AN UNUSUAL MINIMIZATION PRINCIPLE FOR PARABOLIC GRADIENT FLOWS*

LAWRENCE C. EVANS†

Abstract. We show that for a general parabolic system, generated as the gradient flow of a rank-one convex energy functional, the energy at any time is less than or equal to the energy "smoothly sampled" at earlier times. This generalizes the classical assertion that energy cannot increase along flows.

Key words. gradient flow, rank-one convexity, energy decrease

AMS subject classifications. 35K55, 49M10

This short note shows how a small modification of a computation due to Ball and Murat [2] yields an unusual dynamic minimization principle for smooth solutions of certain parabolic partial differential equation (PDE) systems, corresponding to gradient flows governed by appropriate energy functionals.

The set-up is this. Let U denote a smooth, bounded, open subset of $\mathbb{R}^n$. We define the *energy* of a mapping $\mathbf{v} : U \to \mathbb{R}^m$ to be

$$I[\mathbf{v}] = \int_U F(D\mathbf{v}, \mathbf{v}, x)dx, \tag{1.1}$$

where $F : M^{m\times n} \times \mathbb{R}^m \times U \to \mathbb{R}$ is a given smooth function, $F = F(P, z, x)$, and $M^{m\times n}$ denotes the space of real $m \times n$ matrices. We write $x = (x_1, \dots, x_n)$, $\mathbf{v} = (v^1, \dots, v^m)$, and

$$D\mathbf{v} = ((v^i_{x_\alpha}))_{\substack{1\le i\le m\\ 1\le\alpha\le n}}.$$

Below, we implicitly sum repeated Greek indices from 1 to n and Latin indices from 1 to m.

We are concerned with the system of PDE

$$u^i_t - \frac{\partial}{\partial x_\alpha}\left(\frac{\partial F}{\partial p^i_\alpha}(D\mathbf{u}, \mathbf{u}, x)\right) + \frac{\partial F}{\partial z^i}(D\mathbf{u}, \mathbf{u}, x) = 0 \qquad (i = 1, \dots, m) \tag{1.2}$$

in $U \times [0, \infty)$, which is the gradient flow on $L^2(U)$ generated by $I[\cdot]$. Let us henceforth suppose $\mathbf{u} = \mathbf{u}(x, t)$ to be a smooth solution of (1.2), subject to the time-independent boundary conditions

$$\mathbf{u} = \mathbf{g} \quad \text{on } \partial U \times [0, \infty), \tag{1.3}$$

$\mathbf{g} : \partial U \to \mathbb{R}$ being given. We also suppose that the mapping $P \mapsto F(P, z, x)$ is *rank-one convex* for each z, x; this means $f(t) = F(P + t\xi \otimes \eta, z, x)$ is convex for each $P \in M^{m\times n}$, $\xi \in \mathbb{R}^m$, $\eta \in \mathbb{R}^n$, $z \in \mathbb{R}^m$, $x \in U$. The system (1.2) is then parabolic, at least in some weak sense.

The minimization principle is given below.

THEOREM. *Fix a time $t_0 > 0$ and suppose $\theta : \overline{U} \to [0, t_0]$ is a smooth function. Define*

$$\mathbf{v}(x) = \mathbf{u}(x, \theta(x)) \qquad (x \in \overline{U}). \tag{1.4}$$

Then

$$I[\mathbf{u}(\cdot, t_0)] \leq I[\mathbf{v}]. \tag{1.5}$$

The case $\theta(\cdot) \equiv t \leq t_0$ becomes the classical assertion that the energy $I[\cdot]$ is nonincreasing in time. More generally, (1.5) says that no matter how we "sample" the values of $\mathbf{u}$ at times previous to t_0, we cannot lower the energy below that of $\mathbf{u}(\cdot, t_0)$.

In the illustration (Fig. 1) below, the energy of $\mathbf{u}$ at the top is less than or equal to the energy of $\mathbf{u}$ computed along any curved surface (= the graph of $\theta(\cdot)$), as drawn.

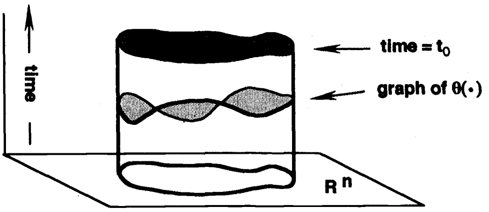

FIG. 1.

Proof. In view of (1.4),

$$v^i_{x_\alpha} = u^i_{x_\alpha} + u^i_t \theta_{x_\alpha} \qquad (1 \leq i \leq m,\ 1 \leq \alpha \leq n).$$

Therefore

$$\begin{aligned} I[\mathbf{v}] &= \int_U F(D\mathbf{u} + \mathbf{u}_t \otimes D\theta, \mathbf{v}, x)dx \\ &\geq \int_U F(D\mathbf{u}, \mathbf{v}, x) + \frac{\partial F}{\partial p^i_\alpha}(D\mathbf{u}, \mathbf{v}, x) u^i_t \theta_{x_\alpha}\, dx, \end{aligned}$$

the inequality a consequence of the rank-one convexity. Hence

$$\begin{aligned} I[\mathbf{v}] - I[\mathbf{u}(\cdot, t_0)] \geq \int_U & F(D\mathbf{u}, \mathbf{v}, x) + \frac{\partial F}{\partial p^i_\alpha}(D\mathbf{u}, \mathbf{v}, x) u^i_t \theta_{x_\alpha} \\ & - F(D\mathbf{u}(\cdot, t_0), \mathbf{u}(\cdot, t_0), x)dx, \end{aligned} \tag{1.6}$$

where $D\mathbf{u}$ and $\mathbf{u}_t$ are evaluated at $(x, \theta(x))$ in the first two integrands. Similarly to

Ball–Murat [2], let us now compute

$$\begin{aligned}
&\frac{\partial}{\partial x_\alpha}\left(\int_{t_0}^{\theta(x)} \frac{\partial F}{\partial p^i_\alpha}(D\mathbf{u}(x,t),\mathbf{u}(x,t),x)u^i_t(x,t)dt\right)\\
&\qquad - \frac{\partial F}{\partial p^i_\alpha}(D\mathbf{u}(x,\theta(x)),\mathbf{v}(x),x)u^i_t(x,\theta(x))\theta_{x_\alpha}(x)\\
&\qquad = \int_{t_0}^{\theta(x)} \frac{\partial}{\partial x_\alpha}\left(\frac{\partial F}{\partial p^i_\alpha}(D\mathbf{u},\mathbf{u},x)\right)u^i_t(x,t)\\
&\qquad + \frac{\partial F}{\partial p^i_\alpha}(D\mathbf{u},\mathbf{u},x)u^i_{x_\alpha t}(x,t)dt\\
&\qquad = \int_{t_0}^{\theta(x)} |\mathbf{u}_t|^2 + \frac{\partial F}{\partial z^i}(D\mathbf{u},\mathbf{u},x)u^i_t + \frac{\partial F}{\partial p^i_\alpha}(D\mathbf{u},\mathbf{u},x)u^i_{x_\alpha t}dt \qquad \text{(by (1.2))}\\
&\qquad = \int_{t_0}^{\theta(x)} |\mathbf{u}_t|^2 + \frac{d}{dt}F(D\mathbf{u},\mathbf{u},x)dt\\
&\qquad = \int_{t_0}^{\theta(x)} |\mathbf{u}_t|^2dt + F(D\mathbf{u}(x,\theta(x)),\mathbf{v}(x),x) - F(D\mathbf{u}(x,t_0),\mathbf{u}(x,t_0),x).
\end{aligned}$$

Plugging this identity into (1.6), we discover

$$I[\mathbf{v}] - I[\mathbf{u}(\cdot,t_0)] \geq \int_U \frac{\partial}{\partial x_\alpha}\left(\int_{t_0}^{\theta} \frac{\partial F}{\partial p^i_\alpha}u^i_t dt\right) - \int_{t_0}^{\theta} |\mathbf{u}_t|^2 dt\, dx.$$

Since $\mathbf{u}_t = 0$ on ∂U according to (1.3), the integral of the divergence term is zero. Consequently

$$I[\mathbf{v}] - I[\mathbf{u}(\cdot,t_0)] \geq \int_U \int_{\theta}^{t_0} |\mathbf{u}_t|^2 dt\, dx \geq 0,$$

as $0 \leq \theta \leq t_0$ on U. □

Remarks. Ball and Murat's calculation [2], following Sivaloganathan [4], simplifies and clarifies aspects of classical field theory in the calculus of variations, to determine when a critical point of $I[\cdot]$ embedded in a one-parameter family of critical points is, in fact, a strong local minimizer. The theorem above is a kind of (very crude) dynamic analogue.

Brezis–Ekeland [3] contains an interesting and completely different minimization principle for gradient flows governed by convex energies, and Auchmuty [1] has a related minimax principle.

Example. As an illustration of the Theorem, take $m = 1$ and set

$$I[v] = \int_U \tfrac{1}{2}|Dv|^2 + H(v)\, dx, \tag{1.7}$$

where $H : \mathbb{R} \to \mathbb{R}$. The corresponding gradient flow is the semilinear heat equation

$$u_t - \Delta u + h(u) = 0 \tag{1.8}$$

on $U \times [0,\infty)$, for $h = H'$.

Let $u^0(\cdot) = u(\cdot,0)$ denote the initial values. Now if

$$-\Delta u^0 + h(u^0) = 0 \qquad \text{in } U,$$

that is, if u^0 is a critical point of $I[\cdot]$, then $u(\cdot,t) = u^0(\cdot)$ for all $t \geq 0$ and assertion (1.5) provides no information. Suppose instead

$$-\Delta u^0 + h(u^0) < 0 \qquad \text{in } \overline{V}, \tag{1.9}$$

V denoting some smooth, open subregion of U. Now, if H is convex (1.9) implies the one-sided minimization principle

$$I[u^0] \leq I[v]$$

for any smooth function v such that $v \leq u^0$ and $v = u^0$ on $U - V$. (Proof: Multiply (1.9) by $u^0 - v \geq 0$, integrate by parts, and use convexity.) However, if H is not convex, as we hereafter assume, we can deduce no minimization principle from the differential inequality (1.9).

But now let us evolve u^0 under the flow governed by the PDE (1.8). In light of (1.8), there exists a small time $t_0 > 0$ such that $u_t > 0$ on $\overline{V} \times [0, t_0]$. The graph of u is consequently rising in V during the time interval $[0, t_0]$ and so sweeps out a region R between the graphs of $u(\cdot, 0)$ and $u(\cdot, t_0)$. (See Fig. 2, below.)

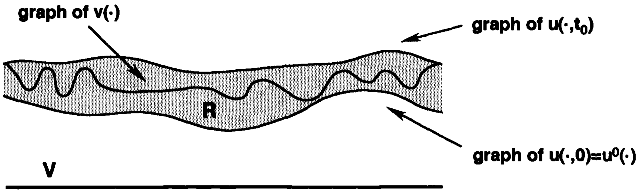

FIG. 2.

Let v be any smooth function whose graph lies within R and agrees with $u(\cdot, t_0)$ on $U - V$. Then according to the Theorem,

$$I[u(\cdot, t_0)] \leq I[v], \tag{1.10}$$

since we can find a smooth mapping $\theta : U \rightarrow [0, t_0]$ such that $v(x) = u(x, \theta(x))$.

In other words, *even for a nonconvex H, the gradient flow evolution causes $u(\cdot, t)$ to become a local one-sided minimizer in any region in which the graph is moving.*

EXISTENCE OF PERIODIC SOLUTIONS FOR EQUATIONS OF EVOLVING CURVES*

YOSHIKAZU GIGA† AND NORIKO MIZOGUCHI‡

Abstract. Evolution equations of curvatures of convex curves are considered by the Gauss map parametrization. A time periodic unstable solution is constructed for a reasonable class of time periodic data. Our solution is arranged to satisfy a constraint so that it yields *closed*, embedded, convex curves moving periodically in time (up to translation) whose normal speed equals the curvature minus a given time periodic function depending on curves only through its normals. For curvatures of periodically evolving curves a priori lower and upper bounds depending only on periodic data are obtained. A new penalty method is introduced so that our solution satisfies the constraint. Solutions of penalized equations are constructed by adapting the degree theory.

Key words. Harnack's inequality, penalty method, periodic solutions, evolving curves

1. Introduction.

We are concerned with positive, periodic solutions of a quasilinear parabolic equation for curvatures u of evolving curves

$$u_t = u^2(u_{xx} + u - f) \quad \text{in} \quad K, \tag{1.1}$$

with $K = (\mathbf{R}/2\pi\mathbf{Z}) \times (\mathbf{R}/T\mathbf{Z})$ for given $T > 0$. Here $f = f(x,t)$ is a given continuous function on K, i.e., $f \in C(K)$. In particular, f is 2π-periodic in space, i.e., $f(x + 2\pi, t) = f(x,t)$ and T-periodic in time i.e., $f(x, t+T) = f(x,t)$ for all $(x,t) \in \mathbf{R}^2$. Our goal is to construct a positive solution of (1.1) satisfying a constraint

$$\int_0^{2\pi} \frac{e^{ix}}{u(x,t)} dx = 0 \quad \text{for all} \quad t \in \mathbf{R} \quad (i = \sqrt{-1}). \tag{1.2}$$

1.1. Main existence theorem. *Suppose that f is in $C(K)$ together with its time derivative f_t. Then there is a positive function u in $\bigcap_{p>1} W_p^{2,1}(K) \subset C(K)$ (which implies $u_x \in C(K)$) such that u solves* (1.1) *with the constraint* (1.2) *if f is positive on K and satisfies*

$$\int_0^{2\pi} f(x,t) e^{ix} dx = 0 \quad \textit{for all} \quad t \in \mathbf{R}. \tag{1.3}$$

If f is smooth, so is u.

Here $W_p^{2,1}(K)$ denotes the space of all functions g in $L^p(K)$ together with g_x, g_{xx}, and g_t and $L^p(K)$ denotes the space of locally L^p functions in $\mathbf{R}^2$ which is 2π-periodic in x and T-periodic in t. The main existence theorem asserts the existence of a positive solution u, 2π-periodic in x and T-periodic in t.

The restriction (1.3) is necessary if u satisfies (1.2). Indeed, dividing both sides of (1.1) by u^2 yields

$$(-u^{-1})_t = u_{xx} + u - f \quad \text{in} \quad K. \tag{1.4}$$

‡ Department of Mathematics, Tokyo Gakugei University, Koganei, Tokyo 184, Japan.

Multiplying (1.4) by e^{ix} and integrating by parts over $(0, 2\pi)$ yields

$$-\frac{d}{dt}\int_0^{2\pi}\frac{e^{ix}}{u}dx = -\int_0^{2\pi} fe^{ix}dx \tag{1.5}$$

since $(e^{ix})_{xx} + e^{ix} = 0$. If u satisfies the constraint (1.2), f must satisfy (1.3).

The positivity assumption on f cannot be dropped completely even if f is smooth so that u is smooth. For example let $f \leq 0$ on K. Then at the minimizer $(x_0, t_0) \in K$ of u the equation (1.1) yields

$$0 = u_t(x_0, t_0) = u^2(x_0, t_0)(u_{xx}(x_0, t_0) + u(x_0, t_0) - f(x_0, t_0)) \geq u^3(x_0, t_0) > 0,$$

so there are no positive solutions of (1.1) for nonpositive (smooth) f.

Our main result yields the existence of a periodic-in-time solution (up to translation) for an evolution equation of curves whose normal speed equals the curvature minus a given time periodic function depending on curves through its normals. Let $\{\Gamma_t\}$ be a smooth one-parameter family of closed, embedded curves bounding a domain in the plane. Let $\mathbf{n}$ denote the inward unit normal vector field on Γ_t. Let V denote the normal velocity of Γ_t in the direction of $\mathbf{n}$. We consider an equation for Γ_t of the form

$$V = k - q(\mathbf{n}, t), \tag{1.6}$$

where k is the inward curvature and q is a given function. The equation (1.6) is an example of a curvature flow equation with anisotropy [Gu]. If Γ_t is convex, one can parametrize Γ_t by a Gauss map by introducing θ, $0 \leq \theta \leq 2\pi$, such that $\mathbf{n} = (\cos\theta, \sin\theta)$. The evolution of curvature k is expressed as

$$k_t = k^2(V_{\theta\theta} + V)$$

if we use θ-coordinate [Gu]. Applying this identity to (1.6) yields an evolution equation of curvature

$$k_t = k^2(k_{\theta\theta} + k - (Q_{\theta\theta} + Q)) \quad \text{with} \quad Q(\theta, t) = q(\cos\theta, \sin\theta, t), \tag{1.7}$$

where k and Q are 2π-periodic in θ. We next recover (1.6) from (1.7). For k a curve is given by the Gauss map

$$\mathbf{Z}(\theta, t) = \left(\int_0^\theta \frac{\sin\sigma}{k(\sigma, t)}d\sigma, -\int_0^\theta \frac{\cos\sigma}{k(\sigma, t)}d\sigma\right).$$

If k solves (1.7), then integrating by parts yields

$$\begin{aligned}\frac{\partial \mathbf{Z}}{\partial t} = ((k - Q)\cos\theta - (k_\theta - Q_\theta)\sin\theta - (k - Q)|_{\theta=0},\\ (k - Q)\sin\theta + (k_\theta - Q_\theta)\cos\theta - (k_\theta - Q_\theta)|_{\theta=0}).\end{aligned}$$

Translate $\mathbf{Z}$ by

$$\mathbf{X}_0(t) = \left(\int_0^t (k - Q)(0, \tau)d\tau, \int_0^t (k_\theta - Q_\theta)(0, \tau)d\tau\right),$$

so that new curve $\mathbf{X}(\theta,t) = \mathbf{Z}(\theta,t) + X_0(t)$ fulfills

$$V = \mathbf{n} \cdot \frac{\partial \mathbf{X}}{\partial t} = (\cos\theta, \sin\theta) \cdot \frac{\partial \mathbf{X}}{\partial t} = k - q.$$

We have thus obtained the curve

$$\Gamma_t = \{\mathbf{X}(\theta,t); 0 \le \theta \le 2\pi\}$$

satisfying (1.6). The equations (1.6) and (1.7) are equivalent through $\mathbf{X}$. However, for Γ_t closed we need $\mathbf{X}(0,t) = \mathbf{X}(2\pi,t)$, which is equivalent to the constraint

$$\int_0^{2\pi} \frac{e^{i\theta}}{k(\theta,t)} d\theta = 0.$$

If we set $u = k$, $x = \theta$, this is nothing but the constraint (1.2). Since the condition (1.3) is automatically satisfied for $f = Q_{\theta\theta} + Q$, the main existence theorem yields a periodic-in-time solution Γ_t (up to translation in space) of (1.6).

1.2. Existence of periodically evolving curves. *Suppose that Q is in $C(K)$ together with $Q_{\theta\theta}$, Q_t, $Q_{\theta\theta t}$ and that*

$$Q_{\theta\theta} + Q > 0 \quad \text{on} \quad K. \tag{1.8}$$

Then there are a constant vector $\mathbf{c} \in \mathbf{R}^2$ and a closed curve evolution Γ_t solving

$$V = k - q(\mathbf{n}, t), \tag{1.9}$$

$$\Gamma_{t+T} = \Gamma_t + \mathbf{c} \tag{1.10}$$

for all $t \in \mathbf{R}$. The curvature of Γ_t is always positive and the quantities in (1.9) are continuous. If Q is smooth, so is Γ_t.

In general, translation by $\mathbf{c}$ is necessary. For example, take

$$Q(\theta,t) = \cos\theta + 1$$

so that $Q_{\theta\theta} + Q = 1$. Suppose that Γ_t solves (1.9), (1.10) for some $\mathbf{c}$. Then it is easy to see that $\hat{\Gamma}_t = \Gamma_t + \mathbf{e}_1 t$ with $\mathbf{e}_1 = (1,0)$ solves $V = k - 1$ with T-periodic k. If $f = 1$ in (1.1), by a uniqueness result summarized in Lemma 1.3 the unique solution of (1.1) with (1.3) is $u \equiv 1$. Thus $\hat{\Gamma}_t$ is a circle C of radius 1 and $V = k - 1 = 0$. We now observe that under the relation $Q(\theta,t) = \cos\theta + 1$ if Γ_t solves (1.9), (1.10) (with positive curvature) then $\Gamma_t = C - \mathbf{e}_1 t$ up to a constant vector (independent of time). Thus $\Gamma_{t+T} = \Gamma_t - \mathbf{e}_1 T$ does not agree with Γ_t so translation is necessary in (1.10).

It turns out that the method developed here applies to a general parabolic equation

$$V = a(\mathbf{n})k - q(\mathbf{n},t)$$

including (1.9). This will be discussed in our forthcoming paper [GM].

1.3. Lemma on time-independent solutions. *Suppose that f in (1.1) is time independent. Then so is a positive solution u. If f is time independent there is at most one positive solution u of (1.1) satisfying (1.2).*

We shall prove this uniqueness result in the appendix. The condition (1.8) on Q is equivalent to saying that the curvature of Frank diagram

$$\mathcal{F} = \{(p_1,p_2) \in \mathbf{R}^2; r = 1/Q(\theta), (p_1,p_2) = r(\cos\theta, \sin\theta)\}$$

is positive. This is also discussed in the appendix.

There seems to be no literature on the existence of nontrivial periodic solutions of quasilinear equations, in particular of equations of evolving curves like (1.6), although there are several results for semilinear equations. Besides, it turns out that the periodic solution we seek is (Lyapunov) unstable. In fact all periodic, convex solutions for a general parabolic surface evolution equation are unstable unless the equation depends on location of surface explicitly. This was recently proved by the first author and Yama-uchi [GY]. Even for semilinear equations several methods for constructing periodic solutions only work for stable ones. For example in [AHM] stable periodic solutions were constructed by using subsolutions and supersolutions. For a class of semilinear equations a possibly unstable periodic solution was first constructed in [Am] as the "third" solution. Existence of unstable periodic solutions were recently proved by Hirano and the second author [HM1, HM2] for a class of semilinear parabolic equations. Their method is based on the Leray–Schauder degree theory. Since our equation is quasilinear and not semilinear, their theory does not apply directly to our setting. However we adapt the idea to construct solutions for approximate equations.

Since the equation (1.1) is degenerate at $u = 0$, we wonder whether positive solutions are bounded away from zero. Fortunately, under the constraint (1.2) we have a priori positive lower bounds for u (or curvature).

1.4. Theorem on bounds for curvature. *There are positive constants δ and M depending only on T, $||f||_\infty$, $||f_t||_\infty$, and $\min_K f > 0$ such that if $u \in C^\infty(K)$ satisfies* (1.1) *and* (1.2) *with $u > 0$ and f, $f_t \in C(K)$ with $f > 0$ on K, then $\delta \leq u \leq M$ on K. The constant M is independent of $\min_K f$. Here $||f||_\infty$ denotes the maximum norm of f in $C(K)$.*

To obtain a priori bounds we derive Harnack-type inequalities in our setting. It roughly asserts that

(i) $u(x,t)$ and $u(x,s)$ are comparable for all $t, s \in \mathbf{R}$ provided that u has an upper a priori bound.

(ii) $u(x,t_0)$ is not small compared with the maximum $u(x_0,t_0)$ of u over K.

Such estimates are derived by a differential identity as in [Ga2]. The derivation of the Harnack inequality from differential identities stems from [LY]. For further development of the Harnack inequality and its applications, especially for geometric evolution equations, the reader is referred to [Ha], a recent article of Andrews [And], and references therein. We note that a higher-dimensional version of (1.1) with $f = 0$ is found in [And] as the harmonic mean curvature flow equation.

The equation (1.1) admits a couple of integral bounds of solutions. If maximum of u is large, the Harnack inequality (ii) says its integral must be also large. Thus integral bounds yield an upper bound for solutions. The constraint is not invoked to get an upper bound but without (1.2) we do not get a lower bound. Indeed, suppose that $f = 1$. Then by Remark 1.3 every positive solution of (1.1) is independent of t and it solves

$$u_{xx} + u = 1 \quad \text{in} \quad \mathbf{R}/2\pi\mathbf{Z}.$$

Of course, $u_\sigma(x) = (1-\sigma)\cos x + 1$ $(2 > \sigma > 0)$ is a positive solution but $\{u_\sigma\}$ is not bounded away from zero.

To get a lower bound we integrate (1.4) over $(0,T)$ and obtain

$$U_{xx} + U > 0 \quad \text{in} \quad \mathbf{R}/2\pi\mathbf{Z} \quad \text{with} \quad U(x) = \int_0^T u(x,t)dt.$$

The constraint (1.2) implies

$$\int_0^{2\pi} \sin(x-\zeta)u^{-1}dx = 0 \quad \text{for all} \quad \zeta \in \mathbf{R}.$$

The key observation is that the integrals where the integrand is negative and positive are balanced or both integrals have the same growth order as u tends to zero. By the Harnack inequality (i) such a growth balance is true for U. We shall prove that if U satisfies $U_{xx} + U > 0$ together with integral balance, then U must have a lower bound away from zero. This is in turn gives a lower bound for u by (i). A rigorous proof is given in §4. Although bounds obtained here do not directly apply to construct solutions, the idea of proof is fundamental to finding uniform bounds for solutions of approximate equations.

1.5. Penalty method and approximate equations. We seek a solution of (1.1) satisfying the nonlinear constraint (1.2). Since not all solutions satisfy (1.2), we shall select the desired one by introducing a kind of penalty method. It is heuristically explained as follows. For small $\varepsilon > 0$ we consider a penalized equation

$$(1.11) \qquad u_t = u^2\left(u_{xx} + u + \frac{\varepsilon}{u} - f\right) \quad \text{in} \quad K.$$

For a positive solution u^ε of this equation we observe that (1.3) implies

$$-\frac{d}{dt}\int_0^{2\pi} \frac{e^{ix}}{u^\varepsilon}dx = \varepsilon \int_0^{2\pi} \frac{e^{ix}}{u^\varepsilon}dx$$

in the same way used to derive (1.5). Since u^ε is periodic in time, this implies that our approximate solution $u^\varepsilon > 0$ satisfies the constraint (1.2). It is possible to construct a positive solution of (1.11) mainly because $1/u$ has a strong stabilizing effect near $u = 0$; the derivative of $1/u$ tends to minus infinity as $u \to 0$. However, there is a serious drawback for (1.11). Since we do not know that $f - \varepsilon/u$ is positive, it seems to be impossible to derive a uniform bound from below for u^ε by the method sketched in the previous section. To overcome this difficulty a naive idea may be to replace (1.11) by

$$(1.12) \qquad u_t = u^2\left(u_{xx} + u + \frac{\varepsilon}{u \vee m\varepsilon} - f\right), \quad 0 < \frac{1}{m} < \min f$$

so that $f - \varepsilon(u \vee m\varepsilon)^{-1}$ is positive, where $a \vee b = \max(a,b)$. The solution u^ε of this equation has a priori bounds and it is not difficult to prove that $\{u^\varepsilon\}$ has a convergent subsequence and the limit satisfies (1.1) and (1.2). However, it seems to be difficult to construct a positive solution of (1.12) because the new term $\varepsilon(u \vee m\varepsilon)^{-1}$ is constant near $u = 0$ and has no stabilizing effect for small u.

We adapt the method of finding unstable solutions for semilinear equations developed by Esteban [E1], [E2] as well as Hirano and the second author [HM1], [HM2]. Unfortunately, their method does not apply to solve (1.12). We explain the reason by sketching our method. For fixed $b > 0$ we consider a uniformly parabolic equation

$$(1.13) \qquad u_t = a(u)(u_{xx} - bu + h) \quad \text{in} \quad K$$

where u has now no sign conditions and h is for the moment a given data. If a is continuous, one can prove that the solution operator $S : h \mapsto u$ is well defined in

$C(K)$. If $h = H(u)$ depends on u, a solution of (1.13) with $h = H(u)$ is interpreted as a fixed point of $S \circ H$. If we prove that

$$\deg(I - S \circ H, 0, B_R(0)) = 0,$$
$$\deg(I - S \circ H, 0, B_r(0)) = 1$$

for large ball $B_R(0)$ and small ball $B_r(0)$ centered at zero in $C(K)$, then there is a solution of (1.13) with $h = H(u)$ in $B_R(0) \setminus B_r(0)$. This method is used by Esteban [E1], [E2] for semilinear parabolic equations with superlinear nonlinearity. To implement this program for our equation we should at least modify our equation (1.12) so that it is uniformly parabolic for all $u \in C(K)$. However, not all modification of the u^2 term is good to derive Harnack-type inequalities. Also we should be careful to choose approximate equations so that degree of $I - S \circ H$ has desired properties. We should construct a homotopy of equations in a clever way. For example, to prove the degree in a large ball, equations appearing in the homotopy should be arranged so that solutions have an upper bound uniformly in the homotopy parameter. Our choice of the approximate equation is

(1.14)
$$u_t = (u + \varepsilon^2)^2(u_{xx} - bu + h) \text{ with } h = H(u) = bu + \frac{u^2}{(u+\varepsilon^2)^2}\left(u + \frac{\varepsilon}{\xi(u+\varepsilon^2)} - f\right).$$

Here ξ is a mollified function of $u \vee m\varepsilon$. The multiplier u^2 in H is necessary to calculate local degree near zero since it vanishes faster than u. The multiplier $(u + \varepsilon^2)^2$ is good both for Harnack inequalities and uniform parabolicity. The shift term ε^2 should vanish faster than the parameter ε of penalization so that the limit of approximate solution satisfies the constraint (1.2).

A penalty method is adapted in various evolution equations to introduce constraints of solutions. Rather than to present a huge list we point out one typical example for the harmonic gradient flow equations for mapping into a unit sphere. The requirement of values of mapping u is considered as the constraint $|u| = 1$. A global weak solution was constructed independently by Chen [Ch], Keller et al. [KRS], and Shatah [S] by using a penalty method; see also [CS] for a generalization.

The initial value problem for (1.7) with $q = 0$ was derived in [Ga1] and extensively studied by Gage and Hamilton [GH] for the curve shortening problem. Since a circle shrinks to a point in a finite time for the curve shortening equation ((1.6) with $q = 0$), the curvature may blow up in a finite time. Blow up profiles for convex immersed curves were classified by Angenent [An] based on results of [AL] and [EW] under the self-similar growth assumption for curvatures. It may happen that curvature growth is faster than self-similar rate. Its asymptotic profile is studied in [An] via (1.7) (with $q = 0$). Recently a more precise profile was obtained by Angenent and Velázquez [AV] by studying (1.6) itself. The initial-boundary value problem for a higher-dimensional version of (1.1) (with $f = 0$),

$$u_t = u^2(\triangle u + u), \quad u > 0,$$

in a bounded domain with zero boundary data was studied in [FM] and [Ga2] for positive initial data. The existence of blow up phenomena now depends on the first eigenvalue of the Laplace operator with zero boundary condition. These authors studied whether a solution blows up and they estimated the size of blow up sets. Recently, Wiegner [W] extended the first part

$$u_t = u^\gamma(\triangle u + u)$$

for $\gamma > 2$. There are interesting nonuniqueness results for $\gamma = 1$ by [U] (for the one-dimensional case) and [DL]. Among other results these authors proved that weak solutions may not be unique if initial data takes zero in some open set of the domain because of degeneracy of the equation. They discussed a class of solutions so that uniqueness holds.

This paper is organized as follows. In §2 we derive the Harnack-type inequalities. In §3 an upper bound of solutions is obtained for a general equation so that it applies to our approximate equations. In §4 we establish a lower bound and prove Theorem 1.4. In §5 a lower bound is derived for a general equation. Section 6 is devoted to constructing solutions for approximate equations based on a degree theory. The main theorem is proved there. In §7 we study the property of the solution operator S defined through (1.12). For the existence of S it may be possible to apply the a priori estimate for quasilinear parabolic equations in [LSU]. However, since the space dimension is one, we present a simple proof based only on L^p estimates for linear parabolic equations. In the appendix we give a geometric interpretation of the assumption (1.8); we also give a proof of Lemma 1.3.

2. Harnack-type inequalities. We consider a positive smooth solution u of

$$u_t = u^\gamma(u_{xx} + g(u,x,t)) \quad \text{in} \quad Q = I \times (a,b] \tag{2.1}$$

with $\gamma \in \mathbf{R}$ and smooth g, where I denotes an open interval. We study the behavior of the function $z = (\log u)_t$ to show that the growth of $\log u$ does not become too negative. Such an analysis was done by [Ga2, §2] when $\gamma = 2$ and $g = u$. We adapt his method in our setting. As in [Ga2] our results also extend to the case of several space dimensions, where u_{xx} is replaced with Δu; see §2.5.

For $z = (\log u)_t = u_t/u$ a straightforward calculation yields

$$\begin{aligned} z_x &= \frac{u_{tx}}{u} - \frac{u_t u_x}{u^2}, \\ z_{xx} &= \frac{u_{txx}}{u} - \frac{u_x u_{tx}}{u^2} - \frac{u_{tx}u_x + u_t u_{xx}}{u^2} + 2\frac{u_t u_x^2}{u^3} \\ &= \frac{u_{txx}}{u} - \frac{2u_x z_x}{u} - \frac{u_t u_{xx}}{u^2}. \end{aligned}$$

We thus observe that

$$u_{txx} = u z_{xx} + 2u_x z_x + u_{xx} z.$$

Differentiating $z = u^{\gamma-1}(u_{xx} + g)$ in t yields

$$\begin{aligned} z_t &= u^{\gamma-1}(u_{xxt} + g_u u_t + g_t) + (\gamma - 1)u^{\gamma-2}u_t(u_{xx} + g) \\ &= u^{\gamma-1}(u_{xxt} + g_u uz + g_t) + (\gamma - 1)u^{\gamma-2}uzu^{1-\gamma}z. \end{aligned}$$

Using the expression of u_{xxt} by z's, we end up with a parabolic differential equation for z.

2.1. Differential identity. *Suppose that $u > 0$ solves $u_t = u^\gamma(u_{xx} + g)$ in Q. Then $z = u_t/u$ solves*

$$z_t = u^\gamma z_{xx} + 2u^{\gamma-1}u_x z_x + \gamma z^2 + u^{\gamma-1}(g_u u - g)z + g_t u^{\gamma-1} \quad \textit{in} \quad Q.$$

2.2. Estimate of minimum of z. *Suppose that $u > 0$ solves* (2.1) *in Q with $\gamma > 0$. Suppose that z takes its minimum over Q at $(x_0, t_0) \in Q$. Then*

$$z \geq -\gamma^{-1} u^{\gamma-1}(g_u u - g)_+ - \gamma^{-1/2} u^{(\gamma-1)/2} |g_t|^{1/2} \quad at \quad (x_0, t_0),$$

where f_+ denotes the positive part of f, i.e., $f_+ = f \vee 0$.

Proof. Applying the maximum principle for the differential identity of z yields

$$\gamma z^2 + u^{\gamma-1} G z + g_t u^{\gamma-1} \leq 0 \quad \text{at} \quad (x_0, t_0) \quad \text{with} \quad G = g_u u - g.$$

Since $\gamma > 0$, this quadratic inequality for z implies

$$\begin{aligned} z &\geq -(2\gamma)^{-1}\{u^{\gamma-1} G + (u^{2(\gamma-1)} G^2 - 4\gamma u^{\gamma-1} g_t)^{1/2}\} \\ &\geq -(2\gamma)^{-1}\{u^{\gamma-1} 2G_+ + 2\gamma^{1/2} u^{(\gamma-1)/2} |g_t|^{1/2}\}. \qquad \square \end{aligned}$$

We apply the estimate of $\min z$ to get Harnack-type inequalities. We consider a positive, smooth solution of

$$u_t = u^\gamma (u_{xx} + g(u, x, t)) \quad \text{in} \quad K, \tag{2.2}$$

where $K = (\mathbf{R}/2\pi\mathbf{Z}) \times (\mathbf{R}/T\mathbf{Z})$ and g is a smooth function in each variable.

2.3. Harnack's inequality in time direction. *Assume that $\gamma \geq 1$ and $\alpha \geq 0$. Assume that there are constants c_0, $c_1 > 0$ such that*

$$v g_v(v, x, t) - g(v, x, t) \leq c_0, \qquad |g_t(v, x, t)|^{1/2} \leq c_1 \tag{2.3}$$

for all $(v, x, t) \in (\alpha, \infty) \times K$. Assume that there is a constant $c_2 > 0$ such that $\max_K u \geq c_2$ *for all solutions u of* (2.2) *with $u > \alpha$. Then there is a positive constant $C = C(c_0, c_1, c_2, \gamma) > 0$ such that any solution u of* (2.2) *with $u > \alpha$ fulfills*

$$u(x, t) \leq u(x, t_0) \exp(-C M^{\gamma-1}(t - t_0)), \quad M = \max_K u \tag{2.4}$$

for all (x, t_0), $(x, t) \in K$ with $t_0 - T \leq t \leq t_0$.

Proof. Since K is compact, the minimum of z in K is attained. Using the estimate for $\min_K z$, together with (2.3), we observe that

$$\min_K z \geq -\gamma^{-1} c_0 M^{\gamma-1} - \gamma^{-1/2} c_1 M^{(\gamma-1)/2} \tag{2.5}$$

if $\gamma \geq 1$. Since $M \geq c_2 > 0$, this yields

$$\min_K z \geq -C M^{\gamma-1}$$

with $C = \gamma^{-1} c_0 + \gamma^{-1/2} c_1 c_2^{-(\gamma-1)/2}$. We now obtain a differential inequality

$$-(u^{-1})_t = u_t/u^2 = z/u \geq -C M^{\gamma-1}/u \quad \text{in} \quad K$$

which becomes

$$(u^{-1})_t / u^{-1} \leq C M^{\gamma-1} \quad \text{in} \quad K.$$

For fixed $(x, t_0) \in K$, integrating the differential inequality over (t, t_0) with $t_0 - T \leq t \leq t_0$ yields

$$\log u^{-1}(x, t_0) - \log u^{-1}(x, t) \leq C M^{\gamma-1}(t_0 - t),$$

which is the same as (2.4). □

2.4. Harnack's inequality in space direction. *Assume that $\gamma \geq 1$, $\alpha \geq 0$, and* (2.3) *holds for g. Let u be a solution of* (2.2) *with $u > \alpha$. Let $(x_0, t_0) \in K$ be a maximizer of u. Then*

$$u(x,t_0)^\gamma \geq M^\gamma - \gamma C_M (x-x_0)^2/2 \tag{2.6}$$

with

$$C_M = \frac{c_0}{\gamma} M^{\gamma-1} + \frac{c_1}{\gamma^{\frac{1}{2}}} M^{(\gamma-1)/2} + M^{\gamma-1} g_M, \quad M = \max_K u = u(x_0,t_0),$$
$$g_M = \max\{(g(v,x,t))_+; \alpha < v \leq M, (x,t) \in K\}.$$

Proof. Since $u^{\gamma-1}u_{xx} = z - u^{\gamma-1}g$, it follows from (2.5) that

$$u^{\gamma-1}u_{xx} \geq -C_M \quad \text{in} \quad K. \tag{2.7}$$

This, in particular, implies

$$(u^\gamma)_{xx} = (\gamma u^{\gamma-1}u_x)_x = \gamma(\gamma-1)u^{\gamma-2}u_x^2 + \gamma u^{\gamma-1}u_{xx} \geq -\gamma C_M. \tag{2.8}$$

Integrating over (x_0, x) yields

$$(u^\gamma)_x(x,t_0) \geq (u^\gamma)_x(x_0,t_0) - \gamma C_M(x-x_0) = -\gamma C_M(x-x_0)$$

since (x_0,t_0) is a critical point of u^γ. Integrating again over (x_0,x) yields (2.6). □

2.5. Remarks. The results in §§2.1–2.4 can be extended to a multidimensional problem. Indeed §§2.1 and 2.2 are still valid for

$$u_t = u^\gamma(\Delta u + g(u,x,t)) \quad \text{in} \quad Q = \Omega \times (a,b], \quad \Omega \subset \mathbf{R}^n \tag{2.9}$$

if the first and second derivative in x is replaced by the gradient and the Laplacian, respectively. We consider T-periodic positive solution u of (2.9) with $a = 0$, $b = T$. If u is periodic in space, the same technique yields Harnack's inequality (2.4) provided that $W = \Omega \times (\mathbf{R}/T\mathbf{Z})$ replaces K, where Ω is an n-dimensional torus. However, Harnack's inequality (2.6) should be altered for W. Instead of (2.7) and (2.8), we obtain

$$u^{\gamma-1}\Delta u \geq -C_M, \quad \Delta u^\gamma \geq -\gamma C_M \quad \text{in } W. \tag{2.10}$$

Contrary to the one-dimensional problem, (2.10) does not yield (2.6). Instead of (2.6) we observe that

$$(u^\gamma)_\sharp(r,t) \geq M^\gamma - \gamma C_M r^2/2n, \quad r = |x - x_0| \tag{2.11}$$

for the maximizer (x_0,t_0) of u over W. Here $f_\sharp(r)$ denotes the mean of f on the sphere of radius r centered at x_0, i.e.,

$$f_\sharp(r) = \int_{|\omega|=1} f(r\omega + x_0)d\omega a^{-1}, \quad a = \text{area of the unit sphere.}$$

Indeed, using the identity

$$\triangle_x(f_\sharp(r(x)) = \int_{|\omega|=1} (\triangle f)(r(x)\omega + x_0)d\omega a^{-1}, \quad r(x) = |x - x_0|, \tag{2.12}$$

we observe that $(2.10)_2$ yields

$$(r^{n-1}((u^\gamma)_\sharp)')' \geq -\gamma C_M r^{n-1}$$

since $\triangle_x g(r(x)) = r^{1-n}(r^{n-1}g')'$. Here, the left-hand side of (2.12) is the Laplacian of $f_\sharp(r(x))$ as a function of x. Since (x_0, t_0) is a critical point of $(u^\gamma)_\sharp$, integrating over $(0, r)$ yields $((u^\gamma)_\sharp)' \geq -\gamma C_M r/n$. Integrating over $(0, r)$ again yields (2.11).

Now we must prove (2.12). We may assume $x_0 = 0$. A direct calculation shows

$$\triangle_x(f(r(x)\omega)) = ((\omega \cdot \nabla)(\omega \cdot \nabla)f)(r(x)\omega), \tag{2.13}$$

$$[\nabla - \omega(\omega \cdot \nabla)] \cdot ([\nabla - \omega(\omega \cdot \nabla)]f) = [\triangle - (\omega \cdot \nabla)(\omega \cdot \nabla)]f \tag{2.14}$$

for a given unit n-vector ω. If the left-hand side of (2.14) is evaluated at $r(x)\omega$, it agrees with $\triangle_s g(\omega)$, $g(\omega) = f(r(x)\omega)$, where $\triangle_s$ is the Laplace–Beltrami operator on the unit spheres. By the divergence theorem, integrating (2.14) over the sphere yields

$$0 = \int_{|\omega|=1} [(\triangle - (\omega \cdot \nabla)(\omega \cdot \nabla))f](r(x)\omega)d\omega.$$

This together with (2.13) yields (2.12). □

3. Upper bounds. We shall derive an a priori upper bound for a positive smooth solution $u > \alpha > 0$ of

$$u_t = u^\gamma\{u_{xx} + \varphi(u)(u + \psi(u) - f(x,t))\} \quad \text{in} \quad K. \tag{3.1}$$

Here φ and ψ are smooth functions on (α, ∞) and f is smooth on K, i.e., $f \in C^\infty(K)$ with $f > 0$; $\alpha \geq 0$ and $\gamma \in \mathbf{R}$.

3.1. Lemma on integral bounds. *Assume that* $\psi \geq 0$, $f \geq 0$, *and that* $0 \leq \varphi \leq c_3$, $v - \varphi(v)v \leq c_4$ *on* (α, ∞), $(\alpha \geq 0)$ *with some positive constants* c_3 *and* c_4. *Then*

$$\iint_K u dx dt \leq 2\pi T(c_3 \|f\|_\infty + c_4) \equiv C_1,$$

$$\iint_K \frac{u_t^2}{u^\gamma} dx dt \leq c_3 C_1 \|f_t\|_\infty \equiv C_2$$

holds for all solutions $u \in C^\infty(K)$ *of* (3.1) *with* $u > \alpha$ *on* K.

Proof. Multiplying $u^{-\gamma}$ with (3.1) and integrating by parts on K yields

$$\begin{aligned}\iint_K \frac{u_t}{u^\gamma} dx dt &= \iint_K \{u_{xx} + \varphi(u)(u + \psi(u) - f)\} dx dt \\ &= \iint_K \{\varphi(u)u - \varphi(u)(f - \psi(u))\} dx dt.\end{aligned}$$

Since u is T-periodic, we see

$$\int_0^T \frac{u_t}{u^\gamma} dt = (1-\gamma)^{-1} \int_0^T (u^{1-\gamma})_t dt = 0 \quad \text{for all} \quad x \in \mathbf{R}.$$

We thus observe that

$$\iint_K \varphi(u)udxdt = \iint_K \varphi(u)(f - \psi(u))dxdt \leq \iint_K \varphi(u)fdxdt \leq 2\pi Tc_3||f||_\infty$$

since $\psi \geq 0$ and $\varphi \geq 0$. From $v - \varphi(v)v \leq c_4$ it follows that

$$\iint_K udxdt \leq \iint_K (\varphi(u)u + c_4)dxdt \leq C_1.$$

It remains to prove the second inequality of Lemma 3.1. Multiplying u_t/u^γ with (3.1) and integrating over K yields

$$\iint_K \frac{u_t^2}{u^\gamma}dxdt = \iint_K \{u_{xx}u_t + \varphi(u)(u + \psi(u) - f)u_t\}dxdt.$$

Integrating by parts, we see

$$\iint_K u_{xx}u_tdxdt = -\iint_K u_xu_{xt}dxdt = -\frac{1}{2}\int_0^T \frac{d}{dt}\int_0^{2\pi} u_x^2dxdt = 0$$

by T-periodicity of u_x. We also observe that

$$\int_0^T \varphi(u)(u + \psi(u))u_tdt = 0 \quad \text{for all} \quad x \in \mathbf{R}.$$

We thus conclude by integration by parts in t that

$$\iint_K \frac{u_t^2}{u^\gamma}dxdt = -\iint_K \varphi(u)fu_tdxdt = \iint_K \Phi(u)f_tdxdt$$

by T-periodicity of u, where Φ is a primitive of φ defined by

$$\Phi(v) = \int_0^v \varphi(r)dr$$

so that $\Phi(v)_t = \varphi(v)v_t$ and $\Phi(v) \leq c_3v$. It now follows that

$$\iint_K \frac{u_t^2}{u^\gamma}dxdt \leq ||f_t||_\infty \cdot \iint_K c_3udxdt \leq c_3C_1||f_t||_\infty.$$

This is the same as the second inequality of Lemma 3.1. □

3.2. Upper bound theorem. *Assume that* $1 \leq \gamma < 3$ *and that* $\alpha \geq 0$. *Assume the hypotheses in Lemma* 3.1 *on* f, ψ, φ. *Assume furthermore that*

$$\varphi'(v)(\psi(v) - f) + \varphi(v)\psi'(v) \leq 0, \tag{3.2}$$

$$0 \leq \varphi'(v)v^2 \leq c_5, \quad \varphi(v)(\psi(v) - \min_K f) \leq c_6(v + 1) \tag{3.3}$$

on (α, ∞) *with constants* c_5 *and* $c_6 > 0$. *Then there is a positive constant* $M_0 = M_0(c_j,\ 3 \leq j \leq 6,\ T,\ ||f||_\infty,\ ||f_t||_\infty,\ \gamma)$ *such that if* $u \in C^\infty(K)$ *with* $\min_K u > \alpha$ *solves* (3.1), *then* $\max_K u \leq M_0$.

Proof. We shall combine Harnack's inequality (2.6) with integral bounds. We set

$$g(v, x, t) = \varphi(v)(v + \psi(v) - f(x, t)) \tag{3.4}$$

so that

$$\begin{aligned} g_v v - g &= \{\varphi'(v)(v+\psi(v)-f)+\varphi(v)(1+\psi'(v))\}v - \varphi(v)(v+\psi(v)-f) \\ &\le \varphi'(v)v^2 + \varphi(v)(f-\psi(v)) \quad \text{by} \quad (3.2) \\ &\le c_5 + c_3\|f\|_\infty \equiv c_0 \quad \text{for} \quad v > \alpha \end{aligned}$$

since $\psi \ge 0$. Moreover,

$$|g_t| \le \varphi(v)\|f_t\|_\infty \le c_3\|f_t\|_\infty \equiv c_1^2 \quad \text{for} \quad v > \alpha.$$

Applying Harnack's inequality (2.6), we have

$$u(x,t_0)^\gamma \ge M^\gamma - \gamma C_M(x-x_0)^2/2 \quad \text{for all} \quad x \in \mathbf{R} \tag{3.5}$$

with $M = \max_K u = u(x_0,t_0)$ and

$$C_M = \frac{c_0}{\gamma}M^{\gamma-1} + \frac{c_1}{\gamma^{1/2}}M^{(\gamma-1)/2} + M^{\gamma-1}g_M.$$

Here

$$\begin{aligned} g_M &= \max\{g(v,x,t)_+; \alpha < v \le M,\ (x,t) \in K\} \\ &\le c_3 M + c_6(M+1) \quad \text{by} \quad (3.3)_2. \end{aligned}$$

It follows that

$$C_M \le 2c'M^\gamma \qquad (c' = c_3 + c_6)$$

for large M, say, $M \ge M_1 = M_1(c_0,c_1,c_3,c_6,\gamma)$.

We now integrate (3.5) (assuming $M \ge M_1$) to get

$$\begin{aligned} \int_0^{2\pi} u(x,t_0)^\gamma dx = \int_{x_0-\pi}^{x_0+\pi} u(x,t_0)^\gamma dx &\ge \int_{x_0}^{x_0+\sigma} (M^\gamma - \gamma c' M^\gamma (x-x_0)^2)dx \\ &= M^\gamma \sigma(1-\gamma c'\sigma^2/3) \quad \text{for} \quad 0<\sigma<\pi \\ &\ge M^\gamma\sigma/2 \quad \text{for small} \quad \sigma, \quad \text{say,} \quad \sigma \le (3/2\gamma c')^{1/2} \equiv \sigma_0. \end{aligned}$$

We shall fix $\sigma = \sigma_0$ in the rest of our argument. By Lemma 3.1 there is t_1 such that

$$\begin{aligned} \int_0^{2\pi} u(x,t_1)^\gamma dx &\le \frac{1}{T}\int_0^T \int_0^{2\pi} u(x,t)^\gamma dxdt \\ &\le \frac{M^{\gamma-1}}{T}\iint_K udxdt \le \frac{C_1 M^{\gamma-1}}{T}. \end{aligned}$$

We now observe that

$$\begin{aligned} \int_0^{2\pi} u(x,t)^\gamma dx &= \int_0^{2\pi} u(x,t_1)^\gamma dx + \int_0^{2\pi}\int_{t_1}^t \gamma u^{\gamma-1}u_t(x,\tau)d\tau dx \\ &\le \int_0^{2\pi} u(x,t_1)^\gamma dx + \gamma\left(\iint_K u^{3\gamma-2}dxdt\right)^{1/2}\left(\iint_K \frac{u_t^2}{u^\gamma}dxdt\right)^{1/2} \\ &\le \frac{C_1}{T}M^{\gamma-1} + \gamma C_1^{1/2}M^{(3\gamma-3)/2}C_2^{1/2} \quad \text{for all} \quad t \in \mathbf{R} \end{aligned}$$

since $\iint u_t^2/u^\gamma$ is estimated by Lemma 3.1. Setting $t = t_0$ now yields

$$\frac{M^\gamma \sigma_0}{2} \le \int_0^{2\pi} u(x,t_0)^\gamma dx \le \frac{C_1}{T} M^{\gamma-1} + \gamma C_1^{1/2} C_2^{1/2} M^{(3\gamma-3)/2}.$$

Since $\gamma < 3$, i.e., $(3\gamma - 3)/2 < \gamma$, this inequality for M yields a bound for M, say $M \le M_2 = M_2(\sigma_0, C_1, C_2, T, \gamma)$. We thus conclude that $M \le M_0$ by setting $M_0 = \max(M_1, M_2)$. □

3.3. Remark. The assumptions of Theorem 3.2 are clearly satisfied for $u_t = u^\gamma(u_{xx} + u - f)$ with $f > 0$, which is a particular example of (3.1) found by setting $\varphi \equiv 1$ and $\psi \equiv 0$. We study general equations because we need to have a bound of solutions for solutions of equations which appear in the homotopy of approximate equations. These technical looking assumptions are really useful in what follows.

3.4. Remark. We obtain an upper bound as in §3.2 for the multidimensional problem where K is replaced by W as in §2.5. Note that the integral bounds in §3.1 hold for W with no changes. The only place to be altered in the proof of Theorem 3.2 is the estimate of space integral of u^γ from below since (2.6) should be replaced by (2.11). By (2.11) it holds that

$$\begin{aligned}\int_\Omega u^\gamma(x,t_0)dx &\ge \int_{|x-x_0|<\sigma} u^\gamma(x,t_0)dx \ge \int_0^\sigma r^{n-1}(M^\gamma - \gamma c' M^\gamma r^2/n)dr \\ &\ge M^\gamma \sigma^n/2n \quad \text{for small} \quad \sigma.\end{aligned}$$

The remaining argument is the same as in the proof of Theorem 3.2.

4. Constraints and lower bounds. We consider a positive (periodic) solution $u \in C^\infty(K)$ of (1.1) with the constraint (1.2). Our goal in this section is to establish an a priori lower bound for u when $f > 0$. Since an upper bound is obtained in Theorem 3.2, this will complete the proof of Theorem 1.4. As noted in the introduction, the constraint (1.2) plays an important role for a lower bound. We first study the stationary problem of (1.1),

$$U_{xx} + U = F \quad \text{in} \quad \mathbf{T} = \mathbf{R}/2\pi\mathbf{Z}. \tag{4.1}$$

4.1. Lemma on distance of zeros. *For $a \in \mathbf{R}$ and $d > 0$ suppose that V solves*

$$V_{xx} + V \ge 0 \quad on \quad (a, a+d)$$

with $V(a) = V_x(a) = 0$ and $V(a+d) = 0$. Suppose that

$$V \ge 0 \quad on \quad (a, a+d) \quad and \quad V \not\equiv 0.$$

Then $d > \pi$. Here V_x is assumed to be Lipschitz on $[a, a+d]$.

Proof. We may assume $a = 0$. Since $V(0) = V(d) = 0$, integration by parts yields

$$\int_0^d \sin\left(\frac{\pi x}{d}\right)\left\{V_{xx} + \left(\frac{\pi}{d}\right)^2 V\right\} dx = 0.$$

Suppose that $\pi/d \ge 1$. Since $\sin(\pi x/d) \ge 0$, $V \ge 0$ on $(0,d)$, we now observe that

$$\int_0^d \sin\left(\frac{\pi x}{d}\right)(V_{xx} + V)dx \le \int_0^d \sin\left(\frac{\pi x}{d}\right)\left\{V_{xx} + \left(\frac{\pi}{d}\right)^2 V\right\} dx = 0.$$

Since $V_{xx}+V \geq 0$, this implies

$$V_{xx}+V=0 \quad \text{on} \quad (0,d).$$

By $V(0)=V(d)=0$ we see that

$$V(x)=R\sin(\pi x/d)$$

with some constant R. Since $V_x(0)=0$, this implies $V\equiv 0$, which contradicts $V\not\equiv 0$. We thus proved $\pi/d<1$. □

We next discuss the way to get a lower bound of solutions of (4.1) from constraints. For later convenience we state here a general version. Let $\mu^{\pm}=\{\mu_\varepsilon^{\pm}\}_{\varepsilon>0}$ be a sequence of nonincreasing, continuous, positive functions on $(0,\infty)$ such that $\mu_\varepsilon^{\pm}$ converges to some (nonincreasing, positive,) function $\mu_0^{\pm}$ on $(0,\infty)$. We assume that μ_0^- is continuous in $(0,\infty)$ and that the convergence $\mu_\varepsilon^-\to\mu_0^-$ is uniform in every compact subset of $(0,\infty)$ as $\varepsilon\to 0$. Let $h^-=\{h_\varepsilon^-\}_{\varepsilon>0}$ be a bounded sequence in $L^\infty(0,\infty)$ such that $0\leq h_\varepsilon^-\leq 1$. Assume that h_ε^- converges to $h_0^-\equiv 1$ *uniformly* in every compact subset of $(0,\infty)$ as $\varepsilon\to 0$. For $U>0$ in (4.1) and $\varepsilon\geq 0$ we set

$$A_\varepsilon^{\pm}(\zeta,U)=\int_0^{2\pi}\sin_{\pm}(x-\zeta)\mu_\varepsilon^{\pm}(U)h_\varepsilon^{\pm}(U)dx, \quad \zeta\in\mathbf{R}, \tag{4.2}$$

where $\sin_+ z=\max(\sin z,0)$, $\sin_- z=-\min(\sin z,0)$, and $h_\varepsilon^+\equiv 1$ for $\varepsilon\geq 0$.

4.2. Lemma on a lower bound for stationary solutions. *Let k_j $(0\leq j\leq 4)$ be a positive constant. Suppose that*

$$\int_0^1 \mu_0^-(x^2)dx=\infty. \tag{4.3}$$

Then there are positive constants ε_0, δ_0 depending only on k_j and $\mu^{\pm}$, h^- such that a positive solution $U\in C^2(\mathbf{T})$ of (4.1) satisfies $\min_{\mathbf{T}} U\geq\delta_0$ if U and ε $(0\leq\varepsilon<\varepsilon_0)$ fulfill the following properties:

(U1) $0\leq F\leq k_0$, *where* $F=U_{xx}+U$,

(U2) $k_1\leq\max_{\mathbf{T}} U\leq k_2$,

(U3) $A_\varepsilon^-(\zeta,U)\leq k_3A_\varepsilon^+(\zeta,U)+k_4$ *for all* $\zeta\in\mathbf{R}$.

Proof. We argue by contradiction. Suppose that for some k_j $(0\leq j\leq 4)$ there would exist sequences $\{U_n\}$, $\{\varepsilon_n\}$ $(\varepsilon_n\geq 0)$ satisfying (U1)–(U3) with $U=U_n$, $\varepsilon=\varepsilon_n$, $F=F_n$ such that

$$0<\min_{\mathbf{T}} U_n\to 0 \quad \text{and} \quad \varepsilon_n\to 0 \quad \text{as} \quad n\to\infty. \tag{4.4}$$

Let $x_n\in\mathbf{T}$ be a point such that $\min_{\mathbf{T}} U_n=U_n(x_n)$. We may assume $x_n\to x_0$ for some $x_0\in\mathbf{T}$ by taking a subsequence if necessary. Since F_n and U_n are bounded by (U1) and (U2), the equation (4.1) implies that $\{U_{nxx}\}$ is bounded in $C(\mathbf{T})$. By Ascoli–Arzela's theorem U_n converges to some function U in $C^1(\mathbf{T})$, by taking a subsequence if necessary. Since $\{U_{nxx}\}$ is bounded, U_x is Lipschitz in $\mathbf{T}$ and solves

$$U_{xx}+U\geq 0 \quad (\text{by } F_n\geq 0).$$

By (4.4) we obtain

$$U(x_0)=\lim_{n\to\infty}U_n(x_n)=0$$

since the convergence $U_n \to U$ is uniform. By (U2) we see $U \not\equiv 0$, i.e., there is $x_* \in \mathbf{R}$ with $U(x_*) > 0$. We set

$$a = \sup\{x \in \mathbf{R}; U(x) = 0, x < x_*\} \in \mathbf{R}.$$

Since U takes zero at x_0 this is well defined. By continuity of U_x we see $U(a) = U_x(a) = 0$ and $U(x) > 0$ for $a < x \leq x_*$. We now apply Lemma 4.1 to observe that the distance of another zero (bigger than a) of U and a is more than π. Thus there is a small $0 < \rho_0 < \pi/2$ such that if $0 < \rho < \rho_0$ then

$$\lambda_\rho = \inf\{U(x); a + \rho \leq x \leq a + \rho + \pi\} > 0.$$

We fix $0 < \rho < \rho_0$ and set $\zeta = a + \rho$. Since $U_n \to U$ is uniform, we have a uniform lower bound for U_n,

$$U_n \geq \kappa = \lambda_\rho/2 \quad \text{on} \quad [\zeta, \zeta + \pi] \tag{4.5}$$

for sufficiently large n.

Since U_{xx} is bounded, $U_x(a) = U(a) = 0$ implies that

$$0 \leq U(x) \leq R(x-a)^2 \qquad \text{for all} \quad x \in \mathbf{R} \tag{4.6}$$

with some $R > 0$. From a bound (4.5) it follows that

$$\overline{\lim}_{n\to\infty} A_n^+ = \overline{\lim}_{n\to\infty} \int_\zeta^{\zeta+\pi} \sin(x-\zeta)\mu_{\varepsilon_n}^+(U_n)dx \leq \int_\zeta^{\zeta+\pi} \sin(x-\zeta)dx\mu_0^+(\kappa) = 2\mu_0^+(\kappa),$$

where $A_n^\pm = A_\varepsilon^\pm(\zeta, U_n)$ with $\varepsilon = \varepsilon_n$. By (U3) this implies

$$\overline{\lim}_{n\to\infty} A_n^- \leq 2k_3\mu_0^+(\kappa) + k_4 \equiv L < \infty.$$

Using Fatou's lemma, we observe that

$$\begin{aligned}\int_a^\zeta (-\sin(x-\zeta))\mu_0^-(U)dx &\leq \underline{\lim}_{n\to\infty} \int_a^\zeta (-\sin(x-\zeta))\mu_{\varepsilon_n}^-(U_n)h_{\varepsilon_n}^-(U_n)dx \\ &\leq \underline{\lim}_{n\to\infty} A_n^- \leq L,\end{aligned}$$

since the uniform convergence $\mu_\varepsilon^- \to \mu_0^-$, $h_\varepsilon^- \to h_0^-$ on every compact set in $(0, \infty)$ implies that

$$\lim_{n\to\infty} \mu_{\varepsilon_n}^-(U_n(x)) = \mu_0^-(U(x)), \quad \lim_{n\to\infty} h_{\varepsilon_n}^-(U_n(x)) = 1$$

for $a < x < \zeta$. From (4.6) it follows that

$$\int_a^\zeta (-\sin(x-\zeta))\mu_0^-(R(x-a)^2)dx \leq L.$$

Since $-\sin(x-\zeta) > 0$ on $(\zeta - \pi, \zeta) \ni a$, this contradicts (4.3). We have thus obtained a lower bound δ_0 for U for small $\varepsilon \geq 0$. □

4.3. Corollary. *Let $f \in C(\mathbf{T})$ be a positive function and $\sigma > 0$. There are positive constants δ_0, M_0 (depending only on σ, $\|f\|_\infty$ and $\min_{\mathbf{T}} f$) such that if a positive function $u \in C^2(\mathbf{T})$ solves*

$$u_{xx} + u = f \quad \textit{in} \quad \mathbf{T} \quad \textit{with} \quad \int_0^{2\pi} e^{ix}u^{-\sigma}dx = 0,$$

then $\delta_0 \le u \le M_0$ *provided that* $1/2 \le \sigma$.

Proof. Although an upper bound M_0 is obtained by a general Theorem 3.2, we sketch the proof in this context which reflects an essential step of the proof of Theorem 3.2. Clearly $uu_{xx} = fu - u^2 \ge -M^2$ with $M = \max_{\mathbf{T}} u$. This implies that

$$(u^2)_{xx} = 2u_x^2 + 2uu_{xx} \ge -2M^2,$$

which yields

$$u^2(x) \ge M^2 - M^2(x-x_0)^2, \qquad M = \max_{\mathbf{T}} u = u(x_0).$$

We now integrate to get

$$M^2 \int_{x_0}^{x_0+1} (1-(x-x_0)^2)dx \le \int_0^{2\pi} u^2 dx \le M \int_0^{2\pi} udx.$$

This yields a bound M_0 of M since we observe that

$$\int_0^{2\pi} udx = \int_0^{2\pi} fdx \le 2\pi ||f||_\infty$$

by integrating $u_{xx} + u = f$ on $\mathbf{T}$.

By the maximum principle we have

$$\max u \ge \min f.$$

Since the constraint $\int e^{ix} u^{-\sigma} dx = 0$ is equivalent to

$$\int_0^{2\pi} \sin(x-\zeta) u^{-\sigma} dx = 0 \quad \text{for all} \quad \zeta \in \mathbf{R},$$

(U3) is fulfilled with $k_3 = 1$, $k_4 = 0$, $\mu_\varepsilon^\pm(v) = v^{-\sigma}$, $h_\varepsilon^\pm(v) \equiv 1$ for all $\varepsilon \ge 0$. We observe that (U2) is fulfilled with $k_1 = \min_{\mathbf{T}} f > 0$, $k_2 = M_0$. Since (4.3) is fulfilled for $\mu_0^-(v) = v^{-\sigma}$, we now apply Lemma 4.2 with $k_0 = ||f||_\infty$ to get a desired lower bound δ_0 of u. □

We now study the time-dependent problem (1.1) or its general form

$$u_t = u^\gamma(u_{xx} + u - f) \quad \text{in} \quad K. \tag{4.7}$$

For $u \in C(K)$ it is convenient to define

$$U(x) = \int_0^T u(x,t)dt.$$

Divide (4.7) by u^γ and integrate over $(0,T)$ to get

$$U_{xx} + U = F \quad \text{in} \quad \mathbf{T} \quad \text{with} \quad F = \int_0^T f(x,t)dt, \tag{4.8}$$

since u is T-periodic in time. Harnack's inequality (2.4) allows us to compare u and U.

4.4. Lemma. *Suppose that* $u \in C(K)$ *satisfies* (2.4). *Then there are* λ, $\Lambda > 0$ (*depending only on* C, γ, M, T) *such that* $\lambda u(x,t) \le U(x) \le \Lambda u(x,t)$ *for* $(x,t) \in K$.

Proof. Since u is T-periodic, integrating (2.4) on $(t_0 - T, t_0)$ yields

$$U(x) = \int_{t_0-T}^{t_0} u(x,t)dt \le u(x,t_0)\Lambda, \quad \Lambda = \int_{t_0-T}^{t_0} \exp(-CM^{\gamma-1}(t-t_0))dt;$$

Λ is indepenent of t_0. The inequality $\lambda u \le U$ is similarly obtained by integrating

$$u(x,t_0)\exp(CM^{\gamma-1}(t_0-t)) \le u(x,t) \quad \text{on} \quad t_0 \le t \le t_0 + T. \qquad \square$$

4.5. Proof of Theorem 1.4. Since an upper bound of a positive smooth solution of (1.1) or (4.7) with $1 \le \gamma < 3$ is obtained by Theorem 3.2, it suffices to establish a lower bound assuming the constraint (1.2).

By the maximum principle we see that

$$\max_K u \ge \min_K f \equiv c_2. \tag{4.9}$$

Since Harnack's inequality (2.4) is available for (4.7) with $c_0 = ||f||_\infty$, $c_1 = ||f_t||_\infty$, $\gamma = 2$, Lemma 4.4 now yields

$$\max_T U \ge U(x_0) \ge \lambda u(x_0,t_0) \ge \lambda c_2 \equiv k_1 \tag{4.10}$$

by taking (x_0,t_0) as a maximizer of u over K. From an upper bound M_0 of u, it follows that U fulfills (U2) with $k_2 = M_0 T$. Since $0 \le f \le ||f||_\infty$, we see that (U1) is fulfilled with $k_0 = T||f||_\infty$. If $U \ge \delta_0$ on K, Lemma 4.4 gives a lower bound $\delta = \Lambda^{-1}\delta_0$ for u.

Finally, we check (U3) with (4.3) by choosing $\mu_\varepsilon^\pm(v) = v^{-1}$, $h_\varepsilon^\pm(v) \equiv 1$ for $\varepsilon \ge 0$, so that (4.3) is fulfilled. We shall drop subscript ε since all quantities we handle are independent of ε. We estimate A^- by Lemma 4.4 to get

$$A^-(\zeta, U) \le \lambda^{-1} \int_0^{2\pi} \frac{\sin_-(x-\zeta)}{u(x,t)}dx.$$

By the constraint (1.2) we have

$$\int_0^{2\pi} \frac{\sin_-(x-\zeta)}{u(x,t)}dx = \int_0^{2\pi} \frac{\sin_+(x-\zeta)}{u(x,t)}dx, \quad \zeta \in \mathbf{R}$$

since $\int_0^{2\pi} \sin(x-\zeta)u^{-1}dx = 0$. Using Lemma 4.4 again, we get

$$A^-(\zeta, U) \le \lambda^{-1}\Lambda A^+(\zeta, U),$$

which is (U3) with $k_3 = \lambda^{-1}\Lambda$ and $k_4 = 0$. This enables us to apply Lemma 4.2 to get a lower bound δ_0 for U. If we examine properties of all constants, we conclude that the constant δ_0 has the desired property.

4.6. Generalization. If we examine the proof, it turns out that the assumptions in Theorem 1.4 are weakened. First of all we may replace (1.1) by (4.7) with $1 \le \gamma < 3$. Second, (1.2) may be replaced by

$$\int_0^{2\pi} \frac{e^{ix}}{u^\sigma(x,t)}dx = 0$$

for some $\sigma \ge 1/2$ and some t. Here $\mu_\varepsilon^\pm(v)$ should be $v^{-\sigma}$ in the proof.

5. Approximate penalized equations. To solve (1.1) with (1.2) for positive $f \in C^\infty(K)$ satisfying (1.3) we consider an approximate penalized equation. Let $m > 1$ be a large number such that

$$\min_K f - \frac{1}{m} \geq \frac{1}{2} \min_K f. \tag{5.1}$$

For $0 < \varepsilon,\ \varepsilon' < 1$ we take a smooth nondecreasing function $\xi = \xi_\varepsilon$ on $[0, \infty)$ such that

$$\xi(v) = v \quad \text{for} \quad v \geq m\varepsilon + \varepsilon', \tag{5.2}$$

$$v \vee m\varepsilon \leq \xi(v) \leq \ell(v \vee m\varepsilon) \quad \text{for} \quad v \geq 0 \tag{5.3}$$

$$\text{with some} \quad 1 < \ell < 2 \quad \text{independent of} \quad \varepsilon, \varepsilon', \text{and}\, v.$$

Our approximate penalized equation is of the form

$$w_t = (w + \varepsilon')^2 \left(w_{xx} + \frac{w^2}{(w+\varepsilon')^2} \left(w + \frac{\varepsilon}{\xi(w + \varepsilon')} - f \right) \right) \quad \text{in} \quad K. \tag{5.4}$$

The term $\varepsilon/\xi(w + \varepsilon')$ plays the role of a penalty term. (If we do not need to have smoothness of this term, we may take $\varepsilon/(w + \varepsilon') \vee m\varepsilon$.) The cutting off by $m\varepsilon$ of ξ is introduced so that $f - \varepsilon/\xi(w + \varepsilon')$ is always positive, which will be important to get a lower bound. The parameter ε' is taken so that equation (5.4) is uniformly parabolic, while ε is for penalization. To get a lower bound for w, the penalization effect must dominate the other approximation so ε' should tend to zero faster than ε when $\varepsilon \to 0$. For simplicity we shall take $\varepsilon' = \varepsilon^2$ for the rest of our argument. We set $w + \varepsilon^2 = u$ in (5.4) to get

$$u_t = u^2(u_{xx} + \varphi_\varepsilon(u)(u + \psi_\varepsilon(u) - f - \varepsilon^2)) \quad \text{in} \quad K \tag{5.5}$$

with

$$\varphi_\varepsilon(v) = \frac{(v - \varepsilon^2)^2}{v^2}, \; \psi_\varepsilon(v) = \frac{\varepsilon}{\xi(v)} \quad \text{for} \quad v > 0. \tag{5.6}$$

A direct calculation shows

$$\varphi_\varepsilon(v) = 1 - \frac{2\varepsilon^2}{v} + \frac{\varepsilon^4}{v^2} \tag{5.7}$$

$$\varphi'_\varepsilon(v) = \frac{2\varepsilon^2}{v^2}\left(1 - \frac{\varepsilon^2}{v}\right). \tag{5.8}$$

Since φ_ε and ψ_ε satisfy

(5.9)
$$0 \leq \varphi_\varepsilon(v) \leq 1, \quad 0 \leq \varphi'_\varepsilon(v)v^2 \leq 2\varepsilon^2 \leq 2, \quad v(1 - \varphi_\varepsilon(v)) \leq 2\varepsilon^2 \leq 2, \quad \text{for}\, v > \alpha = \varepsilon^2,$$

$$\min_K f - \psi_\varepsilon(v) > 0, \; \psi'_\varepsilon(v) \leq 0 \quad \text{for} \quad v > \alpha, \tag{5.10}$$

all assumptions in Theorem 3.2 are fulfilled with $c_3 = 1$, $c_4 = 2$, $c_5 = 2$, $c_6 = 0$; to get $(5.10)_1$ we use (5.1)–(5.3).

5.1. Upper bound proposition. *There is a positive constant* $M_0 = M_0(T, ||f||_\infty, ||f_t||_\infty)$ *such that if* $u \in C^\infty(K)$ *solves* (5.5) *with* φ_ε, ψ_ε *satisfying* (5.9), (5.10), *and*

$u > \varepsilon^2$ on K, then $u \le M_0$ on K. Here and hereafter, φ_ε and ψ_ε are assumed to be smooth on $(0, \infty)$.

As in §4 we set

$$U(x) = \int_0^T u(x,t)dt.$$

Applying the maximum principle for (5.5) we see

$$\max_K u \ge \min_K f - \psi_\varepsilon(u) \ge \min_K f - \frac{1}{m} \ge \frac{1}{2}\min_K f \equiv c_2$$

by (5.1)–(5.3). Since other assumptions for Harnack's inequality (2.4) hold by (5.9) and (5.10), U and u are compared by Lemma 4.4.

5.2. Comparison lemma. *Assume that φ_ε and ψ_ε fulfill* (5.9) *and* (5.10) *and that*

$$\min_K f - \psi_\varepsilon(v) \ge c_2 > 0 \quad \text{for} \quad v > \varepsilon^2$$

for some constant c_2. Then there are positive constants λ and Λ (depending only on T, $||f||_\infty$, $||f_t||_\infty$, c_2) such that if $u \in C^\infty(K)$ solves (5.5) *with $u > \varepsilon^2$ on K, then*

$$\lambda u(x,t) \le U(x) \le \Lambda u(x,t) \quad \textit{for} \quad (x,t) \in K. \tag{5.11}$$

We shall derive a uniform lower bound of u independent of ε by assuming (1.3) for f, i.e.,

$$\int_0^{2x} f(x,t)\sin(x-\zeta)dx = 0 \quad \text{for all} \quad \zeta, t \in \mathbf{R}. \tag{5.12}$$

5.3. Lemma on approximate constraints. *Assume that $f \in C^\infty(K)$ satisfies* (5.12). *Assume* $(5.9)_1$ *and*

$$1 - \varphi_\varepsilon(v) \le c_7\varepsilon^2 v^{-1} \quad \text{for} \quad v > \varepsilon^2 \tag{5.13}$$

with some $c_7 > 0$. Then if $u \in C^\infty(K)$ solves (5.5) *with $u > \varepsilon^2$ on K, we have*

$$\left| \int_0^T \int_0^{2\pi} \{\varphi_\varepsilon(u)\psi_\varepsilon(u) + (1 - \varphi_\varepsilon(u))(f + \varepsilon^2)\} \sin(x - \zeta)dxdt \right| \le 4Tc_7\varepsilon^2 \tag{5.14}$$

for all $\zeta \in \mathbf{R}$.

Proof. Since u is T-periodic in t, we have

$$\int_0^T \frac{u_t}{u^2}dt = \int_0^T \left(-\frac{1}{u}\right)_t dt = 0.$$

Since u is 2π-periodic in x, integrating by parts yields

$$\int_0^{2\pi} (u_{xx} + u)\sin(x - \zeta)dx = 0 \quad \text{for all} \quad \zeta \in \mathbf{R}.$$

Multiply (5.5) by u^{-2} to get

$$u_t u^{-2} = u_{xx} + u - (f + \varepsilon^2) + \varphi_\varepsilon(u)\psi_\varepsilon(u) + (1 - \varphi_\varepsilon(u))(f + \varepsilon^2) + (\varphi_\varepsilon(u) - 1)u.$$

Multiplying both sides by $\sin(x-\zeta)$ and integrating over K now yields

$$\int_0^T\int_0^{2\pi}\{\varphi_\varepsilon(u)\psi_\varepsilon(u)+(1-\varphi_\varepsilon(u))(f+\varepsilon^2)\}\sin(x-\zeta)dxdt$$
$$=\int_0^T\int_0^{2\pi}(1-\varphi_\varepsilon(u))u\sin(x-\xi)dxdt.$$

We use (5.13) to get (5.14). □

Since φ_ε in (5.6) satisfies (5.7), property (5.13) with $c_7=2$ holds for φ_ε defined by (5.6). By its form of φ_ε and ψ_ε in (5.6), it is clear that

(5.15)
$$\varphi_\varepsilon(v)\to 1,\ \psi_\varepsilon(v)/\varepsilon\to v^{-1}\ \text{uniformly on every compact subset of } (0,\infty)$$

as $\varepsilon\to 0$.

5.4. Lemma on constraints for the limit of approximate solutions. *Assume that φ_ε and ψ_ε fulfill* $(5.9)_1$, (5.13), *and* (5.15). *Assume that $u_\varepsilon\in C^\infty(K)$ $(u_\varepsilon>\varepsilon^2)$ solves* (5.5) *with $f=f_\varepsilon\in C^\infty(K)$ satisfying* (5.12). *Assume that $||f_\varepsilon||_\infty$ is bounded for $0<\varepsilon<1$. Suppose that u_ε converges to a positive $u\in C(K)$ uniformly in K. Then*

$$\int_0^T\int_0^{2\pi}\sin(x-\zeta)u^{-1}(x,t)dxdt=0\quad\text{for all}\quad \zeta\in\mathbf{R}. \tag{5.16}$$

Proof. Dividing (5.14) ($f=f_\varepsilon$, $u=u_\varepsilon$) by $0<\varepsilon<1$ and using (5.13), we observe that

(5.17)
$$\left|\int_0^T\int_0^{2\pi}\sin(x-\zeta)\varphi_\varepsilon(u_\varepsilon)\psi_\varepsilon(u_\varepsilon)\varepsilon^{-1}dxdt\right|\le c_7\varepsilon+c_7||f_\varepsilon+1||_\infty\int_0^T\int_0^{2\pi}\frac{\varepsilon}{u_\varepsilon}dxdt.$$

Since $u>0$, u_ε is bounded away from zero, say $u_\varepsilon\ge\delta_0>0$ uniformly for sufficiently small $\varepsilon>0$. The right-hand side of (5.17) now converges to zero as $\varepsilon\to 0$. By the convergence (5.15), sending ε to zero in (5.17) yields (5.16), since $u_\varepsilon\ge\delta_0$. □

The basic strategy to get a lower bound for u in (5.5) is similar to the proof of Theorem 1.4. This time we should check assumptions of Lemma 4.2 by using our approximate constraint (5.14). For this purpose we note a property of φ_ε of $(5.6)_1$. The assumptions on φ_ε in the following lemma are automatically satisfied for φ_ε of $(5.6)_1$.

5.5. Lemma. *Assume that φ_ε fulfills* (5.9) *and* (5.15). *Let Λ_0 be a positive number. There exists a sequence of continuous functions h_ε, $0\le h_\varepsilon\le 1$ on $(0,\infty)$ such that h_ε converges to one uniformly in every compact subset of $(0,\infty)$ as $\varepsilon\to 0$ and that*

$$\int_0^T\varphi_\varepsilon(v(t))dt\ge Th_\varepsilon(V),\quad V=\int_0^T v(t)dt$$

for all $v\in C[0,T]$ with $v>\varepsilon^2$ and $V\le\Lambda_0 v(t)$, $0\le t\le T$.

Proof. We set a continuous function

$$h_\varepsilon(\rho)=\varphi_\varepsilon(\rho\Lambda_0^{-1}\vee\varepsilon^2),\quad \rho>0$$

and observe that $h_\varepsilon \to 1$ uniformly in every compact subset of $(0,\infty)$ and that $0 \leq h_\varepsilon \leq 1$. Since φ_ε is nondecreasing on (ε^2,∞) by $(5.9)_2$, we thus conclude

$$\int_0^T \varphi_\varepsilon(v(t))dt \geq \int_0^T h_\varepsilon(V)dt = Th_\varepsilon(V). \qquad \square$$

We set

$$I_\varepsilon^\pm = I_\varepsilon^\pm(\zeta,u) = \varepsilon^{-1}\int_0^T\int_0^{2\pi}\{\varphi_\varepsilon(u)\psi_\varepsilon(u) + (1-\varphi_\varepsilon(u))(f+\varepsilon^2)\}\sin_\pm(x-\zeta)dxdt.$$

The approximate constraint (5.14) is rewritten as

$$|I_\varepsilon^+ - I_\varepsilon^-| \leq 4Tc_7\varepsilon. \tag{5.18}$$

5.6. Proposition on estimate of $A_\pm$. *Assume that $u \in C(K)$ satisfies the comparison* (5.11) *with U and $u > \varepsilon^2$ on K and that $f \geq 0$.*

(i) *Suppose that φ_ε fulfills* (5.9) *and* (5.15). *Suppose that $\psi_\varepsilon(v) \geq \varepsilon\nu_\varepsilon(v)/\ell$ for $v > 0$, where $\nu_\varepsilon(v) = 1/(v \vee m\varepsilon)$ with some $m > 0$, $\ell > 0$. Let h_ε be as in Lemma* 5.5 *and set $h_\varepsilon^- = h_\varepsilon$ and $\mu_\varepsilon^-(v) = \nu_\varepsilon(\lambda^{-1}v)$. Let A_ε^- be defined by* (4.2). *Then*

$$TA_\varepsilon^-(\zeta,U) \leq \ell I_\varepsilon^-(\zeta,u), \quad \zeta \in \mathbf{R}.$$

(ii) *Suppose that φ_ε satisfies* $(5.9)_1$ *and* (5.13). *Suppose that ψ_ε satisfies $\psi_\varepsilon(v) \leq \varepsilon v^{-1}$ for $v > 0$. Let A_ε^+ be defined by* (4.2) *with $\mu_\varepsilon^+(v) = v^{-1}$. Then*

$$I_\varepsilon^+(\zeta,u) \leq T\Lambda(1+\varepsilon c_7\|f+\varepsilon^2\|_\infty)A_\varepsilon^+(\zeta,U), \quad \zeta \in \mathbf{R}.$$

Proof. (i) Since $\ell\varepsilon^{-1}\psi_\varepsilon(u) \geq \nu_\varepsilon(u) \geq \mu_\varepsilon^-(U)$ we see

$$\begin{aligned} I_\varepsilon^- &\geq \varepsilon^{-1}\int_0^T\int_0^{2\pi}\varphi_\varepsilon(u)\psi_\varepsilon(u)\sin_-(x-\zeta)dxdt \quad (\text{by } f \geq 0, \varphi_\varepsilon \leq 1) \\ &\geq \ell^{-1}\int_0^{2\pi}\left(\int_0^T \varphi_\varepsilon(u)dt\right)\mu_\varepsilon^-(U)\sin_-(x-\zeta)dxdt. \end{aligned}$$

Apply Lemma 5.5 to get $\ell I_\varepsilon^- \geq TA_\varepsilon^-$.

(ii) We estimate φ_ε, $\psi_\varepsilon\varepsilon^{-1}$, $1-\varphi_\varepsilon$ from above to get

$$\begin{aligned} I_\varepsilon^+ &\leq \int_0^T\int_0^{2\pi}\left(\frac{1}{u} + \frac{\varepsilon c_7}{u}\|f+\varepsilon^2\|_\infty\right)\sin_+(x-\zeta)dxdt \\ &\leq T\Lambda(1+\varepsilon c_7\|f+\varepsilon^2\|_\infty)\int_0^{2\pi}\frac{1}{U}\sin_+(x-\zeta)dx \end{aligned}$$

which completes the proof. $\square$

5.7. Lower bound theorem. *Assume that $f \in C^\infty(K)$ fulfills* (5.12) *with $f > 0$. Let φ_ε and ψ_ε be defined by* (5.6) *with* (5.2), (5.3), *and $m > 1$. Then there are positive constants ε_0, δ depending only on T, $\|f\|_\infty$, $\|f_t\|_\infty$, $\min_K f$ such that if $u \in C^\infty(K)$ solves* $(5.5)_\varepsilon$ *with m satisfying* (5.1), *then $u \geq \delta$ on K for $0 < \varepsilon < \varepsilon_0$ provided that $u > \varepsilon^2$ on K.*

Proof. Since φ_ε and ψ_ε in (5.6) fulfill all assumptions on φ_ε and ψ_ε in §§5.1–5.6 including Proposition 5.6, we may apply all these results. By the comparison lemma (Lemma 5.2), it suffices to apply Lemma 4.2 to get a lower bound for U for sufficiently small ε.

We shall prove (U1)–(U3) in Lemma 4.2. Dividing (5.5) by u^2 and integrating over $(0,T)$ yields

$$\begin{aligned}
&0 = U_{xx} + U - F \quad \text{on} \quad \mathbf{T},\\
&F = \int_0^T \{(f + \varepsilon^2 - \psi_\varepsilon(u))\varphi_\varepsilon(u) + (1 - \varphi_\varepsilon(u))u\}dt.
\end{aligned}$$

Since $f - \psi_\varepsilon(u) > 0$ by (5.10) and $\varphi_\varepsilon(u) \leq 1$ we see $F \geq 0$. Moreover, by (5.13) with $c_7 = 2$, we observe that

$$F \leq \int_0^T \left(\|f + \varepsilon^2\|_\infty + \frac{2\varepsilon^2}{u}u\right) dt = T(\|f\|_\infty + 3) \equiv k_0 \quad (0 < \varepsilon < 1),$$

which proves (U1). By (5.1)–(5.3) applying the maximum principle yields

$$\max_K u (= u(x_0, t_0)) \geq \frac{1}{\sqrt{2}} \min_K f \equiv c_2$$

as in §5.1. By Lemma 5.2 we see

$$\max_{\mathbf{T}} U \geq U(x_0) \geq \lambda u(x_0, t_0) \geq \frac{\lambda}{2} \min_K f \equiv k_1 > 0$$

(cf. the proof of (4.10)). Since $u \leq M_0$ by Proposition 5.1, (U2) is now fulfilled with $k_2 = TM_0$.

It remains to show (U3) since $\mu_\varepsilon^\pm$, h_ε^- satisfy the desired properties including (4.3). Applying the approximate constraint (5.18) to Proposition 5.6 we observe that

$$\begin{aligned}
A_\varepsilon^-(\zeta, U) &\leq T^{-1}\ell I_\varepsilon^-(\zeta, u) \leq 2T^{-1} I_\varepsilon^-(\zeta, u)\\
&\leq 2T^{-1}(I_\varepsilon^+(\zeta, u) + 8T\varepsilon) \leq 2T^{-1} I_\varepsilon^+(\zeta, u) + 2 \cdot 8\\
&\leq 2\Lambda(1 + 2(\|f\|_\infty + 1))A_\varepsilon^+(\zeta, U) + 16
\end{aligned}$$

where we have used $0 < \varepsilon < 1$, $\ell < 2$, $c_7 = 2$. We have thus proved (U3). The proof is now complete. □

6. Existence of periodic solutions. We shall construct a positive solution $w \in C^\infty(K)$ of the approximate penalized equation (5.4) (with $\varepsilon' = \varepsilon^2$) for arbitrary positive $f \in C^\infty(K)$. We always assume (5.1)–(5.3) and positivity of $f \in C^\infty(K)$ in this section. Also we fix $\varepsilon > 0$ except in the proof of the main theorem given in §6.8. We begin with a solvability result for a uniformly parabolic equation since (5.4) is uniformly parabolic for $w > 0$. For $\omega > 0$, $T > 0$ we set

$$K_\omega = (\mathbf{R}/\omega\mathbf{Z}) \times (\mathbf{R}/T\mathbf{Z}).$$

We consider a uniform parabolic equation

$$(6.1) \qquad v_t = a(v)(v_{xx} - bv + h) \quad \text{in} \quad K_\omega.$$

6.1. Unique solvability lemma. *Assume that b is a positive constant and that a is a continuous function on $\mathbf{R}$ such that $a(\sigma) \geq a_0 > 0$ for all $\sigma \in \mathbf{R}$ with some constant a_0. For each $h \in C(K_\omega)$ there is a unique solution $v \in \bigcap_{q>1} W_q^{2,1}(K_\omega) \subset C(K_\omega)$ of (6.1). Moreover, the solution operator $h \mapsto v$ is a continuous, compact operator from $C(K_\omega)$ into itself. There exist $\theta_0 = \theta_0(a_0, ||h||_\infty, b, \omega, T) > 0$ and $C_0 = C_0(a_0, ||h||_\infty, b, \omega, T) > 0$ such that estimate*

$$||v||_{W_p^{2,1}} \leq C_0 ||h||_\infty$$

holds for all $2 \leq p \leq 2 + \theta_0$ and $h \in C(K_\omega)$.

We postpone the proof until the next section.

6.2. Mappings. We next interpret a solution w of (5.4) as a fixed point of a mapping. Let $b > 0$ be taken so that

$$\phi(w,x,t) \equiv bw_+ + \frac{(w_+)^2}{(w_+ + \varepsilon^2)^2}\left(w_+ + \frac{\varepsilon}{\xi(w_+ + \varepsilon^2)} - f(x,t)\right) \geq 0, \qquad w_+ = w \vee 0,$$

for all $w \in \mathbf{R}$, $(x,t) \in K$, and $\phi > 0$ on K if $w > 0$. It is possible to choose $b > 0$ because $(w_+)^2$ vanishes *faster* than w_+. Indeed, $w \leq 0$ implies $\phi \equiv 0$. If $w \geq \max_K f > 0$, then $\phi > 0$ for any $b > 0$ since $\xi > 0$. If otherwise (but $w > 0$), we observe that

$$\begin{aligned}\phi(w,x,t) &= \frac{w}{(w+\varepsilon^2)^2}\left\{b(w+\varepsilon^2)^2 + w^2 + \left(\frac{\varepsilon}{\xi(w+\varepsilon^2)} - f\right)w\right\} \\ &\geq \frac{w}{(w+\varepsilon^2)^2}(2b\varepsilon^2 w - fw) > 0\end{aligned}$$

provided that $b > ||f||_\infty / 2\varepsilon^2$.

For this choice of b let S denote the solution operator of

$$v_t = (v_+ + \varepsilon^2)^2(v_{xx} - bv + h) \quad \text{in} \quad K,$$

i.e., $S(h) = v$. By Lemma 6.1 S is well defined as an operator from $C(K)$ into itself. Lemma 6.1 also yields

(i) $S : C(K) \to C(K)$ is compact and continuous.

(ii) $S(h)$ is Hölder continuous on K for $h \in C(K)$.

The second assertion follows from the Sobolev embedding since $S(h) \in W_p^{2,1}(K)$ for all $p > 1$. Using (ii) and the Schauder theory of linear parabolic equations [LSU] we observe that

(iii) $v = S(h) \in C^{2,1}(K)$ (i.e., $v, v_{xx}, v_t \in C(K)$) provided that h is Hölder continuous in K.

By the strong maximum principle for classical solutions we see

(iv) $v = S(h) > 0$ in K if $h \geq 0$ and $h \not\equiv 0$, where h is Hölder continuous.

For $u \in C(K)$ we define a continuous operator $H : C(K) \to C(K)$ by

$$H(u)(x,t) \equiv \phi(u(x,t), x, t).$$

Since ϕ is locally Lipschitz in w, we observe that

(v) if u is Hölder continuous in K so is $H(u)$.

Suppose that $w \in C(K)$ is a fixed point of $S \circ H$, i.e., $S \circ H(w) = w$. Then by (ii) w is Hölder continuous. This implies $S(H(w)) \in C^{2,1}(K)$ by (iii), (v). Since $\phi > 0$ for $w > 0$,

(vi) $H(u) \geq 0$ and $H(u) \not\equiv 0$ unless $u \equiv 0$, so $w = S(H(w)) > 0$ in K if $w \not\equiv 0$ by (iv).

The equivalence of (5.4) and $S \circ H(w) = w$ is formally easy. We now obtain a positive solution $w \in C^{2,1}(K)$ of (5.4). Of course, this solution is in $C^\infty(K)$ since $f \in C^\infty(K)$ by the higher regularity theory [LSU].

6.3. Lemma on the local degree near zero. *There is a constant* $r_0 > 0$ *such that the (Leray–Schauder) degree of* $I - S \circ H$ *of the value zero in* $B_r(0)$ *equals one for* $0 < r < r_0$, *i.e.,*

$$\deg(I - S \circ H, B_r(0), 0) = 1,$$

where I *denotes the identity operator and*

$$B_r(0) = \{h \in C(K); ||h||_\infty \leq r\}.$$

Proof. Since S is compact and S, H are continuous, the degree of $I - S \circ \tau H$ is well defined for $0 \leq \tau \leq 1$. Since $S(0) = 0$ by $b > 0$, the homotopy invariance of degree implies

$$\deg(I - S \circ H, B_r(0), 0) = \deg(I, B_r(0), 0) = 1$$

provided that

$$(S \circ \tau H)(u) \neq u \tag{6.2}$$

for all $u \in \partial B_r(0)$, $0 \leq \tau \leq 1$ if r is sufficiently small.

It remains to prove (6.2). We argue by contradiction. We may assume that there are $\{\tau_n\}$ $(0 < \tau_n \leq 1)$ and $\{u_n\}$ such that $u_n \not\equiv 0$ and

$$(S \circ \tau_n H)(u_n) = u_n \quad \text{with} \quad ||u_n||_\infty \to 0 \quad \text{as} \quad n \to \infty.$$

By §6.2 (iv)–(vi) we observe that $u_n > 0$ and solves

$$u_t = (u + \varepsilon^2)^2(u_{xx} - bu + \tau H(u)) \quad \text{in} \quad K \tag{6.3}$$

with $\tau = \tau_n$ in a classical sense. By (5.1)–(5.3) we see

$$f - \frac{\varepsilon}{\xi(u_n + \varepsilon^2)} \geq \frac{1}{2} \min_K f > 0.$$

Since $||u_n||_\infty \to 0$, this implies

$$G_n \equiv f - \frac{\varepsilon}{\xi(u_n + \varepsilon^2)} - u_n > 0 \quad \text{for large} \quad n.$$

Multiplying $(6.3)_\tau$ by $(u + \varepsilon^2)^{-2}$ and integrating over K with $u = u_n$ and $\tau = \tau_n$ yields

$$0 = \int_0^T \int_0^{2\pi} u_n \left\{ b(1 - \tau_n) + \frac{\tau_n u_n}{(u_n + \varepsilon^2)^2} G_n \right\} dxdt$$

as in the proof of Lemma 3.1. Since $0 < \tau_n \leq 1$, $b > 0$, and $u_n > 0$, this implies $G_n = 0$. This contradicts the positivity of G_n for large n. We have proved (6.2). □

6.4. Lemma on the degree in a large ball. *There is an* $R_0 > 0$ *such that*

$$\deg(I - S \circ H, B_R(0), 0) = 0 \quad \textit{for} \quad R > R_0.$$

Proof. We set

$$\Phi(w) = bw_+ + \frac{w^2}{(w_+ + \varepsilon^2)^2} w_+ + 1 \quad \text{for} \quad w \in \mathbf{R}$$

and its affine homotopy to H

$$\Phi_\tau(w) = \tau H(w) + (1 - \tau)\Phi(w), \ 0 \le \tau \le 1$$

for $w \in C(K)$. We first observe that

$$\deg(I - S \circ \Phi, B_R(0), 0) = 0 \quad \text{for} \quad R > 0.$$

Indeed, since Φ_τ also satisfies (v) and (vi) of §6.2 with $H = \Phi_\tau$, if $S \circ \Phi(u) = u$, then $u > 0$ and it is a $C^{2,1}$ solution of

$$u_t = (u + \varepsilon^2)^2 \left(u_{xx} + \frac{u^2}{(u + \varepsilon^2)^2} u + 1 \right) \quad \text{in} \quad K.$$

At the minimum point of u we see $u_t = 0$ and $u_{xx} \ge 0$ but this is impossible by the equation for u. So there is no fixed point of $S \circ \Phi$.

By the homotopy invariance of degree the proof will be complete if we prove the a priori bound (indepenent of τ) for w satisfying $S \circ \Phi_\tau(w) = w$ so that we set

$$R_0 = \sup\{||w||_\infty; S \circ \Phi_\tau(w) = w, 0 \le \tau \le 1\}.$$

As in §6.2, $S \circ \Phi_\tau(w) = w$ implies that w is positive and it is a $C^{2,1}$ solution of

$$w_t = (w + \varepsilon^2)^2 \{w_{xx} - bw + \Phi_\tau(w)\} \quad \text{in} \quad K. \tag{6.4}$$

Since f is smooth, so is w. The following a priori bound is sufficient for our purpose.

6.5. Upper bound lemma. *There is a constant* $R_1 > 0$ *such that if* $w \in C^\infty(K)$ *with* $w > 0$ *solves* (6.4), *then* $w \le R_1$ *in* K.

Proof. In (6.4) we set $w + \varepsilon^2 = u$ to get

$$u_t = u^2[u_{xx} + \varphi_\varepsilon(u)\{u + \tau\psi_\varepsilon(u) + (1 - \tau)/\varphi_\varepsilon(u) - \tau f - \varepsilon^2\}]$$

with φ_ε, ψ_ε satisfying (5.6). If we denote

$$\varphi = \varphi_\varepsilon, \quad \psi = \tau\psi_\varepsilon + (1 - \tau)/\varphi_\varepsilon,$$

then $u > \varepsilon^2$ solves

$$u_t = u^2(u_{xx} + \varphi(u)\{u + \psi(u) - \tau f - \varepsilon^2\}.$$

It is sufficient to check the assumptions of Theorem 3.2 by setting $\alpha = \varepsilon^2$. By (5.9) all we have to prove are

$$\varphi'(v)(\psi(v) - \tau f - \varepsilon^2) + \varphi(v)\psi'(v) \le 0, \quad \text{for } v > \varepsilon^2, \tag{6.5}$$

$$\varphi(v)(\psi(v) - \min_K(\tau f + \varepsilon^2)) \le c_6(v + 1), \quad \text{for } v > \varepsilon^2. \tag{6.6}$$

The left-hand side of (6.5) is

$$\begin{aligned}&\varphi'(\tau(\psi_\varepsilon - f) - \varepsilon^2 + (1-\tau)\varphi^{-1}) + \varphi(\tau\psi_\varepsilon' + (1-\tau)(\varphi^{-1})')\\ &\quad \le \varphi'\varphi^{-1}(1-\tau) + \varphi(\varphi^{-1})'(1-\tau) = (1-\tau)(\varphi'\varphi^{-1} - \varphi\varphi'\varphi^{-2}) = 0\end{aligned}$$

since $\varphi' \ge 0$, $\psi_\varepsilon - f < 0$, $\psi_\varepsilon' \le 0$ on $[\varepsilon^2, \infty)$ by (5.1)–(5.3); here $\varphi^{-1} = 1/\varphi$. The left-hand side of (6.6) is

$$\varphi(\tau(\psi_\varepsilon - \min_K f) + (1-\tau)\varphi^{-1} - \varepsilon^2) \le \varphi\varphi^{-1}(1-\tau) \le 1.$$

We have thus proved (6.5) and (6.6) (with $c_6 = 1$). □

6.6. Remark. For the semilinear equation

$$\begin{aligned} u_t &= \Delta u + m(t)u^p && \text{in} \quad (0,T)\times\Omega,\\ u &= 0 && \text{on} \quad (0,T)\times\partial\Omega \end{aligned}$$

with T-periodic m, Esteban [E1], [E2] obtained a positive T-periodic solution u provided that $1 < p < n/(n-2)$ where Ω is a smoothly bounded domain in $\mathbf{R}^n$. The key argument is to prove similar statements for Lemmas 6.4 and 6.5. The method to get an upper bound in [E1], [E2] is based on a blow up argument. This is used in [Gi] to get a bound for positive solutions of the initial-boundary value problem

$$u_t = \Delta u + u^p \quad \text{in} \quad (0,\infty)\times\Omega$$

with $u = 0$ on $(0,\infty)\times\partial\Omega$ for $1 < p < (n+2)/(n-2)$. However, it seems to be difficult to obtain an upper bound by this method in our problem. The application of Harnack's inequality to get a bound seems to be a new approach.

6.7. Existence Theorem for approximate penalized equation. *Assume that $f \in C^\infty(K)$ and $f > 0$. Then for every $\varepsilon > 0$ there is a positive solution $w \in C^\infty(K)$ of* (5.4) *with $\varepsilon' = \varepsilon^2$ and* (5.1)–(5.3).

Proof. By Lemmas 6.3 and 6.4 we have

$$\deg(I - S\circ H, B_R(0)\setminus B_r(0), 0) = -1$$

for $r < R$ with $r < r_0$, $R > R_0$. It now follows that there exists $w \not\equiv 0$ such that $S\circ H(w) = w$. This yields a desired solution w of equation (5.4) as remarked at the end of §6.2. □

6.8. Proof of Theorem 1.1. We approximate f by $f_\varepsilon \in C^\infty(K)$ satisfying (1.3) such that

$$f_\varepsilon \to f \text{ in } C(K) \text{ as } \varepsilon \to 0 \quad \text{with} \quad \|f_{\varepsilon t}\|_\infty \le 2\|f_t\|_\infty,\ \|f_\varepsilon\|_\infty \le 2\|f\|_\infty, 0 < \varepsilon < 1.$$

Of course, this is possible by convoluting f with a mollifier in space and a mollifier in time so that (1.3) is inherent to f_ε.

Let w_ε be a solution of the approximate penalized equation (5.4) (with $\varepsilon' = \varepsilon^2 > 0$ and $f = f_\varepsilon$) obtained in Theorem 6.7. By Proposition 5.1 and Theorem 5.7 we have $\delta \le w_\varepsilon + \varepsilon^2 \le M_0$ with M_0, $\delta > 0$ independent of sufficiently small $\varepsilon > 0$, say, $\varepsilon < \varepsilon_0$. This implies that w_ε solves

$$w_t = a_\varepsilon(w)(w_{xx} - w + F_\varepsilon) \quad \text{in} \quad K$$

with $a_\varepsilon(\sigma) = ((\sigma + \varepsilon^2)^2 \vee \delta^2) \wedge M_0^2$ and $||F_\varepsilon||_\infty \leq N_0$ for $0 < \varepsilon < \varepsilon_0$, where N_j is a constant depending only on T, $||f||_\infty$, $||f_t||_\infty$, $\min_K f$. Since $a_\varepsilon(\sigma) \geq \delta^2$, from Lemma 6.1 it follows that

$$||w_\varepsilon||_{W_p^{2,1}} \leq C_0||F_\varepsilon||_\infty \leq N_1, \quad 0 < \varepsilon < \varepsilon_0$$

at least for some $p > 2$. Applying the Sobolev inequality yields a bound on the ν-Hölder norm of w_ε for some $0 < \nu < 1$,

$$||w_\varepsilon||_{C^\nu} \leq N_2, \quad 0 < \varepsilon < \varepsilon_0.$$

By the Banach–Alaoglu theorem and the Ascoli–Arzela theorem there is a subsequence (still denoted w_ε) and $u \in W_p^{2,1} \cap C^\nu$ such that

$$w_\varepsilon \to u \quad \text{weakly in} \quad W_p^{2,1}, \quad w_\varepsilon \to u \quad \text{strongly in } C(K).$$

Letting $\varepsilon \to 0$ in (5.4) now yields (1.1) for u since $\varepsilon/\xi(w_\varepsilon + \varepsilon^2) \to 0$ by $w_\varepsilon + \varepsilon^2 \geq \delta$. The higher regularity

$$\begin{aligned} &u \in W_p^{2,1}(K) \quad \text{for} \quad \text{all } p > 1 \quad \text{or} \\ &u \in C^\infty(K) \quad \text{for} \quad f \in C^\infty(K) \end{aligned}$$

follows from the standard linear L^p and Schauder regularity theory [LSU] since the equation (1.1) is uniformly parabolic if $\delta^2 \leq u \leq M^2$.

It remains to prove the constraint (1.2). As in the introduction, if u solves (1.1) and f satisfies (1.3), then

$$-\frac{d}{dt}\int_0^{2\pi} \frac{\sin(x-\zeta)}{u(x,t)}dx = -\int_0^{2\pi} f\sin(x-\zeta)dx = 0, \quad t, \zeta \in \mathbf{R}.$$

Applying Lemma 5.4 yields

$$\int_0^T \int_0^{2\pi} \frac{\sin(x-\zeta)}{u(x,t)}dxdt = 0.$$

We thus conclude that

$$\int_0^{2\pi} \frac{\sin(x-\zeta)}{u(x,t)}dx = 0 \quad \text{for all} \quad t, \zeta \in \mathbf{R}$$

which is the same as (1.2).

7. Unique solvability of a class of quasilinear equations. Our goal in this section is to prove Lemma 6.1. We first prove uniqueness of solution by reflecting Lipschitz continuity of solutions w.r.t. data in L^1. In the proof we use smoothed signature functions which were often used to prove L^1 contractivity for scalar conservation law; see Crandall [Cr]. We next establish a priori bounds for linear parabolic equations by a perturbation method. Such a method is often used in a different context; see Campanato [Ca] and Giga and Yoshida [GYo].

7.1. Uniqueness lemma. *Suppose that $v_i \in C(K_\omega)$ solves (6.1) with $h = h_i \in C(K_\omega)$ with $i = 1, 2$, where $b > 0$. Suppose that $v_i \in W_q^{2,1}(K_\omega)$ for some $1 < q < \infty$ for $i = 1, 2$. Then*

$$b\int_0^T \int_0^\omega |v_1 - v_2|dxdt \leq \int_0^T \int_0^\omega |h_1 - h_2|dxdt.$$

In particular, the solution of (6.1) *is unique in* $C(K_\omega) \cap W_q^{2,1}(K_\omega)$.

Proof. Divide $(6.1)_i$ by $a(v_i)$ and subtract one equation from the other to get

$$A(v_1)_t - A(v_2)_t - w_{xx} + bw + k = 0 \quad \text{in} \quad K = K_\omega \tag{7.1}$$

with $w = v_1 - v_2$, $k = h_2 - h_1$, and $A(s) = \int_0^s a^{-1}(r)dr$. Let $\operatorname{sgn}_\rho(s)$, $\rho > 0$ denote the piecewise linear continuous function such that $\operatorname{sgn}_\rho(s) = 1$ for $s \geq \rho$, $\operatorname{sgn}_\rho(s) = -1$ for $s \leq -\rho$, and sgn_ρ is linear for $|s| \leq \rho$. Multiplying (7.1) by $\operatorname{sgn}_\rho(w)$ and integrating it over K yields

(7.2)
$$0 = \int_0^T \int_0^\omega \{(A(v_1) - A(v_2))_t \operatorname{sgn}_\rho(w) - w_{xx} \operatorname{sgn}_\rho w + bw \operatorname{sgn}_\rho w + k \operatorname{sgn}_\rho w\} dxdt.$$

Note that

$$-\int_0^\omega w_{xx} \operatorname{sgn}_\rho w dx = \int_0^\omega w_x \operatorname{sgn}'_\rho(w) w_x dx \geq 0$$

since $\operatorname{sgn}'_\rho \geq 0$. Sending ρ to 0 in (7.2) yields

$$\int_0^T \int_0^\omega \{(A(v_1) - A(v_2))_t \operatorname{sgn}(w) + b|w|\} dxdt \leq \int_0^T \int_0^\omega |k| dxdt.$$

It remains to prove

$$\int_0^T \int_0^\omega \{(A(v_1) - A(v_2))_t \operatorname{sgn}(w)\} \, dxdt = 0. \tag{7.3}$$

Since $a(r) > 0$ we observe that $\operatorname{sgn} w = \operatorname{sgn}(W)$ with

$$W = A(v_1) - A(v_2).$$

Thus

$$\int_0^T \int_0^\omega W_t \operatorname{sgn} W dxdt = \int_0^T \int_0^\omega |W|_t dxdt = 0,$$

since W is T-periodic in time. This is the same as (7.3). □

We next derive a priori estimates for linear parabolic equations of the form

$$u_t = a(x,t)(u_{xx} - bu + h) \quad \text{in} \quad K_\omega \tag{7.4}$$

with a constant $b > 0$. We use a perturbation method.

7.2. Linear estimate lemma. *Let a_i be a positive constant* $(i = 0, 1)$. *There exist positive constants $\theta_1 = \theta_1(a_i, b, \omega, T)$ and $C_* = C_*(a_i, b, \omega, T)$ such that the following estimate holds. For $a, h \in C(K_\omega)$ with $a_0 \leq a \leq a_1$ there is a unique solution $u \in W_p^{2,1}(K_\omega)$ satisfying*

$$||u||_{W_p^{2,1}} \leq C_* ||h||_\infty, \quad \text{for} \quad 2 \leq p \leq \theta_1 + 2. \tag{7.5}$$

The solution u always satisfies

$$||u||_\infty \leq b^{-1} ||h||_\infty. \tag{7.6}$$

Proof. We may assume $a_1 = 1$ by dilation of the time variable. We may assume that $a, h \in C^\infty(K)$ with $K = K_\omega$. Indeed, for $a, h \in C(K)$ there are $a_\varepsilon, h_\varepsilon \in C^\infty(K)$ such that $a_\varepsilon \to a$, $h_\varepsilon \to h$ in $C(K)$ as $\varepsilon \to 0$ and that $a_0 \le a_\varepsilon \le a_1 = 1$. There is a unique solution u_ε of (7.4) with $a = a_\varepsilon$, $h = h_\varepsilon$. By our results for u_ε we have

$$||u_\varepsilon||_{W_p^{2,1}} \le C_* ||h_\varepsilon||_\infty, \quad ||u_\varepsilon||_\infty \le b^{-1}||h_\varepsilon||_\infty \tag{7.7}$$

for $2 \le p \le 2 + \theta$. We thus observe that

$$u_\varepsilon \to u_0 \text{ weakly in } W_p^{2,1} \text{ and } u_\varepsilon \to u_0 \text{ strongly in } C(K)$$

as $\varepsilon \to 0$ by taking a subsequence if necessary. If $w \in W_2^{2,1}(K)$ solves

$$w_t = a(w_{xx} - bw) \quad \text{in} \quad K$$

then we see $w = 0$. Indeed, multiplying the equation by w_t/a and integrating by parts over K yields $w_t = 0$ so that $w = 0$. Thus, the solution $u \in W_2^{2,1}$ for (7.4) is unique. Since u_0 solves (7.4) it follows that $u = u_0$. Sending $\varepsilon \to 0$ in (7.7) yields (7.5), (7.6).

We first admit that for (smooth) a there is a unique solution $u \in W_2^{2,1}(K)$ of (7.4) for $h \in L^2(K)$. This solution u belongs to $C^\infty(K)$ if h is smooth by the standard regularity theory.

By the maximum principle for $u \in C^\infty(K)$, we see that

$$\min_K h \le bu \le \max_K h.$$

This yields (7.6).

We next consider the L^2 estimate of the linear equation with constant coefficients,

$$u_t = u_{xx} - bu + g \quad \text{on} \quad K. \tag{7.8}$$

Multiplying (7.8) with u_{xx} and integrating by parts over K yields

$$\int_0^T \int_0^\omega (u_{xx}^2 + bu_x^2)dxdt = -\int_0^T \int_0^\omega gu_{xx}dxdt.$$

Thus by the Cauchy inequality we have

$$\iint (u_{xx}^2 + bu_x^2)dxdt \le \frac{1}{2} \iint (u_{xx}^2 + g^2)dxdt,$$

which in particular yields estimates of the $L^2(K)$ norm

$$||u_{xx}||_2 \le 1 \cdot ||g||_2. \tag{7.9}$$

Let L_3 denote the operator norm of $g \mapsto u_{xx}$ from $L^3(K)$ into itself. By L^p theory [LSU] L_3 is finite and depends only on ω, T, and b. Applying Riesz's interpolation between $L^2(K)$ and $L^3(K)$ to (7.9) yields

$$||u_{xx}||_p \le L_p ||g||_p \tag{7.10}$$

with $L_p \to 1$ as $p \to 2$, $p > 2$, where $L_p = L_p(\omega, T, b)$.

We shall use a perturbation argument. Rewrite (7.4) as $u_t = u_{xx} - bu + g$ with $g = (a-1)(u_{xx} - bu + h) + h$ and apply (7.10) to get

$$||u_{xx}||_p \le L_p[||h||_p + (1-a_0)(||u_{xx}||_p + b||u||_p + ||h||_p].$$

We take θ_1 such that $2 \le p \le 2 + \theta_1$ implies

$$c = \sup\{L_p; 2 \le p \le 2+\theta_1\} < \frac{1}{1-a_0}$$

since $L_p \to 1$ as $p \to 2$. We thus have the estimate

$$||u_{xx}||_p \le c_* L_p(2||h||_p + b||u||_p) \quad \text{with} \quad c_* = (1 - c(1-a_0))^{-1}.$$

Since (7.6) yields

$$||u||_p \le S||u||_\infty \le Sb^{-1}||h||_\infty \quad \text{with} \quad S = S(T, \omega, p),$$

we now observe that

$$||u_{xx}||_p \le c_* L_p(2+1)S||h||_\infty \quad \text{for} \quad 2 \le p \le 2+\theta_1.$$

Interpolating (7.6) with this inequality, we conclude that

$$||u||_{W_p^{2,1}} \le C_* ||h||_\infty$$

for $2 \le p \le 2 + \theta_1$ by estimating u_t by the equation (7.4).

It remains to prove the unique existence of solution in $W_2^{2,1}$ of (7.4) for $h \in L^2$. As in the first paragraph of the proof, we have the uniqueness of solution of

$$-\varphi_t = (a\varphi)_{xx} - b(a\varphi) \quad \text{in} \quad K.$$

By the regularity theory only the L^2 solution is zero. This implies that the dual operator L^* of the bounded linear operator $L : u \mapsto h$ (defined by (7.4)) from $W_2^{2,1}$ to L^2 is injective. The closed range theorem now implies that L is surjective provided that the range of L is closed. Using (7.4) in the same way we did to obtain (7.9), we get

$$||u_{xx}||_2 + ||u_x||_2 \le c||Lu||_2.$$

Multiplying u_t by (7.4) and integrating now yields

$$||u_t||_2 \le C'||Lu||_2,$$

since $\int uu_t dt = 0$. Use (7.4) to get

$$||u||_{W_2^{2,1}} \le C''||Lu||_2,$$

which implies the range of L is closed, and the proof is now complete. □

7.3. A priori estimate. We consider

$$v_t = a_T(v)(v_{xx} - bv + h) \quad \text{in} \quad K = K_\omega \tag{7.11}$$

with $a_\tau(p) = \tau a(p) + (1-\tau)a_0$, $0 \leq \tau \leq 1$, where $a(p) \geq a_0$ is given in Lemma 6.1 and $b > 0$. The estimate (7.6) yields

$$||v||_\infty \leq b^{-1}||h||_\infty$$

for a $W_2^{2,1}$ solution v of (7.11) with $v \in C(K)$. We set

$$a_1 = \max\{a(p); |p| \leq b^{-1}||h||_\infty\} < \infty \tag{7.12}$$

to get

$$a_0 \leq a_\tau(v) \leq a_1$$

for a solution $v \in C(K)$ of (7.11). By Lemma 7.2 there are positive constants θ_1 and C_* such that for $2 \leq p \leq 2+\theta_1$ a solution $v \in C(K) \cap W_2^{2,1}(K)$ fulfills

$$||v||_{W_p^{2,1}} \leq C_*||h||_\infty. \tag{7.13}$$

Here θ_1 and C_* depend only on $||h||_\infty$, a_0, b, ω, T.

7.4. A homotopy of mappings. We fix p such that $2 < p < 2+\theta_1$. Since $K = K_\omega$ is two dimensional, there is $0 < \nu < 1$ such that the inclusion $W_p^{2,1}(K)$ into $C^\nu(K)$ is continuous by the Sobolev inequality. We fix ν and set $X = C^\nu(K)$. For $(v,\tau) \in X \times [0,1]$, let $w = R(v,\tau)$ be the unique solution of

$$w_t = a_\tau(v)(w_{xx} - bw + \tau h) \quad \text{in} \quad K. \tag{7.14}$$

7.5. Proposition. *The mapping R gives a compact, continuous mapping from $X \times [0,1]$ into X. The image of R is contained in $\bigcap_{q>1} W_q^{2,1}(K)$. Moreover $R(v,0) = 0$ for all $v \in X$.*

Proof. For $v \in X$, (7.6) implies

$$a_0 \leq a_\tau(v) \leq a_1,$$

where a_1 is defined by (7.12). Suppose that $||v||_X \leq M$. Then $a(v)$ has a modulus of continuity m depending on v only through M. Since m is a modulus of continuity of a_τ for $0 \leq \tau \leq 1$, L^q theory of linear parabolic equation provides

$$||R(v,\tau)||_{W_q^{2,1}} \leq Z||h||_q \quad \text{for} \quad ||v||_X \leq M$$

for $1 < q < \infty$ with $Z = Z(a_0, a_1, q, M)$ where a_1 is as in (7.12). We observe that the image of R is contained in $W_q^{2,1}(K)$ for all q. Take q large so that $W_q^{2,1} \subset X$ is compact. Thus

$$\{R(v,\tau); ||v||_X \leq M, 0 \leq \tau \leq 1\}$$

is compact in X, so $R : X \times [0,1] \to X$ is compact.

From (7.14) it is clear that $R(v,0) = 0$.

Now we must prove the continuity of R. Suppose that $v_j \to v$ in X, $\tau_j \to \tau$ as $j \to \infty$. We apply L^q theory to estimate (for $1 < q < \infty$)

$$||u_j||_{W_q^{2,1}} \leq B, \quad u_j = R(v_j, \tau_j)$$

with $B = B(a_0, a_1, q, ||h||_\infty)$ since $\{v_j\}$ is bounded so that $a_{\tau_j}(v_j)$ has a modulus of continuity independent of j.

For sufficiently large q we observe that

$$(7.15) \qquad u_j \to u \quad \text{weakly in} \quad W_q^{2,1}(K) \quad \text{and} \quad u_j \to u \quad \text{in} \quad C^\nu(K)$$

for some $u \in X \cap W_q^{2,1}(K)$ by taking a subsequence if necessary. Sending $j \to \infty$ in

$$u_{jt} = a_{\tau_j}(v_j)(u_{jxx} - bu_j + \tau_j h)$$

now yields (7.14) with $w = u$. Since (7.14) admits a unique solution for given v, we see $u = R(v, \tau)$. We have thus proved that $R : X \times [0, 1] \to X$ is continuous. □

7.6. Proof of Lemma 6.1. Since ν is chosen so that $W_p^{2,1}(K) \subset C^\nu(K) = X$ is continuous, a priori estimate (7.13) yields

$$||v||_X \leq SC_*||h||_\infty$$

with $S = S(p, \nu, \omega, T)$. By Proposition 7.5 and this estimate the Leray–Schauder fixed point theorem yields $v \in X$ such that $R(v, 1) = v$. By (7.15) we see $v \in \bigcap_{q>1} W_q^{2,1}(K) \subset C(K)$. $R(v, 1) = v$ means v solves (6.1). A priori estimate of Lemma 6.1 follows from (7.13). Since the solution of (6.1) is unique, it remains to prove that $h \mapsto v$ is compact, continuous from $C(K)$ into itself.

The compactness follows from a priori estimates in Lemma 6.1 since K is two dimensional. Suppose that $h_j \to h$ in $C(K)$ and that v_j is a solution of (6.1) with $h = h_j$. By a priori estimates there is a v such that

$$v_j \to v \quad \text{weakly in} \quad W_p^{2,1} \quad \text{and} \quad v_j \to v \quad \text{in} \quad C(K)(j \to \infty)$$

by taking some subsequence if necessary, since K is two dimensional. Letting $j \to \infty$ in (6.1) with $v = v_j$, $h = h_j$ yields (6.1) for v and h. This implies the continuity of $h \mapsto v$.

8. Appendix.

We shall prove that (1.1) with constraint (1.2) admits at most one positive solution if f is time independent. We shall also give a geometric interpretation of the assumption (1.8).

8.1. Proof of Lemma 1.3. Multiplying (1.4) by u_t and integrating by parts over K yields

$$\int_0^T \int_0^{2\pi} \frac{u_t}{u^2}^2 dxdt = \int_0^T \int_0^{2\pi} \left\{ -\frac{1}{2}(u_x^2)_t + \frac{1}{2}(u^2)_t - fu_t \right\} dxdt = 0$$

if f is time independent. This implies $u_t = 0$ on K.

It remains to prove that

$$(8.1) \qquad u_{xx} + u = f(x) \quad \text{on} \quad \mathbf{T} = \mathbf{R}/2\pi\mathbf{Z}$$

admits at most one positive solution satisfying (1.2). Suppose that $u > 0$ solves (8.1) with (1.2). Then all positive solutions U of (8.1) are of the form

$$U(x; \xi, \eta) = u(x) + \xi \cos x + \eta \sin x$$

for some $\xi, \eta \in \mathbf{R}$. It is easy to see that

$$D = \{(\xi, \eta); U(x; \xi, \eta) > 0 \quad \text{for all} \quad x \in \mathbf{T}\} \subset \mathbf{R}^2$$

is open and convex. Since $-\log$ is strictly convex, so is the function

$$E(\xi,\eta)=\int_0^{2\pi}-\log U(x,\xi,\eta)dx \quad \text{on} \quad D.$$

The strict convexity of E on D implies that E has at most one critical point. Since

$$\frac{\partial E}{\partial \xi}=\int_0^{2\pi}-\frac{\cos x}{U}dx, \quad \frac{\partial E}{\partial \eta}=\int_0^{2\pi}-\frac{\sin x}{U}dx,$$

$U(x;\xi,\eta)$ satisfies (8.1) with (1.2) if and only if (ξ,η) is a critical point of E in D. By the choice of u, E takes its critical point at the origin, so there is no other critical point of E on D. In other words, there is no $U(x,\xi,\eta)$ satisfying (1.2) unless (ξ,η) is the origin. We have thus proved the uniqueness of positive solution u of (8.1) fulfilling the constraint (1.2).

8.2. Curvature of Frank diagram. *Let $\mathcal{F}$ be the Frank diagram of $Q>0$ as in §1.3. Let $\kappa(\theta)$ be the inward curvature of $\mathcal{F}$ at $p=(Q(\theta))^{-1}(\cos\theta,\sin\theta)$. Then*

$$\kappa = Q^3(Q+Q'')/(Q'^2+Q^2)^{3/2}. \tag{8.2}$$

In particular, (1.8) *is equivalent to saying that the curvature of $\mathcal{F}$ is positive.*

Proof. For $p\in\mathbf{R}^2$ we define $q(p)$ by

$$p=q(p)(Q(\theta))^{-1}(\cos\theta,\sin\theta),$$

where θ is the argument of p. Thus q is a well-defined positive function (except the origin) and is positively homogeneous of degree one. Moreover, $\mathcal{F}$ is a one-level set of q. We observe that

$$\kappa=\operatorname{div}\left(\frac{\nabla q}{|\nabla q|}\right)=\frac{1}{(q_1^2+q_2^2)^{3/2}}(q_2^2q_{11}-2q_1q_2q_{12}+q_1^2q_{22}), \tag{8.3}$$

where $q_i=\partial q/\partial p_i$, $i=1,2$.

We may assume that $\theta=0$ and $Q(0)=1$ by rotation and dilation of coordinates. Since q is homogeneous of degree one so that q_i is of degree zero, we see

$$q=q_1\cos\theta+q_2\sin\theta, \quad 0=q_{11}\cos\theta+q_{12}\sin\theta, \quad 0=q_{21}\cos\theta+q_{22}\sin\theta, \tag{8.4}$$

where functions are evaluated at $(\cos\theta,\sin\theta)$. From these identities it follows that $q_{21}(p_*)=0$, $q_{11}(p_*)=0$, and $q_1(p_*)=q(p_*)=1$ for $p_*=(1,0)$ since $Q(\theta)=q(\cos\theta,\sin\theta)$. Differentiate Q in θ and use $(8.4)_1$ to get

$$Q'(\theta)=-q_1\sin\theta+q_2\cos\theta,$$
$$Q''(\theta)+Q(\theta)=q_{11}\sin^2\theta-2q_{12}\cos\theta\sin\theta+q_{22}\cos^2\theta,$$

which yields

$$q_2(p_*)=Q'(0) \quad \text{and} \quad q_{22}(p_*)=Q''(0)+Q(0)=Q''(0)+1.$$

Plugging these values into (8.3) we obtain

$$\kappa(0)=\frac{1}{(1+Q'(0)^2)^{3/2}}(Q''(0)+1).$$

This completes the proof. □

FULLY NONLINEAR STOCHASTIC PARTIAL DIFFERENTIAL EQUATIONS*

G. DA PRATO† AND L. TUBARO‡

Abstract. The authors study a class of fully nonlinear stochastic partial differential equations by the reduction to a family of deterministic fully nonlinear equations using the stochastic characteristic method.

Key words. stochastic partial differential equations

AMS subject classification. 60H15

1. Introduction.

We are concerned with the stochastic equation

$$(1)\qquad \begin{cases} du(t,\cdot) = L(t,\cdot,u,Du,D^2u)\,dt \;+ \langle b(t,\cdot)Du + h(t,\cdot)u, dW(t)\rangle, \\ u(0) = u_0 \end{cases}$$

where

$$L : [0,+\infty[\times\mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N \times \mathbb{R}^{N^2} \to \mathbb{R},\;\; (t,x,u,p,q) \to L(t,x,u,p,q),$$

$$b : [0,T] \times \mathbb{R}^N \;\to L(\mathbb{R}^N;\mathbb{R}^M),\;\; (t,x) \to b(t,x),$$

$$h : [0,T] \times \mathbb{R}^N \to \mathbb{R}^M,\;\; (t,x) \to h(t,x)$$

are suitable functions, (see Hypothesis 2.1 below), and W is an $\mathbb{R}^M$-valued standard Brownian motion in a given probability space $(\Omega,\mathcal{E},\mathbb{P})$ adapted to a filtration $\mathcal{F} = \{\mathcal{F}_t\}_{t\geq 0}$ and such that, for any $t \geq 0$ and any $\varepsilon > 0$, $\mathcal{F}_t$ and $W(t+\varepsilon) - W(t)$ are independent. Moreover, $L(\mathbb{R}^N)$ and $L(\mathbb{R}^N;\mathbb{R}^M)$ denote, respectively, the space of the square matrices or order N and the space of the $M \times N$ rectangular matrices.

Problem (1) has been extensively studied in the semilinear case, where the operator L is simply

$$L(t,x,u,p,q) = \sum_{i,j=1}^{N} a_{ij}(t,x)q_{ij} + a_0(t,x,u,p),$$

and matrix $a(t,x)$ is positive definite; see, for instance, [4] and the references therein.

To our knowledge, in the quasilinear case

$$L(t,x,u,p,q) = \sum_{i,j=1}^{N} a_{ij}(t,x,p)q_{ij} + a_0(t,x,u,p),$$

only a few papers have been devoted to the subject. We recall [1] for quasilinear equations in divergence form, where a "splitting up" method was used, and [3] and [5], where an abstract quasilinear equation was solved, under suitable hypotheses, using a semigroup approach.

In this paper we proceed, as in [15] and [19], by transforming problem (1) in a deterministic fully nonlinear equation for almost all $\omega \in \Omega$ (see §2 below). This equation can be solved in a maximal time interval by using recent results about (deterministic) fully nonlinear equations (see [11] and [13]). One can also show that the solution is global, provided a suitable (sharp) a priori estimate holds. We will give an application in §4.

We shall use the following notation. If φ is a mapping from $\mathbb{R}^N$ into $\mathbb{R}$, we shall denote its gradient by $D\varphi$ and the Jacobian matrix by $D^2\varphi$.

If α is a mapping from $\mathbb{R}^N$ into $\mathbb{R}^N$, we shall denote its first and second derivatives, provided they exist, by α' and α''. We shall denote the trace of a matrix α by Tr α and we denote the vector of components

$$(\text{TR}\ [\alpha'(x)\alpha(x)])_i \quad = \quad \text{Tr}\ [(\alpha'(x)e_i)\alpha(x)]$$

by $\text{TR}[\alpha'(x)\alpha(x)]$, where $e_1, \dots, e_n$ is the canonical basis of $\mathbb{R}^N$.

Moreover we shall denote the Banach space of all real bounded functions in $\mathbb{R}^N$ endowed with the "sup" norm by $C(\mathbb{R}^N)$, the subset of $C(\mathbb{R}^N)$ of all α-Hölder continuous functions by $C^\alpha(\mathbb{R}^N)$, and the subset of $C(\mathbb{R}^N)$ of all functions that are k-times differentiable with continuous and bounded derivatives of order less or equal to k by $C^k(\mathbb{R}^N), k = 1, 2 \dots.$

It is convenient to introduce two special classes of functions.

DEFINITION 1.1. (i) *A mapping*

$$a : [0, +\infty[\times \mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N \times \mathbb{R}^{N^2} \to \mathbb{R}, \quad (t, x, u, p, q) \to a(t, x, u, p, q)$$

belongs to the class $(0,0)$ *if it is continuous and, for any* $T > 0$ *and* $r > 0$, *there exists a constant* $N_{T,r}$ *such that*

$$|a(t, x, u, p, q)| \leq N_{T,r}$$

for all $t \in [0, T]$, $x \in \mathbb{R}^N$, *and* u, p, *and* q *with norms not greater than* r.

(ii) *The mapping* a *belongs to the class* (α, β), *with* $\alpha \in]0, 1[$ *and* $\beta \in]0, 1[$, *if for any* $T > 0$ *and* $r > 0$, *there exists a constant* $M_{T,r}$ *such that*

$$|a(t, x, u, p, q) - a(s, x', u', p', q')| \leq M_{T,r}(|t-s|^\alpha + |x-x'|^\beta + |u-u'| + |p-p'| + |q-q'|)$$

for all $t, s \in [0, T]$, $x, x' \in \mathbb{R}^N$, *and* u, u', p, p', q, *and* q' *with norms not greater than* r.

Roughly speaking, a function $a(t, x, u, p, q)$ belongs to the class (α, β), if it is α-Hölder continuous in t, β-Hölder continuous in x, and locally Lipschitz continuous in u, p, and q uniformly in the other variables.

Finally we give the definition of solution of problem (1).

DEFINITION 1.2. *Let* T *be a stopping time with respect to the filtration* $\{\mathcal{F}_t\}_{t \geq 0}$. *A* strong solution *of problem* (1) *in* $[0, T]$ *is a mapping*

$$u : [0, T] \times \mathbb{R}^N \times \Omega \to \mathbb{R}, \quad (t, x, \omega) \to u(t, x),$$

such that the following hold:

(i) $u(t, \cdot)$ *is* $\mathcal{F}_t$*-Bochner measurable, for all* $t \geq 0$; *that is,* $u(t, \cdot)$ *is the a.s. limit of simple random variables with values in* $C^{2+\beta}(\mathbb{R}^N)$.

(ii) *For all $x \in \mathbb{R}^N$, the real stochastic process $u(\cdot, x)$ is such that*

$$L(t, x, u, Du, D^2u) \in L^1([0,T] \times \Omega),$$

$$b(\cdot, x)Du, \ h(\cdot, x)u \in L^2([0,T] \times \Omega; \mathbb{R}^M).$$

(iii) *For any $t \in [0,T]$, it holds that*

$$u(t, \cdot) = u_0 + \int_0^t L(s, \cdot, u, Du, D^2u)\, ds + \int_0^t \langle b(s, \cdot)Du(t, \cdot) + h(s, \cdot)u(t, \cdot), dW(s)\rangle$$

almost surely.

A *strong solution* of problem (1) in a stochastic interval $[0, \tau[$, is defined in the obvious way.

2. Reduction to a deterministic problem. In this section we transform problem (1) into a deterministic one. For the sake of clarity the transformation will be defined in two steps. We assume that the following hypothesis holds.

HYPOTHESIS 2.1. (i) *For some $\alpha, \beta \in]0,1[$, the mapping*

$$L : [0, +\infty[\times\mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N \times \mathbb{R}^{N^2} \to \mathbb{R}, \quad (t, x, u, p, q) \to L(t, x, u, p, q)$$

belongs to the class (α, β) together with its partial derivatives of the type[1] $D_x^h D_u^k D_p^l D_q^m L$, *for $|h| + |k| + |l| + |m| \le 2$.*

(ii) *There exists $\varepsilon > 0$ such that, for any $r > 0$, there is $C_r > 0$ satisfying*

$$|L(0, x, u, p, q) - L(0, y, u, p, q)| \le C_r|x - y|^{\beta+\varepsilon}$$

for all $x, y \in \mathbb{R}^N$ and u, p, and q with norms not greater than r.

(iii) *L belongs to the class $(0, 0)$ together with all its partial derivatives of the type $D_x^h D_u^k D_p^l D_q^m L$, with $|h| + |k| + |l| + |m| = 3$.*

(iv) *b and h are uniformly continuous and bounded in $[0,T] \times \mathbb{R}^N$ together with all their partial derivatives with respect to x, u of order less or equal to 4.*

(v) *All partial derivatives of b and h with respect to x, u of order less or equal to 4 are of class C^1 in time, uniformly in x.*

(vi) *For all $T, r > 0$, there exists $\nu_{T,r} > 0$ such that*

$$\frac{\partial L}{\partial q}(t, x, u, p, q) - \frac{1}{2}b(t, x)b^*(t, x) \ge \nu_{T,r}I,$$

for all $t \in [0,T]$, $x \in \mathbb{R}^N$, and u, p, and q with norms not greater than r.

In the following we set

$$\widetilde{L}(t, x, u, p, q) = L(t, x, u, p, q) - \frac{1}{2}\operatorname{Tr}\,[b(t, x)b^*(t, x)q].$$

Assumption 2.1(vi) implies that the nonlinear operator

$$u \to \widetilde{L}(t, x, u, Du, D^2u)$$

is elliptic.

[1] Here, following usual notation, the indices are multiindices.

We now define

$$y(t,x) = u(t,\xi(t,x)),$$

where ξ is the solution to the system

$$\text{(2)} \qquad \begin{cases} d\xi = -b(t,\xi)\, dW(t) + \text{ TR } [b'(t,\xi)b(t,\xi)]\, dt, \\ \xi(0) = x. \end{cases}$$

In virtue of Hypothesis 2.1(v) there exists a.s. the inverse of $\xi(t,\cdot)$ for all $t \geq 0$ which we denote by $\eta(t,\cdot)$ (see for instance [9]), so that

$$u(t,x) = y(t,\eta(t,x)), \;\; t \geq 0, x \in \mathbb{R}^N.$$

By the Itô–Ventzell formula (see [15], [14], [19]), it follows that y is the solution to the stochastic partial differential equation

$$\begin{aligned} dy(t,x) \;\; = \;\; & \widetilde{L}(t,\xi,u(t,\xi),Du(t,\xi),D^2u(t,\xi))\, dt \\ & - \langle b(t,\xi)Du(t,\xi),h(t,\xi)\rangle\, dt \, - \text{Tr}(Dh(t,\xi)\cdot b(t,\xi))\, u(t,\xi)\, dt \\ & + u(t,\xi)\langle h(t,\xi),dW(t)\rangle. \end{aligned}$$

Now we go to the second step by setting $v(t,x) = \rho(t,x)y(t,x)$, where

$$\rho(t,x) = \exp\left[-\int_0^t \langle h(s,\xi(s,x)),dW(s)\rangle + \frac{1}{2}\int_0^t |h(s,\xi(s,x))|^2 ds \right].$$

By using the fact that ρ is the solution to the stochastic differential equation

$$d\rho = -\rho\langle h,dW(t)\rangle + |h|^2\rho\, dt, \;\; \rho(0) = 1,$$

it is not difficult to check that v fulfills

$$\text{(3)} \qquad \begin{aligned} D_t v(t,x) \;\; = \;\; & \rho(t,x)\, \widetilde{L}(t,\xi(t,x),u(t,\xi(t,x)),Du(t,\xi(t,x)),D^2u(t,\xi(t,x))) \\ & - \rho(t,x)\langle b(t,\xi(t,x))Du(t,\xi(t,x)),h(t,\xi(t,x))\rangle \\ & - \text{Tr}(Dh(t,\xi(t,x))\cdot b(t,\xi(t,x)))\, v(t,x). \end{aligned}$$

In order to get a (deterministic) partial differential equation for v, we now have to express u and its first and second derivatives in terms of v by using the identity

$$\text{(4)} \qquad u(t,x) = \frac{v(t,\eta(t,x))}{\rho(t,\eta(t,x))}.$$

Setting $\zeta = 1/\rho$ and recalling that, by [9], the flow $\eta(t,\cdot), t \geq 0$ is regular, we obtain by a straightforward computation

$$Du(t,x) = (\eta'(t,x))^* D\zeta(t,\eta(t,x))v(t,\eta(t,x)) + (\eta'(t,x))^* Dv(t,\eta(t,x))\zeta(t,\eta(t,x))$$

and

$$\begin{aligned} D^2u(t,x) &= (\eta'(t,x))^*D^2\zeta(t,\eta(t,x))\eta'(t,x)v(t,\eta(t,x)) \\ &\quad + (\eta'(t,x))^*D^2v(t,\eta(t,x))\eta'(t,x)\zeta(t,\eta(t,x)) \\ &\quad + 2(\eta'(t,x))^*D\zeta(t,\eta(t,x)) \otimes \eta'(t,x)Dv(t,\eta(t,x)) \\ &\quad +\langle D\zeta(t,\eta(t,x)), \eta''(t,x)(\cdot,\cdot)\rangle v(t,\eta(t,x)) \\ &\quad +\langle Dv(t,\eta(t,x)), \eta''(t,x)(\cdot,\cdot)\rangle \zeta(t,\eta(t,x)). \end{aligned}$$

It follows that

$$u(t,\xi(t,x)) = \zeta(t,x)v(t,x), \tag{5}$$

$$Du(t,\xi(t,x)) = (\eta'(t,\xi(t,x)))^*D\zeta(t,x)v(t,x) + (\eta'(t,\xi(t,x)))^*Dv(t,x)\zeta(t,x), \tag{6}$$

and

$$\begin{aligned} D^2u(t,\xi(t,x)) &= (\eta'(t,\xi(t,x)))^*D^2\zeta(t,x)\eta'(t,\xi(t,x))v(t,x) \\ &\quad + (\eta'(t,\xi(t,x)))^*D^2v(t,x)\eta'(t,\xi(t,x))\zeta(t,x) \\ &\quad + 2(\eta'(t,\xi(t,x)))^*D\zeta(t,x) \otimes \eta'(t,\xi(t,x))Dv(t,x) \\ &\quad +\langle D\zeta(t,x), \eta''(t,\xi(t,x))(\cdot,\cdot)\rangle v(t,x) \\ &\quad +\langle Dv(t,x), \eta''(t,\xi(t,x))(\cdot,\cdot)\rangle \zeta(t,x). \end{aligned} \tag{7}$$

By substituting (5)–(7) in (3), we finally obtain that v is the solution to the problem

$$\begin{cases} D_tv = \Lambda(t,x,v,Dv,D^2v), \\ v(0) = u_0, \end{cases} \tag{8}$$

where

(9)

$$\begin{aligned} \Lambda(t,x,v,p,q) = \rho\,(t,x)\widetilde{L}\Big(t,\ &\xi(t,x),\ \zeta(t,x)v,\ (\eta'(t,\xi(t,x)))^*D\zeta(t,x)v \\ &+(\eta'(t,\xi(t,x)))^*\zeta(t,x)p, \eta'(t,\xi(t,x)))^*D^2\zeta(t,x)\eta'(t,\xi(t,x))v \\ &+(\eta'(t,\xi(t,x)))^*q\eta'(t,\xi(t,x))\zeta(t,x) \\ &+2\,(\eta'(t,\xi(t,x)))^*D\zeta(t,x)\otimes\eta'(t,\xi(t,x))p \\ &+\langle D\zeta(t,x), \eta''(t,\xi(t,x))(\cdot,\cdot)\rangle v \\ &+\langle p, \eta''(t,\xi(t,x))(\cdot,\cdot)\rangle\zeta(t,x)\,\Big) \\ -\rho(t,x)\langle b(t,\xi(\,t,x))&\Big((\eta'(t,\xi(t,x)))^*D\zeta(t,x)v + (\eta'(t,\xi(t,x)))^*\zeta(t,x)p\Big),\ h(t,\xi(t,x))\rangle \\ -\mathrm{Tr}(Dh(t,\xi(t,x))&\cdot b(t,\xi(t,x)))\,v(t,x). \end{aligned}$$

Now, by using the Itô formula and by proceeding as in [15] and [19], we can prove the following proposition.

PROPOSITION 2.2. *Let $u_0 \in C^{2+\beta}(\mathbb{R}^N)$ and let $\tau \leq T$ be a stopping time with respect to the filtration $\{\mathcal{F}_t\}_{t\geq 0}$. If u is a strong solution of* (1) *in* $[0,\tau]$ *then the function $v(\cdot,\cdot) = \rho(\cdot,\cdot)\, u(\cdot,\xi(\cdot,\cdot))$ is a strict solution of* (8).

Conversely, if v belongs to $C([0,\tau];C^{2+\beta}(\mathbb{R}^N)) \cap C^1([0,\tau];C^{\beta}(\mathbb{R}^N))$ a.s. and is a strict solution of (8) *such that $v(t,\cdot)$ is $\mathcal{F}_t$-Bochner measurable for any $t \geq 0$, then u, defined by* (4)*, is a strong solution of* (1).

In order to state the Markov property we need to extend Proposition 2.2 to the case of initial datum given at time $s \geq 0$. This is a straightforward task. Then, with obvious notation, (4) is meant as

$$u(t,x,\omega;s,u_0(\cdot,\omega)) = \frac{v(t,\eta(t,\omega;s,x),\omega;s,u_0(\cdot,\omega))}{\rho(t,\eta(t,\omega;s,x),\omega;s)}. \tag{10}$$

In what follows, we will omit the ω-dependence for brevity.

PROPOSITION 2.3. *Assume that problem* (1) *has a unique strong solution u. Define $\mathcal{M}_s = \mathcal{F}_s \cap \{\tau > s\}$, $s \geq 0$ and let $\Psi\colon C^{2+\beta}(\mathbb{R}^N) \to \mathbb{R}$ be a bounded Bochner-measurable function. Then $u(t,\cdot;0,u_0)$ is $\mathcal{M}_t$-Bochner measurable and*

$$\mathbb{E}\left[\Psi(u(t,\cdot;0,u_0))|\mathcal{M}_s\right] = \mathbb{E}\left[\Psi(u(t,\cdot;s,\varphi))\right]\Big|_{\varphi=u(s,\cdot;0,u_0)}. \tag{11}$$

In formula (11) $u(s,\cdot;0,\varphi)$ is the the strong solution to problem (1) with deterministic initial datum $\varphi \in C^{2+\beta}(\mathbb{R}^N)$.

Proof. We exploit the fact that the solution u to problem (1) can be expressed by mean of the solution v to problem (8); then we can apply known results about deterministic evolution equations available for v, to state corresponding results for u. First we remark that the semigroup property of the process u follows from Proposition 2.2 and the uniqueness of problem (8).

Finally, let us prove the Markov property (11). Arguing as in the proof of Theorem 9.8 in [4], we have

$$\begin{aligned}\mathbb{E}\left[\Psi(u(t,\cdot;0,u_0)|\mathcal{M}_s\right] &= \mathbb{E}\left[\Psi(u(t,\cdot;s,u(s,\cdot;0,u_0)))\Big|\mathcal{M}_s\right]\\ &= \mathbb{E}\left[\Psi(u(t,\cdot;s,\varphi))\Big|\mathcal{M}_s\right]\Bigg|_{\varphi=u(s,\cdot;0,u_0)}\\ &= \mathbb{E}\left[\Psi(u(t,\cdot;s,\varphi))\right]\Big|_{\varphi=u(s,\cdot;0,u_0)}.\end{aligned}$$

Note that the second equality is a consequence of

$$\mathbb{E}\left[\Psi(u(t,\cdot;s,\mathcal{Z}))\Big|\mathcal{M}_s\right] = \mathbb{E}\left[\Psi(u(t,\cdot;s,\varphi))\Big|\mathcal{M}_s\right]\Bigg|_{\varphi=\mathcal{Z}},$$

where $\mathcal{Z}\colon\Omega \to C^{2+\beta}(\mathbb{R}^N)$ is $\mathcal{M}_s$-Bochner measurable. In fact, this can be easily checked when $\mathcal{Z}$ is a simple function. Now let Z be a general random variable and

$\{Z_n\}$ a sequence of simple functions coverging a.s. to Z; then we are allowed to pass to the limit for $n \to \infty$ on the equality

$$\mathbb{E}\left[\Psi(u(t,\cdot;s,\mathcal{Z}_n))\Big|\mathcal{M}_s\right] = \mathbb{E}\left[\Psi(u(t,\cdot;s,\varphi))\Big|\mathcal{M}_s\right]\Bigg|_{\varphi=\mathcal{Z}_n},$$

thanks to continuous dependence on the initial data in equation (8) and recalling that (10) holds. □

3. Local existence and maximal solution. Here we are concerned with problem (8). We start by proving existence for almost any fixed $\omega \in \Omega$ in a maximal interval $[0,\tau(\omega)[$.

PROPOSITION 3.1. *Assume that Hypothesis* 2.1 *holds with* $\alpha \in]0,1/2[$, *and that* $u_0 \in C^{2+\beta+\varepsilon}(\mathbb{R}^N)$ *a.s.; moreover, let* u_0 *be* $\mathcal{F}_0$*-measurable. Then for all* $\omega \in \Omega$, *there exists a maximal interval* $[0,\tau(\omega)[$, *depending on* $u_0(\omega)$, *and a unique regular solution* v *of problem* (8). *Moreover,* $v(t)$ *is* $\mathcal{F}_t$*-Bochner measurable for all* $t \geq 0$ *and* τ *is a stopping time.*

Proof. Consider problem (8) for any fixed $\omega \in \Omega$. To solve it we are going to use Theorem A.2 in Appendix A. We set

$$X = C^\beta(\mathbb{R}^N), \quad D = C^{2+\beta}(\mathbb{R}^N)$$

and consider the mapping $F : [0,T] \times D \to X$, defined by

$$F(t,v) = \Lambda(t,x,v,Dv,D^2v), \ \forall\, t \geq 0. \tag{12}$$

Now we check that Hypothesis A.1 is fulfilled.

Hypothesis A.1(i) follows from Hypothesis 2.1, Proposition B.6 and standard arguments.

Hypothesis A.1(ii), with $\theta = \min\{\alpha, 1/2\}$, follows again from Hypothesis 2.1 and Proposition B.6, recalling that the trajectories of Brownian motion are θ-Hölder continuous for any $\theta < 1/2$.

We now consider Hypothesis A.1(iii). Let $t \geq 0$ and $v_0 \in C^{2+\beta}(\mathbb{R}^N)$. Then we have

$$\begin{aligned}F_v(t,v_0)v = {} & D_v\Lambda(t,\cdot,v_0,Dv_0,D^2v_0)v + D_p\Lambda(t,\cdot,v_0,Dv_0,D^2v_0)Dv \\ & + D_q\Lambda(t,\cdot,v_0,Dv_0,D^2v_0)D^2v.\end{aligned}$$

We claim that the linear operator $F_v(t,v_0)$ is uniformly elliptic. Due to formula (9) and Hypothesis 2.1(vi), it is enough to show that $\|\eta'(t,\xi(t,x))^{-1}\|$ is uniformly bounded in t and x. This follows from Hypothesis 2.1(v) and from the identity

$$\eta'(t,\xi(t,x))^{-1} = \xi'(t,x).$$

Now we notice that, due to the regularity of its coefficients, the realization of the operator $F_v(t,v_0)$ in $C(\mathbb{R}^N)$ is the generator of an analytic semigroup on $C(\mathbb{R}^N)$, thanks to [17]. By interpolation arguments (see, e.g., [12, §3.1]), it follows that $F_v(t,v_0) : D \to X$ generates an analytic semigroup in X and that

$$D_{F_v(t,v_0)}(\alpha,\infty) = C^{\beta+2\alpha}(\mathbb{R}^N), \alpha \in]0,1[, \ \beta + 2\alpha \text{ not integer.}$$

So, A.1(ii) follows. Moreover, thanks to 2.1(i) and (ii), we have

$$F(0,u_0) \in C^{\beta+\varepsilon}(\mathbb{R}^N) = D_{F_v(t,v_0)}(\varepsilon/2,\infty),$$

so that A.1(v) is satisfied with $\alpha = \varepsilon/2$. Finally, A.1(iv) follows from the Schauder's Theorem. So, Hypothesis A.1 is satisfied, with $\theta = \min\{\alpha, 1/2, \varepsilon/2\}$.

Now, fix $T > 0$, then, by Theorem A.2 there is a unique solution of problem (8) in a maximal interval, $[0,\tau(\omega)[$ included in $[0,T]$. Since the proof of Theorem A.2 (see [11]), is based on an iteration procedure which involves $\mathcal{F}_T$-Bochner measurable functions, then the solution v is $\mathcal{F}_T$-Bochner measurable too. Now, fix $T_1 \in [0,T[$, then, by the same argument and by the uniqueness, the maximal solution in $[0,T_1]$ is $\mathcal{F}_{T_1}$-Bochner measurable and defined in $[0,T_1 \wedge \tau(\omega)[$. It follows that $T_1 \wedge \tau$ is $\mathcal{F}_{T_1}$-Bochner measurable and so τ is a stopping time. □

In order to prove global existence (that is $\tau = T$ a.s.) for problem (1), we need global existence for problem (8) a.s. We now show that to accomplish this, it is enough to prove an a priori estimate for the norm $\|v(t,\cdot)\|_{C^{2+\beta+\varepsilon}(\mathbb{R}^N)}$ of the solution.

PROPOSITION 3.2. *Assume that Hypothesis* 2.1 *holds. Let* $u_0 \in C^{2+\beta+\varepsilon}(\mathbb{R}^N)$ *a.s. Let* $v(\cdot,\omega) : [0,\tau(\omega)[$ *be the maximal solution of problem* (8) *given by Proposition* 3.1. *Assume moreover that there exists a constant* $M > 0$ *such that*

$$\|v(t,\cdot)\|_{C^{2+\beta+\varepsilon}(\mathbb{R}^N)} \leq M, \text{ for all } t \in [0,\tau(\omega)[. \tag{13}$$

Then we have $\tau(\omega) = +\infty$.

Proof. We still put $X = C^\beta(\mathbb{R}^N)$ and $D = C^{2+\beta}(\mathbb{R}^N)$ and apply Theorem A.2. Thus, to have a global solution, we have to prove that the mapping

$$v : [0,\tau[\to D,$$

is uniformly continuous. By estimate (13), we have, in fact, where $B(0,T;X)$ denote the space of bounded function with value in the Banach space X,

$$v \in B(0,\tau; C^{2+\beta+\varepsilon}(\mathbb{R}^N)),$$

which implies, since $D_t v = F(t,v)$,

$$D_t v \in L^\infty(0,\tau; C^{\beta+\varepsilon}(\mathbb{R}^N)).$$

By an interpolation result (see [16, Prop. 2.7]), it follows that

$$v \in C^{1-\theta}([0,\tau]; C^{\beta+\epsilon+2\theta}(\mathbb{R}^N)).$$

Choosing $\theta = 1 - \varepsilon/2$, it follows

$$v \in C([0,\tau]; C^{2+\beta}(\mathbb{R}^N)),$$

which yields the conclusion. □

Remark 3.3. Sufficient conditions to get a priori estimates of type (13) for the deterministic problem (8) may be found in [6] and [8]. However, it is not easy to express such conditions in terms of the coefficients of the original problem (1).

Nevertheless, in the next section, we present an application where it is possible to prove global existence.

4. An application. We consider here the special case

$$\text{(14)} \qquad \begin{cases} du = a(t,x,u)u_{xx}dt + (b(t,x)u_x + h(t,x)u)dW(t), \\ u(0) = u_0, \end{cases}$$

where $W(t)$ is a scalar Brownian motion and a, b, and h satisfy the following hypothesis.

HYPOTHESIS 4.1. (i) *For any $T > 0$ the mappings*

$$a : [0,T] \times \mathbb{R} \times \mathbb{R} \to \mathbb{R}, \quad (t,x,u) \to a(t,x,u),$$

$$b : [0,T] \times \mathbb{R} \to \mathbb{R}, \quad (t,x) \to b(t,x),$$

$$h : [0,T] \times \mathbb{R} \to \mathbb{R}, \quad (t,x) \to h(t,x)$$

are of class C^∞ and are bounded together with all their derivatives.

(ii) *There exists $\nu > 0$ such that*

$$a(t,x,u) - \frac{1}{2}b^2(t,x) \geq \nu, \quad \forall\, t \geq 0, \quad x, u \in \mathbb{R}.$$

Under this hypothesis, we can easily see that, setting $N = 1$ and

$$L(t,x,u,p,q) = a(t,x,u)q,$$

hypothesis (2.1) holds.

Now we can prove the following result.

PROPOSITION 4.2. *Assume that Hypothesis* 4.1 *holds, and let $u_0 \in C^3(\mathbb{R})$. Then there exists a unique strong solution of problem* (14).

Proof. We first remark that in this case problem (2) becomes

$$\begin{cases} d\xi = -b(t,\xi)dW(t) + b(t,\xi)\, b_x(t,\xi)dt, \\ \xi(0) = x. \end{cases}$$

Proceeding as in §2, we set

$$u(t,x) = \frac{v(t,\eta(t,x))}{\rho(t,\eta(t,x))},$$

where $\eta(t,x)$ is the inverse of $\xi(t,x)$, and

$$\rho(t,x) = \exp\left\{-\int_0^t h(s,\xi(s,x))dW(s) + \frac{1}{2}\int_0^t h^2(s,\xi(s,x))ds\right\}.$$

Then v is the solution of the problem

$$\text{(15)} \qquad \begin{cases} v_t = R(t,x,v)v_{xx} + S(t,x,v)v_x + T(t,x,v), \\ v(0) = u_0, \end{cases}$$

where, setting

$$\widetilde{a}(t,x,v) = a(t,x,v) - \frac{1}{2}b^2(t,x),$$

we have

$$R(t,x,v) = \widetilde{a}\Big(t,\xi(t,x),\,\frac{1}{\rho(t,x)}v\Big)\ \eta_x^2(t,\xi(t,x)),$$

$$S(t,x,v) = \widetilde{a}\Big(t,\xi(t,x),\,\frac{1}{\rho(t,x)}v\Big)\ \Big(\eta_{xx}(t,\xi(t,x)) - 2\eta_x^2(t,\xi(t,x))\frac{\rho_x(t,x)}{\rho(t,x)}\Big)$$
$$-b(t,\xi(t,x))h(t,\xi(t,x))\eta_x(t,\xi(t,x)),$$

$$T(t,x,v) = \widetilde{a}\Big(t,\xi(t,x),\,\frac{1}{\rho(t,x)}v\Big)\ \Big(\eta_x^2(t,\xi(t,x))\frac{2\rho_x^2(t,x) - \rho(t,x)\rho_{xx}(t,x)}{\rho^2(t,x)}$$
$$-\eta_{xx}(t,\xi(t,x))\frac{\rho_x(t,x)}{\rho(t,x)}\Big)$$
$$-b(t,\xi(t,x))h_x(t,\xi(t,x)) + b(t,\xi(t,x))h(t,\xi(t,x))\eta_x(t,\xi(t,x))\frac{\rho_x(t,x)}{\rho(t,x)}.$$

In view of Proposition 3.1, given $\beta \in\,]0,1[$, problem (15) has a unique adapted solution in a maximal interval $[0,\tau[$. We want to prove that, with a suitable choice of β, there exists $K_1 > 0$ such that

$$\|v(t)\|_{C^{2+\beta}} \le K_1, \quad \forall\, t \in [0,\tau[. \tag{16}$$

We first remark that, by the maximum principle, there exists a positive constant $K(\|v_0\|_\infty)$ such that

$$\|v(t,\cdot)\|_\infty \le K(\|v_0\|_\infty),\ t \in [0,\tau[.$$

It follows that the operator

$$\mathcal{L}v = R(t,x,v)v_{xx} + S(t,x,v)v_x + T(t,x,v)$$

is an elliptic operator with L^∞ coefficients; so, from the well-known Krylov–Safonov theorem (see [7]), v belongs to $C^\beta([0,\tau[;\mathbb{R}^N)$ for some $\beta \in\,]0,1[$. Consequently, $\mathcal{L}$ is an elliptic operator with Hölder-continuous coefficients. Now the required a priori estimate (16) follows from the classical parabolic Schauder theory, which can be found in [8]. □

Appendix A. Fully nonlinear equations. Let D and X be Banach spaces such that

$$D \subset X,$$

with the embedding being continuous but not necessarily dense. We are given a mapping

$$F : [0,+\infty[\times D \to X,\ \ (t,v) \to F(t,v),$$

and we are concerned with the initial value problem

$$\text{(A.17)} \qquad \begin{cases} v'(t) = F(t, v(t)), & t \geq 0, \\ v(0) = v_0 \in D. \end{cases}$$

We shall consider only regular solutions. Let J be an interval in $[0, +\infty[$ such that $\min J = 0$, and fix $\theta \in]0,1[$. By definition, a *solution* of (A.17) on J is a function v such that, for some $\theta \in]0,1[$,

(i) $v \in C^{1+\theta}(J_1; X) \cap C^{\theta}(J_1; D)$, for any closed and bounded subinterval J_1 of J, and

(ii) $v'(t) = F(t, v(t)), t \in J$, and $v(0) = v_0$,

We assume the following hypothesis

HYPOTHESIS A.1. (i) *F is continuous together with its partial derivatives F_v and F_{vv}.*

(ii) *For every $T > 0$ and $v_0 \in D$, $F(\cdot, v_0)$ and $F_v(\cdot, v_0)$ are θ-Hölder continuous in $[0,T]$ locally uniformly with respect to v_0.*

(iii) *For all $(t,v) \in [0, +\infty[\times D$, $F_v(t,v)$ generates an analytic semigroup in X; that is, there are $\rho \in \mathbb{R}$, $\eta \in]\pi/2, \pi[$, and $M > 0$, possibly depending on t and v, such that the resolvent set of $F_v(t,v)$ contains the sector*

$$S_{\eta,\rho} = \{\lambda \in \mathbf{C} : \ \lambda \neq \rho, | \arg(\lambda - \rho) \ | < \eta\}$$

and

$$\|\lambda(\lambda - F_v(t,v))^{-1}\|_{L(X)} \leq M \quad \text{for } \lambda \in S_{\theta,\omega}.$$

(iv) *For all $(t,v) \in [0, +\infty[\times D$, there exists a constant $a > 0$ (possibly depending on t and v), such that*

$$a\|z\|_D \leq \|F_v(t,v) \cdot z\|_X \leq \frac{1}{a}\|z\|_D, \quad \textit{for all } z \in D.$$

(v) *We have*

$$F(0, v_0) \in D_A(\theta, \infty),$$

where $A = F_v(0, v_0)$ and $D_A(\theta, \infty)$ is the real interpolation space defined by

$$D_A(\theta, \infty) = \{z \in X : \sup_{\xi \in \ ]0,1]} \|\xi^{1-\theta} A e^{\xi A} z\|_X < +\infty\}.$$

The following result is proved in [11, Prop. 2.3 and 2.4].

THEOREM A.2. *Assume that Hypothesis* A.1 *holds. Then there exists a unique solution*

$$v(\cdot, v_0)$$

of problem (A.17) *in a maximal interval $[0, \tau_{v_0}[$, with $\tau_{v_0} > 0$.*

If, in addition, $v(\cdot, v_0) : [0, \tau_{v_0}[\to D$ is uniformly continuous, then $\tau_{v_0} = +\infty$.

Appendix B. Composition of Hölder-continuous functions. Let $\beta \in]0,1[$. For any function $u : \mathbb{R}^n \to \mathbb{R}, x \to u(x)$ we set

$$\|u\|_\infty = \sup\{|u(x)| : x \in \mathbb{R}^n\},$$

$$[u]_\beta = \sup\left\{\frac{|u(x)-u(y)|}{|x-y|^\beta} : x,y \in \mathbb{R}^n, x \neq y\right\},$$

$$\|u\|_\beta = \|u\|_\infty + [u]_\beta,$$

$$[u]'_\beta = \sup\left\{\frac{|u(x)-u(y)|}{|x-y|^\beta} : x,y \in \mathbb{R}^n, x \neq y,\ |x-y| \leq 1\right\},$$

$$\|u\|'_\beta = \|u\|_\infty + [u]'_\beta.$$

We remark that, since

$$[u]_\beta \leq [u]'_\beta + 2\|u\|_\infty,$$

the norms $\|\cdot\|_\beta$ and $\|\cdot\|'_\beta$ are equivalent.

If u is k times differentiable, $k \geq 1$, we set

$$\|u\|_{\beta,k} = \|u\|_\infty + \sum_{h=1}^{k} \|D^h\|_\infty + [D^k u]_\beta$$

and

$$C^{k+\beta}(\mathbb{R}^n) = \{u : \|u\|_{\beta,k} < +\infty\}.$$

We are given a mapping

$$\Lambda : [0,+\infty[\times \mathbb{R}^N \times \mathbb{R} \times \mathbb{R}^N \times \mathbb{R}^{N^2} \to \mathbb{R},\quad (t,x,u,p,q) \to \Lambda(t,x,u,p,q),$$

and we set

$$\text{(B.18)}\quad F(t,u)(x) = \Lambda(t,x,u(x),Du(x),D^2u(x)),\ \forall\, u \in C^{2+\beta}(\mathbb{R}^N), t \in [0,T].$$

We are interested in the regularity properties of F.

LEMMA B.1. *Assume that* Λ *belongs to the class* $(0,0)$ *together with its partial derivatives* $D_{x_i}\Lambda$, $i = 1,\dots,N$, $D_u\Lambda$, $D_{p_i}\Lambda$, $i = 1,\dots,N$, *and* $D_{q_{i,j}}\Lambda$, $i,j = 1,\dots,N$. *Then, for any* $\beta \in]0,1[$, F *belongs to* $C([0,T] \times C^{2+\beta}(\mathbb{R}^N); C^\beta(\mathbb{R}^N))$.

Proof. We have to prove that $\|F(t,u) - F(t_0,u_0)\|_\beta \to 0$ when $t \to t_0$ and $u \to u_0$ in $C^{2+\beta}(\mathbb{R}^n)$. Since clearly

$$\lim_{\substack{t \to t_0 \\ u \to u_0}} \|F(t,u) - F(t_0,u_0)\|_\infty = 0,$$

it suffices to show that

$$\lim_{\substack{t \to t_0 \\ u \to u_0}} [F(t,u) - F(t_0,u_0)]'_\beta = 0.$$

Let $\|x-y\| \le 1$. We have to estimate

$$I = F(t,u)(x) - F(t_0,u_0)(x) - F(t,u)(y) + F(t_0,u_0)(y).$$

To simplify the next formulae, we introduce the notation

$$\lambda = \xi \ \left(t, x, u(x), Du(x), D^2u(x)\right) + (1-\xi) \ \left(t, y, u(y), Du(y), D^2u(y)\right)$$

and

$$\lambda_0 = \xi \ \left(t_0, x, u_0(x), Du(x), D^2u_0(x)\right) + (1-\xi) \ \left(t_0, y, u_0(y), Du_0(y), D^2u_0(y)\right).$$

Then we have

$$\begin{aligned} I = & \int_0^1 [D_x\Lambda(\lambda)(x-y) + D_u\Lambda(\lambda)(u(x)-u(y)) \\ & \quad + D_p\Lambda(\lambda)(Du(x)-Du(y)) + D_q\Lambda(\lambda)(D^2u(x)-D^2u(y))]d\xi \\ & - \int_0^1 [D_x\Lambda(\lambda_0)(x-y) + D_u\Lambda(\lambda_0)(u_0(x)-u_0(y)) \\ & \quad + D_p\Lambda(\lambda_0)(Du_0(x)-Du_0(y)) + D_q\Lambda(\lambda)(D^2u_0(x)-D^2u_0(y))]d\xi \\ = & \int_0^1 [D_x\Lambda(\lambda) - D_x\Lambda(\lambda_0)](x-y)d\xi \\ & + \int_0^1 [D_u\Lambda(\lambda) - D_u\Lambda(\lambda_0)](u_0(x)-u_0(y))]d\xi \\ & + \int_0^1 [D_p\Lambda(\lambda) - D_p\Lambda(\lambda_0)](Du_0(x)-Du_0(y))]d\xi \\ & + \int_0^1 [D_q\Lambda(\lambda) - D_q\Lambda(\lambda_0)](D^2u_0(x)-D^2u_0(y))]d\xi \\ & + \int_0^1 D_u\Lambda(\lambda)(u(x)-u(y)-u_0(x)+u_0(y))d\xi \\ & + \int_0^1 D_p\Lambda(\lambda)(Du(x)-Du(y)-Du_0(x)+Du_0(y))d\xi \\ & + \int_0^1 D_q\Lambda(\lambda)(D^2u(x)-D^2u(y)-D^2u_0(x)+D^2u_0(y))d\xi. \end{aligned}$$

It follows that

$$\begin{aligned} |I| \le & \int_0^1 |D_x\Lambda(\lambda) - D_x\Lambda(\lambda_0)||x-y|^\beta d\xi \\ & + \int_0^1 |D_p\Lambda(\lambda) - D_p\Lambda(\lambda_0)|[u]_\beta|x-y|^\beta d\xi \\ & + \int_0^1 |D_q\Lambda(\lambda) - D_q\Lambda(\lambda_0)|[u]_{\beta,1}|x-y|^\beta d\xi \\ & + \int_0^1 |D_q\Lambda(\lambda) - D_q\Lambda(\lambda_0)|[u]_{\beta,2}|x-y|^\beta d\xi \\ & + \int_0^1 |D_u\Lambda(\lambda_0)|[u-u_0]_\beta|x-y|^\beta d\xi \end{aligned}$$

$$+\int_0^1 |D_p\Lambda(\lambda_0)|[u-u_0]_{\beta,1}|x-y|^\beta d\xi$$

$$+\int_0^1 |D_q\Lambda(\lambda_0)|[u-u_0]_{\beta,2}|x-y|^\beta d\xi,$$

which yields the conclusion. □

The proof of the following lemma is similar and is left to the reader.

LEMMA B.2. *Assume that Λ belongs to the class $(0,0)$ together with its partial derivatives of the type $D_x^h D_u^k D_p^l D_q^m \Lambda$, with $|h|+|k|+|l|+|m| \leq 3$. Then for any $\beta \in]0,1[$, F is a mapping of class C^2 from $[0,+\infty[\times C^{2+\beta}(\mathbb{R}^n)$ into $C^\beta(\mathbb{R}^n)$.*

We now give sufficient conditions in order that $F(t,u)$ is α-Hölder continuous in t.

LEMMA B.3. *Assume that Λ belongs to the class (α,β) together with its partial derivatives $D_{x_i}\Lambda$, $i=1,\dots,N$, $D_u\Lambda$, $D_{p_i}\Lambda$, $i=1,\dots,N$, and $D_{q_{i,j}}\Lambda$, $i,j=1,\dots,N$. Then for all $u \in C^{\beta+2}(\mathbb{R}^n)$ there exists a constant $C(u)$ such that*

$$\|F(t,u)-F(s,u)\|_\beta \leq C(u)|t-s|^\alpha, \text{ for all } t,s \in [0,T]. \tag{B.19}$$

Proof. Let $u \in C^{\beta+2}(\mathbb{R}^n)$ and $r=\|u\|_{2,\beta}$. We first remark that

$$\|F(t,u)-F(s,u)\|_\infty \leq M_{T,r}|t-s|^\alpha, \text{ for all } t,s \in [0,T]. \tag{B.20}$$

Now we want to estimate $[F(t,u)-F(s,u)]'_\beta$. To do this, we have to estimate

$$J=\Lambda(t,x,u(x),Du(x),D^2u(x))-\Lambda(s,x,u(x),Du(x),D^2u(x))$$

$$-\Lambda(t,y,u(y),Du(y),D^2u(y))+\Lambda(s,y,u(y),Du(y),D^2u(y)).$$

We have

$$J=\Lambda(t,x,u(x),Du(x),D^2u(x))-\Lambda(t,y,u(x),Du(x),D^2u(x))$$

$$-\Lambda(s,x,u(x),Du(x),D^2u(x))+\Lambda(s,y,u(x),Du(x),D^2u(x))$$

$$+\Lambda(t,y,u(x),Du(x),D^2u(x))-\Lambda(t,y,u(y),Du(y),D^2u(y))$$

$$-\Lambda(s,y,u(x),Du(x),D^2u(x))+\Lambda(s,y,u(y),Du(y),D^2u(y)),$$

and so, setting

$$\mu_t=(t,\xi x+(1-\xi)y,u(x),Du(x),D^2u(x)),$$

$$\zeta_t=(t,y,\xi u(x)+(1-\xi)u(y),\xi Du(x)+(1-\xi)Du(y),\xi D^2u(x)+(1-\xi)D^2u(y)),$$

we have

$$J=\int_0^1 [D_x\Lambda(\mu_t)-D_x\Lambda(\mu_s)](x-y)d\xi$$

$$+\int_0^1 [D_u\Lambda(\zeta_t)-D_u\Lambda(\zeta_s)](u(x)-u(y))d\xi$$

$$+\int_0^1 [D_p\Lambda(\zeta_t)-D_p\Lambda(\zeta_s)](Du(x)-Du(y))d\xi$$

$$+\int_0^1 [D_q\Lambda(\zeta_t)-D_q\Lambda(\zeta_s)](D^2u(x)-D^2u(y))d\xi.$$

If $|x-y| \leq 1$ and $r = \|u\|_{2,\beta}$, we get

$$|J| \leq M_{T,r}(1+\|u\|_{2,\beta})|t-s|^{\alpha}|x-y|^{\beta},$$

which yields

$$[F(t,u)-F(s,u)]'_{\beta} \leq M_r(1+\|u\|_{\beta,2})|t-s|^{\alpha}. \qquad \square$$

The following result is proved similarly.

LEMMA B.4. *Assume that* Λ *belongs to the class* (α,β) *together with its partial derivatives of the type* $D_x^h D_u^k D_p^l D_q^m \Lambda$, *for* $|h|+|k|+|l|+|m| \leq 2$. *Then, for all* $r>0$ *and for all* $v \in C^{\beta+2}(\mathbb{R}^n)$ *such that* $\|v\|_{2,\beta} \leq r$, *there exists* $M_{T,r}^1$ *such that*

$$\|F_v(t,v)-F_v(s,v)\|_{\beta} \leq M_{T,r}^1|t-s|^{\alpha}, \text{ for all } t,s \in [0,T]. \tag{B.21}$$

We end this section by giving a sufficient condition in order that F fulfills Hypothesis A.1 (i) and (ii). For this, we need the following hypothesis.

HYPOTHESIS B.5. (i) Λ *belongs to the class* (α,β) *together with its partial derivatives of the type* $D_x^h D_u^k D_p^l D_q^m \Lambda$, *for* $|h|+|k|+|l|+|m| \leq 2$.

(ii) Λ *belongs to the class* $(0,0)$ *together with its partial derivatives of the type* $D_x^h D_u^k D_p^l D_q^m \Lambda$, *for* $|h|+|k|+|l|+|m| = 3$.

Then the following proposition holds.

PROPOSITION B.6. *Let* F *be defined by* (B.18) *and assume that Hypothesis* B.5 *holds. Then* F *fulfills Hypothesis* A.1(i) *and* (ii).

CAPILLARY WEDGES REVISITED*

PAUL CONCUS† AND ROBERT FINN‡

Abstract. Equilibrium capillary surfaces in zero gravity in cylindrical containers whose sections are (wedge) domains with corners are studied. Necessary and also sufficient conditions are developed for the existence or nonexistence of surfaces that are locally graphs over the base at the corner, with (prescribed) contact angles that may differ on the two sides. It is shown that the behavior can depart in significant qualitative ways from that which occurs when the two contact angles are the same. Conditions are derived under which such qualitative changes must occur, and illustrative examples are given.

Key words. capillarity, contact angle, free surface, mean curvature, microgravity, wedge domain

AMS subject classifications. 76B45, 53A10, 35B30, 49Q99

1. Introduction.

This paper is devoted to the results announced in our earlier note [1], concerning existence and nonexistence of capillary surfaces over domains with corners, when the data on the two sides of the corner may differ. The behavior of the solutions can differ in significant qualitative ways from that which occurs in the previously considered case of constant data; we are able to a large extent to characterize the conditions under which such qualitative changes must occur.

For background considerations, we refer the reader to our earlier papers [2], [3] and to Chapters 1, 5, and 6 in [4]. In general terms, we consider a cylindrical capillary tube Z with section Ω, closed at one end and partly filled with fluid in the absence of gravity, forming a free surface $\mathcal{S}$. We suppose the boundary Σ of Ω to be piecewise smooth and to have an isolated corner P of opening 2α, $0 < 2\alpha < \pi$, forming a local "wedge domain" at P; see Fig. 1. We seek conditions under which, for prescribed constant (contact) angles γ_1 and γ_2 in the interval $[0, \pi]$, there will exist an $\mathcal{S}$ that can be (locally) represented by a function $z = u(x, y)$ over a neighborhood Ω^* of P in Ω and which meets the sides Z_1 and Z_2, over adjacent segments Σ_1 and Σ_2 of $\partial\Omega$ that abut at P, in the angles γ_1 and γ_2.

Specifically, we seek a solution of

$$\operatorname{div} Tu = 2H \tag{1}$$

in some Ω^*, with

$$Tu = \frac{Du}{\sqrt{1 + |Du|^2}} \tag{2}$$

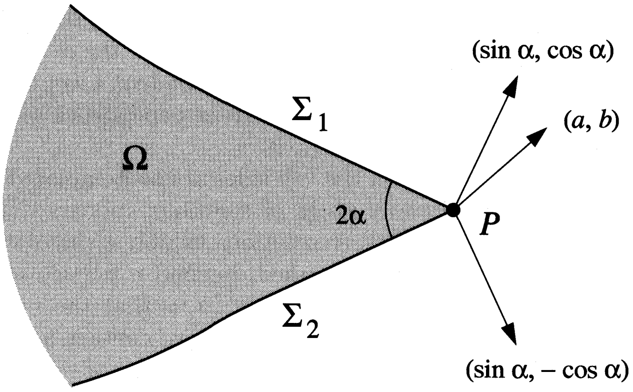

FIG. 1. *The wedge configuration.*

and H an arbitrary prescribed constant, such that

$$(3)\qquad \begin{aligned} \nu \cdot Tu &= \cos\gamma_1 \quad \text{on } \Sigma_1, \\ \nu \cdot Tu &= \cos\gamma_2 \quad \text{on } \Sigma_2, \end{aligned}$$

ν being unit exterior normal vector. Geometrically, H is the *mean curvature* of $\mathcal{S}$; when $H = 0$, $\mathcal{S}$ becomes a minimal surface. In a physical situation, H is determined by the global configuration of Ω and by the boundary conditions over the entire boundary. One sees easily that meaningful physical conditions can give rise to any desired value of H. It is worth noting that if $\gamma_1 = \gamma_2 \neq \pi/2$ over the entire boundary, then $H \neq 0$; if $\gamma_1 = \gamma_2 = \pi/2$ over the entire boundary, then the global problem admits the solution $u \equiv 0$ in Ω, which is unique up to an additive constant.

It is important to observe that in the statement of the problem, $\mathcal{S}$ is not assumed to be defined over P, and no growth conditions are imposed as P is approached from within Ω.

2. Relation to previous work. In earlier work [2], [3], we have shown that if $\gamma_1 = \gamma_2 = \gamma$, then a solution of the local problem (1)–(3) can exist only if $\alpha \geq \left|\frac{\pi}{2} - \gamma\right|$; if $H \neq 0$ and if Σ_1 and Σ_2 are linear segments, then this condition also suffices, while if $H = 0$, then $\alpha > \left|\frac{\pi}{2} - \gamma\right|$ suffices for existence. Again we emphasize that no growth restriction is required at P. Tam [5] showed that whenever a solution exists, then the surface $\mathcal{S}$ is continuous and has a continuous unit normal $\vec{N}$ up to P, see also Simon [6] for earlier work and Miersemann [7] and Lieberman [8] for further developments. This remarkable behavior is the underlying reason that Vreeburg obtained in [9] the identical expression $\alpha \geq \left|\frac{\pi}{2} - \gamma\right|$ as condition for existence of a surface with normal vector continuous to the vertex, without any use of the differential equation.

In the interim, Keller, King, and Merchant [10, §2] studied again the question of a capillary surface $u(x, y)$ defined in a wedge, with (possibly) differing angles γ_1, γ_2 on the two sides. Statements given in that paper conflict basically with a previous result of ours to which the authors refer and of which they assert a simplified proof. The new results of our present study disagree in turn with those announced in [10] for the corresponding general case. Our results are also to some extent at variance with the work by Vreeburg [9] indicated above; these differences are discussed in our paper [1].

It is a curious accident that, when the contact angles on the two wedge sides are equal, all the procedures lead to criteria that look formally similar to those we originally obtained. The criteria do nevertheless differ, even in the equal angle case, in an important respect. This discrepancy presumably lies at the source of the statement in the abstract of [10] that *"the height of the free surface at the corner tends to infinity as the wedge angle decreases to a critical value dependent upon the contact angle."* The statement is in conflict with the discontinuous dependence on the data that is characteristic for the behavior of the solutions.

When differing contact angles on the two sides are contemplated, the distinctions become still more marked. A whole range of solutions appears that is not encompassed in the results stated in [10]; these solutions exhibit a singular behavior at the vertex that has not been previously remarked, beyond a particular case that arose peripherally in [11]. For this reason, it appears to us that the proposal of [10], to use its criterion as a basis for experiments to measure contact angle, would lead to incorrect results in many cases. Examples of the new range of solutions are described in §5 below, and some numerically computed illustrations are given in [12]. It should be of considerable interest to test the results with physical experiments, which could be carried out in a suitable microgravity environment.

A more complete discussion of some of the above material appears in [13].

3. Conditions for existence. We proceed to discuss the problem posed in §1. In the (B_1, B_2) plane, we introduce the closed elliptical domain

$$\mathcal{E}: \ B_1^2 + B_2^2 + 2B_1B_2\cos 2\alpha \le \sin^2 2\alpha \tag{4}$$

inscribed in a square $\mathcal{Q}$ as indicated in Fig. 2. $\mathcal{E}$ cuts off domains $\mathcal{D}_1^+, \mathcal{D}_1^-$ of $\mathcal{Q}$ that are interior to the strip $\mathcal{A}: |B_1 - B_2| < 2\cos^2\alpha$, and domains $\mathcal{D}_2^+, \mathcal{D}_2^-$ of $\mathcal{Q}$ that are exterior to $\mathcal{A}$. Note that the lines $B_1 - B_2 = \pm 2\cos^2\alpha$ pass through the intersection points of $\partial\mathcal{E}$ with $\partial\mathcal{Q}$. We then have

THEOREM 1. *Set $B_1 = \cos\gamma_1$, $B_2 = \cos\gamma_2$. A necessary condition for existence of a solution surface $\mathcal{S}$: $u(x, y)$ of (1)–(3) with unit normal $\vec{N}$ continuous up to P is that the point (B_1, B_2) lie in $\mathcal{E}$; the boundary of $\mathcal{E}$ corresponds to those configurations for which $\mathcal{S}$ is vertical ($\vec{N}$ horizontal) at P. On $\partial\mathcal{E}\cap\partial\mathcal{D}_1^+$, there holds $\gamma_1+\gamma_2 = \pi-2\alpha$; on $\partial\mathcal{E}\cap\partial\mathcal{D}_1^-$, there holds $\gamma_1 + \gamma_2 = \pi + 2\alpha$. On $\partial\mathcal{E}\cap\partial\mathcal{D}_2^-$ and $\partial\mathcal{E}\cap\partial\mathcal{D}_2^+$, there hold, respectively, $\gamma_1 - \gamma_2 = \pi - 2\alpha$ and $\gamma_1 - \gamma_2 = -\pi + 2\alpha$. For existence of such a solution in a domain Ω^* of the type considered and for arbitrary H, it suffices that Σ_1 and Σ_2 be linear segments, and that (B_1, B_2) lie interior to $\mathcal{E}$. If $(B_1, B_2) \in \partial\mathcal{E}\cap\partial\mathcal{D}_1^+\cap\mathcal{A}$, then there is a solution (in some Ω^*) for any $H > 0$; if $(B_1, B_2) \in \partial\mathcal{E}\cap\partial\mathcal{D}_1^-\cap\mathcal{A}$, there is a solution for any $H < 0$.*

Any solution $u(x, y)$, corresponding to interior points of $\mathcal{E}$ or to points of $\partial\mathcal{E}$ interior to $\mathcal{A}$, is continuous and admits a continuous unit normal vector up to P.

Proof. Write $\vec{N} = \langle a, b, c\rangle$ with $c \le 0$, $a^2 + b^2 + c^2 = 1$. Referring to Fig. 1, we find

$$\begin{aligned}\cos\gamma_1 &= \ a\sin\alpha + b\cos\alpha,\\ \cos\gamma_2 &= \ a\sin\alpha - b\cos\alpha,\end{aligned}$$

and the first sentence of the necessary condition follows immediately from the observation that $a^2+b^2 \le 1$, equality holding if and only if $c = 0$. For any $(B_1, B_2) \in \partial\mathcal{E}\cap\partial\mathcal{D}_1^+$, there corresponds a unique (γ_1, γ_2) with γ_1, γ_2 in $[0, \pi]$. We rewrite

$$B_1^2 + B_2^2 + 2B_1B_2\cos 2\alpha = \sin^2 2\alpha \tag{5}$$

in the form

$$(1 - B_1^2)(1 - B_2^2) = (B_1B_2 + \cos 2\alpha)^2. \tag{6}$$

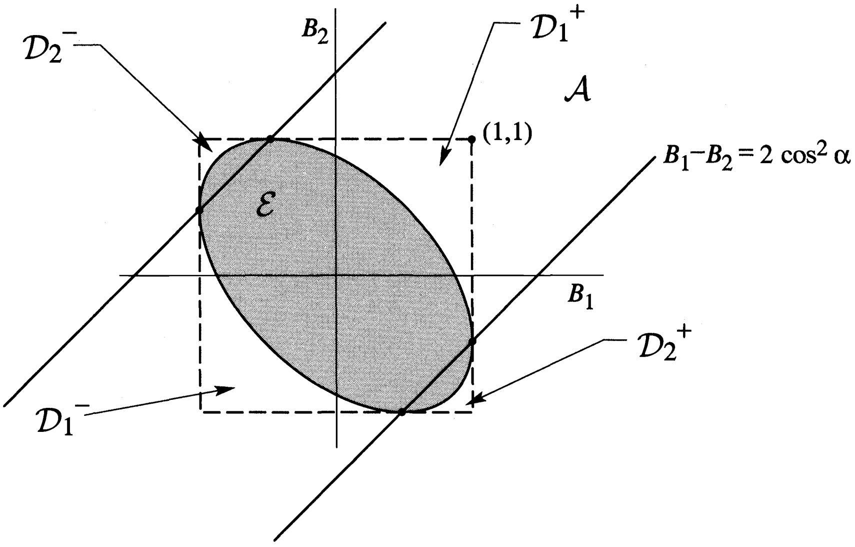

FIG. 2. *Elliptical domain $\mathcal{E}$, reference strip $\mathcal{A}$, square $\mathcal{Q}$, and domains $\mathcal{D}_i^{\pm}$; case $2\alpha < \frac{\pi}{2}$. If $2\alpha > \frac{\pi}{2}$, the directions of major and minor axes interchange.*

Since on the indicated arc we have

$$(7)\qquad (B_1 - B_2)^2 < 4\cos^4\alpha,$$

there follows from (5)

$$(8)\qquad B_1B_2 + \cos 2\alpha > 0.$$

Thus, using positive square roots, we obtain from (6)

$$(9)\qquad \sqrt{1-B_1^2}\sqrt{1-B_2^2} = B_1B_2 + \cos 2\alpha,$$

which is equivalent to

$$(10)\qquad \cos(\gamma_1 + \gamma_2) = \cos(\pi - 2\alpha),$$

so that either $\gamma_1 + \gamma_2 = \pi - 2\alpha$ or $\gamma_1 + \gamma_2 = \pi + 2\alpha$. But from (5), we find at the symmetry point $B_1 = B_2 = B > 0$ on $\partial\mathcal{E} \cap \partial\mathcal{D}_1^+$ that $B = \sin\alpha = \cos(\frac{\pi}{2} - \alpha)$. Thus, the former relation must hold at the symmetry point, and hence it holds throughout the arc. Similarly, on $\partial\mathcal{E} \cap \partial\mathcal{D}_1^-$, there holds $\gamma_1 + \gamma_2 = \pi + 2\alpha$.

On the remaining two arcs $\partial\mathcal{E} \cap \partial\mathcal{D}_2^-$ and $\partial\mathcal{E} \cap \partial\mathcal{D}_2^+$, we obtain by analogous reasoning that $\gamma_1 - \gamma_2 = \pi - 2\alpha$ and $-\pi + 2\alpha$, respectively.

To prove the sufficiency, observe that if (B_1, B_2) is interior to $\mathcal{E}$, then a, b, and c are uniquely determined by the conditions just given, and observe that $c < 0$. The plane Π through P with normal $\vec{N}$ then solves the problem when $H = 0$. If $H > 0$, then a lower hemisphere of radius $1/H$ and tangent to Π at P provides an explicit local solution, while if $H < 0$, then an upper hemisphere yields a solution (see Fig. 3).

If (B_1, B_2) is a boundary point of $\mathcal{E}$, then this procedure always fails when $H = 0$; if $H \neq 0$, then the procedure can under some circumstances yield a solution, provided the trace of Π on the plane of Ω does not enter the (closed) wedge domain. That is,

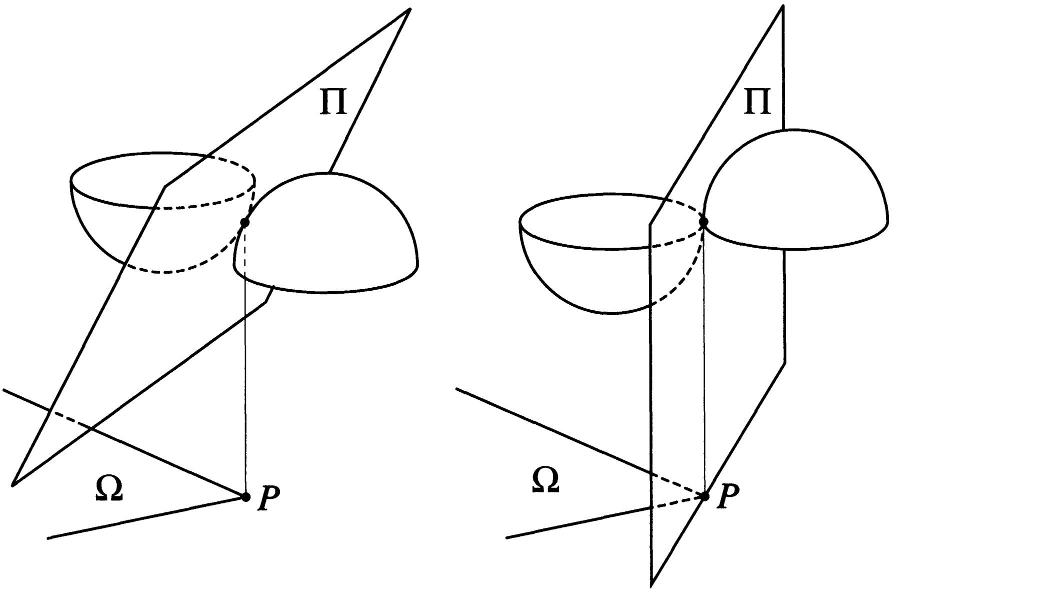

FIG. 3. *Covering of neighborhoods of P by hemispheres; when Π is vertical (corresponding to points on $\partial\mathcal{E}$), only one of the two hemispheres achieving the boundary data at P covers a neighborhood of P in Ω.*

the vector $\langle a, b\rangle$ of Fig. 1 must be a linear combination, with positive coefficients, of the two other vectors in the figure. Since $c = 0$ in this case, the condition becomes $|b| < \cos\alpha$, or equivalently $|B_1 - B_2| < 2\cos^2\alpha$; that is, $(B_1, B_2) \in \mathcal{A}$. But even with that restriction, not all possibilities can be achieved, as the signs of u_x, u_y now reverse for the two hemispheres tangent to Π at P that cover a neighborhood of P in Ω (see Fig. 3), and thus changing the sign of H also reverses the signs of u_x, u_y. Nevertheless, on $\partial\mathcal{E}\cap\partial\mathcal{D}_1^+$ the condition $\gamma_1+\gamma_2 = \pi - 2\alpha$ can be realized by an explicit construction with a lower hemisphere of arbitrary radius; the construction is indicated in Fig. 4.

Similarly, on $\partial\mathcal{E}\cap\partial\mathcal{D}_1^-$, there must hold $\gamma_1 + \gamma_2 = \pi + 2\alpha$, and an explicit construction can be achieved with an upper hemisphere of arbitrary radius.

With regard to the remaining two arcs $\partial\mathcal{E}\cap\partial\mathcal{D}_2^+$ and $\partial\mathcal{E}\cap\partial\mathcal{D}_2^-$, it will be shown below (in §5) that solutions exist, at least at the symmetry points of these arcs; these solutions are, however, not known explicitly.

The final statement of the theorem follows from the method of Tam [5], which applies without essential change to the extended situation considered here. □

It should be emphasized that we have not excluded the possibility of solutions with negative H achieving the data on the segment $\partial\mathcal{E}\cap\partial\mathcal{D}_1^+$ or with positive H achieving the data on the segment $\partial\mathcal{E}\cap\partial\mathcal{D}_1^-$.

In view of the four relations just obtained for γ_1 and γ_2 on $\partial\mathcal{E}$, we see that $\mathcal{E}$ appears as a rectangle in the γ_1, γ_2 coordinates, with sides inclined at 45° to the axes (Fig. 5).

4. Nonexistence. In the above discussion, the requirement that Σ_1 and Σ_2 be linear was introduced solely to facilitate a simple explicit sufficiency proof; it is not essential to the substance of the problem. It is less clear under what conditions solutions with discontinuities at P are excluded, as happens in the equal angle case. To study that point, we attempt to extend the method we introduced for that case to this more general situation. Following in general outline our earlier procedure, we

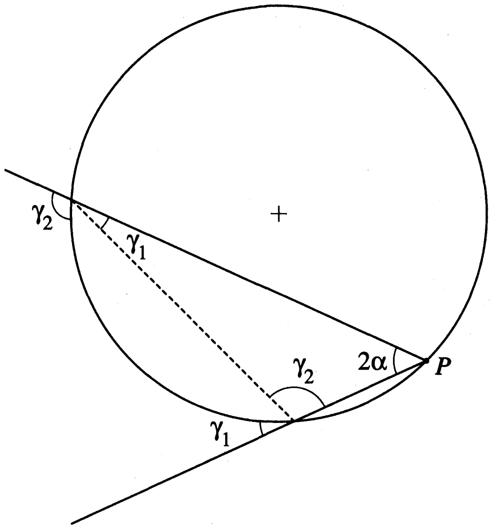

FIG. 4. *Construction of solution as lower hemisphere*; $\gamma_1 + \gamma_2 = \pi - 2\alpha$, $H > 0$.

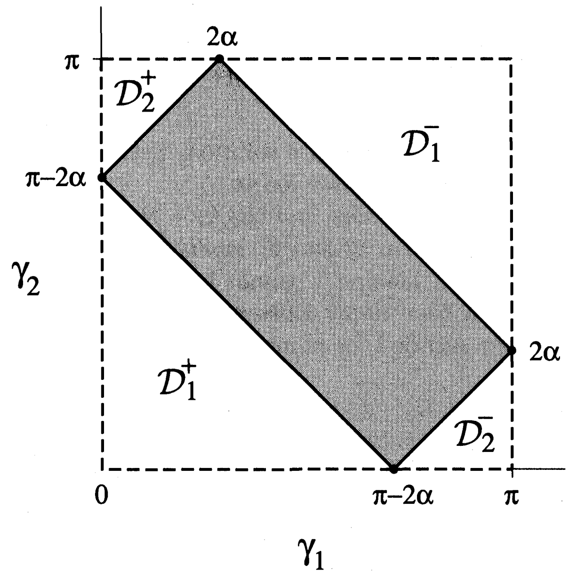

FIG. 5. *Image of $\mathcal{E}$ and of $\mathcal{Q}$ in* (γ_1, γ_2) *coordinates.*

apply Green's identity to (1) in the subdomain $\Omega^{(\Lambda)}$ indicated in Fig. 6, cut off by Γ and Λ (the segment Λ is introduced to exclude possible singularities at the vertex P). We obtain

$$(11) \qquad 2H\left|\Omega^{(\Lambda)}\right| = \left|\Sigma_1^{(\Lambda)}\right| \cos\gamma_1 + \left|\Sigma_2^{(\Lambda)}\right| \cos\gamma_2 + \int_\Gamma \nu \cdot Tu\, ds + \int_\Lambda \nu \cdot Tu\, ds.$$

The crucial observation in what follows is that $|\nu \cdot Tu| < 1$ for any function $u(x, y)$. This inequality permits us initially to move Λ to the vertex P, with the integral over that segment disappearing in the limit. Our next step is to replace $\nu \cdot Tu$ in the other integral by its positive and negative bounds and then to let Γ move to P by parallel translation. Referring to Fig. 6, we choose α_1 and α_2 in $\left(2\alpha - \frac{\pi}{2}, \frac{\pi}{2}\right)$ such that

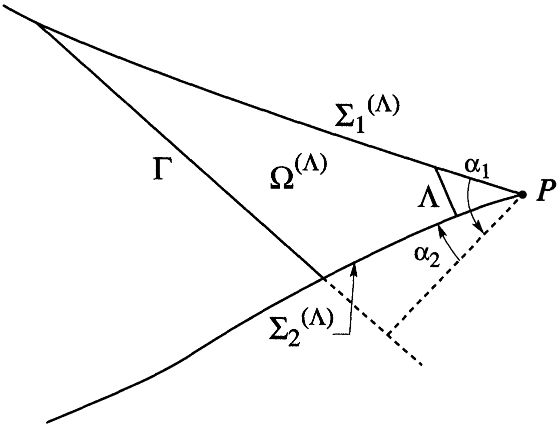

FIG. 6. *Configuration for Theorem 2. Note that* $\alpha_1 > 0$, $\alpha_2 < 0$; *both are in the range* $(2\alpha - \frac{\pi}{2}, \frac{\pi}{2})$.

$\alpha_1 + \alpha_2 = 2\alpha$. Since the area term in (11) tends to zero faster than any of the lengths and since Σ_1 and Σ_2 are asymptotically linear, we are led to the inequality

$$\left|\frac{\cos\gamma_1}{\cos\alpha_1} + \frac{\cos\gamma_2}{\cos\alpha_2}\right| \le \tan\alpha_1 + \tan\alpha_2$$

as a necessary condition for existence of a solution. Setting $A_1 = \cos\alpha_1$, $A_2 = \cos\alpha_2$ and introducing B_1, B_2 as above, we are led to

LEMMA 1. *If* α_1, α_2 *are as above and* $|B_2A_1 + B_1A_2| > \sin 2\alpha$ *then there is no solution to the problem, regardless of growth conditions at* P.

Clearly the conditions of Lemma 1 cannot be satisfied when (B_1, B_2) is interior to $\mathcal{E}$, as Theorem 1 would then imply existence of a solution. We ask whether the conditions are necessarily satisfied for points exterior to $\mathcal{E}$. In formal terms, we have the

QUESTION. *Given* (B_1, B_2) *disjoint from* $\mathcal{E}$, *do there exist* α_1 *and* α_2 *in* $\left(2\alpha - \frac{\pi}{2}, \frac{\pi}{2}\right)$ *such that* $\alpha_1 + \alpha_2 = 2\alpha$ *and* $|B_2A_1 + B_1A_2| > \sin 2\alpha$?

To answer the question, we first prove the following lemma.

LEMMA 2. *For* α_1 *and* α_2 *in* $(-\frac{\pi}{2}, \frac{\pi}{2})$, *the constraint* $\alpha_1 + \alpha_2 = 2\alpha$ *implies the relation*

$$A_1^2 + A_2^2 - 2A_1A_2\cos 2\alpha = \sin^2 2\alpha; \quad A_1, A_2 > 0 \tag{12}$$

describing that portion of an elliptical arc $\mathcal{F}$ *partly inscribed in a unit square in the* (A_1, A_2) *plane, that lies in the first quadrant* (*see Fig.* 7). *Conversely, whenever* (12) *holds there is a unique pair* α_1, α_2 (*up to permutation*) *such that* $\alpha_1 + \alpha_2 = 2\alpha$ *and* α_1 *and* α_2 *are in* $\left(2\alpha - \frac{\pi}{2}, \frac{\pi}{2}\right)$.

Proof. From $\alpha_1 + \alpha_2 = 2\alpha$, we find $A_1A_2 - \cos 2\alpha = \pm\sqrt{1 - A_1^2}\sqrt{1 - A_2^2}$, from which (12) follows on squaring both sides. Conversely, if (12) holds, it can be rewritten in the form just indicated. Choosing $\alpha_1 = \cos^{-1}(A_1)$ and $\alpha_2 = \cos^{-1}(A_2)$ in $[0, \pi/2)$, we find $\cos(\alpha_1 \pm \alpha_2) = \cos 2\alpha$, from which $\alpha_1 \pm \alpha_2 = \pm 2\alpha$. By changing the signs of α_1 or α_2 or both, we can arrange to have $\alpha_1 + \alpha_2 = 2\alpha$, with α_1 and α_2 in $(-\frac{\pi}{2}, \frac{\pi}{2})$. If $\alpha_1 < 2\alpha - \frac{\pi}{2}$ or $\alpha_2 < 2\alpha - \frac{\pi}{2}$, then $\alpha_1 + \alpha_2 < 2\alpha$. This contradiction completes the proof. □

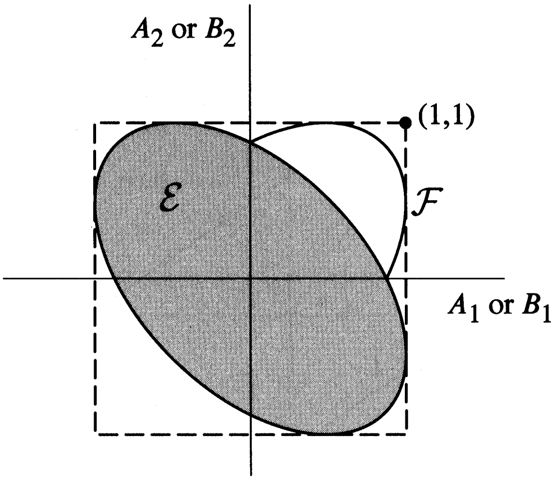

FIG. 7. *Elliptical domain $\mathcal{E}$, elliptical constraint arc $\mathcal{F}$; case $2\alpha < \frac{\pi}{2}$.*

We set

$$A_1 = \frac{x}{\cos\alpha} + \frac{y}{\sin\alpha}, \qquad A_2 = \frac{-x}{\cos\alpha} + \frac{y}{\sin\alpha}, \tag{13}$$

transforming the elliptical arc (12) into a circular arc $\mathcal{C}$ centered at the origin, of radius $R = \sin\alpha\cos\alpha$, and restricted to the upper sector between the lines

$$y = \pm x \tan\alpha \tag{14}$$

(see Fig. 8). The two lines L_1 and L_2 determined by $B_2A_1 + B_1A_2 = \pm\sin 2\alpha$ now become

$$\frac{B_1 - B_2}{\cos\alpha}x + \frac{B_1 + B_2}{\sin\alpha}y = \pm\sin 2\alpha. \tag{15}$$

The inequality $|B_2A_1 + B_1A_2| > \sin 2\alpha$ holds if and only if (x, y) lies outside the strip $\mathcal{W}$ bounded by the lines, and each line has distance

$$d = \frac{\sin^2 2\alpha}{2\sqrt{B_1^2 + B_2^2 + 2B_1B_2\cos 2\alpha}} \tag{16}$$

from the origin. When (B_1, B_2) is exterior to $\mathcal{E}$, we find

$$d < \sin\alpha\cos\alpha = R. \tag{17}$$

Despite the inequality in this last result, it can happen that $\mathcal{C}$ lies strictly interior to $\mathcal{W}$, as $\mathcal{C}$ contains only a portion of the full circle. In such a case, the method yields no information. But it can also occur that interior points of $\mathcal{C}$ lie exterior to $\mathcal{W}$; whenever that happens, any such point of $\mathcal{C}$ yields by Lemma 2 a suitable pair α_1, α_2 and excludes the possibility of any solution to the original problem. We summarize what we have found in the following theorem.

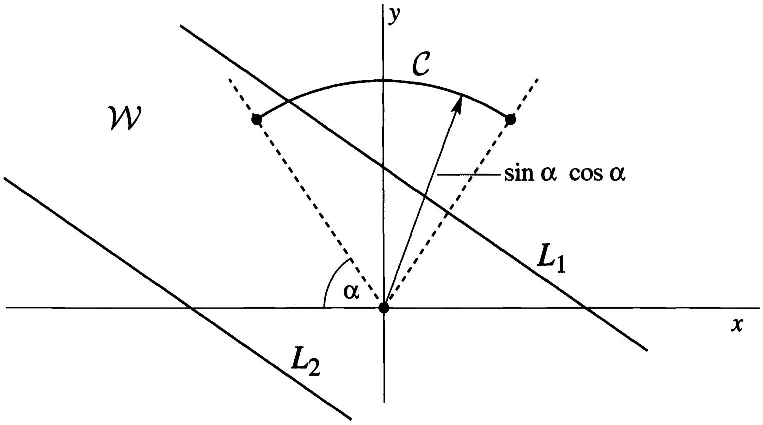

FIG. 8. *Normalized configuration* (*tentative*); *reference lines.*

THEOREM 2. *If C contains points exterior to the closed strip W determined by* (15), *then there is no solution of* (1)–(3) *in any neighborhood Ω^* of P in Ω, for any constant H; this result holds without growth condition at P. If C lies interior to W, then the method provides no information.*

The final statement of the theorem does not reflect a technical failure of the method, but rather arises from actual properties of the solutions. This will be apparent from the second of the following examples.

5. Four examples.

Example 1. Σ_1 and Σ_2 are linear, $\gamma_1 = \gamma_2 = \gamma$ (equivalently, $B_1 = B_2 = B$). Then (15) becomes the pair of horizontal lines $y = \pm(\sin^2\alpha\cos\alpha)/B$. The arc C is independent of B and is indicated in Fig. 9. If (B, B) is exterior to $\mathcal{E}$ then one of the lines crosses C as indicated and points of C will lie exterior to W; hence by Theorem 2 no solution can exist. If (B, B) is in the closure of $\mathcal{E}$ then C lies in the closed strip and Theorem 2 yields no information. However in this case we clearly have $|B_1 - B_2| < 2\cos^2\alpha$ and hence, by Theorem 1, a solution with continuous normal exists. Since (B, B) is exterior to $\mathcal{E}$ if and only if $\alpha < \left|\frac{\pi}{2} - \gamma\right|$ we retrieve exactly our earlier result for the constant angle case, from a more general point of view.

Example 2. Σ_1 and Σ_2 are linear, $\gamma_1 = \pi - \gamma_2 \neq \frac{\pi}{2}(B_1 = -B_2 = B \neq 0)$. Now C is as before, but (15) now yields the two vertical lines $Bx = \pm\sin\alpha\cos^2\alpha$. Since $|B| \leq 1$, C *always* lies interior to W, and thus Theorem 2 yields no information.

If in addition $B > \cos\alpha$, then $(B, -B)$ is exterior to $\mathcal{E}$, and according to Theorem 1 no solution with continuous normal can exist. Nevertheless, a solution to the original problem without growth hypotheses can exist, at least in a significant family of cases. Examples with $B = 1$ and any α are provided by the "moonies", whose existence is proved in [11]. These surfaces have $\gamma_1 = 0$ and $\gamma_2 = \pi$ on adjacent circular arcs of differing radius, see Fig. 10. Theorem 1 provides a new proof independent of the one given in [11], that these surfaces have discontinuous normals at P.

The existence proof in [11] can be modified without essential change to show that if the data $\gamma = 0$ and $\gamma = \pi$ are modified to γ and $\pi - \gamma$, with $0 \leq \gamma \leq \frac{\pi}{2}$, then a solution exists in the identical domain. Thus we obtain a solution of the problem just formulated for any B with $0 \leq B \leq 1$; these solutions have normal vectors discontinuous at P if $B > \cos\alpha$. It can be shown that, if $B < 1$, then the surface is bounded above and below in Ω; if $B = 1$, then $u(x, y) \to -\infty$ for any approach to the

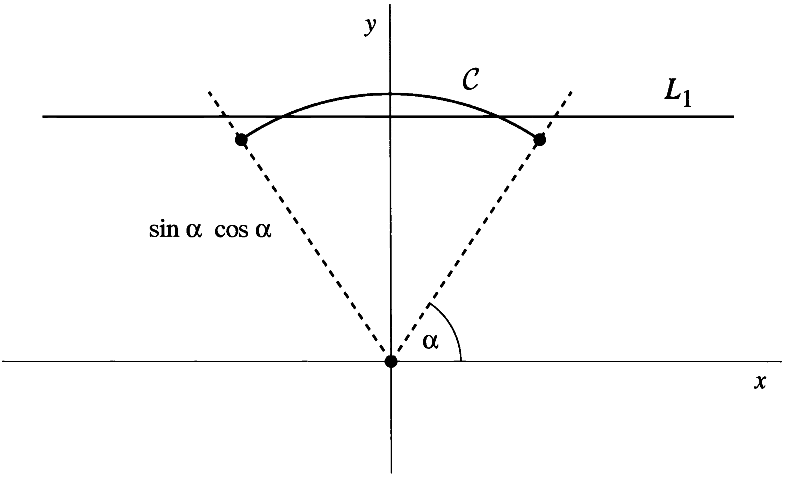

FIG. 9. *Configuration for Example* 1.

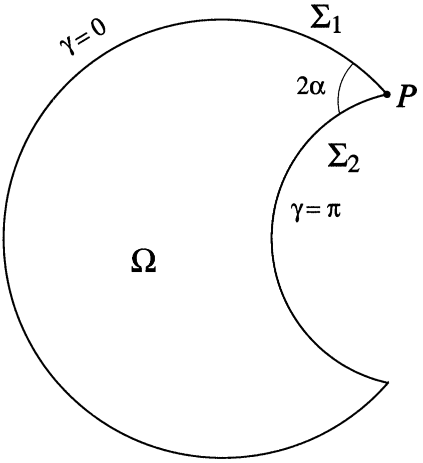

FIG. 10. *Domain for moonie.*

smaller circle, but remains bounded above and below on the larger one.

Thus, in a configuration with differing contact angles, solutions may appear whose behavior at P is very different from that which can occur in the equal angle case. These solutions could not have been obtained by the procedures used for Theorem 1. □

We observe that if $B_1 = -B_2$, then according to Theorem 1 solutions that are smooth up to P can be obtained with successively larger values of $|B|$ tending to unity, as the opening angle 2α closes down to zero. This is despite the discontinuity that occurs when $|B| > \cos\alpha$, and in contrast with the equal angle case, where the admissible B necessarily become small in magnitude with α.

Example 3. Σ_1 and Σ_2 are linear, $B_1 = B$, $B_2 = 0$, $\alpha < \frac{\pi}{4}$. We obtain once more the same $\mathcal{C}$, but (15) yields the sloping lines

$$\frac{B}{\cos\alpha}x + \frac{B}{\sin\alpha}y = \pm\sin 2\alpha.$$

These two lines will enclose $\mathcal{C}$ if and only if $|B| \le \sin 2\alpha$ (see Fig. 11). This is exactly the condition that $(B, 0)$ should be in the closure of $\mathcal{E}$ and also that $|B_1 - B_2| < 2\cos^2\alpha$

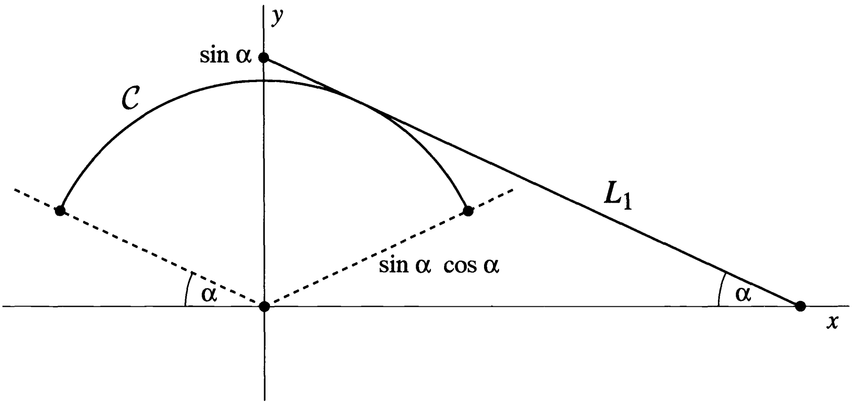

FIG. 11. *Configuration for Example* 3; $|B| = \sin 2\alpha$.

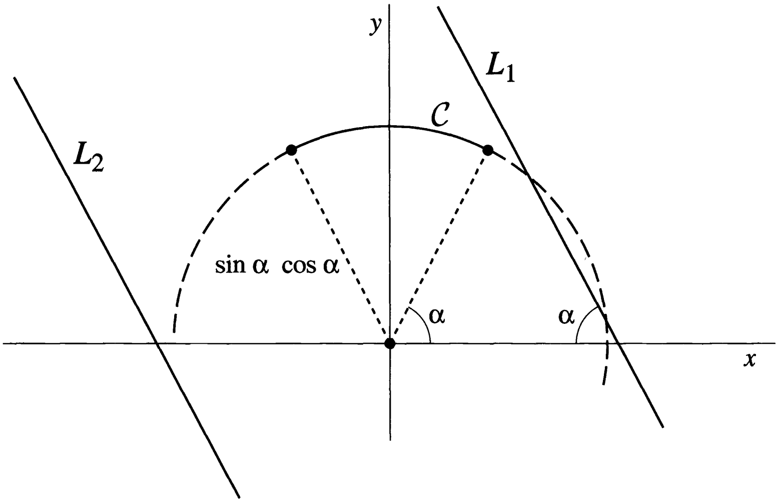

FIG. 12. *Configuration for Example* 4.

(in the given range of α). Thus, by Theorems 1 and 2, there is a solution if and only if $|B| \leq \sin 2\alpha$, and in this case, a solution can be found with continuous normal up to P.

This configuration connects naturally with the equal angle case, as any solution can be reflected across Σ_2 to obtain a solution with equal angles on the edges of a wedge of opening 4α, and conversely, every symmetric solution in such a wedge yields a solution for the given data $(B, 0)$ in the half angle. But the existence criterion for the equal angle problem is $2\alpha \geq \left|\frac{\pi}{2} - \gamma\right|$, which is equivalent to $|B| \leq \sin 2\alpha$. Thus, we obtain once more (as in Example 1) the existence theorem for the equal angle case from a more general point of view.

Example 4. Σ_1 and Σ_2 are linear, $B_1 = B$, $B_2 = 0$, $\frac{\pi}{4} < \alpha < \frac{\pi}{2}$. In this case, even though the lines L_1 and L_2 cut through the completed circle containing $\mathcal{C}$, the arc $\mathcal{C}$ itself lies between the lines (see Fig. 12), and thus Theorem 2 yields no information. If $|B| < \sin 2\alpha$, then Theorem 1 still guarantees the existence of a solution smooth to P. But in this case, $\sin 2\alpha > 2\cos^2 \alpha$, and hence we can no longer be assured of existence of solutions corresponding to data points on the boundary of $\mathcal{E}$.

If $B > \sin 2\alpha$, then Theorem 2 yields no information while Theorem 1 guarantees that no smooth solution can exist. As in Example 3, any solution would yield a solution of the constant angle problem in a wedge of opening 4α. For such a case, for which $4\alpha > \pi$, Korevaar [14] has shown the existence in a gravity field of solutions that are bounded but discontinuous at the vertex. Computations we have made [15] indicate that jump discontinuities can occur in the absence of gravity for values $\left|\frac{\pi}{2} - \gamma\right|$ that exceed a critical one, depending on α and on the global geometry. In a forthcoming work, Lancaster and Siegel [16] characterize the local qualitative behavior of the solutions at such points. □

It should be observed that not only can discontinuities appear at reentrant corners with constant data as above; discontinuities occasioned by abruptly changing data can occur for smooth boundaries, at least in the presence of gravity fields; an example is given on p. 15 of [17].

6. Other properties. We note that in all the above examples, the endpoints of $\mathcal{C}$ lie interior to the closed strip determined by L_1 and L_2. This behavior is in fact quite general.

LEMMA 3. *Let L_1 and L_2 be determined, respectively, by the plus and minus signs in* (15). *Then the right-hand endpoint of $\mathcal{C}$ lies on L_1 if and only if $B_1 = 1$; it lies on L_2 if and only if $B_1 = -1$. The left-hand endpoint of $\mathcal{C}$ lies on L_1 if and only if $B_2 = 1$; it lies on L_2 if and only if $B_2 = -1$. Both endpoints lie always interior to the closed strip $\mathcal{W}$.*

Proof. Setting

$$F(x,y) = \frac{B_1 - B_2}{\cos\alpha}x + \frac{B_1 + B_2}{\sin\alpha}y - \sin 2\alpha,$$

$$G(x,y) = \frac{B_1 - B_2}{\cos\alpha}x + \frac{B_1 + B_2}{\sin\alpha}y + \sin 2\alpha,$$

the lines L_1 and L_2 are characterized, respectively, by $F(x,y) = 0$ and by $G(x,y) = 0$. Choosing for x, y the coordinates of the right-hand endpoint of $\mathcal{C}$, we find $F(x,y) = (B_1 - 1)\sin 2\alpha$, $G(x,y) = (B_1 + 1)\sin 2\alpha$. This proves the assertions relating to B_1; those relating to B_2 are proved analogously. The same relations show that if $|B_1| < 1$, then the right-hand endpoint of $\mathcal{C}$ lies strictly between the two lines; similarly, the left-hand endpoint lies between the lines when $|B_2| < 1$. □

As a consequence of Lemma 3, we see that *the configuration indicated in* Fig. 8, *which was drawn to be indicative of a general situation, cannot occur as shown, as one of the endpoints of $\mathcal{C}$ lies exterior to the strip in that configuration.*

Referring to Fig. 2, we introduce $\mathcal{D}_1^+, \mathcal{D}_1^-, \mathcal{D}_2^+$, and $\mathcal{D}_2^-$ as in that figure. We adjoin to these domains all the boundary points that lie on the boundary of the square. On the line segment $B_1 = B_2 = B > 0$, L_1 takes the form $y = (\sin^2\alpha\cos\alpha)/B$, a horizontal line that is tangent to $\mathcal{C}$ at its midpoint when (B, B) is on the boundary of $\mathcal{E}$, and cuts through $\mathcal{C}$ when (B, B) lies exterior to $\mathcal{E}$, as in Fig. 9. Thus, according to Theorem 2, the wedge problem admits no solution corresponding to the segment $1 \geq B > \sin\alpha$ (cf., Example 1). We now allow (B_1, B_2) to move along the arc of $\partial\mathcal{E}$ between the two nearest contact points with the square. According to (16), the distance of L_1 to the origin remains unchanged, and thus we obtain a family of lines tangent to the circle on which $\mathcal{C}$ lies. Since $|B_1| < 1$ and $|B_2| < 1$ interior to the arc of $\partial\mathcal{E}$ considered, we find by Lemma 3 that all corresponding contact points with the circle actually lie interior to $\mathcal{C}$. Again by Lemma 3, as the points on $\partial\mathcal{E}$ move to the contact points with the square, L_1 becomes tangent to $\mathcal{C}$ at the respective endpoints; thus, all of $\mathcal{C}$ is covered. It is easy to see that the covering is 1−1.

Through each of the considered points of $\partial\mathcal{E}$, we construct the extended line segment from the origin. Repeating the reasoning given above for the $B_1 = B_2 > 0$ configuration, we find that, for all points of that line segment exterior to $\mathcal{E}$, there exists no solution to the wedge problem. Since these lines sweep out $\mathcal{D}_1^+$, there can be no solution for any point of $\mathcal{D}_1^+$. An identical reasoning excludes solutions for any point of $\mathcal{D}_1^-$.

We now consider the two remaining complementary domains $\mathcal{D}_2^+$ and $\mathcal{D}_2^-$, which have $(1,-1)$ and $(-1,1)$ as boundary points. In Example 2 above, we have shown the existence of solutions for every point on the line segment $-1 \le B_1 = -B_2 \le 1$; thus $\mathcal{C}$ lies between L_1 and L_2 for all points on that segment (see Fig. 12). These solution surfaces have discontinuous normals at P for all points exterior to $\mathcal{E}$. Essentially, a repetition of the reasoning directly above shows that $\mathcal{C}$ lies between L_1 and L_2 for all points of $\mathcal{D}_2^+$ and of $\mathcal{D}_2^-$. We have proved the following theorem.

THEOREM 3. *For any points (B_1, B_2) in the domains $\mathcal{D}_1^+$ and $\mathcal{D}_1^-$ defined above, there are points of $\mathcal{C}$ exterior to the strip $\mathcal{W}$, and hence there exists no solution to the wedge problem* (1)–(3) *in any neighborhood of the vertex P, for any constant H. In $\mathcal{D}_2^+$ and $\mathcal{D}_2^-$, $\mathcal{C}$ lies interior to $\mathcal{W}$; solutions do exist, at least on the symmetry line $B_1 = -B_2$ of those domains. For all points of that line exterior to $\mathcal{E}$, the unit normals to the solution surfaces are discontinuous at P.*

For all interior points of $\mathcal{E}$ and any H, solutions exist and all such solutions are smooth up to P. We conjecture that for any α in the range $0 < \alpha < \frac{\pi}{2}$ considered, there exist wedge domains for which solutions (with discontinuous normal) exist for all (B_1, B_2) lying in $\mathcal{D}_2^+$ or in $\mathcal{D}_2^-$.

We close with the following theorem.

THEOREM 4. *Whenever a bounded solution exists in a wedge domain, then every solution is bounded.*

This is an immediate formal consequence of the general comparison principle for capillary surfaces; see [17, §2] or [4, Chap. 5]. Unbounded solutions can occur, as in the "moonie" example above. In such a case, every solution is unbounded.

Acknowledgment. We wish to thank Erich Miersemann for helpful discussions.

GLOBAL EXISTENCE OF SOLUTIONS FOR THE SYSTEM OF COMPRESSIBLE ADIABATIC FLOW THROUGH POROUS MEDIA*

L. HSIAO[†] AND D. SERRE[‡]

Abstract. Consider the quasilinear hyperbolic system

$$(1)\qquad \begin{cases} v_t - u_x = 0, \\ u_t + p(v,s)_x = -\alpha u, \quad \alpha > 0, \quad p_v < 0 \text{ for } v > 0, \\ s_t = 0 \end{cases}$$

with initial data

$$(2)\qquad u(x,0) = u_0(x), \quad v(x,0) = \bar{v} + v_o(x), \quad s(x,0) = \bar{s} + s_0(x),$$

where $\bar{v} > 0, \bar{v}$ and $\bar{s}$ are constants, $(u_0(x), v_0(x)) \in C^1$ with a compact support, and $s_0(x) \in C^2$ with a compact support.

It is proved in this paper that there exists a globally defined classical solution for the Cauchy problem if the C^1-norm of $(u_0(x), v_0(x))$ and the C^2-norm of $s_0(x)$ are small.

Key words. global existence, the system of compressible adiabatic flow, damping dissipation, L_2-estimates, L_∞-esitmates.

AMS subject classifications. 35, 76

1. Introduction.

Consider the system

$$(1.1)\qquad \begin{cases} v_t - u_x = 0, \\ u_t + p(v,s)_x = -\alpha u, \\ s_t = 0, \end{cases}$$

which can be used to model the adiabatic gas flow through a porous medium, where v denotes the specific volume, u denotes the velocity, s denotes the entropy, and p denotes the pressure, with $p_v < 0$ for $v > 0$. This system is strictly hyperbolic, with eigenvalues $\lambda_1 = -\sqrt{-p_v}$, $\lambda_2 \equiv 0$, and $\lambda_3 = \sqrt{-p_v}$.

For the case $\alpha = 0$, namely

$$(1.2)\qquad \begin{cases} v_t - u_x = 0, \\ u_t + p(v,s)_x = 0, \\ s_t = 0, \end{cases}$$

there is no globally defined classical solution, in general. In fact, consider the initial data

$$(1.3)\qquad u(x,0) = \varepsilon u_0(x), \quad v(x,0) = \overline{v} + \varepsilon v_0(x), \quad s(x,0) = \varepsilon s_0(x)$$

such that $\overline{v}$ is a positive constant, and $(u_0(x), v_0(x), s_0(x)) \in C^1$ with a compact support. It is shown in [LI] and [LZ] that there exists a small $\varepsilon_0 > 0$ such that for any $\varepsilon : 0 < \varepsilon \leq \varepsilon_0$, the C^1 solution of this Cauchy problem blows up at a finite time and the life span is $\tilde{T}(\varepsilon) = O(\varepsilon^{-1})$.

For system (1.1) with a damping term, however, the situation is different. Consider any initial data

$$u(x,0)=u_0(x), v(x,0)=\overline{v}+v_0(x), s(x,0)=\overline{s}+s_0(x), \tag{1.4}$$

where $\overline{v}>0, \overline{v}$ and $\overline{s}$ are constants, $(u_0(x),v_0(x))\in C^1$ with a compact support, and $s_0(x)\in C^2$ with a compact support. We prove that there exists a globally defined classical solution for the Cauchy problem if the C^1-norm of $(u_0(x),v_0(x))$ and the C^2-norm of $s_0(x)$ are small. This means that the damping dissipation is strong enough to preserve the smoothness of the initial data when it is small.

Another concern is the influence of the damping mechanism on the large-time behavior of solutions. For the case of isentropic flow, namely $s(x,t)\equiv$ constant, it has been proven [HL] that the solution of the Cauchy problem

$$\begin{cases} v_t-u_x=0, \\ u_t+p(v)_x=-\alpha u, \quad \alpha>0, \quad p'(v)<0 \quad \text{for } v>0, \\ v(x,0)=v_0(x), \qquad u(x,0)=u_0(x) \text{ with } \lim\limits_{x\to\mp\infty}(v_0(x),u_0(x))=(v^{\mp},u^{\mp}) \end{cases} \tag{1.5}$$

can be described by the solution of the problem

$$\begin{cases} v_t=-\frac{1}{\alpha}p(v)_{xx}, \\ u=-\frac{1}{\alpha}p(v)_x, \\ v(x,0)=\tilde{v}_0(x) \quad \text{with} \quad \lim\limits_{x\to\mp\infty}\tilde{v}_0(x)=v^{\mp} \end{cases} \tag{1.6}$$

time asymptotically. The system in (1.6) is obtained from (1.5) by approximating the momentum equation in $(1.5)_2$ with Darcy's law. Moreover, the L_2-norm and L_∞-norm of the difference between these two solutions tend to zero with a rate $t^{-\frac{1}{2}}$ as time t tends to infinity [HL]. This shows that certain nonlinear diffusive phenomena occur for the solution of (1.5), which is caused by the damping mechanism.

For system (1.1), the corresponding simplified system takes the form

$$\begin{cases} v_t=-\frac{1}{\alpha}p(v,s)_{xx}, \\ u=-\frac{1}{\alpha}p(v,s)_x, \\ s=s(x)=\overline{s}+s_0(x). \end{cases} \tag{1.7}$$

Consider the initial data

$$v(x,0)=\overline{v}+\tilde{v}_0(x), \qquad \tilde{v}_0\in C^1 \text{ with a compact support.} \tag{1.8}$$

It is expected that the large-time behavior of the solution for (1.1) and (1.4) can be described by the solution of (1.7) and (1.8). This is discussed in [HS].

The global existence result in this paper is established by the L_2-estimates for the solutions and L_∞-estimates on the first derivatives, which are given in the second section. The third section is devoted to the global existence theorem.

2. The a priori estimates. Denote $c=(-p_v(v,s))^{\frac{1}{2}}$. Let

$$\begin{cases} w=u-h(v,s), \\ z=u+h(v,s), \end{cases} \tag{2.1}$$

where $h(v,s)$ satisfies the equation

$$ch_v-p_v=0. \tag{2.2}$$

Then system (1.1) can be written as

$$(2.3)\qquad \begin{cases} w_t - cw_x = -\frac{\alpha}{2}(z+w) + (ch_s - p_s)s_x, \\ z_t + cz_x = -\frac{\alpha}{2}(z+w) + (ch_s - p_s)s_x, \\ s_t = 0, \end{cases}$$

which is equivalent to (1.1) for classical solutions.

For the system of gas dynamics,

$$(2.4)\qquad p(v,s) = (\gamma - 1)v^{-\gamma}e^s (1 < \gamma < 3),$$

and it is easy to find that

$$h(v,s) = 2\sqrt{\frac{\gamma}{\gamma-1}}v^{\frac{1-\gamma}{2}} \cdot e^{\frac{s}{2}}$$

and

$$ch_s - p_s = v^{-\gamma}e^s.$$

Thus, system (2.3) takes the form

$$(2.5)\qquad \begin{cases} D^- w = -\frac{\alpha}{2}(z+w) + f(z-w,s,s_x), \\ D^+ z = -\frac{\alpha}{2}(z+w) + f(z-w,s,s_x), \\ s(t,x) = s(0,x), \end{cases}$$

where

$$D^- = \partial_t - c\partial_x, \quad D^+ = \partial_t + c\partial_x,$$

$$f(z-w,s,s_x) = A(\gamma)(z-w)^{\frac{2\gamma}{\gamma-1}} \cdot e^{\frac{-s}{\gamma-1}} \cdot s_x,$$

$$c(z-w,s) = B(\gamma) \cdot e^{\frac{-s}{\gamma-1}} \cdot (z-w)^{\frac{\gamma+1}{\gamma-1}},$$

$$A(\gamma) = \left(\frac{\gamma-1}{16\gamma}\right)^{\frac{\gamma}{\gamma-1}},$$

$$B(\gamma) = \sqrt{\gamma(\gamma-1)} \cdot \left(\frac{\gamma-1}{16\gamma}\right)^{\frac{\gamma+1}{2(\gamma-1)}}.$$

For simplicity, we will only discuss system (1.1) for gas dynamics from now on.

Introduce $g(z-w,s,s_x) = g_1(z-w,s) + g_2(z-w,s)s_x$, in which g_1 and g_2 are chosen so that

$$g'_1 = -\frac{\alpha}{4}c^{-\frac{1}{2}},$$

$$g'_2 = -\frac{1}{4(\gamma-1)}c^{\frac{1}{2}},$$

where g'_i denotes $\frac{\partial g_i}{\partial(z-w)} (i = 1,2)$ (let us recall that c may be viewed as a function of $z - w$ only).

We may choose

$$(2.6)\qquad g_1(z-w,s) = \frac{\alpha(\gamma-1)}{2(3-\gamma)}[B(\gamma)]^{-\frac{1}{2}} e^{\frac{s}{2(\gamma-1)}} \cdot (z-w)^{\frac{\gamma-3}{2(\gamma-1)}},$$

$$(2.7)\qquad g_2(z-w,s) = \frac{-1}{2(3\gamma-1)}[B(\gamma)]^{-\frac{1}{2}} e^{\frac{-s}{2(\gamma-1)}} \cdot (z-w)^{\frac{3\gamma-1}{2(\gamma-1)}}.$$

Then it can be shown that

$$D^+[c^{\frac{1}{2}}z_x+g]=-l[c^{\frac{1}{2}}z_x+g]^2+m_F[c^{\frac{1}{2}}z_x+g]-G_F, \tag{2.8}$$

$$D^-[c^{\frac{1}{2}}w_x+g]=-l[c^{\frac{1}{2}}w_x+g]^2+m_B[c^{\frac{1}{2}}w_x+g]-G_B, \tag{2.9}$$

where

$$\begin{aligned}
&l(z-w,s)=c^{-\frac{1}{2}}\cdot c'\\
&m_F(z-w,s,s_x)=-\tfrac{\alpha}{2}+2g\cdot c^{-\frac{1}{2}}c'+\frac{cs_x}{\gamma-1},\\
&m_B(z-w,s,s_x)=-\tfrac{\alpha}{2}+2g\cdot c^{-\frac{1}{2}}c'-\frac{cs_x}{\gamma-1},\\
&G_F(z-w,s,s_x,s_{xx})=n(z-w,s)+Q_{1F}(z-w,s)s_x\\
&\qquad\qquad +Q_{2F}(z-w,s)s_x^2+Q_{3F}(z-w,s)s_{xx},\\
&G_B(z-w,s,s_x,s_{xx})=n(z-w,s)+Q_{1B}(z-w,s)s_x\\
&\qquad\qquad +Q_{2B}(z-w,s)s_x^2+Q_{3B}(z-w,s)s_{xx},\\
&n(z-w,s)=\frac{\alpha(\gamma-1)}{3-\gamma}g_1(z-w,s),\\
&Q_{1F}(z-w,s)=2g_1g_2\cdot c^{-\frac{1}{2}}c'-\tfrac{\alpha}{2}g_2+\frac{c}{2(\gamma-1)}g_1,\\
&Q_{1B}(z-w,s)=2g_1g_2\cdot c^{-\frac{1}{2}}c'-\tfrac{\alpha}{2}g_2-\frac{c}{2(\gamma-1)}g_1,\\
&Q_{2F}(z-w,s)=-g_{2s}c+\frac{(z-w)}{4\gamma(\gamma-1)}c^{\frac{3}{2}}+g_2\left[g_2\cdot c^{-\frac{1}{2}}c'+\frac{c}{\gamma-1}\right],\\
&Q_{2B}(z-w,s)=g_{2s}c+\frac{(z-w)}{4\gamma(\gamma-1)}c^{\frac{3}{2}}+g_2\left[g_2\cdot c^{-\frac{1}{2}}c'-\frac{c}{\gamma-1}\right],\\
&Q_{3F}(z-w,s)=-g_2c-\frac{(z-w)}{4\gamma}\cdot c^{\frac{3}{2}},\\
&Q_{3B}(z-w,s)=g_2c-\frac{(z-w)}{4\gamma}\cdot c^{\frac{3}{2}}.
\end{aligned}$$

Furthermore, it can be shown that

$$m_F^2-4lG_F=\frac{\alpha^2}{4}+c_{1F}(z-w,s)s_x+c_{2F}(z-w,s)s_x^2+c_{3F}(z-w,s)s_{xx}, \tag{2.10}$$

$$m_B^2-4lG_B=\frac{\alpha^2}{4}+c_{1B}(z-w,s)s_x+c_{2B}(z-w,s)s_x^2+c_{3B}(z-w,s)s_{xx}, \tag{2.11}$$

where

$$c_{1F}(z-w,s)=\frac{2\alpha}{3-\gamma}c-\frac{2\alpha(\gamma+1)}{(3-\gamma)g_1}\cdot Q_{1F},$$

$$c_{2F}(z-w,s)=\frac{4c^2}{(3\gamma-1)^2}-\frac{2\alpha(\gamma+1)}{(3-\gamma)g_1}\cdot Q_{2F},$$

$$c_{3F}(z-w,s)=-\frac{2\alpha(\gamma+1)}{(3-\gamma)g_1}\cdot Q_{3F},$$

$$c_{1B}(z-w,s) = -\frac{4\alpha\gamma}{(3-\gamma)(\gamma-1)}c - \frac{2\alpha(\gamma+1)}{(3-\gamma)g_1}Q_{1B},$$

$$c_{2B}(z-w,s) = \frac{16\gamma^2c^2}{(3\gamma-1)^2(\gamma-1)^2} - \frac{2\alpha(\gamma+1)}{(3-\gamma)g_1} \cdot Q_{2B},$$

$$c_{3B}(z-w,s) = -\frac{2\alpha(\gamma+1)}{(3-\gamma)g_1} \cdot Q_{3B}.$$

It is easy to see that $l(z-w,s) > 0$ for $z-w>0$. Moreover, $m_F^2 - 4lG_F > 0$ and $m_B^2 - 4lG_B > 0$ if $|s_x|$ and $|s_{xx}|$ are small.

Denote $c^{\frac{1}{2}}z_x + g = y$. (2.8) implies that

$$D^+[y] = -l(y-y_1)(y-y_2), \tag{2.12}$$

where

$$y_1 = \frac{(3-\gamma)}{\alpha(\gamma+1)}g_1\{m_F - \sqrt{m_F^2 - 4lG_F}\},$$
$$y_2 = \frac{(3-\gamma)}{\alpha(\gamma+1)}g_1\{m_F + \sqrt{m_F^2 - 4lG_F}\}.$$

Similarly, denote $c^{\frac{1}{2}}w_x + g = Y$. (2.9) implies that

$$D^-[Y] = -l(Y-Y_1)(Y-Y_2), \tag{2.13}$$

where

$$Y_1 = \frac{(3-\gamma)}{\alpha(\gamma+1)}g_1 \cdot \{m_B - \sqrt{m_B^2 - 4lG_B}\},$$
$$Y_2 = \frac{(3-\gamma)}{\alpha(\gamma+1)}g_1 \cdot \{m_B + \sqrt{m_B^2 - 4lG_B}\}.$$

Define

$$D = \{(z,w,s) : a_1 h(\bar{v},\bar{s}) < z-w < a_2 h(\bar{v},\bar{s}), |s-\bar{s}| < 1,$$
$$0 < a_1 < 2 < a_2 < +\infty,\ a_i \text{ is a constant, } i=1,2\},$$

where a_1 and a_2 are chosen so close to 2 such that for a given constant $b : \frac{1}{4} \le b < \frac{1}{2}$, it holds that

$$\sup_D g_1 < \frac{(1+b)\gamma + (1-3b)}{(2-b)\gamma - (2-3b)} \inf_D g_1. \tag{2.14}$$

Thus, it can be shown with a careful calculation that there exists a positive constant δ_1 depending only on D, b, α, and γ such that if, for any $x \in R$,

$$|s'_0(x)| \le \delta_1, \quad |s''_0(x)| \le \delta_1,$$

then it holds that

$$\sup_D y_1 < \inf_D y_2, \tag{2.15}$$

$$\sup_D Y_1 < \inf_D Y_2. \tag{2.16}$$

Furthermore, it can be claimed, with the help of (2.14) and the range of b, that there exist positive constants ε_0 and δ_2, depending only on D, b, α, and γ, such that if, for any $x \in R$,

$$|u'{}_0(x)| \le \varepsilon_0, \qquad |v'{}_0(x)| \le \varepsilon_0, \qquad |s'{}_0(x)| \le \delta_2, \qquad |s''{}_0(x)| \le \delta_2,$$

then it holds that, for any $x \in R$,

$$\begin{aligned} y(x,0) &> \sup_D y_1, \\ Y(x,0) &> \sup_D Y_1, \end{aligned} \tag{2.17}$$

provided $(z, w, s)(x, 0) \in D$.

In view of (2.12)–(2.17), it is not difficult to prove the following lemma.

LEMMA 2.1. *Suppose that the solution of* (1.1) *and* (1.4) *defined for* $0 \le t \le T$ *satisfies* $(z, w, s) \in D$. *Then the following estimates hold if*

$$\begin{aligned} &|u'{}_0(x)| \le \varepsilon_0, \quad |v'{}_0(x)| \le \varepsilon_0, \\ &|s'{}_0(x)| \le \delta_3, \quad |s''{}_0(x)| \le \delta_3, \end{aligned}$$

where $\delta_3 = \min\{\delta_1, \delta_2\}$.

For any $(t, x) \in [0, T] \times R$,

$$\begin{aligned} &\min\left\{ (c^{\frac{1}{2}} z_x + g)(0, x_3(0;t,x)), \inf_{\substack{x_3(\tau;t,x) \\ 0 \le \tau \le t}} y_2 \right\} \\ &\le \quad (c^{\frac{1}{2}} z_x + g)(t,x) \le \max\left\{ (c^{\frac{1}{2}} z_x + g)(0, x_3(0;t,x)), \sup_{\substack{x_3(\tau;t,x) \\ 0 \le \tau \le t}} y_2 \right\}, \\ &\min\left\{ (c^{\frac{1}{2}} w_x + g)(0, x_1(0;t,x)), \inf_{\substack{x_1(\tau;t,x) \\ 0 \le \tau \le t}} Y_2 \right\} \\ &\le \quad (c^{\frac{1}{2}} w_x + g)(t,x) \le \max\left\{ (c^{\frac{1}{2}} w_x + g)(0, x_1(0;t,x)), \sup_{\substack{x_1(\tau;t,x) \\ 0 \le \tau \le t}} Y_2 \right\}, \end{aligned} \tag{2.18}$$

where $x = x_3(\tau; t, x)$ denotes the forward characteristic passing through (t, x) at $\tau = t$ and meeting $(0, x_3(0; t, x))$ at $\tau = 0$ and $x = x_1(\tau; t, x)$ denotes the backward characteristic passing through (t, x) at $\tau = t$ and meeting $(0, x_1(0; t, x))$ at $\tau = 0$.

In order to get the L_2-norm of the solution, we use a different form of system (1.1), namely

$$\begin{cases} v_t - u_x = 0, \\ u_t + p(v,s)_x = -\alpha u, \alpha > 0, \\ [e(v,s) + \frac{u^2}{2}]_t + (pu)_x = -\alpha u^2, \end{cases} \tag{2.19}$$

where e denotes the specific internal energy for which $e_s \ne 0$ and $e_v + p = 0$ holds due to the second law of thermodynamics. In the present discussion, $e(v, s) = \frac{v}{\gamma - 1} p(v, s)$ and $p(v, s)$ is expressed by (2.4).

System (2.19) is equivalent to (1.1) for smooth solutions. $(2.19)_3$ can be written as

$$\left[\frac{1}{2}u^2 + e(v,s) - e(\overline{v},s) + \overline{p}v - \overline{pv}\right]_t + [p - p(\overline{v},\overline{s})u]_x = -\alpha u^2, \tag{2.20}$$

where $\overline{p} = p(\overline{v},\overline{s})$.

Integrate (2.20) over $[0,T] \times R$. By using the Cauchy inequality and the fact that $e_v(\overline{v},\overline{s}) + \overline{p} = 0$, Lemma 2.2 follows.

LEMMA 2.2. *Suppose that the solution of* (1.1) *and* (1.4) *is defined for* $0 \le t \le T$, *with* $(z,w,s) \in D$; *then it holds that*

$$\begin{aligned}&\frac{1}{2}\int_{-\infty}^{\infty} u^2(t,x)dx + \frac{a}{4}\int_{-\infty}^{\infty}(v-\overline{v})^2(t,x)dx\\ &\le \int_{-M}^{M}\left[\frac{1}{2}u_0^2(x) + \frac{3\hat{a}}{4}\cdot v_0^2(x) + \left(\frac{d^2}{a} + \frac{d^2}{\hat{a}}\right)s_0^2(x)\right]dx,\end{aligned} \tag{2.21}$$

where $a = \inf_{(z,w,s)\in D} e_{vv} > 0, \hat{a} = \sup_{(z,w,s)\in D} e_{vv} > 0, d = \sup_{(z,w,s)\in D} |e_v|$, *and* $[-M,M] \supset$ *the compact supports for* $(u_0(x), v_0(x))$ *and* $s_0(x)$, *respectively.*

3. The existence theorem.

THEOREM 3.1. *There exists a globally defined classical solution of* (1.1) *and* (1.4) *with* (2.4) *if the* C_1*-norm of* $(u_0(x), v_0(x))$ *is small and the* C_2*-norm of* $s_0(x)$ *is small.*

Proof. By a routine argument, it can be proved that there exists a local solution of (1.1) (1.4) for $0 \le t \le t_0$ which satisfies $(z,w,s) \in D$ if the C_0-norm of $(u_0(x), v_0(x), s_0(x))$ is so small that

(3.1)

$$\begin{aligned}(z(x,0), w(x,0), s(x,0)) \in D^* = \{&(z,w,s) : A_1 h(\overline{v},\overline{s}) < z - w < A_2 h(\overline{v},\overline{s}),\\ &|s-\overline{s}| < 1, \text{ where } a_1 < A_1 < 2, 2 < A_2 < a_2\}.\end{aligned}$$

Thus, Lemma 2.1 implies that

$$|(u_x, v_x)|_{L_\infty} \le M^* \tag{3.2}$$

if the C_1-norm of $(u_0(x), v(x))$ is small and the C_2-norm of $s_0(x)$ is small, where M^* only depends on D.

Therefore, Lemma 2.2 implies that

$$(z,w,s) \in D^* \tag{3.3}$$

if

$$\int_{-M}^{M}\left[\frac{1}{2}u_0^2(x) + \frac{3\hat{a}}{4}v_0^2(x) + \left(\frac{1}{a} + \frac{1}{\hat{a}}\right)d^2 \cdot s_0^2(x)\right]dx \le \frac{1}{3M^*}[h(\overline{v},\overline{s})]^3 \cdot (4\beta)^{-3}, \tag{3.4}$$

where $\beta = \sup_D |h_v|$.

Thus, there exists a positive τ_0 such that the solution of (1.1) (1.4) can be defined for $0 \le t \le t_0 + \tau_0$, where $(z,w,s) \in D$. Repeat the above argument, the Theorem 3.1 follows.

REMARK 3.2. *The assumption* $\gamma < 3$ *in* (2.4) *is crucial, since* (2.14) *would not be possible otherwise.*

A SPATIAL DECAY ESTIMATE FOR THE HYPERBOLIC HEAT EQUATION*

R. QUINTANILLA†

Abstract. In this paper we establish a spatial decay estimate for the hyperbolic heat equation similar to other known estimates for the parabolic equations. Alternatively, the results may be viewed as theorems of Phragmen–Lindelof type [J. B. Conway, *Functions of One Complex Variable*, Graduate Texts in Mathematics, 2nd ed., Springer-Verlag, New York, 1978], [R. Quintanilla, *Publ. Mat.*, 37 (1993), pp. 443–463], [C. O. Horgan and L. E. Payne, *Arch. Rational Mech. Anal.*, 122 (1993), pp. 123–144] for this kind of equation. We conclude the paper by extending the results for a type of semilinear wave equation.

Key words. Phragmen–Lindelof principle, hyperbolic heat equation, spatial decay estimate, semilinear damped hyperbolic equation

1. Introduction.

In the last three decades many papers have studied spatial decay estimates for several types of partial differential equations and systems, but very little attention has been devoted to the study of the hyperbolic problems (see [1], [2]). We should mention the works of Flavin and Knops [3] and Flavin, Knops, and Payne [4], [5] as pioneering contributions for this kind of equation. We also recall the recent work [28] on elasticity with voids. Many authors (see [1]–[4]) seem to accept that for hyperbolic problems describing elastic wave propagation, one should not expect spatial decay estimates similar to those obtained for the elliptic and parabolic problems. In this paper we prove that for hyperbolic equations describing dynamical problems with damping effects, we have results similar to those which were obtained in the study of parabolic and pseudoparabolic equations [9]–[21]. In fact we derive a spatial decay estimate for a functional defined on the solutions of an initial-boundary value problem associated with the equation

$$\rho\ddot{u} + \eta\dot{u} = \Delta u, \tag{1.1}$$

where ρ and η are two positive numbers.

We recall that equation (1.1), among others, arises in the studies of heat propagation for an isotropic and homogeneous rigid body for the theories of Muller [6], [7] or Green and Laws [8]. Thus, it seems appropriate to mention some works dedicated to the study of spatial decay estimates for the parabolic linear heat conduction equation [9], [11]–[15], [21] and the nonlinear heat conduction equation [17]–[20]. Spatial decay estimates for the solutions of equation (1.1) for large time have been obtained in [3]. We also mention the papers of Rauch [22] and Cox and Zuazua [29], where the time exponential decay of solutions of equation (1.1) for bounded domains is proved. In [23], Lindsay and Straughan studied wave propagation for the nonlinear hyperbolic heat conduction equation.

Alternatively, the results may be viewed as theorems of Phragmen–Lindelof type [24], [26], [27] for equation (1.1).

We would like to emphasize that the energy decay estimate known for the Laplace equation (see [1]) is quicker than the one obtained here for our hyperbolic equation when the cross-section is small. Thus, the estimate for the parabolic heat equation is also quicker than the estimate for the hyperbolic heat equation.

Though the equation we study in this paper agrees with the one studied in [3], our results apply to the transient function, while the object of [3] was the study of the low frequency range effects.

The method is based on the study of a nonhomogeneous first-order differential inequality. In our case the unknown of the differential inequality is related to a cross-sectional integral involving the temperature scalar field, its time derivative, and its gradient.

In §2, we state the notation and basic definitions. We also prove two lemmas. These lemmas will be used in §3, where the main result of the paper is stated and proved. Thus a spatial decay estimate is obtained. In §4 we obtain an upper bound for a quantity arising in the estimates we have found in §3. This bound is given in terms of the boundary and initial conditions of the problem. We finish the paper in §5 by describing some possible extensions of the methods and results for a class of semilinear wave equations.

2. Preliminaries. In what follows letters in boldface stand for vectors. We shall employ the usual summation and differentiation conventions: Latin subscripts are understood to range over the integers (1,2,3), while Greek subscripts take only the values (2,3); summation over repeated subscripts is implied and subscripts preceded by a comma denote partial differentiation with respect to the corresponding Cartesian coordinate. We use an overdot to denote partial differentiation with respect to the time. As usual ∇ denotes the three-dimensional gradient operator and by $\nabla.$ we denote the three-dimensional divergence operator.

Let B be the interior of a semiinfinite cylinder. We choose the Cartesian coordinates in such a way that the origin lies in the finite end of the cylinder. We can express B as the union of its simply connected two-dimensional cross-sections $D(x_1)$ for all $x_1 \geq 0$ and such that $D(0)$ is contained in the $x_2 0 x_3$ plane. We suppose that the boundary of the cross-sections $\partial D(x_1)$ allows the use of the divergence theorem. By $B(z, z')$ we denote the subset of points $(x_1, x_2, x_3) \in B$ such that $z \leq x_1 \leq z'$.

We shall be concerned with the problem defined by equation (1.1), the boundary conditions

$$u = 0 \text{ on } \partial D(x_1) \times [0, T), \qquad x_1 \geq 0, \qquad T > 0,$$

$$u = f(x_2, x_3, t) \text{ on } D(0) \times [0, T), \tag{2.1}$$

where $f(x_2, x_3, t)$ is a prescribed function, and the initial conditions

$$u(\mathbf{x}, 0) = u^0(\mathbf{x}), \qquad \dot{u}(\mathbf{x}, 0) = v^0(\mathbf{x}), \quad \mathbf{x} \in B. \tag{2.2}$$

We restrict our attention to initial conditions which satisfy

$$\int_B R^0(\mathbf{x}) dv < \infty, \tag{2.3}$$

where

$$R^0(\mathbf{x}) = \frac{\eta}{(1+\rho)} \left(\rho u^0 v^0 + \frac{\eta}{2} u^0 u^0 \right) + \frac{1}{2} (u^0{}_{,i} u^0{}_{,i} + \rho v^0 v^0). \tag{2.4}$$

Now, we define a function on the solutions of the initial-boundary value problem (1.1), (2.1), (2.2). This function is a measure on the solutions. The knowledge of its asymptotic behavior is the objective of §3.

First we state a couple of equalities. Let u be a solution to the equation (1.1); we have

$$\nabla.(u\nabla u) = u\Delta u + u_{,i}u_{,i} = \rho u\ddot{u} + \eta u\dot{u} + u_{,i}u_{,i} = \rho\left\{\frac{d}{dt}(u\dot{u}) - \dot{u}^2\right\} + \frac{\eta}{2}\frac{d}{dt}u^2 + u_{,i}u_{,i}.$$

After an integration from 0 to t_0, we obtain

$$(2.5)\quad \int_0^{t_0} \nabla.(u\nabla u)dt = \int_0^{t_0} (u_{,i}u_{,i} - \rho\dot{u}^2)dt + \rho u\dot{u} + \frac{\eta}{2}u^2 - \rho u^0 v^0 - \frac{\eta}{2}u^0u^0 \text{ for all } t_0 \geq 0.$$

By a similar method we also obtain

$$(2.6)$$
$$\int_0^{t_0} \nabla.(\dot{u}\nabla u)dt = \eta\int_0^{t_0} \dot{u}^2 dt + \frac{1}{2}(u_{,i}u_{,i} + \rho\dot{u}^2) - \frac{1}{2}(u^0{}_{,i}u^0{}_{,i} + \rho v^0 v^0) \text{ for all } t_0 \geq 0.$$

Let $\lambda_0 = \frac{\eta}{1+\rho}$; we may consider

$$(2.7)\qquad F(\mathbf{x}, t_0) = \int_0^{t_0} \nabla.[(\dot{u} + \lambda_0 u)\nabla u]dt \text{ for } \mathbf{x} \in B \text{ and } 0 \leq t_0 < T.$$

LEMMA 2.1. *The function F satisfies the inequality*

$$F(\mathbf{x}, t_0) \geq \lambda_0 \int_0^{t_0} (u_{,i}u_{,i} + \rho\dot{u}^2)dt + \frac{\rho}{2(1+\rho)}\dot{u}^2 + \frac{1}{2}u_{,i}u_{,i} - R^0(\mathbf{x}) \textit{ for all } 0 \leq t_0 < T,$$

where $R^0(\mathbf{x})$ is defined at (2.4).

Proof. For all positive constants ϵ we have the equality

$$\frac{1}{2}\rho\dot{u}^2 + \rho\lambda_0 u\dot{u} + \frac{\lambda_0\eta}{2}u^2$$
$$= \frac{1}{2}\left(\rho\epsilon\dot{u} + \frac{\eta}{(1+\rho)\epsilon}u\right)^2 + \frac{1}{2}(\rho - \rho^2\epsilon^2)\dot{u}^2 + \frac{\eta^2}{2(1+\rho)}(1 - (\epsilon^2(1+\rho))^{-1})u^2.$$

Now, by taking $\epsilon^2 = (1+\rho)^{-1}$ we obtain

$$(2.8)\qquad \frac{1}{2}\rho\dot{u}^2 + \rho\lambda_0 u\dot{u} + \frac{\lambda_0\eta}{2}\dot{u}^2 \geq \frac{\rho}{2(1+\rho)}\dot{u}^2.$$

On the other hand, we also have the equalities

$$(2.9)\quad \lambda_0(u_{,i}u_{,i} - \rho\dot{u}^2) + \eta\dot{u}^2 = \lambda_0 u_{,i}u_{,i} + \frac{1}{1+\rho}(\eta(1+\rho) - \eta\rho)\dot{u}^2 = \lambda_0(u_{,i}u_{,i} + \dot{u}^2).$$

Lemma 2.1 is a direct consequence of equalities (2.5), (2.6), and (2.9) and inequality (2.8).

We now state a lemma which gives some information on the asymptotic behavior of the solutions of a nonhomogeneous first-order ordinary differential inequality. This abstract lemma will be applied to our problem in the next section to conclude spatial decay estimates for the solutions of (1.1).

LEMMA 2.2. *Let ω and R be two positive functions defined on the nonnegative real line such that*

$$\lim_{z\to\infty}\int_z^\infty R(t)\exp\Big[-\int_0^t \omega^{-1}(\chi)d\chi\Big]dt = 0. \tag{2.10}$$

Let $G(t)$ be a C^1 function satisfying

$$G \le \omega(t)\left(\frac{dG}{dt}+R(t)\right),$$

$$\lim_{t\to\infty} G(t)\Big[-\int_0^t \omega^{-1}(\chi)d\chi\Big] = 0. \tag{2.11}$$

Then

$$\limsup_{t\to\infty} G(t) \le 0.$$

Proof. First we consider the function

$$\begin{aligned} R_1(t) = & R_1(t_0)\exp\Big[\int_{t_0}^t \omega^{-1}(\chi)d\chi\Big] \\ & + \exp\Big[\int_0^t \omega^{-1}(\chi)d\chi\Big]\int_{t_0}^t R(\chi)\exp\Big[-\int_0^\chi \omega^{-1}(\xi)d\xi\Big]\,d\chi. \end{aligned}$$

After some calculations we get

$$\omega R = \omega\frac{d}{dt}R_1 - R_1.$$

Thus we conclude

$$G + R_1 \le \omega(t)\frac{d}{dt}(G+R_1) \text{ for all } t \ge t_0 \ge 0.$$

Let us suppose that there exists t_0 such that $G(t_0) > 0$; we obtain

$$(G+R_1)(t) \ge (G+R_1)(t_0)\exp\Big[\int_{t_0}^t \omega^{-1}(\chi)d\chi\Big] \text{ for all } t \ge t_0.$$

Thus we deduce

$$G(t) \ge \exp\Big[\int_{t_0}^t \omega^{-1}(\chi)d\chi\Big]\left\{G(t_0) - \int_{t_0}^t R(\chi)\exp\Big[-\int_0^\chi \omega^{-1}(\xi)d\xi\Big]\,d\chi\right\} \text{ for all } t \ge t_0.$$

Now if there exists t_0 such that

$$G(t_0) > \int_{t_0}^\infty R(\chi)\exp\Big[-\int_0^\chi \omega^{-1}(\xi)d\xi\Big]\,d\chi,$$

the asymptotic condition (2.11) on G would not be satisfied. Thus we obtain

$$G(t) \le \int_t^\infty R(\chi)\exp\Big[-\int_0^\chi \omega^{-1}(\xi)d\xi\Big]\,d\chi \text{ for all } t \ge 0.$$

In view of (2.10) Lemma 2.2 is proved.

3. A decay theorem. In this section we state a spatial decay estimate for the solutions of the problem defined by (1.1), (2.1), (2.2). We define a function on the cross-sections

$$G(z,t_0)=\int_0^{t_0}\int_{D(z)} u_{,1}(\dot{u}+\lambda_0 u)\,dadt \text{ for all } z\geq 0 \text{ and } t_0>0. \tag{3.1}$$

Using the divergence theorem we obtain

$$G(z+h,t_0)=G(z,t_0)+\int_{B(z,z+h)} F(\mathbf{x},t_0)\,dv \text{ for all } h>0 \text{ and } t_0>0. \tag{3.2}$$

Direct differentiation gives

$$\frac{\partial G}{\partial z}(z,t_0)=\int_{D(z)} F(\mathbf{x},t_0)\,da.$$

Using the Schwarz inequality we find

$$|G(z,t_0)|\leq\int_0^{t_0}\left[\left(\int_{D(z)} u_{,1}u_{,1}da\right)^{\frac{1}{2}}\left\{\left(\int_{D(z)}\dot{u}^2da\right)^{\frac{1}{2}}+\lambda_0\left(\int_{D(z)}u^2da\right)^{\frac{1}{2}}\right\}\right]dt.$$

From Poincaré and the arithmetic-geometric mean inequalities we deduce

$$\begin{aligned}|G(z,t_0)|&\leq\frac{1}{2}[(\epsilon_1)^{-1}+(\epsilon_2)^{-1}]\int_0^{t_0}\int_{D(z)}u_{,1}u_{,1}dadt\\&+\frac{\epsilon_1}{2}\int_0^{t_0}\int_{D(z)}\dot{u}^2dadt+\lambda_0^2\alpha(z)^{-1}\frac{\epsilon_2}{2}\int_0^{t_0}\int_{D(z)}u_{,\alpha}u_{,\alpha}dadt,\end{aligned}$$

where $\alpha(z)$ is the first nonzero eigenvalue of the Laplacian operator in $D(z)$ with homogeneous Dirichlet boundary condition. Now, if we take $\epsilon_1(z)=\epsilon_2(z)\rho\lambda_0^2\alpha(z)^{-1}$ and $\epsilon_2(z)=\lambda_0^{-1/2}\alpha(z)^{1/2}(1+\alpha(z)\rho^{-1}\lambda_0^{-2})^{1/2}$, we obtain

$$\begin{aligned}|G(z,t_0)|&\leq\frac{1}{2}[\lambda_0^{-1}\rho^{-1}+\lambda_0\alpha(z)^{-1}]^{1/2}\frac{\partial G}{\partial z}(z,t_0)\\&+\frac{1}{2}\int_{D(z)}[\lambda_0^{-1}\rho^{-1}+\lambda_0\alpha(z)^{-1}]^{1/2}R^0(\mathbf{x})da.\end{aligned}\tag{3.3}$$

Now we recall the Faber–Krahn inequality

$$\alpha(z)\geq\pi j_0^2A^{-1}(z),\tag{3.4}$$

where j_0 is the smallest positive zero of the Bessel function J_0 and $A(z)$ is the area of the section $D(z)$. Inequalities (3.3) and (3.4) lead to the estimates

$$G(z,t_0)\leq\omega(z)^{1/2}\frac{\partial G}{\partial z}(z,t_0)+\omega(z)^{1/2}\int_{D(z)}R^0(\mathbf{x})da,$$

$$-G(z,t_0)\leq\omega(z)^{1/2}\frac{\partial G}{\partial z}(z,t_0)+\omega(z)^{1/2}\int_{D(z)}R^0(\mathbf{x})da,\tag{3.5}$$

where $\omega(z)=\frac{1}{4}[\lambda_0^{-1}\rho^{-1}+\lambda_0A(z)/\pi j_0^2]$.

If we suppose that the initial condition satisfies (2.3) as well as the following asymptotic condition on the solutions

$$\lim_{z\to\infty} G(z,t_0)\exp\left[-\int_0^z \omega(\tau)^{-1/2}d\tau\right]=0, \tag{3.6}$$

then Lemma 2.2 and the first inequality of (3.5) imply

$$\limsup_{z\to\infty} G(z,t_0)\le 0. \tag{3.7}$$

From the second inequality in (3.5) we get

$$\begin{aligned}&-G(z,t_0)\le -G(z_0,t_0)\exp\left[-\int_{z_0}^z \omega(\tau)^{-1/2}d\tau\right]\\ &\quad+\exp\left[-\int_0^z \omega(\tau)^{-1/2}d\tau\right]\int_{z_0}^z \exp\left[\int_0^{x_1}\omega(\tau)^{-1/2}d\tau\right]\Big(\int_{D(x_1)}R^0(\mathbf{x})da\Big)dx_1\end{aligned} \tag{3.8}$$

for all $z\ge z_0\ge 0$.

Equalities (3.2) and (3.4) imply

$$\begin{aligned}&\int_{B(z,z^*)}F(\mathbf{x},t_0)dv\le G(z^*,t_0)\\ &\quad+\left[\int_{B(z_0,z^*)}F(\mathbf{x},t_0)dv-G(z^*,t_0)\right]\exp\left[-\int_{z_0}^z \omega(\tau)^{-1/2}d\tau\right]\\ &\quad+\exp\left[-\int_0^z \omega(\tau)^{-1/2}d\tau\right]\int_{z_0}^z \exp\left[\int_0^{x_1}\omega(\tau)^{-1/2}d\tau\right]\Big(\int_{D(x_1)}R^0(\mathbf{x})da\Big)dx_1\end{aligned} \tag{3.9}$$

for all $z^*\ge z\ge z_0\ge 0$.

Thus we have proved the following result.

PROPOSITION 3.1. *Let u be a solution of the initial-boundary value problem* (1.1), (2.1), (2.2) *that satisfies the asymptotic condition* (3.6). *We also suppose that the initial conditions satisfy* (2.3). *Then the estimate* (3.9) *is satisfied for all $z^*\ge z\ge z_0\ge 0$.*

In case there exists $z^*>0$ such that $G(z^*,t_0)=0$, the following estimate holds for all $z^*\ge z\ge z_0\ge 0$:

$$\begin{aligned}&\int_{B(z,z^*)}F(\mathbf{x},t_0)dv\le\left[\int_{B(z_0,z^*)}F(\mathbf{x},t_0)dv\right]\exp\left[-\int_{z_0}^z \omega(\tau)^{-1/2}d\tau\right]\\ &\quad+\exp\left[-\int_0^z \omega(\tau)^{-1/2}d\tau\right]\int_{z_0}^z \exp\left[\int_0^{x_1}\omega(\tau)^{-1/2}(\tau)d\tau\right]\Big(\int_{D(x_1)}R^0(\mathbf{x})da\Big)dx_1.\end{aligned} \tag{3.10}$$

Remark. If we relax condition (2.3) on the initial conditions to the asymptotic condition

$$\lim_{z\to\infty}\int_z^\infty\Big(\int_{D(x_1)}R^0(\mathbf{x})da\Big)\exp\left[-\int_0^{x_1}(\omega(\tau))^{-1/2}d\tau\right]dx_1=0, \tag{3.11}$$

then inequalities (3.9) and (3.10) also hold.

Now if we suppose

$$\int_0^{\infty} \omega(\tau)^{-1/2} d\tau = \infty \tag{3.12}$$

and

$$\lim_{z\to\infty} \omega(z) \int_{D(z)} R^0(\mathbf{x}) da = 0, \tag{3.13}$$

then after l'Hôpital's rule we have

$$\lim_{z\to\infty} \exp\Big[-\int_0^z \omega(\tau)^{-1/2} d\tau\Big] \int_{z_0}^z \exp\Big[\int_0^{x_1} \omega(\tau)^{-1/2} d\tau\Big] \Big(\int_{D(x_1)} R^0(\mathbf{x}) da\Big) dx_1 = 0.$$

Inequalities (3.7) and (3.8) imply that $G(\infty, t_0) = 0$. Thus, we may state the following result.

THEOREM 3.1. *Let u be a solution of the initial-boundary value problem* (1.1), (2.1), (2.2) *that satisfies the asymptotic condition* (3.6). *If the cylinder satisfies* (3.12) *and the initial conditions satisfy* (2.3) *and* (3.13), *then the following estimate holds:*

(3.14)

$$\begin{aligned}&\int_{B(z,\infty)} \Big[\eta \int_0^{t_0} (u_{,i}u_{,i} + \rho \dot{u}^2) d\tau + \frac{\rho}{2}\dot{u}^2 + \frac{1+\rho}{2} u_{,i}u_{,i}\Big] dv \\ &\leq (1+\rho)\Big[\int_{B(z,\infty)} R^0(\mathbf{x}) dv + \Big[\int_{B(z_0,\infty)} F(\mathbf{x}, t_0) dv\Big] \exp\Big[-\int_{z_0}^z \omega(\tau)^{-1/2} d\tau\Big] \\ &+ \exp\Big[-\int_0^z \omega(\tau)^{-1/2} d\tau\Big] \int_{z_0}^z \exp\Big[\int_0^{x_1} \omega(\tau)^{-1/2}(\tau) d\tau\Big] \Big(\int_{D(x_1)} R^0(\mathbf{x}) da\Big) dx_1\Big]\end{aligned}$$

for all $z_0 \leq z \leq \infty$.

The methods used to prove Theorem 3.1 can be adapted for bounded cylinders whenever we adjoin the condition to the boundary conditions (2.1):

$$u = 0 \text{ on } D(z^*) \times [0, T),$$

where $D(z^*)$ is the other plane face of the cylinder.

If the area of the cross-sections satisfies the inequality

$$A(z) \leq Cz^2 \text{ for all } z \geq 0,$$

condition (3.12) holds. Now condition (3.13) will be satisfied whenever

$$\lim_{z\to\infty} z \int_{D(z)} R^0(\mathbf{x}) da = 0.$$

Many other sufficient conditions can be given to satisfy (3.12), (3.13).

In the case in which the initial conditions for the temperature and the time derivative of the temperature are zero, inequality (3.14) implies

$$\begin{aligned}&\int_{B(z,z^*)} \Big[\eta \int_0^{t_0} (u_{,i}u_{,i} + \rho \dot{u}^2) d\tau + \frac{\rho}{2}\dot{u}^2 + \frac{1+\rho}{2} u_{,i}u_{,i}\Big] dv \\ &\leq (1+\rho) \left[\int_{B(z_0,z^*)} F(\mathbf{x}, t_0) dv\right] \exp\Big[-\int_{z_0}^z \omega(\tau)^{-1/2} d\tau\Big]\end{aligned}$$

for all $z^* \geq z \geq z_0$.

4. A bound for $\int_B F(\mathbf{x},t)dv$. Estimate (3.11) is not of practical use unless the quantity

$$\mathcal{Q}(t_0) = \int_B F(\mathbf{x},t)dv$$

is bounded in terms of the prescribed data. The object of this section is to obtain an estimate for $\mathcal{Q}(t_0)$ in terms of boundary conditions (2.1) and initial conditions (2.2). For simplicity, we assume that the cylinder is semiinfinite and prismatic. We follow the methods used in [25] (see also [26]).

Let ξ be a function defined on $B \times [0,t_0]$, chosen to satisfy boundary conditions (2.1). The divergence theorem shows

$$\mathcal{Q}(t_0) = \int_0^{t_0} \int_{D(0)} u_{,1}(\dot{\xi}+\lambda_0\xi)dadt = \int_0^{t_0} \int_B \{u_{,i}(\dot{\xi}_{,i}+\lambda_0\xi_{,i})+(\rho\ddot{u}+\eta\dot{u})(\dot{\xi}+\lambda_0\xi)\}dvdt.$$

Use of the Schwarz inequality and integration by parts allows us to obtain the next inequality

$$\begin{aligned}\mathcal{Q}(t_0) \leq & \Big(\int_0^{t_0} \int_B u_{,i}u_{,i}dvdt\Big)^{\frac{1}{2}} \times \Big(\int_0^{t_0} \int_B (\dot{\xi}_{,i} + \lambda_0\xi_{,i})(\dot{\xi}_{,i} + \lambda_0\xi_{,i})dvdt\Big)^{\frac{1}{2}} \\ & + \int_B \rho[\dot{u}(t_0)\dot{\xi}(t_0) + \lambda_0\dot{u}(t_0)\xi(t_0) - (\dot{u}(0)\dot{\xi}(0) + \lambda\dot{u}(0)\xi(0))]dv \\ & + \int_0^{t_0} \int_B \left[\dot{u}\left(\lambda_0\eta\xi + \frac{\eta}{1+\rho}\dot{\xi} - \rho\ddot{\xi}\right)\right] dvdt.\end{aligned} \tag{4.1}$$

Using the Schwarz inequality again we obtain

$$\int_B \rho[\dot{u}\dot{\xi} + \lambda_0\dot{u}\xi]dv \leq \Big(\int_B \rho\dot{u}\dot{u}\Big)^{\frac{1}{2}} \times \Big(\int_B \rho(\dot{\xi} + \lambda_0\xi)^2 dv\Big)^{\frac{1}{2}}$$

and

$$\begin{aligned}&\int_0^{t_0} \int_B \left[\dot{u}\left(\lambda_0\eta\xi + \frac{\eta}{\rho}\dot{\xi} - \rho\ddot{\xi}\right)\right] dvdt \\ &\leq \Big(\int_0^{t_0} \int_B \dot{u}\dot{u}dvdt\Big)^{\frac{1}{2}} \times \Big(\int_0^{t_0} \int_B \Big(\lambda_0\eta\xi + \frac{\eta}{1+\rho}\dot{\xi} - \rho\ddot{\xi}\Big)^2 dvdt\Big)^{\frac{1}{2}}.\end{aligned}$$

Thus we have

$$\begin{aligned}\mathcal{Q}(t_0) \leq & \Big[\int_0^{t_0} \int_B (u_{,i}u_{,i} + \dot{u}\dot{u})dvdt + \int_B \rho\dot{u}\dot{u}dv\Big]^{\frac{1}{2}} \\ & \times \Big[\Big(\int_0^{t_0} \int_B (\dot{\xi}_{,i} + \lambda_0\xi_{,i})(\dot{\xi}_{,i} + \lambda_0\xi_{,i})dvdt\Big)^{\frac{1}{2}} \\ & \quad + \Big(\int_B \rho(\dot{\xi} + \lambda_0\xi)^2 dv\Big)^{\frac{1}{2}} + \Big(\int_0^{t_0} \int_B \Big(\lambda_0\eta\xi + \frac{\eta}{1+\rho}\dot{\xi} - \rho\ddot{\xi}\Big)^2 dvdt\Big)^{\frac{1}{2}}\Big] \\ & \quad - \int_B \Big[\rho(\dot{u}(0)\dot{\xi}(0) + \lambda_0\dot{u}(0)\xi(0))\Big]dv.\end{aligned}$$

Using Lemma 2.1 we deduce

(4.2)

$$\begin{aligned}\mathcal{Q}(t_0) \leq & \kappa\Big[Q(t_0) + \int_B R^0(\mathbf{x})dv\Big]^{\frac{1}{2}} \\ & \times \Big[\Big(\int_0^{t_0}\int_B (\dot{\xi}_{,i} + \lambda_0\xi_{,i})(\dot{\xi}_{,i} + \lambda_0\xi_{,i})dvdt\Big)^{\frac{1}{2}} \\ & + \Big(\int_B \rho(\dot{\xi} + \lambda_0\xi)^2 dv\Big)^{\frac{1}{2}} + \Big(\int_0^{t_0}\int_B \Big(\lambda_0\eta\xi + \frac{\eta}{1+\rho}\dot{\xi} - \rho\ddot{\xi}\Big)^2 dvdt\Big)^{\frac{1}{2}}\Big] \\ & - \int_B \Big[\rho(\dot{u}(0)\dot{\xi}(0) + \lambda_0\dot{u}(0)\xi(0))\Big]dv,\end{aligned}$$

where $\kappa = 3\{\max(\frac{1+\rho}{\eta}, 2(1+\rho), \frac{1+\rho}{\eta\rho})\}^{1/2}$ and $R^0(\mathbf{x})$ is defined in (2.4). Because of the positivity of $R^0(\mathbf{x})$, we obtain the inequality

$$\begin{aligned}& \Big[\Big\{\mathcal{Q}(t_0)) + \int_B R^0(\mathbf{x})dv\Big\}^{\frac{1}{2}} - \frac{\kappa}{2}\Big(\Big(\int_0^{t_0}\int_B (\dot{\xi}_{,i} + \lambda_0\xi_{,i})(\dot{\xi}_{,i} + \lambda_0\xi_{,i})dvdt\Big)^{\frac{1}{2}} \\ & \quad + \Big(\int_B \rho(\dot{\xi} + \lambda_0\xi)^2 dv\Big)^{\frac{1}{2}} + \Big(\int_0^{t_0}\int_B \Big(\lambda_0\eta\xi + \frac{\eta}{1+\rho}\dot{\xi} - \rho\ddot{\xi}\Big)^2 dvdt\Big)^{\frac{1}{2}}\Big)\Big]^2 \\ & \leq \Big|\int_B \rho(\dot{u}(0)\dot{\xi}(0) + \lambda_0\dot{u}(0)\xi(0))]dv\Big| + \int_B R^0(\mathbf{x})dv \\ & \quad + \frac{\kappa^2}{4}\Big(\Big(\int_0^{t_0}\int_B (\dot{\xi}_{,i} + \lambda_0\xi_{,i})(\dot{\xi}_{,i} + \lambda_0\xi_{,i})dvdt\Big)^{\frac{1}{2}} + \Big(\int_B \rho(\dot{\xi} + \lambda_0\xi)^2 dv\Big)^{\frac{1}{2}} \\ & \quad + \Big(\int_0^{t_0}\int_B \Big(\lambda_0\eta\xi + \frac{\eta}{1+\rho}\dot{\xi} - \rho\ddot{\xi}\Big)^2 dvdt\Big)^{\frac{1}{2}}\Big)^2\end{aligned}$$

Now we may deduce the estimate

(4.3)

$$\begin{aligned}\mathcal{Q}(t_0) \leq & -\int_B R^0(\mathbf{x})dv + \Big[\Big(\Big|\int_B \rho(\dot{u}(0)\dot{\xi}(0) + \lambda_0\dot{u}(0)\xi(0))]dv\Big| + \int_B R^0(\mathbf{x})dv \\ & + \frac{\kappa^2}{4}\Big(\Big(\int_0^{t_0}\int_B (\dot{\xi}_{,i} + \lambda_0\xi_{,i})(\dot{\xi}_{,i} + \lambda_0\xi_{,i})dvdt\Big)^{\frac{1}{2}} + \Big(\int_B \rho(\dot{\xi} + \lambda_0\xi)^2 dv\Big)^{\frac{1}{2}} \\ & + \Big(\int_0^{t_0}\int_B \Big(\lambda_0\eta\xi + \frac{\eta}{1+\rho}\dot{\xi} - \rho\ddot{\xi}\Big)^2 dvdt\Big)^{\frac{1}{2}}\Big)^2\Big)^{\frac{1}{2}} \\ & + \frac{\kappa}{2}\Big(\Big(\int_0^{t_0}\int_B (\dot{\xi}_{,i} + \lambda_0\xi_{,i})(\dot{\xi}_{,i} + \lambda_0\xi_{,i})dvdt\Big)^{\frac{1}{2}} + \Big(\int_B \rho(\dot{\xi} + \lambda_0\xi)^2 dv\Big)^{\frac{1}{2}} \\ & + \Big(\int_0^{t_0}\int_B \Big(\lambda_0\eta\xi + \frac{\eta}{1+\rho}\dot{\xi} - \rho\ddot{\xi}\Big)^2 dvdt\Big)^{\frac{1}{2}}\Big)\Big]^2.\end{aligned}$$

We make the following choice:

$$\xi(\mathbf{x}, t) = f(x_\beta, t)\exp(-\alpha x_1),$$

where α is a positive constant and $f(x_\beta, t)$ is defined in (2.1).

Easy calculations lead to

$$
\begin{aligned}
(4.4)\qquad &\dot\xi(\mathbf{x},t) = \dot f(x_\beta,t)\exp(-\alpha x_1), \quad \ddot\xi(\mathbf{x},t) = \ddot f(x_\beta,t)\exp(-\alpha x_1),\\
&\xi_{,\omega}(\mathbf{x},t) = f_{,\omega}(x_\beta,t)\exp(-\alpha x_1), \quad \xi_{,1}(\mathbf{x},t) = -\alpha f(x_\beta,t)\exp(-\alpha x_1),\\
&\dot\xi_{,\omega}(\mathbf{x},t) = \dot f_{,\omega}(x_\beta,t)\exp(-\alpha x_1), \quad \text{and } \dot\xi_{,1}(\mathbf{x},t) = \alpha\dot f(x_\beta,t)\exp(-\alpha x_1).
\end{aligned}
$$

By using equalities (4.4) we may obtain the following equalities for the right-hand side terms of (4.3):

$$
\int_B(\dot u(0)\dot\xi(0) + \lambda_0\dot u(0)\xi(0))dv = \int_B v^0(\mathbf{x})(\dot f(x_\beta,0) + \lambda_0 f(x_\beta,0))\exp(-\alpha x_1)dv,
$$

$$
\begin{aligned}
&\int_0^{t_0}\int_B(\dot\xi_{,i} + \lambda_0\xi_{,i})(\dot\xi_{,i} + \lambda_0\xi_{,i})dvdt\\
&= \frac{1}{2\alpha}\int_0^{t_0}\int_D(\dot f_{,\omega}(x_\beta,t) + \lambda_0 f_{,\omega}(x_\beta,t))(\dot f_{,\omega}(x_\beta,t) + \lambda_0 f_{,\omega}(x_\beta,t))dadt\\
&\quad + \frac{\alpha}{2}\int_0^{t_0}\int_D(\dot f(x_\beta,t) + \lambda_0 f(x_\beta,t))^2 dadt,
\end{aligned}
$$

$$
\int_B\rho(\dot\xi + \lambda_0\xi)^2dv = \frac{1}{2\alpha}\int_D(\dot f(x_\beta,t) + \lambda_0 f(x_\beta,t))^2 da,
$$

and

$$
\begin{aligned}
&\int_0^{t_0}\int_B\Big(\lambda_0\eta\xi + \frac{\eta}{1+\rho}\dot\xi - \rho\ddot\xi\Big)^2 dvdt\\
(4.5)\qquad &= \frac{1}{2\alpha}\int_0^{t_0}\int_D\Big(\lambda_0\eta f(x_\beta,t) + \frac{\eta}{1+\rho}\dot f(x_\beta,t) - \rho\ddot f(x_\beta,t)\Big)^2 dvdt.
\end{aligned}
$$

Inequality (4.3) and equalities (4.5) give the desired estimate for $\mathcal{Q}(t_0)$ in terms of boundary conditions (2.1) and initial conditions (2.2). Thus we have

(4.6)

$$
\begin{aligned}
&\mathcal{Q}(t_0)\\
&\leq -\int_B R^0(\mathbf{x})dv + \Big[\Big(\Big|\int_B\rho v^0(\mathbf{x})(\dot f(x_\beta,0) + \lambda_0 f(x_\beta,0))\exp(-\alpha x_1))dv\Big| + \int_B R^0(\mathbf{x})dv\\
&\quad + \frac{\kappa^2}{4}\Big(\Big(\int_0^{t_0}\int_D\Big[\frac{1}{2\alpha}(\dot f_{,\omega}(x_\beta,t) + \lambda_0 f_{,\omega}(x_\beta,t))(\dot f_{,\omega}(x_\beta,t) + \lambda_0 f_{,\omega}(x_\beta,t))\\
&\quad + \frac{\alpha}{2}(\dot f(x_\beta,t) + \lambda_0 f(x_\beta,t))^2\Big]dadt\Big)^{\frac{1}{2}} + \Big(\frac{1}{2\alpha}\int_D(\dot f(x_\beta,t) + \lambda_0 f(x_\beta,t))^2 da\Big)^{\frac{1}{2}}\\
&\quad + \Big(\frac{1}{2\alpha}\int_0^{t_0}\int_D\Big(\lambda_0\eta f(x_\beta,t) + \frac{\eta}{1+\rho}\dot f(x_\beta,t) - \rho\ddot f(x_\beta,t)\Big)^2 dvdt\Big)^{\frac{1}{2}}\Big)^2\Big)^{\frac{1}{2}}\\
&\quad + \frac{\kappa}{2}\Big(\Big(\int_0^{t_0}\int_D\Big[\frac{1}{2\alpha}(\dot f_{,\omega}(x_\beta,t) + \lambda_0 f_{,\omega}(x_\beta,t))(\dot f_{,\omega}(x_\beta,t) + \lambda_0 f_{,\omega}(x_\beta,t))\\
&\quad + \frac{\alpha}{2}(\dot f(x_\beta,t) + \lambda_0 f(x_\beta,t))^2\Big]dadt\Big)^{\frac{1}{2}} + \Big(\frac{1}{2\alpha}\int_D(\dot f(x_\beta,t) + \lambda_0 f(x_\beta,t))^2 da\Big)^{\frac{1}{2}}\\
&\quad + \Big(\frac{1}{2\alpha}\int_0^{t_0}\int_D\Big(\lambda_0\eta f(x_\beta,t) + \frac{\eta}{1+\rho}\dot f(x_\beta,t) - \rho\ddot f(x_\beta,t)\Big)^2 dvdt\Big)^{\frac{1}{2}}\Big)\Big]^2.
\end{aligned}
$$

Remark. To obtain inequality (4.3), we have not made use of the prismatic form of the cylinder. Estimates like (4.6) could be deduced by changing the choice of the function ξ in a suitable way. In the case in which the section $D(x_1)$ can be obtained from $D(0)$ by a homothetic motion of ratio $1 + cx_1$ (where $c > 0$), we may take

$$\xi(\mathbf{x}, t) = f\left(\frac{x_2}{1+cx_1}, \frac{x_3}{1+cx_1}, t\right) \exp(-\alpha x_1),$$

where α is a positive constant and f is given in (2.1). The reader can conclude the analysis in a way similar to that in the appendix of [26].

5. An extension for semilinear wave equations. In this section we discuss some possible extensions of the previous methods and results to nonlinear damped hyperbolic equations. Let us consider the semilinear wave equation of the form

$$\ddot{u} + g(\dot{u}) = \Delta u, \tag{5.1}$$

where g is a nonlinear function.

Some recent papers devoted to the study of temporal decay estimates for semilinear wave equations are [30]–[34] (see also the references therein). Now we suppose that g satisfies

$$g(s)s \geq c_1|s|^2 \text{ and } |g(s)| \leq c_2|s|. \tag{5.2}$$

To avoid cumbersome calculations we will make a couple of simplifications in the statement of the problem. We consider the problem determined by equation (5.1), boundary conditions (2.1), and the initial conditions

$$u(\mathbf{x}, 0) = 0, \quad \dot{u}(\mathbf{x}, 0) = 0, \quad \mathbf{x} \in B. \tag{5.3}$$

We suppose that the cross-section is constant for all $x_1 \geq 0$ and we denote that cross-section by D. Similar calculations to those used in §2 lead to the equalities

$$\int_0^{t_0} \nabla.(u\nabla u)dt = u\dot{u} + \int_0^{t_0} (u_{,i}u_{,i} + ug(\dot{u}) - \dot{u}\dot{u})dt,$$

$$\int_0^{t_0} \nabla.(\dot{u}\nabla u)dt = \frac{1}{2}(\dot{u}\dot{u} + u_{,i}u_{,i}) + \int_0^{t_0} g(\dot{u})\dot{u}dt.$$

In a way similar to the definition of the function G in §3, we define the function

$$H(z, t_0) = \int_0^{t_0} \int_{D(z)} u_{,1}(\dot{u} + \lambda_1 u)dadt \text{ for all } z \geq 0 \text{ and } t_0 > 0,$$

where λ_1 is a positive constant to be specified later. Also, the use of the divergence theorem leads to the equality

(5.4)
$$H(z+h, t_0) = H(z, t_0) + \int_{B(z,z+h)} \int_0^{t_0} \nabla.[(\dot{u} + \lambda_1 u)\nabla u]dtdv \text{ for all } h > 0 \text{ and } t_0 > 0.$$

Direct differentiation gives

$$\frac{\partial H}{\partial z}(z, t_0) = \int_D \int_0^{t_0} \nabla.[(\dot{u} + \lambda_1 u)\nabla u]dtda.$$

Now we take λ_1, a positive number which is less than $\alpha(0)^{\frac{1}{2}}$. As in §3, $\alpha(0)$ is the first nonzero eigenvalue of the Laplacian operator in D with homogeneous boundary conditions. We also recall estimate (3.4), which relates $\alpha(0)$ with the area of D. Thus we obtain

$$\frac{\partial}{\partial z}H(z,t) \geq \int_D \int_0^{t_0} \Big(\lambda_1(u_{,i}u_{,i} + ug(\dot{u}) - \dot{u}\dot{u}) + g(\dot{u})\dot{u}\Big)dtds. \tag{5.5}$$

Using the Schwarz inequality and the second inequality in (5.2) we have

$$\int_D ug(\dot{u})ds \leq c_2\Big(\int_D u^2ds\Big)^{\frac{1}{2}}\Big(\int_D \dot{u}^2ds\Big)^{\frac{1}{2}}.$$

After using the arithmetic-geometric mean and Poincaré inequalities we conclude

$$\int_D ug(\dot{u})ds \leq \frac{c_2}{2\epsilon\alpha(0)}\int_D u_{,i}u_{,i}ds + \frac{c_2\epsilon}{2}\int_D \dot{u}^2ds \tag{5.6}$$

for all positive ϵ. From (5.5) and (5.6) we deduce

$$\frac{\partial}{\partial z}H(z,t) \geq \int_D \int_0^{t_0} \Big(\lambda_1\Big(1 - \frac{c_2}{2\epsilon\alpha(0)}\Big)u_{,i}u_{,i} + \Big(c_1 - \lambda_1\Big(1 + \frac{c_2\epsilon}{2}\Big)\Big)\dot{u}^2\Big)dtds.$$

We may always take $\epsilon > 0$ so large that

$$1 - \frac{c_2}{2\epsilon\alpha(0)} \geq \beta_1 > 0$$

and $\lambda_1 > 0$ so small that

$$c_1 - \lambda_1\Big(1 + \frac{c_2\epsilon}{2}\Big) \geq \beta_2 > 0.$$

Then we obtain

$$\frac{\partial}{\partial z}H(z,t) \geq \omega\int_D \int_0^{t_0} \Big(u_{,i}u_{,i} + \dot{u}^2\Big)dtds \text{ for all } z \geq 0 \text{ and } 0 \leq t_0 < T, \tag{5.7}$$

where $\omega = \min(\lambda_1\beta_1, \beta_2)$. Now we may proceed in a way similar to §3 to deduce spatial exponential decay for the solutions to the problem determined by equation (5.1), boundary conditions (2.1), and initial conditions (5.3).

Remark. The methods used in the previous sections could be extended to this kind of equation. We could consider other initial conditions and more general geometries. Of course, new initial conditions and new geometries imply new decay estimates. We also may obtain bounds for

$$\int_{B(0,\infty)} \int_0^{t_0} \nabla.[(\dot{u} + \lambda_1 u)\nabla u]dtdv$$

in terms of the initial and boundary conditions using the methods of §4.

We apologize for the fact that the results presented in this section cannot be applied to the case $g(s) = s^{2n+1}$, where n is a positive natural number. This kind of problem and some natural extensions will be the object of a future paper.

CONVERGENCE OF THE CHILD–LANGMUIR ASYMPTOTICS OF THE BOLTZMANN EQUATION OF SEMICONDUCTORS*

NAOUFEL BEN ABDALLAH†

Abstract. In a previous paper, the Child–Langmuir asymptotics of the Boltzmann equation of semiconductors were presented, a limit problem was then derived, and its well posedness was analyzed. In this paper, the convergence of the perturbed problem to the limit one is proved. The proof is done in three steps. In the first step, we prove uniform bounds by using supersolution and support estimates. The second step involves combining the supersolution technique and semiexplicit formulas derived from the phase portrait of the Boltzmann equation to improve the regularity results. Finally, the limit equation is integrated and the convergence is proved in the third step.

Key words. Child–Langmuir, Boltzmann, singular perturbation, convergence, support, supersolution, bounded measure

1. Introduction and main result.

Various models are used to describe electron transport in a semiconductor. The simplest one is the drift–diffusion model consisting of the charge conservation equation and a phenomenological relation expressing the current as the sum of a drift term due to the electrostatic field and a term related to the density diffusion. Many mathematical results are available for this model (see [13], [14], and references therein) but its validity is not very clear, especially in short devices. Another kind of model is the hydrodynamic model, which includes an equation on the energy and is valid when the mean free path is very small compared to the characteristic length of the device. The main difficulty related to this model is that the physical coefficients appearing in the equations are not well known and are often experiment dependent. In short devices, a kinetic description is necessary to model correctly the transport of particles: the population of charged particles is described not only by the position variable, but also by the velocity. A wide variety of problems is treated with these models [17], [15] and numerical solutions are computed with Monte Carlo techniques [11], [20] or deterministic particle methods [16], [9], [6]. The kinetic models are in fact generalizations of the drift–diffusion and hydrodynamic models; indeed one can derive the drift–diffusion and the hydrodynamic models as asymptotic approximations of the kinetic ones when the mean free path tends to zero (see, for example, [18], [19]).

In the situation we are interested in here, the mean free path is not so small that a complete kinetic model need be used. This presents a serious drawback when numerical resolution is considered since kinetic models are very costy (the dimension is multipied by two) and present oscillations in the interface between lowly doped and highly doped regions. This singular behavior is often due to the existence of different scales in the physical parameters and lead mathematically speaking to singular perturbation problems.

In this paper, we deal with a special singular perturbation problem which arises when the velocity of injected particles is small compared to the velocity they reach

This research was performed while the author was a member of Centre de Mathėmatiques Appliquėes, Ecole Polytechnique, France.

after being accelerated by the electric field. These asymptotics are called the Child–Langmuir asymptotics and were first introduced to analyze a vacuum diode under high voltages (see [10], [7], and [8] for mathematical treatment and [12] for physical background). The asymptotics lead to a reduced problem much simpler than the complete one and which contains most of the physics. Our aim here is to extend the analysis to semiconductors where specific issues, namely the collisions, enter into account and complicate seriously the analysis of the problem.

In a previous paper [3], P. Degond and the author introduced a model for electron transport in a unipolar $N^+ - N^- - N^+$ junction at low temperatures taking into account the collisions with the lattice. This model consists of the linear Boltzmann equation of semiconductors (with nondegeneracy assumption), in the parabolic band, and in relaxation time approximations, coupled with the Poisson equation. We introduced a scaling of the equations describing the model and got a singular perturbation problem for the Boltzmann–Poisson equation (the so called Child–Langmuir asymptotics). These asymptotics are intended to model the device behavior when the lattice temperature is *small* or equivalently when the applied voltage is *large.* A limit problem was formally derived [3] and its well posedness was analyzed. However, we did not prove any convergence result of the perturbed system to the limit one. In this paper we fill this gap and prove the convergence. Let us first recall the scaled one-dimensional stationary Vlasov–Poisson–Boltzmann system

$$v\frac{\partial f^\varepsilon}{\partial x} + \frac{1}{2}\frac{d\varphi^\varepsilon}{dx}\frac{\partial f^\varepsilon}{\partial v} = -\frac{1}{\tau}\left(f^\varepsilon - n^\varepsilon \frac{1}{\varepsilon} M_0\left(\frac{v}{\varepsilon}\right)\right), \tag{1.1}$$

$$\frac{d^2\varphi^\varepsilon}{dx^2} = n^\varepsilon(x), \quad x \in [0,1], \tag{1.2}$$

$$n^\varepsilon(x) = \int_{-\infty}^{+\infty} f^\varepsilon(x,v)\,dv, \quad x \in [0,1], \tag{1.3}$$

$$f^\varepsilon(0,v) = g^\varepsilon(v) = \frac{1}{\varepsilon^2} g\left(\frac{v}{\varepsilon}\right), \quad v > 0, \tag{1.4}$$

$$f^\varepsilon(1,v) = 0, \quad v < 0, \tag{1.5}$$

$$\varphi^\varepsilon(0) = 0, \quad \varphi^\varepsilon(1) = 1, \tag{1.6}$$

where

$$M_0(v) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{v^2}{2}\right) \tag{1.7}$$

and

$$g(v) \le C_1 \exp\left(-\frac{v^2}{2}\right). \tag{1.8}$$

In these equations f^ε is the distribution function and φ^ε is the electric potential. We refer to [3] or [5] for the derivation and the scaling of the equations. Here, ε is a small parameter and stands for the temperature of the crystal lattice. Notice that the singularity of this system appears not only in the boundary condition as in the collisionless case, but also in the equations themselves.

Remark 1.1. We notice that in the Poisson equation (1.2), the doping density was neglected. This hypothesis is highly questionable from the phyiscal point of view since the scaled doping density is of the order of 0.5 in the test case we considered (see [1]). The reason we neglect it is mathematical since this assumption guarantees the monotonicity of the limiting potential as we shall see it later. However, we can conjecture that the monotonicity still holds for the small doping profile (this is in fact the case when there is no collision [2]). For physical applications, a reduced model including the doping density was implemented and the results so obtained are in very good agreement with experimental measures (see [4]). But in this case we do not yet have any mathematical result.

Let us now come back to our problem and begin with the following existence theorem proved by F. Poupaud [17].

THEOREM 1.1 (see [17]). *The system* (1.1)–(1.8) *has a solution* $(\varphi^\varepsilon, f^\varepsilon) \in W^{2,\infty}(0,1) \times [L^1 \cap L^\infty(0,1) \times \mathbb{R}]$ *such that*

$$f^\varepsilon(x,v) \leq \frac{C_1}{\varepsilon^2} \exp \frac{-v^2 + \varphi^\varepsilon(x)}{2\varepsilon^2}. \tag{1.9}$$

The main topic of this paper is the analysis of the behavior of the solutions $(f^\varepsilon, \varphi^\varepsilon)$ as ε tends to zero. The limit problem was derived formally in [3] where the limit distribution function f was written in the following form:

$$f(x,v) = n_1(x)\,\delta(v - \sqrt{\varphi(x)}) + \int_0^x \overline{n}_2(x,y)\delta(v - \sqrt{\varphi(x) - \varphi(y)})\,dy. \tag{1.10}$$

The first part of the distribution function represents the so-called ballistic electrons which simply drift along the principal characteristics $v = \sqrt{\varphi(x)}$, whereas the second part stands for electrons which collide with the crystal lattice. The integral representing them can be interpreted as a change of variable. Indeed, if we set $u = \sqrt{\varphi(x) - \varphi(y)}$, then

$$\begin{aligned}\int_0^x \overline{n}_2(x,y)\delta(v - \sqrt{\varphi(x) - \varphi(y)})\,dy &= \int_0^{\sqrt{\varphi(x)}} \overline{n}_2(x,y)\delta(v-u)\,\frac{2udu}{\varphi'(y)} \\ &= \overline{n}_2(x,x^*)\,\frac{2v}{\varphi'(x^*)},\end{aligned}$$

where x^* is given by the equation $\varphi(x^*) = \varphi(x) - v^2$. Now if we replace f by the expression (1.10) in the formal limit of the Boltzmann equation (see [3] for the formal computations), we end up with the following semilinear (and nonlocal) elliptic equation for the electric potential:

$$\frac{d^2\varphi}{dx^2} = n(x), \tag{1.11}$$

$$n(x) = n_1(x) + n_2(x), \tag{1.12}$$

$$n_1(x) = \frac{j}{\sqrt{\varphi(x)}}\, g_\varphi(x,0), \tag{1.13}$$

$$n_2(x) - \int_0^x \frac{g_\varphi(x,y)}{\tau\sqrt{\varphi(x)-\varphi(y)}} n_2(y)\,dy = \int_0^x \frac{g_\varphi(x,y)}{\tau\sqrt{\varphi(x)-\varphi(y)}} n_1(y)\,dy, \tag{1.14}$$

$$\varphi(0) = 0, \qquad \varphi(1) = 1, \tag{1.15}$$

where

$$g_\varphi(x,y) = \exp\left(-\frac{1}{\tau}\int_y^x \frac{dz}{\sqrt{\varphi(z)-\varphi(y)}}\right), \tag{1.16}$$

and

$$n_2(x) = \int_0^x \overline{n}_2(x,y)dy, \quad \overline{n}_2(x,y) = \frac{n(y)}{\tau}\frac{g_\varphi(x,y)}{\sqrt{\varphi(x)-\varphi(y)}}. \tag{1.17}$$

Notice that (1.10) can be rewritten using the above expression of $\overline{n}_2$

$$f(x,v) = n_1(x)\,\delta(v-\sqrt{\varphi(x)}) + \frac{2n(x^*)}{\varphi'(x^*)} g_\varphi(x,x^*), \quad \varphi(x^*) = \varphi(x) - v^2. \tag{1.18}$$

We proved [3] the following results for the limit problem. They state that the limit problem has a unique Child–Langmuir current (corresponding to a vanishing electric field at $x = 0$) and no solution if the current j is large.

THEOREM 1.2 (see [3]). *There exist $\tau_1 \geq 7/9$ and $\tau_2 \leq 4/5$ such that for every $\tau \in (0,\tau_1] \cup [\tau_2,\infty)$, there exists a unique value $j = j_{CL}(\tau)$ such that the problem* (1.11)–(1.16) *has a unique solution φ satisfying $d\varphi/dx(0) = 0$. Moreover, $j_{CL}(\tau) \sim 4/9$ when τ tends to ∞ and $j_{CL}(\tau) \sim \tau 9/16$ when τ tends to zero.*

THEOREM 1.3 (see [3]). *There exists a value $j_{\max}(\tau)$ such that the system* (1.11)–(1.16) *has no solution for $j > j_{\max}(\tau)$. This value satisfies the following estimate:*

$$j_{CL}(\tau) \leq j_{\max}(\tau) < \min\left(\frac{4}{9}, \frac{9}{16}\tau\right).$$

Since the derivation of the limit problem was purely formal, we did not prove any convergence theorem in [3]. The aim of this paper is then to prove the convergence of the perturbed problem toward the above limit problem when ε tends to zero. Before stating the main theorem of this paper, we introduce some notation which will be used throughout the paper. We define, respectively, the injected current, the total current, the kinetic energy, and the total energy by

$$j_g = \int_0^{+\infty} vg(v)dv, \tag{1.19}$$

$$j^\varepsilon(x) = \int_{-\infty}^{+\infty} vf^\varepsilon(x,v)dv, \tag{1.20}$$

$$k^\varepsilon(x) = \int_{-\infty}^{+\infty} v^2 f^\varepsilon(x,v)dv, \tag{1.21}$$

$$h^\varepsilon(x) = k^\varepsilon(x) - \frac{1}{4}\left(\frac{d\varphi^\varepsilon}{dx}(x)\right)^2 + \frac{j^\varepsilon x}{\tau}. \tag{1.22}$$

Now we are able to give the main result of this paper.

THEOREM 1.4. *Let τ be in $(0,\tau_1] \cup [\tau_2,+\infty)$.*

(i) *Suppose that $j_g > j_{\max}(\tau)$. Then, the solutions $(f^\varepsilon,\varphi^\varepsilon)$ defined in Theorem 1.1 converge as ε goes to zero to (f,φ) where f is given by* (1.10) *and φ is the unique solution of* (1.11)–(1.16) *corresponding to $j = j_{CL}(\tau)$.*

(ii) *Suppose that $j_g \leq j_{CL}(\tau)$, then there exists a subsequence $(f^\varepsilon,\varphi^\varepsilon)$ converging as ε goes to zero to (f,φ) where f is given by* (1.10) *and φ is a solution of* (1.11)–(1.16) *corresponding to $j = j_g$.*

(iii) *In the case $j_g \in (j_{CL}, j_{\max})$, the convergence holds for a subsequence but the limit current is not fully determined. However, we have $j \in \{j_g, j_{CL}\}$.*

The convergence holds in the $C^1([0,1])$ strong topology for φ^ε and in the weak $*$ topology of bounded measures for f^ε.

The scheme of the proof follows closely, at the beginning, the previous works on collisionless Child–Langmuir asymptotics [10], [7], [8], [2]. Using the supersolution technique and the maximum principle, we first prove some energy identities and deduce from these identities and support estimates the boundedness of the L^1 norm of the density. This implies the weak convergence of the distribution function f^ε in the bounded measure topology.

Besides, the nonlinear term in the weak formulation of the Boltzmann equation reads

$$\frac{1}{2}\int \frac{d\varphi^\varepsilon}{dx} f^\varepsilon \psi \, dx dv,$$

where ψ is a test function. Since f^ε tends weakly toward a bounded measure, the electric potential has to converge strongly in the C^1 topology, otherwise the nonlinear term does not pass to the limit. Hence, the L^1 bound on the density is not sufficient since the maximum regularity of the electric potential allowed by the L^1 estimate on the density is $W^{1,\infty}$.

In the collisionless case, this difficulty was solved by using the energy invariance which implies that the electric field φ' can be expressed by means of the kinetic energy k. Indeed, in the collisionless case, the limiting distribution function is monokinetic which allows us to express in a simple way the kinetic energy by means of the current. With this expression, one can prove the uniform convergence of the kinetic energy which in turn implies the C^1 strong convergence of the electric potential. Unfortunately, in the collisional case, the distribution function is no longer monokinetic because of the collisions. Therefore there is no hope for the kinetic energy to be expressed in a simple way and the energy invariance does not help to prove the C^1 convergence of the potential.

An alternative approach lies in the use of the Poisson equation. We first prove that the density is bounded in $L^\infty[\alpha,1]$ for every $\alpha > 0$. We deduce from this (using the Poisson equation), that the potential converges in $C^1[\alpha,1]$ for every $\alpha > 0$ and using the convexity of the potential we prove that the C^1 convergence actually holds on the whole interval $[0,1]$. The main difficulty in proving the L^∞ bound on the density is that the supersolution introduced in Theorem 1.1 is almost of no use since it is much larger than the solution in the regions where we intended to use it. The solution we propose is to combine the supersolution bound with semiexplicit formulas derived from the knowledge of the phase portrait of the Boltzmann equation.

Afterward, we pass to the limit in the Boltzmann equation and determine the structure of the limit problem by integrating the equations. The final step in the proof is the knowledge of the current and is achieved by using the results of [3].

The outline of the paper is as follows. In §2, we first establish uniform bounds on the solution of the perturbed problem using energy invariants and supersolution bounds. Then we give some qualitative properties satisfied by the limit solution. In a third part we prove, using these properties, the C^1 strong convergence of the potential. In §3, we pass to the limit in the equations and prove the main theorem. In §4, we summarize our results.

2. Regularity and support estimates. This section is divided into three parts. In the first part, we prove some preliminary estimates following essentially from the supersolution exhibited in Theorem 1.1. From these estimates, we deduce the convergence of the solution by a compactness argument. In the second part, we give some information on the structure of the limiting problem: support of the distribution function, positivity of the current and of the limit potential. Finally, in the third part we prove the C^1 convergence of the potential.

2.1. Preliminary estimates. We begin with an immediate result obtained by taking the 0th and the first moments of the Boltzmann equation with respect to v.

LEMMA 2.1. (i) *The current* $j^\varepsilon(x)$ *does not depend on* x *and* $0 \le j^\varepsilon \le j_g$.

(ii) *The total energy* h^ε *does not depend on* x.

LEMMA 2.2. *For* ε *small enough, we have the following:*

(i) $8\varepsilon^2 \ln\varepsilon \le \varphi^\varepsilon(x) \le 1$.

(ii) $(j^\varepsilon - C\varepsilon^5)/\sqrt{\varphi^\varepsilon(x) - 10\varepsilon^2\ln\varepsilon} \le n^\varepsilon(x) \le \frac{C}{\varepsilon}\exp(\frac{\varphi^\varepsilon(x)}{2\varepsilon^2})$.

(iii) $-C\sqrt{-\varepsilon\ln\varepsilon} \le {\varphi^\varepsilon}'(0) \le 1$.

(iv) *There exits* $C > 0$ *such that the following implications hold:*

$$\begin{aligned} \varphi^\varepsilon(x) \ge -10\varepsilon^2\ln\varepsilon \quad &\Longrightarrow \quad ({\varphi^\varepsilon}'(x))^2 \ge C(j^\varepsilon - C\varepsilon^5)\sqrt{\varphi^\varepsilon(x)}, \\ \varphi^\varepsilon(x) \ge \varepsilon^2 \quad &\Longrightarrow \quad ({\varphi^\varepsilon}'(x))^2 \ge C(j^\varepsilon - C\varepsilon^5)\sqrt{\frac{\varphi^\varepsilon(x)}{-\ln\varepsilon}}. \end{aligned}$$

Proof. (i) The integration of (1.9) with respect to v gives

$$0 \le n^\varepsilon(x) \le \frac{C}{\varepsilon}\exp\left(\frac{\varphi^\varepsilon(x)}{2\varepsilon^2}\right).$$

Therefore φ^ε is a supersolution of the following semilinear elliptic equation

$$\left\{\begin{array}{l} -\psi'' + \dfrac{C}{\varepsilon}\exp\left(\dfrac{\psi}{2\varepsilon^2}\right) = 0, \\ \psi(0) = 0, \quad \psi(1) = 1. \end{array}\right. \tag{2.23}$$

It is easy to check that the function

$$\psi^\varepsilon(x) = 8\varepsilon^2\ln\varepsilon + \varepsilon^2x^2$$

is a subsolution of this equation and thus $\varphi^\varepsilon(x) \ge \psi^\varepsilon(x)$; the upper bound on φ^ε is a direct consequence of the positivity of n^ε.

(ii) We have

$$\begin{aligned} n^\varepsilon(x) &\ge \frac{1}{\sqrt{\varphi^\varepsilon(x) - 10\varepsilon^2\ln\varepsilon}} \int_0^{\sqrt{\varphi^\varepsilon(x) - 10\varepsilon^2\ln\varepsilon}} vf^\varepsilon(x,v)dv \\ &\ge \frac{1}{\sqrt{\varphi^\varepsilon(x) - 10\varepsilon^2\ln\varepsilon}}\left[j^\varepsilon - \int_{\sqrt{\varphi^\varepsilon(x)-10\varepsilon^2\ln\varepsilon}}^{+\infty} vf^\varepsilon(x,v)dv\right]. \end{aligned}$$

We deduce from (1.9) that

$$\int_{\sqrt{\varphi^\varepsilon(x)-10\varepsilon^2\ln\varepsilon}}^{+\infty} vf^\varepsilon(x,v)dv \leq C\varepsilon^5,$$

which ends the proof of (ii).

(iii) The second inequality is easily deduced from the convexity of φ^ε. For the first inequality, we suppose that ${\varphi^\varepsilon}'(0) < 0$. Then, there exists $r^\varepsilon > 0$ such that φ^ε is negative on $[0, r^\varepsilon]$. Therefore $n^\varepsilon \leq \frac{C}{\varepsilon}$ on $[0, r^\varepsilon]$. This implies that

$${\varphi^\varepsilon}'(x) \leq {\varphi^\varepsilon}'(0) + \frac{C}{\varepsilon}x$$

and

$$\varphi^\varepsilon(x) \leq {\varphi^\varepsilon}'(0)x + \frac{C}{2\varepsilon}x^2.$$

Let $x_\varepsilon = -\frac{\varepsilon}{C}{\varphi^\varepsilon}'(0)$, then $x^\varepsilon < r^\varepsilon$ and

$$\varphi^\varepsilon(x_\varepsilon) \leq -\frac{\varepsilon}{2C}({\varphi^\varepsilon}'(0))^2.$$

The result follows easily since $\varphi^\varepsilon \geq 10\varepsilon^2\ln\varepsilon$.

(iv) We first remark that ${\varphi^\varepsilon}'$ is positive on the set $\varphi^\varepsilon > 0$ (because φ^ε is convex and is equal to zero at $x = 0$). Let x_0 be the largest point where φ^ε vanishes. Then the set $\{\varphi^\varepsilon > 0\}$ is equal to $(x_0, 1]$. We consider now $x > x_0$, we multiply the first inequality of (ii) by ${\varphi^\varepsilon}'$, and integrate it between x_0 and x. We end up with the following inequality:

$$({\varphi^\varepsilon}')^2(x) \geq 4(j^\varepsilon - C\varepsilon^5)(\sqrt{\varphi^\varepsilon(x) - 10\varepsilon^2\ln\varepsilon} - \sqrt{-10\varepsilon^2\ln\varepsilon}), \quad x > x_0.$$

This yields the results of (iv). □

PROPOSITION 2.1. *We have the following uniform estimate*

$$|h^\varepsilon| + ||k^\varepsilon||_{L^\infty} + ||\varphi^\varepsilon||_{W^{1,\infty}\cap W^{2,1}} + ||n^\varepsilon||_{L^1} \leq C.$$

Proof. First, we have

$$h^\varepsilon = k^\varepsilon(0) - \frac{1}{4}\left(\frac{d\varphi^\varepsilon}{dx}(0)\right)^2;$$

then since the integration of (1.9) gives

$$k^\varepsilon(x) \leq C\varepsilon\exp\left(\frac{\varphi^\varepsilon(x)}{2\varepsilon^2}\right), \tag{2.24}$$

we deduce from Lemma 2.2(iii) that h^ε is bounded. Assume for the moment that $k^\varepsilon(1)$ is bounded. Then we deduce from the definition of h^ε that ${\varphi^\varepsilon}'(1)$ is bounded. Now since φ^ε is convex, this leads to the boundedness of $||{\varphi^\varepsilon}'||_{L^\infty}$. Using h^ε once more, we deduce that $||k^\varepsilon||_{L^\infty}$ is bounded. Additionally, since $||n^\varepsilon||_{L^1} = {\varphi^\varepsilon}'(1) - {\varphi^\varepsilon}'(0)$, we conclude that $||n^\varepsilon||_{L^1}$ is bounded.

Now we prove that $k^\varepsilon(1)$ is bounded. Since $f^\varepsilon(1,v)$ vanishes for negative v's, then

$$\begin{aligned} k^\varepsilon(1) &= \int_0^{+\infty} v^2 f^\varepsilon(1,v)dv \\ &= \int_0^2 v^2 f^\varepsilon(1,v)dv + \int_2^{+\infty} v^2 f^\varepsilon(1,v)dv \\ &\leq 2j^\varepsilon + \frac{C_1}{\varepsilon^2}\int_2^{+\infty} v^2 \exp\left(\frac{-v^2+1}{2\varepsilon^2}\right) dv. \end{aligned}$$

Hence

$$k^\varepsilon(1) \leq 2j^\varepsilon + O(\varepsilon), \tag{2.25}$$

and the result holds since j^ε is bounded. □

At this stage we can conclude that for a subsequence we have

$$\begin{array}{ll} f^\varepsilon \rightharpoonup f & \mathcal{M}_b([0,1]\times \mathbb{R}) \text{ weak } * \\ n^\varepsilon \rightharpoonup n & \mathcal{M}_b([0,1]) \text{ weak } * \\ \varphi^\varepsilon \rightarrow \varphi & W^{1,p}([0,1]) \text{ strong } \forall 1<p<\infty \\ \varphi^\varepsilon \rightharpoonup \varphi & W^{1,\infty}([0,1]) \text{ weak } * \\ k^\varepsilon \rightharpoonup k & L^\infty([0,1]) \text{ weak } * \\ j^\varepsilon \rightarrow j & \\ h^\varepsilon \rightarrow h & \end{array}$$

and we have obviously

$$n = \langle f, 1\rangle_{\mathcal{M}_b,C_0}, \quad j = \langle f, v\rangle_{\mathcal{M}_b,C_0}, \quad k = \langle f, v^2\rangle_{\mathcal{M}_b,C_0}$$

and

$$h = k(x) - \frac{1}{4}\left(\frac{d\varphi}{dx}(x)\right)^2 + \frac{jx}{\tau}, \quad \varphi \geq 0,$$

where $\langle\cdot,\cdot\rangle_{\mathcal{M}_b,C_0}$ denotes the duality product between the bounded measures and the continuous compactly supported functions (the duality is taken with respect to the velocity variable only). Of course, the functions $1, v, v^2$ are not compactly supported, but the duality product still holds because thanks to (1.9) the support of f is compact ($f = 0$ for $v^2 > \varphi(x)$).

2.2. The limiting solution: Qualitative structure. In this section we prove that the limiting current cannot vanish. We deduce from this that the limiting electric potential vanishes only at $x = 0$. Finally, using this result we characterize completely the support of the limiting distribution function. We begin with the following lemma.

LEMMA 2.3. *Let us assume that φ^ε converges uniformly to φ in the $C^1([0,1])$ strong topology and that $\varphi'(0) > 0$. Then the limit current j is equal to the injected current j_g.*

Proof. Since the convergence holds in $C^1([0,1])$, then for ε small enough, the function $\varphi^\varepsilon(x) \geq \alpha x$, with $\alpha > 0$. Since φ^ε is positive, then the characteristics passing through a point (x,v) with $v < 0$ are issued from the boundary $x = 1$. Hence, writing the Boltzmann equation

$$v\frac{\partial f^\varepsilon}{\partial x} + \frac{1}{2}\frac{d\varphi^\varepsilon}{dx}\frac{\partial f^\varepsilon}{\partial v} + \frac{1}{\tau}f^\varepsilon = n^\varepsilon \frac{1}{\tau\varepsilon}M_0\left(\frac{v}{\varepsilon}\right),$$

we can express $f^\varepsilon(x,v)$ explicitly in terms of the density

$$f^\varepsilon(x,v)=\int_x^1 \frac{n^\varepsilon(y)}{\varepsilon\tau\sqrt{2\pi}}\frac{\exp(-\frac{v^2+\varphi^\varepsilon(y)-\varphi^\varepsilon(x)}{2\varepsilon^2})}{\sqrt{v^2+\varphi^\varepsilon(y)-\varphi^\varepsilon(x)}}\exp\left(\frac{-1}{\tau}\int_x^y\frac{dz}{\sqrt{v^2+\varphi^\varepsilon(z)-\varphi^\varepsilon(x)}}\right)dy$$

for v negative. Hence

$$\begin{aligned}|j^\varepsilon-j_g|&=\left|\int_{-\infty}^0 vf^\varepsilon(0,v)dv\right|\\ &\le C\int_0^{+\infty}\int_0^1 n^\varepsilon(y)\frac{v}{\varepsilon}\frac{\exp(-\frac{v^2+\varphi^\varepsilon(y)}{2\varepsilon^2})}{\sqrt{v^2+\varphi^\varepsilon(y)}}dy\,dv\\ &\le C\varepsilon\int_0^1 n^\varepsilon(y)\frac{\exp(-\frac{\varphi^\varepsilon(y)}{2\varepsilon^2})}{\sqrt{\varphi^\varepsilon(y)}}\,dy. \end{aligned}\tag{2.26}$$

We split the integral of the right-hand side into two integrals, the first from zero to ε and the second from ε to one. To estimate the first integral, we use Lemma 2.2(ii); this yields

$$C\varepsilon\int_0^\varepsilon n^\varepsilon(y)\frac{\exp(-\frac{\varphi^\varepsilon(y)}{2\varepsilon^2})}{\sqrt{\varphi^\varepsilon(y)}}\,dy\le C\int_0^\varepsilon\frac{dy}{\sqrt{\varphi^\varepsilon(y)}},$$

and using the estimate $\varphi^\varepsilon(y)\ge\alpha y$, we obtain

$$C\varepsilon\int_0^\varepsilon n^\varepsilon(y)\frac{\exp(-\frac{\varphi^\varepsilon(y)}{2\varepsilon^2})}{\sqrt{\varphi^\varepsilon(y)}}\,dy\le C\sqrt{\varepsilon}.\tag{2.27}$$

For the second integral, we recall that φ^ε is increasing so that

$$C\varepsilon\int_\varepsilon^1 n^\varepsilon(y)\frac{\exp(-\frac{\varphi^\varepsilon(y)}{2\varepsilon^2})}{\sqrt{\varphi^\varepsilon(y)}}\,dy\le C\varepsilon\frac{\exp(-\frac{\varphi^\varepsilon(\varepsilon)}{2\varepsilon^2})}{\sqrt{\varphi^\varepsilon(\varepsilon)}}||n^\varepsilon||_{L^1}$$

and taking once more into account the estimate $\varphi^\varepsilon(y)\ge\alpha y$, we have

$$C\varepsilon\int_\varepsilon^1 n^\varepsilon(y)\frac{\exp(-\frac{\varphi^\varepsilon(y)}{2\varepsilon^2})}{\sqrt{\varphi^\varepsilon(y)}}\,dy\le C\sqrt{\varepsilon}\exp\left(-\frac{\alpha}{2\varepsilon}\right).\tag{2.28}$$

In view of (2.26), inequalities (2.27) and (2.28) lead to $j=j_g$. □

The following proposition is a direct consequence of this lemma.

PROPOSITION 2.2. (i) *The limit current j is strictly positive.*

(ii) *The limit potential φ is strictly positive on* $(0,1]$.

Proof. (i) Assume that the current j^ε tends to zero. Then we deduce from (2.24) and (2.25) that $\lim k^\varepsilon(0)=\lim k^\varepsilon(1)=0$. Therefore, (1.22) implies

$$\lim\left(\frac{d\varphi^\varepsilon}{dx}(0)\right)^2=\lim\left(\frac{d\varphi^\varepsilon}{dx}(1)\right)^2=-4h.$$

Since φ^ε is convex, we deduce that $\lim(\varphi^{\varepsilon\prime})^2(1)=-4h\ge 1$. Hence, Lemma 2.2(iii) implies that $\varphi^{\varepsilon\prime}(0)\ge 0$ for ε small enough. Therefore

$$\lim\frac{d\varphi^\varepsilon}{dx}(0)=\lim\frac{d\varphi^\varepsilon}{dx}(1),$$

which implies, since φ^ε is convex, that $d\varphi^\varepsilon/dx$ converges uniformly to a constant on $[0,1]$. We deduce finally that $\varphi^\varepsilon(x)$ converges to x in $C^1([0,1])$, therefore the preceding lemma applies and gives $j = j_g$, which obviously contradicts the above hypothesis.

(ii) Assume that there exists $r > 0$ such that $\varphi(r) = 0$. Then, since φ is convex and nonnegative, it vanishes on the whole interval $[0,r]$. Using (i) and Lemma 2.2 (ii), we claim that the following estimate holds for ε small enough:

$$n^\varepsilon(x) \geq \frac{j}{2\sqrt{\varphi^\varepsilon(x) - 10\varepsilon^2 \ln \varepsilon}}.$$

Since φ^ε converges uniformly toward φ, we deduce from the last estimate that

$$\lim_{\varepsilon\to 0} \inf_{[0,r]} n^\varepsilon = +\infty,$$

which contradicts the boundedness of $||n^\varepsilon||_{L^1}$. □

The following lemma characterizes completely the support of the limit distribution function and shows that the first moment of f^ε is bounded.

LEMMA 2.4. (i) *The sequence* $\int_{-\infty}^{+\infty} |v| f^\varepsilon(x,v)dv$ *is bounded in* $L^\infty([0,1])$.

(ii) *The limit distribution function f is supported by the set*

$$\left\{(x,v),\ 0 \leq v \leq \sqrt{\varphi(x)}\right\}.$$

(iii) *There exists a constant C independent of ε such that*

$$k^\varepsilon \leq C\sqrt{|\varphi^\varepsilon|} + o(1).$$

Proof. (i) Let $\theta_\alpha(v)$ be a decreasing C^1 function such that $\theta_\alpha(v) = 0$ for $v \geq 0$ and $\theta_\alpha(v) = 1$ for $v \leq -\alpha$ with $\alpha > 0$ and $0 \leq \theta_\alpha \leq 1$. Then, since

$$v\frac{\partial f^\varepsilon}{\partial x} + \frac{1}{2}\frac{d\varphi^\varepsilon}{dx}\frac{\partial f^\varepsilon}{\partial v} + \frac{f^\varepsilon}{\tau} = \frac{n^\varepsilon}{\tau\varepsilon}M_0\left(\frac{v}{\varepsilon}\right),$$

we have

$$\frac{d}{dx}\int v\theta_\alpha(v)f^\varepsilon dv - \frac{1}{2}\frac{d\varphi^\varepsilon}{dx}\int \theta'_\alpha(v)f^\varepsilon(v)dv + \frac{\int \theta_\alpha(v)f^\varepsilon(v)dv}{\tau} = \frac{n^\varepsilon}{\tau}\int M_0(v)\theta_\alpha(\varepsilon v)dv.$$

Let $x \geq r^\varepsilon$, where r^ε is defined by

$$\varphi^\varepsilon(r^\varepsilon) = \varepsilon^2. \tag{2.29}$$

Then since ${\varphi^\varepsilon}'(x) > 0$ on $[r^\varepsilon, 1]$, we deduce from the above formula that

$$\frac{d}{dx}\int v\theta_\alpha(v)f^\varepsilon dv \leq \frac{n^\varepsilon}{\tau}\int M_0(v)\theta_\alpha(\varepsilon v)dv, \quad x \geq r_\varepsilon.$$

Integrating this inequality between x and 1, we obtain

$$\frac{-||n^\varepsilon||_{L^1}}{\tau}\int M_0(v)\theta_\alpha(\varepsilon v)dv \leq \int v\theta_\alpha(v)f^\varepsilon(x,v)dv \leq 0, \quad x \in [r^\varepsilon, 1]. \tag{2.30}$$

Letting α tend to zero implies that $\sup_{x\in[r^\varepsilon,1]} |\int_{-\infty}^0 vf^\varepsilon(x,v)dv|$ is bounded and since the total current is bounded, this leads to the boundedness of

$$\sup_{x\in[r^\varepsilon,1]}\int_{-\infty}^{+\infty} |v| f^\varepsilon(x,v)dv.$$

On $[0, r^\varepsilon]$ the boundedness can be proved by the use of (1.9), since $\varphi^\varepsilon \le \varepsilon^2$ on $[0, r^\varepsilon]$.

(ii) It is readily seen that the estimate (1.9) implies

$$\operatorname{supp} f \subset \left\{(x,v),\ v^2 \le \varphi(x)\right\}.$$

Let us now show that $f(x,v) = 0$ for every $v < 0$. For $x = 0$ there is nothing to show. For $x > 0$, the estimate (2.30) holds for every fixed α and for ε small enough. Since, for $\alpha > 0$ the integral

$$\int M_0(v)\theta_\alpha(\varepsilon v)dv$$

is exponentially small, then we pass to the limit (with a fixed α) and get

$$\langle f, v\theta_\alpha(v)\rangle_{\mathcal{M}_b, C_0} = 0, \quad \forall \alpha > 0,$$

which implies that $f(x,v) = 0$ if $v < 0$.

The proof of (iii) is a consequence of (1.9) and (i). Indeed,

$$k_\varepsilon(x) = \int_{|v| \le \sqrt{\varphi(x) - 10\varepsilon^2 \ln \varepsilon}} v^2 f^\varepsilon dv + \int_{|v| \ge \sqrt{\varphi(x) - 10\varepsilon^2 \ln \varepsilon}} v^2 f^\varepsilon dv.$$

The first integral is bounded by

$$\sqrt{\varphi(x) - 10\varepsilon^2 \ln \varepsilon} \int |v| f^\varepsilon dv$$

and the second one is small in view of (1.9). □

2.3. Showing the C^1 strong convergence. Up to now, the results we obtained in §2.1 needed essentially the estimate (1.9) and the procedure used to obtain them is an adaptation of [7] (the collisionless case). In the collisionless case, the support of the limit distribution function is the set $v = \sqrt{\varphi(x)}$. This allows us to express the kinetic energy by means of the current and to obtain the C^1 regularity result for the potential. In fact, this regularity result could be proven (still in the collisionless case) by expressing the density by means of the current which yields that n^ε is bounded in L^∞ far from the point where φ vanishes. This is not straightforward when the collisions are taken into account, because the Maxwellian M_ε tends to a delta measure which implies that the distribution function does not vanish on the axis $v = 0$. Besides, the estimate (1.9) is very bad when $v^2 < \varphi(x)$ (the support of f is a part of this region) and this is a serious limitation of the supersolution method which, alone, does not allow us to prove a sharper estimate on the density. We shall show this estimate by using semiexplicit formulas for the distribution function. This is stated in the following proposition, for which the proof is somewhat lengthy and could be skipped in a first reading.

PROPOSITION 2.3. (i) *The function* $n^\varepsilon\sqrt{|\varphi^\varepsilon|}$ *is bounded in* $L^\infty([0,1])$.

(ii) *The distribution function* f^ε *is bounded in* $L^\infty_{loc}([0,1] \times \mathrm{IR} - \{v = \sqrt{\varphi(x)}\})$.

Proof. (i) Let r^ε be defined in (2.29). Then since $\varphi^\varepsilon \le \varepsilon^2$ on $[0, r^\varepsilon]$, the estimate (1.9) gives

$$\sup_{[0,r^\varepsilon]} n^\varepsilon \sqrt{|\varphi^\varepsilon|} \le C.$$

Hence, we focus on the interval $[r^\varepsilon, 1]$. We first rewrite the Boltzmann equation in the following form:

$$v\frac{\partial f^\varepsilon}{\partial x} + \frac{1}{2}\frac{d\varphi^\varepsilon}{dx}\frac{\partial f^\varepsilon}{\partial v} + \frac{f^\varepsilon}{\tau} = \frac{n^\varepsilon(x)}{\tau\,\varepsilon}M_0\left(\frac{v}{\varepsilon}\right),$$

where the right-hand side is considered as a source term. The integration of this equation over the characteristics gives, for $(x,v) \in [r^\varepsilon, 1] \times \mathbb{R}_-$,

(2.31)

$$f^\varepsilon(x,v) = \int_x^1 \frac{n^\varepsilon(y)}{\varepsilon\tau\sqrt{2\pi}}\frac{\exp(-\frac{v^2+\varphi^\varepsilon(y)-\varphi^\varepsilon(x)}{2\varepsilon^2})}{\sqrt{v^2+\varphi^\varepsilon(y)-\varphi^\varepsilon(x)}}\exp\left(\frac{-1}{\tau}\int_x^y \frac{dz}{\sqrt{v^2+\varphi^\varepsilon(z)-\varphi^\varepsilon(x)}}\right)dy$$

and, for $(x,v) \in [r^\varepsilon, 1] \times [0, \sqrt{\varphi^\varepsilon})$,

(2.32)

$$f^\varepsilon(x,v) = f(x^*,0)\exp\left(\frac{-1}{\tau}\int_{x^*}^x \frac{dz}{\sqrt{v^2+\varphi^\varepsilon(z)-\varphi^\varepsilon(x)}}\right)$$
$$+\int_{x^*}^x \frac{n^\varepsilon(y)}{\varepsilon\tau\sqrt{2\pi}}\frac{\exp(-\frac{\varphi^\varepsilon(y)-\varphi^\varepsilon(x^*)}{2\varepsilon^2})}{\sqrt{\varphi^\varepsilon(y)-\varphi^\varepsilon(x^*)}}\exp\left(\frac{-1}{\tau}\int_y^x \frac{dz}{\sqrt{\varphi^\varepsilon(z)-\varphi^\varepsilon(x^*)}}\right)dy,$$

where x^* is uniquely defined by

$$\varphi^\varepsilon(x^*) = \varphi^\varepsilon(x) - v^2. \tag{2.33}$$

These relations follow from the integration of the Boltzmann equation over the characteristics and can be understood by viewing Fig. 1 which represents the phase portrait.

Estimating the distribution function. Let us now estimate (2.31). For v negative, we first remark that

$$\int_x^1 \frac{\varphi^{\varepsilon\prime}(y)\exp(-\frac{\varphi^\varepsilon(y)-\varphi^\varepsilon(x)}{2\varepsilon^2})}{\varepsilon\sqrt{\varphi^\varepsilon(y)-\varphi^\varepsilon(x)}}dy = \int_0^{\frac{\sqrt{1-\varphi^\varepsilon(x)}}{\varepsilon}}\exp\left(-\frac{u^2}{2}\right)du \le C. \tag{2.34}$$

We then remark that $\sqrt{\varphi^\varepsilon}\varphi^{\varepsilon\prime}$ is increasing on $(r^\varepsilon, 1]$ so that (2.31) leads to

$$f^\varepsilon(x,v) \le \frac{Ce^{-\frac{v^2}{2\varepsilon^2}}}{\varepsilon\sqrt{\varphi^\varepsilon(x)}\varphi^{\varepsilon\prime}(x)}\int_x^1 \frac{n^\varepsilon(y)\sqrt{\varphi^\varepsilon(y)}\varphi^{\varepsilon\prime}(y)\exp(-\frac{\varphi^\varepsilon(y)-\varphi^\varepsilon(x)}{2\varepsilon^2})}{\sqrt{\varphi^\varepsilon(y)-\varphi^\varepsilon(x)}}dy.$$

The term $\sqrt{\varphi^\varepsilon}\varphi^{\varepsilon\prime}$ is introduced in the integral to make the quantity $||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty}$ appear and to use the estimate (2.34). This leads to the following estimate:

$$f^\varepsilon(x,v) \le \frac{Ce^{-\frac{v^2}{2\varepsilon^2}}||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty}}{\sqrt{\varphi^\varepsilon(x)}\varphi^{\varepsilon\prime}(x)}.$$

Moreover, since $j > 0$, we deduce from Lemma 2.2(iv) that for ε small enough, we have

$$f^\varepsilon(x,v) \le \frac{Ce^{-\frac{v^2}{2\varepsilon^2}}||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty}}{\sqrt{\varphi^\varepsilon(x)}(\varphi^\varepsilon(x))^{1/4}}, \quad \varphi^\varepsilon(x) \ge -10\varepsilon^2\ln\varepsilon, v \le 0 \tag{2.35}$$

$$\le \frac{Ce^{-\frac{v^2}{2\varepsilon^2}}||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty}}{\sqrt{\varphi^\varepsilon(x)}(\varphi^\varepsilon(x))^{1/4}}(-\ln\varepsilon)^{1/4}, \quad \varepsilon^2 \le \varphi^\varepsilon(x), v \le 0. \tag{2.36}$$

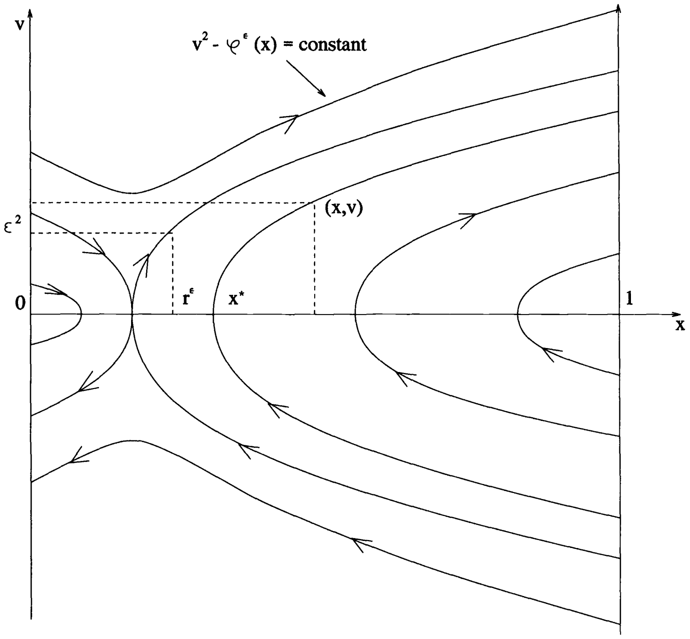

FIG. 1. *Phase portrait.*

For v positive, we obtain, in view of (2.32), the same estimates as above with v replaced by zero and x by x^*. Hence

$$f^\varepsilon(x,v) \le \frac{C||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty}}{\sqrt{\varphi^\varepsilon(x^*)}(\varphi^\varepsilon(x^*))^{1/4}}, \quad \varphi^\varepsilon(x^*) \ge -10\varepsilon^2 \ln\varepsilon, v \in [0, \sqrt{\varphi^\varepsilon(x)}) \tag{2.37}$$

$$\le \frac{C||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty}}{\sqrt{\varphi^\varepsilon(x^*)}(\varphi^\varepsilon(x^*))^{1/4}}(-\ln\varepsilon)^{1/4}, \quad \varepsilon^2 \le \varphi^\varepsilon(x), v \in [0, \sqrt{\varphi^\varepsilon(x)}). \tag{2.38}$$

Estimating the density. Let us now estimate $n_-^\varepsilon(x) = \int_{-\infty}^0 f^\varepsilon(x,v)dv$. To this end, we do not need the sharp estimate (2.35). Estimate (2.36) is sufficient and gives after integration on $\mathbb{R}_-$

$$\sqrt{\varphi^\varepsilon(x)}n_-^\varepsilon(x) \le C\frac{\varepsilon(-\ln\varepsilon)^{1/4}}{(\varphi^\varepsilon(x))^{1/4}}||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty} \le C\varepsilon^{1/2}(-\ln\varepsilon)^{1/4}||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty}. \tag{2.39}$$

For positive v's, more care should be taken since $\varphi(x^*) = 0$ if $v = \sqrt{\varphi(x)}$. Then let $k \ge 2$ be a constant (to be fixed later) and $0 \le v \le \sqrt{\varphi^\varepsilon(x)}/k$. Then $\varphi^\varepsilon(x^*) \ge \frac{3}{4}\varphi^\varepsilon(x)$ and therefore, we can replace x^* by x in (2.38) and (2.37) (modulo a change in C). By integration this leads to

$$\sqrt{\varphi^\varepsilon(x)}\int_0^{\frac{\sqrt{\varphi^\varepsilon(x)}}{k}} f^\varepsilon \le \frac{C}{k}||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty}(\varphi^\varepsilon(x))^{1/4}, \quad \varphi^\varepsilon(x) \ge -10\varepsilon^2\ln\varepsilon$$

$$\le \frac{C}{k}||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty}(-\varphi^\varepsilon(x)\ln\varepsilon)^{1/4}, \quad \varepsilon^2 \le \varphi^\varepsilon(x) \le -10\varepsilon^2\ln\varepsilon.$$

This implies that

$$\sqrt{\varphi^\varepsilon(x)}\int_0^{\frac{\sqrt{\varphi^\varepsilon(x)}}{k}} f^\varepsilon dv \leq \frac{C}{k}||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty}, \quad x \in [r^\varepsilon, 1],$$

which together with (2.39) leads to

$$(2.40) \qquad \sqrt{\varphi^\varepsilon(x)}\int_{-\infty}^{\frac{\sqrt{\varphi^\varepsilon(x)}}{k}} f^\varepsilon(x,v)\,dv \leq \left(\frac{C}{k}+o(1)\right)||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty}.$$

Additionally, we have

$$\sqrt{\varphi^\varepsilon(x)}\int_{\frac{\sqrt{\varphi^\varepsilon(x)}}{k}}^{+\infty} f^\varepsilon(x,v)\,dv \leq k\int_{\frac{\sqrt{\varphi^\varepsilon(x)}}{k}}^{+\infty} vf^\varepsilon(x,v)\,dv,$$

and by Lemma 2.4(i), we deduce that

$$\sqrt{\varphi^\varepsilon(x)}\int_{\frac{\sqrt{\varphi^\varepsilon(x)}}{k}}^{+\infty} f^\varepsilon(x,v)\,dv \leq Ck, \quad x \geq r^\varepsilon.$$

This, combined with (2.40), implies that

$$||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty} \leq Ck + \left(\frac{C}{k}+o(1)\right)||n^\varepsilon\sqrt{|\varphi^\varepsilon|}||_{L^\infty}.$$

Now, to prove the L^∞ bound, we just have to choose $k > C$ and the result follows immediately.

(ii) follows from estimate (2.35) and (2.37) which give a uniform bound for f^ε as long as $\varphi(x) > 0$ (i.e. $x \neq 0$) and $v < \sqrt{\varphi(x)}$. □

PROPOSITION 2.4. *The convergence of φ^ε toward φ holds in the $C^1([0,1])$ strong topology and $n \in L^\infty_{loc}((0,1]) \cap L^1([0,1])$.*

Proof. (i) First since φ^ε converges uniformly to φ, then $n^\varepsilon\sqrt{|\varphi^\varepsilon|}$ converges in the bounded measure weak topology to $n\sqrt{\varphi}$. We deduce from the preceding lemma that $n\sqrt{\varphi}$ is in $L^\infty(0,1)$ and by a diagonal extraction we deduce that n^ε converges to n in the weak $*$ L^∞ topology on any interval $[\alpha, 1]$ with $\alpha > 0$. This implies that φ^ε converges in $C^1[\alpha,1]$ for $\alpha > 0$. Since $\varphi' \geq 0$ and increasing, then it has a limit $\varphi'(0)$ when x tends to zero. Suppose first that $\varphi'(0) = \lim \varphi^{\varepsilon\prime}(0)$ has already been shown. Then by the use of Dini's theorem, we deduce that the convergence of $\varphi^{\varepsilon\prime}$ to φ' holds in $C^0([0,1])$. Let us show now that $\lim \varphi^{\varepsilon\prime}(0) = \varphi'(0)$. It is sufficient, in view of Lemma 2.2, to prove the equality for absolute values. We have

$$h^\varepsilon + \frac{1}{4}\left(\frac{d\varphi^\varepsilon}{dx}(x)\right)^2 = k^\varepsilon(x) + \frac{j^\varepsilon x}{\tau}.$$

Therefore, passing to the limit for $x > 0$ and taking into account point (iii) of Lemma 2.4, we get

$$\left|h + \frac{1}{4}\left(\frac{d\varphi}{dx}(x)\right)^2\right| \leq C\sqrt{\varphi(x)} + \frac{jx}{\tau}.$$

Afterward, we let x tend to zero and obtain

$$h + \frac{1}{4}\left(\frac{d\varphi}{dx}(0)\right)^2 = 0.$$

Furthermore, using (2.24), we have

$$\left| h^\varepsilon + \frac{1}{4}\left(\frac{d\varphi^\varepsilon}{dx}(0)\right)^2 \right| = k^\varepsilon(0) \le C\varepsilon$$

which leads to

$$h + \lim \frac{1}{4}\left(\frac{d\varphi^\varepsilon}{dx}(0)\right)^2 = 0.$$

Therefore $\lim |\frac{d\varphi^\varepsilon}{dx}(0)| = |\frac{d\varphi}{dx}(0)|$, which is the expected result.

(ii) Since $n\sqrt{\varphi} \in L^\infty([0,1])$ and φ vanishes only at $x = 0$, we can deduce that

$$n(x) = n_{reg}(x) + n_0\delta(x),$$

where n_{reg} is an $L^\infty_{loc}((0,1]) \cap L^1([0,1])$ function and n_0 is a nonnegative constant. Since by the weak convergence of n^ε to n we have

$$\varphi'(x) = \varphi'(0) + n_0 + \int_0^x n_{reg},$$

we deduce by letting x tend to zero that

$$\varphi'(0) = n_0 + \varphi'(0),$$

which implies that $n_0 = 0$ and ends the proof. □

3. Characterization of the limit problem. We can pass to the limit in the Boltzmann equation since the nonlinear term passes to the limit. Indeed, for every test function $\theta(x,v) \in C^1([0,1] \times \mathbb{R})$ such that $\theta = 0$ is in the neighborhood of $\{0\} \times \mathbb{R} \cup \{1\} \times \mathbb{R}_+$, we have

$$\int_{x,v} f^\varepsilon \left[v\frac{\partial \theta}{\partial x} + \frac{1}{2}\frac{d\varphi^\varepsilon}{dx}\frac{\partial \theta}{\partial v} - \frac{\theta}{\tau} \right] dxdv + \frac{1}{\tau}\int_x \left(\int_v M_0(v)\theta(x,\varepsilon v)dv \right) n^\varepsilon(x)dx = 0.$$

Since $\varphi^{\varepsilon\prime}$ converges uniformly and f^ε converges weakly, the nonlinear term

$$f^\varepsilon \frac{d\varphi^\varepsilon}{dx}\frac{\partial \theta}{\partial v}$$

passes to the limit and we obtain finally

$$\left\langle\left\langle f, v\frac{\partial \theta}{\partial x} + \frac{1}{2}\frac{d\varphi}{dx}\frac{\partial \theta}{\partial v} - \frac{\theta}{\tau} \right\rangle\right\rangle_{\mathcal{M}_b, C_0} + \frac{1}{\tau}\int_x \theta(x,0)n(x)dx = 0. \tag{3.41}$$

This equation means that for $(x,v) \in (0,1] \times \mathbb{R}_+$ f is a solution of the equation

$$v\frac{\partial f}{\partial x} + \frac{1}{2}\frac{d\varphi}{dx}\frac{\partial f}{\partial v} + \frac{f}{\tau} = 0$$

with the boundary condition

$$f(x,0) = \frac{2n(x)}{\tau\varphi'(x)}.$$

Notice that φ is in $W^{2,\infty}_{loc}(0,1]$ and that the characteristics passing through a point (x,v) such that $0 < x$ and $0 \leq v < \sqrt{\varphi(x)}$ are issued from the axis $(0,1]$. Therefore, $f(x,v)$ has a unique expression in terms of the potential and the density (obtained after an integration of the equation over the characteristics)

(3.42)
$$f(x,v) = f_2(x,v) = \frac{2n(x^*)}{\tau\varphi'(x^*)} \exp\left(-\frac{1}{\tau}\int_{x^*}^{x} \frac{dz}{\sqrt{\varphi(z)-\varphi(x^*)}}\right), \ v \in [0, \sqrt{\varphi(x)}),$$

where x^* is uniquely defined by

$$\varphi(x^*) = \varphi(x) - v^2.$$

Since f is a bounded measure supported in the set $\{0 \leq v \leq \sqrt{\varphi(x)}\}$ and since $f = f_2$ almost everywhere in the set $\{0 \leq v < \sqrt{\varphi(x)}\}$, then we can conclude that

$$f = f_1 + f_2,$$

where f_1 is a bounded measure supported in the set $\{v = \sqrt{\varphi(x)}\}$. We now determine the measure f_1 by noticing that the current is constant. Since f_1 is supported in the set $\{v = \sqrt{\varphi(x)}\}$, then it reads

$$f_1 = n_1(x)\delta(v - \sqrt{\varphi(x)}),$$

where n_1 is a bounded measure on $[0,1]$. We have obviously $n_1 = \langle f_1, 1\rangle_v$. Let j_1 be the current associated with f_1

$$j_1 = \langle f_1, v\rangle_v.$$

We have obviously

$$j_1(x) = n_1(x)\sqrt{\varphi(x)}.$$

Let n_2 and j_2 be the density and the current corresponding to f_2 defined above. We have

$$f(x,v) = f_1(x,v) + f_2(x,v),$$

$$n(x) = n_1(x) + n_2(x),$$

$$j = j_1(x) + j_2(x).$$

Moreover, we have

$$n_2 = \langle f_2, 1\rangle_v = \int_0^{\sqrt{\varphi(x)}} f_2(x,v)dv.$$

The change of variable $y = x^*(x, v)$ gives

$$n_2(x) = \int_0^x \frac{n(y)}{\tau\sqrt{\varphi(x) - \varphi(y)}} \exp\left(-\frac{1}{\tau}\int_y^x \frac{dz}{\sqrt{\varphi(z) - \varphi(y)}}\right) dy. \tag{3.43}$$

Analogously, we get

$$j_2(x) = \int_0^x \frac{n(y)}{\tau} \exp\left(-\frac{1}{\tau}\int_y^x \frac{dz}{\sqrt{\varphi(z) - \varphi(y)}}\right) dy. \tag{3.44}$$

Therefore

$$j_2(x) \leq \frac{1}{\tau}\int_0^x n(y)dy$$

and since n is an L^1 function, then

$$\lim_{x \to 0} j_2(x) = 0.$$

Thus

$$j_1(0) = j. \tag{3.45}$$

Notice that this identity was an *assumption* in the derivation of the limit problem in [3]. Here it is *proved.* The differentiation of (3.44) using (3.43) implies that

$$\frac{dj_2}{dx} = \frac{n}{\tau} - \frac{n_2}{\tau} = \frac{n_1}{\tau} = \frac{j_1}{\tau\sqrt{\varphi}}$$

and since $j = j_1 + j_2$ is constant, we deduce that

$$\frac{dj_1}{dx} + \frac{j_1}{\tau\sqrt{\varphi}} = 0,$$

which together with the condition (3.45) gives

$$j_1(x) = j \exp\left(-\frac{1}{\tau}\int_0^x \frac{dz}{\sqrt{\varphi(z)}}\right) \tag{3.46}$$

and

$$n_1(x) = \frac{j}{\sqrt{\varphi(x)}} \exp\left(-\frac{1}{\tau}\int_0^x \frac{dz}{\sqrt{\varphi(z)}}\right). \tag{3.47}$$

Proof of Theorem 1.4. At this stage, we have proven that (1.11)–(1.18) are satisfied. To prove Theorem 1.4, it remains now to determine the current. Point (iii) is straightforward since $j = j_g$ if $\varphi'(0) > 0$ (Lemma 2.3) and $j = j_{CL}$ if $\varphi'(0) = 0$ (Theorem 1.2). To prove point (i), we suppose that $j \neq j_{CL}$. Then $j = j_g$ and this is not possible in view of Theorem 1.3. Point (ii) follows easily from the fact that $j \leq j_g$, which implies that $j < j_{CL}$. □

4. Conclusion. In this paper we gave a mathematical justification of a formal model derived in a previous paper [3] from a singular perturbation problem. The convergence result is not complete because the limit problem is not fully solved; namely, the uniqueness of the solution of the limit problem is not shown and the possible difference between the Child–Langmuir current j_{CL} and the maximal current $j_{\max}$ is not known. Such problems were already noted in [7] and [8] where the authors show that the maximal current can be different from the Child–Langmuir one in some particular situations. In that case, statement (iii) of Theorem 1.4 cannot be improved.

Acknowledgments. The author would like to thank Pierre Degond and Frédéric Poupaud for many encouraging discussions and enlightening remarks.

RIGOROUS WKB FOR FINITE-ORDER LINEAR RECURRENCE RELATIONS WITH SMOOTH COEFFICIENTS*

OVIDIU COSTIN[†] AND RODICA COSTIN[†]

Abstract. The $\epsilon \to 0$ behavior of recurrence relations of the type $\sum_{j=0}^{l} a_j(k\epsilon, \epsilon) y_{k+j} = 0$, $k \in \mathbf{Z}$ (l fixed) is studied. The a_j are C^∞ functions in each variable on $I \times [0, \epsilon_0]$ for a bounded interval I and $\epsilon_0 > 0$. Under certain regularity assumptions we find the asymptotic behavior of the solutions of such recurrences. In typical cases, there exists a fundamental set of solutions in the form $\{\exp(\epsilon^{-1} F_m(k\epsilon, \epsilon))\}_{m=1,\ldots,l}$, where the functions F_m are C^∞ in each variable on the same domain as the a_j, showing in particular that the formal perturbation-series solutions are asymptotic to true solutions of these recurrences. Some applications are also briefly discussed.

Key words. recurrence relations, asymptotic behavior

AMS subject classifications. 41A60, 65M06, 65M12

1. Introduction.

In this paper, we study the asymptotic behavior to all orders in $\epsilon \to 0$ of the solutions of one-dimensional recurrence relations of the form

$$\sum_{j=0}^{l} a_j(k\epsilon, \epsilon) y_{k+j} = 0, \tag{1}$$

which we may interpret as follows: for each fixed k, y_{k+l} is determined from its predecessors $y_k, \ldots, y_{k+l-1}$ (this is assumed possible—see condition (6) below).

Under some further regularity assumptions, we prove that the general solution of the recurrence can be piecewise represented as a sum

$$y_{k,\epsilon} = \sum_{m=1}^{l} C_{m,p} \exp[\epsilon^{-1} F_m(k\epsilon, \epsilon)], \tag{2}$$

where the functions F_m are everywhere smooth with the exception of a small neighborhood of the points where two characteristic roots (24) cross and where the representation is different (Proposition 2.2) . In particular, a fundamental system of solutions can be chosen such that each of them has, for small ϵ and between crossings, a Wentzel–Kramer–Brillouin (WKB)-like expansion

$$y_k \sim \exp\left(\epsilon\phi(k\epsilon)\right)\left(A_0(k\epsilon) + \epsilon A_1(k\epsilon) + \cdots\right), \tag{3}$$

where ϕ is the root of the eikonal equation

$$\exp(\phi'(x)) = \lambda(x),$$

λ is one of the l roots of the characteristic equation (24), and the successive amplitudes A_i can be determined by perturbation–expansion.

For technical reasons, we prefer the less familiar notation (2). It is essential for our arguments that a continuous branch of ln A_0 can be chosen.

One of the applications of the rigorous WKB approach for discrete schemes is in determining the spectrum of large matrices with slowly varying entries. Such problems appear for instance in the continuum limit of the Toda lattice. This system, described by the Hamiltonian $H = \frac{1}{2}\sum_{k=1}^{n} p_k^2 + \sum_{k=1}^{n-1} \exp(x_k - x_{k-1})$, is completely integrable; this can be expressed in terms of the constancy of the spectrum of the matrix

$$\begin{pmatrix} a_1 & b_1 & 0 & \cdots & 0 \\ b_1 & a_2 & b_2 & \cdots & 0 \\ 0 & b_2 & a_3 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots \end{pmatrix}. \tag{4}$$

The spectral problem in the case where the coefficients are of the form $a_k = a(k\epsilon)$, $b_k = b(k\epsilon)$, with a and b smooth and satisfying some regularity conditions, leads to a recurrence of the type of (1) that is solved asymptotically by the methods described below [1].

In (1) the number l of steps of the recurrence is fixed, $\epsilon > 0$ is a small parameter, and $k \in \mathbb{Z}$ is such that $k\epsilon \in I$ where $I \subset \mathbb{R}$ is a compact interval. Some initial or boundary conditions are assumed.

The coefficients $a_0(x,\epsilon), \ldots, a_l(x,\epsilon) : I \times [0,\epsilon_0] \to \mathbb{C}$ are assumed C^∞ in x and in ϵ in some domain $I \times [0,\epsilon_0]$. We also require the existence of a uniformly asymptotic series for a_j: for any $t \in \mathbb{N}$,

$$\left| a_j(x,\epsilon) - \sum_{s=0}^{t} a_{j,s}(x)\epsilon^s \right| < M_{j,s}\epsilon^{t+1}, \tag{5}$$

where the functions $a_{j,s}$ are C^∞ in x (for instance, $a_j \in C^\infty(I \times [0,\epsilon_0])$).

We are also imposing the nonsingularity condition

$$\inf_{x\in I}\{|a_0(x,0)|\} > 0 \text{ and } \inf_{x\in I}\{|a_l(x,0)|\} > 0. \tag{6}$$

We begin by giving some simple examples and deriving heuristically their small-ϵ behavior. The contents of the paper will subsequently make the given solutions rigorous.

Example a. Consider the one-step recurrence relation

$$y_{k+1} = e^{f(k\epsilon)} y_k, \tag{7}$$

where $y_0 = 1$, $0 \le k \le \epsilon^{-1}$, and f is a C^∞ function on $[0,1]$. It has the explicit solution

$$y_k = \exp\left(\sum_{j=0}^{k-1} f(j\epsilon)\right). \tag{8}$$

When $f = f_0$ is constant, $y_k = \exp(\epsilon^{-1} f_0 k\epsilon)$ and this should also be the order of magnitude of y_k for a general smooth f when ϵ is very small; we then try a formal asymptotic solution

$$y_k \sim \exp(\epsilon^{-1}\Phi_0(k\epsilon) + \Phi_1(k\epsilon) + \epsilon\,\Phi_2(k\epsilon) + \cdots) \tag{9}$$

in (7) . To be consistent with (7) we must have

$$\exp\left[\sum_{m=0}^{\infty}\epsilon^{m-1}\Phi_m(k\epsilon+\epsilon)\right]\sim\exp\left[f(k\epsilon)+\sum_{m=0}^{\infty}\epsilon^{m-1}\Phi_m(k\epsilon)\right],\ \epsilon\to 0. \tag{10}$$

Expanding the exponent in the left-hand side of (10) in a Taylor series around $k\epsilon$ and then identifying the corresponding powers of ϵ in (10) we obtain

$$\Phi_0'=f,\quad \Phi_1'=-\frac{1}{2}f',\ldots,\Phi_j'=C_j\ f^{(j)},\ldots, \tag{11}$$

where the constants C_j are seen to be f-independent and can thus be determined by choosing a particular f for which the sum in (8) can be explicitly evaluated. Taking, e.g., $f(x)=\exp(x)$, this sum is

$$(\exp(x)-1)(\exp(\epsilon)-1)^{-1}\sim\epsilon^{-1}(\exp(x)-1)\sum_{j=0}^{\infty}\frac{B_{2j}}{(2j)!}\epsilon^{2j},\quad \epsilon\to 0, \tag{12}$$

where B_n are the Bernoulli numbers. It follows that $C_j=B_j$ ($B_{2j+1}=0$) and thus, for any smooth f,

$$\sum_{j=0}^{k-1}f(j\epsilon)\sim\frac{1}{\epsilon}\sum_{n=0}^{\infty}\frac{B_{2n}}{(2n)!}\epsilon^{2n}\int_0^x f^{(n)}(t)dt,\quad \epsilon\to 0, \tag{13}$$

which is, of course, the Euler–Maclaurin summation formula. Proposition 2.1 below justifies the derivation of (13).

Example b. Analogously, we can easily obtain the asymptotic behavior of special functions from their generating recurrence relation. For instance, the recurrence relation

$$y_{k+1}+y_{k-1}=2(1+k\epsilon)y_k \tag{14}$$

has for a fundamental set of solutions the Bessel functions $J_{k+\epsilon^{-1}}(\epsilon^{-1})$ and $Y_{k+\epsilon^{-1}}(\epsilon^{-1})$.

Let $x=k\epsilon$, $\nu=k+\epsilon^{-1}$, $a=\epsilon^{-1}\nu^{-1}$. We fix $\rho<\frac{2}{3}$ and for $x>\epsilon^{\rho}$ we take y of the form (9) determining the successive terms by substituting the formal series in (14). To leading order,

$$e^{\Phi_0'(x)}+e^{-\Phi_0'(x)}=2(1+x) \tag{15}$$

and we can choose two independent solutions

$$\epsilon^{-1}\Phi_{0;\pm}=\pm\nu(\alpha-\tanh(\alpha))\quad(\alpha\equiv(\cosh)^{-1}(1/a)). \tag{16}$$

For the next order $\Phi_{1;\pm}$, we obtain

$$\Phi_{1;\pm}'/\Phi_{1;\pm}=-\frac{1}{2}\Phi_{0;\pm}''\coth(\Phi'), \tag{17}$$

which can again be integrated explicitly to give $\exp(\Phi_{1;\pm})=\text{const}\sinh(\alpha)^{-1/2}$. That is, the asymptotic behavior is

$$(\nu\tanh(\alpha))^{-1/2}(A\exp[\nu(\alpha-\tanh(\alpha))+\cdots]+B\exp[-\nu(\alpha-\tanh(\alpha))+\cdots]) \tag{18}$$

and we get the familiar expressions in the theory of Bessel functions (see [2], [3]). All the successive orders are easily obtained in the same way. For $x < -\epsilon^{\rho}$ we obtain from the same equations (15), (17) similar expressions but with trigonometric instead of hyperbolic functions. For small values of $|x|$, $|x| \lesssim \epsilon^{2/3}$, the above asymptotic series becomes singular. The appropriate WKB-like series in this region is in powers of $\epsilon^{1/3}$ and the coefficients will be smooth functions of $\epsilon^{1/3}k$, but otherwise the calculation can be done explicitly in the same way; there is a region of overlap where both asymptotic series are valid, namely $\epsilon^{2/3} < |x| < \epsilon^{1/2}$, and where the series can be matched.

Proposition 2.2 can be used to make the above approach rigorous.

Example c. Finally, let q be a smooth function and consider the Cauchy problem

$$y'' = q(x)y, \quad y(0) = 0, \quad y'(0) = 1. \tag{19}$$

Assume for simplicity that $q : [0, 1] \to \mathbb{R}^+$ and consider the associated Euler scheme

$$y_{k+\epsilon;\epsilon} + y_{k-\epsilon;\epsilon} = (2 + \epsilon^2 q(k\epsilon))y_{k;\epsilon}, \quad y_{0;\epsilon} = 0, \quad y_{1;\epsilon} = \epsilon. \tag{20}$$

To characterize $y_{k;\epsilon}$ for small ϵ we substitute

$$y_{k;\epsilon} \sim \sum_{m=0}^{\infty} \epsilon^m \Xi_m(k\epsilon) \tag{21}$$

in (20). Note that if $\Xi_0 \neq 0$ we obtain this type of series from (9), when $\Phi_0 = 0$, by expanding the exponential.

The substitution leads to the equations

$$\Xi_m'' = q(x)\Xi_m - 2 \sum_{1 \le s; 2s \le m} \frac{\Xi_{m-2s}^{(2s)}}{(2s)!} \tag{22}$$

with the initial conditions

$$\Xi_m(0) = 0, \quad \Xi_m'(0) = -\sum_{k=1}^{m} \frac{\Xi_{m-k}^{(k+1)}(0)}{(k+1)!}. \tag{23}$$

In particular, it follows that the scheme converges to the solution of the given Cauchy problem (as it should) and because, as it is easily seen, $\Xi_1 \equiv 0$, the error $|y_{k+\epsilon} - \Xi_0(k\epsilon)|$ is $O(\epsilon^2)$. Proposition 2.3 applies to this example.

2. Main results. In this section, we consider the problem (1) and the assumptions following it and give conditions under which the exact solutions of the recurrence have asymptotic series to all orders in ϵ.

PROPOSITION 2.1. *Let $\lambda_1(x), \dots, \lambda_l(x)$ be the roots of the characteristic polynomial*

$$\sum_{j=0}^{l} a_j(x, 0)\lambda^j = 0 \tag{24}$$

and assume that they are simple throughout I

$$\inf_{x \in I}\{| \lambda_m(x) - \lambda_n(x) |\} > 0 \quad \textit{if } m \neq n. \tag{25}$$

(consequently, we will choose λ_m to be C^∞ functions). Suppose also that the interval I is a finite union of (closed) intervals such that in each one of them the ordering of the moduli of the roots does not change, i.e.,

$$\begin{gathered} I = \bigcup_{p=1}^{P} I_p \quad \textit{and } \forall p \leq P \; \exists (i_1, \ldots, i_l) \textit{ such that} \\ |\lambda_{i_1}(x)| \leq |\lambda_{i_2}(x)| \leq \cdots \leq |\lambda_{i_l}(x)| \quad \textit{for all } x \in I_p, \end{gathered} \tag{26}$$

where $(i_1, \ldots, i_l)$ is a permutation of $(1, \ldots, l)$. Then there exists $\epsilon' \leq \epsilon_0$ and l functions $F_1(x,\epsilon), \ldots, F_l(x,\epsilon)$ on $I \times [0,\epsilon']$, C^∞ in each variable, such that for each ϵ, $\{\exp(\epsilon^{-1} F_m(k\epsilon,\epsilon))\}_{m=1,\ldots,l}$ form a fundamental set of solutions of the recurrence relation (1), in the sense that for any solution $y_{k,\epsilon}$ of (1), there exist constants $C_1^{(p)}, \ldots, C_l^{(p)}$ such that in each I_p,

$$y_{k,\epsilon} = \sum_{m=1}^{l} C_m^{(p)} \exp[\epsilon^{-1} F_m(k\epsilon,\epsilon)]. \tag{27}$$

REMARK 1. *In particular, this means that for small ϵ,*

$$F_m(x,\epsilon) \sim \sum_{s=0}^{\infty} \Phi_{m,s}(x) \epsilon^s, \tag{28}$$

where the $\Phi_{m,s}$ are smooth; they can be computed from (1) by usual perturbation expansions in ϵ. For example, the first term is obtained from the eikonal equation,

$$\exp(\Phi'_{m,0}(x)) = \lambda_m(x), \tag{29}$$

giving the connection between the functions F_m and the roots λ_m of the characteristic polynomial. The second term is obtained from

$$\Phi'_{n,1}(x) = -\frac{\sum_{j=0}^{l} [j^2 \Phi_{n,0}(x)''/2 A_{j,0}(x) + \exp(\Phi'_{j,0}(x)) A_{j,1}(x)]}{\sum_{j=0}^{l} j A_{j,0}(x) \exp(\Phi'_{j,0}(x))} \tag{30}$$

and so on.

Note also that if not all the functions F_m have the same real part, then there exist solutions of the recurrence which are exponentially small relative to the dominant ones and which will therefore be unstable in the sense that a small "generic" perturbation of the initial condition will completely change the behavior of these solutions; a perturbation series not involving terms beyond all orders will only see the component of the solution along the dominant directions. However, the relative size of the solutions could change with x and then all the coefficients in the expansion (27) could be important for matching different regions.

We now address the question of the asymptotic behavior of the solutions of the recurrence when two characteristic roots cross. Proposition 2.1 is generalized below to the case when two of the roots of the characteristic polynomial become equal at some point in I provided the roots do not coalesce too quickly (condition (31)). In this case a fundamental set of solutions has a more complicated structure. Not too close to the crossing point, a solution is still a linear combination of the form (27) but the coefficients $C_m^{(p)}$ can change at the crossing (Stokes phenomenon). Very close to the crossing, the coalescing roots bring in the asymptotic expression of the solution series in noninteger powers of ϵ. This is in some sense the discrete counterpart of the turning-point behavior of the solution of a differential equation depending on a small parameter.

Consider a subinterval I_0 of I such that two roots of the characteristic polynomial cross once in I_0 (say, at $x = 0$) and except for this, the ordering of the moduli of the characteristic roots is constant in I_0. The crossing is assumed to be generic:

$$|\lambda_m(x) - \lambda_n(x)| > \mathrm{const}\sqrt{|x|} \quad (\text{for } m \neq n). \tag{31}$$

To avoid excessive branching of the discussion and formuli, we also assume that the coalescing roots are *complex conjugate* for negative x and *real valued* for x positive. The general case is treated in a very similar way.

PROPOSITION 2.2. *Fix two constants* $\frac{1}{3} < \beta < \alpha < \frac{1}{2}$. *Then,*

(i) *For* $|k| > \epsilon^{-\beta}$ *the general solution of the recurrence can be written in the form*

$$y_k = \sum_{j=1}^{l} C_j \exp(\epsilon^{-1} F_j(k\epsilon, \epsilon)) \tag{32}$$

with F_j *as in Lemma* 3.2. *The constants* C_j *depend, in general, on the sign of* k.

(ii) *For* $|k| < \epsilon^{-\alpha}$ *a fundamental set of solutions can be chosen such that* $l-2$ *solutions are of the form* $\exp(\epsilon^{-1}F_j(k\epsilon,\epsilon))$ *and two special solutions are of the form*

$$\exp(F_{\pm}(k\epsilon^{1/3}, \epsilon^{1/3})),$$

where the functions F_j *and* $F_{\pm}$ *are smooth and* $\exp(F_{\pm}(x,0)) = \mathrm{Ai}(\Theta\, x) \pm \mathrm{Bi}(\Theta\, x)$, *where* Ai *and* Bi *are the Airy functions* (*for the value of* Θ, *see equation* (89)).

Moreover there is a particular solution of the recurrence which has the behavior

$$y_k \sim \mathrm{Ai}(\Theta\, k\epsilon^{1/3})(1 + \epsilon^{1/3} A_1(\Theta\, k\epsilon^{1/3}) + \cdots)$$

for large $k < \epsilon^{-\alpha}$.

The representations in (i) *and* (ii) *are simultaneously valid in the region* $\epsilon^{-\beta} < |k| < \epsilon^{-\alpha}$, *where the asymptotic series can be matched.*

Note. A similar result can be proven if condition (31) is replaced by

$$|\lambda_m(x) - \lambda_n(x)| > \mathrm{const}\, x^{\mathrm{const}'} \tag{33}$$

for some const > 0. Another case which is interesting for schemes that converge to differential equations for small ϵ is covered by the following proposition, in which we assume that the roots of the *complete* characteristic polynomial

$$\sum_{j=0}^{l} a_j(x,\epsilon)\lambda^j, \qquad m = 1, \dots, l \tag{34}$$

are nondegenerate in a *higher* order in ϵ.

PROPOSITION 2.3. *Assume that the roots* $\lambda_1(x,\epsilon), \dots, \lambda_l(x,\epsilon)$ *of* (34) *satisfy the estimates*

$$|\lambda_m(x,\epsilon) - 1| = \epsilon^q (Q_m(x) + o(\epsilon)), \quad m \leq l \tag{35}$$

for some $q \in \mathbb{N}$, where the smooth functions Q_i verify

$$\inf_{x\in I} Q_m(x) > 0, \ \inf_{x\in I} |Q_m(x) - Q_n(x)| > 0 \qquad (m \neq n)\ m,n \leq l.$$

Then the conclusion of Proposition 2.1 *holds and, furthermore, for any formal series solution of the recurrence relation* (1), *there exists a true solution which is asymptotic to it.*

In this particular case, since, as we shall see, $F_m(x,0) = 0$, it is more natural to represent the formal solutions as power series

$$\Gamma = \sum_{i=0}^{\infty} \Psi_i(x)\epsilon^i, \tag{36}$$

where the Ψ_i are smooth and subject to the condition

$$\sum_{j=0}^{l} a_j(x,\epsilon)\Gamma_s(x+j\epsilon;\epsilon) = o(\epsilon^s) \qquad \forall s,\ x \in I, \tag{37}$$

where $\Gamma_s(x) = \sum_{i=0}^{s} \Psi_i(x)\epsilon^i$. The series (36) and those appearing in the previous WKB expansions are usually divergent and one could imagine that by iterating the recurrence the small error appearing in the local condition (37) could quickly reach O(1). Under the given restrictions, however, Proposition 2.3 guarantees that Γ_s is indeed an $o(\epsilon^s)$ approximation to a genuine solution.

It can now be checked without difficulty that Propositions 2.1–2.3 apply to Examples a, b, and c, respectively.

The layout of the remainder of this paper is as follows: in §3 we prove our main results and in §4 we discuss some further applications of these results.

3. Proof of the results. To prove Proposition 2.1, we show (Lemma 3.1) the existence of l formal series solutions of the form (9) to the recurrence.

We then show (Lemma 3.2) that the proposition is true if $P = 1$ (cf. (26)). The proof is by induction on the order l of the recurrence. First, we choose the particular formal solution corresponding (cf. (39)) to the root with maximum modulus, which gives the "stable" direction, and show that there is a true solution with this asymptotic behavior. Next, we use this particular solution to decrease the order of the recurrence by 1.

3.1. The functions $\Phi_{m,s}$ of the following lemma will turn out to be the functions giving the asymptotic expansions (28) and can be obtained by requiring that (1) is satisfied in all orders in ϵ by the formal solution $y_m = \exp(\epsilon^{-1}\sum_s \Phi_{m,s}(x)\epsilon^s)$.

LEMMA 3.1. *For each $m = 1,\dots,l$ there exists a sequence $\{\Phi_{m,s}\}_{s\in\mathbb{N}}$ of functions in $C^\infty(I)$ such that*

$$\exp(-\epsilon^{-1}\Phi_{m,0}(k\epsilon))\sum_{j=0}^{l} a_j(k\epsilon,\epsilon)\exp\left(\epsilon^{-1}\sum_{t=0}^{s}\epsilon^t\Phi_{m,t}((k+j)\epsilon)\right) = O(\epsilon^{s+1}) \tag{38}$$

and

$$\exp(\Phi'_{m,0}(x)) = \lambda_m(x) \tag{39}$$

for $\epsilon \leq \epsilon_0$, $s \in \mathbb{N}$, and $k\epsilon \in I$.

The proof of Lemma 1 is by induction on the expansion order s. In view of (5) and (6), we can define for each characteristic root $\lambda_m(x)$ (i.e., root of (24)), a function $\Phi_{m,0} \in C^\infty(I)$ such that (39) holds.

It is then straightforward to show that $\exp(\epsilon^{-1}\Phi_{m,0})$ verifies the recurrence (1) to $O(\epsilon)\exp(\epsilon^{-1}\Phi_{m,0}(x))$ so that (38) holds for $s = 0$. Assuming now that $\Phi_{m,0}, \Phi_{m,1}, \ldots, \Phi_{m,s_0}$ are already defined so that for all $s \leq s_0$ (38) is verified, one can easily check that for any $\Psi \in C^\infty(I)$,

(40)

$$\exp[-\epsilon^{-1}\Phi_{m,0}(k\epsilon)]\sum_{j=0}^{l}\exp\left\{\epsilon^{-1}\sum_{t=0}^{s_0}\Phi_{m,t}((k+j)\epsilon)\epsilon^t + \epsilon^{s_0+1}\Psi((k+j)\epsilon)\right\}a_j(k\epsilon,\epsilon)$$

$$= \epsilon^{s_0+1}\left[\Psi'(k\epsilon)\sum_{j=0}^{l} j\exp\{j\Phi'_{m,o}(k\epsilon)\}a_j(k\epsilon,0) + H_{s_0}(k\epsilon,\epsilon)\right] + O(\epsilon^{s_0+2}),$$

where H_{s_0} is a smooth function.

Since by (6) and (25)

$$\inf_{x\in I}\left|\sum_{j=0}^{l} j a_j(x,0)\lambda_m^j(x)\right| > 0, \tag{41}$$

one can define a smooth function $\Psi(x) \equiv \Phi_{s_0+1}(x)$ such that the term in square brackets in the right-hand side of (40) vanishes. □

We note at this point that the series $\sum_{s=0}^{\infty}\Phi_{m,s}(x)\epsilon^s$ is usually not convergent and there does not yet follow the existence of a solution asymptotic to it.

Now we address the question of existence of true solutions of the recurrence having the prescribed asymptotic behavior. In what follows, we shall define, by a formal solution, an expression $\tilde{Y} = \exp(\epsilon^{-1}\sum_{s=0}^{\infty}\Phi_{m,s}(x))\epsilon^s$ satisfying the conclusions of Lemma 3.1. Given $\Phi_{m,0}$, the $\Phi_{m,s}$ are uniquely determined up to integration constants.

Assume first $P = 1$ (cf. (26)). Relabelling if necessary, we assume that for $m \leq n$, $|\lambda_m(x)| \leq |\lambda_n(x)|$ on I.

LEMMA 3.2. *Let $\tilde{Y}$ be a formal solution of* (1) *($m \in \{1, \ldots, l\}$ fixed). There exists a sequence $\{Y_{m,k;\epsilon}\}_{k,\epsilon}$ such that for any $\epsilon \leq \epsilon_0$, $Y_{m,k;\epsilon}$ is a solution of* (1) *for $k\epsilon \in I$ having Γ_m as an asymptotic series in the sense that there is a sequence of positive constants $\{C_s\}_s$ such that*

$$\left|Y_{m,k;\epsilon}\exp\left[-\epsilon^{-1}\sum_{t=0}^{s}\Phi_{m,t}(k\epsilon)\epsilon^t\right] - 1\right| < C_s\,\epsilon^{s+1}, \quad \textit{for all } s \in \mathbb{N}. \tag{42}$$

REMARK 2. *The previous lemma can be restated as follows: For each $m = 1, \ldots, l$ there is a function $F_m(x,\epsilon) : I \times [0,\epsilon_0] \to \mathbb{C}$, smooth in each variable, such that $\exp(\epsilon^{-1}F_m(k\epsilon,\epsilon))$ is a solution of the recurrence* (1) *for every ϵ, $k\epsilon \in I$ and, as $\epsilon \to 0$,*

$$F_m(x,\epsilon) \sim \sum_{t=0}^{\infty}\Phi_{m,t}(x)\epsilon^t. \tag{43}$$

This remark follows easily from a classical result (see, e.g., [4, p. 33] and [5]) stating that for any sequence of numbers there is a smooth function having that sequence for its derivatives at the origin and from the easily proven fact that for each sequence $\{(x_n, a_n)\}_{n\in\mathbb{N}}$, $x_n \searrow 0$ and $a_n n^k \to 0$ $\forall k$, one can construct a C^∞ "interpolation" function f such that $f^{(k)}(0) = 0$ $\forall k$ and $f(x_n) = a_n$ for all n.

Some of the estimates that we need for proving Lemma 2 become to a certain extent easier by the remark that a global shift in the estimates defining an asymptotic series is unimportant.

REMARK 3. *Let F be a function such that for a fixed $s_0 \geq 0$ and any s in $\mathbb{N}$*

$$\limsup_{\epsilon\to 0} \epsilon^{-s-1} \left| F(\epsilon) - \sum_{t=0}^{s+s_0} C_t \epsilon^t \right| = D_s. \tag{44}$$

Then

$$\limsup_{\epsilon\to 0} \epsilon^{-s-1} \left| F(\epsilon) - \sum_{t=0}^{s} C_t \epsilon^t \right| \leq D_s + |C_{s+1}|. \tag{45}$$

Thus, to prove (42) we need only show that for some fixed s_0 (we drop the subscript ϵ to ease the notation),

$$\left| Y_{m,k} \exp\left(-\epsilon^{-1} \sum_{t=0}^{s} \Phi_{m,t}(k\epsilon)\epsilon^t \right) - 1 \right| < C_s\ \epsilon^{s+1-s_0}. \tag{46}$$

REMARK 4. *In view of condition* (25), *it is easy to check that, for small ϵ, the solutions* $\exp(\epsilon^{-1}F_m(k\epsilon,\epsilon))$ *are linearly independent, thus forming a fundamental set of solutions on I.*

Proof of Lemma 3.2. The proof is by induction on the order l of the recurrence.

Step 1. For any l, in the same conditions as in Lemma 3.1, the estimate (42) holds for $m = 1$ (recall that $\lambda_1(x)$ is the largest in absolute value). First we show that if a solution is asymptotic to the formal solution corresponding to λ_1 at the left end of I it remains asymptotic to it throughout I. We can assume without loss of generality that the left end of I is at $x = 0$. At this point, we choose appropriate initial conditions.

Let η_p, $p = 1, \ldots, l$ be any functions such that as $\epsilon \to 0$

$$\eta_p(\epsilon) \sim \exp\left(\epsilon^{-1} \sum_{t=0}^{\infty} \Phi_{1,t}(p\epsilon)\epsilon^t \right) \tag{47}$$

(see Remark 2) and let

$$\tilde{Y}_{\epsilon;s}(x) = \exp\left(\epsilon^{-1} \sum_{t=0}^{s} \Phi_{1,t}(x)\epsilon^t \right). \tag{48}$$

Let also $Y_{1,k}$ be the solution of (1) satisfying the initial conditions $Y_{1,p} = \eta_p(\epsilon)$, $p = 1, \ldots, l$.

It is natural to rescale the recurrence relative to its approximate solution. Let

$$C_{k;s} = Y_{1,k}/\tilde{Y}_{\epsilon;s}(k\epsilon). \tag{49}$$

Then the recurrence relation for $C_{k;s}$ can be written

$$\sum_{j=0}^{l} \tilde{a}_{j,s}(k\epsilon,\epsilon) C_{k+j;s} = 0, \tag{50}$$

where $\tilde{a}_{j,s}(k\epsilon,\epsilon) = a_j(k\epsilon,\epsilon)\tilde{Y}_{\epsilon;s}((k+j)\epsilon)/\tilde{Y}_{\epsilon;s}(k\epsilon)$. It can be seen that (50) is of the same type as (1) and that, for ϵ small enough, it satisfies the corresponding assumptions (6), (25), and (26) on I.

Also, $\max\{|\tilde{\lambda}_m(x)|; x \in I,\ m = 1,\dots,l\} = 1$. Now, (46) means that for some fixed s_0,

$$|C_{k;s} - 1| < \text{const}_s\epsilon^{s-s_0+1}. \tag{51}$$

From the definition of $\tilde{Y}_{\epsilon;s}$, it follows that

$$\sum_{j=0}^{l} \tilde{a}_{j,s}(k\epsilon,\epsilon) = O(\epsilon^s). \tag{52}$$

Rewriting the recursion relation (50) in matrix form $\mathbf{C}_{k+1} = \tilde{A}_k\mathbf{C}_k$, where

$$\tilde{A}_k = \begin{pmatrix} \frac{-\tilde{a}_{l-1}(k\epsilon,\epsilon)}{\tilde{a}_l(k\epsilon,\epsilon)} & \frac{-\tilde{a}_{l-2}(k\epsilon,\epsilon)}{\tilde{a}_l(k\epsilon,\epsilon)} & \cdots & \frac{-\tilde{a}_0(k\epsilon,\epsilon)}{\tilde{a}_l(k\epsilon,\epsilon)} \\ 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 1 & 0 \end{pmatrix}, \tag{53}$$

and also rewriting (52) as

$$\tilde{A}_k\mathbf{1} = \mathbf{1} + \epsilon^s\mathbf{E}_k, \tag{54}$$

where $\mathbf{1}_j = 1$ and $\|\mathbf{E}_k\| < \text{const}$ uniformly in k, ϵ, we have

$$\mathbf{C}_k = \mathbf{1} + \epsilon^s \sum_{j=1}^{k} \tilde{A}_k\tilde{A}_{k-1}\dots\tilde{A}_{j+1}\mathbf{E}_k. \tag{55}$$

Step 1 is completed by showing (51) (and thus (46)), which follows from the stability lemma below.

LEMMA 3.3. *Let $\tilde{A}_k$ be a family of matrices of the form of* (53), *where $\tilde{a}_j : I \times [0,\epsilon_0] \to \mathbb{C}$ (I is an interval) as in Lemma* 3.2. *Suppose further that the roots $\tilde{\lambda}_m(k\epsilon,\epsilon)$ of the polynomial*

$$\sum_{j=0}^{l} \tilde{a}_j(k\epsilon,\epsilon)\tilde{\lambda}^j = 0, \qquad m = 1,\dots,l \tag{56}$$

satisfy

$$\sup_{k\epsilon\in I}\{|\tilde{\lambda}_m(k\epsilon,\epsilon)|\} \le 1 + \text{const}\ \epsilon,\ m = 1,\dots,l \tag{57}$$

and that the condition corresponding to (25) *is fulfilled on I. Then there is an ϵ-independent constant C such that*

$$\|\tilde{A}_k\tilde{A}_{k-1}\dots\tilde{A}_{j+1}\| \le 1 + C|k-j|\epsilon. \tag{58}$$

Proof of Lemma 3. The eigenvalues of the matrix (53) are the $\tilde{\lambda}_m(k\epsilon,\epsilon)$ and the corresponding eigenvectors matrix is $(\tilde{\Lambda}_k)_{i,j} = \tilde{\lambda}_j(k\epsilon,\epsilon)^{l-i}$. We then write the product on the left-hand side of (58) as

$$\tilde{\Lambda}_k D_k \tilde{\Lambda}_k^{-1}\tilde{\Lambda}_{k-1}D_{k-1}\dots\tilde{\Lambda}_{j+1}D_{j+1}\tilde{\Lambda}_{j+1}^{-1}, \tag{59}$$

where

$$D_p = \operatorname{diag}(\{\tilde{\lambda}_m(p\epsilon,\epsilon)\}_{m=1,\dots,l}), \tag{60}$$

and the proof follows from (57) and the estimate

$$\|\tilde{\Lambda}_p^{-1}\tilde{\Lambda}_{p-1}\| \le 1 + \text{const } \epsilon, \tag{61}$$

which can be checked, for instance, using the following explicit formula, whose elementary proof we omit.

REMARK 5. *Let X and Y be two nonsingular Vandermonde-type matrices $X_{i,j} = x_j^{l-i}$, $Y_{i,j} = y_j^{l-i}$, $i,j = 1,\dots,l$. Then*

$$(X^{-1}Y)_{i,j} = \prod_{n\neq i} \frac{y_j - x_n}{x_i - x_n}. \tag{62}$$

Step 2. The conclusion of Lemma 3.2 for $l = 1$ follows from Step 1. Now we assume that the conclusion of the lemma holds for all recurrences of order less than l and prove it for order l by reduction to the $l-1$ case. In view of the first step, we know that to $|\lambda_1|$ there corresponds a true solution Y_1 for which the asymptotic behavior is the formal solution $\tilde{Y}_1$. We shall use this solution to reduce the order of the recurrence by 1. Let

$$C_k = y_k/Y_{1,k}. \tag{63}$$

The recurrence relation for C_k is then of the form (50), where now

$$\tilde{a}_j(k\epsilon,\epsilon) = a_j(k\epsilon,\epsilon)Y_{1,k+j}/Y_{1,k} \tag{64}$$

and, obviously, the asymptotic behavior to all orders is the same as if we had made the rescaling with respect to a formal solution. The point is that now instead of (52), we have

$$\sum_{j=0}^{l} \tilde{a}_j(k\epsilon,\epsilon) = 0 \tag{65}$$

so that the $y = 1$ is an actual solution. To use this fact, let $d_k = C_{k+1} - C_k$. We get

$$\sum_{s=0}^{l-1} b_s(k\epsilon,\epsilon)d_{k+s} = 0, \tag{66}$$

where $b_s(k\epsilon,\epsilon) = \sum_{j=s+1}^{l} \tilde{a}_j(k\epsilon,\epsilon)$.

The characteristic equation for (66) can be written as

$$\sum_{j=1}^{l} \tilde{a}_j(x,0) \sum_{s=0}^{j-1} \tilde{\lambda}^s = 0$$

or, for $\lambda \neq 1$, as it easily follows from (65),

$$\sum_{j=0}^{l} \tilde{a}_j(x,0)\tilde{\lambda}^j = 0. \tag{67}$$

We first check that the new recurrence satisfies the hypothesis of the lemma. But this is easy since the new coefficients are finite combinations of a_j and in particular $b_0 = \sum_{j=1}^{l} \tilde{a}_j = -a_0$ and $b_{l-1} = a_l$, and in view of (67) the same arguments as in Step 1 apply to ensure that the characteristic roots have the required properties. Then we want to check that we have the required number of appropriate formal solutions. This is also straightforward because we can derive them from the formal solutions of the original equation. Indeed,

$$d_k = y_{k+1}/Y_{1,k+1} - y_k/Y_{1,k}. \tag{68}$$

If we substitute for y a *formal* solution $\tilde{Y}_m$ we obtain the formal expression

$$\begin{aligned} \tilde{d}_k &= \exp\left\{\epsilon^{-1}\sum_{t=0}^{\infty}[\Phi_{m,t}((k+1)\epsilon) - \Phi_{1,t}((k+1)\epsilon)]\epsilon^t\right\} \\ &\quad - \exp\left\{\epsilon^{-1}\sum_{t=0}^{\infty}[\Phi_{m,t}(k\epsilon)) - \Phi_{1,t}(k\epsilon)]\epsilon^t\right\} \\ &= \exp\left\{\epsilon^{-1}(\Phi_m(x) - \Phi_1(x)) + \text{ series}\right\}[\lambda_m(x)/\lambda_1(x)](1+\epsilon\times\text{series}), \end{aligned} \tag{69}$$

which, since $\lambda_m(x)/\lambda_1(x)$ does not vanish, can be written as an exponential of a formal series in the form required by our arguments

$$\exp\left(\epsilon^{-1}\sum_{t=0}^{\infty}\Delta_{m,t}(k\epsilon)\right). \tag{70}$$

Then the expressions (70) for $m = 2, \dots, l$ are formal solutions for the recurrence of order $l-1$ (66) because, by construction, (69) are. It then follows by the induction hypothesis that there exist true solutions of (66) of the form

$$d_{m,k} = \exp(\epsilon^{-1}D_m(k\epsilon, \epsilon)), \tag{71}$$

where $D_m(\,\cdot\,,\,\cdot\,)$ are smooth functions having the asymptotic behavior given by (70).

Step 3. To complete the proof of Lemma 2, it remains only to check that

$$\exp\left(\epsilon^{-1}F_1(k\epsilon,\epsilon)\right)\sum_{p=0}^{k}\exp(\epsilon^{-1}D_m(p\epsilon,\epsilon)) \tag{72}$$

has the asymptotic behavior needed for the original recurrence, i.e.,

$$\exp(\epsilon^{-1}\sum_{t=0}^{\infty}(\Phi_{m,t}(k\epsilon)\epsilon^t)). \tag{73}$$

We let k_1 (k_2) be the left (right, respectively) end of the interval. Both k_1 and k_2 might depend on ϵ. By the definition of the $d_{k;m}$, we have

$$C_{m;k} = C_{m;k_1} + \sum_{i=k_1}^{k} d_{m;i}.$$

With the choice

$$C_{m;k_1} = -\sum_{i=k_1}^{k_2} d_{m;i},$$

we get the particular solution

$$C_{m;k} = \sum_{i=k}^{k_2} d_{m;i},$$

from which, referring to the definition of the $C_{m;k}$, we get a solution of the $l-1$ recurrence in the form (the choice of the sign will become clear later)

$$Y_{m;k} = -Y_{1;k} \sum_{i=k}^{k_2} d_{m;i}$$

whose asymptotic behavior is given by the formal solution $\tilde{Y}_m$. Indeed, for any fixed large s, we have

$$\begin{aligned}
Y_{m;k} &= -Y_{1;k} \left[\sum_{i=k}^{k_2} \exp\left(\epsilon^{-1} \sum_{t=0}^{s} \Delta_t(i\epsilon)\epsilon^t \right) \left(1 + O(\epsilon^{s-1})\right) \right] \\
&= -Y_{1;k} \left[\sum_{i=k}^{k_2} \left(\exp\left(\epsilon^{-1} \sum_{t=0}^{s} \Phi_{m;t}(i\epsilon+\epsilon)\epsilon^t - \Phi_{1;t}(i\epsilon+\epsilon)\epsilon^t \right) \right. \right. \\
&\quad \left. \left. - \exp\left(\epsilon^{-1} \sum_{t=0}^{s} \Phi_{m;t}(i\epsilon)\epsilon^t - \Phi_{1;t}(i\epsilon)\epsilon^t \right) \right) \left(1 + O(\epsilon^{s-1})\right) \right] \\
&= Y_{1;k} \left[\exp\left(\epsilon^{-1} \sum_{t=0}^{s} \Phi_{m;t}(k\epsilon)\epsilon^t - \Phi_{1;t}(k\epsilon)\epsilon^t \right) \right. \\
&\quad \left. - \exp\left(\epsilon^{-1} \sum_{t=0}^{s} \Phi_{m;t}(k_2) - \Phi_{1;t}(k_2)\epsilon^t \right) \right] \\
&\quad + (k_2 - k) \max_k \left| \exp\left(\epsilon^{-1} \sum_{t=0}^{s} \Delta_t(i\epsilon)\epsilon^t \right) \right| O(\epsilon^{s-1}). \qquad (74)
\end{aligned}$$

Because, by assumption, λ_1 has the largest modulus, $\Re(\Phi_{m;0}(k\epsilon) - \Phi_{1;0}(k\epsilon))$ is nonincreasing in k in the given region. Therefore, (74) equals

$$\begin{aligned}
&Y_{m;k} \left(1 + \text{const} \max_k \left\{ \left| \exp\left(\Phi_{m;1}(k\epsilon) - \Phi_{1;1}(k\epsilon) \right) \right| \right\} o(\epsilon^{s-2}) \right) \\
&\quad = Y_{m;k} \left(1 + o(\epsilon^{s-2}) \right) \qquad \square \qquad (75)
\end{aligned}$$

The proof of Proposition 2.2 follows essentially the same steps but is, as expected, more involved in the regions of near breakdown of the asymptotic series. The details are given in the next section.

The proof of Proposition 2.3 is very easy, using an estimate of the form (58) for the matrices corresponding to the original recurrence, an estimate which can be obtained directly from Remark 5 and the hypothesis of the proposition.

4. Proof of Proposition 2.2. We assume at first that the crossing occurs between the two largest characteristic roots and explain at the end of the proof how the general case is reduced to this one.

The layout is as follows. We first study the small region around the crossing point (the interior region), where $\exp(\epsilon^{-1} \sum \Phi_{1,2;t}(x)\epsilon^t)$ fail to be formal solutions (and the series occurring at the exponent cease to be asymptotic series). The new formal solutions are to leading order combinations of Airy functions. Their formal properties (domain of asymptoticity, growth in x) are examined. Next we show that there exist true solutions of the recurrence that are asymptotic to them. It is also shown that there exists a particular true solution which is asymptotic, to leading order, to the function $\mathrm{Ai}(x\epsilon^{-2/3})$ and is important for the matching problem (it gives the exponentially decaying formal solution).

We then show that the formal solutions coming from the exterior region continue to represent correctly the solutions of the recurrence far enough into the interior region (down to $|x| \sim \epsilon^{2/3}$) to allow for matching with the interior ones, which are valid up to $|x| \sim \epsilon^{1/2}$.

4.1. The interior region of the crossing interval. This is the region $|x| \ll \epsilon^{1/2}$; for definiteness we fix $\alpha \in (\frac{1}{2}, \frac{2}{3})$ and take it to be

$$D_\alpha = \{k : |k| < \epsilon^{-\alpha}\}$$

or, in terms of $\xi := k\epsilon^{1/3} := k\delta$, which is, for reasons that will become clear later, the natural variable in this region,

$$D_\alpha = \{\xi : |\xi| < \delta^{1-3\alpha}\}. \tag{76}$$

The basic steps of the proof of existence of solutions with given asymptotics are the same as for Lemma 3.2. We will first obtain a solution corresponding to (one of the two) largest eigenvalues and with it reduce the problem to a lower order, nondegenerate recurrence.

Because the variable of ξ D_α is unbounded, a slight extension of Lemma 3.2 is needed for the interior region. We now allow the interval I in Lemma 3.2 to be of the form (76) but strengthen the other hypothesis. Corresponding to Lemma 3.2, ξ plays the role of x and δ is the counterpart of ϵ. We require the following three conditions in addition to those of Lemma 3.2.

(a) $a_j(\xi, \delta)$ are assumed to have asymptotic series $\sum_t a_{j,t}(\xi)\delta^t$ valid throughout the region D_α which are smooth in the sense that all their formal derivatives with respect to ξ, $\sum_t a_{j,t}^{(m)}(\xi)\delta^t$, exist and $|a_{j,t}^{(m)}(\xi)| < \mathrm{const}\,\delta^{\mathrm{const}'\,t}$.

(b) The roots of the characteristic polynomial

$$\sum_{j=0}^{l} a_j(\xi, 0)\lambda(\xi)^j = 0 \tag{77}$$

are nondegenerate,

$$\inf\nolimits_{D_\alpha} |\lambda_m(\xi) - \lambda_n(\xi)| > \mathrm{const} > 0 \ (m \neq n), \tag{78}$$

and the polynomial itself is nondegenerate in the sense

$$\inf\nolimits_{D_\alpha} \left\{ |a_0(k\delta)|, |a_l(k\delta)|, \frac{1}{|a_j(k\delta)|} \right\} > \mathrm{const} > 0. \tag{79}$$

(c) Finally,

$$|\lambda_m((k+1)\delta, \delta) - \lambda_m(k\delta, \delta)| < \frac{\mathrm{const}}{|k| + 1}$$

in D_α, where $\lambda_m((k+1)\delta,\delta)$ are the roots of the complete polynomial $\sum_{j=0}^{l} a_j(\xi,\delta)\lambda^j$.

LEMMA 4.1. *Under these assumptions for any formal solution of* (1) *of the form*

$$S := \exp\left(\delta^{-1}\Phi_0(\xi) + \sum_{m=0}^{\infty} \Phi_m(\xi)\,\delta^m\right),$$

where the exponent is assumed to be a smooth asymptotic series in the sense defined in (a), *there exists a true solution of the recurrence which is asymptotic to it in* D_a.

Proof. The proof follows closely the proof of Lemma 3.2. We emphasize only the differences: For the recurrence (50), we also have to verify condition (c),

$$\begin{aligned}\left|\tilde{\lambda}_m((k+1)\delta,\delta) - \tilde{\lambda}_m(k\delta,\delta)\right| &= \left|\frac{\lambda_m((k+1)\delta,\delta)}{\lambda_1((k+1)\delta,\delta)} - \frac{\lambda_m(k\delta,\delta)}{\lambda_1(k\delta,\delta)}\right| \\ &< \text{const } (|k|+1)^{-1}.\end{aligned}$$

The equivalent of Lemma 3.3 states now that there is a δ-independent constant C such that

$$\|A_k A_{k-1}\ldots A_{j+1}\| \le (1 + C|k-j|^{\text{const}}). \tag{80}$$

Indeed, by Remark 5 a diagonal term of the matrix $T := \Lambda_p^{-1}\Lambda_{p-1}$ is of the form

$$\begin{aligned}T_{m,m} &= \prod_{n\neq m} \frac{\lambda_m((p-1)\delta,\delta) - \lambda_n(p\delta,\delta)}{\lambda_m(p\delta,\delta) - \lambda_n(p\delta,\delta)} \\ &= \prod_{n\neq m}\left(1 + \frac{\lambda_m((p-1)\delta,\delta) - \lambda_m(p\delta,\delta)}{\lambda_m(p\delta,\delta) - \lambda_n(p\delta,\delta)}\right) = 1 + O((|k|+1)^{-1})\end{aligned} \tag{81}$$

by (c). Similarly, the moduli of the nondiagonal terms are seen to be less than const$/(|k|+1)$. Therefore, $T = \mathbf{I} + R$ where the $\|R\|$ is $O((|k|+1)^{-1})$, and hence the inequality (80) follows.

The last part of the proof of Lemma 3.3 applies here without any significant change. □

Next, we discuss the reduction to the nondegenerate case. We consider the initial recurrence in the neighborhood of a crossing point, say $x = 0$, where $\lambda_1(0) = \lambda_2(0) = 1$ (the value at zero can be chosen through a trivial global rescaling of the recurrence). It is convenient to consider rescaled variables $\delta = \epsilon^{1/3}$ and $\xi = k\delta$. In these variables, the coefficients $a_j(x,\epsilon) = a_j(\xi\delta^2,\delta^3)$ have smooth asymptotic series in δ in D_α which are in fact obtained through series expansion in x from (5)

$$a_j(\xi\delta^2,\delta^3) \sim \sum_{s\ge 0} P_{j,s}(\xi)\delta^s, \tag{82}$$

where

$$P_{j,0} = a_j(0,0), \quad P_{j,1}(\xi) = 0, \quad P_{j,2}(\xi) = (D_x a_j)(0,0)\xi,$$

and in general $P_{j,s}(\xi)$ are polynomials in ξ of degree at most $s/2$ for s even and $(s-3)/2$ for s odd. To avoid complicating the notation we write $a_j(\xi,\delta) \equiv a_j(\xi\delta^2,\delta^3)$. We have first to find formal solutions for this new recurrence.

LEMMA 4.2. *There exist l linearly independent formal solutions in D_α of the form*

$$\exp\left(\delta^{-1}\sum_{t=0}^{\infty}\Psi_{m,t}(\xi)\delta^t\right), \tag{83}$$

where $\Psi_{m,t}(\xi)$ are smooth in ξ and satisfy the estimates

$$|\Psi_{m,t}(\xi)| < \mathrm{const}_{m,t} + \mathrm{const}'_{m,t}|\xi|^{t/2+1}.$$

This means in particular that the domain of formal validity of the power series is then $\xi^{1/2}\delta \ll 1$, i.e., $x \ll 1$. The domain in which it is actually asymptotic to the solution is however much smaller ($x \ll \sqrt{\epsilon}$), as we shall see.

Proof of Lemma 4.2. The formal solutions corresponding to the nondegenerate roots give rise automatically to acceptable formal solutions in the new variables ξ, δ. Indeed,

$$\begin{aligned}\exp\left(\epsilon^{-1}\sum_{t=0}^{\infty}\Phi_{m,t}(x)\epsilon^t\right) &= \exp\left(\delta^{-3}\sum_{t=0}^{\infty}\Phi_{m,t}(\xi\,\delta^2)\delta^{3\,t}\right)\\ &= \exp\left(\delta^{-3}\Phi_{m,t}(0) + \delta^{-1}\sum_{s,t\geq 0}^{\infty}\Phi^{(s)}_{m,t}(0)\xi^s\delta^{2\,s+3\,t-2}\right).\end{aligned} \tag{84}$$

The term in δ^{-3} is merely a multiplicative constant so it can be dropped and we are left with a formal solution of the form

$$\exp\left(\delta^{-1}\sum_{t=0}^{\infty}\chi_{m,t}(\xi)\delta^t\right), \tag{85}$$

where the $\chi_{m,t}(\xi)$ are in fact polynomials in ξ of degree $\leq t/2+1$.

For $m = 1, 2$ it is more convenient to write first the possible formal series solutions for the equation in the form

$$\sum_{t=0}^{\infty}\chi_t(\xi)\delta^t \tag{86}$$

and then show that we can write them in the form (85).

Substituting (86) in the recurrence, we get

$$\sum_{j=0}^{l}a_{j,\xi,\delta}\sum_{t=0}^{\infty}\chi_t(\xi + j\delta)\delta^t.$$

The term of order s in (86) is obtained by differentiating the auxilliary equation

$$\sum_{j=0}^{l}a_j(\xi,\delta)\chi(\xi + j\delta,\delta) = 0$$

s times with respect to δ. We get (see (82))

$$\sum_{j=0}^{l}\sum_{t=0}^{s}P_{s-t}(\xi)\left(D_\xi + D_\delta\right)^t\chi\Big|_{\delta=0} = 0,$$

which, after expansion, change of order of summation, and use of (82), gives

$$\sum_{j=0}^{l}\left[\frac{1}{\binom{s}{s-2}}\sum_{\sigma=0}^{s-3}\sum_{t=\sigma}^{s}\left(\binom{s}{t}\binom{t}{\sigma}P_{s-t}(\xi)j^{t-\sigma}D_\xi^{t-\sigma}\chi_\sigma(\xi)\right)\right.$$

$$\left.+D_x a_j(0,0)\xi\,\chi_{s-2}+a_j(0,0)j^2\chi_{s-2}\right]=0. \tag{87}$$

It follows that χ_0 is obtained as a solution of the homogeneous Airy equation

$$\chi''(\xi)=\Theta^3\xi\,\chi(\xi), \tag{88}$$

where

$$\Theta^3=\frac{\sum_{j=0}^{l}D_x a_j(0,0)}{\sum_{j=0}^{l}a_j(0,0)\,j^2}, \tag{89}$$

and that, given $\chi_0,\dots,\chi_{s-3}$, we get χ_{s-2} as a solution of an inhomogeneous Airy equation of the form

$$\chi''(\xi)=\Theta^3\xi\,\chi(\xi)+R(\xi),$$

where $R(\xi)$ is a linear combination of higher derivatives of $\chi_0,\dots,\chi_{s-3}$. To avoid cumbersome notation, we shall assume in the following that Θ is 1. We can check that the assumption of genericity ($|\lambda_1(x)-\lambda_2(x)|>\text{const}\sqrt{x}$) implies $\sum_{j=0}^{l}D_x a_j(0,0)\neq 0$. We shall assume for definiteness that it is negative.

It follows by an obvious induction that the χ_s are smooth. Now we show that they satisfy the inequalities stated in the Lemma 4.2.

Remark. Consider the inhomogeneous Airy equation $f''(\xi)=\xi f(\xi)+R(\xi)$ and assume $R(\xi)\sim\xi^p\exp(2A/3\xi^{3/2})$ with $A=\pm1$ for $x\to\infty$ and $A=\pm i$ at $-\infty$. Then $f(\xi)\sim\xi^{p-1}\exp(2A/3\xi^{3/2})$. This estimate follows immediately from the explicit form of the solution

$$f(\xi)=\ \mathrm{Ai}(\xi)\int^{\xi}R(t)\mathrm{Bi}(t)\,dt-\mathrm{Bi}(\xi)\int^{\xi}R(t)\mathrm{Ai}(t)\,dt.$$

At this point we can show by induction that the solution $\chi_n(\xi)$ grows at most like $\exp(2A/3\xi^{3/2})\xi^{n/2}$. So we assume that this holds for $s\le n$ and we show that it is true for $n+1$. Using the remark above and (87), the induction step is as follows: with $p_n=n/2$,

$$\max_{0\le\sigma\le n;\sigma\le t\le n+3}\left\{\left[\frac{1}{2}(n+1-t)\right]+\frac{(-1)^n+1}{2}+\frac{1}{2}(t-\sigma)+p_n\right\}\le p_{n+1}+1,$$

which is straightforward.

Finally, we argue that there are two linear independent formal solutions of this type that can be written in the form (85) which is convenient for our approach. For this we have to choose χ_0, which is a solution of the homogeneous Airy equation such that it does not vanish in D_α. Since the Wronskian of the couple $\mathrm{Ai}(\xi)$, $\mathrm{Bi}(\xi)$ is a nonzero constant, any combination with real nonzero constants of the form $C_1\mathrm{Ai}(\xi)+i\,C_2\,\mathrm{Bi}(\xi)$ is an everywhere nonzero solution (and the derivative is also nonzero). We can choose two linear independent solutions in this way, say the ones for which χ_0 =Ai(ξ)$\pm i$Bi(ξ). That they are formally linearly independent with respect to the solutions obtained from (84) follows easily, for instance from the fact that they correspond to different roots of the characteristic polynomial.

To show that there is an actual solution for each formal solution in this region, we first single out a true solution corresponding to the dominant characteristic root and then use it to reduce the problem to a regular one. Then we show that they give the expected asymptotic behavior for the solutions of the original equation.

The ideas are similar to those used in the regular case with the exception that extra care is needed along the degenerate directions.

Choose

$$\chi_0(\xi) = \mathrm{Ai}(\xi) + i\,\mathrm{Bi}(\xi)$$

and consider the nonzero formal solution that has the leading order χ_0. We proceed as in Step 1 of §3 to construct a rescaled recurrence with respect to the truncation of our formal solution. The same argument used there shows that the new coefficients $\tilde{a}$ have smooth asymptotic series.

What is new here is that we must provide for the estimate of the type (c) to which end we examine the complete characteristic equation $P(\xi, \delta; \tilde{\lambda}) = 0$. P is a polynomial in $\tilde{\lambda}$ (actually it is, to leading order, a polynomial with constant coefficients), C^∞ in ξ and δ. P(0,0,$\tilde{\lambda}$) has a double root $\tilde{\lambda} = 1$ but by assumption the second derivative does not vanish so that we can obtain the roots of the polynomial perturbatively. After series expansion, we obtain

$$\sum_{j=0}^{l} \{ [a_j(0,0) \left(1 + \delta\, C_j + \delta^2 E_j + O(\delta^3)\right) + \xi D_x a_j \delta^2 + O(\delta^3)]$$

$$\cdot \left(1 + j\chi_1(\xi)\delta + \left(j\chi_2(\xi)\delta^2 + j(j-1)/2\chi_1^2\right) + O(\delta^3)\right)\} = 0, \tag{90}$$

where we have taken $\tilde{\lambda} \sim 1 + \chi_1(\xi)\delta + \chi_2(\xi)\delta^2 + O(\delta^3)$ and

$$\begin{aligned} C_j &= \frac{1}{\chi_0}\left(j\chi_0' + \chi_1\right), \\ E_j &= \frac{1}{\chi_0^2}\left(j^2\chi_0''\chi_0 + j\chi_1'\chi_0 - j\chi_1\chi_0' - \chi_1^2\right). \end{aligned}$$

Using the relations in (82), we get two solutions for χ_1: $\chi_1 = 0$ (actually, as expected, we get a root $\tilde{\lambda}_1 = 1 + O(\delta^s)$) and $\chi_1 = 1 - 2\chi_0'\chi_0^{-1}\delta + O(\delta^2)$. We see that in the first order in δ there is no root crossing, which is not a surprise since a generic perturbation tends separate coalescing roots. The asymptotic series are uniformly valid in our domain D_α. Now we show that

$$\left| \frac{\lambda_2((k+1)\epsilon) - \lambda_2(k\epsilon)}{\lambda_1(k\epsilon) - \lambda_2(k\epsilon)} \right| < \frac{\text{const}}{|k| + 1} \tag{91}$$

(this explains the condition (c) at the begining of this section).

We have

1.

$$\left|(\log \chi_0(\xi))'\right| > \text{const}\sqrt{\xi} + \text{const}'.$$

This is obvious since it holds asymptotically and the function does not vanish. Hence

$$\left|\tilde{\lambda}_2(\delta\, k)) - \tilde{\lambda}_1(\delta\, k)\right| > \text{const}\sqrt{\delta|k|+1},$$

2.

$$\left|(\log h_0(\xi))''\right| < \text{const}/\sqrt{\xi+1} + \text{const}'.$$

Using the asymptotic series for the $\tilde{\lambda}_{1,2}$ and the above estimates (1) and (2) we see that

$$\left|\frac{\tilde{\lambda}_2(\delta\,(k+1)) - \tilde{\lambda}_2(\delta\, k)}{\tilde{\lambda}_2(\delta\, k) - \tilde{\lambda}_1(\delta\, k)}\right| < \frac{(\sqrt{\xi+1}+\text{const}')\delta^2}{(\text{const}\sqrt{\xi}+\text{const}')\delta} < \frac{\text{const}}{|k|+1}.$$

The similar estimates for the other roots are better but this of course does not improve the overall rate of convergence. $\tilde{\lambda}_1 = 1 + O(\delta^s)$ and can be obviously made less than $1+\text{const}\,\delta^2$ in D_α so that also $|\tilde{\lambda}_1((k+1)\delta) - \tilde{\lambda}_1(k\delta)| < 1+\text{const}'\,\delta^2$, which is enough for our purposes. For $m \neq 1, 2$ we can for instance use the fact that the derivative of the polynomial at these points does not vanish and settle for a crude bound $|\tilde{\lambda}_m(\delta\,(k+1)) - \tilde{\lambda}_m(\delta\, k)| < \text{const}\,\delta^2$, which can be obtained immediately from (90).

Now, to see that there is a true solution of the recurrence which is asymptotic to our formal series starting with $\mathrm{Ai} + i\mathrm{Bi}$, we only have to repeat the same arguments used in the regular case.

The next step is to use this particular solution to lower the order of the recurrence. We mimic the construction done in the proof of Lemma 3.2 to get a lower-order recurrence in the variable d_k

$$\sum_{s=0}^{l-1} b_s(k\delta,\delta)d_{k+s} = 0$$

(see (66)) and want to check that this new recurrence satisfies the hypothesis of Lemma 4.1. To leading order, the characteristic polynomial of the above equation has no double roots (it now has only one root equal to 1).

As in the regular case, $b_0(\xi, 0) = -\tilde{a}(\xi, 0) = -a_0(0, 0)$; $b_{l-1}(\xi, 0) = -\tilde{a}_l(\xi, 0) = -a_l(0, 0)$.

Noting that the coefficients of the recurrence (66) have asymptotic series valid throughout the domain (as finite sums of terms of the series of $\alpha_j(\xi,\delta)Y_{1,k+j}/Y_{1,k}$), the boundedness of the coefficients is also trivial.

As in the proof of Lemma 3.2, the polynomial in b_j has the same roots as the polynomial in $\tilde{a}_j$ (except for the eliminated one), for which we have already obtained the estimates of type (c).

Now we have a regular problem for which we know that to each formal solution there is a genuine solution asymptotic to it.

It remains to check that we can recover the asymptotic behavior of the solutions of the original recurrence from those of the reduced one. For the solutions corresponding to the characteristic roots that are less than 1, exactly the same proof as in Step 3 of Lemma 3.2 works. For any formal solution of our original equation that corresponds to the largest eigenvalue and which does not vanish, the proof is the one given in Lemma 4.1.

In the crossing region however there might be a special interest in finding a particular solution which is not of exponential type and which is small for large ξ (the Airy-like solution). To this end, a slightly different argument is necessary. We can obtain a formal solution of the reduced equation which is, to leading order,

$$\frac{\mathrm{Bi}(\xi+\delta)\mathrm{Ai}(\xi)-\mathrm{Bi}(\xi)\mathrm{Ai}(\xi+\delta)}{(\mathrm{Ai}(\xi)-i\mathrm{Bi}(\xi))(\mathrm{Ai}(\xi+\delta)-i\mathrm{Bi}(\xi+\delta))} \tag{92}$$

(suggested by computing (68) for two formal solutions of the original equation, corresponding to Ai ± iBi)). The asymptotic behavior of (92) for large ξ is

$$\frac{\delta}{(\mathrm{Ai}(\xi)-i\mathrm{Bi}(\xi))^2}(1+\text{power series}) \quad (1 \ll |\xi| \ll \delta^{-1/2}). \tag{93}$$

Writing the asymptotic representation of Ai ± iBi in the form

$$\sim \xi^{-1/4}\exp(2/3\xi^{3/2})(1+\text{series})$$

is sufficient to see this. It is important to note that there are no powers of ξ multiplying the asymptotics (93); its leading order does not vanish, and (93) can be written as an exponential of a formal series, the form required by our arguments.

We now apply the construction in Step 3 of §3 to recover the solutions of the initial recurrence.

Using the asymptotic behavior of the Airy functions for large argument, we get for the reconstructed solution the representation

$$Y \sim \xi^{(-1/4)}\exp\left(\frac{2}{3}\xi^{3/2}\right)\sum_{k=j}^{\delta^{-\alpha}}(k\delta)^{1/2}\exp\left(-\frac{4}{3}(k\delta)^{3/2}\right)(1+\text{power series}),$$

for which the Euler–Maclaurin summation formula gives the asymptotic representation

$$\xi^{-1/4}\exp\left(-\frac{2}{3}\xi^{3/2}\right)$$

for large positive ξ.

In conclusion, there is a true solution of the recurrence which behaves like the Airy function for positive k (also for negative k when this is properly interpreted) and our argument shows what initial conditions have to be chosen to obtain it. For negative k we see that, in fact, all the solutions corresponding to the largest two eigenvalues are comparable.

4.2. The exterior region. Now we want to show that the solutions coming from the exterior region remain asymptotic to the true solutions as long as $|x| \gg \epsilon^{2/3}$.

The problem that arises here is that the characteristic polynomial has a virtually degenerate root for small x and this leads to a lesser smoothness of the asymptotic series and ultimately to its collapse at $|x| \sim \epsilon^{2/3}$. Let β be as in Proposition 2.2 and define the exterior region by

$$E_\beta = \{x : |x| > \epsilon^\beta\}.$$

In what follows, we make the following conventions. We write

$$g(\epsilon) = O(\epsilon^\infty)$$

if $\lim_{\epsilon\to 0}\epsilon^{-k}\, g(\epsilon)=0$ for all k; also $\mathcal{F}(x^{\gamma})$ will denote a generic function such that it and its derivatives of arbitrary order s satisfy the estimates

$$\left|\mathcal{F}(x^{\gamma})^{(s)}(x)\right| < A_s + B_s x^{\gamma-s} \tag{94}$$

with the convention that $|\mathcal{F}(x^0)\equiv\mathcal{F}(\ln(x))| < A + B|\ln|x||$.

The first step is to study the asymptotic properties of the formal solutions, i.e., of the (possibly divergent) expressions for which

$$\sum_{j=0}^{l} a_j(x;\epsilon)\exp\left(\sum_{t=0}^{\infty}\Phi_t(x+j\epsilon)\epsilon^t\right)\equiv 0. \tag{95}$$

We show by induction that Φ_t and their derivatives behave like $x^{\frac{3}{2}(1-t)}$ and its derivatives. We place ourselves in the assumption of genericity of the crossing which means in particular that $\frac{\partial P(\lambda;x)}{\partial\lambda} > \text{const}\sqrt{|x|}$.

LEMMA 4.3. (i) *If in* (95) *the asymptotic series for the* a_j *are of the form* $\sum_{k=0}^{\infty}\mathcal{F}_k(x^{1-\frac{3}{2}k})\epsilon^k$, *then, in the formal solution* (95), *we have* $\Phi_t{=}\mathcal{F}(x^{\frac{3}{2}(1-t)})$.

(ii) *The same conclusion is true if* $\frac{\partial P(\lambda;x)}{\partial\lambda} >$ const > 0 *uniformly in* x *and* $a_j\sim\sum_{k=0}^{\infty}\mathcal{F}_k(x^{\frac{1}{2}-\frac{3}{2}k})\epsilon^k$.

Note that the coefficients a_j of our initial recurrence are smoother than it is assumed in (i) but this smoothness does not withstand a rescaling as done for (65).

The proof of Lemma 4.3 is by induction on t.

(i) It is easy to see from the eikonal equation that $\Phi_0{=}\mathcal{F}(x^{3/2})$. Assume that the conclusions of the lemma hold for all $t'<t$. After a formal series expansion of the exponent of (95), one gets

$$\sum_{j=0}^{l} a_j(x;\epsilon)\exp\left[\epsilon^t\left(j\Phi_t^{(s)}+\sum_{\substack{s\,\geq\,1\\ t'\,+\,s\,=\,t\,+\,1}}\frac{j^s}{s!}\Phi_{t'}^{(s)}\right)+\sum_{k=0}^{t}\epsilon^{k-1}\sum_{\substack{s\,\geq\,1\\ t'\,+\,s\,\leq\,t\,+\,1}}\frac{j^s}{s!}\Phi_{t'}^{(s)}+O(\epsilon^{t+1})\right]=0, \tag{96}$$

which, using the induction hypothesis, can be rewritten as

$$\begin{aligned}\sum_{j=0}^{l}\left(\sum\mathcal{F}_{k;j}(x^{1-\frac{3}{2}k})\epsilon^k\right)\exp\Bigg(j\Phi_0'+\epsilon^t\left(j\Phi_t'+\mathcal{F}(x^{1-\frac{3}{2}t})\right)\\ +\sum_{k=1}^{t-1}\epsilon^k\mathcal{F}_k(x^{\frac{1-3k}{2}})+O(\epsilon^{t+1})\Bigg)=0.\end{aligned} \tag{97}$$

After expanding in powers of ϵ and collecting the term in ϵ^t, we obtain the equation for Φ_t in the form

$$\sum_{j=0}^{l}\left(ja_{j;0}(x)\epsilon^{\Phi_0'(x)}\,\Phi_t'(x)+\mathcal{F}(x^{1-\frac{3t}{2}})\right)=0 \tag{98}$$

or

$$\Phi_t'(x)=\frac{\mathcal{F}(x^{1-\frac{3t}{2}})}{\frac{\partial P(\lambda;x)}{\partial\lambda}}, \tag{99}$$

where the derivative of the polynomial is evaluated at $\epsilon = 0, \lambda = \exp(\Phi_0')$ thus proving (i).

For (ii) the same proof works, replacing everywhere $\mathcal{F}(x^{1-\frac{3t}{2}})$ with $\mathcal{F}(x^{\frac{1}{2}-\frac{3t}{2}})$.

4.2.1. Rescaling first the recurrence with respect to the approximate solution, we show that there is a genuine solution corresponding to the maximal eigenvalue. Let Ψ_m be any function such that $\Psi_m(x;\epsilon) \sim \sum_0^\infty \Phi_{m;t}(x)\epsilon^t$ and take

$$\tilde{Y}_m := \exp(\epsilon^{-1}\,\Psi_m(x;\epsilon)). \tag{100}$$

The existence of a solution corresponding to the asymptotics $\exp(\epsilon^{-1}\,\Psi_1(x;\epsilon))$ is again equivalent to a solution which is 1 to all orders in ϵ of the recurrence

$$\sum_{j=0}^{l} \tilde{a}_{j,s}(k\epsilon,\epsilon)C_{k+j} = 0, \tag{101}$$

where $\tilde{a}_{j,s}(k\epsilon,\epsilon) = a_j(k\epsilon,\epsilon)\tilde{Y}_1((k+j)\epsilon)/\tilde{Y}_1(k\epsilon)$. The formal solutions of the equation (101) are $\tilde{Y}_m/\tilde{Y}_1$. We need the roots of the new characteristic polynomial

$$\tilde{P}(\tilde{\lambda}) := \sum_{j=0}^{l} \tilde{a}_{j,s}(k\epsilon,\epsilon)\tilde{\lambda}^j = 0. \tag{102}$$

It is easy to see that the polynomial (102) has a root which is 1 to all orders in ϵ. Now let $G(x;\epsilon)$ be one of the differences $G_m(x;\epsilon) = \Psi_m(x;\epsilon) - \Psi_1(x;\epsilon)$. We have

$$\sum_{j=0}^{l} \tilde{a}_{j,s}(k\epsilon,\epsilon)\exp(\epsilon^{-1}G(x+j\epsilon;\epsilon)) = o(\epsilon^t)$$

for all t and so, after series expansion,

$$\sum_{j=0}^{l} \tilde{a}_{j,s}(k\epsilon,\epsilon)\lambda_0^j(1+\epsilon H_j(x;\epsilon)) = o(\epsilon^\infty), \tag{103}$$

where $H_j(x;\epsilon)$ are some smooth functions of x,ϵ and $\lambda_0 := \exp(G_x(x;\epsilon))$. Using Lemma 4.3 and the genericity assumptions, it is not difficult to see that

$$|H_j(x;\epsilon)| < \text{const}\,|x|^{-1/2}. \tag{104}$$

If we look for solutions of the characteristic polynomial (102) in the form $\lambda_0 + \gamma$, we get

$$0 = \tilde{P}(\tilde{\lambda}) = \sum_{j=0}^{l} P^{(j)}(\lambda_0)\gamma^j$$

(where the derivatives are taken with respect to λ). Using (103) we obtain γ as the unique small solution of the equation

$$\gamma = \frac{\epsilon\sum_{j=0}^{l} \tilde{a}_j(x;\epsilon)\lambda_0^j H_j(x;\epsilon)}{\sum_{j=1}^{l} P^{(j)}(\lambda_0)\gamma^{j-1}}, \tag{105}$$

which is a contraction for small enough ϵ (and small γ) in the region $|x| > \epsilon^\beta$ as it is easy to check. We then obtain from (104) and (105)

$$|\gamma| < \text{const}\frac{\epsilon}{|x|}, \tag{106}$$

again valid for $|x| > \epsilon^\beta$.

We shall also need estimates for $\gamma(x+\epsilon)-\gamma(x)$. Differentiating (105) with respect to x and using Lemma 4.3,

$$|\gamma(x+\epsilon) - \gamma(x)| < \text{const}\,\epsilon\,|x|^{-2}. \tag{107}$$

Now we proceed as in the regular case in rewriting the recurrence in matrix form and evaluating the terms in the product (59). In the matrices $T := \tilde{\Lambda}_k^{-1}\tilde{\Lambda}_{k-1}$, the off-diagonal elements are estimated by $T_{mn} < \text{const}\,\epsilon|x|^{-1}$ and for the diagonal elements we have $T_{mm} = 1 + O(\epsilon/x)$. Indeed,

$$T_{mm} = \prod_{n\neq m}\left(1 + \frac{\lambda_m((p-1)\epsilon,\epsilon) - \lambda_n(p\epsilon,\epsilon)}{\lambda_m(p\epsilon,\epsilon) - \lambda_n(p\epsilon,\epsilon)}\right).$$

Since by the assumption of genericity the roots of the polynomial are separated by at least $\text{const}\sqrt{(|x|)}$, each term in the product above can be estimated by

$$\begin{aligned}1 + \text{const}\,\epsilon(\lambda_0'(x) + \gamma'(x))|x|^{-1/2} + O\left(\epsilon(\lambda_0'(x) + \gamma'(x))|x|^{-1/2}\right)\\ < 1 + \text{const}\left(\epsilon|x|^{-1} + \epsilon^2|x|^{-5/2}\right) < 1 + \text{const}\,\epsilon|x|^{-1}\end{aligned}$$

in our region E_β. The nondiagonal terms are estimated in a very similar way.

We derive the estimate $\|T(x) - \mathbf{I}\| < K\epsilon/x$ for some constant K. Assume for definiteness that we are on the left of the crossing point. We get

$$\left\|\prod_{k;-k\epsilon>\epsilon^\beta} T(k\epsilon)\right\| < \text{const}\,\epsilon^{-K/3}.$$

Finally, we have to control the product of the norms of the diagonal matrices D_k. Since they all have one eigenvalue equal to 1 to all orders in ϵ and for $i > 2$ $|\tilde{\lambda}_i(x;\epsilon)| < 1 - \text{const}$, the only nontrivial contribution comes from $\tilde{\lambda}_2$ and this only if $\tilde{\lambda}_1$ and $\tilde{\lambda}_2$ have the same modulus to leading order in ϵ. Referring to the decomposition $\tilde{\lambda} = \lambda_0 + \gamma$, we have in this case, using the Euler–Maclaurin summation formula,

$$\begin{aligned}\prod_{k;-k\epsilon>\epsilon^\beta} |\lambda_0(k\epsilon)| &= \exp\left(\epsilon^{-1}\sum_k \Re((\Psi_2)_x(k\epsilon;\epsilon) - (\Psi_1)_x(k\epsilon;\epsilon))\right)\\ &\sim \exp\left\{\Re\left(\Phi_{2;1}(-\epsilon^{2/3}) - \Phi_{1;1}(-\epsilon^{2/3})\right)\right\} < \epsilon^{-\text{const}}.\end{aligned}$$

Also,

$$\prod_{k;-k\epsilon>\epsilon^\beta}\left|1 + \frac{\gamma(k\epsilon)}{\lambda_0(k\epsilon)}\right| < \prod_{k;-k\epsilon>\epsilon^\beta}\left|1 + \frac{\text{const}}{|k|}\right| < \epsilon^{-\text{const}}$$

so that also $\prod\tilde{\lambda}$ is less than $\epsilon^{-\mathrm{const}}$. At this point, the same arguments as in the regular case show that there is a true solution behaving asymptotically as the formal solution corresponding to the largest eigenvalue.

4.2.2. Let Y_1 be a solution of the recurrence relation such that $Y_1 \sim \exp(\epsilon^{-1}\cdot \sum \Phi_{1;t}\epsilon^t)$ in E_β. We now follow the same steps that led to equations (65) and (66).

It is a matter of straightforward induction to determine by Lemma 4.3 that the coefficients $\tilde{a}_j$ have the behavior

$$\tilde{a}_j(x;\epsilon) \sim a_{j;0}(x)e^{j\,\Phi_0'(x)} + \sum_{k\geq 1}\mathcal{F}_{j;k}(x^{\frac{1}{2}-\frac{3}{2}k})\epsilon^k,$$

and then clearly

$$b_j(x;\epsilon) \sim \sum_{k\geq 0}\mathcal{F}_{j;k}(x^{\frac{1}{2}-\frac{3}{2}k})\epsilon^k. \tag{108}$$

It is also easy to check that the recurrence (66) is now nondegenerate in the sense that

$$\inf_{E_\beta}\left\{|b_0(k\epsilon)|, |b_{l-1}(k\epsilon)|, \frac{1}{|b_j(k\epsilon)|}\right\} > \mathrm{const} > 0 \tag{109}$$

and the characteristic polynomial of the new recurrence does not have coalescing roots (the root $\lambda = 1$ of (65) has been eliminated in the reduction):

$$\inf_{E_\beta}\{|\,|\lambda_m(x)| - |\lambda_n(x)|\,|\} > \mathrm{const} > 0 \quad (m \neq n). \tag{110}$$

We are now left with a problem of the following type. Taking a recurrence of the form

$$\sum_{j=0}^{l} a_j(x;\epsilon)y_{k+j} = 0 \tag{111}$$

under conditions

$$\tilde{a}_j(x;\epsilon) \sim \sum_{k\geq 0}\mathcal{F}_{j;k}(x^{\frac{1}{2}-\frac{3}{2}k})\epsilon^k, \tag{112}$$

$$\inf_{E_\beta}\left\{|a_0(k\epsilon)|, |a_{l-1}(k\epsilon)|, \frac{1}{|a_j(k\epsilon)|}\right\} > \mathrm{const} > 0, \tag{113}$$

$$\inf_{E_\beta}\{|\,|\lambda_m(x)| - |\lambda_n(x)|\,| > \mathrm{const} > 0\ (m \neq n)\}, \tag{114}$$

where $\lambda_m(x)$ are the roots of the polynomial

$$P(\lambda) := \sum_{j=0}^{l} a_{j,0}(k\epsilon)\lambda^j = 0, \tag{115}$$

we want to show the following.

LEMMA 4.4. *Given a formal solution to* (111)

$$\exp\left(\epsilon^{-1}\sum_{t=0}^{\infty}\epsilon^{t}\Phi_t(x)\right),$$

where $\Phi_t(x)=\mathcal{F}_t(x^{\frac{3}{2}(1-t)})$, *there is a solution asymptotic to it for* $0<x\in E_\beta$ (*and correspondingly, one when* x *is negative*).

Proof. We prove Lemma 4.4 by using induction on l.

(a) We show that we can find a solution corresponding to the root that has the largest modulus (this will simultaneously prove the lemma for $l=1$). All the arguments in §4.2.1 above apply here. Actually, now we could get some better estimates since we do not have small denominators in (106), (107), and in the estimates of the matrices, but this would not affect the final result.

(b) We assume that the conclusion is true for all recurrences of order less than $l-1$ and show it holds for recurrences of order l. By the arguments above, there is a true solution asymptotic to the formal solution defined by the maximum eigenvalue. Using it to reduce the order of the recurrence, we obtain an order $l-1$ scheme, which satisfies the conditions of Lemma 4.4 as it is easy to check and for which we thus know the asymptotic behavior of the solutions. It remains to verify that they can be used to produce solutions of the higher-order recurrence with the stated asymptotic behavior. For definiteness we study the subregion $x<-\epsilon^{\beta}$. All the arguments in Step 3 of §3 apply if we take k_1 to be $-\epsilon^{\beta}$. The only change is that in (75) $\Phi_{m;1}(x)$ are not uniformly bounded. Instead, using Lemma 4.3 we get $|\Phi_{j;1}|=\mathcal{F}(\ln(|x|))<K|\ln\epsilon|$ for some fixed constant K so the right-hand side of (75) changes to $Y_{m;k}\left(1+O(\epsilon^{s-2-K})\right)$.

Finally, after the first reduction we end up with a recurrence that is nondegenerate in the sense of Lemma 4.4 and for which we can control the small-ϵ behavior of the solutions. Now, the reconstruction of the solutions of the original recurrence from the solutions of the reduced one amounts to merely repeating, without any significant change, the construction and estimates in part (b) above. At this point in the proof, it is clear that if the crossing roots are not the largest, one can reduce the order of the recurrence to the actual level at which the roots cross and then apply the arguments above.

TIME-PERIODIC QUASI-LINEAR REACTION-DIFFUSION EQUATIONS*

MARY M. LEGNER† AND VICTOR L. SHAPIRO†

Abstract. A resonance result for a time-periodic quasi-linear reaction-diffusion system with (possibly) different diffusion coefficients is established. The driving force of the system may depend upon the dependent variables as well as their derivatives. Also a nonresonance result below the common first associated eigenvalue is stated and proved, and an example of an autocatalytic system illustrating this result is presented. Two other examples for the resonance result are also presented.

Key words. reaction-diffusion, time-periodic, quasi-linear partial differential equations, nonlinear driving force

AMS subject classifications. 35K55, 35K35

1. Introduction.

It is the purpose of this paper to present a resonance-type existence theorem for a system of time-periodic quasi-linear parabolic differential equations with a driving force that depends upon the derivatives of the dependent variables. The result obtained appears to be new, even in the semilinear parabolic case. The quasi-linear parabolic system that we study is of the following form with N_1 a positive integer:

$$(1.1)\qquad \begin{aligned} D_t u_i + \rho_i Q_i u_i = \rho_i \lambda_1^* u_i &+ f_i(x,t,\xi_m(u_1),\dots,\xi_m(u_{N_1})) \\ &+ G_{1i}(D_t u_i) G_{2i}(u_i) g_i(x,t), \qquad i = 1,\dots,N_1, \end{aligned}$$

for $(x,t) \in \Omega \times (-\pi,\pi)$, where each $Q_i u$ is a $2m$th-order quasi-linear elliptic differential operator, λ_1^* is its common associated first eigenvalue, $D_t u = \frac{\partial u}{\partial t}, \xi_m(u) = \{D^\alpha u : |\alpha| \le m\}$, and ρ_i is a positive diffusion coefficient. We shall also give a nonresonance-type result for a quasi-linear system closely related to (1.1).

Systems of the form (1.1) play an important role in applied mathematics and are generally referred to in the literature as reaction-diffusion equations. In particular, in mathematical biology when the diffusion coefficients (i.e., the ρ_i) are different they give rise to the Turing mechanism, which is important in the theory of pattern formation (see the interesting article [14] and a further discussion in [15, pp. 375–379]). Also, in predator–prey problems autocatalytic systems (see [2, pp. 116–120]) are important. In §2 we give a quasi-linear autocatalytic system that is covered by Theorem 2 and two other examples that illustrate Theorem 1.

The two theorems that are proven in this paper are motivated by the work of Shapiro [17], de Figueiredo and Gossez [6], Lefton and Shapiro [12], and de Figueiredo [5]. In [17] the notion of a first eigenvalue for a higher-order quasi-linear elliptic operator is introduced (evidently for the first time), and this gives the aforementioned λ_1^*. (See also (1.5) and (1.6).) In [6], techniques for solving semilinear higher-order elliptic boundary value problems below and at the first eigenvalue (called problems at resonance) are developed. In [12], a time-periodic result at resonance for quasi-linear parabolic operators is obtained; and in [5], a resonance theorem for semilinear

elliptic partial differential equations with derivatives in the nonlinear forcing term is established.

To be quite explicit about the various aspects of each of the quasi-linear partial differential equations in (1.1), let $\Omega \subset \mathbb{R}^N, N \geq 1$, be a bounded open connected set. The points of Ω will be designated by $x = (x_1, \dots, x_N)$ and the elementary differential operators by $D^\alpha = \prod_{j=1}^N (\frac{\partial}{\partial x_j})^{\alpha_j}$ for an ordered N-tuple $\alpha = (\alpha_1, \dots, \alpha_N)$ of nonnegative integers with the order of the operator D^α written as $|\alpha| = \sum_{j=1}^N \alpha_j$. To write nonlinear partial differential operators in a convenient form, we introduce the vector space $\mathbb{R}^{s_m}$ whose elements are $\xi_m = \{\xi_\alpha : |\alpha| \leq m\}$ and divide each ξ_m into two parts: $\xi_m = (\eta_{m-1}, \zeta_m)$, where $\eta_{m-1} = \{\eta_\beta : |\beta| \leq m-1\} \in \mathbb{R}^{s_{m-1}}$ is the lower order part of ξ_m and $\zeta_m = \{\zeta_\alpha : |\alpha| = m\}$ is the part of ξ_m corresponding to the mth derivatives. In particular, $\zeta_m \in \mathbb{R}^{q_m}$, where $q_m = s_m - s_{m-1}$. For $u \in W_0^{m,2}(\Omega), \xi_m(u)(x) = \{D^\alpha u(x) : |\alpha| \leq m\}$. (Note $D^{(0,0,\dots,0)}u = u$.)

$Q_i u$ will designate a $2m$th-order differential operator of the generalized divergence form

$$Q_i u = \sum_{1 \leq |\alpha| \leq m} (-1)^{|\alpha|} D^\alpha A_\alpha^i(x, \xi_m(u)) + a_0^i(x, \xi_m(u))u, \tag{1.2}$$

and the following hypotheses will be imposed on the functions $A_\alpha^i(x, \xi_m), 1 \leq |\alpha| \leq m$, and a_0^i appearing in (1.2).

(Q-1) $A_\alpha^i(x, \xi_m) : \Omega \times \mathbb{R}^{s_m} \to \mathbb{R}$ satisfies the Carathéodory conditions (i.e., $A_\alpha^i(x, \xi_m)$ is measurable in x $\forall \xi_m \in \mathbb{R}^{s_m}$ and continuous in ξ_m for a.e. $x \in \Omega$ for $1 \leq |\alpha| \leq m$).

(Q-2) $\exists c_0 > 0$ and $h^\# \in L^2(\Omega)$ with $h^\#$ nonnegative such that $|A_\alpha^i(x, \xi_m)| \leq h^\#(x) + c_0|\xi_m|$ $\forall \xi_m \in \mathbb{R}^{s_m}, 1 \leq |\alpha| \leq m$, and a.e. $x \in \Omega$ for $i = 1, \dots, N_1$.

(Q-3) $\sum_{|\alpha|=m} [A_\alpha^i(x, \eta_{m-1}, \zeta_m) - A_\alpha^i(x, \eta_{m-1}, \zeta_m')](\zeta_\alpha - \zeta_\alpha') > 0$ for a.e. $x \in \Omega$, $\forall (\eta_{m-1}, \zeta_m), (\eta_{m-1}, \zeta_m') \in \mathbb{R}^{s_m}$ with $\zeta_m \neq \zeta_m'$, where $\xi_m = (\eta_{m-1}, \zeta_m)$, and for $i = 1, \dots, N_1$.

(Q-4) $\exists c_1 > 0$ such that $\sum_{|\alpha|=m} A_\alpha^i(x, \xi_m)\zeta_\alpha \geq c_1 |\zeta_m|^2$ $\forall \xi_m \in \mathbb{R}^{s_m}$ and a.e. $x \in \Omega$ for $i = 1, \dots, N_1$.

(Q-5) $a_0^i(x, \xi_m) : \Omega \times \mathbb{R}^{s_m} \to \mathbb{R}$ satisfies the Carathéodory conditions and $a_0^i(x, \xi_m) \in L^\infty(\Omega \times \mathbb{R}^{s_m})$.

The notation we have introduced is the standard type used. (See [4].)

Next, we introduce the Hilbert space $\tilde{H}$ as follows. Set $\mathcal{A} = \{v(x,t) \in C^\infty(\Omega \times \mathbb{R}) : v(x,t)$ is real-valued and satisfies ($\mathcal{A}$-1) and ($\mathcal{A}$-2)$\}$, where

($\mathcal{A}$-1) $v(x,t) = v(x, t + 2\pi)$ $\forall x \in \Omega$ and $\forall t \in \mathbb{R}$,

($\mathcal{A}$-2) $\exists E$, a compact subset of Ω, such that $v(x,t) = 0$ $\forall x \in \Omega \backslash E$ and $\forall t \in \mathbb{R}$.

Set $\tilde{\Omega} = \Omega \times T$ where $T = (-\pi, \pi)$, and introduce the following inner product, where we write L^2 for $L^2(\tilde{\Omega})$,

$$\langle u, v \rangle_{\tilde{H}} = \langle D_t u, D_t v \rangle_{L^2} + \sum_{|\alpha| \leq m} \langle D^\alpha u, D^\alpha v \rangle_{L^2} \tag{1.3}$$

for $u, v \in \mathcal{A}$, where $\langle \cdot, \cdot \rangle_{L^2}$ is the usual L^2-inner product over $\tilde{\Omega}$. With this inner product $\mathcal{A}$ becomes a pre-Hilbert space. $\tilde{H}$ will designate the Hilbert space that we obtain by completing $\mathcal{A}$ using Cauchy sequences with respect to the norm $\|u\|_{\tilde{H}} = \langle u, u \rangle_{\tilde{H}}^{\frac{1}{2}}$.

For our quasi-linear operator $Q_i u$ in (1.2) we shall also suppose

(Q-6)

$$\int_{\tilde{\Omega}} \sum_{1\leq|\alpha|\leq m} A^i_\alpha(x,\xi_m(v))D^\alpha D_t v + \int_{\tilde{H}} a^i_0(x,\xi_m(v))vD_tv = 0 \quad \forall v \in \mathcal{A}.$$

In (Q-6), we note that $\xi_m(v) = \{D^\alpha(v(x,t)) : |\alpha| \leq m\}$.

From (1.1), (Q-1), and (Q-2) we see that the two-form

$$(1.4) \qquad Q_i(u,v) = \sum_{1\leq|\alpha|\leq m} \int_{\tilde{\Omega}} A^i_\alpha(x,\xi_m(u))D^\alpha v + \int_{\tilde{\Omega}} a^i_0(x,\xi_m(u))uv$$

is well defined for $u, v \in \tilde{H}$ and $i = 1,\ldots,N_1$.

Motivated by Shapiro [17, p. 1821], we define

$$(1.5) \qquad \lambda^*_{1i} = \liminf_{\|u\|_{L^2}\to\infty} \frac{Q_i(u,u)}{\|u\|^2_{L^2}}, \quad u \in \tilde{H}.$$

The same proof used in [17, p. 1822] shows that λ^*_{1i} is a finite real-valued number. λ^*_{1i} plays the role of the first (or principal) eigenvalue of Q_i. We shall suppose throughout this paper that

$$(1.6) \qquad \lambda^*_{11} = \cdots = \lambda^*_{1N_1} = \lambda^*_1.$$

Next we set

$$(1.7) \qquad Lu = \sum_{|\alpha|,|\beta|\leq m} (-1)^{|\alpha|}D^\alpha(b_{\alpha\beta}(x)D^\beta u),$$

where we have the following hypotheses on $b_{\alpha\beta}(x)$.

(L-1) $b_{\alpha\beta}$ are real-valued functions in $L^\infty(\Omega)$ for $|\alpha|, |\beta| \leq m$. Also, if $|\alpha| = |\beta| = m$, then $b_{\alpha\beta}$ is uniformly continuous in Ω.

(L-2) $\exists c_2$ such that $\sum_{|\alpha|=|\beta|=m} b_{\alpha\beta}\mu^\alpha\mu^\beta \geq c_2|\mu|^{2m}$ $\forall x \in \Omega$ and $\forall \mu \in \mathbb{R}^N$ where $\mu = (\mu_1,\ldots,\mu_N)$ and $|\mu|^2 = \mu_1^2 + \cdots + \mu_N^2$.

Observe that with (L-1) and (L-2), L is a higher-order linear elliptic operator. Associated to L is the bilinear form

$$(1.8) \qquad \mathcal{L}_\Omega(u,v) = \sum_{|\alpha|,|\beta|\leq m} \int_\Omega b_{\alpha\beta}(x)D^\alpha uD^\beta v \quad \forall u,v \in W^{m,2}_0(\Omega)$$

where $W^{m,2}_0(\Omega)$ is the well-known Sobolev space obtained by taking the closure of $C^m_0(\Omega)$ in $W^{m,2}(\Omega)$ with inner product $\langle u,v\rangle = \int_\Omega \sum_{|\alpha|\leq m} D^\alpha uD^\beta v$.

We will also assume throughout this paper that L satisfies (L-1) and (L-2) as well as the following conditions.

(L-3) L is symmetric; that is, $\mathcal{L}_\Omega(u,v) = \mathcal{L}_\Omega(v,u)$ $\forall u, v \in W^{m,2}_0(\Omega)$.

Also, we have the following well-known facts about L (see [8] and [18, p. 858]):

$\exists\{\lambda_n\}^\infty_{n=1}$ a nondecreasing sequence with $\lambda_n \underset{n\to\infty}{\longrightarrow} \infty$ and a

(1.9) sequence of real-valued functions $\{\phi_n\}^\infty_{n=1}$ in $W^{m,2}_0(\Omega)$ such that

$\mathcal{L}_\Omega(u,\phi_n) = \lambda_n\langle u,\phi_n\rangle_{L^2(\Omega)}$ $\forall u \in W^{m,2}_0(\Omega)$;

$$\{\phi_n\}_{n=1}^{\infty} \text{ is a } CONS \text{ on } L^2(\Omega); \tag{1.10}$$

$$\lambda_1 = \inf_{u\neq 0} \frac{\mathcal{L}_\Omega(u,u)}{\|u\|_{L^2(\Omega)}}, \quad u \in W_0^{m,2}(\Omega). \tag{1.11}$$

Extending the bilinear form $\mathcal{L}_\Omega(\cdot,\cdot)$ from $W_0^{m,2}(\Omega)$ to $\tilde{H}$ by

$$\mathcal{L}(u,v) = \int_T \mathcal{L}_\Omega(u,v) = \int_{\tilde{\Omega}} \sum_{|\alpha|,|\beta|\leq m} b_{\alpha\beta} D^\alpha u D^\beta v \tag{1.12}$$

for $u, v \in \tilde{H}$, where $T = (-\pi, \pi)$, we see from (1.11) that

$$\lambda_1 = \inf_{u\neq 0} \frac{\mathcal{L}(u,u)}{\|u\|_{L^2}}, \quad u \in \tilde{H}. \tag{1.13}$$

Also, we set $\|u\|_{\mathcal{L}}^2 = |\mathcal{L}(u,u)|$ for $u \in \tilde{H}$ and

$$\|u\|^2_{W^{m,2,\sim}} = \int_{\tilde{\Omega}} |\xi_m(u)|^2. \tag{1.14}$$

Let κ be given with $0 \leq \kappa < 1$.

We shall say Q_i is $\kappa*$-related to L if the following conditions hold.

$$\lambda^*_{1i} = \lambda_1. \tag{1.15}$$

$$\begin{aligned} &\text{(i)} \quad u \in \tilde{H}, \liminf_{\|u\|_{W^{m,2,\sim}}\to\infty} \frac{Q_i(u,u) - \mathcal{L}(u,u)}{\|u\|^{1+\kappa}_{W^{m,2,\sim}}} \geq 0. \\ &\text{(ii)} \quad \text{There exist positive constants } c_1^\#, c_2^\# \text{ such that} \\ &\qquad Q_i(u,u) - \mathcal{L}(u,u) \geq -c_1^\# \|u\|^{\kappa+1}_{W^{m,2,\sim}} - c_2^\# \ \forall u \in \tilde{H}. \end{aligned} \tag{1.16}$$

(Q_i being $\kappa*$-related to L comes from the notion introduced in [12, p. 153] where in (1.19) in this last-named reference, $\|u\|_{\mathcal{L}}$ should be replaced by $\|u\|_{W^{m,2,\sim}}$. In case $\lambda_1 > 0$, $\|u\|_{\mathcal{L}}$ and $\|u\|_{W^{m,2,\sim}}$ are equivalent norms.)

Let n_1 be the largest integer such that $\lambda_1 = \cdots = \lambda_{n_1} < \lambda_{n_1+1}$. This implies that

$$\mathcal{L}_\Omega(v,\phi_i) = \lambda_1\langle v,\phi_i\rangle_{L^2(\Omega)} \quad \forall v \in W_0^{m,2}(\Omega) \text{ for } i = 1,\ldots,n_1. \tag{1.17}$$

We set

$$S^\#_{\lambda_1} = \left\{ v = \sum_{j=1}^{n_1} d_j\phi_j : d_j \text{ is a real constant } j = 1,\ldots,n_1 \right\}. \tag{1.18}$$

We shall impose the following hypotheses upon the f_i given in (1.1) for $i = 1,\ldots,N_1$.

$$f_i(x,t,\xi_{m1},\ldots,\xi_{mN_1}) : \tilde{\Omega} \times \underbrace{\mathbb{R}^{s_m} \times \cdots \times \mathbb{R}^{s_m}}_{N_1} \to \mathbb{R} \tag{f-1}$$

satisfies the Carathéodory conditions.

(f-2) $\exists\kappa$ with $0 \le \kappa < 1$ and $\exists$ nonnegative constants c_α and an L^2-function $d(x,t)$ such that

$$|f_i(x,t,\xi_{m1},\dots,\xi_{mN_1})| \le \sum_{|\alpha|\le m} c_\alpha|\xi_{\alpha i}|^\kappa + d(x,t) \;\; \forall(\xi_{m1},\dots,\xi_{mN_1}) \in \underbrace{\mathbb{R}^{s_m}\times\cdots\times\mathbb{R}^{s_m}}_{N_1},$$

a.e. in $\tilde{\Omega}$ for $i = 1,\dots,N_1$ where $\xi_{mi} = \{\xi_{\alpha i}\}_{|\alpha|\le m}$.

(f-3) Let $S_1' = \{\xi_m \in \mathbb{R}^{s_m} : |\xi_m| = 1 \text{ and } \xi_{(0,\dots,0)} \ne 0\}$. $\exists\tilde{\Omega}_0 \subset \tilde{\Omega}$ with meas $(\tilde{\Omega} - \tilde{\Omega}_0) = 0$ such that the following uniform limit holds for each $(x,t) \in \tilde{\Omega}_0$:

$$\text{(1.19)}\quad \begin{aligned} &\lim_{n\to\infty} \frac{f_i(x,t,\xi_{m1},\dots,r_n\xi_{mi}^{(n)},\dots,\xi_{mN_1})}{r_n^\kappa} = h_i(x,t,\xi_{mi}) \\ &\text{uniformly for } (\xi_{m1},\dots,\xi_{m(i-1)},\xi_{m(i+1)},\dots,\xi_{mN_1}) \in \underbrace{\mathbb{R}^{s_m}\times\cdots\times\mathbb{R}^{s_m}}_{N_1-1} \end{aligned}$$

for all sequences $\{r_n\} \subset \mathbb{R}$ and $\{\xi_{mi}^{(n)}\} \subset S_1'$ such that $r_n \to \infty$ and $\xi_{mi}^{(n)} \to \xi_{mi} \in S_1'$, where $h_i(x,t,\xi_{mi})$ is a Carathéodory function on $\tilde{\Omega} \times S_1'$ that is uniformly bounded by a function in $L^2(\tilde{\Omega})$.

For the G's on the right-hand side of (1.1) we make the following assumptions for $i = 1,\dots,N_1$.

(G-1) $G_{1i} : L^2(\tilde{\Omega}) \to \mathbb{R}$ is sequentially weakly continuous and $\exists\kappa$ with $0 \le \kappa < 1$ such that $|G_{1i}(u)| \le c_1'\|u\|_{L^2}^\kappa + c_2'$ $\forall u \in L^2(\tilde{\Omega})$, where c_1' and c_2' are nonnegative constants.

(G-2) $G_{2i} : L^2(\tilde{\Omega}) \to \mathbb{R}$ is strongly continuous and $\exists c_3'$ such that $|G_{2i}(u)| \le c_3'$ $\forall u \in L^2(\tilde{\Omega})$. Also in case $\kappa = 0$ in either Theorem 1 or Theorem 2, $\lim_{\|u\|_{L^2}\to\infty} |G_{2i}(u)| = 0$.

We shall establish the following resonance theorem for the time-periodic quasi-linear parabolic differential system (1.1).

THEOREM 1. *Let $\Omega \subset \mathbb{R}^N, N \ge 1$, be a bounded open connected set; and let κ be given with $0 \le \kappa < 1$. Suppose that the coefficients of Q_i satisfy* (Q-1)–(Q-6); *Q_i is $\kappa*$-related to L; f_i satisfies* (f-1)–(f-3); *$g_i \in L^2(\tilde{\Omega})$; G_{1i} and G_{2i} satisfy* (G-1) *and* (G-2), *respectively; and $\rho_i > 0$ for $i = 1,\dots,N_1$. Also suppose*

$$\text{(1.20)}\quad \int_{\tilde{\Omega}(v)} h_i\left(x,t,\frac{\xi_m(v)}{|\xi_m(v)|}\right)|\xi_m(v)|^\kappa v < 0 \quad \textit{for every nontrivial } v \in S_{\lambda_1}^\#$$

for $i = 1,\dots,N_1$, where h_i is given in (f-3) *and $\tilde{\Omega}(v) = \{(x,t) \in \tilde{\Omega} : v(x,t) \ne 0\}$. Then $\exists(u_1,\dots,u_{N_1}) \in \tilde{H}^{N_1}$, which is a weak solution to the system* (1.1) *on $\tilde{\Omega}$.*

What we mean by $(u_1,\dots,u_{N_1}) \in \tilde{H}^{N_1}$ is a weak solution to the system (1.1) on $\tilde{\Omega}$ is that

$$\text{(1.21)}\quad \begin{aligned} \langle D_tu_i,v\rangle_{L^2} + \rho_iQ_i(u_i,v) = \rho_i\lambda_1^*\langle u_i,v\rangle_{L^2} &+ \langle f_i(\cdot,\xi_m(u_1),\dots,\xi_m(u_{N_1})),v\rangle_{L^2} \\ &+ G_{1i}(D_tu_i)G_{2i}(u_i)\langle g_i,v\rangle_{L^2} \end{aligned}$$

$\forall v \in \tilde{H}$ and $i = 1,\dots,N_1$.

The nonresonance-type theorem that we shall prove will deal with the system

$$\text{(1.22)}\quad \begin{aligned} D_tu_i + \rho_iQ_iu_i = \rho_i(\lambda_1^* - \delta_i)u_i &+ f_i(x,t,\xi_m(u_1),\dots,\xi_m(u_{N_1})) \\ &+ G_{1i}(D_tu_i)G_{2i}(u_i)g_i(x,t), \quad i = 1,\dots,N_1, \end{aligned}$$

where each δ_i is a positive constant. To handle the system (1.22) we do not need the condition (f-3) nor the condition (1.20). In particular, we shall prove the following theorem.

THEOREM 2. *Suppose the conditions in the hypothesis of Theorem* 1 *hold, except for* (f-3) *and the condition in* (1.20). *Then* $\exists(u_1,\ldots,u_{N_1}) \in \tilde{H}^{N_1}$, *which is a weak solution to the system* (1.22).

In Theorems 1 and 2, besides dealing with a system, we also allow derivatives of the dependent variables to appear in the forcing terms on the right-hand side of the equations. Also, we allow derivatives of order m as well as derivatives of lower order of the dependent variable to appear in the coefficients of each of the Q_i on the left-hand side of the equations. Neither of these situations were handled in the paper by Lefton and Shapiro [12], and some new ideas of the type presented in the current paper are needed. In the next section, we give examples of Q's and f's that are relevant for Theorems 1 and 2 but are not covered in [12]. The extension of our results to almost-periodic reaction-diffusion equations is left as an open problem.

2. Some examples. If L satisfies (L-1)–(L-3) and $m = 1$, then L is automatically $\kappa*$-related to itself. For $m \geq 2$, if L also satisfies (L-4) below, then L also is $\kappa*$-related to itself; this is the first situation we deal with in this section. Next, we give two examples of a Q that has derivatives of order lower than m involved in its coefficients (as well as of order m) and a corresponding L to which Q is $\kappa*$-related. Finally we consider three different systems, the first of which is autocatalytic and involves Theorem 2 and the second and third of which illustrate condition (1.20) in Theorem 1.

We first show that if Lu is given by (1.7) and L meets (L-1)–(L-3), then

$$\mathcal{L}(v, D_t v) = 0 \quad \forall v \in \mathcal{A}, \tag{2.1}$$

where $\mathcal{L}(\cdot,\cdot)$ is defined by (1.12).

To see that (2.1) is true, we observe from (L-3) that for $v \in \mathcal{A}, \mathcal{L}(v, D_t v) = \mathcal{L}(D_t v, v)$. Also, we see that $D_t[D^\beta v D^\alpha v] = (D^\alpha D_t v)D^\beta v + (D^\alpha v)D^\beta D_t v$. Hence from (1.12)

$$\begin{aligned} 2\mathcal{L}(v, D_t v) &= \sum_{|\alpha|,|\beta|\leq m} \int_{\tilde{\Omega}} b_{\alpha\beta}[(D^\alpha v)(D^\beta D_t v) + (D^\alpha D_t v)(D^\beta v)] \\ &= \sum_{|\alpha|,|\beta|\leq m} \int_{\Omega} b_{\alpha\beta}(x) \int_T D_t[D^\beta v D^\alpha v] \\ &= 0, \end{aligned}$$

which establishes (2.1). Next, we say L meets (L-4) if

(L-4)

$$\sum_{|\alpha|=|\beta|=m} b_{\alpha\beta}(x)(\zeta_\beta - \zeta'_\beta)(\zeta_\alpha - \zeta'_\alpha) \geq c'_1 \sum_{|\alpha|=m} (\zeta_\alpha - \zeta'_\alpha)^2 \quad \forall \zeta_m, \zeta'_m \in \mathbb{R}^{q_m}$$

where c'_1 is a positive constant and $q_m = s_m - s_{m-1}$.

(In the special case $m = 1$, it is easy to see that (L-2) implies (L-4).)

We now show if

$$\begin{aligned} Lu = &\sum_{|\alpha|=|\beta|=m} (-1)^{|\alpha|} D^\alpha[b_{\alpha\beta}(x)D^\beta u] \\ &+ \sum_{1\leq|\alpha|,|\beta|\leq m-1} (-1)^{|\alpha|} D^\alpha[b_{\alpha\beta}(x)D^\beta u] + b_{00}(x)u \end{aligned} \tag{2.2}$$

and

(2.3) if L meets (L-1)–(L-4), then L is $\kappa*$-related to itself.

In order to establish (2.3), what we have to do is show that L given by (2.2) satisfies (Q-1)–(Q-6). To do this we define

$$\begin{aligned} A_\alpha(x,\xi_m) &= \sum_{|\beta|=m} b_{\alpha\beta}(x)\zeta_\beta \quad \text{for } |\alpha| = m, \\ &= \sum_{1\le|\beta|\le m-1} b_{\alpha\beta}(x)\eta_\beta \quad \text{for } 1 \le |\alpha| \le m-1, \\ a_0(x,\xi_m) &= b_{00}(x). \end{aligned} \tag{2.4}$$

It is clear from (2.4) that $A_\alpha(x,\xi_m)$ satisfies (Q-1), (Q-2), (Q-5), and (Q-6); this latter fact holds because of (2.1). Taking $\zeta'_m = 0$ in (L-4), we see from (2.4) that

$$\sum_{|\alpha|=m} A_\alpha(x,\xi_m)\zeta_\alpha \ge c'_1 \sum_{|\beta|=m} |\zeta_\alpha|^2;$$

so (Q-4) holds. It is also clear from (L-4) that (Q-3) holds. Hence L is indeed $\kappa*$-related to itself since (1.15) and (1.16) obviously hold. So Theorems 1 and 2 hold when Q_i is an L of the form (2.2) satisfying (L-1)–(L-4). If all the Q_i's are L's of this nature, our quasi-linear result is actually a semilinear result and appears to be new even in this case.

For $m = 1$, any Lu of the form (2.2) that also satisfies (L-1)–(L-3) automatically is $\kappa*$-related to itself by (2.3) since (L-2) then implies (L-4) as we noted earlier. For $m \ge 2$, suppose Lu of the form (2.2) satisfies (L-1) and in addition

$$\begin{aligned} &b_{\alpha\beta}(x) = 0 \quad \text{if } |\alpha| = |\beta| = m \text{ and } \alpha \ne \beta, \\ &b_{\alpha\alpha}(x) \ge c'_2 \quad \forall x \in \Omega \text{ if } |\alpha| = m, \\ &b_{\alpha\beta}(x) = b_{\beta\alpha}(x) \quad \text{if } 1 \le |\alpha|, |\beta| \le m-1, \end{aligned} \tag{2.5}$$

where c'_2 is a positive constant. Then it is easy to see from [9, p. 55] that (L-2), (L-3), and (L-4) also hold. Hence by (2.3) such an L is $\kappa*$-related to itself. In particular, we observe that $Lu = (-1)^m\Delta^m u$, where Δ^m is the familiar mth-iterated Laplacian, satisfies (2.5) and, therefore, is $\kappa*$-related to itself.

In [12, pp. 154–160], two quasi-linear examples, one of second order and one of higher order, were given that meet the criteria for the $\kappa*$-relationship. We now give some quasi-linear examples that are not covered by the theorems in [12] because $A_\alpha(x,\xi_m)$ for $|\alpha| = m$ will be allowed to depend on derivatives or order $m-1$. However, these examples will be covered by Theorems 1 and 2.

We first consider the case when Qu is a second-order quasi-linear differential expression, that is, $m = 1$ in (1.2). For this situation, we can designate the A_α when $|\alpha| = 1$ by A_j for $j = 1, \ldots, N$ and ξ_1 by $(\eta_0, \zeta_1, \ldots, \zeta_N)$ with $|\xi_1|^2 = \eta_0^2 + \zeta_1^2 + \cdots + \zeta_N^2$; so $\eta_0(u) = u$ and $\zeta_j(u) = \frac{\partial u}{\partial x_j}$. In particular, we set

$$\begin{aligned} A_j(x,\xi_1) &= \zeta_j + \frac{\zeta_j}{(1+|\xi_1|^2)^{\frac{1}{2}}}, \qquad j = 1, \ldots, N; \\ a_0(x,\xi_1) &= (1+|\xi_1|^2)^{-\frac{1}{2}}. \end{aligned} \tag{2.6}$$

It is clear from the start that (2.6) implies that (Q-1), (Q-2), (Q-4), and (Q-5) are automatically satisfied. To see that (Q-3) holds, we observe that for $c > 0$, $[c^2 + \zeta_1^2 + \cdots + \zeta_N^2]^{\frac{1}{2}}$ is a convex function in $\mathbb{R}^N$. Hence by [11, p. 16], the gradient of this last-named function is monotone. This fact plus an easy computation show that (Q-3) holds for the A_j in (2.6).

To see that (Q-6) holds we observe from (2.6) that for $v \in \mathcal{A}$

$$\begin{aligned}(2.7)\qquad &\sum_{j=1}^{N} A_j(x,\xi_1(v))D_tD_jv + a_0(x,\xi_1(v))vD_tv \\ &\quad = D_t[1+|v|^2+|\nabla v|^2]^{\frac{1}{2}} + \frac{1}{2}D_t|\nabla v|^2.\end{aligned}$$

Hence, the periodicity of v shows that the integral over $\tilde{\Omega}$ of the expression on the left-hand side of the equal sign in (2.7) is zero and (Q-6) is established.

We set $Lu = -\Delta u$ where Δ stands for the Laplace operator. To complete this example we must show that Qu given by (2.6) is $\kappa *$-related to L. An easy computation using (1.4) and (2.6) shows that

$$(2.8)\qquad \mathcal{Q}(u,u) - \mathcal{L}(u,u) = \int_{\tilde{\Omega}} \frac{|\nabla u|^2 + u^2}{(1+u^2+|\nabla u|^2)^{\frac{1}{2}}}.$$

Since the right-hand side of (2.8) is nonnegative, it follows that conditions (1.16) hold. In a similar manner it follows from (1.5), (1.13), and (2.8) that $\lambda_1^* \geq \lambda_1$. Next, with ϕ_1 given in (1.9), we have that $\mathcal{L}(n\phi_1, n\phi_1) = n^2\lambda_1 2\pi$. Consequently, we obtain from (2.8) that

$$\frac{\mathcal{Q}(n\phi_1,n\phi_1)}{\langle n\phi_1,n\phi_1\rangle_{L^2}} \leq \lambda_1 + \int_\Omega \frac{[|\nabla\phi_1|^2+\phi_1^2]^{\frac{1}{2}}}{n}.$$

Taking the lim inf of both sides of this last inequality as $n \to \infty$, we infer from (1.5) that $\lambda_1^* \leq \lambda_1$. Hence $\lambda_1^* = \lambda_1$, (1.15) is established, Q is $\kappa *$-related to L, and our example is complete.

For our next example, we let $m \geq 2$ and let $\alpha = (\alpha_1,\ldots,\alpha_N), \beta = (\beta_1,\ldots,\beta_N)$ designate N-tuples or orders $(m-1)$ and m, respectively. $i\alpha$ will stand for the N-tuple β where $\beta_j = \alpha_j$ for $j \neq i$ and $\beta_i = \alpha_i + 1$. Also, for each β with $|\beta| = m$, let $F_\beta(s)$ be a mapping of the following nature:

$$(2.9)\qquad F_\beta : [0,\infty) \to \mathbb{R} \text{ is continuous and nondecreasing;}$$

$$(2.10)\qquad 0 \leq F_\beta(s) \leq 1 \quad \forall s \in [0,\infty);$$

$$(2.11)\qquad \lim_{s\to\infty} s[1-F_\beta(s)] = 0.$$

Examples of such an $F_\beta(s)$ are

$$\frac{s}{(1+s^2)^{\frac{1}{2}}},\ \frac{s^2}{1+s^2},\quad \text{and}\quad \left[\frac{1+s^2}{2+s^2}\right]^{\frac{1}{2}}.$$

We shall also suppose

$$b_\beta(x) \in C(\bar{\Omega}) \quad \text{with } b_\beta(x) \geq c_1' \ \forall x \in \Omega, \tag{2.12}$$

where c_1' is a positive constant. Next, we set

$$\begin{aligned} &\text{(i)} \quad \Gamma(\beta) = \{\alpha : |\alpha| = m-1 \text{ and } \exists i \text{ such that } i\alpha = \beta\}, \\ &\text{(ii)} \quad \nu(\beta) = \text{ the number of } \alpha \text{ in } \Gamma(\beta). \end{aligned} \tag{2.13}$$

We define

$$A_\beta(x, \xi_m) = \xi_\beta + b_\beta(x) \sum_{\alpha \in \Gamma(\beta)} F_\beta[(\xi_\alpha^2 + \xi_\beta^2)^{\frac{1}{2}}]\xi_\beta \quad \text{for } |\beta| = m, \tag{2.14}$$

$$A_\alpha(x, \xi_m) = \sum_{i=1}^{N} b_{i\alpha}(x) F_{i\alpha}[(\xi_\alpha^2 + \xi_{i\alpha}^2)^{\frac{1}{2}}]\xi_\alpha \quad \text{for } |\alpha| = m-1, \tag{2.15}$$

and

$$Qu = \sum_{|\beta|=m} (-1)^m D^\beta A_\beta(x, \xi_m(u)) + \sum_{|\alpha|=m-1} (-1)^{m-1} D^\alpha A_\alpha(x, \xi_m(u)). \tag{2.16}$$

Now, it is clear that the coefficients Q satisfy (Q-1), (Q-2), (Q-4), and (Q-5). From (2.9), we see that $sF_\beta[(s^2 + c^2)^{\frac{1}{2}}]$ is a nondecreasing function of s for $s \in \mathbb{R}$ and $c \in \mathbb{R}$. Hence it follows from (2.12) and (2.14) that the condition (Q-3) is also satisfied. To see that the condition (Q-6) holds, we observe from (2.13) that the following equality of sets holds:

$$\{(\beta, \alpha) : |\beta| = m, \alpha \in \Gamma(\beta)\} = \{(i\alpha, \alpha) : |\alpha| = m-1, i = 1, \ldots, N\}. \tag{2.17}$$

From (2.17), it consequently follows that for $v \in \mathcal{A}$

$$\begin{aligned} &\sum_{|\beta|=m} \sum_{\alpha \in \Gamma(\beta)} b_\beta F_\beta \left\{ [(D^\alpha v)^2 + (D^\beta v)^2]^{\frac{1}{2}} \right\} D^\beta v D^\beta D_t v \\ &\quad = \sum_{|\alpha|=m-1} \sum_{i=1}^{N} b_{i\alpha} F_{i\alpha} \left\{ [(D^\alpha v)^2 + (D_i D^\alpha v)^2]^{\frac{1}{2}} \right\} D_i D^\alpha v D_i D^\alpha D_t v. \end{aligned} \tag{2.18}$$

It therefore follows from (2.14)–(2.16) and this last fact that

$$\begin{aligned} 2Q(v, D_t v) = &\sum_{|\alpha|=m-1} \sum_{i=1}^{N} \int_\Omega b_{i\alpha} \int_T F_{i\alpha} \left\{ [(D^\alpha v)^2 + (D_i D^\alpha v)^2]^{\frac{1}{2}} \right\} \\ &\times 2[D_i D^\alpha v D_i D^\alpha D_t v + D^\alpha v D^\alpha D_t v]. \end{aligned} \tag{2.19}$$

Set $G_{i\alpha}(s) = \int_0^s F_{i\alpha}(r^{\frac{1}{2}})\,dr$ for $s \geq 0$. Then it is clear that $D_t G_{i\alpha}[(D^\alpha v)^2 + (D_i D^\alpha v)^2] =$ the integrand for $\int_T$ in (2.19). Hence the periodicity of v implies that $Q(v, D_t v) = 0$ for $v \in \mathcal{A}$, and we see that the condition (Q-6) does indeed hold for Q.

Next, we set

$$L_1 u = (-1)^m \sum_{|\beta|=m} D^\beta[D^\beta u] \tag{2.20}$$

and with $\nu(\beta)$ defined in (2.13) (ii),

$$\begin{aligned} Lu = L_1 u &+ (-1)^m \sum_{|\beta|=m} \nu(\beta) D^\beta[b_\beta D^\beta u] \\ &+ (-1)^{m-1} \sum_{|\alpha|=m-1} \sum_{i=1}^{N} D^\alpha[b_{i\alpha} D^\alpha u]. \end{aligned} \tag{2.21}$$

Consequently, it follows from (2.13)–(2.16), (2.20), and (2.21) that for $u \in \tilde{H}$,

$$\begin{aligned} &\mathcal{L}(u,u) - \mathcal{Q}(u,u) \\ &= \sum_{|\beta|=m} \sum_{\alpha \in \Gamma(\beta)} \int_{\tilde{\Omega}} \{1 - F_\beta[(|D^\alpha u|^2 + |D^\beta u|^2)^{\frac{1}{2}}]\} b_\beta |D^\beta u|^2 \\ &+ \sum_{|\alpha|=m-1} \sum_{i=1}^{N} \int_{\tilde{\Omega}} \{1 - F_{i\alpha}[(|D^\alpha u|^2 + |D_i D^\alpha u|^2)^{\frac{1}{2}}]\} b_{i\alpha} |D^\alpha u|^2. \end{aligned} \tag{2.22}$$

Our example will be complete if we can show Q is $\kappa*$-related to L. To accomplish this we first observe that

$$u \in \tilde{H}, \quad \lim_{\|u\|_{W^{m,2,\sim}} \to \infty} \int_{\tilde{\Omega}} \frac{\left\{1 - F_\beta\left[(|D^\alpha u|^2 + |D^\beta u|^2)^{\frac{1}{2}}\right]\right\} |D^\beta u|^2}{\|u\|^{1+\kappa}_{W^{m,2,\sim}}} = 0, \tag{2.23}$$

where $\|u\|^2_{W^{m,2,\sim}}$ is defined in (1.14). Equation (2.23) follows easily from the fact that given $\varepsilon > 0$, there is an s_0 by (2.11) such that the numerator of the integrand in (2.23) is majorized by $\varepsilon|D^\beta u|$ if $|D^\beta u| \geq s_0$. Consequently, using (2.10) and (2.12) joined with (2.23), we see that each of the integrals in the first term on the right-hand side of (2.22) when divided by $\|u\|^{1+\kappa}_{W^{m,2,\sim}}$ tends to zero as $\|u\|_{W^{m,2,\sim}} \to \infty$. A similar situation prevails for each of the integrals in the second term. We conclude that

$$\frac{\mathcal{Q}(u,u) - \mathcal{L}(u,u)}{\|u\|^{1+\kappa}_{W^{m,2,\sim}}} \to 0 \quad \text{as } \|u\|_{W^{m,2,\sim}} \to \infty.$$

Hence (1.16) (i) holds. A similar argument using (2.22) shows that $\exists K > 0$ such that $\mathcal{L}(u,u) - \mathcal{Q}(u,u) \leq \|u\|_{W^{m,2,\sim}} + K$ $\forall u \in \tilde{H}$. Hence (1.16) (ii) holds.

It remains to show that $\lambda_1^* = \lambda_1$. From (2.10), (2.16), and (2.22) we see that $0 \leq \mathcal{Q}(u,u) \leq \mathcal{L}(u,u)$ $\forall u \in \tilde{H}$. Hence for ϕ_1 given in (1.10),

$$\frac{Q(n\phi_1, n\phi_1)}{\|n\phi_1\|^2_{L^2}} \leq \lambda_1 \quad \text{for every positive integer } n.$$

Consequently, from (1.5), we have that

$$0 \leq \lambda_1^* \leq \lambda_1. \tag{2.24}$$

Next, we set

$$\mathcal{L}_1(u,u) = \sum_{|\beta|=m} \int_{\tilde{\Omega}} |D^\beta u|^2 \tag{2.25}$$

and observe from (2.10), (2.12), and (2.14)-(2.16) that

$$\mathcal{L}_1(u,u) \le \mathcal{Q}(u,u) \quad \forall u \in \tilde{H}. \tag{2.26}$$

Also, we see from Poincaré's inequality and (2.25) that there is a positive constant c_2' such that

$$\sum_{|\alpha|=m-1} \int_{\tilde{\Omega}} |D^\alpha u|^2 \le c_2' \mathcal{L}_1(u,u) \quad \forall u \in \tilde{H}. \tag{2.27}$$

Let $\{u_n\}_{n=1}^\infty$ be a sequence of elements in $\tilde{H}$ with the property that

$$\|u_n\|_{L^2} \to \infty \quad \text{and} \quad \lim_{n\to\infty} \frac{\mathcal{Q}(u_n,u_n)}{\|u_n\|_{L^2}^2} = \lambda_1^*. \tag{2.28}$$

Hence, for $n \ge n_2$, $\mathcal{Q}(u_n,u_n) \le (\lambda_1^* + 1)\|u_n\|_{L^2}^2$. Consequently, it follows from (2.25) and this last inequality that $\mathcal{L}_1(u_n,u_n) \le (\lambda_1^*+1)\|u_n\|_{L^2}^2$ for $n \ge n_2$. Therefore, it follows that for $|\beta| = m$

$$\begin{aligned} &\int_{\tilde{\Omega}} \frac{\left\{1 - F_\beta\left[(|D^\alpha u_n|^2 + |D^\beta u_n|^2)^{\frac{1}{2}}\right]\right\} |D^\beta u_n|^2}{\|u_n\|_{L^2}^2} \\ &\quad \le (\lambda_1^*+1) \int_{\tilde{\Omega}} \frac{\left\{1 - F_\beta\left[(|D^\alpha u_n|^2 + |D^\beta u_n|^2)^{\frac{1}{2}}\right]\right\} |D^\beta u_n|^2}{\mathcal{L}_1(u_n,u_n)} \end{aligned} \tag{2.29}$$

for $n \ge n_2$. Now in a manner similar to that used to establish (2.23), we obtain from (2.25) that the right-hand side of the inequality in (2.29) tends to zero as $n \to \infty$. Therefore, the limit as $n \to \infty$ of the left-hand side of (2.29) is zero. In a similar manner, using (2.27) we obtain that

$$\lim_{n\to\infty} \int_{\tilde{\Omega}} \frac{\left\{1 - F_{i\alpha}\left[(|D^\alpha u_n|^2 + |D_i D^\alpha u_n|^2)^{\frac{1}{2}}\right]\right\} |D^\alpha u_n|^2}{\|u_n\|_{L^2}^2} = 0 \quad \text{for } |\alpha| = m-1.$$

We conclude from (2.22) that

$$\lim_{n\to\infty} \frac{\mathcal{Q}(u_n,u_n) - \mathcal{L}(u_n,u_n)}{\|u_n\|_{L^2}^2} = 0. \tag{2.30}$$

But $(\mathcal{L}(u_n,u_n)/\|u_n\|_{L^2}^2) \ge \lambda_1$ and we obtain from (2.28) and (2.30) that $\lambda_1 \le \lambda_1^*$. This fact coupled with (2.24) give that $\lambda_1 = \lambda_1^*$. Hence Q is $\kappa*$-related to L and our example is complete.

Next we take $N_1 = 2$ in (1.1) and give two examples of an f_1 and f_2 that satisfy the conditions of our theorems. Our first example will be a simple autocatalytic system that qualifies under Theorem 2. For this system we also take $N = 1, \Omega = (0, \pi)$,

$$\begin{aligned}
Q_1(u_1) &= -D_x \left[D_x u_1 + \frac{D_x u_1}{(1 + u_1^2 + D_x u_1^2)^{\frac{1}{2}}} \right] + \frac{u_1}{(1 + u_1^2 + D_x u_1^2)^{\frac{1}{2}}}, \\
Q_2(u_2) &= -\frac{1}{2} D_x \left[1 + \frac{|D_x u_2|^2}{(1 + |D_x u_2|^2)} \right] D_x u_2, \\
Lu &= -D_x(D_x u), \\
f_1(x, t, u_1, u_2) &= -\frac{\arctan u_2}{1 + u_1^2} + b_1(x, t), \\
f_2(x, t, u_1, u_2) &= \frac{\tanh u_1}{1 + u_2^2} + b_2(x, t),
\end{aligned}$$

where $b_1(x,t)$ and $b_2(x,t)$ are in $C\{[0,\pi] \times [0, 2\pi], \mathbb{R}\}$. It follows from our earlier discussion in this section and from [12, pp. 156–157] that Q_1 and Q_2 are $\kappa*$-related to L and that $\lambda_{11}^* = \lambda_{12}^* = \lambda_1 = 1$. Hence with

$$\begin{aligned}
F_1(x, t, u_1, u_2) &= \rho_1(1 - \delta_1)u_1 + f_1(x, t, u_1, u_2), \\
F_2(x, t, u_1, u_2) &= \rho_2(1 - \delta_2)u_2 + f_2(x, t, u_1, u_2)
\end{aligned} \tag{2.31}$$

we see from Theorem 2 with $\kappa = 0$ that there exist $(u_1, u_2) \in \tilde{H}^2$, which is a weak solution to the system

$$\begin{aligned}
\frac{\partial u_1}{\partial t} + \rho_1 Q_1 u_1 &= F_1(x, t, u_1, u_2), \\
\frac{\partial u_2}{\partial t} + \rho_2 Q_2 u_2 &= F_2(x, t, u_1, u_2)
\end{aligned} \tag{2.32}$$

on the interval $(0, \pi) \times (0, 2\pi)$, where ρ_1, ρ_2, δ_1, and δ_2 are positive real numbers. An easy computation shows that $\frac{\partial F_1}{\partial u_2} < 0$ and $\frac{\partial F_2}{\partial u_1} > 0$ for all values of u_1, u_2 in $\mathbb{R}$ and (x, t) in $[0, \pi] \times [0, 2\pi]$. Likewise we see that

$$\frac{\partial F_1}{\partial u_1} = \rho_1(1 - \delta_1) + 2u_1 \frac{\arctan u_2}{(1 + u_1^2)^2}. \tag{2.33}$$

Since the second term on the right-hand side of the equality in (2.33) is bounded in absolute value by π, our system (2.32) will be autocatalytic (see [2, p. 116]) as long as $\rho_1 > \pi/(1 - \delta_1)$, where we now also assume that $0 < \delta_1 < 1$.

We next give an example of an f_1 and f_2 with corresponding h_1 and h_2 that meet (f-3) and the condition (1.20) of Theorem 1. For this example we use the notation of (2.6) and take $m = 1, 0 < \kappa < 1, \xi_1 = (\eta_0, \zeta_1, \ldots, \zeta_N)$, and

$$Qu = -\sum_{j=1}^{N} D_j A_j(x, \xi_1(u)) + a_0(x, \xi_1(u))u, \tag{2.34}$$

where $A_j(x, \xi_1)$ and $a_0(x, \xi_1)$ are defined in (2.6). Also, we take $Lu = -\Delta u$ and $\Omega = (0, \pi)^N, N \geq 1$. As we have shown, Q is $\kappa*$-related to L. In the system (1.1) with which we shall be dealing in this example $N_1 = 2, Q_1 = Q_2 = Q$, and $g_1(x,t) = g_2(x,t) = 0$. With $b_1(x) \in C(\bar{\Omega})$ and $b_2(t) \in C(T)$ we take

$$
\begin{aligned}
f_1(x,t,\xi_{11},\xi_{12}) &= -b_1(x)b_2(t)\left[c_{01}|\eta_{01}|^\kappa \arctan \eta_{01} + \sum_{j=1}^{N} c_{j1}|\zeta_{j1}|^\kappa \arctan \zeta_{j1}\right] \\
&\quad + \frac{\arctan(\eta_{02}^2 + \zeta_{12}^2 + \cdots + \zeta_{N2}^2)}{(1+\eta_{01}^2)^{\frac{1}{2}}} + d_1(x,t), \\
f_2(x,t,\xi_{11},\xi_{12}) &= -b_1(x)b_2(t)\left[c_{02}|\eta_{02}|^\kappa \tanh \eta_{02} + \sum_{j=1}^{N} c_{j2}|\zeta_{j2}| \tanh \zeta_{j2}\right] \\
&\quad + \frac{\tanh(\eta_{01}^2 + \zeta_{11}^2 + \cdots + \zeta_{N1}^2)}{(1+\eta_{02}^2)^{\frac{1}{2}}} + d_2(x,t),
\end{aligned} \tag{2.35}
$$

where $c_{0i}, c_{1i}, \ldots, c_{Ni}$ are constants with $c_{0i} > 0$ and $d_i(x,t) \in L^2(\tilde{\Omega})$ for $i = 1,2$. It is clear that f_i, for $i = 1,2$, satisfy (f-1) and (f-2). Also, since $0 < \kappa < 1$, an easy computation using (1.19) in (f-3) in conjunction with (2.35) shows that

$$
\begin{aligned}
h_1(x,t,\xi_1) &= -\frac{\pi}{2} b_1(x)b_2(t)\left[c_{01}|\eta_0|^\kappa \operatorname{sgn} \eta_0 + \sum_{j=1}^{N} c_{j1}|\zeta_j|^\kappa \operatorname{sgn} \zeta_j\right], \\
h_2(x,t,\xi_1) &= -b_1(x)b_2(t)\left[c_{02}|\eta_0|^\kappa \operatorname{sgn} \eta_0 + \sum_{j=1}^{N} c_{j2}|\zeta_j|^\kappa \operatorname{sgn} \zeta_j\right],
\end{aligned} \tag{2.36}
$$

where $|\xi_1| = 1$ and $\eta_0 \neq 0$. Hence f_i also meets (f-3) for $0 < \kappa < 1$ for $i = 1,2$.

We show that condition (1.20) holds for h_1. Similar reasoning shows that it holds for h_2. To show that condition (1.20) holds for h_1, we observe that if $v \in S^{\#}_{\lambda_1}$ is nontrivial, then v is a positive multiple of $\prod_{i=1}^{N} \sin x_i$ or $-\prod_{i=1}^{N} \sin x_i$. It therefore follows that

$$
\frac{\zeta_1(v)}{|\xi_1(v)|} = \pm \frac{\cos x_1 \prod_{i=2}^{N} \sin x_i}{\left\{\prod_{i=1}^{N} \sin^2 x_i + \cos^2 x_1 \prod_{i=2}^{N} \sin^2 x_i + \cdots + \cos^2 x_N \prod_{i=1}^{N-1} \sin^2 x_i\right\}^{\frac{1}{2}}}. \tag{2.37}
$$

Consequently from (2.36), we see that the integral involving $\zeta_1(v)/|\xi_1(v)|$ in (1.20) is a constant multiple of

$$
\int_0^\pi b_2(t)\,dt \underbrace{\int_0^\pi \cdots \int_0^\pi}_{N} b_1(x)|\zeta_1(v)|^\kappa v \operatorname{sgn}\left[\frac{\zeta_1(v)}{|\xi_1(v)|}\right] dx_1 \cdots dx_N. \tag{2.38}
$$

At this point we impose two further conditions on $b_1(x)$ and $b_2(t)$ that we know are in $C(\bar{\Omega})$ and $C(T)$, respectively. We shall also suppose

(2.39)
(i) $b_1(x) > 0 \ \forall x \in \bar{\Omega}$ and $b_2(t) > 0 \ \forall t \in T$;
(ii) in each variable $x_j, j = 1, \ldots, N, b_1(x)$ is even around $\frac{\pi}{2}$.

In particular, for the x_1-variable, (2.39) (ii) means $b_1(\frac{\pi}{2}+x_1,x_2,\dots,x_N)=b_1(\frac{\pi}{2}-x_1,x_2,\dots,x_N)$ for $0<x_1<\frac{\pi}{2}$ and $0<x_j<\pi, j=2,\dots,N$. For example, $b_1(x)=\prod_{j=1}^N \sin^4 x_j$.

It follows from (2.37) that $\zeta_1(v)/|\xi_1(v)|$ is odd in x_1 around $\frac{\pi}{2}$. Hence from (2.39) (ii), the integrand for

$$\underbrace{\int_0^\pi \cdots \int_0^\pi}_{N}$$

in (2.38) is odd in x_1 around $\frac{\pi}{2}$. Hence the corresponding integral is zero. A similar remark is valid for the integrals involving $\zeta_i(v)/|\xi_1(v)|, i=2,\dots,N$. Consequently, it follows that the integral in (1.20) is a positive multiple of

$$\text{(2.40)} \qquad -\int_0^\pi b_2(t)\,dt \underbrace{\int_0^\pi \cdots \int_0^\pi}_{N} b_1(x)|\eta_0(v)|^\kappa v \text{ sgn } \left[\frac{\eta_0(v)}{|\xi_1(v)|}\right] dx_1 \dots dx_N,$$

where $v=\pm\prod_{i=1}^N \sin x_i$ and

$$\frac{\eta_0(v)}{|\xi_1(v)|}=\frac{v}{\left\{\prod_{j=1}^N \sin^2 x_j+\cos^2 x_1 \prod_{j=2}^N \sin^2 x_j+\cdots+\cos^2 x_N \prod_{j=1}^{N-1}\sin^2 x_j\right\}^{\frac{1}{2}}}.$$

It is clear that regardless of the choice of $\pm, v$ sgn $[\eta_0(v)/|\xi_1(v)|]$ is strictly positive. Hence, from (2.39) (i), it follows that the integrand for

$$\underbrace{\int_0^\pi \cdots \int_0^\pi}_{N}$$

is strictly positive. Likewise $\int_0^{2\pi} f_2(t)\,dt>0$. We conclude that the full expression in (2.40) is strictly negative, and therefore the condition in (1.20) prevails for h_1 and likewise for h_2. Hence a weak solution to (1.1) exists where $N_1=2$ and $Q_1=Q_2=Q$ with Q given by (2.31), f_1 and f_2 by (2.35) and (2.39), and $g_1=g_2=0$.

In the previous example, $0<\kappa<1$ and $m=1$. We now allow κ to take on the value 0, so that $0\le\kappa<1$. Also, we take $m\ge 2, N_1$ an arbitrary positive integer, Qu to be given by (2.16), and Lu to be given by (2.21). Furthermore, we set $Q_1=Q_2=\cdots=Q_{N_1}=Q$. With $0=(0,\dots,0)$, we then define
(2.41)

$$f_i(x,t,\xi_{m1},\dots,\xi_{mN_1})=-\frac{b_i(x,t)\xi_{0i}|\xi_{0i}|^\kappa+\sum_{j=1}^{N_1}\sum_{1\le|\alpha|\le m}\frac{c^i_{\alpha j}\xi_{\alpha j}}{\sqrt{1+\xi^2_{\alpha j}}}}{\sqrt{1+\xi^2_{0i}}} \quad i=1,\dots,N_1,$$

where

$$\text{(2.42)} \qquad b_i(x,t)\in C(\tilde\Omega)\cap L^\infty(\tilde\Omega) \quad \text{and} \quad b_i(x,t)>0 \quad \forall (x,t)\in\tilde\Omega.$$

In the example under consideration $\Omega\subset\mathbb{R}^N$ is a general bounded open connected set and the $c^i_{\alpha j}$ in (2.41) are real constants. It is clear that f_i given by (2.41) satisfy (f-1) and (f-2) with $0\le\kappa<1$. Suppose $\xi^{(n)}_{mi}\to\xi_{mi}$, where $|\xi^{(n)}_{mi}|=1, |\xi_{mi}|=1$, and $\xi_{0i}\ne 0$.

Further suppose that $r_n \to \infty$. Then an easy computation using (2.41) shows that (1.19) holds with

$$h_i(x,t,\xi_m) = -b_i(x,t)\frac{\xi_0}{|\xi_0|^{1-\kappa}} \quad \text{for } |\xi_m| = 1 \text{ with } \xi_0 \neq 0. \tag{2.43}$$

Consequently, f_i also meets (f-3) for $i = 1,\dots,N_1$.

Next, we take

$$G_{1i}(u) = \left[\int_{\tilde\Omega} u(x,t)\phi_i(x)\sin it\right]^{\kappa} + 1 \quad \forall u \in L^2(\tilde\Omega) \text{ and } i = 1,\dots,N_1, \tag{2.44}$$

where $\phi_i(x)$ is the ith element in the sequence (1.10) corresponding to the L given by (2.21). It is clear that G_{1i} meets (G-1) for $i = 1,\dots,N_1$.

We define

$$G_{2i}(u) = \frac{1}{\|u\|_{L^2} + 1} \quad \forall u \in L^2(\tilde\Omega) \text{ and } i = 1,\dots,N_1. \tag{2.45}$$

It is clear that $G_{2i}(u)$ meets (G-2) for $i = 1,\dots,N_1$. Hence with Q_i defined as above; with f_i, G_{1i}, and G_{2i} defined, respectively, by (2.41), (2.44), and (2.45), and with g_i arbitrary functions in $L^2(\tilde\Omega)$ to show that $\exists(u_1,\dots,u_{N_1}) \in \tilde H^{N_1}$, which is a weak solution to (1.1), it remains to demonstrate that the h_i given by (2.43) each satisfies the condition in (1.20).

To show this, let $v \in S^{\#}_{\lambda_1}$ with v nontrivial, i.e.,

$$\int_{\tilde\Omega} v^2 \neq 0. \tag{2.46}$$

Now for $(x,t) \in \tilde\Omega(v), \xi_0(v(x,t)) = v(x,t)$. Hence it follows from (2.43) that

$$\int_{\tilde\Omega(v)} h_i\left(x,t,\frac{\xi_m(v)}{|\xi_m(v)|}\right)|\xi_m(v)|^{\kappa}v = -\int_{\tilde\Omega(v)} b_i(x,t)|v|^{1+\kappa} \tag{2.47}$$

for $i = 1,\dots,N_1$. From (2.42), (2.46), and the definition of $\tilde\Omega(v)$, it follows that the integral on the right-hand side of the equality in (2.47) is strictly positive. Hence it follows that the integral on the left-hand side is strictly negative and the condition in (1.20) is established for every i. We conclude that with the conditions just enumerated above, a weak solution to system (1.1) in $\tilde\Omega$ exists and our final example is complete.

3. Fundamental lemmas. To establish the theorems in this paper we use a Galerkin technique that depends upon a *CONS* for $\tilde\Omega$ that comes from our elliptic operator L introduced in (1.8) and (1.9). To do this, we introduce a *CONS* on $\tilde\Omega$ in the following manner.

Define

$$\begin{aligned}
&\text{(i)} \quad \tilde\phi^c_{nk}(x,t) = \frac{\phi_n(x)\cos kt}{\sqrt{\pi}}, \quad n,k = 1,2,\dots, \\
&\qquad\qquad\qquad\;\; = \frac{\phi_n(x)}{\sqrt{2\pi}}, \quad k = 0, n = 1,2,\dots; \\
&\text{(ii)} \quad \tilde\phi^s_{nk}(x,t) = \frac{\phi_n(x)\sin kt}{\sqrt{\pi}}, \quad n,k = 1,2,\dots.
\end{aligned} \tag{3.1}$$

Note that $\tilde{\phi}^c_{nk}, \tilde{\phi}^s_{nk} \in \tilde{H}$.

For $u \in L^2(\tilde{\Omega})$, set

$$\text{(3.2)} \qquad \begin{aligned} &\text{(i)} \quad \hat{u}^c(n,k) = \langle u, \tilde{\phi}^c_{nk} \rangle_{L^2} = \int_{\tilde{\Omega}} u(x,t)\tilde{\phi}^c_{nk}(x,t).,\\ &\text{(ii)} \quad \hat{u}^s(n,k) = \langle u, \tilde{\phi}^s_{nk} \rangle_{L^2}. \end{aligned}$$

From (1.9) we see that if $\hat{u}^c(n,0) = 0$ for $n = 1, 2, \ldots$ and $\hat{u}^c(n,k) = \hat{u}^s(n,k) = 0$ for $n, k = 1, 2, \ldots$, then $u = 0$ a.e. on $\tilde{\Omega}$. Therefore,

$$\text{(3.3)} \qquad \{\tilde{\phi}^c_{nk}\}^{\infty,\infty}_{n=1,k=0} \cup \{\tilde{\phi}^s_{nk}\}^{\infty,\infty}_{n=1,k=1} \quad \text{is a } CONS \text{ for } L^2(\tilde{\Omega}).$$

We first state the following lemma proved by Lefton and Shapiro in [12, pp. 160–162].

LEMMA 1. *Let Lu be the elliptic operator given by* (1.7) *satisfying* (L-1)–(L-3), *$\mathcal{L}(u,v)$ be the bilinear form given by* (1.12), *and $\{\tilde{\phi}^c_{nk}\}^{\infty,\infty}_{n=1,k=0} \cup \{\tilde{\phi}^s_{nk}\}^{\infty,\infty}_{n=1,k=1}$ be the $CONS$ for $L^2(\tilde{\Omega})$ given by* (3.1). *With λ_1 defined by* (1.11), *suppose furthermore that $\lambda_1 > 0$. For $v \in L^2(\tilde{\Omega})$, set*

$$\text{(3.4)} \qquad \sigma_n(v) = \sum_{j=1}^{n} \hat{v}(j,0)\tilde{\phi}^c_{j0} + \sum_{j=1}^{n}\sum_{k=1}^{n} [\hat{v}^c(j,k)\tilde{\phi}^c_{jk} + \hat{v}^s(j,k)\tilde{\phi}^s_{jk}],$$

where $\hat{v}^c(n,k)$ and $\hat{v}^s(n,k)$ are given by (3.2). *Then*

$$\text{(3.5)} \qquad \begin{aligned} &\text{(i)} \quad \lim_{n\to\infty} \int_{\tilde{\Omega}} [D_t\sigma_n(v) - D_t v]^2 = 0 \quad \forall v \in \tilde{H},\\ &\text{(ii)} \quad \lim_{n\to\infty} \int_{\tilde{\Omega}} \sum_{|\alpha|\le m} |D^\alpha[\sigma_n(v) - v]|^2 = 0 \quad \forall v \in \tilde{H}. \end{aligned}$$

Next, we observe that the following easily obtainable facts hold.

Fact 1. For $0 \le \kappa < 1$ and some positive constant $K_1(\kappa)$,

$$\text{(3.6)} \qquad \||u|^\kappa\|_{L^2} \le K_1\|u\|^\kappa_{L^2} \quad \forall u \in L^2.$$

Fact 2. Set $\|u\|^2_{W^{m,2,\sim}} = \int_{\tilde{\Omega}} \sum_{|\alpha|\le m} |D^\alpha u|^2 = \int_{\tilde{\Omega}} |\xi_m(u)|^2$ (see (1.14)) for $u \in \tilde{H}$. Then for $0 \le \kappa < 1$,

$$\text{(3.7)} \qquad \sum_{|\alpha|\le m} \|D^\alpha u\|^{2\kappa}_{L^2} \le s_m\|u\|^{2\kappa}_{W^{m,2,\sim}} \quad \forall u \in \tilde{H},$$

where s_m is the constant introduced in the fourth paragraph of §1.

Also, we record for future use the following fact, which is a consequence of the well-known Gårding's inequality on Ω [8, p. 34].

Fact 3. There are two positive constants c_0^* and c_1^* such that

$$\text{(3.8)} \qquad c_1^*\|u\|^2_{W^{m,2,\sim}} \le \mathcal{L}(u,u) + c_0^*\|u\|^2_{L^2} \quad \forall u \in \tilde{H}.$$

Next, we prove the following lemma.

LEMMA 2. *Suppose that $Q, L, f, g, G_{1i}, G_{2i}, h_i$, and ρ_i meet the conditions stated in the hypothesis of Theorem 2. (Hence by (1.6), $\lambda_1^* = \lambda_{1i} = \lambda_1 > 0$ for $i = 1, \ldots, N_1$.) Then for each positive integer n, $\exists(u_{1n}, \ldots, u_{N_{1}n}) \in S_n^{N_1}$ such that*

$$\begin{aligned} &D_t\langle u_{in}, v\rangle_{L^2} + \rho_i Q_i(u_{in}, v) \\ &\quad = \rho_i\left(\lambda_1^* - \frac{1}{n}\right)\langle u_{in}, v\rangle_{L^2} + \langle f_i(\cdot, \xi_m(u_{1n}), \ldots, \xi_m(u_{N_{1}n})), v\rangle_{L^2} \\ &\quad + G_{1i}(D_t u_{in})G_{2i}(u_{in})\langle g_i, v\rangle_{L^2} \quad \forall v \in S_n \end{aligned} \tag{3.9}$$

for $i = 1, \ldots, N_1$, where we define for $n \geq 1$

$$S_n = \left\{ v = \sum_{j=1}^{n} \tau_{j0}^c \tilde{\phi}_{j0}^c + \sum_{j=1}^{n}\sum_{k=1}^{n} (\tau_{jk}^c \tilde{\phi}_{jk}^c + \tau_{jk}^s \tilde{\phi}_{jk}^s), \right. \\ \left. \textit{where } \tau_{jk}^c, \tau_{jk}^s \in \mathbb{R}, j = 1, \ldots, n, k = 0, 1, \ldots n \right\}. \tag{3.10}$$

To prove the lemma we first note from (3.1) that

$$\begin{aligned} D_t\tilde{\phi}_{n0}^c &= 0, \\ D_t\tilde{\phi}_{nk}^c &= -k\tilde{\phi}_{nk}^s \quad \text{for } k \geq 1, \\ D_t\tilde{\phi}_{nk}^s &= k\tilde{\phi}_{nk}^c \quad \text{for } k \geq 1. \end{aligned} \tag{3.11}$$

Hence by (2.10)

$$v \in S_n \Rightarrow D_t v \in S_n. \tag{3.12}$$

For ease of notation, set $\{\psi_j\}_{j=1}^{2n^2+n} = \{\tilde{\phi}_{jk}^c\}_{j=1,k=0}^{n,n} \cup \{\tilde{\phi}_{jk}^s\}_{j=1,k=1}^{n,n}$, where $\{\psi_j\}_{j=1}^{n^2}$ corresponds to $\{\tilde{\phi}_{jk}^c\}_{j=1,k=1}^{n,n}$, $\{\psi_j\}_{j=n^2+1}^{2n^2}$ corresponds to $\{\tilde{\phi}_{jk}^s\}_{j=1,k=1}^{n,n}$, and $\{\psi_j\}_{j=2n^2+1}^{2n^2+n}$ corresponds to $\{\tilde{\phi}_{j0}^c\}_{j=1}^{n}$. Hence we can rewrite S_n as

$$S_n = \left\{ v \in \tilde{H} : v = \sum_{j=1}^{2n^2+n} \gamma_j\psi_j \text{ where } \gamma_j \in \mathbb{R}, j = 1, \ldots, 2n^2 + n \right\}. \tag{3.13}$$

Let $\gamma = (\gamma_k^i)_{k=1,\ldots,2n^2+n, i=1,\ldots,N_1} \in \mathbb{R}^{2N_1n^2+N_1n}$. Set

$$\begin{aligned} B_k^i(\gamma) &= \langle D_t(\gamma_j^i\psi_j), \psi_k\rangle_{L^2} + \rho_i Q(\gamma_j^i\psi_j, \psi_k) + \rho_i\left(\frac{1}{n} - \lambda_1^*\right)\langle\gamma_j^i\psi_j, \psi_k\rangle_{L^2} \\ &\quad - \langle f_i(\cdot, \xi_m(\gamma_j^1\psi_j), \ldots, \xi_m(\gamma_j^{N_1}\psi_j)), \psi_k\rangle_{L^2} \\ &\quad - G_{1i}(D_t\gamma_j^i\psi_j)G_{2i}(\gamma_j^i\psi_j)\langle g_i, \psi_k\rangle_{L^2} \end{aligned} \tag{3.14}$$

for $k = 1, \ldots, 2n^2 + n, i = 1, \ldots, N_1$, where we use the summation convention in (3.14) for $j = 1, \ldots, 2n^2 + n$. We shall use the summation convention also on $k = 1, \ldots, 2n^2 + n$.

Set $B(\gamma) = (B_k^i(\gamma))_{k=1,\dots,2n^2+n,i=1,\dots,N_1}$. Observing that $\mathcal{Q}_i(\cdot,\cdot)$ is linear in the second variable and using the summation convention on j and k, we have

$$\begin{aligned} B(\gamma)\cdot\gamma &= \sum_{i=1}^{N_1} B_k^i(\gamma)\gamma_k^i \\ &= \sum_{i=1}^{N_1}\Big[\langle D_t(\gamma_j^i\psi_j),\gamma_k^i\psi_k\rangle_{L^2} + \rho_i\mathcal{Q}_i(\gamma_j^i\psi_j,\gamma_k^i\psi_k) \\ &\qquad + \rho_i\left(\frac{1}{n}-\lambda_1^*\right)\langle\gamma_j^i\psi_j,\gamma_k^i\psi_k\rangle_{L^2} \\ &\qquad - \langle f_i(\cdot,\xi_m(\gamma_j^1\psi_j),\dots,\xi_m(\gamma_j^{N_1}\psi_j)),\gamma_k^i\psi_k\rangle_{L^2} \\ &\qquad - G_{1i}(D_t\gamma_j^i\psi_j)G_{2i}(\gamma_j^i\psi_j)\langle g_i,\gamma_k^i\psi_k\rangle_{L^2}\Big]. \end{aligned} \tag{3.15}$$

From (Q-1), (Q-2), (f-1), (f-2), (G-1), and (G-2) we see that

$$B = (B_k^i)_{k=1,\dots,2n^2+n,i=1,\dots,N_1} : \mathbb{R}^{2N_1n^2+N_1n} \to \mathbb{R}^{2N_1n^2+N_1n}$$

is continuous in γ. Also, it follows from the orthogonality of the $\{\psi_j\}_{j=1}^{2n^2+n}$ that there is a positive constant c_0' such that

$$\|\gamma_j^i\psi_j\|_{L^2} \geq c_0'[\gamma_1^{i2}+\cdots+\gamma_{2n^2+n}^{i2}]^{\frac{1}{2}}. \tag{3.16}$$

We propose to show that for γ sufficiently large

$$B(\gamma)\cdot\gamma > 0. \tag{3.17}$$

To show that (3.17) is true, we first observe that $0 = \int_{\tilde{\Omega}} D_tv^2 = 2\langle D_tv, v\rangle_{L^2}$ $\forall v \in \mathcal{A}$. Hence it follows that

$$\sum_{i=1}^{N_1}\langle D_t\gamma_j^i\psi_j,\gamma_k^i\psi_k\rangle_{L^2} = 0 \quad \forall\gamma\in\mathbb{R}^{2N_1n^2+N_1n}. \tag{3.18}$$

Also, it is easy to see from (f-1), (f-2), Fact 1, and Fact 2 that

$$\begin{aligned} &\sum_{i=1}^{N_1}|\langle f_i(\cdot,\xi_m(\gamma_j^1\psi_j),\dots,\xi_m(\gamma_j^{N_1}\psi_i)),\gamma_k^i\psi_k\rangle_{L^2}| \\ &\leq\left(C_1\sum_{i=1}^{N_1}\|\gamma_k^i\psi_k\|_{W^{m,2,\sim}}^{\kappa}+C_2\right)\sum_{i=1}^{N_1}\|\gamma_k^i\psi_k\|_{L^2} \quad \forall\gamma\in\mathbb{R}^{2N_1n^2+N_1n}, \end{aligned} \tag{3.19}$$

where C_1 and C_2 are positive constants.

Next, we note from (1.9), (1.10), (3.1), and (3.3) that

$$\begin{aligned} \mathcal{L}(\tilde{\phi}_{j_1k_1}^c,\tilde{\phi}_{j_2k_2}^s) &= 0 \quad \forall(j_1,k_1),(j_2,k_2), \\ \mathcal{L}(\tilde{\phi}_{j_1k_1}^c,\tilde{\phi}_{j_2k_2}^c) &= 0 \quad \forall(j_1,k_1)\neq(j_2,k_2), \\ \mathcal{L}(\tilde{\phi}_{j_1k_1}^s,\tilde{\phi}_{j_2k_2}^s) &= 0 \quad \forall(j_1,k_1)\neq(j_2,k_2), \end{aligned} \tag{3.20}$$

$$\mathcal{L}(\tilde{\phi}^c_{j_1k_1},\tilde{\phi}^c_{j_1k_1}) = \lambda_{j1}, \qquad \mathcal{L}(\tilde{\phi}^s_{j_1k_1},\tilde{\phi}^s_{j_1k_1}) = \lambda_{j1}.$$

Since n is fixed and we are assuming that $\lambda_1 > 0$, it follows from (1.13) and (3.20) that

$$\begin{aligned}&\exists C_3 > 0 \text{ such that } \lambda_1|\nu|^2 \le \mathcal{L}(\nu_j\psi_j,\nu_k\psi_k) \le C_3|\nu|^2\\ &\forall \nu = (\nu_1,\ldots,\nu_{2n^2+n}) \in \mathbb{R}^{2n^2+n}.\end{aligned}\tag{3.21}$$

Consequently, we see from Fact 3 and (3.21) coupled with (3.19) that there are positive constants C_4 and C_5 such that

$$\begin{aligned}&\sum_{i=1}^{N_1} |\langle f_i(\cdot,\xi_m(\gamma^1_j\psi_j),\ldots,\xi_m(\gamma^{N_1}_j\psi_j)),\gamma^i_k\psi_k\rangle_{L^2}| \le C_4|\gamma|^{\kappa+1} + C_5|\gamma|\\ &\forall\gamma \in \mathbb{R}^{2N_1n^2+N_1n}.\end{aligned}\tag{3.22}$$

Next, we note from (3.1), (3.3), and (3.11) that there exists a positive constant C_6 such that

$$\|D_t(\nu_j\psi_j)\|_{L^2} \le C_6|\nu| \quad \forall\nu \in \mathbb{R}^{2n^2+n}.$$

Hence it follows from (G-1) and this last inequality that there is a positive constant C_7 such that

$$\sum_{i=1}^{N_1} |G_{1i}(D_t\gamma^i_j\psi_j)| \le C_7|\gamma|^{\kappa} + C_7 \quad \forall\gamma \in \mathbb{R}^{2N_1n^2+N_1n}.$$

Using this last inequality in conjunction with (G-2) and the fact that $g_i \in L^2(\tilde{\Omega})$, we finally obtain that

(3.23)

$$\sum_{i=1}^{N_1} |G_{1i}(D_t\gamma^i_j\psi_j)G_{2i}(\gamma^i_j\psi_j)\langle g_i,\gamma^i_k\psi_k\rangle_{L^2}| \le C_8|\gamma|^{\kappa+1} + C_8|\gamma| \quad \forall\gamma \in \mathbb{R}^{2N_1n^2+N_1n},$$

where C_8 is a positive constant.

Next we see from (3.21), Fact 3, and the fact that $\lambda_1 > 0$ that $\|\nu_j\psi_j\|^2_{W^{m,2,\sim}} \le c^*_2\mathcal{L}(\nu_j\psi_j,\nu_k\psi_k)$ $\forall\nu \in \mathbb{R}^{2n^2+n}$, where c^*_2 is a positive constant. Therefore, it follows from (1.16) (ii) that there are positive constants C'_3 and C'_4 such that

$$\mathcal{Q}_i(\gamma^i_j\psi_j,\gamma^i_k\psi_k) - \mathcal{L}(\gamma^i_j\psi_j,\gamma^i_k\psi_k) \ge -C'_3|\mathcal{L}(\gamma^i_j\psi_j,\gamma^i_k\psi_k)|^{\frac{(\kappa+1)}{2}} - C'_4\tag{3.24}$$

for $i = 1,\ldots,N_1$. Also from the fact that $\lambda^*_1 = \lambda_1$ we obtain from (1.13) that

$$\mathcal{L}(\gamma^i_j\psi_j,\gamma^i_k\psi_k) - \lambda^*_1\langle\gamma^i_j\psi_j,\gamma^i_k\psi_k\rangle_{L^2} \ge 0.$$

We conclude from the above inequality and (3.24) that

$$\begin{aligned}&\sum_{i=1}^{N_1}\left[\rho_i\mathcal{Q}_i(\gamma^i_j\psi_j,\gamma^i_k\psi_k) - \rho_i\left(\lambda^*_1 - \frac{1}{n}\right)\langle\gamma^i_j\psi_j,\gamma^i_k\psi_k\rangle_{L^2}\right]\\ &\quad\ge \frac{\rho_0}{n}|\gamma|^2 - C'_3\sum_{i=1}^{N_1}\rho_i|\mathcal{L}(\gamma^i_j\psi_j,\gamma^i_k\psi_k)|^{\frac{(\kappa+1)}{2}} - C'_4\sum_{i=1}^{N_1}\rho_i,\end{aligned}\tag{3.25}$$

where $\rho_0 = \min(\rho_1, \dots, \rho_{N_1}) > 0$. Now it follows from (3.21) that there is a constant $C_5' > 0$ such that

$$C_3' \sum_{i=1}^{N_1} \rho_i |\mathcal{L}(\gamma_j^i \psi_j, \gamma_k^i \psi_k)|^{\frac{(\kappa+1)}{2}} \leq C_5' |\gamma|^{\kappa+1}.$$

Using this last inequality in conjunction with (3.15), (3.18), (3.22), (3.23), and (3.25), we obtain that

$$B(\gamma) \cdot \gamma \geq \frac{\rho_0}{n} |\gamma|^2 - (C_4 + C_8 + C_5') |\gamma|^{\kappa+1} - (C_5 + C_8)|\gamma| - C_4' \sum_{i=1}^{N_1} \rho_i$$
$$\forall \gamma \in \mathbb{R}^{2N_1 n^2 + N_1 n}.$$

Since $0 \leq \kappa < 1$, we conclude that there exists $\Gamma_0 > 0$ such that

$$B(\gamma) \cdot \gamma \geq \frac{\rho_0}{2n} |\gamma|^2 \quad \text{for } |\gamma| \geq \Gamma_0. \tag{3.26}$$

This establishes the inequality in (3.17).

Since $B(\gamma)$ is a continuous map from $\mathbb{R}^{2N_1 n^2 + N_1 n}$ into $\mathbb{R}^{2N_1 n^2 + N_1 n}$, it follows from (3.26) and a well-known theorem in nonlinear analysis (see [10, p. 219] or [16, p. 18]) that $\exists \gamma^\# = (\gamma_j^{\# i})_{j=1,\dots,2n^2+n, i=1,\dots,N_1}$ with $|\gamma^\#| < \Gamma_0$ such that $B_k^i(\gamma^\#) = 0$ for $k = 1, \dots, 2n^2 + n$ and $i = 1, \dots, N_1$. Hence

$$\begin{aligned} D_t(\gamma_j^{\# i} \psi_j, \psi_k) &+ \rho_i Q_i(\gamma_j^{\# i} \psi_j, \psi_k) \\ &= \rho_i \left(\lambda_1^* - \frac{1}{n} \right) \langle \gamma_j^{\# i} \psi_j, \psi_k \rangle_{L^2} \\ &+ \langle f_i(\cdot, \xi_m(\gamma_j^{\# 1} \psi_j), \dots, \xi_m(\gamma_j^{\# N_1} \psi_j)), \psi_k \rangle_{L^2} \\ &+ G_{1i}(D_t \gamma_j^{\# i} \psi_j) G_{2i}(\gamma_j^{\# i} \psi_j) \langle g_i, \psi_k \rangle_{L^2} \end{aligned} \tag{3.27}$$

for $k = 1, \dots, 2n^2 + n$. Since every element in S_n is a finite linear combination of the ψ_k's, the conclusion to the lemma follows immediately from (3.27).

Remark 1. It is clear from the proof of Lemma 2 that $\frac{1}{n}$ in (3.9) can be replaced by $\delta_i > 0$ for $i = 1, \dots, N_1$ and the conclusion of Lemma 2 will still prevail. So, in particular, we have that under the conditions in the hypothesis of Lemma 2 with $\delta_i > 0$ for $i = 1, \dots, N_1, \exists (u_{1n}, \dots, u_{N_1 n}) \in S_n^{N_1}$ such that (3.9) holds with $\left(\lambda_1^* - \frac{1}{n}\right)$ replaced by $(\lambda_1^* - \delta_i)$.

4. Proof of Theorem 1. We notice that if we add a large positive constant $c*$ to $a_0^i(x, \xi_m(u))$ in (1.2) and to $b_{0,0}(x)$ in (1.7) where $0 = (0, \dots, 0)$ and $\rho_i c * u_i$ to the right-hand side of (1.1), then with no loss in generality we can assume that

$$\begin{aligned} a_0^i(x, \xi_m) &\geq \varepsilon_0 > 0 \quad \forall \xi_m \in \mathbb{R}^{s_m} \text{ and a.e. } x \in \Omega, \\ b_{00}(x) &\geq \varepsilon_0 > 0 \quad \text{a.e. } x \in \Omega \end{aligned} \tag{4.1}$$

and that

$$\lambda_{1i}^* = \lambda_1 > 0 \quad \text{for } i = 1, \dots, N_1. \tag{4.2}$$

Since $\lambda_1 > 0$, we see from (L-1), (1.13), and (3.8) in Fact 3 that there is a positive constant c_3^* such that

$$\frac{\|u\|^2_{W^{m,2,\sim}}}{c_3^*} \leq \|u\|^2_{\mathcal{L}} \leq c_3^* \|u\|^2_{W^{m,2,\sim}} \quad \forall u \in \tilde{H}, \tag{4.3}$$

where $\|u\|^2_{\mathcal{L}} = \mathcal{L}(u,u) > 0$ for $u \neq 0$. As a consequence of (4.3), we see that (1.16) (i) is equivalent to

$$u \in \tilde{H}, \qquad \liminf_{\|u\|_{\mathcal{L}} \to \infty} \frac{Q_i(u,u) - \mathcal{L}(u,u)}{\|u\|^{1+\kappa}_{\mathcal{L}}} \geq 0 \quad \text{for } i = 1, \dots, N_1. \tag{4.4}$$

To prove Theorem 1, we invoke Lemma 2 and have a sequence $\{(u_{1n}, \dots, u_{N_1 n})\}_{n=1}^{\infty}$ with each $u_{in} \in S_n$ (defined in (3.10)) such that (3.9) holds. We claim there is a constant K_1 such that

$$\|u_{in}\|_{\mathcal{L}} \leq K_1 \quad \forall n \text{ and for } i = 1, \dots, N_1. \tag{4.5}$$

For ease of notation, we shall establish (4.5) for the case $i = 1$. A similar proof will prevail for the other values of i. Suppose then (4.5) is false when $i = 1$. Then without loss of generality, we can suppose

$$\lim_{n \to \infty} \|u_{1n}\|_{\mathcal{L}} = \infty. \tag{4.6}$$

We propose to show that (4.6) leads to a contradiction of the inequality in (1.20) when $i = 1$. To accomplish this we put u_{1n} in place of v in (3.9) to obtain

$$\begin{aligned} \rho_1 Q_1(u_{1n}, u_{1n}) = \rho_1 \left(\lambda_1^* - \frac{1}{n} \right) \|u_{1n}\|^2_{L^2} + \langle f_1(\cdot, \xi_m(u_{1n}), \dots, \xi_m(u_{N_1 n})), u_{1n} \rangle_{L^2} \\ + G_{11}(D_t u_{1n}) G_{21}(u_{1n}) \langle g_1, u_{1n} \rangle_{L^2}, \end{aligned} \tag{4.7}$$

where we have used the fact established in (3.18) that

$$\langle D_t v, v \rangle_{L^2} = 0 \quad \forall v \in \tilde{H}. \tag{4.8}$$

With $\varepsilon > 0$, we have from (4.4) and (4.6) that

$$Q_1(u_{1n}, u_{1n}) \geq \mathcal{L}(u_{1n}, u_{1n}) - \varepsilon \|u_{1n}\|^{1+\kappa}_{\mathcal{L}} \quad \text{for } n \geq n_2. \tag{4.9}$$

Also, we note from (3.2) that

$$\mathcal{L}(u_{1n}, \tilde{\phi}^c_{jk}) = \lambda_j \langle u_{1n}, \tilde{\phi}^c_{jk} \rangle_{L^2} = \lambda_j \hat{u}^c_{1n}(j,k) \tag{4.10}$$

with a similar situation for $\tilde{\phi}^s_{jk}$. Thus

$$\mathcal{L}(u_{1n}, u_{1n}) = \sum_{j=1}^{n} \lambda_j \left\{ \sum_{k=0}^{n} |\hat{u}^c_{1n}(j,k)|^2 + \sum_{k=1}^{n} |\hat{u}^s_{1n}(j,k)|^2 \right\}. \tag{4.11}$$

Now $\lambda_1 = \cdots = \lambda_{n_1}$ and $\exists \gamma > 0$ such that

$$\gamma \lambda_j < (\lambda_j - \lambda_1) \quad \text{for } j \geq n_1 + 1. \tag{4.12}$$

Thus, we see from (4.2), (4.7), (4.11), and (4.12) that

$$\begin{aligned}\rho_1\gamma \sum_{j=n_1+1}^{n} \lambda_j &\left\{ \sum_{k=0}^{n} |\hat{u}^c_{1n}(j,k)|^2 + \sum_{k=1}^{n} |\hat{u}^s_{1n}(j,k)|^2 \right\} \\ &\le \langle f_1(\cdot,\xi_m(u_{1n}),\dots,\xi_m(u_{N_1n})),u_{1n}\rangle_{L^2} \\ &+ G_{11}(D_tu_{1n})G_{21}(u_{1n})\langle g_1,u_{1n}\rangle_{L^2} + \varepsilon\rho_1\|u_{1n}\|_{\mathcal{L}}^{1+\kappa} \\ &\forall n \ge \max(n_1,n_2),\end{aligned} \tag{4.13}$$

where $\gamma > 0$.

Next, we note from (f-2), (4.3), and (4.6) that there is a constant $K_2 > 0$ such that

$$|\langle f_1(\cdot,\xi_m(u_{1n}),\dots,\xi_m(u_{N_1n})),u_{1n}\rangle_{L^2}| \le K_2[\|u_{1n}\|^\kappa_{\mathcal{L}} + 1]\|u_{1n}\|_{L^2} \quad \forall n. \tag{4.14}$$

Likewise from (G-1) and (G-2), we see there is a constant K_3 such that

$$|G_{11}(D_tu_{1n})G_{21}(u_{1n})\langle g_1,u_{1n}\rangle_{L^2}| \le K_3[\|D_tu_{1n}\|^\kappa_{L^2} + 1]\|u_{1n}\|_{L^2} \quad \forall n. \tag{4.15}$$

We define

$$y_{1n} = \sum_{j=1}^{n_1} \left\{ \sum_{k=0}^{n} \hat{u}^c_{1n}(j,k)\tilde{\phi}^c_{jk} + \sum_{k=1}^{n} \hat{u}^s_{1n}(j,k)\tilde{\phi}^s_{jk} \right\} \tag{4.16}$$

and

$$z_{1n} = u_{1n} - y_{1n}. \tag{4.17}$$

Since u_{1n} has the same form as y_{1n} in (4.16) with n_1 replaced by n we see from (3.20) that

$$\|u_{1n}\|^2_{\mathcal{L}} = \|y_{1n}\|^2_{\mathcal{L}} + \|z_{1n}\|^2_{\mathcal{L}}. \tag{4.18}$$

Next, we observe from (3.11) that $D_tu_{1n} \in S_n \ \forall n$. Hence taking $v = D_tu_{1n}$ in (3.9) with $i = 1$, we see from (Q-6) and (4.8) that

$$\begin{aligned}\|D_tu_n\|^2_{L^2} &= \langle f_1(\cdot,\xi_m(u_{1n}),\dots,\xi_m(u_{N_1n})),D_tu_{1n}\rangle_{L^2} \\ &+ G_{11}(D_tu_{1n})G_{21}(u_{1n})\langle g_1,D_tu_{1n}\rangle_{L^2}.\end{aligned} \tag{4.19}$$

It therefore follows from (f-2), (4.6), (G-1), and (G-2) that there is a positive constant K_4 such that

$$\|D_tu_{1n}\|_{L^2} \le K_4\|u_{1n}\|^\kappa_{\mathcal{L}} + K_4\|D_tu_{1n}\|^\kappa_{L^2} + K_4 \quad \forall n.$$

It follows from this last inequality, (4.6), and the fact that $0 \le \kappa < 1$ that

$$\lim_{n\to\infty} \frac{\|D_tu_{1n}\|_{L^2}}{\|u_{1n}\|_{\mathcal{L}}} = 0. \tag{4.20}$$

From (4.13) and (4.16)–(4.18), we see that

$$\rho_1\gamma\|z_{1n}\|^2_{\mathcal{L}} \le \text{the right-hand side of (4.13)},$$

where $\gamma > 0$. Consequently, it follows from this last inequality, (4.14), (4.15), and (4.20) that

$$\rho_1 \gamma \lim_{n\to\infty} \|Z_{1n}\|_{\mathcal{L}}^2 \leq 0, \tag{4.21}$$

where

$$U_{1n} = \frac{u_{1n}}{\|u_{1n}\|_{\mathcal{L}}}, \quad Y_{1n} = \frac{y_{1n}}{\|u_{1n}\|_{\mathcal{L}}}, \quad Z_{1n} = \frac{z_{1n}}{\|u_{1n}\|_{\mathcal{L}}}. \tag{4.22}$$

Since $\gamma > 0$ and $\rho_1 > 0$, we conclude from (4.21) that

$$\lim_{n\to\infty} \|Z_{1n}\|_{\mathcal{L}} = 0. \tag{4.23}$$

Next, we observe from (1.3) and (1.14) that

$$\|U_{1n}\|_{\tilde{H}}^2 = \|D_t U_{1n}\|_{L^2}^2 + \|U_{1n}\|_{W^{m,2,\sim}}^2. \tag{4.24}$$

From (4.20) and (4.22) we have that

$$\lim_{n\to\infty} \|D_t U_{1n}\|_{L^2} = 0. \tag{4.25}$$

We conclude from this last fact in conjunction with (4.3), (4.22), and (4.24) that

$$\{\|U_{1n}\|_{\tilde{H}}\}_{n=1}^{\infty} \text{ is a bounded sequence.} \tag{4.26}$$

It follows from (4.26), standard Hilbert space theory, and the compact imbedding theorem for Sobolev spaces that there exists a subsequence (which for ease of notation we take to be the full sequence) and

$$U \in \tilde{H} \tag{4.27}$$

such that

$$\lim_{n\to\infty} \|U_{1n} - U\|_{L^2} = 0; \tag{4.28}$$

$$\lim_{n\to\infty} U_{1n}(x,t) = U(x,t) \quad \text{a.e. in } \tilde{\Omega}; \tag{4.29}$$

$$\lim_{n\to\infty} \int_{\tilde{\Omega}} D^\alpha U_{1n}(x,t) w = \int_{\tilde{\Omega}} D^\alpha U(x,t) w, \qquad 1 \leq |\alpha| \leq m, \forall w \in L^2(\tilde{\Omega}). \tag{4.30}$$

Since $\|Z_{1n}\|_{L^2}^2 \leq (\lambda_1)^{-1} \|Z_{1n}\|_{\mathcal{L}}^2$ and $Y_{1n} = U_{1n} - Z_{1n}$, it follows from (4.23) and (4.28) that

$$\lim_{n\to\infty} \|Y_{1n} - U\|_{L^2} = 0. \tag{4.31}$$

Next, we observe from (4.16) that $\hat{Y}_{1n}^c(j,k) = \hat{Y}_{1n}^s(j,k) = 0$ for $j \geq n_1 + 1$. Consequently, it follows from (4.31) that

$$\hat{U}^c(j,k) = \hat{U}^s(j,k) = 0 \quad \text{for } j \geq n_1 + 1 \text{ and } k = 0, 1, 2, \ldots. \tag{4.32}$$

Next, we observe from (3.1) that for $j \geq 1$ and $k \geq 1$

$$\begin{aligned} k\hat{U}^s_{1n}(j,k) &= -\int_{\tilde{\Omega}} U_{1n}(x,t) D_t \tilde{\phi}^c_{jk}(x,t) \\ &= \int_{\tilde{\Omega}} \tilde{\phi}^c_{jk}(x,t) D_t U_{1n}(x,t). \end{aligned}$$

Consequently, it follows from (4.25) that for $j \geq 1$ and $k \geq 1, \lim_{n\to\infty} \hat{U}^s_{1n}(j,k) = 0$. We conclude from (4.28) that

$$\hat{U}^c(j,k) = \hat{U}^s(j,k) = 0 \quad \text{for } j,k \geq 1. \tag{4.33}$$

From (4.32), (4.33), and (3.3), it follows that

$$U(x,t) = \sum_{j=1}^{n_1} \hat{U}^c(j,0)\frac{\phi_j(x)}{\sqrt{2\pi}} \quad \text{a.e. in } \tilde{\Omega}. \tag{4.34}$$

Next, we note from (4.16) that

$$\mathcal{L}(Y_{1n}, Y_{1n}) = \lambda_1 \langle Y_{1n}, Y_{1n}\rangle_{L^2}$$

and from (4.22) that

$$1 = \|U_{1n}\|^2_{\mathcal{L}} = \|Y_{1n}\|^2_{\mathcal{L}} + \|Z_{1n}\|^2_{\mathcal{L}}.$$

From these last two equalities and (4.23), we see that

$$\lim_{n\to\infty} \|Y_{1n}\|^2_{L^2} = \lambda_1^{-1}.$$

Hence it follows from (4.31) that

$$\|U\|^2_{L^2} = \lambda_1^{-1} > 0. \tag{4.35}$$

From (1.18), (4.34), and (4.35), we see that U is a nontrivial function in $S^{\#}_{\lambda_1}$. With $\tilde{\Omega}(U)$ defined in the statement of Theorem 1, we set

$$\tilde{\Omega}_1(U) = \tilde{\Omega}(U) \cap \tilde{\Omega}_0, \tag{4.36}$$

where $\tilde{\Omega}_0$ is defined in (f-3).

Next, we return to (4.16) and write

$$y_{1,1n} = y_{1n} - y_{2,1n}, \tag{4.37}$$

where

$$y_{2,1n} = \sum_{j=1}^{n_1} \left\{ \sum_{k=1}^{n} \hat{u}^c_{1n}(j,k)\tilde{\phi}^c_{jk} + \hat{u}^s_{1n}(j,k)\tilde{\phi}^s_{jk} \right\}.$$

Then with $Y_{i,1n} = \frac{y_{i,1n}}{\|u_{1n}\|_{\mathcal{L}}}$ for $i = 1,2$, we see from (4.37) that

$$Y_{1,1n}(x,t) = \sum_{j=1}^{n_1} \hat{U}^c_{1n}(j,0)\frac{\phi_j(x)}{\sqrt{2\pi}}. \tag{4.38}$$

From (4.28), $\hat{U}^c_{1n}(j,0) \to \hat{U}^c(j,0)$ for $j = 1, \ldots, n_1$ as $n \to \infty$. Consequently, we obtain from (4.34) that

$$\text{(4.39)} \qquad \begin{aligned} &\text{(i)} \quad \lim_{n\to\infty} D^\alpha Y_{1,1n}(x,t) = D^\alpha U(x,t) \text{ a.e. in } \tilde{\Omega} \text{ for } |\alpha| \le m, \\ &\text{(ii)} \quad \lim_{n\to\infty} \|D^\alpha Y_{1,1n} - D^\alpha U\|_{L^2} = 0 \text{ for } |\alpha| \le m. \end{aligned}$$

From (4.31) and (4.37), we also have that

$$\|Y_{2,1n}\|_{L^2} \le \|Y_{1n} - U\|_{L^2} + \|U - Y_{1,1n}\|_{L^2}.$$

But then it follows from (4.31) and (4.39) (ii) that $\lim_{n\to\infty} \|Y_{2,1n}\|_{L^2} = 0$. On the other hand, it follows from (4.37) that $\mathcal{L}(Y_{2,1n}, Y_{2,1n}) = \lambda_1 \|Y_{2,1n}\|^2_{L^2}$. We conclude that

$$\text{(4.40)} \qquad \lim_{n\to\infty} \|Y_{2,1n}\|_{\mathcal{L}} = 0.$$

From (4.23) and (4.40) joined with (4.3), we in turn obtain that

$$\text{(4.41)} \qquad \begin{aligned} &\text{(i)} \quad \lim_{n\to\infty} [\|D^\alpha Y_{2,1n}\|_{L^2} + \|D^\alpha Z_{1n}\|_{L^2}] = 0 \text{ for } |\alpha| \le m, \\ &\text{(ii)} \quad \lim_{n\to\infty} D^\alpha Y_{2,1n}(x,t) = 0 \text{ a.e. in } \Omega \text{ for } |\alpha| \le m, \\ &\text{(iii)} \quad \lim_{n\to\infty} D^\alpha Z_{1n}(x,t) = 0 \text{ a.e. in } \Omega \text{ for } |\alpha| \le m \end{aligned}$$

where we have used full sequences in (4.41) (ii) and (iii) rather than subsequences for ease of notation.

Since $U_{1n} = Y_{1,1n} + Y_{2,1n} + Z_{1n}$, we see from (4.39) and (4.41) that (4.28), (4.29), and (4.30) can be replaced by the stronger assertions

$$\text{(4.42)} \qquad \lim_{n\to\infty} \|D^\alpha U_{1n} - D^\alpha U\|_{L^2} = 0 \quad \text{for } |\alpha| \le m,$$

$$\text{(4.43)} \qquad \lim_{n\to\infty} D^\alpha U_{1n}(x,t) = D^\alpha U(x,t) \quad \text{a.e. in } \tilde{\Omega} \text{ for } |\alpha| \le m.$$

Next, we return to (4.13) and observe that since ρ_1, γ, and λ_1 are all positive, the left-hand side of the inequality is nonnegative. Consequently, upon dividing both sides by $\|u_{1n}\|^{1+\kappa}_{\mathcal{L}}$, we obtain that

(4.44)

$$-\varepsilon\rho_1 \le \frac{\langle f_1(\cdot, \xi_m(u_{1n}), \ldots, \xi_m(u_{N_1 n})), U_{1n}\rangle_{L^2} + G_{11}(D_t u_{1n}) G_{21}(u_{1n}) \langle g_1, U_{1n}\rangle_{L^2}}{\|u_{1n}\|^\kappa_{\mathcal{L}}}.$$

Since

$$\frac{\|u_{1n}\|_{L^2}}{\|u_{1n}\|_{\mathcal{L}}} \xrightarrow[n\to\infty]{} \lambda_1^{-\frac{1}{2}}$$

by (4.22), (4.35), and (4.42), we have that $\lim_{n\to\infty} \|u_{1n}\|_{L^2} = \infty$. Consequently it follows from (G-1), (G-2), (4.20), and (4.42) that

$$\lim_{n\to\infty} \frac{G_{11}(D_t u_{1n}) G_{21}(u_{1n}) \langle g_1, U_{1n}\rangle_{L^2}}{\|u_{1n}\|^\kappa_{\mathcal{L}}} = 0.$$

We therefore conclude from (4.44) that

$$0 \leq \limsup_{n\to\infty} \frac{\langle f_1(\cdot, \xi_m(u_{1n}), \dots, \xi_m(u_{N_1 n})), U_{1n}\rangle_{L^2}}{\|u_{1n}\|_{\mathcal{L}}^{\kappa}} \tag{4.45}$$

because ε is an arbitrary positive constant.

Next, we observe that

$$\left\{ \frac{f_1(\cdot, \xi_m(u_{1n}), \dots, \xi_m(u_{N_1 n}))U_{1n}}{\|u_{1n}\|_{\mathcal{L}}^{\kappa}} \right\}_{n=1}^{\infty} \tag{4.46}$$

is an absolutely equi-integrable sequence;

that is, given $\varepsilon > 0, \exists\delta$ such that if $E \subset \tilde{\Omega}$ and meas $(E) < \delta$, then

$$\int_E \frac{|f_1(\cdot, \xi_m(u_{1n}), \dots, \xi_m(u_{N_1 n}))U_{1n}|}{\|u_{1n}\|_{\mathcal{L}}^{\kappa}} < \varepsilon \quad \forall n.$$

To establish (4.46), we see from (f-2) that it is sufficient to show

(4.47) $\{|D^\alpha(U_{1n})|^\kappa |U_{1n}|\}_{n=1}^\infty$ is an absolutely equi-integrable sequence for $0 \leq |\alpha| \leq m$.

From (4.42) we see that $\{|U_{1n}|^2\}_{n=1}^\infty$ is an absolutely equi-integrable sequence and that $\{|D^\alpha U_{1n}|^{2\kappa}\}_{n=1}^\infty$ is a bounded sequence in $L^1(\tilde{\Omega})$. Equation (4.47) follows immediately from Schwarz's inequality and these last two facts. Hence, (4.46) is established.

Next, with $\tilde{\Omega}(U)$ defined in the statement of Theorem 1, we see from (4.43) that

$$\lim_{n\to\infty} D^\alpha U_{1n}(x,t)^\kappa U_{1n}(x,t) = 0 \quad \text{a.e. in } \tilde{\Omega}\backslash\tilde{\Omega}(U) \text{ for } |\alpha| \leq m.$$

Consequently, from (f-2) and this last fact, it follows that

$$\lim_{n\to\infty} \frac{f_1(x,t,\xi_m(u_{1n}), \dots, \xi_m(u_{N_1 n}))U_{1n}(x,t)}{\|u_{1n}\|_{\mathcal{L}}^{\kappa}} = 0 \quad \text{a.e. in } \tilde{\Omega}\backslash\tilde{\Omega}(U).$$

Hence, it follows from (4.46) and Vitali's theorem [7, p. 325] that

$$\lim_{n\to\infty} \int_{\tilde{\Omega}\backslash\tilde{\Omega}(U)} \frac{f_1(x,t,\xi_m(u_{1n}), \dots, \xi_m(u_{N_1 n}))U_{1n}}{\|u_{1n}\|_{\mathcal{L}}^{\kappa}} = 0. \tag{4.48}$$

Observing from (f-3) that meas $(\tilde{\Omega}\backslash\tilde{\Omega}_0) = 0$, we conclude from (4.36), (4.45), and (4.48) that

$$0 \leq \limsup_{n\to\infty} \int_{\tilde{\Omega}_1(U)} \frac{f_1(x,t,\xi_m(u_{1n}), \dots, \xi_m(u_{N_1 n}))U_{1n}}{\|u_{1n}\|_{\mathcal{L}}^{\kappa}}. \tag{4.49}$$

Next, set

$$\tilde{\Omega}_2(U) = \{(x,t) \in \tilde{\Omega}_1(U) : \lim_{n\to\infty} D^\alpha U_{1n}(x,t) = D^\alpha U(x,t) \text{ for } |\alpha| \leq m\}. \tag{4.50}$$

From (4.43), we have $\operatorname{meas}(\tilde{\Omega}_1(U)\backslash\tilde{\Omega}_2(U)) = 0$. We consequently obtain from (4.49) that

$$0 \leq \limsup_{n\to\infty} \int_{\tilde{\Omega}_2(U)} \frac{f_1(x,t,\xi_m(u_{1n}),\ldots,\xi_m(u_{N_1 n}))U_{1n}}{\|u_{1n}\|_{\mathcal{L}}^{\kappa}}. \tag{4.51}$$

Next, we observe from (4.36) and (4.50) that

$$\begin{aligned} &\text{(i)} \quad U(x,t) \neq 0 \text{ for } (x,t) \in \tilde{\Omega}_2(U), \\ &\text{(ii)} \quad \lim_{n\to\infty} \xi_m(U_{1n}(x,t)) = \xi_m(U(x,t)) \text{ for } (x,t) \in \tilde{\Omega}_2(U). \end{aligned} \tag{4.52}$$

Let $(x,t) \in \tilde{\Omega}_2(u)$. It follows from (4.52) that $|U_{1n}(x,t)| > 0$ for $n \geq n_0(x,t)$. Consequently $(\xi_m(U_{1n}(x,t))/|\xi_m(U_{1n}(x,t))|) \in S_1'$ as defined in (f-3) for $n \geq n_0(x,t)$. Also from (4.52) for $(x,t) \in \tilde{\Omega}_2(U)$,

$$\lim_{n\to\infty} \frac{\xi_m(U_{1n}(x,t))}{|\xi_m(U_{1n}(x,t))|} = \frac{\xi_m(U(x,t))}{|\xi_m(U(x,t))|}, \tag{4.53}$$

where the right-hand side of (4.53) is in S_1'. Next, set

$$r_n = \|u_{1n}\|_{\mathcal{L}} |\xi_m(U_{1n}(x,t))| \quad \text{for } (x,t) \in \tilde{\Omega}(U). \tag{4.54}$$

It follows from (4.6) and (4.52) that $\lim_{n\to\infty} r_n = \infty$. Consequently, from (f-2), (4.53), and (4.54) we have that

$$\lim_{n\to\infty} \frac{f_1\left(x,t,r_n\frac{\xi_m(U_{1n})}{|\xi_m(U_{1n}(x,\ t))|},\ldots,\xi_m(u_{N_1 n})\right)}{r_n^{\kappa}} = h_1\left(x,t,\frac{\xi_m(U(x,t))}{|\xi_m(U(x,t))|}\right)$$

for $(x,t) \in \tilde{\Omega}_2(U)$. Observing that

$$\xi_m(u_{1n}(x,t)) = |\xi_m(U_{1n}(x,t))| \frac{\xi_m(u_{1n}(x,t))}{|\xi_m(U_{1n}(x,t))|} = r_n \frac{\xi_m(U_{1n}(x,t))}{|\xi_m(U_{1n}(x,t))|},$$

we see that it then follows from (4.53), (4.44), and this last fact that

$$\begin{aligned} &\lim_{n\to\infty} \frac{f_1(x,t,\xi_m(u_{1n}(x,t)),\ldots,\xi_m(u_{N_1 n}))U_{1n}(x,t)}{\|u_{1n}\|_{\mathcal{L}}^{\kappa}} \\ &\quad = h_1\left(x,t,\frac{\xi_m(U(x,t))}{|\xi_m(U(x,t))|}\right) |\xi_m(U(x,t))|^{\kappa} U(x,t) \end{aligned} \tag{4.55}$$

for $(x,t) \in \tilde{\Omega}_2(U)$. We conclude from (4.46), (4.55), and Vitali's theorem that

$$\begin{aligned} &\lim_{n\to\infty} \int_{\tilde{\Omega}_2(U)} \frac{f_1(x,t,\xi_m(u_{1n}(x,t)),\ldots,\xi_m(u_{N_1 n}(x,t)))U_{1n}(x,t)}{\|u_{1n}\|_{\mathcal{L}}^{\kappa}} \\ &\quad = \int_{\tilde{\Omega}_2(U)} h_1\left(x,t,\frac{\xi_m(U)}{|\xi_m(U)|}\right) |\xi_m(U)|^{\kappa} U. \end{aligned} \tag{4.56}$$

From (4.51) we conclude that the integral on the right-hand side of (4.56) is nonnegative, that is, ≥ 0. But $U \in S_{\lambda_1}^{\#}$ and U is nontrivial by (4.35). Also meas

$(\tilde{\Omega}(U)\backslash\tilde{\Omega}_2(U)) = 0$. Hence by (1.20) the integral on the right-hand side of (4.56) is negative, that is, strictly < 0. We have arrived at a contradiction. We conclude that (4.6) is false and that (4.5) is indeed true when $i = 1$. A proof similar to that above prevails for $i = 2, \ldots, N_1$. Hence, we have that (4.5) holds for all values of i.

Next, we return to (4.19) and obtain from (4.3), (4.5), (f-2), (G-1), and (G-2) that a positive constant K_5 exists such that

$$\|D_t u_{in}\|_{L^2} \le K_5 \|D_t u_{in}\|_{L^2}^{\kappa} + K_5 \quad \text{for } i = 1, \ldots, N_1 \text{ and } n = 1, 2, \ldots.$$

But $0 \le \kappa < 1$. Therefore, from this last inequality, we obtain that $\{\|D_t u_{in}\|_{L^2}\}_{n=1}^{\infty}$ is a bounded sequence for $i = 1, \ldots, N_1$. This fact coupled with (4.5) implies that

$$\|u_{in}\|_{\tilde{H}} \le K_6 \quad \text{for } i = 1, \ldots, N_1 \text{ and } n = 1, 2, \ldots, \tag{4.57}$$

where K_6 is a positive constant.

We next use Lemma A in §6 (the Appendix) and standard Hilbert space theory to obtain the following from (4.57): There exists a subsequence of $\{(u_{1n}, \ldots, u_{N_1 n})\}_{n=1}^{\infty}$ (which for ease of notation we take to be the full sequence) and functions

$$(u_1, \ldots, u_{N_1}) \in \tilde{H}^{N_1} \tag{4.58}$$

such that

$$\lim_{n\to\infty} \|D^{\alpha} u_{in} - D^{\alpha} u_i\|_{L^2} = 0 \quad \text{for } |\alpha| \le m - 1, \tag{4.59}$$

$$\lim_{n\to\infty} D^{\alpha} u_{in}(x,t) = D^{\alpha} u_i(x,t) \quad \text{a.e. in } \tilde{\Omega} \text{ for } |\alpha| \le m - 1, \tag{4.60}$$

$$\lim_{n\to\infty} \langle D_t u_{in}, w\rangle_{L^2} = \langle D_t u_i, w\rangle_{L^2} \quad \forall w \in L^2, \tag{4.61}$$

$$\lim_{n\to\infty} \langle D^{\alpha} u_{in}, w\rangle_{L^2} = \langle D^{\alpha} u_i, w\rangle_{L^2} \quad \forall w \in L^2 \text{ and } |\alpha| = m, \tag{4.62}$$

for $i = 1, \ldots, N_1$.

We next propose to show that for a subsequence (4.60) also holds for $|\alpha| = m$, that is,

$$\begin{gathered} \exists \{u_{in_k}\}_{k=1}^{\infty} \text{ such that } \lim_{k\to\infty} \zeta_m(u_{in_k}(x,t)) = \zeta_m(u_i(x,t)) \\ \text{a.e. in } \tilde{\Omega} \text{ for } i = 1, \ldots, N_1. \end{gathered} \tag{4.63}$$

Once (4.63) is shown, it will be an easy matter when this fact is coupled with (4.60) to show that the conclusion of Theorem 1 holds.

To establish (4.63) for the case $i = 1$, it is sufficient to establish the following two facts:

$$\begin{gathered} \exists \text{ a subsequence } \{u_{1n_k}\}_{k=1}^{\infty} \text{ such that} \\ \lim_{k\to\infty} \sum_{|\alpha|=m} [A_{\alpha}(x, \eta_{m-1}(u_{1n_k}), \zeta_m(u_{1n_k})) - A_{\alpha}(x, \eta_{m-1}(u_{1n_k}), \zeta_m(u_1))] \\ \cdot [D^{\alpha} u_{1n_k} - D^{\alpha} u_1] = 0 \quad \text{a.e. in } \tilde{\Omega}; \end{gathered} \tag{4.64}$$

$$\begin{array}{l}\text{With } \{u_{1n_k}\}_{k=1}^{\infty} \text{ designating the same subsequence as in (4.64)}\\ \{|\zeta_m(u_{1n_k}(x,t))|\}_{k=1}^{\infty} \text{ is pointwise bounded for a.e. } (x,t) \text{ in } \tilde{\Omega}.\end{array} \tag{4.65}$$

Using (4.60) in conjunction with (4.64) and (4.65) to obtain (4.63) via the monotonicity assumption (Q-3) is standard fare in nonlinear partial differential equations (see [4, p. 30] or [13, p. 104]). It therefore remains to show that (4.64) and (4.65) hold.

To establish (4.64), the key idea is to show that the summation in (4.64) with u_{1n_k} replaced by u_{1n} converges to zero in L^1-norm over $\tilde{\Omega}$ and then to apply the monotonicity condition (Q-3) in conjunction with a standard theorem in Lebesgue theory to reach the conclusion in (4.64). The technique for accomplishing this follows the lines of [17, pp. 1830–1833] and [12, pp. 168–171] and makes use of Lemma 1. We leave the details to the reader.

Next, we show that (4.65) for $i = 1$ follows from (4.60) and (4.64). To accomplish this, we observe from (Q-4) that

$$c_1|\zeta_m(u_{1n}(x,t))|^2 \leq \sum_{|\alpha|=m} A^1_\alpha(x, \eta_{m-1}(u_{1n}), \zeta_m(u_{1n}))D^\alpha u_{1n} \tag{4.66}$$

for a.e. $(x,t) \in \tilde{\Omega}$ where $c_1 > 0$. Also, we see that

$$\begin{aligned} &A^1_\alpha(x, \eta_{m-1}(u_{1n}), \zeta_m(u_{1n}))D^\alpha u_{1n}(x,t)\\ &\quad = A^1_\alpha(x, \eta_{m-1}(u_{1n}), \zeta_m(u_{1n}))D^\alpha u_1(x,t)\\ &\quad + A^1_\alpha(x, \eta_{m-1}(u_{1n}), \zeta_m(u_1))[D^\alpha u_{1n}(x,t) - D^\alpha u_1(x,t)]\\ &\quad + [A^1_\alpha(x, \eta_{m-1}(u_{1n}), \zeta_m(u_{1n}) - A^1_\alpha(x, \eta_{m-1}(u_{1n}), \zeta_m(u_1)))]\\ &\quad \times [D^\alpha u_{1n}(x,t) - D^\alpha u_1(x,t)]. \end{aligned} \tag{4.67}$$

If (x,t) is a point such that (4.60) holds for $|\alpha| \leq m-1$, where $D^\alpha u_1(x,t)$ is finite-valued for $|\alpha| \leq m$, and such that (4.64) holds, and furthermore such that the inequalities given by (Q-2) hold, then it follows on dividing both sides of (4.66) by $|\zeta_m(u_{1n}(x,t))|^{\frac{3}{2}}$ and using (4.67) that a subsequence of $|\zeta_m(u_{1n_k}(x,t))|$ cannot tend to $+\infty$, for then we would have that this same subsequence also tends to zero. Since these aforementioned conditions hold almost everywhere in $\tilde{\Omega}$, (4.65) is established for $i = 1$. A similar argument prevails for $i = 1, \dots, N_1$. Hence, (4.65) holds for $i = 2, \dots, N_1$. As we have stated earlier, (4.63) then holds because it is a standard consequence of (4.64) and (4.65).

We now show that (4.57)–(4.63) along with the fact that $\{(u_{1n}, \dots, u_{N_1 n})\}_{n=1}^{\infty}$ satisfies (3.9) gives (1.21), which is our desired result.

To accomplish this, let n_3 be a fixed but arbitrary positive integer and let $w \in S_{n_3}$. Then it follows that

$$\text{(3.9) holds for } i = 1, \dots, N_1 \text{ and } n \geq n_3 \text{ when } v \text{ is replaced by } w. \tag{4.68}$$

We observe that (f-1), (4.60), and (4.63) imply that

$$f_i(x,t,\xi_m(u_{1n}), \dots, \xi_m(u_{N_1 n}))w(x,t) \underset{n\to\infty}{\longrightarrow} f_i(x,t,\xi_m(u_1), \dots, \xi_m(u_{N_1}))w(x,t)$$

for a.e. $(x,t) \in \tilde{\Omega}$. Also, we see from (f-2), (4.57), and the fact that $w \in L^2(\tilde{\Omega})$ that $\{f_i(x,t,\xi_m(u_{1n}), \dots, \xi_m(u_{N_1 n}))w\}_{n=1}^{\infty}$ is an absolutely equi-integrable sequence for $i = 1, \dots, N_1$. Hence it follows from Vitali's theorem [7, p. 325] that

$$\lim_{n\to\infty} \langle f_i(\cdot, \xi_m(u_{1n})), \dots, \xi_m(u_{N_1 n}), w\rangle_{L^2} = \langle f_i(\cdot, \xi_m(u_1), \dots, \xi_m(u_{N_1})), w\rangle_{L^2}. \tag{4.69}$$

In a similar manner using (Q-1) and (Q-2), it follows that

$$\begin{aligned}\lim_{n\to\infty}\langle A^i_\alpha(\cdot,\xi_m(u_{in})),D^\alpha w\rangle_{L^2}&=\langle A^i_\alpha(\cdot,\xi_m(u_i)),D^\alpha w\rangle_{L^2},\\ \lim_{n\to\infty}\langle a^i_0(\cdot,\xi_m(u_{in}))u_{in},w\rangle_{L^2}&=\langle a^i_0(\cdot,\xi_m(u_i))u_i,w\rangle_{L^2}\end{aligned}\tag{4.70}$$

for $i=1,\dots,N_1$.

Also, we have from (4.61) that $\lim_{n\to\infty}G_{1i}(D_tu_{in})=G_{1i}(D_tu_i)$ and from (4.59) that $\lim_{n\to\infty}G_{2i}(u_{in})=G_{2i}(u_i)$. In a similar manner, we have that $\lim_{n\to\infty}\langle D_tu_{in}, w\rangle_{L^2}=\langle D_tu_i,w\rangle_{L^2}$. Putting all these facts together, we conclude from (4.68), (1.4), (4.60), and (4.68)–(4.70) upon taking the limit as $n\to\infty$ of both sides of (3.9) with v replaced by w that

(4.71)

$$\begin{aligned}\langle D_tu_i,w\rangle_{L^2}+\rho_iQ_i(u_i,w)&=\lambda^*_1\rho_i\langle u_i,w\rangle_{L^2}\\ &\quad+\langle f_i(\cdot,\xi_m(u_1),\dots,\xi_m(u_{N_1})),w\rangle_{L^2}\\ &\quad+G_{1i}(D_tu_1)G_{2i}(u_i)\langle g_i,w\rangle_{L^2}\quad\text{for } i=1,\dots,N_1,\end{aligned}$$

and for $w\in S_{n_3}$. However, n_3 was an arbitrary positive integer. So we see that (4.71) holds $\forall w\in\bigcup_{n=1}^{\infty}S_n$.

Next, let $v\in\tilde H$. Then it follows from (4.71) and our last observation that (4.71) holds when w is replaced by $\sigma_n(v)$ where $\sigma_n(v)$ is defined in (3.4). From (3.5) (ii) and (1.4), it follows that $\lim_{n\to\infty}Q_i(u_i,\sigma_n(v))=Q_i(u_i,v)$. We consequently obtain from (3.5) (i) and this last remark upon replacing w in (4.71) by $\sigma_n(v)$ and taking the limit of both sides as $n\to\infty$ that

$$\begin{aligned}\langle D_tu_i,v\rangle_{L^2}+\rho_1Q_i(u_i,v)&=\lambda^*_1\rho_i\langle u_i,v\rangle_{L^2}+\langle f_i(\cdot,\xi_m(u_1),\dots,\xi_m(u_{N_1})),v\rangle_{L^2}\\ &\quad+G_{1i}(D_tu_i)G_{2i}(u_i)\langle g_i,v\rangle_{L^2}\quad\forall v\in\tilde H.\end{aligned}$$

But this is precisely (1.21), and the proof of Theorem 1 is complete.

5. Proof of Theorem 2. To prove Theorem 2 we can assume as in the proof of Theorem 1 that (4.1) and (4.2) hold. As a consequence we have that (4.3) and (4.4) hold. Next we invoke Remark 1 and have a sequence $\{(u_{1n},\dots,u_{N_1n})\}_{n=1}^{\infty}$ with each $u_{in}\in S_n$ such that

$$\begin{aligned}\langle D_tu_{in},v\rangle_{L^2}+\rho_iQ_i(u_{in},v)&=\rho_i(\lambda^*_1-\delta_i)\langle u_{in},v\rangle_{L^2}\\ &\quad+\langle f_i(\cdot,(\xi_m(u_{1n}),\dots,\xi_m(u_{N_1n}))),v\rangle_{L^2}\\ &\quad+G_{1i}(D_tu_{in})G_{2i}(u_{in})\langle g_i,v\rangle_{L^2}\\ &\quad\forall v\in S_n\text{ and } i=1,\dots,N_1.\end{aligned}\tag{5.1}$$

We claim there is a constant K_1 such that

$$\|u_{in}\|_{\mathcal L}\le K_1\quad\forall n\text{ and for } i=1,\dots,N_1.\tag{5.2}$$

For ease of notation, we shall establish (5.2) for the case $i=1$. A similar proof will prevail for the other values of i. Suppose then that (5.2) is false for $i=1$. Then with no loss in generality we can suppose

$$\lim_{n\to\infty}\|u_{1n}\|_{\mathcal L}=\infty.\tag{5.3}$$

We propose to show that (5.3) is false, and we shall do this without using (f-3) and (1.20). First, we observe as in the proof of Theorem 1 that $D_t u_{1n} \in S_n$. Hence taking $v = D_t u_{1n}$ in (5.1) for $i = 1$, we obtain that (4.19) holds and, as a consequence, since (4.6) is the same as (5.3), that (4.20) holds. We record this as

$$\lim_{n\to\infty} \frac{\|D_t u_{1n}\|_{L^2}}{\|u_{1n}\|_{\mathcal{L}}} = 0. \tag{5.4}$$

Next, we claim that $\exists K_2 > 0$ such that

$$\|u_{1n}\|_{L^2} \leq K_2 \|u_{1n}\|_{\mathcal{L}}^{\kappa} \quad \forall n. \tag{5.5}$$

To see that (5.5) is true, we first observe from (5.1) with $v = u_{1n}$ and $i = 1$ that

$$\begin{aligned} \rho_1 \mathcal{Q}_1(u_{1n}, u_{1n}) = {} & \rho_1(\lambda_1^* - \delta_1)\|u_{1n}\|_{L^2}^2 \\ & + \langle f_1(\cdot, (\xi_m(u_{1n}), \ldots, \xi_m(u_{N_1 n}))), u_{1n}\rangle_{L^2} \\ & + G_{11}(D_t u_{1n}) G_{21}(u_{1n}) \langle g_1, u_{1n}\rangle_{L^2}. \end{aligned} \tag{5.6}$$

If $\|u_{1n}\|_{L^2} \to \infty$, it follows from (1.5) that

$$\rho_1\left(\lambda_1^* - \frac{\delta_1}{2}\right)\|u_{1n}\|_{L^2}^2 \leq \rho_1 \mathcal{Q}_1(u_{1n}, u_{1n}) \quad \text{for } n \geq n_2.$$

But then from (5.4) and (5.6) we have that there is a constant K_3 such that

$$\rho_1 \frac{\delta_1}{2}\|u_{1n}\|_{L^2}^2 \leq K_3 \|u_{1n}\|_{\mathcal{L}}^{\kappa}\|u_{1n}\|_{L^2} + K_3\|u_{1n}\|_{L^2} \quad \text{for } n \geq n_2, \tag{5.7}$$

where we have also used (f-2), (G-1), and (G-2) to establish this last inequality. From (5.3) and (5.7), we infer that (5.5) is indeed true.

Now we have that Q_1 is $\kappa*$-related to L. So it follows from (1.16) (i) and (4.3) that for $n \geq n_3$

$$\|u_{1n}\|_{\mathcal{L}}^2 \leq \mathcal{Q}_1(u_{1n}, u_{1n}) + \delta_1 \|u_{1n}\|_{\mathcal{L}}^{1+\kappa}.$$

Using this last inequality in conjunction with (f-2), (G-1), (G-2), and (5.3)–(5.6), we obtain that there is a constant K_4 such that

$$\|u_{1n}\|_{\mathcal{L}}^2 \leq K_4[\|u_{1n}\|_{\mathcal{L}}^{2\kappa} + \|u_{1n}\|_{\mathcal{L}}^{1+\kappa}] \quad \text{for } n \geq n_3.$$

As a consequence of this last inequality and the fact that $0 \leq \kappa < 1$, we obtain that $\|u_n\|_{\mathcal{L}}^{1-\kappa} \leq 2K_4$ for $n \geq n_3$. But this is a contradiction to (5.3). Hence (5.2) does indeed hold for $i = 1$. A similar proof prevails for $i = 2, \ldots, N_1$. Hence (5.2) holds for $i = 1, \ldots, N_1$.

But this last situation is the same as (4.5) in Theorem 1. After (4.5) was established, the rest of the proof of Theorem 1 did not depend upon (f-3) and the condition in (1.20). So the remainder of the proof of Theorem 2 follows exactly the lines of Theorem 1 and the proof of Theorem 2 is complete.

6. Appendix.

In this section, we shall prove the following lemma.

LEMMA A. *Let $\{u_n\}_{n=1}^{\infty}$ be a sequence of elements in $\tilde{H}$ with*

$$\|u_n\|_{\tilde{H}} \leq K \quad for\, n = 1, 2, \ldots. \tag{6.1}$$

Then $\exists u \in \tilde{H}$ *and a subsequence* $\{u_{n_q}\}_{q=1}^{\infty}$ *such that*

$$\lim_{n\to\infty} \int_{\tilde{\Omega}} |D^\alpha u_{n_q} - D^\alpha u|^2 = 0 \quad \textit{for}\, |\alpha| \le m-1.$$

For $m = 1$, the above lemma is an easy consequence of the familiar compact imbedding theorem for Sobolev spaces [1, p. 97]. Therefore, to prove the lemma, we can assume from the start that the m used in the definition $\tilde{H}$ is a positive integer with $m \ge 2$. Also since for $u_n \in \tilde{H}, \exists v_n \in \mathcal{A}$ such that $\|u_n - v_n\|_{\tilde{H}} \le n^{-1}$, we can assume from the start that

$$(6.2) \qquad u_n \in \mathcal{A} \quad \text{for } n = 1, 2 \ldots.$$

Furthermore, since Ω is a bounded open set, we can suppose that Ω is contained in the interior of an open cube with each side of length 2π. In particular, we shall suppose $\Omega \subset (-\pi,\pi)^N$. Since by (6.2) each $u_n \in \mathcal{A}$, we have that for each $n, \exists$ a compact set $E_n \subset (-\pi,\pi)^N$ such that $u_n(x,t) = 0$ in $(-\pi,\pi)^N \backslash E_n$ and $t \in \mathbb{R}$. Also, $u_n(x,t)$ is $C^\infty((-\pi,\pi)^N \times \mathbb{R})$ and periodic of period 2π in t. Hence we can view each $u_n(x,t)$ as a real-valued function in $C^\infty(T^N \times T) = C^\infty(T^{N+1})$, where T^N is the N-dimensional torus.

Next, we introduce the complete orthogonal trigonometric series $\{e^{i[(j,x)+kt]}\}$, where $j = (j_1, \ldots, j_N)$ with $j_1, \ldots, j_N$ and k integers running from $-\infty$ to ∞ and $(j,x) = j_1x_1 + \cdots + j_Nx_N$. We set $\hat{u}_n(j,k) = (2\pi)^{-(N+1)} \int_T \int_{T^N} u_n(x,t)e^{i[(j,x)+kt]}$. From (6.1) and [9, p. 55] we have that

$$(6.3) \qquad \sum_{(j,k)\in M} [|j|^{2m} + k^2]|\hat{u}_n(j,k)|^2 \le K^2 \quad \forall n = 1, 2, \ldots$$

where $|j|^2 = (j,j)$ and $M = \{(j,k) : -\infty < j_l < \infty, -\infty < k < \infty, l = 1, \ldots, N\}$ is the set of integral lattice points in $\mathbb{R}^{N+1}$. Also for future use we record the fact that we are assuming

$$(6.4) \qquad m \ge 2 \text{ is a positive integer.}$$

Since $\int_{T^{N+1}} |u_n|^2 \le K^2$, we see there exists a subsequence (which for ease of notation, we take to be the full sequence) and a $u \in L^2(T^N \times T)$ such that

$$\lim_{n\to\infty} \int_T \int_{T^N} u_n w = \int_T \int_{T^N} uw \quad \forall w \in L^2(T^N \times T).$$

In particular, taking $w = e^{-i[(j,x)+kt]}$, we have that

$$(6.5) \qquad \lim_{n\to\infty} \hat{u}_n(j,k) = \hat{u}(j,k) \quad \forall (j,k) \in M.$$

Next, let $\rho > 0$ be any positive number. It follows from (6.3) and (6.5) that $\sum_{|j|^2+k^2\le\rho} [|j|^{2m} + k^2]|\hat{u}(j,k)|^2 \le K^2$. Hence,

$$(6.6) \qquad \sum_{(j,k)\in M} [|j|^{2m} + k^2]|\hat{u}(j,k)|^2 \le K^2.$$

We therefore conclude that $D^\alpha u$ exists in the distributional sense [3, Chap. 3] and $D^\alpha u \in L^2(T^N \times T)$ for $|\alpha| \leq m$. The conclusion to Lemma A will follow if we can show

$$\lim_{n\to\infty} \int_T \int_{T^N} |D^\alpha u_n - D^\alpha u|^2 = 0 \quad \text{for } |\alpha| \leq m-1. \tag{6.7}$$

Now from a Fourier series point of view

$$D^\alpha u_n - D^\alpha u = \sum_{(j,k)\in M} (ij_1)^{\alpha_1} \dots (ij_N)^{\alpha_N} [\hat{u}_n(j,k) - \hat{u}(j,k)] e^{i[(j,x)+kt]}.$$

Therefore (6.7) will follow if we can show

$$\lim_{n\to\infty} \sum_{(j,k)\in M} j_1^{2\alpha_1} \dots j_N^{2\alpha_n} |\hat{u}_n(j,k) - \hat{u}(j,k)|^2 = 0 \quad \text{for } |\alpha| \leq m-1. \tag{6.8}$$

Now

$$j_1^{2\alpha_1} \dots j_N^{2\alpha_N} \leq j_1^{2(m-1)} + \dots + j_N^{2(m-1)} \leq N|j|^{2(m-1)} \quad \text{for } |\alpha| \leq m-1 \text{ and } (j,k) \in M.$$

Hence (6.8) will follow if we can show

$$\lim_{n\to\infty} \sum_{(j,k)\in M} |j|^{2(m-1)} |\hat{u}_n(j,k) - \hat{u}(j,k)|^2 = 0. \tag{6.9}$$

We now show that (6.9) follows from (6.3)–(6.5).

To accomplish this, we first set

$$y(s) = s^m - \rho^{\frac{1}{m}} s^{m-1} + \rho, \tag{6.10}$$

where $\rho \geq 2$ and $m \geq 2$. Then

$$y(s) > 0 \quad \text{for } 0 \leq s \leq \rho. \tag{6.11}$$

To see that this is the case, we observe that both $y(0)$ and $y(\rho)$ are positive numbers. Also the only place where $y'(s) = 0$ inside the interval $(0, \rho)$ is when $s = ((m-1)\rho^{1/m})/m$. But

$$y\left[\frac{(m-1)\rho^{\frac{1}{m}}}{m}\right] \geq \left[1 - \left(\frac{m-1}{m}\right)^{m-1}\right] \rho > 0.$$

Hence, $y(s)$ does not have a nonpositive minimum inside $(0, \rho)$ and (6.11) is established.

To show that (6.9) is indeed true let I_n be the summation in (6.9) and let $\varepsilon > 0$ be given. (6.9) will follow if we can show

$$\overline{\lim_{n\to\infty}} I_n \leq 2\varepsilon. \tag{6.12}$$

Choose $\rho \geq 2$ such that also

$$\frac{4K^2}{\rho^{\frac{1}{m}}} \leq \varepsilon, \tag{6.13}$$

and set

$$
\begin{aligned}
&M_1(\rho) = \{(j,k) \in M : |j|^2 + k^2 \leq 2\rho\},\\
(6.14) \qquad &M_2(\rho) = \{(j,k) \in M : |j|^2 > \rho\},\\
&M_3(\rho) = \{(j,k) \in M : |j|^2 \leq \rho, k^2 > \rho\}.
\end{aligned}
$$

It is clear that $M = M_1(\rho) \cup M_2(\rho) \cup M_3(\rho)$ because $[M_1(\rho) \cup M_2(\rho)]^C \subset M_3(\rho)$. Set

$$(6.15) \qquad I_n^{(p)} = \sum_{(j,k)\in M_p(\rho)} |j|^{2(m-1)}|\hat{u}_n(j,k) - \hat{u}(j,k)|^2, \qquad p = 1,2,3.$$

Therefore

$$(6.16) \qquad I_n \leq I_n^{(1)} + I_n^{(2)} + I_n^{(3)}.$$

Since there are only a finite number of lattice points in $M_1(\rho)$, it follows from (6.5) and (6.15) that

$$(6.17) \qquad \lim_{n\to\infty} I_n^{(1)} = 0.$$

Also from the fact that $|a - b|^2 \leq 2a^2 + 2b^2$, it follows from (6.3) and (6.6) that

$$(6.18) \qquad \sum_{(j,k)\in M} [|j|^{2m} + k^2]|\hat{u}_n(j,k) - \hat{u}(j,k)|^2 \leq 4K^2.$$

This fact coupled with the fact that

$$\frac{|j|^{2(m-1)}}{|j|^{2m} + k^2} \leq \rho^{-1} \quad \text{for } (j,k) \in M_2$$

give that $\overline{\lim}_{n\to\infty} I_n^{(2)} \leq \frac{4K^2}{\rho}$. But both $\rho \geq 2$ and $m \geq 2$. It follows therefore from (6.13) that

$$(6.19) \qquad \overline{\lim}_{n\to\infty} I_n^{(2)} \leq \varepsilon.$$

Next, we observe from (6.14) that

$$(6.20) \qquad \frac{|j|^{2(m-1)}}{|j|^{2m} + k^2} \leq \frac{|j|^{2(m-1)}}{|j|^{2m} + \rho}$$

for $(j,k) \in M_3(\rho)$. Also, we observe from (6.10) and (6.11) that for $|j|^2 \leq \rho$, the expression on the right-hand side of the inequality in (6.20) in majorized by $\rho^{-\frac{1}{m}}$. Therefore we have that

$$\frac{|j|^{2(m-1)}}{|j|^{2m} + k^2} \leq \rho^{-\frac{1}{m}} \quad \text{for } (j,k) \in M_3(\rho).$$

Consequently, we obtain from (6.15), (6.18), and this last inequality that

$$\overline{\lim_{n\to\infty}} I_n^{(3)}(\rho) \leq \frac{4K^2}{\rho^{1/m}}.$$

But this fact coupled with (6.13), (6.16), (6.17), and (6.19) give that $\overline{\lim}_{n\to\infty} I_n \leq 2\varepsilon$. Hence, (6.12) is established and the proof of Lemma A is complete.

PERIODIC AND POSITIVE WAVE FRONT SOLUTIONS OF SEMILINEAR DIFFUSION EQUATIONS*

JOSÉ M. FRAILE† AND JOSÉ SABINA DE LIS‡

Abstract. The objective of this work is to study the existence of positive and T-periodic undulatory solutions of the form $u(x,t) = u(x - c(t))$ to the equation

$$\frac{\partial u}{\partial t} = \Delta u + b(t)\nabla u + f(u), \quad x \in \Omega,$$

where $b = b(t)$ is T-periodic and the reaction term $f = f(u)$ is supposed to satisfy $f(u) \le 0$ for $0 < u_o \le u$. The waves are analyzed in bounded domains Ω wherein they are subject to special homogeneous Dirichlet conditions. The average μ of $b(t)$ over the interval $(0, T)$ and the size of Ω are observed as bifurcation parameters. The one-dimensional version of this Dirichlet problem is deeply and geometrically studied by means of chains of travelling waves to the equation $u_t = u_{xx} + f(u)$, which connect (infinitely many in some cases) zeros of $f(u)$.

Key words. travelling waves, subsolutions, supersolutions, semilinear elliptic equations, variational methods, phase space analysis

1. Introduction. In this work we analyze the existence and some properties of bifurcation of a certain kind of periodic undulatory solution to semilinear parabolic equations, with *periodic transport* terms, with the specific form,

$$\frac{\partial u}{\partial t} = \Delta u + b(t)\nabla u + f(u). \tag{1.1}$$

In (1.1)

$$\begin{aligned} u: \quad & \Omega \times \mathbf{R} \to \mathbf{R}, \\ & (x,t) \to u(x,t) \end{aligned}$$

where $\Omega \subset \mathbf{R}^n$ is a bounded domain (i.e., an open connected set), Δ and ∇ stand for the usual Laplacian $\Delta = \Sigma_{i=1}^{n} \frac{\partial^2}{\partial x_i^2}$ and gradient $\nabla = (\frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_n})$ n-dimensional operators, respectively. We will assume that

$$\begin{aligned} b: \quad & \mathbf{R} \to \mathbf{R}^n \\ & t \to b(t) \end{aligned}$$

is a continuous and periodic function with period $T > 0$ and average $\mu = \frac{1}{T}\int_0^T b(\tau)\, d\tau$. As for $f = f(u)$ it will be assumed that it belongs to a certain general kind of C^1 nonlinearities (see §3.1).

The main objective of the work is to study the undulatory solutions

$$w(x,t) = u(x - c(t)) = u(y), \quad x \in \Omega, \quad t \in \mathbf{R} \tag{1.2}$$

where $c = c(t)$ is a C^1 periodic function with period $T > 0$. Notice that the solutions with the form (1.2) are those profiles which are stationary regarding the mobil reference frame,

$$\begin{cases} y = x - c(t), \\ t' = t. \end{cases}$$

However, a suitable choice of $c(t)$ must be made.

The study of periodic undulatory solutions to reaction–diffusion systems has been a very active research area in recent years. The plane wave fronts, i.e., solutions with the form $w(x,t) = u(kx - ct) = u(\theta)$, $k \in \mathbf{R}^n$, $|k| = 1$, and $c \in \mathbf{R}$, have been perhaps the most studied. In this case the periodicity of the wave comes from the character of u as a periodic function of θ (a free oscillation of an ordinary differential equation). See for instance [Ba-P], [Co-H-M], [Du], [Fr-S,89], [Ko-H,73], [Ko-H,75], and the books by Murray [M] and Fife [F]. However, it should be remarked that the dimension of the variable x is not preserved in the phase $y = kx - ct$ of the plane wave fronts, except when $x \in \mathbf{R}$. Therefore, these kinds of waves are incompatible with any types of boundary conditions. If $x \in \mathbf{R}$, $u(x - ct)$ is called a *travelling wave* (see [F]) and their role as asymptotic states to parabolic equations (1.1) has been widely analyzed (see [Ar-W,75], [F-M,77], [F-M,81], [F], and [He] for the cases $b(t) \equiv 0$ and $\Omega = \mathbf{R}$).

Wave solutions with an n-dimensional phase y (as those of type (1.2)) have already been considered in the literature. For instance [A-A], [Be-L,83], [St] deal with $w(x,t) = u(x - ct)$, $x, c \in \mathbf{R}^n$ and $b(t) \equiv 0$ in (1.1). However, in [Fr-S,84], [S-F,87], and [S] a new aspect exhibited by the more general kinds of waves $u(x,t) = u(Kx - ct)$, with K an $n \times n$ matrix, $c \in \mathbf{R}^n$, was studied. Namely, the possibility of subjecting those waves to boundary conditions when they are observed in bounded domains $\Omega \subset \mathbf{R}^n$. In those references, boundary conditions of Dirichlet and Neumann type were defined on a certain piece Γ of the boundary $\partial\Omega$ and the bifurcation properties and asymptotic behaviour of the corresponding problems were analyzed under the assumptions $b(t) \equiv 0$ or $b(t) = \textit{constant}$. It should be remarked that such boundary value problems (BVPs) lead to the analysis of semilinear elliptic BVPs in cylindrical domains of $\mathbf{R}^n$ (the unboundedness being caused by the condition $t \in \mathbf{R}$). In the context of waves such types of cylindrical BVPs have been considered in [G] and more recently in [V] and [Ca-M-S].

In the present work the compatibility of the waves (1.2), $w(x,t) = u(x - c(t))$, with certain kinds of boundary conditions defined in bounded domains Ω is studied. However, such boundary conditions will be defined in a time T-periodic varying piece Γ_t of the boundary $\partial\Omega$, and the corresponding BVPs will be lead again to semilinear elliptic BVPs in bounded domains Ω_ω for the phase $y = x - c(t)$, rather than in cylindrical ones. Notice that the T-periodicity is an intrinsic property of $w(x,t)$ in (1.2). As for the applications, it should be remarked that the study of waves (1.2) under periodic convection has been suggested by several reaction–diffusion models related to respiratory phenomena occurring in living beings (see [B], [N-N-B], [Sh-A-S]). Specifically, the reacting substances (hemoglobin and hemoglobin compounds) are periodically pumped into the chemical reactor (the lungs' capillarities) in the model considered in [Sh-A-S]. Fluid dynamics and combustion theory also provide a natural source of models where the waves of type (1.2) under periodic convection could be observed [Li].

The organization of the material and the main results in the work are now described. The study of the boundary conditions to be imposed to the waves $w(x,t)$ is performed in §2. This study entails a careful analysis of the geometry of the boundary $\partial\Omega_\omega$ of the domain $\Omega_\omega = \{y = x - c(t)/x \in \Omega, t \in \mathbf{R}\}$ of the phase y to connect $\partial\Omega_\omega$ with a periodic region $\Gamma_t \subset \partial\Omega$. Precise conditions to determine Γ_t are also given in §2. The homogeneous Dirichlet conditions are introduced in §2.2 and the corresponding BVP for the waves (1.2) to equation (1.1) is stated there as follows:

$$\text{(DW)} \qquad \begin{cases} \frac{\partial w}{\partial t} = \Delta w + b(t)\nabla w + f(w), & (x,t) \in \Omega \times \mathbf{R}, \\ w(x,t) = u(x - c(t)), & \\ w(x,t) = 0, & t \in \mathbf{R}, x \in \Gamma_t. \end{cases}$$

In this work the existence and other qualitative properties of positive solutions $w = w(x,t)$ to (DW) are studied in detail. It is important to remark that the analysis of (DW) leads to the following semilinear elliptic problem:

$$\text{(D)} \qquad \begin{cases} \Delta u + \mu\nabla u + f(u) = 0 & \text{in } G, \\ u = 0 & \text{on } \partial G, \end{cases}$$

where $u(y)$ is the wave $w(x,t)$ observed in the phase y, $G = \Omega_\omega$ (the domain of the phase), and $\mu = \frac{1}{T}\int_0^T b(\sigma)\, d\sigma$. Thus, the results in this work are also concerned with the existence of positive solutions to (D) and its bifurcation properties regarding μ and the domain G.

An important role in the work is played by the one-dimensional version of (DW), which is introduced in §2.2 and leads to the one-dimensional version of (D)

$$\text{(D)}_1 \qquad \begin{cases} u_{yy} + \mu u_y + f(u) = 0, & y \in (-b, b), \\ u(-b) = u(b) = 0. \end{cases}$$

The main results of the paper are concerned with the one-dimensional Dirichlet problem for waves $w(x,t)$ and will be summarized below. Observe that the equation in (D)_1 is that satisfied by the travelling wave solutions $u(x,t) = u(x - \mu t)$ to semilinear diffusion equations of the form

$$\text{(1.3)} \qquad \frac{\partial u}{\partial t} = u_{xx} + f(u).$$

Therefore part of the results in this paper give existence and other qualitative properties of travelling waves to equation (1.3).

The statements of the results, the definitions to be used, and the class of nonlinearities to be considered are given in §3. Regarding $f = f(u)$ we will assume that $f(u) < 0$ for u greater than certain u_o. In addition we assume the positivity of $\int_0^u f(s)\, ds$ for certain $u = u_1 > 0$. However we should remark that $f(u)$ will be allowed to have infinitely many zeros in $u > 0$. The main features concerning the n-dimensional (DW) can be described as follows. (DW) does not admit positive solutions in any bounded domain Ω provided $|\mu|$ is greater than a certain positive value μ_1, which only depends on the nonlinearity f. On the other hand, it is possible to find domains Ω where (DW) exhibits positive solutions, provided $|\mu|$ is not too large. These facts motivate the introduction of the parameter μ_o which is the largest $|\mu|$ so that (DW) has a positive solution $w(x,t)$ in some domain Ω. The precise expression for μ_1, the positivity of μ_o, as well as an optimum a priori estimate for all positive solutions to (DW) are stated in Theorem 1, whose proof is postponed until §4.

The main results of the work focus on giving a geometrical interpretation of the value μ_o. This is done for the one-dimensional (DW). First, μ_o is identified as the propagation velocity of a monotone travelling wave when $f(u)$ is the logistic or the bistable nonlinearity (see Theorem 2). Actually, this result remains valid if the nonlinearity $f(u)$ exhibits a finite number of zeros. However, this is no longer true for general nonlinearities $f(u)$, in particular if $f(u)$ exhibits infinitely many zeros. Therefore, objects more general than monotone travelling waves must be introduced for describing μ_o. In Definition 2 of §3, the required generalization of travelling waves, the monotone chains of travelling waves, is presented. In the main result of the work, Theorem 3, μ_o is identified as the propagation velocity of a monotone chain to (1.3), which could connect infinitely many zeros of $f(u)$. Properties of continuity and monotonicity of monotone chains are stated in Theorem 4. The proof of Theorem 3 is based upon phase space analysis and the strategy consists of two steps. First, we study the one-dimensional (DW) when $\mu = 0$. Then we study the perturbation of this problem to positive values of μ, $0 < \mu < \mu_o$. Regarding the first step, existence and multiplicity results of solutions to (DW) are contained in Theorem 5. To describe the structure of the set of solutions to (D), with $\mu = 0$, it is also important to take into account certain distinguished zeros for $f(u)$, which are defined here as *critical* zeros (see Definition 3), together with their associate invariant stable and unstable manifolds (see Definition 5). That kind of zero, when isolated, coincides with the standard saddle points (see [C-H]). As for the second step, a study of the perturbation of those manifolds is required to analyze the existence of solutions to (D) for $0 < \mu < \mu_o$. The precise concept of perturbation needed for the work is introduced in Definition 6. Actually, the properties of perturbation of the unstable manifolds of critical zeros are the required information for the existence of solutions to (D), $\mu > 0$. However, the perturbation of stable manifolds is considered here for the sake of completeness. In fact, a sharp version of a well-known result due to Kannel (see [F]) concerning the perturbability and monotonicity of invariant manifolds is presented (see Proposition 1 and Lemma 3). The main technical results for the proof of Theorem 3 show the relation between the existence of solutions to (D), the perturbability of unstable manifolds, and the formation of monotone chains. Roughly speaking, it is shown that the progressive loss of solutions to (D) when $\mu > 0$ increases (see Propositions 3 and 4) is caused by the monotone chains generated by perturbation of unstable manifolds in the presence of infinitely many zeros for $f(u)$. On the other hand, a characterization of perturbability of unstable manifolds is given in Proposition 2 (Examples 3.1 and 5.1 furnish situations of nonperturbability). The proofs of Theorems 3 and 4 are contained in §6. A preliminary version of these theorems without proofs was presented in [S-F,89].

2. Boundary value conditions for the undulatory solutions.

2.1. The domain of the phase: Structure and smoothness properties. Let us begin with finding out the equation for classical solutions to (1.1) with the form (1.2), i.e., $w(x,t) = u(x - c(t)) = u(y)$. Since it will always be assumed in this work that $b = b(t)$ is continuous and $b(t+T) = b(t)$ for all $t \in \mathbf{R}$ (T-periodicity), then $b(t)$ can be written in the form

$$b(t) = \mu + b_o(t),$$

where $\mu = \frac{1}{T}\int_0^T b(\sigma)\, d\sigma \in \mathbf{R}^n$ is the average of $b(t)$ and the average of $b_o(t)$ is zero. Thus, the waves (1.2) satisfy the equation,

$$\Delta u + (\mu + b_o(t) + c'(t))\nabla u + f(u) = 0 \tag{2.1}$$

or, equivalently,

$$\Delta u + \mu \nabla u + f(u) = 0, \tag{2.2}$$

provided that the choice $c(t) = c_o - \int_o^t b_o(\sigma)\, d\sigma$ has been made. Remark that $c(t)$ is also T-periodic and unique up to an additive constant c_o. Notice also that the existence of the waves (1.2) requires that selection of $c(t)$. In (2.1) and (2.2) derivatives are computed with regard to the phase variable y.

Now, let us study the domain of the phase of the waves. It will be assumed that the spatial variable x belongs to a bounded domain (open and connected) $\Omega \subset \mathbf{R}^n$. We are interested in *permanent* (see [F]) waves, i.e., we want $w(x,t)$ to be defined for all $x \in \Omega$ and $t \in \mathbf{R}$, as is usual in the theory of reaction–diffusion systems. Therefore, the phase $y = x - c(t)$ runs the domain

$$\Omega_\omega = \bigcup_{t \in [0,T]} \Omega_{\omega,t},$$

where $\Omega_{\omega,t} = \Omega - c(t) = \{y \in \mathbf{R}^n / \exists x \in \Omega \text{ with } y = x - c(t)\}$. On the other hand, every regular solution $u = u(y)$ to (2.2), $y \in \Omega_\omega$, defines a wave $w(x,t)$, $x \in \Omega$, $t \in \mathbf{R}$, by means of the identity $w(\cdot,t) = u_{|\Omega_\omega,t}$ ($|$ = restriction). Moreover, remark that the perturbation $u(y_o)$, $y_o \in \Omega_\omega$, propagates with T-periodicity in Ω. In fact, $x = y_o + c(t)$ is the propagation path and $c'(t)$ is the propagation velocity. This shows the undulatory and T-periodic character of the solutions $w(x,t)$ to (1.1) of type (1.2).

Now we are going to prepare the way to endow the waves (1.2), $w(x,t)$, with boundary conditions. The first step consists of finding subregions $\Gamma_t \subset \partial\Omega$ ($\partial\Omega$ the boundary of Ω) so that

$$\partial\Omega_\omega = \bigcup_{t \in [0,T]} \Gamma_t - c(t).$$

This equality must be taken as the definition of the family $\{\Gamma_t\}_{t\in[0,T]}$, which turns out to be necessarily T-periodic in t. Thus the knowledge of $\{\Gamma_t\}_{t\in[0,T]}$ permits us to define certain kinds of boundary conditions on $\Gamma_t \subset \partial\Omega$. The rule is to consider the same type of boundary condition in $\partial\Omega_\omega$ regarding the equation (2.2) (see [Fr-S,84] and [S-F,87] for related ideas).

Therefore, it is important to analyze the structure and regularity of $\partial\Omega_\omega$ and give analytical rules to determine $\{\Gamma_t\}_{t\in[0,T]}$ in $\partial\Omega$. A necessary condition for determining Γ_t, together with some basic properties of Ω_ω, are given in the next result. We recall that a bounded domain $\Omega \subset \mathbf{R}^n$ is said to be C^1 and to be located on one side of its boundary $\partial\Omega$ (see [W]) if there exists a finite open covering $\{U_i\}_{1\le i\le N}$ and a family of C^1 functions $\varphi_i : U_i \to \mathbf{R}$, $\nabla\varphi_i(x) \neq 0$ for all $x \in U_i$, such that $\Omega \cap U_i = \{x \in U_i/\varphi_i(x) < 0\}$, $\partial\Omega \cap U_i = \{x \in U_i/\varphi_i(x) = 0\}$, and $(\mathbf{R}^n\backslash\overline{\Omega}) \cap U_i = \{x \in U_i/\varphi_i(x) > 0\}$ for each $1 \le i \le N$.

LEMMA 1. *Let Ω be a bounded domain of $\mathbf{R}^n$, $b : \mathbf{R} \to \mathbf{R}^n$ a continuous T-periodic function, and $c(t)$ as introduced above. Then the following hold:*

(i) $\Omega_\omega = \cup_{t\in[0,T]} \Omega_{\omega,t}$ *is a bounded domain of* $\mathbf{R}^n$.

(ii) $\overline{\Omega}_\omega = \cup_{t\in[0,T]} \overline{\Omega}_{\omega,t}$ *($\overline{A}$ = the adherence of A).*

(iii) *A certain point $y \in \partial\Omega_\omega$ if and only if $\exists x \in \partial\Omega, \exists t \in [0,T]$ such that $y = x - c(t)$. In other words,*

$$\Gamma_t = \{x \in \partial\Omega / x - c(t) \in \partial\Omega_\omega\}$$

for each $t \in [0,T]$.

(iv) *Assume that Ω is a C^1 domain. With the notation introduced above*

$$\text{(2.3)} \qquad \textit{if a point } x \in \Gamma_t \Rightarrow \exists i \in \{1, \ldots, n\} \textit{ such that } \nabla\varphi_i(x) \cdot c'(t) = 0.$$

Remark 2.1. (a) The proof of points (i)–(iii) is straightforward and that of (iv) is standard and is not given for the sake of briefness.

(b) The structure of Γ_t could undergoe strong variations depending on the geometry of Ω. In this sense, the one-dimensional case exhibits a particular behaviour (see §2.3). The situation is better described by the following example.

Example 2.1. Let $\Omega = B_\epsilon$ be an open ball centered at $(0,0)$ with radius $\epsilon > 0$. Let us take $c(t) = (\cos t, \sin t)$. Then $\Gamma_t = \{(\epsilon\cos t, \epsilon \sin t), (-\epsilon\cos t, -\epsilon\sin t)\}$ for $0 < \epsilon \ \leq 1$ and $t \in [0, 2\pi]$. For ϵ in this range, $\Omega_\omega = B_{1+\epsilon} \backslash B_{1-\epsilon}$. Observe that a piece of $\partial\Omega_\omega$ collapses to $(0,0)$ at $\epsilon = 1$. If $\epsilon > 1$, then $\Gamma_t = \{(-\epsilon\cos t, -\epsilon\sin t)\}$ for $t \in [0, 2\pi]$ and $\Omega_\omega = B_{1+\epsilon}$.

(c) Condition (2.3) is not sufficient, in general, to ensure that an $x \in \partial\Omega$ belongs to Γ_t. For instance, Example 2.1 with $\epsilon > 1$ exhibits points in $\partial\Omega$ satisfying (2.3) and not lying in Γ_t.

In the next result, some conditions on $c(t)$ and Ω are given to show that Γ_t is characterized by (2.3). As a consequence of the proof, the smooth character of the domain Ω_ω is also shown. For the sake of simplicity, we will only consider the case where Ω is a ball in $\mathbf{R}^n$. In this case $\partial\Omega_\omega$ is the so-called tubular surface around the curve $\gamma(t) = -c(t)$ (see [Do]). However, the same study can be developed for bounded smooth enough domains $\Omega \subset \mathbf{R}^n$.

It will be assumed that $\gamma(t) = -c(t)$ defines a *Jordan* curve of class C^n such that the condition

$$\text{(2.4)} \qquad \left\{\frac{d\gamma}{dt}, \ldots, \frac{d^{n-1}\gamma}{dt^{n-1}}\right\} \text{ is linearly independent for every } t \in [0, T]$$

is satisfied. By performing the change $t \to s$, $s(t) = \int_0^t |\frac{d\gamma}{dt}|\, dt$ ($| \cdot |$ the euclidean norm, s the arc length), it is well known that (2.4) entails the existence of a mobil orthonormal reference $\Sigma_s = \{t_1(s), \ldots, t_n(s)\}$ at every point of the curve γ. Moreover, the so-called Frenet Formulae follow from (2.4), i.e.,

$$\frac{dt_i}{ds} = -k_{i-1}(s)t_{i-1}(s) + k_i(s)t_{i+1}(s), \quad 1 \leq i \ \leq n$$

where the functions $k_{-1} \equiv 0$, $k_n \equiv 0$, and the so-called curvature functions $k_1, \ldots, k_{n-1}$ are positive everywhere (see [Kl]).

LEMMA 2. *Assume that $\gamma(t) = -c(t)$ defines a Jordan curve in $\mathbf{R}^n$, $n \geq 2$, which satisfies* (2.4) *and has arc length $\Lambda > 0$. Let Ω be the open ball $B_R(O)$. Provided that the condition*

$$\text{(2.5)} \qquad |\gamma(s) - \gamma(s_o)|^2 \geq \ 2(\gamma(s) - \gamma(s_o)) \cdot \left(\sum_{i=2}^{n} \sigma_i t_i(s_o)\right)$$

holds for every $s, s_o \in [0, \Lambda)$ and $\overline{\sigma} = (\sigma_2, \ldots, \sigma_n) \in \mathbf{R}^{n-1}$ with $|\overline{\sigma}| = 1$, then, for each $R > 0$ such that $R < \inf_{[0,\Lambda]} {k_1}^{-1}(\cdot)$, the set Ω_ω is a C^1 bounded domain whose boundary is given by

$$\text{(2.6)} \qquad \partial\Omega_\omega = \left\{ y \in \mathbf{R}^n / y = \gamma(s) + \sum_{i=2}^{n} \sigma_i t_i(s), s \in [0, \Lambda), |\overline{\sigma}| = R \right\}.$$

Remark 2.2. (a) The Jordan curve hypothesis on $\gamma(t)$ is clearly needed to avoid self-intersections of $\partial\Omega_\omega$. On the other hand, it can be checked that (2.5) holds if $R < \inf_{[0,\Lambda]} {k_1}^{-1}(\cdot)$ is small enough. For a two-dimensional curve $\gamma(t)$, (2.5) means that $\gamma(t)$ does not meet any interior tangent circle with radius R except at the tangent point. For instance, if $\gamma(t) = (a\cos t, b\sin t)$ (an ellipse), (2.5) holds for $0 < R < \frac{b^2}{a}$.

(b) The estimate $0 < \min_{[0,\Lambda]} {k_1}^{-1}(\cdot)$ in Lemma 2 is optimum (recall that $\rho_1(t) = {k_1}^{-1}(t)$ is the curvature radius of $\gamma(t)$ at t, see [Do]). For instance, consider any plane Jordan curve $\gamma(t)$, $t \in [0,T]$, so that $\gamma(t) = A + r(\cos t, \sin t)$ for $0 < t_1 < t < t_2$ and certain t_1, t_2, $t_2 - t_1 = \frac{\pi}{2}$, $r > 0$ and $A = (a_1, a_2) \in \mathbf{R}^2$. Assume in addition that $\rho_1(t) > r$ for $t \notin [t_1, t_2]$ (see Fig. 1). Then for $\Omega = B_R(O)$, $R = r$, the boundary $\partial\Omega_\omega$ of Ω_ω has a *corner* point in A.

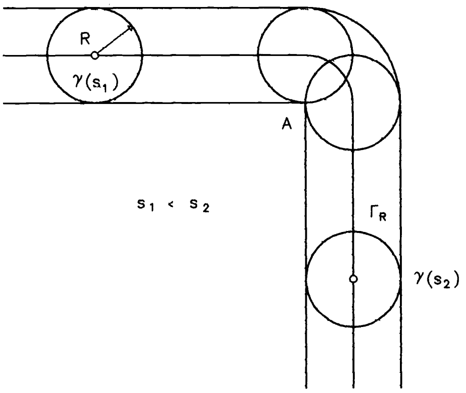

FIG. 1.

(c) We remark that under the hypotheses of Lemma 2, the sets Γ_t are characterized by the condition (2.3).

Proof of Lemma 2. First, let us prove that Ω_ω can be written as

$$\Omega_\omega = \left\{ y \in \mathbf{R}^n / y = \gamma(s) + \sum_{i=2}^{n} \sigma_i t_i(s), s \in [0,\Lambda), |\overline{\sigma}| < R \right\},$$

where $\overline{\sigma} = (\sigma_2, \dots, \sigma_n) \in \mathbf{R}^{n-1}$. In fact, it is clear that the right-hand side of the equality is contained in Ω_ω. On the other hand, if $y \in \Omega_\omega$ then $y \in B_R(\gamma(s_o))$ for some $s_o \in [0,\Lambda)$. Thus, the distance $d(y,\gamma)$ from y to the trace γ of $\gamma(s)$ satisfies $d(y,\gamma) < R$. The periodicity of $\gamma(s)$ implies that $\exists s^* \in (-\epsilon, \Lambda + \epsilon)$ such that $d(y,\gamma) = |y - \gamma(s^*)|$. Hence,

$$\frac{d}{ds}|y - \gamma(s)|^2_{s=s^*} = 0. \tag{2.7}$$

Therefore, (2.7) implies that $y - \gamma(s^*) = \sum_{i=2}^{n} \sigma_i t_i(s^*)$ for certain $\overline{\sigma} = (\sigma_2, \dots, \sigma_n)$, $|\overline{\sigma}| < R$.

Obtaining the desired expression for $\partial\Omega_\omega$ is a little more complicated. Observe that $\partial\Omega_\omega = \{y \in \mathbf{R}^2 / y = (-\cos s - \epsilon\cos s, -\sin s - \epsilon \sin s)\}$ in Example 2.1, $\epsilon > 1$. Thus $\partial\Omega_\omega$ does not agree with the expression (2.6).

If $y \in \partial\Omega_\omega$, point (ii) in Lemma 1 and the same argument employed above give $d(y,\gamma) = R$. As in (2.7), $\exists s^* \in [0,\Lambda), \overline{\sigma} \in \mathbf{R}^{n-1}$ with $|\overline{\sigma}| = R$ such that $y = \gamma(s^*) + \sum_{i=2}^{n} \sigma_i t_i(s^*)$. On the other hand, $y \in \overline{\Omega_\omega}$ provided that $y = \gamma(s^*) + \sum_{i=2}^{n} \sigma_i t_i(s^*)$

for some $s^* \in [0, \Lambda)$ and $\overline{\sigma} \in \mathbf{R}^{n-1}$, $|\overline{\sigma}| = R$. If such $y \in \Omega_\omega$ then $\exists s_o \neq s^*$ such that $y = \gamma(s_o) + \sum_{i=2}^n \sigma_i^o t_i(s_o)$ for certain $\overline{\sigma}_o = (\sigma_i^o)$, $|\overline{\sigma}_o| < R$. This implies

$$|\gamma(s^*) - \gamma(s_o)|^2 < 2(\gamma(s^*) - \gamma(s_o)) \cdot \left(\sum_{i=2}^n \sigma_i t_i(s_o) \right),$$

where $\overline{\sigma} \in \mathbf{R}^{n-1}$, $|\overline{\sigma}| = R$. This contradicts (2.5).

Let us now prove the smoothness of $\partial\Omega_\omega$. By the compacity of Ω_ω it is sufficient to find a neighbourhood $U(y_o)$ of every $y_o \in \partial\Omega_\omega$ and a C^1 function $\varphi : U(y_o) \to \mathbf{R}$ with the properties introduced just before the statement of Lemma 1. To accomplish this, for a fixed $y_o \in \partial\Omega_\omega$ let us write

$$y_o = \gamma(s_o) + \sum_{n=2}^n \sigma_i^o t_i(s_o),$$

with $\overline{\sigma}_o = (\sigma_i^o) \in B_R^{n-1}$ (B_R^{n-1} the ball with radius $R > 0$ and center O in $\mathbf{R}^{n-1}$). Define the map

$$\begin{aligned} T : (-\epsilon, \Lambda) \times B_{R-\epsilon}^{n-1} &\longrightarrow \quad \mathbf{R}^n, \\ (s, \sigma) \quad &\longrightarrow \quad y = T(s, \sigma) = \gamma(s) + \textstyle\sum_{i=2}^n \sigma_i t_i(s). \end{aligned}$$

T is locally invertible at (s_o, σ_o). In fact,

$$dT(s_o, \sigma_o) = col \left[\frac{\partial T}{\partial s}, \frac{\partial T}{\partial \sigma_2}, \dots, \frac{\partial T}{\partial \sigma_n} \right].$$

Since,

$$\begin{aligned} \frac{\partial T}{\partial s} &= (1 - \sigma_2 k_1) t_1 + \sum_{i=3}^n (\sigma_{i-1} k_{i-1} - \sigma_{i+1} k_i) t_i + \sigma_{n-1} k_{n-1} t_n, \\ \frac{\partial T}{\partial \sigma_i} &= t_i, \quad 2 \leq i \leq n, \end{aligned}$$

then

$$\left| \det col \left[\frac{\partial T}{\partial s}, \frac{\partial T}{\partial \sigma_2}, \dots, \frac{\partial T}{\partial \sigma_n} \right] \right| = (1 - \sigma_2^o k_1(s_o)) \geq \ 1 - R k_1(s_o) > 0.$$

By using the inverse function theorem, $\exists \delta > 0$ such that, if we set $V(s_o, \sigma_o) = (s_o - \delta, s_o + \delta) \times \prod_{i=2}^n (\sigma_i^o - \delta, \sigma_i^o + \delta)$, then $U(y_o) = T(V(s_o, \sigma_o))$ is a neighbourhood of y_o and $G = T^{-1}$ is a well-defined C^1 function. By writing $G(y) = (s, \sigma)$ with $s = G_1(y)$ and $\sigma = G_2(y)$, it is sufficient to define $\varphi(y) = |G_2(y)|^2 - R^2$. This completes the proof of Lemma 2. □

2.2. Boundary value conditions for the undulatory solutions. Let us now define the homogeneous Dirichlet and Neumann problems for the undulatory solutions (1.2), $w(x,t) = u(x - c(t))$, to (1.1).

A wave (1.2), $w(x,t) = u(x - c(t))$, is said to satisfy the homogeneous Dirichlet condition in the domain $\Omega \subset \mathbf{R}^n$ provided that

$$w(x,t) = 0, \quad \forall t \in \mathbf{R}, \forall x \in \Gamma_t.$$

A wave (1.2), $w(x,t) = u(x-c(t))$, satisfies the homogeneous Neumann condition in $\Omega \subset \mathbf{R}^n$ if the relation

$$\frac{\partial w}{\partial \nu}(x,t) = 0, \quad \forall t \in \mathbf{R}, \forall x \in \Gamma_t$$

holds ($\nu = \nu(x)$ stands for the exterior unit normal to $\partial\Omega$ at $x \in \partial\Omega$).

Thus, the homogeneous Dirichlet problem for the waves (1.2) is defined as

$$\text{(DW)} \qquad \begin{cases} \frac{\partial w}{\partial t} = \Delta w + b(t)\nabla w + f(w), & (x,t) \in \Omega \times \mathbf{R}, \\ w(x,t) = u(x-c(t)), & \\ w(x,t) = 0, & t \in \mathbf{R}, x \in \Gamma_t. \end{cases}$$

Similarly, the homogeneous Neumann problem for the waves (1.2) consists in solving,

$$\text{(NW)} \qquad \begin{cases} \frac{\partial w}{\partial t} = \Delta w + b(t)\nabla w + f(w), & (x,t) \in \Omega \times \mathbf{R}, \\ w(x,t) = u(x-c(t)), & \\ \frac{\partial w}{\partial \nu}(x,t) = 0, & t \in \mathbf{R}, x \in \Gamma_t. \end{cases}$$

In the present work we will restrict ourselves to analyzing positive and classical solutions to the Dirichlet problem (DW). According to §2.1 it will always be assumed that the necessary choice $c'(t) = -b_o(t)$ has been made. Therefore, it will always be assumed in the work that a wave (1.2), $w(x,t) = u(x-c(t)) = u(y)$, is a solution to (DW) if and only if $u(y)$ solves

$$\text{(D)} \qquad \begin{cases} \Delta u + \mu\nabla u + f(u) = 0, & y \in \Omega_\omega, \\ u = 0, & y \in \partial\Omega_\omega. \end{cases}$$

We should remark that a similar study could have been developed for the Neumann problem or even for another kind of homogeneous boundary condition. On the other hand, it is also possible to define and study the notion of *weak* solution (in the Sobolev spaces sense) to (DW) and (NW). However, the consideration of these facts is beyond the scope of the present work.

The main results of this paper concern the one-dimensional version of (DW). For this reason, the special features exhibited by this problem deserve a separate section.

2.3. The one-dimensional Dirichlet problem. In the one-dimensional case Ω is an open interval, $\Omega = (-a,a)$, $a > 0$. However, in general, the sets Γ_t are either empty or are $\{a\}$ or $\{-a\}$ for finitely many $t \in [0,T]$. More specifically, the constant c_o in §2.1 will always be chosen so that $M = \max_{[0,T]} -c(t) = -\min_{[0,T]} -c(t)$, $M > 0$. Observe that this choice amounts to a phase translation in $u(y)$ and the equation for $u(y)$ is invariant under phase translations. After this normalization, $\Omega_\omega = (-a-M, a+M)$ and the boundary sets are $\Gamma_t = \{-a\}$ for $t \in M_1$ and $\Gamma_t = \{a\}$ for $t \in M_2$, where $M_1 = \{t \in \mathbf{R}/c(t) = M\}$ and $M_2 = \{t \in \mathbf{R}/c(t) = -M\}$. Thus, the one-dimensional (DW) can be written as

$$\text{(DW)} \qquad \begin{cases} w_t = w_{xx} + b(t)w_x + f(w), & (x,t) \in (-a,a) \times \mathbf{R}, \\ w(x,t) = u(x-c(t)), & \\ \begin{cases} w(-a,t) = 0, & t \in M_1, \\ w(a,t) = 0, & t \in M_2. \end{cases} \end{cases}$$

The classical positive solutions to (DW) are precisely the classical solutions to the problem

$$\text{(D)}_1 \qquad \begin{cases} u_{yy} + \mu u_y + f(u) = 0, & y \in (-a,a), \\ u(\pm(a+M)) = 0, & \end{cases}$$

where $y = x - c(t)$ designates the phase. To obtain a geometrical description of the behaviour of a solution to (DW), assume that the profile of a positive solution $u(y)$ to (D) is as in Fig. 2a, being $c(t)$ as in Fig. 2b.

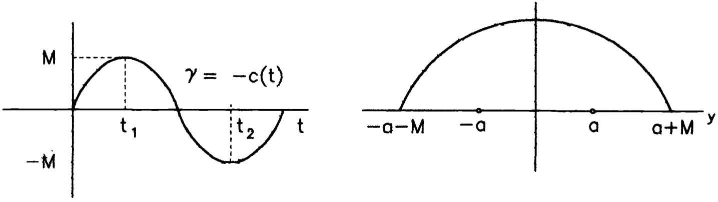

FIG. 2.

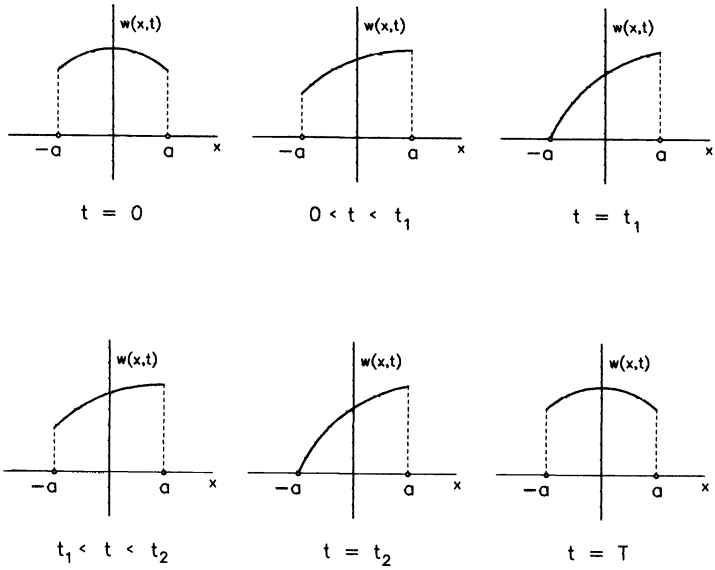
This implies that $M_i = \{t_i + kT/k \in \mathbf{Z}\}$, $i = 1, 2$. The behaviour of $w(\cdot, t)$ is given by the restriction $u(\cdot)|_{I(t)}$, where $I(t) = (-c(t) - a, c(t) + a)$. A sketch of the wave along a period $t \in [0, T]$ is given in Fig. 3.



$t = 0$ $0 < t < t_1$ $t = t_1$

$t_1 < t < t_2$ $t = t_2$ $t = T$

FIG. 3.

Remark 2.3. In the study of (DW), i.e., of $(D)_1$, it is sufficient to consider μ nonnegative. In fact, a positive $u(y)$ solves $(D)_1$ in $\Omega = (-a, a)$ with $\mu = \mu_1 < 0$, provided that $\tilde{u}(y) = u(-y)$ solves $(D)_1$ in Ω with $\mu = -\mu_1 > 0$.

3. Statement of the main results. First let us introduce the hypotheses required for the nonlinearity $f(u)$. It will always be assumed that $f : \mathbf{R} \to \mathbf{R}$ is a C^1 function that satisfies

$$(H_f) \qquad \begin{cases} \text{(i) } f(0) = 0, \\ \text{(ii) } \exists u_o > 0 \text{ such that } f(u) < 0 \text{ for } u \geq u_o, \\ \text{(iii) } \exists u_1 > 0 \text{ such that} \int_0^{u_1} f(s)\, ds > 0. \end{cases}$$

As is usual in the literature, the following functions associated with $f(u)$ will be used in the work:

$$V(u) = \int_0^u f(s)\, ds, \quad E(u, v) = \frac{1}{2}v^2 + V(u). \tag{3.1}$$

Let us also introduce two parameters associated to $f(u)$ for later reference. They are

$$V_M = \max_{[0,+\infty)} V(u) \quad \text{and} \quad u_M = \min\{u \in \mathbf{R}^+/V(u) = V_M\}.$$

Observe that $u = u_M$ is a zero of $f(u)$.

Remark 3.1. (a) The hypotheses (H_f) on $f(u)$ are usual in the literature of positive solutions to semilinear elliptic and parabolic equations. See for instance [Am], [Be-L,83], [L], [R], [Sm-W,86], [Sm-W,87]. As it will be seen later, the class of nonlinearities $f(u)$ satisfying (H_f) considerably enlarges the kind of nonlinear terms $f(u)$ considered in the theory of travelling waves to semilinear parabolic equations, as those in [Ar-W,75], [Ar-W,78], [F-M,77], [F-M,81], [F]. For later use it is worthwhile to mention two outstanding examples in that class, i.e., the *logistic* (or *Fisher's*) nonlinearity

$$f_1(u) = u(1-u),$$

and the *bistable* nonlinearity

$$f_2(u) = -u(\alpha - u)(1-u), \quad \alpha \in \left(0, \frac{1}{2}\right),$$

which have also been deeply studied in the dynamical theory of semilinear parabolic equations (see [He], [Sm]). However, in the literature of travelling waves quoted above, the discrete character of the set of zeros of $f(u)$ plays an important role. It should be remarked that (H_f) allows $f(u)$ to exhibit infinitely many zeros in the results of travelling waves to the equation

$$\frac{\partial u}{\partial t} = u_{xx} + f(u) \tag{1.3}$$

contained in this paper (see Theorem 3).

(b) The condition (i) is usual in the literature. With regard to (iii), observe that it is a necessary condition for the existence of positive solutions to the problem (D) with $\mu = 0$ and Ω_ω starshaped relative to some point. This is a consequence of the Pohozaev's identity [P]. In the one-dimensional case of (D), (iii) is still necessary even when $\mu \neq 0$.

(c) The condition (ii) is responsible for an interesting phenomenon, namely, the fact that no positive solutions to (DW) exist in *any* bounded domain Ω, provided that the average μ is larger in *modulus* than a certain critical value μ_o. We study this phenomenon extensively in this paper. It is possible, however, to have positive solutions if $|\mu|$ is small enough and Ω is conveniently large. To state these facts precisely in the next result, it is suitable to introduce the following value, associated to a bounded domain $\Omega \subset \mathbf{R}^n$:

$$\mu_o(\Omega) = \sup\left\{ r > 0 / \begin{array}{l} \text{There exists a positive solution to (DW)} \\ \text{in } \Omega \text{ for some } \mu \in \mathbf{R}^n;\ 0 \leq |\mu| \leq r \end{array} \right\}.$$

THEOREM 1. *Let $b : \mathbf{R} \to \mathbf{R}^n$ be a continuous and T-periodic function with average μ. Let us write $b(t) = \mu + b_o(t)$ and choose $c(t)$ such that $c'(t) = -b_o(t)$. Let $f(u)$ be a C^1 function satisfying* (H_f) *and assume that Ω is a bounded domain of $\mathbf{R}^n$ so that Ω_ω is a smooth enough domain. Then,*

(a) *The problem* (DW) *admits nonnegative classical solutions $w(x,t) = u(x-c(t))$ which satisfy the estimate*

$$\|w(\cdot,t)\|_{\infty,\overline{\Omega}} < u_M, \quad \forall t \in [0,T].$$

(b) *$\exists\mu_1 > 0$, μ_1 not depending on Ω, such that $\mu_o(\Omega) < \mu_1$ for every bounded domain $\Omega \subset \mathbf{R}^n$. In other words,* (DW) *does not admit positive solutions in Ω provided that $|\mu| \geq \mu_1$. Moreover,*

$$\mu_1 = \sqrt{4\left(f'(0) + \sup_{[0,u_M]} \frac{g(u)}{u}\right)},$$

where $g(u) = f(u) - f'(0)u$.

(c) *Let us keep $b_o(t)$ fixed in the expression for $b(t)$ and consider $\mu \in \mathbf{R}^n$ as a parameter. For a fixed point $x_o \in \mathbf{R}^n$ consider also the family of domains $\Omega_\lambda = x_o + \lambda(\Omega - \{x_o\})$, where $\Omega - \{x_o\} = \{x - x_o / x \in \Omega\}$ and $\lambda \in \mathbf{R}^+$. Then there exists $\overline{\lambda} > 0$ such that*

$$0 < \mu_o(\Omega_\lambda) \quad \textit{for each} \quad \lambda \geq \overline{\lambda}.$$

Moreover, for every $\lambda \geq \overline{\lambda}$, there exists $r(\lambda) > 0$ such that (DW) *admits a positive solution in Ω_λ for each $\mu \in \mathbf{R}^n$, $0 \leq |\mu| \leq r(\lambda) \leq \mu_o(\Omega_\lambda)$, and $\lambda \geq \overline{\lambda}$.*

Remark 3.2. (a) Parts (b) and (c) of Theorem 1 motivate the introduction of an important parameter for the problem (DW). In Definition 1, $b_o(t)$ is kept fixed while $\mu \in \mathbf{R}^n$ is observed as a parameter. Notice that the domain Ω_ω does not depend on μ.

DEFINITION 1. *The largest existence value μ_o for positive solutions to* (DW) *is defined as*

$$\mu_o = \sup \mu_o(\Omega), \tag{3.2}$$

where the supremum is taken over all bounded domains $\Omega \in \mathbf{R}^n$.

The condition (ii) is crucial for part (b). For instance, the problem (DW) with $f(u) = u^m$, $m \geq 1$, admits a positive solution $w(x,t)$ in a certain domain $\Omega = (-a(\mu), a(\mu))$ for each positive μ, i.e., $\mu_o = +\infty$. On the other hand, Theorem 1 holds under slight variations of (H$_f$). For instance, keep (i) and (iii) in (H$_f$), and replace (ii) by,

$$\text{(ii)}' \quad \exists u_n > u_1 > 0 \quad \text{such that} \quad f(u_n) < 0.$$

Then the conclusions of Theorem 1 hold for the solutions to (DW) which satisfy in addition $0 < w(x,t) < u_n$, $x \in \Omega$, $t \in \mathbf{R}$.

(b) μ_1 is positive. Indeed, $\varphi(u) = \frac{g(u)}{u}$ for $u \neq 0$ and $\varphi(0) = 0$ is continuous in $u \geq 0$. Since $\varphi(u_M) + f'(0) = 0$ then $\mu_1 \geq 0$, but (iii) in (H$_f$) implies the existence of $u_p \in [0, u_M]$ with $\varphi(u_p) > 0$. Thus $\mu_1 > 0$. Observe that part (b) in Theorem 1 implies that $\mu_o \leq \mu_1$, while part (c) asserts that $\mu_o > 0$. It is possible to show the equality $\mu_o = \mu_1$ in the one-dimensional (DW) with $f(u) = f_1(u)$.

In the next two results a geometrical description of the constant μ_o in (3.2) is given. The following concept is key: Assume that $f(u)$ in equation (1.3) satisfies $f(0) = f(1) = 0$. A *monotone travelling wave* (MTW) to (1.3), which *connects* the zeros $u = 1$ and $u = 0$ of $f(u)$ with *propagation velocity* $c > 0$, is a solution $w(x,t) = u(x - ct) = u(y)$ to (1.3) which satisfies

(a) $0 < u(y) < 1$, $u'(y) < 0$, $\forall y \in \mathbf{R}$,

(b) $\lim_{y \to +\infty} u(y) = 0$; $\lim_{y \to -\infty} u(y) = 1$.

For $f = f_1(u)$ a well-known result due to Kolmogoroff et al. (see [F]) ensures the existence of MTWs with propagation velocities $c \geq c_1^* > 0$ (c_1^* is the minimum propagation velocity). As for $f = f_2(u)$, the existence of MTWs with a unique propagation velocity $c_2^* > 0$ is well known (see [F-M,77]). A first result, identifying μ_o with c_1^* and c_2^* is stated now.

THEOREM 2. *Let $b : \mathbf{R} \to \mathbf{R}$, $b(t) = \mu + b_o(t)$, be a continuous and T-periodic function with average μ. Define $M = \max_{[0,T]} \int_0^t b_o(s)\,ds$.*

(A) *The problem* (DW) *with the nonlinearity $f = f_2(u)$ has the following properties:*

(a) *The constant μ_o in* (3.2) *satisfies $\mu_o = c_2^*$. For $|\mu| \geq \mu_o$ the problem* (DW) *does not admit positive solutions in any domain $\Omega = (-a, a)$.*

(b) *Let us assume that $|\mu| < \mu_o$. Then, there exists $T_o > 0$ and $a(\mu) > 0$ for each $|\mu| < \mu_o$ such that*

(i) *for $a \geq a(\mu)$ there exists at least a positive solution $w(x,t) = u(x - c(t))$ to* (DW) *in $\Omega = (-a, a)$. Moreover,*

$$\|w(\cdot,\cdot)\|_{\infty,\Omega\times\mathbf{R}} > \alpha.$$

(ii) *If $M < T_o$ then $\inf_{[0,\mu_o]} a(\mu) > 0$. Furthermore,* (DW) *does not admit positive solutions in $\Omega = (-a, a)$ provided that $0 < a < a(\mu)$.*

(B) *The problem* (DW) *with $f = f_1(u)$ has the following properties:*

(a) *The constant $\mu_o = c_1^*$. For $|\mu| \geq \mu_o$* (DW) *does not admit positive solutions in any domain $\Omega = (-a, a)$.*

(b) *Assuming that $|\mu| < \mu_o$ there exist $T_o > 0$ and $a = a(\mu) > 0$ such that*

(i) *for $a \geq a(\mu)$ there exists a unique positive solution $w(x,t) = u(x - c(t))$ to* (DW) *in $\Omega = (-a, a)$. Moreover,*

$$\lim_{a \to a(\mu)+} \|w(\cdot,\cdot)\|_{\infty,\Omega\times\mathbf{R}} = 0.$$

(ii) *if $M < T_o$ then $\inf_{[0,\mu_o]} a(\mu) > 0$. Furthermore,* (DW) *does not admit positive solutions in $\Omega = (-a, a)$ for $0 < a < a(\mu)$.*

Remark 3.3. (a) In parts (A) and (B) two different kinds of bifurcation phenomena are shown regarding the domain $(-a, a)$. In the case of $f_2(u)$, the positive waves appear spontaneously when a crosses $a(\mu)$. As for $f_1(u)$ they bifurcate from 0 at the critical value $a(\mu)$ of a.

(b) The constant μ_o has been identified in Theorem 2 as a propagation velocity in the problem (D), provided the nonlinearities are $f(u) = f_i(u)$, $i = 1, 2$. The proof is based upon phase space analysis, in which the formation of MTWs to (1.3) in the range $0 < u < 1$ plays an important role (see §6). However, when $f(u)$ is so general as in (H$_f$) the possible existence of infinitely many zeros of $f(u)$ in the interval $(0, u_M)$ could cause the appearance of complex phenomena in the structure of the MTWs to (1.3). For instance, infinitely many MTWs, connecting infinitely many zeros of $f(u)$, with the same propagation velocity c, could be exhibited by the equation (1.3) (see Example 3.1 below and Example 5.1 in §5). Therefore, to identify the constant μ_o for general $f(u)$, a convenient extension of the concept of MTW is required. That is the objective of the next definition.

DEFINITION 2. *Let*

$$\left\{ \begin{aligned} \frac{du}{dy} &= v, \\ \frac{dv}{dy} &= -cv - f(u) \end{aligned} \right. \tag{3.3}$$

be the equation of the solutions $w(x,t) = u(x - ct) = u(y)$ of (1.3), *$x, t \in \mathbf{R}$, $c \in \mathbf{R}$, and let $0 \leq u_1 < u_2 \leq u_M$ be two zeros of $f(u)$. A* chain of monotone travelling waves (CW) *to* (1.3) *which connects u_1 to u_2 with propagation velocity c is defined as a set $C(c) \subset \mathbf{R}^2$ with the following properties:*

(i) $C(c) \subset [0,+\infty) \times (-\infty, 0]$ *and* $(u_i, 0) \in C(c)$, $i = 1, 2$.

(ii) $C(c)$ *is an invariant set regarding* (3.3) *with the form*

$$C(c) = \{(u,v)/v = g(u), a \leq u \leq b\}$$

for some numbers $0 \leq a < b$ *and some continuous real function* $g(u)$ *defined in the interval* $[a, b]$.

Remark 3.4. Notice that Definition 2 is given in terms of orbits rather than solutions of (3.3). Obviously, the orbit of a MTW to (1.3) together with its α- and ω-limit sets give the simpler example of a CW. On the other hand, it is implicit in the definition that a CW consists of the union of the orbits of (possibly) infinitely many MTWs, together with their limit sets. Observe that the only possible limit set of such an MTW into a CW is $\{(z, 0)\}$ with $f(z) = 0$. Finally, standard ordinary differential equation (ODE) arguments show that $u = u_-$ and $u = u_+$ defined as

$$u_-(\text{resp., } u_+) = \min \ (\text{resp., } \max) \ C(c) \cap ([0, +\infty) \times \{0\})$$

are the *first* and the *last* zeros of $f(u)$ connected by $C(c)$ with propagation velocity c. A more complex example of a CW follows.

Example 3.1. Consider $\varphi \in C_o^\infty(\mathbf{R})$, $0 \leq \varphi(x) \leq 1$, supp $\varphi = [-\frac{1}{2}, \frac{1}{2}]$ such that $\varphi(x) = 0$ for $|x| \geq \frac{1}{2}$ and $\varphi(x) = 1$ for $|x| \leq \frac{1}{4}$. Define $f_o(u) = u(1-u)\varphi(u - \frac{1}{2})$.

By taking $f(u) = f_o(u)$ in the equation (3.3), it is known (cf. [F]) that there exists $c_o^* \geq 2\sqrt{\sup_{[0,1]} f(u)/u} \geq 0$ and an MTW connecting $(u, v) = (1, 0)$ to $(0, 0)$ with velocity c, for each $c \geq c_o^*$. On the other hand, we claim that every MTW to equation (3.3) with $f = f_o$, which connects $(1, 0)$ to $(0, 0)$ with velocity c, generates an MTW to (3.3) with $f = \epsilon^2 f_o$ exhibiting the same properties but having velocity ϵc. In fact, observe that $u(y)$ solves

$$u''(y) + cu'(y) + f_o(u(y)) = 0, \qquad \left(' = \frac{d}{dy}\right),$$

provided that $U(z) = u(\epsilon z)$ solves

$$U''(z) + c^* U'(z) + \epsilon^2 f_o(U(z)) = 0, \qquad \left(' = \frac{d}{dz}\right),$$

with $c^* = \epsilon c$.

By using this remark, it is possible to build up nonlinearities $f(u)$ that exhibit interesting CW connections. In fact, let $\{\epsilon_n\}_{n \geq 1}$ be a positive decreasing sequence such that $\sum_{n=1}^\infty \epsilon_n < +\infty$. Let us choose $\epsilon_1 = 1$ and define $\{u_n\}_{n \geq 0}$ as follows: $u_o = 0$, $u_n = u_{n-1} + \epsilon_n$, $n \in \mathbf{N}$. Define $u_\infty = \sum_{n=1}^\infty \epsilon_n$. Observe that $\lim u_n = u_\infty$.

Let us define

$$f_n(u) = f_o\left(\frac{u - u_{n-1}}{u_n - u_{n-1}}\right), \quad n \in \mathbf{N}.$$

Observe that supp $f_n = [u_{n-1}, u_n]$. Finally, let us introduce

$$f(u) = \sum_{n=1}^\infty \epsilon_n^2 f_n(u).$$

First, observe that $f \in C_o^1(\mathbf{R})$. Its first zero with maximum energy is $u_M = u_\infty$ (see (3.1)). On the other hand, for each pair of points $(u_n, 0)$ and $(u_{n-1}, 0)$ the equation (3.3) with $f(u)$ exhibits MTWs connecting them with propagation velocities c, for each $c \geq \mu_n = \epsilon_n c_o^*$. On the other hand $\lim \epsilon_n = 0$. Therefore, for each fixed $c > 0$ there exists a CW, $C(c)$, connecting $u_+(c) = u_\infty$ to $u_-(c) = \inf\{u_m/c \geq \epsilon_m c_o^*;\ m \geq\ 1\}$. Notice that $C(c)$ also contains the orbits of all those MTWs quoted above, which exist provided $c \geq \epsilon_n c_o^*$. Finally, the zero $u_-(c)$ is nonincreasing regarding c. For $c \geq \max\{\epsilon_n c_o^*\}$ there exists a CW, $C(c)$, connecting $u_+(c) = u_\infty$ to $u_-(c) = 0$ and all the zeros of $f(u)$ in the interval $[0, u_\infty]$ (see Fig. 4).

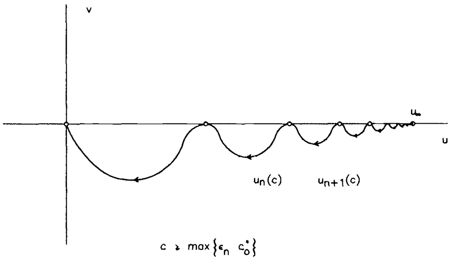


FIG. 4.

Another interesting example of CW is given in §5 (see Example 5.1).

With the concept of a CW in mind, it is already possible to furnish an interpretation of the constant μ_o associated to (DW) for general nonlinearities. In this sense, Theorem 2 is sharpened in the next result.

THEOREM 3. *Assume that $f(u)$ is a C^1 function satisfying* (H_f). *Consider the largest existence value μ_o associated to the problem* (DW). *Then the following alternatives hold:*

(i) *Either equation* (1.3) *exhibits a CW, $C(c)$, which connects a zero $u = u_+$ of $f(u)$, $u_+ \in\ [0, u_M]$, to the zero $u_- = 0$ with propagation velocity $c = \mu_o$, or*

(ii) *equation* (1.3) *exhibits a sequence $\{C_n(c_n)\}$ of CWs such that* (a) *$C_n(c_n)$ connects a pair of zeros of $f(u)$, $u_- = u_n^- < u_+ = u_n^+$; $u_n^-, u_n^+ \in\ [0, u_M]$,* (b) *the sequences $\{u_n^-\}$ and $\{u_n^+\}$ are decreasing and* $\lim u_n^- = 0$, *and* (c) *the propagation velocities sequence $\{c_n\}$ is increasing and* $\lim c_n = \mu_o$.

Some additional uniqueness and monotonicity properties of the CWs are given in the next result. The following convention will be used. It is said that two CWs to (1.3) satisfy $C \leq C'$ if $\forall (u, v') \in C'$ such that $\exists v \leq 0$ with $(u, v) \in C$ then $v \leq v'$. If $C \leq C'$ and $v < v'$ for some pair $(u, v) \in C$, $(u, v') \in C'$ we will put $C < C'$.

THEOREM 4. *Assume that the function $f(u)$ in equation* (3.3) *is of class C^1. Then,*

(i) *if $u_1 < u_2$ are two zeros of $f(u)$ in $[0, \infty)$ then, for every $c \geq 0$, there exists at most a unique CW, $C(c)$, connecting u_1 to u_2;*

(ii) *if $C(c)$ and $C'(c')$ are two CWs to equation* (1.3) *with velocities $c < c'$, then $C(c) < C'(c')$ provided that their last zeros satisfy $u_+(c') \leq\ u_+(c)$.*

Finally, let us introduce some results describing qualitative properties about the one-dimensional (DW) with zero average $\mu = 0$. The results are, to some extent, a partial continuation to general $f(u)$ of those contained in Theorem 2. However, the study of the same properties for μ positive is beyond the objectives of this work.

To state the next result, it is convenient to mention a few facts concerning the problem (DW) with $\mu = 0$. In this case, the equation in $(D)_1$,

$$u''(y) + f(u(y)) = 0,$$

is conservative. In fact, every solution $w(x, t) = u(x - c(t)) = u(y)$ to (DW) with $\mu = 0$ makes constant the energy $E(u, v)$ (see (3.1)), i.e., $E(u(\cdot), u'(\cdot)) \equiv \beta$. However, not all values of β are energy values of solutions to (DW). For instance, such values β

must belong to $[0, V_M)$ (see §4). On the other hand, a number $\alpha \in [0, V_M)$ could not be the energy of any solution to (DW). These are just the values introduced in the next definition.

DEFINITION 3. *A number $\alpha \in [0, V_M)$ is said to be a* critical value *for the energy $V(u) = \int_0^u f(s)\, ds$ if the number,*

$$u_\alpha = \min\{u/u > 0, V(u) = \alpha\}$$

is a zero of $f(u)$, i.e., $f(u_\alpha) = 0$. We will also say that u_α is the critical zero *associated to α.*

The set of critical values associated to certain f will be designated by Φ. Thus, the information about the solvability of (DW) is contained in $[0, V_M) - \Phi$. The structure of $[0, V_M) - \Phi$ and other features about (DW) are discussed in the next result.

THEOREM 5. *Assume that $f = f(u)$ satisfies* (H_f) *and $b : \mathbf{R} \to \mathbf{R}$ is continuous, T-periodic, and has average $\mu = 0$. Then,*

(i) *if $\alpha \in [0, V_M)$ is a critical value of $V(u)$ then there exist no solutions to* (DW) *in any domain $\Omega = (-a, a)$ satisfying $E \equiv \alpha$.*

(ii) *let $\Phi \subset [0, V_M)$ be the set of critical values of $V(u)$. Then $[0, V_M) - \Phi$ can be written as the union of a countable family of disjoint open intervals $I_n = (\alpha_n^-, \alpha_n^+)$, i.e.,*

$$[0, V_M) - \Phi = \bigcup_{n \in \mathbf{N}} I_n.$$

(iii) *assume that there are infinitely many intervals in statement (ii) and set $M = \max_{[0,T]} \int_0^u b(s)\, ds$. Then, there exist $T_o > 0$ and a sequence $\{a_n\}$, $a_n \geq 0$, such that*

(a) *the problem* (DW) *admits a positive solution in a domain $\Omega = (-a, a)$, $a > 0$, provided that there exists $n \in \mathbf{N}$ such that $a \geq a_n$.*

(b) *if $M < T_o$ then $a_n > 0$ for every $n \in \mathbf{N}$, and the number $a_o \doteq \inf\{a_n\}$ is positive. Moreover,* (DW) *does not admit positive solutions in a domain $\Omega = (-a, a)$ when $0 < a < a_o$.*

(c) $\forall N \in \mathbf{N}, \exists a(N) > 0$ *such that* (DW) *admits at least N positive solutions in a domain $\Omega = (-a, a)$ for every $a > a(N)$.*

4. The n-dimensional case: The proofs of Theorems 1 and 5.

Proof of Theorem 1. Let us begin with part (a). First, recall the equivalence between (DW) and (D). From part (ii) of $\overline{(\mathrm{H})_f}$, a direct computation implies that every positive solution $u \in C^2(\Omega_\omega) \cap C^o(\overline{\Omega_\omega})$ to (D) satisfies the estimate

$$0 \leq u(y) \leq u_o \quad \forall y \in \Omega_\omega. \tag{4.1}$$

Since $\varphi = 0$ and $\psi = u_o$ are, respectively, lower and upper solutions to (D), the existence of two nonnegative weak solutions $0 \leq \overline{u}(y) \leq \tilde{u}(y) \leq u_o$, $y \in \Omega_\omega$, follows from Theorem 9.4 in [Am]. Moreover, $\overline{u}$ and $\tilde{u}$ are, respectively, the minimal and the maximal nonnegative solutions to (D). From that inequality, the smoothness of the nonnegative solutions up to the boundary of Ω_ω follows from a well-known bootstrap argument (see [Am], [R]) provided $\partial\Omega_\omega$ is of class $C^{2+\alpha}$, $\alpha \in [0, 1)$. Since it could happen that $\overline{u}(y) = \tilde{u}(y) = 0$, $\forall y \in \Omega_\omega$, the existence of positive solutions will be studied later.

To prove the estimate by $u = u_M$, the first zero of $f(u)$ maximizing the energy

$V(u)$, consider first the one-dimensional case of (D)

$$(D)_1 \qquad \begin{cases} u_{yy} + \mu u_y + f(u) = 0, & y \in (-b,b), \\ u(\pm b) = 0. \end{cases}$$

If $u(y)$ is a positive solution to (D)$_1$ then $(u(y),v(y)) = (u(y),u_y(y))$ solves (3.3) and (i) $u(y) \geq 0, |y| \leq b$, (ii) $(u(\pm b),v(\pm b)) = (0,v_{\mp})$, $v_- < 0$, $v_+ > 0$. Assume, by contradiction, that $u_m \doteq \max_{|y|\leq b} u(y) \geq u_M$. Then $(u(y_o),v(y_o)) = (u_m,0)$ for a certain $y_o \in (-b,b)$. Since $(u_M,0)$ is a critical point to (3.3) then, by uniqueness, $u_M < u_m$. In addition, since $\frac{dE}{dy} = -\mu v^2(y)$, the function $E(y) = E(u(y),v(y))$ (see (3.1)) decreases. Thus, $u(y_1) = u_M$ and $v(y_1) < 0$ for a certain $y_1 \in (y_o,b)$. However, $E(y_o) = V(u_m) \leq V(u_M) = V_M < E(y_1)$, which is a contradiction. Therefore, $|u(y)| < u_M$ $\forall y \in (-b,b)$ for every positive solution to (D)$_1$.

For the proof of the estimate in the n-dimensional case, consider the special solutions to (2.2), $u_+(y) = u(k\cdot(y-y_o)) = u(\theta)$, $k \in \mathbf{R}^n$, $|k|=1$, defined in the ball $B_R(y_o)$. $u(\theta)$ solves

$$u_{\theta\theta} + f(u) = 0, \quad \theta \in (-R,R), \tag{4.2}$$

provided $k\cdot\mu = 0$. Take $y_o \in \mathbf{R}^N$ and $R_o > 0$ so large that $\Omega_\omega \subset B_R(y_o)$. As it will be seen in the proof of Theorem 5, there exists $R \geq R_o$ such that a positive solution $u_R(\theta)$ to (4.2) exists in $(-R,R)$ and satisfies $u_R(\pm R) = 0$. Therefore, $u_+(y) = u_R R.(y-y_o)$ is an upper solution to (D). If $u(y)$ is a positive solution to (D), the previous one-dimensional estimate for $u_R(\theta)$ gives $0 \leq u(y) \leq u_+(y) < u_M, \forall y \in \Omega_\omega$, as wished.

Let us now prove part (b). The problem (D) can be written in the form,

$$\begin{cases} -\Delta v + \left(\frac{|\mu|^2}{4} - f'(0) - g(y,v,\mu)\right) v = 0 & \text{in } \Omega_\omega, \\ v = 0 & \text{on } \partial\Omega_\omega, \end{cases} \tag{4.3}$$

where $v(y) = e^{\frac{\mu y}{2}} u(y)$, $g(v) = f(v) - f'(0)v$, so $g(v) = o(v)$ as $v \to 0$, and $g(y,v,\mu) = e^{\frac{\mu y}{2}} g(e^{-\frac{\mu y}{2}} v)/v$. Assume that $u(y)$ is a nonnegative solution to (D). Since the estimate in part (a) holds we obtain

$$\left(\frac{|\mu|^2}{4} - f'(0) - \sup_{[0,u_M]} \frac{g(v)}{v}\right) \leq \left(\frac{|\mu|^2}{4} - f'(0) - g(y,v,\mu)\right), \tag{4.4}$$

for each $y \in \Omega_\omega$. Hence, via the maximum principle and (4.4), the unique nonnegative solution to (4.3) is $v \equiv 0$, provided that the following inequality holds:

$$|\mu| \geq \mu_1 \doteq \sqrt{4\left(f'(0) + \sup_{[0,u_M]} \frac{g(v)}{v}\right)}.$$

Therefore, the same conclusion holds for $u(y)$.

Finally, let us show part (c). To begin with, consider the case $f'(0) > 0$. As usual, define $\lambda_1(Q)$ as the principal eigenvalue of $-\Delta$ subject to homogeneous Dirichlet conditions in the bounded domain $Q \subset \mathbf{R}^n$. Designate by $\varphi_1(\cdot,Q)$ the positive associated eigenfunction. By using $\epsilon\varphi_1(y,\Omega_\omega)$, $\epsilon > 0$ conveniently small, as a lower solution to (4.3) (see [Am]), it is seen that the inequality

$$0 < \lambda_1(\Omega_\omega) < \left(f'(0) - \frac{|\mu|^2}{4}\right) \tag{4.5}$$

provides a sufficient condition for the existence of positive solutions both to (4.3) and (D), when $|\mu| < \sqrt{4f'(0)}$. Since $\sup_{[0,u_M]}\frac{g(u)}{u} \geq 0$ observe that $\sqrt{4f'(0)} \leq \mu_1$.

Consider now the problem (D) in the domains $\Omega_\lambda = \lambda\Omega$, $\lambda > 0$, and set $(\Omega_\lambda)_\omega = \bigcup_{[0,T]} \Omega_\lambda - c(t)$. Then $\Omega_\lambda \subset (\Omega_\lambda)_\omega$ so $0 < \lambda_1((\Omega_\lambda)_\omega) < \lambda_1(\Omega_\lambda)$. Since $\lambda_1(\Omega_\lambda) = \frac{\lambda_1(\Omega)}{\lambda^2}$ then (DW) admits positive solutions in Ω_λ provided that

$$\lambda \geq \sqrt{4\frac{\lambda_1(\Omega)}{(4f'(0) - |\mu|^2)}}$$

and $0 < |\mu| < \sqrt{4f'(0)}$. To obtain the desired result it is sufficient to take $\bar{\lambda} = \sqrt{\lambda_1(\Omega)/f'(0)}$ and $r(\lambda) = \sqrt{4(f'(0) - \lambda_1(\Omega))/\lambda^2}$.

As for the case when $f'(0) \leq 0$ let us introduce the auxiliary problem

$$\text{(4.6)} \qquad \begin{cases} -\Delta u + \lambda^2 \frac{|\mu|^2}{4} u = \lambda^2 \tilde{f}(y, \mu, u) & \text{in } Q \\ u = 0 & \text{on } \partial Q, \end{cases}$$

where $Q \subset \mathbf{R}^n$ is certain domain, $\tilde{f}(y,\mu,u) = e^{\frac{\mu y}{2}} \tilde{f}(e^{-\frac{\mu y}{2}} u)$, and the C^1 function $\tilde{f} = f$ in $[0, u_M]$ while $\tilde{f} \equiv 0$ outside $(-\epsilon, u_M + \epsilon)$, $\epsilon > 0$, and $\tilde{f} \geq 0$ for $u \leq 0$. Note that from the estimate in part (a), (4.6) is equivalent to (4.3) and hence to the problem (D), provided $\lambda = 1$ and $Q = \Omega_\omega$.

We claim the existence of $\bar{\lambda} > 0$ and $0 < r(\lambda) < \mu_1$ for each $\lambda \geq \bar{\lambda}$ such that (4.6) admits a positive solution $u_o(y, \lambda, \mu)$ in Q provided that $|\mu| \leq r(\lambda)$. The conclusion in part (c) follows from this claim as it is shown now. In fact, assume without loss of generality that $0 \in \Omega$ and choose $Q = B_\delta(0) \subset \Omega$. Then $Q_\lambda = B_{\lambda\delta}(0) \subset \Omega_\lambda \subset (\Omega_\lambda)_\omega$ for each $\lambda \geq \bar{\lambda}$. On the other hand, observe that $\tilde{u}_o(y, \lambda, \mu) \doteq u_o(\frac{y}{\lambda}, \lambda, \mu)$ solves $(4.6)_{\lambda=1}$ in $Q_\lambda = B_{\lambda\delta}(0)$ and, from Hopf's maximum principle $\frac{\partial \tilde{u}_o}{\partial \rho} < 0$ at $\rho = \lambda\delta$. This fact and Theorem II.3 in [Be-L,80] allow us to assert that the continuous function

$$u_{o,-}(y) = \begin{cases} \tilde{u}_o(y, \lambda, \mu), & y \in B_{\lambda\delta}(0), \\ 0, & y \in (\Omega_\lambda)_\omega - B_{\lambda\delta}(0) \end{cases}$$

defines a nonnegative lower solution to $(4.6)_{\lambda=1}$ in the domain $(\Omega_\lambda)_\omega$. Therefore, (D) admits a positive solution in $(\Omega_\lambda)_\omega$ for each $\lambda \geq \bar{\lambda}$ and $|\mu| \leq r(\lambda)$, as wished.

Finally let us prove the claim. The essential ideas in the variational argument employed are similar to those in [R], therefore the details will be omitted. Consider the problem

$$\text{(4.7)} \qquad \operatorname{minimize}_{u \in W_o^{1,2}(Q)} \Phi(\lambda, \mu, u),$$

where

$$\begin{aligned} \Phi(\lambda,\mu,u) &= \frac{1}{2}\int_Q \left\{ |\nabla u|^2 + \lambda^2 \frac{|\mu|^2}{4} u^2 \right\} dy - \lambda^2 \int_Q \tilde{V}(y, \mu, u)\, dy \\ &\doteq \Phi_1(\lambda, \mu, u) - \lambda^2 \Phi_2(\mu, u), \quad \lambda > 0, \ |\mu| \leq \mu_1, \end{aligned}$$

and where $\tilde{V}(y,\mu,u) = \int_0^u \tilde{f}(y,\mu,s)\, ds$. Now, assuming that $Q \subset \mathbf{R}^n$, $n \geq 3$, then Φ_2 is weakly continuous in $W_o^{1,2}(Q)$, while Φ_1 is always weakly lower semicontinuous in $W_o^{1,2}(Q)$ (see Chapter 4 in [C-H]). On the other hand, positive constants K_2 and K_3 exist such that $\Phi_1(\lambda, \mu, u) \geq K_2 |u|^2_{W_o^{1,2}(Q)}$ and $|\Phi_2(\mu, u)| \leq |u|_{W_o^{1,2}(Q)}$ for each

$u \in W_o^{1,2}(Q)$. Therefore, (4.7) is equivalent to

$$\text{minimize}_{|u|_{W_o^{1,2}(Q)} \leq R}\ \Phi(\lambda, \mu, u), \tag{4.8}$$

for a certain $R > 0$ ($|\mu| \leq \mu_1$). Thus, classical variational arguments [R] imply the existence of a solution $u_o(y, \lambda, \mu)$ to (4.8), which is also a weak solution to (4.6). Actually, by a bootstrap argument and the estimate in part (a), $u_o(y, \lambda, \mu)$ is a classical solution to (4.7). The choice of $\tilde{f}(u)$ together with the maximum principle imply that $u_o(y, \lambda, \mu) \geq 0$ in Q. On the other hand, it is possible to construct a function $\varphi \in W_o^{1,2}(Q)$, $|u|_{W_o^{1,2}(Q)} \leq R$ such that $\Phi_2(0, \varphi) > 0$ (see Theorem 1.13 in [R]). Thus, there exist $\bar{\lambda} > 0$ and $0 < r(\lambda) < \mu_1$ for each $\lambda \geq \bar{\lambda}$, such that $\Phi(\lambda, \mu, \varphi) < 0$ for $|\mu| \leq r(\lambda)$. Therefore the solution $u_o(y, \lambda, \mu)$ to (4.7) is positive in this range of the parameters. Finally, see [Ab-R] for the details of the proof of the case $n = 2$. □

Proof of Theorem 5. First, let us prove (i). If $w(x,t) = u(x - c(t)) = u(y)$ solves (DW) and it is positive in $\Omega = (-a, a)$, then $(u, v) = (u(y), u_y(y))$ is a solution to equation (3.3) with $c = 0$. Moreover, $u(\pm a \pm M) = 0$, $0 < u(y) < u_M$ for $|y| < M + a$, and the orbit Γ of $(u(y), v(y))$ meets $\{u > 0\}$ in a unique point $(u_o, 0)$. Thus, $E(u(\cdot), v(\cdot)) \equiv V(u_o)$ which implies $u_o = \min\{u > 0 / V(u) = V(u_o)\}$ and

$$a + M = \int_0^{u_o} \frac{du}{\sqrt{2(V(u_o) - V(u))}}. \tag{4.9}$$

If $V(u_o) = \alpha$ were critical then $f(u_o) = 0$. Since f is C^1 this would imply that the integral in (4.9) diverges, which is not possible.

As for (ii), note that $\Phi \subset \{V(u)/V'(u) = 0\}$ and then Sard's theorem implies that the Lebesgue measure $|\Phi| = 0$. Thus, $[0, V_M] \backslash \Phi$ is nonempty. Moreover, as a consequence of the continuous dependence of solutions to $(3.3)_{c=0}$ on initial conditions and parameters, $(0, V_M) \backslash \Phi$ is open. Thus, well-known topological properties of the real line $\mathbf{R}$ imply that $(0, V_M) \backslash \Phi$ has a countable quantity of connected pieces $\{I_n\}$, $I_n = (\alpha_n^-, \alpha_n^+)$, i.e., $(0, V_M) \backslash \Phi = \cup\, I_n$. Moreover, Sard's theorem again implies that $\Phi = \overline{\{\alpha_n^\pm\}}$.

To prove point (iii) it is necessary to introduce $u_n^\pm$ as u_n^-(resp. u_n^+) = max (resp., min)$\{u/V(u) = \alpha_n^-(\text{r. } \alpha_n^+)\}$. For $\alpha \in (\alpha_n^-, \alpha_n^+)$ the solution to $(3.3)_{c=0}$ starting at $(u(0), v(0)) = (0, \sqrt{2\alpha})$ reaches, at first time, the negative semiaxis $\{v < 0\}$ in finite time $y = T(\alpha)$. Previously, its orbit Γ_α meets $\{u > 0\}$ at $(u, v) = (u(\alpha), 0)$ with $V(u(\alpha)) = \alpha$ (see Fig. 5). Thus

$$T(\alpha) = 2 \int_0^{u(\alpha)} \frac{ds}{\sqrt{2(\alpha - V(u))}}\ ds.$$

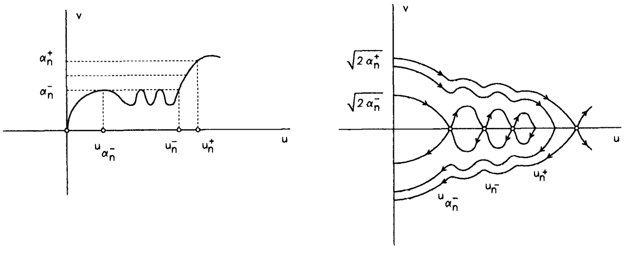

FIG. 5.

Therefore $w(x,t) = u(x - c(t))$ is a positive solution to (DW) in $\Omega = (-a,a)$ where $a = \frac{T(\alpha)}{2} - M$ and $M = \max \int_0^{\cdot} b(s)\,ds$. Since $T(\alpha) > 0$ for $\alpha \in (\alpha_n^-, \alpha_n^+)$ and $\lim_{\alpha \to \alpha_n^- +} T(\alpha) = \lim_{\alpha \to \alpha_n^+ -} T(\alpha) = +\infty$, the continuity of $T(\alpha)$ implies that $T_n \doteq \min_{\alpha \in (\alpha_n^-, \alpha_n^+)} T(\alpha) > 0$. This implies that (DW) has at least two positive solutions in $\Omega = (-a,a)$ provided $a > a_n \doteq \max\{0, \frac{T_n}{2} - M\}$.

We claim now that $T_o = \inf T_n > 0$. That fact will imply $\inf a_n > 0$ provided $T_o > M$, as desired. To prove the claim, write $T_n = T(V(\tilde{u}_n))$ for some $\tilde{u}_n \in (u_n^-, u_n^+)$ and set $\tilde{u} = \lim\ \inf \tilde{u}_n \geq 0$. Assume, by contradiction, that $T_o = 0$. We claim that $\tilde{u} = 0$. Otherwise,

$$\lim \int_0^{\tilde{u}_{n_1}} \frac{ds}{\sqrt{2(V(\tilde{u}_{n_1}) - V(s))}} = 0, \tag{4.10}$$

for a certain subsequence $\{\tilde{u}_{n_1}\}$ of $\{\tilde{u}_n\}$, with $\lim \tilde{u}_{n_1} = 0$. On the other hand,

$$\int_0^{\tilde{u}_n} \frac{ds}{\sqrt{2(V(\tilde{u}_n) - V(s))}} \geq \sqrt{\frac{\tilde{u}_n^2}{2V(\tilde{u}_n)}} > 0, \quad \forall n \in \mathbf{N}.$$

However, 0 accumulates zeros of $f(u)$ and then $\lim_{u \to 0+} \frac{V(u)}{u^2} = 0$. This contradicts (4.10) and the claim is proved. On the other hand, since $\tilde{u} > 0$ we arrive at

$$\int_0^{\tilde{u}} \frac{ds}{\sqrt{2(V(\tilde{u}) - V(s))}} = 0.$$

This fact together with $V(u) < V(\tilde{u})$ for $u \in (0, \tilde{u}]$ also lead to a contradiction.

Finally, the points (a)–(c) in part (iii) are now straightforward consequence of the discussion developed above. □

Remark 4.1. As a consequence of the nice results contained in [Sm-W,81] (see also [Sm]) it follows that the bistable $(\mathrm{DW})_{\mu=0}$, i.e., $f(u) = f_2(u)$, has exactly two positive solutions in $\Omega = (-a,a)$ provided that $a > a_1$ and $T_1 > 2M$.

5. Perturbation near critical zeros: Generation of chains. In the present section, the definitions and preliminary facts to prove the results concerning the one-dimensional (DW) are introduced. We should recall that solving (DW) in $\Omega = (-a,a)$ is equivalent to finding positive solutions to $(\mathrm{D})_1$ in $\Omega_\omega = (-a - M, a + M)$ (see §2). Thus, a solution $u(y)$ to $(\mathrm{D})_1$ defines a solution $(u(y), v(y)) = (u(y), u_y(y))$ to $(3.3)_{c=\mu}$ whose orbit Γ meets $\{u > 0, v = 0\}$ at a unique point $(u,v) = (u_1, 0)$. On the other hand, the orbit Γ can be described in terms of the orbital equation associated with (3.3) (see the equation (5.1) below). Finally, recall that it is sufficient to study (DW) for nonnegative μ (see Remark 2.3). For later use, some of those facts are summarized in the next definition.

DEFINITION 4. *A point $u_1 > 0$ is said to satisfy the condition $(\mathrm{S})_\mu$, $\mu \geq 0$, if there exists a solution $v(u)$, $v \in C^1([0,u_1)) \cap C^o([0,u_1])$, to the equation*

$$\frac{dv}{du} = -\mu - \frac{f(u)}{v} \tag{5.1}$$

such that $v(u_1) = 0$ and $v < 0$ in $[0, u_1)$.

Remark 5.1. (a) By using ODE arguments we can show that if u_1 satisfies $(\mathrm{S})_\mu$, then the unique orbit Γ to $(3.3)_{c=\mu}$ passing through $(u_1, 0)$ is such that the intersection $\Gamma^+ = \Gamma \cap \{u > 0\}$ can be written as $\Gamma^+ = \{(\tilde{u}(y), \tilde{v}(y))/y \in (-a,a)\}$, where $\tilde{u}(y)$

solves $(\mathrm{D})_1$ in $\Omega = (-a, a)$. Moreover, $\tilde{v}(y) = v(\tilde{u}(y))$ for $y_1 \leq\ y \leq\ a$ and certain $y_1 \in \Omega$ with $\tilde{u}(y_1) = u_1$.

(b) A certain u_1 satisfies $(\mathrm{S})_{\mu=0}$ provided it satisfies $(\mathrm{S})_\mu$, $\mu > 0$. In fact, since $E(u, v)$ decreases along solutions to $(3.3)_\mu$, then $v_o(u) = -\sqrt{2(V(u_1) - V(u))} < v(u) < 0$ for $u \in [0, u_1]$. A more elaborate argument proves that u_1 also satisfies $(\mathrm{S})_{\bar{\mu}}$ for each $\bar{\mu} \in [0, \mu]$.

In the proof of the existence of an MTW to (1.3) in the logistic ($f = f_1(u)$) and bistable ($f = f_2(u)$) cases, an outstanding role is played by the zero $u = 1$. It generates a saddle critical point $(u, v) = (1, 0)$ to equation (3.3) whose unstable manifold (see [C-H]) generates the MTW when c increases from $c = 0$ to $c = c_1^*$ or $c = c_2^*$ (see [F], [F-M,77]). In the next definition, the concept of saddle point is slightly extended to accomplish the objectives of the present work (compare with [C-H]).

DEFINITION 5. *Let $u_\alpha \in [0, u_M]$ be a critical zero of $f(u)$. The unstable (resp., stable) manifold $W_u^o(u_\alpha)$ (resp., $W_s^o(u_\alpha)$) associated to the critical point $(u, v) = (u_\alpha, 0)$, with regard to equation $(3.3)_{c=0}$, is defined as*

$$\begin{aligned} &W_u^o(u_\alpha)(\mathit{resp.},\ W_s^o(u_\alpha)) \\ &\quad = \{(u, v) \in \mathbf{R}^2 / 0 \leq\ u \leq\ u_\alpha, v = -(\mathit{resp.},\ +)\sqrt{2(V(u_\alpha) - V(u))}\}. \end{aligned}$$

To describe the process of CW generation, a suitable notion of perturbable manifolds is needed. Indeed, complex CWs arise in some cases when the unstable manifold $W_u^o(u_\alpha)$, associated to a critical zero $u = u_\alpha$, which accumulates zeros of $f(u)$ from the left, is perturbed from $c = 0$ to $c > 0$.

DEFINITION 6. *Let $u_\alpha \in [0, u_M]$ be as in Definition 5. The manifold $W_s^o(u_\alpha)$ (resp., $W_u^o(u_\alpha)$) is said to be perturbable to $\mu > 0$ if $\exists \epsilon > 0, \delta > 0$ and a unique solution $v = v^+(u, \mu)$ (resp., $v^-(u, \mu)$), with $0 \leq\ u(\mu) \leq\ u \leq\ u_\alpha$ and $\mu \in (0, \epsilon)$. In addition, $v^+(u, \mu)$ (resp., $v^-(u, \mu)$) must satisfy*

(i) $v^+(u, \mu)$ (resp., $v^-(u, \mu)$) $>$ (resp., $<$) $0, u \in [u(\mu), u_\alpha)$,

(ii) $\lim_{u \to u_\alpha(-)}\ v^+(u, \mu)$ (resp., $v^-(u, \mu)) = 0$.

If $W_s^o(u_\alpha)$ (resp., $W_u^o(u_\alpha)$) is perturbable, the stable (resp., unstable) manifold associated to $(u, v) = (u_\alpha, 0)$ regarding the equation $(3.3)_\mu$, $\mu \in\ (0, \epsilon)$, is defined as

$$\begin{aligned} &W_s^\mu(u_\alpha)(\mathit{resp.},\ W_u^\mu(u_\alpha)) \\ &\quad = \{(u, v) \in \mathbf{R}^2 / u(\mu) \leq\ u \leq\ u_\alpha,\ v = v^+(u, \mu)\ (\mathit{resp.},\ v^-(u, \mu))\}. \end{aligned}$$

Remark 5.2. (a) The manifolds $W_s^o(u_\alpha)$ and $W_u^o(u_\alpha)$ are perturbable provided that the critical zero $u = u_\alpha$ is isolated from the left (see Chapter 4 in [F]). Moreover, a result due to Kannel (see [F]) establishes that both $W_s^\mu(u_\alpha)$ and $W_u^\mu(u_\alpha)$ are monotonic with respect to μ.

(b) It will be shown later that $W_s^o(u_\alpha)$ is always perturbable (see Proposition 1). However, if the critical zero u_α accumulates zeros of $f(u)$ from the left, $W_u^o(u_\alpha)$ may not be perturbable. More precisely, a monotone chain $C(\mu)$ is generated when $W_u^o(u_\alpha)$ is not perturbable. Let us now give an example describing that situation.

Example 5.1. Let us proceed as in Example 3.1 to construct a suitable $f(u)$ in the equation (3.3). To accomplish this, let us choose similar sequences $\{\epsilon_n\}$, $\{u_n\}$, $\{f_n\}$ but now taking $f_o(u) = -u(\alpha - u)(1 - u)\varphi(u - \frac{1}{2})$, $0 < \alpha < \frac{1}{2}$, $\varphi(u)$ being the same function as in Example 3.1. Now, in addition to $\{u_n\}$, $f(u)$ has another sequence $\{w_n\}$ of zeros, where $w_1 = \alpha$ and $w_n = w_{n-1} + \epsilon_n$ for $n \geq\ 2$.

If we consider $u_\alpha\ =\ u_\infty\ =\ \lim\ u_n$ as the critical zero, then $W_u^o(u_\alpha)$ is not perturbable. In fact, if $W_u^o(u_\alpha)$ were perturbable, then for each $\mu > 0$, $\mu \to 0$, there would exist a negative solution $v(u,\mu)$ to (5.1), $u_\infty - \delta \leq u < u_\infty$, such that $\lim_{u\to u_\infty(-)} v(u,\mu) = 0$. Now, let $v(u,\mu,\epsilon)$ be the solution $v(u)$ to (5.1) such that $v(u_\infty) = -\epsilon$. Then, $v(u,\mu) > v(u,\mu,\epsilon)$ $\forall\ \epsilon > 0$ and $u \in [u_\infty - \delta, u_\infty]$ (see Fig. 6).

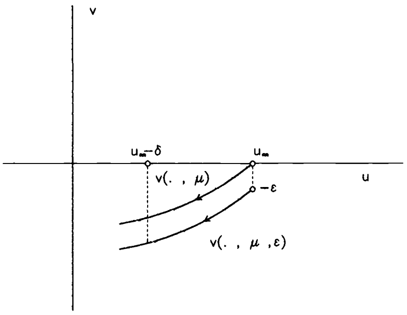

FIG. 6.

However, that behaviour of the family $\{v(\cdot,\mu,\epsilon)\}_{\epsilon>0}$ is not possible. In fact, arguing as in Example 3.1, it can be shown that the behaviour of equation $(5.1)_\mu$ in the strip $u_{n-1} \leq u \leq u_n$ is the same as that of $(5.1)_{\frac{\mu}{\epsilon_n}}$ in the strip $0 \leq u \leq 1$, but with the nonlinearity $f = f_o(u)$. Observe that (5.1) (or equivalently (3.3)) with $f = f_o(u)$ is an equation of bistable type. Therefore, there exists a unique $c_o^* > 0$ such that the equation (1.3), with $f = f_o(u)$, admits an MTW connecting $u = 1$ to $u = 0$ with velocity $c = c_o^*$ (see [F-M,77]). This fact implies that (1.3) with $f(u)$ as constructed here exhibits an MTW $C(\mu_n)$, connecting u_n to u_{n-1} with velocity $\mu_n = \epsilon_n c_o^*$. On the other hand, a careful analysis of the equation $(5.1)_\mu$ in the strip $u_{n-1} \leq u \leq u_n$ reveals the existence, for μ arbitrarily small, of a family of solutions $v_n(u)$ of $(5.1)_\mu$ with the following properties (see Fig. 7):

(i) $\exists n(\mu) \in \mathbf{N}$ such that $\forall\ n \geq n(\mu), v_n(u) < 0$ for $u_n < u \leq u_\infty$,

(ii) $v_n(u_n) = 0$ and $\lim v_n(u_\infty) = 0$.

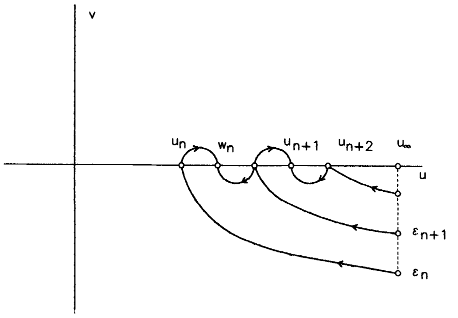

FIG. 7.

The existence of $\{v_n(u)\}$ with properties (i) and (ii) is not compatible with that of $\{v(u,\mu,\epsilon)\}$. Therefore $W_u^o(u_\alpha)$ is not perturbable.

Finally, observe that Example 5.1 shows an explicit case where option (ii) in Theorem 3 holds. In fact, observe that $\mu_n = c_o^*\epsilon_n$ is decreasing, while $C(\mu_n)$ moves toward the left when μ takes the values μ_n in the increasing sense. Observe that the largest existence value μ_o for this $f(u)$ is $\mu_o = c_o^*\epsilon_1$ (see Fig. 8).

5.1. Perturbability of W_s^o. The next result asserts that, under quite general conditions, $W_s^o(u_\alpha)$ is always perturbable.

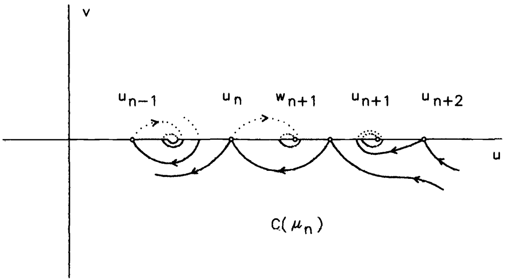

FIG. 8.

PROPOSITION 1. *Let $f(u)$ be a C^1 function with critical zero $u = u_\alpha > 0$. Assume that*

$$(5.2) \qquad f(u) = O((u - u_\alpha)^2), \quad as \quad u \to u_\alpha(-).$$

Then, $W_s^o(u_\alpha)$ is perturbable to every $\mu > 0$. Moreover, $v = v^+(\cdot, \mu)$ is defined in the interval $[0, u_\alpha]$ and is increasing with respect to μ.

Remark 5.3. (a) Condition (5.2) holds provided that $\frac{d^2f}{du^2}$ exists at $u = u_\alpha$.

(b) Proposition 1 furnishes new information when u_α accumulates zeros of $f(u)$ from the left and $f(u)$ exhibits, infinitely many times, both signs in $u < u_\alpha$. Under those conditions, our result sharpens a well-known result due to Kannel (see Lemma 4.14 in [F]), which arrives at the same assertion under the more restrictive requirement

$$f(u)(u - u_\alpha) \leq 0, \quad u \in (u_\alpha - \epsilon, u_\alpha).$$

Proof of Proposition 1. We will assume that $u = u_\alpha$ accumulates zeros from the left. First, let us prove the existence for each $\mu > 0$, of a solution $v(u)$ to $(5.1)_\mu$ such that

$$(5.3) \quad v(u) \in C^o([0, u_\alpha]) \cap C^1([0, u_\alpha)), v(u) > 0 \text{ for } 0 \leq u < u_\alpha, \text{ and } v(u_\alpha) = 0.$$

However, that is equivalent to proving the existence of a solution $(u(y), v(y))$ to $(3.3)_\mu$ such that $(u(0), v(0)) = (u_1, v_1)$, $u_1, v_1 > 0$, and $\lim_{y \to +\infty}(u(y), v(y)) = (u_\alpha, 0)$ with $v(y) > 0$ for $0 \leq y$. In fact, $(u(y), v(y))$ will meet backward $\{u = 0, v > 0\}$ in some point $(0, v^+)$ at a certain negative time y_o. Thus, the orbit Γ of $(u(y), v(y))$ in $\{u > 0\}$ will give the desired solution $v(u)$.

To find out the initial position (u_1, v_1), let us define the set

$$W = \{(u, v) \in \mathbf{R}^2 / v_o(u) \leq v \leq v_1(u), u \in [0, u_\alpha]\},$$

where $v_o(u) = \sqrt{2(\alpha - V(u))}$, $V(u_\alpha) = \alpha$, and $v_1(u) = \sqrt{2(\gamma - V(u))}$ with $0 < \alpha < \gamma$. Then W is a Wazewsky set (see [Co]) regarding $(3.3)_\mu$. Since the strict exit points set W^- of W is $W^- = E_1 \cup E_2 = \{(u, v) \in W / v = v_o(u)\} \cup \{(u_\alpha, v)/0 < v \leq v_1(u_\alpha)\}$ (see Fig. 9), W^- is not connected. Thus, Wazewsky's theorem (see [Co]) gives the existence of the desired point (u_1, v_1).

Now, we claim that if $v_i(u)$ are solutions to $(5.1)_{\mu_i}$, $i = 1, 2$, which satisfy (5.3), and $0 \leq \mu_1 < \mu_2$, then $0 < v_1(u) < v_2(u)$ for $0 \leq u < u_\alpha$. Indeed, the uniqueness, monotonicity, and perturbability properties of $W_s^o(u_\alpha)$ follow from that fact.

To prove the claim we first show that a solution $v(u)$ to (5.1), which satisfies (5.3), is also C^1 in the interval $[0, u_\alpha]$. In fact, $v_o(u) = \sqrt{2(\alpha - V(u))}$, i.e., $W_s^o(u_\alpha)$, is C^1 in that interval and $v'(u_\alpha) = 0$ (recall that u_α accumulates zeros of $f(u)$). The

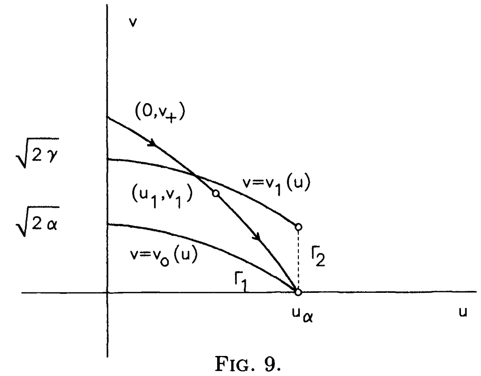

FIG. 9.

last assertion follows from the limit

$$\lim_{u\to u_\alpha(-)} \frac{f(u)}{\sqrt{\int_u^{u_\alpha} f(s)\,ds}} = 0. \tag{5.4}$$

However, since u_α accumulates zeros of $f(u)$, (5.4) is not obvious and its proof is delayed until Lemma 3 below. Finally observe that $0 < v_o(u) < v(u)$ in $[0, u_\alpha)$. Hence,

$$|v'(u) + \mu| = \left|\frac{f(u)}{v(u)}\right| < \left|\frac{f(u)}{v_o(u)}\right|, \quad u \in [0, u_\alpha).$$

Thus $v'(u_\alpha) = -\mu$ and $v(u)$ is C^1 up to $u = u_\alpha$.

On the other hand, set $w(u) = v_2(u) - v_1(u)$ and $\Delta\mu = \mu_2 - \mu_1$. From (5.1) we arrive at

$$\frac{dw}{du} = -\Delta\mu + \frac{f}{v_1 v_2}, \quad u \in [0, u_\alpha),$$

which implies that the function $g(u) = w(u)\exp\left\{-\int_{u_1}^{u} \frac{f(s)}{v_1(s)v_2(s)}\,ds\right\}$, $0 < u_1 < u_\alpha$, is decreasing. Since

$$\frac{f(u)}{v_1(u)v_2(u)} = \left\{\frac{1}{\mu_1\mu_2 + o(1)}\right\}\frac{f(u)}{(u-u_\alpha)^2}, \quad \text{as } u \to u_\alpha(-),$$

then the integral $\int_{u_1}^{u} \frac{f(s)}{v_1(s)v_2(s)}\,ds$ converges as $u \to u_\alpha$. Thus, $g(u)$ is bounded and $\lim_{u\to u_\alpha(-)} g(u) = 0$. Therefore, $w(u) > 0$ in $0 \le u < u_\alpha$. □

LEMMA 3. *Under the assumptions of Proposition* 1 *assume that* $u = u_\alpha$ *accumulates zeros of* $f(u)$ *from the left. Then, the limit in* (5.4) *holds true.*

Proof. Since u_α is a critical zero for $f(u)$, then $\int_u^{u_\alpha} f(s)\,ds = V(u_\alpha) - V(u) > 0$ for $u \in (0, u_\alpha)$. From the fact that u_α accumulates zeros of $f(u)$ from the left, it follows that 0 is the unique possible value for the limit in (5.4).

Let us define $G(u) = \frac{f^2(u)}{F(u)}$ where $F(u) = \int_u^{u_\alpha} f(s)\,ds$. Then, (5.4) is equivalent to $\lim_{u\to u_\alpha} G(u) = 0$. Note that the classical L'Hôpital rule cannot be used in this case. To show the existence of the last limit consider the sets

$$U^+ \text{ (resp., } U^-,\ U^o) = \{u/0 < u < u_\alpha, f(u) > \text{(resp., } <,\ =) \ 0\}.$$

Then, it is sufficient to show that

$$\lim_{u\in U^+, u\to u_\alpha} G(u) = 0 \quad \text{and} \quad \lim_{u\in U^-, u\to u_\alpha} G(u) = 0. \tag{5.5}$$

To prove the first limit, define $w(u_o) = \max\{u' \in U^o / u' < u_o\}$ for every $u_o \in U^+$. Since $f(u) > 0$ in the interval $(w(u_o), u_o]$ then $F(u_o) - F(w(u_o)) < F(u_o)$. Thus, Cauchy's mean value theorem gives the existence of $\xi(u_o) \in (w(u_o), u_o)$ such that

$$G(u_o) = \frac{f^2(u_o)}{F(u_o)} \leq \frac{f^2(u_o) - f^2(w(u_o))}{F(u_o) - F(w(u_o))} = \frac{2f(\xi(u_o))f'(\xi(u_o))}{-f(\xi(u_o))} = -2f'(\xi(u_o)).$$

Since $f(u)$ is C^1, that means that the first limit in (5.5) holds true. The second one is proven in a similar way. □

5.2. Perturbability of W_u^o: Chain of waves formation. The relation between the perturbability of the unstable manifold $W_u^s(u_\alpha)$ and the generation of CWs to equation (1.3), will now be studied in detail. Let u_α be a critical zero for $f(u)$. It will be said, for short, that $u = u_\alpha$ is perturbable when $W_u^o(u_\alpha)$ be perturbable.

Our first objective will be to characterize the perturbability property for critical zeros $u = u_\alpha$.

PROPOSITION 2. *Assume that $f(u)$ satisfies $(\mathrm{H})_f$ and let $u = u_\alpha$ be a critical zero of $f(u)$. Then, u_α is perturbable if and only if the following condition holds:*

$$\text{(5.6)} \qquad \begin{aligned} &\exists \mu_\epsilon > 0 \textit{ and } \{u_n\} \subset (0, u_\alpha),\ \lim u_n = u_\alpha, \textit{such} \\ &\textit{that } \forall n \in \mathbf{N}, u = u_n \textit{ satisfies condition } (\mathrm{S})_{\mu=\mu_\epsilon} \end{aligned}$$

Proof. (a) *Necessity of* (5.6). Assume that (5.6) does not hold for $\mu \in (0, \epsilon)$, $\epsilon > 0$. We will arrive at a contradiciton.

First, observe that the set $U = f^{-1}((0, +\infty)) \cap (0, u_\alpha)$ is open. Thus it has, at most, countable many connected pieces $\{I_n\}$, $I_n = (u_n^-, u_n^+)$. Since $u = u_\alpha$ is critical then $\lim u_n^- = \lim u_n^+ = u_\alpha$. Moreover, $\forall n \in \mathbf{N}, f(u_n^\pm) = 0$.

Fix $\mu \in (0, \epsilon)$ and take $n \in \mathbf{N}$ large enough so that no point in $I_n = (u_n^-, u_n^+)$ satisfies $(\mathrm{S})_\mu$. Then, $\forall w \in I_n$ the solution $(u(y), v(y))$ to $(3.3)_\mu$ starting at $(u(0), v(0)) = (w, 0)$ reaches $\{u > 0, v = 0\}$ at $(u, v) = (w^-, 0)$ in finite time or $\lim_{y \to +\infty}(u(y), v(y)) = (w^-, 0)$. In both cases $0 \leq w^- \leq u_n^- < w$.

Next, consider an increasing sequence $\{w_m\} \subset I_n$ with $\lim w_m = u_n^+$. Designate by $v = g_m(u)$ that piece of the orbit to $(3.3)_\mu$ passing through $(u, v) = (w_m, 0)$, which is contained in $\{v \leq 0\}$. Observe that $g_m(u)$ is defined in the interval $[w_m^-, w_m]$. Moreover, $\{w_m^-\}$ is decreasing and $\lim w_m^- = w_n$, with $w_n \leq u_n^-$ (see Fig. 10). Note also that $\forall m \in \mathbf{N}$, $[w_m^-, w_m] \subset [w_{m+1}^-, w_{m+1}]$, and $g_{m+1}(u) < g_m(u)$, for every $u \in [w_m^-, w_m]$. Finally, let us introduce the sequence of functions $\tilde{g}_m(u)$, $u \in [w_n, u_n^+]$, as follows:

$$\tilde{g}_m(u) = \begin{cases} g_m(u) & \text{if } w_m^- \leq u \leq w_m, \\ 0 & \text{if } u \in [w_n, u_n^+] \backslash [w_m^-, w_m]. \end{cases}$$

Since u_α is perturbable, the solution $v^-(u, \mu)$ quoted in Definition 6 exists and $v^-(u, \mu) < \tilde{g}_m(u)$ for every $u \in [w_n, u_n^+]$. Therefore, the limit $h_n(u) = \lim \tilde{g}_m(u)$ exists for every $u \in [w_n, u_n^+]$.

On the other hand we claim that $h_n(\cdot) \in C^o([w_n, u_n^+]) \cap C^1((w_n, u_n^+))$. Moreover, the graph of $v = h_n(u)$ in the interval (w_n, u_n^+) is a piece of an orbit of the equation $(3.3)_\mu$. In fact, by using the equation $(5.1)_\mu$ it follows that $\tilde{g}_m \longrightarrow h_n$ in the topology of $C^1([\alpha, \beta])$, for every $[\alpha, \beta] \subset (w_n, u_n^+)$. Thus, the orbital character of $v = h_n(u)$ follows from applying the continuous dependence on initial data and parameters (see [Cp], especially Theorem 3) to equation $(5.1)_\mu$. In addition, since $h_n(w_n) = h_n(u_n^+) = 0$ it is easily seen that $h_n(u)$ is continuous at $u = w_n$ and $u = u_n^+$ (note that $(5.1)_\mu$ is singular at $v = 0$). Then, Dini's theorem and the continuity of $h_n(u)$ in $[w_n, u_n^+]$ imply that the limit $\tilde{g}_m \to h_n$ is uniform in that interval. Thus, $v = h_n(u)$, $u \in [w_n, u_n^+]$, is an orbit, or a piece of an orbit, of the equation $(3.3)_\mu$. Moreover, $v^-(u, \mu) < h_n(u)$ in $[w_n, u_n^+]$ (see Fig. 10).

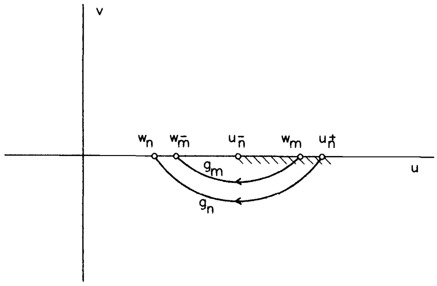

FIG. 10.

Finally, choose $\delta > 0$ and $n_o \in \mathbf{N}$ such that $v^-(\cdot, \mu)$ is defined in $[u_\alpha - \delta, u_\alpha]$, and $I_n \subset [u_\alpha - \delta, u_\alpha]$ for each $n \geq n_o$. Let us define the set Δ_δ which consists of the points (u, v) with $u \in [u_\alpha - \delta, u_\alpha]$ such that $v^-(u, \mu) \leq v \leq h_n(u)$ provided that $u \in I_n$ for some $n \geq n_o$, or $v^-(u, \mu) \leq v \leq 0$ if $u \notin I_n$ for all $n \in \mathbf{N}$. A careful analysis of the boundary $\partial\Delta_\delta$ of Δ_δ reveals that Δ_δ is strictly negatively invariant regarding $(3.3)_\mu$ (see [Co]). That is, $\Delta_\delta \subset \Phi_y(\Delta_\delta)$ and $\Delta_\delta \neq \Phi_y(\Delta_\delta)$ for small $y \geq 0$, where Φ_y stands for the flow of the equation $(3.3)_\mu$. In addition, since div $(v, -\mu v - f(u)) = -\mu < 0$ then $(3.3)_\mu$ is dissipative, which contradicts the fact $|\Delta_\delta| < |\Phi_y(\Delta_\delta)|$ for $y \geq 0$ small ($|A|$ = the Lebesgue measure of A). Thus, the necessity of (5.6) is proven.

(b) *Sufficency of* (5.6). Assume that (5.6) holds and, for each $n \in \mathbf{N}$, let $v_n(u)$ be the negative solution to $(5.1)_{\mu_\epsilon}$ associated to u_n (see Definition 4). Let us now introduce the decreasing sequence of functions $g_n(u) \in C^o([0, u_\alpha])$ defined as

$$g_n(u) = \begin{cases} v_n(u), & 0 \leq u \leq u_n, \\ 0, & u_n < u \leq u_\alpha. \end{cases}$$

If $v(u, \delta)$, $\delta > 0$, designates the solution $v(u)$ to $(5.1)_{\mu_\epsilon}$ such that $v(u_\alpha) = -\delta$ then $g_n(u) > v(u, \delta)$ in $0 \leq u \leq u_\alpha$, for each $n \in \mathbf{N}$ and $\delta > 0$. Thus, the function $g(u) = \lim g_n(u) = \inf g_n(u)$ satisfies the last inequality for $u \in [0, u_\alpha)$, with $g(u_\alpha) = 0$. Moreover, arguing as in part (a) we determine that $g(u) \in C^1([0, u_\alpha))$ and solves $(5.1)_{\mu_\epsilon}$ in $[0, u_\alpha)$ (cf. Theorem 3 in [Cp]). Since $g(u) > v(u, \delta)$ for each $\delta > 0$, then $g(u) \in C^o([0, u_\alpha])$ and $g_n \to g$ uniformly in $[0, u_\alpha]$.

Define now $v(u, \mu_\epsilon) = \sup_{\delta \to 0^+} v(u, \delta)$ in $[0, u_\alpha]$. By using again the arguments of part (a) it follows that $v(u, \mu_\epsilon)$ solves $(5.1)_{\mu_\epsilon}$ in $[0, u_\alpha]$, with $v(u_\alpha, \mu_\epsilon) = 0$. Moreover, $v(u, \mu_\epsilon) \leq g(u) < 0$ for $0 \leq u < u_\alpha$. Thus, every solution $v(u)$ to $(5.1)_{\mu_\epsilon}$ which satifisfies (i) and (ii) in Definition 6, must satisfy in addition the inequality

$$v(u, \mu_\epsilon) \leq v(u) \leq g(u), \quad u \in [0, u_\alpha].$$

We claim that $v(u, \mu_\epsilon) = v(u) = g(u)$ for $u \in [0, u_\alpha]$. Otherwise the set

$$\Delta_\epsilon = \{u/u_\alpha - \epsilon \leq u \leq u_\alpha, \ v(u, \mu_\epsilon) \leq v \leq g(u)\},$$

for $\epsilon > 0$ small enough, has $|\Delta_\epsilon| \neq 0$. That is not compatible with the dissipative character of $(3.3)_{\mu_\epsilon}$ (see part (a)). Therefore, there exists a unique solution $v^-(u, \mu_\epsilon) = v(u, \mu_\epsilon)$ to $(5.1)_{\mu_\epsilon}$ which satisfies (i) and (ii) in Definition 6. Now, by using Remark

5.1(b), the argument given here for the existence of $v^-(u,\mu_\epsilon)$ can be repeated to prove the existence of $v^-(u,\mu)$ for $0<\mu\le\ \mu_\epsilon$ and u_α is perturbable, as wished. □

The next result describes the behaviour near nonperturbable zeros u_α. It is useful to explain how the perturbation of that kind of zero generates a CW of (1.3) (see also Proposition 4 below).

PROPOSITION 3. *Assume that $f(u)$ satisfies* (H)$_f$ *and let $u=u_\alpha$ be a nonperturbable critical zero of $f(u)$. Then $\exists\ \epsilon_o>0$ such that $\forall\mu\in(0,\epsilon_o)$ there exists a perturbable critical zero $u=u(\mu)$ of $f(u)$, $0<u(\mu)<u_\alpha$, such that $\lim_{\mu\to0+}u(\mu)=u_\alpha$. Moreover, no point in the interval $u(\mu)<u<u_\alpha$ satisfies the condition* (S)$_{\tilde\mu}$ *for $\mu\le\ \tilde\mu$.*

Proof. Since $u=u_\alpha$ is a nonperturbable critical zero for $f(u)$ then it accumulates zeros of $f(u)$ from the left. Otherwise, u_α would be isolated from the left and Kannel's result (see Lemma 4.14 in [F]) would imply the perturbabilty of u_α. On the other hand (see the proof of Theorem 5 for the notation) since α is a critical value for $V(u)$, a subsequence $\{\alpha_{n_1}^+\}$ of $\{\alpha_n^+\}$ exists such that $\lim\alpha_{n_1}^+=\alpha$ with $\alpha_{n_1}<\alpha$ for all $n_1\in\mathbf{N}$. Rename $\{\alpha_{n_1}^+\}$ as $\{\alpha_n^+\}$ and let u_n^+ be the critical zero associated to α_n^+. Following Definition 3 we have $\lim u_n^+=u_\alpha$. Recall that, from the proof of Theorem 5, $f(u)>0$ in $u_n^-<u<u_n^+$. Thus, direct computations show that u_n^+ is perturbable for each n. Therefore, $\forall n\in\mathbf{N}$, $\exists\mu_n>0$ such that (5.6) holds for $0<\mu<\mu_n$. For $\mu>0$ small enough, let us define the set

$$\mathcal{S}_\mu(u_\alpha)=\{u/0<u<u_\alpha,\ \text{and } u \text{ satisfies condition } (\mathrm{S})_\mu\ \}. \tag{5.7}$$

$\mathcal{S}_\mu$ (u_α will be omitted for brevity) is a nonempty open set which is bounded from above. If we denote $u(\mu)=\sup\ \mathcal{S}_\mu$ then it is easily seen that $f(u(\mu))=0$. Thus $u(\mu)$ is a zero for $f(u)$ which is also critical (see Definition 3). Finally, since $u(\mu)$ is perturbable (see Proposition 2) then it holds that $u(\mu)<u_\alpha$. Observe that no point $u\in(u(\mu),u_\alpha)$ satisfies condition (S)$_{\tilde\mu}$ for all $\tilde\mu\ge\mu$. □

Remark 5.4. Let us analyze two situations of nonperturbability with different behaviours regarding the CW formation. In both Examples 3.1 and 5.1 $u_\alpha=u_\infty$ is nonperturbable. In Example 3.1, $u(\mu)=u_{n-1}$ for $0<\mu<\mu_{n-1}$ (recall that $\mu_n=c_o^*\epsilon_n$), and no point in the interval (u_{n-1},u_∞) satisfies (S)$_\mu$ due to the existence of a CW, $C(\mu)$, which connects u_∞ to u_{n-1} with velocity $0<\mu<\mu_{n-1}$ (see Fig. 11).

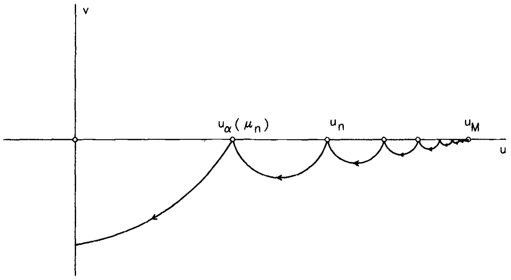

FIG. 11.

In Example 5.1 we have again $u(\mu)=u_{n-1}$ for $0<\mu<\mu_{n-1}$. However, condition (S)$_\mu$ now fails in $(u(\mu_{n-1}),u_\infty)$ for other reasons. In fact, CWs to (1.3) only occur with velocities $0<\mu_m=c_o^*\epsilon_m\le\mu_{m-1}$ and connect u_m to u_{m-1}, where $u_{n-1}\le u_{m-1}<u_m<u_\infty$.

The arising of CWs to (1.3) due to perturbation of $W_u^\mu(u_\alpha)$ at perturbable critical zeros u_α is described in the next result. Recall that (see Definition 6)

$$W_u^\mu(u_\alpha) = \{(u,v)/0 \leq u \leq u_\alpha, v = v^-(u,\mu)\},$$

provided that $\mu > 0$ is small enough, say $0 < \mu < \epsilon$. However, to handle the perturbation of W_u^μ for $\mu > 0$ large, it is convenient to extend the function $v^-(\cdot,\mu)$ for μ not small. To accomplish that, let $v(u,\mu,\delta)$ be the solution $v(u)$ to $(5.1)_\mu$ such that $v(u_\alpha) = -\delta$, $\delta > 0$. Then,

$$v^-(u,\mu) = \sup_{\delta \to 0+} v(u,\mu,\delta), \quad \mu \in (0,\epsilon).$$

However, even when μ is not small, we can still define for $u \in [0,u_\alpha]$ the function

$$g(u,\mu) = \min\{0, \sup_{\delta \to 0+} v(u,\mu,\delta)\},$$

provided that the supremum is defined at $u \in [0,u_\alpha]$ (that is just the case when μ is small). Otherwise we will set $g(u,\mu) = 0$.

PROPOSITION 4. *Let $u = u_\alpha$ be a perturbable critical zero for $f(u)$. Define*

$$\mu(u_\alpha) = \sup\ \{\mu > 0/g(u,\mu) < 0, \textit{for all } 0 \leq u < u_\alpha\},$$

and $u(u_\alpha) = \inf\ \{u \geq 0/g(u,\mu(u_\alpha)) = 0\}$. Then,

$$C = \{(u,v)/u(u_\alpha) \leq u \leq u_\alpha, v = g(u,\mu(u_\alpha))\}$$

is a CW to (1.3), *which connects the zeros $u = u_\alpha$ and $u = u(u_\alpha)$ with propagation velocity $c = \mu(u_\alpha)$. Moreover, the unstable manifold $W_u^\mu(u_\alpha)$ is strictly increasing and depends continuously on μ.*

However, the perturbation process of W_u^μ for $\mu > 0$ exhibits special features when the value $\mu = \mu_o$, i.e., the largest existence value for the problem (DW) (see (3.2)), is reached. That behaviour is precisely stated in the next result. Recall the definition of the set $\mathcal{S}_\mu$ in (5.7).

PROPOSITION 5. *Let u_α be a perturbable critical zero for $f(u)$, and let μ_o be the largest existence value for the problem* (DW). *Then,*

(i) *$\mu(u_\alpha) < \mu_o$ implies that $u = u(u_\alpha)$ is a perturbable critical zero with $u(u_\alpha) > 0$. Moreover, $\mathcal{S}_\mu \subset (0, u(u_\alpha))$ for $\mu(u_\alpha) \leq \mu < \mu_o$.*

(ii) *$\mu(u_\alpha) = \mu_o$ implies that $u(u_\alpha) = 0$.*

The proofs of Propositions 4 and 5 are a direct consequence of the ideas contained in the present section and do not involve special arguments to be explicitly required for the continuity of the exposition. Therefore, they are omitted.

6. The one-dimensional case: The proofs of Theorems 2–4.

Proof of Theorem 2. The proofs of parts (A) and (B) are similar. Thus, it is sufficient to give that of (A) to show the main ideas and techniques involved. Recall that there is no loss of generality if it is assumed that $\mu \geq 0$ (see Remark 2.3).

To prove (a), let us first describe the problem $(\mathrm{DW})_{\mu=0}$. Following the notation of the proof of Theorem 5, observe that a unique interval I_n exists. Namely, $I_1 = (u_1^-, u_1^+)$, where $u_1^- = (2(1+\alpha) - \sqrt{4(1+\alpha)^2 - 18\alpha})/3$, $u_1^+ = 1$. Indeed, only a unique critical zero exists, $u_M = u_1^+ = 1$ with energy $V_M = \frac{1}{6}(\frac{1}{2} - \alpha)$ (recall that $0 < \alpha < \frac{1}{2}$). For $\mu = 0$, the set $\mathcal{S}_\mu = (u_1^-, u_1^+)$ (see (5.7) and Fig. 12(a)).

For $\mu \geq 0$ and $u_1 \in \mathcal{S}_\mu$, designate by $T(u_1,\mu)$ the time $2a$ employed by a solution of $(3.3)_\mu$ in reaching $\{u = 0, v < 0\}$ after starting at $\{u = 0, v > 0\}$, travelling into $\{u \geq 0\}$, and meeting $\{u > 0, v = 0\}$ at $(u,v) = (u_1, 0)$ (see Remark 5.1(a)). Observe that

$$T(u_1,0)=\int_0^{u_1}\frac{ds}{\sqrt{2(V(u_1)-V(s))}}.$$

Now, let us study how the set $\mathcal{S}_\mu$ is perturbed when $\mu\in(0,\epsilon)$ and $\epsilon>0$ is small enough. Observe that $(0,0)$ and $(1,0)$ are saddle critical points for $(3.3)_\mu$. Let $v^-(u,\mu)$, $0\le u\le 1$, be the stable manifold associated to $(1,0)$ and let $v_o^-(u,\mu)$, $0\le u\le u_1^-(\mu)$, be that piece of the stable manifold of $(0,0)$ (see [C-H]), that is contained in the semiplane $\{v\le 0\}$ (see Fig. 12(b)).

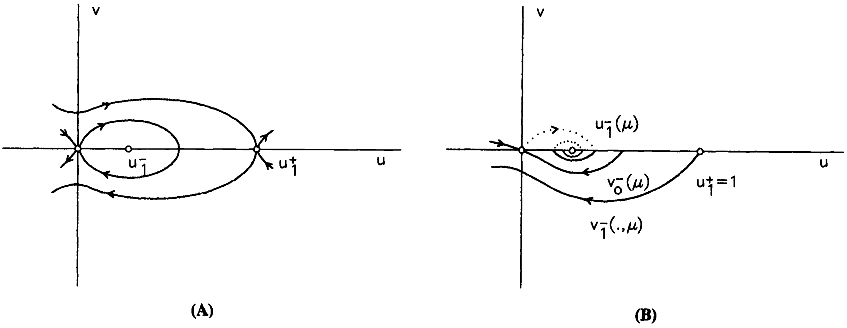

FIG. 12.

From Proposition 4 we have that $v_1^-(\cdot,\mu)$ is increasing with respect to μ. From an argument similar to that given in the proof of Proposition 1, it follows that $v_o^-(\cdot,\mu)$ is decreasing in the interval $[0,u_1^-(\mu)]$. Notice that $u_1^-(0)=u_1^-$. Since $f'(\alpha)>0$, then the behaviour of the orbits to $(3.3)_\mu$ near $(\alpha,0)$ together with Proposition 4 imply that $u(u_M)=0$. Thus, Proposition 5 asserts that $\mu(u_M)=c_2^*=\mu_o$, which implies the existence of a TW which connects $u_M=1$ to $u=0$ with velocity c_2^*. Moreover, from the uniqueness of the stable manifold associated to $(0,0)$ it follows that $v_o^-(u,\mu_o)=v_1^-(u,\mu_o)$ for $0\le u\le 1$. Finally, the set $\mathcal{S}_\mu=(u_1^-(\mu),1)$ for $\mu\in(0,\mu_o)$.

To prove b) observe that $T(\cdot,\mu)$ is continuous and positive in $\mathcal{S}_\mu$. Standard ODE results ensure that $\lim_{u\to u_1^-(\mu)+}T(u,\mu)=\lim_{u\to 1-}T(u,\mu)=+\infty$. Therefore, $T_\mu\doteq\inf_{\mathcal{S}_\mu}T(\cdot,\mu)>0$ for each $\mu\in(0,\mu_o)$. We now claim that $T_\mu>\frac{T_o}{2}>0$ for $0\le\mu<\mu_o$. In fact, following the notation of Remark 5.1(a) define $L(u_1,\mu)=a-y_1$ for every $u_1\in\mathcal{S}_\mu$. Then,

$$L(u_1,\mu)=-\int_0^{u_1}\frac{du}{v(u)}.$$

Now, fix $u_1\in(u_1^-,u_1^+)$. Since $u_1^-(\mu)$ is increasing in μ then $u_1\in\mathcal{S}_\mu$ if $0\le\mu<\tilde\mu(u_1)$, for a unique $\tilde\mu(u_1)$. Moreover, $u_1=u_1^-(\tilde\mu(u_1))$. From the above expression for L we have that $L(u_1,\mu)$ is increasing for $0\le\mu<\tilde\mu(u_1)$. Standard ODE results imply again that $\lim_{\mu\to\tilde\mu(u_1)-}L(u_1,\mu)=+\infty$ (see Fig. 13). Since $L(u_1,0)=\frac{T(u_1,0)}{2}$ for every $u_1^-<u_1<u_1^+$, we conclude that

$$T_\mu=\inf_{\mathcal{S}_\mu}T(\cdot,\mu)>\frac{T_o}{2}>0\quad\forall\mu\in(0,\mu_o).$$

By choosing $a(\mu)=T_\mu-M$ we arrive at the conclusions of part (b). □

Remark 6.1. For $f(u)=f_2(u)$ it was proven in [Sm-W,81] that $T(\cdot,0)$ has a unique local extreme at a certain $\tilde u$. Therefore, (DW) has at least two solutions in

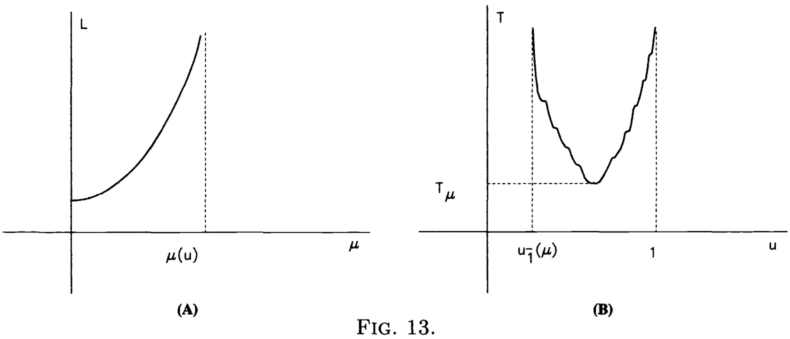

FIG. 13.

$\Omega = (-a, a)$ for $a > a(\mu)$ and $\mu > 0$, while the number of solutions is exactly two when $\mu = 0$ and $a > a(0)$.

Proof of Theorem 3. First, it can be assumed that u_M is perturbable. Otherwise, it is sufficient to work with the pertubable critical zero $u_M(\mu)$, $0 < \mu < \epsilon_o$, whose existence is given by Proposition 3. In the last case recall that $\mathcal{S}_{\tilde{\mu}} = \{u > 0/u < u_M$ and u satisfies $(\mathrm{S})_{\tilde{\mu}}\} \subset (0, u_M(\mu))$, for $\mu \leq \tilde{\mu} < \mu_o$.

The strategy of the proof consists in applying recursively Proposition 4 to generate two sequences $\{u_n\}$ and $\{\mu_n\}$, which take the zero $u = u_M$ as starting point. More precisely, we set $u_1 = u_M$, $\mu_1 = \mu(u_M)$ and $u_n = u(u_{n-1})$, $\mu_n = \mu(u_n)$ for each $n \geq 2$. Thus, $\{u_n\}$ defines a decreasing sequence of peturbable zeros of $f(u)$, while μ_n is increasing. Moreover, $\forall n \in \mathbf{N}$ there exists a CW, $C(\mu_n)$, which connects u_n to u_{n+1} with velocity μ_n.

Observe that both sequences $\{u_n\}$ and $\{\mu_n\}$ could possibly be finite. Indeed, the conclusion of part (i) is obtained when there exists $n_o \in \mathbf{N}$ such that $u_{n_o} = 0$. In this case (see Proposition 5) $\mu_{n_o - 1} = \mu_o$. Therefore, there exists a CW to (1.3) , $C(\mu_o)$, which connects the zero $u_+ = \max\, C(\mu_o) \cap \{(u, 0)/0 \leq\ u \leq\ u_M\}$ to $u = 0$ with velocity μ_o.

Assume now that $\{u_n\}$ is nonfinite. In that case, $u_n > 0$ for every n and Proposition 5 implies that $\mu_n < \mu_{n+1} < \mu_o$, $\forall n \in \mathbf{N}$. Since $\{u_n\}$ is decreasing then the limits $u_\infty = \lim u_n$, $\mu_\infty = \lim \mu_n$ exist and satisfy $u_\infty \geq 0$, $\mu_\infty \leq\ \mu_o$.

We claim that $u_\infty = 0$ implies $\mu_\infty = \mu_o$. In fact, the inequality $\mu_\infty < \mu_o$ would give the existence of some $\tilde{u}$ satisfying condition $(\mathrm{S})_\mu$ for some $\mu \in (\mu_\infty, \mu_o)$. Thus, $\forall n \in \mathbf{N}$ we would get $0 < \tilde{u} < u_n$, which contradicts the fact $\lim u_n = 0$. Therefore μ_∞ must coincide with μ_o. Observe that option (ii) in Theorem 3 is obtained under that asumption.

Next, consider the case where $u_\infty > 0$. First, we will prove that $V(u_\infty) > 0$ (observe that $V(u_\infty) \geq\ 0$). If fact, designate by $v^-(u, \mu_n)$ the unstable manifold associated to $u = u_n$ and designate also $g_n(u)$, the restriction of $v^-(u, \mu_n)$ to the interval $[0, u_\infty]$. If we assume that $V(u_\infty) = 0$ then we arrive to the inequalities

$$-\sqrt{2(V(u_n) - V(u))} < g_n(u) < -\sqrt{-2V(u)}, \quad 0 \leq\ u \leq\ u_\infty,$$

for each $n \in \mathbf{N}$. Observe that $g(u) = \lim g_n(u)$ satisfies $g(u) = -\sqrt{-2V(u)}$. However, that is not possible. In fact, the set $I = \{(u, v)/v = g(u)\}$ should be an invariant set for the equation $(3.3)_{\mu=\mu_\infty}$. On the other hand, the energy $E(u, v) = 0$ for $(u, v) \in I$. This contradicts the fact $\frac{dE}{dy} = -\mu_\infty v^2(y)$, where the derivative is computed over a solution $(u(y), v(y))$ of $(3.3)_{\mu=\mu_\infty}$. Therefore, $V(u_\infty) > 0$.

Let us study the case where $u_\infty > 0$ and $\mu_\infty = \mu_o$. If we keep the notation of the preceding paragraph for the functions $g_n(u)$, it will be shown that $C = \{(u,v)/0 \leq u \leq u_\infty, v = g(u)\}$ where $g(u) = \lim g_n(u)$ is a CW which connects $u = u_\infty$ to $u = 0$ with velocity μ_o. Thus, we arrive to the conclusion of part (i) in this case. In fact, observe that C is an invariant set for the equation $(3.3)_{\mu_\infty}$. On the other hand, the inequality

$$-\sqrt{2(V(u_n) - V(u_\infty))} < g_n(u_\infty) < 0, \quad \forall n \in \mathbf{N}$$

implies that $g(u_\infty) = 0$. In addition, $g(0) = 0$. Otherwise, $g(0) < 0$ and $\tilde{u} = \min\{u/u > 0, g(u) = 0\}$ would be a perturbable critical zero, with unstable manifold $v = v^-(u, \mu_\infty) = g(u)$ defined in $[0, \tilde{u}]$. Thus, due to the fact $\mu_\infty = \mu_o$, Proposition 5 prohibits the existence of such a perturbable zero $\tilde{u}$. Therefore, $g(0) = 0$.

Finally, let us analyze the case $u_\infty > 0$ and $\mu_\infty < \mu_o$. First, let us show that $u = u_\infty$ is a critical zero for $f(u)$ (see Definition 3). In fact, $u = u_n$ is a critical zero for every n. In addition, it is clear that $V(u_\infty) = \inf_{n \in \mathbf{N}} V(u_n)$. Thus $V(u) \leq V(u_\infty)$ for $0 \leq u \leq u_\infty$. We claim that $V(u) < V(u_\infty)$ for $0 \leq u < u_\infty$. Otherwise, a point $\tilde{u} \in (0, u_\infty)$ with $V(\tilde{u}) = V(u_\infty)$ would exist. If, as in the preceding paragraphs, we consider the sequence $g_n(u)_{|[\tilde{u}, u_\infty]} = v^-(u, \mu_n)_{|[\tilde{u}, u_\infty]}$, i.e., restricted to the interval $[\tilde{u}, u_\infty]$, and argue in a similar way we arrive again at a contradiction. Thus, $V(u) < V(u_\infty)$ for $0 \leq u < u_\infty$, i.e., u_∞ is a critical zero. Now, consider again the sequence $g_n(u)$ but defined in the whole interval $[0, u_\infty]$, and set again $g(u) = \lim g_n(u)$ in that interval. We claim that $g(0) < 0$. Otherwise, $C(\mu_\infty) = \{(u,v)/0 \leq u \leq u_\infty, v = g(u)\}$ would define a CW which connects the zeros $u = u_\infty$ to $u = 0$ with velocity μ_∞. Thus, no point $u \in (0, u_\infty)$ could satisfy the condition $(\mathrm{S})_\mu$ for $\mu \geq \mu_\infty$, i.e., $\mathcal{S}_\mu(u_\infty) = \emptyset$ for $\mu \geq \mu_\infty$. However, from the construction of the sequences $\{u_n\}$ and $\{\mu_n\}$ and Proposition 5 it follows that the condition $(\mathrm{S})_\mu$, with $\mu \geq \mu_\infty$ can only be satisfied by points $u \in (0, u_\infty)$. Therefore, no point in the interval $(0, u_M)$ can satisfy $(\mathrm{S})_\mu$ for $\mu \geq \mu_\infty$, which means that $\mu_\infty \geq \mu_o$ (see (3.2)), which is a contradiction. Thus, $g(0) < 0$.

Since $g(0) < 0$ then $\tilde{u}_1 = \min\{u > 0/g(u) = 0\}$ is a positive and perturbable critical zero for $f(u)$ with unstable manifold $v^-(u, \mu_\infty) = g(u)$, $0 \leq u \leq \tilde{u}_1$. Moreover, $C(\mu_\infty) = \{(u,v)/\tilde{u}_1 \leq u \leq u_\infty, v = g(u)\}$ defines a CW which connects u_∞ to $\tilde{u}_1$ with velocity $c = \mu_\infty$.

On the other hand, since $\tilde{u}_1$ is perturbable then the argument developed at the beginning of the proof can be repeated again, taking now $u = \tilde{u}_1$ as the starting point instead of u_M. Thus, a decreasing sequence of perturbable critical zeros $\{u_n^1\}$ is generated again, together with an increasing sequence of values of μ, $\{\mu_n^1\}$, with $\mu_\infty < \mu_n^1$ for each $n \in \mathbf{N}$. In addition, there exists a sequence of CWs, $\{C(\mu_n^1)\}$, which connect $u = u_n^1$ to $u = u_{n+1}^1$ with velocity $c = \mu_n^1$. If $\{u_n^1\}$ is not finite, i.e., $u_n^1 > 0$ for every $n \in \mathbf{N}$ (so option (i) in Theorem 3 does not hold in the first approximation), then we arrive at a new value $\mu_\infty^1 = \lim \mu_n^1$, $\mu_\infty^1 \leq \mu_o$, and a new zero $u_\infty^1 = \lim u_n^1$, $0 \leq u_\infty^1 < \tilde{u}_1$.

In this stage of the proof we can obtain the conclusions of Theorem 3 in two ways, namely, if $u_\infty^1 = 0$ or provided that $u_\infty^1 > 0$ and $\mu_\infty^1 = \mu_o$. If neither of those situations occurs, i.e., $u_\infty^1 > 0$ and $\mu_\infty^1 < \mu_o$, a positive perturbable zero $0 < \tilde{u}_2 < u_\infty^1$ is obtained. The proceeding can be started again at $\tilde{u}_2$ to obtain new sequences of positive perturbable critical zeros $\{u_n^2\}$, μ values $\{\mu_n^2\}$, and CWs $\{C(\mu_n^2)\}$. If neither point (i) nor (ii) holds we again get a new perturbable critical zero $0 < \tilde{u}_3 < u_\infty^2$.

Finally, assume that the proceeding is repeated infinitely many times without achieving the points (i) and (ii) in Theorem 3. That means that two sequences $\{u_\infty^n\}$,

$\{\mu_\infty^n\}$ will have been generated and $0 < u_\infty^n$ and $\mu_\infty^n < \mu_o$ for each $n \in \mathbf{N}$. However, it is implicit in the discussion developed above that $\lim u_\infty^n = 0$. Therefore, by using Proposition 5 as above (see the case $u_\infty = 0$ implies $\mu_\infty = \mu_o$) we get $\lim \mu_\infty^n = \mu_o$. Therefore, we can construct a decreasing sequence of perturbable zeros $\{u_{n_k}^k\}$, $\lim u_{n_k}^k = 0$, with associated μ values $\{\mu_{n_k}^k\}$, $\lim \mu_{n_k}^k = \mu_o$, and a sequence of CWs $\{C(\mu_{n_k}^k)\}$, such that $C(\mu_{n_k}^k)$ connects the zero $u_{n_k}^k$ to the zero $u_{n_k+1}^k$ with velocity $c = \mu_{n_k}^k$. This implies that point (ii) in Theorem 3 holds. Thus, the proof of Theorem 3 is completed. □

Remark 6.2. Observe that the unique possible option in Theorem 3 is (i) when $u = 0$ is an isolated zero.

Proof of Theorem 4. To prove the point (i) let us consider two CWs, C_1 and C_2 of equation (1.3), which connect the zeros $0 < u_1 < u_2 \leq u_M$ of $f(u)$ with velocity c. Then, there exist nonpositive functions $v = g_i(u)$, $g_i \in C([u_1, u_2])$ such that $C_i = \{(u,v)/u_1 \leq u \leq u_2\}$, $i = 1, 2$ (see Definition 2).

On the other hand, observe that the functions $g_i(u)$ are C^1 and solve the equation $(5.1)_c$ in $\{u/g_i(u) < 0\}$ (see the proof of Proposition 5). If D designates the set $D = \{u/g_1(u) \neq g_2(u)\}$ and D is nonempty, let (a, b) be some arbitrary connected piece of D. By the uniqueness of solutions to $(5.1)_c$ we arrive at $g_i(a) = g_i(b) = 0$, $i = 1, 2$. Assume, for instance, that $g_1(u) < g_2(u)$ for $u \in (a, b)$. Then,

$$\Delta = \{(u,v)/g_1(u) \leq v \leq g_2(u)\}$$

is invariant for $(3.3)_c$. That is not compatible with the dissipativeness of $(3.3)_c$ when $c > 0$. If $c = 0$ it is straightforward to show the equality $C_1 = C_2$. Thus, $C_1 = C_2$ in any case.

As for the point (ii) let us write $C(c) = \{(u,v)/u_-(c) \leq u \leq u_+(c), v = g_1(u)\}$ and $C(c') = \{(u,v)/u_-(c') \leq u \leq u_+(c'), v = g_2(u)\}$. The assertion of point (ii) is equivalent to showing that the set $\{u/g_2(u) < g_1(u), u_-(c) < u < u_+(c')\}$ is empty. First, observe that $\frac{dg_1}{du}(u_o) < \frac{dg_2}{du}(u_o)$ provided that C and C' meet at (u_o, v_o). Let (a, b) be a connected piece of that set. Since the function $g(u, \mu)$ (see Definition 1) is increasing in μ, the equality $g_1(b) = g_2(b) = 0$ is excluded. On the other hand, if $g_1(b) = g_2(b) < 0$ then the preceding observation implies $\frac{dg_1}{du}(b) > \frac{dg_2}{du}(b)$, which is not possible. Therefore, that set is empty and the proof is concluded. □

Remark 6.3. Consider the equation (3.3) with the nonlinearity $f(u) = \epsilon f_o(u) + f_o(u-1)$, where $f_o(u)$ is as in Example 5.1 and $0 < \epsilon < 1$. A careful analysis of this example reveals that the conclusion of point (ii) in Theorem 4 is false when $u_+(c) < u_+(c')$.

ANALYSIS OF THE DOMAIN INTEGRAL OPERATOR FOR ANISOTROPIC DIELECTRIC WAVEGUIDES*

H. P. URBACH†

Abstract. The domain integral equation for guided electromagnetic waves in anisotropic inhomogeneous guides is formulated. The spectral properties of the noncompact integral operator are analysed and the existence of guided modes is proved for lossless nonmagnetic media.

Key words. dielectric waveguide, anisotropic, guided wave, domain integral operator, semi-Fredholm

AMS subject classifications. 78A50, 47G10, 47A75, 47A53, 45C05

1. Introduction.

The determination of the propagation constants and field distributions of guided electromagnetic waves in open cylindrical dielectric waveguides is important in telecommunications technology and in integrated optics. In this paper we consider guides consisting of lossless, nonmagnetic, generally anisotropic and inhomogeneous materials.

Several equivalent mathematical formulations of the guided wave problem can be derived from Maxwell's equations by eliminating different components of the electromagnetic field. Neither of these formulations is an eigenvalue problem of standard type. For instance, by eliminating the axial field components one obtains an eigenvalue problem with the propagation constant as eigenvalue, but the operator in this formulation is not normal. On the other hand, in the case of lossless materials formulations exist in which the operators are self-adjoint, but then the propagation constant is not an eigenvalue but enters the problem in a more complicated way.

In spite of the fact that there exists a vast amount of literature on computational methods for dielectric waveguides, the existence of guided modes in waveguides of arbitrary cross-section has been proved only recently. By analysing the partial differential equations for the magnetic field, Bamberger and Bonnet [4] proved that for lossless isotropic media there exist at least two linearly independent guided modes.

In this paper we study the so-called domain integral equation for the electric field. This equation is obtained by applying the method of Green functions to the vector Helmholtz equation for the electric field. The propagation constant appears as parameter in the kernel of the integral operator. The determination of guided waves is then equivalent to tuning the propagation constant such that -1 is eigenvalue of the integral operator.

Guided waves are often computed by applying the finite element method directly to the partial differential equations (see, e.g., the reviews of Saad [9] and Rahman [8]). However, the domain integral equation is in many cases more suitable for numerical computations (Bagby [2], Baken [3], Pichot [7]) and therefore it is appropriate to study the integral operator mathematically.

The operator occurring in the domain integral formulation of the waveguide problem is an interesting example of an integral operator which is symmetric and bounded but not compact. By using a characterisation of semi-Fredholm operators proved in Schechter [10], we show that the nonpositive part of the spectrum of this operator

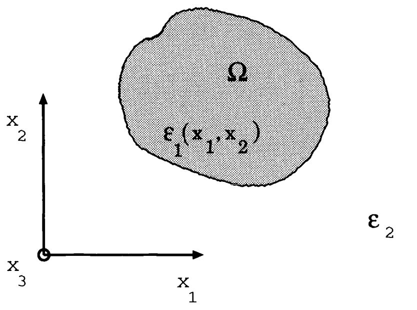

FIG. 2.1. *Cross-section* Ω *of a waveguide in a plane* $x_3 =$ *constant.*

consists of a countable set of negative eigenvalues of finite multiplicity with 0 as unique accumulation point. By applying the mini–max principle to the negative eigenvalues the existence of at least two linearly independent guided modes that propagate in the same axial direction is obtained.

2. The domain integral formulation. Let Ω be the bounded open cross-section of a cylindrical waveguide that is parallel to the x_3-axis of a Cartesian coordinate system (x_1, x_2, x_3) (see Fig. 2.1). Ω may be disconnected, in which case several waveguides with parallel axes are present. The boundary $\partial\Omega$ is assumed Lipschitz.

All materials are nonmagnetic with magnetic permeability μ_0. The guide consists of a lossless, in general inhomogeneous and anisotropic dielectric. For given frequency ω the electric permittivity in point (x_1, x_2) of Ω is given by a positive definite hermitian tensor $\epsilon_1(x_1, x_2)$ of rank 2, of which the components are bounded measurable functions on Ω. We introduce the numbers $\epsilon_{1,\max}$ and $\epsilon_{1,\min}$ by

$$\epsilon_{1,\max} = \sup_{(x_1,x_2)\in\Omega} \max_{\mathbf{V}\in\mathbf{C}^3\setminus\{0\}} \frac{\epsilon_1(x_1,x_2)\mathbf{V}\cdot\bar{\mathbf{V}}}{\mathbf{V}\cdot\bar{\mathbf{V}}}, \tag{2.1}$$

$$\epsilon_{1,\min} = \inf_{(x_1,x_2)\in\Omega} \min_{\mathbf{V}\in\mathbf{C}^3\setminus\{0\}} \frac{\epsilon_1(x_1,x_2)\mathbf{V}\cdot\bar{\mathbf{V}}}{\mathbf{V}\cdot\bar{\mathbf{V}}}. \tag{2.2}$$

The bar denotes complex conjugation and bold letters are used for vectors in $\mathbf{C}^3$.

The exterior of the guide consists of a single homogenous isotropic dielectric with permittivity ϵ_2. It is assumed that

$$\epsilon_{1,\min} \geq \epsilon_2, \tag{2.3}$$

and that for some open set $\tilde{\Omega} \subset \Omega$

$$\inf_{(x_1,x_2)\in\tilde{\Omega}} \min_{\mathbf{V}\in\mathbf{C}^3\setminus\{0\}} \frac{\epsilon_1(x_1,x_2)\mathbf{V}\cdot\bar{\mathbf{V}}}{\mathbf{V}\cdot\bar{\mathbf{V}}} > \epsilon_2. \tag{2.4}$$

In some cases (2.4) holds with $\tilde{\Omega} = \Omega$ and then (2.3) and (2.4) are equivalent to $\epsilon_{1,\min} > \epsilon_2$. However, in other applications the permittivity in the guide varies continuously from a value strictly larger than ϵ_2 to the value ϵ_2 on the boundary of the guide. This is an example for which $\epsilon_{1,\min} = \epsilon_2$ and, to include it in the analysis, we use the assumptions (2.3) and (2.4) instead of $\epsilon_{1,\min} > \epsilon_2$.

Let the permittivity tensor ϵ on $\mathbf{R}^2$ be defined by

$$\epsilon(x_1,x_2)=\begin{cases}\epsilon_1(x_1,x_2) \text{ for } (x_1,x_2)\in\Omega,\\ \\ \epsilon_2 I \text{ for } (x_1,x_2)\in\mathbf{R}^2\backslash\Omega.\end{cases} \tag{2.5}$$

In what follows we will use the symbol ϵ_2 for both the number introduced above and the tensor $\epsilon_2 I$. The meaning will be clear from the context.

For given time frequency ω we seek time harmonic solutions of the source-free Maxwell equations of the form

$$\begin{aligned}\mathcal{E}(x_1,x_2,x_3,t)&=\mathrm{Re}\{\mathbf{E}(x_1,x_2)e^{i(\beta x_3-\omega t)}\},\\ \mathcal{H}(x_1,x_2,x_3,t)&=\mathrm{Re}\{\mathbf{H}(x_1,x_2)e^{i(\beta x_3-\omega t)}\},\end{aligned} \tag{2.6}$$

for some β, where $\mathcal{E}$ and $\mathcal{H}$ are the electric and the magnetic fields, respectively. Substitution of (2.6) into Maxwell's equations yields, after elimination of the magnetic field,

$$\omega^2\mu_0\epsilon\mathbf{E}-\ \mathrm{curl}_\beta\ \mathrm{curl}_\beta\mathbf{E}=\mathbf{0}, \tag{2.7}$$

where curl_β is the differential operator obtained from the curl by replacing $\partial/\partial x_3$ by multiplication by $i\beta$. Hence, with respect to the Cartesian coordinates (x_1,x_2,x_3)

$$\mathrm{curl}_\beta\mathbf{E}=\begin{pmatrix}\frac{\partial E_3}{\partial x_2}-i\beta E_2\\ -\frac{\partial E_3}{\partial x_1}+i\beta E_1\\ \frac{\partial E_2}{\partial x_1}-\frac{\partial E_1}{\partial x_2}\end{pmatrix}. \tag{2.8}$$

The operator in the left-hand side of (2.7) will be denoted by A_β^ϵ:

$$A_\beta^\epsilon(\mathbf{E})=\omega^2\mu_0\epsilon\mathbf{E}-\ \mathrm{curl}_\beta\ \mathrm{curl}_\beta\mathbf{E}. \tag{2.9}$$

It will be considered as operator in $L^2(\mathbf{R}^2)^3$ with domain

$$D(A_\beta^\epsilon)=\{\mathbf{E}\in L^2(\mathbf{R}^2)^3;\ \mathrm{curl}_\beta\ \mathrm{curl}_\beta\mathbf{E}\in L^2(\mathbf{R}^2)^3\}. \tag{2.10}$$

It is easy to see that A_β^ϵ is a densely defined closed operator with $A_{\bar\beta}^{\bar\epsilon}$ as adjoint. In particular, for real β the operator A_β^ϵ is self-adjoint.

We conclude from (2.7) that the problem of determining all time harmonic electromagnetic waves of the form (2.6) is equivalent to determining β such that 0 is in the spectrum of A_β^ϵ. For isotropic guides it is well known [6] that for real β with $-\omega(\mu_0\epsilon_2)^{1/2}\le\beta\le\omega(\mu_0\epsilon_2)^{1/2}$, there exist nontrivial solutions of (2.7) (see Fig. 2.2). The fields $\mathbf{E}(x_1,x_2)$ and $\mathbf{H}(x_1,x_2)$ of these so-called propagating radiation modes are not in $L^2(\mathbf{R}^2)^3$. In addition there exist for all purely imaginary β solutions of (2.7) of which the fields also are not in $L^2(\mathbf{R}^2)^3$. These waves are called evanescent radiation modes. Finally, for a finite number of real β with $\omega^2\mu_0\epsilon_2<\beta^2<\omega^2\mu_0\epsilon_{1,\max}$ there exist solutions of (2.7) that are in $D(A_\beta^\epsilon)$. These solutions propagate a finite amount of energy in the x_3-direction and this energy is confined to the waveguide and its immediate surrounding. Therefore, these modes are called guided modes. The existence of guided modes was proved for isotropic guides in [4]. For $\beta^2>\omega^2\mu_0\epsilon_{1,\max}$ the operator A_β^ϵ can be shown to have a bounded inverse, hence for these β, (2.7) does not have nonzero solutions.

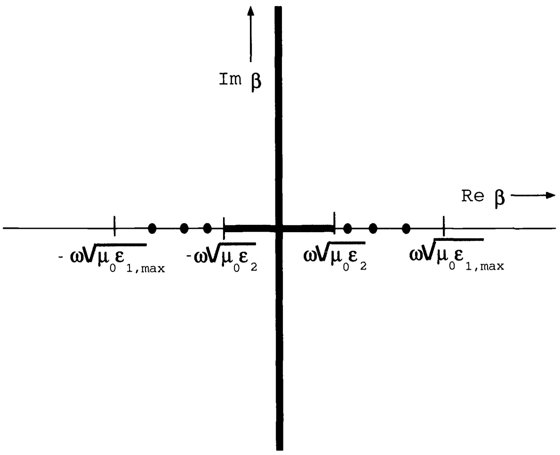

FIG. 2.2. *The set of β's corresponding to propagating radiation modes, evanescent radiation modes, and guided modes.*

It is anticipated (Marcuse [6]) that the propagating radiation modes, evanescent radiation modes, and guided modes together form a complete system. For slab waveguides the completeness of the modes is trivial because the waveguide problem can be formulated as an eigenvalue problem for a self-adjoint operator. In the case of waveguides of bounded cross-section, however, this is not possible and it seems that completeness has not been proved rigorously.

In this paper we study the guided modes and we therefore always assume that β is real and satisfies

$$\beta^2 > \omega^2\mu_0\epsilon_2. \tag{2.11}$$

The other inequality satisfied by propagation constants of guided modes, $\beta^2 < \omega^2\mu_0\epsilon_{1,\max}$, will follow from the analysis.

We use the domain integral formulation of the problem. To derive this we first write (2.7) as

$$A_\beta^{\epsilon_2}(\mathbf{E}) = -\omega^2\mu_0(\epsilon - \epsilon_2)\mathbf{E}. \tag{2.12}$$

The operator $A_\beta^{\epsilon_2}$ has constant coefficients and can thus be analysed using the Fourier transform. Let $\mathcal{F}(\mathbf{E})$ be defined by

$$\mathcal{F}(\mathbf{E})(\xi_1,\xi_2) = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \exp[-2\pi i(\xi_1 x_1 + \xi_2 x_2)]\mathbf{E}(x_1,x_2)\mathrm{d}x_1\mathrm{d}x_2. \tag{2.13}$$

By applying the Fourier transform to $A_\beta^{\epsilon_2}(\mathbf{E}) = \mathbf{G}$, one obtains the matrix multiplication

$$\widehat{A_\beta^{\epsilon_2}}(\xi_1,\xi_2)\mathcal{F}(\mathbf{E})(\xi_1,\xi_2) = \mathcal{F}(\mathbf{G})(\xi_1,\xi_2), \tag{2.14}$$

where $\widehat{A_\beta^{\epsilon_2}}(\xi_1,\xi_2)$ is the matrix

$$\widehat{A_\beta^{\epsilon_2}}(\xi_1,\xi_2) = \begin{pmatrix} \omega^2\mu_0\epsilon_2-4\pi^2\xi_2^2-\beta^2 & 4\pi^2\xi_1\xi_2 & 2\pi\xi_1\beta \\ 4\pi^2\xi_1\xi_2 & \omega^2\mu_0\epsilon_2-4\pi^2\xi_1^2-\beta^2 & 2\pi\xi_2\beta \\ 2\pi\xi_1\beta & 2\pi\xi_2\beta & \omega^2\mu_0\epsilon_2-4\pi^2(\xi_1^2+\xi_2^2) \end{pmatrix}. \tag{2.15}$$

Its determinant is given by

$$D(\xi_1,\xi_2) = \omega^2\mu_0\epsilon_2\{4\pi^2(\xi_1^2+\xi_2^2)+\beta^2-\omega^2\mu_0\epsilon_2\}^2, \tag{2.16}$$

and since $\beta^2 > \omega^2\mu_0\epsilon_2$ it follows that the matrices $\widehat{A_\beta^{\epsilon_2}}(\xi_1,\xi_2)$ are invertible for all (ξ_1,ξ_2). The inverse is

$$\widehat{A_\beta^{\epsilon_2}}(\xi_1,\xi_2)^{-1} = \frac{1}{[\omega^2\mu_0\epsilon_2\, D(\xi_1,\xi_2)]^{1/2}} \begin{pmatrix} 4\pi^2\xi_1^2-\omega^2\mu_0\epsilon_2 & 4\pi^2\xi_1\xi_2 & 2\pi\xi_1\beta \\ 4\pi^2\xi_1\xi_2 & 4\pi^2\xi_2^2-\omega^2\mu_0\epsilon_2 & 2\pi\xi_2\beta \\ 2\pi\xi_1\beta & 2\pi\xi_2\beta & \beta^2-\omega^2\mu_0\epsilon_2 \end{pmatrix}. \tag{2.17}$$

The inverse of the operator $A_\beta^{\epsilon_2}$ is then

$$\left(A_\beta^{\epsilon_2}\right)^{-1}(\mathbf{G}) = \mathcal{F}^{-1}\circ\left(\widehat{A_\beta^{\epsilon_2}}\right)^{-1}\circ\mathcal{F}(\mathbf{G}). \tag{2.18}$$

This is a bounded linear operator $L^2(\mathbf{R}^2)^3 \mapsto L^2(\mathbf{R}^2)^3$ because it is in the Fourier domain given by multiplication by the bounded matrix-valued function $(\xi_1,\xi_2)\mapsto \widehat{A_\beta^{\epsilon_2}}(\xi_1,\xi_2)^{-1}$. Using (2.18) it follows that (2.12) is equivalent to

$$-\mathbf{E} = \omega^2\mu_0\left(A_\beta^{\epsilon_2}\right)^{-1}[(\epsilon-\epsilon_2)\mathbf{E}]. \tag{2.19}$$

Now by assumption (2.3), the tensor $\epsilon(x_1,x_2)-\epsilon_2$ is positive semidefinite for all (x_1,x_2), hence its square root is well defined. We define the field

$$\mathbf{F} = (\epsilon-\epsilon_2)^{1/2}\mathbf{E}, \tag{2.20}$$

which has support contained in $\bar{\Omega}$, and we introduce the operator $T_\beta^\epsilon : L^2(\Omega)^3 \mapsto L^2(\Omega)^3$ by

$$T_\beta^\epsilon(\mathbf{F}) = \omega^2\mu_0(\epsilon-\epsilon_2)^{1/2}\circ\left(A_\beta^{\epsilon_2}\right)^{-1}\circ(\epsilon-\epsilon_2)^{1/2}\mathbf{F}, \tag{2.21}$$

where $\mathbf{F}$ is identified with the field obtained by extension of $\mathbf{F}$ to $\mathbf{R}^2$ by setting it equal to zero in the complement of Ω. Then (2.19) implies

$$-\mathbf{F} = T_\beta^\epsilon(\mathbf{F}), \quad \text{on } \Omega. \tag{2.22}$$

Hence, if $\mathbf{E}$ is the electric field of a guided mode with propagation constant β, then $\mathbf{F}$ defined by (2.20) is eigenfield of the operator T_β^ϵ with eigenvalue -1. Conversely, if $\mathbf{F}\in L^2(\Omega)^3$ is eigenfield of T_β^ϵ with eigenvalue -1, then $\mathbf{E}$ given by

$$\mathbf{E} = -\omega^2\mu_0\left(A_\beta^{\epsilon_2}\right)^{-1}\left[(\epsilon-\epsilon_2)^{1/2}\mathbf{F}\right] \tag{2.23}$$

is the electric field of a guided mode with propagation constant β. Note that for real β, T_β^ϵ is a symmetric operator. The operator in the right-hand side of (2.19) is not symmetric and this is the reason for introducing T_β^ϵ.

By computing the Fourier transforms (2.18), $(A_\beta^{\epsilon_2})^{-1}$ can be written as a matrix of convolution operators in $L^2(\Omega)$ with highly singular kernels that are derivatives with respect to x_1 and x_2 of the function $K_0\left((\beta^2-\omega^2\mu_0\epsilon_2)^{1/2}(x_1^2+x_2^2)^{1/2}\right)$, where K_0 is the modified Bessel function of order 0. We will use expression (2.18) in terms of the Fourier transforms, however.

We conclude that the determination of guided modes is equivalent to finding values for β such that -1 is eigenvalue of the operator T_β^ϵ. The fact that the domain integral equation is an equation for the field $\mathbf{F}$ with support in $\bar{\Omega}$ and is an equation to be satisfied on Ω makes it very suitable for numerical computations. In §§3 and 4 we shall derive properties of the operator T_β^ϵ and its spectrum.

3. Lack of compactness. T_β^ϵ is a bounded symmetric operator in $L^2(\Omega)^3$ but it is not compact. If T_β^ϵ were compact then the quadratic functional

$$\mathbf{F} \mapsto \left(T_\beta^\epsilon(\mathbf{F}), \mathbf{F}\right) \tag{3.1}$$

would be continuous for weakly converging sequences in $L^2(\Omega)^3$. We shall show that the functional does not have this property. The argument leading to this conclusion applies to all permittivity tensors and all cross-sections that were introduced in §2. Hence, the operator T_β^ϵ is never compact, not even when the waveguide has smooth permittivity tensor and smooth boundary.

Let

$$\operatorname{div}_\beta \mathbf{F} = \frac{\partial F_1}{\partial x_1} + \frac{\partial F_2}{\partial x_2} + i\beta F_3. \tag{3.2}$$

Its Fourier transform satisfies

$$\mathcal{F}\left(\operatorname{div}_\beta \mathbf{F}\right) = 2\pi i \xi_1 \mathcal{F}(F_1) + 2\pi i \xi_2 \mathcal{F}(F_2) + i\beta \mathcal{F}(F_3). \tag{3.3}$$

By using (2.17), (2.21), and (3.3) one can derive

$$\begin{aligned} \left(T_\beta^\epsilon(\mathbf{F}), \mathbf{F}\right) &= \omega^2 \mu_0 \left(\left(\widehat{A_\beta^{\epsilon_2}}\right)^{-1} \circ \mathcal{F}\left[(\epsilon - \epsilon_2)^{1/2} \mathbf{F}\right], \mathcal{F}\left[(\epsilon - \epsilon_2)^{1/2}\mathbf{F}\right] \right) \\ &= p_1(\mathbf{F}) - p_2(\mathbf{F}), \end{aligned} \tag{3.4}$$

where p_1 and p_2 are nonnegative continuous quadratic forms on $L^2(\Omega)^3$ defined by

$$p_1(\mathbf{F}) = \frac{1}{\epsilon_2} \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \left| \mathcal{F}\left[\operatorname{div}_\beta \left((\epsilon - \epsilon_2)^{1/2} \mathbf{F} \right) \right] \right|^2 s(|\xi|)^{-1}\, d\xi_1\, d\xi_2 \tag{3.5}$$

and

$$p_2(\mathbf{F}) = \omega^2 \mu_0 \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \left| \mathcal{F}\left[(\epsilon - \epsilon_2)^{1/2} \mathbf{F} \right] \right|^2 s(|\xi|)^{-1}\, d\xi_1\, d\xi_2 \tag{3.6}$$

with

$$s(|\xi|) = 4\pi^2 |\xi|^2 + \beta^2 - \omega^2 \mu_0 \epsilon_2, \qquad |\xi| = (\xi_1^2 + \xi_2^2)^{1/2}. \tag{3.7}$$

When considered as function of $\mathbf{G} \equiv (\epsilon - \epsilon_2)^{1/2}\mathbf{F}$, the right-hand side of (3.6) is the square of a norm which is equivalent to the norm on the space $H^{-1}(\mathbf{R}^2)^3$ (or $W^{-1,2}(\mathbf{R}^2)^3$). Because Ω is a bounded set with Lipschitz boundary, a well-known imbedding theorem (Adams [1]) implies that the inclusion $L^2(\Omega)^3 \hookrightarrow H^{-1}(\mathbf{R}^2)^3$ is compact. Hence, p_2 is continuous for sequences that converge weakly in $L^2(\Omega)^3$.

However, p_1 is not continuous for weakly converging sequences. To show this we assume that (0,0) is in the interior of the set $\tilde{\Omega}$ of property (2.4). Choose R such that the disc with center $(0,0)$ and radius R is contained in $\tilde{\Omega}$. Let (r, φ) be polar coordinates. It follows from assumption (2.4) that for $(x_1^2 + x_2^2)^{1/2} < R$ the matrices $\epsilon(x_1, x_2) - \epsilon_2$ are invertible. For integer n, let $f_n(r)$ be functions with support in $(0, R)$ such that

$$\int_0^R |f_n(r)|^2 r\, dr = 1, \tag{3.8}$$

and

$$\lim_{n\to\infty} f_n = 0 \tag{3.9}$$

weakly in L^2. Let the vector fields $\mathbf{F}_n$ be given by

$$\mathbf{F}_n = (\epsilon - \epsilon_2)^{-1/2} f_n(r)\,\hat{\mathbf{r}}, \tag{3.10}$$

where $\hat{\mathbf{r}}$ is the unit radial vector. Then $\mathbf{F}_n \in L^2(\Omega)^3$ and

$$\lim_{n\to\infty} \mathbf{F}_n = \mathbf{0}, \tag{3.11}$$

weakly in $L^2(\Omega)^3$.

We remark that for an arbitrary function $h(r)$ and integer ν the Fourier transform of the function $h(r)\exp(i\nu\varphi)$ can be written as

$$\mathcal{F}[h(r)\exp(i\nu\varphi)](\varrho,\psi) = 2\pi(-i)^\nu \int_0^\infty J_\nu(2\pi\varrho r)h(r)r\,dr\exp(i\nu\psi), \tag{3.12}$$

where ϱ, ψ are polar coordinates in the Fourier plane and J_ν is the Bessel function of order ν. By using the identity of Parseval it follows from (3.12) that

$$\int_0^\infty \left| \int_0^\infty J_\nu(2\pi\varrho r)h(r)r\,dr \right|^2 \varrho\,d\varrho = \frac{1}{4\pi^2}\int_0^\infty |h(r)|^2 r\,dr. \tag{3.13}$$

Now,

$$\operatorname{div}_\beta(f_n\hat{\mathbf{r}}) = \frac{1}{r}\frac{d}{dr}\left[r f_n(r)\right], \tag{3.14}$$

and by using (3.12) one finds after a partial integration

$$\mathcal{F}\left[\operatorname{div}_\beta(f_n\hat{\mathbf{r}})\right](\varrho,\psi) = 4\pi^2\varrho \int_0^\infty J_1(2\pi\varrho r)f_n(r)r\,dr. \tag{3.15}$$

Hence,

$$\begin{aligned} p_1(\mathbf{F}_n) &= \frac{1}{\epsilon_2}\int_0^\infty\int_0^{2\pi} |\mathcal{F}[\operatorname{div}_\beta(f_n\hat{\mathbf{r}})](\varrho,\psi)|^2 \frac{\varrho}{s(\varrho)}\,d\psi\,d\varrho \\ &= \frac{8\pi^3}{\epsilon_2}\int_0^\infty \left|\int_0^\infty J_1(2\pi\varrho r)f_n(r)r\,dr\right|^2 \frac{4\pi^2\varrho^2}{s(\varrho)}\varrho\,d\varrho \\ &= \frac{8\pi^3}{\epsilon_2}\int_0^\infty \left|\int_0^\infty J_1(2\pi\varrho r)f_n(r)r\,dr\right|^2 \varrho\,d\varrho - q(f_n), \end{aligned} \tag{3.16}$$

where

$$\begin{aligned} q(f_n) &= \frac{8\pi^3}{\epsilon_2}(\beta^2 - \omega^2\mu_0\epsilon_2)\int_0^\infty \left|\int_0^\infty J_1(2\pi\varrho r)f_n(r)r\,dr\right|^2 \frac{\varrho}{s(\varrho)}\,d\varrho \\ &= \frac{(\beta^2-\omega^2\mu_0\epsilon_2)}{\epsilon_2}\int_0^{2\pi}\int_0^\infty |\mathcal{F}[f_n\exp(i\varphi)](\varrho,\psi)|^2 \frac{\varrho}{s(\varrho)}\,d\varrho\,d\psi. \end{aligned} \tag{3.17}$$

In the last equality we used (3.12). Now, as functional of $f_n(r)\exp(i\varphi)$, the right-hand side of (3.17) is the square of a norm that is equivalent to the norm on $H^{-1}(\mathbf{R}^2)$.

Since $\lim_{n\to\infty} f_n(r)\exp(i\varphi) = 0$ weakly in $L^2(\mathbf{R}^2)$ and the supports of these functions are contained in a bounded set, it follows that

$$\lim_{n\to\infty} q(f_n) = 0. \tag{3.18}$$

On the other hand, by using (3.13) with $\nu = 1$, the first term on the right-hand side of (3.16) becomes

$$\frac{8\pi^3}{\epsilon_2}\int_0^\infty \left|\int_0^\infty J_1(2\pi\varrho r) f_n(r) r\,dr\right|^2 \varrho\,d\varrho = \frac{2\pi}{\epsilon_2}\int_0^\infty |f_n(r)|^2 r\,dr = \frac{2\pi}{\epsilon_2}. \tag{3.19}$$

Hence,

$$\lim_{n\to\infty} p_1(\mathbf{F}_n) = \frac{2\pi}{\epsilon_2}. \tag{3.20}$$

This shows that p_1 is not continuous for sequences that converge weakly in $L^2(\Omega)^3$. Hence, T^ϵ_β is not compact.

4. Spectral analysis of the integral operator. We first determine the spectrum of $A^{\epsilon_2}_\beta$ for $\beta^2 > \omega^2\mu_0\epsilon_2$. As mentioned in §2, $A^{\epsilon_2}_\beta$ with domain (2.10) is a self-adjoint operator in $L^2(\mathbf{R}^2)^3$. Let λ be a real number. The operator $A^{\epsilon_2}_\beta - \lambda I$ has constant coefficients and reduces in the Fourier domain to a matrix multiplication with matrices (2.15) in which the number $\omega^2\mu_0\epsilon_2$ is replaced by $\omega^2\mu_0\epsilon_2 - \lambda$. It follows from (2.16) that the determinants of these matrices are

$$(\omega^2\mu_0\epsilon_2 - \lambda)\left[4\pi^2(\xi_1^2+\xi_2^2) + \beta^2 - \omega^2\mu_0\epsilon_2 + \lambda\right]^2. \tag{4.1}$$

The spectrum $\sigma(A^{\epsilon_2}_\beta)$ is the set of all λ such that for some value of $\xi_1^2 + \xi_2^2$ the polynomial (4.1) vanishes. Hence,

$$\sigma(A^{\epsilon_2}_\beta) = (-\infty, \omega^2\mu_0\epsilon_2 - \beta^2] \cup \{\omega^2\mu_0\epsilon_2\}. \tag{4.2}$$

If $\lambda = \omega^2\mu_0\epsilon_2$ then $(A^{\epsilon_2}_\beta - \lambda I)(\mathbf{E}) = \mathbf{0}$ is equivalent to $\mathrm{curl}_\beta\,\mathrm{curl}_\beta\mathbf{E} = \mathbf{0}$. Hence $\lambda = \omega^2\mu_0\epsilon_2$ is eigenvalue with infinite-dimensional eigenspace

$$\mathcal{H}_{\mathrm{grad}_\beta} = \left\{\mathrm{grad}_\beta\psi\ ;\ \psi \in H^1(\mathbf{R}^2)\right\}, \tag{4.3}$$

with grad_β the operator obtained from the gradient by replacing differentiation with respect to x_3 by the multiplication by $i\beta$. On the other hand, for $\lambda \neq \omega^2\mu_0\epsilon_2$, $(A^{\epsilon_2}_\beta - \lambda I)(\mathbf{E}) = \mathbf{0}$ implies that $\mathrm{div}_\beta\mathbf{E} = \mathbf{0}$. Then every component of $\mathbf{E}$ satisfies the scalar Helmholtz equation with wavenumber $k = (\omega^2\mu_0\epsilon_2 - \beta^2 - \lambda)^{1/2}$ in two-dimensional space and the eigenfields are divergence-free vector plane waves. Therefore, the eigenspaces corresponding to the negative part of the spectrum (4.2) together span the space of vector fields that have vanishing divergence

$$\mathcal{H}_{\mathrm{div}_\beta} = \left\{\mathbf{F} \in L^2(\mathbf{R}^2)^3\ ;\ \mathrm{div}_\beta\mathbf{F} = 0\right\}. \tag{4.4}$$

One has the orthogonal decomposition

$$L^2(\mathbf{R}^2)^3 = \mathcal{H}_{\mathrm{grad}_\beta} \oplus \mathcal{H}_{\mathrm{div}_\beta}. \tag{4.5}$$

The spectrum of the inverse of $A_\beta^{\epsilon_2}$ is given by

$$\sigma\left((A_\beta^{\epsilon_2})^{-1}\right) = \left[-\frac{1}{\beta^2 - \omega^2\mu_0\epsilon_2}, 0\right] \cup \left\{\frac{1}{\omega^2\mu_0\epsilon_2}\right\}. \tag{4.6}$$

Hence, the numerical range of $\left(A_\beta^{\epsilon_2}\right)^{-1}$ is the interval

$$\left[-\frac{1}{\beta^2 - \omega^2\mu_0\epsilon_2}, \frac{1}{\omega^2\mu_0\epsilon_2}\right]. \tag{4.7}$$

Since

$$\left(T_\beta^\epsilon(\mathbf{F}), \mathbf{F}\right) = \omega^2\mu_0\left(\left(A_\beta^{\epsilon_2}\right)^{-1}\left[(\epsilon - \epsilon_2)^{1/2}\mathbf{F}\right], (\epsilon - \epsilon_2)^{1/2}\mathbf{F}\right), \tag{4.8}$$

it follows that the numerical range of T_β^ϵ is contained in the interval

$$\left[-\frac{\omega^2\mu_0\epsilon_{1,\max} - \omega^2\mu_0\epsilon_2}{\beta^2 - \omega^2\mu_0\epsilon_2}, \frac{\epsilon_{1,\max} - \epsilon_2}{\epsilon_2}\right]. \tag{4.9}$$

Hence we have

$$\sigma\left(T_\beta^\epsilon\right) \subset \left[-\frac{\omega^2\mu_0\epsilon_{1,\max} - \omega^2\mu_0\epsilon_2}{\beta^2 - \omega^2\mu_0\epsilon_2}, \frac{\epsilon_{1,\max} - \epsilon_2}{\epsilon_2}\right]. \tag{4.10}$$

To proceed with the spectral analysis of T_β^ϵ we shall apply a characterisation of semi-Fredholm operators proved in Schechter [10]. Recall that a bounded operator T is called semi-Fredholm if it has closed range and its kernel has finite dimension. If in addition its cokernel is finite dimensional, then T is called a Fredholm operator. It is clear that for self-adjoint operators there is no distinction between Fredholm and semi-Fredholm operators. For a compact symmetric operator T the operators $T - \lambda I$ are for all nonzero λ Fredholm, but for operators that are not compact this is not true. However, T_β^ϵ has the property that for all negative λ the operator $T_\beta^\epsilon - \lambda I$ is Fredholm. In the proof of this statement we shall use a characterisation of semi-Fredholm operators which we formulate next. We call a seminorm $|.|$ compact with respect to the norm of a Hilbert space $\mathcal{H}$ if every bounded sequence $\{x_n\}$ in $\mathcal{H}$ has a subsequence $\{x_{n_k}\}$ such that $\lim_{k\to\infty}\lim_{l\to\infty}|x_{n_k} - x_{n_l}| = 0$. Then we have the following result (Schechter [10]).

THEOREM 4.1. *Let T be a bounded linear operator in a Hilbert space $\mathcal{H}$. T is semi-Fredholm if and only if there exists a constant $C > 0$ and a seminorm $|.|$ which is compact with respect to the norm on $\mathcal{H}$, such that for all $x \in \mathcal{H}$*

$$\|x\| \le C\|T(x)\| + |x|. \tag{4.11}$$

We apply this theorem in the proof of the following proposition.

PROPOSITION 4.2. *$T_\beta^\epsilon - \lambda I$ is Fredholm for all $\lambda < 0$.*

Proof. We have

$$\begin{aligned}\|T_\beta^\epsilon(\mathbf{F}) - \lambda\mathbf{F}\|^2 &\ge \lambda^2\|\mathbf{F}\|^2 - 2\lambda\left(T_\beta^\epsilon(\mathbf{F}), \mathbf{F}\right)\\ &= \lambda^2\|\mathbf{F}\|^2 - 2\lambda p_1(\mathbf{F}) + 2\lambda p_2(\mathbf{F})\\ &\ge \lambda^2\|\mathbf{F}\|^2 + 2\lambda p_2(\mathbf{F}),\end{aligned} \tag{4.12}$$

where (3.4) and the fact that $p_1 \geq 0$ and $\lambda < 0$ have been used. Hence,

$$\|\mathbf{F}\| \leq \frac{1}{|\lambda|}\|T^{\epsilon}_{\beta}(\mathbf{F}) - \lambda\,\mathbf{F}\| + \left[\frac{2}{|\lambda|}p_2(\mathbf{F})\right]^{1/2}. \tag{4.13}$$

As remarked in §3, p_2 is a quadratic form that is continuous for weakly converging sequences in $L^2(\Omega)^3$.. This implies that the second term on the right-hand side of (4.13) is a seminorm which is compact with respect to the norm of $L^2(\Omega)^3$. Hence, by Theorem 4.1, $T^{\epsilon}_{\beta} - \lambda I$ is Fredholm. □

We conclude therefore that the negative part of the spectrum of T^{ϵ}_{β}, if not empty, consists of eigenvalues with finite-dimensional eigenspaces. In fact there exist infinitely many negative eigenvalues.

PROPOSITION 4.3. *T^{ϵ}_{β} has a countable set of negative eigenvalues.*

Proof. Proposition 4.2 implies that every negative element of $\sigma(T^{\epsilon}_{\beta})$ is eigenvalue with finite-dimensional eigenspace. Using

$$\begin{aligned}\left(T^{\epsilon}_{\beta}(\mathbf{F}),\mathbf{F}\right) &= \omega^2\mu_0\left(\left(\widehat{A^{\epsilon_2}_{\beta}}\right)^{-1}\circ\mathcal{F}\left[(\epsilon-\epsilon_2)^{1/2}\mathbf{F}\right],\mathcal{F}\left[(\epsilon-\epsilon_2)^{1/2}\mathbf{F}\right]\right)\\ &= p_1(\mathbf{F}) - p_2(\mathbf{F}),\end{aligned} \tag{4.14}$$

(3.5), and (3.6) we see that $(T^{\epsilon}_{\beta}(\mathbf{F}),\mathbf{F}) < 0$ for all $\mathbf{F}$ in the set

$$X(\Omega) = \left\{\mathbf{F}\in L^2(\Omega)^3\ ;\ \mathrm{div}_{\beta}[(\epsilon-\epsilon_2)^{1/2}\mathbf{F}] = 0 \text{ on } \Omega,\ (\epsilon-\epsilon_2)^{1/2}\mathbf{F}\neq\mathbf{0}\right\}. \tag{4.15}$$

Using property (2.4) we see that this set has infinite-dimensional span and therefore there must exist a countable set of negative eigenvalues. □

We can now show that the lower bound of the interval (4.10) is not in the spectrum of T^{ϵ}_{β}. If it would be in the spectrum, then it would be an eigenvalue. Let $\mathbf{F}$ be a normalised eigenfield corresponding to this eigenvalue and put

$$\mathbf{G} = \frac{(\epsilon-\epsilon_2)^{1/2}}{(\epsilon_{1,\max}-\epsilon_2)^{1/2}}\mathbf{F}. \tag{4.16}$$

Then $\|\mathbf{G}\| \leq 1$ and

$$\begin{aligned}\left(\left(A^{\epsilon_2}_{\beta}\right)^{-1}(\mathbf{G}),\mathbf{G}\right) &= \frac{1}{\omega^2\mu_0\epsilon_{1,\max}-\omega^2\mu_0\epsilon_2}\left(T^{\epsilon}_{\beta}(\mathbf{F}),\mathbf{F}\right)\\ &= -\frac{1}{\beta^2-\omega^2\mu_0\epsilon_2}.\end{aligned} \tag{4.17}$$

Because $-1/(\beta^2-\omega^2\mu_0\epsilon_2)$ is the lower bound of the numerical range of the operator $(A^{\epsilon_2}_{\beta})^{-1}$ (see (4.7)) and because $\mathbf{G}$ is in $L^2(\mathbf{R}^2)^3$, we conclude that $-1/(\beta^2-\omega^2\mu_0\epsilon_2)$ is eigenvalue of $(A^{\epsilon_2}_{\beta})^{-1}$ with eigenfield $\mathbf{G}$. This contradicts the fact that eigenfields of $(A^{\epsilon_2}_{\beta})^{-1}$ corresponding to the negative part of the spectrum are plane waves, i.e., they are not in $L^2(\mathbf{R}^2)^3$. Hence the lower bound of the interval (4.10) is not in the spectrum of T^{ϵ}_{β}.

PROPOSITION 4.4. *The negative eigenvalues are isolated and* 0 *is the unique nonpositive accumulation point of the spectrum.*

Proof. To prove this we assume that $\lambda < 0$ is accumulation point of $\sigma(T^{\epsilon}_{\beta})$. Let $\{\lambda_n\}$ be a sequence of negative eigenvalues which converge to λ and let $\{\mathbf{F}_n\}$ be a corresponding sequence of normalised eigenfields. Then by using estimate (4.13)

$$
\begin{aligned}
\|\mathbf{F}_n - \mathbf{F}_m\| &\leq \frac{1}{|\lambda|} \| T^{\epsilon}_{\beta}(\mathbf{F}_n - \mathbf{F}_m) - \lambda\,(\mathbf{F}_n - \mathbf{F}_m)\| \\
&\quad + \left[\frac{2}{|\lambda|} p_2(\mathbf{F}_n - \mathbf{F}_m)\right]^{1/2} \\
&\leq \left(|\lambda_n - \lambda| + |\lambda_m - \lambda|\right)/|\lambda| + \left[\frac{2}{|\lambda|} p_2(\mathbf{F}_n - \mathbf{F}_m)\right]^{1/2}. \qquad (4.18)
\end{aligned}
$$

There exists a subsequence, which we assume to be equal to the original sequence, such that $\lim_{n\to\infty} \lim_{m\to\infty} p_2(\mathbf{F}_n - \mathbf{F}_m) = 0$. Then (4.18) implies that $\mathbf{F}_n$ is a Cauchy sequence in $L^2(\Omega)^3$. But this contradicts the fact that $\mathbf{F}_n$ is an orthonormal system in $L^2(\Omega)^3$. This completes the proof. □

We summarise the spectral properties of the operator T^{ϵ}_{β}, with $\beta^2 > \omega^2 \mu_0 \epsilon_2$, in the following theorem.

THEOREM 4.5. *The spectrum of T^{ϵ}_{β} satisfies*

$$
\sigma\left(T^{\epsilon}_{\beta}\right) \subset \left(-\frac{\omega^2 \mu_0 \epsilon_{1,\max} - \omega^2 \mu_0 \epsilon_2}{\beta^2 - \omega^2 \mu_0 \epsilon_2}, \frac{\epsilon_{1,\max} - \epsilon_2}{\epsilon_2}\right]. \qquad (4.19)
$$

The negative part of the spectrum consists of eigenvalues λ_n with finite-dimensional eigenspaces, such that

$$
-\frac{\omega^2 \mu_0 \epsilon_{1,\max} - \omega^2 \mu_0 \epsilon_2}{\beta^2 - \omega^2 \mu_0 \epsilon_2} < \lambda_1 < \lambda_2 < \cdots < \lambda_n < \cdots < 0, \qquad (4.20)
$$

with 0 as unique accumulation point

$$
\lim_{n\to\infty} \lambda_n = 0. \qquad (4.21)
$$

The positive part of the spectrum of T^{ϵ}_{β} is more difficult to characterise than the negative part. The positive spectrum may be (partly) continuous with electric fields that are not in the domain of A^{ϵ}_{β}. In any case, the positive spectrum is not empty and is also not a countable set of eigenvalues with finite-dimensional eigenspaces and with 0 as only possible accumulation point, because then Theorem 4.5 would imply that T^{ϵ}_{β} would be a compact operator. The characterisation of the spectrum of T^{ϵ}_{β} as given in Theorem 4.5 suffices for the determination of the guided modes in the next section.

5. Guided modes. By combining the results of §§2 and 4 we see that the determination of guided modes is equivalent to determining β with $\beta^2 > \omega^2 \mu_0 \epsilon_2$, such that one of the eigenvalues of the operator T^{ϵ}_{β} is -1. In the following the eigenvalues are always numbered in increasing order and counting their multiplicities. To emphasize the dependence on β and on ϵ we denote the nth eigenvalue by $\lambda^{\epsilon}_n(\beta)$.

According to the mini–max principle we have

$$
\lambda^{\epsilon}_n(\beta) = \min_{W_n(\Omega)} \max_{\mathbf{F}\in W_n(\Omega)\setminus\{0\}} R(\mathbf{F}), \qquad (5.1)
$$

where the minimum is taken over all n-dimensional subspaces of $L^2(\Omega)^3$ and where R is the Rayleigh quotient

$$
R(\mathbf{F}) = \left(T^{\epsilon}_{\beta}(\mathbf{F}), \mathbf{F}\right) / (\mathbf{F}, \mathbf{F}). \qquad (5.2)
$$

First we recall the following result.

LEMMA 5.1. *Let A and B be positive definite matrices and let $A - B$ be positive semidefinite. Then $B^{-1} - A^{-1}$ is positive semidefinite.*

Proof. $B^{-1} - A^{-1}$ is positive semidefinite if and only if $I - B^{1/2}A^{-1}B^{1/2}$ is positive semidefinite. Therefore, it is sufficient to show that all eigenvalues of $B^{-1/2}AB^{-1/2}$ are ≥ 1. Let λ and $\mathbf{V} \neq 0$ be such that $B^{-1/2}AB^{-1/2}\mathbf{V} = \lambda\mathbf{V}$. Then $A\mathbf{W} = \lambda B\mathbf{W}$, where $\mathbf{W} = B^{-1/2}\mathbf{V}$. Since $A\mathbf{W}.\bar{\mathbf{W}} \geq B\mathbf{W}.\bar{\mathbf{W}}$ we see that $\lambda \geq 1$. □

Next we prove the following result.

LEMMA 5.2. *Let Ω' be the cross-section of a waveguide that is contained in Ω and let ϵ' be its positive definite permittivity tensor. We assume that ϵ' is identical to ϵ_2 in the exterior of Ω' and that ϵ' has the properties* (2.3) *and* (2.4) *on Ω'. Furthermore, we assume*

$$\epsilon'(x_1, x_2)\mathbf{V}.\bar{\mathbf{V}} \leq \epsilon(x_1, x_2)\mathbf{V}.\bar{\mathbf{V}} \tag{5.3}$$

for all $\mathbf{V} \in \mathbf{C}^3$ and all (x_1, x_2). Then

$$\lambda_n^{\epsilon'}(\beta) \geq \lambda_n^{\epsilon}(\beta) \tag{5.4}$$

for all n and all β with $\beta^2 > \omega^2\mu_0\epsilon_2$.

Proof. We first assume additionally that $\epsilon' - \epsilon_2$ is positive definite on Ω', i.e., that we have $\epsilon'_{1,\min} > \epsilon_2$. Then (5.3) implies that $\epsilon - \epsilon_2$ is also positive definite on Ω' and by Lemma 5.1 we have

$$(\epsilon'(x_1, x_2) - \epsilon_2)^{-1}\mathbf{V}.\bar{\mathbf{V}} \geq (\epsilon(x_1, x_2) - \epsilon_2)^{-1}\mathbf{V}.\bar{\mathbf{V}}, \tag{5.5}$$

for all $(x_1, x_2) \in \Omega'$ and all $\mathbf{V} \in \mathbf{C}^3$. Furthermore, both

$$(\epsilon'(x_1, x_2) - \epsilon_2)^{-1/2} \text{ and } (\epsilon(x_1, x_2) - \epsilon_2)^{-1/2} \tag{5.6}$$

exist and are measurable and bounded on Ω' and hence the mappings

$$\mathbf{G} \mapsto (\epsilon' - \epsilon_2)^{-1/2}\mathbf{G} \text{ and } \mathbf{G} \mapsto (\epsilon - \epsilon_2)^{-1/2}\mathbf{G} \tag{5.7}$$

are isomorphisms of $L^2(\Omega')^3$ onto itself and from n-dimensional subspaces of $L^2(\Omega')^3$ onto n-dimensional subspaces of $L^2(\Omega')^3$. Hence,

$$\begin{aligned}
\lambda_n^{\epsilon'}(\beta) &= \min_{W_n(\Omega')} \max_{\mathbf{F}\in W_n(\Omega')} \frac{\left(T_\beta^{\epsilon'}(\mathbf{F}),\, \mathbf{F}\right)}{(\mathbf{F},\, \mathbf{F})} \\
&= \min_{W_n(\Omega')} \max_{\mathbf{G}\in W_n(\Omega')} \omega^2\mu_0 \frac{\left((A_\beta^{\epsilon_2})^{-1}(\mathbf{G}),\, \mathbf{G}\right)}{\left((\epsilon' - \epsilon_2)^{-1/2}\mathbf{G},\, (\epsilon' - \epsilon_2)^{-1/2}\mathbf{G}\right)} \\
&\geq \min_{W_n(\Omega')} \max_{\mathbf{G}\in W_n(\Omega')} \omega^2\mu_0 \frac{\left((A_\beta^{\epsilon_2})^{-1}(\mathbf{G}),\, \mathbf{G}\right)}{\left((\epsilon - \epsilon_2)^{-1/2}\mathbf{G},\, (\epsilon - \epsilon_2)^{-1/2}\mathbf{G}\right)} \\
&= \min_{W_n(\Omega')} \max_{\mathbf{F}\in W_n(\Omega')} \frac{\left(T_\beta^{\epsilon}(\mathbf{F}),\, \mathbf{F}\right)}{(\mathbf{F},\, \mathbf{F})} \\
&\geq \min_{W_n(\Omega)} \max_{\mathbf{F}\in W_n(\Omega)} \frac{\left(T_\beta^{\epsilon}(\mathbf{F}),\, \mathbf{F}\right)}{(\mathbf{F},\, \mathbf{F})} \\
&= \lambda_n^{\epsilon}(\beta), \qquad (5.8)
\end{aligned}$$

where the first inequality follows from (5.5) and the fact that we may assume that $((A_\beta^{\epsilon_2})^{-1}(\mathbf{G}), \mathbf{G}) < 0$, and where the last inequality is a consequence of $\Omega' \subset \Omega$. Hence (5.4) is proved under the additional assumption that $\epsilon'_{1,\min} > \epsilon_2$.

The general case can be reduced to the previous one by replacing the tensors ϵ'_1 and ϵ_1 on Ω' and Ω by

$$\epsilon'_1 + \delta I \quad \text{and} \quad \epsilon_1 + \delta I, \tag{5.9}$$

respectively, where δ is a positive number. By the proof just given, the eigenvalues corresponding to the modified tensors satisfy (5.4) for all positive δ. Hence, by passing to the limit $\delta \to 0$, Lemma 5.2 follows for the general case. □

With this lemma we can prove Theorem 5.3.

THEOREM 5.3. *There always exist two guided modes that propagate in the same axial direction and that are linearly independent as electromagnetic fields. The propagation constants satisfy* $\beta^2 < \omega^2 \mu_0 \epsilon_{1,\max}$.

Proof. If $\mathbf{E}$ is the electric field corresponding to propagation constant β, then the field $(E_1, E_2, -E_3)^T$ corresponds to $-\beta$. Hence, it is sufficient to consider guided modes corresponding to positive β, i.e., the modes (2.6) travel in the positive x_3-direction. Because of assumption (2.4) there exists a disc Ω_R with radius R that is contained in Ω and such that

$$\epsilon_{R,1} := \inf_{(x_1,x_2)\in\Omega_R} \min_{\mathbf{V}\in\mathbf{C}^3} \frac{\epsilon(x_1,x_2)\mathbf{V}.\bar{\mathbf{V}}}{\mathbf{V}.\bar{\mathbf{V}}} > \epsilon_2. \tag{5.10}$$

We define the piecewise constant permittivity function $\epsilon_R : \mathbf{R}^2 \mapsto [0,\infty)$ by

$$\epsilon_R(x_1,x_2) = \begin{cases} \epsilon_{R,1} \text{ for } (x_1,x_2) \in \Omega_R, \\ \epsilon_2 \text{ for } (x_1,x_2) \in \mathbf{R}^2 \backslash \Omega_R. \end{cases} \tag{5.11}$$

For the isotropic, homogeneous circular waveguide Ω_R with permittivity $\epsilon_{R,1}$, one can derive transcendental equations linking the propagation constant $\beta > \omega(\mu_0\epsilon_2)^{1/2}$ to the eigenvalues $\lambda_n^{\epsilon_R}(\beta)$. These equations are listed in the appendix. We only need the property that the smallest two eigenvalues coincide,

$$\lambda_1^{\epsilon_R}(\beta) = \lambda_2^{\epsilon_R}(\beta), \tag{5.12}$$

and that

$$\lim_{\beta \downarrow \omega(\mu_0\epsilon_2)^{1/2}} \lambda_1^{\epsilon_R}(\beta) = -\infty. \tag{5.13}$$

By applying Lemma 5.2 with Ω_R instead of Ω' and with ϵ_R instead of ϵ', we obtain the inequalitites

$$\lambda_n^{\epsilon}(\beta) \le \lambda_n^{\epsilon_R}(\beta), \tag{5.14}$$

for all n and all $\beta > \omega(\mu_0\epsilon_2)^{1/2}$. Hence

$$\liminf_{\beta \downarrow \omega(\mu_0\epsilon_2)^{1/2}} \lambda_n^{\epsilon}(\beta) = -\infty, \quad \text{for } n = 1, 2. \tag{5.15}$$

Furthermore, by Theorem 4.5 we have for all n and $\beta > \omega(\mu_0\epsilon_2)^{1/2}$

$$\tau(\beta) < \lambda_n^{\epsilon}(\beta), \tag{5.16}$$

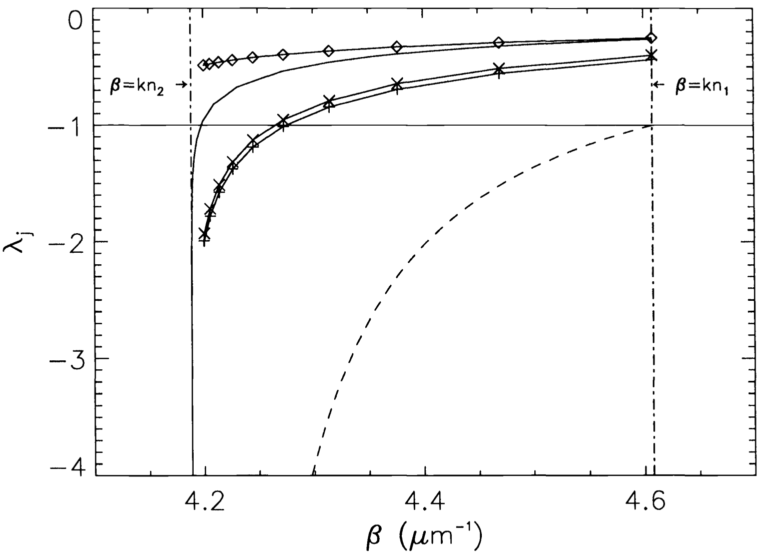

FIG. 5.1. *The smallest three eigenvalues $\lambda_1(\beta)$ (marker $+$), $\lambda_2(\beta)$ (marker $\times$), and $\lambda_3(\beta)$ (marker $\diamond$) for a homogeneous isotropic rectangular waveguide with dimensions $2\mu m \times 1\mu m$ and with refractive index $n_1 = 1.1$. The exterior region has refractive index $n_2 = 1.0$ and the wavenumber in vacuo $k = \omega(\mu_0\epsilon_0)^{1/2} = 4.18880\ (\mu m)^{-1}$. The dashed curve is the function $\tau(\beta)$ and the continuous curve is the smallest eigenvalue $\lambda_1(\beta) = \lambda_2(\beta)$ (counting muliplicity) of the largest circular waveguide contained in the rectangular guide, with refractive index n_1. It is seen that the third mode of the rectangular waveguide does not intersect the line $\lambda = -1$ and hence it is not guided. The eigenvalues of the rectangular guide were computed by applying the Galerkin method to the domain integral operator.*

where

$$\tau(\beta) = -\frac{\omega^2\mu_0\epsilon_{1,\max} - \omega^2\mu_0\epsilon_2}{\beta^2 - \omega^2\mu_0\epsilon_2}. \tag{5.17}$$

Hence

$$\lambda_n^\epsilon\left(\beta = \omega(\mu_0\epsilon_{1,\max})^{1/2}\right) > -1, \tag{5.18}$$

for all n. Because the operator T_β^ϵ depends continuously on $\beta > \omega(\mu_0\epsilon_2)^{1/2}$, so do its eigenvalues and therefore (5.15) and (5.18) imply that $\lambda_1^\epsilon(\beta)$ and $\lambda_2^\epsilon(\beta)$ both intersect the line $\lambda = -1$ at least once (see Fig. 5.1). It is clear that for positive β, points of intersection only occur for $\omega(\mu_0\epsilon_2)^{1/2} < \beta < \omega(\mu_0\epsilon_{1,\max})^{1/2}$. Hence to complete the proof it only remains to show that the modes are linearly independent as electromagnetic fields.

In case the values of β in the points of intersection are identical, the corresponding two fields are eigenfields of the same operator T_β^ϵ and hence they are linearly independent. In case the β are different, the fields are eigenfields of different operators and then the linear independence requires a proof. Now, as has already been pointed out in the introduction, the axial components E_3 and H_3 of the electromagnetic field can be eliminated from Maxwell's equations to obtain an eigenvalue problem for the remaining four components E_1, E_2, H_1, and H_2 with β eigenvalue

$$(\beta I - B^\epsilon)\begin{pmatrix} E_1 \\ E_2 \\ H_1 \\ H_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}. \tag{5.19}$$

Here B^ϵ is the operator

$$B^\epsilon \begin{pmatrix} E_1 \\ E_2 \\ H_1 \\ H_2 \end{pmatrix} = \omega \begin{pmatrix} \mu_0 H_2 \\ -\mu_0 H_1 \\ -\epsilon E_2 \\ \epsilon E_1 \end{pmatrix} + \frac{1}{\omega} \begin{pmatrix} \frac{\partial}{\partial x_1}\left[\frac{1}{\epsilon}\left(\frac{\partial H_2}{\partial x_1} - \frac{\partial H_1}{\partial x_2}\right)\right] \\ \frac{\partial}{\partial x_2}\left[\frac{1}{\epsilon}\left(\frac{\partial H_2}{\partial x_1} - \frac{\partial H_1}{\partial x_2}\right)\right] \\ -\frac{1}{\mu_0}\frac{\partial}{\partial x_1}\left(\frac{\partial E_2}{\partial x_1} - \frac{\partial E_1}{\partial x_2}\right) \\ -\frac{1}{\mu_0}\frac{\partial}{\partial x_2}\left(\frac{\partial E_2}{\partial x_1} - \frac{\partial E_1}{\partial x_2}\right) \end{pmatrix}. \tag{5.20}$$

Because the electromagnetic fields of guided modes satisfy (5.19), we conclude that when the propagation constants differ, the electromagnetic fields are also always linearly independent. Hence Theorem 5.3 is proved. □

Although formulation (5.19) may at first sight seem relatively simple because it is in terms of an ordinary eigenvalue problem with the propagation constant as eigenvalue, it is actually difficult to study because the differential operator B^ϵ is not normal.

It should be noted that for $n = 1$ and for $n = 2$ only we have

$$\liminf_{\beta \downarrow \omega(\mu_0 \epsilon_2)^{1/2}} \lambda_n^\epsilon(\beta) = -\infty. \tag{5.21}$$

For $n \geq 3$ this lim inf is a finite negative number which, depending on the values of the permittivity and on the geometry of the cross-section, can be smaller or larger than -1. This can be verified explicitly for the case of the circular waveguide. Then, by choosing a circular waveguide that encloses the waveguide with cross-section Ω and has homogeneous isotropic permittivity $\epsilon_{R,1}$ with $\epsilon_{R,1} > \epsilon_{1,\max}$, the eigenvalues $\lambda_n^\epsilon(\beta)$ can be estimated from below by the $\lambda_n^{\epsilon_R}(\beta)$ and thus the lim inf in (5.21) is finite for $n \geq 3$ also in the general case. If the lim inf is smaller than -1 for a certain n, then for all $m \leq n$ the curves $\lambda_m^\epsilon(\beta)$ intersect $\lambda = -1$ at least once. Note that the proof of Theorem 5.3 implies that whenever two eigenvalue curves $\lambda_n^\epsilon(\beta)$ and $\lambda_m^\epsilon(\beta)$, with $n \neq m$, intersect $\lambda = -1$, the corresponding guided modes are always linearly independent as electromagnetic fields, whether the propagation constants are equal or not.

Numerical calculations suggest that the eigenvalues are increasing functions of $\beta > \omega(\mu_0\epsilon_2)^{1/2}$, but this has not been proved. It would be interesting to have a general proof because then we could conclude that each curve of eigenvalues $\lambda_n^\epsilon(\beta)$ yields at most one guided mode with positive β. Furthermore, the test whether the lim inf in (5.21) is smaller than -1 would not merely be a sufficient but also a necessary condition for that curve to yield a guided mode.

In addition to the mini–max principle (5.1) the following characterisation of the eigenvalues is useful:

$$\lambda_n^\epsilon(\beta) = \min_{\mathbf{F} \in \mathcal{H}_{n-1}^\perp,\, \|\mathbf{F}\| \leq 1} \left(T_\beta^\epsilon(\mathbf{F}),\, \mathbf{F}\right), \tag{5.22}$$

where $\mathcal{H}_{n-1}^\perp$ is the orthogonal complement in $L^2(\Omega)^3$ of the $(n-1)$-dimensional space of eigenfields corresponding to the smallest $n-1$ eigenvalues (counting multiplicities, of course). It is interesting to note that the existence of a solution of minimization problem (5.22) can be inferred directly from expression (3.4) for the quadratic form $(T^{\epsilon}_{\beta}(\mathbf{F}),\, \mathbf{F})$, without using a priori knowledge about the spectrum of T^{ϵ}_{β}. In fact, by (3.4)

$$\Big(T^{\epsilon}_{\beta}(\mathbf{F}),\, \mathbf{F}\Big) = p_1(\mathbf{F}) - p_2(\mathbf{F}), \tag{5.23}$$

where $p_1, p_2 : L^2(\Omega)^3 \mapsto [0, \infty)$ are continuous convex quadratic forms. The functional p_2 is in addition continuous for sequences that converge weakly in $L^2(\Omega)^3$. Hence both p_1 and $-p_2$ and therefore also the functional on the left-hand side of (5.23) are lower semicontinuous for sequences that converge weakly in $L^2(\Omega)^3$. The set in (5.22) in which the minimum is sought is compact with respect to the weak topology. Hence, the existence of a solution to minimization problem (5.22), and thus of an eigenfield of T^{ϵ}_{β}, follows from the general theorem that a lower semicontinuous functional attains its infimum on a compact set.

Characterisation (5.1) is particularly useful to deduce properties of numerical approximations. When for every fixed β an eigenvalue $\lambda^{\epsilon}_{n}(\beta)$ and the corresponding eigenfields are approximated by applying the Galerkin method to the domain integral equation, then (5.1) holds also for the discretised problem, provided the minimization over the n-dimensional spaces is restricted to subspaces of the finite-dimensional space used in the Galerkin approximation. It is thus evident that in the limit of increasing Galerkin base spaces, the computed eigenvalues approximate the exact eigenvalues from above. The convergence of the corresponding normalised eigenfields can be deduced from decomposition (5.23) of the quadratic form $(T^{\epsilon}_{\beta}(\mathbf{F}),\, \mathbf{F})$, using the fact that p_1 is a nonnegative bounded quadratic form and that p_2 is compact. By employing an appropriate iteration scheme to solve $\lambda^{\epsilon}_{n}(\beta) = -1$, the guided modes are determined. Hence, the Galerkin method applied to the domain integral equation always yields a converging algorithm. This is in contrast to the finite-element method applied directly to the partial differential equations. In the latter case the condition that the field has vanishing divergence has to be taken care of in the discretised equations because otherwise it can happen that the algorithm does not converge [8]. More details on computational aspects of the Galerkin method can be found in [12].

Appendix. Eigenvalues for the isotropic circular waveguide. Let Ω_R be a disc with radius R and let $\epsilon : \mathbf{R}^2 \mapsto [0, \infty)$ be the piecewise constant permittivity given by

$$\epsilon(x_1, x_2) = \begin{cases} \epsilon_1 & \text{for } (x_1, x_2) \in \Omega_R, \\ \epsilon_2 & \text{for } (x_1, x_2) \in \mathbf{R}^2 \backslash \Omega_R, \end{cases} \tag{A.1}$$

where ϵ_1 and ϵ_2 are positive constants with $\epsilon_1 > \epsilon_2$. Let β satisfy (2.11). Let $\lambda < 0$ be an eigenvalue of T^{ϵ}_{β} for the circular waveguide and let $\mathbf{F}$ be the eigenfield

$$\lambda \mathbf{F} = T^{\epsilon}_{\beta}(\mathbf{F}). \tag{A.2}$$

Using definition (2.21) of T^{ϵ}_{β}, it follows that

$$-\mathbf{F} = T^{\epsilon_{|\lambda|}}_{\beta}(\mathbf{F}), \tag{A.3}$$

where $\epsilon_{|\lambda|}$ is given by

$$\epsilon_{|\lambda|} = \epsilon_2 + \frac{\epsilon - \epsilon_2}{|\lambda|}. \tag{A.4}$$

Hence, $\mathbf{F}$ is eigenfield of the guided mode with propagation constant β of the circular waveguide with permittivity $\epsilon_{|\lambda|,1} = \epsilon_2 + (\epsilon_1 - \epsilon_2)/|\lambda|$ and with a cladding having permittivity ϵ_2. The guided modes of the circular waveguide are computed in many textbooks (e.g., [5], [11]). We give the equations that link the propagation constants β to the dielectric constant of the guide $\epsilon_{|\lambda|,1}$ and hence to the eigenvalues λ. Let $u = R\,(\omega^2\mu_0\epsilon_{|\lambda|,1} - \beta^2)^{1/2}$ and $w = R\,(\beta^2 - \omega^2\mu_0\epsilon_2)^{1/2}$. Then for some $m = 0, 1, 2, \dots$

$$\text{(A.5)}\quad \left\{\left[1 + \frac{u^2 + w^2}{R^2\,\omega^2\mu_0\epsilon_2}\right]\mathcal{J}_m(u) + \mathcal{K}_m(w)\right\}\{\mathcal{J}_m(u) + \mathcal{K}_m(w)\} - m^2\,\mathcal{D}(u,w) = 0,$$

where

$$\mathcal{J}_m(u) = \frac{J_m'(u)}{u\,J_m(u)},\quad \mathcal{K}_m(w) = \frac{K_m'(w)}{w\,K_m(w)},$$

$$\text{(A.6)}\qquad \mathcal{D}(u,w) = \left(1 + \frac{w^2}{R^2\,\omega^2\mu_0\epsilon_2}\right)\left(\frac{1}{u^2} + \frac{1}{w^2}\right)^2,$$

with J_m and K_m Bessel and modified Bessel functions, respectively. The eigenfields corresponding to the solutions of (A.5) for given m depend on the angle variable φ through the factor $\exp(i\,m\,\varphi)$ or $\exp(-i\,m\,\varphi)$. For $m \geq 1$ this means that there always exist two linearly independent fields corresponding to the same solution pair β, λ of (A.5). By using an approximation of $\mathcal{K}_1(w)$ for $w \approx 0$, it can be shown that for $m = 1$ there exists for every β with $\omega^2\mu_0\epsilon_2 < \beta^2 < \omega^2\mu_0\epsilon_1$ a solution λ of (A.5), such that if $\beta^2 \downarrow \omega^2\mu_0\epsilon_2$ then $\lambda \to -\infty$ [5], [11]. Furthermore, this solution is the smallest solution for all β. Hence it is equal to the lowest two eigenvalues $\lambda_1(\beta) = \lambda_2(\beta)$ when counting multiplicities.

Acknowledgment. I thank Prof. Ricardo Weder of the Universidad Nacional Autónoma de México for very valuable discussions.

WHEN THE LONG-TIME BEHAVIOR IS INDEPENDENT OF THE INITIAL DENSITY*

ANDRZEJ LASOTA† AND JAMES A. YORKE‡

Abstract. This paper investigates dynamical processes for which the state at time t is described by a density function, and specifically dynamical processes for which the shape of the density becomes largely independent of the initial density as time increases. A sufficient condition (weak ergodic theorem) is given for this "asymptotic similarity" of densities. The processes investigated are in general time dependent, that is, nonhomogeneous in time. Our condition is applied to processes generated by expanding mappings on manifolds, piecewise convex transformations of the unit interval, and integro-differential equations.

Key words. asymptotic behavior, Frobenius–Perron operator, invariant density, expanding mapping, integro-differential equation

AMS subject classifications. Primary 47A35; Secondary 58F11, 46D05

Introduction. A central feature in much of ergodic theory is that there is an invariant density or an invariant measure to which other initial densities are attracted as time evolves. The classical example is the Boltzmann equation and the celebrated H-theorem, which says that the process evolves to the state described by the density which maximalize the entropy. However, in some cases where there may be no stationary density, the long-time behavior is nonetheless independent of the initial distribution. For example, processes that vary in time do not in general have a stationary distribution. Results concerning the asymptotic behavior of such processes are often called weak ergodic theorems. One of the main problems of the weak ergodic theory can be summarized as follows. Consider a sequence of operators $P_1, P_2, \dots$ on a function space $L(X)$ and the ratio

$$q_n(x) = \frac{P_n P_{n-1} \cdots P_1 f(x)}{P_n P_{n-1} \cdots P g(x)} \quad \text{for } f, g \in L(X).$$

Find conditions under which $\{q_n(x)\}$ converges to a constant. In the case of linear operators P_i, answers to this question were given by many authors, see for example [G–K–R] and [C]. A systematic treatment in the special case where P_i are nonnegative matrices can be found in [Se]. The nonlinear case was considered in [F–K] and [N]. These results were obtained in general by quite sophisticated methods in which some topological, geometrical, and analytical properties of the space X and generators P_i played an important role. A particularly useful technique is related with Hilbert projection metric and its extensions [B].

A different method for studying the asymptotic behavior of the quotient $q_n(x)$ was proposed by D. Ruelle in his study of ergodic properties of the lattice gas [Rl]. In

some places, his arguments are close to ours. In particular, he uses as in our proof of Theorem 1 the consecutive evaluation of $q_n(x)$ by a sequence of constants. However, as a whole, the Ruelle proof is based on the specific, delicate properties of the Gibbs measures. Further, in his case, the invariant measure always exists, which allows him to obtain a result corresponding to our formula (1.4).

Our approach is based on a relatively simple lower-bound technique. This method has two advantages. First, we do not need to assume any compactness conditions. Second, in applications a lower bound can be explicitly constructed due to the special properties of systems under consideration.

The paper is organized as follows. In this introductory section we show two examples which illustrate the notion of asymptotic similarity. The precise definition of this notion and the formulation of our main result—a convergence theorem—are given in §1. The next section is devoted to the proof. Section 3 contains an application to processes defined by expanding mappings on manifolds. In §4, we study processes defined by piecewise convex transformations on the unit interval. Finally, in §5, we show an application to integro-differential equations.

We now proceed with the examples.

Example 1. Assume that our state space is the interval [0, 1] and that the system under consideration evolves as follows. We have a sequence of transformations

$$F_i : [a_i, b_i] \xrightarrow{\text{onto}} [0,1], \qquad i = 0, 1, 2, \dots,$$

where $[a_i, b_i]$ are subintervals of [0, 1]. (This is basically a time-dependent process in which F_i is applied at time i.) We assume that F_i are C^1 functions with derivatives that satisfy

$$(0.1) \qquad |F_i'(x)| \geq \lambda > 1 \quad \text{for } x \in [a_i, b_i]; \qquad i = 0, 1, 2, \dots,$$

where λ is a constant independent of i. Given an initial point $x_0 \in [0,1]$, we define

$$(0.2) \qquad x_{n+1} = F_n(x_n) \quad \text{if } x_n \in [a_n, b_n].$$

If $x_n \notin [a_n, b_n]$, the process terminates and x_j is not defined for $j > n$. Now assume that x_0 is not fixed but is a random variable with a density distribution function f_0. Then the densities f_n of x_n are defined by the formula

$$(0.3) \qquad \int_A f_{n+1}(x)\,dx = \int_{F_n^{-1}(A)} f_n(x)\,dx \quad \text{for } A \subset [0,1], \quad A \text{ measurable.}$$

This formula becomes obvious if we observe that x_{n+1} is defined and belongs to A if and only if $x_n \in F_n^{-1}(A)$. Setting $G_i = F_i^{-1}$, we immediately obtain from (0.3)

$$(0.4) \qquad f_{n+1}(x) = |G_n'(x)| f_n(G_n(x)), \qquad n = 0, 1, \dots,$$

where $'$ denotes the derivative. Now choose two strictly positive continuous initial functions f_0 and g_0 and consider the corresponding sequences of distributions f_n and g_n. It is easy to show that the sequence of quotients

$$(0.5) \qquad q_n(x) = \frac{f_n(x)}{g_n(x)}$$

converges uniformly to a constant. In fact, from (0.4) it follows that

$$q_n(x) = \frac{f_0(\varphi_n(x))}{g_0(\varphi_n(x))}, \tag{0.6}$$

where $\varphi_n = G_0 \circ \cdots \circ G_{n-1}$. Further, according to (0.1), we have $|G_i'| \leq \lambda^{-1}$ and consequently, by the chain rule, $|\varphi_n'| \leq \lambda^{-n}$. Thus, the length of the intervals $\varphi_n([0,1])$ is at most λ^{-n}. Since the sequence of intervals $\varphi_n([0,1])$ is decreasing, i.e.,

$$\varphi_{n+1}([0,1]) = \varphi_n(G_n([0,1])) \subset \varphi_n([0,1]),$$

it has a unique common point, which we denote by x_*. This in turn implies that $\varphi_n(x)$ converges to x_* uniformly in x and, finally, due to (0.6),

$$\lim_{n\to\infty} q_n(x) = \frac{f_0(x_*)}{g_0(x_*)} \quad \text{uniformly in } x.$$

Observe that the sequences $\{f_n\}$ and $\{g_n\}$ converge uniformly to zero.

Example 2. Now let our state space be the unit circle S^1. (We obtain S^1 from [0, 1] by identifying the endpoints 0 and 1.) Let $F_i : S^1 \to S^1$ $(i = 0, 1, 2, \ldots)$ be a sequence of C^2 transformations satisfying the inequality $|F_i'(x)| \geq \lambda > 1$ $(x \in S^1, i = 0, 1, \ldots)$, which is analogous to (0.1). We define our dynamics by $x_{n+1} = F_n(x_n)$ $(n = 0, 1, \ldots)$ starting with an initial $x_0 \in S^1$. This time, however, the process never stops. As before, the corresponding sequence of densities f_n is defined by condition (0.3). To find a more explicit formula, observe that the inequality $F_i'(x) \neq 0$ implies that every point $x \in S^1$ has a finite number of counterimages which are functions of x. Thus

$$F_i^{-1}(x) = \{G_{i1}(x), \ldots, G_{ik_i}(x)\},$$

where k_i is the number of primages of each x for the function F_1. In a neighborhood of x, every inverse function $G_{i,j}$ of F_i is C^2 and satisfies the inequality $|G_{ij}'| \leq \lambda^{-1}$. Using these functions and condition (0.3), we immediately obtain

$$f_{n+1}(x) = \sum_{j=1}^{k_n} |G_{nj}'(x)| f_n(G_{nj}(x)). \tag{0.7}$$

Once again we may study the quotient (0.5). We will prove that it converges to the constant

$$c = \frac{\int_0^1 f_0(x)\,dx}{\int_0^1 g_0(x)\,dx}. \tag{0.8}$$

However, this cannot be done immediately. In the simplest case, where $F_n = F$ are the same for all n, the convergence $q_n(x) \to c$ is equivalent to the fact that, under the dynamical system (F, S^1), densities evolve asymptotically to an invariant density—the classical result of ergodic theory ([Re], [Ro], [Li]). We will come back to this example in §4 when our main result, Theorem 1, will be proved. Here we can explain only why the limit of the quotient $q_n(x)$, when it exists, must be equal to (0.8). This is due to the special property of the mapping $f_n \to f_{n+1}$ given by the formula (0.7).

Namely, it preserves the integral. Writing (0.5) in the form $f_{n+1}(x) = q_n(x)f_n(x)$ and integrating, we obtain, under assumption $q_n(x) \to c$, equality (0.8).

1. The asymptotic similarity. Let X be a nonempty set. Let $B(X)$ denote the space of all real-valued bounded functions $f : X \to \mathbb{R}$ with the supremum norm. Let $L = L(X)$ be an arbitrary fixed linear subspace of $B(X)$. For example, X might be a compact space and L could be the space of continuous functions on X. Let $L_+ = L_+(X)$ denote the subset of L consisting of the strictly (uniformly) positive functions, i.e.,

$$L_+ = \{f \in L : \inf f > 0\}.$$

We assume that L_+ is a nonempty set.

A linear operator $P : L \to L$ will be called *positive* if $P(L_+) \subset L_+$. Observe that a positive operator is monotonic, i.e., $Pf \le Pg$ whenever $f \le g$. By linearity, it is sufficient to verify that P positive implies $Pf \ge 0$ when $f \ge 0$. To prove the last property, fix an $f \ge 0$ and choose an arbitrary $h \in L_+$. Then $n^{-1}h + f \in L_+$ for $n = 1, 2, \ldots$, and consequently

$$n^{-1}Ph + Pf = P(n^{-1}h + f) \in L_+;$$

in particular, $n^{-1}Ph + Pf \ge 0$. Passing to the limit as $n \to \infty$, we have $Pf \ge 0$. Furthermore, a positive operator is always bounded. To see this, again choose an $h \in L_+$ and set $\alpha = \inf h$ and $\beta = \sup Ph$. We have

$$Pf = P\left(\frac{f}{h}\, h\right) \le P\left(\frac{\|f\|}{\alpha}\, h\right) \le \frac{\beta}{\alpha}\, \|f\|;$$

analogously

$$-Pf = P\left(-\, \frac{f}{h} h\right) \le \frac{\beta}{\alpha}\, \|f\|.$$

This implies

$$\|Pf\| \le \frac{\beta}{\alpha}\, \|f\|.$$

Our goal is to study a family $P(t,s)$ ($t \ge s$; $t, s \in \mathcal{D}(P)$) of linear positive operators. We will say that $P(t,s)$ is a *process* if $P(s,s) = I$ (identity) and

$$P(t,r)P(r,s) = P(t,s) \quad \text{for } t \ge r \ge s; \qquad t, r, s \in \mathcal{D}(P) \tag{1.1}$$

and if the domain $\mathcal{D}(P)$ is a subset of the real line which contains a sequence converging to $+\infty$. In applications, $\mathcal{D}(P)$ is either the set of nonnegative integers or the half-line $\mathbb{R}_+ = [0, \infty)$. We say the process is *positive* if $P(t,s)$ is a (linear) positive operator for all $t \ge s$ in $\mathcal{D}(P)$.

We now are ready to state our main result.

We will say $P(t,s)$ is an *eventually uniformly positive process* if $P(t,s)$ is a positive process and there is a subset $L_0 \subset L_+$ that is dense in L_+ and a constant $\alpha > 0$ such that, for every $f \in L_0$ and $s \in \mathcal{D}(P)$, the inequality

$$\frac{P(t,s)f}{\|P(t,s)f\|} \ge \alpha \tag{1.2}$$

holds for sufficiently large t, that is, for $t \geq t_0 = t_0(f, s)$. We will say that $P(t, s)$ has the property of *asymptotic similarity* if, for every $f \in L$, $g \in L_+$, and $s \in \mathcal{D}(P)$, there is a constant $c = c(f, g, s)$ such that

$$\lim_{t \to \infty} \left\| \frac{P(t,s)f}{P(t,s)g} - c \right\| = 0. \tag{1.3}$$

THEOREM 1. *Every eventually uniformly positive process has the property of asymptotic similarity.*

The proof will be given in the next section.

Now consider two special cases when $P(t, s)$ is generated by an operator or by a continuous semigroup.

When $P : L \to L$ is a positive operator, then

$$P(n, m) = P^{n-m}, \qquad n \geq m$$

is a process whose domain consists of nonnegative integers. Conditions (1.2) and (1.3) now simplify to

$$\frac{P^n f}{\|P^n f\|} \geq \alpha \quad \text{for } n \geq n_0(f) \tag{1.2$'$}$$

and

$$\lim_{n \to \infty} \left\| \frac{P^n f}{P^n g} - c(f, g) \right\| = 0, \tag{1.3$'$}$$

respectively. Assume now that P has a positive eigenfunction, i.e.,

$$P f_* = \lambda f_*$$

for some $\lambda > 0$ and $f_* \in L_+$. Then according to (1.3′),

$$\lambda^{-n} P^n f = \frac{f_* P^n f}{\lambda^n f_*} = \frac{f_* P^n f}{P^n f_*} \to c(f, f_*) f_*.$$

Since $\lambda^{-n} P^n f$ depends linearly on f and f_* is positive, the functional $\sigma(f) = c(f, f_*)$ is uniquely determined and linear. Thus we have

$$\lim_{n \to \infty} \|\lambda^{-n} P^n f - \sigma(f) f_*\| = 0 \quad \text{for } f \in L. \tag{1.4}$$

This shows that, for large n, the shape of the functions $P^n f$ is nearly the same and the amplitude changes in a geometrical progression.

Now let $P^t : L \to L, t \in \mathbb{R}_+$, be a continuous semigroup. Thus, we have

$$P^0 = I \text{ (identity)}; \qquad P^{t_1+t_2} = P^{t_2+t_2} = P^{t_1} P^{t_2} \quad \text{for } t_1, t_2 \geq 0$$

and

$$\lim_{t \to 0} \|P^t f - f\| = 0 \quad \text{for } f \in L.$$

We define a process $P(t, s)$, setting

$$P(t, s) = P^{t-s} \quad \text{for } t \geq s \geq 0.$$

Again, conditions (1.2) and (1.3) reduce to

$$\text{(1.2}''\text{)} \qquad \frac{P^n f}{\|P^n f\|} \geq \alpha \quad \text{for } t \geq t_0(f)$$

and

$$\text{(1.3}''\text{)} \qquad \lim_{t\to\infty} \left\| \frac{P^t f}{P^t g} - c(f,g) \right\| = 0.$$

Assume that for some $t_0 > 0$ the operator P^{t_0} has a positive eigenvalue λ corresponding to an eigenfunction $f_* \in L_+$. Following [L–R], we can find an explicit formula describing the behavior of $P^t f$. Define $\gamma = (1/t_0)\log\lambda$. According to (1.4), we have

$$\text{(1.5)} \qquad \lim_{n\to\infty} \|e^{-\gamma n t_0} P^{n t_0} f - \sigma(f) f_*\| = 0 \quad \text{for } f \in L.$$

Substituting $f = P^t f_*$ into (1.5), we obtain

$$\text{(1.6)} \qquad P^t f_* = \sigma(P^t f_*) f_* \quad \text{for } t \geq 0.$$

Due to the continuity of $P^t f_*$, with respect to t, the function $\beta(t) = \sigma(P^t f_*)$ is continuous. From (1.6), it follows that β satisfies the Cauchy equation

$$\beta(t_1 + t_2) = \beta(t_1)\beta(t_2) \quad \text{for } t_1 \geq 0; \qquad t_2 \geq 0.$$

Thus β is an exponential function. From (1.6), it follows also that $\beta(t_0) = e^{\gamma t_0}$. Thus $\beta(t) = e^{\gamma t}$ and (1.6) admits the form

$$\text{(1.7)} \qquad P^t f_* = e^{\gamma t} f_*.$$

Now we may repeat the argument used in the discrete time case and write

$$e^{-\gamma t} P^t f = \frac{f_* P^t f}{e^{\gamma t} f_*} = \frac{f_* P^t f}{P^t f_*},$$

and, according to (1.3″), we finally obtain

$$\text{(1.8)} \qquad \lim_{t\to\infty} \|e^{-\gamma t} P^t f - \sigma(f) f_*\| = 0,$$

with $\sigma(f) = c(f, f_*)$, which is the desired formula.

2. Proof of the convergence theorem. The proof will be given in several steps.

Step I. First observe that, for every $f \in L$ and $g \in L_+$, the inequality

$$a \leq \frac{f}{g} \leq b,$$

where a and b are constants, implies

$$a \leq \frac{P(t,s)f}{P(t,s)g} \leq b \quad \text{for } t \geq s; \qquad t, s \in \mathcal{D}(P).$$

To verify this, multiply the first inequality by g, apply operator $P(t,s)$, and then divide by $P(t,s)g$.

Step II. We now show the following extension of inequality (1.2). If the number α is replaced by an arbitrary $\alpha' < \alpha$, then (1.2) holds for every $f \in L_+$. To prove this, fix $\alpha' < \alpha$. For given $f \in L_+$, choose an $\varepsilon > 0$ such that

$$\frac{1+\varepsilon}{1-\varepsilon}\,\alpha' \le \alpha, \qquad \varepsilon < 1$$

and a $\delta > 0$ satisfying

$$\frac{\delta}{\inf f - \delta} \le \varepsilon, \qquad \delta < \inf f.$$

Since L_0 is dense in L_+, there is an $\bar{f} \in L_0$ such that $\|f - \bar{f}\| \le \delta$. We therefore have

$$\left|\frac{f}{\bar{f}} - 1\right| \le \frac{\delta}{\bar{f}} \le \frac{\delta}{\inf f - \delta} \le \varepsilon,$$

and, according to Step I,

$$\left|\frac{P(t,s)f}{P(t,s)\bar{f}} - 1\right| \le \varepsilon \quad \text{for } t \ge s; \qquad t,s \in \mathcal{D}(P).$$

Now let $t_0 = t_0(f,s)$ be chosen such that

$$\frac{P(t,s)\bar{f}}{\|P(t,s)\bar{f}\|} \ge \alpha \quad \text{for } t \ge t_0.$$

Then, finally,

$$\frac{P(t,s)f}{\|P(t,s)f\|} = \frac{P(t,s)f/P(t,s)\bar{f}}{\|P(t,s)f\|/\|P(t,s)\bar{f}\|} \cdot \frac{P(t,s)\bar{f}}{\|P(t,s)\bar{f}\|} \ge \frac{1-\varepsilon}{1+\varepsilon}\,\alpha \ge \alpha' \quad \text{for } t \ge t_0.$$

Step III. Let r be an arbitrary real number satisfying $r \ge 1/(\alpha')^2$. We claim that, for every $f, g \in L_+$ and $s \in \mathcal{D}(P)$, there is a $t_1 = t_1(f,g,s)$ such that

$$\sup \frac{P(t,s)f}{P(t,s)g} \le r \inf \frac{P(t,s)f}{P(t,s)g} \quad \text{for } t \ge t_1. \tag{2.1}$$

To prove this, choose $t_0(f,s)$ and $t_0(g,s)$ according to Step II and set $t_1 = \max(t_0(f,s), t_0(g,s))$. We have

$$\sup \frac{P(t,s)f}{P(t,s)g} \le \frac{\sup P(t,s)f}{\inf P(t,s)g} \le \frac{(\alpha')^{-1} \inf P(t,s)f}{\alpha' \sup P(t,s)g} \le r \inf \frac{P(t,s)f}{P(t,s)g} \quad \text{for } t \ge t_1.$$

Step IV. Choose $r > 1$ according to Step III. Assume that $f, g \in L_+$ and

$$0 < a \le \frac{f}{g} \le b,$$

where a, b are constants. Fix an $s \in \mathcal{D}(P)$. We claim that there is a $t_2 = t_2(f,g,a,b,s)$ and constants a_* and b_* such that

$$a_* \le \frac{P(t,s)f}{P(t,s)g} \le b_* \quad \text{for } t \ge t_2 \tag{2.2}$$

and

$$b_* - a_* \le \left(1 - \frac{1}{2r}\right)(b - a). \tag{2.3}$$

To prove the claim choose a number δ such that

$$0 < \delta < \min\left(a, \frac{b-a}{2(r-1)}\right) \tag{2.4}$$

and define $\rho = a - \delta$. Then $f - \rho g \in L_+$. Applying inequality (2.1) to $f - \rho g$ and g, we obtain

$$\sup \frac{P(t,s)(f-\rho g)}{P(t,s)g} \le r \inf \frac{P(t,s)(f-\rho g)}{P(t,s)g} \quad \text{for } t \ge t_2, \tag{2.5}$$

where $t_2 = t_2(f - \rho g, g, s)$. Now set

$$a_* = \inf \frac{P(t_2,s)f}{P(t_2,s)g}, \qquad b_* = \sup \frac{P(t_2,s)f}{P(t_2,s)g}.$$

Applying the result of Step I to functions $P(t_2,s)f$, $P(t_2,s)g$ and to the operator $P(t,t_2)$, we obtain immediately

$$a_* \le \frac{P(t,t_2)P(t_2,s)f}{P(t,t_2)P(t_2,s)g} \le b_* \quad \text{for } t \ge t_2.$$

From this and the chain rule (1.1), inequality (2.2) follows immediately. Moreover, (2.5) with $t = t_2$ implies

$$b_* - \rho \le r(a_* - \rho),$$

which, according to the definition of ρ, gives

$$b_* - a + \delta \le r(a_* - a + \delta).$$

Using this and the inequality $b - b_* \le r(b - b_*)$, we obtain

$$b - a \le r(b-a) + r(a_* - b_*) + (r-1)\delta.$$

Since, by the definition of δ, we have $(r-1)\delta \le \frac{1}{2}(b-a)$, the last inequality implies (2.3).

Step V. For any $f, g \in L_+$ and $s \in \mathcal{D}(P)$, define

$$a(t) = \inf \frac{P(t,s)f}{P(t,s)g}, \qquad b(t) = \sup \frac{P(t,s)f}{P(t,s)g}.$$

From Step I and the chain rule (1.1), it follows that $a(t)$ is an increasing function of t, $b(t)$ is decreasing, and $a(t) \le b(t)$. Moreover, using the result of Step IV, we can find a sequence $\tau_1 < \tau_2 < \cdots$ which converges to infinity and

$$b(\tau_n) - a(\tau_n) \le \left(1 - \frac{1}{2r}\right)^n (b(s) - a(s)).$$

This implies

$$\lim_{t\to\infty}(b(t)-a(t))=0$$

and proves condition (1.3) in the case when $f \in L_+$.

Step VI. Now let $f \in L$ be arbitrary, $g \in L_+$, and $s \in \mathcal{D}(P)$. In order to prove (1.3), in this case it is sufficient to show that there exist $f_1, f_2 \in L_+$ such that $f = f_1 - f_2$. To verify this, write

$$f_1 = f + kg, \qquad f_2 = kg,$$

where

$$k = 1 + \frac{\|f\|}{\inf g}.$$

The proof of Theorem 1 is completed. □

Analogous results for processes that are homogeneous in time (semigroups) were proved in [Ru] and [L–R]. These proofs were based on an additional assumption that X is a compact metric space.

Remark 1. From the chain rule (1.1), it follows that it is not necessary to verify condition (1.2) for all $s \in \mathcal{D}(P)$. It is sufficient to check it only for s sufficiently large, say $s \geq s_0$ and $f \in L_0$. In fact, for $s < s_0$ and $f \in L_+$, we have

$$\frac{P(t,s)f}{\|P(t,s)f\|} = \frac{P(t,s_0)f_0}{\|P(t,s_0)f_0\|} \quad \text{for } t \geq s,$$

where $f_0 = P(s_0,s)f \in L_+$. Then, applying Step II to the process $P(t,s)$ with $t \geq s \geq s_0$, we obtain

$$\frac{P(t,s_0)f_0}{\|P(t,s_0)f_0\|} \geq \alpha' \quad \text{for } t \geq t_0(f_0,s).$$

3. Expanding mappings. Using Theorem 1, we can easily finish the proof of the asymptotic similarity for the process described in Example 2. Instead, however, we will study a more general situation when the process is defined by a sequence of mappings on a compact manifold. The circle considered in Example 2 is a simple model of such manifold.

Thus, let X be a compact connected smooth (C^∞) manifold of dimension δ with a Riemannian metric $\|\cdot\|$. By ρ and μ we denote the distance and the measure corresponding to this metric. Let a C^2 mapping $F : X \to X$ be given. We define two numbers, the exponential factor λ_F and the second-order bound β_F.

The factor λ_F is defined by formula

$$\lambda_F = \inf \frac{\|dF(x)\xi\|}{\|\xi\|}, \tag{3.1}$$

where the infimum is taken for all $x \in X$ and $\xi \in T_x$, $\xi \neq 0$. Here, as usual, T_x denotes the tangent space to X at the point x and $dF(x)$ denotes the differential of F at x.

The geometrical meaning of λ_F is evident. If $\lambda_F > 0$, then the mapping F is locally invertible and every point $x \in X$ has a finite number of inverse images, a number independent of x. For every fixed x_0, there is a neighborhood U_{x_0} such that

$$F^{-1}(x) = \{G_1(x), \ldots, G_k(x)\} \quad \text{for } x \in U_{x_0}, \tag{3.2}$$

where G_i are smooth functions of the same order of regularity as F. (Thus, in our case, they are C^2.) When $\lambda_F > 1$, the mapping F is called expanding. In the special case when $X = S^1$ (unit circle), $\lambda_F = \inf |F'|$.

The parameter β_F is defined by formula

$$\beta_F = \sup_{x \in X} |\operatorname{grad} |\det dF(x)||. \tag{3.3}$$

In this definition, $|\det dF(x)|$ is the absolute value of the determinant of $dF(x)$. Observe that we do not assume that the manifold X is oriented, and thus only the absolute value of this determinant is well defined. The symbol $|\operatorname{grad} f|$ denotes the length of the gradient of f.

The geometrical interpretation of β_F is a little more complicated. Namely, $|\det dF(x)|$ is approximately equal to the ratio $\mu(F(U))/\mu(U)$, where U is a "small" neighborhood of x. Thus, β_F measures how quickly this ratio can change when x moves. If $X = S^1$, then $\beta_F = \sup |F''|$.

Now assume that $F_n : X \to X$ is a sequence of C^2 mappings ($n = 0, 1, \ldots$) with $\lambda_{F_n} > 0$. The Frobenius–Perron operators P_n corresponding to F_n are defined by a formula analogous to (0.3), namely,

$$\int_A P_n f \, d\mu = \int_{F_n^{-1}(A)} f \, d\mu \quad \text{for } A \subset X, \ A \text{ measurable.} \tag{3.4}$$

Using (3.2), it is easy to derive the explicit formula for P_n, namely,

$$P_n f(x) = \sum_i |\det dG_{ni}(x)| f(G_{ni}(x)), \tag{3.5}$$

where G_{ni} are the inverse functions to F_n defined in a neighborhood of x.

The process $P(n, m)$ is defined by the product

$$P(n, m) = P_{n-1} \cdots P_{m+1} P_m \quad \text{for } n > m > 0, \qquad P(n, n) = I \quad \text{for } n \geq 0$$

on the space $C(X)$ of all continuous functions on X.

THEOREM 2. *If all $\lambda_{F_n} > 0$ and in particular all F_n are locally invertible and if*

$$\liminf_{n \to \infty} \lambda_{F_n} > 1, \quad \sup_n \beta_{F_n} < \infty, \tag{3.6}$$

then $P(n, m)$ has the property of asymptotic similarity. Moroever, the constant c in condition (1.3) *is equal to $\int_X f \, d\mu / \int_X g \, d\mu$.*

Proof. Fix an integer n and consider an inverse transformation G_{ni} of F_n. Then

$$(dF_n)(G_{ni}(x)) dG_{ni}(x) = I$$

and

$$|(\det dF_n)(G_{ni}(x))| |\det dG_{ni}(x)| = 1 \tag{3.7}$$

for x belonging to the domain $\mathcal{D}(G_{ni})$ of G_{ni}. Since the manifold has dimension δ,

$$|\det dF_n(x)| \geq (\lambda_{F_n})^\delta \quad \text{and} \quad |\det dG_{ni}(y)| \leq \left(\frac{1}{\lambda_{F_n}}\right)^\delta \quad \text{for } y \in \mathcal{D}(G_{ni}). \tag{3.8}$$

Calculating the gradient of (3.7), we obtain

$$\begin{aligned}&|\det dG_{ni}(x)|(\mathrm{grad}|\det dF_n|)(G_{ni}(x))dG_{ni}(x)\\ &\quad = -|(\det dF_n)(G_{ni}(x))|\mathrm{grad}|\det dG_{ni}(x)|.\end{aligned}$$

From this and inequality $|vdG_{ni}(x)| \leq \lambda_{F_n}^{-1}|v|$, it follows that

$$\begin{aligned}&|(\det dF_n)(G_{ni}(x))||\mathrm{grad}|\det dG_{ni}(x)||\\ &\quad \leq \lambda_{F_n}^{-1}|\det dG_{ni}(x)||(\mathrm{grad}|\det dF_n|)(G_{ni}(x))|.\end{aligned}$$

Omitting the arguments to simplify notation, condition (3.3) defining β_{F_n} finally implies,

$$\frac{|\mathrm{grad}|\det dG_{ni}||}{|\det dG_{ni}|} \leq \lambda_n^{-1}\frac{|\mathrm{grad}|\det dF_n||}{|\det dF_n|} \leq \beta_n/\lambda_n^{\delta+1},$$

where we are using the abbreviations $\lambda_{F_n} = \lambda_n$ and $\beta_{F_n} = \beta_n$. Furthermore, writing

$$J_{ni} = |\det dG_{ni}|, \qquad |J'_{ni}| = |\mathrm{grad}|\det dG_{ni}||,$$

the second part of (3.8) and the last inequality become

$$J_{ni} \leq \left(\frac{1}{\lambda_n}\right)^{\delta}, \qquad \frac{|J'_{ni}|}{J_{ni}} \leq \frac{\beta_n}{\lambda_n^{\delta+1}}.$$

Now, using formula (3.5) for the Frobenius–Perron operator, we have

$$P_n f = \sum_i J_{ni}(f \circ G_{ni}).$$

Define the "regularity" of f for $f > 0$ to be (see [P–Y])

$$\mathrm{Reg}\ (f) = \sup_{x \in X}\frac{|\mathrm{grad}\ f(x)|}{f(x)}.$$

We may easily evaluate the regularity of $P_n f$. Namely,

$$\begin{aligned}\frac{|\mathrm{grad}\ P_n f|}{P_n f} &\leq \frac{\sum_i |J'_{ni}|(f \circ G_{ni})}{\sum_i J_{ni}(f \circ G_{ni})} + \frac{\sum_i J_{ni}|\mathrm{grad}\ f \circ G_{ni}||dG_{ni}|}{\sum_i J_{ni}(f \circ G_{ni})}\\ &\leq \frac{\beta_n}{\lambda_n^{\delta+1}} + \frac{1}{\lambda_n}\sup\frac{|\mathrm{grad}\ f|}{f} \quad \text{for } f \in C^1(x),\ f > 0.\end{aligned} \tag{3.9}$$

Hence, $\mathrm{Reg}\ (P_n f) \leq \frac{\beta_n}{\lambda_n^{\delta+1}} + \frac{1}{\lambda_n}\ \mathrm{Reg}\ (f)$. Let m_0 be such that $\lambda = \inf_{n \geq m_0}\lambda_n > 1$ and let $\beta = \sup \beta_n$. An induction argument yields the inequality

$$\mathrm{Reg}\ (P(n,m)f) \leq \frac{1}{\lambda^{n-m}}\ \mathrm{Reg}\ (f) + \frac{\beta}{\lambda^{\delta}(\lambda - 1)} \quad \text{for } n \geq m \geq m_0.$$

Set $k = 1 + \beta/(\lambda^{\delta}(\lambda - 1))$. Then for every strictly positive $f \in C^1(X)$ and every $m \geq m_0$, there is an $n_0 = n_0(f,m)$ such that

$$\mathrm{Reg}\ (P(n,m)f) \leq k \quad \text{for } n \geq n_0. \tag{3.10}$$

The last inequality implies that

$$P(n,m)f(y) \le e^{k\rho(x,y)}P(n,m)f(x) \tag{3.11}$$

for arbitrary $x, y \in X$. Thus, in particular,

$$\frac{P(n,m)f(x)}{\|P(n,m)f\|} \ge e^{-kd} \quad \text{for } n \ge n_0, \tag{3.12}$$

where $d = \sup_{x,y\in X} \rho(x,y)$. A straightforward application of Theorem 1 shows that $P(n,m)$ exhibits asymptotic similarity. Now let $g \in C^1(X)$ be strictly positive. From (3.11), it follows that

$$P(n,m)g(x) \le e^{kd} \min P(n,m)g \le \frac{e^{kd}}{\mu(X)} \int_X P(n,m)g\,d\mu.$$

Since $P(n,m)$ is the product of Frobenius–Perron operators which preserve the integral, we have

$$\int_X P(n,m)g\,d\mu = \int_X g\,d\mu,$$

and consequently

$$P(n,m)g(x) \le \frac{e^{kd}}{\mu(X)} \int_X g\,d\mu \quad \text{for } n \ge n_0.$$

This evaluation and (1.3) imply that

$$\lim_{n\to\infty} \|P(n,m)f - cP(n,m)g\| = 0$$

for $f \in C(X)$, $g \in C^1(X)$, $g > 0$. The last condition, in turn, implies

$$\lim_{n\to\infty} \left(\int_X P(n,m)f\,d\mu - c\int_X P(n,m)g\,d\mu \right) = 0. \tag{3.13}$$

Since the operators $P(n,m)$ preserve the integral in this example, they are uniformly continuous in the space of integrable functions on X. Thus, by an approximation argument, (3.13) holds for every integrable f and g. But due to the preservation of the integral, condition (3.13) reduces to

$$\int_X f\,d\mu - c\int_X g\,d\mu = 0,$$

which completes the proof. □

Remark 2. A close look at the proof of Theorem 2 shows that, in fact, we have proved a more general result. Namely, in order to derive (3.10) from (3.9), it is sufficient to assume that

$$\prod_{n=1}^{\infty} \lambda_n = \infty \quad \text{and} \quad \sup_n \sum_{i=1}^{n} \frac{\beta_{n-i}}{\lambda_{n-i}^{\delta+1}\lambda_{n-i+1}\cdots\lambda_n} < \infty, \tag{3.14}$$

and consequently, Theorem 2 is proved under assumptions (3.14), which are essentially weaker than (3.6). In particular, (3.14) can be satisfied even if infinitely many transformations F_n are not expanding but the remaining expand sufficiently strongly.

The asymptotic properties of expanding mappings were first studied by A. Rényi [Re] on interval [0, 1]. In fact, he studied them on S^1, since he assumed that the values at $x = 0$ and $x = 1$ are the same. The results of Rényi concerning the existence of an ergodic invariant measure were extended to manifolds by A. Avez [A], K. Krzyżewski and W. Szlenk [K–S], and K. Krzyżewski [K]. The last authors proved that every C^2 expanding mapping F has an invariant density f_* and that the sequence of iterates $P^n f$, where P is the Frobenius–Perron operator for F, converges uniformly to f_*.

Our Theorem 2 generalizes the convergence part of their results to the case when the densities are transformed by a sequence of transformations.

4. Piecewise-convex transformations. The main purpose for proving Theorem 1 was to establish a criterion implying asymptotic similarity, a criterion that is applicable to processes which fluctuate with time. Such an application was shown in the previous section. It is interesting, however, that even in the case when the process is described by one transformation and thus is homogeneous, we still get new results. In this section, we apply Theorem 1 to an old problem related to the existence of invariant measures for piecewise convex transformations. This problem also dates back to A. Rényi [Re], who prove the existence of an absolutely continuous ergodic invariant measure μ for the so-called r-adic transformations where $r > 1$ is not necessarily an integer,

$$F_r = rx(\text{mod } 1). \tag{4.1}$$

This system (F_r, μ) is exact (V. A. Rochlin [Ro]). From this and the characterization of exact systems of M. Lin [Li], it follows that, for every density f, the sequence of the iterates $\{P_r^n f\}_n$ of the Frobenius–Perron operator P_r of F_r converges strongly (i.e., in the L^1 norm) to the density $f_* = d\mu/dx$. Our goal is to show that, for a class of piecewise convex transformations, this convergence is uniform. This seems to be quite unexpected, since the limiting density, in general, is not continuous. In particular, it is not continuous for the transformation (4.1) if r is not an integer. In our treatment, *the functions are defined* at not just almost every but *at every point, so the uniform convergence will include the points of discontinuity of* f_*.

For simplicity, we will restrict ourselves to transformations F which are piecewise C^1. Recall that a real-valued C^1 function F defined on an interval Δ is *convex* if and only if its derivative F' is nondecreasing on Δ.

Let F be a given transformation on the half-open interval [0, 1) into itself. We will assume that F satisfies the following conditions:

(i) there is a partition $0 = a_0 < \cdots < a_r = 1$ such that for each integer i the restriction F_i of F to half-closed interval $[a_{i-1}, a_i)$ may be extended to the closed interval $[a_{i-1}, a_i]$ as a convex C^1 function;

(ii) $F(a_{i-1}) = 0, F'(a_{i-1}) > 0$ for $i = 1, \ldots, r$; and

(iii) $F([0, a_1)) = [0, 1), F'(0) > 1$.

We denote by P the Frobenius–Perron operator corresponding to F. As usual,

$$\int_A Pf(x)\,dx = \int_{F^{-1}(A)} f(x)\,dx \quad \text{for } A \subset [0, 1),\ A \text{ measurable.} \tag{4.2}$$

An elementary calculation shows that Pf may be written

$$Pf(x) = \sum_{i=1}^{r} G_i'(x) f(G_i(x)) \quad \text{for } 0 \leq x < 1, \tag{4.3}$$

where

$$G_i(x) = \begin{cases} F_i^{-1}(x) & \text{for } x \in F([a_{i-1}, a_i)), \\ a_i & \text{for } x \in [0,1) - F([a_{i-1}, a_i)), \end{cases}$$

and $G_i'(x)$ denotes the derivatives from the right so $G_i' = 0$ outside $F([a_{i-1}, a_i))$.

The functions G_i' are decreasing and are continuous from the right. Thus, if f is decreasing and continuous from the right, then Pf has the same property.

The following properties of the operator P given by formula (4.3) were proved in [L–Y]:

1°. The set

$$S = \bigcup_{n=0}^{\infty} F^{-n}(\{a_0, \ldots, a_r\})$$

is dense in [0, 1).

2°. If $f = 1_{[c,d)}$ is a characteristic function of an interval $[c, d)$ with the endpoints c and d belonging to S, then there exists an integer $n_0 = n_0(c, d)$ such that $P^n f$ for $n \geq n_0$ is a decreasing function on [0, 1).

Consider now the space L_* of all continuous from the right, piecewise-constant functions defined on [0, 1) and such that the points of discontinuity belong to S. In other words, L_* consists of the functions obtained by taking linear combinations of

$$1_{[c_i, d_i)}, \qquad c_i, d_i \in S.$$

Let L be the closure of L_* in the supremum norm topology. Due to property 1°, the space L in particular contains all continuous functions $f : [0,1) \to \mathbb{R}$. We define on L the process $P(n, m) = P^{n-m}$ for $n \geq m \geq 0$.

THEOREM 3. *The process $P(n, m)$ exhibits the property of asymptotic similarity.*

Proof. Let D_0 denote the subset of L_* which contains all normalized densities, i.e., all the functions satisfying

$$\int_0^1 f(x)\,dx = 1, \qquad f(x) \geq 0 \quad \text{for } 0 \leq x < 1. \tag{4.4}$$

Since P is a Frobenius–Perron operator, it preserves these conditions and $P(D_0) \subset D_0$. We shall use the following property of D_0, proved in [L–Y].

3°. There exists a number $M \geq 1$ (independent of f) such that

$$P^n f(x) \leq M \tag{4.5}$$

for every $f \in D_0$ and n sufficiently large, $n \geq n_0(f)$.

According to 2°, we may also assume that $P^n f$ are decreasing on [0, 1). Using this, we may evaluate $P^n f$ from below. Observe first that every decreasing function $g \in D$ with $g(0) \leq M$ satisfies

$$g(x) \geq \frac{1}{2M} \quad \text{for } 0 \leq x \leq \frac{1}{2M}. \tag{4.6}$$

In fact, suppose not and let $g(x_0) < 1/2M$ for an $x_0 \leq 1/2M$. Then

$$\begin{aligned} 1 = \int_0^1 g(x)\,dx &= \int_0^{x_0} g(x)\,dx + \int_{x_0}^1 g(x)\,dx \\ &\leq x_0 g(0) + (1 - x_0) g(x_0) < \frac{1}{2M}\,M + \frac{1}{2M} = \frac{M+1}{2M}, \end{aligned}$$

which contradicts the fact that $M \geq 1$. We may now extend our evaluation to the whole interval [0, 1) by the use of formula (4.3). Fix $f \in D_0$ and choose an $m \geq n_0(f)$. Define $g = P^m f$. From (4.3), it follows that

$$P^k g(x) \geq [\inf G_1']^k g(G_1^k(x)) \quad \text{for } 0 \leq x < 1,$$

where G_1^k is the kth iterate of G_1. Since $G_1(0) = 0$ and

$$G_1'(x) \leq G_1'(0) = 1/F_1'(0) < 1,$$

the integer k may be chosen such that $G_1^k(x) \leq \frac{1}{2M}$ for all $x \in [0, 1)$. Consequently, (4.6) implies

$$P^k g(x) \geq \delta, \qquad \text{where } \delta = \frac{[\inf(G_1')]^k}{2M}. \tag{4.7}$$

Observe that k does not depend on the choice of f. Define $n_1 = k + n_0(f)$. For $n \geq n_1$, we have $P^n f = P^k g$ with $g = P^{n-k} f$. Since $n - k \geq n_0$, we may apply inequality (4.7), which gives

$$P^n f(x) \geq \delta \quad \text{for } n \geq n_1(f), \quad 0 \leq x < 1. \tag{4.8}$$

From (4.5) and (4.8), it follows that, for every $f \in D_0$,

$$\frac{P^n f}{\|P^n f\|} \geq \frac{\delta}{M} \quad \text{for } n \geq n_1(f). \tag{4.9}$$

Now define, as in §1, $L_+ = \{f \in L : \inf f > 0\}$ and $L_0 = L_+ \cap L_*$. It is evident that L_0 is dense in L_+. Further, if $f \in L_0$, then $\lambda f \in D_0$ for some $\lambda > 0$. Thus (4.9) is also valid for every $f \in L_0$, completing the proof. □

We are now going to show that the operator P has a fixed point in the set L_+. To make this statement precise, we need to emphasize a subtle difference between formulas (4.2) and (4.3). For every given integrable f, formula (4.2) defines the function Pf almost everywhere. Formula (4.3) with given f defines $Pf(x)$ at each and every point $x \in [0, 1)$. We have proved Theorem 3 for the "precise" P defined by (4.3), and we want to find a fixed point f_* which satisfies

$$f_*(x) = \sum_{i=1}^{r} G_i'(x) f_*(G_i(x)) = Pf_*(x) \tag{4.10}$$

at every point $x \in [0, 1)$. Thus the classical technique of ergodic theory related with definition (4.2) is not helpful. In particular, we cannot use results proved in [L–Y] and [So], which assure the existence of an invariant density for a large class of piecewise-convex transformations, because the invariance there is understood as the equality $f = Pf$ almost everywhere.

Let $f \in D_0$ be an arbitrary function. We know that $g = P^{n_1} f$ satisfies

$$\delta \leq P^n g(x) \leq M \quad \text{for } n \geq 0, \quad 0 \leq x < 1$$

and that the functions $P^n g$ are continuous from the right and decreasing. Define

$$g_n = \frac{1}{n} \sum_{j=1}^{n} P^j g.$$

The functions g_n are again continuous from the right and are decreasing. They admit the values from the interval $[\delta, M]$. According to Helly's theorem (see [Lo] p. 12, Thm. 1.2.1), every bounded sequence of monotonic (decreasing or increasing) functions defined on an interval of the real line contains a pointwise-convergent subsequence. Thus from g_n we can select a subsequence g_{α_n} which converges to a decreasing function g_*. Further, since

$$|Pg_n(x) - g_n(x)| \leq \frac{2M}{n} \quad \text{for } 0 \leq x < 1,$$

the function g_* is a fixed point of P; that is,

$$g_*(x) = \sum_{i=1}^{r} G_i'(x) g_*(G_i(x)) \tag{4.11}$$

is satisfied in every point $x \in [0, 1)$. We don't know, however, if g_* is continuous from the right. Define

$$f_*(x) = g_*(x+0) = \lim_{\substack{y \to x \\ y > x}} g_*(y).$$

Passing to the right-hand limit in (4.11) and observing that G_i' are continuous from the right, we finally obtain (4.10).

It is evident that the function f_* has the following properties: it is decreasing, continuous from the right, and satisfies

$$\delta \leq f_*(x) \leq M, \qquad \int_0^1 g_*(x)\,dx = 1.$$

The last inequality is the consequence of the Lebesgue dominated convergence theorem. Thus, according to (1.4) with $\lambda = 1$, we have

$$\|P^n f - \sigma(f) f_*\| = 0 \quad \text{for } f \in L. \tag{4.12}$$

Since P preserves the integral and f_* is a normalized density, we have

$$\sigma(f) = \int_0^1 f(x)\,dx.$$

It should be emphasized that the convergence (4.12) holds, in particular, for every continuous bounded f and that the limiting function is in general discontinuous.

5. Integro-differential equations. In previous examples, time was discrete and the operators were generated by one-to-one transformations. We now present an application of Theorem 1 to a continuous-time system generated by an evolution equation of the form

$$\frac{du}{dt} = Au + Q(t)u \quad \text{for } t \geq s \tag{5.1}$$

with the initial condition

$$u(s) = f. \tag{5.2}$$

For simplicity, we will consider only the case when u assumes its values in the space of continuous functions.

Let X be a metric space and μ a finite Borel measure on X. Further, let $L = C(X)$ be the space of all real-valued bounded continuous functions on X with the supremum norm. We assume that A in (5.1) is the generator of a continuous (C_0) semigroup $P^t, t \geq 0$, of positive linear operators on $C(X)$ and that $Q(t)$, for $t \geq 0$, is a family of integral operators given by formula

$$Q(t)f(x) = \int_X K(t,x,y)f(y)\mu(dy), \tag{5.3}$$

where $K : \mathbb{R}_+ \times X \times X \to \mathbb{R}_+$ is a continuous kernel. More specifically, we make the following assumptions:

1°. The semigroup P^t satisfies condition (1.2″) and, in particular, it has the property of asymptotic similarity.

2°. For some value $t_0 > 0$, the operator P^{t_0} has an eigenvalue $\lambda > 0$ corresponding to an eigenfunction $f_* \in C_+(X)$.

3°. The functions

$$k_0(t) = \inf\{K(t,x,y) : x, y \in X\}$$

and

$$k_1(t) = \sup\{K(t,x,y) : x, y \in X\}$$

satisfy

$$\liminf_{t\to\infty} \frac{k_0(t)}{k_1(t)} > 0. \tag{5.4}$$

We define the process $U(t,s)$ by assuming

$$U(t,s)f = u(t)$$

where u is the solution of (5.1) and (5.2). Under our assumptions, $u(t)$ is uniquely defined for $t \geq s$ and strictly positive for strictly positive f. Thus U is a positive process.

The process $U(t,s)$ may be considered as a perturbation of $P(t,s) = P^{t-s}$ since the generator A of P^t is perturbed by the family of integral operators $Q(t)$. An important property of this perturbation is described by the following theorem.

THEOREM 4. *If A and $Q(t)$ satisfy conditions* 1° – 3°, *then $U(t,s)$ exhibits asymptotic similarity.*

Proof. Our main tool is the classical variation of constant formula for (5.1) using $Q(t)u = Q(t)U(t,s)f$. This formula gives

$$U(t,s)f = P^{t-s}f + \int_s^t P^{t-r}Q(r)U(r,s)f\,dr. \tag{5.5}$$

Let γ and f_* be as in formula (1.7). Define

$$\beta_0(t) = \frac{k_0(t)}{\sup f_*}, \qquad \beta_1(t) = \frac{k_1(t)}{\inf f_*}$$

and fix an $f \in C_+(X)$. Then

$$\beta_0(t)m(f)f_* \leq Q(t)f \leq \beta_1(t)m(f)f_*, \tag{5.6}$$

where

$$m(f) = \int_X f\,d\mu.$$

Using (5.5) and the second inequality (5.6), we obtain

$$U(t,s)f \le P^{t-s}f + \int_s^t P^{t-r}[\beta_1(r)m(U(r,s)f)f_*]\,dr.$$

Since $P^{t-r}f_* = e^{\gamma(t-r)}f_*$, this gives

$$U(t,s)f \le P^{t-s}f + \left\{\int_s^t e^{\gamma(t-r)}\beta_1(r)m(U(r,s)f)\,dr\right\} f_*.$$

Analogously, using the first inequality (5.6) we obtain

$$U(t,s)f \ge P^{t-s}f + \left\{\int_s^t e^{\gamma(t-r)}\beta_0(r)m(U(r,s)f)\,dr\right\} f_*,$$

and from this

$$(5.7)\qquad \frac{U(t,s)f(x)}{\|U(t,s)f\|} \ge \frac{e^{-\gamma(t-s)}P^{t-s}f(x) + \left\{\int_s^t e^{\gamma(s-r)}\beta_0(r)m(U(r,s)f)\,dr\right\} f_*(x)}{e^{-\gamma(t-s)}\|P^{t-s}f\| + \left\{\int_s^t e^{\gamma(s-r)}\beta_1(r)m(U(r,s)f)\,dr\right\} \|f_*\|}.$$

Since P^t satisfies condition (1.2″), we have

$$(5.8)\qquad \frac{P^{t-s}f(x)}{\|P^{t-s}f\|} \ge \alpha \quad \text{for } t \ge t_0(f,s).$$

Assume that s_0 is so large that

$$\frac{\beta_0(r)}{\beta_1(r)} = \frac{\inf f_*}{\sup f_*}\frac{k_0(r)}{k_1(r)} \ge \frac{1}{2}\frac{\inf f_*}{\sup f_*}\liminf_{t\to\infty}\frac{k_0(t)}{k_1(t)} =: \delta \quad \text{for } r \ge s_0.$$

From this definition of δ and (5.7) and (5.8), it follows that

$$\frac{U(t,s)f(x)}{\|U(t,s)f\|} \ge \min(\alpha,\delta)\,\frac{\min f_*}{\|f_*\|} \quad \text{for } s \ge s_0 \text{ and } t \ge t_0(f,s).$$

According to Remark 1, this completes the proof. □

Observe that if a semigroup $P^t, t \ge 0$, of positive operators satisfies condition (1.2″), then so does $e^{-\beta t}P^t$ for arbitrary real β. Further, if A generates P^t, then $A - \beta I$ (I = identity) generates $e^{-\beta t}P^t$. Thus, applying Theorem 4 to the equation

$$(5.9)\qquad \frac{du}{dt} + \beta u = Au + Q(t)u,$$

we obtain the following result.

COROLLARY 1. *If A generates a semigroup $P^t, t \ge 0$, satisfying conditions 1° and 2°, and if the family of integral operators* (5.3) *satisfies 3°, then the process generated by equation* (5.9) *and condition* (5.2) *has the property of asymptotic similarity.*

We close this section by showing a specific example of equation (5.9). Consider the integro-differential equation of the form

(5.10)
$$\frac{\partial u(t,x)}{\partial t} + a(x)\,\frac{\partial u(t,x)}{\partial x} + \beta u(t,x) = \int_0^1 K(t,x,y)u(t,y)\,dy, \quad 0 \le x \le 1, \quad t \ge 0.$$

We assume that the coefficient $a(x)$ is a C^1 function and that

$$a(0) = 0, \qquad a(x) > 0 \quad \text{for } x > 0. \tag{5.11}$$

We also assume that the kernel K in (5.10) satisfies condition 3° with $X = [0,1]$. To prove that equation (5.10) generates a process on $C([0,1])$ having the property of asymptotic similarity, it is sufficient to verify that the semigroup P^t generated by

$$Af = -a(x)\,\frac{df}{dx}, \qquad f \in C^1[0,1]$$

satisfies conditions 1° and 2°. This semigroup is given by the equation

$$\frac{\partial u(t,x)}{\partial t} + a(x)\,\frac{\partial u(t,x)}{\partial x} = 0 \quad \text{with } u(0,x) = f(x) \tag{5.12}$$

or more explicitly by formula

$$P^t f(x) = u(t,x) = f(\varphi(0;t,x)),$$

where $\varphi(t) = \varphi(t;t_0,x_0)$ is the solution of the ordinary differential equation $\varphi' = a(\varphi)$ with the initial condition $\varphi(t_0) = x_0$. Due to assumption (5.11), we have

$$\lim_{t\to\infty} \varphi(0;t,x) = 0$$

uniformly for $0 \le x \le 1$. Consequently,

$$\lim_{t\to\infty} \frac{P^t f(x)}{P^t f(y)} = \lim_{t\to\infty} \frac{f(\varphi(0;t,x)}{f(\varphi(0;t,y)} = \frac{f(0)}{f(0)} = 1$$

for every $f \in C_+(X)$, and the convergence is uniform. This implies (1.2″). Then 2° is satisfied with $f_* \equiv 1$ and $\lambda = 1$.

A result analogous to Theorem 4 was proved in [L–R] for homogeneous in time processes with X being a compact space. The proof presented here is much shorter. This is due to the fact that our main tool—Theorem 1—does not require any compactness assumption.

Theorem 4 can be easily generalized. We may replace, for example, the space $C(X)$ by a different subspace of $B(X)$ (bounded functions on X), and we could relax the assumption of the continuity of the kernel. We stated our result in a less general form for the sake of simplicity and to show its close relation to the results proved in [L–R].

A CENTER-UNSTABLE MANIFOLD THEOREM FOR PARAMETRICALLY EXCITED SURFACE WAVES*

LAWRENCE TURYN[†]

Abstract. When fluid in a rectangular tank sits upon a platform which is oscillating with sufficient amplitude, surface waves appear in the "Faraday resonance." Scientists and engineers have done bifurcation analyses which assume that there is a center manifold theory using a finite number of excited spatial modes. We establish such a center manifold theorem for Xiao-Biao Lin's model in which potential flow is assumed but an artificial dissipation term is included in the system of partial differential equations on the free surface. We use interpolation spaces developed by da Prato and Grisvard, establish maximal regularity for a family of evolution operators, and adapt the center manifold theory of Chow, Lin, and Lu.

Key words. parametric resonance, center manifold, surface waves, interpolation spaces, maximal regularity

1. Introduction and summary.

Consider a rectangular tank filled with an incompressible homogeneous fluid to a depth h. If the base of the tank is made to oscillate, then what will be the behavior of the fluid? As long ago as 1831, Faraday observed fluid oscillations at one half the frequency of the base, so this phenomenon of parametric excitation is known as Faraday resonance. This and other historical references can be found in Benjamin and Ursell [3] and Miles and Henderson [18].

Lin [15] has established a mathematical formulation for this problem. As long as the amplitude of the excitation is sufficiently small, he has obtained (i) global existence and uniqueness and (ii) an approximation result which justifies a truncation to a finite number of modes. His model assumes potential flow and includes on the free boundary terms for surface tension and artificial viscosity. The latter is to some extent physically meaningful because Lin showed that at high wave numbers his artificial viscosity produces dissipation proportional to the square of the wave number and proportional to the total kinematic energy, i.e., the dissipation is consistent with that produced by kinematic viscosity.

On the other hand, several authors, e.g., Gu and Sethna [14], Holmes [13], and Silber and Knobloch [23], have analyzed bifurcation equations assumed to hold on a finite-dimensional center manifold corresponding to some neutrally stable mode(s). If there is friction in the system, this is only possible if the amplitude of the excitation is not required to be sufficiently small.

The purpose of this paper is to establish the existence of a local center manifold theorem for this problem. We introduce virtually no new mathematical techniques but instead apply a variety of results established by other authors.

Our mathematical formulation is due to Lin [15]. The velocity potential, as a function of the shape of the free surface and the potential on the free surface,

*Received by the editors May 25, 1993; accepted for publication (in revised form) April 15, 1994.

[†]Department of Mathematics and Statistics, Wright State University, Dayton, OH 45435. This research was partially done while the author was visiting the School of Mathematics, Georgia Institute of Technology, Atlanta, GA 30332.

is substituted into Bernoulli's equation on the free surface. We use this functional relationship from Lin's paper, albeit in a time-independent version, in Theorem 6.1 below. Our techniques diverge from Lin's in that we then consider the problem as an ordinary differential equation in function spaces of space dependence rather than as an implicit equation in a Hilbert function space of both space and time dependence.

For our approach, we use a variation of constants formula in interpolation spaces, as in da Prato and Grisvard [8], Sinestrari [25], and da Prato and Lunardi [9], which gives "maximal regularity." Unfortunately, we could not use the methods of Henry [12] for our nonlinear problem, although we do mimic his methods for periodic, linear problems. The actual local center manifold theorem that we obtain is an application of Chow, Lin, and Lu [7], or we could have used the result of da Prato and Lunardi [9], which is also in the style of Henry [12, Chap. 6]. The method of Liapunov–Perron obtains an invariant manifold as a graph of a function defined by an integral operator.

The paper is organized in this way: In §2, the physical problem and a model for it are presented along with a linearization about the flat surface, i.e., undisturbed, solution. In §3, a semigroup of bounded linear operators is explicitly presented and shown to be analytic. In §4, a brief description is made of a well-known general method for defining interpolation spaces in which our semigroup has a maximal regularity property. In §5, we return to linear, time-periodic problems and show in Proposition 5.2 that there is a family of evolution operators which define integral operators with a generalization of the maximal regularity property for autonomous problems. We show that our linearized, time-periodic problem can be analyzed in this way. These generalizations are the only "new" results we have; all the other work in this paper consists of applying the work of other authors to our specific problem or, in the case of Lin's paper, taking a result in its entirety. In §6, the nonlinearities of our model are found to be nice enough viz. the integral operators of §5; here a result of Lin is essential. In §7, we adapt a center-unstable manifold theorem and an exponential attractivity theorem of other authors to our nonlinear, time-periodic problem. In §8, we mention a result of a sequel in preparation. We have calculated an approximate, local-center manifold for an example involving the (3, 2) and (2, 3) spatial modes.

In fact, experiments of Simonelli and Gollub [24] provide examples where there are a small number of unstable modes. As an aside, when we examined their experimental data for the onset of instability [24, p. 479, Fig. 4(a)] and used a theoretical result for the damped Mathieu equation from Turyn [27, §1], we came to the conclusion that the artificial viscosity term $-\mu\nabla_{\mathbf{x}}^2 u$ in equation (2.5) of our paper would have μ about two to three times the kinematic viscosity, 2.948 centipoises, of n-butyl alcohol at 20°C. This suggests that, although this artificial viscosity is consistent with dissipation of kinetic energy, as in Lin [15, §6], the mechanism may not be so simple.

Our original intention was to discuss regions more general than rectangular tanks, e.g., cylindrical tanks. We ran into difficulties in §6 when discussing boundary conditions to be satisfied by the nonlinearities. We hope to understand this better in the future.

2. The physical problem and its linearization. Let D be a bounded open domain in $\mathbb{R}^2$, with coordinates $\mathbf{x}$. We will define the smoothness we require of its boundary ∂D later. The moving coordinate z is fixed with respect to the oscillating container, with the positive axis pointing upwards. The free boundary is $S_F : z = v(\mathbf{x}, t)$ and we denote

$$\Omega_v = \Omega_v(t) := \{(\mathbf{x}, z) : -h < z < v(\mathbf{x}, t), \mathbf{x} \in D\},$$

with outward unit normal $\mathbf{n}$. We assume the velocity field $\mathbf{V}$ is the gradient of a potential $\phi = \phi(\mathbf{x}, z, t)$ which satisfies

$$\begin{cases} \nabla^2\phi = 0 & \text{in } \Omega_v, \quad (2.1)\\ \phi = u(\mathbf{x},t) & \text{on } S_F : z = v(\mathbf{x},t), \quad (2.2)\\ \frac{\partial\phi}{\partial\mathbf{n}} = 0 & \text{on } \partial\Omega_v \setminus S_F, \quad (2.3)\end{cases}$$

where $\nabla = (\nabla_{\mathbf{x}}, \frac{\partial}{\partial z})$. The latter boundary condition states that the normal velocity is zero on the sides and base of the container.

On the free boundary the potential ϕ and the shape v satisfy the "kinematic" condition

$$v_t = \phi_z - \nabla_{\mathbf{x}}\phi \cdot \nabla_{\mathbf{x}} v \quad \text{on } S_F, \tag{2.4}$$

where subscripts denote differentiation, and Bernoulli's equation

$$\phi_t = -\gamma\nabla\cdot\mathbf{n} - (g - \alpha(t))v - \frac{1}{2}\,|\nabla\phi|^2 + \mu\nabla_{\mathbf{x}}^2 u \quad \text{on } S_F, \tag{2.5}$$

where atmospheric pressure $p_0 \equiv 0$, density $\rho \equiv 1, \gamma$ is the coefficient of surface tension, g is the acceleration of gravity, the parametric excitation $\alpha(t)$ is the effect of the oscillating base of the container, and we have added an artificial dissipative term proportional to $\nabla_{\mathbf{x}}^2 u$, as in Lin [15]. Specifically, we have $\alpha(t) = a(d^2/dt^2)\cos(\omega t)$, where a is the amplitude of the oscillations of the base of the container.

On the free boundary, $u(\mathbf{x},t) = \phi(\mathbf{x}, v(\mathbf{x},t), t)$, so $u_t = \phi_t + \phi_z v_t$, etc. Denote $w(\mathbf{x},t) := \phi_z(\mathbf{x}, v(\mathbf{x},t), t)$, so that $w = N(v)u$ is a linear operator on u which depends nonlinearly on v. In Theorem 6.1, we will borrow from Lin [15] a result on the smooth dependence of w on u and v, in suitable function spaces of spatial dependence.

Denote by [ ] the operation of taking the mean over the domain D, i.e., $D[f] = \int_D f$. First, we modify the model so as to have the property $[u] = 0$ preserved in time; the property $[v] = 0$ is automatically preserved. Second, we replace the nonlinear surface tension term $-\gamma\nabla\cdot\mathbf{n}$, where $\mathbf{n} = (-\nabla_{\mathbf{x}} v, 1)/\sqrt{1 + |\nabla_{\mathbf{x}} v|^2}$ on the free surface, by $\gamma\nabla_{\mathbf{x}}^2 v$, its linearization about the undisturbed solution $v \equiv 0$. In Lin's paper one finds both modifications; however, in his paper the second modification is done purely for convenience. In fact, because his spaces $K(r,s)$ satisfy $K(r,0) \subseteq K(r,2)$ for $r > 2$, he can treat the nonlinear surface tension term as easily as its linearization. In our formulation, it seems we must make this second modification, otherwise the spaces E and F, described in §4, will not be suitable in §6 for $\mathbf{f} : F \to E$. It is not clear if this second modification is acceptable viz. physical experiments, for small oscillations.

In terms of v, u, w these modifications of (2.4) and (2.5) yield

$$\begin{cases} v_t = w + M_1(v,u), & (2.6)\\ u_t = \gamma\nabla_{\mathbf{x}}^2 v + \mu\nabla_{\mathbf{x}}^2 u - (g - \alpha(t))v + M_2(v,u) - [M_2(v,u)], & (2.7)\end{cases}$$

where

$$M_1(v,u) = w|\nabla_{\mathbf{x}} v|^2 - \nabla_{\mathbf{x}} u \cdot \nabla_{\mathbf{x}} v,$$

$$M_2(v,u) = -\frac{1}{2}\,|\nabla_{\mathbf{x}} u|^2 + \frac{1}{2}\,w^2(1 + |\nabla_{\mathbf{x}} v|^2).$$

We take as boundary conditions $\frac{\partial u}{\partial\mathbf{n}} = 0$ on ∂D, which follows from (2.3), and $\frac{\partial v}{\partial\mathbf{n}} = 0$ on ∂D. The latter is somewhat controversial; in fact, one could argue that instead of an artificial dissipation term $\mu\nabla_{\mathbf{x}}^2$ in equation (2.5), one should introduce damping in the boundary conditions. This has been brought to my attention by M. Silber. Recently, Simonelli and Gollub [24] have described experiments in which the free surface is at right-angle contact with the sidewalls of a rectangular container, and this is consistent with $\frac{\partial v}{\partial \mathbf{n}} = 0$ on ∂D. Douady [10] has described experiments in which the free surface is pinned at the boundary, i.e., $v = 0$ on ∂D, by the use of felt on the walls of the container. It appears that this boundary condition cannot be accommodated by our abstract framework.

To linearize equations (2.6) and (2.7), we need only replace w by $N(0)u$ in equation (2.6) and replace M_1 and M_2 by 0. To this end, let $A := -\Delta_N$ denote the Neumann Laplacian on the complex Hilbert space $\tilde{L}^2(D) = \{u \in L^2(D) : \int_D u = 0\}$, with domain $\mathcal{D}(A) = \{u \in \tilde{L}^2(D) : Au \in \tilde{L}^2(D), \frac{\partial u}{\partial \mathbf{n}} = 0 \text{ on } \partial D\}$. Throughout, assume that $D \subseteq \mathbb{R}^2$ is bounded and open and has the uniform C^m regularity property, as in Adams [1, p. 67], with m as large as needed later. It is well known that $A : \mathcal{D}(A) \subseteq \tilde{L}^2(D) \to \tilde{L}^2(D)$ is a strictly positive definite, self-adjoint linear operator with compact inverse. Let $\{\kappa_n^2\}$ be the eigenvalues of A and $\psi_n = \psi_n(\mathbf{x})$ be the corresponding orthonormalized eigenfunctions; without loss of generality, $\kappa_1^2 \leq \kappa_2^2 \leq \cdots$. As in Henry [12] or Pazy [21], one can define the fractional powers A^β, which in this situation are closed linear operators with domain $X^\beta := \{u \in \tilde{L}^2(D) : \sum_{n=1}^\infty \kappa_n^{4\beta}|(u, \psi_n)_{L^2}|^2 < \infty\}$. From now on we will write $\sum_n$ instead of $\sum_{n=1}^\infty$ and denote $u_n = (u, \psi_n)_{L^2(D)}$. X^β is a Hilbert space when given the inner product $(u, v) = \sum_n \kappa_n^{4\beta} u_n \bar{v}_n$.

From inspection of (2.1)–(2.3), Lin [15, §4] obtained the explicit result that

$$N(0)u = \sum_n \kappa_n \tan h(\kappa_n h) u_n \psi_n \quad \text{for } u = \sum_n u_n \psi_n.$$

It follows that for any $\beta, N(0) : X^\beta \to X^{\beta-(1/2)}$ is a bounded linear operator. In fact $N(0)$ is close to being $A^{1/2} = (-\Delta_N)^{1/2}$. To be precise, $N(0) = A^{1/2} + A_1$, where

$$A_1 u = \sum_n \kappa_n (\tan h(\kappa_n h) - 1) u_n \psi_n.$$

Since $0 < \kappa_n \to \infty$ as $n \to \infty, A_1 : X^\beta \to X^\beta$ is a bounded linear operator. Thus, the linearization of (2.6)–(2.7) about $u = v = 0$ is

$$\text{(2.8)} \qquad \frac{d}{dt}\begin{pmatrix} v \\ u \end{pmatrix} = B\begin{pmatrix} v \\ u \end{pmatrix} + B_1(t)\begin{pmatrix} v \\ u \end{pmatrix},$$

where

$$\text{(2.9)} \qquad B = \begin{pmatrix} 0 & A^{1/2} \\ -\gamma A & -\mu A \end{pmatrix}, \qquad B_1(t) = \begin{pmatrix} 0 & A_1 \\ -(g - \alpha(t))I & 0 \end{pmatrix}.$$

Our plan for the rest of the paper is, first, to analyze the semigroup of linear operators e^{tB} on spaces which will be suitable for subsequent analysis; second, to express the solution of (2.8) in terms of a family of evolution operators; third, to establish a local existence and uniqueness theorem for the nonlinear problem (2.6)–(2.7); and finally, to establish a local center manifold theorem for (2.6)–(2.7).

3. The semigroup e^{tB}. First, we analyze the semigroup e^{tB} on the Hilbert space $\mathbf{X} := X^\beta \times X^{\beta-(1/2)}$, for all $\beta \geq \frac{1}{2}$. We will be more specific about β when discussing the nonlinear problem in §6. Other choices of $\mathbf{X}$ are possible but less convenient for our subsequent analysis of $\mathcal{D}(B), \mathcal{D}(B^2)$, and the nonlinear problem. Choose $\mathcal{D}(B) = X^{\beta+(1/2)} \times X^{\beta+(1/2)}$, which is itself a Hilbert space. From (2.9) $B : \mathcal{D}(B) \subset \mathbf{X} \to \mathbf{X}$ is a closed, densely defined linear operator. In addition, B has a compact resolvent, as one can see by explicit calculation of $(\lambda I - B)^{-1}$ as the operator norm limit of natural finite-rank operators. The spectrum of B consists of those $\lambda \in \mathbb{C}$ which are eigenvalues and thus solve, for some $n \geq 1$,

$$\lambda^2 + \mu\kappa_n^2\lambda + \gamma\kappa_n^3 = 0.$$

For future reference, we note that $0 \notin \sigma(B)$. Let

$$\lambda_n^{\pm} := \frac{1}{2}\,\kappa_n^2(-\mu \pm \delta_n), \delta_n := [\mu^2 - 4\gamma\kappa_n^{-1}]^{1/2}.$$

The corresponding eigenfunctions of B are

$$\begin{pmatrix} \mu \pm \delta_n \\ -2\gamma \end{pmatrix} \psi_n.$$

For convenience, assume $\delta_n \neq 0$ for all n. If $\delta_n = 0$ for a single n, the forms of e^{tB} and Be^{tB} would be altered, but the results, (3.3) and following, would not be affected. By diagonalizing B in each of the subspaces spanned by

$$\left\{ \begin{pmatrix} \psi_n \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ \psi_n \end{pmatrix} \right\},$$

after much calculation one finds that

$$e^{tB}\begin{pmatrix} v \\ u \end{pmatrix} = \sum_n \delta_n^{-1}(e^{t\lambda_n^+}C_n^+ + e^{t\lambda_n^-}C_n^-)\begin{pmatrix} v_n \\ u_n \end{pmatrix}\psi_n, \tag{3.1}$$

where $v_n := (v, \psi_n) = \int_D v\psi_n, u_n := (u, \psi_n)$, and

$$C_n^+ := \begin{pmatrix} \mu(\nu_n^+)^{-1} & \kappa_n^{-1} \\ -\gamma & -\frac{\gamma}{\mu}\nu_n^+\kappa_n^{-1} \end{pmatrix}, \qquad C_n^- := \begin{pmatrix} -\frac{\gamma}{\mu}(\nu_n^-)^{-1}\kappa_n^{-1} & -\kappa_n^{-1} \\ \gamma & \mu\nu_n^- \end{pmatrix}, \tag{3.2}$$

and $\nu_n^+ := -\mu\lambda_n^+/(\gamma\kappa_n), \nu_n^- := -\lambda_n^-/(\mu\kappa_n^2)$. One notes that because $\kappa_n \to \infty$ as $n \to \infty, \lim_{n\to\infty} \nu_n^{\pm} = 1$ and, in fact, $1 \leq \nu_n^+ \leq 2$ and $0 < \nu_n^- \leq 1$ for all n, so (3.1) and (3.2) will be convenient for subsequent analysis.

The norm on $\mathbf{X} = X^{\beta} \times X^{\beta-(1/2)}$ is given by

$$\left\| \begin{pmatrix} v \\ u \end{pmatrix} \right\|_{\mathcal{X}}^2 = \sum_n ((\kappa_n^{2\beta}|v_n|)^2 + (\kappa_n^{2\beta-1}|u_n|)^2),$$

so one sees immediately that (3.1) defines a C^0, i.e., strongly continuous, semigroup e^{tB} of bounded linear operators on $\mathbf{X}$. We note that, because $\kappa_n \to \infty$ as $n \to \infty, \sigma(B)$ consists of two infinite sequences of real numbers tending to $-\infty$ and possibly a finite number of complex conjugate pairs of eigenvalues $\{\lambda_n^{\pm}\}_{1 \leq n \leq n_0}$, all with Re $\lambda_n^{\pm} < 0$, so $\{e^{tB}\}_{t \geq 0}$ is uniformly bounded. We calculate that

$$Be^{tB}\begin{pmatrix} v \\ u \end{pmatrix} = \sum_n \delta_n^{-1}(\lambda_n^+ e^{t\lambda_n^+}C_n^+ + \lambda_n^- e^{t\lambda_n^-}C_n^-)\begin{pmatrix} v_n \\ u_n \end{pmatrix}\psi_n,$$

so there exists a constant M such that

$$\|tBe^{tB}\| \leq M \quad \text{for } t \geq 0. \tag{3.3}$$

In addition, e^{tB} is differentiable for $t > 0$ and $0 \notin \sigma(B)$. It follows from Pazy [21, Thm. 2.5.2] that (i) $\{e^{tB}\}_{t \geq 0}$ is an analytic semigroup of bounded linear operators on $\mathbf{X}$ and (ii) $-B$ is a sectorial operator, in the sense of Henry [12].

4. Interpolation spaces for autonomous problems. Throughout this section, θ is a fixed real number, $0 < \theta < 1$.

In the approach of Henry [12] to nonlinear problems and invariant manifolds, for a problem $\frac{dw}{dt} = Bw + f(w), w \in \mathbf{X}$, if $-B$ is a sectorial operator generating an analytic semigroup e^{tB}, then one defines $\mathbf{X}^\rho = \mathcal{D}((-B)^\rho)$ and hypothesizes that $f : \mathbf{X}^\rho \to \mathbf{X}$ for some $0 \leq \rho < 1$. Unfortunately, the nonlinear problem of ours has a specific nonlinearity which does not allow this approach. From Lin [15], we know that our nonlinearity takes $H^r(D) \times H^r(D)$ into $H^{r-1}(D) \times H^{r-1}(D)$ as long as $r > 2$; see Theorem 6.1 below. It seems that if $\mathbf{X} = X^{\beta_1} \times X^{\beta_2}$, whenever we choose $\beta_1, \beta_2 > \frac{1}{2}$, in order to have $H^{r-1}(D) \times H^{r-1}(D) \subseteq \mathbf{X}$, it follows that to have $\mathbf{X}^\rho \subseteq H^r(D) \times H^r(D)$, one must take $\rho = 1$. For example, the calculations of Chen and Triggiani [5] and Rodriguez-Bernal [22] confirm this for many choices of β_1, β_2; the details are omitted except to note that one can introduce $x = v$ and $y = A^{1/2}u$ and define operators

$$\mathcal{A} = A^{3/2} \quad \text{and} \quad B = \begin{pmatrix} 0 & I \\ -\gamma\mathcal{A} & -\mu\mathcal{A}^{2/3} \end{pmatrix}.$$

In addition, the form of e^{tB} leads one to suspect that, for all choices of β_1 and β_2, one must take $\rho = 1$.

We can use another approach using interpolation spaces, as in daPrato and Grisvard [8] and many others, including Butzer and Berens [4], Sinestrari [25], daPrato and Lunardi [9], and Angenent [2]. We will denote $E := D_B(\theta)$, to be defined below, and $F := D_B(\theta + 1) = \{w \in \mathcal{D}(B) : Bw \in D_B(\theta)\}$, and we will show in later sections, first, that the linear periodic problem (2.8) has some nice properties with regard to these spaces E and F and, second, that the nonlinearities in problem (2.6)–(2.7) take F into E nicely. The outstanding property of the spaces E and F is "maximal regularity," which has been put to good use by daPrato and Lunardi [9] to establish a center manifold theorem for autonomous problems.

We follow the exposition by Angenent [2] of the daPrato and Grisvard construction [8]. Suppose E_0 and E_1 are real Banach spaces with E_1 densely included in E_0 and $B : E_1 \to E_0$ is bounded and linear. Considered as an unbounded operator on E_0, we assume that B generates an analytic semigroup e^{tB}. Throughout this section, θ is a fixed real number, $0 < \theta < 1$. We define E_θ to be a space of traces, i.e., initial values, of a certain class of functions

$$Y_\theta := \{y \in C((0,1]; E_1) \cap C^1((0,1]; E_0 : \lim_{t \downarrow 0} t^{1-\theta}(\|y'(t)\|_{E_0} + \|y(t)\|_{E_1}) = 0\}$$

with norm

$$\|y\|_\theta := \sup_{0<t\leq 1} t^{1-\theta}(\|y'(t)\|_{E_0} + \|y(t)\|_{E_1}).$$

Specifically,

$$E_\theta := \{w : w = y(0) \text{ for some } y \in Y_\theta\}$$

with norm

$$\|w\|_\theta = \inf\{\|y\|_\theta : y \in Y_\theta, y(0) = w\}.$$

It is known that E_θ is a Banach space with this norm and that $E_\theta = D_B(\theta)$ as defined in daPrato and Lunardi [9]. Similarly, between the spaces E_1 and $E_2 := \mathcal{D}_{E_1}(B) = \{w \in E_1 : Bw \in E_1\}$, one can define $E_{1+\theta}$. If $E_0 = \mathbf{X}$ and $E_1 = \mathcal{D}(B)$, then $E_2 = \mathcal{D}(B^2), E_{1+\theta} = D_B(\theta+1)$, and $\mathcal{D}(B^2) \subseteq D_B(\theta+1) \subseteq \mathcal{D}(B) \subseteq D_B(\theta) \subseteq \mathbf{X}$, as in daPrato and Grisvard [8] and Sinestrari [25].

These interpolation spaces are defined by using continuous functions, so in the general theory of interpolation, $E_\theta \subseteq (E_1, E_0)_{\theta,\infty}$. The interpolation in Lions and Magenes [16] uses L^2 functions and can be notated $(\quad,\quad)_{1-\theta,2}$.

One should note that, in our problem, $E_0 = \mathbf{X}$ and $E_1 = \mathcal{D}(B)$ are spaces of functions of $\mathbf{x} \in D$, as are $D_B(\theta)$ and $D_B(\theta + 1)$; the time variable appears only in the definition of these spaces as initial values of functions of a time variable.

Because B generates an analytic semigroup e^{tB}, there exists ω, M such that $\|e^{tB}\|_{L(\mathbf{X})} \leq Me^{\omega t}$, where $L(\mathbf{X})$ denotes the space of bounded linear operators from $\mathbf{X}$ to $\mathbf{X}$. It is known that

$$\|e^{tB}\|_{L(Z)} \leq Me^{\omega t} \tag{4.1}$$

and that $-B$ is sectorial on Z, for any choice of Z being $\mathbf{X}, \mathcal{D}(B), D_B(\theta)$, or $D_B(\theta+1)$, although it might be necessary to increase M.

In our specific problem, the spectrum of B consists of $\{\lambda_n^\pm\}_{n\geq 1}$, where

$$\lambda_n^\pm = -\frac{1}{2}\,\kappa_n^2(\mu \mp \sqrt{\mu^2 - 4\gamma\kappa_n^{-1}}.$$

Because $0 < \kappa_1 \leq \kappa_2 \leq \cdots$, there exists $\omega < 0$ such that Re $\sigma(B) < \omega$ and there exists $M \geq 1$ such that (4.1) holds with that $\omega < 0$.

In our problem, we take $E_0 = \mathbf{X} = X^\beta \times X^{\beta-(1/2)}$ and $E_1 = \mathcal{D}(B) = X^{\beta+(1/2)} \times X^{\beta+(1/2)}$. One can calculate that $E_2 = \mathcal{D}(B^2) = \{w \in \mathcal{D}(B) : Bw \in \mathcal{D}(B)\} = X^{\beta+1} \times X^{\beta+1} \cap \{(v,u) : \gamma v + \mu u \in X^{\beta+(3/2)}\}$. The latter expresses an "interaction condition." One can observe that interpolation commutes with the operation of taking direct products, so that

$$\begin{aligned} E_\theta &= (X^{\beta+1/2} \times X^{\beta+1/2}, X^\beta \times X^{\beta-1/2})_{\theta,\infty} \\ &= (X^{\beta+1/2}, X^\beta)_{\theta,\infty} + (X^{\beta+1/2}, X^{\beta-1/2})_{\theta,\infty}. \end{aligned}$$

We recall that $X^\beta = \mathcal{D}(A^\beta)$ where $A = -\Delta_N$ on $\tilde{L}^2(D)$.

It is known from work of Grisvard [11] that, regarding $0 < \beta < 1$,

$$X^\beta = \left\{ \begin{array}{ll} \tilde{H}^{2\beta}(D), & 0 < \beta < \frac{3}{4} \\ \tilde{H}^{2\beta}(D) \cap \{u : \frac{\partial u}{\partial \mathbf{n}} = 0 \quad \text{on} \quad \partial D\}, & \frac{3}{4} < \beta < 1 \end{array} \right\},$$

where $H^s(D)$ is the Sobolev space $W^{s,2}(D)$ and, as before, a $\tilde{}$ indicates "mean value zero." Put loosely, in X^β the boundary condition $\frac{\partial u}{\partial \mathbf{n}} = 0$ applies if it makes sense, i.e., if $\nabla_{\mathbf{x}} u|_{\partial D}$ makes sense as a trace of a distribution on ∂D. For $1 < \beta < 2$,

$$\begin{aligned} X^\beta &= \{u \in X^{\beta-1} : \Delta_N u \in X^{\beta-1}\} \\ &= \left\{ \begin{array}{ll} \tilde{H}^{2\beta} \cap \{u : \frac{\partial u}{\partial \mathbf{n}} = 0 \quad \text{on} \quad \partial D\}, & 1 < \beta < \frac{7}{4} \\ \tilde{H}^{2\beta} \cap \{u : \frac{\partial u}{\partial \mathbf{n}} = \frac{\partial \Delta u}{\partial n} = 0 \quad \text{on} \quad \partial D\}, & \frac{7}{4} < \beta < 2 \end{array} \right\}. \end{aligned}$$

It is known from daPrato and Grisvard [8, §6.1] that

$$(X^{\beta+1/2}, X^{\beta})_{\theta,\infty} \subseteq \{u \in X^{\beta} : A^{\beta}u \in h_2^{\theta}\} \tag{4.2}$$

and

$$(X^{\beta+1/2}, X^{\beta-1/2})_{\theta,\infty} \subseteq \{u \in X^{\beta-1/2} : A^{\beta-1/2}u \in h_2^{2\theta}\}. \tag{4.3}$$

Here $h_2^s(D)$ stands for a Nikolsk'ii space, as in Nikolsk'ii [19], [20], Slobodeckii [26], and Adams [1]. These spaces are actually a subclass of the Besov spaces. The only property of these spaces we will use are the continuous imbeddings

$$H^s(D) \hookrightarrow h^s(D) \hookrightarrow H^{s-\varepsilon}(D) \tag{4.4}$$

for any $\varepsilon > 0$. We will use the property that interpolation preserves bounded linear operators in order to avoid the need for detailed examination of the Nikolsk'ii spaces.

For the moment, we leave our specific operator B and specific space $\mathbf{X}$ and return now to the general situation. We denote $E = E_\theta = D_B(\theta)$ and $F = E_{1+\theta} = D_B(\theta+1)$. The maximal regularity property mentioned above is as follows:

$$\text{for all } f \in C([0,\tau); E), \quad \int_0^{\cdot} e^{(\cdot-s)B} f(s)\, ds \in C([0,\tau]; F).$$

Proofs can be found in daPrato and Grisvard [8], Sinestrari [25], and Angenent [2], among others. We apply results of this sort to our specific operator B and space $\mathbf{X}$ in Propositions 4.1 and 4.2 below.

Many proofs of existence of invariant manifolds explicitly or implicitly involve weighted spaces; see, for example, Chow, Lin, and Lu [7] and van Gils and Vanderbauwhede [28]. For a Banach space $Z, \sigma \in \mathbb{R}, \eta \in \mathbb{R}$, define

$$C_\eta((-\infty,\sigma]; Z) = \{f : f \text{ continuous on } (-\infty,\sigma] \text{ and } \|f\|_{\eta,\sigma,-,Z} < \infty\},$$

where its norm is

$$\|f\|_{\eta,\sigma,-,Z} = \sup_{t\leq\sigma} e^{-\eta t}|f(t)|_Z.$$

Similarly define

$$C_\eta([\sigma,\infty); Z) = \{f : f \text{ continuous on } [\sigma,\infty) \text{ and } \|f\|_{\eta,\sigma,+,Z} < \infty\},$$

where

$$\|f\|_{\eta,\sigma,+,Z} = \sup_{t\geq\sigma} e^{\eta t}|f(t)|_Z.$$

Recall that in our problem $\|e^{tB}\|_{L(Z)} \leq Me^{\omega t}$, for some $\omega < 0$ and $M \geq 1$, from (4.1), where Z is any of $\mathbf{X}, \mathcal{D}(B), D_B(\theta), D_B(\theta+1)$. Here, θ is a fixed real number with $0 < \theta < 1$. We apply two results of daPrato and Lunardi [9, pp. 118–120] to our specific B and $\mathbf{X}$ to get the following propositions.

PROPOSITION 4.1. *With B as in (2.9), $\mathbf{X} = X^\beta \times X^{\beta-(1/2)}, \mathcal{D}(B) = X^{\beta+(1/2)} \times X^{\beta+(1/2)}$, and M, ω as in (4.1), choose any η such that $\omega + \eta < 0$. Then there exists $K_+ = K_+(\eta, \omega, \sigma, \theta)$ such that $f(\cdot) \mapsto \int_\sigma^{\cdot} e^{(\cdot-s)B} f(s)\, ds$ defines a bounded linear operator $\mathcal{L}_+ : C_\eta([\sigma,\infty); E) \to C_\eta([\sigma,\infty); F)$ with $\|\mathcal{L}_+\| \leq K_+$, where $E = D_B(\theta), F = D_B(\theta+1)$.*

PROPOSITION 4.2. *With B, M and ω, as in Proposition* 4.1, *choose any η such that $\omega - \eta < 0$. Then there exists $K_- = K_-(\eta, \omega, \sigma, \theta)$ such that*

$$f(\cdot) \mapsto \int_{-\infty}^{\cdot} e^{(\cdot - s)B} f(s)\, ds$$

defines a bounded linear operator $\mathcal{L}_- : C_\eta((-\infty, \sigma]; E) \to C_\eta((-\infty, \sigma]; F)$ with $\|\mathcal{L}_-\| \leq K_-$, where $E = D_B(\theta)$ and $F = D_B(\theta + 1)$.

These two propositions express a maximal regularity property useful for the proof of the existence of an invariant manifold for an autonomous problem. In the next section, these two propositions will imply similar properties for a periodic problem.

5. A family of evolution operators for equation (2.8). Given two normed linear spaces Z_1 and $Z_2, L(Z_1, Z_2)$ denotes the space of bounded linear operators with the operator norm.

In this section, we establish a new result for periodic problems considered in the framework of interpolation spaces.

DEFINITION. A family of evolution operators $\{\Phi(t,s)\}$ *consists of bounded linear operators on a space Z for $t \geq s$ satisfying $\Phi(s,s) = I, \Phi(t_1, s)\Phi(s, t_2) = \Phi(t_1, t_2)$ for all $t_1 \geq s \geq t_2$ in $\mathbb{R}$, and $\{\Phi(t,s) : t \geq s\}$ is strongly continuous in (t,s) with values in $L(Z)$.*

Assume $-B$ is sectorial on a Banach space .and $t \mapsto B_1(t) : \mathbb{R} \to L(E^\rho, E)$ is Hölder-continuous with exponent < 1. The work of Henry [12, §7.1] shows that the solutions of

$$\left\{ \begin{array}{l} \frac{dw}{dt} = Bw + B_1(t)w, \\ w(s) = w_0 \in E \end{array} \right\} \tag{5.1}$$

are given by $w(t) = \Phi(t,s)w_0$, where $\{\Phi(t,s)\}$ is a family of evolution operators which satisfies

$$\Phi(t,s) = e^{(t-s)B} + \int_s^t e^{(t-\tau)B} B_1(\tau)\Phi(\tau, s)\, d\tau \tag{5.2}$$

for $t \geq s$. Moreover, if $B_1(\cdot)$ is periodic with period T, then $\Phi(t+T, s+T) = \Phi(t,s)$ for $t \geq s$.

In our particular problem (2.8), we can take $\rho = 0$, i.e., $E^\rho = E$.

For the periodic problem (5.1), one can define the period map $U(t) = \Phi(t+T, t)$. In our problem, B has compact resolvent on $\mathbf{X}$. The same argument, approximation in the uniform operator norm by a sequence of finite rank operators, shows that B has compact resolvent on $\mathcal{D}(B)$. By interpolation, we see that B has compact resolvent on $E := D_B(\theta)$, where we fix any $\theta \in (0,1)$. From Henry [12, §7.2], the nonzero eigenvalues of $U(t)$ are independent of time t and constitute all of the spectrum of $U(t)$ with the exception of 0, which is in the continuous spectrum of $U(t)$ since it is a compact operator.

PROPOSITION 5.1 (Henry [12, Thm. 7.2.3 et seq.]). *If all of the characteristic multipliers of the problem* (2.8), *i.e ., problem* (5.1) *in our specific case, are of modulus less than* 1 *and bounded away from* 1, *then there exist $\tilde{M} \geq 1$ and $\tilde{\omega} < 0$ such that*

$$\|\Phi(t,s)\|_{L(E,E^\rho)} \leq \tilde{M}(t-s)^{-\rho} e^{\tilde{\omega}(t-s)}, \quad \text{for } t > s. \tag{5.3}$$

Proof. It suffices to show that $t \mapsto B_1(t) : [0,T] \to L(E^\rho, E)$ is Hölder continuous. Looking at (2.9) we see that $t \mapsto B_1(t) : [0,T] \to L(\mathcal{X})$ and $t \mapsto B_1(t) :$

$[0,T] \to L(\mathcal{D}(B))$ are Hölder continuous, so the desired result follows by interpolation of bounded linear operators. □

PROPOSITION 5.2. *Assume that $B_1(\cdot)$ is periodic with period $T, B_1(\cdot) : [0,T] \to L(E^\rho, E)$ is Hölder continuous, and (5.3) holds, apart from any assumption as to the sign of $\tilde{\omega}$. If η is chosen so that $\tilde{\omega}+\eta < 0$ and $\tilde{\omega}-\eta < 0$, then, for all $\sigma \in \mathbb{R}$, the map*

$$f(\cdot) \mapsto \int_{-\infty}^{\cdot} \Phi(\cdot, s) f(s)\, ds$$

defines a bounded linear operator

$$\mathcal{L}_- : C_\eta((-\infty,\sigma]; E) \to C_\eta((-\infty,\sigma]; F)$$

and the map

$$f(\cdot) \mapsto \int_{\sigma}^{\cdot} \Phi(\cdot, s) f(s)\, ds$$

defines a bounded linear operator

$$\mathcal{L}_+ : C_\eta([\sigma,\infty); E) \to C_\eta([\sigma,\infty); F).$$

Here, $E = D_B(\theta)$ and $F = D_B(\theta+1)$, as in §4.

Proof. We prove the result for $\mathcal{L}_-$; the result for $\mathcal{L}_+$ can be proved similarly. Fix any $f \in C_\eta((-\infty,\sigma]; E)$ and define $u(\cdot) = \int_{-\infty}^{\cdot} \Phi(\cdot, s) f(s)\, ds$. From (5.2),

$$u(t) = \int_{-\infty}^{t} e^{(t-s)B} f(s)\, ds + \int_{-\infty}^{t} \int_{s}^{t} e^{(t-\tau)B} B_1(\tau)\Phi(\tau,s)\, d\tau f(s)\, ds.$$

The first term is in $C_\eta((-\infty,\sigma]; F)$, by Proposition 4.2, with

$$\left\| \int_{-\infty}^{\cdot} e^{(\cdot - s)B} f(s)\, ds \right\|_{\eta,\sigma,-,F} \le K_- \|f\|_{\eta,\sigma,-,E}.$$

Rewrite the second term as

$$\int_{-\infty}^{t} e^{(t-s)B} \int_{-\infty}^{\tau} B_1(\tau)\Phi(\tau,s) f(s)\, ds\, d\tau := \int_{-\infty}^{t} e^{(t-\tau)B} g(\tau)\, d\tau.$$

Using Proposition 4.2 again, to complete the proof it will suffice to show that $g \in C((-\infty,\sigma]; E)$ and that there is a constant C, independent of f, such that $\|g\|_{\eta,\sigma,-,E} \le C\|f\|_{\eta,\sigma,-,E}$. We have for all $\tau \le \sigma$, denoting $m = \max_{0\le\tau\le T} \|B_1(\tau)\|_{L(E^\rho,E)}$,

$$\begin{aligned} e^{-\eta\tau} \left| \int_{-\infty}^{\tau} B_1(\tau)\Phi(\tau,s) f(s)\, ds \right|_E &\le m\tilde{M} \int_{-\infty}^{\tau} (\tau - s)^{-\rho} e^{\tilde{\omega}(\tau-s)} e^{-\eta(\tau-s)} e^{-\eta s} |f(s)|_E\, ds \\ &\le m\tilde{M} \|f\|_{\eta,\sigma,-,E} \cdot \int_{-\infty}^{\tau} (\tau-s)^{-\rho} e^{(\tilde{\omega}-\eta)(\tau-s)}\, ds. \end{aligned}$$

Since $\rho < 1$, $\int_{-\infty}^{\tau} (\tau-s)^{-\rho} e^{(\tilde{\omega}-\eta)(\tau-s)}\, ds < \infty$, and the proposition is proven. □

In our problem we will only use $\rho = 0$, i.e., $E^\rho = E$.

COROLLARY 5.3 (to Proposition 5.1). *For the linear homogeneous periodic problem (2.8), if $\|\alpha\|_\infty := \max_{0\le t\le T} |\alpha(t)|$ is sufficiently small, then the zero solution*

$v \equiv u \equiv 0$ is exponentially asymptotically stable in Z, where Z is any of the spaces $\mathbf{X}, \mathcal{D}(B), E$, and F.

Proof. Problem (2.8) defines $\Phi(t,s)$, which can be considered as a block diagonal matrix $(\Phi_n(t,s))_{n=1}^{\infty}$, where $\Phi_n(t,s)$ is a 2×2 principal fundamental matrix for the problem

$$\begin{pmatrix} \dot{v}_n \\ \dot{u}_n \end{pmatrix} = \begin{pmatrix} 0 & \kappa_n \tan h(\kappa_n h) \\ -\gamma\kappa_n^2 - (g - \alpha(t)) & -\mu\kappa_n^2 \end{pmatrix} \begin{pmatrix} v_n \\ u_n \end{pmatrix}. \tag{5.4}$$

It will suffice to show that the characteristic multipliers $\mu_{n,j}, j = 1,2, n \geq 1$ of (5.4) (i) go to zero as $n \to \infty$ for all $\|\alpha\|_\infty$ and (ii) have modulus less than 1 for all n if $\|\alpha\|_\infty$ is sufficiently small.

Fix an n and denote $c_n = \mu\kappa_n^2, a_n = (\gamma\kappa_n^2 + g)\kappa_n \tan h(\kappa_n h)$. Rescale the time variable by $\tau = c_n t$ and apply Grönwall's inequality to (5.4) with $\alpha \neq 0$ considered as a perturbation of (5.4) with $\alpha \equiv 0$ to conclude that

$$|\mu_n^{\pm}| < \left(-\frac{c_n}{2} + \chi_n + m \frac{\|\alpha\|_\infty}{c_n} \right), \tag{5.5}$$

where $\chi_n := 0$, if $c_n^2 \leq 4a_n$, and $\chi_n := \delta_n$, if $c_n^2 \geq 4a_n$, where $\delta_n := \frac{1}{2}\sqrt{c_n^2 - 4a_n}$, and m is a constant uniformly bounded in n. Results (i) and (ii) follow from easy but tedious asymptotics in (5.5), using $\kappa_n \to \infty$ as $n \to \infty$. □

6. The nonlinearities in equations (2.6)–(2.7). Fix a $\theta \in (0,1)$ and denote $E = D_B(\theta), F = D_B(\theta + 1)$, where B is in equation (2.9). We can write equations (2.6)–(2.7) abstractly as

$$\frac{d\mathbf{w}}{dt} = (B + B_1(t))\mathbf{w} + \mathbf{f}(\mathbf{w}), \tag{6.1}$$

where $\mathbf{f}(\mathbf{w}) = (f_1(\mathbf{w}), f_2(\mathbf{w})), \mathbf{w} = (v,u)$. The purpose of this section is to show that $\mathbf{f} : F \to E$ is C^∞, using a result of Lin [15].

Recall that

$$f_1(v,u) = w|\nabla_{\mathbf{x}} v|^2 - \nabla_{\mathbf{x}} u \cdot \nabla_{\mathbf{x}} v, \tag{6.2}$$

$$f_2(v,u) = M_2(v,u) - [M_2(v,u)], \qquad [\ \ ] = \text{ mean value over } D, \tag{6.3}$$

$$M_2(v,u) = -\frac{1}{2}\, |\nabla_{\mathbf{x}} u|^2 + \frac{1}{2}\, w^2(1 + |\nabla_{\mathbf{x}} v|^2),$$

and

$$w = N(v)u = \phi_z(\mathbf{x}, v(\mathbf{x},t), t)$$

is constructed from the solution ϕ of equations (2.1)–(2.3).

THEOREM 6.1 (Lin [15, Thm. 4.3, "fixed t" part of the proof]). *Fix any $r > 2$. For sufficiently small $|v|_{H^r(D)}$, the map $(v,u) \mapsto N(v)u : \tilde{H}^r(D) \times \tilde{H}^r(D) \to H^r(D)$ exists and is C^∞.*

The proof consists of mapping the region $\Omega_v := \{(\mathbf{x}, z) : -h < z < v(\mathbf{x}), \mathbf{x} \in D\}$ diffeomorphically to $\Omega_0 := \Omega_v|_{v\equiv 0}$ and solving a perturbation of Laplace's equation in Ω_0. The diffeomorphism exists because $|v|_{H^r(D)}$ is small and $r > 2$; the perturbation is small because $|v|_{H^r(D)}$ is, so the implicit function theorem can be applied. The proof uses a result of Zolesio [29] on multiplication of elements of Sobolev spaces of fractional order.

To show $\mathbf{f} : F \to E$ is C^∞, we use the following theorem.

THEOREM 6.2 (daPrato and Grisvard [8, Thm. 2.4]). *Suppose* $0 < \theta < 1, \mathbf{f} : X_1 \to X_2$ *is Fréchet differentiable and* $\mathbf{f}|_{Y_1} : Y_1 \to Y_2$ *is uniformly Lipschitz, where* $Y_i \hookrightarrow X_i$ *are continuously imbedded Banach spaces. Then* $\mathbf{f} : (Y_1, X_1)_{\theta;\infty} \to (Y_2, X_2)_{\theta;\infty}$ *is continuous.*

COROLLARY 6.3. *Suppose* $0 < \theta < 1, E = D_B(\theta), F = D_B(\theta+1)$, $\mathcal{U}_1$ *is an open neighborhood of* $0 \in \mathcal{D}(B)$ *and* $\mathcal{U}_2$ *is an open neighborhood of* $0 \in \mathcal{D}(B^2)$. *If* $\mathbf{f} : \mathcal{U}_1 \subset \mathcal{D}(B) \to \mathcal{X}$ *and* $\mathbf{f}|_{\mathcal{U}_2} : \mathcal{U}_2 \subset \mathcal{D}(B^2) \to \mathcal{D}(B)$ *is* C^∞, *then so is* $\mathbf{f} : \mathcal{V} \subset F \to E$, *for some* $\mathcal{V}$ *an open neighborhood of* $0 \in F$.

COROLLARY 6.4. *Suppose* $0 < \theta < 1, E = D_B(\theta), F = D_B(\theta+1), \mathbf{X} = X^\beta \times X^{\beta-(1/2)}, \mathcal{D}(B) = X^{\beta+(1/2)} \times X^{\beta+(1/2)}, \beta = \frac{r-1}{2}$, *and* $r > 2$. *If the region* D *is a rectangle, then there is an open neighborhood* $\mathcal{V}$ *of* $0 \in F$ *such that* $\mathbf{f}$ *defined by* (6.1)–(6.2) *satisfies* $\mathbf{f} : \mathcal{V} \to E$ *is* C^∞.

Proof. First of all, if $\beta = \frac{r-1}{2}$, then $\mathcal{D}(B) \subset \tilde{H}^r(D) \times \tilde{H}^r(D)$ and $\mathcal{D}(B^2) = (X^{\beta+1} \times X^{\beta+1}) \cap \{v, u) : \gamma v + \mu u \in H^{\beta+(3/2)}\} \subset \tilde{H}^{r+1}(D) \times \tilde{H}^{r+1}(D)$. By Theorem 6.1, for sufficiently small $\delta > 0, \mathbf{f}$ maps $\mathcal{U}_1 = \{(v,u) \in \mathcal{D}(B) : |v|_{\tilde{H}^r(D)} < \delta\}$ into $H^{r-1}(D) \times H^{r-1}(D)$, in fact, it maps into $\tilde{H}^{r-1}(D) \times \tilde{H}^{r-1}(D)$ because clearly $[f_2] = 0$ and $[f_1] = 0$ is noted in Lin [15, §6]. Again the result on multiplication of Zolesio [29] is used. Likewise, $\mathbf{f}$ maps $\mathcal{U}_2 = \{(v,u) \in \mathcal{D}(B^2) : |v|_{\tilde{H}^{r+1}(D)} < \delta\}$ into $\tilde{H}^r(D) \times \tilde{H}^r(D)$. The only thing remaining is to check that $\mathbf{f}(v,u)$ satisfies any boundary conditions required to have (i) $\mathbf{f}(v,u) \in X^\beta \times X^{\beta-(1/2)} = \mathbf{X}$ when $(v,u) \in \mathcal{D}(B) = X^{\beta+(1/2)} \times X^{\beta+(1/2)}$ and (ii) $\mathbf{f}(v,u) \in X^{\beta+(1/2)} \times X^{\beta+(1/2)}$, when $(v,u) \in \mathcal{D}(B^2)$.

The only boundary conditions which might need to be satisfied are of the form $\frac{\partial}{\partial \mathbf{n}} \Delta_N^i f_j = 0$, integer $i \geq 0, j = 1$ or 2. Recall that $\beta = \frac{r-1}{2}$. For example, if $\frac{5}{2} > r > 2$, then $X^{\beta-(1/2)} = \tilde{H}^{r-2}(D), X^\beta = \tilde{H}^{r-1}(D), X^{\beta+(1/2)} = \tilde{H}^r(D) \cap \{u : \frac{\partial u}{\partial \mathbf{n}} = 0 \text{ on } \partial D\}$. Another example is if $\frac{7}{2} > r > \frac{5}{2}$, then $X^{\beta-(1/2)} = \tilde{H}^{r-2}(D), X^\beta = \tilde{H}^{r-1}(D) \cap \{u : \frac{\partial u}{\partial \mathbf{n}} = 0 \text{ on } \partial D\}$, and $X^{\beta+(1/2)} = \tilde{H}^r(D) \cap \{u : \frac{\partial u}{\partial \mathbf{n}} = 0 \text{ on } \partial D\}$. Another example to note is that, if $\frac{9}{2} > r > \frac{7}{2}, X^{\beta+(1/2)} = \tilde{H}^r(D) \cap \{u : \frac{\partial u}{\partial \mathbf{n}} = 0, \frac{\partial \Delta u}{\partial \mathbf{n}} = 0 \text{ on } \partial D\}$.

In our problem, D is a rectangle, say $D = \{\mathbf{x} = (x_1, x_2) : 0 < x_j < \ell_j, j = 1, 2\}$ for some $\ell_1, \ell_2 > 0$. The eigenfunctions are $\psi_n(\mathbf{x}) = \cos(\omega_{1,n} x_1) \cos(\omega_{2,n} x_2)$, where $\omega_{1,n}^2 + \omega_{2,n}^2 = \kappa_n^2$. Because of this explicit information that the ψ_n's are even functions of both x_1 and x_2 with respect to 0, we see that for $r > 2, u, v, w \in \tilde{H}^r(D)$ are even functions in x_1 and x_2 and that

$$f_1 = w|\nabla_{\mathbf{x}} v|^2 - \nabla_{\mathbf{x}} u \cdot \nabla_{\mathbf{x}} v \in \tilde{H}^{r-1}(D),$$

$$M_2 = -\frac{1}{2}\, |\nabla_{\mathbf{x}} u|^2 + \frac{1}{2}\, w^2(1 + |\nabla_{\mathbf{x}} v|^2) \in \tilde{H}^{r-1}(D),$$

$$f_2 = M_2 - [M_2]$$

are even functions of x_1 and x_2. Again, the result on multiplication of Zolesio [29] is used. This implies that $\frac{\partial}{\partial \mathbf{n}} \Delta^i f_j = 0$ on ∂D whenever it makes sense in terms of a trace of a distribution. It follows that (i) $\mathbf{f}$ satisfies the boundary conditions to be in $\mathbf{X} = X^\beta \times X^{\beta-(1/2)}$ whenever $(v,u) \in \mathcal{D}(B) = X^\beta \times X^{\beta-(1/2)}$ and (ii) $\mathbf{f}$ satisfies boundary conditions to be in $\mathcal{D}(B) = X^{\beta+(1/2)} \times X^{\beta+(1/2)}$ whenever $(v,u) \in \mathcal{D}(B^2) = (X^{\beta+1} \times X^{\beta+1}) \cap \{(v,u) : \gamma v + \mu u \in H^{\beta+(3/2)}\}$.

This completes the proof of Corollary 6.4. □

THEOREM 6.5. *For the nonlinear periodic problem* (2.6)–(2.7), *if* $\beta = \frac{r-1}{2} > \frac{1}{2}$, *there is a neighborhood* $\mathcal{U}$ *of* $\mathbf{0} \in F = D_B(\theta+1) \subset \mathcal{D}(B) = X^{\beta+(1/2)} \times X^{\beta+(1/2)}$ *in which there is existence and uniqueness of solutions, locally forward in time.*

We note that if $\beta > 1$, i.e., $r > 3$, the solutions are classical, i.e., $C^2(D) \times C^2(D)$, by the Sobolev imbedding theorem. Theorem 6.5 can be proven by a standard use of the contraction mapping theorem, along with Proposition 4.1 and Corollary 6.4.

We also have the following theorem.

THEOREM 6.6 (linearized stability). *For the nonlinear periodic problem* (2.6)–(2.7), *if* $\beta > \frac{1}{2}$, *then* $(v, u) = 0 \in F$ *is exponentially asymptotically stable in the sense of Liapunov, i.e., locally in* F, *if* $\|\alpha\|_\infty := \max_{0 \le t \le T} |\alpha(t)|$ *is sufficiently small.*

Theorem 6.6 can be proven in the usual way, using Proposition 4.1, Corollary 5.3, and Corollary 6.4; see, e.g., the proof of daPrato and Lunardi [9, Thm. 2.2]. The restriction "locally in F" is due to the same restriction in Corollary 6.4.

7. A local center-unstable manifold theorem for problem (2.6)–(2.7).

As usual, we fix a $\theta \in (0,1)$.

DEFINITION. *A* C^k *local center-unstable manifold in* Z *for a* T*-periodic problem, i.e., periodic with period* T,

$$\frac{d\mathbf{w}}{dt} = (B + B_1(t))\mathbf{w} + \mathbf{f}(\mathbf{w}), \mathbf{w} \in Z \tag{7.1}$$

is a set of the form

$$\mathcal{M} = \{(t, \xi_1 + \mathbf{h}(t, \xi_1)) : \xi_1 \in \mathcal{U}_1(t), t \in \mathbb{R}\} \subseteq \mathbb{R} \times Z,$$

where for all $t, Z = Z_1(t) \oplus Z_2(t), \mathcal{U}_1(t)$ *is a neighborhood of* $0 \in Z_1(t)\, \mathbf{h}(t, \cdot) : \mathcal{U}_1 \to Z_2(t)$ *is* $C^k, \mathbf{h}(t, 0) \equiv \mathbf{0}, d_{\mathbf{z}}\mathbf{h}(t, 0) \equiv 0$, *where* d *denotes a Fréchet derivative, and* $\mathcal{M}$ *is invariant forward in time* t *for* (7.1).

We note from the proof of Corollary 5.3 that, for the linear problem (2.8), there are at most finitely many unstable modes, corresponding to characteristic multipliers of modulus greater than 1, no matter how large $\|\alpha\|_\infty := \max_{0 \le t \le T} |\alpha(t)|$. We assume

(H) α is such that (2.8) has a positive finite number ν of characteristic multipliers greater than or equal to 1.

Correspondingly, there is for each $t \in \mathbb{R}$ a finite-rank projection $P_1(t)$ on the Hilbert space $\mathcal{X}$; we denote $P_2(t) = I - P_1(t)$. In an abuse of notation we use $P_1(t)$ to denote the restriction of $P_1(t)$ to $E = D_B(\theta)$ or $F = D_B(\theta + 1)$; the latter are not Hilbert spaces, but the linear operators $P_1(t)$ are still uniformly bounded in t, by interpolation.

In fact, one can choose $P_1(t)$ so that the evolution family $\{\Phi(t,s)P_1(s)\}$ satisfies

$$\Phi(t,s)P_1(s) = P_1(t)\Phi(t,s), \quad t \ge s.$$

Moreover, because $\dim P_1(s)E = \nu < \infty$ for all s, the evolution family $\{\Phi(t,s)P_1(s)\}$ can be extended to satisfy

$$\Phi(t,s)P_1(s) = P_1(t)\Phi(t,s),$$

$$\Phi(t,s)P_1(s)\Phi(s,\tau)P_1(\tau) = \Phi(t,\tau)P_1(\tau)$$

for all t, s, τ; in an abuse of notation, we have not bothered to renotate this extended family. Recall that $\nu < \infty$. By hypothesis (H), there exists $M_1 \geq 1, \omega_1 > 0$ such that

$$\|\Phi(t,s)P_1(s)\|_{L(E,F)} \leq M_1 e^{-\omega_1(t-s)} \quad \text{for } t \leq s. \tag{7.2}$$

$$\|\Phi(t,s)P_1(s)\|_{L(E)} \leq M_1 e^{-\omega_1(t-s)} \quad \text{for } t \leq s,$$

i.e., backwards in time. In fact, since all of the characteristic multipliers of $\Phi(t+T, T)P_1(t)$ are of modulus greater than or equal to 1, one may choose positive ω_1 as close to 0 as desired, although perhaps at the expense of increasing M_1. Because of estimate (7.2) and the fact that $\dim P_1(s)E = \nu < \infty$ for all s, one has a backwards maximal regularity result, as in daPrato and Lunardi [9, Thm. 2.4].

LEMMA 7.1(corollary to Proposition 5.2). *Assume that $B_1(\cdot)$ is periodic with period $T, B_1(\cdot) : [0,T] \to L(E^\rho, E)$ is Hölder continuous, hypothesis* (H) *holds, and η is chosen so that $\omega_1 - \eta < 0$, where ω_1 is as in* (7.2). *Then for all $\sigma \in \mathbb{R}$, the map*

$$f(\cdot) \mapsto \int_\sigma^\cdot \Phi(\cdot, s)P_1(s)f(s)\,ds$$

defines a bounded linear operator

$$\tilde{\mathcal{L}}_+ : C_\eta((-\infty,\sigma]; E) \to C_\eta((-\infty,\sigma]; F).$$

By hypothesis (H) and the definitions of $P_1(t)$ and $P_2(t)$, we have that there exists $M_2 \geq 1, \tilde{\omega} < 0$ such that

$$\|\Phi(t,s)P_2(s)\|_{L(E,F)} \leq M_2 e^{\tilde{\omega}(t-s)}, \quad \text{for } t \geq s \tag{7.3}$$

by Proposition 5.1.

LEMMA 7.2 (corollary to Proposition 5.2). *Assume that $B_1(\cdot)$ is periodic with period $T, B_1(\cdot) : [0,T] \to L(E^\rho, E)$ is Hölder continuous, hypothesis* (H) *holds, and η is chosen so that $\tilde{\omega} - \eta < 0$, where $\tilde{\omega}$ is as in* (7.3). *Then for all $\sigma \in \mathbb{R}$, the map*

$$f(\cdot) \mapsto \int_{-\infty}^\cdot \Phi(\cdot, s)P_2(s)f(s)\,ds$$

defines a bounded linear operator

$$\tilde{\mathcal{L}}_- : C_\eta((-\infty,\sigma]; E) \to C_\eta((-\infty,\sigma]; F).$$

To help in what follows, here are some comparisons of notation in related papers. Chow and Lu's [6] $-\alpha - \eta, -\beta + \eta$, correspond to our $\omega, \tilde{\omega}$, and their $\eta, C_\eta(\mathbb{R}^-, X)$ correspond to our $\eta, C_\eta((-\infty,\sigma]; F)$. Chow, Lin, and Lu's [7] α and $-\beta$ correspond to our ω_1 and $\tilde{\omega}$, and their γ and $E_\sigma^-(-\gamma, X)$ correspond to our $-\eta$ and $C_\eta((-\infty,\sigma]; F)$. DaPrato and Lunardi's [9, proof of Thm. 3.1] ω_1 and $-\mu$ correspond to our $\tilde{\omega}$ and η. Chow and Lu's [6] condition $\beta + (k-1)\eta > 0$ corresponds to our condition $\tilde{\omega} - k\eta < 0$. Chow, Lin, and Lu's [7] spectral gap conditions $\alpha < \gamma \leq k\gamma < \beta$ correspond to our conditions $\omega_1 + \eta < 0, \eta < 0, \tilde{\omega} - k\eta < 0, \tilde{\omega} < 0$, and hypothesis (H). DaPrato and Lunardi's spectral gap condition $\lambda_1 < 0 \leq \lambda_2$ and $\omega_1 + \mu < 0$ correspond to our conditions $\tilde{\omega} < 0$, hypothesis (H), and $\tilde{\omega} - \eta < 0$.

THEOREM 7.3. *Assume* (H). *For any integer $k \geq 1$, there exists a local center-unstable manifold $\mathcal{M}$ of dimension ν for the nonlinear periodic problem* (2.6)–(2.7) *and hence for a model of the Faraday resonance. If we fix* $0 < \theta < 1, r > 2$, *then* $\mathcal{M} \subset \mathbb{R} \times F$, *where* $F = D_B(\theta + 1) \subset \mathcal{D}(B) = X^{r/2} \times X^{r/2} \subset \tilde{H}^r(D) \times \tilde{H}^r(D)$. *If* $r + \theta > 3$ *then the solutions are classical.*

Proof. Fix any $r > 2$ and $0 < \theta < 1$ and define $E = D_B(\theta), F = D_B(\theta + 1)$. Fix any $\sigma \in \mathbb{R}$. Use Lemma 7.2 to define a bounded linear operator $\tilde{\mathcal{L}}_-$, and use Lemma 7.1 to define a bounded linear operator $\tilde{\mathcal{L}}_+$. The η that one chooses is determined by the ω_1 in Lemma 7.1 and $\tilde{\omega}$ in Lemma 7.2. One chooses $\eta < 0$ such that $\tilde{\omega} - k\eta < 0$ and $\omega_1 - \eta < 0$. By Corollary 6.4, there is a neighborhood of $\mathbf{0} \in \mathcal{U} \subset F$ such that $\mathbf{f} : \mathcal{U} \to E$ is C^∞. The proofs of Chow and Lu [6, §§3 and 4] for autonomous problems and Chow, Lin, and Lu [7, Lem. 3.1 and 3.2 and Thm. 3.3] for nonautonomous problems work just as well. First, one defines a bounded linear operator $\mathcal{T} : C_\eta((-\infty, \sigma]; E) \to C_\eta((-\infty, \sigma]; F)$ by $\mathbf{f}(\cdot) \mapsto \int_\sigma^\cdot \Phi(\cdot, s)P_1(s)\mathbf{f}(s)\,ds + \int_{-\infty}^\cdot \Phi(\cdot, s)P_2(s)\mathbf{f}(s)\,ds$. After making the usual cutoff function alteration of $\mathbf{f}$ to get a function $\tilde{\mathbf{f}}$ with sufficiently small Lipschitz constant, the solution of the integral equation

$$\varphi(t) = \Phi(t, \sigma)\xi_1 + \int_\sigma^t \Phi(t, s)P_1(s)\tilde{\mathbf{f}}(\varphi(s))\,ds + \int_{-\infty}^t \Phi(t, s)P_2(s)\tilde{\mathbf{f}}(\varphi(s))\,ds$$

is denoted by $\varphi(t; \sigma, \xi_1)$ for $t \le \sigma, \xi_1 \in \mathcal{U}_1(\sigma)$. The function $\mathbf{h}$ which gives the integral manifold $\mathcal{M}$ is then defined by

$$\mathbf{h}(\sigma, \xi_1) = \int_{-\infty}^\sigma \Phi(\sigma, s)P_2(s)\tilde{\mathbf{f}}(\varphi(s; \sigma, \xi_1))\,ds = \varphi(\sigma; \sigma, \xi_1) - \xi_1.$$

See also daPrato and Lunardi [9] for autonomous problems. The conclusion about when the solutions are classical follows from (4.2)–(4.4) and the fact that $F = D_B(\theta + 1) = \{\mathbf{w} \in D(B) : B\mathbf{w} \in D_B(\theta)\}$. □

We note that, as usual, $\mathcal{M}$ may depend on k and the choice of the cutoff function used in the proof. If, in addition, $P_1(t+T) \equiv P_1(t)$, then $\mathbf{h}(t+T, \xi_1) \equiv \mathbf{h}(t, \xi_1)$ follows from $\Phi(t + T, s + T) \equiv \Phi(t, s)$. So, if the linearization has only decaying modes and simple periodic solutions, then we get a periodic center manifold.

THEOREM 7.4 (exponential attractivity with asymptotic phase). *For any integer* $k \ge 1$ *the local center-unstable manifold* $\mathcal{M}$ *for problems* (2.6)–(2.7) *is locally exponentially attractive, i.e., there exists a neighborhood* $\mathcal{U}$ *of* $\mathcal{M}$ *such that, if* $\mathbf{w}(t) = (v(t), u(t))$ *is a solution of* (2.6)–(2.7) *which exists for* $t \in [\sigma, \infty)$ *and such that* $(t, \mathbf{w}(t)) \in \mathcal{U}$ *for* $t \in [\sigma, \infty)$, *then there exists a solution* $\mathbf{w}^*(t)$ *of* (2.6)–(2.7), $(\sigma, \mathbf{w}^*(\sigma)) \in \mathcal{M}$, *such that* $|\mathbf{w}(t) - \mathbf{w}^*(t)|_F \to 0$ *as* $t \to \infty$, *exponentially.*

Proof. If necessary, by taking $\mathcal{U}$ smaller than in Theorem 7.3, one can make the Lipschitz constant of $\tilde{\mathbf{f}}$ as small as one needs. The proof is then similar to that of Chow and Lu [6, Thm. 5.1]; again, one uses the integral operators $\tilde{\mathcal{L}}_\pm$. □

The hypothesis that $(t, \mathbf{w}(t)) \in \mathcal{U}$ for $\sigma \le t < \infty$ ensures that the solution of (2.6)–(2.7) also satisfies the problem with a cutoff of $\mathbf{f}$.

8. An example. We mention in passing a result of a sequel in preparation. For a square tank, Silber and Knobloch [23], following experimental work of Simonelli and Gollub [24], studied excitation of the (3, 2) and (2, 3) spatial modes. We were able to calculate an approximate, local center manifold which reduces the dynamics to that of a periodic system of ordinary differential equations

$$\left\{ \begin{array}{l} \dot{x} = xq(t, x, y) \\ \dot{y} = yq(t, y, x) \end{array} \right\},$$

where $q(t, x, y) = a(t)x^2 + b(t)y^2$. Here, x, y correspond to the center directions for the (3, 2) and (2, 3) spatial modes.

Acknowledgments. The hospitality of the School of Mathematics of the Georgia Institute of Technology is gratefully acknowledged. It is my pleasure to thank Shui-Nee Chow, Anibal Rodriguez-Bernal, Wenxian Shen, and Mary Silber for their help; in particular, the impetus for this work came out of discussions with Chow and Silber. I also thank an anonymous referee for some helpful suggestions. The referee also made me aware of a paper by Lunardi [17]; it appears that, for my particular applied problem, my work uses simpler spaces than in her paper on fully nonlinear parabolic equations.

THE REGULARIZATION OF LINEAR DIFFERENTIAL-ALGEBRAIC EQUATIONS*

LEONID V. KALACHEV† AND ROBERT E. O'MALLEY, JR.‡

Abstract. Differential-algebraic equations naturally arise in numerous important applied contexts, e.g., electrical circuits, constrained dynamical motion and fluid dynamics. The authors show how the structure of the solution space for some typical problems can be illuminated through the introduction of various regularizations which often can be given natural physical interpretations.

Key words. differential-algebraic equations, constrained differential equations, regularization

AMS subject classifications. 34A09, 34A12, 34D15

1. An index-one problem.

Consider the constrained differential equation

$$\left\{\begin{aligned} \dot{U}_0 &= A(t)U_0 + B(t)V_0 + f(t), \\ 0 &= C(t)U_0 + D(t)V_0 + g(t) \end{aligned}\right. \tag{1.1}$$

consisting of a linear differential system for the m-vector U_0 and a linear constraint relating U_0 and the n-vector V_0. If we make the strong assumption that

$$\text{the matrix } D(t) \text{ remains nonsingular,} \tag{1.2}$$

we can solve for

$$V_0 = -D^{-1}(CU_0 + g), \tag{1.3}$$

and there simply remains the linear differential system

$$\dot{U}_0 = (A - BD^{-1}C)U_0 + (f - BD^{-1}g) \tag{1.4}$$

for U_0. The standard existence theory for linear ordinary differential equations (cf., e.g., Coddington and Levinson [5]) implies that if the coefficients A, B, f, C, D, and g are continuous functions on some bounded interval of, say, $t \geq 0$, then the solution space for this so-called index-one differential-algebraic equation (or DAE) (1.1) will be m-dimensional, being parameterized, for example, by the m-components of the initial vector $U_0(0)$. Problem (1.1)–(1.2) is usually called index-one because one differentiation of the algebraic constraint in (1.1) provides $\dot{U}_0$ and $\dot{V}_0$ as explicit functions of U_0, V_0, and t.

Such DAEs and their nonlinear generalizations arise in many practical, important contexts, ranging from the Navier–Stokes equations to Euler–Lagrange equations and to Kirchhoff's laws. Constant coefficient problems were classically solved through the use of matrix pencils (cf. Gantmacher [8]), but more general DAEs were seldom

*Received by the editors March 25, 1994; accepted for publication (in revised form) April 25, 1994. This research was supported in part by National Science Foundation grant DMS-9107196.

‡Department of Applied Mathematics, University of Washington, FS-20, Seattle, WA 98195.

studied very thoroughly. DAEs have, however, been of substantial recent interest to the numerical analysis community (cf., e.g., Brenan et al. [2], Hairer et al. [14], Hairer and Wanner [15], and Griepentrog et al. [13]). Our study indicates how regularization can effectively reveal the solution structure for DAEs. Following the general approach of Tikhonov and Arsenin [33], we will define a continuum of problems P_ϵ for small positive ϵ values and determine the DAE's solutions as limiting solutions of P_ϵ for $\epsilon \to 0$ (for, say, $t > 0$). This relates to earlier analytical and numerical studies involving such regularizations by Campbell [3], Lötstedt [22], Knorrenschild [20], Hanke [16], and Eich and Hanke [7], but our approach is more closely based on singular perturbation theory (cf., e.g., O'Malley [26]). Some further nonlinear generalizations are contained in Kalachev and O'Malley [19].

One way to regularize problem (1.1) is to consider it as the limit of the singularly perturbed $(m+n)$-dimensional linear system

$$\begin{cases} \dot{u} = Au + Bv + f, \\ -\epsilon D\dot{v} = Cu + Dv + g \end{cases} \tag{1.5}$$

as $\epsilon \to 0$. Rewriting this as

$$\begin{cases} \dot{u} = Au + Bv + f, \\ \epsilon\dot{v} = -D^{-1}Cu - v - D^{-1}g \end{cases} \tag{1.6}$$

emphasizes that the small *positive* parameter ϵ was introduced in (1.5) in a manner to achieve the appropriate asymptotic stability for (1.6), which implies fast initial dynamics where v generally decays rapidly like a constant vector multiple of the scalar function $e^{-t/\epsilon}$. The well-known Tikhonov–Levinson theory for singularly perturbed initial value problems (cf. Smith [31], O'Malley [26], and Vasil'eva et al. [35]) directly establishes that (1.5) has an $(m+n)$-dimensional solution space, parametrized by any prescribed bounded initial vector

$$\begin{pmatrix} u(0) \\ v(0) \end{pmatrix},$$

with solutions having the asymptotic form

$$\begin{cases} u(t,\epsilon) = U_0(t) + O(\epsilon), \\ v(t,\epsilon) = V_0(t) + \beta_0(t/\epsilon) + O(\epsilon) \end{cases} \tag{1.7}$$

on fixed bounded intervals $0 \le t \le T$, where

$$\begin{pmatrix} U_0 \\ V_0 \end{pmatrix}$$

satisfies the original DAE (1.1) (and therefore (1.3) and (1.4)) and where

$$\beta_0(\tau) = e^{-\tau}[v(0) + D^{-1}(0)C(0)u(0) + D^{-1}(0)g(0)] \tag{1.8}$$

is the decaying solution of the vector initial layer problem $\frac{d\beta_0}{d\tau} = -\beta_0$, $\beta_0(0) = v(0) - V_0(0)$ on the stretched interval $\tau = \frac{t}{\epsilon} \ge 0$. We note that this limiting initial layer correction $\beta_0(\tau)$ will be trivial when the initial value for $v(0)$ is consistent with the constraint $C(0)u(0) + D(0)v(0) + g(0) = 0$, so $\beta_0(0) = 0$. Otherwise, the solution of

(1.6) will feature nonuniform convergence in the v variable at $t = 0$, i.e., an initial Heaviside function discontinuity in the $\epsilon \to 0$ limit. One way to solve the original DAE is to numerically integrate the regularized problem (1.5) using a stiff integrator for a sequence of small $\epsilon > 0$ values. (Using the perturbation term $-\epsilon D(0)\dot{v}$ may be computationally preferable to that used in (1.5), since one won't then need to calculate $D^{-1}(t)$ for all $t > 0$ of interest. Then, however, the t interval must be restricted so that $-D^{-1}(0)D(t)$ remains stable.) More simply, one can just integrate the nonstiff mth-order initial value problem for U_0 (cf. (1.4)) with $U_0(0) = u(0)$ and use (1.3) to obtain V_0.

We note that the artificially introduced parameter ϵ may often by provided a physical interpretation (see below). Indeed, when a DAE (1.1) results from the neglect of rapid transients in a dynamic model, $\frac{1}{\epsilon}$ may represent the size of the smallest neglected decay rate.

2. A pure index-two problem in Hessenberg form. More challenging DAEs than (1.1)–(1.2) arise when the matrix $D(t)$ in (1.1) is identically zero, when it has *fixed* positive rank r less than n, or when it involves isolated turning points where $D(t)$ becomes singular or changes rank. We will first consider the "pure" index-two situation when $D(t) \equiv 0$ and then the case when $0 < r < n$. Specifically, let us first consider the DAE

$$\begin{cases} \dot{U}_0 = A(t)U_0 + B(t)V_0 + f(t), \\ 0 = C(t)U_0 + g(t) \end{cases} \tag{2.1}$$

in the situation that the number m of differential equations is not exceeded by the number n of constraints and that the $n \times n$ matrix

$$C(t)B(t) \text{ remains nonsingular} \tag{2.2}$$

for all $t \geq 0$. We will also assume somewhat more smoothness than before. The classical approach to solving (2.1)–(2.2) involves differentiating the constraint with respect to t to yield $C(AU_0 + BV_0 + f) + \dot{C}U_0 + \dot{g} = 0$ and solving this equation for V_0. Since the remaining problem for U_0 is like the index-one problem (1.1)–(1.2), it is natural to call (2.1)–(2.2) an index-two problem. See Gear and Petzold [10] and Griepentrog et al. [13] for comparisons of various index concepts. Very crudely, the index is the number of differentiations necessary to convert a DAE to an ordinary differential equation in standard form.

Here, let us consider the regularized problem

$$\begin{cases} \dot{u} = Au + Bv + f, \\ -\epsilon CBv = Cu + g, \end{cases} \tag{2.3}$$

where the scaled vector $-\epsilon CBv$ is used as a slack variable, so the given constraint need only be satisfied in the limit as $\epsilon v \to 0$. Eliminating

$$v = -\frac{1}{\epsilon}(CB)^{-1}[Cu + g] \tag{2.4}$$

leaves us with the singularly perturbed differential system

$$\epsilon\dot{u} = [-B(CB)^{-1}C + \epsilon A]u - B(CB)^{-1}g + \epsilon f \tag{2.5}$$

for u. We note that an alternative procedure (cf. Kalachev and O'Malley [18]) would be to differentiate the constraint in (2.3) to obtain a singularly perturbed differential system for u and v. Both approaches suggest more impulsive initial behavior for v than for u.

The Tikhonov–Levinson theory does not apply for the singular singular-perturbation problem (2.5) because the limiting Jacobian matrix

$$-Q(t) \equiv -B(CB)^{-1}C \tag{2.6}$$

generally has a constant rank $n < m$. Note that Q is a projection onto the range of C since $Q^2 = Q$, $CQ = C$, and rank $Q \leq$ rank C. We can, nonetheless, seek an asymptotic solution to the initial value problem for (2.5) in the form

$$u(t, \epsilon) = U(t, \epsilon) + \alpha(\tau, \epsilon), \tag{2.7}$$

where the outer expansion

$$U(t, \epsilon) = U_0(t) + \epsilon U_1(t) + \epsilon^2 U_2(t) + \cdots \tag{2.8}$$

must naturally satisfy (2.5) for all $t > 0$ as a formal power series in ϵ, while the initial layer correction $\alpha(\tau, \epsilon)$ must be a decaying solution of the homogeneous initial layer system

$$\frac{d\alpha}{d\tau} = [-Q(\epsilon\tau) + \epsilon A(\epsilon\tau)]\, \alpha \tag{2.9}$$

on $\tau \equiv \frac{t}{\epsilon} \geq 0$, thereby providing any necessary nonuniform convergence near $t = 0$ if $\alpha(0, \epsilon) = u(0) - U(0, \epsilon)$ is nontrivial (cf. Vasil'eva and Butuzov [34], O'Malley [26], and Vasil'eva et al. [35] for treatments of such singular problems).

Equating coefficients termwise in (2.5) implies that the terms of the outer expansion must successively satisfy

$$\begin{cases} 0 = -QU_0 - B(CB)^{-1}g, \\ \dot{U}_0 - AU_0 = -QU_1 + f, \\ \dot{U}_1 - AU_1 = -QU_2, \\ \text{etc.} \end{cases} \tag{2.10}$$

Introducing the complementary rank-$(m - n)$ projection

$$P(t) \equiv I - B(CB)^{-1}C \tag{2.11}$$

to Q, note that $CP = 0$ and $PQ = 0$. We can naturally seek any m-vector z by first finding Qz, then Pz, and finally z as their sum. We observe the widespread use of more general projection matrices in Griepentrog et al. [13] and in other earlier work cited. Indeed, the direct use of a matrix pseudoinverse of C is naturally suggested by the formulation (2.1).

Note that (2.10)(a) implies that

$$QU_0 = -B(CB)^{-1}g, \tag{2.12}$$

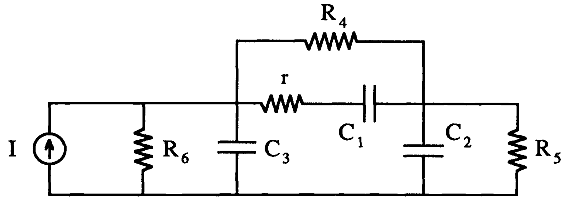

FIG. 1

while multiplication of (2.10)(b) by P yields $P\dot{U}_0 = PAU_0 + Pf$. Substituting $P\dot{U}_0 = (PU_0)^{\bullet} - \dot{P}U_0$ and replacing U_0 by $PU_0 + QU_0$ finally provides the linear differential equation

$$(PU_0)^{\bullet} = (PA + \dot{P})(PU_0) + Pf - (PA + \dot{P})B(CB)^{-1}g \tag{2.13}$$

for the projection PU_0. This implies an $(m - n)$-dimensional solution space for the DAE (2.1)–(2.2), since it remains only to integrate the differential system (2.13) for PU_0 using an *arbitrary* initial vector $P(0)U_0(0)$. Then, we will have

$$U_0 = PU_0 - B(CB)^{-1}g. \tag{2.14}$$

Since $CU_0 = -g$, (2.4) implies that we must still determine the original vector $V_0 = -(CB)^{-1}CU_1$. Note, however, that (2.10)(b) now specifies $QU_1 = f + AU_0 - \dot{U}_0$. But $CP = 0$ implies that $CU_1 = CQU_1$, so

$$\begin{aligned} V_0 &= -(CB)^{-1}C(f + AU_0 - \dot{U}_0) \\ &= -(CB)^{-1}C[(A - PA - \dot{P})(PU_0 - B(CB)^{-1}g) + (B(CB)^{-1}g)^{\bullet} + f - Pf]. \end{aligned} \tag{2.15}$$

To get the limiting solution then requires us to use both derivatives $\dot{P}$ and $(Qg)^{\bullet}$. Integrating the nonstiff m-dimensional system (2.13) for PU_0 would seem far easier numerically than trying to directly integrate the singularly perturbed initial value problem (2.5) to obtain U_0 as its limiting solution for $t > 0$ (since the limiting state matrix $-Q(t)$ has $m - n$ zero eigenvalues as well as n stable ones).

The limiting initial layer correction is necessarily given by

$$\alpha_0(\tau) = e^{-\tau}Q(0)[u(0) + B(0)(C(0)B(0))^{-1}g(0)], \tag{2.16}$$

since $\alpha_0(\tau)$ must be a decaying solution of $\frac{d\alpha_0}{d\tau} = -Q(0)\alpha_0$ with $\alpha_0(0) = u(0) - U_0(0)$ already known. Thus, $\alpha_0(\tau) \equiv Q(0)\alpha_0(\tau)$ and $P(0)\alpha_0(\tau) \equiv 0$, i.e., α_0 remains completely in the n-dimensional stable eigenspace of $Q(0)$. This again shows that we can take

$$P(0)U_0(0) = P(0)u(0) \tag{2.17}$$

to be arbitrary. Moreover, $\alpha_0(\tau)$ will provide the initial Heaviside jump for u, unless $\alpha_0(\tau) \equiv 0$ because the initial value for $u(0)$ is consistent with the constraint, i.e., $Q(0)u(0) = -B(0)(C(0)B(0))^{-1}g(0)$. It will, in turn, imply an initial delta-function impulse $-\frac{1}{\epsilon}(C(0)\ B(0))^{-1}C(0)\alpha_0(\frac{t}{\epsilon})$ for v. Allowing such inconsistency is particularly important for systems with switching (cf. Opal and Vlach [28]) and for stabilizing numerical drift off constraints. It is important to emphasize that the rapid motion in u is orthogonal to the constraint, i.e., in the range of $Q(0)$.

Example 1. Consider the simple linear electrical circuit pictured in Fig. 1 above.

For simplicity, let the capacitances C_j, the resistances R_j, and the input current I all have unit values and, for now, let the resistance r be zero. The voltage-current relations and the Kirchhoff voltage and current laws provide us the DAE:

$$(2.18)\qquad \begin{cases} \dot{v}_j = i_j, j = 1, 2, 3, \\ v_k = i_k, k = 4, 5, 6, \\ v_j = v_{j+3}, j = 1, 2, 3, \\ v_1 + v_2 = v_3, \\ i_1 + i_3 + i_4 + i_6 = 1, \\ \text{and} \\ i_1 - i_2 + i_4 - i_5 = 0. \end{cases}$$

Thus, we have three differential and nine algebraic equations for the twelve unknowns i_ℓ and v_ℓ, $\ell = 1, 2, \ldots, 6$. We naturally eliminate v_k and i_k, $k = 4, 5$, and 6, as well as i_2 and i_3. This leaves us the DAE

$$(2.19)\qquad \begin{cases} \dot{v} = Av + Bi_1 + f, \\ 0 = B^T v, \end{cases}$$

where

$$A = \begin{pmatrix} 0 & 0 & 0 \\ 1 & -1 & 0 \\ -1 & 0 & -1 \end{pmatrix}, \quad v = \begin{pmatrix} v_1 \\ v_2 \\ v_3 \end{pmatrix}, \quad B = \begin{pmatrix} 1 \\ 1 \\ -1 \end{pmatrix}, \quad \text{and} \quad f = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}.$$

Since $B^T B = 3 > 0$, this problem is of the form (2.1)–(2.2) with $C = B^T$, and we therefore proceed to consider the slack variable regularization

$$(2.20)\qquad \begin{cases} \dot{v} = Av + Bi_1 + f, \\ -3\epsilon i_1 = B^T v \end{cases}$$

for an artificial small parameter $\epsilon > 0$. Since we can rewrite the present constraint as $v_1 + v_2 + 3\epsilon i_1 = v_3$, we can physically interpret our regularization as corresponding to the introduction of a small resistance $r = 3\epsilon$ in the circuit in series with the first capacitor or, for example, a resistance ϵ in series with each capacitor. This regularization coincides with the common technique (from Chua [4] and elsewhere) of introducing small parasitics and determining the network's solution through a limiting process.

Our regularization procedure reduces (2.18) to solving the singular singularly perturbed system

$$(2.21)\qquad \epsilon\dot{v} = -\left(\frac{1}{3}BB^T - \epsilon A\right)v + \epsilon f$$

with the limiting Jacobian matrix $-\frac{1}{3}BB^T$ having rank one and one stable and two zero eigenvalues. We naturally seek an asymptotic solution of (2.21) in the form

$$(2.22)\qquad v(t, \epsilon) = V(t, \epsilon) + \alpha(\tau, \epsilon),$$

where the outer expansion satisfies $V \sim \sum_{j\geq 0}^{\infty} V_j \epsilon^j$ and the initial layer correction $\alpha \to 0$ as $\tau \equiv \frac{t}{\epsilon} \to \infty$. Since the outer expansion will solve (2.21) termwise, we will successively need $\frac{1}{3}BB^T V_0 = 0$, $\frac{1}{3}BB^T V_1 = AV_0 + f - \overset{\bullet}{V}_0$, etc. The first condition requires that

$$V_{10} + V_{20} = V_{30}, \tag{2.23}$$

so it simply restricts the limiting outer solution $V_0 = (V_{10} \;\; V_{20} \;\; V_{30})^T$ to the constraint, while the second condition requires the componentwise equations

$$\begin{cases} V_{11} + V_{21} - V_{31} = -\overset{\bullet}{V}_{10}, \\ V_{11} + V_{21} - V_{31} = V_{10} - V_{20} - \overset{\bullet}{V}_{20}, \\ -V_{11} - V_{21} + V_{31} = -V_{10} - V_{30} + 1 - \overset{\bullet}{V}_{30}. \end{cases} \tag{2.24}$$

Eliminating V_{30} (through (2.23)) and then $V_{11} + V_{21} - V_{31}$ provides us the differential equations $\overset{\bullet}{V}_{j0} = -V_{j0} + \frac{1}{3}$, $j = 1$ and 2, for V_{10} and V_{20}. Imposing the initial conditions for $v_1(0)$ and $v_2(0)$, we then have

$$\begin{cases} V_{10}(t) = \dfrac{1}{3} + \left(v_1(0) - \dfrac{1}{3}\right) e^{-t}, \\ V_{20}(t) = \dfrac{1}{3} + \left(v_2(0) - \dfrac{1}{3}\right) e^{-t}, \\ \text{and} \\ V_{30}(t) = \dfrac{2}{3} + \left(v_1(0) + v_2(0) - \dfrac{2}{3}\right) e^{-t}. \end{cases} \tag{2.25}$$

We cannot generally expect the initial value $V_{30}(0)$ to agree with the prescribed $v_3(0)$, so there is a need for an initial layer correction term $\alpha_0(\tau)$. Later terms $V_k(t)$ in the outer expansion can be readily determined successively, up to specifying the initial values $V_{1k}(0)$ and $V_{2k}(0)$, but they will not be physically relevant.

If the initial conditions are consistent, i.e., $v_3(0) = v_1(0) + v_2(0)$, there is no need for $\alpha_0(\tau) = \alpha(\tau, 0)$. Otherwise, we will have a nontrivial limiting initial layer correction $\alpha_0(\tau) = (0 \;\; 0 \;\; \alpha_{30}(\tau))^T$ determined through the resulting scalar problem $\frac{d\alpha_{30}}{d\tau} = -\frac{1}{3}\alpha_{30}, \alpha_{30}(0) = v_3(0) - V_{30}(0)$. Thus,

$$\alpha_{30}(\tau) = e^{-\tau/3}(v_3(0) - v_1(0) - v_2(0)) \tag{2.26}$$

provides an initial Heaviside jump in v_3 in the limit $\epsilon \to 0$.

The slack variable constraint $i_1 = -\frac{B^T}{3\epsilon}(V + \alpha) \equiv I(t, \epsilon) + \frac{1}{\epsilon}\beta(\tau, \epsilon)$ implies the limiting current

$$I_0 \equiv -\frac{1}{3}B^T V_1 = -\frac{1}{3}(V_{11} + V_{21} - V_{31}) = \frac{1}{3}\left(V_{10} - \frac{1}{3}\right) = \frac{1}{3}\left(v_1(0) - \frac{1}{3}\right) e^{-t} \tag{2.27}$$

for $t > 0$ and the initial layer correction

$$\frac{1}{\epsilon}\beta_0\left(\frac{t}{\epsilon}\right) \equiv \frac{1}{3\epsilon}\alpha_{30}\left(\frac{t}{\epsilon}\right), \tag{2.28}$$

which features an initial delta function impulse whenever the initial voltages are inconsistent with the constraint. This reflects the rapid initial charging of the first capacitor when the series resistance r is small.

Example 2. If we linearize the Navier–Stokes equations about an incompressible flow with mean velocity $(U \;\; 0 \;\; 0)^T$ and introduce the moving coordinate $\xi = x - Ut$, we obtain a system of the form

$$(2.29)\qquad \begin{cases} \dfrac{\partial u}{\partial t} = \mu\left(\dfrac{\partial^2 u}{\partial \xi^2} + \dfrac{\partial^2 u}{\partial y^2} + \dfrac{\partial^2 u}{\partial z^2}\right) - \dfrac{\partial p}{\partial \xi} + F_1(\xi, y, z, t), \\ \dfrac{\partial v}{\partial t} = \mu\left(\dfrac{\partial^2 v}{\partial \xi^2} + \dfrac{\partial^2 v}{\partial y^2} + \dfrac{\partial^2 v}{\partial z^2}\right) - \dfrac{\partial p}{\partial \xi} + F_2(\xi, y, z, t), \\ \dfrac{\partial w}{\partial t} = \mu\left(\dfrac{\partial^2 w}{\partial \xi^2} + \dfrac{\partial^2 w}{\partial y^2} + \dfrac{\partial^2 w}{\partial z^2}\right) - \dfrac{\partial p}{\partial \xi} + F_3(\xi, y, z, t), \\ \dfrac{\partial u}{\partial \xi} + \dfrac{\partial v}{\partial y} + \dfrac{\partial w}{\partial z} = 0 \end{cases}$$

(cf. Criminale and Drazin [6]). Note that the latter equation enforces irrotationality. If we next Fourier transform our variables in ξ, y, and z by, for example, setting

$$\widehat{u}(\alpha, \beta, \gamma, t) \equiv \iiint_{-\infty}^{\infty} u(\xi, y, z, t) e^{i(\alpha\xi + \beta y + \gamma z)} d\xi \, dy \, dz,$$

we obtain a DAE of the form

$$(2.30)\qquad \begin{cases} \dfrac{dm}{dt} = \mu(\alpha^2 + \beta^2 + \gamma^2)m - iC^T\widehat{p} + F(\alpha, \beta, \gamma, t), \\ 0 = iCm, \end{cases}$$

where $m = (\widehat{u} \;\; \widehat{v} \;\; \widehat{w})^T$, $C = (\alpha \;\; \beta \;\; \gamma)$, and $F = (\widehat{F_1} \;\; \widehat{F_2} \;\; \widehat{F_3})^T$. We regularize this problem by introducing the scalar slack variable

$$(2.31)\qquad -\epsilon\widehat{p} = iCm,$$

which finally implies the singular singularly perturbed system

$$(2.32)\qquad \epsilon\frac{dm}{dt} = (-C^TC + \epsilon\mu(\alpha^2 + \beta^2 + \gamma^2)I)m + \epsilon F(\alpha, \beta, \gamma, t).$$

Again, we would expect to find a solution in the composite form

$$(2.33)\qquad m(t, \epsilon) = M(t, \epsilon) + \eta(\tau, \epsilon),$$

where $\eta \to 0$ as $\tau = \frac{t}{\epsilon} \to \infty$. The primary physical interest is to obtain the limiting outer solution M_0. The solution of (2.29) could ultimately be obtained by taking the inverse Fourier transform.

A physical interpretation of the regularization parameter can be obtained by realizing that introducing ϵ in (2.31) allowed us to approximate the incompressible solution by a slightly compressible solution. This, then, corresponds to the penalty function method, which has been extremely valuable numerically and analytically (cf.

Hughes et al. [17] and Temam [32]), where $\frac{1}{\epsilon}$ is a Lamé parameter. We note that such a DAE would also be obtained from the Navier–Stokes equations through appropriate discretizations (cf. Gresho et al. [12]).

3. A more complicated index-two problem. A higher index DAE can also occur such that the matrix $D(t)$ in (1.1) is transformable to a block diagonal form of fixed positive rank $r < n$. Specifically, let us suppose that a smooth nonsingular matrix $R(t)$ exists so that D can be decomposed as

$$D(t) = R(t)\begin{pmatrix} \widetilde{E}(t) & 0 \\ 0 & 0 \end{pmatrix} R^{-1}(t), \tag{3.1}$$

where $\widetilde{E}(t)$ remains a nonsingular $r \times r$ matrix. (Allowing nontrivial Jordan blocks in the nullspace of $D(t)$ might naturally be considered later.) If we use the corresponding splitting

$$V_0(t) = R(t)\begin{pmatrix} X_0(t) \\ Y_0(t) \end{pmatrix}, \tag{3.2}$$

the index-two DAE (1.1) will be transformed to the form

$$\begin{cases} \dot{U}_0 = A(t)U_0 + B(t)X_0 + C(t)Y_0 + f(t), \\ 0 = D(t)U_0 + E(t)X_0 + g(t), \\ 0 = F(t)U_0 + h(t) \end{cases} \tag{3.3}$$

(with different coefficient matrices than before). Note that transformations such as (3.2) are common in the singular perturbations literature (cf. Wasow [36], O'Malley [25], and Kreiss et al. [21]). Their numerical implementation is, however, nontrivial, often being carried out through orthogonal transformations.

We will assume that any such preliminary transformations have already been made and shall assume that (3.3) holds with

$$\begin{cases} m \geq n - r > 0, \\ \text{where the } r \times r \text{ matrix } E(t) \text{ and the } (n-r) \times (n-r) \text{ matrix} \\ F(t)C(t) \text{ both remain nonsingular.} \end{cases} \tag{3.4}$$

Our earlier analysis indicates that we should anticipate having an $(m - n + r)$-dimensional solution space for (3.3)–(3.4) which could be obtained by using the regularization

$$\begin{cases} \dot{u} = Au + Bx + Cy + f, \\ -\epsilon E\dot{x} = Du + Ex + g, \\ -\epsilon FCy = Fu + h \end{cases} \tag{3.5}$$

or, equivalently, the singular singularly perturbed system

$$\begin{cases} \epsilon\dot{u} = [-C(FC)^{-1}F + \epsilon A]u + \epsilon Bx - C(FC)^{-1}h + \epsilon f, \\ \epsilon\dot{x} = -E^{-1}Du - x - E^{-1}g, \end{cases} \tag{3.6}$$

which can be solved using the projection matrix $C(FC)^{-1}F$ and its complement to determine the limiting u, x, and y vectors.

The classical way to solve (3.3)–(3.4) is to solve (3.3)(b) for

$$X_0 = -E^{-1}DU_0 - E^{-1}g \tag{3.7}$$

and to differentiate (3.3)(c) to get

$$0 = F(AU_0 + BX_0 + CY_0 + f) + \dot{F}U_0 + \dot{h} = 0.$$

Solving for

$$Y_0 = -(FC)^{-1}[(FA + \dot{F})U_0 + FBX_0 + Ff + \dot{h}], \tag{3.8}$$

there simply remains the DAE

$$\begin{cases} \dot{U}_0 = \mathcal{A}(t)U_0 + b(t), \\ 0 = F(t)U_0 + h(t) \end{cases} \tag{3.9}$$

for U_0, where

$$\mathcal{A}(t) \equiv A - BE^{-1}D - C(FC)^{-1}[FA + \dot{F} - FBE^{-1}D]$$

and

$$b(t) \equiv f - BE^{-1}g - C(FC)^{-1}[-FBE^{-1}g + Ff + \dot{h}].$$

Because $F\mathcal{A} + \dot{F} = 0$ and $Fb + \dot{h} = 0$, it follows that the constraint (3.9)(b) defines an invariant manifold for the differential equation (3.9)(a).

We will use a new method to attack (3.9) which is also successful for nonlinear generalizations (cf. Kalachev and O'Malley [19]). Specifically, we will introduce a scaled Lagrange multiplier $\lambda(t)$ through the singularly perturbed DAE

$$\begin{cases} \dot{u}(t) = \mathcal{A}(t)u + b(t) + F^T(t)\lambda, \\ -\epsilon\lambda = F(t)u + h(t). \end{cases} \tag{3.10}$$

Note Gear's effective introduction of such a multiplier when $\epsilon = 0$ [9] and Lubich's progress for analogous nonlinear problems [23]. Equivalently, we will examine the singular singular-perturbation problem

$$\epsilon\dot{u} = [-F^T(t)F(t) + \epsilon\mathcal{A}(t)]u + [-F^T(t)h(t) + \epsilon b(t)], \tag{3.11}$$

for which the limiting Jacobian $-F^TF$ has rank $n - r$. If we seek an outer power series expansion

$$U(t, \epsilon) \sim \sum_{j=0}^{\infty} U_j(t)\epsilon^j \tag{3.12}$$

for (3.11), we successively need

$$\begin{cases} F^TFU_0 + F^Th = 0, \\ F^TFU_1 = \mathcal{A}U_0 - \dot{U}_0 + b, \\ \text{etc.} \end{cases} \tag{3.13}$$

It is now convenient to directly introduce the rank-$(n-r)$ projection matrix

$$Q(t) \equiv F^T(FF^T)^{-1}F \tag{3.14}$$

(noting that $F^TFQ = F^TF$, $QF^TF = F^TF$, and rank $Q \leq$ rank F) and to denote its complement by

$$P(t) \equiv I - F^T(FF^T)^{-1}F. \tag{3.15}$$

Note that (3.13)(a) implies that

$$QU_0 = -F^T(FF^T)^{-1}h, \tag{3.16}$$

so

$$U_0 = PU_0 - F^T(FF^T)^{-1}h. \tag{3.17}$$

Multiplying (3.13)(b) by P implies that $P(\mathcal{A}U_0 - \dot{U}_0 + b) = 0$, so U_0 will be determined through the resulting differential equation

$$(\dot{PU_0}) = (P\mathcal{A} + \dot{P})(PU_0) + Pb - (P\mathcal{A} + \dot{P})F^T(FF^T)^{-1}h \tag{3.18}$$

for PU_0 using arbitrary initial conditions $P(0)U_0(0) = P(0)u(0)$. Since P has rank $m-n+r$, the solution space for (3.3)–(3.4) is clearly of dimension $m-n+r$. An initial impulse in the range of $Q(0)$ will be necessary if $u(0)$ is inconsistent with the constraint $Fu + h = 0$. A straightforward numerical integration of the nonstiff initial value problem for (3.18) provides a practical method to obtain solutions (3.17) of the DAE (3.3)–(3.4). We note that Ascher and Lin [1] and Petzold et al. [29] discuss the relationship of related regularization techniques to Baumgarte stabilization and trust region methods.

4. Index-three problems.

4.1. An example. For the DAEs considered thus far, the constraints we have been concerned with coincided with the algebraic equations. For higher-index DAEs, "hidden" constraints occur in addition to the obvious explicit ones. A well-known index-three example in Hessenberg form (cf. Brenan et al. [2]) is

$$\begin{cases} \dot{U}_0 = W_0 + f(t), \\ \dot{V}_0 = U_0 + g(t), \\ V_0 = h(t). \end{cases} \tag{4.1}$$

Providing the nonhomogeneous terms are sufficiently smooth, the unique solution

$$\begin{cases} V_0 = h(t), \\ U_0 = \dot{h}(t) - g(t), \\ W_0 = \ddot{h}(t) - \dot{g}(t) - f(t) \end{cases} \tag{4.2}$$

is obtained by backwards substitution. Note that no initial conditions are needed.

If we differentiate (4.1)(c) once to get $\overset{\bullet}{V}_0$, we find the resulting hidden constraint

$$U_0 + g(t) = \overset{\bullet}{h}(t). \tag{4.3}$$

We will now attempt to regularize the DAE (4.1)–(4.3) by using a Lagrange multiplier λ to account for the original constraint and by using a slack variable w in the hidden constraint. Thus, we consider

$$\begin{cases} \overset{\bullet}{u} = w + f, \\ \overset{\bullet}{v} = u + g + \lambda, \\ \epsilon\lambda = -v + h, \\ \epsilon w = -u - g + \overset{\bullet}{h}. \end{cases} \tag{4.4}$$

Eliminating λ and w yields the two-dimensional singularly perturbed system

$$\begin{cases} \epsilon\overset{\bullet}{u} = -u - g + \overset{\bullet}{h} + \epsilon f, \\ \epsilon\overset{\bullet}{v} = \epsilon u + \epsilon g - v + h. \end{cases} \tag{4.5}$$

Its limiting solution will have the form

$$\begin{cases} u(t,\epsilon) = U_0(t) + \alpha_0(t/\epsilon) + O(\epsilon), \\ v(t,\epsilon) = V_0(t) + \beta_0(t/\epsilon) + O(\epsilon), \end{cases} \tag{4.6}$$

where the outer limit satisfies $U_0(t) = -g + \overset{\bullet}{h}$ and $V_0(t) = h$, the decaying initial layer term $\alpha_0(\tau) = e^{-\tau}(u(0) - U_0(0))$ is nontrivial unless we have the consistent initial value $u(0) = -g(0) + \overset{\bullet}{h}(0)$, and $\beta_0(\tau) = e^{-\tau}[v(0) - V_0(0)]$ is decaying, but nontrivial, unless we have the consistent $v(0) = h(0)$. Since $w = -\frac{1}{\epsilon}(u + g - \overset{\bullet}{h})$, (4.6) implies that

$$w(t,\epsilon) = -\frac{1}{\epsilon}\alpha_0\left(\frac{t}{\epsilon}\right) + O(1), \tag{4.7}$$

i.e., w generally involves a delta function impulse at $t = 0$. Thus, the constraints provoke initial jumps in the constrained quantities.

4.2. A more general problem. In previously considering the DAE

$$\begin{cases} \overset{\bullet}{U}_0 = A(t)U_0 + B(t)X_0 + C(t)Y_0 + f(t), \\ 0 = D(t)U_0 + E(t)X_0 + g(t), \\ 0 = F(t)U_0 + h(t), \end{cases} \tag{4.8}$$

we assumed that the matrices E and FC both remained nonsingular. Let us now make the assumption that

$$\begin{cases} m \geq 2(n-r) - k, \text{ that the } r \times r \text{ matrix } E(t) \\ \text{is nonsingular, and that there is a nonsingular matrix} \\ S(t) \text{ such that } FC = S(t)\begin{pmatrix} H(t) & 0 \\ 0 & 0 \end{pmatrix} S^{-1}(t), \\ \text{where } H(t) \text{ is a } k \times k \text{ matrix of full rank.} \end{cases} \tag{4.9}$$

If we differentiate (4.8)(c) and introduce

$$Y_0 = S(t)\begin{pmatrix} Z_0 \\ W_0 \end{pmatrix},$$

we obtain a hidden constraint

$$(FA + \dot{F})U_0 + FBX_0 + FCS\begin{pmatrix} Z_0 \\ W_0 \end{pmatrix} + Ff + \dot{h} = 0.$$

Multiplying by S, it takes the form

$$(4.10) \qquad \begin{cases} 0 = GU_0 + LX_0 + HZ_0 + \ell, \\ 0 = KU_0 + MX_0 + k. \end{cases}$$

Solving (4.8)(b) for X_0 and (4.10)(a) for Z_0 finally gives us an index-two DAE of the form

$$(4.11) \qquad \begin{cases} \dot{U}_0 = \widetilde{A}(t)U_0 + \widetilde{C}(t)W_0 + \widetilde{f}(t), \\ 0 = \widetilde{K}(t)U_0 + \widetilde{g}(t), \\ 0 = F(t)U_0 + h(t), \end{cases}$$

provided we also assume that

(4.12) the matrix $F(t)\widetilde{C}(t)$ remains nonsingular.

Here $\widetilde{K} \equiv K - ME^{-1}D$ and $\widetilde{C}$ consists of the last $n - r - k$ columns of CS. Using a Lagrange multiplier and a slack variable for (4.11), as we did for (4.4), we can readily determine the $(m-2n+2r+k)$-dimensional subspace of solutions for (4.8)–(4.9)–(4.12).

Detailed study of the canonical forms for higher-index DAEs, as well as their solution structure, could be carried out further. It would be quite analogous to the study of singular arc problems in optimal control (cf. Moylan and Moore [24], O'Malley and Jameson [27], Saberi and Sannuti [30], and Geerts [11]). Our use of a regularizing parameter is analogous to the frequent introduction of a cheap control cost for both analytical and numerical study of singular arcs.

4.3. A final example. Consider the motion of a particle which slides under gravity on a moving, but never vertical, plane

$$(4.13) \qquad a(t)x + b(t)y + z = d(t),$$

with a normal constraining force proportional to a scalar M_0. Newton's laws then imply the system

$$(4.14) \qquad \begin{cases} \ddot{x} + a(t)M_0 = 0, \\ \ddot{y} + b(t)M_0 = 0, \\ \ddot{z} + M_0 = g. \end{cases}$$

Introducing the position $U_0 = (x \;\; y \;\; z)^T$ and the corresponding velocity $V_0 = \dot{U}_0$, we can conveniently rewrite (4.14) as the DAE

$$(4.15) \qquad \begin{cases} \dot{P}_0 = \begin{pmatrix} 0 & I \\ 0 & 0 \end{pmatrix} P_0 - \begin{pmatrix} 0 \\ E^T \end{pmatrix} M_0 + \begin{pmatrix} 0 \\ h \end{pmatrix}, \\ 0 = -(E \;\; 0)P_0 + d, \end{cases}$$

where

$$P_0 = \begin{pmatrix} U_0 \\ V_0 \end{pmatrix},$$

$E = (a\ b\ 1)$, and $h = (0\ \ 0\ \ g)^T$. Differentiating the constraint provides us the additional "hidden" constraint

$$(\dot{E}\ E)P_0 = \dot{d}. \tag{4.16}$$

We will regularize the DAE (4.15)–(4.16) by considering

$$\begin{cases} \dot{p} = \begin{pmatrix} 0 & I \\ 0 & 0 \end{pmatrix} p - \begin{pmatrix} 0 \\ E^T \end{pmatrix} m - \begin{pmatrix} E^T \\ 0 \end{pmatrix} \lambda + \begin{pmatrix} 0 \\ h \end{pmatrix}, \\ -\epsilon\lambda = -(E\ 0)p + d, \\ \epsilon(1 + a^2 + b^2)m = (\dot{E}\ E)p - \dot{d}, \end{cases} \tag{4.17}$$

since

$$(\dot{E}\ E)\begin{pmatrix} 0 \\ E^T \end{pmatrix} = EE^T = 1 + a^2 + b^2 > 0.$$

Rewriting (4.17) as $\dot{u} = v - E^T\lambda$, $\dot{v} = -E^Tm + h$, $\epsilon\lambda = Eu - d$, and $\epsilon(1 + a^2 + b^2)m = \dot{E}u + Ev - \dot{d}$. Thus, we finally obtain the singularly perturbed differential system

$$\begin{cases} \epsilon\dot{u} = -E^TEu + \epsilon v + E^Td, \\ \epsilon\dot{v} = -\dfrac{E^T}{1 + a^2 + b^2}(\dot{E}u + Ev - \dot{d}) + \epsilon h. \end{cases} \tag{4.18}$$

It is a singular system because E^TE has rank 1. We nonetheless seek a solution

$$\begin{cases} u(t,\epsilon) = U(t,\epsilon) + \alpha(\tau,\epsilon), \\ v(t,\epsilon) = V(t,\epsilon) + \beta(\tau,\epsilon) \end{cases} \tag{4.19}$$

with exponentially decaying initial layer corrections α and β.

To proceed further, we note that

$$Q \equiv \frac{E^TE}{1 + a^2 + b^2} \tag{4.20}$$

is a projection such that $QE^T = E^T$ and $EQ = E$. Equating coefficients in (4.18), we find that the first two terms of the outer expansion must satisfy

$$\begin{cases} 0 = -QU_0 + \dfrac{E^Td}{1 + a^2 + b^2}, \\ \dfrac{\dot{U}_0}{1 + a^2 + b^2} = -QU_1 + \dfrac{V_0}{1 + a^2 + b^2}, \\ 0 = -\dfrac{E^T\dot{E}}{1 + a^2 + b^2}U_0 - QV_0 + \dfrac{E^T\dot{d}}{1 + a^2 + b^2}, \\ \dot{V}_0 = -\dfrac{E^T\dot{E}}{1 + a^2 + b^2}U_1 - QV_1 + h. \end{cases} \tag{4.21}$$

(4.21)(a) and (c) imply that

$$
(4.22)\qquad \begin{cases} U_0 = PU_0 + \dfrac{E^T d}{1+a^2+b^2} \\ \text{and} \\ V_0 = PV_0 - \dfrac{E^T \dot{E}}{1+a^2+b^2}(PU_0 + \dfrac{E^T d}{1+a^2+b^2}) + \dfrac{E^T \dot{d}}{1+a^2+b^2}, \end{cases}
$$

where P is the complementary projection to Q. Multiplying (4.21)(b) and (d) by P then yields the linear differential system

$$
(4.23)\qquad \begin{cases} (\dot{PU_0}) = \dot{P}(PU_0) + PV_0 + \dfrac{\dot{P}E^T d}{1+a^2+b^2}, \\ (\dot{PV_0}) = -\dfrac{\dot{P}E^T \dot{E}}{1+a^2+b^2}(PU_0) + \dot{P}(PV_0) + \dfrac{E^T}{1+a^2+b^2}\left(\dot{d} - \dfrac{\dot{E}E^T d}{1+a^2+b^2}\right) + Ph. \end{cases}
$$

Since the initial values for PU_0 and PV_0 are arbitrary, the solution space for (4.13)–(4.14) will be four-dimensional. Moreover, u will feature an initial jump if $u(0)$ is inconsistent with the given constraint, i.e., $E(0)u(0) \neq d(0)$, while v will have an initial jump and M_0 will have initial delta-function behavior unless $v(0)$ satisfies the hidden constraint $\dot{E}(0)u(0) + E(0)v(0) = \dot{d}(0)$.

STABILITY AND CONVERGENCE OF EXTENSION SCHEMES TO CONTINUOUS FUNCTIONS IN GENERAL METRIC SPACES*

E. LE GRUYER[†] AND J. C. ARCHER[†]

Abstract. For any E, E' general metric spaces, we formulate the concept of stability of an extension scheme $\mathcal{E}$ (φ continuous mapping from some closed subset of E into E', $\mathcal{E}(\varphi)$ continuous and extending φ). We show that, when $E' = \mathrm{I\!R}$, stable extension schemes always exist and that the classical extension schemes in the literature are instable. We also show that, when E' is complete, any stable extrapolation scheme $\mathcal{E}$ (φ mapping from some discrete and closed subset of E into E', $\mathcal{E}(\varphi)$ continuous and extending φ) has a unique extension to a stable extension scheme: this result establishes a link between the problem of extrapolation, which usually refers to numerical analysis, and the problem of extension, which also concerns pure mathematics.

Key words. stability, convergence, extension of functionals

AMS subject classifications. 41A05, 46A22, 47B50, 65D05

1. Introduction.

This paper concerns the extension of maps, from some subset of a metric space E into some metric space E', to continuous maps from E to E'. We consider schemes, such as Tietze's scheme, which accomplish such extensions. In particular, we are interested in the *stability* of extension schemes: heuristically, an extension scheme $\mathcal{E}$ to continuous functions from E to E' is said to be *stable* if a small alteration of a datum (φ, x) (φ continuous map from some subset of E to E', $x \in E$) has a small impact on the value $\mathcal{E}(\varphi)(x)$ of the extension $\mathcal{E}(\varphi)$ of φ.

In this article, we give a mathematical formulation of this heuristic concept of stability by introducing the following three notions: DV-stability (DV = data value), which controls errors in φ-values; Ω-stability, which controls errors in x; and DS-stability (DS = data site), which controls errors in the domain of φ. Aside from formulation, DV-stability and Ω-stability have been known for a long time. As far as we know, DS-stability appears for the first time in [1].

Our first main result (Theorem 3.3) states that, when $E' = \mathrm{I\!R}$, stable and convergent extension schemes exist for any metric space E. Here the starting point is a paper by Mc Shane [5] . We highlight this result by showing the instability of some extension schemes in the literature [2]–[5], [7], [8]. In fact, we do not know of any other stable extension scheme with the exception of the above result and the case $E = \mathrm{I\!R}$.

In numerical analysis, one is interested in the extension of maps whose domain (the set of data sites) is discrete and closed, in particular finite. In this case data sites are called *poles*, such an extension is called an *extrapolation*, and the corresponding extension scheme is called an *extrapolation scheme.* With this precision of terminology, our other main result (Theorem 5.1) states that any stable extrapolation scheme extends to a unique stable extension scheme. This result shows that the problem of finding stable extrapolation schemes (only such schemes have an interest in numerical analysis) cannot have an elementary solution.

2. Notations, moduli of continuity.

(E,d), (E',d') denote any two metric spaces.

In this paper a *total* (resp., a *partial*) mapping from E to E' is a mapping from E to E' whose domain is E (resp., a subset of E).

$\Pi(E)$ denotes the set of nonempty subsets of E.

$\Delta(E)$ denotes the set of discrete and closed nonempty subsets of E.

$\Omega(E,E')$ denotes the set of Ω-continuous partial mappings (see Definition 2.1) from E to E' whose domain is an element of $\Pi(E)$.

$\mathcal{D}(E,E')$ denotes the set of Ω-continuous partial mappings from E to E' whose domain is an element of $\Delta(E)$ (see Remark 2.1).

We define $\mathcal{C}^o(E,E')$ as the set of total continuous mappings from E to E'.

For $x \in E$, $A \in \Pi(E)$, $d(x,A)$ denotes the usual distance from x to A:

$$d(x,A) := \inf\{d(x,a) : a \in A\}.$$

Let δ denote the (generalised pseudo) Hausdorff distance on $\Pi(E)$:
for $A, B \in \Pi(E)$,

$$\delta(A,B) := \sup\left(\sup_{a\in A} d(a,B), \sup_{b\in B} d(b,A)\right)$$

(in restriction to closed bounded nonempty subsets of E, δ is a distance).

The symbol | denotes restriction to.

For φ, ψ partial mappings from E to E', A a nonempty subset of $\mathrm{dom}(\varphi)\cap\mathrm{dom}(\psi)$, $d'_A(\varphi,\psi)$ denotes the usual (generalised) distance from $\varphi|_A$ to $\psi|_A$:

$$d'_A(\varphi,\psi) := \sup\{d'(\varphi(a),\psi(a)) : a \in A\}.$$

In this paper, a modulus of continuity (resp., a weakly concave modulus of continuity) is a mapping ω from $\mathbb{R}_+$ to $\mathbb{R}_+$ which satisfies

- $\omega(0) = 0$ and ω is continuous at 0,
- ω is increasing : $h_1 \le h_2 \Longrightarrow \omega(h_1) \le \omega(h_2)$,
- ω is subadditive :

$$\forall h_1, h_2 \in \mathbb{R}_+,\ \ \omega(h_1+h_2) \le \omega(h_1) + \omega(h_2) \quad \left(\text{resp.}, h \longmapsto \frac{\omega(h)}{h} \text{ is decreasing}\right).$$

DEFINITION 2.1. *We say that a partial mapping φ from (E,d) to (E',d') is Ω-continuous if a modulus of continuity ω exists which satisfies*

$$\forall x,y \in \mathrm{dom}(\varphi),\ \ d'(\varphi(x),\varphi(y)) \le \omega(d(x,y)). \tag{1}$$

PROPOSITION 2.1. *Let φ be a uniformly continuous partial mapping from E to E'. Then φ is Ω-continuous if and only if $\alpha, \beta \in \mathbb{R}_+$ exist such that, for any $h \in \mathbb{R}_+$, any $x, y \in \mathrm{dom}(\varphi)$, $d(x,y) \le h \Longrightarrow d'(\varphi(x),\varphi(y)) \le \alpha h + \beta$. In particular, if φ is bounded and uniformly continuous then φ is Ω-continuous.*

Proof. Necessity follows from a result by Stechkin which asserts that for any modulus of continuity ω, a weakly concave modulus of continuity $\overline{\omega}$ exists such that $\omega \le \overline{\omega} \le 2\omega$. Sufficiency follows from a lemma by Mc Shane [5, p. 389]. □

Remark 2.1. Any partial mapping from E into E' whose domain is an element of $\Delta(E)$ is continuous but not always Ω-continuous : function $f(n) := n^2$, n an integer, is a simple example of a (uniformly) continuous function that is not Ω-continuous.

Let $\varphi \in \Omega(E,E')$. When $\mathrm{dom}(\varphi)$ is disconnected (it is the general case in extension theory), the usual definition of the modulus of continuity of φ does not apply. We need a slightly stronger definition.

Definition 2.2. *For $\varphi \in \Omega(E, E')$, we define the weakly concave modulus $\overline{\omega}_\varphi$ of continuity of φ as the infimum of the weakly concave moduli of continuity ω which satisfy* (1).

The existence of $\overline{\omega}_\varphi$ follows from Stechkin's result. This outer definition is immediately seen to be equivalent to the following inner one:

$$\overline{\omega}_\varphi := \sup\{\overline{\omega}_{\varphi,a,b} : a, b \in \operatorname{dom}(\varphi)\}$$

where

$$(2) \qquad \begin{array}{rcll} \overline{\omega}_{\varphi,a,b}(h) & := & \inf(h, d(a,b)) \dfrac{d'(\varphi(a), \varphi(b))}{d(a,b)} & \text{for } a \neq b, \\ \overline{\omega}_{\varphi,a,b}(h) & := & 0 & \text{for } a = b. \end{array}$$

We close this section with two properties of weakly concave moduli of continuity which will be essential to the proof of Theorem 3.3.

Proposition 2.2. 1. *Let $\varphi, \psi \in \Omega(E, E')$ with the same domain A. Then*

$$\| \overline{\omega}_\varphi - \overline{\omega}_\psi \|_{\mathbb{R}_+} \leq 2d'_A(\varphi, \psi).$$

2. *Let $\varphi \in \Omega(E, E')$, $A, B \subset \operatorname{dom}(\varphi)$, $A, B \in \Pi(E)$. Then*

$$\| \overline{\omega}_{\varphi|A} - \overline{\omega}_{\varphi|B} \|_{\mathbb{R}_+} \leq 4\overline{\omega}_\varphi(\delta(A, B)).$$

Proof. 1. Let $h \in \mathbb{R}_+$. From Definition 2.2, we have

$$\begin{array}{rcl} |\overline{\omega}_\varphi(h) - \overline{\omega}_\psi(h)| & = & \left| \sup\limits_{a,b \in A} \overline{\omega}_{\varphi,a,b}(h) - \sup\limits_{a,b \in A} \overline{\omega}_{\psi,a,b}(h) \right| \\ & \leq & \sup\limits_{a,b \in A} |\overline{\omega}_{\varphi,a,b}(h) - \overline{\omega}_{\psi,a,b}(h)| . \end{array}$$

But, from (2), we have

$$\begin{array}{rcl} |\overline{\omega}_{\varphi,a,b}(h) - \overline{\omega}_{\psi,a,b}(h)| & \leq & |d'(\varphi(a), \varphi(b)) - d'(\psi(a), \psi(b))| \\ & \leq & d'(\varphi(a), \psi(a)) + d'(\varphi(b), \psi(b)) \\ & \leq & 2d'_A(\varphi, \psi). \end{array}$$

2. First we note that, for any $h \geq 0$, $\overline{\omega}_{\varphi|A}(h) \leq \overline{\omega}_\varphi(h) \leq \overline{\omega}_\varphi(\infty)$. Thus, if $\delta(A, B) = \infty$, we have $\| \overline{\omega}_{\varphi|A} - \overline{\omega}_{\varphi|B} \|_{\mathbb{R}_+} \leq 2\overline{\omega}_\varphi(\delta(A, B))$. Otherwise, set $\delta := \delta(A, B) + \varepsilon$ ($\varepsilon > 0$) and let $h \in \mathbb{R}_+$. Without loss of generality, let us assume that $\overline{\omega}_{\varphi|B}(h) \leq \overline{\omega}_{\varphi|A}(h)$. For each $a \in A$, we choose $b(a) \in B$ such that $d(a, b(a)) \leq \delta$. We have

$$\begin{aligned} \overline{\omega}_{\varphi|A}(h) - \overline{\omega}_{\varphi|B}(h) &\leq \sup_{a_1, a_2 \in A} \overline{\omega}_{\varphi,a_1,a_2}(h) - \sup_{a_1, a_2 \in A} \overline{\omega}_{\varphi,b(a_1),b(a_2)}(h) \\ &\leq \sup_{a_1, a_2 \in A} \left| \overline{\omega}_{\varphi,a_1,a_2}(h) - \overline{\omega}_{\varphi,b(a_1),b(a_2)}(h) \right| . \end{aligned}$$

For the sake of simplicity, from now on, we set $b_1 := b(a_1)$, $b_2 := b(a_2)$, and

$$\delta_{\varphi,a_1,a_2}(h) := |\overline{\omega}_{\varphi,a_1,a_2}(h) - \overline{\omega}_{\varphi,b_1,b_2}(h)|.$$

We must bound $\delta_{\varphi,a_1,a_2}(h)$.

First case. $h \geq d(a_1, a_2)$, $h \geq d(b_1, b_2)$. In this case we have from (2)

$$\delta_{\varphi,a_1,a_2}(h) = |d'(\varphi(a_1), \varphi(a_2)) - d'(\varphi(b_1), \varphi(b_2))|.$$

Thus

$$\delta_{\varphi,a_1,a_2}(h) \leq d'(\varphi(a_1), \varphi(b_1)) + d'(\varphi(a_2), \varphi(b_2)) \leq 2\overline{\omega}_\varphi(\delta).$$

Second case. $h \leq d(a_1, a_2)$, $h \leq d(b_1, b_2)$. In this case, (2) gives

$$\delta_{\varphi,a_1,a_2}(h) = h \left| \frac{d'(\varphi(b_1), \varphi(b_2))}{d(b_1, b_2)} - \frac{d'(\varphi(a_1), \varphi(a_2))}{d(a_1, a_2)} \right|.$$

We write $\delta_{\varphi,a_1,a_2}(h) = |\Delta_1 + \Delta_2|$ where

$$\Delta_1 := h(d(a_1, a_2) - d(b_1, b_2)) \frac{d'(\varphi(b_1), \varphi(b_2)) + d'(\varphi(a_1), \varphi(a_2))}{2d(a_1, a_2)d(b_1, b_2)},$$

$$\Delta_2 := h(d(a_1, a_2) + d(b_1, b_2)) \frac{d'(\varphi(b_1), \varphi(b_2)) - d'(\varphi(a_1), \varphi(a_2))}{2d(a_1, a_2)d(b_1, b_2)}.$$

Since, in our case, $h \leq \inf(d(a_1, a_2), d(b_1, b_2))$ and since, in any case,

$$|d(a_1, a_2) - d(b_1, b_2)| \leq \sup(d(a_1, a_2), d(b_1, b_2)),$$

we have

$$h \frac{|d(a_1, a_2) - d(b_1, b_2)|}{2d(a_1, a_2)d(b_1, b_2)} \leq 1.$$

Using the weak concavity of $\overline{\omega}_\varphi$, we obtain

$$|\Delta_1| \leq \overline{\omega}_\varphi \left(h \frac{|d(a_1, a_2) - d(b_1, b_2)|}{2d(a_1, a_2)} \right) + \overline{\omega}_\varphi \left(h \frac{|d(a_1, a_2) - d(b_1, b_2)|}{2d(b_1, b_2)} \right).$$

Since $h \leq \inf(d(a_1, a_2), d(b_1, b_2))$ and $|d(a_1, a_2) - d(b_1, b_2)| \leq 2\delta$, we obtain

$$|\Delta_1| \leq 2\overline{\omega}_\varphi(\delta).$$

To bound $|\Delta_2|$, we have

$$h \left(\frac{d(a_1, a_2) + d(b_1, b_2)}{2d(a_1, a_2)d(b_1, b_2)} \right) \leq 1.$$

Thus $|\Delta_2| \leq |d'(\varphi(b_1), \varphi(b_2)) - d'(\varphi(a_1), \varphi(a_2))| \leq 2\overline{\omega}_\varphi(\delta)$. Definitively, $\delta_{\varphi,a_1,a_2}(h) \leq 4\overline{\omega}_\varphi(\delta)$ in this second case.

Third case. $d(b_1, b_2) \leq h \leq d(a_1, a_2)$ or $d(a_1, a_2) \leq h \leq d(b_1, b_2)$. Without loss of generality, let us assume that $d(a_1, a_2) \leq h \leq d(b_1, b_2)$. Statement (2) gives in this case

$$\delta_{\varphi,a_1,a_2}(h) = \left| d'(\varphi(a_1), \varphi(a_2)) - \left(\frac{h}{d(b_1, b_2)} \right) d'(\varphi(b_1), \varphi(b_2)) \right|.$$

We write $\delta_{\varphi,a_1,a_2}(h) = |\Delta_3 + \Delta_4|$ where

$$\Delta_3 = \frac{d(b_1,b_2) - h}{d(b_1,b_2)} d'(\varphi(a_1), \varphi(a_2)),$$

$$\Delta_4 = \frac{h}{d(b_1,b_2)} (d'(\varphi(a_1), \varphi(a_2)) - d'(\varphi(b_1), \varphi(b_2)).$$

We have immediately $|\Delta_4| \leq 2\overline{\omega}_\varphi(\delta)$.

Since

$$|\Delta_3| \leq \frac{d(b_1,b_2) - h}{d(b_1,b_2)} \overline{\omega}_\varphi(d(a_1,a_2)),$$

we obtain, using the weak concavity of $\overline{\omega}_\varphi$ again,

$$|\Delta_3| \leq \overline{\omega}_\varphi \left(\frac{d(a_1,a_2)(d(b_1,b_2) - h)}{d(b_1,b_2)} \right).$$

Now, in our case, we have $d(b_1,b_2) - h \leq d(b_1,b_2) - d(a_1,a_2) \leq 2\delta$. Thus $|\Delta_3| \leq 2\overline{\omega}_\varphi(\delta)$. Finally $\delta_{\varphi,a_1,a_2}(h) \leq 4\overline{\omega}_\varphi(\delta)$ in this third case.

As $\varepsilon > 0$ is arbitrary and $\overline{\omega}_\varphi$ is continuous, the stated conclusion follows. □

3. Extension schemes.

DEFINITION 3.1. *We call C^o-extension (resp., C^o-extrapolation) scheme from E to E' any mapping*

$$\mathcal{E} : \Omega(E,E')(resp., \mathcal{D}(E,E')) \longrightarrow C^o(E,E') : \varphi \longmapsto \mathcal{E}(\varphi)$$

which satisfies

$$\forall x \in \mathrm{dom}(\varphi), \quad \mathcal{E}(\varphi)(x) = \varphi(x). \tag{3}$$

We give the following definitions for C^o-extension schemes. Similar definitions hold for C^o-extrapolation schemes.

DEFINITION 3.2. *Let $\mathcal{E}$ be a C^o-extension scheme from E to E'.*

(i) *We say that $\mathcal{E}$ reproduces the constants iff*

$$\forall \varphi \in \mathrm{dom}(\mathcal{E}), \quad \varphi = constant \Longrightarrow \mathcal{E}(\varphi) = (the\ same)\ constant.$$

(ii) *$\mathcal{E}$ is said to be DV-stable iff a positive constant C exists such that for any φ, $\psi \in \mathrm{dom}(\mathcal{E})$ with the same domain A, we have*

$$d'_E(\mathcal{E}(\varphi), \mathcal{E}(\psi)) \leq C d'_A(\varphi, \psi). \tag{4}$$

(iii) *$\mathcal{E}$ is said to be Ω-stable iff a positive constant C exists such that, for any $\varphi \in \mathrm{dom}(\mathcal{E})$,*

$$\overline{\omega}_{\mathcal{E}(\varphi)} \leq C\overline{\omega}_\varphi. \tag{5}$$

(iv) *$\mathcal{E}$ is said to be DS-stable iff a positive constant C exists such that, for any $\varphi \in \mathrm{dom}(\mathcal{E})$, any $A, B \subset \mathrm{dom}(\varphi)$, $A, B \in \Pi(E)$,*

$$d'_E(\mathcal{E}(\varphi|_A), \mathcal{E}(\varphi|_B)) \leq C\overline{\omega}_\varphi(\delta(A,B)). \tag{6}$$

(v) *$\mathcal{E}$ is said to be strongly convergent iff a constant positive C exists such that, for any $\varphi \in \Omega(E,E')$, for any $A \subset \mathrm{dom}(\varphi)$, $A \in \Pi(E)$,*

$$d'_{\mathrm{dom}(\varphi)}(\mathcal{E}(\varphi|_A),\varphi) \leq C\overline{\omega}_\varphi(\delta(A,\mathrm{dom}(\varphi))). \tag{7}$$

The smallest such C (which are attained), in (4)–(7), are called the constants *of DV-stability, Ω-stability, DS-stability, strong convergence.*

Let us remember here the usual definition of a convergent scheme : $\mathcal{E}$ is said to be convergent if, for any total Ω-continuous function f from E into E', for any $F \in \Pi(E)$,

$$\lim_{A\in\Delta(E),\delta(A,F)\to 0} d'_F(\mathcal{E}(f|_A),f) = 0. \tag{8}$$

Remark 3.1. It is easy to check that the univariate piecewise linear extrapolation scheme is a DV-stable, Ω-stable, DS-stable, strongly convergent $\mathcal{C}^o$-extrapolation scheme. The constants of DV-stability, strong convergence, DS-stability are resp., 1, 2, 2. The constant of Ω-stability is smaller than 2 (this constant is 1 if we use concave moduli of continuity in place of weakly concave ones).

The following proposition contains elementary formal consequences of above definitions. Here, $\mathcal{E}$ denotes any extrapolation or extension scheme from E to E'.

PROPOSITION 3.1. 1. *If $\mathcal{E}$ is strongly convergent, then $\mathcal{E}$ is convergent and $\mathcal{E}$ reproduces the constants.*

2. *If $\mathcal{E}$ is DS-stable or Ω-stable, then $\mathcal{E}$ is strongly convergent.*

Proof. 1. The proof of part (1) is obvious.

2. The result is immediate if $\mathcal{E}$ is DS-stable. Let us assume now that $\mathcal{E}$ is Ω-stable and let $\varphi \in \Omega(E,E')$, $A \in \Pi(E)$, $A \subset \mathrm{dom}(\varphi)$, $x \in \mathrm{dom}(\varphi)$. For any $\eta > 0$, we choose $y \in A$ such that $d(x,y) \leq d(x,A) + \eta$. Since $y \in A$, $A \subset B$ and since $\mathcal{E}$ is an extrapolation (or extension) scheme, we have

$$\varphi(y) = \mathcal{E}(\varphi|_A)(y) = \mathcal{E}(\varphi|_B)(y).$$

Thus

$$d'(\mathcal{E}(\varphi|_A)(x),\varphi(x)) \leq d'(\mathcal{E}(\varphi|_A)(x),\mathcal{E}(\varphi|_A)(y)) + d'(\varphi(y),\varphi(x)).$$

Applying the Ω-stability of $\mathcal{E}$, we obtain

$$\begin{array}{rcl} d'(\mathcal{E}(\varphi|_A)(x),\varphi(x)) & \leq & (1+C)\overline{\omega}_\varphi(d(x,A)+\eta) \\ & \leq & (1+C)\overline{\omega}_\varphi(\delta(A,\mathrm{dom}(\varphi))+\eta). \end{array}$$

The result follows since $\overline{\omega}_\varphi$ is continuous and η is arbitrary and since the above inequality holds for any $x \in \mathrm{dom}(\varphi)$. □

Now, we turn to the first main result of this paper. Our starting point is the following result by Mc Shane [5] (see also [8, p. 63, footnote]).

THEOREM 3.2. *Let (E,d) be any metric space and ω be a modulus of continuity. Then, for any partial mapping φ from E to $\mathbb{R}$ which satisfies*

$$\forall y,z \in \mathrm{dom}(\varphi),\ \ |\varphi(y)-\varphi(z)| \leq \omega(d(y,z)), \tag{9}$$

the mapping $\mathcal{M}(\varphi)$ defined, for any $x \in E$, by

$$\mathcal{M}(\varphi)(x) := \sup\{\varphi(a)-\omega(d(x,a)) : a \in \mathrm{dom}(\varphi)\}, \tag{10}$$

extends φ and satisfies

$$\forall y, z \in E, \quad |\mathcal{M}(\varphi)(y) - \mathcal{M}(\varphi)(z)| \leq \omega(d(y.z)). \tag{11}$$

This scheme $\mathcal{M}$, restricted to those φ which satisfy (9), is Ω-instable and DS-instable; see §4.6. We can however adapt (10) to obtain a stable $\mathcal{C}^o$-extension scheme.

THEOREM 3.3. *Let (E, d) be any metric space. Let us define a scheme $\mathcal{E}$ as follows. For $\varphi \in \Omega(E, \mathbb{R})$, $x \in E$,*

$$\mathcal{E}(\varphi)(x) := \sup\{\varphi(a) - \overline{\omega}_\varphi(d(x,a)) : a \in \mathrm{dom}(\varphi)\}. \tag{12}$$

Then $\mathcal{E}$ is a $\mathcal{C}^o$-extension scheme which is Ω-stable with 1 as constant of Ω-stability, DV-stable with a constant of DV-stability smaller than 3, and DS-stable with a constant of DS-stability smaller than 6. Moreover, for bounded φ, we have, for any $x \in E$,

$$\inf\{\varphi(a) : a \in \mathrm{dom}(\varphi)\} \leq \mathcal{E}(\varphi)(x) \leq \sup\{\varphi(a) : a \in \mathrm{dom}(\varphi)\}. \tag{13}$$

Proof. Let $\varphi \in \Omega(E, \mathbb{R})$. Since, by the definition of $\overline{\omega}_\varphi$, we have

$$|\varphi(y) - \varphi(z)| \leq \overline{\omega}_\varphi(d(y,z))$$

for any $y, z \in \mathrm{dom}(\varphi)$, Mc Shane's theorem applies. Therefore $\mathcal{E}$ is Ω-stable with 1 as a constant of Ω-stability.

Now let $\varphi, \psi \in \Omega(E, \mathbb{R})$ with the same domain A. From (12) we have, for any $x \in E$,

$$\begin{aligned}|\mathcal{E}(\varphi)(x) - \mathcal{E}(\psi)(x)| &\leq \sup\{|\varphi(a) - \overline{\omega}_\varphi(d(x,a)) - \psi(a) + \overline{\omega}_\psi(d(x,a))| : a \in A\} \\ &\leq \sup\{|\varphi(a) - \psi(a)| : a \in A\} \\ &\quad + \sup\{|\overline{\omega}_\varphi(d(x,a)) - \overline{\omega}_\psi(d(x,a))| : a \in A\}.\end{aligned}$$

Now, using Proposition 2.2(1), we have

$$\sup\{\overline{\omega}_\varphi(d(x,a)) - \overline{\omega}_\psi(d(x,a))| : a \in A\} \leq 2d'_A(\varphi, \psi).$$

Therefore $\mathcal{E}$ is DV-stable with a constant of DV-stability smaller than 3.

Now we prove the DS-stability of $\mathcal{E}$. Let $\varphi \in \Omega(E, \mathbb{R})$, A, B be nonempty subsets of $\mathrm{dom}(\varphi)$, and $x \in E$. Without loss of generality, let us assume that

$$\mathcal{E}(\varphi|_B)(x) \leq \mathcal{E}(\varphi|_A)(x).$$

If $\delta(A, B) = \infty$, let $b \in B$. From (12), we have

$$|\mathcal{E}(\varphi|_A)(x) - \mathcal{E}(\varphi|_B)(x)| \leq \sup\{|\varphi(a) - \overline{\omega}_{\varphi|_A}(d(x,a)) - \varphi(b) + \overline{\omega}_{\varphi|_B}(d(x,b))| : a \in A\}.$$

Now, for any $a \in A$, we have

$$\sup\{|\varphi(a) - \varphi(b)|, \overline{\omega}_{\varphi|_A}(d(x,a)), \overline{\omega}_{\varphi|_B}(d(x,b))\} \leq \overline{\omega}_\varphi(\infty).$$

Therefore, in this case, we obtain $\mathcal{E}(\varphi|_A)(x) - \mathcal{E}(\varphi|_B)(x)| \leq 3\overline{\omega}_\varphi(\delta(A, B))$.

If $\delta(A, B) < \infty$, let us set $\delta := \delta(A, B) + \eta$ ($\eta > 0$). For each $a \in A$, we choose $b(a) \in B$ such that $d(a, b(a)) \leq \delta$. From (12) we have

$$\begin{aligned}&|\mathcal{E}(\varphi|_A)(x) - \mathcal{E}(\varphi|_B)(x)| \\ &\quad\leq \sup_{a \in A}\{|\varphi(a) - \overline{\omega}_{\varphi|_A}(d(x,a)) - \varphi(b(a)) + \overline{\omega}_{\varphi|_B}(d(x, b(a)))|\} \\ &\quad\leq \sup\{|\varphi(a) - \varphi(b(a))| : a \in A\} \\ &\qquad + \sup\{|\overline{\omega}_{\varphi|_B}(d(x, b(a))) - \overline{\omega}_{\varphi|_A}(d(x,a))| : a \in A\}.\end{aligned}$$

By definition of $\overline{\omega}_\varphi$, we have $|\varphi(a)-\varphi(b(a))| \le \overline{\omega}_\varphi(\delta)$.

Now, setting $h := d(x,a)$, $k := d(x,b(a))$, we have

$$|\overline{\omega}_{\varphi|_B}(k) - \overline{\omega}_{\varphi|_A}(h)| \le |\overline{\omega}_{\varphi|_B}(k) - \overline{\omega}_{\varphi|_B}(h)| + |\overline{\omega}_{\varphi|_B}(h) - \overline{\omega}_{\varphi|_A}(h)|.$$

Since $\overline{\omega}_{\varphi|_B}$ is subadditive, we have

$$|\overline{\omega}_{\varphi|_B}(k) - \overline{\omega}_{\varphi|_B}(h)| \le \overline{\omega}_{\varphi|_B}(|h-k|) \le \overline{\omega}_{\varphi|_B}(\delta) \le \overline{\omega}_\varphi(\delta),$$

and, using Proposition 2.2(2),

$$|\overline{\omega}_{\varphi|_B}(h) - \overline{\omega}_{\varphi|_A}(h)| \le 4\overline{\omega}_\varphi(\delta).$$

Since $\eta > 0$ is arbitrary and since $\overline{\omega}_\varphi$ is continuous, we infer that $\mathcal{E}$ is DS-stable with a constant of DS-stability smaller than 6.

Finally, let us assume that $\varphi \in \Omega(E,\mathrm{I\!R})$ is bounded. By (12), we have $\mathcal{E}(\varphi)(x) \le \sup\{\varphi(a) : a \in \mathrm{dom}(\varphi)\}$. Now let $\eta > 0$ and choose $b \in A$ such that

$$\varphi(b) \ge \sup\{\varphi(a) : a \in \mathrm{dom}(\varphi)\} - \eta.$$

We have, from (12) again,

$$\mathcal{E}(\varphi)(x) \ge \varphi(b) - \overline{\omega}_\varphi(d(x,b)).$$

Now, by definition of $\overline{\omega}_\varphi$, we have

$$\begin{aligned} \overline{\omega}_\varphi(d(x,b)) &\le \sup\{\varphi(a) : a \in \mathrm{dom}(\varphi)\} - \inf\{\varphi(a) : a \in \mathrm{dom}(\varphi)\} \\ &\le \varphi(b) - \inf\{\varphi(a) : a \in \mathrm{dom}(\varphi)\} + \eta. \end{aligned}$$

Therefore $\mathcal{E}(\varphi)(x) \ge \inf\{\varphi(a) : a \in \mathrm{dom}(\varphi)\} - \eta$. The result follows since η is arbitrary. □

Remark 3.2. Henceforth, we denote by $\overline{\mathcal{E}}^-$ the $\mathcal{E}$ described in (12). We also define, for $\varphi \in \Omega(E,\mathrm{I\!R})$, $x \in E$,

$$\overline{\mathcal{E}}^+(\varphi)(x) := \inf\{\varphi(y) + \overline{\omega}_\varphi(d(x,y)) : y \in \mathrm{dom}(\varphi)\}. \tag{14}$$

It can be seen that $\overline{\mathcal{E}}^+$ satisfies Theorem 3.3, that $\overline{\mathcal{E}}^-(\varphi) \le \overline{\mathcal{E}}^+(\varphi)$ for any $\varphi \in \Omega(E,\mathrm{I\!R})$, and that $\overline{\mathcal{E}}^-(\varphi) < \overline{\mathcal{E}}^+(\varphi)$ for most of $\varphi \in \Omega(E,\mathrm{I\!R})$.

4. Study of the stability of some $\mathcal{C}^o$-extension schemes in the literature.

4.1. We begin with the scheme $\mathcal{T}$ yielded by the proof of Urysohn–Tietze's extension theorem from Dieudonné's handbook [2, pp. 89, 90]. We need a description of $\mathcal{T}(\varphi)$ only for those $\varphi \in \Omega(E,\mathrm{I\!R})$ such that $\inf\{\varphi(x) : x \in \mathrm{dom}(\varphi)\} = 1$ and $\sup\{\varphi(x) : x \in \mathrm{dom}(\varphi)\} = 2$:

$$\begin{aligned} \mathcal{T}(\varphi)(a) &:= \varphi(a) && \text{for } a \in \mathrm{dom}(\varphi), \\ \mathcal{T}(\varphi)(x) &:= \inf_{a \in \mathrm{dom}(\varphi)} \left\{ \frac{\varphi(a)d(x,a)}{d(x,\mathrm{dom}(\varphi))} \right\} && \text{for } x \notin \mathrm{dom}(\varphi). \end{aligned}$$

Let us show that $\mathcal{T}$ is Ω-instable in every metric space into which a compact interval $[\alpha,\beta]$ of $\mathrm{I\!R}$ can be metrically embedded. It is sufficient to prove the result when $E = [1,2]$. For $A := \{1, a, b, 2\} (1 \leq a \leq b \leq 2)$ and $f :=$ identity, we obtain from the definition of $\mathcal{T}$

$$\mathcal{T}(f|_A)(x) = \frac{a(x-a)}{b-x} \quad \text{for} \quad \frac{a+b}{2} \leq x \leq \frac{a^2+b^2}{a+b}.$$

Now, for any strictly positive integer n, let us set

$$a_n := \frac{3}{2} - \frac{1}{2n}, \quad b_n := \frac{3}{2} + \frac{1}{2n}, \quad A_n := \{1, a_n, b_n, 2\}, \quad x_n := \frac{3}{2}, \quad y_n := \frac{a_n^2 + b_n^2}{a_n + b_n}.$$

A calculation shows that

$$y_n - x_n = \frac{1}{6n^2} \quad \text{and} \quad \mathcal{T}(f|_{A_n})(y_n) - \mathcal{T}(f|_{A_n})(x_n) = \frac{1}{n}.$$

Thus $\mathcal{T}$ cannot be Ω-stable.

4.2. Now we consider the original proof of the Urysohn–Tietze extension theorem. In the metric case, this proof induces a $\mathcal{C}^o$-extension scheme $\mathcal{U}$ which is DS-instable in every metric space in which a compact interval $[\alpha, \beta]$ $(\alpha < \beta)$ of $\mathbb{R}$ can be metrically embedded. It is sufficient to prove the result when $E = [-1, 1]$. Let us recall the definition of $\mathcal{U}(\varphi)$ for $\varphi \in \mathcal{D}(E, E)$. Setting

$$A := \left\{x \in \operatorname{dom}(\varphi) : -1 \leq \varphi(x) \leq -\frac{1}{3}\right\}, \quad B := \left\{x \in \operatorname{dom}(\varphi) : \frac{1}{3} \leq \varphi(x) \leq 1\right\},$$

we first define

$$g_0 : E \longrightarrow E : x \longmapsto \frac{1}{3} \frac{d(x,A) - d(x,B)}{d(x,A) + d(x,B)}.$$

Noticing that $\frac{3}{2}(\varphi - g_0) \in \mathcal{D}(E, E)$, we can reiterate this definition with $\frac{3}{2}(\varphi - g_0)$ in place of φ, producing g_1 in place of g_0, etc. Then $\mathcal{U}(\varphi)$ is defined as $\sum_{n=0}^{\infty} g_n$.

Now, let $A_\varepsilon := \{-1, -\frac{1}{3} - \frac{\varepsilon}{2}, \frac{1}{3} + \frac{\varepsilon}{2}, 1\}$, $B_\varepsilon := \{-1, -\frac{1}{3} + \frac{\varepsilon}{2}, \frac{1}{3} - \frac{\varepsilon}{2}, 1\}$, and $f :=$ identity. Computer-aided computations show that

$$\lim_{\varepsilon \to 0} \left| \mathcal{U}(f|_{A_\varepsilon}) \left(\frac{2}{3}\right) - \mathcal{U}(f|_{B_\varepsilon}) \left(\frac{2}{3}\right) \right| \simeq \frac{1}{6}.$$

Since $\lim_{\varepsilon \to 0} \delta(A_\varepsilon, B_\varepsilon) = 0$, we infer that $\mathcal{U}$ cannot be DS-stable.

4.3. Valentine [7, p. 107] proved, in a way different from Mc Shane, that any partial Ω-continuous function φ from a metric space (E, d) to $\mathbb{R}$ can be extended to the whole space by a function $\overline{\varphi}$ which has the same weakly concave modulus of continuity. His proof is an adaptation of the proof of the Hahn–Banach extension theorem; the axiom of choice is used via Zorn's lemma. Now, using the axiom of choice again, we can select such a $\overline{\varphi}$ for each φ and therefore obtain an Ω-stable $\mathcal{C}^o$-extension scheme with 1 as the constant of Ω-stability. It is hopeless to try to prove the DV-stability and the DS-stability of such a scheme.

4.4. Dugundji [3] proved that any continuous partial function φ of closed domain from a metric space to a locally convex linear space can be extended to a continuous function on the whole space (it is, as far as we know, the strongest result about the extension problem to continuous functions). The construction of the extension needs a locally finite refinement of a certain covering of the open set complement of $\operatorname{dom}(\varphi)$. Since the construction of this refinement [6] uses the axiom of choice (via Zermelo's theorem), it is hopeless to prove the DS-stability of this scheme. Notice that Dugundji's extension scheme is linear.

4.5. When $E = \mathbb{R}^d$, $d \geq 1$, and E' is any real Banach space, there exist *linear* DV-stable and Ω-stable extension schemes. This result, which holds in the more general context of extension to $\mathcal{C}^m$-functions, is essentially due to Glaeser [4]. In fact, the linear scheme described in Whitney's original extension theorem [8] is DV-instable and Ω-instable but a slight modification of Whitney's construction yields a linear, DV-stable, and Ω-stable extension scheme. Both original and modified schemes are DS-instable.

Excluding the univariate case, we do not know of any linear DV+Ω+DS-stable extension scheme to continuous functions.

4.6. Let us fix a modulus of continuity ω and consider the extension scheme $\mathcal{M}$ defined by (10) for partial functions φ satisfying (9). It can be seen that $\mathcal{M}$ is DV-stable with 1 as the constant of DV-stability and that, for any φ satisfying (9), any $A, B \in \Pi(E)$, $A, B \subset \operatorname{dom}(\varphi)$,

$$d'_E(\mathcal{M}(\varphi|_A), \mathcal{M}(\varphi|_B)) \leq 2\omega(\delta(A,B)). \tag{15}$$

Proofs begin as in Theorem 3.3 but Proposition 2.2 is useless. We notice that (15) is not DS-stable and (11) is not Ω-stable. Heuristically, we can say that (15) (resp., (11)) is as far from DS-stability (resp., Ω-stability) as $\overline{\omega}_\varphi$ is far from ω.

5. Link between stable extrapolation schemes and stable extension schemes.

THEOREM 5.1. *Let (E', d') be a complete metric space. Let us assume that $\mathcal{E}$ is a DS-stable $\mathcal{C}^o$-extrapolation scheme. Then $\mathcal{E}$ extends to a unique $\mathcal{C}^o$-extension scheme $\overline{\mathcal{E}}$ which is also DS-stable with the same constant of DS-stability. Moreover, if $\mathcal{E}$ is DV-stable and/or Ω-stable, $\overline{\mathcal{E}}$ also is with the same constants of stability.*

Proof. Let $\varphi \in \Omega(E, E')$ and set $K := \operatorname{dom}(\varphi)$,

$$\Delta(K) := \{A \in \Delta(E) : A \subset K\}, \quad \Pi(K) := \{A \in \Pi(E) : A \subset K\}.$$

Let us choose a sequence $(A_n)_{n \in \mathbb{N}}$ of elements of $\Delta(K)$ such that

$$\lim_{n \to +\infty} \delta(A_n, K) = 0.$$

Such a sequence exists because E is paracompact [6]. Using the DS-stability of $\mathcal{E}$, the sequence $\mathcal{E}(\varphi|_{A_n})(x)$ is, for any $x \in E$, a Cauchy sequence. Let us denote the limit by $\overline{\mathcal{E}}(\varphi)(x)$. Again by DS-stability of $\mathcal{E}$, the sequence $(\mathcal{E}(\varphi|_{A_n}))_{n \in \mathbb{N}}$ converges uniformly to $\overline{\mathcal{E}}(\varphi)$. Therefore $\overline{\mathcal{E}}(\varphi)$ is continuous. By DS-stability of $\mathcal{E}$ once more, $\overline{\mathcal{E}}(\varphi)$ does not depend on the sequence $(A_n)_{n \in \mathbb{N}}$. Choosing, for each $a \in K$, a sequence $(A_n)_{n \in \mathbb{N}}$ such that $a \in A_n$, for any $n \in \mathbb{N}$, we infer that

$$\overline{\mathcal{E}}(\varphi) = \lim_{n \to +\infty} \mathcal{E}(\varphi|_{A_n})(a) = \varphi(a)$$

because $\mathcal{E}$ is an extrapolation scheme. Therefore $\overline{\mathcal{E}}$ is an extension scheme.

Now let $A, B \in \Pi(K)$. Let us choose

$$(A_n)_{n\in\mathbb{N}},\ A_n \in \Delta(K),\ A_n \subset A,\ \lim_{n\to+\infty} \delta(A_n, A) = 0,$$

$$(B_n)_{n\in\mathbb{N}},\ B_n \in \Delta(K),\ B_n \subset B,\ \lim_{n\to+\infty} \delta(B_n, B) = 0.$$

We have

$$\begin{aligned} d'_E(\overline{\mathcal{E}}(\varphi|_A), \overline{\mathcal{E}}(\varphi|_B)) \leq\ & d'_E(\overline{\mathcal{E}}(\varphi|_A), \mathcal{E}(\varphi|_{A_n})) \\ & + d'_E(\mathcal{E}(\varphi|_{A_n}), \mathcal{E}(\varphi|_{B_n})) \\ & + d'_E(\mathcal{E}(\varphi|_{B_n}), \overline{\mathcal{E}}(\varphi|_B)). \end{aligned}$$

Since $\mathcal{E}$ is DS-stable, we have

$$d'_E(\mathcal{E}(\varphi|_{A_n}), \mathcal{E}(\varphi|_{B_n})) \leq C\overline{\omega}_\varphi(\delta(A_n, B_n)) \leq C\overline{\omega}_\varphi(\delta(A, B) + \delta(A, A_n) + \delta(B, B_n)),$$

where C denotes the constant of DS-stability of $\mathcal{E}$. Letting $n \longrightarrow \infty$, using the definition of $\overline{\mathcal{E}}$ and the continuity of $\overline{\omega}_\varphi$, we obtain

$$d'_E(\overline{\mathcal{E}}(\varphi|_A), \overline{\mathcal{E}}(\varphi|_B)) \leq C\overline{\omega}_\varphi(\delta(A, B)).$$

This last inequality means that $\overline{\mathcal{E}}$ is DS-stable and that $\mathcal{E}$ and $\overline{\mathcal{E}}$ have the same constant of DS-stability.

Now, let us assume that $\mathcal{E}$ is Ω-stable with D as constant of Ω-stability and let $\varphi \in \Omega(E, E')$, $x, y \in E$. Set $A := \mathrm{dom}(\varphi)$ and let us choose $A_n \in \Delta(E)$, $A_n \subset A$, $\lim_{n\to\infty} \delta(A_n, A) = 0$. We have

$$\begin{aligned} d'(\overline{\mathcal{E}}(\varphi)(x), \overline{\mathcal{E}}(\varphi)(y)) \leq\ & d'(\overline{\mathcal{E}}(\varphi)(x), \mathcal{E}(\varphi|_{A_n})(x)) \\ & + d'(\mathcal{E}(\varphi|_{A_n})(x), \mathcal{E}(\varphi|_{A_n})(y)) \\ & + d'(\mathcal{E}(\varphi|_{A_n})(y), \overline{\mathcal{E}}(\varphi)(y)). \end{aligned}$$

Since $\mathcal{E}$ is Ω-stable, we have

$$d'(\mathcal{E}(\varphi|_{A_n})(x), \mathcal{E}(\varphi|_{A_n})(y)) \leq D\overline{\omega}_\varphi(d(x, y)).$$

The Ω-stability of $\overline{\mathcal{E}}$ follows by letting $n \longrightarrow \infty$. The proof of DV-stability is similar. □

PROPOSITION 5.2. *Let $\mathcal{E}$ be an Ω-stable and DV-stable extrapolation scheme from a compact metric space (E, d) to a complete metric space (E', d') in which any closed and bounded subset is compact. Then $\mathcal{E}$ extends to an Ω-stable extension scheme with the same constant of Ω-stability.*

Proof. Let $f \in \Omega(E, E')$ and set $A := \mathrm{dom}(f)$. We have to define $\mathcal{E}(f)$ for $A \in \Pi(E)\backslash\Delta(E)$. Since E is compact, elements of $\Delta(E)$ are finite nonempty subsets of E. Let $(A_n)_{n\in\mathbb{N}}$ be a sequence of finite nonempty subsets of A such that $\lim_{n\to\infty} \delta(A_n, A) = 0$. Since $\mathcal{E}$ is Ω-stable and DV-stable, sequence $(\mathcal{E}(f|_{A_n}))_{n\in\mathbb{N}}$ is equicontinuous and equibounded. Therefore, by Ascoli's theorem, there exists a subsequence $(B_n)_{n\in\mathbb{N}}$ of $(A_n)_{n\in\mathbb{N}}$ such that $\lim_{n\to\infty} \delta(B_n, A) = 0$ and $(\mathcal{E}(f|_{B_n}))_{n\in\mathbb{N}}$ converges for the supremun norm. It remains to check that the limit of this subsequence is the desired $\mathcal{E}(f)$ with the required property. □

Remark 5.1. The use of Ascoli's theorem does not allow us to say anything about the uniqueness of the extension. In fact, we cannot expect uniqueness from the hypotheses of Proposition 5.2. A counterexample is as follows. For E a compact infinite metric space, let us define an *extrapolation* scheme $\mathcal{E}$: for $\varphi \in \mathcal{D}(E, \mathrm{I\!R})$, $\mathcal{E}(\varphi)$ is $\overline{\mathcal{E}}^{-}(\varphi)$ (resp., $\overline{\mathcal{E}}^{+}(\varphi)$) ($\overline{\mathcal{E}}^{-}$ and $\overline{\mathcal{E}}^{+}$ have been defined in Remark 3.2) if the number of elements of dom(φ) is even (resp., odd). Now, let us define two *extension* schemes $\mathcal{E}_1$ and $\mathcal{E}_2$ by

$$\begin{array}{ll} \mathcal{E}_1(\varphi) = \mathcal{E}_2(\varphi) = \mathcal{E}(\varphi) & \text{for } \varphi \in \mathcal{D}(E, \mathrm{I\!R}), \\ \mathcal{E}_1(\varphi) = \overline{\mathcal{E}}^{-}(\varphi),\ \mathcal{E}_2(\varphi) = \overline{\mathcal{E}}^{+}(\varphi) & \text{for } \varphi \in \Omega(E, \mathrm{I\!R}) \backslash \mathcal{D}(E, \mathrm{I\!R}). \end{array}$$

Using Theorem 3.3 and since DV-stability and Ω-stability involve only *fixed* sets of data sites, $\mathcal{E}$ is a DV-stable and Ω-stable extrapolation scheme and $\mathcal{E}_1$ and $\mathcal{E}_2$ are distinct (see Remark 3.2) DV-stable and Ω-stable extension schemes which both extend $\mathcal{E}$. This remark highlights Theorem 5.1 and, in fact, the very notion of DS-stability.

Acknowledgments. The authors thank the referees for their helpful suggestions and comments on improving the original manuscript.

CONVOLUTION OPERATORS FOR RADIAL BASIS APPROXIMATION*

JEREMY LEVESLEY[†], YUAN XU[‡], WILL LIGHT[†], AND WARD CHENEY[§]

Abstract. We construct a large class of continuous integrable functions on $\mathbb{R}^n$ to serve as kernels for approximations to the identity. These kernels are associated with convolution operators that produce approximations to arbitrary continuous functions on $\mathbb{R}^n$ by linear combinations of shifted and dilated radial functions.

Key words. radial basis, convolution, quasi-interpolation

AMS subject classifications. 41A30, 41A35, 41A45, 65D10

1. Introduction. A *radial function* on $\mathbb{R}^n$ is any function of the form $x \mapsto \phi(\|x\|)$, in which $\|\cdot\|$ is the Euclidean norm and ϕ is any real-valued function defined on $[0,\infty)$. A *shifted radial function* is a function of the form $x \mapsto \phi(\|x-v\|)$, where v is a specified point in $\mathbb{R}^n$. The radial function is then sometimes described as being *centered* at v.

It was discovered in the 1970s by Roland Hardy [Ha] that such functions were useful in the interpolation of scattered data. For some time their use rested on empirical results. It was observed, for example, that the surfaces produced by the interpolants possessed very good visual qualities (Franke [F]). In addition, the interpolation matrix seemed always to be nonsingular for the common choice of ϕ (the multiquadric). The important papers of Micchelli [M] and Madych and Nelson [MN], as well as the rediscovery of work by Schoenberg [S1]–[S4], showed that the observation about nonsingularity had a very firm theoretical basis.

Once the interpolation problem was better understood, there arose another important question as to the approximating power of shifted radial functions. Two fundamental tools for studying this problem are convolution techniques (when the centers can be arbitrary) and quasi-interpolation or interpolation techniques, which work best when the centers are regularly distributed throughout $\mathbb{R}^n$. The regularly distributed centers are assumed to be located on the scaled integer grid $h\mathbb{Z}^n$, where $h > 0$. In this case, Fourier transform methods can be used, and results which measure the quality of approximation offered by the set

$$(1.1) \qquad \{\phi(\|\tfrac{\cdot}{h} - z\|) : z \in \mathbb{Z}^n\}$$

in terms of some power of h are obtained. Major developments in this field are due to Jackson and Buhmann [Ji], [Bu], and these results are often somewhat surprising. Neither convolution nor quasi-interpolation can be used in a crude way, as most of the common radial functions exhibit growth at infinity, whereas both these techniques need functions which have rapid decay. However, if we *did* have sufficiently rapid decay

at infinity, then the convolution method is as follows. Suppose that ϕ is continuous and positive on $[0,\infty)$. Assume also that

$$\int_0^\infty t^{n-1}|\phi(t)|\,dt < \infty. \tag{1.2}$$

Then for any $f \in C_0(\mathbb{R}^n)$ and any x,

$$\lim_{k\to\infty} c_k \int_{\mathbb{R}^n} \phi(k\|x-y\|)f(y)\,dy = f(x). \tag{1.3}$$

(Here c_k are certain coefficients depending on ϕ only.) This result is a classical theorem on convolution in disguise. Indeed, if we set $G(x) = \phi(\|x\|)$, we find that G is in $L^1(\mathbb{R}^n)$ since (by passing to polar coordinates),

$$\begin{aligned}\int_{\mathbb{R}^n} |G(x)|\,dx &= \int_0^\infty \int_{S_r^{n-1}} |G(v)|\,dS_r^{n-1}(v)\,dr \\ &= \omega_{n-1}\int_0^\infty \phi(r)r^{n-1}\,dr < \infty.\end{aligned} \tag{1.4}$$

The positivity of ϕ ensures that $\alpha \equiv \int G(x)\,dx \neq 0$. Hence $\alpha^{-1}G$ is a suitable kernel, giving rise to the approximate identity $G_k(x) = \alpha^{-1}k^nG(kx)$. Then by the classical theory, $G_k * f \to f$ pointwise for each $f \in C_0(\mathbb{R}^n)$. The convergence is uniform on compact sets. Refer to [SW, p. 11] for further details. After approximating the integral in equation (1.3) by a quadrature formula, one obtains approximations to f of the form

$$x \mapsto \sum_{j=1}^m a_j\phi(\|kx - v_j\|) \quad (k \in \mathbb{R},\ x, v_j \in \mathbb{R}^n).$$

Such functions are a linear combination of shifted, dilated radial functions. The shifts are the v_j, and the dilation factor is $k > 0$. A byproduct of this analysis is that the set of functions

$$x \mapsto \phi(k\|x-y\|) \qquad (k \in \mathbb{N},\ y \in \mathbb{R}^n)$$

is fundamental in $C_0(\mathbb{R}^n)$; i.e., its linear span is dense. In such assertions, the topology of uniform convergence on compact sets is assumed to be in force on the linear space $C_0(\mathbb{R}^n)$.

As we have already pointed out, when one considers the radial functions used in practice one sees that (1.2) is far too stringent an assumption. For example, (1.2) is clearly not satisfied for the multiquadric referred to previously, where $\phi(t) = \sqrt{t^2+c}$, $c > 0$. Because of this, one needs alternative methods of manufacturing kernels $G \in L^1(\mathbb{R}^n)$. The technique of Jackson was to define G as a finite linear combination of shifts of the radial function. Thus Jackson sought coefficients $a_1, \ldots, a_m$ in $\mathbb{R}$ and centers $u_1, \ldots, u_m$ in $\mathbb{R}^n$ such that the function $G \in C(\mathbb{R}^n)$ defined by

$$G(x) = \sum_{j=1}^m a_j\phi(\|x - u_j\|)$$

satisfies $G \in L^1(\mathbb{R}^n)$ and $\int_{\mathbb{R}^n} G \neq 0$. One of the surprises of the theory is that this apparently easy goal is often unattainable. In a manner which depends critically on the parity of n, one often finds that $G \in L^1(\mathbb{R}^n)$ implies $\int_{\mathbb{R}^n} G = 0$.

Our procedure for creating a useful kernel from a given function ϕ is more general than that of Jackson. First, we average $\phi(\|x-tv\|)$ as v ranges over the unit sphere S^{n-1} in $\mathbb{R}^n$

$$g(x,t)=\frac{1}{\omega_{n-1}}\int_{S^{n-1}}\phi(\|x-tv\|)\,dS^{n-1}(v)\qquad(x\in\mathbb{R}^n,\ t\in\mathbb{R}).\tag{1.5}$$

In this equation, $dS^{n-1}(v)$ represents the rotationally invariant measure on S^{n-1} that is consistent with Lebesgue measure in $\mathbb{R}^n$ (via the standard polar coordinate system). The symbol ω_{n-1} represents the measure of S^{n-1}. Equation (1.5) appears frequently in the literature. See, for example, [Jo, p. 2], [SW, p. 38], [GS, p. 78]. It is readily seen that $g(x,t)$ is a radial function of x and an even function of t.

In the second step, we construct our kernel by putting

$$G(x)=\int_{\mathbb{R}}g(x,t)\,d\mu(t)\qquad(x\in\mathbb{R}^n),\tag{1.6}$$

where μ is a finite, signed, regular, Borel measure having compact support. By manipulating this measure we hope to produce a kernel G such that $G\in L^1(\mathbb{R}^n)$ and $\int_{\mathbb{R}^n}G\neq 0$.

Our subsequent analysis will have the following features:

1. Very weak assumptions are made on ϕ. Roughly speaking, we assume that $\phi=\phi_1+\phi_2$ where $x\mapsto\phi_1(\|x\|)$ is in $L^1(\mathbb{R}^n)$ and ϕ_2 has a power series form for large values of its argument. See Lemma 3.1 for details.
2. Despite the significant increase in generality over Jackson's approach, we still find that $G\in L^1(\mathbb{R}^n)$ often implies $\int_{\mathbb{R}^n}G=0$. Again, the parity of n plays a role, indicating that the reason for this phenomenon is the *compact support* of the measure μ. See Theorem 4.7 for example.
3. We give very general conditions for $\int_{\mathbb{R}^n}G\neq 0$. We suspect these conditions are necessary.

Our analysis needs quite a few preliminary results. Some of these are technical facts about hypergeometric functions. Such results are collected in §2. In §3 we examine the possibility of the kernel constructed being in $L^1(\mathbb{R}^n)$. Finally in §4 we study $\int_{\mathbb{R}^n}G$. We conclude this section with some examples of cases when kernels with nonzero integrals can be constructed.

2. The function *h*.

LEMMA 2.1. *If ϕ and g are as described in §1, then, with $r=\|x\|$ and $\lambda=(n-3)/2$, we have*

$$g(x,t)=\omega_{n-2}\omega_{n-1}^{-1}\int_{-1}^{1}\phi\big[(r^2+t^2-2rst)^{1/2}\big](1-s^2)^{\lambda}\,ds.\tag{2.1}$$

Proof. Fix x,r, and t. Define

$$\psi(s)=\phi\big[(r^2+t^2-2ts)^{1/2}\big]\qquad(-1\le s\le 1).$$

By an equation in [Jo, p. 8] or equation (2.1) in [XLC] we have

$$\begin{aligned}g(x,t)&=\omega_{n-1}^{-1}\int_{S^{n-1}}\Big[\big\{\|x\|^2-2t\langle x,v\rangle+t^2\|v\|^2\big\}^{1/2}\Big]\,dS^{n-1}(v)\\&=\omega_{n-1}^{-1}\int_{S^{n-1}}\psi\big(\langle x,v\rangle\big)\,dS^{n-1}(v)\\&=\omega_{n-2}\omega_{n-1}^{-1}\int_{-1}^{1}\psi(rs)(1-s^2)^{\lambda}\,ds.\qquad\square\end{aligned}$$

A central role in this paper is played by the function

$$h(z) = h(\beta, \lambda, z) = \int_{-1}^{1} (1 + z^2 - 2zs)^{\beta}(1 - s^2)^{\lambda}\, ds \qquad (|z| < 1). \tag{2.2}$$

Here $\beta \in \mathbb{R}$ and $\lambda > -1$. In this section, we shall prove that h is a hypergeometric function and use that information to study the coefficients in its Maclaurin series. We adopt the following standard notation for the Gauss hypergeometric function:

$$F(a, b, c, z) = \sum_{k=0}^{\infty} \frac{(a, k)(b, k)}{(c, k)k!}\, z^k \qquad (|z| < 1). \tag{2.3}$$

In this equation, the Pochhammer symbols are defined by

$$(a, k) = a(a + 1)(a + 2) \cdots (a + k - 1) \qquad (k \geq 1). \tag{2.4}$$

By convention, $(a, 0) = 1$. See [AS, Chap. 15] for information about the hypergeometric function.

LEMMA 2.2. *The function h is even and analytic in the open unit disk of the complex plane.*

Proof. With the substitution $t = -s$ in equation (2.2) we obtain

$$\begin{aligned} h(-z) &= \int_{-1}^{1} (1 + z^2 + 2zs)^{\beta}(1 - s^2)^{\lambda}\, ds \\ &= \int_{-1}^{1} (1 + z^2 - 2zt)^{\beta}(1 - t^2)^{\lambda}\, dt = h(z). \end{aligned}$$

Hence h is even. Since $\lambda > -1$, the factor $(1 - s^2)^{\lambda}$ is integrable. Furthermore, a singularity can occur in the integrand only when $z^2 - 2zs + 1 = 0$, i.e., when $z = s \pm i\sqrt{1 - s^2}$, $s \in [-1, 1]$. These singular points lie on the unit circle, and hence h is analytic in the open disk. □

THEOREM 2.3. *If $\beta \in \mathbb{R}$ and $\lambda > -1$, then for $|z| < 1$,*

$$h(\beta, \lambda, z) = \frac{\Gamma(\lambda + 1)\Gamma(\frac{1}{2})}{\Gamma(\lambda + \frac{3}{2})} F(-\beta, -\lambda - \beta - \tfrac{1}{2}, \lambda + \tfrac{3}{2}, z^2). \tag{2.5}$$

Proof. Make the change of variable $s = 2t - 1$ in equation (2.2) to obtain

$$\begin{aligned} h(\beta, \lambda, z) &= 2 \int_0^1 \left[1 + z^2 - 2z(2t - 1)\right]^{\beta} (2 - 2t)^{\lambda}(2t)^{\lambda}\, dt \\ &= 2^{2\lambda+1} \int_0^1 \left[(1 + z)^2 - 4zt\right]^{\beta} t^{\lambda}(1 - t)^{\lambda}\, dt \qquad (2.6) \\ &= 2^{2\lambda+1}(1 + z)^{2\beta} \int_0^1 \left[1 - \frac{4zt}{(1 + z)^2}\right]^{\beta} t^{\lambda}(1 - t)^{\lambda}\, dt. \end{aligned}$$

We shall now employ several formulæ from [AS]. Each is valid in some neighborhood of the origin, and the result of using them will be a representation of h that is valid in a neighborhood of the origin. Formula 15.3.1 from [AS] is

$$F(a, b, c, z) = \frac{\Gamma(c)}{\Gamma(b)\Gamma(c - b)} \int_0^1 t^{b-1}(1 - t)^{c-b-1}(1 - tz)^{-a}\, dt. \tag{2.7}$$

Employing equations (2.6) and (2.7) we have

$$h(\beta,\lambda,z)=\frac{2^{2\lambda+1}[\Gamma(\lambda+1)]^2}{\Gamma(2\lambda+2)}(1+z)^{2\beta}F\left(-\beta,\lambda+1,2\lambda+2,\frac{4z}{(1+z)^2}\right). \tag{2.8}$$

Formula 6.1.18 from [AS] is

$$\Gamma(z)\Gamma\left(z+\tfrac{1}{2}\right)=2^{1-2z}\sqrt{\pi}\,\Gamma(2z). \tag{2.9}$$

This leads to

$$\frac{2^{2\lambda+1}[\Gamma(\lambda+1)]^2}{\Gamma(2\lambda+2)}=\frac{\Gamma(\lambda+1)\Gamma(\frac{1}{2})}{\Gamma(\lambda+\frac{3}{2})}. \tag{2.10}$$

Formula 15.3.27 from [AS] is

$$F(a,b,a-b+1,z^2)=(1+z)^{-2a}F\left(a,a-b+\tfrac{1}{2},2a-2b+1,\frac{4z}{(1+z)^2}\right). \tag{2.11}$$

In (2.11) we set $a=-\beta$ and $b=-\lambda-\beta-\frac{1}{2}$. Using equation (2.8), we are led to equation (2.5), valid in some neighborhood of the origin. Since h is analytic in the unit disk, equation (2.5) is valid in the unit disk. □

In the future, we denote $[\Gamma(\lambda+1)\Gamma(\frac{1}{2})]/[\Gamma(\lambda+\frac{3}{2})]$ by γ. It is not zero because the Gamma function has no zeros, and its poles are at $0,-1,-2,\dots$, whereas $\lambda+\frac{3}{2}>\frac{1}{2}$.

LEMMA 2.4. *Let $\beta\in\mathbb{R}$ and let $\lambda>-1$. Let*

$$h(\beta,\lambda,z)=\int_{-1}^{1}(1+z^2-2sz)^{\beta}(1-s^2)^{\lambda}\,ds=\sum_{j=0}^{\infty}c_j(\beta)z^{2j}.$$

The condition $c_j(\beta)=0$ occurs if and only if $j>\beta\in\mathbb{Z}_+$ or $j>\lambda+\beta+\frac{1}{2}\in\mathbb{Z}_+$.

Proof. By Theorem 2.3,

$$c_j(\beta)=\gamma\,\frac{(-\beta,j)(-\lambda-\beta-\frac{1}{2},j)}{(\lambda+\frac{3}{2},j)j!}.$$

Since $\gamma\neq 0$, we see that $c_j(\beta)=0$ if and only if $(-\beta,j)=0$ or $(-\lambda-\beta-\frac{1}{2},j)=0$. Since

$$(-\beta,j)=-\beta(-\beta+1)(-\beta+2)\cdots(-\beta+j-1),$$

we have $(-\beta,j)=0$ if and only if $\beta\in\{0,1,2,\dots,j-1\}$. Equivalently, $j>\beta\in\mathbb{Z}_+$. The other Pochhammer symbol vanishes if and only if $j>\lambda+\beta+\frac{1}{2}\in\mathbb{Z}_+$. □

LEMMA 2.5. *Let $F(a,b,c,x)=\sum_{k=0}^{\infty}A_kx^k$, where $-c\notin\mathbb{Z}_+$. If $b\neq 1$ then*

$$(b-1)^{-1}F(a,b-1,c,x)=\sum_{k=0}^{\infty}A_k(k+b-1)^{-1}x^k.$$

If $1-b\in\mathbb{N}$, the singularity when $k=1-b$ is removable.

Proof. The coefficients in $(b-1)^{-1}F(a,b-1,c,x)$ are

$$\frac{(a,k)(b-1,k)}{(c,k)k!(b-1)}=\frac{(a,k)(b,k-1)}{(c,k)k!}=\frac{(a,k)(b,k)}{(c,k)k!(b+k-1)}=\frac{A_k}{k+b-1}.$$

Since $(b,k-1) = b(b+1)(b+2)\cdots(b+k-2)$, the zeros of $(b,k-1)$ are $b = 0,-1,-2,\ldots,2-k$. Thus if $1-b \in \mathbb{N}$, we have $(b,k-1) = 0$ for $k \geq 2-b$. The last nonzero term in the series will correspond to $k = 1-b$. This term is

$$\frac{(a,k)(b,k-1)}{(c,k)k!}x^k = \frac{(a,k)(1-k,k-1)}{(c,k)k!}x^k = \frac{(a,k)(-1)^{k-1}}{(c,k)k}x^k = \frac{(a,1-b)(-1)^b}{(c,1-b)(1-b)}x^{1-b}.$$

The proof is thus completed. □

LEMMA 2.6. *Define A_k as in Lemma* 2.5. *If $-c \notin \mathbb{Z}_+$ then*

$$c^{-1}F(a,b,c+1,x) = \sum_{k=0}^{\infty} \frac{A_k}{k+c}x^k \qquad (|x|<1). \tag{2.12}$$

Proof. The hypothesis on c ensures that $F(a,b,c,x)$ is well defined. The equality asserted rests upon this identity between the coefficients of x^k on the two sides

$$\frac{(a,k)(b,k)}{(c+1,k)k!c} = \frac{(a,k)(b,k)}{(c,k)k!(k+c)}. \qquad \Box$$

LEMMA 2.7. *Consider the hypergeometric function*

$$F(a,b,c,z) = \sum_{k=0}^{\infty} A_k z^k \qquad (|z|<1). \tag{2.13}$$

If the real part of $(c-a-b)$ is positive, then the series converges absolutely on the circle $|z| = 1$, and Gauss' formula is valid

$$\lim_{x\uparrow 1} F(a,b,c,x) = \frac{\Gamma(c-a-b)\Gamma(c)}{\Gamma(c-a)\Gamma(c-b)}. \tag{2.14}$$

Proof. See [AS, p. 556]. □

LEMMA 2.8. *Let $n \geq 2$, $\alpha > -n$, $\beta = \alpha/2$, $\lambda = (n-3)/2$. Define $c_k(\beta)$ as in Lemma* 2.4. *Then these series converge absolutely*

$$\sum_{k=0}^{\infty} \frac{c_k(\beta)}{n+2k}, \qquad \sum_{k=0}^{\infty} \frac{c_k(\beta)}{n+\alpha-2k}. \tag{2.15}$$

Proof. By Lemmas 2.4 and 2.3, using $c_k = c_k(\beta)$, we have

$$\sum c_k z^{2k} = h(\beta,\lambda,z) = \frac{\Gamma(\lambda+1)\Gamma(\frac{1}{2})}{\Gamma(\lambda+\frac{3}{2})}F(-\beta,-\lambda-\beta-\tfrac{1}{2},\lambda+\tfrac{3}{2},z^2).$$

Let $a = -\beta$, $b = -\lambda-\beta-\frac{1}{2}$, $c = \lambda+\frac{3}{2}$, and $x = z^2$. Then

$$\sum c_k x^k = \gamma F(a,b,c,x).$$

We note that $c \notin -\mathbb{Z}_+$. Hence Lemma 2.6 applies, and we have

$$\sum \frac{c_k}{k+c}x^k = c^{-1}F(a,b,c+1,x).$$

We note also that $b \neq 1$. Hence Lemma 2.5 applies, and we have

$$\sum \frac{c_k}{k+b-1} x^k = (b-1)^{-1} F(a, b-1, c, x).$$

Both of these last two series converge absolutely for $|x| = 1$ by Lemma 2.7. Hence the series $\sum c_k (k+c)^{-1} \equiv 2 \sum c_k (n+2k)^{-1}$ converges. Similarly, the series $\sum c_k (n+\alpha - 2k)^{-1}$ converges. □

LEMMA 2.9. *Define A_k by equation* (2.13), *and assume that* $0 < c-a = 1-b$ *and that* $-c \notin \mathbb{Z}_+$. *Then*

$$\sum_{k=0}^{\infty} \frac{A_k}{k+c} = \sum_{k=0}^{\infty} \frac{A_k}{1-b-k}. \tag{2.16}$$

Proof. Note that $b \neq 1$. Hence, by Lemma 2.5,

$$(1-b)^{-1} F(a, b-1, c, z) = \sum_{k=0}^{\infty} A_k (1-b-k)^{-1} z^k \qquad (|z| < 1). \tag{2.17}$$

Since $c - a - (b-1) = 2(1-b) > 0$, Lemma 2.7 applies, and we conclude that the series in equation (2.17) converges absolutely when $|z| = 1$. In particular, it converges at $z = 1$. Hence by Abel's Theorem [W, p. 320],

$$\lim_{x \uparrow 1} (1-b)^{-1} F(a, b-1, c, x) = \sum_{k=0}^{\infty} A_k (1-b-k)^{-1}.$$

Using Gauss' formula in Lemma 2.7, we obtain

$$\frac{\Gamma(c+1-a-b)\Gamma(c)}{(1-b)\Gamma(c-a)\Gamma(c-b+1)} = \sum_{k=0}^{\infty} A_k (1-b-k)^{-1}. \tag{2.18}$$

In exactly the same way, starting with Lemma 2.6 we obtain

$$\frac{\Gamma(c+1-a-b)\Gamma(c+1)}{c\Gamma(c+1-a)\Gamma(c+1-b)} = \sum_{k=0}^{\infty} A_k (k+c)^{-1}. \tag{2.19}$$

By using the identity $x\Gamma(x) = \Gamma(x+1)$ we see that the left sides in equations (2.19) and (2.18) are equal. □

LEMMA 2.10. *Let* $n \geq 2$, $\lambda = (n-3)/2$, *and* $\beta > -n/2$. *Define* $c_j(\beta)$ *as in Lemma* 2.4. *Then*

$$\sum_{j=0}^{\infty} c_j(\beta)(n+2j)^{-1} = \sum_{j=0}^{\infty} c_j(\beta)(n+2\beta-2j)^{-1}.$$

Proof. Define a, b, c, and x as in the proof of Lemma 2.8. Then the assertion of Lemma 2.8 is valid. The hypotheses of Lemma 2.9 are now fulfilled since

$$\begin{aligned} c - a &= \lambda + \frac{3}{2} + \beta = \frac{n}{2} + \beta > 0, \\ 1 - b &= 1 + \lambda + \beta + \frac{1}{2} = \frac{n}{2} + \beta = c - a, \\ -c &= -\frac{n}{2} \notin \mathbb{Z}_+. \end{aligned}$$

By Lemma 2.9,

$$\sum_{k=0}^{\infty} A_k(k+c)^{-1} = \sum_{k=0}^{\infty} A_k(1-b-k)^{-1}.$$

Here A_k are the Taylor coefficients of $F(a,b,c,x)$. Hence $A_k = \frac{1}{\gamma}c_k(\beta)$. Inserting the values of c and b in the preceding series, we obtain the equation to be proved. □

LEMMA 2.11. *Let $n \geq 2$ and $\alpha > -n$. Define $c_k(\beta)$ as in Lemma 2.4. Define*

$$R(n,\alpha) = \sum_{\substack{j=0 \\ 2j \neq n+\alpha}}^{\infty} c_j\left(\frac{\alpha}{2}\right)\left[\frac{1}{n+2j} - \frac{1}{n+\alpha-2j}\right].$$

For $R(n,\alpha)$ to be nonzero, it is necessary and sufficient that $n+\alpha \in 2\mathbb{N}$ and $\alpha \notin 2\mathbb{Z}_+$.

Proof. If $n+\alpha \notin 2\mathbb{Z}_+$, then in the sum defining $R(n,\alpha)$ the condition $2j \neq n+\alpha$ is vacuous (and can be omitted). In this case, $R(n,\alpha) = 0$ by Lemma 2.10.

Assume, therefore, that $n+\alpha = 2m \in 2\mathbb{Z}_+$. Since $n+\alpha > 0$ this means $n+\alpha \in 2\mathbb{N}$. By Lemma 2.10 we see that

$$-R(n,\alpha) = c_m\left(\frac{\alpha}{2}\right)\left[\frac{1}{n+2m} - \frac{1}{n+\alpha-2m}\right].$$

This is precisely the term in which we must cope with the removable singularity mentioned in Lemma 2.5. As in Lemma 2.8, let $a = -\alpha/2$, $b = -\lambda - \alpha/2 - 1/2$, and $c = n/2$. Then we have

$$c_m\left(\frac{\alpha}{2}\right) = \frac{(a,m)(b,m)}{(c,m)m!} = \frac{(a,m)}{(c,m)m!}(b,m-1)(b+m-1).$$

Since $2m - n - \alpha = 2(b+m-1)$ we have

$$-R(n,\alpha) = \frac{(a,m)}{(c,m)m!}\,\frac{(b,m-1)}{2}.$$

Therefore $R(n,\alpha) = 0$ if and only if $(a,m)(b,m-1) = 0$. Recall that a Pochhammer symbol (x,k) vanishes if and only if $x \in \mathbb{Z}$ and $1-k \leq x \leq 0$. It follows that $(b,m-1) \neq 0$, because

$$b = (-n-\alpha+2)/2 = -m+1 < 1-(m-1).$$

Thus we conclude that $R(n,\alpha) = 0$ if and only if $(a,m) = 0$. This is equivalent in turn to

(i) $a \in \mathbb{Z}$ and $1-m \leq a \leq 0$,
(ii) $\alpha \in 2\mathbb{Z}$ and $1-m \leq -\alpha/2 \leq 0$,
(iii) $\alpha \in 2\mathbb{Z}$ and $0 \leq \alpha \leq n+\alpha-2$,
(iv) $\alpha \in 2\mathbb{Z}_+$. □

3. The integrability of G. Recall from §1 that if a function ϕ has been prescribed, we define a function G on $\mathbb{R}^n$ by the formula

$$G(x) = \frac{\omega_{n-2}}{\omega_{n-1}}\int_{\mathbb{R}}\int_{-1}^{1}\phi\Big(\big[\|x\|^2+t^2-2\|x\|st\big]^{1/2}\Big)(1-s^2)^{\lambda}\,ds\,d\mu(t). \tag{3.1}$$

Here μ is a regular, signed, Borel measure having finite total variation and compact support. Let a be chosen so that the interval $[-a, a]$ contains the support of μ. To ensure the local integrability of G, we assume that $\phi \in C(0,\infty)$ and that $\phi(r) = O(r^\theta)$ as $r \to 0$, for some $\theta > -n$.

Our analysis involves the moments of the measure μ, defined by

$$m_j = \int_{\mathbb{R}} t^j \, d\mu(t) \qquad (j = 0, 1, 2, \ldots).$$

We also require the function $h(z) = h(\beta, \lambda, z)$ from equation (2.2), in which $\lambda = (n-3)/2$.

LEMMA 3.1. *Let ϕ be a function as described above that is expressible for sufficiently large values of r in the form*

$$\phi(r) = \sum_{k=0}^{[n+\alpha]} a_k r^{\alpha-k} + \phi_1(r), \tag{3.2}$$

where $a_0 \neq 0$, $\alpha \in \mathbb{R}$, and $\phi_1(\|x\|) \in L^1(\mathbb{R}^n)$. Let h, μ, G, m_j, a, and c_j be as above. For G to be integrable it is necessary and sufficient that

$$\sum_{k+2j=\nu} a_k c_j \left(\frac{\alpha-k}{2}\right) m_{2j} = 0 \qquad \big(0 \leq \nu \leq n + [\alpha]\big). \tag{3.3}$$

Proof. The process that generates G from ϕ is linear and produces an integrable function from ϕ_1. Hence, without loss of generality, we shall assume that for $r > A$,

$$\phi(r) = \sum_{k=0}^{[n+\alpha]} a_k r^{\alpha-k}.$$

Since G is a radial function

$$\omega_{n-2}^{-1} \int_{\rho \leq \|x\| \leq M} |G(x)| \, dx = \frac{\omega_{n-1}}{\omega_{n-2}} \int_\rho^M r^{n-1} |G_0(r)| \, dr$$

$$= \int_\rho^M r^{n-1} \left| \int_{-a}^{a} \phi\big([r^2 + t^2 - 2rst]^{1/2}\big)(1-s^2)^\lambda \, ds \, d\mu(t) \right| dr$$

$$= \int_\rho^M r^{n-1} \left| \sum_{k=0}^{[n+\alpha]} a_k \int_{-a}^{a} \int_{-1}^{1} (r^2 + t^2 - 2rst)^{(\alpha-k)/2} (1-s^2)^\lambda \, ds \, d\mu(t) \right| dr$$

$$= \int_\rho^M r^{n-1} \left| \sum_{k=0}^{[n+\alpha]} a_k r^{\alpha-k} \int_{-a}^{a} h\left(\frac{\alpha-k}{2}, \lambda, \frac{t}{r}\right) d\mu(t) \right| dr$$

$$= \int_\rho^M \left| \sum_{k=0}^{[n+\alpha]} a_k r^{n-1+\alpha-k} \int_{-a}^{a} \sum_{j=0}^{\infty} c_j \left(\frac{\alpha-k}{2}\right) \left(\frac{t}{r}\right)^{2j} d\mu(t) \right| dr$$

$$= \int_\rho^M \left| \sum_{k=0}^{[n+\alpha]} \sum_{j=0}^{\infty} a_k c_j \left(\frac{\alpha-k}{2}\right) m_{2j} r^{n-1+\alpha-k-2j} \right| dr$$

$$= \int_\rho^M \left| \sum_{\nu=0}^{\infty} r^{n+\alpha-1-\nu} \sum_{k+2j=\nu} a_k c_j \left(\frac{\alpha-k}{2}\right) m_{2j} \right| dr.$$

It is straightforward to prove that

$$\left|c_j\left(\frac{\alpha-k}{2}\right)\right| \le \text{const.}\, k^{2j} \le \text{const.}[n+\alpha+1]^{2j}.$$

Therefore, the double series in the penultimate line of the above calculation is absolutely convergent if ρ is sufficiently large. This justifies the rearrangement of series in the ultimate line.

Our calculation shows that $G \in L^1(\mathbb{R}^n)$ if and only if the coefficient of $r^{n+\alpha-\nu}$ is zero whenever $n+\alpha-1-\nu \ge -1$. This leads to equation (3.3). □

We shall require in our analysis the following result in linear algebra.

LEMMA 3.2. *Define linear functionals $L_\nu(x) = \sum_{k+2j=\nu} a_{kj}x_j$, in which $0 \le \nu \le N$, $k \ge 0$, $j \ge 0$, $a_{00} \ne 0$, and $a_{kj} = 0 \Rightarrow a_{ki} = 0$ for $i \ge j$. Let s be the largest integer for which $\sum_{k=0}^{N-2s} |a_{ks}| > 0$. The following properties of the x-vector are equivalent: (1) $L_\nu(x) = 0$ for $0 \le \nu \le N$; (2) $x_j = 0$ for $0 \le j \le s$.*

Proof. Assume that (2) is true. Then for each ν we have $L_\nu(x) = \sum_{k+2j=\nu,\, j>s} a_{kj}x_j$. By the definition of s, $a_{kj} = 0$ if $j > s$ and $0 \le k \le N-2j$. Hence $L_\nu(x) = 0$.

Now assume that (2) is false. Let α be the first integer for which $x_\alpha \ne 0$. Thus $0 \le \alpha \le s$. By the definition of s, $\sum_{k=0}^{N-2s} |a_{ks}| > 0$. Hence there is an index $\mu \in [0, N-2s]$ for which $a_{\mu s} \ne 0$. By the hypothesis on the array (a_{ij}), we have $a_{\mu\alpha} \ne 0$. Let β be the smallest integer for which $a_{\beta\alpha} \ne 0$. Thus $\beta \le \mu \le N-2s$. Put $\nu = \beta + 2\alpha$. Thus $\nu \le (N-2s)+2s = N$. Also $a_{\nu-2\alpha,\alpha} = a_{\beta\alpha} \ne 0$. If $j > \alpha$, then $\nu - 2j < \nu - 2\alpha = \beta$, and by the definition of β, $a_{\nu-2j,\alpha} = 0$. Since $j > \alpha$, $a_{\nu-2j,j} = 0$. If $j < \alpha$ then by the definition of α, $x_j = 0$. Consequently,

$$L_\nu(x) = \sum_{k+2j=\nu} a_{kj}x_j = \sum_j a_{\nu-2j,j}x_j = a_{\nu-2\alpha,\alpha}x_\alpha = a_{\beta\alpha}x_\alpha \ne 0.$$

Thus (1) is false. □

THEOREM 3.3. *For G to belong to $L^1(\mathbb{R}^n)$ it is necessary and sufficient that $m_{2j} = 0$ for $0 \le j \le s$, where*

$$s = \max\left\{ j : \sum_{k=0}^{n+[\alpha]-2j} \left| a_k c_j\left(\frac{\alpha-k}{2}\right)\right| > 0 \right\}.$$

Proof. We intend to use Lemmas 3.1 and 3.2. Define

$$a_{kj} = a_k c_j\left(\frac{\alpha-k}{2}\right), \quad N = n+[\alpha], \quad \text{and} \quad x_j = m_{2j}.$$

We verify the hypotheses of Lemma 3.2 in the present case. We have $a_{00} = a_0c_0(\alpha/2) \ne 0$ because a_0 has explicitly been assumed to be nonzero, and $c_0(\alpha/2) \ne 0$ by Lemma 2.4. To verify the other hypothesis, suppose that it fails. Let $a_{kj} = 0$, $i > j$, and $a_{ki} \ne 0$. Then $a_k \ne 0$ and $c_j(\frac{\alpha-k}{2}) = 0$. By Lemma 2.4, $c_k(\frac{\alpha-k}{2}) = 0$ also, contradicting the assumption $a_{ki} \ne 0$. By applying Lemma 3.2 to the system of equations (3.3) we obtain the desired conclusion. □

An alternative version of Theorem 3.3 can be obtained by establishing a different formula for the parameter s. Having fixed n and α as above, we define

$$p_k = \max\left\{ j \in \mathbb{Z}_+ : j \le (n+\alpha-k)/2 \text{ and } c_j\left(\frac{\alpha-k}{2}\right) \ne 0\right\}, \tag{3.4}$$

$$Q = \max\{p_k : 0 \le k \le n+\alpha \text{ and } a_k \ne 0\}. \tag{3.5}$$

LEMMA 3.4. $s = Q$.

Proof. By the definition of Q, there is an integer k such that $a_k \neq 0$ and $p_k = Q$. By the definition of p_k, $c_{p_k}(\frac{\alpha-k}{2}) \neq 0$. Hence $a_{k,p_k} \neq 0$. By the definition of s, $a_{kj} = 0$ for $j > s$. Hence $p_k \leq s$ and $Q \leq s$. To prove that $s \leq Q$, we note first that by the definition of s, $\sum_{k=0}^{n+\alpha-2s} |a_{ks}| > 0$. Select an index $k \in [0, n+\alpha-2s]$ such that $a_{ks} \neq 0$. It follows that $a_k \neq 0$ and $c_s(\frac{\alpha-k}{2}) \neq 0$. Since $s \leq (n+\alpha-k)/2$, the definition of p_k yields immediately $p_k \geq s$. Since $k \leq n+\alpha-2s \leq n+\alpha$ and $a_k \neq 0$, the definition of Q yields $Q \geq p_k$. Hence $Q \geq s$. □

LEMMA 3.5. *Define* $p(\beta) = \max\{j \in \mathbb{Z}_+ : j \leq \frac{n}{2} + \beta$ *and* $c_j(\beta) \neq 0\}$. *Then*

$$p(\beta) = \begin{cases} \beta & \text{if } \beta \in \mathbb{Z}_+, \\ \frac{n}{2} + \beta - 1 & \text{if } \beta \notin \mathbb{Z}_+ \text{ and } \frac{n}{2} + \beta \in \mathbb{N}, \\ \left[\frac{n}{2} + \beta\right] & \text{if } \beta \notin \mathbb{Z}_+ \text{ and } \frac{n}{2} + \beta \notin \mathbb{N}. \end{cases}$$

Proof. As a consequence of Lemma 2.4 we know that $c_j(\beta) = 0$ if and only if

(1) either $(j > \beta \in \mathbb{Z}_+)$ or $(j > \frac{n}{2} + \beta - 1 \in \mathbb{Z}_+)$.

Consequently, $c_j(\beta) \neq 0$ if and only if

(2) $\sim (j > \beta \in \mathbb{Z}_+)$ and $\sim (j > \frac{n}{2} + \beta - 1 \in \mathbb{Z}_+)$,

in which $\sim$ signifies logical negation. Thus we have the following formula for $p(\beta)$:

(3) $p(\beta) = \max\{j \in \mathbb{Z}_+ : (j \leq \frac{n}{2} + \beta)$ and $\sim (j > \beta \in \mathbb{Z}_+)$ and $\sim (j > \frac{n}{2} + \beta - 1 \in \mathbb{Z}_+)\}$.

If $\beta \in \mathbb{Z}_+$, then from (3) we have

$$\begin{aligned} p(\beta) &= \max\left\{j \in \mathbb{Z}_+ : \left(j \leq \tfrac{n}{2} + \beta\right), \ (j \leq \beta), \left(j \leq \tfrac{n}{2} + \beta - 1 \text{ or } \tfrac{n}{2} + \beta - 1 \notin \mathbb{Z}_+\right)\right\} \\ &= \max\{j \in \mathbb{Z}_+ : j \leq \beta\} = \beta. \end{aligned}$$

The other two cases are treated similarly. □

The point of this analysis is that we can now reformulate Theorem 3.3 in a way which is usually easier to apply.

COROLLARY 3.6. *The quantities* p_k *defined by equation* (3.4) *are given explicitly by the formula*

$$p_k = \begin{cases} (\alpha - k)/2 & \text{if } \alpha - k \in 2\mathbb{Z}_+, \\ (n + \alpha - k - 2)/2 & \text{if } \alpha - k \notin 2\mathbb{Z}_+ \text{ and } n + \alpha - k \in 2\mathbb{N}, \\ [(n + \alpha - k)/2] & \text{if } \alpha - k \notin 2\mathbb{Z}_+ \text{ and } n + \alpha - k \notin 2\mathbb{N}. \end{cases}$$

For G *to belong to* $L^1(\mathbb{R}^n)$, *it is necessary and sufficient that* $m_{2j} = 0$ *for* $0 \leq j \leq Q$, *where* Q *is given in equation* (3.5).

4. The integral of G. As discussed in §1, the two conditions required of a mapping $G : \mathbb{R}^n \to \mathbb{R}$ for it to be a suitable kernel are that $G \in L^1(\mathbb{R}^n)$ and that $\int G(x)\,dx \neq 0$. In §3, we elaborated on the first of these conditions. Now we address the second. The main results are Theorems 4.7, 4.10, and 4.12.

We recall the manner in which a kernel G has been constructed from a function $\phi \in C(0, \infty)$

$$G(x) = \omega_{n-1}^{-1} \int_{\mathbb{R}} \int_{S^{n-1}} \phi(\|x - tv\|)\, dS^{n-1}(v)\, d\mu(t). \tag{4.1}$$

Here μ is a regular, signed, Borel measure on $\mathbb{R}$ having compact support and finite total variation.

The first result indicates that there is a delicate balance between the two desiderata that $G \in L^1$ and $\int G \neq 0$.

THEOREM 4.1. *Suppose that the function $x \mapsto \phi(\|x\|)$ is in $L^1(\mathbb{R}^n)$. Then $G \in L^1(\mathbb{R}^n)$. If $\int_{\mathbf{R}} d\mu(t) = 0$, then $\int_{\mathbf{R}^n} G(x)\,dx = 0$.*

Proof. The function G is obtained by applying two averaging processes to the L^1 function $x \mapsto \phi(\|x\|)$, and consequently $G \in L^1$. By the Fubini theorem we have

$$\begin{aligned} \int_{\mathbf{R}^n} G(x)\,dx &= \omega_{n-1}^{-1} \int_{\mathbf{R}} \int_{S^{n-1}} \int_{\mathbf{R}^n} \phi(\|x - tv\|)\,dx\,dS^{n-1}(v)\,d\mu(t) \\ &= \omega_{n-1}^{-1} \int_{\mathbf{R}} \int_{S^{n-1}} \int_{\mathbf{R}^n} \phi(\|x\|)\,dx\,dS^{n-1}(v)\,d\mu(t) \\ &= \int_{\mathbf{R}^n} \phi(\|x\|)\,dx \int_{\mathbf{R}} d\mu(t). \end{aligned} \tag{4.2}$$

This calculation proves the second assertion of the theorem. □

Theorem 4.1 indicates that if the function ϕ is "too nice," i.e., $\int_{\mathbf{R}^n} |\phi(\|x\|)|\,dx < \infty$, then our procedure may lead to a function G having a zero integral.

With the aid of Lemma 2.1 we have, using $G_0(\|x\|) = G(x)$ and $g_0(\|x\|, t) = g(x,t)$,

(4.3)

$$\begin{aligned} \int_{\mathbf{R}^n} G(x)\,dx &= \omega_{n-1} \int_0^\infty r^{n-1} G_0(r)\,dr \\ &= \omega_{n-1} \int_0^\infty r^{n-1} \int_{\mathbf{R}} g_0(r,t)\,d\mu(t)\,dr \\ &= \omega_{n-2} \int_0^\infty r^{n-1} \int_{\mathbf{R}} \int_{-1}^1 \phi\big([r^2 + t^2 - 2rst]^{1/2}\big)(1-s^2)^\lambda\,ds\,d\mu(t)\,dr \\ &= \omega_{n-2} \lim_{M\to\infty} \int_{\mathbf{R}} I(M,t)\,d\mu(t), \end{aligned}$$

in which we have introduced the abbreviations

$$I(M,t) = \int_0^M \int_{-1}^1 k(r,s,t)\,ds\,dr, \tag{4.4}$$

$$k(r,s,t) = r^{n-1}\phi\big([r^2 + t^2 - 2rst]^{1/2}\big)(1-s^2)^\lambda. \tag{4.5}$$

LEMMA 4.2. *Let $0 < t \le a < M$, where a is chosen so that* supp$(\mu) \subset [-a,a]$, *and M is fixed. Let $f(r,t) = (r^2 + t^2 - M^2)/(2rt)$. Let k be as above. Then the expression*

$$J = \left[\int_0^{M+t} \int_{-1}^1 - \int_{M-t}^{M+t} \int_{-1}^{f(r,t)}\right] k(r,s,t)\,ds\,dr \tag{4.6}$$

is independent of t.

Proof. Put $e(r,t) = \max\{-1, f(r,t)\}$. Then

$$J = \int_0^{M+t} \int_{e(r,t)}^1 r^{n-1}\phi\big([r^2+t^2-2rst]^{1/2}\big)(1-s^2)^\lambda \, ds\, dr. \tag{4.7}$$

Change variables from s to v by setting $v = (r^2+t^2-2rst)^{1/2}$;

$$J = \int_0^{M+t} \int_{|r-t|}^{\min(r+t,M)} r2^{-2\lambda}t^{2-n}\phi(v)\big[v^2-(r-t)^2\big]^\lambda \big[(r+t)^2-v^2\big]^\lambda v\, dv\, dr. \tag{4.8}$$

Now reverse the order of integration;

$$J = \int_0^{M} \int_{|v-t|}^{v+t} r2^{-2\lambda}t^{2-n}\phi(v)\big[(v+t)^2-r^2\big]^\lambda \big[r^2-(v-t)^2\big]^\lambda v\, dr\, dv. \tag{4.9}$$

Finally, change variables from r to w by $r = (v^2+t^2-2vtw)^{1/2}$;

$$J = \int_0^M \phi(v)v^{n-1}\, dv \int_{-1}^1 (1-w^2)^\lambda \, dw. \tag{4.10}$$

In this argument the following identity is useful:

$$\big[v^2-(r-t)^2\big]\big[(r+t)^2-v^2\big] = \big[(v+t)^2-r^2\big]\big[r^2-(v-t)^2\big]. \qquad \Box$$

LEMMA 4.3. *Let $-a \le t \le a$ and $M > 4a$. Let $I(M,t)$ and J $(= J(M))$ be as defined above. Then $I(M,t) - J(M)$ does not depend on the values of ϕ in $[0, M/2]$.*

Proof. Note that $I(M,t)$ is an even function of t Lemma 2.2. It is therefore sufficient to consider $t > 0$. We have, as in the preceding proof,

$$\begin{aligned}
I(M,t) &= \int_0^M \int_{-1}^1 k(r,s,t)\, ds\, dr \\
&= \left(\int_0^{M-t} + \int_{M-t}^{M+t} - \int_M^{M+t}\right)\int_{-1}^1 k(r,s,t)\, ds\, dr \\
&= \left(\int_0^{M-t}\int_{-1}^1 + \int_{M-t}^{M+t}\int_{f(r,t)}^1 + \int_{M-t}^{M+t}\int_{-1}^{f(r,t)} - \int_M^{M+t}\int_{-1}^1\right) k(r,s,t)\, ds\, dr \\
&= \left(\int_0^{M+t}\int_{e(r,t)}^1 + \int_{M-t}^{M+t}\int_{-1}^{f(r,t)} - \int_M^{M+t}\int_{-1}^1\right) k(r,s,t)\, ds\, dr \\
&= J(M) + \left(\int_{M-t}^{M+t}\int_{-1}^{f(r,t)} - \int_M^{M+t}\int_{-1}^1\right) k(r,s,t)\, ds\, dr.
\end{aligned}$$

In both integrals on this last line, we have $0 \le t \le a$, $-1 \le s \le 1$, and $r \ge M - t$. Hence the argument of ϕ satisfies

$$\begin{aligned}
(r^2+t^2-2rst)^{1/2} &\ge (r^2+t^2-2rt)^{1/2} = |r-t| \ge r-t \ge M-2t \\
&\ge M-2a > M - M/2 = M/2. \qquad \Box
\end{aligned}$$

LEMMA 4.4. *Adopt all the preceding notation, and assume that $m_0 = 0$. If the function G in equation (4.1) belongs to $L^1(\mathbb{R}^n)$ then its integral does not depend on the values of ϕ in any bounded subset of $(0, \infty)$.*

Proof. Let $I(M,t)$ and $J(M)$ be as defined in equations (4.4) and (4.6). Let $\operatorname{supp}(\mu) \subset [-a, a]$. Since $\mu(\mathbb{R}) = 0$, we have, from equation (4.3),

$$\int_{\mathbb{R}^n} G(x)\,dx = \lim_{M\to\infty} \omega_{n-2} \int_{-a}^{a} I(M,t)\,d\mu(t)$$

$$= \lim_{M\to\infty} \omega_{n-2} \int_{-a}^{a} \left[I(M,t) - J(M)\right] d\mu(t).$$

By Lemma 4.3, if $M > 4a$, then $I(M,t) - J(M)$ does not depend on the values of ϕ in $(0, M/2]$. For sufficiently large M, this last interval contains any given bounded subset of $(0, \infty)$. □

LEMMA 4.5. *Let $n \geq 2$, $\alpha > -n$, $\phi(t) = t^\alpha$ for $t > 0$. Define $I(M,t)$ by equation (4.4) and let $c_j = c_j(\alpha/2)$. Then*

$$I(M,t) = |t|^{n+\alpha} \sum_{\substack{j=0 \\ 2j \neq n+\alpha}}^{\infty} c_j \left\{ \frac{1}{n+2j} - \frac{1}{n+\alpha-2j} \right\}$$

$$+ M^{n+\alpha} \sum_{\substack{j=0 \\ 2j \neq n-\alpha}}^{\infty} \frac{c_j}{n+\alpha-2j} \left(\frac{t}{M}\right)^{2j}.$$

Proof. Recall (from the proof of Lemma 4.3) that $I(M,t)$ is an even function of t. Write

$$I(M,t) = \int_0^M \int_{-1}^1 k(r,s,t)\,ds\,dr.$$

The integrand can have singularities at $r = 0$, $t = r$, and $s = \pm 1$. When $t = 0$, the integrand contains the factor $r^{n-1} r^\alpha$. This is integrable since $n - 1 + \alpha > -1$. Since $n \geq 2$, we have $\lambda \geq -1/2$; thus $(1 - s^2)^\lambda$ is integrable. To treat the singularity at $r = t$, we write

$$I(M,t) = \lim_{\varepsilon,\delta\downarrow 0} \left(\int_0^{t-\varepsilon} + \int_{t+\delta}^{M} \right) \int_{-1}^1 k(r,s,t)\,ds\,dr.$$

By using Lemma 2.4, we can compute the first summand on the right as follows:

$$\lim_{\varepsilon\downarrow 0} \int_0^{t-\varepsilon} \int_{-1}^1 r^{n-1} t^\alpha \left[\left(\frac{r}{t}\right)^2 + 1 - 2s\left(\frac{r}{t}\right) \right]^{\alpha/2} (1 - s^2)^\lambda\,ds\,dr$$

$$= \lim_{\varepsilon\downarrow 0} \int_0^{t-\varepsilon} h\left(\frac{\alpha}{2}, \lambda, \frac{r}{t}\right) r^{n-1} t^\alpha\,dr$$

$$= \lim_{\varepsilon\downarrow 0} t^\alpha \int_0^{t-\varepsilon} r^{n-1} \sum_{j=0}^{\infty} c_j \left(\frac{r}{t}\right)^{2j} dr$$

$$= \lim_{\varepsilon\downarrow 0} t^{n+\alpha} \sum_{j=0}^{\infty} \frac{c_j}{n+2j} \left(\frac{t-\varepsilon}{t}\right)^{n+2j}$$

$$= t^{n+\alpha} \lim_{x\uparrow 1} \sum_{j=0}^{\infty} \frac{c_j}{n+2j}\, x^{n+2j}.$$

By Lemma 2.7, the series $\sum c_j/(n+2j)$ converges. By Abel's theorem [W, p. 320], the evaluation of the limit above yields

$$t^{n+\alpha}\sum_{j=0}^{\infty}\frac{c_j}{n+2j}.$$

A similar analysis, appealing to Lemma 2.8 and Abel's theorem, gives

$$\lim_{\delta\downarrow 0}\int_{t+\delta}^{M}\int_{-1}^{1}k(r,s,t)\,ds\,dr=\sum_{\substack{j=0\\ 2j\neq n+\alpha}}^{\infty}\frac{c_j}{n+\alpha-2j}\left[M^{n+\alpha}\Big(\frac{t}{M}\Big)^{2j}-t^{n+\alpha}\right].$$

Notice that by Lemma 2.4, $c_j=0$ when $2j=n+\alpha$. □

LEMMA 4.6. *Let f and k be as in Lemma 4.2 and equation (4.5). If $t>0$ and $\phi(t)=t^{-n}$, then*

$$\lim_{M\to\infty}\int_{M}^{M+t}\int_{-1}^{1}k(r,s,t)\,ds\,dr=0,$$

$$\lim_{M\to\infty}\int_{M-t}^{M+t}\int_{-1}^{f(r,t)}k(r,s,t)\,ds\,dr=0.$$

Proof. We assume that $M>3t$. Then it is easily verified that $-1\le f(r,t)\le 1$. Also, in the integrals above, we have $s\le 1$, $r\ge M-t\ge 2t>0$. Hence

$$1+(t/r)^2-2s(t/r)\ge 1+(t/r)^2-2(t/r)=(1-t/r)^2\ge 1/4.$$

If we write

$$\begin{aligned}k(r,s,t)&=r^{n-1}(r^2+t^2-2srt)^{-n/2}(1-s^2)^{\lambda}\\&=r^{-1}\big[1+(t/r)^2-2s(t/r)\big]^{-n/2}(1-s^2)^{\lambda},\end{aligned}$$

then we see that

$$0\le k(r,s,t)\le r^{-1}(1/4)^{-n/2}(1-s^2)^{\lambda}.$$

Hence, an upper bound for both integrals is

$$\int_{M-t}^{M+t}\int_{-1}^{1}k(r,s,t)\,ds\,dr\le 2^n\int_{M-t}^{M+t}r^{-1}\,dr\int_{-1}^{1}(1-s^2)^{\lambda}\,ds\to 0.\qquad\square$$

THEOREM 4.7. *Let ϕ be an element of $C(0,\infty)$ that can be represented as*

$$\phi(r)=\sum_{k=0}^{[n+\alpha]}a_k r^{\alpha-k}+\phi_1(r),$$

where $a_0\neq 0$, $\alpha\in\mathbb{R}\backslash\mathbb{Z}$, and $\phi_1(\|\cdot\|)\in L^1(\mathbb{R}^n)$. Assume also that $G\in L^1(\mathbb{R}^n)$ and $Q\ge 0$ (definition in equation (3.5)). Then $\int G=0$.

Proof. Since $G\in L^1$, Theorem 3.3 implies that $m_{2j}=0$ for $0\le j\le s$. By Lemma 3.4, $s=Q$. Hence $m_0=0$. By the definition of Q in equation (3.5), $n+\alpha\ge 0$. Since $\alpha\notin\mathbb{Z}$, $n+\alpha>0$. Let $\theta=\phi-\phi_1$, and set $G=F+H$, where

$$H(x)=\omega_{n-1}^{-1}\int_{-a}^{a}\int_{S^{n-1}}\theta(\|x-tv\|)\,dS^{n-1}(v)\,d\mu(t),$$

$$F(x)=\omega_{n-1}^{-1}\int_{-a}^{a}\int_{S^{n-1}}\phi_1(\|x-tv\|)\,dS^{n-1}(v)\,d\mu(t).$$

Since $m_0 = 0$, it follows from Theorem 4.1 that $\int F = 0$. Now consider $\int H$. Recall that $\operatorname{supp}(\mu) \subset [-a, a]$. Choose L so that $L > 3a$. By Lemma 2.1, equation (4.4), and Lemma 4.5, we have, for $M > L$,

$$\begin{aligned}
&\frac{\omega_{n-1}}{\omega_{n-2}} \int_{\|x\| \le M} H(x)\, dx \\
&= \int_{-a}^{a} \int_{0}^{M} r^{n-1} \int_{-1}^{1} \theta\big([r^2 + t^2 - 2rst]^{1/2}\big)(1 - s^2)^{\lambda}\, ds\, dr\, d\mu(t) \\
&= \sum_{k=0}^{[n+\alpha]} a_k \int_{-a}^{a} \int_{0}^{M} r^{n-1} \int_{-1}^{1} (r^2 + t^2 - 2rst)^{(\alpha-k)/2}(1 - s^2)^{\lambda}\, ds\, dr\, d\mu(t) \\
&= \sum_{k=0}^{[n+\alpha]} a_k \biggl\{ \int_{-a}^{a} |t|^{n+\alpha-k}\, d\mu(t) \sum_{j=0}^{\infty} c_j\Big(\frac{\alpha-k}{2}\Big)\Big[\frac{1}{n+2j} - \frac{1}{n+\alpha-k-2j}\Big] \\
&\qquad + M^{n+\alpha-k} \sum_{j=0}^{\infty} \frac{c_j\big(\frac{\alpha-k}{2}\big)}{n+\alpha-k-2j} \int_{-a}^{a} \Big(\frac{t}{M}\Big)^{2j} d\mu(t) \biggr\}.
\end{aligned}$$

By Lemma 2.10 we have

$$\sum_{j=0}^{\infty} c_j\Big(\frac{\alpha-k}{2}\Big)\Big[\frac{1}{n+2j} - \frac{1}{n+\alpha-k-2j}\Big] = 0 \qquad (0 \le k \le n+\alpha).$$

Since $H \in L^1(\mathbb{R}^n)$ the expression

$$\sum_{k=0}^{[n+\alpha]} a_k M^{n+\alpha-k} \sum_{j=0}^{\infty} \frac{c_j\big(\frac{\alpha-k}{2}\big)}{n+\alpha-k-2j}\, M^{-2j} \int_{-a}^{a} t^{2j}\, d\mu(t)$$

cannot contain any positive power of M. Hence the highest term present has a negative exponent since α is not an integer. Thus the expression under consideration converges to 0 as M tends to ∞. It follows that

$$\int_{\mathbb{R}^n} H = \lim_{M \to \infty} \int_{\|x\| \le M} H = 0. \qquad \Box$$

LEMMA 4.8. *Adopt the hypotheses of Theorem 4.7, except that now $\alpha \in \mathbb{Z}$. Define $m_\beta = \int |t|^\beta\, d\mu(t)$ and*

$$R(n, \beta) = \sum_{\substack{j=0 \\ 2j \ne n+\beta}}^{\infty} c_j\Big(\frac{\beta}{2}\Big)\Big(\frac{1}{n+2j} - \frac{1}{n+\beta-2j}\Big).$$

Then there is an index ν such that

$$\int G(x)\, dx = \omega_{n-2} a_\nu m_{n+\alpha-\nu} R(n, \alpha - \nu).$$

Proof. Proceed as in the preceding proof, and define

$$\theta_1(r) = \theta(r) - a_{n+\alpha} r^{-n} \qquad (r > 0).$$

Then we have $G = H + F + K$, where

$$H(x) = \omega_{n-1}^{-1} \int_{-a}^{a} \int_{S^{n-1}} \theta_1(\|x - tu\|)\, dS^{n-1}(u)\, d\mu(t),$$

$$F(x) = \omega_{n-1}^{-1} \int_{-a}^{a} \int_{S^{n-1}} \phi_1(\|x - tu\|)\, dS^{n-1}(u)\, d\mu(t),$$

$$K(x) = \omega_{n-1}^{-1} \int_{-a}^{a} \int_{S^{n-1}} a_{n+\alpha} \|x - tu\|^{-n}\, dS^{n-1}(u)\, d\mu(t).$$

Then, by Theorem 4.1, $\int F = 0$, and by Lemma 4.6, $\int K = 0$. Note that when $\alpha = -n$, $H = 0$, and so we shall henceforward consider only the case $\alpha > -n$. Now,

$$\begin{aligned}
I(M) &= \int_{\|x\| \le M} H(x)\, dx \\
&= \omega_{n-2} \int_0^M \int_{-a}^{a} \int_{-1}^{1} \theta_1\big([r^2 + s^2 - 2rst]^{1/2}\big)(1 - s^2)^{\lambda}\, ds\, d\mu(t)\, dr \\
&= \omega_{n-2} \int_0^M \int_{-a}^{a} \sum_{k=0}^{n+\alpha-1} a_k \int_{-1}^{1} (r^2 + t^2 - 2rst)^{\frac{\alpha-k}{2}} (1 - s^2)^{\lambda}\, ds\, d\mu(t)\, dr \\
&= \omega_{n-2} \int_{-a}^{a} \sum_{k=0}^{n+\alpha-1} a_k |t|^{n+\alpha-k} \sum_{\substack{j=0 \\ 2j \ne n+\alpha-k}}^{\infty} c_j\Big(\frac{\alpha-k}{2}\Big)\Big[\frac{1}{n+2j} - \frac{1}{n+\alpha-k-2j}\Big]\, d\mu(t) \\
&\quad + \omega_{n-2} \int_{-a}^{a} \sum_{k=0}^{n+\alpha-1} a_k M^{n+\alpha-k} \sum_{\substack{j=0 \\ 2j \ne n+\alpha-k}}^{\infty} \frac{c_j(\frac{\alpha-k}{2})}{n+\alpha-k-2j}\Big(\frac{t}{M}\Big)^{2j}\, d\mu(t) \\
&= \omega_{n-2} \sum_{k=0}^{n+\alpha-1} a_k m_{n+\alpha-k} R(n, \alpha - k) \\
&\quad + \omega_{n-2} \sum_{k=0}^{n+\alpha-1} a_k M^{n+\alpha-k} \sum_{\substack{j=0 \\ 2j \ne n+\alpha-k}}^{\infty} \frac{c_j(\frac{\alpha-k}{2})}{n+\alpha-k-2j} M^{-2j} m_{2j}.
\end{aligned}$$

The penultimate step above utilizes Lemma 4.5.

Since $G \in L^1$ and

$$\int G = \int H = \lim_{M \to \infty} I(M),$$

we see that in the final equation for $I(M)$, any term $M^{n+\alpha-k-2j}$ with positive exponent must have zero coefficient. The term with 0 exponent is missing because

$2j \neq n+\alpha-k$. Hence only negative exponents occur, and all terms involving M are either zero or converge to 0. Thus

$$\int G = \omega_{n-1} \sum_{k=0}^{n+\alpha-1} a_k m_{n+\alpha-k} R(n, \alpha-k).$$

It remains to be established that this sum contains at most one nonzero summand. Define

$$\nu = \min\{k : a_k R(n, \alpha-k) \neq 0\}.$$

If there is no index k such that $a_k R(n,\alpha-k) \neq 0$, then $\int G = 0$ and the proof ends by setting $\nu = 0$. We assert that only the summand corresponding to $k=\nu$ can be nonzero. Since $R(n,\alpha-\nu) \neq 0$, either $\alpha-\nu$ is odd or $\alpha-\nu$ is even and negative, by Lemma 2.10. In any case, $(\alpha-\nu)/2 \notin \mathbb{Z}_+$. Hence, by Corollary 3.6, $p_\nu \geq (n+\alpha-\nu-2)/2$. By equation (3.5), $Q \geq (n+\alpha-\nu-2)/2$. By Theorem 3.3 and Lemma 3.4, we have $m_{2j} = 0$ for $0 \leq 2j \leq n+\alpha-\nu-2$. Now let $0 \leq k < \nu$. The corresponding summand is 0 by the definition of ν. Next, let $\nu < k \leq n+\alpha-1$. Then $1 \leq n+\alpha-k < n+\alpha-\nu$. If $n+\alpha-k$ is even then $m_{n+\alpha-k} = 0$. If $n+\alpha-k$ is odd, then n and $\alpha-k$ are of opposite parity, and $R(n,\alpha-k) = 0$ by Lemma 2.9. Thus in either case, the term $a_k R(n,\alpha-k) m_{n+\alpha-k}$ is 0. □

We now apply the results of §§3 and 4 to a number of examples. When we do not make any explicit statement about ϕ, but rather refer to the parameters n and α, ϕ is assumed to have the form given in Theorem 4.7. An important feature of Theorem 4.7 is that we only make assumptions about the behaviour of ϕ "at infinity," and so many of our results need no information about the behaviour of ϕ in any bounded neighbourhood of zero. This is a substantial generalisation of the work of Jackson [Ji]. We begin with an easy case in which we can be completely prescriptive.

Example 4.9. Let $\phi \in C[0,\infty)$, $\phi \geq 0$, and $\phi(t) = t^\alpha$ for large t, where $\alpha < -n$. Then $G \in L^1(\mathbb{R}^n)$ by Lemma 3.1. To have $\int G(x)\,dx \neq 0$ it is necessary and sufficient that $m_0 \neq 0$. (See the proof of Theorem 4.1 for this fact.)

The next two results encompass some of the examples mentioned by Jackson [Ji].

THEOREM 4.10. *Let n and α be odd, $\alpha+n > 0$. In order that $G \in L^1(\mathbb{R}^n)$ and $\int G(x)\,dx \neq 0$ it is necessary and sufficient that $m_{2j} = 0$ for $0 \leq 2j \leq n+\alpha-2$ and $m_{n+\alpha} \neq 0$.*

Proof. By Lemma 2.11, $R(n,\alpha) \neq 0$. By hypothesis, $a_0 \neq 0$. Hence by the definition of ν (in the proof of Lemma 4.8), $\nu = 0$. By Lemma 4.8,

$$\int G(x)\,dx = \frac{\omega_{n-2}}{\omega_{n-1}} a_0 m_{n+\alpha} R(n,\alpha).$$

Since $\alpha \notin 2\mathbb{Z}_+$, and $\alpha+n \in 2\mathbb{N}$, we see by Corollary 3.6 that $p_0 = (n+\alpha-2)/2$. Also by Corollary 3.6 we have $p_k \leq p_0$. Hence (by equation (3.5)), $Q = p_0$. In order that $G \in L^1$, it is necessary and sufficient that $m_{2j} = 0$ for $0 \leq 2j \leq 2Q$. Hence the condition $m_{n+\alpha} \neq 0$ is equivalent to $\int G(x)\,dx \neq 0$. □

Example 4.11. For the multiquadrics mentioned in the introduction, we let $\phi(t) = (a^2+t^2)^{1/2}$. For this function the asymptotic series has $\alpha = 1$. Hence in odd dimensions we can obtain a suitable kernel and give a constructive proof of the fundamentality of the set $\{x \mapsto (a^2 + \|\lambda x + y\|^2)^{1/2} : \lambda \in \mathbb{R} \text{ and } y \in \mathbb{R}^n\}$. Similar remarks pertain to $(a^2+t^2)^{k/2}$, k odd, $k > -n$.

We conclude with a result and an application of this result which leads to kernels of a form not previously considered by other authors.

THEOREM 4.12. . *Let n and α be even, $0 > \alpha > -n$. In order that $G \in L^1(\mathbb{R}^n)$ and $\int G \neq 0$ it is necessary and sufficient that $m_{2j} = 0$ for $0 \leq 2j \leq n + \alpha - 2$ and $m_{n+\alpha} \neq 0$.*

Proof. Proceed as in the proof of Theorem 4.10. Since $n + \alpha \in 2\mathbb{N}$ and $\alpha \notin 2\mathbb{Z}_+$, we have $R(n, \alpha) \neq 0$ by Lemma 2.11. Again we find that $\int G \neq 0$ if and only if $m_{n+\alpha} \neq 0$. In order that $G \in L^1$ we must have $m_{2j} = 0$ for $0 \leq 2j \leq 2Q$. Obviously we require $Q < n + \alpha$, so that we can stipulate $m_{n+\alpha} \neq 0$ as a condition on μ. By Corollary 3.6, $p_0 = (n + \alpha - 2)/2$. Also $p_1 = [(n + \alpha - 1)/2] = (n + \alpha - 2)/2$, and in general $p_k \leq p_0$. Hence $Q = p_0 < (n + \alpha)/2$. □

Example 4.13. In dimensions $n = 4, 6, 8, \ldots$ we can let $\phi(t) = (a^2 + t^2)^{-1}$. For this example, $\alpha = -2$. According to Theorem 4.12, a suitable kernel can be formed, and we can prove constructively the fundamentality of the set of functions $x \mapsto (a^2 + \|\lambda x - y\|^2)^{-1}$.

ORTHOGONAL WAVELETS ON THE CANTOR DYADIC GROUP*

W. CHRISTOPHER LANG†

Abstract. Based upon the shift operator as a dilation operator, multiresolution analyses are built on the Cantor dyadic group. A regularity condition is given for wavelets and sufficient conditions are given on scaling filters for regular orthonormal wavelets to occur. Examples of wavelets given include the Haar functions and certain lacunary Walsh function series analogous to the compactly supported wavelets of I. Daubechies.

Key words. orthogonal wavelets, locally compact Abelian groups, Cantor dyadic group

AMS subject classifications. 42C05, 43A70

1. Introduction.

We wish to construct orthogonal wavelets on locally compact Abelian (LCA) groups, resembling the familiar constructions of Y. Meyer [9] or S. Mallat [8] on n-dimensional Euclidean space. We are interested in general groups, not necessarily with Lie structure. Very general constructions have already been given of wavelets on stratified Lie groups based on spline approximations [7] and of wavelet bases for Hilbert spaces with unitary operators representing dilation and translation [1]. In [8] and [9], orthogonal wavelets are built in terms of scaling filters. Conditions are given there on scaling filters for multiresolution analyses (MRAs) to be generated and for the orthogonality of wavelets. We shall define translation, dilation, and MRAs in the setting of LCA groups. On the locally compact Cantor dyadic group, we shall give a definition of the regularity of a wavelet and give sufficient conditions on scaling filters for regular MRAs and orthogonal wavelets to occur. Our main result, Theorem 2.2, resembles [8, Thm. 2].

In §2, we describe the locally compact Cantor dyadic group. Our wavelets on this group will include wavelets corresponding to the Haar wavelets on the line; 2^nth partial sums of Walsh series are nth resolutions (approximations or resolutions at scale 2^{-n}) in these wavelets. Another example of wavelets on the dyadic group consists of certain lacunary Walsh series which are analogous to the continuous compactly supported wavelets of I. Daubechies [2] in that they are generated by scaling filters consisting of (Walsh-) trigonometric polynomials. See §3 below.

We now give our axioms for dilation and translation. These are similar to those of [1], specialized to the case of the Hilbert space $L^2(G)$. In the case of $G = R$, the dilation is the usual $x \to 2x$, and the translation is the usual translation by integer units. There is nothing special about requiring the dilation to be dyadic, but our construction will be general enough to accomodate wavelets on the locally compact Cantor dyadic group as well as wavelets on the plane R^2.

We let G be an LCA group with automorphisms ρ and σ (inverse to each other), Haar measure m, and a subgroup Λ. We assume
(1.1.1) Λ is countably infinite and closed,
(1.1.2) G/Λ is compact,
(1.1.3) $\rho(\Lambda) \subseteq \Lambda$,

† Department of Mathematics, Indiana University Southeast, New Albany, IN 47150 (clang@iusmail.ius.indiana.edu).

(1.1.4) $m(\rho(E)) = 2m(E)$ for all Borel $E \subseteq G$ (so $m(\sigma(E)) = \frac{1}{2}m(E)$),
(1.1.5) $\Lambda/\rho(\Lambda) \approx Z/(2)$.

We will call Λ a *lattice subgroup* of G, and ρ the *dilation operator*. (A simple example is provided by $G = R$, $\Lambda = Z$, and $\rho(x) = 2x$.) We also define the notation for translation $\tau_y f(x) = f(x+y)$ for functions f on G.

We write ρ^j for the jth composition of ρ: if $j < 0$, we set $\rho^j = \sigma^j$. Then let $\Lambda_j = \rho^j(\Lambda)$. It follows from (1.1.5) that $\Lambda_j/\Lambda_{j+1} \approx Z/(2)$ for all j.

In this setting, we define a *multiresolution analysis* of $L^2(G)$ to be a sequence $(V_j)_{j\in Z}$ of closed subspaces of $L^2(G)$ such that
(1.2.1) $V_j \subseteq V_{j+1}$ for all j in Z,
(1.2.2) $\cup V_j$ is dense in $L^2(G)$ and $\cap V_j = \{0\}$,
(1.2.3) $f \in V_j$ if and only if $\rho f = f \circ \rho \in V_{j+1}$ for all $j \in Z$,
(1.2.4) $f \in V_0$ if and only if $\tau_n f \in V_0$ for all n in Λ; $f \in V_0$ if and only if $\rho^j \tau_n f \in V_j$,
(1.2.5) there is a function $g \in L^2(G)$ such that $\{\tau_n g : n \in \Lambda\}$ is a Riesz basis of V_0.

We say that a function f on G is Λ-*periodic* if $\tau_n f = f$ for all $n \in \Lambda$.

See [6] for basic information about sampling of functions and approximations on LCA groups.

We now consider resolution (or scale) filters. For $\phi \in L^2(G)$, we may define V_j to be the L^2-closure of the linear span of $\{\phi(\rho^j(x) + n) : n \in \Lambda\}$, $j \in Z$. We require that $V_j \subseteq V_{j+1}$ for all $j \in Z$. In particular, we require $V_0 \subseteq V_1$. This entails

$$\phi(x) = \sum_{n\in\Lambda} c_n \phi(\rho(x) + n) \tag{1.3}$$

for some choice of coefficients $\{c_n\}$. Under the Fourier transform, we have

$$\hat{\phi}(\omega) = m_0(\omega)\hat{\phi}(\sigma(\omega)). \tag{1.4}$$

We seek conditions on our "resolution filter" $m_0(\omega)$ such that $\{\tau_n\phi : n \in \Lambda\}$ is an orthonormal set and such that

$$\hat{\phi}(\omega) = m_0(\omega)m_0(\sigma(\omega))m_0(\sigma^2(\omega))\cdots$$

converges to an $L^2(\hat{G})$-function $\hat{\phi}$ such that ϕ (the inverse Fourier transform) produces an MRA. Thus, we seek an analogue of Theorem 2 of [8]. Theorem 2.2 below is an analogue of that theorem for the Cantor dyadic group.

2. The Cantor dyadic group. The Cantor dyadic group is $D = \prod_{n=-\infty}^{-1} Z/(2)$ under the cartesian product topology, where $Z/(2)$ is the integers modulo 2, that is, $\{0,1\}$ with addition modulo 2. We will write an element of D as $(x_j)_{j<0}$, where $x_j \in \{0,1\}$ for each j. We make the index j range over the negative integers, so that we may think of $x = (x_j)_{j<0}$ as $x = 0.x_{-1}x_{-2}x_{-3}\cdots$, a binary fraction expansion. We may thus identify D with the unit interval as a measure space by the map $x \to |x| : D \to [0,1]$, where $|x| = \sum_{j<0} x_j 2^j$. This induces the Haar measure on D.

We will actually work on the locally compact version of the Cantor dyadic group, namely

$$\begin{aligned} G &= \prod_{n=-\infty}^{\infty}{}^{*} Z/(2) \\ &= \{(x_j)_{j\in Z} : x_j \in \{0,1\} \text{ for all } j \text{ and } x_j = 0 \text{ for all } j > n, \text{ for some } n \in Z\}. \end{aligned}$$

(See Chapter 6 of [5].) So we may think of $x = x_n x_{n-1}\cdots x_1 x_0.x_{-1}x_{-2}\cdots$, and we identify G with $[0,\infty)$ as a measure space by $x \to |x| : G \to [0,\infty)$, where $|x| = \sum_{j\in Z} x_j 2^j$. Again, this induces the Haar measure on G.

Note that D is a subgroup of G, so $D = \{x \in G : x_j = 0 \text{ for } j \geq 0\}$.

Let $\Lambda \subseteq G$ be the lattice subgroup $\Lambda = \{x \in G : x_j = 0 \text{ for } j < 0\}$. Thus Λ is countable and closed and $G/\Lambda = D$ is compact. Under the map $x \to |x|$, Λ is identified with the nonnegative integers in the half-line.

We now define the dilation $\rho : G \to G$ by $\rho(x)_j = x_{j-1}$ for $x \in G$. We also define $\sigma : G \to G$ to be $\sigma(x)_j = x_{j+1}$ for $x \in G$. So ρ and σ are topological automorphisms inverse to each other. Let $\Lambda_j = \rho^j(\Lambda)$ for $j > 0$, let $\Lambda_0 = \Lambda$, and let $\Lambda_j = \sigma^j(\Lambda)$ for $j < 0$. It is easy to see that Λ_j/Λ_{j+1} is isomorphic to $Z/(2)$ for all j in Z. Also, if $E \subseteq G$ is Borel, then $m(\rho(E)) = 2m(E)$, where m is the Haar measure.

The Pontryagin dual group $\hat{G}$ of G is topologically isomorphic to G. We may write

$$\hat{G} = \{\omega = (\omega_j)_{j\in Z} : \omega_j \in \{0,1\} \text{ for all } j \text{ and } \omega_j = 0 \text{ for all } j > n \text{ for some } n\}$$

and define $\omega(x) = \prod_{j\in Z}(-1)^{\omega_{-1-j}x_j}$ for $x = (x_j)_j$ in G. This gives $\omega \in G$ as a group character on G. Note the minus sign in the exponent in the subscript of ω, so that the product is actually finite.

We may consider dilation on $\hat{G}$ just as on G; let $\sigma(\omega)_j = \omega_{j+1}$ and $\rho(\omega)_j = \omega_{j-1}$ for $\omega = (\omega_j)_j$ in $\hat{G}$. We find that the character $\rho(\omega)$ evaluated at $x = (x_j)_j$ is equal to ω evaluated at $\rho(x)$, i.e., $\omega \circ \rho = \rho(\omega)$. This is analogous to the situation for characters on the real line; $e^{i(2x)y} = e^{ix(2y)}$. We also find that the integers Λ in $\hat{G}$ (defined just as they are on G) correspond exactly to the set Γ of Λ-periodic characters on G. The Λ-periodic characters on G, where G is identified with the real half-line under $x \to |x|$, turn out to be exactly the Walsh functions.

We will use the notation $W_\omega(x) = \omega(x)$ for $\omega \in \hat{G}$ and $x \in G$. If $\omega \in \Gamma$, then $|\omega|$ is an (ordinary) integer and W_ω is identified with an ordinary Walsh function on the real line. Here we will use the Paley enumeration; if we let $r_k(x) = \text{sign}(\sin(2\pi 2^k x))$ be the kth Rademacher function, then the Walsh function W_n is the product of the functions r_k such that the kth bit in the binary expansion of n is a 1. (Note that the least significant bit of the binary expansion of an integer occupies position zero. Thus W_1 is the function constantly equal to 1 on the interval $0 \leq x < 1/2$ and constantly equal to -1 on $1/2 < x < 1$.)

We will also use the notation $W_x(\omega) = \omega(x)$ for $x \in G$ and $\omega \in \hat{G}$ to write characters on $\hat{G}$; by Pontryagin duality, all characters on $\hat{G}$ arise in this way.

It will be convenient to write for both G and $\hat{G}$ specific elements as binary expansions. Thus, for example, by $x = 11.1$ in G, we mean the element $x = (x_j)_j$ such that $x_j = 1$ for $j = 1, 0, -1$ and $x_j = 0$ otherwise.

See [3], [10], or [11] for development of the harmonic analysis of these groups. In [11], the locally compact group G is an example of a local field, the 2-series field; in [10, Chap. 9], G is treated under the name "dyadic field."

For the Cantor dyadic group, we give a regularity condition similar to that of [8]. (Also compare Definition 2 of §II.2 in [9]; we of course do not give a definition involving bounds on the derivative since the Cantor dyadic group has no derivative per se.)

DEFINITION 2.1. *$g \in L^2(G)$ is said to be* regular *if $|g(x)| \leq c(1+|x|)^{-2}$ for all $x \in G$, for some constant $c > 0$. (Recall $|x| = \sum_{j\in Z} x_j 2^j$ for $x \in G$.)*

We also define $\Delta_k = \{\omega \in \hat{G} : \omega_j = 0 \text{ for } j \geq k\}$. (This is analogous to the interval $-2^k\pi \leq \omega \leq 2^k\pi$ in Lemma 2 of [8].)

We may now state our analogue of Theorem 2 of [8].

THEOREM 2.2. *Let $m_0(\omega) = \sum_{n\in\Lambda} h_n W_n(\omega)$ be such that*
(2.2.1) $|h_n| = O(1+|n|^{2+\epsilon})^{-1}$ *for some* $\epsilon > 0$,
(2.2.2) $m_0(0) = 1$,
(2.2.3) $M(\omega) + M(\omega + 0.1) \equiv 1$, *where* $M(\omega) = |m_0(\omega)|^2$,
(2.2.4) $m_0(\omega) \neq 0$ *on* Δ_{-1}.

Define $\hat{\phi}(\omega) = \prod_{k=1}^{\infty} m_0(\sigma^k(\omega))$. Then the function $\hat{\phi}(\omega)$ is an $L^2(\hat{G})$-function. The inverse Fourier transform $\phi(x)$ of $\hat{\phi}(\omega)$ has the property that $\{\tau_n\phi : n \in \Lambda\}$ is an orthonormal basis for a closed subspace V_0 of $L^2(G)$. If ϕ is regular, then a regular MRA $(V_j)_{j\in Z}$ is produced.

The proof of this proceeds essentially as in [8], suitably translated, via analogues of Lemma 1 and Lemma 2 of [8].

3. Wavelets on LCA groups. We return now to the general situation of §1. Suppose we have an MRA $(V_j)_{j\in Z}$ of $L^2(G)$. We shall show how orthogonal wavelets may be constructed from this MRA. (This will be very similar to [8] or [9, Chap. III, §2]. We will also present examples of MRAs and orthogonal wavelets on various groups.

We know that $V_j \subseteq V_{j+1}$ for all j. So, let W_j be the orthogonal complement of V_j in V_{j+1}, so $V_j \oplus W_j = V_{j+1}$. Let ϕ be the "father wavelet," whose translates span V_0. We seek ψ, whose translates span W_0 and are orthogonal, such that the translates of ψ are orthogonal to the translates of ϕ. Now ϕ and ψ belong to V_1, so

$$\phi(x) = \sum_{n\in\Lambda} a_n \phi(\rho(x)+n) \quad \text{and} \quad \psi(x) = \sum_{n\in\Lambda} b_n \phi(\rho(x)+n).$$

Upon taking Fourier transforms, we find

$$\hat{\phi}(\omega) = m_0(\omega)\hat{\phi}(\sigma(\omega)) \quad \text{and} \quad \hat{\psi}(\omega) = m_1(\omega)\hat{\phi}(\sigma(\omega)),$$

where

$$m_0(\omega) = \sum_{n\in\Lambda} \tfrac{1}{2} a_n \omega(\sigma(n)) \quad \text{and} \quad m_1(\omega) = \sum_{n\in\Lambda} \tfrac{1}{2} b_n \omega(\sigma(n)).$$

We may show that ψ and ϕ obey the desired orthogonality conditions when

$$\begin{bmatrix} m_0(\omega) & m_1(\omega) \\ m_0(\omega+\theta) & m_1(\omega+\theta) \end{bmatrix}$$

is a unitary matrix, where θ is an odd Λ-periodic character, i.e., θ is not Λ_{-1}-periodic.

To make this matrix unitary, it is enough to let $m_1(\omega) = W(\omega)\overline{m_0(\omega+\theta)}$, where $W(\omega) = \omega(k)$ for some $k \in \Lambda_{-1} \setminus \Lambda_0$ (k is a "half integer").

Taking inverse Fourier transforms of

$$\hat{\psi}(\omega) = W(\omega)\overline{m_0(\omega+\theta)\hat{\phi}(\sigma(\omega))},$$

we obtain

$$\psi(x) = \sum_{n\in\Lambda} (-1)^{\operatorname{sgn}(n)} \overline{a_{\overline{n}}} \phi(\rho(x) - n - \rho(k)), \tag{3.1}$$

where $\operatorname{sgn}(n) = 1$ if n is even (i.e., $n \in \Lambda_1$) or -1 if n is odd ($n \in \Lambda \setminus \Lambda_1$).

It now becomes clear (as in the usual case) that

$$\{2^{j/2}\psi(\rho^j(x) - n) : n \in \Lambda, j \in Z\}$$

is an orthogonal system of wavelets, for the MRA $(V_j)_{j\in Z}$.

Example 1. If we let $G = R$, $\Lambda = Z$, and $\rho(x) = 2x$, we find that (3.1) becomes equation (3.8) [9, Chap. III, §2].

Example 2. For G the locally compact Cantor group, (3.1) may be written

$$\psi(x) = \sum_{n\in\Lambda} \overline{a_n}(-1)^{|n|}\phi(\rho(x) + n + 1.0). \tag{3.2}$$

If we set $\phi(x) = 1_I(x)$, where I is the "unit" interval in G given by $I = \{x \in G : x_j = 0 \text{ for all } j \geq 0\}$, we find that $\phi(\sigma(x)) = \phi(x) + \phi(x + 1.0)$. Then our wavelet is

$$\psi(x) = \phi(\rho(x) + 1.0) - \phi(\rho(x)),$$

which is, of course, the Haar wavelet (when G is identified with the half-line under the mapping $x \to |x|$). Note that the multiresolution analysis here can be described without reference to the dual group as

$$V_j = \{f \in L^2(G) : f \text{ is constant on cosets of } D_j\ \},$$

where D_j is the subgroup of G consisting of all $x \in G$ such that $x_i = 0$ for $i \geq j$.

Example 3. We construct a different example of wavelets on the Cantor dyadic group by defining the scaling filter

$$m_0(\omega) = \begin{cases} 1 & \text{if } \omega_{-1} = \omega_{-2} = 0, \\ a & \text{if } \omega_{-1} = 0 \text{ and } \omega_{-2} = 1, \\ 0 & \text{if } \omega_{-1} = 1 \text{ and } \omega_{-2} = 0, \\ b & \text{if } \omega_{-1} = \omega_{-2} = 1, \end{cases}$$

where $|a|^2 + |b|^2 = 1$.

This filter is actually the Walsh-trigonometric polynomial

$$m_0 = c_0W_{00.0} + c_1W_{01.0} + c_2W_{10.0} + c_3W_{11.0},$$

where $c_0 = (1+a+b)/4$, $c_1 = (1+a-b)/4$, $c_2 = (1-a-b)/4$, and $c_3 = (1-a+b)/4$.

It is easy to see that the hypotheses of Theorem 2.2 are met. Wavelets corresponding to the compactly supported orthogonal wavelets of I. Daubechies result; in fact, we find that

$$\begin{aligned}\hat{\phi}(\omega) &= m_0(\sigma(\omega))m_0(\sigma^2(\omega))m_0(\sigma^3(\omega))\cdots \\ &= f(\omega) + af(0.1 + \omega) + abf(1.1 + \omega) + ab^2f(11.1 + \omega) + ab^3f(111.1 + \omega) + \cdots\end{aligned}$$

where $f = \chi_{\Delta_{-1}}$.

So the scaling function becomes a lacunary Walsh series

$$\phi(x) = \tfrac{1}{2}F(x)(1 + aW_{0.1}(x) + abW_{1.1}(x) + ab^2W_{11.1}(x) + ab^3W_{111.1}(x) + \cdots),$$

where $F = \chi_{\Delta_1}$. If we identify G with the real half-line, we get the literal Walsh function series

$$\phi(x) = \tfrac{1}{2}\chi_{[0,1)}(x/2)\left(1 + aW_1(x/2) + abW_3(x/2) + ab^2W_7(x/2) + ab^3W_{15}(x/2) + \cdots\right)$$

for $x \geq 0$.

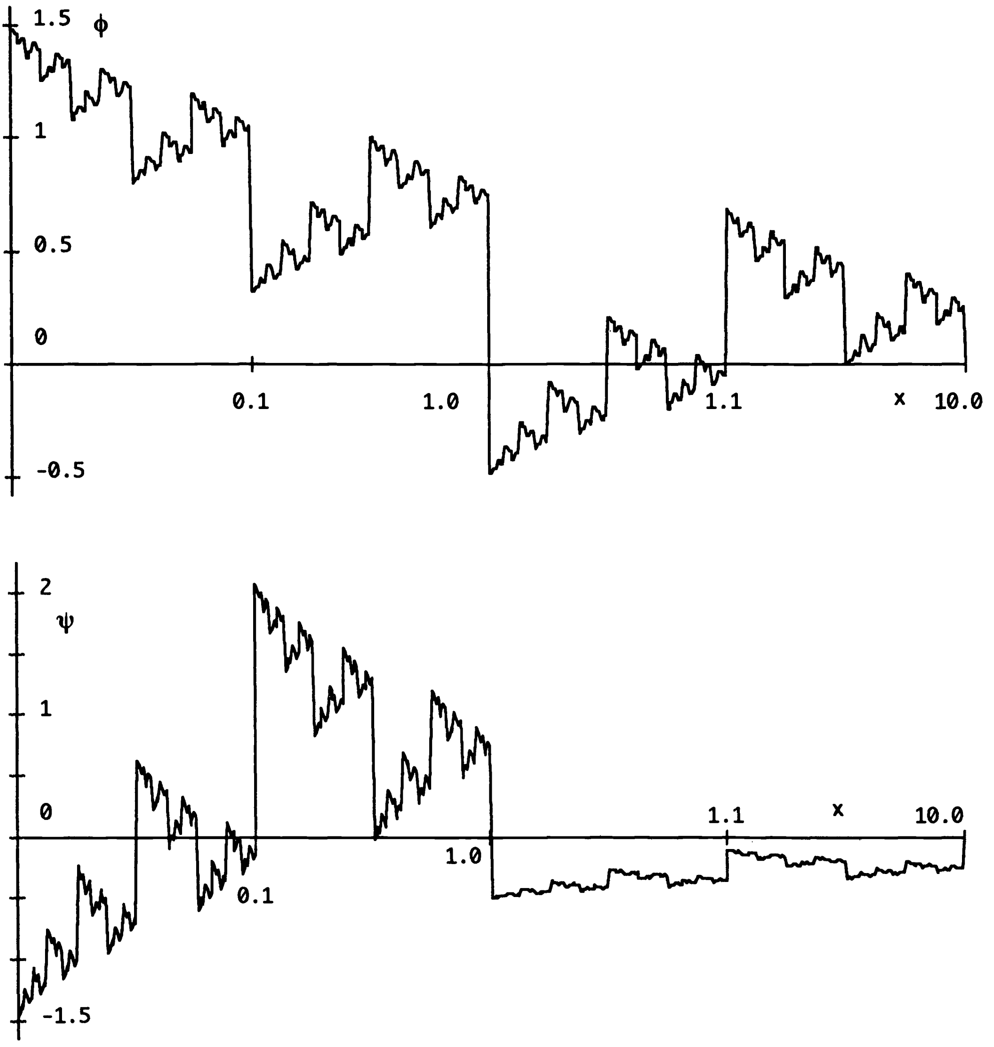

FIG. 1. *The dyadic scaling function ϕ of example* 3 (*top*) *and the corresponding dyadic wavelet ψ* (*bottom*), *with a set equal to* 0.8. *The horizontal axis is the group G identified as the half real line*; *as functions on the real line, ϕ and ψ have discontinuities at dyadic rational points, indicated here in binary notation.* (*These plottings were generated using Maple* V.)

Note that if $a = 1$ and $b = 0$, we recover the Haar scaling function $\phi(x) = \chi_{[0,1]}$. Plottings of these scaling functions for certain values of a are given in Figs. 1 and 2.

The corresponding wavelet ψ is given by (3.2) as in Example 2. Viewed as a function on the real half-line, we may write

$$\psi(x) = 2\bar{a}_0\phi(T_1(2x)) - 2\bar{a}_1\phi(2x) + 2\bar{a}_2\phi(T_3(2x)) - 2\bar{a}_3\phi(T_2(2x)),$$

where T_n is the function representing translation by n in the sense of the group G. (So the jth digit of the binary expansion of $T_n(x)$ is the sum modulo 2 of the jth binary digits of n and x. Thus, for example, $T_1(x)$ equals $x - 1$ if $j \leq x < j + 1$ for odd j and $T_1(x)$ equals $x + 1$ if $j \leq x < j + 1$ for even j.)

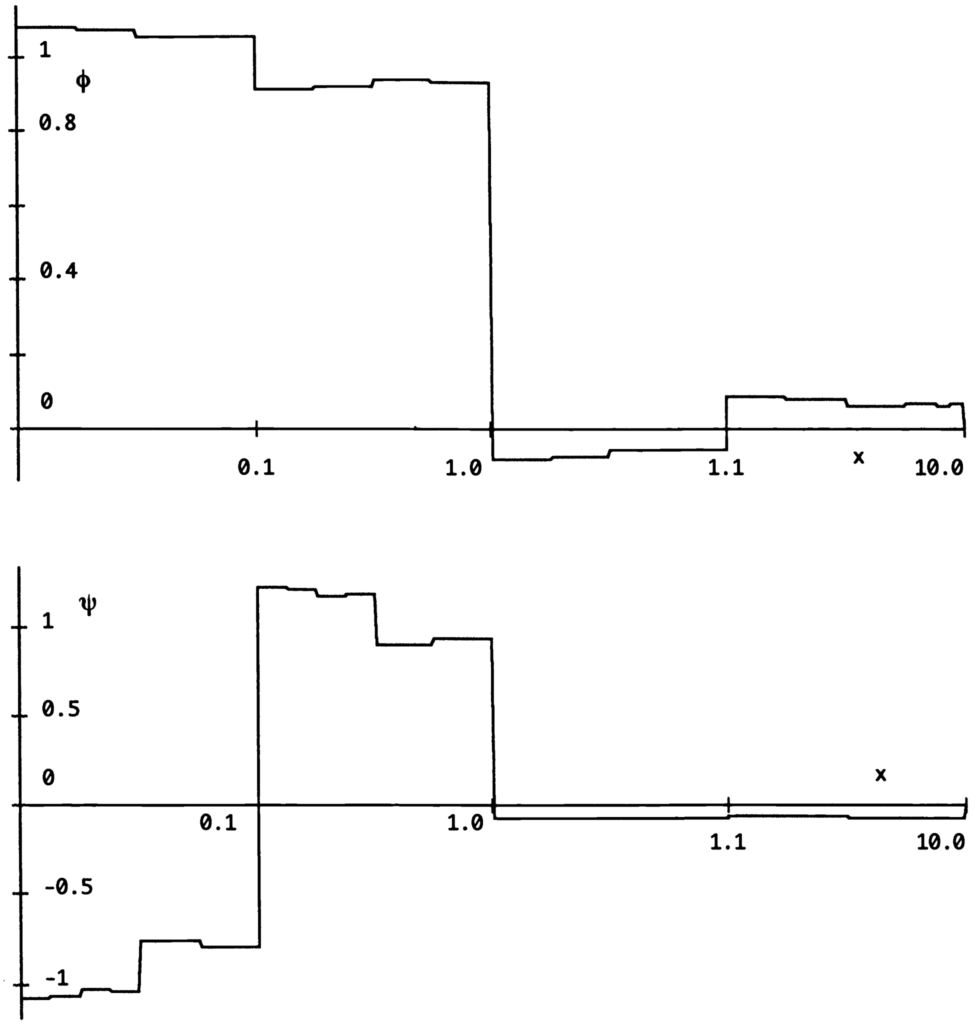

FIG. 2. *The dyadic scaling function ϕ of example* 3 (*top*) *and the corresponding dyadic wavelet* ψ (*bottom*), *with a set equal to* 0.99. *Note that for a close to* 1, *these should approach the Haar scaling function and wavelet.* (*These plottings were generated using Maple* V).

Plottings of these wavelets are given below for certain values of a; for a close to 1, the wavelet approaches the Haar wavelet.

Example 4. Our axioms (1.1.1)–(1.1.5) for dilations and translation appear to be (in some sense) one-dimensional. However, wavelets based on these axioms can be constructed on the plane or on R^n. See [4] for remarkable examples of wavelets on the plane or on R^2 based upon "matrix dilations". Their examples include the following:

Let $G = R^2$, $\Lambda = Z^2$ and $\rho(x, y) = (y, 2x)$; this choice of G, Λ, and ρ meet all the axioms. Let ϕ to be the indicator function of the unit square $0 \leq x \leq 1$, $0 \leq y \leq 1$, so

$$\phi((x, y)) = \phi(\rho(x, y) - (0, 1)) + \phi(\rho(x, y))$$

and ϕ generates an MRA of $L^2(R^2)$ as above. The "mother wavelet" ψ is then

$$\psi(x,y) = \phi(\rho(x,y) - (1,0)) - \phi(\rho(x,y))$$
$$= \begin{cases} 1 & \text{if } \frac{1}{2} < x \leq 1, 0 \leq y \leq 1, \\ -1 & \text{if } 0 \leq x \leq \frac{1}{2}, 0 \leq y \leq 1, \\ 0 & \text{otherwise.} \end{cases}$$

Of course, the axioms for dilation need not be dyadic on R^n. In fact, there may be a system of more than one mother wavelet in more general constructions; see [1].

4. Conclusions. We note that the results of this paper bear generalization in a number of ways.

We may seek to construct wavelets on other groups of this sort, such as Vilenkin groups (compact zero-dimensional Abelian metric groups), or on local fields. This presumably would require different frameworks for orthogonal wavelets; the structure of the group as well as the structure of its group of automorphisms would determine the possibilities, and we need not limit ourselves to the dyadic dilation of our axioms here.

We also anticipate that our results for the Cantor dyadic group may be strengthened to provide wavelet bases for spaces beyond $L^2(G)$. For example, [3] already provides a Littlewood–Paley theorem for the Cantor dyadic group (as well as a variety of other groups), suggesting that our wavelets might be a basis for $L^p(G)$ for $p > 1$.

Acknowledgments. I wish to express my thanks for the helpful suggestions and comments of the referee, in particular for the observation at the end of Example 2 of §3.

ON L_p-THEORY OF STOCHASTIC PARTIAL DIFFERENTIAL EQUATIONS IN THE WHOLE SPACE*

N. V. KRYLOV†

Abstract. It is shown that equations like

$$du = (a^{ij}u_{x^ix^j} + b^iu_{x^i} + cu + f)\,dt + (\sigma^{ik}u_{x^i} + \nu^k u + g^k)\,dw_t^k, \quad t > 0,$$

with variable random coefficients and with zero initial condition have unique solutions in the Sobolev spaces W_p^2, $p \in [2, \infty)$, under natural ellipticity condition and under conditions that (i) a is uniformly continuous with respect to x, (ii) σ, ν have bounded first derivatives in x and all other coefficients are bounded, (iii) $f \in L_p$, $g \in W_p^1$. A corresponding result in the spaces of Bessel potentials H_p^n is proved, which implies that better differentiability properties of the coefficients and free terms of the equations lead to the better regularity of solutions. Applications to equations with space–time white noise are given.

Key words. stochastic equations, Bessel potentials, cylindrical white noise

AMS subject classifications. 60H15, 35R60

1. Introduction.

Evolutional stochastic partial differential equations (SPDEs) arise in many applications of probability theory and have been treated since long ago (see [14]). An example of a linear second-order SPDE is given by the following equation:

$$(1.1)\qquad du = (a^{ij}u_{x^ix^j} + b^iu_{x^i} + cu + f)\,dt + (\sigma^{ik}u_{x^i} + \nu^k u + g^k)\,dw_t^k, \quad t > 0.$$

The main purpose of this article is to develop a theory of solvability of the Cauchy problem for linear and some quasi-linear equations like (1.1) in spaces of summable functions with exponent of summability $p \geq 2$. If $p = 2$, so that we are concerned with solutions belonging to the Sobolev spaces $W_2^n(\mathbb{R}^d)$, such a theory does exist and is rather complete and satisfactory (see, for instance, [14]). Some results concerning the solvability of the first boundary-value problem in spaces like $W_2^n(D)$, where D is a smooth domain, can be found in [10] and [13]. Roughly speaking, the main tool in W_2^n-theory is integration by parts. There are also approaches based on semigroup methods [2], which work well for the equations with nonrandom leading coefficients and again in the Hilbert-space framework.

One of inconveniences of W_2^n-theory is that $W_2^n(\mathbb{R}^d) \subset C^{n-d/2}(\mathbb{R}^d)$ only if $2n > d$, and one can prove that the solutions belong to $W_2^n(\mathbb{R}^d)$ only if the coefficients are $n-2$ times continuously differentiable. Therefore, if we want to get the solutions m times continuously differentiable with respect to $x \in \mathbb{R}^d$, we have to suppose that the coefficients of the equation are more than $m + d/2 - 2$ times continuously differentiable even if the free terms are of class $C_0^\infty(\mathbb{R}^d)$. At the same time, $W_p^n(\mathbb{R}^d) \subset C^{n-d/p}(\mathbb{R}^d)$ if $pn > d$, and by taking p sufficiently large, one sees that the solutions have almost as many usual derivatives as generalized ones. Actually, exactly for this purpose the spaces $W_p^n(\mathbb{R}^d)$ with $p \geq 2$ have already been used in SPDE theory (see, for instance [14]), but the corresponding results obtained again by integration by parts were not sharp.

Another advantage of the W_p^n setting with $p \geq 2$ can be seen in the case of very popular equations with so-called cylindrical white noise (see, for instance, [15], [16],

* Received by the editors February 16, 1994; accepted for publication (in revised form) August 8, 1994. This research was partially supported by National Science Foundation grant DMS-9302516.

† School of Mathematics, University of Minnesota, Minneapolis, MN 55455.

[19], and references therein). Although these equations can be included in the general W_p^n-theory as particular examples for any $p \geq 2$ (see §4), for $p = 2$ we get only the solutions summable to any degree, and the solutions become continuous only for $p > 2$. By the way, as in [14] we consider n positive and negative, but in contrast with [14] we allow noninteger values for n. For general n we are working in the spaces of Bessel potentials $H_p^n(\mathbb{R}^d)$, and in the case of equations with cylindrical white noise, we take n slightly less than $(-3/2)$.

Our main tool is the theory of spaces $H_p^n(\mathbb{R}^d)$, borrowed from [17], together with a result from [9] which is an analog of the so-called maximal regularity property of stochastic convolutions in Hilbert spaces obtained by Da Prato (cf. [1]).

The article is organized as follows: In §2 we investigate equations with constant coefficients, which not only leads us to a class of equations which can be treated but also allows us to find a Banach space $\mathcal{H}_p^n(T)$ in which equations with variable coefficients make perfect sense. These spaces play the same role as spaces $W_p^{1,2}$ in the theory of parabolic second-order PDEs, and their properties, stated in §3, present one part of our main results. Section 3 also contains other main results, two of which are proved in §5. In §4 we consider an application of our main results to equations with cylindrical white noise. In particular, we obtain an existence theorem which extends corresponding known results (see [19]) to equations with random and variable coefficients. We also give a short proof of a generalization of a result from [15] concerning the nonexplosion of solutions of a nonlinear SPDE.

We finish the section by introducing several notations to be used throughout the paper.

Let $(\Omega, \mathcal{F}, P)$ be a complete probability space, $(\mathcal{F}_t, t \geq 0)$ be an increasing filtration of σ-algebras $\mathcal{F}_t \subset \mathcal{F}$ containing all P-null subsets of Ω, and $\mathcal{P}$ be the predictable σ-field related to $(\mathcal{F}_t, t \geq 0)$.

We fix a separable Hilbert space H. By using a well-known procedure, we identify the space of all bounded linear functionals on H with H. We also fix numbers $p \geq 2$, $K, \delta > 0$, and an integer $d \geq 1$.

Let w be an H-valued $\mathcal{F}_t$-adapted Wiener process with covariance operator $\mathbb{Q}$. Define E as the set of all real-valued linear functions e on $\mathbb{Q}^{1/2}H$ such that $|e|_E := |e\mathbb{Q}^{1/2}|_H < \infty$. Obviously, E is a Hilbert space.

Denote $L_p = L_p(\mathbb{R}^d)$, $||\cdot||_p = ||\cdot||_{L_p}$. In the case of functions $g = g(x)$ taking values in E, we write

$$||g||_p := ||\,|g|_E||_p.$$

We will need the spaces of Bessel potentials (also called the Sobolev spaces with fractional derivatives) $H_p^n = H_p^n(\mathbb{R}^d)$ for all values of $n \in (-\infty, \infty)$. We recall (see, for instance [17]) that for integers $n \geq 0$ the space H_p^n coincides with the Sobolev space $W_p^n = W_p^n(\mathbb{R}^d)$, and in general H_p^n is the closure of $C_0^\infty = C_0^\infty(\mathbb{R}^d)$ with respect to the norm

$$||u||_{n,p} := ||(I - \Delta)^{n/2}u||_p.$$

Observe that by definition the set C_0^∞ is dense in H_p^n and by Theorem 2.3 (ii) of [17] the latter is a subset of the space $\mathcal{D}$ of real-valued Schwartz distributions on $\mathbb{R}^d$ defined on C_0^∞. It is also useful to note that $||\cdot||_{n,p} \leq ||\cdot||_{m,p}$ for $m \geq n$. We apply the same definitions to E-valued functions g, specifically,

$$||g||_{n,p} := ||\,|(I - \Delta)^{n/2}g|_E||_p.$$

Finally, for a stopping time τ, we denote $(\!(0,\tau]\!] = \{(\omega,t) : 0 < t \leq \tau(\omega)\}$,

$$\mathbb{H}^n_p(\tau) = L_p((\!(0,\tau]\!], \mathcal{P}, H^n_p), \ \ \mathbb{H}^n_p = \mathbb{H}^n_p(\infty),$$

$$\mathbb{H}^n_p(\tau, E) = L_p((\!(0,\tau]\!], \mathcal{P}, H^n_p(\mathbb{R}^d, E)), \ \ \mathbb{H}^n_p(E) = \mathbb{H}^n_p(\infty, E), \ \ \mathbb{L}_{\dots}\dots = \mathbb{H}^0_{\dots}\dots .$$

The norms in these spaces are defined in an obvious way. As is conventional, elements of spaces like $\mathbb{H}^n_p$ are treated as functions rather than distributions or classes of equivalent functions, and if we know that a function of this class has a modification with better properties, then we always consider this modification. For instance, if we take $u \in H^n_p$ and $n - d/p > 0$, then u has a bounded continuous modification, but we talk about $\sup_x u(x)$ instead of sup of this modification.

2. Equations with coefficients independent of x. In this section, we consider equation (1.1) when $b^i = c = \nu^k = 0$ and the coefficients a and σ do not depend on x. Throughout the section, we fix real-valued functions $a^{ij}(t)$ and E-valued functions $\sigma^i(t)$ defined for $i, j = 1, \dots, d$ on $\Omega \times (0, \infty)$. Define

$$\alpha^{ij}(t) = \frac{1}{2}(\sigma^i(t), \sigma^j(t))_E$$

and assume that a and σ are $\mathcal{P}$-measurable functions, and in the matrix sense

$$(a^{ij}) = (a^{ij})^*, \ \ K(\delta^{ij}) \geq (a^{ij}) \geq (a^{ij} - \alpha^{ij}) \geq \delta(\delta^{ij}).$$

More precisely, our goal in this section is to investigate the equation

(2.1)
$$du(t,x) = (a^{ij}(t)u_{x^ix^j}(t,x) + f(t,x))\,dt + (\sigma^i(t)u_{x^i}(t,x) + g(t,x))\,dw_t, \ \ t > 0.$$

DEFINITION 2.1. *Denote by $\mathfrak{D}$ the set of all $\mathcal{D}$-valued functions u (written as $u(t,x)$ in a common abuse of notation) on $\Omega \times [0,\infty)$ such that for any $\phi \in C_0^\infty$,*

(i) *the function (u,ϕ) is $\mathcal{P}$-measurable,*

(ii) *for any $\omega \in \Omega$ and $T \in (0,\infty)$ we have*

$$\int_0^T \sup_{x\in\mathbb{R}^d} |(u(t,x+\cdot),\phi)|^2\,dt < \infty. \tag{2.2}$$

In the same way, we define $\mathcal{D}(E)$ and $\mathfrak{D}(E)$ by considering E-valued linear functionals on C_0^∞ (or bilinear forms $(u,\phi)(h)$, $\phi \in C_0^\infty$, $h \in \mathbb{Q}^{1/2}H$) and replacing $|\cdot|$ in (2.2) by $|\cdot|_E$.

DEFINITION 2.2. *Let $f, u \in \mathfrak{D}$, $g \in \mathfrak{D}(E)$. We say that the equality*

$$du(t,x) = f(t,x)\,dt + g(t,x)\,dw_t, \ \ t > 0 \tag{2.3}$$

holds in the sense of distributions if for any $\phi \in C_0^\infty$, with probability 1 we have

$$(u(t,\cdot),\phi) = (u(0,\cdot),\phi) + \int_0^t (f(s,\cdot),\phi)\,ds + \int_0^t (g(s,\cdot),\phi)\,dw_s \tag{2.4}$$

for all $t \geq 0$, where the last stochastic integral is understood as an Itô stochastic integral of the E-valued function $(g(s,\cdot),\phi)$ with respect to w_s.

We will understand equation (2.1) in the sense of distributions. We start with the following simple statement related to Definition 2.2.

LEMMA 2.1. *Let $f, u \in \mathfrak{D}$, $g \in \mathfrak{D}(E)$. Define*

$$x_t = \int_0^t \sigma(s)\, dw_s.$$

Then equality (2.3) *holds (in the sense of distributions) if and only if (in the sense of distributions) for the function $v(t,x) = u(t, x - x_t)$, we have*

$$dv(t,x) = [f(t, x - x_t) + a^{ij}(t) v_{x^i x^j}(t,x) - (g_{x^i}(t, x - x_t), \sigma^i(t))_E]\, dt$$

$$+ [g(t, x - x_t) - v_{x^i}(t,x)\sigma^i(t)]\, dw_t, \quad t > 0.$$

Proof. First notice that obviously $v(t,x)$, $f(t, x - x_t)$, and $(g_{x^i}(t, x - x_t), \sigma^i(t))_E$ belong to $\mathfrak{D}$ and $g(t, x - x_t)$ $v_{x^i}(t,x)\sigma^i(t)$ belong to $\mathfrak{D}(E)$. Furthermore, for any $\phi \in C_0^\infty$ the function $(u(t, x + \cdot), \phi)$ has a stochastic differential in t for any x and is infinitely differentiable with respect to x. Now our assertion immediately follows from the Itô–Wentzell formula. The lemma is proven. □

LEMMA 2.2. *Let $f \in \mathfrak{D}$, $g \in \mathfrak{D}(E)$, u_0 be a $\mathcal{D}$-valued function on Ω. Then the following assertions hold.*

(i) *In $\mathfrak{D}$ there can exist only one (up to evanescence) solution of equation* (2.1) *with the initial condition $u(0, \cdot) = u_0$.*

(ii) *Let $u \in \mathfrak{D}$ satisfy equation* (2.1) *(in the sense of distributions). Let $\{\mathcal{G}_t, t \geq 0\}$ be an increasing family of σ-fields $\mathcal{G}_t \subset \mathcal{F}_t$ and assume that $w_t = w_t^{(1)} + w_t^{(2)}$, where $w^{(i)}$ are Wiener processes such that $w^{(1)}$ is $(\mathcal{G}_t)$-adapted and the process $w^{(2)}$ is independent of $(\mathcal{G}_t)$. Assume that the processes a, f, σ, and g are $\mathcal{G}_t$-adapted, and that there exists an $n \in (-\infty, \infty)$ such that $f \in \mathbb{H}_2^n(T)$, $g \in \mathbb{H}_2^n(T, E)$ for any $T \in (0, \infty)$ and*

$$E\|u(0, \cdot)\|_{n,2}^2 < \infty.$$

Then the function $\tilde{u}(t,x) := E\{u(t,x)|\mathcal{G}_t\}$ is a solution of the equation

$$d\tilde{u} = (a^{ij}\tilde{u}_{x^i x^j} + f)\, dt + (\sigma^i \tilde{u}_{x^i} + g)\, dw_t^{(1)}, \quad t > 0. \tag{2.5}$$

Proof. (i) As always we can take $f \equiv 0, g \equiv 0$, and $u_0 \equiv 0$, and by Lemma 2.1, it suffices to consider only the case $\sigma \equiv 0$. But then we are left with a parabolic equation with coefficients independent of x, and the uniqueness of its solution in our class of functions is a standard fact.

(ii) Actually, the statement means that there exists a solution $\tilde{u}$ of equation (2.5) such that for any $\phi \in C_0^\infty$ and $t \geq 0$,

$$(\tilde{u}(t, \cdot), \phi) = E\{(u(t, \cdot), \phi)|\mathcal{G}_t\} \quad \text{(a.s.)}.$$

To prove this version of our statement, we first notice that, according to [14], equation (2.1) has a unique solution v in the space $\mathbb{H}_2^{n+1}(T)$ for any T. Moreover, v is continuous (a.s.) as an H_2^n-valued process and

$$E \sup_{t \leq T} \|v(t, \cdot)\|_{n,2}^2 < \infty \quad \forall T < \infty, \tag{2.6}$$

so that v is a $\mathfrak{D}$-solution of (2.1). From (i), it follows that our function u belongs to $\mathbb{H}_2^{n+1}(T)$ for any T, and (2.6) holds for u. Furthermore, in the sense of the Hilbert space H_2^{n-1} with probability 1 for all t at once,

$$u(t) = u_0 + \int_0^t [a^{ij}(s)u_{x^ix^j}(s) + f(s)]\,ds + \int_0^t [\sigma^i(s)u_{x^i}(s) + g(s)]\,dw_s.$$

By Theorem 1.4.7 of [14], or rather by its Hilbert-space counterpart, there exists an H_2^n-valued, $\mathcal{G}_t$-predictable function $\bar{u}(t)$ such that for almost any t we have $\bar{u}(t) = E\{u(t)|\mathcal{G}_t\}$ (a.s.) and

$$\bar{u}(t) = u_0 + \int_0^t [a^{ij}(s)\bar{u}_{x^ix^j}(s) + f(s)]\,ds + \int_0^t [\sigma^i(s)\bar{u}_{x^i}(s) + g(s)]\,dw_s^{(1)} \tag{2.7}$$

for almost all t and ω. The right-hand side here is a continuous H_2^{n-1}-valued process; therefore, we can and will take $\bar{u}(t)$ to be a continuous process in H_2^{n-1}. We denote this version of $\bar{u}(t)$ by $\tilde{u}(t)$, and we show that $\tilde{u}$ is the function we need.

By construction, $\tilde{u} \in \mathfrak{D}$ and $\tilde{u}$ is a solution of (2.5). It remains only to observe that, again by [14, Thm. 1.4.7], for any t the expression $E\{u(t)|\mathcal{G}_t\}$ can be represented by the right-hand side of (2.7) almost surely. The lemma is proven. □

THEOREM 2.1. *Take $n \in \mathbb{R}$ and let $f \in \mathbb{H}_p^{n-1}$, $g \in \mathbb{H}_p^n(E)$. Then*

(i) *equation* (2.1) *with zero initial condition has a (unique) solution*

$$u \in \bigcap_T \mathbb{H}_p^{n+1}(T);$$

(ii) *for this solution, we have $u \in C((0,\infty), H_p^n)$ almost surely, and*

$$||u_{xx}||_{\mathbb{H}_p^{n-1}} \le N(d,n,p,\delta,K)(||f||_{\mathbb{H}_p^{n-1}} + ||g||_{\mathbb{H}_p^n(E)}); \tag{2.8}$$

(iii) *for any $\lambda, t > 0$,*

$$E\sup_{s\le t}(e^{-p\lambda s}||u(s,\cdot)||_{n,p}^p) \le N(||e^{-\lambda s}f||_{\mathbb{H}_p^{n-1}(t)}^p + ||e^{-\lambda s}g||_{\mathbb{H}_p^n(t,E)}^p), \tag{2.9}$$

where $N = N(d,p,\delta,K,\lambda)$.

To prove the theorem, we will invoke two lemmas. The first of them is the first main result of [9]. Take an $\mathbb{R}^d$-valued (standard) Wiener process B_t and define

$$T_t h(x) = Eh(x + B_t).$$

LEMMA 2.3. *Let $-\infty \le a < b \le \infty$, $g \in L_p((a,b) \times \mathbb{R}^d, E)$. Then*

$$\int_{\mathbb{R}^d}\int_a^b \left[\int_a^t |\nabla T_{t-s}g(s,\cdot)(x)|_E^2\,ds\right]^{p/2} dt\,dx \le N\int_{\mathbb{R}^d}\int_a^b |g(t,x)|_E^p\,dt\,dx,$$

where the constant N depends only on d and p.

LEMMA 2.4. *Let $\sigma^k \equiv 0, a^{ij} \equiv (1/2)\delta^{ij}$, $n = 0$. Then the assertions of Theorem* 2.1 *hold true. Moreover,*

(iii)$'$ *for any $\lambda, t > 0$, we have*

$$E\sup_{s\le t}(e^{-p\lambda s}||u(s,\cdot)||_p^p) + E\int_0^t e^{-p\lambda s}||\,|u|^{(p-2)/p}|u_x|^{2/p}(s,\cdot)||_p^p\,ds$$

$$\leq N(d,p,\delta,K,\lambda)(||e^{-\lambda s}f||^p_{\mathbb{H}^{-1}_p(t)} + ||e^{-\lambda s}g||^p_{\mathbb{L}_p(t,E)}). \tag{2.10}$$

Proof. It is well known that there exists a continuous linear operator

$$P : H^{-1}_p \to (L_p)^{d+1}$$

such that if $h \in H^{-1}_p$ and $Ph = (h_0, \tilde{h}^1, \dots, \tilde{h}^d)$, then $h = h_0 + \operatorname{div}\tilde{h}$ and

$$||\tilde{h}||_p + ||h_0||_p \leq N(d,p)||h||_{-1,p}. \tag{2.11}$$

Actually, one can take $\tilde{h} = -\operatorname{grad}(1-\Delta)^{-1}h$ and $h_0 = h - \operatorname{div}\tilde{h}$.

Define $(f_0, \tilde{f}) = Pf$. Then equation (2.1) takes the form

$$du = \left(\frac{1}{2}\Delta u + f_0 + \operatorname{div}\tilde{f}\right) dt + g\, dw_t \tag{2.12}$$

and we supply it with zero initial condition. We will prove that for arbitrary $f_0, \tilde{f}^i \in \mathbb{L}_p$, assertions (i), (ii) (with $n = 0$), and (iii)$'$ hold for (2.12) in place of (2.1). Of course, in (2.8) and (2.10) we take $f = f_0 + \operatorname{div}\tilde{f}$.

We can certainly confine ourselves to the case in which

$$f_0(t,x) = \sum_{i=1}^m I_{(\tau_{i-1},\tau_i]}(t) f_{0i}(x), \quad \tilde{f}(t,x) = \sum_{i=1}^m I_{(\tau_{i-1},\tau_i]}(t)\tilde{f}_i(x),$$

$$g(t,x) = \sum_{j=1}^m g^j(t,x)h_j, \quad g^j(t,x) = \sum_i^m I_{(\tau_{i-1},\tau_i]}(t) g_{ij}(x), \tag{2.13}$$

where (h_j) is an orthonormal basis in H of eigenvectors of $\mathbb{Q}$, $m < \infty$, τ_i are bounded stopping times, $\tau_{i-1} \leq \tau_i$, and $f_{0i}, \tilde{f}_i, g_{ij} \in C^\infty_0$.

Set $w^j_t = (h_j, w_t)_H$,

$$v(t,x) = \int_0^t g(s,x)\, dw_s = \sum_{i,j=1}^m g_{ij}(x)(w^j_{t\wedge\tau_i} - w^j_{t\wedge\tau_{i-1}}),$$

$$u(t,x) = v(t,x) + \int_0^t T_{t-s}\left[\frac{1}{2}\Delta v + f\right](s,\cdot)(x)\, ds, \quad \forall t \geq 0.$$

As easy to see the function $u - v$ is infinitely differentiable in (t,x) and satisfies the equation

$$\frac{\partial z}{\partial t} = \frac{1}{2}\Delta z + \frac{1}{2}\Delta v + f.$$

It follows that for any x the function $u(t,x)$ satisfies (2.12) almost surely. From our explicit formulas and from the finiteness of f and g, it also follows that $u \in C([0,\infty), H^n_p)$ for any n (and for any ω), that $u \in \mathfrak{D}$, and that u is a solution of (2.12).

Next, we want to obtain some bounds of norms of u. Let

$$u_1(t,x) = \int_0^t T_{t-s} f(s,x)\,ds.$$

According to [12] (for any ω),

$$\tag{2.14} ||u_{1xx}||_{L_p(\mathbb{R}_+,H_p^{-1})} \le N||f||_{L_p(\mathbb{R}_+,H_p^{-1})}.$$

Furthermore,

(2.15)
$$N^{-1}||u_{xx} - u_{1xx}||^p_{\mathbb{H}_p^{-1}} \le ||u_x - u_{1x}||^p_{\mathbb{L}_p} = \int_0^\infty \int_{\mathbb{R}^d} E|u_x - u_{1x}|^p(t,x)\,dx\,dt.$$

To make some further transformations of this formula, we note that if $z^k = z^k(x)$ are bounded $\mathcal{B}(\mathbb{R}^d)$-measurable functions, then by Itô's formula applied to the increment over $[0,t]$ of

$$\left(\int_r^t T_{t-s} z^k\,ds\right)(w^k_{r\wedge\tau_2} - w^k_{r\wedge\tau_1})$$

as a function of r, we obtain (a.s.)

$$0 = -\int_0^t (w^k_{r\wedge\tau_2} - w^k_{r\wedge\tau_1}) T_{t-r} z^k\,dr + \int_0^t I_{(\tau_1,\tau_2]}(r)\left(\int_r^t T_{t-s} z^k\,ds\right) dw^k_r.$$

By using this for our particular g or by using the stochastic version of the Fubini theorem, for any $t \ge 0$ and $x \in \mathbb{R}^d$ we get

$$u_x(t,x) - u_{1x}(t,x) = v_x(t,x) + \int_0^t T_{t-s} \sum_{k=1}^m \int_0^s \frac{1}{2}\Delta g^k_x(r,x)\,dw^k_r\,ds$$

$$= v_x(t,x) - \sum_{k=1}^m \int_0^t \int_r^t \frac{d}{ds} T_{t-s} g^k_x(r,x)\,ds\,dw^k_r = \sum_{k=1}^m \int_0^t T_{t-r} g^k_x(r,x)\,dw^k_r \quad \text{(a.s.)}.$$

Hence by the Burkholder–Davis–Gundy inequality,

$$\begin{aligned} E|u_x - u_{1x}|^p(t,x) &\le NE\left[\int_0^t \sum_{k=1}^m \lambda_k |T_{t-r} g^k_x(r,x)|^2\,dr\right]^{p/2} \\ &= NE\left[\int_0^t |T_{t-r} g_x(r,x)|^2_E\,dr\right]^{p/2}, \end{aligned}$$

λ_k being the eigenvalue of $\mathbb{Q}$ corresponding to h_k, so that $E|w^k_t|^2 = \lambda_k t$, $k = 1,2,3,\ldots$.

By plugging this into (2.15) and by applying Lemma 2.3, we obtain

$$||u_x - u_{1x}||^p_{\mathbb{L}_p} \le NE\int_0^\infty \int_{\mathbb{R}^d} \left[\int_0^t |\nabla T_{t-s} g(s,x)|^2_E\,ds\right]^{p/2} dx\,dt \le N||g||^p_{\mathbb{L}_p(E)}.$$

This along with (2.14) gives us (2.8) for $n = 0$.

To prove (2.10) with a sufficiently large λ, it suffices to repeat the corresponding arguments from [11] or [14] related to integration by parts in a formula for $|u(t,x)|^p \exp(-\lambda pt)$, which one gets from equation (2.12) satisfied pointwise. One might only observe that by denoting $q = p/(p-1)$ and using the Hölder inequality and (2.11), one gets

$$\int_{\mathbb{R}^d} |u(s,x)|^{p-2} u_x(s,x) \cdot \tilde{f}(s,x)\,dx \le \int_{\mathbb{R}^d} (|u|^{(p-2)/2}|u_x|)^q |u|^{q(p-2)/2}\,dx$$

$$+ \|\tilde{f}(s,\cdot)\|_p^p \le N\|f(s,\cdot)\|_{-1,p}^p + N_1\|u(s,\cdot)\|_p^p + \frac{1}{2}\|\,|u(s,\cdot)|^{(p-2)/p}|u_x(s,\cdot)|^{2/p}\|_p^p,$$

$$\int_{\mathbb{R}^d} |u(s,x)|^{p-2}u(s,x)f_0(s,x)\,dx \le \|f_0(s,\cdot)\|_p^p + \|u(s,\cdot)\|_p^p$$
$$\le N\|f(s,\cdot)\|_{-1,p}^p + \|u(s,\cdot)\|_p^p.$$

From estimates (2.10) and (2.8), we conclude that $u \in \bigcap_T \mathbb{H}_p^1(T)$. Finally, the assertion about the arbitrariness of λ in (2.10) can be easily justified by rescaling arguments when instead of f, g, and w one takes $(c^2 f, cg)(c^2 t, cx)$ and $c^{-1}w_{c^2 t}$ and gets $u(c^2 t, cx)$ instead of $u(t,x)$. The lemma is proven. □

Remark 2.1. Although (2.14) holds for all $p \in (1,\infty)$, it follows from [9] that (2.8) is not true if $p < 2$.

Proof of Theorem 2.1. Since one can apply the operator $(I-\Delta)^{n/2}$ to both sides of (2.1), it suffices to prove assertions (i) and (ii) only for $n = 0$. Furthermore, our norms are translation invariant and $\bigcap_T \mathbb{H}_p^{n+1}(T) \subset \mathfrak{D}$; hence by Lemma 2.1, we need to consider only the case $\sigma \equiv 0$. As in Lemma 2.4, we can assume that f and g are as in (2.13). In this case, as we know from [11] and [14], equation (2.1) has a unique solution u which belongs to $C_b([0,T] \times \mathbb{R}^d)$ and $C([0,T], L_2)$ almost surely for any $T < \infty$. It follows that $u \in C([0,T], L_p)$ almost surely for any $T < \infty$.

Since the matrix a is uniformly nondegenerate, by making a nonrandom time change, we can reduce the general case to the case $2a \ge I$. In this case, define the matrix-valued function $\bar{\sigma}(t) = \bar{\sigma}^*(t) \ge 0$ as a solution of the equation $\bar{\sigma}^2(t) + I = 2a(t)$. Furthermore, without loss of generality, we assume that on our probability space we are also given a d-dimensional Wiener process B_t independent of $\mathcal{F}_t$.

Now consider the equation

$$dv(t,x) = \left[\frac{1}{2}\Delta v(t,x) + f\left(t, x - \int_0^t \bar{\sigma}(s)\,dB_s\right)\right]dt + g\left(t, x - \int_0^t \bar{\sigma}(s)\,dB_s\right)dw_t$$

with zero initial condition. By Lemmas 2.4, 2.1, and 2.2, there is a function v possessing properties (i) through (iii) listed in Theorem 2.1 such that

$$u(t,x) = E\left\{v\left(t, x + \int_0^t \bar{\sigma}(s)\,dB_s\right)|\mathcal{F}_t\right\}$$

in the sense explained in the proof of Lemma 2.2. We use this representation of u and the already mentioned relation $u \in C([0,T], L_p)$. Bearing also in mind the properties of v and using the Hölder inequality, we immediately get all the needed properties of u, thus finishing the proof of our theorem. □

Remark 2.2. By using the self-similarity of equation (2.1), one can obtain further estimates from estimates like (2.9). For instance, bearing in mind that $H^1_p = W^1_p$, one sees that for $n = 1$ and $\lambda = 1/p$, estimate (2.9) implies that

$$E\sup_{s\le t}\{||u_x(s,\cdot)||^p_p + ||u(s,\cdot)||^p_p\} \le N(d,p,\delta,K)e^t(||f||^p_{\mathbb{L}_p(t)} + ||g_x||^p_{\mathbb{L}_p(t,E)} + ||g||^p_{\mathbb{L}_p(t,E)}).$$

Let us take a constant $c > 0$ and consider $(c^2f, cg)(c^2t, cx), c^{-1}w_{c^2t}$, and $u(c^2t, cx)$ instead of f, g, w, and u. Then from the last estimate, we get

$$E\sup_{s\le t}\{c^{p-d}||u_x(c^2s,\cdot)||^p_p + c^{-d}||u(c^2s,\cdot)||^p_p\}$$

$$\le Ne^t(c^{2p-(d+2)}||f||^p_{\mathbb{L}_p(c^2t)} + c^{2p-(d+2)}||g_x||^p_{\mathbb{L}_p(c^2t,E)} + c^{p-(d+2)}||g||^p_{\mathbb{L}_p(c^2t,E)}),$$

the constant N taken the same as above. It follows that for $c, t \ge 0$,

$$E\sup_{s\le t}\{||u_x(s,\cdot)||^p_p + c^{-p}||u(s,\cdot)||^p_p\}$$

$$\le Ne^{t/c^2}c^{p-2}(||f||^p_{\mathbb{L}_p(t)} + ||g_x||^p_{\mathbb{L}_p(t,E)} + c^{-p}||g||^p_{\mathbb{L}_p(t,E)}).$$

Upon setting $c^2 = t$ and considering $(I - \Delta)^{(n-1)/2}u$ instead of u, we conclude that under the conditions of Theorem 2.1 for any $t > 0$,

$$E\{\sup_{s\le t}||u_x(s,\cdot)||^p_{n-1,p} + t^{-p/2}\sup_{s\le t}||u(s,\cdot)||^p_{n-1,p}\}$$

$$\le N(d,p,\delta,K)t^{(p-2)/2}(||f||^p_{\mathbb{H}^{n-1}_p(t)} + ||g_x||^p_{\mathbb{H}^{n-1}_p(t,E)} + t^{-p/2}||g||^p_{\mathbb{H}^{n-1}_p(t,E)}).$$

We will later prove a much deeper estimate than (2.9).

3. A Banach-space setting and main results. Here we state our main results, the first two of which are proved in §5. Fix a number $T \in (0,\infty)$ and a stopping time $\tau \le T$. For $n \in \mathbb{R}$ and

$$(f,g) \in \mathcal{F}^n_p(\tau) := \mathbb{H}^n_p(\tau) \times \mathbb{H}^{n+1}_p(\tau, E),$$

set

$$||(f,g)||_{\mathcal{F}^n_p(\tau)} := ||f||_{\mathbb{H}^n_p(\tau)} + ||g||_{\mathbb{H}^{n+1}_p(\tau,E)}.$$

DEFINITION 3.1. *For a function $u \in \mathbb{H}^n_p(\tau)$, we write $u \in \mathcal{H}^n_p(\tau)$ if there exists $(f,g) \in \mathcal{F}^{n-2}_p(\tau)$ such that for any $\phi \in C^\infty_0$, equality* (2.4) *holds almost surely for all $t \le \tau$ and $u(0,\cdot) \in L_p(\Omega, H^n_p)$. In this case, we define $\mathcal{H}^n_{p,0}(\tau) = \mathcal{H}^n_p(\tau) \cap \{u : u(0,\cdot) = 0\}$,*

$$||u||_{\mathcal{H}^n_p(\tau)} = ||u_{xx}||_{\mathbb{H}^{n-2}_p(\tau)} + ||(f,g)||_{\mathcal{F}^{n-2}_p(\tau)} + (E||u(0,\cdot)||^p_{n,p})^{1/p}. \tag{3.1}$$

Remark 3.1. Since ordinary and stochastic integrals are "incomparable," the function u defines the couple f, g uniquely. Therefore, the norm in (3.1) is well defined. In (3.1) we use such a restrictive norm of the initial value as $||u(0,\cdot)||_{n,p}$

only for simplicity. Actually, we will always get rid of the initial condition by considering $u(t,x) - u(0,x)$ instead of u, and in (3.1) we could replace $||u(0,\cdot)||_{n,p}$ by $||u(0,\cdot)||_{n-2/p,p}$ if instead of $u(t,x)-u(0,x)$ we take $u(t,x) - T_t u(0,x)$.

The following theorem contains some basic properties of the spaces $\mathcal{H}_p^n(\tau)$. As we will see in §5, assertion (ii) in this theorem is a simple consequence of Theorem 2.1. By using Theorem 2.1, it can obviously be obtained not only for $p=2$ but for any $p \geq 2$. However, for $p > 2$ the much stronger statement (iii) is available.

THEOREM 3.1. (i) *The spaces* $\mathcal{H}_p^n(\tau)$ *and* $\mathcal{H}_{p,0}^n(\tau)$ *are Banach spaces with the norm given by* (3.1).

(ii) *For any function* $u \in \mathcal{H}_2^n(\tau)$, *we have* $u \in C([0,\tau], H_2^{n-1})$ *(a.s.) and*

$$E \sup_{t \leq \tau} ||u(t,\cdot)||_{n-1,2}^2 \leq N(d,n,T)||u||_{\mathcal{H}_2^n(\tau)}^2.$$

(iii) *If* $p > 2$, $1/2 > \beta > \alpha > 1/p$, *then for any function* $u \in \mathcal{H}_p^n(\tau)$, *we have* $u \in C^{\alpha-1/p}([0,\tau], H_p^{n-2\beta})$ *(a.s.) and for any stopping time* $\eta \leq \tau$,

(3.2)
$$E||u(t\wedge\eta,\cdot) - u(s\wedge\eta,\cdot)||_{n-2\beta,p}^p \leq N(d,\beta,p,T)|t-s|^{\beta-1/p}||u||_{\mathcal{H}_p^n(\tau)}^p \quad \forall t,s \leq T;$$

$$E||u(t,\cdot)||_{C^{\alpha-1/p}([0,\tau],H_p^{n-2\beta})}^p \leq N(d,\beta,\alpha,p,T)||u||_{\mathcal{H}_p^n(\tau)}^p. \tag{3.3}$$

(iv) *If* $\alpha := n - d/p > 0$ *and* $u \in \mathcal{H}_p^n(\tau)$, *then* $u \in L_p(\Omega \times (0,\tau), \mathcal{C}^\alpha(\mathbb{R}^d))$, *where* $\mathcal{C}^\alpha(\mathbb{R}^d)$ *is the Zygmund space (which differs from the ordinary Hölder spaces* $C^\alpha(\mathbb{R}^d)$ *only if* α *is an integer). In addition,*

$$E\int_0^\tau ||u(t,\cdot)||_{\mathcal{C}^\alpha(\mathbb{R}^d)}^p\,dt \leq N(d,n,p,T)||u||_{\mathcal{H}_p^n(\tau)}^p.$$

(v) *If* $m < n$, $n - d/p = m - d/q$, *and* $u \in \mathcal{H}_p^n(\tau)$, *then*

$$E\int_0^\tau ||u(t,\cdot)||_{m,q}^p\,dt \leq N(d,n,m,p,T)||u||_{\mathcal{H}_p^n(\tau)}^p.$$

(vi) *If* $q \geq p > 2$ *and* $\theta \in (0,1)$, *then for*

$$m < n + \frac{d}{q} - \frac{d+2(1-\theta)}{p}, \quad u \in \mathcal{H}_p^n(\tau),$$

we have $u \in L_{p/\theta}((0,\tau), H_q^m)$ *(a.s.) and*

$$E\left(\int_0^\tau ||u(t,\cdot)||_{m,q}^{p/\theta}\,dt\right)^\theta \leq N(d,p,q,n,m,\theta,T)||u||_{\mathcal{H}_p^n(\tau)}^p.$$

In particular (take $\theta = p/q$*),*

$$E\left(\int_0^\tau ||u(t,\cdot)||_{m,q}^q\,dt\right)^{p/q} \leq N(d,p,q,n,m,T)||u||_{\mathcal{H}_p^n(\tau)}^p$$

if

$$q > p > 2, \quad m < n - (d+2)\left(\frac{1}{p} - \frac{1}{q}\right).$$

Remark 3.2. Assertions (ii) and (iii) obviously imply that $\mathcal{H}_p^n(\tau) \subset \mathbb{H}_p^n(\tau)$ and

$$||u||_{\mathbb{H}_p^n(\tau)} \leq N(d,n,T)||u||_{\mathcal{H}_p^n(\tau)}.$$

We are now going to state our main results concerning SPDEs. Fix $n \in (-\infty,\infty)$ and fix a number $\gamma \in [0,1)$ such that $\gamma = 0$ if $n = 0, \pm 1, \pm 2, \dots$; otherwise $\gamma > 0$ and is such that $|n| + \gamma$ is not an integer. Consider the general equation

(3.4)

$$du(t,x) = [a^{ij}(t,x)u_{x^ix^j}(t,x) + f(u,t,x)]\,dt + [\sigma^i(t,x)u_{x^i}(t,x) + g(u,t,x)]\,dw_t,$$

where a^{ij} and f are real-valued and σ^i and g are E-valued functions defined for $\omega \in \Omega$, $t \geq 0$, $x \in \mathbb{R}^d$, $u \in H_p^{n+2}$, $i,j = 1,\dots,d$.

We make the following assumptions, where as in §2 we define

$$\alpha^{ij}(t,x) = \frac{1}{2}(\sigma^i(t,x), \sigma^j(t,x))_E.$$

Assumption 3.1 (coercivity). For any $\omega \in \Omega$, $t \geq 0$, $x, \lambda \in \mathbb{R}^d$, we have

$$K|\lambda|^2 \geq [a^{ij}(t,x) - \alpha^{ij}(t,x)]\lambda^i\lambda^j \geq \delta|\lambda|^2.$$

Assumption 3.2 (uniform continuity of a and σ). For any $\varepsilon > 0, i, j$, there exists a $\kappa_\varepsilon > 0$ such that

$$|a^{ij}(t,x) - a^{ij}(t,y)| + ||\sigma^i(t,x) - \sigma^i(t,y)||_E^2 \leq \varepsilon \tag{3.5}$$

whenever $|x - y| \leq \kappa_\varepsilon, t \geq 0, \omega \in \Omega$.

Actually, below we impose much stronger conditions on σ.

Assumption 3.3. For any $x \in \mathbb{R}^d$ and $e \in \mathbb{Q}^{1/2}H$, the functions $a^{ij}(t,x)$ and $\sigma^i(t,x)e$ are real-valued predictable functions, and for any $\omega \in \Omega$ and $t \geq 0$, we have

$$a^{ij}(t,\cdot) \in C^{|n|+\gamma}, \quad \sigma^i(t,\cdot) \in C^{|n|+\gamma+1}(\mathbb{R}^d, E).$$

Assumption 3.4. For any $u \in H_p^{n+2}$, the functions $f(u,t,x)$ and $g(u,t,x)$ are predictable as functions taking values in H_p^n and $H_p^{n+1}(\mathbb{R}^d, E)$, respectively.

Assumption 3.5. For any $t \geq 0, \omega, i, j$,

$$||a^{ij}(t,\cdot)||_{C^{|n|+\gamma}} + ||\sigma^i(t,\cdot)||_{C^{|n|+\gamma+1}(\mathbb{R}^d,E)} \leq K, \quad (f(0,\cdot,\cdot), g(0,\cdot,\cdot)) \in \mathcal{F}_p^n(\tau).$$

Assumption 3.6. For any $\varepsilon > 0$, there exists a constant K_ε such that for any $u, v \in H_p^{n+2}$, t, ω, we have

$$\begin{aligned} ||f(u,t,\cdot) - f(v,t,\cdot)||_{n,p} &+ ||g(u,t,\cdot) - g(v,t,\cdot)||_{n+1,p} \\ &\leq \varepsilon||u - v||_{n+2,p} + K_\varepsilon||u - v||_{n,p}. \end{aligned} \tag{3.6}$$

THEOREM 3.2. *Let Assumptions* 3.1–3.6 *be satisfied and let*

$$u_0 \in L_p(\Omega, \mathcal{F}_0, H_p^{n+2}).$$

Then the Cauchy problem for equation (3.4) *on* $[0,\tau]$ *with the initial condition* $u(0,\cdot) = u_0$ *has a unique solution* $u \in \mathcal{H}_p^{n+2}(\tau)$. *For this solution, we have*

$$||u||_{\mathcal{H}_p^{n+2}(\tau)} \leq N(||f(0,\cdot,\cdot)||_{\mathbb{H}_p^n(\tau)} + ||g(0,\cdot,\cdot)||_{\mathbb{H}_p^{n+1}(\tau)} + (E||u_0||_{n+2,p}^p)^{1/p}),$$

where the constant N depends only on $d, n, \gamma, p, \delta, K, T$, and the functions κ_ε and K_ε.

To discuss the theorem we need the following lemma.

LEMMA 3.1. *For real-valued (measurable) functions a on $\mathbb{R}^d$, define $\bar{a} = ||a||_{C^{|n|+\gamma}}$ if $n \neq 0$, $\bar{a} = \sup_x |a(x)| =: ||a||_B$ if $n = 0$. Let $\zeta \in C_0^\infty$ be a nonnegative function such that $\int \zeta(x)\,dx = 1$ and define $\zeta_k(x) = k^{-d}\zeta(x/k)$, $k = 1, 2, 3, \dots$. We assert that for any $u \in H_p^n$, we have the following:*

(i) $||au||_{n,p} \leq N\bar{a}||u||_{n,p}$, *where the constant N depends only on d, p, n, and γ;*

(ii) $||u * \zeta_k||_{n,p} \leq ||u||_{n,p}$, $||u - u * \zeta_k||_{n,p} \to 0$.

Proof. If $n \neq 0, \pm1, \pm2, \dots$ (and $\gamma > 0$), then one gets (i) by Corollary 2.8.2 (ii) of [17]. If n is a nonnegative integer, then (i) follows from the Leibnitz rule (and the fact that $H_p^n = W_p^n$). For negative integers (and generally for negative n) (i) follows easily by duality.

As for (ii), the first inequality follows from the Minkowski inequality and the second one is derived as usual owing to denseness of C_0^∞ in H_p^n. The lemma is proven. □

Remark 3.3. Of course, by a solution to the Cauchy problem for equation (3.4) on $[0, \tau]$ with the given initial condition u_0, we understand a function $u \in \mathcal{H}_p^{n+2}(\tau)$ such that for any test function $\phi \in C_0^\infty$, almost surely one has

$$\begin{aligned}(u(t,\cdot), \phi) = (u_0, \phi) &+ \int_0^t (a^{ij}(s,\cdot)u_{x^ix^j}(s,\cdot) + f(u,s,\cdot), \phi)\,ds \\ &+ \int_0^t (\sigma^i(s,\cdot)u_{x^i}(s,\cdot) + g(u,s,\cdot), \phi)\,dw_s, \quad \forall t \in [0,\tau],\end{aligned}$$

where by Lemma 3.1 $a^{ij}u_{x^ix^j} \in H_p^n$, $\sigma^i u_{x^i} \in H_p^{n+1}(\mathbb{R}^d, E)$ whenever $u \in H_p^{n+2}$.

Remark 3.4. Two main ideas in the proof of this theorem are quite standard. The first one, reduction to equations with constant coefficients, will be seen very clearly. The second one, which is somewhat hidden, actually, consists of the introduction of the new unknown function $v = (I - \Delta)^{n/2}u$, which reduces the case of general n to the case $n = 0$. The equation for v is pseudodifferential, and we note that more general pseudodifferential equations can be considered too.

Remark 3.5. By Theorem 14.2 of [5], for any $u \in H_p^{n+2}$ and $m \in [n, n+2]$, we have

$$||u||_{m,p} \leq N||u||^{\theta}_{n+2,p}||u||^{1-\theta}_{n,p},$$

where $\theta = (m - n)/2$ and N depends only on d, n, m, and p. This shows that the last norm in (3.6) can be replaced by $||u - v||_{n+\varepsilon+1,p}$ once $|\varepsilon| < 1$.

Remark 3.6. A typical application of Theorem 3.2 occurs when $f(u,t,x) = b^i(t,x)u_{x^i} + c(t,x)u + f(t,x)$ and $g(u,t,x) = \nu(t,x)u + g(t,x)$, so that (3.4) becomes

$$du = (a^{ij}u_{x^ix^j} + b^iu_{x^i} + cu + f)\,dt + (\sigma^iu_{x^i} + \nu u + g)\,dw_t. \tag{3.7}$$

To describe the appropriate assumptions, we take $\varepsilon \in (0,1)$ and denote

$$\begin{array}{llll} n_b = n + \gamma & \text{if} \ \ n \geq 0, & n_b = 0 & \text{if} \ \ n \in (-1, 0], \\ n_\nu = n + 1 + \gamma & \text{if} \ \ n \geq -1, & n_\nu = 0 & \text{if} \ \ n \in (-2, -1], \\ n_c = n + \gamma & \text{if} \ \ n \geq 0, & n_c = 0 & \text{if} \ \ n \in (-2, 0], \end{array}$$

$$\begin{array}{ll} n_b = -n - 1 + \varepsilon & \text{if} \ \ n \leq -1, \\ n_\nu = -n - 2 + \varepsilon & \text{if} \ \ n \leq -2, \\ n_c = -n - 2 + \varepsilon & \text{if} \ \ n \leq -2. \end{array}$$

Assume that b, c,and ν are appropriately measurable and

$$b^i(t,\cdot) \in C^{n_b}, \;\; c(t,\cdot) \in C^{n_c}, \;\; \nu(t,\cdot) \in C^{n_\nu}(\mathbb{R}^d, E),$$

$$f(t,\cdot) \in H^n_p, \;\; g(t,\cdot) \in H^{n+1}_p(\mathbb{R}^d, E),$$

$$||b^i(t,\cdot)||_{C^{n_b}} + ||c(t,\cdot)||_{C^{n_c}} + ||\nu(t,\cdot)||_{C^{n_\nu}(\mathbb{R}^d,E)} \leq K, \quad (f(\cdot,\cdot), g(\cdot,\cdot)) \in \mathcal{F}^n_p(\tau),$$

where we understand the space C^m as $B(\mathbb{R}^d)$ if $m = 0$. It turns out then that the assumptions of Theorem 3.2 about $f(u,t,x)$ and $g(u,t,x)$ are satisfied. To show this, it suffices to apply Remark 3.5 and to notice that, for instance, if $n \geq -1$, then $||\nu u||_{n+1,p} \leq N||u||_{n+1,p}$ by Lemma 3.1; if $n \in (-2,-1]$, then obviously $||\nu u||_{n+1,p} \leq ||\nu u||_p \leq N||u||_p = N||u||_{n+1+(-n-1),p}$, and $-n-1 \in [0,1)$; if $n \leq -2$, then Lemma 3.1 yields $||\nu u||_{n+1,p} \leq ||\nu u||_{n+2-\varepsilon_1,p} \leq N||u||_{n+2-\varepsilon_1,p} \leq N||u||_{n+2-\varepsilon,p}$, where $\varepsilon_1 \in (0,\varepsilon)$. The terms $||b^i u_{x^i}||_{n,p}, ||cu||_{n,p}$ are considered similarly.

Actually, the above conditions on b, c, and ν can be considerably relaxed if in addition one applies deeper theorems about multiplyers from [17].

THEOREM 3.3. *Assume that for $m = 1,2,3,\ldots$, we are given a^{ij}_m, σ^i_m, f_m, g_m, and u_{0m} having the same sense as in Theorem 3.2 and verifying the same assumptions as a^{ij}, σ^i, f, g and u_0 with the same constants $\delta, K, \kappa_\varepsilon$, and K_ε. Let (h_k) be an orthonormal basis in H consisting of eigenvectors of $\mathbb{Q}$ and let P_m be the operator of orthogonal projection of H onto* Span $(h_1,\ldots,h_m)$. *Let $\zeta(x)$ be a real function of class C^∞_0 such that $\zeta(x) = 1$ if $|x| \leq 1$ and $\zeta(x) = 0$ if $|x| \geq 2$. Define $\zeta_k(x) = \zeta(x/k)$ and assume that for any $k = 1,2,3,\ldots, t \geq 0$, $\omega \in \Omega$,*

$$||\zeta_k\{a^{ij}(t,\cdot) - a^{ij}_m(t,\cdot)\}||_{n,p} + ||\zeta_k\{\sigma^i(t,\cdot) - \sigma^i_m(t,\cdot)\}||_{n+1,p} \to 0$$

as $m \to \infty$. Finally, let $E||u_{0m} - u_0||^p_{n+2,p} \to 0$ and

$$||(f(u,\cdot,\cdot), g(u,\cdot,\cdot)) - (f_m(u,\cdot,\cdot), g_m(u,\cdot,\cdot))||_{\mathcal{F}^n_p(\tau)} \to 0$$

whenever $u \in \mathcal{H}^{n+2}_p(\tau)$. Take the function u from Theorem 3.2 and for any m define $u_m \in \mathcal{H}^{n+2}_p(\tau)$ as the (unique) solution of the Cauchy problem for the equation

$$du_m(t,x) = [a^{ij}_m(t,x)u_{mx^ix^j}(t,x) + f_m(u_m,t,x)]\,dt$$

$$+ [\sigma^i_m(t,x)u_{mx^i}(t,x) + g_m(u_m,t,x)]\,dP_m w_t$$

on $[0,\tau]$ with the initial condition $u_m(0,\cdot) = u_{0m}$. Then $||u - u_m||_{\mathcal{H}^{n+2}_p(\tau)} \to 0$ as $m \to \infty$.

Proof. We have

$$d(u(t) - u_m(t)) = [a^{ij}_m(u - u_m)_{x^ix^j} + (a^{ij} - a^{ij}_m)u_{x^ix^j} + (f(u) - f_m(u_m))]\,dt$$

$$+ [\sigma^i_m P_m(u - u_m)_{x^i} + (\sigma^i - \sigma^i_m P_m)u_{x^i} + (g(u) - g_m(u_m)P_m)]\,dw_t,$$

$$f(u) - f_m(u_m) = [f_m(u) - f_m(u_m)] + [f(u) - f_m(u)],$$

$$g(u)-g_m(u_m)P_m=[g_m(u)-g_m(u_m)]P_m+g(u)[I-P_m]+[g(u)-g_m(u)]P_m,$$

$$\sigma^i-\sigma^i_mP_m=(\sigma^i-\sigma^i_m)P_m+\sigma^i(I-P_m).$$

Hence from our assumptions by Theorem 3.2 for any $t\geq 0$, we obtain

$$\|u-u_m\|_{\mathcal{H}^{n+2}_p(\tau\wedge t)}\leq\frac{1}{2}\|u-u_m\|_{\mathcal{H}^{n+2}_p(\tau\wedge t)}+N\|u-u_m\|_{\mathbb{H}^{n+1}_p(\tau\wedge t)}+NI_m,$$

where

$$I_m=(E\|u_0-u_{0m}\|^p_{n+2,p})^{1/p}+\|f(u)-f_m(u)\|_{\mathbb{H}^n_p(\tau)}+\|(a^{ij}-a^{ij}_m)u_{x^ix^j}\|_{\mathbb{H}^n_p(\tau)}$$

$$+\|(\sigma^i-\sigma^i_m)u_{x^i}\|_{\mathbb{H}^{n+1}_p(\tau,E)}+\|\sigma^i(I-P_m)u_{x^i}\|_{\mathbb{H}^{n+1}_p(\tau,E)}$$

$$+\|g(u)(I-P_m)\|_{\mathbb{H}^{n+1}_p(\tau,E)}+\|g(u)-g_m(u)\|_{\mathbb{H}^{n+1}_p(\tau,E)}.$$

We collect like terms in the last inequality and then apply Theorem 3.1. This yields

$$E\|u-u_m\|^p_{n+1,p}(\tau\wedge t)\leq N\|u-u_m\|^p_{\mathcal{H}^{n+2}_p(\tau\wedge t)}\leq NI^p_m+N\int_0^t E\|u-u_m\|^p_{n+1,p}(\tau\wedge s)\,ds,$$

where $t\leq T$ and N is independent of m. Gronwall's inequality allows us to drop the last term on the right. Next, we let m go to infinity and use our assumptions. Then we get

(3.8)
$$\limsup_{m\to\infty}\|u-u_m\|_{\mathcal{H}^{n+2}_p(\tau)}\leq N\limsup_{m\to\infty}I_m=N\limsup_{m\to\infty}\{\|(a^{ij}-a^{ij}_m)u_{x^ix^j}\|_{\mathbb{H}^n_p(\tau)}$$

$$+\|(\sigma^i-\sigma^i_m)u_{x^i}\|_{\mathbb{H}^{n+1}_p(\tau,E)}+\|\sigma^i(I-P_m)u_{x^i}\|_{\mathbb{H}^{n+1}_p(\tau,E)}+\|g(u)(I-P_m)\|_{\mathbb{H}^{n+1}_p(\tau,E)}\}.$$

Here, by the dominated convergence theorem,

$$\|g(u)(I-P_m)\|^p_{\mathbb{H}^{n+1}_p(\tau,E)}=E\int_0^T\int_{\mathbb{R}^d}\left[\sum_{k>m}((I-\Delta)^{(n+1)/2}g(u)\mathbb{Q}^{1/2},h_k)^2_H\right]^{p/2}dxdt\to 0,$$

and the same is true for $\|\sigma^i(I-P_m)u_{x^i}\|_{\mathbb{H}^{n+1}_p(\tau,E)}$ ($\sigma^iu_{x^i}\in\mathbb{H}^{n+1}_p(\tau,E)$ by Remark 3.3).

Next, by Lemma 3.1 for any $v\in C^\infty_0$ and k so large that $v\zeta_k=v$, we have

(3.9) $$\|(a^{ij}-a^{ij}_m)u_{x^ix^j}\|_{n,p}\leq N\|(u-v)_{x^ix^j}\|_{n,p}+\|(a^{ij}-a^{ij}_m)v_{x^ix^j}\|_{n,p},$$

$$\|(a^{ij}-a^{ij}_m)v_{x^ix^j}\|_{n,p}=\|\zeta_k(a^{ij}-a^{ij}_m)v_{x^ix^j}\|_{n,p}\leq N\|\zeta_k(a^{ij}-a^{ij}_m)\|_{n,p}\|v\|_{C^{|n|+2+\gamma}},$$

where the constants N do not depend on m and k. Thus,

$$\lim_{m\to\infty}\|(a^{ij}-a^{ij}_m)u_{x^ix^j}\|_{n,p}\leq N\|(u-v)_{x^ix^j}\|_{n,p},$$

and from the arbitrariness of v, we conclude that the left-hand side is zero for those ω and t for which $u \in H_p^{n+2}$. If we again apply Lemma 3.1, then we see that the pth power of the left-hand side of (3.9) is bounded by an integrable function. This and the dominated convergence theorem imply that

$$\lim_{m \to \infty} ||(a^{ij} - a^{ij}_m)u_{x^ix^j}||_{\mathbb{H}_p^n(\tau)} = 0.$$

Similar arguments take care of the remaining term in (3.8). The theorem is proven. □

COROLLARY 3.1. *Let Assumptions* 3.1–3.5 *be satisfied and take $f(u,t,x)$ and $g(u,t,x)$ satisfying the conditions from Remark* 3.6. *Also take the functions ζ_k from Lemma* 3.1 *and define*

$$(a_k, b_k, c_k, \sigma_k, \nu_k, f_k, g_k) = (a, b, c, \sigma, \nu, f, g) * \zeta_k.$$

Finally, define $u_k \in \mathcal{H}_p^{n+2}(T)$ as solutions of the Cauchy problem for the equations

$$du_k = (a_k^{ij} u_{kx^ix^j} + b_k^i u_{kx^i} + c_k u_k + f_k)\,dt + (\sigma_k^i u_{kx^i} + \nu_k u_k + g_k)\,dP_k w_t$$

with the initial conditions $u_k(0,\cdot) = u_0 * \zeta_k$. Then $||u - u_k||_{\mathcal{H}_p^{n+2}(\tau)} \to 0$.

To show this, it suffices to apply Lemma 3.1, repeat our argument about (3.9), and notice that

$$(\sigma_k^i, \sigma_k^j)_E \lambda^i \lambda^j = |(\sigma^i \lambda^i) * \zeta_k|_E^2 \le \zeta_k * [(\sigma^i, \sigma^j)_E \lambda^i \lambda^j].$$

COROLLARY 3.2. *Let Assumptions* 3.1–3.5 *be satisfied and also let them be satisfied for a $p = q$, where $q \ge 2$. Take $f(u,t,x)$ and $g(u,t,x)$ satisfying the conditions from Remark* 3.6. *Then the solution u from Theorem* 3.2 *belongs also to $\mathcal{H}_q^{n+2}(\tau)$.*

Without loss of generality, assume $p < q$ and let v be the solution of the same initial value problem but belonging to $\mathcal{H}_q^{n+2}(\tau)$ (such a unique v exists by Theorem 3.2). We have only to show that $v = u$. In light of Corollary 3.1, we can suppose that our assumptions are satisfied for any n. In this case, by Theorem 3.1,

$$E \sup_{t \le \tau} ||u||_{C^m}^p < \infty, \quad E \int_0^\tau ||u_{xx}(t,\cdot)||_{m,p}^p\,dt < \infty$$

for any $m = 1, 2, 3, \dots$. It follows that

$$\int_0^\tau ||u_{xx}(t,\cdot)||_{m,r}^r\,dt < \infty \quad \text{(a.s.)}$$

for any $r \ge p$. Take $m = 0$ and $r = q$ here and define

$$\tau_k = \tau \wedge \inf\left\{t : \int_0^t ||u_{xx}(s,\cdot)||_q^q\,ds \ge k\right\}.$$

Then obviously $u \in \mathcal{H}_q^2(\tau_k)$. Since v lies in the same class, by uniqueness $u(t,\cdot) = v(t,\cdot)$ for $t \le \tau_k$ (a.s.). It remains only to observe that $\tau_k \uparrow \tau$ when $k \to \infty$.

Our last result concerns the maximum principle. Its proof is absolutely standard. One needs only to apply Corollary 3.1 (along with statements (ii) and (iii) of Theorem 3.1) and the maximum principle from [14] or [11].

THEOREM 3.4 (maximum principle). *Let Assumptions* 3.1–3.5 *be satisfied and take $f(u,t,x)$ and $g(u,t,x)$ satisfying the conditions from Remark* 3.6. *Suppose that for any ω and t we have $u_0 \ge 0$, $f(t,\cdot) \ge 0$ (in the sense of distributions), and $g(t,\cdot) \equiv 0$. Then the solution u of the Cauchy problem for the* linear *equation* (3.7) *with the initial condition $u(0,\cdot) = u_0$ verifies $u(t,\cdot) \ge 0$ for all $t \in [0,\tau]$ almost surely.*

4. An application. In this section, we consider the one-dimensional equation with space–time white noise. Thus $d = 1$. Fix a number $\kappa \in (0, 1/2]$ and define $n = -\kappa - 3/2$.

4.1. Let $a(t, x) = a(\omega, t, x)$ and $b(t, x) = b(\omega, t, x)$ be real-valued functions defined on $\Omega \times \mathbb{R}_+ \times \mathbb{R}$. Assume that

(i) for any ω and t, the function a is twice continuously differentiable with respect to x and the function b is once continuously differentiable with respect to x and $||a||_{C^2} + ||b||_{C^1} \leq K$, $K \geq a \geq \delta$;

(ii) for any $x \in \mathbb{R}$, the processes a and b are predictable.

Suppose also that we are given measurable real functions $f(t, x, u)$ and $g(t, x, u)$ on $\Omega \times \mathbb{R}_+ \times \mathbb{R}^2$ such that

(iii) for any x and u, the processes $f(t, x, u)$ and $g(t, x, u)$ are predictable;

(iv) for any ω, t, and x, the functions $f(t, x, u)$ and $g(t, x, u)$ satisfy the Lipschitz condition with the constant K with respect to u;

(v) $E\int_0^T\{||f(t,\cdot,0)||_p^p + ||g(t,\cdot,0)||_p^p\}\,dt < \infty$ for all $T < \infty$.

We also take an $\mathcal{F}_t$-adapted Wiener process B_t in L_2 with unit covariance operator (the so-called cylindrical Wiener process) and consider the equation

(4.1)
$$du(t,x) = [a(t,x)u''(t,x) + b(t,x)u'(t,x) + f(t,x,u(t,x))]\,dt + g(t,x,u(t,x))\,dB_t,$$

which as always is understood in the sense of distributions. Specifically, by the solution of this equation we mean a real-valued function $u(\omega, t, x)$ of class $\mathfrak{D}$ such that for any $\phi \in C_0^\infty$, we have $u\phi \in L_2([0,T], L_2)$, $T > 0$ almost surely, the process $(u(t,\cdot), \phi)$ is continuous, and

$$(u(t,\cdot),\phi) = (u(0,\cdot),\phi) + \int_0^t ((u(s,\cdot),(a(s,\cdot)\phi(\cdot))'' - (b(s,\cdot)\phi(\cdot))' + f(s,\cdot,u(s,\cdot)))\,ds$$
$$+ \int_0^t (g(s,\cdot,u(s,\cdot))\phi(\cdot), dB_s),$$

for all t almost surely, where the last stochastic integral is a stochastic integral of the L_2-valued function $g(t,\cdot,u(t,\cdot))\phi(\cdot)$ with respect to B_t.

In order to apply Theorem 3.2, we have to find the corresponding objects H, E, and w_t and rewrite the equation in our terms. First of all, we make a standard imbedding of B_t into a Hilbert space. To this end, we take an orthonormal basis $(\psi_k, k \geq 1)$ in L_2 and define H to be the space of all formal series $h = \sum_k h^k\psi_k$, where h^k are real numbers such that $|h|_H^2 := \sum_k k^{-20}(h^k)^2 < \infty$. Observe that the functions $\tilde{\psi}_k := k^{10}\psi_k$ form an orthonormal basis in H. Next, let

$$B_t^k := (B_t, \psi_k), \quad w_t := \sum_{k=1}^{\infty} \psi_k B_t^k.$$

Since $E\sum_k k^{-20}(\psi_k, B_t)^2 = t\sum_k k^{-20} < \infty$, the process w_t takes values in H. Its covariance operator $\mathbb{Q}$ can be found from the formula

$$t(h_1, \mathbb{Q}h_2)_H = E(h_1, w_t)_H(h_2, w_t)_H$$
$$= E\left(\sum_{k=1}^{\infty} k^{-20}h_1^k B_t^k\right)\left(\sum_{k=1}^{\infty} k^{-20}h_2^k B_t^k\right) = t\sum_{k=1}^{\infty} k^{-40}h_1^k h_2^k.$$

Hence

$$\mathbb{Q}h = \sum_{k=1}^{\infty} \frac{1}{k^{20}} h^k \psi_k, \quad \mathbb{Q}^{1/2}h = \sum_{k=1}^{\infty} \frac{1}{k^{10}} h^k \psi_k, \quad \mathbb{Q}^{1/2}\tilde{\psi}_k = \psi_k.$$

If $h \in H$, then $\mathbb{Q}^{1/2}h$ (as an element of H) is represented by a formal series which converges in L_2. Therefore, we sometimes identify $\mathbb{Q}^{1/2}h$ with the corresponding element of L_2. In the following lemma, we also set

$$R(x) = \frac{1}{2\sqrt{\pi}} |x|^{-(1-2\kappa)/2} \int_0^\infty t^{-(5-2\kappa)/4} e^{-tx^2 - 1/(4t)}\, dt.$$

Observe that R is infinitely differentiable outside the origin, decreases exponentially fast as $|x| \to \infty$, and behaves near the origin like $|x|^{-(1-2\kappa)/2}$ if $\kappa < (1/2)$ and $-\log|x|$ if $\kappa = 1/2$.

LEMMA 4.1. (i) *Let $f \in L_{2,\mathrm{loc}}$. For $\phi \in C_0^\infty$ define (Gf, ϕ) as a function on L_2 by the formula*

$$(Gf, \phi)(h) = (f\phi, h)_{L_2} = \int_{\mathbb{R}} fh\phi\, dx.$$

Then $G : L_{2,\mathrm{loc}} \to \mathcal{D}(E)$ and $|(Gf, \phi)|_E = ||f\phi||_2$.

(ii) *If $f \in L_p$, then $Gf \in H_p^{n+1}(E)$ and*

(4.2)

$$||Gf||_{n+1,p}^2 = \left(\int_{\mathbb{R}} \left\{ \int_{\mathbb{R}} R^2(y) f^2(x-y)\, dy \right\}^{p/2} dx \right)^{2/p} \le (N||f||_p^2) \wedge (||f||_2^2 \cdot ||R||_p^2),$$

where $N = ||R||_2^2 < \infty$, and if $p(1-2\kappa) > 2$, then

$$||Gf||_{n+1,p} \le N(\kappa) ||f||_2^{2\kappa p/(p-2)} ||f||_p^{1-2\kappa p/(p-2)}. \tag{4.3}$$

(iii) *If $f(t)$ is an $L_{2,\mathrm{loc}}$-valued predictable function such that*

$$\int_0^T \sup_y ||f(t) I_{|\cdot - y| \le R}||_2^2\, dt < \infty \quad \forall R, T \in (0, \infty),$$

then $Gf(\cdot) \in \mathfrak{D}(E)$ and for any $T > 0, \phi \in C_0^\infty$, we have

$$\int_0^T (\phi f(t), dB_t) = \int_0^T (Gf(t), \phi)\, dw_t \quad (a.s.). \tag{4.4}$$

Proof. (i) As we have explained above, functions on L_2 can be considered as functions on $\mathbb{Q}^{1/2}H$; therefore, linear functions on L_2 are linear functions on $\mathbb{Q}^{1/2}H$. Next,

$$|(Gf, \phi)|_E = |(Gf, \phi) \circ \mathbb{Q}^{1/2}|_H = \sup_{|h|_H = 1} (Gf, \phi)(\mathbb{Q}^{1/2}h) = \sup_{|h|_H=1} \sum_k \frac{1}{k^{10}} h^k \int_{\mathbb{R}} f\phi\psi_k\, dx,$$

and the last expression equals $||f\phi||_2$. In particular, this implies that $Gf \in \mathcal{D}(E)$.

(iii) The relation $Gf(\cdot) \in \mathfrak{D}(E)$ follows from (i). By one of definitions, in the mean-square sense, we have

(4.5)

$$\int_0^T (Gf(t),\phi)\,dw_t = \sum_k \int_0^T (Gf,\phi)(\tilde\psi_k)\,d(w_t,\tilde\psi_k)_H = \sum_k \int_0^T (Gf,\phi)(\tilde\psi_k)k^{-10}\,dB_t^k$$
$$= \sum_k \int_0^T (Gf,\phi)(\psi_k)\,dB_t^k = \sum_k \int_0^T (f(t)\phi,\psi_k)_{L_2}\,dB_t^k.$$

It remains only to observe that the last expression coincides with the left-hand side of (4.4) (a.s.).

(ii) We know that for any $\phi \in C_0^\infty$, we have

$$(I-\Delta)^{(n+1)/2}\phi(x) = (I-\Delta)^{-(1+2\kappa)/4}\phi(x) = \int_{\mathbb{R}} R(x-y)\phi(y)\,dy.$$

This implies that for any $h \in L_2$, $\phi \in C_0^\infty$,

$$((I-\Delta)^{(n+1)/2}Gf,\phi)(h) = (R*Gf,\phi)(h) := (Gf,R*\phi)(h)$$
$$= \int_{\mathbb{R}} f(R*\phi)h\,dx = \int_{\mathbb{R}} \phi(R*(fh))\,dx,$$

and $(I-\Delta)^{(n+1)/2}Gf$ is a usual function on $\mathbb{R}$ with values in E defined by

$$(I-\Delta)^{(n+1)/2}Gf(x)(h) = R*(fh)(x) = (Gf,R(x-\cdot))(h).$$

By (i) (or as in (i)), it follows that

$$|(I-\Delta)^{(n+1)/2}Gf(x)|_E = ||fR(x-\cdot)||_2.$$

We thus get the equality in (4.2). The inequality in (4.2) follows from the Minkowski inequality. To prove (4.3), we use that $R^2(y) \le N|y|^{2\kappa-1}$ and we minimize with respect to $\varepsilon > 0$ after the following computations:

$$\left(\int_{\mathbb{R}}\left\{\int_{\mathbb{R}} R^2(y)f^2(x-y)\,dy\right\}^{p/2} dx\right)^{2/p} \le \left(\int_{\mathbb{R}}\left\{\int_{\mathbb{R}} I_{|y|\le\varepsilon}R^2(y)f^2(x-y)\,dy\right\}^{p/2} dx\right)^{2/p}$$
$$+\left(\int_{\mathbb{R}}\left\{\int_{\mathbb{R}} I_{|y|\ge\varepsilon}R^2(y)f^2(x-y)\,dy\right\}^{p/2} dx\right)^{2/p}$$
$$\le ||I_{|y|\le\varepsilon}R^2||_1||f||_p^2 + ||I_{|y|\ge\varepsilon}R^p||_1^{2/p}||f||_2^2$$
$$\le N\varepsilon^{2\kappa}||f||_p^2 + N\varepsilon^{-(1-2\kappa-2/p)}||f||_2^2.$$

The lemma is proven. □

Remark 4.1. The method of converting integrals with respect to B_t into integrals with respect to w_t can be generalized. In [6] a similar construction is used in order to reduce general (not necessarily continuous) stochastic integrals with respect to *martingale measures* to integrals with respect to Hilbert-space-valued processes.

THEOREM 4.1. *Take* $\kappa \in (0,1/2)$ *and* $u_0 \in L_p(\Omega,\mathcal{F}_0,H_p^{(1/2)-\kappa})$. *Then for any* T, *in the space* $\mathcal{H}_p^{(1/2)-\kappa}(T)$, *equation* (4.1) *with the initial condition* u_0 *has a unique solution* u. *Moreover,*

$$||u||_{\mathcal{H}_p^{1/2-\kappa}(T)} \le N(||f(\cdot,\cdot,0)||_{\mathbb{H}_p^{-3/2-\kappa}(T)} + ||g(\cdot,\cdot,0)||_{\mathbb{L}_p(T)} + (E||u_0||^p_{1/2-\kappa,p})^{1/p}),$$

where the constant N depends only on κ, p, δ, K, and T.

Proof. By Lemma 4.1 (iii) for functions from $\mathcal{H}_p^{1/2-\kappa}(T)$, equation (4.1) takes the form

$$du = [au'' + bu' + f(u)]\,dt + \bar{g}(u)\,dw_t,$$

where $\bar{g}(u)(t,x) := G(g(t,\cdot,u(t,\cdot)))(x)$. We will apply Theorem 3.2 to this equation. Its assumptions concerning a and σ are obviously satisfied. Next, if $u \in H_p^{n+2}$, then $bu' \in H_p^{n+1} \subset H_p^n$, $u \in L_p$, $f(u) \in L_p \subset H_p^n$. Furthermore, by Lemma 3.1 (cf. Remark 3.6),

$$||bu'||_{n,p} \le ||bu'||_{-1,p} \le N||u'||_{-1,p} \le N||u||_p = N||u||_{n+2-((1/2)-\kappa),p},$$

$$||f(u) - f(v)||_{n,p} \le ||f(u) - f(v)||_p \le K||u - v||_p.$$

Consequently (see Remark 3.5), the assumptions of Theorem 3.2 concerning $bu' + f(u)$ are satisfied. To check the remaining assumptions about $\bar{g}(u)$, it suffices to notice that by Lemma 4.1 (ii) we have

$$||\bar{g}(0)(t,\cdot)||_{n+1,p} \le N||g(t,\cdot,0)||_p,$$

$$||\bar{g}(u)(t,\cdot) - \bar{g}(v)(t,\cdot)||_{n+1,p} \le ||\bar{g}(u)(t,\cdot) - \bar{g}(v)(t,\cdot)||_p \le K||u(t,\cdot) - v(t,\cdot)||_p.$$

The theorem is proven. □

Remark 4.2. In order to apply the approximation theorem (Theorem 3.3) or Theorem 3.4 on the maximum principle, it is useful to notice that if instead of w_t we take its approximations by $P_m w_t$ as in Theorem 3.3, then the corresponding equation becomes

$$du(t,x) = [a(t,x)u''(t,x) + b(t,x)u'(t,x) + f(t,x,u(t,x))]\,dt + \sum_{k=1}^{m} g(t,x,u(t,x))\,dB_t^k.$$

This follows immediately from (4.5).

Remark 4.3. Additional information about Hölder continuity properties of the solution is readily obtained from the properties of elements of $\mathcal{H}$ listed in Theorem 3.1.

Remark 4.4. We could take a noise even "whiter" than B_t. Indeed it is not hard to see that B_t above can be cylindrical Wiener process in $H_2^{-\varepsilon}$ with unit covariance operator, where $\varepsilon \in (0, 1/2)$.

4.2. Take a, b, and g as in §4.1, and take a bounded real-valued $\mathcal{P} \times \mathcal{B}(\mathbb{R})$-measurable function $c(t,x) = c(\omega,t,x)$. Assume that $g(t,x,u) = 0$ for $u \le 0$, fix a number $\lambda \in [0, 1/2)$, and define $h(t,x,u) = g(t,x,u)u^\lambda$.

Theorem 4.1 can be easily applied to prove that the equation

$$du = (au'' + bu' + cu)\,dt + h(u)\,dB_t \tag{4.6}$$

has a unique solution defined for all t if the initial condition u_0 is nonnegative and, say, is nonrandom and belongs to C_0^∞. Furthermore, $\sup_{t \le T, x} |u(t,x)|$ is finite (a.s.) for any $T < \infty$. These facts for equation (4.6) considered on a finite space interval with $a \equiv 1$, $b \equiv c \equiv 0$, and $h(u) = u_+^{1+\lambda}$ and with zero boundary data were discovered in [15] with the help of a quite different approach. By using the maximum principle, it is not hard to show that our assertion implies the result of [15].

To begin our investigation of (4.6), let us fix $T \in (0, \infty)$ and take $\kappa \in (0, 1/2)$ and $p > 6$ such that

$$\frac{1}{2} - \kappa - \frac{3}{p} > 0, \quad \eta := 1 + \lambda - \kappa - \frac{1}{p} < 1.$$

By Theorem 4.1 for any $m = 1, 2, 3 \dots$, the equation

$$du_m = (au_m'' + bu_m' + cu_m)\,dt + h(u_m \wedge m)\,dB_t \tag{4.7}$$

with the initial condition $u_m(0, \cdot) = u_0$ has a unique solution $u_m \in \mathcal{H}_p^{1/2-\kappa}(T)$. By Theorem 3.1 (iii) and since $H_p^r \subset C^{r-d/p}$ whenever $r - d/p > 0$, we have that $u_m \in C([0,T] \times \mathbb{R})$ (a.s.) and $E||u_m||^p_{C([0,T]\times\mathbb{R})}$ is finite. We need only to show that for a constant $r > 0$ the expression $E\sup_{t\leq T,x}|u_m(t,x)|^r$ is bounded by a constant independent of m. Indeed, then, for large m with probability as close to 1 as we like, the function u_m satisfies (4.6) on $[0, T]$.

From Theorem 3.4 on the maximum principle (also use that $h(u_m \wedge m) = u_m\nu$, where ν is a bounded function), we get $u_m \geq 0$. Next take $\zeta_k(x)$ from Theorem 3.3, multiply (4.7) by $\zeta_k e^{-Kt}$, where $K = \sup(|a''| + |b'| + |c|)$, integrate by parts (that is, use the definition of solutions), and take expectations. Then for any stopping time $\tau \leq T$, we obtain

$$\begin{aligned}
e^{-KT}E(\zeta_k, u_m(\tau,\cdot)) &\leq E(\zeta_k, u_m(\tau,\cdot))e^{-K\tau} \\
&= (\zeta_k, u_0) + E\int_0^\tau (a\zeta_k'' + (2a' - b)\zeta_k' + (a'' - b' + c - K)\zeta_k, u_m)e^{-Kt}\,dt \\
&\leq N + NE\int_0^T (|\zeta_k''| + |\zeta_k'|, u_m)\,dt \leq N + \frac{N}{k}k^{1-1/p}E\int_0^T ||u_m(t,\cdot)||_p\,dt,
\end{aligned}$$

$$E(\zeta_k, u_m(\tau,\cdot)) \leq N + Nk^{-1/p}\left(E\int_0^T ||u_m(t,\cdot)||_p^p\,dt\right)^{1/p} \leq N + Mk^{-1/p},$$

where the last constant N is independent of m, k, and τ and M is independent of k. Since this inequality is true for any stopping time $\tau \leq T$, with the same N and M for any number $r \in (0, 1)$,

$$E\sup_{t\leq T}\left(\int_{\mathbb{R}} \zeta_k(x)u_m(t,x)\,dx\right)^r \leq \frac{N + Mk^{-1/p}}{1-r}, \quad E\sup_{t\leq T}\left(\int_{\mathbb{R}} u_m(t,x)\,dx\right)^r \leq \frac{N}{1-r},$$

where the latter relation is obtained from the former one by the monotone convergence theorem.

After this, for $\alpha := 2\kappa p/(p-2)$ and for any stopping time $\tau \leq T$, by Theorems 3.1 (iii) and 3.2 and Lemma 4.1 (ii), we obtain

$$\begin{aligned}
E||u_m||^p_{C([0,\tau]\times\mathbb{R})} &\leq N\left(1 + E\sup_{t\leq\tau}||Gh(u_m \wedge m)(t,\cdot)||^p_{n+1,p}\right) \\
&\leq N + NE\sup_{t\leq\tau}\{||h(u_m)(t,\cdot)||_2^{p\alpha}||h(u_m)(t,\cdot)||_p^{p(1-\alpha)}\} \\
&\leq N + NE\sup_{t\leq\tau}\{||u_m^{1+\lambda}(t,\cdot)||_2^{p\alpha}||u_m^{1+\lambda}(t,\cdot)||_p^{p(1-\alpha)}\},
\end{aligned}$$

where the constants N are independent of τ and m. Since this is true for any $\tau \leq T$, by the well-known martingale inequality (see, for instance, Lemma 1.1 in [8]), for any stopping time $\tau \leq T$ and any number $\beta \in (0,1)$, it also holds that

$$E||u_m||^{p\beta}_{C([0,\tau]\times\mathbb{R})} \leq N + NE\sup_{t\leq\tau}\{||u^{1+\lambda}(t,\cdot)||_2^{p\alpha\beta}||u^{1+\lambda}(t,\cdot)||_p^{p(1-\alpha)\beta}\}.$$

Take $\beta = (1-\eta)(\kappa p+1)^{-1}$ and use the simple relations

$$||u^{\mu}||_p \leq \sup|u|^{\mu-1/p}||u||_1^{1/p}, \quad \left(\lambda+\frac{1}{2}\right)\alpha+\left(\lambda+1-\frac{1}{p}\right)(1-\alpha) = \eta, \quad \frac{p\alpha}{2}+1-\alpha = \kappa p+1.$$

Then it is seen that

$$E||u_m||^{p\beta}_{C([0,\tau]\times\mathbb{R})} \leq N + NE||u||^{p\beta\eta}_{C([0,\tau]\times\mathbb{R})}\sup_{t\leq\tau}||u(t,\cdot)||_1^{1-\eta}$$

$$\leq N + N(E||u_m||^{p\beta}_{C([0,\tau]\times\mathbb{R})})^{\eta}(E\sup_{t\leq T}||u(t,\cdot)||_1)^{1-\eta} \leq N + N(E||u_m||^{p\beta}_{C([0,\tau]\times\mathbb{R})})^{\eta}.$$

We emphasize that all constants N are independent of m and τ. Therefore, the last inequality implies the desired absolute estimate of $E||u_m||^{p\beta}_{C([0,T]\times\mathbb{R})}$.

Remark 4.5. If we first let $p \to \infty$ and then let $\kappa \uparrow 1/2$, then we see that $p\beta$ can be made as close to $1-2\lambda$ as we wish.

5. Proofs of Theorems 3.1 and 3.2.

In this section, we prove our main results.

Proof of Theorem 3.1. We will prove assertions (ii)–(vi) only when $u \in \mathcal{H}^n_{p,0}(T)$. The reader can easily obtain these assertions in the general case by considering $u(t,x)-u(0,x)$ instead of u and making obvious modifications in our arguments.

Take $u \in \mathcal{H}^n_{p,0}(\tau)$, $\bar{f}$, and g such that (2.3) is satisfied with $\bar{f}$ and g instead of f and g. Notice that on $[0,\tau]$, the function u satisfies the equation

$$du = (\Delta u + f)\,dt + g\,dw_t, \tag{5.1}$$

where $f = \bar{f} - \Delta u \in \mathbb{H}^{n-2}_p(\tau)$. By Theorem 2.1, the equation

$$dv = (\Delta v + fI_{t\leq\tau})\,dt + gI_{t\leq\tau}\,dw_t$$

on $[0,T]$ with zero initial condition has a unique solution $v \in \mathcal{H}^n_{p,0}(T)$. The difference $u-v$ satisfies the heat equation on $[0,\tau]$ with zero initial condition. It follows that $u(t,\cdot) = v(t,\cdot)$ on $[0,\tau]$, and by Theorem 2.1 (ii),

$$||v||_{\mathcal{H}^n_p(T)} \leq N(d,n,p)(||f||_{\mathbb{H}^{n-2}_p(\tau)} + ||g||_{\mathbb{H}^{n-1}_p(\tau,E)}) \leq N(d,n,p)||u||_{\mathcal{H}^n_p(\tau)},$$

$$||f||_{\mathbb{H}^{n-2}_p(\tau)} + ||g||_{\mathbb{H}^{n-1}_p(\tau,E)} \leq N(d,n,p)||v||_{\mathcal{H}^n_p(\tau)}$$

The former inequality shows that we can confine ourselves to the case when $\tau \equiv T$. The latter one allows us to consider solutions of equations (5.1) only and to prove our assertions with $||(f,g)||_{\mathcal{F}^{n-2}_p(T)}$ in place of $||u||_{\mathcal{H}^n_p(T)}$. Therefore, below we take $\tau = T$ and take the function $u \in \mathcal{H}^n_{p,0}(T)$ as a solution of (5.1), and we notice at once that assertion (ii) immediately follows from Theorem 2.1.

(iii) We can and will suppose that $n = 2\beta$. As in Lemma 2.4, it suffices to consider the case of f and g as in (2.13). This will justify our later computations.

By one of imbedding theorems for the Slobodetsky spaces (see, for instance, [17] or [3]), for any continuous L_p-valued function $h(t)$ and $s \le t$, we have

$$||h(t) - h(s)||_p^p \le N(\alpha,p)(t-s)^{\alpha p-1} \int_s^t \int_s^t I_{r_2 > r_1} \frac{||h(r_2) - h(r_1)||_p^p}{|r_2 - r_1|^{1+\alpha p}}\, dr_1 dr_2$$

$$= N(\alpha,p)(t-s)^{\alpha p-1} \int_0^{t-s} \frac{dy}{y^{1+\alpha p}} \int_s^{t-y} ||h(r+y) - h(r)||_p^p\, dr. \tag{5.2}$$

Actually, the space L_p here can be replaced by any Banach space. We will also need Theorem 14.11 from [5], which implies that for any $h \in L_p$, $\theta \in (0,1]$, and $y \in [0,T]$,

$$\begin{aligned} ||e^{-y/2}T_y h||_p &= ||(1-\Delta)^{1-\theta} e^{-y/2} T_y[(1-\Delta)^{-(1-\theta)}h]||_p \\ &\le N(d,p,\theta)\frac{1}{y^{1-\theta}}||(I-\Delta)^{-(1-\theta)}h||_p, \\ ||(T_y - I)h||_p &\le \int_0^y |||[\Delta(I-\Delta)^{-1}](I-\Delta)^{1-\theta}T_v[(1-\Delta)^{\theta}h]|||_p\, dv \\ &\le N\int_0^y ||(I-\Delta)^{1-\theta}T_v[(1-\Delta)^{\theta}h]||_p\, dv \\ &\le N(d,p,\theta,T)\int_0^y v^{\theta-1}\, dv||h||_{2\theta,p} = Ny^{\theta}||h||_{2\theta,p}. \end{aligned} \tag{5.3}$$

We apply (5.2) to u_1 and $u_2 := u - u_1$, where u_1 is introduced in Lemma 2.4. In order to avoid repetitions of some arguments, we denote $f^{(1)} = f$, $f^{(2)} = g$, $dw_t^{(1)} = dt$, and $dw_t^{(2)} = dw_t$. It is easy to see that

$$u_i(r+y) - u_i(r) = (T_y - I)u_i(r) + \int_0^y T_{y-v}f^{(i)}(r+v)\, dw_{r+v}^{(i)}.$$

Therefore,

$$E||u_i(r+y) - u_i(r)||_p^p \le N(A_i(r,y) + B_i(r,y)),$$

$$E||u_i(t) - u_i(s)||_p^p \le N(t-s)^{\alpha p-1}(I_i(t,s) + J_i(t,s)),$$

where

$$A_i(r,y) = E||(T_y - I)u_i(r)||_p^p, \quad B_i(r,y) = E\left\|\int_0^y T_{y-v}f^{(i)}(r+v)\, dw_{r+v}^{(i)}\right\|_p^p,$$

$$I_i(t,s) = \int_0^{t-s} \frac{dy}{y^{1+\alpha p}} \int_s^{t-y} A_i(r,y)\, dr, \quad J_i(t,s) = \int_0^{t-s} \frac{dy}{y^{1+\alpha p}} \int_s^{t-y} B_i(r,y)\, dr.$$

By using the Burkholder–Davis–Gundy inequality, the Hölder inequality, and (5.3), we get

$$\begin{aligned} B_2(r,y) &\le NE\int_{\mathbb{R}^d}\left[\int_0^y v^{2\beta-1}v^{1-2\beta}|T_v g(r+y-v)|_E^2\, dv\right]^{p/2} dx \\ &\le Ny^{\beta p-1}E\int_0^y ||(I-\Delta)^{\beta-1/2}g(r+y-v)||_p^p\, dv, \end{aligned}$$

$$
\begin{aligned}
J_2 &\le NE\int_0^{t-s}\frac{dy}{y^{2-(\beta-\alpha)p}}\int_s^{t-y}dr\int_0^y ||g(r+y-v)||^p_{n-1,p}\,dv\\
&\le NE\int_0^{t-s}\frac{dy}{y^{2-(\beta-\alpha)p}}\int_0^y dv\int_s^t ||g(r)||^p_{n-1,p}\,dr\\
&= N(t-s)^{(\beta-\alpha)p}E\int_s^t ||g(r)||^p_{n-1,p}\,dr,
\end{aligned}
$$

$$
\begin{aligned}
B_1(r,y) &= E\int_{\mathbb{R}^d}\left|\int_0^y v^{\beta-1}v^{1-\beta}T_v f(r+y-v)\,dv\right|^p\,dx\\
&\le Ny^{\beta p-1}E\int_0^y ||f(r+y-v)||^p_{n-2,p}\,dv,\\
J_1(t,s) &\le N(t-s)^{(\beta-\alpha)p}E\int_s^t ||f(r)||^p_{n-2,p}\,dr.
\end{aligned}
$$

Finally, by again using (5.3) and results from [9] and [12], we conclude

$$
\begin{aligned}
I_2(t,s) &\le NE\int_0^{t-s}\frac{dy}{y^{1-(\beta-\alpha)p}}\int_s^{t-y} ||u_2(r)||^p_{2\beta,p}\,dr\\
&\le N(t-s)^{(\beta-\alpha)p}E\int_0^t ||g(r)||^p_{2\beta-1,p}\,dr,\\
I_1(t,s) &\le N(t-s)^{(\beta-\alpha)p}E\int_0^t ||f(r)||^p_{2\beta-2,p}\,dr.
\end{aligned}
$$

Collecting all these estimates, we get (3.2) at least for $\eta = T\,(=\tau)$. In the general case, it suffices to notice that instead of points t and s on the left in estimate (5.2), one can obviously take any two points between them.

The proof of (3.3) goes exactly the same way, the only difference being that this time we use the following consequence of (5.2):

$$
\sup_{0\le s<t\le T}\frac{||h(t)-h(s)||^p_p}{(t-s)^{\alpha p-1}} \le N(\alpha,p)\int_0^T\int_0^T I_{r_2>r_1}\frac{||h(r_2)-h(r_1)||^p_p}{|r_2-r_1|^{1+\alpha p}}\,dr_1dr_2.
$$

Assertions (ii) and (iii) imply (i) almost automatically. They also imply (iv) and (v) in view of well-known imbedding theorems saying that under conditions in (iv) and (v), we have $H^n_p \subset C^\alpha$ and $H^n_p \subset H^m_q$, respectively (see, for instance, Remarks 2.7.1/2 and 2.7.1/3 in [17]). From the same imbedding theorems and from the interpolation theorem (Theorem 2.4.2) in [17], we have

$$
||u||_{m(\theta)-d/p+d/q,q} \le N(d,p,q,m(0),m(1),\theta)||u||^{1-\theta}_{m(0),p}||u||^{\theta}_{m(1),p}
$$

whenever $1 < p < q < \infty$, $\theta \in (0,1)$, $m(\theta) := (1-\theta)m(0) + \theta m(1) \ne m(0)$, and $u \in H^n_p$. Theorem 14.2 from [5] shows that the case $p = q$ actually needs not to be excluded. Note also that under the conditions in (vi), there is a β such that

$1/2 > \beta > 1/p$ and $m \le k := n - 2\beta(1-\theta) - d/p + d/q$. Therefore,

$$E\left(\int_0^T ||u(t,\cdot)||_{m,q}^{p/\theta}\,dt\right)^\theta \le E\left(\int_0^T ||u(t,\cdot)||_{k,q}^{p/\theta}\,dt\right)^\theta$$
$$\le NE\left(\int_0^T ||u(t,\cdot)||_{n-2\beta,p}^{(1-\theta)p/\theta}||u(t,\cdot)||_{n,p}^{p}\,dt\right)^\theta$$
$$\le NE\sup_{t\le T}||u(t,\cdot)||_{n-2\beta,p}^{(1-\theta)p}\left(\int_0^T ||u(t,\cdot)||_{n,p}^{p}\,dt\right)^\theta .$$

To prove (vi) it remains only to apply the Hölder inequality and assertion (iii). The theorem is proven. □

To prove Theorem 3.2, we need some auxiliary constructions.

DEFINITION 5.1. *Assume that for $\omega \in \Omega$ and $t \ge 0$, we are given operators*

$$L(t,\cdot) : H_p^{n+2} \to H_p^n, \quad \Lambda(t,\cdot) : H_p^{n+2} \to H_p^{n+1}(\mathbb{R}^d, E).$$

Assume that

(i) *for any ω and t, the operators $L(t,u)$ and $\Lambda(t,u)$ are continuous (with respect to u);*

(ii) *for any $u \in H_p^{n+2}$, the processes $L(t,u)$ and $\Lambda(t,u)$ are predictable;*

(iii) *for any $\omega \in \Omega$, $t \ge 0$, and $u \in H_p^{n+2}$, we have*

$$||L(t,u)||_{n,p} + ||\Lambda(t,u)||_{n+1,p} \le N_{L,\Lambda}(1 + ||u||_{n+2,p}),$$

where $N_{L,\Lambda}$ is a constant.

Then for a function $u \in \mathcal{H}_p^{n+2}(T)$, we write

$$(L,\Lambda)u = -(f,g)$$

if $(f,g) \in \mathcal{F}_p^n(T)$, and in the sense of distributions for $t \in [0,T]$, we have that

$$u(t) = u(0) + \int_0^t (L(s,u(s)) + f(s))\,ds + \int_0^t (\Lambda(s,u(s)) + g(s))\,dw_s \quad \text{(a.s.)}.$$

Remark 5.1. By virtue of our conditions on L and Λ, for any $u \in \mathcal{H}_p^{n+2}(T)$, we have $(L(u),\Lambda(u)) \in \mathcal{F}_p^n(T)$. It immediately follows that the operator (L,Λ) is well defined on $\mathcal{H}_p^{n+2}(T)$, and

$$||(L,\Lambda)u||_{\mathcal{F}_p^n(T)} \le (1 + N_{L,\Lambda})||u||_{\mathcal{H}_p^{n+2}(T)} + N_{L,\Lambda}T^{1/p}.$$

Observe that $||u_x||_{n,p} \le N||(I-\Delta)^{1/2}u||_{n,p}$ for any $u \in H_p^{n+1}$. This shows that, in terms of Definition 5.1, Theorem 2.1 has the following version.

THEOREM 5.1. *Let a and σ satisfy the assumptions from §2. Define*

$$Lu = a^{ij}u_{x^ix^j}, \quad \Lambda u = \sigma^i u_{x^i}.$$

Then the operator (L,Λ) is a one-to-one operator from $\mathcal{H}_{p,0}^{n+2}(T)$ onto $\mathcal{F}_p^n(T)$ and the norm of its inverse is less than a constant depending only on d, p, δ, and K (thus independent of T).

Next we prove a perturbation result. It needs a proof because we do not allow ε to depend on T.

THEOREM 5.2. *Take the operators L and Λ from Theorem 5.1, and let some operators L_1 and Λ_1 satisfy the requirements from Definition 5.1. We assert that there exists a constant $\varepsilon \in (0,1)$ depending only on d, p, δ, and K such that if for a constant K_1 and any $u, v \in H_p^{n+2}$, $t \geq 0$, $\omega \in \Omega$, we have*

$$||L_1(t,u) - L_1(t,v)||_{n,p} + ||\Lambda_1(t,u) - \Lambda_1(t,v)||_{n+1,p}$$

$$\leq \varepsilon||u_{xx} - v_{xx}||_{n,p} + K_1||u - v||_{n+1,p}, \tag{5.4}$$

then for any $(f,g) \in \mathcal{F}_p^n(T)$, there exists a unique solution $u \in \mathcal{H}_{p,0}^{n+2}(T)$ of the equation

$$(L + L_1, \Lambda + \Lambda_1)u = -(f,g).$$

Furthermore, for this solution u, we have

$$||u||_{\mathcal{H}_p^{n+2}(T)} \leq N||(L_1(\cdot,0) + f, \Lambda_1(\cdot,0) + g)||_{\mathcal{F}_p^n(T)},$$

where N depends only on d, p, δ, K, K_1, and T and N is independent of T if $K_1 = 0$.

Proof. Take $u \in \mathcal{H}_{p,0}^{n+2}(T)$, observe that $(L_1(u), \Lambda_1(u)) \in \mathcal{F}_p^n(T)$, and by using Theorem 5.1, define $v \in \mathcal{H}_{p,0}^{n+2}(T)$ as the unique solution of the equation $(L,\Lambda)v = -(f + L_1(u), g + \Lambda_1(u))$. By denoting $v = Ru$, we define an operator $R : \mathcal{H}_{p,0}^{n+2}(T) \to \mathcal{H}_{p,0}^{n+2}(T)$. The only thing we have to establish is that for an integer $m > 0$ (under control), the operator R^m is a contraction in $\mathcal{H}_{p,0}^{n+2}(T)$.

By Theorem 5.1, for $t \leq T$,

$$\begin{aligned}||Ru - Rv||^p_{\mathcal{H}_p^{n+2}(t)} &\leq N||(L_1(u) - L_1(v), \Lambda_1(u) - \Lambda_1(v))||^p_{\mathcal{F}_p^n(t)} \\ &\leq N_0\varepsilon^p||u - v||^p_{\mathcal{H}_p^{n+2}(t)} + N_0K_1^p\int_0^t E||u(s) - v(s)||^p_{n+1,p}\,ds,\end{aligned}$$

with the constant N_0 depending only on d, p, δ, and K. This gives the desired result if $K_1 = 0$. In the general case, by Theorem 3.1 (or by Theorem 2.1),

$$E||u(s) - v(s)||^p_{n+1,p} \leq N_1||u - v||^p_{\mathcal{H}_p^{n+2}(s)},$$

where $s \leq T$ and N_1 depends only on d, p, and T. It follows that for $t \leq T$ and $\theta := N_0\varepsilon^p$, we have

$$||Ru - Rv||^p_{\mathcal{H}_p^{n+2}(t)} \leq \theta||u - v||^p_{\mathcal{H}_p^{n+2}(t)} + N_2\int_0^t ||u - v||^p_{\mathcal{H}_p^{n+2}(s)}\,ds,$$

where N_2 depends only on d, p, δ, K, K_1, and T. Hence, by induction,

$$\begin{aligned}||R^m u - R^m v||^p_{\mathcal{H}_p^{n+2}(t)} &\leq \theta^m||u - v||^p_{\mathcal{H}_p^{n+2}(t)} \\ &+\sum_{k=1}^m \binom{m}{k}\theta^{m-k}N_2^k\int_0^t \frac{(t-s)^{k-1}}{(k-1)!}||u - v||^p_{\mathcal{H}_p^{n+2}(s)}\,ds,\end{aligned}$$

$$||R^m u - R^m v||^p_{\mathcal{H}^{n+2}_p(T)} \leq \sum_{k=0}^{m} \binom{m}{k} \theta^{m-k} \frac{1}{k!} (TN_2)^k ||u - v||^p_{\mathcal{H}^{n+2}_p(T)}$$
$$\leq 2^m \theta^m \max_k \frac{1}{k!} (TN_2/\theta)^k ||u - v||^p_{\mathcal{H}^{n+2}_p(T)}.$$

This allows us to find a needed m, and the theorem is proven. □

We finish our preparations by showing how Lemma 3.1 will be used.

Remark 5.2. To some extent, in what follows, the most important consequence of assertion (i) in Lemma 3.1 is that for any a from the lemma there exists a new norm $]|\cdot|[_{n,p}$ in H^n_p such that

$$]|au|[_{n,p} \leq 2N||a||_B]|u|[_{n,p},$$

where N is the same constant as in Lemma 3.1. To show this, it suffices to observe that for $a_m(x) = a(x/m)$ and $u_m(x) = u(x/m)$, we have

$$||(m^2 I - \Delta)^{n/2}(au)||_p = m^{n-d/p}||(I - \Delta)^{n/2}(a_m u_m)||_p$$
$$\leq N\bar{a}_m m^{n-d/p}||(I - \Delta)^{n/2} u_m||_p = N\bar{a}_m||(m^2 I - \Delta)^{n/2} u||_p$$
$$\leq N\left(||a||_B + \frac{1}{m^{(|n|+\gamma)\wedge 1}}\bar{a}\right)||(m^2 I - \Delta)^{n/2} u||_p.$$

Alternatively, it would be sufficient for our needs to know that

$$||au||_{n,p} \leq N(||a||_B||u||_{n,p} + ||a||_{C^{|n|+\gamma}}||u||_{n-1,p}).$$

Unfortunately, the author could not find the last inequality in the literature, though some very interesting information related to the subject can be found in [7].

Now we perform the main step in proving Theorem 3.2. Below we suppose that its assumptions are satisfied.

LEMMA 5.1. *There exists an $\varepsilon = \varepsilon(d, p, n, \gamma, \delta, K) > 0$ such that if $\tau = T$ and*

(i) *condition* (3.5) *is satisfied with this ε for all x, y, t, and ω and*

(ii) *f and g are independent of u,*

then there exists a unique solution $u \in \mathcal{H}^{n+2}_{p,0}(T)$ of equation (3.4). *Furthermore, for this solution u, we have*

$$||u||_{\mathcal{H}^{n+2}_p(T)} \leq N||(f, g)||_{\mathcal{F}^n_p(T)},$$

where N depends only on d, p, δ, K, and T.

Proof. Define $a(t) = a(t, 0)$ and $\sigma(t) = \sigma(t, 0)$, take operators L and Λ from Theorem 5.1 corresponding to $a(t)$ and $\sigma(t)$, and let

$$L_1(t, u)(x) = [a^{ij}(t, x) - a^{ij}(t)]u_{x^i x^j}(x), \quad \Lambda_1(t, u)(x) = [\sigma^i(t, x) - \sigma^i(t)]u_{x^i}(x).$$

In view of Theorem 5.2, to prove existence and uniqueness, we have only to check that if ε in (3.5) is sufficiently small, then the operators L_1 and Λ_1 satisfy condition (5.4) with as small ε as we like and with K_1 under control. Observe that by Lemma 3.1,

$$||[a^{ij}(t, \cdot) - a^{ij}(t)]u_{x^i x^j}||_{n,p} \leq N||a(t, \cdot) - a(t, 0)||_{C^{|n|+\gamma}}||u_{xx}||_{n,p},$$

$$||[\sigma^i(t, \cdot) - \sigma^i(t)]u_{x^i}||_{n+1,p} \leq N||\sigma(t, \cdot) - \sigma(t, 0)||_{C^{|n|+\gamma+1}}||u_x||_{n+1,p}.$$

Since $||u_x||_{n+1,p} \leq N(||u_{xx}||_{n,p} + ||u||_{n+1,p})$, the lemma holds true if

$$||a(t,\cdot)-a(t,0)||_{C^{|n|+\gamma}} + ||\sigma(t,\cdot)-\sigma(t,0)||_{C^{|n|+\gamma+1}(\mathbb{R}^d,E)} \leq \varepsilon_0 = \varepsilon_0(d,p,n,\gamma,\delta,K) \quad \forall\, t.$$

Next, observe that for $a_m(t,x) = a(t/m^2, x/m)$, we have

$$||a_m(t,\cdot) - a_m(t,0)||_{C^{|n|+\gamma}} \leq \varepsilon + 2m^{-[((|n|+\gamma)\wedge 1]}K,$$

and an analogous inequality holds for σ. It follows that for m sufficiently large, the statements of the lemma are true if we replace a, σ, w_t, f, g, and T in equation (3.4) by $a_m, \sigma_m, mw_{t/m^2}$, $m^{-2}f(t/m^2, x/m)$, $m^{-1}g(t/m^2, x/m)$, and m^2T, respectively. After this, it remains only to fix an appropriate m and make an obvious change of variables in the above-mentioned modification of equation (3.4) (and use that $I-\Delta \sim m^2I-\Delta$). The lemma is proven. □

Finally, we need the following result from [9], which in a sense is essentially covered by Theorem 2.4.7 from [18].

LEMMA 5.2. *Let $\delta > 0$ and let $\zeta_k \in C^\infty$, $k = 1,2,3,\ldots$. Assume that for any multiindex α and $x \in \mathbb{R}^d$,*

$$\sup_{x\in\mathbb{R}^d} \sum_k |D^\alpha \zeta_k(x)| \leq M(\alpha),$$

where $M(\alpha)$ are some constants. Then there exists a constant $N = N(d,n,M,\delta)$ such that for any $f \in H_p^n$,

$$\sum_k ||\zeta_k f||^p_{H_p^n} \leq N||f||^p_{H_p^n}.$$

If in addition

$$\sum_k |\zeta_k(x)|^p \geq \delta,$$

then for any $f \in H_p^n$,

$$||f||^p_{n,p} \leq N \sum_k ||\zeta_k f||^p_{n,p}.$$

Proof of Theorem 3.2. First observe that by considering $u(t,x) - u_0(x)$ and using Lemma 3.1, one easily reduces the general situation to the case $u_0 = 0$. For an obvious reason, we can assume that $\tau \equiv T$. In this case, define

$$Lu = a^{ij}(t,x)u_{x^ix^j}(t,x), \quad \Lambda u = \sigma^i(t,x)u_{x^i}(t,x),$$

and let $\{\zeta_k : k = 1,2,3,\ldots\}$ be a standard partition of unity such that for any k, condition (3.5) is satisfied for x and y in the support of ζ_k with ε from Lemma 5.1. Then by this lemma, for any $u \in \mathcal{H}^{n+2}_{p,0}(T)$ and for any k,

$$\begin{aligned} ||u\zeta_k||_{\mathcal{H}_p^{n+2}(T)} &\leq N||(L,\Lambda)(u\zeta_k)||_{\mathcal{F}_p^n(T)} \\ &\leq N||\zeta_k(L,\Lambda)u||_{\mathcal{F}_p^n(T)} + N||(uL\zeta_k + 2(a\zeta_{kx}, u_x), u\Lambda\zeta_k)||_{\mathcal{F}_p^n(T)}. \end{aligned}$$

By summing up the pth powers of the extreme terms and applying Lemma 5.2, we conclude that for any $u \in \mathcal{H}^{n+2}_{p,0}(T)$,

$$||u||_{\mathcal{H}_p^{n+2}(T)} \leq N(||(L,\Lambda)u||_{\mathcal{F}_p^n(T)} + ||u||_{\mathcal{H}_p^{n+1}(T)}).$$

Actually, the last term in parentheses on the right can be dropped, which follows from Gronwall's inequality and assertions (ii) and (iii) in Theorem 3.1 (cf. the proof of Theorem 3.3). Hence, the standard method of continuity (cf., for instance, [4]) (when one considers $(1-\lambda)\delta^{ij}+\lambda a^{ij}$ and λw instead of a^{ij} and w and makes λ vary in $[0,1]$) and the above a priori estimate as usual yield the existence and uniqueness of solution for equation (3.4) when f and g are independent of u. To consider general f and g, it remains only to repeat the proof of Theorem 5.2 taking $f(u,t,x)$ and $g(u,t,x)$ instead of $f+L_1(u)$ and $g+\Lambda_1(u)$ there. The theorem is proven. □

Acknowledgment. The author thanks S. Lapic for pointing out several mistakes and misprints in the original version of the article.

BEHAVIOUR IN THE LIMIT, AS $p \to \infty$, OF MINIMIZERS OF FUNCTIONALS INVOLVING p-DIRICHLET INTEGRALS[*]

ULF JANFALK[†]

Abstract. The purpose of this paper is to study the behaviour, as $p \to \infty$, of minimizers of functionals involving p-Dirichlet integrals in a bounded Lipschitz domain, $\Omega \subset \mathbf{R}^n$. In the case where Ω is a convex ring it is proved that the minimizers converge monotonically and uniformly. In the paper by T. Bhattacharya, E. DiBenedetto, and J. Manfredi [Limits as $p \to \infty$ of $\Delta_p u_p = f$ and related extremal problems, *Rend. Sem. Mat. Univ. Politec. Torino*, (1989), pp. 15–68], the problem of torsional creep is studied. Here the situation is generalized by introducing a more general functional and relaxing the boundary conditions. Various aspects of the Green function of the p-laplacian are considered and it is proved that the Green function is not symmetric if p is sufficiently large. Finally, it is proved that the extremals to the dual problem tend to zero in the mean as $p \to \infty$, outside a well-specified subset of Ω.

1. Introduction.

In this paper we will investigate the behaviour and convergence properties as $p \to \infty$ of sequences of minimizers of certain convex minimization problems in Ω involving p-Dirichlet integrals. Throughout the paper Ω will be a bounded domain in $\mathbf{R}^n$ with Lipschitz boundary $\partial\Omega$.

The paper by Bhattacharya et al. [BDM] constitutes an important background for this work. There the limits as $p \to \infty$ of solutions to the equation $\Delta_p u = f$, where Δ_p is the p-laplace or p-harmonic operator, are studied in connection with the problem of torsional creep. The limit process leads to the study of the operator Δ_∞ which is obtained as a formal limit of the operator Δ_p as $p \to \infty$ (see §2 for a more detailed description of these operators). Note that Δ_∞ is not of a variational nature. This leads to some complications in finding a suitable solution concept. In [BDM], four different solution concepts are considered. These are classical solutions, absolute minimals, viscosity solutions, and variational solutions. Their mutual relations are also investigated. Classical solutions and absolute minimals have been studied in some detail by Aronsson in two papers, [Ar1] and [Ar2], and among other things, it was shown that classical solutions to the Dirichlet problem for $\Delta_\infty u = 0$ are in some sense rare. Recently, Jensen has shown that absolute minimals are viscosity solutions of $\Delta_\infty u = 0$ [J, Thm. 1.15] and that the Dirichlet problem for $\Delta_\infty u = 0$ has a unique viscosity solution [J, Thm. 2.22, p. 70] provided the boundary values are in the space

$$\mathrm{Lip}(\partial\Omega) = \left\{ g \in C(\partial\Omega) \colon \sup_{x,y \in \partial\Omega} \frac{|g(x) - g(y)|}{d_\Omega(x,y)} < \infty \right\},$$

where d_Ω denotes the distance within Ω. This condition on the boundary values is also necessary for an absolute minimal and a variational solution to exist. By [BDM, Prop. 2.2, p. 27] variational solutions are viscosity solutions so the results of Jensen thereby show that the solution concept's absolute minimal, variational solution and viscosity solution are equivalent. Here we will use the variational solution approach since it is better suited for our purposes.

[†] Department of Mathematics, Linköping University, S-581 83 Linköping, Sweden.

The paper is organized as follows. In §2 we consider variational solutions of the limit equation, derived from capacitary functions for a particular type of condensers, called ring domains. We prove monotone and uniform convergence of the capacitary functions when Ω is a convex ring. This also implies uniqueness of the variational solution.

In §3 we generalize the situation in [BDM], e.g., we consider a slightly more general functional and relax the boundary conditions somewhat. We also introduce a weight function. We study the problem using methods from convex analysis. We derive a dual problem and investigate the relation between the primal and dual problems. The majority of the results we prove are related to those of [BDM] and so are the proofs. We end the section by proving that, if μ is a finite, positive Borel measure then the family $\{u_p\}_{p>n}$ of solutions of $-\Delta_p u = \mu$, $u = 0$ on $\partial\Omega$, has a unique limit as $p \to \infty$.

Section 4 deals with various aspects of the Green function for the p-laplacian. An interesting detail regarding the Green function is that it fits into the setting of both §§2 and 3. It is well known that the Green function is symmetric if $p = 2$. We show here that if p is sufficiently large then the Green function is not symmetric.

We finish this paper in §5 with a theorem concerning the asymptotic behaviour of the extremals of the dual problems. We prove, roughly speaking, that the "mass" of the solution to the dual problem concentrates on the set of uniqueness as $p \to \infty$ $(q \to 1+)$.

2. On the monotone convergence of capacitary functions in a convex ring and a comparison principle. The variational equation

$$\int_\Omega |\nabla u|^{p-2}\nabla u \cdot \nabla\varphi\, dx = 0, \quad \text{for all } \varphi \in C_0^\infty(\Omega), \tag{2.1}$$

also written $\operatorname{div}(|\nabla u|^{p-2}\nabla u) = 0$, is the Euler equation for the p-Dirichlet integral

$$I_p(u) = \int_\Omega |\nabla u|^p\, dx \quad (1 < p < \infty).$$

The nonlinear operator associated with (2.1) is called the p-laplacian or the p-harmonic operator and will be denoted by Δ_p. Any function $u \in W^{1,p}_{loc}(\Omega)$ satisfying (2.1) will be called p-harmonic. The equation $\Delta_\infty u = 0$ is obtained as a formal limit of $\Delta_p u = 0$ as $p \to \infty$. To be explicit, suppose u is p-harmonic, $u \in C^2(\Omega)$, and $\nabla u \neq 0$; then

$$\begin{aligned} \Delta_p u &= \operatorname{div}(|\nabla u|^{p-2}\nabla u) \\ &= |\nabla u|^{p-4}\left((p-2)\sum_{i,j=1}^n u_{x_i}u_{x_j}u_{x_ix_j} + |\nabla u|^2\Delta u\right) = 0. \end{aligned} \tag{2.2}$$

Thus, dividing both sides by $(p-2)|\nabla u|^{p-4}$ and letting $p \to \infty$ we get formally

$$\Delta_\infty u = \sum_{i,j=1}^n u_{x_i}u_{x_j}u_{x_ix_j} = 0.$$

In [Ar2, Thm. 13, p. 425] it was shown that if $\Omega \subset \mathbf{R}^2$ then the class $C^2(\Omega)$ is too small to solve the Dirichlet problem

$$\begin{cases} \Delta_\infty u = 0 \text{ in } \Omega, \\ u = g \quad \text{on } \partial\Omega \end{cases} \tag{2.3}$$

if, e.g., Ω is the unit disk and g is any nonconstant function satisfying $g(x,y) = g(-x,-y)$ for x,y on the unit circle. Instead, an alternative solution concept, the so-called absolute minimals, was introduced. In [BDM] the concept of a variational solution was introduced. A variational solution of (2.3) is obtained by the following limit procedure. Let $g \in W^{1,\infty}(\Omega)$ be given. Denote by u_p the unique solution in $W^{1,p}(\Omega)$ of the boundary value problem

$$\begin{cases} \Delta_p u = 0 & \text{in } \Omega, \\ u - g \in W_0^{1,p}(\Omega). \end{cases} \tag{2.4}$$

Let $m > n$ and put $G_m = \{u_p : p > m\}$. In [BDM, pp. 25, 26] it is shown that there is an element $u_\infty \in W^{1,\infty}(\Omega)$ and a sequence $\{u_{p_k}\}_{k=1}^{\infty}$ from G_m such that

$$u_{p_k} \to u_\infty \quad \text{weakly in } W^{1,m}(\Omega), \tag{2.5}$$

$$u_{p_k} \to u_\infty \quad \text{in } C^{0,\lambda}(\overline{\Omega}), \text{ for any } \lambda \in \left(0, 1 - \frac{n}{m}\right) \tag{2.6}$$

as $p_k \to \infty$. Following the terminology of [BDM] we will call any element u_∞ obtained in this way a variational solution of $\Delta_\infty u = 0$. By [BDM, Prop. 2.2, p. 27] variational solutions are viscosity solutions. Thus by [J, Thm. 2.22, p. 70], we get that a variational solution is unique and it is easy to see that (2.5) and (2.6) hold with u_{p_k} replaced by u_p (see the proof of Theorem 2.5).

In this section we will study the variational solutions obtained from capacitary functions of a special type of condensers, called ring domains. By a ring domain Ω we mean a bounded doubly connected domain in $\mathbf{R}^n$. Denote by K the bounded component of $\mathbf{R}^n \setminus \Omega$ and put $D = \Omega \cup K$. We say that Ω is a convex ring if D and K are convex. Note that the definition requires that K is compact and contained in the open set D. Further, a convex ring is not a convex set.

DEFINITION 1. Let $1 < p < \infty$ and let K be a compact subset of the open set D. The quantity

$$\operatorname{cap}_p(K,D) = \inf\left\{ \int_D |\nabla v|^p \, dx : v \in W_0^{1,p}(D) \cap C(D),\ v \geq 1 \text{ on } K \right\}$$

is called the p-capacity of the condenser (K,D). A function $u \in W_0^{1,p}(D)$, $u \geq 1$ on K, such that

$$\operatorname{cap}_p(K,D) = \int_D |\nabla u|^p \, dx$$

is called a capacitary function with respect to p and (K,D). This is the definition of capacity according to [HKM]. If $p > n$ then the capacitary function with respect to p and (K,D) is equal to 1 on K. In [L, pp. 202–204], Lewis proves that the capacitary function of a ring domain is unique and that it is p-harmonic in Ω. The definition of capacity according to Lewis is somewhat different but yields the same result. In particular, the capacitary function of the convex ring $\Omega = D \setminus K$ is the same as the capacitary function of the condenser (K,D). The following theorem is also proved (see [L, Thm. 1, p. 204]).

THEOREM 2.1. *Given a convex ring $\Omega = D \setminus K$ and a constant p, $1 < p < \infty$, let u be the capacitary function corresponding to p and Ω. Then u has a continuous representative in $W_0^{1,p}(D)$ such that*

(1) *the set* $\{x : u(x) > t\}$ *is convex for* $0 \leq t < 1$,
(2) u *is real analytic in* Ω,
(3) *if* $u \not\equiv 0$ *and* $x \in \Omega$, *then all normal curvatures at* x *of the level surface* $\{y : u(y) = u(x)\}$ *are positive,*
(4) *if* $u \not\equiv 0$ *then* ∇u *is univalent in* Ω *and maps* $\{x : u(x) = t\}$, $0 < t < 1$, *onto a surface which is star shaped with respect to the origin.*

In particular, $\nabla u \neq 0$ in Ω (see [L, Lem. 2, p. 207]). In $\mathbf{R}^2$ the regularity part of Theorem 2.1 holds for any ring domain as follows from Theorem 2.2.

THEOREM 2.2. *Let* $\Omega = D \setminus K \subset \mathbf{R}^2$ *be a ring domain* (*not necessarily convex*) *and let* $1 < p < \infty$. *Then the corresponding capacitary function* u_p *is real analytic in* Ω.

Proof. We first observe that Ω being a ring domain implies that K is either a continuum of positive diameter or a single point. If K is a single point and $1 < p \leq 2$ then $\text{cap}_p(K, D) = 0$ so that $u_p \equiv 0$. We can thus assume that $\text{cap}_p(K, D) > 0$. If $p = 2$ the result is classical. In the case $p \neq 2$ we first claim that u_p can be extended continuously to K by $u_p = 1$ on K. For $p > 2$ this is obvious and in the case $1 < p < 2$ we do as follows. By [M1, 9.1.2, Prop. 1, p. 392] we have for any continuum e that

$$\text{cap}_p(e, \mathbf{R}^2) \sim d^{2-p}$$

where d is the diameter of e. Let $B_r(x)$ be the disc with radius r centered at x. Obviously, for every $x \in K$ and every $r > 0$ such that $B_r(x) \subset \Omega$ there is a continuum $K_r(x) \subset K \bigcap B_r(x)$ such that $r \leq \text{diam} K_r(x) \leq 2r$. Clearly, $\text{cap}_p(K \bigcap B_r(x), B_{2r}(x)) \geq \text{cap}_p(K \bigcap B_r(x), \mathbf{R}^2) \geq \text{cap}_p(K_r(x), \mathbf{R}^2)$ and by, e.g., [HKM, p. 35] we have that $\text{cap}_p(B_r(x), B_{2r}(x)) = c_p r^{2-p}$ where $c_p > 0$ is a constant. Hence, for every $x \in K$ the Wiener-type integral

$$\int_0^1 \left(\frac{\text{cap}_p(K \bigcap B_r(x), B_{2r}(x))}{\text{cap}_p(B_r(x), B_{2r}(x))} \right)^{\frac{1}{p-1}} \frac{dr}{r} = \infty.$$

By [M2, Thm., p. 236] the claim follows (see also [HKM, 6.17, p. 114; Cor. 6.28, p. 122]). For $0 < t < 1$, put $\Omega_t = \{x \in D \colon u_p(x) > t\}$. It is enough to show that $\nabla u_p(x) \neq 0$ for every $x \in \Omega$ (see [L, pp. 207–208]). Clearly, Ω_t is open. Further, Ω_t can have one component only. To see this, let V_1 be a component of Ω_t that intersects K and put $V_2 = \Omega_t \setminus V_1$. Since u_p is continuous on $\overline{\Omega}$ and $u_p = 1$ on K it is clear that $K \subset V_1$. This implies that $\overline{V}_2 \subset \Omega$. By the comparison principle (see [T, p. 312]) we then get that u_p is constant on V_2, which is impossible.

Suppose x_1 is such that $u_p(x_1) = t$ and $\nabla u_p(x_1) = 0$. Let N denote the order of the zero of ∇u_p at x_1, as defined in [Ar3, p. 76]. Using [Ar3, Thm. 4, pp. 83–84], we see that there is a $\delta > 0$ such that $\varphi(x) = u_p(x) - t$ has a representation in hodograph coordinates valid for $B_\delta = \{x : |x - x_1| < \delta\}$. From this representation it is evident that B_δ can be split into $2N$ parts such that φ is nonnegative in N parts, nonpositive in N parts, and the parts where φ has the same sign have x_1 as their only common point. Since Ω_t has only one component this situation is obviously impossible. Thus $\nabla u_p \neq 0$ on Ω. □

Before we proceed we need two more definitions.

DEFINITION 2. (1) A function $u \in W^{1,p}_{loc}(\Omega)$ is a p-supersolution of Δ_p if $-\Delta_p u \geq 0$ in the weak sense, i.e., if

$$\int_\Omega |\nabla u|^{p-2} \nabla u \cdot \nabla \varphi \, dx \geq 0$$

for all $\varphi \in C_0^\infty(\Omega)$ such that $\varphi \geq 0$.

(2) A function $u : \Omega \to \mathbf{R} \bigcup \{\infty\}$ is p-superharmonic if

(i) u is lower semicontinuous,

(ii) $u \not\equiv \infty$ in each component of Ω,

(iii) for each bounded open set D, such that $\overline{D} \subset \Omega$ and for each p-harmonic function $h \in C(\overline{D})$ the inequality $u \geq h$ on ∂D implies $u \geq h$ on D.

In [HKM, pp. 136–138] it is shown that a p-supersolution is always p-superharmonic, possibly after a change on a set of measure zero and that if the p-superharmonic function is in $W^{1,p}_{loc}(\Omega)$ then it is also a p-supersolution.

Lemma 2.4 relies heavily on Theorem 2.1(3). Therefore we digress a bit from the main subject of this section and study the normal curvature of the level sets of a smooth function. We will now derive the identity (2.7).

Let u be a C^2 function on an open subset of $\mathbf{R}^n$ and suppose $|\nabla u(x)| \neq 0$ for some x. Put $E_x = \{y : u(y) = u(x)\}$ and denote the tangent space at x by $T(x)$. The normal curvature, according to Lewis, of E_x at x in the direction of the unit vector $t \in T(x)$ is defined to be

$$K(t, x) = -\frac{u_{tt}(x)}{|\nabla u(x)|}$$

where the subscript t denotes differentiation in the direction given by $t \in T(x)$. Then

$$u_{tt} = t \cdot \nabla(t \cdot \nabla u) = \sum_{i,j=1}^{n} t_i t_j u_{x_i x_j}.$$

For $1 \leq r < k \leq n$ define the $n \times n$-matrix $A_{r,k} = (a_{i,j})_{i,j=1}^n$ by $a_{r,k} = 1$, $a_{k,r} = -1$, and $a_{i,j} = 0$ otherwise, i.e., $A_{r,k}\nabla u(x)$ is a vector in $\mathbf{R}^n$ having $-u_{x_k}$ and u_{x_r} as rth and kth components, respectively. Thus $\nabla u(x) \cdot A_{r,k}\nabla u(x) = 0$. Since $\nabla u(x) \neq 0$ it follows that $T(x)$ is spanned by $\{A_{r,k}\nabla u(x)\}_{1 \leq r < k \leq n}$. This is easily seen if one parametrizes the hyperplane $y \cdot \nabla u(x) = 0$. Put

$$t_{r,k} = \frac{A_{r,k}\nabla u(x)}{|A_{r,k}\nabla u(x)|}$$

if $A_{r,k}\nabla u(x) \neq 0$ and $t_{r,k} = 0$ otherwise. Here, as before, $1 \leq r < k \leq n$. With this choice of tangent directions we obtain

$$\begin{aligned}
&|\nabla u(x)| \sum_{r=1}^{n-1} \sum_{k=r+1}^{n} |A_{r,k}\nabla u(x)|^2 K(t_{r,k}, x) \\
&= -\sum_{r=1}^{n-1} \sum_{k=r+1}^{n} |A_{r,k}\nabla u(x)|^2 t_{r,k} \cdot \nabla(t_{r,k} \cdot \nabla u)(x) \\
&= -\sum_{r=1}^{n-1} \sum_{k=r+1}^{n} \left(u_{x_k}^2 u_{x_r x_r} + u_{x_r}^2 u_{x_k x_k} - 2u_{x_r} u_{x_k} u_{x_r x_k}\right) \\
&= -\sum_{i=1}^{n} \left(|\nabla u|^2 - u_{x_i}^2\right) u_{x_i x_i} + \sum_{\substack{i,j=1 \\ i \neq j}} u_{x_i} u_{x_j} u_{x_i x_j} \\
&= \Delta_\infty u - |\nabla u|^2 \Delta u.
\end{aligned}$$

Above, u and the derivatives of u that occur are to be evaluated at x. We have proved the following lemma.

LEMMA 2.3. *Suppose that u is a C^2 function in a neighbourhood of the point $x \in \mathbf{R}^n$ and that $\nabla u(x) \neq 0$. Then*

$$(2.7)\quad |\nabla u(x)| \sum_{r=1}^{n-1} \sum_{k=r+1}^{n} |A_{r,k}\nabla u(x)|^2 K(t_{r,k}, x) = (\Delta_\infty u)(x) - |\nabla u(x)|^2 (\Delta u)(x).$$

Note that the right-hand side of (2.7) is invariant under orthogonal coordinate transformations.

We now have sufficient background to prove the following fundamental lemma.

LEMMA 2.4. *Let $\Omega = D \setminus K$ be a convex ring and suppose $\operatorname{cap}_p(K, D) > 0$. For $1 < p < \infty$, denote by u_p the capacitary function corresponding to p and Ω. If $1 < p_1 < p_2$ then u_{p_2} is both p_1-superharmonic and a p_1-supersolution. Furthermore, u_{p_1} is both p_2-subharmonic and a p_2-subsolution. Hence $u_{p_1}(x) \leq u_{p_2}(x)$ in Ω.*

Proof. By Theorem 2.1, u_p is real analytic and $\nabla u_p(x) \neq 0$ for all $x \in \Omega$. Thus the p-laplacian can be interpreted in the classical sense. Hence, by (2.2) we have

$$(2.8)\qquad \Delta u_p = -\frac{p-2}{|\nabla u_p|^2} \Delta_\infty u_p$$

for all $p > 1$. When dealing with u_p we add the subscript p whenever needed. By Theorem 2.1, $K_p(t, x) > 0$. Since u_p is p-harmonic we get by inserting (2.8) into (2.7) that

$$(2.9)\qquad |\nabla u_p(x)| \sum_{r=1}^{n-1} \sum_{k=r+1}^{n} |A_{r,k}\nabla u_p(x)|^2 K_p(t_{r,k}, x) = (p-1)\Delta_\infty u_p > 0,$$

for all $p > 1$.

Now let $p_1 < p_2$. Then by (2.8) and (2.9) we get

$$\begin{aligned} -\Delta_{p_1} u_{p_2} &= -|\nabla u_{p_2}|^{p_1 - 4} \left((p_1 - 2)\Delta_\infty u_{p_2} + |\nabla u_{p_2}|^2 \Delta u_{p_2} \right) \\ &= -|\nabla u_{p_2}|^{p_1 - 4} \left((p_1 - 2)\Delta_\infty u_{p_2} - (p_2 - 2)\Delta_\infty u_{p_2} \right) \\ &= (p_2 - p_1)|\nabla u_{p_2}|^{p_1 - 4} \Delta_\infty u_{p_2} > 0. \end{aligned}$$

Consequently, u_{p_2} is a p_1-supersolution and therefore u_{p_2} is p_1-superharmonic. That u_{p_1} is a p_2-subsolution follows directly from above by replacing p_1 by p_2 and vice versa. □

By (2.5) and basic properties of p-superharmonic functions we get the following consequences.

THEOREM 2.5. *Let $\Omega = D \setminus K$ be a convex ring and let $f \in W^{1,\infty}(\Omega)$ be such that $f = 0$ on ∂D and $f = 1$ on K. Then the boundary value problem*

$$(2.10)\qquad \begin{cases} \Delta_\infty u = 0 & \text{in } \Omega, \\ u - f \in W_0^{1,\infty}(\Omega) \end{cases}$$

has a unique variational solution u_∞. Moreover, $u_p \to u_\infty$ in $C^{0,\lambda}(\overline{\Omega})$ for any $\lambda \in (0, 1)$ as $p \to \infty$ and $u_p(x) \nearrow u_\infty(x)$ as $p \to \infty$ for every $x \in \Omega$.

Proof. Let u_p be the solution to (2.4) and consider the set $G_n = \{u_p\}_{p>n}$. By Lemma 2.4 we have that u_p is p_1-superharmonic for any $1 < p_1 < p$. Let $\{u_{p_k}\}_{k=1}^{\infty} \subset$

G_n be a sequence with limit element u_∞ as in (2.5) and (2.6). From Definition 2(2(iii)) it then follows that $u_{p_i}(x) \leq u_p(x) \leq u_{p_j}(x)$ for all $x \in \Omega$ if $p_i \leq p \leq p_j$. Thus,

$$u_p \longrightarrow u_\infty \tag{2.11}$$

uniformly as $p \to \infty$ since $u_{p_k} \to u_\infty$ in $C^{0,\lambda}(\overline{\Omega})$, $\lambda \in (0, 1 - \frac{n}{p_1})$. To see that this holds for the entire net G_n, suppose on the contrary that there exists a sequence $\{u_{p_k^*}\}_{k=1}^\infty$ with $p_1^* > p_1$ and a $\delta > 0$ such that

$$\| u_{p_k^*} - u_\infty \|_{C^{0,\lambda}} \geq \delta \tag{2.12}$$

for all k and some $\lambda \in (0, 1 - \frac{n}{p_1})$. The sequence $\{u_{p_k^*}\}_{k=1}^\infty$ is bounded in $W_0^{1,p_1}(\Omega)$ (see [BDM, pp. 25–26]) and by the Rellich–Kondrachov theorem it has a subsequence converging to a function u_∞^* in $C^{0,\lambda}(\overline{\Omega})$. It follows immediately from (2.11) that

$$u_\infty^* = u_\infty$$

which contradicts (2.12).

To finish the proof, take $\lambda \in (0, 1)$ arbitrary and choose k large enough so that $\lambda < 1 - \frac{n}{p_k}$. Clearly the above reasoning can be repeated and we deduce

$$u_p \longrightarrow u_\infty$$

in $C^{0,\lambda}(\overline{\Omega})$ for any $\lambda \in (0, 1)$. □

Remark. By [BDM, p. 29], a variational solution is also a viscosity solution. Thus the uniqueness part of this theorem also follows from [J, Thm. 2.22, p. 70].

By applying Lemma 7.3 of [HKM, p. 132] we also obtain the following result.

COROLLARY 2.6. *The variational solution u_∞ of* (2.10) *is p-superharmonic for all $p > 1$.*

3. On the asymptotic behaviour of solutions to $-\Delta_p u = \mu$. Let $\Omega \subset \mathbf{R}^n$ be a bounded domain with Lipschitz boundary $\partial\Omega = \Gamma_0 \cup \Gamma_1$ where $\Gamma_0 \cap \Gamma_1 = \emptyset$ and $\Gamma_0 \neq \emptyset$. Let μ be a Borel measure on Ω such that $0 < |\mu|(\Omega) < \infty$ and let $f \in L^\infty(\Omega)$ be such that $0 < C \leq f \leq D < \infty$. For $n < p < \infty$ and $u \in W^{1,p}(\Omega)$, put

$$J_p(u) = \frac{1}{p} \int_\Omega f(x) |\nabla u|^p \, dx - \int_\Omega u \, d\mu$$

and define the class $\mathcal{K}_p = \{u \in W^{1,p}(\Omega) \ : \ u = 0 \text{ on } \Gamma_0\}$. Clearly $\mathcal{K}_p$ is a closed subspace of $W^{1,p}(\Omega)$ and hence it is itself a Banach space. Since the functions in $\mathcal{K}_p$ are continuous we can also assume that Γ_0 is closed. Consider the problem $\mathcal{P}_p$: Find $u_p \in \mathcal{K}_p$ such that

$$(\mathcal{P}_p) \qquad J_p(u_p) = \inf_{u \in \mathcal{K}_p} J_p(u).$$

When treating this problem we adopt the methods of convexity as described in [ET, Chap. 1–4] and we can, without loss of generality, assume that $D = 1$. By [Z, Cor. 4.5.2, p. 195; Rem., p. 75] there is a constant $C > 0$ depending on p, n, and the Bessel capacity of Γ_0 (which is bounded away from zero as long as $\Gamma_0 \neq \emptyset$, since $p > n$) such that

$$\| u \|_p \leq C \| \nabla u \|_p, \quad \text{for all } u \in \mathcal{K}_p \tag{3.1}$$

and by the Rellich–Kondrachov theorem (see, e.g., [Ad, Thm. 6.2, p. 144]) we have

$$\| u \|_\infty \leq C \| u \|_{W^{1,p}(\Omega)}, \text{ for all } u \in W^{1,p}(\Omega)$$

for $p > n$. Thus, for $p > n$ the functional J_p is coercive over $\mathcal{K}_p$ since

$$J_p(u) \geq \frac{1}{p} \| \nabla u \|_p^p - \| u \|_\infty |\mu|(\Omega) \to \infty \text{ as } \| u \|_{W^{1,p}(\Omega)} \to \infty$$

and strictly convex. Let $\frac{1}{p} + \frac{1}{q} = 1$. The problem $\mathcal{P}_p$ has a dual convex problem which we will denote $\mathcal{P}_q^*$. The dual problem is obtained using the method described in [ET, pp. 60–61]. We begin with another definition.

DEFINITION 3. Let V be a Banach space with dual space V^* and dual pairing $\langle \cdot, \cdot \rangle$. For any convex functional $J : V \to \mathbf{R}$ define a conjugate functional $J^* : V^* \to \mathbf{R}$ by

$$J^*(v^*) = \sup_{u \in V} [\langle u, v^* \rangle - J(u)].$$

Define functionals $F : \mathcal{K}_p \to \mathbf{R}$, $G : \mathrm{L}^p(\Omega; \mathbf{R}^n) \to \mathbf{R}$ by

$$F(u) = - \int_\Omega u \, d\mu, \quad G(v) = \frac{1}{p} \int_\Omega f |v|^p \, dx,$$

so that $J_p(u) = F(u) + G(\nabla u)$. Using the above definition one easily derives

$$F^*(u^*) = \begin{cases} 0 & \text{if } u^* = -\mu \\ +\infty & \text{otherwise} \end{cases}, \quad G^*(r) = \frac{1}{q} \int_\Omega f^{1-q} |r|^q \, dx$$

for $u^* \in (\mathcal{K}_p)^*$ and $r \in (\mathrm{L}^p(\Omega; \mathbf{R}^n))^* = \mathrm{L}^q(\Omega; \mathbf{R}^n)$, respectively (see [ET, pp. 19–20, p. 81]). The operator $\nabla : \mathcal{K}_p \to \mathrm{L}^p(\Omega; \mathbf{R}^n)$ has an adjoint operator

$$\nabla^* : (\mathrm{L}^p(\Omega; \mathbf{R}^n))^* = \mathrm{L}^q(\Omega; \mathbf{R}^n) \to (\mathcal{K}_p)^*$$

defined by

$$\langle \nabla u, v \rangle = \langle u, \nabla^* v \rangle \quad \text{for every } u \in \mathcal{K}_p \text{ and } v \in \mathrm{L}^q(\Omega; \mathbf{R}^n).$$

According to [ET, p. 61], the dual problem, $\mathcal{P}_q^*$, can be written as follows: find $r_q \in \mathrm{L}^q(\Omega; \mathbf{R}^n)$ such that

$$\sup_{r \in \mathrm{L}^q(\Omega; \mathbf{R}^n)} [-F^*(\nabla^* r) - G^*(-r)]$$

is attained for $r = r_q$. For the supremum to be finite we must have that $F^*(\nabla^* r)$ is finite, i.e.,

$$\int_\Omega r \cdot \nabla u \, dx = - \int_\Omega u \, d\mu \tag{3.2}$$

for all $u \in \mathcal{K}_p$. Put $\mathcal{K}_q^* = \{r \in \mathrm{L}^q(\Omega; \mathbf{R}^n) : \text{ (3.2) holds for } r\}$. Then the final version of the problem $\mathcal{P}_q^*$ can be written as follows: find $r_q \in \mathcal{K}_q^*$ such that

$$(\mathcal{P}_q^*) \qquad \sup_{r \in \mathcal{K}_q^*} \left[-\frac{1}{q} \int_\Omega f^{1-q} |r|^q \, dx \right] = -\frac{1}{q} \int_\Omega f^{1-q} |r_q|^q \, dx\,.$$

Denote the infimum in $\mathcal{P}_p$ by $\inf \mathcal{P}_p$ and the supremum in $\mathcal{P}_q^*$ by $\sup \mathcal{P}_q^*$.

THEOREM 3.1. *The problems $\mathcal{P}_p$ and $\mathcal{P}_q^*$ are uniquely solvable and*

$$\inf \mathcal{P}_p = \sup \mathcal{P}_q^* .$$

Let u_p be the solution to $\mathcal{P}_p$ and r_q be the solution to $\mathcal{P}_q^*$. Then

$$r_q = -f|\nabla u_p|^{p-2}\nabla u_p \ \textit{a.e.} \quad \textit{and} \quad \int_\Omega f|\nabla u_p|^p\,dx = \int_\Omega f^{1-q}|r_q|^q\,dx = \int_\Omega u_p\,d\mu .$$

Proof. The existence and uniqueness of the two solutions, u_p and r_q, follow from [ET, Prop. 1.2, p. 35], since J_p and G^* are coercive and strictly convex. The relation $\inf \mathcal{P}_p = \sup \mathcal{P}_q^*$ follows from [ET, Thm. 4.2, p. 60]. By that theorem we also have the following extremality relation: Let u_p be the solution to $\mathcal{P}_p$ and r_q be the solution to $\mathcal{P}_q^*$. Then

$$\begin{aligned} 0 &= \langle r_q, \nabla u_p\rangle + G(\nabla u_p) + G^*(-r_q) \\ &\geq \int_\Omega f\left(\frac{1}{p}|\nabla u_p|^p + \frac{1}{q}\frac{|r_q|^q}{f^q} - \frac{|r_q|}{f}|\nabla u_p|\right)\,dx \geq 0. \end{aligned}$$

Here, we have used the fact that $ab \leq \frac{a^p}{p} + \frac{b^q}{q}$ for all $a, b \in \mathbf{R}^+$, i.e., Young's inequality and the Schwarz inequality. Thus we have equality if and only if $|r_q| = f|\nabla u_p|^{p-1}$ and r_q is antiparallel to ∇u_p. Hence, $r_q = -f|\nabla u_p|^{p-2}\nabla u_p$ a.e. Since $\inf \mathcal{P}_p = \sup \mathcal{P}_q^*$ we immediately get

$$\frac{1}{p}\int_\Omega f|\nabla u_p|^p\,dx - \int_\Omega u_p\,d\mu = -\frac{1}{q}\int_\Omega f|\nabla u_p|^p\,dx$$

which completes the proof. □

By (3.2) and Theorem 3.1 we conclude that u_p is a solution to the equation

$$\int_\Omega f|\nabla u|^{p-2}\nabla u \cdot \nabla\varphi\,dx = \int_\Omega \varphi\,d\mu \tag{3.3}$$

for all $\varphi \in \mathcal{K}_p$. Hence if we restrict φ to C_0^∞ it follows that u_p is a solution to the problem

$$\begin{cases} -\operatorname{div}(f|\nabla u|^{p-2}\nabla u) = \mu \text{ in } \mathcal{D}'(\Omega), \\ u|_{\Gamma_0} = 0. \end{cases}$$

Actually, (3.3) contains implicitly a natural boundary condition and under suitable smoothness assumptions one can show that $\nabla u_p \cdot \nu = 0$ on Γ_1, where ν is the outward normal.

In what follows we will study the limiting behaviour of solutions of (3.3) as $p \to \infty$. The results we will prove in this section, apart from Theorem 3.5, are slight generalizations of Proposition 2.1 and Theorems 4.1 and 4.2 in [BDM] (Theorem 3.3 and Corollary 3.4 here). The proofs are analogous but will be given for completeness. We start with a lemma on the convergence of sequences of solutions to problem $\mathcal{P}_p$.

LEMMA 3.2. *For $p > n$, let u_p be the solution to problem $\mathcal{P}_p$. Then there exists a sequence $\{p_k\}_{k=1}^\infty : p_1 > n$, $p_k \nearrow \infty$ as $k \to \infty$ and a function $u_\infty \in \mathcal{K}_\infty$ such that*

(a) *$u_{p_k} \to u_\infty$ weakly in $W^{1,m}(\Omega)$ for every $m \geq 1$,*

(b) *$u_{p_k} \to u_\infty$ in $C^{0,\lambda}(\overline{\Omega})$ for any $\lambda \in (0,1)$,*

as $k \to \infty$. Further, $\| \nabla u_\infty \|_\infty \leq 1$.

Conversely, if $\{p_k\}_{k=1}^\infty$ is any sequence tending to ∞ such that $\{u_{p_k}\}_{k=1}^\infty$ converges weakly to u_∞ in $W^{1,m}(\Omega)$ for some $m > n$, then the above statements hold.

Remarks. (1) In the case where $f \equiv 1$ and $\Gamma_0 = \partial\Omega$, the above lemma can be found in [BDM] with essentially the same proof (see, e.g., pp. 26, 33–34).

(2) Observe that different subsequences may a priori yield different limits.

(3) By applying Mazur's lemma (see, e.g., [ET, p. 6]) and Cantor's diagonalization process, it is possible to obtain a sequence $\{v_k\}_{k=1}^\infty$ of convex combinations of $\{u_{p_k}\}_{k=1}^\infty$ such that $v_k \to u_\infty$ strongly in $W^{1,m}(\Omega)$ for every $m \geq 1$. Further, v_k is almost optimal for $\mathcal{P}_p$ in the following sense: Given $\varepsilon > 0$ there exists a K such that $|J_p(u_p) - J_p(v_k)| < \varepsilon$ for all p and k with $k > p > K$.

Proof. Let u_p be a solution to (3.3) and put $\mathcal{E}_p = \int_\Omega f|\nabla u_p|^p \, dx$. From Theorem 3.1 we then deduce that

$$\mathcal{E}_p = \inf_{r \in \mathcal{K}_q^*} \int_\Omega f^{1-q}|r|^q \, dx. \tag{3.4}$$

Now, let $n < s < p$, $\frac{1}{s} + \frac{1}{t} = 1$, and let r_t be the extremal for $\mathcal{P}_t^*$. Then, by Hölders inequality and (3.4)

$$\left(\frac{1}{|\Omega|}\mathcal{E}_p\right)^{\frac{1}{q}} \leq \left(\frac{1}{|\Omega|}\int_\Omega f^{1-q}|r_t|^q \, dx\right)^{\frac{1}{q}} \leq \left(\frac{1}{|\Omega|}\int_\Omega f^{1-t}|r_t|^t \, dx\right)^{\frac{1}{t}} = \left(\frac{1}{|\Omega|}\mathcal{E}_s\right)^{\frac{1}{t}}.$$

Hence, the function

$$p \mapsto \left(\frac{1}{|\Omega|}\mathcal{E}_p\right)^{\frac{p-1}{p}}$$

is monotonically decreasing and therefore $\lim_{p\to\infty} \mathcal{E}_p$ exists and is finite. See [BDM, p. 34].

Put $\mathcal{E}_\infty = \lim_{p\to\infty} \mathcal{E}_p$. By Theorem 3.1 we have that $J_p(u_p) = -\frac{1}{q}\mathcal{E}_p \to -\mathcal{E}_\infty$ as $p \to \infty$. Clearly, $\mathcal{E}_\infty > 0$. Let $m > n$ and put $G_m = \{u_p : \ p \geq m\} \subset W^{1,m}(\Omega)$. Further, there exists a constant C, independent of m and p, such that

$$\left(\frac{1}{|\Omega|}\int_\Omega f|\nabla u_p|^m \, dx\right)^{\frac{1}{m}} \leq \left(\frac{1}{|\Omega|}\mathcal{E}_p\right)^{\frac{1}{p}} \leq C, \quad \forall p \geq m. \tag{3.5}$$

Hence, from (3.1) it follows that G_m is bounded in $W^{1,m}(\Omega)$. By the Rellich–Kondrachov theorem (see, e.g., [Ad, Thm. 6.2, p. 144]) the embedding

$$W^{1,m}(\Omega) \hookrightarrow C^{0,\lambda}(\overline{\Omega}), \quad 0 < \lambda < 1 - \frac{n}{m}$$

is compact. Thus, since $W^{1,m}(\Omega)$ is weakly sequentially compact, we obtain a sequence $\{u_{p_k}\}_{k=1}^\infty$, $p_k \nearrow \infty$ as $k \to \infty$, that converges to a function u_∞ weakly in $W^{1,m}(\Omega)$ and strongly in $C^{0,\lambda}(\overline{\Omega})$, $0 < \lambda < 1 - \frac{n}{m}$, as $k \to \infty$. Furthermore, we claim that $u_{p_k} \to u_\infty$ weakly in $W^{1,m_1}(\Omega)$ for any $m_1 > m$. Suppose this is false. Then there is a functional $\ell \in (W^{1,m_1}(\Omega))^*$ and a subsequence $\{u_{p_{k_j}}\}_{j=1}^{\infty}$, $p_{k_1} > m_1$, such that $|\langle \ell, u_{p_{k_j}} - u_\infty \rangle| \geq \delta > 0$. By (3.5) this subsequence is bounded in $W^{1,m_1}(\Omega)$ and therefore contains a subsequence that converges to an element u_∞^* weakly in $W^{1,m_1}(\Omega)$. Since $u_{p_k} \to u_\infty$ uniformly and since this last subsequence is also a subsequence of $\{u_{p_k}\}_{k=1}^{\infty}$, we immediately get that $u_\infty = u_\infty^*$, which is a contradiction. Thus $u_{p_k} \to u_\infty$ weakly in $W^{1,m_1}(\Omega)$ for all $m_1 > m$. Since the embedding of $W^{1,m}(\Omega)$ into $W^{1,m_1}(\Omega)$ is continuous if $1 \leq m_1 < m$ (by Hölder's inequality) it then follows that we in fact have weak convergence in $W^{1,m_1}(\Omega)$ for any $m_1 \geq 1$.

Finally, by the weak convergence we get

$$\| \nabla u_\infty \|_m \leq \liminf_{k\to\infty} \| \nabla u_{p_k} \|_m \leq \liminf_{k\to\infty} |\Omega|^{\frac{1}{m}} \left(\frac{1}{|\Omega|} \mathcal{E}_{p_k} \right)^{\frac{1}{p_k}} = |\Omega|^{\frac{1}{m}}$$

for every $m > n$. Thus, $\| \nabla u_\infty \|_\infty \leq 1$, i.e., $u_\infty \in \mathcal{K}_\infty$. □

Note that we cannot expect to have convergence in $C^{0,1}$, as shown by the following example. Let $\Gamma_0 = \partial\Omega$, $f \equiv 1$, and $\mu = \delta_{x_0}$ for some $x_0 \in \Omega$. Then u_p is the Green function for $-\Delta_p$ with pole at x_0 in Ω (see §4). In a neighbourhood of x_0 we have by [S, Thm. 1, p. 79] that

$$|u_p(x) - u_p(x_0)| \approx |x - x_0|^{\frac{p-n}{p-1}}$$

which is not Lipschitz continuous for any $p > n$.

Before we proceed we need to study some geometric properties of Ω.

DEFINITION 4. The *ridge*, $\mathcal{R}(\Omega)$, is the set of points $x \in \Omega$ such that there exist $y_1, y_2 \in \partial\Omega$, $y_1 \neq y_2$ with $|x - y_1| = |x - y_2| = \operatorname{dist}(x, \partial\Omega)$. This set can also be characterized as the set of $x \in \Omega$ such that $\operatorname{dist}(\cdot, \partial\Omega)$ is not differentiable at x (see [EH, Thm. 3.3, p. 149]).

Let $x, y \in \overline{\Omega}$. By [B, p. 25, 5.18] there exists a shortest curve in $\overline{\Omega}$ joining x and y. We denote by $d_{\overline{\Omega}}(x,y)$ the distance within $\overline{\Omega}$ from x to y and define it by

$$d_{\overline{\Omega}}(x,y) = \inf\{\text{length}(\gamma) : \gamma \subset \overline{\Omega} \text{ is a curve joining } x \text{ and } y\}.$$

For a general domain in $\mathbf{R}^n$ one usually uses a different definition for $d_{\overline{\Omega}}(x,y)$ to make $d_{\overline{\Omega}}(x,y)$ comparable with the distance within Ω (see [BDM, pp. 22–23]). However, with the above definition they are in our case comparable, since Ω is a Lipschitz domain. We then define the distance from $x \in \Omega$ to Γ_0 as

$$d_{\Gamma_0}(x) = \inf_{y\in\Gamma_0} d_{\overline{\Omega}}(x,y).$$

We can thus choose a minimizing sequence of curves, γ_n, with terminal points $y_n \in \Gamma_0$. By [B, Thm. 5.16, p. 24] there is a subsequence γ_{n_k} and a curve $\gamma_0 \subset \overline{\Omega}$ with terminal point $y_0 \in \Gamma_0$ (since Γ_0 is closed) such that γ_{n_k} converges uniformly to γ_0 and $\text{length}(\gamma_0) \leq \liminf \text{length}(\gamma_{n_k})$, i.e., $d_{\Gamma_0}(x) = \text{length}(\gamma_0)$.

Let L_z be the set of shortest curves in $\overline{\Omega}$ connecting $z \in \operatorname{supp}\mu$ and Γ_0, and let E be the subset of $\overline{\Omega}$ covered by the curves in L_z as z varies over $\operatorname{supp}\mu$. Clearly $\operatorname{supp}\mu \subset E$. Further, E is closed. Indeed, let $\{x_k\}_{k=1}^{\infty} \subset E$ and suppose $x_k \to x$ as $k \to \infty$. By the definition of E, each x_k lies on a shortest curve joining a point $z_k \in \operatorname{supp}\mu$ and a point $y_k \in \Gamma_0$. Since $\operatorname{supp}\mu$ and Γ_0 are closed we can also assume that there are $z \in \operatorname{supp}\mu$ and $y \in \Gamma_0$ such that $z_k \to z$ and $y_k \to y$ as $k \to \infty$, possibly after choosing an appropriate subsequence of $\{x_k\}_{k=1}^{\infty}$. By the continuity of

$d_{\overline{\Omega}}$ it follows that $d_{\overline{\Omega}}(y_k, x_k) \to d_{\overline{\Omega}}(y, x)$ and $d_{\overline{\Omega}}(x_k, z_k) \to d_{\overline{\Omega}}(x, z)$. Since x_k lies on a shortest curve joining z_k and y_k, we have $d_{\overline{\Omega}}(y_k, z_k) = d_{\overline{\Omega}}(y_k, x_k) + d_{\overline{\Omega}}(x_k, z_k) \to d_{\overline{\Omega}}(y, x) + d_{\overline{\Omega}}(x, z)$. From this it follows that $d_{\overline{\Omega}}(z, y) = d_{\overline{\Omega}}(y, x) + d_{\overline{\Omega}}(x, z)$, i.e., $x \in E$ since we would otherwise have a contradiction to the assumption $x_k \in E$.

For reasons explained below, E will be called the set of uniqueness. We now formulate the main theorem of this section.

THEOREM 3.3. *Let $p > n$ and let u_p be the corresponding solution to problem $\mathcal{P}_p$. Let u_∞ be the limit element of some subsequence $\{u_{p_k}\}_{k=1}^{\infty}$ as in Lemma* 3.2. *Then the following hold:*

(1) $\| \nabla u_\infty \|_\infty = 1$ *and* $|u_\infty(x)| \le d_{\Gamma_0}(x)$ *for every* $x \in \Omega$.

(2) *Suppose μ is a positive measure. Then $u_\infty(x) = d_{\Gamma_0}(x)$ for every $x \in E$.*

(3) *If in addition to* (2), $\Gamma_0 = \partial\Omega$ *and* $\mathcal{R}(\Omega) \subset \operatorname{supp}\mu$, *then* $u_\infty(x) \equiv \operatorname{dist}(x, \partial\Omega)$. *In this case, the entire net $\{u_p\}_{p>n}$ converges to* $\operatorname{dist}(\cdot, \partial\Omega)$ *in* $W^{1,m}(\Omega)$ *for any $m \ge 1$ and in $C^{0,\lambda}(\overline{\Omega})$ for any $\lambda \in (0,1)$ as $p \to \infty$, i.e., without choosing subsequences.*

Remark. In the case $\Gamma_0 = \partial\Omega$ and $f \equiv 1$ on Ω the above theorem can be found in [BDM, Thms. 1.1, p. 33, 4.1, and 4.2, p. 42]. See also [K, Thm. 1, p. 5].

Proof. Let u_∞ be the limit of some subsequence, $\{u_{p_k}\}_{k=1}^{\infty}$. Using Theorem 3.1 and the fact that $u_{p_k} \to u_\infty$ in $C^{0,\lambda}(\overline{\Omega})$ as $k \to \infty$ we can conclude

$$\mathcal{E}_\infty = \lim_{k\to\infty} \mathcal{E}_{p_k}^{\frac{p_k-1}{p_k}} = \lim_{k\to\infty} \mathcal{E}_{p_k}^{-\frac{1}{p_k}} \int\limits_\Omega u_{p_k}\, d\mu = \int\limits_\Omega u_\infty\, d\mu. \tag{3.6}$$

Using (3.3), Theorem 3.1, and Hölder's inequality we get

$$\int\limits_\Omega \varphi\, d\mu \le \mathcal{E}_p^{\frac{1}{q}} \| \nabla\varphi \|_p, \quad \forall\varphi \in \mathcal{K}_\infty$$

and hence

$$\frac{1}{\| \nabla\varphi \|_\infty} \int\limits_\Omega \varphi\, d\mu \le \mathcal{E}_\infty, \quad \forall\varphi \in \mathcal{K}_\infty. \tag{3.7}$$

Since $u_\infty \in \mathcal{K}_\infty$ and $\| \nabla u_\infty \|_\infty \le 1$ by Lemma 3.2, it follows from (3.6) and (3.7) that

$$\| \nabla u_\infty \|_\infty = 1,$$

which in turn implies

$$|u_\infty(x)| \le d_{\Gamma_0}(x) \tag{3.8}$$

for every $x \in \Omega$. This proves (1).

Suppose now that μ is a positive measure on Ω. Since $d_{\Gamma_0} \in \mathcal{K}_\infty$ and $|\nabla d_{\Gamma_0}| = 1$ whenever it exists, we have that d_{Γ_0} is an admissible test function for $\mathcal{P}_p$ for any $p > n$. Hence, by Theorem 3.1 (recall $\frac{1}{p_k} + \frac{1}{q_k} = 1$)

$$J_{p_k}(u_{p_k}) = -\frac{1}{q_k} \int\limits_\Omega u_{p_k}\, d\mu \le J_{p_k}(d_{\Gamma_0}) = \frac{1}{p_k}|\Omega| - \int\limits_\Omega d_{\Gamma_0}\, d\mu,$$

since u_p is the solution to $\mathcal{P}_p$. Thus, using (3.6), we obtain as $p_k \to \infty$

$$\int_\Omega d_{\Gamma_0}\, d\mu \leq \int_\Omega u_\infty\, d\mu,$$

since $u_{p_k} \to u_\infty$ uniformly as $k \to \infty$, which by (3.8) yields

$$u_\infty(x) = d_{\Gamma_0}(x), \quad \text{for every } x \in \operatorname{supp}\mu. \tag{3.9}$$

This proves (2).

Suppose that $\Gamma_0 = \partial\Omega$ and that suppμ is a proper subset of $\overline{\Omega}$ and consider the Lipschitz extension problem as formulated in [Ar1]. Here, the given compact set $F = \operatorname{supp}\mu \cup \partial\Omega$ and the function to be extended, g, equals $\operatorname{dist}(x, \partial\Omega)$ on F. It is clear that both u_∞ and $\operatorname{dist}(\cdot, \partial\Omega)$ are solutions to this extension problem.

Suppose $\mathcal{R}(\Omega) \subset \operatorname{supp}\mu$. Then $\operatorname{dist}(\cdot, \partial\Omega) \in C^1(\Omega \setminus \operatorname{supp}\mu)$ and by [Ar1, Thm. 4, p. 555], it is the unique solution. Thus $u_\infty(x) = \operatorname{dist}(x, \partial\Omega)$ for every $x \in \Omega$.

If $\operatorname{supp}\mu = \overline{\Omega}$ then by (3.9) we have uniqueness of the limit function. That the net $\{u_p\}_{p>n}$ converges to u_∞ in $W^{1,m}(\Omega)$ for any $m \geq 1$ as $p \to \infty$ then follows by the same arguments as in [BDM, p. 36]. The proof of the Hölder convergence is analogous to the proof of Lemma 3.2(b). □

We can now state a sensible limiting problem $\mathcal{P}_\infty$ of the problems $\mathcal{P}_p$: find $u_\infty \in \mathcal{K}_\infty$ such that $\| \nabla u_\infty \|_\infty \leq 1$ and

$$(\mathcal{P}_\infty) \qquad \int_\Omega u_\infty\, d\mu = \sup_{\substack{u \in \mathcal{K}_\infty \\ \|\nabla u\|_\infty \leq 1}} \int_\Omega u\, d\mu.$$

Observe that the weight function f has "disappeared" in the limit process and does not occur in $\mathcal{P}_\infty$. We immediately get the following corollary.

COROLLARY 3.4. *Any function u_∞, as described above, is an extremal to the problem $\mathcal{P}_\infty$. If μ is positive then d_{Γ_0} is clearly an extremal.*

The uniqueness result of R. Jensen [J, Thm. 2.22, p. 70] and the fact that variational solutions are viscosity solutions of $\Delta_\infty u = 0$ [BDM, Prop. 2.2, p. 27] enables us to prove the following theorem.

THEOREM 3.5. *Let $\Gamma_0 = \partial\Omega$, $f \equiv 1$, and suppose μ is positive. Then the entire net $\{u_p\}_{p>n}$ converges to a unique limit element u_∞ in $C^{0,\lambda}(\overline{\Omega})$ for any $\lambda \in (0,1)$ as $p \to \infty$, i.e., without choosing subsequences.*

Proof. Let u_∞ be the limit element of some subsequence $\{u_{p_k}\}_{k=1}^\infty$ ($p_k \nearrow \infty$ as $k \to \infty$). Then $u_\infty(x)$=$\operatorname{dist}(x, \partial\Omega)$ for every $x \in E$ by Theorem 3.3. Let U be a component of $\Omega \setminus E$ and let v_p be the solution of the problem

$$\begin{cases} \Delta_p v = 0 & \text{in } U, \\ v = \operatorname{dist}(\cdot, \partial\Omega) & \text{on } \partial U. \end{cases}$$

Denote by v_∞ the unique variational solution corresponding to $\{v_p\}_{p>n}$. By the weak comparison principle for p-harmonic functions we then get

$$\| u_{p_k} - v_{p_k} \|_{\infty,U} = \| u_{p_k} - v_{p_k} \|_{\infty,\partial U} \to \| u_\infty - \operatorname{dist}(\cdot, \partial\Omega) \|_{\infty,\partial U} = 0,$$

i.e., $u_\infty = v_\infty$, and it follows that u_∞ is independent of the actual subsequence chosen. That $\{u_p\}_{p>n}$ has the stated convergence properties then follows exactly as in the proof of Theorem 2.5. □

Remark. Note that $\Delta_\infty u_\infty = 0$ on $\Omega \setminus E$ in both the variational and viscosity senses.

4. Green functions. Let $x_0 \in \Omega$, $\Gamma_0 = \partial\Omega$, $f \equiv 1$, and let $\mu = c_0\delta_{x_0}$. For any extremal $u_p \in W_0^{1,p}(\Omega)$ of problem $\mathcal{P}_p$, $p > n$, we then have that $-\Delta_p u_p = c_0\delta_{x_0}$. If $c_0 = 1$ then u_p is a so-called Green function of Δ_p with pole at x_0 in Ω. The Green function will be denoted $G_p(x; x_0, \Omega)$. For $p = 2$ we get the classical Green function. Thus, by Theorem 3.5, the family $\{G_p(\cdot\,; x_0, \Omega)\}_{p>n}$ has a unique limit as $p \to \infty$.

We now turn to the question of symmetry for the Green function. For $p = 2$ it is well known that the Green function is symmetric in any domain Ω, i.e., $G_2(x; y, \Omega) = G_2(y; x, \Omega)$. However, it is not as well known that if $p = n \geq 3$ and $\Omega = B_r(x_0)$ (ball with radius r and center at x_0) then the Green function is still symmetric! Symmetry holds because Möbius transformations preserve n-harmonic functions, i.e., if we perform a conformal change of coordinates, then the transformed function is still n-harmonic (see [HKM, p. 286]). (The author would like to thank Professor Peter Lindqvist, Trondheim, for pointing out this fact.) Indeed, let $r = 1$ and $x_0 = 0$. Then

$$G_n(x; 0, B_1(0)) = \omega_n^{\frac{1}{n-1}} \log \frac{1}{|x|},$$

where ω_n is the area of the unit sphere in $\mathbf{R}^n$. A mapping is said to be a Möbius transformation if it can be written as a finite composition of translations, homotheties, orthogonal linear transformations, and inversions in spheres. Verification of the statements below requires some very elementary but tedious calculations. These calculations will be omitted. To show the invariance of the n-harmonic functions under Möbius transformations we need only show that it holds when the transformation is an inversion in a sphere. This is done by changing coordinates in the integral on the left-hand side of (3.3). Now, the mapping

$$M_\xi(x) = \frac{(1 - |\xi|^2)(x - \xi) - |x - \xi|^2\xi}{1 - 2x \cdot \xi + |x|^2|\xi|^2}$$

is a Möbius transformation since it can be written as

$$M_\xi = S \circ H \circ T_2 \circ S \circ T_1,$$

where $S(x) = \frac{x}{|x|^2}$, $H(x) = (1 - |\xi|^2)x$, $T_1(x) = x - \xi$, and $T_2(x) = x - \frac{\xi}{1-|\xi|^2}$. Further,

$$|M_\xi(x)| = \frac{|(1 - |\xi|^2)(x - \xi) - |x - \xi|^2\xi|}{1 - 2x \cdot \xi + |x|^2|\xi|^2} = \frac{|x - \xi|}{|x|\left|\dfrac{x}{|x|^2} - \xi\right|}$$

if $x \neq 0$ and $|M_\xi(0)| = |\xi|$. Note that the square of the denominator of the right-hand side equals the denominator of the fraction in the middle. Hence $|M_\xi(x)| = |M_x(\xi)|$, M_ξ takes $B_1(0)$ onto $B_1(0)$, and $M_\xi(\xi) = 0$. Thus if $|\xi| < 1$ then

$$G_n(x; \xi, B_1(0)) = \omega_n^{\frac{1}{n-1}} \log \left(\frac{|x|}{|x - \xi|} \left| \frac{x}{|x|^2} - \xi \right| \right)$$

is the Green function for $B_1(0)$ with pole at ξ. Thus the Green function for the n-laplacian is symmetric. Below we will show that the Green function is not symmetric if p is sufficiently large.

THEOREM 4.1. *Let $B_1(0) = \{x \in \mathbf{R}^n : |x| < 1\}$. For every $x \in B_1(0)$, $x \neq 0$, there is a $p_x > n$ such that*

$$G_p(x; 0, B_1(0)) > G_p(0; x, B_1(0))$$

if $p > p_x$.

Remark. We chose $B_1(0)$ for simplicity. A similar result holds for a more general class of domains, e.g., convex domains. Indeed, let $x \in \Omega$ and suppose Ω is convex. Take a point $y \in \Omega$ such that y lies on a shortest ray from x to $\partial\Omega$. Then $G_p(y; x, \Omega) > G_p(x; y, \Omega)$ if p is sufficiently large.

Proof. Let $a \in B_1(0)$, put $y_0=(1,0,\dots,0)$, and let $\mathbf{R}^n \ni x=(x_1,\dots,x_n)$. The p-laplacian is invariant under rotations and therefore it is no restriction to assume that a lies on the positive x_1-axis. Further, $B_1(0)$ is convex and thus there is a family of affine functions, $\{f_p\}_{p>n}$, such that $f_p(-y_0)=0$, $f_p(0)=G_p(a; a, B_1(0))$ and since f_p is p-harmonic we get that $f_p(x) \geq G_p(x; a, B_1(0))$ by the weak comparison principle. By Theorem 3.3, $G_p(x; 0, B_1(0)) \to \operatorname{dist}(x, \partial B_1(0))$ in $W_0^{1,p}(\Omega)$ and $G_p(x; a, B_1(0)) \to \operatorname{dist}(x, \partial B_1(0))$ for x on the segment from a to y_0, as $p \to \infty$. Clearly,

$$G_p(0; a, B_1(0)) \leq f_p(0) = \frac{G_p(a; a, B_1(0))}{|a|+1} \to \frac{\operatorname{dist}(a, \partial B_1(0))}{|a|+1}, \quad \text{as } p \to \infty,$$

by construction and since

$$G_p(a; 0, B_1(0)) \to \operatorname{dist}(a, \partial B_1(0)) > \frac{\operatorname{dist}(a, \partial B_1(0))}{|a|+1}$$

the statement follows. □

We end this section with some observations that relate Green functions and the p-capacity of a condenser.

PROPOSITION 4.2. *Let $x_0 \in \Omega \subset \mathbf{R}^n$ and $p > n$. Then*

$$\operatorname{cap}_p(\{x_0\}, \Omega) = G_p(x_0; x_0, \Omega)^{1-p}.$$

Proof. Since p-capacitary functions are p-harmonic it follows by the comparison principle that the function

$$u(x) = \frac{G_p(x; x_0, \Omega)}{G_p(x_0; x_0, \Omega)}$$

is the capacitary function corresponding to p and $(\{x_0\}, \Omega)$. Thus

$$\begin{aligned}\operatorname{cap}_p(\{x_0\}, \Omega) &= \int_\Omega |\nabla u|^p \, dx = \frac{1}{G_p(x_0; x_0, \Omega)^p} \int_\Omega |\nabla G_p(x; x_0, \Omega)|^p \, dx \\ &= G_p(x_0; x_0, \Omega)^{1-p},\end{aligned}$$

since $-\Delta_p G_p = \delta_{x_0}$ and $G_p \in W_0^{1,p}(\Omega)$. □

LEMMA 4.3. *Let $\Omega \subset \mathbf{R}^n$ be a bounded domain with Lipschitz boundary $\partial\Omega$ and let $p > n$. There are constants $C_1, C_2 > 0$ such that*

$$C_1 \operatorname{dist}(x, \partial\Omega)^{n-p} \leq \operatorname{cap}_p(\{x\}, \Omega) \leq C_2 \operatorname{dist}(x, \partial\Omega)^{n-p}$$

for every $x \in \Omega$.

Proof. Put $B_r(y) = \{x \in \mathbf{R}^n : |x-y| < r\}$. By [HKM, Thm. 2.2, p. 28; Ex. 2.12, p. 35], we have $\operatorname{cap}_p(\{x\}, \Omega) \leq \operatorname{cap}_p(\{x\}, B_{\operatorname{dist}(x,\partial\Omega)}(x)) = C_2 \operatorname{dist}(x, \partial\Omega)^{n-p}$.

Take $x_0 \in \Omega$, put $d = \operatorname{dist}(x_0, \partial\Omega)$, and denote by u_0 the capacitary function corresponding to $(\{x_0\}, \Omega)$. Extend u_0 to all of $\mathbf{R}^n$ by $u_0(x) = 0$ if $x \notin \Omega$ and let

$v(x) = u_0(x_0 + \delta x)$. Then

$$\text{(4.1)} \quad \operatorname{cap}_p(\{x_0\},\Omega) = \int_{\Omega} |\nabla u_0|^p \, dx \geq \int_{\Omega \cap B_\delta(x_0)} |\nabla u_0|^p \, dx = \delta^{n-p} \int_{B_1(0)} |\nabla v|^p \, dx.$$

It only remains to estimate the last integral from below. Since $p > n$ we have by the Rellich–Kondrachov theorem (see, e.g., [Ad, Thm. 6.2, p. 144]) that the embedding $W^{1,p}(B_1(0)) \hookrightarrow C(B_1(0))$ is compact, i.e., there is a constant $A > 0$ such that

$$\text{(4.2)} \qquad 1 = \sup_{x \in B_1(0)} |v(x)| \leq A \parallel v \parallel_{W^{1,p}(B_1(0))} .$$

Now, choose $\delta = 2d$ and put $E = \{x \in B_1(0) : v(x) = 0\}$. Since $\partial\Omega$ is Lipschitz we claim that there is a constant $C > 0$ depending only on Ω such that

$$\text{(4.3)} \qquad C \leq |E| \leq |B_1(0)|$$

for all $x_0 \in \Omega$. To see this, put

$$h(x) = \frac{|B_{2d}(x) \cap \Omega^c|}{|B_{2d}(x)|}.$$

Since Ω is a bounded Lipschitz domain it has both the interior and the exterior cone property (see [Ad, pp. 66–67]). Here we shall make use of the exterior cone property, i.e., there is a finite cone S such that every $x \in \partial\Omega$ is the vertex of a cone $S_x \subset \Omega$ which is congruent to S. Now, for every $x \in \Omega$ we have that

$$1 \geq h(x) \geq \frac{|B_{2d}(x) \cap S_{\tilde{x}}|}{|B_{2d}(x)|} \geq \frac{|B_d(\tilde{x}) \cap S_{\tilde{x}}|}{|B_{2d}(x)|},$$

which is clearly bounded away from zero. Here $\tilde{x} \in \partial\Omega$ is such that $\operatorname{dist}(x, \partial\Omega) = |x - \tilde{x}|$.

From [Z, Thm. 4.4.2, p. 188] we have that for every $u \in W^{1,p}(B_1(0))$ that is equal to 0 on E

$$\parallel u \parallel_{L^p(B_1(0))} \leq C \parallel \nabla u \parallel_{L^p(B_1(0))},$$

where $C > 0$ depends only on p and $|E|$. Using (4.3) we then get that there is a $C' > 0$ independent of the particular E such that

$$\text{(4.4)} \qquad \parallel u \parallel_{W^{1,p}(B_1(0))} \leq C' \parallel \nabla u \parallel_{L^p(B_1(0))}$$

for all $u \in W^{1,p}(B_1(0))$ such that $u = 0$ on E.

Inserting (4.2) and (4.4) into (4.1) yields

$$\begin{aligned} \operatorname{cap}_p(\{x_0\},\Omega) &\geq (2\operatorname{dist}(x_0,\partial\Omega))^{n-p} \parallel \nabla v \parallel^p_{L^p(B_1(0))} \\ &\geq C''\operatorname{dist}(x_0,\partial\Omega)^{n-p} \parallel v \parallel^p_{W^{1,p}(B_1(0))} \\ &\geq C\operatorname{dist}(x_0,\partial\Omega)^{n-p} \end{aligned}$$

and we conclude $C_1\operatorname{dist}(x,\partial\Omega)^{n-p} \leq \operatorname{cap}_p(\{x\},\Omega) \leq C_2\operatorname{dist}(x,\partial\Omega)^{n-p}$. □

Combining Proposition 4.2 and Lemma 4.3 we immediately get the following result.

PROPOSITION 4.4. *Let $\Omega \subset \mathbf{R}^n$. Then there are constants $C_1, C_2 > 0$ such that*

$$C_1 \mathrm{dist}(x, \partial\Omega)^{\frac{p-n}{p-1}} \leq G_p(x; x, \Omega) \leq C_2 \mathrm{dist}(x, \partial\Omega)^{\frac{p-n}{p-1}}$$

for every $x \in \Omega$, which in turn implies

$$G_p(x; x, \Omega) \to 0 \text{ as } \mathrm{dist}(x, \partial\Omega) \to 0.$$

For further results on Green functions for a more general class of operators we refer to [Ho]. There, the case where $1 < p \leq n$ is considered but most of the results carry over to the case where $p > n$, with essentially the same proofs.

5. On the "thinning" behaviour of the extremals to the $\mathcal{P}_q^*$ problem. Below we will show that if the set of uniqueness $E \neq \overline{\Omega}$, then $r_q \to 0$ in the mean as $q \to 1+$ on sets that "stay away" from the set of uniqueness. As a corollary of this result (or rather, its proof) we will find that in this case the $\mathcal{P}_\infty$ problem has several different extremals.

A proof of the theorem below, in the case of two dimensions and a single Dirac measure, was suggested to the author by Professor Gunnar Aronsson, Linköping.

THEOREM 5.1. *Let μ be a positive Borel measure with $\mu(\Omega) < \infty$. Let $p > n$, $\frac{1}{p} + \frac{1}{q} = 1$, and let u_p and r_q denote the extremals of problems $\mathcal{P}_p$ and $\mathcal{P}_q^*$, respectively. Suppose that the set of uniqueness E is a proper subset of $\overline{\Omega}$ and let $F_\varepsilon = \{x \in \Omega : d_{\overline{\Omega}}(x, E) > \varepsilon\}$ for any $\varepsilon > 0$. Then*

$$\int_{F_\varepsilon} |r_q| \, dx = \int_{F_\varepsilon} f |\nabla u_p|^{p-1} \, dx \to 0, \quad \text{as } q \to 1+ \quad (p \to \infty)$$

for each $\varepsilon > 0$.

Remark. In some cases the sets F_ε can be chosen in a different way so that $\overline{F}_\varepsilon \cap E \neq \emptyset$, e.g., if $\mu = \sum_{k=1}^N c_k \delta_{x_k}$, $c_k > 0$ and $\Gamma_0 = \partial\Omega$. Then we can choose F_ε so that $\overline{F}_\varepsilon \cap E = \bigcup_{k=1}^N \{x_k\}$ and each component of $\Omega \setminus F_\varepsilon$ is the intersection of Ω and a cone with vertex at some x_k (see Fig. 1).

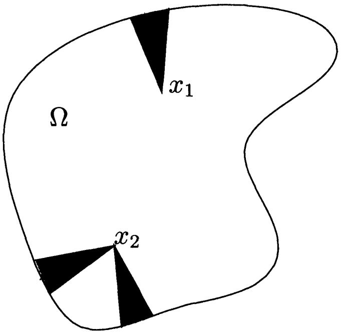

FIG. 1. *A typical example of the situation described in the remark above. The shaded areas indicate $\Omega \setminus F_\varepsilon$.*

Proof. The idea of this proof is to construct a function $\varphi_0 \in \mathcal{K}_\infty$ such that $|\nabla \varphi_0(x)| \leq 1 - \delta$ on F_ε for some $\delta > 0$, $\| \nabla \varphi_0 \|_{\infty,\Omega} = 1$, and $\varphi_0(x) = d_{\Gamma_0}$ for

$x \in \operatorname{supp}\mu$. Suppose that we have carried out this construction. From Lemma 3.1 and (3.2) it then follows that

$$-\int_\Omega r_q \cdot \nabla\varphi\, dx = \int_\Omega \varphi\, d\mu, \quad \forall\varphi \in \mathcal{K}_\infty.$$

Thus,

$$\int_\Omega \varphi_0\, d\mu = -\int_\Omega r_q \cdot \nabla\varphi_0\, dx \le \int_{\Omega\setminus F_\varepsilon} |r_q|\, dx + (1-\delta)\int_{F_\varepsilon} |r_q|\, dx \tag{5.1}$$

and since $\int_\Omega u_p\, d\mu \to \int_\Omega d_{\Gamma_0}\, d\mu$ by Theorem 3.3 as $p \to \infty$, it follows from (5.1) that (recall $0 < C \le f \le 1$)

$$\begin{aligned}\delta\int_{F_\varepsilon} |r_q|\, dx &\le \int_\Omega |r_q|\, dx - \int_\Omega \varphi_0\, d\mu \le |\Omega|^{\frac{1}{p}}\left(\int_\Omega f^{1-q}|r_q|^q\, dx\right)^{\frac{1}{q}} - \int_\Omega \varphi_0\, d\mu \\ &= |\Omega|^{\frac{1}{p}}\left(\int_\Omega u_p\, d\mu\right)^{\frac{p-1}{p}} - \int_\Omega d_{\Gamma_0}\, d\mu \to 0\end{aligned}$$

as $q \to 1+$ $(p \to \infty)$.

Put

$$\varphi_0(x) = d_{\Gamma_0}(x) \sup_{z\in\operatorname{supp}\mu} \frac{d_{\Gamma_0}(z)}{d_{\Gamma_0}(x) + d_{\overline{\Omega}}(x,z)} \tag{5.2}$$

(see Fig. 2). Now it only remains to prove that φ_0 has the properties stated. Clearly,

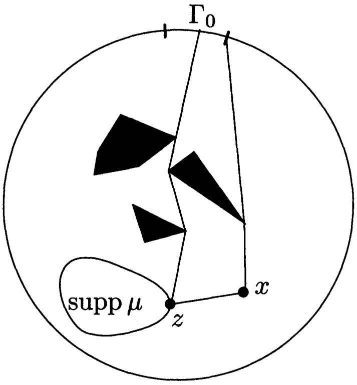

FIG. 2. *Illustration of the curves involved when calculating* $\varphi_0(x)$. *The shaded areas are parts of the complement of* Ω.

φ_0 is continuous on $\overline{\Omega}$ and $\varphi_0(x) \le d_{\Gamma_0}(x)$ with equality if and only if $x \in E \cup \Gamma_0$ since E is closed. Let $a, b \in \Omega$ and suppose $\varphi_0(a) > \varphi_0(b)$. Let $z_a \in \operatorname{supp}\mu$ be such that the supremum in the expression for φ_0 is attained. Then it follows from the triangle inequality that

$$0 < \varphi_0(a) - \varphi_0(b) \le d_{\Gamma_0}(z_a) \frac{d_{\overline{\Omega}}(a,b) d_{\overline{\Omega}}(b,z_a) + d_{\Gamma_0}(b) \left[d_{\overline{\Omega}}(b,z_a) - d_{\overline{\Omega}}(a,z_a)\right]}{\left[d_{\Gamma_0}(a) + d_{\overline{\Omega}}(a,z_a)\right] \left[d_{\Gamma_0}(b) + d_{\overline{\Omega}}(b,z_a)\right]}$$
$$\le d_{\overline{\Omega}}(a,b) \frac{d_{\Gamma_0}(z_a)}{d_{\Gamma_0}(a) + d_{\overline{\Omega}}(a,z_a)}$$

since $d_{\overline{\Omega}}(\cdot,\cdot)$ is a metric on Ω. Thus

$$\| \nabla\varphi_0 \|_{\infty,\Omega} = \sup_{a,b\in\Omega} \frac{|\varphi_0(a) - \varphi_0(b)|}{d_{\overline{\Omega}}(a,b)} = 1$$

and $\varphi_0 \in \mathcal{K}_\infty$. Finally,

$$\| \nabla\varphi_0 \|_{\infty,F_\varepsilon} = \sup_{a,b\in F_\varepsilon} \frac{|\varphi_0(a) - \varphi_0(b)|}{d_{\overline{\Omega}}(a,b)} \le 1 - \delta$$

where obviously

$$1 - \delta = \sup_{x\in F_\varepsilon} \sup_{z\in \operatorname{supp}\mu} \left[\frac{d_{\Gamma_0}(z)}{d_{\Gamma_0}(x) + d_{\overline{\Omega}}(x,z)} \right] < 1. \qquad \square$$

Now, we know from Corollary 3.4 that d_{Γ_0} is an extremal to the $\mathcal{P}_\infty$ problem. Clearly, the same holds for the function φ_0 defined in (5.2). Since $\varphi_0(x) < d_{\Gamma_0}(x)$ for every $x \in \Omega \setminus E$ (since E is closed) we conclude with the following corollary.

COROLLARY 5.2. *The $\mathcal{P}_\infty$ problem has a unique extremal if and only if $E = \overline{\Omega}$.*

DETERMINING LINEAR CRACKS BY BOUNDARY MEASUREMENTS: LIPSCHITZ STABILITY*

GIOVANNI ALESSANDRINI[†], ELENA BERETTA[‡], AND SERGIO VESSELLA[§]

Abstract. We consider the inverse boundary value problem of crack detection in a two-dimensional electrical conductor. We prove an estimate of Lipschitz type on the continuous dependence of an unknown linear crack from the boundary measurements.

Key words. inverse boundary value problem, stability, crack

AMS subject classifications. 35R30, 31A25

1. Introduction.

The inverse problem of detecting a crack in an electrically conducting body can be modeled as the determination of a curve σ in a planar domain Ω from boundary measurements of solutions u (potentials) to the problem

$$\Delta u = 0 \qquad \text{in } \Omega\backslash\sigma, \tag{1.1a}$$

$$u = \text{const.} \qquad \text{on } \sigma, \tag{1.1b}$$

$$\frac{\partial u}{\partial \nu} = \psi \qquad \text{on } \partial\Omega, \tag{1.1c}$$

when various profiles ψ (currents) are assigned.

Friedman and Vogelius have proved that a crack σ is uniquely determined when boundary measurements corresponding to two appropriate profiles ψ are known; see [F-V]. They also observe, by a duality argument, that a similar result holds when (1.1b) is replaced with

$$\frac{\partial u}{\partial \nu} = 0 \quad \text{on } \sigma. \tag{1.1b$'$}$$

When (1.1b) holds, the crack σ is said to be perfectly conducting, whereas in (1.1b′), it is said to be perfectly insulating. They also address the stability issue, discuss the relevance for the actual reconstruction of the crack, and give some initial results in this direction.

A stability estimate for perfectly conducting cracks has been obtained in [A1] and generalized by Diaz Valenzuela to the perfectly insulating case [DV]. Unfortunately, such estimates are of logarithmic type; see [A2] for a partial improvement. In [A1], [DV], and [A2], bounds on the smoothness and the size of the unknown crack are assumed, but they involve only a finite number of derivatives of the crack parametrization. One can expect that better stability estimates might be obtained when stronger

a priori information is prescribed. Linear cracks have been the object of interesting and successful numerical reconstruction algorithms by Santosa, Vogelius, Liepa, and Bryan [S-V], [L-S-V], [B-V]. Therefore, it seems interesting to complement such procedures with a theoretical study of the stability in this special case.

In this paper we prove a Lipschitz-type continuous dependence of the crack σ from the $L^2(\Gamma)$ traces of two solutions u^1 and u^2 of (1.1) when two appropriate profiles ψ^1 and ψ^2 are assigned and are as follows. Fixing three distinct points P_0, P_1, and P_2 on $\partial\Omega$, ψ^1 and ψ^2 are the two-electrode current configurations with electrodes at P_0, P_1, and P_0, P_2, respectively (see (2.3)–(2.5)). Here Γ is a fixed portion of the boundary $\partial\Omega$.

We have chosen to treat the perfectly conducting case as in [A1] and [A2] just for the sake of convenience, but we wish to stress that a completely analogous result could be obtained for the perfectly insulating case due to the results in [DV]. Let us also emphasize the fact that the measurements u^1 and u^2 need not to be taken on all of the boundary $\partial\Omega$, but just on a portion Γ of it.

Let us illustrate the main line of our argument. Considering $u^3 = u^2 - u^1$, that is, the solution with electrodes at P_1, P_2, we find that there exists at least one index $j = 1, 2, 3$ such that, setting $u = u^j$, $\partial_z u$ has a singularity of the type $z^{-1/2}$ at both endpoints V and W of σ. This fact suffices already to prove the unique determination of σ from the boundary data. This is a consequence of the unique harmonic continuation of the Cauchy data u, $\frac{\partial u}{\partial \nu}$ on Γ.

In order to prove our Lipschitz-type estimate, we study the Frechet derivative u' of $u = u(z)$ as a function of the crack σ. We write the asymptotic formula of $u' = u'(z)$ when z is near the endpoints of σ, for instance,

$$u'(z)\delta\sigma = Re(\alpha(z - V)^{-1/2}\delta V) + \text{lower-order terms} \quad \text{as } z \to V. \tag{1.2}$$

Here δV denotes the variation of the endpoint V and $\alpha \neq 0$ is a complex number. From (1.2) we deduce a lower bound on the derivative of the map

$$\sigma \to (u^1, u^2) \in L^2(\Gamma) \times L^2(\Gamma)$$

(see Proposition 4.1). By coupling this lower bound with upper bounds on the second directional derivative of the same map, we are able to estimate the derivative of the inverse mapping. This estimate, combined with the general stability estimate in [A1] (slightly adapted to our setting; see Lemma 4.6), yields the desired Lipschitz stability result.

Let us recall that Friedman and Vogelius already studied the stability problem for linear cracks and they proved a Lipschitz-type bound for the line containing the crack. Unfortunately, their approach does not give sufficient information about the location of the endpoints of the crack along the line. This difficulty is circumvented here by evaluating formula (1.2) on appropriate points z near V and also in the case when δV is parallel to σ.

The plan of the paper is as follows: In §2 we state our assumptions and the main theorem (Theorem 2.1). In §3 we describe, through a sequence of lemmas, the asymptotic behaviour of the solutions $u^j, j = 1, 2, 3$, near the endpoints of the crack. The main results of this section are contained in Proposition 3.4. Section 4 contains the main body of the proof of Theorem 2.1. The final section, §5, is devoted to the proof of two auxiliary results, Lemma 4.6 and Proposition 4.5.

2. The main result. Given positive constants L_1, L_2, M, and α, $0 < \alpha < 1$, which we shall name a priori data, we suppose that Ω is a bounded simply connected domain in $\mathbf{R}^2$ satisfying the following:

$$\text{perimeter of } \Omega \leq L_1, \tag{2.1a}$$

$$\begin{gathered}\forall z \in \partial\Omega \text{ there exist two circles of radius} L_2 \text{ tangent in } z, \\ \text{the first contained in } \overline{\Omega} \text{ and the second in } C\Omega.\end{gathered} \tag{2.1b}$$

If $z = z(s)$ is the arclength parametrization of $\partial\Omega$, we have

$$||z||_{C^{2,\alpha}} \leq M. \tag{2.1c}$$

We consider the class Σ of linear cracks in Ω which is made of the linear segments $\sigma \subset \Omega$ satisfying the following:

$$\text{length of } \sigma \geq L_2, \tag{2.2a}$$

$$\text{dist}(z, \partial\Omega) \geq L_2, \quad \forall z \in \sigma. \tag{2.2b}$$

Given three points $P_0, P_1, P_2 \in \partial\Omega$ such that

$$|P_i - P_j| \geq L_2 \quad \forall i, j, i \neq j, \tag{2.3}$$

we consider three smooth nonnegative functions η_0, η_1, and η_2 on $\partial\Omega$ satisfying

$$\int_{\partial\Omega} \eta_i \, ds = 1, \quad i = 0, 1, 2, \tag{2.4a}$$

and

$$\text{supp } \eta_i \subset \partial\Omega \cap B_h(P_i), \tag{2.4b}$$

where $B_h(P_i)$ denotes the ball centered at P_i with radius h, $0 < h < \frac{L_2}{2}$.

We denote

$$\begin{aligned} \psi^1 &= \eta_0 - \eta_1, \\ \psi^2 &= \eta_0 - \eta_2, \\ \psi^3 &= \eta_1 - \eta_2 = (\psi^2 - \psi^1). \end{aligned} \tag{2.5}$$

Let $\Gamma \subset \partial\Omega$ be a simple arc such that

$$\text{length of } \Gamma \geq L_2. \tag{2.6}$$

Given two cracks $\sigma_0, \sigma_1 \in \Sigma$, we consider $u_i^j \in H^1(\Omega)$, $i = 0, 1$, $j = 1, 2, 3$, as the unique solution of the following boundary value problem:

$$\Delta u_i^j = 0 \qquad \text{in } \Omega \backslash \sigma_i, \tag{2.7a}$$

$$u_i^j = \text{const.} \qquad \text{on } \sigma_i, \tag{2.7b}$$

$$\frac{\partial u_i^j}{\partial \nu} = \psi^j \qquad \text{on } \partial\Omega, \tag{2.7c}$$

$$\int_{\partial\Omega} u_i^j \, ds = 0. \tag{2.7d}$$

Here ν denotes the exterior unit normal to $\partial\Omega$. Notice that the constant value in (2.7b) is also unknown, but it is uniquely determined in view of (2.7d). Observe also that

$$u_i^3 = u_i^2 - u_i^1. \tag{2.8}$$

THEOREM 2.1. *Assume conditions* (2.1)–(2.6). *There exist* h_0, $C > 0$, *depending on the a priori data only, such that if* $h \leq h_0$ *and* $\sigma_0, \sigma_1 \in \Sigma$, *then we have*

$$d(\sigma_0, \sigma_1) \leq C \sum_{j=1}^{2} ||u_0^j - u_1^j||_{L^2(\Gamma)}. \tag{2.9}$$

Here $d(.,.)$ denotes the Hausdorff distance between bounded closed sets of the plane. If we denote by V_i and W_i the endpoints of σ_i, $i = 0, 1$, then we see that

$$d(\sigma_0, \sigma_1) = \min\{\max\{|V_0 - V_1|, |W_0 - W_1|\},\ \max\{|V_0 - W_1|, |W_0 - V_1|\}\}.$$

Hence, up to a renaming of the endpoints, we can assume that

$$d(\sigma_0, \sigma_1) = |V_0 - V_1|,$$

and

$$|W_0 - W_1| \leq d(\sigma_0, \sigma_1).$$

Remark. Observe that the hypothesis $h \leq h_0$ means that we require the electrodes to be concentrated. On the other hand, the constant C does not diverge as $h \to 0$ and thus, in the limit, (2.9) remains valid when the functions η_j are replaced with the Dirac deltas.

3. Some preliminary lemmas. When it is convenient we shall use the usual identification of $\mathbf{R}^2$ with the complex plane: $z = x + iy$, $\partial_z = \frac{1}{2}(\frac{\partial}{\partial x} - i\frac{\partial}{\partial y})$. Also, we shall choose an orientation of coordinates in such a way that $W_0 - V_0$ is real and negative.

Let us denote

$$\begin{aligned} \tilde{\psi}^1 &= \delta_{P_0} - \delta_{P_1}, \\ \tilde{\psi}^2 &= \delta_{P_0} - \delta_{P_2}, \\ \tilde{\psi}^3 &= \delta_{P_1} - \delta_{P_2}, \end{aligned} \tag{3.1}$$

and let us name v_i^j the solution to (2.7) when ψ^j is replaced with $\tilde{\psi}^j$. Set $c_i^j = v_i^j|\sigma_i$.

From [A1, Thm. 2.1] we know that the level line $\{v_i^j = c_i^j\}$ in $\Omega\backslash\sigma_i$ is composed of two simple arcs, each of which has one endpoint on $\partial\Omega$ and the other on σ_i. The latter ones are called branching points. We also know that the branching points are distinct when considered as points on $\tilde{\sigma}_i$, the closed curve obtained by glueing at the endpoints two copies of σ_i (that is, if we distinguish one-sided limit points on σ_i). The following lemma gives a new formulation to arguments already used in [A1, Lem. 4.1].

LEMMA 3.1. *There exists* $C > 0$, *depending on the a priori data only, and at least one index* $j = 1, 2, 3$ *such that the branching points on* v_0^j *have distance larger than or equal to* C *from both the endpoints of* σ_0.

Proof. Let B_l^j, $l = 1, 2$, be the branching points of v_0^j on $\tilde{\sigma}_0$. From [A1, Thm. 2.1] we have that, up to a rearrangement of the points P_0, P_1, and P_2, the branching points have the following circular ordering on $\tilde{\sigma}_0$,

$$\cdots < B_1^1 < B_1^2 < B_1^3 < B_2^1 < B_2^2 < B_2^3 < \cdots,$$

and that the distance along $\tilde{\sigma_0}$ between any two consecutive branching points dominates a positive constant K, only depending on the a priori data.

Now we show that there exists $j = 1, 2, 3$ such that

$$|V_0 - B_l^j|, |W_0 - B_l^j| \geq \frac{K}{2}, \quad \forall l = 1, 2.$$

Suppose that for some $h = 1, 2, 3$, and $m = 1, 2$, we have

$$|V_0 - B_m^h| < \frac{K}{2};$$

therefore, we get

$$|V_0 - B_l^j| \geq \frac{K}{2} \quad \forall j \neq h, \ l = 1, 2.$$

Next, if for some $k \neq h$ and some $m = 1, 2$, we have

$$|W_0 - B_m^h| < \frac{K}{2},$$

then we are left with one index j, $j \neq h, k$, such that

$$|W_0 - B_l^j| \geq \frac{K}{2} \quad \forall l = 1, 2,$$

and our thesis follows with $C = \frac{K}{2}$. □

LEMMA 3.2. *Let $j = 1, 2, 3$ be as in Lemma* 3.1. *There exist ρ, $C > 0$, depending on the a priori data only, such that*

$$|\nabla v_0^j(z)| \geq C|z - V_0|^{-1/2}, \quad \forall z \in B_\rho(V_0) \backslash \sigma_0. \tag{3.2}$$

Proof. See [A1, Lem. 4.2].

LEMMA 3.3. *Let C, $\rho > 0$ be fixed. Let $u, v \in H^1(B_\rho(V_0))$ be harmonic in $B_\rho(V_0) \backslash \sigma_0$ and constant on $\sigma_0 \cap B_\rho(V_0)$.*

There exist $A, B, \delta_0 > 0$, depending on C and ρ only, such that, if we have

$$|\nabla v(z)| \geq C|z - V_0|^{-1/2}, \quad \forall z \in B_\rho(V_0) \backslash \sigma_0 \tag{3.3}$$

and

$$||v - u||_{H^1(B_\rho(V_0))} \leq \delta_0, \tag{3.4}$$

then we have

$$\partial_z u(z) = i\alpha(z - V_0)^{-1/2} + R(z), \quad \forall z \in B_\rho(V_0) \backslash \sigma_0, \tag{3.5}$$

where

$$\alpha \in \mathbf{R}, \qquad |\alpha| \geq A, \tag{3.6}$$

$$|\alpha| + |R(z)| \leq B||u||_{H^1(B_\rho(V_0))}, \quad \forall z \in B_\rho(V_0) \backslash \sigma_0. \tag{3.7}$$

We defer the proof of Lemma 3.3 until after Proposition 3.4, which contains the main results of this section.

Remark. Let us observe that an analogous statement could be obtained when V_0 is replaced with W_0.

PROPOSITION 3.4. *There exist constants A, B, ρ, $h_0 > 0$, depending on the a priori data only, and an index $j = 1, 2, 3$, such that if $0 < h < h_0$ and u_0^j is the solution of* (2.7) *when $i = 0$, then we have*

$$\partial_z u_0^j(z) = i\alpha(z - V_0)^{-1/2} + R(z), \quad \forall z \in B_\rho(V_0)\backslash\sigma_0, \tag{3.8}$$

with $\alpha \in \mathbf{R}$ and

$$|\alpha| \geq A; \ |\alpha| + |R(z)| \leq B||u||_{H^1(B_\rho(V_0))}, \quad \forall z \in B_\rho(V_0)\backslash\sigma_0. \tag{3.9}$$

Proof. We can fix two open subsets U_0 and U_1 of Ω such that

$$\sigma \subset U_0 \subset\subset U_1 \subset\subset \Omega, \qquad \forall \sigma \in \Sigma.$$

The weak formulation of (2.7) for $u = u_0^j - v_0^j$ gives

$$u \in H^1(\Omega), \qquad u = \text{const.} \quad \text{on } \sigma_0,$$

$$\int_\Omega \nabla u \cdot \nabla \phi = 0 \quad \forall \phi \in H_0^1(\Omega) \text{ such that } \phi = \text{const. on } \sigma_0.$$

Notice that the proof of the Caccioppoli inequality and of the weak maximum principle follow as in the usual case when no constraint is imposed on σ_0. Therefore, we have

$$\int_{U_0} |\nabla(u_0^j - v_0^j)|^2 \leq C \int_{U_1} |u_0^j - v_0^j|^2$$

and

$$\max_{U_1} |u_0^j - v_0^j| \leq \max_{\partial U_1} |u_0^j - v_0^j|$$

and hence

$$||u_0^j - v_0^j||_{H^1(U_0)} \leq C \max_{\partial U_1} |u_0^j - v_0^j|,$$

and by interior estimates in H^s-spaces,

$$\max_{\partial U_1} |u_0^j - v_0^j| \leq C||u_0^j - v_0^j||_{H^{1/2}(\Omega\backslash U_0)}.$$

This last norm can be bounded by the $H^{-1}(\partial\Omega)$ norm of the Neumann data for $u_0^j - v_0^j$. Therefore, we get

$$||u_0^j - v_0^j||_{H^1(U_0)} \leq C||\psi^j - \tilde{\psi}^j||_{H^{-1}(\partial\Omega)}.$$

Recalling (2.5) and (3.1), we have

$$||\psi^j - \tilde{\psi}^j||_{H^{-1}(\partial\Omega)} \leq 2 \max_{j=1,2,3} ||\eta_j - \delta_{P_j}||_{H^{-1}(\partial\Omega)}.$$

Now we see that

$$||\eta_j - \delta_{P_j}||_{H^{-1}(\partial\Omega)} = \sup_{||\phi||_{H^1(\partial\Omega)}=1} \left| \int_{\partial\Omega} \eta_j \phi \, ds - \phi(P_j) \right|.$$

By (2.4) and the standard estimate

$$||\phi||_{C^{1/2}(\partial\Omega)} \leq C||\phi||_{H^1(\partial\Omega)},$$

we obtain

$$||\eta_j - \delta_{P_j}||_{H^{-1}(\partial\Omega)} \leq Ch^{1/2}.$$

Therefore, we get

$$||u_0^j - v_0^j||_{H^1(U_0)} \leq Ch^{1/2},$$

and, by similar arguments,

$$||u_0^j||_{H^1(U_0)} \leq C.$$

Now we pick $j = 1, 2, 3$ as in Lemmas 3.1 and 3.2. The proposition follows from Lemma 3.3. □

Proof of Lemma 3.3. Without loss of generality, we may set $u = v = 0$ on $\sigma_0 \cap B_\rho(V_0)$. We may assume $V_0 = 0$; hence $\sigma_0 \subset \{y = 0, x < 0\}$.

Consider $\xi + i\eta = \zeta = \sqrt{z}$ as the analytic branch of the square root which maps $\mathbf{C}\backslash\{y = 0, x < 0\}$ onto $\{\xi = Re\zeta > 0\}$. That is, in polar coordinates $z = re^{i\theta}$, $|\theta| < \pi$, $\zeta = r^{1/2}e^{i\theta/2}$. By abuse of notation, we set $u(\zeta) = u(z)$ and $v(\zeta) = v(z)$.

By the conformal invariance of the Dirichlet integral, we get

$$\int_{|\zeta|<\rho^{1/2},\xi>0} |\partial_z(u - v)|^2 \, d\xi d\eta < \delta_0^2,$$

and we have $u = v = 0$ when $\xi = 0$. Let us continue u and v harmonically to $\{\xi < 0\}$ by an odd reflection. By standard interior bounds, we have

$$|\partial_\zeta(u - v)| \leq K\delta_0, \quad \forall\zeta \in B_{(\rho/2)^{1/2}}(0),$$

and therefore, when $\delta_0 < \frac{C}{2K}$

$$|\partial_\zeta u| \geq \frac{C}{2} \quad \forall\zeta, |\zeta| < \rho^{1/2}$$

and

$$\max_{|\zeta|<(\rho/2)^{1/2}} |\partial_\zeta u| \leq K \left(\frac{1}{\rho} \int_{|\zeta|<\rho^{1/2}} |\partial_\zeta u|^2 \right)^{1/2}.$$

Notice that

$$\frac{\partial u}{\partial \xi}(0) = 0, \qquad \frac{C}{2} \leq \left| \frac{\partial u}{\partial \eta}(0) \right| \leq K||\partial_\zeta u||_{L^2(B_\rho(0))}.$$

Therefore, the Taylor formula gives

$$\partial_\zeta u(\zeta) = -\frac{1}{2} i \frac{\partial u}{\partial \eta}(0) + R(\zeta), \quad \forall\zeta \in B_{(\rho/2)^{1/2}}(0)$$

with

$$|R(\zeta)| \leq |\zeta| \max_{|\zeta|<(\rho/2)^{1/2}} |\partial_\zeta^2 u| \leq |\zeta| \left(\frac{C}{\rho^2} \int_{|\zeta|<\rho^{1/2}} |\partial_\zeta u|^2 \right)^{1/2}.$$

Hence, setting $\alpha = -\frac{1}{4}\frac{\partial u}{\partial \eta}(0)$, by the chain rule $\partial_z u = \frac{1}{2\sqrt{z}}\partial_\zeta u$, we have

$$\left| \partial_z u - \frac{i\alpha}{\sqrt{z}} \right| \leq \frac{C}{\rho}||u||_{H^1(B_\rho(0))} \quad \forall z, |z| < \frac{\rho}{2},$$

and (3.5)–(3.7) follow. □

4. Proof of Theorem 2.1. From now on, we shall restrict our attention to the solutions u_i^j to (2.7) when j is the index found in Proposition 3.4. Therefore, we shall drop the superscript j from ψ^j and u_i^j.

Denote by σ_t, $0 \le t \le 1$, the line segment with endpoints

$$V_t = V_0 + t(V_1 - V_0), \qquad W_t = W_0 + t(W_1 - W_0).$$

Denote by $u_t \in H^1(\Omega)$, $0 \le t \le 1$, the weak solution to

$$\Delta u_t = 0 \quad \text{in } \Omega \backslash \sigma_t, \tag{4.1a}$$

$$u_t = \text{const.} \quad \text{on } \sigma_t, \tag{4.1b}$$

$$\frac{\partial u_t}{\partial \nu} = \psi \quad \text{on } \partial\Omega, \tag{4.1c}$$

$$\int_{\partial\Omega} u_t \, ds = 0. \tag{4.1d}$$

Let us also consider $v_t \in H^1(\Omega)$, given as the solution to

$$\Delta v_t = 0 \quad \text{in } \Omega \backslash \sigma_t, \tag{4.2a}$$

$$v_t = 0 \quad \text{on } \sigma_t, \tag{4.2b}$$

$$\frac{\partial v_t}{\partial \nu} = \psi \quad \text{on } \partial\Omega. \tag{4.2c}$$

If we set $c_t = u_t|\sigma_t$, then we have

$$u_t = v_t + c_t, \; c_t = -\frac{1}{|\partial\Omega|} \int_{\partial\Omega} v_t \, ds. \tag{4.3}$$

LEMMA 4.1. *There exist $C, \delta_0 > 0$, depending on the a priori data only, such that if $d(\sigma_0, \sigma_1) \le \delta_0$, then there exists a one parameter family of invertible C^∞ mappings $\zeta_t : \Omega \to \Omega$, $0 \le t \le 1$, which satisfies the following properties:*

(i) *There exists a neighborhood U of $\cup_{0 \le t \le 1} \sigma_t$, $U \subset\subset \Omega$, such that*

$$U \ni z \to \zeta_t(z) \in \Omega$$

is a complex linear function for all t, $0 \le t \le 1$.

(ii)

$$\zeta_t(\sigma_t) = \sigma_0 \quad \forall t, 0 \le t \le 1.$$

(iii) *There is a neighborhood V of $\partial\Omega$, $V \subset\subset \overline{\Omega} \backslash U$, such that*

$$\zeta_t(z) = z \quad \forall z \in V, \; \forall t, 0 \le t \le 1. \tag{4.4}$$

(iv) *Denoting $\zeta_t(z) = \xi_t(x, y) + i\eta_t(x, y)$, we have*

$$\left| \frac{\partial(\xi_t, \eta_t)}{\partial(x, y)} - I \right| \le C d(\sigma_0, \sigma_1) t, \; \forall z \in \Omega, \quad \forall t \in [0, 1]. \tag{4.5}$$

(v) *ζ_t is twice continuously differentiable with respect to t, and we have*

$$|\zeta_t'(z)| \le C d(\sigma_0, \sigma_1), \tag{4.6a}$$

$$|\zeta_t''(z)| \le C d^2(\sigma_0, \sigma_1). \tag{4.6b}$$

Proof. Let T_1 be the linear mapping

$$T_1 z = \frac{V_1 - W_1}{V_0 - W_0} z + \frac{V_0 W_1 - V_1 W_0}{V_0 - W_0}. \tag{4.7}$$

We have $T_1\sigma_0 = \sigma_1$. Hence, if we set $T_t = I + t(T_1 - I)$, we obtain $T_t^{-1}\sigma_t = \sigma_0$ for every $t \in [0, 1]$. Observe that

$$||T_t^{-1} - I|| \leq Cd(\sigma_0, \sigma_1)t \tag{4.8a}$$

and

$$\frac{d}{dt}T_t^{-1} = T_t^{-1}(I - T_1)T_t^{-1}, \quad 0 \leq t \leq 1. \tag{4.8b}$$

Next, fixing U and V in such a way that

$$\cup_{0 \leq t \leq 1}\sigma_t \subset U \subset\subset \Omega, \qquad \partial\Omega \subset V \subset\subset \overline{\Omega}\backslash U,$$

consider a $C_0^\infty(\Omega)$ function ϕ such that $0 \leq \phi \leq 1$ in Ω, $\phi = 0$ in V, and $\phi = 1$ in U. We define

$$\zeta_t(z) = (1 - \phi(z))z + \phi(z)T_t^{-1}z. \tag{4.9}$$

The estimates (4.5)–(4.6) follow by direct computation. The invertibility of ζ_t follows from (4.5) provided that $d(\sigma_0, \sigma_1) \leq \delta_0$ with $\delta_0 > 0$ sufficiently small depending on the a priori data only. Statements (i)–(iii) follow from the construction. □

Let us introduce $w_t = v_t \circ \zeta_t^{-1}$; setting $J_t = \frac{\partial(\xi_t, \eta_t)}{\partial(x,y)}$ and $A_t = \frac{J_t J_t^T}{\det J_t}$, we obtain from (4.2) that $w_t \in H^1(\Omega)$ is the unique solution to the following problem:

$$\text{div}(A_t \nabla w_t) = 0 \quad \text{in } \Omega\backslash\sigma_0, \tag{4.10a}$$

$$w_t = 0 \quad \text{on } \sigma_0, \tag{4.10b}$$

$$\frac{\partial w_t}{\partial \nu} = \psi \quad \text{on}\partial\Omega. \tag{4.10c}$$

Notice that, if the hypotheses of Lemma 4.1 are fulfilled, then the matrix A_t satisfies a uniform ellipticity condition which depends on the a priori data only. Let us denote by $K = \frac{\Omega}{\text{V}}$ (V as in (iii) of Lemma 4.1).

LEMMA 4.2. *Let $d(\sigma_0, \sigma_1) \leq \delta_0$. Then the solution $w_t \in H^1(\Omega)$ to* (4.10) *satisfies the following estimates:*

$$||w_t||_{L^2(\Omega)} \leq C, \tag{4.11}$$

$$||w_t||_{H^1(K)} \leq C. \tag{4.12}$$

Here $C > 0$ depends on the a priori data only.

Remark. Obviously we have

$$||w_t||_{H^1(\Omega)} \leq C||\psi||_{H^{-1/2}(\partial\Omega)}.$$

However, the right-hand side cannot be bounded uniformly with respect to h, the size of the support of ψ.

Proof. We introduce the Robin function for problem (4.10). For every $y \in \Omega\backslash\sigma_0$, $R_t(x, y)$ is given as the distributional solution to

$$\text{div}(A_t \nabla R_t(., y)) = -\delta_y \quad \text{in } \Omega\backslash\sigma_0,$$

$$R_t(., y) = 0 \quad \text{on } \sigma_0,$$

$$\frac{\partial R_t}{\partial \nu}(., y) = 0 \quad \text{on } \partial\Omega.$$

Observe that for $x \in \Omega$, $y \to R_t(x,y)$ extends continuously to $\partial\Omega$. Moreover, the asymptotic behaviour near $\partial\Omega$ is the same as that of the Neumann function for the Laplacian in Ω, and therefore we have the bound

$$|R_t(x,y)| \leq C(1 + |\ln|x-y||) \quad \forall x \in \Omega,\ y \in \partial\Omega.$$

We have

$$w_t(x) = \int_{\partial\Omega} R_t(x,y)\psi(y)\, ds(y);$$

thus (4.11) follows easily by recalling that $||\psi||_{L^1(\partial\Omega)} \leq 2$. Finally, (4.12) follows from the Caccioppoli inequality. □

LEMMA 4.3. *Let $d(\sigma_0, \sigma_1) \leq \delta_0$. The mapping $[0,1] \ni t \to w_t \in H^1(\Omega)$ is differentiable, and its derivative w_t' is Lipschitz continuous with respect to t. Moreover, there exists $C > 0$, depending on the a priori data only, such that*

$$||w_t'||_{H^1(\Omega)} \leq Cd(\sigma_0,\sigma_1), \quad \forall t \in [0,1], \tag{4.13}$$

$$||w_t''||_{H^1(\Omega)} \leq Cd^2(\sigma_0,\sigma_1), \quad \textit{for almost every } t \in [0,1]. \tag{4.14}$$

Proof. From Lemma 4.1 we have that $t \to A_t$ is C^2. First, we show that $t \to w_t$ is Lipschitz continuous by taking finite differences of w_t. Using (4.10) and (4.12), we prove that such finite differences are uniformly bounded in $H^1(\Omega)$. Therefore, for almost every t, w_t' exists and satisfies

$$\begin{aligned} \operatorname{div}(A_t \nabla w_t' + A_t' \nabla w_t) &= 0 && \text{in } \Omega \backslash \sigma_0, \\ w_t' &= 0 && \text{on } \sigma_0, \\ \frac{\partial w_t'}{\partial \nu} &= 0 && \text{on } \partial\Omega. \end{aligned} \tag{4.15}$$

Notice that $A_t = I$ in $U \cup V$. Therefore $A_t' = 0$ there. Hence

$$||w_t'||_{H^1(\Omega)} \leq C||A_t' \nabla w_t||_{L^2(K)}$$

and therefore, by (4.5) and (4.12), (4.13) follows for almost every t. We can repeat the argument to prove that w_t' is Lipschitz continuous. Hence (4.13) holds for every t and, for almost every t, the second derivative satisfies

$$\begin{aligned} \operatorname{div}(A_t \nabla w_t'' + 2A_t' \nabla w_t' + A_t'' \nabla w_t) &= 0 && \text{in } \Omega \backslash \sigma_0, \\ w_t'' &= 0 && \text{on } \sigma_0, \\ \frac{\partial w_t''}{\partial \nu} &= 0 && \text{on } \partial\Omega. \end{aligned} \tag{4.16}$$

By arguments similar to those above and recalling (4.6), (4.12), and (4.13), we obtain (4.14). □

Now we can use the chain rule to differentiate $v_t = w_t \circ \zeta_t$. We obtain

$$v_t' = w_t'(\zeta_t) + (\nabla w_t)(\zeta_t) \cdot \begin{pmatrix} \xi_t' \\ \eta_t' \end{pmatrix}, \tag{4.17}$$

and also

$$v_t'' = w_t''(\zeta_t) + 2(\nabla w_t')(\zeta_t) \cdot \begin{pmatrix} \xi_t' \\ \eta_t' \end{pmatrix} + (\nabla w_t)(\zeta_t) \cdot \begin{pmatrix} \xi_t'' \\ \eta_t'' \end{pmatrix} + (D^2 w_t)(\zeta_t)\begin{pmatrix} \xi_t' \\ \eta_t' \end{pmatrix} \cdot \begin{pmatrix} \xi_t' \\ \eta_t' \end{pmatrix}. \tag{4.18}$$

Remark. We easily see that

$$\begin{aligned} &\Delta v_t' = \Delta v_t'' = 0 && \text{in } \Omega\backslash\sigma_t, \\ &\frac{\partial v_t'}{\partial\nu} = \frac{\partial v_t''}{\partial\nu} = 0 && \text{on } \partial\Omega, \end{aligned} \tag{4.19}$$

but on the other hand, v_t' and v_t'' verify somewhat complicated boundary conditions on σ_t. For instance, v_t' satisfies

$$(v_t')^{+}_{-} = \left((\nabla w_t)(\zeta_t) \cdot \begin{pmatrix} \xi_t' \\ \eta_t' \end{pmatrix}\right)^{+}_{-} \quad \text{on } \sigma^{+}_{-}.$$

Here the $^{+}_{-}$ sign distinguishes the one-sided traces on σ_t; moreover, the right-hand side must be interpreted in a delicate distributional sense. We avoid this approach by deriving estimates on v_t' and v_t'' directly from those on w_t' and w_t''.

LEMMA 4.4. *Assume that $d(\sigma_0, \sigma_1) \leq \delta_0$. There exists $C > 0$, depending on the a priori data only, such that*

$$||u_t'||_{L^2(\partial\Omega)} \leq Cd(\sigma_0, \sigma_1), \tag{4.20}$$

$$||u_t''||_{L^2(\partial\Omega)} \leq Cd^2(\sigma_0, \sigma_1). \tag{4.21}$$

Proof. We start by proving the following estimates on v_t' and v_t'':

$$||v_t'||_{L^2(\Omega)} \leq Cd(\sigma_0, \sigma_1), \tag{4.22}$$

$$||v_t''||_{H^{-1}(\Omega)} \leq Cd^2(\sigma_0, \sigma_1). \tag{4.23}$$

(4.22) follows from (4.17) by using (4.12) and (4.13) and by noticing that ζ_t' has support in K. (4.23) is a consequence of (4.18) via the estimates (4.13) and (4.14). Observe that the first three summands on the right-hand side of (4.18) can be bounded in $L^2(\Omega)$, whereas the last one can be estimated in $H^{-1}(\Omega)$ by an integration by parts.

Next, recalling the smoothness of $\partial\Omega$ and (4.19), we have a higher regularity near $\partial\Omega$, for instance

$$||v_t'||_{H^1(V)} \leq Cd(\sigma_0, \sigma_1),$$

$$||v_t''||_{H^1(V)} \leq Cd^2(\sigma_0, \sigma_1).$$

Consequently, by the trace theorem, we derive

$$||v_t'||_{L^2(\partial\Omega)} \leq Cd(\sigma_0, \sigma_1), \tag{4.24}$$

$$||v_t''||_{L^2(\partial\Omega)} \leq Cd^2(\sigma_0, \sigma_1). \tag{4.25}$$

Observe that (4.24) and (4.25) also imply that $c_t = -\frac{1}{|\partial\Omega|}\int_{\partial\Omega} v_t$ is twice differentiable:

$$\begin{aligned} c_t' &= -\frac{1}{|\partial\Omega|}\int_{\partial\Omega} v_t' \quad \forall t \in [0,1], \\ c_t'' &= -\frac{1}{|\partial\Omega|}\int_{\partial\Omega} v_t'' \quad \text{for almost every } t \in [0,1]. \end{aligned} \tag{4.26}$$

Therefore, we also obtain that $t \rightarrow u_t \in L^2(\partial\Omega)$ is twice differentiable, and we obtain (4.20) and (4.21). Finally, notice also that by (4.19) and the regularity estimates at the boundary, we have

$$\|u_t'\|_{H^2(\partial\Omega)} \le Cd(\sigma_0,\sigma_1). \qquad \square \tag{4.27}$$

The Taylor formula gives us

$$u_1 - u_0 = u_0' + R \quad \text{on } \Gamma, \tag{4.28}$$

where $R = \int_0^1 (t-1)u_t''\,dt$ satisfies

$$\|R\|_{L^2(\Gamma)} \le Cd^2(\sigma_0,\sigma_1). \tag{4.29}$$

The following statements, whose proof we defer until §5, allow us to conclude the proof of Theorem 2.1.

PROPOSITION 4.5. *Let $d(\sigma_0,\sigma_1) \le \delta_0$. There exists $c > 0$, depending on the a priori data only, such that*

$$\|u_0'\|_{L^2(\Gamma)} \ge cd(\sigma_0,\sigma_1). \tag{4.30}$$

LEMMA 4.6. *There exists a continuous, increasing function $\omega : [0,\infty) \to [0,\infty)$, with $\omega(0) = 0$, such that*

$$d(\sigma_0,\sigma_1) \le \omega\left(\sum_{j=1}^{2} \|u_1^j - u_0^j\|_{L^2(\Gamma)}\right). \tag{4.31}$$

Let us conclude now the proof of Theorem 2.1. In fact, if $d(\sigma_0,\sigma_1) \le \delta_0$, then from (4.28)–(4.30), we obtain

$$\|u_1 - u_0\|_{L^2(\Gamma)} \ge d(\sigma_0,\sigma_1)(c - Cd(\sigma_0,\sigma_1)).$$

Let $\delta_1 = \min\{\delta_0, \frac{c}{2C}\}$. If $d(\sigma_0,\sigma_1) \le \delta_1$, then (2.9) follows (recall (2.8)). On the other hand, by (4.31) of Lemma 4.6, when $d(\sigma_0,\sigma_1) \ge \delta_1$, we have that

$$d(\sigma_0,\sigma_1) \le \text{diam}\ \Omega \le \frac{\text{diam}\Omega}{\omega^{-1}(\delta_1)} \sum_{j=1}^{2} \|u_1^j - u_0^j\|_{L^2(\Gamma)}$$

and (2.9) again follows. $\square$

5. Proofs of Lemma 4.6 and Proposition 4.5.

Proof of Lemma 4.6. The estimate (4.31) is a slight variation of the estimate in [A1, Thm. 1.4]. In [A1] only the Dirac-type boundary data (3.1) are considered, and the $L^2(\Gamma)$ norm is replaced by the $L^\infty(\Gamma)$ norm.

In view of the considerations made in §3, Theorem 1.4 in [A1] also applies when the boundary data are of the type in (2.5) when $h \le h_0$, the number appearing in Proposition 3.4.

The change of the norm on the right-hand side of (4.31) can also be easily adjusted. In fact, by (4.27) we have

$$\|u_1 - u_0\|_{H^2(\partial\Omega)} \le C,$$

and therefore we can use the interpolation inequality

$$\|u_1 - u_0\|_{L^\infty(\Gamma)} \le C(\|u_1 - u_0\|_{H^2(\Gamma)})^{1/2}(\|u_1 - u_0\|_{L^2(\Gamma)})^{1/2}. \qquad \square$$

Proof of Proposition 4.5. Our proof will be based on the following two steps:

(I) There exist $r_0, c > 0$, depending on the a priori data only, and a point z_0, such that $B_{r_0}(z_0) \subset \Omega \backslash \sigma_0$ and

$$|u_0'(z_0)| \geq c d(\sigma_0, \sigma_1). \tag{5.1}$$

(II) There exist C, δ, $C > 0$, $0 < \delta < 1$, depending on the a priori data only such that

$$|u_0'(z_0)| \leq C ||u_0'||^{1-\delta}_{L^2(\Omega)} ||u_0'||^{\delta}_{L^2(\Gamma)}. \tag{5.2}$$

In fact, by (4.22), (4.24), and (4.26), we deduce

$$||u_0'||_{L^2(\Omega)} \leq C d(\sigma_0, \sigma_1), \tag{5.3}$$

and therefore, by combining (5.1)–(5.3), we get (4.30).

Proof of step (I). We use formula (4.17) near V_0. We have

$$|u_0'(z_0)| \geq \left| \nabla w_0(\zeta_0(z) \cdot \begin{pmatrix} \xi_0' \\ \eta_0' \end{pmatrix} \right| - |w_0'(\zeta_0(z))| - |c_0'|.$$

Recalling (4.9) and (4.8b), we have that

$$\zeta_0'(z) = (I - T_1)z, \quad \forall z \in U.$$

Therefore,

$$|\zeta_0'(z) - \zeta_0'(V_0)| = \left| \frac{(z - V_0)(V_0 - V_1 + W_1 - W_0)}{V_0 - W_0} \right| \leq |z - V_0| C d(\sigma_0, \sigma_1).$$

Let $\varphi \in [-\frac{\pi}{2}, \frac{\pi}{2}]$ be such that $e^{i\varphi} = \pm \frac{V_1 - V_0}{|V_1 - V_0|}$. Now, recall that ζ_0 is the identity mapping and, therefore, $w_0 = v_0 = u_0 - c_0$. Hence

$$\begin{aligned} \left| \nabla w_0(\zeta_0) \cdot \begin{pmatrix} \xi_0' \\ \eta_0' \end{pmatrix} \right| &= 2 |Re(\partial_z u_0 \zeta_0')| \\ &\geq 2 d(\sigma_0, \sigma_1) |Re(\partial_z u_0 e^{i\varphi})| - |\partial_z u_0| |\zeta_0'(z) - \zeta_0'(V_0)| \\ &\geq d(\sigma_0, \sigma_1) \left(2 |Re(\partial_z u_0)| - C |\partial_z u_0| |z - V_0| \right). \end{aligned}$$

Let $\theta \in [-\frac{\pi}{2}, \frac{\pi}{2}]$ to be chosen later on, and consider $z_r = V_0 + 2re^{i\theta}$, with $0 < r < r_1$, where r_1, depending on the a priori data only, is such that $B_{3r_1}(V_0) \subset U$ and $3r_1 < \rho$ (with ρ as in Proposition 3.4). By (3.8) and (3.9) on $z = z_r$, we have

$$\left| Re(\partial_z u_0 e^{i\varphi}) + \alpha (2r)^{-1/2} \sin \left(\varphi - \frac{\theta}{2} \right) \right| \leq B.$$

Notice that, as $|\theta| \leq \frac{\pi}{2}$, $\varphi - \frac{\theta}{2}$ spans an interval of length $\frac{\pi}{2}$; therefore, we shall fix θ in such a way that $|\sin(\varphi - \frac{\theta}{2})| \geq \frac{1}{\sqrt{2}}$. We obtain, on $z = z_r$,

$$\left| \nabla w_0(\zeta_0) \cdot \begin{pmatrix} \xi_0' \\ \eta_0' \end{pmatrix} \right| \geq d(\sigma_0, \sigma_1) \left(\frac{A}{2} r^{-1/2} - B - C r^{1/2} \right).$$

Hence

$$|u_0'(z_r)| \geq d(\sigma_0, \sigma_1) \left(\frac{A}{2} r^{-1/2} - B - C r^{1/2} \right) - |w_0'(z_r)| - |c_0'|.$$

Now, by recalling (4.24) and (4.26) and observing that by (4.13) we have

$$|w_0'(z_r)| \leq C ||w_0'||_{H^1(U)} \leq C d(\sigma_0, \sigma_1),$$

we get

$$|u_0'(z_r)| \geq d(\sigma_0, \sigma_1)(cr^{-1/2} - K).$$

Hence, fixing $r_0 = \min\{r_1, (\frac{c}{2K})^2\}$, we obtain (5.1), with $z_0 = z_{r_0}$.

Proof of step (II). (5.2) consists of a stability estimate for a Cauchy problem for the Laplace equation. From (4.19) we have that $u_0' = v_0' + c_0'$ is harmonic in $\Omega \backslash \sigma_0$ and satisfies a homogeneous Neumann condition on $\partial\Omega$. The estimate (5.2) can be derived from two well-known estimates for harmonic functions (see [P]),

$$\int_{B_r^+(0)} |u|^2 \leq C_1 \left(\int_{B_{2r}^+(0)} |u|^2\right)^{1-\eta} \left(\int_{S_{2r}(0)} (|u|^2 + |\nabla u|^2)\right)^{\eta}, \tag{5.4}$$

$$\int_{B_{2r}(0)} |u|^2 \leq C_2 \left(\int_{B_{4r}(0)} |u|^2\right)^{1-\theta} \left(\int_{B_r(0)} |u|^2\right)^{\theta}. \tag{5.5}$$

Here $B_r^+(0)$ is the half disk $\{z : |z| < r, Imz > 0\}$, $S_r(0) = \{z = x : |x| < r\}$, and $C_1, C_2 > 0$, $0 < \eta, \theta < 1$ are absolute constants. We may conformally map a neighborhood of Γ in Ω onto $B_2^+(0)$ in such a way that the C^2-norm of this map and its inverse are controlled by the a priori data and Γ is mapped onto $S_2(0)$. Now

$$\int_{S_2(0)} (|u_0'|^2 + |\nabla u_0'|^2) = \int_{S_2(0)} (|u_0'|^2 + |u_{0,x}'|^2)$$
$$\leq C\left(\int_{S_2(0)} |u_0'|^2 + \left(\int_{S_2(0)} |u_{0,xx}'|^2\right)^{1/2} \left(\int_{S_2(0)} |u_0'|^2\right)^{1/2}\right).$$

By regularity estimates at the boundary, we see that

$$\int_{S_2(0)} |u_{0,xx}'|^2 \leq C \int_\Omega |u_0'|^2;$$

recall that here we are assuming $u_{0,y}' = 0$ on $S_2(0)$. Therefore, by (5.4) and returning to the original coordinates, we find a disk $B_\rho(w) \subset \Omega \backslash \sigma_0$ near Γ such that

$$\int_{B_\rho(w)} |u_0'|^2 \leq C\left(\int_\Omega |u_0'|^2\right)^{1-\eta/2} \left(\int_\Gamma |u_0'|^2\right)^{\eta/2};$$

here ρ and C depend on the a priori data only. Now we can form a chain of disks $\{B_r(w_j)\}_{j=1}^M$ such that $w_{j+1} \subset B_r(w_j)$ and $B_{4r}(w_j) \subset \Omega \backslash \sigma_0$ for all j, $B_r(w_0) \subset B_\rho(w)$, and $w_M = z_0$, and in such a way that the numbers r and M depend only on the a priori data. By a repeated use of (5.5), we arrive at

$$\int_{B_\rho(z_0)} |u_0'|^2 \leq C\left(\int_\Omega |u_0'|^2\right)^{1-\delta} \left(\int_\Gamma |u_0'|^2\right)^{\delta},$$

where C and δ depend only on η, θ, and the a priori data. The local boundedness estimate

$$|u_0'(z_0)|^2 \leq \frac{C}{r^2} \int_{B_r(z_0)} |u_0'|^2$$

yields (5.2). □

YOUNG MEASURE SOLUTIONS FOR A NONLINEAR PARABOLIC EQUATION OF FORWARD-BACKWARD TYPE*

SOPHIA DEMOULINI†

Abstract. The scope is to study the nonlinear parabolic evolution of forward-backward type

$$u_t \;=\; \nabla \cdot q(\nabla u) \qquad \text{on } Q_\infty \equiv \Omega \times \mathbb{R}^+$$

with initial data u_0 given in $H_0^1(\Omega)$, where $\Omega \subset \mathbb{R}^N$ is open, bounded, and $q \in C(\mathbb{R}^N; \mathbb{R}^N)$, an analogue to heat flux, satisfies $q = \nabla\phi$ with $\phi \in C^1(\mathbb{R}^N)$ of suitable growth. When ϕ is not convex classical solutions do not exist in general; the problem admits *Young measure* solutions. By that is meant a function u in a suitable Sobolev space and a gradient-generated family of probability measures $\nu = (\nu_{x,t})_{(x,t)\in Q_\infty}$ related by $\nabla u = \langle \nu, id\rangle$ almost everywhere (a.e.) (the identity integrated against ν) and such that the equation can be interpreted distributionally in H^{-1} : $\int_0^{+\infty}\int_\Omega \langle \nu, q\rangle \cdot \nabla\zeta + u_t\zeta \, dxdt$ for all $\zeta \in H_0^1(Q_\infty)$. The family ν is not unique, but through its first moment some of the classical properties are preserved: uniqueness of the function u is true; stability is reflected in a maximum principle and a comparison result. The asymptotic analysis yields, as time tends to infinity, a unique limit z and an associated Young measure ν^∞ such that the pair (z, ν^∞) is a Young measure solution of the steady-state problem $\nabla \cdot q(\nabla z) = 0$. The relevant energy function is shown to be monotone decreasing and asymptotically tending to its minimum, globally and locally in space.

Key words. Young measures, forward-backward heat equation, weak convergence, calculus of variations

1. Introduction.

We study the nonlinear evolution problem

$$u_t = \nabla \cdot q(\nabla u) \qquad \text{on } Q_\infty \equiv \Omega \times \mathbb{R}^+, \tag{1}$$

$$u(\cdot, 0) = u_0 \qquad \text{on } \Omega, \tag{2}$$

$$u = 0 \qquad \text{on } \partial\Omega \times \mathbb{R}^+, \tag{3}$$

which will be denoted by $\mathcal{P}$. Here Ω is an open, bounded subset of $\mathbb{R}^N$ such that the cone or the segment property is satisfied on the boundary (as for example in the case of a Lipschitz boundary), and $q : \mathbb{R}^N \to \mathbb{R}^N$, a nonlinear, continuous, potential gradient function, an analogue to heat flux, satisfying $q = \nabla\phi$, where $\phi \in C^1(\mathbb{R}^N)$ (the space of continuously differentiable functions on $\mathbb{R}^N$) is of suitable growth. The initial data function u_0 is given in $H_0^1(\Omega)$ and the zero boundary data (3) can be taken to be a general time-homogeneous function $g \in H^1(\Omega)$. (Here $H^1(\Omega)$ is the Sobolev space of functions on Ω which together with their first-order weak derivatives are in $L^2(\Omega)$, and $H_0^1(\Omega)$ is its subset consisting of the functions with zero trace on the boundary of Ω.)

When ϕ is not convex, in which case the monotonicity condition $(q(x) - q(y)) \cdot (x - y) \geq 0$ for $x, y \in \mathbb{R}^N$ is violated on subsets of $\mathbb{R}^N$, equation (1) then constitutes a *forward-backward* parabolic equation which generally admits no classical strong or distributional solutions. The nonconvexity of the potential is compatible with the usual requirement that $q(\lambda) \cdot \lambda \geq 0$ be imposed on a theory of thermal conductors by the Clausius–Duhem inequality.

A notion of a solution appropriate for the study of $\mathcal{P}$ is that of a *measure-valued* or *Young measure* solution. By that is meant a function u in a Sobolev space and a parametrized family of probability measures $\boldsymbol{\nu} = (\nu_{x,t})_{(x,t)\in Q_\infty}$ generated by the spatial gradients of a sequence in the same space and satisfying

$$\int_0^{+\infty}\int_\Omega \left(\langle \boldsymbol{\nu}, q\rangle \nabla\zeta + \frac{\partial u}{\partial t}\zeta\right) dx\, dt = 0,$$

where

$$\langle \boldsymbol{\nu}, q\rangle \;=\; \int_{\mathbb{R}^N} q(\lambda)\, \boldsymbol{\nu}(d\lambda) \qquad \text{a.e. in } Q_\infty$$

for all ζ in an appropriate subspace of $H^1(Q_\infty)$. In addition, u and $\boldsymbol{\nu}$ satisfy

$$\nabla u \;=\; \langle \boldsymbol{\nu}, \mathrm{id}\rangle \;=\; \int_{\mathbb{R}^N} \lambda\, \boldsymbol{\nu}(d\lambda) \qquad \text{a.e. in } Q_\infty,$$

where $id(\lambda) = \lambda$. So to each point (x,t) in the domain Q_∞ is associated a probability measure $\nu_{x,t}$ on $\mathbb{R}^N$; via this parametrized measure the nonlinearity of $q(\nabla u)$ is replaced by the expected value of q, while the first moment of the measure is the gradient of the solution. To date the term "Young measure solution," although strictly derived from the fundamental theorem of Young measures described in §2, admits slightly different definitions by different authors; the decision of what is a Young measure solution of a problem must necessarily accommodate the way the generating sequence is chosen. In this case, the definition of Young measure solutions for $\mathcal{P}$ appears in §3.

The approach we shall assume in this paper for the study of (1)–(3) is the one employed by Kinderlehrer and Pedregal in [KP1] to establish existence. The method incorporates the explicit methods for solutions of evolution equations (cf. [BC], [HK]) with variational methods used to accommodate and describe the oscillatory behavior (cf. [Ba], [E], [KP1], etc). The combination of the two methods leads to the existence of Young measure solutions of evolution problems that may be of forward-backward type.

The analytical context of our approach to obtain existence is to approximate the dynamics of equation (1) with a sequence of stationary problems the solutions of which are in turn interpreted as minimizers of variational principles. More precisely, the time-discretized version of (1) is the Euler equation of a nonconvex variational principle which at each time step (of size h) is minimized. The minimizer solves the stationary problem and approximates the solution of $\mathcal{P}$ within time h. By taking arbitrarily small time steps we pass from the stationary to the evolution problem. The method is well known in the study of semigroups. It has been implemented by Horihata and Kikuchi in [HK] to construct weak solutions to a quasilinear parabolic problem associated with a convex variational principle. Further, this method has also been employed by Bethuel, Coron, Ghidaglia, and Soyeur in [BC] to establish existence of weak solutions for a nonlinear heat equation associated with weakly harmonic maps in a Sobolev-type space of functions of the unit ball into the sphere in $\mathbb{R}^3$.

In applying this method to treat $\mathcal{P}$ the difficulty that arises is twofold: first, the nonconvexity of the potential ϕ implicating the minimization of a nonconvex variational principle; second, the unwieldiness of the nonlinear dependence of the heat flow q on the gradient of the solution. Both situations call for sensible generalizations, in the former case that of a "minimizer" of a variational principle and in the latter, that of a "weak solution" of a differential equation. Respectively, the pertinent themes implemented in [KP1] to overcome these impediments are first, the *relaxation* of a nonconvex functional and second, replacing the nonlinearity of $q(\nabla u)$ with the expected value of q against a *Young measure.* The sense in which $\mathcal{P}$ has a solution is then that of a Young measure solution.

We review the variational method of Kinderlehrer and Pedregal in [KP1] to obtain existence and following that we investigate deeper the properties of the Young measure solution and establish a *uniqueness* result. It should be remarked that as a rule, nonuniqueness results appear in the literature (for example in [BC] or [HN]) regarding nonlinear parabolic problems, especially of a forward-backward nature. In our case, the uniqueness of the Young measure solution, although not directly dependent on the particular construction scheme of the solution, is contingent upon an *independence* property, namely that the heat flux q and the solution u be independent with respect to the Young measure $\boldsymbol{\nu}$, and furthermore, on a condition regarding the support of the Young measure $\boldsymbol{\nu}$, namely $\langle \boldsymbol{\nu}, q\rangle = \langle \boldsymbol{\nu}, p\rangle$, where $p = \nabla\phi^{**}$ and ϕ^{**} is the convexification of the potential ϕ. The function u is unique but the Young measure is not.

The solution u is also *continuously dependent on the initial data* in the L^2 norm. In addition, $u(\cdot,t)$ satisfies continuity properties in the L^2 norm, both as $t \to 0^+$ (monotone decreasing) and as $t \to +\infty$. Stability of the solution is reflected in the fact that it satisfies a *maximum principle* and a *comparison lemma.*

In §4 we investigate the time-asymptotics of $\mathcal{P}$. As time tends to infinity, the solution $u(\cdot,t)$ converges to z strongly in L^2 (monotonically decreasing) and weakly in H^1, and the measure $\boldsymbol{\nu}$ has a (weak) asymptotic limit $\boldsymbol{\nu}^\infty$ such that the pair $(z, \boldsymbol{\nu}^\infty)$ constitutes a Young measure solution to the steady-state version of $\mathcal{P}$, $\nabla\cdot q(\nabla z) = 0$. This is achieved by showing that the set of all weak limit points of $(u(\cdot,t))_{t\geq 0}$ in H^1 is invariant under the operator $\mathcal{P}$ and further, that there exists exactly one such weak limit point z. The asymptotic Young measure $\boldsymbol{\nu}^\infty$ has restricted support satisfying $supp\, \boldsymbol{\nu}^\infty \subseteq \{q(\lambda)\cdot\lambda = 0\} \cap \{\phi^{**} = \phi\}$.

In §5 we introduce the relevant *energy* function $E(t) = \int_0^\infty \phi^{**}(\nabla u)(x,t)\,dx$. As time tends to infinity, the energy converges to zero, monotonically decreasing globally in space. We show that it also vanishes locally in space, that is, on any subdomain $\omega \subseteq \Omega$ (although not monotonically on ω).

The forward-backward heat equation has also been studied by Höllig [H], Höllig and Nohel [HN], and Slemrod [Sl]. The treatment in [H] and [HN] concerns the Neumann initial value problem in the case of one spatial dimension ($\Omega = [0,1]$). It establishes in the model case of a piecewise linear heat flux q, decreasing on an interval $[a,b] \subset \Omega$, that a continuum of solutions exists for finite time satisfying (1) weakly in the sense of L^2. Each such solution is obtained as the sum of an explicitly constructed oscillating function and a smooth function that solves (weakly in L^2) an inhomogeneous heat equation.

The treatment in [Sl] involves Young measures but the spirit is different from that assumed here. $\mathcal{P}$ with Dirichlet or Neumann boundary conditions is approximated by a sequence of regular, singularly perturbed problems whose solutions are used to extract the Young measure solution. The differences between the Young measure solutions obtained in [Sl] and [KP1] are subtle. In [Sl] the heat flux q and the initial data u_0 are required to be sufficiently smooth, q must have strictly subquadratic growth, and equation (1) is satisfied in the sense of distributions. In [KP1] q is continuous, of linear growth, $u_0 \in H_0^1$, and equation (1) is satisfied in H^{-1}.

A one-dimensional convex analogue to $\mathcal{P}$ associated with a potential of linear growth has been studied by Zhou [Z]. The approach in [Z] differs from a Young measure viewpoint but here also a variational technique is developed to solve the stationary and evolution problems.

2. A result on sequences of gradient-generated Young measures. Lemma 2.4 describes limit points of sequences of parametrized measures. The question asked is whether the limit of a sequence of $W^{1,p}$ gradient Young measures is itself a gradient Young measure. The result applied in the next section shows that the parameterized measure solution derived in [KP1] can further be chosen to have the properties of a gradient Young measure. These properties will be particularly useful in the asymptotic analysis in §4.

We start with the notion of a $W^{1,p}$-gradient Young measure introduced and fully analyzed in [KP2] and state a characterization of such measures in Theorem 2.1. Most statements appear in vectorial formulation although it is their scalar version which we shall make use of subsequently in this paper.

DEFINITION. *A family of probability measures $\boldsymbol{\nu} = (\nu_x)_{x\in\Omega}$ on $\mathbf{M}$, where Ω is an open set in $\mathbb{R}^N$, and is a* $W^{1,p}$-gradient Young measure *for some $p \in [1,\infty]$ if*

(i) *$x \in \Omega \mapsto \int_{\mathbf{M}} f(A)\,\nu_x(dA) \in \mathbb{R}$ is a Lebesgue measurable function for all f bounded continuous on $\mathbf{M}$, the vector space $\mathbb{R}^{M\times N}$ of $M \times N$ matrices over the reals*;

(ii) *there is a sequence of functions $(u^k)_{k>0} \subset W^{1,p}(\Omega;\mathbb{R}^M)$ for which the representation formula*

$$\lim_{k\to+\infty}\int_E \phi(\nabla u^k)(x)\,dx = \int_E\int_{\mathbf{M}} \phi(A)\,\nu_x(dA)\,dx \tag{4}$$

holds for all measurable $E \subseteq \Omega$ and all ϕ in the space

$$\mathcal{E}_0^p(\mathbf{M}) := \left\{\phi \in C(\mathbf{M}) : \lim_{|A|\to+\infty}\frac{\phi(A)}{1+|A|^p} \text{ exists}\right\}$$

for $p < +\infty$, and for all functions ϕ continuous on $\mathbf{M}$ when $p = +\infty$. In the above, $C(\mathbf{M})$ denotes the space of continuous real-valued functions on $\mathbf{M}$. We shall use the notation

$$\overline{\phi} = \langle\boldsymbol{\nu},\phi\rangle : = \int_{\mathbf{M}} \phi(A)\,\boldsymbol{\nu}(dA).$$

Property (i) above is equivalent to weak$*$ measurability of $x \in \Omega \mapsto \nu_x \in$ *Prob*$(\mathbb{R}^N)$ (the set of probability measures on $\mathbf{M}$), that is, measurability with respect to the weak$*$ topology on *Prob*$(\mathbb{R}^N)$. Strong measurability usually will not be true. Property (ii) implies that there exists a sequence of functions $(u^k)_{k>0} \subset W^{1,p}(\Omega;\mathbb{R}^M)$ such that

$$\phi(\nabla u^k) \rightharpoonup \langle\boldsymbol{\nu},\phi\rangle \qquad \text{in } L^1(\Omega;\mathbb{R}^M) \text{ as } k \to +\infty$$

for all $\phi \in \mathcal{E}_0^p$, (where the notation $\rightharpoonup$ is used to denote weak convergence in the space indicated). In particular,

$$|\nabla u^k|^p \rightharpoonup \langle\boldsymbol{\nu},|A|^p\rangle \qquad \text{in } L^1(\Omega) \text{ as } k \to +\infty$$

(a condition not guaranteed for any subsequence by the uniform boundedness of the $(\|u^k\|_{W^{1,p}})_{k>0}$ alone).

As noted in [KP2] the space $\mathcal{E}_0^p(\mathbb{R}^N)$ is a separable Banach space in the norm

$$\|\phi\|_{\mathcal{E}^p} = \sup_{A\in\mathbf{M}} \frac{\phi(A)}{1+|A|^p} = \left\|\frac{\phi}{1+|\cdot|^p}\right\|_{L^\infty(\Omega)}.$$

Separability is desirable when the duals of the spaces such as $L^1(\Omega,\mathcal{E}_0^p(\mathbf{M}))$ are considered and the representation formula (4) remains valid if $\mathcal{E}_0^p(\mathbf{M})$ is replaced by the inseparable space

$$\mathcal{E}^p(\mathbf{M}) = \left\{\phi\in C(\mathbf{M}) : \sup_{A\in\mathbf{M}} \frac{\phi(A)}{1+|A|^p} < +\infty\right\}.$$

There is also the notion of *biting Young measure* defined in [KP2]. Recall that a bounded sequence $(z^k)_k \in L^1(\Omega)$ does not necessarily possess L^1 weak limit points. However, it admits *biting* limit points. That is, there is a decreasing sequence of subsets $E_{j+1} \subset E_j$ of Ω with $meas(E_j) \to 0$ and a subsequence of the $(z^k)_k$ that is convergent weakly in $L^1(\Omega\setminus E_j)$ to $z \in L^1(\Omega)$ for all j. This is Chacon's biting lemma. For details see for example [BM]. This motivates the following definition (cf., [BZ] and [KP2]).

DEFINITION. *A family of probability measures $\boldsymbol{\nu} = (\nu_x)_{x\in\Omega}$ is a* biting Young measure *provided there is a sequence $(z^k)_k \in L^p(\Omega)$ and $z\in L^1(\Omega)$ such that $|z^k|^p \rightharpoonup z$ and $\psi(z^k) \rightharpoonup \langle\nu_x,\psi\rangle$ in the biting sense as $k\to\infty$ for all $\psi\in\mathcal{E}_0^p$ (or $\mathcal{E}^p$).*

When the z^k are gradients of functions in $W^{1,p}$ it is straightforward to establish that a form of Jensen's inequality holds for biting Young measures, a property that characterizes $W^{1,p}$- gradient Young measures as described in the following theorem.

THEOREM 2.1. *Let $\boldsymbol{\nu} = (\nu_x)_{x\in\Omega}$ be a family of probability measures in $C(\mathbf{M})'$ (the dual space of the bounded continuous functions on $\mathbf{M}$). Then $\boldsymbol{\nu}$ is an $W^{1,p}$-gradient Young measure if and only if it is true that*

(i) *there exists $u\in W^{1,p}(\Omega;\mathbb{R}^M)$ such that*

$$\nabla u(x) = \int_{\mathbf{M}} A\,\nu_x(dA) \qquad x \text{ a.e. in } \Omega;$$

(ii) *Jensen's inequality,*

$$\phi(\nabla u(x)) \le \int_{\mathbf{M}} \phi(A)\,\nu_x(dA),$$

holds for all ϕ continuous in the case $p=+\infty$ and all $\phi\in\mathcal{E}^p(\mathbf{M})$ continuous, quasiconvex, and bounded below if $1\le p<+\infty$;

(iii) *the function*

$$x \mapsto \int_{\mathbf{M}} |A|^p\,\nu_x(dA)$$

is in $L^1(\Omega)$ if $1\le p<\infty$ and when $p=\infty$

$$\operatorname{supp}\nu_\alpha \subseteq K \qquad \text{for } \alpha \text{ a.e. in } \Omega,$$

where K is a compact independent of α.

For the proof see [KP2].

Remark. The authors also note that as a consequence *the $W^{1,p}$-biting Young measures are the same as the $W^{1,p}$-gradient Young measures* (but the sequences that will give rise to the measure as a gradient Young measure differ from the one that generates it as a biting Young measure).

The guarantee of the existence of Young measures draws upon a theorem originally proved by Tartar [T] and built on ideas developed by Young[Y]; a version appears in Ball [Ba] and an extension was proved by Schonbek [Sc]. The theorem describes weak limit points of sequences $(f(z^k))_k$, where f is continuous and $(z^k)_k$ is a sequence of measurable functions. Accordingly, the sequence $(z^k)_k$ defined on a $\mathcal{L}^N$-measurable subset $S \subseteq \mathbb{R}^N$ into $\mathbb{R}^M$ gives rise to a subsequence $(z^j)_{j\geq 1}$ and a parametrized family of measures $\boldsymbol{\nu} = (\nu_x)_{x\in S}$ on $\mathbb{R}^M$ such that $f(z^j)$ converge to $\langle \nu_x, f\rangle = \int_{\mathbb{R}^M} f(\lambda)\, \nu_x(d\lambda)$ weakly$*$ in $L^\infty(S)$ for all $f \in C_0(\mathbb{R}^M)$ (the set of continuous functions on $\mathbb{R}^M$ which vanish at infinity). With improved boundedness conditions on the generating sequence $(z^j)_{j\geq 1}$, the convergence of the $(f(z^j))_{j\geq 1}$ is obtained for a larger class of functions f and the measures $\boldsymbol{\nu}$ are probability measures on $\mathbb{R}^M$. For example, if $(z^j)_j$ is bounded in L^∞, then $f(z^j) \rightharpoonup \langle \boldsymbol{\nu}, f\rangle$ in weakly$*$ in L^∞ for any continuous f.

The representation is also valid if instead $(z^j)_j$ is bounded in L^p (actually a milder boundedness condition suffices); in this case, the measures are probability measures and for any measurable $E \subset S$ the sequence $\big(f(z^j)\big)_{j\geq 1}$ converges to $\langle \nu_x, f\rangle$ weakly in $L^1(E)$ for all f continuous such that $(f(z^j))_j$ is weakly sequentially precompact in $L^1(E)$. Hence it is important to establish criteria for the weak sequential precompactness of the $(f(z^j))_{j\geq 1}$ in L^1. When the domain is bounded, a general criterion is provided by de la Vallée Poussin: the $(f(z^j))_{j\geq 1}$ are weakly sequentially precompact in $L^1(E)$ for $E \subseteq \mathbb{R}^N$ bounded if and only if there exists $\psi : [0, +\infty) \mapsto \mathbb{R}$ with superlinear growth at infinity and such that

$$\sup_j \int_E \psi(f(z^j))\, dx \; < \; +\infty.$$

The following theorem of Ascerbi and Fusco in [AF] and Kinderlehrer and Pedregal in [KP1] also serves to characterize weak sequential precompactness in L^1 in a variational setting. It has an important application to minimization problems in variational calculus. The existence of (local) minimizers of a functional of the form

$$I(u) := \int_\Omega f(x, u, \nabla u)\, dx$$

over $W^{1,p}(\Omega; \mathbb{R}^M)$ is very closely related to the lower semicontinuity properties of I, which in turn are reflected in the quasiconvexity properties of f in the last argument. We recall the notion of quasiconvexity introduced by Morrey [Mo]: a Borel measurable locally integrable function $f : \mathbf{M} \longrightarrow \mathbb{R}$ is *quasiconvex* if for all $A \in \mathbf{M}$,

$$f(A) \; \leq \; \frac{1}{\mathcal{L}^N(D)} \int_D f(A + \nabla\zeta)\, dx$$

for all $\zeta \in W_0^{1,\infty}(D; \mathbb{R}^M)$ (in fact, it suffices to consider $\zeta \in C_0^\infty$) and for all D open bounded sets in $\mathbb{R}^N$ with $\mathcal{L}^N(\partial D) = 0$. In general, convexity is a stronger condition than quasiconvexity but in the scalar case, that is, when either $M = 1$ or $N = 1$, the two conditions are equivalent (cf. [D]).

THEOREM 2.2. *Suppose $f \in \mathcal{E}^p(\mathbf{M})$, for some $1 \leq p \leq +\infty$, is quasiconvex and bounded below and let $u^k \rightharpoonup u$ in $W^{1,p}(\Omega; \mathbb{R}^M)$. Then*

(i) *For all measurable $E \subseteq \Omega$,*

$$\int_E f(\nabla u)\, dx \; \leq \; \liminf_{k\to+\infty} \int_E f(\nabla u^k).$$

(ii) *If, in addition,*

$$\int_\Omega f(\nabla u^k)\,dx \overset{k\to+\infty}{\longrightarrow} \int_\Omega f(\nabla u)\,dx,$$

then the $(f(\nabla u^k))_{j>0}$ are weakly sequentially precompact in $L^1(\Omega)$ and the sequence converges (weakly) to $f(\nabla u)$.

The proof can be found in [KP1]. Part (ii) is a consequence of (i) and it implies that if

$$f(\nabla u^{k_j}) \overset{j\to+\infty}{\longrightarrow} f(\nabla u) \qquad \text{in } L^1(\Omega),$$

then the $W^{1,p}$-gradient Young measure $\boldsymbol{\nu} = (\nu_x)_{x\in\Omega}$ generated by $(\nabla u^{k_j})_{j>0}$ satisfies

$$\langle \boldsymbol{\nu}, f\rangle = f(\nabla u) \qquad x \text{ a.e. in } \Omega.$$

The consequence of Theorem 2.2, which we will have occasion to use directly in this paper, occurs when a p-growth condition of the function f from below allows one to obtain information on the L^p norm of the gradients. This is described in the next result and provides a sufficient (but not necessary) condition for a sequence of functions in $W^{1,p}$ to generate a $W^{1,p}$-gradient Young measure.

THEOREM 2.3. *Let f and $(u^k)_{k\geq 1}$ be as in Theorem 2.2(ii) and assume in addition that*

$$(c|A|^p - 1)^+ \leq \phi(A) \leq C|A|^p + 1$$

for $0 < c \leq C$. Let $\boldsymbol{\nu} = (\nu_x)_{x\in\Omega}$ be generated by the gradients $(\nabla u^k)_{k\geq 1}$. Then $\boldsymbol{\nu}$ is a $W^{1,p}$- gradient Young measure.

The proof can be found in [KP1].

We now state and prove a result on the sequences of gradient-generated Young measures. Given such a bounded sequence we extract a (weakly) convergent subsequence using duality so that the representation formula holds for functions of sublinear growth; then we extend the representation to hold for functions of strictly subquadratic growth; finally we show that the limiting measure is itself a biting Young measure and so a gradient-generated Young measure.

We use the following notation in the remainder of this section:

$$\mathcal{E}_0 \equiv \mathcal{E}_0^2(\mathbb{R}^N), \qquad \mathcal{F}_0 \equiv \mathcal{E}_0^1(\mathbb{R}^N), \qquad \text{and } \mathcal{G}_p \equiv \mathcal{E}_0^p(\mathbb{R}^N) \text{ for } 1 \leq p < 2,$$

where functions on $\mathbb{R}^N$ can be replaced with vector-valued functions. We also let $Q_\infty = \Omega \times \mathbb{R}^+$ with Ω an open bounded set in $\mathbb{R}^N$.

LEMMA 2.4. *Suppose that $(\boldsymbol{\nu}^\alpha)_{\alpha\geq 0}$ with $\boldsymbol{\nu}^\alpha = (\nu^\alpha_{x,t})_{(x,t)\in Q_\infty}$ is a sequence of $H^1_{loc}(Q_\infty)$-gradient Young measures and each $\boldsymbol{\nu}^\alpha$ is generated by $(\nabla v^{\alpha,m})_{m\geq 0}$, where $(v^{\alpha,m})_{m\geq 0}$ is a sequence in $H^1_{loc}(Q_\infty)$ uniformly bounded in α and m. Then a subsequence (not relabeled) of the $(\boldsymbol{\nu}^\alpha)_{\alpha>0}$ and an $H^1_{loc}(Q_\infty)$-gradient Young measure $\boldsymbol{\nu} = (\nu_{x,t})_{(x,t)\in Q_\infty}$ exist such that*

$$\boldsymbol{\nu}^\alpha \overset{\alpha\to 0}{\longrightarrow} \boldsymbol{\nu} \tag{5}$$

weakly in $L^1(Q_T;\, \mathcal{G}_p')$, weakly in $L^2(Q_T;\, \mathcal{F}_0')$, and weakly in $L^\infty(Q_T;\, M(\mathbb{R}^N))$ for each $T \geq 0$. That is,*

$$\langle \boldsymbol{\nu}^\alpha, \psi\rangle \overset{\alpha\to 0}{\longrightarrow} \langle \boldsymbol{\nu}, \psi\rangle$$

weakly in $L^1(Q_T)$ for $\psi \in \mathcal{G}_p$, weakly in $L^2(Q_T)$ for $\psi \in \mathcal{F}_0$, and weakly∗ in $L^\infty(Q_T)$ for $\psi \in C_0(\mathbb{R}^N)$. In addition, this convergence also holds in the biting sense for $\psi \in \mathcal{E}_0$.

Remark 1. Recall that the assumption on the $(\boldsymbol{\nu}^\alpha)_{\alpha \geq 0}$ implies that the representation formula

$$\int_0^T \int_\Omega \psi(\nabla v^{\alpha,m})(x,t)\theta(x,t)\,dx\,dt \overset{m\to\infty}{\longrightarrow} \int_0^T \int_\Omega \int_{\mathbf{M}} \psi(A)\,d\nu^\alpha_{x,t}(A)\,\theta(x,t)\,dx\,dt$$

holds for all $\psi \in \mathcal{E}_0$ and $\mathcal{E}^2$, for $\theta \in \mathrm{L}^1(Q_T)$, and for each $\alpha \geq 0$ (not necessarily uniformly in α). This in turn implies that the representation formula also holds for $\psi \in \mathcal{F}$ or $C_0(\mathbb{R}^N)$ weakly in L^2 or weakly∗ in L^∞, respectively.

Remark 2. Assume that a sequence of Young measures is bounded in $L^1_{loc}(Q_\infty;\, \mathcal{E}_0^{'})$. Duality cannot be used here to ensure a limit point. However, we are able to reduce to the case of Lemma 2.4 as follows:

Suppose $(\boldsymbol{\nu}^\alpha)_{\alpha>0}$, with $\boldsymbol{\nu}^\alpha = (\nu^\alpha_{x,t})_{(x,t)\in Q_\infty}$, is a sequence of Young measures bounded in $L^1_{loc}(Q_\infty; \mathcal{E}_0^{'})$. For each α let $(\nabla v^{\alpha,k})_{k>0}$ be the generating gradients, where $v^{\alpha,k} \in L^2_{loc}(\mathbb{R}^+, H^1_0(\Omega))$. Then $(\boldsymbol{\nu}^\alpha)_{\alpha>0}$ is bounded in $L^2_{loc}(Q_\infty; \mathcal{F}_0^{'}) \cap L^\infty_{loc}(Q_\infty; M(\mathbb{R}^N))$ and a diagonal subsequence of the $(v^{\alpha,k})_{\alpha,k}$ is bounded in $L^2_{loc}(\mathbb{R}^+, H^1_0(\Omega))$ uniformly in α and k (and can be taken to be the new generating sequence). Thus Lemma 2.4 applies.

The proof of this remark is straightforward and is omitted.

Proof of Lemma 2.4.

Step 1. Here we extract the subsequence of the measures satisfying (5). Fix $T > 0$. It is straightforward to see that $(\boldsymbol{\nu}^\alpha)_{\alpha \geq 0}$ is bounded in the spaces $L^2(Q_T; \mathcal{F}_0^{'})$ and $L^\infty(Q_T; M(\mathbb{R}^N))$, which are isomorphic to the dual spaces of $L^2(Q_T;\, \mathcal{F}_0)$ and $L^1(Q_T;\, C_0(\mathbb{R}^N))$, respectively. Using this we can extract a subsequence (not relabeled) $(\boldsymbol{\nu}^\alpha)_{\alpha \geq q0}$ and a parametrized probability measure $\boldsymbol{\nu} = (\nu_{x,t})_{(x,t)\in Q_\infty}$ such that

$$\boldsymbol{\nu}^\alpha \overset{\alpha\to 0}{\longrightarrow} \boldsymbol{\nu} \qquad \text{weakly in } L^2(Q_T;\, \mathcal{F}_0^{'}) \text{ and weakly} * \text{ in } L^\infty(Q_T;\, M(\mathbb{R}^N)).$$

We now show that the convergence remains valid if we allow ψ to have higher growth, provided we compensate by higher integrability on the test functions.

Claim. $\langle \nu^\alpha, \psi\rangle \overset{\alpha\to 0}{\longrightarrow} \langle \nu, \psi\rangle$ *weakly in $L^1(Q_T)$ for all $\psi \in \mathcal{G}_p$, $1 \leq p < 2$.*

Proof of Claim. The key idea here is that the sequence $(|\nabla v^{\alpha,m}|^p)_{\alpha,m}$ is weakly precompact in L^1 *uniformly* in α,m for each $1 \leq p \leq 2$. (This is not true for $p = 2$; the sequences $(|\nabla v^{\alpha,m}|^2)_m$ are by assumption weakly precompact in L^1 but not uniformly in α.) We use the same cutoff functions used in Ball [Ba] and Slemrod [Sl]. Set

$$\eta^k(\lambda) := \begin{cases} 1 & \text{if } |\lambda| \leq k-1, \\ k - |\lambda| & \text{if } k-1 \leq |\lambda| \leq k, \\ 0 & \text{if } |\lambda| \geq k. \end{cases}$$

Let $\psi \in \mathcal{G}_p$ and let $\theta \in L^\infty(Q_T)$. Define

$$\psi^k(\lambda) := \psi(\lambda)\eta^k(\lambda), \qquad \psi^k \in C_0(\mathbb{R}^N).$$

$$\left| \int_0^T \int_\Omega \langle \nu^\alpha_{x,t}, \psi\rangle \theta(x,t)\,dx\,dt \;-\; \int_0^T \int_\Omega \langle \nu_{x,t}, \psi\rangle \theta(x,t)\,dx\,dt \right|$$

$$\begin{aligned}
\le\quad & \|\theta\|_{L^\infty(Q_T)} \int_0^T \int_\Omega \left|\langle \boldsymbol{\nu}^\alpha,\, \psi - \psi^k\rangle\right| \,dx\,dt \\
+\quad & \left| \int_0^T \int_\Omega \left(\langle \boldsymbol{\nu}^\alpha,\, \psi^k\rangle - \langle \boldsymbol{\nu},\, \psi^k\rangle\right) dx\,dt \right| \\
+\quad & \|\theta\|_{L^\infty(Q_T)} \int_0^T \int_\Omega \left|\langle \boldsymbol{\nu},\, \psi - \psi^k\rangle\right| \,dx \\
=\quad & I + II + III.
\end{aligned}$$

Fix $\epsilon > 0$. It is a consequence of the Dunford–Pettis theorem that

$$\begin{aligned}
I &= \lim_{m\to+\infty} \|\theta\|_{L^\infty(Q_T)} \int_0^T \int_\Omega |\psi - \psi^k|(\nabla v^{\alpha,m})\,dx\,dt \\
&\le c \lim_{m\to+\infty} \int_{\{(x,t):|\nabla v^{\alpha,m}|\ge k-1\}} |\psi|(\nabla v^{\alpha,m})\,dx\,dt \\
&\le c \sup_{\alpha,m} \int_{\{(x,t):|\nabla v^{\alpha,m}|\ge k-1\}} (1 + c'|\nabla v^{\alpha,m}|^p)\,dx\,dt \\
&\longrightarrow 0
\end{aligned}$$

as $k \to +\infty$ uniformly in α, by the L^1 precompactness mentioned above for $1 \le p < 2$, and using that

$$meas\{(x,t) : |\nabla v^{\alpha,m}| \ge k\} \overset{k\to+\infty}{\longrightarrow} 0,$$

since $\|\nabla v^{\alpha,m}\|_{L^2(Q_T)}$ is uniformly bounded in α, m. For each k, $\psi^k \in C_0(\mathbb{R}^N)$ and so $\exists \delta(k,\epsilon)$ such that $II < \epsilon$ $\forall |\alpha| < \delta(k,\epsilon)$ (but not necessarily uniformly in k).

For III, assume $\psi \ge 0$. Then $0 \le \psi^k \nearrow \psi$ pointwise and so $\langle \nu_{x,t},\, \psi - \psi^k\rangle \to 0$ as $k \to +\infty$. (For general ψ, write $\psi = \psi^+ - \psi^-$ and $(\psi^+)^k = \psi^+\eta^k$, $(\psi^-)^k = \psi^-\eta^k$, and use the monotone convergence of each term.) So $\exists K(\epsilon)$ such that $III < \epsilon$ $\forall k \ge K(\epsilon)$.

We choose k for I and III which is independent of α; using this k we then find $\delta(\epsilon, k)$ for II. This shows that the sequence of $\boldsymbol{\nu}^\alpha$ converges in $L^\infty(Q_T; M(\mathbb{R}^N))$ to $\boldsymbol{\nu}$ and proves the claim.

Step 2. We now show that for each $1 \le p < 2$ the limit point $\boldsymbol{\nu}$ is a gradient Young measure. For this we fix such a p and find a sequence of gradients for which the representation formula holds for all functions in a dense set of $\mathcal{G}_p$ and show that the same sequence works for all ψ in $\mathcal{G}_p$. (It is obvious that for this argument one must work with the separable space $\mathcal{G}_p$ rather than the inseparable space $\mathcal{E}^p$.)

Fix $T > 0$. Let $(\phi_n)_{n\ge1}$ be dense in $\mathcal{G}_p$. For each $n \ge 1$ we have, by Step 1,

$$\phi_n(\nabla v^{\alpha,m}) \quad \overset{m\to+\infty}{\rightharpoonup} \quad \langle \boldsymbol{\nu}^\alpha, \phi_n\rangle \quad \text{in } L^1(Q_T),$$

and also

$$\langle \boldsymbol{\nu}^\alpha, \phi_n\rangle \quad \overset{\alpha\to0}{\rightharpoonup} \quad \langle \boldsymbol{\nu}, \phi_n\rangle \quad \text{in } L^1(Q_T).$$

Therefore a diagonal subsequence indexed by $\mu(n)$ exists such that

$$\phi_n(\nabla v^{\mu(n)}) \quad \overset{\mu(n)\to+\infty}{\rightharpoonup} \quad \langle \boldsymbol{\nu}, \phi^n\rangle \quad \text{in } L^1(Q_T).$$

This way we obtain the sequences $(\nabla v^{\mu(n)})_{\mu(n)\geq 1}$ for each n which we Cantor-diagonalize to obtain a single sequence $(\nabla v^{\mu})_{\mu\geq 1}$ such that the representation formula holds for each ϕ_n, i.e.,

$$\phi_n(\nabla v^{\mu}) \quad \overset{\mu\to+\infty}{\rightharpoonup} \quad \langle \boldsymbol{\nu}, \phi^n\rangle \qquad \text{in } L^1(Q_T) \text{ for all } n.$$

Now using density we show that the sequence of gradients just obtained is a generating sequence for the parametrized measure $\boldsymbol{\nu}$ obtained in Step 1. For this, let $\phi \in \mathcal{G}_p$ and $\epsilon > 0$ be given. Find $N(\epsilon)$ such that $\|\phi - \phi_n\|_{\mathcal{G}_p} < \epsilon \ \forall n \geq N(\epsilon)$. Let $\theta \in \mathrm{L}^{\infty}(Q_T)$. We have

$$\begin{aligned}
&\left| \int_0^T \int_\Omega \theta(x,t)\phi(\nabla v^{\mu})(x,t)\,dx\,dt \; - \; \int_0^T \int_\Omega \theta(x,t)\langle \nu_{x,t}, \phi\rangle\,dx\,dt \right| \\
&\leq \quad \|\,\theta\,\|_{L^\infty(\Omega)} \int_0^T \int_\Omega |\phi(\nabla v^{\mu}) - \phi_n(\nabla v^{\mu})|\,dx\,dt \\
&+ \quad \|\,\theta\,\|_{L^\infty(\Omega)} \int_0^T \int_\Omega |\phi_n(\nabla v^{\mu}) - \langle \boldsymbol{\nu}, \phi_n\rangle|\,dx\,dt \\
&+ \quad \|\,\theta\,\|_{L^\infty(\Omega)} \int_0^T \int_\Omega |\langle \boldsymbol{\nu},\, \phi_n - \phi\rangle|\,dx\,dt \\
&= \quad I + II + III.
\end{aligned}$$

For each term we have

$$\begin{aligned}
&I \leq c\,\|\phi - \phi_n\|_{\mathcal{G}_p} \int_0^T \int_\Omega (1 + |\nabla v^{\mu}|^2)dx\,dt \;\; \leq \;\; c\,\epsilon\,\forall n \geq N(\epsilon), \text{ uniformly in } \mu, \\
&II \leq c\,\epsilon \qquad \forall \mu \geq M(\epsilon, n), \\
&III \leq c\,\|\phi - \phi_n\|_{\mathcal{G}_p} \int_0^T \int_\Omega \langle \boldsymbol{\nu}, 1 + |\mathrm{id}|^p\rangle\,dx\,dt \;\; \leq \;\; c\,\epsilon.
\end{aligned}$$

Thus we may choose n for I and III which is independent of μ and for this n we find M for II.

We conclude that

$$\phi(\nabla v^{\mu}) \quad \overset{\mu\to+\infty}{\rightharpoonup} \quad \langle \nu_{x,t}, \phi\rangle \qquad \text{in } L^1(Q_T) \qquad \forall \phi \in \mathcal{G}_p$$

and by Remark 1 to Lemma 2.4 this finishes the proof of (5).

Step 3. We now extend $\boldsymbol{\nu}$ to $\mathcal{E}_0'$ and show it is a biting gradient Young measure. Then by the Remark to Theorem 2.1 it is an $H^1_{loc}(Q_\infty)$-gradient Young measure. First note that by assumption

$$\sup_{\alpha} \|\langle \boldsymbol{\nu}^{\alpha}, \mathrm{id}^2\rangle\|_{L^1(Q_T)} \leq \infty,$$

so that there exists a subsequence converging in biting. We use its limit to extend $\boldsymbol{\nu}$; there is a decreasing sequence of subsets $E_{j+1} \subset E_j$ of Q_T with $meas(E_j) \to 0$ and a subsequence of the $\boldsymbol{\nu}^{\alpha}$, not relabeled, such that

$$\text{(6)} \qquad \langle \boldsymbol{\nu}^{\alpha}, \mathrm{id}^2\rangle \; \rightharpoonup \; \langle \boldsymbol{\nu}, \mathrm{id}^2\rangle \text{ in } L^1(Q_T \setminus E_j) \text{ for all } j.$$

Accordingly, we may assume henceforth that in Step 1 the subsequence extracted to satisfy (5) also satisfies the above biting convergence. Using the Dunford–Pettis theorem and the growth condition we extend $\boldsymbol{\nu}$ for $\psi \in \mathcal{E}_0$ c anonically; for the same sequence of biting sets E_j and the subsequence as in (6) we see that $(\langle \boldsymbol{\nu}^\alpha, \psi \rangle)_\alpha$ are $L^1(Q_T \setminus E_j)$ weakly convergent for each j, so we denote this biting limit by $\langle n, \psi \rangle$:

$$\langle \boldsymbol{\nu}^\alpha, \psi \rangle \rightharpoonup \langle \boldsymbol{\nu}, \psi \rangle \text{ in } L^1(Q_T \setminus E_j), \text{ for all } j.$$

To see this, fix j, choose $A \subset Q_T$, and assume $\psi \geq 0$, or otherwise consider ψ^+ and ψ^-. Then as $meas(A) \to 0$,

$$\int_A \langle \boldsymbol{\nu}^\alpha, \psi \rangle \, dx \, dt \leq \int_A c\langle \boldsymbol{\nu}^\alpha, \mathrm{id}^2 \rangle + c' \, dx \, dt \longrightarrow 0$$

uniformly in α. In addition, by the growth condition on ψ, the sequence $(\langle \boldsymbol{\nu}^\alpha, \psi \rangle)_\alpha$ is weakly Cauchy in $L^1(Q_T \setminus E_j)$.

We now produce a generating sequence for the measure $\boldsymbol{\nu}$. Recall that

$$|\nabla v^{\alpha,m}|^2 \overset{m \to \infty}{\rightharpoonup} \langle \boldsymbol{\nu}^\alpha, \mathrm{id}^2 \rangle \qquad \text{in } L^1(Q_T)$$

and also

$$\langle \boldsymbol{\nu}^\alpha, \mathrm{id}^2 \rangle \qquad \overset{\alpha \to 0}{\rightharpoonup} \qquad \langle \boldsymbol{\nu}, \mathrm{id}^2 \rangle \qquad \text{in biting.}$$

So for a diagonal subsequence we have

$$|\nabla v^\mu|^2 \qquad \overset{\mu \to \infty}{\rightharpoonup} \qquad \langle \boldsymbol{\nu}, \mathrm{id}^2 \rangle$$

so that $\psi(\nabla v^\mu) \rightharpoonup \langle \boldsymbol{\nu}, \psi \rangle$ in $L^1(Q_T)$ for all $\psi \in \mathcal{E}_0$. Hence $\boldsymbol{\nu}$ is a biting Young measure. Letting ∇v be the $L^2(Q_T)$ weak limit of $(\nabla v^\mu)_\mu$ and using Theorem 2.1, we conclude that $\boldsymbol{\nu}$ is a gradient Young measure. This completes the proof of the lemma. □

3. The variational treatment and the existence of a Young measure solution.

Assumptions. We define the two separable Banach spaces

$$\mathcal{E}_0 \equiv \mathcal{E}_0^2(\mathbb{R}^N) := \left\{ \psi \in C(\mathbb{R}^N) : \lim_{|A| \to +\infty} \frac{|\psi(A)|}{1 + |A|^2} \text{ exists} \right\}$$

and

$$\mathcal{F}_0 \equiv \mathcal{E}_0^1(\mathbb{R}^N; \mathbb{R}^N) := \left\{ \psi \in C(\mathbb{R}^N; \mathbb{R}^N) : \lim_{|A| \to +\infty} \frac{|\psi(A)|}{1 + |A|} \text{ exists} \right\}.$$

We assume the heat flux satisfies $q = \nabla \phi$ on $\mathbb{R}^N$ with $\phi \in C^1(\mathbb{R}^N)$. We impose the growth conditions $\phi \in \mathcal{E}_0$, $q \in \mathcal{F}_0$, and furthermore,

$$(c|a|^2 - 1)^+ \leq \phi(a) \leq C|a|^2 + 1 \qquad \forall a \in \mathbb{R}^N, \tag{7}$$

$$|q(a)| \leq C|a| \qquad \forall a \in \mathbb{R}^N. \tag{8}$$

We let ϕ^{**} denote the *convexification* of ϕ, that is,

$$\phi^{**} = \sup\{f(x) : f \leq \phi, \ f \text{ convex}\}.$$

Since ϕ is in $C^1(\mathbb{R}^N)$, so is ϕ^{**}, and we set

$$p := \nabla\phi^{**}.$$

We note that $q = p$ on the set $\{\phi = \phi^{**}\}$ and that ϕ^{**} and p satisfy the same growth conditions as ϕ and q, respectively. We assume

$$\phi^{**}(0) = 0$$

and hence $p(0) = 0$ follows and by the convexity of ϕ^{**} implies

$$p(\lambda)\cdot\lambda \geq 0 \qquad \forall\lambda \in \mathbb{R}^N.$$

Under these hypotheses we fix ideas by agreeing on the following definition.

DEFINITION. *A* measure solution *to $\mathcal{P}$,*

$$\begin{aligned} u_t &= \nabla\cdot q(\nabla u) \qquad \textit{in } \; Q_\infty := \Omega\times\mathbb{R}^+, \\ u(x,0) &= u_0(x) \qquad \textit{for } x \textit{ in } \; \Omega, \\ u &= 0 \qquad \textit{on } \partial\Omega\times\mathbb{R}^+, \end{aligned}$$

with $u_0 \in H_0^1(\Omega)$ a given function, is a pair $(u, \boldsymbol{\nu})$, where $u \in H^1_{loc}(Q_\infty)\cap L^\infty\left(\mathbb{R}^+;\, H_0^1(\Omega)\right)$ and $\boldsymbol{\nu} = (\nu_{x,t})_{(x,t)\in Q_\infty}$ is a parametrized family of probability measures on $\mathbb{R}^N$ such that the equation

$$\int_0^{+\infty}\int_\Omega \left(\langle\boldsymbol{\nu}, q\rangle\cdot\nabla\zeta + \frac{\partial u}{\partial t}\zeta\right) dx\,dt = 0 \qquad \forall\zeta \in H_0^1(Q_\infty) \tag{9}$$

(where $\langle\nu_{x,t}, q\rangle = \int_{\mathbb{R}^N} q(\lambda)\nu_{x,t}(d\lambda)$) and

$$\langle\nu_{x,t}, \mathrm{id}\rangle = \nabla u(x,t) \qquad (x,t) \textit{ a.e. in } Q_\infty \tag{10}$$

hold. Equivalently stated, equation (9) *is*

$$u_t \;=\; \nabla\cdot\langle\boldsymbol{\nu}, q\rangle \qquad \textit{in } H^{-1}(Q_\infty). \tag{11}$$

If in addition $\boldsymbol{\nu}$ is a Young measure generated by the gradients with respect to x of a sequence in $L^2_{loc}(\mathbb{R}^+; H_0^1(\Omega))$, then the pair $(u, \boldsymbol{\nu})$ is called a Young measure solution to $\mathcal{P}$. We will say that $(u, \boldsymbol{\nu})$ is a solution or solves to indicate that the pair is a Young measure solution *to $\mathcal{P}$.*

The function u is also called a solution and the use of the term is clear from the context. In the above, $\Omega \subset \mathbb{R}^N$ is an open, bounded set, $\partial\Omega\times\mathbb{R}^+$ is the lateral boundary of the parabolic cylinder Q_∞, and *id* stands for the identity function. The notation H^1 stands for the Sobolev space $W^{1,2}$, and $W_0^{1,2}$ for its subspace of functions with zero trace on the boundary. As usual $H^{-1} = W^{-1,2}$ denotes the dual of $W_0^{1,2}$. The space H^1_{loc} stands for the subspace of H^1 of functions which, together with their first weak derivatives, are locally square-integrable and $H^1_{0,loc}(Q_\infty)$ is the space of functions $\zeta \in H^1_{loc}(Q_\infty)$ with t-slices $\zeta(\cdot, t) \in H_0^1(\Omega)$ for $t \geq 0$ a.e.

Remark 1. By the existence proof below there is a Young measure solution to $\mathcal{P}$ such that $u_t \in L^2(Q_\infty)$ and (9) is satisfied also locally in time, that is, for test functions $\zeta \in H_0^1(Q_\infty)$. In particular, the solution u is an admissible test function.

Remark 2. A consequence of the above definition is that an equilibrium equation is also satisfied pointwise in time in $H^{-1}(\Omega)$; indeed, for t a.e. in $[0, T]$ and for all $\zeta \in H_0^1(\Omega)$ we have

$$\int_0^T\int_\Omega \langle\nu_{x,t}, q\rangle\cdot\nabla\zeta(x)\,dx\,dt \;=\; -\int_0^T\int_\Omega \frac{d}{dt}u(x,t)\zeta(x)\,dx\,dt;$$

differentiating in time we obtain

$$\int_\Omega \langle \nu_{x,t}, q\rangle \cdot \nabla\zeta(x)\, dx \;=\; -\int_\Omega u_t(x,t)\zeta(x)\, dx \qquad t \text{ a.e. in } \mathbb{R}^+ \ \forall\zeta \in H_0^1(\Omega).$$

Remark 3. A classical solution to $\mathcal{P}$ which is bounded in time is a measure solution with $\boldsymbol{\nu} = \delta_{\nabla u}$.

THEOREM 3.1 (Existence). *Under the assumptions stated above there exists a Young measure solution $(u, \boldsymbol{\nu})$ to $\mathcal{P}$. In addition, $u_t \in L^2(Q_\infty)$,*

$$\operatorname{supp} \nu_{x,t} \subset \{a \in \mathbb{R}^N : \phi(a) = \phi^{**}(a)\} \qquad (x,t) \text{ a.e. in } Q_\infty,$$

and $(u, \boldsymbol{\nu})$ is also a Young measure solution of the relaxed problem

$$u_t \;=\; \nabla \cdot p(\nabla u) \qquad \text{in } H^{-1}(Q_\infty)$$

with the same initial-boundary data.

Proof. The following existence proof is due to Kinderlehrer and Pedregal [KP1].

Step 1. Let $h > 0$ be fixed and for each $j \geq 0$ consider the functionals

$$\Phi_h(v; u^{h,j-1}) \;:=\; \int_\Omega \phi(\nabla v) + \frac{1}{2h}(v - u^{h,j-1})^2\, dx \qquad \text{for } v \in H_0^1(\Omega)$$

and

$$\Phi_h^{**}(v; u^{h,j-1}) \;:=\; \int_\Omega \phi^{**}(\nabla v) + \frac{1}{2h}(v - u^{h,j-1})^2\, dx \qquad \text{for } v \in H_0^1(\Omega).$$

We drop the explicit dependence on h. By relaxation,

$$I \;:=\; \inf\left\{\Phi(v; u^{h,j-1}) : v \in H_0^1(\Omega)\right\} \;=\; \inf\left\{\Phi^{**}(v; u^{h,j-1}) : v \in H_0^1(\Omega)\right\}.$$

Let $(u^{h,j,k})_{k\geq 1} \subset H_0^1(\Omega)$ be a minimizing sequence for Φ (and Φ^{**}). By the growth condition (7) and the Rellich theorem, together with the H^1-weak sequential lower semicontinuity of Φ^{**}, there exist $u^{h,j} \in H_0^1(\Omega)$ and a subsequence,[1] not relabeled, such that

$$u^{h,j,k} \overset{k\to\infty}{\longrightarrow} u^{h,j} \qquad \text{weakly in } H_0^1(\Omega) \text{ and strongly in } L^2(\Omega),$$

$$I \;=\; \Phi^{**}(u^{h,j}; u^{h,j-1}),$$

and therefore,

$$(12)\quad \int_\Omega \phi^{**}(\nabla u^{h,j})\, dx \;=\; \lim_{k\to+\infty} \int_\Omega \phi^{**}(\nabla u^{h,j,k})\, dx \;=\; \lim_{k\to+\infty} \int_\Omega \phi(\nabla u^{h,j,k})\, dx.$$

Then by Theorem 2.2

$$(13)\qquad \phi^{**}(\nabla u^{h,j,k}) \overset{k\to\infty}{\longrightarrow} \phi^{**}(\nabla u^{h,j}) \qquad \text{in } L^1(\Omega).$$

Let $\boldsymbol{\nu}^{h,j} = (\nu_x^{h,j})_{x\in\Omega}$ be the Young measure generated by the $(\nabla u^{h,j,k})_{k\geq 1}$. By Theorem 2.3 $\boldsymbol{\nu}^{h,j}$ is an $H^1(\Omega)$-gradient Young measure and the sequence $(\phi(\nabla u^{h,j,k}))_k$

[1] In fact, the whole sequence converges (weakly) as the minimizer $u^{h,j}$ is unique.

is also weakly convergent in L^1; the representation formula (4) describes the weak L^1 limits and by (12) and (13) we obtain

$$\int_\Omega \phi^{**}(\nabla u^{h,j})\,dx \;=\; \int_\Omega \langle \boldsymbol{\nu}^{h,j}, \phi^{**}\rangle\,dx \;=\; \int_\Omega \langle \boldsymbol{\nu}^{h,j}, \phi\rangle\,dx,$$

which together with $\phi^{**} \leq \phi$, implies

$$\operatorname{supp} \boldsymbol{\nu}^{h,j} \subseteq \{\phi = \phi^{**}\} \tag{14}$$

and therefore

$$\langle \boldsymbol{\nu}^{h,j}, \phi\rangle \;=\; \langle \boldsymbol{\nu}^{h,j}, \phi^{**}\rangle \;=\; \phi^{**}(\nabla u^{h,j}) \qquad x \text{ a.e. in } \Omega, \tag{15}$$

$$\nabla u^{h,j} \;=\; \langle \boldsymbol{\nu}^{h,j}, id\rangle \qquad x \text{ a.e. in } \Omega. \tag{16}$$

In addition,

$$\langle \boldsymbol{\nu}^{h,j}, q\rangle \;=\; \langle \boldsymbol{\nu}^{h,j}, p\rangle \qquad x \text{ a.e. in } \Omega, \tag{17}$$

which follows from (14). Setting the Gâteaux derivative of $\Phi^{**}(\cdot; u^{h,j-1})$ to zero at the minimizer $u^{h,j}$, we obtain the equilibrium equation

$$\int_\Omega p(\nabla u^{h,j})\cdot\nabla\zeta + \frac{1}{h}(u^{h,j} - u^{h,j-1})\zeta\,dx \;=\; 0 \qquad \forall \zeta \in H_0^1(\Omega),$$

or equivalently the Euler–Lagrange equation $\nabla \cdot p(\nabla u^{h,j}) = \frac{1}{h}(u^{h,j} - u^{h,j-1})$ in $H^{-1}(\Omega)$. By the stability of Young measure minimizers discussed in [KP1], the equilibrium equation holds with $\langle \boldsymbol{\nu}^{h,j}, q\rangle = \langle \boldsymbol{\nu}^{h,j}, p\rangle$ in place of $p(\nabla u^{h,j})$ and thus

$$\nabla \cdot \langle \boldsymbol{\nu}^{h,j}, q\rangle \;=\; \nabla \cdot \langle \boldsymbol{\nu}^{h,j}, p\rangle \;=\; \nabla \cdot p(\nabla u^{h,j}) \qquad \text{in } H^{-1}(\Omega) \tag{18}$$

hold.

Let $I^{h,j} = [hj, h(j+1))$ and $\chi^{h,j}$ be the indicator function of $I^{h,j}$ and for $t > 0$ set

$$\lambda^{h,j}(t) \;=\; \begin{cases} \frac{t}{h} - j & \text{if } hj \leq t < h(j+1), \\ 0 & \text{otherwise.} \end{cases}$$

Define for x a.e. in Ω each $t \in \mathbb{R}^+$,

$$u^h(x,t) :\,= \sum_j \chi^{h,j}(t)\left\{u^{h,j}(x) + \lambda^{h,j}(t)(u^{h,j+1}(x) - u^{h,j}(x))\right\} \tag{19}$$

so that $u^h \in L^\infty(\mathbb{R}^+; H_0^1(\Omega))$ and also

$$u^h = 0 \text{ on } \partial\Omega \times \mathbb{R}^+.$$

We let

$$w^h :\,= \sum_j \chi^{h,j} u^{h,j} \qquad \in L^\infty(\mathbb{R}^+; H_0^1(\Omega)), \tag{20}$$

$$\boldsymbol{\nu}^h = (\nu^h_{x,t})_{(x,t)\in Q_\infty} := \sum_j \chi^{h,j}\boldsymbol{\nu}^{h,j} \quad \in \mathrm{L}^1_{loc}(Q_\infty;\mathcal{E}_0') \tag{21}$$

be probability measures on $\mathbb{R}^N$ (where $\mathcal{E}_0'$ is the dual space of $\mathcal{E}_0$). By (16) we know

$$\nabla w^h = \langle \boldsymbol{\nu}^h, \mathrm{id}\rangle \qquad (x,t) \text{ a.e. in } Q_\infty. \tag{22}$$

We also let

$$\bar{q}^h := \langle \boldsymbol{\nu}^h, q\rangle = \sum_j \chi^{h,j}\langle \boldsymbol{\nu}^{h,j}, q\rangle \quad \in L^2(Q_\infty).$$

Differentiating (19) almost everywhere in time we have

$$\frac{\partial u^h}{\partial t}(x,t) = \sum_j \chi^{h,j}(t)\frac{1}{h}(u^{h,j+1} - u^{h,j})(x) \quad \in L^2(Q_\infty).$$

Then for almost every $t > 0$,

$$\frac{\partial u^h}{\partial t} = \nabla\cdot\langle \boldsymbol{\nu}^h, q\rangle \qquad \text{in } H^{-1}(\Omega)$$

or, equivalently, the equation

$$\int_\Omega \left(\bar{q}^h\cdot\nabla\zeta + \frac{\partial u^h}{\partial t}\zeta\right) dx = 0 \quad \forall\zeta\in H^1_0(\Omega) \tag{23}$$

holds. From (23) it is easy to deduce that

$$\int_0^\tau\int_\Omega \langle \boldsymbol{\nu}^h, q\rangle\cdot\nabla\zeta + \frac{\partial u^h}{\partial t}\zeta\,dx\,dt = 0 \quad \forall\zeta\in H^1_0(Q_\tau)\,\forall\tau\in[0,+\infty] \tag{24}$$

(also for $\zeta(\cdot,t)\in H^1_{0,loc}(Q_\infty)$), that is,

$$\frac{\partial u^h}{\partial t} = \nabla\cdot\langle \boldsymbol{\nu}^h, q\rangle \qquad \text{in } H^{-1}(Q_\tau)\,\forall\tau\in[0,+\infty].$$

By (17), (18), and (20),

$$\langle \boldsymbol{\nu}^h, q\rangle = \langle \boldsymbol{\nu}^h, p\rangle \qquad \text{for each } t>0 \text{ and } x \text{ a.e. in } \Omega, \tag{25}$$

$$\nabla\cdot\langle \boldsymbol{\nu}^h, q\rangle = \nabla\cdot\langle \boldsymbol{\nu}^h, p\rangle = \nabla\cdot p(\nabla w^h), \tag{26}$$

both in $H^{-1}(\Omega)$ for each $t\geq 0$ and in $H^{-1}(Q_\tau)\,\forall\tau\in[0,+\infty]$.

Step 2. Using the growth conditions (7) and (8) on ϕ and q we obtain uniform estimates in h for the $(u^h)_{h>0}$ and $(w^h)_{h>0}$ in $L^\infty\left(\mathbb{R}^+;\, H^1_0(\Omega)\right)$ and $(\bar{q}^h)_{h>0}$ in $L^2(Q_\infty)$. Further we obtain that $(\frac{\partial u^h}{\partial t})_{h>0}\in L^2(Q_\infty)$ is bounded in h and the Young measures $(\boldsymbol{\nu}^h)$ are bounded in $\mathrm{L}^\infty(\mathbb{R}^+;\mathcal{E}_0')$. Using weak compactness we may therefore extract weakly convergent subsequences indexed by $h'\to 0$ and a pair $(u,\boldsymbol{\nu})$ satisfying (9) and (10). By [KP1, Lem. 6.3] u is obtained as the common weak limit in $L^2_{loc}(Q_\infty)$ of $(u^{h'})_{h'>0}$ and $(w^{h'})_{h'>0}$ and it satisfies $\frac{\partial u}{\partial t}\in L^2(Q_\infty)$. Along h' (24) yields the equation

$$\int_0^\tau\int_\Omega \left(\langle \boldsymbol{\nu}, q\rangle\cdot\nabla\zeta + \frac{\partial u}{\partial t}\zeta\right) dx\,dt = 0 \quad \forall\zeta\in H^1_0(Q_\tau)\;\forall\tau\in[0,+\infty] \tag{27}$$

(and as in (24), all $\zeta \in H^1_{loc}(Q_\infty)$ with $\zeta(\cdot,t) \in H^1_0(\Omega)$ for almost all $t > 0$ are admissible). Further, by (25),

$$(28) \qquad \langle \boldsymbol{\nu}, q\rangle = \langle \boldsymbol{\nu}, p\rangle \qquad (x,t) \text{ a.e. in } Q_\infty.$$

In addition, by (14) we have

$$(29) \qquad \operatorname{supp} \boldsymbol{\nu} \subseteq \{\phi = \phi^{**}\}.$$

In [KP1] the measure $\boldsymbol{\nu}$ is extracted as the weak limit of the sequence of Young measures $(\boldsymbol{\nu}^h)_{h>0}$ in $L^\infty(\mathbb{R}^+;\mathcal{E}_0')$. We next establish, in accordance with the definition, that $\boldsymbol{\nu}$ is a Young measure generated by the spatial gradients of a sequence and related to u via

$$\langle \nu_{x,t}, \mathrm{id}\rangle = \nabla u(x,t) \qquad (x,t) \text{ a.e. in } Q_\infty.$$

This is a direct consequence of Lemma 2.4 of the previous section and is proved in the following corollary.

Corollary 3.2. *The measure $\boldsymbol{\nu}$ obtained in the proof of the existence theorem (Theorem 3.1) is a Young measure generated by the gradients with respect to x of a sequence in $L^2_{loc}(\mathbb{R}^+;H^1_0(\Omega))$ and so the pair $(u,\boldsymbol{\nu})$ is a Young measure solution of $\mathcal{P}$ (in the sense of the definition).*

Proof. In the notation of Theorem 3.1 recall that

$$\nu^h_{x,t} := \sum_{j\geq 0} \chi_{[hj,h(j+1))}(t)\nu^{h,j}_x \qquad \text{for } x \text{ a.e. in } \Omega \text{ and } \forall t \geq 0.$$

Then for each $h > 0$ the sequence $(\nabla u^{h,k})_{k\geq 0}$ defined by

$$u^{h,k} := \sum_{j\geq 0} \chi_{[hj,h(j+1))}(t) u^{h,j,k}(x) \qquad \in L^2_{loc}(\mathbb{R}^+;H^1_0(\Omega))$$

generates $\boldsymbol{\nu}^h$. We apply Remark 2 following Lemma 2.4 on $\boldsymbol{\nu}^h$ to extract a subsequence indexed by $h' \to 0$ along which the $\boldsymbol{\nu}^{h'}$ converge to a parametrized measure $\boldsymbol{\nu} = (\nu_{x,t})_{(x,t)\in Q_\infty}$, which is generated by a subsequence of $(\nabla u^{h,k})_{h,k}$. In particular,

$$\langle \boldsymbol{\nu}^{h'}, \mathrm{id}\rangle \rightharpoonup \langle \boldsymbol{\nu}, \mathrm{id}\rangle \qquad \text{in } L^2_{loc}(Q_\infty)$$

(because $\mathrm{id} \in \mathcal{F}_0$), and (22) then gives

$$\langle \nu_{x,t}, \mathrm{id}\rangle = \nabla u(x,t) \qquad (x,t) \text{ a.e. in } Q_\infty,$$

since $\nabla w^{h'} \rightharpoonup \nabla u$ in $L^2(\Omega)$. □

4. Uniqueness and properties of the Young measure solution.

4.1. Uniqueness. The following lemma describes a property of the solution upon which the uniqueness proof relies.

Lemma 4.1 (Independence). *For $(u,\boldsymbol{\nu})$ a solution of (1) and (2) the equality*

$$(30) \qquad \langle \nu_{x,t}, q\cdot \mathrm{id}\rangle = \langle \nu_{x,t}, q\rangle \cdot \langle \nu_{x,t}, \mathrm{id}\rangle \qquad (x,t) \text{ a.e. in } Q_\infty$$

holds, i.e., q and ∇u are independent with respect to the Young measure $\boldsymbol{\nu}$.

Proof.

Step 1 (the time-discretized case). Fix $h > 0$.

CLAIM. $\langle \nu_x^{h,j}, q \cdot \mathrm{id}\rangle = \langle \nu_x^{h,j}, q\rangle \cdot \langle \nu_x^{h,j}, \mathrm{id}\rangle$ *x a.e. in Ω for $j = 0, 1, \ldots$.*

Proof of Claim. Let $(u^{h,j,k})_{k=1}^{\infty}$ be the minimizing sequence to the variational principle $\Phi^{**}(v; u^{h,j-1})$ converging to $u^{h,j}$ weakly in $H_0^1(\Omega)$ and strongly in $L^2(\Omega)$. Recall that $(\nabla u^{h,j,k})_{k=1}^{\infty}$ generates $\boldsymbol{\nu}^{h,j}$. For all $\zeta \in H_0^1(\Omega)$, we have

$$\begin{aligned}\int_\Omega p(\nabla u^{h,j,k}) \cdot \nabla\zeta + \frac{u^{h,j,k} - u^{h,j-1}}{h}\zeta \, dx \overset{k\to\infty}{\longrightarrow} & \int_\Omega \langle \nu_x^{h,j}, p\rangle \cdot \nabla\zeta + \frac{u^{h,j} - u^{h,j-1}}{h}\zeta \, dx \\ = & \int_\Omega p(\nabla u^{h,j}) \cdot \nabla\zeta + \frac{u^{h,j} - u^{h,j-1}}{h}\zeta \, dx \\ = & \ 0,\end{aligned}$$

because $p(\nabla u^{h,j,k}) \overset{k\to\infty}{\rightharpoonup} \langle \nu_x^{h,j}, p\rangle$ in $L^2(\Omega)$ and $\nabla\cdot\langle \nu_x^{h,j}, p\rangle = \nabla\cdot p(\nabla u^{h,j})$ in $H^{-1}(\Omega)$. It follows easily that

(i) $\nabla \cdot p(\nabla u^{h,j,k}) \overset{k\to\infty}{\longrightarrow} \nabla \cdot p(\nabla u^{h,j})$ in $H^{-1}(\Omega)$

by the estimate

$$\begin{aligned}\| \nabla \cdot p(\nabla u^{h,j,k}) - \nabla \cdot p(\nabla u^{h,j}) \|_{H^{-1}(\Omega)} &= \sup_{\|\zeta\|_{H_0^1(\Omega)}=1} \left| \int_\Omega [p(\nabla u^{h,j,k}) - p(\nabla u^{h,j})] \cdot \nabla\zeta \, dx \right| \\ \text{(for all sufficiently large } k) &\le \sup_{\|\zeta\|_{H_0^1(\Omega)}=1} \left| \int_\Omega \frac{u^{h,j,k} - u^{h,j}}{h}\zeta \, dx \right| + \epsilon \\ &\le \frac{1}{h} \| u^{h,j,k} - u^{h,j} \|_{L^2(\Omega)} + \epsilon \\ &\overset{k\to\infty}{\longrightarrow} \epsilon \qquad \text{for any } \epsilon > 0,\end{aligned}$$

since $u^{h,j,k} \overset{k\to\infty}{\longrightarrow} u^{h,j}$ in $L^2(\Omega)$ strongly. Recalling Remark 1 to Lemma 2.4 and noting that p, id $\in \mathcal{F}_0$ and $p \cdot \mathrm{id} \in \mathcal{E}_0$, we have as $k \to \infty$,

(ii) $p(\nabla u^{h,j,k}) \cdot \nabla u^{h,j,k} \rightharpoonup \langle \nu_x^{h,j}, p \cdot \mathrm{id}\rangle$ in $L^1(\Omega)$,

(iii) $p(\nabla u^{h,j,k}) \rightharpoonup \langle \nu_x^{h,j}, p\rangle$ in $L^2(\Omega)$,

(iv) $\nabla u^{h,j,k} \rightharpoonup \langle \nu_x^{h,j}, \mathrm{id}\rangle$ in $L^2(\Omega)$.

Now by the div-curl lemma (see [E], [T], or [Mu]), or by direct computation and using the H^1-strong convergence in (i), we have from (i), (iii), (iv),

$$p(\nabla u^{h,j,k}) \cdot \nabla u^{h,j,k} \overset{k\to+\infty}{\rightharpoonup} \langle \nu_x^{h,j}, p\rangle \cdot \langle \nu_x^{h,j}, \mathrm{id}\rangle$$

in the sense of distributions; by (ii) above and recalling (17) we have the claim.

Step 2 (passing to the limit). By (21) and Step 1 we have

$$\langle \boldsymbol{\nu}^h, q \cdot \mathrm{id}\rangle = \langle \boldsymbol{\nu}^h, q\rangle \cdot \langle \boldsymbol{\nu}^h, \mathrm{id}\rangle \qquad x \text{ a.e. in } \Omega \ \forall t \ge 0.$$

We may apply Lemma 2.4 to $(\boldsymbol{\nu}^h)_{h>0}$ to pass to a limit point as $h \to 0$. We obtain a subsequence, not relabeled, such that for each $T \ge 0$,

(v) $\langle \boldsymbol{\nu}^h, q \cdot \mathrm{id}\rangle \rightharpoonup \langle \boldsymbol{\nu}, q \cdot id\rangle$ in $L^1(Q_T)$,

(vi) $\langle \boldsymbol{\nu}^h, q\rangle \rightharpoonup \langle \boldsymbol{\nu}, q\rangle$ in $L^2(Q_T)$,

(vii) $\langle \boldsymbol{\nu}^h, \mathrm{id}\rangle \rightharpoonup \langle \boldsymbol{\nu}, \mathrm{id}\rangle$ in $L^2(Q_T)$.

Using the div-curl lemma as in Step 1 we obtain (30). □

THEOREM 4.2 (Uniqueness and continuity with respect to initial data). *There is a unique function* $u : Q_\infty \longrightarrow \mathbb{R}$ *with* $u \in H^1_{0,loc}(Q_\infty)$ *and* $u(\cdot, 0) = u_0$ *for which there exists a parametrized probability measure* $\boldsymbol{\nu} = (\nu_{x,t})_{(x,t)\in Q_\infty}$ *so that* (9), (10), (28), *and* (30) *are true. Under the same conditions,* $u_0 \mapsto u(\cdot, t)$ *is continuous from* $L^2(\Omega)$ *into* $L^2(\Omega)$ *for each* $t \geq 0$ (*and also into* $L^2(Q_T)$ *for each* $T > 0$).

Proof. Suppose $(u, \boldsymbol{\nu})$ and $(w, \boldsymbol{\mu})$ are two Young measure solutions to $\mathcal{P}$ with initial data u_0 and w_0, respectively. Apply equation (9) using $(u - w)\chi_{[0,T]}$ as the test function[2] in the previous section and against $\overline{q}^\nu$ and $\overline{q}^\mu$ and subtract to obtain (where the shorthand notation $\overline{q}^\nu$ is used for $\langle \boldsymbol{\nu}, q\rangle$ and similarly for $\overline{q}^\mu$)

$$\int_0^T \int_\Omega (\overline{q}^\nu - \overline{q}^\mu) \cdot (\overline{\mathrm{id}}^\nu - \overline{\mathrm{id}}^\mu)\, dx\, dt = -\int_0^T \int_\Omega \frac{\partial(u-w)}{\partial t}(u - w)\, dx\, dt$$

$$(31) \qquad = -\frac{1}{2}\Big(\| (u(\cdot, T) - w(\cdot, T) \|^2_{L^2(\Omega)} - \|u_0 - w_0\|^2_{L^2(\Omega)}\Big).$$

By Lemma 4.1 and (28),

$$\text{left-hand side (l.h.s.) (31)} = \int_0^T \int_\Omega \Big(\overline{p \cdot \mathrm{id}}^\nu + \overline{p \cdot \mathrm{id}}^\mu - \overline{p}^\nu \cdot \overline{\mathrm{id}}^\mu - \overline{p}^\mu \cdot \overline{\mathrm{id}}^\nu\Big)\, dx\, dt$$
$$\geq 0,$$

because the integrand above is precisely the quantity

$$\int_{\mathbb{R}^N} \int_{\mathbb{R}^N} (\nabla\phi^{**}(\alpha) - \nabla\phi^{**}(\beta)) \cdot (\alpha - \beta)\ \nu_{x,t}(d\alpha)\, \mu_{x,t}(d\beta),$$

which is nonnegative by the convexity of ϕ^{**}. This implies for (31)

$$(32) \qquad \| (u(\cdot, T) - w(\cdot, T) \|^2_{L^2(\Omega)} \leq \|u_0 - w_0\|^2_{L^2(\Omega)} \qquad \forall T > 0,$$

which is the continuity with respect to initial data. When $u_0 = w_0$ is used in (32) we have

$$u(\cdot, T) = w(\cdot, T) \qquad x \text{ a.e. in } \Omega\ \forall T > 0$$

and this shows uniqueness. □

Remark 1 (Comparison between classical and Young measure solutions). The statement of uniqueness does not depend on the method of extracting a Young measure solution for $\mathcal{P}$ and does not require that $\boldsymbol{\nu}$ be a Young measure, only that $\overline{q} = \overline{p}$ and the independence property of Lemma 4.1 hold. In particular, if $(u, \delta_{\nabla u})$ is a classical solution to $\mathcal{P}$ satisfying $q(\nabla u) = p(\nabla u)$, a weaker condition than (29), by uniqueness it coincides with the Young measure solution provided by Theorem 3.1 and (29) follows (the independence property is automatically satisfied by classical solutions). We note that there is no claim that the parametrized measure ν is unique; this is false in general.

[2] This is allowed by Remark 1 to the definition of Young measure solutions to $\mathcal{P}$ and (27).

The following lemma gives some properties of the solution $(u, \boldsymbol{\nu})$ which are consequences of the convexity of ϕ^{**} and the independence property. Most will be useful in establishing the uniqueness of the asymptotic limit (in §3).

LEMMA 4.3 (Further properties of the Young measure solution). *Let $(u, \boldsymbol{\nu})$ be the solution to $\mathcal{P}$ and $(u^h)_{h>0}$ as in the proof of the existence theorem (Theorem 3.1). Then the following are true:*

1. $\nabla \cdot p(\nabla u) = \nabla \cdot \overline{p} = \nabla \cdot \overline{q}$ *in $H^{-1}(Q_\infty)$. These equalities also hold in $L^2(Q_\infty)$ since the existence theorem yields $u_t \in L^2(Q_\infty)$ (recall that by (28) $\overline{p} = \overline{q}$ (x,t) a.e. in Q_τ $\forall \tau \in \mathbb{R}^+$).*
2. (i) *For each $T \geq 0$, $u^h \in C\left([0,T];\, L^2(\Omega)\right)$ and $(u^h)_{h>0}$ is Cauchy in $C\left([0,T];\, L^2(\Omega)\right)$.*
   (ii) *$u \in C\left([0,T];\, L^2(\Omega)\right)$; that is, $u(\cdot,t) \to u(\cdot,t_0)$ in $L^2(\Omega)$ as $t \to t_0$ for each $t_0 \geq 0$. In particular, $u(\cdot,t) \to u_0$ in $L^2(\Omega)$ as $t \to 0$.*
3. (i) *$t \mapsto \|u(\cdot,t)\|_{L^2(\Omega)}$ is decreasing (and therefore has a limit as $t \nearrow +\infty$).*
   (ii) *$t \mapsto \|u(\cdot,\delta+t) - u(\cdot,t)\|_{L^2(\Omega)}$ is decreasing for each $\delta \geq 0$.*
   (iii) *The integral*

$$\int_0^{+\infty}\int_\Omega \overline{q}\cdot \nabla u \, dx\, dt$$

exists.

Proof. 1. Fix $T > 0$, let w^h be given by (20), and let $\zeta \in H^1(Q_T)$ with $\zeta(\cdot,t) \in H_0^1(\Omega)$, for t a.e. in $[0,T]$. By Remark 1 to the definition (see §3) $\zeta - w^h$ is an admissible test function in equation (24). Using the convexity of ϕ^{**} and (24) we know that

$$\int_0^T\int_\Omega p(\nabla\zeta)\cdot\nabla(\zeta - w^h)\,dx\,dt \geq \int_0^T\int_\Omega p(\nabla w^h)\cdot\nabla(\zeta - w^h)\,dx\,dt$$
$$= -\int_0^T\int_\Omega \frac{\partial u^h}{\partial t}(\zeta - w^h)\,dx\,dt.$$

Letting $h \to 0$ we obtain

$$\int_0^T\int_\Omega p(\nabla\zeta)\cdot\nabla(\zeta - u) \;\geq\; -\int_0^T\int_\Omega \frac{\partial u}{\partial t}(\zeta - u) \;=\; \int_0^T\int_\Omega \overline{q}\cdot\nabla(\zeta - u).$$

Choosing $\zeta = u + \lambda(\theta - u)$ for $\theta \in H_0^1(Q_T)$ and letting $\lambda \to 0^+$ we obtain

$$\int_0^T\int_\Omega p(\nabla u)\cdot\nabla(\theta - u) \;\geq\; -\int_0^T\int_\Omega \overline{q}\cdot\nabla(\theta - u) \qquad \forall\theta \in H_0^1(Q_T).$$

Replacing $\theta - u$ with its negative we obtain equality above and this proves 1.

2. Fix $T > 0$. Recall that

$$u^h(x,t) = u^{h,j}(x) + \left(\frac{t}{h} - j\right)(u^{h,j+1} - u^{h,j})(x)$$

for $hj \leq t < h(j+1)$. When $hj \leq t, s < h(j+1)$,

$$\|u^h(\cdot,t) - u^h(\cdot,s)\|_{L^2(\Omega)} \;=\; \frac{|t-s|}{h}\,\|u^{h,j+1} - u^{h,j}\|_{L^2(\Omega)}.$$

Also, by the uniform estimates in [KP1],

$$\sup_{t\geq 0}\|u^h(\cdot,t)\|_{L^2(\Omega)} = \sup_{j\geq 0}\|u^{h,j}\|_{L^2(\Omega)} \leq M,$$

which shows that $t \mapsto u^h(\cdot,t)$ is (uniformly) continuous and bounded on $\mathbb{R}^+$ into $L^2(\Omega)$.

Set $U^{h,h'} := u^h - u^{h'} \in H^1(Q_T)$; we have

$$\begin{aligned}\|U^{h,h'}\|_{L^2(\Omega)}(T) &= \int_0^T\int_\Omega 2U^{h,h'}U_t^{h,h'}\,dx\,dt\\ &\leq \|U^{h,h'}\|_{L^2(Q_T)}\|U_t^{h,h'}\|_{H^1(Q_T)},\end{aligned}$$

and since $(u^h)_{h>0}$ converges in $L^2(Q_T)$ and is bounded in $H^1(Q_T)$, we see

$$\lim_{h,h'\to 0}\ \sup_{t\geq 0}\|u^h - u^{h'}\|_{L^2(\Omega)}(t) \ = \ 0.$$

Therefore, $(u^h)_{h>0}$ is Cauchy in $C\left(\mathbb{R}^+;\ L^2(\Omega)\right)$. This shows 2.

3. For $0 \leq s \leq t$ apply (9) with $u\chi_{[s,t]}$ as the test function and obtain

$$\begin{aligned}\int_s^t\int_\Omega \overline{q}\cdot\nabla u &= -\int_s^t\int_\Omega \frac{\partial u}{\partial t}u\\ &= -\frac{1}{2}\left(\|u(\cdot,t)\|^2_{L^2(\Omega)} - \|u(\cdot,s)\|^2_{L^2(\Omega)}\right).\end{aligned}\tag{33}$$

Using (28), the convexity of ϕ^{**}, and the independence relation (30) as in the proof of Theorem 4.2, together with the assumption $p(0) = 0$, we conclude that the l.h.s. of (33) is nonnegative and (i) follows. Letting $s = 0$ and $t \to +\infty$ in the l.h.s. of (33), we then obtain (iii).

Notice that by the uniqueness of solution the pair $(u^\delta, \boldsymbol{\nu}^\delta) \equiv \left(u(\cdot,\delta+\cdot),\ \boldsymbol{\nu}_{(\cdot,\delta+\cdot)}\right)$ solves $\mathcal{P}$ with initial data $u(\cdot,\delta)$. For fixed $0 \leq s \leq t$ we apply (9) to each of the solution pairs $(u^\delta,\boldsymbol{\nu}^\delta)$ and $(u,\boldsymbol{\nu})$ using $(u^\delta - u)\chi_{[s,t]}$ as a test function and subtract the two equations. Arguing as in (i) yields (ii). □

4.2. Stability: Maximum and comparison principles. We investigate the stability of the Young measure solution. We show that a maximum principle and a comparison result are satisfied. We conclude the section with a localization property of the solution $(u,\boldsymbol{\nu})$, a corollary of the comparison principle.

THEOREM 4.4 (Maximum principle). *Let $(u,\boldsymbol{\nu})$ and $(w,\boldsymbol{\mu})$ solve with initial data u_0 and w_0, respectively. Then (x,t) a.e. in $\overline{Q_\infty}$,*

$$-\operatorname{ess\,sup}_{x\in\overline{\Omega}}(u_0 - w_0)^- \leq u(x,t) - w(x,t) \leq \operatorname{ess\,sup}_{x\in\overline{\Omega}}(u_0 - w_0)^+.\tag{34}$$

Proof. Set

$$K := \operatorname{ess\,sup}_{x\in\overline{\Omega}}(u_0 - w_0)^+.$$

We introduce auxiliary functions as in the proof for a maximum principle for the solution of the heat equation with H^1 data (cf. [Br]). Fix $G \in C^1(\mathbb{R})$ such that $G = 0$

on $(-\infty, 0]$ and is strictly increasing with $0 < G^{'} \leq M$ on $(0, +\infty)$. For $t \geq 0$ define the functions

$$H(t) := \int_0^t G(s)\, ds$$

and

$$\psi(t) := \int_\Omega H\left(u(x,t) - w(x,t) - K\right)\, dx.$$

Then $\psi \in C(\mathbb{R}^+) \cap H^1(\mathbb{R}^+)$, $\psi(0) = 0$ and $\psi \geq 0$ on $\mathbb{R}^+$. Note that $G(u - w - K) \in H_0^1(\Omega)$ so that it is an admissible test function in (9); for all $T \geq 0$,

$$\begin{aligned}\int_0^T \psi'(t)\, dt &= \int_0^T \int_\Omega G\left(u(x,t) - w(x,t) - K\right) \frac{\partial(u-w)}{\partial t}\, dx\, dt \\ &= -\int_0^T \int_\Omega (\overline{q}^\nu - \overline{q}^\mu) \cdot \nabla(u - w)\, G^{'}\left(u - w - K\right) dx\, dt \\ &\leq 0,\end{aligned}$$

because $(\overline{q}^\nu - \overline{q}^\mu) \cdot \nabla(u - w) \geq 0$ (as in the proof of the Uniqueness Theorem 4.2), and $G^{'} \geq 0$. Hence $\psi \equiv 0$ and $H(u - w - K) \;=\; 0$ (x,t) a.e. in $\overline{Q_\infty}$, or

$$\int_0^{u(x,t)-w(x,t)-K} G(s)\, ds \;=\; 0 \qquad (x,t) \text{ a.e. in } \overline{Q_\infty},$$

which by the choice of G implies

$$u(x,t) - w(x,t) - K \;\leq\; 0 \qquad (x,t) \text{ a.e. in } \overline{Q_\infty}.$$

Reversing the roles of u and w we obtain the lower bound in (34). □

LEMMA 4.5 (Comparison principle). *Assume $(u, \boldsymbol{\nu})$ and $(v, \boldsymbol{\mu})$ are the solutions to $\mathcal{P}$ with to initial data u_0 and v_0, respectively. Assume further that*

$$u_0 \;\geq\; v_0 \qquad a.e. \text{ } in\ \Omega.$$

Then

$$u \;\geq\; v \qquad (x,t) \text{ } a.e. \text{ } in\ Q_\infty.$$

Proof. Although this follows directly from the maximum principle (34) we give an independent proof which can also be modified to prove (34). Let $w = \max(u, v)$ in Q_∞. It suffices to show that

$$(v - u)^+ \;=\; 0 \qquad (x,t) \text{ a.e. in } Q_\infty.$$

We apply (9) for each solution noting that $w - u = (v - u)^+$ is admissible as a test function.

$$\int_0^T \int_\Omega \overline{q}^\nu \cdot \nabla(w - u) + u_t(w - u)\ dx\, dt \;=\; 0,$$

$$\int_0^T \int_\Omega \overline{q}^\mu \cdot \nabla(w - u) + v_t(w - u)\ dx\, dt \;=\; 0.$$

By subtraction we obtain

$$\begin{aligned}\int_0^T \int_\Omega (\overline{q}^\mu - \overline{q}^\nu) \cdot \nabla (v-u)^+ &= -\frac{1}{2} \int_0^T \int_\Omega (v_t - u_t)(v-u)^+ \, dx\, dt \\ &= \int_0^T \frac{d}{dt} \int_\Omega (v-u)^+ \, dx\, dt \\ &= -\frac{1}{2} \{ \|(v-u)^+\|^2_{L^2(\Omega)}(T) - \|(v_0 - u_0)^+\|^2_{L^2(\Omega)} \} \\ &= -\frac{1}{2} \|(v-u)^+\|^2_{L^2(\Omega)}(T).\end{aligned}$$

Since $(\overline{q}^\mu - \overline{q}^\nu) \cdot \nabla(v-u)^+ \geq 0$, we conclude that

$$\|(v-u)^+\|^2_{L^2(\Omega)}(T) \;=\; 0 \qquad \forall T \geq 0;$$

that is, $v \leq u$, (x,t) a.e. in Q_∞. □

COROLLARY 4.6 (localization). *Assume $\omega \subseteq \Omega$ is open with Lipschitz boundary and let $(u, \boldsymbol{\nu})$ be the solution to $\mathcal{P}$. Let v be the restriction of u to ω. Then v is a solution with respect to initial data v_0, the restriction of u_0 to ω.*

Proof. Suppose χ is the solution on ω (with v_0 initial data). Apply the comparison result to the differences $\chi - v$ and $v - \chi$. □

5. Asymptotic analysis and the equilibrium Young measure solution.

We investigate the asymptotic behavior of the solution as $t \longrightarrow +\infty$ and establish the following theorem.

THEOREM 5.1. *Let $(u, \boldsymbol{\nu})$ be the unique solution of $\mathcal{P}$; there exists a unique $z \in H^1_0(\Omega)$ and a Young measure $\boldsymbol{\nu}^\infty = (\nu^\infty_{x,t})_{(x,t) \in Q_\infty}$ such that*

$$(35) \qquad u(\cdot, t) \;\longrightarrow\; z \qquad \textit{weakly in } H^1_0(\Omega) \textit{ and strongly in } L^2(\Omega) \textit{ as } t \longrightarrow +\infty$$

(these limits exist without restriction to a subsequence in time).

$$(36) \qquad t \mapsto \|u(\cdot,t) - z\|_{L^2(\Omega)} \qquad \textit{is decreasing,}$$

$$(37) \qquad \nabla \cdot \langle \boldsymbol{\nu}^\infty, q \rangle \;=\; 0 \qquad \textit{in } H^{-1}(Q_\infty),$$

$$(38) \qquad \nabla z = \langle \boldsymbol{\nu}^\infty, \mathrm{id} \rangle \qquad \textit{a.e. in } \Omega \ (\textit{independent of time})$$

so $(z, \boldsymbol{\nu}^\infty)$ is an equilibrium Young measure solution of the steady-state version of $\mathcal{P}$.

$$(39) \qquad \langle \nu^\infty_{x,t}, q \cdot \mathrm{id} \rangle = 0 \qquad \textit{a.e. in } Q_T,$$

$$(40) \qquad \operatorname{supp} \boldsymbol{\nu}^\infty \;\subseteq\; \{\lambda : q(\lambda) \cdot \lambda = 0\} \cap \{\phi^{**} = \phi = 0\}.$$

DEFINITION. *With z, $\boldsymbol{\nu}^\infty$ as in the theorem, we call z the* asymptotic limit *of u and $\boldsymbol{\nu}^\infty$ the* asymptotic Young measure; *we call the pair $(z, \boldsymbol{\nu}^\infty)$ the* equilibrium (Young measure) solution *of $\mathcal{P}$.*

We define the set of weak limit points of $(u(\cdot,t))_{t \geq 0}$ in $H^1_0(\Omega)$

$$W_\omega(u_0) := \{ z \in H^1_0(\Omega) \,|\, \exists (t_n)_{n \geq 1} \nearrow +\infty \text{ with } u(\cdot, t_n) \overset{w-s}{\longrightarrow} z \}.$$

The notation

$$u(\cdot,t_n) \overset{w-s}{\longrightarrow} z \qquad \text{in } H^1 - L^2$$

indicates that the sequence converges weakly in H^1 and strongly in L^2, which we may always achieve by reducing to a subsequence using the Rellich theorem. Note that $W_\omega(u_0)$ is nonempty since $u \in L^\infty\left(\mathbb{R}^+; H_0^1(\Omega)\right)$. Theorem 5.1 establishes that $W_\omega(u_0)$ consists of exactly one function.

We begin by describing some properties of all functions in $W_\omega(u_0)$.

LEMMA 5.2. *Let $z \in W_\omega(u_0)$ and $t_n \to +\infty$ along which $u(\cdot,t_n) \overset{w-s}{\longrightarrow} z$. Then $\forall t \geq 0$*

$$u(\cdot,t_n+t) \overset{w-s}{\longrightarrow} z \qquad in\ H^1(\Omega) - L^2(\Omega), \tag{41}$$

$$u(\cdot,t_n+\cdot) \overset{w-s}{\longrightarrow} z \qquad in\ H^1_{loc}(Q_\infty) - L^2_{loc}(Q_\infty) \tag{42}$$

as $n \to +\infty$ (without restricting to subsequences).

Proof. Fix $t \geq 0$. Since $u \in L^\infty\left(\mathbb{R}^+; H_0^1(\Omega)\right)$, the sequence $(u(\cdot,t_n+t))_{n\geq 1}$ is bounded in $H^1(\Omega)$; hence for a subsequence $(n_j)_{j\geq 1}$ there exists $y(\cdot,t) \in H^1(\Omega)$ such that as $j \to +\infty$,

$$u(\cdot,t_{n_j}+t) \overset{w-s}{\longrightarrow} y(\cdot,t) \qquad \text{in } H^1(\Omega) - L^2(\Omega)$$

and, of course,

$$u(\cdot,t_{n_j}) \overset{w-s}{\longrightarrow} z \qquad \text{in } H^1(\Omega) - L^2(\Omega).$$

Note that $y(\cdot,t) \in W_\omega(u_0)$; we show that $y(\cdot,t) = z$. For all $\zeta \in \mathrm{L}^2(\Omega)$,

$$\begin{aligned}\int_\Omega (y(x,t) - z(x))\zeta(x)\,dx &= \lim_{j\to+\infty} \int_\Omega (u(x,t_{n_j}+t) - u(x,t_{n_j}))\zeta(x)dx \\ &= \lim_{j\to+\infty} \int_\Omega \int_{t_{n_j}}^{t_{n_j}+t} u_t(x,s)\zeta(x)\,ds\,dx \\ &\leq \|\zeta\|_{L^2(\Omega)} \limsup_{j\to+\infty} \|u_t\|_{L^2([t_{n_j},t_{n_j}+t]\times\Omega)}\sqrt{t} \\ &= 0,\end{aligned}$$

since $u_t \in L^2(Q_\infty)$. This shows $y(\cdot,t) = z$ for x a.e. in Ω; as a result the whole sequence converges to z and (41) is true.

Fix $T > 0$. The sequence $(u(\cdot,t_n+\cdot))_{t\geq 0}$ is bounded in $H^1(Q_T)$ and thus we can find $\chi \in H^1(Q_T)$ and a subsequence $(n_j)_{j\geq 1}$ along which

$$u(\cdot,t_{n_j}+\cdot) \overset{w-s}{\longrightarrow} \chi \qquad \text{in } H^1(Q_T) - L^2(Q_T).$$

Choose $\zeta(x)\eta(t) \in H^1(Q_T)$ with $\eta(t)$ defined for each t. By (41),

$$\int_\Omega u(x,t_{n_j}+t)\zeta(x)\,dx \overset{j\to+\infty}{\longrightarrow} \int_\Omega z(x)\zeta(x)\,dx$$

for each $t > 0$. Thus

$$\eta(t)\int_\Omega u(x,t_{n_j}+t)\zeta(x)\,dx \overset{j\to+\infty}{\longrightarrow} \eta(t)\int_\Omega z(x)\zeta(x)\,dx \tag{43}$$

pointwise in t and the Lebesgue dominated convergence theorem applies to (43) to give

$$\int_0^T\int_\Omega \eta(t)\zeta(x)u(x,t_{n_j}+t)\,dx\,dt \overset{n\to+\infty}{\longrightarrow} \int_0^T\int_\Omega \eta(t)\zeta(x)z(x)\,dx\,dt$$

$$\text{(by assumption)} \quad = \quad \int_0^T\int_\Omega \eta(t)\zeta(x)\chi(x,t)\,dx\,dt.$$

By the density of separable functions in L^2 this implies

$$\chi(\cdot,t)=z(\cdot) \quad \forall t>0 \quad x \text{ a.e. in } \Omega.$$

We conclude that no reduction to a subsequence is necessary and (42) obtains. □

Proof of Theorem 5.1. Fix $z\in W_w(u_0)$ and $t_n\to+\infty$ along which $u(\cdot,t_n)\overset{w-s}{\longrightarrow} z$. We define

$$u^n(\cdot,\cdot):=u(\cdot,t_n+\cdot),$$

$$\boldsymbol{\nu}^n \;=\; (\nu^n_{x,t})_{(x,t)\in Q_\infty} \;:=\; (\nu_{x,t_n+t})_{(x,t)\in Q_\infty}.$$

Then $(u^n,\boldsymbol{\nu}^n)$ is the solution with respect to initial data $u(\cdot,t_n)$ for $n\geq 0$. By Lemma 5.2 we know that as $n\to+\infty$,

$$u^n(\cdot,t)\overset{w-s}{\longrightarrow} z \qquad \text{in } H^1_0(\Omega) \;-\; L^2(\Omega)\;\forall t\in\mathbb{R}^+,$$

$$u^n\overset{w-s}{\longrightarrow} z \qquad \text{in } H^1_{loc}(Q_\infty) \;-\; L^2_{loc}(Q_\infty).$$

Since z is independent of t it follows that

$$\frac{\partial u^n}{\partial t} \overset{n\to+\infty}{\longrightarrow} 0 \qquad \text{in } L^2(Q_\infty).$$

In addition, note that $(\boldsymbol{\nu}^n)_{n\geq0}$ is bounded in $L^1(Q_\infty,\mathcal{E}_0')$. By Remark 2 to Lemma 2.4 there exists a Young measure $\boldsymbol{\nu}^\infty=(\nu^\infty_{x,t})_{(x,t)\in Q_\infty}$ (generated by spatial gradients as in the remark) satisfying

$$\nu^\infty \;\in\; L^\infty(Q_\infty;\,M(\mathbb{R}^N)) \;\cap\; L^2_{loc}(Q_\infty;\,\mathcal{F}_0') \;\cap\; L^1_{loc}(Q_\infty;\,\mathcal{E}_0').$$

For each n,

$$\int_0^\tau\int_\Omega \langle\boldsymbol{\nu}^n,q\rangle\cdot\nabla\zeta+\frac{\partial u^n}{\partial t}\zeta\,dx\,dt \;=\; 0 \qquad \forall\zeta\in H^1_0(Q_\tau)\,\forall\tau\in[0,+\infty],$$

and we may pass to the limit as $n\to\infty$. (Note that the nonlocal convergence in n is not guaranteed by Lemma 2.4 but by the boundedness of $(\frac{\partial u^n}{\partial t})_{n\geq0}$ in $L^2(Q_\infty)$); we obtain

$$\int_0^\tau\int_\Omega \langle\boldsymbol{\nu}^\infty,q\rangle\cdot\nabla\zeta\,dx\,dt \;=\; 0 \qquad \forall\zeta\in H^1_0(Q_\tau)\,\forall\tau\in[0,+\infty]$$

or, equivalently,

$$\nabla\cdot\langle\boldsymbol{\nu}^\infty,q\rangle \;=\; 0 \qquad \text{in } H^{-1}(Q_\infty).$$

Recall that $\langle \boldsymbol{\nu}^n, \mathrm{id}\rangle = \nabla u^n$ and converges to ∇z weakly in $L^2_{loc}(Q_\infty)$; in addition, by Lemma 2.4,

$$\langle \boldsymbol{\nu}^n, \mathrm{id}\rangle \rightharpoonup \langle \boldsymbol{\nu}^\infty, \mathrm{id}\rangle \qquad \text{in } L^2_{loc}(Q_\infty).$$

Thus,

$$\nabla z \;=\; \langle \boldsymbol{\nu}^\infty, \mathrm{id}\rangle \qquad x \text{ a.e. in } \Omega.$$

From (37) and (38) we infer that $(z, \boldsymbol{\nu}^\infty)$ solves the stationary problem associated to $\mathcal{P}$ and so the independence lemma (Lemma 4.1) implies

$$\langle \boldsymbol{\nu}^\infty, q\cdot \mathrm{id}\rangle = \langle \boldsymbol{\nu}^\infty, q\rangle \cdot \langle \boldsymbol{\nu}^\infty, \mathrm{id}\rangle \qquad (x,t) \text{ a.e. in } Q_\infty$$

and, as before,

$$\langle \boldsymbol{\nu}^\infty, q\cdot \mathrm{id}\rangle \ge 0 \qquad \text{a.e. in } \Omega. \tag{44}$$

On the other hand, for each $T \ge 0$, by Lemma 4.3 (3i),

$$\begin{aligned}\int_0^T \int_\Omega \langle \nu^n_{x,t}, q\rangle \cdot \nabla u^n(x,t)\, dx\, dt \;&=\; -\frac{1}{2}\left(\|u(\cdot, T+t_n)\|^2 - \|u(\cdot, t_n)\|^2\right)\\ &\overset{n\to+\infty}{\longrightarrow} 0\end{aligned}$$

and applying the independence lemma (Lemma 4.1) on the l.h.s. we obtain

$$\int_0^T \int_\Omega \langle \boldsymbol{\nu}^n, q\cdot \mathrm{id}\rangle\, dx\, dt \;\overset{n\to+\infty}{\longrightarrow}\; 0$$

or

$$\int_0^T \int_\Omega \langle \boldsymbol{\nu}^\infty, q\cdot \mathrm{id}\rangle\, dx\, dt \;=\; 0.$$

This proves (39). By (29) and (44) we conclude

$$\operatorname{supp} \boldsymbol{\nu}^\infty \subseteq \{\lambda : q(\lambda)\cdot\lambda = 0\} \cap \{\phi^{**} = \phi\}.$$

The proof of (40) will be completed by Corollary 6.2 in the next section.

It remains to show (35) and (36). Let $0 \le s \le t$ and apply (9) to the solutions of $\mathcal{P}$ $(u, \boldsymbol{\nu})$ and $(z, \boldsymbol{\nu}^\infty)$ (corresponding to initial data u_0 and z, respectively); we have (using the notation $\bar{q}^\infty = \langle \boldsymbol{\nu}^\infty, q\rangle$),

$$\begin{aligned}\int_s^t \int_\Omega (\bar{q} - \bar{q}^\infty)\cdot \nabla(u - z)\, dx\, dt &= -\int_s^t \int_\Omega \frac{\partial(u-z)}{\partial t}(u - z)\, dx\, dt\\ &= -\frac{1}{2}\left(\|u(\cdot,t) - z\|^2_{L^2(\Omega)} - \|u(\cdot,s) - z\|^2_{L^2(\Omega)}\right)\\ &\ge 0,\end{aligned}$$

so that

$$t \mapsto \|u(\cdot,t) - z\|_{L^2(\Omega)}$$

is decreasing and its limit as $t \to +\infty$ exists; it is zero because $z \in W_w(u_0)$ and by the Rellich theorem a subsequence exists along which $u(\cdot, t_j) \overset{j\to\infty}{\longrightarrow} z$ in $L^2(\Omega)$. This finishes the proof of the theorem. □

CONCLUSION. *Let $(u, \boldsymbol{\nu})$ be the Young measure solution to $\mathcal{P}$ with initial data u_0. Then $W_w(u_0) = \{z\}$, i.e., the $L^2(\Omega)$ asymptotic limit of u is unique and the equilibrium solution $(z, \boldsymbol{\nu}^\infty)$ solves the steady-state problem*

$$\nabla \cdot \langle \boldsymbol{\nu}^\infty, q\rangle = 0 \quad \text{in } H^{-1}(Q_\infty).$$

6. Energy. Define the *energy function*

$$E(t) := \int_\Omega \phi^{**}(\nabla u)(x,t)\,dx \qquad \text{for } t \geq 0. \tag{45}$$

The results in this section serve to justify the term *energy* for the function in (45) and show that it vanishes at infinity. Throughout this section $(u, \boldsymbol{\nu})$ is the solution of $\mathcal{P}$ and $(z, \boldsymbol{\nu}^\infty)$ the equilibrium solution.

THEOREM 6.1. *Let E be given by* (45). *Then $E \in L^1(\mathbb{R}^+)$ and E is a decreasing function of t. Moreover,*

$$\int_\Omega \phi^{**}(\nabla u)(x,t)\,dx \searrow 0 \qquad \text{as } t \nearrow +\infty. \tag{46}$$

Proof. For $0 \leq s \leq t$,

$$\begin{aligned} \int_s^t E(\tau)\,d\tau &= \int_s^t \int_\Omega \phi^{**}(\nabla u)(x,\tau)\,dx\,d\tau \\ \text{(since } \phi^{**} \text{ is convex and } \phi^{**}(0) = 0) \quad &\leq \int_s^t \int_\Omega p(\nabla u)\cdot \nabla u\,dx\,d\tau \\ &= -\int_s^t \int_\Omega u_t u\,dx\,d\tau \\ &= -\frac{1}{2}\left(\|u\|^2_{L^2(\Omega)}(t) - \|u\|^2_{L^2(\Omega)}(s)\right) \\ &\longrightarrow 0^+ \quad \text{as } s,t \to +\infty, \end{aligned}$$

by Lemma 4.3 (3i) and (3iii). Therefore,

$$\int_0^{+\infty} \int_\Omega \phi^{**}(\nabla u)(x,t)\,dx\,dt < +\infty$$

and this shows that the energy is integrable.

Next we give the proof due to P. Pedregal that the energy is decreasing. For $T \geq 0$ fixed we have for all $t > 0$,

$$\begin{aligned} \int_T^{T+t} (E(s) - E(T))\,ds &= \int_T^{T+t} \int_\Omega (\phi^{**}(\nabla u(x,s)) - \phi^{**}(\nabla u(x,T)))\,dx\,ds \\ &\leq \int_T^{T+t} \int_\Omega p(\nabla u(x,s))\cdot(\nabla u(x,s) - \nabla u(x,T))\,dx\,ds \\ &= -\int_T^{T+t} \int_\Omega \frac{\partial(u(x,s) - u(x,T))}{\partial s}(u(x,s) - u(x,T))\,dx\,ds \end{aligned}$$

$$= -\frac{1}{2}\|u(\cdot, T+t) - u(\cdot, T)\|^2_{L^2(\Omega)}$$
$$\leq 0.$$

By the continuity of E this implies

$$E(T+t) \ \leq \ E(T)$$

for all $t > 0$ sufficiently small. Since T is arbitrary, this shows that E is in $L^1(\mathbb{R}^+)$ and decreasing, so (46) follows. □

COROLLARY 6.2. *The energy converges as* $t \to +\infty$ *and attains its minimum, i.e.,*

$$\lim_{t\to+\infty} \int_\Omega \phi^{**}(\nabla u)(x,t)\,dx \ = \ \int_\Omega \phi^{**}(\nabla z)(x)\,dx \ = \ 0. \tag{47}$$

Consequently, the asymptotic Young measure satisfies

$$\operatorname{supp} \boldsymbol{\nu}^\infty \subseteq \{\phi^{**} = \phi = 0\} \tag{48}$$

(*which completes the proof of* (40)).

Proof. Since ϕ^{**} is convex, the functional

$$u \mapsto \int_\Omega \phi^{**}(\nabla u)\,dx$$

is sequentially lower semicontinuous with respect to weak convergence in $H^1_0(\Omega)$. By Theorem 5.1 we have $u(\cdot,t) \rightharpoonup z$ in $H^1(\Omega)$ as $t \to +\infty$ and

$$\begin{aligned} 0 \ \leq \ \int_\Omega \phi^{**}(\nabla z)(x)\,dx &\leq \liminf_{t\to+\infty} \int_\Omega \phi^{**}(\nabla u)(x,t)\,dx \\ &= \lim_{t\to+\infty} \int_\Omega \phi^{**}(\nabla u)(x,t)\,dx \\ &= 0, \end{aligned}$$

because $E \in L^1(\mathbb{R}^+)$ and $\phi^{**} \geq 0$. From Jensen's inequality and (47) we obtain (48). □

The energy is also minimized asymptotically locally in the sense of the following lemma.

LEMMA 6.3. *For all* $A \subseteq \Omega$, *measurable*

$$\lim_{t\to+\infty} \int_A \phi^{**}(\nabla u)(x,t)\,dx \ = \ \int_A \phi^{**}(\nabla z)(x)\,dx \tag{49}$$

(but this limit is not necessarily monotone decreasing).

Proof. By (47) and by Theorem 2.2(ii) we conclude that $((\phi^{**}(\nabla u)(\cdot,t))_{t\geq 0}$ is weakly sequentially precompact in $L^1(\Omega)$ and (49) follows. □

Acknowledgments. The results reported here have also been submitted to the Graduate School of the University of Minnesota in partial fulfillment of the requirements for the degree of Doctor of Philosophy. I wish to express deep gratitude to my thesis supervisor, David Kinderlehrer, whose professional guidance and collaboration played a crucial role in the development of this work. In addition, I want to truly thank Irene Fonseca, Wilfrid Gangbo, William Hrusa, Norman Meyers, Pablo Pedregal, Luc Tartar, Thanos Tzavaras, Noel Walkington, to mention a few, whose assistance I have sought, received, and used repeatedly.

ON THE CAHN–HILLIARD EQUATION WITH DEGENERATE MOBILITY[*]

CHARLES M. ELLIOTT[†] AND HARALD GARCKE[‡]

Abstract. An existence result for the Cahn–Hilliard equation with a concentration dependent diffusional mobility is presented. In particular, the mobility is allowed to vanish when the scaled concentration takes the values ±1, and it is shown that the solution is bounded by 1 in magnitude. Finally, applications of our method to other degenerate fourth-order parabolic equations are discussed.

Key words. Cahn–Hilliard equations, degenerate parabolic equations, nonlinear diffusion, phase transitions.

AMS subject classifications. 35K55, 35K65, 82C26

1. Introduction.

The Cahn–Hilliard equation

$$\begin{aligned} u_t &= -\nabla \cdot \mathbf{J}, \\ \mathbf{J} &= -B(u)\nabla w, \\ w &= -\gamma\Delta u + \Psi'(u), \qquad \gamma \in \mathbb{R}^+, \end{aligned} \tag{1.1}$$

was introduced to study phase separation in binary alloys (see Cahn and Hilliard [8, 9]). Although the Cahn–Hilliard equation has been intensively studied, little mathematical analysis has been done for a diffusional mobility B which depends on u (where u is the difference of the mass density of the two components of the alloy). A concentration-dependent mobility appeared in the original derivation of the Cahn–Hilliard equation (see [9]), and a thermodynamically reasonable choice is $B(u) = 1 - u^2$ (see [10, 11, 18]). The mathematical difficulty in studying the Cahn–Hilliard equation with a mobility like this lies in the degeneracy of B. On the other hand, there is hope that solutions which initially take values in the interval $[-1,1]$ will do so for all positive time (which is not true for fourth-order parabolic equations without degeneracy). We remark that only values in the interval $[-1,1]$ are physically meaningful.

The function Ψ represents the homogeneous free energy in the energy functional

$$\mathcal{E}(u) = \int_\Omega \Big(\frac{\gamma}{2} \mid \nabla u \mid^2 + \Psi(u)\Big)\, dx,$$

where $\Omega \subset \mathbb{R}^n$ ($n \in \mathbb{N}$) is a bounded domain with sufficiently smooth boundary. Possible choices for Ψ are

$$\begin{aligned} &\Psi(u) = (1-u^2)^2 \quad \text{and} \\ &\Psi(u) = \frac{\theta}{2}\left((1+u)\ln(1+u) + (1-u)\ln(1-u)\right) + F_0(u) \end{aligned} \tag{1.2}$$

with a smooth function F_0. In the case $F_0(u) = 1 - u^2$, one gets in the limit as $\theta \searrow 0$ the double obstacle potential (see the papers of Blowey and Elliott [5, 6] and Elliott and Luckhaus [14])

$$\Psi(u) = \begin{cases} 1 - u^2 & \text{if } |u| \leq 1, \\ \infty & \text{otherwise.} \end{cases}$$

In order to formulate an existence result for (1.1) in a general situation we make the following assumptions.

Let

$$\Psi(u) := \Psi_1(u) + \Psi_2(u)$$

with functions Ψ_1 and Ψ_2 such that

$$\|\Psi_2\|_{C^2[-1,1]} \leq C$$

and

$$\Psi_1 : (-1,1) \to \mathbb{R}$$

is convex and of the form

$$\Psi_1''(u) = (1 - u^2)^{-m} F(u) \quad (m \geq 1)$$

with a C^1-function $F : [-1,1] \to \mathbb{R}_0^+$. This means that we allow Ψ to be singular in the convex part as $|u| \to 1$. In particular, the logarithmic form (1.2) is a possible choice. Furthermore, we assume that the mobility is of the form

$$B(u) = (1 - u^2)^m \bar{B}(u)$$

with a C^1-function

$$\bar{B} : [-1,1] \to \mathbb{R}$$

which satisfies

$$b_0 \leq \bar{B}(u) \leq B_0 \qquad (B_0, b_0 > 0)$$

for $u \in [-1,1]$. We extend the defintion of B to all of $\mathbb{R}$ by $B(u) = 0$ for $|u| > 1$. Let

$$\Phi : (-1,1) \to \mathbb{R}_0^+$$

be defined by

$$\Phi''(u) = \frac{1}{B(u)}, \quad \Phi'(0) = 0, \quad \text{and } \Phi(0) = 0.$$

The following theorem states the existence of a weak solution to the Cahn–Hilliard equation with a nonconstant mobility as above on an arbitrary time interval $[0,T]$ ($T \in \mathbb{R}^+$) which fulfills the boundary conditions

$$\mathbf{n} \cdot \mathbf{J} = 0 \quad \text{and} \quad \mathbf{n} \cdot \nabla u = 0 \quad \text{on} \quad \partial\Omega \times (0,T),$$

where $\mathbf{n}$ is the outer normal to $\partial\Omega$.

THEOREM 1. *Let either $\partial\Omega \in C^{1,1}$ or Ω be convex and suppose that $u_0 \in H^1(\Omega)$ with $|u_0| \leq 1$ a.e. and*

$$\int_\Omega (\Psi(u_0) + \Phi(u_0)) \leq C, \qquad C \in \mathbb{R}^+.$$

Then there exists a pair $(u, \mathbf{J})$ such that

(a) $u \in L^2(0,T; H^2(\Omega)) \cap L^\infty(0,T; H^1(\Omega)) \cap C([0,T]; L^2(\Omega))$,

(b) $u_t \in L^2(0,T; (H^1(\Omega))')$,

(c) $u(0) = u_0$ *and* $\nabla u \cdot \mathbf{n} = 0$ *on* $\partial\Omega \times (0,T)$,

(d) $|u| \leq 1$ *a.e in* $\Omega_T := \Omega \times (0,T)$,

(e) $\mathbf{J} \in L^2(\Omega_T, \mathbb{R}^n)$

which satisfies $u_t = -\nabla \cdot \mathbf{J}$ in $L^2(0,T; (H^1(\Omega))')$, i.e.,

$$\int_0^T \langle \zeta(t), u_t(t) \rangle_{H^1,(H^1)'} = \int_{\Omega_T} \mathbf{J} \cdot \nabla\zeta$$

for all $\zeta \in L^2(0,T; H^1(\Omega))$ and

$$\mathbf{J} = -B(u)\nabla \cdot (-\gamma\Delta u + \Psi'(u))$$

in the following weak sense:

$$\int_{\Omega_T} \mathbf{J} \cdot \boldsymbol{\eta} = -\int_{\Omega_T} [\gamma\Delta u \nabla \cdot (B(u)\boldsymbol{\eta}) + (B\Psi'')(u)\nabla u \cdot \boldsymbol{\eta}]$$

for all $\boldsymbol{\eta} \in L^2(0,T; H^1(\Omega, \mathbb{R}^n)) \cap L^\infty(\Omega_T, \mathbb{R}^n)$ which fulfill $\boldsymbol{\eta} \cdot \mathbf{n} = 0$ on $\partial\Omega \times (0,T)$.

We point out that the nonlinearity $(B\Psi'')(u) = \bar{B}(u)F(u) + B(u)\Psi_2''(u)$ is bounded and therefore the last integral in the formulation of the theorem is well defined.

An existence result for the Cahn–Hilliard equation with a degenerate mobility in a one-dimensional situation has been established by Yin Jingxue [23]. The existence result we present is for arbitrary space dimensions and uses a weak formulation which is different from the formulation of Yin Jingxue. Furthermore, we allow the bulk energy Ψ to have singularities when B degenerates. We also refer to the work of Bernis and Friedman [3] for results on fourth-order degenerate parabolic equations in one space dimension.

In §4, we prove a similar existence result for a viscous Cahn-Hilliard-type equation of the form

$$\begin{aligned} u_t &= -\nabla \cdot \mathbf{J}, \\ \mathbf{J} &= -B(u)\nabla w, \\ w &= -\gamma\Delta u + \Psi'(u) + \alpha u_t, \qquad \alpha \in \mathbb{R}^+, \end{aligned}$$

where we assume the mobility B and the homogeneous free energy Ψ to be as above.

We want to point out that our result includes the case $B(u) = 1 - u^2$ and

$$\Psi(u) = \frac{\theta}{2}\left((1+u)\ln(1+u) + (1-u)\ln(1-u)\right) + \frac{1}{2}(1-u^2). \tag{1.3}$$

In a recent work by Cahn, Elliott, and Novick-Cohen [7], a formal asymptotic result for the deep quench limit ($\theta \searrow 0$) of the Cahn–Hilliard equation with $B(u) = 1 - u^2$

and Ψ as in (1.3) has been established (they used the scaling $\gamma = \varepsilon^2, t \to \varepsilon^2 t$). They show that one gets in the limit $\varepsilon \searrow 0$ the following geometric motion for hypersurfaces:

$$V = -D\Delta_S \kappa, \qquad D \in \mathbb{R}^+, \tag{1.4}$$

where V is the normal velocity, κ denotes the mean curvature, and Δ_S is the surface Laplacian. Material scientists refer to this evolution law as motion by surface diffusion (see Cahn and Taylor [10], Davi and Gurtin [12], and Mullins [21]). The two components of the alloy are separated by a sharp free boundary which is evolving according to the law (1.4).

Cahn and Taylor [10, 11] also propose the motions

$$V = \Delta_S \left(\frac{1}{M}\Delta_S - \frac{1}{D} \right)^{-1} \kappa \qquad (M, D \in \mathbb{R}^+), \tag{1.5}$$

which formally give in the limit as $M \to \infty$ ($D \to \infty$, respectively) the laws

$$V = -D\Delta_S \kappa \qquad \text{if} \quad M \to \infty \tag{1.6}$$

and

$$V = M(\kappa - \kappa_\alpha) \qquad \text{if} \quad D \to \infty, \tag{1.7}$$

where κ_α is the average mean curvature on the surface.

Formal asymptotic results suggest that the intermediate motion (1.5) is the asymptotic limit of the viscous Cahn–Hilliard equation with a mobility $B(u) = 1 - u^2$ (as before, with a logarithmic free energy and in the deep quench limit with a scaling $\gamma = \varepsilon^2$ and $t \to \varepsilon^2 t$).

For the geometric motions (1.5)–(1.7), just a few results exist so far. We can prove local existence for the two-dimensional case, i.e., for the evolution of curves in the plane and results for the global behaviour if the initial data are close to a circle (see [13]).

This paper is organized as follows: In §2, we prove the existence of a solution to the Cahn–Hilliard equation with a mobility which is bounded away from zero. This result is used in §3 to establish the existence of approximate solutions to the degenerate problem. We derive energy estimates for the approximate solutions which enable us to pass to the limit in the approximate equation to get the existence of a weak solution as stated in Theorem 1. Section 4 is devoted to other applications of our method. In particular, the viscous Cahn–Hilliard equation and the deep quench limit are studied. Furthermore, our method can be used to establish an existence result for degenerate parabolic equations of fourth order in arbitrary space dimensions. Finally, we discuss some open questions and give suggestions for further research.

2. Existence theorems for positive mobilities. In this section, we study the Cahn–Hilliard equation with a mobility which is bounded away from zero. We prove existence of solutions under various conditions on the bulk energy ψ. In §3, we will use these solutions as approximate solutions for the degenerate case.

We consider the Cahn–Hilliard equation in the form

$$u_t = \nabla \cdot b(u)\nabla w, \tag{2.1}$$

$$w = -\gamma\Delta u + \psi'(u) \tag{2.2}$$

with Neumann and no-flux boundary conditions

$$\nabla u \cdot \mathbf{n} = 0 \quad \text{and} \quad \nabla w \cdot \mathbf{n} = 0 \quad \text{on} \quad \partial\Omega \times (0,T).$$

Here $\Omega \subset \mathbb{R}^n$ ($n \in \mathbb{N}$) is a bounded domain with Lipschitz boundary. We assume b and ψ to be such that

(i) $b \in C(\mathbb{R}, \mathbb{R}^+)$ and there exist $b_1, B_1 > 0$ such that $b_1 \leq |b(u)| \leq B_1$ for all $u \in \mathbb{R}$,

(ii) $\psi \in C^1(\mathbb{R}, \mathbb{R})$ and there exist constants $C_1, C_2, C_3 > 0$ such that

$$|\psi'(u)| \leq C_1 |u|^q + C_2 \quad \text{and} \quad \psi(u) \geq -C_3,$$

where $q = \frac{n}{n-2}$ if $n > 3$ and $q \in \mathbb{R}^+$ arbitrary if $n = 1, 2$.

Under these assumptions we can state the following theorem.

THEOREM 2. *Suppose $u_0 \in H^1(\Omega)$. Then there exists a pair of functions (u, w) such that*

(1) $u \in L^\infty(0,T; H^1(\Omega)) \cap C([0,T]; L^2(\Omega))$,
(2) $u_t \in L^2(0,T; (H^1(\Omega))')$,
(3) $u(0) = u_0$,
(4) $w \in L^2(0,T; H^1(\Omega))$

which satisfies equations (2.1) *and* (2.2) *in the following weak sense:*

$$\int_0^T \langle \zeta(t), u_t(t) \rangle_{H^1,(H^1)'} = -\int_{\Omega_T} b(u) \nabla w \nabla \zeta \tag{2.3}$$

for all $\zeta \in L^2(0,T; H^1(\Omega))$ and

$$\int_\Omega w\phi = \gamma \int_\Omega \nabla u \nabla \phi + \int_\Omega \psi'(u)\phi \tag{2.4}$$

for all $\phi \in H^1(\Omega)$ and almost all $t \in [0,T]$.

Proof. To prove the theorem, we apply a Galerkin approximation. Let $\{\phi_i\}_{i \in \mathbb{N}}$ be the eigenfunctions of the Laplace operator with Neumann boundary conditions, i.e.,

$$-\Delta \phi_i = \lambda_i \phi_i \quad \text{in } \Omega \quad \text{and} \quad \nabla \phi_i \cdot \mathbf{n} = 0 \quad \text{on } \partial\Omega.$$

The eigenfunctions ϕ_i are orthogonal in the $H^1(\Omega)$ and the $L^2(\Omega)$ scalar product. We normalize the ϕ_i such that $(\phi_i, \phi_j)_{L^2(\Omega)} = \delta_{ij}$. Furthermore, we assume without loss of generality that $\lambda_1 = 0$.

Now we consider the following Galerkin ansatz for (2.1) and (2.2):

$$u^N(t,x) = \sum_{i=1}^N c_i^N(t)\phi_i(x)\,, \; w^N(t,x) = \sum_{i=1}^N d_i^N(t)\phi_i(x), \tag{2.5}$$

$$\int_\Omega \partial_t u^N \phi_j = -\int_\Omega b(u^N) \nabla w^N \nabla \phi_j \quad \text{for} \quad j = 1, \ldots, N, \tag{2.6}$$

$$\int_\Omega w^N \phi_j = \gamma \int_\Omega \nabla u^N \nabla \phi_j + \int_\Omega \psi'(u^N)\phi_j \quad \text{for} \quad j = 1, \ldots, N, \quad \text{and} \tag{2.7}$$

$$u^N(0) = \sum_{i=1}^N (u_0, \phi_i)_{L^2(\Omega)} \phi_i. \tag{2.8}$$

This gives an initial value problem for a system of ordinary differential equations for $(c_1, \ldots, c_N)$:

$$\partial_t c_j^N = -\sum_{k=1}^N d_k^N \int_\Omega b\left(\sum_{i=1}^N c_i^N \phi_i\right) \nabla\phi_k \nabla\phi_j, \tag{2.9}$$

$$d_j^N = \gamma\lambda_j c_j^N + \int_\Omega \psi'\left(\sum_{k=1}^N c_k^N \phi_k\right) \phi_j, \quad \text{and} \tag{2.10}$$

$$c_j^N(0) = (u_0, \phi_j)_{L^2(\Omega)}, \tag{2.11}$$

which has to hold for $j = 1, \ldots, N$. Since the right-hand side in (2.9) depends continuously on $c_1, \ldots, c_N$, the initial value problem has a local solution.

In order to derive a priori estimates, we differentiate the energy $\mathcal{E}$ and get

$$\begin{aligned} \frac{d}{dt}\mathcal{E}(t) &= \frac{d}{dt}\int_\Omega \left(\frac{\gamma}{2}|\nabla u^N|^2 + \psi(u^N)\right), \\ &= \int_\Omega \left(\gamma \nabla u^N \nabla u_t^N + \psi'(u^N) u_t^N\right), \\ &= \int_\Omega w^N u_t^N = -\int_\Omega b(u^N)|\nabla w^N|^2. \end{aligned}$$

This implies

$$\begin{aligned} &\int_\Omega \frac{\gamma}{2}|\nabla u^N(t)|^2 + \int_\Omega \psi(u^N(t)) + \int_{\Omega_T} b(u^N)|\nabla w^N|^2 \\ &= \int_\Omega \frac{\gamma}{2}|\nabla u^N(0)|^2 + \int_\Omega \psi(u^N(0)) \leq C. \end{aligned} \tag{2.12}$$

The last inequality follows from (2.8), assumption (ii), and the fact that $u_0 \in H^1(\Omega)$. Since $\frac{d}{dt}\int_\Omega u^N = 0$ (which follows from (2.6) with $j = 1$), Poincaré's inequality yields

$$\operatorname{ess\,sup}_{0<t<T} \|u(t)\|_{H^1(\Omega)} \leq C.$$

This estimate implies that the $(c_1^N, \ldots, c_N^N)$ are bounded and therefore a global solution to the initial value problem (2.9)–(2.11) exists.

If we denote by Π_N the projection of $L^2(\Omega)$ onto $span\{\phi_1, \ldots, \phi_N\}$, we get

$$\begin{aligned} \left|\int_{\Omega_T} \partial_t u^N \phi\right| &= \left|\int_{\Omega_T} \partial_t u^N \Pi_N \phi\right| \\ &= \left|\int_{\Omega_T} b(u^N)\nabla w^N \nabla \Pi_N \phi\right| \\ &\leq \left(\int_{\Omega_T} |b(u^N)\nabla w^N|^2\right)^{\frac{1}{2}} \left(\int_{\Omega_T} |\nabla \Pi_N \phi|^2\right)^{\frac{1}{2}} \\ &\leq B_1 \left(\int_{\Omega_T} b(u^N)|\nabla w^N|^2\right)^{\frac{1}{2}} \|\nabla\phi\|_{L^2(\Omega_T)} \\ &\leq C\|\nabla\phi\|_{L^2(\Omega_T)} \end{aligned}$$

for all $\phi \in L^2(0,T;H^1(\Omega))$. This implies

$$\|\partial_t u^N\|_{L^2(0,T;(H^1(\Omega))')} \leq C.$$

Using compactness results (see Lions [19] and Remark 1 below), we obtain for a subsequence (which we still denote by u^N)

$$\begin{array}{rclllll} u^N & \longrightarrow & u & \text{weak} - * & \text{in} & L^\infty(0,T;H^1(\Omega)), \\ u^N & \longrightarrow & u & \text{strongly} & \text{in} & C([0,T];L^2(\Omega)), \\ \partial_t u^N & \longrightarrow & \partial_t u & \text{weakly} & \text{in} & L^2(0,T;(H^1(\Omega))'), & \text{and} \\ u^N & \longrightarrow & u & \text{strongly} & \text{in} & L^2(0,T;L^p(\Omega)) \text{ and a.e. in } \Omega_T, \end{array}$$

where $p < \frac{2n}{n-2}$. It remains to show the convegence of w^N. Choosing $j = 1$ in (2.7) gives $\int_\Omega w^N(t) = \int_\Omega \psi'(u^N(t))$, which together with (2.12), assumption (ii), and Poincaré's inequality gives

$$\|w^N\|_{L^2(0,T;H^1(\Omega))} \leq C.$$

This implies (again for a subsequence)

$$w^N \longrightarrow w \quad \text{weakly} \quad \text{in} \quad L^2(0,T;H^1(\Omega)).$$

With the convergence properties proved so far and using the assumptions on b and ψ, we can pass to the limit in (2.6) and (2.7) in a standard fashion (see Lions [19] for details) to get that (2.3) and (2.4) hold for (u,w).

The strong convergence of u^N in $C([0,T];L^2(\Omega))$ and the fact that $u^N(0) \to u_0$ in $L^2(\Omega)$ gives $u(0) = u_0$. This proves the theorem. □

Remark 1. (a) Let X, Y and Z be Banach spaces with a compact embedding $X \hookrightarrow Y$ and a continuous embedding $Y \hookrightarrow Z$. Then the embeddings

$$\{u \in L^2(0,T;X) \mid \partial_t u \in L^2(0,T;Z)\} \hookrightarrow L^2(0,T;Y) \tag{2.13}$$

and

$$\{u \in L^\infty(0,T;X) \mid \partial_t u \in L^2(0,T;Z)\} \hookrightarrow C([0,T];Y) \tag{2.14}$$

are compact (for a proof, see Simon [22]).

(b) In the proof of Theorem 2, we applied the above result for the case $X = H^1(\Omega), Y = L^2(\Omega).(Y = L^p(\Omega)$ with $p < \frac{2n}{n-2}$, respectively), and $Z = (H^1(\Omega))'$.

(c) The solution in Theorem 2 lies in $C([0,T];H^\beta(\Omega))$ (where $\beta < 1$). We get this by choosing $X = H^1(\Omega), Y = H^\beta(\Omega)$, and $Z = (H^1(\Omega))'$ in (a). □

The existence result in Theorem 2 requires a bulk energy which is bounded from below. It is possible to generalize this result if we assume further assumptions on $\partial\Omega$ and the growth of ψ.

We assume now either $\partial\Omega \in C^{1,1}$ or Ω is convex. Furthermore, we replace assumption (ii) by the following:

(iii) $\psi \in C^2(\mathbb{R},\mathbb{R})$ and there exists a constant $D > 0$ such that $|\psi''(u)| \leq D$ for all $u \in \mathbb{R}$.

THEOREM 3. *Assume* (i), (iii), *and* $u_0 \in H^1(\Omega)$. *Then there exists a function* u *such that*

(1) $u \in L^2(0,T;H^1(\Omega)) \cap C([0,T];L^2(\Omega))$,
(2) $u_t \in L^2(0,T;(H^1(\Omega))')$,
(3) $u(0) = u_0$ *and* $\nabla u \cdot \mathbf{n} = 0$ *on* $\partial\Omega \times (0,T)$,
(4) $\nabla\Delta u \in L^2(\Omega_T)$

which satisfies the Cahn–Hilliard equation in the following sense:

$$\int_0^T \langle \zeta(t), u_t(t) \rangle_{H^1,(H^1)'} = \int_{\Omega_T} b(u)\nabla(-\gamma\Delta u + \psi'(u))\nabla\zeta$$

for all $\zeta \in L^2(0,T;H^1(\Omega))$.

Proof. As in the proof of Theorem 2, we apply a Galerkin approximation, but now we make an ansatz just in u:

$$u^N(t,x) = \sum_{i=1}^{N} c_i^N(t)\phi_i(x),$$

$$(2.15)\int_\Omega \partial_t u^N \phi_j = -\int_\Omega b(u_N)(-\gamma\nabla\Delta u^N + \psi''(u^N)\nabla u^N)\nabla\phi_j \text{ for } j=1,\dots,N,$$

$$u^N(0) = \sum_{i=1}^{N}(u_0,\phi_i)_{L^2(\Omega)}\phi_i.$$

Instead of differentiating the energy, we use Δu^N as a test function to get

$$\frac{1}{2}\partial_t\int_\Omega |\nabla u^N|^2 + \int_\Omega b(u^N)\gamma|\nabla\Delta u^N|^2 = \int_\Omega b(u^N)\psi''(u^N)\nabla u^N\nabla\Delta u^N.$$

Using Young's inequality and assumptions (i) and (iii), we derive

$$\partial_t\int_\Omega |\nabla u^N|^2 + b_1\gamma\int_\Omega |\nabla\Delta u^N|^2 \le C\int_\Omega |\nabla u^N|^2.$$

A Gronwall argument now gives

$$\int_\Omega |\nabla u^N(t)|^2 + \int_{\Omega_T} |\nabla\Delta u^N|^2 \le C(T).$$

With this estimate, the rest of the proof is straightforward using compactness results (see Lions [19] and Remark 1) and passing to the limit in equation (2.15). □

3. Existence proof for the degenerate case. In this section, we prove Theorem 1. Our approach is to approximate the degenerate problem by nondegenerate equations, i.e., by equations with a positive mobility. Furthermore, we modify the bulk energy Ψ so that it is defined on all $\mathbb{R}$.

We introduce a positive mobility B_ε as

$$B_\varepsilon(u) := \begin{cases} B(-1+\varepsilon) & \text{for} \quad u \le -1+\varepsilon, \\ B(u) & \text{for} \quad |u| < 1-\varepsilon, \\ B(1-\varepsilon) & \text{for} \quad u \ge 1-\varepsilon \end{cases}$$

and we define Φ_ε such that $\Phi_\varepsilon''(u) = \frac{1}{B_\varepsilon(u)}$ and $\Phi_\varepsilon'(0) = \Phi_\varepsilon(0) = 0$. We point out that $\Phi_\varepsilon(u) = \Phi(u)$ when $|u| \le 1-\varepsilon$.

The modified bulk energy $\Psi_\varepsilon : \mathbb{R} \longrightarrow \mathbb{R}$ is taken to be $\Psi_\varepsilon := \Psi_\varepsilon^1 + \Psi^2$, where

$$\left(\Psi_\varepsilon^1\right)''(u) := \begin{cases} \left(\Psi^1\right)''(-1+\varepsilon) & \text{for} \quad u \le -1+\varepsilon, \\ \left(\Psi^1\right)''(u) & \text{for} \quad |u| < 1-\varepsilon, \\ \left(\Psi^1\right)''(1-\varepsilon) & \text{for} \quad u \ge 1-\varepsilon \end{cases}$$

and $\Psi_\varepsilon^1(0) = \Psi^1(0)$, $\left(\Psi_\varepsilon^1\right)'(0) = \left(\Psi^1\right)'(0)$. As for Φ, we get $\Psi_\varepsilon(u) = \Psi(u)$ if $|u| \le 1-\varepsilon$. Furthermore, Ψ^2 is extended to be a function on all $\mathbb{R}$ such that $\|\Psi^2\|_{C^2(\mathbb{R})} \le C$.

With this choice of B_ε and Ψ_ε, Theorem 2 give the existence of a weak solution to the equation

$$\begin{aligned} u_t &= \nabla \cdot B_\varepsilon(u)\nabla w && \text{in } \Omega_T, \\ w &= -\gamma\Delta u + (\Psi_\varepsilon)'(u) && \text{in } \Omega_T, \\ \nabla u \cdot \mathbf{n} &= 0 \quad \text{and} \quad \nabla w \cdot \mathbf{n} = 0 && \text{on } \partial\Omega \times (0,T). \end{aligned}$$

We denote the solution by $(u_\varepsilon, w_\varepsilon)$. From now on, we assume either $\partial\Omega \in C^{1,1}$ or Ω is convex. With this assumption, we can state the following lemma.

LEMMA 1. *The solution u_ε belongs to the space $L^2(0,T;H^2(\Omega))$ and $\nabla\Delta u_\varepsilon \in L^2(\Omega_T)$.*

Proof. Since

$$\int_\Omega w_\varepsilon \phi = \int_\Omega \gamma \nabla u_\varepsilon \nabla \phi + \int_\Omega \Psi'_\varepsilon(u_\varepsilon)\phi$$

for all $\phi \in H^1(\Omega)$ and almost all $t \in (0,T)$, the first assertion follows from elliptic regularity theory. Because $\nabla w_\varepsilon \in L^2(\Omega_T)$ and $\nabla \Psi'_\varepsilon(u_\varepsilon) = \Psi''_\varepsilon(u_\varepsilon)\nabla u_\varepsilon \in L^2(\Omega_T)$, the identity $w_\varepsilon = -\gamma\Delta u_\varepsilon + \Psi'_\varepsilon(u_\varepsilon)$ gives $\nabla\Delta u_\varepsilon \in L^2(\Omega_T)$. □

Therefore, we get

$$(3.1) \qquad \int_0^T \langle \zeta, \partial_t u_\varepsilon \rangle_{H^1,(H^1)'} = -\int_{\Omega_T} B_\varepsilon(u_\varepsilon)\nabla(-\gamma\Delta u_\varepsilon + \Psi'_\varepsilon(u_\varepsilon))\nabla\zeta$$

for all $\zeta \in L^2(0,T;H^1(\Omega))$.

In the next step, we prove the following energy estimates.

LEMMA 2. *There exists an ε_0 such that for all $0 < \varepsilon \le \varepsilon_0$ the following estimates hold with a constant C independent of ε:*

$$\text{(a)} \qquad \operatorname{ess\,sup}_{0\le t\le T} \int_\Omega \left(\frac{\gamma}{2}|\nabla u_\varepsilon(t)|^2 + \Psi_\varepsilon(u_\varepsilon(t))\right) + \int_{\Omega_T} B_\varepsilon(u_\varepsilon)|\nabla w_\varepsilon|^2 \le C,$$

$$\text{(b)} \qquad \operatorname{ess\,sup}_{0\le t\le T} \int_\Omega \Phi_\varepsilon(u_\varepsilon(t)) + \int_{\Omega_T} \left(\gamma|\Delta u_\varepsilon|^2 + \left(\Psi^1_\varepsilon\right)''(u_\varepsilon)|\nabla u_\varepsilon|^2\right) \le C,$$

$$\text{(c)} \qquad \operatorname{ess\,sup}_{0\le t\le T} \int_\Omega (|u_\varepsilon| - 1)_+^2 \le C\varepsilon^m,$$

$$\text{(d)} \qquad \int_{\Omega_T} |\mathbf{J}_\varepsilon|^2 \le C, \quad \textit{where} \quad \mathbf{J}_\varepsilon := B_\varepsilon(u_\varepsilon)\nabla w_\varepsilon\,.$$

Proof. The function $w_\varepsilon = -\gamma\Delta u_\varepsilon + \Psi'_\varepsilon(u_\varepsilon) \in L^2(0,T;H^1(\Omega))$ is a valid test function in (3.1). Therefore, we obtain

$$(3.2) \qquad \int_0^t \langle -\gamma\Delta u_\varepsilon + \Psi'_\varepsilon(u_\varepsilon), \partial_t u_\varepsilon \rangle_{H^1,(H^1)'} = -\int_{\Omega_t} B_\varepsilon(u_\varepsilon)|\nabla w_\varepsilon|^2$$

for all $t \in [0,T]$.

CLAIM. *For almost all $t \in [0,T]$,*

$$(3.3) \qquad \begin{aligned} &\int_0^t \langle -\gamma\Delta u_\varepsilon + \Psi'_\varepsilon(u_\varepsilon), \partial_t u_\varepsilon \rangle_{H^1,(H^1)'} \\ &\quad = \int_\Omega |\nabla u_\varepsilon(t)|^2 + \int \Psi_\varepsilon(u_\varepsilon(t)) - \int_\Omega |\nabla u_0|^2 - \int_\Omega \Psi_\varepsilon(u_0) \end{aligned}$$

holds.

To prove this, we define functions

$$u_{\varepsilon h}(t,x) := \frac{1}{h}\int_{t-h}^{t} u_\varepsilon(\tau,x)d\tau, \tag{3.4}$$

where we set $u_\varepsilon(t,x) = u_0(x)$ when $t \leq 0$. It is easily proved that

$$\begin{aligned} \Delta u_{\varepsilon h} &\longrightarrow \Delta u_\varepsilon \quad \text{strongly in} \quad L^2(0,T;H^1(\Omega)) \text{ and}\\ \Psi'(u_{\varepsilon h}) &\longrightarrow \Psi'(u_\varepsilon) \quad \text{strongly in} \quad L^2(0,T;H^1(\Omega)) \end{aligned}$$

for at least a subsequence (as $h \searrow 0$). Furthermore, we can show $\partial_t u_{\varepsilon h} \longrightarrow \partial_t u_\varepsilon$ strongly in $L^2(0,T;(H^1(\Omega))')$. For any $\zeta \in L^2(0,T;H^1(\Omega))$ we have

$$\begin{aligned} |\langle \zeta, \partial_t u_{\varepsilon h} - \partial_t u_\varepsilon \rangle_{L^2(H^1),L^2((H^1)')}| &= \frac{1}{h}\left| \int_0^T \left\langle \zeta, \int_{t-h}^{t} (\partial_t u_\varepsilon(\tau) - \partial_t u_\varepsilon(t))d\tau \right\rangle_{H^1,(H^1)'} dt \right|\\ &= \frac{1}{h}\left| \int_0^T \left\langle \zeta, \int_{-h}^{0} (\partial_t u_\varepsilon(t+s) - \partial_t u_\varepsilon(t)ds \right\rangle dt \right|\\ &\leq \frac{1}{h}\int_{-h}^{0} \left| \int_0^T \int_\Omega \nabla\zeta \cdot (\mathbf{J}_\varepsilon(t+s) - \mathbf{J}_\varepsilon(t))dx\,dt \right| ds\\ &\leq \|\nabla\zeta\|_{L^2(\Omega_T)} \sup_{-h\leq s\leq 0} \|\mathbf{J}_\varepsilon(.+s) - \mathbf{J}_\varepsilon(.)\|_{L^2(\Omega_T)}. \end{aligned}$$

Since

$$\sup_{-h\leq s\leq 0} \|\mathbf{J}_\varepsilon(.+s) - \mathbf{J}_\varepsilon(.)\|_{L^2(\Omega_T)} \longrightarrow 0 \quad \text{as} \quad h \longrightarrow 0,$$

it follows that

$$\partial_t u_{\varepsilon h} \longrightarrow \partial_t u_\varepsilon \quad \text{strongly in} \quad L^2(0,T;(H^1(\Omega))').$$

Using $\partial_t u_{\varepsilon h} \in L^2(\Omega_T)$, we have for almost all $t \in [0,T]$

$$\begin{aligned} &\int_0^t \langle -\gamma\Delta u_{\varepsilon h} + \Psi_\varepsilon'(u_{\varepsilon h}), \partial_t u_{\varepsilon h} \rangle_{H^1,(H^1)'}\\ &= \int_{\Omega_t} \left(-\gamma\Delta u_{\varepsilon h} + \Psi_\varepsilon'(u_{\varepsilon h})\right) \partial_t u_{\varepsilon h}\\ &= \partial_t \int_0^t \int_\Omega \left(\frac{\gamma}{2}|\nabla u_{\varepsilon h}|^2 + \Psi(u_{\varepsilon h})\right)\\ &= \int_\Omega \left(\frac{\gamma}{2}|\nabla u_{\varepsilon h}(t)|^2 + \Psi(u_{\varepsilon h}(t))\right) - \int_\Omega \left(\frac{\gamma}{2}|\nabla u_0|^2 + \Psi_\varepsilon(u_0)\right). \end{aligned}$$

Passing to the limit ($h \searrow 0$) in this equation, where we apply the convergence properties of $u_{\varepsilon h}$ proved above, and using (3.2) gives for almost all t

$$\int_\Omega \left(\frac{\gamma}{2}|\nabla u_\varepsilon(t)|^2 + \Psi_\varepsilon(u_\varepsilon(t))\right) + \int_{\Omega_t} B_\varepsilon(u_\varepsilon)|\nabla w_\varepsilon|^2 = \int_\Omega \left(\frac{\gamma}{2}|\nabla u_0|^2 + \Psi_\varepsilon(u_0)\right).$$

Noting that $\Psi_\varepsilon(u) \leq \Psi(u)$ for ε sufficiently small proves (a).

To prove (b), we want to use $\Phi'_\varepsilon(u_\varepsilon)$ as a test function in (3.1). Since Φ''_ε is bounded, we have $\Phi'_\varepsilon(u_\varepsilon) \in L^2(0,T;H^1(\Omega))$ and therefore is an admissible test function. With a similar argument as in the proof of (a), we can prove that

$$\int_0^t \langle \Phi'_\varepsilon(u_\varepsilon), \partial_t u_\varepsilon \rangle_{H^1,(H^1)'} = \int_\Omega \Phi_\varepsilon(u_\varepsilon(t)) - \int_\Omega \Phi_\varepsilon(u_0)$$

is true for almost all $t \in [0,T]$. On the other hand, we derive

$$\begin{aligned}
&\int_{\Omega_t} B_\varepsilon(u_\varepsilon)\nabla(-\gamma\Delta u_\varepsilon + \Psi'_\varepsilon(u_\varepsilon))\nabla\Phi'_\varepsilon(u_\varepsilon) \\
&= \int_{\Omega_t} (-\gamma\nabla\Delta u_\varepsilon + \Psi''_\varepsilon(u_\varepsilon)\nabla u_\varepsilon)\, B_\varepsilon(u_\varepsilon)\Phi''_\varepsilon(u_\varepsilon)\nabla u_\varepsilon \\
&= \int_{\Omega_t} (\gamma|\Delta u_\varepsilon|^2 + \Psi''_\varepsilon(u_\varepsilon)|\nabla u_\varepsilon|^2)\,.
\end{aligned}$$

It follows that

$$\begin{aligned}
&\int_\Omega \Phi_\varepsilon(u_\varepsilon(t)) + \int_{\Omega_t} \gamma|\Delta u_\varepsilon|^2 + \int_{\Omega_t} \left(\Psi^1_\varepsilon\right)''(u_\varepsilon)|\nabla u_\varepsilon|^2 \\
&\le \int_\Omega \Phi_\varepsilon(u_0) + \int_{\Omega_t} \left|\left(\Psi^2\right)''(u_\varepsilon)\right| |\nabla u_\varepsilon|^2.
\end{aligned}$$

Since $\Phi_\varepsilon(u) \le \Phi(u)$ for ε sufficiently small and $\left(\Psi^2\right)''$ is bounded, we have proved (b) (note that we have estimated $\int_\Omega |\nabla u_\varepsilon|^2$ in (a)).

Now we can use the bound for $\int_\Omega \Phi_\varepsilon(u_\varepsilon)$ to derive a bound for $\int_\Omega (|u_\varepsilon| - 1)_+^2$. If $z > 1$ and $\varepsilon < 1$, then we have

$$\begin{aligned}
\Phi_\varepsilon(z) &= \underbrace{\Phi(1-\varepsilon)}_{\ge 0} + \underbrace{\Phi'(1-\varepsilon)}_{\ge 0}\underbrace{(z-(1-\varepsilon))}_{\ge 0} + \frac{1}{2}\Phi''(1-\varepsilon)\,(z-(1-\varepsilon))^2 \\
&\ge \frac{1}{2}\Phi''(1-\varepsilon)(z-1)^2 = \frac{1}{2}\frac{1}{B(1-\varepsilon)}(z-1)^2 \\
&= \frac{1}{2}\frac{1}{(1-(1-\varepsilon)^2)^m\,\bar{B}(1-\varepsilon)}(z-1)^2 \ge C^{-1}\varepsilon^{-m}(z-1)^2.
\end{aligned}$$

It follows now that $(z-1)^2 \le C\varepsilon^m\Phi_\varepsilon(z)$. Similarly, we obtain $(|z|-1)^2 \le C\varepsilon^m\Phi_\varepsilon(z)$ for $z < -1$. This implies

$$\int_\Omega (|u_\varepsilon| - 1)_+^2 \le C\varepsilon^m \int_\Omega \Phi_\varepsilon(u_\varepsilon) \le C\varepsilon^m,$$

which proves (c).

Assertion (d) follows easily from (a), and this finishes the proof of Lemma 2. □

Since Δu_ε is uniformly bounded in $L^2(\Omega_T)$, $\nabla u_\varepsilon \cdot \mathbf{n} = 0$, and $\int_\Omega u_\varepsilon = \int_\Omega u_0$, elliptic regularity theory yields

$$\|u_\varepsilon\|_{L^2(0,T;H^2(\Omega))} \le C.$$

Now we apply the compactness result mentioned in Remark 1 (2.13) with $X = H^2(\Omega)$, $Y = H^1(\Omega)$, and $Z = (H^1(\Omega))'$ to conclude the existence of a subsequence of $(u_\varepsilon)_{\varepsilon>0}$ (which we still denote by $(u_\varepsilon)_{\varepsilon>0}$) such that

$$u_\varepsilon, \nabla u_\varepsilon \longrightarrow u, \nabla u \quad \text{strongly in} \quad L^2(\Omega_T) \quad \text{and a.e. in } \Omega_T.$$

Furthermore, using standard compactness properties, we obtain the convergence

$$\begin{aligned} \partial_t u_\varepsilon &\longrightarrow \partial_t u \quad \text{weakly in} \quad L^2(0,T;(H^1(\Omega))'), \\ \Delta u_\varepsilon &\longrightarrow \Delta u \quad \text{weakly in} \quad L^2(\Omega_T), \text{ and} \\ \mathbf{J}_\varepsilon &\longrightarrow \mathbf{J} \quad\ \ \text{weakly in} \quad L^2(\Omega_T). \end{aligned}$$

Passing to the limit in

$$\int_\Omega (|u_\varepsilon| - 1)_+^2 \le C\varepsilon^m$$

yields $|u| \le 1$ a.e. in Ω_T.

It remains to show that u fulfills the limit equation. The weak convergence of $\partial_t u_\varepsilon$ and $\mathbf{J}_\varepsilon$ gives in the limit

$$\int_0^T \langle \zeta, \partial_t u \rangle_{H^1,(H^1)'} = \int_{\Omega_T} \mathbf{J} \cdot \nabla\zeta$$

for all $\zeta \in L^2(0,T;H^1(\Omega))$. Now we have to identify $\mathbf{J}$. Therefore, we want to pass to the limit in the equation

$$\int_{\Omega_T} \mathbf{J}_\varepsilon \cdot \boldsymbol{\eta} = \int_{\Omega_T} B_\varepsilon(u_\varepsilon)\nabla\left(-\gamma\Delta u_\varepsilon + \Psi'_\varepsilon(u_\varepsilon)\right)\boldsymbol{\eta}, \tag{3.5}$$

where $\boldsymbol{\eta} \in L^2(0,T;H^1(\Omega,\mathbb{R}^n)) \cap L^\infty(\Omega_T,\mathbb{R}^n)$ with $\boldsymbol{\eta}\cdot\mathbf{n} = 0$ on $\partial\Omega \times (0,T)$. The left-hand side converges to $\int_{\Omega_T} \mathbf{J}\cdot\boldsymbol{\eta}$. Since $\nabla\Delta u_\varepsilon$ may not have a limit in $L^2(\Omega_T)$, we integrate the first term on the right-hand side of (3.5) by parts to get

$$\int_{\Omega_T} B_\varepsilon(u_\varepsilon)\nabla(-\gamma\Delta u_\varepsilon)\boldsymbol{\eta} = \int_{\Omega_T} \gamma\Delta u_\varepsilon B_\varepsilon(u_\varepsilon)\nabla\cdot\boldsymbol{\eta} + \int \gamma\Delta u_\varepsilon B'_\varepsilon(u_\varepsilon)\nabla u_\varepsilon\cdot\boldsymbol{\eta} =: \mathrm{I} + \mathrm{II}.$$

Using the fact that for all $z \in \mathbb{R}$

$$|B_\varepsilon(z) - B(z)| \le \sup_{1-\varepsilon\le|y|\le1} |B(y)| \longrightarrow 0 \quad \text{as} \quad \varepsilon \longrightarrow 0,$$

it follows that $B_\varepsilon \longrightarrow B$ uniformly.

Hence we have

$$B_\varepsilon(u_\varepsilon) \longrightarrow B(u) \quad \text{a.e. in } \Omega_T.$$

Since $\Delta u_\varepsilon \longrightarrow \Delta u$ weakly in $L^2(\Omega_T)$ and B_ε is uniformly bounded, we conclude

$$\int_{\Omega_T} \gamma\Delta u_\varepsilon B_\varepsilon(u_\varepsilon)\nabla\cdot\boldsymbol{\eta} \longrightarrow \int_{\Omega_T} \gamma\Delta u B(u)\nabla\cdot\boldsymbol{\eta} \quad \text{as} \quad \varepsilon \longrightarrow 0.$$

Now we pass to the limit in II. First of all, we consider the case $m > 1$. As for B, we have $B'_\varepsilon \longrightarrow B'$ uniformly, which gives

$$B'_\varepsilon(u_\varepsilon) \longrightarrow B'(u) \quad \text{a.e. in } \Omega_T.$$

By using

$$\nabla u_\varepsilon \longrightarrow \nabla u \quad \text{in} \quad L^2(\Omega_T) \quad \text{and a.e. in } \Omega_T,$$

and the fact that B'_ε is uniformly bounded a generalized version of the Lebesgue convergence theorem yields

$$B'_\varepsilon(u_\varepsilon)\nabla u_\varepsilon \longrightarrow B'(u)\nabla u \quad \text{in} \quad L^2(\Omega_T).$$

Hence

$$\int_{\Omega_T} \gamma \Delta u_\varepsilon B'_\varepsilon(u_\varepsilon)\nabla u_\varepsilon \cdot \boldsymbol{\eta} \longrightarrow \int_{\Omega_T} \gamma \Delta u B'(u)\nabla u \cdot \boldsymbol{\eta},$$

where we use the fact that $\boldsymbol{\eta} \in L^\infty(\Omega_T)$.

In the case $m = 1$, the function B' is discontinuous and we have to use a more subtle argument.

Claim. $B'_\varepsilon(u_\varepsilon)\nabla u_\varepsilon \longrightarrow B'(u)\nabla u$ *in* $L^2(\Omega_T)$.

We analyze the following integrals:

$$\begin{aligned}&\int_{\Omega_T} |B'_\varepsilon(u_\varepsilon)\nabla u_\varepsilon - B'(u)\nabla u|^2 \\ &\quad = \int_{\Omega_T \cap \{|u|<1\}} |B'_\varepsilon(u_\varepsilon)\nabla u_\varepsilon - B'(u)\nabla u|^2 + \int_{\Omega_T \cap \{|u|=1\}} |B'_\varepsilon(u_\varepsilon)\nabla u_\varepsilon - B'(u)\nabla u|^2.\end{aligned}$$

Since $\nabla u = 0$ on the set $\{|u| = 1\}$ (see [16, Lem. 7.7]), we obtain

$$\begin{aligned}\int_{\Omega_T \cap \{|u|=1\}} |B'_\varepsilon(u_\varepsilon)\nabla u_\varepsilon - B'(u)\nabla u|^2 &= \int_{\Omega_T \cap \{|u|=1\}} |B'_\varepsilon(u_\varepsilon)\nabla u_\varepsilon|^2 \\ &\leq C \int_{\Omega_T \cap \{|u|=1\}} |\nabla u_\varepsilon|^2 \longrightarrow C \int_{\Omega_T \cap \{|u|=1\}} |\nabla u|^2 = 0.\end{aligned}$$

On the set $\{|u| < 1\}$, we know $B'_\varepsilon(u_\varepsilon) \longrightarrow B'(u)$ a.e.

Hence we have

$$B'_\varepsilon(u_\varepsilon)\nabla u_\varepsilon \longrightarrow B'(u)\nabla u \quad \text{a.e. in } \Omega_T.$$

The generalized Lebesgue convergence theorem now gives

$$\int_{\Omega_T \cap \{|u|<1\}} |B'_\varepsilon(u_\varepsilon)\nabla u_\varepsilon - B'(u)\nabla u|^2 \longrightarrow 0,$$

which proves our claim. Furthermore, this proves that we can pass to the limit in II.

To complete the proof of Theorem 1, we have to show

$$\int_{\Omega_T} B_\varepsilon(u_\varepsilon)\Psi''_\varepsilon(u_\varepsilon)\nabla u_\varepsilon \cdot \boldsymbol{\eta} \longrightarrow \int_{\Omega_T} (B\Psi'')(u)\nabla u \cdot \boldsymbol{\eta}. \tag{3.6}$$

First of all, we want to point out that $B_\varepsilon \Psi''_\varepsilon$ is uniformly bounded. Therefore, it is sufficient to show

$$B_\varepsilon(u_\varepsilon)\Psi''_\varepsilon(u_\varepsilon) \longrightarrow (B\Psi'')(u) = \bar{B}(u)F(u) + B(u)\Psi''_2(u) \quad \text{a.e. in } \Omega_T. \tag{3.7}$$

If $|u(t,x))| < 1$, the convergence in (3.7) follows from the definition of B_ε and Ψ_ε ($B_\varepsilon(z) = B(z)$ and $\Psi_\varepsilon(z) = \Psi(z)$ if $|z| < 1 - \varepsilon$). Now let us consider points (t,x), where $|u(t,x)| = 1$. Without loss of generality, we assume $u_\varepsilon(t,x) \longrightarrow 1 = u(t,x)$.

For ε with $u_\varepsilon(t,x) \geq 1-\varepsilon$, we have

$$\begin{aligned} B_\varepsilon(u_\varepsilon(t,x))\Psi''_\varepsilon(u_\varepsilon(t,x)) &= \bar{B}(1-\varepsilon)F(1-\varepsilon) + B(1-\varepsilon)\Psi''_2(u_\varepsilon(t,x)) \\ &\longrightarrow \bar{B}(1)F(1) + B(1)\Psi''_2(1) = (B\Psi'')(u(t,x)). \end{aligned}$$

On the other side, if $u_\varepsilon(t,x) \leq 1-\varepsilon$ and $u_\varepsilon(t,x) \longrightarrow 1$, we have

$$\begin{aligned} B_\varepsilon(u_\varepsilon(t,x))\Psi''_\varepsilon(u_\varepsilon(t,x)) &= B(u_\varepsilon(t,x))\Psi''(u_\varepsilon(t,x)) \\ &= \bar{B}(u_\varepsilon(t,x))F(u_\varepsilon(t,x)) + B(u_\varepsilon(t,x))\Psi''_2(u_\varepsilon(t,x)) \\ &\longrightarrow (B\Psi'')(u(t,x)). \end{aligned}$$

We proved $B_\varepsilon(u_\varepsilon)\Psi''_\varepsilon(u_\varepsilon) \longrightarrow (B\Psi'')(u)$ a.e. in Ω_T, which together with the strong convergence of ∇u_ε in $L^2(\Omega_T)$ gives (3.6). This shows that u solves the Cahn–Hilliard equation in the sense of Theorem 1. The facts that $u \in C([0,T]; L^2(\Omega))$ and $u_\varepsilon(0) = u_0$ follow as in the proof of Theorem 2 from an application of the compactness result mentioned in Remark 1. In fact, it holds that $u \in C([0,T]; H^\beta(\Omega))$ with $\beta < 1$. □

Remark 2 (generalized Lebesgue convergence theorem). Assume $E \subset \mathbb{R}^n$ is measurable, $g_n \longrightarrow g$ in $L^q(E)$ with $1 \leq q < \infty$ and $f_n, f : E \longrightarrow \mathbb{R}^n$ are measurable functions such that

$$\begin{aligned} f_n &\longrightarrow f \quad \text{a.e. in } E, \\ |f_n|^p &\leq |g_n|^q \quad \text{a.e. in } E \end{aligned}$$

with $1 \leq p < \infty$. Then $f_n \longrightarrow f$ in $L^p(E)$.

For a proof see [1, A 1.26]. □

Remark 3. For $m \in [1,2)$, the functions Φ and Ψ are bounded on the interval $[-1,1]$ and therefore the assumption

$$\int_\Omega (\Phi(u_0) + \Psi(u_0)) \leq C$$

imposes no restrictions on the initial data. This is in particular true for the case $B(u) = 1-u^2$ and Ψ of the logarithmic form (1.2). □

The following corollary gives an additional result in the case $m \geq 2$.

COROLLARY. *Assume $m \geq 2$ and u is the solution constructed in Theorem* 1. *Then*

(a) $$\operatorname{ess\,sup}_{0\leq t\leq T} \int_\Omega (\Phi(u(t)) + \Psi(u(t))) \leq C,$$

(b) *the set* $\{x \mid |u(t,x)| = 1\}$ *has zero measure for almost all* $t \in [0,T]$.

Proof. We have proved

$$\int_\Omega \Phi_\varepsilon(u_\varepsilon(t)) \leq C$$

for almost all $t \in [0,T]$. Since $\Phi_\varepsilon(u_\varepsilon) \geq 0$, the Lemma of Fatou gives

$$\int_\Omega \liminf_{\varepsilon\searrow 0} \Phi_\varepsilon(u_\varepsilon(t)) \leq \liminf_{\varepsilon\searrow 0} \int_\Omega \Phi_\varepsilon(u_\varepsilon(t)) \leq C.$$

CLAIM.

$$\liminf_{\varepsilon\searrow 0} \Phi_\varepsilon(u_\varepsilon) = \begin{cases} \Phi(u) & \textit{if } |u| < 1, \\ \infty & \textit{elsewhere.} \end{cases}$$

If $|u| < 1$, it is clear that $\lim_{\varepsilon\searrow 0}\Phi_\varepsilon(u_\varepsilon) = \Phi(u)$. Now we consider points (t,x), where $\lim_{\varepsilon\searrow 0} u_\varepsilon(t,x) = 1$. In this case, we have

$$\Phi_\varepsilon(u_\varepsilon(t,x)) \geq \min\left(\Phi(1-\varepsilon), \Phi(u_\varepsilon(t,x))\right) \longrightarrow \infty$$

as $\varepsilon \longrightarrow 0$. The same argument can be applied for $\lim_{\varepsilon\searrow 0} u_\varepsilon(t,x) = -1$, which proves the claim. Therefore, the set $\{x \mid |u(t,x)| = 1\}$ has zero measure and

$$\liminf_{\varepsilon\searrow 0} \Phi_\varepsilon(u_\varepsilon) = \lim_{\varepsilon\searrow 0}\Phi_\varepsilon(u_\varepsilon) = \Phi(u) \quad \text{a.e. in } \Omega_T.$$

The estimate $\int_\Omega \Psi(u(t)) \leq C$ is proved similarly. □

Remark 4. Since F can vanish at ±1, Ψ'' can be less singular than of order m. In particular, the smooth double-well potential $\Psi(u) = (1-u^2)^2$ and the double-obstacle potential are possible choices for all $m \geq 1$.

4. Some generalizations.

4.1. The viscous Cahn–Hilliard equation. In this subsection, we consider the viscous Cahn–Hilliard equation with a nonconstant mobility

$$\begin{aligned} u_t &= -\nabla\cdot\mathbf{J},\\ \mathbf{J} &= -B(u)\nabla w,\\ w &= -\gamma\Delta u + \Psi'(u) + \alpha u_t, \qquad \alpha\in\mathbb{R}^+, \end{aligned}$$

supplemented with the boundary conditions $\mathbf{J}\cdot\mathbf{n} = 0$ and $\nabla u\cdot\mathbf{n} = 0$ on $\partial\Omega\times(0,T)$. For a mobility $B \equiv 1$, this is the usual viscous Cahn–Hilliard equation as studied by Novick-Cohen, Elliott, Stuart, and others [2, 15, 20].

In a first step, we state a theorem for the nondegenerate case. Therefore, we assume b and ψ to fulfill assumptions (i) and (ii) in §2.

THEOREM 4. *Suppose $u_0 \in H^1(\Omega)$ and $\partial\Omega$ Lipschitz. Then there exists a pair (u,w) such that*

(1) $u \in L^\infty(0,T;H^1(\Omega)) \cap C([0,T];L^2(\Omega))$,
(2) $u_t \in L^2(\Omega_T)$,
(3) $u(0) = u_0$,
(4) $w \in L^2(0,T;H^1(\Omega))$

which satisfies

$$\int_{\Omega_T} \zeta u_t = -\int_{\Omega_T} b(u)\nabla w\nabla\zeta$$

for all $\zeta \in L^2(0,T;H^1(\Omega))$ and

$$\int_\Omega w\phi = \gamma\int_\Omega \nabla u\nabla\phi + \int_\Omega \psi'(u)\phi + \int_\Omega \alpha u_t\phi$$

for all $\phi \in H^1(\Omega)$ and almost all $t \in [0,T]$.

Proof. As in the proof of Theorem 2, we apply a Galerkin approximation

$$u^N(t,x) = \sum_{i=1}^N c_i^N(t)\phi_i(x)\ ,\ w^N(t,x) = \sum_{i=1}^N d_i^N(t)\phi_i(x),$$

$$\int_\Omega \partial_t u^N\phi_j = -\int_\Omega b(u_N)\nabla w^N\nabla\phi_j \quad \text{for} \quad j = 1,\ldots,N,$$

$$\int_\Omega w^N\phi_j = \gamma\int_\Omega \nabla u^N\nabla\phi_j + \int_\Omega \psi'(u^N)\phi_j + \alpha\int_\Omega \partial_t u^N\phi_j \quad \text{for} \quad j=1,\dots,N,$$
$$u^N(0) = \sum_{i=1}^N (u_0,\phi_i)_{L^2(\Omega)}\phi_i,$$

which gives

$$\partial_t c_j^N = -\sum_{k=1}^N d_k^N \int_\Omega b\left(\sum_{i=1}^N c_i^N\phi_i\right)\nabla\phi_k\nabla\phi_j, \tag{4.1}$$

$$d_j^N = \gamma\lambda_j c_j^N + \int_\Omega \psi'\left(\sum_{l=1}^N c_l^N\phi_l\right)\phi_j + \alpha\partial_t c_j, \quad \text{and} \tag{4.2}$$

$$c_j^N(0) = (u_0,\phi_j)_{L^2(\Omega)}. \tag{4.3}$$

These equations have to hold for $j=1,\dots,N$. This yields to the following initial value problem for $(c_1^N,\dots,c_N^N)$:

$$\begin{aligned}\partial_t c_j^N &+ \alpha\sum_{k=1}^N \partial_t c_k\int_\Omega b\left(\sum_{i=1}^N c_i^N\phi_i\right)\nabla\phi_k\nabla\phi_j \\ &= -\sum_{k=1}^N\left(\gamma\lambda_k c_k^N + \int_\Omega\psi'\left(\sum_{l=1}^N c_l^N\phi_l\right)\phi_k\right)\int_\Omega b\left(\sum_{i=1}^N c_i^N\phi_i\right)\nabla\phi_k\nabla\phi_j,\end{aligned} \tag{4.4}$$

$$c_j^N(0) = (u_0,\phi_j)_{L^2(\Omega)}. \tag{4.5}$$

Since the matrix $(g_{jk})_{j,k=1,N}$ with

$$g_{jk} = \int_\Omega b\left(\sum_i c_i^N\phi_i\right)\nabla\phi_k\nabla\phi_j$$

is positive definite, the initial value problem (4.4), (4.5) has a local solution.

Now we use

$$\begin{aligned}\frac{d}{dt}\int_{\Omega_T}\left(|\nabla u^N|^2 + \psi(u^N)\right) &= \int_{\Omega_T}\left(-\gamma\Delta u^N + \psi'(u^N)\right)u_t^N \\ &= \int_\Omega w^N u_t^N - \int_\Omega \alpha\left(u_t^N\right)^2 \\ &= -\int_\Omega b(u^N)|\nabla w^N|^2 - \int_{\Omega_T}\alpha\left(u_t^N\right)^2\end{aligned}$$

to establish a priori estimates. The rest is proved in a similar way as in the proof of Theorem 2. □

Having proved an existence theorem for a positive mobility, we are now in a position to prove existence for the degenerate case. We assume Ψ and B to be as in the introduction. Furthermore, we assume either $\partial\Omega \in C^{1,1}$ or Ω convex.

THEOREM 5. *Let $u_0 \in H^1(\Omega)$ satisfy $|u_0| \le 1$ a.e. in Ω_T and*

$$\int_\Omega (\Psi(u_0) + \Phi(u_0)) \le C, \quad C \in \mathbb{R}^+.$$

Then there exists a pair $(u, \mathbf{J})$ *such that*

(a) $u \in L^2(0,T;H^2(\Omega)) \cap L^\infty(0,T;H^1(\Omega)) \cap C([0,T];L^2(\Omega))$,
(b) $u_t \in L^2(\Omega_T)$,
(c) $u(0) = u_0$ *and* $\nabla u \cdot \mathbf{n} = 0$ *on* $\partial\Omega \times (0,T)$,
(d) $|u| \le 1$ *a.e in* $\Omega_T := \Omega \times (0,T)$,
(e) $\mathbf{J} \in L^2(\Omega_T, \mathbb{R}^n)$

which satisfies $u_t = -\nabla \cdot \mathbf{J}$ *in* $L^2(0,T;(H^1(\Omega))')$, *i.e.,*

$$\int_{\Omega_T} \zeta u_t = \int_{\Omega_T} \mathbf{J} \cdot \nabla \zeta$$

for all $\zeta \in L^2(0,T;H^1(\Omega))$ *and*

$$\mathbf{J} = -B(u)\nabla\left(-\gamma\Delta u + \Psi'(u) + \alpha u_t\right)$$

in the following weak sense:

$$\int_{\Omega_T} \mathbf{J} \cdot \boldsymbol{\eta} = -\int_{\Omega_T} \left[(\gamma\Delta u - \alpha u_t)\,\nabla \cdot (B(u)\boldsymbol{\eta}) + (B\Psi'')(u)\nabla u \cdot \boldsymbol{\eta}\right]$$

for all $\boldsymbol{\eta} \in L^2(0,T;H^1(\Omega,\mathbb{R}^n)) \cap L^\infty(\Omega_T,\mathbb{R}^n)$ *which fulfill* $\boldsymbol{\eta} \cdot \mathbf{n} = 0$ *on* $\partial\Omega \times (0,T)$.

Proof. We modify B and Ψ in the same manner as in the proof of Theorem 1 to get functions B_ε and Ψ_ε. For the modified equation, we proved existence in Theorem 4. In a similar fashion as in the proof of Theorem 1, we can derive the following identities for the approximating solutions $(u_\varepsilon, w_\varepsilon)$:

$$\operatorname{ess\,sup}_{0\le t\le T} \int_\Omega \left(\frac{\gamma}{2}|\nabla u_\varepsilon(t)|^2 + \Psi(u_\varepsilon(t))\right) + \int_{\Omega_T} B_\varepsilon(u_\varepsilon)|\nabla w_\varepsilon|^2 + \\ + \alpha\int_{\Omega_T} (\partial_t u_\varepsilon)^2 = \int_\Omega \left(\frac{\gamma}{2}|\nabla u_0|^2 + \Psi_\varepsilon(u_0)\right)$$

and

$$\operatorname{ess\,sup}_{0\le t\le T} \int_\Omega \left(\Phi_\varepsilon(u_\varepsilon(t)) + \frac{\alpha}{2}|\nabla u_\varepsilon(t)|^2\right) + \int_{\Omega_T} \gamma|\Delta u_\varepsilon|^2 + \\ \int_{\Omega_T} \psi_\varepsilon''(u_\varepsilon)|\nabla u_\varepsilon|^2 = \int_\Omega \left(\Phi_\varepsilon(u_0) + \frac{\alpha}{2}|\nabla u_0|^2\right).$$

With these estimates, the remaining part of the proof follows the outline of the proof of Theorem 1. One uses compactness results to conclude the existence of a converging subsequence and passes to the limit in the approximating equation. □

4.2. The deep quench limit. Now we consider the case $B(u) = 1 - u^2$ and

$$\Psi_\theta(u) = \frac{\theta}{2}\left((1+u)\ln(1+u) + (1-u)\ln(1-u)\right) + \frac{1}{2}(1-u^2), \tag{4.6}$$

where $\theta > 0$. Let us denote the solution we constructed in the proof of Theorem 1 by u_θ. Cahn, Elliott, and Novick-Cohen [7] studied the deep quench limit ($\theta \searrow 0$) of these solutions. The purpose of this subsection is to show that the solutions u_θ converge to weak solutions of the Cahn–Hilliard equation with a mobility $B(u) = 1 - u^2$ and a bulk energy $\Psi(u) = 1 - u^2$, which is the case where we set $\theta = 0$ in (4.6).

For u_θ, we have the following a priori estimates, which follow from the estimates derived in Lemma 2 and the weak lower semicontinuity of the L^2-norm:

$$\operatorname{ess\,sup}_{0\le t\le T}\int_\Omega |\nabla u_\theta(t)|^2 + \int_{\Omega_T} |\mathbf{J}_\theta|^2 \le \int_\Omega \left(\frac{\gamma}{2}|\nabla u_0|^2 + \Psi_\theta(u_0)\right) \le C$$

and

$$\int_{\Omega_T} \gamma|\Delta u_\theta|^2 \le \int_\Omega \Phi(u_0) + \int_{\Omega_T} |\nabla u_\theta|^2 \le C$$

with a constant C independently of θ. From these estimates, we obtain

$$\|\partial_t u_\theta\|_{L^2(0,T;(H^1(\Omega))')} + \|u_\theta\|_{L^2(0,T;H^2(\Omega))} \le C.$$

Using the same compactness results as before, we get (for a subsequence $\theta \searrow 0$)

$$\begin{array}{rcllll} u_\theta, \nabla u_\theta & \longrightarrow & u, \nabla u & \text{strongly} & \text{in} & L^2(\Omega_T) \text{ and a.e. in } \Omega_T, \\ \Delta u_\theta & \longrightarrow & \Delta u & \text{weakly} & \text{in} & L^2(\Omega_T), \\ \partial_t u_\theta & \longrightarrow & \partial_t u & \text{weakly} & \text{in} & L^2(0,T;(H^1(\Omega))'), \quad \text{and} \\ \mathbf{J}_\theta & \longrightarrow & \mathbf{J} & \text{weakly} & \text{in} & L^2(\Omega_T). \end{array}$$

Since $|u_\varepsilon| \le 1$ a.e. in Ω_T, the same is true for u. Furthermore, we get $\partial_t u = \nabla\cdot\mathbf{J}$ in $L^2(0,T;(H^1(\Omega))')$. It remains to pass to the limit in

$$\int_{\Omega_T} \mathbf{J}_\theta\cdot\boldsymbol{\eta} = -\int_{\Omega_T} \left[\gamma\Delta u_\theta\nabla\cdot(B(u_\theta)\boldsymbol{\eta}) + \theta\nabla u_\theta\boldsymbol{\eta} - B(u_\theta)\nabla u_\theta\boldsymbol{\eta}\right].$$

The fact that ∇u_θ is uniformly bounded in $L^2(\Omega_T)$ yields

$$\int_{\Omega_T} \theta\nabla u_\theta\boldsymbol{\eta} \longrightarrow 0.$$

All other terms can be handled as in the proof of Theorem 1 to get

$$\int_{\Omega_T} \mathbf{J}\cdot\boldsymbol{\eta} = -\int_{\Omega_T} \left[\gamma\Delta u\nabla\cdot(B(u)\boldsymbol{\eta}) - B(u)\nabla u\cdot\boldsymbol{\eta}\right].$$

This proves that u is a weak solution in the case $B(u) = 1-u^2$ and $\Psi(u) = \frac{1}{2}(1-u^2)$.

We note that we have not proved the convergence of the whole sequence. This is due to the fact that so far there is no uniqueness result for the Cahn–Hilliard equation with a degenerate mobility.

4.3. Other applications. In a paper by Bernis and Friedman [3], the equation

$$u_t = -(f(u)u_{xxx})_x, \tag{4.7}$$

where

$$f(u) = |u|^m f_0(u), \qquad f_0 \in C^{1+\alpha}(\mathbb{R}),\ f_0 > 0, \quad \text{and} \quad m \ge 1, \tag{4.8}$$

was studied. They proved the existence of a nonnegative continuous solution and properties of the support of the solution. For example, they proved that the support increases when $m \ge 2$. We also refer to [3] for other applications of degenerate parabolic equations of higher order.

With straightforward modifications, we can apply our techniques to the following generalization of (4.7) in several space dimensions

$$u_t = \nabla \cdot (f(u)\nabla(-\Delta u + \Psi'(u)))$$

supplemented with Neumann- and no-flux boundary conditions. Under appropriate conditions on the nonlinearities f and Ψ, our method gives the existence of a nonnegative solution in the sense of Theorem 1. In particular, we have to assume that f, f', and $\Psi'' f$ are bounded.

Degenerate parabolic equations of the form

$$u_t = -\nabla \cdot (f(u)(\nabla\Delta u + \nabla u)) + g(t, x, u) \tag{4.9}$$

arising in the theory of plasticity have been independently studied by Grün [17].

5. Conclusion. We proved the existence of a weak solution to the Cahn–Hilliard equation with a degenerate mobility. As was pointed out, our method is also applicable for other fourth-order degenerate parabolic equations. So far, a uniqueness result for fourth-order degenerate parabolic equations has not been established. Methods for proving uniqueness in the case of second-order degenerate parabolic equations seem not to be applicable directly.

Besides studying the question of uniqueness, it is important to get a better understanding of the qualitative behaviour of solutions. Questions are, for example, the following: What kind of singularities occur when $|u| \longrightarrow 1$? What is the evolutionary behaviour of the set $\{|u| = 1\}$? In the case of the deep quench limit, for example, one would expect that the set $\{|u| = 1\}$ develops an interior. If this is the case, one would get a free boundary problem for $\partial\{|u| = 1\}$.

Furthermore, we are interested in the asymptotic behaviour of solutions as $t \longrightarrow \infty$. For second-order degenrate parabolic equations, similarity solutions were important for the understanding of the asymptotic behaviour of solutions. There are results by Bernis, Peletier, and Williams [4] on similarity solutions in one space dimension. It would be interesting to study if similarity solutions in higher space dimensions exist.

ANALYTICITY OF ESSENTIALLY BOUNDED SOLUTIONS TO SEMILINEAR PARABOLIC SYSTEMS AND VALIDITY OF THE GINZBURG–LANDAU EQUATION[*]

P. TAKÁČ[†], P. BOLLERMAN[‡], A. DOELMAN[§], A. VAN HARTEN[¶], AND E. S. TITI[‖]

Abstract. Some analytic smoothing properties of a general strongly coupled, strongly parabolic semilinear system of order $2m$ in $\mathbb{R}^D \times (0,T)$ with analytic entries are investigated. These properties are expressed in terms of holomorphic continuation in space and time of essentially bounded global solutions to the system. Given $0 < T' < T \leq \infty$, it is proved that any weak, essentially bounded solution $\mathbf{u} = (u_1, \dots, u_N)$ in $\mathbb{R}^D \times (0,T)$ possesses a bounded holomorphic continuation $\mathbf{u}(x+iy, \sigma + i\tau)$ into a region in $\mathbb{C}^D \times \mathbb{C}$ defined by $(x,\sigma) \in \mathbb{R}^D \times (T',T)$, $|y| < A'$ and $|\tau| < B'$, where A' and B' are some positive constants depending upon T'. The proof is based on analytic smoothing properties of a parabolic Green function combined with a contraction mapping argument in a Hardy space H^∞. Applications include weakly coupled semilinear systems of complex reaction-diffusion equations such as the complex Ginzburg–Landau equations. Special attention is given to the problem concerning the validity of the derivation of amplitude equations which describe various instability phenomena in hydrodynamics.

Key words. weak L^∞-solution, analytic Green function, holomorphic continuation, Hardy space, Ginzburg–Landau equation

1. Introduction.

In this article we investigate analyticity of weak L^∞-solutions $\mathbf{u}(x,t) \in \mathbb{R}^N$ (or $\mathbb{C}^N$), for $(x,t) \in \mathbb{R}^D \times (0,T)$, of a general strongly coupled, strongly parabolic system of N semilinear partial differential equations of order $2m$ (where $m \geq 1$ is an integer) having the following form:

$$(1.1)\qquad \begin{aligned} &\frac{\partial \mathbf{u}}{\partial t} + \mathbf{P}\Big(\frac{1}{i}\frac{\partial}{\partial x}\Big)\mathbf{u} = \mathbf{F}\Big(x,t,\Big(\frac{\partial^{|\alpha|}\mathbf{u}}{\partial x^\alpha}\Big)_{|\alpha|\leq \ell}\Big) \quad \text{for } (x,t) \in \mathbb{R}^D \times (0,T),\\ &\mathbf{u}(x,0) = \mathbf{u}_0(x) \quad \text{for } x \in \mathbb{R}^D. \end{aligned}$$

Here, $\partial/\partial x = (\partial/\partial x_1, \dots, \partial/\partial x_D)$ is the gradient and $(\partial^{|\alpha|}\mathbf{u}/\partial x^\alpha)_{|\alpha|\leq\ell}$ denotes the collection of all partial derivatives $\partial^{|\alpha|}\mathbf{u}/\partial x^\alpha = \frac{\partial^{|\alpha|}\mathbf{u}}{\partial x_1^{\alpha_1}\dots\partial x_D^{\alpha_D}}$ of $\mathbf{u}$ up to order ℓ (where ℓ is an integer, $0 \leq \ell < 2m$), where $\alpha = (\alpha_1, \dots, \alpha_D) \in (\mathbb{Z}_+)^D$ is a multiindex of order $|\alpha| = \alpha_1 + \dots + \alpha_D$.

As usual, $\mathbb{R}^N$ and $\mathbb{C}^N$, respectively, denote the N-dimensional real and complex Euclidean spaces, $i = \sqrt{-1}$ and $D, N \in \mathbb{N}$, where $\mathbb{N} = \mathbb{Z}_+ \setminus \{0\}$ and $\mathbb{Z}_+ = \{0, 1, 2, \dots\}$.

Our main objective is to cover the following prototype problem which inspired our work reported here, namely, the complex Ginzburg–Landau equation (derived in Newell and Whitehead [29]):

$$\begin{aligned} (1.2) \qquad & \frac{\partial u}{\partial t} - (1 + i\nu)\Delta u = Ru - (1 + i\mu)|u|^2 u \quad \text{for } (x, t) \in \mathbb{R}^D \times (0, T), \\ & u(x, 0) = u_0(x) \quad \text{for } x \in \mathbb{R}^D, \end{aligned}$$

and weakly coupled systems of such equations as well. Here, $\Delta = \frac{\partial^2}{\partial x_1^2} + \cdots + \frac{\partial^2}{\partial x_D^2}$ denotes the Laplacian, $\mu, \nu, R \in \mathbb{R}$ are given constants, and $u(x, t) \in \mathbb{C}$ is the unknown function. We assume that $u \in L^\infty(\mathbb{R}^D \times (0, T))$ is a weak L^∞-solution of (1.2) which we define later in §2, Definition 2.1.

Although $|u|^2 = u_1^2 + u_2^2$ is not a holomorphic (i.e. complex analytic) function of $u \equiv u_1 + iu_2 \in \mathbb{C} \equiv \mathbb{R} \oplus i\mathbb{R}$, it is still real analytic in u_1 and u_2. The following example shows how (1.2) can be turned into a system of two real equations with real analytic nonlinearities satisfying all hypotheses we impose below on our general system (1.1).

Example 1.1. Let $u \equiv u_1 + iu_2$ be the unknown function in (1.2), where $u_1 = \Re\mathfrak{e}\, u$ and $u_2 = \Im\mathfrak{m}\, u$, and set $\mathbf{u} = \binom{u_1}{u_2}$. Then (1.2) is equivalent to the following system for the unknown $\mathbf{u}$:

$$\begin{aligned} (1.3) \quad & \frac{\partial \mathbf{u}}{\partial t} - \begin{pmatrix} 1 & -\nu \\ \nu & 1 \end{pmatrix} \Delta \mathbf{u} = R\mathbf{u} - |\mathbf{u}|^2 \begin{pmatrix} 1 & -\mu \\ \mu & 1 \end{pmatrix} \mathbf{u} \quad \text{for } (x, t) \in \mathbb{R}^D \times (0, T), \\ & \mathbf{u}(x, 0) = \mathbf{u}_0(x) \quad \text{for } x \in \mathbb{R}^D. \end{aligned}$$

As usual, $\Delta\mathbf{u} = \binom{\Delta u_1}{\Delta u_2}$ and $|\mathbf{u}|^2 = u_1^2 + u_2^2$. Both components of the nonlinearity

$$\mathbf{F}(\mathbf{u}) \equiv \begin{pmatrix} F_1(\mathbf{u}) \\ F_2(\mathbf{u}) \end{pmatrix} = (u_1^2 + u_2^2) \begin{pmatrix} u_1 - \mu u_2 \\ \mu u_1 + u_2 \end{pmatrix}$$

are now third-degree polynomials in u_1 and u_2. Hence, (1.3) is a real analytic system with an obvious canonical extension to a holomorphic one.

Rigorous investigation of the validity of (1.2) presented in van Harten [15] and Bollerman [3] exploits the kind of analyticity results we show in the present article. Typically, (1.2) is an amplitude equation which is formally derived by means of asymptotic expansion from other equations of mathematical physics, such as the Navier–Stokes equations or the Rayleigh–Bénard convection equations and many others, in the context of studying weakly nonlinear instabilities of particular solutions of those equations. This derivation involves an asymptotic expansion of the solution in terms of a small control parameter $\varepsilon > 0$, which in turn makes use of the analyticity and asymptotics (as $|x| \to \infty$) of the solution, cf. [3], [6], [15], [22], [29], [31], and [32]. To give a rigorous validation of the formal derivation one needs to prove suitable analyticity results for the solution of (1.2). This is the content of §5 in our article.

With the notation of Example 1.1, in [15] (and similarly in [3]) it is assumed that $D = 1$ and the initial distribution $\mathbf{u}(\cdot, 0) = \mathbf{u}_0 \colon \mathbb{R} \to \mathbb{C}^2$ has a bounded holomorphic continuation $\mathbf{u}_0(x + iy)$ into a strip $S_a = \{z = x + iy \in \mathbb{C} \colon |y| < a\}$ for some constant $a \in (0, \infty)$. This analyticity hypothesis on $\mathbf{u}_0$ is weakened in our present work. We assume only $\mathbf{u}_0 \in L^\infty(\mathbb{R} \to \mathbb{C}^2)$ and prove an analytic smoothing property for time $t \in (0, T)$.

In order to be able to treat our general system (1.1) in a simple but reasonably general way, we assume that

$$\mathbf{P}\Big(\frac{1}{i}\frac{\partial}{\partial x}\Big) = \sum_{|\alpha|\le 2m} i^{-|\alpha|}\mathbf{P}^{(\alpha)}\frac{\partial^{|\alpha|}}{\partial x^{\alpha}} \tag{1.4}$$

is a strongly elliptic, linear, partial differential operator of order $2m$ with constant coefficients $i^{-|\alpha|}\mathbf{P}^{(\alpha)}$, where each $i^{-|\alpha|}\mathbf{P}^{(\alpha)} = (i^{-|\alpha|}P_{jk}^{(\alpha)})_{j,k=1}^{N}$ is an $N \times N$ matrix with real (or complex) entries $i^{-|\alpha|}P_{jk}^{(\alpha)}$. The strong ellipticity hypothesis for $\mathbf{P}$ means that there exists a constant $c \in (0,\infty)$ such that the following inequality holds for all $\xi = (\xi_1, \dots, \xi_D) \in \mathbb{R}^D$ and $\boldsymbol{\eta} = (\eta_1, \dots, \eta_N) \in \mathbb{R}^N$ (or $\mathbb{C}^N$):

$$\Re e\Big(\sum_{j=1}^{N}\sum_{k=1}^{N}\sum_{|\alpha|=2m} P_{jk}^{(\alpha)}\xi^{\alpha}\eta_k\eta_j^{*}\Big) \ge c|\xi|^{2m}|\boldsymbol{\eta}|^2, \tag{1.5}$$

where $\xi^{\alpha} = \xi_1^{\alpha_1}\dots\xi_D^{\alpha_D}$ for $\alpha = (\alpha_1, \dots, \alpha_D) \in (\mathbb{Z}_+)^D$. We use an asterisk (*) to denote the complex conjugate of a number in the complex plane $\mathbb{C}$.

The nonlinear mapping $\mathbf{F}\colon \mathbb{R}^D \times (0,T) \times \mathbb{R}^{N(1+D+\cdots+D^{\ell})} \to \mathbb{R}^N$ (or $\mathbb{R}^D \times (0,T) \times \mathbb{C}^{N(1+D+\cdots+D^{\ell})} \to \mathbb{C}^N$) is assumed to be real (or complex) analytic in all its variables

$$(x,t) \in \mathbb{R}^D \times (0,T) \quad \text{and} \quad \boldsymbol{\zeta}_{\alpha} = \frac{\partial^{|\alpha|}}{\partial x^{\alpha}}\mathbf{u}(x,t) \in \mathbb{R}^N \text{ (or } \mathbb{C}^N) \quad \text{for } |\alpha| \le \ell.$$

Moreover, we assume that $\mathbf{F}$ possesses a holomorphic continuation $\mathbf{F}(x+iy, \sigma + i\tau, (\boldsymbol{\xi}_{\alpha} + i\boldsymbol{\eta}_{\alpha})_{|\alpha|\le\ell})$ into a region $\Omega_{\mathbf{F}} = \Omega'_{\mathbf{F}} \times \mathbb{C}^{N(1+D+\cdots+D^{\ell})}$, where $\Omega'_{\mathbf{F}} \subset \mathbb{C}^D \times \mathbb{C}$ is defined by

$$\Omega'_{\mathbf{F}} = \{(x+iy, \sigma+i\tau)\colon (x,\sigma) \in \mathbb{R}^D \times (0,T),\ |y| < A \ \text{ and } \ |\tau| < B\},$$

such that $\mathbf{F}$ and all partial Fréchet derivatives $\partial\mathbf{F}/\partial\boldsymbol{\zeta}_{\alpha}$, for $|\alpha| \le \ell$, are bounded in $\Omega'_{\mathbf{F}} \times \mathbf{B}$ for every bounded set $\mathbf{B} \subset \mathbb{C}^{N(1+D+\cdots+D^{\ell})}$. Here, $A, B \in (0,\infty)$ are some constants.

A brief, weaker version of our main result, Theorem 2.1 in §2, can be stated as follows.

THEOREM 1.1. *Let A and B be as above, and $0 < T' < T \le \infty$. Assume that $\mathbf{u}$ is a weak L^{∞}-solution of our system (1.1) in $\mathbb{R}^D \times (0,T)$ such that*

$$M'_{\alpha} \overset{\text{def}}{=} \operatorname*{ess\,sup}_{\mathbb{R}^D\times(0,T)}\left|\frac{\partial^{|\alpha|}\mathbf{u}}{\partial x^{\alpha}}\right| < \infty \quad \textit{for } |\alpha| \le \ell.$$

Then the function $\mathbf{u}$ has a bounded holomorphic continuation $\mathbf{u}(x+iy, \sigma+i\tau)$ into a region $\Omega'_{\mathbf{u}} \subset \mathbb{C}^D \times \mathbb{C}$ defined by

$$\Omega'_{\mathbf{u}} = \{(x+iy, \sigma+i\tau)\colon (x,\sigma) \in \mathbb{R}^D \times (T',T),\ |y| < A' \ \textit{ and } \ |\tau| < B'\},$$

such that all partial derivatives $\partial^{|\alpha|}\mathbf{u}/\partial x^{\alpha}$, for $|\alpha| \le \ell$, are bounded in $\Omega'_{\mathbf{u}}$. Here, $A' \in (0,A]$ and $B' \in (0,B]$ are some constants depending upon T' and $\mathbf{u}$ solely through the numbers $M'_{\alpha} \in [0,\infty)$ for $|\alpha| \le \ell$.

Remark 1.1. In our Theorem 2.1 below, we specify also the dependence of the constants $A' \equiv A'(T')$ and $B' \equiv B'(T')$ upon $T' \in (0,T)$. In general, we cannot take

$T' = 0$ unless $A' = 0$ or $B' = 0$. Namely, given any $A' \in (0, A]$ and $B' \in (0, B]$, the holomorphic continuation $\mathbf{u}(x+iy, \sigma+i\tau)$ of the solution $\mathbf{u}$ into the region $\Omega_{\mathbf{u}} \subset \mathbb{C}^D \times \mathbb{C}$ defined by

$$\Omega_{\mathbf{u}} = \{(x+iy, \sigma+i\tau)\colon (x,\sigma) \in \mathbb{R}^D \times (0,T),\ |y| < A' \text{ and } |\tau| < B'\}$$

may either fail to exist or else fail to be bounded, cf. Remark 2.6 below, unless $\mathbf{u}_0$ has a bounded holomorphic continuation $\mathbf{u}_0(x+iy)$ into the strip $S_{A'} = \{z = x+iy \in \mathbb{C}^D\colon |y| < A'\}$, in which case one can apply the results of [15].

Some results about the analyticity of solutions of nonlinear parabolic systems, which are related to ours, are stated in Friedman [13, Thms. 3 and 4] without proofs. For the Navier–Stokes equations, such analyticity results are proved in Masuda [26]. These results state local analyticity of infinitely differentiable solutions without any description of their domain of holomorphy (i.e., domain of complex analyticity). Our present article provides such a description in Theorem 2.1.

As we have already indicated, our main result, Theorem 2.1, is stated in §2 and proved in §3. Its proof is based on some well-known analytic smoothing properties of the Green function corresponding to the initial value problem for the linear part of System (1.1), which are stated and proved in the Appendix. These properties are combined with a standard contraction-mapping argument in a Hardy space H^∞ of bounded holomorphic functions (rather than a commonly used Hölder or Sobolev space). The contractivity is obtained via Cauchy's theorem (path independence of the integral). In §4 we suggest possible generalizations of our main result to a wider class of systems (1.1) involving a much more general pseudodifferential operator as their linear part. In §5 we discuss direct applications of our main result to the validity problem for the complex Ginzburg–Landau equation (1.2). Finally, §6 contains a discussion about further applications of our results to some current issues in mathematical physics and dynamical systems. We also compare previously known results to ours.

2. Statement of the main result. Recalling $D, N \in \mathbb{N}$ and $\ell, m \in \mathbb{Z}_+$ with $0 \le \ell < 2m$, we introduce the following notation: The complexifications of the space and time variables, respectively, are denoted by $z = x + iy \in \mathbb{C}^D \equiv \mathbb{R}^D \oplus i\mathbb{R}^D$ and $t = \sigma + i\tau \in \mathbb{C} \equiv \mathbb{R} \oplus i\mathbb{R}$. As usual, $|\cdot|$ denotes the Euclidean norm in a real or complex Euclidean space.

Given any Lebesgue-measurable set Ω in a Euclidean space, we denote by $\mathbf{L}^\infty(\Omega) = L^\infty(\Omega \to \mathbb{C}^N)$ the Lebesgue space of all (equivalence classes of) Lebesgue-measurable, essentially bounded functions $\mathbf{f} = (f_1, \dots, f_N)\colon \Omega \to \mathbb{C}^N$ endowed with the norm

$$\|\mathbf{f}\|_\infty = \operatorname*{ess\,sup}_{\omega \in \Omega} |\mathbf{f}(\omega)| < \infty.$$

Recall that $\mathbf{L}^\infty(\Omega)$ is the dual space of $\mathbf{L}^1(\Omega) = L^1(\Omega \to \mathbb{C}^N)$. Hence, any bounded closed ball in $\mathbf{L}^\infty(\Omega)$ endowed with the weak*-topology is a compact metrizable space. In particular, a sequence $\{\mathbf{f}^n\}_{n=1}^\infty \subset \mathbf{L}^\infty(\Omega)$ converges to $\mathbf{f}^0 \in \mathbf{L}^\infty(\Omega)$ $(n \to \infty)$ in the weak*-topology on $\mathbf{L}^\infty(\Omega)$ if and only if

$$\int_\Omega f_j^n(x)\phi(x)\,dx \to \int_\Omega f_j^0(x)\phi(x)\,dx \qquad \text{as } n \to \infty,$$

for every $\phi \in L^1(\Omega)$ and $j = 1, \dots, N$.

We define the notion of a weak L^∞-solution of our system (1.1) as follows.

Definition 2.1. *Let $T \in (0, \infty]$. A function $\mathbf{u}\colon \mathbb{R}^D \times (0,T) \to \mathbb{C}^N$ is called a weak L^∞-solution of system* (1.1) *if it satisfies the following four conditions:*

(i) $\mathbf{u}$ *and all distributional partial derivatives* $\partial^{|\alpha|}\mathbf{u}/\partial x^{\alpha}$, *for* $|\alpha| \le \ell$, *belong to* $\mathbf{L}^{\infty}(\mathbb{R}^D \times (0,T))$.

(ii) $t \in [0,T) \mapsto \mathbf{u}(\cdot,t) \in \mathbf{L}^{\infty}(\mathbb{R}^D)$ *is a weakly* continuous function of* t *with the weak*-limit* $\mathbf{u}_0 \in \mathbf{L}^{\infty}(\mathbb{R}^D)$ *as* $t \to 0+$. *The function* $\mathbf{u}(\cdot,0) = \mathbf{u}_0$ *is called the initial value of* $\mathbf{u}$.

(iii) $(x,t) \in \mathbb{R}^D \times (0,T) \mapsto \mathbf{F}\big(x,t,\big(\frac{\partial^{|\alpha|}}{\partial x^{\alpha}}\mathbf{u}(x,t)\big)_{|\alpha|\le\ell}\big) \in \mathbb{C}^N$ *is a locally integrable function.*

(iv) *Equation* (1.1) *is satisfied in the sense of distributions over* $\mathbb{R}^D \times (0,T)$.

Remark 2.1. If $0 < \ell < 2m$, Conditions (i) and (ii) from Definition 2.1 above imply also that each distributional partial derivative $t \in (0,T) \mapsto \partial^{|\alpha|}\mathbf{u}(\cdot,t)/\partial x^{\alpha} \in \mathbf{L}^{\infty}(\mathbb{R}^D)$, for $0 < |\alpha| \le \ell$, is a weakly* continuous function of t with the weak*-limit $\partial^{|\alpha|}\mathbf{u}_0/\partial x^{\alpha} \in \mathbf{L}^{\infty}(\mathbb{R}^D)$ as $t \to 0+$. This claim is obvious since each of these functions is valued in a bounded closed ball in $\mathbf{L}^{\infty}(\mathbb{R}^D)$, i.e., in a metrizable weak*-compact set. In particular, we have also $\partial^{|\alpha|}\mathbf{u}_0/\partial x^{\alpha} \in \mathbf{L}^{\infty}(\mathbb{R}^D)$ for $|\alpha| \le \ell$.

Remark 2.2. Condition (iii) from Definition 2.1 is automatically satisfied provided $\mathbf{F}$ satisfies Hypothesis (H2) below and $\mathbf{u}$ satisfies condition (i) from Definition 2.1.

The reader is referred to Edwards [11, Chap. 5] for the theory of distributions and weak topologies.

Let $\kappa_0, \nu_0 \in (0,\infty)$ be two constants to be specified later, and $s \in [0,\infty]$. We set

$$\Pi^{(s)}(\kappa_0) = \{z = x + iy \in \mathbb{C}^D \colon |y|^{2m} < \kappa_0 s\}, \tag{2.1}$$

$$\Sigma^{(s)}(\nu_0) = \{t = \sigma + i\tau \in \mathbb{C} \colon \nu_0|\tau| < \sigma = s\}, \tag{2.2}$$

and introduce the open parabolic region

$$\Lambda^{(s)}(\kappa_0,\nu_0) = \cup\{\Pi^{(r)}(\kappa_0) \times \Sigma^{(r)}(\nu_0) \colon r \in (0,s)\} \subset \mathbb{C}^D \times \mathbb{C}, \tag{2.3}$$

together with its time translation by r units, for $0 \le r < \infty$,

$$\Lambda_r^{(s)}(\kappa_0,\nu_0) = \{(z,t) \in \mathbb{C}^D \times \mathbb{C} \colon (z,t-r) \in \Lambda^{(s)}(\kappa_0,\nu_0)\}. \tag{2.4}$$

We now define our most important region in $\mathbb{C}^D \times \mathbb{C}$, for $0 \le s \le T \le \infty$,

$$\Gamma_T^{(s)}(\kappa_0,\nu_0) = \begin{cases} \cup\{\Lambda_r^{(s)}(\kappa_0,\nu_0) \colon r \in [0,T-s]\} & \text{if } s < T, \\ \Lambda^{(s)}(\kappa_0,\nu_0) & \text{if } s = T. \end{cases} \tag{2.5}$$

Given any $r \in [0,T)$, we observe that the time r section of $\Gamma_T^{(s)}(\kappa_0,\nu_0)$ is given by

$$\begin{aligned} \Theta^{(r,s)}(\kappa_0,\nu_0) &\overset{\text{def}}{=} \{(z,t) \in \Gamma_T^{(s)}(\kappa_0,\nu_0) \colon \Re\mathfrak{e}\, t = r\} \\ &= \Pi^{(r')}(\kappa_0) \times \Sigma^{(r')}(\nu_0), \qquad \text{where } r' = \min\{r,s\}. \end{aligned} \tag{2.6}$$

When discussing the validity of the derivation of (1.2) in §5, we will keep in mind that the regions defined above depend also on $2m$. In particular, we write $\Gamma_T^{(s)}(\kappa_0,\nu_0;2m) \equiv \Gamma_T^{(s)}(\kappa_0,\nu_0)$.

Finally, we denote by $\mathbf{B}(M)$ the open ball in $\mathbb{C}^N$ of radius M centered at the origin, and by $\overline{\mathbf{B}}(M)$ its closure.

Hypothesis. From now on we assume that $T \in (0,\infty]$ is fixed. We impose the following hypotheses on $\mathbf{P}$ and $\mathbf{F}$, respectively:

(H1) $\mathbf{P}$ satisfies (1.4) and (1.5).

(H2) There exist constants $\kappa_0, \nu_0 \in (0,\infty)$, $T_0 \in (0,T]$, and $M_\alpha \in (0,\infty)$, for $|\alpha| \leq \ell$, such that $\mathbf{F}\colon \mathbb{R}^D \times (0,T) \times \mathbb{R}^{N(1+D+\cdots+D^\ell)} \to \mathbb{R}^N$ (or $\mathbb{R}^D \times (0,T) \times \mathbb{C}^{N(1+D+\cdots+D^\ell)} \to \mathbb{C}^N$) possesses a holomorphic continuation $\mathbf{F}(x+iy, \sigma+i\tau, (\boldsymbol{\xi}_\alpha + i\boldsymbol{\eta}_\alpha)_{|\alpha|\leq\ell})$ into the region (cf. (2.5))

$$\Omega_{\mathbf{F}} = \Gamma_T^{(T_0)}(\kappa_0,\nu_0) \times \prod_{|\alpha|\leq\ell} \mathbf{B}(M_\alpha) \subset (\mathbb{C}^D \times \mathbb{C}) \times \mathbb{C}^{N(1+D+\cdots+D^\ell)}$$

such that $\mathbf{F}$ and all partial Fréchet derivatives $\partial\mathbf{F}/\partial\boldsymbol{\zeta}_\alpha$ with respect to $\boldsymbol{\zeta}_\alpha = \boldsymbol{\xi}_\alpha + i\boldsymbol{\eta}_\alpha \in \mathbb{C}^N$, for $|\alpha| \leq \ell$, are bounded in $\Omega_{\mathbf{F}}$.

We set

$$C_{\mathbf{F}} \overset{\text{def}}{=} \sup_{\Omega_{\mathbf{F}}} |\mathbf{F}| < \infty \quad \text{and} \quad C'_{\mathbf{F}} \overset{\text{def}}{=} \max_{|\alpha|\leq\ell} \sup_{\Omega_{\mathbf{F}}} \left|\frac{\partial\mathbf{F}}{\partial\boldsymbol{\zeta}_\alpha}\right| < \infty. \tag{2.7}$$

Of course, a holomorphic continuation into $\Omega_{\mathbf{F}}$ of a real- (or complex-) valued function that is analytic in $\mathbb{R}^D \times (0,T) \times \mathbb{R}^{N(1+D+\cdots+D^\ell)}$ is always unique, cf. John [21, Chap. 3, §3(c), pp. 70–72]. We refer to Hörmander [17, Chap. 2] for basic facts about complex analysis in several variables.

Remark 2.3. For instance, all constants $M_\alpha \in (0,\infty)$ in Hypothesis (H2) may be chosen arbitrarily large in case $\mathbf{F}(x+iy, \sigma+i\tau, (\boldsymbol{\xi}_\alpha + i\boldsymbol{\eta}_\alpha)_{|\alpha|\leq\ell})$ is an entire function (e.g., a polynomial) in all the variables $\boldsymbol{\zeta}_\alpha = \boldsymbol{\xi}_\alpha + i\boldsymbol{\eta}_\alpha \in \mathbb{C}^N$, $|\alpha| \leq \ell$ having a power series expansion all of whose coefficients are bounded holomorphic functions from $\Gamma_T^{(T_0)}(\kappa_0,\nu_0)$ to $\mathbb{C}^{N\times N}$. It is easy to see that (H2) is true in most practical applications.

The main result in this article can be stated as follows.

THEOREM 2.1. *Let* $\mathbf{P}$ *and* $\mathbf{F}$ *satisfy Hypotheses* (H1) *and* (H2) *above, where* $0 < T_0 \leq T \leq \infty$, $\kappa_0, \nu_0 \in (0,\infty)$, *and* $M_\alpha \in (0,\infty)$ *for* $|\alpha| \leq \ell$. *Then there exist three constants* $\nu'_0 \in [\nu_0,\infty)$, $C_{\mathbf{P}} \equiv C_{\mathbf{P}}(\kappa_0,\nu'_0) \in (1,\infty)$, *and* $T'_0 \in (0,T_0]$ *with the following property:*

Assume that $\mathbf{u}$ *is a weak* L^∞*-solution of our system* (1.1) *in* $\mathbb{R}^D \times (0,T)$ *such that*

$$\operatorname*{ess\,sup}_{\mathbb{R}^D\times(0,T)} \left|\frac{\partial^{|\alpha|}\mathbf{u}}{\partial x^\alpha}\right| \leq M'_\alpha \overset{\text{def}}{=} \frac{M_\alpha}{C_{\mathbf{P}}} \quad \textit{for } |\alpha| \leq \ell. \tag{2.8}$$

Then the function $\mathbf{u}$ *has a holomorphic continuation* $\mathbf{u}(x+iy, \sigma+i\tau)$ *into the region* $\Omega'_{\mathbf{u}} = \Gamma_T^{(T'_0)}(\kappa_0,\nu'_0) \subset \mathbb{C}^D \times \mathbb{C}$ *such that*

$$\sup_{\Omega'_{\mathbf{u}}} \left|\frac{\partial^{|\alpha|}\mathbf{u}}{\partial x^\alpha}\right| < M_\alpha \quad \textit{for } |\alpha| \leq \ell. \tag{2.9}$$

Furthermore, the continuation of $\mathbf{u}$ *satisfies* (1.1) *in* $\Omega'_{\mathbf{u}}$.

The constant $\nu'_0 \in [\nu_0,\infty)$ *is completely determined by* $\mathbf{P}$, *whereas* $C_{\mathbf{P}} \in (1,\infty)$ *is completely determined by* $\mathbf{P}$, κ_0, *and* ν'_0. *In particular, both* ν'_0 *and* $C_{\mathbf{P}}$ *are independent from the nonlinearity* $\mathbf{F}$ *and* M_α.

Remark 2.4. Strictly speaking, in Theorem 2.1 we do not need the existence of a weak L^∞-solution $\mathbf{u}$ of (1.1) in $\mathbb{R}^D \times (0,T)$. We need only the a priori bounds (2.8). Nevertheless, in our proof of Theorem 2.1 we will need the uniqueness of a weak L^∞-solution of (1.1), subject to a given initial condition. In case the a priori bounds

(2.8) can be established for a particular weak L^∞-solution $\mathbf{u}$ of (1.1) in $\mathbb{R}^D \times (0,T)$, subject to a given initial condition $\mathbf{u}(\cdot,0) = \mathbf{u}_0(\cdot) \in \mathbf{L}^\infty(\mathbb{R}^D)$, then the existence and uniqueness of such a solution is obtained by a well-known contraction mapping argument (identical with ours in the proof of Theorem 3.1, Step 4, except for the choice of space) in a closed ball in the Sobolev space $\mathcal{W}^{\ell,\infty} \equiv \mathcal{W}^{\ell,\infty}(\mathbb{R}^D \times (0,T))$. Here, $\mathcal{W}^{\ell,\infty}$ consists of all functions $\mathbf{f}\colon \mathbb{R}^D \times (0,T) \to \mathbb{C}^N$ of $(x,t) \in \mathbb{R}^D \times (0,T)$ such that $\mathbf{f}$ satisfies Conditions (i) and (ii) from Definition 2.1. Regarding the derivatives in Condition (i) as distributions, we observe that $\mathcal{W}^{\ell,\infty}$ is isomorphic to a closed linear subspace of the L^∞-product space $(\mathbf{L}^\infty(\mathbb{R}^D \times (0,T)))^{1+D+\cdots+D^\ell}$, the isomorphism being defined by $\mathbf{f} \mapsto (\partial^{|\alpha|}\mathbf{f}/\partial x^\alpha)_{|\alpha|\le\ell}$. In particular, $\mathcal{W}^{\ell,\infty}$ is a complex Banach space endowed with the norm

$$(2.10)\qquad \|\mathbf{f}\|_{\mathcal{W}^{\ell,\infty}} \overset{\text{def}}{=} \max_{|\alpha|\le\ell} \operatorname*{ess\,sup}_{\mathbb{R}^D\times(0,T)} \left|\frac{\partial^{|\alpha|}\mathbf{f}}{\partial x^\alpha}\right|.$$

Notice that $\mathcal{W}^{0,\infty}$ is a proper, closed linear subspace of $\mathbf{L}^\infty(\mathbb{R}^D \times (0,T))$.

We refer to Stein [33, Chap. V] for the basic theory of Sobolev spaces.

Remark 2.5. By Definition 2.1 and Remark 2.1, the inequalities (2.8) imply that the initial value $\mathbf{u}_0$ of a weak L^∞-solution of (1.1) satisfies $\partial^{|\alpha|}\mathbf{u}_0/\partial x^\alpha \in \mathbf{L}^\infty(\mathbb{R}^D)$ for all $|\alpha| \le \ell$, together with

$$(2.11)\qquad \operatorname*{ess\,sup}_{\mathbb{R}^D}\left|\frac{\partial^{|\alpha|}\mathbf{u}_0}{\partial x^\alpha}\right| \le M'_\alpha \overset{\text{def}}{=} \frac{M_\alpha}{C_{\mathbf{P}}} \qquad \text{for } |\alpha| \le \ell.$$

Only these bounds, not (2.8), will be used in our proof of the local (in time) version of Theorem 2.1 below, i.e., Theorem 3.1, for some $T = T_0 = T'_0 \in (0,\infty)$ small enough. The bounds (2.8) will be used subsequently to extend the local solution to the entire time interval $(0,T)$.

Remark 2.6. In Theorem 2.1 above we have specified also the dependence of the constants $A' \equiv A'(T')$ and $B' \equiv B'(T')$ upon $T' \in (0,T)$, used in its weaker version, Theorem 1.1. We have $A'(T') = (\kappa_0 T')^{1/2m}$ and $B'(T') = T'/\nu'_0$ for $T' \in (0,T'_0)$, and $A'(T') = (\kappa_0 T'_0)^{1/2m}$ and $B'(T') = T'_0/\nu'_0$ for $T' \in [T'_0,T)$. In general, we cannot take $T' = 0$ unless $A' = 0$ or $B' = 0$, even if the nonlinear system (1.1) takes the following simple form:

$$(2.12)\qquad \begin{aligned} \frac{\partial u}{\partial t} - \frac{\partial^2 u}{\partial x^2} &= 0 \quad \text{for } (x,t) \in \mathbb{R} \times (0,\infty),\\ u(x,0) &= u_0(x) \quad \text{for } x \in \mathbb{R}. \end{aligned}$$

The function (cf. John [21, Chap. 7, §1(a), p. 213])

$$u(x,t) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{x/\sqrt{4t}} e^{-\xi^2}\, d\xi, \qquad (x,t) \in \mathbb{R} \times (0,\infty)$$

is a real analytic solution to (2.12) satisfying $0 < u < 1$ in $\mathbb{R} \times (0,\infty)$ and $u(x,t) \to u_0(x)$ as $t \to 0+$, for every $x \in \mathbb{R}$, where

$$u_0(x) = \begin{cases} 0 & \text{if } x < 0,\\ 1/2 & \text{if } x = 0,\\ 1 & \text{if } x > 0. \end{cases}$$

We take $\ell = 0$ in Theorem 2.1 since there is no nonlinearity. By Cauchy's theorem (path independence of the integral), the holomorphic continuation of u into the region $\mathbb{C} \times ((0,\infty) + i\mathbb{R})$ is given by

$$u(x+iy,t) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{x/\sqrt{4t}} e^{-\xi^2}\, d\xi + \frac{1}{\sqrt{\pi}} \int_0^{y/\sqrt{4t}} e^{-((x/\sqrt{4t})+i\eta)^2}\, d\eta \tag{2.13}$$
$$\text{for } (x+iy,t) \in \mathbb{C} \times \mathbb{C} \text{ with } \mathfrak{Re}\, t > 0.$$

It is easy to see that the second integral is unbounded as $t \to 0+$, $t \in \mathbb{R}$, for any fixed $x+iy \in \mathbb{C}$ with $y \neq 0$. Furthermore, its upper bound $y/\sqrt{4(\sigma+i\tau)}$ clearly shows the optimality of our choice of a region in which $u(x+iy, \sigma+i\tau)$ is bounded.

We now return to Example 1.1 to illustrate a possible choice of the constant $\nu_0' \in [\nu_0, \infty)$ in Theorem 2.1 above.

Example 2.1. Let us consider system (1.3) again. The Green's function $\mathbf{G}(x,x';t)$ corresponding to the linear initial value problem

$$\frac{\partial \mathbf{u}}{\partial t} - \begin{pmatrix} 1 & -\nu \\ \nu & 1 \end{pmatrix} \Delta \mathbf{u} = \mathbf{0} \quad \text{for } (x,t) \in \mathbb{R}^D \times (0,\infty), \tag{2.14}$$
$$\mathbf{u}(x,0) = \mathbf{u}_0(x) \quad \text{for } x \in \mathbb{R}^D$$

is given by the formula (cf. John [21, Chap. 7, §1(a), p. 209])

$$\mathbf{G} = \begin{pmatrix} G_1 & -G_2 \\ G_2 & G_1 \end{pmatrix}, \quad \text{where } G_1 = \mathfrak{Re}\, G,\ G_2 = \mathfrak{Im}\, G \text{ and} \tag{2.15}$$
$$G(x,x';t) \equiv G(x-x';t) \overset{\text{def}}{=} (4\pi(1+i\nu)t)^{-D/2} \exp\Big(-\frac{|x-x'|^2}{4(1+i\nu)t}\Big)$$
$$\text{for } x, x' \in \mathbb{R}^D \text{ and } t \in (0,\infty).$$

Hence, the solution of the Cauchy problem (2.14) is given by the convolution $\mathbf{u}(t) = \mathbf{G}(\cdot;t) * \mathbf{u}_0$ for $t \geq 0$. Given any $s \in (0,\infty)$ fixed, the family of functions $|G(\cdot;t)|$, for $t = s+i\tau \in \Sigma^{(s)}(\nu_0')$, has a common integrable majorant over $\mathbb{R}^D$ if and only if there is a constant $\gamma > 0$ such that $\gamma\, \mathfrak{Re}((1+i\nu)t) = \gamma(s-\nu\tau) > s$ for every $t \in \Sigma^{(s)}(\nu_0')$. This is the case if and only if $|\nu| < \nu_0'$. Then such a majorant can be taken to be the function $Cs^{-D/2}\exp(-\gamma|\cdot|^2/s)$, where $C \in (0,\infty)$ is a constant. Moreover, if $|\nu| < \nu_0'$ and $\kappa_0 \in (0,\infty)$ is arbitrary, we can choose the constants $\gamma, C \in (0,\infty)$ so that the holomorphic continuation of G to $\Lambda^{(\infty)}(\kappa_0, \nu_0')$, cf. (2.3), satisfies

$$|G(z;t)| \leq C\sigma^{-D/2} e^{-\gamma|x|^2/\sigma}, \quad (z,t) = (x+iy, \sigma+i\tau) \in \Lambda^{(\infty)}(\kappa_0, \nu_0'). \tag{2.16}$$

This estimate plays a crucial role in our proof of Theorem 2.1. It provides the following bound on the holomorphic continuation to $\Lambda^{(\infty)}(\kappa_0, \nu_0')$ of the solution $\mathbf{u}$ of (2.14):

$$|\mathbf{u}(z,t)| \leq C_1 \operatorname*{ess\,sup}_{\mathbb{R}^D} |\mathbf{u}_0| \quad \text{for } (z,t) \in \Lambda^{(\infty)}(\kappa_0, \nu_0'), \tag{2.17}$$

where $C_1 \in (0,\infty)$ is a constant independent from $\mathbf{u}_0 \in \mathbf{L}^\infty(\mathbb{R}^D)$.

3. Proof of the main result. We implement our contraction-mapping argument (Banach's fixed-point theorem) in a closed ball in a Hardy space H^∞. Given any open set Ω in a complex Euclidean space, we write $\mathbf{H}^\infty(\Omega) = H^\infty(\Omega \to \mathbb{C}^N)$ to denote the Hardy space of all bounded holomorphic functions $\mathbf{f} = (f_1, \dots, f_N)\colon \Omega \to \mathbb{C}^N$

endowed with the $\mathbf{L}^\infty$-norm $\|\mathbf{f}\|_\infty$. It is well known that $\mathbf{H}^\infty(\Omega)$ is a closed linear subspace of $\mathbf{L}^\infty(\Omega)$, cf. Hörmander [17, Thm. 2.2.3].

Given $0 < T_0' \le T \le \infty$, $\kappa_0, \nu_0' \in (0,\infty)$, and an integer $\ell \in [0, 2m)$, we set $\mathcal{L}^\infty \overset{\text{def}}{=} \mathbf{L}^\infty(\Gamma_T^{(T_0')}(\kappa_0,\nu_0'))$, cf. (2.5), and define $\mathcal{H}^{\ell,\infty} \equiv \mathcal{H}^{\ell,\infty}(\Gamma_T^{(T_0')}(\kappa_0,\nu_0'))$ to be the space of all bounded holomorphic functions $\mathbf{f}\colon \Gamma_T^{(T_0')}(\kappa_0,\nu_0') \to \mathbb{C}^N$ of $(z,t) = (x+iy, \sigma+i\tau) \in \mathbb{C}^D \times \mathbb{C}$ such that $\mathbf{f}$ satisfies the following two conditions (cf. Definition 2.1):

(i) $\partial^{|\alpha|}\mathbf{f}/\partial z^\alpha \in \mathbf{L}^\infty(\Gamma_T^{(T_0')}(\kappa_0,\nu_0'))$ for $|\alpha| \le \ell$.

(ii) The restriction $t \in (0,T) \mapsto \mathbf{f}(\cdot,t) \in \mathbf{L}^\infty(\mathbb{R}^D)$ is a weakly* continuous function of t with a weak*-limit $\mathbf{f}(\cdot,0) \in \mathbf{L}^\infty(\mathbb{R}^D)$ as $t \to 0+$. The function $\mathbf{f}_0 = \mathbf{f}(\cdot,0)$ is called the *initial value* of $\mathbf{f}$.

Regarding these derivatives as distributions, we observe that $\mathcal{H}^{\ell,\infty}$ is isomorphic to a closed linear subspace of the L^∞-product space $(\mathcal{L}^\infty)^{1+D+\cdots+D^\ell}$, the isomorphism being defined by $\mathbf{f} \mapsto (\partial^{|\alpha|}\mathbf{f}/\partial z^\alpha)_{|\alpha|\le\ell}$. In particular, $\mathcal{H}^{\ell,\infty}$ is a complex Banach space endowed with the norm

$$\|\mathbf{f}\|_{\mathcal{H}^{\ell,\infty}} \overset{\text{def}}{=} \max_{|\alpha|\le\ell} \sup_{\Gamma_T^{(T_0')}(\kappa_0,\nu_0')} \left|\frac{\partial^{|\alpha|}\mathbf{f}}{\partial z^\alpha}\right|. \tag{3.1}$$

Notice that $\mathcal{H}^{0,\infty}$ is a proper, closed linear subspace of $\mathbf{H}^\infty(\Gamma_T^{(T_0')}(\kappa_0,\nu_0'))$.

Proof of Theorem 2.1. In the conclusion of Theorem 2.1 we claim that $T_0' \in (0,T_0]$ is a constant independent from $\mathbf{u}$, provided $\mathbf{u}$ satisfies the bounds (2.8) for $|\alpha| \le \ell$. In other words, only L^∞-bounds on the partial derivatives $\partial^{|\alpha|}\mathbf{u}/\partial x^\alpha$ in $\mathbb{R}^D \times (0,T)$, for $|\alpha| \le \ell$, influence the value of T_0', but not $\mathbf{u}$ itself. Consequently, if we can prove the local (in time) version of Theorem 2.1, claiming that $\mathbf{u}$ admits a holomorphic continuation with the desired properties into a region (cf. (2.5))

$$\begin{aligned}\Omega_{\mathbf{u}}' = \Gamma_{T_0'}^{(T_0')}(\kappa_0,\nu_0') = \Lambda^{(T_0')}(\kappa_0,\nu_0') = \{&(x+iy, \sigma+i\tau) \in \mathbb{C}^D \times \mathbb{C}\colon \\ &(x,\sigma) \in \mathbb{R}^D \times (0,T_0'),\ |y|^{2m} < \kappa_0\sigma \text{ and } \nu_0'|\tau| < \sigma\},\end{aligned} \tag{3.2}$$

for some $T_0' \in (0,T_0]$ sufficiently small, then by uniqueness (cf. Remark 2.4) we can extend $\mathbf{u}$ from $\Lambda^{(T_0')}(\kappa_0,\nu_0')$ to all its time r translations $\Lambda_r^{(T_0')}(\kappa_0,\nu_0')$, for $0 \le r \le T - T_0'$, in order to obtain the full conclusion of Theorem 2.1. Thus, it suffices to prove the following local result, where we may take $T = T_0 \in (0,\infty)$.

THEOREM 3.1. *Let* $\mathbf{P}$ *and* $\mathbf{F}$ *satisfy Hypotheses* (H1) *and* (H2), *where* $0 < T_0 = T < \infty$ *and* $\kappa_0, \nu_0, M_\alpha \in (0,\infty)$. *Then there exist three constants* $\nu_0' \in [\nu_0,\infty)$, $C_{\mathbf{P}} \equiv C_{\mathbf{P}}(\kappa_0,\nu_0') \in (1,\infty)$, *and* $T_0' \in (0,T_0]$ *with the following property:*

Assume that $\mathbf{u}_0 \in \mathbf{L}^\infty(\mathbb{R}^D)$ *satisfies* $\partial^{|\alpha|}\mathbf{u}_0/\partial x^\alpha \in \mathbf{L}^\infty(\mathbb{R}^D)$ *for* $|\alpha| \le \ell$, *together with*

$$\operatorname*{ess\,sup}_{\mathbb{R}^D}\left|\frac{\partial^{|\alpha|}\mathbf{u}_0}{\partial x^\alpha}\right| \le M_\alpha' \overset{\text{def}}{=} \frac{M_\alpha}{C_{\mathbf{P}}} \quad \textit{for } |\alpha| \le \ell. \tag{3.3}$$

Then there exists a unique weak L^∞*-solution* $\mathbf{u}$ *of our system* (1.1) *in* $\mathbb{R}^D \times (0,T_0')$ *such that the initial condition* $\mathbf{u}(\cdot,0) = \mathbf{u}_0 \in \mathbf{L}^\infty(\mathbb{R}^D)$ *and the bounds* $\|\partial^{|\alpha|}\mathbf{u}/\partial x^\alpha\|_\infty < M_\alpha$ *for* $|\alpha| \le \ell$ *are satisfied, and moreover, the function* $\mathbf{u}$ *has a holomorphic continuation* $\mathbf{u}(x+iy, \sigma+i\tau)$ *into the region* $\Omega_{\mathbf{u}}' = \Lambda^{(T_0')}(\kappa_0,\nu_0') \subset \mathbb{C}^D \times \mathbb{C}$ *satisfying the bounds* (2.9). *Furthermore, the continuation of* $\mathbf{u}$ *satisfies* (1.1) *in* $\Omega_{\mathbf{u}}'$.

The constant $\nu_0' \in [\nu_0, \infty)$ is completely determined by $\mathbf{P}$, whereas $C_{\mathbf{P}} \in (1, \infty)$ is completely determined by $\mathbf{P}$, κ_0, and ν_0'. In particular, both ν_0' and $C_{\mathbf{P}}$ are independent from the nonlinearity $\mathbf{F}$ and M_α.

Proof of Theorem 3.1. Let $T = T_0 \in (0, \infty)$ be fixed. We divide the proof into four steps.

Step 1. We start with the following three lemmas which are concerned with the Green function $\mathbf{G}(x, x'; t) \equiv \mathbf{G}(x - x'; t) \in \mathbb{C}^{N \times N}$, for $(x, x', t) \in \mathbb{R}^D \times \mathbb{R}^D \times (0, \infty)$, corresponding to the linear initial value problem

$$\begin{aligned} \frac{\partial \mathbf{u}}{\partial t} + \mathbf{P}\Big(\frac{1}{i}\frac{\partial}{\partial x}\Big)\mathbf{u} = \mathbf{0} \quad &\text{for } (x, t) \in \mathbb{R}^D \times (0, T), \\ \mathbf{u}(x, 0) = \mathbf{u}_0(x) \quad &\text{for } x \in \mathbb{R}^D. \end{aligned} \tag{3.4}$$

It is well known that $\mathbf{G}(x; t)$ is given by the inverse Fourier transform

$$\mathbf{G}(x; t) = (2\pi)^{-D} \int_{\mathbb{R}^D} e^{ix\cdot\xi} e^{-t\mathbf{P}(\xi)}\, d\xi \quad \text{for } (x, t) \in \mathbb{R}^D \times (0, \infty). \tag{3.5}$$

Recall that $\mathbf{P}(\xi) = \sum_{|\alpha| \le 2m} \xi^\alpha \mathbf{P}^{(\alpha)} \in \mathbb{C}^{N \times N}$ by (1.4), where $\xi^\alpha = \xi_1^{\alpha_1} \dots \xi_D^{\alpha_D}$. An extensive treatment of the Green function is offered in Hörmander [19, Chaps. 10 and 11].

LEMMA 3.2. *There exist constants $\nu_0' \in (0, \infty)$ and $c' \in \mathbb{R}$ with the following property: Given any $\kappa_0 \in (0, \infty)$, the function $\mathbf{G}\colon \mathbb{R}^D \times (0, \infty) \to \mathbb{C}^{N \times N}$ has a holomorphic continuation $\mathbf{G}(x + iy; \sigma + i\tau)$ into the region $\Lambda^{(\infty)}(\kappa_0, \nu_0')$ such that*

$$\Big|\frac{\partial^{|\alpha|}}{\partial z^\alpha}\mathbf{G}(z; t)\Big| \le C_n(\kappa_0, \nu_0') e^{c'\sigma} \sigma^{-(D+|\alpha|)/2m} \Big(1 + \frac{|x|}{\sigma^{1/2m}}\Big)^{-n} \tag{3.6}$$

$$\textit{for all } (z, t) = (x + iy, \sigma + i\tau) \in \Lambda^{(\infty)}(\kappa_0, \nu_0') \textit{ and } |\alpha| \le \ell,$$

where $C_n \equiv C_n(\kappa_0, \nu_0') \in (0, \infty)$ is a constant for every $n = 0, 1, 2, \dots$.

Proof. Making use of the Fourier representation (3.5), we obtain the conclusion of the present lemma from Proposition A.4 in the Appendix. For system (1.3) one obtains an easy proof of Lemma 3.2 directly from (2.15). □

We set

$$C_{\mathbf{G}}' \equiv C_{\mathbf{G}}'(\kappa_0, \nu_0') \overset{\text{def}}{=} C_{D+1}(\kappa_0, \nu_0') e^{c'T_0} \int_{\mathbb{R}^D} (1 + |x|)^{-D-1}\, dx \in (0, \infty). \tag{3.7}$$

Now let $T_0' \in (0, \infty)$ be a constant to be determined later. In the situation of Lemma 3.2 we define a mapping $\mathcal{G}\colon \mathbf{L}^\infty(\mathbb{R}^D) \to \mathbf{L}^\infty(\Lambda^{(T_0')}(\kappa_0, \nu_0'))$ by

$$(\mathcal{G}\mathbf{f})(z, t) \overset{\text{def}}{=} \int_{\mathbb{R}^D} \mathbf{G}(z - x'; t)\mathbf{f}(x')\, dx' \tag{3.8}$$

$$\text{for } (z, t) \in \Lambda^{(T_0')}(\kappa_0, \nu_0') \text{ and } \mathbf{f} \in \mathbf{L}^\infty(\mathbb{R}^D).$$

LEMMA 3.3. *The mapping $\mathcal{G}$ is an everywhere-defined, bounded linear operator from $\mathbf{L}^\infty(\mathbb{R}^D)$ to $\mathcal{H}^{0,\infty}(\Lambda^{(T_0')}(\kappa_0, \nu_0'))$ satisfying*

$$\Big|\frac{\partial^{|\alpha|}}{\partial z^\alpha}(\mathcal{G}\mathbf{f})(z, t)\Big| \le C_{\mathbf{G}}'(\kappa_0, \nu_0')\sigma^{-|\alpha|/2m} \operatorname*{ess\,sup}_{\mathbb{R}^D} |\mathbf{f}| \tag{3.9}$$

$$\textit{for } (z, t) = (z, \sigma + i\tau) \in \Lambda^{(T_0')}(\kappa_0, \nu_0'),\ |\alpha| \le \ell \textit{ and } \mathbf{f} \in \mathbf{L}^\infty(\mathbb{R}^D).$$

Proof. Complex analyticity of $\mathcal{G}\mathbf{f}$ as well as the bounds (3.9) follow from Lemma 3.2. It remains to show that the restriction of $\mathcal{G}\mathbf{f}$ to $\mathbb{R}^D \times (0, T_0')$ satisfies

$$\operatorname*{weak^*\text{-}lim}_{t\to 0+}[(\mathcal{G}\mathbf{f})(\cdot,t)] = \mathbf{f} \quad \text{in } \mathbf{L}^\infty(\mathbb{R}^D),$$

or equivalently,

$$\text{(3.10)} \quad \int_{\mathbb{R}^D} \mathbf{g}(x)\cdot(\mathcal{G}\mathbf{f})(x,t)\,dx \to \int_{\mathbb{R}^D} \mathbf{g}(x)\cdot\mathbf{f}(x)\,dx \quad \text{as } t\to 0+ \quad \text{for all } \mathbf{g}\in\mathbf{L}^1(\mathbb{R}^D).$$

Since we have already established the bounds (3.9), it suffices to prove (3.10) for all $\mathbf{g}$ from a (strongly) dense set $\mathbf{S}^1 \subset \mathbf{L}^1(\mathbb{R}^D)$ and for all $\mathbf{f}$ from a weak*-dense set $\mathbf{S}^\infty \subset \mathbf{L}^\infty(\mathbb{R}^D)$. Because the Fourier transformation $\mathcal{F}$ multiplied by $(2\pi)^{-D/2}$ is a unitary operator on the Hilbert space $\mathbf{L}^2(\mathbb{R}^D) = L^2(\mathbb{R}^D \to \mathbb{C}^N)$, we choose $\mathbf{S}^1 = \mathbf{L}^1(\mathbb{R}^D)\cap\mathbf{L}^2(\mathbb{R}^D)$ and $\mathbf{S}^\infty = \mathbf{L}^\infty(\mathbb{R}^D)\cap\mathbf{L}^2(\mathbb{R}^D)$. Then, for $(\mathbf{g},\mathbf{f})\in\mathbf{S}^1\times\mathbf{S}^\infty$, we compute as follows (cf. (3.5)):

$$\begin{aligned}\int_{\mathbb{R}^D} \mathbf{g}(x)\cdot(\mathcal{G}\mathbf{f})(x,t)\,dx &= \int_{\mathbb{R}^D}\int_{\mathbb{R}^D} \mathbf{g}(x)\cdot[\mathbf{G}(x-x';t)\mathbf{f}(x')]\,dx\,dx' \\ &= (2\pi)^{-D}\int_{\mathbb{R}^D}\int_{\mathbb{R}^D}\int_{\mathbb{R}^D} e^{i(x-x')\cdot\xi}\mathbf{g}(x)\cdot[e^{-t\mathbf{P}(\xi)}\mathbf{f}(x')]\,dx\,dx'\,d\xi \\ &= \int_{\mathbb{R}^D} (\mathcal{F}^{-1}\mathbf{g})(\xi)\cdot[e^{-t\mathbf{P}(\xi)}(\mathcal{F}\mathbf{f})(\xi)]\,d\xi \xrightarrow{t\to 0+} \int_{\mathbb{R}^D}(\mathcal{F}^{-1}\mathbf{g})(\xi)\cdot(\mathcal{F}\mathbf{f})(\xi)\,d\xi \\ &= \int_{\mathbb{R}^D} \mathbf{g}(x)\cdot\mathbf{f}(x)\,dx.\end{aligned}$$

All integrals in this computation are absolutely convergent. Consequently, we have also proved $\mathcal{G}f \in \mathcal{H}^{0,\infty}(\Lambda^{(T_0')}(\kappa_0,\nu_0'))$ for every $\mathbf{f}\in\mathbf{L}^\infty(\mathbb{R}^D)$. □

Imposing an analyticity hypothesis on $\mathbf{f}$ we can extend the estimate (3.9) from Lemma 3.3 as follows.

LEMMA 3.4. *For all $s\in(0,T_0')$ and $\mathbf{f}\in\mathbf{H}^\infty(\Pi^{(s)}(\kappa_0))$, we have*

$$\text{(3.11)} \quad \left|\frac{\partial^{|\alpha|}}{\partial z^\alpha}(\mathcal{G}\mathbf{f})\Big(z,\Big(1-\frac{s}{\sigma}\Big)t\Big)\right| \le C_{\mathbf{G}}'(\kappa_0,\nu_0')\sigma^{-|\alpha|/2m}\sup_{\Pi^{(s)}(\kappa_0)}|\mathbf{f}|$$

for $(z,t)\in\Lambda^{(T_0')}(\kappa_0,\nu_0')$ with $\sigma = \Re\mathfrak{e}\, t > s$, and for $|\alpha|\le\ell$.

Proof. Fix any $s\in(0,T_0')$ and $(z,t) = (x+iy,\sigma+i\tau)\in\Lambda^{(T_0')}(\kappa_0,\nu_0')$ with $s<\sigma$. Set $\theta = s/\sigma\in(0,1)$. By (3.8), the integrand

$$\text{(3.12)} \qquad x'\in\mathbb{R}^D \mapsto \frac{\partial^{|\alpha|}}{\partial z^\alpha}\mathbf{G}(z-x';(1-\theta)t)\mathbf{f}(x')\in\mathbb{C}^N$$

of the integral $\frac{\partial^{|\alpha|}}{\partial z^\alpha}(\mathcal{G}\mathbf{f})(z,(1-\theta)t)$ has a holomorphic continuation to the region $\Pi^{(s)}(\kappa_0)$, cf. (2.1). The continuation $\mathbf{G}(z-x'-iy';(1-\theta)t)$ of $\mathbf{G}(z-x';(1-\theta)t)$ to $\Pi^{(s)}(\kappa_0)$ satisfies the bounds (3.6) with κ_0 replaced by $(1-\theta)^{-1}\kappa_0$. (Notice that the constant $C_n((1-\theta)^{-1}\kappa_0,\nu_0')$, for $n=0,1,2,\ldots$, may be unbounded as $\theta\to 1-$, and so is $C_{\mathbf{G}}'((1-\theta)^{-1}\kappa_0,\nu_0')$.) Using the decay of the continuation of the integrand

(3.12) as $|x'| \to \infty$, uniformly in $|y'|^{2m} < (1-\theta)^{-1}\kappa_0(1-\theta)\sigma = \kappa_0\sigma$, where $z' = x' + iy' \in \mathbb{C}^D$, we are able to apply Cauchy's theorem (coordinatewise) to shift the domain of integration from $\mathbb{R}^D$ to $\mathbb{R}^D + iy'$, for any fixed $y' \in \mathbb{R}^D$ with $|y'|^{2m} < \kappa_0 s$. We arrive at

(3.13)
$$\begin{aligned}\frac{\partial^{|\alpha|}}{\partial z^\alpha}(\mathcal{G}\mathbf{f})(z,(1-\theta)t) &= \int_{\mathbb{R}^D}\left[\frac{\partial^{|\alpha|}}{\partial z^\alpha}\mathbf{G}(z-x';(1-\theta)t)\right]\mathbf{f}(x')\,dx' \\ &= \int_{\mathbb{R}^D}\left[\frac{\partial^{|\alpha|}}{\partial z^\alpha}\mathbf{G}(z-x'-iy';(1-\theta)t)\right]\mathbf{f}(x'+iy')\,dx'.\end{aligned}$$

Since $(z,t) = (x+iy,\sigma+i\tau) \in \Lambda^{(T_0')}(\kappa_0,\nu_0')$ implies $|y|^{2m} < \kappa_0\sigma$, we choose $y' = \theta^{1/2m}y = (s/\sigma)^{1/2m}y$. Hence $|y'|^{2m} < \kappa_0 s$, and consequently $z' = x' + iy' \in \Pi^{(s)}(\kappa_0)$ for all $x' \in \mathbb{R}^D$. On the other hand, we have

$$z - z' = x - x' + i(y-y') = x - x' + i(1-\theta^{1/2m})y \equiv x'' + iy'',$$

where

$$|y''|^{2m} = (1-\theta^{1/2m})^{2m}|y|^{2m} < (1-\theta^{1/2m})^{2m}\kappa_0\sigma \le (1-\theta)\kappa_0\sigma = \kappa_0(\sigma - s).$$

Thus $(z-z',(1-\theta)t) \in \Lambda^{(T_0')}(\kappa_0,\nu_0')$, so we may apply the bounds (3.6) to the integrand in the second integral in (3.13) above to obtain the desired estimate (3.11). □

Step 2. Next we treat two linear operators that appear in the variation-of-constants formula for a weak L^∞-solution of system (1.1). Given $0 < T_0' \le T_0 = T < \infty$, we recall and adjust our notation

$$\mathcal{L}^\infty \overset{\text{def}}{=} \mathbf{L}^\infty(\Gamma_{T_0'}^{(T_0')}(\kappa_0,\nu_0')) = \mathbf{L}^\infty(\Lambda^{(T_0')}(\kappa_0,\nu_0'))$$

and

$$\mathcal{H}^{\ell,\infty} \equiv \mathcal{H}^{\ell,\infty}(\Gamma_{T_0'}^{(T_0')}(\kappa_0,\nu_0')) = \mathcal{H}^{\ell,\infty}(\Lambda^{(T_0')}(\kappa_0,\nu_0')).$$

Recalling (2.2), we write

(3.14) $\Sigma_{\cup}^{(T_0')}(\nu_0') = \cup\{\Sigma^{(s)}(\nu_0') \colon s \in (0,T_0')\} = \{\sigma + i\tau \in \mathbb{C} \colon \nu_0'|\tau| < \sigma < T_0'\}$.

Making use of Lemmas 3.3 and 3.4, respectively, we define the mappings $\mathcal{K}_0, \mathcal{K} \colon \mathcal{H}^{0,\infty} \to \mathcal{L}^\infty$ by

(3.15)
$$(\mathcal{K}_0\mathbf{f})(z,t) \overset{\text{def}}{=} \int_{\mathbb{R}^D}\mathbf{G}(z-x';t)\mathbf{f}(x',0)\,dx' = (\mathcal{G}\mathbf{f}(\cdot,0))(z,t)$$

and

(3.16)
$$\begin{aligned}(\mathcal{K}\mathbf{f})(z,t) &\overset{\text{def}}{=} \int_0^t\int_{\mathbb{R}^D}\mathbf{G}(z-x';t-t')\mathbf{f}(x',t')\,dx'\,dt' \\ &= \int_0^t(\mathcal{G}\mathbf{f}(\cdot,t'))(z,t-t')\,dt',\end{aligned}$$

for $(z,t) \in \Lambda^{(T_0')}(\kappa_0,\nu_0')$ and $\mathbf{f} \in \mathcal{H}^{0,\infty}$. By Cauchy's theorem, the last integral $\int_0^t \cdots dt'$ is path independent provided $t' \in \Sigma_{\cup}^{(T_0')}(\nu_0')$, cf. (3.14). We choose the path

$\{t' = \theta t \in \mathbb{C}\colon \theta \in [0,1]\}$. The integrals in (3.15) and (3.16) above converge absolutely as Lebesgue integrals by Lemmas 3.3 and 3.4.

PROPOSITION 3.5. (a) *The mapping $\mathcal{K}_0$ is an everywhere defined, bounded linear operator from $\mathcal{H}^{\ell,\infty}$ into itself satisfying*

$$\text{(3.17)}\quad \left|\frac{\partial^{|\alpha|}}{\partial z^\alpha}(\mathcal{K}_0\mathbf{f})(z,t)\right| \le C'_{\mathbf{G}} \operatorname*{ess\,sup}_{x\in\mathbb{R}^D}\left|\frac{\partial^{|\alpha|}}{\partial x^\alpha}\mathbf{f}(x,0)\right| \le C'_{\mathbf{G}} \sup_{\Lambda^{(T'_0)}(\kappa_0,\nu'_0)}\left|\frac{\partial^{|\alpha|}\mathbf{f}}{\partial z^\alpha}\right|$$

$$\textit{for } (z,t) \in \Lambda^{(T'_0)}(\kappa_0,\nu'_0),\ |\alpha| \le \ell \textit{ and } \mathbf{f} \in \mathcal{H}^{\ell,\infty}.$$

(b) *The mapping $\mathcal{K}$ is an everywhere defined, bounded, linear operator from $\mathcal{H}^{0,\infty}$ into $\mathcal{H}^{\ell,\infty}$ satisfying*

$$\text{(3.18)}\quad \left|\frac{\partial^{|\alpha|}}{\partial z^\alpha}(\mathcal{K}\mathbf{f})(z,t)\right| \le C'_{\mathbf{G}}(1+(\nu'_0)^2)^{1/2}\left(1-\frac{|\alpha|}{2m}\right)^{-1}(T'_0)^{1-(|\alpha|/2m)} \sup_{\Lambda^{(T'_0)}(\kappa_0,\nu'_0)}|\mathbf{f}|$$

$$\textit{for } (z,t) \in \Lambda^{(T'_0)}(\kappa_0,\nu'_0),\ |\alpha| \le \ell \textit{ and } \mathbf{f} \in \mathcal{H}^{0,\infty}.$$

Proof. (a) Take any $\mathbf{f} \in \mathcal{H}^{\ell,\infty}$ and $|\alpha| \le \ell$. We have $\mathcal{K}_0\mathbf{f} \in \mathcal{H}^{0,\infty}$ by Lemma 3.3. Integration by parts in the convolution integral (3.15), combined with (3.9), yields

$$\text{(3.19)}\quad \left|\frac{\partial^{|\alpha|}}{\partial z^\alpha}(\mathcal{K}_0\mathbf{f})(z,t)\right| = \left|\left(\mathcal{K}_0\frac{\partial^{|\alpha|}\mathbf{f}}{\partial z^\alpha}\right)(z,t)\right| \le C'_{\mathbf{G}} \operatorname*{ess\,sup}_{x\in\mathbb{R}^D}\left|\frac{\partial^{|\alpha|}}{\partial x^\alpha}\mathbf{f}(x,0)\right|$$

$$\text{for } (z,t) \in \Lambda^{(T'_0)}(\kappa_0,\nu'_0).$$

By Remark 2.1, the function $t \in (0,T'_0) \mapsto \partial^{|\alpha|}\mathbf{f}(\cdot,t)/\partial x^\alpha \in \mathbf{L}^\infty(\mathbb{R}^D)$ is weakly* continuous with the weak*-limit $\partial^{|\alpha|}\mathbf{f}(\cdot,0)/\partial x^\alpha \in \mathbf{L}^\infty(\mathbb{R}^D)$ as $t \to 0+$. Hence, the duality between $\mathbf{L}^1(\mathbb{R}^D)$ and $\mathbf{L}^\infty(\mathbb{R}^D)$ yields

$$\text{(3.20)}\quad \operatorname*{ess\,sup}_{x\in\mathbb{R}^D}\left|\frac{\partial^{|\alpha|}}{\partial x^\alpha}\mathbf{f}(x,0)\right| \le \liminf_{t\to 0+}\ \operatorname*{ess\,sup}_{x\in\mathbb{R}^D}\left|\frac{\partial^{|\alpha|}}{\partial x^\alpha}\mathbf{f}(x,t)\right| \le \sup_{\Lambda^{(T'_0)}(\kappa_0,\nu'_0)}\left|\frac{\partial^{|\alpha|}\mathbf{f}}{\partial z^\alpha}\right|.$$

We combine (3.19) and (3.20) to obtain the estimate (3.17).

(b) Now take any $\mathbf{f} \in \mathcal{H}^{0,\infty}$ and $|\alpha| \le \ell$. By Lemma 3.4, we have $\mathcal{K}\mathbf{f} \in \mathcal{L}^\infty$ and

$$\text{(3.21)}\quad (\mathcal{K}\mathbf{f})(z,t) = t\int_0^1\int_{\mathbb{R}^D}\mathbf{G}(z-x';(1-\theta)t)\mathbf{f}(x',\theta t)\,dx'\,d\theta$$
$$= t\int_0^1(\mathcal{G}\mathbf{f}(\cdot,\theta t))(z,(1-\theta)t)\,d\theta \quad \text{for } (z,t) \in \Lambda^{(T'_0)}(\kappa_0,\nu'_0).$$

By Lemma 3.3, the function $(z,t) \in \Lambda^{(T'_0)}(\kappa_0,\nu'_0) \mapsto (\mathcal{G}\mathbf{f}(\cdot,\theta t))(z,(1-\theta)t) \in \mathbb{C}^N$ belongs to $\mathcal{H}^{0,\infty}$ for every fixed $\theta \in (0,1)$. Consequently, applying Lemma 3.4 to (3.21) we arrive at $\partial^{|\alpha|}(\mathcal{K}\mathbf{f})/\partial z^\alpha \in \mathcal{H}^{0,\infty}$, together with (3.18), as desired. Here we have used that $|\alpha| < 2m$ and $t = \sigma + i\tau \in \Sigma_{\mathrm{U}}^{(T'_0)}(\nu'_0)$ imply $|t|\sigma^{-|\alpha|/2m} \le (1+(\nu'_0)^2)^{1/2}(T'_0)^{1-(|\alpha|/2m)}$. □

Step 3. Making use of well-known arguments from the theory of distributions, we combine Definition 2.1 with Lemma 3.2 to obtain the following variation-of-constants formula: A function $\mathbf{u}\colon \mathbb{R}^D \times (0,T_0') \to \mathbb{C}^N$ is a weak L^∞-solution of system (1.1) if and only if $\mathbf{u}$ satisfies conditions (i), (ii), and (iii) from Definition 2.1, together with the following integral equation:

$$
\begin{aligned}
(3.22)\quad \mathbf{u}(x,t) &= \int_{\mathbb{R}^D} \mathbf{G}(x-x';t)\mathbf{u}(x',0)\,dx' \\
&+ \int_0^t \int_{\mathbb{R}^D} \mathbf{G}(x-x';t-t')\mathbf{F}\Big(x',t',\Big(\frac{\partial^{|\alpha|}}{\partial x^\alpha}\mathbf{u}(x',t')\Big)_{|\alpha|\le \ell}\Big)\,dx'\,dt' \\
&\qquad\qquad \text{for almost every } (x,t) \in \mathbb{R}^D \times (0,T_0').
\end{aligned}
$$

Step 4. Now we are ready to implement our contraction mapping argument. We choose $C_{\mathbf{P}} \equiv C_{\mathbf{P}}(\kappa_0,\nu_0') \stackrel{\text{def}}{=} 1 + C_{\mathbf{G}}'(\kappa_0,\nu_0') \in (1,\infty)$. Next we fix the initial value $\mathbf{u}_0 \in \mathbf{L}^\infty(\mathbb{R}^D)$ satisfying (3.3). For $(z,t) \in \Lambda^{(T_0')}(\kappa_0,\nu_0')$ and $\mathbf{u} \in \mathcal{W}^{\ell,\infty}$ we set

$$
\mathbf{u}_1(z,t) \stackrel{\text{def}}{=} \int_{\mathbb{R}^D} \mathbf{G}(z-x';t)\mathbf{u}_0(x')\,dx'
$$

and

$$
\begin{aligned}
(3.23)\quad (\mathcal{T}(\mathbf{u}))(z,t) &\stackrel{\text{def}}{=} \mathbf{u}_1(z,t) \\
&+ \int_0^t \int_{\mathbb{R}^D} \mathbf{G}(z-x';t-t')\mathbf{F}\Big(x',t',\Big(\frac{\partial^{|\alpha|}}{\partial x^\alpha}\mathbf{u}(x',t')\Big)_{|\alpha|\le \ell}\Big)\,dx'\,dt'.
\end{aligned}
$$

Here, $\mathcal{W}^{\ell,\infty} \equiv \mathcal{W}^{\ell,\infty}(\mathbb{R}^D \times (0,T_0'))$ is the Sobolev space defined in Remark 2.4. Thus, a function $\mathbf{u} \in \mathcal{W}^{\ell,\infty}$ satisfies (3.22) if and only if $\mathcal{T}(\mathbf{u}) = \mathbf{u}$. Combining (2.7) with (3.6) we deduce that $\mathcal{T}$ is a contraction from a closed ball $\overline{\mathcal{B}} \subset \mathcal{W}^{\ell,\infty}$ into itself, provided $T_0' \in (0,T_0]$ is sufficiently small. Our more sophisticated estimates (3.17) and (3.18) from Proposition 3.5 show that $\mathcal{T}$ is also a contraction from a closed ball $\overline{\mathcal{B}} \subset \mathcal{H}^{\ell,\infty}$ into itself, provided $T_0' \in (0,T_0]$ is sufficiently small. We choose $\overline{\mathcal{B}} = \{\mathbf{f} \in \mathcal{H}^{\ell,\infty} \colon \|\mathbf{f} - \mathbf{u}_1\|_{\mathcal{H}^{\ell,\infty}} \le \delta\}$, where $0 < \delta < \min\{M_\alpha' \colon |\alpha| \le \ell\}$. Notice that by (3.9),

$$
\begin{aligned}
(3.24)\qquad \sup_{\Lambda^{(T_0')}(\kappa_0,\nu_0')} \left|\frac{\partial^{|\alpha|}\mathbf{u}_1}{\partial z^\alpha}\right| + \delta &\le C_{\mathbf{G}}' \operatorname*{ess\,sup}_{\mathbb{R}^D}\left|\frac{\partial^{|\alpha|}\mathbf{u}_0}{\partial x^\alpha}\right| + \delta \le C_{\mathbf{G}}' M_\alpha' + \delta \\
&< C_{\mathbf{G}}' M_\alpha' + M_\alpha' = C_{\mathbf{P}} M_\alpha' = M_\alpha \qquad \text{for } |\alpha| \le \ell.
\end{aligned}
$$

In order that $\mathcal{T}$ be a contraction on $\overline{\mathcal{B}}$, the constant $T_0' \in (0,T_0]$ must be chosen so small that, by (2.7) and (3.18),

$$
(3.25)\qquad K C_{\mathbf{F}} \le \delta \quad\text{and}\quad K(1 + D + \cdots + D^\ell)C_{\mathbf{F}}' < 1,
$$

where

$$
K \equiv K(T_0') = C_{\mathbf{G}}'(1 + (\nu_0')^2)^{1/2} \max_{a\in[0,\ell]}\left\{\left(1 - \frac{a}{2m}\right)^{-1}(T_0')^{1-(a/2m)}\right\}.
$$

Observe that $0 < T_0' \le 1$ and $1 - (\ell/2m) > 0$ entail

$$
K(T_0') = C_{\mathbf{G}}'(1 + (\nu_0')^2)^{1/2}\left(1 - \frac{\ell}{2m}\right)^{-1}(T_0')^{1-(\ell/2m)}.
$$

Consequently, the integral equation (3.22) possesses a unique solution $\mathbf{u} \in \overline{\mathcal{B}}$ by Banach's fixed-point theorem. The restriction of $\mathbf{u}$ to $\mathbb{R}^D \times (0, T_0')$ is the unique weak L^∞-solution of system (1.1), the uniqueness being obtained by replacing $\mathcal{H}^{\ell,\infty}$ by $\mathcal{W}^{\ell,\infty}$ above. In the latter case we may replace $\nu_0' > 0$ by $\nu_0' = 0$ in (3.25).

Our proof of Theorem 3.1 is now complete. In Step 4 of this proof we have also justified the reduction of Theorem 2.1 to its local (in time) version, Theorem 3.1.

4. Some generalizations of the main result. We discuss and suggest possible generalizations of our results to a wider class of systems (1.1) involving a much more general pseudodifferential operator as their linear part.

Remark 4.1. It is clear from our auxiliary results (cf. the Appendix) about the Green function corresponding to the linear initial value problem (3.4) that $\mathbf{P}\left(\frac{1}{i}\frac{\partial}{\partial x}\right)$can be replaced by a much more general pseudodifferential operator $\mathbf{P}\left(x, t, \frac{1}{i}\frac{\partial}{\partial x}\right)$, with a matrix-valued symbol $\mathbf{P}(x,t,\xi) \in \mathbb{C}^{N\times N}$ of class C^∞ satisfying certain analyticity hypotheses in $(x,t) \in \mathbb{R}^D \times (0,T)$, growth conditions in $\xi \in \mathbb{R}^D$, and the uniform strong ellipticity condition (in place of inequality (1.5))

$$\Re\mathfrak{e}\left(\sum_{j=1}^{N}\sum_{k=1}^{N} P_{jk}(x,t,\xi)\eta_k\eta_j^*\right) \geq (c_1|\xi|^\mu - c_2)|\eta|^2 \tag{4.1}$$

$$\text{for all } \xi \in \mathbb{R}^D \text{ and } \eta \in \mathbb{C}^N,$$

where $c_1 > 0$, $c_2 \geq 0$ and $\mu > 1$ are some constants. We refer to Trèves [37, Chap. V, §5, pp. 288–299] for details. The nonlinearity $\mathbf{F}$ may depend upon the derivatives $\partial^{|\alpha|}\mathbf{u}/\partial x^\alpha$ of $\mathbf{u}$ up to order ℓ, where $0 \leq \ell < \mu$.

For instance, we may take $\mathbf{P}(x,t,\xi)$ to be an inhomogeneous polynomial in $\xi \in \mathbb{R}^D$ of the form

$$\mathbf{P}(x,t,\xi) = \sum_{n=1}^{D} \xi_n^{2m_n}\mathbf{P}^{(n)}(x,t), \quad \xi = (\xi_1, \dots, \xi_D) \in \mathbb{R}^D,$$

where $m_n \in \mathbb{N}$ and $\mathbf{P}^{(n)}(x,t) \in \mathbb{C}^{N\times N}$ are uniformly strictly positive-definite matrices, i.e., there is a constant $c > 0$ such that, for all $(x,t) \in \mathbb{R}^D \times (0,T)$,

$$\Re\mathfrak{e}\left(\sum_{j=1}^{N}\sum_{k=1}^{N} P_{jk}^{(n)}(x,t)\eta_k\eta_j^*\right) \geq c|\eta|^2 \quad \text{for all } \eta \in \mathbb{C}^N.$$

In this case, the nonlinearity $\mathbf{F}$ may depend upon the derivatives $\partial^{|\alpha|}\mathbf{u}/\partial x^\alpha = \frac{\partial^{|\alpha|}\mathbf{u}}{\partial x_1^{\alpha_1}\dots\partial x_D^{\alpha_D}}$ of $\mathbf{u}$ such that $\alpha_n < 2m_n$ for all $n = 1, \dots, D$.

5. Applications to the validity problem. Here we discuss the validity problem for the complex Ginzburg–Landau equation (1.2).

The main result of this paper (for $2m = 2$) justifies one of the basic assumptions made in van Harten [15] and Bollerman [3]. In these papers, as in e.g. Kirrmann, Schneider, and Mielke [22] and Schneider [31, 32], the validity of the Ginzburg–Landau equation as a universal modulation equation for nonlinear stability problems at near-critical conditions has been studied. In [15] the following general equation is considered:

$$\frac{\partial u}{\partial t} = -\mu\Big(\frac{1}{i}\frac{\partial}{\partial x}; R\Big)u + 2\pi\varrho\Big(\frac{1}{i}\frac{\partial}{\partial x}; R\Big)u^2 \quad \text{for } (x,t) \in \mathbb{R} \times [0,\infty), \tag{5.1}$$
$$u(x,0) = u_0(x) \quad \text{for } x \in \mathbb{R}.$$

Here $\mu\left(\frac{1}{i}\frac{\partial}{\partial x};R\right)$ is again a strongly elliptic linear operator in x of order $2m$, and $\varrho\left(\frac{1}{i}\frac{\partial}{\partial x};R\right)$ is a linear differential operator in x of order $\ell \leq 2m-1$. Both polynomials $\mu(\cdot;R)$ and $\varrho(\cdot;R)$ depend upon a real control parameter R possessing a critical value R_c above which the trivial solution $u \equiv 0$ becomes unstable. By assuming $R = R_c + \varepsilon^2$ with $\varepsilon > 0$ small enough and

$$u(x,t) = 2\varepsilon\,\mathfrak{Re}\big(A(\varepsilon x, \varepsilon^2 t)e^{i(k_c x+\omega t)}\big) + O(\varepsilon^2),$$

it is possible to derive rigorously that the amplitude $A(X,T)$ satisfies the complex Ginzburg–Landau equation

$$(5.2)\quad \frac{\partial A}{\partial T} = (\tau_2 - i\nu_2)\frac{\partial^2 A}{\partial X^2} + (\tau_0 + i\nu_0 - \beta|A|^2)A \quad \text{for } (X,T) \in \mathbb{R}\times(0,T_0).$$

This formal approach is based on an observation of certain physical effects leading to amplitude modulations on a long time scale $T = \varepsilon^2 t$ and a long space scale moving with group velocity $X = \varepsilon(x + \varepsilon\nu_1 t)$. The constants $k_c, \omega, \tau_0, \tau_2, \nu_0, \nu_2 \in \mathbb{R}$ are completely determined by μ, whereas $\beta \in \mathbb{C}$ is completely determined by μ, ρ, k_c, and ω. The constants τ_0 and τ_2 are obtained from the Taylor expansion at $k = k_c$, the critical wavelength, of the form

$$-\mathfrak{Re}\,\mu(k, R_c + \varepsilon^2) = \varepsilon^2\left(\tau_0 - \tau_2\Big(\frac{k-k_c}{\varepsilon}\Big)^2\right) + \cdots,$$

whereas ω, ν_0, and ν_2 are obtained from

$$-\mathfrak{Im}\,\mu(k, R_c + \varepsilon^2) = \omega + \varepsilon^2\left(\nu_0 + \nu_2\Big(\frac{k-k_c}{\varepsilon}\Big)^2\right) + \cdots.$$

In accordance with the physical situation we find out that $\tau_2 > 0$ (whence $-\mathfrak{Re}\,\mu(\cdot,R)$ attains a local maximum at $k = k_c$), which guarantees the strong parabolicity of (5.2). From the point of view of physics, we are studying a marginally unstable basic state; cf. Doelman [6]. In [15] a rigorous proof of the validity of this approximation has been given.

The main result in van Harten [15] can be stated as follows.

THEOREM 5.1. *Let $S_a = \{z = x + iy \in \mathbb{C}\colon |y| < a\}$ for some constant $a \in (0,\infty)$, and $R \equiv R(\varepsilon) = R_c + \varepsilon^2$ for $\varepsilon \in (0,\infty)$.*

(a) *There exists $T_0 > 0$ such that, for any initial value $A(\cdot,0) = A_0\colon \mathbb{R} \to \mathbb{C}$ satisfying*

(i$_0$) *A_0 is holomorphic in S_a and*

(ii$_0$) *$\sup_{Z\in S_a}|A_0(Z)| < \infty$,*

there exists a unique classical solution A of (5.2) *in $\mathbb{R}\times[0,T_0]$ such that*

(i) *$A(\cdot,T)$ is holomorphic in S_a for each $T \in [0,T_0]$, $A\colon S_a\times[0,T_0] \to \mathbb{C}$ is continuous, and*

(ii) *$\sup_{(Z,T)\in S_a\times[0,T_0]}|A(Z,T)| < \infty$.*

(b) *Let A be a solution of* (5.2) *as in* (a), *and for each $\varepsilon > 0$ set*

$$\psi_\varepsilon(z,t) = 2\varepsilon\,\mathfrak{Re}\left(A(\varepsilon z, \varepsilon^2 t)e^{i(k_c z+\omega t)}\right) \quad \textit{for } (z,t) \in S_{a/\varepsilon}\times[0, T_0/\varepsilon^2].$$

Then $\psi_\varepsilon(x+iy,t) \equiv \psi_\varepsilon(x,y,t)$ is a real-valued, real analytic function of $(x,y) \in S_{a/\varepsilon}$, for each $t \in [0,T_0/\varepsilon^2]$, and for each $\varepsilon > 0$ small enough, there exists a solution $u \equiv u_\varepsilon$ of (5.1) *in $\mathbb{R}\times[0,T_0/\varepsilon^2]$ with the following properties:*

(i$_\varepsilon$) *$u_\varepsilon(\cdot,t)$ ($t \in [0,T_0/\varepsilon^2]$) is real analytic in $S_{a'/\varepsilon}$ for $a' \in (0,a)$, $u_\varepsilon\colon S_{a'/\varepsilon} \times [0,T_0/\varepsilon^2] \to \mathbb{R}$ is continuous and bounded, and*

(ii$_\varepsilon$) *there is a constant $C > 0$ independent from ε such that*

$$\sup_{(z,t)\in S_{a'/\varepsilon}\times[0,T_0/\varepsilon^2]} |u_\varepsilon(z,t) - \psi_\varepsilon(z,t)| \le C\varepsilon^2.$$

The proof in [15] is based on an application of a contraction-mapping argument which proves the existence of the remainder term $\varepsilon^2 w_\varepsilon = u_\varepsilon - \psi_\varepsilon$ of order $O(\varepsilon^2)$ by subtracting the appropriate rescaled form of (1.2) from (5.1). The application of the contraction-mapping argument hinges upon making the correct estimates for the operators $\mathcal{K}$ and $\mathcal{K}_\varrho$, where

$$(\mathcal{K}f)(z,t) = \frac{1}{2\pi}\int_0^t \int_{\mathbb{R}} e^{iz\xi} e^{-(t-t')\mu(\xi)} \int_{\mathbb{R}} e^{-ix'\xi} f(x',t')\,dx'\,d\xi\,dt',$$

$$(\mathcal{K}_\varrho f)(z,t) = \frac{1}{2\pi}\int_0^t \int_{\mathbb{R}} e^{iz\xi} e^{-(t-t')\mu(\xi)} \varrho(\xi) \int_{\mathbb{R}} e^{-ix'\xi} f(x',t')\,dx'\,d\xi\,dt'.$$

There are two fundamental assumptions in this theorem.

Assumption 1. The first one is the assumption that A_0, the initial value of the solution A of (5.2), is holomorphic on a strip S_a. Due to the results of the present paper, this analyticity assumption can be weakened significantly, while the conclusion of the theorem can be improved in the following way.

THEOREM 5.2. (a) *There exist positive constants κ_0, ν_0', T_0', and T_0 with $0 < T_0' \le T_0$ and the following property: Given any initial value $A_0 \in L^\infty(\mathbb{R})$, there exists a unique weak L^∞-solution A of* (5.2) *in $\mathbb{R} \times (0,T_0)$ satisfying the initial condition $A(\cdot,0) = A_0$ and such that* $\operatorname{ess\,sup}_{(X,T)\in\mathbb{R}\times(0,T_0)} |A(X,T)| < \infty$. *Furthermore, A has a holomorphic continuation $A(X+iY, S+iT)$ into the region $\Omega_A' = \Gamma_{T_0}^{(T_0')}(\kappa_0,\nu_0';2) \subset \mathbb{C}\times\mathbb{C}$ for which $\sup_{\Omega_A'} |A| < \infty$ is satisfied.*

(b) *Let κ_0, ν_0', T_0', and T_0 be as in* (a), *let A be a solution of* (5.2), *and let*

$$\psi_\varepsilon(z,t) = 2\varepsilon\,\Re\mathfrak{e}\left(A(\varepsilon z,\varepsilon^2 t)e^{i(k_c z+\omega t)}\right)$$

be defined in $\Omega_{\psi_\varepsilon}' = \Gamma_{T_0/\varepsilon^2}^{(T_0'/\varepsilon^2)}(\kappa_0,\nu_0';2)$ for each $\varepsilon > 0$. Assume that

(i) *the initial distribution $A(\cdot,0) = A_0\colon \mathbb{R} \to \mathbb{C}$ has uniformly Lipschitz continuous derivatives up to order $\ell - 1$, and*

(ii) $\operatorname{ess\,sup}_{(X,T)\in\mathbb{R}\times(0,T_0)} |A(X,T)| < \infty$.

Then there exist positive constants $\tilde\kappa_0$, $\tilde\nu_0'$, and $\tilde T_0'$ with $0 < \tilde T_0' \le T_0$ and the following property: For each ε small enough, $0 < \varepsilon \le 1$, there exist a solution $u \equiv u_\varepsilon$ of (5.1) *holomorphic in $\Omega_{u_\varepsilon}' = \Gamma_{T_0/\varepsilon^2}^{(\tilde T_0')}(\tilde\kappa_0,\tilde\nu_0';2m)$ and a constant $C > 0$ independent from ε such that*

$$\sup_{(z,t)\in\Omega_{u_\varepsilon}'\cap\Omega_{\psi_\varepsilon}'} |u_\varepsilon(z,t) - \psi_\varepsilon(z,t)| \le C\varepsilon^2. \tag{5.3}$$

Since the (5.1) and (5.2) have possibly different orders $2m$ and 2, respectively, we have introduced the notation $\Gamma_T^{(s)}(\kappa_0,\nu_0;2m) \equiv \Gamma_T^{(s)}(\kappa_0,\nu_0)$ for $0 \le s \le T \le \infty$; cf. (2.5).

The following few remarks explain some statements made in Theorem 5.2.

Remark 5.1. Conditions (i) and (ii) from Theorem 5.2(b) imply that there exist constants C_n, $0 \leq n \leq \ell$, such that

$$\sup_{\Omega'_A} \left| \frac{\partial^n A}{\partial Z^n} \right| \leq C_n \quad \text{for } n = 0, 1, \ldots, \ell. \tag{5.4}$$

Indeed, assume that the initial distribution $A(\cdot, 0)$ has essentially bounded derivatives up to order ℓ, and A is essentially bounded in $\mathbb{R} \times (0, T_0)$. Define $A_n \stackrel{\text{def}}{=} \frac{\partial^n A}{\partial X^n}$, $n \leq \ell$. Differentiating (5.2) n times with respect to X, $1 \leq n \leq \ell$, we arrive at the following linear system of equations for $\mathfrak{Re}\, A_n$ and $\mathfrak{Im}\, A_n$:

$$\begin{aligned}
&\frac{\partial A_n}{\partial T} = (\tau_2 - i\nu_2) \frac{\partial^2 A_n}{\partial X^2} + (\tau_0 + i\nu_0) A_n \\
&- \beta \left[N_n \left((A_i)_{i \leq n-1}, (A_i^*)_{i \leq n-1} \right) A_n + N_n' \left((A_i)_{i \leq n-1}, (A_i^*)_{i \leq n-1} \right) A_n^* \right] && \text{in } \mathbb{R} \times (0, T_0), \\
&A_n(\cdot, 0) = \frac{\partial^n A}{\partial X^n}(\cdot, 0) && \text{in } \mathbb{R}.
\end{aligned}$$

Here, both $N_n \left((A_i)_{i \leq n-1}, (A_i^*)_{i \leq n-1} \right)$ and $N_n' \left((A_i)_{i \leq n-1}, (A_i^*)_{i \leq n-1} \right)$ are polynomials in all their variables. Hence, we use induction on $n = 1, \ldots, \ell$ to obtain

$$\operatorname*{ess\,sup}_{(X,T) \in \mathbb{R} \times (0, T_0)} \left| \frac{\partial^n A}{\partial X^n}(X, T) \right| \leq C_n' = \text{const} < \infty \quad \text{for } n = 0, 1, \ldots, \ell. \tag{5.5}$$

Finally, we can apply our Theorem 2.1 to conclude (5.4), as desired.

Remark 5.2. In Theorem 5.2(a) above we are allowed to take $T_0 = \infty$ for the spatial dimension $D \leq 2$, provided $\mathfrak{Re}\, \beta > 0$ holds, by the global existence results in Bartuccelli et al. [2]. However, we can prove the estimate (5.3) for $0 < T_0 < \infty$ only.

Remark 5.3. Observe that the intersection $\Omega'_{u_\varepsilon} \cap \Omega'_{\psi_\varepsilon}$ contains the region

$$\Omega' = \Gamma_{T_0/\varepsilon^2}^{(\bar{T}_0')}(\bar{\kappa}_0, \bar{\nu}_0'; 2), \quad 0 < \varepsilon \leq 1,$$

where $\bar{\kappa}_0 = \min\{\kappa_0, \tilde{\kappa}_0\}$, $\bar{\nu}_0' = \max\{\nu_0', \tilde{\nu}_0'\}$ and $\bar{T}_0' = \min\{T_0', \tilde{T}_0', 1/\tilde{\kappa}_0\}$.

In [22] and [31, 32], it is shown that it is possible to prove the validity of (5.2) for initial values A_0 that are not necessarily holomorphic, but are sufficiently smooth. However, in these papers it was necessary to impose a certain rate of decay as $|x| \to \infty$ on the initial values $A_0(x)$. As a consequence it turned out to be impossible to prove validity for such interesting basic cases as periodic and front solutions of (5.2) studied, e.g. in Doelman [6], Doelman and Titi [7], and Takáč [35].

Assumption 2. The second fundamental assumption in van Harten's theorem [15] (Theorem 5.1 above) is on the structure of the initial values u_0 for (5.1),

$$u_0(x) = 2\varepsilon\, \mathfrak{Re}\big(A_0(\varepsilon x) e^{i k_c x}\big) + O(\varepsilon^2). \tag{5.6}$$

In Eckhaus [10] it has been shown that, on a time scale faster than the $1/\varepsilon^2$ Ginzburg–Landau time scale, any solution of (5.1) with L^∞ initial values small enough (like $O(\varepsilon)$) first collapses toward a solution having the special structure of (5.6) (clustered mode distribution) before this solution starts to evolve on the Ginzburg–Landau time scale. In [10] this phenomenon is called "the attractivity of the Ginzburg–Landau manifold."

It should be possible to obtain the same results by applying the main result of this paper. From the estimates (3.6) it is clear that in the linearized case the only values of $\xi \in \mathbb{R}$ for which the Fourier transform $\hat{u}(\xi, t) \equiv (\mathcal{F}u)(\xi, t)$ has any chance of retaining its order of magnitude on such time scales,

$$0 < t < \tilde{T}/\varepsilon^{\nu} \quad \text{for some } \nu \in (0, 2) \text{ and } \tilde{T} = O(1),$$

are those in the $O(\varepsilon)$-neighborhood of $\pm k_c$ in which $-\,\mathfrak{Re}\,\mu(\xi)$ assumes positive values, while for the other values, $\hat{u}(\xi, t)$ seems to become exponentially small. Adding the nonlinearity to the equation will only result in preventing $\hat{u}(\xi, t)$ from descending to that order of magnitude in $O(\varepsilon)$-neighborhoods of multiples of k_c. For the remaining values of ξ we find that $\hat{u}(\xi, t)$ becomes exponentially small, which is a slightly stronger result than the one obtained in [10].

6. Discussion. We conclude our article with a brief discussion about further applications of our results to some current issues in mathematical physics and dynamical systems.

Our main result simplifies the proof of the validity of the time-dependent amplitude approximation for the Swift–Hohenberg equation given in Collet and J.-P. Eckmann [4]. Analyticity of spatially periodic solutions to the Kuramoto–Sivashinsky equation was studied in Collet et al. [5, Thm. 1.2] and Liu [25]. Our results cover this case also.

An important model for convecting fluids between poorly conducting slabs was derived by Proctor [30, Eq. (4.15)]. Our analyticity result applies to the simplified version of the Proctor equation studied in Hoyle [20].

Our results apply also to the generalized Ginzburg–Landau equation studied in Duan and Holmes [8].

A stronger version of analyticity in the space variable is obtained by considering the Gevrey classes of functions (cf. Lions and Magenes [23, 24]). For the Ginzburg–Landau equation, a priori Gevrey-class regularity of solutions on bounded domains was shown in Doelman and Titi [7] and in Duan, Holmes, and Titi [9] for a generalized Ginzburg–Landau equation. For the Navier-Stokes equations, it was proved by Foias and Temam [12] (see also Henshaw, Kreiss, and Reyna [16]). For the Euler equations, i.e., the Navier–Stokes equations with vanishing kinematic viscosity (no diffusion), the domain of holomorphy (in the space variable) of solutions on bounded domains was investigated in Bardos and Benachour [1].

Besides the analyticity results of Friedman [13] for solutions of nonlinear parabolic systems mentioned in §1 above, a number of analyticity results for solutions of linear parabolic systems can be found in Friedman [14, Chap. 3, §3, pp. 212–216], Hörmander [18, Chap. 9, §4, pp. 346–353], Lions and Magenes [23, 24], and Tanabe [36].

The analyticity of solutions to analytic, strongly elliptic systems of both linear and quasilinear partial differential equations in a bounded open domain, with analytic boundary and assigned analytic Dirichlet boundary data, is treated in the monograph by Morrey [28, Chap. 6, §§6 and 7, pp. 258–277]. Shorter alternate proofs of some of these results are given in Masuda [27].

Our last remark concerns possible extensions of our main result, Theorem 2.1, to

(a) an arbitrary bounded open domain $\Omega \subset \mathbb{R}^D$ with analytic boundary $\partial\Omega$ and assigned analytic Dirichlet boundary data, and to

(b) an arbitrary (unbounded) cylindrical domain $\Omega = \mathbb{R}^{D_1} \times \Omega_2$, where $\Omega_2 \subset \mathbb{R}^{D_2}$ is a bounded open domain with analytic boundary $\partial\Omega_2$, $D = D_1 + D_2$, and the assigned Dirichlet boundary data on $\mathbb{R}^{D_1} \times \partial\Omega_2$ are analytic.

The latter case is of interest in the validity problem for the Ginzburg–Landau equation (5.2); cf. Bollerman [3].

It is not difficult to see from our proof of Theorem 2.1 (and its local-in-time version, Theorem 3.1) that all we need in this proof are the analyticity and decay-at-infinity properties of the Green's function $\mathbf{G}(z, z'; t) \in \mathbb{C}^{N\times N}$ corresponding to the linear initial value problem (3.4). However, we can apply the analyticity results of Friedman [14, Chap. 3, §3, pp. 212–216] to obtain all desired properties of the Green's function $\mathbf{G}(z, z'; t)$ in any domain $\Omega \subset \mathbb{R}^D$ of type (a) or (b) specified above, in place of $\mathbb{R}^D$.

Moreover, knowing the analyticity results for solutions to analytic, strongly elliptic systems in a bounded open domain, cf. Morrey [28, Chap. 6, §§6 and 7, pp. 258–277], we may restrict ourselves to Dirichlet (zero) boundary data. Consequently, our main trick in the proof of Lemma 3.4, shifting the domain of integration from $\mathbb{R}^D$ to $\mathbb{R}^D + iy'$, for any fixed $y' \in \mathbb{R}^D$ with $|y'|^{2m} < \kappa_0 s$, can be used in any domain $\Omega \subset \mathbb{R}^D$ of type (a) or (b). Therefore *we conjecture* that our main result, Theorem 2.1, is valid also in any such domain Ω. We leave the details to the reader.

Appendix. The Green function. We establish some standard results about the inverse Fourier transform

$$\text{(A.1)} \qquad \mathbf{G}(x;t) \overset{\text{def}}{=} (2\pi)^{-D} \int_{\mathbb{R}^D} e^{ix\cdot\xi} e^{-t\mathbf{P}(\xi)}\, d\xi \quad \text{for } (x,t) \in \mathbb{R}^D \times (0,\infty).$$

The reader is referred to Stein and Weiss [34] regarding the Fourier transformation. Recall that $\mathbf{P}(\xi) = \sum_{|\alpha|\le 2m} \xi^\alpha \mathbf{P}^{(\alpha)} \in \mathbb{C}^{N\times N}$ is a polynomial in $\xi = (\xi_1, \dots, \xi_D) \in \mathbb{R}^D$ by (1.4), where $\xi^\alpha = \xi_1^{\alpha_1} \dots \xi_D^{\alpha_D}$ for $\alpha = (\alpha_1, \dots, \alpha_D) \in (\mathbb{Z}_+)^D$. Each $\mathbf{P}^{(\alpha)} = (P_{jk}^{(\alpha)})_{j,k=1}^N$ is an $N \times N$ real (or complex) matrix. We assume that $\mathbf{P}$ is strongly elliptic, i.e., inequality (1.5) is valid. Consequently, we can find a constant $\nu_0' \in (0,\infty)$ so large that there exist two additional constants $c_1 > 0$ and $c_2 \ge 0$ such that the following inequality holds for all $1 + i\tau \in \Sigma^{(1)}(\nu_0')$, $\xi = (\xi_1, \dots, \xi_D) \in \mathbb{R}^D$ and $\boldsymbol{\eta} = (\eta_1, \dots, \eta_N) \in \mathbb{C}^N$:

$$\text{(A.2)} \qquad \mathfrak{Re}\left((1+i\tau)\sum_{j=1}^N \sum_{k=1}^N \sum_{|\alpha|\le 2m} P_{jk}^{(\alpha)} \xi^\alpha \eta_k \eta_j^*\right) \ge (c_1|\xi|^{2m} - c_2)|\boldsymbol{\eta}|^2.$$

Here $\Sigma^{(s)}(\nu_0') = \{t = \sigma + i\tau \in \mathbb{C} : \nu_0'|\tau| < \sigma = s\}$ for $0 < s < \infty$, by (2.2), and $|\boldsymbol{\eta}| = \left(\sum_{j=1}^N |\eta_j|^2\right)^{1/2}$ is the Euclidean norm in $\mathbb{C}^N$. We set

$$\Sigma_\cup^{(\infty)}(\nu_0') = \cup\{\Sigma^{(s)}(\nu_0') : s \in (0,\infty)\} = \{t = \sigma + i\tau \in \mathbb{C} : \nu_0'|\tau| < \sigma\}.$$

We will investigate the holomorphic continuation of $\mathbf{G}(x;t)$ into the region

$$\Lambda^{(\infty)}(\kappa_0, \nu_0') = \{(x+iy, \sigma+i\tau) \in \mathbb{C}^D \times \mathbb{C} : \\ (x,\sigma) \in \mathbb{R}^D \times (0,\infty),\ |y|^{2m} < \kappa_0\sigma \text{ and } \nu_0'|\tau| < \sigma\},$$

where $\kappa_0 \in (0,\infty)$ is an arbitrary constant, cf. (2.5).

As usual, we denote by $\mathbf{I} = (\delta_{jk})_{j,k=1}^N$ the $N \times N$ identity matrix. We define the ℓ^2-operator norm of a matrix $\mathbf{M} \in \mathbb{C}^{N\times N}$ by

$$\|\mathbf{M}\| \overset{\text{def}}{=} \sup_{|\mathbf{f}|\le 1} |\mathbf{M}\mathbf{f}| \quad \text{for } \mathbf{f} \in \mathbb{C}^N.$$

We need the following lemma in order to be able to estimate the norm of $e^{-t\mathbf{P}(\xi)}$ in (A.1).

LEMMA A.1. *For all $\xi \in \mathbb{R}^D$, and for all $t, \lambda \in \mathbb{C}$ satisfying $\nu_0' |\Im\mathfrak{m}\, t| < \Re\mathfrak{e}\, t$ and $\Re\mathfrak{e}\,\lambda > c_2 \Re\mathfrak{e}\, t$, the matrix $\lambda\mathbf{I} + t\mathbf{P}(\xi) \in \mathbb{C}^{N\times N}$ is invertible with the norm*

$$\|(\lambda\mathbf{I} + t\mathbf{P}(\xi))^{-1}\| \le (\Re\mathfrak{e}\,\lambda + (c_1|\xi|^{2m} - c_2)\Re\mathfrak{e}\, t)^{-1}. \tag{A.3}$$

Proof. Let $1+i\tau \in \Sigma^{(1)}(\nu_0')$, $\lambda' \in \mathbb{C}$ and $\xi = (\xi_1, \dots, \xi_D) \in \mathbb{R}^D$ be fixed. Applying the Cauchy–Schwartz inequality to (A.2) we arrive at

$$\begin{aligned}(c_1|\xi|^{2m} + \Re\mathfrak{e}\,\lambda' - c_2)|\boldsymbol{\eta}|^2 &\le \Re\mathfrak{e}\left(\sum_{j=1}^N\sum_{k=1}^N\left(\lambda'\delta_{jk} + (1+i\tau)\sum_{|\alpha|\le 2m} P_{jk}^{(\alpha)}\xi^\alpha\right)\eta_k\eta_j^*\right)\\ &\le \left(\sum_{j=1}^N\left|\sum_{k=1}^N\left(\lambda'\delta_{jk} + (1+i\tau)\sum_{|\alpha|\le 2m} P_{jk}^{(\alpha)}\xi^\alpha\right)\eta_k\right|^2\right)^{1/2}\left(\sum_{j=1}^N|\eta_j|^2\right)^{1/2}\\ &= |(\lambda'\mathbf{I} + (1+i\tau)\mathbf{P}(\xi))\boldsymbol{\eta}|\,|\boldsymbol{\eta}| \quad \text{for all } \boldsymbol{\eta} = (\eta_1, \dots, \eta_N) \in \mathbb{C}^N.\end{aligned}$$

In particular, taking $\tau = (\Im\mathfrak{m}\, t)/(\Re\mathfrak{e}\, t)$ and $\lambda' = \lambda/(\Re\mathfrak{e}\, t)$ we obtain $\Re\mathfrak{e}\,\lambda' > c_2$ together with (A.3). □

Now we can estimate the norm of $e^{-t\mathbf{P}(\xi)}$ in $(A.1)$.

LEMMA A.2. *For all $\xi \in \mathbb{R}^D$ and $t \in \mathbb{C}$ satisfying $\nu_0'|\Im\mathfrak{m}\, t| < \Re\mathfrak{e}\, t$, we have*

$$\|e^{-t\mathbf{P}(\xi)}\| \le e^{(c_2 - c_1|\xi|^{2m})\Re\mathfrak{e}\, t}. \tag{A.4}$$

Proof. Let us fix any $\xi \in \mathbb{R}^D$ and $t \in \mathbb{C}$ such that $\nu_0'|\Im\mathfrak{m}\, t| < \Re\mathfrak{e}\, t$. By $(A.3)$ in Lemma A.1, for every $\lambda \in \mathbb{C}$ satisfying $\Re\mathfrak{e}\,\lambda > c_2 \Re\mathfrak{e}\, t$, we have

$$\|(\lambda\mathbf{I} + t\mathbf{P}(\xi))^{-n}\| \le (\Re\mathfrak{e}\,\lambda + (c_1|\xi|^{2m} - c_2)\Re\mathfrak{e}\, t)^{-n}, \quad n = 1, 2, 3, \dots.$$

Taking $\lambda = n$ for $n > c_2 \Re\mathfrak{e}\, t$ we arrive at

$$\|(\mathbf{I} + (t/n)\mathbf{P}(\xi))^{-n}\| \le (1 + (c_1|\xi|^{2m} - c_2)(\Re\mathfrak{e}\, t/n))^{-n}.$$

Finally, we let $n \to \infty$ in order to obtain (A.4) for the limits

$$(\mathbf{I} + (t/n)\mathbf{P}(\xi))^{-n} \to e^{-t\mathbf{P}(\xi)}$$

and

$$(1 + (c_1|\xi|^{2m} - c_2)\Re\mathfrak{e}(t/n))^{-n} \to e^{(c_2 - c_1|\xi|^{2m})\Re\mathfrak{e}\, t}. \qquad \square$$

Remark A.1. Making use of Lemma A.2, for any fixed $t \in \mathbb{C}$ with $\nu_0'|\Im\mathfrak{m}\, t| < \Re\mathfrak{e}\, t$, we easily deduce that the function $\xi \in \mathbb{R}^D \mapsto e^{-t\mathbf{P}(\xi)} \in \mathbb{C}^{N\times N}$ is in the Schwartz space $\mathcal{S}(\mathbb{R}^D \to \mathbb{C}^{N\times N})$ and its inverse Fourier transform $\mathbf{G}(x,t)$ has a holomorphic continuation to the entire complex space $\mathbb{C}^D$. Recall that $\mathcal{S}(\mathbb{R}^D \to \mathbb{C}^{N\times N})$ denotes the Schwartz space of all functions $M\colon \mathbb{R}^D \to \mathbb{C}^{N\times N}$ that are infinitely many times continuously differentiable with all partial derivatives having faster than polynomial decay at intinity. Also $\mathcal{F}^{\pm 1}(\mathcal{S}(\mathbb{R}^D \to \mathbb{C}^{N\times N})) = \mathcal{S}(\mathbb{R}^D \to \mathbb{C}^{N\times N})$, cf. Edwards [11, §5.15.1, p. 375].

In order to establish certain upper bounds on the norm of the holomorphic continuation of the Green function $\mathbf{G}$ and all its partial derivatives $\partial^{|\alpha|}\mathbf{G}/\partial x^\alpha$ to the region $\Lambda^{(\infty)}(\kappa_0, \nu_0')$, we need the following estimate.

LEMMA A.3. *Given any multiindex $\beta \in (\mathbb{Z}_+)^D$, there exists a constant $C' \equiv C'(\beta) \in (0,\infty)$ such that*

$$\text{(A.5)} \quad \left\| \frac{\partial^{|\beta|}}{\partial(\xi')^\beta} e^{-s(1+i\tau)\mathbf{P}(s^{-1/2m}\xi')} \right\| \le C'(\beta)(1+s^{1/2m}+|\xi'|)^{(2m-1)|\beta|} e^{c_2 s - c_1|\xi'|^{2m}}$$

for all $\xi' \in \mathbb{R}^D$, $s \in (0,\infty)$ and $1+i\tau \in \mathbb{C}$ satisfying $\nu_0'|\tau| < 1$.

Proof. By induction on $|\beta|$ we derive the formula

$$\text{(A.6)} \quad \frac{\partial^{|\beta|}}{\partial(\xi')^\beta} e^{-s(1+i\tau)\mathbf{P}(s^{-1/2m}\xi')} = e^{-s(1+i\tau)\mathbf{P}(s^{-1/2m}\xi')} \sum_{n=0}^{(2m-1)|\beta|} s^{n/2m}\mathbf{Q}^{(n)}(\xi'),$$

where each

$$\mathbf{Q}^{(n)}(\xi') = \sum_{|\alpha| \le (2m-1)|\beta|-n} (\xi')^\alpha \mathbf{Q}^{(n,\alpha)}, \quad n = 0,1,\dots,(2m-1)|\beta|$$

is a polynomial of order $\le (2m-1)|\beta| - n$ in $\xi' \in \mathbb{R}^D$ with the coefficients $\mathbf{Q}^{(n,\alpha)} \in \mathbb{C}^{N\times N}$. Consequently, in order to obtain (A.5), we estimate the sum in (A.6) as follows, for all $\xi' \in \mathbb{R}^D$ and $s \in (0,\infty)$:

$$\left\| \sum_{n=0}^{(2m-1)|\beta|} s^{n/2m}\mathbf{Q}^{(n)}(\xi') \right\| \le C'(\beta)(1+s^{1/2m}+|\xi'|)^{(2m-1)|\beta|}.$$

The exponential in (A.6) can be estimated by (A.4) with $\xi = s^{-1/2m}\xi'$ and $t = s(1+i\tau)$. □

From (A.1) combined with Lemma A.2, we deduce that the formula

$$\text{(A.7)} \quad \mathbf{G}(z;t) = (2\pi)^{-D} \int_{\mathbb{R}^D} e^{iz\cdot\xi} e^{-t\mathbf{P}(\xi)}\, d\xi,$$

$$\text{for } (z,t) = (x+iy, \sigma+i\tau) \in \Lambda^{(\infty)}(\kappa_0, \nu_0')$$

defines the holomorphic continuation $\mathbf{G}(x+iy,\sigma+i\tau)$ of the Green function $\mathbf{G}$ into the region $\Lambda^{(\infty)}(\kappa_0,\nu_0')$. Notice that in (A.7) we have

$$\mathfrak{Re}(iz\cdot\xi) = -y\cdot\xi \le \kappa_0\sigma^{1/2m}|\xi|.$$

Next we set

$$\Lambda'(\kappa_0,\nu_0') = \Pi^{(1)}(\kappa_0) \times \Sigma_U^{(\infty)}(\nu_0') = \{(x'+iy', \sigma+i\tau) \in \mathbb{C}^D \times \mathbb{C}:$$
$$(x',\sigma) \in \mathbb{R}^D \times (0,\infty),\ |y'|^{2m} < \kappa_0 \text{ and } \nu_0'|\tau| < \sigma\}.$$

In order to estimate the norms of the functions $z^\beta(\partial^{|\alpha|}\mathbf{G}/\partial z^\alpha)$, for $\alpha,\beta \in (\mathbb{Z}_+)^D$, we make the substitution

$$\text{(A.8)} \quad \mathbf{G}(z;t) = \sigma^{-D/2m}\mathbf{G}'(\sigma^{-1/2m}z;t)$$

for $(z,t) = (x+iy,\sigma+i\tau) \in \Lambda^{(\infty)}(\kappa_0,\nu_0')$, where

$$\text{(A.9)} \quad \mathbf{G}'(z';t) \overset{\text{def}}{=} (2\pi)^{-D} \int_{\mathbb{R}^D} e^{iz'\cdot\xi'} e^{-t\mathbf{P}(\sigma^{-1/2m}\xi')}\, d\xi'$$

$$\text{for } (z',t) = (x'+iy', \sigma+i\tau) \in \Lambda'(\kappa_0,\nu_0').$$

Combining integration by parts with Lemma A.3, we arrive at

$$(z')^{\beta}\frac{\partial^{|\alpha|}}{\partial(z')^{\alpha}}\mathbf{G}'(z';t)=(2\pi)^{-D}i^{|\alpha|+|\beta|}\int_{\mathbb{R}^D}e^{iz'\cdot\xi'}(\xi')^{\alpha}\frac{\partial^{|\beta|}}{\partial(\xi')^{\beta}}e^{-t\mathbf{P}(\sigma^{-1/2m}\xi')}\,d\xi'.$$

Taking $(z',t)=(x'+iy',\sigma+i\tau)\in\Lambda'(\kappa_0,\nu_0')$ we obtain, by Lemma A.3,

$$\begin{aligned}
&|(z')^{\beta}|\left\|\frac{\partial^{|\alpha|}}{\partial(z')^{\alpha}}\mathbf{G}'(z';t)\right\|\\
&\le(2\pi)^{-D}\int_{\mathbb{R}^D}e^{-y'\cdot\xi'}|(\xi')^{\alpha}|\left\|\frac{\partial^{|\beta|}}{\partial(\xi')^{\beta}}e^{-t\mathbf{P}(\sigma^{-1/2m}\xi')}\right\|d\xi'\\
&\le(2\pi)^{-D}C'(\beta)\int_{\mathbb{R}^D}e^{\kappa_0|\xi'|}|\xi'|^{|\alpha|}(1+\sigma^{1/2m}+|\xi'|)^{(2m-1)|\beta|}e^{c_2\sigma-c_1|\xi'|^{2m}}\,d\xi'\\
&\le(2\pi)^{-D}C'(\beta)\int_{\mathbb{R}^D}(1+\sigma^{1/2m}+|\xi'|)^{|\alpha|+(2m-1)|\beta|}e^{c_2\sigma-c_1|\xi'|^{2m}+\kappa_0|\xi'|}\,d\xi'.
\end{aligned}$$

Consequently, given any $\kappa_0\in(0,\infty)$, $c'\in(c_2,\infty)$, and $\alpha,\beta\in(\mathbb{Z}_+)^D$, there exists a constant $C'(\kappa_0,c',|\alpha|,|\beta|)\in(0,\infty)$ such that

$$\text{(A.10)}\quad |(z')^{\beta}|\left\|\frac{\partial^{|\alpha|}}{\partial(z')^{\alpha}}\mathbf{G}'(z';t)\right\|\le C'(\kappa_0,c',|\alpha|,|\beta|)e^{c'\sigma}$$
$$\text{for } (z',t)=(x'+iy',\sigma+i\tau)\in\Lambda'(\kappa_0,\nu_0').$$

Furthermore, by (A.8) we have

$$\text{(A.11)}\quad (\sigma^{-1/2m}z)^{\beta}\frac{\partial^{|\alpha|}}{\partial z^{\alpha}}\mathbf{G}(z;t)=\sigma^{-(D+|\alpha|)/2m}(z')^{\beta}\frac{\partial^{|\alpha|}}{\partial(z')^{\alpha}}\mathbf{G}'(z';t),$$
$$\text{where } z'=\sigma^{-1/2m}z \text{ for } (z,t)=(x+iy,\sigma+i\tau)\in\Lambda^{(\infty)}(\kappa_0,\nu_0').$$

Finally, we combine (A.10) with (A.11) to derive the main result of the Appendix.

PROPOSITION A.4. *Formula* (A.7) *defines a holomorphic function* $\mathbf{G}\colon\Lambda^{(\infty)}(\kappa_0,\nu_0')\to\mathbb{C}^{N\times N}$. *Recall that* $\nu_0'\in(0,\infty)$ *is fixed, whereas* $\kappa_0\in(0,\infty)$ *is an arbitrary constant. Choose any* $c'\in(c_2,\infty)$, *where* $c_2\ge0$ *appears in* (A.2).

Then, given any $\kappa_0\in(0,\infty)$, $\alpha\in(\mathbb{Z}_+)^D$, *and* $n\in\mathbb{Z}_+$, *there exists a constant* $C'_{\alpha,n}\equiv C'_{\alpha,n}(\kappa_0,\nu_0')\in(0,\infty)$ *such that*

$$\text{(A.12)}\quad \left(1+\frac{|x|}{\sigma^{1/2m}}\right)^{n}\left|\frac{\partial^{|\alpha|}}{\partial z^{\alpha}}\mathbf{G}(z;t)\right|\le C'_{\alpha,n}(\kappa_0,\nu_0')e^{c'\sigma}\sigma^{-(D+|\alpha|)/2m}$$
$$\textit{for all } (z,t)=(x+iy,\sigma+i\tau)\in\Lambda^{(\infty)}(\kappa_0,\nu_0').$$

Remark A.2. We recall that $|\mathbf{M}|=\left(\sum_{j,k=1}^{N}|M_{jk}|^2\right)^{1/2}$ is the Euclidean norm, whereas $\|\mathbf{M}\|$ denotes the ℓ^2-operator norm of a matrix $\mathbf{M}=(M_{jk})_{j,k=1}^{N}\in\mathbb{C}^{N\times N}$. Of course, both these norms are equivalent in $\mathbb{C}^{N\times N}$.

LARGE-TIME BEHAVIOR IN INCOMPRESSIBLE NAVIER–STOKES EQUATIONS*

ANA CARPIO†

Abstract. We give a development up to the second order for strong solutions u of incompressible Navier–Stokes equations in $\mathbb{R}^n$, $n \geq 2$. By combining estimates obtained from the integral equation with a scaling technique, we prove that, for initial data satisfying some integrability conditions (and small enough, if $n \geq 3$), u behaves like the solution of the heat equation taking the same initial data as u plus a corrector term that we compute explicitely.

Key words. incompressible Navier–Stokes equations, strong solutions, large-time behavior, asymptotic development, heat equation

AMS subject classifications. 76D05, 35B40, 35K05

Introduction and main results. This paper is devoted to the study of the large-time behavior of the solutions of the incompressible Navier–Stokes equations in the whole space $\mathbb{R}^n$, $n \geq 2$,

$$\text{(NS)}\qquad \begin{cases} u_t - \Delta u + u^i \partial_i u + \nabla p = 0 & \text{in } \mathbb{R}^+ \times \mathbb{R}^n, \\ u(x) \to 0, & |x| \to \infty, \\ \operatorname{div} u = 0 & \text{in } \mathbb{R}^+ \times \mathbb{R}^n, \\ u(x,0) = u_0, \ \operatorname{div} u_0 = 0 & \text{in } \mathbb{R}^n, \end{cases}$$

where $u = (u^1, \ldots, u^n)$ stands for the velocity of the fluid and p for its pressure.

Let us first recall some facts on solutions of (NS). It is known that for any initial data $u_0 \in (L^2(\mathbb{R}^n))^n$ with div $u_0 = 0$, global weak solutions of (NS) exist. This was first proved by Leray ([18], [19]) for $n \leq 3$ and then by Hopf [13] for all n by means of a Galerkin method. By a weak solution of (NS), we mean a function u such that

$$u \in C_{\text{weak}}([0,\infty); (L^2(\mathbb{R}^n))^n) \quad \text{with} \quad \operatorname{div} u = 0,$$

$$\partial_i u \in L^2(0,\infty; (L^2(\mathbb{R}^n))^n), \quad i = 1, \ldots, n,$$

$$\langle u(0), \varphi(0) \rangle = -\int_0^\infty \langle u, \varphi_t \rangle dt + \int_0^\infty \langle \nabla u, \nabla \varphi \rangle dt + \int_0^\infty \langle u \cdot \nabla u, \varphi \rangle dt$$

for every $\varphi \in (C_c^\infty([0,\infty) \times \mathbb{R}^n))^n$ with div $\varphi = 0$, where $\langle\ \rangle$ denotes the scalar product in $(L^2(\mathbb{R}^n))^n$. From now on, we shall drop the superscript n and denote by X both the spaces X and X^n.

Weak solutions are known to be unique and smooth (hence, strong) when $n = 2$. For higher dimensions, uniqueness and smoothness remain open problems.

Besides the Leray–Hopf construction, there are several methods for proving the existence of weak solutions in $\mathbb{R}^n$ (see [3], [17], [26]). They all construct strong solutions u_k of some approximating problems which converge weakly in $L^2_{\text{loc}}(0,\infty; H^1(\mathbb{R}^n))$ and

*Received by the editors October 8, 1993; accepted for publication (in revised form) July 26, 1994. This research was partially supported by DGICYT (Spain) project PB90-0245.

†Departamento de Matemática Aplicada, Universidad Complutense, 28040 Madrid, Spain (carpio @sunma4.mat.ucm.es).

strongly in $L^2_{\text{loc}}(\mathbb{R}^+ \times \mathbb{R}^n)$ to some weak solution u of (NS). Those u_k fulfill the energy inequality, that is,

$$\|u_k(t)\|^2_{L^2(\mathbb{R}^n)} + 2\int_s^t \|\nabla u_k(\sigma)\|^2_{L^2(\mathbb{R}^n)} d\sigma \leq \|u_k(s)\|^2_{L^2(\mathbb{R}^n)}$$

for $0 \leq s \leq t$. In case $n \leq 4$, the energy inequality also holds for the limit u for every $t > s$ and a.e. $s > 0$ and $s = 0$ (see [14], [26]). Following Leray's terminology, those weak solutions verifying the energy inequality are called turbulent.

For initial data $u_0 \in H^{\frac{1}{2}}(\mathbb{R}^n)$ (see [16]), $u_0 \in L^p(\mathbb{R}^n)$, $p > n$ (see [10], [11], [2], [8]), or $u_0 \in L^n(\mathbb{R}^n)$ (see [14]), strong local solutions are known to exist. They turn out to be global if the norm of the initial data is small. We call them strong since they belong to classes where regularity and uniqueness hold. Besides, they satisfy the equation in the classical sense and both the energy inequality and the associated integral equation are satisfied.

There are some uniqueness criteria allowing to relate strong and weak solutions, provided that they both verify the energy inequality. For instance, if a weak solution u is known to fulfill the energy inequality and we have a strong solution $w \in C([0,T];(L^n(\mathbb{R}^n))^n)$ (see [25]) or $w \in L^r(0,T;L^q(\mathbb{R}^n))$ (see [23]) for some adequate q and r, then w agrees with the weak solution u on $[0,T]$.

We must distinguish the cases $n > 2$ and $n = 2$. For $n = 2$, we shall study the asymptotic behavior of weak solutions of (NS) without smallness assumptions on the data. When $n > 2$, we are concerned with the study of the asymptotic behavior of global strong solutions of (NS) like those constructed in [14] with data in $L^n(\mathbb{R}^n)$ of small norm. If u_0 also belongs to some $L^p(\mathbb{R}^n)$ with $1 < p \leq n$, Kato obtains decay rates for the $L^q(\mathbb{R}^n)$ norms, $q \geq p$, similar to those which hold for the heat equation (see also [2]), provided that $\frac{n}{2}(\frac{1}{p} - \frac{1}{q}) < 1$, which always holds when $n = 2$. We shall remove this restriction and extend the decay estimates to reach the case $p = 1$.

Let us consider first the case $n = 2$. In this case, weak solutions of (NS) turn out to also be strong. For data in $L^p \cap L^2(\mathbb{R}^n)$, $1 \leq p \leq 2$, an argument involving the use of Fourier transforms allows to prove (see [26], [17]) that the weak solutions of (NS) behave in L^2 like the solutions of the heat equation with the same initial data when $t \to \infty$. We extend this result to L^q with $q \neq 2$.

THEOREM 0.1. *Let u be a weak solution of the two-dimensional* (NS) *with initial data $u_0 \in L^p \cap L^2(\mathbb{R}^2)$, $1 \leq p \leq 2$, such that* div $u_0 = 0$. *Then for any $q \geq p$,*

(i) *if $1 < p < 2$,*

$$\|G(t) * u_0 - u(t)\|_q \leq Ct^{-\frac{2}{p}+\frac{1}{q}+\frac{1}{2}}, \quad t > 0,$$

(ii) *if $p = 1$,*

$$\|G(t) * u_0 - u(t)\|_q \leq Ct^{\frac{-3}{2}+\frac{1}{q}} \log\, t, \quad t > 0,$$

(iii) *if $p = 2$,*

$$t^{\frac{1}{2}-\frac{1}{q}}\|u(t)\|_q \to 0 \quad as\ t \to \infty,$$

where we denote the heat kernel by $G(t)$.

In this theorem and what follows, C denotes a positive constant independent of time.

In cases (i) and (ii) $\|G(t)*u_0\|_q$ decays at a slower rate than the powers appearing in the right-hand side when $t \to \infty$. Therefore, we may say that $G(t) * u_0$ is the first term in the asymptotic development of u when $t \to \infty$.

Both (i) and (ii) follow easily from the integral equation satisfied by u thanks to the decay estimates on the L^q norms of u obtained by Kato for data of small L^2 norm. Since the L^2 norm of u is known to tend to 0 as $t \to \infty$, we can spare this smallness hypothesis.

Kato's estimates together with the covergence to zero of the L^2 norm yield (iii), which also holds for $\|G(t) * u_0\|_q$. In fact, at least when $q = 2$, this decay estimate turns out to be optimal for both the heat and Navier–Stokes equations in the sense that no uniform decay rate can be found for the L^2 norm of solutions with initial data $u_0 \in L^2(\mathbb{R}^2)$ (see [21]). However, we ignore whether it is possible to find functions $g(t)$ and $\delta(t)$ with $\delta(t) \to \infty$ as $t \to \infty$ such that

$$\delta(t)\, t^{\frac{1}{2}-\frac{1}{q}} \|u(t) - g(t)\|_q \to 0 \quad \text{as } t \to \infty$$

under the only assumption $u_0 \in L^2(\mathbb{R}^2)$ (see remarks in §1.2). The first term in this case (other than 0) is unknown.

In some cases we can make the above result more precise.

THEOREM 0.2. *Let u be a solution of the two-dimensional* (NS) *with initial data $u_0 \in L^p \cap L^2(\mathbb{R}^2)$, $\frac{6}{5} < p < 2$, and v a solution of*

$$(\mathcal{L}_2) \qquad \begin{cases} v_t - \Delta v = -h^i\partial_i h - \partial_j \nabla E_2 * h^i \partial_i h^j & \text{in } \mathbb{R}^+ \times \mathbb{R}^2, \\ \operatorname{div} v = 0 & \text{in } \mathbb{R}^+ \times \mathbb{R}^2, \\ v(x,0) = u_0, \ \operatorname{div} u_0 = 0 & \text{in } \mathbb{R}^2, \end{cases}$$

where $h(t) = G(t) * u_0$ is the solution of the heat equation with data u_0 and E_2 stands for the fundamental solution of $-\Delta$ in $\mathbb{R}^2$. Then for any $q \geq p$, we have

$$\|(u - v)(t)\|_q \leq Ct^{-\frac{3}{p}+\frac{1}{q}+1}.$$

We see that, when $\frac{6}{5} < p < 2$, the function v, that can be written as

$$v(t) = G(t) * u_0 - \int_0^t G(t-s) * (h^i\partial_i h + \partial_j \nabla E_2 * h^i \partial_i h^j)(s)ds,$$

that is, $G(t) * u_0$ plus a corrector term $I(t)$ approaches u better that $G(t) * u_0$. The restriction on p is needed to make some integrals finite when estimating the difference by using the integral equations.

For initial data $u_0 \in L^p \cap L^2(\mathbb{R}^2)$ with $1 < p \leq \frac{6}{5}$, Theorem 0.2 implies

$$\|(u - v)(t)\|_q \leq Ct^{-\frac{3}{r}+\frac{1}{q}+1}$$

when $q \geq r$, for any $\frac{6}{5} < r < 2$. This decay is faster that the decay $t^{-\frac{2}{p}+\frac{1}{q}+\frac{1}{2}}$ observed for $\|G(t) * u_0 - u(t)\|_q$. Therefore, the second term in the development, in norm L^q, $q \geq \frac{6}{5}$, is again $I(t)$.

When $p = 1$, Theorem 0.1 yields the decay rate $Ct^{\frac{-3}{2}+\frac{1}{q}} \log\, t$ for $\|G(t) * u_0 - u(t)\|_q$, $q \geq 1$. By Theorem 0.2, we get the slower decay rate $Ct^{-\frac{3}{r}+\frac{1}{q}+1}$ with $r > \frac{6}{5}$ for $\|v(t) - u(t)\|_q$ $q \geq r$. However, in this case $p = 1$ and, provided some integrability hypotheses on the data are added, we can use a scaling technique to find the second term in the development of u. We have the following theorem.

THEOREM 0.3. *Set $q \geq 1$. Let u be a solution of the two-dimensional* (NS) *with initial data $u_0 \in (L^2 \cap L^1)(\mathbb{R}^2, 1+|x|)$ such that* $\operatorname{div} u_0 = 0$ *and $u_0 \in L^{2r}(\mathbb{R}^2)$ for some*

r satisfying $q \geq r > \frac{2q}{q+2}$. We set $M = \int_{\mathbb{R}^2} u_0(x)dx = (M^1, M^2)$ and $E_2 = \frac{1}{2\pi}\log|x|$. Then,

$$\frac{t^{\frac{3}{2}-\frac{1}{q}}}{\log t}\|u(t) - MG(t) + R(t)\|_q \to 0 \quad as\ t \to \infty,$$

where

$$R(t) = \log t\ \left(\frac{M^iM}{2}\partial_i G(t) + \frac{M^iM^j}{2}\partial_i G(t) * \nabla\partial_j E_2\right).$$

This result remains true when replacing u with the solution v of $(\mathcal{L}_2)$ so that $R(t)$ is also the second term in the development of v. The term $MG(t)$ comes from $G(t) * u_0$, while $R(t)$ is the contribution due to the integral term $I(t)$. Note that, formally, we have set $h(t) = MG(t)$ in the expresion of $I(t)$. It is clear then that, for u_0 as in Theorem 0.3,

$$\frac{t^{\frac{3}{2}-\frac{1}{q}}}{\log t}\|u(t) - v(t)\|_q \to 0 \quad \text{as } t \to \infty$$

so that, again, v approaches u better than $G(t) * u_0$.

When the mass of the initial data is zero, Theorem 0.3 reduces to

$$\frac{t^{\frac{3}{2}-\frac{1}{q}}}{\log t}\|u(t)\|_q \to 0 \quad \text{as } t \to \infty$$

It was proved in [22] that, if $u_0 \in L^1(\mathbb{R}^2, 1 + |x|^2) \cap L^2(\mathbb{R}^2, |x|^{\frac{1}{2}}) \cap H(\mathbb{R}^2)$, where $H(\mathbb{R}^2)$ denotes the closure in L^2 of $C_0^\infty(\mathbb{R}^2) \cap \{u \text{ s.t. div } u = 0\}$ and the mass of u_0 is 0, that is, $\mathcal{F}u_0 = 0$, then $\|u(t)\|_2 \leq C(1+t)^{-1}$. Solutions may decay faster, even exponentially, depending on the order of the zero of $\mathcal{F}u$ at time 0.

We shall also extend the above theorems to higher dimensions.

THEOREM 0.4. *For $n \geq 3$, let u be a global strong solution of* (NS) *with data $u_0 \in L^p \cap L^n(\mathbb{R}^n)$, $1 \leq p < n$, of L^n norm small enough and such that* div $u_0 = 0$. *Then for $q \geq p$, we have*

$$\|G(t) * u_0 - u(t)\|_q \leq Ct^{(-\frac{2}{p}+\frac{1}{q})\frac{n}{2}+\frac{1}{2}}.$$

For weak solutions satisfying the energy inequality (or that can be approached by solutions of approximating problems verifying it), the above decay estimate on $\|G(t) * u_0 - u(t)\|_q$ was known to hold for $q = 2$ and $1 \leq p \leq 2$ (see [17], [26]). For divergence free data u_0 belonging to $L^2 \cap L^n(\mathbb{R}^n)$ with small $L^n(\mathbb{R}^n)$ norm, there exists a unique strong global solution and at least one global weak solution. They both agree when the weak solution satisfies the energy inequality. These kinds of weak solutions are known to exist when $n \leq 4$ (see, for instance, [26]). Therefore, Theorem 0.4 extends the results known for weak solutions.

Denoting the n-dimensional analogues of problem $(\mathcal{L}_2)$ by $(\mathcal{L}_n)$, we get that in some cases the solution v of $(\mathcal{L}_n)$ approaches u better than $G(t) * u_0$, furnishing the second term in the development of u.

THEOREM 0.5. *For $n \geq 3$, let u be a global strong solution of* (NS) *with data $u_0 \in L^p \cap L^n(\mathbb{R}^n)$, $\frac{3n}{n+3} < p < n$, whose L^n norm is small enough and such that* div $u_0 = 0$. *Then for any $q \geq p$, we have*

$$\|(u - v)(t)\|_q \leq Ct^{(-\frac{3}{p}+\frac{1}{q})\frac{n}{2}+1},$$

where v is the solution of $(\mathcal{L}_n)$ with data u_0.

Taking $u_0 \in L^p \cap L^n(\mathbb{R}^n)$, $\frac{2n}{n+2} < p \leq \frac{3n}{n+3}$, of small L^n norm such that div $u_0 = 0$, we conclude that

$$\|(u-v)(t)\|_q \leq Ct^{(-\frac{3}{r}+\frac{1}{q})\frac{n}{2}+1}$$

for $q \geq r$ and $\frac{3n}{n+3} < r < n$. This decay rate is faster than that observed for $\|G(t) * u_0 - u(t)\|_q$. However, we ignore what happens when $p \leq q \leq \frac{3n}{n+3}$ or $1 < p \leq \frac{2n}{n+2}$.

Theorems 0.4 and 0.5 are obtained estimating the norms by using the integral equations and the known decay estimates. We can handle the case $p = 1$ by using a scaling technique, provided that some integrability hypotheses are added.

THEOREM 0.6. *For $n \geq 3$, let u be a strong solution of* (NS) *with data $u_0 \in L^1(\mathbb{R}^n, 1+|x|) \cap L^n(\mathbb{R}^n)$, $1 \leq p \leq n$, of L^n norm small enough and such that* div $u_0 = 0$ *and $q \geq 1$. If $u_0 \in L^{2r}(\mathbb{R}^n)$ for some $q \geq r > \frac{nq}{q+n}$, then*

$$t^{\frac{1}{2}+\frac{n}{2}(1-\frac{1}{q})}\|u(t) - MG(t) + m^i\partial_i G(t) + R(t)\|_q \to 0$$

as $t \to \infty$, where

$$M = \int_{\mathbb{R}^n} u_0(x)dx; \quad m_i = \int_{\mathbb{R}^n} x^i u_0(x)dx, \ i = 1, \ldots, n,$$

$$R(t) = \left(\int_0^\infty \int_{\mathbb{R}^n} u^i u(\sigma, y)dyd\sigma\right) \partial_i G(t) + \left(\int_0^\infty \int_{\mathbb{R}^n} u^i u^j(\sigma, y)dyd\sigma\right) \partial_i G(t) * \nabla\partial_j E_n,$$

and E_n stands for the fundamental solution of $-\Delta$ in $\mathbb{R}^n$.

The same result holds if we replace u by v so that, in particular, we see that v approaches u better than $G(t) * u_0$. Both Theorem 0.3 and Theorem 0.6 extend to (NS) the results proved in [27] for the following scalar convection-diffusion equations:

$$u_t - \Delta u + a|u| \cdot \nabla u = 0 \quad \text{in } \mathbb{R}^+ \times \mathbb{R}^n, \quad a \in \mathbb{R}^n,$$

where the same difference between the case $n = 2$ and $n \geq 3$ appears. We remark that the solutions we are dealing with satisfy the decay estimate $\|u(t)\|_2 \leq C(1+t)^{\frac{-n}{4}}$. When $n \geq 3$, this decay ensures the existence of $\int_0^\infty \int_{\mathbb{R}^n} u^i u^j(\sigma, y)dyd\sigma$ for $i, j = 1, \ldots, n$. For $n = 2$, we obtain an upper bound for $\int_0^t \int_{\mathbb{R}^n} u^i u^j(\sigma, y)dyd\sigma$ which grows as log t grows. The results in [27] were proved changing to self-similar variables and then making eigenvalue expansions in some weighted Sobolev spaces. Our technique can be adapted to yield another proof of these results.

Theorem 0.6 is related to a result obtained by Schonbek in [22]. When $n = 3$, she proved that $k_1(1+t)^{\frac{-5}{4}} \leq \|u(t)\|_2 \leq k_2(1+t)^{\frac{-5}{4}}$ for a special class of data. Theorem 0.6 implies that $u(t,x) = MG(t,x) + m^i\partial_i G(t,x) + R(t,x) + r(t,x)$ where $\|r(t,x)\|_2 = o(t^{\frac{-5}{4}})$ as $t \to \infty$ and $\|MG(t,x) + m^i\partial_i G(t,x) + R(t,x)\|_2 = Ct^{\frac{-5}{4}}$.

The paper is organized as follows. In §1, we briefly recall some known results which will be of use to us in what follows. The next two sections are devoted to the proof of Theorems 0.1 and 0.2, respectively. In §4, we study some related linear problems and prove Theorem 0.3. The last section deals with the asymptotic behavior in higher dimensions.

1. Known results.

1.1. Strong solutions. The following results are taken from [14]. They are established by using an iterative scheme that goes back to Leray. The idea is to convert (NS) to an integral equation

$$u(t) = G(t) * u_0 + \int_0^t \partial_i G(t-s) * P(u_i u(s))ds = Su(t),$$

where $G(t)$ denotes the heat kernel and P the projection on the space of divergence free vectors, which is a bounded operator from L^p to L^p for $1 < p < \infty$. Taking $u_0 \in L^n(\mathbb{R}^n)$, the sequence $u^{m+1} = Su^m$, $m \geq 1$, with $u^1 = G(t) * u_0$ converges strongly to a solution u of the integral equation on some time interval $[0,T]$. If $\|u_0\|_n$ is small enough, we can take $T = \infty$. The construction also yields the estimates below.

THEOREM 1.1 (see [14]). *Let* $u_0 \in L^n(\mathbb{R}^n)$ *be such that* div $u_0 = 0$ *and* $\|u_0\|_n$ *is small enough. Then there exists a unique solution* u *of* (NS) *such that*

(i)

$$t^{\frac{n}{2}(\frac{1}{n}-\frac{1}{q})}u \in BC([0,\infty);L^q(\mathbb{R}^n)) \quad \forall n \leq q \leq \infty,$$

(ii)

$$t^{\frac{n}{2}(\frac{1}{n}-\frac{1}{q})+\frac{1}{2}}\nabla u \in BC([0,\infty);L^q(\mathbb{R}^n)) \quad \forall n \leq q < \infty.$$

Moreover,

(iii)

$$u \in L^r((0,\infty);L^q(\mathbb{R}^n)), \quad \frac{1}{r} = \frac{n}{2}\left(\frac{1}{n}-\frac{1}{q}\right), \quad n < q < \frac{n^2}{n-2},$$

(iv)

$$\lim_{T\to\infty}\frac{1}{T}\int_0^T \|u(s)\|_n ds = 0.$$

Remark 1.1. When $n = 2$, $\|u(t)\|_2$ is monotonically nonincreasing (the energy inequality holds) and (iv) implies that $\|u(t)\|_2 \to 0$ as $t \to \infty$ if $\|u_0\|_2$ is small.

THEOREM 1.2 (see [14]). *Let* $u_0 \in L^n(\mathbb{R}^n) \cap L^p(\mathbb{R}^n)$ *such that* div $u_0 = 0$ *and* $\|u_0\|_n$ *is small enough, with* $1 < p < n$. *Then*

(i)

$$t^{\frac{n}{2}(\frac{1}{p}-\frac{1}{q})}u \in BC([1,\infty);L^q(\mathbb{R}^n)) \quad \forall p \leq q \leq \infty,$$

(ii)

$$t^{\frac{n}{2}(\frac{1}{p}-\frac{1}{q})+\frac{1}{2}}\nabla u \in BC([1,\infty);L^q(\mathbb{R}^n)) \quad \forall p \leq q < \infty$$

if $\frac{n}{2}(\frac{1}{p}-\frac{1}{q}) < 1$ *in* (i) *or* $\frac{n}{2}(\frac{1}{p}-\frac{1}{q}) + \frac{1}{2} < 1$ *in* (ii); *otherwise, we replace them by any positive number less than* 1.

(iii)

$$\|u(t) - G(t) * u_0\|_p \leq C_\delta t^{\frac{-\delta}{2}}, \quad 0 < \delta < \text{Min}\left(1, n\left(1-\frac{1}{p}\right), \frac{n}{p}-1\right).$$

Remarks 1.2.

- In view of Theorem 1.1(i) and the fact that $u \in BC([0,\infty);L^p(\mathbb{R}^n))$ (see [14]) when $u_0 \in L^p, 1 < p < n$, we can replace $BC([1,\infty);L^q(\mathbb{R}^n))$ in Theorem 1.2(i) by $BC([0,\infty);L^q(\mathbb{R}^n))$ for any $q \geq p$.
- If $\|u_0\|_n$ is small then $\|u(t)\|_n \to 0$ as $t \to \infty$ (see Masuda's remark in [14]).
- Strong solutions have been also obtained for data $u_0 \in L^r(\mathbb{R}^n)$, $r > n$ (see [10], [8])
- In [2], strong solutions with data $u_0 \in L^2 \cap L^n(\mathbb{R}^n)$ are constructed in a different way. A decay estimate $\|u(t)\|_n \leq Ct^{\frac{n}{2}(\frac{1}{2}-\frac{1}{n})}$ without restrictions on the size of $\frac{n}{2}(\frac{1}{2}-\frac{1}{n})$ is also obtained.
- When $n = 2$, Theorem 1.2(i) holds for any $q \geq p$. If $n \geq 3$ it holds for any $q \geq p$ when $p \geq \frac{n}{2}$ and for $p \leq q \leq \frac{pn}{n-2p}$ when $p < \frac{n}{2}$.

1.2. Weak solutions. The use of Fourier transform allows us to obtain decay estimates for weak solutions with initial data $u_0 \in L^2(\mathbb{R}^n)$ without smallness hypotheses, provided that they satisfy the energy inequality or can be approached by solutions of related problems verifying it. The first results in that direction are due to Schonbek [20]. The idea consists in taking the Fourier transform of the equation and splitting the frequency domain in order to get differential inequalities yielding some decay. We do this first for some approached solutions and in the limit we get a decay estimate for u. This result has been successively improved and extended in [21], [22], [17], and [26]. The following theorem is taken from [26].

THEOREM 1.3 (see [26]). *Let u be a weak solution of the incompressible* (NS) *equations which satisfies the energy inequality (or can be approached by solutions of approximated problems satisfying it) for any $n \geq 2$. Then for every $u_0 \in L^2(\mathbb{R}^n)$ with* $\operatorname{div} u_0 = 0$,

(i) $\|u(t)\|_2 \to 0$ *as* $t \to \infty$.

If, further, $\|G(t) * u_0\|_2^2 \leq C(1+t)^{-\alpha_0}$ *for all* $t \geq 0$, *then*

(ii) $\|u(t)\|_2^2 \leq C(1+t)^{-\alpha}$ *with* $\alpha = \operatorname{Min}(\frac{n}{2}+1, \alpha_0)$, $t \geq 0$, *and*

(iii) $\|u(t) - G(t) * u_0\|_2^2 \leq h(t)(1+t)^{-d}$ *for all* $t \geq 0$, *where*

$$d = \frac{n}{2} + 1 - 2\operatorname{Max}(1-\alpha_0, 0) \quad \left(d > \alpha = \alpha_0 \; \textit{if} \; \frac{n}{2} + 1 > \alpha_0\right),$$

$$h(t) \;=\; \begin{cases} \varepsilon(t) \to 0, \quad t \to \infty & \textit{if}\; \alpha = 0, \\ C \ln^2(t+c) & \textit{if}\; \alpha = 1, \\ C & \textit{if}\; \alpha \neq 0, 1. \end{cases}$$

Remark 1.3. Therefore, if $u_0 \in L^p \cap L^2$, $1 \leq p \leq 2$, we have $\alpha_0 = \frac{n}{2}(\frac{1}{p} - \frac{1}{2})$ and

$$\|u(t) - G(t) * u_0\|_{L^2(\mathbb{R}^2)} \;\leq\; g(t)(1+t)^{-\frac{n}{2}(\frac{1}{p}-\frac{1}{2})} \quad \forall t \geq 0$$

with

$$g(t) \;=\; \begin{cases} \varepsilon(t) \to 0, \quad t \to \infty & \text{if } p = 2, \\ C \ln(t+c)(1+t)^{\frac{-1}{2}} & \text{if } p = 1, \\ (1+t)^{(\frac{1}{2} - \frac{n}{2p})} & \text{if } 1 < p < 2. \end{cases}$$

Remark 1.4. Some results on the behavior of weak solutions in exterior domains are also known. See, for instance, [1] and the references therein.

Remark 1.5. As we said in the introduction, lower bounds for the decay of the L^2 norm and faster decay rates when $n = 2$ and the mass of the data is 0 have been obtained in [22].

Remark 1.6. Concerning the case $p = 2$ in Remark 1.3, it is known that both $\|G(t) * u_0\|_2$ and $\|u(t)\|_2$ tend to zero as t goes to infinity. Moreover, in both cases no uniform decay rate can be found. This is well known for the heat equation, where $\|G(t) * u_0\|_2$ can decay at an arbitrarily slow algebraic rate or even exponentially by choosing an adequate $u_0 \in L^2(\mathbb{R}^n)$ (see [21], for instance). For Navier–Stokes equations in dimensions two and three, the proof of the lack of uniformity is due to Schonbek [21]. When $n \geq 3$ a function $\delta(t) \to \infty$, $t \to \infty$ can be found in such a way that

$$\delta(t)\|G(t) * u_0 - u(t)\|_2 \to 0 \quad \text{as } t \to \infty.$$

By Theorem 2 (iii) of [17], we may choose $\delta(t) = t^{\frac{n}{4}-\frac{1}{2}}$. However, we ignore whether such a $\delta(t)$ exists when $n = 2$.

1.3. Solutions with singular data. When $n = 2$, solutions of this kind have been constructed in [11] and its asymptotic behavior is studied in [12] and [6], where the following result is proved.

THEOREM 1.4. *Let u be a solution of* (NS) *with initial data $u_0 \in L^{2,\infty}(\mathbb{R}^2)$ such that* div $u_0 = 0$ *and $v_0 =$* curl $u_0 \in M(\mathbb{R}^2)$. *If the total variation of v_0 is small (see* [12]) *or, more generally, the mass of v_0, $|\int_{\mathbb{R}^2} v_0|$ is small (see* [6]), *then*

$$t^{\frac{1}{2}-\frac{1}{q}} \,\|u(t) - G(t) * u_0\|_q \to 0, \quad t \to \infty \quad \forall q > 2,$$

$$t^{1-\frac{1}{q}} \,\|\nabla u(t) - \nabla G(t) * u_0\|_q \to 0, \quad t \to \infty, \quad \forall 1 < q < \infty.$$

We denote the space of finite measures by $M(\mathbb{R}^2)$ and the usual Lorenz space by $L^{2,\infty}(\mathbb{R}^2)$.

The energy of these solutions is not necessarily finite. If we take $u_0 \in L^2(\mathbb{R}^2) \subset L^{2,\infty}(\mathbb{R}^2)$ with div $u_0 = 0$ and without hypothesis on curl u_0, then Theorem 1.3 asserts that

$$\|u(t) - G(t) * u_0\|_{L^2(\mathbb{R}^2)} \to 0 \quad \text{as } t \to \infty$$

but it gives no information on L^q norms with $q \neq 2$ or on the behavior of $\nabla u(t)$.

In higher dimensions, solutions with data in Morrey spaces have been constructed in [24] and [15]. However, little is known about the asymptotic behavior.

2. Dimension two: First term.

Let us take $u_0 \in L^2(\mathbb{R}^2)$ such that div $u_0 = 0$ and let u be the corresponding weak solution of (NS), which is known to be unique and smooth. Since $\|u(t)\|_2 \to 0$ as $t \to \infty$ (Theorem 1.3) we can choose t_0 such that $\|u(t_0)\|_2$ is small enough to apply the estimates of Theorem 1.1.

If we also assume $u_0 \in L^p(\mathbb{R}^2)$ for some $1 \leq p < 2$, then we know that $u(t) \in L^p$ for $t \geq 0$ (see [17]). Therefore, the decay estimates furnished by Theorem 1.2 also apply.

First, we are going to extend Theorem 1.2 to the case $p = 1$. In order to do that, we need the following result.

LEMMA 2.1. *Let $G(t)$ be the n-dimensional heat kernel. Then, for every $i = 1, \ldots, n$ and every $t > 0$, $\partial_i G(t)$ belongs to the Hardy space $\mathcal{H}^1(\mathbb{R}^n)$ and*

$$\|\partial_i G(t)\|_{\mathcal{H}^1(\mathbb{R}^n)} \leq C t^{\frac{-1}{2}}.$$

Proof. There are several equivalent definitions of $\mathcal{H}^1$ (see [9]).

$$\begin{aligned}\mathcal{H}^1(\mathbb{R}^n) &= \{u \in L^1(\mathbb{R}^n) \text{ s.t. } R_i * u \in L^1(\mathbb{R}^n),\ i = 1, \ldots, n\} \\ &= \{u \in L^1(\mathbb{R}^n) \text{ s.t. } \operatorname*{Sup}_{s>0} |h_s * u| \in L^1(\mathbb{R}^n)\},\end{aligned}$$

where $R_i(x) = \frac{x_i}{|x|^n}$ and $h_s(x) = s^{-n} h(\frac{x}{s})$ with $h \in \mathcal{S}(\mathbb{R}^n)$ such that $0 \leq h \leq 1$ and $\int h = 1$. We may endow $\mathcal{H}^1(\mathbb{R}^n)$ with either of the equivalent norms

$$\|u\|_{L^1(\mathbb{R}^n)} + \sum_{i=1}^{n} \|R_i * u\|_{L^1(\mathbb{R}^n)}$$

or

$$\|u\|_{L^1(\mathbb{R}^n)} + \left\| \operatorname*{Sup}_{s>0} |h_s * u| \right\|_{L^1(\mathbb{R}^n)}.$$

Let us fix any $i \in 1, \dots, n$. In order to prove that $\partial_i G(t) \in \mathcal{H}^1$, it suffices to verify that $\mathrm{Sup}_{s>0}|h_s * \partial_i G(t)| \in L^1(\mathbb{R}^n)$, where $h_s(x) = s^{-n}h(\frac{x}{s})$ and $h \in \mathcal{S}(\mathbb{R}^n)$ is such that $0 \le h \le 1$ and $\int_{\mathbb{R}^n} h(x)dx = 1$. We take $h = G(1)$ and then

$$|h_s * \partial_i G(t)(x)| = |\partial_i(G(t+s,x))| = \frac{|x_i|}{(4\pi(t+s))^{\frac{n}{2}}} e^{\frac{-|x|^2}{4(t+s)}}$$

so that

$$\operatorname*{Sup}_{s>0} |h_t * \partial_i G(t)| = |\partial_i G(t)| \in L^1(\mathbb{R}^n)$$

and

$$\|\partial_i G(t)\|_{\mathcal{H}^1} \le C t^{\frac{-1}{2}} \qquad \square$$

PROPOSITION 2.2. *Let u be a solution of* (NS) *in dimension two with initial data $u_0 \in L^1 \cap L^2(\mathbb{R}^2)$ such that* $\operatorname{div} u_0 = 0$. *Then*

(i) $u(t) \in L^q, \quad t > 0, \quad 1 \le q \le 2,$

(ii) $\|u(t)\|_q \le C t^{-1+\frac{1}{q}}, \quad t > 0, \quad q > 1,$

(iii) $\|u(t)\|_1 \le C, \quad t \ge 0.$

Remark 2.1. These estimates extend the estimates known for $q = 2$ (see [26], [17]).

Proof. (i) It is well known that $u \in L^\infty([0,\infty); L^2(\mathbb{R}^2))$. By taking the divergence of the equation we get the following equation for the pressure:

$$-\Delta\, p = \partial_j(u^i \partial_i u^j),$$

so that, up to a function of time, the pressure is given by $p = E_2 * \partial_j(u^i\partial_i u^j)$, where E_2 denotes the fundamental solution of $-\Delta$ in $\mathbb{R}^2$. Let us write the associated integral equation

$$\begin{aligned} u(t) = {} & G(t) * u_0 + \int_0^t \partial_i G(t-s) * u^i u(s) ds \\ & + \int_0^t \partial_i G(t-s) * \partial_j \nabla E_2 * u^i u^j(s) ds. \end{aligned}$$

Since $u_0 \in L^1$, $G(t) * u_0 \in L^q$ for all $q \ge 1$ and $t > 0$. On the other hand, $u(s) \in L^2$ implies that $u^i u(s) \in L^1$ and

$$\left\| \int_0^t \partial_i G(t-s) * u^i u(s) ds \right\|_q \le C \int_0^t (t-s)^{-1+\frac{1}{q}-\frac{1}{2}} \|u(s)\|_2^2 ds \le C t^{\frac{1}{q}-\frac{1}{2}},$$

provided that $1 \le q < 2$. Therefore, the first integral belongs to L^q for all $1 \le q < 2$.

As far as the second integral is concerned, since $\partial_i G(t)$ (Lemma 2.1) belongs to the Hardy space $\mathcal{H}^1(\mathbb{R}^2)$ and $\partial_j \nabla E_2$ is a Calderon–Zygmund kernel, we conclude that $\partial_i G(t-s) * \partial_j \nabla E_2 \in L^1$ and

$$\|\partial_i G(t-s) * \partial_j \nabla E_2\|_1 \le C \|\partial_i G(t-s)\|_{\mathcal{H}^1} \le C(t-s)^{\frac{-1}{2}}$$

(see [5]). Then

$$\left\| \int_0^t \partial_i G(t-s) * \partial_j \nabla E_2 * u^i u^j(s) ds \right\|_1 \le \int_0^t (t-s)^{\frac{-1}{2}} \|u(s)\|_2^2 ds \le C t^{\frac{1}{2}}.$$

In the same way, since $\partial_j \nabla E_2$ is a Calderon–Zygmund kernel, we have

$$\|\partial_i G(t-s) * \partial_j \nabla E_2\|_q \leq C_q \|\partial_i G(t-s)\|_q, \quad 1 < q < \infty$$

(see [5]) so that we get

$$\left\| \int_0^t \partial_j \nabla E_2 * \partial_i G(t-s) * u^i u^j(s) ds \right\|_q \leq \int_0^t (t-s)^{-1+\frac{1}{q}-\frac{1}{2}} \|u(s)\|_2^2 ds \leq C t^{\frac{1}{q}-\frac{1}{2}}$$

for $1 < q \leq 2$. Thus, the second integral belongs also to L^q for all $1 \leq q < 2$.

Remark 2.2. It is known that if $A \in (L^p)^n$, $B \in (L^{p'})^n$ are such that $\operatorname{div} A = 0$, $\operatorname{curl} B = 0$ (see [4]). Then, $A \cdot B$ belongs to the Hardy space $\mathcal{H}^1$ and

$$\|A \cdot B\|_{\mathcal{H}^1} \leq C \|A\|_p \|B\|_{p'}.$$

In our case, for a.e. $s \geq 0$ and every $j = 1, \dots, n$, we have $u(s), \nabla u^j(s) \in L^2$ with $\operatorname{div} u = 0$ and $\operatorname{curl}(\nabla\, u^j) = 0$. Therefore, $u^i \partial u^j(s) \in \mathcal{H}^1$. Taking into account that $\partial_j \nabla E_2$ is a Calderon–Zygmund kernel, we conclude that $\partial_j \nabla E_2 * u^i \partial_i u^j(s) \in L^1$ for a.e. $s > 0$.

(ii) Taking norms in the integral equation,

$$\begin{aligned} u(t) = {} & G(t) * u_0 + \int_0^t \partial_i G(t-s) * u^i u(s) ds \\ & + \int_0^t \partial_i G(t-s) * \partial_j \nabla E_2 * u^i u^j(s) ds, \end{aligned}$$

we get

$$\|u(t)\|_q \leq \|G(t) * u_0\|_q + \int_0^t \|\partial_i G(t-s) * u^i u(s)\|_q ds.$$

Taking into account some classical estimates on the heat kernel when $n = 2$,

$$\|\partial^\alpha G(t) * a\|_q \leq C t^{-\frac{|\alpha|}{2}-\frac{1}{r}+\frac{1}{q}} \|a\|_r, \quad q \geq r$$

together with the fact that

$$\|\partial_j \nabla E_2 * u^i u^j(s)\|_r \leq C \|u^i u^j(s)\|_r, \quad 1 < r < \infty,$$

it follows that

$$\|u(t)\|_q \leq C t^{-1+\frac{1}{q}} + C \int_0^t (t-s)^{-\frac{1}{2}-\frac{1}{r}+\frac{1}{q}} s^{\frac{-2}{p}+\frac{1}{r}} ds$$

thanks to the estimates

$$\|u(t)\|_{2r}^2 \leq C t^{2(\frac{-1}{p}+\frac{1}{2r})}$$

valid for $2 > p > 1$ if $2r \geq p$. To prove these estimates, it suffices to observe that (Theorem 1.3) the L^2 norm of u tends to 0 as t goes to infinity and then apply Theorem 1.1 and Remark 1.2.

We split the integral appearing in the inequality as follows:

(a)

$$\int_{\frac{t}{2}}^t (t-s)^{-\frac{1}{2}-\frac{1}{r}+\frac{1}{q}} s^{\frac{-2}{p}+\frac{1}{r}} \leq C\, t^{\frac{1}{2}+\frac{1}{q}-\frac{2}{p}},$$

choosing r such that $\frac{1}{2} - \frac{1}{r} + \frac{1}{q} > 0$, that is, $q \geq r > \frac{2q}{q+2}$.

(b)

$$\int_0^{\frac{t}{2}} (t-s)^{-\frac{1}{2}-\frac{1}{r}+\frac{1}{q}} s^{\frac{-2}{p}+\frac{1}{r}} \; \leq \; C\, t^{\frac{1}{2}+\frac{1}{q}-\frac{2}{p}},$$

choosing r such that $\frac{-2}{p} + \frac{1}{r} + 1 > 0$, that is, $1 < r < \frac{p}{2-p}$, which is possible if $p > 1$.

Therefore,

$$\|u(t)\|_q \; \leq \; Ct^{-1+\frac{1}{q}} + Ct^{\frac{1}{2}+\frac{1}{q}-\frac{2}{p}} \; \leq \; Ct^{-1+\frac{1}{q}}$$

if $1 < p \leq \frac{4}{3}$, where C is a constant depending on q and on the data.

(iii) Taking norms in

$$u(t) = G(t) * u_0 \; + \; \int_0^t \partial_i G(t-s) * u^i u(s) ds$$
$$+ \int_0^t \partial_i G(t-s) * \partial_j \nabla E_2 * u^i u^j(s) ds,$$

we get

$$\|G(t) * u_0\|_1 \leq C,$$

$$\left\| \int_0^t \partial_i G(t-s) * u^i u(s) ds \right\|_1 \leq C \int_0^t (t-s)^{\frac{-1}{2}} s^{\frac{-2}{p}+1} \leq Ct^{\frac{3}{2}-\frac{2}{p}} \leq C$$

if $p = \frac{4}{3}$ and also

$$\left\| \int_0^t \partial_i G(t-s) * \partial_j \nabla E_2 * u^i u^j(s) ds \right\|_1 \leq \int_0^t \|\partial_i G(t-s) * \partial_j \nabla E_2\|_1 \|u^i u^j(s) ds\|_1 \leq C$$

when $p = \frac{4}{3}$ since $\partial_i G$ belongs to the Hardy space $\mathcal{H}^1$. □

We prove now that, in a first approximation and for some classes of initial data, the solutions of the incompressible Navier–Stokes equations behave like the solutions of the heat equation with the same initial data.

THEOREM 2.3. *Let u be a weak solution of* (NS) *in dimension two with initial data $u_0 \in L^p \cap L^2(\mathbb{R}^2)$, $1 \leq p \leq 2$, such that* div $u_0 = 0$. *Then for any $q \geq p$,*

(i) *if $1 < p < 2$,*

$$\|G(t) * u_0 - u(t)\|_q \leq Ct^{-\frac{1}{p}+\frac{1}{q}} t^{-\frac{1}{p}+\frac{1}{2}}, \quad t > 0,$$

(ii) *if $p = 1$,*

$$\|G(t) * u_0 - u(t)\|_q \leq Ct^{-1+\frac{1}{q}} t^{-\frac{1}{2}} \log\, t, \quad t > 0,$$

(iii) *if $p = 2$,*

$$t^{\frac{1}{2}-\frac{1}{q}} \|u(t)\|_q \to 0 \quad as\, t \to \infty.$$

Remark 2.3. All the estimates were known when $q = 2$ for any $1 \leq p \leq 2$ ([26], [17]). We can replace the powers of t by powers of $t+1$ (and also log t by log $(t+1)$) when $p \leq q \leq 2$. In case $p = 2$, (iii) is known to hold for the solutions of the heat equation; hence, it holds for the difference $G(t) * u_0 - u(t)$, but this gives no extra information.

Proof. (i) From the integral equation we get

$$\|G(t) * u_0 - u(t)\|_q \leq C \int_0^t (t-s)^{-\frac{1}{2}-\frac{1}{r}+\frac{1}{q}} s^{\frac{-2}{p}+\frac{1}{r}}$$

for $q \geq r > 1$ and $2r \geq p$. As in the proof of (ii) below, we split the integral in two intervals $[0, \frac{t}{2}]$ and $[\frac{t}{2}, t]$. By choosing an adequate r we conclude that

$$\|G(t) * u_0 - u(t)\|_q \leq C t^{-\frac{1}{p}+\frac{1}{q}} t^{-\frac{1}{p}+\frac{1}{2}}.$$

(ii) Taking norms in the integral equation, we get

$$\begin{aligned} \|G(t) * u_0 - u(t)\|_q \leq & \int_0^t \|\partial_i G(t-s) * u^i u(s)\|_q ds \\ & + \int_0^t \|\partial_i G(t-s) * \partial_j \nabla E_2 * u^i u^j(s)\|_q ds. \end{aligned}$$

Since

$$\|\partial_i G(t-s) * \partial_j \nabla E_2\|_{r'} \leq \begin{cases} C\|\partial_i G(t-s)\|_{r'}, & 1 < r' < \infty, \\ C\|\partial_i G(t-s)\|_{\mathcal{H}^1}, & r' = 1, \end{cases}$$

both integrals are bounded by

$$C \int_0^t (t-s)^{-\frac{1}{2}-\frac{1}{r}+\frac{1}{q}} s^{-2+\frac{1}{r}}$$

for $q \geq r,\ 2r \geq 1,\ r \geq 1$. We split this integral as follows:

(a)

$$\int_{\frac{t}{2}}^t (t-s)^{-\frac{1}{2}-\frac{1}{r}+\frac{1}{q}} s^{-2+\frac{1}{r}} \ \leq\ C\, t^{\frac{1}{2}+\frac{1}{q}-2},$$

choosing r such that $\frac{1}{2} - \frac{1}{r} + \frac{1}{q} > 0$, that is, $q \geq r > \frac{2q}{q+2}$.

(b)

$$\int_0^{\frac{t}{2}} (t-s)^{-\frac{1}{2}-\frac{1}{r}+\frac{1}{q}} s^{-2+\frac{1}{r}} \ \leq\ C\, t^{\frac{1}{2}+\frac{1}{q}-2} \log\, t,$$

choosing $r = 1$. Therefore, (ii) holds.

(iii) It is known that $\|u(t)\|_2 \to 0$ as $t \to \infty$. Interpolating and taking into account that $t^{\frac{1}{2}-\frac{1}{r}}\|u(t)\|_r \leq C$ (see Theorem 1.1), we get

$$t^{\frac{1}{2}-\frac{1}{q}}\|u(t)\|_q \leq C(\|u(t)\|_2)^{1-\alpha}(t^{\frac{1}{2}-\frac{1}{r}}\|u(t)\|_r)^\alpha \leq C(\|u(t)\|_2)^{1-\alpha}$$

for any $2 < q < r$, which yields the result. $\square$

3. Dimension two: Second term. Let u be again a weak solution of (NS) and v a solution of

$$(\mathcal{L}_2) \quad \begin{cases} v_t - \Delta v = -h^i \partial_i h - \partial_j \nabla E_2 * h^i \partial_i h^j & \text{in } \mathbb{R}^+ \times \mathbb{R}^2, \\ \operatorname{div} v = 0 & \text{in } \mathbb{R}^+ \times \mathbb{R}^2, \\ v(x,0) = u_0, \ \operatorname{div} u_0 = 0 & \text{in } \mathbb{R}^2, \end{cases}$$

where $h(t) = G(t) * u_0$ so that v can be written as h plus a corrector term. Let us see whether the difference $u(t) - v(t)$ tends to 0 faster than $u(t) - h(t)$. We assume again that $u_0 \in L^2(\mathbb{R}^2) \cap L^p(\mathbb{R}^2)$, $1 \leq p < 2$.

Taking norms in the integral equation satisfied by the difference $u(t) - v(t)$ we get

$$\begin{aligned}
\|u(t) - v(t)\|_q \leq & \, \| \int_0^t \partial_i G(t-s) * (u^i(u-h) + h(u^i - h^i))(s) ds \|_q \\
& + \| \int_0^t \partial_i G(t-s) * \partial_j \nabla E_2 * (u^i(u-h) + h(u^i - h^i))(s) ds \|_q \\
\leq & \int_0^t \|\partial_i G(t-s)\|_{r'} (\|u(s)\|_{2r} + \|h(s)\|_{2r}) \|(u-h)(s)\|_{2r} ds \\
& + \int_0^t \|\partial_i G(t-s) * \partial_j \nabla E_2\|_{r'} (\|u(s)\|_{2r} + \|h(s)\|_{2r}) \|(u-h)(s)\|_{2r} ds
\end{aligned}$$

for $q \geq r$, $r' \geq 1$ such that $\frac{1}{r} + \frac{1}{r'} = \frac{1}{q}$. In view of the estimates

$$\begin{aligned}
\|u(t)\|_{2r} &\leq Ct^{-\frac{1}{p}+\frac{1}{2r}}, \\
\|h(t)\|_{2r} &\leq Ct^{-\frac{1}{p}+\frac{1}{2r}}, \\
\|(u-h)(t)\|_{2r} &\leq Ct^{-\frac{1}{p}+\frac{1}{2r}} t^{-\frac{1}{p}+\frac{1}{2}},
\end{aligned}$$

valid when $q \geq p$, $q \geq r \geq 1$, and $2r \geq p$, and the fact that

$$\|\partial_i G(t-s) * \partial_j \nabla E_2\|_{r'} \leq \begin{cases} C\|\partial_i G(t-s)\|_{r'}, & 1 < r' < \infty, \\ C\|\partial_i G(t-s)\|_{\mathcal{H}^1}, & r' = 1, \end{cases}$$

we get

$$\|u(t) - v(t)\|_q \leq C \int_0^t (t-s)^{-\frac{1}{2}-\frac{1}{r}+\frac{1}{q}} s^{-\frac{2}{p}+\frac{1}{r}} s^{-\frac{1}{p}+\frac{1}{2}} ds.$$

We split the integral as follows:

(a)

$$\int_{\frac{t}{2}}^t (t-s)^{-\frac{1}{2}-\frac{1}{r}+\frac{1}{q}} s^{-\frac{3}{p}+\frac{1}{r}+\frac{1}{2}} \leq Ct^{-\frac{3}{p}+\frac{1}{q}+1}$$

if $r > \frac{2q}{q+2}$;

(b)

$$\int_0^{\frac{t}{2}} (t-s)^{-\frac{1}{2}-\frac{1}{r}+\frac{1}{q}} s^{-\frac{3}{p}+\frac{1}{r}+\frac{1}{2}} \leq Ct^{-\frac{3}{p}+\frac{1}{q}+\frac{1}{2}}$$

if $-\frac{3}{p} + \frac{1}{r} + \frac{3}{2} > 0$, that is, $r \leq q$ and $1 \leq r < \frac{2p}{3(2-p)}$, provided that $p > \frac{6}{5}$.

Therefore,

$$\|(u-v)(t)\|_q \leq Ct^{-\frac{1}{p}+\frac{1}{q}} t^{-\frac{1}{p}+\frac{1}{2}} t^{-\frac{1}{p}+\frac{1}{2}}$$

if $2 > p > \frac{6}{5}$. This decay is faster than that corresponding to $u(t) - h(t)$.

Thus, we have proved the following theorem.

THEOREM 3.1. *Let u be a solution of the two-dimensional* (NS) *with initial data* $u_0 \in L^p \cap L^2(\mathbb{R}^2)$ $\frac{6}{5} < p < 2$ *and v a solution of* $(\mathcal{L}_2)$. *Then for any $q \geq p$, we have*

$$\|(u-v)(t)\|_q \leq Ct^{-\frac{3}{p}+\frac{1}{q}+1}.$$

4. Dimension two: Explicit second term. In this section, we shall obtain an explicit approximation up to the second term of both u and v. Let us consider the following three problems:

$$(\mathcal{P}_1) \qquad \begin{cases} w_t - \Delta w = 0 & \text{in } \mathbb{R}^+ \times \mathbb{R}^2, \\ \operatorname{div} w = 0 & \text{in } \mathbb{R}^+ \times \mathbb{R}^2, \\ w(x,0) = u_0, \ \operatorname{div} u_0 = 0 & \text{in } \mathbb{R}^2, \end{cases}$$

$$(\mathcal{P}_2) \qquad \begin{cases} w_t - \Delta w = -f^i \partial_i f & \text{in } \mathbb{R}^+ \times \mathbb{R}^2, \\ \operatorname{div} w = 0 & \text{in } \mathbb{R}^+ \times \mathbb{R}^2, \\ w(x,0) = 0 & \text{in } \mathbb{R}^2, \end{cases}$$

$$(\mathcal{P}_3) \qquad \begin{cases} w_t - \Delta w = -\partial_j \nabla E_2 * f^i \partial_i f^j & \text{in } \mathbb{R}^+ \times \mathbb{R}^2, \\ \operatorname{div} w = 0 & \text{in } \mathbb{R}^+ \times \mathbb{R}^2, \\ w(x,0) = 0 & \text{in } \mathbb{R}^2, \end{cases}$$

where $w = (w^1, w^2)$ and $f = (f^1, f^2)$. We assume that $u_0 \in L^1(\mathbb{R}^2)$, $\partial_j \nabla E_2 * f^i \partial_i f^j$, $f^i \partial_i f \in L^1(0,\infty; L^1(\mathbb{R}^2))$, and $\operatorname{div} f = 0$. Let us denote by w_i the solution of each $(\mathcal{P}_i)$. Then, $w = w_1 + w_2 + w_3$ is a solution of

$$(\mathcal{P}) \qquad \begin{cases} w_t - \Delta w = -f^i \partial_i f - \partial_j \nabla E_2 * f^i \partial_i f^j & \text{in } \mathbb{R}^+ \times \mathbb{R}^2, \\ \operatorname{div} w = 0 & \text{in } \mathbb{R}^+ \times \mathbb{R}^2, \\ w(x,0) = u_0, \ \operatorname{div} u_0 = 0 & \text{in } \mathbb{R}^2, \end{cases}$$

and satisfies the integral equation

$$w(t) = G(t) * u_0 - \int_0^t G(t-s) * f^i \partial_i f(s) ds - \int_0^t G(t-s) * \nabla \partial_j E_2 * f^i \partial_i f^j(s) ds.$$

Therefore, we may think of the solutions u of (NS) or v of $(\mathcal{L}_2)$ as being the sum of the following three terms:

- a term w_1 which solves $(\mathcal{P}_1)$,
- a term w_2 which solves $(\mathcal{P}_2)$ with $f = u$ (resp., $f = h$),
- a term w_3 which solves $(\mathcal{P}_3)$ with $f = u$ (resp., $f = h$).

We will study the asymptotic behavior of the solutions of these problems in order to get information on u and v with initial data $u_0 \in L^1 \cap L^2(\mathbb{R}^2)$.

4.1. Problem $(\mathcal{P}_1)$. The solution of this heat equation is $w_1 = G(t) * u_0$, whose asymptotic behavior is well known. In case $u_0 \in L^1(\mathbb{R}^2)$,

$$t^{1-\frac{1}{q}} \|G(t) * u_0 - MG(t)\|_q \to 0 \quad \text{as } t \to \infty$$

for any $1 \leq q \leq \infty$, where $M = \int_{\mathbb{R}^2} u_0$. Thus, the first term in the development of w_1 when $t \to \infty$ is $MG(t)$. If $u_0 \in L^1(1+|x|;\mathbb{R}^2)$, we know further that

$$t^{1-\frac{1}{q}+\frac{1}{2}}\|G(t) * u_0 - MG(t)\|_q \leq C\|u_0\|_{L^1(|x|,\,\mathbb{R}^2)}.$$

In fact, setting $M^i = \int_{\mathbb{R}^2} x^i u_0$, we have

$$t^{\frac{3}{2}-\frac{1}{q}}\|G(t) * u_0 - MG(t) + M^i\partial_i G(t)\|_q \to 0 \quad \text{as } t \to \infty.$$

We can obtain more terms when more moments of the initial data are finite (see [7]).

In case $u_0 \in L^p(\mathbb{R}^2)$, $1 < p < \infty$, we have

$$t^{\frac{1}{p}-\frac{1}{q}}\|G(t) * u_0\|_q \to 0 \quad \text{as } t \to \infty$$

for any $p \leq q \leq \infty$, so that the first term in the development is 0.

This convergence is clear when $u_0 \in \mathcal{D}(\mathbb{R}^n)$, since $u_0 \in L^1(\mathbb{R}^n)$ and then $\|G(t) * u_0\|_p \leq C(1+t)^{-1+\frac{1}{p}}$. Thanks to the fact that $\|G(t) * u_0\|_p$ decreases as time grows, we can extend the result to any $u_0 \in L^p(\mathbb{R}^n)$ by density. Given $u_0 \in L^p(\mathbb{R}^n)$, we take a sequence $u_{0,k} \subset \mathcal{D}(\mathbb{R}^n)$ such that $u_{0,k} \to u_0$ in $L^p(\mathbb{R}^n)$. Let u_k be the solution of the heat equation with data $u_{0,k}$. Then

$$\|u(t)\|_p \leq \|u_k(t)\|_p + \|u(t) - u_k(t)\|_p \leq \|u_k(t)\|_p + \|u_0 - u_{0,k}\|_p.$$

Given $\varepsilon > 0$, we can choose k large enough to have

$$\|u_0 - u_{0,k}\|_p \leq \frac{\varepsilon}{2}$$

and, fixing that k, we get

$$\|u_k(t)\|_p \leq \frac{\varepsilon}{2}$$

for $t \geq t_\varepsilon$. Therefore, $\|u(t)\|_p \to 0$ as $t \to \infty$. Once this is proved, it is clear that

$$t^{\frac{1}{p}-\frac{1}{q}}\|G(t) * u_0\|_q \to 0 \quad \text{as } t \to \infty$$

for any $p \leq q \leq \infty$.

4.2. Problem ($\mathcal{P}_2$). In order to describe the asymptotic behavior of w_2, we are going to use a scaling technique. In the following, we shall drop the subscript 2 and write only w. Since we want to take $f = u$, u being a weak solution of (NS) with data $u_0 \in L^1 \cap L^2(\mathbb{R}^2)$, we shall assume that

$$f(t) \in BC(0,\infty;L^2(\mathbb{R}^2)), \quad \|f(t)\|_2 \leq C(1+t)^{\frac{-1}{2}}, \quad t \geq 0,$$

so that we can rewrite the integral expression for w,

$$w(t) = -\int_0^t \partial_i G(t-s) * f^i f(s) ds.$$

By rescaling, we see that the functions $w_\lambda(t,x) = \lambda^2 w(\lambda^2 t, \lambda x)$ satisfy

$$w_\lambda(t) \;=\; -\lambda^{-1}\int_0^t \partial_i G(t-s) * f^i_\lambda f_\lambda(s) ds.$$

We remark that

$$\|w_\lambda(t)\|_q = \lambda^{2(1-\frac{1}{q})}\|w(\lambda^2 t)\|_q.$$

Thus, if we want to make precise the asymptotic behavior of w when $t \to \infty$, it suffices to find a function g such that

$$\|w_\lambda(t) - g_\lambda(t)\|_q \delta(\lambda) \to 0 \quad \text{as } \lambda \to \infty$$

for some $\delta(\lambda)$ tending to ∞ as $\lambda \to \infty$, where $g_\lambda(t,x) = \lambda^2 g(\lambda^2 t, \lambda x)$. That implies

$$\|w(t) - g(t)\|_q t^{1-\frac{1}{q}} \delta(t^{\frac{1}{2}}) \to 0 \quad \text{as } t \to \infty.$$

It is easy to prove that

$$\|w_\lambda\|_q \;=\; \lambda^{-1}\| \int_0^t \partial_i G(t-s) * f_\lambda^i f_\lambda(s) ds\|_q$$

is bounded by $C \ \log \lambda^2 \ \lambda^{-1}$. Therefore, the same kind of bound should hold for g_λ, but the difference $\|g_\lambda(t) - w_\lambda(t)\|_q$ should go to 0 faster. Under certain conditions, it is possible to take $g(t) = (\frac{M^i M}{2}) \log \ t \ \partial_i G(t)$ with $M = (M^1, M^2)$ and $\delta(t) = t^{\frac{1}{2}} / \log \ t$. More precisely, we prove the following theorem.

THEOREM 4.1. *Let w be a solution of $(\mathcal{P}_2)$ and $q \geq 1$. Let us assume that*

(i)

$$(1+t)^{\frac{1}{2}+\varepsilon}\|f(t) - G * u_0(t)\|_2 \leq C, \quad t \geq 0$$

for some $\varepsilon > 0$, and

(ii)

$$\|f(t)\|_{2r} \;\leq\; C(1+t)^{-1+\frac{1}{2r}}, \qquad t \geq 0,$$

where $q \geq r > \frac{2q}{q+2}$.

Then

$$\frac{t^{\frac{3}{2}-\frac{1}{q}}}{\log(t)} \left\| w(t) - \log \ t \ \partial_i G(t) \left(\frac{M^i M}{2}\right) \right\|_q \to 0 \quad \textit{as } t \to \infty,$$

where $M = (M^1, M^2) = \int_{\mathbb{R}^2} u_0(x) dx$, provided that $|x|^{\frac{\alpha}{2}} u_0 \in L^1$ and $|x|^{\frac{\alpha}{2}} u_0 \in L^2$ for some $\alpha \geq 2$.

Remark 4.1. It follows from (i) that (ii) holds, replacing $2r$ by 2, and that

$$t^{\frac{1}{2}}\|f(t) - MG(t)\|_2 \to 0 \quad \text{as } t \to \infty.$$

Proof. Setting

$$g_\lambda(1) = \lambda^{-1} \ \log \ \lambda^2 \ \partial_i G(1) \left(\frac{M^i M}{2}\right) = \left(\log(\cdot) \ \partial_i G(\cdot) \left(\frac{M^i M}{2}\right)\right)_\lambda (1),$$

we see that

$$\frac{t^{1+\frac{1}{2}-\frac{1}{q}}}{\log(t)} \left\| \int_0^t \partial_i G(t-s) * f^i f(s) ds - \log(t) \ \partial_i G(t) \left(\frac{M^i M}{2}\right) \right\|_q \to 0 \quad \text{as } t \to \infty$$

is equivalent to

$$\left\| \lambda^{-1} \int_0^1 \partial_i G(1-s) * f_\lambda^i f_\lambda(s) ds - g_\lambda(1) \right\|_q \;=\; o(1) \log(\lambda^2) \lambda^{-1} \quad \text{as } \lambda \to \infty.$$

Making the change of variables $z(s,y) = e^s f(e^s - 1, e^{\frac{s}{2}} y)$, it follows from (i) that

$$\lim_{\sigma\to\infty}\left\{\frac{1}{\sigma}\int_0^\sigma\int_{\mathbb{R}^2} z^i z\right\} = M^iM\int G(1)^2 = \frac{M^iM}{2}.$$

Thus, we must prove

$$\left\|\int_0^1 \partial_i G(1-s) * \frac{f^i_\lambda f_\lambda(s)}{\log\,\lambda^2}ds - \partial_i G(1)\lim_{\sigma\to\infty}\left\{\frac{1}{\sigma}\int_0^\sigma\int_{\mathbb{R}^2} z^i z\right\}\right\|_q \to 0 \quad \text{as } \lambda\to\infty$$

We remark first that

$$\begin{aligned}
&\int_0^1\left(\partial_i G(1-s) * \frac{f^i_\lambda f_\lambda(s)}{\log\,\lambda^2}\right)(x)ds\\
&\qquad = \int_0^1\int_{\mathbb{R}^2}\partial_i G(1-s, x-y)\frac{f^i f(\lambda^2 s, \lambda x)}{\log\,\lambda^2}\lambda^4 dsdy\\
&\qquad = \int_0^{\lambda^2}\int_{\mathbb{R}^2}\partial_i G\left(1-\frac{s}{\lambda^2}, x-\frac{y}{\lambda}\right)\frac{f^i f(s,y)}{\log\,\lambda^2}dsdy\\
&\qquad = \int_0^{\log(\lambda^2+1)}\int_{\mathbb{R}^2}\partial_i G\left(1-\frac{e^s-1}{\lambda^2}, x-\frac{ye^{\frac{s}{2}}}{\lambda}\right)\frac{z^i z(s,y)}{\log\,\lambda^2}dsdy.
\end{aligned}$$

Therefore, it is enough to prove that

$$\int_0^{\lambda^2}\int_{\mathbb{R}^2}\partial_i G\left(1-\frac{s}{\lambda^2}, x-\frac{y}{\lambda}\right)\frac{f^i f(s,y)}{\log\,\lambda^2}dsdy \;-\; \partial_i G(1,x)\int_0^{\lambda^2}\int_{\mathbb{R}^2}\frac{f^i f(s,y)}{\log\,\lambda^2}dsdy$$

and

$$\partial_i G(1,x)\int_0^{\lambda^2}\int_{\mathbb{R}^2}\frac{f^i f(s,y)}{\log\,\lambda^2}dsdy \;-\; \partial_i G(1,x)\lim_{\sigma\to 0}\left\{\frac{1}{\sigma}\int_0^\sigma\int_{\mathbb{R}^2} z^i z(s,y)\right\}$$

tend to 0 in L^q_x when $\lambda\to\infty$. Since

$$\int_0^{\lambda^2}\int_{\mathbb{R}^2}\frac{f^i f(s,y)}{\log\,\lambda^2}dsdy = \frac{1}{\log\,\lambda^2}\int_0^{\log(1+\lambda^2)}\int_{\mathbb{R}^2} z^i z(s,y)dsdy,$$

the last convergence is clear. We must prove only the first one. In order to do that, we split the integral as follows:

$$\begin{aligned}
&\int_0^{\lambda^2}\int_{\mathbb{R}^2}\left(\partial_i G\left(1-\frac{s}{\lambda^2}, x-\frac{y}{\lambda}\right) - \partial_i G(1,x)\right)\frac{f^i f(s,y)}{\log\,\lambda^2}dsdy\\
&\qquad = \int_0^{\lambda^2\delta}\int_{|y|\le\lambda\delta}\left(\partial_i G\left(1-\frac{s}{\lambda^2}, x-\frac{y}{\lambda}\right) - \partial_i G(1,x)\right)\frac{f^i f(s,y)}{\log\,\lambda^2}dsdy\\
&+ \int_{\lambda^2\delta}^{\lambda^2}\int_{\mathbb{R}^2}\partial_i G\left(1-\frac{s}{\lambda^2}, x-\frac{y}{\lambda}\right)\frac{f^i f(s,y)}{\log\,\lambda^2}dsdy + \int_{\lambda^2\delta}^{\lambda^2}\int_{\mathbb{R}^2}\partial_i G(1,x)\frac{f^i f(s,y)}{\log\,\lambda^2}dsdy\\
&+ \int_0^{\lambda^2\delta}\int_{|y|>\lambda\delta}\partial_i G\left(1-\frac{s}{\lambda^2}, x-\frac{y}{\lambda}\right)\frac{f^i f(s,y)}{\log\,\lambda^2}dsdy\\
&+ \int_0^{\lambda^2\delta}\int_{|y|>\lambda\delta}\partial_i G(1,x)\frac{f^i f(s,y)}{\log\,\lambda^2}dsdy\\
&\qquad = I^1_{\delta,\lambda} + I^2_{\delta,\lambda} + J^2_{\delta,\lambda} + I^3_{\delta,\lambda} + J^3_{\delta,\lambda}.
\end{aligned}$$

Estimate $I^1_{\delta,\lambda}$.

$$\|I^1_{\delta,\lambda}\|_{L^q_x} \le C \int_0^{\lambda^2\delta} \int_{|y|<\lambda\delta} \left\| \partial_i G\left(1-\frac{s}{\lambda^2}, x-\frac{y}{\lambda}\right) - \partial_i G(1,x)\right\|_{L^q_x} \frac{|f^i||f|(s,y)}{\log \lambda^2} dsdy.$$

Thanks to the continuity of translations in L^q_x and the continuity with respect to t, given $\varepsilon > 0$ we can choose $\delta > 0$ such that

$$\operatorname*{Sup}_{s\le\lambda^2\delta,\ |y|\le\lambda\delta} \left\| \partial_i G\left(1-\frac{s}{\lambda^2}, x-\frac{y}{\lambda}\right) - \partial_i G(1,x)\right\|_{L^q_x} \le \varepsilon.$$

Therefore,

$$\|I^1_{\delta,\lambda}\|_{L^q_x} \le \varepsilon \int_0^{\lambda^2\delta}\int_{|y|\le\lambda\delta} \frac{|f|^2(s,y)}{\log\lambda^2} dsdy \le \varepsilon \int_0^{\log(1+\lambda^2\delta)} \int_{\mathbb{R}^2} \frac{|z|^2(s,y)}{\log\lambda^2} dsdy \le \varepsilon C$$

uniformly with respect to λ, since

$$\|z(s)\|_2 = e^{\frac{s}{2}}\ \|f(e^s-1)\|_2 \le C.$$

Estimate $J^2_{\delta,\lambda}$.

$$\begin{aligned}\|J^2_{\delta,\lambda}\|_{L^q_x} &\le C\|\nabla G(1)\|_{L^q_x} \int_{\lambda^2\delta}^{\lambda^2}\int_{\mathbb{R}^2} \frac{|f|^2(s,y)}{\log\lambda^2} dsdy \\ &\le \|\nabla G(1)\|_{L^q_x} \int_{\log(1+\lambda^2\delta)}^{\log(1+\lambda^2)} \int_{\mathbb{R}^2} \frac{|z|^2(s,y)}{\log\lambda^2} dsdy \le C\frac{\log(\frac{1+\lambda^2}{1+\lambda^2\delta})}{\log\lambda^2}.\end{aligned}$$

Therefore, it tends to 0 when $\lambda \to \infty$ and δ is fixed.

Estimate $I^2_{\delta,\lambda}$.

$$\|I^2_{\delta,\lambda}\|_{L^q_x} \le \frac{1}{\log(\lambda^2)} \int_{\log(1+\lambda^2\delta)}^{\log(1+\lambda^2)} \left\| \int_{\mathbb{R}^2} \partial_i G\left(1-\frac{e^s-1}{\lambda^2}, x-\frac{e^{\frac{s}{2}}y}{\lambda}\right) z^i z(y,s) dy\right\|_{L^q_x} ds.$$

We first observe that

$$\begin{aligned}&\int_{\mathbb{R}^2} \partial_i G\left(1-\frac{e^s-1}{\lambda^2}, x-\frac{e^{\frac{s}{2}}y}{\lambda}\right) z^i z(y,s)dy \\ &= \left(\partial_i G\left(1-\frac{e^s-1}{\lambda^2}, y\right) *_y (\lambda e^{\frac{-s}{2}})^2\ z^i z(s,\lambda e^{\frac{-s}{2}}y)\right)(x).\end{aligned}$$

Thus,

$$\begin{aligned}&\left\| \int_{\mathbb{R}^2} \partial_i G\left(1-\frac{e^s-1}{\lambda^2}, x-\frac{e^{\frac{s}{2}}y}{\lambda}\right) z^i z(y,s)dy\right\|_{L^q_x} \\ &\le C\left(1-\frac{e^s-1}{\lambda^2}\right)^{-(\frac{1}{r}-\frac{1}{q})-\frac{1}{2}} \|(\lambda e^{\frac{-s}{2}})^2 z^i z(s,\lambda e^{\frac{-s}{2}}y)\|_{L^r_x}\end{aligned}$$

for $r \le q$. Since

$$\|z(s)\|_{2r} = e^{\frac{s}{2}(2-\frac{1}{r})}\ \|f(e^s-1)\|_{2r}\ \le C,$$

it follows that

$$\|(\lambda e^{\frac{-s}{2}})^2 z^i z(\lambda e^{\frac{-s}{2}} y, s)\|_{L^r_x} \;\leq\; \|z(s)\|^2_{L^{2r}_x}(\lambda e^{\frac{-s}{2}})^{2(1-\frac{1}{r})} \;\leq\; C(\lambda e^{\frac{-s}{2}})^{2(1-\frac{1}{r})}.$$

Therefore,

$$\begin{aligned}\|I^2_{\delta,\lambda}\|_{L^q_x} &\leq \frac{C\lambda^{2(1-\frac{1}{r})}}{\log(\lambda^2)} \int_{\log(1+\lambda^2\delta)}^{\log(1+\lambda^2)} \left(1-\frac{e^s-1}{\lambda^2}\right)^{-(\frac{1}{r}-\frac{1}{q})-\frac{1}{2}} (e^{\frac{-s}{2}})^{2(1-\frac{1}{r})} ds \\ &\leq \frac{C\lambda^{2(1-\frac{1}{r})}(\lambda^2\delta+1)^{(-1+\frac{1}{r})}}{\log(\lambda^2)} \int_{\log(1+\lambda^2\delta)}^{\log(1+\lambda^2)} \left(1-\frac{e^s-1}{\lambda^2}\right)^{-(\frac{1}{r}-\frac{1}{q})-\frac{1}{2}} ds \\ &\leq \frac{C}{\log\ \lambda^2}\left(\frac{\lambda^2}{1+\delta\lambda^2}\right)^{2-\frac{1}{r}} \int_\delta^1 (1-t)^{-(\frac{1}{r}-\frac{1}{q})-\frac{1}{2}} dt \;\leq\; \frac{C}{\log\ \lambda^2},\end{aligned}$$

where C is a constant depending on δ but not on λ, taking $r > \frac{2q}{q+2}$ in order to have $-(\frac{1}{r}-\frac{1}{q})+\frac{1}{2} > 0$.

We conclude that

$$\|I^2_{\delta,\lambda}\|_{L^q_x} \;\leq\; \frac{C}{\log \lambda^2} \longrightarrow 0 \quad \text{as } \lambda \longrightarrow \infty$$

for a fixed δ.

Estimate $J^3_{\delta,\lambda}$.

$$\|J^3_{\delta,\lambda}\|_{L^q_x} \;\leq\; \|\nabla G(1)\|_{L^q_x} \int_0^{\lambda^2\delta} \int_{|y|\geq\delta\lambda} \frac{|f|^2(s,y)}{\log\ \lambda^2}.$$

We must prove that

$$\int_0^{\lambda^2\delta} \int_{|y|\geq\delta\lambda} \frac{|f|^2(s,y)}{\log\ \lambda^2} \longrightarrow 0 \quad \text{as } \lambda \longrightarrow \infty$$

for δ fixed. For any $\alpha \geq 2$ we have

$$\||y|^{\frac{\alpha}{2}} G * u_0(t,y)\|_2^2 \;\leq\; C(t^{\frac{\alpha}{2}-1} + (t+1)^{-1}) \;\leq\; C(t^{\frac{\alpha}{2}-1})$$

provided that u_0, $|x|^{\frac{\alpha}{2}} u_0 \in L^1$ and $|x|^{\frac{\alpha}{2}} u_0 \in L^2$. It follows that if $f = G * u_0$,

$$\int_0^{\lambda^2\delta} \int_{|y|\geq\delta\lambda} \frac{|y|^\alpha |f|^2(y,s)}{\lambda^\alpha\ \log\ \lambda^2} \;\leq\; C\frac{(\lambda^2\delta)^{\frac{\alpha}{2}}}{\lambda^\alpha\ \log\ \lambda^2} \;\leq\; \frac{C}{\log\ \lambda^2}.$$

Since $\|f(t) - G * u_0(t)\|_2 \leq C(1+t)^{\frac{-1}{2}-\varepsilon}$,

$$\int_0^{\lambda^2\delta} \int_{|y|\geq\delta\lambda} \frac{|f(s,y) - G * u_0(s,y)|^2}{\log\ \lambda^2} \;\leq\; \frac{C}{\log\ \lambda^2}.$$

Therefore, for a fixed δ,

$$\|J^3_{\delta,\lambda}\|_{L^q_x} \longrightarrow 0 \quad \text{as } \lambda \longrightarrow \infty.$$

Estimate $I^3_{\lambda,\delta}$.

$$\|I^3_{\lambda,\delta}\|_{L^q_x} \le \int_0^{\lambda^2\delta} \left\| \int_{|y|\ge\delta\lambda} \partial_i G\left(1-\frac{s}{\lambda^2}, x-\frac{y}{\lambda}\right) \frac{f^i f(s,y)}{\log\ \lambda^2} \right\|_{L^q_x} .$$

As in Estimate $I^2_{\lambda,\delta}$, but taking $r = 1$, we get

$$\begin{aligned}\|I^3_{\lambda,\delta}\|_{L^q_x} &\le C \int_0^{\lambda^2\delta} \left(1-\frac{s}{\lambda^2}\right)^{-1+\frac{1}{q}-\frac{1}{2}} \left\|\frac{f^i f(s,y)}{\log\ \lambda^2}\right\|_{L^1(|y|\ge\lambda\delta)} \\ &\le C \int_0^{\lambda^2\delta} \int_{|y|\ge\delta\lambda} \frac{|f|^2(s,y)}{\log\ \lambda^2} dyds\end{aligned}$$

and we finish in the same way as in estimate $J^3_{\lambda,\delta}$. □

4.3. Problem ($\mathcal{P}_3$). In the following, we shall drop the subscript 3 and write only w. As before, we shall assume that

$$f(t) \in BC(0,\infty; L^2(\mathbb{R}^2)), \quad \|f(t)\|_2 \le C(1+t)^{\frac{-1}{2}}, \quad t \ge 0,$$

so that we can rewrite the integral expression for w,

$$w(t) \ = \ -\int_0^t \partial_i G(t-s) * \nabla\partial_j E_2 * f^i f^j(s) ds.$$

By rescaling, we see that the functions $w_\lambda(t,x) = \lambda^2 w(\lambda^2 t, \lambda x)$ satisfy

$$w_\lambda(t) \ = \ -\lambda^{-1} \int_0^t \partial_i G(t-s) * \nabla\partial_j E_2 * f^i_\lambda f^j_\lambda(s) ds.$$

Since $\|\partial_i G(t-s) * \nabla\partial_j E_2\|_1 \le C\|\partial_i G(t-s)\|_{\mathcal{H}^1}$, it is easy to prove that

$$\| \int_0^t \partial_i G(t-s) * \nabla\partial_j E_2 * f^i_\lambda f^j_\lambda(s) ds\|_q$$

is bounded by $C\ \log\lambda^2\ \lambda^{-1}$.

It suffices to rewrite step by step the proof of Theorem 4.1, replacing the L^q norms of $\partial_i G(t-s)$ by the L^q norms of $\partial_i G(t-s) * \nabla\partial_j E_2$ to get the following theorem.

THEOREM 4.2. *Let w be a solution of ($\mathcal{P}_3$) and $q \ge 1$. Let us assume that*

(i)

$$(1+t)^{\frac{1}{2}+\varepsilon}\|f(t) - G * u_0(t)\|_2 \le C, \quad t \ge 0$$

for some $\varepsilon > 0$, and

(ii)

$$\|f(t)\|_{2r} \ \le \ C(1+t)^{-1+\frac{1}{2r}}, \quad t \ge 0,$$

where $q \ge r > \frac{2q}{q+2}$. Then

$$\frac{t^{\frac{3}{2}-\frac{1}{q}}}{\log\ t} \left\| w(t) - \left(\frac{M^i M^j}{2}\right) \log\ t\ \partial_i G(t) * \nabla\partial_j E_2 \right\|_q \to 0 \quad as\, t \to \infty,$$

provided that $u_0 \in L^1 \cap L^2(\mathbb{R}^2, |x|)$.

Remark 4.2. If we take u to be a solution of (NS) and v a solution of $(\mathcal{L}_2)$ with initial data $u_0 \in (L^1 \cap L^2)(\mathbb{R}^2, 1+|x|) \cap L^{2r}(\mathbb{R}^2)$, then we can apply the theorem with $f = u$ or $f = G(t) * u_0$ and $M = \int_{\mathbb{R}^2} u_0(x)dx$ to obtain the behavior of the third term, which is the same for both of them.

4.4. Conclusion. Putting together the previous results we obtain the following theorem.

THEOREM 4.3. *Let u be a solution of the two-dimensional* (NS) *with initial data $u_0 \in (L^1 \cap L^2)(\mathbb{R}^2, 1+|x|)$ such that* div $u_0 = 0$ *and set $M = \int_{\mathbb{R}^2} u_0(x)dx$. Then for a given $q \geq 1$,*

$$\frac{t^{\frac{3}{2}-\frac{1}{q}}}{\log(t)} \left\| u(t) - MG(t) + \log(t) \, \left(\partial_i G(t) \left(\frac{M^i M}{2} \right) + \partial_i G(t) * \nabla \partial_j E_2 \left(\frac{M^i M^j}{2} \right) \right) \right\|_q$$

tends to 0 *as t goes to infinity provided that $u_0 \in L^{2r}(\mathbb{R}^2)$ for some $q \geq r > \frac{2q}{q+2}$.*

Remark 4.3. When $u_0 \in (L^1 \cap L^2)(\mathbb{R}^2, 1+|x|)$ we can take $r = 1$ and then the result holds for $1 \leq q < 2$.

5. Higher dimensions: $n > 2$. In what follows, we shall be concerned with solutions u of (NS) taking data $u_0 \in L^p \cap L^n$ such that div $u_0 = 0$, $\|u_0\|_n$ is small and $1 \leq p \leq n$. For that kind of data, unique global strong solutions are known to exist.

5.1. Decay estimates. We improve Theorem 1.2(i) here by proving the following result.

THEOREM 5.1. *Let u be a strong solution of* (NS) *with data $u_0 \in L^p \cap L^n(\mathbb{R}^n)$, $1 \leq p \leq n$, of small L^n norm such that* div $u_0 = 0$. *Then*

$$\|u(t)\|_q \leq Ct^{(-\frac{1}{p}+\frac{1}{q})\frac{n}{2}}$$

if $q \geq p$.

Proof. Taking norms in the integral equation associated to (NS) we get

$$\|u(t)\|_q \;\leq\; Ct^{(-\frac{1}{p}+\frac{1}{q})\frac{n}{2}} \;+\; C\int_0^t (t-s)^{-\frac{1}{2}+(-\frac{1}{r}+\frac{1}{q})\frac{n}{2}} s^{(\frac{-2}{k}+\frac{1}{r})\frac{n}{2}}$$

for $q \geq p$, $q \geq r$, $2r \geq k$, $r \geq 1$. Here we have used the fact that

$$\|\partial_i G * \partial_j \nabla E_2\|_r \;\leq\; \begin{cases} C\|\partial_i G\|_r, & 1 < r < \infty, \\ C\|\partial_i G\|_{\mathcal{H}^1}, & r = 1 \end{cases}$$

and the estimates (see Theorem 1.2 and Remarks 1.2)

$$\|u(t)\|_{2r}^2 \;\leq\; Ct^{2(\frac{-1}{k}+\frac{1}{2r})\frac{n}{2}},$$

known to be valid for $1 \leq k \leq n$, $2r \geq k \geq p$ and, if $k < \frac{n}{2}$, $2r \leq \frac{kn}{n-2k}$. We have also used some classical estimates on the heat kernel,

$$\|\partial^\alpha G(t) * a\|_q \;\leq\; Ct^{-\frac{|\alpha|}{2}+(-\frac{1}{r}+\frac{1}{q})\frac{n}{2}} \|a\|_r$$

for $q \geq r$. We remark that $2r \geq k$ yields a restriction on r if $k > 2$.

We split the integral as follows:

(a)

$$\int_{\frac{t}{2}}^{t} (t-s)^{-\frac{1}{2}+(-\frac{1}{r}+\frac{1}{q})\frac{n}{2}} s^{(\frac{-2}{k}+\frac{1}{r})\frac{n}{2}} \leq C\, t^{\frac{1}{2}+(\frac{1}{q}-\frac{2}{k})\frac{n}{2}},$$

choosing r such that $\frac{1}{2}+(-\frac{1}{r}+\frac{1}{q})\frac{n}{2} > 0$, that is, $q \geq r > \frac{nq}{q+n}$.

(b)

$$\int_{0}^{\frac{t}{2}} (t-s)^{-\frac{1}{2}+(-\frac{1}{r}+\frac{1}{q})\frac{n}{2}} s^{(\frac{-2}{k}+\frac{1}{r})\frac{n}{2}} \leq C\, t^{\frac{1}{2}+(\frac{1}{q}-\frac{2}{k})\frac{n}{2}},$$

choosing r such that $(\frac{-2}{k}+\frac{1}{r})\frac{n}{2}+1 > 0$, that is, $1 \leq r < \frac{nk}{2(n-k)}$.

Those conditions imply $k > \frac{2n}{n+2}$ and $q \geq \frac{k}{2}$.

Supposing the above restrictions to be verified, we should get

$$\|u(t)\|_q \leq Ct^{(-\frac{1}{p}+\frac{1}{q})\frac{n}{2}} + Ct^{\frac{1}{2}+(\frac{1}{q}-\frac{2}{k})\frac{n}{2}} \leq Ct^{(-\frac{1}{p}+\frac{1}{q})\frac{n}{2}}$$

if $k = \frac{2pn}{n+p}$, where C is a constant depending on q and on the data. This is valid for any $q \geq \frac{k}{2} = \frac{pn}{n+p}$. Since $\frac{np}{n+p} \leq p$, it is valid for any $q \geq q$. On the other hand $k = \frac{2pn}{n+p} > \frac{2n}{n+2}$. It remains to check that, when $k < \frac{n}{2}$, the conditions $q \geq r > \frac{nq}{q+n}$ and $1 \leq r < \frac{nk}{2(n-k)}$ are compatible with the restriction $2r \leq \frac{kn}{n-2k}$. The following possibilities arise:

- $p \geq \frac{n}{3}$. Since $k \geq p$, the restriction is unnecessary so that we can find an adequate r in both cases.
- $p < \frac{n}{3}$. We have $\frac{nk}{2(n-k)} < \frac{kn}{2(n-2k)}$ so that we can find an adequate r for case (b). It remains that $\frac{nq}{q+n} \leq \frac{kn}{2(n-2k)}$, that is, $q(2n-5k) \leq kn$. When $p \geq \frac{n}{4}$, we get $2n-5k \leq 0$ and the inequality holds for any $q \geq p$. When $p < \frac{n}{4}$, we need to take $q \leq \frac{pn}{n-4p}$ in order to find some r for (a).

Therefore, the decay estimate

$$\|u(t)\|_q \leq Ct^{(-\frac{1}{p}+\frac{1}{q})\frac{n}{2}} \tag{$*$}$$

now holds for $q \geq p$ if $p \geq \frac{n}{4}$ and for $\frac{pn}{n-4p} \geq q \geq p$ when $1 \leq p < \frac{n}{4}$. If $n \geq 4$, we have concluded since $p < \frac{n}{4}$ is excluded.

If we iterate this process using these new decay rates when estimating the integrals appearing in the integral equation, we obtain that $(*)$ holds for $q \geq p$ if $p \geq \frac{n}{8}$ and for $\frac{pn}{n-8p} \geq q \geq p$ when $1 \leq p < \frac{n}{8}$. The last possibility is again excluded when $n \geq 8$.

In general, assuming that $(*)$ holds for $q \geq p$ if $p \geq \frac{n}{z}$ and for $\frac{pn}{n-zp} \geq q \geq p$ when $1 \leq p < \frac{n}{z}$, we get from the integral equation that $(*)$ also holds for $q \geq p$ if $p \geq \frac{n}{2z}$ and for $\frac{pn}{n-2zp} \geq q \geq p$ when $1 \leq p < \frac{n}{2z}$, so that when $n \leq 2z$, we are done. Thus, we can get the right decay estimate for any $q \geq p$ by repeating this procedure. The number of iterations we need depends on the dimension. □

5.2. First term. The integral equation yields

$$\|G(t) * u_0 - u(t)\|_q \leq C \int_0^t (t-s)^{-\frac{1}{2}+(-\frac{1}{r}+\frac{1}{q})\frac{n}{2}} s^{(\frac{-2}{p}+\frac{1}{r})\frac{n}{2}}$$

for $q \geq p$, $q \geq r \geq 1$ and $2r \geq p$, that is, $q \geq p$. As we did in the above proof, we split the integral in two intervals $[0, \frac{t}{2}]$ and $[\frac{t}{2}, t]$. By choosing an adequate r, we conclude the following.

THEOREM 5.2. *Let u be a strong solution of* (NS) *with data* $u_0 \in L^p \cap L^n(\mathbb{R}^n)$, $\frac{nq}{n+q} < p \leq n$, *of small* L^n *norm such that* $\operatorname{div} u_0 = 0$. *Then*

$$\|G(t) * u_0 - u(t)\|_q \leq Ct^{(-\frac{1}{p}+\frac{1}{q})\frac{n}{2}} t^{-\frac{n}{2p}+\frac{1}{2}}$$

if $q \geq p$.

5.3. Second term. Let us define u, h, and v as in §3. From the integral equation, we get

$$\begin{aligned}\|u(t) - v(t)\|_q &\leq \| \int_0^t \partial_i G(t-s) * (u^i(u-h) + h(u^i - h^i))(s) ds\|_q \\ &\quad + \| \int_0^t \partial_i G(t-s) * \partial_j \nabla E_2 * (u^i(u-h) + h(u^i - h^i))(s) ds\|_q \\ &\leq C \int_0^t (t-s)^{-\frac{1}{2}+(-\frac{1}{r}+\frac{1}{q})\frac{n}{2}} s^{(-\frac{1}{p}+\frac{1}{2r})\frac{n}{2}} s^{(-\frac{1}{p}+\frac{1}{2r})\frac{n}{2}} s^{-\frac{n}{2p}+\frac{1}{2}}\end{aligned}$$

for $q \geq r \geq 1$, $2r \geq p$, where we have used the estimates

$$\|u(t)\|_{2r} \leq Ct^{(-\frac{1}{p}+\frac{1}{2r})\frac{n}{2}},$$
$$\|(u-h)(t)\|_{2r} \leq Ct^{(-\frac{1}{p}+\frac{1}{2r})\frac{n}{2}} t^{-\frac{n}{2p}+\frac{1}{2}}$$

when $\frac{2n}{n+2} < p \leq n$. We split the integral as follows:

(a)

$$\int_{\frac{t}{2}}^t (t-s)^{-\frac{1}{2}+(-\frac{1}{r}+\frac{1}{q})\frac{n}{2}} s^{(-\frac{3}{p}+\frac{1}{r})\frac{n}{2}+\frac{1}{2}} \ \leq \ Ct^{(-\frac{3}{p}+\frac{1}{q})\frac{n}{2}+1}$$

if $r > \frac{nq}{q+n}$.

(b)

$$\int_0^{\frac{t}{2}} (t-s)^{-\frac{1}{2}+(-\frac{1}{r}+\frac{1}{q})\frac{n}{2}} s^{(-\frac{3}{p}+\frac{1}{r})\frac{n}{2}+\frac{1}{2}} \ \leq \ Ct^{(-\frac{3}{p}+\frac{1}{q})\frac{n}{2}+1}$$

if $(-\frac{3}{p} + \frac{1}{q})\frac{n}{2} + \frac{3}{2} > 0$, that is, $r \leq q$ and $1 \leq r < \frac{np}{3(n-p)}$, provided $p > \frac{3n}{n+3}$.

Therefore, we have the following theorem.

THEOREM 5.3. *Let u be a strong solution of* (NS) *with data* $u_0 \in L^p \cap L^n(\mathbb{R}^n)$, $\frac{3n}{n+3} < p < n$ *of small* L^n *norm such that* $\operatorname{div} u_0 = 0$. *Then*

$$\|(u-v)(t)\|_q \leq Ct^{(-\frac{1}{p}+\frac{1}{q})\frac{n}{2}} t^{-\frac{n}{2p}+\frac{1}{2}} t^{-\frac{n}{2p}+\frac{1}{2}}$$

if $q \geq p$, *where v is the solution of* $(\mathcal{L}_n)$ *with data* u_0.

This decay is faster than that corresponding to $u(t) - h(t)$.

5.4. Explicit second term. Let u be a strong solution of (NS) with data $u_0 \in L^1 \cap L^n(\mathbb{R}^n)$ of small L^n norm such that $\operatorname{div} u_0 = 0$. Making the change of variables

$$u_\lambda(x,t) = \lambda^n(\lambda^2 t, \lambda x,), \quad \lambda > 0,$$

we obtain the integral equation

$$\begin{aligned}u_\lambda(t) &= G(t) * u_{\lambda,0} - \lambda^{1-n} \int_0^t \partial_i G(t-s) * u_\lambda^i \partial_i u_\lambda(s) ds \\ &\quad - \lambda^{1-n} \int_0^t G(t-s) * \nabla \partial_j E_n * u_\lambda^i \partial u_\lambda^j(s) ds \\ &= w_{1,\lambda} + w_{2,\lambda} + w_{3,\lambda}\end{aligned}$$

for u_λ, where E_n stands for the fundamental solution of $-\Delta$ in $\mathbb{R}^n$. We have denoted by $w_{i,\lambda}$ the rescaled solutions of the n-dimensional analogues of problems $(\mathcal{P}_i)$ with $f = u$.

Problem $(\mathcal{P}_1)$. The first term w_1 is the solution of the heat equation with data u_0. If, for instance, $u_0 \in L^1(1+|x|;\mathbb{R}^n)$, we know that

$$t^{\frac{1}{2}+\frac{n}{2}(1-\frac{1}{q})}\|G(t) * u_0 - MG(t) + m^i\partial_i G(t)\|_q \to 0 \quad \text{as } t \to \infty,$$

where $M = \int_{\mathbb{R}^n} u_0$ and $m^i = \int_{\mathbb{R}^n} x^i u_0$ for $i = 1, \ldots, n$ (see [7]).

Problem $(\mathcal{P}_2)$. It is easy to prove that

$$\|w_{2,\lambda}\|_q = \lambda^{-1}\left\|\int_0^t \partial_i G(t-s) * \frac{f_\lambda^i f_\lambda(s)}{\lambda^{n-2}} ds\right\|_q$$

is bounded by $C\lambda^{-1}$. Keeping the notation of §4.2, we shall see that it is possible to take $g(t) = (\int_0^\infty \int_{\mathbb{R}^n} u^i u(y,\sigma) d\sigma dy)\ \partial_i G(t)$ and $\delta(t) = t^{\frac{1}{2}}$. More precisely, we have the following proposition.

PROPOSITION 5.4. *Let w_2 be the solution of $(\mathcal{P}_2)$ and $q \geq 1$. Then*

$$t^{\frac{1}{2}+\frac{n}{2}(1-\frac{1}{q})}\left\|w(t) + \left(\int_0^\infty \int_{\mathbb{R}^n} u^i u(\sigma,y) dy d\sigma\right) \partial_i G(t)\right\|_q \to 0 \quad \textit{as } t \to \infty,$$

provided that $u_0 \in L^{2r}(\mathbb{R}^n)$ for some $q \geq r > \frac{nq}{q+n}$.

Proof. We must prove that

$$\left\|\int_0^1 \partial_i G(1-s) * \frac{u_\lambda^i u_\lambda}{\lambda^{n-2}} - \left(\int_0^\infty \int_{\mathbb{R}^n} u^i u(\sigma,y) d\sigma dt\right) \partial_i G(1)\right\|_q \to 0 \quad \text{as } \lambda \to \infty.$$

Since

$$\int_0^1 \partial_i G(1-s) * \frac{u_\lambda^i u_\lambda}{\lambda^{n-2}} = \int_0^{\lambda^2} \int_{\mathbb{R}^n} \partial_i G\left(1 - \frac{s}{\lambda^2}, x - \frac{y}{\lambda}\right) u^i u,$$

this is equivalent to proving

$$\left\|\int_0^{\lambda^2} \int_{\mathbb{R}^n} \partial_i G\left(1 - \frac{s}{\lambda^2}, x - \frac{y}{\lambda}\right) u^i u - \left(\int_0^\infty \int_{\mathbb{R}^n} u^i u(\sigma,y) d\sigma dt\right) \partial_i G(1)\right\|_q \to 0$$
$$\text{as } \lambda \to \infty.$$

On the other hand,

$$\left(\int_0^\infty \int_{\mathbb{R}^n} u^i u(\sigma,y) d\sigma dt - \int_0^{\lambda^2} \int_{\mathbb{R}^n} u^i u(\sigma,y) d\sigma dt\right) \partial_i G(1,x) \to 0$$

in L_x^q as $\lambda \to \infty$, so that it suffices to prove that

$$\left\|\int_0^{\lambda^2} \int_{\mathbb{R}^n} \left(\partial_i G\left(1 - \frac{s}{\lambda^2}, x - \frac{y}{\lambda}\right) - \partial_i G(1,x)\right) u^i u\right\|_q \to 0 \quad \text{as } \lambda \to \infty.$$

We split the integral as in the proof of Theorem 4.1. We have

$$\|I_{\delta,\lambda}^1\|_{L_x^q} \leq C\varepsilon \int_0^{\lambda^2\delta} \int_{|y|\leq\lambda\delta} |u|^2(s,y) ds dy \ \leq\ \varepsilon C$$

if δ is small enough since

$$\int_0^\infty \int_{\mathbb{R}^n} |u|^2(s,y)dsdy \;\le\; C\int_0^\infty (1+s)^{\frac{-n}{2}}ds \;\le\; C$$

for $n > 2$ (see Theorem 5.1 and Remark 1.2). Next,

$$\|J^2_{\delta,\lambda}\|_{L^q_x} \le C\|\nabla G(t)\|_{L^q_x} \int_{\lambda^2\delta}^{\lambda^2} \int_{\mathbb{R}^n} |u|^2(s,y)dsdy \to 0$$

as $\lambda \to \infty$ for a fixed δ and

$$\|I^2_{\delta,\lambda}\|_{L^q_x} \le C\int_{\lambda^2\delta}^{\lambda^2} \left\| \int_{\mathbb{R}^n} \partial_i G\left(1-\frac{s}{\lambda^2}, x-\frac{y}{\lambda}\right) u^i u(s,y)\; dy \right\|_{L^q_x} ds$$

$$\le C\lambda^{n(1-\frac{1}{r})} \int_{\lambda^2\delta}^{\lambda^2} \left(1-\frac{s}{\lambda^2}\right)^{-\frac{n}{2}(\frac{1}{r}-\frac{1}{q})-\frac{1}{2}} s^{-\frac{n}{2}(2-\frac{1}{r})} \;\le\; C\lambda^{2-n}$$

if $q \ge r > \frac{nq}{q+n}$ and $u_0 \in L^{2r}(\mathbb{R}^n)$ (see Theorem 5.1 and Remark 1.2). Since $n > 2$, it tends to 0 as $\lambda \to \infty$ for a fixed δ.

Concerning $\|J^3_{\delta,\lambda}\|_{L^q_x}$, we have

$$\|J^3_{\delta,\lambda}\|_{L^q_x} \;\le\; C\|\nabla G(t)\|_{L^q_x} \int_0^{\lambda^2\delta} \int_{|y|\ge\delta\lambda} |u|^2(s,y)dsdy.$$

Since

$$\int_0^\infty \int_{\mathbb{R}^n} |u|^2(s,y)dsdy \;\le\; C,$$

it follows that

$$\int_0^\infty \int_{|y|\ge\delta\lambda} |u|^2(s,y)dsdy \quad \to 0 \quad \text{as } \lambda \to \infty.$$

Finally,

$$\|I^3_{\lambda,\delta}\|_{L^q_x} \;\le\; \int_0^{\lambda^2\delta} \left\| \int_{|y|\ge\delta\lambda} \partial_i G\left(1-\frac{s}{\lambda^2}, x-\frac{y}{\lambda}\right) u^i u(y,s) \right\|_{L^q_x}$$

$$\le\; C\int_0^{\lambda^2\delta} \left(1-\frac{s}{\lambda^2}\right)^{-1+\frac{1}{q}-\frac{1}{2}} \|u^i u(y,s)\|_{L^1(|y|\ge\lambda\delta)} \;\le\; C\int_0^{\lambda^2\delta}\int_{|y|\ge\delta\lambda} |u|^2(y,s)dyds$$

and we finish in the same way as before. □

Problem $(\mathcal{P}_3)$. In this case, by slightly modifying the proof above, we get the following proposition.

PROPOSITION 5.5. *Let w be the solution of $(\mathcal{P}_3)$ with $f = u$ and $q \ge 1$. Then*

$$t^{\frac{1}{2}+\frac{n}{2}(1-\frac{1}{q})} \left\| w(t) + \left(\int_0^\infty \int_{\mathbb{R}^n} u^i u^j(\sigma,y)dyd\sigma\right) \partial_i G(t) * \nabla\partial_j E_n \right\|_q \to 0 \quad \textit{as } t \to \infty,$$

provided that $u_0 \in L^{2r}(\mathbb{R}^n)$ for some $q \ge r > \frac{nq}{q+n}$.

As a consequence of these results, we get the following theorem.

THEOREM 5.6. *Let u be a strong solution of* (NS) *with data* $u_0 \in L^1(\mathbb{R}^n, 1+|x|) \cap L^n(\mathbb{R}^n)$ *of small* L^n *norm and* $q \geq 1$. *Then*

$$t^{\frac{1}{2}+\frac{n}{2}(1-\frac{1}{q})}\|u(t) - MG(t) + m^i\partial_i G(t) + R(t)\|_q \to 0$$

as $t \to \infty$, *where*

$$R(t) = \left(\int_0^\infty \int_{\mathbb{R}^n} u^i u(\sigma, y) dy d\sigma\right) \partial_i G(t) + \left(\int_0^\infty \int_{\mathbb{R}^n} u^i u^j(\sigma, y) dy d\sigma\right) \partial_i G(t) * \nabla\partial_j E_n,$$

provided that $u_0 \in L^{2r}(\mathbb{R}^n)$ *for some* $q \geq r > \frac{nq}{q+n}$.

Remark 5.1. If, instead of the problems $(\mathcal{P}_i)$ corresponding to solutions of (NS), we consider those corresponding to solutions v of $(\mathcal{L}_n)$ with $f = G(t) * u_0$ replaced by $f = u$, the analogues of Propositions 5.4 and 5.5 also hold. Therefore, if $u_0 \in L^1(1+|x|; \mathbb{R}^n) \cap L^n(\mathbb{R}^n)$, $q \geq 1$, and $u_0 \in L^{2r}(\mathbb{R}^n)$ for some $q \geq r \geq \frac{nq}{q+n}$, the solution v of $(\mathcal{L}_n)$ satisfies

$$t^{\frac{1}{2}+\frac{n}{2}(1-\frac{1}{q})}\|v(t) - MG(t) - m^i\partial_i G(t) + R(t)\|_q \to 0$$

as $t \to \infty$, where

$$R(t) = \left(\int_0^\infty \int_{\mathbb{R}^n} (G(t) * u_0)^i (G(t) * u_0)(\sigma, y) dy d\sigma\right) \partial_i G(t)$$

$$+ \left(\int_0^\infty \int_{\mathbb{R}^n} (G(t) * u_0)^i (G(t) * u_0)^j (\sigma, y) dy d\sigma\right) \partial_i G(t) * \nabla\partial_j E_n.$$

Acknowledgments. The author would like to thank E. Zuazua for suggesting to her this question.

THE DEGENERACY OF A FAST-DIFFUSION EQUATION AND STABILITY*

YUAN-WEI QI†

Abstract. It is known that for any nonnegative initial value $u_0(x)$, the solution $u(x,t)$ of the initial-boundary value problem $u_t = \operatorname{div}(|\nabla u|^{m-1}\nabla u)$ in a bounded domain $\Omega \subset R^N$ with $u|_{\partial\Omega} = 0$, where $0 < m < 1$, becomes degenerate in finite time $T > 0$, i.e., it tends to zero as $t \to T$. Therefore, it is important to know the spatial pattern of $u(x,t)$ as $t \to T^-$. In this paper we study this problem and prove that the spatial pattern is characterized by solutions which are in the form of separation of variables and have the same extinction time T.

Key words. fast-diffusion equation, finite-time extinction, stability, convergence

AMS subject classifications. 34A10, 35B05, 35B40, 35K55

1. Introduction.

In this paper we study the initial-boundary value problem

$$\begin{aligned} &u_t(x,t) = \operatorname{div}(|\nabla u|^{m-1}\nabla u), && x \in \Omega,\ t > 0,\\ &u(x,0) = u_0(x) \geq 0, && x \in \Omega,\\ &u = 0, && x \in \partial\Omega, \end{aligned} \tag{1}$$

where $0 < m < 1$ and Ω is a bounded domain with smooth boundary. Equation (1) arises from a number of different applications includes non-Newtonian flow fluids [2], [14] and nonlinear filtration [12]. The case is referred as “fast” diffusion since it exhibits behaviour similar to that of the well-known equation

$$u_t = \triangle u^m, \quad 0 < m < 1 \tag{2}$$

(cf. [7]). We refer the interested reader to [5], [13], and the references therein for results on Dirichlet initial-boundary value problem of (2).

Indeed, it was shown in [7] that, like (2), any solution of (1) decays to zero in finite time. Hence it is in strong contrast to the case $m > 1$, where the solution decays to zero as time goes to infinity, like an inverse power of t [1]. However, the spatial pattern of solution $u(x,t)$ of (1) when t approaches the extinction time $T > 0$ was not studied in [7].

The main purpose of this paper is to study the behaviour of solution u when t approaches the extinction time T. Motivated by linear theory, we seek a function $z(x)$, positive for $x \in \Omega$, and a function $R(t)$ such that $z(x)R(t)$ is a separable solution of (1) which becomes extinct at finite time $T > 0$. We expect that for any solution $u(x,t)$ which has the same extinction time $T > 0$, $u(x,t)/R(t) \to z(x)$ as $t \to T$ in suitable function spaces. Indeed, as shown in Theorem 2 below, the conclusion is true provided z is the only positive solution of problem (I) below.

This work was motivated by [7] (in bounded domain) and [11] (in the whole space R^N) on (1). Other works on (2) such as [5] (in bounded domain) and [4] (in the whole space R^N) also influenced the contents and techniques of this paper.

We assume throughout this paper the following.

Assumptions. (i) $u_0(x) \geq 0$ is sufficiently smooth and is zero on $\partial\Omega$.

* Received by the editors December 9, 1993; accepted for publication (in revised form) July 26, 1994.

† Department of Mathematics, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong.

(ii) For some $\alpha > 0$, $u(x,t)$ is a $C^{1+\alpha}$ solution of (1) which is positive on $\Omega \times (0,T)$ and fulfills the initial and boundary value conditions.

(iii) $u(x,T) = 0$ for all $x \in \overline{\Omega}$.

(iv) $u_t \in C(0,T; L^2(\Omega)) \cap C(0,T; W_0^{-1,1+m}(\Omega))$

We note in passing that some of the assumptions can be weakened and the results of this paper still hold. However, since our objective is to find the asymptotic profile of extinction, we will not elaborate on the weakest conditions for all the manipulations to be legitimate. Nevertheless, the estimates in [6]–[8] justify the above assumptions as appropriate.

Consider the homogeneity of equation (1) and the boundary condition. It is natural to seek a separable solution. Indeed, such a solution which becomes extinct at finite time $T > 0$ takes the form $u(x,t) = (1-m)(T-t)^{1/(1-m)} z(x)$. Then z is a solution of the following boundary value problem

$$\text{(I)} \begin{cases} \operatorname{div}((| \nabla z|^{m-1} \nabla z) + \lambda z = 0, & x \in \Omega, \\ z > 0, & x \in \Omega, \\ z = 0, & x \in \partial\Omega, \end{cases}$$

where $\lambda = 1/(1-m)^m$.

The existence of (I) can be studied by using a variational argument and a Pohozaev type identity. The special case where Ω is a ball and z is radial symmetric was studied in [15]. In spite of the fact that the study of (I) can be done by simply modifying the argument on the semilinear equation $\triangle u + f(u) = 0$, we cannot find the result for general domain Ω in the literature. Therefore, we show the following result on the existence of (I) in the next section.

THEOREM 1. *Let* $0 < m < 1$.

(i) *If* $N \le 2$ *or* $m > (N-2)/(N+2)$ *for* $N \ge 3$, *then there exists a positive solution of* (I).

(ii) *If* $N = 1$ *or* $N \ge 2$ *and* $\Omega = B_r(x_0)$, *a ball with center* x_0 *and radius* $r > 0$, *then the positive radial solution is unique.*

(iii) *If* $m \le (N-2)/(N+2)$, $N \ge 3$, *and* Ω *is star shaped, then* (I) *has no positive classical solution.*

(iv) *If* $m \le (N-2)/(N+2)$, $N \ge 3$, *and* Ω *is an annulus, then there exists a positive classical solution of* (I).

Remark. By a *classical solution* of (I) we mean the one which belongs to $C^{1+\alpha}$, for some $\alpha > 0$. In this case the differential equation is satisfied pointwise in the classical sense.

Once the existence on (I) is settled, the question is whether the separable solutions characterize the spatial pattern of the general solution when $t \to T$. The following result answers this question and will be proved in §3.

THEOREM 2. *Let* $0 < m < 1$. $v(x,t) = u(x,t)/(T-t)^{1/(1-m)}$.

(i) *Suppose* $N \le 2$ *or* $m > (N-2)/(N+2)$ *and* $N \ge 3$. *Then there exists an increasing sequence of times* $t_n \to T^-$ *and a positive classical solution* z *of* (I) *such that* $v(\cdot, t_n) \to z$ *in* $W_0^{1,1+m}(\Omega)$.

(ii) *In case* (i), *if there is a unique solution to* (I), *then* $v(\cdot,t) \to z(\cdot)$ *as* $t \to T^-$ *in* $W_0^{1,1+m}(\Omega)$.

2. The steady state. In this section we study (I) and prove Theorem 1.

Proof of Theorem 1. (i) The standard way to prove existence is to consider the following minimization problem.

Problem A. Minimize $\int_\Omega |\bigtriangledown h|^{1+m}\,dx$ over the class of functions in $W_0^{1,1+m}(\Omega)$ satisfying $\int_\Omega h^2\,dx = k$, where $k > 0$ is a constant.

Since the embedding $W_0^{1,1+m}(\Omega) \hookrightarrow L^2(\Omega)$ is compact in case (i), the Palais–Smale (PS) condition holds. Hence the minimum is achieved and is a $C^{1+\alpha}(\overline{\Omega})$ solution of $\operatorname{div}(|\bigtriangledown u|^{m-1}\bigtriangledown u) + \mu u = 0$ (see [9]), where $\mu > 0$. A scaling gives a solution of (I). This completes the proof of (i).

(ii) Uniqueness in the case where $N = 1$ and $\Omega = (0,1)$ follows from the fact that if z is a solution of (I), then the solution to the initial value problem

$$(|Q'|^{m-1}Q')' = -\lambda Q, \quad Q(0) = 0, \quad Q'(0) = \eta^{2/(1+m)}z'(0)$$

is given by $Q^\eta(x) = \eta z(\eta^\alpha x)$ with $\alpha = (1-m)/(1+m)$. Hence there is only one value, $\eta = 1$, for which $Q(1) = 0$. Likewise, the uniqueness is true in the case where Ω is a ball and z is radial symmetric.

(iii) The proof of this part is based on a Pohozaev identity. We note that although z may not belong to $C^2(\Omega)$, $\operatorname{div}(\bigtriangledown z|^{m-1}\bigtriangledown z)$ is in $C^{1+\alpha}(\overline{\Omega})$ and therefore the following formal manipulation is rigorous.

Multiplying (I) by u and integrating by parts we have

$$-\int_\Omega |\bigtriangledown z|^{m+1}\,dx + \int_\Omega z^2\,dx = 0. \tag{3}$$

Likewise, multiplying (I) by $x\cdot\bigtriangledown u$ we obtain

$$-\frac{N-1-m}{1+m}\int_\Omega |\bigtriangledown z|^{m+1}\,dx + \frac{N}{2}\int_\Omega z^2\,dx = -\int_{\partial\Omega} |\bigtriangledown z|^{m+1}(x\cdot\nu)\,ds, \tag{4}$$

where ν is the outward normal of $\partial\Omega$. Subtracting (3) from (4) we find

$$\left(\frac{N}{2} - \frac{N-1-m}{1+m}\right)\int_\Omega |\bigtriangledown z|^{m+1}\,dx = \int_{\partial\Omega} |\bigtriangledown z|^{m+1}(x\cdot\nu)\,ds. \tag{5}$$

But by our assumption on m, $N/2-(N-1-m)/(1+m) \le 0$. Therefore, the left-hand side is nonpositive, whereas the right-hand side is positive for z nontrivial because Ω is star shaped and $\bigtriangledown z \neq 0$ on $\partial\Omega$. This proves (iii).

(iv) When Ω is an annulus we can consider the radial solutions $z(x) = z(r)$, where $r = |x|$. In this case (I) takes the form

$$\text{(IR)}\begin{cases} \frac{1}{r^{N-1}}(r^{N-1}|z'|^{m-1}z')' + \lambda z = 0, & R_1 < r < R_0, \\ z > 0, & R_1 < r < R_0, \\ z = 0, & r = R_1 \text{ and } r = R_0. \end{cases}$$

Let

$$\xi = \left[\frac{N-1-m}{m} r^{(N-1-m)/m}\right]^{-1}, \quad y(\xi) = z(r). \tag{6}$$

Then (IR) takes the form

$$\begin{cases} (|y'|^{m-1}y')' + \rho(\xi)y = 0, & \xi_0 < \xi < \xi_1, \\ y > 0, & \xi_0 < \xi < \xi_1, \\ y = 0, & \xi = \xi_0 \text{ and } \xi = \xi_1, \end{cases}$$

where

$$\rho(\xi)=\left(\frac{N-1-m}{m}\xi\right)^{-k},\qquad k=\frac{N(1+m)}{N-1-m}, \tag{7}$$

$$\xi_i=\left(\frac{N-1-m}{m}R_i^{(N-1-m)/m}\right)^{-1},\qquad i=0,1. \tag{8}$$

The existence of a solution to (I) can be proved by using a shooting argument. For this purpose we shall examine the family of solutions of the initial value problem

$$\text{(II)}\begin{cases} (|y'|^{m-1}y')'+\rho(\xi)y=0, & \xi<\xi_1,\\ y(\xi_1)=0, & y'(\xi)=-b<0.\end{cases}$$

Here ξ_1 is a positive number that will be kept fixed throughout.

It is clear that if y is positive in some interval (β,ξ_1) with $\beta\geq 0$, then

$$y(\xi)\leq b(\xi_1-\xi)\qquad \text{in } (\beta,\xi_1). \tag{9}$$

Consequently, if $\beta>0$ the solution can be extended to the left of β. Denote

$$\xi_0(b)=\inf\{\xi_0>0: u(\xi;b)>0\quad \text{in } (\xi_0,\xi_1)\}. \tag{10}$$

It is a standard ordinary differential equation (ODE) result that the function $b\to\xi_0(b)$ is continuously differentiable in the neighborhood of every $b>0$ such that $\xi_0(b)>0$. This is because $y'(\xi_0(b);b)>0$. Then we can use the energy functionals

$$J_1(\xi)=\frac{|y'(\xi)|^{1+m}}{1+m}+\frac{1}{2}\rho(\xi)y^2, \tag{11}$$

$$J_2(\xi)=\frac{|y'(\xi)|^{1+m}}{(1+m)\rho(\xi)}+\frac{1}{2}y^2 \tag{12}$$

and the Sturm–Liouville comparison theorem to prove the following technical result.

THEOREM 3. (i) *If* $b>0$ *and* $y(\cdot,b)$ *is defined and positive in* $(0,\xi_1)$ *then* $\lim_{\xi\to 0^+}y(\xi;b)=0$.

(ii) $\lim_{b\to 0}\xi_0(b)=0$.

(iii) $\lim_{b\to\infty}\xi_0(b)=\infty$

The proof of the result is technical and lengthy. We omit it here. It will be proved in [16]. The interested reader may also consult [3], where the semilinear case $m=1$ was treated. The argument there may be modified to work for the case $0<m<1$.

The direct consequence of the above is the existence of (I) for the annulus case. Thus the proof of Theorem 1 is complete.

3. The main results. We will prove Theorem 2 through a series of lemmas.

LEMMA 1. *Let* $m>0$ *if* $N\leq 2$ *or* $m>(N-2)/(N+2)$ *if* $N\geq 3$. *Then there exists a positive constant* $B=B(m,N,\Omega)$ *such that every solution* $u(x,t)$ *of* (1) *with finite extinction time* $T>0$ *satisfies*

$$(T-t)^{\frac{2}{1-m}}\leq B\int_\Omega u^2. \tag{13}$$

Proof. Multiplying equation (1) by u and integrating by parts, we obtain the identity

$$\frac{d}{dt}\int_\Omega u^2\,dx = -2\int_\Omega |\nabla u|^{m+1}\,dx. \tag{14}$$

The Sobolev embedding lemma guarantees that there exists a constant $c = c(m, N, \Omega)$ such that for any $h \in W_0^{1,1+m}(\Omega)$,

$$\left(\int_\Omega h^2\,dx\right)^{1/2} \le c\left(\int_\Omega |\nabla h|^{m+1}\,dx\right)^{1/(1+m)}. \tag{15}$$

We obtain a differential inequality by substituting (15) into (14), which after integration yields

$$\left(\int_\Omega u(x,t')^2\,dx\right)^{(1-m)/2} - \left(\int_\Omega u(x,t)^2\,dx\right)^{(1-m)/2} \le -B(t-t')$$

for $t \le t' < T$, where $B = (1-m)/c^{1+m}$. Letting $t' \to T$ and multiplying by -1, we get the lemma.

LEMMA 2. *Let u and m be as in Lemma* 1. *Then the solution u satisfies*

$$\int_\Omega u^2(x,t)\,dx \le (1-t/T)^{(1-m)/2}\int_\Omega u^2(x,0)\,dx. \tag{16}$$

Proof. First, we observe that

$$\begin{aligned}\frac{d}{dt}\int_\Omega |\nabla u|^{m+1}\,dx &= (1+m)\int_\Omega |\nabla u|^{m-1}\nabla u\cdot(\nabla u)_t\,dx\\ &= -(1+m)\int_\Omega \operatorname{div}(|\nabla u|^{m-1}\nabla u)u_t dx \qquad (17)\\ &= -(1+m)\int_\Omega |\operatorname{div}(|\nabla u|^{m-1}\nabla u)|^2 dx, \qquad (18)\end{aligned}$$

$$\int_\Omega |\nabla u|^{m+1}\,dx = -\int_\Omega \operatorname{div}(|\nabla u|^{m-1}\nabla u)u dx. \tag{19}$$

We used the condition $u = u_t = 0$ on $\partial\Omega$ in the above manipulation. Applying the Cauchy–Schwarz inequality, we find

$$\left(\int_\Omega |\nabla u|^{m+1}\right)^2 \le \int_\Omega |\operatorname{div}(|\nabla u|^{m-1}\nabla u)|^2 \int_\Omega u^2. \tag{20}$$

Combining (14), (17), and (20), we have

$$-\frac{\frac{d}{dt}\int_\Omega u^2\,dx}{2\int_\Omega u^2\,dx} \le -\frac{\frac{d}{dt}\int_\Omega |\nabla u|^{m+1}\,dx}{(1+m)\int_\Omega |\nabla u|^{m+1}\,dx}. \tag{21}$$

Integrating the above inequality, we have

$$\frac{\int_\Omega u^2(x,t)\,dx}{\int_\Omega u^2(x,s)\,dx} \ge \frac{(1+m)}{2}\frac{\int_\Omega |\nabla u(x,t)|^{m+1}\,dx}{\int_\Omega |\nabla u(x,s)|^{m+1}\,dx} \tag{22}$$

for $0 \le s < t \le T$. Set

$$J(t) = \left(\int_\Omega u^2(x,t)\,dx\right)^{(1-m)/2}. \tag{23}$$

Then (22) is just $J'(s) \le J'(t)$ for all $s \le t$, and therefore $J'' \ge 0$ and J is convex. Hence

$$\frac{J(T)-J(t)}{T-t} \ge \frac{J(t)-J(0)}{t}, \tag{24}$$

which is just (16).

Remark. Lemmas 1 and 2 with $t = 0$ provide estimates of the extinction time T in terms of the initial value. Note also that inequality (22) in the proof of Lemma 2 gives the following corollary.

COROLLARY 1. *Let*

$$G(h) = \int_\Omega |\nabla h(x,t)|^{m+1}\,dx \Big/ \left(\int_\Omega h^2(x,t)\,dx\right)^{(1+m)/2}. \tag{25}$$

Then the function $G(u(\cdot,t))$ is a nonincreasing function of t.

The functional G can be regarded as a generalization of the Rayleigh–Ritz quotient when $m \ne 1$. If $N \le 2$ or if $N \ge 3$ and $m > (N-2)/(N+2)$, then $G(h)$ has a positive minimum over $W_0^{1,1+m}(\Omega)$. If $N \ge 3$ and $m \le (N-2)/(N+2)$, the infimum of G is zero on $W_0^{1,1+m}$ but the minimum does not exist.

Proof of Theorem 2. Let

$$w(x,s) = \frac{T^\lambda}{(T-t)^\lambda}u(x,t),$$

where $s = -\log(T-t) + \log T$. In order to prove (i) of the theorem, we must show that there exists a sequence of times $s_n \to \infty$ such that $w(\cdot,s_n) \to z(\cdot)$ in $W_0^{1,1+m}(\Omega)$, where z is a solution of (I). To prove (ii), we have to show that $w(\cdot,s) \to z(\cdot)$.

The function $w(x,s)$ satisfies

$$w_s(x,t) = \operatorname{div}(|\nabla w|^{m-1}\nabla w) + \lambda w \tag{26}$$

in $\Omega \times (0,\infty)$, with $w = 0$ on $\partial\Omega$ and $w(x,0) = u(x,0)$, $x \in \Omega$.

We define the functional

$$I(h) = \int_\Omega \left(\frac{1}{1+m}|\nabla h|^{m+1}\,dx - \frac{\lambda}{2}h^2\right)\,dx \tag{27}$$

and $f(s) = I(w(\cdot,s))$. It is easy to verify that

$$f'(s) = -\int_\Omega w_s(x,s)^2\,dx \le 0. \tag{28}$$

Lemma 2 shows that $\int_\Omega w(x,s)^2\,dx$ is bounded for all $s > 0$. Hence $f(s)$ is bounded. Consequently, $\int_\Omega |\nabla w(x,s)|^{m+1}$ is uniformly bounded. Thus $\lim_{s\to\infty} f(s)$ exists and there exists a sequence of times $s_n \to \infty$ such that $f'(s_n) \to 0$ by (28).

We proceed to show that for a subsequence of s_n, again labelled s_n, $w(\cdot,s_n) \to z(\cdot)$ in $W_0^{1,1+m}(\Omega)$. Since $w(\cdot,s_n)$ is a bounded sequence in $W_0^{1,1+m}$, there exists a subsequence, again labelled by $w(\cdot, s_n)$, such that $w(\cdot, s_n)$ converges weakly to $z(\cdot)$ in $W_0^{1,1+m}(\Omega)$. In addition, from the compact-embedding theorem, we have

$$\int_\Omega w(x, s_n)^2\,dx \to \int_\Omega z(x)^2\,dx, \tag{29}$$

since $m > (n-2)/(n+2)$ if $N \geq 3$ or $m > 0$ if $N \leq 2$. In fact,

$$\int_\Omega w(x, s)^2\,dx \to \int_\Omega z(x)^2\,dx, \tag{30}$$

since $\int_\Omega w(x,s)^2\,dx$ is nonincreasing by Lemma 2.

Next we show that $z(x)$ is a classical solution of (I) and $w(x, s_n) \to z(x)$ in $W_0^{1,1+m}(\Omega)$. To prove that z is a classical solution of (I), we note that since

$$w(\cdot, s_n) \to v(\cdot), \quad w_s(\cdot, s_n) \to 0 \qquad \text{in } L^2(\Omega),$$

$\operatorname{div}(|\nabla u|^{m-1}\nabla u)(\cdot, s_n)$ is convergent in $L^2(\Omega)$. Moreover, when we multiply (1) by $\eta \in C_c^\infty(\Omega)$ and integrate by parts, we find

$$-\int_\Omega |\nabla w|^{m-1}\nabla w \cdot \nabla w\eta\,dx + \lambda\int_\Omega w\eta\,dx = \int_\Omega w_s\eta\,dx.$$

Let $s_n \to \infty$. It then follows that

$$-\int_\Omega |\nabla z|^{m-1}\nabla z \cdot \nabla\eta\,dx + \lambda\int_\Omega z\eta\,dx = 0.$$

Therefore z is a weak solution of (I) in $W_0^{1,1+m}(\Omega)$. The standard bootstrap technique (see [9]) yields that z is a classical solution. Here again, the condition $N \leq 2$ or $m > (n-2)/(n+2)$ if $N \geq 3$ is used.

We now show that $w(\cdot, s_n) \to z$ in $W_0^{1,1+m}(\Omega)$. As is clear from (26) and the fact that $w(\cdot, s_n) \to z(\cdot)$ in $L^2(\Omega)$ and $w_s(\cdot, s_n) \to 0$,

$$\operatorname{div}(|\nabla w|^{m-1}\nabla w)(\cdot, s_n) \to \operatorname{div}(|\nabla z|^{m-1}\nabla z)(\cdot) \qquad \text{in } L^2(\Omega).$$

On the other hand, we find, by using Hölder's inequality,

(31)

$$\begin{aligned}
&\int_\Omega |\nabla w - \nabla z|^{1+m}dx \\
&\leq \left[\int_\Omega (|\nabla w| + |\nabla z|)^{1+m}\right]^p \left[\int_\Omega (|\nabla w| + |\nabla z|)^{m-1}|\nabla(w-z)|^2\right]^q \\
&\leq C\left[\int_\Omega |\nabla w|^{1+m} + |\nabla z|^{1+m}\right]^p \left[\int_\Omega (|\nabla w|^{m-1}\nabla w - |\nabla z|^{m-1}\nabla z)(\nabla(w-z))\right]^q \\
&\leq C\left[\int_\Omega |\nabla w|^{1+m} + |\nabla z|^{1+m}\right]^p \left[\int_\Omega \operatorname{div}(|\nabla w|^{m-1}\nabla w - |\nabla z|^{m-1}\nabla z)(z-w)\right]^q \\
&\longrightarrow 0 \qquad \text{as } s_n \to \infty,
\end{aligned}$$

where $p = \frac{1-m}{2}$, $q = \frac{1+m}{2}$. Thus $w(\cdot, s_n) \to z$ in $W_0^{1,1+m}(\Omega)$.

It is clear that since $w(x, s_n) \geq 0$, $z(x) \geq 0$. Moreover, since $\int_\Omega w^2(x,s)dx \geq C > 0$ for some $C > 0$ by Lemma 1 and $w(\cdot, s_n) \to z(\cdot)$ in $L^2(\Omega)$, we know that z is not identically zero. It then follows from a Harnack-type inequality (see Proposition 1 below) that z is strictly positive in Ω. Thus $z > 0$.

PROPOSITION 1. *Let z be a nonnegative solution of* (I) *which is not identically zero. Suppose $B_{4R}(y) \subset \Omega$ and $1 \leq p < N/(N-1-m)$; then*

$$R^{-n/p}||z||_{L^p(B_{2R}(y))} \leq C \inf_{B_R(y)} z, \tag{32}$$

where $C = C(N, p, R, ||z||_\infty)$.

Proof. The argument is essentially the same as that of [17] and Theorems 8.17 and 8.18 in [10]. Nevertheless, those works concern more general problems and the estimates obtained there are not sharp. Therefore, we present a proof which gives the result of Proposition 1.

Let $\phi = \eta^{1+m}\overline{z}^\beta$, $\overline{z} = z + \epsilon$, where $\beta < 0$ and $\epsilon > 0$.

$$\nabla\phi = (1+m)\eta^m \nabla \eta \overline{z}^\beta + \beta\overline{z}^{\beta-1} \nabla z \eta^{1+m}. \tag{33}$$

Multiplying (I) by ϕ and integrating by parts, we find

$$\begin{aligned} &\int_\Omega \eta^{1+m}\overline{z}^{\beta-1}|\nabla z|^{(1+m)}dx \\ &\quad + (1+m)\int_\Omega \eta^m \nabla\eta\cdot\nabla z|\nabla z|^{m-1}\overline{z}^\beta\, dx - \int_\Omega \eta^{1+m}\overline{z}^\beta z dx = 0. \end{aligned} \tag{34}$$

We can estimate, for any $0 < \epsilon \leq 1$,

$$\begin{aligned} |\eta^m \nabla\eta\cdot\nabla z||\nabla z|^{m-1}\overline{z}^\beta &\leq |\nabla z|^m|\nabla\eta|\eta^m\overline{z}^\beta \\ &\leq \frac{m\epsilon}{1+m}|\nabla z|^{1+m}\eta^{1+m}\overline{z}^{\beta-1} + \frac{\epsilon^{-m}}{1+m}|\nabla\eta|^{1+m}\overline{z}^{\beta+m}. \end{aligned} \tag{35}$$

By setting $\epsilon = \min\{1, |\beta|/3\}$, we obtain from (34) and (35)

$$\begin{aligned} \int_\Omega \eta^{1+m}\overline{z}^{\beta-1}|\nabla z|^{1+m} &\leq C(|\beta|)\int_\Omega \overline{z}^{\beta+m}(\overline{z}^{1-m}\eta^{1+m} + |\nabla\eta|^{1+m})dx \\ &\leq C(|\beta|)(||\overline{z}||_\infty^{1-m}+1)\int_\Omega \overline{z}^{\beta+m}(\eta^{1+m} + |\nabla\eta|^{1+m})dx \\ &\leq C(|\beta|, ||\overline{z}||_\infty)\int_\Omega \overline{z}^{\beta+m}(\eta^{1+m} + |\nabla\eta|^{1+m})dx, \end{aligned} \tag{36}$$

where $C(|\beta|)$ is bounded provided $|\beta|$ is bounded away from zero and $C(|\beta|, ||\overline{z}||_\infty) = C(|\beta|)(||\overline{z}||_\infty^{1-m}+1)$. Let $\delta = \beta + 1$,

$$w = \begin{cases} \overline{z}^{\frac{\beta+m}{1+m}} & \text{if } \beta \neq -m, \\ \log\overline{z} & \text{if } \beta = -m. \end{cases}$$

We may rewrite (36) as

$$\int_\Omega |\eta\nabla w|^{1+m}dx \leq \delta^{1+m}C(|\beta|, ||\overline{z}||_\infty)\int_\Omega w^{1+m}(\eta^{1+m} + |\nabla\eta|^{1+m})dx. \tag{37}$$

Then, we find from the Sobolev inequality

$$||\eta w||_{N(1+m)/(N-1-m)}^{1+m} \leq C\int_\Omega (|\eta\nabla w|^{1+m} + |w\nabla\eta|^{1+m})dx. \tag{38}$$

Hence, substituting (37) into (38), we get

$$||\eta w||_{N(1+m)/(N-1-m)} \leq C(1+\delta)||(\eta + |\bigtriangledown \eta|)w||_{1+m}. \tag{39}$$

We now specify the cutoff function η more precisely. Let $0 < r_1 < r_2$ be two positive numbers. Set $\eta = 1$ in B_{r_1}, $\eta = 0$ in $\Omega \setminus B_{r_2}$ with $|\bigtriangledown \eta| \leq 2/(r_2 - r_1)$. Writing $\sigma = N/(N-1-m)$, we have

$$||w||_{L^{\sigma(1+m)}(B_{r_1})} \leq \frac{C(1+\delta)}{r_2 - r_1}||w||_{L^{(1+m)}(B_{r_2})}. \tag{40}$$

Thus we can start an iteration procedure and follow exactly the argument of Theorems 8.17 and 8.18 in [10] to derive (32).

We now prove (ii). Suppose the contrary, that $w(\cdot, s)$ do not tend to $R(\cdot)$, where $R(x)$ is the unique positive classical solution. We note that R is a minimizer of Problem A, where

$$K = \int_\Omega R^2(x)\,dx = \lim_{s\to\infty}\int_\Omega w^2(x,s)\,dx. \tag{41}$$

Since $||w(\cdot,s)||_{1,1+m} \leq M$ for some constant $M > 0$, we can extract a sequence of times S_n such that $w(\cdot, S_n)$ tends weakly in $W_0^{1,1+m}(\Omega)$ to a function $Q \neq R$. Moreover, $K = \int_\Omega Q^2(x)\,dx$ by (21) and (41). Since $\int_\Omega |\bigtriangledown h|^{1+m}\,dx$ is lower semicontinuous with respect to weak convergence, we also have

$$\int_\Omega |\bigtriangledown Q|^{1+m}\,dx \leq \liminf_{n\to\infty}\int_\Omega |\bigtriangledown w(x,S_n)|^{1+m}\,dx. \tag{42}$$

But from the proof of (i), we see that

$$f(s) \downarrow \frac{1}{1+m}\int_\Omega |\bigtriangledown R|^{1+m}\,dx - \frac{\lambda}{2}\int_\Omega |\bigtriangledown R|^2\,dx \tag{43}$$

as $s \to \infty$. Hence

$$\int_\Omega |\bigtriangledown Q|^{1+m}\,dx \leq \int_\Omega |\bigtriangledown R|^{1+m}\,dx. \tag{44}$$

Therefore, Q is also a minimizer for Problem A, which is a contradiction. Thus $w(\cdot, s)$ converge to $R(\cdot)$ in $W_0^{1,1+m}(\Omega)$ as $s \to \infty$. This completes the proof of (ii).

ASYMPTOTIC ANALYSIS OF THE BOUNDARY LAYER FOR THE REISSNER–MINDLIN PLATE MODEL*

DOUGLAS N. ARNOLD† AND RICHARD S. FALK‡

Abstract. We investigate the structure of the solution of the Reissner–Mindlin plate equations in its dependence on the plate thickness in the cases of soft and hard clamped, soft and hard simply supported, and traction free boundary conditions. For the transverse displacement, rotation, and shear stress, we develop asymptotic expansions in powers of the plate thickness. These expansions are uniform up to the boundary for the transverse displacement, but for the other variables there is a boundary layer, which is stronger for the soft simply supported and traction-free plate and weaker for the soft clamped plate than for the hard clamped and hard simply supported plate. We give rigorous error bounds for the errors in the expansions in Sobolev norms. As an application, we derive new regularity results for the solutions and new estimates for the difference between the Reissner–Mindlin solution and the solution to the corresponding biharmonic model.

Key words. Reissner, Mindlin, plate, boundary layer

1. Introduction.

The Reissner–Mindlin model for the bending of an isotropic elastic plate in equilibrium determines ω, the transverse displacement of the midplane, and ϕ, the rotation of fibers normal to the midplane, as the solution of the partial differential equations

$$-t^3 \,\mathbf{div}\, \mathcal{C}\,\mathcal{E}(\boldsymbol{\phi}) - \lambda t\,(\mathbf{grad}\,\omega - \boldsymbol{\phi}) = \boldsymbol{F},$$
$$-\lambda t \,\mathrm{div}\,(\mathbf{grad}\,\omega - \boldsymbol{\phi}) = G.$$

Here $\boldsymbol{F}$ is the applied couple per unit area, G is the applied transverse load density per unit area, t is the plate thickness, $\lambda = Ek/2(1+\nu)$ with E the Young's modulus, ν the Poisson ratio, and k the shear correction factor, $\mathcal{E}(\boldsymbol{\phi})$ is the symmetric part of the gradient of $\boldsymbol{\phi}$, and the fourth-order tensor $\mathcal{C}$ is defined by

$$\mathcal{C}\mathcal{T} = D\left[(1-\nu)\mathcal{T} + \nu\,\mathrm{tr}(\mathcal{T})\mathcal{I}\right], \quad D = \frac{E}{12(1-\nu^2)},$$

for any 2×2 matrix $\mathcal{T}$ ($\mathcal{I}$ denotes the 2×2 identity matrix). These equations are satisfied on the plane region Ω occupied by the midsection of the plate. In this paper, we investigate the dependence on the plate thickness of solutions to some boundary value problems associated to these equations.

We consider various homogeneous boundary conditions of physical interest:

$$\boldsymbol{\phi}\cdot\boldsymbol{n}=\boldsymbol{\phi}\cdot\boldsymbol{s}=\omega=0 \qquad \text{(hard clamped)}, \tag{1.1}$$

$$\boldsymbol{\phi}\cdot\boldsymbol{n}=M_{\boldsymbol{s}}(\boldsymbol{\phi})=\omega=0 \qquad \text{(soft clamped)}, \tag{1.2}$$

$$M_{\boldsymbol{n}}(\boldsymbol{\phi})=\boldsymbol{\phi}\cdot\boldsymbol{s}=\omega=0 \qquad \text{(hard simply supported)}, \tag{1.3}$$

$$M_{\boldsymbol{n}}(\boldsymbol{\phi})=M_{\boldsymbol{s}}(\boldsymbol{\phi})=\omega=0 \qquad \text{(soft simply supported)}, \tag{1.4}$$

$$M_{\boldsymbol{n}}(\boldsymbol{\phi})=M_{\boldsymbol{s}}(\boldsymbol{\phi})=\partial\omega/\partial n-\boldsymbol{\phi}\cdot\boldsymbol{n}=0 \qquad \text{(free)}, \tag{1.5}$$

in which $\boldsymbol{n}$ and $\boldsymbol{s}$ denote the unit normal and counterclockwise tangent vectors, respectively, and $M_{\boldsymbol{n}}(\boldsymbol{\phi}) := \boldsymbol{n}\cdot \mathcal{C}\,\mathcal{E}(\boldsymbol{\phi})\boldsymbol{n}$, $M_{\boldsymbol{s}}(\boldsymbol{\phi}) := \boldsymbol{s}\cdot \mathcal{C}\,\mathcal{E}(\boldsymbol{\phi})\boldsymbol{n}$. Each of the first four boundary value problems admits a unique solution $\omega \in H^1(\Omega)$, $\boldsymbol{\phi}\in \boldsymbol{H}^1(\Omega)$ for any $\boldsymbol{F}\in \boldsymbol{L}^2(\Omega)$ and $G \in L^2(\Omega)$. The existence theory for the free plate is slightly more complicated and will be discussed in §6.

We do not treat the Reissner–Mindlin model in its full generality. In addition to the assumption of homogeneous boundary conditions, we shall assume that there is no applied couple, so $\boldsymbol{F}\equiv 0$, and that the constitutive parameters E, ν, and k are independent of t. It seems clear that the techniques developed here apply to more general situations as well.

We also suppose that $G = gt^3$, where the function g does not depend on t. This is a convenient normalization, which leads to $\boldsymbol{\phi}$ and ω having a nonzero limit as t tends to zero. Given that the first differential equation and the boundary conditions are taken to be homogeneous, this normalization is not restrictive. If G were to be proportional to some other function $h(t)$, we could make the change of dependent variables $\bar{\boldsymbol{\phi}} = t^3\boldsymbol{\phi}/h(t)$, $\bar{\omega} = t^3\omega/h(t)$ and the new variables would satisfy the Reissner–Mindlin equations with load proportional to t^3.

With these assumptions, the Reissner–Mindlin equations become

$$-\operatorname{\mathbf{div}} \mathcal{C}\,\mathcal{E}(\boldsymbol{\phi}) - \lambda t^{-2}(\operatorname{\mathbf{grad}}\omega - \boldsymbol{\phi}) = 0, \tag{1.6}$$

$$-\lambda t^{-2}\operatorname{div}(\operatorname{\mathbf{grad}}\omega - \boldsymbol{\phi}) = g. \tag{1.7}$$

After a similar normalization of the load, the biharmonic model for plate bending may be written

$$D\,\Delta^2\omega_0 = g \quad \text{in } \Omega,$$

and so its solution ω_0 is independent of the plate thickness. In contrast, the solution of the Reissner–Mindlin model exhibits a complex dependence on the plate thickness, which we investigate in the present paper. In previous work [1], we gave an analysis of the boundary layer for the Reissner–Mindlin model of hard clamped and hard simply supported plates. There are many additional complications in the case of more general boundary conditions, and so the analysis of [1] is not easily extended to the soft simply supported and free plates, for example. In this paper, we analyze the boundary layer for all the boundary conditions mentioned above in a unified fashion. While the approach here is more complete, it is also simpler than that of [1] in a number of ways. Thus the present paper essentially supersedes that one. We shall show that the boundary layer is strongest for the soft simply supported and free plate, somewhat weaker for the clamped and hard simply supported plate, and weakest for the soft clamped plate. In addition, we shall demonstrate that for the soft clamped and hard simply supported plates, there is no boundary layer near a flat portion of the boundary.

We shall develop asymptotic expansions with respect to t for ω and ϕ (as well as for other quantities associated with the solution such as the shear strain). The expansions take the forms

$$\omega \sim \omega_0 + t\omega_1 + t^2\omega_2 + \cdots ,$$
$$\phi \sim \phi_0 + \chi\boldsymbol{\Phi}_0 + t(\phi_1 + \chi\boldsymbol{\Phi}_1) + t^2(\phi_2 + \chi\boldsymbol{\Phi}_2) + \cdots ,$$

where the interior expansion functions ω_i and ϕ_i are independent of t and the boundary correctors $\boldsymbol{\Phi}_i$ depend on t only through the quantity ρ/t, ρ being the distance of a point of Ω from the boundary. More specifically,

$$\boldsymbol{\Phi}_i = \hat{\boldsymbol{\Phi}}_i(\rho/t, \theta),$$

where θ is a coordinate which roughly gives arc length parallel to the boundary (see §2), and the function $\hat{\boldsymbol{\Phi}}_i(\eta, \theta)$ has the form of a polynomial with respect to η with coefficients depending smoothly on θ times $\exp(-\sqrt{12k}\eta)$. Thus $\boldsymbol{\Phi}_i$ represents a boundary-layer function, which essentially lives in a strip of width t around the boundary. Finally, χ is a cutoff function which is independent of t and identically equal to unity in a neighborhood of $\partial\Omega$.

After some preliminary material in §2, we construct the terms of the asymptotic expansions in §3 (for all of the boundary conditions except for those of the free plate, which are treated in §6). Then, in the following two sections, we justify the expansions rigorously in the case of the soft simply supported plate, proving a priori bounds for the terms of the expansions in §4 and performing the error analysis in §5. This analysis can be adapted easily to the cases of hard simply supported and hard and soft clamped plates and somewhat less easily to the case of the free plate. The necessary modifications are discussed in §6. To make it easier for the reader to follow some of the computations performed in the derivation and analysis of the asymptotic expansions, we have included in an appendix a summary of the main formulas we have used. In the remainder of this introduction, we summarize some of the principal results.

For each of the boundary conditions, ω_0 is the solution of the biharmonic equation

$$D\Delta^2\omega_0 = g$$

determined by appropriate boundary conditions, namely

$$\omega_0 = \frac{\partial\omega_0}{\partial n} = 0$$

for the hard and soft clamped plates,

$$\omega_0 = (1-\nu)\frac{\partial^2\omega_0}{\partial n^2} + \nu\Delta\omega_0 = 0$$

for the hard and soft simply supported plates, and

$$(1-\nu)\frac{\partial^2\omega_0}{\partial n^2} + \nu\Delta\omega_0 = \frac{\partial\Delta\omega_0}{\partial n} + (1-\nu)\frac{\partial}{\partial s}\left(\frac{\partial^2\omega_0}{\partial s\partial n} - \kappa\frac{\partial\omega_0}{\partial s}\right) = 0$$

for the free plate. In the last expression, κ denotes the curvature of the boundary.

The next term in the expansion of the transverse displacement, ω_1, vanishes for the hard and soft clamped plates and the hard simply supported plate but not for the soft simply supported or free plates. In these cases, it is the solution of the homogeneous biharmonic problem

$$\Delta^2\omega_1 = 0 \quad \text{in } \Omega$$

with the inhomogeneous boundary conditions

$$\omega_1 = 0, \quad (1-\nu)\frac{\partial^2\omega_1}{\partial n^2} + \nu\,\Delta\,\omega_1 = -\frac{(1-\nu)}{\sqrt{3k}}\,\frac{\partial^3\omega_0}{\partial s^2\partial n}$$

for the soft simply supported plate and

$$(1-\nu)\frac{\partial^2\omega_1}{\partial n^2} + \nu\,\Delta\,\omega_1 = \frac{1}{\sqrt{3k}}\,\frac{\partial\,\Delta\,\omega_0}{\partial n},$$

$$\frac{\partial\,\Delta\,\omega_1}{\partial n} + (1-\nu)\frac{\partial}{\partial s}\left(\frac{\partial^2\omega_1}{\partial s\partial n} - \kappa\frac{\partial\omega_1}{\partial s}\right) = -\frac{(1-\nu)}{\sqrt{3k}}\,\frac{\partial}{\partial s}\left(\kappa\left[\frac{\partial^2\omega_0}{\partial s\partial n} - \kappa\frac{\partial\omega_0}{\partial s}\right]\right)$$

for the free plate.

Note that the expansions for the soft and hard simply supported plates differ already in the term ω_1. For the soft and hard clamped plates the terms ω_0, ω_1, and ω_2 all agree, but $\omega_3 = 0$ for the soft clamped plate and is generally nonzero for the hard clamped plate.

Turning to the expansion of ϕ, we find that in all five cases that $\phi_0 = \mathbf{grad}\,\omega_0$ and $\phi_1 = \mathbf{grad}\,\omega_1$ while $\phi_2 - \mathbf{grad}\,\omega_2 = \lambda^{-1}D\,\Delta\,\omega_0$, which is never zero (except in the trivial case $g \equiv 0$). For the boundary correctors, we find that $\boldsymbol{\Phi}_0$ vanishes in all five cases. For the soft simply supported and free plates,

$$\hat{\boldsymbol{\Phi}}_1(\eta,\theta) = -\frac{1}{\sqrt{3k}}\exp(-\sqrt{12k}\eta)\left(\frac{\partial^2\omega_0}{\partial s\partial n} - \kappa\frac{\partial\omega_0}{\partial s}\right)(0,\theta)\boldsymbol{s}.$$

For the hard clamped and hard simply supported plate, $\boldsymbol{\Phi}_1$ vanishes as well as $\boldsymbol{\Phi}_0$ and we have

$$\hat{\boldsymbol{\Phi}}_2(\eta,\theta) = -\frac{1}{6k(1-\nu)}\exp(-\sqrt{12k}\eta)\frac{\partial}{\partial s}\,\Delta\,\omega_0(0,\theta)\boldsymbol{s}$$

in both cases. For the soft clamped plate $\boldsymbol{\Phi}_0$, $\boldsymbol{\Phi}_1$, and $\boldsymbol{\Phi}_2$ all vanish. In all five cases, the first nonzero boundary corrector is purely tangential. Table 1 summarizes the terms in the asymptotic expansions of ω and ϕ which vanish.

TABLE 1
Vanishing terms in the asymptotic expansions.

soft simply supported	—	—	$\boldsymbol{\Phi}_0$	$\boldsymbol{\Phi}_1 \cdot \boldsymbol{n}$
free	—	—	$\boldsymbol{\Phi}_0$	$\boldsymbol{\Phi}_1 \cdot \boldsymbol{n}$
hard clamped	ω_1	ϕ_1	$\boldsymbol{\Phi}_0$, $\boldsymbol{\Phi}_1$	$\boldsymbol{\Phi}_2 \cdot \boldsymbol{n}$
hard simply supported	ω_1	ϕ_1	$\boldsymbol{\Phi}_0$, $\boldsymbol{\Phi}_1$	$\boldsymbol{\Phi}_2 \cdot \boldsymbol{n}$
soft clamped	ω_1, ω_3	ϕ_1, ϕ_3	$\boldsymbol{\Phi}_0$, $\boldsymbol{\Phi}_1$, $\boldsymbol{\Phi}_2$	$\boldsymbol{\Phi}_3 \cdot \boldsymbol{n}$

Using symbolic computation, we have computed exact solutions to the Reissner–Mindlin system on circular and semiinfinite plates for particular choices of the load function g, and have explicitly computed the asymptotic expansions of ω and ϕ through terms of order 6. These computations verify the sharpness of the results in this paper in that no terms of the expansions vanish except those given in the table. These results have been reported in [2].

As an application of our asymptotic analysis, we can determine the asymptotic behavior of Sobolev norms of solutions of the Reissner–Mindlin system. Supposing that g is sufficiently smooth, we have the following estimates, valid for both the soft simply supported and free plate, in which the constant C depends on g, Ω, and the elastic constants but is independent of t. Here $\|\cdot\|_s$ and $|\cdot|_s$ denote the norms in the Sobolev spaces $H^s(\Omega)$ and $H^s(\partial\Omega)$ (see §2).

The transverse displacement ω and all of its derivatives are bounded uniformly in t, that is,

$$\|\omega\|_s \le C, \quad s \in \mathbb{R},$$

but the regularity of the rotation $\boldsymbol{\phi}$ is limited by the boundary layer. For example, for the soft simply supported and free plates, we have

$$\|\boldsymbol{\phi}\|_s \le Ct^{\min(0,3/2-s)}, \quad s \in \mathbb{R},$$

so derivatives of order greater than 1 will generally tend to infinity in L^2 as $t \to 0$.

The quantity $\boldsymbol{\zeta} := t^{-2}(\mathbf{grad}\,\omega - \boldsymbol{\phi})$, which is proportional to the shear strain, is often of interest. From the above expansions, we get

$$\boldsymbol{\zeta} \sim -t^{-1}\chi\boldsymbol{\Phi}_1 + (\mathbf{grad}\,\omega_2 - \boldsymbol{\phi}_2 - \chi\boldsymbol{\Phi}_2) + \cdots,$$

so it has a stronger boundary layer. Indeed, for the soft simply supported and free plates, $\boldsymbol{\zeta}$ is not uniformly bounded in L^2, or even in H^s for $s > -1/2$:

$$\|\boldsymbol{\zeta}\|_s \le Ct^{\min(0,-1/2-s)}, \quad s \in \mathbb{R}.$$

The corresponding estimates for the hard clamped and hard simply supported plates are

$$\|\boldsymbol{\phi}\|_s \le Ct^{\min(0,5/2-s)}, \quad s \in \mathbb{R}, \qquad \|\boldsymbol{\zeta}\|_s \le Ct^{\min(0,1/2-s)}, \quad s \in \mathbb{R},$$

and for the soft clamped plate

$$\|\boldsymbol{\phi}\|_s \le Ct^{\min(0,7/2-s)}, \quad s \in \mathbb{R}, \qquad \|\boldsymbol{\zeta}\|_s \le Ct^{\min(0,3/2-s)}, \quad s \in \mathbb{R}.$$

Of course, the boundary layer does not limit the regularity of $\boldsymbol{\phi}$ or $\boldsymbol{\zeta}$ at a positive distance from $\partial\Omega$ nor does it affect the smoothness of their restrictions to $\partial\Omega$. Thus

$$\|\boldsymbol{\phi}\|_{H^s(\Omega_c)} + |\boldsymbol{\phi}|_s + \|\boldsymbol{\zeta}\|_{H^s(\Omega_c)} + |\boldsymbol{\zeta}|_s \le C, \quad s \in \mathbb{R},$$

for any compact subdomain Ω_c of Ω.

In the limit as $t \to 0$, the variables ω and $\boldsymbol{\phi}$ tend in L^2 to the leading terms of their asymptotic expansions. The number of derivatives which converge and the rate of convergence may be determined by examining the first neglected interior and boundary terms of the expansions. For any $s \in \mathbb{R}$, we get for the soft simply supported and free plate

$$\|\omega - \omega_0\|_s \le Ct, \qquad \|\boldsymbol{\phi} - \boldsymbol{\phi}_0\|_s \le Ct^{\min(1,3/2-s)}.$$

Note that the rate of convergence for $\boldsymbol{\phi}$ depends on the Sobolev norm under consideration. For each of the variables, taking more terms from the expansion increases the rate of convergence and taking sufficiently many terms in the expansions gives approximation of any desired algebraic order of convergence in t in any desired Sobolev space (provided g is sufficiently regular). For example,

$$\|\omega - \omega_0 - t\omega_1\|_s \le Ct^2, \qquad \|\boldsymbol{\phi} - \boldsymbol{\phi}_0 - t(\boldsymbol{\phi}_1 + \chi\boldsymbol{\Phi}_1)\|_s \le Ct^{\min(2,5/2-s)}.$$

For the hard clamped and hard simply supported plates, the analogous results are

$$\|\omega - \omega_0\|_s \le Ct^2, \qquad \|\boldsymbol{\phi} - \boldsymbol{\phi}_0\|_s \le Ct^{\min(2,5/2-s)},$$
$$\|\omega - \omega_0 - t^2\omega_2\|_s \le Ct^3, \qquad \|\boldsymbol{\phi} - \boldsymbol{\phi}_0 - t^2(\boldsymbol{\phi}_2 + \chi\boldsymbol{\Phi}_2)\|_s \le Ct^{\min(3,7/2-s)}.$$

For the soft clamped plate,

$$\|\omega-\omega_0\|_s \le Ct^2, \qquad \|\phi-\phi_0\|_s \le Ct^{\min(2,7/2-s)},$$
$$\|\omega-\omega_0-t^2\omega_2\|_s \le Ct^3, \qquad \|\phi-\phi_0-t^2\phi_2\|_s \le Ct^{\min(3,7/2-s)}.$$

It is also possible to use our asymptotic expansions to derive estimates in function spaces other than H^s. The technique for doing this is described in [1]. Further references for the Reissner–Mindlin model and its boundary-layer behavior can also be found there. Many of the results in this paper were described without proof in [2], where explicit illustrations of the theory are constructed.

2. Notation and preliminaries. The letter C denotes a generic constant, not necessarily the same in each occurrence. We assume that Ω is a smooth, bounded, and simply connected domain in $\mathbb{R}^2$. The $L^2(\Omega)$ and $L^2(\partial\Omega)$ inner products are denoted by $(\cdot\,,\,\cdot)$ and $\langle\cdot\,,\,\cdot\rangle$, respectively. We also use the usual L^2-based Sobolev spaces $H^s(\Omega)$ and $H^s(\partial\Omega)$, real $s\ge 0$, with norms denoted by $\|\cdot\|_s$ and $|\cdot|_s$. When the domain argument is omitted, L^2 and H^s refer to $L^2(\Omega)$ and $H^s(\Omega)$. The space $\mathring{H}^s=\mathring{H}^s(\Omega)$ is the closure of C_0^∞ in H^s. The interpolation inequality

$$\|g\|_{s+v}^u \le C\|g\|_s^{u-v}\|g\|_{s+u}^v, \quad s\ge 0,\ u\ge v\ge 0, \tag{2.1}$$

holds. If $g\in L^2$ and $\Delta^{-1}g$ denotes the unique function in $H^2\cap\mathring{H}^1$ whose Laplacian is equal to g, then

$$C^{-1}\|\,\Delta^{-1}g\|_{s+2} \le \|g\|_s \le C\|\,\Delta^{-1}g\|_{s+2}, \quad s\ge 0,$$

where the constant C may depend on s and Ω but not on g. In other words, $g\mapsto \|\,\Delta^{-1}g\|_{s+2}$ defines an equivalent norm on H^s for $s\ge 0$. We also define some negatively indexed norms which maintain this equivalence:

$$\|g\|_s := \|\,\Delta^{-1}g\|_{s+2}, \quad -2\le s<0.$$

For $s=-1$, this is equivalent to the norm in the dual space of $\mathring{H}^1$. For $s=-2$, it is equivalent to the norm in the dual space of $H^2\cap\mathring{H}^1$. With this definition, (2.1) holds for $s\ge -2$. We shall make frequent use of this fact to bound sums of the form $\sum_{i=0}^n t^i\|g\|_{s+i}$ by a multiple of the sum of the first and last terms.

We also require the quotient space $H^s/\mathbb{R}$. An element $p\in H^s/\mathbb{R}$ is a coset consisting of all functions in H^s differing from a fixed function by a constant. The quotient norm is given by

$$\|p\|_{s/\mathbb{R}} = \min_{q\in p}\|q\|_s.$$

(In fact, $\|p\|_{s/\mathbb{R}}=\|\bar{p}\|_s$, where $\bar{p}$ is the unique function in the coset p having mean value zero.)

We use boldface type to denote 2-vector-valued functions, operators whose values are vector-valued functions, and spaces of vector-valued functions. Script type is used in a similar way for 2 × 2-matrix objects. Thus, for example, $\operatorname{div}\boldsymbol{\psi}\in L^2$ for $\boldsymbol{\psi}\in\boldsymbol{H}^1$, while $\mathbf{div}\,\mathcal{T}\in\boldsymbol{L}^2$ for $\mathcal{T}\in\mathcal{H}^1$. Finally, we use various standard differential operators:

$$\mathbf{grad}\,r=\begin{pmatrix}\partial r/\partial x\\ \partial r/\partial y\end{pmatrix}, \qquad \operatorname{div}\boldsymbol{\psi}=\frac{\partial\psi_1}{\partial x}+\frac{\partial\psi_2}{\partial y},$$

$$\mathbf{div}\begin{pmatrix}t_{11} & t_{12}\\ t_{21} & t_{22}\end{pmatrix}=\begin{pmatrix}\partial t_{11}/\partial x+\partial t_{12}/\partial y\\ \partial t_{21}/\partial x+\partial t_{22}/\partial y\end{pmatrix},$$

$$\mathbf{curl}\, p = \begin{pmatrix} -\partial p/\partial y \\ \partial p/\partial x \end{pmatrix}, \qquad \operatorname{rot} \psi = \frac{\partial \psi_1}{\partial y} - \frac{\partial \psi_2}{\partial x}.$$

Note that these differential operators annihilate constants and consequently induce operators on the quotient space $H^s/\mathbb{R}$ for each s. We denote the induced operator in the same way as the original. Thus, for example, if $p \in H^1/\mathbb{R}$, $\mathbf{curl}\, p$ denotes the element of $\boldsymbol{L}^2$ obtained by applying the curl to any element in the coset p.

We record here for later reference the identity

$$\sum_{i=0}^{n}\sum_{j=0}^{i} f(i-j,j) = \sum_{i=0}^{n}\sum_{j=0}^{n-i} f(i,j). \tag{2.2}$$

To describe the boundary layer, we define the usual boundary-fitted coordinates in a neighborhood of the boundary. Let ρ_0 be a positive number less than the minimum radius of curvature of $\partial\Omega$ and define

$$\Omega_0 = \{\, \boldsymbol{z} - \rho \boldsymbol{n}_{\boldsymbol{z}} \mid \boldsymbol{z} \in \partial\Omega, 0 < \rho < \rho_0 \,\},$$

where $\boldsymbol{n}_{\boldsymbol{z}}$ is the outward unit normal to Ω at $\boldsymbol{z}$. Let $\boldsymbol{z}(\theta) = (X(\theta), Y(\theta))$, $\theta \in [0, L)$, be a parametrization of $\partial\Omega$ by arclength which we extend L-periodically to $\theta \in \mathbb{R}$. The correspondence

$$(\rho, \theta) \mapsto \boldsymbol{z} - \rho \boldsymbol{n}_{\boldsymbol{z}} = (X(\theta) - \rho Y'(\theta), Y(\theta) + \rho X'(\theta))$$

is a diffeomorphism of $(0, \rho_0) \times \mathbb{R}/L$ on Ω_0. Let $\kappa(\theta)$ denote the curvature of $\partial\Omega$ at $\boldsymbol{z}(\theta)$ and set

$$\sigma(\rho, \theta) := \frac{1}{1 - \kappa(\theta)\rho}.$$

The unit vector fields of the outward normal and the counterclockwise tangent extend from $\partial\Omega$ to Ω_0 as functions of θ, independent of ρ, and satisfy

$$\boldsymbol{n} = -\,\mathbf{grad}\, \rho = -\sigma(\rho, \theta)^{-1}\, \mathbf{curl}\, \theta, \qquad \boldsymbol{s} = \sigma(\rho, \theta)^{-1}\, \mathbf{grad}\, \theta = -\,\mathbf{curl}\, \rho.$$

We shall also use the stretched variable $\hat{\rho} = \rho/t$. When required for clarity, we use hats to denote the change of variables to $(\hat{\rho}, \theta)$ coordinates, that is,

$$\hat{f}(\hat{\rho}, \theta) := f(x, y).$$

3. An asymptotic expansion of the solution. We now develop asymptotic expansions of $\boldsymbol{\phi}$ and ω with respect to the plate thickness. Such expansions normally consist of two parts, an interior expansion and a boundary-layer expansion. Now it follows easily from (1.6) and (1.7) that the transverse displacement ω satisfies the biharmonic equation

$$D\,\Delta^2 \omega = g - \lambda^{-1} D t^2\, \Delta\, g, \tag{3.1}$$

which indicates that ω admits no boundary layer and hence can be described by an interior expansion alone. However, the rotation vector $\boldsymbol{\phi}$ satisfies the singular perturbation equation given in (1.6) and hence can be expected to include a boundary layer. Thus we shall seek expansions of the form

$$\omega \sim \sum_{i=0}^{\infty} t^i \omega_i, \qquad \boldsymbol{\phi} \sim \sum_{i=0}^{\infty} t^i \boldsymbol{\phi}_i + \sum_{i=1}^{\infty} t^i \boldsymbol{\Phi}_i,$$

where ω_i and $\boldsymbol{\phi}_i$ are smooth functions independent of t, while $\boldsymbol{\Phi}_i(x,y) = \hat{\boldsymbol{\Phi}}_i(\hat{\rho},\theta)$ with $\hat{\boldsymbol{\Phi}}$ a smooth function on $[0,\infty) \times \partial\Omega$. We have suppressed the term $\boldsymbol{\Phi}_0$ since it turns out to be zero in all cases. In order that the expansion for $\boldsymbol{\phi}$ is defined everywhere in Ω even though $\boldsymbol{\Phi}_i$ is defined only on Ω_0, we introduce a smooth cutoff function χ which is a function of ρ alone, independent of θ and t, and identically one for $0 \le \rho \le \rho_0/3$, identically zero for $\rho > 2\rho_0/3$.

In this section, we give precise definitions of all the functions $\boldsymbol{\phi}_i$, ω_i, and $\boldsymbol{\Phi}_i$. In §5 (Theorems 5.1–5.3), we shall prove the validity of the expansions. More precisely, we shall show that by choosing n large enough we can make the corresponding remainder terms

$$\omega_n^E := \omega - \sum_{i=0}^{n} t^i \omega_i, \qquad \boldsymbol{\phi}_n^E := \boldsymbol{\phi} - \sum_{i=0}^{n} t^i \boldsymbol{\phi}_i - \chi \sum_{i=1}^{n} t^i \boldsymbol{\Phi}_i$$

smaller than any desired power of t in any Sobolev norm.

Taking the divergence of (1.6) and using (1.7), we see that $\operatorname{div}\boldsymbol{\phi}$ satisfies Poisson's equation:

$$D\,\Delta \operatorname{div}\boldsymbol{\phi} = g.$$

This suggests an alternate form for the asymptotic expansion of $\boldsymbol{\phi}$ in which the terms of the boundary-layer expansion are divergence free and hence can be written as the curls of scalar functions. Inserting some convenient factors, the alternate expansion is

$$\boldsymbol{\phi} \sim \sum_{i=0}^{\infty} t^i \boldsymbol{\phi}_i - \lambda^{-1}\chi t^2 \sum_{i=0}^{\infty} t^i \,\mathbf{curl}\, P_i$$

with $P_i(x,y) = \hat{P}_i(\hat{\rho},\theta)$ with $\hat{P}_i : [0,\infty) \times \partial\Omega \to \mathbb{R}$ smooth. Now

$$\mathbf{curl}\, P_i = \frac{\partial P_i}{\partial \rho}\,\mathbf{curl}\,\rho + \frac{\partial P_i}{\partial \theta}\,\mathbf{curl}\,\theta = -t^{-1}\frac{\partial \hat{P}_i}{\partial \hat{\rho}}\boldsymbol{s} - \sigma(\rho,\theta)\frac{\partial \hat{P}_i}{\partial \theta}\boldsymbol{n}.$$

Formally inserting the Taylor expansion

$$\sigma(\rho,\theta) = \sum_{j=0}^{\infty} [\kappa(\theta)\rho]^j = \sum_{j=0}^{\infty} [\kappa(\theta)t\hat{\rho}]^j$$

and equating the two forms of the boundary-layer expansion, we get that

$$-\lambda^{-1} t^2 \sum_{i=0}^{\infty} t^i \,\mathbf{curl}\, P_i = \sum_{i=1}^{\infty} t^i \boldsymbol{\Phi}_i. \tag{3.2}$$

This gives the relation between $\boldsymbol{\Phi}_i$ and P_i:

$$\boldsymbol{\Phi}_i = \lambda^{-1}\left\{ \frac{\partial \hat{P}_{i-1}}{\partial \hat{\rho}}\boldsymbol{s} + \sum_{j=0}^{i-2} [\kappa(\theta)\hat{\rho}]^j \frac{\partial \hat{P}_{i-j-2}}{\partial \theta}\boldsymbol{n} \right\}, \quad i \ge 1. \tag{3.3}$$

We now proceed to the definitions of w_i, $\boldsymbol{\phi}_i$, and P_i (with $\boldsymbol{\Phi}_i$ determined from P_i by (3.3)).

In order to motivate the definitions of the expansion functions, we shall reason formally. Let $\boldsymbol{\phi}^I$ denote $\sum_{i=0}^{\infty} t^i \boldsymbol{\phi}_i$ and let p^B denote $\sum_{i=0}^{\infty} t^i P_i$ (these definitions are only formal, since the sums need not be convergent). We want pairs $(\boldsymbol{\phi}^I, \omega)$ to solve the Reissner–Mindlin differential equations and $-\lambda^{-1}t^2(\mathbf{curl}\, p^B, 0)$ to solve the corresponding homogeneous differential equations, so that the pair $(\boldsymbol{\phi}, \omega)$, which (when $\chi \equiv 1$) is formally their sum, will satisfy the inhomogeneous equations. Inserting the expansions for ϕ^I and ω into the Reissner–Mindlin equations and equating like powers of t gives the equations

$$\lambda(\phi_i - \mathbf{grad}\,\omega_i) = \mathbf{div}\, C\,\mathcal{E}(\phi_{i-2}), \tag{3.4}$$

$$\lambda\,\mathrm{div}(\phi_i - \mathbf{grad}\,\omega_i) = \delta_{i2}g, \tag{3.5}$$

where δ_{ij} is the Kronecker symbol. These equations are to hold for $i = 0, 1, \ldots$ with the convention that $\phi_j = 0$ for $j < 0$. From (3.4) and (3.5), we easily deduce that ω_i satisfies the biharmonic problem

$$D\,\Delta^2\,\omega_i = \delta_{i0}g - \delta_{i2}\lambda^{-1}D\,\Delta\,g, \tag{3.6}$$

as is to be expected in view of (3.1). It follows from (3.4) that

$$\phi_i = \mathbf{grad}\sum_{k=0}^{[i/2]}(\lambda^{-1}D)^k\,\Delta^k\,\omega_{i-2k}$$

or, in light of (3.6),

$$\phi_i = \mathbf{grad}\, z_i, \tag{3.7}$$

with

$$z_i = \omega_i + \lambda^{-1}D\,\Delta\,\omega_{i-2} + \delta_{i4}\lambda^{-2}Dg. \tag{3.8}$$

To obtain differential equations satisfied by the boundary-layer functions, we note that $(\mathbf{curl}\,P, 0)$ solves the homogeneous Reissner–Mindlin system if and only if P solves the differential equation

$$-t^2\lambda^{-1}D\frac{1-\nu}{2}\,\Delta\,P + P = 0. \tag{3.9}$$

In (ρ, θ) coordinates, we have (on Ω_0)

$$\begin{aligned}\Delta\,P &= |\,\mathbf{grad}\,\rho|^2\frac{\partial^2 P}{\partial\rho^2} + \Delta\,\rho\frac{\partial P}{\partial\rho} + |\,\mathbf{grad}\,\theta|^2\frac{\partial^2 P}{\partial\theta^2} + \Delta\,\theta\frac{\partial P}{\partial\theta}\\ &= \frac{\partial^2 P}{\partial\rho^2} - \kappa(\theta)\sigma(\rho,\theta)\frac{\partial P}{\partial\rho} + \sigma(\rho,\theta)^2\frac{\partial^2 P}{\partial\theta^2} + \rho\kappa'(\theta)\sigma(\rho,\theta)^3\frac{\partial P}{\partial\theta}\\ &= \frac{\partial^2 P}{\partial\rho^2} + \sum_{j=0}^{\infty}\rho^j\left(a_1^j\frac{\partial P}{\partial\rho} + a_2^j\frac{\partial^2 P}{\partial\theta^2} + a_3^j\frac{\partial P}{\partial\theta}\right).\end{aligned}$$

In the last step, we have (formally) replaced each coefficient with its Taylor series in ρ. It is easy to check that

$$a_1^j = -[\kappa(\theta)]^{j+1}, \qquad a_2^j = (j+1)[\kappa(\theta)]^j, \qquad a_3^j = \frac{j(j+1)}{2}[\kappa(\theta)]^{j-1}\kappa'(\theta). \tag{3.10}$$

Switching to the stretched variable $\hat{\rho}$, this becomes

$$\Delta\,P = t^{-2}\frac{\partial^2 P}{\partial\hat{\rho}^2} + \sum_{j=0}^{\infty}(t\hat{\rho})^j\left(a_1^j t^{-1}\frac{\partial P}{\partial\hat{\rho}} + a_2^j\frac{\partial^2 P}{\partial\theta^2} + a_3^j\frac{\partial P}{\partial\theta}\right).$$

Thus if we write (3.9) in $(\hat{\rho},\theta)$ variables, insert $\sum_{i=0}^{\infty} t^i P_i$ for P, and equate like powers of t, we get

$$\begin{aligned}(3.11)\qquad -\lambda^{-1}D\frac{1-\nu}{2}\frac{\partial^2 P_i}{\partial \hat{\rho}^2} + P_i &= \hat{F}_i(\hat{\rho},\theta)\\ &:= \lambda^{-1}D\frac{1-\nu}{2}\sum_{j=0}^{i-1}\hat{\rho}^j\left(a_1^j\frac{\partial P_{i-j-1}}{\partial\hat{\rho}} + a_2^j\frac{\partial^2 P_{i-j-2}}{\partial\theta^2} + a_3^j\frac{\partial P_{i-j-2}}{\partial\theta}\right), \quad i = 0,1,\dots,\end{aligned}$$

where again P_j is to be interpreted as 0 for $j < 0$. Note that (3.11) is an ordinary differential equation for the function P_i in the independent variable $\hat{\rho}$ in which θ enters as a parameter. We shall only consider solutions which satisfy the decay condition

$$(3.12)\qquad \lim_{\hat{\rho}\to\infty} P_i = 0.$$

This will ensure that each P_i decays exponentially with $\hat{\rho}$ and is therefore negligible outside of Ω_0.

The differential equations (3.6) and (3.11), together with appropriate boundary conditions, will be used to define the functions ω_i and P_i. Then the $\boldsymbol{\phi}_i$ are given by (3.7) and the $\boldsymbol{\Phi}_i$ by (3.3).

We now derive the boundary conditions and, for each of the boundary value problems we consider, show that the ω_i and P_i are uniquely determined. The boundary conditions for ω_i and P_i will be obtained from the boundary conditions for the Reissner–Mindlin system by inserting the asymptotic expansions and equating like powers of the thickness, and then using (3.7) to eliminate the $\boldsymbol{\phi}_i$.

The hard clamped plate. The boundary condition $\omega = 0$ leads, of course, to

$$(3.13)\qquad \omega_i = 0 \quad \text{on } \partial\Omega.$$

The boundary conditions $\boldsymbol{\phi}\cdot\boldsymbol{n} = 0$ and $\boldsymbol{\phi}\cdot\boldsymbol{s} = 0$ give $\boldsymbol{\phi}_i\cdot\boldsymbol{n} + \boldsymbol{\Phi}_i\cdot\boldsymbol{n} = 0$ and $\boldsymbol{\phi}_i\cdot\boldsymbol{s} + \boldsymbol{\Phi}_i\cdot\boldsymbol{s} = 0$. Using (3.3), these become

$$(3.14)\qquad \boldsymbol{\phi}_i\cdot\boldsymbol{n} = -\lambda^{-1}\frac{\partial P_{i-2}}{\partial\theta} \quad \text{on } \partial\Omega$$

and

$$(3.15)\qquad \boldsymbol{\phi}_i\cdot\boldsymbol{s} = -\lambda^{-1}\frac{\partial P_{i-1}}{\partial\hat{\rho}} \quad \text{on } \partial\Omega.$$

In view of (3.7), (3.14) can be expressed equivalently as

$$(3.16)\qquad \frac{\partial\omega_i}{\partial n} = -\lambda^{-1}\frac{\partial P_{i-2}}{\partial\theta} - \lambda^{-1}D\frac{\partial\,\Delta\,\omega_{i-2}}{\partial n} - \delta_{i4}\lambda^{-2}D\frac{\partial g}{\partial n} \quad \text{on } \partial\Omega,$$

and, using (3.13) and (3.7), we can write (3.15) as

$$(3.17)\qquad -\frac{\partial P_i}{\partial\hat{\rho}} = D\frac{\partial\,\Delta\,w_{i-1}}{\partial s} + \delta_{i3}\lambda^{-1}D\frac{\partial g}{\partial s} \quad \text{on } \partial\Omega.$$

We now show that all the ω_i and P_i are uniquely determined by (3.6), (3.11), (3.13)–(3.15), and (3.12). Indeed, from (3.11), (3.12), and (3.17), we immediately infer that $P_0 = 0$. We can then uniquely determine ω_i for $i = 0,1,2$ from (3.6), (3.13), and (3.16). These being known, P_i, $i = 1$, 2, 3 are uniquely determined, from which we can in turn compute ω_i for $i = 3$, 4, 5 and so forth. Note that ω_0 is determined from the usual boundary value problem for a clamped Kirchhoff plate. Also, (3.6), (3.13), and (3.16) all have vanishing right-hand sides for $i = 1$, so ω_1 and therefore $\boldsymbol{\phi}_1$ vanish.

The soft clamped plate. In this case, the boundary conditions (3.13) and (3.14) apply, but instead of $\boldsymbol{\phi} \cdot \boldsymbol{s} = 0$ we must enforce $M_{\boldsymbol{s}}\boldsymbol{\phi} = 0$ on $\partial\Omega$. Using (3.3) and the fact that

$$M_{\boldsymbol{s}}\boldsymbol{\Phi} = \frac{D(1-\nu)}{2}\left(-t^{-1}\frac{\partial \boldsymbol{\Phi}}{\partial \hat{\rho}} \cdot \boldsymbol{s} + \frac{\partial \boldsymbol{\Phi}}{\partial \theta} \cdot \boldsymbol{n}\right),$$

we get

(3.18)

$$\begin{aligned}\frac{\partial^2 P_i}{\partial \hat{\rho}^2} &= -\kappa\frac{\partial P_{i-1}}{\partial \hat{\rho}} + \frac{\partial^2 P_{i-2}}{\partial \theta^2} + \frac{2\lambda}{D(1-\nu)} M_{\boldsymbol{s}}\boldsymbol{\phi}_i \\ &= -\kappa\frac{\partial P_{i-1}}{\partial \hat{\rho}} + \frac{\partial^2 P_{i-2}}{\partial \theta^2} + 2\left(\frac{\partial^2}{\partial s \partial n} - \kappa\frac{\partial}{\partial s}\right)(\lambda\omega_i - D\,\Delta\,\omega_{i-2} + \delta_{i4}\lambda^{-1}Dg).\end{aligned}$$

We conclude that ω_0 is uniquely determined and that ω_1 again vanishes. Now since $\partial^2\omega_0/\partial s\partial n = \partial\omega_0/\partial s = 0$, we infer that P_0 and P_1 vanish as well and therefore that ω_3 does also. The other terms can be computed as follows: first ω_2, then P_2 and P_3, then ω_4 and ω_5, then P_4 and P_5, etc. It is interesting to note that ω_0, ω_1, ω_2, and P_0 are the same for the hard and soft clamped plates but ω_3 and P_1 are not (they vanish for the latter but not for the former).

We now show that for the soft clamped plate all the P_i vanish for any values of θ such that $\kappa(\theta) = 0$. Thus there is no boundary layer near a flat portion of the boundary. (This property holds as well for the hard simply supported plate but not for the other boundary conditions we consider.) To prove it in the case of the soft clamped plate, we note first that by (3.7), $\boldsymbol{\phi}_i$ is a gradient for all i. Using this fact, one computes that

$$M_{\boldsymbol{s}}\boldsymbol{\phi}_i = D(1-\nu)\left(\frac{\partial\boldsymbol{\phi}_i \cdot \boldsymbol{n}}{\partial s} - \kappa\boldsymbol{\phi}_i \cdot \boldsymbol{s}\right).$$

In view of (3.14), we have

$$M_{\boldsymbol{s}}\boldsymbol{\phi}_i = -\lambda^{-1}D(1-\nu)\frac{\partial^2 P_{i-2}}{\partial\theta^2}$$

wherever $\kappa = 0$. Our claim then follows from the defining equations for the P_i and induction.

The hard simply supported plate. For the hard simply supported plate, the boundary conditions are (3.13), (3.15), and, arising from the condition $M_{\boldsymbol{n}}\boldsymbol{\phi} = 0$,

$$M_{\boldsymbol{n}}\boldsymbol{\phi}_i = \lambda^{-1}D(1-\nu)\left(\kappa\frac{\partial P_{i-2}}{\partial\theta} + \frac{\partial^2 P_{i-1}}{\partial\theta\partial\hat{\rho}}\right) \quad \text{on } \partial\Omega, \tag{3.19}$$

where we have used (3.3) and the fact that

$$M_{\boldsymbol{n}}\boldsymbol{\Phi} = D\left(-t^{-1}\frac{\partial\boldsymbol{\Phi}}{\partial\hat{\rho}} \cdot \boldsymbol{n} + \nu\frac{\partial\boldsymbol{\Phi}}{\partial\theta} \cdot \boldsymbol{s}\right).$$

Using (3.7) and (3.8), we may rewrite this as

$$
\begin{aligned}
(3.20) \qquad D\left[(1-\nu)\frac{\partial^2}{\partial n^2}+\nu\,\Delta\right]&\left(\omega_i+\lambda^{-1}D\,\Delta\,\omega_{i-2}+\delta_{i4}\lambda^{-2}Dg\right)\\
&=\lambda^{-1}D(1-\nu)\left(\kappa\frac{\partial P_{i-2}}{\partial\theta}+\frac{\partial^2 P_{i-1}}{\partial\theta\partial\hat\rho}\right).
\end{aligned}
$$

Since (3.17) holds, we again have $P_0=0$. Using (3.13) and (3.20), we see that ω_0 is determined from the usual boundary value problem for a simply supported Kirchhoff plate and that ω_1 vanishes. We can then continue by computing P_1 and P_2, then ω_2 and ω_3, etc.

Now since ϕ_i is a gradient, one can verify that

$$
\mathbf{div}\,C\,\mathcal{E}(\phi_i)\cdot\mathbf{s}=\frac{\partial M_{\mathbf{n}}\phi_i}{\partial s}+D(1-\nu)\frac{\partial}{\partial s}\left[\frac{\partial\phi_i\cdot\mathbf{s}}{\partial s}-\kappa\phi_i\cdot\mathbf{n}\right].
$$

If we assume that κ vanishes on a nondegenerate interval, then, combining this equation with (3.19) and (3.15), we can express $\mathbf{div}\,C\,\mathcal{E}(\phi_i)\cdot\mathbf{s}$ in terms of P_{i-2} and P_{i-1} for θ in this interval. Now (3.15) and (3.4) combine to give

$$
\frac{\partial P_i}{\partial\hat\rho}=-\,\mathbf{div}\,C\,\mathcal{E}(\phi_i)\cdot\mathbf{s}.
$$

Thus, on an interval where κ vanishes, $\partial P_i/\partial\hat\rho$ may be expressed in terms of P_{i-1} and P_{i-2} on that interval. A simple induction allows us to conclude that all the P_i vanish for such θ.

The soft simply supported plate. In this case, the boundary conditions are (3.13), (3.18), and (3.19). We can compute ω_0 and ϕ_0 from the same equations as for the hard simply supported case. Then P_0 can be computed (it need not vanish), and then ω_1 (which also need not vanish), P_1, etc.

4. A priori estimates for the soft simply supported plate. We now consider in detail the case of the soft simply supported plate. An easy computation shows that

$$
\hat P_0(\hat\rho,\theta)=D(1-\nu)\widehat{\frac{\partial^2\omega_0}{\partial s\partial n}}(0,\theta)e^{-c\hat\rho},\qquad \text{where } c=\sqrt{\frac{2\lambda}{D(1-\nu)}}=\sqrt{12k}.
$$

We may show in general that $\hat P_i$ are polynomials in $\hat\rho$ times the decaying exponential $e^{-c\hat\rho}$. The specific form is given in the following theorem.

THEOREM 4.1. *For $i\in\mathbb{N}$,*

$$
\hat P_i(\hat\rho,\theta)=e^{-c\hat\rho}\sum_{k=0}^{i}\sum_{j=0}^{i}\sum_{l=0}^{i-j}\alpha_{ijkl}(\theta)\hat\rho^k\frac{\partial^l}{\partial\theta^l}\widehat{M_{\mathbf{s}}\phi_j}(0,\theta),
$$

where the α_{ijkl} are smooth functions of θ which depend only upon the domain Ω.

Proof. Let us say that a function is of type (m,n) if it is a sum of terms of the form

$$
\alpha(\theta)\hat\rho^k\frac{\partial^l}{\partial\theta^l}\widehat{M_{\mathbf{s}}\phi_j}(0,\theta)
$$

with $k,j,l\in\mathbb{N}$ satisfying $k\le m$, $j+l\le n$, and α a smooth function of θ depending only on Ω. We wish to show that P_i is of type (i,i) for $i\in\mathbb{N}$. We shall use induction on i. The result is known for $i=0$. If we assume its validity for $0,1,\dots,i-1$, we easily check that F_i defined in (3.11) is of type $(i-1, i)$ and that the right-hand side of (3.18) is of type $(0, i)$ (there is no ρ dependence since this is on the boundary). It is then easy to see that the unique solution P_i of (3.11), (3.12), and (3.18) must be of type (i, i), as desired. □

Using this formula, we now turn to the derivation of a priori estimates for the interior expansions and boundary correctors. The following estimates are obtained immediately from the form of P_i.

THEOREM 4.2. *For any $i \in \mathbb{N}$ and $s \in \mathbb{R}$ there exists a constant C depending only on Ω, E, ν, k, s, and i, such that*

$$|P_i|_s + \left|\frac{\partial P_i}{\partial \hat{\rho}}\right|_s \le C \sum_{j=0}^{i} |M_s \phi_j|_{s+i-j}.$$

Using this result, we next obtain bounds for the terms in the interior expansions of ϕ and ω.

THEOREM 4.3. *For all real $s \ge 0$ and $i \in \mathbb{N}$, there exists a constant C such that*

$$\|\omega_i\|_{s+2} + \|\phi_i\|_{s+1} \le C \|g\|_{s+i-2}.$$

Proof. Let B_2 denote the boundary differential operator

$$B_2 \omega = D[(1-\nu)\frac{\partial^2 \omega}{\partial n^2} + \nu \, \Delta \, \omega].$$

It easily follows from (3.8), (3.6), (3.13), and (3.20) that

$$D \, \Delta^2 z_i = \delta_{i0} g \quad \text{in } \Omega, \qquad z_i = \lambda^{-1} D \, \Delta \, \omega_{i-2} + \delta_{i4} \lambda^{-2} D g \quad \text{on } \partial\Omega,$$
$$B_2 z_i = \lambda^{-1} D(1-\nu) \left(\kappa \frac{\partial P_{i-2}}{\partial \theta} + \frac{\partial^2 P_{i-1}}{\partial \theta \partial \hat{\rho}} \right) \quad \text{on } \partial\Omega.$$

Applying standard estimates for the biharmonic, we obtain for $s \ge 0$ that

$$\begin{aligned} &\|z_i\|_{s+2} \\ &\le C \left(\delta_{i0} \|g\|_{s-2} + |\, \Delta \, \omega_{i-2}|_{s+3/2} + \delta_{i4} |g|_{s+3/2} + |\frac{\partial P_{i-2}}{\partial \theta}|_{s-1/2} + \left| \frac{\partial^2 P_{i-1}}{\partial \theta \partial \hat{\rho}} \right|_{s-1/2} \right) \\ &\le C \left(\delta_{i0} \|g\|_{s-2} + \|\omega_{i-2}\|_{s+4} + \delta_{i4} \|g\|_{s+2} + |P_{i-2}|_{s+1/2} + \left| \frac{\partial P_{i-1}}{\partial \hat{\rho}} \right|_{s+1/2} \right) \\ &\le C \left(\delta_{i0} \|g\|_{s-2} + \|\omega_{i-2}\|_{s+4} + \delta_{i4} \|g\|_{s+2} + \sum_{j=0}^{i-1} |M_s \phi_j|_{s+i-j-1/2} \right) \\ &\le C \left(\delta_{i0} \|g\|_{s-2} + \|\omega_{i-2}\|_{s+4} + \delta_{i4} \|g\|_{s+2} + \sum_{j=0}^{i-1} \|\phi_j\|_{s+i-j+1} \right). \end{aligned}$$

Now $\phi_i = \mathbf{grad}\, z_i$ and by the definition of z_i and the triangle inequality, it easily follows that

$$\|\omega_i\|_{s+2} \le C \left(\|z_i\|_{s+2} + \|\omega_{i-2}\|_{s+4} + \delta_{i4} \|g\|_{s+2} \right).$$

Combining these results, we obtain

$$\|\omega_i\|_{s+2} + \|\phi_i\|_{s+1} \le C\left(\delta_{i0}\|g\|_{s-2} + \|\omega_{i-2}\|_{s+4} + \delta_{i4}\|g\|_{s+2} + \sum_{j=0}^{i-1}\|\phi_j\|_{s+i-j+1}\right).$$

The result for $i = 0$ follows directly and the result for $i \ge 1$ is then obtained by induction. □

COROLLARY 4.4. *For real $s \ge -1/2$ and $i \in \mathbb{N}$, there exists a constant C such that*

$$|P_i|_s + \left|\frac{\partial P_i}{\partial \hat{\rho}}\right|_s + |M_s\phi_i|_s \le C\|g\|_{s+i-3/2}.$$

Proof. Since

$$M_s\phi_j = M_s(\mathbf{grad}\, z_j) = D(1-\nu)\left(\frac{\partial^2}{\partial s\partial n} - \kappa\frac{\partial}{\partial s}\right)z_j$$

on $\partial\Omega$, we have

$$\begin{aligned}|M_s\phi_j|_{s+i-j} &\le C\left(\left|\frac{\partial z_j}{\partial n}\right|_{s+i-j+1} + |z_j|_{s+i-j+1}\right) \le C\|z_j\|_{s+i-j+5/2}\\ &\le C\left(\|\omega_j\|_{s+i-j+5/2} + \|\omega_{j-2}\|_{s+i-j+9/2} + \delta_{j4}\|g\|_{s+i-j+5/2}\right)\\ &\le C\|g\|_{s+i-3/2}, \quad j = 0, 1, \ldots, i.\end{aligned}$$

The result follows from this estimate and Theorem 4.2.

We next consider the derivation of interior norm estimates for the boundary correctors. To get these results, we make use of the following elementary lemma.

LEMMA 4.5. *Suppose $a > 0$, $b \ge 1$, and $p(x)$ is a polynomial of degree $\le n$ with positive coefficients. Then there exists a constant $K_n(a)$ depending only on n and a such that*

$$\int_b^\infty p(x)e^{-ax}\,dx \le K_n(a)e^{-ab}p(b).$$

Proof. It clearly suffices to prove the result for $p(x) = x^n$. In this case, it reduces to showing that

$$\int_0^\infty (1 + x/b)^n e^{-ax}\,dx \le K_n(a) \quad \text{for all } b \ge 1,$$

which is obvious. □

Next recall that

$$\Omega_0 = \{\, \boldsymbol{z} - \rho\boldsymbol{n}_{\boldsymbol{z}} \mid \boldsymbol{z} \in \partial\Omega, \quad 0 < \rho < \rho_0 \,\}$$

and set

$$\Omega_1 = \{\, \boldsymbol{z} - \rho\boldsymbol{n}_{\boldsymbol{z}} \mid \boldsymbol{z} \in \partial\Omega, \quad \rho_0/3 < \rho < \rho_0 \,\},$$

so $\chi \equiv 1$ on $\Omega_0 \setminus \Omega_1$ and $\chi \equiv 0$ on a neighborhood of $\Omega \setminus \Omega_0$. The following result is similar to results previously derived in [1] (cf. Theorems 4.1 and 4.5).

LEMMA 4.6. *Suppose $k, l, n, s \in \mathbb{N}$,*

$$\hat{P}(\hat{\rho}, \theta) = \hat{\alpha}(\theta)\exp(-c\hat{\rho})p(\hat{\rho}),$$

and

$$\hat{f}(\hat{\rho},\theta) = \hat{\rho}^k \frac{\partial^{l+n}}{\partial\hat{\rho}^l \partial\theta^n} \hat{P}(\hat{\rho},\theta),$$

where α is a smooth function depending on $\partial\Omega$ and p is a polynomial. Then there exists a constant C depending only on Ω, p, k, l, n, and s such that

$$\|f\|_{s,\Omega_0} \le Ct^{1/2-s} \sum_{m=0}^{s} t^m |\alpha|_{m+n}.$$

Moreover, for any $j \ge 0$, there exists a constant C' depending on C and j such that

$$\|f\|_{s,\Omega_1} \le C't^{1/2+j-s} \sum_{m=0}^{s} t^m |\alpha|_{m+n}.$$

We now obtain bounds on the P_i in Ω.

THEOREM 4.7. *For any $i, j, k, l, n, s \in \mathbb{N}$, there is a constant C such that*

$$\|\hat{\rho}^k \frac{\partial^{l+n}}{\partial\hat{\rho}^l \partial\theta^n} P_i\|_{s,\Omega_0} \le C(t^{1/2-s}\|g\|_{n+i-3/2} + t^{1/2}\|g\|_{n+s+i-3/2}), \tag{4.1}$$

$$\|\hat{\rho}^k \frac{\partial^{l+n}}{\partial\hat{\rho}^l \partial\theta^n} P_i\|_{s,\Omega_1} \le Ct^j(t^{1/2-s}\|g\|_{n+i-3/2} + t^{1/2}\|g\|_{n+s+i-3/2}). \tag{4.2}$$

Proof. From Lemma 4.6 and Theorem 4.1, we get

$$\|\hat{\rho}^k \frac{\partial^{l+n}}{\partial\hat{\rho}^l \partial\theta^n} P_i\|_{s,\Omega_0} \le Ct^{1/2-s} \sum_{m=0}^{s} t^m \sum_{j=0}^{i} |M_s\phi_j|_{n+m+i-j}.$$

By Corollary 4.4, this is bounded by

$$Ct^{1/2-s} \sum_{m=0}^{s} t^m \|g\|_{n+m+i-3/2} \le C(t^{1/2-s}\|g\|_{n+i-3/2} + t^{1/2}\|g\|_{n+s+i-3/2}).$$

Similarly,

$$\begin{aligned} \|\hat{\rho}^k \frac{\partial^{l+n}}{\partial\hat{\rho}^l \partial\theta^n} P_i\|_{s,\Omega_1} &\le C_j t^{1/2+j-s} \sum_{m=0}^{s} t^m \sum_{j=0}^{i} |M_s\phi_j|_{n+m+i-j} \\ &\le C_j t^{1/2+j-s} \sum_{m=0}^{s} t^m \|g\|_{n+m+i-3/2} \\ &\le C_j t^j (t^{1/2-s}\|g\|_{n+i-3/2} + t^{1/2}\|g\|_{n+s+i-3/2}). \qquad \square \end{aligned}$$

Using (3.3), we easily obtain the following, where $\phi_n^B = \sum_{i=0}^n t^i \Phi_i$ and $p_n^B = \sum_{i=0}^n t^i P_i$.

COROLLARY 4.8. *For any $s, n, j \in \mathbb{N}$, there is a constant C such that*

$$\|p_n^B\|_{s,\Omega_0} \le C(t^{1/2-s}\|g\|_{-3/2} + t^{n+1/2}\|g\|_{n+s-3/2}), \tag{4.3}$$

$$\|\boldsymbol{\Phi}_n\|_{s,\Omega_0} \le C(t^{1/2-s}\|g\|_{n-5/2} + t^{1/2}\|g\|_{n+s-5/2}), \tag{4.4}$$

$$\|\boldsymbol{\phi}_n^B\|_{s,\Omega_0} \le C(t^{3/2-s}\|g\|_{-3/2} + t^{n+1/2}\|g\|_{n+s-5/2}), \tag{4.5}$$

$$\|p_n^B\|_{s,\Omega_1} \le Ct^j(t^{1/2-s}\|g\|_{-3/2} + t^{n+1/2}\|g\|_{n+s-3/2}), \tag{4.6}$$

$$\|\boldsymbol{\Phi}_n\|_{s,\Omega_1} \le Ct^j(t^{1/2-s}\|g\|_{n-5/2} + t^{1/2}\|g\|_{n+s-5/2}), \tag{4.7}$$

$$\|\boldsymbol{\phi}_n^B\|_{s,\Omega_1} \le Ct^j(t^{3/2-s}\|g\|_{-3/2} + t^{n+1/2}\|g\|_{n+s-5/2}). \tag{4.8}$$

5. Error estimates for the soft simply supported plate. In this section, we shall derive estimates for differences between the solution components of the Reissner–Mindlin equations and finite sums of the asymptotic expansions. We shall not bound these differences directly but rather first bound their images under a differential operator and then apply a priori estimates for the operator. The differential operator we employ is not the Reissner–Mindlin operator but rather a singularly perturbed Stokes-like operator which arises in an equivalent formulation of the Reissner–Mindlin equations due to Brezzi and Fortin [3].

The Brezzi–Fortin formulation begins with the Helmholtz decomposition of the transverse shear stress vector

$$\lambda t^{-2}(\mathbf{grad}\,\omega - \boldsymbol{\phi}) = \mathbf{grad}\,r + \mathbf{curl}\,p, \quad r \in \mathring{H}^1,\ p \in H^1/\mathbb{R}. \tag{5.1}$$

Then it is easy to see that r may be determined by the Poisson equation

$$-\Delta r = g \tag{5.2}$$

together with the homogeneous Dirichlet boundary condition, and then $\boldsymbol{\phi}$ and p may be determined from the perturbed Stokes-like system

$$-\mathbf{div}\,\mathcal{C}\,\mathcal{E}(\boldsymbol{\phi}) - \mathbf{curl}\,p = \mathbf{grad}\,r, \tag{5.3}$$

$$-\operatorname{rot}\boldsymbol{\phi} + \lambda^{-1}t^2\,\Delta p = 0 \tag{5.4}$$

together with the boundary conditions

$$M_{\boldsymbol{n}}\boldsymbol{\phi} = 0, \qquad M_{\boldsymbol{s}}\boldsymbol{\phi} = 0, \qquad \boldsymbol{\phi}\cdot\boldsymbol{s} + \lambda^{-1}t^2\frac{\partial p}{\partial n} = 0. \tag{5.5}$$

Note that p is only determined modulo $\mathbb{R}$, i.e., up to an additive constant. Finally, ω satisfies

$$-\Delta\omega = -\operatorname{div}\boldsymbol{\phi} - \lambda^{-1}t^2\,\Delta r \tag{5.6}$$

and vanishes on the boundary.

The weak formulation of (5.3), (5.4), and the boundary conditions (5.5) seeks $\boldsymbol{\phi} \in \boldsymbol{H}^1$, $p \in H^1/\mathbb{R}$ such that

$$a(\boldsymbol{\phi}, \boldsymbol{\psi}) - (\mathbf{curl}\,p, \boldsymbol{\psi}) = (\mathbf{grad}\,r, \boldsymbol{\psi}) \quad \text{for all } \boldsymbol{\psi} \in \boldsymbol{H}^1, \tag{5.7}$$

$$-(\boldsymbol{\phi} + \lambda^{-1}t^2\,\mathbf{curl}\,p, \mathbf{curl}\,q) = 0 \quad \text{for all } q \in H^1/\mathbb{R}, \tag{5.8}$$

where

$$a(\boldsymbol{\phi}, \boldsymbol{\psi}) = (\mathcal{C}\,\mathcal{E}(\boldsymbol{\phi}), \mathcal{E}(\boldsymbol{\psi})).$$

To continue, we need to define an asymptotic approximation to p. From (3.5), we see that $\lambda(\phi_{i+2} - \mathbf{grad}\,\omega_{i+2}) + \delta_{i0}\,\mathbf{grad}\,r$ is divergence free. Therefore, we can determine a function p_i, unique modulo $\mathbb{R}$, by

$$\mathbf{curl}\,p_i = -\lambda(\phi_{i+2} - \mathbf{grad}\,\omega_{i+2}) - \delta_{i0}\,\mathbf{grad}\,r = -\,\mathbf{div}\,C\,\mathcal{E}(\phi_i) - \delta_{i0}\,\mathbf{grad}\,r. \tag{5.9}$$

It follows immediately from Theorem 4.3 and regularity for the Dirichlet problem that

$$\|p_n\|_{s/\mathbb{R}} \le C\|g\|_{s+n-2}, \quad s \in \mathbb{R},\ s \ge 0. \tag{5.10}$$

Note that, by (3.7), $\mathbf{curl}\,p_i$ is a gradient, so p_i is harmonic for all i. We may now write our asymptotic expansion of p:

$$p \sim \sum_{i=0}^{\infty} t^i p_i + \chi \sum_{i=0}^{\infty} t^i P_i.$$

Let us now introduce some notation for the finite interior and boundary expansion sums. Set

$$\omega_n^I = \sum_{i=0}^{n} t^i w_i, \quad \phi_n^I = \sum_{i=0}^{n} t^i \phi_i, \quad p_n^I = \sum_{i=0}^{n} t^i p_i, \quad \phi_n^B = \sum_{i=0}^{n} t^i \boldsymbol{\Phi}_i, \quad p_n^B = \sum_{i=0}^{n} t^i P_i,$$

and

$$\omega_n^E = \omega - \omega_n^I, \qquad \phi_n^E = \phi - \phi_n^I - \chi\phi_n^B, \qquad p_n^E = p - p_n^I - \chi p_{n-1}^B.$$

Note that we deliberately choose one less term in the boundary-layer expansion for p than for the other terms.

The following three theorems give estimates in Sobolev norms of general index for the differences between ϕ, p, and ω and their finite asymptotic approximations. Note that the rates of convergence for ϕ and p decline as the index of the Sobolev norm increases, but this is not true for ω. This reflects the presence of a boundary layer for the first two variables but not the third.

THEOREM 5.1. *For any $n \in \mathbb{N}$, there exists a constant C independent of t such that*

$$\|\phi_n^E\|_1 + \|p_n^E\|_{0/\mathbb{R}} + t\|\,\mathbf{curl}\,p_n^E\|_0 \le C(t^{n+1/2}\|g\|_{n-3/2} + t^{n+3/2}\|g\|_{n-1/2}).$$

THEOREM 5.2. *For any $n, s \in \mathbb{N}$, $s \ge 2$, there exists a constant C independent of t such that*

$$\|\phi_n^E\|_s + t\|p_n^E\|_{s/\mathbb{R}} \le C(t^{n+3/2-s}\|g\|_{n-3/2} + t^{n+1}\|g\|_{n+s-2}).$$

THEOREM 5.3. *For any $n, s \in \mathbb{N}$, $s \ge 2$, there exists a constant C independent of t such that*

$$\|\omega_n^E\|_2 \le C(t^{n+1}\|g\|_{n-1} + t^{n+5/2}\|g\|_{n+1/2}),$$
$$\|\omega_n^E\|_s \le C(t^{n+1}\|g\|_{n+s-3} + t^{n+s}\|g\|_{n+2s-4}), \quad s \ge 3.$$

The proofs depend on a number of estimates and equations which we collect here and prove at the end of the section. These results show that the formal equations (3.2) and (3.9) and the moment boundary conditions are indeed satisfied, at least to high order, by the finite boundary-layer expansions.

LEMMA 5.4. *For any $n, s \in \mathbb{N}$, there exists a constant C for which*

$$\|\chi\phi_n^B + \lambda^{-1}t^2\,\mathbf{curl}(\chi p_{n-1}^B)\|_s \le C(t^{n+3/2-s}\|g\|_{n-3/2} + t^{n+3/2}\|g\|_{n+s-3/2}), \tag{5.11}$$

$$\|\operatorname{div}(\chi\phi_n^B)\|_s \le C(t^{n+1/2-s}\|g\|_{n-3/2} + t^{n+1/2}\|g\|_{n+s-3/2}), \tag{5.12}$$

$$\|D\frac{1-\nu}{2}\operatorname{rot}(\chi\phi_n^B) - p_{n-1}^B\|_s \le C(t^{n+1/2-s}\|g\|_{n-3/2} + t^{n+1/2}\|g\|_{s+n-3/2}), \tag{5.13}$$

$$D\frac{1-\nu}{2}\operatorname{rot}(\chi\phi_n^B) - p_{n-1}^B + t^n\left(\lambda^{-1}\frac{D(1-\nu)}{2}\frac{\partial^2\hat{P}_n}{\partial\hat{\rho}^2} - \hat{P}_n\right) = 0 \quad \text{on } \partial\Omega, \tag{5.14}$$

$$M_{\boldsymbol{n}}(\phi_n^I + \phi_n^B) = D\operatorname{div}\phi_n^B \quad \text{on } \partial\Omega, \tag{5.15}$$

$$M_{\boldsymbol{s}}(\phi_n^I + \phi_n^B) = \lambda^{-1}\frac{D(1-\nu)}{2}t^n\frac{\partial^2\hat{P}_n}{\partial\hat{\rho}^2} \quad \text{on } \partial\Omega, \tag{5.16}$$

$$M_{\boldsymbol{s}}(\phi_n^I + \phi_n^B) + D\frac{1-\nu}{2}\operatorname{rot}(\chi\phi_n^B) - p_{n-1}^B = t^n\hat{P}_n \quad \text{on } \partial\Omega. \tag{5.17}$$

In the interest of brevity, we introduce the following notation for the quantity on the right-hand side of the estimate in Theorem 5.1:

$$\Lambda = t^{n+1/2}\|g\|_{n-3/2} + t^{n+3/2}\|g\|_{n-1/2}.$$

Proof of Theorem 5.1. It follows immediately from (5.9) that

$$-\mathbf{div}\,C\,\mathcal{E}(\phi_n^I) - \mathbf{curl}\,p_n^I = \mathbf{grad}\,r, \quad n = 0, 1, \ldots .$$

Therefore,

$$-a(\phi_n^I, \psi) + (\mathbf{curl}\,p_n^I, \psi) = -(\mathbf{grad}\,r, \psi) - \langle M_{\boldsymbol{n}}\phi_n^I, \psi\cdot\boldsymbol{n}\rangle - \langle M_{\boldsymbol{s}}\phi_n^I, \psi\cdot\boldsymbol{s}\rangle, \quad \psi \in \boldsymbol{H}^1. \tag{5.18}$$

Using the identity

$$\begin{aligned} a(\phi, \psi) = D\frac{1-\nu}{2}(\operatorname{rot}\phi, \operatorname{rot}\psi) + D(\operatorname{div}\phi, \operatorname{div}\psi) \\ + \langle M_{\boldsymbol{n}}\phi - D\operatorname{div}\phi, \psi\cdot\boldsymbol{n}\rangle + \left\langle M_{\boldsymbol{s}} + D\frac{1-\nu}{2}\operatorname{rot}\phi, \psi\cdot\boldsymbol{s}\right\rangle, \end{aligned}$$

we get

$$\begin{aligned} &-a(\chi\phi_n^B, \psi) + (\mathbf{curl}\,\chi p_{n-1}^B, \psi) \\ &= -(D\frac{1-\nu}{2}\operatorname{rot}(\chi\phi_n^B) - \chi p_{n-1}^B, \operatorname{rot}\psi) - D(\operatorname{div}(\chi\phi_n^B), \operatorname{div}\psi) \\ &- \langle M_{\boldsymbol{n}}\phi_n^B - D\operatorname{div}\phi_n^B, \psi\cdot\boldsymbol{n}\rangle - \left\langle M_{\boldsymbol{s}}\phi_n^B + D\frac{1-\nu}{2}\operatorname{rot}\phi_n^B - p_{n-1}^B, \psi\cdot\boldsymbol{s}\right\rangle, \quad \psi \in \boldsymbol{H}^1. \end{aligned} \tag{5.19}$$

Adding (5.7), (5.18), and (5.19) and using (5.15) and (5.17) gives the error equation corresponding to (5.7):

$$\begin{aligned} a(\phi_n^E, \psi) - (\mathbf{curl}\,p_n^E, \psi) = -\left(D\frac{1-\nu}{2}\operatorname{rot}(\chi\phi_n^B) - \chi p_{n-1}^B, \operatorname{rot}\psi\right) \\ - D\left(\operatorname{div}(\chi\phi_n^B), \operatorname{div}\psi\right) - t^n\langle\hat{P}_n, \psi\cdot\boldsymbol{s}\rangle, \quad \psi \in \boldsymbol{H}^1. \end{aligned} \tag{5.20}$$

Turning to the second equation, we have from (5.9) that

$$\phi_n^I = \mathbf{grad}\,\omega_n^I - \lambda^{-1}t^2\,\mathbf{grad}\,r - \lambda^{-1}t^2\,\mathbf{curl}\,p_{n-2}^I.$$

Combining this with (5.1), we obtain

$$\begin{aligned}\phi_n^E = \mathbf{grad}(\omega - \omega_n^I) - \lambda^{-1}t^2\,\mathbf{curl}\,p_n^E&\\ - \lambda^{-1}(t^{n+1}\,\mathbf{curl}\,p_{n-1} + t^{n+2}\,\mathbf{curl}\,p_n) - [\chi\phi_n^B + \lambda^{-1}t^2\,\mathbf{curl}(\chi p_{n-1}^B)]&.\end{aligned}$$

Multiplying by $\mathbf{curl}\,q$ for $q \in H^1$, using the orthogonality of gradients and curls, and rearranging, gives the error equation corresponding to (5.8):

$$\begin{aligned}(\phi_n^E + \lambda^{-1}t^2\,\mathbf{curl}\,p_n^E, \mathbf{curl}\,q) = -\lambda^{-1}(t^{n+1}\,\mathbf{curl}\,p_{n-1} + t^{n+2}\,\mathbf{curl}\,p_n, \mathbf{curl}\,q)&\\ - \left(\chi\phi_n^B + \lambda^{-1}t^2\,\mathbf{curl}(\chi p_{n-1}^B), \mathbf{curl}\,q\right), \quad q \in H^1&. \qquad (5.21)\end{aligned}$$

The desired error estimate will be obtained from (5.20) and (5.21) using a few choices of the test functions ψ and q. For this we will need to bound various terms arising on the right-hand sides.

Our first choice of test functions is $\psi = \phi_n^E$ in (5.20) and $q = p_n^E - t^n\chi P_n$ in (5.21). (The more obvious test function $q = p_n^E$ could also be used here, but not for the case of the free plate, since there we will need q to vanish on the boundary.) Adding these equations and rearranging terms, we get

$$a(\phi_n^E, \phi_n^E) + \lambda^{-1}t^2\|\,\mathbf{curl}\,p_n^E\|_0^2 = T_1 + T_2 + \cdots + T_9,$$

where

$$\begin{aligned}
T_1 &= -\left(D\frac{1-\nu}{2}\,\mathrm{rot}(\chi\phi_n^B) - \chi p_{n-1}^B, \mathrm{rot}\,\phi_n^E\right),\\
T_2 &= -D\left(\mathrm{div}(\chi\phi_n^B), \mathrm{div}\,\phi_n^E\right),\\
T_3 &= -t^n\langle \hat{P}_n, \phi_n^E\cdot s\rangle,\\
T_4 &= -\lambda^{-1}\left(t^{n+1}\,\mathbf{curl}\,p_{n-1} + t^{n+2}\,\mathbf{curl}\,p_n, \mathbf{curl}\,p_n^E\right),\\
T_5 &= \lambda^{-1}t^n\left(t^{n+1}\,\mathbf{curl}\,p_{n-1} + t^{n+2}\,\mathbf{curl}\,p_n, \mathbf{curl}(\chi\hat{P}_n)\right),\\
T_6 &= -\left(\chi\phi_n^B + \lambda^{-1}t^2\,\mathbf{curl}(\chi p_{n-1}^B), \mathbf{curl}\,p_n^E\right),\\
T_7 &= t^n\left(\chi\phi_n^B + \lambda^{-1}t^2\,\mathbf{curl}(\chi p_{n-1}^B), \mathbf{curl}(\chi\hat{P}_n)\right),\\
T_8 &= t^n\left(\phi_n^E, \mathbf{curl}(\chi\hat{P}_n)\right) = t^n(\mathrm{rot}\,\phi_n^E, \chi\hat{P}_n) + t^n\langle \hat{P}_n, \phi_n^E\cdot s\rangle,\\
T_9 &= \lambda^{-1}t^{n+2}\left(\mathbf{curl}\,p_n^E, \mathbf{curl}(\chi\hat{P}_n)\right).
\end{aligned}$$

By (5.13) and (5.12), we get

$$|T_1| + |T_2| \le C\Lambda\|\phi_n^E\|_{1/\mathbb{R}}. \qquad (5.22)$$

Next, from (4.1),

$$|T_3 + T_8| = |t^n(\mathrm{rot}\,\phi_n^E, \chi\hat{P}_n)| \le C\Lambda\|\phi_n^E\|_{1/\mathbb{R}}. \qquad (5.23)$$

Since the p_n are harmonic, using (5.10) we obtain for any q that

$$\begin{aligned}|(t^{n+1}\,\mathbf{curl} p_{n-1}+t^{n+2}\,\mathbf{curl}\,p_n,\mathbf{curl}\,q)| &= \left|\left\langle t^{n+1}\frac{\partial p_{n-1}}{\partial n}+t^{n+2}\frac{\partial p_n}{\partial n},\bar{q}\right\rangle\right| \\ &\le |\bar{q}|_0\left|t^{n+1}\frac{\partial p_{n-1}}{\partial n}+t^{n+2}\frac{\partial p_n}{\partial n}\right|_0 \le |\bar{q}|_0\left(t^{n+1}\|p_{n-1}\|_{3/2}+t^{n+2}\|p_n\|_{3/2}\right) \\ &\le C\|\bar{q}\|_0^{1/2}(t\|\,\mathbf{curl}\,q\|_0)^{1/2}\Lambda \le C\Lambda^2+\delta(\|q\|_{0/\mathbb{R}}^2+t^2\|\,\mathbf{curl}\,q\|_0^2),\end{aligned}$$

where $\bar{q}$ is the difference between q and its mean value and δ can be any positive number and will be chosen later. Applying this twice and using (4.1), we get

$$|T_4| \le C\Lambda^2+\delta(\|p_n^E\|_{0/\mathbb{R}}^2+t^2\|\,\mathbf{curl}\,p_n^E\|_0^2), \qquad |T_5| \le C\Lambda^2. \tag{5.24}$$

Finally, by (5.11),

$$|T_6| \le Ct\Lambda\|\,\mathbf{curl}\,p_n^E\|_0, \qquad |T_7| \le C\Lambda^2, \tag{5.25}$$

and, using (4.1),

$$|T_9| \le Ct\Lambda\|\,\mathbf{curl}\,p_n^E\|_0. \tag{5.26}$$

Combining (5.22)–(5.26) gives

$$a(\phi_n^E,\phi_n^E)+\lambda^{-1}t^2\|\,\mathbf{curl}\,p_n^E\|_0^2 \le C_\epsilon\Lambda^2+\epsilon(\|\phi_n^E\|_{1/\mathbb{R}}^2+\|p_n^E\|_{0/\mathbb{R}}^2+t^2\|\,\mathbf{curl}\,p_n^E\|_0^2), \tag{5.27}$$

where $\epsilon > 0$ is arbitrary and $C_\epsilon > 0$ depends on ϵ.

To get control over the L^2 norm of p_n^E, we use another test function in (5.20). Namely, we select $\psi \in \overset{\circ}{\boldsymbol{H}}{}^1$ with $\operatorname{rot}\psi = \bar{p}_n^E$ and $\|\psi\|_1 \le C\|p_n^E\|_{0/\mathbb{R}}$ (this is always possible). Then

$$\|p_n^E\|_{0/\mathbb{R}}^2 = \|\bar{p}_n^E\|_0^2 = (p_n^E,\operatorname{rot}\psi) = (\mathbf{curl}\,p_n^E,\psi) = a(\phi_n^E,\psi)-[a(\phi_n^E,\psi)-(\mathbf{curl}\,p_n^E,\psi)].$$

Using (5.20) and noting that ψ vanishes on $\partial\Omega$, we may write the term in brackets as

$$\left(D\frac{1-\nu}{2}\operatorname{rot}(\chi\phi_n^B)-\chi p_{n-1}^B,\mathbf{curl}\,\psi\right)+D\left(\operatorname{div}(\chi\phi_n^B),\operatorname{div}\psi\right).$$

Using (5.13), (5.12), and Schwarz's inequality, we easily conclude

$$\|p_n^E\|_{0/\mathbb{R}}^2 \le C\Lambda^2+C_1\|\phi_n^E\|_1^2. \tag{5.28}$$

The above estimates give us control over $a(\phi_n^E,\phi_n^E)$, $\|p_n^E\|_0/\mathbb{R}$, and $t\|\,\mathbf{curl}\,p_n^E\|_0$. The theorem would follow easily were $\psi \mapsto a(\psi,\psi)^{1/2}$ equivalent to the $\boldsymbol{H}^1$ norm. But this is not so, since $a(\psi,\psi)$ vanishes for ψ in the three-dimensional space

$$\boldsymbol{R} := \{\,(a-by,c+bx)\mid a,b,c\in\mathbb{R}\,\}$$

of plane rigid motions. However, $\psi \mapsto a(\psi,\psi)^{1/2}+\|\boldsymbol{P}\psi\|_0$ is equivalent to the $\boldsymbol{H}^1$ norm, with $\boldsymbol{P}$ the $\boldsymbol{L}^2$-projection onto $\boldsymbol{R}$. Therefore, we choose q in (5.21) of mean value zero such that $\mathbf{curl}\,q = \boldsymbol{P}\phi_n^E$, which is possible since the functions in $\boldsymbol{R}$ are divergence free. Then

$$\|\boldsymbol{P}\phi_n^E\|_0^2 = (\phi_n^E,\mathbf{curl}\,q) = (\phi_n^E+\lambda^{-1}t^2\,\mathbf{curl}\,p_n^E,\mathbf{curl}\,q)-\lambda^{-1}t^2(\mathbf{curl}\,p_n^E,\boldsymbol{P}\phi_n^E).$$

Using (5.21), (5.11), (5.10), and Schwarz's inequality, we conclude

$$\|\boldsymbol{P}\phi_n^E\|_0^2 \le C\Lambda^2+C_2t^2\|\,\mathbf{curl}\,p_n^E\|_0^2. \tag{5.29}$$

It is a fairly easy matter to conclude the proof from (5.27)–(5.29). Adding $1/(2C_2)$ times (5.29) to (5.27), we get after simple manipulations

$$\|\phi_n^E\|_1^2 + t^2\|\,\mathbf{curl}\,p_n^E\|_0^2 \le C\Lambda^2 + C_3\epsilon(\|\phi_n^E\|_1^2 + \|p_n^E\|_{0/\mathbb{R}}^2 + t^2\|\,\mathbf{curl}\,p_n^E\|_0^2),$$

for some constant C_3. Then adding $1/(2C_1)$ times (5.28) to this equation and similarly manipulating, we obtain

$$\|\phi_n^E\|_1^2 + \|p_n^E\|_{0/\mathbb{R}}^2 + t^2\|\,\mathbf{curl}\,p_n^E\|_0^2 \le C\Lambda^2 + C_4\epsilon(\|\phi_n^E\|_1^2 + \|p_n^E\|_{0/\mathbb{R}}^2 + t^2\|\,\mathbf{curl}\,p_n^E\|_0^2).$$

Finally, choosing ϵ sufficiently small we obtain the theorem. □

Proof of Theorem 5.2. By standard regularity results for plane elasticity,

$$\|\phi_n^E\|_s \le C\left(\|\,\mathbf{div}\,\mathcal{C}\,\mathcal{E}(\phi_n^E)\|_{s-2} + |M_{\boldsymbol{n}}\phi_n^E|_{s-3/2} + |M_{\boldsymbol{s}}\phi_n^E|_{s-3/2} + \|\boldsymbol{P}\phi_n^E\|_0\right).$$

From (5.20),

$$-\,\mathbf{div}\,\mathcal{C}\,\mathcal{E}(\phi_n^E) = \mathbf{curl}\,p_n^E - \mathbf{curl}\left[D\frac{1-\nu}{2}\operatorname{rot}(\chi\phi_n^B) - \chi p_{n-1}^B\right] + D\,\mathbf{grad}\operatorname{div}(\chi\phi_n^B).$$

Then applying (5.13), (5.12), (5.15), (5.16), (4.1), Theorem 5.1, and the trace theorem, we get

$$\|\phi_n^E\|_s \le C\left(\|p_n^E\|_{s-1/\mathbb{R}} + t^{n+3/2-s}\|g\|_{n-3/2} + t^{n+1/2}\|g\|_{s+n-5/2}\right).$$

Next, using regularity for the Neumann problem for the Laplacian, we know that

$$\|p_n^E\|_{s/\mathbb{R}} \le C\left(\|\,\Delta p_n^E\|_{s-2} + \left|\frac{\partial p_n^E}{\partial n}\right|_{s-3/2}\right).$$

By (5.21),

$$\Delta p_n^E = \lambda t^{-2}\left\{\operatorname{rot}\phi_n^E + \operatorname{rot}[\chi\phi_n^B + \lambda^{-1}t^2\,\mathbf{curl}(\chi p_{n-1}^B)]\right\}$$

and

$$\frac{\partial p_n^E}{\partial n} =$$

$$-\lambda t^{-2}\left\{\phi_n^E\cdot\boldsymbol{s} + \lambda^{-1}\left(t^{n+1}\frac{\partial p_{n-1}}{\partial n} + t^{n+2}\frac{\partial p_n}{\partial n}\right) + [\chi\phi_n^B + \lambda^{-1}t^2\,\mathbf{curl}(\chi p_{n-1}^B)]\cdot\boldsymbol{s}\right\}.$$

Applying (5.11), (5.10), the trace theorem, and (2.1), we obtain

$$\|p_n^E\|_{s/\mathbb{R}} \le C(t^{-2}\|\phi_n^E\|_{s-1} + t^{n+1/2-s}\|g\|_{n-3/2} + t^n\|g\|_{s+n-2}).$$

Combining these bounds, we have

$$\|\phi_n^E\|_s + t\|p_n^E\|_{s/\mathbb{R}} \le C(t^{-1}\|\phi_n^E\|_{s-1} + \|p_n^E\|_{s-1/\mathbb{R}} + t^{n+1/2-s}\|g\|_{n-3/2} + t^n\|g\|_{s+n-2}).$$

For $s = 2$, the theorem follows from this relation and Theorem 5.1, and for $s > 2$, it follows by induction on s. □

Proof of Theorem 5.3. From (5.6) and (3.5), we get

$$\Delta(\omega - \omega_n^I) = \operatorname{div}(\phi - \phi_n^I) = \operatorname{div}\left(\phi_{n+s-1}^E + \chi\phi_{n+s-1}^B + \sum_{j=n+1}^{n+s-1} t^j\phi_j\right).$$

The theorem follows by elliptic regularity for Poisson's problem, Lemma 4.3, (5.12), and Theorems 5.1 and 5.2. □

We conclude this section with the proof of Lemma 5.4.

Proof of Lemma 5.4. From (3.3) and (2.2), we can express ϕ_n^B in terms of the P_i:

$$\begin{aligned}\lambda\phi_n^B &= \sum_{i=1}^{n} t^i \frac{\partial \hat{P}_{i-1}}{\partial \hat{\rho}}\boldsymbol{s} + \sum_{i=2}^{n}\sum_{j=0}^{n-i} t^i (\kappa\hat{\rho}t)^j \frac{\partial \hat{P}_{i-2}}{\partial \theta}\boldsymbol{n} \\ &= \sum_{i=1}^{n} t^i \frac{\partial \hat{P}_{i-1}}{\partial \hat{\rho}}\boldsymbol{s} + \sum_{i=2}^{n} t^i \sigma[1-(\kappa\hat{\rho}t)^{n-i+1}] \frac{\partial \hat{P}_{i-2}}{\partial \theta}\boldsymbol{n}.\end{aligned} \tag{5.30}$$

Applying the identity

$$M_{\boldsymbol{n}}\boldsymbol{\psi} - D\operatorname{div}\boldsymbol{\psi} = -D(1-\nu)\left[\frac{\partial(\hat{\boldsymbol{\psi}}\cdot\boldsymbol{s})}{\partial\theta} + \kappa(\hat{\boldsymbol{\psi}}\cdot\boldsymbol{n})\right] \quad \text{on } \partial\Omega$$

and (3.19), we get that

$$M_{\boldsymbol{n}}\phi_n^B - D\operatorname{div}\phi_n^B = -\lambda^{-1}D(1-\nu)\sum_{i=0}^{n} t^i\left[\frac{\partial^2 \hat{P}_{i-1}}{\partial\theta\partial\hat{\rho}} + \kappa\frac{\partial \hat{P}_{i-2}}{\partial\theta}\right] = -M_{\boldsymbol{n}}\phi_n^I,$$

which proves (5.15).

Applying the identity

$$M_{\boldsymbol{s}}\boldsymbol{\psi} = \frac{D(1-\nu)}{2}\left[-t^{-1}\frac{\partial(\hat{\boldsymbol{\psi}}\cdot\boldsymbol{s})}{\partial\hat{\rho}} + \frac{\partial(\hat{\boldsymbol{\psi}}\cdot\boldsymbol{n})}{\partial\theta} - \kappa(\hat{\boldsymbol{\psi}}\cdot\boldsymbol{s})\right]$$

to (5.30) and using (3.18), we get

$$\begin{aligned}\lambda M_{\boldsymbol{s}}\phi_n^B &= \frac{D(1-\nu)}{2}\sum_{i=0}^{n} t^i\left[-t^{-1}\frac{\partial^2\hat{P}_{i-1}}{\partial\hat{\rho}^2} + \frac{\partial^2\hat{P}_{i-2}}{\partial\theta^2} - \kappa\frac{\partial\hat{P}_{i-1}}{\partial\hat{\rho}}\right] \\ &= \frac{D(1-\nu)}{2}\sum_{i=0}^{n} t^i\left(-t^{-1}\frac{\partial^2\hat{P}_{i-1}}{\partial\hat{\rho}^2} + \frac{\partial^2\hat{P}_{i}}{\partial\hat{\rho}^2}\right) - \lambda M_{\boldsymbol{s}}\phi_n^I \\ &= \frac{D(1-\nu)}{2}t^n\frac{\partial^2\hat{P}_n}{\partial\hat{\rho}^2} - \lambda M_{\boldsymbol{s}}\phi_n^I,\end{aligned}$$

which proves (5.16).

Using (5.30) and the expansion

$$t^2\,\mathbf{curl}\,p_{n-1}^B = -\sum_{i=0}^{n-1} t^{i+2}\left(t^{-1}\frac{\partial\hat{P}_i}{\partial\hat{\rho}}\boldsymbol{s} + \sigma\frac{\partial\hat{P}_i}{\partial\theta}\boldsymbol{n}\right) = -\sum_{i=1}^{n} t^i\frac{\partial\hat{P}_{i-1}}{\partial\hat{\rho}}\boldsymbol{s} - \sum_{i=2}^{n+1} t^i\sigma\frac{\partial\hat{P}_{i-2}}{\partial\theta}\boldsymbol{n},$$

we get

$$\lambda\phi_n^B + t^2\,\mathbf{curl}\,p_{n-1}^B = -t^{n+1}\sigma\sum_{i=0}^{n-1}(\kappa\hat{\rho})^{n-i-1}\frac{\partial\hat{P}_i}{\partial\theta}\boldsymbol{n}. \tag{5.31}$$

It now follows directly from Theorem 4.7 that

$$\|\lambda\phi_n^B + t^2\,\mathbf{curl}\,p_{n-1}^B\|_{s,\Omega_0} \le C(t^{n+3/2-s}\|g\|_{n-3/2} + t^{n+3/2}\|g\|_{n+s-3/2}).$$

Finally, using (4.6), we get

$$\begin{aligned}\|\lambda\chi\boldsymbol{\phi}_n^B + t^2\,\mathbf{curl}(\chi p_{n-1}^B)\|_s &\le \|\chi(\lambda\boldsymbol{\phi}_n^B + t^2\,\mathbf{curl}\,p_{n-1}^B)\|_s + t^2\|p_{n-1}^B\cdot\mathbf{curl}\,\chi\|_s\\ &\le C(\|\lambda\boldsymbol{\phi}_n^B + t^2\,\mathbf{curl}\,p_{n-1}^B\|_{s,\Omega_0} + t^2\|p_{n-1}^B\|_{s,\Omega_1})\\ &\le C(t^{n+3/2-s}\|g\|_{n-3/2} + t^{n+3/2}\|g\|_{n+s-3/2}),\end{aligned}$$

which proves (5.11).

Now for any $\boldsymbol{\psi}$,

$$\operatorname{div}\boldsymbol{\psi} = -\frac{\partial\boldsymbol{\psi}}{\partial\rho}\cdot\boldsymbol{n} + \sigma\frac{\partial\boldsymbol{\psi}}{\partial\theta}\cdot\boldsymbol{s} = \left(-t^{-1}\frac{\partial}{\partial\hat\rho} + \sigma\kappa\right)(\hat{\boldsymbol{\psi}}\cdot\boldsymbol{n}) + \sigma\frac{\partial(\hat{\boldsymbol{\psi}}\cdot\boldsymbol{s})}{\partial\theta}.$$

From (5.31), we then have

$$\operatorname{div}\boldsymbol{\phi}_n^B = \left(-t^{-1}\frac{\partial}{\partial\hat\rho} + \sigma\kappa\right)\left[-t^{n+1}\sigma\sum_{i=0}^{n-1}(\kappa\hat\rho)^{n-i-1}\frac{\partial\hat P_i}{\partial\theta}\right].$$

It then follows easily from Theorem 4.7 that

$$\|\operatorname{div}(\chi\boldsymbol{\phi}_n^B)\|_{s,\Omega_0} \le C(t^{n+1/2-s}\|g\|_{n-3/2} + t^{n+1/2}\|g\|_{n+s-3/2}).$$

To complete the proof of (5.12), we use (4.8).

Finally, we give the proof of (5.13) and (5.14). For $i = 0, 1, \dots, n$, we get by simple identities that

$$\operatorname{rot}\boldsymbol{\Phi}_i = \frac{\partial\boldsymbol{\Phi}_i}{\partial\rho}\cdot\boldsymbol{s} + \sigma\frac{\partial\boldsymbol{\Phi}_i}{\partial\theta}\cdot\boldsymbol{n} = \frac{\partial\boldsymbol{\Phi}_i}{\partial\rho}\cdot\boldsymbol{s} + \left\{\sum_{j=0}^{n-i}(\kappa\rho)^j + \sigma(\kappa\rho)^{n-i+1}\right\}\frac{\partial\boldsymbol{\Phi}_i}{\partial\theta}\cdot\boldsymbol{n}.$$

Hence,

$$\begin{aligned}\operatorname{rot}\boldsymbol{\phi}_n^B &= \sum_{i=0}^{n} t^i\operatorname{rot}\hat{\boldsymbol{\Phi}}_i = \sum_{i=0}^{n} t^i\left\{t^{-1}\frac{\partial\hat{\boldsymbol{\Phi}}_i}{\partial\hat\rho}\cdot\boldsymbol{s} + \left[\sum_{j=0}^{n-i}(\kappa\rho)^j + \sigma(\kappa\rho)^{n-i+1}\right]\frac{\partial\hat{\boldsymbol{\Phi}}_i}{\partial\theta}\cdot\boldsymbol{n}\right\}\\ &= \lambda^{-1}\sum_{i=0}^{n-1} t^i\frac{\partial^2\hat P_i}{\partial\hat\rho^2} + \sum_{i=0}^{n} t^i\left[\sum_{j=0}^{n-i}(\kappa\rho)^j + \sigma(\kappa\rho)^{n-i+1}\right]\frac{\partial\hat{\boldsymbol{\Phi}}_i}{\partial\theta}\cdot\boldsymbol{n},\end{aligned}$$

where we used (3.3) and reindexed the first sum in the last step. Turning to the double sum on the left-hand side, we use the identity (2.2) to obtain

$$\begin{aligned}&\sum_{i=0}^{n} t^i\left[\sum_{j=0}^{n-i}(\kappa\hat\rho t)^j + \sigma(\kappa\hat\rho t)^{n-i+1}\right]\frac{\partial\hat{\boldsymbol{\Phi}}_i}{\partial\theta}\cdot\boldsymbol{n}\\ &\quad= \sum_{i=0}^{n}\sum_{j=0}^{i} t^{i-j}(\kappa\hat\rho t)^j\frac{\partial\hat{\boldsymbol{\Phi}}_{i-j}}{\partial\theta}\cdot\boldsymbol{n} + t^{n+1}\sum_{i=0}^{n}\sigma(\kappa\hat\rho)^{n-i+1}\frac{\partial\hat{\boldsymbol{\Phi}}_i}{\partial\theta}\cdot\boldsymbol{n}\\ &\quad= \sum_{i=0}^{n} t^i\sum_{j=0}^{i}(\kappa\hat\rho)^j\frac{\partial\hat{\boldsymbol{\Phi}}_{i-j}}{\partial\theta}\cdot\boldsymbol{n} + t^{n+1}\sum_{i=0}^{n}\sigma(\kappa\hat\rho)^{n-i+1}\frac{\partial\hat{\boldsymbol{\Phi}}_i}{\partial\theta}\cdot\boldsymbol{n}.\end{aligned}$$

Using (3.3) and (2.2), we further obtain that

$$
\begin{aligned}
\sum_{j=0}^{i}(\kappa\hat\rho)^j \frac{\partial\hat{\boldsymbol{\Phi}}_{i-j}}{\partial\theta}\cdot\boldsymbol{n} &= \sum_{j=0}^{i}(\kappa\hat\rho)^j\left[\frac{\partial(\hat{\boldsymbol{\Phi}}_{i-j}\cdot\boldsymbol{n})}{\partial\theta} - \kappa\hat{\boldsymbol{\Phi}}_{i-j}\cdot\boldsymbol{s}\right]\\
&= \lambda^{-1}\sum_{j=0}^{i}(\kappa\hat\rho)^j\left\{\frac{\partial}{\partial\theta}\left[\sum_{l=0}^{i-j}(\kappa\hat\rho)^l\frac{\partial\hat P_{i-j-l-2}}{\partial\theta}\right] - \kappa\frac{\partial\hat P_{i-j-1}}{\partial\hat\rho}\right\}\\
&= \lambda^{-1}\sum_{j=0}^{i}\sum_{l=0}^{j}(\kappa\hat\rho)^{j-l}\frac{\partial}{\partial\theta}\left[(\kappa\hat\rho)^l\frac{\partial\hat P_{i-j-2}}{\partial\theta}\right] - \lambda^{-1}\sum_{j=0}^{i}\kappa(\kappa\hat\rho)^j\frac{\partial\hat P_{i-j-1}}{\partial\hat\rho}\\
&= \lambda^{-1}\sum_{j=0}^{i}\sum_{l=0}^{j}\left[(\kappa\hat\rho)^j\frac{\partial^2\hat P_{i-j-2}}{\partial\theta^2} + l\kappa^{j-1}\kappa'\hat\rho^j\frac{\partial\hat P_{i-j-2}}{\partial\theta}\right] - \lambda^{-1}\sum_{j=0}^{i}\kappa(\kappa\hat\rho)^j\frac{\partial\hat P_{i-j-1}}{\partial\hat\rho}\\
&= \lambda^{-1}\sum_{j=0}^{i}\left[(j+1)(\kappa\hat\rho)^j\frac{\partial^2\hat P_{i-j-2}}{\partial\theta^2} + \frac{j(j+1)}{2}\kappa^{j-1}\kappa'\hat\rho^j\frac{\partial\hat P_{i-j-2}}{\partial\theta} - \kappa(\kappa\hat\rho)^j\frac{\partial\hat P_{i-j-1}}{\partial\hat\rho}\right]\\
&= \lambda^{-1}\sum_{j=0}^{i}\hat\rho^j\left[a_2^j\frac{\partial^2\hat P_{i-j-2}}{\partial\theta^2} + a_3^j\frac{\partial\hat P_{i-j-2}}{\partial\theta} + a_1^j\frac{\partial\hat P_{i-j-1}}{\partial\hat\rho}\right]\\
&= -\lambda^{-1}\frac{\partial^2\hat P_i}{\partial\hat\rho^2} + \frac{2}{D(1-\nu)}\hat P_i,
\end{aligned}
$$

where the a_i^j are defined in (3.10) and we used (3.11) in the last step. Collecting these results, we have

$$
\begin{aligned}
&\operatorname{rot}\phi_n^B\\
&= \lambda^{-1}\sum_{i=0}^{n-1}t^i\frac{\partial^2\hat P_i}{\partial\hat\rho^2} - \sum_{i=0}^{n}t^i\left[\lambda^{-1}\frac{\partial^2\hat P_i}{\partial\hat\rho^2} - \frac{2}{D(1-\nu)}\hat P_i\right] + t^{n+1}\sum_{i=0}^{n}\sigma(\kappa\hat\rho)^{n-i+1}\frac{\partial\hat{\boldsymbol{\Phi}}_i}{\partial\theta}\cdot\boldsymbol{n}\\
&= -\lambda^{-1}t^n\frac{\partial^2\hat P_n}{\partial\hat\rho^2} + \frac{2}{D(1-\nu)}p_n^B + t^{n+1}\sum_{i=0}^{n}\sigma(\kappa\hat\rho)^{n-i+1}\frac{\partial\hat{\boldsymbol{\Phi}}_i}{\partial\theta}\cdot\boldsymbol{n},
\end{aligned}
$$

and so

$$
D\frac{1-\nu}{2}\operatorname{rot}\phi_n^B - p_{n-1}^B = t^n\left[-D\frac{1-\nu}{2}\lambda^{-1}\frac{\partial^2\hat P_n}{\partial\hat\rho^2} + \hat P_n\right] + t^{n+1}\sum_{i=0}^{n}\sigma(\kappa\hat\rho)^{n-i+1}\frac{\partial\hat{\boldsymbol{\Phi}}_i}{\partial\theta}.
$$

Equation (5.14) follows directly. Using Theorem 4.7 and (4.4), we then obtain

$$
\|D\frac{1-\nu}{2}\operatorname{rot}\phi_n^B - p_{n-1}^B\|_{s,\Omega_0} \le C(t^{n+1/2-s}\|g\|_{n-3/2} + t^{n+1/2}\|g\|_{s+n-3/2}).
$$

Finally, using (4.8), we obtain

$$
\begin{aligned}
&\|D\frac{1-\nu}{2}\operatorname{rot}(\chi\phi_n^B) - \chi p_{n-1}^B\|_s\\
&\qquad\le \|\chi\left(D\frac{1-\nu}{2}\operatorname{rot}\phi_n^B - p_{n-1}^B\right)\|_s + \|D\frac{1-\nu}{2}\phi_n^B\cdot\mathbf{curl}\,\chi\|_s\\
&\qquad\le C(\|D\frac{1-\nu}{2}\operatorname{rot}\phi_n^B - p_{n-1}^B\|_{s,\Omega_0} + \|\phi_n^B\|_{s,\Omega_1})\\
&\qquad\le C(t^{n+1/2-s}\|g\|_{n-3/2} + t^{n+1/2}\|g\|_{s+n-3/2}).
\end{aligned}
$$

This completes the verification of (5.13). □

6. Other boundary conditions. In this section, we discuss the modifications to the foregoing analysis necessary to handle the remaining four other boundary conditions discussed in the introduction: the hard clamped plate, the soft clamped plate, the hard simply supported plate, and the free plate. We shall see that Theorems 5.1–5.3 remain true as stated in all cases.

For the *hard clamped* and *hard simply supported* plates, these were proved in [1]. (The method of proof was somewhat different and required slightly more regularity to obtain the estimates for ω. However, the present method of proof can easily be adapted to correct this.) Since $\phi_1 = 0$ for these boundary conditions, it follows from (5.9) that $p_1 = 0$ as well. Exploiting this, one may slightly improve the regularity requirements for the estimates of $\boldsymbol{\phi}_1^E$ and p_1^E. See [1] for the precise result.

The analysis for the soft clamped plate is very close to that presented here. The space $\boldsymbol{H}^1$ in which $\boldsymbol{\phi}$ is sought is replaced by the subspace of $\boldsymbol{H}^1$ consisting of functions whose normal component vanishes on the boundary. Because of this, a few terms which we estimated in §5 are zero, so the analysis is slightly simpler. A more essential difference between the soft clamped and soft simply supported plates is that the boundary layer for the former is much weaker. In fact, the boundary layer for the soft clamped plate is weaker than for any of the other four boundary conditions we consider. Specifically, as shown in §3, the boundary-layer expansion functions P_0 and P_1 and consequently $\boldsymbol{\Phi}_0$, $\boldsymbol{\Phi}_1$, and $\boldsymbol{\Phi}_2$ all vanish. Moreover, the interior expansion functions ω_i, ϕ_i, and p_i, $i = 1$ and 3, vanish as well. Consequently, $\boldsymbol{\phi}_0^E = \boldsymbol{\phi}_1^E = \boldsymbol{\phi}_2^E + t^2\phi_2$ and $p_0^E = p_1^E = p_2^E + t^2 p_2$. Thus, for example, we see from Theorem 5.1 that $\phi - \phi_0$ is $O(t^2)$ in H^1 and $p - p_0$ is $O(t^2)$ in L^2. (These quantities are only order $O(t^{1/2})$ for the soft simply supported plate and the free plate and $O(t^{3/2})$ for the hard clamped and hard simply supported plates.)

It remains to consider the case of the free plate. First we summarize some basic existence results for the biharmonic and Reissner–Mindlin plate models with traction boundary conditions. Given functions $g \in L^2(\Omega)$, $f, h \in L^2(\partial\Omega)$, the variational problem to find $\omega \in H^2(\Omega)$ satisfying

$$(\mathcal{C}\,\mathcal{E}(\mathbf{grad}\,\omega), \mathcal{E}(\mathbf{grad}\,\mu)) = (g, \mu) - \langle f, \mu \rangle + \left\langle h, \frac{\partial \mu}{\partial n} \right\rangle \quad \text{for all } \mu \in H^2(\Omega)$$

has a solution if and only if the given data is compatible in the sense that

$$(g, \mu) - \langle f, \mu \rangle + \left\langle h, \frac{\partial \mu}{\partial n} \right\rangle = 0 \quad \text{for all } \mu \in \mathbb{L},$$

where $\mathbb{L}$ denotes the three-dimensional space of linear polynomial functions on Ω. In this case, the solution is determined up to the addition of an arbitrary element of $\mathbb{L}$. Performing integration by parts, one obtains the identity

$$(\mathcal{C}\,\mathcal{E}(\mathbf{grad}\,\omega), \mathcal{E}(\mathbf{grad}\,\mu)) = (D\,\Delta^2\,\omega, \mu) - \langle B_3\omega, \mu \rangle + \left\langle B_2\omega, \frac{\partial \mu}{\partial n} \right\rangle, \quad \omega, \mu \in H^2,$$

where

$$B_2\omega := M_{\boldsymbol{n}}\,\mathbf{grad}\,\omega, \qquad B_3\omega := \frac{\partial}{\partial s} M_{\boldsymbol{s}}\,\mathbf{grad}\,\omega + [\mathbf{div}\,\mathcal{C}\,\mathcal{E}(\mathbf{grad}\,\omega)] \cdot \boldsymbol{n}.$$

From this we deduce the boundary value problem corresponding to the weak formulation just discussed:

$$D\,\Delta^2\omega = g \quad \text{in } \Omega, \qquad B_2\omega = h, \quad B_3\omega = f \quad \text{on } \partial\Omega.$$

Note that the traction-free biharmonic plate problem, i.e., the case when $f = h = 0$, has a solution if and only if the load function g is orthogonal to $\mathbb{L}$.

Analogously, the Reissner–Mindlin boundary value problem for a traction-free plate, given by equations (1.6) and (1.7) and the boundary conditions (1.5), has a solution if and only if the load g is compatible with the traction-free conditions, i.e., it is L^2-orthogonal to $\mathbb{L}$. The solution pair $(\omega, \boldsymbol{\phi})$ is then determined up to the addition of a pair in

$$\mathbb{L}_\nabla := \{\,(l, \mathbf{grad}\, l) \mid l \in \mathbb{L}\,\}.$$

We henceforth assume that g is compatible. We now proceed to the construction of the expansion functions ω_i, $\boldsymbol{\phi}_i$, P_i, and p_i in the case of the free plate. The boundary conditions we use are (3.18), (3.19), and, from the last equality in (1.5),

$$(\boldsymbol{\phi}_i - \mathbf{grad}\,\omega_i)\cdot \boldsymbol{n} = -\lambda^{-1}\frac{\partial \hat{P}_{i-2}}{\partial\theta} \tag{6.1}$$

or, in view of (3.4),

$$\mathbf{div}\, \mathcal{C}\,\mathcal{E}(\boldsymbol{\phi}_i)\cdot\boldsymbol{n} = -\frac{\partial \hat{P}_i}{\partial\theta}. \tag{6.2}$$

Now, from (3.18) and (6.2), we have

$$\begin{aligned}\frac{\partial}{\partial s}M_s\boldsymbol{\phi}_i + \mathbf{div}\,\mathcal{C}\,\mathcal{E}(\boldsymbol{\phi}_i)\cdot\boldsymbol{n} &= \lambda^{-1}D\frac{1-\nu}{2}\frac{\partial}{\partial\theta}\left(\frac{\partial^2\hat{P}_i}{\partial\hat{\rho}^2} + \kappa\frac{\partial\hat{P}_{i-1}}{\partial\hat{\rho}} - \frac{\partial^2\hat{P}_{i-2}}{\partial\theta^2}\right) - \frac{\partial\hat{P}_i}{\partial\theta}\\ &= \lambda^{-1}D(1-\nu)\frac{\partial}{\partial\theta}\left(\kappa\frac{\partial\hat{P}_{i-1}}{\partial\hat{\rho}} - \frac{\partial^2\hat{P}_{i-2}}{\partial\theta^2}\right),\end{aligned}$$

where we used (3.11) with $\hat{\rho} = 0$ in the last step. Using (3.7), we convert this to a boundary condition on ω_i:

$$B_3\omega_i = -B_3(\lambda^{-1}D\,\Delta\,\omega_{i-2} + \delta_{i4}\lambda^{-2}Dg) + \lambda^{-1}D(1-\nu)\frac{\partial}{\partial\theta}\left(\kappa\frac{\partial\hat{P}_{i-1}}{\partial\hat{\rho}} - \frac{\partial^2\hat{P}_{i-2}}{\partial\theta^2}\right). \tag{6.3}$$

The construction of expansion functions satisfying (3.6), (3.7), (3.11), (5.9), (3.18), (3.19), (6.1), and (3.12) proceeds as follows. First we define $\omega_i \in H^2$ from the biharmonic equation (3.6) together with the boundary conditions (3.20), which we may write as

$$B_2\omega_i = -B_2(\lambda^{-1}D\,\Delta\,\omega_{i-2} + \delta_{i4}\lambda^{-2}Dg) + \lambda^{-1}D(1-\nu)\left(\kappa\frac{\partial\hat{P}_{i-2}}{\partial\theta} + \frac{\partial^2\hat{P}_{i-1}}{\partial\theta\partial\hat{\rho}}\right), \tag{6.4}$$

and (6.3). Note that for $i = 0$ this is simply the biharmonic problem for a traction-free plate with load g, so ω_0 is determined up to addition of a linear function. As we shall show shortly, this problem always admits a solution, so that once P_j is known for $j < i$, ω_i is determined up to addition of a linear function. Then $\boldsymbol{\phi}_i$ is given by (3.7) and (3.8) as before, so the pair $(\omega_i, \boldsymbol{\phi}_i)$ is determined up to addition of an element of $\mathbb{L}_\nabla$. Note that $M_s\boldsymbol{\phi}_i$ is determined completely, and so we can uniquely determine P_i by the differential equation (3.11), the boundary condition (3.18), and the decay condition (3.12). Thus we compute, in order, ω_0, ϕ_0, P_0, ω_1, ϕ_1, P_1, ..., always with (ω_i, ϕ_i) determined up to addition of an element of $\mathbb{L}_\nabla$, and P_i determined completely.

To see that the biharmonic problems for the ω_i admit solutions, we must show that

$$(6.5) \qquad (\delta_{i0} g - \delta_{i2}\lambda^{-1} D \,\Delta\, g, \mu) - \langle f, \mu\rangle + \left\langle h, \frac{\partial \mu}{\partial n}\right\rangle = 0 \quad \text{for all } \mu \in \mathbb{L},$$

when f is given by the right-hand side of (6.3) and h by the right-hand side of (6.4). Setting $u = \lambda^{-1} D\,\Delta\,\omega_{i-2} + \delta_{i4}\lambda^{-2} D g$ and using the biharmonic equation satisfied by ω_{i-2} (which we can assume by induction), we get $D\,\Delta^2\, u = \delta_{i2}\lambda^{-1} D g$. Hence if $\mu \in \mathbb{L}$,

$$(\delta_{i0} g - \delta_{i2}\lambda^{-1} D g, \mu) = -\langle B_3 u, \mu\rangle + \left\langle B_2 u, \frac{\partial \mu}{\partial n}\right\rangle.$$

Thus, to complete the verification of (6.5), it suffices to show

$$\left\langle \frac{\partial}{\partial \theta}\left(\kappa \frac{\partial \hat{P}_{i-1}}{\partial \hat{\rho}}\right), \mu \right\rangle = \left\langle \frac{\partial^2 \hat{P}_{i-1}}{\partial \theta \partial \hat{\rho}}, \frac{\partial \mu}{\partial n}\right\rangle$$

and

$$\left\langle \frac{\partial \hat{P}_{i-2}}{\partial \theta^3}, \mu \right\rangle = -\left\langle \kappa \frac{\partial \hat{P}_{i-2}}{\partial \theta}, \frac{\partial \mu}{\partial n}\right\rangle,$$

for all $\mu \in \mathbb{L}$. These may be verified with elementary calculus, independent of the particular functions P_{i-1} and P_{i-2}.

We now define functions p_i and r, as was done in the beginning of §5 for the soft simply supported plate. From (3.7), (3.8), and (3.6), we see that $\operatorname{div} \mathbf{div}\, C\,\mathcal{E}(\phi_i) = \delta_{i0} g$. Hence, defining $r \in H^1/\mathbb{R}$ by

$$-\Delta\, r = g \quad \text{in } \Omega, \qquad \frac{\partial r}{\partial n} = 0 \quad \text{on } \partial\Omega,$$

we see that $\mathbf{div}\, C\,\mathcal{E}(\phi_i) + \delta_{i0}\, \mathbf{grad}\, r$ is divergence free. Hence we may again define a function $p_i \in H^1$, unique modulo $\mathbb{R}$, by (5.9). Now from (5.9) and (6.2), we see that $\partial(p_i + P_i)/\partial s = 0$. Therefore, we may normalize p_i so that

$$(6.6) \qquad p_i + P_i = 0 \quad \text{on } \partial\Omega.$$

This completes the construction of the expansion functions.

In §§4 and 5, we presented the analysis of the asymptotic expansions in such a way that they adapt with a minimum of effort to the case of the free plate. Due to the different boundary conditions, we need to use different negatively indexed Sobolev norms. Instead of the definition given in §2, we define $\|\cdot\|_s$ to be the norm in the dual space H^s. With this understanding, all of the results of §4 hold with essentially the same proofs. Of course, in the proof of Theorem 4.3, we use the traction problem for the biharmonic rather than the simply supported plate problem.

Turning to the error analysis in §5, we again use the Helmholtz decomposition as in (5.1), except that now $r \in H^1/\mathbb{R}$ and $p \in \overset{\circ}{H}{}^1$. We then recover the differential equations (5.2)–(5.4), and (5.6), now with the boundary conditions

$$\frac{\partial r}{\partial n} = M_n \phi = M_s \phi = p = \frac{\partial \omega}{\partial n} - \phi \cdot \boldsymbol{n} = 0.$$

These determine (r, ϕ, p, ω) up to an additive constant in r and addition of an element of $\mathbb{L}_\nabla$ to (ω, ϕ).

The norms on the left-hand sides of the estimates in Theorems 5.1–5.3 need to be modified in the obvious ways because of the indeterminancy in (ϕ, ω) and the determinancy of p. That is, the norms of ϕ_n^E are in the Sobolev spaces modulo $\mathbb{R}$, those on ω_n^E in the Sobolev spaces modulo $\mathbb{L}$, and those on p_n^E in the full Sobolev spaces. The proofs of these theorems carry over easily. In particular, Lemma 5.4 holds without change.

The main part of the proof of Theorem 5.1 involved the choice of test functions $\psi = \phi_n^E$ in (5.20) and $q = p_n^E - t^n \chi P_n$ in (5.21). Notice that this choice of q vanishes on the boundary because of (6.6) and so is an allowable test function. This part of the proof carries over to the free case without problem.

Two more choices of test functions complete the proof of the theorem. For the second one, we take $\psi \in \boldsymbol{H}^1$ with $\operatorname{rot} \psi = p_n^E$, which allows us to get control over the full L^2 norm of p_n^E. Finally, to control the infinitesimal rotation in ϕ_n^E, we choose a test function $q \in \mathring{H}^1$ in (5.21) with nonvanishing integral and use the fact that

$$\psi \to a(\psi, \psi)^{1/2} + \left| \int_\Omega q \operatorname{rot} \psi \right|$$

defines a norm equivalent to the usual norm in $\boldsymbol{H}^1/\mathbb{R}^2$.

The proof of Theorem 5.2 adapts easily. Naturally, we use a Dirichlet rather than a Neumann problem to obtain bounds on p_n^E, using that fact that $p_n^E = t^n P_n$ on $\partial\Omega$. Analogously, to prove Theorem 5.3, we use a Neumann problem for ω_n^E and the fact that

$$\frac{\partial \omega_n^E}{\partial n} = \phi_n^E \cdot \boldsymbol{n} = \phi_{n+s-1}^E \cdot \boldsymbol{n} + \sum_{n+1}^{n+s-1} t^j (\phi_j + \boldsymbol{\Phi}_j) \cdot \boldsymbol{n}.$$

Appendix. In this appendix, we collect some elementary formulas for the convenience of the reader.

It follows immediately from the definitions of rot and **curl** that

$$\operatorname{rot} \mathbf{curl}\, q = -\Delta q, \qquad \mathbf{curl}\, q \cdot \boldsymbol{n} = -\frac{\partial q}{\partial s}, \qquad \mathbf{curl}\, q \cdot \boldsymbol{s} = \frac{\partial q}{\partial n},$$

and

$$(\operatorname{rot} \psi, q) = (\psi, \mathbf{curl}\, q) - \langle \psi \cdot \boldsymbol{s}, q \rangle.$$

Simple computations show that

$$\begin{aligned} \mathbf{div}\, \mathcal{C}\,\mathcal{E}(\mathbf{grad}\, v) &= D\, \mathbf{grad}\, \Delta v, & \mathbf{div}\, \mathcal{C}\,\mathcal{E}(\mathbf{curl}\, p) &= D \frac{1-\nu}{2}\, \mathbf{curl}\, \Delta p, \\ \operatorname{div} \mathbf{div}\, \mathcal{C}\,\mathcal{E}(\phi) &= D\, \Delta \operatorname{div} \phi, & \Delta \phi &= \mathbf{grad} \operatorname{div} \phi - \mathbf{curl} \operatorname{rot} \phi, \end{aligned}$$

and on $\partial\Omega$,

$$
\begin{aligned}

TWO PROBLEMS FROM DRAINING FLOWS INVOLVING THIRD-ORDER ORDINARY DIFFERENTIAL EQUATIONS*

F. BERNIS[†] AND L. A. PELETIER[‡]

Abstract. A mathematical analysis is given of two third-order ordinary differential equations which arise in models for flows of thin viscous films over solid surfaces. Questions about existence, uniqueness, and qualitative properties of solutions are discussed.

Key words. differential equations, nonlinear, fluid mechanics, coating flow

AMS subject classifications. 34B15, 34E05, 76D99

1. Introduction.

In a recent survey paper, Tuck and Schwartz [12] discussed a series of third-order ordinary differential equations (ODEs) arising in the study of the flow of a thin film of viscous fluid over a solid surface. When such a film drains down a vertical wall and the effects of surface tension and gravity as well as viscosity are taken into account, one is led to an equation of the form

$$\frac{d^3u}{dx^3} = f(u)$$

for the film profile $u(x)$ in a coordinate frame moving with the fluid.

In [12] different possible choices of the function f are given. For drainage down a dry surface with the x-axis pointing downwards, this function becomes

$$\text{(A)} \qquad f(u) = -1 + \frac{1}{u^2}.$$

This function is singular at $u = 0$, that is, at the tip of the film. If the surface is prewetted by a very thin film of thickness $\delta > 0$, the function f becomes

$$\text{(B)} \qquad f(u) = -1 + \frac{1+\delta+\delta^2}{u^2} - \frac{\delta+\delta^2}{u^3}.$$

Since u may now be expected to be bounded away from zero, the singularity at $u = 0$ is no longer relevant.

When the surface is dry, insight into the shape of the film close to the tip may be obtained by studying the limit of solutions of equation (B) as $\delta \to 0$. In suitably scaled coordinates this leads to equations involving the functions [1, 2, 11, 12]

$$\text{(C),(D)} \qquad f(u) = \frac{1}{u^2} \quad \text{and} \quad f(u) = \frac{1}{u^2} - \frac{1}{u^3}.$$

Equation (A) also occurs in different film flows, such as spin coating and spray coating [7, 8]. In addition to the asymptotic context given above, equation (C) is interesting in its own right in that it describes the spreading of certain oil drops on horizontal surfaces [9].

In [12] the authors formulate a series of well-posed mathematical problems arising from the study of these draining flows. In this paper we address two of them. The

first, problem (I), involves the simpler function (C) and occurs in the asymptotic analysis near the tip. The second, problem (II), involves the original function (A) and describes the draining of a film along a dry wall, which is uniform far upstream.

The objective of our analyses is to prove some basic properties of these problems, such as the existence of a solution and the domain on which it exists, its uniqueness and such qualitative properties as monotonicity or oscillatory behaviour, and asymptotics far up- and downstream.

A comparable analysis for equations (B) and (D) has been given by Troy [11].

Let us now state the first problem in detail. We look for a smooth function $u(x)$, defined for all $x \in (-\infty, \infty)$, which has the following properties:

$$\text{(I)} \qquad \begin{cases} u''' = \dfrac{1}{u^2}, \\ u(0) = 1 \quad \text{and} \quad u'(0) = 0, \\ u''(x) \to 0 \quad \text{as} \quad x \to -\infty. \end{cases}$$

We shall prove that such a solution indeed exists, is also unique, and has the following asymptotic behaviour at $-\infty$ and at $+\infty$:

$$u(x) \sim -x(3 \log |x|)^{1/3} \quad \text{as} \quad x \to -\infty, \tag{1.1}$$

$$u(x) \sim \frac{1}{2} K x^2 \quad \text{as} \quad x \to +\infty. \tag{1.2}$$

Here K is a positive constant. In fact, $K = \lim_{x \to +\infty} u''(x)$. The associated numerical values given in [12] are

$$u''(0) = 1.2836 \qquad \text{and} \qquad K = 2.1591.$$

It is interesting to note that the behaviour near $x = -\infty$ is the same as that found in [11] for equation (D).

These asymptotic estimates have been obtained before by formal methods [1, 5, 12].

We shall prove these results by transforming the third-order differential equation to the classical Emden–Fowler equation,

$$y'' + t^{-k} y^{\sigma} = 0, \quad t > 0,$$

with $k = 2$ and $\sigma = -\frac{1}{2}$. Studying this equation instead and making use of its specific properties, such as the convexity of its solutions, we obtain the required information about u.

It is interesting to mention here a somewhat related transformation, recently proposed in [4], which casts the equation into an autonomous system of two first-order equations.

The second problem we consider is

$$\text{(II)} \qquad \begin{cases} u''' = -1 + \dfrac{1}{u^2}, \\ u(x) \to 1 \quad \text{as} \quad x \to -\infty. \end{cases}$$

Clearly this problem has the trivial solution $u(x) = 1$.

Numerical studies [12] suggest that nontrivial solutions of (II) exist and are positive and oscillatory for all $x \in (-\infty, \infty)$, with increasing maxima and decreasing minima. The objective of our analysis of problem (II) is to confirm these observations and explore the character of the oscillations. Specifically, we shall prove the following sequence of results about nontrivial solutions u:

A. u exists and is positive on the whole line.

B. $u-1$ has infinitely many zeros; these zeros form an increasing sequence $\{a_n\}$, $-\infty < n < +\infty$ and $a_n \to -\infty$ as $n \to -\infty$, while $a_n \to +\infty$ as $n \to +\infty$.

C. u has a unique minimum in each interval (a_{2n}, a_{2n+1}), attained at a point b_{2n}. The sequence of minima $u(b_{2n})$ is decreasing and

$$u(b_{2n}) \to 0 \quad \text{as} \quad n \to +\infty.$$

D. u has a unique maximum in each interval (a_{2n+1}, a_{2n+2}), attained at a point b_{2n+1}. The sequence of maxima $u(b_{2n+1})$ is increasing and

$$u(b_{2n+1}) \to \infty \quad \text{as} \quad n \to +\infty.$$

E. The length of the intervals in which $u < 1$ tends to zero, while the length of the intervals in which $u > 1$ tends to infinity. More precisely,

$$a_{2n+1} - a_{2n} \to 0 \quad \text{as} \quad n \to +\infty,$$

$$a_{2n+2} - a_{2n+1} \to \infty \quad \text{as} \quad n \to +\infty.$$

F. The sequences

$$|u'(a_n)|, \quad |u'(c_n)|, \quad |u''(a_n)|, \quad |u''(b_n)|$$

in which the points c_n are the zeros of u'', are increasing and tend to infinity as $n \to +\infty$.

It is remarkable that property **F** does not discriminate between the intervals in which $u > 1$ and those in which $u < 1$.

2. Problem (I): Existence and uniqueness. We recall that problem (I) is

$$u''' = \frac{1}{u^2}, \tag{2.1}$$

$$u(0) = 1 \quad \text{and} \quad u'(0) = 0, \tag{2.2}$$

$$u''(x) \to 0 \quad \text{as} \quad x \to -\infty. \tag{2.3}$$

THEOREM 2.1. *There exists a unique solution $u = u(x)$ of problem* (2.1)–(2.3). *This solution is defined for all $x \in \mathbf{R}$.*

We begin with some preliminary observations. Suppose that $u(x)$ is a solution of (2.1)–(2.3). Then, because $u'''(x) > 0$ everywhere and $u''(-\infty) = 0$, we can inmediately conclude that

$$u(x) \geq 1 \quad \text{and} \quad u''(x) > 0 \quad \text{for all} \quad x \in \mathbf{R}, \tag{2.4}$$

$$u'(x) \begin{cases} < 0 & \text{if} \quad x < 0, \\ > 0 & \text{if} \quad x > 0, \end{cases} \tag{2.5}$$

and

$$u(x) \to +\infty \quad \text{as} \quad x \to -\infty.$$

Thus, since any solution is strictly decreasing on $(-\infty, 0)$, we may introduce u as an independent variable and, as in [6], introduce the function

$$y(u) = \{u'(x)\}^2 \tag{2.6}$$

as a dependent variable. (Notice that $u' = -\sqrt{y}$.) Carrying out the transformation, we obtain for y the problem

$$y'' + \frac{2}{u^2}\frac{1}{\sqrt{y}} = 0, \quad y > 0 \quad \text{for} \quad 1 < u < \infty, \tag{2.7}$$

$$y(1) = 0, \quad y'(u) \to 0 \quad \text{as} \quad u \to +\infty. \tag{2.8}$$

It will be sufficient to prove the existence and uniqueness of a solution of problem (2.7)–(2.8). We shall do this by means of a shooting argument, replacing the condition at $u = +\infty$ by a second condition at $u = 1$, so that we then have

$$y(1) = 0 \quad \text{and} \quad y'(1) = \alpha > 0. \tag{2.9}$$

We could also use Proposition 2.4 of [10], which establishes existence and uniqueness by a different argument.

It is readily seen that for any $\alpha > 0$, problem (2.7), (2.9) has a unique local solution $y(u, \alpha)$ which can be continued as long as $y > 0$. Because the graph of $y(u, \alpha)$ is concave, it follows that if y exists on the whole half line $[1, \infty)$, then

$$y'(u, \alpha) > 0 \text{ for all } u > 1 \quad \text{and} \quad \lim_{u \to \infty} y'(u, \alpha) \text{ exists.}$$

Moreover, we have the following monotonicity lemma.

LEMMA 2.2. *Suppose that $\alpha_1 < \alpha_2$. Then, as long as $y(u, \alpha_1)$ exists,*

$$y(u, \alpha_1) < y(u, \alpha_2) \quad \textit{and} \quad y'(u, \alpha_1) < y'(u, \alpha_2).$$

In addition, if $y(u, \alpha_1)$ exists for all $u \geq 1$, then

$$0 \leq y'(\infty, \alpha_1) < y'(\infty, \alpha_2) < \infty.$$

Proof. For convenience we shall write $y_i(u) = y(u, \alpha_i)$, $i = 1, 2$. It is enough to prove that $y_1'(u) < y_2'(u)$.

Since $\alpha_1 < \alpha_2$, the assertion is true near $u = 1$. Suppose it first fails to hold at some point $u_0 > 1$. Then

$$y_1'(u_0) = y_2'(u_0) \quad \text{and} \quad y_1' < y_2' \quad \text{on} \quad (1, u_0). \tag{2.10}$$

However, if we integrate the equations for y_1 and y_2 over $(1, u_0)$ and subtract, we obtain

$$y_1'(u_0) - y_2'(u_0) = \alpha_1 - \alpha_2 - 2\int_1^{u_0} \left(\frac{1}{\sqrt{y_1}} - \frac{1}{\sqrt{y_2}} \right) \frac{ds}{s^2} < 0 \tag{2.11}$$

because $y_1 < y_2$ on $(1, u_0)$. This contradicts (2.10).

The second assertion follows from (2.11) when we set $u_0 = \infty$. Observe that $y_i'(\infty)$ must be finite and nonnegative.

We now define two sets of initial slopes:

$$S_+ = \{\alpha > 0 \ : \ y \text{ exists on } [1, \infty) \text{ and } y'(\infty, \alpha) > 0\},$$
$$S_- = \{\alpha > 0 \ : \ y \text{ vanishes at some } u_0 \in [1, \infty)\}.$$

It is clear that $S_+ \cap S_- = \emptyset$ and by continuous dependence on the initial data, both sets are open. In the next two lemmas, we shall show that they are nonempty.

LEMMA 2.3. $S_+ \neq \emptyset$.

Proof. Suppose that $S_+ = \emptyset$. Then for any $\alpha > 0$ there exists a point u_α, which may be infinite, such that $y(\cdot, \alpha)$ is increasing on $(1, u_\alpha)$ and $y'(u_\alpha, \alpha) = 0$. If we integrate (2.7) over $(1, u_\alpha)$, we obtain

$$\alpha = 2 \int_1^{u_\alpha} \frac{ds}{s^2 \sqrt{y(s,\alpha)}}.$$

Define

$$\hat{y}(u) = \begin{cases} y(u,1) & \text{for } 1 < u < u_1, \\ y(u_1,1) & \text{for } u_1 \leq u < \infty. \end{cases}$$

Then, for $\alpha > 1$,

$$\alpha < 2 \int_1^{u_\alpha} \frac{ds}{s^2 \sqrt{\hat{y}(s)}} < 2 \int_1^{\infty} \frac{ds}{s^2 \sqrt{\hat{y}(s)}} < \infty$$

and we have a contradiction.

LEMMA 2.4. $S_- \neq \emptyset$.

Proof. Observe that by concavity,

$$y(u,\alpha) < \alpha(u-1) \quad \text{on} \quad (1, \sigma_\alpha),$$

where $[1, \sigma_\alpha)$ is the maximal interval of existence of $y(\cdot, \alpha)$. Hence

$$y''(u,\alpha) < -\frac{2}{\sqrt{\alpha}} \frac{1}{u^2 \sqrt{u-1}} \quad \text{on} \quad (1, \sigma_\alpha)$$

and so

$$y'(u,\alpha) < \alpha - \frac{2}{\sqrt{\alpha}} \int_1^u \frac{ds}{s^2 \sqrt{s-1}} \quad \text{for} \quad 1 < u < \sigma_\alpha.$$

Thus, if S_- were empty and so $y'(u,\alpha) > 0$ for all $u \geq 1$ and all $\alpha > 0$, then

$$\alpha^{3/2} \geq 2 \int_1^{\infty} \frac{ds}{s^2 \sqrt{s-1}} = \pi$$

for all $\alpha > 0$. This is clearly a contradiction.

COROLLARY 2.5. $(0, \pi^{2/3}] \subset S_-$.

From Lemmas 2.3 and 2.4, we conclude that there exists a shooting angle α_0 such that $y_0(u) = y(u, \alpha_0)$ has the properties

$$y_0(u) > 0 \quad \text{and} \quad y_0'(u) > 0 \quad \text{for all} \quad u > 1$$

and

$$\lim_{u \to +\infty} y_0'(u) = 0.$$

This is the desired solution of problem (2.7), (2.8), from which we deduce at once that problem (2.1)–(2.3) has a solution $u(x)$ defined for $x \in (-\infty, 0]$. But this solution $u(x)$ can be continued to the whole line $\mathbf{R}$ because, as explained above, $u(x) \geq 1$ and hence u''' remains bounded.

By the strict monotonicity of $y'(\infty, \alpha)$ with respect to α, established in Lemma 2.2, the solution $y_0(u)$ must be unique and hence $u(x)$ is also unique.

The proof of Theorem 2.1 is now complete.

3. Problem (I): Asymptotic behaviour. Most of this section is devoted to proving the asymptotic estimate (1.1), which by definition means that

$$\lim_{x\to-\infty} \frac{u(x)}{-x(3\log|x|)^{1/3}} = 1. \tag{3.1}$$

To study the behaviour of the solution $u(x)$ of problem (I) as $x \to -\infty$ we consider again the change of variables (2.6) and equation (2.7) and recall that $x \to -\infty$ for $u(x)$ corresponds to $u \to +\infty$ for $y(u)$.

We present a self-contained proof of Theorem 3.3 below, which could also be derived from [10, Thm. 3.6].

In what follows $y(u)$ stands for a solution of (2.7) such that $y'(u) \to 0$ as $u \to +\infty$.

LEMMA 3.1. *We have*

$$\limsup_{u\to\infty} \frac{y(u)}{(\log u)^{2/3}} \ge 3^{2/3} \equiv M.$$

Proof. Suppose to the contrary that

$$\limsup_{u\to\infty} \frac{y(u)}{(\log u)^{2/3}} \le M - 2\varepsilon \tag{3.2}$$

for some $\varepsilon > 0$. Then there exists a $u_\varepsilon > 0$ such that

$$y(u) \le (M-\varepsilon)(\log u)^{2/3} \quad \text{if} \quad u > u_\varepsilon.$$

Hence

$$y''(u) \le -\frac{2}{\sqrt{M-\varepsilon}}\frac{1}{u^2}(\log u)^{-1/3} \quad \text{if} \quad u > u_\varepsilon$$

and, because by assumption $y'(\infty) = 0$,

$$y'(u) \ge \frac{2}{\sqrt{M-\varepsilon}} J(u),$$

where

$$J(u) = \int_u^\infty \frac{dt}{t^2(\log t)^{1/3}} \sim \frac{1}{u(\log u)^{1/3}} \quad \text{as} \quad u \to \infty.$$

Thus

$$y(u) \ge y(u_\varepsilon) + \frac{2}{\sqrt{M-\varepsilon}} \int_{u_\varepsilon}^u J(t)\,dt,$$

whence

$$\liminf_{u\to\infty} \frac{y(u)}{(\log u)^{2/3}} \ge \frac{2}{\sqrt{M-\varepsilon}} \lim_{u\to\infty} \frac{\int_{u_\varepsilon}^u J(t)\,dt}{(\log u)^{2/3}} = \frac{3}{\sqrt{M-\varepsilon}}, \tag{3.3}$$

because by l'Hôpital's rule

$$\lim_{u\to\infty} \frac{\int_{u_\varepsilon}^u J(t)\,dt}{(\log u)^{2/3}} = \lim_{u\to\infty} \frac{J(u)}{\frac{2}{3}(\log u)^{-1/3}\frac{1}{u}} = \frac{3}{2}.$$

Remark. Note that

$$\int_{u_\varepsilon}^u J(t)\,dt \to \infty \quad \text{as} \quad u \to \infty.$$

We conclude from (3.3) that

$$\limsup_{u\to\infty}\frac{y(u)}{(\log u)^{2/3}} \geq \frac{3}{\sqrt{M-\varepsilon}} > \frac{3}{\sqrt{M}} = 3^{2/3}, \tag{3.4}$$

which contradicts the assumption (3.2).

Similarly one can prove the following lemma.

LEMMA 3.2. *We have*

$$\liminf_{u\to\infty}\frac{y(u)}{(\log u)^{2/3}} \leq 3^{2/3}.$$

Define

$$\varphi(u) = (3\log u)^{2/3}.$$

Then

$$\varphi'' + \frac{2}{u^2}\frac{1}{\sqrt{\varphi}} = -\frac{2}{u^2\varphi^2} < 0. \tag{3.5}$$

We proceed to compare $y(u)$ and $\varphi(u)$.

THEOREM 3.3. *Let $y(u)$ be a solution of* (2.7) *such that $y'(u) \to 0$ as $u \to \infty$. Then*

$$\lim_{u\to\infty}\frac{y(u)}{\varphi(u)} = 1. \tag{3.6}$$

Proof. We distinguish two cases:

(a) $y(u) - \varphi(u) \neq 0$ for all $u > 1$;

(b) $\exists u_0 > 1$ such that $y(u_0) - \varphi(u_0) = 0$.

Case (a). Suppose that $y < \varphi$. Then

$$\limsup_{u\to\infty}\frac{y(u)}{\varphi(u)} \leq 1.$$

Proceeding as is the proof of Lemma 3.1, with $\varepsilon = 0$, we conclude that

$$\liminf_{u\to\infty}\frac{y(u)}{\varphi(u)} \geq 1,$$

from which we deduce (3.6). If $y > \varphi$ the argument is the same.

Case (b). Let

$$y(u_0) - \varphi(u_0) = 0$$

and let $y > \varphi$ in a right neighbourhood of u_0. We assert that $y > \varphi$ on (u_0, ∞). In fact, assume for contradiction that

$$u_1 \equiv \sup\{u > u_0 \,:\, y > \varphi \text{ on } (u_0, u)\} < \infty.$$

Setting $z = y - \varphi$ and taking (3.5) into account, we find that

$$z'' > 0 \quad \text{and} \quad z > 0 \quad \text{on} \quad (u_0, u_1).$$

This and $z(u_0) = z(u_1) = 0$ contradict the maximum principle (or the convexity of z). Thus $y > \varphi$ on (u_0, ∞) and as in Case (a) we conclude that (3.6) holds.

Finally, let $y < \varphi$ on $(u_0, u_0 + \delta)$ for some $\delta > 0$. If $y \leq \varphi$ in (u_0, ∞), then (3.6) follows as before. On the other hand, if

$$u_1 \equiv \sup\{u > u_0 \,:\, y \leq \varphi \text{ on } (u_0, u)\} < \infty,$$

then $y > \varphi$ on (u_1, ∞) and (3.6) follows again. This completes the proof of Theorem 3.3.

Remark. Theorem 3.3 only involves local arguments near $u = +\infty$. In particular, the condition $y(1) = 0$ of (2.8) is not assumed.

THEOREM 3.4. *The solution of problem* (I) *satisfies* (1.1).

Proof. Using the change of variables (2.6), the relation between $u(x)$ and $y(u)$ can be written as

$$u'(x) = -\sqrt{y(u(x))}, \qquad -\infty < x \leq 0.$$

We divide by $\sqrt{y}$ and integrate over $(x, 0)$. This yields

$$\int_1^{u(x)} \frac{dv}{\sqrt{y(v)}} = -x,$$

and by Theorem 3.3

$$\int_1^{u(x)} \frac{dv}{(3\log v)^{1/3}} \sim -x \quad \text{as} \quad x \to -\infty. \tag{3.7}$$

On the other hand, by l'Hôpital's rule

$$\int_1^u \frac{dv}{(3\log v)^{1/3}} \sim \frac{u}{(3\log u)^{1/3}} \quad \text{as} \quad u \to +\infty.$$

Therefore, (3.7) yields

$$\frac{u(x)}{\{3\log u(x)\}^{1/3}} \sim -x \quad \text{as} \quad x \to -\infty$$

and hence

$$\log u(x) \sim \log|x| \quad \text{as} \quad x \to -\infty.$$

The last two relations imply that

$$u(x) \sim -x(3\log|x|)^{1/3} \quad \text{as} \quad x \to -\infty,$$

which is what we set out to prove.

Remark. It also follows that as $x \to -\infty$

$$u'(x) \sim -(3\log|x|)^{1/3} \quad \text{and} \quad u''(x) \sim -\frac{1}{x(3\log|x|)^{2/3}}.$$

Finally, we briefly deal with the behaviour as $x \to +\infty$.

THEOREM 3.5. *Let* $u(x)$ *be the solution of problem* (I). *Then*

$$K \equiv \lim_{x\to+\infty} u''(x) \ \textit{exists.}$$

Moreover, K is positive and finite so that

$$u(x) \sim \frac{1}{2}Kx^2 \quad \textit{as} \quad x \to +\infty$$

Proof. Since $u''' > 0$ and $u''(-\infty) = 0$, it is clear that the limit K exists and that it is positive. Thus, we only need to prove that it is finite. Because K is positive, it follows that $u(x) > Cx^2$ for some positive constant C and x sufficiently large. This implies by the differential equation (2.1) that $u'''(x) < C^{-2}x^{-4}$ so that u''' is integrable near infinity and hence that u'' tends to a finite limit.

4. Problem (II).

We recall that problem (II) is

$$u''' = -1 + \frac{1}{u^2}, \tag{4.1}$$

$$u(x) \to 1 \quad \text{as} \quad x \to -\infty. \tag{4.2}$$

In this section we always assume that u is a nontrivial solution of problem (II). By definition, we require that u be of class C^3. This implies that u must be positive because of the singularity at $u = 0$ of the differential equation (4.1). Hence, the assertion that u is everywhere positive is included in global existence (Theorem 4.5 below).

The linearization of equation (4.1) about $u = 1$ is $u''' = -2u$ and has the eigenvalues

$$-\sqrt[3]{2}, \qquad \sqrt[3]{2}\left(\frac{1}{2} \pm i\frac{\sqrt{3}}{2}\right).$$

Hence, by standard linearization theory, nontrivial solutions of problem (II) actually exist, have infinitely many zeros near $-\infty$, and satisfy

$$u(x) \to 1, \quad u'(x) \to 0, \quad u''(x) \to 0 \qquad \text{as} \qquad x \to -\infty. \tag{4.3}$$

Notice that for the moment we only know that these solutions are defined near $-\infty$.

We define the following four auxiliary functions:

$$\Phi_1 \equiv (1-u)u'' + \frac{1}{2}u'^2,$$

$$\Phi_2 \equiv u + \frac{1}{u} + u'u'',$$

$$\Phi_3 \equiv -u'u''' + \frac{1}{2}u''^2,$$

$$\Phi_4 \equiv \frac{3}{2}\left(u + \frac{1}{u}\right) + \frac{1}{2}u'u''.$$

LEMMA 4.1. *If u is a nontrivial solution of problem* (II) *then the functions Φ_1, $\Phi_2 - 2$, Φ_3 and $\Phi_4 - 3$ are strictly increasing and positive. Furthermore, Φ_4 is convex.*

Proof. Since Φ_1, $\Phi_2 - 2$, Φ_3 and $\Phi_4 - 3$ tend to zero as $x \to -\infty$ by (4.3), it is enough to prove that they are strictly increasing and that Φ_4 is convex. Taking into account the differential equation, we obtain

$$\Phi_1' = (1-u)u''' = \frac{(1-u)^2(1+u)}{u^2} \geq 0,$$

$$\Phi_2' = u''^2 \quad \text{because} \quad \frac{d}{dx}\left(u + \frac{1}{u}\right) = -u'u''',$$

$$\Phi_3' = -u'u^{(4)} = \frac{2u'^2}{u^3},$$

$$\Phi_4' = \Phi_3 > 0 \quad \text{and hence} \quad \Phi_4'' = \Phi_3' \geq 0.$$

Notice that the monotonicity of these functions is strict. In fact, if one of the derivatives Φ_i' were zero in an interval, then equation (4.1) would imply that $u = 1$ in that interval and hence u would be the trivial solution by standard ODE uniqueness theorems.

We proceed to analyze the structure of the arches of u.

LEMMA 4.2. *Suppose that a_n and a_{n+1} are two consecutive zeros of $u-1$. Then in the interval $[a_n, a_{n+1}]$, the derivative u' has a unique zero b_n and also u'' has a unique zero c_n. Furthermore,*

$$u'(a_n)u''(a_n) > 0 \quad \text{and} \quad a_n < c_n < b_n < a_{n+1}.$$

Proof. Assume that $u > 1$ in (a_n, a_{n+1}). (The case in which $u < 1$ is analogous.) Then $u''' < 0$, u'' is decreasing, and u' is concave in this interval. From the positivity of $\Phi_2 - 2$, we deduce that

$$u'(a_n) > 0, \quad u''(a_n) > 0, \quad u'(a_{n+1}) < 0, \quad \text{and} \quad u''(a_{n+1}) < 0.$$

This proves the existence and uniqueness of b_n and c_n. Finally, $u''(b_n) < 0$ by the positivity of Φ_1 and hence $c_n < b_n$.

In what follows a_n, b_n, and c_n stand for zeros of $u-1$, u', and u'', respectively, and we introduce the notation

$$\begin{aligned} &(a_{2n}, a_{2n+1}) && \text{for intervals where} && u < 1, \\ &(a_{2n+1}, a_{2n+2}) && \text{for intervals where} && u > 1. \end{aligned}$$

LEMMA 4.3. *As n increases, the minima $u(b_{2n})$ are decreasing and the maxima $u(b_{2n+1})$ are increasing.*

Proof. From the monotonicity of Φ_2 (Lemma 4.1), we deduce that

$$u(b_n) + \frac{1}{u(b_n)} \quad \text{is increasing.}$$

The lemma follows by observing that the numeric function

$$s \mapsto s + \frac{1}{s}$$

is decreasing if $0 < s < 1$ and increasing if $s > 1$.

LEMMA 4.4. *For all n,*

$$u(b_{2n+1}) - 1 \leq (a_{2n+2} - a_{2n+1})^3. \tag{4.4}$$

Proof. Observe that in the intervals where $u > 1$, we have that $\sup |u'''| \leq 1$. The lemma follows by integration, since u'', u', and $u-1$ have zeros in $[a_{2n+1}, a_{2n+2}]$.

Our next result is global existence.

THEOREM 4.5. *All solutions of problem* (II) *exist on the whole line* $\mathbf{R}$.

Proof. Let $(-\infty, b)$ be the maximal interval of existence of u. Assume (for contradiction) that $b < \infty$. We consider two cases.

Case 1. Suppose that $u - 1$ and hence u''' have infinitely many zeros near b. By Lemma 4.3

$$\lim_{n\to\infty} u(b_{2n}) \text{ exists.}$$

This limit can only be zero. Otherwise equation (4.1) implies that u''' would be bounded in a neighbourhood of b and the interval would not be maximal. Hence by Lemma 4.1 $\Phi_2(b^-) = \infty$, and by Lemma 4.3

$$\lim_{n\to\infty} u(b_{2n+1}) = \infty.$$

But this and (4.4) contradict $b < \infty$.

Case 2. If u''' has constant sign near b, then $u'(b^-)$ and $u(b^-)$ exist. As before $u(b^-) = 0$ since $(-\infty, b)$ is maximal, and $u'(b^-) \leq 0$. Furthermore, $u'(b^-) \neq -\infty$ because $u'''(b^-) = +\infty$. Thus, $u'(b^-)$ is *finite* and in a left neighbourhood of b, we have

$$u(x) \leq C(b-x).$$

This implies by equation (4.1) and one integration that

$$u'''(x) \geq \frac{C}{(b-x)^2} \qquad \text{and} \qquad u''(x) \geq \frac{C}{b-x},$$

where C denotes a positive constant, possibly a different one at each occurrence. The last inequality implies that $u'(b^-) = \infty$. This contradiction completes the proof of Theorem 4.5.

Remark. The exponent 2 in the denominator of equation (4.1) is a borderline value in the sense that the above argument of Case 2 works for the equation $u''' = -1 + 1/u^p$ if and only if $p \geq 2$ (cf. [3]).

LEMMA 4.6. *The function $u - 1$ has infinitely many zeros near $+\infty$.*

Proof. By linearization theory we know that $u - 1$ has zeros. Hence it is enough to prove that

$$u(a) = 1 \quad \Longrightarrow \exists b > a \quad \text{such that} \quad u(b) = 1.$$

Assume (for contradiction) that $u > 1$ in $(a, +\infty)$. Then $u''' < 0$ and the limits $u''(+\infty)$, $u'(+\infty)$, and $u(+\infty)$ exist. This and the differential equation (4.1) imply that

$$u'''(+\infty) = 0\,, \ u(+\infty) = 1\,, \ u'(+\infty) = 0, \ \text{and} \quad u''(+\infty) = 0.$$

Hence u'' is decreasing and positive, u' increasing and negative, and $u - 1$ decreasing and positive in $(a, +\infty)$. This contradicts $u(a) = 1$.

A similar argument excludes the possibility that $u < 1$ on (a, ∞) and completes the proof of Lemma 4.6.

LEMMA 4.7. *As $n \to +\infty$,*

$$u(b_{2n}) \to 0 \quad \textit{and} \quad u(b_{2n+1}) \to \infty.$$

Proof. By Lemma 4.3 we know that these limits exist. On the other hand, Lemma 4.1 states that Φ_4 is increasing and convex, and hence

$$\Phi_4(x) \to \infty \quad \text{as} \quad x \to +\infty. \tag{4.5}$$

Letting $x \to +\infty$ along the sequence $\{b_n\}$, we obtain that

$$u(b_n) + \frac{1}{u(b_n)} \to \infty \quad \text{as} \quad n \to +\infty,$$

from which the desired conclusions follow.

LEMMA 4.8. *The sequences $|u'(a_n)|$ and $|u''(a_n)|$ are increasing and tend to infinity as $n \to +\infty$.*

Proof. The sequences are increasing because the functions Φ_1 and Φ_3 are increasing by Lemma 4.1. Notice that $u'''(a_n) = 0$. By (4.5)

$$|u'(a_n)\, u''(a_n)| \to \infty \quad \text{as} \quad n \to +\infty. \tag{4.6}$$

Let us show that each of the factors also tends to infinity. Since the functions Φ_i of Lemma 4.1 are increasing, we may compute their limits as $x \to +\infty$ along different sequences. Considering Φ_1 and using Lemma 4.7, we obtain that as $n \to +\infty$

$$\frac{1}{2}\lim\{u'(a_n)\}^2 = \lim u''(b_{2n}),$$

while considering Φ_3 it follows that

$$\lim u''(b_{2n}) = \lim |u''(b_n)| = \lim |u''(a_n)|.$$

The last two relations and (4.6) conclude the proof.

Remark. It follows that as $x \to +\infty$, the four functions Φ_i of Lemma 4.1 tend to infinity so that the sequences $|u'(c_n)|$ and $|u''(b_n)|$ are also increasing and tend to infinity as $n \to +\infty$.

LEMMA 4.9. *We have*

$$a_{2n+2} - a_{2n+1} \to \infty \quad \textit{as} \quad n \to +\infty.$$

Proof. This limit follows at once from (4.4) and Lemma 4.7.

LEMMA 4.10. *We have*

$$a_{2n+1} - a_{2n} \to 0 \quad \textit{as} \quad n \to +\infty.$$

The proof follows from the inequality

$$1 - u(b_{2n}) > \frac{1}{4}|u'(a_{2n})|(a_{2n+1} - a_{2n}) \tag{4.7}$$

and Lemmas 4.7 and 4.8, according to which $u(b_{2n}) \to 0$, $|u'(a_{2n})| \to \infty$ as $n \to \infty$.

Proof of (4.7). We are going to perform a comparison argument in the intervals where $u < 1$. To simplify the notation we set

$$h = a_{2n+1} - a_{2n}, \quad b = b_{2n}, \quad \alpha = -u'(a_{2n}) > 0$$

and translate the origin to a_{2n}. In this setting we have that

$$u(0) = 1, \qquad u(h) = 1, \qquad u < 1 \quad \text{in} \quad (0, h),$$

and (4.7) takes the form

$$1 - u(b) > \frac{1}{4}\alpha h.$$

We define a polynomial of second degree P such that

$$P(0) = 0, \qquad P(h) = 0, \qquad P'(0) = \alpha.$$

Hence

$$P(x) = \alpha x\left(1 - \frac{x}{h}\right).$$

Next we consider the function

$$Q = 1 - u - P.$$

Since

$$Q(0) = Q(h) = Q'(0) = 0 \qquad \text{and} \qquad Q''' = -u''' < 0 \quad \text{in} \quad (0, h),$$

it readily follows that $Q > 0$ in $(0, h)$ and, in particular,

$$1 - u(b) > P(h/2) = \frac{1}{4}\alpha h.$$

This completes the proof of (4.7).

5. Properties A–F of §1. The lemmas and theorems of §4 prove all the properties of solutions of problem (II) stated in §1 as follows:

Property **A** is Theorem 4.5.

Property **B** includes Lemma 4.6; the remainder follows from a standard linearization analysis near $x = -\infty$.

Properties **C** and **D** are Lemmas 4.2, 4.3, and 4.7.

Property **E** is contained in Lemmas 4.9 and 4.10.

Property **F** is dealt with in Lemma 4.8 and its associated remark.

GLOBAL BIFURCATION OF AN ELASTIC CONDUCTING ROD IN A MAGNETIC FIELD*

PETER WOLFE †

Abstract. We study the equilibrium states of a nonlinearly elastic conducting rod in a magnetic field, a problem we have considered in several previous papers. We are now able to prove a global bifurcation theorem for this problem. To do this, two difficulties must be overcome. The first is the presence of the rotation group $SO(2)$ as a symmetry group for the problem. The second is that, for some values of certain parameters, the linearized problem is a nonstandard eigenvalue problem. The former difficulty is overcome by applying an idea due to Healey, who observed the existence of an additional symmetry in a related problem first posed by the present author. The latter problem is handled by using some nonstandard tools from functional analysis.

1. Introduction. In this paper we contine our study, begun in [6] and [7], of the equilibrium states of a nonlinearly elastic conducting rod in a magnetic field. The rod is assumed to be welded to fixed supports. The magnetic field is assumed to be constant and directed parallel to the line between the supports. The rod can undergo flexure, tension, shear, and extension. The elastic properties of the rod are embodied in the the constitutive functions which relate the strains which measure the above quantities to the contact force and contact couple. We assume the rod is homogeneous and transversely isotropic. We will also assume that the rod is hyperelastic so that the constitutive functions are derived from a strain energy function. This assumption was essential in previous work but is less so here. However it is convenient to retain this assumption. The fundamental parameter is $\lambda = IB$, where I is the current in the rod and B is the strength of the magnetic field. For all real λ there exists a trivial state in which the rod is straight and untwisted. We are interested in the existence of nontrivial solutions. This problem can be posed as a boundary value problem for a system of nonlinear ordinary differential equations. In order to study bifurcation from the trivial solution (corresponding to the trivial state), we must study the linear eigenvalue problem obtained by linearization about the trivial solution. It was at this point in our previous work that we ran into an obstruction. In order to apply the standard results of bifurcation theory [2], it is necessary that the eigenspace corresponding to an eigenvalue be one dimensional. However, in our case this condition cannot hold since the problem admits $SO(2)$ as a symmetry group. We are now able to surmount this obstruction. For this we use an idea of Healey [5]. In [5] Healey considered a problem previously posed by the present author [8], that of a rotating conducting wire in a magnetic field. Healey noticed that in addition to the $SO(2)$ symmetry, that problem also possesses a Z_2 symmetry which he called a "subtle symmetry." This observation enabled him to reduce the problem to one in which the eigenvalues of the linearized sytem are simple and thus amenable to standard global bifurcation analysis. We show

*Received by the editors February 15, 1994; accepted for publication (in revised form) July 25, 1994.

†Department of Mathematics, University of Maryland, College Park, MD 20742 (pnw@math.umd.edu).

that the same symmetry is present in our problem. Thus we are able to obtain a global bifurcation result in this case.

In the study of the linearized system in [7], we assumed that the parameters appearing in the linearized eigenvalue problem satisfy an inequality, which enabled us to use standard techniques to prove the existence of (real) eigenvalues. Here we show that, by using some nonstandard tools from functional analysis, we can mostly dispense with this condition (which from a physical point of view is completely artificial).

In §2 we will formulate the problem. In §3 we will outline the theory of global bifurcation in the presence of symmetry. In §4 we will discuss the symmetries of the problem. In §5 we will deal with the linearized problem, while in §6 we present our global bifurcation result.

Vectors (elements of three-dimensional Euclidean space E^3) will be denoted by $\mathbf{r}, \mathbf{d_p}$, etc., while elements of $\mathbf{R}^n$ (n-tuples of real numbers) will be denoted by $\boldsymbol{u}$,$\boldsymbol{v}$, etc. The summation convention will be used throughout. An equation containing an index which is not repeated (and therefore not summed) is assumed to hold for the values 1, 2, 3 of that index.

2. Formulation of the problem. Our model for the rod is the *special Cosserat theory.* In this theory, the configuration of the rod is specified by a position vector $\mathbf{r}$ and an orthonormal pair of vector functions $\mathbf{d_1}$ and $\mathbf{d_2}$ of the real variable $s \in [0,1]$. We interpret s as a scaled arclength parameter of the line of centroids of the rod (a slender three-dimensional body) in a reference configuration, so s identifies material sections of the rod. Thus $\mathbf{r(s)}$ is the position in a deformed configuration of the material point at the centroid of the section s. The vectors $\mathbf{d_1(s)}$ and $\mathbf{d_2(s)}$, which determine a plane in space and a line in that plane, characterize the deformed configuration of the section s. We set

$$\mathbf{d_3} = \mathbf{d_1} \times \mathbf{d_2} \tag{2.1}$$

to obtain an orthonormal triple, called the *directors.* Let derivatives with respect to s be denoted by primes. Since $\{\mathbf{d_p}\}$ is orthonormal there exists a vector function $\mathbf{u}$ such that

$$\mathbf{d_p'} = \mathbf{u} \times \mathbf{d_p}. \tag{2.2}$$

Conversely, given an artbitrary vector function $\mathbf{u}$, any solution $\{\mathbf{d_p}\}$ of (2.2) is orthonormal if $\{\mathbf{d_p(0)}\}$ is. The components of $\mathbf{u}$ with respect to $\{\mathbf{d_p}\}$ are

$$u_p = \frac{1}{2} e_{pqr} \mathbf{d_q'} \cdot \mathbf{d_r}, \tag{2.3}$$

where $\{e_{pqr}\}$ are components of the alternating symbol. We decompose the vector $\mathbf{r}'$ into its components with respect to the basis $\{\mathbf{d_p}\}$ by

$$\mathbf{r}' = v_p \mathbf{d_p} \tag{2.4}$$

and set

$$\boldsymbol{u} = (u_1, u_2, u_3)^T, \quad \boldsymbol{v} = (v_1, v_2, v_3)^T. \tag{2.5}$$

The triples $\boldsymbol{u}$ and $\boldsymbol{v}$ are the *strains* of the theory. They determine the configuration of the rod uniquely to within a rigid body motion by integration of (2.2) and (2.4).

The physical interpretation of these quantities is as follows: v_1 and v_2 measure the amount of shear, $v_3 = \mathbf{r}' \cdot (\mathbf{d_1} \times \mathbf{d_2})$ measures volume change, $(v_k v_k)^{1/2}$ measures axial stretch, u_1 and u_2 measure *flexure*, and u_3 measures *twist*.

Let $\{\mathbf{i_1} = \mathbf{i}, \mathbf{i_2} = \mathbf{j}, \mathbf{i_3} = \mathbf{k}\}$ represent the standard orthonormal basis for E^3. Let

$$d_{ij} = \mathbf{d_j} \cdot \mathbf{i_i}. \tag{2.6}$$

Then we may consider $D = (d_{ij})$ as an element of $SO(3)$, the group of 3×3 orthogonal matrices with determinant 1. We can then write (2.2) as

$$D' = DU, \tag{2.7}$$

where

$$U = \begin{pmatrix} 0 & -u_3 & u_2 \\ u_3 & 0 & -u_1 \\ -u_2 & u_1 & 0 \end{pmatrix}. \tag{2.8}$$

We write

$$\mathbf{r} = x_1\mathbf{i} + x_2\mathbf{j} + x_3\mathbf{k} = x_i\mathbf{i_i}. \tag{2.9}$$

Then if we set

$$\boldsymbol{r} = (x_1, x_2, x_3)^T, \tag{2.10}$$

we may rewrite (2.4) as

$$\boldsymbol{r}' = D\boldsymbol{v}. \tag{2.11}$$

For later developments it (unfortunately) becomes necessary to introduce Euler angles in order to parameterize D. The ones we introduce here are slightly different from those of [7]. Thus we set

$$D = \begin{pmatrix} c(\psi)c(\phi) - s(\psi)s(\theta)s(\phi) & -s(\psi)c(\theta) & c(\psi)s(\phi) + s(\psi)s(\theta)c(\phi) \\ s(\psi)c(\phi) + c(\psi)s(\theta)s(\phi) & c(\psi)c(\theta) & s(\psi)s(\phi) - c(\psi)s(\theta)c(\phi) \\ -c(\theta)s(\phi) & s(\theta) & c(\phi)c(\theta) \end{pmatrix}, \tag{2.12}$$

where $c(\psi) = \cos\psi$, $s(\psi) = \sin\psi$, etc. These angles are such that $\theta = \phi = \psi = 0$ corresponds to $D = I$. Also, the polar singularities occur at $\theta = (n + \frac{1}{2})\pi$. From (2.7) and (2.12),

$$\begin{aligned} u_1 &= \theta' \cos\phi - \psi' \cos\theta \sin\phi, \\ u_2 &= \phi' + \psi' \sin\theta, \\ u_3 &= \theta' \sin\phi + \psi' \cos\theta \cos\phi, \end{aligned} \tag{2.13}$$

while $\boldsymbol{v}$ can be written as a function of $\boldsymbol{r}'$ and (θ, ϕ, ψ) by rewriting (2.11) as

$$\boldsymbol{v} = D^T \boldsymbol{r}' \tag{2.14}$$

and using (2.12).

The set of admissible strains is restricted by the inequality

$$v_3 > H(u_1, u_2). \tag{2.15}$$

The inequality (2.15) is the rod-theoretic analogue of the requirement that the Jacobian of the transformation in three-dimensional kinematics be positive. Here H is a given function which depends on the cross-sectional shape. We require that H satisfies

$$\begin{gathered} H(0,0) = 0, \\ H(u_1, u_2) > 0 \text{ for } u_1^2 + u_2^2 > 0, \\ H \text{ is homogeneous of degree 1.} \end{gathered} \tag{2.16}$$

If the cross sections of the rod are disks of radius h, then

$$H(u_1, u_2) = h\sqrt{u_1^2 + u_2^2}.$$

For $s \in (0,1)$, let

$$\mathbf{n(s)} = n_k(s)\mathbf{d_k(s)} \tag{2.17}$$

be the contact force and

$$\mathbf{m(s)} = m_k(s)\mathbf{d_k(s)} \tag{2.18}$$

be the contact couple exerted by the material of $[0, s)$ on the material of $[s, 1]$ in the configuration $\{\mathbf{r}, \mathbf{d_k}\}$. We let

$$\int_s^1 \mathbf{f(t)}\, dt$$

be the resultant of all other forces exerted on the material of $[s, 1]$ in this configuration. We assume that the resultant of all other couples exerted on the material of $[s, 1]$ in this configuration is $\mathbf{0}$. Then the classical equilibrium equations for forces and moments are

$$\mathbf{n}' + \mathbf{f} = \mathbf{0}, \tag{2.19}$$

$$\mathbf{m}' + \mathbf{r}' \times \mathbf{n} = \mathbf{0}. \tag{2.20}$$

In this paper we assume that the rod is a conductor carrying a current I. There is also a constant magnetic field $\mathbf{B} = B\mathbf{k}$ present. (Recall that $\mathbf{k} = \mathbf{i_3}$.) The force on the rod is then given by

$$\mathbf{f(s)} = I\mathbf{r}'\mathbf{(s)} \times B\mathbf{k} = \lambda\mathbf{r}'\mathbf{(s)} \times \mathbf{k}, \tag{2.21}$$

where

$$\lambda = IB. \tag{2.22}$$

The elastic properties of the rod are embodied in the constitutive equations relating the stresses $\boldsymbol{m} = (m_1, m_2, m_3)^T$ and $\boldsymbol{n} = (n_1, n_2, n_3)^T$ to the strains $\boldsymbol{u}$ and

$\boldsymbol{v}$. Thus we assume that twice continuously differentiable functions $\widehat{\boldsymbol{m}}$ and $\widehat{\boldsymbol{n}}$ taking values in $\mathbf{R}^3$ are defined on the set

$$S = \{(\boldsymbol{u}, \boldsymbol{v}) \in \mathbf{R}^3 \times \mathbf{R}^3 : v_3 > H(u_1, u_2)\} \tag{2.23}$$

so that

$$\boldsymbol{m}(s) = \widehat{\boldsymbol{m}}(\boldsymbol{u}(s), \boldsymbol{v}(s)), \quad \boldsymbol{n}(s) = \widehat{\boldsymbol{n}}(\boldsymbol{u}(s), \boldsymbol{v}(s)). \tag{2.24}$$

We further assume that the rod is *hyperelastic*, meaning that there exists a *stored-energy function* $\Phi : S \to \mathbf{R}$ such that

$$\widehat{\boldsymbol{m}}(\boldsymbol{u}, \boldsymbol{v}) = \frac{\partial \Phi(\boldsymbol{u}, \boldsymbol{v})}{\partial \boldsymbol{u}}, \quad \widehat{\boldsymbol{n}}(\boldsymbol{u}, \boldsymbol{v}) = \frac{\partial \Phi(\boldsymbol{u}, \boldsymbol{v})}{\partial \boldsymbol{v}}. \tag{2.25}$$

We assume that Φ is three times continuously differentiable and convex. We assume that $\widehat{\boldsymbol{m}}$ and $\widehat{\boldsymbol{n}}$ tend to infinity as $|\boldsymbol{u}| + |\boldsymbol{v}| \to \infty$ or as $v_3 - H(u_1, u_2) \to 0$.

We also assume that the material of the rod is *transversely isotropic*, i.e.,

$$\widehat{\boldsymbol{m}}(Q\boldsymbol{u}, Q\boldsymbol{v}) = Q\widehat{\boldsymbol{m}}(\boldsymbol{u}, \boldsymbol{v}), \quad \widehat{\boldsymbol{n}}(Q\boldsymbol{u}, Q\boldsymbol{v}) = Q\widehat{\boldsymbol{n}}(\boldsymbol{u}, \boldsymbol{v}) \tag{2.26}$$

for each orthogonal matrix Q of the form

$$Q = \begin{pmatrix} Q_{11} & Q_{12} & 0 \\ Q_{21} & Q_{22} & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{2.27}$$

Finally, we assume

$$\widehat{\boldsymbol{m}}(\mathbf{0}, \boldsymbol{v}) = \mathbf{0}, \quad \hat{n}_\alpha = 0 \text{ if } v_\alpha = 0, \ \alpha = 1, 2. \tag{2.28}$$

It follows from these assumptions [1] that $\hat{m}_3$ and $\hat{n}_3$ depend on

$$u_1^2 + u_2^2, \ v_1^2 + v_2^2, \ u_1 v_1 + u_2 v_2, \ u_3, \ v_3 \tag{2.29}$$

and that $\{\hat{m}_\beta, \hat{n}_\beta, \beta = 1, 2\}$ have the form

$$\hat{m}_\beta = \hat{\sigma} u_\beta, \quad \hat{n}_\beta = \hat{\tau} v_\beta, \tag{2.30}$$

where $\hat{\sigma}$ and $\hat{\tau}$ depend on the arguments listed in (2.29). The convexity of Φ together with (2.30) implies that

$$\hat{\sigma} > 0, \quad \hat{\tau} > 0. \tag{2.31}$$

We assume that the rod is welded to fixed supports at $\mathbf{0}$ and $b\mathbf{k}$, where $b > 1$. Thus the boundary conditions are

$$\mathbf{r}(\mathbf{0}) = \mathbf{0}, \quad \mathbf{r}(\mathbf{1}) = b\mathbf{k}, \tag{2.32a}$$

$$\mathbf{d}_\mathbf{k}(\mathbf{0}) = \mathbf{i}_\mathbf{k}, \quad \mathbf{d}_\mathbf{k}(\mathbf{1}) = \mathbf{i}_\mathbf{k}. \tag{2.32b}$$

It terms of the Euler angles, (2.32b) becomes

$$\theta(0) = \phi(0) = \psi(0) = 0, \ \theta(1) = \phi(1) = \psi(1) = 0. \tag{2.32c}$$

In order to convert the equilibrium equations (2.19) and (2.20) to a form which is amenable to further analysis, we take the dot product of these equations with $\mathbf{d}_i$ and use (2.2). The result is

$$n_1' - u_3n_2 + u_2n_3 + \lambda(x_2'd_{11} - x_1'd_{21}) = 0, \tag{2.33a}$$

$$n_2' + u_3n_1 - u_1n_3 + \lambda(x_2'd_{12} - x_1'd_{22}) = 0, \tag{2.33b}$$

$$n_3' - u_2n_1 + u_1n_2 + \lambda(x_2'd_{13} - x_1'd_{23}) = 0, \tag{2.33c}$$

$$m_1' - u_3m_2 + u_2m_3 + v_2n_3 - v_3n_2 = 0, \tag{2.33d}$$

$$m_2' + u_3m_1 - u_1m_3 + v_3n_1 - v_1n_3 = 0, \tag{2.33e}$$

$$m_3' - u_2m_1 + u_1m_2 + v_1n_2 - v_2n_1 = 0. \tag{2.33f}$$

In (2.33) the arguments of $\boldsymbol{m}$ and $\boldsymbol{n}$ are $\boldsymbol{u}$ and $\boldsymbol{v}$. The convexity of Φ implies that the symmetric matrix

$$\begin{pmatrix} \partial m_i/\partial u_j & \partial m_i/\partial v_j \\ \partial n_i/\partial u_j & \partial n_i/\partial v_j \end{pmatrix} \tag{2.34}$$

is positive definite. Thus equation (2.33) can be solved for $\boldsymbol{u}'$ and $\boldsymbol{v}'$. Furthermore, as long as $|\theta| < \pi/2$, we can differentiate (2.13) and (2.14) and solve these equations for the second derivatives of $x_1, x_2, x_3, \theta, \phi, \psi$. Thus if we let

$$\boldsymbol{X} = (x_1, x_2, z, \theta, \phi, \psi)^T, \tag{2.35}$$

where

$$z(s) = x_3(s) - bs, \tag{2.36}$$

we arrive at an equation of the form

$$-\boldsymbol{X}'' = \boldsymbol{F}(\boldsymbol{X}, \boldsymbol{X}', \lambda), \tag{2.37}$$

which is equivalent to (2.33). The boundary conditions (2.32) can be restated as

$$\boldsymbol{X}(0) = \boldsymbol{X}(1) = \mathbf{0}. \tag{2.38}$$

Thus our boundary value problem consists of (2.33), (2.13), and (2.14) along with the constitutive equations (2.24) and the boundary conditions (2.32) or, alternatively, (2.37) with the boundary condition (2.38).

For every real value of λ, the problem admits a *trivial solution* in which the rod is straight and untwisted. In this solution $\boldsymbol{u} = \mathbf{0}, v_1 = v_2 = 0, v_3 = b, \mathbf{r} = bs\mathbf{k}, \theta = \phi = \psi = 0, \boldsymbol{m} = \mathbf{0}, n_1 = n_2 = 0$, and

$$n_3 = \hat{n}_3(\mathbf{0}, (0,0,b)^T) \equiv n_0, \tag{2.39}$$

where

$$n_0 > 0. \tag{2.40}$$

Inequality (2.40) is consistent with the assumption that the rod is in tension when no force is applied, that is, the assumption $b > 1$. The object of this paper is to study the existence of nontrivial solutions.

3. The global bifurcation theorem. In this section we state the global bifurcation theorem which we will use to obtain our results. We follow the treatment in [4]. For further references, please refer to that paper.

Let B be a real Banach space, Ω an open connected subset of $B \times R$ such that $(0, \lambda) \in \Omega$ for all $\lambda \in R$ and $f : \Omega \to B$ be m times Fréchet differentiable. We consider the problem

$$f(x, \lambda) = 0. \tag{3.1}$$

We wish to determine Σ, the solution set of (3.1).

We assume that (3.1) models a system characterized by a symmetry group $\mathcal{G}$. In particular, we assume that (3.1) is *equivariant* under a specific representation T of $\mathcal{G}$ on B, i.e.,

$$f(T_g x, \lambda) = T_g f(x, \lambda), \quad \forall g \in \mathcal{G}, \tag{3.2}$$

where it is assumed that if $(x, \lambda) \in \Omega$ then $(T_g x, \lambda) \in \Omega$ for all $g \in \mathcal{G}$. Let $\mathcal{H}$ be a (not necessarily proper) subgroup of $\mathcal{G}$. We define the *$\mathcal{H}$-fixed point set $B_{\mathcal{H}}$* as

$$B_{\mathcal{H}} = \{u \in B : T_g u = u \ \ \forall g \in \mathcal{H}\}.$$

If $\mathcal{H}$ is a compact group, $B_{\mathcal{H}}$ is a Banach space. We let $\Omega_{\mathcal{H}} = \Omega \cap (B_{\mathcal{H}} \times R)$. It then follows from (3.1) and (3.2) that if $(u, \lambda) \in \Omega_{\mathcal{H}}$, $g \in \mathcal{H}$, then

$$T_g f(u, \lambda) = f(T_g u, \lambda) = f(u, \lambda). \tag{3.3}$$

Thus $f(u, \lambda) \in B_{\mathcal{H}}$ for all $(u, \lambda) \in \Omega_{\mathcal{H}}$ and $f : \Omega_{\mathcal{H}} \to B_{\mathcal{H}}$. So we see that a point $(x_0, \lambda) \in \Omega_{\mathcal{H}}$ is a solution of (3.1) if and only if it is a solution of the *$\mathcal{H}$-reduced problem*

$$f_{\mathcal{H}}(u, \lambda) = 0, \tag{3.4}$$

where $f_{\mathcal{H}} = f|_{\Omega_{\mathcal{H}}}$. The solution set of (3.4), denoted by $\Sigma_{\mathcal{H}}$, is called the *$\mathcal{H}$-solution set.*

We assume that $f_{\mathcal{H}}$ has the form

$$f_{\mathcal{H}} \equiv u - c_{\mathcal{H}}(u, \lambda), \tag{3.5}$$

where $c_{\mathcal{H}} : \Omega_{\mathcal{H}} \to B_{\mathcal{H}}$ is completely continuous. Suppose

$$f(0, \lambda) = 0, \quad \forall \lambda \in R. \tag{3.6}$$

The set $\Sigma_t \equiv (\{0\} \times R)$ is called the trivial solution branch of (3.1). A solution $(0, \lambda_0) \in \Sigma_t$ is said to be a *bifurcation point* of (3.1) if every neighborhood of $(0, \lambda_0)$ contains solution pairs $(u_*, \lambda_*) \in \Sigma$ with $u_* \neq 0$. Define $L(\lambda) \equiv D_1 f(0, \lambda)$, the Fréchet derivative of f with respect to u at $(0, \lambda)$. A necessary condition for $(0, \lambda_0)$ to be a bifurcation point is that $L(\lambda_0) : B \to B$ be noninvertible.

For any subgroup $\mathcal{H} \subset \mathcal{G}$, since $0 \in B_{\mathcal{H}}$, we have

$$f_{\mathcal{H}}(0, \lambda) = 0, \ \forall \lambda \in R. \tag{3.7}$$

Suppose $L(\lambda_0)$ is singular, $y \in \mathcal{N}(L(\lambda_0))$ is such that the *isotropy subgroup* of $\mathcal{G}$ at y

$$\mathcal{H} = \{g \in \mathcal{G} \mid T_g y = y\} \tag{3.8}$$

is proper. It then follows that $L_{\mathcal{H}}(\lambda_0) = D_1 f_{\mathcal{H}}(0, \lambda_0) = L(\lambda_0)|_{B_{\mathcal{H}}}$ is singular. We then have the *equivariant bifurcation theorem.*

THEOREM 3.1 [4]. *Suppose that $f \in C^2$ and there exists a vector $y \in \mathcal{N}(L(\lambda_0))$ which defines a proper isotropy subgroup $\mathcal{H}$. Assume*

(i) $\dim \mathcal{N}(L_{\mathcal{H}}(\lambda_0))$ *is odd, and*

(ii) $L'_{\mathcal{H}}(\lambda_0)v \notin \mathcal{R}(L_{\mathcal{H}}(\lambda_0))\ \forall v \in (L_{\mathcal{H}}(\lambda_0))\backslash\{0\}$,

where prime denotes differentiation with respect to λ. Then $(0, \lambda_0)$ is a bifurcation point of (3.1) such that in every sufficiently small neighborhood of $(0, \lambda_0)$ there are nontrivial solutions $(u_*, \lambda_*) \in \Sigma_{\mathcal{H}}$. In particular, if $\dim \mathcal{N}(L_{\mathcal{H}}(\lambda_0)) = 1$, there exists a unique, local bifurcating branch of solutions of the form $\sigma \to (\hat{u}(\sigma), \hat{\lambda}(\sigma))$. Moreover there exists a connected subset $\zeta_{\mathcal{H}} \subseteq \Sigma_{\mathcal{H}} \cap \overline{\Sigma\backslash\Sigma_t}$ containing $(0, \lambda)$ that is characterized by at least one of the following properties:

(a) $\zeta_{\mathcal{H}}$ *is unbounded in $B \times R$.*

(b) $\overline{\zeta_{\mathcal{H}}} \cap \partial\Omega \neq \emptyset$

(c) *There exists a pair $(0, \lambda_*) \in \zeta_{\mathcal{H}} \cap \Sigma_t$ with $\lambda_* \neq \lambda_0$.*

The set $\zeta_{\mathcal{H}}$ is called a global $\mathcal{H}$-symmetric bifurcating branch *of* (3.1) *through* $(0, \lambda_0)$.

The rest of the paper consists of verifying that we can apply Theorem (3.1) to the problem described in §2.

4. Symmetries of the problem. In this section we examine the symmetries of the problem. There are two types of symmetry, the "obvious" rotational symmetry and the "subtle" reflection symmetry. It is the latter which we will use to obtain our results.

We first consider the action of the group $SO(2)$ on the problem. The action of an element of this group $T_\alpha, \alpha \in R(\text{mod}2\pi)$ is defined by the matrix

$$Q_\alpha = \begin{pmatrix} \cos\alpha & \sin\alpha & 0 \\ -\sin\alpha & \cos\alpha & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{4.1}$$

T_α acts on the vector $\mathbf{r}$ by counterclockwise rotation through the angle α about the x_3 axis. If $\boldsymbol{r}$ is given by (2.10), the components of $T_\alpha \mathbf{r}$ are given by $Q_\alpha \boldsymbol{r}$. Similarly, T_α acts on the triples $\boldsymbol{u}$ and $\boldsymbol{v}$ by

$$(4.2) \qquad T_\alpha(\boldsymbol{u}, \boldsymbol{v}) = (Q_\alpha \boldsymbol{u}, Q_\alpha \boldsymbol{v}).$$

The action of T_α on the matrices D and U is

$$T_\alpha D = Q_\alpha D Q_\alpha^T, \quad T_\alpha U = Q_\alpha U Q_\alpha^T. \tag{4.3}$$

(The second equation of (4.3) is equivalent to $T_\alpha \boldsymbol{u} = Q_\alpha \boldsymbol{u}$.) By (4.2), (2.24), and (2.26) it follows that

$$T_\alpha(\boldsymbol{m}, \boldsymbol{n}) = (Q_\alpha \boldsymbol{m}, Q_\alpha \boldsymbol{n}). \tag{4.4}$$

It is easily checked that if the configuration $\{\mathbf{r}, D\}$ is a solution of our problem (in the form (2.33), (2.32a,b)), so is $\{T_\alpha \mathbf{r}, T_\alpha D\}$. It does not appear that the Euler angles transform in a nice (i.e., geometric) way under the transformation T_α. Since we do not intend to use the rotational invarience in our global bifurcation theorem, we shall not identify a mapping f which is equivarient under $SO(2)$. Of course, as has been noted in [7], this $SO(2)$ symmetry is a source of difficulty when one attempts to apply standard bifurcation theory since it forces the kernel of the linearized operator (at a singular point) to have an even dimension. However, as in [5], this problem also admits a "subtle symmetry" (Healey's term), which we now describe. This symmetry corresponds to a 180° rotation of the rod about the line $x_2 = 0$, $x_3 = b/2$. If we denote this mapping by R (so that $R^2 = I$), we have

$$R(x_1, x_2, x_3)(s) = (x_1, -x_2, b - x_3)(1 - s). \tag{4.5}$$

Let

$$E = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{4.6}$$

Then R acts on the triples $\boldsymbol{u}$ and $\boldsymbol{v}$ by

$$R(\boldsymbol{u}, \boldsymbol{v})(s) = (E\boldsymbol{u}, E\boldsymbol{v})(1 - s). \tag{4.7}$$

The action of R on the matrices D and U is given by

$$RD(s) = EDE(1 - s), \quad RU(s) = -EUE(1 - s). \tag{4.8}$$

As regards the Euler angles, if we let $\Psi = (\theta, \phi, \psi)^T$, the action of R on Ψ is given by

$$R\Psi(s) = -E\Psi(1 - s). \tag{4.9}$$

Again, by (4.2), (2.24), and (2.26) with $Q = E$,

$$R(\boldsymbol{m}, \boldsymbol{n})(s) = (E\boldsymbol{m}, E\boldsymbol{n})(1 - s). \tag{4.10}$$

We are now ready to cast our problem into the form suitable for applying Theorem 3.1.

We let $C_0^1 = C_0^1[0, 1]$ be the space of continuously differentable functions vanishing at $s = 0$ and $s = 1$. For $x \in C_0^1[0, 1]$, we define

$$\|x\|_{C^1} = \max_{0 \le s \le 1} |x(s)| + \max_{0 \le s \le 1} |x'(s)|.$$

We let $B = (C_0^1[0, 1])^6$. For $\boldsymbol{X} = (\xi_1, \ldots, \xi_6)^T \in B$, we define

$$\|\boldsymbol{X}\|_B = \sum_{i=1}^{6} \|\xi_i\|_{C^1}. \tag{4.11}$$

We identify our state variables with $\boldsymbol{X} \in B$ by (2.35),(2.36). Associated with $\boldsymbol{X} \in B$ are the variables D defined by (2.12), $\boldsymbol{u}$ by (2.13), and $\boldsymbol{v}$ by (2.14). Note that when $\boldsymbol{X} = \boldsymbol{0}$, $\boldsymbol{v} = (0, 0, b)^T$. The set Ω is defined as

$$\Omega = \{(\boldsymbol{X}, \lambda) : v_3 > h(u_1, u_2), |\theta| < \pi/2, \lambda \in R\}. \tag{4.12}$$

For the mapping $\boldsymbol{f}(\boldsymbol{X}, \lambda) : \Omega \to B$, we let $K(s, t)$ be the Green's function for the problem $-x''(s) = g(s)$, $0 \le s \le 1$, $x(0) = x(1) = 0$. Then (2.37), (2.38) is equivalent to

$$\boldsymbol{f}(\boldsymbol{X}, \lambda)(s) \equiv \boldsymbol{X}(s) - \int_0^1 K(s, t)\boldsymbol{F}(\boldsymbol{X}(t), \boldsymbol{X}'(t), \lambda)\, dt = \boldsymbol{0}. \tag{4.13}$$

Clearly, $\boldsymbol{f}$ is of the form (3.5). Thus we are now ready to apply the theory of §3.

For $\boldsymbol{X} \in B$, we define $R\boldsymbol{X}$ by

$$(R\boldsymbol{X})(s) = (x_1, -x_2, -z, \theta, -\phi, -\psi)^T(1-s). \tag{4.14}$$

Remark. The transformation law for z given in (4.14) is consistent with (4.5) since $RZ(s) = R(x_3(s) - bs) = Rx_3(s) - R(bs) = b - x_3(1-s) - (b - b(1-s)) = b(1-s) - x_3(1-s) = -z(1-s)$.

We also have

$$\frac{d}{ds}(R\boldsymbol{X}))(s) = (-x_1', x_2', z', -\theta', \phi', \psi')^T(1-s) \tag{4.15}$$

THEOREM 4.1. *The mapping* (4.13) *is equivarient under the representation of* Z_2 *defined by* R, *i.e.,*

$$\boldsymbol{f}(R\boldsymbol{X}, \lambda) = R\boldsymbol{f}(\boldsymbol{X}, \lambda). \tag{4.16}$$

Proof. Observe that if the left sides of (2.33) are formed into a 6-vector (in the order in which they appear), this 6-vector is equivarient under the mapping (4.14). It follows that this equivariance is preserved in the transformation to (2.37). If we write (2.37) as

$$\boldsymbol{X}'' + \boldsymbol{F}(\boldsymbol{X}, \boldsymbol{X}', \lambda) = \mathbf{0}, \tag{4.17}$$

the transformed left-hand side of (4.17) must be of the form

$$\pm((R\boldsymbol{X})'' + \boldsymbol{f}(R\boldsymbol{X}, (R\boldsymbol{X})', \lambda)) = \mathbf{0}. \tag{4.18}$$

But by (4.15) we see that the + sign must obtain in (4.18), so the operator on the left side of (4.17) is equivariant under R. Therefore, so is $\boldsymbol{f}$. □

Thus our reduced problem consists of restricting the mapping (4.13) to functions $\boldsymbol{X} \in B$ satisfying $R\boldsymbol{X} = \boldsymbol{X}$. Note that the full symmetry group for the problem is $O(2) \simeq \{T_\alpha, RT_\alpha : \alpha \in R(\text{mod} 2\pi)\}$. We next turn to the linearization of the problem.

5. The linearized problem. In this section we will consider the linearization of the problem about the trivial solution. For this we set $\boldsymbol{r} = (0,0,bs)^T + \epsilon(x_1, x_2, x_3)^T, \boldsymbol{v} = (0,0,b)^T + \epsilon(v_1, v_2, v_3), \boldsymbol{u} = \epsilon(u_1, u_2, u_3)^T$, and $\Psi = \epsilon(\theta, \phi, \psi)^T$. Linearization of (2.12) gives $D = I + \epsilon D_1 + O(\epsilon^2)$, where

$$D_1 = \begin{pmatrix} 0 & -\psi & \phi \\ \psi & 0 & -\theta \\ -\phi & \theta & 0 \end{pmatrix}, \tag{5.1}$$

while linearization of (2.13) gives

$$u_1 = \theta', \; u_2 = \phi', \; u_3 = \psi'. \tag{5.2}$$

Finally, linearization of (2.11) yields

$$x_1' = v_1 + b\phi, \; x_2' = v_2 - b\theta, \; x_3' = v_3. \tag{5.3}$$

At the trivial solution, the matrix (2.34) is given by

$$\operatorname{diag}(\sigma, \sigma, m_{33}, \tau, \tau, n_{33}), \tag{5.4}$$

where σ and τ are the values of $\hat{\sigma}$ and $\hat{\tau}$ (defined by (2.30)) evaluated at the trivial solution, while $m_{33} = \partial m_3/\partial u_3$, $n_{33} = \partial n_3/\partial v_3$ evaluated there. Of course all the constants in (5.4) are positive. We now use (5.1)–(5.4) to linearize (2.33). The result is

$$\tau x_1'' + (n_0 - \tau b)\phi' + \lambda x_2' = 0, \tag{5.5a}$$
$$\tau x_2'' - (n_0 - \tau b)\theta' - \lambda x_1' = 0, \tag{5.5b}$$
$$n_{33} x_3'' = 0, \tag{5.5c}$$
$$\sigma\theta'' + b(n_0 - \tau b)\theta + (n_0 - \tau b)x_2' = 0, \tag{5.5d}$$
$$\sigma\phi'' + b(n_0 - \tau b)\phi - (n_0 - \tau b)x_1' = 0, \tag{5.5e}$$
$$m_{33}\psi'' = 0. \tag{5.5f}$$

The boundary conditions are

$$x_1 = x_2 = x_3 = \theta = \phi = \psi = 0 \text{ at } s = 0 \text{ and } s = 1. \tag{5.6}$$

Our linearized problem is (5.5), (5.6). Of course it follows immediately from (5.5c), (5.5f), and (5.6) that $x_3 \equiv 0$, $\phi \equiv 0$. The remaining equations can be simplified. We let

$$a = n_0 - \tau b, \quad X = x_1 + i x_2, \quad W = \theta + i\phi. \tag{5.7}$$

Then equations (5.5a), (5.5b), (5.5d), and (5.5f) can be written in *complex* form;

$$\tau X'' - iaW' - i\lambda X' = 0, \tag{5.8a}$$
$$\sigma W'' + abW - iaX' = 0. \tag{5.8b}$$

The boundary conditions become

$$X(0) = X(1) = W(0) = W(1) = 0. \tag{5.9}$$

Our problem is to find the eigenvalues of (5.8), (5.9). The form (5.8) shows that the dimension of the eigenspaces for (5.5), (5.6) must be even. This is because the dimension of an eigenspace for (5.5), (5.6) is twice the dimension of the corresponding eigenspace for (5.8), (5.9). In [7] we proved the existence of an infinite set of real eigenvalues of this system under the assumption that

$$a < \frac{1}{2}(\sqrt{b^2\tau^2 + 4\pi^2\tau\sigma} - b\tau). \tag{5.10}$$

This assumption implies that, if we write our system in the form $Au = \lambda Bu$ with u in a suitable Hilbert space, the operator A is positive definite. In this paper we show that we can, for the most part, dispense with the condition (5.10). Here we only assume

$$ab \neq n^2\pi^2\sigma, \quad n = 1, 2, 3, \ldots. \tag{5.11}$$

(It is by no means clear that the result is false if (5.11) is violated. Of course, if (5.11) is false but (5.10) holds, we can still appeal to the argument of [7].)

Under the assumption that (5.10) holds, we can solve (5.8b) for W in terms of X:

$$W = iaK_1(X'), \tag{5.12}$$

where K_1 is the Green's operator for (5.8b) with the boundary conditions $W(0) = W(1) = 0$. We next insert this into (5.8a) to obtain

$$\tau X'' + a^2 K_1(X')' - i\lambda X' = 0. \tag{5.13}$$

We let K_0 be the Green's operator which inverts the operator $\tau X''$ with the boundary conditions $X(0) = X(1) = 0$. Then (5.8), (5.9) is equivalent to

$$X + a^2 K_0[K_1(X')'] - i\lambda K_0(X') = 0. \tag{5.14}$$

We consider (5.14) on the space $H_1^0[0,1]$ equipped with the norm

$$\|x\|^2 = \int_0^1 |x'(s)|^2\, ds.$$

LEMMA 5.1. *The mapping $u \to K_0[K_1(u')']$ is self-adjoint and compact on H_1^0.*

Proof. Let $\langle \cdot, \cdot \rangle$ denote the H_1^0 inner product and $(\cdot,\cdot)$ denote the L_2 inner product, so that $\langle u, v\rangle = (u', v')$. Then if $u, v \in C^2 \cap H_1^0$, a dense subset of H_1^0,

$$\begin{aligned}\langle u, K_0[K_1(v')']\rangle &= (u', K_0[K_1(v')']') = -(u'', K_0[K_1(v')']) = -\frac{1}{\tau}(u, K_1(v')')\\ &= \frac{1}{\tau}(u', K_1(v')') = \frac{1}{\tau}(K_1(u'), v') = -\frac{1}{\tau}(K_1(u')', v) = -(K_1(u')', K_0(v''))\\ &= -(K_0[K_1(u')'], v'') = (K_0[K_1(u')']', v') = \langle K_0[K_1(u')], v\rangle.\end{aligned}$$

To prove compactness we need only count derivatives. We find that the mapping maps H_1^0 into H_3, thus is compact on H_1^0. □

LEMMA 5.2. *The mapping $u \to iK_0(u')$ is self-adjoint, compact and injective on H_1^0.*

Proof. Let u and v be as in the proof of Lemma 5.15. Then

$$\begin{aligned}\langle u, iK_0(v')\rangle &= (u', iK_0(v')') = -(u'', iK_0(v')) = -(K_0(u''), iv)') = -\frac{1}{\tau}(u, iv')\\ &= -\frac{1}{\tau}(iu', v) = -(iu', K_0(v'')) = -(iK_0(u'), v'') = -(iK_0(u')', v') = \langle iK_0(u'), v\rangle.\end{aligned}$$

The compactness and injectivity are clear. □

From Lemmas 5.1 and 5.2 we see that (5.13) can be written in the form

$$M(\lambda)u = 0, \tag{5.15}$$

where $M(\lambda)$ is the linear pencil

$$M(\lambda) = I - T - \lambda H \tag{5.16}$$

with T and H compact and self-adjoint and H injective with its set of eigenvalues square summable. Of course, if $I - T$ or H were positive definite, the spectral theory of (5.15), (5.16) would be straightforward. (This is essentially the case considered in [7].) The theory of such pencils is treated in [3, Chap. V]. This theory is a chapter in the theory of operators on an inner product space with an indefinite inner product, in particular a *Pontryagin space.*

It is shown in [3] that, without loss of generality, we may assume that $I - T$ is invertible. We then introduce a new (possibly indefinite) inner product on H_1^0 by setting

$$\{u, v\} = \langle (I - T)^{-1}u, v\rangle. \tag{5.17}$$

With respect to this inner product, the operator $A = H(I - T)^{-1}$ is self-adjoint and (5.15) is equivalent to

$$(I - \lambda A)v = 0, \quad v = (I - T)u. \tag{5.18}$$

If $I - T$ and therefore $(I - T)^{-1}$ are positive definite, then $\{u, u\}$ is equivalent to $\langle u, u\rangle$ and the usual theory applies. In the case where this is not true, we have the following result.

THEOREM 5.3 [3]. *Under the above hypotheses, we can write*

$$H_1^0 = N \oplus P,$$

where the following hold:

- *N and P are invariant subspaces with respect to the operator A.*
- *N is finite dimensional.*
- *The inner product $\{\cdot, \cdot\}$ is positive on P.*
- *The operator $A|_P$ has a complete set of eigenvectors which correspond to real eigenvalues and are orthogonal with respect to the inner product $\{\cdot, \cdot\}$.*

From this result, it follows immediately that (5.14) and hence (5.8), (5.9) have infinitely many real eigenvalues.

In the next section, when we apply all of this to prove our main result, we will need to verify condition (ii) of Theorem 3.1. We will now do this for the operator L, the linearization of (4.13). It will then hold a fortiori for the operator $L_{\mathcal{H}}$ which we shall define in the next section.

So suppose we have

$$L(\lambda)v_0 = 0, \ L'(\lambda)v_0 = L(\lambda)v_1, \ v_0, v_1 \in B, \ v_0 \neq 0, \ \lambda \neq 0. \tag{5.19}$$

The components of v_0 and v_1 are in H_1^0. Thus, if we retrace the steps which led to (5.15), (5.16), we see that (5.19) is equivalent to

$$(I - T - \lambda H)y_0 = 0, \ (I - T - \lambda H)y_0 = Hy_0, \ y_0 \neq 0. \tag{5.20}$$

We take the inner product of the second equation of (5.20) with y_0 and use the fact that $I - T - \lambda H$ is self-adjoint. The result is $\langle Hy_0, y_0\rangle = 0$. But

$$\langle Hy_0, y_0\rangle = \frac{1}{\lambda}\langle (I - T)y_0, y_0\rangle = \frac{1}{\lambda}\{(I - T)y_0, (I - T)y_0\} \neq 0$$

by Theorem 5.3 since $(I - T)y_0 \in P$. Thus we have proven the following.

PROPOSITION 5.4. *If $v \in N(L(\lambda))\backslash\{0\}$, $\lambda \neq 0$, then $L'(\lambda)v \notin R(L(\lambda))$.*

6. Global bifurcation. We are now ready to prove our main result by applying Theorem 3.1. As our subgroup of $O(2)$, $\mathcal{H}$, we of course take Z_2, whose representation on B is given by $\{I, R\}$. Thus $B_{\mathcal{H}}$ consists of all elements of B which are invariant under the mapping R defined by (4.14). We need only check that $\dim(L_{\mathcal{H}}(\lambda_0)) = 1$, where λ_0 is an eigenvalue of the linearized equation (5.8), (5.9). In terms of the complex variables X and W, the $\mathcal{H}$-invariance condition is

$$(6.1) \qquad \overline{X}(1-s) = X(s), \ \overline{W}(1-s) = W(s).$$

Now it may happen that for certain values of the parameters in (5.8), the eigenspace corresponding to an eigenvalue λ_0 has dimension greater that one (over the complex numbers). However, generically this will not happen. (In principle, the eigenvalues can be found by algebraic means since (5.8) is a system of ordinary differential equations with constant coefficients.) So let us suppose that λ_0 is an eigenvalue of (5.8), (5.9) whose eigenspace is one dimensional over C (two dimensional over R). Let $\{X(s), W(s)\}$ be an eigenfunction of (5.8), (5.9). Then there is a complex constant C such that

$$(6.2) \qquad \overline{X}(1-s) = CX(s), \ \overline{W}(1-s) = CW(s).$$

We must have $|C| = 1$. To see this, take absolute values in (6.2) and integrate from 0 to 1. Let

$$(6.3) \qquad \{X_1(s), W_1(s)\} = \alpha\{X(s), W(s)\}.$$

In order for $\{X_1, W_1\}$ to satisfy (6.1), we observe that

$$\overline{X_1}(1-s) = \overline{\alpha}\overline{X}(1-s) = \overline{\alpha}CX(s) = \frac{\overline{\alpha}}{\alpha}CX_1(s),$$

so that we must have

$$\frac{\overline{\alpha}}{\alpha}C = 1.$$

Hence $\{X_1, W_1\}$ satisfies (6.1) if

$$(6.4) \qquad \alpha = e^{i\gamma/2} \text{ where } C = e^{i\gamma}.$$

We therefore have proven the following theorem.

THEOREM 6.1 (global bifurcation theorem). *Suppose the parameters appearing in* (5.8) *satisfy* (5.10) *or* (5.11). *Then the system* (5.8), (5.9) *has an infinite set of real eigenvalues and, except for perhaps an exceptional set of these parameters, for each of these eigenvalues λ, the point $(\mathbf{0}, \lambda)$ is a bifurcation point for the problem* (2.32), (2.33). *Moreover, there is a global bifurcating branch $\zeta_{\mathcal{H}}$ of solutions through $(\mathbf{0}, \lambda)$ which are invariant under the mapping* (4.14). *$\zeta_{\mathcal{H}}$ is at least locally a curve and satisfies the conclusion of Theorem* 3.1 *where Ω is defined by* (4.12).

Remarks.

1. It seems likely that (5.11) is needed only for the proof we give, and even if it is violated, the conclusion of Theorem 6.1 remains valid. Likewise, if for some value of the parameters (5.8), (5.9) does have an eigenvalue of complex multiplicity greater than one, most of the eigenvalues should be simple.

2. Since the Euler angles represent local coordinates on $SO(3)$, it should be possible to remove the restriction $|\theta| < \pi/2$ from the definition of Ω.
3. By the rotational invariance, if $(\boldsymbol{X}, \lambda) \in \zeta_{\mathcal{H}}$, then $(T_\alpha \boldsymbol{X}, \lambda)$ is a solution of the problem. Thus the branch of solutions bifurcating from $(\mathbf{0}, \lambda)$ is, in fact, $\zeta_{\mathcal{H}} \times R(\mathrm{mod} 2\pi)$.

ON SEMILINEAR PROBLEMS WITH NONLINEARITIES DEPENDING ONLY ON DERIVATIVES*

A. CAÑADA[†] AND P. DRÁBEK[‡]

Abstract. In this paper we deal with the semilinear boundary value problems (BVPs)

$$u''(t) + \lambda_1 u(t) + g(t, u'(t)) = f(t), \ t \in I, \ \ (Bu)(t) = 0, \ \ t \in \partial I,$$

where $I = [0, \pi]$, B denotes either the Dirichlet or the Neumann or the periodic boundary conditions, respectively, and λ_1 is the first eigenvalue of the corresponding linear problem

$$u'' + \lambda u(t) = 0, \ \ t \in I, \ \ (Bu)(t) = 0, \ \ t \in \partial I.$$

This kind of problem is very important in applications where the quantity $g(t, u')$ may be regarded as a nonlinear damping term. The nonlinear function g is supposed to be bounded and, in some cases, satisfies additional differentiability assumptions and asymptotic conditions. We emphasize the dependence of g on the derivative of the solution $u'(t)$ in order to show the qualitative difference of this case and the "classical" Landesman–Lazer-type problem in which the nonlinearity g depends only on the solution $u(t)$.

Key words. semilinear boundary value problems, ordinary differential equations of second order, solvability, nonlinear damping, bounded nonlinearities, alternative method

AMS subject classifications. 34B15, 34C25

1. Introduction.

In this paper we study semilinear problems of the type

$$\begin{cases} u''(t) + \lambda_1 u(t) + g(t, u'(t)) = f(t), & t \in I, \\ (Bu)(t) = 0, & t \in \partial I, \end{cases} \tag{1.1}$$

where I is a closed interval $[0, \pi]$, B denotes either the *Dirichlet boundary conditions*

$$u(0) = u(\pi) = 0, \tag{1.2}$$

or the *Neumann boundary conditions*

$$u'(0) = u'(\pi) = 0, \tag{1.3}$$

or the *periodic boundary conditions*

$$u(0) = u(\pi), \ u'(0) = u'(\pi), \tag{1.4}$$

respectively, and λ_1 is the first eigenvalue of the eigenvalue problem

$$\begin{cases} u'' + \lambda u(t) = 0, & t \in I, \\ (Bu)(t) = 0, & t \in \partial I. \end{cases} \tag{1.5}$$

The main purpose of this work is to *emphasize the qualitative difference* between our case and the "classical" Landesman–Lazer-type problem where the nonlinearity g depends only on the solution u and not on its derivative u'. This qualitative difference

will be shown by describing the range of the operator $u''(t)+\lambda_1 u(t)+g(t,u'(t))$ (under $(Bu)(t)=0$) and then comparing the obtained results with the corresponding ones for the case $g(t,u(t))$. Our paper is not an exhaustive treatment of the problems of this kind (in fact, after reading §4 of this paper, one would have the impression that such a paper would be too long); we deal only with the case of ordinary differential equations (ODEs) of the second order and with the boundary conditions of the type (1.2)–(1.4). Note that the *techniques* used here are *typical for ODEs.* In the case of Neumann or periodic boundary value problems (BVPs), respectively, we use the *shooting method* (more precisely, the continuous dependence of the solution of an associated initial-value problem on the parameter and on the initial conditions, and some differentiability property of this dependence—see, e.g., [7]). The Dirichlet problem is studied by an *alternative method* combined with the method of *lower* and *upper* solutions (which should also be applied in the case of partial differential equations (PDEs)) but here we use *essentially the shape* of the *first eigenfunction* $\sin t$ and *its derivative* $\cos t$.

Many *natural questions* arise during the proofs; that is why we formulate some of them explicitly *in the last section* of this paper.

It should be also mentioned here that this is not the first attempt to give some satisfactory answer to the question of solvability of problems like (1.1). Motivated by the celebrated papers [15] and [13], various authors dealt with semilinear problems where the nonlinearity depends not only on the solution but also on the derivatives (or on the gradient) of it. Let us mention, e.g., papers [3], [4], [9], [19], [6], and [5]. In all these papers different variants of Landesman–Lazer conditions were considered in order to give (at least) sufficient conditions for the solvability of investigated BVPs (for analogous results concerning the nonlinearity g depending only on the solution u we refer the reader to [8] and [10] and to the references therein). However, these results were not completely satisfactory, because they do not allow one to deal with the most simple case $g=g(u')$ (i.e., g does not depend on t). Thus it was not clear up to now how to characterize the solvability of the BVP

$$\begin{gathered} u''(t)+u(t)+g(u'(t))=f(t), \quad t\in(0,\pi), \\ u(0)=u(\pi)=0 \end{gathered}$$

(see [3]) or related problems with boundary conditions (1.3) and (1.4), respectively.

Note that semilinear problems of the type (1.1) are very important in applications. Let us mention the problems arising in viscosity, nonlinear oscillations, electric circuits, etc. The term $g(u')$ may be regarded as a *nonlinear damping term* in *resonance problems* and it appears, e.g., in Rayleigh's equation (which is closely connected with a theory of oscillation of a violin string), in oscillations of a simple pendulum under the action of viscous damping, in dry (or Coulomb) friction (which occurs when the surfaces of two solids are in contact and in relative motion without lubrication), and in some cases of van der Pol oscillators. (Refer to [11], [20], [14], and [18] for bibliography).

2. Preliminaries. Let us assume that $g: I\times\mathbb{R}^2\to\mathbb{R}$ is a continuous function, bounded by a constant $M>0$:

$$|g(t,\eta,\xi)|\le M \tag{2.1}$$

for $t\in I$ and $(\eta,\xi)\in\mathbb{R}^2$. Consider the BVP

$$\left\{\begin{aligned} u''(t)+\lambda_1 u(t)+g(t,u(t),u'(t))&=f(t), \quad t\in I, \\ (Bu)(t)&=0, \quad t\in\partial I. \end{aligned}\right. \tag{2.2}$$

Let $u_1 = u_1(t)$ be the *positive eigenfunction* associated with $\lambda = \lambda_1$ of the eigenvalue problem (1.5), which satisfies $\int_0^\pi u_1^2(t)dt = 1$.

PROPOSITION 2.1. *Let $f \in C(I)$ be written in the form $f(t) = su_1(t) + \tilde{f}(t)$, $s \in$ $\mathbb{R}$, $\tilde{f} \in C(I)$, $\int_0^\pi \tilde{f}(t)u_1(t)dt = 0$. Then, for any $\tilde{f}$ there exists a nonempty, connected, and bounded set $\mathcal{J}_{\tilde{f}} \subset \mathbb{R}$ such that the BVP (2.2) has at least one solution $u \in C^2(I)$ if and only if $s \in \mathcal{J}_{\tilde{f}}$.*

Sketch of the proof of Proposition 2.1. Let Z denote the Banach space $Z = C(I)$ with the norm $\|z\|_0 = \max_{t\in I} |z(t)|$ for any $z \in Z$. By U we denote the Banach space $U = \{u \in C^1(I) : (Bu)(t) = 0,\ t \in \partial I\}$ with the norm $\|u\|_1 = \max\{\|u\|_0, \|u'\|_0\}$. If we define $L : \mathrm{dom}L \subset U \to Z$ by $\mathrm{dom}L = \{u \in U : \ u \in C^2(I)\}$, $Lu = u'' + \lambda_1 u$ and $N : \ U \to Z$ by $(Nu)(t) = f(t) - g(t, u(t), u'(t))$, for any $u \in U$, and $t \in I$, then our problem (2.2) is equivalent to solving the operator equation $Lu = Nu$. It is well known (see, e.g., [10]) that there exist continuous projections $P : \ U \to U$ and $Q : \ Z \to Z$ such that $Lu = Nu$ is equivalent to the alternative system

$$u - Pu = K(I - Q)Nu,$$

$$QNu = 0,$$

where K is the (continuous) inverse of the mapping $L : \ \mathrm{dom}L \cap \mathrm{Ker}P \to \mathrm{Im}L \equiv \mathrm{Ker}Q$. Now, writing $u \in U$ in the form $u(t) = cu_1(t) + v(t)$, $c \in \mathbb{R}$, $\int_0^\pi v(t)u_1(t)\ dt = 0$, the BVP (2.2) is equivalent to the system

$$v = K(I - Q)N(cu_1(\cdot) + v), \tag{2.3}$$

$$QN(cu_1(\cdot) + v) = 0. \tag{2.4}$$

Applying the Schauder fixed-point theorem we get that for any fixed $c \in \mathbb{R}$ there exists at least one $v_c \in U \cap C^2(I)$ such that (2.3) holds (see, e.g., [10]).

Equation (2.4) is now

$$QN(cu_1(\cdot) + v_c) = 0,$$

which, taking into account the expression for Q (see again [10]), becomes

$$\int_0^\pi g(t, cu_1(t) + v_c(t), cu_1'(t) + v_c'(t))u_1(t)\ dt = s. \tag{2.4a}$$

Hence, for a given $\tilde{f} \in C(I)$, $\int_0^\pi \tilde{f}(t)u_1(t)\ dt = 0$, the BVP (2.2) with $f(t) = su_1(t) + \tilde{f}(t)$ has at least one solution if and only if s belongs to the range of the (multivalued, in general) function $\Gamma_{\tilde{f}} : \mathbb{R} \to \Gamma_{\tilde{f}}(\mathbb{R})$,

$$\Gamma_{\tilde{f}}(c) = \int_0^\pi g(t, cu_1(t) + v_c(t), cu_1'(t) + v_c'(t))u_1(t)\ dt, \tag{2.5}$$

where $v_c \in \{v \in U \cap C^2(I) : \ v \text{ is a solution of (2.3) for fixed } c\}$. But $\mathcal{J}_{\tilde{f}} \equiv \Gamma_{\tilde{f}}(\mathbb{R})$ is a connected set. In fact, let s^* and $s^\sharp$ belong to $\mathcal{J}_{\tilde{f}}$ and $s^* \leq s^\sharp$. Then the BVP (2.2) with $f^* = s^*u_1 + \tilde{f}$ and $f^\sharp = s^\sharp u_1 + \tilde{f}$ has solutions u^* and $u^\sharp$, respectively. If we consider now the BVP (2.2) with $f = su_1 + \tilde{f}$, where $s \in [s^*, s^\sharp]$, then u^* is an upper solution and $u^\sharp$ is a lower solution to this problem. Due to a result in [1], there exists at least one solution, i.e., s belongs to $\mathcal{J}_{\tilde{f}}$. Moreover, since g is bounded, the range of $\Gamma_{\tilde{f}}$ is bounded.

Remark 2.1. The proof of Proposition 2.1 is based on the alternative method (see, e.g., [10]) and on an interesting result related to the method of lower and upper solutions due to the authors in [1]. In fact, it follows from [1] that the same assertion as in Proposition 2.1 holds true also for *more general* BVPs of the type

$$\begin{aligned} \Delta u + \lambda_1 u + g(x,u,\nabla u) = f(x) \quad &\text{in} \quad \Omega,\\ Bu = 0 \quad &\text{on} \quad \partial\Omega, \end{aligned}$$

with g bounded.

Remark 2.2. Note that we have used the fact that *existence* for the BVP (2.2) follows even if u^* and $u^\sharp$ *are not ordered* (see [1]). The periodic problem is not considered in [1] but the reasoning is the same.

Remark 2.3. Further information concerning the properties of the "solution set" $\mathcal{J}_{\tilde{f}}$ from Proposition 2.1 will be obtained from the *concrete form* of the nonlinearity g in next section. For this purpose, it is useful to define $s_1(\tilde{f}) = \inf \mathcal{J}_{\tilde{f}}$, $s_2(\tilde{f}) = \sup \mathcal{J}_{\tilde{f}}$.

Remark 2.4. We must also remark that the bounded interval $\mathcal{J}_{\tilde{f}}$ may be open, or closed, or open from below and closed from above (or vice versa) (see next section).

3. Main results. Let us point out that there are *many results* concerning the structure of the range of a multivalued function $\Gamma_{\tilde{f}}$ in the case when *nonlinearity g does not depend on the derivative* of the solution u'. One of the most illustrative characterizations of the range of $\Gamma_{\tilde{f}}$ is given by Landesman–Lazer-type conditions formulated at first in [13]. This result has been generalized in many subsequent papers (see the bibliographies in [10] and [8]). Many papers document that the structure of the right-hand sides f for which the BVP (2.2) has at least one solution is closely related to the shape of nonlinearity g and to its qualitative properties (the growth or limits at infinity, smoothness, oscillatory properties, sign condition, etc.).

On the other hand there are *few results* for the case when *nonlinearity g depends also on the derivative.* Only several attempts have been made to adopt Landesman–Lazer-type conditions to guarantee the solvability of (2.2). However, in these cases either the fact that $g = g(t,u,u')$ depends also on u is essential (see, e.g., [9]), or an additional monotonicity hypothesis on g is considered (see [19]), or a suitable dependence of g on $t \in I$ is required (see, e.g., [3, 4]). To illustrate the latter case let us consider the BVP (1.1), where $\lambda_1 = 1$ and B denotes the Dirichlet boundary condition. Then the Landesman–Lazer-type conditions

$$\begin{aligned} &\int_0^{\pi/2} g(t,+\infty)\sin t\,dt + \int_{\pi/2}^{\pi} g(t,-\infty)\sin t\,dt < \int_0^{\pi} f(t)\sin t\,dt \\ &\qquad < \int_{\pi/2}^{\pi} g(t,+\infty)\sin t\,dt + \int_0^{\pi/2} g(t,-\infty)\sin t\,dt \end{aligned} \tag{3.1}$$

are sufficient for the solvability of (1.1) (see [3, 4]) (here we denote $g(t,\pm\infty) = \lim_{\xi\to\pm\infty} g(t,\xi)$). Observe that if, moreover,

$$\begin{aligned} g(t,+\infty) < g(t,u'), &\quad \forall t \in (0,\pi/2), \quad \forall u' \in \mathbb{R},\\ g(t,-\infty) < g(t,u'), &\quad \forall t \in (\pi/2,\pi), \quad \forall u' \in \mathbb{R},\\ g(t,+\infty) > g(t,u'), &\quad \forall t \in (\pi/2,\pi), \quad \forall u' \in \mathbb{R},\\ g(t,-\infty) > g(t,u'), &\quad \forall t \in (0,\pi/2), \quad \forall u' \in \mathbb{R}, \end{aligned}$$

then the previous condition is not only sufficient but also necessary to the solvability of (1.1). So that, if for $f \in C(I)$ we write $f(t) = s\sqrt{2/\pi}\sin t + \tilde{f}(t)$,

$s = \sqrt{2/\pi}\int_0^\pi f(t)\sin t\,dt$, $\int_0^\pi \tilde{f}(t)\sin t\,dt = 0$, then (1.1) has solution if and only if $s \in (s_1(\tilde{f}), s_2(\tilde{f}))$, where

$$s_1(\tilde{f}) = \sqrt{\frac{2}{\pi}}\left[\int_0^{\pi/2} g(t,+\infty)\sin t\,dt + \int_{\pi/2}^{\pi} g(t,-\infty)\sin t\,dt\right],$$

$$s_2(\tilde{f}) = \sqrt{\frac{2}{\pi}}\left[\int_{\pi/2}^{\pi} g(t,+\infty)\sin t\,dt + \int_0^{\pi/2} g(t,-\infty)\sin t\,dt\right]$$

(realize that now $s_1(\tilde{f})$ and $s_2(\tilde{f})$ are both independent of $\tilde{f}$!), which shows that $\mathcal{J}_{\tilde{f}}$, in Proposition 2.1, may be open.

However, it should be verified immediately that *conditions* (3.1) *are empty* in the case $g = g(u')$ (i.e., when g does not depend on t). Hence this approach does not apply in this more simple case, which establishes a deep difference with respect to the case where g depends only on u.

It appears that the question of *solvability* of the BVP

$$\begin{aligned} u''(t) + \lambda_1 u(t) + g(u'(t)) &= f(t), \quad t \in I,\\ (Bu)(t) &= 0, \quad t \in \partial I \end{aligned}$$

is *qualitatively different* from the case

$$\begin{aligned} u''(t) + \lambda_1 u(t) + g(u(t)) &= f(t), \quad t \in I,\\ (Bu)(t) &= 0, \quad t \in \partial I. \end{aligned}$$

Since this difference depends essentially on the type of boundary conditions, we consider separately B of the forms (1.2), (1.3), and (1.4).

3.1. The Dirichlet problem. Let us study the BVP

$$\left\{\begin{aligned} u''(t) + u(t) + g(u'(t)) &= f(t), \quad t \in (0,\pi),\\ u(0) &= u(\pi) = 0. \end{aligned}\right. \tag{3.2}$$

We will consider nonlinear function g which will document the difference between the situation considered here and in [13].

In this subsection we will write the right-hand side of the BVP (3.2) in the following form:

$$f(t) = s\sqrt{\frac{2}{\pi}}\sin t + \tilde{f}(t),\ \ s \in \mathbb{R},\quad \int_0^\pi \tilde{f}(t)\sin t\,dt = 0.$$

THEOREM 3.1. *Let g be a bounded and continuous real function of a real variable satisfying $g(+\infty) = g(-\infty)$ and $g(\xi) < g(+\infty)$ for any $\xi \in \mathbb{R}$. Then for any $\tilde{f} \in C(I)$, $\int_0^\pi \tilde{f}(t)\sin t\,dt = 0$ there exists a real number $g_{\tilde{f}} < 2\sqrt{2/\pi}g(+\infty)$ such that the Dirichlet BVP* (3.2) *has at least one solution $u \in C^2(I)$ if and only if*

$$s \in \left[g_{\tilde{f}}, 2\sqrt{\frac{2}{\pi}}g(+\infty)\right).$$

Proof. The starting point is Proposition 2.1. First, note that now $u_1(t) = \sqrt{2/\pi}\sin t$. Due to the considerations in the sketch of the proof of Proposition 2.1, it is sufficient to show that for a given $\tilde{f} \in C(I)$, $\int_0^\pi \tilde{f}(t)\sin t\, dt = 0$ we have

$$\Gamma_{\tilde{f}}(\mathbb{R}) = \left[g_{\tilde{f}}, 2\sqrt{\frac{2}{\pi}}g(+\infty)\right).$$

The (possibly multivalued) function $\Gamma_{\tilde{f}}$ has the following form:

$$\Gamma_{\tilde{f}}(c) = \sqrt{\frac{2}{\pi}}\int_0^\pi g(c\cos t + v_c'(t))\sin t\, dt,$$

where $c \in \mathbb{R}$ and $v_c \in C^2(I)$ verify the equation (2.3). In particular, it follows from the boundedness of g that there exists a constant $D > 0$ such that

$$\|v_c\|_{C^1} \leq D \tag{3.3}$$

for any $c \in \mathbb{R}$ (see, e.g., [10] for related estimates). Thus we have

$$c\cos t + v_c'(t) \to \pm\infty \text{ for } t \in \left(0, \frac{\pi}{2}\right) \text{ and } c \to \pm\infty,$$

$$c\cos t + v_c'(t) \to \mp\infty \text{ for } t \in \left(\frac{\pi}{2}, \pi\right) \text{ and } c \to \pm\infty.$$

Applying the Lebesgue-dominated convergence theorem we obtain

$$\int_0^\pi g(c\cos t + v_c'(t))\sin t\, dt \to \int_0^{\pi/2} g(\pm\infty)\sin t\, dt + \int_{\pi/2}^\pi g(\mp\infty)\sin t\, dt \tag{3.4}$$

for $c \to \pm\infty$. Due to $g(+\infty) = g(-\infty)$ we get

$$\Gamma_{\tilde{f}}(c) \to 2\sqrt{\frac{2}{\pi}}g(+\infty) \text{ for } c \to \pm\infty.$$

The assumption $g(\xi) < g(+\infty)$, $\xi \in \mathbb{R}$, and (3.3) yield

$$\Gamma_{\tilde{f}}(c) < 2\sqrt{\frac{2}{\pi}}g(+\infty)$$

for any $c \in \mathbb{R}$. Let us denote

$$g_{\tilde{f}} = \inf_{c\in\mathbb{R}} \Gamma_{\tilde{f}}(c).$$

It is sufficient to prove that this infimum is achieved. We use the standard compactness argument. Let $\{s_n\} \subset \Gamma_{\tilde{f}}(\mathbb{R})$ be such that $s_n \to g_{\tilde{f}}$ and $\{c_n\}$ be the corresponding minimizing sequence, i.e., $u_n = c_n\sqrt{2/\pi}\sin t + v_{c_n}(t)$ are the solutions of the BVP (3.2) with the right-hand sides $f_n = s_n\sqrt{2/\pi}\sin t + \tilde{f}(t)$. Then the sequence $\{c_n\}$ is bounded due to $g(\xi) < g(+\infty)$, $\xi \in \mathbb{R}$, (3.3), and (3.4). Applying a standard compactness argument usual in alternative methods (see, e.g., [10]), we show that $c_n \to c$ (at least for a subsequence) and that $u(t) = c\sqrt{2/\pi}\sin t + v_c(t)$ is a solution of the BVP (3.2) with $f(t) = g_{\tilde{f}}\sqrt{2/\pi}\sin t + \tilde{f}(t)$. Hence the infimum is achieved in c. □

Remark 3.1. The necessary and sufficient condition from Theorem 3.1 can be written in the following equivalent form:

$$\sqrt{\frac{\pi}{2}}g_{\tilde{f}} \leq \int_0^\pi f(t)\sin t\, dt < 2g(+\infty). \tag{3.5}$$

Note that the solvability is determined not only by the asymptotic behavior of g but also that the behavior of g on bounded intervals in $\mathbb{R}$ is essential (a similar result for the case where g depends only on u may be seen in [2], which shows that, in some particular cases, the solvability of problem (3.2) may be like the case $g = g(u)$). Observe also that $g_{\tilde{f}}$ depends, in general, on $\tilde{f}$. The exact determination of $g_{\tilde{f}}$, for g and $\tilde{f}$ in general seems to be a difficult question.

Example 3.1. Let $g(\xi) = \arctan\xi$ for $\xi \geq 0$, $g(\xi) = g(-\xi)$ for $\xi < 0$. Then the condition (3.5) has the form

$$\sqrt{\frac{\pi}{2}}g_{\tilde{f}} \leq \int_0^\pi f(t)\sin t\, dt < \pi,$$

where $0 \leq g_{\tilde{f}} < \sqrt{2\pi}$ for any $\tilde{f} \in C(I)$, $\int_0^\pi \tilde{f}(t)\sin t\, dt = 0$. Moreover, it should be easily verified that $g_{\tilde{f}} = 0$ for $\tilde{f} \equiv 0$ in $(0, \pi)$.

Remark 3.2. The assumptions on g from Theorem 3.1 imply that the "solution set" $\mathcal{J}_{\tilde{f}}$ is an interval

$$\mathcal{J}_{\tilde{f}} = [s_1(\tilde{f}), s_2(\tilde{f})).$$

Considering nonlinearity $-g$ in Theorem 3.1, we obtain that $\mathcal{J}_{\tilde{f}}$ is of the following form:

$$\mathcal{J}_{\tilde{f}} = (s_1(\tilde{f}), s_2(\tilde{f})].$$

Last, it is clear that if $g \equiv 0$, then $s_1(\tilde{f}) = s_2(\tilde{f}) = 0$, and in this case $\mathcal{J}_{\tilde{f}}$ is a degenerated interval.

As we have pointed out in Theorem 3.1, the solvability of problem (3.2) may be, in some particular cases, like the case $g = g(u)$. The following result (where $g(-\infty) \neq g(+\infty)$ is allowed) shows that in other situations the conditions for solvability of (3.2) may be completely different with respect to the case $g = g(u)$ (see Proposition 6.4 in [2]).

THEOREM 3.2. *Let g be a bounded and continuous function satisfying*

$$g(0) = 0 < g(+\infty) + g(-\infty).$$

Then, there exist two numbers $g_1 \leq 0$, $g_2 \geq \sqrt{(2/\pi)}(g(+\infty) + g(-\infty))$ such that the BVP

$$\begin{aligned} u''(t) + u(t) + g(u'(t)) &= s\sqrt{\tfrac{2}{\pi}}\sin t, \quad t \in (0, \pi), \\ u(0) \;=\; u(\pi) &= 0 \end{aligned}$$

satisfies

(i) *If* $s \in [g_1, g_2)$, *it has a solution.*

(ii) *If* $s \notin [g_1, g_2]$, *it has no solution.*

Proof. As in Theorem 3.1, we have

$$\Gamma_0(c) \to \sqrt{\frac{2}{\pi}}(g(+\infty) + g(-\infty)) \text{ for } c \to \pm\infty.$$

Since $g(0) = 0$, $0 \in \Gamma_0(0)$, which proves that $g_1 \equiv \inf_{c \in \mathbb{R}} \Gamma_0(c) = s_1(0)$ verifies $g_1 \leq 0 < \sqrt{(2/\pi)}(g(+\infty) + g(-\infty))$. Again, as in Theorem 3.1, one may see that g_1 is achieved, i.e., $g_1 \in \Gamma_0(\mathbb{R})$. So, the theorem is proved if we denote $g_2 \equiv \sup_{c \in \mathbb{R}} \Gamma_0(c) = s_2(0)$. □

The case where $g_1 = 0$, $g_2 = \sqrt{(2/\pi)}(g(+\infty) + g(-\infty))$ is possible (see Theorem 3.1 and Example 3.1).

3.2. The Neumann problem. Let us study the BVP

$$\left\{ \begin{array}{l} u''(t) + g(u'(t)) = f(t), \ t \in (0,\pi), \\ u'(0) \ = u'(\pi) = 0. \end{array} \right. \tag{3.6}$$

In this case $\lambda_1 = 0$ and $u_1 \equiv 1/\sqrt{\pi}$. It should be mentioned here that the alternative method does not provide enough information concerning the structure of the "solution set" $\mathcal{J}_{\tilde{f}}$. This is due to the fact that u_1 is a constant function and consequently $u_1' = 0$, which means that we cannot obtain information from the alternative equation (2.4). Instead, we apply a change of variables and then a shooting method.

It is possible to observe immediately that the solution of the BVP (3.6) is invariant under the translation $v = u + c$, where $c \in \mathbb{R}$ is an arbitrary constant, i.e., u is the solution of (3.6) if and only if v is the solution of (3.6). Thus we can restrict ourselves to the functions with mean value zero. Let us denote $\tilde{C}^i(I) = \{u \in C^i(I); \int_0^\pi u(t)\,dt = 0\}$, $i = 0, 1, 2$ with the norm $\|\cdot\|_i$, where $\|\cdot\|_0$ means the uniform norm, $\|u\|_1 = \|u\|_0 + \|u'\|_0$, and $\|u\|_2 = \|u\|_0 + \|u'\|_0 + \|u''\|_0$. For $u \in \tilde{C}^2(I)$ let us introduce a new function, $w \in C^1(I)$, by $w(t) = u'(t)$. Then the BVP (3.6) transforms to

$$w'(t) + g(w(t)) = f(t), \ t \in (0,\pi), \ w(0) = w(\pi) = 0. \tag{3.7}$$

Let us split the right-hand side $f \in C(I)$ as follows:

$$f(t) = s + \tilde{f}(t), \ s \in \mathbb{R}, \ \tilde{f} \in \tilde{C}(I). \tag{3.8}$$

Define the map $\mathcal{F} : C^1(I) \times \mathbb{R} \times \tilde{C}(I) \to C^1(I) \times \mathbb{R}$ in the following way:

$$\mathcal{F}(w, s, \tilde{f}) = \begin{pmatrix} F_1(w, s, \tilde{f}) \\ F_2(w, s, \tilde{f}) \end{pmatrix} = \begin{pmatrix} w(t) - st - \int_0^t \tilde{f}(\tau)\,d\tau + \int_0^t g(w(\tau))\,d\tau \\ w(\pi) \end{pmatrix}.$$

Let us assume that $g : \mathbb{R} \to \mathbb{R}$ satisfies

$$|g(\xi)| \leq M \tag{3.9}$$

for any $\xi \in \mathbb{R}$ with some constant $M > 0$.

THEOREM 3.3. *Let g be a continuously differentiable function satisfying* (3.9) *and let $f(t)$ in* (3.6) *be of the form* (3.8). *Then for any $\tilde{f} \in \tilde{C}(I)$ there exists precisely one $s = s(\tilde{f})$ such that* (3.6) *has a solution. In this case, the Neumann BVP* (3.6) *has a family of solutions*

$$u_c(t) = u(t) + c;$$

$c \in \mathbb{R}$ is arbitrary, where

$$u(t) = \int_0^t w_{s(\tilde f)}(\tau)\,d\tau,$$

and $w_{s(\tilde f)}$ is the unique solution of (3.7). *Moreover, the map $\tilde C(I) \to \mathbb{R}$, $\tilde f \to s(\tilde f)$ is continuously differentiable and $s(\tilde f) \in [-M, M]$ for any $\tilde f \in \tilde C(I)$.*

Proof. The idea of the proof consists in the application of the implicit function theorem to $\mathcal{F}$. Note that $\mathcal{F}(w, s, f) = \boldsymbol{o}$ is equivalent to (3.7). Let us divide the proof into two steps.

Step 1. For any $\tilde f \in \tilde C(I)$ there exist precisely one $s = s(\tilde f) \in [-M, M]$ and $w = w_{s(\tilde f)} \in C^1(I)$ such that

$$\mathcal{F}(u_{s(\tilde f)}, s(\tilde f), \tilde f) = \boldsymbol{o}. \tag{3.10}$$

Consider the initial-value problem (IVP)

$$w'(t) = s + \tilde f(t) - g(w(t)), \qquad t \in [0, \pi], \qquad w(0) = 0, \tag{3.11}$$

with parameter $s \in \mathbb{R}$. The existence and uniqueness theorems and the continuous dependence of the solution to the IVP (3.11) on the parameter s (see, e.g., [7]) yield the following facts: the solution $w = w_s$ of the IVP (3.11) is uniquely determined and depends continuously on $s \in \mathbb{R}$. In particular, $\varphi(s) = w_s(\pi)$ is well defined and it is a continuous function. It follows from (3.11) that

$$w_s(t) = st + \int_0^t \tilde f(\tau)\,d\tau - \int_0^t g(w_s(\tau))\,d\tau, \qquad t \in [0, \pi],$$

and hence we have

$$\varphi(s) > 0 \text{ for } s > M \text{ and } \varphi(s) < 0 \text{ for } s < -M, \tag{3.12}$$

due to (3.9). To prove Step 1 it is sufficient to show that $\varphi'(s) > 0$ for any $s \in \mathbb{R}$. Really, then, this fact together with (3.12) and the continuity of φ imply the existence of a unique $s \in [-M, M]$ satisfying $\varphi(s) = w_s(\pi) = 0$. Let us fix $s_0 \in \mathbb{R}$. Since the right-hand side of (3.11) is a continuously differentiable function of variables s and w, we obtain (see [7]) that $w_s = w_s(t)$ is a continuously differentiable function of s and, moreover, $\frac{dw_s(t)}{ds}\big|_{s=s_0}$ is the solution of the linear IVP

$$\begin{aligned} z'(t) &= 1 - g'(w_{s_0}(t))z(t), \\ z(0) &= 0. \end{aligned} \tag{3.13}$$

Then

$$\left.\frac{dw_s(t)}{ds}\right|_{s=s_0} = \int_0^t e^{\int_0^\tau g'(w_{s_0}(\sigma))\,d\sigma}\,d\tau \cdot e^{-\int_0^t g'(w_{s_0}(\tau))\,d\tau}.$$

In particular, it follows from here that $\frac{dw_s(\pi)}{ds}\big|_{s=s_0} > 0$, i.e., $\varphi'(s)\big|_{s=s_0} > 0$. This completes the proof of Step 1.

Step 2. The assumptions of the implicit function theorem are satisfied at any point $(w, s, \tilde f)$ satisfying (3.10).

Let $(w_0, s_0, \tilde{f}_0) \in C^1(I) \times \mathbb{R} \times \tilde{C}(I)$ be a fixed point satisfying $\mathcal{F}(w_0, s_0, \tilde{f}_0) = \boldsymbol{o}$. Then the function $\mathcal{F}$ and the partial Fréchet differentials $\partial\mathcal{F}/\partial w, \partial\mathcal{F}/\partial s, \partial\mathcal{F}/\partial\tilde{f}$ are continuous in the neighborhood of $(w_0, s_0, \tilde{f}_0)$, and we have

$$\mathcal{T}(w,s) = \frac{\partial\mathcal{F}}{\partial(w,s)}\bigg|_{(w_0,s_0,\tilde{f}_0)} = \left.\begin{pmatrix} \dfrac{\partial F_1}{\partial w} & \dfrac{\partial F_1}{\partial s} \\[2ex] \dfrac{\partial F_2}{\partial w} & \dfrac{\partial F_2}{\partial s} \end{pmatrix}\right|_{(w_0,s_0,\tilde{f}_0)} \begin{pmatrix} w \\ s \end{pmatrix}$$
$$= \begin{pmatrix} w(t) + \int_0^t g'(w_0(\tau))w(\tau)\,d\tau - st \\ w(\pi) \end{pmatrix}.$$

It follows from here that $\mathcal{T} : C^1(I) \times \mathbb{R} \to C^1(I) \times \mathbb{R}$ is *a continuous linear map.* Let $(h, r) \in C^1(I) \times \mathbb{R}$. Then the equation $\mathcal{T}(w, s) = (h, r)^T$ is equivalent to the problem of finding the solution of the IVP

$$w'(t) + g'(w_0(t))w(t) = s + h'(t), w(0) = h(0) \tag{3.14}$$

satisfying

$$w(\pi) = r. \tag{3.15}$$

It is easy to see that the solution of (3.14) is of the form

$$w(t) = h(0)e^{-\int_0^t g'(w_0(\tau))\,d\tau} + se^{-\int_0^t g'(w_0(\tau))\,d\tau}\int_0^t e^{\int_0^\sigma g'(w_0(\tau))\,d\tau}\,d\sigma$$
$$+ e^{-\int_0^t g'(w_0(\tau))\,d\tau}\int_0^t h'(\sigma)e^{\int_0^\sigma g'(w_0(\tau))\,d\tau}\,d\sigma.$$

It follows from this expression that for any $(h, r) \in C^1(I) \times \mathbb{R}$ we can find a unique $s \in \mathbb{R}$ and the solution $w = w_s(t)$ of the IPV (3.14) satisfying (3.15). This proves the *surjectivity* of $\mathcal{T}$. It follows also from this explicit form of w that for $h(t) = 0, t \in [0, \pi]$, and $r = 0$, the relations (3.14) and (3.15) are verified only by $w(t) = 0, t \in [0, \pi]$, and $s = 0$. Thus $\mathcal{T}$ is *injective.* Applying the Banach open mapping theorem (see, e.g., [21]) we get that $\mathcal{T}^{-1}$ is continuous. Thus $\mathcal{T} : C^1(I) \times \mathbb{R} \to C^1(I) \times \mathbb{R}$ is an *isomorphism.* This completes the proof of Step 2.

The assertion of Theorem 3.3 follows immediately from Steps 1 and 2 and from the considerations at the beginning of this subsection. □

Remark 3.3. From the results of the previous two subsections we can assert that the structure of the range of the operator $u''(t) + \lambda_1 u(t) + g(u'(t))$ with the Dirichlet boundary conditions is completely different from the case of the Neumann ones.

Remark 3.4. Also, the qualitative structure of the range of the operator $u''(t) + g(u'(t))$ under the Neumann boundary conditions is quite distinct from the case $g = g(u)$ (see [17]), where, in many cases, infinitely many values of the parameter s exist for a given $\tilde{f} \in \tilde{C}(I)$, for which (3.6) has a solution.

3.3. The periodic problem.

In this subsection we will study the BVP

$$\begin{cases} u''(t) + g(u'(t)) = f(t), & t \in (0, \pi), \\ u(0) = u(\pi), & u'(0) = u'(\pi). \end{cases} \tag{3.16}$$

Again, the alternative method is not a useful tool to study this type of problem (realize that, as in the case of Neumann problems, the positive eigenfunction associated with the first eigenvalue, $\lambda_1 = 0$, is a constant function). We shall also apply a change of variables and a shooting method. In any event, the periodic boundary conditions make the problem a little more complicated than the Neumann ones, although the final conclusion about the range of the corresponding operator will be the same. By the same reasoning as in the previous subsection, we can restrict ourselves to the functions $u \in \tilde{C}^2(I)$, and by introducing the function $w(t) = u'(t)$, we transform the BVP (3.16) to the problem

$$(3.17) \qquad w'(t) + g(w(t)) = f(t), \quad t\in(0,\pi), \quad w(0) = w(\pi), \quad \int_0^\pi w(t)\,dt = 0.$$

Using the same notation as in the previous subsection let us define the map

$$\mathcal{G} : C^1(I) \times \mathbb{R}^2 \times \tilde{C}(I) \to C^1(I) \times \mathbb{R}^2$$

in the following way:

$$\mathcal{G}(w, s, \alpha, \tilde{f}) = \begin{pmatrix} G_1(w, s, \alpha, \tilde{f}) \\ G_2(w, s, \alpha, \tilde{f}) \\ G_3(w, s, \alpha, \tilde{f}) \end{pmatrix} = \begin{pmatrix} w(t) - st - \int_0^t \tilde{f}(\tau)\,d\tau + \int_0^t g(w(\tau))\,d\tau - \alpha \\ \int_0^\pi w(\tau)\,d\tau \\ w(\pi) - \alpha \end{pmatrix}.$$

THEOREM 3.4. *Let g be a continuously differentiable function satisfying* (3.9) *and let $f(t)$ in* (3.16) *be of the form* (3.8). *Then for any $\tilde{f} \in \tilde{C}(I)$ there exists precisely one $s = s(\tilde{f})$ such that* (3.16) *has a solution. In this case, the periodic BVP* (3.16) *has a family of solutions $u_c(t) = u(t) + c, c \in \mathbb{R}$ is arbitrary, where*

$$u(t) = \int_0^t w_{s(\tilde{f})}(\tau)\,d\tau,$$

and $w_{s(\tilde{f})}$ is the unique solution of (3.17). *Moreover, the map $\tilde{C}(I) \to \mathbb{R}$, $\tilde{f} \to s(\tilde{f})$ is continuously differentiable and $s(\tilde{f}) \in [-M, M]$ for any $\tilde{f} \in \tilde{C}(I)$.*

Proof. The idea is again to apply the implicit function theorem to $\mathcal{G}$ because the equation $\mathcal{G}(w, s, \alpha, \tilde{f}) = o$ is equivalent to (3.17).

Let us consider the IVP

$$(3.18) \qquad w'(t) = s + \tilde{f}(t) - g(w(t)), \qquad t \in [0, \pi], \qquad w(0) = \alpha,$$

with s and α as parameters. Integrating (3.18) we get the integral equation

$$(3.19) \qquad w(t) = st + \int_0^t \tilde{f}(\tau)\,d\tau - \int_0^t g(w(\tau))\,d\tau + \alpha, \qquad t \in [0, \pi]$$

for all solutions of the IVP (3.18). On the other hand, every solution of (3.19) (belonging to $C^1(I)$) is the solution of the IVP (3.18). Let $w = w_{s,\alpha}(t)$ be the solution of the IVP (3.18) and define $\tilde{G}_2, \tilde{G}_3 : \mathbb{R}^2 \to \mathbb{R}$ by

$$\tilde{G}_2(s, \alpha) = \int_0^\pi w_{s,\alpha}(\tau)\,d\tau \qquad \tilde{G}_3(s, \alpha) = w_{s,\alpha}(\pi) - \alpha.$$

The proof of the theorem follows in three steps.

Step 1. There exists at least one $(s, \alpha) \in \mathbb{R}^2$ such that

$$\tilde{G}_2(s, \alpha) = \tilde{G}_3(s, \alpha) = 0. \tag{3.20}$$

Observe that $\tilde{G}_2$ and $\tilde{G}_3$ are C^1 functions due to the continuous and differentiable dependence of the solution of the IVP (3.18) on the parameter and on the initial condition (see [7]). It follows from (3.9) and (3.19) that for any $\alpha \in \mathbb{R}$ and arbitrarily small $\varepsilon > 0$ we have $\tilde{G}_3(-M - \varepsilon, \alpha) < 0$ and $\tilde{G}_3(M + \varepsilon, \alpha) > 0$; therefore, for any $\alpha \in \mathbb{R}$ the equation

$$\tilde{G}_3(s, \alpha) = 0$$

has at least one solution $s \in [-M, M]$. As in the Neumann problem, one may prove that

$$\frac{\partial \tilde{G}_3(s, \alpha)}{\partial s} > 0 \qquad \text{for any } (s, \alpha) \in \mathbb{R}^2, \tag{3.21}$$

so that for any $\alpha \in \mathbb{R}$ there exists precisely one $s = s(\alpha) \in [-M, M]$ such that

$$\tilde{G}_3(s(\alpha), \alpha) = 0 \qquad \text{for any } \alpha \in \mathbb{R}.$$

Clearly, the mapping $\mathbb{R} \overset{\varphi_1}{\to} [-M, M]$, $\varphi_1(\alpha) = s(\alpha)$ is continuous.

On the other hand, for any fixed $s \in \mathbb{R}$ we get a constant $\alpha_{s,\tilde{f}} > 0$ such that $\tilde{G}_2(s, -\alpha_{s,\tilde{f}}) < 0$ and $\tilde{G}_2(s, \alpha_{s,\tilde{f}}) > 0$; therefore, for any $s \in \mathbb{R}$ the equation

$$\tilde{G}_2(s, \alpha) = 0$$

has at least one solution. Moreover the function $v_0(t) \equiv \frac{\partial w_{s,\alpha}(t)}{\partial \alpha} |_{\alpha = \alpha_0}$, $t \in [0, \pi]$, is the solution of the linear IVP

$$v'(t) + g'(w_{s,\alpha_0}(t))v(t) = 0, \quad t \in [0, \pi], \quad v(0) = 1$$

(see [7]), and it is easy to see that $v_0(t) > 0$ for $t \in [0, \pi]$. In particular this implies that

$$\frac{\partial \tilde{G}_2(s, \alpha)}{\partial \alpha} > 0 \text{ for any } (s, \alpha) \in \mathbb{R}^2, \tag{3.22}$$

so that for any $s \in \mathbb{R}$ there exists a unique $\alpha = \alpha(s)$ such that

$$\tilde{G}_2(s, \alpha(s)) = 0 \text{ for any } s \in \mathbb{R}.$$

Also, the mapping $\mathbb{R} \overset{\varphi_2}{\to} \mathbb{R}$, $\varphi_2(s) = \alpha(s)$ is continuous. Now, if we consider the continuous mapping $\varphi_1 \circ \varphi_2 : [-M, M] \to [-M, M]$, then there is at least one point $s_0 \in [-M, M]$ such that $\varphi_1(\varphi_2(s_0)) = s_0$. Lastly, $(s_0, \varphi_2(s_0))$ satisfies (3.20).

Step 2. The point (s, α) with the property (3.20) is unique.

We argue by contradiction. Let (s_1, α_1) and (s_2, α_2) be two points satisfying (3.20). We can assume, without loss of generality, that $\alpha_1 > \alpha_2$. Then due to the fact that both $w_{s_i,\alpha_i}, i = 1, 2$ must solve (3.17), we have to find two points $t_1, t_2 \in (0, \pi)$ such that

$$w_{s_1,\alpha_1}(t_i) = w_{s_2,\alpha_2}(t_i), \ i = 1, 2$$

and

$$w'_{s_1,\alpha_1}(t_1) \le w'_{s_2,\alpha_2}(t_1), \qquad w'_{s_1,\alpha_1}(t_2) \ge w'_{s_2,\alpha_2}(t_2).$$

Then the first inequality implies $s_1 \le s_2$ and the second one implies $s_1 \ge s_2$. Hence $s_1 = s_2$, but this contradicts $\alpha_1 > \alpha_2$ and (3.22).

Step 3. The assumptions of the implicit function theorem are satisfied at any point $(w_0, s_0, \alpha_0, \tilde{f}_0) \in C^1(I) \times \mathbb{R}^2 \times \tilde{C}(I)$ satisfying

$$\mathcal{G}(w_0, s_0, \alpha_0, \tilde{f}_0) = \boldsymbol{o}.$$

The function $\mathcal{G}$ and the partial Fréchet differentials $\frac{\partial \mathcal{G}}{\partial w}$, $\frac{\partial \mathcal{G}}{\partial s}$, $\frac{\partial \mathcal{G}}{\partial \alpha}$, and $\frac{\partial \mathcal{G}}{\partial f}$ are continuous in the neighborhood of $(w_0, s_0, \alpha_0, \tilde{f}_0)$. We have

$$\mathcal{S}(w,s,\alpha) = \left.\frac{\partial \mathcal{G}}{\partial(w,s,\alpha)}\right|_{(w_0,s_0,\alpha_0,\tilde{f}_0)} = \begin{pmatrix} w(t) + \int_0^t g'(w_0(\tau))w(\tau)\,d\tau - st - \alpha \\ \int_0^\pi w(\tau)\,d\tau \\ w(\pi) - \alpha \end{pmatrix}.$$

Then $\mathcal{S} : C^1(I) \times \mathbb{R}^2 \to C^1(I) \times \mathbb{R}^2$ is a *continuous linear map.* Let $(h, \beta, r) \in C^1(I) \times \mathbb{R}^2$. Then the equation $\mathcal{S}(w,s,\alpha) = (h,\beta,r)^T$ is equivalent to the problem of finding the solution of the IVP

$$w'(t) + g'(w_0(t))w(t) = s + h'(t), \ w(0) = \alpha + h(0) \tag{3.23}$$

satisfying

$$\int_0^\pi w(\tau)\,d\tau = \beta, \ w(\pi) = \alpha + r. \tag{3.24}$$

Since the solution of the linear IVP (3.23) is of the explicit form

$$w(t) = [\alpha + h(0)]e^{-\int_0^t g'(w_0(\tau))\,d\tau} + e^{-\int_0^t g'(w_0(\tau))\,d\tau} \cdot \int_0^t h'(\sigma)e^{\int_0^\sigma g'(w_0(\tau))\,d\tau}\,d\sigma$$

$$+ s{\cdot}e^{-\int_0^t g'(w_0(\tau))\,d\tau} \cdot \int_0^t e^{\int_0^\sigma g'(w_0(\tau))\,d\tau}\,d\sigma,$$

we derive from here that

(i) for any $(h, \beta, r) \in C^1(I) \times \mathbb{R}^2$ we can find $(s, \alpha) \in \mathbb{R}^2$ and the solution $w = w_{s,\alpha}(t)$ of the IVP (3.23) satisfying (3.24);

(ii) for $h(t) = 0$, $t \in [0, \pi]$, $r = \beta = 0$, the relations (3.23) and (3.24) are verified only by $w(t) = 0$, $t \in [0, \pi]$, and $s = \alpha = 0$.

It follows from (i) that $\mathcal{S}$ is *surjective* and from (ii) that $\mathcal{S}$ is *injective.* Then $\mathcal{S}$ is an *isomorphism* due to the Banach open mapping theorem. This completes the proof of Step 3 and also the proof of Theorem 3.4. □

Remark 3.5. Taking into account the results obtained in previous subsections we can affirm that the structure of the range of the operator $u''(t)+\lambda_1 u(t)+g(u'(t))$ under periodic boundary conditions is similar to the Neumann case and completely different from the case of Dirichlet boundary conditions. Also, the qualitative structure of such a range is quite distinct from the case $g = g(u)$ (see [16], [12]) where, in many cases, infinitely many values of the parameter s exist for a given $\tilde{f} \in \tilde{C}(I)$ for which (3.16) has a solution.

4. Concluding remarks, possible extensions, and generalizations.

Remark 4.1. Obviously, the results of Theorems 3.1–3.4 should be formulated also for nonlinearities of the type $g = g(t, u')$ (with g depending also on $t \in [0, \pi]$).

Remark 4.2. It follows from the results in §3 that the "solution set" $\mathcal{J}_{\tilde{f}}$ from Proposition 2.1 has a structure that depends on the nonlinearity of g and on the type of boundary conditions. In the case of a Dirichlet problem adding some appropriate asymptotic conditions on g, it is, in general, an interval with a *nonempty interior*, while in the case of a Neumann (or periodic) problem, it is a point without any assumptions on the asymptotic behavior of g.

Remark 4.3. Let us point out that further assumptions on g may allow us to get more information about the behavior of the maps $\tilde{f} \to s_i(\tilde{f})$, $i = 1, 2$ (e.g., the limits of $s_i(\tilde{f})$ for $\| \tilde{f} \| \to 0$ or $\| \tilde{f} \| \to \infty$, etc.).

Remark 4.4. In the case of the Dirichlet BVP we restrict ourselves only to the case of bounded nonlinearity with the *finite limits* in $\pm\infty$. We had several reasons to do so:

(i) to avoid tedious calculations and to keep the idea clear,

(ii) to give not only sufficient but also necessary conditions for the solvability,

(iii) to emphasize the difference between the BVP (1.1) and the "classical" Landesman–Lazer-type problem with nonlinearity depending only on the solution u.

However, by using the *Fatou lemma* instead of the *Lebesgue theorem* in the proof of Theorem 3.1 one can deal with more general nonlinearities (e.g., unbounded ones) and formulate sufficient conditions for the solvability of the BVP (3.3) in terms of $\liminf_{\xi \to \pm\infty} g(\xi)$ and $\limsup_{\xi \to \pm\infty} g(\xi)$. It should also be mentioned that the *alternative method does not provide enough information* concerning the *solvability* of *Neumann* and *periodic* problems. That is why we use a different approach based on the implicit function theorem in these cases.

Remark 4.5. It should be interesting to study related problems for *higher-order equations* or for the *systems of equations.* One can expect that similar results also hold true in the case of boundary value problems for *partial differential equations.* However, a *different approach* should be applied because our method works only in the case of ordinary differential equations. Another possible extension of our result is to consider the solvability of the BVP (1.1) with λ_n instead of λ_1, with general $n \geq 1$.

TRACKING INVARIANT MANIFOLDS UP TO EXPONENTIALLY SMALL ERRORS*

C. K. R. T. JONES[†], TASSO J. KAPER[‡], AND NANCY KOPELL[§]

Abstract. This work establishes a new tool for proving the existence of multiple-pulse homoclinic orbits in perturbed Hamiltonian systems and general multidimensional singular-perturbation problems. The center-stable and center-unstable manifolds of slow manifolds in these problems intersect transversely at angles that are of the same order as the asymptotically small parameter in the problem, which can be either an amplitude or a frequency. To deal with the difficulties associated with small angles of intersection, we develop the exchange lemma with exponentially small error (ELESE), which is the main technical result of this work. This lemma enables highly accurate tracking of invariant manifolds while orbits on them spend long intervals of time near slow manifolds.

Key words. multiple-pulse heteroclinic orbits, singular perturbations, Fenichel coordinates, tracking invariant manifolds, exchange lemma, Hamiltonian systems

1. Introduction.

Homoclinic orbits play central roles in many systems. For reaction-diffusion systems and nerve impulse equations, for example, travelling waves are realized as homoclinic orbits in associated systems of ordinary differential equations. In addition, for finite-dimensional systems, transverse homoclinic and heteroclinic orbits are the source of Smale horseshoe chaos in the ambient phase space.

In singularly perturbed systems with two asymptotically distinct time scales, one can construct formal homoclinic orbits in the limit in which the small parameter vanishes. These orbits are formal in that they consist of a finite number of fast $\mathcal{O}(1)$-time-duration jumps, or "pulses," between manifolds of critical points interspersed with appropriate slow $\mathcal{O}(\frac{1}{\varepsilon})$-time-duration orbit segments on those manifolds, where $0 < \varepsilon \ll 1$. These jumps and orbit segments are obtained from the "fast" and "slow" limiting version of the equations, respectively, which are individually easier to study than the entire system. One of the major goals of geometric singular-perturbation theory is to establish conditions under which such formally constructed singular homoclinic and heteroclinic orbits perturb to real orbits for small, nonzero values of the perturbation parameter.

The problem of constructing heteroclinic orbits in the context of singularly perturbed systems has been attacked with many techniques. Topological methods for proving the existence of orbits homoclinic to fixed points near a singular limit were pioneered in [5]. The results of [5] concerned the Fitzhugh–Nagumo and Hodgkin–Huxley systems, in which the homoclinic orbit models the travelling nerve impulse. Similar, but more analytic, methods were simultaneously developed in [17]. The authors of [14] extended the topological methods to systems with more diffusing variables. A combination of analytic and other techniques have been developed by many

authors for determining homoclinic orbits and related structures in singular systems; among these authors' works are [6]–[8], [9], [15], [19], [28], and [33]. We refer the reader to [34] for a more complete list of references.

Recently, two of us established a technical tool known as the exchange lemma for tracking invariant manifolds in singularly perturbed systems; see [21]. This work was motivated by a large class of travelling-wave problems. The exchange lemma is a general tool that makes it possible to demonstrate the existence of multiple-pulse orbits homoclinic to fixed points even when these points lie on higher-dimensional center manifolds. The pulses are the fast excursions the orbit makes going from a neighborhood of one slow manifold to a neighborhood of another slow manifold. These results are obtained under the assumption that certain transversality conditions hold between the center-stable and center-unstable manifolds of the slow manifolds in the space of the dependent variables and the wave speed. In particular, the relevant intersections of the center-stable and center-unstable manifolds of the slow manifolds occur at an angle of $\mathcal{O}(1)$.

There are many interesting classes of singularly perturbed systems, however, in which the center-stable and center-unstable manifolds of invariant sets on the slow manifolds coincide in the $\varepsilon = 0$ limit of the equations, so that the leading $\mathcal{O}(1)$ term of an expansion of the distance between the perturbed stable and unstable manifolds is identically zero. These systems include perturbed Hamiltonian problems and coupled travelling wave problems. A partial listing includes [1]–[4], [10]–[12], [16], [23]–[27], and [29]–[32]. See also Chapter 4 of [35]. In these systems, the perturbations lift the degeneracy at $\varepsilon = 0$, and the stable and unstable manifolds intersect at an $\mathcal{O}(\varepsilon)$ angle.

Our goal in this work is to produce a technique that is applicable to a wide range of problems, such as those listed above. We call this technique the exchange lemma with exponentially small error (henceforth referred to by the acronym ELESE). The sharpness of the error estimates given by ELESE enables us to overcome the previously unsurmounted difficulties associated with transverse intersections at angles of order $\mathcal{O}(\varepsilon)$ between the relevant center-stable and center-unstable manifolds. Moreover, our technique also applies to problems in which the angle of intersection is order $\mathcal{O}(\varepsilon^{\alpha})$ for any $\alpha \geq 0$.

As introduced in [20] and [21], the exchange lemma tracks invariant manifolds while trajectories on them spend long intervals of time near slow manifolds. Consider a trajectory which lies on a locally invariant manifold M and which spends an $\mathcal{O}(\frac{1}{\varepsilon})$ interval of time in the neighborhood of a slow manifold S. In order for an orbit to spend an $\mathcal{O}(\frac{1}{\varepsilon})$ amount of time in this neighborhood, it must be exponentially close to the stable manifold of S on entry into the neighborhood and for at least half of the time interval it is in the neighborhood. Now, if one assumes that M is transverse to the stable manifold of S at the point where the orbit enters the neighborhood; then the exchange lemma states that at the point where the orbit exits the neighborhood, M is C^1–$\mathcal{O}(\varepsilon)$ close to the unstable manifold of S restricted to an orbit segment on S. In particular, at the exit point, the tangent hyperplane to M is $\mathcal{O}(\varepsilon)$ close to the space spanned by the unstable directions and by the one center direction tangent to the restricted flow on the slow manifold.

As a consequence of the exchange lemma, we know that when the unstable manifold of one slow manifold, restricted to a slow orbit segment, transversely intersects at an angle of $\mathcal{O}(1)$ the stable manifold of another (not necessarily distinct) slow manifold, then the tracked manifold M will also be transverse to the stable manifold of this second slow manifold. In this sense, transversality information is exchanged. By induction, this process can be repeated finitely many times to study homoclinic orbits with finitely many pulses. In particular, when orbits on the tracked manifold M leave the neighborhood of the second slow manifold, M and its tangent plane are exponentially close to the unstable manifold of that second slow manifold restricted to the appropriate slow orbit segment. Thus, since the restricted unstable manifold transversely intersects the stable manifold of a third slow manifold, the tracked manifold will as well.

The exchange lemma enables one to capture the dynamics in all of the fast and slow directions. By contrast, following the tangents to individual trajectories one loses information about the dynamics in the center directions because all trajectories exit the neighborhood of the slow manifold approximately tangent to the fast unstable space.

By establishing ELESE, we improve on the result of the exchange lemma. In particular, we demonstrate that, at the point at which the orbit on M exits the neighborhood, M is actually C^1– $\mathcal{O}(e^{-\frac{c}{\varepsilon}})$ close to the unstable manifold of S restricted to an orbit segment on S. Therefore, when the unstable manifold of one slow manifold transversely intersects at an angle of $\mathcal{O}(\varepsilon^{\alpha})$ the stable manifold of another (not necessarily distinct) slow manifold for any $\alpha \geq 0$, then the tracked manifold M will also be transverse to the stable manifold of this second slow manifold. In fact, ELESE is precisely the result needed to establish the existence of multipulse orbits in the problems listed above. Finally, the sets to which these multipulse orbits are asymptotic can consist of unstable equilibria, periodic orbits, tori, or more complicated invariant sets on the slow manifolds. They can also be an entire slow manifold.

The improvements obtained here are made without requiring further assumptions on the equations (see (1) below) under consideration. Rather, we take fuller advantage of the structure in the normal form for the flow near a slow normally hyperbolic invariant manifold. See equations (4) and the discussion in §2.

Finally, in order to illustrate the technique, we use ELESE to obtain the existence of multiple-pulse heteroclinic orbits in a model problem which consists of a quasiperiodic, slowly modulated, nonlinear pendulum. In particular, we demonstrate the existence of orbits that (i) are forward and backward asymptotic to periodic orbits on the two-dimensional tori that are the slow manifolds in this problem and (ii) have finitely many pulses, or fast excursions from one slow torus to another. Furthermore, in between each pair of adjacent excursions, these heteroclinic orbits spend long $\mathcal{O}(\frac{1}{\varepsilon})$ intervals of time near the slow torus.

The central feature of this model is that the stable and unstable manifolds of the slow manifolds intersect transversely at an angle of $\mathcal{O}(\varepsilon)$. Hence, error estimates that are sharper than those of existing work are necessary in order to obtain useful bounds from tracking the invariant manifolds during their long passages near slow manifolds. The exponentially small error estimates of ELESE are more than sharp enough.

Geometric simplicity guided the construction of this model. In particular, the number of dimensions and the qualitative features have been kept to a minimum. The model is intended only to elucidate the essential ideas. We refer the reader to the references cited above for several important problems exhibiting $\mathcal{O}(\varepsilon)$ and $\mathcal{O}(\varepsilon^2)$ transversality in which ELESE can be used.

This paper is organized as follows. In §2, we state the equations under study and their normal forms near the slow manifolds. In §3, we establish a C^0 version of the main result. Then, using differential forms, we prove the full ELESE in §4. Finally, the example is discussed in §5.

2. Fenichel coordinates. We study systems with two time (or length) scales for which the governing equations have the form

$$\mathbf{x}' = \mathbf{f}(\mathbf{x}, \mathbf{y}, \varepsilon),$$

$$\mathbf{y}' = \varepsilon \mathbf{g}(\mathbf{x}, \mathbf{y}, \varepsilon), \tag{1}$$

where $\mathbf{x} \in \mathbb{R}^m$ and $\mathbf{y} \in \mathbb{R}^n$ with $n > 0$ and $\mathbf{f}$ and $\mathbf{g}$ are smooth.

The unperturbed equations, (1) with $\varepsilon = 0$, are autonomous and are parametrized by the $\mathbf{y}$ variables. The relation $\mathbf{f}(\mathbf{x}, \mathbf{y}, 0) = \mathbf{0}$ determines a manifold of equilibria. For this work, we are interested in the case in which some subset of this manifold is normally hyperbolic; i.e., we assume that there exists a subset S_0 of the manifold of equilibria such that the eigenvalues of $D_{\mathbf{x}}\mathbf{f}(\mathbf{p}, 0)$ have nonzero real parts for all points $\mathbf{p} \in S_0$. The reason for this choice is that a normally hyperbolic manifold S_0 persists as an invariant manifold S_ε in the full system (1) along with its local stable and unstable manifolds for $0 < \varepsilon \ll 1$. See [13] and [18]. Furthermore, S_ε lies $\mathcal{O}(\varepsilon)$ close to S_0 and may be expressed as a graph over S_0 when the eigenvalues of $D_{\mathbf{x}}\mathbf{f}(\mathbf{p}, 0)$ are uniformly bounded away from zero for all $\mathbf{p} \in S_0$. In addition, the perturbed local stable and unstable manifolds of S_ε lie $\mathcal{O}(\varepsilon)$ close to their unperturbed counterparts. Finally, Fenichel theory states that the vector field restricted to S_ε has magnitude $\mathcal{O}(\varepsilon)$, which leads to the label slow manifold for S_ε.

We briefly discuss the structure of the unperturbed vector field near S_0. For a fixed $\mathbf{y}$, the local stable and unstable manifolds of S_0 give rise to a new coordinate system in which the dynamics near S_0 are best studied. Let $\mathbf{a} \in \mathbb{R}^{\mathbf{k}}$ and $\mathbf{b} \in \mathbb{R}^{\ell}$, where $k + \ell = m$, be a new coordinate system such that the local stable and unstable manifolds of S_0 are the axes $\mathbf{a} = \mathbf{0}$ and $\mathbf{b} = \mathbf{0}$, respectively. Then the equations are

$$\mathbf{a}' = \Lambda(\mathbf{a}, \mathbf{b}, \mathbf{y})\mathbf{a},$$

$$\mathbf{b}' = \Gamma(\mathbf{a}, \mathbf{b}, \mathbf{y})\mathbf{b},$$

$$\mathbf{y}' = \mathbf{0}, \tag{2}$$

where Λ and Γ are matrix-valued functions. The normal hyperbolicity of S_0 implies that for any $\Delta > 0$ sufficiently small, there are constants λ_0 and γ_0 such that for any eigenvalue $\tilde{\lambda}_i$ of $\Lambda(\mathbf{0}, \mathbf{0}, \mathbf{y})$ or any eigenvalue $\tilde{\gamma}_i$ of $\Gamma(\mathbf{0}, \mathbf{0}, \mathbf{y})$, we have $\text{Re}\tilde{\lambda}_i > \lambda_0 > 0$ and $\text{Re}\tilde{\gamma}_i < \gamma_0 < 0$ for all points in the box $\mathcal{B} \equiv \{(\mathbf{a}, \mathbf{b}, \mathbf{y}) | |\mathbf{a}|, |\mathbf{b}| \leq \Delta\}$, where the $\mathbf{y}$ variables lie in a compact subset of $\mathbb{R}^{\mathbf{n}}$.

The persistence theory cited above gives an explicit constructon of the perturbed counterpart of this local coordinate system. In particular, there exist $(\mathbf{a}, \mathbf{b}, \mathbf{y})$ coordinates, which have been dubbed Fenichel coordinates (see [21]) such that the perturbed local stable and unstable manifolds correspond to the manifolds $\mathbf{a} = \mathbf{0}$ and $\mathbf{b} = \mathbf{0}$, respectively. Furthermore, these manifolds are $\mathcal{O}(\varepsilon)$ close, as functions of the variables $(\mathbf{x}, \mathbf{y}, \varepsilon)$, to the corresponding unperturbed manifolds. Using equations (11.6)(a) and (11.7)(a) from Theorem 11.1 of [13], the equations near S_ε may be written as

$$\mathbf{a}' = \Lambda(\mathbf{a}, \mathbf{b}, \mathbf{y}, \varepsilon)\mathbf{a},$$

$$\mathbf{b}' = \Gamma(\mathbf{a}, \mathbf{b}, \mathbf{y}, \varepsilon)\mathbf{b},$$

$$\mathbf{y}' = \varepsilon \mathbf{m}(\mathbf{y}, \varepsilon) + \varepsilon \mathbf{h}(\mathbf{a}, \mathbf{b}, \mathbf{y}, \varepsilon)\mathbf{ab}, \tag{3}$$

where $\mathbf{h}(\mathbf{a}, \mathbf{b}, \mathbf{y}, \varepsilon)$ is a rank-three tensor. In component notation, the third equation is $y_i{}' = \varepsilon m_i(\mathbf{y}, \varepsilon) + \varepsilon \sum_{m=1}^{\ell} \sum_{j=1}^{k} h_{ijm} a_j b_m$.

The terms $\mathbf{a}$ and $\mathbf{b}$ factor out in the slow ($\mathbf{y}$) equations in (3) because the coordinate system is determined by the perturbed center manifold and its fast stable and unstable foliations. Furthermore, it is precisely this factoring that makes the tracking with exponentially small error possible, since the product of these two terms remains exponentially small during an orbit's $\mathcal{O}(\frac{1}{\varepsilon})$ long time of passage near a slow manifold.

Finally, we make a technical refinement of (3). If one first rectifies $\mathcal{S}_\varepsilon$ in (1) (taking into account that this may have to be done using more than one chart) so that the slow flow of (1) is in the y_1 direction, as is done in [21], then the normal form has the following useful structure:

$$\begin{aligned} \mathbf{a}' &= \Lambda(\mathbf{a}, \mathbf{b}, \mathbf{y}, \varepsilon)\mathbf{a}, \\ \mathbf{b}' &= \Gamma(\mathbf{a}, \mathbf{b}, \mathbf{y}, \varepsilon)\mathbf{b}, \\ \mathbf{y}' &= \varepsilon \left(\mathbf{U} + \mathbf{h}(\mathbf{a}, \mathbf{b}, \mathbf{y}, \varepsilon)\mathbf{a}\mathbf{b}\right), \end{aligned} \tag{4}$$

where $\mathbf{U} = (1, 0, \ldots, 0)$. This is the normal form we shall use throughout the paper.

Remark 1. In October 1992, Fenichel pointed out to one of us (C. Jones) that the C^0 and C^1 ELESE of §§3 and 4 also hold when the factor of ε in front of the second term of the $\mathbf{y}'$ equations in (3) is not present.

Remark 2. The technical refinement used in (4) is made without loss of generality. The flow on $\mathcal{S}_\varepsilon$ can, and in general does, exhibit nontrivial dynamics, including fixed points, periodic orbits, homoclinic orbits, etc.

3. The C^0 ELESE. In this section, we establish the C^0 version of the main result, namely that, in the coordinates of (4), the $\mathbf{b}$ coordinates are exponentially close in ε to $\mathbf{b} = \mathbf{0}$ and that the y_i ($i > 0$) coördinates are exponentially close in ε to the values of y_i they have on entry into $\mathcal{B}$.

PROPOSITION 3.1. *Let q be a point in $M \cap \{|\mathbf{b}| = \Delta\}$ whose trajectory exits $M \cap \{|\mathbf{a}| = \Delta\}$ at $\bar{q}$ after a time τ that is $\mathcal{O}(\frac{1}{\varepsilon})$. Let V be a neighborhood of q in M. Then for V sufficiently small, the image of V under the time τ map is $\mathcal{O}(e^{-\frac{c}{\varepsilon}})$ C^0 close for some $c > 0$ to $\{|\mathbf{b}| = 0, y_i - y_i(0) = 0, i > 1\}$, where $y_i(0)$ denotes the value of y_i at q.*

Remark. $\mathcal{O}(\varepsilon)$ C^0-closeness is established in Corollary 3.1 of [21]. See also [6] and [8]. Here we are able to refine the estimate since both an $\mathbf{a}$ and a $\mathbf{b}$ factor out in the normal form (4).

Before proving this proposition, we state a technical result which gives bounds on the rate of growth and decay of the variables $\mathbf{a}$ and $\mathbf{b}$, respectively, while the orbit is in $\mathcal{B}$. Most importantly, the proposition shows that the integral of the product of $|\mathbf{a}|$ and $|\mathbf{b}|$ over any subinterval of the time a trajectory is in $\mathcal{B}$ is exponentially small. This proof uses the fact that solutions spending long times in $\mathcal{B}$ must have exponentially small $\mathbf{a}$ components for at least the first half of the subinterval and exponentially small $\mathbf{b}$ components for at least the second half of the subinterval, so that the product of $\mathbf{a}$ and $\mathbf{b}$ is exponentially small during the orbits entire stay in $\mathcal{B}$.

LEMMA 3.1. *For ε sufficiently small, there exist positive constants c_a, c_b, c, and K such that, for $s \le t$,*

$$|\mathbf{b}(t)| \le c_b |\mathbf{b}(s)| e^{\gamma_0 (t-s)}, \tag{i}$$

(ii) $$|\mathbf{a}(t)| \geq c_a |\mathbf{a}(s)| e^{\lambda_0 (t-s)},$$

(iii) $$\int_s^t |\mathbf{a}(\zeta)||\mathbf{b}(\zeta)| d\zeta \leq K e^{c(s-t)},$$

independently of ε, *where* $K = 2\Delta^2 \max(\frac{1}{c_a \lambda_0}, \frac{c_b}{|\gamma_0|})$ *and* $c = \frac{1}{2}\min(\lambda_0, |\gamma_0|)$, *so long as the trajectory stays in* $\mathcal{B}$.

Remark. Parts (i) and (ii) of this lemma are identical to parts (i) and (ii) of Proposition 3.1 in [21], and so we refer the reader there for their proofs. We prove part (iii) here.

Proof of part (iii). Split the integral on the left hand side of (iii) in two pieces: (I) from s to $\frac{s+t}{2}$ and (II) from $\frac{s+t}{2}$ to t. For (I), we first rewrite part (ii) of the lemma as

(5) $$|\mathbf{a}(\zeta)| \leq \frac{|\mathbf{a}(t)|}{c_a} e^{\lambda_0(\zeta - t)},$$

where $s \leq \zeta \leq t$. Then, using (5), $|\mathbf{b}(\zeta)| \leq \Delta$, and $|\mathbf{a}(t)| \leq \Delta$, we get

(6) $$\int_s^{\frac{s+t}{2}} |\mathbf{a}(\zeta)||\mathbf{b}(\zeta)| d\zeta \leq \frac{\Delta^2}{c_a} \int_s^{\frac{s+t}{2}} e^{\lambda_0(\zeta - t)} d\zeta = \frac{\Delta^2}{c_a \lambda_0} e^{\frac{\lambda_0}{2}(s-t)} \left[1 - e^{\frac{\lambda_0}{2}(s-t)}\right].$$

Also, since we have $|\mathbf{b}(\zeta)| \leq c_b |\mathbf{b}(s)| e^{\gamma_0(\zeta - s)}$ from using (i) with $s \leq \zeta \leq t$, the second part of the integral (II) yields

(7) $$\int_{\frac{s+t}{2}}^t |\mathbf{a}(\zeta)||\mathbf{b}(\zeta)| d\zeta \leq \frac{c_b \Delta^2}{|\gamma_0|} e^{\frac{\gamma_0}{2}(t-s)} \left[1 - e^{\frac{\gamma_0}{2}(t-s)}\right].$$

Putting (6) and (7) together proves the lemma.

Remark. As a consequence of (5), the fact that $|\mathbf{a}|$ is bounded by Δ at time t implies that $|\mathbf{a}|$ is exponentially small at least in the first half of the interval. Similarly, the fact that $|\mathbf{b}(\zeta)|$ is bounded by Δ at time s implies that $|\mathbf{b}|$ is exponentially small during at least the second half of the time interval.

This technical lemma leads to the following proof.

Proof of Proposition 3.1. The variable $\mathbf{b}(t)$ is exponentially small at $\bar{q}$ by part (i) of Lemma 3.1 because the trajectory spends an $\mathcal{O}(\frac{1}{\varepsilon})$ amount of time in $\mathcal{B}$. Hence, we only need to consider y_i for $i > 1$. From (4), we know

(8) $$y_i{}' = \varepsilon h_i(\mathbf{a}, \mathbf{b}, \mathbf{y}, \varepsilon)\mathbf{ab}.$$

Thus,

$$\int_0^t y_i{}' d\tau = \varepsilon \int_0^t h_i(\mathbf{a}, \mathbf{b}, \mathbf{y}, \varepsilon)\mathbf{ab} d\zeta,$$

(9) $$|y_i(t) - y_i(0)| \leq \varepsilon d_i \int_0^t |\mathbf{a}||\mathbf{b}| d\zeta,$$

where d_i is a bound on $|h_i|$. Finally, because $t = \mathcal{O}(\frac{1}{\varepsilon})$, part (iii) of Lemma 3.1 implies that the right-hand side of (9) is $\mathcal{O}(e^{-\frac{c}{\varepsilon}})$ as $\varepsilon \to 0$ for some $c > 0$, which establishes the proposition.

4. The C^1 ELESE. In order to get the C^1 version of the main result, which we present in this section, we follow [21] and study the vector field induced on the $(k+1)$-dimensional tangent planes of invariant manifolds using the $(k+1)$-forms which are dual to them. By tracking $(k+1)$-dimensional manifolds and their tangent planes, we capture the dynamics in all directions, including all of the center directions.

We are interested in the $(k+1)$-forms

$$P_{\sigma_1,\ldots,\sigma_{k+1}} \equiv \delta\sigma_1 \wedge \cdots \wedge \delta\sigma_{k+1},$$

where the σ_j range over the variables a_i, b_i, and y_i and where $\delta\sigma_i$ is the 1-form dual to the coordinate σ_i. Each $(k+1)$-form associates with the $(k+1)$-dimensional plane Q a number that is proportional to the volume of the projection of a unit cube of Q onto the coordinate plane of the $k+1$ coordinates specified by P. We assume that the σ_i are ordered in P according to the rule

$$a_1 < a_2 < \cdots < a_k < b_1 < \cdots < b_\ell < y_1 < \cdots < y_n,$$

and we work with the projectivized version of the $(k+1)$-forms

$$\hat{P}_{\sigma_1,\ldots,\sigma_{k+1}} \equiv \frac{P_{\sigma_1,\ldots,\sigma_{k+1}}}{P_{a_1,a_2,\ldots,a_k,y_1}}.$$

We are now in a position to state the main result.

ELESE. *Let M be a $(k+1)$-dimensional invariant manifold. Assume that $\rho_\varepsilon = M \cap \{|\mathbf{b}| = \Delta\}$ intersects $\{\mathbf{a} = \mathbf{0}\}$ transversely. Let $q \in \rho_\varepsilon$ be a point whose trajectory exits from $\{|\mathbf{a}| = \Delta\}$ at $\bar{q}$ after a time $t = \mathcal{O}(\frac{1}{\varepsilon})$. Then, for ε sufficiently small, the manifold M is $\mathcal{O}(e^{-\frac{c}{\varepsilon}})$-$C^1$ close for some $c > 0$ to $\{\mathbf{b} = \mathbf{0}, y_i - y_i(0) = 0, i > 1\}$ at $\bar{q}$.*

Remark. The conclusion of the ELESE may be restated as: Upon exiting the box $\mathcal{B}$ at the point $\bar{q}$, the projectivized $(k+1)$-form $\hat{P}_{\sigma_1,\sigma_2,\ldots,\sigma_{k+1}}$ is $\mathcal{O}(e^{-\frac{c}{\varepsilon}})$ for some constant $c > 0$ and for all $(\sigma_1, \ldots, \sigma_{k+1}) \neq (a_1, \ldots, a_k, y_1)$.

Before proving ELESE, we develop the working estimates that we will need for the differential forms. After these are established, the proof of ELESE requires three short steps.

Let $\mathbf{z} \equiv (\mathbf{a}, \mathbf{b}, \mathbf{y})$. Let Λ_{ij} and Γ_{ij} denote the i,jth entries of Λ and Γ, resp., and let Λ_i and Γ_i denote their ith rows. In addition, let $L_{ij} \equiv \nabla_z \Lambda_{ij} \cdot \delta\mathbf{z}$ and $G_{ij} \equiv \nabla_z \Gamma_{ij} \cdot \delta\mathbf{z}$, where for each i,j pair, $\nabla_z \Lambda_{ij} \in \mathbb{R}^{k+\ell+n}$ and $\nabla_z \Gamma_{ij} \in \mathbb{R}^{k+\ell+n}$. Finally, let $\mathbf{L}_i = (L_{i1}, \ldots, L_{ik})$ and $\mathbf{G}_i = (G_{i1}, \ldots, G_{i\ell})$.

The development of the working estimates begins with the equations of variation of (4):

$$(\delta a_i)' = \Lambda_i \cdot \delta\mathbf{a} + \mathbf{a} \cdot \mathbf{L}_i,$$

$$(\delta b_i)' = \Gamma_i \cdot \delta\mathbf{b} + \mathbf{b} \cdot \mathbf{G}_i,$$

$$(\delta y_i)' = \varepsilon \sum_{j=1}^{k} \sum_{m=1}^{\ell} \{h_{ijm} \delta a_j b_m + h_{ijm} a_j \delta b_m + (\nabla h_{ijm} \cdot \delta\mathbf{z}) a_j b_m\}. \tag{10}$$

These equations of variation readily yield the evolution equations for each of the possible $(k+1)$-forms $\hat{P}_{\sigma_1,\ldots,\sigma_{k+1}}$. We split the forms into two blocks: block I consists of the forms $Z_i \equiv \hat{P}_{a_1 a_2,\ldots,a_k y_i}$ for all i, and block II contains all of the others, which we denote $\mathbf{X}$. From the definition of Z_i and the product rule for differentiation, we have

$$Z_i{}' = \sum_{j=1}^{k} \delta a_1 \wedge \cdots \wedge (\delta a_j)' \wedge \cdots \wedge \delta y_i + \delta a_1 \wedge \cdots \wedge \delta a_k \wedge (\delta y_i)'.$$

Then, using the fact that the wedge product of a 1-form by itself vanishes, specifically that

$$\delta a_1 \wedge \cdots \wedge \delta a_k \wedge \left(\sum_{m=1}^{\ell} \sum_{j=1}^{k} h_{ijm} \delta a_j b_m \right) \equiv 0 \qquad \text{for all } i,$$

we obtain

$$Z_i{}' = (\mathrm{Tr}\Lambda)\, Z_i + \eta_{1i}(\mathbf{Z}, \mathbf{X}, t), \tag{11}$$

where

$$\eta_{1i} = F_i(Z_i, \mathbf{X}, t) + G_i(\mathbf{Z}, \mathbf{X}, t) + Q_i(\mathbf{X}, t) \tag{12}$$

and

$$F_i \equiv \sum_{j=1}^{k} \delta a_1 \wedge \cdots \wedge (\mathbf{a} \cdot \mathbf{L}_j) \wedge \cdots \wedge \delta y_i,$$

$$G_i \equiv \varepsilon \delta a_1 \wedge \cdots \wedge \delta a_k \wedge \left\{ \sum_{m=1}^{\ell} \sum_{j=1}^{k} (\nabla h_{ijm} \cdot \delta \mathbf{z}) a_j b_m \right\},$$

$$Q_i \equiv \varepsilon \delta a_1 \wedge \cdots \wedge \delta a_k \wedge \left\{ \sum_{m=1}^{\ell} \sum_{j=1}^{k} h_{ijm} a_j \delta b_m \right\}. \tag{13}$$

We have kept the dependence of η_{1i} on $\mathbf{a}, \mathbf{b}$, and $\mathbf{y}$ implicit. Clearly, the inhomogeneous term η_{1i} vanishes for each i at $\mathbf{a} = \mathbf{0}$. In addition, the terms in F_i from block I involve only Z_i and are $\mathcal{O}(|\mathbf{a}|)$, and those in F_i from block II are also $\mathcal{O}(|\mathbf{a}|)$. All of the terms in G_i are $\mathcal{O}(\varepsilon|\mathbf{a}||\mathbf{b}|)$. Finally, the terms in Q_i can only be in block II, and they are $\mathcal{O}(\varepsilon|\mathbf{a}|)$. Thus, we have proved the following lemma.

LEMMA 4.1.

$$|F_i(Z_i, \mathbf{X}, t)| \le C_F |\mathbf{a}| (|Z_i| + |\mathbf{X}|),$$

$$|G_i(\mathbf{Z}, \mathbf{X}, t)| \le \varepsilon C_G |\mathbf{a}||\mathbf{b}| (|\mathbf{Z}| + |\mathbf{X}|),$$

$$|Q_i(\mathbf{X}, t)| \le \varepsilon C_Q |\mathbf{a}||\mathbf{X}| \tag{14}$$

for some $C_F, C_G, C_Q < \infty$ and for each i.

Remark. The factor of $|\mathbf{b}|$ in the bound on G_i plays a vital role in the working estimates of Lemma 4.3.

In a similar fashion, one derives the evolution equation for the $(k+1)$-forms $\mathbf{X}$:

$$\mathbf{X}' = B\mathbf{X} + \eta_2(\mathbf{Z}, \mathbf{X}, t), \tag{15}$$

where

$$\eta_2(\mathbf{Z},\mathbf{X},t) \equiv \mathbf{E}(\mathbf{X},t) + \mathbf{H}(\mathbf{Z},\mathbf{X},t) \tag{16}$$

and where $B = B(\mathbf{a},\mathbf{b},\mathbf{y},\varepsilon)$ is a matrix that satisfies

$$\|\exp\left\{\int_0^t (B - \mathrm{Tr}\Lambda)d\zeta\right\}\| \leq \bar{M}e^{-\mu(t-s)} \tag{17}$$

for some $\bar{M} \geq 1$ and $\mu > 0$. The terms included in $\mathbf{E}$ come from those $(k+1)$-forms that have the $\mathbf{a}\cdot\mathbf{L_i}$ term in them from a factor with $(\delta a_i)'$ and from those that have the $\varepsilon\sum_{m=1}^{\ell}\sum_{j=1}^{k} h_{ijm}a_j\delta b_m$ terms in them from a factor with $(\delta y_i)'$. The term $H(\mathbf{Z},\mathbf{X},t)$ consists of the remaining terms, each of which has a a factor of $|\mathbf{b}|$ in them. Therefore, recalling that $\varepsilon|\mathbf{a}| \leq \epsilon\Delta$, we have established the following lemma.

LEMMA 4.2.

$$|E(\mathbf{X},t)| \leq C_E|\mathbf{a}||\mathbf{X}|,$$

$$|H(\mathbf{Z},\mathbf{X},t)| \leq C_H|\mathbf{b}|\left(|\mathbf{Z}| + |\mathbf{X}|\right). \tag{18}$$

for some C_E, $C_H < \infty$.

Next, we use the bounds from Lemmas 4.1 and 4.2 to derive the working estimates. Let $\hat{\mathbf{X}} \equiv \frac{\mathbf{X}}{Z_1}$, and $\hat{Z}_i \equiv \frac{Z_i}{Z_1}$. We show the following.

LEMMA 4.3. *There exist constants $C, K > 0$ such that the following hold:*

$$|Z_1|' \geq \left\{(\mathrm{Tr}\Lambda) - C|\mathbf{a}|(1 + |\hat{\mathbf{X}}| + \varepsilon|\mathbf{b}||\hat{\mathbf{Z}}|)\right\}|Z_1|; \tag{19}$$

$$|\hat{Z}_i|' \leq \{2C|\mathbf{a}| + \alpha(t)\}|\hat{Z}_i| + \alpha(t), \tag{20}$$

where

$$\alpha(t) \equiv C|\mathbf{a}|\left[|\hat{\mathbf{X}}| + \varepsilon|\mathbf{b}||\hat{\mathbf{Z}}|\right]; \tag{21}$$

and

$$|\hat{\mathbf{X}}| \leq \bar{M}\left\{e^{\int_0^t \beta_1(s)ds}|\hat{\mathbf{X}}_0| + \int_0^t e^{\int_s^t \beta_1(r)dr}\beta_2(s)ds\right\}, \tag{22}$$

where

$$\beta_1 \equiv -\mu + C|\mathbf{a}||\hat{\mathbf{X}}| + C\Delta,$$

$$\beta_2 \equiv K|\mathbf{b}|\left[\left(1 + \varepsilon|\mathbf{a}||\hat{\mathbf{X}}|\right)|\hat{\mathbf{Z}}| + 1 + 2\varepsilon|\mathbf{a}||\hat{\mathbf{X}}|\right], \tag{23}$$

and μ and $\bar{M}$ are as stated in (17).

Proof of Lemma 4.3. The proof of this lemma is virtually identical to that of Lemma 3.3 in [21]. We state only the differences. In (19) and (21), there are factors of $|\mathbf{b}|$ in front of the $|\hat{\mathbf{Z}}|$ terms due to the bound on $|G_i|$ given by (14) that are not present in (3.11) and (3.12) of [21]. In addition, there is an overall factor of $|\mathbf{b}|$ in front of the first term in β_2 in (23), due to the sharper bound on H given by (18), and in the proof their β_3 is replaced by $\beta_3 \equiv C^*|\mathbf{a}|(1+|\hat{\mathbf{X}}|) + \varepsilon C^*|\mathbf{a}||\mathbf{b}|(1+|\hat{\mathbf{X}}|) + K|\mathbf{b}|$, for some constant C^*.

The last preliminary result we shall need is an estimate of the initial conditions.

LEMMA 4.4 *There exists a constant $K_1 > 0$ such that $|Z_1| > K_1\varepsilon^{\alpha+1}$, $|\hat{\mathbf{X}}| < \frac{1}{\bar{K}\varepsilon^{\alpha+1}}$, and $|\hat{Z}_i|$ are exponentially small at T_qM.*

Proof of Lemma 4.4. Since $|\mathbf{X}| < 1$ by the choice of normalization, the fact that the tracked manifold M and the stable manifold $\{\mathbf{a} = \mathbf{0}\}$ intersect transversely at an angle of $\mathcal{O}(\varepsilon^\alpha)$ implies that there exists a constant K_1 such that $|Z_1| > K_1\varepsilon^{\alpha+1}$ at T_qM. Therefore, using $|\mathbf{X}| < 1$, and the definition of $\hat{X}$, we also have $|\hat{X}| < \frac{1}{K_1\varepsilon^{\alpha+1}}$ at T_qM.

To establish the third result, we apply the argument given in the proof of Lemma 3.2 in [21]. We observe also that here the situation is even better in that the y_i component of the tangent vector is $\mathcal{O}(|\mathbf{a}||\mathbf{b}|)$ by (4) for each $i > 1$.

This concludes the proof of Lemma 4.4.

We finish the proof of the C^1 ELESE in three steps. Let $T = \mathcal{O}(\frac{1}{\varepsilon})$ denote the time required for the trajectory to pass through $\mathcal{B}$ from q to $\bar{q}$. We assume $t = 0$ corresponds to the time at which the trajectory in question is at the point q.

Remark. Although the same in spirit as those in [21], all three steps involve different estimates. The differences can be traced back to the term $\mathbf{b}$ that is factored out in the normal form (4) and to the fact that our technique is designed to apply to any problem in which ρ_ε and $\{\mathbf{a} = \mathbf{0}\}$ intersect transversely at an angle of $\mathcal{O}(\varepsilon^\alpha)$ for any $\alpha \geq 0$.

Step I. Let $0 < T_1 < T$ be any time of size $\mathcal{O}(\frac{1}{\varepsilon})$ such that $|\mathbf{a}|$ is exponentially small for $t \leq T_1$. Then at $t = T_1$, $|\hat{\mathbf{X}}| = \mathcal{O}(\varepsilon + \Delta)$ and $|\hat{\mathbf{Z}}|$ is exponentially small.

Proof of Step I. In Lemma 4.4, we showed that since the angle of intersection of ρ_ε and $\{\mathbf{a} = \mathbf{0}\}$ is $\mathcal{O}(\varepsilon^\alpha)$, with $\alpha \geq 0$, at $t = 0$, the quantities $|\hat{\mathbf{X}}|$ and $|\hat{\mathbf{Z}}|$ satisfy the bounds $|\hat{\mathbf{X}}| \leq \frac{K_1}{\varepsilon^{\alpha+1}}$ and $|\hat{\mathbf{Z}}| \leq 1$ at $t = 0$. Thus, since $|\mathbf{a}|$ is exponentially small at $t = 0$, it follows that $\beta_1 = -\mu + \mathcal{O}(\Delta) +$ exp small and $\beta_2 \leq 2K\Delta +$ exp small at $t = 0$. Then, as long as $|\hat{\mathbf{Z}}| \leq 1$,

$$\beta_1 \leq -\frac{\mu}{2}, \tag{24}$$

and

$$\beta_2 \leq 3K\Delta, \tag{25}$$

(22)–(25) imply

$$|\hat{\mathbf{X}}| \leq \bar{M}\left\{e^{-\frac{\mu}{2}t} \cdot \frac{1}{\bar{K}\varepsilon^{\alpha+1}} + \frac{6K\Delta}{\mu}\right\}. \tag{26}$$

Hence the a priori estimate $|\hat{\mathbf{X}}| \leq \frac{K_1}{\varepsilon^{\alpha+1}}$ continues to hold.

Next, we observe that since $|\hat{\mathbf{Z}}|$ is exponentially small at q by Lemma 4.4, not only does the a priori bound $|\hat{\mathbf{Z}}| \leq 1$ continue to hold for all t up to and including T_1, but $|\hat{\mathbf{Z}}|$ is exponentially small at $t = T_1$. This follows immediately from applying Gronwall's inequality to (20) and recalling that $|\mathbf{a}|$ is exponentially small for $t \leq T_1$ so that $\alpha(t) + 2C|\mathbf{a}| \leq K_2 e^{-\frac{c_2}{\varepsilon}} \equiv \kappa$:

$$|\hat{Z}_i(t)| \leq |\hat{Z}_i(0)|e^{\kappa t} + \left(e^{\kappa t} - 1\right).$$

Finally, (26) implies that $|\hat{\mathbf{X}}| = \mathcal{O}(\varepsilon + \Delta)$ at $t = T_1$.

Step II. Let $T_1 < T_2 < T$ be any time of size $\mathcal{O}(\frac{1}{\varepsilon})$ such that $T - T_2 = \mathcal{O}(\frac{1}{\varepsilon})$ and $|\mathbf{a}|$ and $|\mathbf{b}|$ are exponentially small for $T_1 \le t \le T_2$. Then at $t = T_2$, $|\hat{\mathbf{X}}|$ and $|\hat{\mathbf{Z}}|$ are exponentially small.

Proof of Step II. The result of Step I implies that the a priori bounds $|\hat{\mathbf{X}}| \le \frac{K_1}{\varepsilon^{\alpha+1}}$ and $|\hat{\mathbf{Z}}| \le 1$ hold at $t = T_1$. We now establish these a priori bounds up to T_2.

From the definition of β_2 in (23) and the fact that $|\mathbf{b}|$ is exponentially small, we know

$$\beta_2 \le K_4 e^{-\frac{c_4}{\varepsilon}}. \tag{27}$$

Hence, as long as $|\hat{\mathbf{Z}}| \le 1$, the estimate (27) on β_2 holds up to T_2, implying that $|\hat{\mathbf{X}}| \le \frac{K_1}{\varepsilon^{\alpha+1}}$ at T_2. Also, while $|\hat{\mathbf{X}}| \le \frac{K_1}{\varepsilon^{\alpha+1}}$ continues to hold in this step, we know that $|\hat{\mathbf{Z}}| \le 1$. This establishes the a priori bounds for the entire step.

Next, using (27) and substituting $t = T_2$ in the inequality (22), we obtain that $|\hat{\mathbf{X}}|$ is exponentially small at $t = T_2$, which is as desired, since T_2 is $\mathcal{O}(\frac{1}{\varepsilon})$. Finally, $|\hat{\mathbf{Z}}|$ is also exponentially small at $t = T_2$, since application of Gronwall's inequality to (20) (in a fashion similar to the application of Gronwall's inequality in Step I) yields $|\hat{Z}_i(t)| \le |\hat{Z}_i(0)|e^{\kappa t} + (e^{\kappa t} - 1)$, where

$$\alpha(t) + 2C|\mathbf{a}| \le K_2 e^{-\frac{c_2}{\varepsilon}} \equiv \kappa.$$

Step III. At $t = T$, $|\hat{\mathbf{X}}|$ and $|\hat{\mathbf{Z}}|$ are exponentially small.

Proof of Step III. During this final step, $|\mathbf{b}|$ is exponentially small while $|\mathbf{a}| \le \mathcal{O}(\Delta)$. We first establish the a priori bounds $|\hat{\mathbf{Z}}| \le 1$ and $|\hat{\mathbf{X}}| \le K_3 e^{-\frac{c_3}{\varepsilon}}$. From Step II, we know that these bounds are more than satisfied at $t = T_2$.

If $|\hat{\mathbf{X}}| \le K_3 e^{-\frac{c_3}{\varepsilon}}$ for some K_3 and c_3, then the bound $\beta_1 \le -\frac{\mu}{2}$ and Lemma 4.3 imply

$$|\hat{\mathbf{X}}| \le \bar{M}\left[e^{-\frac{\mu}{2}(t-T_2)}|\hat{\mathbf{X}}(T_2)| + \text{exp small}\right]. \tag{28}$$

Hence, for $K_3 e^{-\frac{c_3}{\varepsilon}} > \bar{M} \cdot (\text{exp small})$, the a priori bound continues to hold as long as $|\hat{\mathbf{Z}}| \le 1$.

Next, we verify that $|\hat{\mathbf{Z}}| \le 1$ holds throughout this step. Recalling (21),

$$\alpha(t) \equiv C|\mathbf{a}|\left[|\hat{\mathbf{X}}| + \varepsilon|\mathbf{b}||\hat{\mathbf{Z}}|\right],$$

we know that for $|\hat{\mathbf{Z}}| \le 1$ and $|\hat{\mathbf{X}}|$ exponentially small,

$$\alpha(t) \le C|\mathbf{a}|K_5 e^{-\frac{c_5}{\varepsilon}}$$

because $|\mathbf{b}|$ is exponentially small. Therefore, (20) implies

$$|\hat{Z}_i(t)| \le \frac{\tilde{C}}{\varepsilon}|\hat{Z}_i(T_2)| + \varepsilon\int_{T_2}^{t} (\text{exp small})\, ds, \tag{29}$$

which guarantees $|\hat{\mathbf{Z}}| \le 1$. Note that in deriving this bound, we took advantage of the fact that the integrals of $|\mathbf{a}|$ stay finite as $\varepsilon \to 0$.

Observing that the first term on the right-hand side of (29) is exponentially small and that the second term is also exponentially small at $t = T$, we have thus concluded the proof of the C^1 ELESE.

Remark 1. T. Kaper has shown that ELESE can be extended to manifolds M of dimension $k + 2$. After that work was completed, the generalization to the $(k + \sigma)$-dimensional case, with $1 \leq \sigma \leq n$, was carried out by S. K. Tin using our methods. Furthermore, he has removed the rectification requirement by working in Plücker coordinates.

Remark 2. In the applications listed in the introduction, the slow manifolds have two or more dimensions and the flows on them range from simple flows with fixed points to complex flows exhibiting resonance bands. Also, these systems depend on parameters, such as the speed of the travelling wave or the amplitude of forcing or damping. See [23] in particular for an example of two coupled nonlinear oscillators in which there is a two-dimensional slow manifold with a resonance band on it and in which the $k + 2$ version of ELESE is used to establish the existence of eight different types of multipulse orbits heteroclinic to fixed points and periodic orbits, including multipulse Silnikov orbits.

5. Multipulse orbits heteroclinic to periodic orbits: An application of ELESE. We present a model problem, consisting of a quasiperiodically modulated pendulum, to illustrate how ELESE with $k = 1$ can be applied. In particular, we prove the existence of multipulse orbits heteroclinic to periodic orbits. Recall that pulses are defined to be those segments of an orbit which are the fast excursions from one slow manifold to another that the orbit makes in between the long intervals of time it spends near the slow manifolds.

The equations of motion are

$$\ddot{q} + A(\tau_1, \tau_2; \omega_1, \beta_1, \beta_2) \sin q = 0, \tag{30a}$$

$$\dot{\tau}_1 = \epsilon, \tag{30b}$$

$$\dot{\tau}_2 = \epsilon \sin(2\pi\tau_2), \tag{30c}$$

where $q \in \mathbb{R}$, $A(\tau_1, \tau_2; \omega_1, \beta_1, \beta_2) = 1 + \beta_1 \sin(2\pi\omega_1\tau_1) + \beta_2 \sin(2\pi\tau_2)$ with $\omega_1 > 1$ and irrational, and $\beta_1, \beta_2 > 0$ such that $0 < \beta_1 + \beta_2 < 1$, $(\tau_1, \tau_2) \in T^2$, and $0 < \varepsilon \ll 1$.

When $\varepsilon = 0$, the parameters τ_1 and τ_2 are frozen, and the system reduces to that of the classical nonlinear pendulum with Hamiltonian

$$H(q, p, \tau_1, \tau_2) = \frac{p^2}{2} - A(\tau_1, \tau_2; \omega_1, \beta_1, \beta_2) \cos q - A(\tau_1, \tau_2; \omega_1, \beta_1, \beta_2). \tag{31}$$

The term $-A(\tau_1, \tau_2; \omega_1, \beta_1, \beta_2)$, independent of q and p, is included in the Hamiltonian H so that H vanishes identically at the fixed points $H(\pm\pi, 0, \tau_1, \tau_2) \equiv 0$ for all $(\tau_1, \tau_2) \in T^2$. Of course, on the cylinder $S^1 \times \mathbb{R}$, these two saddle fixed points coincide, but they are distinct on the universal cover $\mathbb{R}^2$, which is where we shall study the global geometry.

In the $\varepsilon = 0$ phase space, there exists a pair of normally hyperbolic invariant two-tori, which are the Cartesian products of the saddle fixed points $(q = \pm\pi, p = 0)$ with the two-torus T^2:

$$S_0^1 \equiv (-\pi, 0) \times T^2, \tag{32a}$$

$$S_0^2 \equiv (\pi, 0) \times T^2. \tag{32b}$$

Moreover, every point on S_0^1 is connected by two heteroclinic orbits

$$\Gamma^{\text{up}}_{\tau_1,\tau_2} \equiv (q_h^{\text{up}}(t), p_h^{\text{up}}(t), \tau_1, \tau_2), \tag{33a}$$

$$\Gamma^{\text{down}}_{\tau_1,\tau_2} \equiv (q_h^{\text{down}}(t), p_h^{\text{down}}(t), \tau_1, \tau_2) \tag{33b}$$

to the point on S_0^2 which has the same τ_1 and τ_2 coordinates. The orbit $\Gamma^{\text{up}}_{\tau_1,\tau_2}$ (resp., $\Gamma^{\text{down}}_{\tau_1,\tau_2}$) is asymptotic to the point $(-\pi, 0, \tau_1, \tau_2)$ as $t \to -\infty$ (resp., $t \to +\infty$) and to the point $(\pi, 0, \tau_1, \tau_2)$ as $t \to \infty$ (resp., $t \to -\infty$). The normally hyperbolic invariant manifolds S_0^1 and S_0^2 have smooth three-dimensional stable and unstable manifolds, $W^S(S_0^1)$ and $W^U(S_0^1)$; $W^S(S_0^2)$ and $W^U(S_0^2)$, respectively. One branch of each of $W^U(S_0^1)$ and $W^S(S_0^2)$ and one branch of each of $W^U(S_0^2)$ and $W^S(S_0^1)$ coincide in the homoclinic manifolds

$$\Xi^{\text{up}} \equiv W^U(S_0^1) \bigcap W^S(S_0^2) \equiv \bigcup_{\tau_1,\tau_2 \in T^2} \Gamma^{\text{up}}_{\tau_1,\tau_2}, \tag{34a}$$

$$\Xi^{\text{low}} \equiv W^U(S_0^2) \bigcap W^S(S_0^1) \equiv \bigcup_{\tau_1,\tau_2 \in T^2} \Gamma^{\text{down}}_{\tau_1,\tau_2}. \tag{34b}$$

Now, for $0 < \varepsilon \ll 1$, the persistence theory for normally hyperbolic invariant manifolds presented in [13] guarantees that there exist manifolds S_ε^1 and S_ε^2 that are differentiably $\mathcal{O}(\varepsilon)$ close to S_0^1 and S_0^2. In fact, for (30), we have $S_\varepsilon^1 \equiv S_0^1$ and $S_\varepsilon^2 \equiv S_0^2$ since the perturbation in (30a) was chosen to be in the form of slow amplitude modulation.

The slow flow on S_ε^1 is illustrated in Fig. 1. On S_ε^1, there are two periodic orbits

$$\gamma^{1a} \equiv \left\{ (\tau_1, \tau_2) | \tau_2 = \frac{1}{2} \bmod 1 \right\}, \tag{35a}$$

$$\gamma^{1r} \equiv \{ (\tau_1, \tau_2) | \tau_2 = 0 \bmod 1 \}, \tag{35b}$$

which are attracting and repelling, respectively, for the system (30b) and (30c). The slow flow on S_ε^2 is the same, and we denote its attracting and repelling periodic orbits by γ^{2a} and γ^{2r}, respectively.

The persistent hyperbolic manifolds S_ε^1 and S_ε^2 have smooth local stable and unstable manifolds—$W^S_{\text{loc}}(S_\varepsilon^1)$, and $W^U_{\text{loc}}(S_\varepsilon^1)$; $W^S_{\text{loc}}(S_\varepsilon^2)$, and $W^U_{\text{loc}}(S_\varepsilon^2)$—which are $\mathcal{O}(\varepsilon)$ close to their unperturbed counterparts. However, the perturbed global stable and unstable manifolds no longer coincide. Instead, they intersect transversely along two-dimensional surfaces spanned by heteroclinic orbits connecting one of the slow manifolds to the other. These heteroclinic orbits have only one pulse and may be detected by the adiabatic Melnikov theory; see [31], [30], and [22]. We briefly review the relevant one-pulse results, since we need to know some details about the perturbed global geometry for our construction of multipulse heteroclinic orbits. We refer the reader to [35] for new results and a complete exposition of Melnikov theory in perturbed Hamiltonian systems.

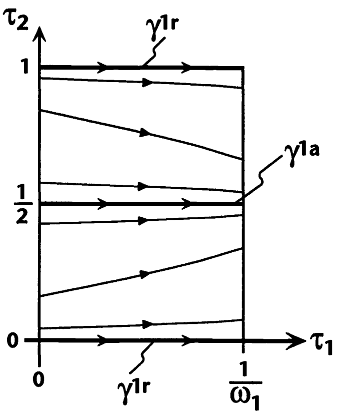

FIG. 1. *The phase portrait of the slow flow on the perturbed slow manifold S^1_ε in the example of* §5.

We work only with the upper pair of manifolds $W^U(S^1_\varepsilon)$ and $W^S(S^2_\varepsilon)$. The work and result for the lower pair are almost identical. The Melnikov function is

$$M(\tau_1,\tau_2;\omega_1,\beta_1,\beta_2) = \int_{-\infty}^{\infty} \left(\nabla_{(\tau_1,\tau_2)}H \cdot \mathbf{g}^\tau\right)(q_h^{\text{up}}(t),p_h^{\text{up}}(t),\tau_1,\tau_2)dt, \tag{36}$$

where $\mathbf{g}^\tau$ is the two-component vector consisting of the coefficients on the $\mathcal{O}(\varepsilon)$ terms in the vector field (30b) and (30c). Melnikov theory implies that if there exists a point $(\bar{\tau}_1,\bar{\tau}_2) \in T^2$ and parameter values $(\bar{\omega}_1,\bar{\beta}_1,\bar{\beta}_2)$ such that

$$M(\bar{\tau}_1,\bar{\tau}_2;\bar{\omega}_1,\bar{\beta}_1,\bar{\beta}_2) = 0, \tag{37a}$$

$$\nabla_{(\tau_1,\tau_2)}M(\bar{\tau}_1,\bar{\tau}_2;\bar{\omega}_1,\bar{\beta}_1,\bar{\beta}_2) \text{ has rank } 1, \tag{37b}$$

then, for sufficiently small ε, $W^U(S^1_\varepsilon)$ intersects $W^S(S^2_\varepsilon)$ in a two-dimensional surface near $(\bar{\tau}_1,\bar{\tau}_2;\bar{\omega}_1,\bar{\beta}_1,\bar{\beta}_2)$. Furthermore, this two-dimensional intersection surface varies smoothly with ε for $0<\varepsilon\ll 1$, and at every point on it, the intersection of $W^U(S^1_\varepsilon)$ and $W^S(S^2_\varepsilon)$ is transverse, with the angle between the tangent planes being $\mathcal{O}(\varepsilon)$. See [35, Thm. 4.1.14], where our example corresponds to the case of $m=2$, $n=1$, and $l=0$.

For (30), an explicit computation of (36) yields

$$M(\tau_1,\tau_2;\omega_1,\beta_1,\beta_2) = -\pi\left[2\beta_1\omega_1\cos(2\pi\omega_1\tau_1)+\beta_2\sin(4\pi\tau_2)\right]\int_{-\infty}^{\infty}\left(1+\cos(q_h^{\text{up}}(t)\right)dt. \tag{38}$$

Since the improper integral in (38) is a finite positive number, one readily verifies that, for fixed ω_1,β_1, and β_2, the Melnikov function M has two smooth curves, η^{11} and η^{12}, of simple zeroes on T^2. For β_2 sufficiently small, the curves η^{11} and η^{12} stay bounded away from each other. The curve η^{11} passes through the points $(\tau_1=\frac{1}{4\omega_1},\tau_2=0)$, $(\tau_1=\frac{1}{4\omega_1},\tau_2=\frac{1}{4})$, $(\tau_1=\frac{1}{4\omega_1},\tau_2=\frac{1}{2})$, and $(\tau_1=\frac{1}{4\omega_1},\tau_2=\frac{3}{4})$. Similarly, the curve η^{12} passes through the points $(\tau_1=\frac{3}{4\omega_1},\tau_2=0)$, $(\tau_1=\frac{3}{4\omega_1},\tau_2=\frac{1}{4})$, $(\tau_1=\frac{3}{4\omega_1},\tau_2=\frac{1}{2})$, and $(\tau_1=\frac{3}{4\omega_1},\tau_2=\frac{3}{4})$. The zero set on S^1_0 is shown schematically in Fig. 2.

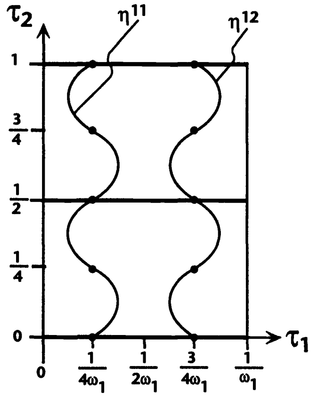

FIG. 2. *The zero set of the Melinkov function* (38) *on* S_0^1.

Hence, Melnikov theory implies that there exist two families of surviving one-pulse heteroclinic orbits. Each orbit is asymptotic to S_ε^1 as $t \to -\infty$ and to S_ε^2 as $t \to \infty$.

The Melnikov function for the lower separatrix $\Gamma_{\tau_1,\tau_2}^{\mathrm{down}}$ is identical to the Melnikov function given by (38) for the upper separatrix since the integral in (38) with $q_h^{\mathrm{down}}(t)$ replacing $q_h^{\mathrm{up}}(t)$ is the same. Thus, $W^U(S_\varepsilon^2)$ and $W^S(S_\varepsilon^1)$ also intersect transversely at an angle of $\mathcal{O}(\varepsilon)$ near the simple zeroes of the Melnikov function (38), and there are two families of one-pulse heteroclinic orbits that asymptote to S_ε^2 as $t \to -\infty$ and to S_ε^1 as $t \to \infty$.

We observe that the curves η^{11} and η^{12} transversely intersect each of the periodic orbits $\gamma^{1a}, \gamma^{1r}, \gamma^{2a}$, and γ^{2r}. Therefore, among the surviving orbits in the abovementioned families, there exist eight distinguished one-pulse orbits that are actually heteroclinic to the periodic orbits γ^{1a} and γ^{2a}; and γ^{1r} and γ^{2r}. Each of these is the unique orbit close on finite-time intervals to one of the eight distinguished unperturbed heteroclinic orbits

$$\text{(39a)} \qquad \Gamma^1 \equiv \Gamma^{\mathrm{up}}_{\frac{1}{4\omega_1},\frac{1}{2}}, \qquad \Gamma^2 \equiv \Gamma^{\mathrm{up}}_{\frac{3}{4\omega_1},\frac{1}{2}},$$

$$\text{(39b)} \qquad \Gamma^3 \equiv \Gamma^{\mathrm{up}}_{\frac{1}{4\omega_1},0}, \qquad \Gamma^4 \equiv \Gamma^{\mathrm{up}}_{\frac{3}{4\omega_1},0},$$

and $\Gamma^5 - \Gamma^8$, which are defined as $\Gamma^1 - \Gamma^4$ are, respectively, but with the superscript down replacing up. These are distinguished because their takeoff and touchdown points (limits as $t \to \mp\infty$) are the eight points on S_0^1 and S_0^2 in which the zero curves η^{11} and η^{22} intersect the periodic orbits $\gamma^{1a}, \gamma^{1r}, \gamma^{2a}$, and γ^{2r}.

This concludes our brief review of the one-pulse results.

We now turn our attention to multipulse orbits and establish the existence of many heteroclinic orbits connecting the periodic orbits γ^{1a}, γ^{1r}, γ^{2a}, and γ^{2r} to each other which have finitely many fast pulses interspersed with slow segments. The main idea in proving their existence is to track the unstable manifolds of these periodic orbits through each passage near the slow manifolds S_ε^1 and S_ε^2 using ELESE.

We begin by constructing *singular* multipulse heteroclinic orbits. Two examples of three-pulse singular heteroclinic orbits (see Fig. 3) are

$$\text{(40)} \qquad \gamma^{2a} \bigcup \Gamma^5 \bigcup \tilde{\gamma}^{1a} \bigcup \Gamma^2 \bigcup \tilde{\tilde{\gamma}}^{2a} \bigcup \Gamma^5 \bigcup \gamma^{1a}$$

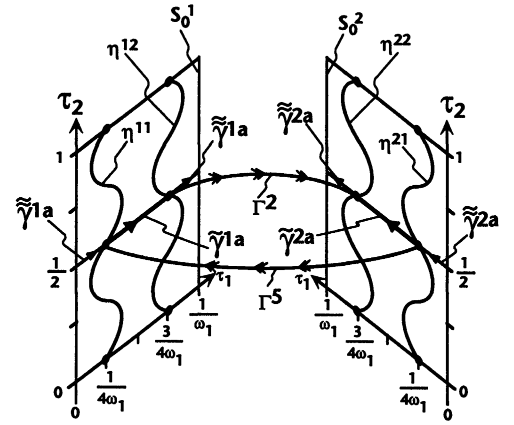

FIG. 3. *The geometry of the triple-pulse singular heteroclinic orbit given by* (40) : $\gamma^{2a} \cup \Gamma^5 \cup \tilde{\gamma}^{1a} \cup \Gamma^2 \cup \tilde{\tilde{\gamma}}^{2a} \cup \Gamma^5 \cup \gamma^{1a}$.

and

$$\gamma^{1r} \bigcup \Gamma^3 \bigcup \tilde{\tilde{\gamma}}^{2r} \bigcup \Gamma^8 \bigcup \gamma^{1r} \bigcup \Gamma^4 \bigcup \gamma^{2r}, \tag{41}$$

where $\tilde{\gamma}^{ij}$ denotes the segment of the periodic orbit γ^{ij} with $\frac{1}{4\omega_1} \leq \tau_1 \leq \frac{3}{4\omega_1}$ and $\tilde{\tilde{\gamma}}^{ij}$ denotes the remaining piece of the periodic orbit γ^{ij}.

In general, an N-pulse singular orbit hetero- or homoclinic to the attracting periodic orbits consists of the following:

A. the slow attracting periodic orbits, γ^{ia} and γ^{ja}, to which the orbit will be hetero- or homoclinic
and

B. the N unperturbed heteroclinic orbits chosen from $\{\Gamma^1, \Gamma^2, \Gamma^5, \Gamma^6\}$ that are alternatingly "up" and "down" and that connect points on γ^{1a} and γ^{2a},
which are interspersed with

C. segments of γ^{1a} and γ^{2a}, where a segment of γ^{ia} may consist of going around γ^{ia} finitely many (including fractional) times, i.e., any finite string of alternating segments $\tilde{\gamma}^{ia}$ and $\tilde{\tilde{\gamma}}^{ia}$.

In the same fashion, one constructs N-pulse singular orbits hetero- and homoclinic to the repelling periodic orbits, except that the unperturbed heteroclinics are chosen from the set $\{\Gamma^3, \Gamma^4, \Gamma^7, \Gamma^8\}$.

Remark. Of course, in A, $i = j$ if N is even, and $i \neq j$ if N is odd.

We now prove the following theorem.

THEOREM. *For all ε sufficiently small, there exists a unique true multipulse heteroclinic orbit $\mathcal{O}(\varepsilon)$ close to every singular multipulse heteroclinic orbit.*

Remark. The true and singular multipulse orbits are only $\mathcal{O}(\varepsilon)$ close because the stable and unstable manifolds of the perturbed tori are $\mathcal{O}(\varepsilon)$ close to their unperturbed counterparts. Furthermore, for general problems of the form (1), $\mathcal{O}(\varepsilon)$ closeness of these orbits is the best that can be expected since the perturbed and unperturbed slow manifolds in (1) are $\mathcal{O}(\varepsilon)$ apart, in contrast to the situation here where they coincide.

Proof of the theorem. For the sake of exposition, we prove the existence of the unique three-pulse heteroclinic orbit connecting γ^{2a} and γ^{1a} that lies near the singular heteroclinic orbit (40):

$$\gamma^{2a}\bigcup\Gamma^5\bigcup\tilde{\gamma}^{1a}\bigcup\Gamma^2\bigcup\tilde{\tilde{\gamma}}^{2a}\bigcup\Gamma^5\bigcup\gamma^{1a}. \tag{42}$$

The generalization to all of the other orbits in the theorem is given at the end of the proof.

Let $\mathcal{M}_\varepsilon$ denote the two-dimensional manifold $W^U(S^2_\varepsilon)|_{\gamma^{2a}}$ that we will track in this proof using ELESE with $k = 1$.

First, Melnikov theory immediately implies that

(43) $W^U(S^2_\varepsilon)|_{\gamma^{2a}}$ transversely intersects $W^S(S^1_\varepsilon)$ at an angle of $\mathcal{O}(\varepsilon)$

since this is a one-dimensional subset of the one-pulse intersection surface. Part of this intersection is near Γ^5.

Next, due to the existence of this transverse intersection, it follows by a continuous-dependence argument that there exist initial conditions on $\mathcal{M}_\varepsilon$ whose trajectories satisfy the hypotheses of ELESE, i.e., initial conditions whose trajectories spend $\mathcal{O}(\frac{1}{\varepsilon})$ time inside a Δ neighborhood of S^1_ε. Namely, the initial conditions actually in the intersection never leave the neighborhood, and there are initial conditions that leave the neighborhood in $\mathcal{O}(\ln\frac{1}{\varepsilon})$ time, due to the exponential expansion in the a direction. Hence, by continuity of the manifold, there exist initial conditions which spend the desired amount of time near S^1_ε. More specifically, there exists a point q on $\mathcal{M}_\varepsilon \cap \{|b| = \Delta\}$ such that the trajectory through q exits the Δ-neighborhood of S^1_ε at a point $\bar{q} \in \mathcal{M}_\varepsilon \cap \{|a| = \Delta\}$ after a time $(\frac{1}{2\omega_1\varepsilon}) + \mathcal{O}(1)$.

Therefore, the hypotheses of ELESE are satisfied, and ELESE implies that at the point $\bar{q}$, the manifold $\mathcal{M}_\varepsilon$ and its tangent space are $\mathcal{O}(e^{-\frac{c}{\varepsilon}})$ close to the local unstable manifold $W^U_{\text{loc}}(S^1_\varepsilon)|_{\gamma^{1a}}$ and its tangent space.

Now, the process repeats, but in the other direction. First, since $\mathcal{M}_\varepsilon$ and $W^U_{\text{loc}}(S^1_\varepsilon)|_{\gamma^{1a}}$ are so close by the previous step, and since $W^U_{\text{loc}}(S^1_\varepsilon)|_{\gamma^{1a}}$ transversely intersects $W^S(S^2_\varepsilon)$ at an angle of $\mathcal{O}(\varepsilon)$ by Melnikov theory (part of this intersection being close to Γ^2), it follows immediately that the tracked manifold $\mathcal{M}_\varepsilon$ transversely intersects $W^S(S^2_\varepsilon)$ at an angle of $\mathcal{O}(\varepsilon)$ as well. Then, as above, there exist orbits which spend the desired amount of time, $(\frac{1}{2\omega_1\varepsilon}) + \mathcal{O}(1)$ in the case of this example, in a Δ-neighborhood of S^2_ε and which satisfy the hypotheses of ELESE. Thus, ELESE implies that, at the point where these trajectories exit that neighborhood, $\mathcal{M}_\varepsilon$ and its tangent hyperplane are $\mathcal{O}(e^{-\frac{c}{\varepsilon}})$ close to $W^U_{\text{loc}}(S^2_\varepsilon)|_{\gamma^{2a}}$.

Finally, we use once more the first step in the process: since $\mathcal{M}_\varepsilon$ and $W^U_{\text{loc}}(S^2_\varepsilon)|_{\gamma^{2a}}$ are so close by the previous step, and since $W^U(S^2_\varepsilon)|_{\gamma^{2a}}$ transversely intersects $W^S(S^1_\varepsilon)$ at an angle of $\mathcal{O}(\varepsilon)$ by Melnikov theory (part of this intersection being near Γ^5), it follows immediately that the tracked manifold $\mathcal{M}_\varepsilon$ transversely intersects $W^S(S^1_\varepsilon)$ at an angle of $\mathcal{O}(\varepsilon)$, as well. Hence, we have constructed a three-pulse orbit backwards asymptotic to γ^{2a} and forwards asymptotic to γ^{1a}. Furthermore, this orbit is unique due to the transversality of the above intersections, and it is $\mathcal{O}(\varepsilon)$ close to the singular heteroclinic orbit (40).

The proof just given for the three-pulse example readily extends to a proof of the existence of all of the orbits in the theorem. Let $\mathcal{M}_\varepsilon$ denote the two-dimensional manifold $W^U(S^i_\varepsilon)|_{\gamma^{ia}}$ (where $i = 1$, or $i = 2$ is the index of the slow periodic orbit to which the desired hetero- or homoclinic orbit is backwards asymptotic). The above proof explicitly shows the existence of the first pulse near the first fast piece of the singular orbit. Then, by transversality of the intersections and by the same continuous-dependence argument given above, there exist initial conditions on $\mathcal{M}_\varepsilon$ whose trajectories spend long time intervals near the other slow manifold S^j_ε (i.e., $i \neq j$) and whose trajectories satisfy the hypotheses of ELESE. We are especially interested in those trajectories which spend time intervals of length $(\frac{k}{2\omega_1})\frac{1}{\varepsilon} + \mathcal{O}(1)$ near S^j_ε for any fixed positive integer k, since these leave the neighborhood of S^j_ε near the valid takeoff points given by the curves η^{j1} and η^{j2} of the Melnikov function zeroes.

Then, by ELESE, when these trajectories exit the neighborhood of S^j_ε, $\mathcal{M}_\varepsilon$ is C^1-$\mathcal{O}(e^{-\frac{c}{\varepsilon}})$ close to the fast unstable foliation $W^U_{\text{loc}}(S^j_\varepsilon)|_{\gamma^{ja}}$. Hence, a portion of $\mathcal{M}_\varepsilon$ is brought back into the neighborhood of the first slow manifold, S^i_ε, due to the fact that $W^U(S^j_\varepsilon)$ and $W^S(S^i_\varepsilon)$ intersect transversely at an angle of $\mathcal{O}(\varepsilon)$. By induction, this process can be repeated finitely many times until one completes the hetero- or homoclinic orbit with the desired finite number of pulses and slow segments in between. □

Remark. In addition to the heteroclinic multipulse orbits found above, there exist other types of multipulse orbits in this model which may be treated with similar methods. Above, we found orbits that are either backward and forward asymptotic to the periodic orbits that are attracting on the slow tori or orbits that are backward and forward asymptotic to the periodic orbits that are repelling on the slow tori. Another type of multipulse orbit consists of those that are backward asymptotic to a repelling periodic orbit and forward asymptotic to an attracting periodic orbit. The singular orbits for these consist of the union of finitely many segments of slow orbits on the tori (orbit segments that are disjoint from the periodic orbits) interspersed with the appropriate up and down heteroclinic connections. The segments of slow orbits start at the touchdown point $(\tau_1^{\text{touchdown}}, \tau_2^{\text{touchdown}})$ of the heteroclinic orbit $\Gamma^{\text{up or down}}_{\tau_1^{\text{touchdown}}, \tau_2^{\text{touchdown}}}$ and end at the takeoff point $(\tau_1^{\text{takeoff}}, \tau_2^{\text{takeoff}})$ of the next heteroclinic encountered in the singular orbit.

In contrast to the situation of the theorem in this section, the singular orbits discussed in the previous paragraph are not locally unique; there is a two-dimensional surface of each type of multipulse heteroclinic orbit, parametrized by the value of the τ_2 coordinate at their first takeoff points. The existence of real multipulse heteroclinic orbits near these singular ones may be established using the $k+2$ ELESE, where $(k+2)$-dimensional manifolds are tracked and where 2 is the number of center directions that are followed. Note, of course, that there are only two center directions. Equivalently a λ-lemma argument may be employed where the entire slow manifold is treated as the fixed point of some map associated with the vector field, say the time-1 map of the flow.

Appendix. In this appendix, we briefly review the relevant Melnikov theory. For fixed $(t = 0, \tau_1, \tau_2) \in \mathbb{R} \times T^2$, let $r \equiv (q_h^{\text{up}}(0), p_h^{\text{up}}(0), \tau_1, \tau_2)$ denote the point on the unperturbed homoclinic manifold $\Xi^{\text{up}} - (S^1_0 \cup S^2_0)$. At the point r, there is a three-dimensional hyperplane

$$\Pi_r \equiv \text{span}\left\{(0,0,\tau_1 = 1, 0), (0,0,0,\tau_2 = 1), \left(\frac{\partial H}{\partial q}, \frac{\partial H}{\partial p}, 0, 0\right)\right\} \tag{44}$$

transverse to Ξ^{up}, where the derivatives of H are evaluated at the point r. We will measure the splitting distance between the perturbed unstable and stable manifolds $W^U(S^1_\varepsilon)$ and $W^S(S^2_\varepsilon)$ in the transverse hyperplane Π_r.

First, we observe that the coincident unperturbed manifolds $W^U(S^1_0)$ and $W^S(S^2_0)$ intersect Π_r transversely in a two-dimensional surface. Hence, we also know that the perturbed manifolds $W^U_{\text{loc}}(S^1_\varepsilon)$ and $W^S_{\text{loc}}(S^2_\varepsilon)$ intersect Π_r transversely in two-dimensional surfaces, $\Sigma^U_{r,\varepsilon}$ and $\Sigma^S_{r,\varepsilon}$, since they are $\mathcal{O}(\varepsilon)$ away from their unperturbed counterparts. Let r_ε^U and r_ε^S denote two points on the surfaces $\Sigma_{r,\varepsilon}^U$ and $\Sigma_{r,\varepsilon}^S$, respectively, that have the same values of τ_1 and τ_2. Geometrically, the distance between the points r_ε^U and r_ε^S is

$$(45)\quad d(\tau_1,\tau_2;\omega_1,\beta_1,\beta_2;\varepsilon) \equiv \frac{\left(\nabla_{(q,p)} H(q_h^{\mathrm{up}}(0), p_h^{\mathrm{up}}(0), \tau_1, \tau_2)\right) \cdot (q_\varepsilon^U - q_\varepsilon^S, p_\varepsilon^U - p_\varepsilon^S)^T}{\|\nabla_{(q,p)} H(q_h^{\mathrm{up}}(0), p_h^{\mathrm{up}}(0), \tau_1, \tau_2), \|},$$

where $\cdot$ denotes the usual inner product in $\mathbb{R}^2$. Finally, we use the fact that the leading order term $d(\tau_1,\tau_2;\omega_1,\beta_1,\beta_2;0)$ in the Taylor expansion of the numerator of $d(\tau_1,\tau_2;\omega_1,\beta_1,\beta_2;\varepsilon)$ about $\varepsilon = 0$ is identically zero since the unperturbed unstable and stable manifolds are coincident, and we use Melnikov's original idea. These lead to

$$(46)\qquad d(\tau_1,\tau_2;\omega_1,\beta_1,\beta_2;\varepsilon) = \varepsilon \frac{M(\tau_1,\tau_2;\omega_1,\beta_1,\beta_2)}{\|\nabla_{(q,p)} H(q_h^{\mathrm{up}}(0), p_h^{\mathrm{up}}(0), \tau_1, \tau_2)\|} + \mathcal{O}(\varepsilon^2)$$

as $\varepsilon \to 0$, where the Melnikov function (i.e., the numerator of $\frac{\partial d}{\partial \varepsilon}|_{\varepsilon=0}$) is

$$(47)\qquad M(\tau_1,\tau_2;\omega_1,\beta_1,\beta_2) = \int_{-\infty}^{\infty} \left(\nabla_{(\tau_1,\tau_2)} H \cdot \mathbf{g}^\tau\right) (q_h^{\mathrm{up}}(t), p_h^{\mathrm{up}}(t), \tau_1, \tau_2) dt,$$

as reported above in (36).

ON SUBDIVISION INTERPOLATION SCHEMES*

GUSTAF GRIPENBERG†

Abstract. Subdivision cardinal interpolation schemes that preserve functions of positive type are shown to be related to orthonormal multiresolutions. The interpolating function is the solution to a certain optimization problem, and this makes it possible to derive error estimates, in particular for Lagrange iterative interpolation schemes.

Key words. interpolation, subdivision, error estimate, wavelet, positive type, Lagrange

AMS subject classifications. 65D05, 42C15

1. Introduction.

The purpose of this paper is to study subdivision cardinal interpolation schemes of the form

$$f(2^{-j-1}m) = 2\sum_{k\in\mathbb{Z}}\gamma(m-2k)f(2^{-j}k), \quad m\in\mathbb{Z}, \quad j\geq 0, \tag{1}$$

where the sequence $\{\gamma(k)\}_{k\in\mathbb{Z}}$ is the mask that determines the interpolation scheme in question. (The normalizing factor 2 is for convenience introduced here so that it does not appear in the equations one obtains after taking Fourier transforms.) Such schemes have been studied by several authors, and various conditions for the mask to generate an interpolation scheme are known; see e.g., [1], [5], [6], [16], and the references mentioned there. It is clear that if the restriction $F = f_{|\mathbb{Z}}$ of f to the integers is known, then one finds from (1) the values of f at the half-integer values $\mathbb{Z}+\frac{1}{2}$ (by taking $j=0$), then the values at $\mathbb{Z}+\frac{1}{4}$ and $\mathbb{Z}+\frac{3}{4}$ (by taking $j=1$), and so on. (If the values of f are not given on $\mathbb{Z}$ but on some other set of evenly spaced points, one can use a simple transformation of the argument to reduce the problem to the one considered here.) If $m=2p$ in (1) is even, then one has

$$f(2^{-j}p) = 2\gamma(0)f(2^{-j}p) + 2\sum_{\substack{k\in\mathbb{Z}\\ k\neq p}}\gamma(2(p-k))f(2^{-j}k).$$

Since we are studying an interpolation and not a refinement scheme (that is, we do not want to change values of f already calculated), we have to require that

$$\gamma(2k) = \frac{1}{2}\delta_{0,k}, \quad k\in\mathbb{Z}$$

(where $\delta_{i,j}=1$ if $i=j$ and 0 otherwise).

Observe that the interpolation scheme in (1) is linear and translation invariant. Therefore, it suffices to find the fundamental interpolation function Φ that interpolates the sequence $\{\delta_{k,0}\}_{k\in\mathbb{Z}}$. Provided the sequence $\{F(n)\}_{n\in\mathbb{Z}}$ is known, one can then take as the desired interpolant $I_\Phi(F)$ the function

$$I_\Phi(F)(\underline{t}) \overset{\text{def}}{=} \sum_{k\in\mathbb{Z}}F(k)\Phi(\underline{t}-k).$$

† Department of Mathematics, University of Helsinki, P.O. Box 4 (Regeringsgatan 15), 00014 University of Helsinki, Finland (gustaf.gripenberg@helsinki.fi).

(Here and below we use underlined arguments like $\underline{t}$ to denote arguments used for defining functions so that, for example, $\underline{t}^2$ denotes the function that maps each real number t to the real number t^2.) It turns out (see [4, pp. 208–209]) that Φ should satisfy the equation

$$\Phi(\underline{t}) = 2\sum_{k\in\mathbb{Z}} \gamma(k)\Phi(2\underline{t}-k), \quad \Phi(\underline{k}) = \delta_{\underline{k},0}, \tag{2}$$

and we let Φ be defined by this relation. From (2), one immediately sees that

$$\gamma(\underline{k}) = \tfrac{1}{2}\Phi(\tfrac{\underline{k}}{2}). \tag{3}$$

We will only consider the case where Φ and hence γ are real functions, and the main restriction we put on Φ (in some of the results below) is that it is of positive type (and continuous), which just means that $\hat{\Phi}$ and $\hat{\gamma}$ are nonnegative functions.

Recall that a function $g : \mathbb{A} \to \mathbb{C}$ (where $\mathbb{A}$ is some additive group) is said to be of positive type if

$$\sum_{i=1}^{M}\sum_{j=1}^{M} g(t_i - t_j)c_i\overline{c_j} \geq 0, \quad t_i \in \mathbb{A}, \quad c_i \in \mathbb{C}, \quad i = 1, 2, \ldots, M$$

(see, e.g., [12]). We say that the subdivision interpolation scheme given by (1) is of positive type if the fundamental interpolation function Φ given by (2) is of positive type. It is straightforward to check that if this is the case, then $I_\Phi(F)$ is of positive type whenever the sequence F is of positive type.

One way to construct a subdivision interpolation scheme of positive type is to take

$$\Phi(\underline{t}) = \int_{\mathbb{R}} \varphi(s+\underline{t})\varphi(s)\,\mathrm{d}s, \tag{4}$$

where φ is the scaling function of an orthonormal multiresolution (or a multiresolution analysis) of $L^2(\mathbb{R};\mathbb{R})$ (for simplicity we consider only the real case), i.e., the pair $(\{V_m\}_{m\in\mathbb{Z}}, \varphi)$ satisfies the following properties:

(5) $\varphi \in L^2(\mathbb{R};\mathbb{R})$ and V_m is, for each $m \in \mathbb{Z}$, the closed subspace of $L^2(\mathbb{R};\mathbb{R})$ spanned by $\{\varphi(2^{-m}\underline{t} - k)\}_{k\in\mathbb{Z}}$;

(6) $V_m \subset V_{m-1}$, $m \in \mathbb{Z}$;

(7) $\lim_{m\to-\infty} V_m = L^2(\mathbb{R};\mathbb{R})$, i.e., $\lim_{m\to-\infty} P_m f = f$ for every $f \in L^2(\mathbb{R};\mathbb{R})$, where P_m is the orthogonal projection of $L^2(\mathbb{R};\mathbb{R})$ onto V_m;

(8) $\{\varphi(\underline{t} - k)\}_{k\in\mathbb{Z}}$ is an orthonormal basis in V_0.

(Concerning (7), note that it follows from the other assumptions that for all f one has $\lim_{m\to\infty} P_m f = 0$ as well; see, e.g., [2].) By (6) and (8), we have

$$\varphi(\underline{t}) = 2\sum_{k\in\mathbb{Z}} \alpha(k)\varphi(2\underline{t} - k), \tag{9}$$

where the filter α is given by

$$\alpha(\underline{k}) = \int_{\mathbb{R}} \varphi(s)\varphi(2s-\underline{k})\,\mathrm{d}s.$$

It is straightforward to check that if (4) and (8) hold, then Φ is a continuous function of positive type. Combining (4) and (9), we conclude that

$$\gamma(\underline{k}) = \sum_{j\in\mathbb{Z}} \alpha(\underline{k}+j)\alpha(j). \tag{10}$$

Note that in practice, one often follows the reverse reasoning: starting from Φ and γ, one constructs φ and α such that (4) and (10) hold.

If we were to consider a complex multiresolution (of $L^2(\mathbb{R};\mathbb{C})$), then the only difference is that we would introduce complex conjugates at appropriate places in the formulas above. For further results on multiresolutions, see e.g., [4], [10], and [11].

We shall first give necessary and sufficient conditions for a sequence γ to be the mask of an interpolation scheme of positive type, and we shall prove (the not very surprising result) that essentially every subdivision interpolation scheme of positive type is associated with a multiresolution scheme by means of (4).

It is possible to prove that $\Phi \in L^2(\mathbb{R};\mathbb{R})$ and $\gamma \in \ell^2(\mathbb{Z};\mathbb{R})$. In general, one does not have $\Phi \in L^1(\mathbb{R};\mathbb{R})$ and $\gamma \in \ell^1(\mathbb{Z};\mathbb{R})$, which can be seen by considering the example $\varphi(\underline{t}) = \sin(\pi\underline{t})/(\pi\underline{t})$, in which case $\Phi = \varphi$ and $\alpha(\underline{k}) = \gamma(\underline{k}) = \sin(\pi\underline{k}/2)/(\pi\underline{k})$. Below, however, we shall make the stronger assumption that $\sum_{k\in\mathbb{Z}} \log(|k|+1)|\gamma(k)| < \infty$. Observe that if one wants the interpolation scheme to reproduce constants, then one must have $\sum_{k\in\mathbb{Z}} \gamma(k) = 1$, and this is also a necessary condition for (2) to have a nontrivial integrable solution.

The second and main problem is to find error estimates. To accomplish this, we first consider another problem. Find a norm $\|\bullet\|$ so that

$$\|I_\Phi(F)\| \le \|g\|, \quad \text{for all functions } g \text{ with } \quad g(n) = F(n), \quad n \in \mathbb{Z}.$$

It turns out that one should choose the norm to be of the form $\|\underline{g}\|^2 = \int_{\mathbb{R}} |\hat{\underline{g}}(\omega)|^2 \eta(\omega)\,\mathrm{d}\omega$ (where η is such that $\eta(\underline{\omega})\hat{\Phi}(\underline{\omega})$ is bounded and periodic), and one gets an error estimate of the form $\|f - I_\Phi(f_{|\mathbb{Z}})\| \le \|f\|$. From this inequality one can derive more useful results where one gets inequalities involving other norms (in, e.g., Sobolev spaces) of the error, but in any case, one must have enough information about the function η. These estimates become more precise if Φ becomes more regular. Observe that these results do not assume that the fundamental interpolation function Φ is of positive type.

For other approaches to error estimates involving wavelets, see, e.g., [14] and the references mentioned there.

2. Statement of results.

It is clear that the interpolation scheme (1) is easiest to use if γ has compact support, but nevertheless we state some of our results in greater generality. First, we study what the necessary assumptions on γ are. We define the Fourier transform of a function in $L^1(\mathbb{R};\mathbb{C})$ to be $\hat{f}(\underline{\omega}) = \int_{\mathbb{R}} \mathrm{e}^{-2\pi\mathrm{i}\underline{\omega}t} f(t)\,\mathrm{d}t$, and we use corresponding definitions for periodic functions and sequences, that is, we have the factor 2π in the exponent and not somewhere else. By $\widehat{L^1}(\mathbb{R};\mathbb{R})$, we denote the set of those functions in $C_0(\mathbb{R};\mathbb{R})$ (the set of continuous functions with limit 0 at $\pm\infty$) that are Fourier transforms of functions in $L^1(\mathbb{R};\mathbb{C})$.

PROPOSITION 1. *Assume that* $\Phi \in C(\mathbb{R};\mathbb{R})$ *is of positive type with* $\Phi(\underline{k}) = \delta_{0,\underline{k}}$*, and let* γ *be given by* (3). *Then* $\Phi \in L^2(\mathbb{R};\mathbb{R}) \cap \widehat{L^1}(\mathbb{R};\mathbb{R})$, $\gamma \in \ell^2(\mathbb{Z};\mathbb{R})$,

$$\hat{\gamma}(\underline{\omega}) + \hat{\gamma}(\underline{\omega} + \tfrac{1}{2}) \overset{a.e.}{=} 1, \tag{11}$$

and

$$\gamma \textit{ is of positive type.} \tag{12}$$

If, in addition,

$$\sup_{|s|\geq \underline{t}} |\Phi(s)| \in L^1(\mathbb{R}^+;\mathbb{R}) \tag{13}$$

and (2) *holds, then* $\gamma \in \ell^1(\mathbb{Z};\mathbb{R})$ *and*

$$\sum_{k\in\mathbb{Z}} \gamma(k) = 1, \tag{14}$$

and

(15) *there is a compact set* $C \subset \mathbb{R}$ *with* $\mathrm{m}(C) = 1$ *such that* $\hat{\gamma}$ *does not vanish on* $\bigcup_{k=1}^{\infty} 2^{-k}C$*, and for each* $\omega \in [0,1]$*, there is an integer* j *such that* $\omega + j \in C$*,*

The following result is closely related to corresponding results for multiresolutions where an assumption of the form (15) is seen to be of crucial importance; see [2].

THEOREM 2. *Let* $\gamma \in \ell^1(\mathbb{Z};\mathbb{R})$ *be such that* (11), (12), (14), *and* (15) *hold and*

$$\sum_{k\in\mathbb{Z}} \log(|k|+1)|\gamma(k)| < \infty. \tag{16}$$

Then there exists a function $\Phi \in C_0(\mathbb{R};\mathbb{R})$ *of positive type such that* (2) *holds. Moreover, there is a multiresolution* $(\{V_m\}_{m\in\mathbb{Z}}, \varphi)$ *of* $L^2(\mathbb{R};\mathbb{R})$ *such that* (4) *holds.*

If γ *has compact support, so do* Φ *and* φ.

Condition (15) can be given in other, equivalent forms; see, e.g., [4, Thm. 6.3.6] for the corresponding multiresolution case. It follows from the argument in [2, p. 452] that it is satisfied provided $\hat{\gamma}$ is continuous and $\hat{\gamma}(\omega) \neq 0$ for $|\omega| \leq \frac{1}{6}$. On the other hand, the standard example of a mask γ that satisfies all required conditions of Theorem 2 except (15) is the one where $\gamma(0) = \frac{1}{2}$, $\gamma(\pm 3) = \frac{1}{4}$, and $\gamma(k) = 0$ for all other k, in which case we have $\hat{\gamma}(\underline{\omega}) = (1 + \cos(6\pi\underline{\omega}))/2$.

The main problem considered in this paper is, however, what error estimates one can derive for subdivision interpolation schemes, and a related question is to what problem, if any, the subdivision interpolation scheme is an extremal solution. For example, the cubic spline interpolant minimizes the L^2-norm of the second derivative. In general, we cannot, of course, expect to get anything as simple as this, but we can get something that enables us to derive error estimates.

We use the notation $\mathbb{T} = \mathbb{R}/\mathbb{Z}$, that is, a function with domain $\mathbb{T}$ can equivalently be considered to be a function defined on $\mathbb{R}$ which is periodic with period 1. For example, when we below assume that $\eta(\underline{\omega})\hat{\Phi}(\underline{\omega}) \in L^\infty(\mathbb{T};\mathbb{R})$, this means that $\eta(\underline{\omega})\hat{\Phi}(\underline{\omega}) \in L^\infty(\mathbb{R};\mathbb{R})$ and $\eta(\underline{\omega}+1)\hat{\Phi}(\underline{\omega}+1) \overset{\text{a.e.}}{=} \eta(\underline{\omega})\hat{\Phi}(\underline{\omega})$.

THEOREM 3. *Let* $\Phi \in L^2(\mathbb{R};\mathbb{R}) \cap \widehat{L^1}(\mathbb{R};\mathbb{R})$ *be a fundamental interpolation function, i.e.,* $\Phi(\underline{k}) = \delta_{0,\underline{k}}$. *Let* $\eta : \mathbb{R} \to \mathbb{R}^+$ *be a nonnegative measurable function* *such that* $\eta(\underline{\omega})\hat{\Phi}(\underline{\omega}) \in L^{\infty}(\mathbb{T};\mathbb{R})$. *If* $F \in \ell^1(\mathbb{Z};\mathbb{R})$, *then*

$$\int_{\mathbb{R}} \left|\widehat{I_{\Phi}(F)}(\omega)\right|^2 \eta(\omega)\,\mathrm{d}\omega + \int_{\mathbb{R}} \left|\hat{g}(\omega) - \widehat{I_{\Phi}(F)}(\omega)\right|^2 \eta(\omega)\,\mathrm{d}\omega = \int_{\mathbb{R}} |\hat{g}(\omega)|^2 \eta(\omega)\,\mathrm{d}\omega, \tag{17}$$

for all $g \in L^2(\mathbb{R};\mathbb{R}) \cap \widehat{L^1}(\mathbb{R};\mathbb{R})$ *satisfying* $\int_{\mathbb{R}} |\hat{g}(\omega)|^2 \eta(\omega)\,\mathrm{d}\omega < \infty$ *and* $g(n) = F(n)$ *for* $n \in \mathbb{Z}$. *In particular,*

$$\int_{\mathbb{R}} \left|\widehat{I_{\Phi}(F)}(\omega)\right|^2 \eta(\omega)\,\mathrm{d}\omega \leq \int_{\mathbb{R}} |\hat{g}(\omega)|^2 \eta(\omega)\,\mathrm{d}\omega,$$

and if $f \in L^2(\mathbb{R};\mathbb{R}) \cap \widehat{L^1}(\mathbb{R};\mathbb{R})$, $\int_{\mathbb{R}} \left|\hat{f}(\omega)\right|^2 \eta(\omega)\,\mathrm{d}\omega < \infty$, *and* $f_{|\mathbb{Z}} \in \ell^1(\mathbb{Z};\mathbb{R})$, *then*

$$\int_{\mathbb{R}} \left|\hat{f}(\omega) - \widehat{I_{\Phi}(f_{|\mathbb{Z}})}(\omega)\right|^2 \eta(\omega)\,\mathrm{d}\omega \leq \int_{\mathbb{R}} \left|\hat{f}(\omega)\right|^2 \eta(\omega)\,\mathrm{d}\omega. \tag{18}$$

Note that we do not assume here that the interpolation scheme is of positive type and that if η grows sufficiently rapidly, then it follows from the assumption $\int_{\mathbb{R}} |\hat{g}(\omega)|^2 \eta(\omega)\,\mathrm{d}\omega < \infty$ that $\hat{g} \in L^1(\mathbb{R};\mathbb{C})$. Recall also that by scaling these error estimates (as well as those given below), one gets results for the interpolation of a function at nodes $2^{-j}\underline{k}$, where one can then let $j \to \infty$.

Let us as an example consider the well-known case of cubic splines. In this case, the basic interpolation function Φ satisfies (4), where φ is the scaling function or father wavelet of the Battle–Lemarié wavelets constructed from the piecewise linear splines by orthonormalization, that is,

$$\hat{\varphi}(\underline{\omega}) = \frac{\sqrt{3}}{\pi^2} \frac{\sin(\pi\underline{\omega})^2}{\underline{\omega}^2\sqrt{1 + 2\cos(\pi\underline{\omega})^2}};$$

see [4, §5.4]. Since $\hat{\Phi}(\underline{\omega}) = |\hat{\varphi}(\underline{\omega})|^2$, we see that we can take $\eta(\underline{\omega}) = \underline{\omega}^4$, that is, the cubic splines minimize the L^2-norm of the second derivative. It is straightforward to extend this result to the other odd splines, that is, interpolation with splines of order $2N-1$ leads to $\eta(\underline{\omega}) = \underline{\omega}^{2N}$.

Next we consider the so-called Lagrange iterative interpolation schemes (see, e.g., [5]) where the filter γ is chosen so that $\gamma(k) = 0$ when $|k| \geq 2N$ and (1) holds for all polynomials of degree at most $2N-1$, i.e., these polynomials are reconstructed exactly in the interpolation scheme. As shown in [13, Thm. 5.2], the fundamental interpolation function Φ_N of such a Lagrange subdivision interpolation scheme of order $2N-1$, and the scaling function φ constructed in [3] with support width $2N-1$ such that the corresponding wavelets have N vanishing moments, are linked via (4). Thus we have, by [4, Prop. 6.1.2, p. 216],

$$\widehat{\Phi_N}(\underline{\omega}) = \left(\frac{\sin(\pi\underline{\omega})}{\pi\underline{\omega}}\right)^{2N} \Pi_{j=1}^{\infty} L_N(2^{-j}\underline{\omega}),$$

where

$$L_N(\underline{\omega}) = P_N\left(\sin(\pi\underline{\omega})^2\right) \quad \text{and} \quad P_N(\underline{y}) = \sum_{k=0}^{N-1} \binom{N-1+k}{k} \underline{y}^k.$$

Thus we see that the function η in Theorem 3 can be chosen to be

$$\eta_N(\underline{\omega}) = \frac{\underline{\omega}^{2N}}{\Pi_{j=1}^{\infty} L_N(2^{-j}\underline{\omega})}, \tag{19}$$

and we have the following estimate that follows easily from the ones in [4, §7.1].

PROPOSITION 4. *If $N \geq 1$ and η_N is given by* (19), *then*

$$C_N \frac{\omega^{2N}}{(1+|\omega|)^{\log_2(P_N(3/4))}} \leq \eta_N(\omega) \leq \omega^{2N}, \quad \omega \in \mathbb{R}, \tag{20}$$

where

$$C_N > \frac{N}{16^N e^{2N}}.$$

By a result in [4, p. 226], we have

$$\frac{1}{\sqrt{N}} 3^{N-1} \leq P_N\big(\tfrac{3}{4}\big) \leq 3^{N-1}.$$

It is not difficult to see that the exponents in the estimate (20) are the best possible ones; see [4, Lem. 7.1.3] for the lower bound and take $\omega = 2^k$ in the upper bound.

It is clear that (18) as such is not very useful, and therefore we record some quite easy consequences of it.

THEOREM 5. *Let the assumptions of Theorem* 3 *hold and let $f \in L^1(\mathbb{R};\mathbb{R}) \cap \widehat{L^1}(\mathbb{R};\mathbb{R})$ be such that $f_{|\mathbb{Z}} \in \ell^1(\mathbb{Z};\mathbb{R})$ and $\int_{\mathbb{R}} |\hat{f}(\omega)|^2 \eta(\omega)\,\mathrm{d}\omega < \infty$. Then for every $q \geq 0$, we have*

$$\int_{|\omega|\geq 1/2} |\omega|^q \big|\hat{f}(\omega) - \widehat{I_\Phi(f_{|\mathbb{Z}})}(\omega)\big|^2 \,\mathrm{d}\omega \leq \operatorname*{ess\,sup}_{|\omega|\geq 1/2} \frac{|\omega|^q}{\eta(\omega)} \int_{\mathbb{R}} \big|\hat{f}(\omega)\big|^2 \eta(\omega)\,\mathrm{d}\omega \tag{21}$$

and

$$\int_{|\omega|\geq 1/2} |\omega|^q \big|\hat{f}(\omega) - \widehat{I_\Phi(f_{|\mathbb{Z}})}(\omega)\big| \,\mathrm{d}\omega \leq \sqrt{\int_{|\omega|\geq 1/2} \frac{|\omega|^{2q}}{\eta(\omega)}\,\mathrm{d}\omega \int_{\mathbb{R}} \big|\hat{f}(\omega)\big|^2 \eta(\omega)\,\mathrm{d}\omega}. \tag{22}$$

If

$$C_\eta \overset{\text{def}}{=} \operatorname*{ess\,sup}_{|\omega|\leq 1/2} \sum_{\substack{k\in\mathbb{Z}\\ k\neq 0}} \frac{1}{\eta(\omega+k)} < \infty, \tag{23}$$

then

$$\int_{-1/2}^{1/2} \big|\hat{f}(\omega) - \widehat{I_\Phi(f_{|\mathbb{Z}})}(\omega)\big|^2 \,\mathrm{d}\omega \leq C_\eta \int_{\mathbb{R}} \big|\hat{f}(\omega)\big|^2 \eta(\omega)\,\mathrm{d}\omega \tag{24}$$

and

$$\int_{-1/2}^{1/2} \big|\hat{f}(\omega) - \widehat{I_\Phi(f_{|\mathbb{Z}})}(\omega)\big| \,\mathrm{d}\omega \leq \sqrt{C_\eta \int_{\mathbb{R}} \big|\hat{f}(\omega)\big|^2 \eta(\omega)\,\mathrm{d}\omega}. \tag{25}$$

Note that by Proposition 4, we have (23) at least for Lagrange iterative interpolation schemes and one gets an upper bound for the constant $\operatorname{ess\,sup}_{|\omega|\geq 1/2}(|\omega|^q/\eta(\omega))$ in (21). From Proposition 4, one can get some results about when the crucial constant $\int_{|\omega|\geq 1/2}(|\omega|^{2q}/\eta(\omega))\,\mathrm{d}\omega$ in (22) is finite as well. It is possible, however, to get better and more general results for this term, and we shall consider that problem below.

Observe also that if $\kappa = n + \nu$, where $n \in \mathbb{N}$ and $0 \leq \nu < 1$, and we define

$$C^\kappa(\mathbb{R};\mathbb{R}) \overset{\text{def}}{=} \Big\{\, f \in C^n(\mathbb{R};\mathbb{R}) \;\Big|\; \|f\|_{C^\kappa(\mathbb{R})} \overset{\text{def}}{=} \sup_{t\in\mathbb{R}} |f(t)| + \sup_{t,s\in\mathbb{R},t\neq s} \frac{|f^{(n)}(t)-f^{(n)}(s)|}{|t-s|^\nu} < \infty \,\Big\},$$

then it is easy to check that

$$\|f\|_{C^{\kappa}(\mathbb{R})} \leq \sup_{t\in\mathbb{R}}|f(t)| + 2^{\lceil\kappa\rceil}\pi^{\kappa}\int_{\mathbb{R}}|\omega|^{\kappa}|\hat{f}(\omega)|\,\mathrm{d}\omega$$

when $f \in \widehat{L^1}(\mathbb{R};\mathbb{R})$, for example. As a partial converse, one can prove that if $\hat{f}(\omega) \geq 0$ for $\omega \in \mathbb{R}$, and $f \in C^{\kappa}(\mathbb{R};\mathbb{R})$ with $\kappa > 0$, then $\int_{\mathbb{R}}|\omega|^{\kappa'}\hat{f}(\omega)\,\mathrm{d}\omega < \infty$ for all $\kappa' \in [0,\kappa)$. This is one reason for studying error estimates of the form (22).

THEOREM 6. *Assume that $\Phi \in C(\mathbb{R};\mathbb{R})$ is of positive type such that* (2) *and* (13) *hold, and let γ be given* (3). *Suppose there is a positive integer M such that $\underline{k}^{2M+1}\gamma(\underline{k}) \in \ell^1(\mathbb{Z};\mathbb{R})$,*

$$\hat{\gamma}^{(j)}\left(\tfrac{1}{2}\right) = 0, \quad j = 0,1,\dots,2M-1, \tag{26}$$

and

$$\hat{\gamma}^{(2M)}\left(\tfrac{1}{2}\right) \neq 0. \tag{27}$$

If one takes $\eta(\underline{\omega}) \overset{\text{def}}{=} \sin(\pi\underline{\omega})^{2M}/\hat{\Phi}(\underline{\omega})$ and $r \geq 0$, then the following three conditions are equivalent:

(i) $\displaystyle\int_{|\omega|\geq 1/2}\frac{|\omega|^r}{\eta(\omega)}\,\mathrm{d}\omega < \infty$;

(ii) $\displaystyle\int_{\mathbb{R}}|\omega|^r|\hat{\Phi}(\omega)|\,\mathrm{d}\omega < \infty$;

(iii) *$r < 2M - \log_2(\rho)$, where ρ is the spectral radius of the operator $A : C([0,1];\mathbb{C}) \to C([0,1];\mathbb{C})$ defined by*

$$(Af)(\underline{\omega}) = a\left(\tfrac{\underline{\omega}}{2}\right)f\left(\tfrac{\underline{\omega}}{2}\right) + a\left(\tfrac{\underline{\omega}+1}{2}\right)f\left(\tfrac{\underline{\omega}+1}{2}\right),$$

where

$$a(\underline{\omega}) \overset{\text{def}}{=} \frac{\hat{\gamma}(\underline{\omega})}{\cos(\pi\underline{\omega})^{2M}}.$$

This is not really a new result because equivalences similar to (ii) $\Leftrightarrow$ (iii) can be found in, e.g., [7]–[9] and [15].

Observe that if γ has compact support, then the spectral radius ρ of A is the spectral radius of a matrix and can easily be calculated; see the proof below. For a method to compute ρ when γ does not have compact support, see [9].

3. Proofs.

Proof of Proposition 1. Since we assume that $\Phi \in C(\mathbb{R};\mathbb{R})$ is of positive type and $\Phi(0) = 1$, there exists by Bochner's theorem (see, e.g., [12, p. 19]) a nonnegative Borel measure μ with $\mu(\mathbb{R}) = 1$ such that

$$\Phi(\underline{t}) = \int_{\mathbb{R}} \mathrm{e}^{2\pi\mathrm{i}\underline{t}\omega}\mu(\mathrm{d}\omega).$$

Define another nonnegative measure μ_* by $\mu_*(E) = \sum_{k\in\mathbb{Z}}\mu(E+k)$ for every Borel set E. It follows that

$$\int_{[0,1)} \mathrm{e}^{-2\pi\mathrm{i}\underline{k}\omega}\mu_*(\mathrm{d}\omega) = \Phi(-\underline{k}) = \delta_{0,\underline{k}},$$

and this in turn implies that μ_* is the Lebesgue measure. This means that μ is absolutely continuous with respect to Lebesgue measure, and then we can use the

Radon–Nikodym theorem and the uniqueness of the Fourier transform to show that $\hat{\Phi} \in L^1(\mathbb{R};\mathbb{R}^+)$ and that

$$\sum_{k\in\mathbb{Z}} \hat{\Phi}(\underline{\omega}+k) \overset{\text{a.e.}}{=} 1. \tag{28}$$

In particular, it follows that

$$\hat{\Phi} \in L^p(\mathbb{R};\mathbb{R}), \quad 1 \le p \le \infty, \tag{29}$$

and we conclude that $\Phi \in \widehat{L^1}(\mathbb{R};\mathbb{R}) \cap L^2(\mathbb{R};\mathbb{R})$.

By (3), it follows that γ is of positive type as well, which again by Bochner's theorem implies that γ is the Fourier transform of a positive measure on $[0,1)$. But from (3) and (29), we can easily conclude that this measure is in fact absolutely continuous with respect to Lebesgue measure (so that $\hat{\gamma}$ is a function), and we have

$$\hat{\gamma}(\underline{\omega}) = \sum_{k\in\mathbb{Z}} \hat{\Phi}(2\underline{\omega}+2k),$$

and therefore (11) is a direct consequence of (28). Because $0 \overset{\text{a.e.}}{\le} \hat{\gamma}(\underline{\omega}) \overset{\text{a.e.}}{\le} 1$, we have $\gamma \in \ell^2(\mathbb{Z};\mathbb{R})$ by Plancherel's theorem.

Let us now assume that (13) holds. It follows that we have $\gamma \in \ell^1(\mathbb{Z};\mathbb{R})$, and from (2), we get

$$\hat{\Phi}(2\underline{\omega}) = \hat{\gamma}(\underline{\omega})\hat{\Phi}(\underline{\omega}). \tag{30}$$

From (11) and (12), it follows that we must have $0 \le \hat{\gamma}(0) \le 1$, but if $\hat{\gamma}(0) < 1$, then we see from (30) that $\hat{\Phi}(\omega) = 0$ for all $\omega \in \mathbb{R}$, which is impossible. Therefore, we have (14).

In order to prove (15), we first show that the series $\sum_{k\in\mathbb{Z}} \hat{\Phi}(\underline{\omega}+k)$ that appears in (28) converges uniformly on $[0,1]$. Therefore, we consider the function $g_n(\underline{t}) \overset{\text{def}}{=} \max\{0, \min\{n-n\underline{t}, n+n\underline{t}\}\}$ (the graph of g_n and the t-axis thus form a triangle with corners at $(\pm 1/n, 0)$ and $(0,n)$) and note that it is a standard result that $\widehat{g_n}(\underline{\omega}) = \sin(\pi\underline{\omega}/n)^2/(\pi\underline{\omega}/n)^2$. It follows that the Fourier transform of the sequence $\{c_n(k)\}_{k\in\mathbb{Z}}$, where

$$c_n(\underline{k}) = \Phi(\underline{k}) - \int_{\mathbb{R}} g_n(\underline{k}-t)\Phi(t)\,\mathrm{d}t, \tag{31}$$

is given by

$$\widehat{c_n}(\underline{\omega}) = \sum_{k\in\mathbb{Z}} (1-\widehat{g_n}(\underline{\omega}+k))\hat{\Phi}(\underline{\omega}+k). \tag{32}$$

From (13), (31), and from the uniform continuity of Φ, we are able to deduce that $\lim_{n\to\infty} \|c_n\|_{\ell^1(\mathbb{Z})} = 0$, and this gives by (32) the uniform convergence of the series in (28) because all terms are nonnegative.

It follows that $\sum_{k\in\mathbb{Z}} \hat{\Phi}(\omega+k) = 1$ for every $\omega \in \mathbb{R}$, and hence for each $\omega \in [0,1]$, there exist numbers $k_\omega \in \mathbb{Z}$ and $\epsilon_\omega > 0$ such that $\hat{\Phi}(\xi + k_\omega) > 0$ when $|\xi - \omega| < \epsilon_\omega$. Since $[0,1]$ is compact, we can choose finitely many of these points ω_j, $j = 1, 2, \dots, n$ such that $[0,1] \subset \bigcup_{j=1}^{n}(\omega_j - \epsilon_{\omega_j}, \omega_j + \epsilon_{\omega_j})$. But then we can construct the set C as the finite union of closed intervals on which Φ does not vanish. Since it follows from

(30) that

$$\hat{\Phi}(\underline{\omega}) = \hat{\Phi}(2^{-k}\underline{\omega}) \prod_{j=1}^{k} \hat{\gamma}(2^{-j}\underline{\omega}),$$

we see from (14) and the fact that $\hat{\Phi}$ does not vanish on $\mathcal{C}$ that $\hat{\gamma}$ cannot vanish on $\bigcup_{k=1}^{\infty}(2^{-k}\mathcal{C})$. Thus we have established (15). □

Proof of Theorem 2. We have $\hat{\gamma}(\underline{\omega}) - 1 = \sum_{k\in\mathbb{Z}}(\mathrm{e}^{-2\pi\mathrm{i}\underline{\omega}k} - 1)\gamma(k)$ since $\hat{\gamma}(0) = 1$ by (14), and hence

$$|\hat{\gamma}(\underline{\omega}) - 1| \le \sum_{k\in\mathbb{Z}} 2|\sin(\pi\underline{\omega}k)||\gamma(k)|.$$

Let m be a positive integer and let $\omega \in \mathbb{R}$. Now it is clear from the preceding inequality, Fubini's theorem, and the fact that $|\sin(\underline{t})| \le \min\{1, |\underline{t}|\}$ that

$$\begin{aligned}\sum_{j=m}^{\infty}|\hat{\gamma}(2^{-j}\omega) - 1| &\le 2\sum_{j=m}^{\infty}\sum_{k\in\mathbb{Z}}|\sin(2^{-j}\pi\omega k)||\gamma(k)| \\ &\le 2\sum_{k\in\mathbb{Z}}\left(\sum_{j=m}^{\lceil\log_2(\pi|\omega k|)\rceil} 1 + \sum_{j=|\lceil\log_2(\pi|\omega k|)\rceil+1-m|_+ +m}^{\infty} 2^{-j}\pi|\omega k|\right)|\gamma(k)| \qquad (33) \\ &\le 2\sum_{k\in\mathbb{Z}}\left(|\lceil\log_2(\pi|\omega k|)\rceil + 1 - m|_+ + 2^{-|m-\lceil\log_2(\pi|\omega k|)\rceil-1|_+}\right)|\gamma(k)|.\end{aligned}$$

(Here we used the notation $|\bullet|_+ = \max\{0, \bullet\}$.) We let

$$\begin{aligned}P_m(\underline{\omega}) &= \chi_{2^m\mathcal{C}}(\underline{\omega})\Pi_{j=1}^{m}\hat{\gamma}(2^{-j}\underline{\omega}), \\ P(\underline{\omega}) &= \Pi_{j=1}^{\infty}\hat{\gamma}(2^{-j}\underline{\omega}),\end{aligned}$$

and observe that because $\hat{\gamma}(0) = 1$, we may assume that 0 belongs to the interior of the set $\mathcal{C}$. From (16) and (33), we therefore conclude that the sequence $\{P_m\}_{m\in\mathbb{N}}$ converges uniformly on compact intervals toward P, and this shows that P is continuous.

An immediate consequence of assumption (15) is that if $f \in L^1(\mathbb{T};\mathbb{C})$ (that is, $f \in L^1_{\mathrm{loc}}(\mathbb{R};\mathbb{C})$ is periodic with period 1), then

$$\int_{\mathcal{C}} f(x)\,\mathrm{d}x = \int_0^1 f(x)\,\mathrm{d}x.$$

Using (11) and the fact that $\hat{\gamma}$ is periodic with period 1, we therefore get

$$\begin{aligned}\int_{\mathbb{R}} P_m(\omega)\mathrm{e}^{2\pi\mathrm{i}\underline{k}\omega}\,\mathrm{d}\omega &= \int_{2^m\mathcal{C}}\prod_{j=1}^{m}\hat{\gamma}\left(2^{-j}\omega\right)\mathrm{e}^{2\pi\mathrm{i}\underline{k}\omega}\,\mathrm{d}\omega = 2^m\int_{\mathcal{C}}\prod_{j=0}^{m-1}\hat{\gamma}(2^j\omega)\mathrm{e}^{2\pi\mathrm{i}2^m\underline{k}\omega}\,\mathrm{d}\omega \\ &= 2^m\int_0^1\prod_{j=0}^{m-1}\hat{\gamma}(2^j\omega)\mathrm{e}^{2\pi\mathrm{i}2^m\underline{k}\omega}\,\mathrm{d}\omega \\ &= 2^m\int_0^{1/2}\prod_{j=1}^{m-1}\hat{\gamma}(2^j\omega)\left(\hat{\gamma}(\omega) + \hat{\gamma}(\omega + \tfrac{1}{2})\right)\mathrm{e}^{2\pi\mathrm{i}2^m\underline{k}\omega}\,\mathrm{d}\omega \\ &= 2^{m-1}\int_0^1\prod_{j=0}^{m-2}\hat{\gamma}(2^j\omega)\mathrm{e}^{2\pi\mathrm{i}2^{m-1}\underline{k}\omega}\,\mathrm{d}\omega = \int_{\mathbb{R}} P_{m-1}(\omega)\mathrm{e}^{2\pi\mathrm{i}\underline{k}\omega}\,\mathrm{d}\omega.\end{aligned}$$

Since $\int_{\mathbb{R}} P_0(\omega)\mathrm{e}^{2\pi \mathrm{i}\underline{k}\omega}\,\mathrm{d}\omega = \int_{\mathcal{C}} \mathrm{e}^{2\pi \mathrm{i}\underline{k}\omega}\,\mathrm{d}\omega = \delta_{0,\underline{k}}$, it follows by induction that

$$\int_{\mathbb{R}} P_m(\omega)\mathrm{e}^{2\pi \mathrm{i}\underline{k}\omega}\,\mathrm{d}\omega = \delta_{0,\underline{k}}, \tag{34}$$

and in particular that

$$\|P_m\|_{L^1(\mathbb{R})} = 1,$$

(because $P_m(\underline{\omega}) \geq 0$). Thus we also conclude from Fatou's lemma that $P \in L^1(\mathbb{R};\mathbb{R})$ and $\|P\|_{L^1(\mathbb{R})} \leq 1$.

The function P is continuous and does not vanish on $\mathcal{C}$, hence there is a constant ϵ such that $P(\omega) \geq \epsilon > 0$ for all $\omega \in \mathcal{C}$. Because P_m vanishes outside $2^m\mathcal{C}$ and satisfies $P_m(\underline{\omega}) = P(\underline{\omega})/P(2^{-m}\underline{\omega})$ on $2^m\mathcal{C}$, it follows that

$$P_m(\omega) \leq \frac{P(\omega)}{\epsilon}, \quad \omega \in \mathbb{R}.$$

This inequality allows us to apply the dominated convergence theorem, and we conclude that

$$P_m \to P \quad \text{in} \quad L^1(\mathbb{R};\mathbb{R}). \tag{35}$$

Now we can choose Φ so that $\hat{\Phi} = P$. From the definition of P it follows that (30) holds. By (35), we see that (34) holds with P_m replaced by P, and this is equivalent to (28) or $\Phi(\underline{k}) = \delta_{0,\underline{k}}$, that is, Φ is a fundamental interpolation function which is of positive type because $\hat{\Phi}(\underline{\omega})$ is nonnegative.

If γ has compact support, we can use a lemma by Riesz (see [4, Lem. 6.1.3]) and the fact that γ is real and of positive type to find a real sequence α with compact support such that

$$\left|\hat{\alpha}(\underline{\omega})\right|^2 = \hat{\gamma}(\underline{\omega}).$$

We may, of course, assume that $\hat{\alpha}(0) = 1$, and we can define the function φ by $\hat{\varphi}(\underline{\omega}) = \Pi_{j=1}^{\infty}\hat{\alpha}(2^{-j}\underline{\omega})$. It follows from [4, Lem. 6.2.2] that Φ and φ have compact support as well. If γ does not have compact support, we define α and φ by $\hat{\alpha}(\underline{\omega}) = \sqrt{\hat{\gamma}(\underline{\omega})}$ and $\hat{\varphi}(\underline{\omega}) = \sqrt{\hat{\Phi}(\underline{\omega})}$, so that we in any case have

$$\left|\hat{\varphi}(\underline{\omega})\right|^2 = \hat{\Phi}(\underline{\omega})$$

and

$$\hat{\varphi}(2\underline{\omega}) = \hat{\alpha}(\underline{\omega})\hat{\varphi}(\underline{\omega}).$$

Because $\hat{\alpha} \in L^\infty(\mathbb{T};\mathbb{C})$, it is clear that $\alpha \in \ell^2(\mathbb{Z};\mathbb{R})$ and $\varphi \in L^2(\mathbb{R};\mathbb{R})$ because $\Phi \in \widehat{L^1}(\mathbb{R};\mathbb{R})$. Moreover, it follows from (28) that (8) holds (see [4, p. 132]), and hence (9) holds too. If one uses the notation in (5), this implies that (6) is satisfied. Finally, we get (7) from the fact that $\hat{\Phi}$ is continuous and $\hat{\Phi}(0) = 1$ by [4, Prop. 5.3.2]. This completes the proof. □

Proof of Theorem 3. It is clear that we have $I_\Phi(F) \in L^2(\mathbb{R};\mathbb{R}) \cap C(\mathbb{R};\mathbb{R})$ and that $\widehat{I_\Phi(F)}(\underline{\omega}) = \hat{F}(\underline{\omega})\hat{\Phi}(\underline{\omega})$. Moreover, we have $\int_{\mathbb{R}}|\widehat{I_\Phi(F)}(\omega)|^2\eta(\omega)\,\mathrm{d}\omega < \infty$. Let $h \overset{\text{def}}{=} g - I_\Phi(F)$. We observe that $h(n) = 0$ for all $n \in \mathbb{Z}$ and that $\hat{h} \in L^1(\mathbb{R};\mathbb{C})$.

Let $p(\underline{\omega}) \overset{\text{def}}{=} \eta(\underline{\omega})\hat{\Phi}(\underline{\omega})\hat{F}(\underline{\omega})$. A straightforward calculation shows that

$$\int_{\mathbb{R}} \widehat{I_\Phi(F)}(\omega)\overline{\hat{h}(\omega)}\eta(\omega)\,\mathrm{d}\omega = \int_{\mathbb{R}} \hat{F}(\omega)\hat{\Phi}(\omega)\overline{\hat{h}(\omega)}\eta(\omega)\,\mathrm{d}\omega = \int_{\mathbb{R}} p(\omega)\overline{\hat{h}(\omega)}\,\mathrm{d}\omega. \tag{36}$$

If p_* is a trigonometric polynomial, i.e., a finite linear combination of the functions $e^{2\pi i k \underline{\omega}}$, where $k \in \mathbb{Z}$, then it follows from the fact that $h(n) = 0$ for all $n \in \mathbb{Z}$ that $\int_{\mathbb{R}} p_*(\omega)\overline{\hat{h}(\omega)}\,\mathrm{d}\omega = 0$. Since $p \in L^\infty(\mathbb{T};\mathbb{C})$, it is possible to find a sequence $\{p_n(\underline{\omega})\}_{n\in\mathbb{N}}$ of trigonometric polynomials such that $p_n(\underline{\omega}) \to p(\underline{\omega})$ almost everywhere and $\sup_{n\in\mathbb{N}}\|p_n\|_{L^\infty(\mathbb{T})} < \infty$. But then we see that

$$\int_{\mathbb{R}} p(\omega)\overline{\hat{h}(\omega)}\,\mathrm{d}\omega = \lim_{n\to\infty}\int_{\mathbb{R}} p_n(\omega)\overline{\hat{h}(\omega)}\,\mathrm{d}\omega = 0.$$

If we combine this result with (36) and recall the definition of h, then we easily see that (17) holds. The remaining claims now follow immediately. □

Proof of Proposition 4. Since we have $L_N(\underline{\omega}) \geq 1$, the upper bound in (20) is obvious. It follows from [4, Lem. 7.1.8] and an argument similar to the one used in [4, Lem. 7.1.6] that for every $m \geq 1$, we get

$$\Pi_{j=1}^{\infty} L_N(2^{-j}\underline{\omega}) \leq P_N\left(\tfrac{3}{4}\right)^{m-1} P_N(1)\Pi_{j=m+1}^{\infty} L_N(2^{-j}\underline{\omega}). \tag{37}$$

We observe that by the convexity of P_N, we have on the interval $[0, \frac{1}{2}]$ the inequality $P_N(\underline{y}) \leq 1 - 2\underline{y} + 2\underline{y}P_N(\frac{1}{2}) = 1 + (2^N - 2)\underline{y}$ since $P_N(\frac{1}{2}) = 2^{N-1}$ (see [4, p. 219]), and therefore, we have for every $\omega \in \mathbb{R}$ and $m \geq 1$ satisfying $2^{-m}|\omega| \leq 1$ that

$$\Pi_{j=m+1}^{\infty}\left|L_N(2^{-j}\omega)\right| \leq P_N(1)\Pi_{j=m+2}^{\infty}\left(1 + (2^N - 2)\pi^2 4^{-j}\omega^2\right) < P_N(1)e^{2^N}. \tag{38}$$

We can choose the integer m such that $2^{-m}|\omega| \leq 1$ and $2^{m-1} \leq |\omega| + 1$ so that we get

$$P_N\left(\tfrac{3}{4}\right)^{m-1} \leq (|\omega| + 1)^{\log_2(P_N(\frac{3}{4}))}.$$

The claimed result now follows by (37) and (38) because we have

$$P_N(1) = \binom{2N-1}{N} < \frac{4^N}{\sqrt{N}};$$

see [4, p. 223]. □

Proof of Theorem 5. Inequality (21) follows directly from (18), and in order to get (22), one must first invoke Hölder's inequality. Moreover, (25) follows from (24), again by Hölder's inequality. Thus it remains to prove (24).

We let $e \overset{\mathrm{def}}{=} f - I_\Phi(f_{|\mathbb{Z}})$, and we define the function $p \in L^\infty(\mathbb{T};\mathbb{C})$ by requiring that $p(\omega) = \overline{\hat{e}(\omega)}$ when $-\frac{1}{2} < \omega \leq \frac{1}{2}$. By the same argument that was used in the proof of Theorem 3, we find that

$$\int_{\mathbb{R}} \hat{e}(\omega)p(\omega)\,\mathrm{d}\omega = 0.$$

Recalling the definition of p, we therefore get the following result with the aid of

Hölder's inequality:

$$\begin{aligned}\int_{-1/2}^{1/2} |\hat{e}(\omega)|^2 \,\mathrm{d}\omega &= -\int_{|\omega|\geq 1/2} \hat{e}(\omega)p(\omega)\,\mathrm{d}\omega \\ &\leq \sqrt{\int_{\mathbb{R}} |\hat{e}(\omega)|^2 \eta(\omega)\,\mathrm{d}\omega}\sqrt{\sum_{\substack{k\in\mathbb{Z}\\ k\neq 0}} \int_{-1/2}^{1/2} |\hat{e}(\omega)|^2 \frac{1}{\eta(\omega+k)}\,\mathrm{d}\omega} \\ &\leq \sqrt{\int_{\mathbb{R}} |\hat{e}(\omega)|^2 \eta(\omega)\,\mathrm{d}\omega}\sqrt{\int_{-1/2}^{1/2} |\hat{e}(\omega)|^2 \,\mathrm{d}\omega}\sqrt{\operatorname*{ess\,sup}_{|\omega|\leq 1/2} \sum_{\substack{k\in\mathbb{Z}\\ k\neq 0}} \frac{1}{\eta(\omega+k)}}.\end{aligned}$$

Inequality (24) now follows from Theorem 3, and the proof is completed. □

The proof of Theorem 6 is essentially the same as the proof of [8, Thm. 1], but for completeness we give it here. We begin by proving a lemma that could be derived from more general results as well.

LEMMA 7. *Let $\kappa > 0$ and let $a \in C^{\kappa}(\mathbb{T};\mathbb{R})$ be nonnegative. Then there exists an eigenvalue λ of the operator $A : C([0,1];\mathbb{C}) \to C([0,1];\mathbb{C})$, defined by*

$$Af(\underline{\omega}) = a(\tfrac{\underline{\omega}}{2})f(\tfrac{\underline{\omega}}{2}) + a(\tfrac{\underline{\omega}+1}{2})f(\tfrac{\underline{\omega}+1}{2})$$

such that $|\lambda|$ is the spectral radius of A.

Proof of Lemma 7. Assume, without loss of generality, that $\kappa \in (0,1)$. We choose a sequence $\{\epsilon_n\}_{n\in\mathbb{N}}$ of positive numbers such that $\lim_{n\to\infty} \epsilon_n = 0$ and so that the functions a_n, defined by

$$a_n(\underline{\omega}) \overset{\text{def}}{=} \frac{1}{n+1}\int_0^1 \left(\frac{\sin((n+1)\pi t)}{\sin(\pi t)}\right)^2 a(\underline{\omega} - t)\,\mathrm{d}t + \epsilon_n, \quad n \in \mathbb{N},$$

satisfy

$$a_n(\underline{\omega}) \geq a(\underline{\omega}), \quad n \in \mathbb{N}. \tag{39}$$

Furthermore, we see that the functions a_n belong to $C^{\kappa}(\mathbb{T};\mathbb{R})$ and

$$\sup_{n\in\mathbb{N}} \|a_n\|_{C^{\kappa}(\mathbb{T})} < \infty, \tag{40}$$

and

$$\lim_{n\to\infty} \|a_n - a\|_{L^{\infty}(\mathbb{T})} = 0. \tag{41}$$

We define the operator $A_n : C([0,1];\mathbb{C}) \to C([0,1];\mathbb{C})$ by

$$(A_n f)(\underline{\omega}) = a_n(\tfrac{\underline{\omega}}{2})f(\tfrac{\underline{\omega}}{2}) + a_n(\tfrac{\underline{\omega}+1}{2})f(\tfrac{\underline{\omega}+1}{2}).$$

Because $\widehat{a_n}(\underline{k}) = \max\{0, 1 - \frac{|\underline{k}|}{n+1}\}\hat{a}(\underline{k}) + \epsilon_n\delta_{0,\underline{k}}$, it follows that a_n is a trigonometric polynomial. Now if $f \in C([0,1];\mathbb{C})$ is a trigonometric polynomial, then

$$a_n(\underline{\omega})f(\underline{\omega}) = \sum_{k\in\mathbb{Z}} \mathrm{e}^{2\pi i k\underline{\omega}} \sum_{j=-n}^{n} \widehat{a_n}(j)\hat{f}(k-j),$$

where the sum is actually a finite one. Then

$$(A_nf)(\underline{\omega}) = 2\sum_{k\in\mathbb{Z}} e^{2\pi ik\underline{\omega}} \sum_{j=-n}^{n} \widehat{a_n}(j)\hat{f}(2k-j)$$

because the odd terms cancel. Thus we see that if the support of the Fourier transform of f is contained in $[-n+1, n-1]$, then the same holds true for the support of the Fourier transform of A_nf. Thus A_n maps a finite-dimensional space of trigonometric polynomials into itself, and therefore there is an eigenvalue λ_n of A_n such that $|\lambda_n| = \rho_n$, where ρ_n is the spectral radius of A_n restricted to this space. We denote the corresponding eigenfunction by v_n, and we normalize it so that $\|v_n\|_{C([0,1])} = 1$. We note that ρ_n is also equal to the spectral radius of A_n in the space $C([0,1];\mathbb{C})$ because by the nonnegativity of a_n, we have $\|A_n^m\| = \|A_n^m 1\|_{C([0,1])}$, where $\|\bullet\|$ is the operator norm in any one of these spaces. By (39), we have $\rho_n \geq \rho$ (where ρ is the spectral radius of A), and from (41), we conclude that $A_n \to A$ in operator norm as $n \to \infty$ and hence also that

$$\lim_{n\to\infty} \rho_n = \rho. \tag{42}$$

(Observe that the fact that $\rho_n \geq \rho$ is needed to derive (42) was not noted in [8].)

Define a new operator $B_n : C([0,1] \times [0,1];\mathbb{C}) \to C([0,1] \times [0,1];\mathbb{C})$ by

$$(B_nh)(\underline{\omega}, \underline{\eta}) = a_n\big(\tfrac{\underline{\omega}}{2}\big)h\big(\tfrac{\underline{\omega}}{2}, \tfrac{\underline{\eta}}{2}\big) + a_n\big(\tfrac{\underline{\omega}+1}{2}\big)h\big(\tfrac{\underline{\omega}+1}{2}, \tfrac{\underline{\eta}+1}{2}\big).$$

We can also define B in a similar way with a_n replaced by a. We note that B_n, applied to a function that does not depend on its second argument, gives the same result (as a function of its first argument) as A_n applied to the same function (with only one argument). Since $\|B_n^m\| = \|B_n^m 1\|_{C([0,1]^2)}$ and $\|A_n^m\| = \|A_n^m 1\|_{C([0,1])}$, we therefore conclude that $\|B_n^m\| = \|A_n^m\|$, and these operators have the same spectral radius. Define the function $g_n \in C([0,1] \times [0,1];\mathbb{C})$ by

$$g_n(\underline{\omega}, \underline{\eta}) = \frac{v_n(\underline{\omega}) - v_n(\underline{\eta})}{|\underline{\omega} - \underline{\eta}|^{\kappa}}.$$

Then we get

$$2^{-\kappa}B_ng_n - \rho_ng_n = b_n,$$

where

$$b_n(\underline{\omega}, \underline{\eta}) = \frac{\big(a_n\big(\tfrac{\underline{\eta}}{2}\big) - a_n\big(\tfrac{\underline{\omega}}{2}\big)\big)v_n\big(\tfrac{\underline{\eta}}{2}\big) + \big(a_n\big(\tfrac{\underline{\eta}+1}{2}\big) - a_n\big(\tfrac{\underline{\omega}+1}{2}\big)\big)v_n\big(\tfrac{\underline{\eta}+1}{2}\big)}{|\underline{\omega} - \underline{\eta}|^{\kappa}}.$$

Because $B_n \to B$ as $n \to \infty$ by (41), $\sup_{\eta\in[0,1]}|v_n(\eta)| = 1$, and (40) and (42) hold, we conclude that

$$\sup_{n\geq 1}\ \sup_{\omega,\eta\in[0,1]} |g_n(\omega, \eta)| < \infty.$$

But this means that the functions v_n are uniformly Hölder continuous—in particular, equicontinuous—and we may pass to the limit and obtain a nontrivial function $v \in C([0,1];\mathbb{C})$ such that $Av = \lambda v$, where $|\lambda| = \rho$. □

Proof of Theorem 6. First, we consider the operator A. By changing variables and using the periodicity of a, we easily see that for all f, $g \in C(\mathbb{T};\mathbb{C})$, we have

$$\int_0^1 (Af)(\omega)g(\omega)\,\mathrm{d}\omega = \int_0^1 f(\omega)2a(\omega)g(2\omega)\,\mathrm{d}\omega. \tag{43}$$

In particular, this implies that if we define numbers $\sigma_{p,m}$ by

$$\sigma_{p,m} \overset{\text{def}}{=} 2^m \int_0^1 \sin(\pi 2^m \omega)^{2p} \prod_{k=0}^{m-1} a(2^k\omega)\,\mathrm{d}\omega, \quad p \in \{0, M\}, \quad m \geq 1, \tag{44}$$

then it follows from m applications of (43) that

$$\sigma_{p,m} = \int_0^1 (A^m 1)(\omega)\sin(\pi\omega)^{2p}\,\mathrm{d}\omega, \quad p \in \{0, M\}, \quad m \geq 1. \tag{45}$$

Thus we have

$$\sigma_{p,m} \leq \|A^m\|, \quad p \in \{0, M\}, \quad m \geq 1, \tag{46}$$

where $\|\bullet\|$ denotes the operator norm.

From the moment assumption on γ, it follows that $\hat{\gamma} \in C^{2M+1}(\mathbb{T};\mathbb{R})$, and hence it is clear that if we want to prove that $a \in C^1(\mathbb{T};\mathbb{R})$, then the only points where there may be problems are the points $\frac{1}{2} + \mathbb{Z}$, and by periodicity, it suffices to consider the point $\frac{1}{2}$. By (26) and Taylor's formula, we have

$$\hat{\gamma}(\underline{\omega}) = \frac{\hat{\gamma}^{(2M)}(\frac{1}{2})}{(2M)!}(\underline{\omega} - \tfrac{1}{2})^{2M} + \int_{1/2}^{\underline{\omega}} \hat{\gamma}^{(2M+1)}(\sigma)\frac{(\underline{\omega} - \sigma)^{2M}}{(2M)!}\,\mathrm{d}\sigma.$$

Now a straightforward calculation, where we use the fact that $\hat{\gamma} \in C^{2M+1}(\mathbb{T};\mathbb{R})$, shows that $\lim_{\omega\to 1/2} a(\omega)$ and $\lim_{\omega\to 1/2} a'(\omega)$ both exist, and this gives the desired conclusion that $a \in C^1(\mathbb{T};\mathbb{R})$.

Thus we can apply Lemma 7, and we conclude that there is a nontrivial function $v \in C([0,1];\mathbb{C})$ and a number $\lambda \in \mathbb{C}$ such that $Av(\underline{\omega}) = \lambda v(\underline{\omega})$ and $|\lambda| = \rho$, the spectral radius of A. Because we may assume that $\sup_{\omega\in[0,1]}|v(\omega)| = 1$, we therefore see by (45) that

$$\begin{aligned}\rho^m \int_0^1 |v(\omega)|^2 \sin(\pi\omega)^{2p}\,\mathrm{d}\omega &= \left|\int_0^1 (A^m v)(\omega)\overline{v(\omega)}\sin(\pi\omega)^{2p}\,\mathrm{d}\omega\right| \\ &\leq \int_0^1 (A^m 1)(\omega)\sin(\pi\omega)^{2p}\,\mathrm{d}\omega = \sigma_{p,m}, \quad p \in \{0, M\}, \quad m \geq 1.\end{aligned}$$

Combining this result with (46) and the fact that $\lim_{m\to\infty}\|A^m\|^{1/m} = \rho$, we conclude that for $p = 0$ or M, we have

$$\sum_{m=1}^{\infty} 2^{-sm}\sigma_{p,m} < \infty \quad \text{iff} \quad s > \log_2(\rho). \tag{47}$$

Let

$$\mu \overset{\text{def}}{=} \inf_{\omega\in\mathbb{R}}\Big(a(\omega) + a\big(\omega + \tfrac{1}{2}\big)\Big).$$

It is clear that $(A^m 1)(\omega) \geq \mu^m$, $\omega \in [0,1]$, hence $\|A^m\| \geq \mu^m$, and it follows that the spectral radius of A is at least μ. Since $|\cos(\pi\omega)| \leq 1$ for all ω, we conclude from (11) and the definition of a that $\mu \geq 1$. By (27), we have $a(\frac{1}{2}) \neq 0$, and we see that

$a(0) = 1$ because $\hat{\gamma}(0) = 1$ by (14). Since $|\cos(\pi\omega)| < 1$ when $\omega \notin \mathbb{Z}$, it therefore follows from (11) and the definition of a that $\mu > 1$, and hence $\rho > 1$.

Let us define the function Q by

$$Q(\underline{\omega}) = \frac{(\pi\underline{\omega})^{2M}\hat{\Phi}(\underline{\omega})}{\sin(\pi\underline{\omega})^{2M}\hat{\Phi}(0)}.$$

Our assumption (13) implies that $\Phi \in L^1(\mathbb{R};\mathbb{R})$, and hence we get (30) from (2) and we have $\hat{\Phi}(\underline{\omega}) = \hat{\Phi}(2^{-k}\underline{\omega})\Pi_{j=1}^{k}\hat{\gamma}(2^{-j}\underline{\omega})$, where $1 \le k \le \infty$. Therefore, it follows from (26) that Q is continuous. The important point, however, is that since $\prod_{k=1}^{\infty}\cos(\pi 2^{-k}\underline{\omega}) = \sin(\pi\underline{\omega})/(\pi\underline{\omega})$, we get in addition that

$$Q(\underline{\omega}) = \prod_{k=1}^{\infty} a(2^{-k}\underline{\omega}). \tag{48}$$

Let $s = 2M - r$ and assume that $s > 0$. It follows from the definition of Q that

$$\text{(i) holds iff } \int_{\mathbb{R}} (1+\omega^2)^{-s/2} Q(\omega)\,\mathrm{d}\omega < \infty, \tag{49}$$

and

$$\text{(ii) holds iff } \int_{\mathbb{R}} (1+\omega^2)^{-s/2} Q(\omega)\sin(\pi\omega)^{2M}\,\mathrm{d}\omega < \infty. \tag{50}$$

Because $s > 0$, after integrating by parts we get that

$$\int_{\mathbb{R}} (1+\omega^2)^{-s/2} Q(\omega)\sin(\pi\omega)^{2p}\,\mathrm{d}\omega$$
$$= \int_0^{\infty} s\omega(1+\omega^2)^{-1-s/2}\int_{-\omega}^{\omega} Q(\eta)\sin(\pi\eta)^{2p}\,\mathrm{d}\eta\,\mathrm{d}\omega, \quad p \in \{0, M\},$$

where equality holds in the case where one of the integrals diverges too. There are positive constants C_1 and C_2 such that $C_1 \le 2^{sm}\int_{2^{m-1}J}^{2^m J} s\omega(1+\omega^2)^{-1-s/2}\,\mathrm{d}\omega \le C_2$, and hence we see that for $p \in \{0, M\}$,

$$\begin{aligned} &\int_{\mathbb{R}} (1+\omega^2)^{-s/2} Q(\omega)\sin(\pi\omega)^{2p}\,\mathrm{d}\omega < \infty \\ &\qquad\qquad \text{iff} \quad \sum_{m=1}^{\infty} 2^{-sm}\int_{-2^m J}^{2^m J} \sin(\pi\omega)^{2p} Q(\omega)\,\mathrm{d}\omega < \infty. \end{aligned} \tag{51}$$

Using (48), changing variables, and invoking the periodicity of a, we get

$$\begin{aligned} &\int_{-2^m J}^{2^m J} \sin(\pi\omega)^{2p} Q(\omega)\,\mathrm{d}\omega \\ &\qquad = \int_{-2^m J}^{2^m J} \sin(\pi\omega)^{2p}\prod_{k=1}^{m} a(2^{-k}\omega) Q(2^{-m}\omega)\,\mathrm{d}\omega \\ &\qquad = 2^m \int_{-J}^{J} \sin(\pi 2^m\omega)^{2p}\prod_{k=0}^{m-1} a(2^k\omega) Q(\omega)\,\mathrm{d}\omega \\ &\qquad = 2^m \int_0^1 \sin(\pi 2^m\omega)^{2p}\prod_{k=0}^{m-1} a(2^k\omega)\sum_{j=-J}^{J-1} Q(\omega+j)\,\mathrm{d}\omega. \end{aligned} \tag{52}$$

In the proof of Proposition 1, we showed that the series in (28) converges uniformly and therefore there exists an integer J such that $\sum_{j=-J}^{J-1} \hat{\Phi}(\omega + j) \geq \frac{1}{2}$ for all $\omega \in [0,1]$. Moreover, from (28) we get $\hat{\Phi}(0) = 1$ because by (26) and (30) we have $\hat{\Phi}(n) = 0$ when $n \in \mathbb{Z} \setminus \{0\}$. Hence $Q(\underline{\omega}) \geq \hat{\Phi}(\underline{\omega})$, and we have for some constant C_3

$$\frac{1}{2} \leq \sum_{j=-J}^{J-1} \Phi(\omega + j) \leq C_3, \quad \omega \in [0,1].$$

If we use this result in (52), then we see from (44) and (51) that for $p \in \{0, M\}$,

$$\int_{\mathbb{R}} (1+\omega^2)^{-s/2} Q(\omega) \sin(\pi\omega)^{2p} \, \mathrm{d}\omega < \infty \qquad \text{iff} \qquad \sum_{m=1}^{\infty} 2^{-sm} \sigma_{p,m} < \infty.$$

Thus the claimed equivalence follows from (47), (49), and (50). □

WAVELETS FROM SQUARE-INTEGRABLE REPRESENTATIONS*

DAVID BERNIER† AND KEITH F. TAYLOR†

Abstract. The continuous wavelet decompositions that arise from square-integrable representations of certain Lie groups on $L^2(\mathbb{R}^n)$ are investigated. The groups are formed as the semidirect product of $\mathbb{R}^n$ with an n-dimensional subgroup H of $GL_n(\mathbb{R})$. There is a natural "translation and dilation" representation of such groups on $L^2(\mathbb{R}^n)$. The basic formulas of Duflo and Moore, which lead to the resolution of the identity via a square-integrable representation, are given an elementary proof for this special case. Several two-dimensional examples are described. A method for discrete decompositions via frames is given using the representations under study.

Key words. wavelet, square-integrable representation, resolution of the identity, frame

AMS subject classifications. 42C15, 22D10

1. Introduction.

This paper is concerned with higher-dimensional analogs of the theory of continuous and discrete affine wavelets in $L^2(\mathbb{R})$. We emphasize the role of a locally compact group acting on $\mathbb{R}^n$ in such a way that square-integrable representations of the associated semidirect product group arise. These square-integrable representations are the source of existence of (at least) the continuous wavelets.

An introduction to the theory of wavelets in $L^2(\mathbb{R})$ can be found in the book by Daubechies [6] or the survey article by Heil and Walnut [16], which includes an explanation of the role of a certain pair of square-integrable representations of the affine group on $L^2(\mathbb{R})$. The affine group can be viewed as the semidirect product of $\mathbb{R}^+$, the multiplicative group of positive real numbers, acting on $\mathbb{R}$ as dilations. There is a natural representation of this semidirect product on $L^2(\mathbb{R})$ by "translations and dilations" that is the direct sum of two square-integrable representations. The abstract orthogonality relations of Duflo and Moore [9] then say that there exist vectors in $L^2(\mathbb{R})$ which can serve as continuous wavelets. The details are described in §1 below and can also be found in [15] and [16].

In order to generalize this to higher dimensions, we consider closed subgroups H of $GL_n(\mathbb{R})$ which act on $\mathbb{R}^n$ in such a manner that the natural representation of $\mathbb{R}^n \rtimes H$ on $L^2(\mathbb{R}^n)$ contains square-integrable representations. Here $\mathbb{R}^n \rtimes H$ denotes the semidirect product of $\mathbb{R}^n$ with H. The exact definition is given in §2, where we go on to give a very elementary proof of the basic Duflo–Moore theorem for the square-integrable representations in question. Our proof also makes the so-called admissibility condition very explicit.

In §3, examples in two dimensions are considered. Two of the examples have already found use in applications; one leads to wavelets which are tensor products of one-dimensional wavelets and the other gives wavelets for $L^2(\mathbb{R}^2)$ which are moved by translation, dilation, and rotation [2]. In addition to these two examples, a whole new class of examples is discussed.

In §4, we consider methods for discretizing the reconstruction formulas to obtain frames in $L^2(\mathbb{R}^n)$. In Theorem 3, we describe discrete subsets of $\mathbb{R}^n$ and H and conditions on a $g \in L^2(\mathbb{R}^n)$ which lead to the translates and dilates of g providing a frame

in $L^2(\mathbb{R}^n)$. The general conditions are then made specific for the two-dimensional examples in §5. The new methods of constructing frames from a group representation are obtained in this paper by considering more general groups that still have square-integrable representations in the strict sense. Generalizations have also been studied by DeBièvre in [7] and Ali, Antoine, and Gazeau in [1], where the motivation is to generalize the concept of a coherent state. The representation that underlies their concept of a frame is not necessarily square integrable.

1. Foundational harmonic analysis.

The reader is referred to Chapter III of [11] for the general theory of locally compact groups; we present only what is necessary to establish the notation. Let G be a locally compact group with left Haar integral denoted $\int_G \cdots dx$. Let $C_c(G)$ denote the function space consisting of continuous compactly supported complex-valued functions on G. For $f \in C_c(G)$, let $\|f\|_p = \left(\int_G |f(x)|^p dx\right)^{1/p}$ for $1 \leq p < \infty$. Let $L^p(G)$ denote the completion of the normed linear space $\left(C_c(G), \|\cdot\|_p\right)$ for $1 \leq p < \infty$. We are most interested in $L^1(G)$ and $L^2(G)$. As usual, we identify elements in $L^p(G)$ with measurable functions.

The left Haar integral on G satisfies, for any $f \in C_c(G)$ and $y \in G$,

$$\int_G f(x)dx = \int_G f(yx)dx. \tag{1.1}$$

In this study, G will not usually be unimodular and the modular function on G plays a significant role (see [11, §III.8] for information on modular functions). The modular function is a continuous homomorphism $\triangle_G : G \to \mathbb{R}^+$ such that, for any $f \in C_c(G)$ and $y \in G$,

$$\int_G f(x)dx = \triangle_G(y) \int_G f(xy)dx. \tag{1.2}$$

A unitary representation of G is a homomorphism π of G into $\mathcal{U}(\mathcal{H}_\pi)$, the group of unitary operators on a Hilbert space $\mathcal{H}_\pi$. We will always require that π is continuous when $\mathcal{U}(\mathcal{H}_\pi)$ is equipped with the weak operator topology. That is, for any $\xi, \eta \in \mathcal{H}_\pi$, the coefficient function $v_{\xi,\eta}(x) = \langle \eta, \pi(x)\xi \rangle$ is a continuous function of $x \in G$. A good source of fundamental results on unitary representations is Dixmier's book [8]. For the rest of this paper, representation will mean unitary representation.

A representation π is called irreducible if $\{0\}$ and $\mathcal{H}_\pi$ are the only closed subspaces of $\mathcal{H}_\pi$ which are invariant under $\pi(x)$ for each $x \in G$. A vector $\xi \in \mathcal{H}_\pi$ is called a cyclic vector for π if $\{\pi(x)\xi : x \in G\}$ is a total set in $\mathcal{H}_\pi$. That is, for $\eta \in \mathcal{H}_\pi, \eta \perp \pi(x)\xi$, for all $x \in G$, implies $\eta = 0$. Equivalently, ξ is a cyclic vector for π if and only if $v_{\xi,\eta} = 0$ implies $\eta = 0$ for $\eta \in \mathcal{H}_\pi$. It is easy to see that π is irreducible if and only if every nonzero vector in $\mathcal{H}_\pi$ is a cyclic vector for π. In many cases, this is the most convenient method for establishing irreducibility of a representation.

From the point of view of wavelet analysis, the key concept involving representations is square integrability. A representation π of G is called square integrable if (i) π is irreducible and (ii) there exist $\xi, \eta \in \mathcal{H}_\pi$, both nonzero, such that $v_{\xi,\eta} \in L^2(G)$. The most important theorem concerning square-integrable representations was established by Duflo and Moore [9] and is stated here for easy reference. A vector $\xi \in \mathcal{H}_\pi$ is called admissible if there exists a nonzero $\eta \in \mathcal{H}_\pi$ such that $v_{\xi,\eta} \in L^2(G)$.

THEOREM (Duflo and Moore, [9, Thm. 3]). *Let π be a square-integrable representation of a locally compact group G on a Hilbert space $\mathcal{H}_\pi$. Then there exists a unique operator K on $\mathcal{H}_\pi$, self-adjoint positive and satisfying the following:*

(i) $\pi(x)K\pi(x)^{-1} = \triangle_G(x)^{-1}K$ *for all $x \in G$.*

(ii) dom$K^{-\frac{1}{2}} = \{\xi \in \mathcal{H}_\pi : \xi$ *is admissible*$\}$.

(iii) *If* ξ *is admissible, then* $v_{\xi,\eta} \in L^2(G)$ *for all* $\eta \in \mathcal{H}_\pi$.

(iv) *If* ξ_1 *and* ξ_2 *are admissible and* $\eta_1, \eta_2 \in \mathcal{H}_\pi$, *then*

$$\langle v_{\xi_1,\eta_1}, v_{\xi_2,\eta_2}\rangle_{L^2(G)} = \langle \eta_1, \eta_2\rangle_{\mathcal{H}_\pi}\langle K^{-\frac{1}{2}}\xi_2, K^{-\frac{1}{2}}\xi_1\rangle_{\mathcal{H}_\pi}. \tag{1.3}$$

The proof in [9] used details of the Mackey analysis to prove this theorem. Alternate proofs were also provided by Carey [5] using reproducing kernel Hilbert-space methods and by Phillips [17] using quasi-Hilbert algebras.

In [15], it was recognized that this theorem allows one to represent arbitrary elements of $\mathcal{H}_\pi$ in terms of a fixed admissible element and its images under the representation. In particular, if ξ is admissible and normalized so that $\|K^{-\frac{1}{2}}\xi\| = 1$, then we can define a linear mapping $V_\xi : \mathcal{H}_\pi \to L^2(G)$ by $V_\xi\eta = v_{\xi,\eta}$, for $\eta \in \mathcal{H}_\pi$. The notation V_ξ follows [10], where it is called the voice transform defined by ξ. Using (1.3), we get, for $\eta_1, \eta_2 \in \mathcal{H}_\pi$, since $\|K^{-\frac{1}{2}}\xi\| = 1$,

$$\langle V_\xi\eta_1, V_\xi\eta_2\rangle_{L^2(G)} = \langle \eta_1, \eta_2\rangle_{\mathcal{H}_\pi}. \tag{1.4}$$

Let $\mathcal{K}_\xi$ denote the range of V_ξ, a closed subspace of $L^2(G)$. Then $V_\xi : \mathcal{H}_\pi \to \mathcal{K}_\xi$ is a unitary map between Hilbert spaces. Let l_G denote the left regular representation of G on $L^2(G)$ defined by $[l_G(x)f](y) = f(x^{-1}y)$ for all $y \in G, f \in L^2(G)$, and $x \in G$. An easy calculation shows that $l_G(x)(V_\xi\eta) = V_\xi(\pi(x)\eta)$ for all $\eta \in \mathcal{H}_\pi$. Thus $\mathcal{K}_\xi$ is a l_G-invariant subspace of $L^2(G)$ and V_ξ defines a unitary equivalence of π with the subrepresentation of l_G formed by restricting $l_G(x)$ to $\mathcal{K}_\xi$ for each $x \in G$.

The reconstruction of $\eta \in \mathcal{H}_\pi$ from $V_\xi\eta$ is implicit in (1.4). If Hilbert-space-valued integrals are considered in the weak sense and $\eta \in \mathcal{H}_\pi$, then (1.4) implies

$$\int_G V_\xi\eta(x)\pi(x)\xi dx = \eta$$

or

$$\int_G \langle \eta, \pi(x)\xi\rangle_{\mathcal{H}_\pi}\pi(x)\xi\, dx = \eta. \tag{1.5}$$

This can be further refined to give a resolution of the identity operator I on $\mathcal{H}_\pi$. If $\mathcal{H}$ is a Hilbert space and $\nu \in \mathcal{H}, \nu \neq 0$, let $\nu \otimes \nu$ denote the rank-1 operator given by $(\nu\otimes\nu)(\mu) = \langle \mu, \nu\rangle_{\mathcal{H}}\nu$ for all $\mu \in \mathcal{H}$. With operator-valued integrals interpreted in the weak-operator topology sense, (1.5) becomes

$$\int_G (\pi(x)\xi) \otimes (\pi(x)\xi)dx = I. \tag{1.6}$$

This completes our summary of the known theory of square-integrable representations. Formula (1.5) is useful when the Hilbert space $\mathcal{H}_\pi$ is realized as a meaningful function space. One of the important questions is: which ξ are admissible, or, equivalently, what is the domain of the unbounded (if G is not unimodular) operator $K^{-\frac{1}{2}}$? In the next section, we will study a class of groups which have square-integrable representations for which the operator K has an easily understood form and, consequently, the admissibility condition is easily stated.

2. A class of semidirect products. Let $GL_n(\mathbb{R})$ denote the group of invertible $n \times n$ real matrices with the usual topology. Let H be a closed subgroup of

$GL_n(\mathbb{R})$. We will consider the elements $\underline{x}$ of $\mathbb{R}^n$ as column vectors and the elements h of H as $n \times n$ matrices. Then the matrix product $(h, \underline{x}) \rightarrow h\underline{x}$ gives a natural action of H on $\mathbb{R}^n$. For $h \in H$, let $\delta(h) = |\det(h)|$. For any integrable function g on $\mathbb{R}^n$,

$$(2.1) \qquad \int_{\mathbb{R}^n} g(\underline{x})d\underline{x} = \delta(h) \int_{\mathbb{R}^n} g(h\underline{x})d\underline{x}.$$

We will use $\widehat{\mathbb{R}^n}$ for n-dimensional Euclidean space with the elements written as row vectors. For $\underline{\gamma} = (\gamma_1, \gamma_2, \ldots, \gamma_n) \in \widehat{\mathbb{R}^n}$ and

$$\underline{x} = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} \in \mathbb{R}^n,$$

we have $\underline{\gamma}\underline{x} = \sum_{j=1}^{n} \gamma_j x_j$. This facilitates calculations with the Fourier transform. For $f \in L^1(\mathbb{R}^n)$, its Fourier transform, $\hat{f} : \widehat{\mathbb{R}^n} \rightarrow \mathbb{C}$, is given, for $\underline{\gamma} \in \widehat{\mathbb{R}^n}$, by

$$(2.2) \qquad \hat{f}(\underline{\gamma}) = \int_{\mathbb{R}^n} f(\underline{x}) e^{2\pi i \underline{\gamma}\underline{x}}\, d\underline{x}.$$

If $g \in L^1(\mathbb{R}^n) \cap L^2(\mathbb{R}^n)$, let $\mathcal{P}g = \hat{g}$. The Plancherel theorem says that $\mathcal{P}$ extends to a unitary map of $L^2(\mathbb{R}^n)$ onto $L^2(\widehat{\mathbb{R}^n})$.

The dual action of H on $\widehat{\mathbb{R}^n}$ is also very important to us and is given by the natural product $(h, \underline{\gamma}) \rightarrow \underline{\gamma}h$ for $h \in H$, $\underline{\gamma} \in \widehat{\mathbb{R}^n}$. Then, for any integrable ξ on $\widehat{\mathbb{R}^n}$ and $h \in H$,

$$(2.3) \qquad \int_{\widehat{\mathbb{R}^n}} \xi(\underline{\gamma})d\underline{\gamma} = \delta(h) \int_{\widehat{\mathbb{R}^n}} (\underline{\gamma}h)d\underline{\gamma}.$$

The group H and its action on $\mathbb{R}^n$ can be used to form a new locally compact group $G = \mathbb{R}^n \rtimes H$, the semidirect product of $\mathbb{R}^n$ and H (see [11, §§III.4.7 and III.9.4]). The elements of G are all the ordered pairs $(\underline{x}, h)$ with $\underline{x} \in \mathbb{R}^n$ and $h \in H$. The product rule for G is, for $(\underline{x}, h), (\underline{y}, k) \in G$,

$$(2.4) \qquad (\underline{x}, h)(\underline{y}, k) = (\underline{x} + h\underline{y}, hk).$$

We will make heavy use of left-invariant (Haar) integration on H and G. Let $\int_H \cdots dh$ denote a fixed left Haar integral on H. Then left Haar integration on G is given, for any $f \in C_c(G)$, by

$$(2.5) \qquad \int_G f(\underline{x}, h)d(\underline{x}, h) = \int_H \int_{\mathbb{R}^n} f(\underline{x}, h)\delta(h)^{-1} d\underline{x}\, dh.$$

It is easily checked that (2.5) defines a left-invariant integral on G. However, this integral will not usually be right invariant. If $\triangle_H$ denotes the modular function on H, then a short calculation shows that the modular function on G is given by

$$(2.6) \qquad \triangle_G(\underline{x}, h) = \triangle_H(h)/\delta(h), \quad \text{for all} \quad (\underline{x}, h) \in G.$$

There is a very natural and important representation of G on $L^2(\mathbb{R}^n)$ that combines translation by vectors in $\mathbb{R}^n$ with the action of H. For $(\underline{x}, h) \in G$ and $g \in L^2(\mathbb{R}^n)$, define

$$(2.7) \qquad \rho(\underline{x}, h)g(\underline{y}) = \delta(h)^{-\frac{1}{2}} g\big(h^{-1}(\underline{y} - \underline{x})\big)$$

for all $\underline{y} \in \mathbb{R}^n$. The basic representation of the affine group $\mathbb{R} \rtimes \mathbb{R}^+$ on $L^2(\mathbb{R})$ that plays a fundamental role in affine wavelets in $L^2(\mathbb{R})$ is essentially a special case of (2.7) (see [16, §3.3.2]). It is routine to show that ρ is a (continuous unitary) representation of G on $L^2(\mathbb{R}^n)$. It will be very useful to know the equivalent representation π on $L^2(\widehat{\mathbb{R}^n})$ obtained from using the Plancherel transform $\mathcal{P}$. That is,

$$\pi(\underline{x}, h) = \mathcal{P}\rho(\underline{x}, h)\mathcal{P}^{-1} \quad \text{for all} \quad (\underline{x}, h) \in G. \tag{2.8}$$

Proposition 1. *For $(\underline{x}, h) \in G$ and $\xi \in L^2(\widehat{\mathbb{R}^n})$,*

$$\pi(\underline{x}, h)\xi(\underline{\gamma}) = \delta(h)^{\frac{1}{2}} e^{2\pi i \underline{\gamma}\underline{x}} \xi(\underline{\gamma} h) \quad \textit{for all} \quad \underline{\gamma} \in \widehat{\mathbb{R}^n}. \tag{2.9}$$

Proof. It suffices to check (2.9) for $\xi = \hat{g}$ with $g \in L^1(\mathbb{R}^n) \cap L^2(\mathbb{R}^n)$. For such a $\xi = \hat{g}$ and $\underline{\gamma} \in \widehat{\mathbb{R}^n}$,

$$\begin{aligned}
\pi(\underline{x}, h)\xi(\underline{\gamma}) &= \big(\mathcal{P}\rho(\underline{x}, h)\mathcal{P}^{-1}\big)(\mathcal{P}g)(\underline{\gamma}) \\
&= \int_{\mathbb{R}^n} \rho(\underline{x}, h)g(\underline{y})e^{2\pi i \underline{\gamma}\,\underline{y}}\, d\underline{y} \\
&= \int_{\mathbb{R}^n} \delta(h)^{-\frac{1}{2}} g\big(h^{-1}(\underline{y} - \underline{x})\big)e^{2\pi i \underline{\gamma}\,\underline{y}}\, d\underline{y} \\
&= e^{2\pi i \underline{\gamma}\underline{x}}\delta(h)^{\frac{1}{2}} \int_{\mathbb{R}^n} g(\underline{y})e^{2\pi i \underline{\gamma} h \underline{y}}\, d\underline{y} \\
&= \delta(h)^{\frac{1}{2}} e^{2\pi i \underline{\gamma}\underline{x}} \xi(\underline{\gamma} h). \qquad \square
\end{aligned}$$

We denote the unitary equivalence of two representations with a $\sim$. Thus, $\pi \sim \rho$.

If U is an open subset of $\widehat{\mathbb{R}^n}$, let $L^2(U)$ denote the closed subspace of $L^2(\widehat{\mathbb{R}^n})$ consisting of elements supported on U and let $\mathcal{H}^2_U = \mathcal{P}^{-1}\big(L^2(U)\big)$. Then $\mathcal{H}^2_U$ can be thought of as a generalized Hardy space. If U is an H-invariant open subset of $\widehat{\mathbb{R}^n}$ (that is, $\underline{\gamma} \in U$ and $h \in H$ imply $\underline{\gamma} h \in U$), then $L^2(U)$ is seen to be a π-invariant subspace of $L^2(\widehat{\mathbb{R}^n})$ by (2.9) and $\mathcal{H}^2_U$ is ρ-invariant. In this case, let π_U and ρ_U denote the subrepresentations of π and ρ, respectively, formed by restricting to $L^2(U)$ and $\mathcal{H}^2_U$. Note that $\rho_U \sim \pi_U$. The open H-invariant subsets of $\widehat{\mathbb{R}^n}$ which are single H-orbits are of special interest.

An H-orbit in $\widehat{\mathbb{R}^n}$ is a set of the form $\underline{\gamma} H = \{\underline{\gamma} h : h \in H\}$ for $\underline{\gamma} \in \widehat{\mathbb{R}^n}$. Clearly, $\underline{\gamma}_1 H = \underline{\gamma}_2 H$ if and only if there exists $k \in H$ such that $\underline{\gamma}_1 = \underline{\gamma}_2 k$ and H-orbits are H-invariant sets. An H-orbit $\underline{\gamma} H$ is called free if $\underline{\gamma} h = \underline{\gamma}$ implies $h = e$, the identity element of H. It doesn't matter which element of the H-orbit is used to check for freeness. If $\underline{\gamma} \in \widehat{\mathbb{R}^n}$ and $\underline{\gamma} H$ is a free orbit, then $h \rightarrow \underline{\gamma} h$ is a continuous bijection of H with $\underline{\gamma} H$. In general, this bijection need not be a homeomorphism. However, if $\underline{\gamma} H$ is not only free but open in $\widehat{\mathbb{R}^n}$, then $h \rightarrow \underline{\gamma} h$ is a homeomorphism of H onto $\underline{\gamma} H$ by Theorem 1 of [12]. Most of the rest of this paper is based on situations where we have open free H-orbits in $\widehat{\mathbb{R}^n}$. The next theorem shows why.

Theorem 1. *Let H be a closed subgroup of $GL_n(\mathbb{R})$ and let $G = \mathbb{R}^n \rtimes H$. Let U be an open free H-orbit in $\widehat{\mathbb{R}^n}$. Then ρ_U is a square-integrable representation of G on $\mathcal{H}^2_U$.*

Remarks. Several examples of H and U satisfying the hypothesis of Theorem 1 will be given in §3. The proof given here for Theorem 1 is adapted from the proof for the affine group, $\mathbb{R} \rtimes \mathbb{R}^+$, given in [16, §§3.3.5 and 3.3.6]. Besides being elementary and giving a simple admissibility condition, the proof leads the way to a very simple proof of (1.3) for the representation ρ_U, as we will see in Theorem 2. Before proving Theorem 1, we study the relationship between the Lebesgue measure on the open free H-orbit U and the measure on U obtained by transferring the left Haar measure of H to U. Let λ^n denote the Lebesgue measure on $\widehat{\mathbb{R}^n}$, which, by restriction, we view as a regular Borel measure on U. For $\underline{\gamma} \in U$, define $m_{\underline{\gamma}}$, a measure on U, by transferring the left Haar measure of H to U via the homeomorphism $h \to \underline{\gamma} \cdot h$. That is, for a Borel subset B of U, let $\tilde{B}_{\underline{\gamma}} = \{h \in H : \underline{\gamma} h \in B\}$ and $m_{\underline{\gamma}}(B) = \int_H \chi_{\tilde{B}_{\underline{\gamma}}}(h)dh$.

LEMMA 1. *$m_{\underline{\gamma}}$ is independent of $\underline{\gamma} \in U$.*

Proof. If $\underline{\gamma}_1, \underline{\gamma}_2 \in U$, then there exists a $k \in H$ such that $\underline{\gamma}_1 = \underline{\gamma}_2 k$. Now, for $h \in H$, and any Borel set $B \subseteq U$, $h \in \tilde{B}_{\underline{\gamma}_1}$ iff $\underline{\gamma}_1 h \in B$ iff $\underline{\gamma}_2 kh \in B$ iff $h \in k^{-1}\tilde{B}_{\underline{\gamma}_2}$. By left invariance of the Haar integral on H, $m_{\underline{\gamma}_1}(B) = m_{\underline{\gamma}_2}(B)$ for any Borel $B \subseteq U$. □

Let $m = m_{\underline{\gamma}}$, for any $\underline{\gamma} \in U$.

LEMMA 2. *The measures λ^n and m are mutually absolutely continuous on U.*

Proof. Now, it is convenient to move λ^n and m to H. Fix a $\underline{\gamma} \in U$ and define, for a Borel subset A of H,

$$\lambda_H^n(A) = \lambda^n(\underline{\gamma} \cdot A) \quad \text{and} \quad m_H(A) = m(\underline{\gamma} \cdot A),$$

where $\underline{\gamma} \cdot A = \{\underline{\gamma} h : h \in A\}$. Of course, m_H is just the left Haar measure on H and, for $k \in H$,

$$\lambda_H^n(Ak) = \lambda^n(\underline{\gamma} \cdot Ak) = \lambda^n\big((\underline{\gamma} \cdot A)k\big) = \delta(k)\lambda^n(\underline{\gamma} \cdot A) = \delta(k)\lambda_H^n(A).$$

Thus λ_H^n is a (right) quasi-invariant measure on H. Of course, m_H is also quasi-invariant under right translations; so, by uniqueness of quasi-invariant measures on a coset space (in this case H, itself) (see [11, §III.4.9]), this means that λ_H^n is mutually absolutely continuous with m_H. Transferring back to U via the homeomorphism completes the proof. □

Let Ψ denote the Radon–Nikodym derivative of m with respect to λ^n. The properties of Ψ are collected in the following proposition.

PROPOSITION 2. *Let H be a closed subgroup of $GL_n(\mathbb{R})$ and let U be an open free H-orbit in $\widehat{\mathbb{R}^n}$. Then there exists a Borel measurable function Ψ on U with the following properties:*

(i) $0 < \Psi(\underline{\gamma}) < \infty$, *for all* $\underline{\gamma} \in U$.

(ii) *If η is either a continuous function or a nonnegative measurable function on U, then, for any $\underline{\gamma}_0 \in U$,*

$$\int_H \eta(\underline{\gamma}_0 h)dh = \int_U \eta(\underline{\gamma})\Psi(\underline{\gamma})d\underline{\gamma}. \tag{2.10}$$

(iii) *For any $k \in H$,*

$$\Psi(\underline{\gamma} k) = \frac{\Delta_H(k)}{\delta(k)}\Psi(\underline{\gamma}) \quad \textit{for a.e.} \quad \underline{\gamma} \in U. \tag{2.11}$$

Proof. Properties (i) and (ii) are easily checked from the properties of Radon–Nikodym derivatives. To verify (iii), let $\underline{\gamma}_0 \in U$ be fixed and let $\eta \in C_c(U)$. Then, by

(2.10), (2.3), and (1.2),

$$\begin{aligned}\int_U \eta(\underline{\gamma})\Psi(\underline{\gamma}k)d\underline{\gamma} &= \delta(k)^{-1}\int_U \eta(\underline{\gamma}k^{-1})\Psi(\underline{\gamma})d\underline{\gamma}\\ &= \delta(k)^{-1}\int_H \eta(\underline{\gamma}_0 hk^{-1})dh\\ &= \triangle_H(k)\delta(k)^{-1}\int_H \eta(\underline{\gamma}_0 h)dh\\ &= \triangle_H(k)\delta(k)^{-1}\int_U \eta(\underline{\gamma})\Psi(\gamma)d\gamma.\end{aligned}$$

Thus, $\Psi(\underline{\gamma}k) = \triangle_H(k)\delta(k)^{-1}\Psi(\underline{\gamma})$, for a.e. $\underline{\gamma} \in U$. □

We are now ready to prove Theorem 1.

Proof of Theorem 1. Let $f, g \in \mathcal{H}^2_U$. Then, using $\hat{f} = \mathcal{P}f$ and $\hat{g} = \mathcal{P}g$ for simplicity,

$$\begin{align*}&\int_G \left|\langle f, \rho_U(\underline{x}, h)g\rangle_{L^2(\mathbb{R}^n)}\right|^2 d(\underline{x}, h)\\ &\quad= \int_G \left|\langle \hat{f}, \pi_U(\underline{x}, h)\hat{g}\rangle_{L^2(\widehat{\mathbb{R}^n})}\right|^2 d(\underline{x}, h)\\ &\quad= \int_G \left|\int_{\widehat{\mathbb{R}^n}} \hat{f}(\underline{\gamma})\delta(h)^{\frac{1}{2}}e^{-2\pi i\underline{\gamma}\underline{x}}\,\overline{\hat{g}}(\underline{\gamma}h)d\underline{\gamma}\right|^2 d(\underline{x}, h). \tag{2.12}\end{align*}$$

For each $h \in H$, let $\phi_h(\underline{\gamma}) = \hat{f}(\underline{\gamma})\overline{\hat{g}}(\underline{\gamma}h)$ for all $\underline{\gamma} \in \widehat{\mathbb{R}^n}$. Then $\phi_h \in L^1(\widehat{\mathbb{R}^n})$ for each $h \in H$. Let $\phi_h^\vee$ denote its "inverse" Fourier transform on $\mathbb{R}^n$. Then (2.12) becomes

$$\begin{align*}&\int_G \left|\langle f, \rho_U(\underline{x}, h)g\rangle_{L^2(\mathbb{R}^n)}\right|^2 d(\underline{x}, h)\\ &\quad= \int_G \delta(h)\left|\phi_h^\vee(\underline{x})\right|^2 d(\underline{x}, h)\\ &\quad= \int_H\int_{\mathbb{R}^n} \left|\phi_h^\vee(\underline{x})\right|^2 d\underline{x}\,dh \tag{by 2.5}\\ &\quad= \int_H\int_{\widehat{\mathbb{R}^n}} \left|\phi_h(\underline{\gamma})\right|^2 d\underline{\gamma}dh\\ &\quad= \int_H\int_{\widehat{\mathbb{R}^n}} \left|\hat{f}(\gamma)\right|^2\left|\hat{g}(\underline{\gamma}h)\right|^2 d\underline{\gamma}\,dh\\ &\quad= \int_U \left|\hat{f}(\gamma)\right|^2\left(\int_H \left|\hat{g}(\underline{\gamma}h)\right|^2 dh\right) d\underline{\gamma}\\ &\quad= \int_U \left|\hat{f}(\underline{\gamma})\right|^2\left(\int_U \left|\hat{g}(\underline{\nu})\right|^2 \Psi(\underline{\nu})d\underline{\nu}\right) d\underline{\gamma} \tag{by 2.10}\\ &\quad= \|\hat{f}\|^2_{L^2(U)}\,\|\hat{g}\Psi^{\frac{1}{2}}\|_2^2\\ &\quad= \|f\|^2_{\mathcal{H}^2_U}\|\hat{g}\Psi^{\frac{1}{2}}\|_2^2. \tag{2.13}\end{align*}$$

Note that $\|\hat{g}\Psi^{\frac{1}{2}}\|_2^2$ may be infinite for $g \in \mathcal{H}^2_U$, but $\|\hat{g}\Psi^{\frac{1}{2}}\|_2^2 = 0$ if and only if $g = 0$.

If g is any nonzero element of $\mathcal{H}^2_U$ and $f \in \mathcal{H}^2_U$ satisfies $f \perp \rho_U(\underline{x}, h)g$ for all $(\underline{x}, h) \in G$, then (2.13) implies that $\|f\|^2_{\mathcal{H}^2_U}\,\|\hat{g}\psi^{\frac{1}{2}}\|_2^2 = 0$. Since $g \neq 0$, this implies $f = 0$. Therefore, any nonzero vector in $\mathcal{H}^2_U$ is a cyclic vector for ρ_U. Hence, ρ_U is an irreducible representation of G.

On the other hand, if $\xi \in C_c(U)$, $\xi \neq 0$, and $g \in \mathcal{H}^2_U$ is such that $\hat{g} = \xi$, then $\|\hat{g}\Psi^{\frac{1}{2}}\|_2^2 < \infty$. So (2.13) implies that, for any $f \in \mathcal{H}^2_U, v_{g,f} \in L^2(G)$. Therefore, ρ_U is a square-integrable representaiton of G. □

The following two corollaries are clear from the proof of Theorem 1.

COROLLARY 1. *For $g \in \mathcal{H}^2_U, g$ is admissible if and only if $\hat{g}\Psi^{\frac{1}{2}} \in L^2(U)$.*

COROLLARY 2. *If $f, g \in \mathcal{H}^2_U$ and $\phi_h(\underline{\gamma}) = \hat{f}(\underline{\gamma})\overline{\hat{g}}(\underline{\gamma}h)$ for all $\underline{\gamma} \in \widehat{\mathbb{R}^n}$ and $h \in H$, then g admissible implies $\phi_h \in L^2(\widehat{\mathbb{R}^n})$ for a.e. $h \in H$.*

We are now in a position to give an elementary proof the theorem of Duflo and Moore described in §1 for the square-integrable representation ρ_U.

THEOREM 2. *Let H be a closed subgroup of $GL_n(\mathbb{R})$ and let $G = \mathbb{R}^n \rtimes H$. Let U be an open free H-orbit in $\widehat{\mathbb{R}^n}$. Then there exists a self-adjoint positive operator K on $\mathcal{H}^2_U$ satisfying the following:*

(i) $\rho_U(\underline{x}, h)K\ \rho_U(\underline{x}, h)^{-1} = \triangle_G(\underline{x}, h)^{-1}K$ *for all* $(\underline{x}, h) \in G$.

(ii) $\operatorname{dom} K^{-\frac{1}{2}} = \{g \in \mathcal{H}^2_U : g$ *is admissible*$\}$.

(iii) *If g is an admissible element of $\mathcal{H}^2_U$, then $v_{g,f} \in L^2(G)$ for all $f \in \mathcal{H}^2_U$.*

(iv) *If g_1 and g_2 are admissible elements of $\mathcal{H}^2_U$ and $f_1, f_2 \in \mathcal{H}^2_U$, then*

$$\langle v_{g_1,f_1}, v_{g_2,f_2}\rangle_{L^2(G)} = \langle f_1, f_2\rangle_{\mathcal{H}^2_U}\ \langle K^{-\frac{1}{2}}g_2, K^{-\frac{1}{2}}g_1\rangle_{\mathcal{H}^2_U}.$$

Proof. Recall that Ψ denotes the Radon-Nikodym derivative of the left Haar measure on H, transfered to U, with respect to the Lebesgue measure of $\widehat{\mathbb{R}^n}$ restricted to U. Thus Ψ^{-1} is the Radon–Nikodym derivative of these measures in the other order. Let Ψ^{-1} also denote the operator on $L^2(U)$ defined by pointwise multiplication. Define K to be $\mathcal{P}^{-1}\Psi^{-1}\mathcal{P}$. Thus,

$$\operatorname{dom} K = \{g \in \mathcal{H}^2_U : \hat{g}/\Psi \in L^2(U)\}$$

and, for $g \in \operatorname{dom} K$, $\widehat{Kg} = \hat{g}/\Psi$.

For $\eta \in \operatorname{dom}\Psi^{-1}$ and $(\underline{x}, h) \in G$, using (2.9), we get

$$\pi_U(\underline{x}, h)\left[\Psi^{-1}\pi_U(\underline{x}, h)^{-1}\eta\right](\underline{\gamma}) = \Psi^{-1}(\underline{\gamma}h)\eta(\underline{\gamma}) \tag{2.14}$$

for all $\underline{\gamma} \in U$. By 2.11, $\Psi^{-1}(\underline{\gamma}h) = \frac{\delta(h)}{\triangle_H(h)}\Psi^{-1}(\underline{\gamma})$. Recall from (2.6) that $\triangle_G = \triangle_H/\delta$, and the definition of K establishes (i).

Now, for $g \in \mathcal{H}^2_U, g \in \operatorname{dom} K^{-\frac{1}{2}}$ iff $\hat{g}\Psi^{\frac{1}{2}} \in L^2(U)$ iff g is admissible by Corollary 1. Thus (ii) holds and (iii) follows immediately from the calculation (2.13). It remains to prove (iv).

Let g_1 and g_2 be admissible elements of $\mathcal{H}^2_U$ and $f_1, f_2 \in \mathcal{H}^2_U$. Let $\phi^j_h(\underline{\gamma}) = \hat{f}_j(\underline{\gamma})\overline{\hat{g}}_j(\underline{\gamma}h)$ for $\underline{\gamma} \in \widehat{\mathbb{R}^n}, h \in H$, and $j = 1, 2$. By Corollary 2, $\phi^1_h, \phi^2_h \in L^1(\widehat{\mathbb{R}^n}) \cap L^2(\widehat{\mathbb{R}^n})$ for almost all $h \in H$. Again let $\phi^{j\vee}_h = \mathcal{P}^{-1}\phi^j_h$, for $j = 1, 2$. The computation is similar to (2.13), so we leave some steps to the reader.

$$\begin{aligned}
&\langle v_{g_1,f_1}, v_{g_2,f_2}\rangle_{L^2(G)} = \int_G \langle \hat{f}_1, \pi_U(\underline{x}, h)\hat{g}_1\rangle_{L^2(U)}\overline{\langle \hat{f}_2, \pi_U(\underline{x}, h)\hat{g}_2\rangle}_{L^2(U)} d(\underline{x}, h)\\
&= \int_G \int_{\widehat{\mathbb{R}^n}} \hat{f}_1(\underline{\mu})\delta(h)^{\frac{1}{2}} e^{-2\pi i \underline{\mu}\underline{x}}\,\overline{\hat{g}}_1(\underline{\mu}h)d\underline{\mu} \int_{\widehat{\mathbb{R}^n}} \overline{\hat{f}}_2(\underline{\nu})\delta(h)^{\frac{1}{2}} e^{2\pi i \underline{\nu}\,\underline{x}}\hat{g}_2(\underline{\nu}h)d\underline{\nu}\, d(\underline{x}, h)\\
&= \int_H \int_{\mathbb{R}^n} \phi^{1\vee}_h(\underline{x})\overline{\phi^{2\vee}_h}(\underline{x})d\underline{x}dh
\end{aligned}$$

$$\begin{aligned}
&= \int_H \int_{\widehat{\mathbb{R}^n}} \phi_h^1(\underline{\gamma})\overline{\phi_h^2(\underline{\gamma})}d\underline{\gamma}dh \\
&= \int_H \int_U \hat{f}_1(\underline{\gamma})\overline{\hat{f}}_2(\underline{\gamma})\hat{g}_2(\underline{\gamma}h)\overline{\hat{g}}_1(\underline{\gamma}h)d\underline{\gamma}dh \\
&= \int_U \hat{f}_1(\underline{\gamma})\overline{\hat{f}}_2(\underline{\gamma}) \int_U \hat{g}_2(\underline{\mu})\overline{\hat{g}}_1(\underline{\mu})\Psi(\underline{\mu})\, d\underline{\mu}d\underline{\gamma} \qquad \text{(by 2.10)} \\
&= \langle \hat{f}_1, \hat{f}_2\rangle_{L^2(U)} \langle \hat{g}_2\Psi^{\frac{1}{2}}, \hat{g}_1\Psi^{\frac{1}{2}}\rangle_{L^2(U)} \\
&= \langle f_1, f_2\rangle_{\mathcal{H}_U^2} \langle K^{-\frac{1}{2}}g_2, K^{-\frac{1}{2}}g_1\rangle_{\mathcal{H}_U^2}. \qquad \square
\end{aligned}$$

Remarks. (1) The only part of the Duflo–Moore theorem that has not been established for ρ_U, by these elementary methods is the uniqueness of K.

(2) The forms that the reproducing formulas (1.5) and (1.6) take in the present setting are now obvious.

Our final remarks in this section concern the assumption that there exists an open free H-orbit in $\widehat{\mathbb{R}^n}$. This forces the dimension of H, as a Lie group, to be n. There are several questions which arise concerning such groups H and their action on $\mathbb{R}^n$(and $\widehat{\mathbb{R}^n}$).

(3) If H is a closed n-dimensional subgroup of $GL_n(\mathbb{R})$, must there exist an open H-orbit in $\widehat{\mathbb{R}^n}$? The answer is no; an example for $n = 2$ is easily found. Let

$$H = \left\{ \begin{pmatrix} a & 0 \\ b & 1 \end{pmatrix} : a, b \in \mathbb{R}, a > 0 \right\}.$$

Then, for $(\gamma_1, \gamma_2) \in \widehat{\mathbb{R}^2}$, $(\gamma_1, \gamma_2)\left(\begin{smallmatrix} a & 0 \\ b & 1 \end{smallmatrix}\right) = (a\gamma_1 + b\gamma_2, \gamma_2)$, from which it is easy to see that there are no open H-orbits in $\widehat{\mathbb{R}^2}$. Nevertheless, the answer seems to be yes for "most" H. It would be interesting to make this precise.

(4) If H is a closed n-dimensional subgroup of $GL_n(\mathbb{R})$ and if there exists at least one open free H-orbit in $\widehat{\mathbb{R}^n}$, then a multivariate calculus argument shows that the union of the open free H-orbits is dense in $\widehat{\mathbb{R}^n}$. Thus, if there is one open free H-orbit, then $L^2(\mathbb{R}^n)$ is a direct sum of ρ-invariant subspaces, the $\mathcal{H}_U^2$'s, on each of which ρ_U is square integrable. In such cases, it turns out that the regular representation of G is then a direct sum of irreducible subrepresentations, see [3] where several examples are given. Groups with this property were also studied in [4] and [18].

(5) In any dimension n, can one classify, up to inner equivalence in $GL_n(\mathbb{R})$, those closed n-dimensional subgroups H for which there exists an open orbit?

3. Two-dimensional examples. In this short section, we present some examples of two-dimensional subgroups of $GL_2(\mathbb{R})$, describe open orbits in $\widehat{\mathbb{R}^2}$ for these groups, and give admissibility conditions for vectors in the associated Hilbert spaces. We will return to these examples in §5, where we discuss frames arising from these group actions.

Example 1. Let A denote the diagonal subgroup of $GL_2(\mathbb{R})$. That is,

$$A = \left\{ \begin{pmatrix} a_1 & 0 \\ 0 & a_2 \end{pmatrix} : a_1, a_2 \in \mathbb{R}\backslash\{0\} \right\}.$$

Let $G = \mathbb{R}^2 \rtimes A$. Clearly, G factors as a direct product of two copies of the (disconnected) affine group of one dimension. The map $\left(\begin{smallmatrix} a_1 & 0 \\ 0 & a_2 \end{smallmatrix}\right) \to (1,1)\left(\begin{smallmatrix} a_1 & 0 \\ 0 & a_2 \end{smallmatrix}\right) = (a_1, a_2)$ is a homeomorphism of A onto $U = \left\{(\gamma_1, \gamma_2) \in \widehat{\mathbb{R}^2} : \gamma_1\gamma_2 \neq 0\right\}$. Since U is dense in

$\widehat{\mathbb{R}^2}, \mathcal{H}_U^2 = L^2(\mathbb{R}^2)$ and, by Theorem 1, ρ is a square-integrable representation of G on $L^2(\widehat{\mathbb{R}^2})$, where ρ is given by (2.7), which in this case becomes

$$\rho\left[\begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \begin{pmatrix} a_1 & 0 \\ 0 & a_2 \end{pmatrix}\right] g\begin{pmatrix} y_1 \\ y_2 \end{pmatrix} = \frac{1}{\sqrt{|a_1 a_2|}}\, g\begin{pmatrix} (y_1 - x_1)/a_1 \\ (y_2 - x_2)/a_2 \end{pmatrix}$$

for all $\left(\begin{smallmatrix} y_1 \\ y_2 \end{smallmatrix}\right) \in \mathbb{R}^2$, $g \in L^2(\mathbb{R}^2)$, and $[\left(\begin{smallmatrix} x_1 \\ x_2 \end{smallmatrix}\right), \left(\begin{smallmatrix} a_1 & 0 \\ 0 & a_2 \end{smallmatrix}\right)] \in G$.

The Radon–Nikodym derivative of Proposition 2 is given by

$$\Psi(\gamma_1, \gamma_2) = \frac{1}{|\gamma_1 \gamma_2|} \quad \text{for} \quad (\gamma_1, \gamma_2) \in U$$

and $g \in L^2(\mathbb{R}^2)$ is an admissible vector for ρ if and only if

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left| \frac{\hat{g}(\gamma_1, \gamma_2)}{\sqrt{|\gamma_1 \gamma_2|}} \right|^2 d\gamma_1\, d\gamma_2 < \infty.$$

Example 2. Let

$$K_1 = \left\{ \begin{pmatrix} a & b \\ -b & a \end{pmatrix} : (a, b) \in \mathbb{R}^2 \backslash \{(0,0)\} \right\}.$$

Let $G = \mathbb{R}^2 \rtimes K_1$. The map $\left(\begin{smallmatrix} a & b \\ -b & a \end{smallmatrix}\right) \to (1,0)\left(\begin{smallmatrix} a & b \\ -b & a \end{smallmatrix}\right) = (a, b)$ is a homeomorphism of K_1 onto the open orbit $U = \widehat{\mathbb{R}^2} \backslash \{(0,0)\}$. Again $\mathcal{H}_U^2 = L^2(\mathbb{R}^2)$ and ρ, as given by (2.7), is square integrable. We leave it to the reader to calculate the explicit form of ρ in this case. We prefer to give the equivalent representation π on $L^2(\widehat{\mathbb{R}^2})$.

For $\eta \in L^2(\widehat{\mathbb{R}^2})$, $[\left(\begin{smallmatrix} x_1 \\ x_2 \end{smallmatrix}\right), \left(\begin{smallmatrix} a & b \\ -b & a \end{smallmatrix}\right)] \in G$, and $(\gamma_1, \gamma_2) \in \widehat{\mathbb{R}^2}$,

$$\pi\left[\begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \begin{pmatrix} a & b \\ -b & a \end{pmatrix}\right] \eta(\gamma_1, \gamma_2) = \sqrt{a^2 + b^2}\; e^{2\pi i(\gamma_1 x_1 + \gamma_2 x_2)} \eta(a\gamma_1 - b\gamma_2,\ b\gamma_1 + a\gamma_2).$$

An $\eta \in L^2(\widehat{\mathbb{R}^2})$ is an admissible vector for π if and only if

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left| \frac{\eta(\gamma_1, \gamma_2)}{\sqrt{\gamma_1^2 + \gamma_2^2}} \right|^2 d\gamma_1 d\gamma_2 < \infty.$$

Remark. K_1 is just the direct product of the dilations and rotations. That is,

$$K_1 = \{aR_\theta : a > 0 \text{ and } 0 \leq \theta < 2\pi\},$$

where $R_\theta = \left(\begin{smallmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{smallmatrix}\right)$.

For any $r > 0$, define

$$K_r = \left\{ \begin{pmatrix} a & b \\ -rb & a \end{pmatrix} : (a, b) \in \mathbb{R}^2 \backslash \{(0,0)\} \right\}.$$

Then K_r has properties very similar to K_1 and, in fact, K_r is inner conjugate to K_1 in $GL_2(\mathbb{R})$ since

$$K_r = \begin{pmatrix} 1/\sqrt{r} & 0 \\ 0 & 1 \end{pmatrix} K_1 \begin{pmatrix} \sqrt{r} & 0 \\ 0 & 1 \end{pmatrix}.$$

Thus, any K_r, $r > 0$ is equivalent to K_1 via a change of scale on the horizontal axis (cf. Remark (5) in §2).

Example 3. This is a family of examples. For each $c \in \mathbb{R}$, let

$$H_c = \left\{ \begin{pmatrix} a & 0 \\ b & a^c \end{pmatrix} : a, b \in \mathbb{R},\ a > 0 \right\}.$$

If $c \neq 0$, there are two open orbits U_+ and U_- in $\widehat{\mathbb{R}^2}; U_+ = \{(\gamma_1, \gamma_2) : \gamma_2 > 0\}$ and $U_- = \{(\gamma_1, \gamma_2) : \gamma_2 < 0\}$. Note that when $c = 0$, we have the example in Remark (3) at the end of §2. Fix $c \neq 0$. Let $G = \mathbb{R}^2 \rtimes H_c$.

As with the group in example 2, the formula for π, the representation on $L^2(\widehat{\mathbb{R}^2})$ is simpler than that for ρ. For $[(\begin{smallmatrix} x_1 \\ x_2 \end{smallmatrix}), (\begin{smallmatrix} a & 0 \\ b & a^c \end{smallmatrix})] \in G$, $\eta \in L^2(\widehat{\mathbb{R}^2})$, and $(\gamma_1, \gamma_2) \in \widehat{\mathbb{R}^2}$,

$$\pi\left[\begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \begin{pmatrix} a & 0 \\ b & a^c \end{pmatrix}\right] \eta(\gamma_1, \gamma_2) = a^{\frac{c+1}{2}} e^{2\pi i(\gamma_1 x_1 + \gamma_2 x_2)} \eta(a\gamma_1 + b\gamma_2,\ a^c\gamma_2).$$

Then $\pi = \pi_{U_+} \oplus \pi_{U_-}$, where π_{U_+} and π_{U_-} are the subrepresentations of π formed by restriction to $L^2(U_+)$ and $L^2(U_-)$, respectively.

For π_{U_+}, the admissibility condition for $\eta \in L^2(U_+)$ is

$$\int_0^\infty \int_{-\infty}^\infty \left| \frac{\eta(\gamma_1, \gamma_2)}{\gamma_2} \right|^2 d\gamma_1\, d\gamma_2 < \infty.$$

The condition for U_- is similar.

For this family of examples, the case of $c = 1$ leads to the simplest formulas and is representative of the general case in terms of the nature of the action on $\widehat{\mathbb{R}^2}$.

4. Discrete frames. We begin this section by recalling the definition of a frame. If $\mathcal{H}$ is a Hilbert space, a frame in $\mathcal{H}$ is a family of vectors $(\omega_j)_{j \in J}$ such that there exist $A > 0$ and $B < \infty$, called frame bounds, with

$$A\|\eta\|^2 \leq \sum_{j \in J} |\langle \eta, \omega_j \rangle|^2 \leq B\|\eta\|^2 \tag{4.1}$$

for all $\eta \in \mathcal{H}$. For a good discussion of frames constructed from the affine group, see [16, Chap. 3]. In this section, we show how to generate a frame in $\mathcal{H}^2_U$ for the groups $\mathbb{R}^n \rtimes H$ and the square-integrable representations ρ_U discussed in §2. The results are of a general nature and we do not attempt to obtain tight frames (where $A = B$ in (4.1)). For any particular group H that proves useful, detailed analyses can be carried out in later work.

For this section, fix a closed subgroup H of $GL_n(\mathbb{R})$ such that there exists an open free H-orbit U in $\widehat{\mathbb{R}^n}$. Let $\mathcal{H}^2_U$ denote the Hardy space of elements in $L^2(\mathbb{R}^n)$ with Fourier transform supported on U. Let ρ be defined as in (2.7) and ρ_U be the subrepresentation of ρ determined by restriction to $\mathcal{H}^2_U$ as in §2. Our aim is to describe guidelines for selecting an admissible $g \in \mathcal{H}^2_U$ and a discrete set $\left((\underline{x}_j, h_j)\right)_{j \in J}$ in $G = \mathbb{R}^n \rtimes H$ so that $\left(\rho(\underline{x}_j, h_j)g\right)_{j \in J}$ is a frame in $\mathcal{H}^2_U$. In what follows, we have been heavily influenced by [10] and [16].

DEFINITION. *A subset P of H is called* separated *if there exists a neighbourhood V of the identity e in H such that $l^{-1}V \cap k^{-1}V = \emptyset$ for $l \neq k$ and $l, k \in P$.*

It will be convenient for us to express this condition in terms of the action of H on U.

LEMMA 3. *A subset P of H is separated if and only if there exists a compact subset B of U with nonempty interior such that $Bl \cap Bk = \emptyset$ for $l, k \in P, l \neq k$.*

Proof. Fix $\underline{\gamma}_0 \in U$. Suppose P is separated by a neighbourhood V of e in H. We may assume that V is a compact neighbourhood of e. Let

$$B = \{\underline{\gamma}_0 h^{-1} : h \in V\}.$$

Then, the map, $h \to \underline{\gamma}_0 h^{-1}$, is a homeomorphism of H onto U; so B is a compact subset of U with nonempty interior. For $k \in P$, $Bk = \{\underline{\gamma}_0 h^{-1} k : h \in V\} = \{\underline{\gamma}_0 h^{-1} : h \in k^{-1}V\}$. Thus $l^{-1}V \cap k^{-1}V = \emptyset$ implies $Bl \cap Bk = \emptyset$. The converse is similar. □

We will say that P is separated by B in U if the condition of Lemma 3 holds.

LEMMA 4. *Let P be a separated subset of H and let D be a compact subset of U. Then $\sup_{k \in P} \left(\#\{l \in P : Dl \cap Dk \neq \emptyset\}\right) < \infty$.*

Proof. This follows from (i) ⇒ (iii) of Lemma 3.3 in [10], or the reader can show it directly with an easy compactness argument. □

DEFINITION. *A* frame generator *is a pair (P, F), where P is a separated subset of H and F is a compact subset of U, such that $\bigcup_{k \in P} Fk = U$.*

We now describe how to obtain a frame in $\mathcal{H}_U^2$ from a frame generator (P, F) and the square-integrable representation ρ_U. Let D be a compact subset of U with nonempty interior D^0 and $F \subseteq D^0$. Let R be an n-dimensional parallelepiped with $D \subseteq R$. By R being an n-dimensional parallelepiped, we mean there are vectors $\underline{\lambda}^1, \underline{\lambda}^2, \ldots, \underline{\lambda}^n \in \widehat{\mathbb{R}^n}$, linearly independent, and real numbers $a_1 < b_1, a_2 < b_2, \ldots, a_n < b_n$ such that

$$R = \left\{\underline{\gamma} = \sum_{j=1}^{n} \gamma_j \underline{\lambda}^j : a_j \leq \gamma_j \leq b_j,\ 1 \leq j \leq n\right\}.$$

Since $\{\underline{\lambda}^1, \underline{\lambda}^2, \ldots, \underline{\lambda}^n\}$ forms a basis of $\widehat{\mathbb{R}^n}$, we have a dual basis $\{\underline{y}^1, \underline{y}^2, \ldots, \underline{y}^n\}$ for $\mathbb{R}^n$. Let $I = \mathbb{Z}^n$ considered as an index set for the following discrete set in $\mathbb{R}^n$. For each $\underline{i} = (i_1, i_2, \ldots, i_n) \in I$, let

$$\underline{x}^{\underline{i}} = \sum_{j=1}^{n} \left(\frac{i_j}{b_j - a_j}\right) \underline{y}^j$$

and

$$e_{\underline{i}}(\underline{\gamma}) = \begin{cases} 0 & \text{if } \ \underline{\gamma} \in \widehat{\mathbb{R}^n} \backslash R, \\ \dfrac{1}{\sqrt{\lambda(R)}} e^{2\pi i \underline{\gamma} \underline{x}^{\underline{i}}} & \text{if } \ \underline{\gamma} \in R, \end{cases}$$

where $\lambda(R)$ denotes the Lebesgue measure of R. Identify $L^2(R)$ with $\{\eta \in L^2(\widehat{\mathbb{R}^n}) : \eta(\underline{\gamma}) = 0$ for almost all $\underline{\gamma} \in \widehat{\mathbb{R}^n} \backslash R\}$. Then $\{e_{\underline{i}} : \underline{i} \in I\}$ is an orthonormal basis for $L^2(R)$. Let

$$M = \sup_{k \in P} \left(\#\{l \in P : Dl \cap Dk \neq \emptyset\}\right).$$

which is finite by Lemma 4.

Now suppose $g \in \mathcal{H}_U^2$ satisfies the following conditions:

(i) Support of $\hat{g} \subseteq D$. (That is, $\hat{g}(\underline{\gamma}) = 0$ for almost all $\underline{\gamma} \in \widehat{\mathbb{R}^n} \backslash D$.)

(ii) $a = \inf\left\{|\hat{g}(\underline{\gamma})| : \underline{\gamma} \in F\right\} > 0$.

(iii) $b = \sup\left\{|\hat{g}(\underline{\gamma})| : \underline{\gamma} \in D\right\} < \infty$.

Let $A = \lambda(R)a^2$ and $B = \lambda(R)Mb^2$.

THEOREM 3. *With the notation which has been established above,* $\{\rho(\underline{x}^{\underline{i}},k)^{-1}g : \underline{i}\in I, k\in P\}$ *is a frame for* $\mathcal{H}^2_U$ *with frame bounds* A *and* B.

Proof. For $(\underline{x},h)\in G, (\underline{x},h)^{-1} = \big((\underline{x},e)(\underline{o},h)\big)^{-1} = (\underline{o},h^{-1})(-\underline{x},e)$. Thus, for $f\in\mathcal{H}^2_U$, $\underline{i}\in I$, and $k\in P$,

$$\begin{aligned}
\langle f,\rho(\underline{x}^{\underline{i}},k)^{-1}g\rangle_{\mathcal{H}^2_U} &= \langle\rho(\underline{o},k)f,\ \rho(-\underline{x}^{\underline{i}},e)g\rangle_{\mathcal{H}^2_U}\\
&= \langle\pi(\underline{o},k)\hat f,\pi(-\underline{x}^{\underline{i}},e)\hat g\rangle_{L^2(U)}\\
\text{(by 2.9)}\qquad &= \int_U \delta(k)^{\frac{1}{2}}\hat f(\underline{\gamma}k)e^{2\pi i\underline{\gamma}\underline{x}^{\underline{i}}}\,\overline{\hat g}(\underline{\gamma})d\underline{\gamma}.
\end{aligned}$$

Thus,

$$\begin{aligned}
\sum_{k\in P}\sum_{\underline{i}\in I}\left|\langle f,\rho(\underline{x}^{\underline{i}},k)^{-1}g\rangle_{\mathcal{H}^2_U}\right|^2 &= \sum_{k\in P}\delta(k)\lambda(R)\sum_{\underline{i}\in I}\left|\int_R \overline{\hat f}(\underline{\gamma}k)\hat g(\underline{\gamma})\overline{e_{\underline{i}}}(\underline{\gamma})d\underline{\gamma}\right|^2\\
&= \lambda(R)\sum_{k\in P}\int_R \delta(k)\left|\hat f(\underline{\gamma}k)\right|^2\left|\hat g(\underline{\gamma})\right|^2 d\underline{\gamma}\\
\text{(by 2.3)}\qquad &= \lambda(R)\sum_{k\in P}\int_U \left|\hat f(\underline{\gamma})\right|^2\left|\hat g(\underline{\gamma}k^{-1})\right|^2 d\underline{\gamma}\\
\text{(4.2)}\qquad &= \lambda(R)\int_U \left|\hat f(\underline{\gamma})\right|^2\sum_{k\in P}\left|\hat g(\underline{\gamma}k^{-1}\right|^2 d\underline{\gamma}.
\end{aligned}$$

On the one hand, using the fact that (P,F) is a frame generator, we have $\sum_{k\in P}\left|\hat g(\underline{\gamma}k^{-1})\right|^2 \geq a^2$, for all $\underline{\gamma}\in U$. Thus, by (4.2),

$$\begin{aligned}
\sum_{k\in P}\sum_{\underline{i}\in I}\left|\langle f,\rho(\underline{x}^{\underline{i}},k)^{-1}g\rangle_{\mathcal{H}^2_U}\right|^2 &\geq \lambda(R)a^2\int_U\left|\hat f(\underline{\gamma})\right|^2 d\underline{\gamma}\\
\text{(4.3)}\qquad &= A\|f\|^2_{\mathcal{H}^2_U}.
\end{aligned}$$

On the other hand, for a given $\underline{\gamma}\in U$, $\hat g(\underline{\gamma}k^{-1})\neq 0$ for at most M values of $k\in P$ and $\left|\hat g(\underline{\gamma}k^{-1})\right|\leq b$, for any of those values. Thus,

$$\begin{aligned}
\sum_{k\in P}\sum_{\underline{i}\in I}\left|\langle f,\rho(\underline{x}^{\underline{i}},k)^{-1}g\rangle_{\mathcal{H}^2_U}\right|^2 &\leq \lambda(R)Mb^2\int_U\left|\hat f(\underline{\gamma})\right|^2 d\underline{\gamma}\\
\text{(4.4)}\qquad &= B\|f\|^2_{\mathcal{H}^2_U}.
\end{aligned}$$

Together, (4.3) and (4.4) mean that $\{\rho(\underline{x}^{\underline{i}},k)^{-1}g : \underline{i}\in I, k\in P\}$ is a frame for $\mathcal{H}^2_U$ with frame bounds A and B. □

Remark. The proof of Theorem 3 is clearly an easy adaptation of the standard arguments for the affine group (see, for example, [16, §5.1.2]).

5. Frame generators in two dimensions. We now use the two dimensional examples from §3 to illustrate how frame generators, as described in the previous section, can be easily found in particular examples.

Example 1. In this case, $A = \{\left(\begin{smallmatrix}a_1 & 0\\ 0 & a_2\end{smallmatrix}\right) : a_1,a_2\in\mathbb{R}\backslash\{0\}\}$ and $G = \mathbb{R}^2\rtimes A$. Note that, by including negatives of the dilations, there is a unique open A-orbit $U = \{(\gamma_1,\gamma_2)\in\widehat{\mathbb{R}^2} : \gamma_1\neq 0, \gamma_2\neq 0\}$ in $\widehat{\mathbb{R}^2}$. Let

$$P = \left\{\begin{pmatrix}\pm 2^m & 0\\ 0 & \pm 2^n\end{pmatrix} : m,n\in\mathbb{Z}\right\}$$

and let $F = [1,2] \times [1,2]$. Then P is separated (by $[1-\varepsilon, 1+\varepsilon] \times [1-\varepsilon, 1+\varepsilon]$ as long as $0 < \varepsilon < \frac{1}{3}$) and $\bigcup_{k \in P} Fk = U$. Thus (P, F) is a frame generator for $\mathbb{R}^2 \rtimes A$ and the associated square-integrable representation ρ on $L^2(\mathbb{R}^2)$.

Example 2. We now study $K_1 = \{aR_\theta : a > 0,\ 0 \leq \theta < 2\pi\}$. One can easily form P by separately discretizing the a's and θ's and then find an appropriate "fundamental domain" F. However, it is important to note that P can be of the form $\{h^n : n \in \mathbb{Z}\}$ for a single fixed h. Let

$$h = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix} = \sqrt{2} \begin{pmatrix} \cos\frac{\pi}{4} & \sin\frac{\pi}{4} \\ -\sin\frac{\pi}{4} & \cos\frac{\pi}{4} \end{pmatrix}$$

and let $P = \{h^n : n \in \mathbb{Z}\}$. The action on $\widehat{\mathbb{R}^2}$ of h is a simultaneous rotation and dilation. It is easily verified that P is a separated set, with respect to $U = \widehat{\mathbb{R}^2} \backslash \{(0,0)\}$, which is the open orbit for K_1. Let F be the trapezoid with vertices at $(\frac{1}{16}, 0), (1,0), (\frac{1}{16}, \frac{1}{16})$, and $(1,1)$. Then $U = \bigcup_{n \in \mathbb{Z}} Fh^n$. That is, (P, F) is a frame generator.

Remark. It is known that one can do much better in this situation (see [13], for example). If we let $\Gamma = \mathbb{Z}^2 \subseteq \mathbb{R}^2$, combining translations by elements of Γ and dilations by powers of h admits a multiresolution analysis and leads to an orthonormal basis in $L^2(\mathbb{R}^2)$, not just a frame as is given by Theorem 3.

Example 3. We select one representative example from the family $\{H_c : c \neq 0\}$ of groups from Example 3 in §3. If $c = 1$,

$$H_1 = \left\{ \begin{pmatrix} a & 0 \\ b & a \end{pmatrix} : a, b \in \mathbb{R},\ a > 0 \right\}.$$

There are two open H_1-orbits in $\widehat{\mathbb{R}^2}$. We will consider one of them

$$U_+ = \{(\gamma_1, \gamma_2) : \gamma_2 > 0\}$$

for illustration. Let

$$P = \left\{ \begin{pmatrix} 2^n & 0 \\ m2^n & 2^n \end{pmatrix} : m, n \in \mathbb{Z} \right\}$$

and let F denote the trapezoid with vertices at $(0,1), (1,1), (0,2)$ and $(2,2)$. It is a pleasant exercise to show that the open upper half-plane is tiled by the translates of F under P. That is, $U_+ = \bigcup_{m,n \in \mathbb{Z}} F\left(\begin{smallmatrix} 2^n & 0 \\ m2^n & 2^n \end{smallmatrix}\right)$. It is also easily checked that P is a separated set relative to U_+. Therefore, (P, F) is a frame generator.

6. Concluding remarks. Our purpose was to show the wide availability of square-integrable representations on $\mathbb{R}^n$. The group that is being represented is of the form $\mathbb{R}^n \rtimes H$ with the elements of $\mathbb{R}^n$ acting on $\mathbb{R}^n$ as translations and the elements of H acting as generalized dilations. There is a great deal of liberty in selecting H. Among the n-dimensional closed subgroups of $GL_n(\mathbb{R})$, many (perhaps most) will act in such a manner that open free H-orbits exist in $\widehat{\mathbb{R}^n}$. We have illustrated this point with two-dimensional examples.

Once H has been selected so that there exists an open free H-orbit U in $\widehat{\mathbb{R}^n}$, then a representation ρ_U is naturally defined on the Hardy space $\mathcal{H}^2_U$. We showed that this ρ_U is square integrable and gave an elementary proof of the Duflo–Moore relations for such a representation. Moreover, for ρ_U, the admissibility conditions are particularily easy to check and the "formal dimension" operator has an explicit description.

We made the first steps towards constructing good frames in $\mathcal{H}_U^2$ in §4. There is clearly much remaining to be done. Especially, in cases where one knows that a particular dilation group H is well suited to an application at hand, one needs to refine the analysis to obtain tight frames or even an orthonormal basis.

Acknowledgments. We would like to acknowledge useful conversations with James Brooke, Patrick Browne, Qingde Yang, and Eberhard Kaniuth while we were developing these ideas.

POLYCONVEX FUNCTIONALS FOR NEARLY CONFORMAL DEFORMATIONS*

TADEUSZ IWANIEC† AND ADAM LUTOBORSKI†

Abstract. Variational integrals whose absolute minima are conformal deformations are studied. Polyconvexity and mean coercivity of these functionals are proved in even dimensions. Existence of nearly conformal deformations is established.

Key words. polyconvex functions, mean coercive functionals, nearly conformal deformations

AMS subject classifications. 49A, 30C60, 73C60

1. Introduction. In this article, we investigate a class of variational integrals with nonconvex and noncoercive integrands. Such functionals arise naturally in quasiconformal analysis and nonlinear elasticity. They are referred to as energy functionals for a deformation $f : \Omega \subset \mathbb{R}^n \to \mathbb{R}^n$ and take the form

$$\mathcal{E}[f] = \int_\Omega E(\nabla f)dx. \tag{1.1}$$

In elasticity, the integrand $E : \mathbb{R}^{n\times n} \to \mathbb{R}_+$ is called the stored-energy function and it encodes the mechanical properties of the material. The minimum points $A \in \mathbb{R}^{n\times n}$ of E are called potential wells. Obviously, the derivative $E' : \mathbb{R}^{n\times n} \to \mathbb{R}^{n\times n}$ vanishes on the potential wells and E posesses stress-free states. Our basic assumption is that E vanishes exactly on the matrices of linear conformal mappings, that is, on the set $\mathcal{C}^+(n) = \{\lambda A\,; A \in SO(n),\ \lambda \geq 0\}$. Therefore, $\mathcal{E}[f]$ measures (in an average sense) how far is f from a conformal deformation. If f is conformal, then $\mathcal{E}[f] = 0$ and we say that f is an absolute minimizer of $\mathcal{E}$. The minimizers (with prescribed boundary values) of our energy functional will be referred to as nearly conformal mappings.

The simplest example of such a functional is the complex p-harmonic intergral

$$\mathcal{E}[f] = \int_\Omega \left|\frac{\partial f}{\partial \bar{z}}\right|^p, \qquad 1 < p < \infty,$$

for functions $f : \Omega \subset \mathbb{C} \to \mathbb{C}$ of Sobolev class $W^{1,p}(\Omega)$. Its minima, called the complex p-harmonic functions, are found by solving the nonhomogeneous Cauchy–Riemann equation

$$\frac{\partial f}{\partial \bar{z}} = |h(z)|^{q-2}\overline{h(z)},$$

where h is a holomorphic function and q is the Hölder conjugate to p.

Define a nonlinear operator $H : \mathbb{R}^{n\times n} \to \mathbb{R}_+$ acting on gradient matrices as

$$H(\nabla f) = |\nabla f|^n - n^{\frac{n}{2}} \det \nabla f. \tag{1.2}$$

Its differential $H' : \mathbb{R}^{n\times n} \to \mathbb{R}^{n\times n}$ induces another operator

$$H'(\nabla f) = n|\nabla f|^{n-2}\nabla f - n^{\frac{n}{2}}\ \mathrm{adj}\nabla f. \tag{1.3}$$

*Received by the editors March 18, 1994; accepted for publication (in revised form) September 26, 1994.

Both H and H' vanish on conformal matrices. H is nonnegative due to Hadamard's inequality. When $n = 2$, we find that $H(\nabla f) = |\partial f/\partial \bar{z}|^2$ and $H'(\nabla f) = 2\partial f/\partial \bar{z}$. Therefore, a natural generalization of the complex p-harmonic integral to higher dimensions might be the functional

$$\mathcal{I}_p[f] = \int_\Omega (|\nabla f|^n - n^{\frac{n}{2}} \det \nabla f)^{p/2}, \quad 1 < p < \infty, \tag{1.4}$$

defined for all mappings $f : \Omega \to \mathbb{R}^n$ in the Sobolev class $W^{1,\frac{np}{2}}(\Omega, \mathbb{R}^n)$.

For $n > 2$, the function $H : \mathbb{R}^{n\times n} \to \mathbb{R}_+$ is not convex. Another serious obstacle in proving the existence of minima for $\mathcal{I}_p$ is the lack of coercivity of H. In [IL], using polyconvexity and *mean coercivity*, we succeeded in showing that for $p \geq 2$ the functional $\mathcal{I}_p$ attains its minimum in the Sobolev class $W^{1,\frac{np}{2}}(\Omega, \mathbb{R}^n)$ with prescribed boundary values of $g \in W^{1,\frac{np}{2}}(\Omega, \mathbb{R}^n)$. The case $1 < p < 2$ is still open. For $p \geq 2$, Liouville's theorem asserts that the absolute minimizers of $\mathcal{I}_p$ in the class $W^{1,\frac{np}{2}}(\Omega, \mathbb{R}^n)$ must be Möbius transformations (or constant mappings); see [G], [R1], [BI], and [IM].

Let $f = (f^1, \ldots, f^n) : \Omega \to \mathbb{R}^n$, $n = 2l$, be a mapping of the Sobolev class $W^{1,l}(\Omega, \mathbb{R}^n)$. Set $N = \binom{n}{l}$ and denote by ∇f^{l*l} the $N \times N$ matrix of all $l \times l$ minors of ∇f. More precisely, the entries of ∇f^{l*l} are indexed by ordered l-tuples $I = (i_1, \ldots, i_l)$, $1 \leq i_1 < \cdots < i_l \leq n$, $J = (j_1, \cdots, j_l)$, $1 \leq j_1 < \cdots < j_l \leq n$, and

$$(\nabla f^{l*l})_I^J = \begin{vmatrix} \frac{\partial f^{j_1}}{\partial x_{i_1}} & \cdots & \frac{\partial f^{j_1}}{\partial x_{i_l}} \\ \vdots & & \vdots \\ \frac{\partial f^{j_l}}{\partial x_{i_1}} & \cdots & \frac{\partial f^{j_l}}{\partial x_{i_l}} \end{vmatrix}.$$

These determinants are integrable functions on Ω. For $p \geq 1$, we introduce the class $\mathcal{L}^{p,l}(\Omega, \mathbb{R}^n)$ of mappings $f \in W^{1,l}(\Omega, \mathbb{R}^n)$ such that $\nabla f^{l*l} \in L^p(\Omega, \mathbb{R}^{N\times N})$.

In Lemma 2.1 of §2 we show that the expression $H_l(A) = |A^{l*l}|^2 - N \det A$ for $A \in \mathbb{R}^{n\times n}$ is nonnegative and vanishes only when A is either a conformal matrix or of rank less than l. Thus an alternative to the p-harmonic integral in the complex plane is the functional

$$\mathcal{F}_p[f] = \int_\Omega (|\nabla f^{l*l}|^2 - N \det \nabla f)^{\frac{p}{2}} \tag{1.5}$$

for mappings $f \in \mathcal{L}^{p,l}(\Omega, \mathbb{R}^n)$. $\mathcal{F}_p$ is polyconvex for all $1 \leq p < \infty$; see Lemma 2.3. $\mathcal{F}_p$ is possibly mean coercive, as it is if $p \geq 2 - \epsilon$ for some $\epsilon = \epsilon(n) > 0$; see [IL].

Another functional of interest to us is

$$\mathcal{W}_\alpha[f] = \int_\Omega |\nabla f^{l*l}(x)|^{2\alpha} [|\nabla f^{l*l}(x)|^2 - N \det \nabla f(x)]\, dx \tag{1.6}$$

for mappings $f \in \mathcal{L}^{2\alpha+2,l}(\Omega, \mathbb{R}^n)$. The case $l = 1$ reduces to the functional offered by Alibert and Dacorogna [AD] in two dimensions,

$$\mathcal{W}_\alpha[f] = \int_\Omega |\nabla f|^{2\alpha} (|\nabla f|^2 - 2 \det \nabla f) = \int (|f_z|^2 + |f_{\bar{z}}|^2)^\alpha |f_{\bar{z}}|^2 \tag{1.7}$$

Our main result addresses the polyconvexity of the functional $\mathcal{W}_\alpha$.

THEOREM 1.1. *Let l be a positive integer, $n = 2l$, $0 \leq \alpha \leq 1$, and $A, B \in \mathbb{R}^{n\times n}$. Then*

$$W_\alpha(A) - W_\alpha(B) \geq \langle \mathcal{M}, A^{l*l} - B^{l*l} \rangle + \lambda(\det A - \det B), \tag{1.8}$$

where $\mathcal{M} = \mathcal{M}(B^{l*l}) \in \mathbb{R}^{N\times N}$ *and* $\lambda = \lambda(B^{l*l}) \in \mathbb{R}$ *are given explicitly by the formulas*

$$\mathcal{M}(X) = 4|X|^{2\alpha-2}(|X|^2 + 2\alpha|X^-|^2)X^+, \tag{1.9}$$

$$\lambda(X) = -4|X|^{2\alpha-2}(|X|^2 + \alpha|X^-|^2) \tag{1.10}$$

for $X \in \mathbb{R}^{N\times N}$ *(see* §2 *for notation used here).*

This result is new even in two dimensions. Only the cases of $\alpha = 1$ (see [AD], [IL]) and the case $\alpha = 0$, which is obvious, have been known. Our next result deals with the mean coercivity of $\mathcal{W}_\alpha$.

THEOREM 1.2. *Suppose* $f, g \in \mathcal{L}^{2\alpha+2,l}(\Omega, \mathbb{R}^n)$ *are mappings such that* $f - g \in \overset{\circ}{W}{}^{1,l}(\Omega, \mathbb{R}^n)$. *Then*

$$\delta \int_\Omega |\nabla f^{l*l}|^{2\alpha+2} \le \mathcal{W}_\alpha[f] + \int_\Omega |\nabla^{l*l} g|^{2\alpha+2}, \tag{1.11}$$

where we point out that $\delta = \delta(l, \alpha) > 0$ *is independent of* $f, g,$ *and* Ω.

In particular, we see that a minimizer f of $\mathcal{W}_\alpha$ subject to the Dirichlet condition $f - g \in \overset{\circ}{W}{}^{1,l}(\Omega, \mathbb{R}^n)$ automatically belongs to $\mathcal{L}^{2\alpha+2,l}(\Omega, \mathbb{R}^n)$.

Theorems 1.1 and 1.2 allow us to apply the direct method in solving the following minimization problem.

THEOREM 1.3. *Let* $0 \le \alpha \le 1$, $\epsilon > 0$, *and* $g \in \mathcal{L}^{2\alpha+2,l}(\Omega, \mathbb{R}^n)$ *be given. Then the functional*

$$\mathcal{F}[f] = \epsilon\Big(\int_\Omega |\nabla f|^l\Big)^{2\alpha+2} + \mathcal{W}_\alpha[f] \tag{1.12}$$

attains its minimum in the class of mappings $f \in W^{1,l}(\Omega, \mathbb{R}^n)$ *such that* $f - g \in \overset{\circ}{W}{}^{1,l}(\Omega, \mathbb{R}^n)$.

Although we have shown that $\mathcal{W}_\alpha$ is coercive in the mean for all $\alpha \ge 0$, it ceases to be polyconvex for large α. We address this problem in two dimensions in §4. Therein we examine the range of parameter α for which W_α is rank-one convex.

2. Preliminaries from multilinear algebra. We begin by introducing some matrix notations. Let l be a positive integer and $n = 2l$, $N = \binom{n}{l}$. We denote by $\mathbb{R}^{n\times n}$ the space of $n \times n$ matrices $A, B, C, \dots$ and by $\mathbb{R}^{N\times N}$ the space of $N \times N$ matrices $X, Y, Z, \dots$. Spaces of matrices are equipped with the inner product $\langle X, Y\rangle = \operatorname{trace}(X^T Y)$ for $X, Y \in \mathbb{R}^{N\times N}$ and an associated norm $|X|^2 = \langle X, X\rangle$. We also define the matrix signum function

$$\operatorname{sgn}(X) = \begin{cases} \frac{X}{|X|} & \text{if } X \ne 0, \\ 0 & \text{if } X = 0. \end{cases}$$

For $A \in \mathbb{R}^{n\times n}$, we define $A^{l*l} \in \mathbb{R}^{N\times N}$

$$(A^{l*l})^I_J = \begin{vmatrix} a^{i_1}_{j_1} & \cdots & a^{i_1}_{j_l} \\ \vdots & & \vdots \\ a^{i_l}_{j_1} & \cdots & a^{i_l}_{j_l} \end{vmatrix},$$

where $I = (i_1, \dots, i_l)$ and $J = (j_1, \dots, j_l)$ are l-tuples such that $1 \le i_1 < \cdots < i_l \le n$ and $1 \le j_1 < \cdots < j_l \le n$.

It is standard in the theory of determinants that for $A, B \in \mathbb{R}^{n\times n}$, we have $(A^T)^{l*l} = (A^{l*l})^T$ and $(AB)^{l*l} = B^{l*l}A^{l*l}$. Hence if U is orthogonal, then U^{l*l} is also orthogonal. We will need the following version of the Hadamard inequality, which follows from [IL, Lem. 2.1].

LEMMA 2.1. *Let $n = 2l$, $N = \binom{n}{l}$, and $A \in \mathbb{R}^{n\times n}$. Then*

$$H_l(A) = |A^{l*l}|^2 - N \det A \geq 0 \tag{2.1}$$

and equality occurs iff one of the following two conditions holds:

(i) *$A^{l*l} = 0$, that is, rank$(A) < l$;*

(ii) *$A^T A = \lambda I$, where $\lambda > 0$, that is, A is a similarity matrix.*

For $X = (X^I_J) \in \mathbb{R}^{N\times N}$, we define the complementary matrix $\tilde{X} \in \mathbb{R}^{N\times N}$ by $\tilde{X}^I_J = (-1)^{|I|+|J|}X^{I'}_{J'}$ where I' and J' denote the l-tuples complementary to I and J. Clearly, the transformation $\tilde{}: \mathbb{R}^{N\times N} \to \mathbb{R}^{N\times N}$ is an idempotent self-adjoint operator, which is an isometry with respect to the inner product in $\mathbb{R}^{N\times N}$,

$$\tilde{\tilde{X}} = X, \tag{2.2}$$

$$\langle X, \tilde{Y}\rangle = \langle \tilde{X}, Y\rangle, \tag{2.3}$$

$$\langle \tilde{X}, \tilde{Y}\rangle = \langle X, Y\rangle \tag{2.4}$$

for all $X, Y \in \mathbb{R}^{N\times N}$.

Indeed, (2.2) follows directly from the definition, whereas (2.4) is implied by (2.2) and (2.3).

$$\begin{aligned}\langle X, \tilde{Y}\rangle &= \sum_{I,J}(-1)^{|I|+|J|}X^I_J Y^{I'}_{J'} = \sum_{I',J'}(-1)^{|I'|+|J'|}X^{I'}_{J'}Y^I_J\\ &= \langle \tilde{X}, Y\rangle.\end{aligned}$$

For $X \in \mathbb{R}^{N\times N}$, we define the matrices X^+ and X^-, called the conformal and anticonformal parts of X, by

$$X^+ = \frac{1}{2}(X + \tilde{X}), \qquad X^- = \frac{1}{2}(X - \tilde{X}), \tag{2.5}$$

and hence

$$X = X^+ + X^-. \tag{2.6}$$

For any $X, Y \in \mathbb{R}^{N\times N}$,

$$\langle X^+, Y^-\rangle = 0. \tag{2.7}$$

Indeed, by (2.3) and (2.4),

$$4\langle X^+, Y^-\rangle = \langle X, Y\rangle - \langle X, \tilde{Y}\rangle + \langle \tilde{X}, Y\rangle - \langle \tilde{X}, \tilde{Y}\rangle = 0.$$

In other words, the decomposition of X into conformal and anticonformal parts defines an orthogonal decomposition of $\mathbb{R}^{N\times N}$. Hence, if $X = X^+ + X^-$, then

$$|X|^2 = |X^+|^2 + |X^-|^2. \tag{2.8}$$

LEMMA 2.2. *For any $X, Y \in \mathbb{R}^{N\times N}$,*

$$|X^+| - |Y^+| \geq \langle sgn\, Y^+, X - Y\rangle. \tag{2.9}$$

Proof. From the Cauchy–Schwarz inequality, we see that $|X^+| \geq \langle \text{sgn } Y^+, X^+\rangle$ and $|Y^+| = \langle \text{sgn } Y^+, Y^+\rangle$. Hence (2.7) yields

$$|X^+| - |Y^+| \geq \langle \text{sgn } Y^+, X^+ - Y^+\rangle = \langle \text{sgn } Y^+, X - Y\rangle.$$

LEMMA 2.3. *Let $n = 2l$, $N = \binom{n}{l}$. For $A \in \mathbb{R}^{n\times n}$, let $X = A^{l*l}$. Then*

$$|X^+|^2 - |X^-|^2 = N \det A. \tag{2.10}$$

In particular, the form $[H_l(A)]^{p/2} = 2^{p/2}|X^-|^p$ is convex with respect to the $l \times l$ minors of A for all $p \geq 1$.

Proof. Using the Laplace expansion formula [DS, p. 46], in the penultimate step, we get

$$\begin{aligned}|X^+|^2 - |X^-|^2 = \langle X, \tilde{X}\rangle &= \sum_{I,J}(-1)^{|I|+|J|}X_J^I X_{J'}^{I'} \\ &= \sum_I \det A = N \det A.\end{aligned}$$

Remark 1. For $A \in \mathbb{R}^{n\times n}$, and $X = A^{l*l}$ we have that $X^T\tilde{X} = \det A\, I$

3. Polyconvex conformal stored energies in even dimensions. Polyconvex integrands have been introduced by J. M. Ball [B] as a generalization of null Lagrangians. For a thorough discussion of the subject, we refer the reader to [D] and [IL].

DEFINITION 3.1. *A function $W : \mathbb{R}^{n\times n} \to \mathbb{R}$ is said to be polyconvex if for every $B \in \mathbb{R}^{n\times n}$ there exists $\mathcal{B} \in \mathbb{R}^{2^n\times 2^n}$ such that*

$$W(A) - W(B) \geq \langle \mathcal{B}, T(A) - T(B)\rangle$$

for any $A \in \mathbb{R}^{n\times n}$, where $T(A)$ denotes the $2^n \times 2^n$ matrix of all minors of A of all orders.

The main result of this section is the following.

THEOREM 3.1. *Let $0 \leq \alpha \leq 1$, $n = 2l$, $N = \binom{n}{l}$, where l is a positive integer. Then the matrix function $W_\alpha : \mathbb{R}^{n\times n} \to \mathbb{R}$ given by*

$$W_\alpha(A) = |A^{l*l}|^{2\alpha}\Big(|A^{l*l}|^2 - N \det A\Big) \tag{3.1}$$

is polyconvex. More precisely,

$$W_\alpha(A) - W_\alpha(B) \geq \langle \mathcal{M}, A^{l*l} - B^{l*l}\rangle + \lambda(\det A - \det B), \tag{3.2}$$

where $\mathcal{M} = \mathcal{M}(B^{l*l})$, $\lambda = \lambda(B^{l*l})$, and

$$\mathcal{M}(X) = 4|X|^{2\alpha-2}(|X|^2 + 2\alpha|X^-|^2)X^+, \tag{3.3}$$

$$\lambda(X) = -4|X|^{2\alpha-2}(|X|^2 + \alpha|X^-|^2) \tag{3.4}$$

for $X \in \mathbb{R}^{N\times N}$.

Our proof is preceeded by two lemmas.

LEMMA 3.2. *Let S be an open subset of $\mathbb{R}^n$ and let $h \in C^2(\overline{S})$ be a nonnegative function vanishing on the boundary of S whose Hessian matrix is positive in S. Then*

$$h(a) - h(b) \geq \langle \nabla h(b), a - b \rangle \tag{3.5}$$

for all $a, b \in \overline{S}$.

Proof. Inequality (3.5) is well known in the theory of convex functions if the segment $[a, b]$ is contained in $\overline{S}$. To generalize it, we denote by $[x, b] \subset [a, b]$ the largest subsegment contained in $\overline{S}$. If $x \neq a$, then x belongs to the boundary of S. Accordingly,

$$h(x) - h(b) \geq \langle \nabla h(b),\ x - b \rangle.$$

Since $h(x) = 0$ and $a - b = \lambda(x - b)$ for some $\lambda > 1$, we obtain

$$\begin{aligned}\langle \nabla h(b)\ ,\ a - b \rangle &= \lambda \langle \nabla h(b),\ x - b \rangle \\ &\leq \lambda h(x) - \lambda h(b) \leq h(a) - h(b).\end{aligned}$$

LEMMA 3.3. *For $0 \leq \alpha \leq 1$, consider the function*

$$h(t, d) = (t^2 - 2d)^\alpha (t^2 - 4d) \tag{3.6}$$

in $S = \{(t, d) \in \mathbb{R}^2 : t^2 - 4d \geq 0\}$.

Then its Hessian matrix

$$H = \begin{pmatrix} h_{dd} & h_{dt} \\ h_{td} & h_{tt} \end{pmatrix}$$

is positive definite.

Proof. The zero set and the support S of the function h are depicted in Fig. 1. An elementary calculation shows that

$$h_{dd} = 2^{4-\alpha} \alpha [2t^2 - 4d]^{\alpha - 2} [2t^2 + (1 + \alpha)(t^2 - 4d)] \geq 0 \tag{3.7}$$

and

(3.8)
$$\det H = 4\alpha [2t^2 - 4d]^{2\alpha - 3} [(\alpha + 1) 3t^2 (t^2 - 4d) + (\alpha + 1)(2\alpha + 1)(t^2 - 4d)^2 - 2(\alpha - 1) t^4] \\ \geq 0$$

as desired.

Proof of Theorem 3.1. From Lemmas 3.2 and 3.3, we infer that

$$h(t_A, d_A) - h(t_B, d_B) \geq \tau(t_B, d_B)(t_A - t_B) + \delta(t_B, d_B)(d_A - d_B) \tag{3.9}$$

for all pairs (t_A, d_A) and (t_B, d_b) from S, where τ and δ are the partials of h with respect to t and d. More explicitly,

$$\tau(t, d) = 2t(t^2 - 2d)^{\alpha - 1} \Big[\alpha(t^2 - 4d) + t^2 - 2d\Big], \tag{3.10}$$

$$\delta(t, d) = -2(t^2 - 2d)^{\alpha - 1} \Big[\alpha(t^2 - 4d) + 2(t^2 - 2d)\Big] \tag{3.11}$$

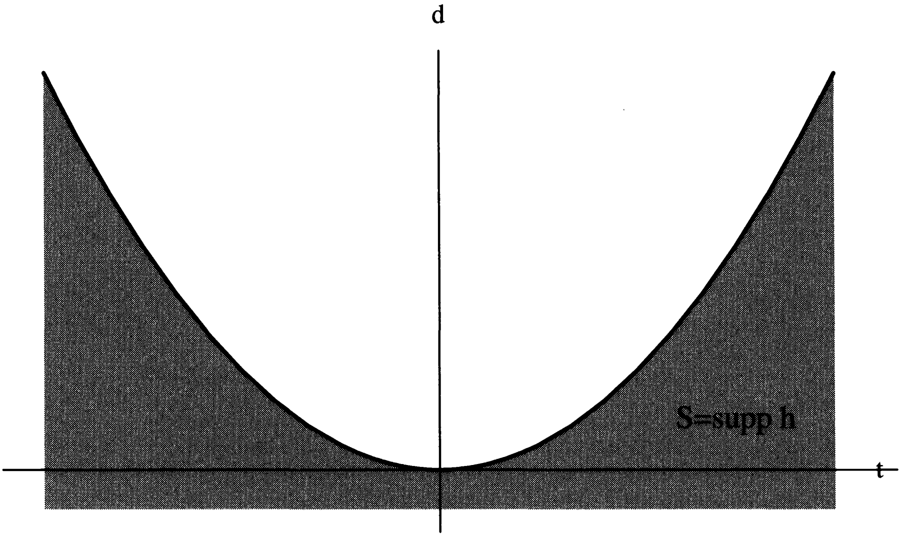

FIG. 1.

for all (t_A, d_A), $(t_B, d_B) \in S$. Next, we define two real functions $t, d : \mathbb{R}^{N\times N} \to \mathbb{R}$,

$$t(X) = \sqrt{2}|X^+| \tag{3.12}$$

$$d(X) = \frac{1}{2}(|X^+|^2 - |X^-|^2) \tag{3.13}$$

for $X \in \mathbb{R}^{N\times N}$.

To shorten notations, we write $X = A^{l*l}$ and $Y = B^{l*l}$ for $A, B \in \mathbb{R}^{n\times n}$.

According to (2.8),

$$(t^2 - 2d)(X) = |X|^2, \tag{3.14}$$

$$(t^2 - 4d)(X) = 2|X^-|^2. \tag{3.15}$$

Hence for $0 \leq \alpha \leq 1$ in the definition of the function h introduced in Lemma 3.3, we obtain that

$$\begin{aligned} W_\alpha(A) &= 2|X|^{2\alpha}|X^-|^2 \\ &= (t^2(X) - 2d(X))^\alpha (t^2(X) - 4d(X)) \\ &= h(t(X), d(X)) \end{aligned} \tag{3.16}$$

Due to Lemma 3.3, for any $A, B \in \mathbb{R}^{n\times n}$, we have

$$W_\alpha(A) - W_\alpha(B) \geq \tau_B(t(X) - t(Y)) + \delta_B(d(X) - d(Y)), \tag{3.17}$$

where

$$\tau_B = 2\sqrt{2}|Y|^{2(\alpha-1)}|Y^+|(2\alpha|Y^-|^2 + |Y|^2), \tag{3.18}$$

$$\delta_B = -4|Y|^{2(\alpha-1)}(\alpha|Y^-|^2 + |Y|^2). \tag{3.19}$$

We note that $\tau_B \geq 0$, because $\alpha \geq 0$ for all $B \in \mathbb{R}^{n\times n}$.

We may now use Lemma 2.2. Accordingly,

$$\begin{aligned} t(X) - t(Y) &= \sqrt{2}(|X^+| - |Y^+|) \\ &\geq \sqrt{2}\langle \operatorname{sgn} Y^+, X - Y\rangle. \end{aligned}$$

Finally, we conclude with the desired estimate

$$W_\alpha(A) - W_\alpha(B) \geq \langle \mathcal{M}, A^{l*l} - B^{l*l}\rangle + \lambda(\det A - \det B), \tag{3.20}$$

where

$$\mathcal{M} = 4|B^{l*l}|^{2(\alpha-1)}\Big[2\alpha|(B^{l*l})^-|^2 + |B^{l*l}|^2\Big](B^{l*l})^+, \tag{3.21}$$

$$\lambda = -4|B^{l*l}|^{2(\alpha-1)}\Big[\alpha|(B^{l*l})^-|^2 + |B^{l*l}|^2\Big]. \tag{3.22}$$

4. Mean coercivity. In this section we prove Theorem 1.2.

Proof of Theorem 1.2. To each ordered l-tuple $I = (i_1, \ldots, i_l)$, $1 \leq i_1 < \cdots < i_l \leq 1$, we assign two l-forms on Ω, namely,

$$\varphi_I = df^{i_1} \wedge \cdots \wedge df^{i_l}, \qquad \psi_I = dg^{i_1} \wedge \cdots \wedge dg^{i_l}. \tag{4.1}$$

The coefficients of these forms are the $l \times l$ minors of ∇f and ∇g, respectively. Of course, $(\sum |\varphi_I|^2)^{\frac{1}{2}} = |\nabla f^{l*l}| \in L^{2\alpha+2}(\Omega)$ and $(\sum |\psi_I|^2)^{\frac{1}{2}} = |\nabla g^{l*l}| \in L^{2\alpha+2}(\Omega)$. The hypothesis that $f, g \in W^{1,l}(\Omega, \mathbb{R}^n)$ are essential to ensure that the forms φ_I and ψ_I are closed in the distributional sense. Notice also that

$$\varphi_I - \psi_I = d\sum_{k=1}^{l}(-1)^k(f^{i_k} - g^{i_k})dg^{i_1} \wedge \cdots \wedge dg^{i_k - 1} \wedge df^{i_k + 1} \wedge \cdots \wedge df^{i_l}. \tag{4.2}$$

Since $f - g \in \overset{\circ}{W}{}^{1,l}(\Omega, \mathbb{R}^n)$, it follows that the zero extension of $\varphi_I - \psi_I$,

$$\omega_I = \begin{cases} \varphi_I - \psi_I & \text{in } \Omega, \\ 0 & \text{in } \mathbb{R}^n - \Omega, \end{cases}$$

remains exact in the entire space $\mathbb{R}^n$. For each ordered l-tuple I, we consider its complementary l-tuple I' ordered in such a way that $\operatorname{sgn}(I, I') = 1$. Therefore,

$$\varphi_I \wedge \varphi_{I'} = df^{i_1} \wedge \cdots \wedge df^{i_l} \wedge df^{i'_1} \wedge \cdots \wedge df^{i'_l} = \det \nabla f. \tag{4.3}$$

As before, the form $\omega_{I'} \in \mathcal{L}^{2\alpha+2}(\mathbb{R}^n)$ is also exact. We now use Proposition 9.1 in [IL] with $n = 2l$. Accordingly,

$$(1-\delta)\int_\Omega (|\omega_I|^2 + |\omega_{I'}|^2)^{\alpha+1} \leq \int_\Omega (|\omega_I|^2 + |\omega_{I'}|^2)^\alpha[|\omega_I|^2 + |\omega_{I'}|^2 - 2\omega_I \wedge \omega_{I'}], \tag{4.4}$$

where $\delta = \delta(l, \alpha) \in [0, 1)$.

Recalling that $\omega_I = \varphi_I - \psi_I$ and $\omega_{I'} = \varphi_{I'} - \psi_{I'}$, with the aid of Young's inequality, we routinely arrive at the estimate

$$\begin{aligned} \epsilon\int_\Omega (|\varphi_I|^2 + |\varphi_{I'}|^2)^{\alpha+1} &\leq \int_\Omega (|\varphi_I|^2 + |\varphi_{I'}|^2)^\alpha[|\varphi_I|^2 + |\varphi_{I'}|^2 - 2\varphi_I \wedge \varphi_{I'}] \\ &\quad + C_\epsilon \int_\Omega (|\psi_I|^2 + |\psi_{I'}|^2)^{\alpha+1} \end{aligned} \tag{4.5}$$

for some $\epsilon = \epsilon(l, \alpha) > 0$.

On the other hand, for each l-tuple I, we have

$$0 \leq |\varphi_I|^2 + |\varphi_{I'}|^2 - 2\varphi_I \wedge \varphi_{I'} \leq \sum_I (|\varphi_I|^2 + |\varphi_{I'}|^2 - 2\varphi_I \wedge \varphi_{I'}) \tag{4.6}$$
$$= 2\Big[|\nabla f^{l*l}|^2 - N \det \nabla f\Big].$$

Hence, summing (4.5) with respect to I, we conclude with the desired inequality

$$\delta \textstyle\int_\Omega |\nabla f^{l*l}|^{2\alpha+2} \leq \displaystyle\int_\Omega |\nabla f^{l*l}|^{2\alpha}\Big[|\nabla f^{l*l}|^2 - N \det \nabla f\Big] + \int_\Omega |\nabla g^{l*l}|^{2\alpha+2}$$

for some $\delta = \delta(l,\alpha) > 0$.

5. Existence of nearly conformal deformations. Having at our disposal the polyconvexity and mean coercivity of the integrand W_α, we may now implement the direct method of the calculus of variations.

Proof of Theorem 1.3. Let $\{f_j\}_{j\geq 1}$ be a minimizing sequence in $\mathcal{L}^{2\alpha+2,l}(\Omega, \mathbb{R}^n)$ for the functional $\mathcal{F}$ such that $f_j - g \in \overset{\circ}{W}{}^{1,l}(\Omega, \mathbb{R}^n)$.

Mean coercivity yields

$$\epsilon\Big(\int_\Omega |\nabla f_j|^l\Big)^{2\alpha+2} + \delta \int_\Omega |\nabla f_j^{l*l}|^{2\alpha+2} \leq \mathcal{F}[f_j] + \int_\Omega |\nabla g^{l*l}|^{2\alpha+2}. \tag{5.1}$$

This estimate, together with the boundary condition $f_j - g \in \overset{\circ}{W}{}^{1,l}(\Omega, \mathbb{R}^n)$, implies that the minimizing sequence is bounded in $W^{1,l}(\Omega, \mathbb{R}^n)$. Therefore, there is no loss of generality in assuming that $\{f_j\}_{j\geq 1}$ converges weakly to a mapping f. Of course, f satisfies the Dirichlet boundary condition $f - g \in \overset{\circ}{W}{}^{1,l}(\Omega, \mathbb{R}^n)$. It remains to be shown that f minimizes $\mathcal{F}$.

Clearly,

$$\Big(\int_\Omega |\nabla f|^l\Big)^{2\alpha+2} \leq \liminf_{j\to\infty}\Big(\int_\Omega |\nabla f_j|^l\Big)^{2\alpha+1}. \tag{5.2}$$

Using weak continuity of the minors (see [R2], [B]), we observe that $\nabla f_j^{l*l} \to \nabla f^{l*l}$ in the sense of Schwarz distributions. On the other hand, by (5.1), the sequence ∇f_j^{l*l} is bounded in $L^{2\alpha+2}(\Omega, \mathbb{R}^{N\times N})$. These facts ensure that ∇f_j^{l*l} is actually weakly convergent in $L^{2\alpha+2}(\Omega, \mathbb{R}^{N\times N})$ and hence $f \in \mathcal{L}^{2\alpha+2,l}(\Omega, \mathbb{R}^n)$.

Also, by Proposition 5.2 of [IL], we see that $\det \nabla f_j \to \det \nabla f$ in the sense of distributions. By Hadamard's inequality (2.1), we see that $\det \nabla f_j$ is a bounded sequence in $L^{1+\alpha}(\Omega)$, where we note that $1+\alpha > 1$. These arguments show that $\det \nabla f_j \to \det \nabla f$ weakly in $L^{1+\alpha}(\Omega)$.

The final step requires the polyconvexity of W_α established in Theorem 3.1.

$$\int_\Omega W_\alpha(\nabla f_j) - \int_\Omega W_\alpha(\nabla f) \geq \int_\Omega \langle \mathcal{M}, \nabla f_j^{l*l} - \nabla f^{l*l}\rangle \tag{5.3}$$
$$+ \int_\Omega \lambda(\det \nabla f_j - \det \nabla f).$$

From (3.21), we see at once that $\mathcal{M} = \mathcal{M}(\nabla f^{l*l})$ belongs to $L^{\frac{2\alpha+2}{2\alpha+1}}(\Omega, \mathbb{R}^{N\times N})$, which is the dual of $L^{2\alpha+2}(\Omega, \mathbb{R}^{N\times N})$. Similarly, by (3.22), $\lambda = \lambda(\nabla f^{l*l})$ belongs to $L^{(\alpha+1)/\alpha}(\Omega)$, which is dual to $L^{\alpha+1}(\Omega)$. Consequently, the right-hand side of (5.3) converges to zero, which implies the inequality

$$\int_\Omega W_\alpha(\nabla f) \geq \liminf_{j\to\infty} \int_\Omega W_\alpha(\nabla f_j). \tag{5.4}$$

Combining (5.4) with (5.2) yields

$$\mathcal{F}[f] \leq \liminf_{j\to\infty} \mathcal{F}[f_j],$$

completing the proof of Theorem 1.3.

6. Rank-one convexity. Considerable progress has been made in the study of nonconvex variational problems in two dimensions. Specific classes of integrands have been analyzed in great detail [AD], [A], [DDGR], [DK], [DM], [RS], [Š2].

These efforts resulted in showing that the sets of convex, polyconvex, quasiconvex, and rank-one-convex matrix functions form an increasing sequence. All but the last inclusion have been shown to be strict in two dimensions. In higher dimensions, the fact that rank-one convexity does not imply quasi convexity has been established by V. Šverák in [Š1].

In the context of the quoted work, it is appropriate to summarize the results of §3 in two dimensions. When $n = 2l = N = \binom{n}{l} = 2$, Theorem 3.1 becomes the following.

PROPOSITION 6.1. *The function $W_\alpha : \mathbb{R}^{2\times 2} \to \mathbb{R}$ given by*

$$W_\alpha(A) = |A|^{2\alpha}(|A|^2 - 2\det A) \tag{6.1}$$

is polyconvex for all $0 \leq \alpha \leq 1$.

Polyconvexity in the case $\alpha = 1$ has been proved in [AD] and [IL], and the case $\alpha = 0$ is obvious. The precise values of α for which W_α is polyconvex, quasi-convex, and rank-one convex remain unknown. A new step in this direction is the following.

PROPOSITION 6.2. *If $-\frac{1}{8} \leq \alpha \leq \frac{3+\sqrt{13}}{4}$, then the function W_α is rank-one convex.*

Proof. Polyconvexity implies rank-one convexity. Hence it follows from Proposition 6.1 that W_α is rank-one convex for $0 \leq \alpha \leq 1$.

In [DDGR, Prop. 1.1], Dacorogna, Douchet, Gangbo and Rappaz found the necessary and sufficient conditions for rank-one convexity in two dimensions. Accordingly, W_α is rank-one convex iff

$$\Phi_\alpha(u,v,y) = 2[(\alpha+1)\alpha - 2\alpha(\alpha-1)y]u^2 - 4\alpha uv + \alpha + 1 - 2\alpha y \geq 0 \tag{6.2}$$

for all $y, u, v \in \mathbb{R}$ satisfying $u^2 + v^2 \leq 1$, $(u+v)^2 - 1 \leq 2y \leq 1 - (u-v)^2$.

Part 1: *Proof of* (6.2) *for* $1 < \alpha \leq \frac{3+\sqrt{13}}{4}$. Since $\Phi_\alpha(u,v,y)$ is linear in y, it is enough to show that (6.2) holds for the maximal value of y, namely, $y^+ = \frac{1}{2}(1-(u-v)^2)$. Therefore, (6.2) is reduced to proving that for all $u^2+v^2 \leq 1$,

$$\frac{1}{\alpha}\Phi_\alpha(u,v,y^+) = \frac{1}{\alpha} + (u-v)(5u-v) + 2(\alpha-1)u^2(u-v)^2 \geq 0. \tag{6.3}$$

Using our assumption on α and dropping a nonnegative term, we get

$$\frac{1}{\alpha}\Phi_\alpha(u,v,y^+) \geq \sqrt{13} - 3 + (u-v)(5u-v) \geq (\sqrt{13}-3)(u^2+v^2) + (u-v)(5u-v)$$
$$= \left(u\sqrt{\sqrt{13}+2} - v\sqrt{\sqrt{13}-2}\right)^2 \geq 0.$$

Part 2: *Proof of* (6.2) *for* $-\frac{1}{8} \leq \alpha < 0$. It suffices to prove (6.2) for $|2y| \leq 1$, hence

$$\begin{aligned}\Phi_\alpha(u,v,y) &\geq 1 - |\alpha|(4 + 2|\alpha - 1| + 2|\alpha + 1|) \\ &= 1 + 8\alpha \geq 0\end{aligned}$$

as desired.

PROPOSITION 6.3. *For* $\alpha = 2$ *and* $\alpha < -\frac{1}{3}$, *the integrand* W_α *is not rank-one convex.*

Indeed, when $\alpha = 2$ in Part 1, then $\Phi_2(\frac{\sqrt{5}}{5}, \frac{2\sqrt{5}}{5}, \frac{2}{5}) = -\frac{1}{25} < 0$. In Part 2, if $u = -v = \frac{\sqrt{2}}{2}$ and $2y = -1$ and α is rank-one convex, then we infer that $\alpha > \frac{\sqrt{2}-2}{2} > -\frac{1}{3}$.

Acknowledgment. Both authors thank Vladimir Šverák for discussions at Cortona and at the Institute for Advanced Study, respectively.

THE GRADIENT THEORY OF THE PHASE TRANSITIONS IN CAHN–HILLIARD FLUIDS WITH DIRICHLET BOUNDARY CONDITIONS*

KAZUHIRO ISHIGE†

Abstract. We are interested in the asymptotic behavior of minimizers (as $\epsilon \to 0$) of the variational problems under the Dirichlet condition

$$\inf\left\{ \int_\Omega \left[\epsilon|\nabla u|^2 + \frac{1}{\epsilon}W(x,u)\right] dx \;\middle|\; u \in W^{1,2}(\Omega : \mathbf{R}^n),\, u = g \quad \text{on } \partial\Omega \right\},$$

where $W(x,\cdot)$ is a nonnegative function with only two zeros α and β. Here α and β are independent of the space variable x. In this paper, we will show that the limit of a sequence of minimizers $\{u_\epsilon\}_{\epsilon>0}$ (as $\epsilon \to 0$) is a solution of another variational problem without boundary condition. However the limit variational problem has a boundary integral corresponding to transition layers near $\partial\Omega$. Our analysis relies mainly on the theory of gamma convergence. In order to overcome the difficulty of inhomogeneity of the boundary condition, we approximate $g(x)$ by suitable piecewise smooth functions near the boundary $\partial\Omega$.

1. Introduction.

In this paper, we will investigate the asymptotic behavior of minimizers $\{u_\epsilon\}_{\epsilon>0}$ (as $\epsilon \to 0$) of the following variational problem:

$$(P_\epsilon) \qquad \inf\left\{ \int_\Omega \left[\epsilon|\nabla u|^2 + \frac{1}{\epsilon}\, W(x,u)\right] dx \;\middle|\; u \in W^{1,2}(\Omega : \mathbf{R}^n),\, u = g \text{ on } \partial\Omega \right\},$$

where Ω is a bounded domain in $\mathbf{R}^N$ with C^2 smooth boundary $\partial\Omega$ and g is a Lipschitz continuous function from $\partial\Omega$ into $\mathbf{R}^n$. Here $W(x,\cdot)$ is a nonnegative continuous function with only two zeros $\alpha, \beta \in \mathbf{R}^n$, and α, β are independent of the space variable x. This type of problem is related to the study of the phase transitions of Cahn–Hilliard fluids. See [13], [18], and [20].

In [12], R. V. Kohn and P. Sternberg conjectured that minimizers of the variational problem

$$(SP_\epsilon) \qquad \inf\left\{ \int_\Omega \left[\epsilon|\nabla u|^2 + \frac{1}{\epsilon}(u^2-1)^2\right] dx \;\middle|\; u \in W^{1,2}(\Omega),\, u|_{\partial\Omega} = g \right\},$$

which is a special case of (P_ϵ), converge to a solution of

$$\inf\left\{ \frac{8}{3}P_\Omega\{u=1\} + 2\int_{\partial\Omega} |d(u)-d(g)|d\mathcal{H}_{N-1} \;\middle|\; u \in BV(\Omega),\, |u| = 1 \text{ a.e.} \right\},$$

where $d(t) = \int_{-1}^t |s^2-1|ds$ and $\mathcal{H}_{N-1}$ is the $N-1$-dimensional Hausdorff measure. This conjecture was affirmatively solved by N. C. Owen, J. Rubinstein, and P. Sternberg in [18].

In this paper, we will study the asymptotic behavior of minimizers of (P_ϵ) and extend the result of [18] to the vector case ($n \geq 2$). Our proof for the vectorial case is more complicated than that for the scalar case ($n = 1$).

*Received by the editors March 30, 1994; accepted for publications (in revised form) August 24, 1994.

†Graduate School of Information Sciences, Tohoku University, Aoba-ku, Sendai 980-77, Japan (ishige@math.is.tohoku.ac.jp).

Our approach is based on the theory of gamma convergence, in which the asymptotic behavior of minimizers $\{u_\epsilon\}_{\epsilon>0}$ of the variational problem (P_ϵ) is characterized by a solution of another variational problem without the Dirichlet conditions.

Recently, using the theory of gamma convergence, several authors have studied the asymptotic behavior of the minimizers of the problem

$$(E_\epsilon) \qquad \inf\left\{ \int_\Omega \left[\epsilon|\nabla u|^2 + \frac{1}{\epsilon} W(u) \right] dx \;\middle|\; u \in W^{1,2}(\Omega : \mathbf{R}^n), \int_\Omega u(x)dx = m \right\},$$

where m is a constant vector in $\mathbf{R}^n$. For the scalar case (i.e., $n = 1$), see [1], [6], [10], [12]–[17], and [19]. For the vector case (i.e., $n \geq 2$), see [3], [4], [9], and [11]. Our results on the problem (P_ϵ) depend mainly on the study of the asymptotic-behavior of minimizers of (E_ϵ). However, there are several different aspects between the asymptotic-behavior of minimizers of (P_ϵ) and those of (E_ϵ). In fact, minimizers of (E_ϵ) generate only an interior layer, while minimizers of (P_ϵ) generate both an interior and a boundary layer as $\epsilon \to 0$.

On the other hand, we can easily see that minimizers of (SP_ϵ) satisfy the equation

$$(CP_\epsilon) \qquad \begin{cases} \epsilon^2 \Delta u - u(u-1)(u+1) = 0 & \text{in } \Omega, \\ u(x) = g(x) & \text{on } \partial\Omega. \end{cases}$$

In this case, there are several results for the solutions of (CP_ϵ) obtained by using the method of matched expansion. Our results also seem to be closely related to [5] and [8].

We give the precise hypotheses on the functions $W(x,u)$ and $g(x)$. Let $W(x,u) : \overline{\Omega} \times \mathbf{R}^n \to \mathbf{R}$ be a continuous nonnegative function, and for any $x \in \overline{\Omega}$, $W(x,u) = 0$ if and only if $u = \alpha$ or β. Here we denote two constant vectors independent of x by α and β . We assume that there exist two constants K_1 and K_2 such that

$$(1.1) \qquad \sup_{u \in \partial[K_1,K_2]^n} W(x,u) \leq W(x,v) \qquad \text{for all } x \in \overline{\Omega},\ v \notin [K_1,K_2]^n$$

and

$$(1.2) \qquad g(x) \in [K_1,K_2]^n \qquad \text{for all } x \in \partial\Omega.$$

Moreover, we assume that for any $\epsilon > 0$, there exists a positive constant δ such that

$$(1.3) \qquad |W^{1/2}(x,u) - W^{1/2}(y,u)| \leq \epsilon W^{1/2}(x,u)$$

for all $x, y \in \overline{\Omega}$ with $|x-y| \leq \delta$ and for all $u \in \mathbf{R}^n$.

In order to state our main theorem, we will introduce a Riemannian metric d on $\mathbf{R}^n$, which is a modification of the one introduced in [3] and [9]. For $x \in \overline{\Omega}$ and $a, b \in \mathbf{R}^n$, let $d(x,a,b)$ be the metric defined by

$$(1.4) \qquad d(x,a,b) = \inf\left\{ \int_0^1 W^{1/2}(x,\gamma(t))|\,\dot\gamma(t)\,|\,dt \;\middle|\; \gamma \in C^1([0,1] : \mathbf{R}^n), \gamma(0) = a,\ \gamma(1) = b \right\}.$$

For example, in the case of $W(x,u) = (u^2-1)^2$ and $n = 1$, we have

$$d(x,-1,b) = \int_{-1}^{b} |s^2 - 1| ds \qquad \text{for} \quad b \geq -1.$$

We now state our main theorem in this paper.

THEOREM 1. *Let $g : \partial\Omega \to \mathbf{R}^n$ be a Lipschitz-continuous function which satisfies* (1.2). *Suppose that the function W satisfies* (1.1) *and* (1.3). *For $\epsilon > 0$, let u_ϵ be a solution of the variational problem*

$$(P_\epsilon)\qquad \inf\left\{ \int_\Omega \left[\epsilon|\nabla u|^2 + \frac{1}{\epsilon} W(x,u)\right] dx \;\middle|\; u \in W^{1,2}(\Omega : \mathbf{R}^n),\ u|_{\partial\Omega}(x) = g(x)\right\}.$$

If there exist a positive sequence $\{\epsilon_i\}_{i=1}^\infty$ and a function $u_0(x) \in L^1(\Omega : \mathbf{R}^n)$ such that

$$(1.5)\qquad \lim_{i\to\infty} \epsilon_i = 0 \quad \text{and} \quad \lim_{i\to\infty} u_{\epsilon_i} = u_0 \quad \text{in } L^1(\Omega : \mathbf{R}^n),$$

then

$$W(x, u_0(x)) = 0 \quad \text{for almost all } x \in \Omega,$$

that is, $u_0(x) = \alpha$ or β for almost all $x \in \Omega$. Moreover, the set $E_0 = \{x \in \Omega \,|\, u_0(x) = \alpha\}$ is a solution of the following variational problem:

$$(P_0)\qquad \inf\left\{ \int_{\Omega\cap\partial^* E} d(x,\alpha,\beta)d\mathcal{H}_{N-1} + \int_{\partial\Omega} d(x, v|_{\partial\Omega}(x), g(x))d\mathcal{H}_{N-1} \;\middle|\; E \subset \Omega,\ P_\Omega(E) < \infty,\ v = \alpha\chi_E + \beta\chi_{\Omega\setminus E}\right\},$$

where $P_\Omega(E)$ is the perimeter of E in Ω and $v|_{\partial\Omega}$ is the trace of v on $\partial\Omega$. Furthermore, we have

$$\lim_{i\to\infty}\int_\Omega \left[\epsilon_i|\nabla u_{\epsilon_i}|^2 + \frac{1}{\epsilon_i} W(x,u_{\epsilon_i})\right] dx = 2\int_{\Omega\cap\partial^* E_0} d(x,\alpha,\beta)d\mathcal{H}_{N-1}$$
$$+ 2\int_{\partial\Omega\cap\partial^* E_0} d(x,\alpha,g(x))d\mathcal{H}_{N-1} + 2\int_{\partial\Omega\setminus\partial^* E_0} d(x,\beta,g(x))d\mathcal{H}_{N-1}.$$

Here $\partial^* E_0$ is the reduced boundary of E_0.

Remark 1. It is not restrictive to assume that there exists a subsequence $\{u_{\epsilon_i}\}_{i=1}^\infty$ satisfying (1.5). In fact, the following is proved in [9] and [11]: if there exist constants C and R such that

$$(1.6)\qquad \inf_{x\in\overline{\Omega}} W(x,u) \geq C|u| \qquad \text{for} \quad |u| \geq R,$$

then there exists a subsequence $\{u_{\epsilon_i}\}_{i=1}^\infty$ satisfying (1.5).

Remark 2. Consider two continuous functions $W(u)$ and $h(x)$, where $W(u)$ satisfies condition (1.1) and $h(x)$ is positive function in $\overline{\Omega}$. If the function $W(x,u)$ has a form of $h(x)W(u)$, then $W(x,u)$ satisfies conditions (1.1) and (1.3).

It is worth noting that the proof of the vector case has completely different difficulties relative to that of the scalar case ($n = 1$). For the vector case, it is important to select a minimizing sequence $\{\gamma_k(x,t)\}_{k=1}^\infty$ achieving the value of $d(x,\alpha,g(x))$. One of the difficulties in the treatment of the vector case is that $\gamma_k(x,t)$ is not necessary continuous in the space variable x. Hence it seems difficult to apply the method of [18] directly. In order to overcome this difficulty, we approximate $W(\cdot,u)$ and $g(\cdot)$ by suitable piecewise smooth functions near the transition layer and the boundary $\partial\Omega$. For further details, see Step 2 in §4.

The plan of this paper is as follows: In §2, we present some preliminary results and state Propositions A and B, which are crucial in our analysis. In §3, adopting the method of [4] to our problem, we will prove Proposition A. In §4, we will construct approximate functions $\{w_\epsilon\}_{\epsilon>0}$ to the minimizers $\{u_\epsilon\}_{\epsilon>0}$ and prove Proposition B. In §5, we give some direct applications of the results obtained in the previous sections.

2. Preliminary results and main propositions. We first introduce the notation used in this paper. Let Ω be an open bounded set in $\mathbf{R}^N$ with C^2 smooth boundary $\partial\Omega$. For any $\nu \in \mathbf{S}^{N-1}$, we denote the open unit cube centered at the origin with two of its surfaces normal to ν by Q_ν, i.e., if $\{\nu_1, \dots, \nu_{N-1}, \nu\}$ is a orthonormal system of $\mathbf{R}^N$, then

$$Q_\nu \equiv \left\{ x \in \mathbf{R}^N \,\middle|\, |x \cdot \nu_i| < \frac{1}{2}, |x \cdot \nu| < \frac{1}{2}, i = 1, \dots, N-1 \right\}.$$

We denote the Banach space of functions of bounded variation by $BV(\Omega)$. We denote the Lebesgue N-dimensional measure by $\mathcal{L}_N$ and set $|E| = \mathcal{L}_N(E)$ for any measurable set E of $\mathbf{R}^N$. Furthermore, we denote the $N-1$-dimensional Hausdorff measure by $\mathcal{H}_{N-1}$.

In this section, we recall some properties of functions in $BV(\Omega)$ and state two propositions which are the hearts of the matter in our analysis.

For $u \in L^1(\Omega)$, we say $u \in BV(\Omega)$ if and only if there are Radon measures $\mu_1, \mu_2, \dots, \mu_N$ defined in Ω such that for $i = 1, 2, \dots, N$, the total variation of $\mu_i < \infty$ and

$$\int_\Omega u \frac{\partial}{\partial x_i} \varphi dx = -\int_\Omega \varphi d\mu_i \qquad \text{for all} \quad \varphi \in C_0^\infty(\Omega).$$

In what follows, we write $\nabla u = (\mu_1, \mu_2, \dots, \mu_N)$. For any positive continuous function h defined on $\overline{\Omega}$, we set

$$\int_\Omega h(x)|\nabla u| \equiv \sup\left\{ \int_\Omega u \operatorname{div} g dx \,\middle|\, g \in C_0^1(\Omega : \mathbf{R}^N),\ |g| \le h \right\}.$$

If $u_\epsilon \to u$ in $L^1(\Omega)$, then we have

$$\liminf_{\epsilon \to 0_+} \int_\Omega h(x)|\nabla u_\epsilon| \ge \int_\Omega h(x)|\nabla u|. \tag{2.1}$$

On the other hand, for $u \in BV(\Omega)$ and any continuous function $\varphi(x, y) \in C(\Omega \times \mathbf{R})$, the co-area formula is read as

$$\int_\Omega \varphi(x, u(x))|\nabla u| = \int_{-\infty}^{+\infty} dt \int_{\{u(x)=t\}} \varphi(x, t) d\mathcal{H}_{N-1}(x). \tag{2.2}$$

Furthermore, even if $\partial\Omega$ is a Lipschitz-continuous boundary, we can define the trace of u on $\partial\Omega$ for $u \in BV(\Omega)$.

For any measurable subset E of $\mathbf{R}^N$, let χ_E be the characteristic function of E. If $\chi_E \in BV(\Omega)$, we say that E has finite perimeter in Ω. Then we set

$$P_\Omega(E) = \int_\Omega |\nabla \chi_E|, \qquad \nu_r = -\int_{B(x,r)} \nabla \chi_E \Big/ \int_{B(x,r)} |\nabla \chi_E|. \tag{2.3}$$

We define the reduced boundary of E as $\partial^* E$. We say $x \in \partial^* E$ if and only if

$$\int_{B(x,r)} |\nabla \chi_E| > 0 \qquad \text{for all} \quad r > 0$$

and the limit $\nu(x) = \lim_{r \to 0} \nu_r(x)$ exists with $|\nu(x)| = 1$. We have

$$\int_\Omega h(x)|\nabla \chi_E| = \int_{\partial^* E} h(x) d\mathcal{H}_{N-1}. \tag{2.4}$$

For further details on functions of bounded variation, see [7] and [21].

For $u \in L^1(\Omega : \mathbf{R}^n)$ and $\epsilon > 0$, we define $F_\epsilon(u)$, $F_0(u)$ by

$$F_\epsilon(u) = \begin{cases} \int_\Omega \left[\epsilon|\nabla u|^2 + \frac{1}{\epsilon}W(x,u)\right] dx & \text{if } u \in W^{1,2}(\Omega : \mathbf{R}^n) \text{ and } u = g \text{ on } \partial\Omega, \\ +\infty & \text{otherwise,} \end{cases}$$

$$F_0(u) = \begin{cases} 2\int_\Omega d(x,\alpha,\beta)|\nabla \chi_{\{u(x)=\alpha\}}| + 2\int_{\partial\Omega} d(x, u|_{\partial\Omega}(x), g(x)) d\mathcal{H}_{N-1} \\ \qquad \text{if } u \in BV(\Omega : \mathbf{R}^n) \text{ and } W(x,u(x)) = 0 \text{ for almost all } x \in \Omega, \\ +\infty \qquad \text{otherwise.} \end{cases}$$

In order to prove our main theorem, we need the following two propositions, which are crucial in our analysis.

PROPOSITION A. *Suppose that $\{v_\epsilon\}_{\epsilon>0}$ is a sequence in $L^1(\Omega : \mathbf{R}^n)$ which converges in $L^1(\Omega : \mathbf{R}^n)$ as $\epsilon \to 0_+$ to a function v_0. If*

$$\liminf_{\epsilon \to 0_+} F_\epsilon(v_\epsilon) < +\infty, \tag{2.5}$$

then v_0 is a function in $BV(\Omega : \mathbf{R}^n)$ such that $W(x, v_0(x)) = 0$ a.e. $x \in \Omega$, $E = \{x \in \Omega \,|\, v_0(x) = \alpha\}$ has finite perimeter, and

$$F_0(v_0) \le \liminf_{\epsilon \to 0_+} F_\epsilon(v_\epsilon). \tag{2.6}$$

PROPOSITION B. *Suppose that $w_0 \in L^1(\Omega : \mathbf{R}^n)$ can be written as $w_0 = \alpha\chi_E + \beta\chi_{\Omega \setminus E}$, where E is a measurable subset of Ω with finite perimeter. Then there exists a sequence $\{w_\epsilon\}_{\epsilon>0}$ in $W^{1,2}(\Omega : \mathbf{R}^n)$ which converges in $L^1(\Omega : \mathbf{R}^n)$ as $\epsilon \to 0_+$ to w_0 and such that*

$$\limsup_{\epsilon \to 0_+} F_\epsilon(w_\epsilon) \le F_0(w_0). \tag{2.7}$$

Using Propositions A and B, we can prove Theorem 1 in the same manner as in [13]. For completeness, we will give the proof of Theorem 1.

Proof of Theorem 1. Let $\{u_{\epsilon_i}\}_{i=0}^\infty$ be a sequence in $W^{1,2}(\Omega : \mathbf{R}^n)$ with $\lim_{i \to \infty} u_{\epsilon_i} = u_0$ in $L^1(\Omega : \mathbf{R}^n)$, where each u_{ϵ_i} is a solution of (P_{ϵ_i}). From Proposition B, there exists a sequence $\{v_\epsilon\}_{\epsilon>0}$ such that $\lim_{\epsilon \to 0} v_\epsilon = \alpha$ in $L^1(\Omega : \mathbf{R}^n)$ and $\limsup_{\epsilon \to 0} F_\epsilon(v_\epsilon) \le F_0(\alpha) < \infty$. Then we have $\limsup_{i \to \infty} F_{\epsilon_i}(u_{\epsilon_i}) < \infty$, and from Proposition A, we see that

$$F_0(u_0) \le \liminf_{i \to \infty} F_{\epsilon_i}(u_{\epsilon_i}), \tag{2.8}$$

$W(x, u_0(x)) = 0$ a.e. $x \in \Omega$, and $E_0 = \{x \in \Omega \,|\, u_0(x) = \alpha\}$ has finite perimeter. Assume that u_0 is not a solution of (P_0), i.e., there exists $\tilde{u}_0 \in BV(\Omega : \mathbf{R}^n)$ such that

$$F_0(\tilde{u}_0) < F_0(u_0).$$

From Proposition B, there exists a sequence $\{\tilde{u}_\epsilon\}_{\epsilon>0}$ in $W^{1,2}(\Omega : \mathbf{R}^n)$ such that

$$\limsup_{\epsilon\to 0} F_\epsilon(\tilde{u}_\epsilon) \le F_0(\tilde{u}_0) < F_0(u_0) \le \liminf_{i\to\infty} F_{\epsilon_i}(u_{\epsilon_i}). \tag{2.9}$$

Then (2.9) contradicts to the minimality of u_{ϵ_i}. Therefore, u_0 is a solution of (P_0). Furthermore, from Proposition B and the minimality of u_{ϵ_i}, we have

$$\lim_{i\to\infty} F_{\epsilon_i}(u_{\epsilon_i}) = F_0(u_0).$$

From the definition of the functional F_0, we obtain

$$\begin{aligned}\lim_{i\to\infty} F_{\epsilon_i}(u_{\epsilon_i}) = 2\int_{\Omega\cap\partial^* E_0} d(x,\alpha,\beta)d\mathcal{H}_{N-1} &+ 2\int_{\partial\Omega\cap\partial^* E_0} d(x,\alpha,g(x))d\mathcal{H}_{N-1} \\ &+ 2\int_{\partial\Omega\setminus\partial^* E_0} d(x,\beta,g(x))d\mathcal{H}_{N-1},\end{aligned}$$

and the proof of Theorem 1 is completed. □

It remains to prove Proposition A and B, which we will undertake in §§3 and 4, respectively.

3. Proof of Proposition A. From (2.5), it follows that there exists a positive sequence $\{\epsilon_i\}_{i=1}^\infty$ such that $\lim_{i\to\infty}\epsilon_i = 0$ and $\lim_{i\to\infty} F_{\epsilon_i}(v_{\epsilon_i}) = \liminf_{\epsilon\to 0_+} F_\epsilon(v_\epsilon) < \infty$. Furthermore, by taking a subsequence if necessary, we can assume that $\{v_{\epsilon_i}\}_{i=1}^\infty$ converges to v_0 a.e. $x \in \Omega$ as $i \to +\infty$. Then by Fatou's lemma, we have

$$\begin{aligned}0 \le \int_\Omega W(x, v_0(x))\,dx &\le \liminf_{i\to\infty} \int_\Omega W(x, v_{\epsilon_i}(x))\,dx \\ &\le \liminf_{i\to\infty} \int_\Omega [{\epsilon_i}^2|\nabla v_{\epsilon_i}| + W(x, v_{\epsilon_i}(x))]\,dx \\ &\le \liminf_{i\to\infty} \epsilon_i F_{\epsilon_i}(v_{\epsilon_i}) = 0.\end{aligned} \tag{3.1}$$

Therefore, we obtain $W(x, v_0(x)) = 0$ for a.e. x in Ω.

In order to prove the remaining part of Proposition A, we can assume without loss of generality that $v_{\epsilon_i}(x) \in [K_1, K_2]^n$ for all $x \in \Omega$. In fact, let $v_{\epsilon_i}^\#$ be a function which is obtained by truncation of each scalar component of v_{ϵ_i} by K_1 and K_2 given in (1.1), i.e., for $v_{\epsilon_i} = (v_{\epsilon_i}^1, v_{\epsilon_i}^2, \dots, v_{\epsilon_i}^n)$,

$$v_{\epsilon_i}^{\#^j} = \max\{K_1, \min\{v_{\epsilon_i}^j, K_2\}\}, \quad j = 1, 2, \dots, n.$$

Then from (1.1) and (1.2), we have the following relations:

$$\lim_{i\to+\infty} v_{\epsilon_i}^\# = v_0 \quad \text{in} \quad L^1(\Omega : \mathbf{R}^n), \qquad v_{\epsilon_i}^\# = g \quad \text{on} \quad \partial\Omega,$$

$$\int_\Omega \left[\epsilon_i|\nabla v_{\epsilon_i}^\#|^2 + \frac{1}{\epsilon_i} W(x, v_{\epsilon_i}^\#)\right] dx \le \int_\Omega \left[\epsilon_i|\nabla v_{\epsilon_i}|^2 + \frac{1}{\epsilon_i} W(x, v_{\epsilon_i})\right] dx.$$

For the purpose of proving that $v_0 \in BV(\Omega : \mathbf{R}^n)$, we will introduce a function $d_\infty : \mathbf{R}^{2n} \to \mathbf{R}^+$ as follows:

$$(3.2)\qquad d_\infty(a,b) = \inf\left\{ \int_0^1 W_\infty^{1/2}(\gamma(s))\,|\,\dot\gamma(s)\,|\,ds \;\middle|\; \gamma \in C^1([0,1] : \mathbf{R}^n),\ \gamma(0) = a, \gamma(1) = b \right\}$$

for all $a, b \in \mathbf{R}^n$, where $W_\infty(\cdot) = \inf_{x\in\overline{\Omega}} W(x,\cdot)$. Here we set $\psi_\infty(\xi) = d_\infty(a,\xi)$ for $\xi \in \mathbf{R}^n$ and for fixed $a \in \mathbf{R}^n$, and we can easily see that $\psi_\infty(\xi)$ is continuous. Then from Proposition 2–1 in [3], we have $\psi_\infty(v_{\epsilon_i}) \in W^{1,1}(\Omega)$ and

$$\begin{aligned}\liminf_{i\to\infty} \int_\Omega |\nabla(\psi_\infty(v_{\epsilon_i}))|dx &\le \liminf_{i\to\infty} \int_\Omega W_\infty^{1/2}(v_{\epsilon_i})|\nabla v_{\epsilon_i}|\,dx \\ &\le \lim_{i\to\infty} \frac{1}{2} \int_\Omega [\epsilon_i|\nabla v_{\epsilon_i}|^2 + \frac{1}{\epsilon_i} W_\infty(v_{\epsilon_i})]\,dx \\ &\le \lim_{i\to\infty} \frac{1}{2} F_{\epsilon_i}(v_{\epsilon_i}) < \infty.\end{aligned}$$

On the other hand, from the equiboundedness of $\{v_{\epsilon_i}\}_{i=1}^\infty$ in $L^\infty(\Omega : \mathbf{R}^n)$, we can see that $\psi_\infty(v_{\epsilon_i}) \to \psi_\infty(v_0)$ in $L^1(\Omega)$. Thus we have from (2.1)

$$\int_\Omega |\nabla\psi_\infty(v_0)| \le \liminf_{i\to\infty} \int_\Omega |\nabla(\psi_\infty(v_{\epsilon_i}))|dx < \infty,$$

and so $\psi_\infty(v_0) \in BV(\Omega)$. Therefore, by (3.1), we have $\psi_\infty(v_0) \in \{\psi_\infty(\alpha), \psi_\infty(\beta)\}$ for almost all x in Ω, and we deduce that $v_0 \in BV(\Omega : \mathbf{R}^n)$.

Next we will prove inequality (2.6). In order to give the estimates of $|\nabla v_{\epsilon_i}|\cdot W^{1/2}(x, v_{\epsilon_i})$ on the boundary $\partial\Omega$ of Ω, we need to extend the domain Ω.

Let Ω' be any bounded open set in $\mathbf{R}^N$ with $\overline{\Omega} \subset \Omega'$. From the regularity of $\partial\Omega$, without loss of generality, we can extend the function $W(x,v)$ to the domain $\Omega' \times \mathbf{R}^n$. Then from the uniform continuity of $W(x,v)$ on $\overline{\Omega'} \times [K_1, K_2]^n$, for any $\epsilon > 0$, there exists a constant $\delta > 0$ such that

$$(3.3)\qquad |W^{1/2}(x,v) - W^{1/2}(y,v)| \le \epsilon[1 + W^{1/2}(x,v)]$$

for all $x, y \in \Omega'$ with $|x-y| \le \delta$ and for all $v \in [K_1, K_2]^n$. Furthermore, from the regularity of $\partial\Omega$ and g, there exists a function G in $W^{1,\infty}(\Omega' : \mathbf{R}^n)$ whose trace on $\partial\Omega$ equals to g. Here for any $v \in L^1(\Omega : \mathbf{R}^n)$, we set

$$(3.4)\qquad \tilde v = \begin{cases} v & \text{if } x \in \Omega, \\ G & \text{if } x \in \Omega' \setminus \overline{\Omega}. \end{cases}$$

In particular, $\tilde v_{\epsilon_i} \in W^{1,2}(\Omega' : \mathbf{R}^n)$ and we have

$$\sup_i \int_{\Omega'} |\nabla \tilde v_{\epsilon_i}| W^{1/2}(x, \tilde v_{\epsilon_i})dx < \infty.$$

Therefore, from the weak compactness for measures (see [7, Thm. 2, p. 55]) and the definition of $\tilde v_{\epsilon_i}$, there exists a nonnegative Radon measure μ on $\overline{\Omega}$ and a subsequence $\{\epsilon_{i'}\}_{i'=1}^\infty$ of $\{\epsilon_i\}_{i=1}^\infty$ such that for any $\varphi \in C_0^\infty(\Omega')$,

$$(3.5)\qquad \int_{\Omega'} \varphi|\nabla\tilde v_{\epsilon_{i'}}|W^{1/2}(x, \tilde v_{\epsilon_{i'}})\,dx \to \int_{\overline{\Omega}} \varphi d\mu + \int_{\Omega'\setminus\overline{\Omega}} \varphi|\nabla G|W^{1/2}(x,G)\,dx$$

as $i' \to \infty$. In what follows, we omit the prime of $\epsilon_{i'}$ for simplicity.

From the Lebesgue decomposition theorem (see [7, Thm. 3, p. 42]), we can write μ as a sum of the singular nonnegative measures $\mu = \mu_1 \mathcal{H}_{N-1} \lfloor ((\Omega \cap \partial^* E) \cup \partial\Omega) + \mu_2$. Then we can prove the following lemma. The proof of the following lemma is given by modifying the arguments of [4].

LEMMA 3.1. *The singular measure* μ_1 *has the following properties:*

$$\mu_1(x) \geq d(x, \alpha, \beta) \qquad \mathcal{H}_{N-1} - \text{ a.e. } x \text{ in } \Omega \cap \partial^* E; \tag{3.6}$$

$$\mu_1(x) \geq d(x, \alpha, g(x)) \qquad \mathcal{H}_{N-1} - \text{ a.e. } x \text{ in } \partial\Omega \cap \partial^* E; \tag{3.7}$$

$$\mu_1(x) \geq d(x, \beta, g(x)) \qquad \mathcal{H}_{N-1} - \text{ a.e. } x \text{ in } \partial\Omega \setminus \partial^* E. \tag{3.8}$$

Proof. We begin by proving the inequality (3.6). Let x_0 be any point in $\Omega \cap \partial^* E$. From the Radon–Nikodym theorem, we have $\mu_1(x) < \infty$ for $\mathcal{H}_{N-1}-$ a.e. x in $(\Omega \cap \partial^* E) \cup \partial\Omega$, and so we can assume $\mu_1(x_0) < \infty$. Then we have

$$+\infty > \mu_1(x_0) = \limsup_{\delta \to 0} \mu(x_0 + \delta B_1)/\mathcal{H}_{N-1}(\{x_0 + \delta B_1\} \cap \{\Omega \cap \partial^* E\}) \tag{3.9}$$

and for any $\varphi \in C_0^\infty(B_1)$ with $0 \leq \varphi \leq 1$, we get

$$\begin{aligned} \mu(x_0 + \delta B_1) &\geq \int_{x_0 + \delta B_1} \varphi\left(\frac{y - x_0}{\delta}\right) d\mu(y) \\ &\geq \lim_{i \to 0} \int_{x_0 + \delta B_1} \varphi\left(\frac{y - x_0}{\delta}\right) |\nabla v_{\epsilon_i}| W^{1/2}(y, v_{\epsilon_i}(y)) dy \\ &\geq \liminf_{i \to 0} I_1^i + \liminf_{i \to 0} I_2^i, \end{aligned} \tag{3.10}$$

where

$$I_1^i = \int_{x_0 + \delta B_1} \varphi\left(\frac{y - x_0}{\delta}\right) |\nabla v_{\epsilon_i}| W^{1/2}(x_0, v_{\epsilon_i}(y)) dy$$

and

$$I_2^i = \int_{x_0 + \delta B_1} \varphi\left(\frac{y - x_0}{\delta}\right) |\nabla v_{\epsilon_i}| [W^{1/2}(y, v_{\epsilon_i}(y)) - W^{1/2}(x_0, v_{\epsilon_i}(y))] dy.$$

From Proposition 2–1 in [3], we have

$$\begin{aligned} &\int_{x_0 + \delta B_1} \varphi\left(\frac{y - x_0}{\delta}\right) |\nabla v_{\epsilon_i}|\, W^{1/2}(x_0, v_{\epsilon_i}(y)) dy \\ &\qquad \geq \int_{x_0 + \delta B_1} \varphi\left(\frac{y - x_0}{\delta}\right) |\nabla_y d(x_0, \alpha, v_{\epsilon_i}(y))|, \end{aligned}$$

and so from (2.1), we obtain

$$\begin{aligned} \liminf_{i \to \infty} I_1^i &\geq \int_{x_0 + \delta B_1} \varphi\left(\frac{y - x_0}{\delta}\right) |\nabla_y d(x_0, \alpha, v_0(y))| \\ &\geq \int_{(x_0 + \delta B_1) \cap \partial^* E} \varphi\left(\frac{y - x_0}{\delta}\right) d(x_0, \alpha, \beta) d\mathcal{H}_{N-1}(y). \end{aligned} \tag{3.11}$$

On the other hand, from (1.3), there exists a nonnegative function $\epsilon(\delta)$ with $\lim_{\delta\to 0}\epsilon(\delta) = 0$ such that

$$(3.12)\qquad |I_2^i| \leq \epsilon(\delta)\int_{x_0+\delta B_1}\varphi\Big(\frac{y-x_0}{\delta}\Big)|\nabla v_{\epsilon_i}|W^{1/2}(y,v_\epsilon(y))dy \leq \epsilon(\delta)\mu(x_0+\delta B_1).$$

In what follows, we denote $\epsilon(\delta)$ by $0_\delta(1)$. Therefore, from (3.10)–(3.12), we have

$$\mu(x_0+\delta B_1) \geq d(x_0,\alpha,\beta)\mathcal{H}_{N-1}(\{x_0+\delta B_1\}\cap\partial^* E) + 0_\delta(1)\mu(x_0+\delta B_1),$$

and so from (3.9), we obtain

$$\mu_1(x_0) \geq d(x_0,\alpha,\beta)$$

and we conclude inequality (3.6).

Next we will prove the equality (3.7). Let x_0 be a point in $\partial^* E\cap\partial\Omega$. Without loss of generality, we can assume $\mu_1(x_0) < +\infty$, and we have

$$\begin{aligned}(3.13)\qquad \mu(x_0+\delta B_1) &\geq \lim_{i\to\infty}\int_{x_0+\delta B_1}\varphi\Big(\frac{x_0-y}{\delta}\Big)|\nabla\tilde{v}_{\epsilon_i}|W^{1/2}(y,\tilde{v}_{\epsilon_i})dy \\ &\quad -\int_{(x_0+\delta B_1)\cap(\Omega'\setminus\overline{\Omega})}\varphi\Big(\frac{x_0-y}{\delta}\Big)|\nabla G|W^{1/2}(x,G)dx \\ &= \lim_{i\to\infty}J_1^i + \lim_{i\to\infty}J_2^i + 0(\delta^N),\end{aligned}$$

where

$$J_1^i \equiv \int_{x_0+\delta B_1}\varphi\Big(\frac{x_0-y}{\delta}\Big)|\nabla\tilde{v}_{\epsilon_i}|W^{1/2}(x_0,\tilde{v}_{\epsilon_i})dy$$

and

$$J_2^i \equiv \int_{x_0+\delta B_1}\varphi\Big(\frac{x_0-y}{\delta}\Big)|\nabla\tilde{v}_{\epsilon_i}|[W^{1/2}(y,\tilde{v}_{\epsilon_i}) - W^{1/2}(x_0,\tilde{v}_{\epsilon_i})]dy.$$

By means of an argument similar to the one we used to prove (3.6), we have

$$\begin{aligned}(3.14)\qquad \lim_{i\to\infty}J_1^i &\geq \lim_{i\to\infty}\int_{x_0+\delta B_1}\varphi\Big(\frac{x_0-y}{\delta}\Big)|\nabla d(x_0,\alpha,\tilde{v}_{\epsilon_i})| \\ &\geq \int_{x_0+\delta B_1}\varphi\Big(\frac{x_0-y}{\delta}\Big)|\nabla d(x_0,\alpha,\tilde{v}_0)| \\ &\geq \int_{\{x_0+\delta B_1\}\cap(\partial\Omega\cap\partial^* E)}\varphi\Big(\frac{x_0-y}{\delta}\Big)d(x_0,\alpha,g(y))d\mathcal{H}_{N-1}(y)\end{aligned}$$

and from (1.3) and (3.3),

$$\begin{aligned}(3.15)\qquad |J_2^i| &\leq 0_\delta(1)\int_{x_0+\delta B_1}\varphi\Big(\frac{x_0-y}{\delta}\Big)|\nabla\tilde{v}_{\epsilon_i}|W^{1/2}(y,\tilde{v}_{\epsilon_i})dy \\ &\qquad + 0_\delta(1)\int_{\{x_0+\delta B_1\}\cap(\Omega'\setminus\Omega)}\varphi\Big(\frac{x_0-y}{\delta}\Big)dy \\ &\leq 0_\delta(1)[\mu(x_0+\delta B_1) + \delta^N].\end{aligned}$$

Therefore, from [21, Lem. 5.5.4, p. 236] and (3.13)–(3.15), we obtain

$$\mu_1(x_0) \geq d(x_0, \alpha, g(x_0)),$$

and so we prove inequality (3.7). Furthermore, we can prove (3.8) in just the same way as (3.9).

For any $\varphi \in C_0^\infty(\Omega')$, $0 \leq \varphi \leq 1$, we have from (3.4)

$$\begin{aligned}(3.16)\qquad \lim_{i\to\infty} \int_\Omega \left[\epsilon_i |\nabla v_{\epsilon_i}|^2 + \frac{1}{\epsilon_i} W(x, v_{\epsilon_i})\right] dx &\geq 2 \lim_{i\to\infty} \int_\Omega |\nabla v_{\epsilon_i}| W^{1/2}(x, v_{\epsilon_i}) dx \\ &\geq 2 \lim_{i\to\infty} \int_{\Omega'} \varphi |\nabla \tilde{v}_{\epsilon_i}| W^{1/2}(x, \tilde{v}_{\epsilon_i}) dx - 2 \int_{\Omega'\setminus\overline{\Omega}} |\nabla G| W^{1/2}(x, G) dx \\ &\geq 2 \int_{\overline{\Omega}} \varphi d\mu - 2 \int_{\Omega'\setminus\overline{\Omega}} (1-\varphi) |\nabla G| W^{1/2}(x, G) dx.\end{aligned}$$

Consider an increasing sequence φ_j, $j = 1, 2, \ldots$, such that $\lim_{j\to\infty} \varphi_j(x) = 1$ for all $x \in \Omega'$, and taking the limit of (3.16) as $j \to \infty$, we have

$$\liminf_{i\to\infty} F_{\epsilon_i}(v_{\epsilon_i}) \geq 2 \int_{\overline{\Omega}} d\mu.$$

Therefore, from Lemma 3.1, we obtain

$$\begin{aligned}\liminf_{i\to\infty} F_{\epsilon_i}(v_{\epsilon_i}) \geq 2 &\int_{\Omega\cap\partial^* E} d(x, \alpha, \beta) d\mathcal{H}_{N-1} \\ &+ 2 \int_{\partial\Omega\cap\partial^* E} d(x, \alpha, g(x)) d\mathcal{H}_{N-1} + 2 \int_{\partial\Omega\setminus\partial^* E} d(x, \beta, g(x)) d\mathcal{H}_{N-1},\end{aligned}$$

and the proof of Proposition A is completed. □

4. Proof of Proposition B. First we prove Proposition B for the special case where $w_0 \equiv \alpha$ in Ω. We divide the proof into three steps. The arguments used to prove the second and third steps are completely different from and more complicated than the ones used in the scalar case. In the second step, we construct the essential parts of w_ϵ, whose energy tends to $F_0(w_0)$ as $\epsilon \to 0$. In the third step, we complete the construction of w_ϵ, matching the trace on $\partial\Omega$ to coincide with the given function g on $\partial\Omega$.

Before starting a proof of Proposition B, we present the following two lemmas. The first lemma is obtained easily by means of the inverse-mapping theorem.

LEMMA 4.1. *Let Ω be a bounded domain with C^2-smooth boundary $\partial\Omega$. For $x \in \partial\Omega$, let $\nu(x)$ be a inner normal vector to $\partial\Omega$ at x. Define a mapping $\pi : \partial\Omega \times [0, \infty) \to \mathbf{R}^N$ by*

$$(4.1)\qquad \pi(x, t) = \pi_t(x) = x + t\nu(x).$$

Then there exists a constant s_0 such that $\pi(\partial\Omega \times (0, s_0])$ is contained in Ω and the C^1-smooth inverse mapping π^{-1} of π exists on $\pi(\partial\Omega \times [0, s_0])$.

LEMMA 4.2. (*See* [13] *and* [20].) *Let Ω be an open bounded subset of $\mathbf{R}^N$ with Lipschitz-continuous boundary. Let A be an open subset of $\mathbf{R}^N$ with C^2 and with a compact, nonempty boundary such that $\mathcal{H}_{N-1}(\partial A \cap \partial\Omega) = 0$. Define a distance function to ∂A, $d_{\partial A} : \Omega \to \mathbf{R}$, by*

$$d_{\partial A}(x) = \text{ dist } (x, A).$$

Then, for some $s_1 > 0$, $d_{\partial A}$ *is a* C^2 *function in* $\{0 < d_{\partial A}(x) < s_1\}$ *with*

$$|\nabla d_{\partial A}| = 1. \tag{4.2}$$

Furthermore, $\lim_{s\to 0}\mathcal{H}_{N-1}(\{d_{\partial A}(x) = s\}) = \mathcal{H}_{N-1}(\partial A \cap \Omega)$ *and*

$$|\{x \mid |d_{\partial A}(x)| < s\}| = O(s). \tag{4.3}$$

Here $d_{\partial\Omega}(x)$ denotes the distance function $\operatorname{dist}(x,\partial\Omega)$. From Lemma 4.2, we see that $d_{\partial\Omega}$ is a C^2 function in a neighborhood of $\partial\Omega$. We set $s^* = \min\{s_0, s_1\}$. Furthermore, for $x \in \partial\Omega$, $\eta > 0$, and sufficiently small δ with $0 < \delta < s^*$, we set $\partial\Omega_\eta(x) = \partial\Omega \cap (x + \eta Q_{\nu(x)})$ and $\Omega^\delta_\eta(x) = \cup_{\delta<t<s^*}\pi_t(\partial\Omega_\eta(x))$.

Now we begin the proof of Proposition B in the special case where $w_0 \equiv \alpha$.

Step 1. Let x_0 be any point in $\partial\Omega$. In this step, for any sufficiently small $\eta > 0$, we will construct a family $\{w^\delta_\epsilon\}_{\epsilon,\delta>0} \subset W^{1,2}(\Omega^\delta_\eta(x_0) : \mathbf{R}^n)$ such that

$$\limsup_{\epsilon,\delta\to 0} \int_{\Omega^\delta_\eta} \left[\epsilon|\nabla w^\delta_\epsilon|^2 + \frac{1}{\epsilon}W(x_0, w^\delta_\epsilon)\right] dx \le 2d(x_0, \alpha, g(x_0))\mathcal{H}_{N-1}(\partial\Omega_\eta(x_0)). \tag{4.4}$$

In this step, for simplicity, we set $\Omega^\delta_\eta = \Omega^\delta_\eta(x_0)$.

In order to construct $\{w^\delta_\epsilon\}_{\epsilon,\delta>0}$, we fix $\epsilon, \delta > 0$, and we consider the following ordinary differential equation:

$$\begin{cases} \dfrac{d}{dt} y_\epsilon(t) = \dfrac{[\epsilon^{1/2} + W(x_0, \gamma(y_\epsilon(t)))]^{1/2}}{\epsilon|\,\dot\gamma(y_\epsilon(t))\,|}, \\ y_\epsilon(\delta) = 0. \end{cases} \tag{4.5}$$

Here we denote $d\gamma(t)/dt$ by $\dot\gamma$, and we assume that $\gamma \in C^1([0,1] : [K_1, K_2]^n)$, $\gamma(0) = \alpha$, $\gamma(1) = g(x_0)$. We set

$$\psi_\epsilon(t) = \int_0^t \frac{\epsilon|\dot\gamma(t)|}{[\epsilon^{1/2} + W(x_0, \gamma(t))]^{1/2}} dt$$

for $t \in (0,1)$ and set $\tau_\epsilon = \psi_\epsilon(1)$. Then $\psi_\epsilon(t)$ is a monotone increasing function and

$$\tau_\epsilon = \psi_\epsilon(1) \le \epsilon^{3/4} \cdot \text{ length of } \gamma. \tag{4.6}$$

We set $\tilde y_\epsilon(t) = \psi_\epsilon^{-1}(t - \delta)$, and we can see that $\tilde y_\epsilon(t)$ satisfies (4.5) in $[\delta, \delta + \tau_\epsilon]$; we define $y_\epsilon(t)$ by

$$y_\epsilon(t) \equiv \max\{0, \min\{1, \tilde y_\epsilon(t)\}\} = \begin{cases} 0, & t \le \delta, \\ \tilde y_\epsilon(t), & \delta \le t \le \delta + \tau_\epsilon, \\ 1, & t \ge \delta + \tau_\epsilon. \end{cases} \tag{4.7}$$

We partition Ω^δ_η into three subdomains $\Omega^\delta_{\eta,i}$, $i = 1, 2, 3$ as follows:

$$\begin{aligned} \Omega^\delta_{\eta,1} &\equiv \{x \in \Omega^\delta_\eta : d_{\partial\Omega}(x) < \delta + \tau_\epsilon,\ d_S(x) \le \eta\tau_\epsilon\}, \\ \Omega^\delta_{\eta,2} &\equiv \{x \in \Omega^\delta_\eta : d_{\partial\Omega}(x) < \delta + \tau_\epsilon,\ d_S(x) \ge \eta\tau_\epsilon\}, \\ \Omega^\delta_{\eta,3} &\equiv \{x \in \Omega^\delta_\eta : d_{\partial\Omega}(x) \ge \delta + \tau_\epsilon\}, \end{aligned} \tag{4.8}$$

where $d_S(x)$ is a distance function to $\cup_{\delta<t<s^*}\pi_t[\partial\Omega\cap(x_0+\eta\partial Q_{\nu(x_0)})]$. Here we define $w_\epsilon(x)$ on $\cup_{i=2,3}\Omega^\delta_{\eta,i}$ as follows:

$$w_\epsilon(x) = \begin{cases} \gamma(y_\epsilon(d_{\partial\Omega}(x))), & \text{if } x \in \Omega^\delta_{\eta,2}, \\ \alpha, & \text{if } x \in \Omega^\delta_{\eta,3}. \end{cases} \tag{4.9}$$

We extend w_ϵ to $\Omega^\delta_{\eta,1}$ in such a way that for any $x \in \Omega^\delta_\eta$ with $d_S(x) = 0$ or $d_{\partial\Omega}(x) = \delta + \tau_\epsilon$, $w_\epsilon(x) = \alpha$ and

$$|\nabla w_\epsilon| \leq 2/(K_2 - K_1)\eta\tau_\epsilon + C/\epsilon \leq C(\eta\tau_\epsilon)^{-1} + C\epsilon^{-1}.$$

For sufficiently small $\epsilon > 0$, we have the length of $\gamma < \epsilon^{-1/8}$ and $\tau_\epsilon \leq \epsilon^{5/8}$. Therefore, we obtain

$$\begin{aligned} \int_{\Omega^\delta_{\eta,1}} \left[\epsilon|\nabla w_\epsilon|^2 + \frac{1}{\epsilon}W(x_0, w_\epsilon)\right] dx &\leq C[\epsilon/\eta^2\tau_\epsilon^2 + 1/\epsilon]\tau_\epsilon^N \mathcal{H}_{N-1}(\partial\Omega_\eta) \\ &\leq C(\epsilon/\eta^2 + \epsilon^{1/4})\tau_\epsilon^{N-2}\mathcal{H}_{N-1}(\partial\Omega_\eta). \end{aligned} \tag{4.10}$$

We note that constants C are independent of ϵ and η. On the other hand, for sufficiently small $\delta > 0$ and $\epsilon > 0$, we have $\delta + \tau_\epsilon < s^* \equiv \min\{s_0, s_1\}$ and we obtain from Lemma 4.2 and (4.9)

$$\begin{aligned} &\int_{\cup_{i=2,3}\Omega^\delta_{\eta,i}} \left[\epsilon|\nabla w_\epsilon|^2 + \frac{1}{\epsilon}W(x_0, w_\epsilon)\right] dx \\ &\qquad \leq \int_{\Omega^\delta_{\eta,2}} \frac{2}{\epsilon}[\epsilon^{1/2} + W(x_0, \gamma(y_\epsilon(d_{\partial\Omega}(x))))]|\nabla d_{\partial\Omega}(x)|dx, \end{aligned}$$

and from (2.2), we get

$$\begin{aligned} &\int_{\cup_{i=2,3}\Omega^\delta_{\eta,i}} \left[\epsilon|\nabla w_\epsilon|^2 + \frac{1}{\epsilon}W(x_0, w_\epsilon)\right] dx \\ &\qquad \leq 2\int_\delta^{\tau_\epsilon+\delta} dt \int_{\Omega^\delta_\eta\cap\{d_{\partial\Omega}(x)=t\}} \epsilon^{-1}[\epsilon^{1/2} + W(x_0, \gamma(y_\epsilon(t)))]d\mathcal{H}_{N-1} \\ &\qquad \leq 2\kappa^\delta_\epsilon \int_\delta^{\tau_\epsilon+\delta} \epsilon^{-1}(\epsilon^{1/2} + W(x_0, \gamma(y_\epsilon(t))))dt, \end{aligned}$$

where $\kappa^\delta_\epsilon = \sup_{\delta\leq d_S(x)\leq\delta+\epsilon}(\Omega^\delta_\eta \cap \pi_t(\partial\Omega))$. Then from (4.5), we obtain

$$\int_{\cup_{i=1,2}\Omega^\delta_{\eta,i}} \left[\epsilon|\nabla w_\epsilon|^2 + \frac{1}{\epsilon}W(x_0, w_\epsilon)\right] dx \leq 2\kappa^\delta_\epsilon \int_0^1 [\epsilon^{1/2} + W(x_0, \gamma(t))]^{1/2}|\dot\gamma(t)|dt. \tag{4.11}$$

From the regularity of $\partial\Omega$ and the definition of $\Omega^0_\eta(x_0)$, there exists a constant η_0 independent of x_0 (dependent only on $\partial\Omega$) such that for any $0 < \eta < \eta_0$, we have $\mathcal{H}_{N-1}(\partial\Omega^0_\eta(x_0)\cap\partial\Omega) = 0$. So from Lemma 4.2, we have $\lim_{\epsilon,\delta\to 0}\kappa^\delta_\epsilon = \mathcal{H}_{N-1}(\partial\Omega_\eta(x_0))$ for any $\eta \in (0, \eta_0)$. Here we set $w^{\delta,\gamma}_\epsilon = w_\epsilon$. Therefore, from (4.10) and (4.11), for any $\eta \in (0, \eta_0)$ we obtain

$$\begin{aligned} &\int_{\Omega^\delta_\eta(x_0)} \left[\epsilon|\nabla w^{\delta,\gamma}_\epsilon|^2 + \frac{1}{\epsilon}W(x_0, w^{\delta,\gamma}_\epsilon)\right] dx \\ &\qquad \leq 2\mathcal{H}_{N-1}(\partial\Omega_\eta)\int_0^1 W^{1/2}(x_0, \gamma(t))|\,\dot\gamma(t)\,|dt \\ &\qquad\qquad + \mathcal{H}_{N-1}(\partial\Omega_\eta)[0(\epsilon/\eta^2) + 0(\epsilon^{1/4}) + 0_{\sqrt{\epsilon^2+\delta^2}}(1)]. \end{aligned} \tag{4.12}$$

Since for any $\epsilon > 0$ there exists a sequence of C^1-curves $\{\gamma_i\}_{i=1}^{\infty}$ such that the length of $\gamma_i \leq \epsilon^{-1/8}$ and

$$\lim_{i\to\infty}\int_0^1 W^{1/2}(x_0,\gamma_i(t))|\,\dot{\gamma}_i(t)\,|\,dt = d(x_0,\alpha,g(x_0)),$$

by the diagonal argument and (4.12), we can construct a sequence $\{w_\epsilon^\delta\}_{\epsilon,\delta>0}$ satisfying (4.4). Therefore, the aim of the first step is completed. □

Step 2. Let Ω_δ be the domain $\{x \in \Omega : \delta < d_{\partial\Omega}(x) < s^*\} = \cup_{\delta<t<s^*}\pi_t(\partial\Omega)$. In this step, we construct a sequence $\{w_\epsilon^\delta\}_{\epsilon,\delta>0}$ in $W^{1,2}(\Omega_\delta, \mathbf{R}^n)$ such that

$$\limsup_{\delta,\epsilon\to\infty}\int_{\Omega_\delta}\left[\epsilon|\nabla w_\epsilon^\delta|^2 + \frac{1}{\epsilon}W(x,w_\epsilon^\delta)\right]dx \leq 2\int_{\partial\Omega} d(x,a,g(x))d\mathcal{H}_{N-1}. \tag{4.13}$$

In order to construct this sequence $\{w_\epsilon^\delta\}_{\epsilon,\delta>0}$, we partition $\partial\Omega$ into subdomains. In view of the regularity of $\partial\Omega$, for sufficiently small $\eta > 0$, there exist p points $\{x_i\}_{i=1}^p \subset \partial\Omega$ and a subset ω_η of $\partial\Omega$ such that

$$\partial\Omega\setminus\cup_{1\leq i\leq p}\partial\Omega_\eta(x_i)\subset\omega_\eta,\quad \partial\Omega_\eta(x_i)\cap\partial\Omega_\eta(x_j)=\emptyset,\quad i\neq j,\ i,j=1,2,\ldots,p \tag{4.14}$$

and $\lim_{\eta\to 0}\mathcal{H}_{N-1}(\omega_\eta) = 0$. Here we note that p depends on η and $\lim_{\eta\to 0}p(\eta) = \infty$.

Fix $\eta, \delta, \epsilon > 0$. For any $i \in \{1, 2, \ldots, p\}$, from (4.12) we can construct functions $w_\epsilon^{i,\delta,\eta} \in W^{1,2}(\Omega_\eta^\delta(x_i))$ such that

$$\begin{aligned}\int_{\Omega_\eta^\delta(x_i)}&\left[\epsilon|\nabla w_\epsilon^i|^2 + \frac{1}{\epsilon}W(x_i,w_\epsilon^i)\right]dx \\ &\leq 2\mathcal{H}_{N-1}(\partial\Omega_\eta(x_i))d(x_i,\alpha,g(x_i)) \\ &\qquad + \mathcal{H}_{N-1}(\partial\Omega_\eta(x_i))[0(\epsilon/\eta^2) + 0(\epsilon^{1/4}) + 0_{\sqrt{\epsilon^2+\delta^2}}(1)].\end{aligned} \tag{4.15}$$

Then we define $w_\epsilon^{\delta,\eta} \in W^{1,2}(\Omega_\delta : \mathbf{R}^n)$ as follows:

$$w_\epsilon^{\delta,\eta} = \begin{cases} w_\epsilon^{i,\delta,\eta} & \text{if } x \in \Omega_\eta^\delta(x_i), \\ \alpha & \text{otherwise.}\end{cases}$$

By the argument of Step 1, we can easily see that $w_\epsilon^{\delta,\eta} \in W^{1,2}(\Omega_\delta : \mathbf{R}^n)$. Then we have

$$\begin{aligned}\int_{\Omega_\delta}&\left[\epsilon|\nabla w_\epsilon^{\delta,\eta}|^2 + \frac{1}{\epsilon}W(x,w_\epsilon^{\delta,\eta})\right]dx \\ &= \sum_{i=1}^p\int_{\Omega_\eta^\delta(x_i)}\left[\epsilon|\nabla w_\epsilon^{i,\delta,\eta}|^2 + \frac{1}{\epsilon}W(x,w_\epsilon^{i,\delta,\eta})\right]dx.\end{aligned} \tag{4.16}$$

On the other hand, we have

$$\begin{aligned}&\int_{\Omega_\eta^\delta(x_i)}\left[\epsilon|\nabla w_\epsilon^i|^2 + \frac{1}{\epsilon}W(x,w_\epsilon^i)\right]dx \\ &= \int_{\Omega_\eta^\delta(x_i)}\left[\epsilon|\nabla w_\epsilon^i|^2 + \frac{1}{\epsilon}W(x_i,w_\epsilon^i)\right]dx + \int_{\Omega_\eta^\delta(x_i)}\frac{1}{\epsilon}\left[W(x,w_\epsilon^i) - W(x_i,w_\epsilon^i)\right]dx \\ &\equiv I_1^i + I_2^i\end{aligned}$$

(for simplicity we omit the index δ,η of $w_\epsilon^{i,\delta,\eta}$). From (4.15), we obtain

$$\sum_{i=1}^{p(\eta)} I_1^i \leq 2\sum_{i=1}^{p(\eta)}[d(x_i,\alpha,g(x_i))\mathcal{H}_{N-1}(\partial\Omega_\eta(x_i))] \\ + 0(\epsilon/\eta^2) + 0(\epsilon^{1/4}) + 0_{\sqrt{\epsilon^2+\delta^2}}(1), \tag{4.17}$$

and from (1.3) and (4.15),

$$\sum_{i=1}^{p(\eta)} |I_2^i| \leq \sum_{i=1}^{p(\eta)} \int_{\Omega_\eta^\delta(x_i)} 0_{|x-x_i|}(1)\frac{1}{\epsilon}W(x_i,w_\epsilon^i)dx \leq 0_\eta(1)\sum_{i=1}^{p(\eta)} I_1^i.$$

We set $\eta^2 = \epsilon^{3/4}$. This inequality, together with (4.16) and (4.17), yields

$$\limsup_{\delta,\epsilon\to 0} \int_{\Omega_\delta} \left[\epsilon|\nabla w_\epsilon^{\delta,\eta(\epsilon)}|^2 + \frac{1}{\epsilon}W(x,w_\epsilon^{\delta,\eta(\epsilon)})\right] dx \\ \leq \limsup_{\epsilon\to 0} 2\sum_{i=1}^{p(\eta)} d(x_i,\alpha,g(x_i))\mathcal{H}_{N-1}(\partial\Omega_\eta(x_i)). \tag{4.18}$$

On the other hand, for any $x \in \partial\Omega_\eta(x_i)$, we have

$$|d(x_i,\alpha,g(x_i)) - d(x,\alpha,g(x))| \\ \leq |d(x,\alpha,g(x)) - d(x_i,\alpha,g(x))| + |d(x_i,\alpha,g(x)) - d(x_i,\alpha,g(x_i))| \leq 0_\eta(1).$$

Thus we obtain

$$\sum_{i=1}^{p(\eta)} d(x_j,\alpha,g(x_j))\mathcal{H}_{N-1}(\partial\Omega_\eta(x_i)) \leq \int_{\cup_{1\leq j\leq p}\partial\Omega_\eta(x_i)} d(x,\alpha,g(x))d\mathcal{H}_{N-1} + 0_\eta(1) \\ \leq \int_{\partial\Omega} d(x,\alpha,g(x))d\mathcal{H}_{N-1} + 0_\eta(1).$$

Recalling (4.18), we can see that the sequence $\{w_\epsilon^{\delta,\eta(\epsilon)}\}_{\epsilon,\delta>0}$ satisfies (4.13). Hence we set $w_\epsilon^\delta = w_\epsilon^{\delta,\eta(\epsilon)}$, and the claim of Step 2 is proved. □

Step 3. In this step, we complete the proof of Proposition B for the special case $w_0 \equiv \alpha$. For any $\delta,\epsilon > 0$, we define w_ϵ^δ as follows:

$$w_\epsilon^\delta = \begin{cases} \alpha & \text{if } x \in \Omega\setminus\Omega_0, \\ {w^*}_\epsilon^\delta & \text{if } x \in \Omega_\delta, \end{cases}$$

where $\Omega_0 = \cup_{0<t<s^*}\pi_t(\partial\Omega)$ and ${w^*}_\epsilon^\delta$ is a function constructed in Step 2. In $\Omega^\delta \equiv \Omega_0\setminus\Omega_\delta$, we construct w_ϵ^δ using a convex combination between $g(x)$ and ${w^*}_\epsilon^\delta(\pi_\delta(x))$, i.e., for $x \in \Omega_0\setminus\Omega_\delta$,

$$w_\epsilon^\delta(x) = \frac{d_{\partial\Omega}(x)}{\delta}{w^*}_\epsilon^\delta|_{(\partial\Omega)_\delta}(\pi_\delta\circ\pi_{d_{\partial\Omega}(x)}^{-1}(x)) + \left(1-\frac{d_{\partial\Omega}(x)}{\delta}\right)g(\pi_{d_{\partial\Omega}(x)}^{-1}(x)). \tag{4.19}$$

Here $\pi_\delta(x)$ and $\pi_{d_{\partial\Omega}}(x)$ are the functions appearing in Lemma 4.1. Then we can easily see that $w_\epsilon^\delta \in W^{1,2}(\Omega)$ and $w_\epsilon^\delta(x) = g(x)$ for all $x \in \partial\Omega$.

In order to estimate the gradient of w_ϵ^δ, we fix ϵ, δ, $\{\Omega_\eta^\delta(x_i)\}_{i=1}^p$, and ω_η. We set

$$\begin{aligned}\Omega_1^\delta &= \{x \in \Omega^\delta : \pi_\delta \circ \pi_{d_{\partial\Omega}(x)}^{-1}(x) \in \cup_{1\le i\le p}\partial(\Omega_{\eta,1}^\delta(x_i))\},\\ \Omega_2^\delta &= \{x \in \Omega^\delta : \pi_\delta \circ \pi_{d_{\partial\Omega}(x)}^{-1}(x) \in \cup_{1\le i\le p}\partial(\Omega_{\eta,2}^\delta(x_i))\},\\ \omega_\eta^\delta &= \cup_{0<t<\delta}\pi_t(\omega_\eta)\end{aligned} \tag{4.20}$$

and have $\Omega^\delta = \Omega_1^\delta \cup \Omega_2^\delta \cup \omega_\eta^\delta$. Here $\Omega_{\eta,i}^\delta(x)$, $i = 1, 2$ is the domain appearing in Step 1. Furthermore, for simplicity, we set

$$\begin{aligned}\hat{g}(x) &= g(\pi_{d_{\partial\Omega}(x)}^{-1}(x)),\\ \hat{w}_\epsilon^\delta(x) &= {w^*}_\epsilon^\delta|_{(\partial\Omega)_\delta}(\pi_\delta \circ \pi_{d_{\partial\Omega}(x)}^{-1}(x)), \qquad x \in \Omega^\delta.\end{aligned}$$

Then from Lemma 4.1, we can see that there exists a constant C such that $|\nabla\hat{g}(x)| \le C$ for almost all $x \in \Omega^\delta$.

Now in the domains $\Omega_{\eta,1}^\delta$, $\Omega_{\eta,2}^\delta$, and Ω^δ, we will estimate the gradient of w_ϵ^δ and obtain the inequality (2.7). If $x \in \omega_\eta^\delta$, then from the construction of w_ϵ in Step 2, we see $v_\epsilon^{\delta,\eta} \equiv \alpha$ in a neighborhood of x, and so for almost all $x \in \omega_\eta^\delta$, we have

$$|\nabla w_\epsilon^{\delta,\eta}| \le \frac{C}{\delta} + C.$$

So we obtain

$$\int_{\omega^\delta}\left[\epsilon|\nabla w_\epsilon^{\delta,\eta}|^2 + \frac{1}{\epsilon}W(x, w_\epsilon^{\delta,\eta})\right]dx \le C\left(\frac{\epsilon}{\delta^2} + \epsilon + \frac{1}{\epsilon}\right)\delta\mathcal{H}_{N-1}(\omega). \tag{4.21}$$

For almost all $x \in \Omega_{\eta,1}^\delta(x_i)$, we have

$$\begin{aligned}|\nabla w_\epsilon^{\delta,\eta}| \le \frac{|\nabla d_{\partial\Omega}(x)|}{\delta}\hat{w}_\epsilon^{\delta,\eta}(x) &+ \frac{d_{\partial\Omega}(x)}{\delta}|\nabla\hat{w}_\epsilon^{\delta,\eta}(x)|\\ &+ \frac{|\nabla d_{\partial\Omega}(x)|}{\delta}\hat{g}(x) + \left(1 - \frac{d_{\partial\Omega}(x)}{\delta}\right)|\nabla\hat{g}(x)|.\end{aligned}$$

Here from the argument in Step 1, there exists a constant C_2 such that $|\nabla v_\epsilon^{\delta,\eta}(x)| \le C/(\epsilon^{5/8}\eta)$ for all $x \in \Omega_{\eta,1}^\delta$. Moreover, we have

$$|\Omega_{\eta,1}^\delta| \le C\delta(\epsilon^{5/8}\eta^{N-1})(\mathcal{H}_{N-1}(\partial\Omega)/\eta^{N-1}) \le C\delta\epsilon^{5/8}.$$

So we obtain

$$\begin{aligned}\int_{\Omega_1^\delta}\left[\epsilon|\nabla w_\epsilon^{\delta,\eta}|^2 + \frac{1}{\epsilon}W(x, w_\epsilon^{\delta,\eta})\right]dx &\le C\left[\epsilon\left(\frac{1}{\delta} + \frac{1}{\epsilon^{5/8}\eta} + 1\right)^2 + \frac{1}{\epsilon}\right]\delta\epsilon^{5/8}\\ &\le C\left(\frac{\epsilon}{\delta} + \frac{\delta}{\eta^2\epsilon^{1/4}} + \frac{\delta}{\epsilon}\right)\epsilon^{5/8}.\end{aligned} \tag{4.22}$$

For any $x \in \Omega_{\eta,2}^\delta(x_i)$, from Step 1 we see $w_\epsilon^*(x) \equiv g(x_i)$ in a neighborhood of x. Then from the Lipschitz continuity of $g(x)$ on $\partial\Omega$ and (4.19), we have

$$\begin{aligned}|\nabla w_\epsilon^{\delta,\eta}| &\le \frac{|\nabla d_{\partial\Omega}(x)|}{\delta}|g(x_i) - \hat{g}(x)| + \left(1 - \frac{d_{\partial\Omega}(x)}{\delta}\right)|\nabla\hat{g}|\\ &\le \frac{C}{\delta}|g(x_i) - \hat{g}(x)| + C \le C\frac{\eta}{\delta} + C.\end{aligned}$$

Therefore, we obtain

$$(4.23)\qquad \int_{\Omega_2^\delta}\left[\epsilon|\nabla w_\epsilon^{\delta,\eta}|^2+\frac{1}{\epsilon}W(x,w_\epsilon^{\delta,\eta})\right]dx\le C\left(\epsilon\left(\frac{\eta}{\delta}\right)^2+\epsilon+\frac{1}{\epsilon}\right)\delta\mathcal{H}_{N-1}(\partial\Omega).$$

Let $\sigma(\cdot)$ be a positive function with $\sigma(0)=0$ such that $\lim_{\epsilon\to 0}\mathcal{H}_{N-1}(\omega_{\eta(\epsilon)})/\sigma(\epsilon)=0$ and $\lim_{\epsilon\to 0}\epsilon^{5/8}/\sigma(\epsilon)=0$. Set $\delta_\epsilon=\epsilon\sigma(\epsilon)$ and define $w_\epsilon=w_\epsilon^{\delta_\epsilon}$. Then from (4.21)–(4.23), we obtain

$$(4.24)\qquad \lim_{\epsilon\to 0}\int_{\Omega^{\epsilon\sigma(\epsilon)}}\left[\epsilon|\nabla w_\epsilon|^2+\frac{1}{\epsilon}W(x,w_\epsilon)\right]dx=0.$$

Therefore, from (4.13) and (4.24), we obtain

$$\limsup_{\epsilon\to 0}\int_{\Omega}\left[\epsilon|\nabla w_\epsilon|^2+\frac{1}{\epsilon}W(x,w)\right]dx\le 2\int_{\partial\Omega}d(x,\alpha,g(x))d\mathcal{H}_{N-1}.$$

Hence the proof of Proposition B for the special case $w_0=\alpha$ is completed. □

Next, using the arguments of Steps 1–3, we will prove Proposition B. First we recall an approximation theorem for sets of finite perimeter by sets with smooth boundary. See [13].

LEMMA 4.3. *Let Ω be an open bounded subset of $\mathbf{R}^N$ with Lipschitz-continuous boundary. Let $A\subset\Omega$ be a set of finite perimeter in Ω with $0<|A|<|\Omega|$. Then there exists a sequence of open sets $\{A_k\}$ satisfying the following conditions:*

(i) $\partial A_k\cap\Omega\in C^2$;

(ii) $|(A_k\cap\Omega)\Delta A|\to 0$ *as* $k\to\infty$;

(iii) $P_\Omega(A_k)\to P_\Omega(A)$ *as* $k\to\infty$;

(iv) $\mathcal{H}_{N-1}(\partial A_k\cap\partial\Omega)=0$;

(v) $|A_k\cap\Omega|=|A|$ *for all sufficiently large* k.

We assume that the measurable set E has a C^2-smooth boundary in Ω; otherwise, the proof of Proposition B follows from Lemma 4.3 and the diagonal argument.

Using the same argument as in [14], we separate the domain Ω into six domains as follows:

$$\Omega_\alpha=\{x\in\Omega: d_{\partial\Omega}(x)\ge\tau_\epsilon+\delta_\epsilon,\ d_{\partial E}(x)<0\},$$
$$\Omega_\beta=\{x\in\Omega: d_{\partial\Omega}(x)\ge\tau_\epsilon+\delta_\epsilon,\ d_{\partial E}(x)>\tau_\epsilon+\delta'_\epsilon\},$$
$$\Omega_{\alpha,\beta}=\{x\in\Omega: d_{\partial\Omega}(x)\ge\tau_\epsilon+\delta_\epsilon,\ 0\le d_{\partial E}(x)\le\tau_\epsilon+\delta'_\epsilon\},$$
$$\Omega_{\alpha,g}=\{x\in\Omega: d_{\partial\Omega}(x)\le\tau_\epsilon+\delta_\epsilon,\ d_{\partial E}(x)<0\},$$
$$\Omega_{\beta,g}=\{x\in\Omega: d_{\partial\Omega}(x)\le\tau_\epsilon+\delta_\epsilon,\ d_{\partial E}(x)>\tau_\epsilon+\delta'_\epsilon\},$$
$$\Omega_r=\{x\in\Omega: d_{\partial\Omega}(x)\le\tau_\epsilon+\delta_\epsilon,\ 0\le d_{\partial E}(x)\le\tau_\epsilon+\delta'_\epsilon\},$$

where $d_{\partial E}(x)$ is a distance function to ∂E appearing in Lemma 4.2. We note that δ_ϵ and δ'_ϵ depend on $\partial\Omega$ and ∂E respectively. Here we set $w_\epsilon=\alpha$ in Ω_α and $w_\epsilon=\beta$ in Ω_β. In the domains $\Omega_{\alpha,\beta}$, $\Omega_{\alpha,g}$, and $\Omega_{\beta,g}$, by using the argument of Steps 1–3, we construct w_ϵ such that

$$(4.25)\qquad \limsup_{\epsilon\to 0}\int_{\Omega_{\alpha,\beta}}\left[\epsilon|\nabla w_\epsilon|^2+\frac{1}{\epsilon}W(x,w_\epsilon)\right]dx\le 2\int_{\partial E\cap\Omega}d(x,\alpha,\beta)d\mathcal{H}_{N-1},$$

$$(4.26)\qquad \limsup_{\epsilon\to 0}\int_{\Omega_{\alpha,g}}\left[\epsilon|\nabla w_\epsilon|^2+\frac{1}{\epsilon}W(x,w_\epsilon)\right]dx\le 2\int_{\partial E\cap\partial\Omega}d(x,\alpha,g(x))d\mathcal{H}_{N-1},$$

and

$$\limsup_{\epsilon\to 0}\int_{\Omega_{\beta,g}}\left[\epsilon|\nabla w_\epsilon|^2+\frac{1}{\epsilon}W(x,w_\epsilon)\right]dx\le 2\int_{\partial\Omega\setminus\partial E}d(x,\beta,g(x))d\mathcal{H}_{N-1}. \tag{4.27}$$

Furthermore, we separate the domain Ω_r into two domains Ω_r^1 and Ω_r^2 as follows:

$$\Omega_r^1=\Omega_r\cap\{x\in\Omega:d_{\partial\Omega}(x)\ge\delta_\epsilon,\ d_{\partial E}(x)\ge{\delta'}_\epsilon\},$$
$$\Omega_r^2=\Omega_r\cap\{x\in\Omega:d_{\partial\Omega}(x)\le\delta_\epsilon\ \text{or}\ d_{\partial E}(x)\le{\delta'}_\epsilon\}.$$

By means of the same argument used to obtain ω^δ in Step 3, we can construct w_ϵ such that $w_\epsilon(x)=\beta$ for $x\in\Omega_r^1$ and

$$|\nabla w_\epsilon|\le C/\delta_\epsilon+C/{\delta'}_\epsilon+C\qquad\text{for almost all } x\in\Omega_r^2,$$

and we have, as $|\Omega_r^2|=0(\tau_\epsilon\delta_\epsilon+\tau_\epsilon{\delta'}_\epsilon+\delta_\epsilon{\delta'}_\epsilon)$,

$$\lim_{\epsilon\to 0}\int_{\Omega_r}\left[\epsilon|\nabla w_\epsilon|^2+\frac{1}{\epsilon}W(x,w_\epsilon)\right]dx=\lim_{\epsilon\to 0}\left[\frac{C\epsilon}{\delta_\epsilon{\delta'}_\epsilon}+C\epsilon+\frac{C}{\epsilon}\right]|\Omega_r^2|=0. \tag{4.28}$$

Here we use the fact $\lim_{\epsilon\to 0}\epsilon^{1+5/8}/\delta_\epsilon=0$ and $\lim_{\epsilon\to 0}\epsilon^{1+5/8}/{\delta'}_\epsilon=0$.

Therefore, we have from (4.25)–(4.28) that

$$\limsup_{\epsilon\to 0}\int_\Omega\left[\epsilon|\nabla w_\epsilon|^2+\frac{1}{\epsilon}W(x,w_\epsilon)\right]dx\le 2\int_{\partial E\cap\Omega}d(x,\alpha,g(x))d\mathcal{H}_{N-1}$$
$$+2\int_{\partial\Omega\cap\partial E}d(x,\alpha,\beta)d\mathcal{H}_{N-1}+2\int_{\partial\Omega\setminus\partial E}d(x,\beta,g(x))d\mathcal{H}_{N-1}.$$

Furthermore, by the construction of w_ϵ, we can easily see that $w_\epsilon(x)=g(x)$ for all $x\in\partial\Omega$ and $\lim_{\epsilon\to 0}w_\epsilon=w_0$ in $L^1(\Omega:\mathbf{R}^n)$. Hence the proof of Proposition B is complete. □

5. Corollaries of Theorem 1. In this section, we will give some corollaries obtained from Theorem 1. From the definition of gamma convergence and by Propositions A and B, the result below follows.

THEOREM 2. *Let F_ϵ and F_0 be the functionals from $L^1(\Omega:\mathbf{R}^n)$ into $[0,\infty]$, which are given in §2. Then*

$$\Gamma-\lim_{\epsilon\to 0_+}F_\epsilon=F_0\quad\textit{in } L^1(\Omega:\mathbf{R}^n)\ \textit{topology}.$$

We recall the definition of gamma convergence (see [2]).

DEFINITION. *Given (X,τ), a topological space, and $F_n,F_\infty:X\to\overline{\mathbf{R}}$, a family of real (extended) valued functions, the sequence $\{F_n\}_{n=1}^\infty$ is said to* gamma converge *to F_∞ at $x\in X$ if the following two conditions hold:*

(i) *for every convergent sequence $x_n\to x$ in (X,τ),*

$$F_\infty(x)\le\liminf_{n\to\infty}F_\epsilon(x_n);$$

(ii) *there exists a convergent sequence $x_n\to x$ in (X,τ) such that*

$$\limsup_{n\to\infty}F_n(x_n)\le F_\infty(x).$$

When this property holds for every $x \in X$, the sequence $\{F_n\}_{n=1}^{\infty}$ is said to gamma converge to F_{∞} and $F_{\infty} = \Gamma(\tau) - \lim_{n\to\infty} F_n$.

On the other hand, in Theorem 1, the sequence of minimizers $\{u_\epsilon\}_{\epsilon>0}$ does not always generate interior layers. For example, if we consider problem (SP_ϵ) with $g \equiv 0$, we have $E_0 = \Omega$ or $\emptyset$. In addition, considering the family of *local* minimizers, from Theorem 2 and the results of [12], we obtain the following theorem.

THEOREM 3. *Let $u_0 \in L^1(\Omega : \mathbf{R}^n)$ be a isolated L^1-local minimizer of F_0, that is,*

$$\text{there exists a positive constant } \delta \text{ such that } F_0(u_0) < F_0(v)$$
$$\text{whenever} \quad u_0 \neq v \quad \text{and} \quad \|u_0 - v\|_{L^1(\Omega:\mathbf{R}^n)} \leq \delta.$$

Then there exist a constant $\epsilon_0 > 0$ and a sequence $\{u_\epsilon\}_{\epsilon<\epsilon_0}$ such that u_ϵ is a local minimizer of F_ϵ and $u_\epsilon \to u_0$ in $L^1(\Omega : \mathbf{R}^n)$ as $\epsilon \to 0$.

SOME A PRIORI ESTIMATES FOR A SINGULAR EVOLUTION EQUATION ARISING IN THIN-FILM DYNAMICS*

STEPHEN H. DAVIS†, EMMANUELE DIBENEDETTO‡, AND DAVID J. DILLER‡

Abstract. This paper considers the singular evolution equation $u_t - \Delta \ln u = 0$, particularly the corresponding Cauchy problem. This equation arises in the study of thin film dynamics and as the formal limit as $m \to 0$ of the porous-medium equation. Through the use of local sup-estimates, similar to those for the porous-medium equation (see E. DiBenedetto and Y. L. Kwong, Intrinsic Harnack estimates and extinction profile for certain parabolic equations, *Trans. Amer. Math. Soc.*, 330 (1992), pp. 783–811), and a global Harnack-type inequality, a critical decay rate for solutions in three or more space dimensions as $|x| \to \infty$ is found. In particular, if the initial data decays faster than this critical rate, there is no solution to the Cauchy problem.

Key words. thin-film dynamics, ill-posed problem, porous-medium equation, global Harnack inequality, finite extinction time

AMS subject classifications. 35B45, 35K65, 35Q35

1. Introduction.

We establish a spectrum of qualitative and quantitative properties of nonnegative solutions to the singular evolution equation

$$u_t - \Delta \ln u = 0 \qquad \text{in } \mathbb{R}^N \times \mathbb{R}^+. \tag{1}$$

Singular equations of this type have been studied, primarily in one space dimension, in, for example, [5] and [11]. This equation is singular since its modulus of ellipticity, u^{-1}, blows up at points where $u = 0$. At such points, ln u is not defined. We regard ln u as an element of $L^p_{\text{loc}}(\mathbb{R}^N \times \mathbb{R}^+)$, for some $p \geq 1$, so that (1) can be interpreted in the sense of distributions. Precisely, we say that a measurable function $u : \mathbb{R}^N \times \mathbb{R}^+ \to \mathbb{R}^+$ is a weak solution to (1) if

$$\begin{cases} u, \ln u \in L^1_{\text{loc}}(\mathbb{R}^N \times \mathbb{R}^+) \text{ and, for all } \phi \in C_0^\infty(\mathbb{R}^N \times \mathbb{R}^+), \\ \displaystyle\iint_{\mathbb{R}\times\mathbb{R}^+} (u\phi_t + \ln u \Delta\phi)dx\,dt = 0. \end{cases} \tag{2}$$

The equation has theoretical significance as it arises in the two-dimensional Ricci flow (see [10], [16]) and a physical significance in connection with the dynamics of thin liquid films (see [3], [4], [15]). In one space dimension, it has also been proposed as a model for the limiting density distribution in the kinetics of two gases moving against each other and obeying the Boltzmann equation (see [6], [12]). Since our interest is mainly in the physical aspects of the partial differential equation (PDE), we will describe below some currently proposed models of film rupture and their connection with (1). The equation can also be viewed, at least formally, as a limiting case of the porous medium equation,

$$v_\tau - \Delta v^m = 0, \qquad v \geq 0, \qquad m > 0, \tag{3}$$

when $m \to 0$. Indeed, the formal change of variables,

$$\tau = mt, \qquad u(x,t) = v(x,mt),$$

transforms (3) into

$$u_t - \Delta \frac{u^m - 1}{m} = 0,$$

from which (1) follows, formally, by letting $m \to 0$. This formal connection prompts some of our analysis below. We will show that some peculiar properties of the porous-medium equation, such as sup-bounds, semiconvexity estimates, and extinction in finite time, continue to hold for solutions of (1), whereas others, such as behavior at infinity, do not. A dramatic difference is that while the Cauchy problem in $\mathbb{R}^N \times \mathbb{R}^+$ for the porous-medium equation (3) can always be solved globally in time for every initial datum

$$u_0 \geq 0 \quad u_0 \in C_0^\infty(\mathbb{R}^N),$$

the corresponding Cauchy problem for (1) cannot be solved for this datum in space dimensions $N \geq 3$. Another difference is the behavior of the solutions as $|x| \to \infty$. For any $m > 0$, however small, solutions of (3) have unrestricted behavior as $|x| \to \infty$ (see [7]), whereas the behavior of solutions of (1) as $|x| \to \infty$ is rather rigid. One of the results of this note is that if $N \geq 3$, any solution of (1) in $\mathbb{R}^N \times (0,T)$ as $|x| \to \infty$ decays no faster than $|x|^{-2}$.

In this note, we assume that u is a classical solution of (1) and derive some a priori estimates on its behavior. The point here is to find estimates and properties that are *independent* of any sort of lower bound on u. Thus, by a limiting process, these are indeed a priori estimates and properties of the weak solutions in the sense of (2).

1.1. Main results: Upper bounds and behavior at infinity. Nonnegative solutions of (1) are locally bounded in $\mathbb{R}^N \times \mathbb{R}^+$ if

$$u \in L^r_{\text{loc}}(\mathbb{R}^N \times \mathbb{R}^+), \qquad r > \max\left\{1, \frac{N}{2}\right\}. \tag{4}$$

We show by a counterexample that the indicated order of integrability is optimal for a sup-bound to hold (see Remark 2.6). One of the interests of this result is that if $u_0 \in L^r_{\text{loc}}(\mathbb{R}^n)$, then (4) holds, and then the local boundedness of u can be established. This supplies necessary conditions for the forward Cauchy problem to have a locally bounded solution.

For the porous-medium equation (3), local boundedness is guaranteed if (see [7])

$$v \in L^r_{\text{loc}}(\mathbb{R}^N \times \mathbb{R}^+), \qquad N(m-1) + 2r > 0. \tag{5}$$

Thus the integrability condition (4) can be regarded as the limiting case of the integrability condition prescribed by (5).

These estimates are *global* in $\mathbb{R}^N$ if, for some $t_0 > 0$, the function $x \to u(x,t_0)$, roughly speaking, does not decay slower than $|x|^{-2}$ as $x \to \infty$. This is meant in the sense that

$$\sup_{\rho > 1} \fint_{B_\rho} [|x|^2 u(x,t_0)]^r \, dx < \infty, \quad \text{for some } r > \max\left\{1, \frac{N}{2}\right\}. \tag{6}$$

Here, for a region Ω of finite Lebesgue measure and for $f \in L^1(\Omega)$,

$$⨍_\Omega f\,dx = \frac{1}{\text{meas}\ \Omega}\int_\Omega f\,dx$$

denotes the integral average of f over Ω. If (6) holds, the solution $u(\cdot, t)$ decays, for $t > t_0$, pointwise no slower than $|x|^{-2}$ as $x \to \infty$. Such an upper bound, in the growth of u, is optimal as shown by the lower bounds described below.

1.2. Main results: Lower bounds and behavior at infinity. We first establish that a solution u for which $\ln u \in L^\infty_{\text{loc}}(\mathbb{R}^+; L^1_{\text{loc}}(\mathbb{R}^N))$ is bounded away from 0, locally in $\mathbb{R}^N \times \mathbb{R}^+$. Here, we say that $f \in L^\infty_{\text{loc}}(\mathbb{R}^+; L^1_{\text{loc}}(\mathbb{R}^N))$ if, for each $\rho > 0$ and $0 < t_0 < t_1 < \infty$,

$$\sup_{t_1 \le t \le t_2} \int_{B_\rho} |f(x,t)|\,dx \le C(\rho, t_0, t_1).$$

This is the content of §3.1. Then, using the estimates leading to this fact, we prove in §3.3–3.5 that if $N \ge 3$, solutions of (1) decrease, as $|x| \to \infty$, no faster than $|x|^{-2}$. Thus the rate $|x|^{-2}$ of increase/decrease of $u(\cdot, t)$ as $x \to \infty$ is optimal.

1.3. Ill-posed problems. A key fact is that the results indicated in the previous sections hold for solutions of (1) originating from either initial or final data. Thus, if $N \ge 3$, *neither* the forward nor the backward Cauchy problem is well posed if the data decay faster than $|x|^{-2}$ as $|x| \to \infty$. Thus, in particular, if $N \ge 3$ and if the initial datum is compactly supported, neither the forward nor the backward Cauchy problem associated with (1) is well posed.

1.4. Extinction in finite time. We can show that, if $u_0 \in L^{N/2}(\mathbb{R}^N)$ and $N \ge 3$, then any classical solution with this initial data must become extinct after some finite time T. Furthermore, T is bounded by a constant depending only on N and the $L^{N/2}(\mathbb{R}^N)$ norm of u_0. We also indicate through a family of examples why a result of this type is impossible for an initial datum $u_0 \in L^r(\mathbb{R}^N) r > \frac{N}{2}$. This result is merely a sufficient condition to guarantee that a solution has a finite extinction time. The explicit solutions given by Example 1.5 below show that this condition is not necessary for finite extinction to occur. This result can be viewed as the limiting case of the corresponding result for the porous-medium equation. For the latter, finite extinction occurs when the initial data is in $L^r(\mathbb{R}^N)$, where $r = \frac{N(1-m)}{2}$, as long as $r > 1$ (see [2]).

1.5. Background on thin-film dynamics. When a uniform viscous-liquid film lies on a rigid plate, small disturbances to the planar interface can grow, leading to the rupture of the film locally and laying bare the substrate. The instability is driven by the presence in ultrathin films ($100\overset{\circ}{A}$–$1000\overset{\circ}{A}$) of van der Waals attractions that drive thin regions to zero thickness. The van der Waals attractions can be modeled as a potential, ϕ, of an extra body force, $\phi \sim u^3$, where u is the local film thickness. Williams and Davis [15] derive an evolution equation governing the dynamics, viz.

$$u_t \pm \Delta \ln u + \text{ div } (u^3 \nabla(\Delta u)) = 0 \quad \text{in } \mathbb{R}^2 \times \mathbb{R}^+, \tag{7}$$

with the upper sign corresponding to the unstable case above. When the lower sign holds, the van der Waals forces are repulsive and the uniform film is stable. The last term represents the stabilizing effects of surface tension on the liquid–gas interface.

Williams and Davis [15] numerically integrated the unstable version of equation (7) in $\mathbb{R} \times \mathbb{R}^+$ and found that in a finite time, $t = t_R$, there is a value of x for which $u = 0$, i.e., the film ruptures. Burelbach et al. [4] did more extensive numerical computations and found that, at a rupture point, as $t \to t_R^-$, $u \sim t_R - t$, suggesting that locally $u \sim (t_R - t)f(x)$, which corresponds to a solution of the unstable version of (7) with the surface tension neglected. Thus the equations, locally, should be

$$u_t \pm \Delta \ln u = 0 \quad \text{in } \mathbb{R}^2 \times \mathbb{R}^+. \tag{8}$$

As mentioned in §1.3, most of our results hold for both the stable and unstable versions of (7).

1.6. Some explicit solutions. As a way of checking our analysis, we list here some known explicit solutions of (1) in $\mathbb{R}^N \times \mathbb{R}^+$. Some are obtained from the explicit Barenblatt–Pattle (see [13]) solutions by formally letting $m \to 0$, and others are new.

Example 1.1. For $N = 1$ and $\lambda > 0$,

$$u(x,t) = \frac{\lambda^2 (T-t)_+}{1+\cosh(\lambda x)}.$$

Example 1.2. For $N = 1$ and $\lambda > 0$,

$$u(x,t) = \frac{2t}{\lambda t^2 + |x|^2}.$$

Example 1.3. For $N = 2$ and $T > 0$,

$$u(x,t) = \frac{8\lambda (T-t)_+}{(\lambda + |x|^2)^2}.$$

Example 1.4. For $N = 2$, $\beta > 0$, and $\alpha > 0$,

$$u(x,t) = \frac{\beta}{e^{\frac{4\alpha t}{\beta}} + \alpha |x|^2}.$$

Example 1.5. For $N \geq 3$, $\lambda \geq 0$, and $T > 0$,

$$u(x,t) = \frac{2(N-2)(T-t)_+^{\frac{N}{N-2}}}{\lambda + (T-t)_+^{\frac{2}{N-2}} |x|^2}.$$

2. Some sup-bounds. For what follows, we assume that we have a classical solution to the Cauchy problem

$$\begin{cases} u_t - \Delta \ln u = 0 & \text{in } \mathbb{R}^N \times \mathbb{R}^+, \\ u(x,0) = u_0(x), & u_0 \in C^\infty(\mathbb{R}^N). \end{cases} \tag{9}$$

In addition, we assume that $u_0 > 0$ to make sense out of (9). Our estimates in this section are entirely local and hold for classical solutions of (9) with no specification of the behavior of $u(x,t)$ as $|x| \to \infty$. These a priori estimates can be used to actually construct weak solutions of (9) and to infer the asymptotic behavior of $u(x,t)$ as $|x| \to \infty$.

For $\rho > 0$ and $x_0 \in \mathbb{R}^N$, we let $B_\rho(x_0) = \{|x - x_0| < \rho\}$ denote the ball of radius ρ about x_0. If $x_0 = 0$, then we write $B_\rho(0) = B_\rho$. We let r be a real number satisfying

$$r > \max\left\{1, \frac{N}{2}\right\} \tag{10}$$

and set

$$\kappa_r = 2r - N. \tag{11}$$

For $N \geq 2$, the requirement (10) is equivalent to $\kappa_r > 0$. In the estimates to follow, we will denote by γ and b generic positive constants depending only on N and r.

2.1. Local sup-bounds.

PROPOSITION 2.1. *Let u be a classical solution to* (9) *and let r satisfy* (10). *Then there exists a constant γ depending only on N and r such that*

$$\|u(\cdot, t)\|_{\infty, B_\rho(x_0)} \leq \gamma \left\{ (t-\tau)^{-\frac{N}{\kappa_r}} \sup_{\tau < s < t} \|u(\cdot, t)\|_{r, B_{2\rho}(x_0)}^{\frac{2r}{\kappa_r}} + \frac{t-\tau}{\rho^2} \right\}, \tag{12}$$

for all $x_0 \in \mathbb{R}^N$ and for all $0 \leq \tau < t$.

Proof. Without loss of generality, we may assume that $x_0 = 0$ and $\tau = 0$. Let $0 < \sigma < 1$ and consider the sequences of radii and time levels

$$\rho_n = \rho(1 + \sigma 2^{-n}) \quad \text{and} \quad t_n = \frac{t}{2}(1 - 2^{-n-1}).$$

Then $\rho_0 = \rho(1+\sigma)$ and $t_0 = t/4$. Also, as $n \to \infty$, ρ_n decreases to ρ, and t_n increases to $\frac{t}{2}$. So, with $Q_n = B_{\rho_n} \times (t_n, t)$, we have the following relations:

$$B_{\rho(1+\sigma)} \times \left(\frac{t}{4}, t\right) = Q_0 \supseteq Q_1 \supseteq \cdots \subseteq Q_{n-1} \supseteq Q_n \supseteq \cdots \supseteq Q_\infty = B_\rho \times \left(\frac{t}{2}, t\right).$$

Let $\zeta_n \in C_0^\infty(Q_n)$ satisfy

$$\begin{cases} 0 \leq \zeta_n \leq 1 & \text{in } Q_n, \\ \zeta_n = 1 & \text{in } Q_{n+1}, \\ |D\zeta_n|^2, |\Delta\zeta_n| \leq \dfrac{\gamma 4^n}{(\sigma\rho)^2} & \text{in } Q_n, \\ 0 \leq \dfrac{\partial \zeta_n}{\partial t} \leq \dfrac{\gamma 2^n}{t} & \text{in } Q_n. \end{cases}$$

Multiply the first term of (9) by the test function $(u - k_{n+1})_+^{r-1}\zeta_n^2$ and integrate over Q_n^s. Here $k_n = k(1 - 2^{-n})$, where $k > 0$ will be chosen later, and $Q_n^s = B_{\rho_n} \times (t_n, s)$, where $t_n \leq s \leq t$. Note that $k_0 = 0$ and, as $n \to \infty$, k_n increases to k. Set

$$M = \sup_{Q_0} u.$$

Then

$$\begin{aligned}
0 &= \iint_{Q_n^s} (u_t - \Delta \ln u)(u - k_{n+1})_+^{r-1}\zeta_n^2\, dx\, d\tau \\
&= \frac{1}{r}\iint_{Q_n^s} \frac{\partial (u - k_{n+1})_+^r}{\partial t}\zeta_n^2\, dx\, d\tau \\
&\quad + \iint_{Q_n^s} \frac{Du}{u}[D(u - k_{n+1})_+^{r-1}\zeta_n^2 + 2(u - k_{n+1})_+^{r-1}\zeta_n D\zeta_n]\, dx\, d\tau \\
&= \frac{1}{r}\int_{B_{\rho_n}} (u - k_{n+1})_+^r(x, s)\zeta_n^2(x, s)\, dx - \frac{2}{r}\iint_{Q_n^s} (u - k_{n+1})_+^r\zeta_n\zeta_{n,t}\, dx\, d\tau \\
&\quad + \frac{4(r-1)}{r^2}\iint_{Q_n^s} \frac{1}{u}|D(u - k_{n+1})_+^{\frac{r}{2}}|^2\zeta_n^2\, dx\, d\tau \\
&\quad + 2\iint_{Q_n^s} \frac{Du}{u}(u - k_{n+1})_+^{r-1}\zeta_n D\zeta_n\, dx\, d\tau \\
&= \frac{1}{r}T_1 - \frac{2}{r}T_2 + \frac{4(r-1)}{r^2}T_3 + 2T_4.
\end{aligned} \tag{13}$$

$$|T_2| \le \gamma\frac{2^n}{t}\iint_{Q_n^s} (u - k_{n+1})_+^r\, dx\, d\tau. \tag{14}$$

$$\begin{aligned}
\iint_{Q_n^s} |D[(u - k_{n+1})_+^{\frac{r}{2}}\zeta_n]|^2\, dx\, d\tau \le \iint_{Q_n^s} &|D(u - k_{n+1})_+^{\frac{r}{2}}|^2\zeta_n^2\, dx\, d\tau \\
&+ \frac{\gamma 4^n}{\sigma^2\rho^2}\iint_{Q_n^s} (u - k_{n+1})_+^r\, dx\, d\tau.
\end{aligned}$$

Thus

$$\begin{aligned}
T_3 &\ge \frac{1}{M}\iint_{Q_n^s} |D(u - k_{n+1})_+^{\frac{r}{2}}|^2\zeta_n^2 dx d\tau \\
&\ge \frac{1}{M}\iint_{Q_n^s} |D[(u - k_{n+1})_+^{\frac{r}{2}}\zeta_n|^2 dx d\tau - \frac{\gamma 4^n}{M\sigma^2\rho^2}\iint_{Q_n^s} (u - k_{n+1})_+^r dx d\tau.
\end{aligned} \tag{15}$$

Set

$$f_n(\delta) = \int_{k_{n+1}}^{\delta} \frac{(s - k_{n+1})_+^{r-1}}{s} ds.$$

Then

$$|f_n(\delta)| \le \frac{(\delta - k_{n+1})_+^r}{k_{n+1}} \le \frac{2(\delta - k_{n+1})_+^r}{k}.$$

Thus

$$\begin{aligned}
T_4 &= \iint_{Q_n^s} Df_n(u)\zeta_n D\zeta_n dx d\tau \\
&= -\iint_{Q_n^s} f_n(u)(|D\zeta_n|^2 + \zeta_n\Delta\zeta_n) dx d\tau.
\end{aligned}$$

$$
\begin{aligned}
|T_4| &\le \gamma \frac{4^n}{\sigma^2\rho^2} \iint_{Q_n^s} |f_n(u)| dx d\tau \\
&\le \gamma \frac{4^n}{k\sigma^2\rho^2} \iint_{Q_n^s} (u-k_{n+1})_+^r dx d\tau.
\end{aligned} \tag{16}
$$

Then, by combining (13)–(16), taking the supremum for $s \in (t_n, t)$, and assuming that $\frac{t}{\rho^2} \le k \le M$, we find

$$
\begin{aligned}
\sup_{t_n \le s \le t} \int_{B_{\rho n}} (u-k_{n+1})_+^r(x,s)\zeta_n^2(x,s)dx &+ \frac{1}{M} \iint_{Q_n} \left|D[(u-k_{n+1})_+^{\frac{r}{2}}\zeta_n]\right|^2 dx d\tau \\
&\le \gamma \frac{4^n}{\sigma^2 t} \iint_{Q_n} (u-k_{n+1})_+^r \, dx d\tau \\
&\le \gamma \frac{4^n}{\sigma^2 t} Y_n,
\end{aligned} \tag{17}
$$

where

$$
Y_n = \iint_{Q_n} (u-k_n)_+^r dx d\tau.
$$

Since $(u-k_{n+1})_+^r \zeta_n^2$ vanishes on the lateral boundary of Q_n, we can apply the space–time version of the Sobolev Embedding Theorem (see [7, Chap. 1, §3]), that is,

$$
\begin{aligned}
\iint_{Q_n} [(u-k_{n+1})_+^{\frac{r}{2}}\zeta_n]^{2\frac{N+2}{N}} dx d\tau &\le \gamma \left(\iint_{Q_n} |D[(u-k_{n+1})_+^{\frac{r}{2}}\zeta_n]|^2 dx d\tau \right) \\
&\times \left(\sup_{t_n \le s \le t} \int_{B_{\rho n}} [(u-k_{n+1})_+^{\frac{r}{2}}\zeta_n]^2(x,s)dx \right)^{\frac{2}{N}}.
\end{aligned} \tag{18}
$$

By Hölder's inequality,

$$
\begin{aligned}
Y_{n+1} &= \iint_{Q_{n+1}} (u-k_{n+1})_+^r \, dx d\tau \\
&\le \iint_{Q_n} (u-k_{n+1})_+^r \zeta_n^2 dx d\tau \\
&\le \left(\iint_{Q_n} [(u-k_{n+1})_+^r \zeta_n^2]^{\frac{N+2}{N}} dx d\tau \right)^{\frac{N}{N+2}} |A_n|^{\frac{2}{N+2}},
\end{aligned}
$$

where $A_n = \{(x,t) \in Q_n | u(x,t) > k_{n+1}\}$. Then, by applying (17) and (18),

$$
Y_{n+1} \le \gamma \frac{4^n}{\sigma^2 t} M^{\frac{N}{N+2}} Y_n |A_n|^{\frac{2}{N+2}}. \tag{19}
$$

To estimate $|A_n|$,

$$\begin{aligned} Y_n &= \iint_{Q_n} (u-k_n)_+^r dx d\tau \\ &\geq \iint_{Q_n} (u-k_n)_+^r \chi_{\{u>k_{n+1}\}} dx d\tau \\ &\geq (k_{n+1}-k_n)^r |A_n| \\ &= \frac{k^r}{2^{(n+1)r}} |A_n|. \end{aligned}$$

Combining this with (19) yields

$$Y_{n+1} \leq \gamma \frac{b^n M^{\frac{N}{N+2}}}{\sigma^2 t k^{\frac{2r}{N+2}}} Y_n^{1+\frac{2}{N+2}},$$

where $b > 1$ is some number depending only on N and r. Thus (see [7, Chap. 1, Lem. 4.1])

$$\lim_{n\to\infty} Y_n = 0 \quad \text{if } k > \gamma \frac{M^{\frac{N}{2r}} Y_0^{\frac{1}{r}}}{(\sigma^2 t)^{\frac{N+2}{2r}}}.$$

Thus, with

$$M = \sup_{B_{\rho(1+\sigma)}\times[\frac{t}{4},t]} u,$$

$$\sup_{B_\rho\times(\frac{t}{2},t)} u \leq \frac{\gamma M^{\frac{N}{2r}}}{(\sigma^2 t)^{\frac{N+2}{2r}}} \left(\int_0^t \int_{B_{\rho(1+\sigma)}} u^r dx d\tau \right)^{\frac{1}{r}} + \frac{t}{\rho^2} \tag{20}$$

for any $\rho > 0$ and $0 < \sigma \leq 1$. Note that the $\frac{t}{\rho^2}$ term is included to satisfy the assumption that $k \geq \frac{t}{\rho^2}$.

Fix $R > 0$ and $T > 0$. Consider the sequences

$$\rho_n = R\sum_{i=0}^{n} 2^{-i} \quad \text{and} \quad t_n = \frac{T}{2^{n+1}}.$$

Thus $B_{\rho_n} \times (t_n, T) \subseteq B_{\rho_{n+1}} \times (t_{n+1}, T)$. Define σ_n so that $\rho_{n+1} = \rho_n(1+\sigma_n)$. Then it follows that $\sigma_n \geq 2^{-n-2}$. By applying (20) with $t = t_n$, $\rho = \rho_n$, and $\sigma = \sigma_n$,

$$\begin{aligned} \sup_{B_{\rho n}\times(t_n,t_{n-1})} u &\leq \gamma \frac{M_{n+1}^{\frac{N}{2r}}}{(\sigma_n^2 t_{n-1})^{\frac{N+2}{2r}}} \left(\int_0^{t_{n-1}} \int_{B_{\rho_{n+1}}} u^r dx d\tau \right)^{\frac{1}{r}} + \frac{t_{n-1}}{\rho^2} \\ &\leq \gamma \frac{M_{n+1}^{\frac{N}{2r}} b^n}{T^{\frac{N+2}{2r}}} \left(\int_0^T \int_{B_{2R}} u^r dx d\tau \right)^{\frac{1}{r}} + \frac{T}{\rho^2}, \end{aligned} \tag{21}$$

where

$$M_n = \sup_{B_{\rho n}\times(t_n,T)} u.$$

Thus, from (21),

$$M_n \leq \gamma M_{n+1}^{\frac{N}{2r}} b^n \left(T^{-\frac{N+2}{2}} \int_0^T \int_{B_{2R}} u^t dx d\tau \right)^{\frac{1}{r}} + \frac{T}{R^2}, \tag{22}$$

where γ and b are constants depending only on N and r. Fix $\eta \in (0,1)$ and apply Young's inequality to (22) to arrive at

$$M_n \leq \eta M_{n+1} + \gamma b^n \left(T^{-\frac{N+2}{2}} \int_0^T \int_{B_{2R}} u^r dx d\tau \right)^{\frac{2}{2r-N}} + \frac{T}{R^2}. \tag{23}$$

Then inductively, with $F = \left(T^{-\frac{N+2}{2}} \int_0^T \int_{B_{2R}} u^r dx d\tau \right)^{\frac{2}{2r-N}}$,

$$M_0 \leq \eta^k M_k + \gamma F \sum_{j=0}^{k-1} b^j \eta^j + \frac{T}{R^2} \sum_{j=0}^{k-1} \eta^j.$$

By selecting $\eta < \frac{1}{b}$ and letting $k \to \infty$,

$$\begin{aligned} \sup_{B_R \times (\frac{T}{2}, T)} u &\leq \gamma \left[T^{-\frac{N+2}{2r-N}} \left(\int_0^T \int_{B_{2R}} u^r dx d\tau \right)^{\frac{2}{2r-N}} + \frac{T}{R^2} \right] \\ &\leq \gamma \left[T^{-\frac{N}{\kappa_r}} \sup_{0 \leq s \leq T} \left(\int_{B_{2r}} u^r(x,s) dx \right)^{\frac{2}{\kappa_r}} + \frac{T}{R^2} \right]. \end{aligned} \tag{24}$$

Then, by replacing T by t and R by ρ, (24) is exactly (12). □

2.2. Local integral estimates.

PROPOSITION 2.2. *Assume that u is a classical solution to* (9) *and that* $r > 1$. *Then there is a constant* γ *depending only on* N *and* r *such that*

$$\sup_{\tau \leq s \leq t} \int_{B_\rho(x_0)} u^r(x,s) dx \leq \gamma \left[\int_{B_{2\rho}(x_0)} u^r(x,\tau) dx + \frac{(t-\tau)^r}{\rho^{\kappa_r}} \right] \tag{25}$$

for all $\rho > 0$, $0 < \tau < t$, *and* $x_0 \in \mathbb{R}^N$.

Remark 2.3. An estimate like (25) is impossible for solutions of the heat equation. To see this, suppose that, for any solution v to the heat equation in $B_{2\rho} \times (0,T)$,

$$\int_{B_\rho} v^r(x,t) dx \leq \gamma(\|v(\cdot,0)\|_{r,B_{2\rho}}, N, r, t, \rho)$$

for any $0 < t < T$. Then fix $y \in \mathbb{R}^N$ such that $|y| > 0$ and consider

$$v_C(x,t) = \frac{C}{t^{\frac{N}{2}}} e^{-\frac{|x-y|^2}{4t}}.$$

Select $0 < \rho < |y|/2$. If the estimate above is true for some r, then

$$\frac{C^r}{t^{\frac{rN}{2}}} \int_{B_\rho} e^{-r\frac{|x-y|^2}{4t}} dx \leq \gamma(0, N, r, t, \rho).$$

Of course, this is impossible, since the left side → ∞ as $C \to \infty$, whereas the right side is independent of C.

Proof of Proposition 2.2. Again, we take $x_0 = 0$ and $\tau = 0$. Fix $\sigma \in (0,1]$ and choose $\zeta \in C_0^\infty(B_{\rho(1+\sigma)})$ satisfying

$$\begin{cases} 0 \leq \zeta \leq 1 & \text{in } B_{\rho(1+\sigma)}, \\ \zeta(x) = 1 & \text{in } B_\rho, \\ |D\zeta|^2, |\Delta\zeta| \leq \dfrac{\gamma}{(\sigma\rho)^2} & \text{in } B_{\rho(1+\sigma)}. \end{cases}$$

Multiply the first term of (9) by $u^{r-1}\zeta$ and integrate over $Q_s = B_{(1+\sigma)\rho} \times (0,s)$.

$$\begin{aligned} 0 &= \iint_{Q_s} (u_t - \Delta \ln u) u^{r-1} \zeta dx d\tau \\ &= \frac{1}{r}\iint_{Q_s} \frac{\partial u^r}{\partial t}\zeta dx d\tau + \iint_{Q_s} \frac{Du}{u}[Du^{r-1}\zeta + u^{r-1}D\zeta] dx d\tau \\ &= \frac{1}{r}\iint_{Q_s} \frac{\partial u^r}{\partial t}\zeta dx d\tau + (r-1)\iint_{Q_s} u^{r-3}|Du|^2\zeta dx d\tau \\ &\quad + \iint_{Q_s} u^{r-2} Du D\zeta dx d\tau \\ &= \frac{1}{r}T_1 + (r-1)T_2 + T_3. \end{aligned} \tag{26}$$

Since ζ is independent of t,

$$T_1 = \int_{B_{(1+\sigma)\rho}} u^r(x,s)\zeta(x)dx - \int_{B_{(1+\sigma)\rho}} u_0^r(x)\zeta(x)dx d\tau. \tag{27}$$

$$\begin{aligned} T_3 &= \frac{1}{r-1}\iint_{Q_s} D(u^{r-1})D\zeta dx d\tau \\ &= \frac{-1}{r-1}\iint_{Q_s} u^{r-1}\Delta\zeta dx d\tau \\ &\geq \frac{-\gamma}{(\sigma\rho)^2}\iint_{Q_s} u^{r-1} dx d\tau. \end{aligned} \tag{28}$$

By combining (26)–(28), using the fact that $T_2 \geq 0$, and taking the supremum for $0 \geq s \geq t$,

$$\sup_{0\leq s\leq t} \int_{B_\rho} u^r(x,s)dx \leq \int_{B_{(1+\sigma)\rho}} u_0^r dx + \frac{\gamma}{(\sigma\rho)^2}\iint_{Q_t} u^{r-1} dx d\tau. \tag{29}$$

Then, by applying Hölder's inequality to the last term of (29),

$$\begin{aligned} \sup_{0\leq s\leq t} \int_{B_\rho} u^r(x,s)dx &\leq \int_{B_{(1+\sigma)\rho}} u_0^r dx \\ &\quad + \frac{\gamma}{\sigma^2}\left(\frac{t^r}{\rho^{2r-N}}\right)^{\frac{1}{r}} \left(\sup_{0\leq s\leq t}\int_{B_{(1+\sigma)\rho}} u^r(x,s)dx\right)^{\frac{r-1}{r}}. \end{aligned} \tag{30}$$

Fix $R > 0$ and consider the sequence of radii

$$\rho_n = R\sum_{i=1}^{n} 2^{-i}.$$

Select σ_n so that $\rho_{n+1} = (1+\sigma_n)\rho_n$. Then

$$\sigma_n = \frac{\rho_{n+1} - \rho_n}{\rho_n} \geq 2^{-n-2}. \tag{31}$$

Set

$$Y_n = \sup_{0 \leq s \leq t} \int_{B_{\rho n}} u^r(x,s)dx.$$

Then, by (30) and (31),

$$Y_n \leq \int_{B_{2R}} u_0^r dx + \gamma 2^n \left(\frac{t^r}{\rho^{\kappa_r}}\right)^{\frac{1}{r}} Y_{n+1}^{\frac{r-1}{r}}.$$

To complete the proof, use an interpolation argument analogous to that in Proposition 2.1. □

COROLLARY 2.4. *If* $u_0 \in L^r(\mathbb{R}^N)$ *and* $r > \max\{1, \frac{N}{2}\}$, *then there is a constant* γ *depending only on* N *and* r *such that*

$$\sup_{0 \leq s \leq t} \int_{\mathbb{R}^N} u^r(x,s)dx \leq \gamma \int_{\mathbb{R}^N} u_0^r(x)dx. \tag{32}$$

Remark 2.5. Note that a closer analysis shows that we can take $\gamma = 1$ in (32).

2.3. Global estimates.

PROPOSITION 2.6. *Let* u *be a classical solution to* (9) *and let* $r > \max\{1, \frac{N}{2}\}$. *Then there is a constant* γ, *depending only on* r *and* N, *such that*

$$\sup_{B_\rho(x_0)} u(\cdot,t) \leq \gamma \left(t^{-\frac{N}{\kappa_r}} \|u_0\|_{r,B_{4\rho}(x_0)}^{\frac{2r}{\kappa_r}} + \frac{t}{\rho^2}\right). \tag{33}$$

Furthermore, if

$$|||u_0|||_r = \sup_{\rho > 1} \fint_{B_\rho} [|x|^2 u_0(x)]^r dx < \infty, \tag{34}$$

then, for all $t > 0$,

$$|||u(\cdot,t)|||_r < \infty \tag{35}$$

and, for all $x \in \mathbb{R}^N$,

$$|x|^2 u(x,t) \leq \gamma \left(t + t^{-\frac{N}{\kappa_r}} |||u_0|||_r^{\frac{2r}{\kappa_r}}\right). \tag{36}$$

Remark 2.7. For $N = 2$, estimate (33) is sharp in the sense that no estimate of this type is possible for $r = 1$. To see this, consider the one parameter family of solutions u_λ given in Example 1.3. As can easily be checked, $\|u_\lambda(\cdot,0)\|_{1,\mathbb{R}^2}$ is independent of λ, whereas $u_\lambda(0,\frac{T}{2}) = \frac{4T}{\lambda}$.

Remark 2.8. For $N \geq 3$, estimate (33) is almost sharp in the sense that no estimate of this type is possible for $r < \frac{N}{2}$. To see this, consider the one-parameter family of solutions given by example (1.5). For $r < \frac{N}{2}$, $\|u_\lambda(\cdot,0)\|_{r,B_1}$ is bounded independently of λ, whereas $u_\lambda(0,\frac{T}{2}) = \frac{\gamma}{\lambda}$ for some fixed number γ.

Proof of Proposition 2.6. (33) follows from Propositions 2.1 and 2.2. Fix $x_0 \in \mathbb{R}^N$ and $t > 0$. If $|x_0| < 2$, then (36) is obvious. So assume $|x_0| > 2$. Then, from (33),

$$\begin{aligned} |x_0|^2 u(x_0,t) &\leq |x_0|^2 \gamma \left(t^{-\frac{N}{\kappa_r}} \left[\int_{B_{\frac{|x_0|}{2}}(x_0)} u_0^r(x)dx \right]^{\frac{2}{\kappa_r}} + \frac{t}{|x_0|^2} \right) \\ &= \gamma \left(t^{-\frac{N}{\kappa_r}} \left[\frac{1}{|x_0|^N} \int_{B_{\frac{|x_0|}{2}}(x_0)} [|x_0|^2 u_0(x)]^r dx \right]^{\frac{2}{\kappa_r}} + t \right) \\ &\leq \gamma \left(t^{-\frac{N}{\kappa_r}} \left[\fint_{B_{2|x_0|}} [|x|^2 u_0(x)]^r dx \right]^{\frac{2}{\kappa_r}} + t \right), \end{aligned}$$

which proves both (35) and (36). □

Let Ω be a bounded domain in $\mathbb{R}^N$ with smooth boundary $\partial\Omega$. For $T > 0$, let $\Omega_T = \Omega \times (0,T)$ and $S_T = \partial\Omega \times (0,T)$. Consider classical solutions to the boundary value problem

$$(37) \qquad \begin{cases} u_t - \Delta \ln u = 0 & \text{in } \Omega_T, \\ u|_{S_T} = g, & \text{where } g \in C^\infty(S_T), \\ u(x,0) = u_0(x), & \text{where } u_0 \in C^\infty(\Omega). \end{cases}$$

We assume here that g and u_0 are strictly positive so that, by the maximum principle, $u > 0$ in Ω_T, and the PDE in (37) is well defined in the classical sense.

PROPOSITION 2.9. *Let u be a classical solution to* (37) *and let* $r > \max\{1, \frac{N}{2}\}$. *There exists a constant γ depending only on N and r such that for all $t > 0$,*

$$(38) \qquad \|u(\cdot,t)\|_{\infty,\Omega} \leq \|g\|_{\infty,S_T} + \gamma t^{-\frac{N}{\kappa_r}} \|u_0\|_{r,\Omega}^{\frac{2r}{\kappa_r}}.$$

The proof is very similar to that of Proposition 2.1. Select $k > \|g\|_{\infty,S_T}$ and multiply the PDE by the test functions

$$(u-k_n)_+^{r-1}\zeta_n^2, \quad \text{where } k_n = k(1-2^{-n}), \quad n = 0,1,2,\ldots.$$

Due to our choice of k, these test functions vanish on S_T, and the cutoff function ζ_n can be chosen to depend only on t. The proof can now be repeated with minor changes.

3. Local lower bounds. In this section, we consider positive classical solutions to (9). In addition, we assume that $u \leq M$ and that u satisfies the semiconvexity inequality,

$$(39) \qquad u_t \leq \frac{u}{t}.$$

Remark 3.1. If u is a classical solution to (37) with $g(x,t) = c > 0$, then the function $W = (\ln u), -\frac{1}{t}$ satisfies

$$W_t - \frac{1}{u}\Delta W = -W\left(W + \frac{2}{t}\right).$$

Clearly, $W \leq 0$ on the lateral portion of Ω_T and for t sufficiently small. If W has a positive maximum at a point P in the interior of Ω_T, then

$$0 < \left(W_t - \frac{1}{u}\Delta W\right)\Big|_P = -W(P)\left(W(P) + \frac{2}{t}\right) < 0.$$

Thus u satisfies (39). Thus any solution to the Cauchy problem which is constructed as the limit of solutions of this type satisfies (39) in the sense of distributions.

The PDE in (9) is well defined for $u > 0$. We will derive some quantitative lower bounds on u. We will do this in two stages. First, we establish some lower bounds in terms of some integral norms of $|\ln u|$, and then we convert these into pointwise estimates.

3.1. Local lower bounds in terms of integral norms.

PROPOSITION 3.2. *Let u be a classical solution of* (9) *satisfying the semiconvexity inequality* (39). *Fix $0 < \epsilon < 1$. Then there is a constant $\gamma(\epsilon)$ depending only on N and ϵ such that, for all $x_0 \in \mathbb{R}^N$ and for all $0 \leq \tau < t$,*

$$(40) \quad -\inf_{B_\rho(x_0)} \ln u(\cdot,t) \leq \max\left\{\gamma(\epsilon)\fint_{B_{2\rho}(x_0)} (\ln u(x,t))_- dx, \quad 1, \quad (1+\epsilon)\ln\frac{\rho^2}{t-\tau}\right\}.$$

Here $\gamma(\epsilon) = \gamma_0\epsilon^{-N(1+\frac{N}{4})}$, where γ_0 depends only on N.

Proof. Fix $0 < \epsilon < 1$. Again, without loss of generality, we set $x_0 = 0$ and $\tau = 0$. If

$$-\inf_{B_\rho(x_0)} \ln u(\cdot,t) \leq \max\left\{1, (1+\epsilon)\ln\frac{\rho^2}{t}\right\},$$

then the proof is complete. So assume the contrary. Set $v = \ln u$, that is, $u = e^v$. Then

$$(41) \qquad \frac{\partial e^v}{\partial t} - \Delta v = 0.$$

For $0 < \sigma \leq 1$, $k < -\max\{1, (1+\epsilon)\ln\frac{\rho^2}{t}\}$, and $\alpha = \frac{\epsilon}{1+\epsilon}$, set

$$\rho_n = \rho(1 + \sigma 2^{-n}) \quad \text{and} \quad k_n = k(1 - \alpha^n).$$

Then $k_{n+1} < k_n$, $k_0 = 0$, and $k_\infty = k$. Also, notice that for our choice of α, $k_{n+1} \leq k_1 = \frac{k}{1+\epsilon}$ for all $n \geq 0$. Furthermore, $\rho_{n+1} < \rho_n$, $\rho_0 = \rho(1+\sigma)$ and $\rho_\infty = \rho$. Then, with $B_n = B_{\rho n}$,

$$B_{\rho(1+\sigma)} \supseteq B_0 \supseteq B_1 \cdots \supseteq B_n \supseteq B_{n+1} \supseteq \cdots \supseteq B_\infty = B_\rho.$$

Let $\zeta_n \in C_0^\infty(B_n)$ be a smooth cutoff function satisfying

$$\begin{cases} 0 \leq \zeta_n \leq 1 & \text{in } B_n, \\ \zeta_n = 1 & \text{in } B_{n+1}, \\ |D\zeta_n|^2, |\Delta\zeta_n| \leq \gamma\dfrac{4^n}{(\sigma\rho)^2} & \text{in } B_n. \end{cases}$$

Multiply (41) by $(k_{n+1}-v)_+\zeta_n^2$ and integrate over B_n.

$$\begin{aligned} 0 &= \int_{B_n} (e^v v_t - \Delta v)(k_{n+1}-v)_+\zeta_n^2 dx \\ &= T_1 + T_2. \end{aligned} \tag{42}$$

$$T_2 = \int_{B_n} Dv\left[\zeta_n^2 D(k_{n+1}-v)_+ + 2(k_{n+1}-v)_+\zeta_n D\zeta_n\right] dx$$

$$\begin{aligned} &= -\int_{B_n} \left[|D(k_{n+1}-v)_+|^2\zeta_n^2 + D(k_{n+1}-v)_+^2\zeta_n D\zeta_n\right] dx \\ &= -\int_{B_n} |D(k_{n+1}-v)_+|^2\zeta_n^2 dx + 2\int_{B_n}(k_{n+1}-v)_+^2(|D\zeta_n|^2+\zeta_n\Delta\zeta_n)dx \\ &\leq -\int_{B_n} |D[(k_{n+1}-v)_+\zeta_n]|^2 dx + \gamma\frac{4^n}{(\sigma\rho)^2}\int_{B_n}(k_{n+1}-v)_+^2 dx. \end{aligned} \tag{43}$$

To estimate T_1, notice that

$$v_t = \frac{u_t}{u} \leq \frac{1}{t}.$$

Thus

$$\begin{aligned} T_1 &\leq \frac{1}{t}\int_{B_n} e^v(k_{n+1}-v)_+\zeta_n^2 dx \\ &\leq \frac{e^{k_{n+1}}}{t}\int_{B_n}(k_{n+1}-v)_+ dx. \end{aligned} \tag{44}$$

Thus, by combining (42)–(44) and using $k_{n+1} \leq k_1 \leq \frac{k}{1+\epsilon}$,

$$\begin{aligned} \int_{B_n} |D[(k_{n+1}-v)_+\zeta_n]|^2 dx &\leq \gamma\frac{4^n}{(\sigma\rho)^2}\int_{B_n}(k_{n+1}-v)_+^2 dx \\ &\quad + \frac{e^{\frac{k}{1+\epsilon}}}{t}\int_{B_n}(k_{n+1}-v)_+ dx. \end{aligned} \tag{45}$$

Notice that

$$\begin{aligned} \int_{B_n}(k_n-v)_+^2 dx &\geq \int_{B_n}(k_{n+1}-v)_+(k_n-v)_+ dx \\ &\geq (k_n-k_{n+1})\int_{B_n}(k_{n+1}-v)_+ dx \\ &\geq |k|\alpha^n(1-\alpha)\int_{B_n}(k_{n+1}-v)_+ dx. \end{aligned} \tag{46}$$

Thus, by combining (45) and (46), we have

$$(47) \qquad \int_{B_n} |D[(k_{n+1}-v)_+\zeta_n]|^2 dx \le \frac{\gamma}{(\sigma\rho)^2\alpha^n} \int_{B_n} (k_n - v)_+^2 dx.$$

Notice here we used the assumption that $-k > \max\{1, (1+\epsilon)\ln\frac{\rho^2}{t}\}$ to get that

$$\frac{e^{\frac{k}{1+\epsilon}}(1+\epsilon)\rho^2}{t|k|} \le 2.$$

By applying Hölder's inequality, the Sobolev inequality, and (47), we get

$$\begin{aligned}
\int_{B_{n+1}} (k_{n+1}-v)_+^2 dx &\le \int_{B_n} (k_{n+1}-v)_+^2 \zeta_n^2 dx \\
&\le \left(\int_{B_n} [(k_{n+1}-v)_+\zeta_n]^{\frac{2N}{N-2}} dx\right)^{\frac{N-2}{N}} |A_n(t)|^{\frac{2}{N}} \\
(48) \qquad &\le \gamma \int_{B_n} |D[(k_{n+1}-v)_+\zeta_n]|^2 dx |A_n(t)|^{\frac{2}{N}} \\
&\le \frac{\gamma b^n}{(\sigma\rho)^2} |A_n(t)|^{\frac{2}{N}} \int_{B_n} (k_n - v)_+^2 dx,
\end{aligned}$$

where $A_n(t) = \{x \in B_n \,|\, v(x,t) < k_{n+1}\}$. Note here that $b > 1$ is some constant depending on α. To estimate $A_n(t)$

$$\begin{aligned}
(49) \qquad \int_{B_n} (k_n - v)_+^2 dx &\ge |A_n(t)|(k_{n+1}-k_n)^2 \\
&= k^2\alpha^{2n}(1-\alpha)^2|A_n(t)|.
\end{aligned}$$

From (48) and (49),

$$(50) \qquad \int_{B_{n+1}} (k_{n+1}-v)_+^2 dx \le \gamma \frac{b^n}{(\sigma\rho)^2 k^{\frac{4}{N}}} \left(\int_{B_n} (k_n - v)_+^2 dx\right)^{1+\frac{2}{N}}.$$

Set

$$Y_n -\!\!\!\!\!\!\int_{B_n} (k_n - v)_+^2 dx.$$

Then, from (50),

$$Y_{n+1} \le \gamma \frac{b^n}{\sigma^2 |k|^{\frac{4}{N}}} Y_n^{1+\frac{2}{N}}.$$

Then, as in the proof of Proposition 2.1, $Y_n \to 0$ as $n \to \infty$ if

$$-k > \gamma \frac{b^{\frac{N^2}{8}}}{\sigma^{\frac{N}{2}}} Y_0^{\frac{1}{2}}.$$

Thus

$$-\inf_{B_\rho} v(x,t) \leq \frac{\gamma}{\sigma^{\frac{N}{2}}} \left(\fint_{B_{(1+\sigma)\rho}} v_-^2(x,t)dx \right)^{\frac{1}{2}}$$

$$\leq \frac{\gamma}{\sigma^{\frac{N}{2}}} \left(\sup_{B_{(1+\sigma)\rho}} v_-(\cdot,t) \right)^{\frac{1}{2}} \left(\fint_{B_{(1+\sigma)\rho}} v_-(x,t)dx \right)^{\frac{1}{2}}.$$

Consider the sequence of radii given by

$$\rho_n = \rho \sum_{j=0}^{n} 2^{-j}.$$

Select σ_n so that $\rho_{n+1} = (1+\sigma_n)\rho_n$. Then $\sigma_n \geq 2^{-n-1}$. Thus, with $M_n = \sup_{B_{\rho_n}} v_-(\cdot,t)$,

$$M_{n+1} \leq \gamma b^n M_n^{\frac{1}{2}} \left(\fint_{B_{(1+\sigma)\rho}} v_-(x,t)dx \right)^{\frac{1}{2}}.$$

To complete the proof, use an interpolation argument analogous to that in Proposition 2.1 to arrive at

$$-\inf_{B_\rho} v(x,t) \leq \gamma \fint_{B_{2\rho}} v_-(x,t)dx$$

when $-\inf_{B_\rho} v(x,t) > \max\{1, (1+\epsilon)\ln \frac{\rho^2}{t}\}$. This proves the proposition. □

3.2. A representation formula. Fix $x_0 \in \mathbb{R}^N$ and consider the Green's-type function for the Laplacian in the ball $B_\rho(x_0)$,

(51)

$$G(|x-x_0|;\rho) = \begin{cases} |x-x_0|^{2-N} - \rho^{2-N} + \dfrac{N-2}{2}\rho^{-N}(|x-x_0|^2 - \rho^2), & N \geq 3, \\ \ln\rho - \ln|x-x_0| + \dfrac{1}{2}\rho^{-2}(|x-x_0|^2 - \rho^2), & N = 2, \\ \rho - |x-x_0| + \dfrac{1}{2}\rho^{-1}(|x-x_0|^2 - \rho^2), & N = 1. \end{cases}$$

One can easily verify that

$$G(|x-x_0|;\rho)|_{\partial B_\rho(x_0)} = 0$$

and that

$$DG(|x-x_0|;\rho) \cdot \frac{x-x_0}{\rho}|_{\partial B_\rho(x_0)} = 0.$$

Moreover,

$$0 \leq G(|x-x_0|;\rho) \leq \begin{cases} |x-x_0|^{2-N} - \rho^{2-N}, & N \geq 3, \\ \ln\rho - \ln|x-x_0|, & N = 2, \\ \rho - |x-x_0|, & N = 1. \end{cases}$$

By direct calculation,

$$\Delta G(|x-x_0|;\rho)=\begin{cases} -\omega_N(N-2)\delta_{x_0}+N(N-2)\rho^{-N}, & N\geq 3,\\ -2\pi\delta_{x_0}+2\rho^{-2}, & N=2,\\ -2\delta_{x_0}+\rho^{-1}, & N=1,\end{cases}$$

where ω_N is the area of the unit sphere in $\mathbb{R}^N$ and δ_{x_0} is the Dirac delta measure with mass centered at x_0. Thus, for all $f\in C^2(\overline{B}_\rho(x_0))$,

$$\text{(52)}\qquad ⨍_{B_\rho(x_0)} f(x)dx = f(x_0)+C_N\int_{B_\rho(x_0)}\Delta f(x)G(|x-x_0|;\rho)dx,$$

where

$$C_N=\begin{cases}\dfrac{1}{\omega_N(N-2)}, & N\geq 3,\\ \dfrac{1}{2\pi}, & N=2,\\ \dfrac{1}{2}, & N=1.\end{cases}$$

Remark 3.3. Pointwise representations, such as (52), have been used by Gilding and Peletier (see [9]) in the context of the continuity of solutions to the porous-medium equation.

Suppose that u is a classical solution to (9) satisfying $u\leq M$. In (52), take $f(x)=\ln u(x,s)$. Then

$$\text{(53)}\qquad ⨍_{B_\rho(x_0)}\ln\frac{u(x,s)}{u(x_0,s)}dx = C_N\int_{B_\rho(x_0)} G(|x-x_0|;\rho)u_t(x,s)dx$$

for all $x_0\in\mathbb{R}^N$ and $s>0$.

From (39), the function

$$s\longrightarrow \ln\frac{u(x,s)}{s}$$

is decreasing. So, by integrating (53) from $\tau\leq s\leq t$,

$$\text{(54)}\qquad ⨍_{B_\rho(x_0)}\ln\frac{tu(x,\tau)}{\tau u(x_0,t)}dx\geq\frac{C_N}{t-\tau}\int_{B_\rho(x_0)}G(|x-x_0|;\rho)\int_\tau^t u_t(x,s)dsdx.$$

By appealing to Proposition 3.2 and selecting ρ so large so that

$$\frac{\rho^2}{\tau}>e,\quad\text{i.e.,}\quad \rho>\sqrt{e\tau},$$

we have, for $x\in B_\rho(x_0)$,

$$\text{(55)}\qquad \ln\frac{1}{u(x,\tau)}\leq\gamma(\epsilon)⨍_{B_{2\rho}(x_0)}\left(\ln\frac{1}{u(y,\tau)}\right)_+dy+(1+\epsilon)\ln\frac{\rho^2}{\tau}.$$

By combining this with (54), we arrive at the following proposition.

PROPOSITION 3.4. *There is a constant $\gamma(\epsilon)$, depending only on N and ϵ, such that, for all $x_0 \in \mathbb{R}^N$, $0 < \tau < t$, $\rho > \sqrt{e\tau}$, and $x \in B_\rho(x_0)$,*

$$\begin{aligned}\ln\frac{1}{u(x,\tau)} \le \frac{-\gamma(\epsilon)}{t-\tau}\int_{B_{2\rho}(x_0)} G(|y-x_0|;2\rho)\int_\tau^t u_t(y,s)ds dy\\ + \gamma(\epsilon)\ln\frac{Mt}{\tau u(x_0,t)} + (1+\epsilon)\ln\rho^2.\end{aligned} \tag{56}$$

Proof. By combining (54) and (55),

$$\begin{aligned}\ln\frac{1}{u(x,\tau)} &\le \frac{-\gamma}{t-\tau}\int_{B_\rho(x_0)} G(|y-x_0|;\rho)\int_\tau^t u_t(y,s)dsdy\\ &\quad + \gamma \fint_{B_{2\rho}(x_0)} (\ln u(y,\tau))_+ dy + (1+\epsilon)\ln\frac{\rho^2}{\tau} + \gamma\ln\frac{t}{\tau u(x_0,t)}\\ &\le \frac{-\gamma}{t-\tau}\int_{B_\rho(x_0)} G(|y-x_0|;\rho)\int_\tau^t u_t(y,s)dsdy\\ &\quad + \gamma\ln\frac{Mt}{\tau u(x_0,t)} + (1+\epsilon\ln\rho^2). \qquad \square\end{aligned}$$

3.3. Pointwise lower bounds. Starting from (56), we estimate

$$\begin{aligned}&-\frac{C_N}{t-\tau}\int_{B_{2\rho}(x_0)} G(|x-x_0|;2\rho)\int_\tau^t u_t(x,s)dsdx\\ &\le \frac{C_N}{t-\tau}\int_{B_{2\rho}(x_0)} G(|x-x_0|;2\rho)u(x,\tau)dx\\ &= I(x_0,\rho,t,\tau).\end{aligned}$$

With this notation and Proposition 3.4,

$$u(x,\tau) \ge \frac{1}{\rho^{2+2\epsilon}}\left(\frac{\tau u(x_0,t)}{Mt}\right)^\gamma e^{-\gamma I(x_0,\rho,t,\tau)} \tag{57}$$

for all

$$\rho \ge \sqrt{e\tau},$$

$x \in B_\rho(x_0)$, and $0 < \tau < t$. Note here that the constant γ still depends on ϵ.

Remark 3.5. If $u(x_0,t) > 0$, for some $x_0 \in \mathbb{R}^N$ and $t > 0$, then (57) guarantees that $u(x,\tau) > 0$ for all $x \in \mathbb{R}^N$ and all $0 < \tau < t$. This can be regarded as a global Harnack-type estimate.

3.4. Asymptotic behavior as $|x| \to \infty$: The case $N \ge 3$.

PROPOSITION 3.6. *Suppose that $N \ge 3$ and that u is a classical solution to* (9) *in $\mathbb{R}^N \times (0,T)$ satisfying* (39). *Suppose that, for some $0 < \tau < T$, $\alpha > 0$, $\gamma_0 > 0$, and $R > 0$,*

$$u(x,\tau) \le \frac{\gamma_0}{|x|^\alpha} \quad \textit{for } |x| > R. \tag{58}$$

Then

$$\lim_{\rho\to\infty}\int_{B_\rho} G(|x|;\rho)u(x,\tau)dx = \infty. \tag{59}$$

Proof. Let $R_0 < 0$ satisfy

$$\begin{cases} \ln\dfrac{R_0^2}{\tau} > 2\ln\dfrac{\gamma_0^{\frac{2}{\alpha}}}{\tau}, \\ R_0^\alpha > \gamma_0, \\ R_0 > \sqrt{e\tau}, \\ R_0 > R. \end{cases}$$

Notice here that R_0 depends on γ_0, α, R, and τ. Let $\rho > R_0$. Then

$$\begin{aligned} \fint_{B_{2\rho}} (\ln u(x,\tau))_- dx &\ge -\frac{\gamma}{\rho^N}\int_{\mathrm{Ann}(\rho;2\rho)} \ln u(x,\tau)dx \\ &\ge \gamma\left(\ln\frac{\rho^2}{\tau} - \ln\frac{\gamma_0^{\frac{2}{\alpha}}}{\tau}\right) \\ &\ge \gamma\ln\frac{\rho^2}{\tau}. \end{aligned}$$

Here

$$\mathrm{Ann}(\rho,2\rho) = \{x \in \mathbb{R}^N \mid \rho \le |x| \le 2\rho\}.$$

So, for $\rho > R_0$, there is a $\gamma_1 > 0$ not depending on ρ such that

$$\fint_{B_{2\rho}} (\ln u(x,\tau))_- dx \ge \gamma_1 \ln\frac{\rho^2}{\tau}.$$

Thus, from Proposition 3.2 with

$$\gamma \ge \max\left\{\gamma(1), \frac{2}{\gamma_1}\right\},$$

we have

$$-\inf_{B_\rho} \ln u(x,\tau) \le \gamma \fint_{B_{2\rho}} (\ln u(x,t))_- dx \tag{60}$$

for all $\rho > R_0$. This constant γ now depends on τ, N, α, R_0, and γ_0. Select t so that $\tau < t < T$. Then we can repeat the arguments beginning with equation (54) using (60) instead of (40). In so doing, we arrive at the following analogue of (57):

$$u(x,\tau) \ge \left(\frac{\tau u(0,t)}{Mt}\right)^\gamma e^{-\gamma I(0,\rho,t,\tau)} \tag{61}$$

for all $\rho > R_0$ and $|x| \le \rho$.

Now $I(0,\rho,t,\tau)$ is an increasing function of ρ. If (59) does not hold, then there is some constant C independent of ρ such that

$$u(x,\tau) \geq C\left(\frac{\tau u(0,t)}{Mt}\right)^{\gamma}$$

for all $x \in \mathbb{R}^N$. This contradicts (58). □

Remark 3.7. Proposition 3.6 is still true for $N = 1$ or 2. But, when $N = 1$ or 2, (59) is true for any $u(\cdot, t)$ unless $u(\cdot, t) = 0$ almost everywhere.

Assume that the initial data u_0 satisfies (34). In view of Proposition 2.6, the corresponding solution decays as $|x| \to \infty$ at least as fast as $|x|^{-2}$. Proposition 3.6 guarantees that $u(x,t)$, in some sense, decays no faster than $|x|^{-2}$. This is meant in the sense that a behavior of the type

$$u(x,\tau) \leq \frac{\gamma(\tau)}{(1+|x|^2)[\ln|x|]^{1+\epsilon}} \quad \text{for } |x| > 1$$

is impossible for any $\epsilon > 0$. Indeed, if behavior of this type did occur, then (58) would be satisfied, whereas (59) would not be satisfied for $0 < \tau < t$.

3.5. Asymptotic behavior as $|x| \to \infty$: The case $N = 2$. As can easily be checked,

$$\lim_{\rho\to\infty} \int_{B_\rho} \frac{G(|x-x_0|;\rho)}{(1+|x|^2)^k} dx = \infty \quad \text{for all } k > 0.$$

Thus, contrary to the case $N \geq 3$, there might exist solutions decaying faster than $|x|^{-2}$ as $|x| \to \infty$. Of course, this agrees with the explicit solution given by Example 1.2.

3.6. Some ill-posed problems for $N \geq 3$. Suppose that the initial data u_0 satisfies (34) and

$$\int_{\mathbb{R}^N} \frac{u_0(x)}{(1+|x|)^{N-2}} dx < \infty.$$

We claim that such a problem can have no solution satisfying (39). First, from Proposition 2.6, we know that any solution to (9) with initial data satisfying (34) must satisfy

$$u(x,t) \leq \frac{\gamma\left(t + t^{-\frac{N}{\kappa r}}|||u_0|||_r\right)^{\frac{2r}{\kappa r}}}{|x|^2}.$$

Now, if we had a solution in $\mathbb{R}^N \times (0,T)$ for some $T > 0$, then let $(x_0, t) \in \mathbb{R}^N \times (0,T)$ be a point such that $u(x_0,t) > 0$. Up to rescaling, we may assume that $u \leq 1$ in $\mathbb{R}^N \times (0,T)$. So $\ln u(x,t) \leq 0$. Then

$$\begin{aligned}\fint_{B_\rho(x_0)} \ln\frac{u(x_0,s)}{u(x,s)} dx &= \fint_{B_\rho(x_0)} \left(\ln\frac{u(x_0,s)}{s} + \ln s - \ln u(x,s)\right) dx \\ &\geq \ln\frac{u(x_0,s)}{s} + \ln s.\end{aligned}$$

Then, by applying (53) and integrating in ds from $0 < s < \tau$, we have

$$\begin{aligned}C_N \int_{B_\rho(x_0)} G(|x-x_0|;\rho) u(x,\tau) dx \leq C_N \int_{B_\rho(x_0)} & G(|x-x_0|;\rho) u_0(x) dx \\ &+ \tau(I - \ln u(x_0,\tau)).\end{aligned}$$

Thus

$$\lim_{\rho\to\infty}\int_{B_\rho(x_0)} G(|x-x_0|;\rho)u(x,\tau)dx < \infty$$

for all $0<\tau<t$. This, of course, contradicts Proposition 3.6. In particular, if $N\ge 3$ and $u_0\in C_0^\infty(\mathbb{R}^N)$, then (9) can have no classical solution satisfying (39). A weaker result, that (9) can have no solution when $u_0\in L^1(\mathbb{R}^N)N\ge 3$, appears in [14].

4. Finite extinction time. In this section, we examine classical solutions of (9) with a finite extinction time, i.e., solutions which become identically zero at some time T. In particular, we find sufficient conditions on the initial data to guarantee a finite extinction time. In addition, we find an upper bound for this extinction time. We have several examples of solutions with finite extinction times. See Examples 1.1, 1.3, and 1.5.

THEOREM 4.1. *Let $N\ge 3$ and $u_0\in L^{\frac{N}{2}}(\mathbb{R}^N)$. Then if u is a classical solution to (9) there is a $T>0$ such that $u(x,T)=0$ for all $x\in\mathbb{R}^N$. Furthermore,*

$$T\le\gamma(N)\|u_0\|_{\frac{N}{2},\mathbb{R}^N}.$$

Proof. Let $\zeta\in C_0^\infty(B_{2\rho})$ satisfy

$$\begin{cases} 0\le\zeta\le 1 & \text{in } B_{2\rho},\\ \zeta=1 & \text{in } B_\rho,\\ |D\zeta|^2, |\Delta\zeta|\le\dfrac{\gamma}{\rho^2} & \text{in } B_{2\rho}.\end{cases}$$

Multiply the first term of (9) by the test function $u^r\zeta^2$.

$$\begin{aligned} 0 &= \int_{\mathbb{R}^N}(u_t-\Delta\ln u)u^r\zeta^2dx\\ &= \frac{1}{r+1}\frac{d}{dt}\left[\int_{\mathbb{R}^N}u^{r+1}\zeta^2dx\right]+\int_{\mathbb{R}^N}\frac{Du}{u}(ru^{r-1}Du\zeta^2+2u^r\zeta D\zeta)dx \qquad (62)\\ &= T_1+T_2+T_3. \end{aligned}$$

$$\begin{aligned} T_2 &= \int_{\mathbb{R}^N}|Du|^2u^{r-2}\zeta^2dx\\ &\ge\frac{4}{r}\int_{\mathbb{R}^N}|D[u^{\frac{r}{2}}\zeta]|^2dx-\frac{\gamma}{\rho^2}\int_{\mathrm{An}(\rho,2\rho)}u^rdx. \end{aligned}\tag{63}$$

Here $\mathrm{An}(\rho,2\rho)=\{x\in\mathbb{R}^N\,|\,\rho\le|x|\le 2\rho\}$.

$$\begin{aligned} T_3 &= \int_{\mathbb{R}^N}Duu^{r-1}\zeta D\zeta dx\\ &= \frac{1}{r}\int_{\mathbb{R}^N}Du^r\zeta D\zeta dx\\ &= -\frac{1}{r}\int_{\mathbb{R}^N}u^r(\zeta\Delta\zeta+|D\zeta|^2)dx. \end{aligned}\tag{64}$$

From (62)–(64), we obtain

$$\frac{d}{dt}\left[\int_{\mathbb{R}^N}u^{r+1}\zeta^2dx\right]+\int_{\mathbb{R}^N}|D[u^{\frac{r}{2}}\zeta]|^2dx\le\frac{\gamma}{\rho^2}\int_{\mathrm{An}(\rho,2\rho)}u^rdx.\tag{65}$$

Since ζ vanishes on the boundary of $B_{2\rho}$, we can apply the Sobolev Embedding Theorem, i.e.,

$$\gamma(N,r)\left(\int_{B_{2\rho}}[u^{\frac{r}{2}}\zeta]^{\frac{2N}{N-2}}dx\right)^{\frac{N-2}{N}} \leq \int_{B_{2\rho}}|D[u^{\frac{r}{2}}\zeta]|^2dx. \tag{66}$$

Thus, with $r = \frac{N-2}{2}$,

$$\gamma(N)\left(\int_{B_{2\rho}}u^{\frac{N}{2}}\zeta^{\frac{2N}{N-2}}dx\right)^{\frac{N-2}{N}} \leq \int_{B_{2\rho}}|D[u^{\frac{r}{2}}\zeta]|^2dx. \tag{67}$$

From (65)–(67),

$$\frac{d}{dt}\left[\int_{B_{2\rho}}u^{\frac{N}{2}}\zeta^2dx\right] + \gamma_0\left[\int_{B_{2\rho}}u^{\frac{N}{2}}\zeta^{\frac{2N}{N-2}}dx\right]^{\frac{N-2}{N}} \leq \frac{\gamma}{\rho^2}\int_{\mathrm{An}(\rho,2\rho)}u^{\frac{N-2}{2}}dx.$$

By Hölder's inequality,

$$\int_{\mathrm{An}(\rho,2\rho)}u^{\frac{N-2}{2}}dx \leq \gamma\rho^2\left(\int_{\mathrm{An}(\rho,2\rho)}u^{\frac{N}{2}}dx\right)^{\frac{N-2}{N}}.$$

Thus

$$\frac{d}{dt}\left[\int_{B_{2\rho}}u^{\frac{N}{2}}\zeta^2dx\right] + \gamma(N)\left[\int_{B_{2\rho}}u^{\frac{N}{2}}\zeta^{\frac{2N}{N-2}}dx\right]^{\frac{N-2}{N}} \geq \gamma\left[\int_{\mathrm{An}(\rho,2\rho)}u^{\frac{N}{2}}dx\right]^{\frac{N-2}{N}}.$$

From Proposition 2.2, if $u_0 \in L^{\frac{N}{2}}(\mathbb{R}^N)$ then $u(\cdot,t) \in L^{\frac{N}{2}}(\mathbb{R}^N)$ for each $t > 0$. Thus, by letting $\rho \to \infty$, we have

$$\frac{df}{dt} + \gamma(N)f^{\frac{N-2}{N}} \leq 0,$$

where

$$f(t) = \int_{\mathbb{R}^N}u^{\frac{N}{2}}(x,t)dx.$$

As long as $f > 0$, this imples

$$f^{\frac{2}{N}}(t) \leq f^{\frac{2}{N}}(0) - \gamma(N)t.$$

Thus we have

$$u(\cdot,t) = 0 \quad \text{if} \quad t \geq \gamma(N)\|u_0\|_{\frac{N}{2},\mathbb{R}^N}.$$

This is the desired result. □

Theorem 4.1 is sharp in the sense that no theorem of this type is possible for $L^r(\mathbb{R}^N)$ for any $r > \frac{N}{2}$. To see this, let $0 < \alpha < 2$, and consider the following initial datum:

$$u_0(x) = \frac{1}{1+|x|^\alpha}.$$

For a wise choice of α, $u_0 \in L^r(\mathbb{R}^N)$ for some fixed $r > \frac{N}{2}$. Choose $\beta > \frac{2}{2-\alpha}$. By Young's inequality, we can show that there is a $C > 0$, depending only on α, β, and N, such that, for any $T > C$,

$$\frac{2(N-2)T}{T^\beta + |x|^2} \leq u_0(x).$$

For $T > C$, consider the explicit solution (see Example 1.5)

$$u_T(x,t) = \frac{2(N-2)(T-t)_+^{\frac{N}{N-2}}}{T^{\beta+\frac{2}{N-2}} + (T-t)_+^{\frac{2}{N-2}}|x|^2}.$$

Then

$$\begin{aligned} u_T(x,0) &= \frac{2(N-2)T}{T^\beta + |x|^2} \\ &\leq u_0(x). \end{aligned}$$

This implies that for each $T > C$ there exists a classical solution to (9) with initial data $u_0(x) = \frac{1}{1+|x|^\alpha}$ which does not vanish at least until time T. Theorem 4.1, however, is not entirely satisfactory because it does not predict an extinction time for the solutions given by Example 1.5.

ON THE DIRICHLET BOUNDARY VALUE PROBLEM FOR A DEGENERATE PARABOLIC EQUATION*

T. KILPELÄINEN[†] AND P. LINDQVIST[‡]

Abstract. The Perron method for degenerate parabolic equations like $u_t = \operatorname{div}(|\nabla u|^{p-2}\nabla u)$ is studied. The regular boundary points for the Dirichlet problem are characterized in terms of barriers. In the particular case of the space–time cylinder $G \times (0, T)$, a geometric characterization in terms of a Wiener-type test is given for regularity.

Key words. parabolic p-Laplacian, the Perron method, regular boundary points

AMS subject classifications. 35K65, 35K60, 31C45

1. Introduction.

It was observed by Sternberg in 1929 that the method developed by Perron [Pn] for solving the Dirichlet boundary value problem for the Laplace equation can readily be extended to the heat equation. It is nowadays well known that the Perron method applies to linear parabolic equations; cf. [F]. In this paper, we study potential theoretic aspects of certain nonlinear parabolic equations; one of our aims is to adapt the Perron method. The typical example that we have in mind is the p-parabolic equation

$$\frac{\partial u}{\partial t} = \operatorname{div}(|\nabla u|^{p-2}\nabla u),$$

where $1 < p < \infty$. This equation is degenerate when $2 < p < \infty$ and singular when $1 < p < 2$. For the regularity theory of such equations, the reader is asked to consult the recent monograph by DiBenedetto [DB].

In the elliptic case, the study of nonlinear potential theory of quasi-linear equations of the type

$$\operatorname{div}(|\nabla u|^{p-2}\nabla u) = 0$$

was initiated by Granlund, Lindqvist, and Martio in a series of papers, of which we mention only [GLM]. An account of the elliptic nonlinear potential theory is given in the monograph [HKM]. Needless to say, some parts of elliptic theory can be carried over to the parabolic situation as such, while for others, parabolic proofs present new difficulties.

In order to keep the presentation within reasonable limits, we have made a few simplifying assumptions. The most noteworthy of them is that we treat the Perron method only for bounded boundary values; this is not a serious restriction. We have not included all of our results in this short outline; for example, the counterpart to the celebrated condition of Petrowsky will be published elsewhere. On the other hand, there are some basic questions that we have not been able to answer yet. One urgent open problem is the parabolic counterpart to Wiener's resolutivity theorem; see [W, Thm. 32, p. 290] for the heat equation.

The paper is organized as follows. Section 2 is merely a discussion about the choice of equations and the admissible extensions for the theory. Section 3 contains

*Received by the editors June 15, 1994; accepted for publication October 3, 1994.

basic definitions and expedient existence theorems. The p-superparabolic functions are introduced in §4. Finally, §5 contains the Perron method; barriers and regularity are discussed in §6.

2. Discussion. A genuine nonlinear parabolic potential theory should include equations like

$$\text{(I)} \qquad \frac{\partial u}{\partial t} = \operatorname{div}(|\nabla u|^{p-2}\nabla u),$$

$$\text{(II)} \qquad \frac{\partial u}{\partial t} = \Delta(|u|^{m-1}u),$$

and

$$\text{(III)} \qquad \frac{\partial(|u|^{p-2}u)}{\partial t} = \operatorname{div}(|\nabla u|^{p-2}\nabla u).$$

They reduce to the ordinary heat equation $u_t = \Delta u$ for $p = 2$ and $m = 1$. On the other hand, they all are special cases[1] of equations of the type

$$\frac{\partial u}{\partial t} = \operatorname{div}(|u|^{m-1}|\nabla u|^{p-2}\nabla u),$$

and so one would be led to construct a potential theory for a wide class of equations

$$\frac{\partial u}{\partial t} = \operatorname{div}\mathcal{A}(x, t, u, \nabla u).$$

In order to keep the presentation short and direct, we have modeled our approach according to equations of the p-parabolic type

$$\frac{\partial u}{\partial t} = \operatorname{div}\mathcal{A}_p(x, t, \nabla u),$$

where $\mathcal{A}_p(x,t,w) \approx |w|^{p-2}w$ and $1 < p < \infty$. This has the advantage that constants can be added to solutions. The precise assumptions about $\mathcal{A}_p$ are listed in the beginning of §3.

It is worth mentioning that, from a potential theoretic point of view, the third equation seems to be the most natural one, for there solutions can be multiplied with constants. As Trudinger has pointed out in [T, p. 225], the parabolic Harnack inequality holds for equation (III) in the same form as it does for the ordinary heat equation; see [M]. This is not the case for the p-parabolic equation (I); its Harnack estimate needs an *intrinsic* formulation depending on the solution in question; cf. [DB]. One of the reasons for basing our approach on the usual p-parabolic equation, rather than on its homogeneous variant, is that disturbances propagate, as it were, with infinite speed for the latter equation, while the p-parabolic equation enjoys the finite-speed propagation property when $p > 2$ but not when $1 < p \leq 2$. For $1 < p < 2$, there is an extinction phenomenon. We have favored this diversity. (See the note added in proof on p. 682.)

To give the reader a feeling for this fascinating phenomenon, we mention the fundamental solution obtained by Barenblatt in 1952 [B]. The Barenblatt solution to the p-parabolic equation (I) is

$$\mathcal{B}_p(x,t) = t^{-\frac{n}{\lambda}} \left(C - \frac{p-2}{p}\lambda^{\frac{1}{1-p}} \left(\frac{|x|}{t^{1/\lambda}} \right)^{\frac{p}{p-1}} \right)_+^{\frac{p-1}{p-2}}.$$

[1] Substitute $v = |u|^{p-2}u$ in (III).

It is defined for $x \in \mathbf{R}^n$ and $t > 0$ and is compactly supported in x. Here $p > 2$ and $\lambda = n(p-2)+p$. The constant C is usually chosen so that

$$\int \mathcal{B}_p(x,t)\,dx = 1,$$

i.e., so that $\mathcal{B}_p(x, 0+) = \delta(x)$, the Dirac delta function. When $p \to 2+$ this approaches the ordinary heat kernel,

$$\frac{1}{(4\pi t)^{n/2}} e^{-\frac{|x|^2}{4t}}.$$

However, the Barenblatt solution to the equation (III) is

$$\mathcal{W}_p(x,t) = Ct^{-\frac{n}{p(p-1)}} \exp\left(-\frac{p-1}{p}\left(\frac{|x|^p}{pt}\right)^{\frac{1}{p-1}}\right),$$

$1 < p < \infty$. It does not have a bounded support.[2]

Another point is that, if u is a solution to equation (III), then the function $v = |u|^k$ is a subsolution to the same equation when $p \geq 2$ and $k \geq 1$. Unfortunately, the corresponding situation is not that simple for equation (I).[3]

3. Solutions and supersolutions. Let us start by giving the precise assumptions about the structure of the equation

$$\frac{\partial u}{\partial t} = \operatorname{div}\mathcal{A}(x,t,\nabla u), \tag{3.1}$$

where $1 < p < \infty$ and $(x,t) \in \Omega$, Ω denoting a domain in $\mathbf{R}^n \times \mathbf{R}$. The solutions are understood in the weak sense, $u = u(x,t)$, and

$$\nabla u = \left(\frac{\partial u}{\partial x_1}, \ldots, \frac{\partial u}{\partial x_n}\right)$$

is the spatial gradient of u. The mapping

$$\mathcal{A} : \mathbf{R}^n \times \mathbf{R} \times \mathbf{R}^n \to \mathbf{R}^n$$

is assumed to satisfy the following conditions:

[2] While the solution $\mathcal{B}_p$ can be normalized so that

$$\int \mathcal{B}_p(x,t)\,dx = 1$$

for each $t > 0$, this is impossible to achieve for $\mathcal{W}_p$ when $p \neq 2$. The conservation law here is

$$\int \mathcal{W}_p(x,t)^{p-1}\,dx = 1$$

for all $t > 0$.

[3] In this respect, the "artificial equation"

$$\left|\frac{\partial u}{\partial t}\right|^{p-2}\frac{\partial u}{\partial t} = \operatorname{div}(|\nabla u|^{p-2}\nabla u),$$

not mentioned above, would be the most favorable.

(A) The mapping $(x,t) \mapsto \mathcal{A}(x,t,\xi)$ is measurable for all $\xi \in \mathbf{R}^n$, and the mapping $\xi \mapsto \mathcal{A}(x,t,\xi)$ is continuous for a.e. $(x,t) \in \mathbf{R}^n \times \mathbf{R}$.

(B) There are constants $0 < \alpha \leq \beta < \infty$ such that

$$\alpha|\xi|^p \leq \mathcal{A}(x,t,\xi) \cdot \xi \leq \beta|\xi|^p$$

for all $\xi \in \mathbf{R}^n$ and a.e. $(x,t) \in \mathbf{R}^n \times \mathbf{R}$.

(C) For a.e. $(x,t) \in \mathbf{R}^n \times \mathbf{R}$,

$$(\mathcal{A}(x,t,\xi) - \mathcal{A}(x,t,\zeta)) \cdot (\xi - \zeta) > 0$$

whenever $\xi \neq \zeta$ and $\xi, \zeta \in \mathbf{R}^n$.

It is sufficient that $\mathcal{A}$ is defined in $\Omega \times \mathbf{R} \times \mathbf{R}^n$. The role of (A) is merely to guarantee that composite functions like $\mathcal{A}(x,t,\nabla u(x,t))$ are measurable. Condition (C) implies uniqueness. For the p-Laplacian, the stronger inequality

$$\left(|\xi|^{p-2}\xi - |\zeta|^{p-2}\zeta\right) \cdot (\xi - \zeta) \geq 2^{1-p}|\xi - \zeta|^p$$

is valid for $p \geq 2$, and the inequality

$$\left(|\xi|^{p-2}\xi - |\zeta|^{p-2}\zeta\right) \cdot (\xi - \zeta) \geq (p-1)|\xi - \zeta|^2 \frac{|\xi|^{p-2} + |\zeta|^{p-2}}{2}$$

holds for $1 < p \leq 2$.

The solutions to equation (3.1) are functions in a local parabolic Sobolev space satisfying

$$\iint_{\Omega} \left(-u\frac{\partial \varphi}{\partial t} + \mathcal{A}(x,t,\nabla u) \cdot \nabla \varphi\right) dt\, dx = 0$$

for all test functions $\varphi \in C_0^1(\Omega)$. The a priori assumptions on u are the same as those in the definition below. It is essential that the time derivative u_t does not appear explicitly in the definition, for u_t is merely a distribution.

From now on, we shall, for instructional purposes, state the definitions and results only for the important p-parabolic equation. The general case is readily interpreted from this. The only exception is the explicit barrier constructed in §6.2, where the more general case is technically harder.

In what follows, Q will always stand for a parallelepiped

$$Q = (a_1, b_1) \times (a_2, b_2) \times \cdots \times (a_n, b_n)$$

in $\mathbf{R}^n$, and the space–time sets

$$Q_T = Q \times (0,T), \quad Q_{t_1,t_2} = Q \times (t_1, t_2)$$

in $\mathbf{R}^n \times \mathbf{R}$ are called "boxes." In order to describe the appropriate function space, we introduce the abbreviation

$$V^p(t_1,t_2;Q) = C(t_1,t_2;L^2(Q)) \cap L^p(t_1,t_2;W^{1,p}(Q)).$$

Thus $u \in V^p(t_1,t_2;Q)$ means that the mapping

$$t \mapsto \int_Q |u(x,t)|^2\, dx$$

is continuous in $[t_1, t_2]$, the Sobolev derivative

$$\nabla u(x,t) = \left(\frac{\partial u(x,t)}{\partial x_1}, \dots, \frac{\partial u(x,t)}{\partial x_n}\right)$$

exists for a.e. $t \in [t_1, t_2]$, and

$$\int_{t_1}^{t_2} \left(\int_Q |\nabla u(x,t)|^p \, dx\right) dt < \infty.$$

In particular, the energy

$$\int_{t_1}^{t_2} \int_Q (|u|^2 + |\nabla u|^p) \, dx \, dt$$

is finite.

DEFINITION. *Let Ω be a domain in $\mathbf{R}^n \times \mathbf{R}$ and suppose that u belongs to $V^p(t_1, t_2; Q)$ whenever the closure of $Q \times (t_1, t_2)$ is contained in Ω. Then u is called a* solution *in Ω of the p-parabolic equation*

$$\frac{\partial u}{\partial t} = \operatorname{div}(|\nabla u|^{p-2} \nabla u) \tag{3.2}$$

if

$$\iint_\Omega (- u\varphi_t + |\nabla u|^{p-2} \nabla u \cdot \nabla \varphi) \, dt \, dx = 0$$

whenever $\varphi \in C_0^1(\Omega)$. If , in addition, u is continuous, then u is called p-parabolic *in Ω. Further, we say that u is a* supersolution *to* (3.2) *if the above integral is nonnegative whenever $\varphi \in C_0^1(\Omega)$ is nonnegative. A function v is a* subsolution *to* (3.2) *if $-v$ is a supersolution.*

By parabolic regularity theory, each locally bounded solution of (3.2) has a p-parabolic representative; for $1 < p < 2n/(2 + n)$, there are solutions that are not locally bounded (see [DB]). (In the pure p-parabolic case, even the spatial gradient ∇u, but not u_t, is Hölder continuous cf. [DB]. This is not true for solutions of the general equation (3.1). We shall not use this feature in what follows.) We will need a quantitative Hölder estimate. If u is p-parabolic in Ω and Ξ is a subdomain with compact closure in Ω, then the *interior Hölder estimate* has the form

$$|u(x, t_1) - u(y, t_2)| \le \gamma ||u||_{\infty,\Omega} (|x - y|^\alpha + |t_1 - t_2|^{\alpha/p}) \tag{3.3}$$

when (x, t_1), $(y, t_2) \in \Xi$. Here the positive exponent α depends only on n and p, while the constant γ depends, in addition, on the distance between Ξ and $\partial\Omega$, see [DB].

There is a principal, well-recognized difficulty with the definition. Namely, in proving any useful estimates, one usually needs a test function φ that depends on the solution u itself, for example, $\varphi = u\eta$, where η is a smooth function. Then the time derivative would contain u_t, but u_t does not necessarily exist as a function, so that φ is not, strictly speaking, admissible. This difficulty can be treated in two different ways: The first option is to use an equivalent definition in terms of Steklov averages as in [DB, pp. 18 and 25]. Second, one can proceed using convolutions of u with smooth mollifiers as in [AS, pp. 119–121]. Whichever the approach, the outcome is virtually the same as if the "forbidden" quantity u_t had been used at the intermediate stages, yet eliminated from the final formulation of the estimates. This remark concerns our proof of Lemma 3.1.

The parabolic boundary plays a crucial role for the Dirichlet boundary value problem. The *parabolic boundary* of $Q_T = Q \times (0,T)$ is

$$\Gamma_T = (\overline{Q} \times \{0\}) \cup (\partial Q \times (0,T]).$$

It consists of the bottom and the lateral sides, but the interior points of the top are excluded. A main feature, distinguishing the parabolic theory from the elliptic one, is that the p-parabolic functions are uniquely determined by their values on the parabolic boundary.

Often it is convenient to use test functions that vanish only on the parabolic boundary of Q_T. If φ is such a test function, then

$$-\int_Q u(x,T)\varphi(x,T)\,dx + \int_0^T \int_Q \big(- u\varphi_t + |\nabla u|^{p-2}\nabla u \cdot \nabla\varphi\big)\,dx\,dt = 0,$$

if u is p-parabolic. This follows easily from the definition by taking $\varphi\eta_\varepsilon$ as the test function, where η_ε is the usual cutoff function that depends only on t. In other words, η_ε is piecewise linear, $0 \le \eta_\varepsilon \le 1$, $\eta_\varepsilon(t) = 1$ for $t \le T-\varepsilon$, $\eta_\varepsilon(T) = 0$, and $|\eta_\varepsilon'(t)| \le 1/\varepsilon$.

We have a preliminary version of the comparison principle.

LEMMA 3.1. *Suppose that u is a supersolution and v a subsolution to* (3.2) *in $Q_T = Q \times (0,T)$. If u and $-v$ are lower semicontinuous on $\overline{Q}_T$ and $v \le u$ on the parabolic boundary of Q_T, then $v \le u$ a.e. in the box Q_T.*

Proof.[4] If $\varphi \in C_0^1(Q_T)$ is nonnegative, then

$$\int_0^T \int_Q \big(- u\varphi_t + |\nabla u|^{p-2}\nabla u \cdot \nabla\varphi\big)\,dx\,dt \ge 0$$

and

$$\int_0^T \int_Q \big(v\varphi_t - |\nabla v|^{p-2}\nabla v \cdot \nabla\varphi\big)\,dx\,dt \ge 0,$$

so that by adding them we have

$$\int_0^T \int_Q \big((v-u)\varphi_t + (|\nabla u|^{p-2}\nabla u - |\nabla v|^{p-2}\nabla v)\cdot\nabla\varphi\big)\,dx\,dt \ge 0.$$

Moreover, these inequalities remain true if u is replaced by $u + \varepsilon$, where ε is any constant.

To complete the proof we choose (formally) the test function φ to be

$$\varphi = (v - u - \varepsilon)_+\eta,$$

where $0 < \varepsilon < T$ is fixed and

$$\eta(t) = \begin{cases} \dfrac{T-\varepsilon-t}{T-\varepsilon} & \text{if } t \le T-\varepsilon, \\ 0 & \text{if } t \ge T-\varepsilon. \end{cases}$$

[4] In the case of two solutions with finite energies (they belong to $V^p(0,T;Q)$), a proof based on Steklov averages is given in [DB, Chap. VI, Lem. 3.1, pp. 160–161].

Then φ has compact support and we refer to the discussion above to justify the use of the time derivative of $(v-u-\varepsilon)_+$ in the calculations. Integrating by parts, we obtain

$$\begin{aligned}
&\int_0^T \int_{\{v\geq u+\varepsilon\}} \eta(|\nabla u|^{p-2}\nabla u - |\nabla v|^{p-2}\nabla v)\cdot(\nabla u - \nabla v)\,dx\,dt \\
&\leq \int_Q \int_0^T (v-u-\varepsilon)_+^2 \eta'\,dt\,dx + \frac{1}{2}\int_Q\int_0^T \eta\frac{\partial}{\partial t}(v-u-\varepsilon)_+^2\,dt\,dx \\
&= \frac{1}{2}\int_Q\int_0^T (v-u-\varepsilon)_+^2\eta'\,dt\,dx \\
&= -\frac{1}{2(T-\varepsilon)}\int_Q\int_0^{T-\varepsilon}(v-u-\varepsilon)_+^2\,dt\,dx \leq 0.
\end{aligned}$$

Since the first integral is nonnegative by the structural inequalities, we have that the last integral is zero, and hence $(v-u-\varepsilon)_+ = 0$ a.e. But this means that

$$v \leq u + \varepsilon$$

a.e. when $0 \leq t \leq T-\varepsilon$. Since $\varepsilon > 0$ was arbitrary, we have the desired inequality $v \leq u$ a.e. in Q_T. □

Remark. The above proof shows that a supersolution u is greater than a subsolution v on Q_T if $v(x,0) \leq u(x,0)$ and for each $t \in (0,T)$ the function $x \mapsto (v(x,t)-u(x,t))_+$ is in the Sobolev space $W_0^{1,p}(Q)$.

We shall need a basic existence theorem.[5]

LEMMA 3.2. *Suppose that θ is a continuous function on $\overline{Q}_T$. Then there is a unique p-parabolic function u that is continuous in $\overline{Q}_T$ and takes the boundary values $u=\theta$ on the parabolic boundary Γ_T. Moreover, if θ belongs to $V^p(0,T;Q)$, so does u.*

Proof. See [AL, Thm. 1.7, p. 318] or [L, pp. 162 and 166]. □

Remark 3.1. Using Lemma 3.2 repeatedly, one easily extends the existence result: *Suppose that Ω is a union of finitely many boxes*

$$Q_i \times (t_i, T_i)$$

and that θ is a continuous function on the parabolic boundary Γ of Ω. Then there is a unique p-parabolic function u, continuous on $\overline{\Omega}$, that coincides with θ on Γ. To verify this, one just has to begin with the earliest boxes. Here the parabolic boundary Γ is understood to be that part of the Euclidean boundary $\partial\Omega$ of Ω that lies in the union of the parabolic boundaries of the boxes $Q_i \times (t_i, T_i)$.

The obstacle problem is of fundamental importance to the nonlinear potential theory. Roughly speaking, one is looking for smallest supersolutions that lie above a given function ψ. Again we require an existence theorem for the box Q_T.

LEMMA 3.3. *Suppose that $\psi \in C^\infty(\overline{Q}_T)$ is given. Consider the class of all functions $v \in V^p(0,T;Q)$, continuous in $\overline{Q}_T$, such that $v \geq \psi$ in Q_T and $v = \psi$*

[5] In the recent literature, existence theorems are usually formulated for the Cauchy problem in $\mathbf{R}^n \times (0,T]$ or $\mathbf{R}^n \times (0,\infty)$; cf. [EV], [KV]. These results cannot easily be adapted to Q_T. A new existence proof should be constructed on the basis of the a priori estimates in [DB], but, to keep the presentation short, we give direct, though not quite adequate, references.

on the parabolic boundary Γ_T. Then there is a unique supersolution u in this class satisfying

$$\int_0^T \int_Q (v_t(v-u) + |\nabla u|^{p-2}\nabla u \cdot (\nabla v - \nabla u))\,dx\,dt$$

$$\geq \frac{1}{2}\int_Q |\psi(x,T) - u(x,T)|^2\,dx$$

for all smooth functions v in the aforementioned class.

Proof. See [AL, Thm. 3.2]. (To ensure that u is continuous, even when $t = T$, one may solve the problem in a slightly larger box, say $Q_{T+\varepsilon}$, $\varepsilon > 0$.) □

The unique supersolution given by the previous lemma is called *the solution to the obstacle problem.* It is p-parabolic in the set $\{u > \psi\}$.

The uniform Hölder estimate combined with the basic existence theorem leads to a convergence result.

LEMMA 3.4. *Suppose that u_k is a locally uniformly bounded sequence of p-parabolic functions in Ω. Then it has a subsequence that converges locally uniformly in Ω to a p-parabolic function.*

Proof. Let Ξ be a subdomain with compact closure in Ω. By the interior Hölder estimate (3.3), the sequence u_k is equicontinuous in $\overline{\Xi}$. Hence Ascoli's theorem allows us to select a subsequence that converges uniformly on Ξ to a continuous function. Exhausting Ω by an increasing sequence of such domains Ξ and performing a standard diagonalization process, we find a subsequence, denoted again by u_k, that converges locally uniformly in Ω to a continuous function, say h.

It sufficies to show that h is p-parabolic in each box $Q_{t_1,t_2} = Q \times (t_1, t_2)$ with closure in Ω. To this end, let H be the p-parabolic function in Q_{t_1,t_2}, continuous in $\overline{Q}_{t_1,t_2}$, taking the boundary values $H = h$ on the parabolic boundary Γ_{t_1,t_2} of Q_{t_1,t_2} (Lemma 3.2). Let $\varepsilon > 0$. For sufficiently large indices, we have

$$H - \varepsilon = h - \varepsilon < u_k < h + \varepsilon = H + \varepsilon$$

on Γ_{t_1,t_2}. Hence, by the comparison principle (Lemma 3.1),

$$H - \varepsilon \leq u_k \leq H + \varepsilon$$

in Q_{t_1,t_2}, so that

$$H - \varepsilon \leq h \leq H + \varepsilon$$

in Q_{t_1,t_2}. In conclusion, $h = H$ and hence h is p-parabolic. □

Remark 3.2. If $h_1 \leq h_2 \leq \cdots$ are p-parabolic in Q_T and

$$p > \frac{2n}{n+1},$$

then there are three possible alternatives for the limit function $h = \lim_{k\to\infty} h_k$:

(1) $h \equiv \infty$;

(2) h is p-parabolic in Q_T; and

(3) there is $\tau \in (0, T)$ such that h is p-parabolic in Q_τ, while $h(x,t) = \infty$ when $\tau < t \leq T$.

This result is obtained by using the intrinsic Harnack estimate [DB, pp. 157 and 184].

4. p-superparabolic functions. The supersolutions to equation (3.2) do not form a good closed class. In particular, the Barenblatt solutions

$$\mathcal{B}_p(x,t) = \begin{cases} t^{-\frac{n}{\lambda}}\left(C - \dfrac{p-2}{p}\lambda^{\frac{1}{1-p}}\left(\dfrac{|x|}{t^{1/\lambda}}\right)^{\frac{p}{p-1}}\right)_+^{\frac{p-1}{p-2}}, & t > 0, \\ 0, & t \leq 0, \end{cases}$$

where $\lambda = n(p-2)+p$, $p > 2$, and C is a real constant, are not supersolutions in any domain containing the origin $(0,0)$. It is the a priori integrability that fails to hold. In the elliptic theory an appropriate class, closed under monotone convergence, is provided by superharmonic functions. We study an analogous definition in this parabolic setting.

DEFINITION 4.1. *A function $u\,\Omega \to (-\infty, \infty]$ is called* p-superparabolic *if*

(i) *u is lower semicontinuous,*

(ii) *u is finite in a dense subset of Ω,*

(iii) *u satisfies the comparison principle on each box $Q_{t_1,t_2} = Q \times (t_1, t_2)$ with closure in Ω: if h is p-parabolic in Q_{t_1,t_2} and continuous on $\overline{Q}_{t_1,t_2}$ and if $h \leq u$ on the parabolic boundary of Q_{t_1,t_2}, then $h \leq u$ in the whole Q_{t_1,t_2}.*

The simplest interesting example is perhaps

$$u(x,t) = \begin{cases} 0 & \text{when } t \leq 0, \\ 1 & \text{when } t > 0. \end{cases}$$

This definition is the same as that used by Gehring [G] and Friedman [F] in their linear theory. The original definition of Sternberg used trapezoids; cf. [S]. Watson [W] has a different definition based on a representation formula, a counterpart to the Poisson formula, with "heat balls" playing the role of fundamental domains. All of these variants result in the same concept. To see this in our nonlinear theory, we will later prove that (iii) can be weakened considerably.

Let Ξ be any domain with compact closure in Ω. If h is p-parabolic in Ξ and continuous in $\overline{\Xi}$ and if $h \leq u$ on the (Euclidean) boundary $\partial\Xi$, then $h \leq u$ in the whole Ξ.

It is easy to see that (iii) implies this. It is clear if Ξ is a box, and it easily follows for a union of finitely many boxes. The case where Ξ is arbitrary is verified by covering the set where $h \geq u + \varepsilon$, $\varepsilon > 0$, with finitely many boxes. It is less obvious that the comparison property above will imply (iii). We will return to this question in Lemma 6.3.

It is immediately seen from the definition that if u and v are p-superparabolic in Ω, then so are the minimum $\min(u,v)$ and the functions $\lambda u + \mu$, where $\lambda \geq 0$ and $\mu \in \mathbf{R}$ are constants.

The result below implies that a proper version of a supersolution is p-superparabolic; in particular, the Barenblatt solution is p-superparabolic in the whole $\mathbf{R}^n \times (-\infty, \infty)$.

LEMMA 4.2. *If u is a lower semicontinuous supersolution to the p-parabolic equation (3.2) in Ω, then there is a p-superparabolic function v in Ω, defined by*

$$v(x,t) = \operatorname{ess} \liminf_{(y,s)\to(x,t)} u(y,s), \tag{4.1}$$

$(x,t) \in \Omega$, such that $v = u$ a.e. in Ω. In particular, if u is continuous, then u is p-superparabolic.

Proof. Since u is lower semicontinuous,

$$u(x,t) \leq \liminf_{(y,s)\to(x,t)} u(y,s) \leq \operatorname{ess} \liminf_{(y,s)\to(x,t)} u(y,s) = v(x,t)$$

for each $(x,t) \in \Omega$, whereas

$$u(x,t) = \lim_{r\to 0} \frac{1}{2r|B(x,r)|} \int_{t-r}^{t+r} \int_{B(x,r)} u(y,s)\,dy\,ds$$
$$\geq \operatorname{ess} \liminf_{(y,s)\to(x,t)} u(y,s) = v(x,t)$$

for a.e. $(x,t) \in \Omega$ by the Lebesgue differentiation theorem. Hence $u = v$ a.e. in Ω. Moreover, it is clear that v is lower semicontinuous and that v is finite a.e.. To see that v is indeed p-superparabolic, fix a box $Q \times (t_1, t_2)$ with closure in Ω. If h is any p-parabolic function, continuous in $\overline{Q} \times [t_1, t_2]$, such that $h \leq v$ on the parabolic boundary of $Q \times (t_1, t_2)$, then h is a subsolution in $Q \times (t_1, t_2)$ and, therefore, $h \leq v$ a.e. on $Q \times (t_1, t_2)$ by the comparison principle (Lemma 3.1). By (4.1), this inequality holds everywhere on $Q \times (t_1, t_2)$. □

We next present two versions of the comparison principle. The first one is "elliptic."

LEMMA 4.3. *Suppose that u is p-superparabolic and v is p-subparabolic in a bounded open set Ω. If u and v are bounded and if*

$$\limsup_{\xi\to\xi_0} v(\xi) \leq \liminf_{\xi\to\xi_0} u(\xi)$$

at each point ξ_0 on the Euclidean boundary $\partial\Omega$ of Ω, then $v \leq u$ in Ω.

Proof. For fixed $\varepsilon > 0$, the set

$$K_\varepsilon = \{\xi \in \Omega : v(\xi) \geq u(\xi) + \varepsilon\}$$

is a compact subset of Ω. Therefore, there is an open set $D_\varepsilon \subset \Omega$ such that $K_\varepsilon \subset D_\varepsilon$, where D_ε is a union of finitely many boxes $Q_i \times (t_{i_1}, t_{i_2})$ and

$$\partial D_\varepsilon \subset \Omega \setminus K_\varepsilon.$$

Because v is upper semicontinuous, u is lower semicontinuous, and the parabolic boundary Γ_ε of D_ε is compact, we find a continuous function θ on Γ_ε such that $v \leq \theta \leq u + \varepsilon$ on Γ_ε. If h is the p-parabolic function in D_ε that coincides with θ on Γ_ε (see Remark 3.1), then we infer from the definition of p-superparabolic and p-subparabolic functions that

$$v \leq h \leq u + \varepsilon$$

in D_ε. Hence $v \leq u + \varepsilon$ in Ω, and the lemma follows by letting $\varepsilon \to 0$. □

In a similar manner, the reader easily establishes the following "parabolic" comparison principle:

LEMMA 4.4. *Suppose that u is p-superparabolic and v is p-subparabolic in a cylinder $\Omega = G \times (t_1, t_2)$, where $G \subset \mathbf{R}^n$ is a bounded domain. If u and v are bounded and if*

$$\limsup_{\xi\to\xi_0} v(\xi) \leq \liminf_{\xi\to\xi_0} u(\xi)$$

at each point ξ_0 on the parabolic boundary[6] *of Ω, then $v \leq u$ in Ω.*

[6] The parabolic boundary is $(\overline{G} \times \{t_1\}) \cup (\partial G \times [t_1, t_2])$.

4.6. Parabolic modification The main tool in the Perron method is the modification of p-superparabolic functions. Let $Q_T = Q \times (0,T)$ be a box with closure in Ω. If u is p-superparabolic in Ω and bounded on Q_T, we define the *p-parabolic modification*

$$U = \begin{cases} u & \text{in } \Omega \setminus \overline{Q_T}, \\ v & \text{in } Q \times [0,T], \end{cases}$$

where

$$v(\xi) = \sup\{h(\xi) : h \in C(\overline{Q_T}) \text{ is } p\text{-parabolic and } h \le u \text{ on } \Gamma_T\}.$$

Then it is clear that $U \le u$ on Ω. Moreover, *U is p-superparabolic in Ω and p-parabolic in Q_T.* To see this, choose an increasing sequence θ_j of continuous functions on Γ_T such that

$$u = \lim_{j \to \infty} \theta_j$$

on Γ_T. Let h_j be the p-parabolic function in Q_T that coincides with θ_j on Γ_T. Then it follows from the comparison principle that the sequence h_j is increasing on $\overline{Q_T}$ and that the limit function is v. Moreover, since the sequence h_j is bounded, the limit function v is p-parabolic by Lemma 3.4. Now it is rather immediate that U is p-superparabolic in Ω.

5. The Perron method. In what follows, we let Ω be a bounded open set in $\mathbf{R}^n \times \mathbf{R}$. Let $f : \partial\Omega \to \mathbf{R}$ be any bounded function; note that f is defined on the Euclidean boundary of Ω. The Perron method aims at constructing a p-parabolic function H in Ω that takes the boundary values f on $\partial\Omega$. Of course, this is not possible in this generality. In this section, we shall construct two functions, the upper and the lower Perron solutions $\overline{H}_f$ and $\underline{H}_f$, that both correspond in a sense to f on $\partial\Omega$.

A function u is said to belong to the *upper class* $\mathcal{U}_f$ if u is p-superparabolic in Ω and bounded below and

$$\liminf_{\eta \to \xi} u(\eta) \ge f(\xi)$$

at each point $\xi \in \partial\Omega$. Observe that the upper class $\mathcal{U}_f$ is never empty, for f is bounded so that large constants are members of $\mathcal{U}_f$.

The *lower class* $\mathcal{L}_f$ is defined analogously. It consists of p-subparabolic functions v, bounded above, satisfying

$$\limsup_{\eta \to \xi} v(\eta) \le f(\xi)$$

at each point $\xi \in \partial\Omega$; also, the constant $-\infty$ is in $\mathcal{L}_f$.

Next, the *upper solution* $\overline{H}_f$ and the *lower solution* $\underline{H}_f$ are defined by

$$\overline{H}_f(\xi) = \inf\{u(\xi) : u \in \mathcal{U}_f\}$$

and

$$\underline{H}_f(\xi) = \sup\{v(\xi) : v \in \mathcal{L}_f\}.$$

It follows from the comparison principle (Lemma 4.3) that $v \le u$ whenever $u \in \mathcal{U}_f$ and $v \in \mathcal{L}_f$. Hence

$$\underline{H}_f \le \overline{H}_f$$

in Ω. Since the boundary function f is bounded, both $\overline{H}_f$ and $\underline{H}_f$ are bounded by the same constants as f.

THEOREM 5.1. *If the boundary function $f : \partial\Omega \to \mathbf{R}$ is bounded, then the Perron solutions $\underline{H}_f$ and $\overline{H}_f$ are p-parabolic.*

Proof. Fix a box $Q_{t_1,t_2} = Q \times (t_1, t_2)$ with closure in Ω; here Q is a rectangle in $\mathbf{R}^n$ as usual. Next, choose a countable, dense subset

$$\Xi = \{\xi_1, \xi_2, \dots\}$$

of Q_{t_1,t_2}. For each $j = 1, 2, \dots$ we choose a sequence of functions $u_{i,j}$ in $\mathcal{U}_f$ such that

$$\lim_{i\to\infty} u_{i,j}(\xi_j) = \overline{H}_f(\xi_j).$$

Moreover, we are free to replace $u_{i,j+1}$ by $\min(u_{i,j}, u_{i,j+1})$, and hence we have that

$$\lim_{i\to\infty} u_{i,j}(\xi_k) = \overline{H}_f(\xi_k) \tag{5.1}$$

for each $k = 1, 2, \dots, j$ and for each j. For the p-parabolic modification $U_{i,j}$ of $u_{i,j}$ in Q_{t_1,t_2}, it holds that

$$\overline{H}_f \le U_{i,j} \le u_{i,j}$$

and $U_{i,j}$ is p-parabolic in Q_{t_1,t_2}. By passing to a subsequence, if necessary, we infer from Lemma 3.4 that $U_{i,j}$ converges locally uniformly to a p-parabolic function v_j in Q_{t_1,t_2}. By again employing Lemma 3.4, we find a subsequence of v_j that converges locally uniformly to a p-parabolic function h in Q_{t_1,t_2}. By the construction, it is clear that

$$h \ge \overline{H}_f$$

in Q_{t_1,t_2}. On the other hand, by (5.1), we have that $h = \overline{H}_f$ in the dense subset Ξ of Q_{t_1,t_2}. Therefore, if u is any function from $\mathcal{U}_f$, then its p-parabolic modification U in Q_{t_1,t_2} is not greater than u, and by continuity, $U \ge h$ in Q_{t_1,t_2}. Hence

$$\overline{H}_f \ge h$$

in Q_{t_1,t_2}. It follows that $\overline{H}_f = h$ is p-parabolic in Q_{t_1,t_2} and hence in Ω.

The lower solution $\underline{H}_f$ is treated completely analogously. □

Remark. Alternative proofs for Theorem 5.1 could be based on the Choquet topological lemma as in [HKM] or on the argument in [GLM].

Example. Let $\Omega = Q \times (0, T)$ and suppose that $f : \partial\Omega \to \mathbf{R}$ is continuous. Then the upper and the lower Perron solutions coincide and

$$H_f = \underline{H}_f = \overline{H}_f$$

is the p-parabolic function that coincides with f on the parabolic boundary of Ω. As anticipated, the values of f at the top of the box Ω do not have any influence on the solution. Indeed, if h is p-parabolic in Ω and takes the values f on the *parabolic boundary* (Lemma 3.2), then the function

$$h(x,t) + \frac{\varepsilon}{T-t}$$

belongs to $\mathcal{U}_f$ for $\varepsilon > 0$ and to $\mathcal{L}_f$ for $\varepsilon < 0$. The result can be restated by saying that f is *resolutive*.

6. Barriers and boundary regularity. We shall define the barrier function for the boundary value problem as in classical theory. It gives a necessary and sufficient condition for the regularity of boundary points. This leads to some useful conditions for regularity; for instance, an exterior sphere condition is established. Furthermore, the regular boundary points of space–time cylinders are completely characterized in terms of a Wiener-type test.

DEFINITION. *Suppose that ξ_0 is a boundary point of a bounded domain $\Omega \subset \mathbf{R}^n \times \mathbf{R}$. A function w is a* barrier in Ω at the point ξ_0 *if*

$$\begin{aligned}
&\text{(i)} && w \text{ is positive and } p\text{-superparabolic in } \Omega,\\
&\text{(ii)} && \liminf_{\zeta\to\xi} w(\zeta) > 0 \quad \text{if } \xi \in \partial\Omega, \quad \xi \neq \xi_0,\\
&\text{(iii)} && \liminf_{\zeta\to\xi_0} w(\zeta) = 0.
\end{aligned}$$

Although we have, for convienence, assumed that the barrier is defined in the whole Ω, *this is completely a local question*: Let $\tilde{\Omega}$ be another domain such that

$$\overline{B} \cap \tilde{\Omega} = \overline{B} \cap \Omega$$

for some open ball B centered at ξ_0. Suppose that there is a barrier, say w, in $\tilde{\Omega}$ at ξ_0. Let

$$m = \inf\{w(\xi) : \xi \in \partial B \cap \tilde{\Omega}\}.$$

Then $m > 0$ and it easily follows that the function

$$v = \begin{cases} \min(w, m) & \text{in } B \cap \tilde{\Omega}, \\ m & \text{in } \Omega \setminus B \end{cases}$$

is a barrier in Ω. Hence there is a barrier in Ω at ξ_0 exactly when there is a barrier in $\tilde{\Omega}$.

THEOREM 6.1. *Suppose that $f : \partial\Omega \to \mathbf{R}$ is bounded and continuous at $\xi_0 \in \partial\Omega$. If there is a barrier in Ω at ξ_0, then*

$$\lim_{\xi\to\xi_0} \underline{H}_f(\xi) = f(\xi_0) = \lim_{\xi\to\xi_0} \overline{H}_f(\xi).$$

Proof. The proof is very classical. Let $|f(\xi) - f(\xi_0)| < \varepsilon$ for $\xi \in \partial\Omega$ with $|\xi - \xi_0| < \delta$ and choose, by the aid of the lower semicontinuity of the barrier w, a constant $M > 0$ such that

$$M\, w(\xi) \geq 2 \sup |f|$$

for $\xi \in \overline{\Omega}$, $|\xi - \xi_0| < \delta$. Then the function $M\,w + \varepsilon + f(\xi_0)$ belongs to the upper class $\mathcal{U}_f$ and has the limit $f(\xi_0) + \varepsilon$ at ξ_0. Similarly, the function $-M\,w - \varepsilon + f(\xi_0)$ belongs to the lower class $\mathcal{L}_f$ and has the limit $f(\xi_0) - \varepsilon$ at ξ_0. The theorem follows. □

We call a boundary point $\xi_0 \in \partial\Omega$ *p-regular* if

$$\lim_{\xi\to\xi_0} \overline{H}_f(\xi) = f(\xi_0)$$

whenever $f : \partial\Omega \to \mathbf{R}$ is continuous. This concept depends heavily on the equation. For instance, it may happen that a point $\xi_0 \in \partial\Omega$ is regular for the equation $\Delta u = u_t$, while it is not regular for the equation $\Delta u = \frac{1}{2}u_t$. Thus the term $\mathcal{A}_p$*-regular* is appropriate in the general case.

Because $\underline{H}_f = -\overline{H}_{-f}$, we could replace $\overline{H}_f$ by $\underline{H}_f$ in the definition above.

We have the classical characterization for regularity in terms of barriers.

THEOREM 6.2. *A boundary point ξ_0 of a bounded open set Ω is p-regular if and only if there is a barrier in Ω at ξ_0.*

Proof. The sufficiency part was already established. To prove the necessity, let $\xi_0 = (x_0, t_0)$ and define

$$\psi(x,t) = \frac{p-1}{p}|x-x_0|^{p/(p-1)} + \varepsilon(t-t_0)^2,$$

where ε is a constant with

$$0 < 2\varepsilon \operatorname{diam}(\Omega) < n.$$

The function ψ is p-subparabolic in Ω (Lemma 4.2). Then $w = \underline{H}_\psi$ is a barrier in Ω at ξ_0 because

$$\lim_{\xi \to \xi_0} w(\xi) = \psi(\xi_0) = 0$$

by the p-regularity of ξ_0, and the other properties are immediate, for $w \geq \psi$ in Ω. The theorem follows. □

Since the existence of a barrier is a local property, so is the regularity of a boundary point. Moreover, if ξ_0 is a p-regular boundary point of Ω, then ξ_0 is p-regular with respect to each subdomain to whose boundary it belongs.

Example. Exterior sphere condition. Let $\xi_0 = (x_0, t_0) \in \partial\Omega$. Suppose that there exists a closed ball

$$\{(x,t) : |x-x'|^2 + (t-t')^2 \leq R_0^2\}$$

that intersects with the closure $\overline{\Omega}$ exactly at ξ_0. We claim that ξ_0 is regular if $x_0 \neq x'$.

For the construction of the barrier, we define

$$w(x,t) = e^{-\alpha R_0^2} - e^{-\alpha R^2}, \quad R = (|x-x'|^2 + (t-t')^2)^{1/2},$$

where the constant $\alpha > 0$ is to be fixed later. For $(x,t) \in \Omega$ sufficiently near to ξ_0, we have that

$$0 < \delta \leq |x-x'|, \quad -2R_0 \leq t-t', \quad R_0 \leq R < 2R_0,$$

where we can take $2\delta \leq |x_0 - x'|$, for instance. Keep in mind that it suffices to construct a local barrier. An easy calculation yields

$$\begin{aligned}
&\operatorname{div}(|\nabla w|^{p-2}\nabla w) \\
&= (2\alpha)^{p-1}|x-x'|^{p-2}e^{-(p-1)\alpha R^2}(n+p-2-2\alpha(p-1)|x-x'|^2) \\
&\leq (2\alpha)^{p-1}(n+p-2-2\alpha(p-1)\delta^2)e^{-(p-1)\alpha R^2}
\end{aligned}$$

and

$$w_t = 2\alpha e^{-\alpha R^2}(t-t') \geq -4\alpha R_0 e^{-\alpha R^2}.$$

Consider first the case $1 < p < 2$. Choose $\alpha > 0$ so large that $n+p-2-2\alpha(p-1)\delta^2 \leq -1$. In order to have

$$\operatorname{div}(|\nabla w|^{p-2}\nabla w) < w_t$$

near ξ_0 in Ω, we have to verify that

$$(2\alpha)^{p-2}e^{-(p-2)\alpha R^2} \geq 2R_0,$$

which is clearly the case if α is large enough, since $p-2<0$. Thus w is p-superparabolic in a neighborhood of ξ_0 in Ω by Lemma 4.2. Consequently, w is a local barrier at ξ_0, and ξ_0 is therefore p-regular.

The case $p=2$ is even simpler, and we leave it for the reader to explore.

Finally, let $p>2$ and choose α so that

$$n+p-2-2\alpha(p-1)\delta^2 = -1.$$

Then

$$\operatorname{div}(|\nabla w|^{p-2}\nabla w) \leq -(2\alpha)^{p-1}e^{-(p-1)4\alpha R_0^2}$$

and

$$w_t \geq -4\alpha R_0 e^{-\alpha R_0^2}$$

so that

$$\operatorname{div}(|\nabla w|^{p-2}\nabla w) \leq Cw_t,$$

where $C = C(p,\alpha,R_0) > 0$. Now, for $\lambda > 0$ small enough, the function λw is p-superparabolic and hence the desired local barrier.

The restriction that $x_0 \neq x'$ is essential only to exclude the south pole $(x', t'-R_0)$ as a tangent point (cf. the example after Theorem 5.1). Indeed, if

$$\xi_0 = (x', t'+R_0)$$

is the north pole (the latest moment on the exterior sphere), then the function w above is a barrier at ξ_0, for

$$w_t = 2\alpha e^{-\alpha R^2}(t-t') > 0$$

near ξ_0 in this case, while

$$\operatorname{div}(|\nabla w|^{p-2}\nabla w) \leq 0$$

for α large enough.

As an application of the exterior sphere condition, we prove the characterization of p-superparabolic functions, referred to in the discussion after Definition 4.1.

LEMMA 6.3. *Suppose that $u : \Omega \to (-\infty, \infty]$ is lower semicontinuous in $\Omega \subset \mathbf{R}^n \times \mathbf{R}$ and finite in a dense subset of Ω. Then u is p-superparabolic if and only if for each domain Ξ with compact closure in Ω and each $h \in C(\overline{\Xi})$, p-parabolic in Ξ, the condition $h \leq u$ on $\partial\Xi$ implies $h \leq u$ in Ξ.*

Proof. The necessity of the condition was discussed right after the definition of p-superparabolic functions. To prove the sufficiency, let $Q_{t_1,t_2} = Q \times (t_1,t_2)$ be a box with closure in Ω and let $h \in C(\overline{Q}_{t_1,t_2})$ be p-parabolic in Q_{t_1,t_2} such that $h \leq u$ on the parabolic boundary Γ_{t_1,t_2} of Q_{t_1,t_2}. Suppose that

$$Q = (a_1,b_1) \times (a_2,b_2) \times \cdots \times (a_n,b_n).$$

For $\delta > 0$, $\delta < t_2 - t_1$, choose a hyperplane P_δ in $\mathbf{R}^n \times \mathbf{R}$ such that the points $(x, t_2-\delta)$, where $x_1 = a_1$, and (y, t_2), where $y_1 = b_1$, belong to P_δ. Then let Ξ be the subset of Q_{t_1,t_2} that contains the points (x,t), where $t < s$ is such that $(x,s) \in P_\delta$. We easily infer from the exterior sphere condition that Ξ is p-regular. For fixed $\varepsilon > 0$, we may choose $\delta > 0$ so small that

$$u(x,t) \geq h(x,t) - \frac{\varepsilon}{t_2 + \frac{\delta}{2} - t}$$

for $(x,t) \in P_\delta \cap \partial\Xi$. Let $\overline{H}$ be the Perron solution in Ξ with

$$h - \frac{\varepsilon}{t_2 + \frac{\delta}{2} - t}$$

as a boundary function. Then $\overline{H}$ is continuous up to the boundary of Ξ. Since we are free to assume that $u \geq 0$, we have that

$$u \geq H$$

in Ξ, since the same inequality holds on $\partial\Xi$. This means that

$$u(x,t) \geq h(x,t) - \frac{\varepsilon}{t_2 + \frac{\delta}{2} - t}$$

for $(x,t) \in \Xi$, and by letting $\delta \to 0$ and $\varepsilon \to 0$, we arrive at the desired inequality

$$u \geq h$$

in Q_{t_1,t_2}. □

Before constructing more barriers, let us recall that it may happen that a point $\xi_0 \in \partial\Omega$ is regular for the equation $\Delta u = u_t$, while it is not regular for $\Delta u = \frac{1}{2}u_t$.

Example: *Heat balls.* The heat balls play a central role for the more refined parts of linear theory. They are defined through the inequality

$$\frac{1}{(4\pi(t_0 - t))^{n/2}} \exp\left(-\frac{|x_0 - x|^2}{4(t_0 - t)}\right) > c,$$

where c is a positive constant and $t < t_0$. In other words, heat balls are level sets of the fundamental solution of the heat equation. It is an essential feature that the "center" (x_0, t_0) is an irregular boundary point of the heat ball, while all the other boundary points are regular.

The p-parabolic balls are, by analogy, defined through the Barenblatt solutions $\mathcal{B}_p$. The inequality is now

$$\mathcal{B}_p(x_0 - x, t_0 - t) > c,$$

where $t < t_0$ and $p > 2$. Then p-parabolic balls are bounded and from the exterior sphere condition, we infer that its boundary points except the "center" (x_0, t_0) are regular. Indeed, *the "center" (x_0, t_0) is an irregular boundary point of the p-parabolic ball.*

To prove the irregularity we are free to assume that (x_0, t_0) is the origin. We have the inequality

$$\left(1 - \frac{p-2}{p}\lambda^{\frac{1}{1-p}}\left(\frac{|x|}{(-t)^{1/\lambda}}\right)^{\frac{p}{p-1}}\right)_+^{\frac{p-1}{p-2}} > c(-t)^{\frac{n}{\lambda}}$$

and $t < 0$. For simplicity, we have taken the normalizing constant in the Barenblatt solution to be 1. Since the irregularity is a local question, we may restrict the range of t further, say,

$$-\left(\frac{c}{2}\right)^{-\lambda/n} < t < 0.$$

It suffices to show that the origin is an irregular boundary point of the subdomain

$$\left(1-\frac{p-2}{p}\lambda^{\frac{1}{1-p}}\left(\frac{|x|}{(-t)^{1/\lambda}}\right)^{\frac{p}{p-1}}\right)_+^{\frac{p-1}{p-2}} > \frac{1}{2},$$

where $-T < t < 0$. This can be written as

$$\left(1+\frac{p-2}{p}\lambda^{\frac{1}{1-p}}\left(\frac{|x|}{(-t)^{1/\lambda}}\right)^{\frac{p}{p-1}}\right)^{\frac{p-1}{p-2}} < \left(2-\left(\frac{1}{2}\right)^{\frac{p-2}{p-1}}\right)^{\frac{p-1}{p-2}}.$$

For a sufficiently small value of the constant K, this contains the subdomain

$$u(x,t) < K,$$

where

$$u(x,t) = \left(1+\frac{p-2}{p}\lambda^{\frac{1}{1-p}}\left(\frac{|x|}{(-t)^{1/\lambda}}\right)^{\frac{p}{p-1}}\right)^{\frac{p-1}{p-2}} - 1 - B(-t)^{\frac{n(p-2)}{\lambda}},$$

Here B is a positive constant, to be specified later. The function u will do as "eine Irregularitätsbarriere," to quote an expression from [Py]. That is,

(i) u is p-superparabolic in the domain, where $u(x,t) < K$ and $-T < t < 0$ (T depending on p),

(ii) $u(0,t) < 0$, when $t < 0$.

Here (ii) is evident. Before proving (i), let us show how this implies that the origin is irregular.

Consider the domain bounded by the surface $u(x,t) = K$ and the hyperplane $t = -T$; in this domain

$$u(x,t) < K.$$

If we assign the boundary values f to be K when $-T < t \leq 0$ and $u(x,-T)$ on the plane $t = -T$, then the function

$$u(x,t) + \frac{\varepsilon}{-t}, \qquad \varepsilon > 0,$$

is in the upper class for f. Thus

$$\overline{H}_f(x,t) \leq u(x,t) + \frac{\varepsilon}{-t},$$

and hence $\overline{H}_f \leq u$. But this implies that

$$\limsup_{t\to 0-} \overline{H}_f(0,t) \leq \limsup_{t\to 0-} u(0,t) \leq 0,$$

so that $\overline{H}_f$ cannot attain the right boundary value K at the origin.

The proof of (i) is a calculation. We may assume that $K \leq 1$. Direct derivations and some minor manipulations with the resulting expressions yield

$$\begin{aligned}
&u_t - \operatorname{div}(|\nabla u|^{p-2}\nabla u) = B\frac{n(p-2)}{\lambda}(-t)^{\frac{n(p-2)}{\lambda}-1}\\
&\quad -\frac{p}{\lambda(p-2)}\left(\frac{1}{(-t)} - \frac{1}{(-t)^{p/\lambda}}\right)\left(1+\frac{p-2}{p}\lambda^{\frac{1}{1-p}}\left(\frac{|x|}{(-t)^{1/\lambda}}\right)^{\frac{p}{p-1}}\right)^{\frac{1}{p-2}}\\
&\quad +\left(\frac{p}{\lambda(p-2)}\left(\frac{1}{(-t)} - \frac{1}{(-t)^{p/\lambda}}\right) - \frac{n}{\lambda(-t)^{p/\lambda}}\right)\left(1+\frac{p-2}{p}\lambda^{\frac{1}{1-p}}\left(\frac{|x|}{(-t)^{1/\lambda}}\right)^{\frac{p}{p-1}}\right)^{\frac{p-1}{p-2}}\\
&\geq B\frac{n(p-2)}{\lambda}(-t)^{\frac{n(p-2)}{\lambda}-1}\\
&\quad -\frac{p}{\lambda(p-2)}\left(\frac{1}{(-t)} - \frac{1}{(-t)^{p/\lambda}}\right)\left(1+\frac{p-2}{p}\lambda^{\frac{1}{1-p}}\left(\frac{|x|}{(-t)^{1/\lambda}}\right)^{\frac{p}{p-1}}\right)^{\frac{p-1}{p-2}}\\
&\quad +\left(\frac{p}{\lambda(p-2)}\left(\frac{1}{(-t)} - \frac{1}{(-t)^{p/\lambda}}\right) - \frac{n}{\lambda(-t)^{p/\lambda}}\right)\left(1+\frac{p-2}{p}\lambda^{\frac{1}{1-p}}\left(\frac{|x|}{(-t)^{1/\lambda}}\right)^{\frac{p}{p-1}}\right)^{\frac{p-1}{p-2}}\\
&= B\frac{n(p-2)}{\lambda}\frac{1}{(-t)^{p/\lambda}} - \frac{n}{\lambda}\frac{1}{(-t)^{p/\lambda}}\left(1+\frac{p-2}{p}\lambda^{\frac{1}{1-p}}\left(\frac{|x|}{(-t)^{1/\lambda}}\right)^{\frac{p}{p-1}}\right)^{\frac{p-1}{p-2}}\\
&\geq B\frac{n(p-2)}{\lambda}\frac{1}{(-t)^{p/\lambda}} - \frac{n}{\lambda}\frac{1}{(-t)^{p/\lambda}}\left(2 + B(-t)^{\frac{n(p-2)}{\lambda}}\right).
\end{aligned}$$

The last expression is nonnegative if

$$B(p-2) \geq 2 + B(-T)^{\frac{n(p-2)}{\lambda}}.$$

Take

$$B = \frac{2}{p-2-(-T)^{n(p-2)/\lambda}}$$

and choose T small enough for this to make sense.

This concludes our proof. □

What is to happen in the future will have no influence on the present time. The regularity or irregularity of a boundary point $\xi_0 = (x_0, t_0) \in \partial\Omega$ is completely determined by times $t < t_0$. Let

$$\Omega_- = \{(x,t) \in \Omega : t < t_0\}$$

and

$$\Omega_+ = \{(x,t) \in \Omega : t > t_0\}.$$

Note that both Ω_- and Ω_+ may be disconnected; however, it is easy to see that the barrier characterization for regularity remains true for disconnected open sets.

THEOREM 6.4. *Let $\xi_0 = (x_0, t_0) \in \partial\Omega$. Then ξ_0 is a regular boundary point of the domain Ω if and only if ξ_0 is a regular boundary point of Ω_- or $\xi_0 \notin \partial\Omega_-$.*

Proof. The necessity of the condition follows since $\Omega_- \subset \Omega$, and therefore, either $\xi_0 \notin \partial\Omega_-$ or a barrier at ξ_0 in Ω is also a barrier in Ω_-.

To establish the converse, suppose first that $\xi_0 \notin \partial\Omega_-$. Then the exterior sphere condition ensures that ξ_0 is a regular boundary point of Ω.

To complete the proof, suppose that ξ_0 is a regular boundary point of Ω_-. Given the p-subparabolic boundary values

$$\psi(x,t) = \frac{p-1}{p}|x - x_0|^{p/(p-1)} + \varepsilon(t - t_0)^2$$

on $\partial\Omega$, where ε is a constant with $0 < 2\varepsilon\mathrm{diam}(\Omega) < n$, the lower Perron solution $H = \underline{H}_\psi$ satisfies the inequality

$$H \geq \psi > 0$$

in Ω. Moreover,

$$\lim_{\substack{\zeta\to\xi_0\\ \zeta\in\Omega_-}} H(\zeta) = \psi(\xi_0) = 0. \tag{6.1}$$

Indeed, let u be any bounded function in the upper class for ψ in Ω_-. Then for each $\varepsilon > 0$, the function

$$v(x,t) = \begin{cases} \sup u & \text{if } t > t_0 - \varepsilon, \\ u(x,t) & \text{if } t \leq t_0 - \varepsilon \end{cases}$$

is in the upper class for ψ in Ω. It follows that the restriction to Ω_- of H coincides with the upper Perron solution of ψ in Ω_-. Hence (6.1) follows, since ξ_0 is a regular boundary point of Ω_-.

This means that H is a barrier at ξ_0 in Ω_-. We claim that H will do as a barrier in Ω. To this end, we have to show that

$$\lim_{\substack{\zeta\to\xi_0\\ \zeta\in\Omega}} H(\zeta) = 0. \tag{6.2}$$

This is easy. If $\xi_0 \notin \partial\Omega_+$, there is nothing to prove. So assume that $\xi_0 \in \partial\Omega_+$ and define

$$\varphi = \begin{cases} \psi & \text{in } \partial\Omega, \\ H & \text{in } \Omega \cap \partial\Omega_+. \end{cases}$$

Then the restriction to $\partial\Omega_+$ of φ is continuous at ξ_0. Let

$$h = \underline{H}_\varphi$$

be the lower Perron solution of φ in Ω_+. Then $h = H$ in Ω_+. Indeed, if $u \in \mathcal{L}_\psi(\Omega)$, then $u|_{\Omega_+} \in \mathcal{L}_\varphi(\Omega_+)$ so that

$$u|_{\Omega_+} \leq h$$

and hence

$$H \leq h$$

in Ω_+. For the reverse inequality, let $v \in \mathcal{L}_\varphi(\Omega_+)$. Then

$$\limsup_{\zeta\to\xi} v(\zeta) \leq \varphi(\xi) \leq \liminf_{\zeta\to\xi} H(\zeta)$$

for each $\xi \in \partial\Omega_+$, so that $v \leq H$ in Ω_+ by the comparison principle. Thus $h \leq H$ and we conclude that $h = H$ in Ω_+.

Since, by the exterior sphere condition, the earliest points are regular, ξ_0 is a regular boundary point of Ω_+. Hence

$$\lim_{\substack{\zeta \to \xi_0 \\ \zeta \in \Omega_+}} h(\zeta) = \varphi(\xi_0) = 0.$$

Since $H = h$ in Ω_+, this and (6.1) yield (6.2). □

Remark 6.1. The previous proof reveals an interesting fact. The restriction to Ω_- of the Perron solution $\overline{H}_f$ in Ω coincides with the upper Perron solution of f in Ω_- no matter how the bounded function f is defined at points on $\partial\Omega_- \setminus \partial\Omega$.

6.1. Space–time cylinders. The regularity in the case of the elliptic p-Laplacian can be characterized by a Wiener-type test [KM], while in the p-parabolic case, no such characterization is known in general domains except for $p = 2$ [EG]. In this section, we characterize p-regular boundary points for space–time cylinders.

Consider the cylinder $\Omega = G \times (0, T)$, where G is a bounded domain in $\mathbf{R}^n$. Then each boundary point lying at the "bottom" of Ω is p-regular. Indeed, if $\xi_0 = (x_0, 0) \in G \times \{0\} \subset \partial\Omega$, then the p-parabolic function

$$w(x,t) = \frac{p-1}{p}|x - x_0|^{p/(p-1)} + nt$$

is a barrier at ξ_0. The boundary points of the bottom, i.e., points on $\partial G \times \{0\}$, are easily seen to be p-regular by employing the exterior sphere condition. Moreover, it is easily seen that none of the points (x_0, T), $x_0 \in G$, on the interior of the "top" is p-regular (cf. the example after Theorem 5.1). To give a geometric characterization for the regularity of the points (x_0, t) on the "sides" $\partial G \times (0, T]$ of the cylinder, we recall that in the elliptic theory, a boundary point $x_0 \in \partial G$ is *regular for the p-Laplacian* if

$$\lim_{x \to x_0} h_f(x) = f(x_0)$$

whenever f is a continuous function on ∂G; here h_f is the Perron solution corresponding to the boundary function of the p-Laplacian

$$\operatorname{div}(|\nabla h_f|^{p-2}\nabla h_f) = 0;$$

see [HKM]. Then a boundary point $x_0 \in \partial G$ is regular for the p-Laplacian if and only if

$$\int_0^1 \left(\frac{\operatorname{cap}_p(\overline{B}(x_0,t) \setminus G, B(x_0, 2t))}{t^{n-p}} \right)^{1/(p-1)} \frac{dt}{t} = \infty, \tag{6.3}$$

where the p-capacity $\operatorname{cap}_p(K, D)$ of a compact set K in D is defined as

$$\operatorname{cap}_p(K, D) = \inf \int_D |\nabla\varphi|^p \, dx,$$

where the infimum is taken over all $\varphi \in C_0^\infty(D)$ such that $\varphi \geq 1$ on C; see [KM], [Ma].

THEOREM 6.5. *Let $x_0 \in \partial G$ and $0 < t_0 \leq T$. Then $\xi_0 = (x_0, t_0)$ is a p-regular boundary point of G_T if and only if x_0 is regular for the p-Laplacian.*

Proof. Since the future does not have any effect on the regularity (Theorem 6.4), we are free to assume that $t_0 < T$.

Suppose first that ξ_0 is p-regular and let φ be a continuous function on ∂G. Let h_φ be the p-harmonic Perron solution in G with boundary values φ. Then the function

$$f(x,t) = \begin{cases} \varphi(x) & \text{if } 0 < t < T, \\ h_\varphi(x) & \text{if } t = 0 \text{ or } t = T \end{cases}$$

is bounded on ∂G_T and continuous at ξ_0. Moreover, if u is a p-superharmonic function from the "elliptic" upper class for φ in G, then the function $v(x,t) = u(x)$ belongs to the "parabolic" upper class for f in G_T. Hence

$$\liminf_{(x,t)\to\xi_0} \overline{H}_f(x,t) \le \liminf_{x\to x_0} h_\varphi(x).$$

By the barrier characterization for regularity, we infer from Theorem 6.1 that

$$\lim_{(x,t)\to\xi_0} \overline{H}_f(x,t) = f(\xi_0);$$

thus

$$\liminf_{x\to x_0} h_\varphi(x) \ge \varphi(x_0)$$

whenever φ is a continuous function on ∂G. Consequently,

$$\varphi(x_0) \le \liminf_{x\to x_0} h_\varphi(x) \le \limsup_{x\to x_0} h_\varphi(x) = -\liminf_{x\to x_0} h_{-\varphi}(x) \le \varphi(x_0)$$

so that x_0 is regular for the p-Laplacian.

To prove the converse, suppose that x_0 is regular for the p-Laplacian. Let $\varphi(x) = |x - x_0|$ and let u be the solution of

$$\begin{cases} \operatorname{div}(|\nabla u|^{p-2}\nabla u) = -1 \text{ in } G, \\ u - \varphi \in W_0^{1,p}(G). \end{cases}$$

Then u is p-superharmonic in G and $u(x) \ge |x - x_0|$, for φ is p-subharmonic. Because the Wiener test (6.3) is satisfied, we infer from [GZ] that

$$\lim_{x\to x_0} u(x) = \varphi(x_0) = 0;$$

therefore u is a barrier for the p-Laplacian in G.

Define

$$v(x,t) = u(x) + (t_0 - t).$$

Then

$$\operatorname{div}(|\nabla v|^{p-2}\nabla v) = -1 = v_t$$

and it follows that v is a barrier at ξ_0 with respect to

$$G_{t_0} = G \times (0, t_0).$$

Hence ξ_0 is a p-regular boundary point of G_{t_0}. Theorem 6.4 now implies that ξ_0 is a p-regular boundary point of G_T. $\square$

6.2. Petrowsky's condition. In 1933, Petrowsky established a sharp condition for the regularity of the latest moment in time on $\partial\Omega$ in connection with the heat equation; cf. [Py]. For example, for the one-dimensional heat equation $u_t = u_{xx}$, the origin is a regular boundary point of the domain defined by

$$\frac{x^2}{-4t} < \log|\log(-t)|, \quad -T < t < 0,$$

while the origin is not a regular boundary point of any domain defined by

$$\frac{x^2}{-4t} < (1+\varepsilon)\log|\log(-t)|, \quad -T < t < 0,$$

if $\varepsilon > 0$.

For the p-parabolic equation with $p > 2$ a good, but perhaps not sharp, condition is that the origin is a regular boundary point of the domain

$$\left(\frac{|x|}{(-t)^{1/\lambda}}\right)^{\frac{p}{p-1}} < A(-t)^{\frac{n(p-2)}{\lambda}}|\log(-t)|^{\alpha(p-2)}, \quad -T < t < 0,$$

where $A > 0$ and $\alpha > 0$ are any constants, and $\lambda = n(p-2)+p$ is as in the Barenblatt solution. (As $p \to 2+$ more elaborate calculations must be done if one wants to achieve the logarithms in Petrowsky's condition.)

The construction of the barrier is based on the choice

$$u(x,t) = f(t)\left(1 + \frac{p-2}{p}\lambda^{\frac{1}{1-p}}\left(\frac{|x|}{(-t)^{1/\lambda}}\right)^{\frac{p}{p-1}}\right)^{\frac{p-1}{p-2}} + \varphi(t),$$

where

$$f(t) = -a|\log(-t)|^{\alpha},$$

$a > 0$, and

$$\varphi(t) = a|\log(-t)|^{\alpha} + C(-t)^{1-\frac{p}{\lambda}}|\log(-t)|^{\alpha(p-1)}.$$

A rather straightforward but lengthy calculation shows that

$$u_t - \operatorname{div}(|\nabla u|^{p-2}\nabla u) \geq 0$$

in the domain, where $u(x,t)$ is positive. Hence u is p-superparabolic in a convenient domain.

This indicates how the barrier is constructed. However, the proof must be omitted here, since the actual calculations would lead us way astray.

Note added in proof. It has come to our attention that the p-parabolic equation has a very strong physical application. The Barenblatt solution describes the propagation of the heat after the explosion of a hydrogen bomb in the atmosphere.

ON THE SIZE AND SMOOTHNESS OF SOLUTIONS TO NONLINEAR HYPERBOLIC CONSERVATION LAWS*

RONALD A. DEVORE[†] AND BRADLEY J. LUCIER[‡]

Abstract. We address the question of which function spaces are invariant under the action of scalar conservation laws in one and several space dimensions. We establish two types of results. The first result shows that if the initial data is in a rearrangement-invariant function space, then the solution is in the same space for all time. Secondly, we examine which smoothness spaces among the Besov spaces are invariant for conservation laws. Previously, we showed in one dimension that if the initial data has bounded variation and the flux is convex and smooth enough, then the Besov spaces $B^\alpha_q(L_q)$, $\alpha > 1$, $q = 1/(\alpha+1)$, are invariant smoothness spaces. Now, in one space dimension, we show that no other Besov space with $\alpha > 1$ is invariant. In several space dimensions, we show that no Besov space $B^\alpha_q(L_q)$ with $\alpha > 1$ is invariant. Combined with previous results, our theorems completely characterize for $\alpha > 1$ which Besov spaces are smoothness spaces for scalar conservation laws.

Key words. conservation laws, regularity, rearrangement-invariant spaces, Besov spaces

1. Introduction.

We are interested in the size and smoothness, as measured in certain function spaces, of solutions $u(x,t)$, $x \in \mathbb{R}^d$, $t \geq 0$, to the scalar hyperbolic conservation law

$$\begin{aligned} &u_t + \nabla_x \cdot f(u) = 0, \quad x \in \mathbb{R}^d,\ t > 0, \\ &u(x,0) = u_0(x), \qquad x \in \mathbb{R}^d. \end{aligned} \tag{1.1}$$

Here, the flux f maps $\mathbb{R}$ into $\mathbb{R}^d$ and $\nabla_x \cdot f(u)$ denotes the divergence of $f(u(x,t))$ with respect to the spatial variables $x \in \mathbb{R}^d$. In general, classical solutions to (1.1) do not exist for all time $t > 0$; indeed, at some time $t > 0$, which depends on f and u_0, the solution u to (1.1) will generally develop discontinuities known as "shocks" even if the flux and the initial condition are smooth. One defines weak solutions to (1.1) as functions $u(x,t)$ that satisfy

$$-\int_0^t \int_{\mathbb{R}^d} [u(x,t)\phi_t(x,t) + f(u(x,t)) \cdot \nabla_x\phi(x,t)]\,dx\,dt + \int_{\mathbb{R}^d} u(x,T)\phi(x,T)\,dx - \int_{\mathbb{R}^d} u(x,0)\phi(x,0)\,dx = 0$$

for all $\phi \in C^1(\mathbb{R}^{d+1})$ with compact support. Weak solutions are not unique; however, by imposing restrictions, known as entropy conditions, on weak solutions u, it is possible to select from these weak solutions the physically relevant solution to (1.1). See [10], [16]. When we speak about the solution to (1.1), we shall mean this entropy solution.

We are interested in the question of which function spaces X, such as the spaces of p-integrable functions $L_p(\mathbb{R}^d)$ or the space of functions of bounded variation $\mathrm{BV}(\mathbb{R}^d)$, are invariant under the differential equation. This means that if we denote the mapping $u_0 \mapsto u(\,\cdot\,,t)$ for fixed $t>0$ by $E(t)$ (i.e., $E(t)u_0 = u(\,\cdot\,,t)$), then we are interested in function spaces X for which there exists a constant C such that for for all $u_0 \in X$

$$\|E(t)u_0\|_X \le C\|u_0\|_X.$$

If the X norm (or quasinorm, or seminorm) in some sense measures smoothness of functions, then we call X a regularity space for (1.1).

We first address the question of how to measure the size of solutions to (1.1). For all convex functions $\eta\colon \mathbb{R} \to \mathbb{R}$ and under suitable conditions on f, entropy solutions $u(x,t)$ of (1.1) satisfy

$$\int_{\mathbb{R}^d} \eta(u(x,t))\,dx \le \int_{\mathbb{R}^d} \eta(u_0(x))\,dx$$

for all $t>0$; see, e.g., [11]. By setting $\eta(u) = |u|^p$ for $1 \le p < \infty$, one sees immediately that

$$\|u(\,\cdot\,,t)\|_{L_p(\mathbb{R}^d)} \le \|u_0\|_{L_p(\mathbb{R}^d)}. \tag{1.2}$$

One can show independently that (1.2) holds also for $p=\infty$. Thus, $L_p(\mathbb{R}^d)$, $1 \le p \le \infty$, are invariant spaces for solutions $u(x,t)$ of (1.1). Actually, one can prove somewhat more, as we now discuss.

The solution operator $E(t)$ of (1.1) is not only bounded on $L_1(\mathbb{R}^d)$, but is a contraction in $L_1(\mathbb{R}^d)$; i.e., if u_0 and v_0 are two initial conditions for (1.1), then

$$\|u(\,\cdot\,,t) - v(\,\cdot\,,t)\|_{L_1(\mathbb{R}^d)} \le \|u_0 - v_0\|_{L_1(\mathbb{R}^d)}, \quad t>0. \tag{1.3}$$

Thus, the nonlinear mapping $E(t)$ is a contraction on $X := L_1(\mathbb{R}^d)$ and is bounded on $Y := L_\infty(\mathbb{R}^d)$. A simple argument, given in §4, shows that if a possibly nonlinear mapping $E(t)$ defined on $X+Y := \{\, f+g \mid f \in X,\ g \in Y \,\}$ is a contraction on X and is bounded on Y, then $E(t)$ is a bounded mapping on all interpolation spaces between X and Y as determined by the method of real interpolation. First results on conservation laws show that $E(t)u_0$ is defined for each locally integrable function u_0, and, in particular, for each function u_0 in $L_1(\mathbb{R}^d) + L_\infty(\mathbb{R}^d)$, if f is globally Lipschitz continuous. In our case, this means that $E(t)$ is bounded on all interpolation spaces between $L_1(\mathbb{R}^d)$ and $L_\infty(\mathbb{R}^d)$, and, in particular on $L_p(\mathbb{R}^d)$ for $1<p<\infty$. In addition, many other spaces, such as the Lorentz spaces $L_{p,q}(\mathbb{R}^d)$, $1 \le p \le \infty$, $1 < q \le \infty$, and the Orlicz spaces defined on $\mathbb{R}^d$, are interpolation spaces for $L_1(\mathbb{R}^d)$ and $L_\infty(\mathbb{R}^d)$. Calderón [2] characterized the interpolation spaces between $L_1(\mathbb{R}^d)$ and $L_\infty(\mathbb{R}^d)$ as the set of all *rearrangement-invariant* function spaces on $\mathbb{R}^d$; see §4. Thus, solutions of (1.1) are bounded on all rearrangement-invariant function spaces on $\mathbb{R}^d$.

The main focus of this paper is the smoothness, or regularity, of solutions to (1.1), which we next describe. Because of the appearance of shocks, $E(t)$ does not map $C(\mathbb{R}^d)$ into itself. The question arises whether there is any other sense in which the solution of (1.1) retains smoothness.

One should note that solutions of (1.1) are translation invariant, i.e., $E(t)(u_0)(x+h) = E(t)(u_0(\cdot + h))(x)$ for all x and h in $\mathbb{R}^d$. Thus, from (1.3) we see that for all $h \in \mathbb{R}^d$,

$$\|u(\cdot + h, t) - u(\,\cdot\,,t)\|_{L_1(\mathbb{R}^d)} \le \|u_0(\cdot + h) - u_0\|_{L_1(\mathbb{R}^d)}. \tag{1.4}$$

Therefore, with the usual norm for the Lipschitz spaces $\mathrm{Lip}(\alpha, L^p(\mathbb{R}^d))$ given by

$$\|v\|_{\mathrm{Lip}(\alpha,L^p(\mathbb{R}^d))} := \sup_{0\neq h\in\mathbb{R}^d} |h|^{-\alpha}\|v(\cdot+h)-v\|_{L_p(\mathbb{R}^d)}, \quad 0<\alpha\leq 1,\ 0<p\leq\infty,$$

(1.4) implies immediately that

$$\|u(\,\cdot\,,t)\|_{\mathrm{Lip}(\alpha,L^1(\mathbb{R}^d))} \leq \|u_0\|_{\mathrm{Lip}(\alpha,L^1(\mathbb{R}^d))}$$

for all $0<\alpha\leq 1$. In particular, the set of functions of bounded variation on $\mathbb{R}^d$, $\mathrm{BV}(\mathbb{R}^d)$, is invariant under $E(t)$, since, by definition, $\mathrm{Lip}(1, L^1(\mathbb{R}^d)) = \mathrm{BV}(\mathbb{R}^d)$.

The Lipschitz spaces $\mathrm{Lip}(\alpha, L^p(\mathbb{R}^d))$, $0<\alpha<1$, are special cases of the more general Besov spaces $B^\alpha_q(L_p(\mathbb{R}^d))$ (see §3 for a definition), which depend on three parameters $0<\alpha<\infty$, $0<p\leq\infty$, and $0<q\leq\infty$. In fact, $\mathrm{Lip}(\alpha, L^p(\mathbb{R}^d)) = B^\alpha_\infty(L_p(\mathbb{R}^d))$ for $0<\alpha<1$ and $0<p\leq\infty$. For a Besov space, the parameter α determines the order of smoothness (roughly speaking, the number of derivatives). The second parameter p specifies the space in which smoothness is measured, namely $L_p(\mathbb{R}^d)$. The third parameter q allows one to make subtle distinctions in smoothness. Of special interest are the spaces $B^\alpha_p := B^\alpha_p(L_p(\mathbb{R}^d))$. These are sometimes called fractional-order Sobolev spaces because of their similarity to the classical Sobolev spaces; in fact, B^r_2 is identical to the Sobolev space W^r_2, $r=1,2,\dots$, consisting of functions from $L_2(\mathbb{R}^d)$ that have all of their rth distributional derivatives in $L_2(\mathbb{R}^d)$.

The main interest of the present paper is the classification of all Besov spaces $X = B^\alpha_p$, $0<p\leq\infty$, $0<\alpha<\infty$, for which $u_0\in X$ implies $u(\,\cdot\,,t)\in X$ for all later times $t>0$. We shall determine all the regularity spaces of conservation laws among these Besov spaces except for a certain set of values of α and p (with $0\leq\alpha\leq 1$). We use the remainder of this introduction to formulate and explain our results.

We have noted that $\mathrm{Lip}(\alpha, L^1(\mathbb{R}^d))$, $0<\alpha\leq 1$, is a regularity space for (1.1) with constant $C=1$. Once one knows the definitions, it is easily shown that all the Besov spaces $B^\alpha_q(L_1(\mathbb{R}^d))$, $0<\alpha<1$, $0<q\leq\infty$, are regularity spaces, again with $C=1$.

Perhaps somewhat more surprising is the fact established in [6], [7], and [14] that the spaces $\mathrm{BV}\cap B^\alpha_{\tau(\alpha)}$, $\tau(\alpha) := (\alpha+1)^{-1}$, $\alpha>0$, are regularity spaces in one space dimension provided that the flux f is suitably smooth. In some cases, for example for the inviscid Burgers equation, the space $B^\alpha_{\tau(\alpha)}$ is itself a regularity space (i.e., it is not necessary to intersect this space with BV).

With these results in hand, the question arises whether any other Besov spaces are regularity spaces for (1.1), to which we now attend. To explain the results of the present paper, it is useful to give a diagram that organizes our knowledge of smoothness spaces. We identify any smoothness space with smoothness α in $L_p(\mathbb{R}^d)$, and in particular the Besov space B^α_p, with the point $(1/p, \alpha)$ in the upper-right quadrant of $\mathbb{R}^2$. The classification of Besov spaces as regularity spaces in one space dimension can then be visualized as in Figure 1. The line segment connecting $(0,0)$ to $(1,0)$ represents the $L_p(\mathbb{R})$ spaces, or more generally the rearrangement-invariant spaces (which we show in §4 are invariant spaces for (1.1)). The line segment with endpoints $(1,0)$ and $(1,1)$ represents the regularity spaces $\mathrm{Lip}(\alpha, L^1(\mathbb{R}))$ or $B^\alpha_q(L_1(\mathbb{R}^d))$, $0<\alpha<1$, $0<q\leq\infty$. The half-line $\mathcal{L}_1$ with slope one emanating from $(1,0)$ represents the regularity spaces B^α_τ, $\tau=\tau(\alpha)=(\alpha+1)^{-1}$ already discussed. Each space to the right of the line $\mathcal{L}_1$ contains some functions that are not locally integrable and hence the conservation law does not have a solution for all initial values from these spaces (i.e., the regularity question does not have a meaning). The line $\mathcal{L}_0$ emanating from the origin with slope one separates spaces embedded in $C(\mathbb{R})$ (those above the line)

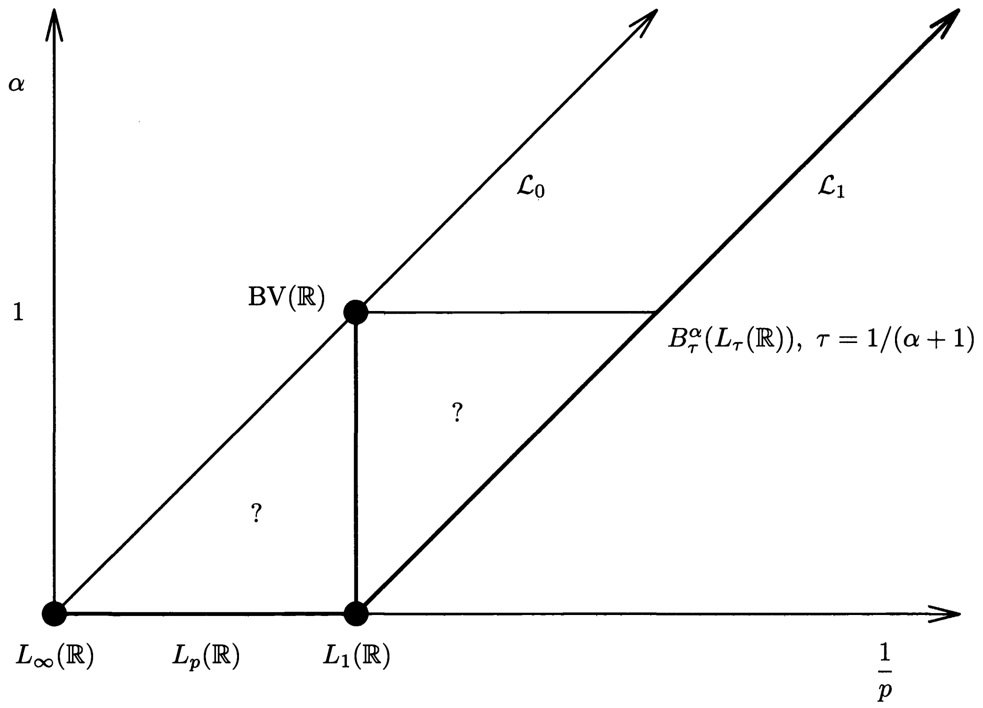

FIG. 1. *Smoothness spaces in one space dimension. The line segment from* $(1,0)$ *to* $(1,1)$ *represents the spaces* $B^\alpha_q(L_1(\mathbb{R}))$, $0 < \alpha < 1$, $0 < q \le \infty$. *The Besov spaces in the open regions not marked by question marks cannot be regularity spaces for* (1.1).

and those not embedded in $C(\mathbb{R})$(below the line). It follows that any space above the line $\mathcal{L}_0$ cannot be a regularity space for (1.1) since, in general, continuous data u_0 generate solutions with shocks. We prove in the present paper that for $\alpha > 1$, none of the Besov spaces $B^\alpha_p(L_p(\mathbb{R}))$ are regularity spaces except for the spaces $B^\alpha_{\tau(\alpha)}$, which corresponds to points on $\mathcal{L}_1$.

In one space dimension, we have not determined whether the spaces represented by points in the parallelogram with vertices $(0,0)$, $(1,0)$, $(1,1)$, and $(2,1)$ are regularity spaces for (1.1). All the same, we conjecture that all these spaces are regularity spaces for (1.1). We are able to use techniques from approximation theory and interpolation of operators to prove this for certain points in this region but will not report on this here since the results are not complete and the arguments are quite technical. One would hope that some nonlinear interpolation argument would settle all these cases.

Our results concerning regularity in one space dimension described above are, for the most part, negative. It is possible, however, to prove some positive results for regularity in one space dimension. We show, using a general argument, that if f is uniformly convex and smooth enough and if $u_0 \in \mathrm{BV}(\mathbb{R}) \cap B^\alpha_\sigma(L_\sigma(\mathbb{R}))$ for $\alpha > 1$ and $\sigma > \tau(\alpha) = 1/(\alpha+1)$, then for all $t > 0$, $u(\cdot, t)$ is in every Besov space $B^\beta_q(L_p(\mathbb{R}))$ with $(1/p, \beta)$ strictly inside the quadrilateral with corners $(0,0)$, $(1,0)$, $(1,1)$, and $(1/\tau(\alpha), \alpha)$.

The situation regarding regularity spaces in several space dimension is quite different. One might suspect that the Besov spaces B^α_τ, $\tau := (\alpha/d + 1)^{-1}$ are regularity spaces for space dimension $d > 1$, since their one-dimensional counterparts ($d = 1$) are. (These are precisely the spaces of minimal smoothness that are embedded into

$L_1(\mathbb{R}^d)$, by a variant of the Sobolev embedding theorem.) However, we shall show in this paper that under very general conditions on the flux f, none of the Besov spaces $B_q^\alpha(L_p(\mathbb{R}^d))$ with $\alpha > 1$ are regularity spaces for (1.1). Again, we are not able to completely settle the case $0 < \alpha \leq 1$. In $\mathbb{R}^d$ the lines $\mathcal{L}_0$ and $\mathcal{L}_1$ are to be replaced by $\mathcal{L}_0'$ and $\mathcal{L}_1'$, which emanate from $(0,0)$ and $(1,0)$, respectively, with slope d. We already noted that the spaces on the line segment with endpoints $(1,0)$, $(1,1)$ are regularity spaces.

We feel that our negative results on regularity spaces in several space dimensions give useful information about the structure of solutions to (1.1) and the behavior of numerical methods for their solutions. In order to bring out this point, we first make a few remarks about the connections between regularity and numerical methods. A typical numerical method creates for discrete time values t_n an approximation u_n to $u(\,\cdot\,,t_n)$. The approximants u_n will lie in certain linear or nonlinear spaces Σ_n associated with the numerical method. Usually, Σ_n is a space of piecewise polynomials with either a fixed or variable grid. The approximation power of such a method is often (although not always) associated with the approximation power from the space Σ_n. In any case, no numerical method can approximate better than the best approximation from Σ_n. The order of best approximation by elements in Σ_n is characterized by the smoothness of the function $u(\,\cdot\,,t_n)$ being approximated. It is therefore important to understand when the solution $u(\,\cdot\,,t)$ is in the smoothness space associated with a given order of best approximation by elements in Σ_n. For example, the regularity spaces $B^\alpha_{\tau(\alpha)}$ characterize the classes of functions that can be approximated with a given approximation order $N^{-\alpha}$ in $L_1(\mathbb{R})$ by free-knot spline functions with N knots. This shows that numerical methods based on moving grids (in one space dimension) should be effective in recovering solutions to scalar conservation laws. This is indeed the case, as is shown in [12], [6], and [14], where numerical methods based on moving grid finite elements are constructed that provide approximation order α for any $\alpha > 0$.

In the multivariate case, there are no regularity spaces among the Besov spaces $B_p^\alpha(L_p(\mathbb{R}^d))$, $\alpha > 1$. The Besov spaces are homogeneous: they measure regularity the same way in all coordinate directions. From another viewpoint, these Besov spaces are characterized by very regular approximation processes such as approximation by wavelets or splines with regular partitions. The elements in these spaces behave the same in all coordinate directions. On the other hand, the "fluid transport" in conservation laws can be very directionally dependent. To approximate well such a solution at later time $t > 0$ requires finer resolution in directions where mass is accumulating. For example, if we were approximating by piecewise constants, we would need elements that are finer in certain directions and coarser in others. This is not possible with splines on regular partitions or wavelets. This is reflected in the fact that their approximation spaces (the Besov spaces) are not regularity spaces for conservation laws in several space dimensions.

2. Properties of entropy solutions to conservation laws. We begin by recalling certain properties of the solution to (1.1) that will be used in what follows. Let $E(t)$ denote the evolution operator that associates to u_0 the solution $E(t)u_0 := u(\,\cdot\,,t)$ of (1.1) at time $t > 0$. Then $E(t)$ maps $L_1(\mathbb{R}^d) + L_\infty(\mathbb{R}^d)$ into itself. Moreover, $E(t)$ is a norm-one, bounded operator on $L_1(\mathbb{R}^d)$ and $L_\infty(\mathbb{R}^d)$:

$$\|E(t)u_0\|_{L_p(\mathbb{R}^d)} \leq \|u_0\|_{L_p(\mathbb{R}^d)}, \quad p = 1, \infty. \tag{2.1}$$

Actually, $E(t)$ is a bounded operator with norm one on each of the $L_p(\mathbb{R}^d)$ spaces

$1 \le p \le \infty$. This can be derived from the study of entropy–entropy flux pairs or proved as in §4.

The operator $E(t)$ is monotone in the sense that $E(t)u_0 \ge E(t)v_0$ whenever $u_0 \ge v_0$ (see, for example, [3]) and preserves integrals

$$\int_{\mathbb{R}^d} E(t)u_0\, dx = \int_{\mathbb{R}^d} u_0\, dx.$$

From these properties, one derives that $E(t)$ is a contraction (see [3])

$$\|E(t)(u_0) - E(t)(v_0)\| \le \|u_0 - v_0\|.$$

Here and later, the unsubscripted norm $\| \cdot \|$ always denotes the $L_1(\mathbb{R}^d)$ norm.

There is no simple description of the solution u of (1.1). However, in one space dimension, the following method of Lax [11] gives a useful analytic method for obtaining u. We assume that the flux f is strictly convex. It follows that the transport velocity $a(u) := f'(u)$ is strictly increasing on $\mathbb{R}$ and is therefore invertible (under composition of functions) on $\mathbb{R}$. We assume further that the initial condition u_0 is continuous with compact support. Any initial condition can be approximated to arbitrary accuracy in the $L_1(\mathbb{R})$ norm by such functions. Under these conditions, Lax [11] shows that the solution $u(x,t)$ of (1.1) can be described by

$$u(x,t) = u_0(y(x,t)), \tag{2.2}$$

where $y = y(x,t)$ satisfies

$$\frac{x-y}{t} = a(u_0(y)). \tag{2.3}$$

In general, there are many solutions y to (2.3). The one that satisfies (2.2) is determined as the solution to an extremal problem (cf. Theorem 3.1 in [11]).

Lax establishes various properties of the selection $y(x,t)$. In particular, he shows that for each fixed $t > 0$,

$$y(\,\cdot\,,t) \text{ is increasing on } \mathbb{R}. \tag{2.4}$$

Shocks occur in the solution to (1.1) at points where $y(\,\cdot\,,t)$ discontinuous. This can occur when there is more than one solution y to (2.3) and we jump down from one piece of the graph of u_0 to another.

3. Besov spaces. In this section, we give the definition of Besov spaces and several equivalent norms for these spaces, which will be used in the sequel. For $\alpha > 0$ and $0 < p, q \le \infty$, the Besov space $B_q^\alpha(L_p(\mathbb{R}^d))$ is a space of functions with smoothness α in L_p. The secondary parameter q gives a finer gradation of these spaces that is important in many applications.

To describe these spaces, we use the difference operators Δ_h^r, $r = 1, 2, \dots$, with step $h \in \mathbb{R}^d$. These are defined inductively with $\Delta_h(v,x) := v(x+h) - v(x)$ and $\Delta_h^r := \Delta_h \Delta_h^{r-1}$. It follows that
