(u,v)|, \tag{3.24}$$

where M is given by (1.21), and define

$$F^\epsilon(t,r,s) = \lambda^\epsilon r + \epsilon^{-1} e^{-\lambda^\epsilon t} f^\epsilon(e^{\lambda^\epsilon t} r, e^{\lambda^\epsilon t} s). \tag{3.25}$$

The following are immediate:

$$\begin{cases}
F_r^\epsilon = \lambda^\epsilon + \epsilon^{-1} f_u^\epsilon(e^{\lambda^\epsilon t} r, e^{\lambda^\epsilon t} s) \geq \lambda^\epsilon/2 \quad \text{if } |r|, |s| \leq e^{-\lambda^\epsilon t} M, \\
F_s^\epsilon = \epsilon^{-1} f_v(e^{\lambda^\epsilon t} r, e^{\lambda^\epsilon t} s) \geq 0.
\end{cases} \tag{3.26}$$

Finally, let

$$\begin{cases}
\hat{u}^\epsilon(x,t) = e^{-\lambda^\epsilon t} u^\epsilon(x,t), \quad \hat{v}^\epsilon(x,t) = e^{-\lambda^\epsilon t} v^\epsilon(x,t), \\
\overline{\varphi}^{a,m,\delta,\epsilon}(x,t) = e^{-\lambda^\epsilon t} \overline{\Phi}^{a,m,\delta,\epsilon}(x,t), \quad \underline{\varphi}^{a,m,\delta,\epsilon}(x,t) = e^{-\lambda^\epsilon t} \underline{\Phi}^{a,m,\delta,\epsilon}(x,t), \\
\tilde{v}(x,t) = e^{-\lambda^\epsilon t} \overline{v}(x,t), \quad \underset{\sim}{v}(x,t) = e^{-\lambda^\epsilon t} \underline{v}(x,t).
\end{cases} \tag{3.27}$$

It is immediate that $(\hat{u}^\epsilon, \hat{v}^\epsilon)$ solves the system

$$\begin{cases}
\text{(i)} \quad \hat{u}_t^\epsilon - \epsilon\Delta\hat{u}^\epsilon + F^\epsilon(t,\hat{u}^\epsilon,\hat{v}^\epsilon) = 0, \\
\text{(ii)} \quad \hat{v}_t^\epsilon - b\Delta\hat{v}^\epsilon + \lambda^\epsilon\hat{v}^\epsilon + e^{-\lambda^\epsilon t} g^\epsilon(u^\epsilon,v^\epsilon) = 0
\end{cases} \quad \text{in } Q_T. \tag{3.28}$$

Moreover, Lemma 3.3 yields that $(\overline{\varphi}^{a,m,\delta,\epsilon}, \underset{\sim}{v})$ satisfies

$$\begin{cases}
\text{(i)} \quad \overline{\varphi}_t - \epsilon\Delta\overline{\varphi} + F^\epsilon(t,\overline{\varphi},\underset{\sim}{v}) \geq 0, \\
\text{(ii)} \quad \underset{\sim}{v}_t - b\Delta\underset{\sim}{v} + \lambda^\epsilon\underset{\sim}{v} = e^{-\lambda^\epsilon t}[-g(u,v) - a(t)S]
\end{cases} \quad \text{in } Q_T, \tag{3.29}$$

where we have once more dropped all of the superscripts. An analogous inequality holds for $(\underline{\varphi}^{a,m,\delta,\epsilon}, \tilde{v})$.

We now proceed as in [Chx] to obtain a comparison result for (3.1), always assuming (3.6).

LEMMA 3.5. *Let the assumptions of Theorem* 3.2 *hold. Then there exists a constant* C, *independent of* ϵ, *such that*

$$\epsilon\lambda^\epsilon \|(\hat{u}^\epsilon - \overline{\varphi}^{a,m,\delta,\epsilon})_+\|_\infty \leq C\|(\underset{\sim}{v} - \hat{v}^\epsilon)_+\|_\infty. \tag{3.30}$$

Proof. The proof is an easy consequence of the assumptions and the above constructions. Indeed, if $(x_0, t_0) \in Q_T$ is a point where $\overline{\varphi} - \hat{u}^\epsilon$ attains a negative minimum—again we drop the superscripts—then, as in the proof of Theorem 3.1, $t_0 > 0$. The assumptions yield that at (x_0, t_0),

$$\begin{aligned} 0 \geq \overline{\varphi}_t - \hat{u}^\epsilon_t &\geq \epsilon(\Delta\overline{\varphi} - \Delta\hat{u}^\epsilon) + F(t_0, \hat{u}^\epsilon, \hat{v}^\epsilon) - F(t_0, \overline{\varphi}, \underset{\sim}{v}) \\ &\geq \frac{\lambda^\epsilon}{2}(\hat{u}^\epsilon - \overline{\varphi}) + F(t_0, \hat{u}^\epsilon, \hat{v}^\epsilon) - F(t_0, \hat{u}^\epsilon, \underset{\sim}{v}) \\ &\geq \frac{\lambda^\epsilon}{2}(\hat{u}^\epsilon - \overline{\varphi}) - \frac{C}{\epsilon}(\underset{\sim}{v} - \hat{v}^\epsilon)_+ , \end{aligned}$$

where $C = \sup_{[-M,M]^2} f_v$. The lemma now easily follows. □

LEMMA 3.6. *Under the assumptions of Theorem* 3.2,

$$\lambda^\epsilon \|(\underset{\sim}{v} - \hat{v}^\epsilon)_+\|_\infty \leq C\|(\underline{\varphi} - \hat{u}^\epsilon)_+\|_\infty \tag{3.31}$$

for some constant C *independent of* ϵ *and for* ϵ *small enough.*

Proof. Here we use (3.28)(ii), (3.29)(ii), and Lemma 3.4. If $V = \underset{\sim}{v} - \hat{v}^\epsilon$, then

$$V_t - b\Delta V + \lambda^\epsilon V = e^{-\lambda^\epsilon t}[a(t)S + g^\epsilon(u^\epsilon, v^\epsilon) - g(u, v)]. \tag{3.32}$$

Multiplying (3.32) by V_+^{p-1} $(p \geq 2)$, integrating over Q_T, and using the periodicity of V, we get

$$\begin{aligned} &\frac{1}{p}\int_\Pi V_+^p dx - \frac{1}{p}\int_\Pi (v_0 - v_0^\epsilon - a)_+^p dx + \int_{Q_T} (b(p-1)V_+^{p-2}|DV_+|^2 + \lambda^\epsilon V_+^p) dxdt \\ &\quad = \int_{Q_T} e^{-\lambda^\epsilon t}[-a(t)S + g^\epsilon(u^\epsilon, v^\epsilon) - g(u, v)]V_+^{p-1} dxdt \\ &\quad \leq \int_{Q_T} e^{-\lambda^\epsilon t}[g^\epsilon(u^\epsilon, v^\epsilon) - g(\underline{\Phi}, \underline{v})]V_+^{p-1} dxdt \\ &\quad = \int_{Q_T} V_+^{p-1}[-I_1(\underline{\Phi}, u^\epsilon)(\underline{\varphi} - \hat{u}^\epsilon) - I_2(\underline{v}, v^\epsilon)(\underset{\sim}{v} - \hat{v}^\epsilon)] dxdt, \end{aligned}$$

where

$$I_1(\underline{\Phi}, u^\epsilon) = \begin{cases} \frac{g(\underline{\Phi},\underline{v}) - g(u^\epsilon,\underline{v})}{\underline{\Phi} - u^\epsilon} & \text{if } \underline{\Phi} \neq u^\epsilon, \\ g_u(u^\epsilon, \underline{v}) & \text{if } u^\epsilon = \underline{\Phi} \end{cases}$$

and

$$I_2(\underline{v}, u^\epsilon) = \begin{cases} \frac{g(u^\epsilon,\underline{v}) - g(u^\epsilon,v^\epsilon)}{\underline{v} - v^\epsilon} & \text{if } \underline{v} \neq v^\epsilon, \\ g_v(u^\epsilon, v^\epsilon) & \text{if } \underline{v} = v^\epsilon. \end{cases}$$

In view of our assumptions, I_1 and I_2 are bounded in Q_T uniformly in ϵ. Finally, if ϵ is so small that $\|v_0^\epsilon - v_0\|_\infty \le a/2$, then

$$\begin{aligned}\lambda^\epsilon \int_{Q_T} V_+^p dxdt &\le C \int_{Q_T} [(\underline{\varphi} - \hat{u}^\epsilon)_+ V_+^{p-1} + V_+^p] dxdt \\ &\le C \left[\|(\underline{\varphi} - \hat{u}^\epsilon)_+\|_p \left(\int_{Q_T} V_+^p dxdt \right)^{1-\frac{1}{p}} + \int_{Q_T} V_+^p dxdt \right].\end{aligned}$$

If ϵ is small enough so that $\lambda^\epsilon - C \ge \lambda^\epsilon/2$, then we conclude the proof, letting $p \to +\infty$. □

Finally, we can state the comparison result for (3.1).

LEMMA 3.7. *Under the assumptions of Theorem* 3.2, *for any $a \le a_0$, $m \ge m_0(a)$, $\delta \le \delta_0(a, m)$, and $\epsilon \le \epsilon_0(a, m, \delta)$,*

$$\underline{\Phi}^{a,m,\delta,\epsilon} \le u^\epsilon \le \overline{\Phi}^{a,m,\delta,\epsilon}$$

and

$$v - a \le v^\epsilon \le v + a.$$

Proof. If, for example, $\overline{\Phi}^{a,m,\delta,\epsilon} - u^\epsilon$ has a negative minimum, then Lemmas 3.5 and 3.6 yield

$$0 < \epsilon(\lambda^\epsilon)^2 \|(\hat{u}^\epsilon - \overline{\varphi})_+\|_\infty \le \lambda^\epsilon C \|(\underline{v} - \hat{v}^\epsilon)_+\|_\infty \le C \|(\underline{\varphi} - \hat{u}^\epsilon)_+\|_\infty,$$

i.e., $\underline{\varphi} - \hat{u}^\epsilon$ has a positive maximum. The comparison for the subsolution pair $(\underline{\Phi}, \underline{v})$ and the definition of λ^ϵ also give

$$0 < \frac{1}{\epsilon^3} \|(\hat{u} - \overline{\varphi})_+\|_\infty \le C \|(\hat{u} - \overline{\varphi})_+\|_\infty,$$

which leads to a contradiction for $\epsilon \to 0$. □

At this point, the proof of Theorem 3.2 follows exactly as the one of Theorem 3.1.

4. The asymptotics $\alpha = \epsilon^{-2}$, $\beta = \epsilon^2$, and $\gamma = \epsilon^{-1}$ of the Fitzhugh–Nagumo system.

Here we present a result about the asymptotics of the system

$$(4.1) \qquad \begin{cases} u_t^\epsilon - \Delta u^\epsilon + \frac{1}{\epsilon^2} f^\epsilon(u^\epsilon, v^\epsilon) = 0, \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{in } \mathbb{R}^N \times (0, \infty), \\ v_t^\epsilon - b\Delta v^\epsilon + g^\epsilon(u^\epsilon, v^\epsilon) = 0 \end{cases}$$

where now we assume that (1.9) holds. The corresponding geometric PDEs is

$$(4.2) \qquad \begin{cases} \theta_t - (\Delta\theta - (D^2\theta D\theta, D\theta)/|D\theta|^2) + \alpha(v)|D\theta| = 0 & \text{in } \mathbb{R}^N \times (0, \infty), \\ \theta = d_0 & \text{on } \mathbb{R}^N \times \{0\}, \end{cases}$$

where v is the limit of the v^ϵ's.

THEOREM 4.1. *Assume* (1.2), (1.4), (1.7), (1.9), (1.10), (1.12), (1.13), *and* (1.17)–(1.21) *and let (u^ϵ, v^ϵ) be the solution of* (4.1). *Then along subsequences, $v^{\epsilon_n} \to v$ in $C(Q_T)$ and $u^{\epsilon_n} \rightharpoonup u$ and $g(u^{\epsilon_n}, v^{\epsilon_n}) \rightharpoonup G$ in $L^\infty(Q_T)$ weak $*$. The pair (u, v) satisfies* (3.3)–(3.5), *where the interface Γ_t now moves with normal velocity equal to its mean* *curvature $\alpha(v)$. Finally, if (3.6) holds for the solution of the corresponding geometric PDE (4.2), then the convergence result holds for the whole family (u^ϵ, v^ϵ).*

The proof of Theorem 4.1 follows along the lines of the proofs of Theorems 3.1 and 3.2 and Proposition 10.2 and Theorem 9.1 of [BaSS]. We therefore omit the details.

GINZBURG–LANDAU EQUATIONS AND STABLE SOLUTIONS IN A ROTATIONAL DOMAIN*

SHUICHI JIMBO† AND YOSHIHISA MORITA‡

Abstract. The Ginzburg–Landau (GL) equations, with or without magnetic effect, are studied in the case of a rotational domain in $\mathbb{R}^3$. It can be shown that there exist rotational solutions which describe the physical state of permanent current of electrons in a ring-shaped superconductor. Moreover, if a physical parameter—called the GL parameter—is sufficiently large, then these solutions are stable, that is, they are local minimizers of an energy functional (GL energy). This is proved by the spectral analysis on the linearized equation.

Key words. Ginzburg–Landau equation, stable solutions, rotational domain

AMS subject classifications. 35B35, 35J50, 35B65

1. Introduction.

Ginzburg and Landau [11] proposed a theory of low-temperature superconductivity. In their theory, the (local) energy density $h(\Phi, A)$ inside a superconductor is given by

$$h(\Phi, A) = \frac{1}{2}|(\nabla - iA)\Phi|^2 + \frac{\alpha}{4}(1 - |\Phi|^2)^2 + \frac{1}{2}|\mathrm{rot}A|^2,$$

where Φ ($\mathbb{C}$-valued) is the wave function of the electrons in the material, A is the vector potential of the magnetic field, and $\alpha > 0$ is the Ginzburg–Landau (GL) parameter. We note that this energy density is written in a nondimensional form. A superconducting state (Φ, A) is formulated as a local minimizer of the total energy functional calculated by $h(\Phi, A)$; namely, it is a solution to the variational equation. This variational equation is called the GL equation. After Ginzburg and Landau's work, many mathematical results for the GL equation have arisen and contributed to the study of the existence of solutions and their detailed properties. We are interested in this problem in the case of bounded superconductors. In this direction of study, there are several works concerning various situations (and boundary conditions). Odeh [20] studied the occurrence of a bifurcation from the zero solution as the parameter α varies. Caroll and Glick [6] proved a unique existence of a solution for a certain restricted range of α. Klimov [14] and Bobylev [5] obtained multiple solutions in another range of α. Chen [7] constructed a nonsymmetric solution in a bounded domain in $\mathbb{R}^2$. Yang [25], [26] constructed solutions in a bounded domain in $\mathbb{R}^3$ under an outer magnetic force and analyzed their regularity. Monvel-Berthier, Georgescu, and Pruce [19] gave a detailed characterization of the configuration space with prescribed total vorticity in a bounded domain in $\mathbb{R}^2$. See also [8].

Despite many important works, the stability analysis has not yet been done well. In this paper, we deal with the GL equation in the case where the superconductor is ring-shaped (cf. Fig. 1) and the external (applied) magnetic field is absent. We construct nontrivial solutions and study their stability for large α by analyzing the second variation of the energy functional. We emphasize that the external field is absent but the magnetic field driven by the current of the electrons is taken into the equation. Hence this magnetic effect might influence the stability of the solutions.

‡ Department of Mathematics and Informatics, Ryukoku University, Ohtsu 520-21, Japan.

However, we can also prove a similar result for the GL equation without the magnetic effect A (cf. equation (1.6) below).

We remark that there are also many works on other important topics. Jaffe and Taubes [12] developed several important methods for analysis of the GL equations, by which they investigated the magnetic screening effect and the quantization phenomena of the total vortices in $\mathbb{R}^2$. Moreover, for the special value of the GL parameter ($\alpha = 1/2$), they solved the prescribed vortices problem in $\mathbb{R}^2$. Berger and Chen [3] constructed a radially symmetric solution (with vortex) in $\mathbb{R}^2$ and showed an elaborate asymptotic behavior for $\alpha \to \infty$. More recently, there have also been extensive studies on the properties of the zero set of the solutions of the equation without the magnetic effect in a domain in $\mathbb{R}^2$ (cf. (1.6) with the boundary condition of the first kind). See [2], [9], [4], and the references therein.

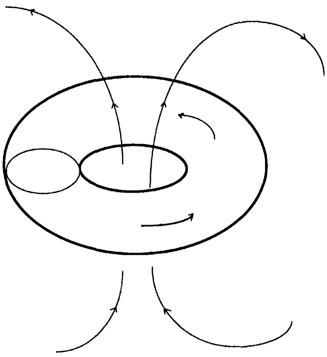

FIG. 1. *Ring-shaped domain* Ω.

We now formulate the problem. Let $\Omega \subset \mathbb{R}^3$ be a bounded domain with a C^3 boundary. We consider the following (GL) functional

$$\mathcal{H}(\Phi, A) = \int_\Omega \left\{ \frac{1}{2}|(\nabla - iA)\Phi|^2 + \frac{\alpha}{4}(1 - |\Phi|^2)^2 \right\} dx + \int_{\mathbb{R}^3} \frac{1}{2}|\mathrm{rot} A|^2 dx. \tag{1.1}$$

Φ is a $\mathbb{C}$-valued function in Ω and A is an $\mathbb{R}^3$-valued function in $\mathbb{R}^3$. The first and second terms correspond to the energy of the electrons confined in Ω and that of the magnetic field caused by the current of electrons, respectively. Note that the magnetic field takes place in the whole space $\mathbb{R}^3$. We suppose $A \in L^2_{\mathrm{loc}}(\mathbb{R}^3; \mathbb{R}^3)$, $\nabla A \in L^2(\mathbb{R}^3; \mathbb{R}^{3\times 3})$, and $\Phi \in H^1(\Omega; \mathbb{C})$. The GL equation is the variational equation of this functional, that is,

$$\begin{cases} (\nabla - iA)^2\Phi + \alpha(1 - |\Phi|^2)\Phi = 0 \quad \text{in} \quad \Omega, \\ \dfrac{\partial \Phi}{\partial \nu} - i\langle A \cdot \nu \rangle \Phi = 0 \quad \text{on} \quad \partial\Omega, \\ \mathrm{rot}\,\mathrm{rot}\, A + \left(i(\overline{\Phi}\nabla\Phi - \Phi\nabla\overline{\Phi})/2 + |\Phi|^2 A \right) \Lambda_\Omega = 0 \quad \text{in} \quad \mathbb{R}^3, \end{cases} \tag{1.2}$$

where $\langle \cdot, \cdot \rangle$ is the standard inner product of vectors in $\mathbb{R}^3$ and $\Lambda_\Omega(x)$ is a discontinuous function such as $\Lambda_\Omega(x) = 1$ for $x \in \Omega$ and $\Lambda_\Omega(x) = 0$ for $x \in \mathbb{R}^3 \setminus \Omega$. We construct nontrivial solutions to (1.2) and prove their stability in the case where Ω is a ring-shaped domain. In the stability analysis, we have to take into account the invariance of gauge transformation. Namely, the transformation $(\Phi, A) \longmapsto (\Phi', A')$ defined by

$$\Phi' = e^{i\rho}\Phi, \qquad A' = A + \nabla\rho \qquad (\rho : \mathbb{R}\text{-valued function in } \mathbb{R}^3) \tag{1.3}$$

leaves $\mathcal{H}$ invariant. Accordingly, if (Φ, A) is a solution to (1.2), (Φ', A') in (1.3) is also a solution of (1.2). Taking various ρ's, we get a continuum of solutions from one solution (Φ, A). We note that all (Φ', A')'s in this continuum correspond to one physical state. In view of this, to see the stability of a solution (Φ, A), we need to study the infinitesimal variation of $\mathcal{H}$ in the direction that is transversal to the continuum at (Φ, A). Consider the second variation of $\mathcal{H}$ obtained by

$$\mathcal{L}(\Phi, A, \Psi, B) = \frac{d^2}{d\epsilon^2}\mathcal{H}(\Phi + \epsilon\Psi, A + \epsilon B)_{|\epsilon=0}. \tag{1.4}$$

We see from the above observation that this quadratic form is degenerate in the tangent space

$$T(\Phi, A) = \{(i\xi\Phi, \nabla\xi) \mid \xi : \mathbb{R}\text{-valued function on } \mathbb{R}^3\}$$

of the continuum at (Φ, A). We take a space $N(\Phi, A)$ which is transversal to $T(\Phi, A)$ and satisfies $T(\Phi, A) \cap N(\Phi, A) = \{(0,0)\}$ and consider whether $\mathcal{L}(\Phi, A, \cdot\,, \cdot\,)$ is positive definite in $N(\Phi, A)$ or not.

In addition to (1.1), we also consider the following functional $\mathcal{H}_0$ (which is given by setting $A = 0$ in (1.1)):

$$\mathcal{H}_0(\Phi) = \int_\Omega \left\{\frac{1}{2}|\nabla\Phi|^2 + \frac{\alpha}{4}(1 - |\Phi|^2)^2\right\} dx. \tag{1.5}$$

In certain situations, the magnetic field is expected to be so small in the interior of Ω that A can be neglected, so this is also a significant model. The variational equation of (1.5) is

$$\begin{cases} \Delta\Phi + \alpha\,(1 - |\Phi|^2)\Phi = 0 & \text{in} \quad \Omega, \\ \dfrac{\partial\Phi}{\partial\nu} = 0 \quad \text{on} \quad \partial\Omega. \end{cases} \tag{1.6}$$

(1.5) and (1.6) are also called the GL functional and the GL equation, respectively. (1.5)–(1.6) has a similar transformation invariance to that of (1.1)–(1.2), that is, if $c \in \mathbb{R}$, the transformation $\Phi \longmapsto \Phi'$ defined by

$$\Phi' = e^{ic}\Phi \tag{1.7}$$

leaves (1.5) and (1.6) invariant. In other words, given any nonzero solution Φ to (1.6), we get a contiuum of solutions $\{e^{ic}\Phi \mid c \in \mathbb{R}\}$ that is a one-dimensional set including Φ. Consider the second variation of $\mathcal{H}_0$ around Φ,

$$\mathcal{L}_0(\Phi, \Psi) = \frac{d^2}{d\epsilon^2}\mathcal{H}_0(\Phi + \epsilon\Psi)_{|\epsilon=0}. \tag{1.8}$$

This quadratic form is degenerate in the direction of the tangent space of the continuum at Φ,

$$T_0(\Phi) = \{ic\Phi \mid c \in \mathbb{R}\}.$$

As in the previous case, we take a space $N_0(\Phi)$ which is transversal to $T_0(\Phi)$ and satisfies $T_0(\Phi) \cap N_0(\Phi) = \{0\}$. We consider $\mathcal{L}_0(\Phi, \cdot\,)$ on $N_0(\Phi)$ and discuss the stability of Φ.

In §2, we formulate several function spaces for the arguments of stability described above. In §3, we specify the rotational domain in $\mathbb{R}^3$ and present our main theorems on the existence of stable solutions. In §4, we construct solutions to (1.2) and (1.6). In §§5 and 6, we prove the stability of the solutions for large α.

2. Formulation. In this section, we formulate $T(\Phi, A)$, $N(\Phi, A)$, $T_0(\Phi)$, and $N_0(\Phi)$ for arbitrary (Φ, A) and Φ. Next, we deduce the concrete expressions of the second variations (1.4) and (1.8) and some of their properties in the above spaces. Let (Φ, A) satisfy $\Phi \in C^1(\overline{\Omega}; \mathbb{C})$, $A \in C^1(\mathbb{R}^3; \mathbb{R}^3)$, and $\nabla A \in L^2(\mathbb{R}^3; \mathbb{R}^{3\times3})$. The solution we construct in §4 satisfies this condition. For convenience, we sometimes deal with the Φ-component in terms of real functions by taking its real and imaginary parts. We set $\Phi = u + vi$ and $\Psi = \phi + \psi i$. Henceforth, we also denote $\mathcal{H}(\Phi, A)$, $\mathcal{L}(\Phi, A, \Psi, B)$, $T(\Phi, A)$, and $N(\Phi, A)$ by $\mathcal{H}(u, v, A)$, $\mathcal{L}(u, v, A, \phi, \psi, B)$, $T(u, v, A)$, and $N(u, v, A)$, respectively. The tangent space $T(\Phi, A)$ is defined as follows:

$$T(\Phi, A) = T(u, v, A) = \{(-v\xi, u\xi, \nabla\xi) \mid \xi \in L^2_{\rm loc}(\mathbb{R}^3),\ \nabla\xi \in H^1(\mathbb{R}^3; \mathbb{R}^3)\}. \tag{2.1}$$

To define a subspace $N(\Phi, A) = N(u, v, A)$ which is transversal to $T(\Phi, A)$, we use the Helmholtz decomposition (cf. [24]). It is known that $L^2(\Omega; \mathbb{R}^3)$ and $L^2(\mathbb{R}^3; \mathbb{R}^3)$ have the following orthogonal decompositions:

$$L^2(\Omega; \mathbb{R}^3) = X_1 \oplus X_2, \quad L^2(\mathbb{R}^3; \mathbb{R}^3) = Y_1 \oplus Y_2,$$

where

$$\begin{aligned} X_1 &= \{\nabla\xi \mid \xi \in L^2(\Omega),\ \nabla\xi \in L^2(\Omega; \mathbb{R}^3)\}, \\ X_2 &= \{B \in L^2(\Omega; \mathbb{R}^3) \mid \operatorname{div} B = 0 \text{ in } H^{-1}(\Omega),\ \langle B \cdot \nu\rangle = 0 \text{ in } H^{-1/2}(\partial\Omega)\}, \\ Y_1 &= \{\nabla\xi \mid \xi \in L^2_{\rm loc}(\mathbb{R}^3),\ \nabla\xi \in L^2(\mathbb{R}^3; \mathbb{R}^3)\}, \\ Y_2 &= \{B \in L^2(\mathbb{R}^3; \mathbb{R}^3) \mid \operatorname{div} B = 0 \text{ in } H^{-1}(\mathbb{R}^3)\}. \end{aligned}$$

Let P and $\widetilde{P}$ be the orthogonal projectors of $L^2(\Omega; \mathbb{R}^3)$ and $L^2(\mathbb{R}^3; \mathbb{R}^3)$ onto X_2 and Y_2, respectively. Let us define

$$\begin{aligned} \overline{N}(u, v, A) &= \left\{(\phi, \psi, B) \in H^1(\Omega)^2 \times H^1(\mathbb{R}^3; \mathbb{R}^3) \mid \int_\Omega (v\phi - u\psi)dx = 0,\ B_{|\Omega} \in X_2\right\}, \\ N(u, v, A) &= \left\{(\phi, \psi, B) \in H^1(\Omega)^2 \times H^1(\mathbb{R}^3; \mathbb{R}^3) \mid \int_\Omega (v\phi - u\psi)dx = 0,\ B \in Y_2\right\}. \end{aligned}$$

For these subspaces, we have the following properties.

Proposition 1.

$$H^1(\Omega) \times H^1(\Omega) \times H^1(\mathbb{R}^3; \mathbb{R}^3) = T(u, v, A) + \overline{N}(u, v, A).$$

Proof. Assume $(u, v) \not\equiv (0, 0)$. Otherwise, the proof is straightforward. Let (ϕ, ψ, B) be any element in the left-hand side. Because $B_{|\Omega} = (I - P)(B_{|\Omega}) + P(B_{|\Omega}) \in X_1 \oplus X_2$, there exists $\xi \in H^2(\Omega)$ such that $\nabla\xi = (I - P)(B_{|\Omega})$. Since $\partial\Omega$ is C^3, there exists $\overline{\xi} \in H^2(\mathbb{R}^3)$ such that $\overline{\xi}_{|\Omega} = \xi$. Set $B_1 = B - \nabla\overline{\xi}$ and

$$c = \int_\Omega (\phi v - u\psi + \overline{\xi}(u^2 + v^2))dx \Big/ \int_\Omega (u^2 + v^2)dx.$$

Setting $\widehat{\xi} = \overline{\xi} - c$, we have

$$(\phi, \psi, B) = \left(-\widehat{\xi}v, \widehat{\xi}u, \nabla\widehat{\xi}\right) + \left(\phi + \widehat{\xi}v, \psi - \widehat{\xi}u, B_1\right) \in T(u, v, A) + \overline{N}(u, v, A). \qquad \square$$

Proposition 2.

$$H^1(\Omega) \times H^1(\Omega) \times H^1(\mathbb{R}^3; \mathbb{R}^3) = T(u, v, A) \oplus N(u, v, A). \tag{2.2}$$

Proof. Assume $(u, v) \not\equiv (0, 0)$. Otherwise, the proof is straightforward. Let (ϕ, ψ, B) be any element in the left-hand side of (2.2). By using the decomposition $B = \nabla\xi + B_1 \in Y_1 \oplus Y_2$, we have

$$(\phi, \psi, B) = (-\xi v, \xi u, \nabla\xi) + (\phi + \xi v, \psi - \xi u, B_1).$$

Modifying ξ by adding an adequate constant to ξ (as in the proof of Proposition 1), we have $(\phi + \xi v, \psi - \xi u, B_1) \in N(u, v, A)$. Hence $(\phi, \psi, B) \in T(u, v, A) + N(u, v, A)$.

If $(-\xi v, \xi u, \nabla \xi)$ belongs to $N(u,v,B)$, ξ is a harmonic function in $\mathbb{R}^3$ and so is $\partial\xi/\partial x_i$ $(1 \le i \le 3)$. Since $\partial\xi/\partial x_i$ is assumed to belong to $L^2(\mathbb{R}^3)$, it is identical to 0 from the Liouville-type theorem. This implies that ξ is a constant function in $\mathbb{R}^3$. On the other hand we have $\int_\Omega (u^2+v^2)\xi dx = 0$ holds and $\xi \equiv 0$ follows. This implies $T(u,v,A) \cap N(u,v,A) = \{(0,0,0)\}$. □

By direct calculation, we can derive a concrete expression of the second variation (1.4).

Formula of the second variation of $\mathcal{H}$.

$$\mathcal{L}(u,v,A,\phi,\psi,B) = \frac{d^2}{d\epsilon^2}\mathcal{H}(u+\epsilon\phi, v+\epsilon\psi, A+\epsilon B)_{|\epsilon=0} \tag{2.3}$$

$$\begin{aligned}
&= \int_\Omega \left\{|\nabla\phi|^2 + |\nabla\psi|^2 - \alpha(1-u^2-v^2)(\phi^2+\psi^2) + 2\alpha(u\phi+v\psi)^2\right\} dx \\
&+ \int_\Omega \left\{A^2(\phi^2+\psi^2) - 2(\phi\langle\nabla\psi\cdot A\rangle - \psi\langle\nabla\phi\cdot A\rangle)\right\} dx \\
&+ \int_{\mathbb{R}^3} |\mathrm{rot}B|^2 dx + \int_\Omega (u^2+v^2)B^2 dx + 4\int_\Omega \langle A\cdot B\rangle(u\phi+v\psi)dx \\
&- 2\int_\Omega \left\{\phi\langle\nabla v\cdot B\rangle - \psi\langle\nabla u\cdot B\rangle + u\langle\nabla\psi\cdot B\rangle - v\langle\nabla\phi\cdot B\rangle\right\} dx.
\end{aligned}$$

Remark. If $\operatorname{div} B = 0$ in Ω and $\langle B\cdot\nu\rangle = 0$ on $\partial\Omega$, then

$$\int_\Omega (u\langle\nabla\psi\cdot B\rangle - v\langle\nabla\phi\cdot B\rangle)\,dx = \int_\Omega (\phi\langle\nabla v\cdot B\rangle - \psi\langle\nabla u\cdot B\rangle)\,dx.$$

This will be used in §6. In the next proposition, we see that the second variation of $\mathcal{H}$ does not depend on the tangential component $T(u,v,A)$. The following property can also be proved by direct calculation.

PROPOSITION 3. *Let* $(\Phi, A) = (u,v,A)$ *be a solution of* (1.2). *Then*

$$\mathcal{L}(u,v,A,\phi,\psi,B) = \mathcal{L}(u,v,A,\phi',\psi',B') \tag{2.4}$$

provided that (ϕ,ψ,B), $(\phi',\psi',B') \in H^1(\Omega)^2 \times H^1(\mathbb{R}^3;\mathbb{R}^3)$, *and* $(\phi-\phi',\psi-\psi',B-B') \in T(u,v,A)$.

We now present a similar formulation for (1.5). Let Φ belong to $C^1(\overline{\Omega};\mathbb{C})$. Similarly to the case of (1.1), we again set $\Phi = u+vi$ and $\Psi = \phi+\psi i$ and denote $\mathcal{H}_0(\Phi)$, $\mathcal{L}_0(\Phi,\Psi)$, $T_0(\Phi)$, and $N_0(\Phi)$ by $\mathcal{H}_0(u,v)$, $\mathcal{L}_0(u,v,\phi,\psi)$, $T_0(u,v)$, and $N_0(u,v)$, respectively. Let us define

$$T_0(\Phi) = T_0(u,v) = \{(-tv,tu) \in H^1(\Omega)\times H^1(\Omega) \mid t\in\mathbb{R}\},$$

$$N_0(\Phi) = N_0(u,v) = \left\{(\phi,\psi)\in H^1(\Omega)\times H^1(\Omega) \mid \int_\Omega (v\phi-u\psi)dx = 0\right\}.$$

We have the following properties.

PROPOSITION 4.

$$H^1(\Omega)\times H^1(\Omega) = T_0(u,v)\oplus N_0(u,v).$$

Proof. The proof is straightforward. □

The following formulas are also proved by a direct calculation.

Formula of the second variation of $\mathcal{H}_0$.

$$\mathcal{L}_0(u,v,\phi,\psi) = \frac{d^2}{d\epsilon^2}\mathcal{H}_0(u+\epsilon\phi, v+\epsilon\psi)_{|\epsilon=0} \tag{2.5}$$

$$= \int_\Omega \left\{ (|\nabla\phi|^2 + |\nabla\psi|^2) - \alpha(1-u^2-v^2)(\phi^2+\psi^2) + 2\alpha(u\phi+v\psi)^2 \right\} dx.$$

PROPOSITION 5. *Let $\Phi = (u,v)$ be a solution of* (1.6). *Then*

$$\mathcal{L}_0(u,v,\phi,\psi) = \mathcal{L}_0(u,v,\phi',\psi')$$

provided that (ϕ,ψ), $(\phi',\psi') \in H^1(\Omega)^2$, and $(\phi-\phi',\psi-\psi') \in T_0(u,v)$.

3. Main results. In this section, we present the main results. Let D be a domain defined by $D \equiv \{(r,z) \in \mathbb{R}^2 \mid r > 0\}$ and let Σ be a bounded domain in D with a C^3 boundary (cf. Fig. 2). Henceforth, we make the following assumption on Σ.

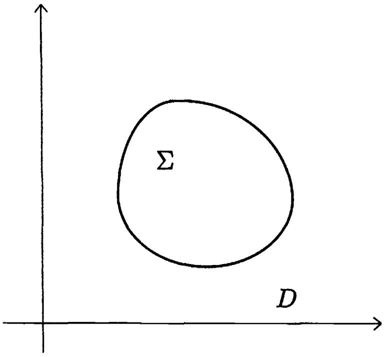

FIG. 2. $\overline{\Sigma} \subset D$.

Assumption. Σ is convex and $\overline{\Sigma} \subset D$.

We now define $\Omega \subset \mathbb{R}^3$ as follows (cf. Fig.1),

$$\Omega = \left\{ (r\cos\theta, r\sin\theta, z) \in \mathbb{R}^3 \mid (r,z) \in \Sigma,\ 0 \le \theta < 2\pi \right\} \simeq \Sigma \times S^1. \tag{3.1}$$

In this section and henceforth, we sometimes use the cylindrical coordinate system (r,θ,z) in $\mathbb{R}^3$ (i.e., $x_1 = r\cos\theta$, $x_2 = r\sin\theta$, $x_3 = z$).

We consider stable rotational solutions to (1.2) and (1.6) for the above domain Ω. In view of the rotationally symmetric situation, we seek for a solution (Φ, A) to (1.2) of the particular form

$$A(r,z,\theta) = Y(r,z)\left(\frac{-\sin\theta}{r}, \frac{\cos\theta}{r}, 0\right), \quad \Phi(r,z,\theta) = W(r,z)e^{im\theta}. \tag{3.2}$$

Here $W = W(r,z) > 0$ and $Y = Y(r,z)$ are real-valued functions in Σ and D, respectively.

The following theorem is the main result of this paper.

THEOREM 6. *Let m be an integer. There exists a $\alpha_0 > 0$ such that for any $\alpha \ge \alpha_0$,* (1.2) *has a solution (Φ_α, A_α) with*

$$\Phi_\alpha(x) = W_\alpha(r,z)e^{im\theta}, \quad A_\alpha(x) = Y_\alpha(r,z)\left(\frac{-\sin\theta}{r}, \frac{\cos\theta}{r}, 0\right),$$

where $W_\alpha \in C^2(\overline{\Sigma})$ and $Y_\alpha \in C^1(D)$, and

$$\lim_{\alpha\to\infty} \sup_{(r,z)\in\Sigma} |W_\alpha(r,z) - 1| = 0. \tag{3.3}$$

Moreover, it is stable in the sense that there exists a constant $\delta > 0$ such that

$$\mathcal{L}(\Phi_\alpha, A_\alpha, \Psi, B) \ge \delta \left(\|\Psi\|^2_{L^2(\Omega;\mathbb{C})} + \|B\|^2_{L^2(\Omega;\mathbb{R}^3)} + \|\nabla B\|^2_{L^2(\mathbb{R}^3;\mathbb{R}^{3\times3})} \right) \tag{3.4}$$

for $(\Psi, B) \in N(\Phi_\alpha, A_\alpha)$ *and* $\alpha \geq \alpha_0$.

We consider a stable solution to (1.6) of the form

$$\Phi(x) = Z(r,z)e^{im\theta} \quad (Z(r,z) > 0), \tag{3.5}$$

and we have the following result.

THEOREM 7. *Let* m *be an integer. Then there exists a constant* $\alpha_1 > 0$ *such that for any* $\alpha \geq \alpha_1$, (1.6) *has a solution* $\Phi_\alpha(x) = Z_\alpha(r,z)e^{im\theta}$ *with*

$$\lim_{\alpha\to\infty} \sup_{(r,z)\in\Sigma} |\, Z_\alpha(r,z) - 1| = 0. \tag{3.6}$$

Moreover, Φ_α *is stable in the sense that there exists a constant* $\delta_0 > 0$ *such that*

$$\mathcal{L}_0(\Phi_\alpha, \Psi) \geq \delta_0 \|\Psi\|^2_{L^2(\Omega;\mathbb{C})} \tag{3.7}$$

for any $\Psi \in N_0(\Phi_\alpha)$ *and* $\alpha \geq \alpha_1$.

We prove these results in §§4–6.

Remark. We can obtain similar theorems for the two-dimensional case, namely for an annulus. The proof can be done in the same manner.

Remark. In our previous paper [13], we constructed a stable solution to (1.6) for a "thin" annulus. Hence Theorem 7 is in an extension of the study in [13].

Remark. With $\Phi = u+vi$ $(u, v:$ real valued$)$, (1.6) becomes a stationary reaction-diffusion system for (u, v). It is interesting to compare our result in Theorem 7 with that obtained by Matano and Mimura [17] for the competition reaction-diffusion system with 2 components. In [17], they constructed nonconstant stable solutions in a special (dumbbell-shaped) domain. Theorem 7 may be regarded as a similar result to theirs. However, there is a significant difference between the competition system (two components) and our case. The competition system does not admit any nonconstant stable solution in an annulus (or ring-shaped domain), whereas the GL equation does.

Remark. Although the range of α in Theorems 6 (i.e., $\alpha \geq \alpha_0$) and 7 (i.e., $\alpha \geq \alpha_1$) might strongly depend on the shape of Ω, it is difficult to specify this range in general. However, it seems to the authors if the ring-shaped domain Ω is very "fat" and its hole is very small, α_0 and α_1 will be taken very large in order that the solutions become stable.

4. Construction of solutions. In this section, we construct solutions to (1.2) and (1.6) of the forms of (3.2) and (3.5), respectively. Moreover, we prove some elaborate asymptotic behaviors of those solutions as $\alpha \to \infty$ (cf. equations (4.2) and (4.4) below), which play essential roles in the stability analysis of the solutions. We begin with (1.6). By direct calculation with (3.5), we get the equation for Z:

$$\begin{cases} L_1 Z - \dfrac{m^2}{r^2} Z + \alpha Z(1-Z^2) = 0 \quad \text{in} \quad \Sigma, \\ \dfrac{\partial Z}{\partial \mathbf{n}} = 0 \quad \text{on} \quad \partial\Sigma, \end{cases} \tag{4.1}$$

where

$$L_1 = \frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right) + \frac{\partial^2}{\partial z^2}$$

and $\mathbf{n}$ is the outward unit normal vector on $\partial\Sigma$ in D.

We have the following result.

PROPOSITION 8. *There exists* $\alpha_0 > 0$ *such that* (4.1) *has a unique solution* $Z =$

$Z_\alpha(r,z) > 0$ *for* $\alpha \geq \alpha_0$ *which satisfies the following asymptotic properties:*

$$(4.2)\qquad \begin{cases} \limsup\limits_{\alpha\to\infty} \sup\limits_{(r,z)\in\Sigma} \alpha|Z_\alpha(r,z)-1| < \infty, \\ \limsup\limits_{\alpha\to\infty} \sup\limits_{(r,z)\in\Sigma} \alpha|\nabla Z_\alpha(r,z)| < \infty, \\ \lim\limits_{\alpha\to\infty} \sup\limits_{(r,z)\in\Sigma} \left|\alpha\,(1 - Z_\alpha(r,z)^2) - \dfrac{m^2}{r^2}\right| = 0. \end{cases}$$

Similarly as above, we get the system of equations for (W,Y) from (1.2) with (3.2):

$$(4.3)\qquad \begin{cases} L_1 W - \dfrac{1}{r^2}(m-Y)^2 W + \alpha W(1-W^2) = 0 \quad \text{in} \quad \Sigma, \\ L_2 Y + (m-Y)W^2 \Lambda_\Sigma = 0 \quad \text{in} \quad D, \\ \dfrac{\partial W}{\partial \mathbf{n}} = 0 \quad \text{on} \quad \partial\Sigma, \quad Y = 0 \quad \text{on} \quad \partial D, \end{cases}$$

where

$$L_2 = \frac{\partial^2}{\partial r^2} - \frac{1}{r}\frac{\partial}{\partial r} + \frac{\partial^2}{\partial z^2}$$

and $\Lambda_\Sigma(r,z) = 1$ for $(r,z) \in \Sigma$ and $\Lambda_\Sigma(r,z) = 0$ for $(r,z) \in D \setminus \Sigma$.

We have the following result.

PROPOSITION 9. *There exists* $\alpha_1 > 0$ *such that* (4.3) *has a solution* $(W,Y) = (W_\alpha(r,z), Y_\alpha(r,z))$ *for* $\alpha > \alpha_1$ *which satisfies the following asymptotic properties:*

$$(4.4)\qquad \begin{cases} \limsup\limits_{\alpha\to\infty} \sup\limits_{(r,z)\in\Sigma} \alpha|W_\alpha(r,z)-1| < \infty, \\ \limsup\limits_{\alpha\to\infty} \sup\limits_{(r,z)\in\Sigma} \alpha|\nabla W_\alpha(r,z)| < \infty, \\ \lim\limits_{\alpha\to\infty} \sup\limits_{(r,z)\in\Sigma} \left|\alpha\,(1 - W_\alpha(r,z)^2) - \dfrac{1}{r^2}(m - Y_\alpha(r,z))^2\right| = 0. \end{cases}$$

We prove these propositions after presenting several auxiliary lemmas.

LEMMA 10. *Let* ρ *be a real-valued function which is* C^3 *in a open set* $E \subset \mathbb{R}^n$. *Then we have*

$$(4.5)\qquad |\nabla\rho|\,\Delta\,|\nabla\rho| \geq \operatorname{grad}\rho\,(\Delta\rho) \quad \textit{in} \quad \{x \in E \mid |\nabla\rho(x)| \neq 0\},$$

where grad ρ *is the following differential operator:*

$$\operatorname{grad}\rho = \sum_{k=1}^n \frac{\partial\rho}{\partial x_k}\frac{\partial}{\partial x_k}.$$

Proof. By direct calculation,

$$\frac{\partial}{\partial x_k}\left(\sum_{j=1}^n \left(\frac{\partial\rho}{\partial x_j}\right)^2\right)^{1/2} = |\nabla\rho|^{-1}\sum_{j=1}^n \frac{\partial\rho}{\partial x_j}\frac{\partial^2\rho}{\partial x_j \partial x_k},$$

$$\begin{aligned} \frac{\partial^2}{\partial x_k^2}|\nabla\rho| &= |\nabla\rho|^{-1}\left(\sum_{j=1}^n \frac{\partial\rho}{\partial x_j}\frac{\partial^3\rho}{\partial x_j \partial x_k^2} + \sum_{j=1}^n \left(\frac{\partial^2\rho}{\partial x_j \partial x_k}\right)^2\right) - |\nabla\rho|^{-3}\left(\sum_{j=1}^n \frac{\partial\rho}{\partial x_j}\frac{\partial^2\rho}{\partial x_j \partial x_k}\right)^2 \\ &\geq |\nabla\rho|^{-1}\sum_{j=1}^n \frac{\partial\rho}{\partial x_j}\frac{\partial^3\rho}{\partial x_j \partial x_k^2}. \end{aligned}$$

Here we used Schwarz's inequality. Summing up the above in $k = 1, 2, \dots, n$, we have the desired inequality. □

LEMMA 11. *Let $E \subset \mathbb{R}^n$ be a domain with C^2 boundary and Γ be a relatively open subset of ∂E. Let $\rho \in C^2(\overline{E})$ be a real-valued function with $\partial\rho/\partial\nu = 0$ on Γ, where ν is the unit outward normal vector on ∂E. Then*

$$\frac{1}{2}\frac{\partial}{\partial\nu}|\nabla\rho|^2 = -h(\operatorname{grad}\rho, \operatorname{grad}\rho) \qquad \text{on} \quad \Gamma, \tag{4.6}$$

where $h(\cdot,\cdot)$ is the second fundamental form of the inclusion $\partial E \hookrightarrow \mathbb{R}^n$ with respect to $-\nu$ (cf. [15, Chap. 7]).

From the Neumann boundary condition of ρ, $\operatorname{grad}\rho_{|\partial\Gamma}$ can be identified with a first-order differential operator on Γ as well as a vector field on Γ.

Proof. First, extend $\nu(x) = (\nu_1(x), \dots, \nu_n(x))$ as a C^2 vector field on some neighborhood of Γ.

$$\frac{1}{2}\frac{\partial}{\partial\nu}|\nabla\rho|^2 = \frac{1}{2}\sum_{k=1}^{n}\nu_k\frac{\partial}{\partial x_k}\sum_{j=1}^{n}\left(\frac{\partial\rho}{\partial x_j}\right)^2 = \sum_{k=1}^{n}\sum_{j=1}^{n}\nu_k\frac{\partial\rho}{\partial x_j}\frac{\partial^2\rho}{\partial x_j\partial x_k}.$$

On the other hand, we have $\sum_{k=1}^{n}\nu_k(x)\partial\rho/\partial x_k = 0$ on Γ. Since $\operatorname{grad}\rho$ is a differential operator on Γ, we can operate $\operatorname{grad}\rho$ on the above equation and we get

$$0 = \operatorname{grad}\rho\left(\sum_{k=1}^{n}\nu_k(x)\partial\rho/\partial x_k\right) = \sum_{k,j}\left(\nu_k\frac{\partial\rho}{\partial x_j}\frac{\partial^2\rho}{\partial x_j\partial x_k} + \frac{\partial\nu_k}{\partial x_j}\frac{\partial\rho}{\partial x_j}\frac{\partial\rho}{\partial x_k}\right).$$

Using this, we have

$$\frac{1}{2}\frac{\partial}{\partial\nu}|\nabla\rho|^2 = -\sum_{j,k}\frac{\partial\nu_k}{\partial x_j}\frac{\partial\rho}{\partial x_j}\frac{\partial\rho}{\partial x_k}.$$

This completes the proof of Lemma 11. □

Proof of Proposition 8. Equation (4.1) is a typical case in the framework given in [1] and [23], so we briefly discuss the existence of a solution. Define two constant functions as follows:

$$Z_{+,\alpha}(r,z) = 1, \quad Z_{-,\alpha}(r,z) = 1 - \frac{d}{\alpha} \quad \text{in} \quad \Sigma.$$

It is easy to check that if $d > 0$ is large enough, $Z_{-,\alpha} \le Z_{+,\alpha}$ are a lower–upper solution pair of (4.1) for $\alpha > d$. Applying [1] or [23], we get a solution Z_α such that $Z_{-,\alpha} \le Z_\alpha \le Z_{+,\alpha}$ in Σ. The uniqueness of the positive solution can be proved in the same manner as in that of Lemma 3.1 in [13], so we omit it. The first estimate in (4.2) directly follows from the inequality

$$1 - \frac{d}{\alpha} \le Z_\alpha(r,z) \le 1 \quad \text{in} \quad \Sigma \tag{4.7}$$

for $\alpha > d$. We prove the remaining estimates of (4.2). Regarding Z_α as a function defined in Ω by $Z(x) = Z(\sqrt{x_1^2 + x_2^2}, x_3)$, we have

$$\Delta_x Z_\alpha - \frac{m^2 Z_\alpha}{x_1^2 + x_2^2} + \alpha Z_\alpha(1 - Z_\alpha^2) = 0 \quad \text{in} \quad \Omega, \tag{4.8}$$

with the Neumann boundary condition on $\partial\Omega$. The nonlinear term in (4.8) is bounded in $C^0(\overline{\Omega})$ for $\alpha > d$ by (4.7), and the Schauder estimate for the elliptic boundary value problem yields that $\{Z_\alpha\}_{\alpha > d}$ is bounded in $C^{1+\gamma}(\overline{\Omega})$, where $\gamma \in [0, 1)$ is an arbitrary constant. This implies that $\{|\nabla Z_\alpha|\}_{\alpha > d}$ is relatively compact in $C^0(\overline{\Omega})$, and hence it follows from (4.7) that $|\nabla Z_\alpha(x)|$ converges to 0 uniformly in $\overline{\Omega}$ as $\alpha \to \infty$. Applying grad Z_α to equation (4.8) with the aid of Lemma 10, we obtain the following differential inequalities:

$$(4.9)\qquad \begin{cases} |\nabla Z_\alpha|\Delta|\nabla Z_\alpha| + g_\alpha(x) \geq 0 \quad \text{in} \quad \Omega\cap G_\alpha, \\ |\nabla Z_\alpha|\dfrac{\partial}{\partial\nu}|\nabla Z_\alpha| = -h(\operatorname{grad} Z_\alpha, \operatorname{grad} Z_\alpha) \leq 0 \quad \text{on} \quad \partial\Omega\cap G_\alpha, \end{cases}$$

where

$$G_\alpha = \{x \in \overline{\Omega} \mid |\nabla Z_\alpha(x)| > 0\},$$

$$g_\alpha(x) = -\frac{m^2|\nabla Z_\alpha|^2}{x_1^2+x_2^2} - \sum_{j=1}^{2}\frac{\partial}{\partial x_j}\left(\frac{m^2}{x_1^2+x_2^2}\right)\frac{\partial Z_\alpha}{\partial x_j}Z_\alpha + \alpha(1-3Z_\alpha^2)|\nabla Z_\alpha|^2.$$

The first inequality in (4.9) is deduced by direct calculation. The second inequality follows from Lemma 11. Recall that grad Z_α is normal to the longitudinal direction of $\partial\Omega$, i.e., $Z_\alpha = Z_\alpha(\sqrt{x_1^2+x_2^2}, x_3)$ is constant in the longitudinal direction. Considering the sign of the second fundamental form and that the cross-section Σ of Ω is convex, we obtain $h(\operatorname{grad} Z_\alpha, \operatorname{grad} Z_\alpha) \geq 0$ on $\partial\Omega$. (4.9) is verified.

We shall prove that $\alpha\|\nabla Z_\alpha\|_{L^\infty}$ is bounded when $\alpha \to \infty$ with the aid of the maximum principle. Z_α is not a constant function and the set F_α defined by

$$F_\alpha = \{x \in \overline{\Omega} \mid 0 < |\nabla Z_\alpha(x)| = \max_{\Omega} |\nabla Z_\alpha|\},$$

is not empty for $\alpha > d$. By virtue of (4.7), there exists $c > 0$ such that $0 \leq \alpha(1-Z_\alpha^2) \leq c$ in Σ for $\alpha > d$. We estimate $|\nabla Z_\alpha|$ in F_α from above. We divide the argument into the following two cases (I and II) of α.

Case I. $F_\alpha \not\subset \partial\Omega$. Take any point $x_0 \in F_\alpha \setminus \partial\Omega$. We have $\Delta|\nabla Z_\alpha| \leq 0$ at $x = x_0$, and we have $g_\alpha(x_0) \geq 0$. By a simple calculation, we get

$$-\frac{m^2|\nabla Z_\alpha|^2}{x_1^2+x_2^2} - \sum_{j=1}^{2}\frac{\partial}{\partial x_j}\left(\frac{m^2}{x_1^2+x_2^2}\right)\frac{\partial Z_\alpha}{\partial x_j}Z_\alpha + \alpha(1-3Z_\alpha^2)|\nabla Z_\alpha|^2 \geq 0 \quad \text{in} \quad F_\alpha,$$

$$-\frac{1}{|\nabla Z_\alpha|}\sum_{j=1}^{2}\frac{\partial}{\partial x_j}\left(\frac{m^2}{x_1^2+x_2^2}\right)\frac{\partial Z_\alpha}{\partial x_j}Z_\alpha + \alpha(1-Z_\alpha^2)|\nabla Z_\alpha| \geq 2\alpha Z_\alpha^2|\nabla Z_\alpha| \quad \text{in} \quad F_\alpha,$$

$$2\alpha Z_\alpha^2|\nabla Z_\alpha| \leq \left(\sum_{j=1}^{2}(\frac{\partial}{\partial x_j}(\frac{m^2}{x_1^2+x_2^2}))^2\right)^{1/2} + 2c|\nabla Z_\alpha|.$$

For $\alpha \geq 2d + 8c$,

$$(4.10)\qquad \alpha|\nabla Z_\alpha| \leq 4\left(\sum_{j=1}^{2}\left(\frac{\partial}{\partial x_j}\left(\frac{m^2}{x_1^2+x_2^2}\right)\right)^2\right)^{1/2} + 2c|\nabla Z_\alpha| \quad \text{in} \quad F_\alpha.$$

Case II. $F_\alpha \subset \partial\Omega$. From Lemma 11,

$$(4.11)\qquad \partial|\nabla Z_\alpha|/\partial\nu \leq 0 \quad \text{on} \quad \partial\Omega\cap G_\alpha.$$

First, we show that $g_\alpha(x) \geq 0$ in F_α. If $g_\alpha(x_0) < 0$ for some $x_0 \in F_\alpha$, we see that $\Delta|\nabla Z_\alpha| > 0$ in some neighborhood of x_0 and we have $\partial|\nabla Z_\alpha|/\partial\nu > 0$ at $x = x_0$ from Hopf's boundary-point lemma (cf. [21]). This is contrary to (4.11). We conclude that g_α is nonnegative in F_α. By this fact, we get a similar estimate to (4.10) in Case I.

This completes the proof of the first two properties in (4.2). From these estimates, $C^1(\Sigma)$ norm of the nonlinear term of (4.1) is bounded when $\alpha \to \infty$. Again applying the Schauder estimate to (4.1), we get that $\|Z_\alpha\|_{C^{2+\gamma}(\overline{\Sigma})}$ is bounded when $\alpha \to \infty$ for any fixed $0 \le \gamma < 1$. This implies that ΔZ_α converges to 0 uniformly in $\overline{\Sigma}$ as $\alpha \to \infty$ and we obtain the last part of (4.2). This completes the proof of Proposition 8. □

Proof of Proposition 9. We remark that for $m = 0$, we can reduce (4.3) to (4.1) by setting $Y \equiv 0$. For $m \neq 0$, if (W, Y) is a solution to (4.3), then $(W, -Y)$ is a solution to (4.3) obtained by replacing m by $-m$. Hence in the construction of solutions, we can assume without loss of generality that m is a positive integer. Since m is positive, (4.3) becomes a so-called cooperation system for functions such that $0 \le W \le 1$, $0 \le Y \le m$. Actually, the nonlinear term in the former equation is nondecreasing in Y and the one in the latter equation is nondecreasing in W provided that W and Y are in the above region. Hence the comparison method (upper–lower solution method) is again applicable. However, in this case, we have the difficulty that D is an unbounded domain and a coefficient of the equation of Y is singular on ∂D (see the operator L_2). We deal with this difficulty by considering an approximation problem by taking a bounded subdomain D_p where the coefficients are bounded and we can thereby get the desired solution in D by taking the limit $p \to \infty$. First, we introduce some auxiliary comparison functions.

$$(4.12) \qquad \begin{cases} W_1(r,z) = 1 - \dfrac{d_1}{\alpha}, \quad W_2(r,z) = 1, \\ Y_1(r,z) = d_2 r^2 e^{-\eta((r-a)^2+(z-b)^2)}, \quad Y_2'(r,z) = \dfrac{r^2}{1+r^2+z^2}, \\ Y_3'(r,z) = \dfrac{r}{(r^2+z^2)^s}, \quad Y_2(r,z) = \min(d_3 Y_2'(r,z), d_3 Y_3'(r,z), m), \end{cases}$$

where $d_1 > 0$, $d_2 > 0$, $d_3 > 0$ and $\eta > 0$ are positive constants and s is a constant such that $4s^2 - 2s - 1 < 0$, $1/2 < s$ (for instance, $s = 3/4$), and (a, b) is an arbitrarily fixed point in Σ. Through easy calculation, we get

(4.13)
$$\begin{cases} L_2 Y_1(r,z) = d_2 \eta r e^{-\eta((r-a)^2+(z-b)^2)} \left(4\eta r(r-a)^2 + 4\eta r(z-b)^2 - 10r + 6a\right), \\ L_2 Y_2'(r,z) = -\dfrac{10r^2 + 2r^2z^2 + 2r^4}{(1+r^2+z^2)^3}, \\ L_2 Y_3'(r,z) = \dfrac{(4s^2-2s-1)r^2 - z^2}{r(r^2+z^2)^{s+1}}. \end{cases}$$

LEMMA 12. *There are constants $d_1 > 0$, $d_2 > 0$, $d_3 > 0$, $\eta > 0$ such that the following inequalities hold for large $\alpha > 0$.*

$$(4.14) \qquad 0 < W_1 \le W_2 \le 1 \quad in \quad \Sigma, \qquad 0 < Y_1 \le Y_2 \le m \quad in \quad D,$$

$$(4.15) \qquad \begin{cases} L_1 W_1 - \dfrac{1}{r^2}(m - Y_1)^2 W_1 + \alpha W_1(1 - W_1^2) \ge 0 \quad in \quad \Sigma, \\ L_2 Y_1 + (m - Y_1) W_1^2 \Lambda_\Sigma \ge 0 \quad in \quad D, \\ \dfrac{\partial W_1}{\partial \mathbf{n}} = 0 \quad on \quad \partial\Sigma, \quad Y_1 = 0 \quad on \quad \partial D, \end{cases}$$

$$(4.16) \qquad \begin{cases} L_1 W_2 - \dfrac{1}{r^2}(m - Y_2)^2 W_2 + \alpha W_2(1 - W_2^2) \le 0 \quad in \quad \Sigma, \\ L_2 Y_2 + (m - Y_2) W_2^2 \Lambda_\Sigma \le 0 \quad in \quad D, \\ \dfrac{\partial W_2}{\partial \mathbf{n}} = 0 \quad on \quad \partial\Sigma, \quad Y_2 = 0 \quad on \quad \partial D, \end{cases}$$

We should remark that Y_2 *does not belong to* $C^2(D)$, *and we have to take the differential inequality of* Y_2 *in* (4.16) *in the weak sense, that is,*

$$\int_D (Y_2 L_2 S + (m - Y_2) W_2^2 \Lambda_\Sigma S) r\, dr dz \le 0 \tag{4.17}$$

for any $S = S(r,z) \in C^\infty(D)$ *satisfying* $S \ge 0$ *in* D *and* $\operatorname{supp} S \Subset D$.

Proof. By taking $\eta > 0$ large, we see that

$$\{(r,z) \in D \mid 4\eta r(r-a)^2 + 4\eta r(z-b)^2 - 10r + 6a < 0\} \subset \Sigma.$$

We take $d_2 > 0$ so small such that $0 < Y_1 \le m$ in D. Then

$$L_1 W_1 - \frac{1}{r^2}(m - Y_1)^2 W_1 + \alpha W_1(1 - W_1^2) \ge W_1 \left(d_1 - \frac{m^2}{r^2}\right) \ge 0$$

for large fixed $d_1 > 0$. We can retake $d_2 > 0$ smaller such that the second inequality of (4.15) is valid. Next, we prove (4.16). The first inequality is trivial. We see that $L_2 Y_2'(r,z)$ and $L_2 Y_3'(r,z)$ are negative in D. Take $d_3 > 0$ large so that $Y_2 = m$ in Σ and $Y_1 \le Y_2$ in D. The first inequality can in the sense of distribution be checked from the definition of Y_2. □

We approximate the domain D. Let $D_p = \{(r,z) \in D \mid 1/p < r,\ r^2 + z^2 < p^2\}$, where $p \in \mathbb{N}$ is a parameter. We consider the following boundary value problem,

$$\begin{cases} L_1 W - \dfrac{1}{r^2}(m - Y)^2 W + \alpha W(1 - W^2) = 0 \quad \text{in} \quad \Sigma, \\ L_2 Y + (m - Y) W^2 \Lambda_\Sigma = 0 \quad \text{in} \quad D_p, \\ \dfrac{\partial W}{\partial \mathbf{n}} = 0 \quad \text{on} \quad \partial\Sigma, \quad Y = Y_1 \quad \text{on} \quad \partial D_p. \end{cases} \tag{4.18}$$

This is a cooperation system in the region $0 < W < 1$, $0 < Y < m$. If we have a lower solution and an upper solution, we can conclude that there exists a solution between them by using the standard theory (cf. [17], [18], [23]). In our case, the situation is a little different from those dealt with in the aforementioned literature because the domains of definition of W and Y are different. However, we can carry out a completely similar argument with using (W_1, Y_1), (W_2, Y_2) as lower–upper solutions and get a solution (W, Y) such that $W_1 \le W \le W_2$ in Σ and $Y_1 \le Y \le Y_2$ in D_p. Thus we have the following approximate sequence of solutions to (4.3).

LEMMA 13. *For large* $p \in \mathbb{N}$, *there exists a solution* $(W^{(p)}, Y^{(p)}) \in C^{2+\gamma}(\overline{\Sigma}) \times C^{1+\gamma}(\overline{D}_p)$ *to* (4.18) *such that*

$$\begin{cases} W_1(r,z) \le W^{(p)}(r,z) \le W_2(r,z) \quad in \quad \Sigma, \\ Y_1(r,z) \le Y^{(p)}(r,z) \le Y_2(r,z) \quad in \quad D_p, \end{cases} \tag{4.19}$$

where $0 \le \gamma < 1$ *is an arbitrarily fixed constant.*

Applying the Schauder estimates with (4.19) to (4.18), we obtain that for any large k, the set of approximate solutions $\{(W^{(p)}, Y^{(p)})\}_{p \ge k+1}$ are relatively compact in $C^2(\overline{\Sigma}) \times C^1(\overline{D}_k)$. Applying the diagonal argument, we get a convergent subsequence and, consequently, a solution $(W_\alpha, Y_\alpha) \in C^2(\overline{\Sigma}) \times C^1(D)$ to equation (4.2) with the same estimate as (4.19), that is,

$$\begin{cases} W_1(r,z) \le W_\alpha(r,z) \le W_2(r,z) \quad \text{in} \quad \Sigma, \\ Y_1(r,z) \le Y_\alpha(r,z) \le Y_2(r,z) \quad \text{in} \quad D, \end{cases} \tag{4.20}$$

for large $\alpha > 0$. The former estimate in (4.20) implies the first property in (4.4). Hence the nonlinear terms of (4.3) are bounded uniformly in α. Using the Schauder estimate, we have a constant $c > 0$ such that

$$|\nabla W_\alpha| + |\nabla Y_\alpha| \le c \quad \text{in} \quad \overline{\Omega} \quad (\text{large } \alpha > 0). \tag{4.21}$$

To deduce the remaining estimates in (4.4), we can carry out a quite similar argument to that in the proof of Proposition 8. Using the orthogonal coordinate (x_1, x_2, x_3), let us set $W_\alpha(x) = W_\alpha((x_1^2 + x_2^2)^{1/2}, x_3)$. The first equation of (4.2) becomes

$$\begin{cases} \Delta W_\alpha - \dfrac{1}{x_1^2 + x_2^2}(m - Y_\alpha)^2 W_\alpha + \alpha W_\alpha(1 - W_\alpha^2) = 0 \quad \text{in} \quad \Omega, \\ \dfrac{\partial W_\alpha}{\partial \nu} = 0 \quad \text{on} \quad \partial\Omega. \end{cases} \tag{4.22}$$

Applying $\operatorname{grad} W_\alpha$ to the above equation and using Lemmas 10 and 11, we get

$$\begin{cases} |\nabla W_\alpha| \Delta |\nabla W_\alpha| + g_\alpha(x) \ge 0 \quad \text{in} \quad \Omega \cap G_\alpha, \\ |\nabla W_\alpha| \dfrac{\partial}{\partial \nu} |\nabla W_\alpha| \le 0 \quad \text{on} \quad \partial\Omega \cap G_\alpha, \end{cases} \tag{4.23}$$

where $G_\alpha = \{x \in \overline{\Omega} \mid |\nabla W_\alpha| > 0\}$ and

$$g_\alpha(x) = -\frac{1}{x_1^2 + x_2^2}(m - Y_\alpha)^2 |\nabla W_\alpha|^2 - \left\langle \nabla W_\alpha \nabla \left(\frac{(m - Y_\alpha)^2}{x_1^2 + x_2^2} \right) \right\rangle W_\alpha$$
$$+ \alpha |\nabla W_\alpha|^2 (1 - 3W_\alpha^2).$$

Consider the set

$$F_\alpha = \left\{ x \in \overline{\Omega} \mid 0 < |\nabla W_\alpha(x)| = \max_{\overline{\Omega}} |\nabla W_\alpha| \right\}$$

and apply the same argument as for Z_α in the proof of Proposition 8; we have $g_\alpha(x) \ge 0$ in F_α for large $\alpha > 0$. Thus we obtain a uniform bound for $\alpha |\nabla W_\alpha|$ in Ω. From this estimate, the $C^1(\overline{\Omega})$ norm of the nonlinear term of (4.22) is bounded when $\alpha \to \infty$. Again from the Schauder estimate, $\{W_\alpha\}_\alpha$ is bounded in $C^{2+\gamma}$ for $0 \le \gamma < 1$. Therefore, ΔW_α uniformly converges to 0 in Ω as $\alpha \to \infty$ and we obtain the desired convergence in the last property of (4.4). □

5. Stability of Φ_α in Theorem 7. In this section, we complete the proof of Theorem 7. We will prove the stability of Φ_α, which was constructed through (4.1) by Proposition 8,

$$\Phi_\alpha(x) = Z_\alpha(r, z) e^{im\theta}. \tag{5.1}$$

To prove the stability of Φ_α in (1.6) for large $\alpha > 0$, we show that $\mathcal{L}_0$ is positive definite in $N_0(\Phi_\alpha)$. For this purpose, we consider the linearized eigenvalue problem of (1.6). For convenience of notation, we discuss the problem in terms of real-valued functions. Let u_α and v_α be the real and the imaginary parts of Φ_α, i.e., $u_\alpha(x) = Z_\alpha(r, z) \cos m\theta$ and $v_\alpha(x) = Z_\alpha(r, z) \sin m\theta$. Thus we consider the following eigenvalue problem:

$$\begin{cases} \Delta \begin{pmatrix} \phi \\ \psi \end{pmatrix} + \alpha \begin{pmatrix} 1 - 3u_\alpha^2 - v_\alpha^2 & -2u_\alpha v_\alpha \\ -2u_\alpha v_\alpha & 1 - u_\alpha^2 - 3v_\alpha^2 \end{pmatrix} \begin{pmatrix} \phi \\ \psi \end{pmatrix} \\ \qquad + \mu \begin{pmatrix} \phi \\ \psi \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \ \text{in } \Omega, \\ \dfrac{\partial \phi}{\partial \nu} = \dfrac{\partial \psi}{\partial \nu} = 0 \quad \text{on} \quad \partial\Omega, \end{cases} \tag{5.2}$$

where

$$\Delta = \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} + \frac{\partial^2}{\partial x_3^2} = \frac{1}{r}\frac{\partial}{\partial r}\left(r \frac{\partial}{\partial r} \right) + \frac{\partial^2}{\partial z^2} + \frac{1}{r^2}\frac{\partial^2}{\partial \theta^2}.$$

ϕ and ψ are real-valued functions in Ω. We can show that (5.2) is a self-adjoint eigenvalue problem with real (countable) eigenvalues $\{\mu_\ell(\alpha)\}_{\ell=1}^{\infty}$ which are arranged in increasing order (counting multiplicity). It is easy to see that the set of eigenvalues contains 0 because $(\phi, \psi) = (-v_\alpha, u_\alpha)$ satisfies (5.11) with $\mu = 0$. This is due to the invariance in (1.7). We will prove that $\mu_1(\alpha) = 0$ and $\mu_2(\alpha) > 0$ is bounded away from 0 when $\alpha > 0$ is large. We change the variables as follows:

$$\text{(5.3)} \quad \begin{pmatrix} \widehat{\phi}(r,\theta,z) \\ \widehat{\psi}(r,\theta,z) \end{pmatrix} = R(-m\theta) \begin{pmatrix} \phi(r,\theta,z) \\ \psi(r,\theta,z) \end{pmatrix}, \quad \text{where } R(\theta) = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}.$$

The eigenvalue problem is written in terms of $\widehat{\phi}$ and $\widehat{\psi}$ as follows.

$$\text{(5.4)} \quad \begin{cases} \Delta \begin{pmatrix} \widehat{\phi} \\ \widehat{\psi} \end{pmatrix} - \dfrac{2m}{r^2} \begin{pmatrix} \partial\widehat{\psi}/\partial\theta \\ -\partial\widehat{\phi}/\partial\theta \end{pmatrix} + \left(\alpha(1 - Z_\alpha^2) - \dfrac{m^2}{r^2}\right) \begin{pmatrix} \widehat{\phi} \\ \widehat{\psi} \end{pmatrix} \\ \qquad - 2\alpha Z_\alpha^2 \begin{pmatrix} \widehat{\phi} \\ 0 \end{pmatrix} + \mu \begin{pmatrix} \widehat{\phi} \\ \widehat{\psi} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \quad \text{in } \Omega, \\ \dfrac{\partial\widehat{\phi}}{\partial\nu} = \dfrac{\partial\widehat{\psi}}{\partial\nu} = 0 \quad \text{on} \quad \partial\Omega, \end{cases}$$

We express $\left(\begin{smallmatrix} \widehat{\phi} \\ \widehat{\psi} \end{smallmatrix}\right)$ in the form of the Fourier expansion

$$\text{(5.5)} \quad \begin{pmatrix} \widehat{\phi}(r,\theta,z) \\ \widehat{\psi}(r,\theta,z) \end{pmatrix} = \frac{1}{\sqrt{2}}\xi_0(r,z) + \sum_{k=1}^{\infty} (\xi_k(r,z)\cos k\theta + \zeta_k(r,z)\sin k\theta),$$

where the vector-valued functions

$$\text{(5.6)} \quad \xi_k(r,z) = \begin{pmatrix} \xi_{k,1}(r,z) \\ \xi_{k,2}(r,z) \end{pmatrix}, \quad \zeta_k(r,z) = \begin{pmatrix} \zeta_{k,1}(r,z) \\ \zeta_{k,2}(r,z) \end{pmatrix}$$

are defined in Σ. Substitute (5.5) into (5.4); we can decompose the eigenvalue problem (5.4) into an infinite series of elliptic eigenvalue problems.

$$\text{(5.7)} \quad \begin{cases} L_1\xi_0 + \left(\alpha(1 - Z_\alpha^2) - \dfrac{m^2}{r^2}\right)\xi_0 - 2\alpha Z_\alpha^2 \begin{pmatrix} \xi_{0,1} \\ 0 \end{pmatrix} + \mu\xi_0 = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \text{ in } \Sigma, \\ \dfrac{\partial}{\partial\mathbf{n}}\xi_0 = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \quad \text{on} \quad \partial\Sigma. \end{cases}$$

$$\text{(5.8)} \quad \begin{cases} L_1\xi_k - \dfrac{k^2}{r^2}\xi_k - \dfrac{2mk}{r^2}\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}\zeta_k + \left(\alpha(1 - Z_\alpha^2) - \dfrac{m^2}{r^2}\right)\xi_k \\ \qquad - 2\alpha Z_\alpha^2 \begin{pmatrix} \xi_{k,1} \\ 0 \end{pmatrix} + \mu\xi_k = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \text{ in } \Sigma, \\ L_1\zeta_k - \dfrac{k^2}{r^2}\zeta_k + \dfrac{2mk}{r^2}\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}\xi_k + \left(\alpha(1 - Z_\alpha^2) - \dfrac{m^2}{r^2}\right)\zeta_k \\ \qquad - 2\alpha Z_\alpha^2 \begin{pmatrix} \zeta_{k,1} \\ 0 \end{pmatrix} + \mu\zeta_k = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \quad \text{in } \Sigma, \\ \dfrac{\partial}{\partial\mathbf{n}}\xi_k = \dfrac{\partial}{\partial\mathbf{n}}\zeta_k = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \quad \text{on} \quad \partial\Sigma \quad (k \geq 1). \end{cases}$$

(5.8) is rewritten as follows:

$$\begin{cases} L_1\begin{pmatrix}\xi_{k,1}\\ \zeta_{k,2}\end{pmatrix} - \dfrac{k^2}{r^2}\begin{pmatrix}\xi_{k,1}\\ \zeta_{k,2}\end{pmatrix} - \dfrac{2mk}{r^2}\begin{pmatrix}0&1\\1&0\end{pmatrix}\begin{pmatrix}\xi_{k,1}\\ \zeta_{k,2}\end{pmatrix}\\ \quad + \left(\alpha(1-Z_\alpha^2) - \dfrac{m^2}{r^2}\right)\begin{pmatrix}\xi_{k,1}\\ \zeta_{k,2}\end{pmatrix} - 2\alpha Z_\alpha^2\begin{pmatrix}\xi_{k,1}\\ 0\end{pmatrix} + \mu\begin{pmatrix}\xi_{k,1}\\ \zeta_{k,2}\end{pmatrix} = \begin{pmatrix}0\\ 0\end{pmatrix} \text{ in } \Sigma,\\ \dfrac{\partial}{\partial \mathbf{n}}\begin{pmatrix}\xi_{k,1}\\ \zeta_{k,2}\end{pmatrix} = \begin{pmatrix}0\\ 0\end{pmatrix} \quad \text{on} \quad \partial\Sigma \qquad (k \geq 1).\end{cases} \tag{5.9}$$

$$\begin{cases} L_1\begin{pmatrix}\zeta_{k,1}\\ -\xi_{k,2}\end{pmatrix} - \dfrac{k^2}{r^2}\begin{pmatrix}\zeta_{k,1}\\ -\xi_{k,2}\end{pmatrix} - \dfrac{2mk}{r^2}\begin{pmatrix}0&1\\1&0\end{pmatrix}\begin{pmatrix}\zeta_{k,1}\\ -\xi_{k,2}\end{pmatrix}\\ \quad + \left(\alpha(1-Z_\alpha^2) - \dfrac{m^2}{r^2}\right)\begin{pmatrix}\zeta_{k,1}\\ -\xi_{k,2}\end{pmatrix} - 2\alpha Z_\alpha^2\begin{pmatrix}\zeta_{k,1}\\ 0\end{pmatrix} + \mu\begin{pmatrix}\zeta_{k,1}\\ -\xi_{k,2}\end{pmatrix} = \begin{pmatrix}0\\ 0\end{pmatrix} \text{ in } \Sigma,\\ \dfrac{\partial}{\partial \mathbf{n}}\begin{pmatrix}\zeta_{k,1}\\ -\xi_{k,2}\end{pmatrix} = \begin{pmatrix}0\\ 0\end{pmatrix} \quad \text{on} \quad \partial\Sigma \qquad (k \geq 1).\end{cases} \tag{5.10}$$

We see that (5.9) and (5.10) are identical as an eigenvalue problem. Both of them are rewritten as follows:

$$\begin{cases} L_1\begin{pmatrix}\tau\\ \sigma\end{pmatrix} - \dfrac{k^2}{r^2}\begin{pmatrix}\tau\\ \sigma\end{pmatrix} - \dfrac{2mk}{r^2}\begin{pmatrix}0&1\\1&0\end{pmatrix}\begin{pmatrix}\tau\\ \sigma\end{pmatrix}\\ \quad + \left(\alpha(1-Z_\alpha^2) - \dfrac{m^2}{r^2}\right)\begin{pmatrix}\tau\\ \sigma\end{pmatrix} - 2\alpha Z_\alpha^2\begin{pmatrix}\tau\\ 0\end{pmatrix} + \mu\begin{pmatrix}\tau\\ \sigma\end{pmatrix} = \begin{pmatrix}0\\ 0\end{pmatrix} \quad \text{in } \Sigma,\\ \dfrac{\partial}{\partial \mathbf{n}}\begin{pmatrix}\tau\\ \sigma\end{pmatrix} = \begin{pmatrix}0\\ 0\end{pmatrix} \quad \text{on} \quad \partial\Sigma,\end{cases} \tag{5.11}$$

where σ and τ are real-valued functions in Σ. We can regard (5.7) as the case where $k = 0$ in (5.11). We consider (5.11) for each $k \geq 0$. Let

$$\{\mu_\ell^{(k)}(\alpha)\}_{\ell=1}^\infty \quad \text{and} \quad \left\{\begin{pmatrix}\tau_{\ell,\alpha}^{(k)}\\ \sigma_{\ell,\alpha}^{(k)}\end{pmatrix}\right\}_{\ell=1}^\infty \subset L^2(\Sigma)\times L^2(\Sigma) \tag{5.12}$$

be the set of the eigenvalues arranged in increasing order (counting multiplicity) and the complete system of the corresponding eigenfunctions orthonormalized in $L^2(\Sigma) \times L^2(\Sigma)$. In this and the following sections, $L^2(\Sigma) = L^2(\Sigma; rdrdz)$ is the space of the real-valued square integrable functions with respect to the measure $rdrdz$, and it is the Hilbert space equipped with the inner product with this measure. Thus we obtain

$$\frac{1}{\sqrt{2\pi}}\begin{pmatrix}\tau_{\ell,\alpha}^{(0)}(r,z)\\ \sigma_{\ell,\alpha}^{(0)}(r,z)\end{pmatrix}, \quad \frac{1}{\sqrt{\pi}}\begin{pmatrix}\tau_{\ell,\alpha}^{(k)}(r,z)\cos k\theta\\ \sigma_{\ell,\alpha}^{(k)}(r,z)\sin k\theta\end{pmatrix}, \quad \frac{1}{\sqrt{\pi}}\begin{pmatrix}\tau_{\ell,\alpha}^{(k)}(r,z)\sin k\theta\\ -\sigma_{\ell,\alpha}^{(k)}(r,z)\cos k\theta\end{pmatrix}$$

($k \geq 1$, $\ell \geq 1$), which form a complete orthonormal system of eigenfunctions of (5.4) in $L^2(\Omega) \times L^2(\Omega)$.

We study the asymptotic properties of these eigenvalues and eigenfunctions for $\alpha \to \infty$.

LEMMA 14. *For each nonnegative integer k,*

$$\lim_{\alpha\to\infty} \mu_\ell^{(k)}(\alpha) = \mu_\ell^{(k)} \quad (k \geq 0,\ \ell \geq 1), \tag{5.13}$$

$$\lim_{\alpha\to\infty} \left(\|\nabla\tau_{\ell,\alpha}^{(k)}\|_{L^2(\Sigma)}^2 + \alpha\|\tau_{\ell,\alpha}^{(k)}\|_{L^2(\Sigma)}^2\right) = 0, \tag{5.14}$$

where $\{\mu_\ell^{(k)}\}_{\ell=1}^\infty$ *is the set of the eigenvalues arranged in increasing order (counting multiplicity) of the following eigenvalue problem:*

$$\begin{cases} L_1\sigma - \dfrac{k^2}{r^2}\sigma + \mu\sigma = 0 & in \quad \Sigma, \\ \dfrac{\partial\sigma}{\partial\mathbf{n}} = 0 & on \quad \partial\Sigma. \end{cases} \tag{5.15}$$

Proof. We prove this lemma by the aid of the variational characterization of the eigenvalues. Let $\{\sigma_\ell^{(k)}\}_{\ell=1}^\infty$ be an orthonormal system of eigenfunctions of (5.15) corresponding to $\{\mu_\ell^{(k)}\}_{\ell=1}^\infty$, i.e., $\int_\Sigma \sigma_i^{(k)}\sigma_j^{(k)} rdrdz = \delta_{i,j}$ for $i, j \geq 1$. For each given k, we prove (5.13) and (5.14). For simplicity of notation, we drop the number k and denote $\mu_\ell^{(k)}$, $\mu_\ell^{(k)}(\alpha)$, $\tau_{\ell,\alpha}^{(k)}$, $\sigma_{\ell,\alpha}^{(k)}$, and $\sigma_\ell^{(k)}$ by μ_ℓ, $\mu_\ell(\alpha)$, $\tau_{\ell,\alpha}$, $\sigma_{\ell,\alpha}$, and σ_ℓ, respectively. We prove that for any sequence $\{\alpha_j\}_{j=1}^\infty$ which tends to ∞ as $j \to \infty$, there exists a subsequence on which the limits in (5.13) and (5.14) hold for any ℓ. From (5.11) and the variational characterization of the eigenvalue of the self-adjoint operator (cf. [22]), we have

$$\mu_1(\alpha) = \inf\left\{ J_\alpha(\tau,\sigma) \mid \sigma,\tau \in H^1(\Sigma), \int_\Sigma (\sigma^2+\tau^2) rdrdz = 1 \right\}, \tag{5.16}$$

where

$$J_\alpha(\tau,\sigma) = \int_\Sigma \left(\left(\frac{\partial\sigma}{\partial r}\right)^2 + \left(\frac{\partial\sigma}{\partial z}\right)^2 + \left(\frac{\partial\tau}{\partial r}\right)^2 + \left(\frac{\partial\tau}{\partial z}\right)^2 + \frac{k^2}{r^2}(\sigma^2+\tau^2) + \frac{4mk}{r^2}\sigma\tau \right.$$
$$\left. - \left(\alpha(1-Z_\alpha^2) - \frac{m^2}{r^2}\right)(\sigma^2+\tau^2) + 2\alpha Z_\alpha^2\tau^2 \right) rdrdz.$$

Using the test function $(\tau,\sigma) = (0,\sigma_1)$, we have $\mu_1(\alpha) \leq J_\alpha(0,\sigma_1)$. Using Proposition 8, we obtain

$$\limsup_{\alpha\to\infty} \mu_1(\alpha) \leq \mu_1. \tag{5.17}$$

On the other hand, the eigenfunction $(\tau_{1,\alpha},\sigma_{1,\alpha})$ satisfies

$$\int_\Sigma \left(\left(\frac{\partial\tau_{1,\alpha}}{\partial r}\right)^2 + \left(\frac{\partial\tau_{1,\alpha}}{\partial z}\right)^2 + \frac{k^2}{r^2}\tau_{1,\alpha}^2 + \frac{2mk}{r^2}\sigma_{1,\alpha}\tau_{1,\alpha} \right.$$
$$\left. - \left(\alpha(1-Z_\alpha^2) - \frac{m^2}{r^2}\right)\tau_{1,\alpha}^2 + 2\alpha Z_\alpha^2\tau_{1,\alpha}^2 \right) rdrdz = \mu_1(\alpha)\|\tau_{1,\alpha}\|_{L^2(\Sigma)}^2, \tag{5.18}$$

$$\int_\Sigma \left(\left(\frac{\partial\sigma_{1,\alpha}}{\partial r}\right)^2 + \left(\frac{\partial\sigma_{1,\alpha}}{\partial z}\right)^2 + \frac{k^2}{r^2}\sigma_{1,\alpha}^2 + \frac{2mk}{r^2}\sigma_{1,\alpha}\tau_{1,\alpha} \right.$$
$$\left. - \left(\alpha(1-Z_\alpha^2) - \frac{m^2}{r^2}\right)\sigma_{1,\alpha}^2 \right) rdrdz = \mu_1(\alpha)\|\sigma_{1,\alpha}\|_{L^2(\Sigma)}^2. \tag{5.19}$$

From Proposition 8 and the boundedness of $\mu_1(\alpha)$ (when $\alpha \to \infty$), it follows that

$$\|\tau_{1,\alpha}\|_{L^2(\Sigma)}^2 \sim O(1/\alpha) \qquad (\alpha \to \infty).$$

Considering this fact with regard to (5.18), we obtain

$$\alpha\|\tau_{1,\alpha}\|_{L^2(\Sigma)}^2 \to 0, \quad \|\nabla\tau_{1,\alpha}\|_{L^2(\Sigma)}^2 \to 0 \quad \text{as} \quad \alpha \to \infty,$$

and

$$\lim_{\alpha\to\infty} \|\sigma_{1,\alpha}\|_{L^2(\Sigma)}^2 = 1.$$

In view of (5.19), $\sigma_{1,\alpha}$ is bounded in $H^1(\Sigma)$ and also relatively compact in the weak topology. Thus there exists a subsequence $\{\eta_j\}_j$ of $\{\alpha_j\}_j$ such that σ_{1,η_j} weakly converges to a certain $\widehat{\sigma}_1 \in H^1(\Sigma)$ and $\mu_1(\eta_j)$ converges to a μ' $(\leq \mu_1)$. From the lower semicontinuity of the H^1 norm in the weak convergence, we see

$$\|\widehat{\sigma}_1\|_{L^2(\Sigma)} = 1, \quad \liminf_{j\to\infty} \|\nabla\sigma_{1,\eta_j}\|^2_{L^2(\Sigma)} \geq \|\nabla\widehat{\sigma}_1\|^2_{L^2(\Sigma)}. \tag{5.20}$$

Taking the limit-inf as $j \to \infty$ in (5.19) for $\alpha = \eta_j$, we get

$$\int_\Sigma \left(\left(\frac{\partial\widehat{\sigma}_1}{\partial r}\right)^2 + \left(\frac{\partial\widehat{\sigma}_1}{\partial z}\right)^2 + \frac{k^2}{r^2}\widehat{\sigma}_1^2 \right) rdrdz \leq \mu' \|\widehat{\sigma}_1\|^2_{L^2(\Sigma)}. \tag{5.21}$$

From the variational characterization of μ_1, (5.21) implies that $\mu' \geq \mu_1$, $\mu' = \mu_1$ follows from (5.17), and $\widehat{\sigma}_1$ is a first eigenfunction of (5.15). Therefore, $\lim_{j\to\infty}\mu_1(\eta_j) = \mu_1$ holds. Moreover, we see from (5.19) that

$$\lim_{j\to\infty} \|\nabla\sigma_{1,\eta_j}\|^2_{L^2(\Sigma)} = \|\nabla\widehat{\sigma}_1\|^2_{L^2(\Sigma)}.$$

This concludes the first step of the induction. Next take an element $\widetilde{\sigma} \in \mathrm{L.h.}[\sigma_1,\sigma_2]$ such that $(\widetilde{\sigma}\cdot\widehat{\sigma}_1)_{L^2(\Sigma)} = 0$ and $\|\widetilde{\sigma}\|_{L^2(\Sigma)} = 1$, where $\mathrm{L.h.}[\sigma_1,\sigma_2]$ is the subspace spanned by σ_1, σ_2. Recall that

$$\mu_2(\alpha) = \inf\{J_\alpha(\tau,\sigma) \mid \|\sigma\|^2_{L^2(\Sigma)} + \|\tau\|^2_{L^2(\Sigma)} = 1, \quad (\sigma\cdot\sigma_{1,\alpha})_{L^2(\Sigma)} + (\tau\cdot\tau_{1,\alpha})_{L^2(\Sigma)} = 0\}.$$

By taking the test function $(\tau,\sigma) = (0,\widetilde{\sigma})$, we have

$$\mu_2(\alpha) \leq \frac{J_\alpha(-(\widetilde{\sigma}\cdot\sigma_{1,\alpha})_{L^2(\Sigma)}\tau_{1,\alpha}, \widetilde{\sigma} - (\widetilde{\sigma}\cdot\sigma_{1,\alpha})_{L^2(\Sigma)}\sigma_{1,\alpha})}{\| - (\widetilde{\sigma}\cdot\sigma_{1,\alpha})_{L^2(\Sigma)}\tau_{1,\alpha}\|^2_{L^2(\Sigma)} + \|\widetilde{\sigma} - (\widetilde{\sigma}\cdot\sigma_{1,\alpha})_{L^2(\Sigma)}\sigma_{1,\alpha}\|^2_{L^2(\Sigma)}}. \tag{5.22}$$

By the result obtained in the first step and taking the sequence $\alpha = \eta_j$ $(j = 1,2,3,\ldots)$, we get, by a direct calculation,

$$\limsup_{j\to\infty} \mu_2(\eta_j) \leq \mu_2.$$

From the above inequality and (4.2),

$$\int_\Sigma \Bigg(\left(\frac{\partial\tau_{2,\alpha}}{\partial r}\right)^2 + \left(\frac{\partial\tau_{2,\alpha}}{\partial z}\right)^2 + \frac{k^2}{r^2}\tau_{2,\alpha}^2 + \frac{2mk}{r^2}\sigma_{2,\alpha}\tau_{2,\alpha} - \left(\alpha(1-Z_\alpha^2) - \frac{m^2}{r^2}\right)\tau_{2,\alpha}^2 + 2\alpha Z_\alpha^2\tau_{2,\alpha}^2 \Bigg) rdrdz = \mu_2(\alpha)\|\tau_{2,\alpha}\|^2_{L^2(\Sigma)},$$

$$\int_\Sigma \Bigg(\left(\frac{\partial\sigma_{2,\alpha}}{\partial r}\right)^2 + \left(\frac{\partial\sigma_{2,\alpha}}{\partial z}\right)^2 + \frac{k^2}{r^2}\sigma_{2,\alpha}^2 + \frac{2mk}{r^2}\sigma_{2,\alpha}\tau_{2,\alpha} - \left(\alpha(1-Z_\alpha^2) - \frac{m^2}{r^2}\right)\sigma_{2,\alpha}^2 \Bigg) rdrdz = \mu_2(\alpha)\|\sigma_{2,\alpha}\|^2_{L^2(\Sigma)};$$

we have

$$\eta_j\|\tau_{2,\eta_j}\|^2_{L^2(\Sigma)} \to 0, \qquad \|\nabla\tau_{2,\eta_j}\|^2_{L^2(\Sigma)} \to 0, \qquad \|\sigma_{2,\eta_j}\|^2_{L^2(\Sigma)} \to 1 \quad \text{as } j\to\infty$$

and

$$\limsup_{j\to\infty} \|\sigma_{2,\eta_j}\|_{H^1(\Sigma)} < +\infty.$$

There exist a subsequence $\{\kappa_j\}_{j=1}^\infty \subset \{\eta_j\}_{j=1}^\infty$, μ'' $(\leq \mu_2)$, and $\widehat{\sigma}_2 \in H^1(\Sigma)$ such that

$$\lim_{j\to\infty} \mu_2(\kappa_j) = \mu'', \quad \lim_{j\to\infty} \sigma_{2,\kappa_j} = \widehat{\sigma}_2 \quad \text{weakly in} \quad H^1(\Sigma).$$

It follows that

$$\|\widehat{\sigma}_2\|_{L^2(\Sigma)} = 1, \quad (\widehat{\sigma}_2, \widehat{\sigma}_1)_{L^2(\Sigma)} = 0, \tag{5.23}$$

$$\int_\Sigma \left(\left(\frac{\partial \widehat{\sigma}_2}{\partial r} \right)^2 + \left(\frac{\partial \widehat{\sigma}_2}{\partial z} \right)^2 + \frac{k^2}{r^2} \widehat{\sigma}_2^2 \right) r dr dz \le \mu'' \|\widehat{\sigma}_2\|^2_{L^2(\Sigma)}. \tag{5.24}$$

By this we conclude that $\mu'' \ge \mu_2$. As in the first step, we obtain that $\mu'' = \mu_2$, $\widehat{\sigma}_2$ is a second eigenfunction of (5.15), and, moreover,

$$\lim_{j \to \infty} \|\nabla \sigma_{2,\kappa_j}\|^2_{L^2(\Sigma)} = \|\nabla \widehat{\sigma}_2\|^2_{L^2(\Sigma)}.$$

For higher eigenvalues ($\ell \ge 3$), we can repeat the similar argument inductively. Consequently, for each ℓ, there exists a subsequence $\{\alpha_{\ell,j}\}_{j=1}^\infty \subset \{\alpha_j\}_{j=1}^\infty$ such that

$$\lim_{j \to \infty} \mu_\ell(\alpha_{\ell,j}) = \mu_\ell, \tag{5.25}$$

$$\lim_{j \to \infty} \left(\|\nabla \tau_{\ell,\alpha_{\ell,j}}\|^2_{L^2(\Sigma)} + \alpha_{\ell,j} \|\tau_{\ell,\alpha_{\ell,j}}\|^2_{L^2(\Sigma)} \right) = 0. \tag{5.26}$$

From the arbitrariness of the sequence $\{\alpha_j\}_{j=1}^\infty$, (5.13) and (5.14) hold. □

Now we are in a position to prove the stability of Φ_α.

Proof of Theorem 7. From (5.15), it is easy to see that

$$\mu_\ell^{(k)} \ge \mu_1^{(k)} \ge \frac{k^2}{r_0^2} \quad \text{and} \quad \mu_\ell^{(k)} \ge \mu_2^{(0)} > 0 \quad (k \ge 0,\ \ell \ge 2),$$

where $r_0 = \inf\{r \mid (r,z) \in \Sigma\} > 0$. By Lemma 14, all $\mu_{\ell,\alpha}^{(k)}$'s except for $\mu_{1,\alpha}^{(0)}$ are positive and bounded away from 0 when $\alpha \to \infty$. On the other hand, $\mu_{1,\alpha}^{(0)} = 0$ because we can take $(\tau, \sigma) = (0, Z_\alpha)$ in (5.11) with $\mu = 0$ and $k = 0$. Then there exist constants $\delta_0 > 0$ and $\alpha_* > 0$ such that

$$J_\alpha(\widehat{\phi}, \widehat{\psi}) \ge \delta_0 \left(\|\widehat{\phi}\|^2_{L^2(\Omega)} + \|\widehat{\psi}\|^2_{L^2(\Omega)} \right) \quad \text{for} \quad (\widehat{\phi}, \widehat{\psi}) \in H^1(\Omega) \times H^1(\Omega) \text{ with } \int_\Omega Z_\alpha \widehat{\psi} dx = 0,$$

for $\alpha > \alpha_*$. Translating this inequality into the one in terms of (ϕ, ψ) (see (5.3)), we obtain

$$\mathcal{L}_0(\phi, \psi) \ge \delta_0 \left(\|\phi\|^2_{L^2(\Omega)} + \|\psi\|^2_{L^2(\Omega)} \right)$$
$$\text{for} \quad (\phi, \psi) \in H^1(\Omega) \times H^1(\Omega) \text{ with } \int_\Omega (\phi v_\alpha - \psi u_\alpha) dx = 0$$

for $\alpha > \alpha_*$. This completes the proof of Theorem 7. □

6. Stability of (Φ_α, A_α) in Theorem 6. In this section, we prove the stability of (Φ_α, A_α), which we constructed in §4.

$$\begin{cases} A_\alpha(x) = Y_\alpha(r,z) \left(\dfrac{-\sin\theta}{r}, \dfrac{\cos\theta}{r}, 0 \right), \\ \Phi_\alpha(x) = W_\alpha(r,z) e^{im\theta}. \end{cases} \tag{6.1}$$

As is the case in §5, we express Φ_α in terms of real-valued functions, i.e., we put $u_\alpha(x) = W_\alpha(r,z)\cos m\theta$, $v_\alpha(x) = W_\alpha(r,z)\sin m\theta$. We estimate the second variation $\mathcal{L}(\phi, \psi, B)$ on $\overline{N}(\Phi_\alpha, A_\alpha) = \overline{N}(u_\alpha, v_\alpha, A_\alpha)$ from below. We change the variables ϕ and ψ into $\widehat{\phi}$ and $\widehat{\psi}$ by

$$\begin{pmatrix} \widehat{\phi} \\ \widehat{\psi} \end{pmatrix} = R(-m\theta) \begin{pmatrix} \phi \\ \psi \end{pmatrix} \quad \text{(cf. (5.3))}.$$

Using formula (2.3), we can express $\mathcal{L}(u_\alpha, v_\alpha, A_\alpha, \phi, \psi, B)$ in terms of $\widehat{\phi}$, $\widehat{\psi}$, and B for the solution $(\Phi_\alpha, A_\alpha) = (u_\alpha, v_\alpha, A_\alpha)$. If $\operatorname{div} B = 0$ and $\langle B \cdot \nu \rangle = 0$ on $\partial\Omega$ (this is valid for $(\phi, \psi, B) \in \overline{N}(u_\alpha, v_\alpha, A_\alpha)$), the second variation is written concretely as follows:

$$\mathcal{L}(u_\alpha, v_\alpha, A_\alpha, \phi, \psi, B) = I_1(\widehat{\phi}, \widehat{\psi}) + I_2(B) + I_3(\widehat{\phi}, \widehat{\psi}, B),$$

where

$$\begin{aligned} &I_1(\widehat{\phi}, \widehat{\psi}) \\ &= \int_\Omega \left(\left(\frac{\partial \widehat{\phi}}{\partial r}\right)^2 + \left(\frac{\partial \widehat{\phi}}{\partial z}\right)^2 + \left(\frac{\partial \widehat{\psi}}{\partial r}\right)^2 + \left(\frac{\partial \widehat{\psi}}{\partial z}\right)^2 - \alpha(1 - W_\alpha^2)(\widehat{\phi}^2 + \widehat{\psi}^2) + 2\alpha W_\alpha^2 \widehat{\phi}^2 \right) dx \\ &\quad + \int_\Omega \left(\frac{(Y_\alpha - m)^2}{r^2} (\widehat{\phi}^2 + \widehat{\psi}^2) + \frac{1}{r^2} \left(\left(\frac{\partial \widehat{\phi}}{\partial \theta}\right)^2 + \left(\frac{\partial \widehat{\psi}}{\partial \theta}\right)^2 \right) + \frac{2(Y_\alpha - m)}{r^2} \left(\widehat{\psi} \frac{\partial \widehat{\phi}}{\partial \theta} - \widehat{\phi} \frac{\partial \widehat{\psi}}{\partial \theta} \right) \right) dx, \end{aligned}$$

$$I_2(B) = \int_{\mathbb{R}^3} |\operatorname{rot} B|^2 dx + \int_\Omega W_\alpha^2 B^2 dx,$$

$$I_3(\widehat{\phi}, \widehat{\psi}, B) = 4 \int_\Omega \left(\frac{(Y_\alpha - m) S_1 W_\alpha \widehat{\phi}}{r^2} + S_2 \frac{\partial W}{\partial r} \widehat{\psi} + S_3 \frac{\partial W}{\partial z} \widehat{\psi} \right) dx,$$

where S_1, S_2, and S_3 are defined from B through

$$B = \left(-S_1 \frac{\sin\theta}{r} + S_2 \cos\theta, S_1 \frac{\cos\theta}{r} + S_2 \sin\theta, S_3 \right).$$

To investigate the coerciveness of I_1, we consider the eigenvalue problem

$$\text{(6.2)} \qquad \begin{cases} \Delta \begin{pmatrix} \widehat{\phi} \\ \widehat{\psi} \end{pmatrix} + \dfrac{2}{r^2}(Y_\alpha - m) \begin{pmatrix} \partial\widehat{\psi}/\partial\theta \\ -\partial\widehat{\phi}/\partial\theta \end{pmatrix} - \dfrac{1}{r^2}(Y_\alpha - m)^2 \begin{pmatrix} \widehat{\phi} \\ \widehat{\psi} \end{pmatrix} \\ \qquad + \alpha(1 - W_\alpha^2) \begin{pmatrix} \widehat{\phi} \\ \widehat{\psi} \end{pmatrix} - 2\alpha W_\alpha^2 \begin{pmatrix} \widehat{\phi} \\ 0 \end{pmatrix} + \mu \begin{pmatrix} \widehat{\phi} \\ \widehat{\psi} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \text{ in } \Omega, \\ \dfrac{\partial \widehat{\phi}}{\partial \nu} = \dfrac{\partial \widehat{\psi}}{\partial \nu} = 0 \quad \text{on} \quad \partial\Omega. \end{cases}$$

As in the proof of Theorem 7, we express $\binom{\widehat{\phi}}{\widehat{\psi}}$ in the Fourier expansion as follows:

$$\text{(6.3)} \qquad \begin{pmatrix} \widehat{\phi}(r, \theta, z) \\ \widehat{\psi}(r, \theta, z) \end{pmatrix} = \frac{1}{\sqrt{2}} \xi_0(r, z) + \sum_{k=1}^{\infty} \left(\xi_k(r, z) \cos k\theta + \zeta_k(r, z) \sin k\theta \right),$$

where the real vector functions

$$\text{(6.4)} \qquad \xi_k(r, z) = \begin{pmatrix} \xi_{k,1}(r, z) \\ \xi_{k,2}(r, z) \end{pmatrix} \quad (k \geq 0), \quad \zeta_k(r, z) = \begin{pmatrix} \zeta_{k.1}(r, z) \\ \zeta_{k,2}(r, z) \end{pmatrix} \quad (k \geq 1).$$

The eigenvalue problem (6.2) is decomposed into the following:

$$\text{(6.5)} \qquad \begin{cases} L_1 \begin{pmatrix} \xi_{k,1} \\ \zeta_{k,2} \end{pmatrix} - \dfrac{k^2}{r^2} \begin{pmatrix} \xi_{k,1} \\ \zeta_{k,2} \end{pmatrix} + \left(\alpha(1 - W_\alpha^2) - \dfrac{1}{r^2}(Y_\alpha - m)^2 \right) \begin{pmatrix} \xi_{k,1} \\ \zeta_{k,2} \end{pmatrix} \\ \quad - \dfrac{2k}{r^2}(Y_\alpha - m) F \begin{pmatrix} \xi_{k,1} \\ \zeta_{k,2} \end{pmatrix} - 2\alpha W_\alpha^2 \begin{pmatrix} \xi_{k,1} \\ 0 \end{pmatrix} + \mu \begin{pmatrix} \xi_{k,1} \\ \zeta_{k,2} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \text{ in } \Sigma, \\ \dfrac{\partial}{\partial \mathbf{n}} \begin{pmatrix} \xi_{k,1} \\ \zeta_{k,2} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \quad \text{on} \quad \partial\Sigma \end{cases}$$

and

$$\text{(6.6)}\quad \begin{cases} L_1\begin{pmatrix}\zeta_{k,1}\\ -\xi_{k,2}\end{pmatrix} - \dfrac{k^2}{r^2}\begin{pmatrix}\zeta_{k,1}\\ -\xi_{k,2}\end{pmatrix} + \left(\alpha(1-W_\alpha^2) - \dfrac{1}{r^2}(Y_\alpha - m)^2\right)\begin{pmatrix}\zeta_{k,1}\\ -\xi_{k,2}\end{pmatrix} \\ \quad - \dfrac{2k}{r^2}(Y_\alpha - m)F\begin{pmatrix}\zeta_{k,1}\\ -\xi_{k,2}\end{pmatrix} - 2\alpha W_\alpha^2\begin{pmatrix}\zeta_{k,1}\\ 0\end{pmatrix} + \mu\begin{pmatrix}\zeta_{k,1}\\ -\xi_{k,2}\end{pmatrix} = \begin{pmatrix}0\\0\end{pmatrix} \text{ in }\Sigma, \\ \dfrac{\partial}{\partial \mathbf{n}}\begin{pmatrix}\zeta_{k,1}\\ -\xi_{k,2}\end{pmatrix} = \begin{pmatrix}0\\0\end{pmatrix} \quad \text{on} \quad \partial\Sigma, \end{cases}$$

respectively, where $F = \left(\begin{smallmatrix}0 & 1\\ 1 & 0\end{smallmatrix}\right)$. It is easy to see that (6.5) and (6.6) are equivalent to each other as eigenvalue problems. Both of them are rewritten as follows:

$$\text{(6.7)}\quad \begin{cases} L_1\begin{pmatrix}\tau\\ \sigma\end{pmatrix} - \dfrac{k^2}{r^2}\begin{pmatrix}\tau\\ \sigma\end{pmatrix} + \left(\alpha(1-W_\alpha^2) - \dfrac{1}{r^2}(Y_\alpha - m)^2\right)\begin{pmatrix}\tau\\ \sigma\end{pmatrix} \\ \qquad - \dfrac{2k}{r^2}(Y_\alpha - m)F\begin{pmatrix}\tau\\ \sigma\end{pmatrix} - 2\alpha W_\alpha^2\begin{pmatrix}\tau\\ 0\end{pmatrix} + \mu\begin{pmatrix}\tau\\ \sigma\end{pmatrix} = \begin{pmatrix}0\\0\end{pmatrix} \text{ in }\Sigma, \\ \dfrac{\partial}{\partial \mathbf{n}}\begin{pmatrix}\tau\\ \sigma\end{pmatrix} = \begin{pmatrix}0\\0\end{pmatrix} \quad \text{on} \quad \partial\Sigma. \end{cases}$$

Let

$$\{\mu_\ell^{(k)}(\alpha)\}_{\ell=1}^\infty \quad \text{and} \quad \left\{\begin{pmatrix}\tau_{\ell,\alpha}^{(k)}(r,z)\\ \sigma_{\ell,\alpha}^{(k)}(r,z)\end{pmatrix}\right\}_{\ell=1}^\infty \subset L^2(\Sigma)\times L^2(\Sigma)$$

be the eigenvalues arranged in increasing order (with counting multiplicity) and a complete system of the corresponding orthonormal eigenfunctions of (6.7). We can apply an argument completely similar to that in Lemma 14 and obtain the following asymptotic behaviors of the eigenvalues and eigenfunctions.

LEMMA 15. *For each nonnegative integer k,*

$$\text{(6.8)}\qquad \lim_{\alpha\to\infty}\mu_\ell^{(k)}(\alpha) = \mu_\ell^{(k)} \quad (k\ge 0,\ \ell\ge 1),$$

$$\text{(6.9)}\qquad \lim_{\alpha\to\infty}\left(\|\nabla\tau_{\ell,\alpha}^{(k)}\|_{L^2(\Sigma)}^2 + \alpha\|\tau_{\ell,\alpha}^{(k)}\|_{L^2(\Sigma)}^2\right) = 0 \quad (k\ge 0,\ \ell\ge 1),$$

where $\{\mu_\ell^{(k)}\}_{\ell=1}^\infty$ is the set of the eigenvalues arranged in increasing order (with counting multiplicity) of the following eigenvalue problem:

$$\text{(6.10)}\qquad \begin{cases} L_1\sigma - \dfrac{k^2}{r^2}\sigma + \mu\sigma = 0 \quad \textit{in} \quad \Sigma, \\ \dfrac{\partial\sigma}{\partial\mathbf{n}} = 0 \quad \textit{on} \quad \partial\Sigma. \end{cases}$$

LEMMA 16. *The family of functions*

$$\text{(6.11)}\quad \frac{1}{\sqrt{2\pi}}\begin{pmatrix}\tau_{\ell,\alpha}^{(0)}(r,z)\\ \sigma_{\ell,\alpha}^{(0)}(r,z)\end{pmatrix}, \quad \frac{1}{\sqrt{\pi}}\begin{pmatrix}\tau_{\ell,\alpha}^{(k)}(r,z)\cos k\theta\\ \sigma_{\ell,\alpha}^{(k)}(r,z)\sin k\theta\end{pmatrix}, \quad \frac{1}{\sqrt{\pi}}\begin{pmatrix}\tau_{\ell,\alpha}^{(k)}(r,z)\sin k\theta\\ -\sigma_{\ell,\alpha}^{(k)}(r,z)\cos k\theta\end{pmatrix}$$

($k\ge 1, \ell\ge 1$) form a complete orthonormal basis in $L^2(\Omega)\times L^2(\Omega)$.

Now we can expand any $\left(\begin{smallmatrix}\widehat{\phi}\\ \widehat{\psi}\end{smallmatrix}\right) \in L^2(\Omega)\times L^2(\Omega)$ in terms of the above basis:

$$\text{(6.12)}\qquad \begin{pmatrix}\widehat{\phi}\\ \widehat{\psi}\end{pmatrix} = \frac{1}{\sqrt{\pi}}\sum_{k\ge 1,\ell\ge 1}\left(c_{k,\ell}\begin{pmatrix}\tau_{\ell,\alpha}^{(k)}\cos k\theta\\ \sigma_{\ell,\alpha}^{(k)}\sin k\theta\end{pmatrix} + d_{k,\ell}\begin{pmatrix}\tau_{\ell,\alpha}^{(k)}\sin k\theta\\ -\sigma_{\ell,\alpha}^{(k)}\cos k\theta\end{pmatrix}\right)$$

$$+\frac{1}{\sqrt{2\pi}}\sum_{\ell\geq 1} g_\ell \begin{pmatrix} \tau^{(0)}_{\ell,\alpha} \\ \sigma^{(0)}_{\ell,\alpha} \end{pmatrix}, \quad g_\ell,\ c_{k,\ell},\ d_{k,\ell} \in \mathbb{R}.$$

Here g_ℓ, $c_{k,\ell}$, and $d_{k,\ell}$ are determined from $\widehat{\phi}$ and $\widehat{\psi}$ by

$$(6.13)\qquad \begin{cases} g_\ell = \dfrac{1}{\sqrt{2\pi}}\left((\widehat{\phi}\cdot\tau^{(0)}_{\ell,\alpha})_{L^2(\Omega)} + (\widehat{\psi}\cdot\sigma^{(0)}_{\ell,\alpha})_{L^2(\Omega)}\right), \\ c_{k,\ell} = \dfrac{1}{\sqrt{\pi}}\left((\widehat{\phi}\cdot\tau^{(k)}_{\ell,\alpha}\cos k\theta)_{L^2(\Omega)} + (\widehat{\psi}\cdot\sigma^{(k)}_{\ell,\alpha}\sin k\theta)_{L^2(\Omega)}\right), \\ d_{k,\ell} = \dfrac{1}{\sqrt{\pi}}\left((\widehat{\phi}\cdot\tau^{(k)}_{\ell,\alpha}\sin k\theta)_{L^2(\Omega)} - (\widehat{\psi}\cdot\sigma^{(k)}_{\ell,\alpha}\cos k\theta)_{L^2(\Omega)}\right), \\ \|\widehat{\phi}\|^2_{L^2(\Omega)} + \|\widehat{\psi}\|^2_{L^2(\Omega)} = \displaystyle\sum_{\ell=1}^{\infty} g_\ell^2 + \sum_{k=1}^{\infty}\sum_{\ell=1}^{\infty}(c^2_{k,\ell} + d^2_{k,\ell}). \end{cases}$$

We prepare an auxiliary result concerning a complete orthonormal basis of a product of Hilbert spaces, which we use in the proof of Lemma 19 below.

LEMMA 17. *Let H_1 and H_2 be two real Hilbert spaces with inner products $(\cdot,\cdot)_{H_1}$ and $(\cdot,\cdot)_{H_2}$, respectively, and let H be the product Hilbert space $H_1 \times H_2$ with the following inner product:*

$$\left(\begin{pmatrix}\phi\\ \psi\end{pmatrix}, \begin{pmatrix}\phi'\\ \psi'\end{pmatrix}\right)_H \equiv (\phi,\phi')_{H_1} + (\psi,\psi')_{H_2} \quad \textit{for} \quad \begin{pmatrix}\phi\\ \psi\end{pmatrix}, \begin{pmatrix}\phi'\\ \psi'\end{pmatrix} \in H.$$

If there exists an orthonormal basis $\{\binom{\phi_n}{\psi_n}\}_{n=1}^{\infty} \subset H$, then

$$(6.14)\qquad \begin{cases} \displaystyle\sum_{n=1}^{\infty}(\phi,\phi_n)_{H_1}(\psi,\psi_n)_{H_2} = 0 \quad \textit{for any} \quad \begin{pmatrix}\phi\\ \psi\end{pmatrix} \in H, \\ \|\phi\|^2_{H_1} = \displaystyle\sum_{n=1}^{\infty}(\phi,\phi_n)^2_{H_1}, \quad \|\psi\|^2_{H_2} = \sum_{n=1}^{\infty}(\psi,\psi_n)^2_{H_2}. \end{cases}$$

Proof. Take any $\binom{\phi}{\psi} \in H$ and expand with respect to the given orthonormal basis. Then

$$(6.15)\qquad \begin{pmatrix}\phi\\ \psi\end{pmatrix} = \sum_{n=1}^{\infty}((\phi,\phi_n)_{H_1} + (\psi,\psi_n)_{H_2})\begin{pmatrix}\phi_n\\ \psi_n\end{pmatrix},$$

$$(6.16)\qquad \left(\begin{pmatrix}\phi\\ \psi\end{pmatrix}, \begin{pmatrix}\phi\\ \psi\end{pmatrix}\right)_H = \|\phi\|^2_{H_1} + \|\psi\|^2_{H_2} = \sum_{n=1}^{\infty}((\phi,\phi_n)_{H_1} + (\psi,\psi_n)_{H_2})^2.$$

Taking $\phi = 0 \in H_1$ or $\psi = 0 \in H_2$, we get the second and third equalities in (6.14). The first equality in (6.14) follows immediately from (6.16). □

The following lemma directly follows from the above lemmas.

LEMMA 18. *For any $(\widehat{\phi},\widehat{\psi}) \in L^2(\Omega) \times L^2(\Omega)$, the following equalities hold:*

$$\sum_{\ell=1}^{\infty}(\widehat{\phi}\cdot\tau^{(0)}_{\ell,\alpha})_{L^2(\Omega)}(\widehat{\psi}\cdot\sigma^{(0)}_{\ell,\alpha})_{L^2(\Omega)} + 2\sum_{k,\ell\geq 1}(\widehat{\phi}\cdot\tau^{(k)}_{\ell,\alpha}\cos k\theta)_{L^2(\Omega)}(\widehat{\psi}\cdot\sigma^{(k)}_{\ell,\alpha}\sin k\theta)_{L^2(\Omega)}$$
$$- 2\sum_{k,\ell\geq 1}(\widehat{\phi}\cdot\tau^{(k)}_{\ell,\alpha}\sin k\theta)_{L^2(\Omega)}(\widehat{\psi}\cdot\sigma^{(k)}_{\ell,\alpha}\cos k\theta)_{L^2(\Omega)} = 0,$$

$$\begin{aligned}&\|\widehat{\phi}\|^2_{L^2(\Omega)}\\&=\frac{1}{2\pi}\left(\sum_{\ell=1}^{\infty}(\widehat{\phi}\cdot\tau^{(0)}_{\ell,\alpha})^2_{L^2(\Omega)}+2\sum_{\ell,k\geq 1}(\widehat{\phi}\cdot\tau^{(k)}_{\ell,\alpha}\cos k\theta)^2_{L^2(\Omega)}+2\sum_{\ell,k\geq 1}(\widehat{\phi}\cdot\tau^{(k)}_{\ell,\alpha}\sin k\theta)^2_{L^2(\Omega)}\right),\end{aligned}$$

$$\begin{aligned}&\|\widehat{\psi}\|^2_{L^2(\Omega)}\\&=\frac{1}{2\pi}\left(\sum_{\ell=1}^{\infty}(\widehat{\psi}\cdot\sigma^{(0)}_{\ell,\alpha})^2_{L^2(\Omega)}+2\sum_{\ell,k\geq 1}(\widehat{\psi}\cdot\sigma^{(k)}_{\ell,\alpha}\sin k\theta)^2_{L^2(\Omega)}+2\sum_{\ell,k\geq 1}(\widehat{\psi}\cdot\sigma^{(k)}_{\ell,\alpha}\cos k\theta)^2_{L^2(\Omega)}\right).\end{aligned}$$

Proof. Set $H_1 = H_2 = L^2(\Omega)$, $(\cdot,\cdot)_{H_1} = (\cdot,\cdot)_{H_2} = (\cdot,\cdot)_{L^2(\Omega)}$, and $(\widehat{\phi}\cdot\widehat{\psi})_{L^2(\Omega)} = \int_\Omega \widehat{\phi}(r,\theta,z)\widehat{\psi}(r,\theta,z)rdrdzd\theta$ for $\widehat{\phi},\widehat{\psi}\in L^2(\Omega)$. Combining Lemmas 16 and 17 concludes the proof. □

$I_1(\widehat{\phi},\widehat{\psi})$ is expressed in terms of the Fourier coefficients of $\widehat{\phi}$ and $\widehat{\psi}$:

$$I_1(\widehat{\phi},\widehat{\psi}) = \sum_{\ell=1}^{\infty}\mu^{(0)}_\ell(\alpha)g_\ell^2 + \sum_{k=1}^{\infty}\sum_{\ell=1}^{\infty}\mu^{(k)}_\ell(\alpha)(c^2_{k,\ell}+d^2_{k,\ell}). \tag{6.17}$$

We remark that $\tau^{(0)}_{1,\alpha}(r,z) = 0$, $\sigma^{(0)}_{1,\alpha}(r,z) = e_\alpha W_\alpha(r,z)$, $\mu^{(0)}_1(\alpha) = \mu^{(0)}_1 = 0$, $\mu^{(0)}_2 > 0$, $e_\alpha \neq 0$, is a certain real number which satisfies $\lim_{\alpha\to\infty} e_\alpha^2 = 1/|\Omega|$.

We have the following coercive inequality.

LEMMA 19. *For any $c > 0$ and $\eta > 0$, there exist constants $\alpha_1 > 0$ and $c' > 0$ such that*

$$I_1(\widehat{\phi},\widehat{\psi}) \geq c\|\widehat{\phi}\|^2_{L^2(\Omega)} + \left(\min(\mu^{(0)}_2(\alpha),\mu^{(1)}_1(\alpha)) - \eta\right)\|\widehat{\psi}\|^2_{L^2(\Omega)} - c'(\widehat{\psi}\cdot W_\alpha)^2_{L^2(\Omega)} \tag{6.18}$$

for any $\widehat{\phi},\widehat{\psi}\in H^1(\Omega)$ and $\alpha\geq\alpha_1$.

Proof. In view of the eigenvalues of (6.10) and Lemma 15, for a given $c > 0$, we can take a natural number N so that $\mu^{(k)}_\ell(\alpha) \geq c+1$ for $k+\ell > N$, $k\geq 0$, $\ell\geq 1$, and for any large $\alpha > 0$. Thus we have,

$$\begin{aligned}I_1(\widehat{\phi},\widehat{\psi}) \geq &\sum_{\ell=1}^{N}\mu^{(0)}_\ell(\alpha)g^2_\ell + \sum_{k+\ell\leq N}\mu^{(k)}_\ell(\alpha)(c^2_{k,\ell}+d^2_{k,\ell})\\&+(c+1)\left(\sum_{\ell>N}g^2_\ell + \sum_{k\geq 1,\ell\geq 1,k+\ell>N}(c^2_{k,\ell}+d^2_{k,\ell})\right).\end{aligned}$$

Substituting (6.13), we have

$$\begin{aligned}2\pi I_1 \geq &\sum_{\ell=1}^{N}\mu^{(0)}_\ell(\alpha)(\widehat{\phi}\tau^{(0)}_{\ell,\alpha})^2_{L^2(\Omega)}\\&+2\sum_{k+\ell\leq N}\mu^{(k)}_\ell(\alpha)\left((\widehat{\phi}\tau^{(k)}_{\ell,\alpha}\cos k\theta)^2_{L^2(\Omega)}+(\widehat{\phi}\tau^{(k)}_{\ell,\alpha}\sin k\theta)^2_{L^2(\Omega)}\right)\\&+(c+1)\left\{\sum_{\ell>N}(\widehat{\phi}\tau^{(0)}_{\ell,\alpha})^2_{L^2(\Omega)}+2\sum_{k+\ell>N}\left((\widehat{\phi}\tau^{(k)}_{\ell,\alpha}\cos k\theta)^2_{L^2(\Omega)}+(\widehat{\phi}\tau^{(k)}_{\ell,\alpha}\sin k\theta)^2_{L^2(\Omega)}\right)\right\}\\&+2\sum_{\ell=1}^{N}\mu^{(0)}_\ell(\alpha)(\widehat{\phi}\tau^{(0)}_{\ell,\alpha})_{L^2(\Omega)}(\widehat{\psi}\sigma^{(0)}_{\ell,\alpha})_{L^2(\Omega)}\\&+4\sum_{k+\ell\leq N}\mu^{(k)}_\ell(\alpha)(\widehat{\phi}\tau^{(k)}_{\ell,\alpha}\cos k\theta)_{L^2(\Omega)}(\widehat{\psi}\sigma^{(k)}_{\ell,\alpha}\sin k\theta)_{L^2(\Omega)}\end{aligned}$$

$$
\begin{aligned}
&-4\sum_{k+\ell\le N}\mu_\ell^{(k)}(\alpha)(\widehat{\phi\tau}^{(k)}_{\ell,\alpha}\sin k\theta)_{L^2(\Omega)}(\widehat{\psi\sigma}^{(k)}_{\ell,\alpha}\cos k\theta)_{L^2(\Omega)}\\
&+2(c+1)\sum_{\ell>N}(\widehat{\phi\tau}^{(0)}_{\ell,\alpha})_{L^2(\Omega)}(\widehat{\psi\sigma}^{(0)}_{\ell,\alpha})_{L^2(\Omega)}\\
&+4(c+1)\sum_{k+\ell>N}\Big((\widehat{\phi\tau}^{(k)}_{\ell,\alpha}\cos k\theta)_{L^2(\Omega)}(\widehat{\psi\sigma}^{(k)}_{\ell,\alpha}\sin k\theta)_{L^2(\Omega)}\\
&\qquad\qquad\qquad\qquad-(\widehat{\phi\tau}^{(k)}_{\ell,\alpha}\sin k\theta)_{L^2(\Omega)}(\widehat{\psi\sigma}^{(k)}_{\ell,\alpha}\cos k\theta)_{L^2(\Omega)}\Big)\\
&+\sum_{\ell=1}^{N}\mu_\ell^{(0)}(\alpha)(\widehat{\psi\sigma}^{(0)}_{\ell,\alpha})^2_{L^2(\Omega)}\\
&+2\sum_{k+\ell\le N}\mu_\ell^{(k)}(\alpha)\Big((\widehat{\psi\sigma}^{(k)}_{\ell,\alpha}\sin k\theta)^2_{L^2(\Omega)}+(\widehat{\psi\sigma}^{(k)}_{\ell,\alpha}\cos k\theta)^2_{L^2(\Omega)}\Big)\\
&+(c+1)\Big\{\sum_{\ell>N}(\widehat{\psi\sigma}^{(0)}_{\ell,\alpha})^2_{L^2(\Omega)}+2\sum_{k+\ell>N}\Big((\widehat{\psi\sigma}^{(k)}_{\ell,\alpha}\sin k\theta)^2_{L^2(\Omega)}+(\widehat{\psi\sigma}^{(k)}_{\ell,\alpha}\cos k\theta)^2_{L^2(\Omega)}\Big)\Big\}.
\end{aligned}
$$

From Lemma 18,

$$
\begin{aligned}
(6.19)\qquad I_1(\widehat{\phi},\widehat{\psi})\ge{}&\frac{c+1}{2\pi}\|\widehat{\phi}\|^2_{L^2(\Omega)}+\frac{1}{2\pi}\sum_{\ell=1}^{N}(\mu_\ell^{(0)}(\alpha)-c-1)(\widehat{\phi\tau}^{(0)}_{\ell,\alpha})^2_{L^2(\Omega)}\\
&+\frac{1}{\pi}\sum_{k+\ell\le N}(\mu_\ell^{(k)}(\alpha)-c-1)\Big((\widehat{\phi\tau}^{(k)}_{\ell,\alpha}\cos k\theta)^2_{L^2(\Omega)}+(\widehat{\phi\tau}^{(k)}_{\ell,\alpha}\sin k\theta)^2_{L^2(\Omega)}\Big)\\
&+\frac{1}{2\pi}\sum_{\ell=1}^{N}2(\mu_\ell^{(0)}(\alpha)-c-1)(\widehat{\phi\tau}^{(0)}_{\ell,\alpha})_{L^2(\Omega)}(\widehat{\psi\sigma}^{(0)}_{\ell,\alpha})_{L^2(\Omega)}\\
&+\frac{1}{2\pi}\sum_{k+\ell\le N}4(\mu_\ell^{(k)}(\alpha)-c-1)(\widehat{\phi\tau}^{(k)}_{\ell,\alpha}\cos k\theta)_{L^2(\Omega)}(\widehat{\psi\sigma}^{(k)}_{\ell,\alpha}\sin k\theta)_{L^2(\Omega)}\\
&+\frac{1}{2\pi}\sum_{k+\ell\le N}(-4)(\mu_\ell^{(k)}(\alpha)-c-1)(\widehat{\phi\tau}^{(k)}_{\ell,\alpha}\sin k\theta)_{L^2(\Omega)}(\widehat{\psi\sigma}^{(k)}_{\ell,\alpha}\cos k\theta)_{L^2(\Omega)}\\
&+\min(\mu_2^{(0)}(\alpha),\mu_1^{(1)}(\alpha))\left(\|\widehat{\psi}\|^2_{L^2(\Omega)}-\frac{1}{2\pi}(\widehat{\psi\sigma}^{(0)}_{1,\alpha})^2_{L^2(\Omega)}\right).
\end{aligned}
$$

We used $\mu_1^{(0)}(\alpha)=0$, $\tau^{(0)}_{1,\alpha}=0$, $\sigma^{(0)}_{1,\alpha}=e_\alpha W_\alpha$. From Lemma 15, equation (6.9), to the right-hand side of (6.19), the terms that include $\tau^{(k)}_{\ell,\alpha}$ can be absorbed in those that include $\|\widehat{\phi}\|^2_{L^2(\Omega)}$ and $\|\widehat{\psi}\|^2_{L^2(\Omega)}$ for large $\alpha>0$. We have

$$
I_1(\widehat{\phi},\widehat{\psi})\ge c\|\widehat{\phi}\|^2_{L^2(\Omega)}+(\min(\mu_2^{(0)}(\alpha),\mu_1^{(1)}(\alpha))-\eta)\|\widehat{\psi}\|^2_{L^2(\Omega)}-c'(\widehat{\psi}\cdot W_\alpha)^2_{L^2(\Omega)}
$$

for large $\alpha>0$. We obtain (6.18). □

LEMMA 20. *For $B\in L^2_{\mathrm{loc}}(\mathbb{R}^3;\mathbb{R}^3)$ such that $\nabla B\in L^2(\mathbb{R}^3;\mathbb{R}^{3\times3})$,*

$$
\|\nabla B\|^2_{L^2(\mathbb{R}^3;\mathbb{R}^{3\times3})}=\|\operatorname{div}B\|^2_{L^2(\mathbb{R}^3)}+\|\operatorname{rot}B\|^2_{L^2(\mathbb{R}^3;\mathbb{R}^3)}.
$$

Proof. This equality is proved by the Fourier transform. □

Now we estimate $\mathcal{L}(\widehat{\phi},\widehat{\psi},B)$ from below.

Proof of Theorem 6. Assume that $(\phi,\psi,B)\in\overline{N}(u_\alpha,v_\alpha,A_\alpha)$.

$$
\mathcal{L}(\phi,\psi,B)=I_1(\widehat{\phi},\widehat{\psi})+I_2(B)+I_3(\widehat{\phi},\widehat{\psi},B).
$$

We prove that $|I_3(\widehat{\phi},\widehat{\psi},B)|$ is dominated by I_1 and I_2.

$$\begin{aligned}|I_3(\widehat{\phi},\widehat{\psi},B)| &\le \left|\int_\Omega \frac{(Y_\alpha - m)S_1 W_\alpha \widehat{\phi}}{r^2} dx\right| + \left|\int_\Omega \left(S_2 \frac{\partial W}{\partial r}\widehat{\psi} + S_3 \frac{\partial W}{\partial z}\widehat{\psi}\right) dx\right| \\ &\le \int_\Omega \frac{|mS_1\widehat{\phi}|}{r^2} dx + \sup_\Omega |\nabla W_\alpha| \int_\Omega |\widehat{\psi}|(|S_2| + |S_3|)dx \\ &\le \frac{|m|}{r_0}\left(\epsilon \int_\Omega \frac{S_1^2}{r^2}dx + \frac{1}{4\epsilon}\int_\Omega \widehat{\phi}^2 dx\right) + \sup_\Omega |\nabla W_\alpha| \int_\Omega \left(\widehat{\psi}^2 + \frac{S_2^2 + S_3^2}{2}\right)dx \\ &= \sup_\Omega |\nabla W_\alpha| \cdot \|\widehat{\psi}\|^2_{L^2(\Omega)} + \frac{|m|}{4\epsilon r_0}\|\widehat{\phi}\|^2_{L^2(\Omega)} \\ &\quad + \frac{|m|\epsilon}{r_0}\int_\Omega \frac{S_1^2}{r^2}dx + \sup_\Omega |\nabla W_\alpha| \int_\Omega \frac{S_2^2 + S_3^2}{2} dx.\end{aligned}$$

From $|B|^2 = S_1^2/r^2 + S_2^2 + S_3^2$ and Proposition 9, take $\epsilon > 0$ so that $\epsilon h|m|/r_0 = 1/2$. Next, take c in Lemma 19 such that $c = |m|/(4\epsilon r_0) + 1$. From Lemma 19 and Proposition 9, we can take α_1 large so that the following inequality is true for $\delta = \min(\mu_2^{(0)}/2, \mu_1^{(1)}/2, 1) > 0$:

$$\begin{aligned}(6.20)\qquad \mathcal{L}(\phi,\psi,B) &\ge \delta\left(\|\widehat{\phi}\|^2_{L^2(\Omega)} + \|\widehat{\psi}\|^2_{L^2(\Omega)} + \|B\|^2_{L^2(\Omega;\mathbb{R}^3)} + \|\mathrm{rot}\, B\|^2_{L^2(\mathbb{R}^3;\mathbb{R}^3)}\right) \\ &= \delta\left(\|\phi\|^2_{L^2(\Omega)} + \|\psi\|^2_{L^2(\Omega)} + \|B\|^2_{L^2(\Omega;\mathbb{R}^3)} + \|\mathrm{rot}\, B\|^2_{L^2(\mathbb{R}^3;\mathbb{R}^3)}\right) \quad \text{for} \quad \alpha \ge \alpha_1.\end{aligned}$$

We used $(\widehat{\psi} \cdot W_\alpha)_{L^2(\Omega)} = 0$ for $(\phi,\psi,B) \in \overline{N}(u_\alpha, v_\alpha, A_\alpha)$. We will get a similar inequality on $N(u_\alpha, v_\alpha, A_\alpha)$. First, we recall the following inequality:

$$\int_{\mathbb{R}^3} \frac{\varphi(x)^2}{|x-y|^2} dx \le 4\int_{\mathbb{R}^3} |\nabla\varphi(x)|^2 dx \quad (\forall y \in \mathbb{R}^3, \forall \varphi \in H^1(\mathbb{R}^3)) \quad \text{(cf. [16])}.$$

Since $\Omega \subset \mathbb{R}^3$ is a bounded domain, by fixing y outside of Ω, we see that there exists a constant $R_1 > 0$ such that

$$(6.21)\qquad R_1 \int_\Omega \varphi^2 dx \le \int_{\mathbb{R}^3} |\nabla\varphi|^2 dx \quad (\forall \varphi \in H^1(\mathbb{R}^3)).$$

From Proposition 9, equation (4.4), there exist constants $R_2 > 0$ and $\alpha_2 > 0$ such that for any $\alpha > \alpha_2$,

$$(6.22)\qquad R_2 \int_\Omega \varphi^2 dx \le \int_\Omega |\nabla\varphi|^2 dx \quad \left(\forall \varphi \in H^1(\Omega);\ \int_\Omega (u_\alpha^2 + v_\alpha^2)\,\varphi dx = 0\right).$$

It is also true that there exists a $R_3 > 0$ such that

$$(6.23)\qquad \int_{\partial\Omega} \varphi^2 dS \le R_3 \int_\Omega (|\varphi|^2 + |\nabla\varphi|^2) dx \quad (\forall \varphi \in H^1(\Omega)\,).$$

Take any $(\phi,\psi,B) \in N(u_\alpha, v_\alpha, A_\alpha)$ and we have

$$(\phi,\psi,B) = (-v\xi, u\xi, \nabla\xi) + (\overline{\phi}, \overline{\psi}, \overline{B}) \in T(u,v,A) + \overline{N}(u,v,A),$$

which is, equivalently, $\phi = -v\xi + \overline{\phi}$, $\psi = u\xi + \overline{\psi}$, $B = \nabla\xi + \overline{B}$, and

$$(6.24)\qquad \int_\Omega (u_\alpha^2 + v_\alpha^2)\,\xi(x)dx = 0, \quad \Delta\xi = 0 \text{ in } \Omega, \quad \frac{\partial\xi}{\partial\nu} = \langle B \cdot \nu\rangle \text{ on } \partial\Omega.$$

From these equations, we see that

$$(6.25)\qquad \mathrm{rot}\, B = \mathrm{rot}\, \overline{B} \quad \text{in} \quad \mathbb{R}^3,$$

$$\phi^2+\psi^2=(-v\xi+\overline{\phi})^2+(u\xi+\overline{\psi})^2\leq 2(\overline{\phi}^2+\overline{\psi}^2)+2\xi^2 \quad \text{in} \quad \Omega. \tag{6.26}$$

By (6.22) and (6.24), we obtain

$$R_2\int_\Omega \xi^2 dx \leq \int_\Omega |\nabla\xi|^2 dx. \tag{6.27}$$

On the other hand, (6.24) yields

$$0=\int_\Omega \xi\Delta\xi dx=\int_{\partial\Omega}\xi\frac{\partial\xi}{\partial\nu}dS-\int_\Omega|\nabla\xi|^2dx$$

and, subsequently,

$$\begin{aligned}\int_\Omega|\nabla\xi|^2dx&=\int_{\partial\Omega}\xi\langle B\cdot\nu\rangle dS\leq\frac{\epsilon}{2}\int_{\partial\Omega}\xi^2dS+\frac{1}{2\epsilon}\int_{\partial\Omega}|B|^2dS\\&\leq\frac{\epsilon R_3}{2}\int_\Omega(\xi^2+|\nabla\xi|^2)dx+\frac{R_3}{2\epsilon}\int_\Omega(|B|^2+|\nabla B|^2)dx.\end{aligned} \tag{6.28}$$

Combining (6.27) and (6.28) and taking $\epsilon=R_2/R_3(R_2+1)$, we have

$$\int_\Omega|\nabla\xi|^2dx\leq\frac{R_3^2(1+1/R_2)}{2h^2}\int_\Omega\left(|B|^2+|\nabla B|^2\right)dx.$$

Using (6.26)–(6.29), we conclude that there exists a constant $c>0$, (which is independent of $(\phi,\psi,B)\in N(u_\alpha,v_\alpha,A_\alpha)$) such that

$$\int_\Omega(\phi^2+\psi^2)dx+\int_\Omega|B|^2dx+\int_{\mathbb{R}^3}|\mathrm{rot}B|^2dx\leq c\int_\Omega(\overline{\phi}^2+\overline{\psi}^2)dx+\int_\Omega|\overline{B}|^2dx+\int_{\mathbb{R}^3}|\mathrm{rot}\overline{B}|^2dx$$

On the other hand, from $\operatorname{div}B=0$ in $\mathbb{R}^3$ and Lemma 20, we see that

$$\|\nabla B\|_{L^2(\mathbb{R}^3;\mathbb{R}^{3\times3})}=\|\mathrm{rot}\,B\|_{L^2(\mathbb{R}^3;\mathbb{R}^3)}$$

and $\mathcal{L}(\phi,\psi,B)=\mathcal{L}(\overline{\phi},\overline{\psi},\overline{B})$ (cf. Proposition 3). Hence we obtain the desired inequality (3.4) from (6.20), which completes the proof of Theorem 6. □

REGULARITY OF THE GAIN TERM AND STRONG L^1 CONVERGENCE TO EQUILIBRIUM FOR THE RELATIVISTIC BOLTZMANN EQUATION*

HÅKAN ANDRÉASSON†

Abstract. The main purpose of the paper is to show that the gain term of the relativistic collision operator is regularizing. This is a generalization of P. L. Lions' analogous result in the nonrelativistic situation. The regularizing theorem has many applications in kinetic theory, and a few are discussed in this paper. In particular, the asymptotic behaviour of periodic solutions to the relativistic Boltzmann equation is studied. We show that such solutions converge strongly in L^1 to a global Jüttner equilibrium solution (sometimes called a relativistic Maxwellian) provided that the initial data satisfy the physically natural bounds of finite energy and entropy.

Key words. relativistic Boltzmann equation, regularity, Fourier integral operators, stationary phase, strong L^1 convergence, Jüttner solution

AMS subject classifications. 76P05, 83A05, 35S30

1. Introduction.

The relativistic Boltzmann equation models the space–time behaviour of the one-particle distribution function, corresponding to a many-particle system obeying the laws of relativistic mechanics. We refer to [ACB] for applications to different fields such as plasma and nuclear physics, and we mention the books of Synge [Sy], deGroot et al. [GLW], and Stewart [St] for background on the relativistic equation.

In §1, the relativistic Boltzmann equation is defined and the assumptions used throughout the paper are specified. Also, some general facts about the equation are presented. Section 2 is the main part of the paper. Here we show that the gain term of the relativistic collision operator is regularizing. In the classical setting, this result was first obtained by P. L. Lions [L]. Recently, a simpler proof has been given by Wennberg [W] by rewriting the gain term via Carleman's representation and using the fact that it then takes the form of a generalized Radon transform. Lions' approach [L] relies on the method of stationary phase and some facts from the theory of Fourier integral operators, and we will also follow this approach in the relativistic situation. The regularizing property of the gain term is a consequence of the specific nature of the collision geometry. For relativistic interactions, the collision geometry is different from the classical one due to the fact that the collison invariants have a different form. It is well known that the collision geometry for classical interactions is spherical and invariant under translations, i.e., the collision sphere is unchanged as long as the relative velocity remains the same. This is not the case in the relativistic situation, where we get ellipsoids instead of spheres and where the eccentricity of an ellipsoid changes with the energies of the particles which take part in the collision process. Therefore, the translation invariance from the classical situation is not carried over to the relativistic case. The translation invariance is used by Lions to simplify the operator to be studied. A simplification in the relativistic case is even more important since the explicit calculations needed in the proof will become quite involved otherwise. We use the Lorentz invariance of the relativistic particle mechanics to perform this simplification.

In §3, we present two applications of the regularizing theorem. First, we discuss

* Received by the editors September 12, 1994; accepted for publication February 27, 1995.

† Department of Mathematics, Chalmers University of Technology, S-412 96 Göteborg, Sweden.

the problem of the asymptotic behaviour of solutions to the relativistic Boltzmann equation. This problem has recently been studied by Glassey and Strauss in [GlS2] and [GlS3]. We extend one of their results by proving strong L^1 convergence to a global Jüttner equilibrium solution when the initial data, periodic in the space variables, satisfy the natural bounds of finite energy and entropy. The analogous problem in the nonrelativistic situation was first solved by Arkeryd [Ar5] using a nonstandard method. A standard proof was then obtained by Lions [L] by applying the regularizing theorem. Both the nonstandard approach and the standard approach will be discussed.

Next, we apply the regularizing theorem to a functional equation important in relativistic kinetic theory. The result obtained, interesting in its own right, is then used in the appendix to discuss a point of connection between Arkeryd's and Lions' approaches to the asymptotic problem discussed above.

We end this introduction with a presentation of the specific assumptions used in this paper for the relativistic Boltzmann equation. Let the speed of light be normalized to $c = 1$ and the particle rest mass to $m = 1$, and let $(+ - - -)$ be the signature. The relativistic Boltzmann equation models the space–time behaviour of the one-particle distribution function, $f = f(x,p,t)$. The equation has the form

$$\left(\partial_t + \frac{p}{p_0}\cdot\nabla_x\right) f = Q(f,f), \tag{1.1}$$

where the collision operator is defined by

$$Q(f,g)(p) = \frac{1}{p_0}\int_{\mathbb{R}^3}\int_{\mathbb{S}^2}(f(p')g(q') - f(p)g(q))B(g,\theta)d\Omega\frac{dq}{q_0}. \tag{1.2}$$

Here $d\Omega$ is the element of surface area on $\mathbb{S}^2$, $p^\mu = (p_0, p)$ is the four-momentum ($p_0 \in \mathbb{R}$, $p \in \mathbb{R}^3$, $\mu = 0,1,2,3$), and $p_0 = \sqrt{1+p^2}$ is the particle energy. The total energy and relative momentum in the center-of-mass system are $s^{1/2} = |q^\mu + p^\mu|$ and $2g = |q^\mu - p^\mu|$, respectively. Primed momenta denote the associated momenta in the scattering process; hence $p^\mu + q^\mu = p^{\mu'} + q^{\mu'}$. The scattering angle θ in the center-of-mass system satisfies

$$\cos\theta = 1 - 2\frac{(p^\mu - q^\mu)(p'_\mu - q'_\mu)}{|p^\mu - q^\mu|^2}. \tag{1.3}$$

The kernel $B(g,\theta)$ and the scattering cross-section $\sigma(g,\theta)$ are related by

$$B(g,\theta) = \frac{gs^{1/2}}{2}\sigma(g,\theta). \tag{1.4}$$

Remark. Introducing the Møller velocity

$$v_M = \frac{gs^{1/2}}{p_0q_0} = \frac{2g\sqrt{1+g^2}}{p_0q_0} \tag{1.5}$$

with the identity $4g^2 = s - 4$, we see that the equation is quite similar to the classical Boltzmann equation. In particular, if we consider the classical limit where $|p|+|q| \ll 1$, we get $2g \approx |p - q|$. Thus the Møller velocity tends to the relative velocity, $v_M \approx 2g \approx |p - q|$, and we have recovered the classical equation.

In order to discuss the trend to equilibrium in §3, we adopt the assumptions on the scattering cross-section used by Dudyński and Ekiel-Jeżewska [DEJ], thereby proving the global existence of equation (1.1), i.e.,

$$B > 0 \text{ a.e.}, \qquad B \in L^1_{\text{loc}}(\mathbb{R}^3 \times \mathbb{S}^2), \tag{1.6}$$

$$\frac{1}{p_0}\int_{\{|q|\le R\}}\int_{\mathbb{S}^2} B(g,\theta)d\Omega\frac{dq}{q_0} \to 0 \quad \text{as } |p| \to \infty \quad \forall R < \infty. \tag{1.7}$$

These assumptions are of the same type as those used by DiPerna and Lions [DPL1] in the nonrelativistic situation but modified in a natural way to the relativistic case.

The collision operator (1.2) is defined in the center of mass system. We could equivalently use a different representation (see Appendix II in [GlS2] for a derivation):

$$\begin{aligned} Q(f,g) = &\int_{\mathbb{R}^3}\int_{\mathbb{S}^2} k(p,q,\omega) \\ &\times[f(p+a(p,q,\omega)\omega)g(q-a(p,q,\omega)\omega) - f(p)g(q)]dpd\omega, \end{aligned} \tag{1.8}$$

where

$$k(p,q,\omega) = 4s\sigma(p_0+q_0)^2\frac{|\omega\cdot(\hat{q}-\hat{p})|}{(e^2-(\omega\cdot(p+q))^2)^2}, \tag{1.9}$$

$$a(p,q,\omega) = \frac{2ep_0q_0(\omega\cdot(\hat{q}-\hat{p}))}{e^2-(\omega\cdot(p+q))^2}. \tag{1.10}$$

Here $e := p_0 + q_0$ is the total energy and $\hat{x} := x/x_0$, so $\hat{q} - \hat{p}$ is the relative velocity. The function a is the distance from p to p' (and from q to q'). The quantities s and $\sigma(g,\theta)$ are defined above. The explicit form of the kernel k is not essential for our purpose, but we want to give a proper definition of the gain term from a kinetic point of view. Furthermore, the transformation property of k under a change of coordinates $(p,q) \to (p',q')$ is important in the study of the relativistic Boltzmann equation, so a short presentation on this topic will be given. For classical interactions, it is well known that the Jacobian of the corresponding transformation is unity and that the cross-section (kernel) is invariant. The behaviour is slightly different in the relativistic situation, but, as is physically necessary, the relation

$$k(p,q,\omega)dpdq = k(p',q',\omega)dp'dq' \tag{1.11}$$

holds, meaning that there is local reversibility. In fact, the Jacobian is given by

$$\frac{\partial(p',q')}{\partial(p,q)} = \frac{p_0'q_0'}{p_0q_0} \tag{1.12}$$

(see [GlS1]), and this in turn implies

$$k(p,q,\omega) = k(p',q',\omega)\frac{\partial(p',q')}{\partial(p,q)} \tag{1.13}$$

(see [GlS2]). Finally, the collision operator can be written in an obvious way as

$$Q(f,g) = Q^+(f,g) - Q^-(f,g),$$

where Q^+ and Q^- are referred to as the gain and loss terms, respectively.

2. A regularity theorem for the gain term. This section generalizes P. L. Lions' result [L] concerning Sobolev estimates of the gain term to the relativistic setting. Some familiarity with [L] will simplify the reading. The estimates obtained in [L] rely on the specific nature of the collision geometry. For relativistic interactions, the collision geometry changes according to the relativistic conservation laws

$$p_0 + q_0 = p_0' + q_0', \tag{2.1}$$

$$p + q = p' + q'. \tag{2.2}$$

For fixed p and q, the possible values of p' and q' will all belong to an ellipsoid instead of a sphere, as is the case for classical interactions. Thus the integration in the gain term is performed over ellipsoids instead of spheres. However, the eccentricity of an ellipsoid depends on the energies of the ingoing particles, whereas the eccentricity is constant ($= 0$) in the classical situation, or, in other words, the translation-invariance is not carried over to the relativistic case. Lions [L] uses this translation invariant property to simplify the operator to be studied. A simplification of the operator is even more important in the relativistic situation since the explicit computations in the proof become quite involved without any reductions. Below we will reduce the complexity of the operator by making use of the Lorentz invariance.

Let us take the dimension arbitrary ($N \geq 2$). The gain term then takes the form

$$Q^+(f,g) = \int_{\mathbb{R}^N} \int_{\mathbb{S}^{N-1}} b(p,q,\omega) f(p + a(p,q,\omega)\omega) g(q - a(p,q,\omega)\omega) dp d\omega. \tag{2.3}$$

Here the notation of the kernel is changed to b instead of k. The kernel b is equipped with specific regularity properties, as will be clear from the formulation of the following main theorem.

THEOREM 1. *Let $b \in C^\infty(\mathbb{R}^N \times \mathbb{R}^N \times \mathbb{S}^{N-1})$, $0 \leq g \in L^1_{\text{loc}}(\mathbb{R}^N)$, $0 \leq f \in L^2_{\text{loc}}(\mathbb{R}^N)$. Assume that b vanishes if $|p|$ is large, if $|q|$ is large, or if $|q-p|$ is small. Also assume that b vanishes if $|(\hat{q} - \hat{p}) \cdot \omega|$ is near 0 or if $|(q-p)\cdot\omega|$ is near $|q-p|$ uniformly in ω. Then*

$$\|Q^+(f,g)\|_{H^{\frac{N-1}{2}}(\mathbb{R}^N)} \leq C\|f\|_{L^2(K_q)}\|g\|_{L^1(K_p)} \tag{2.4}$$

for some $C > 0$ depending only on b. Here K_q and K_p are compact sets in $\mathbb{R}^N$ such that supp $b \subset K_q \times K_p \times \mathbb{S}^{N-1}$.

Remark. The hypotheses in Theorem 1 differ slightly from what one could argue should be the natural extension of [L] to the relativistic case. In [L], b vanishes if the relative velocity is small and large, respectively. It seems natural that a translation of this condition to the relativistic case, i.e., a vanishing of b for small and large relative momentum, should be sufficient. However, uniform control of the eccentricity of the ellipsoids is necessary for carrying out the proof, and that control is not quite achieved with only this hypothesis on b. Indeed, an ellipsoid has its principal axis directed along $p + q$, so the remaining $N - 1$ axes have equal lengths. If we denote by α the length of the principal axis and by β the length of one of the other axes, we have

$$\frac{\beta^2}{\alpha^2} = \frac{e^2 - (p+q)^2}{e^2}. \tag{2.5}$$

Hence the numerator could be fixed as the denominator approaches infinity, so control of the relative momentum does not imply control of the eccentricity.

Let us now consider g as fixed in L^1, and let the linear operator Q_g be given by

$$Q_g(f) = Q^+(f,g). \tag{2.6}$$

We wish to compute the transpose of Q_g in the $L^2 \times L^2$ duality (of real functions). Therefore, for all $\varphi \in C_0^\infty(\mathbb{R}^N)$, consider $\int_{\mathbb{R}^N} Q_g(f)\varphi dp$ or, explicitly,

$$\int_{\mathbb{R}^N} Q_g(f)\varphi dp$$

$$= \iint_{\mathbb{R}^{2N}} dpdq \int_{\mathbb{S}^{N-1}} d\omega b(p,q,\omega) f(q + a(p,q,\omega)\omega) g(p - a(p,q,\omega)\omega)\varphi(p). \tag{2.7}$$

Let us change variables $(p,q) \to (p',q')$ in (2.7), where this map and its inverse (see [GlS2]) are given by

$$\begin{aligned} p' &= p - a(p,q,\omega)\omega, & q' &= q + a(p,q,\omega)\omega, \\ p &= p' + a(p',q',\omega)\omega, & q &= q' - a(p',q',\omega)\omega. \end{aligned} \tag{2.8}$$

We wish to show that the essential properties of the kernel are preserved under this transformation, i.e., $b(p,q,\omega) \to \tilde{b}(p',q',\omega)$ such that $\tilde{b}$ also satisfies the conditions of Theorem 1. We saw above (1.12) that the Jacobian of the map $(p,q) \to (p',q')$ is harmless. Next, we observe from equation (2.8) that a large value of $|p'|$ (or $|q'|$) requires that $|p|$ or $|q|$ is large, i.e., b vanishes, so this property is preserved. And if $|q' - p'|$ is small, then necessarily $|q - p|$ is small and b vanishes, so this property is also preserved. Finally, since we are working in a compact domain, there is uniform control of the eccentricity. This implies that if $|(\widehat{q' - p'}) \cdot \omega|$ is sufficiently small, then $|(\hat{q} - \hat{p}) \cdot \omega|$ is also small, and if $|(q' - p') \cdot \omega|$ is close to $|q' - p'|$, then $|(q - p) \cdot \omega|$ is close to $|q - p|$. Thus all the properties of b are preserved. Since b and $\tilde{b}$ have the same behaviour, we shall use the same notation for the kernel and write b for $\tilde{b}$ below.

Formally, then,

$$\int_{\mathbb{R}^N} Q_g(f)\varphi dp = \int_{\mathbb{R}^N} dq' f(q') \times \left\{ \int_{\mathbb{R}^N} dp' g(p') \int_{\mathbb{S}^{N-1}} d\omega b(p',q',\omega)\varphi(p' + a(p',q',\omega)\omega) \right\}. \tag{2.9}$$

Due to the compact support of the kernel b in the momentum variables, formula (2.9) is trivially justified.

We wish to rewrite the term in brackets in (2.9), considered as an operator in φ. In order to do so, we introduce the Lorentz transformation $\Lambda(p)$ which carries a particle with momentum p to rest. The transformation $\Lambda(p)$, of course, acts on four-vectors (if $N = 3\ldots$), and by the notation $\Lambda(p)x$, where x is a three-vector (if $N = 3\ldots$), i.e., $x \in \mathbb{R}^N$ and $X = (x_0, x) \in \mathbb{R}^{N+1}$, we will intend the projection of $\Lambda(p)X$ onto the N-dimensional momentum space. The notation $x_p := \Lambda(p)x$ will also appear below. Further, if ψ is a function with a momentum variable as an argument, then $(\Lambda(p)\psi)(x) := \psi(\Lambda(p)x)$. The distinction between primed and unprimed variables has no relevance in what follows, so we will drop the primes from here on. The term in brackets in (2.9) can now be reformulated as follows:

$$\int_{\mathbb{R}^N} dp\, g(p) \int_{\mathbb{S}^{N-1}} d\omega b(p,q,\omega)\varphi(p + a(p,q,\omega)\omega)$$

$$= \int_{\mathbb{R}^N} g(p) \left([\Lambda(p) \circ T_p \circ \Lambda(-p)]\, \varphi \right)(q) dp, \tag{2.10}$$

where

$$(2.11) \quad T_p\varphi(q) = \int_{\mathbb{S}^{N-1}} b(p, q_{-p}, \Gamma \circ A(p, q_{-p}, \tilde{\omega}))J(p, q_{-p}, \tilde{\omega})\varphi(a_0(q, \tilde{\omega})\tilde{\omega})d\tilde{\omega}.$$

Before discussing the validity and purpose of this formulation, we define the quantities in (2.11). First, for fixed p and q ($p \neq q$), the map $\Gamma \circ A : \mathbb{S}^{N-1} \to \mathbb{S}^{N-1}$ is defined by

$$(2.12) \qquad A(p, q, \tilde{\omega}) = \Lambda(-p)(a_0(q_p, \tilde{\omega})\tilde{\omega}) - p \quad \text{if } q \cdot \tilde{\omega} > 0.$$

If $q \cdot \tilde{\omega} < 0$, then define $A(p, q, \tilde{\omega}) := -A(p, q, \tilde{\omega})$, where $a_0(q, \omega) := a(0, q, \omega)$. Also, $\Gamma : \mathbb{R}^N \to \mathbb{S}^{N-1}$ is the projection

$$(2.13) \qquad \Gamma(x) = \frac{x}{|x|} \quad \text{if } x \neq 0.$$

$\Gamma \circ A$ is then continuously extended to all of $\mathbb{S}^{N-1}$. Finally, J is the Jacobian of the map $\tilde{\omega} \to \Gamma \circ A(p, q, \tilde{\omega}) = \omega$ for fixed p and q. The map $\Gamma \circ A$ takes care of the aberration occurring under a change of coordinate frames; $\tilde{\omega}$ is the angle of a collision observed from the rest frame of p if the corresponding angle is given by ω in the laboratory frame. Formula (2.11) is now readily verified if one observes that $p + a(p, q, \omega)\omega = \Lambda(-p)(a_0(q_p, \tilde{\omega})\tilde{\omega})$ with $\tilde{\omega} = \Gamma \circ \Lambda(p)(p + a(p, q, \omega)\omega)$.
