ON TRIGONOMETRIC SERIES EXPANSIONS OF TWELVE JACOBIAN ELLIPTIC FUNCTIONS[*]

D. S. TSELNIK[†]

Abstract. Trigonometric series expansions of the Jacobian elliptic functions *snu*, *cnu*, and *dnu*, which are intermediates between the expansions of these functions that are known in the literature, are derived and discussed. Similar expansions for the functions *cdu*, *sdu*, . . . , *scu* are also derived. From these new expansions, a number of interesting infinite series can be obtained. (Some examples are given.) The usage of these new expansions in applications is discussed.

Key words. Jacobian elliptic functions, trigonometric series expansions

AMS subject classifications. 33E05, 42A16

PII. S0036141095291257

1. Introduction.

In this paper, we consider trigonometric series expansions of (twelve) Jacobian elliptic functions [3], [4], [5], [12], $sn(u,k)$, $cn(u,k)$, $dn(u,k)$, $cd(u,k)$, $sd(u,k),\ldots$, and $sc(u,k)$.

We shall start from the expansions of the three "base" functions *snu*, *cnu*, and *dnu*, giving the pertinent derivations with sufficient details. Then we shall present the expansions of the other nine functions in question—without derivations but with an explanation of how these expansions were obtained.

Therefore, let us consider the functions $sn(u,k)$, $cn(u,k)$, and $dn(u,k)$. Each of these is a function of the complex variable u and the (complex) parameter k (called modulus) [12, section 22.11]. In the u-plane, each of the functions *snu*, *cnu*, and *dnu* has poles at points

$$u = 2nK + (2m+1)iK', \tag{1.1}$$

where $n = 0, \pm 1, \pm 2, \ldots, m = 0, \pm 1, \pm 2, \ldots$, and K and K' are the complete and the associated complete elliptic integrals of the first kind [12, section 22.35].

In the literature, the following trigonometric series expansions of $sn(u,k)$, $cn(u,k)$, and $dn(u,k)$ are known:

$$sn(u,k) = \frac{2\pi}{kK}\sum_{n=0}^{\infty}\frac{q^{n+\frac{1}{2}}}{1-q^{2n+1}}\sin\frac{(2n+1)\pi u}{2K}, \tag{1.2}$$

$$cn(u,k) = \frac{2\pi}{kK}\sum_{n=0}^{\infty}\frac{q^{n+\frac{1}{2}}}{1+q^{2n+1}}\cos\frac{(2n+1)\pi u}{2K}, \tag{1.3}$$

$$dn(u,k) = \frac{\pi}{2K} + \frac{2\pi}{K}\sum_{n=0}^{\infty}\frac{q^{n+1}}{1+q^{2n+2}}\cos\frac{(n+1)\pi u}{K}, \tag{1.4}$$

and

$$sn(u,k) = \frac{\pi}{2kK}\sum_{j=-\infty}^{+\infty}\operatorname{cosec}\frac{\pi}{2K}[u-(2j-1)iK'], \tag{1.5}$$

[†] 2416 18th Street South, Apartment 204, Fargo, ND 58103.

$$cn(u,k) = \frac{\pi i}{2kK} \sum_{j=-\infty}^{+\infty} (-1)^j \ \text{cosec}\ \frac{\pi}{2K}[u-(2j-1)iK'], \tag{1.6}$$

$$dn(u,k) = \frac{\pi i}{2K} \lim_{m\to\infty} \sum_{j=-m}^{m} (-1)^j \cot \frac{\pi}{2K}[u-(2j-1)iK'] \tag{1.7}$$

[12, section 22.6], [3, p. 260], [4, sections 8.7 and 8.8].

Here

$$q = \exp(\pi i \tau), \quad \tau = \frac{iK'}{K}, \tag{1.8}$$

and $\text{Im}\tau > 0$ so that

$$|q| = \exp(-\pi \text{Im}\tau) < 1 \tag{1.9}$$

[12, sections 21.1 and 21.6].

Each of the expansions (1.2)–(1.4) is valid in the strip

$$\left|\text{Im}\left(\frac{u}{K}\right)\right| < \text{Im}\left(\frac{iK'}{K}\right) = \text{Im}\tau \tag{1.10}$$

of the u-plane, and each of the expansions (1.5)–(1.7) is valid in the entire finite u-plane, with the poles of snu, cnu, or dnu, respectively, deleted [12, section 22.6], [3, p. 260], [4, sections 8.7 and 8.8].

In this paper, we obtain the following series expansions of $sn(u,k)$, $cn(u,k)$, and $dn(u,k)$:

$$\begin{aligned} sn(u,k) = {} & \frac{\pi}{2kK} \sum_{j=-m+1}^{m} \text{cosec} \frac{\pi}{2K}[u-(2j-1)iK'] \\ & + \frac{2\pi q^{m+\frac{1}{2}}}{kK} \sum_{n=0}^{\infty} \frac{q^{(2m+1)n}}{1-q^{2n+1}} \sin \frac{(2n+1)\pi u}{2K}, \end{aligned} \tag{1.11}$$

$$\begin{aligned} cn(u,k) = {} & \frac{\pi i}{2kK} \sum_{j=-m+1}^{m} (-1)^j \text{cosec}\ \frac{\pi}{2K}[u-(2j-1)iK'] \\ & + (-1)^m \frac{2\pi q^{m+\frac{1}{2}}}{kK} \sum_{n=0}^{\infty} \frac{q^{(2m+1)n}}{1+q^{2n+1}} \cos \frac{(2n+1)\pi u}{2K}, \end{aligned} \tag{1.12}$$

$$\begin{aligned} dn(u,k) = {} & \frac{\pi}{2K} + \frac{\pi i}{2K} \sum_{j=-m+1}^{m} (-1)^j \left\{\cot \frac{\pi}{2K}[u-(2j-1)iK'] - i\alpha(j)\right\} \\ & + (-1)^m \frac{2\pi q^{2m+1}}{K} \sum_{n=0}^{\infty} \frac{q^{(2m+1)n}}{1+q^{2n+2}} \cos \frac{(n+1)\pi u}{K}, \end{aligned} \tag{1.13}$$

where $m = 1, 2, 3, \ldots$, and

$$\alpha(j) = \begin{cases} -1 & \text{if } j \le 0, \\ +1 & \text{if } j > 0. \end{cases} \tag{1.14}$$

Each of the expansions (1.11)–(1.13) is valid (and can be used) in the strip

$$\begin{aligned} \left|\text{Im}\left(\frac{u}{K}\right)\right| & < \text{Im}\left[\frac{(2m+1)iK'}{K}\right] \\ & = \text{Im}[(2m+1)\tau], \end{aligned} \tag{1.15}$$

with the poles of snu, cnu, or dnu, respectively, located within that strip deleted. Strip (1.15) is $(2m+1)$ times wider than strip (1.10) where expansions (1.2)–(1.4) are valid, but, of course, it is "more narrow" than the entire finite u-plane where (with the exception of the poles of snu, cnu, or dnu, respectively) expansions (1.5)–(1.7) are valid.

Expansions (1.11)–(1.13) (obtained in this paper) can be viewed as intermediates between the known expansions (1.2)–(1.4) (on one hand) and expansions (1.5)–(1.7) (on the other hand), and they provide a link between these two sets of expansions known in the literature.

Because of the factors q^{2mn}, the infinite series expansions (1.11)–(1.13) should converge in strip (1.10) more rapidly (and more rapidly the larger m is) than the infinite series of (1.2)–(1.4), respectively. At the same time, the structure of the general terms of the infinite series of (1.11)–(1.13) is as simple as the structure of the general terms of the series (1.2)–(1.4).

Derivations and further discussion of expansions (1.11)–(1.13) follow.

2. Derivation of expansions (1.11) and (1.12). For each of the expansions (1.11)–(1.13), two different methods of obtaining each expansion can be used.

Namely, with regard to expansion (1.11) (for the sake of definiteness), one way to obtain it is to start from expansion (1.5) of $sn(u,k)$, to break the infinite sum of (1.5) into two parts,

$$\sum_{j=-m+1}^{m} \quad \text{and} \quad \left(\sum_{j=-\infty}^{-m} + \sum_{j=m+1}^{\infty}\right), \tag{2.1}$$

and then to represent the second part as the sine series in strip (1.15).

Another way to find (1.11) is to start from expansion (1.2) of $sn(u,k)$, to derive (1.11) for u in strip (1.10) first, and then to use analytic continuation to prove that (1.11) is indeed valid in strip (1.15).

In this paper, we shall use the first method to obtain (1.11) and (1.12) and the second method to obtain (1.13).

Therefore, let us write (1.5) as

$$sn(u,k) = \frac{\pi}{2kK}\sum_{j=-m+1}^{m} \operatorname{cosec} \frac{\pi}{2K}[u-(2j-1)iK'] + R_s, \tag{2.2}$$

where

$$R_s = \frac{\pi}{2kK}\left(\sum_{j=-\infty}^{-m} + \sum_{j=m+1}^{\infty}\right) \operatorname{cosec} \frac{\pi}{2K}[u-(2j-1)iK'] \tag{2.3}$$

and $m = 1, 2, 3, \ldots$.

The expression for R_s may be written as

$$R_s = \frac{\pi}{2kK}\sum_{j=m+1}^{\infty} f_{sn}^{(j)}(v) \quad \left(v = \frac{u}{K}\right), \tag{2.4}$$

where

$$f_{sn}^{(j)}(v) = \operatorname{cosec} \frac{\pi}{2}[v-(2j-1)\tau] + \operatorname{cosec} \frac{\pi}{2}[v+(2j-1)\tau] \tag{2.5}$$

$$= 4\cos\frac{(2j-1)\pi\tau}{2}\,\frac{\sin\left(\frac{\pi v}{2}\right)}{\cos(2j-1)\pi\tau-\cos\pi v} \tag{2.6}$$

$$= \frac{2(1+q^{2j-1})}{q^{j-\frac{1}{2}}}\,\frac{\sin\left(\frac{\pi v}{2}\right)}{\cos(2j-1)\pi\tau-\cos\pi v} \tag{2.7}$$

$$= \frac{4q^{j-\frac{1}{2}}(1+q^{2j-1})\sin\left(\frac{\pi v}{2}\right)}{1-2q^{2j-1}\cos\pi v+q^{4j-2}}. \tag{2.8}$$

The following expansion is cited (and used) in [3, p. 261]:

$$\frac{(1+a)\sin w}{1-2a\cos 2w+a^2} = \sum_{n=0}^{\infty} a^n \sin(2n+1)w. \tag{2.9}$$

Conditions on a and w for (2.9) to be valid are not indicated in [3], however. Let a and w in (2.9) be complex. By D'Alembert's test, one sees that the infinite series on the right-hand side of (2.9) is absolutely convergent if

$$|a|e^{2|\mathrm{Im} w|} < 1, \tag{2.10}$$

and it is divergent if

$$|a|e^{2|\mathrm{Im} w|} > 1. \tag{2.11}$$

Expansion (2.9) is valid if condition (2.10) is satisfied (and it is not valid if (2.11) is satisfied).

Using (2.9)–(2.11), we find that

$$\frac{(1+q^{2j-1})\sin\left(\frac{\pi v}{2}\right)}{1-2q^{2j-1}\cos\pi v+q^{4j-2}} = \sum_{n=0}^{\infty} q^{(2j-1)n}\sin\frac{(2n+1)\pi v}{2}, \tag{2.12}$$

and this is true if

$$|\mathrm{Im} v| < (2j-1)\ \mathrm{Im}\tau \tag{2.13}$$

and false if

$$|\mathrm{Im} v| > (2j-1)\ \mathrm{Im}\tau. \tag{2.14}$$

From (2.4)–(2.8) and (2.12), we get

$$R_s = \frac{2\pi q^{m+\frac{1}{2}}}{kK}\sum_{n=0}^{\infty}\frac{q^{(2m+1)n}}{1-q^{2n+1}}\sin\frac{(2n+1)\pi u}{2K} \tag{2.15}$$

$(m = 1, 2, 3, \ldots)$ for

$$|\mathrm{Im} v| < (2m+1)\ \mathrm{Im}\tau. \tag{2.16}$$

In the process of obtaining (2.15), we changed the order of summation with respect to j and n in infinite sums. The validity of that change can be proved by the usual methods (see [1, section 8.23]).

From (2.2) and (2.15), expansion (1.11) immediately follows.

The derivation of expansion (1.12) for $cn(u,k)$ is similar, only instead of R_s we use

$$R_c = \frac{\pi i}{2kK}\left(\sum_{j=-\infty}^{-m} + \sum_{j=m+1}^{\infty}\right)(-1)^j \operatorname{cosec} \frac{\pi}{2K}[u-(2j-1)iK'] \tag{2.17}$$

$$= \frac{\pi i}{2kK}\sum_{j=m+1}^{\infty}(-1)^j f_{cn}^{(j)}(v) \tag{2.18}$$

($m = 1, 2, 3, \ldots$), where

$$f_{cn}^{(j)}(v) = \operatorname{cosec} \frac{\pi}{2}[v-(2j-1)\tau] - \operatorname{cosec} \frac{\pi}{2}[v+(2j-1)\tau] \tag{2.19}$$

$$= 4\sin\frac{(2j-1)\pi\tau}{2}\,\frac{\cos\left(\frac{\pi v}{2}\right)}{\cos(2j-1)\pi\tau - \cos\pi v} \tag{2.20}$$

$$= \frac{2i(1-q^{2j-1})}{q^{j-\frac{1}{2}}}\,\frac{\cos\left(\frac{\pi v}{2}\right)}{\cos(2j-1)\pi\tau - \cos\pi v} \tag{2.21}$$

$$= \frac{4iq^{j-\frac{1}{2}}(1-q^{2j-1})\cos\left(\frac{\pi v}{2}\right)}{1-2q^{2j-1}\cos\pi v + q^{4j-2}}, \tag{2.22}$$

and instead of (2.9) we use the expansion

$$\frac{(1-a)\cos w}{1-2a\cos 2w + a^2} = \sum_{n=0}^{\infty} a^n \cos(2n+1)w \tag{2.23}$$

(which one can easily obtain from (2.9) by replacing a by $-a$ and w by $w + (\pi/2)$, respectively).

Continuing in this way, we find that

$$R_c = (-1)^m \frac{2\pi q^{m+\frac{1}{2}}}{kK}\sum_{n=0}^{\infty}\frac{q^{(2m+1)n}}{1+q^{2n+1}}\cos\frac{(2n+1)\pi u}{2K} \tag{2.24}$$

and finally obtain expansion (1.12) for u in strip (1.15).

In addition to R_s and R_c, below we shall also use (in section 4) the notation

$$R_d = (-1)^m \frac{2\pi q^{2m+1}}{K}\sum_{n=0}^{\infty}\frac{q^{(2m+1)n}}{1+q^{2n+2}}\cos\frac{(n+1)\pi u}{K} \tag{2.25}$$

($m = 1, 2, 3, \ldots$) for the term with the infinite series in n of the right-hand side of (1.13).

3. Derivation of expansion (1.13). As mentioned in the previous section, here we shall use a different approach. Namely, we start from expansion (1.4) and write it as

$$dn(u,k) = \frac{\pi}{2K} + \frac{2\pi}{K}\sum_{n=0}^{\infty}\frac{q^{n+1}}{1+q^{2n+2}}\cos(n+1)\pi v \tag{3.1}$$
$$+ F_{dn}^{(m)}(v) - F_{dn}^{(m)}(v),$$

with

$$F_{dn}^{(m)}(v) = \frac{\pi i}{2K} \sum_{j=-m+1}^{m} (-1)^j \cot \frac{\pi}{2}[v - (2j-1)\tau] \tag{3.2}$$

$(m = 1, 2, 3, \ldots)$.

The expression for $F_{dn}^{(m)}$ can be rewritten as

$$F_{dn}^{(m)}(v) = \frac{\pi i}{2K} \sum_{j=1}^{m} (-1)^j f_{dn}^{(j)}(v), \tag{3.3}$$

where

$$\begin{aligned} f_{dn}^{(j)}(v) &= \cot \frac{\pi}{2}[v - (2j-1)\tau] - \cot \frac{\pi}{2}[v + (2j-1)\tau] && (3.4)\\ &= 2\sin[(2j-1)\pi\tau] \frac{1}{\cos(2j-1)\pi\tau - \cos \pi v} && (3.5)\\ &= \frac{i(1-q^{4j-2})}{q^{2j-1}} \frac{1}{\cos(2j-1)\pi\tau - \cos \pi v} && (3.6)\\ &= \frac{2i(1-q^{4j-2})}{1 - 2q^{2j-1}\cos \pi v + q^{4j-2}}. && (3.7)\end{aligned}$$

Multiplying (2.9) by $(1-a)\sin w$ and (2.23) by $(1+a)\cos w$ and adding the results, we obtain

$$\frac{(1-a^2)}{1 - 2a\cos 2w + a^2} = 1 + 2\sum_{n=1}^{\infty} a^n \cos 2nw, \tag{3.8}$$

which is valid under condition (2.10) (and is not valid if (2.11) is satisfied).

From (3.8), it follows that

$$\frac{1 - q^{4j-2}}{1 - 2q^{2j-1}\cos \pi v + q^{4j-2}} = 1 + 2\sum_{n=1}^{\infty} q^{(2j-1)n} \cos n\pi v \tag{3.9}$$

$(j = 1, 2, 3, \ldots)$, and this is true under condition (2.13) (and not true if (2.14) is satisfied).

From (3.3), (3.4)–(3.7), and (3.9), we get

$$\frac{K}{\pi} F_{dn}^{(m)}(v) = E(m, n = 0) + 2\sum_{n=1}^{\infty} E(m,n) \cos n\pi v \tag{3.10}$$

$(m = 1, 2, 3, \ldots)$, where

$$E(m,n) = \sum_{j=1}^{m} (-1)^{j-1} q^{(2j-1)n} \tag{3.11}$$

$(n = 0, 1, 2, \ldots)$, and the result (3.10) is certainly valid for $v(= u/K)$ in strip (1.10).

From (3.11), we obtain

$$E(m,n) = q^n \frac{1 - (-1)^m q^{2nm}}{1 + q^{2n}} \tag{3.12}$$

$(m = 1, 2, 3, \ldots, n = 0, 1, 2, \ldots)$. In particular,

$$E(m, n = 0) = \frac{1 - (-1)^m}{2} \tag{3.13}$$

$(m = 1, 2, 3, \ldots)$.

Equation (3.10) can now be rewritten as

$$F_{dn}^{(m)}(v) = \frac{\pi}{2K}[1 - (-1)^m] + \frac{2\pi}{K}\sum_{n=0}^{\infty} q^{n+1} \cdot \frac{1 - (-1)^m q^{(2n+2)m}}{1 + q^{2n+2}} \cos(n+1)\pi v \tag{3.14}$$

$(m = 1, 2, 3, \ldots, v$ in strip (1.10)).

We now substitute for the first $F_{dn}^{(m)}$ of (3.1) its expression (3.2) and for the second $F_{dn}^{(m)}$ its expression (3.14) to get

$$dn(u, k) = (-1)^m \frac{\pi}{2K} + \frac{\pi i}{2K} \sum_{j=-m+1}^{m} (-1)^j \cdot \cot \frac{\pi}{2K}[u - (2j-1)iK'] + (-1)^m \frac{2\pi q^{2m+1}}{K} \cdot \sum_{n=0}^{\infty} \frac{q^{(2m+1)n}}{1 + q^{2n+2}} \cos \frac{(n+1)\pi u}{K} \tag{3.15}$$

$(m = 1, 2, 3, \ldots)$ for u in strip (1.10).

Taking into account the fact that

$$(-1)^m = 1 + 2\sum_{j=1}^{m}(-1)^j = \sum_{j=-m+1}^{m} (-1)^j \alpha(j) + 1 \tag{3.16}$$

$(m = 1, 2, 3, \ldots)$, one can now rewrite (3.15) in the form of (1.13) for u in strip (1.10). Finally, to prove that (1.13) is valid in strip (1.15), one can use analytic continuation.

4. Estimates for *n*-series in (1.11)–(1.13). In (1.11), the n-series is R_s (see (1.11) and (2.15)). For u in strip (1.15), we can write

$$\operatorname{Im}\left(\frac{u}{K}\right) = \gamma \operatorname{Im}[(2m+1)\tau], \tag{4.1}$$

where $-1 < \gamma < +1$ and $m = 1, 2, 3, \ldots$. For u in this strip, we obtain

$$\left|\sin \frac{(2n+1)\pi u}{2K}\right| \le |q|^{-(2m+1)(2n+1)|\gamma|/2} \tag{4.2}$$

and then

$$|R_s| \le \frac{2\pi}{|kK|} \frac{|q|^{(m+\frac{1}{2})(1-|\gamma|)}}{1 - |q|} \frac{1}{1 - |q|^{(2m+1)(1-|\gamma|)}} \tag{4.3}$$

$(m = 1, 2, 3, \ldots)$.

Similarly, for the n-series of (1.12), which is R_c (see (1.12) and (2.24)), we find the same estimate (4.3) in strip (1.15).

Also, in strip (1.15),

$$\left|\cos\frac{(n+1)\pi u}{K}\right| \leq |q|^{-(2m+1)(n+1)|\gamma|}, \tag{4.4}$$

from which we obtain the estimate for R_d (see (2.25)):

$$|R_d| \leq \frac{2\pi}{|K|}\frac{|q|^{(2m+1)(1-|\gamma|)}}{1-|q|^2}\frac{1}{1-|q|^{(2m+1)(1-|\gamma|)}} \tag{4.5}$$

$(m = 1, 2, 3, \ldots)$ in strip (1.15).

If instead of (4.2), we use the estimate

$$\left|\sin\frac{(2n+1)\pi u}{2K}\right| \leq \frac{1}{2}[|q|^{-(2m+1)(2n+1)\gamma/2} + |q|^{(2m+1)(2n+1)\gamma/2}], \tag{4.6}$$

then instead of (4.3), the following bound for $|R_s|$ is obtained:

$$\begin{aligned}|R_s| \leq{}& \frac{\pi}{|kK|}\frac{|q|^{(m+\frac{1}{2})(1-|\gamma|)}}{1-|q|}\\ &\cdot\frac{1}{1-|q|^{(2m+1)(1-|\gamma|)}}\left\{1+|q|^{(2m+1)|\gamma|}\frac{1-|q|^{(2m+1)(1-|\gamma|)}}{1-|q|^{(2m+1)(1+|\gamma|)}}\right\},\end{aligned} \tag{4.7}$$

and this bound is true for $|R_c|$ as well.

Also, if instead of (4.4), we use the estimate

$$\left|\cos\frac{(n+1)\pi u}{K}\right| \leq \frac{1}{2}[|q|^{-(2m+1)(n+1)\gamma} + |q|^{(2m+1)(n+1)\gamma}], \tag{4.8}$$

then instead of (4.5), the following bound for $|R_d|$ is found:

$$\begin{aligned}|R_d| \leq{}& \frac{\pi}{|K|}\frac{|q|^{(2m+1)(1-|\gamma|)}}{1-|q|^2}\\ &\cdot\frac{1}{1-|q|^{(2m+1)(1-|\gamma|)}}\left\{1+|q|^{(4m+2)|\gamma|}\frac{1-|q|^{(2m+1)(1-|\gamma|)}}{1-|q|^{(2m+1)(1+|\gamma|)}}\right\}.\end{aligned} \tag{4.9}$$

5. Obtaining series expansions (1.5)–(1.7) from equations (1.11)–(1.13). From (4.3), it follows that $|R_s| \to 0$ as $m \to \infty$. Accordingly, the limiting form of (1.11) as $m \to \infty$ is (1.5) with the sum written as

$$\lim_{m\to\infty}\sum_{j=-m+1}^{m} \tag{5.1}$$

(and also, of course, (1.5) is known to be true with the sum written as it is written in (1.5)).

Similarly, (1.6) with the sum in it written as in (5.1) is the limiting form of (1.12) as $m \to \infty$.

The bound (4.3) (or the bound (4.7)) for $|R_s|$ and $|R_c|$ can be looked upon as an upper bound for the absolute values of the remainders of the approximations

$$sn(u,k) \simeq \frac{\pi}{2kK} \sum_{j=-m+1}^{m} \operatorname{cosec} \frac{\pi}{2K}[u-(2j-1)iK'] \tag{5.2}$$

and

$$cn(u,k) \simeq \frac{\pi i}{2kK} \sum_{j=-m+1}^{m} (-1)^j \operatorname{cosec} \frac{\pi}{2K}[u-(2j-1)iK'] \tag{5.3}$$

in strip (1.15); these approximations can be viewed as being obtained by truncating the infinite series of (1.5) and (1.6) (in the manner indicated by the extreme values of j in the sums of (5.2) and (5.3)).

Now taking into account (4.5), we find the following expansion as the limiting form of (1.13) as $m \to \infty$:

$$dn(u,k) = \frac{\pi}{2K} + \frac{\pi i}{2K} \lim_{m\to\infty} \sum_{j=-m+1}^{m} (-1)^j \left\{ \cot \frac{\pi}{2K}[u-(2j-1)iK'] - i\alpha(j) \right\} \tag{5.4}$$

($|u| < \infty$, poles of dnu deleted).

This expansion looks different from (1.7) but is equivalent to it. Indeed, for any fixed u of (5.4),

$$\lim_{m\to+\infty} \cot \frac{\pi}{2K}[u+(2m+1)\pi iK'] = -i, \tag{5.5}$$

and by (5.5), equation (5.4) can be reduced to (1.7).

6. Other forms of expansions (1.11)–(1.13). Here are alternative forms of expansions (1.11)–(1.13):

$$\begin{aligned} sn(u,k) = {} & \frac{2\pi q^{1/2}}{kK} \sum_{j=1}^{m} \frac{q^{j-1}(1+q^{2j-1}) \sin \dfrac{\pi u}{2K}}{1-2q^{2j-1}\cos\left(\dfrac{\pi u}{K}\right)+q^{4j-2}} \\ & + \frac{2\pi q^{m+\frac12}}{kK} \sum_{n=0}^{\infty} \frac{q^{(2m+1)n}}{1-q^{2n+1}} \sin \frac{(2n+1)\pi u}{2K}, \end{aligned} \tag{6.1}$$

$$\begin{aligned} sn(u,k) = {} & \frac{\pi q^{1/2}}{kK} \sum_{j=1}^{m} \frac{1+q^{2j-1}}{q^j} \frac{\sin \frac{\pi u}{2K}}{\cosh\left[\dfrac{(2j-1)\pi K'}{K}\right] - \cos\left(\dfrac{\pi u}{K}\right)} \\ & + \frac{2\pi}{kK} q^{m+\frac12} \sum_{n=0}^{\infty} \frac{q^{(2m+1)n}}{1-q^{2n+1}} \sin \frac{(2n+1)\pi u}{2K}, \end{aligned} \tag{6.2}$$

$$\begin{aligned} cn(u,k) = {} & \frac{2\pi q^{1/2}}{kK} \sum_{j=1}^{m} (-1)^{j-1} \frac{q^{j-1}(1-q^{2j-1}) \cos \dfrac{\pi u}{2K}}{1-2q^{2j-1}\cos\left(\dfrac{\pi u}{K}\right)+q^{4j-2}} \\ & + (-1)^m \frac{2\pi q^{m+\frac12}}{kK} \sum_{n=0}^{\infty} \frac{q^{(2m+1)n}}{1+q^{2n+1}} \cos \frac{(2n+1)\pi u}{2K}, \end{aligned} \tag{6.3}$$

$$(6.4)\quad cn(u,k) = \frac{\pi q^{1/2}}{kK}\sum_{j=1}^{m}(-1)^{j-1}\frac{1-q^{2j-1}}{q^j}\frac{\cos\dfrac{\pi u}{2K}}{\cosh\left[\dfrac{(2j-1)\pi K'}{K}\right]-\cos\left(\dfrac{\pi u}{K}\right)}$$
$$+(-1)^m\frac{2\pi q^{m+\frac{1}{2}}}{kK}\sum_{n=0}^{\infty}\frac{q^{(2m+1)n}}{1+q^{2n+1}}\cos\frac{(2n+1)\pi u}{2K},$$

$$(6.5)\quad dn(u,k) = (-1)^m\frac{\pi}{2K}+\frac{\pi}{K}\sum_{j=1}^{m}(-1)^{j-1}\frac{1-q^{4j-2}}{1-2q^{2j-1}\cos\left(\dfrac{\pi u}{K}\right)+q^{4j-2}}$$
$$+(-1)^m\frac{2\pi}{K}q^{2m+1}\sum_{n=0}^{\infty}\frac{q^{(2m+1)n}}{1+q^{2n+2}}\cos\frac{(n+1)\pi u}{K},$$

$$(6.6)\quad dn(u,k) = (-1)^m\frac{\pi}{2K}+\frac{\pi}{2K}\sum_{j=1}^{m}(-1)^{j-1}\frac{1-q^{4j-2}}{q^{2j-1}}\frac{1}{\cosh\left[\dfrac{(2j-1)\pi K'}{K}\right]-\cos\dfrac{\pi u}{K}}$$
$$+(-1)^m\frac{2\pi q^{2m+1}}{K}\sum_{n=0}^{\infty}\frac{q^{(2m+1)n}}{1+q^{2n+2}}\cos\frac{(n+1)\pi u}{K},$$

$$(6.7)\quad dn(u,k) = \frac{\pi}{2K}+\frac{2\pi}{K}\sum_{j=1}^{m}(-1)^{j-1}q^{2j-1}\frac{\cos\dfrac{\pi u}{K}-q^{2j-1}}{1-2q^{2j-1}\cos\dfrac{\pi u}{K}+q^{4j-2}}$$
$$+(-1)^m\frac{2\pi}{K}q^{2m+1}\sum_{n=0}^{\infty}\frac{q^{(2m+1)n}}{1+q^{2n+2}}\cos\frac{(n+1)\pi u}{K},$$

and

$$(6.8)\qquad dn(u,k) = \frac{\pi}{2K}+\frac{\pi}{K}\sum_{j=1}^{m}(-1)^{j-1}\frac{\cos\dfrac{\pi u}{K}-q^{2j-1}}{\cosh\dfrac{(2j-1)\pi K'}{K}-\cos\dfrac{\pi u}{K}}$$
$$+(-1)^m\frac{2\pi q^{2m+1}}{K}\sum_{n=0}^{\infty}\frac{q^{(2m+1)n}}{1+q^{2n+2}}\cos\frac{(n+1)\pi u}{K}.$$

One or another expansion for the same function (sn, cn, or dn) may be preferable to use in certain cases. For example, if τ is purely imaginary (the usual case in applications of elliptic functions in physics and engineering [5]), then K and K' are real, and expansions (6.1) or (6.2) may be more convenient to use than (1.11) for u real.

At $m=\infty$, expansions (6.1)–(6.4) and (6.7) and (6.8) yield

$$(6.9)\qquad sn(u,k) = \frac{2\pi q^{1/2}}{kK}\sum_{j=1}^{\infty}\frac{q^{j-1}(1+q^{2j-1})\sin\dfrac{\pi u}{2K}}{1-2q^{2j-1}\cos\left(\dfrac{\pi u}{K}\right)+q^{4j-2}},$$

$$(6.10)\qquad sn(u,k) = \frac{\pi q^{1/2}}{kK}\sum_{j=1}^{\infty}\frac{1+q^{2j-1}}{q^j}\frac{\sin\dfrac{\pi u}{2K}}{\cosh\left[\dfrac{(2j-1)\pi K'}{K}\right]-\cos\left(\dfrac{\pi u}{K}\right)},$$

$$cn(u,k) = \frac{2\pi q^{1/2}}{kK}\sum_{j=1}^{\infty}(-1)^{j-1}\frac{q^{j-1}(1-q^{2j-1})\cos\dfrac{\pi u}{2K}}{1-2q^{2j-1}\cos\left(\dfrac{\pi u}{K}\right)+q^{4j-2}}, \tag{6.11}$$

$$cn(u,k) = \frac{\pi q^{1/2}}{kK}\sum_{j=1}^{\infty}(-1)^{j-1}\frac{1-q^{2j-1}}{q^j}\frac{\cos\dfrac{\pi u}{2K}}{\cosh\left[\dfrac{(2j-1)\pi K'}{K}\right]-\cos\left(\dfrac{\pi u}{K}\right)}, \tag{6.12}$$

$$dn(u,k) = \frac{\pi}{2K}+\frac{2\pi}{K}\sum_{j=1}^{\infty}(-1)^{j-1}q^{2j-1}\frac{\cos\dfrac{\pi u}{K}-q^{2j-1}}{1-2q^{2j-1}\cos\dfrac{\pi u}{K}+q^{4j-2}}, \tag{6.13}$$

and

$$dn(u,k) = \frac{\pi}{2K}+\frac{\pi}{K}\sum_{j=1}^{\infty}(-1)^{j-1}\frac{\cos\dfrac{\pi u}{K}-q^{2j-1}}{\cosh\dfrac{(2j-1)\pi K'}{K}-\cos\dfrac{\pi u}{K}}, \tag{6.14}$$

respectively ($|u| < \infty$, poles of $sn(u,k)$, $cn(u,k)$, and $dn(u,k)$, respectively, are deleted).

7. Sums of some infinite series. By putting such specific values of u as $u = 0$, $K/2, K, \ldots$ or $u = iK'/2, iK', \ldots$ into the expansions derived above we can obtain results for sums of interesting infinite series. As examples, we cite here the following two results:

$$\sum_{n=0}^{\infty}(-1)^{E(n/2)}\frac{q^{n+m+2nm}}{1-q^{2n+1}} = \frac{kK}{\pi[2q(1+k')]^{1/2}}-\sum_{j=1}^{m}\frac{q^{j-1}(1+q^{2j-1})}{1+q^{4j-2}}, \tag{7.1}$$

$$\sum_{n=1}^{\infty}\frac{q^{(2m+1)n}}{1+q^{2n}} = (-1)^m\left(\frac{K}{2\pi}-\frac{1}{4}\right)-(-1)^m\sum_{j=1}^{m}(-1)^{j-1}\frac{q^{2j-1}}{1-q^{2j-1}}, \tag{7.2}$$

where $m = 1, 2, 3, \ldots$ and $E(x)$ denotes the integral part of the real number x.

This results (7.1) and (7.2) are obtained if one puts $u = K/2$ in (6.1) and $u = 0$ in (6.5), respectively.

8. On the use of trigonometric series expansions of *snu*, *cnu*, and *dnu* in evaluating integrals. In applications, the importance of the trigonometric series expansions of *snu*, *cnu*, and *dnu* is that they can often be used for evaluating integrals of these functions multiplied by another function, like the integral

$$J = \int_0^K \sin\frac{\pi u}{K}\, sn(u,k)\, du \tag{8.1}$$

or similar integrals. Namely, by using trigonometric series expansions of *snu*, *cnu*, and *dnu*, one can often represent the integrals in question as infinite series, or asymptotic expressions for these integrals (say, corresponding to k small) can be found.

Using the example of the integral in (8.1), we shall now explain how the use of different expansions of $sn(u,k)$ may be advantageous. Namely, if we use the expansion (1.2) in (8.1), we get

$$J = 8q^{1/2}k^{-1}\sum_{n=0}^{\infty}\frac{(-1)^{n+1}}{(2n-1)(2n+3)}\frac{q^n}{1-q^{2n+1}}. \tag{8.2}$$

If, on the other hand, we use the expansion (6.2) of $sn(u,k)$ in (8.1), then we get

$$J=\sum_{j=1}^{m} J_j + 8q^{m+\frac{1}{2}}k^{-1}\sum_{n=0}^{\infty}\frac{(-1)^{n+1}}{(2n-1)(2n+3)}\frac{q^{(2m+1)n}}{1-q^{2n+1}}, \tag{8.3}$$

where the sum in j (from $j=1$ to $j=m$) is the result of integration of the term with the sum in j of (6.2) (multiplied by $\sin(\pi u/K)$).

The concrete expressions for J_j are of no importance for the sake of our discussion, and therefore they are not presented here. What is important is that because of the presence of the factors $q^{(2m+1)n}$, the infinite series (in n) of (8.3) is more rapidly convergent than the infinite series of (8.2) (even at $m=1$). Thus using expansion (6.2) for $sn(u,k)$ instead of (1.2) in (8.1), one can obtain a more rapidly convergent series for J.

Of course, if one has already obtained an infinite series representation for some integral, it is possible to try to increase the rapidity of convergence of that series. However, in applications one often wants to (or can) obtain not an entire infinite series expansion but only an asymptotic formula expression (say, corresponding to small k) for an integral. In such cases, the use of a more rapidly convergent series expansion for snu, cnu, and dnu (like (1.11)–(1.13) and (6.1)–(6.8)) is very expedient. Also, the simple structure of the series in n of (1.11)–(1.13) and (6.1)–(6.8) allows for convenient evaluation of the remainder (of the asymptotic formula obtained).

In more complicated situations, if one needs to solve an integral equation with its kernel expressed in terms of sn, cn, or dn, the use of the series expansions (1.11)–(1.13) and (6.1)–(6.8) with their rapidly convergent series in n can be of advantage as well.

9. Expansions of *cdu*, *sdu*, ..., *scu* similar to expansions of *snu*, *cnu*, and *dnu* (1.11)–(1.13). They are as follows:

$$\begin{aligned} cd(u,k) &= \frac{\pi}{2kK}\sum_{j=-m+1}^{m}\sec\frac{\pi}{2K}[u-(2j-1)iK'] \\ &\quad + \frac{2\pi q^{m+\frac{1}{2}}}{kK}\sum_{n=0}^{\infty}(-1)^n\frac{q^{(2m+1)n}}{1-q^{2n+1}}\cos\frac{(2n+1)\pi u}{2K}, \end{aligned} \tag{9.1}$$

$$\begin{aligned} sd(u,k) &= -\frac{\pi i}{2kk'K}\sum_{j=-m+1}^{m}(-1)^j\sec\frac{\pi}{2K}[u-(2j-1)iK'] \\ &\quad + (-1)^m\frac{2\pi q^{m+\frac{1}{2}}}{kk'K}\sum_{n=0}^{\infty}(-1)^n\frac{q^{(2m+1)n}}{1+q^{2n+1}}\sin\frac{(2n+1)\pi u}{2K}, \end{aligned} \tag{9.2}$$

$$\begin{aligned} nd(u,k) &= \frac{\pi}{2k'K} + \frac{\pi i}{2k'K}\sum_{j=-m+1}^{m}(-1)^{j+1}\left\{\tan\frac{\pi}{2K}[u-(2j-1)iK'] + i\alpha(j)\right\} \\ &\quad + (-1)^m\frac{2\pi q^{2m+1}}{k'K}\sum_{n=0}^{\infty}(-1)^{n+1}\frac{q^{(2m+1)n}}{1+q^{2n+2}}\cos\frac{(n+1)\pi u}{K}, \end{aligned} \tag{9.3}$$

$$\begin{aligned} ns(u,k) &= \frac{\pi}{2K}\sum_{j=-m}^{m}\operatorname{cosec}\frac{\pi}{2K}(u-2jiK') \\ &\quad + \frac{2\pi}{K}\sum_{n=0}^{\infty}\frac{q^{(2n+1)(m+1)}}{1-q^{2n+1}}\sin\frac{(2n+1)\pi u}{2K}, \end{aligned} \tag{9.4}$$

$$(9.5)\quad dc(u,k) = \frac{\pi}{2K}\sum_{j=-m}^{m} \sec\frac{\pi}{2K}(u-2jiK') + \frac{2\pi}{K}\sum_{n=0}^{\infty}(-1)^n\frac{q^{(2n+1)(m+1)}}{1-q^{2n+1}}\cos\frac{(2n+1)\pi u}{2K},$$

$$(9.6)\quad ds(u,k) = \frac{\pi}{2K}\sum_{j=-m}^{m}(-1)^j\text{cosec }\frac{\pi}{2K}(u-2jiK') + (-1)^{m+1}\frac{2\pi}{K}\sum_{n=0}^{\infty}\frac{q^{(2n+1)(m+1)}}{1+q^{2n+1}}\sin\frac{(2n+1)\pi u}{2K},$$

$$(9.7)\quad nc(u,k) = \frac{\pi}{2k'K}\sum_{j=-m}^{m}(-1)^j\sec\frac{\pi}{2K}(u-2jiK') + (-1)^{m+1}\frac{2\pi}{k'K}\sum_{n=0}^{\infty}(-1)^n\frac{q^{(2n+1)(m+1)}}{1+q^{2n+1}}\cos\frac{(2n+1)\pi u}{2K},$$

$$(9.8)\quad cs(u,k) = \frac{\pi}{2K}\sum_{j=-m}^{m}(-1)^j\cot\frac{\pi}{2K}(u-2jiK') + (-1)^{m+1}\frac{2\pi}{K}\sum_{n=1}^{\infty}\frac{q^{2n(m+1)}}{1+q^{2n}}\sin\frac{n\pi u}{K},$$

$$(9.9)\quad sc(u,k) = \frac{\pi}{2k'K}\sum_{j=-m}^{m}(-1)^j\tan\frac{\pi}{2K}(u-2jiK') + (-1)^{m}\frac{2\pi}{k'K}\sum_{n=1}^{\infty}(-1)^n\frac{q^{2n(m+1)}}{1+q^{2n}}\sin\frac{n\pi u}{K}.$$

In (9.1)–(9.3), $m = 1, 2, 3, \ldots$, and these expansions are valid in strip (1.15) (with $m = 1, 2, 3, \ldots$). In (9.4)–(9.9), $m = 0, 1, 2, \ldots$, and these are valid in the strip

$$(9.10)\qquad \left|\text{Im}\left(\frac{u}{K}\right)\right| < \text{Im}[(2m+2)\tau]$$

(with $m = 0, 1, 2, \ldots$).

Equations (9.1), (9.2), and (9.3) are obtained by replacing u by $u+K$ in (1.11), (1.12), and (1.13), respectively. Equations (9.4), (9.6), and (9.8) are obtained from the trigonometric series expansions of $ns(u,k)$, $ds(u,k)$, and $cs(u,k)$, respectively, given in [12, section 22.61] by a method similar to how (1.13) was obtained from (1.4) in section 3 above. Instead of $F_{dn}^{(m)}(v)$ (see equation (3.2) above), however, we use

$$(9.11)\qquad F_{ns}^{(m)}(v) = \frac{\pi}{2K}\sum_{j=1}^{m}\left[\text{cosec }\frac{\pi}{2}(v-2j\tau) + \text{cosec }\frac{\pi}{2}(v+2j\tau)\right],$$

$$(9.12)\qquad F_{ds}^{(m)}(v) = \frac{\pi}{2K}\sum_{j=1}^{m}(-1)^j\left[\text{cosec }\frac{\pi}{2}(v-2j\tau) + \text{cosec }\frac{\pi}{2}(v+2j\tau)\right],$$

and

$$(9.13)\qquad F_{cs}^{(m)}(v) = \frac{\pi}{2K}\sum_{j=1}^{m}(-1)^j\left[\cot\frac{\pi}{2}(v-2j\tau) + \cot\frac{\pi}{2}(v+2j\tau)\right]$$

($m = 1, 2, 3, \ldots$) to derive (9.4), (9.6), and (9.8), respectively.

Finally, one obtains equations (9.5), (9.7), and (9.9) by replacing u by $u + K$ in (9.4), (9.6), and (9.8), respectively.

10. Expansions in asymetric strips. Here we shall give pertinent explanations using the example of $sn(u, k)$.

In the $v = u/K$-plane, the function $sn(u, k)$ has poles at points

$$v = 2n + (2m + 1)\tau, \quad n = 0, \pm1, \pm2, \ldots, \quad m = 0, \pm1, \pm2, \ldots, \tag{10.1}$$

(see (1.1)), and all of these poles are located on the horizontal lines

$$\mathrm{Im}v = \mathrm{Im}[(2m + 1)\tau], \quad m = 0, \pm1, \pm2, \ldots, \tag{10.2}$$

in the v-plane.

Now expansion (1.2) (known in the literature) and expansion (1.11) of $sn(u, k)$ (derived in this paper) are valid in the strips

$$|\mathrm{Im}v| < \mathrm{Im}\tau \tag{10.3}$$

and

$$|\mathrm{Im}v| < \mathrm{Im}[(2m + 1)\tau], \quad m = 1, 2, 3, \ldots, \tag{10.4}$$

respectively, and each of these strips is seen to be symmetric with respect to the Rev-axis in the v-plane.

However, using the set of expansions derived in this paper, one can easily obtain expansions of $sn(u, k)$ valid in asymmetric (with respect to the Rev-axis in the v-plane) strips as well. Namely, all the strips between the (horizontal) lines (10.2) of poles of $sn(u, k)$ in the v-plane belong to one of the following categories:

$$\mathrm{Im}[(2s - 1)\tau] < \mathrm{Im}v < \mathrm{Im}[(2s + 1)\tau], \tag{10.5}$$

where $s = 0, \pm1, \pm2, \ldots$, or

$$\mathrm{Im}[(2s - 2m - 1)\tau] < \mathrm{Im}v < \mathrm{Im}[(2s + 2m + 1)\tau], \tag{10.6}$$

where $s = 0, \pm1, \pm2, \ldots$ and $m = 1, 2, 3, \ldots$, or

$$\mathrm{Im}[(2s - 2m + 1)\tau] < \mathrm{Im}v < \mathrm{Im}[(2s + 2m + 1)\tau], \tag{10.7}$$

where $s = 0, \pm1, \pm2, \ldots$ and $m = 1, 2, 3, \ldots$.

To obtain the expansion of $sn(u, k)$ valid in strip (10.5), we use [12, section 22.34]

$$sn(u, k) = sn(u - 2siK', k) \tag{10.8}$$

for $s = 0, \pm1, \pm2, \ldots$. Using (1.2), we find that

$$sn(u, k) = \frac{2\pi}{kK} \sum_{n=0}^{\infty} \frac{q^{n+\frac{1}{2}}}{1 - q^{2n+1}} \sin \frac{(2n + 1)\pi(u - 2siK')}{2K} \tag{10.9}$$

in strip (10.5). Similarly, using (1.11), we find that

$$\begin{aligned} sn(u, k) = \frac{\pi}{2kK} \sum_{j=-m+1}^{m} \operatorname{cosec} \frac{\pi}{2K}[u - (2j - 1)iK' - 2siK'] \\ + \frac{2\pi q^{m+\frac{1}{2}}}{kK} \sum_{n=0}^{\infty} \frac{q^{(2m+1)n}}{1 - q^{2n+1}} \sin \frac{(2n + 1)\pi(u - 2siK')}{2K} \end{aligned} \tag{10.10}$$

for v in strip (10.6).

Finally, using (see [2, equation 122.24])

$$sn(u,k) = k^{-1} dc[u - K - (2s+1)iK', k] \tag{10.11}$$

for $s = 0, \pm 1, \pm 2, \ldots$ and (9.5), we obtain

$$\begin{aligned} sn(u,k) = {} & \frac{\pi}{2kK} \sum_{j=-m+1}^{m-1} \operatorname{cosec} \frac{\pi}{2K}[u - 2jiK' - (2s+1)iK'] \\ & + \frac{2\pi}{kK} \sum_{n=0}^{\infty} \frac{q^{(2n+1)m}}{1 - q^{2n+1}} \sin \frac{(2n+1)\pi[u - (2s+1)iK']}{2K} \end{aligned} \tag{10.12}$$

in strip (10.7).

11. Expansions involving powers of q'. In practical applications of elliptic functions to problems of physics and engineering, τ is usually purely imaginary and $0 < q < 1$. Expansions involving powers of q (such as (1.2)–(1.4)) are used in applications only when $q \ll 1$. Otherwise, expansions involving powers of the parameter q', where [12, section 21.51]

$$q' = e^{\pi i \tau'}, \quad \tau' = -\frac{1}{\tau} = \frac{iK}{K'}, \tag{11.1}$$

are used: when $q \to 1, q' \to 0$.

Expansions involving powers of q' can be obtained (in the general case—not necessarily for purely imaginary τ) from the expansions involving powers of q by the use of Jacobi's imaginary transformation [12, section 22.4]. For example, we have [12, section 22.4]

$$sn(u,k) = -isc(iu, k'), \tag{11.2}$$

and using (9.9) in (11.2), we obtain

$$\begin{aligned} sn(u,k) = {} & \frac{\pi}{2kK'} \sum_{j=-m}^{m} (-1)^j \tanh \frac{\pi}{2K'}(u - 2jK) \\ & + (-1)^m \frac{2\pi}{kK'} \sum_{n=1}^{\infty} (-1)^n \frac{(q')^{2n(m+1)}}{1 + (q')^{2n}} \sinh \frac{n\pi u}{K'} \end{aligned} \tag{11.3}$$

for u in the strip

$$\left| \operatorname{Im}\left(\frac{iu}{K'}\right) \right| < \operatorname{Im}[(2m+2)\tau'] \tag{11.4}$$

with $m = 0, 1, 2, \ldots$, etc.

12. Concluding remarks and acknowledgments. In October 1993, this author submitted a paper entitled "New trigonometric expansions of Jacobian Elliptic Functions *snu*, *cnu*, *dnu*" to *SIAM J. Math. Anal.* That paper (which was the first version of this one) contained, in particular, results given by equations (1.11)–(1.15), (3.2), (3.3), (3.6), (3.7), (3.14) (written for $\xi = \operatorname{Re} v$ instead of v), (3.15), (5.4), (6.1)–(6.8), (7.1), and (7.2) of this paper, as well as a number of other results.

The paper was originally reviewed by one referee and then (in a revised version entitled "On trigonometric series expansions of Jacobian elliptic functions *snu*, *cnu*, *dnu*") by two referees. The referees made valuable comments, for which the author is grateful. The present paper is a revised and expanded version of this previous submission. The referees' comments were taken into account, some material from the first version was deleted, and new material was added. As a result, this paper is twice as long as the original submission.

This paper is based on simple ideas, which—as is often the case with simple ideas—work rather well and give good, usable results. Similar ideas worked out with respect to expansions for meromorphic functions and expansions for the solutions of the functional equations of the second kind (in particular, the Fredholm integral equation) are conveyed in this author's papers [8], [9], [10], and [11]. Also, in the abstract [6],[1] expansions for the logarithmic derivatives of the $\vartheta_{1-4}(\ldots)$ functions (a development similar to the one set forth in the present paper) are described.

The results (1.11)–(1.15), (5.4), and (6.2) of this paper are given (without derivation) and some other results of this paper are mentioned in the abstract [7].

The present paper was reviewed by a referee who has read it extremely thoroughly. The referee checked a large number of the formulas of the paper and also suggested numerous stylistic improvements. The author is very grateful to this referee.

SMOOTH REFINABLE FUNCTIONS PROVIDE GOOD APPROXIMATION ORDERS*

AMOS RON[†]

Abstract. We apply the general theory of approximation orders of shift-invariant spaces of [C. de Boor, R. A. DeVore, and A. Ron, *Trans Amer. Math. Soc.*, 341 (1994), pp. 787–806], [C. de Boor, R. A. DeVore, and A. Ron, *J. Funct. Anal.*, 119 (1994), pp. 37–78], and [C. de Boor, R. A. DeVore, and A. Ron, "Approximation orders of FSI spaces," *Constr. Approx.*, 13 (1997), to appear] to the special case when the finitely many generators $\Phi \subset L_2(\mathbb{R}^d)$ of the underlying space S satisfy an N-scale relation (i.e., they form a "father-wavelet" set). We show that the approximation orders provided by such finitely generated shift-invariant spaces are bounded from below by the smoothness class of each $\psi \in S$ (in particular, each $\phi \in \Phi$), as well as by the decay rate of its Fourier transform. In fact, similar results are valid for refinable shift-invariant spaces that are *not* finitely generated.

Specifically, it is shown that under some mild technical conditions on the scaling functions Φ, approximation order k is provided if either some $\psi \in S$ lies in the Sobolev space W_2^{k-1} or its Fourier transform $\widehat{\psi}(w)$ decays near ∞ like $o(|w|^{1-k})$. No technical side conditions are required if the spatial dimension is $d = 1$, and the functions in Φ are compactly supported.

For the special case of a singleton Φ, our first class of results (which are concerned with the condition $\phi \in W_2^{k-1}$) improve previously known results of Meyer and Cavaretta, Dahmen, and Micchelli.

1. Introduction and statement of main results.

In this article, we consider the problem of determining *the approximation orders of refinable shift-invariant subspaces* of $L_2 := L_2(\mathbb{R}^d)$, $d \geq 1$. By definition, a subspace $S \subset L_2$ is *shift invariant* (SI) if it is invariant under all *shifts*, i.e., integer translations. We discuss only SI spaces that are *closed* (in L_2). The shift-invariant space S is usually defined with the aid of a *generating set* $\Phi \subset L_2$: we say that Φ *generates* S (and write $S = S(\Phi)$) if S is the smallest (closed) SI space that contains Φ. A *finitely generated SI* (FSI) space is a space $S(\Phi)$ generated by a *finite* Φ, and a *principal SI* (PSI) space $S(\phi)$ is a space generated by a singleton ϕ. PSI and FSI spaces play a role in the theory and applications of multivariate splines, radial-basis function approximation, sampling theory, wavelets, and uniform subdivision schemes. The setup and problem addressed in this paper is particularly relevant to the two latter areas.

In all the above-mentioned applications, the SI space serves as a potential source of approximants. In this regard, then, it becomes important to analyze its "approximation power," preferably in terms of properties of its given generators. One convenient quantitative measurement of this "approximation power" (and the most standard one) is via the notion of *approximation orders*, defined with respect to a

ladder of spaces. In the present context, the simplest ladder associated with S is the following *stationary* one.

DEFINITION 1.1. *The* stationary SI ladder generated by Φ *is the directed family*

$$\mathcal{S} := \mathcal{S}(\Phi) := (S_h := \sigma_h S(\Phi))_{h>0},$$

where $S := S(\Phi)$ is the SI space generated by Φ and where σ_h the dilation operator

$$\sigma_h : f \mapsto f(\cdot/h).$$

Note that S_h is "spanned" by the $h\mathbb{Z}^d$-shifts of the dilated functions $\sigma_h\Phi$. (The adjective "stationary" here refers to the fact that finer spaces S_h are obtained from S_1 by dilation. Nonstationary ladders are obtained if one allows each S_h to be spanned by the $h\mathbb{Z}^d$-shifts of some functions $\Phi_h \neq \sigma_h\Phi$.)

DEFINITION 1.2. *Let $\mathcal{S} = (S_h)_h$ be an SI ladder generated by $\Phi \subset L_2$. We say that $\mathcal{S}$* provides approximation order k *to the function space $F \subset W_2^k$ if for every $f \in F$,*

$$\operatorname{dist}(f, S_h) = O(h^k),$$

where "dist" *is the usual L_2-distance between a function and a function set. If the stronger assumption*

$$\operatorname{dist}(f, S_h) = o(h^k)$$

holds, we say that $\mathcal{S}$ provides density order k.

Here and henceforth, W_2^k with k positive is the usual Sobolev/potential space; i.e., if k is an integer, this is the space of all L_2-functions whose weak derivatives up to order k inclusive are in L_2.

The literature concerning L_2- (and, more generally, L_p-) approximation orders of PSI, FSI, and general SI spaces is vast, and reviewing that literature to any extent is not within the scope of this paper. We refer the reader to the introductions and bibliography of [BR], [BDR1], [BDR2], [BDR3], [Jo1], and [Jo2].

The SI ladders that are employed in the context of (the multiresolution approximation approach to) wavelets satisfy an additional important property of refinability.

DEFINITION 1.3. *An SI ladder $\mathcal{S} = (S_h)_h$ is* refinable (*or, more explicitly, N-refinable*) *if for some $N > 1$ and for every integer j,*

$$S_{N^{-j}} \subset S_{N^{-j-1}}.$$

Note that if the ladder is stationary, refinability is implied by the single relation $S_1 \subset S_{1/N}$, and it implies the relation $S_h \subset S_{h/N}$ for all h.

While, in general, the approximation orders of, say, stationary SI ladders $\mathcal{S}(\Phi)$ are unrelated to the smoothness of the generator(s) Φ, it is a known phenomenon that such a relation exists for certain stationary *refinable* PSI ladders. (It is worth mentioning that in the case of a univariate refinable PSI ladder, approximation orders can sometimes be equivalently described in terms of the vanishing moment conditions of the corresponding wavelet.) Results along these lines were proved by people interested in constructing wavelets via multiresolution, as well as by people studying uniform subdivision schemes.

As an example for the former, the following result can be obtained by combining [M, Theorem 2.4] with the quasi-interpolation argument. (Warning: The more explicit result, [M, Theorem 2.6], cannot imply the full approximation order asserted below.)

RESULT 1.4 (see Meyer [M]). *Let k be a positive integer and $\phi \in W_2^{k-1}$. Assume that all derivatives of ϕ of order $< k$ are bounded and rapidly decaying. If the shifts of ϕ are L_2-stable and if the stationary PSI ladder $\mathcal{S}$ generated by ϕ is 2-refinable, then $\mathcal{S}$ provides approximation order k for W_2^k.*

In the context of subdivision, the following result was established by Cavaretta, Dahmen, and Micchelli.

RESULT 1.5 (see [CDM]). *Assume that ϕ is a compactly supported function in $C^{k-1}(\mathbb{R}^d)$, that $\mathcal{S}(\phi)$ is 2-refinable, that the refinement mask of ϕ is finite, and that the underlying subdivision scheme converges uniformly. Then $\mathcal{S}(\phi)$ provides approximation order k for all sufficiently smooth functions.*

We note that the above C^{k-1}-assumption on ϕ appears to be too restrictive. For example, refinable polynomial B-splines as well as refinable polynomial box splines that are not in C^{k-1} (but are in C^{k-2}) provide approximation order k (cf. [BHR] for details). In any event, both results are restricted to PSI spaces and impose fast decay rates on the generator ϕ, together with some kind of stability assumption on its shifts. (We have not defined the notions of L_2-stability or the uniform convergence of subdivision schemes. We do note that the former implies the latter and both imply that $\widehat{\phi}(0) \neq 0$.) We add here that [JM, Theorem 2.4] can be combined with [BDR1, Theorem 1.15] to show that for the specific value $k = 1$, Result 1.4 is valid under very mild decay conditions on ϕ.

Note that all of the above-quoted results show that smoothness may imply approximation orders, and none of them addresses the converse statement. Indeed, there are various examples of high approximation orders of stationary refinable PSI ladders generated by functions of low smoothness (e.g., Daubechies' scaling functions; cf. [D]).

In this paper, we shall establish results concerning the connection between the existence of smooth functions in the refinable S and the corresponding approximation order provided by the ladder $\mathcal{S}$. These results improve their literature counterparts in several ways: First and foremost, they apply to FSI and even to arbitrary SI spaces, while the above-stated results are confined to PSI spaces only. Second, they hardly require any stability or related assumptions on the shifts of a generating set Φ, and they make no assumptions about a possible direct relation between Φ and their dilates. (Recall that the [CDM] result, for example, assumes the relevant mask to be finite.) Third, the results apply to functions Φ that decay only mildly; in fact, the most general results here do not even mention generating sets. Fourth, the results do not require the *generator(s)* to be smooth but only that S contains one smooth function. That latter difference is critically important for SI spaces which are not principal. Further, none of our results restricts the integer value of N in the refinement condition; some of the results do not even require N to be an integer. Finally, the results of this paper remain valid if, instead of assuming that S is refinable and contains smooth functions, we drop the refinability and assume only that $\cap_{i=1}^{\infty} S_{1/N^i}$ contains such smooth function.

The techniques employed also apply to L_p-approximation orders, $p \neq 2$, as well as to nonstationary ladders. However, these extensions will be discussed elsewhere.

We have just mentioned that our results require S to contain smooth functions. We actually use three different conditions to describe "smoothness," only one of which is truly a smoothness condition. We refer to the other two as *pseudosmoothness* *conditions.* The first assumption is that for some k, $W_2^k \cap S \neq 0$. The other two criteria are in terms of the decay of the Fourier transform $\widehat{f}$ of f. Precisely, for some small neighborhood B of the origin, our pseudosmoothness conditions will require the existence of $f \in S$ whose corresponding sequence

$$\lambda_f(m) := \left\| 1 - \frac{|\widehat{f}|^2}{\sum_{j\in 2\pi m\mathbb{Z}^d} |\widehat{f}(\cdot + j)|^2} \right\|_{L_1(B)}^{1/2}, \tag{1.1}$$

or

$$\widetilde{\lambda}_f(m) := \left\| 1 - \frac{|\widehat{f}|^2}{\sum_{j\in 2\pi m\mathbb{Z}^d} |\widehat{f}(\cdot + j)|^2} \right\|_{L_\infty(B)}^{1/2}, \tag{1.2}$$

decays at a certain rate. In the above expressions, $0/0 := 0$.

Discussion. Under mild conditions (e.g., $|\widehat{f}| \geq c >$ a.e. around the origin), there exists a function $g \in S(f)$ such that the decay rate of λ_f at ∞ is the same as the decay rate of the sequence

$$\mu_g : m \mapsto \left\| \sum_{j\in 2\pi m\mathbb{Z}^d\backslash 0} |\widehat{g}(\cdot + j)|^2 \right\|_{L_1(B)}^{1/2}.$$

In particular, if $g \in W_2^k$, then $\mu_g(m) = o(m^{-k})$, and hence also $\lambda_f(m) = o(m^{-k})$. Similarly, if $\widehat{g}(w) = O(|w|^{-k})$, $k > d/2$ (as $|w| \to \infty$), then both $\lambda_f(m)$ and $\widetilde{\lambda}_f(m)$ are $O(m^{-k})$. The discussion thus explains the point of choosing the terminology "pseudosmoothness."

The most general result proved in this paper is as follows.

THEOREM 1.6. *Let $\mathcal{S} = (S_h)_h$ be a stationary SI ladder, and let k' be a positive number. Assume that the following conditions hold:*

(a) *"Pseudorefinability": for some integer N, $S_0 := \cap_{i=1}^{\infty} S_{1/N^i} \neq 0$.*

(b) *"Pseudosmoothness": there exists $\psi \in S_0$ such that with $\widetilde{\lambda}_\psi$ defined as in (1.2), $\widetilde{\lambda}_\psi(N^j) = O(N^{-jk'})$.*

Then $\mathcal{S}$ provides density order k for W_2^k for every $k < k'$.

The highlight of this result lies in the fact that its requirements are almost merely the two basic ones: *pseudorefinability* and *pseudosmoothness.* The space S can be a PSI, FSI, or arbitrary SI space, and the ability to find a "good" generating set for this space is not an issue. The pseudosmoothness assumption on ψ in Theorem 1.6 is satisfied if $\widehat{\psi}$ decays at ∞ like $O(|\cdot|^{-k'})$, provided that $k' > d/2$ and that $1/\widehat{\psi}$ is essentially bounded around the origin. This latter "side condition" (i.e., the essential boundedness of $1/\widehat{\psi}$) cannot be dispensed with: approximation orders of the refinable $\mathcal{S}$ to W_2^k are *not* implied by the mere existence of smooth functions ψ in the refinable S. Here is a simple example.

Example: A refinable analytic PSI space that provides zero approximation order. Let S be the space of all univariate band-limited functions with band in $[0\,..\,2\pi]$. S is a PSI space, and all functions in S are analytic and hence smooth. Moreover, S contains an abundance of rapidly decaying functions. However, the existence of smooth rapidly decaying functions in S cannot be converted to positive assertions concerning approximation orders provided by S: while $\mathcal{S}$ provides very good approximation orders to *some* smooth functions, it provides zero approximation order to many others.

Consequently, already in the PSI context, refinability and smoothness alone cannot ensure good approximation properties. Note that, indeed, all decaying functions (say, L_1) in S must have a zero mean value.

It is quite safe to conjecture that the SI ladder $\mathcal{S}$ in the theorem provides approximation order k' and not only density orders $k < k'$.

The weak aspect of Theorem 1.6 is that the approximation order concluded in this result is bounded above by the "pseudosmoothness parameter" k' of ψ. In comparison, in all other results of this paper, the asserted approximation order will be obtained by "rounding up" this parameter to the next integer. However, it is impossible to achieve such results without further assumptions for the simple reason that there exist refinable spaces whose corresponding (maximal) approximation order is fractional.

We are now ready to present additional selected results from this paper. When reading these subsequent results, it will be convenient to classify the conditions assumed in them as follows: (a) (pseudo)refinability, (b) (pseudo)smoothness, and (c) extra "side conditions."

The first result is a special case of Theorem 3.2.

COROLLARY 1.7. *Let $\mathcal{S}(\Phi)$ be a stationary FSI ladder, and let k be a positive integer. Assume the following:*

(a) *$S(\Phi)$ is refinable: $S_1 \subset S_{1/N}$.*

(b) *$S(\Phi) \cap W_2^{k-1} \neq 0$.*

(c) *The (finite) generating set Φ satisfies the following three "side conditions":*

(c1) *$|\phi(x)| = O(|x|^{-\rho})$ (as $x \to \infty$) for some $\rho > k + d$ and for every $\phi \in \Phi$.*

(c2) *$\widehat{\phi}(0) \neq 0$, for some $\phi \in \Phi$.*

(c3) *The functions $(\sum_{\alpha \in \mathbb{Z}^d} \phi(\cdot - \alpha))_{\phi \in \Phi}$ are linearly independent.*

Then $\mathcal{S}(\Phi)$ provides approximation order k for W_2^k.

The complementary result, which invokes a pseudosmoothness assumption, is the following corollary of Theorem 3.4.

COROLLARY 1.8. *Let $\mathcal{S}(\Phi)$ be a stationary FSI ladder, and let k be a positive integer. Assume the following:*

(a), (c) *These conditions are as in Corollary 1.7, but here N is assumed to be an integer.*

(b) *For some $\psi \in S(\Phi)$, $\lambda_\psi(N^j) = o(N^{-j(k-1)})$, where λ_ψ is defined by (1.1).*

Then $\mathcal{S}(\Phi)$ provides approximation order k for W_2^k.

We remark that for a PSI space $S(\phi)$, condition (c3) is redundant since it is implied by (c2): for a PSI space $S(\phi)$, (c3) is violated if and only if $\sum_{\alpha \in \mathbb{Z}^d} \phi(\cdot - \alpha) = 0$, and it is well known that that can happen only if $\widehat{\phi}(0) = 0$. Thus for the PSI case, Corollaries 1.7 and 1.8 lead to the following result.

COROLLARY 1.9. *Let $S(\phi)$ be a PSI stationary ladder, and let k be a positive integer. Assume the following:*

(a) *$S(\phi)$ is refinable: $S_1 \subset S_{1/N}$.*

(b) *Either of the following two conditions holds:*

(b1) *$S(\phi) \cap W_2^{k-1} \neq 0$.*

(b2) *N is an integer, and $\lambda_\phi(N^j) = o(N^{-j(k-1)})$.*

(c) *The generating function ϕ satisfies the following two "side conditions":*

(c1) *$|\phi(x)| = O(|x|^{-\rho})$ (as $x \to \infty$) for some $\rho > k + d$.*

(c2) *$\widehat{\phi}(0) \neq 0$.*

Then $\mathcal{S}(\phi)$ provides approximation order k for W_2^k.

Discussion. Corollary 1.9 implies that a refinable PSI space $\mathcal{S}(\phi)$ provides approximation order k in the case where $\phi \in W_2^{k-1}$, and the side conditions (c1) and (c2) are met. A comparison of these side conditions with those assumed in Results 1.4 and 1.5 shows that this corollary requires less decay of ϕ and frees the shifts of ϕ almost completely from any "stability" requirements (other than the basic assumption $\widehat{\phi}(0) \neq 0$). In terms of its smoothness requirement, it assumes about the same as Result 1.4 and less than Result 1.5.

Remark. At a late stage, when susbstantial modifications of this paper became prohibitive, R.-Q. Jia brought to my attention the fact that, while I quote [CDM, Theorem 8.3], there is a significantly stronger result there, viz, Theorem 8.4. Indeed, that theorem seems to be on par with the (b1) variant of Corollary 1.9. One should note that our general PSI result (Theorem 3.4 + Proposition 4.1) applies to generating functions of slow decay (such as the sinc function).

Example: B-splines and box splines. The simplest example of a refinable ϕ is the univariate B-spline of order k. It is compactly supported and nonnegative and hence trivially satisfies condition (c) of Corollary 1.9. It is well known that $\mathcal{S}(\phi)$ provides approximation order k. That result is indeed reproduced (twice) by Corollary 1.9. First, $\widehat{\phi}(w) = w^{-k}\tau(w)$ for a certain trigonometric polynomial τ, and hence $\widehat{\phi} = o(|\cdot|^{-k+\varepsilon})$ for any $\varepsilon > 0$, and hence the sequence λ_ϕ also decays at that rate. Second, ϕ can be shown to lie in W_2^s for any $s < k - 1/2$. The situation for box splines (cf. [BHR] for definition and details) is similar.

The B-spline example also shows the sharpness of the pseudosmoothness condition (b2) in Corollary 1.9: the B-spline ϕ of order $k-1$, whose ladder does *not* provide approximation order k, satisfies the condition $\lambda_\phi(m) = O(m^{-(k-1)})$. Corollary 1.9 thus fails to hold if we change the small o in (b2) to big O.

Example: Band-limited functions. Let S be the PSI space of all univariate L_2-functions whose Fourier transform is supported on $[-\pi\,..\,\pi]$. That space is well known to provide all positive approximation orders. Result 1.4 cannot reproduce this fact since S can be easily shown to contain no L_1-function ϕ whose shifts are L_2-stable. In contrast, the space contains an abundance of functions that decay rapidly together with all their derivatives and have nonzero mean value. Hence either one of (b1) and (b2) of Corollary 1.9 can be activated to yield these known spectral orders of approximation. Moreover, we remark that our more general result, Theorem 3.4, requires only the existence of $\psi \in S$ whose Fourier transform is C^∞ around the origin and does not vanish there.

Our next result deals with *univariate FSI ladders generated by compactly supported functions.* This case, though very special, is of much practical interest. The point of the theorem is that in the univariate case, "compact support" is already a "sufficient side condition."

THEOREM 1.10. *Let $\mathcal{S}(\Phi) = (S_h)_h$ be a stationary FSI ladder, and let k be a positive integer. Assume the following:*

(a) *For some $N > 1$, $S_0 := \cap_{i=1}^{\infty} S_{1/N^i} \neq 0$.*

(b) *Either of the following two conditions holds:*

(b1) *$S_0 \cap W_2^{k-1} \neq 0$.*

(b2) *N is an integer and there exists $\psi \in S_0$ such that the sequence λ_ψ defined in* (1.1) *satisfies $|\lambda_\psi(N^j)| = o(N^{-j(k-1)})$.*

(c) *The spatial dimension d is* 1, *and Φ are compactly supported.*

Then $\mathcal{S}(\Phi)$ provides approximation order k for W_2^k.

Example: C^1-cubics. This example is taken from [HSS]. Let S be the space of all univariate piecewise-cubic polynomials with breakpoints at the integers and which are globally C^1. This space is obviously N-refinable (for all integers N). Less obviously, but as is quite well known, it is a local FSI space of length 2, i.e., it is generated by two compactly supported functions. It is fairly obvious that the approximation order here is 4. (The subspace of C^2-cubics already does the job.) That order is recovered from Theorem 1.10 as soon as we realize that the (smooth) B-spline of order 4 is in our space. In contrast, standard generating sets for this space consist of functions each of which neither lies in W_2^3 nor satisfies the alternative requirement, (b2), that appears in Theorem 1.10. Thus it is very important that our results are stated in terms of the smoothness of some function *in the space* and *not* in terms of the smoothness of some function *in the generating set.*

Discussion. The example given after Theorem 1.6 shows that "compact support" in Theorem 1.10 cannot be replaced by "rapid algebraic decay." However, the theorem *is* extendible to exponentially decaying generators.

All results as stated aim at providing *lower* bounds on the approximation order of the ladder $\mathcal{S}(\Phi)$ in terms of either the smoothness of the "smoothest" function in $S(\Phi)$ or the decay of its Fourier transform. Such presentation stems from the typical problem in *spline theory,* where smoothness is a more readily available property than the approximation orders (cf. [BHR]). However, for more general refinable functions, the readily available information (viz, the mask) may appear to be more adequate for computing approximation orders than estimating either the smoothness of, say, $\phi \in \Phi$ or the decay of its Fourier transform. From this point of view, the results in this paper can be regarded as providing *upper* bounds on the possible smoothness of functions in $S(\Phi)$ in terms of the known approximation order of the underlying ladder. As an illustration, we state the following immediate corollary.

COROLLARY 1.11. *Let $S(\Phi)$ be a univariate refinable FSI space generated by compactly supported functions. Then no compactly supported $\psi \in S(\Phi)$ is infinitely many times continuously differentiable.*

Proof. Let $\psi \in S(\Phi)$ be nonzero, compactly supported, and C^∞. Then $\psi \in W_2^k$ for *every* k. By Theorem 1.10, $\mathcal{S}$ then provides all positive approximation orders. By [J, Theorem 5], the shifts of Φ must then span all polynomials, an absurdity in view of the fact that these shifts have finite local dimension. □

The argument extends to more than one variable. One only needs to adopt further conditions. If Φ is a singleton (ϕ), the additional condition is that $\widehat{\phi}(0) \neq 0$ (so that we will be able to apply Corollary 1.9). For a finite Φ, the conditions should be (c2) and (c3) of Corollary 1.7.

As alluded to before, there is a tight connection between the approximation orders of the refinable $\mathcal{S}$ and the vanishing moments of the wavelets. Many of our results can thus be stated in terms of such vanishing moments. Here is one illustration.

COROLLARY 1.12. *Let $\mathcal{S} = (S_h)_h$ be a univariate stationary FSI ladder generated by compactly supported functions, and let k be a positive integer. Assume further that for some $N > 1$, $\cap_{i=1}^{\infty} S_{1/N^i} \cap W_2^{k-1} \neq 0$. Let f be compactly supported. If $f \perp S$, then $\widehat{f}$ has a zero of order k at the origin.*

Proof. From Theorem 1.10, we conclude that $\mathcal{S}$ provides approximation order k. [BDR2, Theorem 4.1] then applies to yield that for some compactly supported supported $\phi \in S$, the ladder $\mathcal{S}(\phi)$ also provides approximation order k. [R2, Theorem 3.7], when combined with [R1, Theorem 1.1], allows us to assume without loss of generality that $\widehat{\phi}$ has no 2π-periodic zero. On the other hand, [BDR1, Theorem 1.14] implies that $\widehat{\phi}$ must have a zero of order k at each $j \in 2\pi\mathbb{Z}\backslash 0$. This forces $\widehat{\phi}(0)$ to be nonzero, and by a standard argument, we may assume that $\widehat{\phi} - 1$ has a k-fold zero at the origin.

The rest of the argument is routine. Let f be a compactly supported L_2-function, and set

$$H := \sum_{j \in 2\pi\mathbb{Z}} \widehat{f}(\cdot + j)\overline{\widehat{\phi}(\cdot + j)}.$$

In general, the above sum is L_1-convergent. However, since f and ϕ are compactly supported, one can show that the above sum can be differentiated term by term and that each such differentiated sum converges uniformly on compactly sets. In view of the properties of $\widehat{\phi}$, this implies that $H - \widehat{f}$ has a zero of order k at the origin. Assuming in addition that $f \perp S(\phi)$ (certainly true if $f \perp S$), Poisson's summation formula yields that $H = 0$ and hence that $\widehat{f}$ indeed has a zero of order k at the origin. □

Finally we comment on the proofs of the main results. Theorem 3.2 and its corollary follow as a strikingly simple consequence of the general theory of [BDR1]. A totally different (and somewhat tricky) argument is employed in the proofs of Theorems 1.6 and 3.4; the latter argument leads to further consequences, which will be discussed elsewhere. The two approaches differ also from a conceptual point of view. In the first approach, the function $f \in S \cap W_2^{k-1}$ is *approximated by* the ladder $\mathcal{S}$. In the second approach, the pseudosmooth function ψ whose Fourier transform decays nicely is used *to provide approximants* to other smooth functions.

The paper is organized as follows. In section 2, we collect general results concerning approximation orders of stationary SI ladders. None of the results of section 2 assume refinability, and all results should be considered "auxiliary" from the standpoint of this paper. The three basic results of this paper—the proof of Theorem 1.6, Theorem 3.2, and Theorem 3.4—comprise section 3. The latter theorems of section 3 assume a new, initially obscure property of the space S, the $H(k)$ property. The study of this property is presented in section 4, where we show that PSI and FSI spaces with "reasonably good" generating sets satisfy it. (The results in section 4 do not rely on refinability, and refinability buys no extra benefit; hence we decided to separate this discussion from that of section 3.)

2. Background on the approximation order of stationary SI ladders.

In this section, we collect all known and new results on approximation from stationary SI ladders that are used as *auxiliary* results in this paper. We emphasize that none of these results use the *refinability* assumption, which is the pillar assumption in the main results of this article.

The following function plays the key role in the determination of the approximation order of the stationary PSI ladder $\mathcal{S}(\phi)$:

$$\Lambda_\phi := \left(1 - \frac{|\widehat{\phi}|^2}{\sum_{j \in 2\pi\mathbb{Z}^d} |\widehat{\phi}(\cdot + j)|^2}\right)^{1/2}. \tag{2.1}$$

In this definition, $0/0 := 0$.

The basic observation of [BDR1] is the following.

(2.2) [BDR1, THEOREM 2.20]. *Let f be a function whose Fourier transform is supported in the cube C/h, $C := [-\pi \,..\, \pi]^d$. Let $\phi \in L_2$. Then*

$$\operatorname{dist}(f, \sigma_h S(\phi)) = (2\pi)^{-d/2} \|\Lambda_\phi(h\cdot)\widehat{f}\|_{L_2(C/h)}.$$

Whenever $\widehat{f}$ is not supported on C/h, the function f is split in [BDR1] into f_1+f_2, where $\widehat{f_1}$ coinciding with $\widehat{f}$ on B/h, $B \subset C$, and is zero elsewhere. This leads (almost immediately) to the following estimates.

COROLLARY 2.1. *Let $\mathcal{S}(\phi) = (S_h)_h$ be a stationary PSI ladder, and let B be a small neighborhood of the origin. Then for every $f \in L_2$ and every $h > 0$,*

$$\operatorname{dist}(f, S_h) \leq (2\pi)^{-d/2}(\|\Lambda_\phi(h\cdot)\widehat{f}\|_{L_2(B/h)} + \|\widehat{f}\|_{L_2(\mathbb{R}^d\backslash(B/h))}).$$

In particular, if $f \in W_2^k$, then

$$\operatorname{dist}(f, S_h) = (2\pi)^{-d/2}\|\Lambda_\phi(h\cdot)\widehat{f}\|_{L_2(B/h)} + o(1)h^k\|f\|_{W_2^k},$$

where the $o(1)$ expression is bounded independently of f.

From that, the following characterization is provided in [BDR1].

(2.3) [BDR1, THEOREM 1.6]. *The following conditions are equivalent for any $k > 0$:*

(a) *The function $|\cdot|^{-k}\Lambda_\phi$ is in $L_\infty(B)$ for some 0-neighborhood B.*

(b) *The stationary PSI ladder $\mathcal{S}(\phi) = (S_h)_h$ provides approximation order k in the strong sense that*

$$\operatorname{dist}(f, S_h) \leq \operatorname{const}\|f\|_{W_2^k}h^k \tag{2.4}$$

for some const *independent of f and h.*

Under some favorable conditions on the generator ϕ, one is able to derive simpler characterizations from the last one. One such simplification in contained in the following statement.

(2.5) [BDR1, COROLLARY 5.15]. *Assume that ϕ satisfies assumption* (c) *of Corollary* 1.9. *Then $\mathcal{S}(\phi)$ provides approximation order k if and only if ϕ satisfies the Strang–Fix conditions of order k, i.e., $\widehat{\phi}$ has a zero of order k at each $j \in 2\pi\mathbb{Z}^d\backslash 0$.*

The treatment of the approximation orders of FSI and SI spaces here is exclusively based on the powerful "superfunction" theory that surrounds the existence of a "superfunction" $\psi \in S$, i.e., a function ψ whose corresponding $\mathcal{S}(\psi)$ provides the same approximation order as the larger ladder $\mathcal{S}$. An overview of the superfunction results in the literature prior to 1991 can be found in [BDR1, section 1]. [BDR1, section 3], [BDR2, section 4], and all of [BDR3] constitute the most advanced progress on this problem.

(2.6) THE STATIONARY CASE OF THE "SUPERFUNCTION" RESULTS OF [BDR1], [BDR2], AND [BDR3]. *Let $\mathcal{S} = (S_h)_h$ be a stationary SI ladder, and let $k > 0$. Then for any $\chi \in L_2$, there exists a stationary PSI ladder $\mathcal{T} = (T_h)_h$ such that $T_1 \subset S_1$ and*

(a) *For every $f \in L_2$,*

$$\operatorname{dist}(f, T_h) \leq \operatorname{dist}(f, S_h) + 2\operatorname{dist}(f, \sigma_h S(\chi)).$$

(b) *If S is finitely generated by compactly supported functions and χ is compactly supported, T is generated by some compactly supported function.*

(c) *If $\mathcal{S}(\chi)$ provides approximation order $k+1$ to W_2^{k+1}, then for every $f \in W_2^k$,*

$$\operatorname{dist}(f, T_h) \leq \operatorname{dist}(f, S_h) + \varepsilon_f(h)h^k\|f\|_{W_2^k},$$

where ε_f is bounded independently of f and h and decays to 0 with h.

(d) *If S provides approximation order k in the sense that*

$$\operatorname{dist}(f, S_h) \leq \text{const}\|f\|_{W_2^k} h^k \quad \forall f \in W_2^k,$$

then it provides density order k' for every $f \in W_2^{k'}$ and every $k' < k$.

Proof. (a) follows from [BDR1, Theorem 3.3]. (b) is the content of [BDR2, Theorem 4.1]. We prove (c) and (d) simultaneously as follows. First, the PSI case of (d) follows from a simple comparison of the characterization of approximation orders [BDR1, Theorem 1.6] (see above) and the characterization of density orders [BDR1, Theorem 1.7]. (c) then follows by an application of (d) to the PSI ladder $\mathcal{S}(\chi)$, with $k+1$ replacing k.

It then remains to show that (d) is valid for a general SI space: assuming that $\mathcal{S}$ satisfies the assumption in (d), we choose χ such that $\mathcal{S}(\chi)$ provides approximation order $k+1$, and we then let $\mathcal{T}$ be the PSI ladder of (a) with respect to the current χ. By (c), the ladder $\mathcal{T}$ provides approximation order k (in the sense required in (d)). Since $\mathcal{T}$ is principal and (d) is known to be valid with respect to principal ladders, we conclude that $\mathcal{T}$ provides density orders $k' < k$; this is true a fortiori for the original ladder $\mathcal{S}$. □

Finally, the following result, which is needed for the proof of Theorem 1.6, cannot be found in the literature.

THEOREM 2.2. *Let $\mathcal{S}$ be a stationary SI ladder, let $m > k > 0$, and let $(h_i)_i$ be decreasing to zero and satisfy*

$$h_i/h_{i+1} \leq A < \infty \quad \forall i.$$

Assume that for every $f \in W_2^m$,

$$\operatorname{dist}(f, S_{h_i}) \leq c h_i^k \|f\|_{W_2^m}, \tag{2.7}$$

with c independent of f (and h). Then $\mathcal{S}$ provides approximation order k for W_2^k in the sense of (2.4).

Proof. Invoking (2.7) together with (2.6)(c) (with k there being our m here), we find $\phi \in S$ such that

$$\operatorname{dist}(f, \sigma_{h_i} S(\phi)) \leq c h_i^k \|f\|_{W_2^m}.$$

This reduces the problem to the PSI ladder $\mathcal{S}(\phi)$ since $\mathcal{S}$ certainly provides approximation order k the moment that $\mathcal{S}(\phi)$ does. Therefore, without loss of generality, we may assume that $S = S(\phi)$, i.e., that our ladder is principal.

We now invoke Corollary 2.1 (with k there being our m here) to conclude that (2.7) implies that

$$\|\Lambda_\phi(h_i\cdot)\widehat{f}\|_{L_2(B/h_i)} \leq c h_i^k \|f\|_{W_2^m}.$$

Since f varies over W_2^m, $(1+|\cdot|)^{2m}\widehat{f}^2$ varies over L_1, and we may then convert the last inequality to

$$\|(1+|\cdot|)^{-2m}\Lambda_\phi(h_i\cdot)^2 f\|_{L_1(B/h_i)} \leq c h_i^{2k}\|f\|_{L_1} \quad \forall f \in L_1.$$

This implies the estimate

$$h_i^{2m}\|(h_i+|\cdot|)^{-2m}\Lambda_\phi^2\|_{L_\infty(B)} = \|(1+|\cdot|)^{-2m}\Lambda_\phi(h_i\cdot)^2\|_{L_\infty(B/h_i)} \leq c h_i^{2k}.$$

Assuming that $h_{i+1} \leq |x| \leq h_i$, we obtain

$$\Lambda_\phi(x)^2 \leq c' h_i^{2k} \leq c' A^{2k} |x|^{2k}.$$

Thus the function $| \cdot |^{-k} \Lambda_\phi$ was proved to be bounded around the origin, which in view of [BDR1, Theorem 1.6] (cf. (2.3)) implies that $\mathcal{S}$ provides approximation order k to all of the functions in W_2^k. □

3. Core. Let S be an SI space. The main results of this paper are based on the presumption that the ladder $\mathcal{S}$ can provide approximation order k to either "almost no" smooth functions or "almost all" smooth functions. The most extreme statement of this nature is contained in the following definition.

DEFINITION 3.1. *Let $\mathcal{S} = (S_h)_h$ be a stationary (not necessarily refinable) SI ladder. Let k be a positive integer. We say that $\mathcal{S}$ has* property H(k) *if it provides approximation k for the entire W_2^k, whenever the following condition holds: There exists a function $f \in W_2^{k-1} \backslash 0$ such that for some sequence $(h_i)_i$ that decreases to zero,*

$$\operatorname{dist}(f, S_h) = o(h^{k-1}), \quad h = h_1, h_2, \ldots.$$

In the language of [BDR1], the satisfaction of property H(k) implies that $\mathcal{S}$ provides *approximation* order k to all reasonably smooth functions as soon as it provides a *density* order $k-1$ to a single *smooth* nonzero function.

The main branch of our approach can be now clearly stated: we will show that "smoothness implies approximation orders" for SI ladders $\mathcal{S}$ that are *refinable* and *satisfy the* H(k) *property.* The two theorems that establish this fact are stated and proved in this section, and they apply to an arbitrary SI ladder (i.e., not an FSI one).

Of course, such results may be deemed useless unless we are able to find feasible side conditions on S that guarantee the satisfaction of property H(k). This complementary study is independent of the refinability or smoothness assumptions and is even independent of the possible approximation order provided by $\mathcal{S}$. In fact, we show that some "mild technical conditions" (which are known to neither imply nor be implied by nor be related in any rigorous way to approximation orders) guarantee the satisfaction of property H(k). *However, this complementary analysis does require our space S to be a PSI or FSI space.*

Our first observation is, actually, trivial.

THEOREM 3.2. *Let k be a positive integer, and let $\mathcal{S} = (S_h)_h$ be a stationary SI ladder. Assume further that*

(a) *for some $N > 1$, $\cap_{i=1}^{\infty} S_{1/N^i} \cap W_2^{k-1} \neq 0$;*

(b) *$\mathcal{S}$ has property* H(k).

Then the ladder $\mathcal{S}$ provides approximation order k for W_2^k.

Proof. Let f be a nonzero function in $\cap_{i=1}^{\infty} S_{1/N^i} \cap W_2^{k-1}$. Setting

$$V_i := S_{N^{-i}} \quad \forall i \geq 0,$$

we know that $f \in V_i$, $\forall i \geq 0$. This means that $\operatorname{dist}(f, V_i) = 0$ for all $i \geq 0$. Thus we may invoke property H(k) with respect to this f to conclude that $\mathcal{S}$ provides approximation order k to W_2^k, as asserted. □

The other two results in this section, the proof of Theorem 1.6 and Theorem 3.4, are very similar each to the other, not only in their pseudosmoothness assumptions but also in their methods of proof. However, they differ quite significantly in their conclusions, and hence Theorems 1.6 and 3.4 have been labeled and situated separately.

Proof of Theorem 1.6. Let $k'' < k'$, and let $k > k''$ be any number of the form $k = (r/(r+1))k'$, where r is an integer. We will prove that there exists a sequence $(h_i = a^i)_i$ $(a < 1)$ and a constant c such that for every $f \in W_2^{(r+1)k}$,

$$\text{dist}(f, S_h) \le c\|f\|_{W_2^{(r+1)k}} h^k, \quad h = h_1, h_2, \ldots. \tag{3.1}$$

Theorem 2.2 would then yield that $\mathcal{S}$ provides approximation order k to W_2^k, and (2.6)(d) would then complete the proof.

In what follows, we set $\widetilde{\lambda} := \widetilde{\lambda}_\psi$ (cf. (1.2)) and prove (3.1). However, since the method here will be needed (with a slight twist) in the proof of Theorem 3.4, we formalize it as a separate lemma.

LEMMA 3.3. *Let $\mathcal{S}$ be a stationary ladder, and let $\psi \in \cap_{i=1}^\infty S_{1/N^i} \backslash 0$, where N is a positive integer. Define the sequences $\lambda := \lambda_\psi$ and $\widetilde{\lambda} := \widetilde{\lambda}_\psi$ as in* (1.1) *and* (1.2). *Let n be a positive power of N, u be a positive number, and $h := u/n$. Then for every $f \in L_2$,*

$$\text{dist}(f, S_h) \le \text{const}(\|\widehat{f}\|_{L_2}\widetilde{\lambda}(n) + \|\widehat{f}\|_{L_2(\mathbb{R}^d\backslash(B/u))})$$

and

$$\text{dist}(f, S_h) \le \text{const}(u^{-d/2}\|\widehat{f}\|_{L_\infty}\lambda(n) + \|\widehat{f}\|_{L_2(\mathbb{R}^d\backslash(B/u))}),$$

with const *depending on d only. Of course, the second estimate is meaningful only when $\widehat{f} \in L_\infty$.*

Proof. We split $f = f_1 + f_2$, with $\widehat{f_1}$ coinciding with $\widehat{f}$ on B/u and $\widehat{f_2}$ coinciding with $\widehat{f}$ on $\mathbb{R}^d\backslash(B/u)$. Since obviously

$$\text{dist}(f, S_h) \le \text{dist}(f_1, S_h) + \|f_2\|$$

and since the Fourier transform is an isometry on L_2, we see that the proof of the theorem is reduced to proving that

$$\text{dist}(f_1, S_h) \le \text{const}\|\widehat{f}\|_{L_2}\widetilde{\lambda}(n) \tag{3.2}$$

and

$$\text{dist}(f_1, S_h) \le \text{const } u^{-d/2}\|\widehat{f}\|_{L_\infty}\lambda(n).$$

We will prove (3.2). The proof will eventually establish the other bound as well.

Let ϕ be any function in $S_{1/n}$. This latter space is invariant under $\mathbb{Z}^d/n$-shifts, and since n is an integer, it is also invariant under integer shifts. Thus we not only have $\phi \in S_{1/n}$ but also $S(\phi) \subset S_{1/n}$. Applying dilation, we obtain that

$$\sigma_u S(\phi) \subset \sigma_u S_{1/n} = S_h.$$

Thus instead of proving (3.2), we are entitled to prove that for some $\phi \in S_{1/n}$,

$$\text{dist}(f_1, \sigma_u S(\phi)) \le \text{const}\|f\|_{L_2}\widetilde{\lambda}(n). \tag{3.3}$$

However, $\widehat{f_1}$ is supported on B/u, and therefore [BDR1, Theorem 2.20] (cf. (2.2)) provides us with the explicit formula

$$\operatorname{dist}(f_1, \sigma_u S(\phi)) = \operatorname{const}\|\Lambda_\phi(u\cdot)\widehat{f_1}\|_{L_2(B/u)},$$

with Λ_ϕ defined as in (2.1). Comparing this with the desired result (3.3) and taking into account the fact that $\|f_1\|_{L_2} \le \|f\|_{L_2}$, we realize that our claim is established as soon as we can find $\phi \in S_{1/n}$ such that

$$\|\Lambda_\phi\|_{L_\infty(B)} \le \widetilde{\lambda}(n). \tag{3.4}$$

(For the complementary case, we need an estimate $\|\Lambda_\phi\|_{L_2(B)} \le \lambda(n)$.) Since $\psi \in S_{N^{-i}}$, $i \ge 1$, and n is a power of N, $\psi \in S_{1/n}$. [BDR1, Theorem 2.14] then entails that any L_2-function ϕ whose Fourier transform is of the form $\widehat{\phi} = \tau\widehat{\psi}$ is in $\sigma_{1/n}S(\psi) \subset S_{1/n}$, provided that τ is $2\pi n$-periodic. We take τ to be the $2\pi n$-periodization of the support function of B and define ϕ accordingly. Then $\widehat{\phi}$ vanishes on each domain of the form $j+B$, $j \in 2\pi(\mathbb{Z}^d\backslash n\mathbb{Z}^d)$, and $\widehat{\phi} = \widehat{\psi}$ on domains of the form $j+B$, $j \in 2\pi n\mathbb{Z}^d$. Therefore, on B,

$$\sum_{j\in 2\pi\mathbb{Z}^d} |\widehat{\phi}(\cdot + j)|^2 = \sum_{j\in 2\pi n\mathbb{Z}^d} |\widehat{\psi}(\cdot + j)|^2.$$

We then conclude that on B,

$$\Lambda_\phi^2 = 1 - \frac{|\widehat{\psi}|^2}{\sum_{j\in 2\pi n\mathbb{Z}^d} |\widehat{\psi}(\cdot + j)|^2}.$$

This shows that $\widetilde{\lambda}(n) = \|\Lambda_\phi\|_{L_\infty(B)}$, thereby implying the desired result. □

We now return to the proof of Theorem 1.6. Remember that we want to show that (3.1) holds. We apply Lemma 3.3 with respect to $n := N^{ir}$ and $u := N^{-i}$, where i is an integer. Since $\widetilde{\lambda}_\psi(n) \le cn^{-k'}$, then with $h_i := N^{-i(r+1)} = u/n$,

$$\operatorname{dist}(f, S_{h_i}) \le \operatorname{const}(n^{-k'}\|f\|_{L_2} + \|\widehat{f}\|_{L_2(\mathbb{R}^d\backslash(N^iB))}). \tag{3.5}$$

We compute that

$$n^{-k'} = N^{-irk'} = N^{-i(r+1)k} = h_i^k,$$

which takes care of the first term in the right-hand side of (3.5). As for the second term, since $f \in W_2^{(r+1)k}$, it is easy to see that

$$\|\widehat{f}\|_{L_2(\mathbb{R}^d\backslash(N^iB))} = o(1)N^{-ik(r+1)}\|f\|_{W_2^{(r+1)k}} = o(1)h_i^k\|f\|_{W_2^{(r+1)k}},$$

with $o(1)$ bounded independently of f. Thus (3.1) follows from (3.5), and the proof is complete. □

THEOREM 3.4. *Let k and N be positive integers, and let $\mathcal{S}$ be a stationary SI ladder. Assume the following:*

(a) *For some $\psi \in \cap_{i=1}^\infty S_{1/N^i}$, $\lambda_\psi(N^j) = o(N^{-(k-1)j})$.*

(b) *$\mathcal{S}$ has property* H(k).

Then $\mathcal{S}$ provides approximation order k for W_2^k.

Proof. To invoke the assumed property H(k), we take f to be any band-limited Schwartz function. We will show that for some sequence $(h_i)_i$,

$$\operatorname{dist}(f, S_{h_i}) = o(h_i^{k-1}).$$

Property H(k) would then yield the approximation order assertion.

We choose $(h_i)_i$ as follows: since $\lambda_\psi(N^j) = o(N^{(1-k)j})$, we have for each integer i and for all sufficiently large j that

$$\lambda_\psi(N^j) \le \frac{1}{i} N^{i(1-k-d/2)} N^{(1-k)j}. \tag{3.6}$$

For each i, we choose j that satisfies (3.6), define

$$h_i := N^{-(i+j)},$$

and invoke Lemma 3.3, with u there being N^{-i} and n there being N^j. Since f is band-limited, we may take i sufficiently large to ensure that $\widehat{f}$ is supported on $N^i B = B/u$. Thus the lemma together with (3.6) provides the estimate

$$\begin{aligned}\operatorname{dist}(f, S_{h_i}) &\le \operatorname{const}|u|^{-d/2}\|\widehat{f}\|_{L_\infty}\lambda_\psi(N^j) \le \operatorname{const}N^{id/2}\frac{1}{i}N^{i(1-k-d/2)}N^{j(1-k)}\\ &= \operatorname{const}\frac{1}{i}h_i^{k-1}.\end{aligned}$$

The last estimate implies the desired estimate

$$\operatorname{dist}(f, S_{h_i}) = o(h_i^{k-1}). \qquad \square$$

4. Property H(k). While two of the three main results of the previous section require $\mathcal{S}$ to satisfy property H(k), some readers may suspect this property to be as complicated and demanding as the notion of approximation orders. (After all, approximation orders appear in its statement.) However, this is not true: basic decay and regularity conditions on the generating set of S, which are totally unrelated to the approximation orders that space may provide, suffice for guaranteeing the satisfaction of property H(k). The section contains three results along these lines: in the first, we treat the PSI case; in the second, we treat the FSI case; and in the last, we treat univariate FSI spaces generated by compactly supported functions. The proofs of these results are postponed until we show how the three results, when combined with Theorems 3.2 and 3.4, yield the various corollaries stated in the introduction.

PROPOSITION 4.1. *Let k be a positive integer and $\phi \in L_2$. Let $\rho > k + d$, and consider the following conditions:*

(a) *$\phi = O(|\cdot|^{-\rho})$ near ∞, and $\widehat{\phi}(0) \neq 0$.*

(b) *Λ_ϕ^2 (defined in (2.1)) is k times continuously differentiable around the origin.*

(c) *The PSI ladder $\mathcal{S}(\phi)$ has property* H(k).

Then (a) $\Longrightarrow$ (b) $\Longrightarrow$ (c).

Proof of Corollary 1.9. We first assume claims (a), (b1), and (c) of the corollary and apply Theorem 3.2. Comparing the assumptions of the theorem to those of the corollary (i.e., (a), (b1), and (c)), we immediately observe that we only need to show that assumption (c) of the corollary implies property H(k). That latter implication follows directly from Proposition 4.1.

The proof of the other case is identical, only here we invoke Theorem 3.4. □

The only difference between the FSI case and its special PSI case is that it is much harder to verify property H(k) in the FSI context. We forgo generalizing Proposition 4.1 completely and prefer instead to focus on its main implication ((a) $\Longrightarrow$ (c)).

PROPOSITION 4.2. *Let $\Phi \subset L_2$ be a finite set that satisfies condition* (c) *of Corollary* 1.7 *with respect to some positive integer k. Then $S(\Phi)$ satisfies property* H(k).

Corollary 1.7 now follows from Theorem 3.2 and Proposition 4.2, while Corollary 1.8 follows from Theorem 3.4 and Proposition 4.2.

Finally, Theorem 1.10 follows from Theorems 3.2 and 3.4 when combined with the following general observation.

PROPOSITION 4.3. *A univariate FSI ladder that is generated by compactly supported functions satisfies property* H(k) *for all integer values k.*

We now turn to the proofs of Propositions 4.1, 4.2, and 4.3.

Proof of Proposition 4.1.

(a) $\Longrightarrow$ (b): Let ρ' be any number between $k+d/2$ and $\rho-d/2$. Since $\rho' < \rho-d/2$, it easily follows from the Plancheral theorem that $\widehat{\phi} \in W_2^{\rho'}$. Since $\rho' > k+d/2$, the Sobolev embedding theorem then implies that

$$\| |\widehat{\phi}|^2 \|_{C^k(j+B)} \leq \text{const} \|\widehat{\phi}\|^2_{W_2^{\rho'}(j+B)}.$$

Summing over all $j \in 2\pi\mathbb{Z}^d$ and using the subadditivity of the $W_2^{\rho'}$-norm (which is valid with respect to a set of disjoint cubes, as is the case here; cf. [A, p.225]), we obtain that

$$\sum_{j\in 2\pi\mathbb{Z}^d} \| |\widehat{\phi}|^2 \|_{C^k(j+B)} \leq \text{const}' \|\widehat{\phi}\|^2_{W_2^{\rho'}(B+2\pi\mathbb{Z}^d)} < \infty.$$

This readily implies that $\sum_{j\in 2\pi\mathbb{Z}^d} |\widehat{\phi}(\cdot + j)|^2$ is k times continuously differentiable on B. Since this function does not vanish at 0 (since $\widehat{\phi}(0) \neq 0$), we finally conclude that $\Lambda_\phi^2 \in C^k(B)$.

(b) $\Longrightarrow$ (c): The proof requires the following elementary lemma.

LEMMA 4.4. *Let $g \in L_2(\mathbb{R}^d)$, and let B be open and bounded. Then as $h \to 0$,*

$$\| |\cdot| g \|_{L_2(B/h)} = o(h^{-1}).$$

Proof. Without essential loss of generality, we may assume that B is the Euclidean unit ball. We fix h and abbreviate $B_1 := B/\sqrt{h}$ and $B_2 := (B/h)\backslash B_1$. Then obviously $B/h = B_1 \cup B_2$, and hence

$$\begin{aligned} \| |\cdot| g \|^2_{L_2(B/h)} &= \| |\cdot| g \|^2_{L_2(B_1)} + \| |\cdot| g \|^2_{L_2(B_2)} \\ &\leq h^{-1} \|g\|^2_{L_2(\mathbb{R}^d)} + h^{-2} \|g\|^2_{L_2(\mathbb{R}^d \backslash B_1)} = O(h^{-1}) + o(h^{-2}) = o(h^{-2}). \end{aligned}$$ □

We now show how to derive (c) from (b). In order to prove that property H(k) holds, we assume that

$$\operatorname{dist}(f, S_h) = o(h^{k-1}), \tag{4.1}$$

with $f \in W_2^{k-1}\backslash 0$, $h = h_1, h_2, \ldots$, and $(h_i)_i$ decreasing to 0. We will show that this assumption, together with assumption (b), implies that $\mathcal{S}(\phi)$ provides approximation order k for all W_2^k. In what follows, h is always selected from the sequence $(h_i)_i$.

First, substituting $k-1$ for k in the second displayed equation of Corollary 2.1 and using (4.1), we obtain

$$\|\Lambda_\phi(h\cdot)\widehat{f}\|_{L_2(B/h)} = o(h^{k-1}). \tag{4.2}$$

We contend that (4.2) forces all derivatives of Λ_ϕ up to order $k-1$ to vanish at the origin. Since a similar argument is needed in the proof of Proposition 4.3, we prove this fact in a separate lemma.

LEMMA 4.5. *Let* M *be any function that is defined on a neighborhood B of the origin and is k times continuously differentiable there. Let $f \in W_2^{k-1}\backslash 0$. If*

$$\|\mathrm{M}(h\cdot)\widehat{f}\|_{L_2(B/h)} = o(h^{(k-1)}), \tag{4.3}$$

then all derivatives of M *up to order $k-1$ must vanish at the origin.*

Proof. Assume to the contrary that some derivatives of order $l < k$ of M do not vanish at the origin, and let l be the minimal integer with that property. Using the Taylor series expansion of M around 0, we find that on B/h we have an estimate of the form

$$|\mathrm{M}(h\cdot)| \geq h^l|p| - ch^{l+1}|\cdot|^{l+1}.$$

Here c depends on ϕ, B, and l but not on h, and p is a homogeneous polynomial of degree l. Thus invoking that estimate, we obtain from (4.3) that

$$\begin{aligned} o(h^{(k-1)}) &= \|\mathrm{M}(h\cdot)\widehat{f}\|_{L_2(B/h)} \\ &\geq h^l\|p\widehat{f}\|_{L_2(B/h)} - ch^{(l+1)}\||\cdot|^{l+1}\widehat{f}\|_{L_2(B/h)}. \end{aligned} \tag{4.4}$$

Since $f \in W_2^{k-1}$ and $l \leq k-1$, we conclude that $g := |\cdot|^l\widehat{f} \in L_2$. Lemma 4.4 then applies to yield that

$$\||\cdot|^{l+1}\widehat{f}\|_{L_2(B/h)} = \||\cdot|g\|_{L_2(B/h)} = o(h^{-1}).$$

Substituting this estimate into (4.4), we finally obtain

$$h_i^l\|p\widehat{f}\|_{L_2(B/h_i)} = o(h_i^l),$$

which can happen only if $p\widehat{f} = 0$, a contradiction. (Since it is in $L_2\backslash 0$, $\widehat{f}$ cannot be supported on the zero set of p since the latter is a null set.) □

We proceed now with the proof of the theorem. Since, as contended, all derivatives of Λ_ϕ of orders $< k$ vanish at the origin, we see that

$$\Lambda_\phi = O(|\cdot|^k)$$

around the origin. Hence [BDR1, Theorem 1.6] (cf. (2.3)) implies that $\mathcal{S}(\phi)$ provides approximation order k to W_2^k. □

Proof of Proposition 4.2. Since we need to prove that property H(k) holds, we assume that for some $f \in W_2^{k-1}\backslash 0$ and a subsequence $(h_i)_i$,

$$\mathrm{dist}(f, \sigma_h\mathcal{S}(\Phi)) = o(h^{k-1}), \quad h = h_1, h_2, \ldots.$$

We then need to show that $\mathcal{S}(\Phi)$ provides approximation order k.

For this, we will find a function ψ in $\mathcal{S}(\Phi)$ that satisfies the following three conditions:

(i) The function

$$\Lambda_\psi^2 := 1 - \frac{|\widehat{\psi}|^2}{\sum_{\alpha \in 2\pi\mathbb{Z}^d} |\widehat{\psi}(\cdot + \alpha)|^2}$$

is k times continuously differentiable around the origin.

(ii) $\operatorname{dist}(f, T_h) = o(h^{k-1})$, $h \in (h_i)_i$, where T_h is the h-dilate of $S(\psi)$.

In view of Proposition 4.1, condition (i) implies that $\mathcal{S}(\psi)$ satisfies property H(k); hence, in view of condition (ii), it must provide approximation order k (for all functions in W_2^k). Since $S(\psi) \subset S(\Phi)$, $\mathcal{S}(\Phi)$ must then provide this approximation order as well.

We need now to prove that ψ as above exists, indeed, in $S(\Phi)$. First, by (2.6)(c), there exists $\psi \in S$ whose stationary PSI ladder $\mathcal{S}(\psi) := (T_h)_h$ satisfies

$$\operatorname{dist}(f, T_h) \leq \operatorname{dist}(f, S_h) + o(h^{k-1}).$$

Therefore,

$$\operatorname{dist}(f, T_h) = o(h^{k-1}), \quad h = h_1, h_2, \ldots, \tag{4.5}$$

and hence ψ satisfies the required condition (ii).

The proof that ψ satisfies condition (i) is as follows. First, we define the bracket product $[f, g]$ of the L_2-functions f and g as follows:

$$[f, g] := \sum_{j \in 2\pi\mathbb{Z}^d} \widehat{f}(\cdot + j)\overline{\widehat{g}(\cdot + j)}.$$

The *Gramian* of Φ is then defined to be the $\Phi \times \Phi$ matrix whose (ϕ, ϕ') entry is $[\widehat{\phi}, \widehat{\phi}']$. It is proved in [BDR3] that under assumption (c) of Corollary 1.7, G is k times continuously differentiable and $G(0)$ is nonsingular. Thus G^{-1} exists on a neighborhood B of the origin and is also smooth there.

Now with τ the 2π-periodization of the restriction of $\widehat{\Phi}$ to B, in [BDR3], $[\widehat{\psi}, \widehat{\psi}]$ is identified (around the origin) as $\tau^* G^{-1} \tau$. Since $\widehat{\Phi} \subset C^k$ (by virtue of the decay assumptions on Φ), it follows that $[\widehat{\psi}, \widehat{\psi}] \in C^k(B)$. In addition, in [BDR3], $\widehat{\psi}$ is computed as $G^{-1}\widehat{\Phi}$, which again shows that $\widehat{\psi} \in C^k(B)$. Combining all these observations, we readily conclude that $\Lambda_\psi^2 \in C^k(B)$ as well. □

Proof of Proposition 4.3. We follow the proof of Proposition 4.2 to obtain the "superfunction" ψ as detailed in that proof. As in that proof, we need only show that $\Lambda_\psi^2 \in C^k(B)$.

We argue the smoothness of Λ_ψ^2 as follows. First, since we know that $S(\Phi)$ is generated by compactly supported functions (viz, Φ), (2.6)(b) allows us to assume that $S(\psi)$ is generated by a compactly supported function, which we may assume without loss to be ψ itself. Furthermore, since we are in a univariate situation, we may invoke of [R1, Theorem 1.1] and [R2, Theorem 3.7]: combined, these results say that every univariate PSI space that is generated by a compactly supported L_2-function ψ is also generated by a compactly supported L_2-function whose Fourier transform does not have a 2π-periodic zero. Again, we may assume without loss of generality that our generator ψ is already the "favorable" generator of [R1] and [R2]. This implies that the denominator in the definition of Λ_ψ vanishes nowhere, and a simple application of Poisson's summation formula then yields that Λ_ψ^2 is real analytic and, in particular, analytic around the origin. □

ANALYTIC FUNCTIONS OPTIMIZING COMPETING CONSTRAINTS*

J. WILLIAM HELTON† AND ANDREI E. VITYAEV‡

Abstract. Optimization of sup-norm-type performance functions over the space of H^∞ functions is an area of extensive research. In electrical engineering, it is central to the subject of H^∞ design, while in several complex variables, it is often required to produce analytic discs with valuable properties.

It has been known for many years that an H^∞-type optimum is frequency independent (flat). In this paper, we study simultaneous (Pareto) optimization of several competing performances $\Gamma_1, \dots, \Gamma_l$.

We find under strong assumptions on the performance functions that if we are optimizing over N functions $(f_1, \dots, f_N)$ in H^∞ and have l performance measures with $l \leq N$, then at a nondegenerate Pareto optimum $(f_1^*, \dots, f_N^*)$, *every* performance is flat.

Besides flatness, there are other *gradient–alignment* conditions which must hold at an optimum. The article presents these and thus gives the precise *first-derivative* test for a natural class of H^∞ Pareto optima.

Such optimality conditions are valuable for assessing how iterations in a computer run are progressing. Also, in the traditional case, optimality conditions have been the base of highly sucessful computer algorithms; see [J. W. Helton, O. Merino, and T. Walker, Indiana U. Math. J., 42 (1993), pp. 839–874].

1. Introduction.

This paper analyzes a problem in which one optimizes objective functions over the space H^∞_N of vector-valued functions $f = (f_1, \dots, f_N)$ defined on the unit circle, $\mathbf{T}$, where each coordinate function f_j belongs to $L^\infty(\mathbf{T})$ and extends to be analytic on the entire unit disk.

The objectives that we optimize are described in terms of nonnegative continuous functions Γ defined on $\mathbf{T} \times \mathbf{C}^N$. Given positive functions $\Gamma_j(e^{i\theta}, z) \in C^1(\mathbf{T}, \mathbf{C}^N)$, $j = 1, \dots, l$, and a function $f \in H^\infty_N$, we define the l performances

$$\gamma_j(f) := \sup_{\theta \in \mathbf{T}} \Gamma_j(e^{i\theta}, f), \quad j = 1, \dots, l.$$

The goals of this paper are best illustrated by restricting our study to the case of two performance functions Γ_1 and Γ_2, even though our results hold for l-performance functions.

Definition. *A function $f^* \in H^\infty_N$ is called a* Pareto optimum *for Γ_1 and Γ_2 if for each $f \in H^\infty_N$ one of the following two inequalities holds:*

$$\gamma_1(f) \geq \gamma_1(f^*) \quad \textit{or} \quad \gamma_2(f) \geq \gamma_2(f^*).$$

The book of Boyd and Barratt [BB] gives a good discussion of Pareto optimality.

1.1. Degenerate versus nondegenerate Pareto optima. A function f^* can be a Pareto optimum for Γ_1 and Γ_2 in two basic ways.

Degenerate optima. The first case is where f^* can optimize Γ_1, that is,

$$\gamma_1(f^*+h) \geq \gamma_1(f^*) \quad \forall h \in H_N^\infty, \quad h \neq 0,$$

in which case Γ_2 is irrelevant. Similarily, f^* can optimize Γ_2, and then Γ_1 is irrelevant. This case has been seriously studied, and the main optimality result is stated in Theorem 1.1 below.

Nondegenerate optima. The second case is when both Γ_1 and Γ_2 are relevant. In this case, there is a pair of analytic functions h_1 and h_2 such that

$$\gamma_1(f^*+h_1) < \gamma_1(f^*),$$

$$\gamma_2(f^*+h_2) < \gamma_2(f^*).$$

In other words, we can improve each performance *separately* by adding h_1 or h_2 to f^*, but we cannot improve both performances at the same time.

The case of nondegenerate optima is the subject of this paper.

Example for $N=2$.

$$\begin{aligned}\Gamma_1(e^{i\theta},z) &= |\psi_1(e^{i\theta})-z_1|^2,\\ \Gamma_2(e^{i\theta},z) &= |\psi_2(e^{i\theta})-z_2|^2,\end{aligned}$$

where ψ_j are rational. In this case, the problem is separable into two completely independent one-dimensional single-performance problems. Therefore, there exists no nondegenerate Pareto optimum for Γ_1 and Γ_2. An example of a degenerate Pareto optimum would be any pair of functions $f=(f_1,f_2)$ such that either f_1 or f_2 is an optimum for Γ_1 alone or Γ_2 alone, respectively.

If, on the other hand, we consider the problem with

$$\begin{aligned}\widetilde{\Gamma_1}(e^{i\theta},z) &= |\psi_1(e^{i\theta})-z_1|^2,\\ \widetilde{\Gamma_2}(e^{i\theta},z) &= |\psi_2(e^{i\theta})-z_1-z_2|^2,\end{aligned}$$

then the problem cannot be separated into two independent single-performance problems, and for generic ψ_1 and ψ_2, almost all Pareto optima are nondegenerate.

1.2. A characterization of Pareto optima. The main result of this paper is that for a special class of Γ_j's ,namely the ones that are the norms of certain rational functions, a nondegenerate local pareto optimum $f^* \in H_N^\infty$ for $N>1$ satisfies

$$\Gamma_1(e^{i\theta}, f^*(e^{i\theta})) = \text{const.}_1$$

and

$$\Gamma_2(e^{i\theta}, f^*(e^{i\theta})) = \text{const.}_2$$

for all θ. *The striking fact is that both performances are flat.* See Theorem 2.1 for the precise statement of this result in the general case of l-performance functions

Note that if $N=1$ then both performances are almost never flat. Also, we give a result that indicates that there is a large class of Γ_j's for which flatness will not hold.

An earlier instance of the flatness condition (Theorem 2.1(I)) for Pareto optima was discovered by Young (see [PY] for proofs). It applies to jointly minimizing the first, second, third, etc. singular values of matrix-valued functions, which is quite a different context from the one in this paper.

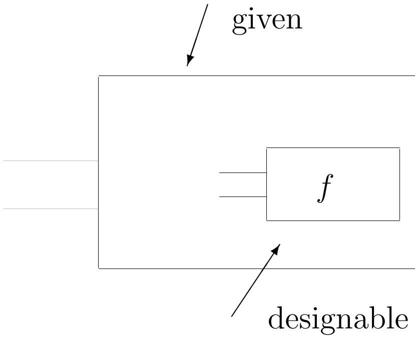

FIG. 1. *For a given plant, we want to find the best designable part, represented by f.*

1.3. Engineering motivation. This type of problem is central to frequency-domain-system design problems, where stability is a key constraint. In particular, it is important to the area of H^∞ control [H], [Fr]. The basic physical idea is simple. Recall that a linear-time-invariant system has a frequency-response function F defined on the imaginary axis and that the system is stable if F has no poles in the closed right half-plane (RHP). The behavior of the system when excited with a pure sine wave of frequency ω is determined by $F(i\omega)$. The following often occurs in a design procedure. We are required to build a system S, but part of the system is given (we are stuck with it) and part of the system is designable (denote its frequency-response function by f); see Figure 1. The performance of the system S at frequency ω is a function $\Gamma(\omega, f(i\omega))$ which depends on ω and on one's choice of the designable subsystem f. Let us adopt the convention that large Γ is bad while small Γ is good. Then in a worst-case "broadband" design, we consider the worst performance over all frequencies

$$\sup_{\omega} \Gamma(\omega, f(i\omega))$$

and try to minimize it over all admissible f. If our main constraint is that the designable subsystem f must be stable, then the design problem becomes the problem of finding a Pareto optimum with one Γ after transforming the RHP to the unit disk. When $N > 1$, these problems usually pose serious difficulties since traditional graphical trial and error methods are inadequate.

A number of authors (Mayne, Polak, and Salucidean; Fan and Tits; Streit; Boyd; Daleh; Pearson; Doyle, Glover, and Packard; Helton, Merino, and Walker; and Sideris) have written computer programs to search for an optimal f^* with certain kinds of Γ; see, e.g., [BB], [D], [FKTW], [HMW], [MNPW], [Si], and [St].

1.4. The classical case: One performance function. If we restrict our attention to the degenerate Pareto optimum, then we end up with a classical case of optimizing a single-performance function.

Now we state an earlier result for a single-performance function which this paper extends. Let $\Gamma(e^{i\theta}, z)$ be continuous nonnegative function. We are trying to find $f^* \in H^\infty_N$ which minimizes the following quantity:

$$\sup_{\theta \in \mathbf{R}} \Gamma(e^{i\theta}, f^*(e^{i\theta})).$$

Theorem 1.1 (see [H1]). *Let Γ be of class C^3 and $f^* \in H^\infty_N \cap C(\mathbf{T})$ be such that $(\partial\Gamma/\partial z)(e^{i\theta}, f^*(e^{i\theta}))$ never equals 0 on $\mathbf{T}$. If f^* is a local minimizer, then*

(I) *the function $\Gamma(\cdot, f^*(\cdot))$ is a constant on $\mathbf{T}$ and*

(II) *there exist functions $F \in H^1_N$ and $\lambda : \mathbf{T} \to \mathbf{R}^+$ measurable and positive almost everywhere on $\mathbf{T}$ such that*

$$\lambda(e^{i\theta})\frac{\partial\Gamma}{\partial z}(e^{i\theta}, f^*(e^{i\theta})) = e^{i\theta}F(e^{i\theta}) \quad \text{a.e. on } \mathbf{T}.$$

When one adds a condition (III) asserting that Γ is convex in some directions, then one obtains a necessary and sufficient condition [HM1]. Indeed, [HM1] is the best reference for this result. Theorem 1.1 is extremely useful in that conditions (I) and (II) are a basis for computer diagnostics and software developed by Helton, Merino, and Walker; see [HMW].

1.5. Smooth performances versus multiple performances. In engineering applications, a single-performance function Γ can be used to incorporate several performance criteria. In particular, a Pareto optimum f^* for performance functions $\Gamma_1, \ldots, \Gamma_l$ can be viewed as a solution to the optimization problem with only one performance function defined by

$$\widetilde{\Gamma}(e^{i\theta}, z) := \max\left\{\frac{\Gamma_1(e^{i\theta}, z)}{\gamma_1(f^*)}, \ldots, \frac{\Gamma_l(e^{i\theta}, z)}{\gamma_l(f^*)}\right\}. \tag{1}$$

Namely, it is easy to check that f^* is a Pareto optimum for $\Gamma_1, \ldots, \Gamma_l$ if it is an optimum for $\widetilde{\Gamma}$. The main disadvantage of introducing $\widetilde{\Gamma}$ is that it is almost never differentiable, even though the Γ_j's are. As a consequence, the results proved for a single-performance-function optimization, reproduced in the theorem above, cannot be applied to $\widetilde{\Gamma}$.

1.6. Outline of the paper. This paper has the following structure. In section 2, we state and prove the main result of this paper. In section 3, we give two auxiliary results on uniqueness and existence of the Pareto optimum. In section 4, we reproduce the proofs of several lemmas which were proved by Trepreau in [T] and which have not been published. Section 4 is completely independent of the rest of the paper. In section 5, we discuss the connection between the M-OPT problem which had its origin in engineering mathematics and the analytic-disc techniques used in the popular several-complex-variables problem of extending a function defined on a manifold M in $\mathbf{C}^N$ to a function analytic in a neighborhood of a given point on M.

2. First-order conditions.

In this section, we give a precise statement of our results in the general case of l-performance functions.

Definition. *A function $f^* \in H^\infty_N$ is called a* local Pareto optimum *for $\Gamma_1, \ldots, \Gamma_l$ if there exists $\epsilon > 0$ such that*

$$\textit{for all } f \in H^\infty_N \textit{ and } \|f - f^*\| < \epsilon, \quad \textit{there exists } j, \quad \gamma_j(f) \geq \gamma_j(f^*).$$

For $l = 1$, this definition means that f^* minimizes $\sup_\theta \Gamma(e^{i\theta}, f(e^{i\theta}))$.

2.1. Main results. We introduce the notation

$$\frac{\partial\Gamma}{\partial z} = \begin{pmatrix} \frac{\partial}{\partial z_1}\Gamma_1 & \cdots & \frac{\partial}{\partial z_N}\Gamma_1 \\ \cdots & \cdots & \cdots \\ \frac{\partial}{\partial z_1}\Gamma_l & \cdots & \frac{\partial}{\partial z_N}\Gamma_l \end{pmatrix}. \tag{2}$$

Denote the unit disc in $\mathbf{C}$ by Δ.

We will impose the following assumption on performance functions.

ASSUMPTION 1. *Suppose $N \geq l$ and suppose $\Gamma_j = |P_j(e^{i\theta}, z)/Q_j(e^{i\theta}, z)|^2$, where P_j and Q_j are holomorphic polynomials in z with coefficients which are rational functions in $e^{i\theta}$. We assume, in addition, that the coefficients do not have poles on $\mathbf{T}$.*

We will consider a candidate for Pareto optimum f^* for which the following assumption holds.

ASSUMPTION 2. *The function $f^* \in H^\infty_N \cap C^\alpha$, $\alpha > 1/2$, with performances $\gamma_1^*, \dots, \gamma_l^*$ satisfies the following condition:*

There exists an analytic direction $h_j \in H^\infty_N \cap C^\alpha$, $\alpha > 1/2$, that improves all performances except for γ_j^*. Namely, there exist $C > 0$ and $t_0 > 0$ such that for every $t < t_0$,

$$\sup_\theta \Gamma_k(e^{i\theta}, f^*(e^{i\theta}) + th_j(e^{i\theta})) - \sup_\theta \Gamma_k(e^{i\theta}, f^*(e^{i\theta})) < -Ct \quad \textit{for } k = 1, \dots, l, \quad k \neq j.$$

Assumption 2 means that f^* is a nondegenerate Pareto optimum as discussed earlier, i.e., all l performances $\Gamma_1, \dots \Gamma_l$ play an active role. If not all of them matter, we have a smaller l.

Now we state the main result of this paper.

THEOREM 2.1. *Suppose the performance functions Γ_j satisfy Assumption* 1. *Suppose that $f^* \in H^\infty_N \cap C^\alpha$ is a local Pareto optimum that satisfies Assumption* 2. *Suppose further that $\frac{\partial \Gamma_j}{\partial z}(e^{i\theta}, f^*(e^{i\theta})) \in C^\alpha$ with $\alpha > 1/2$ and that*

$$\operatorname{rank} \frac{\partial \Gamma(e^{i\theta}, f^*(e^{i\theta}))}{\partial z} = l \tag{3}$$

for every $e^{i\theta} \in \mathbf{T}$.

Then the following hold:

(I) Flatness:

$$\Gamma_j(e^{i\theta}, f^*(e^{i\theta})) = \text{const.}, \quad j = 1, \dots, l.$$

(II) Gradient alignment: *There exists a row-vector-valued function $\lambda \in C^\alpha_l(\mathbf{T}, \mathbf{R})$, $\lambda \not\equiv 0$, with nonnegative entries, such that*

$$\lambda(e^{i\theta}) \frac{\partial \Gamma}{\partial z}(e^{i\theta}, f^*(e^{i\theta})) = e^{i\theta} F, \quad F \in H^2_N.$$

Here $\frac{\partial \Gamma}{\partial z}(e^{i\theta}, f^*(e^{i\theta}))$ denotes the $l \times N$ derivative matrix (2) *evaluated at $z = f(e^{i\theta})$.*

Remark. We will, in fact, show that for (II) to hold, it is enough to assume only that f^* is an optimum such that $f^* \in C^\alpha$ with $\alpha > 1/2$ and the rank condition (3) holds. In other words, Assumptions 1 and 2 are not needed for (II).

2.2. The classical Riemann–Hilbert problem. The main step in the proof of the flatness condition is solving the following version of Riemann–Hilbert problem:

Given an $l \times N$ matrix-valued function $A \in C^\alpha(\mathbf{T})$ with invertible values, given a closed interval $I \subset \mathbf{T}$, $I \neq \mathbf{T}$, find $h \in H^\infty_N$ such that

$$\begin{aligned} (\operatorname{Re}(Ah))_1 &> 0 \quad \text{for } e^{i\theta} \in I, \\ (\operatorname{Re}(Ah))_j &> 0 \quad \text{for all } e^{i\theta}, \quad j = 2, \dots, l. \end{aligned} \tag{4}$$

Here $(\cdot)_j$ stands for taking the jth entry of a vector. (Later the matrix A will be taken to be equal to $\frac{\partial \Gamma}{\partial z}(e^{i\theta}, f^*(e^{i\theta}))$).

(4) is, in fact, a problem about the range of the Riemann–Hilbert map

$$w \longrightarrow 2\mathrm{Re}\,(Aw).$$

Questions about the range of the Riemann–Hilbert map arise in several aspects. For example, the gradient-alignment condition (Theorem 2.1(II)) will be shown to be equivalent to the fact that the range of the derivative map

$$w \longrightarrow 2\mathrm{Re}\left(\frac{\partial\Gamma(e^{i\theta}, f^*(e^{i\theta}))}{\partial z} w\right)$$

does not contain strictly positive functions, i.e., that all performances cannot be improved to first order at the same time.

Questions about the range of the Riemann–Hilbert map also arise in the analytic-disc techniques in one theoretical complex-variables problem; see section 6 for more details. See [Ve] as a standard reference on the theory of the Riemann–Hilbert problem.

In this paper, we give conditions on A which insure that problem (4) always has a solution.

To state our main condition, we need the following definition.

Definition. *A function $u(e^{i\theta}) \in L^\infty(\mathbf{T}, \mathbf{C})$ has a* pseudomeromorphic continuation *inside Δ if there exists a function $\widetilde{u}$, meromorphic in Δ and with finitely many poles in Δ, such that*

$$\lim_{r\to 1} \widetilde{u}(re^{i\theta}) = u(e^{i\theta}) \quad \text{a.e. } \mathbf{T}.$$

Theorem 2.2. *Suppose that $l \le N$. Suppose that an $l \times N$ matrix-valued function $A \in C^\alpha(\mathbf{T}, \mathbf{C})$, $\alpha > 1/2$, takes values of rank l on $\mathbf{T}$. If*

(i) *the entries of A have pseudomeromorphic continuation inside Δ*
or, more generally,

(ii) *the matrix A can be written as $D\widetilde{A}$, where D is an invertible diagonal matrix function and $\widetilde{A}$ has a pseudomeromorphic continuation inside Δ,*
then problem (4) *has a solution h.*

3. Proofs.

3.1. Proof of the flatness condition (Theorem 2.1(I)). First, we observe that every Γ_j has a Taylor expansion

$$\Gamma_j(e^{i\theta}, z + tw) = \Gamma_j(e^{i\theta}, z) + t2\mathrm{Re}\left(\frac{\partial\Gamma_j}{\partial z}(e^{i\theta}, z)\cdot w\right) + O(t^2). \tag{5}$$

Now suppose that $f^* \in H_N^\infty \cap C^\alpha$ is a minimizer which produces performances $\gamma_1^*, \dots, \gamma_l^*$ and that the performance function $\Gamma_1(e^{i\theta}, f^*(e^{i\theta}))$ is not constant. Then we can find $\epsilon_0 > 0$ and $I \subset \mathbf{T}$ so that $\mathbf{T} \setminus I$ is an open, nonempty interval and

$$\Gamma_1(e^{i\theta}, f^*(e^{i\theta}))|_{\mathbf{T}\setminus I} \le \gamma_1^* - \epsilon_0 = \sup_\theta \Gamma_1(e^{i\theta}, f^*(e^{i\theta})) - \epsilon_0. \tag{6}$$

We first want to find a vector-valued function $w \in H_N^\infty \cap C^\alpha$ that satisfies

$$\begin{pmatrix} \dfrac{\partial\Gamma_1}{\partial z_1}(e^{i\theta}, f^*(e^{i\theta})) & \cdots & \dfrac{\partial\Gamma_1}{\partial z_N}(e^{i\theta}, f^*(e^{i\theta})) \\ \cdots & \cdots & \cdots \\ \dfrac{\partial\Gamma_l}{\partial z_1}(e^{i\theta}, f^*(e^{i\theta})) & \cdots & \dfrac{\partial\Gamma_l}{\partial z_N}(e^{i\theta}, f^*(e^{i\theta})) \end{pmatrix} \begin{pmatrix} w_1 \\ \cdots \\ w_N \end{pmatrix} = \begin{pmatrix} \varphi \\ 0 \\ \cdots \\ 0 \end{pmatrix}, \tag{7}$$

where φ is an arbitrary function that never equals 0 on I.

Recall that $\Gamma_j(e^{i\theta}, z) = (P_j/Q_j)\overline{(P_j/Q_j)}$, where $P_j(e^{i\theta}, z)$ and $Q(e^{i\theta}, z)$ are holomorphic polynomials in z with rational coefficients depending on $e^{i\theta}$. The derivative is given by

$$\begin{aligned}\frac{\partial \Gamma_j}{\partial z_k}&(e^{i\theta}, f^*)\\ &= \frac{\dfrac{\partial P_j}{\partial z_k}(e^{i\theta}, f^*)Q_j(e^{i\theta}, f^*) - P_j(e^{i\theta}, f^*)\dfrac{\partial Q_j}{\partial z_k}(e^{i\theta}, f^*)}{[Q_j(e^{i\theta}, f^*)]^2}\overline{P_j(e^{i\theta}, f^*)Q_j(e^{i\theta}, f^*)}^{-1}.\end{aligned}$$

We introduce the notation

$$\Psi_j(e^{i\theta}) := \overline{P_j(e^{i\theta}, f^*(e^{i\theta}))}^{-1}\overline{Q_j(e^{i\theta}, f^*(e^{i\theta}))}[Q_j(e^{i\theta}, f^*(e^{i\theta}))]^2.$$

Note that $P_j \neq 0$ because $\frac{\partial \Gamma}{\partial z}$ has maximal rank. Then $\frac{\partial \Gamma_j}{\partial z_k}(e^{i\theta}, f^*(e^{i\theta}))\Psi_j(e^{i\theta})$ can be extended meromorphically inside the unit disc. By Assumption 1, the meromorphic functions $\frac{\partial \Gamma_j}{\partial z_k}(z, f^*(z))\Psi_j(z)$ do not have poles on the boundary of the unit disc or accumulating to the boundary. Let $\beta(z)$ be the finite Blaschke product such that $\beta(z)\frac{\partial \Gamma_j}{\partial z_k}(z, f^*(z))\Psi_j(z)$ is holomorphic in the unit disc for $j = 1, \dots, l$ and $k = 1, \dots N$.

Multiply both sides of (7) on the left by the $l \times l$ diagonal matrix D, which has the diagonal entries $\Psi_1(e^{i\theta}), \dots, \Psi_l(e^{i\theta})$. Note that each $\Psi_j(e^{i\theta})$ does not vanish anywhere on $\mathbf{T}$.

By our assumptions, the matrix $D\frac{\partial \Gamma}{\partial z}$ has rank l everywhere. Since it is also of class C^α with $\alpha > 1/2$, by Proposition 5.1, there exists the $N \times N$ constant matrix H such that the first l columns of the product $D\frac{\partial \Gamma}{\partial z}H$ are linearly independent everywhere on $\mathbf{T}$.

Denote by B the the first l columns of the holomorphic matrix $D\frac{\partial \Gamma}{\partial z}H\beta$. Let $\widetilde{B}$ be an $l \times l$ holomorphic matrix-valued function such that

$$B\widetilde{B} = (\det B)I_{l\times l}.$$

Then the vector

$$\begin{pmatrix} w_1 \\ w_2 \\ \cdots \\ w_N \end{pmatrix} = \beta H \begin{pmatrix} \widetilde{B} \\ 0 \end{pmatrix}\begin{pmatrix} 1 \\ 0 \\ \cdots \\ 0 \end{pmatrix} \tag{8}$$

satisfies (7) with $\varphi(e^{i\theta}) \neq 0$ for all θ. Here $\binom{\widetilde{B}}{0}$ is an $N \times l$ matrix with the last $N - l$ rows equal to zero.

Since φ is nonzero on I, its argument $\arg\varphi|_I$ is well defined. Extend $\varphi|_I$ to the whole $\mathbf{T}$ in such a way that the extension $\widetilde{\varphi}$ has winding number zero. Let h be a holomorphic function such that $\arg h = -\arg\widetilde{\varphi}$. Then $h\varphi|_I$ is real valued and positive, and therefore the vector $-hw$ has the property that

$$2\mathrm{Re}\left(\frac{\partial}{\partial z}\Gamma_1(e^{i\theta}, f^*(e^{i\theta})) \cdot [-hw]\right) < -\epsilon_1, \quad e^{i\theta} \in I.$$

Choose ϵ_2 small enough so that

$$2\mathrm{Re}\left(\frac{\partial}{\partial z}\Gamma_1(e^{i\theta}, f^*(e^{i\theta})) \cdot [-\epsilon_2 hw]\right) \leq \epsilon_0/2, \quad e^{i\theta} \in \mathbf{T} \setminus I.$$

Then there exist positive constants C and t_0 such that for any $t \leq t_0$, the following holds:

$$\sup_\theta \left[\Gamma_1(e^{i\theta}, f^*(e^{i\theta})) - t2\mathrm{Re}\left(\frac{\partial}{\partial z}\Gamma_1(e^{i\theta}, f^*(e^{i\theta}))hw\right)\right] - \sup_\theta \Gamma_1(e^{i\theta}, f^*(e^{i\theta})) < -Ct,$$

$$2\mathrm{Re}\left(\frac{\partial}{\partial z}\Gamma_j(f^*)hw\right) = 0, \quad j = 2, \dots, l.$$

In other words, we have produced the analytic direction $-hw$ that "improves" the performance γ_1 and leaves the performances $\gamma_2, \dots, \gamma_l$ "unchanged" up to the first order.

By Assumption 2, there exists a direction $v \in H^\infty_N \cap C^\alpha$ that "improves" the performances $\gamma_2, \dots, \gamma_l$:

$$\sup_\theta \Gamma_j(e^{i\theta}, f^*(e^{i\theta}) + tv(e^{i\theta})) - \sup_\theta \Gamma_j(e^{i\theta}, f^*(e^{i\theta})) < -C't, \quad j = 2, \dots, l.$$

Now consider $\widetilde{w} = -hw + \varepsilon v$ for ε small enough. Then the analytic direction $\widetilde{w}$ "improves" all Γ_j's. Therefore, by (5), for small t, the function $f^* + t\widetilde{w}$ has better performances:

$$\gamma_j(f^* + t\widetilde{w}) < \gamma_j(f^*), \quad j = 1, \dots, l.$$

We have reached a contradiction. □

Proof of Theorem 2.2. The proof is a line-by-line repetition of a part of the proof of Theorem 2.1(I). □

3.2. Counterexample. Now we give some indications that we need Assumption 1 on Γ's for flatness to hold. The flatness result, if it holds, would imply that if $\Gamma_2(e^{i\theta}, f(e^{i\theta})), \dots, \Gamma_l(e^{i\theta}, f(e^{i\theta}))$ are constants and $\Gamma_1(e^{i\theta}, f(e^{i\theta}))$ satisfies (6), then we can find an analytic vector h such that

$$\begin{aligned} \mathrm{Re}\left(\tfrac{\partial\Gamma_1}{\partial z}(e^{i\theta}, f(e^{i\theta})) \cdot h\right) > 0 \quad &\text{for } e^{i\theta} \in I, \\ \mathrm{Re}\left(\tfrac{\partial\Gamma_j}{\partial z}(e^{i\theta}, f(e^{i\theta})) \cdot h\right) > 0 \quad &\text{for all } e^{i\theta}, \quad j = 2, \dots, l. \end{aligned}$$

Considering the question of existence of such an h in a little more general setting leads to problem (4).

Proposition 3.2 below shows that there exists an A such that problem (4) is not solvable. While we have not done so, we suspect that one can construct a simple A for which (4) is not solvable and which can be written as $\frac{\partial\Gamma}{\partial z}(e^{i\theta}, f^*(e^{i\theta}))$ for some Γ_j's and f^*.

We start with the following lemma which gives a characterization of the derivative map (see [BRT] and [T]).

Lemma 3.1. *Assume $N \geq l$ and suppose that A is an $l \times N$ complex matrix-valued function on $\mathbf{T}$ of class C^α with $1/2 < \alpha < 1$ and which has maximal rank ℓ at every point on $\mathbf{T}$. Consider the following Riemann–Hilbert operator:*

$$\mathcal{F} : H^2_N \longrightarrow L^2_l(\mathbf{T}, \mathbf{R}), \qquad \mathcal{F}(w) = 2\mathrm{Re}(Aw).$$

Then $(\mathrm{range}\mathcal{F})^\perp \subset L^2(\mathbf{T}, \mathbf{R})$ *consists of all such real-valued ℓ-vectors $g \in L^2$ so that*

$$A^t g \in zH^2_N. \tag{9}$$

Proof. Suppose that $g \in L^2$ belongs to $(\mathrm{range}\mathcal{F})^\perp$. Then

$$\int g \cdot \mathrm{Re} Aw = 0 \quad \forall w \in H^2. \tag{10}$$

Since this is true for iw, we have

$$\int g \cdot Aw = 0 \quad \forall w \in H^2. \tag{11}$$

Therefore, $(\overline{A}^\top g, w) = 0$, where $(\cdot,\cdot)$ is the inner product in $L^2(\mathbf{T},\mathbf{C})$. Then (9) follows. □

Remark. If we denote the restriction of $\mathcal{F}$ to $H^2_N \cap C^\alpha$ by $\mathcal{F}^\alpha$, then the continuity of $\mathcal{F}$ implies that

$$(\mathrm{range}\mathcal{F}^\alpha)^\perp = (\mathrm{range}\mathcal{F})^\perp. \tag{12}$$

Proposition 3.2 below states that problem (4) cannot be solved for every A.

PROPOSITION 3.2. *Suppose that $N = l = 2$. Given any closed $I \subset \mathbf{T}$ with $I \neq \mathbf{T}$, there exists A such that for any $v \in C^\alpha(I)$ with $\alpha > 1/2$, $v > 0$,* on I *and any $\psi \in C^\alpha(\mathbf{T})$ with $\psi > 0$, there exists no solution $h \in H^\infty_2 \cap C^\alpha$ to the following Riemann–Hilbert problem:*

$$2\mathrm{Re}(Ah) = \begin{pmatrix} \varphi \\ \psi \end{pmatrix}, \qquad \varphi|_I = v.$$

Proof. Take $g_0 = (p(e^{i\theta}), 1)$ with $p = 0$ on $\overline{\mathbf{T}\backslash I}$ and $p > 0$ on $\mathrm{int}(I)$. Then $(g_0, (\varphi,\psi))_{L^2} > 0$ for any $\psi > 0$ and any φ with $\varphi|_{\mathrm{int}(I)} > 0$.

Now we take

$$A = \begin{pmatrix} e^{i\theta} & 0 \\ -p(e^{i\theta})e^{i\theta} & e^{i\theta} \end{pmatrix}.$$

Obviously, $g_0 A \in zH^2$, and therefore g_0 belongs to $(\mathrm{range}\mathcal{F})^\perp$. □

3.3. Proof of Theorem 2.1(II). We first need the following theorem.

THEOREM 3.3. *Suppose that a subspace $\mathcal{R} \subset C^\alpha \subset L^2_l(\mathbf{T},\mathbf{R})$ has the property that its complement $(\mathcal{R})^\perp$ is finite dimensional and a subset of C^α_l. Suppose also that its closure in the L^2 topology $\overline{\mathcal{R}}$ satisfies $\overline{\mathcal{R}} \cap C^\alpha = \mathcal{R}$. If $\mathcal{R}$ does not contain vector functions with every component strictly positive, then there exists a function $\lambda \not\equiv 0$ in $(\mathcal{R})^\perp$ with every component positive (but not necessarily strictly positive).*

The proof requires the following.

LEMMA 3.4. *If the vectors $v_1, \ldots, v_m$ satisfy*

$$\{x : \exists j, 1 \leq j \leq m, \quad x \cdot v_j > 0\} = \mathbf{R}^n \backslash \{0\},$$

then the set

$$\mathrm{hull}(v_1, \ldots, v_m) := \{t_1 v_1 + \cdots + t_m v_m : \ t_j \geq 0\}$$

is the whole of $\mathbf{R}^n$

Proof. Abbreviate $\mathrm{hull}(v_1, \ldots, v_m)$ by V. Suppose that $V \neq \mathbf{R}^n$. Take any point x_0 which is not in V. Then there exists a plane $\{x : x \cdot \xi = r\}$ which separates x_0 and V, i.e., $x_0 \cdot \xi > r$ and $x \cdot \xi < r$ for every $x \in V$.

Since V is a cone, the latter implies that $x \cdot \xi \leq 0$ for every $x \in V$. In particular, it means that

$$v_j \cdot \xi \leq 0, \quad j = 1, \ldots, m.$$

We have reached a contradiction. $\square$

Proof of Theorem 3.3. Suppose that the functions $g_1, \ldots, g_n$ form a basis of $(\mathcal{R})^\perp$. We want to prove that there exists a linear combination $a_1 g_1(\zeta) + \cdots + a_n g_n(\zeta)$ in $(\mathcal{R})^\perp$ that is positive on all of $\mathbf{T}$. Here $a_j \in \mathbf{R}$. Denote the $n \times l$ matrix with rows $g_1(\zeta), \ldots, g_n(\zeta)$ by $g(\zeta)$. We claim that it is enough to show the inequality

$$\inf_{a \in \mathbf{R}^n, \|a\|=1} \max_{\zeta \in \mathbf{T}} a^t g(\zeta) \leq 0. \tag{13}$$

Here we use the notation

$$\max_{\zeta \in \mathbf{T}} (b_1(\zeta), \ldots, b_l(\zeta)) = \max(\max_{\zeta \in \mathbf{T}} b_1(\zeta), \ldots, \max_{\zeta \in \mathbf{T}} b_l(\zeta)).$$

Note that we do not take the absolute values of functions.

The quantity $\max_{\zeta \in \mathbf{T}} a^t g(\zeta)$ depends continuously on a, which varies over a compact set in $\mathbf{R}^n$. Therefore, if (13) holds, then there exists $a_0 \in \mathbf{R}^n$ such that

$$\max_{\zeta \in \mathbf{T}} a_0^t g(\zeta) \leq 0.$$

Hence all components of the vector function $-a_0^t g(\zeta)$ are positive and the claim follows.

Now we use a dual extension argument. This uses the fact that for any function $\mu \in C_l^\alpha(\mathbf{T})$,

$$\max_{\zeta \in \mathbf{T}} \mu(\zeta) = \sup_{u \in B_l^+} \int \mu(\zeta) \cdot u(\zeta) d\zeta,$$

where we use the notation $B_l^+ = \{u \in C_l^\alpha(\mathbf{T}, \mathbf{R}) : \|u\|_{L^1} = 1, u_j(\zeta) > 0,\ j = 1, \ldots, l\}$. Therefore, we need to prove the inequality

$$\inf_{a \in \mathbf{R}^n, \|a\|=1} \sup_{u \in B_l^+} \int (a^t g(\zeta)) \cdot u(\zeta) d\zeta \leq 0. \tag{14}$$

Given any $u \in B_l^+$, we define the vector $c(u) \in \mathbf{R}^n$ as follows:

$$c(u) := \left(\int g_1 \cdot u, \ldots, \int g_n \cdot u \right).$$

Lemma 3.5. *The set* $\{x : \exists u \in B_l^+, \ \ x \cdot c(u) > 0\}$ *is not the whole of* $\mathbf{R}^n \setminus \{0\}$.

Proof. Suppose the contrary: $\{x : \exists u \in B_l^+, \ \ x \cdot c(u) > 0\} = \mathbf{R}^n \setminus \{0\}$. Since, in fact, we have an open covering of the unit sphere S^{n-1}, which is compact, there exist $u_1, \ldots, u_m$ such that $\{x : \exists j, 1 \leq j \leq m, \ x \cdot c(u_j) > 0\} = \mathbf{R}^n \setminus \{0\}$. Then by Lemma 3.4, the convex hull $\operatorname{hull}(c(u_1), \ldots, c(u_m)) = \mathbf{R}^n$.

Therefore, there exists a positive, nontrivial linear combination of $c(u_j)$'s which is zero:

$$b \in \mathbf{R}^m, \quad b \neq 0, \quad b_j \geq 0, \quad \sum b_j c(u_j) = 0.$$

We consider $\widetilde{u}(\zeta) = \sum b_j u_j(\zeta)$. Then $\widetilde{u}(\zeta) \in C^\alpha$ would be a vector function with every component strictly positive. However, on the other hand,

$$\int g\widetilde{u} = \int \sum b_j(gu_j) = \sum b_j c(u_j) = 0,$$

which implies that $\widetilde{u} \in \overline{\mathcal{R}} \cap C^\alpha = \mathcal{R}$, i.e., we have reached a contradiction. □

Now we continue with the proof of Theorem 3.3. Take a point a_0 not in $\{x : \exists u \in B_l^+, \quad x \cdot c(u) > 0\}$ with $\|a_0\| = 1$. Then

$$\int (a_0^t g(\zeta)) \cdot u(\zeta) d\zeta = a_0^t \int g(\zeta) u(\zeta) d\zeta = a_0^t c(u) \leq 0 \quad \forall u \in B_l^+,$$

and therefore inequality (14) holds. □

Now we continue with the proof of Theorem 2.1(II). Since f^* is an optimum, there is no strictly positive function in the range of the derivative map

$$\mathcal{F}^\alpha : H_N^2 \cap C^\alpha \to C^\alpha, \qquad \mathcal{F}^\alpha(w)(\zeta) = 2\mathrm{Re}\left(\frac{\partial\Gamma(\zeta, f^*(\zeta))}{\partial z} w(\zeta)\right).$$

We observe that Lemma 5.5 and (12) imply that $(\mathrm{range}\mathcal{F}^\alpha)^\perp$ is a finite-dimensional subset of C^α. We claim that $\overline{\mathrm{range}\mathcal{F}^\alpha} \cap C^\alpha = \mathrm{range}\mathcal{F}^\alpha$. To show the claim, we first note that $\mathrm{range}\mathcal{F}$, where $\mathcal{F}$ is defined as in Lemma 3.1, is closed in L^2. Therefore, $\overline{\mathrm{range}\mathcal{F}^\alpha} = \mathrm{range}\mathcal{F}$. The C^α-hypoellipticity of $\mathcal{F}$ (see Lemma 5.5) implies that $\mathrm{range}\mathcal{F} \cap C^\alpha = \mathrm{range}\mathcal{F}^\alpha$, and the claim follows.

The argument above shows that we can apply Theorem 3.3 with $\mathcal{R} = \mathrm{range}\mathcal{F}^\alpha$. Therefore, there is a vector-valued function λ in $(\mathrm{range}\mathcal{F})^\perp$ with each component positive. By Lemma 3.1, λ must satisfy (9), which implies Theorem 2.1(II). □

4. Additional results.

4. Additional results. In this section, we state the results on uniqueness and existence of the M-OPT problem which are, in fact, easy corollaries of the results proved in [HMar], [HM1], and [V].

4.1. Uniqueness. Consider the sublevel sets

$$\mathcal{S}_\theta^j(\gamma) := \{z \in \mathbf{C}^N : \Gamma_j(e^{i\theta}, z) \leq \gamma\}.$$

THEOREM 4.1. *Suppose that the performance functions $\Gamma_1, \ldots, \Gamma_l$ satisfy Assumption 1. Suppose that the sublevel sets $\mathcal{S}_\theta^j(\gamma_j)$ are strictly convex for every $j = 1, \ldots, l$, every $\theta \in \mathbf{T}$, and every γ_j.*

Assume that the real numbers $\gamma_1^*, \ldots, \gamma_l^*$ have the property that for every function f with performances $\gamma_1(f), \ldots, \gamma_l(f)$ satisfying $\gamma_j(f) \leq \gamma_j^*$, Assumption 2 holds and the matrix $\partial\Gamma(e^{i\theta}, f(e^{i\theta}))/\partial z$ has rank l.

Then if $f^* \in H_N^\infty \cap C^\alpha$ with $\alpha > 1/2$ is a Pareto optimum with performances

$$\sup_\theta \Gamma_j(e^{i\theta}, f^*(e^{i\theta})) = \gamma_j(f^*),$$

this Pareto optimum is unique, namely, there is no other function $f \in H_N^\infty \cap C^\alpha$, $\alpha > 1/2$, with the property that $\gamma_j(f) = \gamma_j(f^*)$ for all $j = 1, \ldots, l$.

Proof. Suppose that such an f does exist. Then

$$f(e^{i\theta}) \in \partial\mathcal{S}_\theta^1(\gamma_1^*) \cap \cdots \cap \partial\mathcal{S}_\theta^l(\gamma_l^*) \quad \forall e^{i\theta} \in \mathbf{T} \tag{15}$$

by the flatness result. Here $\gamma_j^* = \gamma_j(f^*)$. Since (15) is true for f^* as well, the function $h = 1/2f + 1/2f^*$ has the property that

$$h(e^{i\theta}) \in \mathcal{S}_\theta^1(\gamma_1^*) \cap \cdots \cap \mathcal{S}_\theta^l(\gamma_l^*) \quad \forall e^{i\theta} \in \mathbf{T}.$$

Strict convexity implies that there exists θ_0 satisfying

$$h(e^{i\theta_0}) \in \mathrm{int}\mathcal{S}_{\theta_0}^1(\gamma_1^*) \cap \cdots \cap \mathrm{int}\mathcal{S}_{\theta_0}^l(\gamma_l^*). \tag{16}$$

If the performance functions evaluated at h are flat (i.e., the flatness result (Theorem 2.1(I)) holds for h), then (16) should hold for every θ, and therefore f^* is not an optimum. If the performance functions of h are not flat, then by Theorem 2.1, they all can be improved simultaneously, and therefore f^* is not an optimum in this case either. $\square$

4.2. Existence. The following theorem was proved in [HMar].

THEOREM 4.2. *Suppose that $\Gamma(e^{i\theta}, z)$ is a positive continuous function and suppose that the sublevel sets of Γ satisfy $\partial\mathcal{S}_\theta(\gamma) = \{z \in \mathbf{C}^N : \Gamma(e^{i\theta}, z) = \gamma\}$. Suppose further that the sublevel sets $\mathcal{S}_\theta(\gamma)$ are uniformly bounded and polynomially convex. Suppose that $f^n \in H_N^\infty$ satisfy $\lim_n \|\Gamma(e^{i\theta}, f^n(e^{i\theta}))\|_\infty = \gamma$. Let f be a normal limit of f^n. Then $\|\Gamma(e^{i\theta}, f(e^{i\theta}))\|_\infty \le \gamma$.*

As a corollary, we can state the following existence result.

THEOREM 4.3. *Suppose that $\Gamma_j, j = 1, \ldots, l$, are positive C^1 functions. Suppose that the sublevel sets satisfy $\partial\mathcal{S}_\theta^j(\gamma) = \{z \in \mathbf{C}^N : \Gamma_j(e^{i\theta}, z) = \gamma\}$ for $j = 1, \ldots, l$ and for every γ and θ. Suppose further that the sets $\mathcal{S}_\theta^1(\gamma) \cap \cdots \cap \mathcal{S}_\theta^l(\gamma)$ are uniformly bounded and polynomially convex for every γ.*

Then there exists a Pareto optimum for $\Gamma_1, \ldots, \Gamma_l$.

Remark. Note that we do not impose Assumption 1 in this theorem. In particular, the flatness property of the optimum needs not hold.

Proof. First, we reduce the problem to the case of one performance function by introducing

$$\widetilde{\Gamma}(e^{i\theta}, z) := \max\big(\Gamma_1(e^{i\theta}, z), \ldots, \Gamma_l(e^{i\theta}, z)\big).$$

We start with an initial guess $f^1 \equiv 1$. We then make further guesses, f^n's, improving $\widetilde{\Gamma}$ if possible. Since the $\widetilde{\mathcal{S}}_\theta(\gamma)$'s are uniformly bounded, the set $\{f^n\}$ is uniformly bounded in H_N^∞ and therefore has a subsequence, converging locally uniformly in the open unit disc to some limit f. Applying Theorem 4.2, we conclude that f is an optimum for $\widetilde{\Gamma}$ with $\sup_\theta \widetilde{\Gamma}(e^{i\theta}, f(e^{i\theta})) = \gamma$. $\square$

5. Technical lemmas. In this section, we reproduce the proofs of several lemmas that were proved by Trepreau and which have not been published. They can all be found in the preprint [T]. Lemma 5.5 is very close to the results proved in [BG].

PROPOSITION 5.1. *Suppose that $A \in C^\alpha(\mathbf{T})$ with $\alpha > 1/2$ is an $l \times N$ matrix-valued function of maximum rank l at every point on $\mathbf{T}$. Then there exists an $N \times N$ constant complex matrix H such that the first l columns of AH are linearly independent at every point on $\mathbf{T}$.*

To prove this proposition, we will need the following lemma, in which the role of the assumption $\alpha > 1/2$ becomes clear.

LEMMA 5.2. *Given $u(x) \in C^\alpha([0,1], \mathbf{C})$ with $\alpha > 1/2$,* the range *of u has zero Lebesgue measure in $\mathbf{C}$.*

Proof. Divide the interval [0,1] into n equal parts by points j/n, $j = 0, \ldots, n$. Then the range of u can be covered by the n discs of radius $C(1/n)^\alpha$ centered at $u(j/n)$, $j = 0, 1, \ldots, n$, where C is the Hölder constant of u. The total measure of these discs does not exceed

$$n\pi(C(1/n)^\alpha)^2 = C^2\pi n^{1-2\alpha}.$$

Since $\alpha > 1/2$, this quantity tends to zero as n approaches infinity. □

To prove Proposition 5.1, we begin by proving a special case.

LEMMA 5.3. *Let $a \in C^\alpha(\mathbf{T}, \mathbf{C})$, $\alpha > 1/2$, be the N-vector such that $a \neq 0$ anywhere on $\mathbf{T}$. Then there exists $\beta \in \mathbf{C}^N$ such that $a(e^{i\theta}) \cdot \beta$ vanishes nowhere on $\mathbf{T}$.*

Proof. We will prove the statement for any open subset I of $\mathbf{T}$ by induction on N. (We will assume that a is of class C^α *uniformly* on I.) Since the case where $N = 1$ is trivial, we assume that the lemma holds for $N - 1$. Let $Z \subset I$ be the zero set of a_N and $Z_0 \subset I$ be an open neighborhood of Z on which $(a_1, \ldots, a_{N-1}) \neq 0$. By the induction hypothesis, there exists $(\beta_1, \ldots, \beta_{N-1})$ such that $a_1\beta_1 + \cdots + a_{N-1}\beta_{N-1}$ does not vanish on Z_0. Also, the function $(a_1\beta_1 + \cdots + a_{N-1}\beta_{N-1})/a_N \in C^\alpha(I \setminus Z)$ cannot be onto $\mathbf{C}$ by Lemma 5.4 below. (Note that σ/a_N is bounded on $I \setminus Z_0$.)

Therefore, we can find a number $-\beta_N$ that is not in the range of σ/a_N, and so $a_1\beta_1 + \cdots + a_{N-1}\beta_{N-1} + a_N\beta_N$ vanishes nowhere on I. □

LEMMA 5.4. *Let $\sigma := a_1\beta_1 + \cdots + a_{N-1}\beta_{N-1}$. The range of the function $\sigma/a_N \in C^\alpha(Z_0 \setminus Z)$ is not the whole of $\mathbf{C}$.*

Proof. Note that $Z_0 \setminus Z$ is a countable union of open intervals (t_j, t_{j+1}). We will show that the range of each of the restrictions $\sigma/a_N \in C^\alpha((t_j, t_{j+1}))$ is of measure zero in $\mathbf{C}$. Note that $\sigma \neq 0$ on Z_0 and a_N can vanish only at the endpoints t_j. If it vanishes at t_j, then it satisfies

$$|a_N(t) - 0| \leq c|t - t_j|^\alpha, \tag{17}$$

which implies

$$|\sigma(t)/a_N(t)| \geq c'|t - t_j|^{-\alpha}. \tag{18}$$

Divide $\mathbf{C}$ into the annuli $L_k = \{z : k \leq |z| \leq k + 1\}$.

Away from points where a_N vanishes, we use the fact that both σ and a_N are of class C^α uniformly on $Z \setminus Z_0$ to conclude that the restriction of the range of $(\sigma/a_N)\mid_{(t_j,t_{j+1})}$ onto L_k is a curve which is *uniformly* C^α. In the neighborhood of points where a_N vanishes, we use estimate (18) to reach the same conclusion. Therefore, the range of $(\sigma/a_N)\mid_{(t_j,t_{j+1})}$ has zero measure in $\mathbf{C}$ by Lemma 5.2. □

Proof of Proposition 5.1. We write $A = (A_1, \ldots, A_N)$, where the A_j's are the columns of A. For $p = 1, \ldots, l$, we denote the vector formed by the first p components of A_j by A_j^p. By induction on p, we will show that there exists an invertible constant matrix H such that the matrix $((AH)_1^p, \ldots, (AH)_p^p)$ has rank p at every point.

Since A has rank l at every point, $(A_1^1, \ldots, A_N^1)$ has rank 1 and by Lemma 5.3 there exists $\langle\beta_1, \ldots, \beta_N\rangle$ such that $\beta_1A_1^1 + \cdots + \beta_NA_N^1$ does not vanish. Let H_1 be an invertible matrix with the first column $\langle\beta_1, \ldots, \beta_N\rangle^t$. Then $(AH_1)_1^1$ has rank 1 everywhere.

Now we assume that the claim is true for p. Replacing A by AH_p, we can assume that $(A_1^p, \ldots, A_p^p)$ has rank p everywhere. This implies that at every point on $\mathbf{T}$, one of the determinants

$$d_j = \det(A_1^{p+1}, \ldots, A_p^{p+1}, A_j^{p+1}), \quad j = p + 1, \ldots, N, \tag{19}$$

is nonzero. By Lemma 5.3, we can find $\beta_j, j = p+1, \dots, N$, such that $d_{p+1}\beta_{p+1} + \cdots + d_N\beta_N$ is nonzero on $\mathbf{T}$. Let $\widetilde{H}$ be a $(N-p)\times(N-p)$ invertible matrix whose first column is $\beta_{p+1}, \dots, \beta_N$ and set

$$H_{p+1} = \begin{pmatrix} I_{p\times p} & 0 \\ 0 & \widetilde{H} \end{pmatrix} \tag{20}$$

to obtain an N-dimensional matrix. Then the matrix whose columns are $(AH_{p+1})_1^{p+1}$, $\dots, (AH_{p+1})_{p+1}^{p+1}$ has the determinant equal to

$$\det\left(A_1^{p+1}, \dots, A_p^{p+1}, \sum_{j=p+1}^{N} \beta_j A_j^{p+1}\right) = d_{p+1}\beta_{p+1} + \cdots + d_N\beta_N$$

and therefore has rank $p+1$ everywhere. $\square$

Here is one more technical lemma that we used in the proofs.

LEMMA 5.5. *Let the map*

$$\mathcal{F}_A : H_N^2 \to L_l^2(\mathbf{T}, \mathbf{R})$$

be defined by $\mathcal{F}_A(w) = 2\mathrm{Re}(Aw)$, where the $l\times N$ matrix $A \in C^\alpha$ has rank l everywhere on $\mathbf{T}$. Then we have

$$(\mathrm{range}\mathcal{F}_A)^\perp \subset C^\alpha(\mathbf{T}, \mathbf{R}). \tag{21}$$

Proof. First, we prove (21) for the case where $N = l$. We will use the following result.

THEOREM 5.6 (see [Ve]). *Suppose that A is a square $l \times l$ matrix-valued function on $\mathbf{T}$ with invertible values such that $A \in C^\alpha(\mathbf{T})$. Then there exists a holomorphic matrix-valued function $S \in C^\alpha(\mathbf{T})$ such that $S^{-1} \in H_{l\times l}^2$ and such that*

$$\overline{A}^{-1}A = \overline{S}^{-1}DS. \tag{22}$$

Here D is the diagonal matrix with entries $e^{ik_1\theta}, \dots, e^{ik_N\theta}$, where k_j are the integers.

Vekua proved a slightly stronger result in his book [Ve, section 13, p. 97] by constructing the fundamental matrix of solutions for the Hilbert problem. However, he did not state his result in the form above since the Gohberg–Krein factorization, in which form the result is presented here, was discovered much later. The reduction is easy and can be found in, for example, [G].

To prove (21), consider the real-linear map

$$\mathcal{G} : q \in L^2(\mathbf{T}, \mathbf{R}) \to q + i\mathcal{H}(q) = w \to \mathrm{Re}(Aw) \in L^2(\mathbf{T}, \mathbf{R}). \tag{23}$$

Here $\mathcal{H}$ is the Hilbert transform with any particular fixed choice of normalization.

Suppose that $u \in L^2$ belongs to $(\mathrm{range}\mathcal{F}_A)^\perp$. Then $u \in \ker\mathcal{G}^\perp$, where $\mathcal{G}^\perp$ is the operator adjoint to $\mathcal{G}$ in $L^2(\mathbf{T}, \mathbf{R})$, i.e.,

$$\mathcal{G}^\perp(u) = \mathrm{Re}A^t u + \mathcal{H}(\mathrm{Im}A^t u). \tag{24}$$

Note that range$\mathcal{G}$ may be smaller than range$\mathcal{F}_A$ because of the normalization of $\mathcal{H}$. Therefore, $u \in L^2(\mathbf{T}, \mathbf{R})$ satisfies the following equation:

$$\mathrm{Re}A^t u + \mathcal{H}(\mathrm{Im}A^t u) = 0. \tag{25}$$

Let us introduce the holomorphic function $\psi \in H^2_N$:

$$\psi := \mathrm{Im} A^t u + i\mathcal{H}(\mathrm{Im} A^t u). \tag{26}$$

Then (25) and (26) imply that

$$\mathrm{Re} A^t u = -\mathrm{Im}\psi, \qquad \mathrm{Im} A^t u = \mathrm{Re}\psi. \tag{27}$$

Therefore, we have

$$A^t u = \mathrm{Re} A^t u + i\mathrm{Im} A^t u = -\mathrm{Im}\psi + i\mathrm{Re}\psi = i\psi, \tag{28}$$

$$\overline{A}^t u = \mathrm{Re} A^t u - i\mathrm{Im} A^t u = -\mathrm{Im}\psi - i\mathrm{Re}\psi = -i\overline{\psi}, \tag{29}$$

which can be rewritten as

$$u = (A^t)^{-1} i\psi, \tag{30}$$

$$u = -(\overline{A}^t)^{-1} i\overline{\psi}, \tag{31}$$

which implies

$$(A^t)^{-1} i\psi = -(\overline{A}^t)^{-1} i\overline{\psi}. \tag{32}$$

Thus ψ is a solution of the following Riemann–Hilbert problem:

$$\mathrm{Re}((A^t)^{-1}\psi) = 0. \tag{33}$$

By the results of Vekua, $\psi \in C^\alpha(\mathbf{T})$. Then (30) implies that the same is true for u. Inclusion (21) is proved for $N = l$.

For the case where $N > l$, we multiply the $l \times N$ matrix A by the $N \times N$ holomorphic matrix H from Proposition 5.1. Then we consider the operator $\mathcal{F}_{A,l}$ defined by the first l columns of AH. Thus we have

$$(\mathrm{range}\mathcal{F}_A)^\perp \subset (\mathrm{range}\mathcal{F}_{A,l})^\perp \subset C^\alpha(\mathbf{T}, \mathbf{R}). \qquad \square$$

6. Connection with the analytic-disc technique used in the problem of extending Cauchy–Riemann functions.

We discuss some connections between the M-OPT problem and the analytic-disc techniques used for studying the theoretical several-complex-variables problem of extending a function defined on a manifold M in $\mathbf{C}^N$ to a function analytic in a neighborhood of a given point on M.

6.1. Attached analytic discs correspond to the flatness condition of M-OPT.

First, we give some definitions. A smooth manifold $M = \{z \in \mathbf{C}^N : \rho_1(z) = \cdots = \rho_l(z) = 1\}$ is called *generic* if its defining functions $\rho_1, \ldots, \rho_l$ satisfy $\partial\rho_1 \wedge \cdots \wedge \partial\rho_l \neq 0$, where $\partial\rho_j$ are defined as in (2). We say that a continuous function u on M is a *CR function* if it is annihilated by all tangential antiholomorphic vector fields:

$$\sum_j a_j \frac{\partial}{\partial \bar{z}_j} u = 0 \quad \text{if} \quad \sum_j a_j \frac{\partial}{\partial \bar{z}_j} \rho_k = 0 \quad \forall k.$$

We study the question of local extendibility of CR functions on M holomorphically to some neighborhood of a given point p on M. The basic theorem for the analytic-disc method is the approximation theorem by Baouendi and Treves.

Theorem 6.1 (see [BT]). *Suppose that M is a generic manifold, p is a point on M, and u is a CR function on $M \cap \Omega$, where Ω is a neighborhood of p. Then there exists $\Omega' \subset \Omega$, a smaller neighborhood of p, such that u is a* (*uniform on $M \cap \Omega'$*) *limit of holomorphic polynomials.*

It follows from the maximum-modulus theorem that if we can fill some neighborhood of p with the interiors of analytic discs f attached to M (i.e., the boundary $f(\partial\Delta) \subset M$), then the function u can be extended holomorphically to (a part of) that neighborhood.

The construction of analytic discs attached to a manifold was the main tool used by many authors to prove the extendibility results; see [Tu1], [Tu2], and [BRT] as well as [Bog] and the references therein.

The main result of this paper on flatness (Theorem 2.1(I)), when stated geometrically, is an assertion about attached analytic discs. Namely, the flatness condition proved in [HM1] means that the optimal analytic disc f^* is attached to a loop of hypersurfaces $M_\theta = \{\Gamma(e^{i\theta}, z) = c\}$ in $\mathbf{C}^N$. The flatness condition proved in this paper says that f^* is attached to a loop of generic manifolds in $\mathbf{C}^N$, namely $M_\theta = \{\Gamma_j(e^{i\theta}, z) = c_j,\ j = 1, \ldots, l\}$.

6.2. The notion of defect versus the gradient-alignment condition. Since CR functions analytically continue to the set that is the union of "small" analytic discs attached to M, it is clear that this set is important. With this in mind, we let $\mathcal{R}_M$ denote the subset of $\mathbf{C}^N$ which is swept out by analytic discs attached to M. Be aware that not every CR function on M extends to $\mathcal{R}_M$ since the "small"-disc requirement has been dropped. Basic information about extension is provided by the notion of defect.

Definition. *Given an analytic disc f attached to a manifold $M = \{z \in \mathbf{C}^N : \rho_1(z) = \cdots = \rho_l(z) = 0\}$, we define the defect* def$f$ *of the disc f as the real dimension of the space*

$$\left\{\lambda \in C_l^\alpha(\mathbf{T}, \mathbf{R}) : \lambda(e^{i\theta}) \frac{\partial\rho(f(e^{i\theta}))}{\partial z} \in H_N^2\right\}.$$

It can be shown (see, e.g., [BRT]) that for any p on M, there exists $\epsilon(p)$ such that if $\|f\|_{C^\alpha} < \epsilon(p)$ then the defect is an integer between 1 and l.

The notion of defect was introduced for small discs by Tumanov in [Tu1]. The definition that we give was first introduced in [BRT]. The advantage of the latter is that it makes sense for any disc (not just small discs).

It was proved by Tumanov that if for any $\epsilon > 0$ there exists an analytic disc $f \in H_N^\infty \cap C^{1,\alpha}$ of defect zero and such that $\|f(e^{i\theta}) - p\|_{C^{1,\alpha}} < \epsilon$, then the interiors of small analytic discs attached to M sweep out a wedge with edge M near p, and therefore any CR function on M extends to that wedge.

With a given disc f attached to M with $f(0) = q$, we associate an M-OPT problem:

Find $h \in H_N^\infty$, which is a Pareto optimum for l-performance functions $\Gamma_{q1}, \ldots, \Gamma_{ql}$ defined by

$$\Gamma_{qj}(e^{i\theta}, z) = \rho_j(e^{i\theta} z + q), \quad j = 1, \ldots, l. \tag{34}$$

Note that

$$\frac{\partial\Gamma_q(e^{i\theta}, h(e^{i\theta}))}{\partial z} = e^{i\theta} \frac{\partial\rho(f(e^{i\theta}))}{\partial z}.$$

Then the condition that f is of defect zero is equivalent to

$$\lambda(e^{i\theta})\frac{\partial\Gamma(e^{i\theta},f(e^{i\theta}))}{\partial z}\notin e^{i\theta}H^2_N \quad \forall\lambda\in C^\alpha_l(\mathbf{T},\mathbf{R}), \tag{35}$$

which means that Theorem 2.1(II) is violated.

In other words, if disc f is of defect zero, then it cannot be a Pareto optimum for $\Gamma_{q1},\dots,\Gamma_{ql}$, where $q=f(0)$.

We use this observation to prove the following proposition, which shows that we can fill out an open set in $\mathbf{C}^N$ with discs attached to a hypersurface and close to a disc f of defect zero. Similar results of Tumanov require f to be small.

PROPOSITION 6.2. *Suppose that the disc $f\in H^\infty_N\cap C^\alpha$ is attached to a smooth hypersurface $M=\{z\in\mathbf{C}^N:\rho(z)=1\}$. Suppose that the defect of f is equal to zero. Then the set $\{g(0):g\in H^\infty_N, g(\partial\Delta)\subset M\}$ contains a neighborhood of $f(0)$ in $\mathbf{C}^N$.*

Note that we use H^∞ discs rather than $H^\infty\cap C^\alpha$ discs to fill a neighborhood in $\mathbf{C}^N$.

A similar result for the special case where M is a generic manifold of real codimension N can be found in [G]. The theorem in [G] is stated in terms of factorization indices of the matrix $\frac{\partial\rho(f)}{\partial z}$, but it can be restated as above.

Proof of Proposition 6.2. We can assume that $\rho(f(0))>1$. Consider the performance function Γ given by (34). Then (35) implies that Theorem 2.1(II) is violated and the quantity

$$\gamma(q)=\inf_{h\in H^\infty}\sup_\theta\Gamma_q(e^{i\theta},h(e^{i\theta}))$$

is less than 1.

We need the following lemma.

LEMMA 6.3. *The function $q\to\gamma(q)$ is continuous on $\mathbf{C}^N$.*

Proof. For any given ϵ, take $\delta>0$ such that

$$\|h_1-h_2\|_\infty\le\delta \implies \left\|\rho(h_1(e^{i\theta}))-\rho(h_2(e^{i\theta}))\right\|_\infty\le\epsilon.$$

Then by the definition of $\gamma(q)$, the inequality $\|q-\widetilde{q}\|<\delta$ implies $\gamma(\widetilde{q})\ge\gamma(q)-\epsilon$. At the same time, it implies $\gamma(q)\ge\gamma(\widetilde{q})-\epsilon$. Therefore, $\|\gamma(\widetilde{q})-\gamma(q)\|\le\epsilon$. □

Note that the function $q\to f^*_q$, where f^*_q is the optimum for Γ_q, needs not be continuous.

Now we continue with the proof of Proposition 6.2. By Lemma 6.3, there exists U, an open neighborhood of q in $\mathbf{C}^N$, such that $\gamma(\widetilde{q})<1$ for all $\widetilde{q}\in U$. Take a point $\widetilde{q}\in U$. Let $g\in H^\infty_N$ be a solution to the OPT problem with $\Gamma_{\widetilde{q}}$. Then $\rho(e^{i\theta}g(e^{i\theta})+\widetilde{q})<1$ for every θ. Denote by Ω the connected component of the set

$$\{z\in\Delta:\rho(g(z))>1\}$$

containing zero. Construct Ω^*, the set containing Ω, according to the following procedure. Take a point $\xi\in\Delta\setminus\Omega$. If there exists a closed Jordan curve in Ω which encircles ξ, then we set $\xi\in\Omega^*$. If there is no such curve, we set $\xi\notin\Omega^*$. Then Ω^* is an open simply connected region such that $\partial\Omega^*\subset\partial\Omega$, and therefore $g|_{\partial\Omega^*}\equiv 0$.

Let $\Psi:\Omega\to\Delta$ be the Riemann map such that $\Psi(0)=0$. Then $g\circ\Psi^{-1}$ is the analytic disc which is attached to M and which passes through $\widetilde{q}$. □

6.3. Manifolds of analytic discs. Motivated by the successful application mentioned above, the set of analytic discs attached to a manifold was studied in general. It was shown in [BRT] that the set of analytic discs, infinitely close to a point, forms an infinite-dimensional manifold. Namely, it was shown that the derivative map

$$\mathcal{F} : H^\infty_N \cap C^\alpha \to C^\alpha(\mathbf{T}, \mathbf{R}), \qquad \mathcal{F}(w) = 2\mathrm{Re}\left(\frac{\partial \rho(f(e^{i\theta}))}{\partial z} w\right) \tag{36}$$

is onto $C^\alpha(\mathbf{T}, \mathbf{R})$ for f close to a constant disc. Then application of the local-submersion theorem shows that we have a manifold.

In [F], [T], and [O], the restriction on the size of the disc f was removed and it was shown that under certain conditions the map (36) is onto.

In the engineering setup, if the set of discs close to f^* forms a manifold, then f^* is not an optimum. More precisely, suppose we are given a disc f^* attached to a loop of manifolds $M_\theta = \{\Gamma(e^{i\theta}, z) = c\}$. Then if the map (36) is onto, then there exists a holomorphic direction h such that

$$2\mathrm{Re}\left(\frac{\partial \Gamma}{\partial z} h\right) < 0,$$

and therefore $\gamma(f^* + th) < \gamma(f^*)$ for small t, which means that f^* is not an optimum.

The following proposition shows how the defect is connected with the "manifold question" discussed above.

PROPOSITION 6.4 (see [BRT] and [T]). *Suppose that the disc $f \in H^\infty_N \cap C^\alpha$ is attached to a smooth manifold $M = \{z \in \mathbf{C}^N : \rho_1(z) = \cdots = \rho_l(z) = 0\}$. Let E be the set of discs passing through point $f(0)$, i.e., $E = \{g \in H^\infty_N \cap C^\alpha : g(0) = f(0)\}$. If the defect of f is equal to zero, then the derivative map*

$$\mathcal{F}_0 : T_f E \to C^\alpha(\mathbf{T}, \mathbf{R}), \qquad \mathcal{F}_0(h) = 2\mathrm{Re}\left(\frac{\partial \rho(f)}{\partial z} h\right)$$

is onto. Here $T_f E$ denotes the tangent space to E at f, i.e., $T_f E = \{h \in H^\infty_N \cap C^\alpha : h(0) = 0\}$.

The proof of Proposition 6.4 is a line-by-line repetition of the proof of Lemma 3.1.

One can easily verify that Proposition 6.4 implies that the set of discs attached to M and passing through $f(0)$ forms a Banach manifold near f.

Acknowledgment. The authors would like to thank M. S. Baouendi for showing us Trepreau's preprint [T] and for several useful discussions.

VOLUME-PRESERVING MEAN CURVATURE FLOW AS A LIMIT OF A NONLOCAL GINZBURG–LANDAU EQUATION[*]

LIA BRONSARD[†] and BARBARA STOTH[‡]

Abstract. We study the asymptotic behavior of radially symmetric solutions of the nonlocal equation

$$\varepsilon\varphi_t - \varepsilon\Delta\varphi + \frac{1}{\varepsilon}W'(\varphi) - \lambda_\varepsilon(t) = 0$$

in a bounded spherically symmetric domain $\Omega \subset \mathbf{R}^n$, where $\lambda_\varepsilon(t) = \frac{1}{\varepsilon}\fint_\Omega W'(\varphi)\,dx$, with a Neumann boundary condition. The analysis is based on "energy methods" combined with some a priori estimates, the latter being used to approximate the solution by the first two terms of an asymptotic expansion. We only need to assume that the initial data as well as their energy are bounded. We show that, in the limit as $\varepsilon \to 0$, the interfaces move by a nonlocal mean curvature flow, which preserves mass. As a by-product of our analysis, we obtain an L^2 estimate on the "Lagrange multiplier" $\lambda_\varepsilon(t)$, which holds in the nonradial case as well. In addition, we show rigorously (in general geometry) that the nonlocal Ginzburg–Landau equation and the Cahn–Hilliard equation occur as special degenerate limits of a viscous Cahn–Hilliard equation.

Key words. nonlocal mean curvature flow, nonlocal Allen–Cahn equation

AMS subject classifications. 35B25, 35K57

1. Introduction.

We consider the nonlocal reaction-diffusion equation recently introduced by Rubinstein and Sternberg [RS],

$$\begin{aligned} &\varepsilon\varphi_t - \varepsilon\triangle\varphi + \frac{1}{\varepsilon}W'(\varphi) - \lambda_\varepsilon(t) = 0, \\ &\qquad\qquad\qquad \lambda_\varepsilon(t) = \frac{1}{\varepsilon}\fint_\Omega W'(\varphi)\,dx \end{aligned} \tag{1.1}$$

in a bounded domain $\Omega \subset \mathbf{R}^n$, $n \geq 2$, with Neumann boundary condition

$$\left.\frac{\partial\varphi}{\partial n}\right|_{\partial\Omega\times[0,T]} = 0. \tag{1.2}$$

The potential W is a bistable potential, that is, $W \geq 0$ and it vanishes exactly at two points. The typical bistable potential is given by

$$W(\varphi) = \frac{1}{2}(1-\varphi^2)^2, \tag{1.3}$$

and we will present our results for this specific potential. However, we point out that our results can be extended to the more general case.

An important property of this flow is that its mass is preserved, that is,

$$\partial_t \int_\Omega \varphi(x,t)dx = 0. \tag{1.4}$$

Rubinstein and Sternberg [RS] introduced the nonlocal equation (1.1) as a simpler alternative to the classical Cahn–Hilliard equation [CH]

$$\varepsilon\varphi_t = \Delta\left(-\varepsilon\Delta\varphi + \frac{1}{\varepsilon}W'(\varphi)\right), \tag{1.5}$$

to model phase separation after quenching (rapid cooling) of homogeneous binary systems such as glasses and polymers. The function φ represents the difference in concentration of the two species of the binary mixture and hence is a conserved quantity. Using multiple-time-scale asymptotic expansions to study the behavior of the solution to (1.1)–(1.2), Rubinstein and Sternberg [RS] formally obtained that the domain Ω is divided in regions where φ is close to the local minima of W. Moreover, the interfaces $\{\Gamma_i\}$ dividing these regions evolve (in the limit $\varepsilon \to 0$) with normal velocity

$$V_i = \kappa_i - \sum \frac{1}{\sum |\Gamma_j|} \int_{\Gamma_j} \kappa_j,$$

where κ_i is the sum of principal curvatures of Γ_i and $|\Gamma_i|$ is its perimeter. This is a nonlocal volume-preserving mean curvature flow. We propose to use an energy-type method to rigorously justify this picture in a certain radially symmetric setting. More specifically, we assume that Ω is a ball in $\mathbf{R}^n$ and that φ is radial with several "transition" spheres. Equation (1.1) is already written in the time scale for which the above nonlocal mean curvature flow occurs in times of order 1. However, by rescaling, we see that this problem corresponds to the singular perturbation problem $\varphi_\tau - \varepsilon^2\Delta\varphi + W'(\varphi) - \varepsilon\lambda = 0$.

Next, we shall compare the two equations (1.1) and (1.5), as well as their respective asymptotic limiting flows. The Cahn–Hilliard equation is the gradient flow in the dual norm of some suitable subspace of $H^{1,2}(\Omega)$ (cf. [F]) for the functional

$$E_\varepsilon[\varphi] = \int_\Omega \frac{\varepsilon}{2}|\nabla\varphi|^2 + \frac{1}{\varepsilon}W(\varphi)\,dx, \tag{1.6}$$

while the nonlocal equation (1.1) is the gradient flow in $L^2(\Omega)$ for the same functional (1.6) against the mass constraint (1.4). The associated (time-independent) minimization problem, that is, the problem of minimizing (1.6) with a mass constraint, has been studied by Luckhaus and Modica [LM]. They rigorously obtained the first-order expansion in ε of the associated Lagrange multiplier. In this context, we can loosely interpret the nonlocal term $\lambda = \lambda_\varepsilon(t)$ in (1.1) as a Lagrange multiplier. In fact, because of the Neumann boundary condition (1.2), the expression for $\lambda_\varepsilon(t)$ is exactly what is needed for the gradient flow of $E_\varepsilon[\varphi]$ to conserve mass.

The asymptotic behavior of the solutions to (1.1) and (1.5) are very different. The formal analysis of Pego [P] suggests that the asymptotic behavior of (1.5) is given by the so-called Mullins–Sekerka problem [MS] (sometimes called the Hele–Shaw problem):

$$\Delta u = 0 \quad \text{in } \Omega\backslash\Gamma, \qquad u = -\kappa \quad \text{on } \Gamma, \qquad \left[\frac{\partial u}{\partial n}\right]_\Gamma = -V,$$

where Γ is the interface, κ is the sum of its principal curvatures, and V is its normal velocity. This has recently been proved by Stoth [S2] in the radial case in $\mathbf{R}^n$, $n \leq 3$. Alikakos, Bates, and Chen [ABC] have a convergence result in general domains, assuming that the limit flow is smooth and with particular initial and boundary conditions.

Both limiting flows are nonlocal and some existence results are known for each of them. Indeed, Gage [Ga] (for curves) and Huisken [H] have proved that a convex manifold evolving by volume-constrained mean curvature flow eventually becomes a sphere with the prescribed area. Also, there are simple examples which show that nonconvex curves may develop singularities in finite time (see, e.g., [RS]). For the Mullins–Sekerka problem, Chen [C] has proved a weak, local-in-time existence result for general smooth initial curves and a global existence result for curves which are small perturbations of a circle.

The most striking difference between the two limiting geometric flows is the effect of small spheres. Indeed, in the radial case, we can easily calculate the respective evolution laws for the interfaces explicitly. In the three-dimensional case, assuming that there are two interfaces $r_2(t) < r_1(t)$, the nonlocal problem is given by (cf. (6.25))

$$\dot{r}_1 = 2\left(-\frac{1}{r_1} + \frac{r_1 - r_2}{r_1^2 + r_2^2}\right), \qquad \dot{r}_2 = 2\left(-\frac{1}{r_2} - \frac{r_1 - r_2}{r_1^2 + r_2^2}\right), \tag{1.7}$$

while the Mullins–Sekerka problem is given by

$$\dot{r}_1 r_1^2 = \dot{r}_2 r_2^2, \qquad \dot{r}_1 = \frac{-2}{r_1^2}\frac{r_1 + r_2}{r_1 - r_2}. \tag{1.8}$$

Therefore, as r_2 approaches 0, it is clear that $\dot{r}_1$ approaches 0 in (1.7), while it approaches $\frac{-2}{r_1^2}$ in (1.8). However, once the smallest sphere has disappeared, $\dot{r}_1$ must be 0 since mass must be preserved. This means that the flow for r_1 in the Mullins–Sekerka model is strongly affected by asymptotically small spheres. In fact, Rubinstein and Sternberg [RS] used a multiple scattering expansion known as the point-interaction approximation method to suggest that the Mullins–Sekerka problem is not the appropriate approximation of the Cahn–Hilliard equation when there are asymptotically small spheres.

There is an interesting connection between equations (1.1) and (1.5). Indeed, Rubinstein and Sternberg [RS] observed that equations (1.1) and (1.5) arise by formally taking different parameter limits ($\alpha \to 0$ and $\nu \to 0$, respectively) in the viscous Cahn–Hilliard equation $\alpha\varphi_t = \Delta(W'(\varphi) - \beta\Delta\varphi + \nu\varphi_t)$. This equation was introduced by Novick-Cohen [NC] in order to include viscous effects in the Cahn–Hilliard model. We prove these convergence results rigorously in section 7. This suggests that by taking an appropriate choice of the parameter limit in the viscous Cahn–Hilliard equation, one should recover a different limit flow with possibly better properties.

We note that the singular limit of (1.1) provides a notion of a weak solution for the nonlocal mean curvature flow. However, there is no uniqueness theorem in general: different sequences of ε's might produce different limits. The same approach has been used to define a model for mean curvature flow (cf. [BK2], [DS1], and [DS2]) using the Allen–Cahn equation [AC]. In that case, Evans, Soner, and Souganidis [ESS] have shown that this model coincides with the notion of motion by mean curvature flow in the sense of viscosity solutions (cf. [CGG] and [ES]).

We prove the convergence of the nonlocal equation (1.1) to volume-preserving mean curvature flow in a radially symmetric setting. We assume that for $\varphi = \varphi_\varepsilon$,

$$\begin{aligned} \|\varphi(\cdot, 0)\|_\infty &\leq C_0, \\ E_\varepsilon[\varphi](0) &\leq C_0, \\ \left| \int_\Omega \varphi(x, 0)\, dx \right| &< |\Omega| - \omega \end{aligned} \tag{1.9}$$

for some positive constants C_0 and ω. The second assumption means that the initial data must have a "transition-layer structure," i.e., $\varphi_\varepsilon \approx \pm 1$. The third condition ensures that there exists at least one interface. The case of general initial data is much harder; we refer to Soner [So] for the equivalent problem for the Allen–Cahn equation. Our method is an energy-type method similar to the methods developed by Bronsard and Kohn [BK1], [BK2] in order to study the singular limit of the Allen–Cahn equation and the methods developed by Stoth [S1], [S2] in order to study the singular limit of the phase-field model and the Cahn–Hilliard equation. The new feature here is the nonlocal nature of the equation, which does not allow for a comparison principle, and there does not seem to be a monotonicity formula.

We now describe the method in more detail. We first use BV bounds (Proposition 2.1) to obtain the existence of an L^1 limit v for a subsequence of φ_ε (Remark 2.4), and then we restrict our discussion to this subsequence. In addition, we show a uniform L^2 estimate on the Lagrange multiplier (Proposition 2.3), which implies the existence of a weak limit λ_0 for an appropriate subsequence. Next, we establish a monotone L^1 limit E_0 for $E_\varepsilon[\varphi_\varepsilon]$ (Corollary 2.5) which is used to define time intervals on which the variation of $E_\varepsilon[\varphi_\varepsilon]$ is uniformly small (Lemma 2.6). These results are not restricted to the radially symmetric case.

The next step is the foundation of our approach. We show that away from the origin and except at finitely many time points, φ_ε is close to the stationary-wave solution associated with the equation $\partial_t u - \triangle u + W'(u) = 0$. In the typical case where W is given by (1.3), the stationary-wave solution is tanh. More precisely, we obtain a locally uniform-in-time bound on $|| - \varepsilon^2 |\varphi_\varepsilon'|^2 + 2W(\varphi_\varepsilon)||_{L^\infty(R_0, 1)}$ which is valid except at finitely many time points (Proposition 3.2). Since $W(\varphi_\varepsilon)$ is bounded away from 0 in the transition region of φ_ε, this means that $|\varphi_\varepsilon'|$ is strictly bounded away from 0 in that region. Therefore, using the implicit function theorem, the level sets of φ_ε are given by Hölder-$\frac{1}{2}$ graphs $r = r_\varepsilon^i(t)$ (see (4.4)) that converge to some limits $r = \bar{r}^i(t)$ (see (4.5)). The task is to find the evolution equation satisfied by $r = \bar{r}^i(t)$.

We present the idea of the method for the ith interface $\bar{r} = \bar{r}^i$ and its approximation $r_\varepsilon = r_\varepsilon^i$. Let $z = \frac{r - r_\varepsilon}{\varepsilon}$ be a rescaling and $\Phi(z, t) = \varphi(r, t)$. The equation for Φ becomes

$$\varepsilon \partial_t \Phi - \dot{r}_\varepsilon \Phi' - \frac{1}{\varepsilon} \Phi'' - \frac{n-1}{\varepsilon z + r_\varepsilon} \Phi' + \frac{1}{\varepsilon} W'(\Phi) - \lambda_\varepsilon = 0.$$

We multiply it by $\Phi' \zeta$, where ζ is a smooth time-dependent test function, and in order to localize around r_ε, we integrate over $(-\frac{1}{\sqrt{\varepsilon}}, \frac{1}{\sqrt{\varepsilon}})$ and over (t_1, t_2). This gives

$$\begin{aligned} &\iint \zeta \left[\varepsilon \Phi_t \Phi' - \dot{r}_\varepsilon (\Phi')^2 - \frac{n-1}{\varepsilon z + r_\varepsilon} (\Phi')^2 - \lambda_\varepsilon \Phi' \right] dz\, dt \\ &\quad = \int \zeta \frac{1}{\varepsilon} \left[\frac{1}{2} (\Phi')^2 - W(\Phi) \right]_{-\frac{1}{\sqrt{\varepsilon}}}^{\frac{1}{\sqrt{\varepsilon}}} dt. \end{aligned}$$

Now if $\Phi(z)$ were the expected stationary-wave solution $\pm\tanh(z) =: \Phi_0(z)$, this would lead to the following equation for the limit $\bar{r}$:

$$-c_0 \int \zeta \left[\dot{\bar{r}} + \frac{(n-1)}{\bar{r}}\right] dt = 2 \int \zeta \nu(\bar{r}) \lambda_0 \; dt,$$

where $c_0 = \int_{-1}^{1} \sqrt{2W(\varphi)}\, d\varphi$ is the constant surface tension and ν is the direction of the jump. Thus all interfaces $\bar{r}^i$ evolve according to $-c_0(\dot{\bar{r}}^i + \frac{n-1}{\bar{r}^i}) = 2\nu^i \lambda_0$ (Proposition 6.3). However, using the mass-conservation property, we can calculate λ_0 explicitly in terms of $\bar{r}^i$ (Proposition 6.5), thereby deducing the equation for the limiting interface.

This formal derivation was done assuming that $\Phi = \Phi_0$ around each interface. Section 5 is devoted to establishing $H^{1,2}$ and $H^{1,\infty}$ bounds on the difference between Φ and Φ_0 (Corollary 5.9). We need a bound of order $\varepsilon^{\frac{1}{2}+s}$ for some positive s in order to replace Φ by Φ_0 in the above equation. As expected for this type of problem, this means that we have to prove these estimates for a higher-order expansion. It turns out that in our case a second-order expansion is sufficient (Proposition 5.5). The main observation used in the proof is that the linearization of the nonlinear operator around the stationary wave defines a strictly elliptic operator (see Berger and Fraenkel [BF] and Proposition 5.6).

We put everything together in section 6, where we rigorously derive the equation for the limiting interfaces. There are several difficulties to overcome. The most serious one is that we cannot exclude a priori the possibility that several ε-interfaces r_ε^i converge to the same limiting interface as $\varepsilon \to 0$, thereby giving rise to "multiplicities" higher than 1. There are two cases to distinguish. Either an odd number of ε-interfaces form a single limit interface, and this corresponds to a "true" interface, i.e., a jump of the limit v and $\nu = \pm 1$, or an even number of ε-interfaces form a single limit interface, and this corresponds to a "phantom" interface, i.e., $\nu = 0$. The latter correspond to interfaces separating the same phase. We prove that true interfaces evolve by the nonlocal flow and that their multiplicity is 1. Furthermore, we show that phantom interfaces evolve by mean curvature flow, but we do not characterize their multiplicity (Theorem 6.6). We point out that we do not establish the existence of phantom interfaces but only derive their law of motion. For the radial Allen–Cahn equation, it is possible to construct initial data that produce phantom interfaces in the limit (cf. [BS]), whereas for the Cahn–Hilliard equation, no phantom interfaces occur (cf. [S2]). Making use of the properties of nonlocal flow, we also show that all interfaces decrease and that at most two true interfaces can meet or nucleate at a given time point (Theorem 6.6). In fact, there are examples where two interfaces collide and disappear in the interior of the domain (Example 6.8). It is not clear whether they continue as a phantom interface or completely disappear. Their presence does not have an impact on the limit flow, but it accounts for an energy loss in the limit (Remark 6.9).

In the case where $n = 2$, we note that as long as there are an even number of interfaces, the nonlocal flow is simply mean curvature flow. In other words, the mean curvature flow preserves area in that case.

Our estimates of section 5 are strong enough to prove a formula for the limit energy E_0 that counts both true and phantom interfaces together with their multiplicities. From this it follows that there cannot be any nucleation in the interior if there is no nucleation at the origin. However, we cannot rule this out after the first geometric singularity of the nonlocal flow (see Remark 6.9).

Finally, we note that when $n = 1$, the evolution of the interfaces is expected to be exponentially slow in ε. This can easily be proven using the energy method of [BK1] combined with the result of Grant [G]. This exponentially slow motion has already been rigorously proven for the Cahn–Hilliard equation (cf. [ABF], [BH], [G], and [BX]).

2. Energy estimates. In this section, we derive all of the energy estimates necessary for the subsequent sections. We assume that φ_ε is a solution to (1.1) with the boundary data (1.2), that the domain $\Omega \subset \mathbf{R}^n$ is bounded with a Lipschitz boundary, and that for some $C_0 > 0$ and some $\omega > 0$ independent of ε,

$$E_\varepsilon[\varphi_\varepsilon(\cdot, 0)] \le C_0, \tag{2.1}$$

$$\sup_{x\in\overline{\Omega}} |\varphi_\varepsilon(x,0)| \le C_0 \quad \text{and} \quad |\Omega| - \left| \int_\Omega \varphi_\varepsilon(x,0)\, dx \right| \ge \omega. \tag{2.2}$$

Throughout this paper, C will denote positive constants, that depend only on the space dimension n, the size $|\Omega|$, and the final time T as well as on C_0 and ω. We show that the energy

$$E_\varepsilon[\varphi] = \int_\Omega \frac{\varepsilon}{2}|\nabla\varphi|^2 + \frac{1}{\varepsilon}W(\varphi)\, dx$$

is a Lyapunov functional for (1.1)–(1.2), and we use this fact to obtain appropriate BV bounds as well as some “weak” Hölder estimates on φ_ε. Next, we derive an L^2 bound of the Lagrange multiplier. We then produce an L^1 limit of the solution φ_ε and a weak L^2 limit of the Lagrange multiplier λ_ε. In addition, we use the fact that $E_\varepsilon[\varphi]$ is a monotone function to show that it is weakly compact in $\mathrm{BV}(0,T)$ and compact in $L^1(0,T)$. Finally, we use the monotonicity of the energy to construct positive time intervals, where the variation of the energy is uniformly small in ε.

Proposition 2.1 (energy estimates). *Let $\varphi := \varphi_\varepsilon$ be a solution to* (1.1) *with boundary condition* (1.2) *and suppose that the initial data satisfy* (2.1). *Let g be defined via $g'(s) := \sqrt{2W(s)}$ with $g(0) := 0$, and let $0 \le s < \tau \le T$. Then the following statements hold:*

$$\varepsilon \int_s^\tau \int_\Omega |\partial_t\varphi|^2\, dx\, dt + E_\varepsilon[\varphi](\tau) - E_\varepsilon[\varphi](s) = 0, \tag{2.3}$$

$$\sup_{t\in[0,T]} \int_\Omega |\nabla g(\varphi)|\, dx \le \sup_{t\in[0,T]} E_\varepsilon[\varphi](t) \le C \quad \text{(energy bound)}, \tag{2.4}$$

$$\int_s^\tau \int_\Omega |\partial_t g(\varphi)|\, dx\, dt \le C\sqrt{\tau - s}. \tag{2.5}$$

Proof. First, multiplying equation (1.1) by $\partial_t\varphi$ and integrating in x, it follows that

$$\varepsilon \int_\Omega |\partial_t\varphi|^2\, dx - \varepsilon\int_\Omega \partial_t\varphi\Delta\varphi\, dx + \frac{1}{\varepsilon}\int_\Omega \partial_t W(\varphi)\, dx - \lambda_\varepsilon(t)\int_\Omega \partial_t\varphi\, dx = 0.$$

Using the mass-conservation property (1.5) and integrating by parts, this reduces to

$$\varepsilon\int_\Omega |\partial_t\varphi|^2\, dx + \int_\Omega \partial_t\left[\frac{\varepsilon}{2}|\nabla\varphi|^2 + \frac{1}{\varepsilon}W(\varphi)\right]\, dx = 0.$$

Equation (2.3) follows from the definition of E_ε in (1.6) and integration in time from s to τ.

Next, we obtain the BV estimates (2.4) and (2.5). These estimates are not new (see, for example, [M] and [BK1] or [BK2]), but we include them for the sake of completeness. Using the definition of g, we have (cf. [M])

$$\int_\Omega |\nabla g(\varphi)|\,dx = \int_\Omega \sqrt{2W(\varphi)}|\nabla\varphi|\,dx \le E_\varepsilon[\varphi](t).$$

Inequality (2.4) now follows from (2.3) and the initial bound on the energy (2.1). Moreover, we obtain the "weak" Hölder estimate (cf. [BK2])

$$\begin{aligned}\int_s^\tau\int_\Omega |\partial_t g(\varphi)|\,dx\,dt &\le \left(\int_s^\tau\int_\Omega \frac{1}{\varepsilon}W(\varphi)\,dx\,dt\right)^{\frac12}\left(\int_s^\tau\int_\Omega \varepsilon|\partial_t\varphi|^2\,dx\,dt\right)^{\frac12}\\ &\le C\sqrt{\tau-s}.\end{aligned}$$

This completes the proof of Proposition 2.1. □

In particular, it follows that the functional E_ε is a Lyapunov functional for (1.1)–(1.2). From this fact follows the existence of a limit for φ_ε and an a priori bound on the Lagrange multiplier $\lambda_\varepsilon(t)\ \fint_\Omega W'(\varphi)\,dx$.

COROLLARY 2.2. *Under the same hypothesis as in Proposition* 2.1*, the following results hold:*

(2.6) $$\varphi \in L^\infty(0,T,L^4(\Omega)),$$

(2.7) $$\sup_t \lambda_\varepsilon(t) \le \frac{C}{\sqrt{\varepsilon}},$$

(2.8) $$\sup_{t,x}|\varphi(t,x)| \le C\sqrt{\varepsilon} + \sup_x|\varphi(x,0)| + 1.$$

Proof. Statement (2.6) is a direct consequence of Proposition 2.1. Inequality (2.7) follows from (2.6) since

$$\sup_t \lambda_\varepsilon = \sup_t \frac{1}{\varepsilon}\fint_\Omega 2(\varphi^3-\varphi)\,dx \le \sup_t \frac{C}{\varepsilon}\left(\int_\Omega \varphi^2\,dx\right)^{\frac12}\left(\int_\Omega W(\varphi)\,dx\right)^{\frac12} \le \frac{C}{\sqrt{\varepsilon}}.$$

Estimate (2.8) is a consequence of the maximum principle and (2.7). □

PROPOSITION 2.3 (estimate on the Lagrange multiplier). *Let* $\varphi = \varphi_\varepsilon$ *be as in Proposition* 2.1 *and assume in addition that* φ_ε *satisfies* (2.2)*. Then for* λ_ε *as in* (1.1),

$$\int_0^T |\lambda_\varepsilon(t)|^2\,dt \ \le\ C.$$

Proof. We multiply the differential equation (1.1) by $\nabla\varphi\cdot\zeta$, where ζ is a smooth function with values in $\mathbf{R}^n$. If $\zeta\cdot n = 0$ on $\partial\Omega$, we find that

$$\begin{aligned}\varepsilon\int_\Omega \partial_t\varphi\,\zeta\cdot\nabla\varphi\,dx + \varepsilon\int_\Omega \partial_j\varphi\partial_i\zeta_j\partial_i\varphi\,dx - \int_\Omega\left(\frac{\varepsilon}{2}|\nabla\varphi|^2+\frac{1}{\varepsilon}W(\varphi)\right)\mathrm{div}\zeta\,dx\\ = -\lambda_\varepsilon\int_\Omega \varphi\mathrm{div}\zeta\,dx.\end{aligned}$$

We extend φ by reflection to some neighborhood of Ω, and we choose a smooth Dirac sequence ψ_δ. We define $\xi = \xi_\varepsilon^\delta$ to be the solution of

$$\begin{cases} -\Delta\xi &= \varphi(t,\cdot) * \psi_\delta - \fint_\Omega \varphi(t,\cdot) * \psi_\delta \quad \text{in } \Omega, \\ -\dfrac{\partial \xi}{\partial n} &= 0 \quad \text{on } \partial\Omega, \\ \fint_\Omega \xi &= 0. \end{cases}$$

Elliptic regularity theory and (2.8) give

$$||\xi||_{C^{2,\alpha}(\overline{\Omega})} \le ||\varphi(t,\cdot) * \psi_\delta - \fint_\Omega \varphi(t,\cdot) * \psi_\delta||_{C^{0,\alpha}(\overline{\Omega})} \le C(\delta)||\varphi(\cdot,t)||_{L^\infty(\Omega)} \le C(\delta).$$

We now set $\zeta := \nabla\xi$. The energy bound (2.4) and the L^∞ bound (2.8) then imply

$$|\lambda_\varepsilon(t)| \left| \int_\Omega \varphi(\varphi * \psi_\delta - \fint_\Omega \varphi * \psi_\delta)\, dx \right| (t) \le C \left(\varepsilon \int_\Omega |\partial_t \varphi|^2\, dx \right)^{\frac{1}{2}} (t) + C(\delta).$$

However, using the conservation-of-mass property (1.4) and the energy bound (2.4), we obtain

$$\begin{aligned} &\left| \int_\Omega \varphi\Big(\varphi * \psi_\delta - \fint_\Omega \varphi * \psi_\delta\Big)\, dx \right| (t) \\ &\quad = |\Omega| + \int_\Omega (\varphi^2(x,t) - 1)\, dx - \int_\Omega (\varphi - \varphi * \psi_\delta)\varphi(x,t)\, dx \\ &\qquad - \frac{(\int_\Omega \varphi(x,t)\, dx)^2}{|\Omega|} + \frac{\int_\Omega \varphi(x,t)\, dx}{|\Omega|} \int_\Omega (\varphi - \varphi * \psi_\delta)(x,t)\, dx \\ &\quad \ge \frac{1}{|\Omega|}\left(|\Omega|^2 - \Big(\int_\Omega \varphi(x,0)\, dx \Big)^2 \right) - C\Big(\int_\Omega W(\varphi)(x,t)\, dx \Big)^{\frac{1}{2}} \\ &\qquad - C\int_\Omega |\varphi - \varphi * \psi_\delta|(x,t)\, dx \\ &\quad \ge 2\omega - C\sqrt{\varepsilon} - C \sup_{|h|\le\delta} \int_\Omega |\varphi(x+h,t) - \varphi(x,t)|\, dx. \end{aligned}$$

We now use the following result from [S2]: the energy bound (2.4) implies that $\sup_{|h|\le\delta} \int_\Omega |\varphi(x+h,t) - \varphi(x,t)|\, dx \le C\sqrt{\delta}$. Thus we eventually obtain

$$(2\omega - C\sqrt{\delta} - C\sqrt{\varepsilon})|\lambda_\varepsilon(t)| \le C \left(\varepsilon \int_\Omega |\partial_t \varphi|^2\, dx \right)^{\frac{1}{2}} (t) + C(\delta).$$

Taking the square of this expression, integration in time and (2.3) then yield the desired assertion. □

Remark 2.4. The energy estimates imply weak compactness for the sequence $g(\varphi_\varepsilon)$ in $BV(\Omega \times (0,T))$, so we can choose a subsequence $g(\varphi_\varepsilon) \xrightarrow[\varepsilon\to 0]{*} g(v)$ in BV. This in turn implies that for some subsequence $\varphi_\varepsilon \to v$ in $L^1(\Omega \times (0,T))$, since g^{-1} exists and $\varphi_\varepsilon \in L^\infty(0,T;L^4(\Omega))$. In addition, $v = \pm 1$ almost everywhere and it is "weakly" Hölder continuous

$$\int_\Omega |v(x,\tau) - v(x,s)|\, dx \le C\sqrt{\tau - s} \quad \text{for } T \ge \tau \ge s \ge 0.$$

This Hölder continuity of v in L^1 is due to Bronsard and Kohn [BK2]. Here it is a consequence of (2.5) since this estimate carries over to the limit by lower semicontinuity. In addition, we will assume that the initial data $\varphi_\varepsilon(\cdot, 0)$ converge in $L^1(\Omega)$ to $v(\cdot, 0)$.

Next, due to the bound on the Lagrange multiplier, we may select a further subsequence such that λ_ε converges to λ_0 weakly in $L^2(0, T)$.

Henceforth, we will consider only this subsequence, and we will still denote it by $\varphi_\varepsilon, \lambda_\varepsilon$. In what follows, we will select still other subsequences of this one, but this does not have an impact on v and λ_0.

Another important consequence of Proposition 2.1 is that $E_\varepsilon[\varphi](\cdot)$ is monotone decreasing in t and hence weakly compact in $BV(0, T)$.

COROLLARY 2.5. *Let φ_ε be as in Proposition* 2.1. *Then $E_\varepsilon[\varphi_\varepsilon](\cdot)$ is weakly compact in $BV(0,T)$. Therefore, for an appropriate subsequence of ε's, there exists a function $E_0(\cdot)$ such that*

$$\begin{aligned} &E_\varepsilon[\varphi_\varepsilon](\cdot) \longrightarrow E_0(\cdot) \quad \textit{in } L^1(0,T) \textit{ and almost everywhere,} \\ \partial_t &E_\varepsilon[\varphi_\varepsilon](\cdot) \xrightarrow{*} \partial_t E_0(\cdot), \end{aligned} \tag{2.9}$$

where the weak $*$ convergence is in $[C^0(0,T)]'$.

Proof. By (2.4), $E_\varepsilon[\varphi_\varepsilon]$ is clearly uniformly bounded in $L^1(0, T)$. Moreover, identity (2.3) implies that $E_\varepsilon[\varphi_\varepsilon]$ is monotone decreasing and thus uniformly bounded in $BV(0, T)$ by assumption (2.1) on the initial data. Thus we may select a subsequence of ε's as claimed. □

The results of Modica [M], Modica and Mortola [MM], and Sternberg [S] show that E_ε Γ-converges to a functional E_*, which is defined on BV functions by

$$E_*[v] = c_0 \int_\Omega |\nabla v| \, dx, \tag{2.10}$$

where $c_0 := \int_{-1}^{1} \sqrt{2W(\varphi)} \, d\varphi$. In particular, it is easy to see that for almost all t

$$\liminf_{\varepsilon \to 0} E_\varepsilon[\varphi_\varepsilon](t) \geq E_*[v](t). \tag{2.11}$$

From Corollary 2.5, we cannot conclude that E_0 is $E_*[v]$, but we know that for almost all t, we have $E_0(t) \geq E_*[v](t)$.

In Corollary 2.5, we have shown that for almost all t,

$$E_\varepsilon[\varphi_\varepsilon](t) \to E_0(t).$$

We define for any $\eta > 0$ a set $N(\eta) \subset [0, T]$ as the set of all jump points of E_0 with height at least η:

$$N(\eta) := \left\{ t \mid \operatorname*{ess\,inf}_{s<t} E_0(s) - \operatorname*{ess\,sup}_{s>t} E_0(s) \geq \eta \right\}. \tag{2.12}$$

Then for any $\eta > 0$, the set $N(\eta)$ is finite since E_0 is monotone decreasing in an L^1 sense:

$$E_0(t) \geq E_0(s) \quad \text{for almost every } s \geq t. \tag{2.13}$$

In fact, since $E_\varepsilon[\varphi_\varepsilon](t) \leq C$ by (2.4), it follows that

$$\# N(\eta) \leq \frac{C}{\eta}. \tag{2.14}$$

For $t_0 > 0$, we define $T_\varepsilon(\eta, t_0) > 0$ by

$$\varepsilon \int_{(t_0 - T_\varepsilon(\eta,t_0))^+}^{t_0+T_\varepsilon(\eta,t_0)} \int_\Omega (\partial_t \varphi_\varepsilon)^2 \, dx \, dt = \eta. \tag{2.15}$$

The following lemma is very important to our approach. It is based on the fact that E_0 is monotone decreasing. It basically says that given any $t_0 \notin N(\eta)$, we can find an open interval $(t_0 - T_0(\eta, t_0), t_0 + T_0(\eta, t_0))$ on which the variation of the energy $E_\varepsilon[\varphi_\varepsilon](\cdot)$ is uniformly small in ε.

LEMMA 2.6. *Let $\varphi = \varphi_\varepsilon$ be as in Proposition* 2.1. *Let $0 < t_0 \notin N(\eta)$, where $N(\eta)$ is given by* (2.12), *and let $T_\varepsilon(\eta, t_0)$ be as in* (2.15). *Then there exists $T_0(\eta, t_0) > 0$ such that*

$$T_\varepsilon(\eta, t_0) > T_0(\eta, t_0), \qquad \textit{for } \varepsilon \le \varepsilon_0(\eta, t_0).$$

In particular,

$$E_\varepsilon[\varphi_\varepsilon](t_0 - T_0)^+ - E_\varepsilon[\varphi_\varepsilon](t_0 + T_0) \le \eta.$$

Proof. Suppose to the contrary that $T_\varepsilon \to 0$ for some subsequence. Then using (2.3) and the monotonicity of $E_\varepsilon[\varphi_\varepsilon]$, we have for almost any $\tau > 0$ that

$$\begin{aligned} 0 < \eta &= \lim_{\varepsilon \to 0} \varepsilon \int_{t_0 - T_\varepsilon(\eta,t_0)}^{t_0+T_\varepsilon(\eta,t_0)} \int_\Omega (\partial_t \varphi)^2 \, dx \, dt \\ &= \lim_{\varepsilon \to 0} (E_\varepsilon[\varphi](t_0 - T_\varepsilon(\eta, t_0)) - E_\varepsilon[\varphi](t_0 + T_\varepsilon(\eta, t_0))) \\ &\le \lim_{\varepsilon \to 0} (E_\varepsilon[\varphi](t_0 - \tau) - E_\varepsilon[\varphi](t_0 + \tau)) \\ &= E_0(t_0 - \tau) - E_0(t_0 + \tau). \end{aligned}$$

Thus by the choice of t_0,

$$0 < \eta \le \operatorname{ess\,inf}_{s<t_0} E_0(s) - \operatorname{ess\,sup}_{s>t_0} E_0(s) < \eta. \qquad \square$$

3. A first approximation. The subsequent sections will be restricted to radially symmetric solutions; without loss of generality, we will assume that Ω is the unit disk in $\mathbf{R}^n$, $n \ge 2$.

In radial coordinates $r = |x|$, the evolution for $\varphi = \varphi_\varepsilon(r, t)$ becomes

$$\begin{aligned} \varepsilon \partial_t \varphi - \varepsilon \varphi_{rr} - \frac{\varepsilon(n-1)}{r} \varphi_r + \frac{1}{\varepsilon} W'(\varphi) - \lambda_\varepsilon(t) = 0, \\ \varphi(r, 0) = \varphi_\varepsilon^0(r), \end{aligned} \tag{3.1}$$

where as explained in the introduction, we choose $W(\varphi) = \frac{1}{2}(1 - \varphi^2)^2$. Moreover, since we consider the case of a Neumann boundary condition and since φ is smooth,

$$\varphi'(1, t) = 0 \quad \text{and} \quad \varphi'(0, t) = 0. \tag{3.2}$$

Thus mass is preserved. We assume the following conditions on the initial data. There exist some $C_0 > 0$ and some $\omega > 0$ such that for all ε,

$$\|\varphi_\varepsilon^0\|_{L^\infty(0,1)} \le C_0, \tag{3.3}$$

$$E_\varepsilon[\varphi_\varepsilon^0] \le C_0, \tag{3.4}$$

and

$$\left| \int_\Omega \varphi_\varepsilon^0 \, dx \right| < |\Omega| - \omega. \tag{3.5}$$

The following proposition is essential to the approach used in this paper. It is used to show that, away from the origin, the solution φ_ε is a priori close to the function $\pm q(\frac{\xi}{\varepsilon})$, where q solves

$$q_{\xi\xi} = W'(q) \quad \text{ with } \; q(-\infty) = -1, \quad q(\infty) = 1, \quad q(0) = 0.$$

In other words, the solution φ_ε is close to the one-dimensional stationary-wave solution $\pm q(\xi)$ associated with the equation $u_t = u_{\xi\xi} - W'(u)$, as is predicted by the formal asymptotic expansions of Rubinstein and Sternberg (cf. [RS]). For the existence and properties of the stationary-wave solution q, we refer to Aronson and Weinberger [AW] and Fife and McLeod [FM]. When $W(\varphi) = \frac{1}{2}(1-\varphi^2)^2$, this stationary wave is given by $q(\xi) = \tanh(\xi)$.

PROPOSITION 3.1. *Let $\varphi = \varphi_\varepsilon$ and φ_ε^0 satisfy* (3.1)–(3.5). *Let* $0 < R_0 < 1$ *and* $t_1 > t_2$. *Then for any* $t_2 < t < t_1$,

$$\left\| -\frac{\varepsilon^2}{2} |\varphi'|^2 + W(\varphi) \right\|_{L^\infty(R_0,1)} (t)$$
$$\le C(R_0) \left(\sqrt{\varepsilon} + \left(\varepsilon \int_{t_2}^{t_1} \int_\Omega \varphi_t^2 \, dx \, dt \right)^{\frac{1}{2}} + \left(\varepsilon^3 \int_\Omega \varphi_t^2(x, t_2) \, dx \right)^{\frac{1}{2}} \right).$$

Proof. First, we note that $||\varphi||_{L^\infty(\Omega\times(0,T))} \le C$ by assumption (3.3) and Corollary 2.2. Therefore, multiplying (3.1) by $\varepsilon\varphi'$, integrating over $(\eta, \rho) \subset (R_0, 1)$, using the fact that the energy is bounded (cf. (2.4)), and using the bound on $\lambda_\varepsilon(\cdot)$ (cf. (2.8)), it follows that

$$\begin{aligned} (3.6) \qquad & \left| -\frac{\varepsilon^2}{2} |\varphi'(\rho,t)|^2 + W(\varphi(\rho,t)) \right| \\ &= \Bigg| -\frac{\varepsilon^2}{2} |\varphi'(\eta,t)|^2 + W(\varphi(\eta,t)) - \varepsilon^2 \int_\eta^\rho \varphi_t \varphi' \, dr \\ &\quad + 2\varepsilon^2 \int_\eta^\rho \frac{1}{r} |\varphi'|^2 \, dr + \varepsilon\lambda_\varepsilon(t)(\varphi(\rho,t) - \varphi(\eta,t)) \Bigg| \\ &\le \frac{\varepsilon^2}{2} |\varphi'(\eta,t)|^2 + W(\varphi(\eta,t)) + 2\varepsilon|\lambda_\varepsilon(t)| \, ||\varphi||_{L^\infty(\Omega\times(0,T))} \\ &\quad + \frac{\varepsilon^2}{R_0^{n-1}} \left(\int_\eta^\rho (\varphi_t)^{n-1} r^{n-1} \, dr \right)^{\frac{1}{2}} \left(\int_\eta^\rho |\varphi'|^2 r^{n-1} \, dr \right)^{\frac{1}{2}} + \frac{2\varepsilon^2}{R_0^n} \int_\eta^\rho |\varphi'|^2 r^{n-1} \, dr \\ &\le \frac{\varepsilon^2}{2} |\varphi'(\eta,t)|^2 + W(\varphi(\eta,t)) + C \frac{\varepsilon^{\frac{3}{2}}}{R_0^{n-1}} \left(\int_{R_0}^1 (\varphi_t)^2 r^{n-1} \, dr \right)^{\frac{1}{2}} + C\frac{\varepsilon}{R_0^n} + C\sqrt{\varepsilon}. \end{aligned}$$

Next, integrating in η over $(R_0, 1)$ and again using the bound on the energy (2.4), we find for $t_0 \le t \le t_1$ that

$$\left| -\frac{\varepsilon^2}{2} |\varphi'(\rho,t)|^2 + W(\varphi(\rho,t)) \right| \le C(R_0) \left(\sqrt{\varepsilon} + \left(\varepsilon^3 \int_\Omega (\varphi_t(x,t))^2 \, dx \right)^{\frac{1}{2}} \right). \tag{3.7}$$

Thus we are left with estimating the last term in (3.7). For this we follow Stoth [S1] and consider the equation satisfied by $\partial_t\varphi$ on $\Omega \times (t_2, t_1)$:

$$\varepsilon\partial_{tt}\varphi - \varepsilon\Delta\partial_t\varphi + \frac{1}{\varepsilon}W''(\varphi)\partial_t\varphi - \partial_t\lambda_\varepsilon = 0.$$

We multiply this by $\varepsilon\partial_t\varphi$ and integrate over $\Omega\times(t_2,\tau)$ for $\tau < t_1$ to obtain

$$\begin{aligned}&\int_{t_2}^{\tau}\int_\Omega \varepsilon^2\varphi_{tt}\,\varphi_t\,dx\,dt - \int_{t_2}^{\tau}\int_\Omega \varepsilon^2\varphi_t\Delta\varphi_t\,dx\,dt\\ &\quad= -\int_{t_2}^{\tau}\int_\Omega W''(\varphi)(\varphi_t)^2\,dx\,dt + \int_{t_2}^{\tau}\varepsilon\partial_t\lambda_\varepsilon\int_\Omega\varphi_t\,dx\,dt = -\int_{t_2}^{\tau}\int_\Omega W''(\varphi)(\varphi_t)^2\,dx\,dt,\end{aligned}$$

by the mass-conservation property (1.4). Next, we integrate by parts and use the boundary condition (3.2) and the fact that $W''(\varphi) = 2(3\varphi^2-1)$ is bounded:

$$\begin{aligned}\int_\Omega \frac{\varepsilon^2}{2}|\varphi_t(x,\tau)|^2\,dx + &\int_{t_2}^{\tau}\int_\Omega \varepsilon^2|\nabla\varphi_t|^2\,dx\,dt\\ &\leq \int_\Omega\frac{\varepsilon^2}{2}|\varphi_t(x,t_2)|^2\,dx + C\int_{t_2}^{\tau}\int_\Omega(\varphi_t(x,t))^2\,dx\,dt.\end{aligned}$$

The proposition now follows from (3.7). □

Now according to Lemma 2.6, we can choose T_0 small enough such that

$$\varepsilon\int_{t_0-T_0}^{t_0+T_0}\int_\Omega(\varphi_t)^2\,dx\,dt$$

is as small as desired if $t_0 \notin N(\eta)$. This means that, away from the origin, the solution φ_ε is as close as we want to the stationary wave q in (t_0-T_0, t_0+T_0). This is the content of the following important consequence of Proposition 3.1 and Lemma 2.6.

Proposition 3.2 (first approximation). *Let $\varphi = \varphi_\varepsilon$ and φ^0_ε satisfy* (3.1)–(3.5). *Let $0 < R_0 < 1$ and $\delta > 0$. Then there exists $\eta = \eta(\delta, R_0)$ such that for any $0 \neq t_0 \notin N(\eta)$, there exists $T_0 = T_0(\delta, R_0, t_0) > 0$ and $\varepsilon_0 = \varepsilon_0(\delta, R_0, t_0) > 0$ such that*

$$\sup_{t_0-T_0\leq t\leq t_0+T_0}\left\|-\frac{\varepsilon^2}{2}|\varphi'|^2 + W(\varphi)\right\|_{L^\infty(R_0,1)} \leq \delta^2 \quad \textit{for } \varepsilon \leq \varepsilon_0.$$

We then rename $N(\eta(\delta,R_0))$ as $N(\delta,R_0)$.

Proof. Define η via $\sqrt{\eta} = \frac{\delta^2}{2C(R_0)}$, with $C(R_0)$ as in Proposition 3.1, and choose $T_0 = T_0(\delta, R_0, t_0)$ to be as in Lemma 2.6. Then we use Proposition 3.1 with $t_1 = t_0+T_0$ and the mean value over $t_2 \in (t_0 - T_0, t_0 - \frac{T_0}{2})$ to obtain for $t_0 - \frac{T_0}{2} \leq t \leq t_0 + T_0$,

$$\begin{aligned}&\left\|-\frac{\varepsilon^2}{2}|\varphi'(\cdot,t)|^2 + W(\varphi(\cdot,t))\right\|_{L^\infty(R_0,1)}\\ &\leq C(R_0)\left(\sqrt{\varepsilon} + \left(\varepsilon\int_{t_0-T_0}^{t_0+T_0}\int_\Omega\varphi_t^2\,dx\,dt\right)^{\frac12} + \left(\varepsilon^3\int_\Omega\varphi_t^2(x,t_2)\,dx\right)^{\frac12}\right)\\ &\leq C(R_0)\left(\sqrt{\varepsilon} + \left(\varepsilon\int_{t_0-T_0}^{t_0+T_0}\int_\Omega\varphi_t^2\,dx\,dt\right)^{\frac12} + \left(\varepsilon^3\frac{2}{T_0}\int_{t_0-T_0}^{t_0-\frac{T_0}{2}}\int_\Omega\varphi_t^2(x,t_2)\,dx\,dt_2\right)^{\frac12}\right)\\ &\leq C(R_0)\left(\sqrt{\varepsilon} + \frac{\delta^2}{2C(R_0)} + \varepsilon\sqrt{\frac{2}{T_0}}\right) \leq \delta^2\end{aligned}$$

for $\varepsilon \leq \varepsilon_0(\delta, R_0, t_0)$. We then rename $\frac{T_0}{2}$ as T_0. □

Remark 3.3. If $t_0 = 0$, then the same result as Proposition 3.2 holds with $(-T_0, T_0)$ substituted by $[0, T_0)$. A condition for this is that $\varepsilon^3 \int_\Omega \partial_t \varphi_\varepsilon^2(x,0)\,dx \to 0$, which by equation (1.1) is equivalent to the condition $\varepsilon^3 \int_\Omega (\triangle\varphi_\varepsilon - \frac{1}{\varepsilon^2} W'(\varphi_\varepsilon))^2(x,0)\,dx \to 0$. This proposition is crucial to our approach. It has two important consequences. The first is that we can define the interfaces of φ_ε by showing that the level sets of φ_ε are graphs. This is done in section 4. The second consequence is an even better approximation of φ_ε by the stationary-wave solution associated to (1.1), namely, we obtain a second-order approximation for φ_ε. This will be shown in section 5. Finally, this approximation will be used to take the weak limit of equation (3.1) to obtain the desired limiting equation in section 6.

We conclude this section with a final estimate, which gives control over the surface area that vanishes at the origin.

PROPOSITION 3.4. *We have the additional estimate*

$$\text{(3.8)} \quad \int_0^T \int_0^1 |g(\varphi_\varepsilon)'| r^{n-2}\,dr\,dt \leq \int_0^T \int_0^1 \left(\frac{\varepsilon}{2}|\varphi_\varepsilon'|^2 \;+\; \frac{1}{\varepsilon}W(\varphi_\varepsilon)\right) r^{n-2}\,dr\,dt \;\leq\; C.$$

Proof. We multiply the nonlocal equation (3.1) by $(-r^{n-1}\varphi_\varepsilon')$ and integrate over $(0,s)$. This yields

$$\begin{aligned}\varepsilon \int_0^s \varphi_\varepsilon''\varphi_\varepsilon' r^{n-1} dr \;+\; (n-1)\varepsilon \int_0^s {\varphi_\varepsilon'}^2 r^{n-2} dr \;-\; \frac{1}{\varepsilon}\int_0^s W'(\varphi_\varepsilon)\varphi_\varepsilon' r^{n-1} dr \\ =\; -\lambda_\varepsilon \int_0^s \varphi_\varepsilon' r^{n-1} dr \;+\; \varepsilon \int_0^s \partial_t\varphi_\varepsilon \varphi_\varepsilon' r^{n-1} dr.\end{aligned}$$

Hence

$$\begin{aligned}&\frac{n-1}{2}\varepsilon \int_0^s {\varphi_\varepsilon'}^2 r^{n-2} dr \;+\; \frac{n-1}{\varepsilon}\int_0^s W(\varphi_\varepsilon) r^{n-2} dr \\ &\quad\leq\; \left(\frac{\varepsilon}{2}|\varphi_\varepsilon'|^2(s) \;+\; \frac{1}{\varepsilon}W(\varphi_\varepsilon)(s) \;+\; 2|\lambda_\varepsilon|\; ||\varphi_\varepsilon||_{L^\infty}\right) s^{n-1} \\ &\qquad+\; \varepsilon \int_0^s |\partial_t\varphi_\varepsilon \varphi_\varepsilon'|\; r^{n-1} dr.\end{aligned}$$

Now the left-hand side at $s = \frac{1}{2}$ is bounded by the mean value of the right-hand side taken over $s \in (\frac{1}{2}, 1)$. Therefore, the energy estimate (2.4), the L^∞ bound (2.6), and the bound on the Lagrange multiplier (2.3) give

$$\int_0^T \int_0^{1/2} \left(\frac{\varepsilon}{2}|\varphi_\varepsilon'|^2 \;+\; \frac{1}{\varepsilon}W(\varphi_\varepsilon)\right) r^{n-2}\,dr\,dt \;\leq\; C.$$

This establishes the result since in the interval $(\frac{1}{2}, 1)$, there is nothing to prove. □

4. Definition of the interfaces of φ_ε and of the limit v.

In this section, we present the definition and properties of the interfaces of φ_ε and of v. The definition of the interfaces is based on the fact that Proposition 3.2 implies a lower bound on $|\varphi_\varepsilon'|$ such that we can apply the implicit function theorem. Indeed, let

$$\text{(4.1)} \quad \delta^2 < \frac{1}{8} \quad \text{and} \quad 0 < Q < \tanh\left[\frac{1}{2} - \tanh^{-1}\frac{1}{\sqrt{3}}\right] \quad \text{be such that} \quad W(Q) \geq \frac{1}{4}.$$

We will study the level sets of φ_ε of value less than Q. This precise choice of Q is important in the ellipticity proposition (Proposition 6.4) and in the following.

According to Proposition 3.2, $\frac{\varepsilon^2}{2}|\varphi_\varepsilon'|^2 \geq \frac{1}{8}$ in the subset of $(R_0, 1)\times(t_0-T_0, t_0+T_0)$ defined by $|\varphi_\varepsilon| \leq Q$ since in this set $W(\varphi_\varepsilon) \geq \frac{1}{4}$. This means that φ_ε must be monotone in r on each connected component of this set.

We assume that $\varphi = \varphi_\varepsilon$ satisfies (3.1)–(3.5), and for any $R_0 > 0$, we define

$$A_{R_0} := \bigcup_{t_0 \notin N(\delta, R_0)} (t_0 - T_0(\delta, R_0, t_0), t_0 + T_0(\delta, R_0, t_0)), \tag{4.2}$$

where δ is a fixed constant to be chosen later. We remark that by definition A_{R_0} is open and that its complement has at most finitely many points, all of them in $N(\delta, R_0)$. We choose an increasing sequence of open sets $D = D_m$ with $\bigcup D_m = A_{R_0}$.

The set $\overline{D}$ and hence D can be covered by finitely many of the $(t_0-T_0(\delta, R_0, t_0), t_0+T_0(\delta, R_0, t_0))$'s that were used to define A_{R_0}. Thus on D, Proposition 3.2 implies that

$$\sup_D \| -\varepsilon^2|\varphi'|^2 + 2W(\varphi)\|_{L^\infty(R_0,1)} \leq 2\delta^2$$

for all $\varepsilon \leq \varepsilon_0(\delta, R_0, D)$.

We now consider the "ε problem" in the strip $(R_0, 1) \times D$.

Let Q be as in (4.1). Then on $\{|\varphi_\varepsilon| \leq Q\} \cap (R_0, 1) \times D$, we have $\varepsilon^2|\varphi_\varepsilon'|^2 \geq \frac{1}{4}$. Thus for any $-Q < a < Q$, the set $\{\varphi_\varepsilon(r, t) = a\} \cap (R_0, 1) \times D$ consists of a collection of graphs $r_\varepsilon^i(\cdot, a)$.

Moreover, by the implicit function theorem, the following identities hold:

$$\begin{aligned} \partial_t\varphi_\varepsilon(r_\varepsilon^i(t,a),t) + \partial_t r_\varepsilon^i(t,a)\partial_r\varphi_\varepsilon(r_\varepsilon^i(t,a),t) &= 0, \\ \partial_a r_\varepsilon^i(t,a)\partial_r\varphi_\varepsilon(r_\varepsilon^i(t,a),t) &= 1. \end{aligned}$$

Using the coarea formula, this implies an $H^{1,2}$ estimate on r_ε^i. Indeed,

$$\begin{aligned} \int_{\{|\varphi_\varepsilon(\cdot,t)|<Q, r>R_0\}} \frac{|\partial_t\varphi_\varepsilon(r,t)|^2}{|\varphi_\varepsilon'(r,t)|}\,dr &= \int_{-Q}^{Q}\int_{\{\varphi_\varepsilon(\cdot,t)=a, r>R_0\}} \frac{|\partial_t\varphi_\varepsilon(r,t)|^2}{|\varphi_\varepsilon'(r,t)|^2}\,d\mathcal{H}^0\,da \\ &= \int_{-Q}^{Q}\sum_i |\partial_t r_\varepsilon^i(t,a)|^2\,da. \end{aligned}$$

Thus

$$\begin{aligned} \int_D\int_{-Q}^{Q}\sum_i |\partial_t r_\varepsilon^i(t,a)|^2\,da\,dt &\leq \frac{\varepsilon}{\sqrt{\delta}}\int_D\int_{R_0}^{1}|\partial_t\varphi_\varepsilon(r,t)|^2\,dr\,dt \\ &\leq C(R_0,\delta). \end{aligned}$$

Thus we may choose $a_\varepsilon \in (-Q, Q)$ such that (for some bigger $C(R_0, \delta)$)

$$\int_D \sum_i |\partial_t r_\varepsilon^i(t, a_\varepsilon)|^2\,dt \leq C(R_0, \delta).$$

This in turn implies that the graphs $r_\varepsilon^i(\cdot, a_\varepsilon)$ are Hölder-$\frac{1}{2}$ by embedding.

We define the interfaces of the ε problem by

$$r_\varepsilon^i(t) := r_\varepsilon^i(t, a_\varepsilon). \tag{4.3}$$

We note that none of these interfaces hits the fixed boundary $\partial\Omega$ because on the fixed boundary $\varphi_\varepsilon' = 0$ and thus by Proposition 3.2, the values of φ_ε have to be close to ± 1. However, on the interfaces, the values of φ_ε are given by a_ε and hence are uniformly away from ± 1. Thus all of the interfaces exist as long as they do not hit $r = R_0$. This allows us to introduce the ordering

$$(4.4) \qquad r_\varepsilon^i : I_\varepsilon^i \subset D \longrightarrow (R_0, 1) \quad \text{ for } i = 1, \ldots, M_\varepsilon$$

with $r_\varepsilon^i > r_\varepsilon^{i+1}$ and $r_\varepsilon^i = R_0$ on $\partial I_\varepsilon^i \cap D$. In addition $\operatorname{sign}(\varphi_\varepsilon(t,1) - a_\varepsilon)$ is fixed in D.

PROPOSITION 4.1. *The number M_ε of graphs $r_\varepsilon^i(t)$ is finite and bounded independently of D.*

Proof. By definition, $\varphi_\varepsilon(r_\varepsilon^i(t), t) = a_\varepsilon$ and therefore there exist points $c_\varepsilon^i(t)$ such that

$$r_\varepsilon^i(t) < c_\varepsilon^i(t) < r_\varepsilon^{i+1}(t)$$

with the property that $\varphi_\varepsilon'(c_\varepsilon^i(t), t) = 0$. Now the estimates given by Proposition 3.2 imply

$$W(\varphi_\varepsilon(c_\varepsilon^i(t), t)) \le \delta^2,$$

and $\varphi_\varepsilon(c_\varepsilon^i(t), t)$ have opposite signs for consecutive i's. Consequently,

$$|g(\varphi_\varepsilon(c_\varepsilon^{i+1}(t), t)) - g(\varphi_\varepsilon(c_\varepsilon^i(t), t))| = |g(\varphi_\varepsilon(c_\varepsilon^{i+1}(t), t))| + |g(\varphi_\varepsilon(c_\varepsilon^i(t), t))| \ge C(\delta) > 0.$$

Thus

$$\begin{aligned} C(\delta) M_\varepsilon &\le \sum_{i=1}^{M_\varepsilon} |g(\varphi_\varepsilon(c_\varepsilon^{i+1}(t), t)) - g(\varphi_\varepsilon(c_\varepsilon^i(t), t))| \\ &\le \sum_{i=1}^{M_\varepsilon} \left| \int_{c_\varepsilon^i(t)}^{c_\varepsilon^{i+1}(t)} g(\varphi_\varepsilon)' \, dr \right| \le C(R_0), \end{aligned}$$

by the energy estimate (2.4). Thus M_ε is uniformly bounded. □

As a result of this proposition, for a subsequence of ε's (depending on R_0), the number $M_\varepsilon =: M_0$ must be constant, and for $i = 1, \ldots, M_0$, there exist

$$(4.5) \qquad \bar{r}^i : I_{R_0}^i \subset A_{R_0} \to (R_0, 1] \quad \text{such that} \quad r_\varepsilon^i \longrightarrow \bar{r}^i$$

weakly in $H_{\text{loc}}^{1,2}(I_{R_0}^i)$ and locally uniformly.

In view of this, we define for any $R_0 > 0$ the set of limit interfaces

$$(4.6) \qquad \Gamma_{R_0} := \{(\bar{t}_0, \bar{r}_0) \mid \bar{t}_0 \in A_{R_0} \text{ and } \bar{r}_0 = \bar{r}^i(\bar{t}_0) \text{ for some } i = 1, \ldots, M_0\}.$$

This set Γ_{R_0} contains the free boundary $\partial\{v = -1\}$, but it may contain more.

Next, we study the "ε problem" locally around any $(\bar{t}_0, \bar{r}_0) \in \Gamma_{R_0}$.

Let m_0 be given by the property that at time $\bar{t}_0$, there are exactly m_0 graphs r_ε^i which converge to $\bar{r}_0$, i.e.,

$$(4.7) \qquad r_\varepsilon^i(\bar{t}_0) \to \bar{r}_0, \quad k \le i \le m_0 + k - 1.$$

Since all the r_ε^i are uniformly Hölder-$\frac{1}{2}$, there exists a box

$$B := (\bar{t}_1, \bar{t}_2) \times (a, b)$$

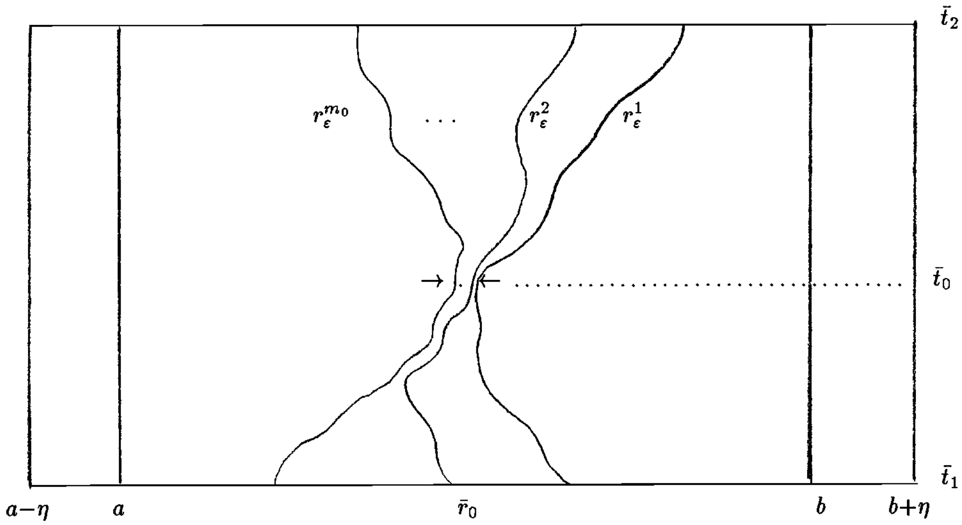

FIG. 1.

around $(\bar{t}_0, \bar{r}_0)$ that contains exactly m_0 graphs, all of them defined over the entire interval $(\bar{t}_1, \bar{t}_2)$. In addition, these graphs in B are $O(1)$ away from all other graphs. (See Figure 1.)

In conclusion, by putting together all of the above results, we have the following.

PROPOSITION/DEFINITION 4.2 (the local geometry). *For all $(\bar{t}_0, \bar{r}_0) \in \Gamma_{R_0}$ with $\bar{r}_0 \neq 1$, there exist natural numbers m_0 and k and a number $\nu \in \{-1, 0, +1\}$, a box $B = (\bar{t}_1, \bar{t}_2) \times (a, b) \subset D \times (R_0, 1)$, and $\eta > 0$ such that for $\varepsilon \leq \varepsilon_0(\bar{t}_0, \bar{r}_0)$, the following hold:*

(1) *$\{\varphi = a_\varepsilon\} \cap B$ consists of m_0 graphs r_ε^i over $(\bar{t}_1, \bar{t}_2)$, which are uniformly Hölder-$\frac{1}{2}$ and with derivatives uniformly in L^2, and $r_\varepsilon^i > r_\varepsilon^{i+1}$.*

(2) *At $\bar{t}_0$, exactly m_0 interfaces converge to $\bar{r}_0$.*

(3) *$r_\varepsilon^i \to \bar{r}^i$ uniformly and $\partial_t r_\varepsilon^i \rightharpoonup \partial_t \bar{r}^i$ weakly in $L^2(\bar{t}_1, \bar{t}_2)$ for $k \leq i \leq m_0+k-1$.*

(4) *$\bar{r}^i(\bar{t}_0) = \bar{r}_0$ for $k \leq i \leq m_0 + k - 1$.*

(5) *$a - \eta > R_0$ and the sets $\{(\bar{t}_1, \bar{t}_2) \times (a-\eta, a]\} \cap \{\varphi^\varepsilon = a_\varepsilon\}$ and $\{(\bar{t}_1, \bar{t}_2) \times [b, b+\eta)\} \cap \{\varphi^\varepsilon = a_\varepsilon\}$ are empty.*

(6)

$$\nu = \begin{cases} +1 & \textit{if } \varphi_\varepsilon(\bar{t}_0, a) < a_\varepsilon \textit{ and } \varphi_\varepsilon(\bar{t}_0, b) > a_\varepsilon, \\ -1 & \textit{if } \varphi_\varepsilon(\bar{t}_0, a) > a_\varepsilon \textit{ and } \varphi_\varepsilon(\bar{t}_0, b) < a_\varepsilon, \\ 0 & \textit{otherwise.} \end{cases}$$

If $\bar{r}_0 = 1$, then $B = (\bar{t}_1, \bar{t}_2) \times (a, b) \not\subset D \times (R_0, 1)$, but if we continue φ_ε by its boundary values, the above definitions remain meaningful.

Due to the symmetry of the argument, later we will explicitly describe only the case where $\varphi_\varepsilon(\bar{t}_0, b) > a_\varepsilon$ such that ν is either $+1$ or 0. The case where $\nu = 0$ corresponds to the case where the limit v has a "phantom" interface at which v "jumps" from 1 to 1 or -1 to -1, whereas the case where $\nu \neq 0$ corresponds to true interfaces of v.

5. A rigorous first-order expansion. Once again, throughout this section, we assume that φ_ε satisfies (3.1)–(3.5) such that the analysis of the preceding sections is valid.

We now have well-defined interfaces. We propose to study the solution near each interface. Our final goal is to pass to the limit in equation (3.1) around each interface. For this we will need a very good approximation of the solution φ_ε in $H^{1,\infty}$. This section is devoted to obtaining this approximation. The idea is to show that the asymptotic expansion is rigorous up to second order, at least in a weak sense. We will show this using appropriate $H^{1,2}$ error estimates. However, we will not prove an approximation of φ_ε everywhere in Ω as in [S1]. Instead, with the use of a cutoff function, we only consider the approximation of φ_ε locally around the interfaces.

In this section, we restrict our discussion to the box B defined in Proposition 4.2. We assume for simplicity of presentation that $k = 1$. First, we introduce a stretched variable around the largest interface $r^1_\varepsilon(t)$ in the box B. Let

$$z := \frac{|x| - r^1_\varepsilon(t)}{\varepsilon} \tag{5.1}$$

such that $z \in (\frac{-r^1_\varepsilon(t)}{\varepsilon}, \frac{1-r^1_\varepsilon(t)}{\varepsilon})$. Henceforth, we shall use *capital letters* for functions defined in the stretched variables and *lower-case letters* for functions written in the original variables so that, for example,

$$\Phi_\varepsilon(z,t) := \varphi_\varepsilon(r,t). \tag{5.2}$$

Moreover, the index ε will be dropped whenever it does not affect the clarity of the text. Then for η as in Proposition 4.2, the rescaling (5.1) maps the collection of points

$$a - \eta < a < r^{m_0}_\varepsilon < \cdots < r^2_\varepsilon < r^1_\varepsilon < b < b + \eta \tag{5.3}$$

onto

$$z^-_\varepsilon - \frac{\eta}{\varepsilon} < z^-_\varepsilon < z^{m_0}_\varepsilon < \cdots < z^2_\varepsilon < z^1_\varepsilon \ (= 0) < z^+_\varepsilon < z^+_\varepsilon + \frac{\eta}{\varepsilon}. \tag{5.4}$$

(See Figure 2.)

Now motivated by the formal analysis of [RS], we make the ansatz that Φ_ε is well approximated near $z = 0$ by

$$\Theta^\varepsilon(z,t) := \Phi^\varepsilon_0(z,t) + \varepsilon\Phi^\varepsilon_1(z,t) \quad \text{for } z \in \left(z^-_\varepsilon - \frac{\eta}{\varepsilon}, z^+_\varepsilon + \frac{\eta}{\varepsilon}\right). \tag{5.5}$$

The zeroth-order term $\Phi^\varepsilon_0(z,t)$ is given by

$$\Phi^\varepsilon_0(z,t) := \sum_{i=1}^{m_0} \Xi^\varepsilon_i(z,t) \underbrace{\tanh((-1)^{i+1}[z - z^i_\varepsilon(t)] + \mu_\varepsilon)}_{=:\Phi^\varepsilon_{0i}(z,t)}, \tag{5.6}$$

where $\mu_\varepsilon = \tanh^{-1} a_\varepsilon$ and Ξ_i is a partition of unity. More precisely, for $2 \le i \le m_0 - 1$, the function Ξ_i has support in $(\frac{z^{i+1}+z^i}{2} - 1, \frac{z^i+z^{i-1}}{2} + 1)$, while Ξ_1 has support in $(\frac{z^2}{2} - 1, \infty)$ and Ξ_{m_0} has support in $(-\infty, \frac{z^{m_0}+z^{m_0-1}}{2} + 1)$. Moreover, Ξ'_i has support in two disjoint intervals, each of length 2, given typically by $(\frac{z^i+z^{i+1}}{2} - 1, \frac{z^i+z^{i+1}}{2} + 1)$. (See Figure 2.)

Remark 5.1. We later prove that $|z_i - z_{i-1}|$ is uniformly larger than 2 (cf. Lemma 5.8) as a consequence of the first approximation proposition (Proposition 3.2), so the above partition of unity is meaningful.

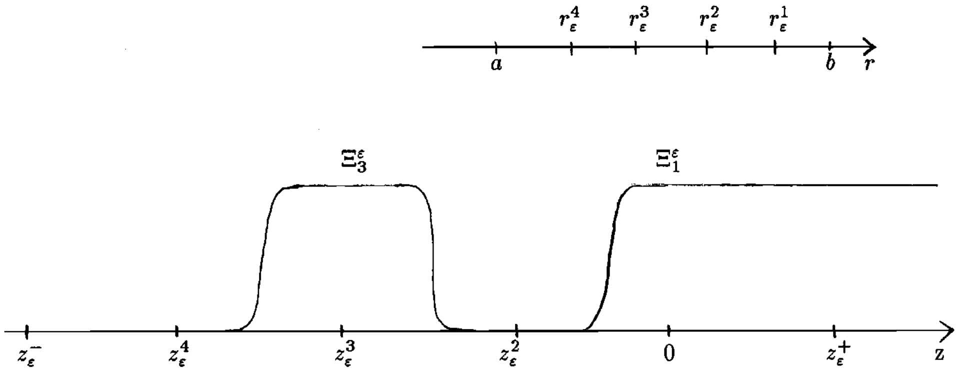

Fig. 2.

The first-order term is given by

$$\Phi_1^\varepsilon(z,t) := \sum_{i=0}^{m_0} \Xi_i^\varepsilon(z,t)\Phi_{1i}^\varepsilon(z,t), \tag{5.7}$$

where $\Phi_{1i} = \Phi_{1i}^\varepsilon(z,t)$ solves

$$\begin{cases} -\Phi_{1i}'' + W''(\Phi_{0i})\Phi_{1i} - \lambda_\varepsilon(t) = 0 & \text{in } (-\infty, z_\varepsilon^i) \cup (z_\varepsilon^i, \infty), \\ \Phi_{1i}\,(z_\varepsilon^i) = 0, \end{cases} \tag{5.8}$$

and $W''(\Phi) = 2(3\Phi^2 - 1)$. We note that equation (5.8) is the equation satisfied by the first-order term in the asymptotic expansion of [RS].

Remark 5.2. We do not impose that the differential equation for Φ_{1i} be satisfied at $z = z_\varepsilon^i$ in order to ensure that the solution remains uniformly bounded over the entire real axis (cf. Lemma 5.7). We refer to the work of Niethammer [N], who determined the expansion of the Lagrange multiplier for the radial, stationary problem with mass constraint by the condition that the equation be satisfied in the whole of $\mathbf{R}$.

Remark 5.3. The approximation depends on the direction of the jump. Here we give the definition for the case as selected in Proposition 4.2. If to the contrary the jump direction were the opposite, the tanh would have to be substituted by −tanh.

Remark 5.4. In the formal inner expansion, one also expands $\lambda_\varepsilon(t) = \lambda_0(t) + \varepsilon\lambda_1(t) + \cdots$ (see [RS]). Here we do not do this since we are interested only in the zeroth-order term. The lowest-order term will be determined later by the mass-conservation property.

The rest of this section is devoted to proving that (5.5) is indeed a good approximation to Φ_ε. To this end, let

$$\Psi^\varepsilon(z,t) := \Phi_\varepsilon(z,t) - \Theta^\varepsilon(z,t) \quad \text{for } \bar{t}_1 \le t \le \bar{t}_2. \tag{5.9}$$

Proposition 5.5 (first-order approximation). *Let ξ_ε be a cutoff function with*

$$\xi_\varepsilon(z,t) = \begin{cases} 1 & \textit{in } (-\varepsilon^{-\alpha} + z_\varepsilon^{m_0}(t), \varepsilon^{-\alpha}), \\ 0 & \textit{in } \mathbf{R}\backslash(-\varepsilon^{-\beta} + z_\varepsilon^{m_0}(t), \varepsilon^{-\beta}) \end{cases} \tag{5.10}$$

for $\frac{1}{2} < \alpha < \beta < 1$ so that

$$\text{supp}\ \xi(\cdot,t) \subset \left(z_\varepsilon^- - \frac{\eta}{\varepsilon}, z_\varepsilon^+ + \frac{\eta}{\varepsilon}\right).$$

Then for Ψ *given by* (5.9)*, we have the following estimates:*

$$\int_{\bar{t}_1}^{\bar{t}_2}\int_{(-\infty,z_\varepsilon^{m_0})\cup(0,\infty)}(|\Psi'|^2+|\Psi|^2)\xi^2\,dz\,dt\le C\varepsilon^{2\beta}, \tag{5.11}$$

$$\int_{\bar{t}_1}^{\bar{t}_2}\int_{z_\varepsilon^{m_0}}^{0}(|\Psi'|^2+|\Psi|^2)\,dz\,dt\to 0, \tag{5.12}$$

where C *depends on the data and the local box* B*.*

The rest of this section is devoted to the proof of this proposition. We first find the equation satisfied by Ψ^ε. Using the definition (5.1) for Φ_ε and equation (3.1), we find (if $z\le\frac{1-r_\varepsilon^1}{\varepsilon}$)

$$\begin{aligned}-\Phi''+W'(\Phi)-\varepsilon\lambda_\varepsilon(t)&=-\varepsilon^2\partial_t\varphi(\varepsilon z+r_\varepsilon^i(t),t)+\frac{2\varepsilon}{\varepsilon z+r_\varepsilon^1(t)}\Phi'\\&=:F_\varepsilon(t,z).\end{aligned}\tag{5.13}$$

We define $F_\varepsilon(t,z)$ by $W'(\varphi_\varepsilon(t,1))-\varepsilon\lambda_\varepsilon(t)$ for $z>\frac{1-r_\varepsilon^1}{\varepsilon}$.

The equation for Θ^ε is more complicated because of the extra terms that come from the partition of unity. To simplify the presentation, we let $\Theta_i:=\Phi_{0i}+\varepsilon\Phi_{1i}$. Then we have

$$-\Theta''+W'(\Theta)-\varepsilon\lambda_\varepsilon(t)=H_\varepsilon(z,t), \tag{5.14}$$

where

(5.15)

$$\begin{aligned}&H_\varepsilon(z,t):=\varepsilon^2\sum_{i=1}^{m_0}\Xi_i\left(6\Phi_{0i}\Phi_{1i}^2+2\varepsilon\Phi_{1i}^3\right)\\&+\sum_{i=1}^{m_0-1}[\Theta_{i+1}-\Theta_i]\left(\Xi_i''+2\Xi_i\Xi_{i+1}\{(1+\Xi_i)\Theta_i^2+(\Xi_i-2)\Theta_{i+1}^2+(1-2\Xi_i)\Theta_i\Theta_{i+1}\}\right)\\&+2\sum_{i=1}^{m_0-1}[\Theta_{i+1}-\Theta_i]'\,\Xi_i'.\end{aligned}$$

This formula comes from a linearization of $W'(\Phi)=-2\Phi(1-\Phi^2)$ around Φ_0. We note that this sum is only taken over two integers at a time because of the definition of Ξ_i. Also, as we will see later, the last two sums are of small order (cf. (5.25) and (5.26)).

Therefore, combining (5.13) and (5.14), the equation for the difference is

$$-\Psi''+W''(\Theta)\Psi=-2(3\Theta\Psi^2+\Psi^3)+F_\varepsilon(z,t)-H_\varepsilon(z,t), \tag{5.16}$$

and it holds in

$$\left(z_\varepsilon^- -\frac{\eta}{\varepsilon},z_\varepsilon^+ +\frac{\eta}{\varepsilon}\right)\backslash\{z_\varepsilon^1,\ldots,z_\varepsilon^{m_0}\} \tag{5.17}$$

with boundary values

$$\Psi^\varepsilon(z_\varepsilon^i,t)=0\quad\text{ for } i=1,\ldots,m_0. \tag{5.18}$$

Next, as in [S1], we follow an idea of Berger and Fraenkel and show that in some sense equation (5.16) for Ψ is uniformly strictly elliptic.

PROPOSITION 5.6 (ellipticity). *There exist $\zeta_1 > 0$ and $\zeta_2 > 0$ such that for $\bar{t}_1 < t < \bar{t}_2$,*

$$\int (-\Psi'' + W''(\Theta)\Psi)\Psi\,\xi^2\,dz \geq \zeta_1 \int |\Psi'|^2\xi^2\,dz + \zeta_2 \int |\Psi|^2\xi^2\,dz - \frac{2}{\zeta_1}\int |\Psi|^2|\xi'|^2\,dz,$$

where integration is either over $(-\varepsilon^{-\beta} + z^{m_0}, z^{m_0})$, $(0, \varepsilon^{-\beta})$, or $(z^{m_0}, 0)$.

This proposition is very similar to the proof of Proposition 8 in [S1] and we include its proof in the appendix.

We are now left with estimating all of the terms in the right-hand side of (5.16). For this we find further estimates on $\Phi_\varepsilon - \Phi_0^\varepsilon$ and on Φ_1^ε. First, we present a bound on Φ_1^ε, which in particular gives the estimate $\|\Theta^\varepsilon - \Phi_0^\varepsilon\|_{H^{1,\infty}(z_\varepsilon^- - \frac{\eta}{\varepsilon}, z_\varepsilon^+ + \frac{\eta}{\varepsilon})\times(\bar{t}_1,\bar{t}_2)} \leq C\sqrt{\varepsilon}$.

LEMMA 5.7.

$$\|\Phi_1^\varepsilon\|_{H^{1,\infty}(z_\varepsilon^- - \frac{\eta}{\varepsilon}, z_\varepsilon^+ + \frac{\eta}{\varepsilon})\times(\bar{t}_1,\bar{t}_2)} \leq C\,|\lambda_\varepsilon(t)|\,.$$

The proof follows the same lines as the proof of Lemma 7 in [S1]. The basic tool is the following representation formula (cf. [BF]):

$$\Phi_{1i}^\varepsilon(z + z_\varepsilon^i, t) = \left(A(z)\int_0^z B + B(z)\int_z^\infty A\right)\lambda_\varepsilon(t),$$

where $A(z) := 1 - \tanh^2(z)$ and $B(z) := -A(z)\int_0^z \frac{1}{A^2}$.

As yet another consequence of Proposition 3.2, we have the following lemma, which implies that Φ is close to Φ_0 in the topology of L^∞.

LEMMA 5.8. *For any $\delta > 0$ there exist $e(\delta) > 0$ and $M(\delta) > 0$ such that*

$$\left|z_\varepsilon^1 - \frac{1 - r_\varepsilon^1}{\varepsilon}\right| \geq e(\delta) \quad \textit{and} \quad |z_\varepsilon^i - z_\varepsilon^{i-1}| \geq e(\delta) \quad \textit{for } 2 \leq i \leq m_0,$$

$$\|(\Psi^\varepsilon\Theta^\varepsilon)_-\|_{L^\infty((z_\varepsilon^- - \frac{\eta}{\varepsilon}, z_\varepsilon^+ + \frac{\eta}{\varepsilon})\times(\bar{t}_1,\bar{t}_2))} \leq M(\delta),$$

with $M(\delta) \to 0$ and $e(\delta) \to \infty$ as $\delta \to 0$.

This lemma is easily derived from explicit integration of the ODE (cf. [S1])

$$\begin{cases} |\Phi'(z,t)|^2 - 2W(\Phi(z,t)) = 2K_\varepsilon(z,t), \\ \Phi(z_i^\varepsilon, t) = a_\varepsilon \end{cases} \tag{5.19}$$

in $z_\varepsilon^- \leq z \leq z_\varepsilon^+$, where $\|K_\varepsilon\|_{L^\infty(z_\varepsilon^- - \frac{\eta}{\varepsilon}, z_\varepsilon^+ + \frac{\eta}{\varepsilon})\times(\bar{t}_1,\bar{t}_2)} \leq \delta^2$ by Proposition 3.2.

We are now ready for the proof of the first-order approximation Proposition 5.5.

Proof of Proposition 5.5. Let S be $(-\varepsilon^{-\beta} + z^{m_0}, z^{m_0})$, $(0, \varepsilon^{-\beta})$, or $(z^{m_0}, 0)$. We multiply equation (5.16) for Ψ by $\xi^2\Psi$, where ξ is defined by (5.10); then we integrate in z and t and use Proposition 5.6 to obtain

$$\begin{aligned} &\zeta_1 \int_{\bar{t}_1}^{\bar{t}_2}\int_S |\Psi'|^2\xi^2\,dz\,dt + \zeta_2 \int_{\bar{t}_1}^{\bar{t}_2}\int_S |\Psi|^2\xi^2\,dz\,dt \\ &\qquad \leq \frac{2}{\zeta_2}\int_{\bar{t}_1}^{\bar{t}_2}\int_S |F_\varepsilon|^2\xi^2 + |H_\varepsilon|^2\xi^2\,dz\,dt + \frac{2}{\zeta_1}\int_{\bar{t}_1}^{\bar{t}_2}\int_S |\Psi|^2|\xi'|^2\,dz\,dt \\ &\qquad\qquad + \left(\frac{\zeta_2}{4} + 6\|(\Psi\Theta)_-\|_{L^\infty}\right)\int_{\bar{t}_1}^{\bar{t}_2}\int_S |\Psi|^2\xi^2\,dz\,dt. \end{aligned} \tag{5.20}$$

Let $M(\delta)$ be given by Lemma 5.8 and choose δ small enough that $6M(\delta) \leq \frac{\zeta_2}{4}$. Incorporating this into (5.20) yields

$$\begin{aligned} &\zeta_1 \int_{\bar t_1}^{\bar t_2} \int_S |\Psi'|^2 \xi^2 \, dz \, dt + \frac{\zeta_2}{2} \int_{\bar t_1}^{\bar t_2} \int_S |\Psi|^2 \xi^2 \, dz \, dt \\ &\leq \frac{2}{\zeta_2} \int_{\bar t_1}^{\bar t_2} \int_S (|F_\varepsilon|^2 + |H_\varepsilon|^2) \xi^2 \, dz \, dt + \frac{2}{\zeta_1} \int_{\bar t_1}^{\bar t_2} \int_S |\Psi|^2 |\xi'|^2 \, dz \, dt. \end{aligned} \tag{5.21}$$

Thus we are left with estimating the right-hand side of (5.21). Using the definition of F_ε given by (5.13), the energy bound implies (if $\bar r_0 \neq 1$)

$$\int_{\bar t_1}^{\bar t_2} \int_{-\varepsilon^{-\beta}+z^{m_0}}^{\varepsilon^{-\beta}} |F_\varepsilon|^2 \, \xi^2 \, dz \, dt \leq C(R_0) \varepsilon^2. \tag{5.22}$$

Moreover, we have the estimate

$$\int_{\bar t_1}^{\bar t_2} \int_{(-\varepsilon^{-\beta}+z^{m_0}, z^{m_0}) \cup (0, \varepsilon^{-\beta})} |H_\varepsilon|^2 \xi^2 \, dz \, dt \leq C(R_0) \varepsilon^{3-\beta} \leq C_(R_0) \varepsilon^{2\beta}. \tag{5.23}$$

Indeed, the last two sums in the definition in (5.15) of H_ε drop out since in $(-\varepsilon^{-\beta} + z^{m_0}, z^{m_0})$, the function $\Xi_{m_0} \equiv 1$ and $\Xi_i \equiv 0$ for $1 \leq i \leq m_0 - 1$, while in $(0, \varepsilon^{-\beta})$, the functions $\Xi_i \equiv 0$ for $2 \leq i \leq m_0$ and $\Xi_1 \equiv 1$. Then (5.23) follows from the fact that $\|\Phi_0\|_\infty \leq 1$, Lemma 5.7, and the L^2 and L^∞ bounds on $\lambda_\varepsilon(t)$ (cf. Corollary 2.2 and Proposition 2.3).

In addition, we claim that

$$\int_{\bar t_1}^{\bar t_2} \int_{z^{m_0}}^{0} |H_\varepsilon|^2 \, dz \, dt \to 0 \tag{5.24}$$

as $\varepsilon \to 0$. To prove this, we need a better estimate on $|z^{i+1} - z^i|$ than the one we obtained in Lemma 5.8. If we go back to formula (3.6) in Proposition 3.1, we can easily obtain the following bound for almost all $t \in (\bar t_1, \bar t_2)$ by using the energy estimates (2.3) and (2.4) and Proposition 4.1 at the small expenditure of an $\ln(\frac{1}{\varepsilon})$ factor:

$$\| -\varepsilon^2 (\varphi'(\cdot, t))^2 + 2W(\varphi(\cdot, t)) \|_{L^\infty(R_0, 1)} \leq C(t, R_0) \varepsilon \ln \left(\frac{1}{\varepsilon} \right). \tag{5.25}$$

Therefore, in fact, we have for almost all $t \in (\bar t_1, \bar t_2)$ that

$$|z^{i+1} - z^i| \to \infty \quad \text{as } \varepsilon \to 0,$$

and therefore

$$|\Theta_{i+1} - \Theta_i| \to 0 \quad \text{in } \{\Xi_i \Xi_{i+1} \neq 0\}.$$

Since Θ_i are uniformly bounded, we can now conclude that $\int_{\bar t_1}^{\bar t_2} \int_{\{\Xi_i \Xi_{i+1} \neq 0\}} |\Theta_{i+1} - \Theta_i|^2 \, dz \, dt \to 0$ as $\varepsilon \to 0$, and hence (5.24) follows.

Finally, since $|\xi'(z)| \leq C\frac{1}{\varepsilon^{-\beta}-\varepsilon^{-\alpha}} < C\varepsilon^{\beta}$, the last term can be estimated as follows:

$$
\begin{aligned}
&\frac{2}{\zeta_1}\int_{\bar{t}_1}^{\bar{t}_2}\int_{-\varepsilon^{-\beta}+z^{m_0}}^{\varepsilon^{-\beta}} |\Psi|^2|\xi'|^2\,dz\,dt \leq C\varepsilon^{2\beta}\iint_{\{\xi\neq 0,1\}} |\Psi|^2\,dz\,dt \\
&\leq C\varepsilon^{2\beta}\iint_{\{\xi\neq 0,1\}} (|\Phi-\Phi_0|^2+\varepsilon^2|\Phi_1|^2)\,dz\,dt \\
&\leq C\frac{\varepsilon^{2\beta-1}}{R_0^{n-1}}\int_{\bar{t}_1}^{\bar{t}_2}\left(\int_{r_\varepsilon^i(t)}^{b+\eta}(\varphi(r,t)-1)^2 r^{n-1}\,dr + \int_{a+\eta}^{r_\varepsilon^{m_0}}(\varphi(r,t)+1)^2 r^{n-1}\,dr\right) dtC\varepsilon^{\beta+1},
\end{aligned}
$$

where we have used the fact that in $\{(z,t)|\xi(z,t)\neq 0,1\}$, the function Φ_0 is exponentially close to ± 1 depending on $z>0$ or $z<z^{m_0}$, while $\varepsilon^2\|\Phi_1\|^2_{L^\infty(z_\varepsilon^- - \frac{\eta}{\varepsilon}, z_\varepsilon^+ + \frac{\eta}{\varepsilon})\times(\bar{t}_1,\bar{t}_2)} < C\varepsilon$. Now using the energy bound (2.4), we obtain

$$
\frac{2}{\zeta_1}\int_{\bar{t}_1}^{\bar{t}_2}\int_{-\varepsilon^{-\beta}+z^{m_0}}^{\varepsilon^{-\beta}} |\Psi|^2|\xi'|^2\,dz\,dt \leq C(R_0)\left(\varepsilon^{2\beta}+\varepsilon^{\beta+1}\right) \leq C(R_0)\varepsilon^{2\beta}. \tag{5.26}
$$

This completes the proof for $\bar{r}_0 < 1$. If $\bar{r}_0 = 1$, all of the above arguments are valid except for those leading to (5.22) and (5.26). If in (5.22) we integrate over $(-\varepsilon^{-\beta} + z_\varepsilon^{m_0}, \frac{1-r_\varepsilon^1}{\varepsilon})$, the result is the same. For $z > \frac{1-r_\varepsilon^1}{\varepsilon}$, we have $F_\varepsilon = W'(\varphi_\varepsilon(t,1)) - \varepsilon\lambda_\varepsilon(t)$. However, with (5.25) and because $\varphi_\varepsilon'(1,t) = 0$, we find $F_\varepsilon^2 \leq C(t)\varepsilon ln(1/\varepsilon)$, and the remaining integral in (5.22) still converges to zero by Lebesgue's convergence theorem. The same reasoning holds for (5.26). □

Finally, we conclude with some $H^{1,\infty}$ bounds from this $H^{1,2}$ bound.

COROLLARY 5.9. *Let* $J = J_{\text{good}}(t) := (-\varepsilon^{-\alpha} + z^{m_0}, z^{m_0}) \cup (0, \varepsilon^{-\alpha})$ *if* $\bar{r}_0 \neq 1$ *and* $J = J_{\text{good}}(t) := (-\varepsilon^{-\alpha} + z^{m_0}, z^{m_0})$ *if* $\bar{r}_0 = 1$. *Then*

$$
\begin{aligned}
&\int_{\bar{t}_1}^{\bar{t}_2} \|\Psi_\varepsilon'\|^2_{H^{1,\infty}(J)}\,dt \leq C\varepsilon^{2\beta}, \\
&\int_{\bar{t}_1}^{\bar{t}_2} \|\Psi_\varepsilon'\|^2_{H^{1,\infty}(0,z^{m_0})}\,dt \to 0, \\
&\int_{\bar{t}_1}^{\bar{t}_2} \|\Phi^\varepsilon(\cdot,t)-\Phi_0^\varepsilon(\cdot,t)\|^2_{H^{1,2}(-\varepsilon^{-\alpha}+z^{m_0},\varepsilon^{-\alpha})}\,dt \to 0, \\
&\int_{\bar{t}_1}^{\bar{t}_2} \|\Phi^\varepsilon(\cdot,t)-\Phi_0^\varepsilon(\cdot,t)\|^2_{H^{1,\infty}(J)}\,dt \leq C\varepsilon^{2\beta}, \\
&\int_{\bar{t}_1}^{\bar{t}_2} \|\Phi^\varepsilon(\cdot,t)-\Phi_0^\varepsilon(\cdot,t)\|^2_{H^{1,\infty}(0,z^{m_0})}\,dt \to 0,
\end{aligned}
$$

where C *depends on the data and* B.

Proof. The first two results follow from Proposition 5.5 by the Sobolev embedding theorem in $\mathbf{R}$ since Ψ satisfies the differential equation (5.16) and thus Ψ'' satisfies the same bounds as Ψ and Ψ'.

The last three results follow from either Proposition 5.5 or the two first results of this corollary using the by now "familiar" estimates

$$
\int_{\bar{t}_1}^{\bar{t}_2} \|\varepsilon\Phi_1^\varepsilon(\cdot,t)\|^2_{H^{1,2}(-\varepsilon^{-\alpha},z^{m_0}+\varepsilon^{-\alpha})}\,dt \leq \varepsilon^2\frac{1}{\varepsilon}\int_{\bar{t}_1}^{\bar{t}_2} |\lambda_\varepsilon(t)|^2\,dt \leq C\varepsilon
$$

and

$$\int_{\bar t_1}^{\bar t_2} \|\varepsilon\Phi_1^\varepsilon(\cdot,t)\|^2_{H^{1,\infty}(-\varepsilon^{-\alpha},z^{m_0}+\varepsilon^{-\alpha})}\,dt \le \varepsilon^2\int_{\bar t_1}^{\bar t_2}|\lambda_\varepsilon(t)|^2\,dt \le C\varepsilon^2. \qquad \square$$

6. The limit equation. In this section, we derive the differential equation of the limiting interface (true or phantom) given by $r=\bar r^i$. Therefore, we once again assume (3.1)–(3.5) for φ_ε, and hence the analysis of the preceding sections applies.

PROPOSITION 6.1. *Let A_{R_0} be as in* (4.2). *Then for all $(\bar t_0,\bar r_0)\in\Gamma_{R_0}$ as in* (4.6), *there exists a box $B=(\bar t_1,\bar t_2)\times(a,b)$ as in Proposition* 4.2 *such that $(\bar r_0,\bar t_0)\in B$ and such that $\Gamma_{R_0}\cap B$ consists of $m_0=m_0(\bar r_0,\bar t_0)$ Hölder-$\frac12$ graphs $\bar r^i:(\bar t_1,\bar t_2)\to(a,b)$ with $\bar r^i(\bar t_0)=\bar r_0$ (where $i=k,\dots,m_0+k-1$). Moreover, if $\bar r_0\neq 1$,*

$$-\sum_{i=k}^{m_0+k-1}\left(\dot{\bar r}^i+\frac{n-1}{\bar r^i}\right)=\frac32\nu(\bar r_0,\bar t_0)\lambda_0 \qquad \textit{in } (\bar t_1,\bar t_2),$$

and $\le$ is true in the above if $\bar r_0=1$.

The constant $m_0(\bar r_0,\bar t_0)$ can be understood as the "multiplicity" of Γ_{R_0}. We shall prove that $m_0=1$ almost everywhere in $\{\nu\neq0\}$, i.e., that the multiplicity of true interfaces is 1. For this we show later that $m_0(\bar r_0,\bar t_0)\neq1$ in B is equivalent to $\nu(\bar r_0,\bar t_0)\lambda_0(\bar t_0)=0$ (cf. Proposition 6.3). Then, using the fact that the mass is preserved in time, we calculate explicitly λ_0 and show that $\lambda_0(\bar t_0)\neq0$ (cf. Proposition 6.5).

Proof of Proposition 6.1. For the simplicity of presentation we assume $k=1$. We first consider the case $\bar r_0\neq1$ and later point out the differences in the other case.

In the z-variable the nonlocal equation (3.1) becomes

$$\varepsilon\partial_t\Phi-\dot r^1\Phi'-\frac1\varepsilon\Phi''-\frac{n-1}{\varepsilon z+r^1}\Phi'+\frac1\varepsilon W'(\Phi)-\lambda_\varepsilon(t)=0. \tag{6.1}$$

Let ζ be a smooth time-dependent test function with compact support in $(\bar t_1,\bar t_2)$. First, we multiply equation (6.1) by $\Phi'\zeta$ and integrate over $(-\varepsilon^{-\alpha}+z^{m_0},\varepsilon^{-\alpha})\times(\bar t_1,\bar t_2)$,

$$\begin{aligned}\int_{\bar t_1}^{\bar t_2}\int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}}\zeta(\varepsilon\Phi_t\Phi'-\dot r^1\Phi'^2)\,dz\,dt-\frac1\varepsilon\int_{\bar t_1}^{\bar t_2}\zeta\left(\frac12(\Phi')^2-W(\Phi)\right)\Bigg|_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}}dt\\ =\int_{\bar t_1}^{\bar t_2}\int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}}\frac{(n-1)\zeta}{\varepsilon z+r^1}|\Phi'|^2\,dz\,dt+\int_{\bar t_1}^{\bar t_2}\int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}}\zeta\lambda_\varepsilon\Phi'\,dz\,dt.\end{aligned} \tag{6.2}$$

The main part of this section is the evaluation of the limit of each term in (6.2) as $\varepsilon\to0$.

Second term. We claim that

$$\int_{\bar t_1}^{\bar t_2}\frac1\varepsilon\left(\frac12(\Phi')^2-W(\Phi)\right)\Bigg|_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}}\zeta\,dt\overset{\varepsilon\to0}{\to}0. \tag{6.3}$$

Indeed, the endpoints $-\varepsilon^{-\alpha}+z^{m_0}$ and $\varepsilon^{-\alpha}$ are in J_{good}, so we can apply Corollary 5.9 and replace Φ by Φ_0 since $\int_{\bar t_1}^{\bar t_2}\|\Phi-\Phi_0\|^2_{H^{1,\infty}(J)}\,dt\le C\varepsilon^{2\beta}$ and $2\beta-1>0$. The claim in (6.3) now follows since $\Phi_0(-\varepsilon^{-\alpha}+z^{m_0},t)=\tanh(\pm\varepsilon^{-\alpha}+\mu^\varepsilon)$ and $\Phi_0(\varepsilon^{-\alpha},t)=\tanh(\varepsilon^{-\alpha}+\mu^\varepsilon)$.

Third term. We claim that

$$(n-1)\int_{\bar{t}_1}^{\bar{t}_2}\int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}} \zeta\,\frac{1}{\varepsilon z + r_\varepsilon^1}|\Phi'|^2\,dz\,dt \overset{\varepsilon\to 0}{\to} \frac{4}{3}(n-1)\int_{\bar{t}_1}^{\bar{t}_2}\zeta\sum_{i=1}^{m_0}\frac{1}{\bar{r}^i}\,dt. \tag{6.4}$$

To prove this, we first replace Φ by Φ_0. We can do this since $|\frac{1}{\varepsilon z + r_\varepsilon^1}| \leq \frac{1}{R_0}$ and since by the approximation proposition (Proposition 5.5), Φ' is well approximated by Φ_0'.

Therefore, we only have to consider the limit of the integral

$$\int_{\bar{t}_1}^{\bar{t}_2}\int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}} \zeta\frac{1}{\varepsilon z + r_\varepsilon^1}|\Phi_0'|^2\,dz\,dt. \tag{6.5}$$

To find this limit, we divide the interval of integration in subintervals each of which contain one interface:

$$\begin{aligned}(-\varepsilon^{-\alpha}+z^{m_0},\varepsilon^{-\alpha}) &= C_{m_0} \cup \bigcup_{i=2}^{m_0-1} C_i \cup C_1 \cup \bigcup_{i=1}^{m_0} B_i \\ &:= \left(-\varepsilon^{-\alpha}+z^{m_0}, \frac{z^{m_0}+z^{m_0-1}}{2}-1\right) \\ &\cup \bigcup_{i=2}^{m_0-1}\left(\frac{z^{i+1}+z^i}{2}+1, \frac{z^i+z^{i-1}}{2}-1\right) \\ &\cup \left(\frac{z^2+z^1}{2}+1, \varepsilon^{-\alpha}\right) \cup \bigcup_{i=1}^{m_0}\{\Xi_i \neq 0,1\}.\end{aligned} \tag{6.6}$$

The set $\{\Xi_i \neq 0,1\}$ is of length 4, we have the estimate $|\frac{1}{\varepsilon z + r_\varepsilon^1}| \leq \frac{1}{R_0}$, and we know that $\|\Phi_0'(z)\|_{L^\infty(\{\Xi_i\neq 0,1\})} \overset{\varepsilon\to 0}{\to} 0$ almost everywhere since by (5.25), $|z^{i+1}-z^i| \overset{\varepsilon\to 0}{\to} \infty$. Thus the integral over B_i gives 0 in the limit.

We note that by the definition in (5.6) of Φ_0, we have $\Phi_0(z+z^i) = \tanh((-1)^{i+1}z+\mu_\varepsilon)$ for $z \in C_i - z^i$; therefore, we claim that

$$\begin{aligned}&\sum_{i=1}^{m_0}\int_{\bar{t}_1}^{\bar{t}_2}\int_{C_i-z^i}\frac{\zeta}{\varepsilon z + r_\varepsilon^i}{\Phi_0'}^2(z+z^i)\,dz\,dt \\ &\overset{\varepsilon\to 0}{\to} \sum_{i=1}^{m_0}\int_{\bar{t}_1}^{\bar{t}_2}\frac{\zeta}{\bar{r}^i}\int_{-\infty}^{\infty}(1-\tanh^2(z))^2\,dz\,dt = \frac{4}{3}\int_{\bar{t}_1}^{\bar{t}_2}\zeta\sum_{i=1}^{m_0}\frac{1}{\bar{r}^i}\,dt\end{aligned} \tag{6.7}$$

since $r_\varepsilon^i \to \bar{r}^i$ uniformly (cf. Proposition 4.2) and since $1-\tanh^2$ decays exponentially.

Last term. We claim that

$$\int_{\bar{t}_1}^{\bar{t}_2}\int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}}\zeta\,\lambda_\varepsilon\Phi'\,dz\,dt \overset{\varepsilon\to 0}{\to} 2\nu\int_{\bar{t}_1}^{\bar{t}_2}\zeta\,\lambda_0\,dt, \tag{6.8}$$

where ν was introduced in Proposition 4.2 and λ_0 was introduced in Remark 2.4. Indeed, integrating by parts yields

$$\int_{\bar{t}_1}^{\bar{t}_2}\int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}}\zeta\,\lambda_\varepsilon\Phi'\,dz\,dt = \int_{\bar{t}_1}^{\bar{t}_2}\zeta\,\lambda_\varepsilon\ \Phi|_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}}\ dt.$$

However,

$$\Phi(\varepsilon^{-\alpha},t) \quad \text{and} \quad \Phi(-\varepsilon^{a}+z^{m_0},t) \longrightarrow \pm 1$$

by the approximation proposition (Proposition 5.5), and since $\lambda_\varepsilon \longrightarrow \lambda_0$ in L^2, the claim in (6.8) is immediate. Note that we allow for $\nu = \{-1,0,1\}$.

First term. We claim that

$$\int_{\bar{t}_1}^{\bar{t}_2} \int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}} \zeta(\varepsilon \Phi_t \Phi' - \dot{r}^1 {\Phi'}^2)\, dz\, dt \overset{\varepsilon \to 0}{\to} -\int_{\bar{t}_1}^{\bar{t}_2} \frac{4}{3} \zeta \sum_{i=1}^{m_0} \partial_t \bar{r}^i\, dt. \tag{6.9}$$

This proof is similar to the convergence of the fourth term. The fourth term splits into two distinctly different parts:

$$\begin{aligned} &\int_{\bar{t}_1}^{\bar{t}_2} \int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}} \zeta \Phi'(\varepsilon \Phi_t - \dot{r}^1 \Phi')\, dz\, dt \\ &\qquad = \int_{\bar{t}_1}^{\bar{t}_2} \int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}} \varepsilon \zeta \Phi' \Phi_t\, dz\, dt - \int_{\bar{t}_1}^{\bar{t}_2} \int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}} \zeta \dot{r}^1 {\Phi'}^2\, dz\, dt. \end{aligned} \tag{6.10}$$

The last term should describe the dynamics in the limit, whereas the first term will vanish. This is the rigorous verification of the traveling-wave structure of the solution. We claim that

$$\begin{aligned} &\int_{\bar{t}_1}^{\bar{t}_2} \int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}} \zeta \dot{r}^1 {\Phi'}^2\, dz\, dt \\ &\qquad = \sum_{i=1}^{m_0} \int_{\bar{t}_1}^{\bar{t}_2} \int_{[C_i \cup B_i]-z^i} \zeta \dot{r}^i (\Phi'(z+z^i,t))^2\, dz\, dt \overset{\varepsilon \to 0}{\to} \int_{\bar{t}_1}^{\bar{t}_2} \frac{4}{3} \zeta \sum_{i=1}^{m_0} \partial_t \bar{r}^i\, dt. \end{aligned} \tag{6.11}$$

We know from Proposition 4.2 that $\partial_t r^i \longrightarrow \partial_t \bar{r}^i$ weakly in $L^2(\bar{t}_1,\bar{t}_2)$. Therefore, (6.11) is true if we show that

$$\int_{[C_i \cup B_i]-z^i} (\Phi'(z+z^i,t))^2\, dz \longrightarrow \frac{4}{3} \quad \text{strongly in } L^2(\bar{t}_1,\bar{t}_2). \tag{6.12}$$

This amounts to showing that we can replace Φ by Φ_0 in (6.11) since $\int_{-\infty}^{\infty} (\Phi_0')^2\, dz = \int_{-\infty}^{\infty} (1-\tanh^2(z))^2\, dz = \frac{4}{3}$, but this follows from Corollary 5.9 and the energy bound.

Next, we claim that

$$\begin{aligned} &\int_{\bar{t}_1}^{\bar{t}_2} \int_{-\varepsilon^{-\alpha}+z^{m_0}}^{\varepsilon^{-\alpha}} \varepsilon \zeta \Phi' \Phi_t\, dz\, dt \\ &\qquad = \sum_{i=1}^{m_0} \int_{\bar{t}_1}^{\bar{t}_2} \int_{[C_i \cup B_i]-z^i} \varepsilon \zeta \Phi'(z+z^i,t) \Phi_t(z+z^i,t)\, dz\, dt \overset{\varepsilon \to 0}{\to} 0. \end{aligned} \tag{6.13}$$

First, as usual, we replace Φ' by Φ_0'. This time this is possible because

$$\varepsilon \left(\int (\Phi_t)^2\, dz\, dt \right)^{\frac{1}{2}} \leq C, \tag{6.14}$$

while $\int(\Phi' - \Phi_0')^2\,dz\,dt \longrightarrow 0$ by Corollary 5.9. In order to show estimate (6.14), we proceed as in [S1] and prove the following a priori estimate on $\partial_t\Phi$:

$$\begin{aligned}\int |\Phi_t|^2\,dz\,dt &\le 2\int |\Phi_t - \frac{\dot r^1}{\varepsilon}\Phi'|^2\,dz\,dt + \frac{2}{\varepsilon^2}\int |\dot r^1|^2|\Phi'|^2\,dz\,dt\\ &\le \frac{2}{\varepsilon R_0^{n-1}}\int_0^T\int_\Omega |\partial_t\varphi(x,t)|^2\,dx\,dt + \frac{2}{\varepsilon R_0^{n-1}}\\ &\underset{t\in(0,T)}{\rightarrow} \sup\int_\Omega |\nabla\varphi(x,t)|^2\,dx\int_0^T |\dot r^1|^2\,dt \le \frac{C(R_0)}{\varepsilon^2}.\end{aligned}$$

Therefore, we may substitute Φ' by Φ_0' in (6.13) and only have to show that

$$\varepsilon\sum_{i=1}^{m_0}\int_{\bar t_1}^{\bar t_2}\int_{[C_i\cup B_i]-z^i}\zeta\Phi_t\Phi_0'(z+z^i,t)\,dz\,dt \overset{\varepsilon\to 0}{\to} 0. \tag{6.15}$$

Since in B_i we know that $\Phi_0' \overset{\varepsilon\to0}{\to} 0$ pointwise, using (6.14), we obtain

$$\left|\int_{\bar t_1}^{\bar t_2}\int_{B_i-z^i}\varepsilon\zeta\Phi_t\Phi_0'(z+z^i,t)\right|\,dz\,dt \le C + \int_{\bar t_1}^{\bar t_2}\int_{B_i}(\Phi_0')^2\,dz\,dt \overset{\varepsilon\to0}{\to} 0.$$

Now we note the essential fact that in $C_i - z^i$ we have $\Phi_0(z+z^i) = \tanh((-1)^{i+1}z+\mu_\varepsilon)$, so $\partial_t\Phi_0' = 0$. Therefore, we obtain

$$\begin{aligned}\varepsilon\sum_{i=1}^{m_0}\int_{\bar t_1}^{\bar t_2}\int_{C_i-z^i}\zeta\Phi_t\Phi_0'(z+z^i,t)\,dz\,dt &= -\varepsilon\sum_{i=1}^{m_0}\int_{\bar t_1}^{\bar t_2}\int_{B_i-z^i}\partial_t\zeta\Phi\Phi_0'(z+z^i,t)\,dz\,dt\\ - \varepsilon\sum_{i=1}^{m_0}\int_{\bar t_1}^{\bar t_2}\zeta\Phi\Phi_0'|_{\frac{z^{i+1}+z^i}{2}+1}\frac{\dot r^{i+1}-\dot r^i}{2\varepsilon}\,dt &+ \varepsilon\sum_{i=1}^{m_0}\int_{\bar t_1}^{\bar t_2}\zeta\Phi\Phi_0'|_{\frac{z^{i-1}+z^i}{2}-1}\frac{\dot r^{i-1}-\dot r^i}{2\varepsilon}\,dt.\end{aligned}$$

Since $\Phi_0'(\cdot + z^i) \in L^1(R)$ and since Φ is bounded, the first sum converges to 0 with ε. For the second and third terms, we use the fact that $\dot r^i$ converge weakly in L^2 and the fact that $\Phi_0'(\frac{z^{i+1}+z^i}{2} - 1) \overset{\varepsilon\to0}{\to} 0$ pointwise and thus in L^2. This finishes the proof of (6.15) and hence of (6.9).

If $\bar r_0 = 1$, the only difference in our strategy is that we integrate (6.1) over $(-\varepsilon^{-\alpha} + z^{m_0}, \min(\varepsilon^{-\alpha}, \frac{1-r_\varepsilon^1}{\varepsilon}))$. Then everything remains the same, only (6.3) must be changed into

$$\lim_{\varepsilon\to0}\int_{\bar t_1}^{\bar t_2}\frac{1}{\varepsilon}\left(\frac{1}{2}(\Phi')^2 - W(\Phi)\right)\Bigg|_{-\varepsilon^{-\alpha}+z^{m_0}}^{\min(\varepsilon^{-\alpha},\frac{1-r_\varepsilon^1}{\varepsilon})}\zeta\,dt \le 0.$$

In summary, we have evaluated the limit of each term in (6.2). Therefore, using equation (6.2) and the limit of each term given by (6.3), (6.4), (6.8), and (6.9), we have shown that in the limit as $\varepsilon \to 0$, we obtain the equation

$$-\int_{\bar t_1}^{\bar t_2}\frac{4}{3}\zeta\sum_{i=1}^{m_0}\left(\dot{\bar r}^i + \frac{n-1}{\bar r^i}\right)dt = 2\nu\int_{\bar t_1}^{\bar t_2}\zeta\lambda_0\,dt, \tag{6.16}$$

or the inequality with $\le$ if $\bar r_0$ was in the fixed boundary of the domain. This limit was obtained in the box B defined in Proposition 4.2. □

The next lemma is essential in studying the issue of multiplicities.

LEMMA 6.2. *Let $(\bar{t}_0, \bar{r}_0)$ be as in Proposition* 6.1. *Then if $\nu(\bar{t}_0, \bar{r}_0) \neq 0$ and $\bar{r}_0 \neq 1$,*

$$-\left(\dot{\bar{r}}^k + \frac{n-1}{\bar{r}^k}\right) \geq \frac{3}{2}\nu(\bar{r}_0, \bar{t}_0)\lambda_0 \geq -\left(\dot{\bar{r}}^{m_0+k-1} + \frac{n-1}{\bar{r}^{m_0+k-1}}\right) \qquad \textit{in } (\bar{t}_1, \bar{t}_2), \tag{6.17}$$

and if $\bar{r}_0 = 1$, then the second of the above inequalities holds.

Proof. We again assume that $k = 1$. Without loss of generality, assume that $\nu = 1$. Now, instead of integrating (6.2) over $(-\varepsilon^{-\alpha} + z^{m_0}, \varepsilon^{-\alpha})$, we integrate only over the last branch of Φ. More precisely, let $c_\varepsilon(t)$ be the first negative point where $\Phi'(\cdot, t)$ vanishes. We note that in the same way that we proved that $|z^{i+1} - z^i| \overset{\varepsilon\to 0}{\to} \infty$ (cf. 5.25), we can show that $c_\varepsilon(t) \overset{\varepsilon\to 0}{\to} -\infty$ pointwise. We integrate (6.2) over $(c_\varepsilon, \varepsilon^{-\alpha})$ and use the same arguments as before to obtain the limit as $\varepsilon \to 0$. This gives an inequality for $\dot{\bar{r}}_1$ similar to (6.16). We only point out the main differences with the previous case. The claim in (6.3) is replaced by

$$\lim_{\varepsilon\to 0}\int_{\bar{t}_1}^{\bar{t}_2} \zeta\frac{1}{\varepsilon}\left(\frac{1}{2}(\Phi')^2 - W(\Phi)\right)\Bigg|_{c_\varepsilon}^{\varepsilon^{-\alpha}} dt = \int_{\bar{t}_1}^{\bar{t}_2} \zeta \lim_{\varepsilon\to 0}\frac{1}{\varepsilon}W(\Phi(c_\varepsilon))\, dt,$$

and the proof is the same as before since $\Phi'(c_\varepsilon(t), t) = 0$.

The claim in (6.4) is replaced by

$$(n-1)\int_{\bar{t}_1}^{\bar{t}_2}\int_{-\varepsilon^{-\alpha}}^{c_\varepsilon} \zeta\frac{1}{\varepsilon z + r^1}|\Phi'|^2\, dz\, dt \overset{\varepsilon\to 0}{\to} \frac{4}{3}(n-1)\int_{\bar{t}_1}^{\bar{t}_2}\zeta\frac{1}{\bar{r}^1}\, dt,$$

and the proof is similar to that above since $c_\varepsilon \overset{\varepsilon\to 0}{\to} -\infty$.

The claim (6.8) is replaced by

$$\int_{\bar{t}_1}^{\bar{t}_2}\int_{-\varepsilon^{-\alpha}}^{c_\varepsilon} \zeta\lambda_\varepsilon\Phi'\, dz\, dt \overset{\varepsilon\to 0}{\to} 2\int_{\bar{t}_1}^{\bar{t}_2}\zeta\lambda_0\, dt.$$

The proof must be modified slightly since we only know that $\Phi(c_\varepsilon, t) \to -1$ pointwise and thus in L^2. However, this is enough to pass to the limit.

The claim (6.9) is replaced by

$$\int_{\bar{t}_1}^{\bar{t}_2}\int_{c_\varepsilon}^{\varepsilon^{-\alpha}} \zeta(\varepsilon\Phi_t\Phi' - \dot{r}^1{\Phi'}^2)\, dz\, dt \overset{\varepsilon\to 0}{\to} -\int_{\bar{t}_1}^{\bar{t}_2}\frac{4}{3}\zeta\partial_t\bar{r}^1\, dt,$$

and the proof is the same.

Thus, in the limit, we find that

$$-\int_{\bar{t}_1}^{\bar{t}_2}\frac{4}{3}\zeta\left(\dot{\bar{r}}^1 + \frac{n-1}{\bar{r}^1}\right)dt - \int_{\bar{t}_1}^{\bar{t}_2}\zeta\lim_{\varepsilon\to 0}\frac{1}{\varepsilon}W(\Phi(c_\varepsilon))\, dt = 2\int_{\bar{t}_1}^{\bar{t}_2}\zeta\lambda_0\, dt.$$

Similarly, we can integrate (6.2) over $(-\varepsilon^{-\alpha} + z^{m_0}, d_\varepsilon)$, where d_ε is the first point to the right of z^{m_0} for which Φ' vanishes. Since $\Phi_0(-\varepsilon^{-\alpha} + z^{m_0}) \overset{\varepsilon\to 0}{\to} -1$ and $\Phi_0(d_\varepsilon) \overset{\varepsilon\to 0}{\to} 1$, this yields

$$-\int_{\bar{t}_1}^{\bar{t}_2}\frac{4}{3}\zeta\left(\dot{\bar{r}}^{m_0} + \frac{n-1}{\bar{r}^{m_0}}\right)dt + \int_{\bar{t}_1}^{\bar{t}_2}\zeta\lim_{\varepsilon\to 0}\frac{1}{\varepsilon}W(\Phi(d_\varepsilon))\, dt = 2\int_{\bar{t}_1}^{\bar{t}_2}\zeta\lambda_0\, dt$$

in the limit. Since $W \geq 0$, we conclude for $\zeta \geq 0$ that

$$-\int_{\bar{t}_1}^{\bar{t}_2} \frac{4}{3}\zeta\left(\dot{\bar{r}}^1 + \frac{n-1}{\bar{r}^1}\right) dt \geq 2\int_{\bar{t}_1}^{\bar{t}_2} \zeta\lambda_0 \, dt,$$
$$-\int_{\bar{t}_1}^{\bar{t}_2} \frac{4}{3}\zeta\left(\dot{\bar{r}}^{m_0} + \frac{n-1}{\bar{r}^{m_0}}\right) dt \leq 2\int_{\bar{t}_1}^{\bar{t}_2} \zeta\lambda_0 \, dt.$$

This proves the lemma. □

Proposition 6.3 (evolution equation). *Let A_{R_0} be as in* (4.2). *Then the interfaces $\bar{r} = \bar{r}^i$ defined in* (4.5) *evolve in their domain of existence $I^i_{R_0} \cap \{\bar{r}^i < 1\}$ according to*

$$-\left(\dot{\bar{r}} + \frac{n-1}{\bar{r}}\right) = \frac{3}{2}\nu(\cdot,\bar{r})\lambda_0. \tag{6.18}$$

In addition, for almost all $(\bar{t}_0, \bar{r}_0) \in \Gamma_{R_0}$ with $\bar{r}_0 < 1$,

$$\textit{either} \quad \nu(\bar{t}_0,\bar{r}_0)\lambda_0(\bar{t}_0) = 0 \quad \textit{or} \quad m_0(\bar{t}_0,\bar{r}_0) = 1. \tag{6.19}$$

Proof. Define for any $M_0 \geq k \geq j \geq 1$ the set (formally setting $\bar{r}^0 = +\infty$ and $\bar{r}^{M_0+1} = -\infty$)

$$I := \{\bar{t}_0 \in A_{R_0} \mid \bar{r}^{j-1} > \bar{r}^j = \cdots = \bar{r}^k > \bar{r}^{k+1} \text{ at } \bar{t}_0\}.$$

There exist only finitely many j and k as above, and any t has to be in one of the corresponding I's. Therefore, if we prove the claim in I, this proves the proposition.

For any $\bar{t}_0 \in I$ and $\bar{r}_0 := \bar{r}^j(\bar{t}_0)$,

$$m_0(\bar{t}_0,\bar{r}_0) = k - j + 1 \quad \text{and} \quad \nu(\bar{t}_0,\bar{r}_0) = \pm 1 \quad \text{if } m_0 \text{ is odd.}$$

Note that almost everywhere in I,

$$\dot{\bar{r}}^j = \cdots = \dot{\bar{r}}^k,$$

and thus Proposition 6.1 implies that almost everywhere in I (if $\bar{r}^j < 1$),

$$-m_0\left(\dot{\bar{r}}^j + \frac{n-1}{\bar{r}^j}\right) = -\sum_{i=j}^{k}\left(\dot{\bar{r}}^i + \frac{n-1}{\bar{r}^i}\right) = \frac{3}{2}\nu(\cdot,\bar{r}^j)\lambda_0. \tag{6.20}$$

If m_0 is even, then $\nu = 0$ almost everywhere in I and thus the differential equation (6.18) is immediate.

If m_0 is odd, then Lemma 6.2 applies, giving

$$-\left(\dot{\bar{r}}^j + \frac{n-1}{\bar{r}^j}\right) \geq \frac{3}{2}\nu(\cdot,\bar{r}^j)\lambda_0 \geq -\left(\dot{\bar{r}}^k + \frac{n-1}{\bar{r}^k}\right) \quad \text{in } I.$$

However, since both sides agree, the differential equation (6.18) is satisfied.

Finally, subtracting the differential equation (6.18) from (6.20) implies

$$(1 - m_0)\left(\dot{\bar{r}}^j + \frac{n-1}{\bar{r}^j}\right) = 0.$$

Thus either $m_0 = 1$ or $\dot{\bar{r}}^j + \frac{n-1}{\bar{r}^j} = 0$, the latter in turn implying that $\lambda_0 = 0$. This completes the proof. □

Now we have to identify the limit Lagrange multiplier λ_0. To determine λ_0 in terms of the interfaces of v, we use the mass-conservation property of nonlocal flow, namely

$$\partial_t \int_\Omega \varphi_\varepsilon(x,t)\, dx = 0 \quad \text{and hence} \quad \partial_t \int_\Omega v(x,t)\, dx = 0.$$

Since these are nonlocal quantities, we have to remove the constraint $r > R_0 > 0$.

Definition 6.4. *In* (4.5) *we defined interfaces*

$$\bar{r}^i : I^i_{R_0} \subset A_{R_0} \to (R_0, 1] \qquad \textit{for } i = 1, \ldots, M_0$$

with the property that $\bar{r}^i \geq \bar{r}^{i+1}$ and $\bar{r}^i = R_0$ on $\partial I^i_{R_0} \cap A_{R_0}$. These interfaces are locally Hölder-$\frac{1}{2}$.

For a sequence $R_0 \to 0$, we now define

$$A := \bigcap_{R_0 \to 0} A_{R_0}. \tag{6.21}$$

Then since this is a countable intersection, the complement of A has at most countably many points. In addition, we define $I^i := \bigcup_{R_0 \to 0} I^i_{R_0}$ and

$$R^i : I^i \longrightarrow (0,1] \qquad \textit{for } i = 1, \ldots \tag{6.22}$$

by $R^i(t) := \bar{r}^i(t)$ if $t \in I^i_{R_0}$. Then, in particular, $I^i_{R_0} \cap A = \{t \in A \mid R^i(t) > R_0\}$.

This definition is reasonable since on the intersections of $I^i_{R_0}$'s with different R_0, the corresponding $\bar{r}^i$'s agree. For any R_0, the $\bar{r}^i$'s were constructed (see section 4) by selecting subsequences, and using a diagonal sequence, we may assume that the subsequence does not depend on R_0. Thus the limit graphs $\bar{r}^i$ coincide in the intersections of the sets $A_{R_0} \times (R_0, 1]$.

We note that by definition, $m_0(\bar{t}_0, \bar{r}_0) = \#\{i \mid R^i(\bar{t}_0) = \bar{r}_0\}$ and $\nu_0(\bar{t}_0, \bar{r}_0) = 0$ if m_0 is even.

Proposition 6.5 (the Lagrange multiplier). *In the set A, the limit Lagrange multiplier is given by*

$$\lambda_0 = -\frac{2}{3} \frac{(n-1) \sum \nu(R^i)(R^i)^{n-2}}{\sum |\nu(R^i)|(R^i)^{n-1}},$$

where summation is over all interfaces of radii strictly less than 1. *If the space dimension is strictly larger than* 2, *then $\lambda_0 \neq 0$. If the space dimension is equal to* 2, *then $\lambda_0 \neq 0$ in case of an odd number of interfaces and identically zero in case of an even number of interfaces.*

Proof. Since $\varphi_\varepsilon \to v$ in L^1 and $v = \pm 1$ almost everywhere, the same is true for

$$\chi_\varepsilon := \frac{\varphi_\varepsilon - a_\varepsilon}{|\varphi_\varepsilon - a_\varepsilon|}.$$

By construction, for $t \in A_{R_0}$, the function $\chi_\varepsilon(t, \cdot)$ has discontinuities at $r^i_\varepsilon(t)$ in $[R_0, 1)$ for $i = 1, \ldots, M_0$ (formally setting $r^i_\varepsilon(t) = R_0$ if $r^i_\varepsilon(t)$ is not defined). Thus for $t \in A_{R_0}$

and $\varepsilon \to 0$,

$$\int_{|x|>R_0} v\,dx \longleftarrow \int_{|x|>R_0} \chi_\varepsilon\,dx = \pm\frac{1}{n}\left\{2\sum_{i=1}^{M_0}(-1)^{i+1}(r_\varepsilon^i)^n + (-1)^{M_0+1}(R_0)^n - 1\right\}$$
$$\longrightarrow \pm\frac{1}{n}\left\{2\sum_{i=1}^{M_0}(-1)^{i+1}(\bar{r}^i)^n + (-1)^{M_0+1}(R_0)^n - 1\right\},$$

where we formally set $\bar{r}^i(t) = R_0$ if $t \notin I^i_{R_0}$. Differentiating the resulting identity yields

$$\partial_t \int_{|x|>R_0} v\,dx = \pm 2\sum_{i=1}^{M_0}(-1)^{i+1}(\bar{r}^i)^{n-1}\dot{\bar{r}}^i \quad \text{for } t \in A_{R_0}.$$

This can be rewritten as

$$\partial_t \int_{|x|>R_0} v\,dx = \left\{\pm 2\sum_{i=1}^{M_0}(-1)^{i+1}(\bar{r}^i)^{n-1}\dot{\bar{r}}^i\right\}\chi + \mu_{R_0}, \tag{6.23}$$

where χ is the characteristic function of A and μ_{R_0} is a measure with support in $(0,T)\backslash A$.

Since $v \in BV((0,T)\times\Omega)$, we know that $\int_{|x|>R_0} v\,dx \in BV(0,T)$ uniformly bounded with respect to R_0 and thus, since $\int_{|x|>R_0} v\,dx \to \int_\Omega v\,dx$,

$$\partial_t \int_{|x|>R_0} v\,dx \overset{*}{\longrightarrow} 0 = \partial_t \int_\Omega v\,dx \quad \text{in } [C^0(0,T)]'. \tag{6.24}$$

We now use the differential equation (6.18) to calculate the limit of the sum in (6.23):

$$\sum_{i=1}^{M_0}(-1)^{i+1}(\bar{r}^i)^{n-1}\dot{\bar{r}}^i$$
$$= -\frac{3}{2}\lambda_0 \sum_{i=M_1(t)}^{M_2(t)}(-1)^{i+1}\nu(\bar{r}^i)(\bar{r}^i)^{n-1} - (n-1)\sum_{i=M_1(t)}^{M_2(t)}(-1)^{i+1}(\bar{r}^i)^{n-2},$$

where $M_2(t) := \#\{i \mid \bar{r}^i(t) > R_0\}$ and $M_1(t)$ is the first index such that the corresponding interface is less than 1.

We assume without loss of generality that v is positive near $\partial\Omega$. Then we remark that if $\nu(\bar{r}^i) \neq 0$, then $(-1)^{i+1} = -\nu(\bar{r}^i)$ because for any i with $\nu(\bar{r}^i) = 0$, an even number of interfaces collide. In the second sum, we may substitute $(-1)^{i+1}$ with $-\nu(\bar{r}^i)$ because either they agree or $(\bar{r}^i)^{n-2}$ is added up an even number of times with alternating signs. Thus

$$\sum_{i=1}^{M_0}(-1)^{i+1}(\bar{r}^i)^{n-1}\dot{\bar{r}}^i$$
$$= -\frac{3}{2}\lambda_0 \sum_{i=M_1(t)}^{M_2(t)}|\nu(\bar{r}^i)|(\bar{r}^i)^{n-1} - (n-1)\sum_{i=M_1(t)}^{M_2(t)}\nu(\bar{r}^i)(\bar{r}^i)^{n-2}.$$

We now want to pass to the limit $R_0 \to 0$. This is possible thanks to the following bounds. Since the jumps of v are exactly given by the interfaces R^i, with $\nu(R^i) \neq 0$, we have the formula

$$\sup_{(0,T)} \int_\Omega |\nabla v| = \sup_A \omega_n \sum_{i=1}^{\infty} |\nu(R^i)|(R^i)^{n-1} \leq C.$$

For the second sum, we apply Proposition 3.4. By lower semicontinuity, estimate (3.12) carries over to the limit $g(v) = \frac{4}{3}v$ and thus

$$\int_0^T \int_0^1 |v'| r^{n-2}\, dr\, dt = \int_A \sum_{i=1}^{\infty} |\nu(R^i)|(R^i)^{n-2}\, dt \leq C.$$

Thus we know that for almost any $t \in A$, all of the sums converge absolutely as $R_0 \to 0$, and by the monotone convergence theorem, this convergence (after multiplication with χ as in (6.23)) is in $L^1(0,T)$:

$$\left\{ \sum_{i=1}^{M_0} (-1)^{i+1} (\bar{r}^i)^{n-1} \dot{\bar{r}}^i \right\} \chi$$
$$\overset{R_0 \to 0}{\longrightarrow} \left\{ -\frac{3}{2}\lambda_0 \sum_{i=M_1(t)}^{\infty} |\nu(R^i)|(R^i)^{n-1} - (n-1) \sum_{i=M_1(t)}^{\infty} \nu(R^i)(R^i)^{n-2} \right\} \chi.$$

This together with (6.23) and (6.24) implies

$$\mu_{R_0} \overset{*}{\longrightarrow} \mu = 0$$

and

$$\frac{3}{2}\lambda_0 \sum_{i=M_1(t)}^{\infty} |\nu(R^i)|(R^i)^{n-1} + (n-1) \sum_{i=M_1(t)}^{\infty} \nu(R^i)(R^i)^{n-2} = 0$$

almost everywhere in A. □

We now summarize the results of this section in the following theorem.

THEOREM 6.6 (the limit equation). *Suppose that φ_ε is a smooth, radial solution of* (1.1) *with boundary condition* (1.2) *which satisfies* (2.1) *and* (2.2). *Then for the limit v of this sequence* (*cf. Remark* 2.4), *the free boundary $\Gamma := \partial\{v = -1\}$ is given by a collection of continuous graphs*

$$r^i : [t_i, T_i] \longrightarrow [0,1]$$

with the following conditions:

(1) $0 < r^i < 1$ *in* (t_i, T_i).

(2) r^i *is locally Lipschitz continuous in* $\{r^i > 0\} \cap [t_i, T_i]$.

(3) $\dot{r}^i \leq 0$ *almost everywhere in* (t_i, T_i).

(4) $t_i = 0$, $r^i(t_i) = 1$, *or* $t_i = t_j$ *for some* $j \neq i$ *and* $r^i(t_i) = r^j(t_j)$.

(5) $T_i = T$, $r^i(T_i) = 0$, *or* $T_i = T_j$ *for some* $j \neq i$ *and* $r^i(T_i) = r^j(T_j)$.

(6) *Two different graphs* r^i *and* r^j *agree at most at finitely many points.*

(7) *The direction of jump* $\nu^i(t) := \nu(t, r^i(t)) = \pm 1$ *is constant for* $t \in (t_i, T_i)$ *and—if the space dimension is larger than* 2 *or if the space dimension is* 2 *and the total number of interfaces is odd—then the multiplicity satisfies* $m_0(t, r^i(t)) = 1$.

(8) r^i *satisfies the nonlocal differential equation*

$$-\frac{4}{3}\left(\dot{r}^i + \frac{n-1}{r^i}\right) = 2\nu^i\lambda_0 \qquad in\ (t_i, T_i). \tag{6.25}$$

(9) *In* (8) *above, the Lagrange multiplier* λ_0 *is given by*

$$\lambda_0 = -(n-1)\frac{2}{3}\frac{\sum \nu^i (r^i)^{n-2}}{\sum (r^i)^{n-1}}$$

and changes sign exactly at times t_i *with* $r^i(t^i) = 1$.

The graphs r^i *correspond (up to renumbering) one to one to the true interfaces* R^j *given by* (6.22). *If the initial data have only finitely many true interfaces, than the number of true interfaces is finite at any given time. There might exist phantom interfaces which all evolve by mean curvature.*

Proof. By Proposition 6.3, we know that in $I^i_{R_0}$ the evolution equation is satisfied, and by Proposition 6.5, we have a formula for the Lagrange multiplier. Combining both propositions, we see

$$\dot{R}^i \le 0 \Longleftrightarrow \sum_j \nu(R^j)\nu(R^i)R^i(R^j)^{n-2} \le \sum_j |\nu(R^j)|(R^j)^{n-1}, \tag{6.26}$$

where summation is over all interfaces of radii less than 1. However, if k is the smallest index such that the corresponding interface has radius less than 1 and nonzero ν, then

$$\begin{aligned} \sum_j \nu(R^j)\nu(R^i)R^i(R^j)^{n-2} &\le \begin{cases} |\nu(R^i)|R^i(R^k)^{n-2} & \text{if } i \le k, \\ 0 \quad \text{otherwise} \end{cases} \\ &\le (R^k)^{n-1} \le \sum_j |\nu(R^j)|(R^j)^{n-1}. \end{aligned} \tag{6.27}$$

This proves that $\dot{R}^i \le 0$ in $I^i_{R_0}$ for any $R_0 > 0$.

Since mass is conserved, the denominator in the formula for λ_0 is bounded from below, and since the nominator is an alternating sum, λ_0 is uniformly bounded.

The sign of λ_0 is given by the sign of the first nonvanishing $\nu(R^j)$ that corresponds to some $R^j < 1$. Thus the sign of λ_0 changes only if some R^j with $\nu(R^j) \neq 0$ emerges from the fixed boundary. Since the number of interfaces larger than any R_0 is finite this may only occur at finitely many points.

Now suppose $t \in A_{R_0}$ for some R_0. Fix $R^j(t)$ and $R^k(t)$ with $j < k$ and assume that there exists for both $(R^j(t), t)$ and $(R^k(t), t)$ a neighborhood such that in these neighborhoods, $\nu(R^j) = \nu_j$ and $\nu(R^k) = \nu_k$ are constant and nonzero. Thus by the differential equation (6.18),

$$\begin{aligned} \dot{R}^j - \dot{R}^k &= \frac{n-1}{R^k} - \frac{n-1}{R^j} + \frac{3}{2}\,\lambda_0(\nu_k - \nu_j) \\ &> \frac{3}{2}\,\lambda_0(\nu_k - \nu_j), \end{aligned} \tag{6.28}$$

and hence the distance between R^j and R^k increases if $\lambda_0(\nu_k - \nu_j) \ge 0$. This is true in particular if $\nu_k = \nu_j$.

In the case where the dimension of the space $n \ge 3$, we know from (6.19) and Proposition 6.5 that for almost every $t \in A_{R_0}$, the condition $\nu(t, R^j(t)) \neq 0$ implies

$m_0 = 1$. By the definition of m_0, this implies that for almost all t and all points $(R^j(t), t)$ with $R^j(t) > R_0$ and $\nu(t, R^j(t)) \neq 0$, there exists a box B such that the set $\Gamma_{R_0} \cap B$ consists exactly of the corresponding R^j. Thus observation (6.28) implies that the distance between all interfaces R^k and R^j increases if they have the same normal, and hence such interfaces can never meet. As a consequence, we find that if two R^j and R^k with a nonvanishing normal meet at some point t, then $\nu_j - \nu_k$ is in either the set $\{2, 0\}$ or the set $\{0, -2\}$ in a whole neighborhood of the meeting point and consequently does not change sign. Thus (6.28) shows that either $\dot{R}^j - \dot{R}^k \geq 0$ or $\dot{R}^j - \dot{R}^k \leq 0$ in any one-sided neighborhood of the meeting point because the sign of λ_0 changes at most at finitely many times and $\frac{n-1}{R^k} - \frac{n-1}{R^j}$ is Lipschitz continuous in the neighborhood. Thus there are exactly three possibilities for geometric singularities in A_{R_0}: (i) two true interfaces meet and then form a single phantom interface; (ii) two interfaces nucleate out of a single phantom interface; or (iii) two true interfaces meet and immediately separate again. Phenomenon (iii) occurs only if λ_0 changes sign at that time point. Of course, phantom interfaces cannot meet each other because they move by mean curvature. Moreover, they can only meet any of the true interfaces where the latter cease to exist because otherwise the density m_0 would be larger than 1 on a true interface.

Similar arguments apply for $n = 2$. Indeed, in that case, the Lagrange multiplier locally either has a fixed sign or is identically zero. In the first case, the same analysis as above applies because the density m_0 of interfaces with nonvanishing normal is 1 again. In the second case, all the interfaces move by mean curvature and cannot meet anyway.

The limit v satisfies the weak Hölder-continuity estimate in Remark 2.11. For true interfaces, it implies that at the points of $N(R_0)$ (see (2.12) and Proposition 3.2 for the definition), only one of the following behaviors of the graphs R^j is possible.

At most two true interfaces can meet or nucleate at a point $t \in N(R_0)$. Two meeting true interfaces can only nucleate into two true interfaces across $t \in N(R_0)$ if λ_0 changes sign at this time point, and this can only happen if a true interface nucleates from the fixed boundary.

Any true interface that does not meet with another one at times in $N(R_0)$ continues as a single true interface across this time point.

When there exists a continuation, it has to be of class Hölder-$\frac{1}{2}$ and thus the differential equation is satisfied across that point.

These arguments allow us to conclude that the free boundary $\partial\{v = -1\}$ consists of a collection of graphs that have properties (1)–(10).

Thus the proof of Theorem 6.6 is complete. □

Remark 6.7. The evolution equation is the radial version of the expected limiting nonlocal geometric problem

$$V_i - k_i = -\frac{1}{\sum_j |\Gamma_j|} \sum_j \int_{\Gamma_j} k_j \, ds,$$

where V_i is the normal velocity and k_i is the sum of the principal curvatures of the interface Γ_i.

Note that in the right-hand side of (6.25), we sum only over interfaces R^i such that $\nu(R^i) \neq 0$. These interfaces represent exactly the free boundary of v. If $\nu(R^i) = 0$, these phantom interfaces are not seen by the limit v and they correspond to collapsing ε-interfaces. They do not have an impact on the evolution of the other interfaces.

Example 6.8. Colliding interfaces are generic to the nonlocal flow. Indeed, if two interfaces are sufficiently close to each other initially, sufficiently close with respect to their distance to the others and to their own size, then they have to meet before the smaller of them has time to shrink to 0.

Let $n = 3$ and assume that there are three initial interfaces. Then their evolution, as long as they all exist, is governed by

$$-\left(\dot{R}^i + \frac{n-1}{R^i}\right) = -(-1)^{i+1}(n-1)\mu_0,$$

where

$$\mu_0 = \frac{R^1 - R^2 + R^3}{(R^1)^2 + (R^2)^2 + (R^3)^2}.$$

Therefore

$$\dot{R}^3 \geq -\frac{n-1}{R^3}$$

and thus $(R^3)^2(t) \geq -2(n-1)t + (R^3)^2(0)$. Thus R^3 cannot disappear at the origin as long as $t \leq t_{\max} = \frac{1}{2(n-1)}(R^3)^2(0)$.

Since mass is preserved, the largest interface is bounded below by some number $R_{\min}$, which is such that the mass of a ball of radius $R_{\min}$ equals the initial mass:

$$(R_{\min})^3 = \left((R^1)^3 - (R^2)^3 + (R^3)^3\right)(0).$$

Since all interfaces are decreasing, this implies the following bound for μ_0:

$$\mu_0 \geq \frac{R_{\min} - R^2(0)}{((R^1)^2 + (R^2)^2 + (R^3)^2)(0)}.$$

Subtracting the equation for the second and third interface results in

$$\dot{R}^2 - \dot{R}^3 = \frac{n-1}{R^3} - \frac{n-1}{R^2} - 2(n-1)\mu_0 \leq -2(n-1)\mu_0.$$

Now suppose the interfaces R^2 and R^3 do not meet before R^3 vanishes. Then we can integrate the above inequality, use the bound for μ_0, and evaluate the result at $t_{\max}$ to find

$$0 \leq (R^2 - R^3)(t_{\max}) \leq -\frac{R_{\min} - R^2(0)}{((R^1)^2 + (R^2)^2 + (R^3)^2)(0)} + (R^2 - R^3)^2(0).$$

If $(R^2 - R^3)^2(0)$ is small, then $R_{\min}$ is approximately $R^1(0)$ and it is clearly possible to choose initial data for R^1 that contradicts the above inequality. Thus R^2 and R^3 have to meet before the smaller one has time to disappear. After the meeting point, the evolution becomes stationary and $R^1 = R_{\min}$.

Remark 6.9. Our estimates of section 5 are strong enough to prove that

$$E_0(t) = \frac{4}{3}\sum (R^i(t))^{n-1},$$

which contains contributions from all interfaces, both true and phantom. Thus jumps in the energy (which are responsible for the set of bad time points in the complement of A) correspond to either jumps in interfaces or jumps in multiplicity, the latter only possible for phantom interfaces. If we impose the condition that initially only finitely many and only true interfaces exist, then by the maximum principle for the ε-equation, no interfaces can nucleate from the origin as long as the smallest of the initial interfaces has not yet disappeared. Thus up to that time, only true interfaces exist and consequently have density 1 and are continuous.

Since the energy $E_*[v]$ of the limit (see (2.10) for the definition) counts only the true interfaces, we may identify any loss of energy in the limit as the appearance of phantom interfaces.

7. The viscous Cahn–Hilliard equation. Here we consider the viscous Cahn–Hilliard equation in $\Omega_T := \Omega \times (0,T)$ as introduced by Novick-Cohen [NC]:

$$\alpha\partial_t\varphi \;-\; \triangle u \;=\; 0, \tag{7.1}$$

$$u \;=\; -\varepsilon\triangle\varphi \;+\; \frac{1}{\varepsilon}W'(\varphi) \;+\; \nu\partial_t\varphi. \tag{7.2}$$

Imposing Neumann-zero boundary conditions for both u and φ and applying the usual techniques, one obtains the equations

$$\frac{1}{\alpha}\int_\Omega |\nabla u|^2\,dx \;+\; \partial_t E_\varepsilon(\varphi) \;+\; \nu\int_\Omega |\partial_t\varphi|^2\,dx \;=\; 0 \tag{7.3}$$

and

$$\int_\Omega \partial_t\varphi\,dx \;=\; 0 \quad\text{ and }\quad \fint_\Omega u\,dx \;=\; \frac{1}{\varepsilon}\fint_\Omega W'(\varphi)\,dx. \tag{7.4}$$

We shall show briefly how the viscous Cahn–Hilliard equation (7.1)–(7.2) relates both to the Cahn–Hilliard and the nonlocal Allen–Cahn equation.

Let us first consider the limit $\nu \to 0$, keeping all of the other parameters fixed. Formally, the limit problem is the standard Cahn–Hilliard equation. If the initial energy is uniformly bounded in ν, this can be shown rigorously. First, we note that estimate (7.3) immediately gives weak compactness in $L^2(\Omega_T)$ for $\nabla\varphi$ and a bound of φ in $L^4(\Omega_T)$. However, since the equation is nonlinear, it is important to have strong compactness in $L^1(\Omega_T)$ for φ. To this end, we note that equation (7.1) implies

$$\alpha||\partial_t\varphi||_{L^2(H^{-1,2})} \;=\; ||\nabla u||_{L^2(\Omega_T)} \;\le\; E_\varepsilon(\varphi)(0) \tag{7.5}$$

and thus (with $E_\varepsilon(\varphi)(0) \le C$)

$$\alpha||\varphi(\cdot,\cdot-h) - \varphi||_{L^2(H^{-1,2})} \;\le\; C\cdot h. \tag{7.6}$$

Now interpolating between $L^2(H^{-1,2})$ and $L^2(H^{1,2})$ yields

$$||\varphi(\cdot,\cdot+h) \;-\varphi||_{L^1(\Omega_T)} \;\le\; Ch^{\frac{1}{2}}. \tag{7.7}$$

This implies strong compactness for φ in $L^1(\Omega_T)$.

Of course the estimate for ∇u in (7.3) together with the bound of its mean value in (7.4) imply weak compactness in $L^2(\Omega_T)$ for both u and ∇u. This convergence is strong enough to pass to the limit $\nu \to 0$ in the viscous Cahn–Hilliard equation (7.1)–(7.2).

If the limit $\alpha \to 0$ is considered, the limit problem will be the nonlocal equation. To see this, assume once again that the energy is uniformly bounded in α. Then estimate (7.3) yields the L^1 compactness of the order parameter φ immediately, and the weak $L^2(\Omega_T)$ compactness of u and ∇u is again obtained from (7.3) and the mean-value condition (7.4). This compactness allows us to pass to the limit in (7.1) and (7.2). The limit of (7.1) gives $\triangle u = 0$ for the limit, and thus u is a constant, but then (7.4) yields the correct formula for u and we find the nonlocal equation in the limit.

Thus we see that both the nonlocal equation and the Cahn–Hilliard equation occur as special degenerate limits of the viscous Cahn–Hilliard equation.

Appendix. Ellipticity of the linearized Allen–Cahn equation. Here we give the proof of the ellipticity proposition (Proposition 5.6).

Proof of Proposition 5.6. Let S be one of the sets of integration as in Proposition 5.6. We start by integrating by parts the left-hand side of the claimed estimate (denoted (LHS)). This results in

$$\begin{aligned}\text{(LHS)} &= \int_S (-\Psi'' \ + \ W''(\Theta)\Psi)\Psi\xi^2 \, dz \\ &= \int_S \left(|\Psi'|^2 \ + \ W''(\Theta)\Psi^2\right)\xi^2 \, dz \ + \ 2\int_S \Psi'\Psi\xi'\xi \, dz. \end{aligned} \tag{A.1}$$

Here we should point out that Ψ is not necessarily smooth at $z = z_\varepsilon^i$, but since Ψ vanishes at these points, the integration by parts is nevertheless valid. Now we note that $W''(\Theta) = 2(3\Theta^2 - 1)$, and in the set where this function is strictly positive, there is nothing to prove. A careful study of Θ will show that the measure of the set where W'' is not strictly positive is small enough that the integral of Ψ^2 over this set can still be controlled by the integral of Ψ'^2.

Thus we introduce for any $a > 0$ the set

$$I_\varepsilon \ := \ \{W''(\Theta) \ < \ 2a\} \cap (-\varepsilon^{-\beta} + z_\varepsilon^{m_\varepsilon}, \varepsilon^{-\beta}). \tag{A.2}$$

We want to estimate the diameter of any connected component of I_ε. By the definitions in (5.5) and (5.6)

$$\Theta(z) \ = \ \sum_i \Xi_i(z)\tanh((-1)^i(z - z_\varepsilon^i) + \mu_\varepsilon) \ + \ \varepsilon\Phi_1^\varepsilon(z)$$

with

$$||\Phi_1||_{L^\infty(-\varepsilon^{-\beta}+z_\varepsilon^{m_\varepsilon}, \varepsilon^{-\beta})} \ \leq \ C||\lambda_\varepsilon|| \ \leq \ \frac{C}{\sqrt{\varepsilon}} \quad \text{uniformly in time}$$

by Corollary 2.2 and Lemma 5.7.

Since $W''(\Theta) < 2a \;\Leftrightarrow\; |\Theta| < \sqrt{\frac{a+1}{3}}$, we thus find that

$$\begin{aligned} I_\varepsilon &\subset \left\{ \sum_i \Xi_i |\tanh((-1)^i(z - z_\varepsilon^i) + \mu_\varepsilon)| \;\le\; \sqrt{\frac{a+1}{3}} \;+\; C\varepsilon \right\} \\ &\subset \bigcup_i \left\{ \;|\tanh((-1)^i(z - z_\varepsilon^i) + \mu_\varepsilon)| \;\le\; \sqrt{\frac{a+1}{3}} \;+\; C\varepsilon \right\} \\ &\subset \bigcup_i \left\{ |z - z_\varepsilon^i| \;\le \tanh^{-1}\left(\sqrt{\frac{a+1}{3}} \;+ C\varepsilon \right) \;+\; |\mu_\varepsilon| \right\} \\ &=: \bigcup_i I^i. \end{aligned} \tag{A.3}$$

We return to (A.1). We continue to estimate as follows:

$$\begin{aligned} \text{(LHS)} \;\ge\; &\int_S |\Psi'|^2 \xi^2 \, dz \;+\; 2a \int_S \Psi^2 \xi^2 \, dz \\ &- (2+2a) \int_{I_\varepsilon} \Psi^2 \xi^2 \, dz \;+\; 2 \int_S \Psi' \Psi \xi' \xi \, dz. \end{aligned} \tag{A.4}$$

However, using $\Psi(z_\varepsilon^i) = 0$ gives

$$\begin{aligned} \int_{I_\varepsilon} \Psi^2 \xi^2 \, dz = \; &\sum_i \int_{I^i \setminus I^{i-1}} \xi^2 \Psi^2 \, dz \\ = \; &\sum_i \int_{I^i \setminus I^{i-1}} \xi^2 \left(\int_{z_\varepsilon^i}^z \Psi' \right)^2 \, dz \\ \le \; &\sum_i \int_{I^i \setminus I^{i-1}} |\Psi'|^2 \frac{1}{2} |I^i| \\ \le \; &\left(\tanh^{-1}\left(\sqrt{\frac{a+1}{3}} + C\varepsilon \right) \;+\; \tanh^{-1} Q \right) \int_S |\Psi'|^2 \xi^2 \, dz \end{aligned} \tag{A.5}$$

by (A.3) and since $|\mu_\varepsilon| = |\tanh^{-1} a_\varepsilon| \le \tanh^{-1} Q$. Note in addition that by construction $\bigcup I^i \subset \{\xi = 1\}$. We enter this into (A.4) and continue to estimate:

$$\begin{aligned} (LHS) \;\ge\; &\underbrace{\left(1 \;-\; (2+2a) \left(tanh^{-1} \left(\sqrt{\frac{a+1}{3}} + C\varepsilon \right) \;+\; tanh^{-1} Q \right) \right)}_{=: c_0(a,\varepsilon)} \int_S |\Psi'|^2 \xi^2 \, dz \\ &+\; 2a \int_S \Psi^2 \xi^2 \, dz \;+\; 2 \int_S \Psi' \Psi \xi' \xi \, dz. \end{aligned} \tag{A.6}$$

The number c_0 turns out to be positive if $\varepsilon = 0$ and $a = 0$ by the choice of Q in (4.1), and thus there exist positive ε_0 and a_0 such that

$$0 \;<\; c_0(\varepsilon_0, a_0) \;<\; c_0(\varepsilon, a_0)$$

for all $\varepsilon < \varepsilon_0$.

This proves the proposition with $\zeta_1 = \frac{1}{2} c_0(\varepsilon_0, a_0)$ and $\zeta_2 = 2a_0$ if we still use the Hölder estimate for $\int \Psi' \Psi \xi' \xi$. □

SPATIAL DECAY ESTIMATES FOR FLOW IN A POROUS MEDIUM*

J. CHADAM† AND Y. QIN‡

Abstract. In the spirit of the recent work of Ames, Payne, and Schaefer [*SIAM J. Math. Anal.*, 24 (1993), pp. 97–116], the decay of flow in a porous medium through a semi-infinite pipe is investigated. The analysis presented in this paper is based on the Brinkman–Forchheimer model. In establishing decay estimate and bounds for the total weighted energy, the nonlinear term in the model equation leads to difficulties which were not encountered in the paper cited above.

Key words. Brinkman–Forchheimer flow, decay estimates

1. Introduction.

In a recent paper [1], Ames et al. investigated the time-dependent Stokes flow of an incompressible viscous fluid in a semiinfinite cylindrical pipe. An exponential decay of a weighted energy expression was derived if the net flow through the finite end of the pipe is assumed to be zero for each t. Modeled on their work, we consider an analogous problem for flow in a porous medium based on a time-dependent nonlinear equation, namely the Brinkman–Forchheimer equation. While non-Darcy models in porous media have been increasingly discussed in the recent engineering literature, the related mathematical analysis for some problems based on these models is much less developed. In this paper, we shall study the spatial decay estimates for the Brinkman–Forchheimer flow.

Although the techniques used in the present study basically follow the suggestions in [1], the work reported here is not a trivial extension. Since the Stokes equation is a linear equation, the interesting feature of this paper is the extension of the analysis of decay estimates to a time-dependent nonlinear problem of pipe flow. An important point of our analysis is to ensure that the estimates depend only on the known data, i.e., the physical parameters, the initial and boundary data, and the geometry of the domain. The presence of the nonlinear term makes the problem considerably more complicated and new techniques must be developed to handle these difficulties. We obtain the bound by two steps. First, we compare the energy of the solution to the Brinkman–Forchheimer problem with the energy of the solution to the linearized Brinkman problem. We then show how to determine bounds on the energy of the linearized problem and the total energy bound to the nonlinear problem in a manner which depends only on the data. Our motivation comes from the earlier work of Horgan and Wheeler [10] and Ames and Payne [2] in studying decay estimates of steady pipe flow. The basic idea is originally due to Payne [14] in his investigation of the uniqueness criteria for steady-state solutions of the Navier–Stokes equation. Spatial decay estimates for similar flow in a planar region have been studied in [16]. This analysis depended heavily on the use of a stream function which could be obtained

through the elimination of the pressure. This trick is not possible in the present case of pipe flow and the interest here is to extend the analysis of the decay estimates without recourse to these methods.

For investigations of the spatial decay of solutions of elliptic and parabolic equations, see, e.g., [3, 4, 5, 6, 7, 9, 12] and the references cited therein.

In the next section, we formulate the initial-boundary value problem, which describes pipe flow in a porous medium. We derive a second-order differential inequality for the energy expression in section 3. A method for finding bounds on the estimates for both the nonlinear problem and corresponding linear problem is given in section 4. For comparison, we discuss the decay results for Darcy pipe flow in the last section.

2. Formulation of the problem. We begin this section by first introducing the model to be used in this paper. Most of the studies in porous media carried out to date have been based on the Darcy law, which is an empirical law for creeping flow through an infinitely extended uniform medium. However, researchers now generally recognize that non-Darcian effects are quite important for certain applications. For a discussion of generalized non-Darcy models, see Vafai and Tien [17], Hsu and Chen [11], and Prasad and Kladias [15]. Despite a difference of opinions as to what is the most appropriate form for modeling flow in porous media, the Brinkman–Forchheimer equation has wide acceptance in the porous media literature. The time-dependent momentum equation describing flow in a porous medium may be written as [13]

$$\rho_f c_a \frac{\partial \mathbf{u}}{\partial t} = -\nabla p_f + \mu_{\text{eff}} \nabla^2 \mathbf{u} - \frac{\mu_f}{k}\mathbf{u} - \frac{F\rho_f \phi}{k^{\frac{1}{2}}}|\mathbf{u}|\mathbf{u}, \tag{2.1}$$

where ρ_f is the density of the fluid, c_a is the acceleration coefficient, p_f is the intrinsic fluid pressure, $\mathbf{u}$ is the Darcy velocity, μ_f is the viscosity, μ_{eff} is the effective viscosity, k is the permeability, F is the Forchheimer coefficient, ϕ is the porosity, and $|\mathbf{u}| = \sqrt{u_1^2 + u_2^2 + u_3^2}$.

After scaling, the nondimensional form of (2.1) is

$$\mathbf{u}_t = \Delta \mathbf{u} - J_1 \mathbf{u} - J_2 |\mathbf{u}|\mathbf{u} - \nabla p, \tag{2.2}$$

where Δ is the three-dimensional Laplacian and J_1 and J_2 are two physical parameters, the first being the coefficient of the Darcy velocity and the second being the coefficient of inertial drag for flow in a porous medium.

Let R denote the interior of a semiinfinite cylindrical pipe of an arbitrary, smooth cross-section with generator parallel to the x_3-axis. The end (entrance) of the pipe in the $x_3 = 0$ plane is denoted by D_0 and comprises part of the boundary ∂R of R.

We let

$$R_z = \{(x_1, x_2, x_3) \mid (x_1, x_2) \in D_0, x_3 > z \geq 0\}$$

denote the subdomain of R for which $x_3 > z$ and let

$$D_z = \{(x_1, x_2, x_3) \mid (x_1, x_2) \in D_0, x_3 = z\}$$

denote the part of ∂R_z in the plane $x_3 = z \geq 0$.

The initial-boundary value problem that we consider here is

$$u_{i,t} = \Delta u_i - J_1 u_i - J_2 |\mathbf{u}| u_i - p_{,i} \quad \text{in } R \times (0, \infty), \tag{2.3}$$

$$u_{i,i} = 0 \quad \text{in} \quad \bar{R} \times (0,\infty), \tag{2.4}$$

$$u_i = 0 \quad \text{on} \quad \partial R \backslash D_0 \times (0,\infty), \tag{2.5}$$

$$u_i = f_i(x_1,\, x_2,\, t) \quad \text{in} \quad \bar{D}_0 \times (0,\infty), \tag{2.6}$$

$$u_i = 0 \quad \text{in } R \times \{0\}, \tag{2.7}$$

$$u_i,\, u_{i,j},\, u_{i,t},\, p = o(x_3^{-1}) \quad \text{uniformly in } x_1,\, x_2,\, t \quad \text{as } x_3 \to \infty. \tag{2.8}$$

Here the comma (partial differentiation) and repeated index (summation) conventions are used. In this work, Latin subscripts range over 1, 2, 3 while Greek subscripts range over 1, 2 unless otherwise noted. We assume that the velocity field $u_i(x_1,\, x_2,\, x_3,\, t)$ for $i = 1,\, 2,\, 3$ and the pressure $p(x_1,\, x_2,\, x_3,\, t)$ are classical solutions of (2.3)–(2.8) and the prescribed functions (entrance profile) f_i are continuously differentiable and vanish on $\partial D_0 \times [0,\, \infty)$. The notation $|\mathbf{u}|$ represents $(u_i u_i)^{\frac{1}{2}}$.

We note that in the special case when $J_1 = 0$ and $J_2 = 0$ (flow in a clear fluid), the problem (2.3)–(2.8) is reduced to that considered in [1].

We define a weighted energy integral for the solution u_i of (2.3)–(2.8) by (no summation on τ)

$$E(z,\, t) = \int_0^t \int_{R_z} (\xi - z)[J_1 u_i u_i + u_{i,j} u_{i,j} + k u_{i,\tau} u_{i,\tau}]\, dx d\tau, \tag{2.9}$$

with k a parameter to be chosen later, and note that

$$\frac{\partial E}{\partial z} = -\int_0^t \int_{R_z} [J_1 u_i u_i + u_{i,j} u_{i,j} + k u_{i,\tau} u_{i,\tau}]\, dx d\tau, \tag{2.10}$$

$$\frac{\partial^2 E}{\partial z^2} = \int_0^t \int_{D_z} [J_1 u_i u_i + u_{i,j} u_{i,j} + k u_{i,\tau} u_{i,\tau}]\, dA d\tau. \tag{2.11}$$

Our task is to obtain a second-order differential inequality for E from which we can deduce an exponential decay estimate.

We remark here that from the point of view of the mathematics, it is not necessary to include the lower-order term of the velocity (the first term in the integrand of integral (2.9)) in the weighted energy because the integral of this term can be controlled by the integral of the spatial derivative term using the Poincaré inequality (see (A.1) in the appendix). However, the parameter J_1 is a relatively large number for most porous media occurring in nature (whereas it is small for a sparse material with many pores), particularly in the limiting case of Darcy's law. Thus the square of the L^2 norm of u_i is the only kinetic energy term (see section 5) and we would like to retain this term in our weighted energy.

3. Energy estimation. We now begin to derive the desired differential inequality for E from which the decay results will follow.

On multiplying (2.3) by $(\xi - z)u_i$ and $k(\xi - z)u_{i,t}$, integrating over R_z, and using the boundary conditions for u_i, it can be shown that

$$\begin{aligned} E(z,t) = &-\int_0^t \int_{R_z} u_i u_{i,3}\, dx d\tau - \int_0^t \int_{R_z} (\xi - z) u_i [u_{i,\tau} + J_2 |\mathbf{u}| u_i + p_{,i}]\, dx d\tau \\ &+ k \int_0^t \int_{R_z} (\xi - z) u_{i,\tau} [\Delta u_i - J_1 u_i - J_2 |\mathbf{u}| u_i - p_{,i}]\, dx d\tau. \end{aligned}$$

Integrating by parts again, using (2.4) and the initial-boundary condition, and dropping five terms which are negative, we have

$$\begin{aligned} E(z,t) &\leq -\int_0^t \int_{R_z} u_i u_{i,3}\, dx d\tau - k\int_0^t \int_{R_z} u_{i,\tau} u_{i,3}\, dx d\tau \\ &\quad + \int_0^t \int_{R_z} u_3 p\, dx d\tau + k\int_0^t \int_{R_z} u_{3,\tau} p\, dx d\tau \\ &= I_1 + I_2 + I_3 + I_4. \end{aligned} \tag{3.1}$$

Estimates of the first two integral terms can easily be obtained by use of the Schwarz, Poincaré, and arithmetic mean–geometric mean (AG) inequalities

$$I_1 \leq \frac{1}{2\sqrt{\lambda_1}} \int_0^t \int_{R_z} u_{i,j} u_{i,j}\, dx d\tau, \tag{3.2}$$

$$I_2 \leq \frac{1}{2\sqrt{\lambda_1}} \left\{ \int_0^t \int_{R_z} k u_{i,\tau} u_{i,\tau}\, dx d\tau + \int_0^t \int_{R_z} u_{i,3} u_{i,3}\, dx d\tau \right\}. \tag{3.3}$$

In (3.3), we have selected $k = 1/\lambda_1$. Thus we have shown that

$$I_1,\ I_2 \leq \frac{1}{2\sqrt{\lambda_1}} \left(-\frac{\partial E}{\partial z} \right). \tag{3.4}$$

We now bound I_3 using the method of [1]. We first note that for any $z^* > 0$, by (2.4) and (2.5),

$$\begin{aligned} \int_{D_z} u_3\, dA &= \int_{D_z^*} u_3\, dA - \int_z^{z^*} \int_{D_\xi} u_{3,3}\, dA d\xi \\ &= \int_{D_{z^*}} u_3\, dA + \int_z^{z^*} \int_{D_\xi} u_{3,3}\, dA d\xi = \int_{D_{z^*}} u_3\, dA, \end{aligned}$$

and thus the area mean value of u_3 is the same over each section. Since u_3 is assumed to vanish at infinity, we conclude that this value is zero for all $z \geq 0$ and hence requires that f_3 satisfy

$$\int_{D_0} f_3\, dA = 0 \quad \text{for all } t \geq 0. \tag{3.5}$$

Under this assumption, there exists a vector function (see (A.3) in the appendix) ω_α which satisfies

$$\begin{aligned} I_3 &= \int_0^t \int_{R_z} \omega_{\alpha,\alpha} p\, dx d\tau = -\int_0^t \int_{R_z} \omega_\alpha p_{,\alpha}\, dx d\tau \\ &= \int_0^t \int_{R_z} \omega_\alpha [u_{\alpha,\tau} - \Delta u_\alpha + J_1 u_\alpha + J_2 |\mathbf{u}| u_\alpha]\, dx d\tau \\ &= \int_0^t \int_{R_z} \omega_\alpha u_{\alpha,\tau}\, dx d\tau + \int_0^t \int_{R_z} \omega_{\alpha,i} u_{\alpha,i}\, dx d\tau + \int_0^t \int_{D_z} \omega_\alpha u_{\alpha,3}\, dA d\tau \\ &\quad + J_1 \int_0^t \int_{R_z} \omega_\alpha u_\alpha\, dx d\tau + J_2 \int_0^t \int_{R_z} \omega_\alpha |\mathbf{u}| u_\alpha\, dx d\tau \\ &= I_{31} + I_{32} + I_{33} + I_{34} + I_{35}. \end{aligned} \tag{3.6}$$

The integrals of the auxiliary function ω_α can be bounded in terms of u_3 by means of (A.1) and (A.3). We can write

$$\begin{aligned}\int_0^t\int_{R_z}\omega_\alpha\omega_\alpha\,dxd\tau &\le \frac{1}{\lambda_1}\int_0^t\int_{R_z}\omega_{\alpha,\beta}\omega_{\alpha,\beta}\,dxd\tau\\ &\le \frac{C}{\lambda_1}\int_0^t\int_{R_z}(u_3)^2\,dxd\tau, \qquad (3.7)\\ \int_0^t\int_{R_z}\omega_{\alpha,3}\omega_{\alpha,3}\,dxd\tau &\le \frac{1}{\lambda_1}\int_0^t\int_{R_z}\omega_{\alpha,\beta 3}\omega_{\alpha,\beta 3}\,dxd\tau\\ &\le \frac{C}{\lambda_1}\int_0^t\int_{R_z}(u_{3,3})^2\,dxd\tau. \qquad (3.8)\end{aligned}$$

Using the Schwarz, Poincaré, and weighted AG inequalities, (3.7) and (3.8), we have the following estimates for the first three integrals (see [1]):

$$\begin{aligned}I_{31}+I_{32}+I_{33} &\le \frac{1}{2}\sqrt{\frac{C}{\lambda_1}}\left\{k\int_0^t\int_{R_z}u_{\alpha,\tau}u_{\alpha,\tau}\,dxd\tau+\int_0^t\int_{R_z}u_{3,\beta}u_{3,\beta}\,dxd\tau\right\}\\ &\quad+\frac{1}{2}\sqrt{\frac{C}{\lambda_1}}\int_0^t\int_{R_z}u_{i,j}u_{i,j}\,dxd\tau\\ &\quad+\frac{\sqrt{C}}{2\lambda_1}\left\{\int_0^t\int_{D_z}u_{\alpha,3}u_{\alpha,3}\,dxd\tau+\int_0^t\int_{D_z}u_{3,\beta}u_{3,\beta}\,dxd\tau\right\}. \qquad (3.9)\end{aligned}$$

For the fourth term on the right side of (3.6), we have

$$\begin{aligned}I_{34} &= J_1\int_0^t\int_{R_z}\omega_\alpha u_\alpha\,dxd\tau\\ &\le J_1\Big(\int_0^t\int_{R_z}\omega_\alpha\omega_\alpha\,dxd\tau\Big)^{\frac{1}{2}}\Big(\int_0^t\int_{R_z}u_\alpha u_\alpha\,dxd\tau\Big)^{\frac{1}{2}}\\ &\le J_1\sqrt{\frac{C}{\lambda_1}}\Big(\int_0^t\int_{R_z}(u_3)^2\,dxd\tau\Big)^{\frac{1}{2}}\Big(\int_0^t\int_{R_z}u_\alpha u_\alpha\,dxd\tau\Big)^{\frac{1}{2}}\\ &\le \frac{J_1}{2}\sqrt{\frac{C}{\lambda_1}}\int_0^t\int_{R_z}u_iu_i\,dxd\tau. \qquad (3.10)\end{aligned}$$

Now we need to estimate the last integral, I_{35}:

$$\begin{aligned}I_{35} &= J_2\int_0^t\int_{R_z}w_\alpha|\mathbf{u}|u_\alpha\,dxd\tau\\ &\le J_2\Big(\int_0^t\int_{R_z}\omega_\alpha\omega_\alpha\,dxd\tau\Big)^{\frac{1}{2}}\Big(\int_0^t\int_{R_z}(u_iu_i)^2\,dxd\tau\Big)^{\frac{1}{2}}. \qquad (3.11)\end{aligned}$$

By means of the Hölder inequality and the Sobolev inequality ((A.5) in the appendix) with $w = (u_iu_i)^{\frac{1}{2}}$ and $\bar{\Omega} = 4\Omega$, we deduce that

$$\begin{aligned}
&\int_0^t \int_{R_z} (u_iu_i)^2 \, dx d\tau \\
&\quad\leq \int_0^t \left(\int_{R_z} (u_iu_i)^{\frac{3}{2}} \, dx \right)^{\frac{2}{3}} \left(\int_{R_z} (u_iu_i)^3 \, dx \right)^{\frac{1}{3}} d\tau \\
&\quad\leq \max_{0\leq\tau\leq t} \left(\int_{R_z} (u_iu_i)^{\frac{3}{2}}(\tau) \, dx \right)^{\frac{2}{3}} \int_0^t \left(\int_{R_z} (u_iu_i)^3 \, dx \right)^{\frac{1}{3}} d\tau \\
&\quad\leq \Omega^{\frac{1}{3}} \max_{0\leq\tau\leq t} \left(\int_{R_z} (u_iu_i)^{\frac{3}{2}}(\tau) \, dx \right)^{\frac{2}{3}} \int_0^t \int_{R_z} u_{i,j}u_{i,j} \, dx d\tau. \qquad (3.12)
\end{aligned}$$

We point out here that to apply (A.5), we have extended u_i as an even function across $x_3 = z$. In fact, let $\tilde{w}$ be an even extension of w about $x_3 = z$, defined by

$$\tilde{w}(x_1, x_2, x_3, t) = \begin{cases} w(x_1, x_2, x_3, t) & \text{if } x_3 \geq z, \\ w(x_1, x_2, 2z - x_3, t) & \text{if } x_3 < z. \end{cases}$$

The Sobolev inequality ((A.5)) provides that

$$\int_{-\infty}^{\infty} \int_{D_\xi} \tilde{w}^6 \, dA d\xi \leq \bar{\Omega} \left(\int_{-\infty}^{\infty} \int_{D_\xi} \tilde{w}_{,j} \tilde{w}_{,j} \, dA d\xi \right)^3.$$

Using the substitution, we have

$$\int_{-\infty}^{\infty} \int_{D_\xi} \tilde{w}^6 \, dA d\xi = 2 \int_z^{\infty} \int_{D_\xi} w^6 \, dA d\xi = 2 \int_{R_z} w^6 \, dx.$$

$$\int_{-\infty}^{\infty} \int_{D_\xi} \tilde{w}_{,j} \tilde{w}_{,j} \, dA d\xi = 2 \int_{R_z} w_{,j} w_{,j} \, dx.$$

Replacing $w = (u_iu_i)^{\frac{1}{2}}$ and further using the Schwarz inequality, we thus deduce that

$$\int_{R_z} (u_iu_i)^3 \, dx \leq \Omega \left(\int_{R_z} u_{i,j}u_{i,j} dx \right)^3,$$

which justifies the last step of (3.2) in using the Sobolev inequality with $\bar{\Omega} = 4\Omega$. Substituting the estimate of (3.12) into (3.11) and employing (3.7) and (A.1), we conclude that

$$I_{35} \leq \frac{J_2 \Omega^{\frac{1}{6}} C^{\frac{1}{2}}}{\lambda_1} \max_{0\leq\tau\leq t} \left(\int_{R_z} (u_iu_i)^{\frac{3}{2}}(\tau) \, dx \right)^{\frac{1}{3}} \int_0^t \int_{R_z} u_{i,j}u_{i,j} \, dx d\tau. \qquad (3.13)$$

Finally, summarizing all of the results in (3.9), (3.10), and (3.13), we obtain

$$I_3 \leq \left\{ \sqrt{\frac{C}{\lambda_1}} + \frac{J_2 \Omega^{\frac{1}{6}} C^{\frac{1}{2}}}{\lambda_1} \max_{0\leq\tau\leq t} \left(\int_{R_z} (u_iu_i)^{\frac{3}{2}}(\tau) \, dx \right)^{\frac{1}{3}} \right\} \left(-\frac{\partial E}{\partial z} \right) + \frac{\sqrt{C}}{2\lambda_1} \frac{\partial^2 E}{\partial z^2}. \qquad (3.14)$$

We now turn to bounding I_4 in terms of $\partial E/\partial z$ and $\partial^2 E/\partial z^2$. Following the ideas in [1], we accomplish this with the aid of two auxiliary functions.

Let φ be a solution of the boundary value problem

$$\Delta\varphi = u_{3,t} \quad \text{in } R_z, \qquad \frac{\partial\varphi}{\partial\mathbf{n}} = 0 \quad \text{on } \partial R_z. \tag{3.15}$$

Since

$$\int_{R_z} u_{3,t}\,dx = \int_z^\infty \int_{D_\xi} u_{3,t} dA d\xi = 0$$

and $u_{3,t} \to 0$ as $x_3 \to \infty$, there exists a solution φ which together with its spatial derivatives vanishes as $x_3 \to \infty$. By means of φ, we can write

$$\begin{aligned} I_4 &= k\int_0^t \int_{R_z} p\Delta\varphi\,dxd\tau = -k\int_0^t \int_{R_z} \varphi_{,i}p_{,i}\,dxd\tau \\ &= k\int_0^t \int_{R_z} \varphi_{,i}\big[u_{i,\tau} - (u_{i,j} - u_{j,i})_{,j} + J_1 u_i + J_2|\mathbf{u}|u_i\big]\,dxd\tau \\ &= k\int_0^t \int_{R_z} \varphi_{,i}u_{i,\tau}\,dxd\tau + k\int_0^t \int_{D_z} \varphi_{,\alpha}(u_{\alpha,3} - u_{3,\alpha})\,dAd\tau \\ &\quad - k\int_0^t \int_z^\infty \int_{\partial D_\xi} \varphi_{,i}(u_{i,j} - u_{j,i})n_j\,dsd\xi d\tau \\ &\quad + kJ_1\int_0^t \int_{R_z} \varphi_{,i}u_i\,dxd\tau + kJ_2\int_0^t \int_{R_z} \varphi_{,i}|\mathbf{u}|u_i\,dxd\tau, \end{aligned}$$

and by Schwarz's inequality, we have

(3.16)

$$\begin{aligned} I_4 \le & k\Big(\int_0^t \int_{R_z} \varphi_{,i}\varphi_{,i}\,dxd\tau\Big)^{\frac12}\Big(\int_0^t \int_{R_z} u_{i,\tau}u_{i,\tau}\,dxd\tau\Big)^{\frac12} \\ &+ k\Big(\int_0^t \int_{D_z} \varphi_{,\alpha}\varphi_{,\alpha}\,dAd\tau\Big)^{\frac12}\Big(\int_0^t \int_{D_z} (u_{\alpha,3} - u_{3,\alpha})(u_{\alpha,3} - u_{3,\alpha})\,dAd\tau\Big)^{\frac12} \\ &+ k\Big(\int_0^t \int_z^\infty \int_{\partial D_\xi} |\mathrm{grad}_s\varphi|^2\,dsd\xi d\tau\Big)^{\frac12}\Big(\int_0^t \int_z^\infty \int_{\partial D_\xi} (u_{i,j} - u_{j,i})u_{i,j}\,dsd\xi d\tau\Big)^{\frac12} \\ &+ kJ_1\Big(\int_0^t \int_{R_z} \varphi_{,i}\varphi_{,i}\,dxd\tau\Big)^{\frac12}\Big(\int_0^t \int_{R_z} u_iu_i\,dxd\tau\Big)^{\frac12} \\ &+ kJ_2\Big(\int_0^t \int_{R_z} \varphi_{,i}\varphi_{,i}\,dxd\tau\Big)^{\frac12}\Big(\int_0^t \int_{R_z} (u_iu_i)^2\,dxd\tau\Big)^{\frac12}, \end{aligned}$$

where $\mathrm{grad}_s\varphi$ denotes the tangential component of the gradient of φ. The integrals involving the auxiliary function φ can be estimated by using (A.6)–(A.8) in the appendix with $f = u_{3,t}$. Using the weighted AG inequality and (3.12), we deduce that

$$\begin{aligned}
I_4 \leq & \left(\frac{3\sqrt{\lambda_1} + J_1^{\frac{1}{2}} + J_2}{2\sqrt{\lambda_1 \mu_2}} + \frac{2}{h_0^2 \sqrt{\lambda_1}} \left[\frac{1}{\mu_2} + \frac{d^2}{4} \right] \right) \int_0^t \int_{R_z} k u_{i,\tau} u_{i,\tau} \, dx d\tau \\
& + \frac{1}{\lambda_1} \int_0^t \int_{D_z} (u_{\alpha,3} - u_{3,\alpha})(u_{\alpha,3} - u_{3,\alpha}) \, dA d\tau \\
& + \frac{h_0}{4\sqrt{\lambda_1}} \int_0^t \int_z^\infty \int_{D_\xi} (u_{i,j} - u_{j,i}) u_{i,j} \, ds d\xi d\tau + \frac{J_1^{\frac{1}{2}}}{2\sqrt{\lambda_1 \mu_2}} \int_0^t \int_{R_z} J_1 u_i u_i \, dx d\tau \\
& + \frac{J_2 \Omega^{\frac{1}{3}}}{2\sqrt{\lambda_1 \mu_2}} \max_{0 \leq \tau \leq t} \left(\int_{R_z} (u_i u_i)^{\frac{3}{2}} (\tau) \, dx \right)^{\frac{2}{3}} \int_0^t \int_{R_z} u_{i,j} u_{i,j} \, dx d\tau.
\end{aligned} \tag{3.17}$$

In order to estimate the third term on the right side of (3.17), a lateral boundary integral, we multiply (2.3) by $(x_k - z\delta_{3k}) u_{i,k}$ and integrate it over R_z:

$$\int_{R_z} (x_k - z\delta_{3k}) u_{i,k} [(u_{i,j} - u_{j,i})_{,j} - u_{i,t} - J_1 u_i - J_2 |\mathbf{u}| u_i - p_{,i}] dx = 0,$$

where δ_{ij} is the Kronecker delta symbol. Integration by parts results in

$$\begin{aligned}
& \int_{\partial R_z} (x_k - z\delta_{3k}) u_{i,k} (u_{i,j} - u_{j,i}) n_j ds \\
& \quad - \frac{1}{2} \int_{\partial R_z} (x_k - z\delta_{3k}) u_{i,k} (u_{i,j} - u_{j,i}) n_k ds \\
& \quad + \frac{1}{2} \int_{R_z} (u_{i,j} - u_{j,i}) u_{i,j} dx - \int_{R_z} (x_k - z\delta_{3k}) u_{i,k} u_{i,t} dx \\
& \quad + \frac{1}{2} J_1 \int_{R_z} u_i u_i dx + \frac{1}{3} J_2 \int_{R_z} (u_i u_i)^{\frac{3}{2}} dx - \int_{\partial R_z} (x_k - z\delta_{3k}) u_{i,k} p n_i ds = 0.
\end{aligned} \tag{3.18}$$

Since $u_{i,k} n_i = u_{i,i} n_k = 0$ on ∂D_ξ for $\xi \geq 0$, we rewrite the last term on the right side as

$$\int_{\partial R_z} (x_k - z\delta_{3k}) u_{i,k} p n_i ds = \int_{D_z} x_\alpha u_{3,\alpha} p dA.$$

Moreover, the first two integrals on the lateral boundary can be combined so that

$$\begin{aligned}
& \int_z^\infty \int_{\partial D_\xi} (x_k - z\delta_{3k}) u_{i,k} (u_{i,j} - u_{j,i}) n_j ds d\xi \\
& \qquad - \frac{1}{2} \int_z^\infty \int_{\partial D_\xi} (x_k - z\delta_{3k}) u_{i,k} (u_{i,j} - u_{j,i}) n_k ds d\xi \\
& \quad = \frac{1}{2} \int_z^\infty \int_{\partial D_\xi} x_\alpha n_\alpha u_{i,j} (u_{i,j} - u_{j,i}) ds d\xi.
\end{aligned}$$

Consequently, (3.18) can be rewritten as

$$\begin{aligned}\frac{1}{2}\int_z^\infty \int_{\partial D_\xi} x_\alpha n_\alpha u_{i,j}(u_{i,j}-u_{j,i})ds d\xi + \frac{1}{2}J_1\int_{R_z} u_i u_i dx \\ + \frac{1}{3}J_2\int_{R_z}(u_i u_i)^{\frac{3}{2}}dx = \int_{D_z} x_\alpha u_{\beta,\alpha}(u_{\beta,3}-u_{3,\beta})dA \\ -\frac{1}{2}\int_{R_z}(u_{i,j}-u_{j,i})u_{i,j}dx + \int_{R_z}(x_3-z)u_{i,3}u_{i,t}dx \\ + \int_{R_z} x_\alpha u_{i,\alpha}u_{i,t}dx + \int_{D_z} x_\alpha u_{3,\alpha} p dA. \qquad (3.19)\end{aligned}$$

We define $\bar{p}$ to be the mean value of p over D_z, i.e.,

$$\bar{p} = \frac{1}{|D_z|}\int_{D_z} p dA,$$

where $|D_z| = |D_0|$ is the measure of D_z. We note that

$$\int_{D_z} x_\alpha u_{3,\alpha} p dA = \int_{D_z} x_\alpha u_{3,\alpha}(p-\bar{p})dA$$

since

$$\int_{D_z} x_\alpha u_{3,\alpha} p dA = -2\int_{D_z} u_3 dA = 0.$$

Using the Schwarz inequality, it follows from (3.19) that

$$\begin{aligned}\frac{h_0}{2}\int_z^\infty \int_{\partial D_\xi} u_{i,j}(u_{i,j}-u_{j,i})ds d\xi + \frac{1}{2}J_1\int_{R_z} u_i u_i dx + \frac{1}{3}J_2\int_{R_z}(u_i u_i)^{\frac{3}{2}}dx \\ \le d\Big(\int_{D_z} u_{\beta,\alpha}u_{\beta,\alpha}\,dA\Big)^{\frac{1}{2}}\Big(\int_{D_z}(u_{\alpha,3}-u_{3,\alpha})(u_{\alpha,3}-u_{3,\alpha})\,dA\Big)^{\frac{1}{2}} \\ + d\Big(\int_{R_z} u_{i,\alpha}u_{i,\alpha}\,dx\Big)^{\frac{1}{2}}\Big(\int_{R_z} u_{i,t}u_{i,t}\,dxd\Big)^{\frac{1}{2}} \\ + \Big(\int_{R_z}(\xi-z)u_{i,3}u_{i,3}\,dx\Big)^{\frac{1}{2}}\Big(\int_{R_z}(\xi-z)u_{i,t}u_{i,t}\,dx\Big)^{\frac{1}{2}} \\ + d\Big(\int_{D_z} u_{3,\alpha}u_{3,\alpha}\,dA\Big)^{\frac{1}{2}}\Big(\int_{D_z}(p-\bar{p})^2\,dA\Big)^{\frac{1}{2}}, \qquad (3.20)\end{aligned}$$

where $h_0 = \min\{x_\alpha n_\alpha\}$ on ∂D_ξ and $d = \text{diameter}\, D_0$. To estimate the last integral on the right side of (3.20), we consider the boundary value problem

$$\Delta\Psi = 0 \quad \text{in } R_z, \qquad \frac{\partial\Psi}{\partial\mathbf{n}} = 0 \quad \text{on } \partial D_\xi, \qquad \frac{\partial\Psi}{\partial\mathbf{n}} = p-\bar{p} \quad \text{in } D_z, \qquad (3.21)$$

where $\xi \ge z \ge 0$. Since $\int_{D_z}(p-\bar{p})dA = 0$, the necessary condition for the existence of a solution Ψ is satisfied. We choose $\lim_{z\to\infty}\int_{D_z}\Psi dA = 0$ such that Ψ is uniquely determined. Using the auxiliary function Ψ, we observe that

$$\begin{aligned}\int_{D_z}(p-\bar{p})^2\,dA = \int_{\partial R_z}(p-\bar{p})\frac{\partial\Psi}{\partial\mathbf{n}}\,ds = \int_{R_z}(p-\bar{p})_{,i}\Psi_{,i}\,dx \\ = \int_{R_z}\Psi_{,i}[(u_{i,j}-u_{j,i})_{,j} - u_{i,t} - J_1 u_i - J_2|\mathbf{u}|u_i]dx.\end{aligned}$$

Then in a manner similar to the derivation of (3.16), we can write

$$\begin{aligned}\int_{D_z}(p-\bar p)^2\,dA \le &\Big(\int_{R_z}\Psi_{,i}\Psi_{,i}\,dx\Big)^{\frac12}\Big(\int_{R_z}u_{i,t}u_{i,t}\,dx\Big)^{\frac12}\\ &+\Big(\int_{D_z}\Psi_{,\alpha}\Psi_{,\alpha}\,dA\Big)^{\frac12}\Big(\int_{D_z}(u_{\alpha,3}-u_{3,\alpha})(u_{\alpha,3}-u_{3,\alpha})\,dA\Big)^{\frac12}\\ &+\Big(\int_z^\infty\int_{\partial D_\xi}|\mathrm{grad}_s\Psi|^2\,dsd\xi\Big)^{\frac12}\Big(\int_z^\infty\int_{\partial D_\xi}(u_{i,j}-u_{j,i})u_{i,j}\,dsd\xi\Big)^{\frac12}\\ &+J_1\Big(\int_{R_z}\Psi_{,i}\Psi_{,i}\,dx\Big)^{\frac12}\Big(\int_{R_z}u_iu_i\,dx\Big)^{\frac12}\\ &+J_2\Big(\int_{R_z}\Psi_{,i}\Psi_{,i}\,dx\Big)^{\frac12}\Big(\int_{R_z}(u_iu_i)^2\,dx\Big)^{\frac12}.\end{aligned}\tag{3.22}$$

The use of (A.9)–(A.11) in the appendix with $g = p - \bar p$ to bound the integrals involving the function Ψ results in an estimate for the integral of the function $p - \bar p$.

$$\begin{aligned}\Big(\int_{D_z}(p-\bar p)^2\,dA\Big)^{\frac12} \le &\Big(\frac{1}{\sqrt{\mu_2}}\int_{R_z}u_{i,t}u_{i,\,t}\,dx\Big)^{\frac12}\\ &+\Big(\int_{D_z}(u_{\alpha,3}-u_{3,\alpha})(u_{\alpha,3}-u_{3,\alpha})\,dA\Big)^{\frac12}\\ &+\Big(\frac{2}{h_0}\Big[d+\frac{1}{\sqrt{\mu_2}}\Big]\int_z^\infty\int_{\partial D_\xi}(u_{i,j}-u_{j,i})u_{i,j}\,dsd\xi\Big)^{\frac12}\\ &+J_1\Big(\frac{1}{\sqrt{\mu_2}}\int_{R_z}u_iu_i\,dx\Big)^{\frac12}+J_2\Big(\frac{1}{\sqrt{\mu_2}}\int_{R_z}(u_iu_i)^2\,dx\Big)^{\frac12}.\end{aligned}\tag{3.23}$$

Substituting (3.23) into (3.20) and using the weighted AG inequalities, we have

$$\begin{aligned}&\frac{h_0}{2}\int_z^\infty\int_{\partial D_\xi}u_{i,j}(u_{i,j}-u_{j,i})dsd\xi\\ &\qquad+\frac12 J_1\int_{R_z}u_iu_idx+\frac13 J_2\int_{R_z}(u_iu_i)^{\frac32}dx\\ &\quad\le\frac{d\gamma_2}{2}\int_{R_z}u_{i,\alpha}u_{i,\alpha}\,dx+\Big(\frac{d}{2\gamma_2}+\frac{d}{2\gamma_4}\Big)\int_{R_z}u_{i,t}u_{i,t}\,dx\\ &\qquad+\frac{\gamma_3}{2}\int_{R_z}(\xi-z)u_{i,3}u_{i,3}\,dx+\frac{1}{2\gamma_3}\int_{R_z}(\xi-z)u_{i,t}u_{i,t}\,dx\\ &\qquad+\Big(\frac{d\gamma_5}{2}+\frac{d^2\gamma_6}{h_0}\Big[d+\frac{1}{\sqrt{\mu_2}}\Big]+\frac{d\gamma_4+d\gamma_7J_1+d^2\gamma_8J_2}{2\sqrt{\mu_2}}\Big)\times\int_{D_z}u_{3,\alpha}u_{3,\alpha}\,dA\\ &\qquad+\frac{d\gamma_1}{2}\int_{D_z}u_{\beta,\alpha}u_{\beta,\alpha}\,dA\\ &\qquad+\Big(\frac{d}{2\gamma_1}+\frac{d}{2\gamma_5}\Big)\int_{D_z}(u_{\alpha,3}-u_{3,\alpha})(u_{\alpha,3}-u_{3,\alpha})\,dA\\ &\qquad+\frac{1}{2\gamma_6}\int_z^\infty\int_{\partial D_\xi}u_{i,j}(u_{i,j}-u_{j,i})dsd\xi+\frac{J_1d}{2\gamma_7}\int_{R_z}u_iu_idx+\frac{J_2}{2\gamma_8}\int_{R_z}(u_iu_i)^2dx.\end{aligned}\tag{3.24}$$

We recall that $k = 1/\lambda_1$ and choose

$$\gamma_1 = \gamma_5 = \frac{d\sqrt{\lambda_1}}{2}, \qquad \gamma_2 = \gamma_4 = \sqrt{2\lambda_1}, \qquad \gamma_3 = \sqrt{\lambda_1},$$
$$\gamma_6 = \frac{2}{h_0}, \qquad \gamma_7 = \frac{1}{\sqrt{2\lambda_1}}, \qquad \gamma_8 = \frac{1}{\sqrt{\lambda_1}}.$$

Integrating (3.24) with respect to τ, we thus have

$$\begin{aligned}
&\frac{h_0}{4}\int_0^t \int_z^\infty \int_{\partial R_z} u_{i,j}(u_{i,j} - u_{j,i})\,ds\,d\xi\,d\tau \\
&\qquad \le \frac{\sqrt{\lambda_1}}{2}E + \sqrt{\lambda_1}\left[\frac{d\sqrt{2}}{2} + \frac{J_2\Omega^{\frac{1}{3}}}{2}\max_{0\le\tau\le t}\left(\int_{R_z}(u_iu_i)^{\frac{3}{2}}\,dx\right)^{\frac{2}{3}}\right]\left(-\frac{\partial E}{\partial z}\right) \\
&\qquad\qquad + \frac{2}{\sqrt{\lambda_1}}\int_0^t\int_{D_z}(u_{\alpha,3} - u_{3,\alpha})(u_{\alpha,3} - u_{3,\alpha})\,dA\,d\tau \\
&\qquad\qquad + \frac{d^2\sqrt{\lambda_1}}{4}\int_0^t\int_{D_z} u_{\beta,\alpha}u_{\beta,\alpha}\,dA\,d\tau + \frac{r_1}{\sqrt{\lambda_1}}\int_0^t\int_{D_z} u_{3,\alpha}u_{3,\alpha}\,dA\,d\tau,
\end{aligned} \tag{3.25}$$

where

$$r_1 = \frac{d\sqrt{\lambda_1}}{2}\left(\frac{d\sqrt{\lambda_1}}{2} + \frac{4d}{h_0^2}\left[d + \frac{1}{\sqrt{\mu_2}}\right] + \frac{\sqrt{2\lambda_1}}{\sqrt{\mu_2}} + \frac{J_1}{\sqrt{2\lambda_1\mu_2}} + \frac{dJ_2}{\sqrt{\lambda_1\mu_2}}\right). \tag{3.26}$$

Now we return to (3.17) and use (3.25) to obtain

$$\begin{aligned}
I_4 &\le \frac{1}{2}E + r_2\left(-\frac{\partial E}{\partial z}\right) + \frac{d^2}{4}\int_0^t\int_{D_z} u_{\beta,\alpha}u_{\beta,\alpha}\,dA\,d\tau \\
&\qquad + \frac{3}{\lambda_1}(1+\eta)\int_0^t\int_{D_z} u_{\alpha,3}u_{\alpha,3}\,dA\,d\tau \\
&\qquad + \frac{3}{\lambda_1}\left(1 + \frac{1}{\eta} + \frac{r_1}{3}\right)\int_0^t\int_{D_z} u_{3,\alpha}u_{3,\alpha}\,dA\,d\tau,
\end{aligned} \tag{3.27}$$

where

$$\begin{aligned}
r_2 &= \frac{3\sqrt{\lambda_1} + J_1^{\frac{1}{2}} + J_2}{2\sqrt{\lambda_1\mu_2}} + \frac{2}{h_0^2\sqrt{\lambda_1}}\left[\frac{1}{\mu_2} + \frac{d^2}{4}\right] + \frac{d\sqrt{2}}{2} \\
&\qquad + \left(\frac{J_2\Omega^{\frac{1}{3}}}{2} + \frac{J_2\Omega^{\frac{1}{3}}}{2\sqrt{\lambda_1\mu_2}}\right)\max_{0\le\tau\le t}\left(\int_{R_z}(u_iu_i)^{\frac{3}{2}}(\tau)\,dx\right)^{\frac{2}{3}}.
\end{aligned} \tag{3.28}$$

We choose η to be the positive root of the quadratic equation $\eta^2 - (r_1/3)\eta - 1 = 0$ so that the coefficients of the last two integrals of the right side of (3.27) are equal. Consequently, we can rewrite (3.27) as

$$I_4 \le \frac{1}{2}E + r_2\left(-\frac{\partial E}{\partial z}\right) + r_3\frac{\partial^2 E}{\partial z^2}, \tag{3.29}$$

where

$$r_3 = \max\left\{\frac{d^2}{4}, \frac{3}{\lambda_1}(1+\eta)\right\}.$$

Combining all of the results in (3.4), (3.14), and (3.29), we arrive at the second-order differential inequality

$$E \leq K_1 \frac{\partial^2 E}{\partial z^2} - K_2 \frac{\partial E}{\partial z}, \tag{3.30}$$

where

$$K_1 = \frac{\sqrt{C}}{\lambda_1} + 2r_3,$$

$$\begin{aligned} K_2 = {} & 2\left(\frac{1+\sqrt{C}}{\sqrt{\lambda_1}}\right) + \frac{3\sqrt{\lambda_1} + J_1^{\frac{1}{2}} + J_2}{\sqrt{\lambda_1 \mu_2}} + \frac{4}{h_0^2 \sqrt{\lambda_1}}\left[\frac{1}{\mu_2} + \frac{d^2}{4}\right] + d\sqrt{2} \\ & + \frac{2J_2 \Omega^{\frac{1}{6}} C^{\frac{1}{2}}}{\lambda_1} \max_{0 \leq \tau \leq t} \left(\int_{R_z} (u_i u_i)^{\frac{3}{2}}(\tau)\, dx \right)^{\frac{1}{3}} \\ & + \left(J_2 \Omega^{\frac{1}{3}} + \frac{J_2 \Omega^{\frac{1}{3}}}{\sqrt{\lambda_1 \mu_2}} \right) \max_{0 \leq \tau \leq t} \left(\int_{R_z} (u_i u_i)^{\frac{3}{2}}(\tau)\, dx \right)^{\frac{2}{3}}. \end{aligned} \tag{3.31}$$

We may rewrite (3.30) as

$$\frac{\partial}{\partial z}\left\{ e^{-k_1 z}\left(\frac{\partial E}{\partial z} + k_2 E \right) \right\} \geq 0, \tag{3.32}$$

where

$$k_1 = \frac{K_2}{2K_1} + \frac{1}{2}\sqrt{\frac{K_2^2}{K_1^2} + \frac{4}{K_1}}, \qquad k_2 = -\frac{K_2}{2K_1} + \frac{1}{2}\sqrt{\frac{K_2^2}{K_1^2} + \frac{4}{K_1}}.$$

Integration of (3.32) from z to ∞ leads to

$$\frac{\partial E}{\partial z} + k_2 E \leq 0,$$

and hence

$$E(z,t) \leq E(0,t) e^{-k_2 z}. \tag{3.33}$$

Direct calculation shows that

$$\frac{\partial k_2}{\partial K_1} = \frac{1}{2}\frac{1}{K_2}\left(\frac{K_1^2}{K_2^2} + \frac{4}{K_2} \right)^{-\frac{1}{2}} \left(-\left(\frac{K_1^2}{K_2^2} + \frac{4}{K_2} \right)^{\frac{1}{2}} + \frac{K_1}{K_2} \right) < 0 \tag{3.34}$$

and

$$\frac{\partial k_2}{\partial K_2} = \frac{1}{2}\frac{K_1}{K_2^2}\left(\frac{K_1^2}{K_2^2} + \frac{4}{K_2} \right)^{-\frac{1}{2}} \left(\left(\frac{K_1^2}{K_2^2} + \frac{4}{K_2} \right)^{\frac{1}{2}} - \left(\frac{K_1}{K_2} + \frac{2}{K_1} \right) \right) < 0. \tag{3.35}$$

Thus we find that

$$\frac{\partial k_2}{\partial J_1} = \frac{\partial k_2}{\partial K_1}\frac{\partial K_1}{\partial J_1} + \frac{\partial k_2}{\partial K_2}\frac{\partial K_2}{\partial J_1} < 0, \qquad \frac{\partial k_2}{\partial J_2} = \frac{\partial k_2}{\partial K_1}\frac{\partial K_1}{\partial J_2} + \frac{\partial k_2}{\partial K_2}\frac{\partial K_2}{\partial J_2} < 0. \tag{3.36}$$

Therefore, the decay rate k_2 is a decreasing function of J_1 and J_2. In the physical sense, this suggests that when Stokes flow is compared to flow in a porous medium, the presence of the porous material as well as the inclusion of the inertial drag force each reduces the spatial decay rate of the end effects.

4. Determination of the bounds. As indicated in the previous section, the definition of the constant K_2 involves the quantity $\max_{0\le\tau\le t}\int_{R_z}(u_iu_i)^{\frac{3}{2}}\,dx$. One of the important aspects in our analysis is that we would like our estimate to depend only on the known data, which for the present problem are the physical parameters J_1 and J_2, the boundary data, and the geometry of the domain. We therefore need to find a bound for the expression $\max_{0\le\tau\le t}\int_R(u_iu_i)^{\frac{3}{2}}\,dx$ as well as for the total weighted energy $E\ (0,\,t)$. Modeled on the analysis used by Ames and Payne [2] in their investigation of decay estimates for the solution of the steady Navier–Stokes equation, we shall consider the solution of the linearized problem, namely the Brinkman flow

$$w_{i,t}=\Delta w_i-J_1w_i-q_{,i}\quad\text{in } R\times(0,\infty),\tag{4.1}$$

$$w_{i,i}=0\quad\text{in } \bar{R}\times(0,\infty),\tag{4.2}$$

$$w_i=u_i\quad\text{on } \partial R\times(0,\infty),\tag{4.3}$$

$$w_i=0\quad\text{in } R\times\{0\},\tag{4.4}$$

$$w_{i},\,w_{i,j},\,w_{i,t},\,q=o(x_3^{-1})\quad\text{uniformly in } x_{1,}\,x_2,\,t\qquad\text{as } x_3\to\infty.\tag{4.5}$$

In what follows, we first compare the solution u_i of problem (2.3)–(2.8), the Brinkman–Forchheimer flow, with the solution w_i of problem (4.1)–(4.5), the Brinkman flow. Next, we explain how one can bound the integrals containing the solution w_i and its derivatives in section 4.2.

4.1. Bound for $\max_{0\le\tau\le t}\int_R(u_iu_i)^{\frac{3}{2}}\,dx$.

To relate the solution u_i of system (2.3)–(2.8) to the solution w_i of system (4.1)–(4.5), we define $v_i=u_i-w_i$ and $s=p-q$. Then the initial-boundary problem governing the differential field is

$$v_{i,t}=\Delta v_i-J_1v_i-J_2|\mathbf{u}|u_i-s_{,i}\quad\text{in } R\times(0,\infty),\tag{4.6}$$

$$v_{i,i}=0\quad\text{in } \bar{R}\times(0,\infty),\tag{4.7}$$

$$v_i=0\quad\text{on } \partial R\times(0,\infty),\tag{4.8}$$

$$v_i=0\quad\text{in } R\times\{0\},\tag{4.9}$$

$$v_{i},\,v_{i,j},\,v_{i,t},\,s=o(x_3^{-1})\quad\text{uniformly in } x_{1,}\,x_2,\,t\qquad\text{as } x_3\to\infty.\tag{4.10}$$

On integration by parts and dropping one term which is negative, we first note for any $0\le t_1\le t$ that

$$\begin{aligned}
0&\le\int_0^{t_1}\int_R v_{i,\tau}v_{i,\tau}\,dxd\tau\\
&\le\int_0^{t_1}\int_R v_{i,\tau}[\Delta v_i-J_1v_i-J_2|\mathbf{u}|u_i-s_{,i}]\,dxd\tau\\
&\le-\frac{1}{2}\int_0^{t_1}\int_R(v_{i,j}v_{i,j})_{,\tau}\,dxd\tau-J_2\int_0^{t_1}\int_R v_{i,\tau}|\mathbf{u}|u_i\,dxd\tau\\
&\le-\frac{1}{2}\int_0^{t_1}\int_R(v_{i,j}v_{i,j})_{,\tau}\,dxd\tau-J_2\int_0^{t_1}\int_R|\mathbf{u}|u_i(u_{i,\tau}-w_{i,\tau})\,dxd\tau.
\end{aligned}\tag{4.11}$$

This yields that

$$\begin{aligned}
&\frac{1}{2}\int_0^{t_1}\int_R(v_{i,j}v_{i,j})_{,\tau}\,dxd\tau+J_2\int_0^{t_1}\int_R|\mathbf{u}|u_iu_{i,\tau}\,dxd\tau+\int_0^{t_1}\int_R v_{i,\tau}v_{i,\tau}\,dxd\tau\\
&\le J_2\int_0^{t_1}\int_R|\mathbf{u}|u_iw_{i,\tau}\,dxd\tau.
\end{aligned}\tag{4.12}$$

For the above inequality, we integrate two terms on the left side with respect to τ and use the initial condition (4.9) and then apply the Schwarz inequality to the integral on the right side. It is then true for any $0 \leq t_1 \leq t$ that

$$\begin{aligned}&\frac{1}{2}\int_R v_{i,j}v_{i,j}(t_1)\,dx + \frac{1}{3}J_2\int_R (u_iu_i)^{\frac{3}{2}}\,(t_1)dx + \int_0^{t_1}\int_R v_{i,\tau}v_{i,\tau}\,dxd\tau \\ &\leq J_2\left(\int_0^t\int_R w_{i,\tau}w_{i,\tau}\,dxd\tau\right)^{\frac{1}{2}}\left(\int_0^t\int_R (u_iu_i)^2\,dxd\tau\right)^{\frac{1}{2}}. \end{aligned}\tag{4.13}$$

We recall the result in (3.12) which provides that

$$\begin{aligned}&\int_0^t\int_R (u_iu_i)^2\,dxd\tau \\ &\leq \Omega^{\frac{1}{3}}\left(\max_{0\leq\tau\leq t}\int_R (u_iu_i)^{\frac{3}{2}}(\tau)\,dx\right)^{\frac{2}{3}}\int_0^t\int_R u_{i,j}u_{i,j}\,dxd\tau. \end{aligned}\tag{4.14}$$

We conclude immediately from (4.13) and (4.14) that

$$\begin{aligned}&\left(\max_{0\leq\tau\leq t}\int_R (u_iu_i)^{\frac{3}{2}}(\tau)\,dx\right)^{\frac{2}{3}} \\ &\leq 3\Omega^{\frac{1}{6}}\left(\int_0^t\int_R w_{i,\tau}w_{i,\tau}\,dxd\tau\right)^{\frac{1}{2}}\left(\int_0^t\int_R u_{i,j}u_{i,j}\,dxd\tau\right)^{\frac{1}{2}}. \end{aligned}\tag{4.15}$$

Using (4.15), we have that the term $\max_{0\leq\tau\leq t}\int_R (u_iu_i)^{\frac{3}{2}}(\tau)\,dx$ can be bounded if the two integrals on the right side of (4.15) are bounded. We shall discuss the bounds of the integral $\int_0^t\int_R w_{i,\tau}w_{i,\tau}\,dxd\tau$ in section 4.2. For the integral $\int_0^t\int_R u_{i,j}u_{i,j}\,dxd\tau$, we want to show that it can be bounded by two integrals of the solution w_i.

On integration by parts and dropping three negative terms, we observe that

$$\begin{aligned}\int_0^t\int_R v_{i,j}v_{i,j}\,dxd\tau &= -\int_0^t\int_R v_iv_{i,jj}\,dxd\tau \\ &= -\int_0^t\int_R v_i[v_{,\tau} + J_1v_i + J_2|\mathbf{u}|u_i + s_{,i}]\,dxd\tau \\ &\leq -J_2\int_0^t\int_R |\mathbf{u}|v_i(v_i+w_i)\,dxd\tau \\ &\leq \frac{J_2}{4}\int_0^t\int_R |\mathbf{u}|w_iw_i\,dxd\tau \\ &\leq \frac{J_2}{4}\int_0^t\left(\int_R (u_iu_i)^{\frac{3}{2}}\,dx\right)^{\frac{1}{3}}\left(\int_R (w_iw_i)^{\frac{3}{2}}\,dx\right)^{\frac{2}{3}}d\tau \\ &\leq \frac{J_2}{4}\max_{0\leq\tau\leq t}\left(\int_R (u_iu_i)^{\frac{3}{2}}\,dx\right)^{\frac{1}{3}}\left\{\int_0^t\left(\int_R (w_iw_i)^{\frac{3}{2}}\,dx\right)^{\frac{2}{3}}d\tau\right\}. \end{aligned}\tag{4.16}$$

Setting $w = (w_iw_i)^{\frac{1}{2}}$ in (A.4), we apply the Sobolev inequality to obtain that

$$\begin{aligned}\int_R (w_iw_i)^2\,dx &= \int_0^\infty\int_{D_\xi}(w_iw_i)^2\,dAd\xi \\ &\leq \frac{1}{2}\int_0^\infty\left[\int_{D_\xi} w_iw_i\,dA\right]\left[\int_{D_\xi} w_{i,\beta}w_{i,\beta}\,dA\right]d\xi. \end{aligned}\tag{4.17}$$

The divergence theorem and boundary conditions for w_i on ∂D_z yield, for each ξ in $z \le \xi < \infty$,

$$\begin{aligned}\int_{D_\xi} w_i w_i \, dA &= -2\int_z^\infty \int_{D_\xi} w_i w_{i,\xi} \, dA d\xi \\ &\le 2\Big(\int_{R_z} w_i w_i \, dx\Big)^{\frac{1}{2}} \Big(\int_{R_z} w_{i,3} w_{i,3} \, dx\Big)^{\frac{1}{2}} \\ &\le 2\Big(\int_{R} w_i w_i \, dx\Big)^{\frac{1}{2}} \Big(\int_{R} w_{i,3} w_{i,3} \, dx\Big)^{\frac{1}{2}}. \end{aligned} \tag{4.18}$$

Using (4.17), (4.18), and (A.1), we obtain

$$\begin{aligned}\int_R (w_i w_i)^2 \, dx &\le \Big(\int_R w_i w_i \, dx\Big)^{\frac{1}{2}} \Big(\int_R w_{i,j} w_{i,j} \, dx\Big)^{\frac{3}{2}} \\ &\le \frac{1}{\sqrt{\lambda_1}} \Big(\int_R w_{i,j} w_{i,j} \, dx\Big)^2. \end{aligned} \tag{4.19}$$

Furthermore, we have

$$\begin{aligned}\Big[\int_R (w_i w_i)^{\frac{3}{2}} \, dx\Big]^{\frac{2}{3}} &\le \Big[\Big(\int_R (w_i w_i) \, dx\Big)^{\frac{1}{2}} \Big(\int_R (w_i w_i)^2 \, dx\Big)^{\frac{1}{2}}\Big]^{\frac{2}{3}} \\ &\le \frac{1}{\sqrt{\lambda_1}} \int_R w_{i,j} w_{i,j} \, dx. \end{aligned} \tag{4.20}$$

Substituting (4.15) and (4.20) in (4.16), we thus obtain

$$\begin{aligned}&\int_0^t \int_R v_{i,j} v_{i,j} \, dx d\tau \\ &\quad \le \frac{J_2}{4\lambda_1{}^{\frac{1}{2}}} \big(\max_{0\le\tau\le t} \int_R (u_i u_i)^{\frac{3}{2}} \, dx\big)^{\frac{1}{3}} \int_0^t \int_R w_{i,j} w_{i,j} \, dx d\tau \\ &\quad \le \frac{3^{\frac{1}{2}} \Omega^{\frac{1}{12}} J_2}{4\lambda_1{}^{\frac{1}{2}}} \Big(\int_0^t \int_R w_{i,j} w_{i,j} \, dx d\tau\Big) \Big(\int_0^t \int_R w_{i,\tau} w_{i,\tau} \, dx d\tau\Big)^{\frac{1}{4}} \\ &\qquad \times \Big(\int_0^t \int_R u_{i,j} u_{i,j} \, dx d\tau\Big)^{\frac{1}{4}}. \end{aligned} \tag{4.21}$$

Note that

$$\int_0^t \int_R u_{i,j} u_{i,j} \, dx d\tau \le 2\int_0^t \int_R v_{i,j} v_{i,j} \, dx d\tau + 2\int_0^t \int_R w_{i,j} w_{i,j} \, dx d\tau, \tag{4.22}$$

and then one has

$$\int_0^t \int_R u_{i,j} u_{i,j} \, dx d\tau \le F\Big(\Big[\int_0^t \int_R w_{i,j} w_{i,j} \, dx d\tau\Big], \Big[\int_0^t \int_R w_{i,\tau} w_{i,\tau} \, dx d\tau\Big]\Big), \tag{4.23}$$

where F is a computable function. In fact, this can be seen from the following arguments. Let $A = \int_0^t \int_R w_{i,j} w_{i,j} \, dx d\tau$, $B = \int_0^t \int_R w_{i,\tau} w_{i,\tau} \, dx d\tau$, and $Y = \int_0^t \int_R u_{i,j} u_{i,j} \, dx d\tau$. From (4.21) and (4.22), it follows that

$$Y \le \Gamma A B^{\frac{1}{4}} Y^{\frac{1}{4}} + 2A, \tag{4.24}$$

where $\Gamma = 3^{1/2}\Omega^{1/12}J_2/2\lambda_1^{1/2}$. Without loss of generality, we can assume that $Y > 1$; otherwise $F(a,b) = 1$. With this assumption, it is easy to see that

$$Y \leq \Gamma A B^{\frac{1}{4}} Y^{\frac{1}{2}} + 2A. \tag{4.25}$$

Solving inequality (4.25), we have

$$Y \leq \frac{1}{4}\left(\Gamma A B^{\frac{1}{4}} + \sqrt{\Gamma^2 A^2 B^{\frac{1}{2}} + 8A}\right)^2,$$

which proves that (4.23) holds provided that $F(A,B) = \max\{1, (1/4)(\Gamma A B^{\frac{1}{4}} + \sqrt{\Gamma^2 A^2 B^{\frac{1}{2}} + 8A})^2\}$.

From (4.13)–(4.15), it also follows that

$$\int_0^t \int_R v_{i,\tau}v_{i,\tau}\,dxd\tau \leq J_2\sqrt{3}\Omega^{\frac{1}{4}}\left(\int_0^t \int_R w_{i,\tau}w_{i,\tau}\,dxd\tau\right)^{\frac{3}{4}}\left(\int_0^t \int_R u_{i,j}u_{i,j}\,dxd\tau\right)^{\frac{3}{4}},$$

and then by using the elementary inequality $\frac{1}{2}a^2 - b^2 \leq (a-b)^2$, it follows that

$$\begin{aligned}\int_0^t \int_R u_{i,\tau}u_{i,\tau}\,dxd\tau \leq{}& 2\sqrt{3}J_2\Omega^{\frac{1}{4}}\left(\int_0^t \int_R w_{i,\tau}w_{i,\tau}\,dxd\tau\right)^{\frac{3}{4}}\left(\int_0^t \int_R u_{i,j}u_{i,j}\,dxd\tau\right)^{\frac{3}{4}}\\ &+ 2\int_0^t \int_R w_{i,\tau}w_{i,\tau}\,dxd\tau.\end{aligned} \tag{4.26}$$

Inequality (4.26) together with (4.23) indicates that the integral $\int_0^t \int_R u_{i,\tau}u_{i,\tau}\,dxd\tau$ is also bounded by the integrals $\int_0^t \int_R w_{i,j}w_{i,j}\,dxd\tau$ and $\int_0^t \int_R w_{i,\tau}w_{i,\tau}\,dxd\tau$.

Although the above arguments are similar to those used in [2] to compare the solution of the nonlinear equation with the solution of the linearized equation, the conclusions reached here do not require restrictions because of the above argument. In studying the Navier–Stokes pipe flow, conditions were imposed by Ames and Payne [2] in order to bound the energy expression, which effectively said that the decay is ensured only for flows with sufficiently large viscosity coefficients (or small Reynolds' number) and for flows whose data are suitably restricted.

4.2. Bounds for the Brinkman flow. In this section, we focus on finding the bounds for the two integrals $\int_0^t \int_R w_{i,j}w_{i,j}v\,dxd\tau$ and $\int_0^t \int_R w_{i,\tau}w_{i,\tau}\,dxd\tau$ in terms of the physical parameters, boundary data, and geometry of the domain. We use E_1, $\partial E_1/\partial z$, and $\partial^2 E_1/\partial z^2$ to denote the weighted energy integral and its first and second derivatives for the solution w_i of system (4.1)–(4.5). They are defined in the same manner as in (2.9)–(2.11), replacing u_i by w_i. For simplicity, we shall not determine the desired bound explicitly but indicate only how the bounds can be found from the known quantities. Here we let ϵ_i denote positive constants which may be chosen arbitrarily small and c_i denote computable constants that may depend on ϵ_i.

Since the solution w_i and the solution u_i have the same initial and boundary data, on integration by parts, we observe that

$$\begin{aligned}\int_0^t\int_R w_{i,j}w_{i,j}\,dxd\tau &= -\int_0^t\int_{D_0} w_iw_{i,3}\,dAd\tau - \int_0^t\int_R w_iw_{i,jj}\,dxd\tau\\ &= -\int_0^t\int_{D_0} w_iw_{i,3}\,dAd\tau - \int_0^t\int_R w_i\big(w_{i,\tau}+J_1w_i+q_{,i}\big)\,dxd\tau\\ &\le -J_1\int_0^t\int_R w_iw_i\,dxd\tau - \int_0^t\int_{D_0} f_3f_{\alpha,\alpha}\,dAd\tau\\ &\quad -\int_0^t\int_{D_0} f_3q\,dAd\tau - \int_0^t\int_{D_0} f_\alpha w_{\alpha,3}\,dAd\tau \end{aligned}\tag{4.27}$$

and

$$\begin{aligned}\int_0^t\int_R w_{i,\tau}w_{i,\tau}\,dxd\tau &= \int_0^t\int_R w_{i,\tau}\big(w_{i,jj}-J_1w_i-q_{,i}\big)\,dxd\tau\\ &\le -\int_0^t\int_{D_0} f_{i,\tau}w_{i,3}\,dAd\tau + \int_0^t\int_{D_0} f_{3,\tau}q\,dAd\tau\\ &= \int_0^t\int_{D_0} f_{3,\tau}f_{\alpha,\alpha}\,dAd\tau - \int_0^t\int_{D_0} f_{\alpha,\tau}w_{\alpha,3}\,dAd\tau\\ &\quad +\int_0^t\int_{D_0} f_{3,\tau}q\,dAd\tau. \end{aligned}\tag{4.28}$$

Thus (4.27) and (4.28) imply that

$$\begin{aligned}-\frac{\partial E_1}{\partial z}(0,\,t) &= \int_0^t\int_R \big(J_1w_iw_i+w_{i,j}w_{i,j}+kw_{i,\tau}w_{i,\tau}\big)\,dxd\tau\\ &\le \text{data} + \epsilon_1\int_0^t\int_{D_0} w_{\alpha,3}w_{\alpha,3}\,dAd\tau + \epsilon_2\int_0^t\int_{D_0}(q-\bar q)^2\,dAd\tau, \end{aligned}\tag{4.29}$$

where $\bar q = (1/|D_0|)\int_{D_0} q\,dA$ is the mean value of q over D_0 and "data" refers to constants involving only the given data and parameters. Since equation (4.1) is the linearized equation of (2.3), all of the derivations in the previous sections can be obtained simply by letting $J_2 = 0$. This means that we could write

$$E_1(0,t) \le c_1\frac{\partial^2 E_1}{\partial z^2}(0,t) - c_2\frac{\partial E_1}{\partial z}(0,t).\tag{4.30}$$

Moreover, direct calculation shows that

$$\frac{\partial^2 E_1}{\partial z^2}(0,t) \le \text{data} + \int_0^t\int_{D_0} w_{\alpha,3}w_{\alpha,3}\,dAd\tau.\tag{4.31}$$

Using (3.22) and (3.23), we can derive in the same manner that

$$\begin{aligned}\int_0^t\int_{D_0}(q-\bar q)^2\,dAd\tau &\le \text{data} + c_3\int_0^t\int_{D_0} w_{\alpha,3}w_{\alpha,3}\,dAd\tau\\ &\quad - c_4\frac{\partial E_1}{\partial z}(0,t) + c_5E_1(0,t). \end{aligned}\tag{4.32}$$

To establish a bound for the term $\int_0^t \int_{D_0} w_{\alpha,3} w_{\alpha,3}\, dA d\tau$, we consider the identity

$$\int_0^t \int_R w_{i,3} \left[(w_{i,j} - w_{j,i})_{,j} - J_1 w_i - q_{,i} - w_{i,\tau} \right] dx d\tau = 0.$$

On integration by parts, we are led to

$$\begin{aligned} &- \int_0^t \int_{D_0} w_{i,3}(w_{i,3} - w_{3,i})\ dA d\tau + \frac{1}{2} \int_0^t \int_{D_0} w_{i,j}(w_{i,j} - w_{j,i})\, dA d\tau \\ &- J_1 \int_0^t \int_R w_i w_{i,3}\ dx d\tau + \int_0^t \int_{D_0} w_{3,3} q\ dA d\tau - \int_0^t \int_R w_{i,3} w_{i,\tau}\ dx d\tau = 0. \end{aligned}$$

Since $w_{3,3} = -f_{\alpha,\alpha}$ on D_0, we can deduce from this identity that

$$\int_0^t \int_{D_0} w_{\alpha,3} w_{\alpha,3}\, dA d\tau \le \text{data} + \epsilon_3 \int_0^t \int_{D_0} (q - \bar{q})^2\, dA d\tau - c_6 \frac{\partial E_1}{\partial z}(0,t). \tag{4.33}$$

From (4.32) and (4.33), it follows that

$$(1 - c_3\epsilon_3) \int_0^t \int_{D_0} w_{\alpha,3} w_{\alpha,3}\, dA d\tau \le \text{data} - c_4 \epsilon_3 \frac{\partial E_1}{\partial z}(0,t) + c_5 \epsilon_3 E_1(0,t) \tag{4.34}$$

and

$$(1 - c_3\epsilon_3) \int_0^t \int_{D_0} (q - \bar{q})^2\, dA d\tau \le \text{data} - (c_4 + c_3 c_6) \frac{\partial E_1}{\partial z}(0,t) + c_5 E_1(0,t). \tag{4.35}$$

Using (4.31) and (4.34), we can rewrite (4.30) as

$$\frac{1 - c_3\epsilon_3 - c_1 c_5 \epsilon_3}{1 - c_3 \epsilon_3} E_1(0,t) \le \text{data} - \left(c_2 + \frac{c_1 c_4 \epsilon_3}{1 - c_1 \epsilon_3} \right) \frac{\partial E_1}{\partial z}(0,t). \tag{4.36}$$

With an appropriate choice for ϵ_3, we have

$$E_1(0,t) \le \text{data} - c_7 \frac{\partial E_1}{\partial z}(0,t),$$

and we then derive from (4.34) and (4.35) that

$$\int_0^t \int_{D_0} w_{\alpha,3} w_{\alpha,3}\, dA d\tau \le \text{data} - c_8 \frac{\partial E_1}{\partial z}(0,t), \tag{4.37}$$

$$\int_0^t \int_{D_0} (q - \bar{q})^2\, dA d\tau \le \text{data} - c_9 \frac{\partial E_1}{\partial z}(0,t). \tag{4.38}$$

Substituting (4.37) and (4.38) into (4.29) and choosing ϵ_1 and ϵ_2 appropriately, we conclude that

$$-\frac{\partial E_1}{\partial z}(0,t) \le \text{data}, \tag{4.39}$$

which concludes the derivation.

4.3. Bounds for $\boldsymbol{E(0,t)}$. In light of the results above, the quantity $\max_{0\leq\tau\leq t}\int_R (u_iu_i)^{\frac{3}{2}}$ can be bounded by the known data, so the constants in (3.31) depend only on these data. Following the same arguments used in [1, section 6] or the discussions given in section 4.2, we are able to conclude that the total weighted energy $E(0,t)$ has an upper bound in terms of the physical parameters, the boundary data, and the geometry of domain.

5. The estimates for Darcy flow.

For comparison, we discuss the limiting case when J_1 is very large. It is believed that the flow is governed by Darcy's law if the porous medium is dense. In other words, in the limiting case when J_1 is very large, the term involving the time derivative, the Brinkman term, and the Fochheimer term can be ignored so that the model equation has a simple form.

We assume u_i and p are solutions of the following boundary value problem:

$$J_1u_i = -p_i \quad \text{in } R, \tag{5.1}$$

$$u_{i,i} = 0 \quad \text{in } \bar{R}, \tag{5.2}$$

$$u_in_i = 0 \quad \text{on } \partial R\backslash D_0, \tag{5.3}$$

$$u_3 = f(x_1,x_2) \quad \text{in } \bar{D_0}, \tag{5.4}$$

$$u_i,\, p = o(x_3^{-1}) \quad \text{uniformly in } x_{1,}\, x_2 \quad \text{as } x_3\to\infty. \tag{5.5}$$

Define a weighted energy integral for the solution u_i of (5.1)–(5.5) by

$$E(z) = \int_{R_z} J_1(\xi - z)u_iu_i\,dx, \tag{5.6}$$

and so

$$\frac{\partial E}{\partial z} = -J_1\int_{R_z} u_iu_idx, \tag{5.7}$$

Using (5.1), we rewrite E as

$$E(z) = -\int_{R_z}(\xi - z)u_ip_{,i}\,dx = \int_{R_z} u_3p\,dx. \tag{5.8}$$

Following the same techniques used in dealing with I_3 in section 3 (see (3.6)), we can estimate the integral on the right side of (5.8) in terms of the auxiliary vector function ω_α (see (A.3)):

$$\begin{aligned}\int_{R_z} u_3p\,dx &= \int_{R_z}\omega_{\alpha,\alpha}p\,dx = -\int_{R_z}\omega_\alpha p_{,\alpha}\,dx\\ &= \int_{R_z} J_1\omega_\alpha u_\alpha\,dx\\ &\leq J_1\left(\int_{R_z}\omega_\alpha\omega_\alpha\,dx\right)^{\frac{1}{2}}\left(\int_{R_z}u_\alpha u_\alpha\,dxd\tau\right)^{\frac{1}{2}}\\ &\leq J_1\sqrt{\frac{C}{\lambda_1}}\left(\int_{R_z}(u_3)^2\,dx\right)^{\frac{1}{2}}\left(\int_{R_z}u_\alpha u_\alpha\,dx\right)^{\frac{1}{2}}\\ &\leq \frac{J_1\sqrt{C}}{2\sqrt{\lambda_1}}\int_{R_z}u_iu_i\,dx.\end{aligned} \tag{5.9}$$

From (5.8) and (5.9), it follows that

$$E(z) \leq \frac{\sqrt{C}}{2\sqrt{\lambda_1}}\Big(-\frac{\partial E}{\partial z}\Big) \quad \text{for } z \geq 0 \tag{5.10}$$

and hence

$$E(z) \leq E(0,t)e^{-\frac{\sqrt{C}}{2\sqrt{\lambda_1}}z}. \tag{5.11}$$

Using the same techniques as in section 4, we can find the total energy bound explicitly. In fact, we observe that

$$\begin{aligned}\int_R J_1 u_i u_i \, dx &= -\int_R u_i p_{,i} \, dx = \int_{D_0} u_3 p \, dA \\ &\leq \Big(\int_{D_0} f^2 \, dA\Big)^{\frac{1}{2}} \Big(\int_{D_0} (p-\bar{p})^2 \, dA\Big)^{\frac{1}{2}},\end{aligned} \tag{5.12}$$

where $\bar{p} = \int_{D_0} p \, dA$. In a manner similar to the derivation of (3.23), we have

$$\Big(\int_{D_0} (p-\bar{p})^2 \, dA\Big)^{\frac{1}{2}} \leq J_1 \Big(\int_R u_i u_i \, dx\Big)^{\frac{1}{2}}. \tag{5.13}$$

Combining (5.12) and (5.13), we obtain

$$\int_R J_1 u_i u_i \, dx \leq \sqrt{J_1} \int_{D_0} f^2 \, dA. \tag{5.14}$$

Using (5.10) and (5.14), a bound for the total weighted energy in terms of the physical parameter J_1, the boundary data f and the first eigenvalue λ_1 can be given by

$$E(0) \leq \frac{\sqrt{J_1 C}}{2\sqrt{\lambda_1}} \int_{D_0} f^2 \, dA. \tag{5.15}$$

Appendix. Auxiliary inequalities and functions. Here we record some standard inequalities and the properties of two auxiliary functions that we need in order to establish our estimates in the previous sections.

Let S be a plane domain with boundary ∂S.

1. If $w = 0$ on ∂S, then we have the Poincaré inequality

$$\lambda_1 \int_S w^2 \, dA \leq \int_S w_{,\alpha} w_{,\alpha} \, dA, \tag{A.1}$$

where λ_1 is the smallest positive eigenvalue of

$$\Delta\phi + \lambda\phi = 0 \quad \text{in } S, \qquad \phi = 0 \quad \text{on } \partial S.$$

2. If $\partial w / \partial \mathbf{n} = 0$ on ∂S and $\int_S w \, dA = 0$, then the Wirtinger inequality has the form

$$\mu_2 \int_S w^2 \, dA \leq \int_S w_{,\alpha} w_{,\alpha} \, dA, \tag{A.2}$$

where μ_2 is the smallest positive eigenvalue of

$$\Delta\phi + \mu\phi = 0 \quad \text{in } S, \qquad \frac{\partial\phi}{\partial\mathbf{n}} = 0 \quad \text{on } \partial S, \qquad \int_S \phi \, dA = 0.$$

3. If g is a continuously differentiable function on $\bar{S}$ and $\int_S g\,dA = 0$, then there exists a vector function w_α such that

$$w_{\alpha,\alpha} = g \quad \text{in } S, \qquad w_\alpha = 0 \quad \text{on } \partial S$$

and a positive constant C depending on the geometry of S such that

$$\text{(A.3)} \qquad \int_S w_{\alpha,\beta} w_{\alpha,\beta} \, dA \leq C \int_S (w_{\alpha,\alpha})^2 \, dA.$$

The implication above asserts the existence of a vector function w_α which is, in fact, not unique. We require only the existence of such a vector function in our derivation and not an explicit solution. We refer the reader to [2] for a brief discussion concerning the constant C and to [8] for an explicit upper bound for the optimal C when S is a star-shaped domain.

4. We shall make use of two Sobolev inequalities that hold for any sufficiently smooth function w with compact support in either R^2 or R^3:

$$\text{(A.4)} \qquad \int \int_{-\infty}^{\infty} w^4 dA \leq \frac{1}{2} \Big(\int \int_{-\infty}^{\infty} w^2 \, dA \Big) \Big(\int \int_{-\infty}^{\infty} w_{,\alpha} w_{,\alpha} \, dA \Big),$$

$$\text{(A.5)} \qquad \int \int \int_{-\infty}^{\infty} w^6 dx \leq \bar{\Omega} \Big(\int \int \int_{-\infty}^{\infty} w_{,j} w_{,j} \, dx \Big)^3.$$

The best constant in (A.5) has been computed to have the value $\bar{\Omega} = (1/27)(2/\pi)^4$. (A.1)–(A.3) are recorded in [1] and (A.4)–(A.5) are listed in [2].

In the following, we also record some properties for the two auxiliary functions which we used in section 3. These functions are exactly the same as ones used in [1] and the derivation of their properties follows from ideas in [1] (see [1, Lemmas 1-3 and 5-7]).

Let R_z and D_z be the notations introduced in section 2. Suppose that φ and Ψ are the solutions of problems (P1) and (P2), respectively.

$$\text{(P1)} \qquad \begin{cases} \Delta\varphi = f \quad \text{in } R_z, \\ \dfrac{\partial\varphi}{\partial\mathbf{n}} = 0 \quad \text{on } \partial R_z, \\ \displaystyle\int_{R_z} f \, dx = 0, \quad f \to 0 \quad \text{as } x_3 \to \infty. \end{cases}$$

$$\text{(P2)} \qquad \begin{cases} \Delta\Psi = 0 \quad \text{in} \quad R_z, \\ \dfrac{\partial\Psi}{\partial\mathbf{n}} = 0 \quad \text{on } \partial D_\xi, \quad \xi \geq z > 0, \\ \dfrac{\partial\Psi}{\partial\mathbf{n}} = g \quad \text{in } D_z \quad \text{with } \displaystyle\int_{D_z} g \, dA = 0. \end{cases}$$

We have the following estimates for the functions φ and Ψ, respectively:

$$\text{(A.6)} \qquad \int_{R_z} \varphi_{,i} \varphi_{,i} \, dx \leq \frac{1}{\mu_2} \int_{R_z} f^2 \, dx,$$

$$\text{(A.7)} \qquad \int_{D_z} \varphi_{,\alpha} \varphi_{,\alpha} \, dx \leq \frac{2}{\sqrt{\mu_2}} \int_{R_z} f^2 \, dx.$$

If, in addition, D_z is star-shaped with respect to a point (origin) in D_z, then

$$\int_z^\infty \int_{\partial D_\xi} |\text{grad}_s \varphi| \, ds d\xi \le \frac{2}{h_0} \left[\frac{1}{\mu_2} + \frac{d^2}{4} \right] \int_{R_z} f^2 \, dx, \tag{A.8}$$

where d is the diameter of D_0 and $h_0 = \min x_\alpha n_\alpha$ on ∂D_ξ. The notation $\text{grad}_s \varphi$ denotes the tangential component of gradient of φ.

Similarly,

$$\int_{D_z} \Psi_{,\alpha} \Psi_{,\alpha} \, dA = \int_{D_z} g^2 \, dA, \tag{A.9}$$

$$\int_{R_z} \Psi_{,i} \Psi_{,i} \, dx \le \frac{1}{\sqrt{\mu_2}} \int_{D_z} g^2 \, dA, \tag{A.10}$$

and if D_z is star-shaped with a point (origin) in D_z, then

$$\int_z^\infty \int_{\partial D_\xi} |\text{grad}_s \Psi| \, ds d\xi \le \frac{2}{h_0} \left[d + \frac{1}{\sqrt{\mu_2}} \right] \int_{D_z} g^2 \, dAr. \tag{A.11}$$

Acknowledgment. The authors would like to thank one of the referees for suggestions leading to the proof of inequality (4.23) which permitted the removal of unnecessary and unphysical restrictions in the original version of this paper.

SELF-SIMILAR SOLUTIONS FOR A MODIFIED BROADWELL MODEL AND ITS FLUID-DYNAMIC LIMITS[*]

HAITAO FAN[†]

Abstract. The existence of self-similar solutions of the Riemann problem for a modified Broadwell model is established. Regularity estimates at the singular points of the problem are obtained. The passing of the fluid-dynamic limit is justified, which yields the Riemann problem for a system of conservation laws.

Key words. Broadwell model, Riemann problem, fluid-dynamic limits, kinetic theory

1. Introduction.

In this paper, we study the Riemann problem of the Broadwell model and its fluid-dynamic limits. The Broadwell model, proposed by Broadwell [B], is a system of equations

$$\begin{aligned}\frac{\partial f_1}{\partial t} + \frac{\partial f_1}{\partial x} &= \frac{1}{\epsilon}(f_3^2 - f_1 f_2),\\ \frac{\partial f_2}{\partial t} - \frac{\partial f_2}{\partial x} &= \frac{1}{\epsilon}(f_3^2 - f_1 f_2),\\ \frac{\partial f_3}{\partial t} &= \frac{1}{2\epsilon}(f_1 f_2 - f_3^2)\end{aligned} \tag{1.1}$$

that provides a simple statistical description of a gas of interacting particles. Here the functions f_1 and f_2 are the densities of particles moving in positive and negative x-directions, respectively, and f_3 is the density of particles moving in each of the positive or negative of y- or z-directions. The mean free path ϵ is the measure of average distance between successive collisions. An important feature of this system of equations is its asymptotic equivalence in small mean free path ϵ to the Euler of compressible fluid dynamics

$$\begin{aligned}\rho_t + (\rho u)_x &= 0,\\ (\rho u)_t + (\rho g(u))_x &= 0,\end{aligned} \tag{1.2}$$

where

$$\begin{aligned}\rho &= (f_1 + f_2 + 4(f_1 f_2)^{1/2}),\\ m = \rho u &= f_1 - f_2,\\ g(u) &= \frac{1}{3}[2(1+3u^2)^{1/2} - 1].\end{aligned} \tag{1.3}$$

The justification of passing the fluid-dynamic limit in Boltzmann equation or some models of Boltzmann equation has been studied by several authors. The reader is referred to Cercignani [Ce] for a survey of the literature of the Boltzmann equation and to Platkowski and Illner [PI] for results on discrete models of kinetic theory. Recently, Bardos, Golse, and Levermore [BGL] proved the validity of the fluid-dynamic limit of the Boltzmann equation to the incompressible Navier–Stokes equations under some hypothesis. For the Broadwell model, Caflisch and Papanicolaou [CP] and Caflisch [Ca] showed that a given smooth solution of the limit equation can be approximated by a solution of the Broadwell model when ϵ is small. For solutions with shocks of the Broadwell model, there are studies on the stability in time for traveling waves [CL], [KM] and rarefaction waves [Ma]. Xin [X] proved that a given piecewise smooth solution with noninteracting shocks of the limit fluid equations can be approximated by solutions of the Broadwell model as $\epsilon \to 0+$. Recently, Liu and Xin [LX] studied the boundary-layer problems for the Broadwell model and revealed some interesting phenomena. They found that there exist boundary layers in the Broadwell model due to purely kinetic effects that cannot be detected by Chapman–Enskog expansion on the viscous level. They classified the boundary layers as compressive and expansive and showed that expansive boundary layers are stable while compressive boundary layers are stable before they leave the boundary. They also obtained the optimal rate of convergence in the L^∞-norm of kinetic solutions to fluid-dynamic solution in terms of ϵ if the interior fluid flow is smooth. Many of above-mentioned works belong to the approximation program, meaning that an admissible solution of the limit equation, which is a system of conservation laws, is used to construct solutions of the Broadwell model and is intended as a method to solve the Broadwell model. Another approach is to construct solutions of the limit conservation laws as the limit of solutions of the Broadwell model. Recently, Slemrod and Tzavaras [ST], [T] studied the self-similar fluid-dynamic limits of a modified Riemann problem of (1.1) with Maxwellian Riemann data. Work done by Chen and Liu [ChL] and Chen et al. [CLL] on relaxation also sheds light on this subject.

In an attempt to gain insight in the latter direction, Slemrod and Tzavaras [ST] studied the self-similar dynamic-limit approach. For Maxwellian Riemann data

$$f(x,0) = \begin{cases} f_+, & x > 0, \\ f_-, & x < 0, \end{cases} \tag{1.4a}$$

$$Q(f_+) = 0, \qquad Q(f_-) = 0, \quad f_{1\pm}, f_{2\pm}, f_{3\pm} > 0, \tag{1.4b}$$

where

$$Q(f) = f_3^2 - f_1 f_2, \tag{1.4c}$$

the solutions of the limit equation (1.2) are expected to be self-similar functions of $\xi = x/t$. Motivated by this reasoning, they considered the modified Broadwell system

$$\begin{aligned} \frac{\partial f_1}{\partial t} + \frac{\partial f_1}{\partial x} &= \frac{1}{\epsilon t}(f_3^2 - f_1 f_2), \\ \frac{\partial f_2}{\partial t} - \frac{\partial f_2}{\partial x} &= \frac{1}{\epsilon t}(f_3^2 - f_1 f_2), \\ \frac{\partial f_3}{\partial t} &= \frac{1}{2\epsilon t}(f_1 f_2 - f_3^2). \end{aligned} \tag{1.5}$$

By making the ansatz $f(x,t) = f(x/t)$ in (1.4) and (1.5), the Riemann problem (1.4)–(1.5) becomes a singular boundary-value problem:

$$\begin{aligned} (1-\xi)f_1' &= \frac{Q(f)}{\epsilon}, \\ -(1+\xi)f_2' &= \frac{Q(f)}{\epsilon}, \\ \xi f_3' &= \frac{Q(f)}{2\epsilon}, \\ f(-1) = f_-, &\qquad f(+1) = f_+, \\ Q(f_+) = 0, &\qquad Q(f_-) = 0, \quad f_{1\pm}, f_{2\pm}, f_{3\pm} > 0, \end{aligned} \tag{1.6}$$

for $\xi \in [-1,1]$. They proved that the total variations of solutions of (1.6) are bounded uniformly in ϵ, and hence there is a sequence $\{f^{\epsilon_n}\}$, $\epsilon_n \to 0+$, such that $f^{\epsilon_n} \to f$ almost everywhere, where f is a weak solution of the Riemann problem (1.2), (1.4). However, the existence of solutions of (1.6) was proved only in the case where $f_{1-} < f_{1+}$, $f_{2-} > f_{2+}$, and $f_{3-} = f_{3+}$. Under these assumptions on the initial data, the limit solution will be continuous and hence precludes the case where shocks are present.

In this paper, we shall prove the existence of a positive continuous solution of (1.6) and hence (1.4)–(1.5) with no restrictions attached. We also prove some regularity estimates for solutions of (1.6). The precise statement of these results is as follows.

Theorem 1.1. *There exists a positive continuous solution of* (1.6). *Moreover, any positive solution $f(\xi)$ of* (1.6) *satisfies the following estimates:*

$$f_1(\xi) - f_{1+} = O(1)(1-\xi)^{\frac{f_{2+}}{\epsilon}} \quad \textit{for } \xi \textit{near} \xi = 1, \tag{1.7a}$$

$$f_2(\xi) - f_{2-} = O(1)(\xi+1)^{\frac{f_{1-}}{\epsilon}} \quad \textit{for} \xi \textit{ near } \xi = -1, \tag{1.7b}$$

and

$$f_3(\xi) - f_3(0) = O(1)|\xi|^{\frac{\min(f_{3-}, f_3(0), f_{3+})}{\epsilon}} \quad \textit{for } \xi \textit{ near } \xi = 0, \tag{1.7c}$$

$$Q(f(\xi)) = O(1)(\xi+1)^{\frac{f_{1-}}{\epsilon}}(1-\xi)^{\frac{f_{2+}}{\epsilon}}|\xi|^{\frac{\min(f_{3-}, f_3(0), f_{3+})}{\epsilon}}. \tag{1.7d}$$

Combining Theorem 1.1 with the results from [ST], we prove the following.

Corollary 1.2. *For any Maxwellian Riemann data* (1.4), *there is a solution of* (1.4)–(1.5) $f^\epsilon(x/t)$. *Further, there is a sequence of solutions of* (1.4)–(1.5), $\{f^{\epsilon_n}\}$, $\epsilon_n \to 0+$, *such that f^{ϵ_n} converges almost everywhere to a weak solution of the limit equations* (1.2) *and* (1.4).

Remark. It is interesting to see that for system (1.1), the discontinuity at $x = 0$ at initial time will propagate along $x/t = \pm 1$ and $x = 0$, which are characteristics of (1.1), while for the modified system (1.5), there is no discontinuity at these locations. In fact, the discontinuities of (1.1) at $x/t = \pm 1$ and $x = 0$ are not intrinsic in the sense that in the limit $\epsilon \to 0+$, there is no shock at $x/t = \pm 1$ due to the stability condition, and there may not be a shock at $x = 0$ in the limit system (1.2).

We organize this paper as follows. In section 2, we recall some results from [ST] and state the main results of this paper. In section 3, we prove that (1.6) has a continuous positive solution. The method we use is a kind of shooting argument. Finally, we prove that for some sequence $\{\epsilon_n\}$, $\epsilon_n \to 0+$ as $n \to \infty$, the solutions of (1.6), f^{ϵ_n}, converge almost everywhere to a weak solution of (1.2), (1.4).

2. Preliminaries.

We see that there are three singular points, $\xi = \pm 1, 0$, in the boundary-value problem (1.6). At $\xi = \pm 1$, two components of f are continuous. Thus the other component must also be continuous due to the boundary condition. Therefore, in what follows, we define the solutions of (1.6) to be weak solutions of (1.6) which are continuous on $[-1, 0) \cup (0, 1]$.

We recall some results on (1.6) obtained in [ST].

Lemma 2.1. *Let $f = (f_1, f_2, f_3)$ be a continuous solution of* (1.6). *Then*

(i) $Q(f(\xi))$ *does not change sign on the intervals* $(-1, 0)$ *or* $(0, 1)$*,*

(ii) $Q(f(-1)) = Q(f(0)) = Q(f(+1)) = 0$*, and*

(iii) f_1*,* f_2*, and* f_3 *are uniformly bounded from above and below by positive constants and of uniformly bounded total variation on* $[-1, 1]$. *These bounds are independent of* $\epsilon > 0$.

In fact, assertion (i) of Lemma 2.1 does not require the continuity of f. For our later use, we revise it as follows.

Lemma 2.2. *Let f be a solution of* (1.6). *Then $Q(f(\xi))$ does not change sign on the interval* $(-1, 0)$ *and* $(0, 1)$. *Furthermore, each component of f is monotone on each interval* $(-1, 0)$ *and* $(0, 1)$.

Proof. A straightforward calculation based on (3.1) shows that

$$\frac{dQ}{d\xi} = \frac{1}{\epsilon}\left(\frac{f_1(\xi)}{\xi + 1} + \frac{f_2(\xi)}{\xi - 1} + \frac{f_3(\xi)}{\xi}\right) Q(\xi), \tag{2.1}$$

from which the assertion follows. □

3. Existence of solutions of (1.6).

In this section, when we refer to solutions of a system of ordinary differential equations, we always mean continuous solutions unless otherwise indicated. We intend to prove the existence of (1.6) by a kind of shooting argument. For this purpose, we consider the trajectories of

$$\begin{aligned} (1 - \xi) f_1' &= \frac{Q(f)}{\epsilon}, \\ -(\xi + 1) f_2' &= \frac{Q(f)}{\epsilon}, \\ \xi f_3' &= \frac{Q(f)}{2\epsilon}, \quad \xi \in (-1, 1), \end{aligned} \tag{3.1}$$

issued from

$$(f_{1-}, f_{2-}, f_{3-}) \quad \text{at } \xi = -1 \tag{3.2}$$

and

$$(f_{1+}, f_{2+}, f_{3+}) \quad \text{at } \xi = +1, \tag{3.3}$$

respectively, where $f_{3\pm} = (f_{1\pm} f_{2\pm})^{1/2}$. It is clear that (3.1) has three singular points, $\xi = -1, 0, +1$. We first need some regularity results of trajectories of (3.1) near these points.

Lemma 3.1.

(i) *Let f be a bounded solution of* (3.1) *and* (3.2) *on* $[-1, 0)$. *Then*

(3.4a)

$$Q = C(1 + \xi)^{\frac{f_{1-}}{\epsilon}} (1 - \xi)^{\frac{f_{2+}}{\epsilon}} |\xi|^{\frac{\min(f_{3-}, f_3(0-))}{\epsilon}} \times \exp\left[\frac{1}{\epsilon}\int_{-1}^{\xi}\left(\frac{f_1(\zeta) - f_{1-}}{\zeta + 1} + \frac{f_2(\zeta) - f_{2+}}{\zeta - 1} + \frac{f_3(\zeta) - \min(f_{3-}, f_3(0-))}{\zeta}\right) d\zeta\right].$$

In fact, the numbers f_1*,* f_{2+}*, and* $\min(f_{3-}, f_3(0-))$ *in* (3.4a) *can be replaced by any other numbers.*

(ii) *Let* f *be a bounded solution of* (3.1) *and* (3.2) *on* $(0, 1]$*. Then*

$$Q = C(1+\xi)^{\frac{f_{1-}}{\epsilon}}(1-\xi)^{\frac{f_{2+}}{\epsilon}}|\xi|^{\frac{\max(f_{3+}, f_3(0+))}{\epsilon}} \times \exp\left[\frac{1}{\epsilon}\int_1^{\xi}\left(\frac{f_1(\zeta)-f_{1-}}{\zeta+1}+\frac{f_2(\zeta)-f_{2+}}{\zeta-1}+\frac{f_3(\zeta)-\max(f_{3+}, f_3(0+))}{\zeta}\right)d\zeta\right]. \tag{3.4b}$$

In fact, the numbers f_{1-}*,* f_{2+}*, and* $\max(f_{3+}, f_3(0+))$ *in* (3.4b) *can be replaced by any other numbers.*

(iii) *Let* f *be a bounded solution of* (3.1) *and* (3.2) *on* $[-1, 0)$*. Then*

$$Q \le O(1)|\xi|^{\frac{\min(f_{3-}, f_3(0-))}{\epsilon}}. \tag{3.5a}$$

(iv) *Let* f *be a bounded solution of* (3.1) *and* (3.3) *on* $(0, 1]$*. Then*

$$Q \le O(1)|\xi|^{\frac{\max(f_{3+}, f_3(0+))}{\epsilon}}. \tag{3.5b}$$

Proof. (i) Since f_3 is bounded and monotone on each of the intervals $[-1, 0)$ and $(0, 1]$, the one-sided limits $f_3(0\pm)$ are well defined and finite. Equation (3.4a) can be obtained from (2.1) as follows:

$$\begin{aligned} Q(f(\epsilon)) &= Q\left(f\left(-\frac{1}{2}\right)\right) \times \exp\left[\frac{1}{\epsilon}\int_{-\frac{1}{2}}^{\xi}\left(\frac{f_1(\zeta)}{\zeta+1}+\frac{f_2(\zeta)}{\zeta-1}+\frac{f_3(\zeta)}{\zeta}\right)d\zeta\right] \\ &= Q\left(f\left(-\frac{1}{2}\right)\right)(\xi+1)^{\frac{f_{1-}}{\epsilon}}(1-\xi)^{\frac{f_{2+}}{\epsilon}}|\xi|^{\frac{\min(f_{3-}, f_3(0-)}{\epsilon}} \\ &\quad \times \exp\left[\frac{1}{\epsilon}\int_{\frac{-1}{2}}^{\xi}\left(\frac{f_1(\zeta)-f_{1-}}{\zeta+1}+\frac{f_2(\zeta)-f_{2+}}{\zeta-1}+\frac{f_3(\zeta)-\min(f_{3-}, f_3(0-))}{\zeta}\right)d\zeta\right] \\ &= C(1+\xi)^{\frac{f_{1-}}{\epsilon}}(1-\xi)^{\frac{f_{2+}}{\epsilon}}|\xi|^{\frac{\min(f_{3-}, f_3(0-))}{\epsilon}} \\ &\quad \times \exp\left[\frac{1}{\epsilon}\int_{-1}^{\xi}\left(\frac{f_1(\zeta)-f_{1-}}{\zeta+1}+\frac{f_2(\zeta)-f_{2+}}{\zeta-1}+\frac{f_3(\zeta)-\min(f_{3-}, f_3(0-))}{\zeta}\right)d\zeta\right]. \end{aligned} \tag{3.6}$$

The proof of (ii) is similar.

(iii) If $Q \ge 0$ on $[-1, 0)$, then f_2 and f_3 are decreasing and

$$f_1' = \frac{Q}{\epsilon(1-\xi)} \le \frac{f_3^2}{\epsilon(1-\xi)} \le \frac{f_{3-}^2}{\epsilon(1-\xi)},$$

and hence the integral in (3.4a) is either negative or bounded. Thus we have the estimate

$$Q \le O(1)|\xi|^{\frac{\min(f_{3-}, f_3(0-))}{\epsilon}}.$$

If $Q < 0$ on $[-1, 0)$, then f_1 is decreasing and f_2 is increasing; hence $f_1(\xi) < f_{1-}$ and $f_2(\xi > f_{2-}$ for $\xi \in [-1, 0)$. A variation of (3.4a) states that

$$Q = C(1+\xi)^{\frac{f_{1-}}{\epsilon}}(1-\xi)^{\frac{f_{2-}}{\epsilon}}|\xi|^{\frac{\min(f_{3-}, f_3(0-))}{\epsilon}} \times \exp\left[\frac{1}{\epsilon}\int_{-1}^{\xi}\left(\frac{f_1(\zeta)-f_{1-}}{\zeta+1}+\frac{f_2(\zeta)-f_{2-}}{\zeta-1}+\frac{f_3(\zeta)-\min(f_{3-}, f_3(0-)}{\zeta}\right)d\zeta\right].$$

Since every term of the integrand is negative, we also have

$$Q = O(1)|\xi|^{\frac{\min(f_{3-}, f_3(0-))}{\epsilon}}.$$

We can prove (iv) similarly. □

Now we need some existence results for the trajectories of (3.1) and (3.2) and those of (3.1) and (3.3). For definiteness, we consider (3.1) and (3.2). The other part can be handled similarly. In view of Lemma 3.1, we let

$$P(\xi) := \frac{Q(f(\xi))}{(1+\xi)^{\frac{f_{1-}}{\epsilon}}}. \tag{3.7}$$

Under this transformation, the initial-value problem (3.1)–(3.2) becomes a regular problem:

$$\begin{aligned} f_1' &= \frac{(1+\xi)^{\frac{f_{1-}}{\epsilon}} P}{\epsilon(1-\xi)}, \\ f_2' &= \frac{-(1+\xi)^{\frac{f_{1-}}{\epsilon}-1} P}{\epsilon}, \\ P' &= \frac{P(\xi)}{\epsilon}\left(\frac{1}{1+\xi}\int_{-1}^{\xi} \frac{(1+s)^{\frac{f_{1-}}{\epsilon}}}{(1-s)\epsilon} P(s)ds \right. \\ &\quad \left. + \frac{f_2}{\xi-1} + \frac{f_{3-} + \int_{-1}^{\xi} \frac{1}{2\epsilon s}(1+s)^{\frac{f_{1-}}{\epsilon}} P(s)ds}{\xi}\right) \end{aligned} \tag{3.8}$$

with initial conditions

$$f_1(-1) = f_{1-}, f_2(-1) = f_{2-}, P(-1) = P_-. \tag{3.9}$$

LEMMA 3.2. *The system of equations* (3.8)–(3.9) *is equivalent to* (3.1)–(3.2).

Proof. It is clear that (3.1) implies (3.8). To see that (3.8) implies (3.1), we let

$$\begin{aligned} Q &= (1+\xi)^{\frac{f_{1-}}{\epsilon}} P(\xi), \\ f_3 &:= f_{3-} + \int_{-1}^{\xi} \frac{Q}{\epsilon s} ds. \end{aligned} \tag{3.10}$$

A straightforward calculation based on (3.8) yields (3.1) and

$$\begin{aligned} \frac{dQ}{d\xi} &= \frac{1}{\epsilon}\left(\frac{f_1}{\xi+1} + \frac{f_2}{\xi-1} + \frac{f_3}{\xi}\right)Q \\ &= -f_1 f_2' - f_2 f_1' + (f_3^2)' \\ &= \frac{d}{d\xi}(f_3^2 - f_1 f_2), \end{aligned}$$

which implies

$$\begin{aligned} Q &= f_2^2 - f_1 f_2 + f_3^2(-1) - f_1(-1) f_2(-1) \\ &= f_3^2 - f_1 f_2. \qquad \square \end{aligned} \tag{3.11}$$

The following lemma indicates how $f(\xi, P_-)$ can be extended to $[-1, 0]$.

LEMMA 3.3. *For any $f_{1-} > 0$, $f_{2-} > 0$, and $P_- = (Q(f(\xi))/(1+\xi)^{\frac{f_{1-}}{\epsilon}})\big|_{\xi=-1}$, problem* (3.8)–(3.9) *has a unique solution on* $[-1, \xi_0)$ *for some* $\xi_0 \in (-1, 0]$.

Proof. System (3.8)–(3.9) is an initial-value problem for systems of regular differential integral equations to which the standard contraction-mapping argument applies, and hence we have the assertion. □

For convenience, we shall denote the trajectory of (3.1)–(3.2) that satisfies (3.18) by

$$f(\xi; f_{1-}, f_{2-}, P_-)$$

or by $f(\xi; P_-)$ when no confusion will arise.

LEMMA 3.4. *Let $f_{1-} > 0$ and $f_{2-} > 0$.*

(i) *If $P_- \le 0$, then problem* (3.8)–(3.9) *has a unique solution on* $[-1, 0]$.

(ii) *For $P_- > 0$, the solution of* (3.8)–(3.9) *exists on* $[-1, 0]$ *if and only if* $f_2(\xi) > 0$ *on* $[-1, 0) \cap$ (*domain of* f).

(iii) *If the solution of* (3.1)–(3.2) *exists on* $[-1, 0]$, *then f is positive on* $[-1, 0)$, *i.e., all of the components of f are positive on* $[-1, 0)$.

Proof. From the structure of (3.1), we can see that if $Q(f(\xi))$ is bounded on $[-1, 0]$ in supremum norm, then $f(\xi)$ is bounded in $[-1, \xi_1]$ for any $\xi_1 \in (-1, 0)$. Then by the standard argument of continuation of contraction mapping, the existence and uniqueness result of Lemma 3.3 can be extended to $[-1, 0)$.

(i) In the case where $P_- \le 0$, we have similarly to (3.4a) that

$$Q(f(\xi)) = P_-(1+\xi)^{\frac{f_{1-}}{\epsilon}}(1-\xi)^{\frac{f_{2-}}{\epsilon}}|\xi|^{\frac{f_{3-}}{\epsilon}} \times \exp\left[\frac{1}{\epsilon}\int_{-1}^{\xi}\left(\frac{f_1(\zeta)-f_{1-}}{\zeta+1} + \frac{f_2(\zeta)-f_{2-}}{\zeta-1} + \frac{f_3(\zeta)-f_{3-}}{\zeta}\right)d\zeta\right] < 0. \tag{3.12}$$

Then equation (3.1) implies that

$$\begin{aligned} f_1(\zeta) &< f_{1-} = f_1(-1),\\ f_2(\zeta) &> f_{2-} = f_2(-1),\\ f_3(\zeta) &> f_{3-} \end{aligned} \tag{3.13}$$

for $\zeta \in (-1, 0]$ and therefore

$$|Q(f(\xi))| \le |P_-|(1+\xi)^{\frac{f_{1-}}{\epsilon}}(1-\xi)^{\frac{f_{2-}}{\epsilon}}|\xi|^{\frac{f_{3-}}{\epsilon}}.$$

Hence f is bounded in $[-1, 0]$, and thus the solution of (3.8)–(3.9) exists on $(-1, 0)$. Further, because of (3.13), the existence can be extended to $[-1, 0]$.

(ii) In the case where $P_- > 0$, we can derive from (3.12) that $Q(f(\xi)) > 0$ on $[-1, 0]$. Then (3.1) shows that

$$\begin{aligned} f_1(\xi) &> f_{1-} > 0,\\ f_2(\xi) &< f_{2-},\\ f_3(\xi) &< f_{3-} \end{aligned}$$

for $\xi \in (-1, 0) \cap$ (domain of existence of f). If $f_2(\xi) > 0$ for $\xi \in (-1, 0)$, then

$$f_{3-} > f_3(\xi) > 0, \quad \xi \in (-1, 0),$$

because otherwise equation $(3.1)_3$ shows that at ξ_0, the infimum of points at which $f_3(\xi)=0$,

$$f_3'(\xi_0)=\frac{-f_1(\xi_0)f_2(\xi_0)}{\epsilon\xi_0}>0,$$

which cannot be true at ξ_0. Thus we have

$$0<Q(f(\xi))<f_3^2(\xi)<f_{3-}^2. \tag{3.14}$$

Conversely, if $f_2(\xi_0)<0$ for some $\xi_0\in(-1,0)$, then

$$f_2'(\xi)=\frac{Q(f)}{\xi}<\frac{-f_1(\xi_0)f_2(\xi_0)}{\xi}<0,$$

where we have used the monotonicity of f_1 and f_2 on $(-1,0)$. It can be seen that $f_2(\xi)\to-\infty$ and hence $Q(f(\xi))\to\infty$ as ξ approaches $0-$. Then the assertion in (ii) follows.

(iii) We first claim that $f_1(\xi)>0$ on $[-1,0)$. Indeed, otherwise, there would be a point $\xi_0\in[-1,0)$ such that $f_1(\xi_0)=0$ and $f_1(\xi)>0$ for $\xi\in[-1,\xi_0)$. Then we have $f_1'(\xi_0)\le 0$. On the other hand, however, equation $(3.1)_1$ implies that $0\le(1-\xi_0)f_1'(\xi_0)=Q(f(\xi_0))=f_3^2(\xi_0)\ge 0$. From (3.4a), we see that $Q(f(\xi)$ remains positive or negative or 0 on $(-1,0)$, which in our case says that $Q\equiv 0$ on $(-1,0)$. This implies that $f_1\equiv f_{1-}$ on $(-1,0)$, which is a contradiction.

When $P_-\le 0$, our assertion holds in view of (3.13).

When $P_->0$, assertion (ii) says that $f_2(\xi)>0$ on $[-1,0)$. Further, the proof of (ii) indicates that if $f_2(\xi)>0$ on $[-1,0)$, then so does f_3. This completes the proof of (iii). □

Theorem 3.5. *For any $f_{1-}>0$ and $f_{2-}>0$, there is P_0, $0<P_0<\infty$, such that problem* (3.8)–(3.9) *has a unique solution on $[-1,0]$ for $P_-\in(-\infty,P_0]$ and*

$$f_2(0;f_{1-},f_{2-},P_0)=0\,. \tag{3.15}$$

Furthermore, the solution $f(\xi,P_-)$ is positive on $[-1,0)$ for all $P_-\in(-\infty,P_0]$.

Proof. From Lemma 3.4(i), we see that problem (3.8)–(3.9) has a unique solution on $[-1,0]$ for all $P_-\le 0$.

Suppose (3.8)–(3.9) has a solution for some $\bar{P}_->0$. We claim that (3.8)–(3.9) has a solution for all $P_-\in(-\infty,\bar{P}_-]$. To this end, without loss of generality, we consider only $\bar{P}_->P_->0$. Let

$$\begin{aligned}\bar{f}(\xi)&:=f(\xi;f_{1-},f_{2-},\bar{P}_-),\\ f(\xi)&:=f(\xi;f_{1-},f_{2-},P_-)\,.\end{aligned}$$

We claim that

$$Q(\bar{f}(\xi))>Q(f(\xi)) \tag{3.16}$$

for all $\xi\in(-1,0)$ if $f(\xi)$ exists. To see this, we recall that

$$\bar{P}(-1)=\frac{Q(f(\xi))}{(1+\xi)^{\frac{f_{1-}}{\epsilon}}}\bigg|_{\xi=-1}=\bar{P}_->P_-=P(-1)=\frac{Q(f(\xi))}{(1+\xi)^{\frac{f_{1-}}{\epsilon}}}\bigg|_{\xi=-1}.$$

Then there is a $\xi_0 \in (-1, 0]$ such that for $\xi \in (-1, \xi_0)$, the solutions $\bar{P}(\xi)$ and $P(\xi)$ to (3.8)–(3.9), with $\bar{P}(-1) = \bar{P}_-$ and $P(-1) = P_-$, respectively, satisfy

$$\bar{P}(\xi) > P(\xi)$$

and hence

$$Q(\bar{f}(\xi)) > Q(f(\xi)).$$

Without loss of generality, we can assume ξ_0 to be the maximum of ξ_0 in the above statement. Then

$$Q(\bar{f}(\xi_0)) = Q(f(\xi_0)) \tag{3.17}$$

and

$$Q(\bar{f}(\xi)) > Q(f(\xi)) \tag{3.18}$$

for $\xi \in (-1, \xi_0)$. From (3.1), we see that

$$\begin{aligned} &\bar{f}_1(\xi) > f(\xi),\\ &\bar{f}_2(\xi) < f_2(\xi),\\ &\bar{f}_3(\xi) < f_3(\xi) \end{aligned} \tag{3.19}$$

for $\xi \in (-1, \xi_0)$. Using the same technique used to derive (3.4), we obtain

$$\begin{aligned} 0 &= Q(\bar{f}(\xi_0)) - Q(f(\xi_0))\\ &= \bar{P}_-(1+\xi)^{\frac{f_{1-}}{\epsilon}} \exp\left[\frac{1}{\epsilon}\int_{-1}^{\xi_0}\left(\frac{\bar{f}_1(\zeta) - f_{1-}}{\zeta+1} + \frac{\bar{f}_2(\zeta)}{\zeta-1} + \frac{\bar{f}_3(\zeta)}{\zeta}\right)d\zeta\right]\\ &\quad - P_-(1+\xi)^{\frac{f_{1-}}{\epsilon}} \exp\left[\frac{1}{\epsilon}\int_{-1}^{\xi}\left(\frac{f_1(\zeta) - f_{1-}}{\zeta+1} + \frac{f_2(\zeta)}{\zeta-1} + \frac{f_3(\zeta)}{\zeta}\right)d\zeta\right]\\ &= Q(f(\xi_0))\left\{\frac{\bar{P}_-}{P_-}\exp\left[\frac{1}{\epsilon}\int_{-1}^{\xi}\left(\frac{\bar{f}_1(\zeta) - f_1(\zeta)}{\zeta+1} + \frac{\bar{f}_2(\zeta) - f_2(\zeta)}{\zeta-1}\right.\right.\right.\\ &\qquad\qquad \left.\left.\left. + \frac{\bar{f}_3(\zeta) - f_3(\zeta)}{\zeta}\right)d\zeta\right] - 1\right\} > 0, \end{aligned}$$

where in the last inequality we used (3.19), which is a contradiction. This proves that if $\bar{P}_- > P_- > 0$,

$$0 < Q(f(\xi)) < Q(\bar{f}(\xi))\,. \tag{3.20}$$

Then by (3.1) and the assumption that $\bar{f}(\xi)$ is a solution of (3.1)–(3.2) on $[-1, 0]$, we have

$$0 \le \bar{f}_2(\xi) < f_2(\xi),$$

and hence $f(\xi, P_-)$ exists in view of Lemma 3.4(ii).

Now we denote

$$\begin{aligned} P_0 := \sup\{\bar{P}_- \ge 0;\ &(3.8)\text{–}(3.9) \text{ has a solution on}\\ &[-1, 0] \text{ with } P_- = \bar{P}_- \text{ on } [-1, 0]\} \ge 0. \end{aligned} \tag{3.21}$$

Then we have proved that (3.8)–(3.9) has a solution on $[-1,0]$ with $P_- \in (-\infty, P_0)$. It remains to prove that $P_0 < +\infty$ and that $f(\xi, f_{1-}, f_{2-}, P_0)$ exists on $[-1,0]$ and $f_2(0,P_0) = 0$. We claim that

$$\lim_{P_- \to P_0} f(\xi; P) \tag{3.22}$$

exists for all $\xi \in [-1,0]$ and is the solution $f(\xi, f_{1-}, f_{2-}, P_0)$. To this end, we observe that $P_0 \geq 0$. If $-1 \leq P \leq 0$, then the proof of Lemma 3.4(i) states that $f(\xi)$ is bounded on $[-1,0]$. If $P_0 > P > 0$, then by (3.19) we have

$$0 \leq Q(f(\xi; P_-)) < f_3^2(\xi; P_-) < f_{3-}^2, \tag{3.23}$$

and hence $f_1(\xi; f_{1-}, f_{2-}, P_-)$ is bounded uniformly in P_-, and so are f_2 and f_3 since

$$\begin{aligned} 0 &< f_2(\xi; P_-) < f_{2-}, \\ 0 &< f_3(\xi; P_-) < f_{3-}. \end{aligned} \tag{3.24}$$

Also, f_1, f_2, and f_3 are monotone in ξ on $[-1,0]$ and hence have total variation bounded independently of $P \in [-1, P_0)$, and hence (3.22) exists. The conclusion that the limit is the solution $f(\xi; f_{1-}, f_{2-}, P_0)$ is obvious from the integral form of (3.8). We claim that $P_0 < +\infty$. Indeed, otherwise, we would have similarly to (3.4) that

$$\begin{aligned} Q(f(\xi; P_-)) &= P_-(1+\xi)^{\frac{f_{1-}}{\epsilon}}(1-\xi)^{\frac{f_{2-}}{\epsilon}}|\xi|^{\frac{f_{3-}}{\epsilon}} \\ &\quad\times \exp\left[\frac{1}{\epsilon}\int_{-1}^{\xi}\left(\frac{f_1(\zeta)-f_{1-}}{\zeta+1} + \frac{f_2(\zeta)-f_{2-}}{\zeta-1} + \frac{f_3(\zeta)-f_{3-}}{\zeta}\right)d\zeta\right] \\ &\quad> P_-(1+\xi)^{\frac{f_{1-}}{\epsilon}}(1-\xi)^{\frac{f_{2-}}{\epsilon}}|\xi|^{\frac{f_{3-}}{\epsilon}} \to \infty \quad \text{as } P_- \to +\infty \end{aligned}$$

for $\xi \in (-1,0)$, where we used (3.24) when $P_- > 0$. Then from $(3.1)_2$, we have

$$f_2(\xi; P_-) = f_{2-} - \int_{-1}^{\xi} \frac{Q(f(\zeta; P_-))}{\zeta+1} d\zeta \to -\infty \qquad \text{as } P_- \to +\infty \tag{3.25a}$$

for $\xi \in (-1,0)$. On the other hand, we have

$$f_2(\xi, P_0) \geq f_2(0; P_0) = \lim_{P_- \to P_0} f_2(0; P_-) \geq 0 \tag{3.25b}$$

for $\xi \in [-1,0]$. The contradiction between (3.25a) and (3.25b) proves the claim that $P_0 < +\infty$. Finally, we verify that

$$f_2(0, P_0) = 0\,.$$

For contradiction, we assume the contrary, which is, in light of (3.25b), that

$$f_2(0; P_0) > 0. \tag{3.26}$$

Consider $f(\xi; f_{1-}, f_{2-}, P_-)$ for any P_- close to P_0 and $P_- > P_0 \geq 0$. The solution $f(\xi; P_-)$ of (3.8)–(3.9) cannot be defined on $[-1,0]$, for otherwise the definition of P_0, (3.21), would be violated. Then by Lemma 3.4(ii),

$$f_2(\xi_0; f_{1-}, f_{2-}, P_-) = 0 \tag{3.27}$$

for some $\xi_0 = \xi_0(P_-) \in (-1, 0)$. Take a sequence of $\{P_{-,k}\}_{k=1}^{\infty}$ such that $P_{-,k} \to P_0+$ and $\xi_k = \xi_0(P_{-,k}) \to \eta$ as $k \to +\infty$. For any small $\tau > 0$, by the definition of η, $f(\xi; f_{1-}, f_{2-}, P_{-,k})$ exists on $[-1, -\tau + \eta]$. Since the right-hand side of (3.8) is continuous and hence its solution is continuous in initial value (3.9), we have

$$|f(-\tau + \eta, P_0) - f(-\tau + \eta, P_{-,k})| \to 0 \quad \text{as } k \to \infty. \tag{3.28}$$

Since $f_2(\xi)$ is decreasing when $P_- > 0$, we infer from (3.26) that

$$f_2(-\tau + \eta, f_{1-}, f_{2-}, P_0) =: f_0 > 0, \tag*{(3.29),}$$

and hence

$$f_2(-\tau + \eta, P_{-,k}) > \frac{1}{2} f_0 \tag{3.30}$$

for large k. Then the mean-value theorem implies that

$$\begin{aligned} |f_2'(\theta; P_{-,k})| &= \left| \frac{f_2(\xi_0(P_{-,k}), P_{-,k}) - f_2(-\tau + \eta, P_{-,k})}{\xi_0(P_{-,k}) + \tau - \eta} \right| \\ &\geq \frac{|0 - \frac{1}{2} f_0|}{2\tau} = \frac{f_0}{4\tau} \end{aligned} \tag{3.31}$$

for some $\theta \in (-\tau + \eta, \xi_0(P_{-,k})) \subset (-1, 0)$. On the other hand, we also have

$$\begin{aligned} |f_2'(\theta; P_{-,k})| &= \frac{Q(f(\theta; P_{-,k}))}{(\theta + 1)\epsilon} \\ &< \frac{f_3^2(\theta, P_{-,k})}{(\theta + 1)\epsilon} < \frac{f_{3-}^2}{(\theta + 1)\epsilon} < \frac{f_{3-}^2}{(1 - \tau + \eta)\epsilon}, \end{aligned} \tag{3.32}$$

where we have used the fact that $f_2(\xi, P_{-,k}) > 0$ and $0 < f_3(\xi, P_{-,k}) < f_{3-}$ for $\xi \in (-\tau + \eta, \xi_0(P_{-,k}))$. Combining (3.31) and (3.32), we obtain a contradiction:

$$\frac{f_{3-}^2}{(1 - \tau + \eta)\epsilon} > \frac{f_0}{4\tau}, \tag{3.33}$$

where $\tau > 0$ can be arbitrarily small. This contradiction proves (3.15). □

We shall establish the Lipschitz-continuous dependence on P_- of $f(\xi, P_-)$. Since the right-hand side of (3.8) is not Lipschitz continuous at $\xi = -1$ and 0, we have to prove it directly.

LEMMA 3.6. *Suppose* $f(\xi) = f(\xi; f_{1-}, f_{2-}, P_-)$ *and* $\bar{f}(\xi) = f(\xi; f_{1-}, f_{2-}, \bar{P}_-)$ *exist on* $[-1, 0]$ *and* $f_2(0-) > 0$ $\bar{f}_2(0-) > 0$. *Then for all* $\xi \in [-1, 0]$,

$$|f(\xi; f_{1-}, f_{2-}, P_-) - f(\xi; f_{1-}, f_{2-}, \bar{P}_-)| \leq C|P_- - \bar{P}_-| \tag{3.34}$$

for some constant $C > 0$.

Proof. By the definition in (3.7), we have

$$P(\xi) = P_- \exp\left[\frac{1}{\epsilon} \int_{-1}^{\xi} \left(\frac{f_1(\zeta) - f_{1-}}{\zeta + 1} + \frac{f_2(\zeta)}{\zeta - 1} + \frac{f_3(\zeta)}{\zeta} \right) d\zeta \right].$$

Consequently,

$$\bar{P}(\xi) - P(\xi) = \frac{P(\xi)}{P_-}\Big\{\bar{P}_- \exp\Big[\frac{1}{\epsilon}\int_{-1}^{\xi}\Big(\frac{\bar{f}_1(\zeta) - f_1(\zeta)}{\zeta+1} + \frac{\bar{f}_2(\zeta) - f_2(\zeta)}{\zeta-1} + \frac{\bar{f}_3(\zeta) - f_3(\zeta)}{\zeta}\Big)d\zeta\Big] - P_-\Big\},$$

where we assumed without loss of generality that $P_- \neq 0$. This leads to

(3.35)
$$\begin{aligned}\bar{P}(\xi) - P(\xi) &= \frac{P(\xi)}{P_-}(\bar{P}_- - P_-) \\ &\quad + \frac{P(\xi)\bar{P}_-}{P_-}\Big\{\exp\Big[\frac{1}{\epsilon}\int_{-1}^{\xi}\Big(\frac{\bar{f}_1(\zeta) - f_1(\zeta)}{\zeta+1} + \frac{\bar{f}_2(\zeta) - f_2(\zeta)}{\zeta-1} + \frac{\bar{f}_3(\zeta) - f_3(\zeta)}{\zeta}\Big)d\zeta\Big] - 1\Big\} \\ &= \frac{P(\xi)}{P_-}(\bar{P}_- - P_-) \\ &\quad + \frac{P(\xi)\bar{P}_-}{P_-}\Big\{\exp\Big[\frac{1}{\epsilon^2}\int_{-1}^{\xi}\int_{-1}^{\zeta}\Big(\frac{(1+s)^{\frac{f_{1-}}{\epsilon}}}{(\zeta+1)(1-s)} + \frac{(1+s)^{\frac{f_{1-}}{\epsilon}-1}}{(\zeta-1)} \\ &\quad + \frac{(1+s)^{\frac{f_{1-}}{2}}}{s\zeta}\Big)(\bar{P}(s) - P(s))ds d\zeta\Big] - 1\Big\}.\end{aligned}$$

We denote

$$\alpha = \frac{\min(f_{3-}, f_3(0-), \bar{f}_3(0-))}{\epsilon}.$$

By the structure of (3.1), the assumption that $f_2(0-) > 0$ and $\bar{f}_2(0-) > 0$ implies that $f_3(0-) > 0$ and $\bar{f}_3(0-) > 0$ and hence that $\alpha > 0$. Furthermore, from (3.5), we see that $P(\xi)/\xi^\alpha$ is bounded. We divide (3.35) by ξ^α to obtain

(3.36)
$$\begin{aligned}\Big|\frac{\bar{P}(\xi) - P(\xi)}{\xi^\alpha}\Big| &\leq |\bar{P}_- - P_-|\Big|\frac{P(\xi)}{P_-\xi^\alpha}\Big| \\ &\quad + \Big|\frac{P(\xi)\bar{P}_-}{\xi^\alpha P_-}\Big|\Big\{\exp\Big[\frac{1}{\epsilon^2}\int_{-1}^{\xi}d\zeta\int_{-1}^{\zeta}\Big(\frac{\frac{(1+s)^{f_{1-}}}{2}}{(\zeta+1)(1-s)} \\ &\quad + \frac{(1+s)^{\frac{f_{1-}}{\epsilon}} - 1}{1-\zeta} - \frac{(1+s)^{\frac{f_{1-}}{2}}}{\zeta}\Big)s^{\alpha-1}\Big|\frac{\bar{P}(s) - P(s)}{s^\alpha}\Big|ds\Big] - 1\Big\} \\ &\leq |\bar{P}_- - P_-|\Big|\frac{P(\xi)}{\xi^\alpha P_-}\Big| \\ &\quad + \Big|\frac{P(\xi)\bar{P}_-}{\xi^\alpha P_-}\Big|\Big\{\exp\Big[M(\alpha)\int_{-1}^{\xi}\max_{s\in[-1,\zeta]}\Big|\frac{\bar{P}(s) - P(s)}{s^\alpha}\Big|d\zeta\Big] - 1\Big\},\end{aligned}$$

where $M(\alpha)$ is a constant bounded for $\alpha > \delta > 0$. This yields that for $\xi \in [-1, 0]$,

$$\begin{aligned}\max_{s\in[-1,\xi]}\left|\frac{\bar{P}(s)-P(s)}{s^{\alpha}}\right| &\leq |P_{-}-\bar{P}_{-}|\max_{s\in[-1,\xi]}\left|\frac{P(s)}{s^{\alpha}P_{-}}\right| \\ &\quad + \max_{s\in[-1,\xi]}\left|\frac{P(s)\bar{P}_{-}}{s^{\alpha}P_{-}}\right|\exp\left(M\int_{-1}^{\xi}\max_{s\in[-1,\zeta]}\left|\frac{\bar{P}(s)-P(s)}{s^{\alpha}}\right|d\zeta\right) \\ &\quad \times\int_{-1}^{\xi}\max_{s\in[-1,\zeta]}\left|\frac{\bar{P}(s)-P(s)}{s^{\alpha}}\right|d\zeta \\ &\leq A+B\int_{-1}^{\xi}\max_{s\in[-1,\zeta]}\left|\frac{\bar{P}(s)-P(s)}{s^{\alpha}}\right|d\zeta.\end{aligned} \tag{3.37}$$

Applying Gronwall's inequality to the above expression, we obtain

$$\max_{s\in[-1,\xi]}\left|\frac{\bar{P}(s)-P(s)}{s^{\alpha}}\right| \leq |\bar{P}_{-}-P_{-}|A\exp[B(\xi+1)]$$

for $\xi \in (-1, 0]$. Then the assertion follows from (3.8), (3.7), and (3.1). □

COROLLARY 3.7. *Let P_0 be as in Theorem 3.5. Then $f(0, f_{1-}, f_{2-}, P_{-})$ is Lipschitz continuous in P_{-} for $P_{-} \in (-\infty, P_0 - \delta]$ for any $\delta > 0$.*

We see from the last theorem that

$$\left\{(f_1(0; f_{1-}, f_{2-}, P_{-}), f_2(0; f_{1-}, f_{2-}, P_{-})) : P_{-} \in (-\infty, P_0)\right\} =: C_{-}(f_{1-}, f_{2-}) \tag{3.38}$$

is a continuous curve in the first quadrant of the (f_1, f_2)-plane for each fixed (f_{1-}, f_{2-}). Taking $P_{-} = 0$, we see that

$$(f_{1-}, f_{2-}) \in C_{-}(f_{1-}, f_{2-}). \tag{3.39}$$

We study the range of this curve in the following theorem.

THEOREM 3.8. *Let $C_{-}(f_{1-}, f_{2-})$ be defined as in (3.36). Then*

$$C_{-}(f_{1-}, f_{2-}) \subset \left\{(f_1, f_2) \in \mathbb{R}^2 : 0 < f_1 \leq f_1(0; P_0), 0 = f_2(0; P_0) \leq f_2\right\}. \tag{3.40}$$

Furthermore,

$$f_2(0, P_{-}) \to +\infty \text{ as } P_{-} \to -\infty. \tag{3.41}$$

Proof. From Lemma 3.4(ii), we see that $f_2(0; P_{-}) \geq 0$ for $P_{-} \in (-\infty, P_0]$. The structure of (3.1) guarantees

$$f_1(0, P_{-}) > 0.$$

To prove (3.40), it suffices to prove that

$$f_1(0; P_{-}) \leq f_1(0; P_0). \tag{3.42}$$

If $P_{-} \leq 0$, then $Q(f(\xi, P_{-})) \leq 0$ on $(-1, 0)$. Equation (3.1) then implies that

$$f_1(0; P_{-}) \leq f_{1-} = f_1(-1; 0). \tag{3.43}$$

For $P_- \in [0;P_0]$, we recall that $Q(f(\xi,P_-))$ is monotone increasing with respect to $P_- > 0$; see (3.16). Equation (3.1) then states that $f_1(0,P_-)$ is increasing with respect to $P_- > 0$. Thus

$$f_{1-} \le f_1(0;P_-) \le f_1(0;P_0) \tag{3.44}$$

for $P_- \in [0,P_0]$. Inequality (3.42) follows from (3.43) and (3.44).

To prove (3.41), we let

$$P_- < 0$$

and consider the following application of (3.4).

$$\begin{aligned}
f_2(\xi;P_-) - f_{2-} &= \frac{-1}{\epsilon}\int_{-1}^{\xi} \frac{Q(f(\zeta))}{\zeta+1}\,d\zeta \\
&= \frac{-P_-}{\epsilon}\int_{-1}^{\xi}(1+\zeta_1)^{\frac{f_{1-}}{\epsilon}-1}(1-\zeta_1)^{\frac{f_{2-}}{\epsilon}}|\zeta_1|^{\frac{f_{3-}}{\epsilon}} \\
\times \exp\biggl[\frac{1}{\epsilon}\int_{-1}^{\zeta_1}\biggl(&\frac{f_1(\zeta_2)-f_{1-}}{\zeta_2+1} + \frac{f_2(\zeta_2)-f_{2-}}{\zeta_2-1} + \frac{f_3(\zeta_2)-f_{3-}}{\zeta_2}\biggr)d\zeta_2\biggr]d\zeta_1 \\
&= \frac{-P_-}{\epsilon}\int_{-1}^{\xi}(1+\zeta_1)^{\frac{f_{1-}}{\epsilon}-1}(1-\zeta_1)^{\frac{f_{2-}}{\epsilon}}|\zeta_1|^{\frac{f_{3-}}{\epsilon}} \\
\times \exp\biggl[\frac{1}{\epsilon^2}\int_{-1}^{\zeta_1}\int_{-1}^{\zeta_2}\biggl(&\frac{1}{(1+\zeta_2)(1-\zeta_3)} + \frac{1}{(1-\zeta_2)(1+\zeta_3)} + \frac{1}{\zeta_2\zeta_3}\biggr)Q(f(\zeta_3))\,d\zeta_3 d\zeta_2\biggr].
\end{aligned}$$

Invoking (3.13),

$$Q(f(\zeta)) \ge P_-(1+\xi)^{\frac{f_{1-}}{\epsilon}}(1-\xi)^{\frac{f_{2-}}{\epsilon}}|\xi|^{\frac{f_{3-}}{\epsilon}}$$

for $P_- < 0$ in the above, we obtain

$$\begin{aligned}
f_2(\xi) - f_{2-} \ge{}& \frac{-P_-}{\epsilon}\int_{-1}^{\xi}(1+\zeta_1)^{\frac{f_{1-}}{\epsilon}-1}(1-\zeta_1)^{\frac{f_{2-}}{\epsilon}}|\zeta|^{\frac{f_{3-}}{\epsilon}} \\
&\times \exp\biggl[\frac{1}{\epsilon^2}\int_{-1}^{\zeta_1}\int_{-1}^{\zeta_2}\biggl(\frac{1}{(1+\zeta_2)(1-\zeta_3)} + \frac{1}{(1-\zeta_2)(1+\zeta_3)} + \frac{1}{\zeta_2\zeta_3}\biggr) \\
&\times P_-(1+\zeta_3)^{\frac{f_{1-}}{\epsilon}}(1-\zeta_3)^{\frac{f_{2-}}{\epsilon}}|\zeta_3|^{\frac{f_{3-}}{\epsilon}}\,d\zeta_2 d\zeta_3\biggr]d\zeta_1 \\
={}& \frac{-P_-}{\epsilon}O(1)\int_{-1}^{\xi}(1+\zeta_1)^{\frac{f_{1-}}{\epsilon}-1}\exp\biggl\{\frac{P_-}{\epsilon^2}\int_{-1}^{\zeta_1}\int_{-1}^{\zeta_2}\biggl[O(1)(1+\zeta_3)^{\frac{f_{1-}}{\epsilon}-1} \\
&+ \frac{O(1)(1+\zeta_3)^{\frac{f_{1-}}{\epsilon}}}{1+\zeta_2} + O(1)(1+\zeta_3)^{\frac{f_{1-}}{\epsilon}}\biggr]d\zeta_2 d\zeta_3\biggr\}d\zeta_1
\end{aligned}$$

for $\xi \in [-1,-1/2]$. A further calculation of the above yields

$$f_2(\xi) - f_{2-} \ge -P_- A(1+\xi)^{\frac{f_{1-}}{\epsilon}}\exp\biggl[P_- B(1+\xi)^{\frac{f_{1-}}{\epsilon}+1}\biggr] \tag{3.45}$$

for $\xi \in [-1,-1/2]$, where $A, B > 0$ are constants depending only on f_- and ϵ. For any $N > 0$, let $P_- < -N^{\frac{\epsilon+f_{1-}}{\epsilon}}$. Then $(N/-P_-)^{\frac{\epsilon}{f_{1-}}} < 1/N$. Choosing

$$\xi_0 = -1 + \left(\frac{N}{-P_-}\right)^{\frac{\epsilon}{f_{1-}}} < -1 + \frac{1}{N},$$

we have

$$-P_-(1+\xi_0)^{\frac{f_{1-}}{\epsilon}} = N,$$
$$P_-(1+\xi_0)^{\frac{f_{1-}}{\epsilon}+1} = -N(1+\xi_0) > -N\cdot\frac{1}{N} = -1.$$

Then (3.45) reads

$$f_2(\xi_0) - f_{2-} \geq NA\exp(-B).$$

Since $P_- < 0$, the function $f_2(\xi; P_-)$ is increasing on $[-1, 0]$, and hence

$$f_2(0; P_-) - f_{2-} \geq NA\exp(-B)$$

if $P_- < -M^{\frac{\epsilon+f_{1-}}{\epsilon}}$. Thus

$$\lim_{P_-\to-\infty} f_2(0; P_-) = \infty. \qquad \square$$

Now we consider trajectories of (3.1) on $[0,1]$ with initial condition (3.3). Under the transformation

$$(\xi, f_1, f_2, f_3) \mapsto (-\xi, f_2, f_1, f_3), \tag{3.46}$$

problem (3.1), (3.3) becomes the initial-value problem of equation (3.1) with initial value $f(-1) = (f_{2+}, f_{1+}, f_{3+})$, which we have already studied. Our previous results then yield the following theorem.

THEOREM 3.9. *There is a $P_{0+} > 0$ such that the initial-value problem* (3.1), (3.3) *has a unique, positive solution $f^+(\xi; P_+)$ on* $[0,1]$ *for any given*

$$P_+ = \left.\frac{Q(f(\xi))}{(1-\xi)^{\frac{f_{2-}}{\epsilon}}}\right|_{\xi=1}, \quad P_+ \in (-\infty, P_{0+}].$$

Furthermore, we have the following:

(i)

$$f_1^+(0; P_{0+}) = 0. \tag{3.47}$$

(ii) $f^+(0; P_+)$ *is continuous with respect to* $P_+ \in (-\infty, P_{0+}]$.

(iii)

(3.48a)
$$C_+(f_{1+}, f_{2+}) := \left\{(f_1^+(0; P_+), f_2^+(0, ; P_+)) \in \mathbb{R}^2 : P_+ \in (-\infty, P_0)\right\}$$
$$\subset \left\{(f_1, f_2) \in \mathbb{R}^2 : f_1 \geq f_1^+(0; P_{0+}) = 0, f_2^+(0; P_{0+}) \geq f_2 > 0\right\}.$$

(iv)

$$\lim_{P_-\to-\infty} f_1^+(0; P_-) = +\infty. \tag{3.48b}$$

THEOREM 3.10. *Problem* (1.6) *always has a continuous positive solution.*

Proof. For any given $f_\pm > 0$, the curve $C_-(f_{1-}, f_{2-})$, parametrized as $(f_1(0; P_-),$ $f_2(0; P_-))$, $P_- \in (-\infty, P_0]$, runs from $f_2(0, P_0) = 0$ to $f_2(0; -\infty) = +\infty$ and $0 <$

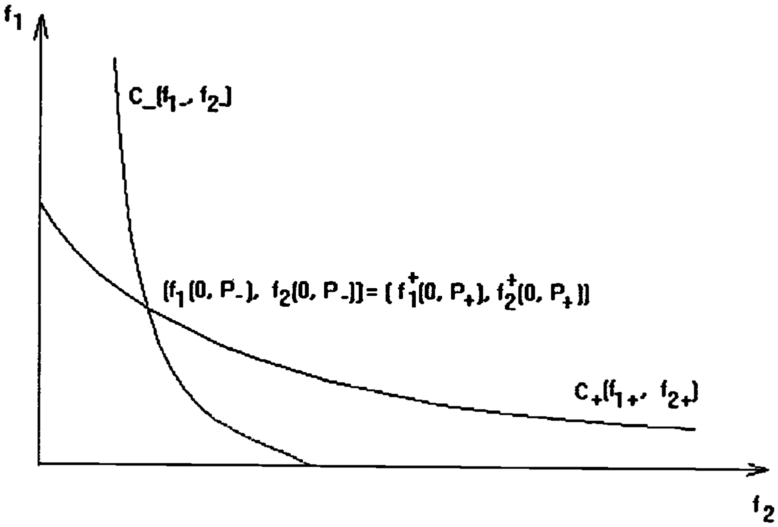

FIG. 1.

$f_1(0; P_-) \leq f_1(0, P_0)$ while $C_+(f_{1+}, f_{2+})$, parametrized by $(f_1^+(0; P_+),\ f_2^+(0; P_+))$, $P_+ \in (-\infty, P_{0+})$, runs from $f_1^+(0; P_{0+}) = 0$ to $f_1^+(0; -\infty) = +\infty$ with $0 < f_2^+(0; P_-) \leq f_2^+(0; P_{0+})$. By using the Lipschitz continuity of $(f_{1\pm}(0; P), f_{2\pm}(0; P))$ obtained in Corollary 3.7, we can prove that

$$C_-(f_{1-}, f_{2-}) \cap C_+(f_{1+}, f_{2+}) \neq \emptyset, \tag{3.49}$$

as shown in Fig. 1.

The proof of (3.49) is given in Lemma 3.11 below. Let

$$\begin{aligned} \big(f_1(0; P_-), f_2(0; P_-)\big) &= \big(f_1^+(0; P_+), f_2^+(0; P_+)\big) \\ &\in C_-(f_{1-}, f_{2-}) \cap C_+(f_{1+}, f_{2+}) \end{aligned} \tag{3.50}$$

for some $P_- \in (-\infty, P_0]$, $P_+ \in (-\infty, P_{0+}]$. Consider the function

$$f(\xi) = \begin{cases} f(\xi; f_{1-}, f_{2-}, P_-) & \text{if } \xi \in [-1, 0], \\ \\ f^+(\xi; f_{1+}, f_{2+}, P_+) & \text{if } \xi \in [0, 1], \end{cases} \tag{3.51}$$

which is continuous and positive on $[-1, 0) \cup (0, 1]$. Furthermore, the matching condition (3.50) says that f_1 and f_2 are continuous on $[-1, 1]$. Thus f_1 and f_2 are bounded and positive on $[-1, 1]$, and hence so is f_3. Since f is positive on $[-1, 0) \cup (0, 1]$, Lemma 3.1 (iii) and (iv) imply that the function $Q(f(\xi)$ is continuous at $\xi = 0$ and $Q|_{\xi=0} = 0$. Then $f_3(\xi)$ must be continuous at $\xi = 0$ as well. Then f defined by (3.51) satisfies the integral form of equation (3.1) and hence (3.1) itself. Thus f is a positive, continuous solution of (1.6). □

LEMMA 3.11.

$$C_-(f_{1-}, f_{2-}) \cap C_+(f_{1+}, f_{2+}) \neq \emptyset. \tag{3.52}$$

Proof. We recall from (3.36), (3.40), and (3.48a) that

$$\begin{aligned} C_-(f_{1-}, f_{2-}) &:= \big\{(f_1(0; f_{1-}, f_{2-}, P_-), f_2(0; f_{1-}, f_{2-}, P_-)) : P_- \in (-\infty, P_0)\big\} \\ &\subset \big\{(f_1, f_2) \in \mathbb{R}^2 : 0 < f_1 \le f_1(0; P_0), 0 = f_2(0; P_0) \le f_2\big\} \end{aligned} \tag{3.53}$$

and

$$\begin{aligned} C_+(f_{1+}, f_{2+}) &:= \big\{(f_1^+(0; P_+), f_2^+(0, ; P_+)) \in \mathbb{R}^2 : P_+ \in (-\infty, P_0)\big\} \\ &\subset \big\{(f_1, f_2) \in \mathbb{R}^2 : f_1 \ge f_1^+(0; P_{0+}) = 0, f_2^+(0; P_{0+}) \ge f_2 > 0\big\}. \end{aligned} \tag{3.54}$$

By Corollary 3.7, the curves $C_-(f_{1-}, f_{2-})$ and $C_+(f_{1+}, f_{2+})$ are Lipschitz continuous in $P_\pm$, respectively. For the curve $C_-(f_{1-}, f_{2-})$, we define the following subsets of $(-\infty, P_0]$:

$$\mathcal{A} := \cup\big\{(p, q) \subset (-\infty, P_0] : (f_!(0; p), f_2(0; p)) = (f_!(0; q), f_2(0; q))\big\}, \tag{3.55}$$

$$\mathcal{B} := (-\infty, P_0]\backslash\mathcal{A}. \tag{3.56}$$

We further define

$$t(P) := P_0 + \int_{P_0}^{P} \chi_{\mathcal{B}}(p)dp, \tag{3.57}$$

$$P(t) := \inf\{P : t(P) = t\}, \tag{3.58}$$

$$\big(\bar{f}_1(t), \bar{f}_2(t)\big) := \big(f_1(0; P(t)), f_2(0; P(t))\big). \tag{3.59}$$

From the definitions in (3.55)–(3.59), we can see that the curve $\big(\bar{f}_1(t), \bar{f}_2(t)\big)$ cannot be self-intersecting. Indeed, otherwise, there would be t_1 and t_2, $t_1 < t_2$, such that

$$\big(\bar{f}_1(t_1), \bar{f}_2(t_1)\big) = \big(\bar{f}_1(t_2), \bar{f}_2(t_2)\big) \tag{3.60}$$

and hence

$$(P(t_1), P(t_2)) \subset \mathcal{A}. \tag{3.61}$$

Then we have from (3.57) and (3.61) that

$$t_2 - t_1 = \int_{P(t_1)}^{P(t_2)} \chi_{\mathcal{B}}(p)dp = 0,$$

which is a contradiction. We notice from (3.57) that $t(P)$ is an increasing function of P and hence $P(t)$ is also an increasing function. We further claim that $\big(\bar{f}_1(t), \bar{f}_2(t)\big)$ is continuous in t. To prove the claim, we let t_0 be any point in the domain of $\big(\bar{f}_1(t), \bar{f}_2(t)\big)$. Since $P(t)$ is increasing, $P(t) \to p_++$ (or $p_-−$) as $t \to t_0+$ (or $t_0−$). This implies that

$$\lim_{t \to t_0+} \bar{f}_1(t) = \lim_{t \to t_0+} f_1(0; P(t)) = f_1(0; p_+) \tag{3.62}$$

and

$$\lim_{t \to t_0-} \bar{f}_1(t) = \lim_{t \to t_0-} f_1(0; P(t)) = f_1(0; p_-). \tag{3.63}$$

From the definition in (3.57), we have

$$t_0 = P_0 + \int_{P_0}^{p_-} \chi_{\mathcal{B}}(y)dy$$

and

$$t_0 = P_0 + \int_{P_0}^{p_+} \chi_{\mathcal{B}}(y)dy,$$

which yield

$$\int_{p_-}^{p_+} \chi_{\mathcal{B}}(y)dy = 0. \tag{3.64}$$

Consider the open set $\mathcal{A} \cap (p_-, p_+)$. It is a union of countably many disjoint open intervals

$$\mathcal{A} \cap (p_-, p_+) = \cup_{n=1}^{\infty} (p_n, q_n).$$

Then (3.64) is equivalent to

$$\sum_{n=1}^{\infty} (q_n - p_n) = p_+ - p_-. \tag{3.65}$$

From the definition of $\mathcal{A}$, it is clear that $f_1(0; p_n) = f_1(0; q_n)$. We consider $\cup_{n=1}^{N} (p_n, q_n)$ for large integer N. We assume without loss of generality—rearranging the notation if necessary—that $p_1 < q_1 < p_2 < q_2 < \cdots < q_N$. The difference of $f_1(0; p_-)$ and $f_1(0; p_+)$ satisfies

$$\begin{aligned}
&|f_1(0; p_-) - f_1(0; p_+)| \\
&\quad = \left| f_1(0; p_-) - \sum_{n=1}^{N} \big(f_1(0; p_n) - f_1(q_n)\big) - f_1(0; p_+) \right| \\
&\quad = \left| f_1(0; p_-) - f_1(0; p_1) + \sum_{n=1}^{N-1} \big(f_1(0; q_n) - f_1(0; p_{n+1})\big) + f_1(0; q_N) - f_1(0; p_+) \right| \\
&\quad \le O(1) \left(|p_1 - p_-| + \sum_{n=1}^{N-1} |q_n - p_{n+1}| + |p_+ - q_N| \right) \\
&\quad = O(1) \left(p_+ - p_- - \sum_{n=1}^{N} (q_n - p_n) \right) \\
&\quad \to 0 \quad \text{as } N \to \infty,
\end{aligned} \tag{3.66}$$

where we used the Lipschitz continuity of f_1 on P and (3.65). This proves the continuity of $\bar{f}_1(t)$. We can prove the continuity of $\bar{f}_2(t)$ similarly.

Now we claim that $\bar{f}_2(t) \to \infty$ as $t \to \inf(\text{domain of definition of } (\bar{f}_1, \bar{f}_2))$. To this end, it suffices to prove that there is a sequence $\{P_n\} \subset \mathcal{B}$ such that $P_n \to -\infty$ as $n \to \infty$ since $f_2(0; P) \to \infty$ as $P \to -\infty$. Indeed, otherwise, by the definition of $\mathcal{B}$, there would be a sequence $\{\bar{P}_n\} \subset \mathcal{A}$ such that $\bar{P}_n \to -\infty$ as $n \to \infty$ and $f_2(0; \bar{P}_n)$

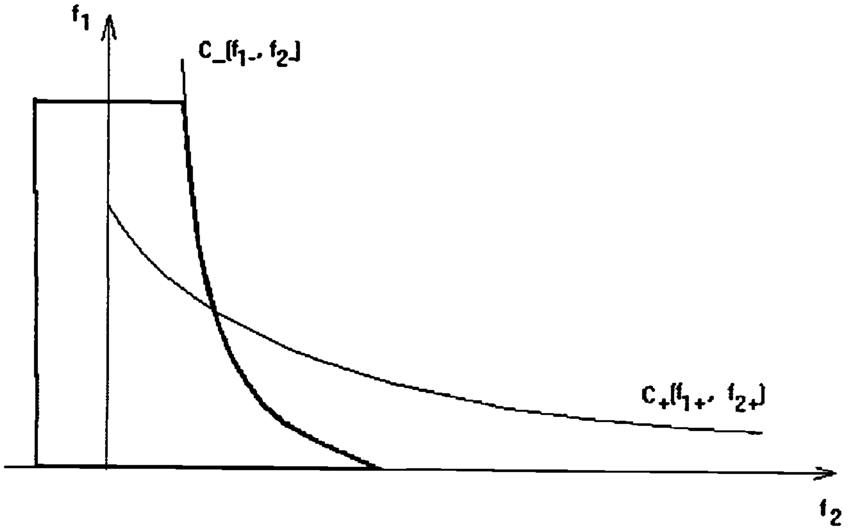

Fig. 2.

is bounded, which is a contradiction to the fact that $f_2(0; P) \to \infty$ as $P \to \infty$. The claim is proved.

The domain of definition of $(\bar{f}_1, \bar{f}_2)$ is the range of $t(P)$ defined in (3.57), which is an interval due to the continuity of $t(P)$. As P runs from P_0 to $-\infty$, the function $t(P)$ decreases from P_0 to inf(domain of definition of $(\bar{f}_1, \bar{f}_2)$) and $\bar{f}_2(t)$ runs from 0 to ∞. There is at least one point $T \in$(domain of definition of $(\bar{f}_1, \bar{f}_2)$) such that $\bar{f}_2(T) = 2f_{2+}(0; P_{0+})$. Let $\mathcal{T}$ be the set of all of these T's and $T_1 \in \mathcal{T}$ be such that $\min_{T \in \mathcal{T}} \bar{f}_1(T)$ is attained. We define a closed curve

$$\begin{aligned}\mathcal{J} := &\{(\bar{f}_1, \bar{f}_2)(t) : t \in [T_1, P_0]\}\\ &\cup \{(f_1, f_2) : f_2 = \bar{f}_2(T_1),\ -1 \le f_1 \le \bar{f}_1(T_1)\}\\ &\cup \{(-1, f_2) : 0 \le f_2 \le \bar{f}_2(T_1)\} \cup \{(f_1, 0) : -1 \le f_1 \le f_1(0; P_0)\},\end{aligned} \tag{3.67}$$

which is depicted in Fig. 2.

From the definition in (3.67), the definition of T_1, and (3.53), we can see that the curve $\mathcal{J}$ is a simple closed curve. Jordan's curve theorem then states that the curve $\mathcal{J}$ divides the whole (f_1, f_2)-plane into two components, an interior component and an exterior component. The curve $C_+(f_{1+}, f_{2+})$ has a point $(0, f_2^+(0; P_{0+}))$ inside the interior component and a point in the exterior component since $(f_1^+(0; P) \to \infty$ as $P \to \infty$. Thus the curve $C_+(1+, f_{2+})$ must intersect the boundary of the interior component, which is the curve $\mathcal{J}$. From (3.54), we see that $C_+(f_{1+}, f_{2+})$ can intersect $\mathcal{J}$ only at the $\{(\bar{f}_1, \bar{f}_2)(t) : t \in [T_1, P_0]\}$ part of $\mathcal{J}$, which is a portion of the curve $C_-(f_{1-}, f_{2-})$. Thus we obtain the desired conclusion. □

The following corollary justifies the passing of the fluid dynamic limit in (1.5) to obtain the limit equation (1.2).

Corollary 3.12. *For any Maxwellian Riemann data* (1.4)*, there is a solution of the equation* (1.4)–(1.5)*, $f^\epsilon(x/t)$. Further, there is a sequence of solutions of* (1.4)–(1.5)*, $\{f^{\epsilon_n}\}$, $\epsilon_n \to 0+$, such that $f^{\epsilon_n} \to f(x/t)$ almost everywhere $(x, t) \in \mathbb{R} \times \mathbb{R}_+$, where $f(x/t)$ is a solution of the limit equation* (1.2), (1.4).

Proof. The first assertion is a restatement of Theorem 3.10. In [ST], Slemrod and

Tzavaras proved that the total variation of solutions of (1.4)–(1.5) bounded uniformly in ϵ. Thus there is a sequence of solutions of (1.4)–(1.5), $\{f^{\epsilon_n}\}$, $\epsilon_n \to 0+$, such that $f^{\epsilon_n} \to f(x/t)$ almost everywhere $(x,t) \in \mathbb{R} \times \mathbb{R}_+$. It is clear that the limit function is a weak solution of (1.2), (1.4). ▯

With help from Lemma 3.1, we can improve the result of Lemma 2.2 as follows.

Theorem 3.13. *Let f be a positive solution of* (3.1) *with boundary condition* (3.2)–(3.3). *Then*

$$f_1(\xi) - f_{1+} = O(1)(1-\xi)^{\frac{f_{2+}}{\epsilon}} \quad \textit{for } \xi \textit{ near } \xi = 1, \tag{3.68}$$

$$f_2(\xi) - f_{2-} = O(1)(\xi+1)^{\frac{f_{1-}}{\epsilon}} \quad \textit{for } \xi \textit{ near } \xi = -1, \tag{3.69}$$

and

$$f_3(\xi) - f_3(0) = O(1)|\xi|^{\frac{\min(f_{3-}, f_3(0), f_{3+})}{\epsilon}} \quad \textit{for } \xi \textit{ near } \xi = 0, \tag{3.70}$$

$$Q(f\xi)) = O(1)(\xi+1)^{\frac{f_{1-}}{\epsilon}}(1-\xi)^{\frac{f_{2+}}{\epsilon}}|\xi|^{\frac{\min(f_{3-}, f_3(0), f_{3+})}{\epsilon}}. \tag{3.71}$$

Proof. From (3.5a, b), we know that

$$Q(f(\xi)) = O(1)|\xi|^{\frac{\min(f_{3-}, f_3(0), f_{3+})}{\epsilon}}. \tag{3.72}$$

Then by integrating $(3.1)_3$, we obtain

$$f_3(\xi) - f_3(0) = \int_0^\xi \frac{Q(f(\zeta)}{\epsilon\zeta} d\zeta = O(1)|\xi|^{\frac{\min(f_{3-}, f_3(0), f_{3+})}{\epsilon}},$$

which is (3.70).

To prove (3.68), we start with (3.4a),

$$\begin{aligned} Q &= C(1+\xi)^{\frac{f_{1-}}{\epsilon}}(1-\xi)^{\frac{f_{2+}}{\epsilon}}|\xi|^{\frac{\min(f_{3-}, f_3(0-))}{\epsilon}} \\ &\quad \times \exp\left[\frac{1}{\epsilon}\int_{-1}^{\xi}\left(\frac{f_1(\zeta) - f_{1-}}{\zeta+1} + \frac{f_2(\zeta) - f_{2+}}{\zeta - 1} + \frac{f_3(\zeta) - \min(f_{3-}, f_3(0-)}{\zeta}\right)d\zeta\right], \end{aligned} \tag{3.73}$$

which holds for $\xi \in [-1,0)$. If $C \geq 0$ and hence $Q \geq 0$ on $[-1,0)$, then f_2 and f_3 are decreasing on $[-1,0)$, and hence

$$f_1' = \frac{Q}{\epsilon(1-\xi)} \leq \frac{f_3^2(\xi)}{\epsilon(1-\xi)} \leq \frac{f_{3-}^2}{\epsilon}.$$

Thus all of the terms in the integrand of (3.71) are either negative or finite, which implies that

$$Q(f(\xi)) = O(1)(1+\xi)^{\frac{f_{1-}}{\epsilon}} \quad \text{for } \xi \in [-1,). \tag{3.74}$$

This together with $(3.1)_2$ yields that

$$f_2(\xi) - f_{2-} = \int_{-1}^{\xi} \frac{-Q(f(\zeta))}{\epsilon(\zeta+1)} = O(1)(1+\xi)^{\frac{f_{1-}}{\epsilon}},$$

which proves (3.68). Similarly, we can prove that

$$Q(f(\xi)) = O(1)(1-\xi)^{\frac{f_{2+}}{\epsilon}} \quad \text{for } \xi \in (0,1] \tag{3.75}$$

and thus (3.69). Combining (3.72), (3.74), and (3.75), we obtain (3.71). ▯

Acknowledgments. I would like to thank Professor Marshall Slemrod for his suggestions. I am grateful to Professor Tai-Ping Liu for his hospitality and for many valuable discussions while I was visiting Stanford University, where this work was done. I also wish to thank the referee, whose comments helped me to revise this paper. My thanks also go to Professor Andrew Vogt of Georgetown University for our discussion of the proof of Lemma 3.11.

RANGE OF THE RADON TRANSFORM ON FUNCTIONS WHICH DO NOT DECAY FAST AT INFINITY*

ALEXANDER I. KATSEVICH[†]

Abstract. Let an integer $m \geq 0$ be fixed. Let $\mathcal{X}_m$ be the space of functions $f \in C^\infty(\mathbb{R}^n)$ that admit an asymptotic expansion $f(r\beta) \sim \sum_{k=m}^{\infty} \psi_k(\beta)/r^{n+k}, r \to \infty$, $\psi_k \in C^\infty(S^{n-1})$, and the expansion can be differentiated with respect to $x = r\beta$ any number of times. In this paper, we derive a precise characterization of the range of the Radon transform R acting on $\mathcal{X}_m$; that is, we explicitly describe the space $\mathcal{Z}_m = R\mathcal{X}_m$. The conditions which describe the space $\mathcal{Z}_m$ are easily verifiable.

Key words. range, Radon transform, moment conditions, asymptotic expansion

1. Introduction and statement of main result.

Consider the Schwartz space $\mathcal{S}(\mathbb{R}^n)$ consisting of $C^\infty(\mathbb{R}^n)$ functions that decay with all derivatives faster than any power of $|x|^{-1}$ as $|x| \to \infty$. If $f \in \mathcal{S}(\mathbb{R}^n)$, then Rf, the Radon transform of f, is defined by the formula

$$Rf(\alpha, p) = \int_{\mathbb{R}^n} f(x)\delta(\alpha \cdot x - p)dx, \quad \alpha \in S^{n-1}, \quad p \in \mathbb{R}. \tag{1.1}$$

Here S^{n-1} is the unit sphere in $\mathbb{R}^n$ and δ is the one-dimensional delta function. If f is a distribution, then Rf is defined via duality $(Rf, \varphi) = (f, R^*\varphi)$, where R^* is the operator dual to R,

$$R^*\varphi(x) = \int_{S^{n-1}} \varphi(\alpha, \alpha \cdot x)d\alpha,$$

and the test functions φ run through a suitable space (see, e.g., [8], [4], and [12]).

Let $\mathcal{S}_{em}(Z)$, $Z := S^{n-1} \times \mathbb{R}$, be the space of $C^\infty(Z)$ functions $g(\alpha, p)$ that satisfy the following conditions:

1. g is even: $g(\alpha, p) = g(-\alpha, -p)$, $(\alpha, p) \in Z$;
2. $g(\alpha, p)$ and all of its derivatives with respect to α and p decay faster than any power of p^{-1} as $p \to \infty$; and
3.

$$\int_{-\infty}^{\infty} g(\alpha, p)p^j dp = \mathcal{P}_j(\alpha), \quad j = 0, 1, 2, \ldots, \tag{1.2}$$

where $\mathcal{P}_j(x), x \in \mathbb{R}^n$, is a homogeneous polynomial of degree j and $\mathcal{P}_j(\alpha)$ is the restriction of $\mathcal{P}_j$ to S^{n-1}.

The conditions in (1.2) are known as the "moment conditions." It was proved in [3] (see also [2] and [8]) that $R : \mathcal{S}(\mathbb{R}^n) \to \mathcal{S}_{em}(Z)$ is an isomorphism. This result gives a complete description of the range of R on the space of smooth rapidly decaying functions. Subsequently, ranges of R on spaces of compactly supported distributions $\mathcal{E}'$ and rapidly decaying distributions $\mathcal{O}'_c$ have been described [5], [6], [7]. Basically, these results state that the range of R on $\mathcal{E}'(\mathbb{R}^n)(\mathcal{O}'_c(\mathbb{R}^n))$ consists of $g \in \mathcal{E}'(Z)(\mathcal{O}'_c(Z))$, which are even and satisfy the moment conditions in (1.2) in a generalized sense. In case of $\mathcal{O}'_c(\mathbb{R}^n)$, it is necessary to assume in addition that g is C^∞ in the α variable [6]. Range theorems on the space of compactly supported H^s-functions have been given in [9], [13], [10], and [11]. In this case, functions from the range of R belong to the corresponding Sobolev space $H^{s+(n-1)/2}(Z)$, are even and compactly supported, and satisfy the moment conditions in (1.2).

A preimage under the Radon transform of $\mathcal{S}(Z)$ even functions that satisfy none or finitely many of the conditions in (1.2) was studied in [14]. Suppose that $g \in \mathcal{S}(Z)$ and g is even. Among other results, it was proved in [14] that the more moment conditions that g satisfies, the faster $f := R^{-1}g$ decays at infinity. Moreover, if g does not satisfy all of the moment conditions, then the decay rate of f is only polynomial. A related result was obtained in [15], where a partial range theorem for R on functions which decay only polynomially was proved. In particular, it was proved in [15] that if $g \in C^r(Z), r < \infty$, satisfies finitely many moment conditions and derivatives of $g(\alpha, p)$ with respect to α decay sufficiently fast as $p \to \infty$ (but not necessarily exponentially fast), then there exists a function f such that $Rf = g$ and the inversion formula $f = (1/2(2\pi)^{n-1})\Lambda^{n-1}R^*g$ holds. Here Λ is the Calderon operator defined by the equation $\Lambda^2 = -\Delta$, where Δ is the Laplacian.

In this paper, we give a precise characterization of the range of R on a certain class of C^∞ functions that decay only polynomially at infinity. Our main result is the following.

THEOREM. *Fix any integer $m \geq 0$. Let $\mathcal{X}_m$ be the space of functions $f \in C^\infty(\mathbb{R}^n)$ that admit an asymptotic expansion*

$$f(r\beta) \sim \sum_{k=m}^{\infty} \frac{\psi_k(\beta)}{r^{n+k}}, \quad r \to \infty, \quad \psi_k \in C^\infty(S^{n-1}), \tag{1.3}$$

and the expansion can be differentiated with respect to $x = r\beta$ any number of times. Let $\mathcal{Z}_m$ be the space of even functions $g \in C^\infty(Z)$ such that

(a) *g satisfies the first m moment conditions* (1.2), *$j = 0, 1, \ldots, m-1$, and*

(b) *g admits an asymptotic expansion*

$$g(\alpha, p) \sim \sum_{k=m}^{\infty} \frac{Q_k(\alpha) + b_k(\alpha)}{p^{k+1}}, \quad p \to +\infty, \tag{1.4}$$

where

$$b_k \in C^\infty(S^{n-1}), \quad b_k(-\alpha) = (-1)^{k+1} \quad b_k(\alpha), \tag{1.5a}$$

$$Q_k \text{ is a homogeneous polynomial of degree } k, \tag{1.5b}$$

and the expansion can be differentiated with respect to p any number of times.

Then $R\mathcal{X}_m = \mathcal{Z}_m$.

Remark. Expansion (1.3) means that $f(r\beta)-\sum_{k=m}^{K-1}\psi_k(\beta)r^{-(n+k)}=O(r^{-(n+K)})$ as $r\to+\infty$ uniformly in $\beta\in S^{n-1}$ for each $K\geq m+1$. Expansion (1.4) means that $g(\alpha,p)-\sum_{k=m}^{K-1}(Q_k(\alpha)+b_k(\alpha))/p^{k+1}=O(p^{-(K+1)})$ as $p\to+\infty$ uniformly in $\alpha\in S^{n-1}$ for each $K\geq m+1$.

We see that the theorem presented is a generalization of the classical range theorem because $\mathcal{S}(\mathbb{R}^n)=\cap_{m\geq0}\mathcal{X}_m$ and $\mathcal{S}_{em}(Z)=\cap_{m\geq0}\mathcal{Z}_m$. One can also see that the conditions on the range of the Radon transform are easily verifiable.

For convenience, we introduce another space of functions. Let $\mathcal{Y}_m$ be the space of even functions $g\in C^\infty(Z)$ such that g admits an asymptotic expansion

$$g(\alpha,p)\sim\sum_{k=m}^{\infty}g_k(\alpha,p),\quad p\to\infty, \tag{1.6}$$

and the expansion can be differentiated with respect to p any number of times. In (1.6), the functions $g_k\in C^\infty(Z)$, $k\geq m$, are even and satisfy the following assumptions:

(1) g_k satisfies the first k moment conditions in (1.2), $j=0,1,\dots,k-1$;

(2) g_k can be represented as

$$\begin{gathered} g_k(\alpha,p)=\frac{Q_k(\alpha)+b_k(\alpha)}{p^{k+1}},\quad p>1,\\ b_k\in C^\infty(S^{n-1}),\quad b_k(-\alpha)=(-1)^{k+1}b_k(\alpha), \end{gathered} \tag{1.7}$$

where Q_k is a homogeneous polynomial of degree k; and

(3) for all $K\geq m$, the difference $g-\sum_{k=m}^{K-1}g_k$ satisfies the first K moment conditions in (1.2), $j=0,1,\dots,K-1$.

Proposition. $\mathcal{Z}_m=\mathcal{Y}_m$.

Proof. The inclusion $\mathcal{Y}_m\subset\mathcal{Z}_m$ is obvious. To prove the inclusion $\mathcal{Z}_m\subset\mathcal{Y}_m$, we have to fix any $g\in\mathcal{Z}_m$ and find functions g_k with properties (1)–(3). Let $h_k\in C^\infty(Z)$, $k\geq m$, be any even functions such that

$$h_k(\alpha,p)=\frac{Q_k(\alpha)+b_k(\alpha)}{p^{k+1}},\quad p>1, \tag{1.8a}$$

(1.8b) h_k satisfies the first k moment conditions.

The functions h_k can be constructed, for example, as follows:

$$h_k(\alpha,p)=Q_k(\alpha)A_k(p)+b_k(\alpha)B_k(p),$$

where $A_k,B_k\in C^\infty(\mathbb{R})$ are chosen so that

$$A_k(p)=B_k(p)=\frac{1}{p^{k+1}},\quad p>1;$$

$$A_k(-p)=(-1)^kA_k(p),\qquad B_k(-p)=(-1)^{k+1}B_k(p),\quad p\in\mathbb{R};$$

$$\int_{-\infty}^{\infty}A_kp^j\,dp=\int_{-\infty}^{\infty}B_kp^j\,dp=0,\quad 0\leq j\leq k-1.$$

Fix any $P_k \in C_0^\infty([-1,1])$ with the properties

$$P_k(-p) = (-1)^k P_k(p), \qquad \int_{-\infty}^{\infty} P_k(p)p^j dp = \begin{cases} 0, & j = 0,1,\dots,k-1, \\ 1, & j = k, \end{cases} \tag{1.9}$$

and define

(1.10)

$$g_k(\alpha,p) := h_k(\alpha,p) + P_k(p) \cdot \int_{-\infty}^{\infty} \left(g(\alpha,t) - \sum_{j=m}^{k-1} g_j(\alpha,t) - h_k(\alpha,t) \right) t^k dt, \quad k \geq m.$$

If $k = m$, the summation on the right-hand side of (1.10) disappears.

Let us check that the functions g_k defined in (1.10) have all of the required properties. Equations (1.4) and (1.8a) ensure that (1.6) is satisfied. Since (1.4) can be differentiated with respect to p, expansion (1.6) can be differentiated with respect to p as well. Using (1.10), it is easy to check that g_k, $k \geq m$, are $C^\infty(Z)$ and even. Property (1) follows immediately from (1.8b) and (1.9). Property (2) follows from (1.8a). Property (3) can be checked by induction.

Let us denote

$$\Delta g_m := g, \qquad \Delta g_k := g - \sum_{k=m}^{k-1} g_j, \quad k \geq m+1.$$

We have to show that Δg_k, $k \geq m$, satisfies k moment conditions. If $k = m$, then $\Delta g_m = g$ and by assumption (a) of the theorem, Δg_m satisfies m moment conditions. Now let $k > m$. Suppose that Δg_k satisfies k moment conditions. We have to show that Δg_{k+1} satisfies $k+1$ moment conditions. From the relation $\Delta g_{k+1} = \Delta g_k - g_k$, it is obvious that Δg_{k+1} satisfies k moment conditions. Let us check the $(k+1)$st moment condition. Using (1.9) and (1.10), which can be rewritten as

$$g_k(\alpha,p) := h_k(\alpha,p) + P_k(p) \cdot \int_{-\infty}^{\infty} (\Delta g_k(\alpha,t) - h_k(\alpha,t))\, t^k dt, \quad k \geq m,$$

we get

$$\begin{aligned} \int_{-\infty}^{\infty} \Delta g_{k+1} p^k dp &= \int_{-\infty}^{\infty} (\Delta g_k - g_k) p^k dp \\ &= \int_{-\infty}^{\infty} (\Delta g_k - h_k) p^k dp - \int_{-\infty}^{\infty} P_k(p) p^k dp \int_{-\infty}^{\infty} (\Delta g_k - h_k) t^k dt = 0. \end{aligned}$$

Since the right-hand side of the last equation is a homogenous polynomial of any degree, the desired assertion is proved. □

In view of the proposition, the assertion $R\mathcal{X}_m = \mathcal{Y}_m$ is equivalent to the theorem. In section 2, a proof of the inclusion $R\mathcal{X}_m \subset \mathcal{Y}_m$ is given. In section 3, we prove the inclusion $\mathcal{Y}_m \subset R\mathcal{X}_m$. Two auxiliary lemmas are proved in section 4.

2. Proof of the inclusion $R\mathcal{X}_m \subset \mathcal{Y}_m$. Let $m \geq 0$ be fixed. Fix any $f \in \mathcal{X}_m$ and show that $Rf \in \mathcal{Y}_m$. Define g by

$$g(\alpha,p) := Rf(\alpha,p) = \int_0^\infty \int_{S_{\alpha^\perp}^{n-2}} f(p\alpha + t\omega) d\omega\, t^{n-2} dt, \tag{2.1}$$

where $S^{n-2}_{\alpha^\perp}$ is the unit sphere in the hyperplane passing through the origin perpendicular to α. Expansion (1.3) ensures that the above integral converges absolutely. Since derivatives of f decay at least as fast as f, one can differentiate with respect to p under the integral sign in (2.1) any number of times. Now let us check that g can be differentiated with respect to α. Fix any $\alpha \in S^{n-1}$, and let $\omega \perp \alpha$. It is sufficient to check that the function $g(\sqrt{1-|\omega|^2}\alpha+\omega, p)$ can be differentiated with respect to ω at $|\omega| = 0$. Let us represent $x \in \mathbb{R}^n$ as follows: $x = s\alpha + y$, $y \perp \alpha$. Differentiating the identity

$$g(\sqrt{1-|\omega|^2}\alpha+\omega, p) = \int_{\mathbb{R}^{n-1}} f\left(\frac{p-\omega\cdot y}{\sqrt{1-|\omega|^2}}\alpha + y\right) dy$$

with respect to $\omega_k, 1 \le k \le n-1$, and setting $|\omega| = 0$, we get

$$\begin{aligned}\frac{\partial}{\partial \omega_k} g(\sqrt{1-|\omega|^2}\alpha+\omega, p)\bigg|_{|\omega|=0} &= -\int_{\mathbb{R}^{n-1}} y_k \frac{\partial}{\partial s} f(s\alpha+y)\bigg|_{s=p} dy \\ &= -R\left[y_k \frac{\partial}{\partial s} f(s\alpha+y)\right](\alpha, p).\end{aligned}$$

Since $|f(x)| \le O(|x|^{-n})$, $|\frac{\partial}{\partial s} f(s\alpha+y)| \le O((s^2+|y|^2)^{-(n+1)/2})$, and therefore $|y_k \frac{\partial}{\partial s} f(s\alpha+y)| \le O((s^2+|y|^2)^{-n/2})$, the integrals on the right-hand sides of the last two equations converge absolutely, and taking the derivative under the integral sign is justified. As a generalization, we get

$$P_m(\partial_\omega) g(\sqrt{1-|\omega|^2}\alpha+\omega, p)\bigg|_{|\omega|=0} = (-1)^m R\left[P_m(y)\frac{\partial^m}{\partial s^m} f(s\alpha+y)\right](\alpha, p),$$

where $P_m(\omega) = P_m(\omega_1, \dots, \omega_{n-1})$ is a homogeneous polynomial of degree m. By assumption, $|\frac{\partial^m}{\partial s^m} f(s\alpha+y)| \le O((s^2+|y|^2)^{-(n+m)/2})$, and therefore $R\big(P_m(y)\frac{\partial^m}{\partial s^m} f(s\alpha+y)\big)$ is well defined for any $m \ge 0$. This shows that $g(\alpha, p)$ is infinitely differentiable with respect to α. Therefore, $g \in C^\infty(Z)$. Clearly, g is even.

Let f_k be any $C^\infty(\mathbb{R}^n)$ function such that $f_k(r\beta) = r^{-(n+k)}\psi_k(\beta)$, $r > 1$ (see (1.3)). Denote $g_k = Rf_k$. Analogously, we check that $g_k \in C^\infty(Z)$ and g_k is even. The functions $f_k(r\beta)r^j$, $j = 0, 1, \dots, k-1$, are absolutely integrable, and therefore the identity

$$\int_{\mathbb{R}^n} f(x)(\alpha\cdot x)^j dx = \int_{-\infty}^{\infty} g(\alpha, p)p^j dp, \quad j = 0, 1, \dots, k-1, \quad g = Rf, \tag{2.2}$$

which follows from the Fubini theorem, implies that g_k satisfies assumption (1) (see below (1.6)). Representing f_k and g_k as $f_k(r\beta) = \sum_{l=0}^\infty R_{kl}(r)Y_l(\beta)$, where Y_l is the spherical harmonic of degree l, $R_{kl}(r) = c_{kl}r^{-(n+k)}$ for $r > 1$, and $g_k(\alpha, p) = \sum_{l=0}^\infty P_{kl}(p)Y_l(\alpha)$, using (1.1) and the Funk–Hecke theorem [12, pp. 18 and 19], we find for $p > 1$ that

$$\begin{aligned}&R\big(R_{kl}(r)Y_l(\beta)\big) \\ &\quad= \gamma_{nl}c_{kl}Y_l(\alpha)\int_p^\infty r^{-(n+k)}C_l^{(\frac{n-2}{2})}(p/r)(1-(p/r)^2)^{\frac{n-3}{2}}r^{n-2}dr \\ &\quad= \gamma_{nl}c_{kl}\frac{Y_l(\alpha)}{p^{k+1}}\int_0^1 t^k C_l^{(\frac{n-2}{2})}(t)(1-t^2)^{\frac{n-3}{2}}dt \\ &\quad= 0 \quad \text{if } k < l \text{ and } k+l \text{ is even,}\end{aligned} \tag{2.3}$$

where γ_{nl} are some nonzero constants. Thus we have verified assumption (2), and we have showed that the kth term of the expansion for f is transformed into the kth term of series (1.6).

Let $f_{\Sigma K} := \sum_{k=m}^{K-1} f_k$ be the sum of the first $K - m$ terms of expansion (1.3). Define $g_{\Sigma K} := Rf_{\Sigma K}$. Since $f(r\beta) - f_{\Sigma K}(r\beta) = O(r^{-(n+K)})$, equation (2.2) implies that assumption (3) is also verified. Moreover, using (2.1), we get

$$\begin{aligned} |g(\alpha,p) - g_{\Sigma K}(\alpha,p)| &\le \int_0^\infty \int_{S^{n-2}_{\alpha^\perp}} |f(p\alpha + t\omega) - f_{\Sigma K}(p\alpha + t\omega)| d\omega\, t^{n-2} dt \\ &\le \int_0^\infty O\Big((p^2+t^2)^{-\frac{n+K}{2}}\Big) t^{n-2} dt = O\big(p^{-(K+1)}\big). \end{aligned}$$

Therefore, the formal series (1.6), which was obtained by taking the Radon transform of (1.3) term by term, is, in fact, the asymptotic expansion. Let us show that (1.6) can be differentiated with respect to p. Let $Q_s(x)$ be a homogeneous polynomial of degree $s \ge 0$. By assumption, the expansion $f(r\beta) \sim \sum_{k=m}^\infty f_k(r\beta)$ can be differentiated any number of times with respect to $x = r\beta$. Then $Q_s(\partial_x) f(r\beta) \sim \sum_{k=m}^\infty Q_s(\partial_x) f_k(r\beta)$. Taking the Radon transform on both sides and using the identity $R(Q_s(\partial_x)f) = Q_s(\alpha)\partial_p^s g(\alpha,p), g = Rf$ (see [14, Lemma 4.3] and [12, equation (2.1.15)]), we get by the already proved part of the theorem that

$$Q_s(\alpha)\partial_p^s g(\alpha,p) \sim \sum_{k=m}^\infty R(Q_s(\partial_x)f_k) = \sum_{k=m}^\infty Q_s(\alpha)\partial_p^s g_k(\alpha,p).$$

In view of the remark following the theorem, this means that

$$Q_s(\alpha)\bigg(\partial_p^s g(\alpha,p) - \sum_{k=m}^{K-1} \partial_p^s g_k(\alpha,p)\bigg) = O(\partial_p^s g_K) = O(p^{-(K+s+1)})$$

uniformly in α. The last equation holds for any homogeneous polynomial Q_s. Substituting two polynomials Q_s with disjoint zeros (e.g., $Q_s(\alpha) = \alpha_i^s$ and $Q_s(\alpha) = \alpha_j^s, i \ne j$), we see that

$$\partial_p^s g(\alpha,p) - \sum_{k=m}^{K-1} \partial_p^s g_k(\alpha,p) = O(p^{-(K+s+1)})$$

uniformly in α. Therefore, expansion (1.6) can be differentiated with respect to p. Thus we have checked that $Rf \in \mathcal{Y}_m$ if $f \in \mathcal{X}_m$. □

3. Proof of the inclusion $\boldsymbol{\mathcal{Y}_m \subset R\mathcal{X}_m}$. Let us show that if $g \in \mathcal{Y}_m$, then $f = R^{-1}g \in \mathcal{X}_m$. Let $\mathcal{F}$ denote the Fourier transform in $\mathbb{R}^n$ and F denote the one-dimensional Fourier transform acting on the p variable. The Fourier slice theorem [12, p. 15] asserts that $\mathcal{F}f = F(Rf)$ if $f \in \mathcal{S}(\mathbb{R}^n)$. In [14], it was shown that this relation holds for a much larger class of functions, which includes, in particular, functions of the type of (1.3) (see Lemma 4.5 in [14]). This yields two convenient formulas: $R = F^{-1}\mathcal{F}$ and $R^{-1} = \mathcal{F}^{-1}F$. Denote $\tilde g(\alpha,\lambda) = F_{p\to\lambda} g(\alpha,p)$. Using the formula for R^{-1} and writing $\mathcal{F}^{-1}$ in spherical coordinates, define

$$(3.1) \quad f(r\beta) := \mathcal{F}^{-1}Fg = \frac{1}{(2\pi)^n}\int_{S^{n-1}}\int_0^\infty \tilde g(\alpha,\lambda) e^{-ir\lambda(\alpha\cdot\beta)} \lambda^{n-1} d\lambda\, d\alpha, \quad g \in \mathcal{Y}_m.$$

Let us compute $R^{-1}g_k$, where g_k is a term from expansion (1.6). Without loss of generality, we may assume that g_k satisfies the first k moment conditions with the corresponding homogeneous polynomials being identically equal zero. Indeed, it is well known (see, e.g., [14, Lemma 7.4] and [12, Exercise 3.1.1 on p. 69]) that there exists $\varphi_k \in C_0^\infty(\mathbb{R}^n)$, $\varphi_k(x) = 0$ for $|x| \geq 1$, such that

$$\int_{-\infty}^{\infty} (g_k(\alpha,p) - R\varphi_k(\alpha,p))p^j\,dp = 0, \quad j = 0, 1, \dots, k-1.$$

Replacing g_k by $g_k - R\varphi_k$ in (1.6), we see that all of the assumptions are still satisfied, and expansion (1.6) remains valid. Let $P_{kl} \in C^\infty(\mathbb{R})$ be a function such that

$$P_{kl}(p) = p^{-(k+1)}, \quad p > 1; \qquad P_{kl}(p) = -p^{-(k+1)}, \quad p < -1; \tag{3.2}$$

$$\int_{-\infty}^{\infty} P_{kl}(p)p^j\,dp = 0, \quad j = 0, 1, \dots, k-1. \tag{3.3}$$

Using (1.7), we get

$$g_k(\alpha,p) = \sum_{l \leq k,\ l+k \text{ even}} a_{kl} P_{kl}(p) Y_l(\alpha) + \Delta g_k(\alpha,p), \tag{3.4}$$

where the constants a_{kl} are determined from the equation $\sum_{l \leq k,\ l+k \text{ even}} a_{kl} Y_l(\alpha) = Q_k(\alpha)$. In view of (3.3), the function $\Delta g_k(\alpha,p)$ has the property

$$\int_{-\infty}^{\infty} \Delta g_k(\alpha,p)p^j\,dp = 0, \quad j = 0, 1, \dots, k-1, \tag{3.5}$$

and in view of (1.7) and (3.2),

$$\Delta g_k(\alpha,p) = b_k(\alpha)p^{-(k+1)}, \quad |p| > 1. \tag{3.6}$$

Let us now compute $R^{-1}(Y_l P_{kl})$ under the assumptions that P_{kl} is as in (3.2) and (3.3), $l \leq k$, and $l+k$ is even. Denoting $\tilde{P}_{kl} = FP_{kl}$, using equation (3.1) and [12, equation (14.4.48)], we get

$$f_{kl}(r\beta) = \frac{i^l}{(2\pi)^{n/2}} Y_l(\beta) \int_0^\infty \lambda^{n-1} \frac{J_{l+\frac{n-2}{2}}(\lambda r)}{(\lambda r)^{\frac{n-2}{2}}} \tilde{P}_{kl}(\lambda)\,d\lambda. \tag{3.7}$$

Using (3.2), (3.3), and the identity

$$\tilde{P}_{kl}^{(s)}(\lambda) = \frac{\partial^s}{\partial\lambda^s}\left[\frac{1}{(-i\lambda)^j}\int_{-\infty}^{\infty} P_{kl}^{(j)}(p)e^{i\lambda p}\,dp\right], \tag{3.8}$$

where $j > 0$ can be made arbitrarily large, we conclude that

(i) $\tilde{P}_{kl} \in \mathcal{S}(\mathbb{R} \setminus 0)$; that is, $\tilde{P}_{kl} \in C^\infty(\mathbb{R} \setminus 0)$ and all derivatives of $\tilde{P}_{kl}$ decay faster than any power of λ^{-1} as $\lambda \to \infty$;

(ii) $\tilde{P}_{kl}$ can be represented as $\tilde{P}_{kl}(\lambda) = (-i\lambda)^k \tilde{\rho}_{kl}(\lambda)$, where $\tilde{\rho}_{kl} \in \mathcal{S}(\mathbb{R} \setminus 0)$; and

(iii) $\tilde{\rho}_{kl}$ has the following asymptotic representation:

$$\tilde{\rho}_{kl}(\lambda) = b_{kl}\ln\lambda + b_{0kl} + b_{1kl}\lambda + \cdots, \quad \lambda \to 0^+. \tag{3.9}$$

Equation (3.7) can be written as

$$f_{kl}(r\beta)=\frac{i^l}{(2\pi)^{n/2}}\frac{Y_l(\beta)}{r^{\frac{n-2}{2}}}I_{kl}(r), \qquad I_{kl}(r)=\int_0^\infty \lambda^{\frac{n}{2}+k}\tilde{\rho}_{kl}(\lambda)J_{l+\frac{n-2}{2}}(\lambda r)d\lambda.$$

Using (3.9) and the result on the asymptotics of the Hankel transform [1, pp. 231–233], we see that the asymptotic expansion of $I_{kl}(r)$ as $r\to\infty$ consists of the terms

$$\frac{\ln r}{r^{1+\frac{n}{2}+k}}M\left[J_{l+\frac{n-2}{2}},1+\frac{n}{2}+k\right] \quad \text{and} \quad r^{-(1+\frac{n}{2}+k+j)}, \quad j\geq 0,$$

where $M[J_\mu,z]$ denotes the Mellin transform of J_μ evaluated at z. It is well known that

$$M[J_\mu,z]=\frac{2^{z-1}\Gamma\left(\frac{z+\mu}{2}\right)}{\Gamma\left(\frac{\mu-z+2}{2}\right)},$$

and the corresponding strip of analyticity is $-\mu<\mathrm{Re}z<1.5$ [1, p. 414]. According to [1, Lemma 4.3.2], $M[J_\mu,z]$ can be analytically continued into the right half-plane $\mathrm{Re}z\geq 1.5$ as a holomorphic function. According to our assumptions, the ratio $(l-k)/2$ can be only either 0 or a negative integer. Since $|\Gamma(t)|\to\infty$ as t approaches any nonpositive integer, we get

$$M\left[J_{l+\frac{n-2}{2}},1+\frac{n}{2}+k\right]=\lim_{z\to 1+\frac{n}{2}+k}M[J_{l+\frac{n-2}{2}},z]=0, \quad (l-k)/2=0,-1,-2,\dots.$$

Therefore, the term containing $\ln r$ in the expansion of $I_{kl}(r)$ vanishes, and an asymptotic expansion of $f_l(r\beta)$ is of the type of (1.3):

$$f_{kl}(r\beta)=Y_l(\beta)\left(\frac{c_{0kl}}{r^{n+k}}+\frac{c_{1kl}}{r^{n+k+1}}+\cdots\right). \tag{3.10}$$

Let us now compute $R^{-1}(\Delta g_k)$. Denote

$$G(\alpha,p)=\int_{-\infty}^p\frac{(p-t)^{k-1}}{(k-1)!}\Delta g_k(\alpha,t)dt. \tag{3.11}$$

Clearly, $G(\alpha,p)\in C^\infty(Z)$ and $\partial_p^kG(\alpha,p)=\Delta g_k(\alpha,p)$. Using (3.5), we get an equivalent expression for $G(\alpha,p)$:

$$G(\alpha,p)=-\int_p^\infty\frac{(p-t)^{k-1}}{(k-1)!}\Delta g_k(\alpha,t)dt. \tag{3.11$'$}$$

Substituting (3.6) into (3.11) and (3.11$'$), we find that

$$G(\alpha,p)=cb_k(\alpha)p^{-1}, \quad |p|>1, \tag{3.12}$$

for some nonzero constant c. Fourier transforms of Δg_k and G are related by the equation

$$\Delta\tilde{g}_k(\alpha,\lambda)=(-i\lambda)^k\tilde{G}(\alpha,\lambda). \tag{3.13}$$

Using an equation analogous to (3.8), equation (3.12) yields that $\tilde{G}(\alpha,\lambda) \in \mathcal{S}(S^{n-1} \times (\mathbb{R} \setminus 0))$. Moreover, equation (3.12) implies that the asymptotics of $\tilde{G}(\alpha,\lambda)$ as $\lambda \to 0^+$ equals

$$\begin{aligned}\tilde{G}(\alpha,\lambda) &\overset{\text{up to a } C^\infty(Z) \text{ function}}{=} cb_k(\alpha)\int_{|p|\geq 1}\frac{1}{p}e^{i\lambda p}dp = 2cb_k(\alpha)\int_1^\infty \frac{\sin(\lambda p)}{p}dp \\ &= 2cb_k(\alpha)\left(\frac{\pi}{2} - \operatorname{Si}(\lambda)\right), \quad \lambda \to 0^+,\end{aligned} \tag{3.14}$$

where $\operatorname{Si} \in C^\infty(\mathbb{R})$ is the integral sine. Defining $\partial_\lambda^k \tilde{G}(\alpha, 0) := \lim_{\lambda\to 0^+} \partial_\lambda^k \tilde{G}(\alpha,\lambda)$, $k \geq 0$, we get $\tilde{G}(\alpha,\lambda) \in \mathcal{S}(S^{n-1} \times [0,\infty))$. Substituting (3.13) into (3.1) and applying Lemma 1 from section 4 to the resulting integral, we conclude that $\Delta f_k := R^{-1}(\Delta g_k)$ admits an asymptotic expansion

$$\Delta f_k(r\beta) \sim \sum_{l=k}^{\infty} \frac{\Delta\psi_{kl}(\beta)}{r^{n+l}}, \quad r \to \infty, \quad \Delta\psi_{kl} \in C^\infty(S^{n-1}).$$

Together with (3.10), this implies that $f_k := R^{-1}g_k$ admits an asymptotic expansion

$$f_k(r\beta) \sim \sum_{l=k}^{\infty} \frac{\psi_{kl}(\beta)}{r^{n+l}}, \quad r \to \infty, \quad \psi_{kl} \in C^\infty(S^{n-1}); \tag{3.15}$$

hence a formal expansion for $f = R^{-1}g$ is

$$f(r\beta) \sim \sum_{k=m}^{\infty} \frac{1}{r^{n+k}}\left(\sum_{l=m}^{k}\psi_{kl}(\beta)\right), \quad r \to \infty. \tag{3.16}$$

Thus the kth term from the expansion of g contributes to the kth and the following terms of the expansion for f, and this expansion is of the type of (1.3). Also, for each fixed k, only finitely many g_j's, $j = 0, 1, \ldots, k$, contribute to the term f_k, $f_k(r\beta) = r^{-(n+k)}\psi_k(\beta)$, $r \to \infty$, in expansion (1.3).

We have proved that $f = R^{-1}g$ can be formally represented as in (1.3). To see that this is indeed an asymptotic expansion, we have to show that $|f(r\beta) - f_{\Sigma K}(r\beta)| \leq cr^{-(n+K)}$, $r \to \infty$, where $f_{\Sigma K} = R^{-1}g_{\Sigma K}$ and $g_{\Sigma K} := \sum_{k=m}^{K-1} g_k$. Let $M > K > m$ be sufficiently large. Then we can write

$$g(\alpha,p) = g_{\Sigma K}(\alpha,p) + \sum_{k=K}^{M-1} g_k + \eta_M(\alpha,p), \quad p \to \infty.$$

By what was proved above,

$$R^{-1}\left(\sum_{k=K}^{M-1} g_k\right) = O(r^{-(n+K)}), \quad r \to \infty.$$

From the assumptions of the theorem, $\eta_M \in C^\infty(Z)$, η is even, η_M satisfies the first M moment conditions, and η_M admits the asymptotic expansion $\eta_M \sim \sum_{k=M}^{\infty} g_k$. Therefore, $\frac{\partial^j}{\partial p^j}\eta_M(\alpha,p) = O(p^{-(M+j+1)})$, $j \geq 0$. Define $\tilde{\eta}_M(\alpha,\lambda) := F_{p\to\lambda}\eta_M(\alpha,p)$.

Using an equation analogous to (3.8), we have $\tilde\eta_M \in \mathcal{S}(S^{n-1}\times(\mathbb{R}\setminus 0))$. Suppose that $J>0$ is even. Using the identity

$$(1+r^2)^{J/2} f_M(r\beta) = \mathcal{F}^{-1}\big((1-\Delta_\xi)^{J/2}\tilde\eta_M(\alpha,\lambda)\big),$$
$$\xi=\lambda\alpha,\quad f_M = R^{-1}\eta_M,$$

we see that f_M decays sufficiently fast if $\tilde\eta_M$ is sufficiently smooth at the origin. By construction, η_M satisfies the first M moment conditions; therefore, $\tilde\eta_M$ is C^M at the origin. Since M can be made arbitrarily large, f_M can be made to decay as fast as needed. Retaining in the asymptotic expansion of $f_{\Sigma K}$ only the terms of order $\le O(r^{-(n+K-1)})$, we prove the desired assertion.

From (1.6) and (1.7), it follows that $\tilde g(\alpha,\lambda)$, which is used in (3.1), has at worst logarithmic singularity at $\lambda=0$. In a standard fashion, we obtain that $\tilde g(\alpha,\lambda)\in \mathcal{S}(S^{n-1}\times(\mathbb{R}\setminus 0))$. Therefore, $f\in C^\infty(\mathbb{R})$.

Let Q_s be a homogeneous polynomial of degree $s\ge 0$. By assumption, (1.6) can be differentiated with respect to p. Integrating by parts and using assumptions (1)–(3), it is easy to verify the inclusion $g_s(\alpha,p):=Q_s(\alpha)\partial_p^s g(\alpha,p)\in\mathcal{Y}_{m+s}$. Hence $f_s := R^{-1}g_s$ admits an asymptotic expansion of the type of (1.3) with m replaced by $m+s$. Therefore, Lemma 2 from section 4 implies that expansion (1.3) can be differentiated with respect to $x=r\beta$ any number of times.

Finally, we have to show that if f is defined by (3.1), then $Rf=g$ and such an f is unique. We have proved that if f is defined by (3.1), then f is of the type of (1.3). As in the proof of the inclusion $R\mathcal{X}_m\subset\mathcal{Y}_m$, we get that f is absolutely integrable over any $(n-1)$-plane and $Rf\in C^\infty(Z)$. By Lemma 4.5 from [14], $F(Rf)=\mathcal{F}f$ almost everywhere. Since $f:=\mathcal{F}^{-1}Fg$, the equality $Rf=g$ holds almost everywhere. By continuity, $Rf=g$ everywhere. The uniqueness of f follows easily from the injectivity of F and $\mathcal{F}$. The theorem is proved.

4. Auxiliary results.

LEMMA 1. *Let $h\in\mathcal{S}(S^{n-1}\times[0,+\infty))$ and fix $k\ge 0$. Define*

$$f(x)=\frac{1}{(2\pi)^n}\int_{S^{n-1}}\int_0^\infty \lambda^k h(\alpha,\lambda)\exp(-i\lambda\alpha\cdot x)d\lambda d\alpha. \tag{4.1}$$

Then f admits an asymptotic expansion

$$f(r\beta)\sim\sum_{l=k+1}^\infty \frac{\psi_l(\beta)}{r^l},\quad r\to\infty,\quad \psi_l\in C^\infty(S^{n-1}). \tag{4.2}$$

Let $h(\alpha,p)=F_{p\to\lambda}g(\alpha,\lambda)$, where $g\in\mathcal{S}(Z)$ and g is even. Then clearly $h\in\mathcal{S}(Z)$ and $f=Rg$. In this case, equation (4.2) follows from the results in [14]. Nevertheless, Lemma 1 is more general because we consider functions $g(\alpha,p)$ which decay only polynomially as $|p|\to\infty$ (see, e.g., (3.12)). In this case, $h(\alpha,p)=F_{p\to\lambda}g(\alpha,\lambda)$ is not smooth across $\lambda=0$ (the one-sided limits of h and its derivatives exist at $\lambda=0$, however), and hence $h\notin\mathcal{S}(Z)$.

Proof of Lemma 1. Fix $\beta\in S^{n-1}$ and let $x=r\beta$, $r>0$. For a function φ defined on S^{n-1}, we have

$$\int_{S^{n-1}}\varphi(\alpha)d\alpha=\int_{-1}^1\int_{\alpha\cdot\beta=t}\varphi(\alpha)d\alpha\frac{dt}{\sqrt{1-t^2}}$$
$$=\int_{-1}^1\int_{S^{n-2}_{\beta^\perp}}\varphi(t\beta+\sqrt{1-t^2}\,\omega)(1-t^2)^{\frac{n-3}{2}}d\omega\,dt.$$

Therefore, equation (4.1) takes the form

$$f(r\beta) = \int_{-1}^{1}\int_{0}^{\infty} \lambda^k (1-t^2)^{\frac{n-3}{2}} A_\beta(\lambda,t) e^{-i\lambda t r} d\lambda\, dt, \tag{4.3}$$

where

$$A_\beta(\lambda,t) = \frac{1}{(2\pi)^n}\int_{\omega\in S^{n-1}_{\beta^\perp}} h(t\beta+\sqrt{1-t^2}\,\omega,\lambda)d\omega. \tag{4.4}$$

Fix any even $\chi \in C_0^\infty([-1,1])$ such that $\chi(t)\equiv 1$ for $|t|\le 0.5$, and denote $B_\beta(\lambda,t) := (1-t^2)^{\frac{n-3}{2}} A_\beta(\lambda,t)\chi(t)$. Then

$$\begin{aligned} f(r\beta) = &\int_{0.5\le|t|\le 1} (1-t^2)^{\frac{n-3}{2}}(1-\chi(t))\int_0^\infty \lambda^k A_\beta(\lambda,t)e^{-i\lambda t r}d\lambda\, dt \\ &+\int_0^\infty\int_{-1}^{1}\lambda^k B_\beta(\lambda,t)e^{-i\lambda t r}dt\, d\lambda := I_1(r\beta)+I_2(r\beta). \end{aligned} \tag{4.5}$$

Since $h\in \mathcal{S}(S^{n-1}\times[0,+\infty))$, we get that $A_\beta(\lambda,t)$ is $\mathcal{S}([0,\infty))$ in the λ variable and $C([-1,1])$ in the t variable. Therefore, integration by parts gives an asymptotic expansion

$$\int_0^\infty \lambda^k A_\beta(\lambda,t)e^{-i\lambda t r}d\lambda \sim \sum_{l=k+1}^{\infty}\frac{a_l(\beta,t)}{r^l}, \quad 0.5\le|t|\le 1, \quad r\to\infty, \tag{4.6}$$

where

$$a_l(\beta,t) = -(it)^{-l}\frac{\partial^{l-1}}{\partial\lambda^{l-1}}\left(\lambda^k A_\beta(\lambda,t)\right)\bigg|_{\lambda=0}, \quad l\ge k+1.$$

Substituting (4.6) into the definition of I_1 (see (4.5)) and integrating with respect to t over $0.5\le|t|\le 1$, we get

$$\begin{aligned} &I_1(r\beta)\sim\sum_{l=k+1}^{\infty}\frac{\psi_{1l}(\beta)}{r^l}, \\ &\psi_{1l}(\beta) = \int_{0.5\le|t|\le 1}(1-t^2)^{\frac{n-3}{2}}(1-\chi(t))a_l(\beta,t)dt \in C^\infty(S^{n-1}). \end{aligned} \tag{4.7}$$

The inclusion $\psi_{1l}\in C^\infty(S^{n-1})$ holds because $A_\beta(\lambda,t)$ and all of its derivatives with respect to λ depend smoothly on β. (According to (4.4), $A_\beta(\lambda,t)$ is the normalized integral of $h\in\mathcal{S}(S^{n-1}\times[0,\infty))$ over the intersection of the plane $x\cdot\beta=t$ and the unit sphere.) Integration of the asymptotic expansion with respect to the parameter t is justified (cf. Theorem 1.7.5 in [1]).

To find the asymptotic expansion of $I_2(r\beta)$, we transform the integral, denoting $s=\lambda t$ and changing the order of integration:

$$I_2(r\beta) = \int_{-\infty}^{\infty} C_\beta(s)e^{-isr}ds, \qquad C_\beta(s) := \int_{|s|}^{\infty}\lambda^{k-1}B_\beta\left(\lambda,\frac{s}{\lambda}\right)d\lambda. \tag{4.8}$$

Differentiating $C_\beta(s)$ and using the fact that $B_\beta(\lambda,t)\equiv 0$ in neighborhoods of $t=\pm1$, we have $C_\beta^{(m)}(s) = \int_{|s|}^\infty \lambda^{k-1-m}B_\beta^{(m)}(\lambda,s/\lambda)d\lambda$, where $B_\beta^{(m)} := \frac{\partial^m B_\beta}{\partial t^m}$. Clearly, all derivatives of C_β are $C^\infty(\mathbb{R}\setminus 0)$. Moreover, the derivatives $C_\beta^{(m)}(s)$, $m \le k-1$, exist and are continuous at $s=0$. For $m=k$,

$$C_\beta^{(k)}(s) = \int_{|s|}^{\infty} \frac{B_\beta^{(k)}(\lambda, \frac{s}{\lambda})}{\lambda} d\lambda. \tag{4.9}$$

The behavior of $C_\beta^{(k)}(s)$ as $s \to 0$ will be obtained later. Integrating by parts k times in (4.8), we get

$$I_2(r\beta) = \frac{1}{(ir)^k} \int_{-\infty}^{\infty} C_\beta^{(k)}(s) e^{-isr} ds. \tag{4.10}$$

Fix any $\varphi \in C^\infty([0,\infty))$ such that $\varphi(\lambda)=1$ for $0 \le \lambda \le 1/2$ and $\varphi(\lambda)=0$ for $\lambda \ge 1$. Rewrite (4.9) as follows:

$$\begin{aligned} C_\beta^{(k)}(s) = &\int_{|s|}^{\infty} \frac{B_\beta^{(k)}(\lambda, \frac{s}{\lambda}) - B_\beta^{(k)}(0, \frac{s}{\lambda})\varphi(\lambda)}{\lambda} d\lambda \\ &+ \int_{|s|}^{\infty} \frac{B_\beta^{(k)}(0, \frac{s}{\lambda})\varphi(\lambda)}{\lambda} d\lambda =: C_1(s) + C_2(s). \end{aligned} \tag{4.11}$$

Clearly, $C_2 \in C^\infty((0,+\infty))$ and $C_2(s)=0$ for $|s| \ge 1$. Furthermore, for $|s| < 1/2$,

$$\begin{aligned} C_2(s) &= \int_{1/2}^{1} \frac{B_\beta^{(k)}(0, \frac{s}{\lambda})}{\lambda} \varphi(\lambda) d\lambda + \int_{|s|}^{1/2} \frac{B_\beta^{(k)}(0, \frac{s}{\lambda})}{\lambda} d\lambda \\ &= (C^\infty - \text{fn}) + \int_{|s|}^{1/2} \frac{B_\beta^{(k)}(0, \frac{s}{\lambda}) - B_\beta^{(k)}(0,0)}{\lambda} d\lambda + B_\beta^{(k)}(0,0) \int_{|s|}^{1/2} \frac{1}{\lambda} d\lambda \\ &= (C^\infty - \text{fn}) - B_\beta^{(k)}(0,0) \ln|s| + \int_{2|s|}^{1} \frac{B_\beta^{(k)}(0, t\text{sgn}s) - B_\beta^{(k)}(0,0)}{t} dt \\ &= (C^\infty - \text{fn}) - B_\beta^{(k)}(0,0) \ln|s| + \int_{0}^{1} \frac{B_\beta^{(k)}(0, t) - B_\beta^{(k)}(0,0)}{t} dt [\text{sgn}s]^k, \end{aligned} \tag{4.12}$$

where we have used the fact that $B_\beta^{(k)}(0,t)$ is even if k is even and $B_\beta^{(k)}(0,t)$ is odd if k is odd. Thus $C_2(s)$ has the asymptotic expansion of the form

$$\begin{aligned} &C_2(s) \sim b_{-2}(\beta)\ln|s| + b_{-1}(\beta)[\text{sgn}s]^k + \sum_{l=0}^{\infty} b_l(\beta)s^l, \quad s \to 0; \\ &b_l \in C^\infty(S^{n-1}), \quad l \ge -2. \end{aligned}$$

Furthermore, this expansion can be differentiated with respect to s. Using the result from [1, pp. 231–233], we get

$$\int_{-\infty}^{\infty} C_2(s) e^{-isr} ds \sim \sum_{l=1}^{\infty} \frac{c_l(\beta)}{r^l}, \quad c_l \in C^\infty(S^{n-1}). \tag{4.13}$$

Let us denote

$$B_1(\lambda, t) := \frac{B_\beta^{(k)}(\lambda, t) - B_\beta^{(k)}(0,t)\varphi(\lambda)}{\lambda}$$

and represent $C_1(s)$ as

$$C_1(s) = \int_{|s|}^{\infty} B_1(\lambda, s/\lambda) d\lambda.$$

Clearly, $B_1 \in C^\infty([0,\infty) \times \mathbb{R})$ and $B_1(\lambda, t)$ with all derivatives decay faster than any power of λ^{-1} as $\lambda \to \infty$. Furthermore, $B_1(\lambda, t) = 0$ in neighborhoods of $t = \pm 1$, and

$$C_1'(s) = \int_{|s|}^{\infty} \frac{B_1^{(1)}(\lambda, \frac{s}{\lambda})}{\lambda} d\lambda. \tag{4.14}$$

From (4.10) and (4.11), we get

$$\int_{-\infty}^{\infty} C_\beta^{(k)}(s) e^{-isr} ds = \frac{1}{ir} \int_{-\infty}^{\infty} C_1'(s) e^{-isr} ds + \int_{-\infty}^{\infty} C_2(s) e^{-isr} ds. \tag{4.15}$$

Comparing (4.14) with (4.9), we see that the asymptotics of $\int_{-\infty}^{\infty} C_1'(s) e^{-isr} ds$ as $r \to \infty$ can be obtained analogously to (4.11)–(4.12) with $B_\beta^{(k)}$ replaced by $B_1^{(1)}$. Moreover, this integral is multiplied by $1/(ir)$ in (4.15). Therefore, the standard argument that is used for the justification of the integration-by-parts procedure for obtaining asymptotic expansions of integrals (see, e.g., [1, p. 71]) shows that iterating the procedure consisting of (4.11)–(4.15), we obtain the asymptotic expansion of $I_2(r\beta)$, and this expansion is of the form

$$I_2(r\beta) \sim \sum_{l=k+1}^{\infty} \frac{\psi_{2l}(\beta)}{r^l}, \quad \psi_{2l} \in C^\infty(S^{n-1}). \tag{4.16}$$

Combining (4.5), (4.7), and (4.16) proves Lemma 1. □

Lemma 2. *Let $f \in C^\infty(\mathbb{R}^n)$ be such that for any homogeneous polynomial Q_s of degree $s \geq 0$, the function $Q_s(\partial_x) f$ admits the asymptotic expansion*

$$Q_s(\partial_x) f(r\beta) \sim \sum_{k=m+s}^{\infty} \frac{\mu_k(\beta)}{r^k}, \quad r \to \infty, \quad \mu_k \in C^\infty(S^{n-1}), \quad x = r\beta, \tag{4.17}$$

for some $m \geq 1$, where μ_k's depend on Q_s. Then the asymptotic expansion of f can be differentiated with respect to x any number of times. More precisely, if

$$f(r\beta) \sim \sum_{k=m}^{\infty} \frac{\psi_k(\beta)}{r^k}, \quad r \to \infty, \quad \psi_k \in C^\infty(S^{n-1}), \quad x = r\beta, \tag{4.18}$$

then

$$Q_s(\partial_x) f(r\beta) \sim \sum_{k=m}^{\infty} Q_s(\partial_x) \left(\frac{\psi_k(\beta)}{r^k} \right), \quad r \to \infty, \quad x = r\beta. \tag{4.19}$$

Proof. Clearly, it is sufficient to prove (4.19) for only $s = 1$ and $Q_s(\partial_x) = \partial_{x_1}$. By assumption,

$$\partial_{x_1} f(r\beta) \sim \sum_{k=m+1}^{\infty} \frac{\mu_k(\beta)}{r^k} \tag{4.20}$$

for some $\mu_k \in C^\infty(S^{n-1})$. Since $f(x) \to 0$ as $|x| \to \infty$ (see (4.18)), we have

$$-f(x_1, y) = \int_{x_1}^{\infty} \partial_t f(t, y)dt, \quad x = (x_1, y), \quad y \in \mathbb{R}^{n-1}, \tag{4.21}$$

for any $x_1 \in \mathbb{R}$ and $y \in \mathbb{R}^{n-1}$. Substitute expansion (4.20) into (4.21) and integrate formally with respect to t to get

$$\begin{aligned}\int_{x_1}^{\infty} \partial_t f(t, y)dt &\sim \sum_{k=m+1}^{\infty} \int_{x_1}^{\infty} \frac{\mu_k\big(\frac{te_1+y}{(t^2+|y|^2)^{1/2}}\big)}{(t^2+|y|^2)^{k/2}}dt \\ &= \sum_{k=m+1}^{\infty} |y|^{-k+1} \int_{v}^{\infty} \frac{\mu_k\big(\frac{qe_1+y_0}{(q^2+1)^{1/2}}\big)}{(q^2+1)^{k/2}}dq,\end{aligned} \tag{4.22}$$

where e_1 is the unit vector along the x_1-axis, $q = t/|y|$, $y_0 = y/|y|$, and $v = x_1/|y|$. In what follows, we suppose that y_0 and v are fixed. Then the right-hand side of (4.22) has the form of an asymptotic expansion as $|y| \to \infty$. To justify the integration with respect to t, we have to show that if

$$\eta(r\beta) := \partial_{x_1} f(r\beta) - \sum_{k=m+1}^{K-1} \frac{\mu_k(\beta)}{r^k} = O(r^{-K}),$$

then $\int_{x_1}^{\infty} \eta(t, y)dt = O(|y|^{-K+1})$. Since $\eta(r\beta) = O(r^{-K})$, we get $|\eta(r\beta)| \leq cr^{-K}$, $r \geq 1$, for some $c > 0$. Using this estimate and integrating with respect to t analogously to (4.22), we obtain the desired assertion.

Using the variables y_0 and v, transform (4.18):

$$f(x_1, y) \sim \sum_{k=m}^{\infty} |y|^{-k} \frac{\psi_k\big(\frac{ve_1+y_0}{(v^2+1)^{1/2}}\big)}{(v^2+1)^{k/2}}. \tag{4.23}$$

Since the asymptotic expansion—if it exists—is unique, we conclude from (4.21)–(4.23) by taking $|y| \to \infty$ that

$$-\frac{\psi_k\big(\frac{ve_1+y_0}{(v^2+1)^{1/2}}\big)}{(v^2+1)^{k/2}} = \int_{v}^{\infty} \frac{\mu_{k+1}\big(\frac{qe_1+y_0}{(q^2+1)^{1/2}}\big)}{(q^2+1)^{(k+1)/2}}dq, \quad k \geq m, \quad v \in \mathbb{R}, \quad y_0 \in S^{n-2}.$$

Therefore,

$$\frac{\partial}{\partial v}\left(\frac{\psi_k\big(\frac{ve_1+y_0}{(v^2+1)^{1/2}}\big)}{(v^2+1)^{k/2}}\right) = \frac{\mu_{k+1}\big(\frac{ve_1+y_0}{(v^2+1)^{1/2}}\big)}{(v^2+1)^{(k+1)/2}}, \quad k \geq m, \quad v \in \mathbb{R}, \quad y_0 \in S^{n-2}.$$

Multiplying the last equation by $|y|^{-k}$ on both sides, returning to the variables x_1 and y, and then denoting $r\beta = x_1e_1 + y$, we get

$$\frac{\partial}{\partial x_1}\left(\frac{\psi_k(\beta)}{r^k}\right) = \frac{\mu_{k+1}(\beta)}{r^{k+1}}.$$

Lemma 2 is proved. □

NONMINIMIZING POSITIVE SOLUTIONS FOR EQUATIONS WITH CRITICAL EXPONENTS IN THE HALF-SPACE*

GIOVANNA CERAMI† AND DONATO PASSASEO‡

Abstract. This paper is concerned with the existence of positive solutions of the nonlinear elliptic problem $-\Delta u + a(x)u = u^{(N+2)/(N-2)}$, $a(x) \geq 0$, with Neumann boundary conditions in a half-space $\Pi \subset \mathbb{R}^N$, $N \geq 3$. The main feature of the problem is a "double" lack of compactness due to the unboundedness of the domain and the presence of the critical Sobolev exponent. The solutions are searched using variational methods, although the functional related to the problem does not satisfy the Palais–Smale compactness condition. We observe that the problem considered has no solutions if $a(x)$ is a positive constant; conditions on $a(x)$ are given sufficient to guarantee existence and multiplicity of positive solutions.

Key words. nonlinear elliptic equations, critical Sobolev exponent, positive solutions

1. Introduction and statement of the results.

This paper deals with the following problem: find solutions of finite energy of

$$\text{(P)} \qquad \begin{cases} -\Delta u + a(x)u = u^p & \text{in } \mathbb{R}^N_+, \\ u > 0 & \text{in } \mathbb{R}^N_+, \\ \partial u/\partial x_N = 0 & \text{on } \partial\mathbb{R}^N_+, \\ u(x) \to 0 & \text{as } |x| \to +\infty, \end{cases}$$

where $p = 2^* - 1$, $2^* = 2N/(N-2)$, $N \geq 3$, $a(x) \geq 0$, $\mathbb{R}^N_+ = \{x = (x_1, x_2, \ldots, x_N) \in \mathbb{R}^N : x_N > 0\}$, and $\partial\mathbb{R}^N_+ = \{x = (x_1, x_2, \ldots, x_{N-1}, 0) \in \mathbb{R}^N\}$.

If $a(x) = 0$, (P) has the positive solution

$$U(x) = \frac{[N(N-2)]^{(N-2)/4}}{(1+|x|^2)^{(N-2)/2}},$$

and all of the positive solutions can be obtained from this one by translations and scale changes, namely, they have the form $\sigma^{-(N-2)/4}U((x-y)/\sqrt{\sigma})$, $\sigma > 0$, $y \in \partial\mathbb{R}^N_+$. On the other hand, if $a(x) = \lambda > 0$ (λ constant), it is not difficult to realize that (P) has no solutions. In fact, if u were a solution of (P), its extension to all of $\mathbb{R}^N$, obtained by reflection, would solve $-\Delta u + \lambda u = u^{2^*-1}$ in $\mathbb{R}^N$, and this problem has no nontrivial solutions, which follows from a generalized version of the Pohozaev identity (see, for instance, [BL] or [BC]).

On the other hand, it has been shown (see [BC], [P]) that the presence of a nonconstant coefficient $a(x)$ plays an important role in finding finite-energy positive solutions of the following equation: $-\Delta u + a(x)u = u^{2^*-1}$ in $\mathbb{R}^N$.

In this paper, we consider functions $a(x)$ that satisfy the following assumption:

$$\tag{1.1} \begin{cases} \text{(i)} \quad \lim_{|x|\to+\infty} a(x) = a_\infty \geq 0, & a_\infty \in \mathbb{R}, \\ \text{(ii)} \quad a(x) \geq a_\infty & \forall x \in \mathbb{R}^N_+, \\ \text{(iii)} \quad a(x) - a_\infty \in L^{N/2}(\mathbb{R}^N_+), & |a(x) - a_\infty|_{L^{N/2}(\mathbb{R}^N_+)} \neq 0. \end{cases}$$

The Hilbert spaces that we obtain as the closure of $\mathcal{C}^\infty(\mathbb{R}^N_+)$ with respect to

$$\|u\|_{\mathcal{D}} = \left(\int_{\mathbb{R}^N_+} |\nabla u|^2 dx\right)^{1/2}, \qquad \|u\|_W = \left[\int_{\mathbb{R}^N_+} (|\nabla u|^2 + u^2) dx\right]^{1/2}$$

are denoted $\mathcal{D}^{1,2}(\mathbb{R}^N_+)$ and $W^{1,2}(\mathbb{R}^N_+)$, respectively. The results that we obtain can be stated as follows.

THEOREM 1.1. *Let $a(x)$ satisfy* (1.1) *and let $a_\infty > 0$. Then there exists a positive number $\mathcal{A}$ such that if $a_\infty \in (0, \mathcal{A})$, then* (P) *admits at least a positive solution $v \in W^{1,2}(\mathbb{R}^N_+)$. Furthermore, if the condition*

$$\tag{1.2} |a(x) - a_\infty|_{L^{N/2}(\mathbb{R}^N_+)} < (1 - 2^{-2/N})S$$

is satisfied, (P) *has at least another solution $u \in W^{1,2}(\mathbb{R}^N_+)$.*

THEOREM 1.2. *Let $a(x)$ satisfy* (1.1) *and let $a_\infty = 0$. Assume that* (1.2) *holds, i.e.,*

$$|a|_{L^{N/2}(\mathbb{R}^N_+)} < (1 - 2^{-2/N})S;$$

then (P) *has at least one solution $u \in \mathcal{D}^{1,2}(\mathbb{R}^N_+)$.*

Problem (P) has a variational structure, so although the lack of compactness (due to the unboundedness of $\mathbb{R}^N_+$ and the presence of the critical Sobolev exponent) gives rise to some difficulties, the investigation is carried out using variational methods. The solutions of (P) correspond to the positive functions that are critical points of the energy functional

$$\tag{1.3} E(u) = \int_{\mathbb{R}^N_+} (|\nabla u|^2 + a(x)u^2) dx$$

constrained on the manifold

$$\tag{1.4} V = \left\{ u \in H : \int_{\mathbb{R}^N_+} |u|^{2^*} dx = 1 \right\},$$

where H is either $W^{1,2}(\mathbb{R}^N_+)$ or $\mathcal{D}^{1,2}(\mathbb{R}^N_+)$ according to whether a_∞ is positive or equal to zero.

In both cases, (P) cannot be solved by minimization. In fact, we shall see in section 2 that E does not achieve its infimum Σ on V. Therefore, the study of the problem needs more subtle tools, such as minimax theory. Clearly, all of the solutions whose existence is stated in Theorems 1.1 and 1.2 correspond to positive functions for which $E(u) > \Sigma$. However, it is worth mentioning their different natures. Indeed, the proofs of these theorems will make clear that the energy of the "first" solution, v, found in the case $a_\infty > 0$, is very near to Σ and that this solution vanishes when

$a_\infty \to 0$. On the other hand, the solutions u are of high energy, namely, their energy is bounded from below by a number that is independent of a_∞ and strictly larger than Σ.

Finally, let us point out that an easy scale change shows that to any solution of (P) with $a(x) = a_\infty + \alpha(x)$ $(\alpha(x) = a(x) - a_\infty)$ there corresponds a solution of (P) with $a(x) = \lambda a_\infty + \lambda\alpha(\sqrt{\lambda}x)$ $\forall\lambda > 0$. Thus the condition on the size of $\lim_{|x|\to+\infty} a(x)$ that appears in Theorem 1.1 also can be expressed by saying that a_∞ can be arbitrarily large, provided that $a(x) - a_\infty$ is a function that is "concentrated" enough. Also, the claims of Theorems 1.1 and 1.2 hold when $\mathbb{R}^N_+$ in (P) is replaced by any half-space Π with the boundary condition $\partial u/\partial\nu = 0$, where ν is the outer normal to $\partial\Pi$.

This paper is organized as follows: In section 2, some useful facts are recalled, a nonexistence theorem is proven, the compactness question is discussed, and some basic estimates are stated. Section 3 contains the proofs of the theorems.

2. Preliminary remarks, some useful facts, and estimates. We begin by recalling some definitions and known facts.

S denotes the best Sobolev constant, i.e.,

$$S = \inf\left\{\int_{\mathbb{R}^N} |\nabla u|^2 dx : u \in \mathcal{D}^{1,2}(\mathbb{R}^N),\ |u|_{L^{2^*}(\mathbb{R}^N)} = 1\right\}. \tag{2.1}$$

S is achieved by the function

$$\Psi_{1,0}(x) = \bar{U}(x)/|\bar{U}|_{L^{2^*}(\mathbb{R}^N)}, \quad \text{where } \bar{U} = \frac{1}{[1+|x|^2]^{\frac{N-2}{2}}},$$

and all of the minimizers for S are the functions

$$\begin{gathered}\Psi_{\sigma,y} = \sigma^{-\frac{N-2}{4}}\Psi_{1,0}\left(\frac{x-y}{\sqrt{\sigma}}\right) = \frac{1}{|\bar{U}|_{L^{2^*}(\mathbb{R}^N)}}\frac{\sigma^{(N-2)/4}}{[\sigma+|x-y|^2]^{\frac{N-2}{2}}}, \\ \sigma \in R^+\backslash\{0\}, \qquad y \in \mathbb{R}^N,\end{gathered} \tag{2.2}$$

obtained from $\Psi_{1,0}$ by translation and rescaling.

We set

$$\Sigma = \inf\left\{\int_{\mathbb{R}^N_+} |\nabla u|^2 dx : u \in \mathcal{D}^{1,2}(\mathbb{R}^N_+),\ |u|_{L^{2^*}(\mathbb{R}^N_+)} = 1\right\}. \tag{2.3}$$

If we consider the definition and properties of S, it is not difficult to verify that

$$\Sigma = 2^{-2/N}S,$$

that Σ is achieved by the function defined $\forall x \in \mathbb{R}^N_+$ by

$$\tilde{\Psi}_{1,0}(x) = 2^{1/2^*}\Psi_{1,0}(x),$$

and that all of the minimizers for Σ are the functions $\tilde{\Psi}_{\sigma,y}$, $\sigma \in \mathbb{R}^+\backslash\{0\}$, $y \in \partial\mathbb{R}^N_+$, defined by

$$\tilde{\Psi}_{\sigma,y}(x) = \sigma^{-\frac{(N-2)}{4}}\tilde{\Psi}_{1,0}\left(\frac{x-y}{\sqrt{\sigma}}\right). \tag{2.4}$$

We remark that the infima in (2.1) and (2.3) do not change if we restrict our consideration to the functions u that belong to $W^{1,2}(\mathbb{R}^N)$ and $W^{1,2}(\mathbb{R}^N_+)$, respectively.

Let us prove now a nonexistence result.

Proposition 2.1. *Let a satisfy* (1.1). *Set*

$$\inf\{E(u):\ u \in V\} = \Sigma_a. \tag{2.5}$$

Then

$$\Sigma_a = \Sigma$$

and the minimization problem (2.5) *has no solution.*

Proof. Since $a(x) \geq 0$ in $\mathbb{R}^N_+$, obviously $\Sigma_a \geq \Sigma$. To show that the equality holds, let us consider the sequence

$$\Phi_{\frac{1}{n},0}(x) = \chi(|x|)\tilde{\Psi}_{\frac{1}{n},0}(x),$$

where $\chi \in \mathcal{C}^\infty([0,+\infty))$ is a nonincreasing real function such that $\chi(t) = 1$ if $t \in [0,1/2]$ and $\chi(t) = 0$ if $t \geq 1$. Well-known computations (see, for example, [BN]) give

$$\frac{\int_{\mathbb{R}^N_+}[|\nabla\Phi_{\frac{1}{n},0}(x)|^2 + a_\infty\Phi^2_{\frac{1}{n},0}(x)]dx}{|\Phi_{\frac{1}{n},0}(x)|^2_{L^{2^*}(\mathbb{R}^N_+)}} = \begin{cases} \Sigma + O\left(\frac{1}{n}\right), & N \geq 5, \\ \Sigma + O\left(\frac{1}{n}|\log\frac{1}{n}|\right), & N = 4, \\ \Sigma + O\left(1/\sqrt{n}\right), & N = 3. \end{cases} \tag{2.6}$$

On the other hand, setting $\alpha(x) = a(x) - a_\infty$ and $B_\rho(0) = \{x \in \mathbb{R}^N : |x| < \rho\}$, we have $\forall\rho > 0$

$$\begin{aligned}\int_{\mathbb{R}^N_+}\alpha(x)\Phi^2_{\frac{1}{n},0}(x)dx &= \int_{\mathbb{R}^N_+\cap B_\rho(0)}\alpha(x)\Phi^2_{\frac{1}{n},0}(x)dx + \int_{\mathbb{R}^N_+\setminus B_\rho(0)}\alpha(x)\Phi^2_{\frac{1}{n},0}(x)dx \\ &\leq |\Phi_{\frac{1}{n},0}(x)|^2_{L^{2^*}(\mathbb{R}^N_+)} \cdot \left[\int_{\mathbb{R}^N_+\cap B_\rho(0)}(\alpha(x))^{N/2}dx\right]^{2/N} \\ &\quad + |\alpha|_{L^{N/2}(\mathbb{R}^N_+)}\left[\int_{\mathbb{R}^N_+\setminus B_\rho(0)}\Phi^{2^*}_{\frac{1}{n},0}(x)dx\right]^{2/2^*},\end{aligned}$$

so

$$\begin{aligned}&\frac{\int_{\mathbb{R}^N_+}\alpha(x)\Phi^2_{\frac{1}{n},0}(x)dx}{|\Phi_{\frac{1}{n},0}|^2_{L^{2^*}(\mathbb{R}^N_+)}} \\ &\leq \left[\int_{\mathbb{R}^N_+\cap B_\rho(0)}(\alpha(x))^{N/2}dx\right]^{2/N} + \frac{|\alpha|_{L^{N/2}(\mathbb{R}^N_+)}\left[\int_{\mathbb{R}^N_+\setminus B_\rho(0)}\Phi^{2^*}_{\frac{1}{n},0}(x)dx\right]^{2/2^*}}{|\Phi_{\frac{1}{n},0}|^2_{L^{2^*}(\mathbb{R}^N_+)}}.\end{aligned}$$

Now

$$\lim_{n\to+\infty}\int_{\mathbb{R}^N_+\setminus B_\rho(0)}\Phi^{2^*}_{\frac{1}{n},0}(x)dx = 0$$

and

$$\lim_{n\to+\infty}|\Phi_{\frac{1}{n},0}|_{L^{2^*}(\mathbb{R}^N_+)} = 1.$$

Hence $\forall \rho > 0$,

$$\lim_{n\to+\infty} \frac{\int_{\mathbb{R}^N_+} \alpha(x)\Phi^2_{\frac{1}{n},0}(x)dx}{|\Phi_{\frac{1}{n},0}|^2_{L^{2^*}(\mathbb{R}^N_+)}} \leq \left[\int_{\mathbb{R}^N_+\cap B_\rho(0)} (\alpha(x))^{N/2}dx\right]^{2/N}.$$

Thus from $\alpha \in L^{N/2}(\mathbb{R}^N_+)$, we deduce

$$\lim_{\rho\to 0} \left[\int_{\mathbb{R}^N_+\cap B_\rho(0)} (\alpha(x))^{N/2}dx\right]^{2/N} = 0$$

and then

$$\lim_{n\to+\infty} \frac{\int_{\mathbb{R}^N_+} \alpha(x)\Phi^2_{\frac{1}{n},0}(x)dx}{|\Phi_{\frac{1}{n},0}|^2_{L^{2^*}(\mathbb{R}^N_+)}} = 0. \tag{2.7}$$

Therefore, equations (2.6) and (2.7) give $\lim_{n\to+\infty} E(\Phi_{1/n,0}(x)/|\Phi_{1/n,0}|_{L^{2^*}(\mathbb{R}^N_+)}) = \Sigma$, as desired. □

Let us now assume that the minimization problem (2.5) has a solution u and—without loss of generality—that $u \geq 0$. Let us denote by u^* and a^* the extensions by reflection to all of $\mathbb{R}^N$ of u and a, respectively. Then

$$\frac{\int_{\mathbb{R}^N}(|\nabla u^*|^2 + a^*(x)(u^*(x))^2)dx}{|u^*|^2_{L^{2^*}(\mathbb{R}^N)}} = S,$$

so we have

$$S \leq \frac{\int_{\mathbb{R}^N}|\nabla u^*|^2 dx}{|u^*|^2_{L^{2^*}(\mathbb{R}^N)}} \leq \frac{\int_{\mathbb{R}^N}(|\nabla u^*|^2 + a^*(x)(u^*(x))^2)dx}{|u^*|^2_{L^{2^*}(\mathbb{R}^N)}} = S.$$

The above relation implies that $\int_{\mathbb{R}^N} a^*(x)(u^*(x))^2dx = 0$ and $u^* = \Psi_{\sigma,y}$ for some $\sigma > 0$ and $y \in \mathbb{R}^N$. Thus, using the assumptions on a and the fact that $\Psi_{\sigma,y}(x) > 0$ $\forall x \in \mathbb{R}^N$, we deduce

$$0 = \int_{\mathbb{R}^N} a^*(x)(u^*(x))^2dx = \int_{\mathbb{R}^N} a^*(x)\Psi^2_{\sigma,y}(x)dx > 0,$$

which is impossible.

The following lemma states a lower bound for the energy of a sign-changing critical point u of E on V.

LEMMA 2.2 *Let a satisfy* (1.1). *Let u be a critical point of E on V. If $E(u) < S$, then the function u does not change sign.*

Proof. We argue by contradiction and assume that $u = u^+ + u^-$, $u^+ \neq 0$, and $u^- \neq 0$. By Proposition 2.1,

$$\Sigma|u^\pm|^2_{L^{2^*}(\mathbb{R}^N_+)} < \int_{\mathbb{R}^N_+}(|\nabla u^\pm|^2 + a(x)(u^\pm)^2)dx$$

and, since u is a critical point of E on V,

$$\int_{\mathbb{R}^N_+}[|\nabla u^\pm|^2 + a(x)(u^\pm)^2]dx = E(u)\int_{\mathbb{R}^N_+}|u^\pm|^{2^*}dx.$$

Then

$$|u^{\pm}|^{2^*}_{L^{2^*}(\mathbb{R}^N_+)} \geq \left(\frac{\Sigma}{E(u)}\right)^{N/2},$$

which, considering that $|u|_{L^{2^*}(\mathbb{R}^N_+)} = 1$, gives

$$E(u) \geq 2^{2/N}\Sigma = S,$$

which contradicts our assumption. □

The following proposition gives useful information about the compactness of E on V.

Proposition 2.3. *Let a satisfy* (1.1). *Then the pair* (E, V) *verifies the Palais–Smale condition in the energy range* (Σ, S), *i.e., any sequence* $\{u_n\}$ *such that*

$$\begin{cases} u_n \in V, \quad \operatorname{grad} E|_V(u_n) \to 0 \qquad \textit{in } H^*, \\ \lim\limits_{n\to+\infty} E(u_n) = c \in (\Sigma, S) \end{cases} \tag{2.8}$$

is relatively compact.

Proof. Let u_n be a sequence of functions that satisfy (2.8). Let us denote by u_n^* and a^* the functions obtained by u_n and a extending to all of $\mathbb{R}^N$ by reflection, respectively. Then we have $u_n^* \in W^{1,2}(\mathbb{R}^N)$ if $a_\infty > 0$, $u_n^* \in \mathcal{D}^{1,2}(\mathbb{R}^N)$ if $a_\infty = 0$, and

$$\left|\frac{u_n^*}{2^{1/2^*}}\right|_{L^{2^*}(\mathbb{R}^N)} = 1, \qquad \frac{1}{2^{2/2^*}}\int_{\mathbb{R}^N}[|\nabla u_n^*|^2 + a^*(x)(u_n^*(x))^2]dx \to 2^{2/N}c,$$

$$\int_{\mathbb{R}^N}[(\nabla u_n^*|\nabla v) + a^*(x)u_n^*v]dx + (2^{2/N}c + o(1))\int_{\mathbb{R}^N}|u_n^*|^{2^*-2}u_n^*v\,dx = o(1)$$

$\forall v \in W^{1,2}(\mathbb{R}^N)$ (respectively, $v \in \mathcal{D}^{1,2}(\mathbb{R}^N)$ if $a_\infty = 0$).

Since $2^{2/N}c \in (S, 2^{2/N}S)$, by Theorem 2.5 and Corollary 2.10 of [BC] and Lemma 1.9 of [P], u_n^* is relatively compact, i.e., converges strongly, up to a subsequence, to a function u^* that verifies $u^*(x_1, x_2, \dots, x_N) = u^*(x_1, x_2, \dots, -x_N)$, and this yields the desired result. □

Let us denote by π the projection on $\partial\mathbb{R}^N_+$, i.e.,

$$\pi : \mathbb{R}^N \to \partial\mathbb{R}^N_+, \quad \pi(x_1, x_2, \dots, x_N) = (x_1, x_2, \dots, x_{N-1}, 0),$$

and $\forall\rho > 0$, set

$$\Lambda_\rho(y) = \{x \in \mathbb{R}^N_+ : |\pi(x) - \pi(y)| < \rho\}.$$

Let us define the maps $\beta : H \to \partial\mathbb{R}^N_+$ and $\gamma : H \to \mathbb{R}$ by

$$\beta(u) = \int_{\mathbb{R}^N_+}\frac{\pi(x)}{1 + |\pi(x)|}|u(x)|^{2^*}dx \Big/ |u|^{2^*}_{L^{2^*}(\mathbb{R}^N_+)},$$

$$\gamma(u) = \int_{\mathbb{R}^N_+}\left|\frac{\pi(x)}{1 + |\pi(x)|} - \beta(u)\right||u(x)|^{2^*}dx \Big/ |u|^{2^*}_{L^{2^*}(\mathbb{R}^N_+)}.$$

The following two propositions provide useful estimates.

PROPOSITION 2.4. *Let $\alpha(x) \in L^{N/2}(\mathbb{R}^N_+)$ be a nonegative function such that $|\alpha|_{L^{N/2}(\mathbb{R}^N_+)} \neq 0$. Then*

$$\inf\left\{ \int_{\mathbb{R}^N_+} [|\nabla u|^2 + \alpha(x)u^2]dx : u \in \mathcal{D}^{1,2}(\mathbb{R}^N_+),\ |u|_{L^{2^*}(\mathbb{R}^N_+)} = 1, \right.$$
$$\left. \beta(u) = 0,\ \gamma(u) = \frac{1}{3} \right\} > \Sigma. \tag{2.9}$$

Proof. Clearly,

$$\inf\left\{ \int_{\mathbb{R}^N_+} [|\nabla u|^2 + \alpha(x)u^2]dx : u \in \mathcal{D}^{1,2}(\mathbb{R}^N_+),\ |u|_{L^{2^*}(\mathbb{R}^N_+)} = 1, \right.$$
$$\left. \beta(u) = 0,\ \gamma(u) = \frac{1}{3} \right\} \geq \Sigma.$$

To prove (2.9), we argue by contradiction and suppose that equality holds in the above relation. Thus we can find a sequence $\{u_n\}$ such that $u_n \in \mathcal{D}^{1,2}(\mathbb{R}^N_+)$ and

$$\begin{cases} \text{(a)} \quad |u_n|_{L^{2^*}(\mathbb{R}^N_+)} = 1, \qquad \beta(u_n) = 0, \qquad \gamma(u_n) = \frac{1}{3}, \\ \text{(b)} \quad \lim_{n\to+\infty} \int_{\mathbb{R}^N_+} [|\nabla u_n|^2 + \alpha(x)u_n^2)]dx = \Sigma. \end{cases} \tag{2.10}$$

Therefore, since $\alpha(x) \geq 0$, from

$$\Sigma = \lim_{n\to+\infty} \int_{\mathbb{R}^N_+} [|\nabla u_n|^2 + \alpha(x)u_n^2)]dx \geq \lim_{n\to+\infty} \int_{\mathbb{R}^N_+} |\nabla u_n|^2 dx \geq \Sigma,$$

we obtain $\lim_{n\to+\infty} \int_{\mathbb{R}^N_+} |\nabla u_n|^2 dx = \Sigma$.

Hence by the uniqueness of the family of functions $\tilde{\Psi}_{\sigma,y}$ (defined in (2.4)) that realize Σ, we deduce that

$$u_n(x) = \tilde{\Psi}_{\sigma_n,y_n}(x) + w_n(x) \quad \forall x \in \mathbb{R}^N_+,$$

where $\sigma_n \in \mathbb{R}^+\backslash\{0\}$, $y_n \in \partial\mathbb{R}^N_+$, and $\{w_n\}$ is a sequence that goes strongly to zero in $\mathcal{D}^{1,2}(\mathbb{R}^N_+)$ and $L^{2^*}(\mathbb{R}^N_+)$.

We claim that, up to subsequences,

$$\text{(a)} \quad \lim_{n\to+\infty} \sigma_n = \bar{\sigma} > 0, \qquad \text{(b)} \quad \lim_{n\to+\infty} y_n = \bar{y} \in \partial\mathbb{R}^N_+. \tag{2.11}$$

Indeed, once (2.11) is shown to be true, the proof can be achieved quickly. In fact, it suffices to observe that in this case $\tilde{\Psi}_{\sigma_n,y_n} \to \tilde{\Psi}_{\bar{\sigma},\bar{y}}$ strongly in $\mathcal{D}^{1,2}(\mathbb{R}^N_+)$ and $L^{2^*}(\mathbb{R}^N_+)$, so from (2.10)(b) it follows that

$$\Sigma = \lim_{n\to+\infty} \int_{\mathbb{R}^N_+} [|\nabla u_n|^2 + \alpha(x)u_n^2)]dx = \lim_{n\to+\infty} \int_{\mathbb{R}^N_+} [|\nabla \tilde{\Psi}_{\sigma_n,y_n}(x)|^2 + \alpha(x)\tilde{\Psi}^2_{\sigma_n,y_n}(x)]dx$$
$$= \int_{\mathbb{R}^N_+} [|\nabla \tilde{\Psi}_{\bar{\sigma},\bar{y}}|^2 + \alpha(x)\tilde{\Psi}^2_{\bar{\sigma},\bar{y}}(x)]dx = \Sigma + \int_{\mathbb{R}^N_+} \alpha(x)\tilde{\Psi}^2_{\bar{\sigma},\bar{y}}(x)dx,$$

which, because of the assumptions on α and the positivity of $\tilde{\Psi}_{\bar{\sigma},\bar{y}}$, is impossible.

Let us now prove the claim in (2.11). To prove (2.11)(a), let us first show that $\{\sigma_n\}$ is bounded. In fact, if for some subsequence (still denoted by σ_n) $\lim_{n\to+\infty}\sigma_n = +\infty$ occurs, then $\forall\rho > 0$,

$$\begin{aligned}\lim_{n\to+\infty}\int_{\Lambda_\rho(0)} |u_n|^{2^*}dx &= \lim_{n\to+\infty}\int_{\Lambda_\rho(0)} \left|\tilde{\Psi}_{\sigma_n,y_n}(x)\right|^{2^*} dx\\ &= \lim_{n\to+\infty}\int_{\Lambda_{\frac{\rho}{\sigma_n}}(0)} \left|\tilde{\Psi}_{1,0}\left(x-\frac{y_n}{\sigma_n}\right)\right|^{2^*} dx = 0.\end{aligned}$$

Then if we consider that $\beta(u_n) = 0$, we have $\forall\rho > 0$

$$\begin{aligned}\gamma(u_n) = \int_{\mathbb{R}^N_+}\frac{|\pi(x)|}{1+|\pi(x)|}|u_n(x)|^{2^*}dx &\geq \int_{\mathbb{R}^N_+\setminus\Lambda_\rho(0)}\frac{|\pi(x)|}{1+|\pi(x)|}|u_n(x)|^{2^*}dx\\ \geq \frac{\rho}{1+\rho}\int_{\mathbb{R}^N_+\setminus\Lambda_\rho(0)}|u_n(x)|^{2^*}dx,\end{aligned}$$

so

$$\liminf_{n\to+\infty}\gamma(u_n) \geq \rho/(1+\rho) \quad \forall\rho > 0,$$

which implies

$$\lim_{n\to+\infty}\gamma(u_n) = 1,$$

which contradicts (2.10)(a).

Thus up to a subsequence, $\lim_{n\to+\infty}\sigma_n = \bar{\sigma}\in\mathbb{R}^+$. If $\bar{\sigma} = 0$ occurs, then $\forall\rho > 0$,

$$\begin{aligned}\lim_{n\to+\infty}\int_{\mathbb{R}^N_+\setminus\Lambda_\rho(y_n)} |u_n|^{2^*}dx &= \lim_{n\to+\infty}\int_{\mathbb{R}^N_+\setminus\Lambda_\rho(y_n)} \left|\tilde{\Psi}_{\sigma_n,y_n}(x)\right|^{2^*} dx\\ &= \lim_{n\to+\infty}\int_{\mathbb{R}^N_+\setminus\Lambda_{\frac{\rho}{\sigma_n}}(\frac{y_n}{\sigma_n})} \left|\tilde{\Psi}_{1,0}\left(x-\frac{y_n}{\sigma_n}\right)\right|^{2^*} dx = 0.\end{aligned}$$

Hence $\forall\rho > 0$,

$$\begin{aligned}\frac{|y_n|}{1+|y_n|} &= \left|\int_{\mathbb{R}^N_+}\left(\frac{y_n}{1+|y_n|}-\frac{\pi}{1+|\pi(x)|}\right)|u_n(x)|^{2^*}dx\right|\\ &\leq \int_{\mathbb{R}^N_+\setminus\Lambda_\rho(y_n)}\left|\frac{y_n}{1+|y_n|}-\frac{\pi}{1+|\pi(x)|}\right||u_n(x)|^{2^*}dx\\ &\quad + \int_{\Lambda_\rho(y_n)}\left|\frac{y_n}{1+|y_n|}-\frac{\pi}{1+|\pi(x)|}\right||u_n(x)|^{2^*}dx \leq \rho + o(1),\end{aligned}$$

which implies $|y_n|\to 0$ as $n\to+\infty$. Now we obtain

$$\begin{aligned}\lim_{n\to+\infty}\gamma(u_n) &= \lim_{n\to+\infty}\int_{\mathbb{R}^N_+}\left|\frac{\pi(x)}{1+|\pi(x)|}-\beta(u_n)\right||u_n(x)|^{2^*}dx\\ &= \lim_{n\to+\infty}\int_{\mathbb{R}^N_+}\left|\frac{\pi(x)}{1+|\pi(x)|}-\frac{y_n}{1+|y_n|}\right||u_n(x)|^{2^*}dx = 0,\end{aligned}$$

which contradicts (2.10)(a). Thus the first part of the claim is proved.

Let us now show that $\{|y_n|\}$ is bounded. We argue by contradiction and suppose that a subsequence $\{y_m\}$ exists for which $\lim_{m\to+\infty}|y_m| = +\infty$. Then $\forall\epsilon > 0$ and $\forall R > 0$, $\exists\bar{m}$ such that $\forall m > \bar{m}$,

$$|\pi(x) - y_m| < R \quad \Rightarrow \quad \left|\frac{\pi(x)}{1+|\pi(x)|} - \frac{y_m}{1+|y_m|}\right| < \epsilon.$$

On the other hand, $\forall\epsilon > 0$, $\exists\bar{R} > 0$ such that $\forall R > \bar{R}$,

$$\int_{\mathbb{R}^N_+\setminus\Lambda_R(y_m)} |\tilde{\Psi}_{\bar{\sigma},y_m}(x)|^{2^*}dx = \int_{\mathbb{R}^N_+\setminus\Lambda_R(0)} |\tilde{\Psi}_{\bar{\sigma},0}(x)|^{2^*}dx < \epsilon. \tag{2.12}$$

Then chose $\epsilon > 0$ arbitrarily and fix $R > 0$ so that (2.12) is verified; if m is large enough, we get

$$\begin{aligned}\left|\beta(u_m) - \frac{y_m}{1+|y_m|}\right| &\le \int_{\mathbb{R}^N_+}\left|\frac{\pi(x)}{1+|\pi(x)|} - \frac{y_m}{1+|y_m|}\right| |u_m(x)|^{2^*}dx \\ &\le \int_{\mathbb{R}^N_+\setminus\Lambda_R(y_m)}\left|\frac{\pi(x)}{1+|\pi(x)|} - \frac{y_m}{1+|y_m|}\right| |\tilde{\Psi}_{\bar{\sigma},y_m}(x)|^{2^*}dx \\ &\quad + \int_{\Lambda_R(y_m)}\left|\frac{\pi(x)}{1+|\pi(x)|} - \frac{y_m}{1+|y_m|}\right| |\tilde{\Psi}_{\bar{\sigma},y_m}(x)|^{2^*}dx + o(1) \le 3\epsilon + o(1).\end{aligned}$$

Thus $|\beta(u_m)| \to 1$ as $m \to +\infty$, which again contradicts (2.10). Thus (2.11)(b) is also true, as desired. □

PROPOSITION 2.5 *Let $k > 0$, $k \in \mathbb{R}$. Then*

$$\inf\left\{\int_{\mathbb{R}^N_+}[|\nabla u|^2 + ku^2]dx : u \in W^{1,2}(\mathbb{R}^N_+),\ |u|_{L^{2^*}(\mathbb{R}^N_+)} = 1,\right.$$
$$\left.\beta(u) = 0,\ \gamma(u) \ge \frac{1}{3}\right\} > \Sigma. \tag{2.13}$$

Proof. Clearly,

$$\inf\left\{\int_{\mathbb{R}^N_+}[|\nabla u|^2 + ku^2]dx : u \in W^{1,2}(\mathbb{R}^N_+),\ |u|_{L^{2^*}(\mathbb{R}^N_+)} = 1,\ \beta(u) = 0,\ \gamma(u) \ge \frac{1}{3}\right\} \ge \Sigma.$$

Then to prove the proposition, it is sufficient to show that in the above relation the equality cannot be true. We argue by contradiction, so we suppose that there exists a sequence $\{u_n\}$, $u_n \in W^{1,2}(\mathbb{R}^N_+)$, such that

$$\begin{cases} \text{(a)} & |u_n|_{L^{2^*}(\mathbb{R}^N_+)} = 1, \qquad \beta(u_n) = 0, \qquad \gamma(u_n) \ge \frac{1}{3}, \\ \text{(b)} & \lim\limits_{n\to+\infty}\int_{\mathbb{R}^N_+}[|\nabla u_n|^2 + ku_n^2]dx = \Sigma. \end{cases} \tag{2.14}$$

Since $k > 0$, from

$$\Sigma = \lim_{n\to+\infty}\int_{\mathbb{R}^N_+}[|\nabla u_n|^2 + ku_n^2]dx \ge \lim_{n\to+\infty}\int_{\mathbb{R}^N_+}|\nabla u_n|^2dx \ge \Sigma,$$

we deduce $\lim_{n\to+\infty}\int_{\mathbb{R}^N_+}|\nabla u_n|^2dx=\Sigma$.

Hence by the uniqueness of the family of functions $\tilde{\Psi}_{\sigma,y}$ (defined in (2.4)) that realize Σ, we deduce that

$$u_n(x)=\tilde{\Psi}_{\sigma_n,y_n}(x)+w_n(x)\quad\forall x\in\mathbb{R}^N_+,$$

where $\sigma_n\in\mathbb{R}^+\backslash\{0\}$, $y_n\in\partial\mathbb{R}^N_+$, and $\{w_n\}$ is a sequence that goes strongly to zero in $W^{1,2}(\mathbb{R}^N_+)$ and $L^{2^*}(\mathbb{R}^N_+)$.

As in the proof of Proposition 2.4, we need to show that (up to subsequences)

$$\text{(2.15)}\qquad \text{(a)}\quad \lim_{n\to+\infty}\sigma_n=\bar{\sigma}>0,\ \bar{\sigma}\in\mathbb{R},\qquad \text{(b)}\quad \lim_{n\to+\infty}y_n=\bar{y}\in\partial\mathbb{R}^N_+.$$

In fact, if the relations in (2.15) hold, the proof can be concluded easily by observing that $\tilde{\Psi}_{\sigma_n,y_n}\to\tilde{\Psi}_{\bar{\sigma},\bar{y}}$ strongly in $W^{1,2}(\mathbb{R}^N_+)$ and $L^{2^*}(\mathbb{R}^N_+)$, which together with (2.14)(b) allows us to obtain the following impossible relation:

$$\begin{aligned}\Sigma&=\lim_{n\to+\infty}\int_{\mathbb{R}^N_+}[|\nabla u_n|^2+ku_n^2]dx=\lim_{n\to+\infty}\int_{\mathbb{R}^N_+}[|\nabla\tilde{\Psi}_{\sigma_n,y_n}|^2+k\tilde{\Psi}^2_{\sigma_n,y_n}]dx\\&=\int_{\mathbb{R}^N_+}[|\nabla\tilde{\Psi}_{\bar{\sigma},\bar{y}}(x)|^2+k\tilde{\Psi}^2_{\bar{\sigma},\bar{y}}(x)]dx>\int_{\mathbb{R}^N_+}|\nabla\tilde{\Psi}_{\bar{\sigma},\bar{y}}(x)|^2dx=\Sigma.\end{aligned}$$

To verify (2.15)(a), we first observe that σ_n must be bounded. In fact, if there were a subsequence (still denoted by σ_n) for which $\lim_{n\to+\infty}\sigma_n=+\infty$, we would obtain

$$\begin{aligned}\Sigma&=\lim_{n\to+\infty}\int_{\mathbb{R}^N_+}[|\nabla u_n|^2+ku_n^2]dx\geq\lim_{n\to+\infty}\left[\int_{\mathbb{R}^N_+}|\nabla\tilde{\Psi}_{\sigma_n,y_n}|^2+k\int_{B_{\sqrt{\sigma_n}(y_n)}}\tilde{\Psi}^2_{\sigma_n,y_n}(x)dx\right]\\&=\lim_{n\to+\infty}\left[\int_{\mathbb{R}^N_+}|\nabla\tilde{\Psi}_{1,0}(x)|^2dx+k\sigma_n\int_{B_1(0)}\tilde{\Psi}^2_{1,0}(x)dx\right]=+\infty.\end{aligned}$$

Then up to a subsequence, $\lim_{n\to+\infty}\sigma_n=\bar{\sigma}\in\mathbb{R}^+$ and $\bar{\sigma}>0$ can be deduced by arguing as in the proof of Proposition 2.4. Analogously, relation (2.15)(b) can be verified by following the argument used in the proof of Proposition 2.4 to prove (2.11)(b). □

3. Proof of the results. In what follows, we suppose that $a(x)$ verifies (1.1), and we use the following notations:

$$c_a=\inf\left\{\int_{\mathbb{R}^N_+}[|\nabla u|^2+a(x)u^2]dx : u\in V,\quad\beta(u)=0,\quad\gamma(u)=\frac{1}{3}\right\}$$

$$c_\infty=\inf\left\{\int_{\mathbb{R}^N_+}[|\nabla u|^2+a_\infty u^2]dx : u\in V,\quad\beta(u)=0,\quad\gamma(u)\geq\frac{1}{3}\right\}$$

$$\begin{aligned}c_{a-a_\infty}=\inf\bigg\{&\int_{\mathbb{R}^N_+}[|\nabla u|^2+(a(x)-a_\infty)u^2]dx : u\in\mathcal{D}^{1,2}(\mathbb{R}^N_+),\\&|u|_{L^{2^*}(\mathbb{R}^N_+)}=1,\quad\beta(u)=0,\quad\gamma(u)=\frac{1}{3}\bigg\}.\end{aligned}$$

By virtue of (1.1) and Propositions 2.4 and 2.5, we have

$$\text{(3.1)}\qquad \begin{cases}\text{(i)}\quad a_\infty=0\ \Rightarrow\ c_{a-a_\infty}=c_a>\Sigma,\quad c_\infty=\Sigma,\\ \text{(ii)}\quad a_\infty>0\ \Rightarrow\ c_a\geq c_{a-a_\infty}>\Sigma,\quad c_\infty>\Sigma.\end{cases}$$

We set

$$\bar{c} = \min\left\{\frac{c_{a-a_\infty} + \Sigma}{2}, \ \frac{\Sigma + S}{2}\right\} \tag{3.2}$$

and remark that

$$\Sigma < \bar{c} < S.$$

We denote by $\varphi(x)$ a function that belongs to $W_0^{1,2}(B_1(0))$ and has the following properties:

$$\begin{cases} \varphi \in \mathcal{C}_0^\infty(B_1(0)), \quad \varphi(x) > 0 \quad \forall x \in B_1(0), \\ \varphi \text{ is radially symmetric} \quad \text{and} \quad |x_1| < |x_2| \Rightarrow \varphi(x_1) > \varphi(x_2), \\ |\varphi|_{L^{2^*}(\mathbb{R}^N_+ \cap B_1(0))} = 1, \\ \Sigma < \int_{\mathbb{R}^N_+ \cap B_1(0)} |\nabla\varphi|^2 dx \equiv \bar{\Sigma} < \bar{c}. \end{cases} \tag{3.3}$$

The existence of such a φ follows from the properties of Σ and from (3.2). Moreover, if $a(x)$ satisfies (1.2), φ is supposed to have been chosen in such a way that the condition

$$\bar{\Sigma} < S - |a(x) - a_\infty|_{L^{N/2}(\mathbb{R}^N_+)} \tag{3.4}$$

is also fulfilled.

For every $\sigma > 0$ and $y \in \mathbb{R}^N$, we set

$$\varphi_{\sigma,y}(x) = \begin{cases} \sigma^{-(N-2)/4}\varphi\left(\frac{x-y}{\sqrt{\sigma}}\right), & x \in B_\sigma(y), \\ 0, & x \notin B_\sigma(y), \end{cases}$$

and we remark that

$$|\varphi_{\sigma,y}|_{L^{2^*}(\mathbb{R}^N)} = |\varphi_{\sigma,y}|_{L^{2^*}(B_\sigma(y))} = |\varphi|_{L^{2^*}(B_1(0))}.$$

Lemma 3.1. *Let $\alpha(x) \in L^{N/2}(\mathbb{R}^N_+)$ be a nonnegative function. Then the following relations hold:*

$$\begin{cases} \text{(a)} \quad \lim_{\sigma\to 0} \sup\left\{\int_{\mathbb{R}^N_+} \alpha(x)\varphi^2_{\sigma,y}(x)dx : y \in \partial\mathbb{R}^N_+\right\} = 0 \\ \text{(b)} \quad \lim_{\sigma\to +\infty} \sup\left\{\int_{\mathbb{R}^N_+} \alpha(x)\varphi^2_{\sigma,y}(x)dx : y \in \partial\mathbb{R}^N_+\right\} = 0 \\ \text{(c)} \quad \lim_{r\to +\infty} \sup\left\{\int_{\mathbb{R}^N_+} \alpha(x)\varphi^2_{\sigma,y}(x)dx : |y| = r, \quad \sigma > 0, \quad y \in \partial\mathbb{R}^N_+\right\} = 0. \end{cases} \tag{3.5}$$

Proof. Let $y \in \partial\mathbb{R}^N_+$ be chosen arbitrarily. Then $\forall\sigma > 0$,

$$\begin{aligned} \int_{\mathbb{R}^N_+} \alpha(x)\varphi^2_{\sigma,y}(x)dx &= \int_{\mathbb{R}^N_+ \cap B_\sigma(y)} \alpha(x)\varphi^2_{\sigma,y}(x)dx \\ &\le |\alpha|_{L^{N/2}(\mathbb{R}^N_+ \cap B_\sigma(y))}|\varphi_{\sigma,y}|^2_{L^{2^*}(\mathbb{R}^N_+ \cap B_\sigma(y))} = |\alpha|_{L^{N/2}(B_\sigma(y)\cap\mathbb{R}^N_+)}, \end{aligned}$$

so

$$\sup\left\{\int_{\mathbb{R}^N_+} \alpha(x)\varphi^2_{\sigma,y}(x)dx : y \in \partial\mathbb{R}^N_+\right\} \le \sup\left\{|\alpha|_{L^{N/2}(B_\sigma(y)\cap\mathbb{R}^N_+)} : y \in \partial\mathbb{R}^N_+\right\}. \tag{3.6}$$

On the other hand, $\forall y \in \mathbb{R}^N$, $\lim_{\sigma\to 0} |\alpha|_{L^{N/2}(\mathbb{R}^N_+ \cap B_\sigma(y))} = 0$, so (3.5)(a) follows from (3.6).

To prove (3.5)(b) let us fix $y \in \partial\mathbb{R}^N_+$ arbitrarily. Then $\forall \rho > 0$, $\forall \sigma > 0$,

$$\begin{aligned}\int_{\mathbb{R}^N_+} & \alpha(x)\varphi^2_{\sigma,y}(x)dx \\ &= \int_{\mathbb{R}^N_+\cap B_\rho(0)} \alpha(x)\varphi^2_{\sigma,y}dx + \int_{\mathbb{R}^N_+\setminus B_\rho(0)} \alpha(x)\varphi^2_{\sigma,y}(x)dx \\ &\leq |\alpha|_{L^{N/2}(B_\rho(0)\cap\mathbb{R}^N_+)}|\varphi_{\sigma,y}|^2_{L^{2^*}(B_\rho(0))} + |\alpha|_{L^{N/2}(\mathbb{R}^N_+\setminus B_\rho(0))}|\varphi_{\sigma,y}|^2_{L^{2^*}(\mathbb{R}^N_+\setminus B_\rho(0))} \\ &\leq |\alpha|_{L^{N/2}(\mathbb{R}^N_+\cap B_\rho(0))} \sup_{y\in\partial\mathbb{R}^N_+} |\varphi_{\sigma,y}|^2_{L^{2^*}(B_\rho(0))} + |\alpha|_{L^{N/2}(\mathbb{R}^N_+\setminus B_\rho(0))}.\end{aligned}$$

Moreover, $\forall y \in \mathbb{R}^N$, $\lim_{\sigma\to+\infty} |\varphi_{\sigma,y}|_{L^{2^*}(B_\rho(0))} = 0$, so we get

$$\lim_{\sigma\to+\infty} \sup\left\{\int_{\mathbb{R}^N_+} \alpha(x)\varphi^2_{\sigma,y}(x)dx : \ y \in \partial\mathbb{R}^N_+\right\} \leq |\alpha|_{L^{N/2}(\mathbb{R}^N_+\setminus B_\rho(0))},$$

and, letting $\rho \to \infty$, (3.5)(b) follows.

To verify (3.5)(c), we argue by contradiction, so we assume that there exist a sequence $\{y_n\}$, $y_n \in \partial\mathbb{R}^N_+$, and a sequence σ_n of positive numbers such that

$$\lim_{n\to+\infty} \int_{\mathbb{R}^N_+} \alpha(x)\varphi^2_{\sigma_n,y_n}(x)dx > 0 \quad \text{and} \quad |y_n| \to +\infty. \tag{3.7}$$

Because (3.5)(a)–(b) pass eventually to a subsequence, we can suppose that $\lim_{n\to+\infty} \sigma_n = \bar{\sigma}$. Then $|y_n| \to +\infty$ and $\alpha \in L^{N/2}(\mathbb{R}^N_+)$ imply $\lim_{n\to+\infty} |\alpha|_{L^{N/2}(\mathbb{R}^N_+\cap B_{\sigma_n}(y_n))} = 0$, from which we deduce

$$\lim_{n\to+\infty} \int_{\mathbb{R}^N_+} \alpha(x)\varphi^2_{\sigma_n,y_n}(x)dx \leq \lim_{n\to+\infty} \left[|\alpha|_{L^{N/2}(\mathbb{R}^N_+\cap B_{\sigma_n}(y_n))}|\varphi_{\sigma_n,y_n}|^2_{L^{2^*}(B_{\sigma_n}(y_n))}\right] = 0,$$

which contradicts (3.7). □

Lemma 3.2. *The following relations hold:*

$$\begin{cases} \text{(a)} \quad \lim_{\sigma\to 0} \sup\{\gamma(\varphi_{\sigma,y}) : y \in \partial\mathbb{R}^N_+\} = 0, \\ \text{(b)} \quad \lim_{\sigma+\infty} \inf\{\gamma(\varphi_{\sigma,y}) : y \in \partial\mathbb{R}^N_+, |y| \leq r\} = 1 \quad \forall r > 0, \\ \text{(c)} \quad (\beta(\varphi_{\sigma,y})|y)_{\mathbb{R}^N} > 0, \quad \forall y \in \partial\mathbb{R}^N_+\setminus\{0\}, \quad \forall \sigma > 0. \end{cases} \tag{3.8}$$

Proof. Let $y \in \partial\mathbb{R}^N_+$ be chosen arbitrarily. For any $\sigma > 0$, we have

$$\begin{aligned}
0 \le \gamma(\varphi_{\sigma,y}) &= \int_{\mathbb{R}^N_+} \left| \frac{\pi(x)}{1+|\pi(x)|} - \beta(\varphi_{\sigma,y}) \right| |\varphi_{\sigma,y}(x)|^{2^*} dx \\
&\le \int_{\mathbb{R}^N_+ \cap B_\sigma(y)} \left| \frac{\pi(x)}{1+|\pi(x)|} - \frac{y}{1+|y|} \right| |\varphi_{\sigma,y}(x)|^{2^*} dx + \left| \frac{y}{1+|y|} - \beta(\varphi_{\sigma,y}) \right| \\
&\le \int_{\mathbb{R}^N_+ \cap B_\sigma(y)} |\pi(x) - y| \, |\varphi_{\sigma,y}(x)|^{2^*} dx \\
&\quad + \left| \int_{\mathbb{R}^N_+} \left(\frac{y}{1+|y|} - \frac{\pi(x)}{1+|\pi(x)|} \right) |\varphi_{\sigma,y}(x)|^{2^*} dx \right| \\
&\le \sigma + \int_{\mathbb{R}^N_+} \left| \frac{y}{1+|y|} - \frac{\pi(x)}{1+|\pi(x)|} \right| |\varphi_{\sigma,y}(x)|^{2^*} dx \le 2\sigma.
\end{aligned}$$

Hence $0 \le \sup\{\gamma(\varphi_{\sigma,y}) : y \in \partial\mathbb{R}^N_+\} \le 2\sigma$, which letting $\sigma \to 0$, yields (3.8)(a).

In order to prove (3.8)(b), let us first show that $\forall y \in \partial\mathbb{R}^N_+$,

$$\lim_{\sigma \to +\infty} |\beta(\varphi_{\sigma,y})| = 0. \tag{3.9}$$

Since $\beta(\varphi_{\sigma,0}) = 0$ because of symmetry, we have

$$\begin{aligned}
|\beta(\varphi_{\sigma,y})| &= |\beta(\varphi_{\sigma,y}) - \beta(\varphi_{\sigma,0})| \\
&= \left| \int_{\mathbb{R}^N_+} \frac{\pi(x)}{1+|\pi(x)|} (\varphi^{2^*}_{\sigma,y}(x) - \varphi^{2^*}_{\sigma,0}(x)) dx \right| \\
&\le \int_{\mathbb{R}^N_+} \frac{|\pi(x)|}{1+|\pi(x)|} |\varphi^{2^*}_{\sigma,y}(x) - \varphi^{2^*}_{\sigma,0}(x)| dx \le \int_{\mathbb{R}^N_+} |\varphi^{2^*}_{1,\frac{y}{\sigma}}(x) - \varphi^{2^*}_{1,0}(x)| dx = O\left(\frac{1}{\sigma}\right),
\end{aligned}$$

which gives (3.9). Now fix $r > 0$ arbitrarily and let $y \in \partial\mathbb{R}^N_+$ so that $|y| \le r$. For any $\sigma > 0$, we have

$$\begin{aligned}
\gamma(\varphi_{\sigma,y}) &= \int_{\mathbb{R}^N_+} \left| \frac{\pi(x)}{1+|\pi(x)|} - \beta(\varphi_{\sigma,y}) \right| |\varphi_{\sigma,y}(x)|^{2^*} dx \\
&\le \int_{\mathbb{R}^N_+} \frac{\pi(x)}{1+|\pi(x)|} |\varphi_{\sigma,y}(x)|^{2^*} dx + |\beta(\varphi_{\sigma,y})| \le 1 + |\beta(\varphi_{\sigma,y})|,
\end{aligned}$$

from which, using (3.9), we deduce

$$\limsup_{\sigma \to +\infty} \inf\{\gamma(\varphi_{\sigma,y}) : y \in \partial\mathbb{R}^N_+, \ |y| \le r\} \le 1. \tag{3.10}$$

Now if

$$\liminf_{\sigma \to +\infty} \inf\{\gamma(\varphi_{\sigma,y}) : y \in \partial\mathbb{R}^N_+, \ |y| \le r\} < 1$$

holds, there exist a sequence of positive numbers $\{\sigma_n\}$ and a sequence of points $\{y_n\}$, $y_n \in \partial\mathbb{R}^N_+$, such that

$$\lim_{n \to +\infty} \gamma(\varphi_{\sigma_n,y_n}) < 1, \quad \sigma_n \xrightarrow[n \to +\infty]{} +\infty, \quad |y_n| \le r. \tag{3.11}$$

On the other hand, considering (3.9), we deduce $\forall\rho > 0$ that

$$\begin{aligned}\gamma(\varphi_{\sigma_n,y_n}) &= \int_{\mathbb{R}^N_+} \left|\frac{\pi(x)}{1+|\pi(x)|} - \beta(\varphi_{\sigma_n,y_n})\right| |\varphi_{\sigma_n,y_n}(x)|^{2^*} dx \\ &\geq \int_{\mathbb{R}^N_+} \frac{|\pi(x)|}{1+|\pi(x)|} |\varphi_{\sigma_n,y_n}(x)|^{2^*} dx - |\beta(\varphi_{\sigma_n,y_n})| \\ &\geq \int_{\mathbb{R}^N_+\setminus\Lambda_\rho(0)} \frac{|\pi(x)|}{1+|\pi(x)|} |\varphi_{\sigma_n,y_n}(x)|^{2^*} dx - o(1) \\ &\geq \frac{\rho}{(1+\rho)} \int_{\mathbb{R}^N_+\setminus\Lambda_\rho(0)} |\varphi_{\sigma_n,y_n}(x)|^{2^*} dx - o(1) \\ &\geq \frac{\rho}{(1+\rho)} \int_{\mathbb{R}^N_+\setminus\Lambda_{\frac{\rho}{\sigma_n}}(0)} |\varphi_{\sigma_n,y_n}(x)|^{2^*} dx - o(1),\end{aligned}$$

which implies that $\lim_{n\to+\infty}\gamma(\varphi_{\sigma_n,y_n}) \geq \rho/(1+\rho)$ $\forall\rho > 0$, and then

$$\lim_{n\to+\infty}\gamma(\varphi_{\sigma_n,y_n}) \geq 1,$$

which contradicts (3.11). Thus in (3.10), equality must hold, and since the above argument does not depend on the choice of r, (3.8)(b) is proven.

Finally, let us remark that if $0 \notin B_\sigma(y)$, (3.8)(c) is immediate. On the other hand, if $0 \in B_\sigma(y)$, $\forall x \in B_\sigma(y) \cap \mathbb{R}^N_+$ such that $(\pi(x)|y) < 0$, the point $\bar{x}$, symmetrical to $-x$ with respect to $\partial\mathbb{R}^N_+$, belongs to $B_\sigma(y)\cap\mathbb{R}^N_+$, $(\pi(\bar{x})|y) > 0$, and $\varphi_{\sigma,y}(\bar{x}) > \varphi_{\sigma,y}(x)$. Thus $\forall\sigma > 0$,

$$(\beta(\varphi_{\sigma,y})|y) = \int_{\mathbb{R}^N_+\cap B_\sigma(y)} \frac{(\pi(x)|y)}{1+|\pi(x)|} |\varphi_{\sigma,y}(x)|^{2^*} dx > 0,$$

as desired. □

Corollary 3.3. *Let $a(x)$ satisfy (1.1). Let $\epsilon > 0$ be a real number such that $\bar{\Sigma} + \epsilon < \bar{c}$. Then there exist real numbers $r > 0$ and $\sigma_1, \sigma_2 : 0 < \sigma_1 < 1/3 < \sigma_2$ such that*

$$\gamma(\varphi_{\sigma_1,y}) < \frac{1}{3}, \qquad \gamma(\varphi_{\sigma_2,y}) > \frac{1}{3} \quad \forall y \in \partial\mathbb{R}^N_+, \tag{3.12}$$

and

$$\sup\left\{\int_{\mathbb{R}^N_+}[|\nabla\varphi_{\sigma,y}(x)|^2 + (a(x)-a_\infty)\varphi^2_{\sigma,y}(x)]dx \ : \ (y,\sigma)\in\partial\mathcal{K}\right\} < \bar{\Sigma} + \frac{\epsilon}{2}, \tag{3.13}$$

where

$$\mathcal{K} = \{(y,\sigma) \in \partial\mathbb{R}^N_+ \times \mathbb{R}^+ : |y| \leq r, \ \sigma \in [\sigma_1,\sigma_2]\}. \tag{3.14}$$

Proof. By (3.8)(a) and (3.5)(a) with (1.1), there exists $\sigma_1 \in (0, 1/3)$ such that $\gamma(\varphi_{\sigma_1,y}) < 1/3$ $\forall y \in \partial\mathbb{R}^N_+$ and the relation

$$\int_{\mathbb{R}^N_+}[|\nabla\varphi_{\sigma,y}(x)|^2 + (a(x)-a_\infty)\varphi^2_{\sigma,y}(x)]dx < \bar{\Sigma} + \frac{\epsilon}{2} \tag{3.15}$$

holds when $\sigma = \sigma_1$ for any $y \in \partial\mathbb{R}^N_+$. Furthermore, (3.5)(c) with (1.1) allows us to choose $r > 0$ such that if $|y| = r$ and $y \in \partial\mathbb{R}^N_+$, (3.15) is satisfied for all $\sigma > 0$. Lastly, fixing r as chosen before, it is possible by (3.8)(b) and (3.5)(b) with (1.1) to find $\sigma_2 > 1/3$ for which $\gamma(\varphi_{\sigma_2,y}) > 1/3$ for any $y \in \partial\mathbb{R}^N_+$, $|y| \leq r$ and relation (3.15) holds with $\sigma = \sigma_2$ for any $y \in \partial\mathbb{R}^N_+$. Clearly, the set $\mathcal{K} = \{y \in \partial\mathbb{R}^N_+ : |y| \leq r\} \times [\sigma_1, \sigma_2]$ with r, σ_1, and σ_2 characterized as before is the desired set that satisfies (3.13). □

COROLLARY 3.4. *Let $a(x)$ satisfy (1.1) and $a_\infty > 0$. Let $\epsilon > 0$ be a real number chosen so that $\bar{\Sigma} + \epsilon < \bar{c}$ and, if (1.2) holds, $\bar{\Sigma} + \epsilon < S - |a(x) - a_\infty|_{L^{N/2}(\mathbb{R}^N_+)}$. Let σ_1, σ_2, and r be the numbers (that depend on ϵ) whose existence is stated in Corollary 3.3, and let $\mathcal{K}$ denote the set defined in (3.14). Then there exists a real number $\mathcal{A} > 0$ such that if $a_\infty \in (0, \mathcal{A})$, the relation*

$$\sup\left\{\int_{\mathbb{R}^N_+} [|\nabla\varphi_{\sigma,y}(x)|^2 + a(x)\varphi^2_{\sigma,y}(x)]dx : \quad (y,\sigma) \in \partial\mathcal{K}\right\} < \bar{\Sigma} + \epsilon < \bar{c} \tag{3.16}$$

holds, and if (1.2) is true,

$$\sup\left\{\int_{\mathbb{R}^N_+} [|\nabla\varphi_{\sigma,y}(x)|^2 + a(x)\varphi^2_{\sigma,y}(x)]dx : \quad (y,\sigma) \in \mathcal{K}\right\} < S \tag{3.17}$$

is also verified.

Proof. Since $\forall k > 0, \ \forall y \in \partial\mathbb{R}^N_+$,

$$\int_{\mathbb{R}^N_+} k\varphi^2_{\sigma,y}(x)dx = k\sigma^2|\varphi_{1,0}|^2_{L^2(B_1(0))},$$

relation (3.16) follows straightly from (3.13) when $a_\infty \in (0, \mathcal{A})$ with $\mathcal{A} = \epsilon(2\sigma_2^2|\varphi_{1,0}|^2_{L^2(B_1(0))})^{-1}$. Analogously, since $\forall y \in \partial\mathbb{R}^N_+$and $\forall\sigma > 0$

$$\int_{\mathbb{R}^N_+} (a(x) - a_\infty)\varphi^2_{\sigma,y}(x)dx \leq |a(x) - a_\infty|_{L^{N/2}(\mathbb{R}^N_+)}|\varphi_{\sigma,y}|^2_{L^{2^*}(\mathbb{R}^N_+)} = |a(x) - a_\infty|_{L^{N/2}(\mathbb{R}^N_+)},$$

when (1.2) is satisfied, (3.17) is true if $a_\infty \in (0, \mathcal{A})$. □

LEMMA 3.5. *Let $\mathcal{K}$ be the set defined in (3.14) with σ_1, σ_2, and r chosen as in Corollary 3.3. Then*

$$\exists(\bar{y}, \bar{\sigma}) \in \partial\mathcal{K} : \beta(\varphi_{\bar{\sigma},\bar{y}}) = 0, \quad \gamma(\varphi_{\bar{\sigma},\bar{y}}) \geq \frac{1}{3},$$
$$\exists(\hat{y}, \hat{\sigma}) \in \overset{\circ}{\mathcal{K}} \ : \beta(\varphi_{\hat{\sigma},\hat{y}}) = 0, \quad \gamma(\varphi_{\hat{\sigma},\hat{y}}) = \frac{1}{3}.$$

Proof. To prove the lemma, define the map $\vartheta : \partial\mathcal{K} \to \mathbb{R}^{N-1} \times \mathbb{R}$ by

$$\vartheta(y,\sigma) = (\beta(\varphi_{\sigma,y}), \gamma(\varphi_{\sigma,y}));$$

it is sufficient to show that its restriction to $\partial\mathcal{K}$ is homotopically equivalent to the identity map in $\mathbb{R}^{N-1} \times \mathbb{R}\backslash\{(0, 1/3)\}$.

Therefore, let us consider the homotopy $\Theta : [0,1] \times \partial\mathcal{K} \to \mathbb{R}^{N-1} \times \mathbb{R}$,

$$\Theta(t, y, \sigma) = (1-t)(y,\sigma) + t(\beta(\varphi_{\sigma,y}), \ \gamma(\varphi_{\sigma,y})). \tag{3.18}$$

Clearly Θ is continuous, $\Theta(0, y, \sigma) = (y, \sigma)$, $\Theta(1, y, \sigma) = \vartheta(y, \sigma)$, so it remains to show that

$$(0, 1/3) \notin \Theta(t, \partial\mathcal{K}) \quad \forall t \in [0, 1] \tag{3.19}$$

or, equivalently,

$$\Theta(t, y, \sigma) \neq (0, 1/3) \quad \forall (y, \sigma) \in \partial\mathcal{K} \quad \forall t \in [0, 1].$$

In fact, set $\partial\mathcal{K} = \mathcal{F}_1 \cup \mathcal{F}_2 \cup \mathcal{F}_3$ with $\mathcal{F}_1 = \{(y, \sigma) : |y| \leq r,\ \sigma = \sigma_1\}$, $\mathcal{F}_2 = \{(y, \sigma) : |y| \leq r,\ \sigma = \sigma_2\}$, and $\mathcal{F}_3 = \{(y, \sigma) : |y| = r,\ \sigma \in [\sigma_1, \sigma_2]\}$. If $(y, \sigma) \in \mathcal{F}_1$, by (3.12), we have $\forall t \in [0, 1]$

$$(1 - t)\sigma_1 + t\gamma(\varphi_{\sigma_1,y}) < (1 - t)\frac{1}{3} + t\frac{1}{3} = \frac{1}{3}.$$

Analogously, if $(y, \sigma) \in \mathcal{F}_2$, by (3.12), $\forall t \in [0, 1]$,

$$(1 - t)\sigma_2 + t\gamma(\varphi_{\sigma_2,y}) > (1 - t)\frac{1}{3} + t\frac{1}{3} = \frac{1}{3}.$$

If $(y, \sigma) \in \mathcal{F}_3$, then $|y| = r$ and $0 < \sigma_1 \leq \sigma \leq \sigma_2$, so using (3.8)(c), we obtain $\forall t \in [0, 1]$

$$((1 - t)y + t\beta(\varphi_{\sigma,y})|y) = (1 - t)|y|^2 + t(\beta(\varphi_{\sigma,y})|y) > 0. \qquad \square$$

Proof of Theorem 1.1. Let $\mathcal{A}$ be the positive number whose existence is stated in Corollary 3.4 and assume that $a_\infty \in (0, \mathcal{A})$. Let $\epsilon > 0$ be chosen as in Corollary 3.4. We recall that in this case the space H in which the functional E is defined is $W^{1,2}(\mathbb{R}^N_+)$, so the constraint is $V = \{u \in W^{1,2}(\mathbb{R}^N_+) : |u|_{L^{2^*}(\mathbb{R}^N_+)} = 1\}$. In the following, we use the notation

$$E^c = \{u \in V : E(u) < c\}, \quad c \in \mathbb{R}.$$

We set

$$\begin{aligned} c_1 &= \inf\left\{E(u) : u \in V,\ \beta(u) = 0,\ \gamma(u) \geq \frac{1}{3}\right\}, \\ b_1 &= \sup\{E(\varphi_{\sigma,y}) : (y, \sigma) \in \partial\mathcal{K}\}, \\ b_2 &= \sup\{E(\varphi_{\sigma,y}) : (y, \sigma) \in \mathcal{K}\}, \end{aligned}$$

and we recall that at the beginning of the section, we defined the numbers c_a, c_∞, and c_{a-a_∞}. By (3.1)(ii), we have $\Sigma < c_\infty \leq c_1$, Lemma 3.5 gives $c_1 \leq E(\varphi_{\bar{\sigma},\bar{y}}) \leq b_1$, and $b_1 < \bar{\Sigma} + \epsilon < \bar{c} < S$ follows from (3.16) and the definition in (3.2). Furthermore, by (3.1)(ii) and the definition in (3.2) $\bar{c} < c_a$, Lemma 3.5 gives $c_a \leq E(\varphi_{\hat{\sigma},\hat{y}}) \leq b_2$, and if (1.2) holds, $b_2 < S$ by (3.17). To summarize,

$$\Sigma < c_1 \leq b_1 < \bar{\Sigma} + \epsilon < \bar{c} < S, \tag{3.20}$$

$$\bar{c} < c_a \leq b_2 \quad \text{and} \quad b_2 < S \quad \text{if (1.2) holds.} \tag{3.21}$$

First, we prove that the functional E constrained on V has a critical level in the energy range $(\Sigma, \bar{\Sigma} + \epsilon)$. Let us choose $\bar{\epsilon} > 0$ so that $\Sigma < c_1 - \bar{\epsilon} < b_1 + \bar{\epsilon} < \bar{\Sigma} + \epsilon$ and, arguing by contradiction, suppose that

$$\{u \in V : c_1 - \bar{\epsilon} \leq E(u) \leq b_1 + \bar{\epsilon}\ ,\ \nabla E_{|V}(u) = 0\} = \emptyset. \tag{3.22}$$

By Proposition 2.3 and (3.20), the pair (E, V) satisfies the Palais–Smale condition in $[c_1 - \bar{\epsilon}, b_1 + \bar{\epsilon}]$. Therefore, using a well-known deformation lemma (see, for instance, [S]), we find a continuous map $\eta : [0,1] \times V \to V$, and a positive number $\epsilon_0 < \bar{\epsilon}$ so that

$$\begin{aligned}\eta(0,u) &= u \quad \forall u \in V,\\ \eta(t,u) &= u \quad \forall u \in E^{c_1-\epsilon_0} \cup (V \backslash E^{b_1+\epsilon_0}) \quad \forall t \in [0,1],\\ E \circ \eta(t,u) &\leq E(u) \quad \forall t \in [0,1],\\ \eta(1, E^{b_1+\epsilon_0}) &\subset E^{c_1-\epsilon_0}.\end{aligned}$$

We remark that in particular

$$(y,\sigma) \in \partial\mathcal{K} \;\Rightarrow\; E(\varphi_{\sigma,y}) < b_1 \;\Rightarrow\; E(\eta(1,\varphi_{\sigma,y})) < c_1 - \epsilon_0. \tag{3.23}$$

Then let us define $\forall t \in [0,1]$ and $\forall (y,\sigma) \in \partial\mathcal{K}$ the map

$$\Gamma(t,y,\sigma) = \begin{cases} \Theta(2t,y,\sigma) & \forall t \in [0,1/2],\\ (\beta \circ \eta(2t-1,\varphi_{\sigma,y}),\ \gamma \circ \eta(2t-1,\varphi_{\sigma,y})) & \forall t \in [1/2,1],\end{cases}$$

where Θ is the map defined in (3.18). Γ is continuous, and $(0,1/3) \neq \Gamma(t,y,\sigma)\ \forall (y,\sigma) \in \partial\mathcal{K}\ \forall t \in [0,1/2]$ as a consequence of (3.19). Moreover, if $(y,\sigma) \in \partial\mathcal{K}$, the inequalities

$$E(\eta(2t-1,\varphi_{\sigma,y})) \leq E(\varphi_{\sigma,y}) \leq b_1 < \bar{c} < c_a = \inf\left\{E(u) :\ u \in V,\ \beta(u) = 0,\ \gamma(u) = \frac{1}{3}\right\}$$

$\forall t \in [1/2,1]$ hold. Thus we also have $(0,1/3) \neq \Gamma(t,y,\sigma)\ \forall (y,\sigma) \in \partial\mathcal{K}\ \ \forall t \in [1/2,1]$. Hence $(\tilde{y},\tilde{\sigma}) \in \partial\mathcal{K}$ must exist such that

$$\beta \circ \eta(1,\varphi_{\tilde{\sigma},\tilde{y}}) = 0, \quad \gamma \circ \eta(1,\varphi_{\tilde{\sigma},\tilde{y}}) \geq \frac{1}{3},$$

and then

$$E(\eta(1,\varphi_{\tilde{\sigma},\tilde{y}})) \geq \inf\{E(u) : u \in V,\ \beta(u) = 0,\ \gamma(u) \geq 1/3\} = c_1 > c_1 - \epsilon_0,$$

which contradicts (3.23), so (3.22) must be false.

Therefore, the functional E constrained on V must have at least one critical point $v \in V$ such that $\Sigma < E(v) < \bar{\Sigma} + \epsilon$, and by Lemma 2.2, v does not change sign. Therefore, because of the symmetry of E, v can be supposed positive.

Let us now assume that (1.2) holds. We shall prove that the functional E constrained on V has another critical level in the interval $(\bar{c}, S)$. As before, we argue by contradiction and suppose that, choosing $\epsilon' > 0$ such that $\bar{c} < c_a - \epsilon' < b_2 + \epsilon' < S$,

$$\{u \in V : c_a - \epsilon' \leq E(u) \leq b_2 + \epsilon',\ (\nabla E_{|V})(u) = 0\} = \emptyset. \tag{3.24}$$

By (3.21) and Proposition 2.3, the pair (E, V) satisfies the Palais–Smale condition in $(c_a - \epsilon', b_2 + \epsilon')$. Thus it is again possible to find a continuous map $\tilde{\eta} : [0,1] \times V \to V$ and a positive number $\epsilon_1 < \epsilon'$ so that

$$\begin{aligned}\tilde{\eta}(0,u) &= u \quad \forall u \in V,\\ \tilde{\eta}(t,u) &= u \quad \forall u \in E^{c_a-\epsilon_1} \cup (V \backslash E^{b_2+\epsilon_1})\ \forall t \in [0,1],\\ E \circ \tilde{\eta}(t,u) &\leq E(u) \quad \forall t \in [0,1],\\ \tilde{\eta}(1, E^{b_2+\epsilon_1}) &\subset E^{c_a-\epsilon_1}.\end{aligned}$$

We remark that in particular

$$(3.25)\qquad (y,\sigma)\in\mathcal{K}\ \Rightarrow\ E(\varphi_{\sigma,y})\le b_2\ \Rightarrow\ E(\tilde\eta(1,\varphi_{\sigma,y}))\le c_a-\epsilon_1.$$

Now define $\forall t\in[0,1]$ and $\forall(y,\sigma)\in\mathcal{K}$ the map

$$\tilde\Gamma(t,y,\sigma)=\begin{cases}\Theta(2t,y,\sigma), & t\in[0,\frac12],\\ (\beta\circ\tilde\eta(2t-1,\varphi_{\sigma,y}),\ \gamma\circ\tilde\eta(2t-1,\varphi_{\sigma,y})), & t\in[\frac12,1],\end{cases}$$

where Θ is the map defined in (3.18).

$\tilde\Gamma$ is continuous and $(0,1/3)\ne\tilde\Gamma(t,y,\sigma)$ $\forall(y,\sigma)\in\partial\mathcal{K}$ and $\forall t\in[0,1/2]$ as a consequence of (3.19). Moreover, since

$$(y,\sigma)\in\partial\mathcal{K}\ \Rightarrow\ E(\varphi_{\sigma,y})\le\bar\Sigma+\epsilon<\bar c<c_a-\epsilon_1\ \Rightarrow\ \tilde\eta(2t-1,\varphi_{\sigma,y})=\varphi_{\sigma,y}\quad\forall t\in\left[\frac12,1\right],$$

we have $\forall t\in[1/2,1],\forall(y,\sigma)\in\partial\mathcal{K}$

$$\tilde\Gamma(t,y,\sigma)=\tilde\Gamma\left(\frac12,y,\sigma\right)=\Theta(1,y,\sigma).$$

Then $(0,1/3)\ne\tilde\Gamma(t,y,\sigma)$ $\forall(y,\sigma)\in\partial\mathcal{K}$ $\forall t\in[1/2,1]$.

Hence a $(y^*,\sigma^*)\in\mathcal{K}$ must exist such that

$$\beta\circ\tilde\eta(1,\varphi_{\sigma^*,y^*})=0,\qquad \gamma\circ\tilde\eta(1,\varphi_{\sigma^*,y^*})=\frac13,$$

and then

$$E(\tilde\eta(1,\varphi_{\sigma^*,y^*}))\ge\inf\left\{E(u):u\in V,\ \beta(u)=0,\ \gamma(u)=\frac13\right\}=c_a>c_a-\epsilon_1,$$

which contradicts (3.25), so (3.24) must be false. Therefore, the functional E constrained on V has at least one critical point $u\in V$ such that $\bar c<E(u)<S$. Clearly, $u\ne v$ because $E(v)<\bar c<E(u)$, and using Lemma 2.2, we deduce $u>0$, concluding the proof. □

Remark 3.6. If we fix a function $\alpha(x)\in L^{N/2}(\mathbb{R}^N_+)$, $|\alpha|_{L^{N/2}(\mathbb{R}^N_+)}\ne0$, and consider the family of functions $a_\lambda(x)=\lambda+\alpha(x)$, $\lambda>0$, Theorem 1.1 insures the existence of a positive solution v_λ of (P) if λ is suitably small. Furthermore, by construction, $\Sigma<E(v_\lambda/|v_\lambda|_{L^{2^*}(\mathbb{R}^N_+)})<\bar\Sigma+\epsilon$, and since ϵ can be taken arbitrarily small and $\bar\Sigma$ taken arbitrarily near to Σ, it is easy to derive $\lim_{\lambda\to0}E(v_\lambda/|v_\lambda|_{L^{2^*}(\mathbb{R}^N_+)})=\Sigma$.

If in addition $\alpha(x)$ verifies the relation $|\alpha|_{L^{N/2}(\mathbb{R}^N_+)}<(1-2^{-2/N})S$, then for λ small, (P) has at least another solution u_λ, and, denoted by

$$c_\alpha=\inf\left\{\int_{\mathbb{R}^N_+}[|\nabla u|^2+\alpha(x)u^2]dx:\ u\in\mathcal{D}^{1,2}(\mathbb{R}^N_+),\ |u|_{L^{2^*}(\mathbb{R}^N_+)}=1,\right.$$
$$\left.\beta(u)=0,\ \gamma(u)=\frac13\right\},$$

the relation

$$\liminf_{\lambda\to0}E\left(\frac{u_\lambda}{|u_\lambda|_{L^{2^*}(\mathbb{R}^N_+)}}\right)>\bar c=\frac{c_\alpha+\Sigma}{2}$$

holds. □

Proof of Theorem 1.2. Let $\epsilon > 0$ be chosen in such a way that $\bar{\Sigma} + \epsilon < \bar{c}$ and the claim of Corollary 3.3 is true. Let c_a be defined as in the beginning of the section, and let us recall that in this case the space H in which the functional E is defined is $\mathcal{D}^{1,2}(\mathbb{R}^N_+)$ and the constraint is $V = \{u \in \mathcal{D}^{1,2}(\mathbb{R}^N_+) : |u|_{L^{2^*}(\mathbb{R}^N_+)} = 1\}$. If we set

$$\hat{b}_2 = \sup\{E(\varphi_{\sigma,y}) : (y,\sigma) \in \mathcal{K}\},$$

we have by (1.2) that $\hat{b}_2 < S$. Therefore, using (3.1)(i), the definition in (3.2), and Lemma 3.5, we obtain

$$\Sigma < \bar{c} < c_a \leq E(\varphi_{\hat{\sigma},\hat{y}}) \leq \hat{b}_2 < S.$$

Then arguing exactly as in the second part of the proof of Theorem 1.1, it is possible to prove the existence of a critical point of E on V which corresponds to a critical level in the energy range $(\bar{c}, S)$, and then it is positive by Lemma 2.2. □

ON THE INVERSE PROBLEM OF A FOURTH-ORDER SELF-ADJOINT BINOMIAL OPERATOR[*]

ALAN ELCRAT[†] AND VASSILIS G. PAPANICOLAOU[†]

Abstract. Let L be the binomial operator

$$L = \left(\frac{d}{dx}\right)^4 + q(x)$$

acting on $(0, \pi)$ with Dirichlet boundary conditions. We study the associated inverse spectral problem under the assumptions that q is symmetric, i.e., $q(\pi - x) = q(x)$.

Our analysis is inspired by the well-known work of Borg for the Sturm–Liouville case. We first derive the eigenfunction asymptotics by an approach that is different from the ones used in the second-order case (WKB, etc.). These asymptotics are then used to obtain the local uniqueness of the inverse problem.

Key words. fourth-order binomial operator, Dirichlet boundary conditions, Green function, eigenfunction asymptotics, inverse spectral problem

1. Introduction.

Consider the Dirichlet eigenvalue problem on $(0, \pi)$:

$$Lu = u'''' + q(x)u = \lambda u, \qquad u(0) = u''(0) = u(\pi) = u''(\pi) = 0 \tag{1}$$

(L is a so-called *binomial* operator), where $q \in C[0, \pi]$ is symmetric, namely, $q(\pi - x) = q(x)$, and without loss of generality,

$$\int_0^\pi q(x)dx = 0. \tag{2}$$

Let λ_n, $n = 1, 2, 3, \ldots$, be the eigenvalues of (1) (there may be finitely many n's such that $\lambda_{n+1} = \lambda_n$) and $\phi_n(x)$, $n = 1, 2, 3, \ldots$, be the corresponding normalized eigenfunctions. A classical inverse question here is whether q is uniquely determined from the spectrum $\{\lambda_n\}_{n=1}^\infty$.

For the corresponding second-order (i.e., the Sturm–Liouville) case, there are many ways to obtain the uniqueness result and, furthermore, reconstruct q. Borg [2] was the first to obtain a general uniqueness result. (He also reconstructed q by a successive-approximation procedure.) Soon after, Levinson [14] gave a very short and elegant uniqueness proof using contour integration and large-$|\lambda|$ asymptotics. (For a brief description of Levinson's idea, also see [10].) The reconstruction of q from a given spectral function was accomplished by Gelfand and Levitan [7] with the help of the celebrated (Volterra-type) transformation operator. (See [6] for the adaptation of the method of Gelfand and Levitan in the case where two spectra are given.) Krein followed a different approach, where the inverse problem is transformed to a moment problem. (For a nice exposition of Krein's method in English, see [13].) Another way to solve the inverse problem is to first obtain evolution equations for the eigenvalues

(with respect to the interval) and then after solving these equations recover q via a trace formula (see [1]), although this method is more popular in the case where q is periodic and the problem is considered on the full line (see, for example, [4]). For a survey on analytic methods for solving inverse problems, see [16].

We believe that among the methods mentioned above, the most promising for (1) is Borg's original approach. It seems that none of the other methods mentioned work for (1) despite the facts that trace formulas are still valid (see, for example, [18]) and the Gelfand–Levitan approach works satisfactorily in the case of two unknown coefficients (see, for example, [9] and [15]). The recent studies of Zachary [23] for the higher-order inverse-scattering problem and Yurko [20], [21], [22], where certain higher-order *non-self-adjoint* binomial inverse problems are solved, suggest that we should expect uniqueness results.

To apply Borg's approach, we need (eigenvalue and) eigenfunction asymptotics for (1). The behavior of the large eigenvalues is known (see, for example, [18]). Our first task, then (in section 2 below), is to obtain the eigenfunction asymptotics. Notice that to derive these asymptotics, we had to introduce a new method since the standard approaches used in the second-order case (WKB, etc.) do not work in the fourth-order case because in the latter there are always solutions such as $\exp\left(\lambda^{1/4}\right)$ growing; hence it is difficult to isolate the eigenfunctions, which are bounded in λ. In section 3, we use the eigenfunction asymptotics to attack the inverse problem. At the end of the paper, we outline a reconstruction procedure based on a work of Hald (see [11]). We believe that the analysis presented in this paper extends to other equations, including higher-dimensional ones; therefore, there are various potential applications (e.g., in elasticity).

2. The eigenfunction asymptotics. For the eigenvalues of (1), it is established (see, for example, [18]) that if $q \in C^r[0,\pi]$, where $r = 0$, 1, 2 or 3, then

$$\lambda_n - n^4 = O\left(n^{-r}\right). \tag{3}$$

Notice that n^4, $n = 1, 2, 3, \ldots$, are the eigenvalues of the *unperturbed* case, namely, when $q \equiv 0$. In this case, the corresponding eigenfunctions are $\psi_n(x) = (2/\pi)^{1/2} \sin nx$.

Our method for computing the asymptotics of the eigenfunctions $\phi_n(x)$ of (1) as $n \to \infty$ is inspired by an approach that we found in some works of Karpeshina (see, for example, [12]).

Let $G(x, y; \lambda)$ be the Green function associated with (1). By definition, $G(x, y; \lambda)$ is the integral kernel of the operator $(L - \lambda)^{-1}$; therefore, we have the eigenfunction expansion

$$G(x, y; \lambda) = \sum_{j=1}^{\infty} \frac{\phi_j(x)\phi_j(y)}{\lambda_j - \lambda}. \tag{4}$$

Thus $G(x, y; \lambda)$ is meromorphic in λ with simple poles at the Dirichlet eigenvalues.

In the unperturbed case, the Green function becomes

$$K(x, y; \lambda) = \begin{cases} \frac{1}{2s^2}\left[\frac{\sin(sx)\sin s(\pi - y)}{s\sin(s\pi)} - \frac{\sinh(sx)\sinh s(\pi - y)}{s\sinh(s\pi)}\right] & \text{if } x \leq y, \\ \\ \frac{1}{2s^2}\left[\frac{\sin(sy)\sin s(\pi - x)}{s\sin(s\pi)} - \frac{\sinh(sy)\sinh s(\pi - x)}{s\sinh(s\pi)}\right] & \text{if } x \geq y, \end{cases} \tag{5}$$

where $s = \lambda^{1/4}$. Observe that $K(x, y; \lambda)$ is a meromorphic function of $s^4 = \lambda$. Hence no matter what fourth root we choose for s, the value of $K(x, y; \lambda)$ is the same.

It is easy to see that $G(x,y;\lambda)$ is the unique solution (as long as $\lambda \neq \lambda_n$) of the integral equation

$$G(x,y;\lambda) = K(x,y;\lambda) - \int_0^\pi K(x,\xi;\lambda)q(\xi)G(\xi,y;\lambda)d\xi. \tag{6}$$

By iterating (6), we obtain a formal (perturbation) series for $G(x,y;\lambda)$, namely,

$$G(x,y;\lambda) = \sum_{m=0}^{\infty}(-1)^m G_m(x,y;\lambda), \tag{7}$$

where

$$\begin{aligned} &G_0(x,y;\lambda) = K(x,y;\lambda), \\ &G_m(x,y;\lambda) = \textstyle\int_0^\pi K(x,\xi;\lambda)q(\xi)G_{m-1}(\xi,y;\lambda)d\xi, \quad m \geq 1. \end{aligned} \tag{8}$$

Notice that if $m \geq 1$, $G_m(x,y;\lambda)$ also can be written as

$$G_m(x,y;\lambda) = \int_0^\pi \cdots \int_0^\pi K(x,\xi_1;\lambda)q(\xi_1)K(\xi_1,\xi_2;\lambda)\cdots q(\xi_m)K(\xi_m,y;\lambda)d\xi_1\cdots d\xi_m. \tag{9}$$

We need to establish the (absolute and uniform) convergence of the series in (7) for certain values of λ. (Notice that if this series converges, then it obviously satisfies (6).) First, we introduce the complex variable s (as in the unperturbed case) so that

$$\lambda = s^4.$$

Next, we consider a family of contours in the s-plane as follows:

$$C_n = \{s = \sigma + i\tau : \, |\sigma - n| \leq 1/2 \text{ and } |\tau| = 1, \text{ or } |\sigma - n| = 1/2 \text{ and } |\tau| \leq 1\},$$

i.e., C_n is a rectangle of horizontal side 1 and vertical side 2, centered at n.

PROPOSITION 1. *If $s \in C_n$ and n is large enough so that*

$$\delta_n \overset{\text{def}}{=} \frac{150\pi \, \|q\|_\infty}{(n-1/2)^3} \leq \frac{1}{2}, \tag{10}$$

then the series in (7) *converges absolutely and uniformly on* $[0,\pi]\times[0,\pi]\times C_n$.

Proof. First, we notice that if $s \in C_n$, then

$$\left|\frac{\sin(sx)\sin s(\pi-y)}{\sin(s\pi)}\right| \leq \left(\frac{e^\pi+1}{2}\right)^2 < 146,$$

and for $x \leq y$ (reminder: σ is the real part of s),

$$\left|\frac{\sinh(sx)\sinh s(\pi-y)}{\sinh(s\pi)}\right| \leq \frac{e^{\sigma(x-y)}+3}{2\,(1-e^{-\sigma\pi})} < 4.$$

Therefore, (5) implies that

$$|K(x,y;\lambda)| < \frac{150}{|s|^3} \leq \frac{150}{(n-1/2)^3}.$$

Thus (9) gives

$$|G_m(x,y;\lambda)| \leq 150\pi\delta_n^m, \tag{11}$$

and since $\delta_n \leq 1/2$, the absolute and uniform convergence of the series in (7) follows immediately. □

We now introduce the contours Γ_n in the λ-plane that correspond to the C_n's, namely,

$$\Gamma_n = \left\{\lambda = s^4 : s \in C_n\right\}.$$

Notice that the length $l\left(\Gamma_n\right)$ of Γ_n satisfies

$$l\left(\Gamma_n\right) \leq cn^3, \tag{12}$$

where c is some (positive) constant.

If n is sufficiently large, a consequence of Proposition 1 above is that

$$\frac{1}{2\pi i}\oint_{\Gamma_n} G(x,y;\lambda)d\lambda = \sum_{m=0}^{\infty}(-1)^m\frac{1}{2\pi i}\oint_{\Gamma_n} G_m(x,y;\lambda)d\lambda.$$

Using the eigenfunction expansion (4) and the fact that (3) implies that Γ_n encloses exactly one λ_n and exactly one eigenvalue of the unperturbed problem, namely n^4, we get

$$\phi_n(x)\phi_n(y) = \frac{2}{\pi}\sin nx \sin ny - \sum_{m=1}^{\infty}(-1)^m\frac{1}{2\pi i}\oint_{\Gamma_n} G_m(x,y;\lambda)d\lambda. \tag{13}$$

Next, we give a bound for the sum in (13). Using (11) and (12), we obtain the estimate

$$\left|\sum_{m=2}^{\infty}(-1)^m\frac{1}{2\pi i}\oint_{\Gamma_n} G_m(x,y;\lambda)d\lambda\right| \leq 75cn^3\sum_{m=2}^{\infty}\delta_n^m = 75cn^3\frac{\delta_n^2}{1-\delta_n}.$$

Thus by (10), there is a constant M (depending on $\|q\|_\infty$) such that

$$\left|\sum_{m=2}^{\infty}(-1)^m\frac{1}{2\pi i}\oint_{\Gamma_n} G_m(x,y;\lambda)d\lambda\right| \leq \frac{M}{n^3}. \tag{14}$$

We now treat the first term of the series in (13). By (8) or (9), we obtain

$$\frac{1}{2\pi i}\oint_{\Gamma_n} G_1(x,y;\lambda)d\lambda = \frac{1}{2\pi i}\oint_{\Gamma_n}\int_0^\pi K(x,\xi;\lambda)q(\xi)K(\xi,y;\lambda)d\xi d\lambda.$$

The eigenfunction expansion of $K(x,y;\lambda)$ together with the residue theorem give

$$\frac{1}{2\pi i}\oint_{\Gamma_n} G_1(x,y;\lambda)d\lambda = -\frac{2}{\pi}\int_0^\pi \sin n\xi\left[K^n(\xi,y;n^4)\sin nx + K^n(x,\xi;n^4)\sin ny\right]q(\xi)d\xi,$$

where we have set

$$K^n(x,y,\lambda) = \frac{2}{\pi}\sum_{\substack{j=1\\ j\neq n}}^{\infty}\frac{\sin nx \sin ny}{j^4-\lambda}.$$

It follows that

$$\left|\frac{1}{2\pi i}\oint_{\Gamma_n} G_1(x,y;\lambda)d\lambda\right| \le \frac{8}{\pi}\,\|q\|_\infty \sum_{\substack{j=1\\ j\neq n}}^{\infty} \frac{1}{|j^4-n^4|}. \tag{15}$$

Lemma 1. As $n\to\infty$,

$$\sum_{\substack{j=1\\ j\neq n}}^{\infty} \frac{1}{|j^4-n^4|} = O\left(\frac{\ln n}{n^3}\right).$$

Proof. We split the series into three terms:

$$\sum_{j=1}^{n-1}\frac{1}{n^4-j^4}+\sum_{j=n+1}^{2n}\frac{1}{j^4-n^4}+\sum_{j=2n+1}^{\infty}\frac{1}{j^4-n^4}. \tag{16}$$

The last term is $O(n^{-3})$. Regarding the first term, we have

$$\sum_{j=1}^{n-1}\frac{1}{n^4-j^4}=\frac{1}{n^3}\sum_{j=1}^{n-1}\frac{1}{1-(j/n)^4}\frac{1}{n}\le\frac{1}{n^3}\int_0^{1-(1/n)}\frac{dx}{1-x^4}+\frac{1}{n^4-(n-1)^4}.$$

Thus

$$\sum_{j=1}^{n-1}\frac{1}{n^4-j^4}=O\left(\frac{\ln n}{n^3}\right).$$

The second term in (16) can be treated similarly. □

Using (14), (15), and Lemma 1 in (13), we arrive at the important formula

$$\phi_n(x)\phi_n(y)=\frac{2}{\pi}\sin nx\sin ny+O\left(\frac{\ln n}{n^3}\right).$$

Let us make the meaning of this formula more precise. For a fixed positive number Q, there is a $d_1>0$ (depending only on Q) such that if $\|q\|_\infty\le Q$, then

$$\left|\phi_n(x)\phi_n(y)-\frac{2}{\pi}\sin nx\sin ny\right|\le\frac{d_1\ln n}{n^3}\,\|q\|_\infty\quad\text{for all } n\ge 2 \tag{17}$$

and d_1 remains bounded as $Q\searrow 0$.

We can go a little further. Consider the linear operator

$$(Tf)(x)=f(\pi-x).$$

The eigenspace V corresponding to an eigenvalue of (1) can have dimension 1 or 2, and T maps V into V. Since $T^2=I$, $T|_V$ (T restricted on V) is diagonalizable (in fact, it is symmetric), and its eigenvalues are $+1$ or -1. Thus T has a complete set of eigenvectors, and each eigenvector ϕ satisfies $\phi(\pi-x)=\pm\phi(x)$. It follows that for each eigenfunction ϕ_n of (1), we can always assume that

$$\phi_n(\pi-x)=c_n\phi_n(x)\quad\text{where } c_n=\pm 1. \tag{18}$$

Furthermore, by substituting $y = \pi - x$ in (17) and using (18), we get that if n is sufficiently large, then

$$\phi_n(\pi - x) = (-1)^{n+1}\phi_n(x). \tag{19}$$

If we set $y = x$ in (17), we obtain

$$\phi_n(x)^2 = \frac{2}{\pi}\sin^2 nx + O\left(\frac{\ln n}{n^3}\right).$$

On the other hand, if we freeze y, (17) implies that (up to an error of size $O(n^{-3}\ln n)$) $\phi_n(x)$ changes sign like $\sin nx$. We have therefore established the main result of this section.

THEOREM 1. *Let Q be a fixed positive number. Then there is a $d_2 > 0$ (depending only on Q) such that if $\|q\|_\infty \leq Q$, the eigenfunctions of* (1) *satisfy*

$$\left|\phi_n(x) - \sqrt{\frac{2}{\pi}}\sin nx\right| \leq \frac{d_2 \ln n}{n^3}\|q\|_\infty, \quad n \geq 2,$$

for all $x \in [0, \pi]$. Furthermore, d_2 remains bounded as $Q \searrow 0$.

3. The inverse problem. Theorem 1 enables us to attack the inverse problem associated with (1). We follow Borg's original approach (see [2]).

Let us consider the two eigenvalue problems

$$u'''' + q(x)u = \lambda u, \qquad u(0) = u''(0) = u(\pi) = u''(\pi) = 0 \tag{20}$$

and

$$u'''' + \widetilde{q}(x)u = \lambda u, \qquad u(0) = u''(0) = u(\pi) = u''(\pi) = 0, \tag{21}$$

where q and $\widetilde{q}$ are continuous and symmetric and without loss of generality,

$$\int_0^\pi q(x)dx = \int_0^\pi \widetilde{q}(x)dx = 0. \tag{22}$$

If a is some quantity associated with (20), the corresponding quantity for (21) is denoted by $\widetilde{a}$. Let λ_n and $\widetilde{\lambda}_n$, $n = 1, 2, 3, \ldots$, be the eigenvalues of (20) and (21), respectively. Here we assume that

$$\lambda_n = \widetilde{\lambda}_n \quad \text{for all } n.$$

Then if $\phi_n(x)$ and $\widetilde{\phi}_n(x)$, $n = 1, 2, 3, \ldots$, are the corresponding normalized eigenfunctions, we have

$$\phi_n'''' + q(x)\phi_n = \lambda_n\phi_n \quad \text{and} \quad \widetilde{\phi}_n'''' + \widetilde{q}(x)\widetilde{\phi}_n = \lambda_n\widetilde{\phi}_n.$$

If we multiply the first equation by $\widetilde{\phi}_n$ and the second by ϕ_n and then subtract the second from the first, we obtain

$$\phi_n''''\widetilde{\phi}_n - \widetilde{\phi}_n''''\phi_n = (\widetilde{q} - q)\,\phi_n\widetilde{\phi}_n.$$

Now we integrate from 0 to π and use integration by parts and the boundary conditions that ϕ_n and $\widetilde{\phi}_n$ satisfy. Thus we get

$$\int_0^{\pi} [\widetilde{q}(x) - q(x)]\, \phi_n(x)\widetilde{\phi}_n(x)dx = 0, \quad n = 1, 2, 3, \ldots. \tag{23}$$

Let $L_s^2(0, \pi)$ be the Hilbert space of all L^2 symmetric functions on $(0, \pi)$, namely,

$$L_s^2(0, \pi) = \left\{f \in L^2(0, \pi) : \, f(\pi - x) = f(x) \text{ a.e. } x\right\}.$$

Then by (23), the uniqueness part for the inverse problem is related to the following question: how much of $L_s^2(0, \pi)$ does the set $\{\phi_n\widetilde{\phi}_n\}_{n=1}^{\infty}$ span?

If in particular the set $\{\phi_n\widetilde{\phi}_n\}_{n=1}^{\infty}$ is complete in $L_s^2(0, \pi)$, then we have uniqueness since (23) then implies that we must have $\widetilde{q}(x) \equiv q(x)$.

Following Borg, we set

$$U_n(x) = \sqrt{\frac{2}{\pi}} \left(\int_0^{\pi} \phi_n\widetilde{\phi}_n\right) - (2\pi)^{1/2}\, \phi_n(x)\widetilde{\phi}_n(x) \tag{24}$$

(so that the average of $U_n(x)$ on $(0, \pi)$ is 0). Then because of (22), formula (23) is equivalent to

$$\int_0^{\pi} [\widetilde{q}(x) - q(x)]\, U_n(x)dx = 0, \quad n = 1, 2, 3, \ldots. \tag{25}$$

Theorem 1 implies that for fixed Q, there is a $d_3 > 0$ (depending only on Q) such that if $\|q\|_{\infty}, \|\widetilde{q}\|_{\infty} \leq Q$, then

$$\left|U_n(x) - \sqrt{\frac{2}{\pi}} \cos(2nx)\right| \leq \frac{d_3 Q\,(1 + \ln n)}{n^3} \quad \text{for all } n. \tag{26}$$

(Notice that $\{1/\sqrt{\pi}\} \cup \{(2/\pi)^{1/2} \cos 2nx\}_{n=1}^{\infty}$ is an orthonormal basis of $L_s^2(0, \pi)$.) By (18), it follows that

$$U_n(\pi - x) = c_n\widetilde{c}_n U_n(x) = \pm U_n(x).$$

If $n \geq n_0(Q)$, formula (19) implies that $c_n = \widetilde{c}_n = (-1)^{n+1}$. Therefore,

$$U_n(\pi - x) = U_n(x) \quad \text{for all } n \geq n_0.$$

Hence $U_n \in L_s^2(0, \pi)$ if $n \geq n_0$ (and $U_n \perp L_s^2(0, \pi)$ or $U_n \in L_s^2(0, \pi)$ if $n < n_0$).

Next, we consider the expansions

$$U_n(x) = \sum_{k=1}^{\infty} r_{nk} \sqrt{\frac{2}{\pi}} \cos 2kx, \quad n \geq n_0,$$

where, of course,

$$r_{nk} = \int_0^{\pi} U_n(x) \sqrt{\frac{2}{\pi}} \cos(2kx)\, dx.$$

We can also set $r_{nk} = 0$ if $n < n_0$. Introduce the operator R acting on $l_2(\mathbf{N})$ with matrix $(r_{nk})_{1 \leq k,n < \infty}$. By (26), R is a bounded operator on $l_2(\mathbf{N})$ (also see Lemma 2 below). We write

$$R = I + T, \tag{27}$$

where

$$T = (t_{nk})_{1 \leq k,n < \infty}\,, \quad t_{nk} = r_{nk} - \delta_{nk}.$$

(δ_{nk} is the Kronecker delta.)

Lemma 2. *The operator T defined above is compact on $l_2(\mathbf{N})$. Furthermore, if Q is sufficiently small* (*where, as usual, Q is an upper bound of $\|q\|_\infty$ and $\|\widetilde{q}\|_\infty$*), *then $\|T\| < 1$.*

Proof. (In fact, we prove a slightly stronger statement). We have

$$\sum_{n=1}^{\infty}\sum_{k=1}^{\infty} t_{nk}^2 = \sum_{n=1}^{\infty}\sum_{k=1}^{\infty} (r_{nk} - \delta_{nk})^2 = \sum_{n=1}^{\infty}\left(1 - 2r_{nn} + \sum_{k=1}^{\infty} r_{nk}^2\right). \tag{28}$$

Since

$$r_{nn} = \int_0^\pi U_n(x)\sqrt{\frac{2}{\pi}}\cos(2nx)\,dx,$$

formula (26) implies that

$$|r_{nn} - 1| \leq \frac{d_4\,(1 + \ln n)}{n^3}\,\|q\|_\infty\,. \tag{29}$$

Next, we observe that the Parseval equation gives

$$\sum_{k=1}^{\infty} r_{nk}^2 = \int_0^\pi U_n^2(x)dx.$$

Thus again using (26), we obtain

$$\left|\sum_{k=1}^{\infty} r_{nk}^2 - 1\right| \leq \frac{d_5\,(1 + \ln n)}{n^3}\,\|q\|_\infty\,.$$

Using this and (29) in (28), we obtain that the double series converges. □

Notice that if $\|T\| < 1$, then (27) implies that R is invertible, and this means that the set $\{1\} \cup \{U_n(x)\}_{n=1}^\infty$ is complete in $L_s^2(0,\pi)$. Thus we have established our second main result, namely the following.

Theorem 2. *There is a $Q > 0$ such that if problems* (20) *and* (21) *have the same spectrum* (*where q and $\widetilde{q}$ are symmetric*), *and if $\|q\|_\infty\,, \|\widetilde{q}\|_\infty \leq Q$, then $q(x) \equiv \widetilde{q}(x)$.*

Remarks. (a) Notice that for our analysis, we needed only q, $\widetilde{q} \in L^\infty(0,\pi)$.

(b) We believe that our analysis can provide a precise numerical value for Q.

(c) If q and $\widetilde{q}$ are not symmetric, then we believe that a theorem analogous to Theorem 2 can be proved using this same method under the assumptions that the operators have two spectra in common and that the norms $\|q\|_\infty$ and $\|\widetilde{q}\|_\infty$ are sufficiently small. In the special case where q and $\widetilde{q}$ have the same Dirichlet spectrum on $(0,\pi)$—say σ_D—and the same spectrum—denoted by σ_{DN}—that corresponds to the boundary conditions $u(0) = u''(0) = u'(\pi) = u'''(\pi) = 0$, we can consider the symmetric extensions q_s and $\widetilde{q}_s$ of q and $\widetilde{q}$, respectively, on $(0, 2\pi)$. It follows that q_s and $\widetilde{q}_s$ have a common Dirichlet spectrum on $(0, 2\pi)$, which is equal to $\sigma_D \cup \sigma_{DN}$. Thus Theorem 2 implies that $q_s(x) \equiv \widetilde{q}_s(x)$ on $[0, 2\pi]$ and therefore $q(x) \equiv \widetilde{q}(x)$ on $[0, \pi]$.

(d) We believe that our approach applies to operators of the form

$$Lu = \left(-\frac{d}{dx}\right)^{2l} u + qu.$$

We end this section with a small result in the spirit of Ambarzumian.

THEOREM 3. *Consider the* (*Neumann*) *eigenvalue problem on the interval* $(0, b)$*,*

$$Lu = u'''' + q(x)u = \mu u, \qquad u'(0) = u'''(0) = u'(b) = u'''(b) = 0$$

with eigenvalues μ_n*,* $n = 0, 1, 2, 3, \ldots$*. If* $q \in C[0, b]$ *and* $\mu_n = n^4$ *for infinitely many* n*'s, including* $n = 0$*, then* $b = \pi$ *and* $q(x) \equiv 0$*.*

Proof. First, we observe that the given behavior of μ_n for large n implies that $b = \pi$ and

$$\int_0^\pi q(x)dx = 0.$$

Next, we consider the associated Rayleigh quotient, namely,

$$N[v] = \frac{\int_0^\pi \left[v''(x)^2 + q(x)v(x)^2\right] dx}{\int_0^\pi v(x)^2 dx}, \qquad v'(0) = v'''(0) = v'(\pi) = v'''(\pi) = 0.$$

We have that $\inf_v N[v] = \mu_0 = 0$. However, $N[1] = 0$. Therefore, $\inf_v N[v] = N[1]$. Thus $v(x) \equiv 1$ is a Neumann eigenfunction corresponding to the eigenvalue 0. Therefore, $q(x) \equiv 0$. □

Appendix. In the second-order case, there is a way to reconstruct q (not mentioned in our introduction) that is due to Hald [11]. Hald's algorithm is a beautiful direct method of solving the inverse problem with symmetric q by a clever discretization. It is suitable for numerical implementation since it gives a stable algorithm for reconstructing q. However, it requires that $||q||_2$ and $\sum_n \left(\lambda_n - n^2\right)^2$ be sufficiently small, and for this reason, its theoretical significance is underestimated since other methods do not impose such restrictions. We believe that Hald's algorithm extends to the fourth-order problem (1).

Here is a telegraphic description of our proposed reconstruction process. First, we mention that if $q \in C^2[0, \pi]$, then the large eigenvalues of (1) obey the asymptotic formula

$$\lambda_n = n^4 + O(n^{-2})$$

(see, for example, [18]). We need to impose the condition

$$\text{(C)} \qquad ||q||_2 \leq Q_2 \quad \text{and} \quad \sum_n \left(\lambda_n - n^4\right)^2 \leq \Lambda_2,$$

where Q_2 and Λ_2 are fixed numerical bounds. (We believe that one can allow bounds that are bigger than the corresponding bounds of [11] for the second-order case.)

Step 1. Let $\lambda_1 < \cdots < \lambda_m$ be the first m eigenvalues of (1). (Condition (C) excludes the possibility of multiple eigenvalues.) Then there is a unique set of real numbers $\beta_1, \dots, \beta_m$ such that if we set

$$b_{jk} = \begin{cases} j^4 \delta_{jk} + \beta_{|k-j|/2} - \beta_{(k+j)/2} & \text{if } k+j = \text{even}, \\ 0 & \text{if } k+j = \text{odd}, \end{cases} \qquad \text{where } \beta_0 = 0,$$

then the $m \times m$ matrix $B = (b_{jk})$ has eigenvalues $\lambda_1, \dots, \lambda_m$ (notice that these β_k's depend on m and that they are not the cosine Fourier coefficients of q), and furthermore,

$$\beta_1^2 + \beta_2^2 + \cdots + \beta_m^2 \leq (2/\pi)\, Q_2^2.$$

Step 2. If we set

$$q_m(x) = 2 \sum_{k=1}^{m} \beta_k \cos(2kx),$$

where β_k, $k = 1, \dots, m$, is as in Step 1, then

$$||q - q_m||_2 \to 0 \quad \text{as } m \to \infty.$$

To justify these steps, we believe that one need only repeat Hald's analysis (see [11]) with basically one modification, namely, the discretization of $-(d/dx)^2$; i.e., the matrix $\operatorname{diag}(1^2, 2^2, 3^2, \dots)$ that appears in [11] should now be replaced by the discretization of $(d/dx)^4$, i.e., the matrix $\operatorname{diag}(1^4, 2^4, 3^4, \dots)$.

Acknowledgments. (i) We want to thank Professor P. Kuchment for showing us certain papers by Yu. Karpeshina.

(ii) Recently, we became aware that Professor Peter Perry and his collaborators, Al Schueller and Lester Caudill, are also working (independently of us) on higher-order inverse spectral problems; some of their methods are similar to those used in this paper.

(iii) Finally, we want to thank the referees for various constructive comments and suggestions.

A LEVINSON-TYPE ALGORITHM FOR DISCRETE STATIONARY RANDOM FIELDS*

A. MAKAGON†, C. A. MENSAH†, AND A. G. MIAMEE†

Abstract. A Levinson-type recursive procedure for updating the predictor of a discrete stationary random field is developed. This considerably reduces the number of equations that one must solve in order to recursively update the predictor as more data and information about the process becomes available and thus saves some resources and time. The procedure extends the well-known Levinson recursive algorithm to the case of random fields.

Key words. stationary random field, prediction, Levinson's algorithm

1. Introduction.

Prediction of random fields requires knowledge of the observed past and the covariance of the process. In practice, one must find the coefficients of the predictor and study the error. In general, finding the coefficients involves solving a system of linear equations at each point in time. As more data and information about the process become available, the predictor must be updated. This requires solving an entirely new and larger system of equations, which becomes increasingly difficult and time consuming.

In the case of a stationary sequence $X = \{x(n) : n \in Z\}$, Levinson [6] developed a simple algorithm for computing the predictor $(x(0)|\mathcal{M}_{n+1})$ of $x(0)$ based on $\mathcal{M}_{n+1} = sp\{x(k) : -n-1 \leq k \leq -1\}$, assuming that $(x(0)|\mathcal{M}_n)$ is known. The purpose of this paper is to present a similar recursive procedure for stationary fields.

As remarked by Kallianpur, Miamee, and Niemi [4], the starting point in the prediction problem is the appropriate definition of the past. In one of the earliest studies, Chiang [1] took the half-plane as the past, whereas Helson and Lowdenslager used the augmented half-plane for past in their study [2, 3]. More recently, Kallianpur and Mandrekar [5] performed a time-domain analysis of a two-parameter weakly stationary random field in which they took the quarter-plane in the southwest corner as the past. Marzetta [7] pointed out that the proper definition of the past must include all of the data points that lie between the data points at (s, t) being predicted and data points at (k, l) that have been observed. In this paper, we will work with the truncated quarter-plane, namely $M_n = \{(i, j) \in Z^2 : -n \leq i, j \leq -1\}$, as the finite past. Having identified our past here, we define the "nearest future" as all those data points that are one step ahead of the finite past, that is, $F_n = \{(i, 0) : -n-1 \leq i \leq 0\} \cup \{(0, j) : -n-1 \leq j \leq -1\}$.

Recall that the Levinson's algorithm (the one-parameter case) is based on the fact that the projection $(x(0)|\mathcal{M}_{n+1})$ of $x(0)$ onto $\mathcal{M}_{n+1}$ can be expressed in terms of $(x(0)|\mathcal{M}_n)$ and the "backward" predictor of the "new observation" $(x(-n-1)|\mathcal{M}_n)$, where the latter can be deduced from the coefficients of $(x(0)|\mathcal{M}_n)$. In the case considered in this paper, the "new observations" consist of $2n+1$ points $x(p, q)$,

$(p,q) \in M_{n+1} \setminus M_n$. Therefore, if one wants to employ Levinson's idea of "backward" prediction, the predictors of all elements $x(p,q)$, $(p,q) \in F_n$, must be available. In other words, the procedure must involve the simultaneous construction of the predictors of all elements in the near future.

2. The problem. Let Z denote the set of integers. A family of complex random variables $X = \{x(i,j) : (i,j) \in Z^2\} \subset L^2(\Omega)$ is said to be a *weakly stationary random field* (*WSRF*) if $E(x(i,j)) = 0$ for all $(i,j) \in Z^2$ and the *correlation function* of X, $E(x(i,j)\overline{x(k,m)}) = R(i-k, j-m)$, depends only on $i-k$ and $j-m$. In what follows, the expectation $E(x\overline{y})$, $x, y \in L^2(\Omega)$, will be denoted by $\langle x, y\rangle$ and $(x|\mathcal{M})$ will stand for the orthogonal projection of x onto a closed subspace $\mathcal{M} \subset L^2(\Omega)$ (with respect to the inner product defined above). Let us recall that

$$y = (x|\mathcal{M}) \quad \Longleftrightarrow \quad y \in \mathcal{M} \text{ and } \langle y, z\rangle = \langle x, z\rangle \tag{1}$$

for each z in a linearly dense subset of $\mathcal{M}$.

For every integer $n > 0$, let $M_n = \{(i,j) \in Z^2 : -n \le i \le -1, -n \le j \le -1\}$ be the finite past, $F_n = \{(i,0) : -n-1 \le i \le 0\} \cup \{(0,j) : -n-1 \le j \le -1\}$ be the nearest future, and $D_n = M_{n+1} \setminus M_n$. Let X be a WSRF and let $\mathcal{M}_n = \operatorname{sp}\{x(i,j) : (i,j) \in M_n\}$, where sp denotes the closed linear span. The *best linear predictor of* $x(p,q)$ *based on* $\mathcal{M}_n$ is the orthogonal projection

$$(x(p,q)|\mathcal{M}_n) = \sum_{(i,j)\in M_n} \alpha_{i,j}^{(n)}(p,q)x(i,j). \tag{2}$$

The coefficients $\alpha_{i,j}^{(n)}(p,q)$, $(i,j) \in M_n$, will be referred to as *predictor coefficients* of the predictor $(x(p,q)|\mathcal{M}_n)$. If we assume that any finite nontrivial subset of X is linearly independent (as vectors in $L^2(\Omega)$), then by (1), the predictor coefficients are the unique solution of the following system of linear equations:

$$R(p-k, q-l) = \sum_{(i,j)\in M_n} \alpha_{i,j}^{(n)}(p,q)R(i-k, j-l), \quad (k,l) \in M_n. \tag{3}$$

Therefore, finding the predictor of the "nearest future" elements $\{x(p,q) : (p,q) \in F_n\}$ based on $\mathcal{M}_n$ requires solving $(2n+3)$ systems of linear equations each with n^2 unknowns. In the next section, we present a recursive Levinson-type algorithm for computing the predictor coefficients.

3. The algorithm. In this section, X is a WSRF with the property that any finite nontrivial subset of X is linearly independent. Let $n > 0$ be fixed and assume that the predictor coefficients $\alpha_{i,j}^{(n)}(p,q)$, $(i,j) \in M_n$, of $(x(p,q)|\mathcal{M}_n)$ are known for every $(p,q) \in F_n$. To get our prediction of the nearest future at the next iteration, we have to find the coefficients $\alpha_{i,j}^{(n+1)}(p,q)$ for $(i,j) \in M_{n+1}$ and $(p,q) \in F_{n+1}$. We first find these coefficients for $(p,q) \in F_n$. The remaining two sets of coefficients, namely $\alpha_{i,j}^{(n+1)}(-n-2, 0)$ and $\alpha_{i,j}^{(n+1)}(0, -n-2)$, will be discussed later.

Denote $e_n(s,t) = x(s,t) - (x(s,t)|\mathcal{M}_n)$ and $\mathcal{E}_n = \operatorname{sp}\{e_n(s,t) : (s,t) \in D_n\}$. Then $e_n(s,t), (s,t) \in D_n$, are linearly independent and $\mathcal{E}_n = \mathcal{M}_{n+1} \ominus \mathcal{M}_n$. Hence for every (p,q),

$$(x(p,q)|\mathcal{M}_{n+1}) = (x(p,q)|\mathcal{M}_n) + \sum_{(s,t)\in D_n} \beta_{s,t}^{(n)}(p,q)e_n(s,t). \tag{4}$$

Substituting $e_n(s,t) = x(s,t) - (x(s,t)|\mathcal{M}_n)$ and then using (2), we obtain

$$(x(p,q)|\mathcal{M}_{n+1}) = \sum_{(i,j)\in M_n} \left[\alpha_{i,j}^{(n)}(p,q) - \sum_{(s,t)\in D_n} \beta_{s,t}^{(n)}(p,q)\alpha_{i,j}^{(n)}(s,t) \right] x(i,j) + \sum_{(i,j)\in D_n} \beta_{i,j}^{(n)}(p,q)x(i,j).$$

This implies that

$$\alpha_{i,j}^{(n+1)}(p,q) = \begin{cases} \alpha_{i,j}^{(n)}(p,q) - \sum\limits_{(s,t)\in D_n} \beta_{s,t}^{(n)}(p,q)\alpha_{i,j}^{(n)}(s,t) & \text{if } (i,j)\in M_n, \\ \beta_{i,j}^{(n)}(p,q) & \text{if } (i,j)\in D_n. \end{cases} \tag{5}$$

Relation (5) shows that for any $(p,q)\in F_n$, in order to obtain the predictor coefficients of $(x(p,q)|\mathcal{M}_{n+1})$, it is enough to find the coefficients $\alpha_{i,j}^{(n)}(s,t)$, $(s,t)\in D_n$, $(i,j)\in M_n$, and $\beta_{s,t}^{(n)}(p,q)$, $(s,t)\in D_n$.

In the next lemma, we show that the coefficients $\alpha_{i,j}^{(n)}(s,t)$, $(s,t)\in D_n$, can be obtained by renumbering the coefficients $\alpha_{i,j}^{(n)}(p,q)$, $(p,q)\in F_n$. This is a simple consequence of the fact that due to the stationarity of X, the inner products $\langle x(s,t),\, x(i,j)\rangle$ and $\langle x(-n-1-i,-n-1-j),\, x(-n-1-s,-n-1-t)\rangle$ are equal. This principle, usually called the principle of backward–forward predictors, is the basis of Levinson's algorithm.

LEMMA 1. *For every $(i,j)\in M_n$ and $(s,t)\in D_n$,*

$$\alpha_{i,j}^{(n)}(s,t) = \overline{\alpha_{-n-1-i,-n-1-j}^{(n)}(-n-1-s,-n-1-t)}.$$

Note that if $(s,t)\in D_n$, then $(-n-1-s,-n-1-t)\in F_n$.

Proof. By (3), it suffices to show that for all $(u,v)\in M_n$,

$$R(s-u,t-v) = \sum_{(i,j)\in M_n} \overline{\alpha_{i,j}^{(n)}(-n-1-s,-n-1-t)}R(i-u,j-v). \tag{6}$$

Using the fact that $R(i,j) = \overline{R(-i,-j)}$ and substituting $i=-n-1-k$ and $j=-n-1-l$, we see that the right-hand side of (6) equals

$$\sum_{(k,l)\in M_n} \overline{\alpha_{k,l}^{(n)}(-n-1-s,-n-1-t)R(k-(-n-1-u),l-(-n-1-v))}.$$

Using (3) again, this time with $p=-n-1-s$ and $q=-n-1-t$, we see that the latter equals $R(u-s,v-t)$. □

The next lemma provides the equations for computing the coefficients $\beta_{s,t}^{(n)}(p,q)$, $(s,t)\in D_n$, $(p,q)\in F_n$, defined in (4). We state the equations in a more general form that is ready to be used later in computing the predictor coefficients of $(x(-n-2,0)|\mathcal{M}_{n+1})$. Let us remark that in the case of a one-parameter stationary sequence, the space $\mathcal{E}_n$ is one dimensional and there is only one coefficient to compute.

LEMMA 2. *Let L_n be the "nearest neighborhood" of M_n, that is, $L_n = F_n\cup D_n$, and let K be a nonempty subset of L_n. Let $\mathcal{K} = \mathrm{sp}\{x(i,j) : (i,j)\in M_n\cup K\}\ominus\mathcal{M}_n$.*

Denote

$$\begin{aligned} A(s,t;u,v) &= R(s-u,t-v) - \sum_{(i,j)\in M_n} \alpha_{i,j}^{(n)}(s,t)R(i-u,j-v) \\ &\quad - \sum_{(i,j)\in M_n} \overline{\alpha_{i,j}^{(n)}(u,v)}R(s-i,t-j) \\ &\quad + \sum_{(i,j)\in M_n}\sum_{(k,l)\in M_n} \alpha_{i,j}^{(n)}(s,t)\overline{\alpha_{k,l}^{(n)}(u,v)}R(i-k,j-l), \\ B(p,q;u,v) &= R(p-u,q-v) - \sum_{(i,j)\in M_n} \overline{\alpha_{i,j}^{(n)}(u,v)}R(p-i,q-j). \end{aligned}$$

Then for every $(p,q)\in F_n$,

$$(x(p,q)|\mathcal{M}_n\oplus\mathcal{K}) = (x(p,q)|\mathcal{M}_n) + \sum_{(s,t)\in K} \kappa_{s,t}^{(n)}(p,q)(x(s,t)-(x(s,t)|\mathcal{M}_n)), \tag{7}$$

where the coefficients $\kappa_{s,t}^{(n)}(p,q)$, $(s,t)\in K$, *satisfy the following system of equations:*

$$\sum_{(s,t)\in K} \kappa_{s,t}^{(n)}(p,q)\ A(s,t;u,v) = B(p,q;u,v), \quad (u,v)\in K. \tag{8}$$

Proof. The summation in (7) represents the orthogonal projection on $\mathcal{K}$, and therefore by (1) the coefficients $\kappa_{s,t}^{(n)}(p,q)$, $(s,t)\in K$, are the unique solutions of the system

$$\begin{aligned} \sum_{(s,t)\in K} \kappa_{s,t}^{(n)}(p,q)\langle(x(s,t)-(x(s,t)|\mathcal{M}_n),(x(u,v)-(x(u,v)|\mathcal{M}_n))\rangle \\ = \langle x(p,q),(x(u,v)-(x(u,v)|\mathcal{M}_n))\rangle, \quad (u,v)\in K. \end{aligned}$$

Substituting (2) into the last equation completes the proof. □

If $K=D_n$, Lemma 2 shows that the coefficients $\beta_{s,t}^{(n)}(p,q)$, $(s,t)\in D_n$, $(p,q)\in F_n$, needed in (5), are the solutions of the system

$$\sum_{(s,t)\in D_n} \beta_{s,t}^{(n)}(p,q)\ A(s,t;u,v) = B(p,q;u,v), \quad (u,v)\in D_n, \tag{9}$$

and hence we can compute $(x(p,q)|\mathcal{M}_{n+1})$ for $(p,q)\in F_n$ via formula (7).

It remains to compute the two predictors $(x(-n-2,0)|\mathcal{M}_{n+1})$ and $(x(0,-n-2)|\mathcal{M}_{n+1})$. If we apply Lemma 2 for $K=R_n := \{(0,j) : j=-1,\dots,-n-1\}\cup\{(i,-n-1) : i=-n,\dots,-1\}$ and denote the solutions to (8) by $\rho_{s,t}^{(n)}(p,q)$, we obtain

$$\begin{aligned} &(x(-n-1,0)|\mathcal{M}_n\oplus\mathcal{R}_n) \\ &\quad = (x(-n-1,0)|\mathcal{M}_n) + \sum_{(s,t)\in R_n} \rho_{s,t}^{(n)}(-n-1,0)(x(s,t)-(x(s,t)|\mathcal{M}_n)), \end{aligned} \tag{10}$$

where the coefficients $\rho_{s,t}^{(n)}(-n-1,0)$, $(s,t)\in R_n$, satisfy

$$\sum_{(s,t)\in R_n} \rho_{s,t}^{(n)}(-n-1,0)\ A(s,t;u,v) = B(-n-1,0;u,v), \quad (u,v)\in R_n. \tag{11}$$

The coefficients $\rho_{s,t}^{(n)}$ are needed to compute the coefficients $\alpha_{i,j}^{(n+1)}(-n-2,0)$ and $\alpha_{i,j}^{(n+1)}(0,-n-2)$, $(i,j) \in M_{n+1}$, and this is done in the next lemma. In fact, from the remark preceeding Lemma 1, it follows that it is enough to compute only one of these two sets of coefficients.

Lemma 3. *Let $\rho_{s,t}^{(n)}(-n-1,0)$, $(s,t) \in R_n$, be as above.*

1. *If $(i,j) \in \{-n-1, \ldots, -2\} \times \{-n, \ldots, -1\}$, then*

$$\alpha_{i,j}^{(n+1)}(-n-2,0) = \alpha_{i+1,j}^{(n)}(-n-1,0) + \sum_{(s,t)\in R_n} \rho_{s,t}^{(n)}(-n-1,0)\alpha_{i+1,j}^{(n)}(-n-1,0).$$

2. *If $(i,j) \in \{(-1,j) : -n-1 \le j \le -1\} \cup \{(i,-1-n) : -n-1 \le i \le -2\}$, then*

$$\alpha_{i,j}^{(n+1)}(-n-2,0) = \rho_{i+1,j}^{(n)}(-n-1,0).$$

3. *If $(i,j) \in M_{n+1}$, then*

$$\alpha_{i,j}^{(n+1)}(0,-n-2) = \overline{\alpha_{-n-2-i,-n-2-j}^{(n+1)}(-n-2,0)}.$$

Proof. Consider the unitary operator U defined by $Ux(i,j) = x(i-1,j)$, $(i,j) \in Z^2$. Then by (10), $(x(-n-2,0)|\mathcal{M}_{n+1}) = U(x(-n-1,0)|\mathcal{M}_n \oplus \mathcal{R}_n) = U((x(-n-1,0)|\mathcal{M}_n) + \sum_{(s,t)\in R_n} \rho_{s,t}^{(n)}(-n-1,0)(x(s,t) - (x(s,t)|\mathcal{M}_n))$. Substituting (2), we obtain parts 1 and 2. Part 3 of the lemma follows immediately from the fact that $\langle x(-n-2,0), x(i,j)\rangle = \langle x(0,-n-2), x(n+2+i,-n-2+j)\rangle$ (cf. Lemma 1). □

The following theorem summarizes the algorithm presented in this note.

Theorem 1 (Levinson algorithm for random fields). *Let X be a WSRF with the property that any finite nontrivial subset of X is linearly independent. Assume that the predictor coefficients $\alpha_{i,j}^{(n)}(p,q)$, $(i,j) \in M_n$, of $(x(p,q)|\mathcal{M}_n)$ are known for each $(p,q) \in F_n$. Let the functions $A(\cdot,\cdot\,;\,\cdot,\cdot)$ and $B(\cdot,\cdot\,;\,\cdot,\cdot)$ be as in Lemma 2. Then for every $(p,q) \in F_{n+1}$, the coefficients $\alpha_{i,j}^{(n+1)}(p,q)$, $(i,j) \in M_{n+1}$, appearing in*

$$(x(p,q)|\mathcal{M}_{n+1}) = \sum_{(i,j)\in M_{n+1}} \alpha_{i,j}^{(n+1)}(p,q)x(i,j)$$

can be computed via the following procedure:

(i) *If $(p,q) \in F_{n+1} \setminus \{(-n-2,0),(0,-n-2)\}$, then $\alpha_{i,j}^{(n+1)}(p,q)$ are given by (5), where $\alpha_{i,j}^{(n)}(s,t)$, $(s,t) \in D_n$, are related to $\alpha_{i,j}^{(n)}(p,q)$, $(p,q) \in F_n$, by Lemma 1 and $\beta_{s,t}^{(n)}(p,q)$, $(s,t) \in D_n$, are solutions of the system*

$$\sum_{(s,t)\in D_n} \beta_{s,t}^{(n)}(p,q)\; A(s,t;u,v) = B(p,q;u,v), \quad (u,v) \in D_n. \tag{12}$$

(ii) *If $(p,q) \in \{(-n-2,0),(0,-n-2)\}$, then the coefficients $\alpha_{i,j}^{(n+1)}(p,q)$ are calculated as in Lemma 3.*

From Theorem 1, it follows that in order to find $\alpha_{i,j}^{(n+1)}(p,q)$, $(i,j) \in M_{n+1}$, for a fixed $(p,q) \in F_{n+1}$, the algorithm requires solving system (12) (or (11)) consisting of $2n+1$ equations whose coefficients are obtained by renumbering, multiplying, and summing known predictor coefficients $\alpha_{i,j}^{(n)}(u,v)$, $(u,v) \in F_n$, $(i,j) \in M_n$, while direct computation would involve solving system (3) (with n replaced by $n+1$) with

$(n+1)^2$ equations. In the case of stationary sequences, the original Levinson algorithm required computing only one new coefficient, and this is because in that case there is just one "new observation," while in our case there are $2n+1$ "new observations."

THE GENERAL ANALYTIC SOLUTION OF A FUNCTIONAL EQUATION OF ADDITION TYPE[*]

H. W. BRADEN[†] AND V. M. BUCHSTABER[‡]

Abstract. The general analytic solution to the functional equation

$$\phi_1(x+y) = \frac{\begin{vmatrix} \phi_2(x) & \phi_2(y) \\ \phi_3(x) & \phi_3(y) \end{vmatrix}}{\begin{vmatrix} \phi_4(x) & \phi_4(y) \\ \phi_5(x) & \phi_5(y) \end{vmatrix}}$$

is characterized. Up to the action of the symmetry group, this is described in terms of Weierstrass elliptic functions. We illustrate our theory by applying it to the classical addition theorems of the Jacobi elliptic functions and the functional equations

$$\phi_1(x+y) = \phi_4(x)\phi_5(y) + \phi_4(y)\phi_5(x)$$

and

$$\Psi_1(x+y) = \Psi_2(x+y)\phi_2(x)\phi_3(y) + \Psi_3(x+y)\phi_4(x)\phi_5(y).$$

1. Introduction.

The purpose of this article is to describe the general analytic solution to the functional equation

$$\phi_1(x+y) = \frac{\begin{vmatrix} \phi_2(x) & \phi_2(y) \\ \phi_3(x) & \phi_3(y) \end{vmatrix}}{\begin{vmatrix} \phi_4(x) & \phi_4(y) \\ \phi_5(x) & \phi_5(y) \end{vmatrix}}. \tag{1.1}$$

Although this equation appears to depend on five a priori unknown functions, we shall show that (1.1) is invariant under a large group of symmetries $\mathcal{G}$ and that each orbit has a solution of a particularly nice form, expressible in terms of elliptic functions.

THEOREM 1. *The general analytic solution to the functional equation* (1.1) *is, up to a* $\mathcal{G}$*action given by* (2.1)–(2.4) (see section 2)*, of the form*

$$\phi_1(x) = \frac{\Phi(x;\nu_1)}{\Phi(x;\nu_2)}, \qquad \begin{pmatrix} \phi_2(x) \\ \phi_3(x) \end{pmatrix} = \begin{pmatrix} \Phi(x;\nu_1) \\ \Phi(x;\nu_1)' \end{pmatrix}, \quad \textit{and} \quad \begin{pmatrix} \phi_4(x) \\ \phi_5(x) \end{pmatrix} = \begin{pmatrix} \Phi(x;\nu_2) \\ \Phi(x;\nu_2)' \end{pmatrix}.$$

Here

$$\Phi(x;\nu) \equiv \frac{\sigma(\nu - x)}{\sigma(\nu)\sigma(x)}\, e^{\zeta(\nu)x}, \tag{1.2}$$

where $\sigma(x) = \sigma(x|\omega, \omega')$ *and* $\zeta(x) = \sigma(x)'/\sigma(x)$ *are the Weierstrass sigma and zeta functions.*

The group $\mathcal{G}$ of symmetries of (1.1) will be described further below. Our proof is constructive and indeed yields more.

Theorem 2. *Let* x_0 *be a generic point for* (1.1). *Then for* $k = 1, 2$, *we have*

$$\partial_y \ln \left| \begin{matrix} \phi_{2k}(x+x_0) & \phi_{2k}(y+x_0) \\ \phi_{2k+1}(x+x_0) & \phi_{2k+1}(y+x_0) \end{matrix} \right| \Bigg|_{y=0} = \zeta(\nu_k) - \zeta(x) - \zeta(\nu_k - x) - \lambda_k$$

$$= -\frac{1}{x} - \lambda_k + \sum_{l=0} F_l \, \frac{x^{l+1}}{(l+1)!},$$

and the Laurent expansion determines the parameters g_1 *and* g_2 *(which are the same for both* $k = 1, 2$*) characterizing the elliptic functions of* (1.2) *by*

$$g_2 = \frac{5}{3}\left(F_2 + 6F_0^2\right), \qquad g_3 = 6F_0^3 - F_1^2 + \frac{5}{3} F_0 F_2$$

and the parameters ν_k *via* $F_0 = -\wp(\nu_k)$. *Further, we have*

$$\phi_1(x + 2x_0) = \phi_1(2x_0)\, e^{(\lambda_2 - \lambda_1)x} \, \frac{\Phi(x;\nu_1)}{\Phi(x;\nu_2)}$$

and

$$\begin{pmatrix} \phi_{2k}(x+x_0) \\ \phi_{2k+1}(x+x_0) \end{pmatrix} = \frac{e^{-\lambda_k x}}{f(x)} \begin{pmatrix} \phi'_{2k}(x_0) & \phi_{2k}(x_0) \\ \phi'_{2k+1}(x_0) & \phi_{2k+1}(x_0) \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \lambda_k & -1 \end{pmatrix} \begin{pmatrix} \Phi(x;\nu_k) \\ \Phi'(x;\nu_k) \end{pmatrix}.$$

Here the function

$$f(x) = \frac{e^{-\lambda_k x}}{\Phi(x;\nu_k)} \; \frac{\left| \begin{matrix} \phi'_{2k}(x_0) & \phi_{2k}(x_0) \\ \phi'_{2k+1}(x_0) & \phi_{2k+1}(x_0) \end{matrix} \right|}{\left| \begin{matrix} \phi_{2k}(x+x_0) & \phi_{2k}(x_0) \\ \phi_{2k+1}(x+x_0) & \phi_{2k+1}(x_0) \end{matrix} \right|}$$

is, in fact, the same for $k = 1, 2$.

The term "generic" will be defined below, and we will give more expressions for the quantities appearing in the theorem.

One merit of writing (1.1) in this general form is that several different functional equations may now be seen as different points on a $\mathcal{G}$ orbit of (1.1). Thus, for example,

$$\phi_1(x+y) = \phi_1(x)\phi_1(y), \tag{1.3}$$

$$\phi_1(x+y) = \phi_4(x)\phi_5(y) + \phi_4(y)\phi_5(x), \tag{1.4}$$

$$A(x+y)[B(x) - B(y)] = A(x)A'(y) - A(y)A'(x) \tag{1.5}$$

are particular[1] examples of (1.1). The functional equation for the exponential (1.3) corresponds to $\nu_1 = \nu_2$ in our solution and the exponential comes wholly from $\mathcal{G}$.

[1] These correspond to
(a) $\phi_2(x) = \phi_1(x)\phi_4(x)$ and $\phi_3(x) = \phi_1(x)\phi_5(x)$,
(b) $\phi_2(x) = \phi_4^2(x)$ and $\phi_3(x) = \phi_5^2(x)$, and
(c) $\phi_1(x) = \phi_2(x) = A(x)$, $\phi_3(x) = A'(x)$, $\phi_4(x) = B(x)$, and $\phi_5(x) = 1$.

Particular cases of (1.4) have been studied in [8] and we shall determine (see Lemma 4) the general solution to (1.4) as an application of our work.

More interesting is equation (1.5), which has been studied by various authors with assumptions of evenness/oddness on the functions appearing [12, 18, 19] or assumptions on the nature of B [16]. The general solution [4, 5] $A(x) = \Phi(x;\nu)$ now corresponds to the limit $\nu_2 \to 0$ together with a $\mathcal{G}$ action. This will be illustrated later.

Finally, when $\phi_1(x) = \alpha(x)$, $\phi_2(x) = \alpha(x)\tau(x)$, $\phi_4(x) = \tau(x)$, $\phi_3(x) = \phi_2'(x)$, and $\phi_5(x) = \phi_4'(x)$, we obtain the functional equation

$$\alpha(x+y) = \alpha(x)\alpha(y) + \tau(x)\tau(y)\psi(x+y). \tag{1.6}$$

The function $\psi(x)$ will be described in more detail in what follows. This equation was studied by Bruschi and Calogero [4] and will be used in our analysis.

Let us remark that both (1.4) and (1.6) may be viewed as limiting cases of the functional equation

$$\Psi_1(x+y) = \Psi_2(x+y)\phi_2(x)\phi_3(y) + \Psi_3(x+y)\phi_4(x)\phi_5(y), \tag{1.7}$$

which a priori depends on seven unknown functions. Later we shall show how (1.1) may be used to solve this.

It remains to place (1.1) in some form of context. The last decade has seen a remarkable confluence of ideas from completely integrable systems, geometry, field theory, and functional equations that is still being assimilated. To make some of these matters concrete, let us consider how such functional equations arise in the context of integrable systems of particles on the line. A pair of matrices L and M such that $\dot{L} = [L, M]$ is known as a Lax pair; this is a zero-curvature condition. Starting with an ansatz for the matrices L and M, one seeks restrictions necessary to obtain equations of motion of some desired form. These restrictions typically involve the study of functional equations. The paradigm for this approach is the Calogero–Moser system [11]. Beginning with the ansatz (for $n \times n$ matrices)

$$\begin{aligned} L_{jk} &= p_j\delta_{jk} + g\,(1-\delta_{jk})A(q_j - q_k), \\ M_{jk} &= g\left[\delta_{jk}\sum_{l\neq j} B(q_j - q_l) - (1-\delta_{jk})C(q_j - q_k)\right], \end{aligned}$$

one finds that $\dot{L} = [L, M]$ yields the equations of motion for the Hamiltonian system ($n \geq 3$)

$$H = \frac{1}{2}\sum_j p_j^2 + g^2 \sum_{j<k} U(q_j - q_k), \quad U(x) = A(x)A(-x) + \text{constant},$$

provided that $C(x) = -A'(x)$ and that $A(x)$ and $B(x)$ satisfy the functional equation (1.5). With this ansatz and assuming $B(x)$ to be even,[2] Calogero [12] found $A(x)$ to be given by (1.2). In this case, the corresponding potential is the Weierstrass $\wp$-function: $A(x)A(-x) = \wp(\nu) - \wp(x)$. The functional equation (1.6) is associated with a different ansatz and yields the relativistic Calogero–Moser systems [3, 21]. Similarly,

[2] This assumption can, in fact, be removed [2].

(1.1) arises from a more general ansatz [2] associated with equations of motion of the form

$$\ddot{q}_j = \sum_{k\neq j}(a + b\dot{q}_j)(a + b\dot{q}_k)V_{jk}(q_j - q_k),$$

which combines both relativistic ($b \neq 0$) and nonrelativistic ($b = 0$) systems together with potentials that can vary between particle pairs. This unifies, for example, Calogero–Moser and Toda systems [20, 21, 22]. The relativistic examples yield the functional equation (1.1), while the nonrelativistic situation involves the functional equation

$$\phi_6(x+y) = \phi_1(x+y)(\phi_4(x) - \phi_5(y)) + \begin{vmatrix} \phi_2(x) & \phi_3(y) \\ \phi_2'(x) & \phi_3'(y) \end{vmatrix}. \tag{1.8}$$

The general analytic solution to (1.8) has yet to be determined, although particular solutions are known. We remark that (1.1) and, after suitable symmetrizing, (1.8) are particular cases of the functional equation

$$\sum_{i=0}^{N} \phi_{3i}(x+y)\begin{vmatrix} \phi_{3i+1}(x) & \phi_{3i+1}(y) \\ \phi_{3i+2}(x) & \phi_{3i+2}(y) \end{vmatrix} = 0, \tag{1.9}$$

with $N = 1$ in the former case and $N = 2$ in the latter. When $\phi_{3i+2} = \phi_{3i+1}'$, Buchstaber and Krichever have discussed (1.9) in connection with functional equations satisfied by Baker–Akhiezer functions [10].

Lax pairs are only one way in which functional equations are associated with integrable systems, and we mention [7, 13, 9, 14] for others. There also appears to be a close connection between these functional equations and the elliptic genera associated with the string-inspired Witten index [15, 17]. Krichever, for example, used the functional equation (1.5) in his proof of the "rigidity" property of elliptic genera [17], and it also appears when discussing rational and pole solutions of the Kadomtsev–Petviashvili (KP) and Korteweg–deVries (KdV) equations [16, 1]. We feel that this connection between functional equations and completely integrable systems is part of a broader and less well-understood aspect of the subject that deserves further attention.

An outline of the paper is as follows. First, we will discuss the group of symmetries of (1.1). These will be used in the proof of Theorem 1. Before turning to the proof, we show in section 3 how the indicated solution indeed satisfies (1.1), using this as a vehicle to recall some of the properties of elliptic functions that we will need throughout. Section 4 is devoted to the proof of Theorem 1 and section 5 to that of Theorem 2. Several applications of our theorems, including the general analytic solution to (1.4) and a discussion of (1.7), are then given in section 6. An appendix is given that contains various elliptic function formulas that we shall make use of.

Various versions of Theorem 1 have appeared in unpublished preprints. In [6], the form of $\phi_1(x)$ only was stated. In [2], we introduced the $\mathcal{G}$ action to give Theorem 1 in its present form. In improving the proof of this, we obtained Theorem 2, given here alongside the better proof of Theorem 1.

2. The group of symmetries.

We next describe the group $\mathcal{G}$ of invariances of (1.1). Theorem 1 gives a representative of each $\mathcal{G}$ orbit on the solutions of (1.1) with a particularly nice form. First, observe that a large group of symmetries $\mathcal{G}$ act on the solutions of (1.1). The transformation

(2.1)
$$\left(\phi_1(x), \begin{pmatrix}\phi_2(x)\\ \phi_3(x)\end{pmatrix}, \begin{pmatrix}\phi_4(x)\\ \phi_5(x)\end{pmatrix}\right) \to \left(c\, e^{\lambda x}\phi_1(x), U\begin{pmatrix}e^{-\lambda' x}\phi_2(x)\\ e^{-\lambda' x}\phi_3(x)\end{pmatrix}, V\begin{pmatrix}e^{\lambda'' x}\phi_4(x)\\ e^{\lambda'' x}\phi_5(x)\end{pmatrix}\right)$$

clearly preserves (1.1), provided that

$$\lambda + \lambda' + \lambda'' = 0, \qquad U, V \in GL_2, \quad \text{and} \quad \det U = c \det V. \tag{2.2}$$

Further, (1.1) is also preserved by

$$\left(\phi_1(x), \begin{pmatrix}\phi_2(x)\\ \phi_3(x)\end{pmatrix}, \begin{pmatrix}\phi_4(x)\\ \phi_5(x)\end{pmatrix}\right) \to \left(\frac{1}{\phi_1(x)}, \begin{pmatrix}\phi_4(x)\\ \phi_5(x)\end{pmatrix}, \begin{pmatrix}\phi_2(x)\\ \phi_3(x)\end{pmatrix}\right) \tag{2.3}$$

and

$$\left(\phi_1(x), \begin{pmatrix}\phi_2(x)\\ \phi_3(x)\end{pmatrix}, \begin{pmatrix}\phi_4(x)\\ \phi_5(x)\end{pmatrix}\right) \to \left(\phi_1(x), f(x)\begin{pmatrix}\phi_2(x)\\ \phi_3(x)\end{pmatrix}, f(x)\begin{pmatrix}\phi_4(x)\\ \phi_5(x)\end{pmatrix}\right). \tag{2.4}$$

We will use these symmetries in our proof of Theorem 1 to find a solution of (1.1) on each $\mathcal{G}$ orbit with a particularly nice form.

3. Illustration of the solution. Before proceeding to the proof, it is instructive to see how the stated solution satisfies (1.1). This will also allow us to introduce some elliptic function identities needed throughout. From the definition of the zeta function, we have

$$\big(\ln\Phi(x;\nu)\big)' = -\zeta(\nu - x) - \zeta(x) + \zeta(\nu). \tag{3.1}$$

Thus

$$\begin{aligned}\begin{vmatrix}\Phi(x;\nu) & \Phi(y;\nu)\\ \Phi(x;\nu)' & \Phi(y;\nu)'\end{vmatrix} &= \Phi(x;\nu)\Phi(y;\nu)\Big[\big(\ln\Phi(y;\nu)\big)' - \big(\ln\Phi(x;\nu)\big)'\Big]\\ &= \Phi(x;\nu)\Phi(y;\nu)\Big[\zeta(\nu - x) + \zeta(x) + \zeta(-y) + \zeta(y-\nu)\Big].\end{aligned}$$

Upon using the definition of Φ, the right-hand side of this equation takes the form

$$\Phi(x+y;\nu)\frac{\sigma(\nu - x)\sigma(\nu - y)\sigma(x+y)}{\sigma(\nu - x - y)\sigma(\nu)\sigma(x)\sigma(y)}\Big[\zeta(\nu - x) + \zeta(x) + \zeta(-y) + \zeta(y-\nu)\Big]. \tag{3.2}$$

After noting the two identities [23]

$$\zeta(x) + \zeta(y) + \zeta(z) - \zeta(x+y+z) = \frac{\sigma(x+y)\sigma(y+z)\sigma(z+x)}{\sigma(x)\sigma(y)\sigma(z)\sigma(x+y+z)} \tag{3.3}$$

and

$$\wp(x) - \wp(y) = \frac{\sigma(y-x)\sigma(y+x)}{\sigma^2(y)\sigma^2(x)}, \tag{3.4}$$

we find that (3.2) simplifies to $\Phi(x+y;\nu)\big[\wp(x)-\wp(y)\big]$, where $\wp(x)=-\zeta'(x)$ is the Weierstrass $\wp$-function. Putting these together yields the addition formula

$$\Phi(x+y;\nu)=\frac{\begin{vmatrix}\Phi(x;\nu) & \Phi(y;\nu)\\ \Phi(x;\nu)' & \Phi(y;\nu)'\end{vmatrix}}{\wp(x)-\wp(y)} \tag{3.5}$$

and consequently a solution of (1.1) with the stated form. Further, from (3.5), we see the solution to (1.5) mentioned in section 1.

The general solution (1.2) involves the two nonzero constants ν_1 and ν_2. Let us see how our group of symmetries enables $\phi_1(x)=\Phi(x;\nu_1)$ to occur as a limit $\nu_2\to 0$. Consider the $\mathcal{G}$ action on the general solution $\phi_i(x)$ of Theorem 1 given by $\phi_i(x)\to\tilde\phi_i(x)$, where

$$\left(\tilde\phi_1(x),\begin{pmatrix}\tilde\phi_2(x)\\ \tilde\phi_3(x)\end{pmatrix},\begin{pmatrix}\tilde\phi_4(x)\\ \tilde\phi_5(x)\end{pmatrix}\right)=\left(\frac{e^{\zeta(\nu_2)x}}{-\nu_2}\phi_1(x),\begin{pmatrix}\Phi(x;\nu_1)\\ \Phi'(x;\nu_1)\end{pmatrix},\begin{pmatrix}e^{-\zeta(\nu_2)x}\Phi(x;\nu_2)\\ -\nu_2\, e^{-\zeta(\nu_2)x}\Phi'(x;\nu_2)\end{pmatrix}\right).$$

Now

$$\lim_{\nu_2\to 0}\tilde\phi_1(x)=\Phi(x;\nu_1)$$

and

$$\lim_{\nu_2\to 0}\begin{vmatrix}\tilde\phi_4(x) & \tilde\phi_4(y)\\ \tilde\phi_5(x) & \tilde\phi_5(y)\end{vmatrix}=\wp(x)-\wp(y).$$

Thus (1.5) arises as the $\nu_2\to 0$ of (1.1).

4. Proof of Theorem 1.

Our proof of Theorem 1 proceeds in two stages. First, we will use the symmetry (2.2) to transform (1.1) into a particularly simple canonical form. This form may be immediately integrated to yield a functional equation studied by Bruschi and Calogero [4]; by appealing to their result, our Theorem 1 will follow. The first stage of this process is entirely algorithmic, and consequently we may readily identify the parameters that appear in our solution. We begin with the following definition.

DEFINITION 1. *A point $x_0\in\mathbb{C}$ is said to be generic for* (1.1) *if*

(1) *$\phi_k(x)$ is regular at x_0 for $k=2,\dots,5$,*

(2) *$\phi_1(x)$ is regular at $2x_0$, and*

(3) $$\begin{vmatrix}\phi_2(x_0) & \phi_2'(x_0)\\ \phi_3(x_0) & \phi_3'(x_0)\end{vmatrix}\neq 0,\qquad \begin{vmatrix}\phi_4(x_0) & \phi_4'(x_0)\\ \phi_5(x_0) & \phi_5'(x_0)\end{vmatrix}\neq 0.$$

Now let x_0 be a generic point. Using at first the matrices U and V of transformation (2.2), we may choose linear combinations of ϕ_k $(k:2,\dots,5)$ such that (1.1) becomes

$$\tilde\phi_1(x+y)=\frac{\begin{vmatrix}\tilde\phi_2(x) & \tilde\phi_2(y)\\ \tilde\phi_3(x) & \tilde\phi_3(y)\end{vmatrix}}{\begin{vmatrix}\tilde\phi_4(x) & \tilde\phi_4(y)\\ \tilde\phi_5(x) & \tilde\phi_5(y)\end{vmatrix}}$$

and such that (for $k=1,2$)

$$\tilde\phi_{2k}(0)=\tilde\phi_{2k+1}'(0)=0,\qquad \tilde\phi_{2k}'(0)=\tilde\phi_{2k+1}(0)=1. \tag{4.1}$$

The arguments of the functions have been shifted to be centered on x_0 (or $2x_0$ in the case of $\tilde{\phi}_1(x)$). Here we have set

$$\tilde{\phi}_1(x) = c\,\phi_1(x + 2x_0)$$

and (for $k = 1, 2$)

$$\begin{pmatrix} \tilde{\phi}_{2k}(x) \\ \tilde{\phi}_{2k+1}(x) \end{pmatrix} = \begin{pmatrix} \phi'_{2k}(x_0) & \phi_{2k}(x_0) \\ \phi'_{2k+1}(x_0) & \phi_{2k+1}(x_0) \end{pmatrix}^{-1} \begin{pmatrix} \phi_{2k}(x + x_0) \\ \phi_{2k+1}(x + x_0) \end{pmatrix}.$$

The constant c here is just the ratio of the appropriate determinants specified in (2.1). We next observe the following result.

Lemma 1. *For $k = 1, 2$, we may write*

$$\begin{pmatrix} \tilde{\phi}_{2k}(x) \\ \tilde{\phi}_{2k+1}(x) \end{pmatrix} = \frac{1}{\gamma_k(x)} \begin{pmatrix} \xi_k(x) \\ \xi'_k(x) \end{pmatrix},$$

where $\gamma_k(x), \xi_k(x)$ are regular at 0 and

$$\xi_k(0) = 0, \qquad \xi'_k(0) = \gamma_k(0) = 1.$$

Further, upon writing $\xi_k(x) = e^{\lambda_k x}\tilde{\xi}_k(x)$ with $\lambda_k = -\tilde{\phi}''_{2k}(0)/2$, the function $\tilde{\xi}_k(x)$, regular at 0, satisfies

$$\tilde{\xi}_k(0) = \tilde{\xi}''_k(0) = 0, \qquad \tilde{\xi}'_k(0) = 1.$$

Proof. Upon differentiating $\xi_k(x) = \gamma_k(x)\tilde{\phi}_{2k}(x)$ and comparing with $\xi'_k(x) = \gamma_k(x)\tilde{\phi}_{2k+1}(x)$, we see that

$$\frac{\gamma'_k(x)}{\gamma_k(x)} = \frac{\tilde{\phi}_{2k+1}(x) - \tilde{\phi}'_{2k}(x)}{\tilde{\phi}_{2k}(x)}. \tag{4.2}$$

The only issue is whether the right-hand side of this differential equation is regular at $x = 0$. Using (4.1) and l'Hôpital's rule, we find that

$$\frac{\gamma'_k(0)}{\gamma_k(0)} = \frac{\tilde{\phi}'_{2k+1}(0) - \tilde{\phi}''_{2k}(0)}{\tilde{\phi}'_{2k}(0)} = -\tilde{\phi}''_{2k}(0),$$

and so $\gamma_k(x)$ and hence $\xi_k(x)$ are regular at 0. Now $\gamma_k(x)$ is determined by (4.2) given an initial condition, which we choose to be $\gamma_k(0) = 1$. The remaining initial conditions for $\xi_k(x)$ follow from (4.1). Indeed, from

$$\tilde{\phi}'_{2k+1}(x) = \frac{\xi''_k(x)\gamma_k(x) - \xi'_k(x)\gamma'_k(x)}{\gamma_k^2(x)},$$

we also find that

$$\xi''_k(0) = -\tilde{\phi}''_{2k}(0).$$

Now upon writing $\xi_k(x) = e^{\lambda_k x}\tilde{\xi}_k(x)$ with $\lambda_k = -\tilde{\phi}''_{2k}(0)/2$, we obtain the final statement of the lemma. □

Thus far we have not used the exponential part of the symmetry (2.2). Utilizing this symmetry, we set $\tilde\xi_0(x) = e^{(\lambda_1-\lambda_2)x}\tilde\phi_1(x)$ and $\gamma(x) = e^{2(\lambda_1-\lambda_2)x}\gamma_2(x)/\gamma_1(x)$. This scaling has (upon noting that $2\lambda_k = \gamma_k'(0)$) the effect of making $\gamma'(0) = 0$. Thus we obtain the following result.

Corollary 1. *At any generic point, we may rewrite* (1.1) *using the symmetry* (2.1) *as*

$$\tilde\xi_0(x+y) = \gamma(x)\gamma(y)\frac{\begin{vmatrix}\tilde\xi_1(x) & \tilde\xi_1(y)\\ \tilde\xi_1'(x) & \tilde\xi_1'(y)\end{vmatrix}}{\begin{vmatrix}\tilde\xi_2(x) & \tilde\xi_2(y)\\ \tilde\xi_2'(x) & \tilde\xi_2'(y)\end{vmatrix}}, \tag{4.3}$$

where for $k = 1, 2$,

$$\tilde\xi_k(0) = \tilde\xi_k''(0) = \gamma'(0) = 0, \qquad \tilde\xi_k'(0) = \gamma(0) = 1. \tag{4.4}$$

Given the complexity of the differential equation (4.2), one may wonder whether (4.3) simplifies much further. In fact, we find the following.

Lemma 2. *The functional equation* (4.3)*—and consequently* (1.1)*—may be written as*

$$\partial\left(\frac{\tilde\xi_1(x+y)}{\tilde\xi_1(x)\tilde\xi_1(y)}\right) = \partial\left(\frac{\tilde\xi_2(x+y)}{\tilde\xi_2(x)\tilde\xi_2(y)}\right), \tag{4.5}$$

where $\partial = \partial_x - \partial_y$. *Further,*

$$\tilde\xi_0(x) = \frac{\tilde\xi_2(x)}{\tilde\xi_1(x)}. \tag{4.6}$$

Proof. Taking the logarithmic derivative of (4.3) with respect to $\partial = \partial_x - \partial_y$, we obtain

$$0 = \frac{\gamma'(x)}{\gamma(x)} - \frac{\gamma'(y)}{\gamma(y)} + \frac{\partial^2\left(\tilde\xi_1(x)\tilde\xi_1(y)\right)}{\partial\left(\tilde\xi_1(x)\tilde\xi_1(y)\right)} - \frac{\partial^2\left(\tilde\xi_2(x)\tilde\xi_2(y)\right)}{\partial\left(\tilde\xi_2(x)\tilde\xi_2(y)\right)}. \tag{4.7}$$

Now employing (4.4), one finds

$$\partial\big(\tilde\xi_k(x)\tilde\xi_k(y)\big)|_{y=0} = \tilde\xi_k'(x)\tilde\xi_k(y) - \tilde\xi_k(x)\tilde\xi_k'(y)|_{y=0} = -\tilde\xi_k(x)$$

and, similarly,

$$\partial^2\big(\tilde\xi_k(x)\tilde\xi_k(y)\big)|_{y=0} = -2\tilde\xi_k'(x).$$

Upon setting $y = 0$ in (4.7) and with these simplifications, we obtain the differential equation

$$0 = \frac{\gamma'(x)}{\gamma(x)} + \frac{2\tilde\xi_1'(x)}{\tilde\xi_1(x)} - \frac{2\tilde\xi_2'(x)}{\tilde\xi_2(x)}$$

with solution

$$\gamma(x) = c\,\frac{\tilde\xi_2^2(x)}{\tilde\xi_1^2(x)}. \tag{4.8}$$

Again using l'Hôpital's rule and (4.4), we find the constant $c = 1$. Therefore, (4.3) may be rewritten as

$$\tilde{\xi}_0(x+y) = \frac{\tilde{\xi}_2^2(x)}{\tilde{\xi}_1^2(x)}\frac{\tilde{\xi}_2^2(y)}{\tilde{\xi}_1^2(y)}\frac{\begin{vmatrix}\tilde{\xi}_1(x) & \tilde{\xi}_1(y)\\ \tilde{\xi}_1'(x) & \tilde{\xi}_1'(y)\end{vmatrix}}{\begin{vmatrix}\tilde{\xi}_2(x) & \tilde{\xi}_2(y)\\ \tilde{\xi}_2'(x) & \tilde{\xi}_2'(y)\end{vmatrix}} = \frac{\begin{vmatrix}\frac{1}{\tilde{\xi}_1(x)} & \frac{1}{\tilde{\xi}_1(y)}\\ \left(\frac{1}{\tilde{\xi}_1(x)}\right)' & \left(\frac{1}{\tilde{\xi}_1(y)}\right)'\end{vmatrix}}{\begin{vmatrix}\frac{1}{\tilde{\xi}_2(x)} & \frac{1}{\tilde{\xi}_2(y)}\\ \left(\frac{1}{\tilde{\xi}_2(x)}\right)' & \left(\frac{1}{\tilde{\xi}_2(y)}\right)'\end{vmatrix}} = \frac{\partial\left(\frac{1}{\tilde{\xi}_1(x)\tilde{\xi}_1(y)}\right)}{\partial\left(\frac{1}{\tilde{\xi}_2(x)\tilde{\xi}_2(y)}\right)}. \tag{4.9}$$

Letting $y \to 0$, we find that

$$\tilde{\xi}_0(x) = \frac{\tilde{\xi}_2(x)}{\tilde{\xi}_1(x)}$$

as required. Utilizing (4.6), we may immediately rewrite (4.9) in the stated form (4.5). □

We observe that at this stage, the symmetry (2.2) has enabled us to transform (1.1) into the form specified by Theorem 1. The solution will follow once we show $1/\tilde{\xi}_k(x) = \Phi(x;\nu_k)$. Now (4.5) may be immediately integrated to give

$$\frac{\tilde{\xi}_1(x+y)}{\tilde{\xi}_1(x)\tilde{\xi}_1(y)} = \frac{\tilde{\xi}_2(x+y)}{\tilde{\xi}_2(x)\tilde{\xi}_2(y)} + \Theta(x+y).$$

Upon setting $\alpha(x) = \tilde{\xi}_2(x)/\tilde{\xi}_1(x)$ and $\psi(x) = \Theta(x)/\tilde{\xi}_2(x)$, this may be rearranged into the form

$$\frac{\alpha(x+y)}{\alpha(x)\alpha(y)} = 1 + \tilde{\xi}_2(x)\tilde{\xi}_2(y)\psi(x+y), \tag{4.10}$$

which is the functional equation studied by Bruschi and Calogero [4]. Calling upon the general analytic solution obtained by these authors together with our initial conditions (4.4), we find that[3] $1/\tilde{\xi}_k(x) = \Phi(x;\nu_k)$ as required.

5. Proof of Theorem 2. It is useful at the outset to gather together the various transformations introduced in the last section:

$$\begin{pmatrix}\tilde{\phi}_{2k}(x)\\ \tilde{\phi}_{2k+1}(x)\end{pmatrix} = \begin{pmatrix}\phi_{2k}'(x_0) & \phi_{2k}(x_0)\\ \phi_{2k+1}'(x_0) & \phi_{2k+1}(x_0)\end{pmatrix}^{-1}\begin{pmatrix}\phi_{2k}(x+x_0)\\ \phi_{2k+1}(x+x_0)\end{pmatrix} \tag{5.1}$$

$$= \frac{1}{\gamma_k(x)}\begin{pmatrix}\xi_k(x)\\ \xi_k'(x)\end{pmatrix} = \frac{e^{\lambda_k x}}{\gamma_k(x)}\begin{pmatrix}1 & 0\\ \lambda_k & 1\end{pmatrix}\begin{pmatrix}\tilde{\xi}_k(x)\\ \tilde{\xi}_k'(x)\end{pmatrix} \tag{5.2}$$

$$= \frac{e^{\lambda_k x}}{\gamma_k(x)\Phi^2(x;\nu_k)}\begin{pmatrix}1 & 0\\ \lambda_k & -1\end{pmatrix}\begin{pmatrix}\Phi(x;\nu_k)\\ \Phi'(x;\nu_k)\end{pmatrix}, \tag{5.3}$$

$$\tilde{\xi}_0(x) = e^{(\lambda_1-\lambda_2)x}\,\frac{\phi_1(x+2x_0)}{\phi_1(2x_0)} = \frac{\Phi(x;\nu_1)}{\Phi(x;\nu_2)}. \tag{5.4}$$

Let us introduce the function

$$f(x) = \gamma_k(x)\Phi^2(x;\nu_k)e^{-2\lambda_k x}. \tag{5.5}$$

[3] For example, from [4], we obtain $\tilde{\xi}_2(x) = Ae^{cx}\sigma(ax|\omega,\omega')/\sigma(ax+\nu|\omega,\omega')$. Using the property $\sigma(ax|a\omega,a\omega') = a\sigma(ax|\omega,\omega')$ and the definition of $\Phi(x;\nu)$, we may rewrite this as $\tilde{\xi}_2(x) = (A/\sigma(\nu/a))e^{(c-\zeta(\nu/a))x}/\Phi(z;-\nu/a)$. Now the $x \to 0$ limit shows $(A/\sigma(\nu/a))e^{(c-\zeta(\nu/a))x} = 1$.

Observe that (4.8) entails that the function $f(x)$ is independent of k:

$$\gamma_1(x)\Phi^2(x;\nu_1)e^{-2\lambda_1 x} = \gamma_2(x)\Phi^2(x;\nu_k)e^{-2\lambda_k x}.$$

With this definition, we may rewrite (5.1) and (5.3) to give

$$\begin{aligned}\begin{pmatrix}\phi_{2k}(x+x_0)\\ \phi_{2k+1}(x+x_0)\end{pmatrix} &= \frac{e^{-\lambda_k x}}{f(x)}\begin{pmatrix}\phi'_{2k}(x_0) & \phi_{2k}(x_0)\\ \phi'_{2k+1}(x_0) & \phi_{2k+1}(x_0)\end{pmatrix}\begin{pmatrix}1 & 0\\ \lambda_k & -1\end{pmatrix}\begin{pmatrix}\Phi(x;\nu_k)\\ \Phi'(x;\nu_k)\end{pmatrix}\\ &= \frac{e^{-\lambda_k x}}{f(x)}\begin{pmatrix}\begin{vmatrix}\Phi(x;\nu_k) & \phi_{2k}(x_0)\\ \Phi'(x;\nu_k) & \phi'_{2k}(x_0)+\lambda_k\phi_{2k}(x_0)\end{vmatrix}\\ \begin{vmatrix}\Phi(x;\nu_k) & \phi_{2k+1}(x_0)\\ \Phi'(x;\nu_k) & \phi'_{2k+1}(x_0)+\lambda_k\phi_{2k+1}(x_0)\end{vmatrix}\end{pmatrix}\end{aligned} \tag{5.6}$$

and

$$\begin{aligned}\begin{pmatrix}\Phi(x;\nu_k)\\ \Phi'(x;\nu_k)\end{pmatrix} &= f(x)e^{\lambda_k x}\begin{pmatrix}1 & 0\\ \lambda_k & -1\end{pmatrix}\begin{pmatrix}\phi'_{2k}(x_0) & \phi_{2k}(x_0)\\ \phi'_{2k+1}(x_0) & \phi_{2k+1}(x_0)\end{pmatrix}^{-1}\begin{pmatrix}\phi_{2k}(x+x_0)\\ \phi_{2k+1}(x+x_0)\end{pmatrix}\\ &= \frac{f(x)e^{\lambda_k x}}{\begin{vmatrix}\phi'_{2k}(x_0) & \phi_{2k}(x_0)\\ \phi'_{2k+1}(x_0) & \phi_{2k+1}(x_0)\end{vmatrix}}\begin{pmatrix}\begin{vmatrix}\phi_{2k}(x+x_0) & \phi_{2k}(x_0)\\ \phi_{2k+1}(x+x_0) & \phi_{2k+1}(x_0)\end{vmatrix}\\ \begin{vmatrix}\phi_{2k}(x+x_0) & \phi'_{2k}(x_0)+\lambda_k\phi_{2k}(x_0)\\ \phi_{2k+1}(x+x_0) & \phi'_{2k+1}(x_0)+\lambda_k\phi_{2k+1}(x_0)\end{vmatrix}\end{pmatrix}.\end{aligned} \tag{5.7}$$

Now (5.4) and (5.6) are of the form stated in Theorem 2, provided that we can show that $f(x)$, defined in (5.5), can also be put into the form of the theorem. To see this, note that (5.1) shows

$$\begin{aligned}\tilde{\phi}_{2k}(x) &= \frac{\phi_{2k+1}(x_0)\phi_{2k}(x+x_0)-\phi_{2k}(x_0)\phi_{2k+1}(x+x_0)}{\phi_{2k+1}(x_0)\phi'_{2k}(x_0)-\phi_{2k}(x_0)\phi'_{2k+1}(x_0)}\\ &= \frac{\begin{vmatrix}\phi_{2k}(x+x_0) & \phi_{2k}(x_0)\\ \phi_{2k+1}(x+x_0) & \phi_{2k+1}(x_0)\end{vmatrix}}{\begin{vmatrix}\phi'_{2k}(x_0) & \phi_{2k}(x_0)\\ \phi'_{2k+1}(x_0) & \phi_{2k+1}(x_0)\end{vmatrix}},\end{aligned} \tag{5.8}$$

while from (5.3), we see that

$$\gamma_k(x) = \frac{e^{\lambda_k x}}{\Phi(x;\nu_k)\tilde{\phi}_{2k}(x)}. \tag{5.9}$$

Combining these thus shows that

$$f(x) = \frac{e^{-\lambda_k x}}{\Phi(x;\nu_k)}\frac{\begin{vmatrix}\phi'_{2k}(x_0) & \phi_{2k}(x_0)\\ \phi'_{2k+1}(x_0) & \phi_{2k+1}(x_0)\end{vmatrix}}{\begin{vmatrix}\phi_{2k}(x+x_0) & \phi_{2k}(x_0)\\ \phi_{2k+1}(x+x_0) & \phi_{2k+1}(x_0)\end{vmatrix}} \tag{5.10}$$

as required. Also, from (5.8) and the definition $\lambda_k = -\tilde{\phi}''_{2k}(0)/2$, we find that

$$-2\lambda_k = \frac{\phi_{2k+1}(x_0)\phi''_{2k}(x_0) - \phi_{2k}(x_0)\phi''_{2k+1}(x_0)}{\phi_{2k+1}(x_0)\phi'_{2k}(x_0) - \phi_{2k}(x_0)\phi'_{2k+1}(x_0)} \tag{5.11}$$

$$= \partial_x \ln \left. \begin{vmatrix} \phi'_{2k}(x+x_0) & \phi_{2k}(x_0) \\ \phi'_{2k+1}(x+x_0) & \phi_{2k+1}(x_0) \end{vmatrix} \right|_{x=0}. \tag{5.12}$$

At this stage, we then see that if we can determine $\Phi(x;\nu_k)$, all of the terms in (5.1)–(5.4) are determined and we obtain the stated expressions for $\phi_1(x)$, $\phi_2(x)$, $\phi_3(x)$, $\phi_4(x)$, $\phi_5(x)$, and $f(x)$ given in Theorem 2. It therefore remains to determine the parameters g_2 and g_3 specifying the elliptic functions $\Phi(x;\nu_k)$ as well as ν_1 and ν_2. To this end, we utilize (5.7) to give

$$\frac{\Phi'(x;\nu_k)}{\Phi(x;\nu_k)} - \lambda_k = \frac{\begin{vmatrix} \phi_{2k}(x+x_0) & \phi'_{2k}(x_0) \\ \phi_{2k+1}(x+x_0) & \phi'_{2k+1}(x_0) \end{vmatrix}}{\begin{vmatrix} \phi_{2k}(x+x_0) & \phi_{2k}(x_0) \\ \phi_{2k+1}(x+x_0) & \phi_{2k+1}(x_0) \end{vmatrix}}$$

$$= \partial_y \ln \left. \left| \begin{vmatrix} \phi_{2k}(x+x_0) & \phi_{2k}(y+x_0) \\ \phi_{2k+1}(x+x_0) & \phi_{2k+1}(y+x_0) \end{vmatrix} \right| \right|_{y=0}.$$

Upon using (3.1) to simplify the left-hand side of this equality, we obtain the first equality of Theorem 2,

$$\partial_y \ln \left. \left| \begin{vmatrix} \phi_{2k}(x+x_0) & \phi_{2k}(y+x_0) \\ \phi_{2k+1}(x+x_0) & \phi_{2k+1}(y+x_0) \end{vmatrix} \right| \right|_{y=0} = \zeta(\nu_k) - \zeta(x) - \zeta(\nu_k - x) - \lambda_k, \tag{5.13}$$

and consequently

$$\partial_x\partial_y \ln \left. \left| \begin{vmatrix} \phi_{2k}(x+x_0) & \phi_{2k}(y+x_0) \\ \phi_{2k+1}(x+x_0) & \phi_{2k+1}(y+x_0) \end{vmatrix} \right| \right|_{y=0} = \wp(x) - \wp(\nu_k - x). \tag{5.14}$$

In fact, we have the more general result

$$\begin{aligned} \partial_x\partial_y \ln \begin{vmatrix} \phi_{2k}(x+x_0) & \phi_{2k}(y+x_0) \\ \phi_{2k+1}(x+x_0) & \phi_{2k+1}(y+x_0) \end{vmatrix} &= \partial_x\partial_y \ln \begin{vmatrix} \Phi(x;\nu_k) & \Phi(y;\nu_k) \\ \Phi'(x;\nu_k) & \Phi'(y;\nu_k) \end{vmatrix} \\ &= \partial_x\partial_y \ln[\Phi(x+y;\nu_k)(\wp(x)-\wp(y))] \\ &= \wp(x+y) - \wp(\nu_k - x - y) + \frac{\wp'(x)\wp'(y)}{(\wp(x)-\wp(y))^2}, \end{aligned}$$

from which (5.14) arises as the $y \to 0$ limit.

It remains to show that the Laurent series of (5.13) (or, equivalently, of (5.14)) determines the parameters of $\Phi(x;\nu_k)$. Set

$$\zeta(\nu_k) - \zeta(x) - \zeta(\nu_k - x) - \lambda_k = -\frac{1}{x} - \lambda_k + \sum_{l=0} F_l \, \frac{x^{l+1}}{(l+1)!} \tag{5.15}$$

or, equivalently,

$$\wp(x) - \wp(\nu_k - x) = \frac{1}{x^2} + \sum_{l=0} \frac{F_l}{l!} \, x^l. \tag{5.16}$$

While the coefficients F_l in these expansions depend on $k = 1, 2$, we will avoid including this in our notation; certainly, the combinations of these coefficients that give g_2 and g_3 are independent of k. Now the left-hand side of (5.15) has the expansion

$$-\frac{1}{x} - \lambda_k - \wp(\nu_k)\,x + \wp'(\nu_k)\,\frac{x^2}{2} + (2c_2 - \wp''(\nu_k))\,\frac{x^3}{3!} + \cdots,$$

while that of (5.16) begins with

$$\frac{1}{x^2} + c_2\,x^2 + c_3\,x^4 + \cdots - \left\{\wp(\nu_k) - x\wp'(\nu_k) + \frac{x^2}{2}\wp''(\nu_k) + \cdots\right\}.$$

From either of these, we see that

$$F_0 = -\wp(\nu_k), \qquad F_1 = \wp'(\nu_k), \qquad F_2 = 2c_2 - \wp''(\nu_k),$$

whereupon utilizing (A.4) (see the appendix) we obtain

$$c_2 = \frac{F_2 + 6F_0^2}{12} = \frac{g_2}{20} \quad \text{and} \quad g_3 = 6F_0^3 - F_1^2 + \frac{5}{3}F_0F_2. \tag{5.17}$$

Thus, as stated in Theorem 2, we may obtain the parameters of the elliptic functions from the Laurent expansion (5.15) for either choice of k, the combinations of the coefficients in (5.17) being independent of k. The constant terms in the two expansions then determine ν_1 and ν_2 via $F_0 = -\wp(\nu_k; g_2, g_3)$.

We have now established all of Theorem 2. It is perhaps useful to conclude the section with a lemma that implements the theorem.

LEMMA 3. *Let*

$$\partial_x\partial_y \ln \begin{vmatrix} \phi_{2k}(x+x_0) & \phi_{2k}(y+x_0) \\ \phi_{2k+1}(x+x_0) & \phi_{2k+1}(y+x_0) \end{vmatrix}_{y=0} = -\frac{1}{x} - \lambda_k + \sum_{l=0} F_l\,\frac{x^{l+1}}{(l+1)!}$$
$$= \frac{h'(0)h'(x)}{(h(x)-h(0))^2},$$

where $h(x) = \phi_{2k}(x+x_0)/\phi_{2k+1}(x+x_0)$. *Set* $h_k = h^{(k+1)}(0)/(k+1)!\,h'(0)$. *Then*

$$F_0 = -\begin{vmatrix} h_1 & 1 \\ h_2 & h_1 \end{vmatrix}, \qquad F_1 = 2\begin{vmatrix} h_1 & 1 & 0 \\ h_2 & h_1 & 1 \\ h_3 & h_2 & h_1 \end{vmatrix}, \qquad F_2 = -6\begin{vmatrix} h_1 & 1 & 0 & 0 \\ h_2 & h_1 & 1 & 0 \\ h_3 & h_2 & h_1 & 1 \\ h_4 & h_3 & h_2 & h_1 \end{vmatrix}.$$

6. Examples. We shall now consider the classical addition theorems of the Jacobi elliptic functions and then the functional equations (1.4) and (1.7) as examples of our theory. We have collected several standard results pertaining to elliptic functions that are of use in our computations in the appendix.

Example 1. As a first application of our theory, we consider the addition theorems for the Jacobi elliptic functions $\mathrm{dn}(x)$, $\mathrm{cn}(x)$, and $\mathrm{sn}(x)$, where $\mathrm{dn}(x) \equiv \mathrm{dn}(x|m)$ and so on. These may be cast in the form of (1.1) as

$$\mathrm{dn}(x+y) = \frac{\begin{vmatrix} \mathrm{cn}'(x) & \mathrm{cn}'(y) \\ \mathrm{cn}(x) & \mathrm{cn}(y) \end{vmatrix}}{\begin{vmatrix} \mathrm{sn}'(x) & \mathrm{sn}'(y) \\ \mathrm{sn}(x) & \mathrm{sn}(y) \end{vmatrix}} \quad \text{(Jacobi)}, \qquad \mathrm{cn}(x+y) = \frac{1}{k^2}\frac{\begin{vmatrix} \mathrm{dn}'(x) & \mathrm{dn}'(y) \\ \mathrm{dn}(x) & \mathrm{dn}(y) \end{vmatrix}}{\begin{vmatrix} \mathrm{sn}'(x) & \mathrm{sn}'(y) \\ \mathrm{sn}(x) & \mathrm{sn}(y) \end{vmatrix}},$$

and

$$\operatorname{sn}(x+y) = \frac{\begin{vmatrix} 1 & 1 \\ \operatorname{sn}^2(x) & \operatorname{sn}^2(y) \end{vmatrix}}{\begin{vmatrix} \operatorname{sn}'(x) & \operatorname{sn}'(y) \\ \operatorname{sn}(x) & \operatorname{sn}(y) \end{vmatrix}} \quad \text{(Cayley)}.$$

Let us now apply our theorem to the first equality. The first step is to choose an appropriate generic point x_0. This means that we wish x_0 to be a regular point for $\operatorname{cn}(x)$, $\operatorname{sn}(x)$, and $\operatorname{dn}(2x)$ as well as

$$0 \neq \begin{vmatrix} \operatorname{cn}'(x_0) & \operatorname{cn}''(x_0) \\ \operatorname{cn}(x_0) & \operatorname{cn}'(x_0) \end{vmatrix} = 1 - m + m \operatorname{cn}^4(x_0),$$

$$0 \neq \begin{vmatrix} \operatorname{sn}'(x_0) & \operatorname{sn}''(x_0) \\ \operatorname{sn}(x_0) & \operatorname{sn}'(x_0) \end{vmatrix} = 1 - m \operatorname{sn}^4(x_0).$$

Thus we can take $x_0 = 0$ for this example.

Using (5.11), we find that

$$-2\lambda_1 = \partial_x \ln \operatorname{cn}'(x)\big|_{x=0} = 0 \quad \text{and} \quad -2\lambda_2 = \partial_x \ln \operatorname{sn}'(x)\big|_{x=0} = 0.$$

Further, with $h(x) = \phi_2(x)/\phi_3(x) = \operatorname{cn}'(x)/\operatorname{cn}(x)$, we obtain

$$F(x) = \frac{1 - m + m \operatorname{cn}^4(x)}{\operatorname{sn}^2(x)\operatorname{dn}^2(x)} = \frac{1}{x^2} + \frac{1-2m}{3} + \frac{1 + 14m - 14m^2}{15}x^2 + \cdots,$$

while with $h(x) = \phi_4(x)/\phi_5(x) = \operatorname{sn}'(x)/\operatorname{sn}(x)$, we obtain

$$F(x) = \frac{1 - m \operatorname{sn}^4(x)}{\operatorname{sn}^2(x)} = \frac{1}{x^2} + \frac{1+m}{3} + \frac{1 - 16m + m^2}{15}x^2 + \cdots.$$

In both cases, we find that

$$g_2 = \frac{4}{3}(1 - m + m^2) \quad \text{and} \quad g_3 = \frac{4}{27}(m-2)(2m-1)(m+1)$$

(the required equality providing a nontrivial check), which means that

$$e_1 = \frac{2-m}{3}, \qquad e_2 = \frac{2m-1}{3}, \quad \text{and} \quad e_3 = \frac{-1-m}{3}.$$

Further,

$$\wp(\nu_1) = \frac{2m-1}{3} \quad \text{and} \quad \wp(\nu_2) = \frac{-1-m}{3}.$$

Comparison with (A.7) and (A.9) (see the appendix) shows that $\omega = K(m)$, $\omega' = iK'(m)$, $\nu_1 = K(m) + iK'(m)$, and $\nu_2 = K'(m)$. We may also calculate $f(x) = 1/\operatorname{sn}^2(x)$, and upon using (A.13) (see the appendix), our identity may be rewritten as

$$\operatorname{dn}(x+y) = \frac{\Phi(x+y; K(m) + iK'(m))}{\Phi(x+y; iK'(m))}$$

$$= \frac{\begin{vmatrix} \Phi(x;K(m)+iK'(m)) & \Phi(y;K(m)+iK'(m)) \\ \Phi(x;K(m)+iK'(m))' & \Phi(y;K(m)+iK'(m))' \end{vmatrix}}{\begin{vmatrix} \Phi(x;iK'(m)) & \Phi(y;iK'(m)) \\ \Phi(x;iK'(m))' & \Phi(y;iK'(m))' \end{vmatrix}}$$

$$= \frac{\frac{1}{\mathrm{sn}^2(x)}\begin{vmatrix} \mathrm{cn}'(x) & \mathrm{cn}'(y) \\ \mathrm{cn}(x) & \mathrm{cn}(y) \end{vmatrix}}{\frac{1}{\mathrm{sn}^2(x)}\begin{vmatrix} \mathrm{sn}'(x) & \mathrm{sn}'(y) \\ \mathrm{sn}(x) & \mathrm{sn}(y) \end{vmatrix}}.$$

The second identity may be treated in the same manner, yielding $\nu_1 = K(m)$ and $\nu_2 = K'(m)$. The third identity is a little different. It may be rewritten as

$$\Phi(x+y;iK'(m)) = \frac{1}{\mathrm{sn}(x+y)} = \frac{\frac{1}{\mathrm{sn}^2(x)}\begin{vmatrix} \mathrm{sn}'(x) & \mathrm{sn}'(y) \\ \mathrm{sn}(x) & \mathrm{sn}(y) \end{vmatrix}}{\frac{1}{\mathrm{sn}^2(x)}\begin{vmatrix} 1 & 1 \\ \mathrm{sn}^2(x) & \mathrm{sn}^2(y) \end{vmatrix}}$$

$$= \frac{\begin{vmatrix} \Phi(x;iK'(m)) & \Phi(y;iK'(m)) \\ \Phi(x;iK'(m))' & \Phi(y;iK'(m))' \end{vmatrix}}{\begin{vmatrix} \Phi^2(x;iK'(m)) & \Phi^2(y;iK'(m)) \\ 1 & 1 \end{vmatrix}}.$$

Now

$$\Phi^2(x;iK'(m)) - \Phi^2(y;iK'(m)) = \wp(x) - \wp(y),$$

and the required identity follows from the general solution by the limiting procedure described in section 3.

Example 2. We shall now determine the general analytic solution of

$$\phi_1(x+y) = \phi_4(x)\phi_5(y) + \phi_4(y)\phi_5(x) = \frac{\begin{vmatrix} \phi_2(x) & \phi_2(y) \\ \phi_3(x) & \phi_3(y) \end{vmatrix}}{\begin{vmatrix} \phi_4(x) & \phi_4(y) \\ \phi_5(x) & \phi_5(y) \end{vmatrix}},$$

where $\phi_2(x) = \phi_4^2(x)$ and $\phi_3(x) = \phi_5^2(x)$. The particular case $\phi_1(x) = \phi_4(x)$ was treated in [8].

Suppose that x_0 is a generic point. Then from

$$0 \neq \begin{vmatrix} \phi_2(x_0) & \phi_2'(x_0) \\ \phi_3(x_0) & \phi_3'(x_0) \end{vmatrix} = 2\phi_4(x_0)\phi_5(x_0)\begin{vmatrix} \phi_4(x_0) & \phi_4'(x_0) \\ \phi_5(x_0) & \phi_5'(x_0) \end{vmatrix},$$

we see that $\phi_4(x_0) \neq 0$, $\phi_5(x_0) \neq 0$, and $\phi_1(2x_0) = 2\phi_4(x_0)\phi_5(x_0) \neq 0$. Further, from (5.11), we find

$$\lambda_1 = \lambda_2 - \frac{1}{2}\left(\frac{\phi_4'(x_0)}{\phi_4(x_0)} + \frac{\phi_5'(x_0)}{\phi_5(x_0)}\right). \tag{6.1}$$

Our strategy is as follows. We will first determine ν_1, ν_2, λ_1, and λ_2, the parameters that describe the elliptic functions and the ratio $\phi_4(x+x_0)\phi_5(x_0)/\phi_5(x+$

$x_0)\phi_4(x_0)$. Then from

$$\begin{aligned}\phi_1(x+2x_0) &= \phi_4(x+x_0)\phi_5(x_0)+\phi_4(x_0)\phi_5(x+x_0)\\ &= \phi_4(x+x_0)\phi_5(x_0)\left(1+\frac{\phi_5(x+x_0)\phi_4(x_0)}{\phi_4(x+x_0)\phi_5(x_0)}\right)\\ &= e^{(\lambda_2-\lambda_1)x}\,\frac{\Phi(x;\nu_1)}{\Phi(x;\nu_2)}\phi_1(2x_0),\end{aligned}$$

we will obtain

$$\phi_4(x+x_0) = \frac{2\phi_4(x_0)e^{(\lambda_2-\lambda_1)x}}{1+\phi_5(x+x_0)\phi_4(x_0)/\phi_4(x+x_0)\phi_5(x_0)}\,\frac{\Phi(x;\nu_1)}{\Phi(x;\nu_2)}, \tag{6.2}$$

with $\phi_5(x+x_0)$ immediately following.

Now from (5.6), we obtain

$$\frac{\phi_{2k}(x+x_0)}{\phi_{2k+1}(x+x_0)}\,\frac{\phi_{2k+1}(x_0)}{\phi_{2k}(x_0)} = 1+\frac{N_k}{D_k}, \tag{6.3}$$

where

$$N_k = \frac{\phi'_{2k}(x_0)}{\phi_{2k}(x_0)}-\frac{\phi'_{2k+1}(x_0)}{\phi_{2k+1}(x_0)}, \qquad D_k = \frac{\phi'_{2k+1}(x_0)}{\phi_{2k+1}(x_0)}+\lambda_k-\frac{\Phi'(x;\nu_k)}{\Phi(x;\nu_k)}.$$

Here $N_1 = 2N_2$ and by our assumption that x_0 was a generic point, these are nonvanishing. Further, from $\phi_2(x)=\phi_4^2(x)$ and $\phi_3(x)=\phi_5^2(x)$, we see that

$$1+\frac{N_1}{D_1} = \left(1+\frac{N_2}{D_2}\right)^2.$$

Expanding this shows that $D_2^2 = (D_2+N_2/2)D_1$, which upon using (6.1) yields

$$\begin{aligned}\left(\frac{\phi'_5(x_0)}{\phi_5(x_0)}+\lambda_2-\frac{\Phi'(x;\nu_2)}{\Phi(x;\nu_2)}\right)^2 = &\left(\frac{\phi'_5(x_0)}{\phi_5(x_0)}+\lambda_2+\frac{N_2}{2}-\frac{\Phi'(x;\nu_2)}{\Phi(x;\nu_2)}\right)\\ &\times\left(\frac{\phi'_5(x_0)}{\phi_5(x_0)}+\lambda_2-\frac{N_2}{2}-\frac{\Phi'(x;\nu_1)}{\Phi(x;\nu_1)}\right).\end{aligned} \tag{6.4}$$

Suppose that ν_2 is finite. Comparing the pole behavior of each side of (6.5) shows that $\nu_1=\nu_2$ and consequently that $N_2=0$, a contradiction. The remaining possibility is that ν_2 is infinite, which we now show to be a consistent solution. This can happen only if the elliptic function degenerates into a hyperbolic or trigonometric function, and without loss of generality we choose the former. In this case

$$\Phi(x;\nu) = \frac{\kappa\sinh\kappa(\nu-x)}{\sinh\kappa\nu\sinh\kappa x}e^{x\kappa\coth\kappa\nu} \quad\text{and}\quad \Phi(x;\infty)=\frac{\kappa}{\sinh\kappa x}. \tag{6.5}$$

Let us then suppose that $\nu_2=\infty$. Utilizing (A.14) and (A.15) (see the appendix), we then must solve

$$\begin{aligned}\left(\frac{\phi'_5(x_0)}{\phi_5(x_0)}+\lambda_2+\kappa\coth\kappa x\right)^2 = &\left(\frac{\phi'_5(x_0)}{\phi_5(x_0)}+\lambda_2+\frac{N_2}{2}+\kappa\coth\kappa x\right)\\ \times&\left(\frac{\phi'_5(x_0)}{\phi_5(x_0)}+\lambda_2-\frac{N_2}{2}+\kappa\coth\kappa(\nu_1-x)+\kappa\coth\kappa x-\kappa\coth\kappa\nu_1\right).\end{aligned}$$

This holds provided that

$$N_2^2 = \frac{4\kappa^2}{\sinh \kappa\nu_1}, \qquad \frac{\phi_5'(x_0)}{\phi_5(x_0)} + \lambda_2 + \frac{N_2}{2} + \kappa \coth\kappa\nu_1 = 0,$$

which determines ν_1, λ_2, and (via (6.1)) λ_1 in terms of $\phi_4(x_0)$, $\phi_5(x_0)$, $\phi_4'(x_0)$, and $\phi_5'(x_0)$. The choice of sign in taking the square root here is arbitrary (just defining ν_1), and we will take $N_2 = -2\kappa/\sinh \kappa\nu_1$. Substituting these into (6.3), we find that

$$\begin{aligned}\frac{\phi_4(x+x_0)}{\phi_5(x+x_0)}\frac{\phi_5(x_0)}{\phi_4(x_0)} &= \frac{\kappa \coth \kappa x - \kappa \coth \kappa\nu_1 + \frac{N_2}{2}}{\kappa \coth \kappa x - \kappa \coth \kappa\nu_1 - \frac{N_2}{2}} \\ &= \coth\left(\frac{\kappa\nu_1}{2}\right) \tanh \kappa \left(\frac{\nu_1}{2} - x\right).\end{aligned}$$

Now employing (6.5) shows

$$\phi_1(x+2x_0) = e^{(\lambda_2 - \lambda_1 + \kappa \coth \kappa\nu_1)x} \frac{\sinh \kappa(\nu_1 - x)}{\sinh \kappa\nu_1} \phi_1(2x_0), \tag{6.6}$$

where the exponential may be rewritten to yield

$$\begin{aligned}\lambda_2 - \lambda_1 + \kappa \coth \kappa\nu_1 &= \frac{\phi_4'(x_0)}{\phi_4(x_0)} - \frac{N_2}{2} + \kappa \coth \kappa\nu_1 = \frac{\phi_4'(x_0)}{\phi_4(x_0)} + \kappa \coth\left(\frac{\kappa\nu_1}{2}\right) \\ &= \frac{\phi_5'(x_0)}{\phi_5(x_0)} + \frac{N_2}{2} + \kappa \coth \kappa\nu_1 = \frac{\phi_5'(x_0)}{\phi_5(x_0)} + \kappa \tanh\left(\frac{\kappa\nu_1}{2}\right).\end{aligned}$$

We now have the information needed to determine $\phi_4(x)$ and $\phi_5(x)$ via (6.2), which gives

$$\phi_4(x+x_0) = \frac{\sinh \kappa(\frac{\nu_1}{2} - x)}{\sinh(\frac{\kappa\nu_1}{2})} e^{\left(\phi_4'(x_0)/\phi_4(x_0) + \kappa \coth(\kappa\nu_1/2)\right)x} \phi_4(x_0), \tag{6.7}$$

$$\phi_5(x+x_0) = \frac{\cosh \kappa(\frac{\nu_1}{2} - x)}{\cosh(\frac{\kappa\nu_1}{2})} e^{\left(\phi_5'(x_0)/\phi_5(x_0) + \kappa \tanh(\kappa\nu_1/2)\right)x} \phi_5(x_0). \tag{6.8}$$

Assembling this provides the following result.

LEMMA 4. *The general analytic solution to* (1.4) *is given by* (6.6), (6.7), *and* (6.8)*, where x_0 is a generic point.*

Example 3. We conclude by showing how our results determine the solutions of the functional equation (1.7):

$$\Psi_1(x+y) = \Psi_2(x+y)\phi_2(x)\phi_3(y) + \Psi_3(x+y)\phi_4(x)\phi_5(y).$$

This equation encompasses as particular cases equations (1.4) (with $\Psi_2 = \Psi_3 = 1$, $\phi_2(x) = \phi_4(x)$, and $\phi_3(x) = \phi_5(x)$) and (1.6) (with ($\phi_2(x) = \phi_3(x)$ and $\phi_4(x) = \phi_5(x)$), which have already been discussed. Because of this, we will consider only the generic case where $\phi_2(x) \neq \lambda\phi_3(x)$, $\phi_4(x) \neq \gamma\phi_5(x)$, and $\Psi_2(x) \neq \delta\Psi_3(x)$ (where λ, γ, and δ are constants) rather than these limits. Our first step is to relate (1.7) to (1.1).

LEMMA 5. *The functions $\Psi_m(x)$ $(m = 1, 2, 3)$ and $\phi_n(x)$ $(n = 2, 3, 4, 5)$ give a solution of equation* (1.7) *if and only if*

$$\frac{\Psi_3(x+y)}{\Psi_2(x+y)} = -\frac{\begin{vmatrix}\phi_2(x) & \phi_2(y) \\ \phi_3(x) & \phi_3(y)\end{vmatrix}}{\begin{vmatrix}\phi_4(x) & \phi_4(y) \\ \phi_5(x) & \phi_5(y)\end{vmatrix}} \tag{6.9}$$

and

$$\frac{\Psi_1(x+y)}{\Psi_2(x+y)} = -\frac{\begin{vmatrix} \phi_2(x)\phi_5(x) & \phi_2(y)\phi_5(y) \\ \phi_3(x)\phi_4(x) & \phi_3(y)\phi_4(y) \end{vmatrix}}{\begin{vmatrix} \phi_4(x) & \phi_4(y) \\ \phi_5(x) & \phi_5(y) \end{vmatrix}}. \tag{6.10}$$

Proof. First, assume that the functions Ψ_m and ϕ_n give a solution of equation (1.7). Then after interchanging x and y in (1.7) and subtracting the result from (1.7), we obtain equation (6.9). Upon substituting the formula for $\Psi_3(x+y)/\Psi_2(x+y)$ into (1.7), we arrive at formula (6.10).

In the other direction, let the functions Ψ_m and ϕ_n now satisfy (6.9) and (6.10). Upon writing the right-hand side of (1.7) as

$$\begin{aligned} &\Psi_2(x+y)\phi_2(x)\phi_3(y) + \Psi_3(x+y)\phi_4(x)\phi_5(y) \\ &\qquad = \Psi_2(x+y)\left(\phi_2(x)\phi_3(y) + \frac{\Psi_3(x+y)}{\Psi_2(x+y)}\phi_4(x)\phi_5(y)\right) \end{aligned} \tag{6.11}$$

and using expression (6.9) for $\Psi_3(x+y)/\Psi_2(x+y)$, we find that the term in brackets in (6.11) rearranges to give precisely the right-hand side of (6.10); substituting for this then yields (1.7) and therefore the required solution. □

We may now apply Theorem 1 to show that if the functions $\Psi_m(x)$ $(m = 1, 2, 3)$ give a solution of (1.7), then we must have the ratios

$$\frac{\Psi_1(x)}{\Psi_2(x)} = c_1 e^{\lambda_1 x}\frac{\Phi(x;\mu_1)}{\Phi(x;\mu_2)}, \qquad \frac{\Psi_3(x)}{\Psi_2(x)} = c_2 e^{\lambda_2 x}\frac{\Phi(x;\mu_3)}{\Phi(x;\mu_4)}. \tag{6.12}$$

Further, because the denominators of (6.9) and (6.10) are the same, Theorem 2 shows that $\mu_4 = \mu_2$. Theorem 1 also determines the functions $\phi_n(x)$ $(n = 2, 3, 4, 5)$ up to a $\mathcal{G}$ action. In fact, given three functions $\Psi_m(x)$ $(m = 1, 2, 3)$ whose ratios satisfy (6.12) with $\mu_4 = \mu_2$, this is also sufficient to guarantee that there are functions $\phi_n(x)$ $(n = 2, 3, 4, 5)$ for which (1.7) holds. To see this, let us substitute these ratios into equation (1.7) to give

$$\begin{aligned} c_1 e^{\lambda_1(x+y)}\Phi(x+y;\mu_1) = {}& \Phi(x+y;\mu_2)\phi_2(x)\phi_3(y) \\ & + c_2 e^{\lambda_2(x+y)}\Phi(x+y;\mu_3)\phi_4(x)\phi_5(y). \end{aligned} \tag{6.13}$$

We will have established sufficiency once we have shown how to construct the functions $\phi_n(x)$. This will be achieved by utilizing various properties of the functions $\Phi(x;\nu)$.

Lemma 6. *The Baker–Akhiezer functions $\Phi(x;\nu)$ satisfy the equations*

$$\Phi(x+\alpha;\nu) = -e^{(\zeta(\alpha-\nu)+\zeta(\nu)-\zeta(\alpha))x}\Phi(\alpha;\nu)\,\frac{\Phi(x;\nu-\alpha)}{\Phi(-x;\alpha)} \tag{6.14}$$

and

$$\begin{aligned} ce^{\gamma(x+y)}\,\Phi(x+y;\nu_1+\nu_2) = {}& \Phi(x+y;\nu_1)\,\Phi(x;\nu_2)\,\Phi(y;\nu_2) \\ & - \Phi(x+y;\nu_2)\,\Phi(x;\nu_1)\,\Phi(y;\nu_1), \end{aligned} \tag{6.15}$$

where $c = \wp(\nu_2) - \wp(\nu_1)$ and $\gamma = \zeta(\nu_1) + \zeta(\nu_2) - \zeta(\nu_1+\nu_2)$.

These follow directly from the definition of $\Phi(x;\nu)$ and the properties of the Weierstrass sigma function; in particular, (6.15) is a consequence of the "three term relation" of the sigma function [23, Chapter 20.53, Example 5].

Upon setting $x \to x+\alpha$ in (6.15), we obtain

$$\begin{aligned} ce^{\gamma(x+y+\alpha)}\Phi(x+y+\alpha;\nu_1+\nu_2) &= \Phi(x+y+\alpha;\nu_1)\Phi(x+\alpha;\nu_2)\Phi(y;\nu_2) \\ &\quad - \Phi(x+y+\alpha;\nu_2)\Phi(x+\alpha;\nu_1)\Phi(y;\nu_1). \end{aligned} \tag{6.16}$$

Now by substituting (6.14) in (6.16) and setting $\mu_1 = \nu_1+\nu_2-\alpha$, $\mu_2 = \nu_1 - \alpha$, and $\mu_3 = \nu_2 - \alpha$, after some rearrangement, we obtain

$$\begin{aligned} c'e^{\lambda'(x+y)}\Phi(x+y;\mu_1) &= \Phi(x+y;\mu_2)\frac{\Phi(x;\mu_3)}{\Phi(-x;\mu_1-\mu_2-\mu_3)}\Phi(y;\mu_1-\mu_2) \\ &\quad + c''e^{\lambda''(x+y)}\Phi(x+y;\mu_3)\frac{\Phi(x;\mu_2)}{\Phi(-x;\mu_1-\mu_2-\mu_3)}\Phi(y;\mu_1-\mu_3) \end{aligned} \tag{6.17}$$

for appropriate constants c', c'', λ', and λ''. This is precisely of the desired form (6.13). Therefore, we have shown the following.

THEOREM 3. *Given functions $\Psi_m(x)$ $(m = 1,2,3)$, there are functions $\phi_n(x)$ $(n = 2,3,4,5)$ for which the functional equation* (1.7) *is true if and only if the following ratios take place:*

$$\frac{\Psi_1(x)}{\Psi_2(x)} = c_1 e^{\lambda_1 x}\frac{\Phi(x;\mu_1)}{\Phi(x;\mu_2)}, \qquad \frac{\Psi_3(x)}{\Psi_2(x)} = c_2 e^{\lambda_2 x}\frac{\Phi(x;\mu_3)}{\Phi(x;\mu_2)}, \tag{6.18}$$

where c_m, λ_m $(m = 1,2)$, and μ_n $(n = 1,2,3)$ are free parameters.

Appendix. Elliptic functions.

A.1. The Weierstrass elliptic functions. The Weierstrass elliptic functions are based on a lattice with periods 2ω and $2\omega'$, where $\Im(\omega'/\omega) > 0$. They satisfy the homogeneity relations

$$\sigma(tx|t\omega,t\omega') = t\sigma(x|\omega,\omega'), \qquad \zeta(tx|t\omega,t\omega') = t^{-1}\zeta(x|\omega,\omega'), \tag{A.1}$$

$$\wp(tx|t\omega,t\omega') = t^{-2}\wp(x|\omega,\omega'). \tag{A.2}$$

Here $\zeta(x) = (\ln\sigma(x))'$ and $\wp(x) = -\zeta'(x)$. These homogeneity relations mean that our function $\Phi(x;\nu) \equiv \Phi(x;\nu|\omega,\omega')$ satisfies

$$\Phi(tx;t\nu|t\omega,t\omega') = t^{-1}\Phi(x;\nu|\omega,\omega').$$

The parameters g_2 and g_3, alternately used to describe the elliptic function, are given by

$$g_2 = 60\sum_{m,n\in\mathbb{Z}}{}' \,\Omega^{-4}, \qquad g_3 = 140\sum_{m,n\in\mathbb{Z}}{}' \,\Omega^{-6},$$

where $\Omega = 2m\omega + 2n\omega'$.

The Weierstrass $\wp$-function, $\wp(x) \equiv \wp(x|\omega,\omega') = \wp(x;g_2,g_3)$, satisfies the differential equation

$$\wp'^2(x) = 4\wp^3(x) - g_2\wp(x) - g_3 = 4\big(\wp^3(x) - 5c_2\wp(x) - 7c_3\big), \tag{A.3}$$

where $c_2 = g_2/20$ and $c_3 = g_3/28$. This means that

$$\wp''(x) = 6\wp^2(x) - 10c_2. \tag{A.4}$$

The terms c_k $(k \geq 4)$ in the Laurent expansion of the Weierstrass $\wp$ function,

$$\wp(x) = \frac{1}{x^2} + \sum_{l=2} c_l\, x^{2l-2}, \tag{A.5}$$

are expressible in terms of c_2 and c_3.

If $e_i \equiv e_i(\omega, \omega')$ $(i = 1, 2, 3)$ denote the roots of the cubic

$$4x^3 - g_2 x - g_3 = 0, \tag{A.6}$$

where

$$\wp'^2(x) = 4(\wp(x) - e_1)(\wp(x) - e_2)(\wp(x) - e_3),$$

the half-periods ω_i are defined by

$$\wp(\omega_i) = e_i, \quad \text{where } \omega_1 = \omega, \quad \omega_2 = \omega + \omega', \quad \text{and} \quad \omega_3 = \omega'.$$

Clearly,

$$e_i(t\omega, t\omega') = t^{-2} e_i(\omega, \omega'). \tag{A.7}$$

Assuming that g_2 and g_3 are real and that the discriminant of (A.6) is positive (the case of interest in this paper), the e_i's are real and may be ordered $e_1 \geq e_2 \geq e_3$.

A.2. The Jacobi elliptic functions. The Jacobi elliptic functions are characterized by a parameter m. Thus, for example, $\mathrm{sn}(x) \equiv \mathrm{sn}(x|m)$ has periods $4K(m)$ and $2iK'(m)$, where $K(m)$ is the complete elliptic function of the first kind. The e_i's are related to the parameter m of the Jacobi elliptic functions by

$$e_1 = \frac{2-m}{3}\frac{K^2(m)}{\omega^2}, \qquad e_2 = \frac{2m-1}{3}\frac{K^2(m)}{\omega^2}, \quad \text{and} \quad e_3 = \frac{-1-m}{3}\frac{K^2(m)}{\omega^2}. \tag{A.8}$$

Thus

$$g_2 = \frac{4}{3}(1 - m + m^2)\frac{K^4(m)}{\omega^4}, \qquad g_3 = \frac{4}{27}(m-2)(2m-1)(m+1)\frac{K^6(m)}{\omega^6}, \tag{A.9}$$

and

$$\frac{\omega}{\omega'} = \frac{iK'(m)}{K(m)}, \qquad \omega = \frac{K(m)}{\sqrt{e_1 - e_3}}. \tag{A.10}$$

We find that

$$\Phi(x;\omega') = \frac{a}{\mathrm{sn}(a\,x)}, \qquad \Phi(x;\omega) = a\,\frac{\mathrm{cn}(a\,x)}{\mathrm{sn}(a\,x)}, \quad \text{and} \quad \Phi(x;\omega+\omega') = a\,\frac{\mathrm{dn}(a\,x)}{\mathrm{sn}(a\,x)}.$$

Here $a = \sqrt{e_1 - e_3}$ converts the periods of Φ based on ω and ω' to those of the Jacobi functions based on $K(m)$ and $iK'(m)$. Equally, we may write this as

$$\Phi(x; t\omega' | t\omega, t\omega') = \frac{1}{\mathrm{sn}(x|m)}, \quad \text{with } t = \sqrt{e_1 - e_3} = \frac{K(m)}{\omega}. \tag{A.11}$$

Thus with these periods in mind, we write

$$\Phi(x; iK'(m)) = \frac{1}{\mathrm{sn}(x)}, \qquad \Phi(x; K(m) + iK'(m)) = \frac{\mathrm{dn}(x)}{\mathrm{sn}(x)}, \tag{A.12}$$

$$\Phi(x; K(m)) = \frac{\mathrm{cn}(x)}{\mathrm{sn}(x)}. \tag{A.13}$$

A.3. Degenerations. When the discriminant of (A.6) vanishes, one (or both) of the periods of the elliptic function vanishes, yielding hyperbolic, trigonometric (or rational) functions. If $e_1 = e_2 = c$, $e_3 = -2c$ (and so $g_2 = 12c^2$, $g_3 = -8c^3$), we then have

$$\sigma(x; 12c^2, -8c^3) = \frac{\sinh \kappa x}{\kappa} e^{-\kappa^2 x^2/6} \quad \text{and} \quad \wp(x; 12c^2, -8c^3) = \frac{\kappa^2}{3} + \frac{\kappa^2}{\sinh^2 \kappa x},$$

where $\kappa = \sqrt{3c}$. In this case,

$$\text{(A.14)} \quad \begin{aligned} \Phi(x;\nu) &= \frac{\kappa \sinh \kappa(\nu - x)}{\sinh \kappa\nu \sinh \kappa x} e^{x\kappa \coth \kappa\nu} = \kappa \left(\coth \kappa x - \coth \kappa\nu\right) e^{x\kappa \coth \kappa\nu}, \\ \Phi'(x;\nu) &= -\kappa\, \Phi(x;\nu) \left(\coth \kappa(\nu - x) + \coth \kappa x - \coth \kappa\nu\right). \end{aligned}$$

In particular,

$$\text{(A.15)} \qquad \Phi(x;\infty) = \frac{\kappa}{\sinh \kappa x} \quad \text{and} \quad \frac{\Phi'(x;\infty)}{\Phi(x;\infty)} = -\kappa \coth \kappa x.$$

GLOBAL ESTIMATES FOR SOLUTIONS OF PARTIAL DIFFERENTIAL EQUATIONS[*]

CHANGMEI LIU[†]

Abstract. For a polynomial $P(\xi)$ in ξ in $\mathbf{R}^n$ with constant complex coefficients, the operator defined by $R(z)f = \mathcal{F}^{-1}((P(\cdot)-z)^{-1}\hat{f})$, where $\wedge$ denotes the Fourier transform and $\mathcal{F}^{-1}$ denotes its inverse, is not bounded from L^2 to L^2 when z is in the spectrum of $P(D)$. What are suitable spaces B and C so that $R(z)$ is bounded from B to C? When $P(\xi)$ is *simply characteristic*, we prove that the operator $R(z)$ is bounded from B_s to B^*_{1-s}, $0 \leq s \leq 1$, where B_s are spaces reasonably smaller than L^2 and B^*_{1-s} are spaces reasonably larger than L^2.

Key words. solutions, estimates, simply characteristic, critical value, Besov space, Fourier transform, inverse Fourier transform

1. Introduction and statements of results.

In recent years, a method for obtaining uniqueness results (and even giving a theoretical inversion procedure) for a class of inverse problems in potential scattering has been developed very successfully. Sylvester and Uhlmann treated an inverse boundary-value problem from electric impedance tomography (see [13]). Nachman and Ablowitz, Beals and Coifman, and Novikov and Henkin studied some problems in inverse scattering (see [11, 3, 12]). These have yielded a breakthrough on some problems for which only linearized approximation had been treatable before and led to the solution of a great number of related inverse problems.

Most of these works treat problems which can, by one device or another, be reduced to problems for the Schrödinger operator $-\Delta+q$. One of the crucial ingredients is a family of solutions $\phi(x,\zeta)$ of $(-\Delta+q)\phi = E\phi$ which behave like so-called inhomogeneous plane waves $\exp(ix\cdot\zeta)$ for large values of the complex vector ζ. One motivation for the study of such solutions comes from the observation that it is possible to have $\Delta e^{ix\cdot\zeta} = Ee^{ix\cdot\zeta}$ with $\zeta^2 = E$ and the energy E fixed, while ζ is made arbitrarily large. Then fixed-energy uniqueness follows from a complex version of the Born limit, first observed in [11]. Following this key idea, inverse boundary-value problems for parabolic, hyperbolic, and other more general partial differential operators were investigated by Isakov [5]. An inverse boundary-value problem for the biharmonic operator at zero energy was considered by Ikehata [6]. More related inverse boundary-value problems and inverse scattering problems can be found in [9, 7, 10] and the references therein.

The direct scattering theory for operators of the form $P_0(D) + V(x,D)$, where $P_0(D)$ is a partial differential operator with real constant coefficients and simply characteristic (see Definition 1.1 below) and V is a short-range perturbation, has been developed successfully by Agmon and Hörmander (see [4]) and many other authors. One of the key ingredients of such a theory is an estimate for the resolvent $(P_0(D) - z)^{-1}$ which remains valid as z approaches the real axis. This clearly cannot happen on

[*] Received by the editors August 15, 1995; accepted for publication (in revised form) February 28, 1996.

[†] Biometrics Unit, Cornell University, 432 Warren Hall, Ithaca, NY 14853 (cl103@cornell.edu).

the space L^2 when z approaches the spectrum of $P_0(D)$, but if $R_0(z) = (P_0(D)-z)^{-1}$ is viewed as an operator from a suitable space X smaller than L^2 to another space Y larger than L^2, then its norm can be shown to remain bounded, independent of the distance from z to the real axis (if z stays in a bounded subset K contained in the complex plane $\mathbf{C}$),

$$\|(P_0(D)-z)^{-1}f\|_Y \leq C\|f\|_X. \tag{1.1}$$

The result of the form of (1.1) is known as the "limiting-absorption principle." To see what spaces X and Y are appropriate, we note, for example, that when $P_0(D) = -\Delta$ in $\mathbf{R}^3$, the operator $(P_0(D)-z^2)^{-1}$, where $z \in \mathbf{C}\backslash\{0\}$, corresponds to convolution by

$$G_0^+(x-y) = \frac{e^{iz|x-y|}}{4\pi|x-y|}.$$

Even for $f \in C_0^\infty$,

$$G_0^+ * f = O(1/|x|) \quad \text{as } |x| \to \infty.$$

Thus $G_0^+ * f$ is in general not in L^2, but it can be shown that $(1+x^2)^{-\frac{\delta}{2}}(G_0^+ * f)$ does belong to L^2 whenever $(1+x^2)^{\frac{\delta}{2}} f$ is in L^2 if $\delta > 1/2$. This motivates the introduction of the weighted L^2 spaces:

$$L_\delta^2 = \left\{ v \in L^2(\mathbf{R}^n) : \int_{\mathbf{R}^n} (1+|x|^2)^\delta |v(x)|^2 dx < \infty \right\}.$$

Estimates of the form (1.1), with $X = L_\delta^2$, $Y = L_{-\delta}^2$, $\delta > 1/2$, and P_0 simply characteristic, were first proved by Agmon in [1]. In [2], Agmon and Hörmander showed that the following class of spaces B_s (the Fourier transform of Besov space $B_2^{s,1}$) and their duals B_s^* (the Fourier transform of Besov space $B_2^{-s,\infty}$) $(-\infty < s < \infty)$,

$$B_s = \left\{ v \in L_{\text{loc}}^2(\mathbf{R}^n) : \sum_{j=1}^\infty R_j^s \left(\int_{\Omega_j} |v|^2 dx \right)^{1/2} < \infty \right\}, \tag{1.2}$$

$$B_s^* = \left\{ u \in L_{\text{loc}}^2(\mathbf{R}^n) : \sup_{j\geq 1} R_j^{-s} \left(\int_{\Omega_j} |u|^2 dx \right)^{1/2} < \infty \right\}, \tag{1.3}$$

where

$$R_0 = 0, \qquad R_j = 2^{j-1}, \quad j = 1, 2, \dots,$$

$$\Omega_j = \{x \in \mathbf{R}^n : R_{j-1} < |x| < R_j\}, \quad j = 1, 2, \dots,$$

capture quite precisely the behavior of the resolvent operator at infinity. The relationship between L_δ^2 and B_s is

$$L_\delta^2 \subset B_s \subset L_s^2 \quad \text{and} \quad L_{-s}^2 \subset B_s^* \subset L_{-\delta}^2$$

for $\delta > s \geq 0$.

Definition 1.1. *Let $P(\xi)$ be a real-valued polynomial of degree m in $\xi \in \mathbf{R}^n$ such that*

$$\Lambda(P_0) = \{\eta \in \mathbf{R}^n : P_0(\xi+\eta) \equiv P_0(\xi)\} = \{0\}.$$

P_0 will be called simply characteristic if

$$\tilde{P}_0(\xi) \le C \left(\sum_{|\alpha|\le 1} |P_0^{(\alpha)}(\xi)| + 1 \right), \quad \xi \in \mathbf{R}^n, \tag{1.4}$$

where

$$\tilde{P}_0(\xi) = \sum_{0\le|\alpha|\le m} |P_0^{(\alpha)}(\xi)|.$$

To study fixed-energy inverse problems in potential scattering for a general class of differential operators $P_0(D)$, we want solutions $\phi(x,\zeta)$ of $(P_0(D)+q)\phi = \lambda\phi$ which behave like $e^{ix\cdot\zeta}$ with $\zeta \in \mathbf{C}^n$, $P_0(\zeta) = \lambda$. The construction of such solutions requires a generalized limiting-absorption estimate for $P_0(D,\zeta) = P_0(D+\zeta) - \lambda$. The first such estimate was obtained by Sylvester and Uhlmann [13] for the Laplacian $-\Delta$ at zero energy ($\zeta^2 = 0$):

$$\|(-\Delta - 2i\zeta\cdot\nabla)^{-1} f\|_{L^2_{-\delta}} \le \frac{C}{|\zeta|} \|f\|_{L^2_{1-\delta}}, \quad 0<\delta<1. \tag{1.5}$$

To obtain an estimate of the form of (1.5) for a general class of differential operators $P_0(D,\zeta) = P_0(D+\zeta) - \lambda$, we first need an analogue of the Agmon–Hörmander estimate (1.1) for complex polynomials. Our main goal in this paper is to give such an estimate. Note that the key point for the validity of estimate (1.5) is that the real and imaginary parts of the symbol $(\xi^2 + 2\xi\cdot\zeta)$ of the differential operator $(-\Delta - 2i\zeta\cdot\nabla)$ with $\zeta = 0$ are linearly independent on the zero set $\{\xi \in \mathbf{R}^n, \xi^2 + 2\xi\cdot\zeta = 0\}$, which allows one to reduce the resolvent operator $(-\Delta - 2i\zeta\cdot\nabla)^{-1}$ to the inverse of the Cauchy–Riemann operator. Inspired by the same spirit, we first classify a class of *simply characteristic* polynomials (see Definition 1.3 below) and then obtain an estimate similar to (1.1) for such complex polynomials. For clarity, let us stress that emphasized *simply characteristic* refers to Definition 1.3 and nonemphasized simply characteristic refers to Definition 1.1 given by Agmon and Hörmander. We also distinguish *critical values* in Definition 1.4 from critical values in the normal sense. We will denote by $\mathcal{F}$ or $\hat{\ }$ the Fourier transform and by $\mathcal{F}^{-1}$ or $\vee$ its inverse. Our main estimate in this paper is as follows.

Theorem 1.2. *Assume that P is* simply characteristic *and let K be a compact subset of $\mathbf{C}$ containing no* critical value *of P in the sense given in Definition* 1.4 *below. If $f \in B_s$, $0 \le s \le 1$, it follows that $R(z)f = \mathcal{F}^{-1}((P(\cdot)-z)^{-1}\hat{f})$ belongs to B^*_{1-s} for $z \in K$ and we have the bound*

$$\|R(z)f\|_{B^*_{1-s}} \le C(n,s,c_P) \sup_{\xi\in\mathbf{R}^n} \frac{1}{\tilde{P}_*(\xi)} \|f\|_{B_s}, \quad z \in K, \tag{1.6}$$

where $C(n,s,c_P)$ depends only on the dimension n, s, and the constant c_P in condition (1.7) *in Definition* 1.3.

Definition 1.3. *Let $P(\xi) = P_1(\xi) + iP_2(\xi)$, $\xi \in \mathbf{R}^n$, be an mth-order polynomial with complex coefficients. We define a* simply characteristic *polynomial P to be one that satisfies*

$$\tilde{P}_*(\xi) \leq c_P(|P(\xi) - z_0| + |\nabla P(\xi)|_*) \tag{1.7}$$

for all $\xi \in \mathbf{R}^n$ and some $z_0 \in \mathbf{C}$, where

$$\tilde{P}_*(\xi) = \sum_{|\alpha| \leq m, |\alpha| \neq 1} |P^{(\alpha)}(\xi)| + |\nabla P(\xi)|_*$$

and

$$|\nabla P(\xi)|_* \overset{\text{def.}}{=} \left[\sum_{i \neq j, 1 \leq i,j \leq m} \left| \det \begin{pmatrix} \frac{\partial P_1}{\partial \xi_i} & \frac{\partial P_1}{\partial \xi_j} \\ \frac{\partial P_2}{\partial \xi_i} & \frac{\partial P_2}{\partial \xi_j} \end{pmatrix} \right|^2 \right]^{1/4}. \tag{1.8}$$

Definition 1.4. *If $\nabla P_1(\xi)$ and $\nabla P_2(\xi)$ are not linearly independent at some point $\xi \in \{\xi \in \mathbf{R}^n : P(\xi) - z = 0\}$, we say that the value z is a* critical value *of P.*

Note that the estimates in Theorem 1.2 are from spaces B_s to spaces B^*_{1-s} for all $0 \leq s \leq 1$. In particular, two endpoints $s = 0$ and $s = 1$ are included, i.e., $(P(D) - z)^{-1}$ is bounded from B_1 to B^*_0 and from B_0 to B^*_1. As in direct-scattering theory, the spaces B_s and B^*_{1-s} capture the behavior of the operator $R(z)f$ at infinity more precisely than weighted L^2 spaces do. Estimates in (1.6) from B_s to B^*_{1-s} for $R(z)f$ also match the "B_s-version limiting-absorption principle" better than weighted L^2 estimates do.

The idea of the proof of Theorem 1.2 basically follows the same idea given by Sylvester and Uhlmann for the operator $(-\Delta - 2i\zeta \cdot \nabla)^{-1}$ in [13]. Using a partition of unity and a change of variables, we reduce the problem to the Cauchy–Riemann equation, for which the symbol is $\xi_1 + i\xi_2$. However, since we deal with estimates in the spaces B_s and B^*_{1-s} instead of weighted L^2 spaces—in particular, the endpoint spaces B_1 and B^*_0—the techniques we use are quite different from those that Sylvester and Uhlmann used. To generalize the estimates to the class of *simply characteristic* polynomials, we follow the approach used by Agmon and Hörmander in obtaining the B_s-version limiting-absorption principle [2].

The details of the proof of Theorem 1.2 are given in sections 2–4. In section 5, we briefly discuss the behavior of the resolvent of a *simply characteristic* differential operator $P(D)$ at infinity, which is a simple application of estimate (1.6).

Estimates of the form of (1.5), the construction of exponentially growing solutions for $P_0(D, \zeta) = P_0(D + \zeta) - \lambda$, and a uniqueness result for a general class of inverse problems were also studied by the author. In particular, an estimate similar to (1.5) for the Laplacian operator Δ at fixed nonzero energy is an immediate consequence of such estimates for a general class of partial differential operators. Then combining the estimate for Δ with estimate (1.6) will derive an estimate like (1.5) for the biharmonic operator Δ^2 at fixed nonzero energy. Therefore, exponentially growing solutions for Δ^2 can be constructed as well. We refer to [8] for the technical details and more applications.

2. Estimates for the model $1/(x_1 + ix_2)$. In this section, we will obtain the main estimate for the special model $1/(x_1 + ix_2)$. First, we recall that the norm for

$v \in B_s$ (introduced in (1.2)) is

$$\|v\|_{B_s} = \sum_{j=1}^{\infty} R_j^s \left(\int_{\Omega_j} |v|^2 dx \right)^{1/2}$$

and the norm for $u \in B_s^*$ (see (1.3)) is defined as

$$\|u\|_{B_s^*} = \sup_{j \geq 1} R_j^{-s} \left(\int_{\Omega_j} |u|^2 dx \right)^{1/2}.$$

For $s > 0$, since

$$\|u\|_{B_s^*}^2 \leq \sup_{R \geq 1} R^{-2s} \int_{|x|<R} |u|^2 dx \leq \frac{2^{2s}}{(1-2^{-2s})} \|u\|_{B_s^*}^2,$$

the norm $\|u\|_{B_s^*}$ is equivalent to $[\sup_{R\geq 1} R^{-2s} \int_{|x|<R} |u|^2 dx]^{1/2}$.

THEOREM 2.1. *Let $f \in B_1(\mathbf{R}^n)$, $n \geq 2$. Define*

$$u = \left(\frac{1}{\xi_1 + i\xi_2} \hat{f}(\xi) \right)^{\vee} = \frac{i}{2\pi} f * \left(\frac{1}{x_1 + ix_2} \right), \tag{2.1}$$

where $*$ represents the convolution with respect to the first two variables. Then there is a constant $C > 0$, depending only on the dimension n, such that

$$\|u\|_{B_0^*} \leq C \|f\|_{B_1}. \tag{2.2}$$

Proof. Write $x = (x', x'')$, where $x' = (x_1, x_2)$ and $x'' = (x_3, \ldots, x_n)$. Then

$$u(x) = \frac{i}{2\pi} \int_{y_1, y_2} \frac{f(y, x'')}{(x_1 - y_1) + i(x_2 - y_2)} dy.$$

To prove (2.2), we first prove the following two lemmas.

LEMMA 2.2. *Assume that $f \in L^1(\mathbf{R}^2) \cap L^2_{\text{loc}}(\mathbf{R}^2)$. Let u be defined by (2.1). Then*

(i)

$$\int_{|x|<R_j} |u(x)|^2 dx \leq C \left[R_j^2 \int_{|y| \leq R_{j+1}} |f(y)|^2 dy + \|f\|_{L^1}^2 \right],$$

and for any integer m with $j - 1 \geq m \geq 0$, we have

(ii)

$$\int_{R_{j-m-1}<|x_1|<R_j} \int_{|x_2|<R_j} |u(x)|^2 dx \leq C \left[R_j^2 \int_{\Omega_j^*} |f(x)|^2 dx + (4^{m+2}) \|f\|_{L^1}^2 \right],$$

where $\Omega_j^* = \{(x_1, x_2) \in \mathbf{R}^2 : R_{j-m-2} \leq |x_1| \leq R_{j+1}, |x_2| \leq R_{j+1}\}$ and the numbers C in both estimates are constants independent of j and m.

Proof. To prove estimate (i), we note that

$$\begin{aligned}\int_{|x|<R_j} |u(x)|^2 dx &= \frac{1}{4\pi^2} \int_{|x|<R_j} \Big[\int_{|y|\le R_{j+1}} \frac{f(y)}{(x_1-y_1)+i(x_2-y_2)} dy \\ &\qquad + \int_{|y|>R_{j+1}} \frac{f(y)}{(x_1-y_1)+i(x_2-y_2)} dy \Big]^2 dx \\ &\le \frac{1}{2\pi^2} \Big[\int_{|x|<R_j} \Big| \int_{|y|\le R_{j+1}} \frac{f(y)}{(x_1-y_1)+i(x_2-y_2)} dy \Big|^2 dx \\ &\qquad + \int_{|x|<R_j} \Big| \int_{|y|>R_{j+1}} \frac{f(y)}{(x_1-y_1)+i(x_2-y_2)} dy \Big|^2 dx \Big].\end{aligned}$$

For the first integral, we have

$$\begin{aligned}&\int_{|x|<R_j} \Big| \int_{|y|\le R_{j+1}} \frac{f(y)}{(x_1-y_1)+i(x_2-y_2)} dy \Big|^2 dx \\ &\quad = \underbrace{\int_{|x|<R_j} \Big| \int_{|y|\le R_{j+1}}}_{|x-y|\le 3R_j} \frac{f(y)}{(x_1-y_1)+i(x_2-y_2)} dy \Big|^2 dx \\ &\quad \text{(by Young's inequality)} \\ &\quad \le \left(\int_{|t|<3R_j} \frac{1}{|t|} dt \right)^2 \int_{|y|\le R_{j+1}} |f(y)|^2 dy \\ &\quad \le (6\pi)^2 R_j^2 \int_{|y|\le R_{j+1}} |f(y)|^2 dy.\end{aligned}$$

For the second integral, we have

$$\begin{aligned}&\underbrace{\int_{|x|<R_j} \Big| \int_{|y|>R_{j+1}}}_{|x-y|\ge R_j} \frac{f(y)}{(x_1-y_1)+i(x_2-y_2)} dy \Big|^2 dx \\ &\qquad \le \frac{1}{R_j^2} \int_{|x|<R_j} \left(\int_{\mathbf{R}^2} |f(y)| dy \right)^2 dx \\ &\qquad = \pi \left(\int_{\mathbf{R}^2} |f(y)| dy \right)^2.\end{aligned}$$

Combining the two terms, we have

$$\begin{aligned}\int_{|x|<R_j} |u(x)|^2 dx &\le \frac{1}{2\pi^2} \left[(6\pi)^2 R_j^2 \int_{|y|\le R_{j+1}} |f(y)|^2 dy + \pi \|f(\cdot)\|^2_{L^1(\mathbf{R}^2)} \right] \\ &\le 18 R_j^2 \int_{|y|\le R_{j+1}} |f(y)|^2 dy + \frac{1}{2\pi} \|f(\cdot)\|^2_{L^1(\mathbf{R}^2)}.\end{aligned}$$

To prove the second estimate, we rewrite the integral in the left-hand side as:

$$\int_{R_{j-m-1}\le|x_1|\le R_j} \int_{|x_2|\le R_j} |u(x)|^2 dx$$

$$= \frac{1}{4\pi^2}\int_{R_{j-m-1}\le|x_1|\le R_j}\int_{|x_2|\le R_j}\left|\int_{\mathbf{R}^2}\frac{f(y)}{(x_1-y_1)+i(x_2-y_2)}dy\right|^2 dx$$
$$= \frac{1}{4\pi^2}\left[\int_{R_{j-m-1}\le|x_1|\le R_j}\int_{|x_2|\le R_j}\left|\left(\int_{\Omega_j^*}+\int_{\mathbf{R}^2\backslash\Omega_j^*}\right)\frac{f(y)}{(x_1-y_1)+i(x_2-y_2)}dy\right|^2 dx\right].$$

For the first integral, we have by Young's inequality that

$$\int_{R_{j-m-1}\le|x_1|\le R_j}\int_{|x_2|\le R_j}\left|\int_{\Omega_j^*}\frac{f(y)}{(x_1-y_1)+i(x_2-y_2)}dy\right|^2 dx$$
$$\le\left(\int_{|t|\le 6R_j}\frac{1}{|t|}dt\right)^2\int_{\Omega_j^*}|f(y)|^2dy$$

since when $R_{j-m-1}<|x_1|<R_j$, $|x_2|\le R_j$, and $y\in\Omega_j^*$,

$$|x-y|\le|x_1-y_1|+|x_2-y_2|\le|x_1|+|y_1|+|x_2|+|y_2|=6R_j.$$

For the second integral, we have

$$\int_{R_{j-m-1}\le|x_1|\le R_j}\int_{|x_2|\le R_j}\left|\int_{\mathbf{R}^2\backslash\Omega_j^*}\frac{f(y)}{(x_1-y_1)+i(x_2-y_2)}dy\right|^2 dx$$
$$\le\frac{1}{R_{j-m-2}^2}\int_{R_{j-m-1}\le|x_1|\le R_j}\int_{|x_2|\le R_j}\left(\int_{\mathbf{R}^2\backslash\Omega_j^*}|f(y)|dy\right)^2dx$$
$$\le\frac{R_j^2}{R_{j-m-2}^2}\|f(\cdot)\|^2_{L^1(\mathbf{R}^2)},$$

since when $R_{j-m-1}<|x_1|<R_j$, $|x_2|\le R_j$, and $y\in\mathbf{R}^2\backslash\Omega_j^*$,

$$|x-y|\ge|x_1-y_1|\ge R_{j-m-2}.$$

Combing the two terms, we have

$$\int_{R_{j-m-1}\le|x_1|\le R_j}\int_{|x_2|\le R_j}|u(x)|^2dx$$
$$\le\left(\frac{144}{2}\right)R_j^2\int_{\Omega_j^*}|f(y)|^2dy+\frac{1}{2\pi^2}\frac{R_j^2}{R_{j-m-2}^2}\|f(\cdot)\|^2_{L^1(\mathbf{R}^2)}$$
$$=72R_j^2\int_{\Omega_j^*}|f(x)|^2dx+\frac{1}{2\pi^2}(4^{m+2})\|f(\cdot)\|^2_{L^1(\mathbf{R}^2)}.\qquad\square$$

LEMMA 2.3. *Let $n\ge 3$ and let $x=(x',x'')$, where $x'=(x_1,x_2)$ and $x''=(x_3,\dots,x_n)$. If $f\in B_1(\mathbf{R}^n)$, then*

(i) $\int_{\mathbf{R}^2}\|f(x',\cdot)\|_{L^2(\mathbf{R}^{n-2})}dx'\le\sqrt{\pi}\|f\|_{B_1}$ *and*

(ii) $(\int_{\mathbf{R}^{n-2}}\|f(\cdot,x'')\|^2_{L^1(\mathbf{R}^2)}dx'')^{1/2}\le\sqrt{\pi}\|f\|_{B_1}$.

Proof. (i) Let $f_j=f$ in Ω_j and $f_j=0$ elsewhere. Then by the Cauchy–Schwartz inequality,

$$\int_{\mathbf{R}^2}\|f_j(x',\cdot)\|_{L^2(\mathbf{R}^{n-2})}dx'\le(\pi R_j^2)^{1/2}\left(\int_{\mathbf{R}^2}\|f_j(x',\cdot)\|^2_{L^2(\mathbf{R}^{n-2})}dx'\right)^{1/2}$$
$$\le\sqrt{\pi}R_j\left(\int_{\Omega_j}|f(x)|^2dx\right)^{1/2}.$$

Thus since $f = \sum_j f_j$, we obtain

$$\int_{\mathbf{R}^2} \|f(x',\cdot)\|_{L^2(\mathbf{R}^{n-2})} dx' \le \sum_j \int_{\mathbf{R}^2} \|f_j(x',\cdot)\|_{L^2(\mathbf{R}^{n-2})} dx' \le \sqrt{\pi}\|f\|_{B_1},$$

where the second inequality follows from the definition of the B_1 norm.

(ii) The Minkowski's inequality for integrals shows that

$$\left(\int_{\mathbf{R}^{n-2}} \|f(\cdot,x'')\|^2_{L^1(\mathbf{R}^2)} dx''\right)^{1/2} \le \int_{\mathbf{R}^2} \|f(x',\cdot)\|_{L^2(\mathbf{R}^{n-2})} dx',$$

and then (ii) follows from (i). □

Lemma 2.3 shows that the norm in B_1 is a majorant for the above mixed L^1 and L^2 norms (compare with Theorem 14.1.2 in [4]).

Now we are in a position to prove (2.2). By the definition of the B_0^* norm, we need to show that $\sup_j \int_{\Omega_j} |u|^2 dx$ can be bounded by $C\|f\|_{B_1}$. For dimension $n = 2$, (2.2) follows immediately from Lemma 2.2(i). For $n \ge 3$, we cover Ω_j in the following way:

$$\begin{aligned} \Omega_j &= \{x \in \mathbf{R}^n :\ R_{j-1} < |x| < R_j\} \\ &\subset \cup_{k=1}^n \{x \in \mathbf{R}^n : a_j < |x_k| < R_j,\ |x_l| < R_j,\ 1 \le l \le n,\ l \ne k\} \\ &\overset{\text{def.}}{=} \sum_{k=1}^n W_k^j, \end{aligned} \tag{2.3}$$

where $a_j = R_{j-1}/\sqrt{n}$ and for each k,

$$W_k^j \subset \{x \in \mathbf{R}^n : a_j < |x| < b_j\} \tag{2.4}$$

with $b_j = \sqrt{n}R_j$ (see Figure 2.1).

Let m be a positive integer such that $2^{m-1} \le \sqrt{n} \le 2^m$. Then

$$\begin{aligned} \int_{\Omega_j} |u(x',x'')|^2 dx &\le \sum_{k=1}^n \int_{W_k^j} |u(x',x'')|^2 dx \\ &= \sum_{k=1}^n \int_{a_j<|x_k|<R_j} \int_{|x_l|<R_j, l\ne k} |u(x',x'')|^2 dx_1 \cdots d\hat{x}_k \cdots dx_n dx_k. \end{aligned} \tag{2.5}$$

If $k = 1$ or 2—say $k = 1$—then

$$\begin{aligned} &\int_{a_j<|x_1|<R_j} \int_{|x_l|<R_j, l\ge 2} |u(x',x'')|^2 dx_1 \cdots dx_n \\ &\qquad \le C_1 \int_{|x''|<R_j} \left(\int_{R_{j-m-1}<|x_1|<R_j} \int_{|x_2|<R_j} |u(x',x'')|^2 dx'\right) dx'' \\ &\qquad\qquad \text{(by Lemma 2.2(ii))} \\ &\qquad \le C_2 \int_{|x''|<R_j} \left[R_j^2 \int_{\Omega_j^*} |f(y,x'')|^2 dy + \|f(\cdot,x'')\|^2_{L^1(\mathbf{R}^2)}\right] dx'' \\ &\qquad\qquad \text{(by(2.4))} \\ &\qquad \le C_2 R_j^2 \int_{R_{j-m-2}<|(y,x'')|<\sqrt{n}R_{j+1}} |f(y,x'')|^2 dy dx'' \end{aligned} \tag{2.6}$$

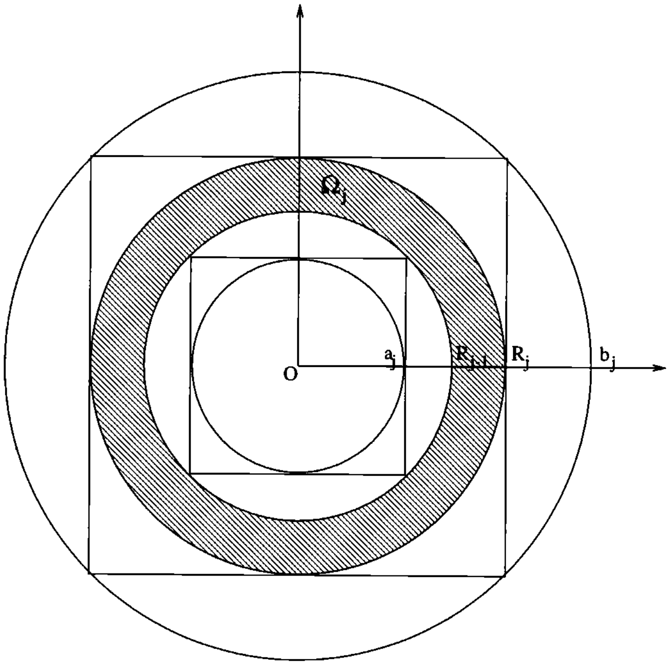

FIG. 2.1. *The graph of* Ω_j.

$$
\begin{aligned}
&+C_2 \int_{|x''|<R_j} \|f(\cdot, x'')\|^2_{L^1(\mathbf{R}^2)} dx'' \\
&\text{(by Lemma 2.3(ii))} \\
\le\ & C(4^{m+2})\|f\|^2_{B_1(\mathbf{R}^n)} + C\|f\|^2_{B_1(\mathbf{R}^n)}.
\end{aligned}
$$

If $k \geq 3$—say $k = 3$—then

$$
\begin{aligned}
&\int_{R_{j-1}/\sqrt{n}<|x_3|<R_j} \int_{|x_l|<R_j, l\neq 3} |u(x', x'')|^2 dx_1 \cdots d\hat{x}_3 \cdots dx_n dx_3 \\
&\quad \le C_3 \int_{R_{j-m-1}<|x_3|<R_j} \int_{|x_l|<R_j, l\neq 3,1,2} \left(\int_{|x'|<R_j} |u(x', x'')|^2 dx' \right) dx'' \\
&\quad \text{(by Lemma 2.2(i))} \\
&\quad \le C_3 \int_{R_{j-m-1}<|x_3|<R_j} \int_{|x_l|<R_j, l\neq 3,1,2} \left[18R_j^2 \int_{|y|<R_{j+1}} |f(y, x'')|^2 dy \right. \\
&\quad \left. + \frac{1}{2\pi} \|f(\cdot, x'')\|^2_{L^1(\mathbf{R}^2)} \right] dx'' \\
&\quad \text{(by (2.4))} \qquad (2.7) \\
&\quad \le C_3 R_j^2 \int_{R_{j-m-1}<|(y,x'')|<\sqrt{n}R_{j+1}} |f(y, x'')|^2 dy dx'' \\
&\quad + C_3 \int_{|x''|<R_j} \|f(\cdot, x'')\|^2_{L^1(\mathbf{R}^2)} dx'' \\
&\quad \text{(by Lemma 2.3(ii))} \\
&\quad \le C_3(4^{m+2})\|f\|^2_{B_1(\mathbf{R}^n)} + C_3\|f\|^2_{B_1(\mathbf{R}^n)}.
\end{aligned}
$$

Thus for each k,

$$\int_{W_k^j} |u(x',x'')|^2 dx \leq C_k(4^{m+2}\|f\|^2_{B_1(\mathbf{R}^n)} + \|f\|^2_{B_1(\mathbf{R}^n)}), \tag{2.8}$$

with m depending only on the dimension n.

Returning to (2.5), we obtain

$$\|u\|_{B_0^*} = \sup_{j\geq 1}\left(\int_{\Omega_j} |u(x)|^2 dx\right)^{1/2} \leq C\|f\|_{B_1(\mathbf{R}^n)}. \qquad \square$$

COROLLARY 2.4. *If $f \in B_0$ and $u = f * (1/(x_1 + ix_2))$, then*

$$\|u\|_{B_1^*} \leq C\|f\|_{B_0}.$$

Proof. Note that B_1^* is the dual space of B_1. Thus

$$\begin{aligned}
\|u\|_{B_1^*} &= \sup_{\|g\|_{B_1}=1}\left|\int u(x)\overline{g(x)}dx\right| \\
&= \frac{1}{2\pi}\sup_{\|g\|_{B_1}=1}\left|\int_{x''}\int_{x'}\left(\int_y \frac{f(y,x'')}{(x_1-y_1)+i(x_2-y_2)}dy\right)\overline{g(x',x'')}dx'dx''\right| \\
&= \frac{1}{2\pi}\sup_{\|g\|_{B_1}=1}\left|\int_{x''}\int_{x'}\int_y \frac{f(y,x'')\overline{g(x',x'')}}{(x_1-y_1)+i(x_2-y_2)}dydx'dx''\right| \\
&\quad \text{(by Fubini's Theorem)} \\
&= \frac{1}{2\pi}\sup_{\|g\|_{B_1}=1}\left|\int_{x''}\int_y\left(\int_{x'} \frac{\overline{g(x',x'')}}{(x_1-y_1)+i(x_2-y_2)}dx'\right)f(y,x'')dydx''\right| \\
&\leq \frac{1}{2\pi}\sup_{\|g\|_{B_1}=1}\sum_{j=1}^{\infty}\int_{\Omega_j}|f(y,x'')|\left|\int_{x'} \frac{\overline{g(x',x'')}}{(x_1-y_1)+i(x_2-y_2)}dx'\right|dydx'' \\
&\leq \frac{1}{2\pi}\sup_{\|g\|_{B_1}=1}\sum_{j=1}^{\infty}\left(\int_{\Omega_j}|f(y,x'')|^2dydx''\right)^{1/2} \\
&\times\left(\int_{\Omega_j}\left|\int_{x'} \frac{\overline{g(x',x'')}}{(x_1-y_1)+i(x_2-y_2)}dx'\right|^2dydx''\right)^{1/2} \\
&\leq \frac{1}{2\pi}\sup_{\|g\|_{B_1}=1}\left[\sum_{j=1}^{\infty}\left(\int_{\Omega_j}|f(y,x'')|^2dydx''\right)^{1/2}\right. \\
&\times\left.\sup_{j\geq 1}\left(\int_{\Omega_j}\left|\int_{x'} \frac{\overline{g(x',x'')}}{(x_1-y_1)+i(x_2-y_2)}dx'\right|^2dydx''\right)^{1/2}\right] \\
&\quad \text{(by Theorem 2.1)} \\
&\leq \left[\sum_{j=1}^{\infty}\int_{\Omega_j}|f(y,x'')|^2dydx''\right)^{1/2}\Bigg]\sup_{\|g\|_{B_1}=1}(C\|\bar{g}\|_{B_1}) \\
&= C\|f\|_{B_0}.
\end{aligned}$$

Thus $u = f * (1/(x_1 + ix_2))$ is in B_1^*. $\square$

Corollary 2.5. *Let $0 < s < 1$. If $f \in B_{1-s}$, then $f * (1/(x_1 + ix_2)) \in B_s^*$ and*

$$\left\| f * \left(\frac{1}{x_1 + ix_2} \right) \right\|_{B_s^*} \leq C_s \|f\|_{B_{1-s}},$$

where C_s depends only on s and the dimension n.

Proof. First if $u \in B_0^*$, we have

$$\begin{aligned}
\|u\|_{L^2_{-s}}^2 &= \int (1 + |x|^2)^{-s} |u(x)|^2 dx \\
&= \sum_{j=1}^{\infty} \int_{\Omega_j} (1 + |x|^2)^{-s} |u(x)|^2 dx \\
&\leq \sum_{j=1}^{\infty} R_{j-1}^{-2s} \int_{\Omega_j} |u(x)|^2 dx \\
&= 2^{2s} \sum_{j=1}^{\infty} R_j^{-2s} \int_{\Omega_j} |u(x)|^2 dx \\
&\leq 4 \left[\sum_{j \leq k} R_j^{-2s} \int_{\Omega_j} |u(x)|^2 dx + \sum_{j > k} R_j^{-2s} \int_{\Omega_j} |u(x)|^2 dx \right] \\
&= 4 \left[\sum_{j \leq k} R_j^{2-2s} \frac{1}{R_j^2} \int_{\Omega_j} |u(x)|^2 dx + \sum_{j > k} R_j^{-2s} \int_{\Omega_j} |u(x)|^2 dx \right] \\
&\leq C \left[R_k^{2-2s} \frac{1}{1 - 2^{-(2-2s)}} \|u\|_{B_1^*}^2 + R_k^{-2s} \|u\|_{B_0^*}^2 \right]
\end{aligned}$$

for each $k \geq 1$, where C is independent of k. Thus

$$\|u\|_{L^2_{-s}} \leq \sqrt{C_s}/2 [R_k^{1-s} \|u\|_{B_1^*} + R_k^{-s} \|u\|_{B_0^*}].$$

Now let $f = \sum_{k=1}^{\infty} f_k$, where $f_k = f|_{\Omega_k}$. Then with $u_k = f_k * 1/(x_1 + ix_2)$,

$$\begin{aligned}
\|u\|_{L^2_{-s}} &= \left\| \sum_{k=1}^{\infty} u_k \right\|_{L^2_{-s}} \\
&\leq \sum_{k=1}^{\infty} \|u_k\|_{L^2_{-s}} \\
&\leq C_s \sum_k [R_k^{1-s} \|u_k\|_{B_1^*} + R_k^{-s} \|u_k\|_{B_0^*}] \\
&\quad \text{(by Theorem 2.1 and Corollary 2.4)} \\
&\leq C_s \sum_k [R_k^{1-s} \|f_k\|_{B_0} + R_k^{-s} \|f_k\|_{B_1}] \\
&= C_s \sum_k \left[R_k^{1-s} \left(\int_{\Omega_k} |f(x)|^2 dx \right)^{1/2} + R_k^{-s} R_k \left(\int_{\Omega_k} |f(x)|^2 dx \right)^{1/2} \right] \\
&= C_s \sum_k R_k^{1-s} \left(\int_{\Omega_k} |f(x)|^2 dx \right)^{1/2} \\
&= C_s \|f\|_{B_{1-s}}.
\end{aligned}$$

Since $L^2_{-s} \subset B^*_s$,

$$\|u\|_{B^*_s} \le C\|u\|_{L^2_{-s}} \le C_s\|f\|_{B_{1-s}}. \qquad \square$$

Note that although the map $f \to f * (1/(x_1 + ix_2))$ is bounded from L^2_δ to $L^2_{-1+\delta}$ for $0 < \delta < 1$, it is bounded from neither L^2_1 to L^2_0 nor L^2_0 to L^2_{-1}. Thus the spaces B_s provide appropriate endpoint substitutes for the weighted L^2 spaces.

3. Estimate for general distribution $(1/(H_1(\xi) + iH_2(\xi)))$.

We now generalize the result for the particular model $1/(x_1 + ix_2)$ to a general distribution $(1/(H_1(\xi)+ iH_2(\xi)))^\vee(x)$. Before doing so, we need some additional definitions and lemmas, which can be found in [4, Chapter 14].

Let $c_1, c_2, \ldots$ be a sequence of positive numbers such that for some constant $M > 0$,

$$\frac{c_j}{M} \le c_{j+1} \le Mc_j, \quad j = 1, 2, \ldots. \tag{3.1}$$

Define

$$B_{\{c\}} = \left\{ v \in L^2_{\text{loc}}(\mathbf{R}^n) : \sum_{j=1}^\infty c_j \left(\int_{\Omega_j} |v|^2 dx \right)^{1/2} < \infty \right\}.$$

Then its dual space is

$$B^*_{\{c\}} = \left\{ u \in L^2_{\text{loc}}(\mathbf{R}^n) : \sup_{j \ge 1} c_j^{-1} \left(\int_{\Omega_j} |u|^2 dx \right)^{1/2} < \infty \right\}.$$

Lemma 3.1. *Let N be the smallest integer such that $2^N > M$. Then there is a constant C_M such that if*

$$T : \ L^2_{-N} \to L^2_{-N}$$

is bounded and

$$T : \ L^2_N \to L^2_N$$

is bounded with both norms $\le A$, it follows that

$$T : \ B_{\{c\}} \to B_{\{c\}}$$

is bounded with norm $\le C_M A$.

Lemma 3.2. *Let $r \in C^N(\mathbf{R}^n)$ and assume that $D^\alpha r$ is bounded when $|\alpha| \le N$. Then the operator $r(D) = \mathcal{F}^{-1} r \mathcal{F}$ is bounded in $B_{\{c\}}$ and*

$$\|r(D)u\|_{B_{\{c\}}} \le C_M \sum_{|\alpha| \le N} \sup |D^\alpha r| \|u\|_{B_{\{c\}}}, \quad u \in B_{\{c\}},$$

where $\mathcal{F}$ is the Fourier transform operator.

Lemma 3.3. *Let X_1 and X_2 be open sets in $\mathbf{R}^n$ and Ψ be a C^{N+1} diffeomorphism $X_1 \to X_2$. Choose $\chi \in C^N_0(X_1)$ and set*

$$Tu = \mathcal{F}^{-1}(\chi(\hat{u} \circ \Psi)).$$

Then T is bounded in $B_{\{c\}}$ with a norm which can be estimated in terms of the maximum of the derivatives of χ of order $\leq N$ and the derivatives of Ψ and Ψ^{-1} of order $\leq N+1$.

The above three lemmas are Theorems 14.1.4, 14.1.5, and 14.1.6 in [4].

For the spaces B_s, $s \geq 0$, we can choose $\{c\}_s = \{R_j^s\} = \{2^{(j-1)s}\}$ and $M_s = 2^s$. Then

$$2^{(j-2)s} = \frac{c_j}{M_s} \leq c_{j+1} = 2^{js} = M_s c_j.$$

In Lemma 3.1, we can choose $N = 2$ if $s = 1$. If $0 \leq s < 1$, we can choose $N = 1$. For the discussions in the rest of the paper, we always pick $N = 2$.

THEOREM 3.4. *Let $H(\xi) = H_1(\xi) + iH_2(\xi) \in C^3(\Omega)$, where Ω is an open set in $\mathbf{R}^n$; assume that* $\operatorname{Re}(\nabla H(\xi)) = \nabla H_1(\xi)$ *and* $\operatorname{Im}(\nabla H(\xi)) = \nabla H_2(\xi)$ *are linearly independent when $H(\xi) = 0$ in Ω, i.e., $|\nabla H(\xi)|_* \neq 0$ when $H(\xi) = 0$ in Ω. Then for fixed $\chi \in C_0^2(\Omega)$, there exists a constant C such that when $u \in B_1$ and $v \in B_0$,*

$$\left| \int \chi(\xi) H(\xi)^{-1} \hat{u}(\xi) \overline{\hat{v}(\xi)} d\xi \right| \leq C \|u\|_{B_1} \|v\|_{B_0} \tag{3.2}$$

and the constant C can be estimated in terms of the dimension n, the maximum of the derivatives of χ of order ≤ 2 and the derivatives of H of order ≤ 3 on $\operatorname{supp}(\chi)$, *the maximum of $|\nabla H(\xi)|_*^{-1}$ (see (1.8)) on* $\operatorname{supp}(\chi) \cap \bar{O}$ *(O is a neighborhood of $\{\xi \in \mathbf{R}^n : H(\xi) = 0\}$) and the maximum of $|H(\xi)|^{-1}$ on* $\operatorname{supp}(\chi) \backslash O$.

Proof. First, suppose that $\operatorname{supp} \chi$ is sufficiently small and $|\nabla H(\xi)|_* \neq 0$ on $\operatorname{supp} \chi$ such that for an open set $\Omega' \supset \operatorname{supp} \chi$ there is a C^3 diffeomorphism $\psi : \Omega'' \to \Omega'$, depending on H, $|\nabla H|_*$, and $|\nabla H|_*^{-1}$, with $H(\psi(\eta)) = \eta_1 + i\eta_2$. Then χ can be rewritten as $\chi = \chi_1 \chi_2$ for some functions $\chi_1, \chi_2 \in C_0^2(\Omega')$. Thus

$$\begin{aligned} &\int \chi_1(\xi) \chi_2(\xi) H(\xi)^{-1} \hat{u}(\xi) \overline{\hat{v}(\xi)} d\xi \\ &\quad = \int \frac{1}{\eta_1 + i\eta_2} \chi_1(\psi(\eta)) \hat{u}(\psi(\eta)) \chi_2(\psi(\eta)) \overline{\hat{v}(\psi(\eta))} |\det(\psi'(\eta))| d\eta. \end{aligned}$$

From Lemma 3.3 ($\psi \in C^3$ is used here to apply Lemma 3.3 since in our situation, $N = 2$), $\mathcal{F}^{-1}(\chi_1 \circ \psi \cdot \hat{u} \circ \psi) \in B_1$ and $\mathcal{F}^{-1}(\chi_2 \circ \psi \cdot \hat{v} \circ \psi) \in B_0$. Then Theorem 2.1 and Corollary 2.4 imply that

$$\mathcal{F}^{-1}\left(\frac{1}{\eta_1 + i\eta_2} \chi_1 \circ \psi \cdot \hat{u} \circ \psi \right) \in B_0^*.$$

Therefore,

$$\left| \int \chi_1(\xi) \chi_2(\xi) H(\xi)^{-1} \hat{u}(\xi) \overline{\hat{v}(\xi)} d\xi \right| \leq C \|u\|_{B_1} \|v\|_{B_0}.$$

In general, if $|\nabla H(\xi)|_* = 0$ at some points ξ in $\operatorname{supp}\chi$, write $\chi(\xi) = \chi_1(\xi) + \chi_2(\xi)$, where $|\nabla H(\xi)|_* \neq 0$ in $\operatorname{supp}\chi_1$ and $H(\xi) \neq 0$ in $\operatorname{supp}\chi_2$. Then it is clear that

$$\begin{aligned} \left| \int \chi_2(\xi) H(\xi)^{-1} \hat{u}(\xi) \overline{\hat{v}(\xi)} d\xi \right| &\leq C_1 \int |\hat{u}(\xi) \overline{\hat{v}(\xi)}| d\xi \\ &\leq C_1 \|u\|_{L_0^2} \|v\|_{L_0^2} \\ &\leq C_1 \|u\|_{B_1} \|v\|_{B_0}, \end{aligned}$$

with C_1 depending on $\max|\chi_2(\xi)|$ and the maximal lower bound of $|H(\xi)|$ on $\operatorname{supp}(\chi_2)$. On $\operatorname{supp}\chi_1$, using a partition of unity and the proof for small $\operatorname{supp}\chi$, we have

$$\left|\int \chi_1(\xi)H(\xi)^{-1}\hat{u}(\xi)\overline{\hat{v}(\xi)}d\xi\right| \leq C_2\|u\|_{B_1}\|v\|_{B_0},$$

where C_2 can be estimated in terms of the quantities stated in the theorem. Combining the estimates for χ_1 and χ_2 yields (3.2). □

Theorem 3.4 says that $Tu = \mathcal{F}^{-1}(\chi H^{-1}\hat{u})$ is bounded from B_1 to B_0^* and also from B_0 to B_1^*. Then by interpolation, we have the following result.

COROLLARY 3.5. *The operator $T_s u = \mathcal{F}^{-1}(\chi H^{-1}\hat{u})$, $u \in B_s$, is bounded from B_s to B_{1-s}^* for each $0 < s < 1$, that is,*

$$\|\mathcal{F}^{-1}(\chi H^{-1}\hat{u})\|_{B_{1-s}^*} \leq C_s\|u\|_{B_s}, \quad u \in B_s,$$

where c_s depends on n, s, and the quantities described in Theorem 3.4.

4. Estimate for complex simply characteristic polynomials. Let $P(\xi) = P_1(\xi) + iP_2(\xi)$ be a polynomial with constant complex coefficients, and assume that $|\nabla P(\xi)|_* \neq 0$ on $\{\xi \in \mathbf{R}^n : P(\xi) = 0\}$. Then for $\chi \in C_0^2(\mathbf{R}^n)$, we have shown in the previous section that

$$\|\mathcal{F}^{-1}(\chi P^{-1}\hat{f})\|_{B_{1-s}^*} \leq C_s\|f\|_{B_s}, \quad f \in B_s, \tag{4.1}$$

for $0 \leq s \leq 1$.

Now we want to impose a stronger condition on P to control the behavior of $|P(\xi)|$ at large ξ and thus allow an estimate like (4.1) without the cutoff function χ. A *simply characteristic* complex polynomial, defined in Definition 1.3, is exactly the kind of suitable condition that we want to impose, and it turns out to be an analogue of the one introduced by Agmon and Hörmander for real polynomials (Definition 1.1).

Now let us analyze condition (1.7). We may assume that there is no real vector $\eta \neq 0$ such that $P(\xi + t\eta) \equiv P(\xi)$ because if there is such a vector η, we can take it as a coordinate direction and obtain a polynomial in fewer variables. Our condition implies that $\tilde{P}_*(\xi) \to \infty$ as $\xi \to \infty$.

1. For each $\xi \in \mathbf{R}^n$, set $P_\xi(\eta) = P(\xi+\eta)/\tilde{P}_*(\xi)$. Then it is clear that the family $\{P_\xi(\eta) : \xi \in \mathbf{R}^n\}$ is uniformly bounded and equicontinuous on any compact set in $\mathbf{R}^n$. Thus by the Arzela–Ascoli theorem, the set M of all polynomials P_ξ and their limits form a compact set of polynomials. Straightforward calculations (the uniform boundedness of coefficients of all polynomials in M plays an essential role here; it allows us to interchange the limit operation with derivative operations and other operations involved in $|\nabla P_\xi(\eta)|_*$) give that

$$\partial_\eta^\alpha P_\xi(\eta) = \frac{P^{(\alpha)}(\xi+\eta)}{\tilde{P}_*(\xi)} \quad \text{for any multi-index } \alpha$$

and

$$|\nabla_\eta P_\xi(\eta)|_* = \frac{|\nabla P(\xi+\eta)|_*}{\tilde{P}_*(\xi)}.$$

If Q is any limit of P_ξ as $\xi \to \infty$, then

$$\partial_\eta^\alpha Q(\eta) = \lim_{\xi\to\infty} \frac{P^{(\alpha)}(\xi+\eta)}{\tilde{P}_*(\xi)}$$

and

$$|\nabla_\eta Q(\eta)|_* = \lim_{\xi\to\infty} \frac{|\nabla P(\xi+\eta)|_*}{\tilde{P}_*(\xi)}.$$

Therefore,

$$\tilde{Q}_*(\eta) = \lim_{\xi\to\infty} \frac{\sum_{|\alpha|\le m, |\alpha|\ne 1} |P^{(\alpha)}(\xi+\eta)| + |\nabla P(\xi+\eta)|_*}{\tilde{P}_*(\xi)},$$

and for any fixed $\theta \in \mathbf{R}^n$,

$$\begin{aligned} Q_\theta(\eta) &= \lim_{\xi\to\infty} \left[\left(\frac{P(\xi+\theta+\eta)}{\tilde{P}_*(\xi)} \right) \Big/ \left(\frac{\sum_{|\alpha|\le m, |\alpha|\ne 1} |P^{(\alpha)}(\xi+\theta)| + |\nabla P(\xi+\theta)|_*}{\tilde{P}_*(\xi)} \right) \right] \\ &= \lim_{\xi\to\infty} \frac{P(\xi+\theta+\eta)}{\sum_{|\alpha|\le m, |\alpha|\ne 1} |P^{(\alpha)}(\xi+\theta)| + |\nabla P(\xi+\theta)|_*} \\ &= \lim_{\xi+\theta\to\infty} P_{\xi+\theta}(\eta). \end{aligned} \tag{4.2}$$

This means that $Q_\theta(\eta)$ is also such a limit. In view of (1.7), we have

$$1 \le C(|Q(0)| + |\nabla Q(0)|_*) \tag{4.3}$$

if Q is any limit of P_ξ as $\xi \to \infty$. From (4.2), we also see that if $Q(\theta) = Q_1(\theta) + iQ_2(\theta) = 0$ at θ, then $|\nabla Q(\theta)|_* \ne 0$. This means that $\nabla Q_1(\theta)$ and $\nabla Q_2(\theta)$ are linearly independent on the zero set of Q.

2. Let z be any complex number in $\mathbf{C}$. Then condition (1.7) is valid for large $|\xi|$ if z_0 is replaced by z. Otherwise, we can find a limit Q with $|\nabla Q(0)|_* = 0$ and this contradicts (4.3). Thus the validity of (1.7) for large $|\xi|$ is independent of $z \in \mathbf{C}$ and means precisely that large real zeros ξ of $P(\xi) - z$ are *simple* in the sense that the real part $\nabla P_1(\xi)$ and the imaginary part $\nabla P_2(\xi)$ of $\nabla P(\xi)$ are linearly independent. For a *simply characteristic* complex polynomial, we conclude that (1.7) is uniformly valid when z belongs to a compact set that does not contain any *critical values* of P.

3. If $z \in \mathbf{C}$ is not a *critical value* of P, then when we set $P_\xi(\eta) = P(\xi+\eta) - z/\tilde{P}_*(\xi)$, condition (1.7) means that

$$P_\xi(0) = 0, \qquad |\nabla P_\xi(0)|_* \ge \frac{1}{C} \tag{4.4}$$

for $\xi \in \{\xi \in \mathbf{R}^n : P(\xi) - z = 0\}$. Combining (4.3) and (4.4), we see that the polynomials P_ξ and their limits as $\xi \to \infty$ either have a *simple* zero at $\eta = 0$ or do not equal 0 at $\eta = 0$. Furthermore, from (4.3), (4.4), and the uniform boundedness of the coefficients of all polynomials in M, we find that for some $r > 0$, independent of ξ, such that on $\Omega = \{|\eta| < r\}$, any Q in M either satisfies $|\nabla Q|_* \ne 0$ or else is uniformly bounded below.

Remark. If $P(\xi)$ is a hypoelliptic polynomial,

$$P^{(\alpha)}(\xi)/P(\xi) \to 0$$

when $\xi \to \infty$ in $\mathbf{R}^n$ for $\alpha \ne 0$. Thus hypoelliptic polynomials satisfy condition (1.7) for large ξ. Therefore if $z \in \mathbf{C}$ is not a *critical value* of P, condition (1.7) is satisfied for all $\xi \in \mathbf{R}^n$.

Theorem 4.1. *Assume that P is* simply characteristic *and let K be a compact subset of $\mathbf{C}$ containing no* critical values *of P. If $f \in B_1$, it follows that*

$$R(z)f = \mathcal{F}^{-1}((P(\cdot) - z)^{-1}\hat{f})$$

is in B_0^*, and we have the estimate

$$\|R(z)f\|_{B_0^*} \leq C \sup_{\xi \in \mathbf{R}^n} \frac{1}{\tilde{P}_*(\xi)} \|f\|_{B_1} \tag{4.5}$$

for $z \in K$, where C depends only on the dimension n, the compact set K, and the constant c_P in condition (1.7).

Proof. It suffices to prove the theorem for some neighborhood $\tilde{K}$ of 0 in $\mathbf{C}$ when 0 is not a *critical value*. On account of the previous analysis and the proof of Theorem 3.4, we see that if $\chi \in C_0^\infty(\Omega)$, $\Omega = \{\eta \in \mathbf{R}^n : |\eta| < r\}$, there is a constant C (depending on the maximum of the derivatives of χ of order ≤ 2, a uniform bound of derivatives of all polynomials Q in M, a uniform bound of $|Q(\eta)|^{-1}$ on $\bar{\Omega}$ when $Q \neq 0$ in Ω, and a uniform bound of $|\nabla Q(\eta)|_*^{-1}$ on $\bar{\Omega}$ when Q has zeros in Ω) and a compact neighborhood K' of 0 in $\mathbf{C}$, both independent of ξ, such that

$$\left| \int |\chi(\eta)|^2 \left(\frac{1}{P_\xi - z/\tilde{P}_*(\xi)} \right) \hat{f}(\eta)\overline{\hat{g}(\eta)} d\eta \right| \leq C \|\mathcal{F}^{-1}(\chi \hat{f})\|_{B_1} \|\mathcal{F}^{-1}(\chi \hat{g})\|_{B_0}$$

if f, $g \in \mathcal{S}$, where $\mathcal{S}$ is the Schwartz space, and $z/\tilde{P}_*(\xi) \in K'$. Let $\tilde{K}$ be a neighborhood of 0 in $\mathbf{C}$ contained in $\tilde{P}_*(\xi)K'$ for all ξ. Making a translation of $\hat{f}$ and $\hat{g}$ and writing $\chi_\xi(\eta) = \chi(\eta - \xi)$, we have for any $z \in \tilde{K}$ that

$$\begin{aligned} &\left| \int \tilde{P}_*(\xi) \frac{1}{P(\eta) - z} \chi_\xi(\eta) \hat{f}(\eta) \overline{\chi_\xi(\eta)\hat{g}(\eta)} d\eta \right| \\ &\quad = \left| \int |\chi(\eta)|^2 \left(\frac{1}{P_\xi - z/\tilde{P}_*(\xi)} \right) \hat{f}(\eta + \xi) \overline{\hat{g}(\eta + \xi)} d\eta \right| \\ &\quad \leq C \|\mathcal{F}^{-1}(\chi \hat{f}(\xi + \cdot))\|_{B_1} \|\mathcal{F}^{-1}(\chi \hat{g}(\xi + \cdot))\|_{B_0} \\ &\quad \leq C \|\mathcal{F}^{-1}(\chi_\xi \hat{f})\|_{B_1} \|\mathcal{F}^{-1}(\chi_\xi \hat{g})\|_{B_0}. \end{aligned}$$

If we then write $\hat{f}_\xi = \chi_\xi \hat{f}$, $\hat{g}_\xi = \chi_\xi \hat{g}$, it follows that

$$\left| \int \frac{1}{P(\eta) - z} \chi_\xi(\eta) \hat{f}(\eta) \overline{\chi_\xi(\eta)\hat{g}(\eta)} d\eta \right| \leq C \sup_{\xi \in \mathbf{R}^n} \frac{1}{\tilde{P}_*(\xi)} \|f_\xi\|_{B_1} \|g_\xi\|_{B_0}.$$

If we integrate with respect to ξ and use Lemma 4.2 below, we obtain

$$|(R(z)f, g)| \leq C \sup_{\xi \in \mathbf{R}^n} \frac{1}{\tilde{P}_*(\xi)} \|f\|_{B_1} \|g\|_{B_0}. \tag{4.6}$$

From (4.3) and (4.4), we also see that a uniform bound of derivatives of all polynomials Q in M, a uniform bound of $|Q(\eta)|^{-1}$ on $\bar{\Omega}$ when $Q \neq 0$ in Ω, and a uniform bound of $|\nabla Q(\eta)|_*^{-1}$ on $\bar{\Omega}$ when Q has zeros in Ω can be estimated in terms of c_P in (1.7). Thus the constant C here depends only on the dimension n, the compact set K, and c_P in (1.7), and the proof is completed. □

LEMMA 4.2. *Let* $\chi \in C_0^\infty(\mathbf{R}^n)$ *and set* $\chi(D-\eta)u = \mathcal{F}^{-1}\chi(\cdot - \eta)\hat{u}$, $u \in \mathcal{S}'$. *Then we have*

$$\int \|\chi(D-\eta)u\|^2_{B_{\{c\}}} d\eta \le C_{M,\chi}\|u\|^2_{B_{\{c\}}}, \quad u \in B_{\{c\}},$$

for all $\{c\}$ *satisfying condition* (3.1).

This lemma is Theorem 14.1.7 in Hörmander's book [4].

From estimate (4.6), we see that $R(z)$ is bounded from B_0 to B_1^* as well. Then by interpolation, we obtain that $R(z)$ is also bounded from B_s to B_{1-s}^* for $0 < s < 1$. This completes the proof of Theorem 1.2.

Remark.

1. If $\{P(\xi,\zeta)\}$ is a family of polynomials of $\xi \in \mathbf{R}^n$ depending on a parameter ζ in a subset $M_\zeta \subset \mathbf{C}^n$ and condition (1.7) is valid for all $\zeta \in M_\zeta$, with the constant $c_P(\zeta)$ depending on ζ, then

$$|(R(z,\zeta)f,g)| \le C(s,c_P(\zeta)) \sup_{\xi\in\mathbf{R}^n} \frac{1}{\tilde{P}_*(\xi,\zeta)}\|f\|_{B_s}\|g\|_{B_{1-s}} \tag{4.7}$$

for all $f \in B_s$ and $g \in B_{1-s}$ $(0 \le s \le 1)$ with $C(s,c_P(\zeta))$ dependent on ζ.

2. If c_P is independent of $\zeta \in M_\zeta$, then

$$|(R(z,\zeta)f,g)| \le C(s,c_P) \sup_{\xi\in\mathbf{R}^n} \frac{1}{\tilde{P}_*(\xi,\zeta)}\|f\|_{B_s}\|g\|_{B_{1-s}} \tag{4.8}$$

for all $f \in B_s$ and $g \in B_{1-s}$ $(0 \le s \le 1)$ with $C(s,c_P)$ independent of ζ.

These two remarks will be useful in constructing exponentially growing solutions of a partial differential equation $(P(D+\zeta)-\lambda)u = f$ to study inverse problems. Some examples can be found in [8].

5. The uniqueness of solutions and the behavior at infinity. In this section, we use the estimate in Theorem 1.2 to discuss the uniqueness and the asymptotic behavior in an average sense of solutions of the partial differential equation

$$P(D)u = f \in B_s, \quad 0 \le s \le 1. \tag{5.1}$$

We assume that the symbol $P(\xi) = P_1(\xi) + iP_2(\xi)$ of $P(D)$ is *simply characteristic* and 0 is not a *critical value*. Then from Theorem 1.2, we have

$$R(0)f = \mathcal{F}^{-1}((P(\cdot))^{-1}\hat{f}) \in B_{1-s}^*$$

with the bound

$$\|R(0)f\|_{B_{1-s}^*} \le C(s,c_P) \sup_{\xi\in\mathbf{R}^n} \frac{1}{\tilde{P}_*(\xi)}\|f\|_{B_s}$$

for $0 \le s \le 1$.

THEOREM 5.1. *Let* $P(\xi) = P_1(\xi) + iP_2(\xi)$ *be a* simply characteristic *complex polynomial and let* 0 *not be a* critical value *of* P. *Suppose that the zero set* M *of* $P(\xi)$ *is a* C^1 *submanifold of codimension* 2. *Then the solution to* (5.1) *in* B_{1-s}^* *is unique if* $0 < s \le 1$ *and* $u = \mathcal{F}^{-1}(P(\cdot)^{-1}\hat{f})$. *Moreover, if* $f \in B_s$ *and* $0 < s < 1$, *then*

$$\lim_{R\to\infty} \sup \frac{1}{R^{2(1-s)}} \int_{|x|<R} |u(x)|^2 dx = 0.$$

In particular, if $f \in B_1$, *then*

$$\lim_{R\to\infty} \sup \frac{1}{R^{2(1-s)}} \int_{|x|<R} |u(x)|^2 dx = 0$$

for all $0 < s < 1$.

Proof. To prove uniqueness, we need the following lemma, proved in [2].

LEMMA 5.2. *Let* $u \in \mathcal{S}' \cap L^2_{\text{loc}}$ *and assume that*

$$\lim_{R\to\infty} \sup \frac{1}{R^k} \int_{|x|<R} |u(x)|^2 dx < \infty.$$

If the restriction of the Fourier transform $\hat{u}$ *to an open subset* Ω *of* $\mathbf{R}^n$ *is supported by a* C^1 *submanifold* M *of codimension* k, *then it is an* L^2 *density* $\hat{u}_0 ds$ *on* M *and*

$$\int_M |\hat{u}_0|^2 ds \leq c \lim_{R\to\infty} \sup \frac{1}{R^k} \int_{|x|<R} |u(x)|^2,$$

where c *depends only on the dimension* n.

Suppose that we have u_1 and u_2 in B^*_{1-s} satisfying equation (5.1). Set $u = u_1 - u_2$. Then

$$P(D)u = 0.$$

This implies that $\hat{u}$ is supported on $M = \{\xi \in \mathbf{R}^n : P(\xi) = 0\}$, which is a C^1 submanifold of codimension 2. Since $u \in B^*_{1-s}$, $(0 < s \leq 1)$,

$$\begin{aligned}
&\lim_{R\to\infty} \sup \frac{1}{R^2} \int_{|x|<R} |u(x)|^2 dx \\
&\quad = \lim_{R\to\infty} \sup \frac{1}{R^{2s}} \frac{1}{R^{2(1-s)}} \int_{|x|<R} |u(x)|^2 dx \\
&\quad = \lim_{R\to\infty} \frac{1}{R^{2s}} \lim_{R\to\infty} \sup \frac{1}{R^{2(1-s)}} \int_{|x|<R} |u(x)|^2 dx \\
&\quad = 0.
\end{aligned}$$

The last equality follows from

$$\sup_{R\geq 1} \frac{1}{R^{2(1-s)}} \int_{|x|<R} |u(x)|^2 dx \leq \frac{2^{2(1-s)}}{(1-2^{-2(1-s)})} \|u\|^2_{B^*_{1-s}} < \infty.$$

By Lemma 5.2,

$$\int_M |\hat{u}|^2 ds \leq c \lim_{R\to\infty} \sup \frac{1}{R^2} \int_{|x|<R} |u(x)|^2 dx = 0.$$

This proves uniqueness.

To prove that the limit is 0, we note that if $0 < s < 1$ and $f \in B_s$, $R(0)f \in L^2_{-1+s}$ (see the proof of Corollary 2.5), that is,

$$\int_{\mathbf{R}^n} (1+|x|^2)^{-1+s} |\mathcal{F}^{-1}(P(\cdot)^{-1}\hat{f})(x)|^2 dx < \infty,$$

then

$$\lim_{j\to\infty}\sup\int_{x\in\Omega_j}(1+|x|^2)^{-1+s}|\mathcal{F}^{-1}(P(\cdot)^{-1}\hat{f})(x)|^2dx=0.$$

This implies that

$$\lim_{j\to\infty}\sup\frac{1}{R_j^{2(1-s)}}\int_{x\in\Omega_j}|\mathcal{F}^{-1}(P(\cdot)^{-1}\hat{f})(x)|^2dx=0.$$

For any $\epsilon>0$, there is an integer $N>0$ such that when $m>N$,

$$\frac{1}{R_m^{2(1-s)}}\int_{\Omega_m}|u(x)|^2dx<\epsilon,$$

where $u(x)=\mathcal{F}^{-1}(P(\cdot)^{-1}\hat{f})(x)$. Then

$$\begin{aligned}\frac{1}{R_m^{2(1-s)}}\int_{|x|<R_m}|u(x)|^2dx &= \frac{1}{R_m^{2(1-s)}}\sum_{j=1}^{m}\int_{\Omega_j}|u(x)|^2dx\\ &=\sum_{j=1}^{m}\frac{1}{(2^{2(1-s)})^{m-1}}\int_{\Omega_j}|u(x)|^2dx\\ &=\sum_{j=1}^{m}\frac{1}{(2^{2(1-s)})^{m-j}}\frac{1}{(2^{2(1-s)})^{j-1}}\int_{\Omega_j}|u(x)|^2dx\\ &=\sum_{j=1}^{N}\frac{1}{(2^{2(1-s)})^{m-j}}\frac{1}{R_j^{2(1-s)}}\int_{\Omega_j}|u(x)|^2dx\\ &\quad+\sum_{j=N+1}^{m}\frac{1}{(2^{2(1-s)})^{m-j}}\frac{1}{R_j^{2(1-s)}}\int_{\Omega_j}|u(x)|^2dx\\ &\le\|u\|^2_{B^*_{1-s}}\sum_{j=1}^{N}\frac{1}{(2^{2(1-s)})^{m-j}}+\epsilon\sum_{j=N+1}^{m}\frac{1}{(2^{2(1-s)})^{m-j}}\\ &\le\|u\|^2_{B^*_{1-s}}\frac{1}{(2^{2(1-s)})^{m-N}}\frac{1}{1-2^{-2(1-s)}}+\epsilon\frac{1}{1-2^{-2(1-s)}}\\ &\le\frac{\epsilon}{1-2^{-2(1-s)}}(1+\|u\|^2_{B^*_{1-s}})\end{aligned}$$

for $m>N$ large enough. Therefore,

$$\begin{aligned}&\lim_{R\to\infty}\sup\frac{1}{R^{2(1-s)}}\int_{|x|<R}|u(x)|^2dx\\ &\quad=\lim_{R\to\infty}\sup_{R'\ge R}\frac{1}{(R')^{2(1-s)}}\int_{|x|<R'}|u(x)|^2dx=0. \qquad\square\end{aligned}$$

Acknowledgments. This paper is part of my Ph.D. dissertation at the University of Rochester. I am greatly indebted to my Ph.D. advisor, Professor Adrian Nachman, for his guidance and many helpful ideas. It is also a pleasure to thank Professors Richard Lavine and Allan Greenleaf for their useful suggestions. I would also like to thank the referees for spending time reading my paper carefully and giving some useful suggestions.

MULTIFRACTAL FORMALISM FOR FUNCTIONS PART I: RESULTS VALID FOR ALL FUNCTIONS*

S. JAFFARD†

Abstract. The multifractal formalism for functions relates some functional norms of a signal to its "Hölder spectrum" (which is the dimension of the set of points where the signal has a given Hölder regularity). This formalism was initially introduced by Frisch and Parisi in order to numerically determine the spectrum of fully turbulent fluids; it was later extended by Arneodo, Bacry, and Muzy using wavelet techniques and has since been used by many physicists. Until now, it has only been supported by heuristic arguments and verified for a few specific examples. Our purpose is to investigate the mathematical validity of these formulas; in particular, we obtain the following results:

- The multifractal formalism yields for any function an upper bound of its spectrum.
- We introduce a "case study," the *self-similar functions*; we prove that these functions have a concave spectrum (increasing and then decreasing) and that the different formulas allow us to determine either the whole increasing part of their spectrum or a part of it.
- One of these methods (the wavelet-maxima method) yields the complete spectrum of the self-similar functions.

We also discuss the implications of these results for fully developed turbulence.

Key words. multifractal formalism, self-similarity, wavelet transform

1. Introduction and statement of results.

One-dimensional multifractal measures have been the object of many investigations by mathematicians and theoretical physicists (see, for instance, [5], [7], [12], [23], and the references therein). Basically, such measures have very different "scalings" from point to point, i.e., for such a measure μ, if I is an interval, the quantity $\mu(I)$ scales like $|I|^\alpha$, where the exponent α differs very much following the position of the center of the interval I. Such measures are important because they are natural measures carried by some strange attractors and thus appear in the modeling of many natural phenomena (diffusion-limited aggregates, invariant measures of dynamical systems, voltage drop across a random transistor network, etc.; see [2] and the references therein).

It may happen that the natural, fractal-like object that one wants to understand is not a set or a measure but a function. The study of multifractal functions has proved important in several domains of physics. Examples include plots of random walks, interfaces developing in reaction-limited growth processes, and turbulent velocity signals at inertial range (see [3]). The relevant mathematical tool studied in this context is the *Hölder spectrum*, also frequently called *spectrum of singularities*; this function associates with each positive α the Hausdorff dimension of the set where F is approximately Hölder of order α (in a sense to be made precise). The most important example where one would like to determine the spectrum of singularities of a function is the velocity of fully developed turbulence. The reason is that turbulent flows are not spatially homogeneous: the irregularity of the velocity seems to differ widely from point to point. This phenomenon, called "intermittency," suggests that the determination of the Hölder spectrum of the velocity of the fluid might be

a nontrivial function and thus would yield important information on the nature of turbulence.

The first problem in this ambitious program is the numerical determination of the spectrum. Obviously, it is almost impossible to deduce it from the mathematical definition since it involves the successive determination of several intricate limits. The only method is to find some "reasonable" assumptions under which the spectrum could be derived using only "averaged quantities" (which should be numerically stable) extracted from the signal. Such formulas for the spectrum can be guessed heuristically using similarities with statistical physics. Frisch and Parisi [14] proposed, in one dimension, a formula using the L^p modulus of continuity of the velocity along one axis. Arneodo, Bacry, and Muzy (in [2], [3], and [26]) proposed, also in one dimension, other formulas based on the wavelet transform of the signal, and they proved their formulas' validity when the function considered is the indefinite integral of a multinomial measure or a C^∞ perturbation of such a measure. The origin of this method may be traced to the seminal work of Mandelbrot [23], and it has been used a great deal by physicists (see for instance [4], [12], [24], and the references therein), so the scope of its mathematical validity has become an important issue.

Our purpose in this paper is twofold:

- In Part I, we give some general results concerning the multifractal formalism. We show that for any function, it yields an upper bound of its Hölder spectrum, but we also show via some explicit counterexamples that, in general, it does not yield the exact spectrum.

- In Part II, we introduce and study a model case, "self-similar functions," and prove that the multifractal formalism holds for these functions. Examples of such functions include the indefinite integrals of self-similar measures, but they also include widely oscillating, several-dimensional functions—two requirements which are obviously needed, for instance, in any realistic model of turbulence.

Before describing the multifractal formalism, we need to recall some definitions and notation concerning the Hölder regularity of functions.

Suppose that α is a positive real number; a function $F : \mathbb{R}^m \to \mathbb{R}$ is $C^\alpha(x_0)$ if there exists a polynomial P of degree less than α such that

$$|F(x) - P(x - x_0)| \leq C|x - x_0|^\alpha \tag{1.1}$$

and F belongs to $\Gamma^\alpha(x_0)$ if (see [18])

$$\begin{cases} \forall\beta > \alpha, & F \notin C^\beta(x_0), \\ \forall\beta < \alpha, & F \in C^\beta(x_0). \end{cases}$$

A function F is C^α (or $C^\alpha(\mathbb{R}^m)$) if (1.1) holds for any x in $\mathbb{R}^m$, the constant C being uniform. (Using *this* definition C^1 means Lipschitz.) We also need the two following definitions which assert (in two slightly different ways) that the singularity of F at x_0 can be measured on a "large" set near x_0. We denote by mes$A$ the Lebesgue measure of a set A.

Definition 1.1. *Let $\alpha > -m$; a point x_0 is a strong α-singularity of F if there* *exist* $C, C' > 0$ *such that* $\forall P$ *polynomial of degree at most* α, $\forall j, \exists A_j, B_j$,

$$\text{(1.2)} \quad \begin{cases} \text{mes} A_j \geq C2^{-mj}, \qquad \text{mes} B_j \geq C2^{-mj}, \\ \forall x \in A_j \cup B_j, \quad |x - x_0| \leq 2^{-j}, \\ \forall x \in A_j, \forall y \in B_j, \quad (F(x) - P(x - x_0)) - (F(y) - P(y - x_0)) \geq C'2^{-\alpha j}. \end{cases}$$

Note that if $\alpha < 1$, the last condition reduces to $F(x) - F(y) \geq C'2^{-\alpha j}$. The *wavelet transform* of a function F is defined as follows:

$$C(a, b) = \frac{1}{a^m} \int F(t) \psi\left(\frac{t - b}{a}\right) dt,$$

where ψ is a radial function with moments of order less than K vanishing and with derivatives of order less than K having fast decay (with a K "large enough" depending on the properties of F that we want to analyze).

Definition 1.2. *A point* x_0 *is a wavelet* α*-singularity of* F *if there exist wavelet coefficients* $C(a_n, b_n)$ *in a cone pointing towards* x_0 *(i.e.,* $\mid b_n - x_0 \mid \leq Ca_n$*) such that* $a_n \to 0$, $a_n/a_{n+1} \leq C$, *and*

$$\text{(1.3)} \qquad |C(a_n, b_n)| \geq Ca_n^\alpha.$$

We will prove in section 2 that the two previous definitions are related and that if F is $C^\alpha(x_0)$ and x_0 is a wavelet α-singularity of F, then x_0 is a strong α-singularity of F.

We can now define the object of our study.

Definition 1.3. *The Hölder spectrum of a function* F *is the function* $d(\alpha)$ *defined for each* $\alpha \geq 0$ *as follows:*

$d(\alpha)$ *is the Hausdorff dimension of the set of points* x_0 *where* F *belongs to* $\Gamma^\alpha(x_0)$.

Remark. We will sometimes also call the function $D(\alpha)$, which is the packing dimension of the strong α-singularities, the *packing dimension spectrum.*

The two definitions of dimension that we use will be recalled when needed. Note that $d(\alpha)$ and $D(\alpha)$ are defined point by point. We will consider mainly $d(\alpha)$ except in section 4 of Part I and section 6 of Part II.

We are now in a position to describe the methods used by Frisch and Parisi on one side and Arneodo, Bacry, and Muzy on the other in order to determine the spectrum of singularities of functions.

- The *structure function* method first requires the computation of

$$S_q(l) = \int_{\mathbb{R}^m} |F(x + l) - F(x)|^q dx.$$

Assuming that the order of magnitude of $S_q(l)$ is $|l|^{\zeta(q)}$ when $l \to 0$, the Hölder spectrum is computed using the formula

$$\text{(1.4)} \qquad d(\alpha) = \inf_q (q\alpha - \zeta(q) + m).$$

(We will define $\zeta(q)$ precisely below.)

- In the *wavelet-transform integral* method, one computes

$$\tilde{Z}(a, q) = \int_{\mathbb{R}^m} |C(a, b)|^q db,$$

and then if the order of magnitude of $\tilde{Z}(a,q)$ is $a^{\eta(q)}$,

$$d(\alpha) = \inf_q (q\alpha - \eta(q) + m). \tag{1.5}$$

• In order to describe the *wavelet-transform maxima* method, we first have to introduce the notion of a *line of maxima*; consider for a given $a' > 0$ the local maxima of the function $b \to C(a', b)$; generically, they belong to a line of maxima $b = l(a)$ defined in a small left-neighborhood $[a'', a']$ of a' by the condition that $b \to C(a,b)$ has a local maximum for $b = l(a)$. Usually, one cannot choose $a'' = 0$ because the lines of maxima have ramifications called "fingerprints." The wavelet-transform maxima method first requires the computation of

$$Z(a,q) = \sum_l \sup_{(b=l(a))} |C(a,b)|^q, \tag{1.6}$$

where l is a line of maxima of the wavelet transform defined on $[a'', a']$ and where the sum is taken on all lines of local maxima defined in left-neighborhoods $[a'', a']$ of a'. If the order of magnitude of $Z(a,q)$ is $a^{\theta(q)}$, then

$$d(\alpha) = \inf_q (qh - \theta(q)). \tag{1.7}$$

Numerically, according to [3], the most reliable method seems to be the last one, probably because the restriction of the computation to the maxima insures that small errors are less likely to be taken into account since at the maxima, they are relatively less important. More generally, methods that involve the wavelet transform are numerically more stable, probably because they involve only averaged quantities and not the direct values of the function. The use of such quantities has been advocated in [15]. The structure function method involves only order-one differences so that it is clearly unfit for computing the spectrum $d(\alpha)$ when α is larger than 1.

Since the scalings assumed above do not necessarily hold, we use the following definitions. Let

$$\zeta(q) = \liminf_{l \to 0} \frac{\log S_q(l)}{\log |l|}; \tag{1.8}$$

$$\eta(q) = \liminf_{a \to 0} \frac{\log \tilde{Z}(a,q)}{\log a}; \tag{1.9}$$

$$\theta(q) = \liminf_{a \to 0} \frac{\log Z(a,q)}{\log a}, \tag{1.10}$$

The multifractal formalism may seem surprising at first glance because it relates pointwise behaviors to global estimates. Before giving some mathematical explanations for it, it may be enlightening to give the heuristic classical argument from which it is derived. Although this argument cannot be transformed into a correct mathematical proof, it at least shows why these formulas can be expected to hold, and a careful study of its defects shows under which type of additional conditions it should be mathematically correct.

We calculate the contribution of singularities of order α to the integral

$$\int_{\mathbb{R}^m} |F(x+l) - F(x)|^q dx.$$

Near a singularity of order α, we have, in a small box of size $|l|$,

$$|F(x+l)-F(x)|^q \sim |l|^{\alpha q}.$$

If the dimension of these singularities is $d(\alpha)$, it means that there are about $|l|^{-d(\alpha)}$ such boxes, each of volume $|l|^m$, so that the total contribution to the integral is $|l|^{\alpha q+m-d(\alpha)}$. The real order of magnitude of the integral is given by the largest contribution, which, since $l \to 0$ is given by the smallest exponent, is such that

$$\zeta(q) = \inf_{\alpha}(\alpha q + m - d(\alpha)). \tag{1.11}$$

This formula is not the one that we are looking for since we know $\zeta(q)$ and are looking for $d(\alpha)$, but if it holds and if d is concave (we will see that in general this assumption need not be verified; however in many cases it is), $d(\alpha)$ is recovered by an inverse Legendre transform formula which yields (1.4). Of course, if $d(\alpha)$ is not concave, one expects the right-hand side of (1.4) to yield only the convex hull of the spectrum.

In all cases, (1.11) is more likely to hold because the concavity problem does not appear there. (A straightforward application of Young's formula shows that $\zeta(q)$ is always concave.)

In the first part of this paper, the following results will be proved.

THEOREM 1.4. *If $q > 1$ and $\zeta(q) < q$, then $\zeta(q) = \eta(q)$ for any function F. In general, these functions need not be related to $\theta(q)$.*

If F is a function of one real variable, and $0 < \eta(1) < 1$, the box dimension of the graph of F is $2 - \eta(1)$.

The following upper bound holds for any function F such that $\eta(p) > m$ $\forall p$:

$$d(\alpha) \le \inf_{p}(m - \eta(p) + \alpha p). \tag{1.12}$$

Also, without any assumption on η,

$$D(\alpha) \le \inf_{p}(m - \eta(p) + \alpha p).$$

In general, (1.12) *cannot be an equality*; *more precisely, let $d(\alpha)$ be a Riemann-integrable positive function on $\mathbb{R}^+$. There exists F_1 and F_2 which share the same function η, but the spectrum of F_1 is $d(\alpha)$ and F_2 is C^∞ except at the origin* (*so that its spectrum is equal to $-\infty$ everywhere except at one point*).

Some counterexamples will show that a smooth function (with a large $\eta(p)$) may nonetheless be such that $\theta(p)$ can be arbitrarily small. (The case $\theta(p) = -\infty$ $\forall p > 0$ can even happen.) The wavelet-transform maxima method need not be correct, even in the more precise framework of self-similar functions, where the other methods will work. However, after a slight modification, it yields the correct spectrum for self-similar functions. The mathematical problem with using (1.6) is that the lines of maxima can be too close to each other. In that case, we should instead keep for each interval of width a only one line passing through this interval that yields the largest contribution. However, the reader will see that the mathematical counterexamples where $\eta(q) \ne \theta(q)$ are very contrived, and the author's belief is that for practical applications, (1.5) and (1.7) have the same range of validity.

The last assertion in the theorem is stronger than the mere failure of the Legendre transform formulas. It asserts that there is not enough information in the function η to determine the spectrum. In particular, contrary to a common belief, the fact that

η is not linear does not imply that the signal has a multifractal structure. It also shows that, mathematically, "any" function $d(\alpha)$ can be a spectrum. It is surprising to notice that in several different fields of application, this does not seem to be the case. The spectra computed numerically have always the same shape—roughly speaking, the upper part of an ellipse. This is actually the shape we will find for self-similar functions. There can be several explanations to this analogy. Either (a) these physical signals satisfy some "scaling-invariance" properties which makes them fit in the framework (perhaps generalized in some ways) of self-similar functions or (b) a pessimistic explanation could be that, these spectra being (perhaps wrongly) calculated using a Legendre transform, the convex hull of the true spectrum is actually calculated and not the spectrum itself—hence this "generic" concave shape. We will also see that these examples answer the following problem raised by Daubechies and Lagarias in [9], which is somehow converse to the multifractal formalism: Is η the Legendre transform of $m-d(\alpha)$? Positive answers to this problem find fewer applications than the multifractal formalism since in practice one wants to obtain $d(\alpha)$ knowing $\eta(p)$ or $\zeta(p)$ and not the converse; nonetheless, it might hold more generally (see [9]). The problem raised by Daubechies and Lagarias is to find explicit counterexamples. We will see that in most cases, F_1 and F_2 are such counterexamples.

One of the referees of this paper raised the problem of a relationship between $\theta(q)$ and $\eta(q)$ such as

$$\theta(q) \leq \eta(q) - m.$$

This is true for self-similar functions satisfying the closed-set condition because then the regions where the wavelet transform is large (and these are the regions taken into account to estimate $\eta(q)$) are isolated so that there must exist a local maximum of the wavelet transform in the neighborhood. In general, however, we have no answer to this problem.

We now define self-similar functions by analogy with self-similar sets.

Recall that a set K is *strictly self-similar* if it is a finite union of disjoint subsets $K_1, \dots, K_d$ which can be deduced from K by similitudes. For instance, the triadic Cantor set and the Van Koch curve are self-similar. These sets have been widely studied, as have the measures supported on them. They play an important role in the modeling of several physical phenomena (see, for instance, [5], [16], [12], and [3]).

Suppose that F is continuous and compactly supported and let Ω be the bounded open subset of $\mathbb{R}^n$ such that $\bar{\Omega} = \operatorname{supp}(F)$. The intuitive idea of a self-similar function is that there should exist disjoint subsets $\Omega_1, \dots, \Omega_d$ of Ω such that the graph of F restricted to each Ω_i is a "contraction" of the graph of F, modulo a certain error, which is supposed to be smooth. First, suppose that "smooth" means Lipschitz, and let us formalize this definition.

There should exist similitudes $(S_i)_{i=1,\dots,d}$ such that if $S_i(\Omega) = \Omega_i$,

$$\begin{aligned} &\forall i, \quad \Omega_i \subset \Omega, \\ &\Omega_i \cap \Omega_j = \phi \text{ if } i \neq j, \\ \forall x \in \Omega_j, \quad &F(x) = \lambda_j F(S_j^{-1}(x)) + g_j(x) \quad \text{with } g_j \text{ Lipschitz on } \bar{\Omega}_j. \end{aligned} \tag{1.13}$$

We suppose that S_i are *contractions*, i.e., the product of an isometry by the mapping $x \to \mu_i x$, where $\mu_i < 1$.

Equation (1.13) does not tell how F behaves outside Ω_i. We make the assumption that it is smooth, i.e., Lipschitz, outside $\bigcup \Omega_i$.

Since $F(S_j^{-1}(x)) = 0$ if $x \notin \Omega_j$,

$$F(x) = \sum_{i=1}^{d} \lambda_j F(S_j^{-1}(x)) + g(x),$$

where $g = g_j$ on Ω_j, $g = F$ outside $\bigcup \Omega_j$, and g is obviously continuous since F is continuous; since it is Lipschitz on $\bigcup \bar{\Omega}_j$ and outside $\bigcup \Omega_j$, g is uniformly Lipschitz.

This equation holds for any Lipschitz function F (use it as a definition for g when all $\lambda_j = 0$) so that it is interesting only if F is not uniformly Lipschitz, and in that case, we will be interested in determining the points where F is C^α for $\alpha < 1$.

We will generalize this model slightly by assuming that g is $C^k(\mathbb{R}^m)$ and not necessarily compactly supported but also that the derivatives of g of order less than k have fast decay. The same remark shows that in this case, we should suppose that F is not $C^k(\mathbb{R}^m)$, and we will be interested in determining where F is C^α for $\alpha < k$. We will thus use the following definition.

Definition 1.5. *A function $F : \mathbb{R}^m \to \mathbb{R}$ is self-similar (of order $k \in \mathbb{R}^+$) if the three following conditions hold:*

- *There exists a bounded open set Ω and $S_1, \dots, S_d$ contractive similitudes such that*

$$S_i(\Omega) \subset \Omega, \tag{1.14}$$

$$S_i(\Omega) \cap S_j(\Omega) = \emptyset \quad \text{if } i \neq j. \tag{1.15}$$

(The S_i's are the product of an isometry with the mapping $x \to \mu_i x$, where $\mu_i < 1$.)

- *There exists a C^k function g such that g and its derivatives of order less than k have fast decay and F satisfies*

$$F(x) = \sum_{i=1}^{d} \lambda_i F(S_i^{-1}(x)) + g(x). \tag{1.16}$$

- *The function F is not uniformly C^k in a certain closed subset of Ω.*

Recall that g has fast decay if

$$\forall n \in \mathbb{N}, \quad |g(x)| \leq \frac{C_n}{(1+|x|)^n}.$$

Let

$$\alpha_{\min} = \inf_{i=1,\dots,d} \left(\frac{\log \lambda_i}{\log \mu_i} \right), \qquad \alpha_{\max} = \sup_{i=1,\dots,d} \left(\frac{\log \lambda_i}{\log \mu_i} \right).$$

We use this notation because $\alpha_{\min}$ will turn out to be the smallest pointwise Hölder regularity exponent of F and $\alpha_{\max}$ the largest (lower than k). Let τ be the function defined by

$$\sum_{i=1}^{d} \lambda_i^a \mu_i^{-\tau(a)} = 1.$$

Some results concerning the multifractal formalism for self-similar functions are summed up in the following theorem and will be proved in the second part of the paper.

Theorem 1.6. *Suppose that F is self-similar. If $\alpha_{\min} > 0$, the function $d(\alpha)$ vanishes outside $[\alpha_{\min}, \alpha_{\max}] \cup [k, +\infty)$ and is analytic and concave on $[\alpha_{\min}, \alpha_{\max}]$. Its maximal value $d_{\max}$ on this interval satisfies*

$$\sum \mu_i^{d_{\max}} = 1.$$

Let α_0 be the value for which this maximum is attained. First, suppose that g is C^∞. If $\alpha \leq \alpha_0$, $d(\alpha)$ can be obtained by computing the Legendre transform of either $\eta(q) - m$ or $\zeta(q) - m$.

If g is only C^k, let p_0 be defined by $\eta(p_0) = kp_0$ and let $\alpha_1 < \alpha_0$ be the value of the inverse Legendre transform of $\eta(q) - m$ at p_0; if $\alpha \leq \alpha_1$, $d(\alpha)$ can be obtained by computing the Legendre transform of either $\eta(q) - m$ or $\zeta(q) - m$.

Without any assumption on $\alpha_{\min}$, if $\sum \mid \lambda_j \mid \mu_j^m < 1$, the same results hold if we replace $d(\alpha)$ by $D'(\alpha)$, the packing dimension of the wavelet α-singularities (or by $D(\alpha)$ if g and λ_i are positive and if furthermore the separated open-set condition holds).

We will also prove that in some cases, the wavelet-maxima method can be modified so that it yields the whole spectrum of self-similar functions (see Theorem 2.2 in Part II).

Corollary 8.5 in Part II of this paper will extend this result to a larger class of functions than self-similar functions.

Before we begin to study the multifractal formalism for functions, we show its relationship to the multifractal formalism for measures. We recall that if μ is a probability measure on $[0, 1]$, one defines

$$\tau(q) = \lim_{j \to +\infty} \frac{1}{j \log 2} \log \sum \left(\mu\left(\left[\frac{k}{2^j}, \frac{k+1}{2^j} \right] \right) \right)^q$$

and

$$E_\alpha = \left\{ t : \frac{\log \mu(I_n(t))}{\log |I_n(t)|} \to \alpha \right\},$$

where $I_n(t)$ is the interval $[k/2^j, (k+1)/2^j]$ which contains t. The multifractal formalism for measures asserts that the dimension of E_α is the Legendre transform of τ (see, for instance, [5] and [12] for mathematical results concerning this assertion). Let F be an indefinite integral of μ ($F(x) = \mu([0, x])$). Clearly,

$$t \in E_\alpha \Leftrightarrow |F(x+h) - F(x)| \sim h^\alpha$$

and

$$\sum \left(\mu\left(\left[\frac{k}{2^j}, \frac{k+1}{2^j} \right] \right) \right)^q \sum \left| F\left(\frac{k}{2^j} \right) - F\left(\frac{k+1}{2^j} \right) \right|^q \sim 2^j \int |F(x+2^{-j}) - F(x)|^q dx.$$

Thus if F is the indefinite integral of a probability measure supported on $[0, 1]$, the two multifractal formalisms are identical. However, in dimensions larger than one or for functions that are not of bounded variation, the multifractal formalism for functions cannot be obtained as a consequence of the multifractal formalism for measures.

Our purpose in Part I of this paper is to prove Theorem 1.4. In section 2, we make explicit the relation between the size of the wavelet transform and the local regularity of the function. In section 3, we identify the quantities $S_q(l)$ or $Z(a, q)$ with some functional norms, thus proving the first point of Theorem 1.4. In section 4, we prove the upper estimate for the dimensions of singularities and the formula for the box dimension of the graph of F. In section 5, we study the wavelet-maxima method. In section 6, we construct counterexamples to the validity of the multifractal formalism in all generality.

The two parts of this paper can be read independently. Some results of this paper have been announced in [18], [19], and [20].

2. Regularity, singularities, and two-microlocalization. The results of Theorems 1.4 and 1.6 relate the pointwise behavior of a function to estimates on its wavelet transform. Our purpose in this section is to recall existing results on this topic and prove new ones concerning either negative exponents α or strong α-singularities. We first recall the basic properties of the wavelet transform.

Let ψ be in $C^{k+1}(\mathbb{R}^m)$, radial, with moments of order less than $k+1$ vanishing, and such that the derivatives of ψ of order less than $k+1$ have fast decay. The wavelet transform of F is defined by

$$C(a,b)(F) = \frac{1}{a^m}\int_{\mathbb{R}^m} F(t)\psi\left(\frac{t-b}{a}\right) dt, \tag{2.1}$$

and if $C(\psi) = \int |\hat{\psi}(\xi)|^2 d\xi/|\xi|$, F is recovered from its wavelet transform by

$$F(t) = C(\psi)\int_{a>0}\int C(a,b)(F)\psi\left(\frac{t-b}{a}\right) db\frac{da}{a^{m+1}}.$$

An intuitive idea is that a large wavelet coefficient means that the corresponding function locally has an oscillation at the corresponding scale of a corresponding amplitude. Although there does not seem to be a straightforward relationship between the two notions, Propositions 2.2 and 2.5 can be seen as a mathematical formulation of this idea. The following results can be found in [25] and [17]. Suppose that $s>0$.

- $F \in C^s(\mathbb{R}^m)$ if and only if

$$|C(a,b)(F)| \leq Ca^s. \tag{2.2}$$

(Recall that if $s=1$, the space $C^s(\mathbb{R}^m)$ must be replaced by the Zygmund class, which is composed of the continuous functions F such that $|F(x+h)+F(x-h)-2F(x)| \leq Ch$, or, more generally, if s is a positive integer, then it must be replaced by the corresponding indefinite integrals of the Zygmund class.)

- If $F \in C^s(x_0)$, then

$$|C(a,b)(F)| \leq Ca^s\left(1+\frac{|b-x_0|}{a}\right)^s. \tag{2.3}$$

- If (2.3) holds and if $F \in C^\varepsilon(\mathbb{R}^m)$ for an $\varepsilon>0$, there exists a polynomial P such that if $|x-x_0| \leq 1/2$,

$$|F(x)-P(x-x_0)| \leq C|x-x_0|^s \log\left(\frac{1}{|x-x_0|}\right). \tag{2.4}$$

Due partly to physical motivations (the study of the velocity of turbulent fluids, for instance), we do not want to consider only bounded functions, and thus we want to be able to consider points where F has a singularity (i.e., in a neighborhood in which it is unbounded). We first want to obtain results similar to (2.3) or (2.4) for singularities. A first problem is the definition of singularities that we should adopt.

The following definition is a straightforward generalization of (1.1) to negative exponents.

DEFINITION 2.1. *Suppose that $-m < s \leq 0$. F is $C^s(x_0)$ if*

$$|F(x)| \leq C|x - x_0|^s. \tag{2.5}$$

We have to make the assumption $-m < s \leq 0$ because if $s \leq m$, F might not be locally integrable and thus might not be a distribution. In that case, no computation on F (such as defining wavelet coefficients) would make sense. We will nonetheless see later how to define singularities of order less than $-m$.

We now relate (2.5) to conditions on the wavelet transform of F. We first check that if (2.5) holds, then

$$|C(a,b)(F)| \leq Ca^s \left(1 + \frac{|b - x_0|}{a}\right)^s; \tag{2.6}$$

First, suppose that ψ is supported in $B(0,1)$. Then

$$|C(a,b)| \leq \frac{C}{a^m} \int_{B(b,a)} |x - x_0|^s dx,$$

where $B(x,r)$ is the ball centered at x of radius r. If $|b - x_0| \geq 2a$ and $x \in B(b,a)$, then $|x - x_0| \sim |b - x_0|$ and $|C(a,b)|$ is bounded by $(C/a^m)4^m a^m |b - x_0|^s$. Otherwise, $|x - x_0| \sim a$ and the integral is bounded by $(C/a^m)4^m a^m a^s$, and hence we have (2.6). The general case holds because condition (2.6) does not depend on the particular wavelet chosen (see [21]).

Note that we will often use the notation $a \sim b$ for positive quantities, which will always mean that the quotient a/b is bounded from below and above by positive constants.

If (2.6) holds, one can easily check that it implies no regularity for F. In that case, of course, we refuse to make a minimal smoothness assumption like $F \in C^\varepsilon(\mathbb{R}^m)$, which was needed in a similar situation in order to get (2.4). Let us show intuitively how to obtain a converse estimate. Suppose that $\text{supp}\psi \subset B(0,1)$, (2.5) holds, and $|\nabla F(x)| \leq C|x - x_0|^{s-1}$; we further have $|C(a,b)| \leq Ca|b - x_0|^{s-1}$ for $|b - x_0| > a$.

Conversely, one can easily check that this last estimate together with (2.6) implies that $|F(x)| \leq C|x - x_0|^s$. We actually prove a slightly more general result.

PROPOSITION 2.2. *Let $-m < s \leq 0$. If $|F(x)| \leq C|x - x_0|^s$, then*

$$|C(a,b)(F)| \leq Ca^s \left(1 + \frac{|b - x_0|}{a}\right)^s.$$

Conversely, suppose that $\exists s' < s$ such that

$$|C(a,b)(F)| \leq Ca^s \left(1 + \frac{|b - x_0|}{a}\right)^{s'}. \tag{2.7}$$

Then $|F(x)| \leq C|x - x_0|^s$.

Proof. We already proved the first part. Suppose that (2.7) holds. Using the reconstruction formula for F,

$$|F(t)| \leq C \int \left[\int_{B(t,a)} |C(a,b)| db\right] \frac{da}{a^{m+1}}.$$

If $|t-x_0| \geq 2a$, $|b-x_0| \geq a$ and the right-hand side is bounded by

$$C \int_{a \leq \frac{|t-x_0|}{2}} a^{s-s'} |t-x_0|^{s'} \frac{a^m}{a^{m+1}} da \leq C|t-x_0|^s.$$

If $|t-x_0| \leq 2a$, $|b-x_0| \leq 4a$ and we get the bound

$$C \int_{a \geq \frac{|t-x_0|}{2}} a a^s a^m \frac{da}{a^{m+1}} \leq C|t-x_0|^s.$$

Hence Proposition 2.2 follows. □

Let us now recall the following definition of the two-microlocal spaces $C^{s,s'}(x_0)$ (see [17]):

$$F \in C^{s,s'}(x_0) \Longleftrightarrow |C(a,b)| \leq C a^s \left(1 + \frac{|b-x_0|}{a}\right)^{-s'}. \tag{2.8}$$

Proposition 2.2 generalizes to negative exponents the continuous embeddings

$$C^s(x_0) \hookrightarrow C^{s,-s'}(x_0) \quad \text{if } s' < s, \tag{2.9}$$

proved in [21], so that it also yields a justification of Definition 2.1 (and thus to the definition of strong α-singularities when $\alpha \leq 0$).

The problem of defining Hölder exponents for $s \leq -m$ is not straightforward. As mentioned before, we cannot consider only conditions such as $|F(x)| \leq C|x-x_0|^s$ since this does not imply that F is a distribution. The following definition has sometimes been proposed:

$$F \in C^s(x_0) \Longleftrightarrow (-\Delta)^{-\frac{[s]}{2}} F \in C^{s-[s]}(x_0). \tag{2.10}$$

There are two problems with this definition. The first is that it is not consistent with the definition for $s > 0$. Let us present an example. Consider $F(x) = x^{1/2}\cos(1/x)$; the integral of F is $O(x^{5/2})$ at the origin. Nonetheless, we would not consider F to be a $C^{3/2}$ function at the origin. Furthermore, this definition is also not consistent with the "natural" definition (2.5) when $-n < \alpha \leq 0$ for essentially the same reasons (we leave this verification to the reader). In order to go further, we interpret (2.10) as a two-microlocal condition. It implies $(-\Delta)^{-\frac{[s]}{2}} F \in C^{s-[s],-s+[s]}(x_0)$ so that $F \in C^{s,-s+[s]}(x_0)$. This condition is very far from $f \in C^{s,-s}$ which because of Proposition 2.2 should be "close" to the condition $F \in C^s(x_0)$. We show how to obtain a definition which is consistent with the definition for $s > -m$ and with the imbeddings in (2.9).

First, note that if s' is positive, $C^{s,s'}(x_0) \hookrightarrow C^s(\mathbb{R}^m)$, where by extension we define for a negative s

$$C^s(\mathbb{R}^m) = \dot{B}^{s,\infty}_{\infty} = \{F : \; |C(a,b)| \leq C a^s\}.$$

Thus the condition $F \in C^s(x_0)$, where s is negative, implies a global (negative) regularity for F. For $s \leq -m$, we will suppose that this regularity holds, which will guarantee that F is a distribution. In [11], Eyink proposed the definition $f \in C^{s,-s}(x_0)$. The advantage is that Proposition 4.1 can immediately be extended, which one uses with this definition of a pointwise Hölder exponent. The drawback is that this condition implies no pointwise regularity, even for positive s. Thus we adopt the following definition.

Definition 2.3. *Suppose that $s \leq -m$. F belongs to $C^s(x_0)$ if $F \in \dot{B}^{s,\infty}_{\infty}$ and if F restricted to $\mathbb{R}^m - \{x_0\}$ is a function that satisfies*

$$|F(x)| \leq C|x - x_0|^s.$$

Note that this definition is slightly redundant since any function defined on $\mathbb{R}^m - \{x_0\}$ is the restriction of a distribution (defined on $\mathbb{R}^m$) which belongs to $\dot{B}^{s,\infty}_{\infty}$.

If we define $\dot{C}^s(\mathbb{R}^m) = \dot{B}^{s,\infty}_{\infty}(\mathbb{R}^m)$, we have the surprising continuous embedding

$$\dot{C}^s(x_0) \hookrightarrow \dot{C}^s(\mathbb{R}^m),$$

which goes in the opposite direction than it would for positive s.

This definition coincides with Definition 2.1 when $-m < s \leq 0$ since in that case the function F itself is the corresponding distribution, so

$$|F(x)| \leq C|x - x_0|^s \implies F \in \dot{B}^{s,\infty}_{\infty}.$$

Suppose that $F \in C^s(x_0)$. If $|b - x_0| \geq 2a$, as in the case where $s > -m$, we get $|C(a,b)| \leq C|b - x_0|^s$. Since $|C(a,b)| \leq a^s$ by hypothesis, we see that $C^s(x_0) \hookrightarrow C^{s,-s}(x_0)$.

Proposition 2.4. *Using the previous definition of negative Hölder regularity, if $s \leq -m$, the following embeddings hold:*

$$\begin{cases} F \in C^s(x_0) \Rightarrow F \in C^{s,-s}(x_0), \\ F \in C^{s,-s'}(x_0) \quad \textit{for an } s' < s \Rightarrow F \in C^s(x_0). \end{cases} \tag{2.11}$$

The proof of the second implication is similar to the case where $s > -m$. It is interesting to check that some distributions which "should" belong to these generalized Hölder spaces satisfy these conditions. For instance, the distribution $p.p.(1/x)$ defined by

$$\left\langle p.p.\left(\frac{1}{x}\right) \mid \phi \right\rangle = \lim_{\epsilon \to 0} \int_{\mathbb{R} - [-\epsilon, \epsilon]} \frac{\phi(x)}{x} dx$$

is C^{-1} at 0 and $f.p.(1/x^2)$ defined by

$$\left\langle f.p.\left(\frac{1}{x^2}\right) \mid \phi \right\rangle = \lim_{\epsilon \to 0} \left(\int_{\mathbb{R} - [-\epsilon, \epsilon]} \frac{\phi(x)}{x^2} dx - \frac{2\phi(0)}{\epsilon} \right)$$

is C^{-2} at the origin. We leave these verifications as an exercise.

We now prove the following proposition, which relates the size of the wavelet transform to the existence of strong α-singularities when the wavelet used is compactly supported.

Proposition 2.5. *Suppose that F is $C^\alpha(x_0)$ and that x_0 is a wavelet α-singularity of F. Then x_0 is a strong α-singularity of F.*

For the sake of simplicity, we restrict our focus to the case where $0 < \alpha < 1$. Suppose that F is $C^\alpha(x_0)$ and that x_0 is not a strong α-singularity of F. Let $\epsilon > 0$

be fixed and $a > 0$ be such that (1.3) does not hold for any (a, b) in the cone over x_0. For any x in the ball $B(x_0, Ca)$ (except on an exceptional set E_a of measure at most ϵa^m), we have

$$|F(x) - \bar{F}| \leq \epsilon a^{\alpha},$$

where $\bar{F}$ is the mean value of F in the ball $B(x_0, Ca)$. Also, if $x \in E_a$,

$$|F(x) - \bar{F}| \leq |x - x_0|^{\alpha}.$$

If the support of the wavelet $\psi((x - b)/a)$ is included in $B(x_0, Ca)$,

$$|C(a,b)| = \frac{1}{a^m} \left| \int F(x) \psi\left(\frac{x-b}{a}\right) dx \right| \leq \frac{1}{a^m} \int_{B(x_0, Ca)} |F - \bar{F}|,$$

the integral on E_a is bounded by $a^{\alpha} \epsilon a^m$ and outside E_a by $\epsilon a^{\alpha} a^m$, so $|C(a, b)| \leq 2C\epsilon a^{\alpha}$ and (1.3) does not hold. Hence we have a contradiction, and thus Proposition 2.5 holds.

The condition that F is $C^{\alpha}(x_0)$ is necessary in Proposition 2.5, as shown by the following counterexample. Suppose that ψ (perhaps after a translation) is compactly supported in an interval of the form $[2^l, 2^{l+1}]$, and suppose that the $2^{j/2}\psi(2^j x - k)$'s form an orthonormal wavelet basis of $L^2(\mathbb{R})$ (see [8] for such functions). Let I be an interval such that $\psi(x) \geq C > 0$ on I. Define $F(x) = \sum_j 2^{-(\alpha-1)j} 1_{A_j}(x)$, where $A_j = 2^{-j} I_j$ and I_j is a subinterval of I of length 2^{-j}. Then clearly $2^{-j} \int F(x)\psi(2^j x) dx \geq C 2^{-\alpha l j}$ but F has no strong singularity at 0 (but is only $C^{\alpha-1}(0)$).

3. Some functional norm estimates. We first show the link between quantities such as $S_p(l)$ or $\tilde{Z}(a, q)$ and Sobolev or Besov-type norms. We recall a few definitions and characterizations.

Suppose that $s \in \mathbb{R}$ and $p, q > 0$. A function F belongs to the homogeneous Besov space $B_p^{s,q}$ if

$$\int_{a>0} \left[\int |C(a,b)|^p db \right]^{q/p} \frac{da}{a^{sq+1}} < +\infty \tag{3.1}$$

(which follows directly from [25]).

Since $\eta(p)$ is the infimum of all numbers τ verifying, for a small enough,

$$\tilde{Z}(a,p) \left(= \int |C(a,b)|^p db \right) \leq C a^{\tau},$$

we see that if $p > 0$,

$$\eta(p) = \sup\{\tau : F \in B_p^{\tau/p, \infty}\}. \tag{3.2}$$

A similar characterization exists for the function $\zeta(p)$. The spaces $H^{s,p}$ introduced by Nikol'skii (see [1] or [27]) are defined as follows.

Let $s \geq 0$. If s is not an integer, $s = m + \sigma$ with m integer and $0 < \sigma < 1$. Let $p \geq 1$, $F \in H^{s,p}$ if $F \in L^p$ and for any multiindex α such that $|\alpha| = m$,

$$\int \frac{|\partial^{\alpha} F(x+h) - \partial^{\alpha} F(x)|^p}{|h|^{\sigma p}} dx \leq C. \tag{3.3}$$

Recall that $\zeta(p)$ is the lim sup of the numbers ξ such that

$$S_p(h)\left(=\int |F(x+h)-F(x)|^p dx\right) \leq Ch^{\xi(p)}$$

for h small enough. Thus if $p \geq 1$, $\zeta(p) = \sup\{s : F \in H^{s/p,p}\}$.

Of course, we see here that the formula in the structure function method must be modified as follows in order to be consistent with (3.3): If $\zeta(p)$ is less than 1, the formula is all right; if it is equal to 1, one should use the same formula but with the gradient of F; and so on until $\zeta(p)$ falls between two integers. (Note that this procedure is obviously difficult to handle numerically if $\zeta(p)$ is large.)

The following embeddings hold if $p \geq 1$:

$$\forall \epsilon > 0, \quad H^{s+\epsilon,p} \hookrightarrow B_p^{s,\infty} \hookrightarrow H^{s-\epsilon,p} \tag{3.4}$$

(because (3.4) holds between $H^{s,p}$ and $W^{s,p}$ spaces (see [1]), between $W^{s,p}$ and $L^{p,s}$ spaces (see [1]), and between $L^{p,s}$ and $B^{s,\infty}$ spaces (see [21] or [25])). Thus, if $p > 1$, $\zeta(p) = \eta(p)$ and the function η can be defined by

$$\eta(p) = \sup\{s : F \in B_p^{s/p,p}\} = \sup\{s : F \in L^{p,s/p}\} \tag{3.5}$$

(where $L^{p,s}$ is defined for $s > 0$ by $f \in L^{p,s} \Leftrightarrow f \in L^p$ and $(-\Delta)^{s/2} f \in L^p$), and if $0 < p \leq 1$, it can be defined by the first equality only, so the last characterization of $\eta(p)$ in (3.5) is again a straightforward consequence of Sobolev-type embeddings.

PROPOSITION 3.1. *The following characterizations hold:*

$$\forall p > 0, \quad \eta(p) = \sup\{s : F \in B_p^{s/p,\infty}\},$$
$$\forall p > 1, \quad \eta(p) = \zeta(p) = \sup\{s : F \in H^{s/p,p}\} = \sup\{s : F \in L^{s/p,p}\}.$$

Remark. The number $\eta(2)$ can be interpreted as follows:

$$\eta(2) = \sup\left\{s : \int |\hat{F}(\xi)|^2 (1+|\xi|^2)^{s/2} d\xi \leq C\right\}.$$

This holds because $B_2^{s,2} = L^{2,s}$, and $\forall q, q', q''$, $B_p^{s+\epsilon,q} \subset B_p^{s,q'} \subset B_p^{s-\epsilon,q''}$, so

$$\begin{aligned}\eta(2) &= \sup\{s : F \in B_2^{s,\infty}\} = \sup\{s : F \in B_2^{s,2}\} \\ &= \sup\{s : F \in L^{2,s/2}\} = \sup\left\{s : \int |\hat{F}(\xi)|^2 (1+|\xi|^2)^{s/2} d\xi \leq C\right\}.\end{aligned}$$

Note that this result differs from [3], where the interpretation given for $\eta(2)$ is $|\hat{F}(\xi)|^2 \sim |\xi|^{-\eta(2)-2}$. Nonetheless, the interpretation given in [3] is correct provided that such a scaling holds. An interpretation of $\eta(1)$ of very different nature will be given in section 4.

We will show in section 6 that "any" function $d(\alpha)$ can be a Hölder spectrum. It is interesting to notice that this is not the case with the function $\eta(p)$, which because of the Sobolev imbeddings between $L^{p,s}$ spaces cannot be arbitrary. Since $L^{p,s} \subset L^{t,q}$ if $t \leq s$ and $q = mp/(m-(s-t)p)$ (see [1]), if $q \geq p$,

$$\frac{\eta(q)-\eta(p)}{q-p} \geq \frac{\eta(p)-m}{p}. \tag{3.6}$$

In particular, we see that $\eta'(p) \geq \eta(p) - m/p$. Conversely, it is easy to check that any function $\eta(p)$ that satisfies (3.6) can be associated with a function F so that (3.6) characterizes all possible functions $\eta(p)$.

4. Upper bounds for dimensions of spectrums. A first problem that we meet is that of which mathematical definition of "dimension" we should use. The physical literature is often unclear about this point, sometimes using the term *Hausdorff dimension* but computing it using coverings by boxes of the same size. Of course, a given set of points (a potential "set of Hölder singularities" of our function) can have very different dimensions depending on the definition considered. We will see that the "good definition" depends on the kind of singularities that we look for. For Hölder singularities, we will get bounds on Hausdorff dimensions, and for strong α-singularities, we will get bounds on packing dimensions. An important difference between the two settings is that in the first we necessarily have to suppose some minimal uniform regularity for F, which is not required in the second. We first recall the definition of the Hausdorff dimension and Hausdorff measure.

Let $A \subset \mathbb{R}^n$ and R_ε be the set of all coverings of A by sets of diameter at most ε. Let

$$M(\varepsilon, d) = \inf_{r \in R_\varepsilon} \sum_{A_i \in r} (\operatorname{diam} A_i)^d.$$

Then by definition,

$$d - \operatorname{Mes}(A) = \limsup_{\varepsilon \to 0} \; M(\varepsilon, d)$$

is the d-dimensional Hausdorff measure. The *Hausdorff dimension* of A is

$$D = \inf\{d : d - \operatorname{Mes}(A) = 0\} = \sup\;\{d : d - \operatorname{Mes}(A) = +\infty\}.$$

If the coverings are done using only balls or only dyadic cubes, we obtain an equivalent quantity for the d-measure, and thus D is not changed.

Proposition 4.1. *Let $s - m/p > 0$ and $p > 0$. If $F \in B_p^{s,\infty}$, $d(\alpha) \le m - (s-\alpha)p$. Thus if $\eta(p)$ satisfies $\eta(p) > m \;\forall p$, $d(\alpha) \le \inf_p(m - \eta(p) + \alpha p)$.*

This proposition is reminiscent of [5], where Brown, Michon, and Peyrière proved similar results for measures (in dimension 1). If $s \le m/p$, a function in $L^{p,s}$ or $B_p^{s,\infty}$ can be infinite on a dense set and thus smooth at no point (see [21]), so that no such result can hold if we do not make the assumption $s - m/p > 0$.

Proof of Proposition 4.1. we use a slight modification of the two-microlocal space, for convenience. We thus define

$$(4.1)\quad F \in C_p^{s,s'}(x_0) \quad \text{if and only if } |C_{j,k}| \le C 2^{-(\frac{m}{2}+s)j} j^{2/p} (1 + |2^j x - k|)^{-s'}.$$

We will prove that if $F \in B_p^{s,\infty}$, then $d > 0$. Outside a set of d-measure 0, $F \in C_p^{s-m-d/p,-d/p}(x)$. Thus if $0 < s - m/p < \alpha < s$, the set $\{x : \;\; F \notin C^\alpha(x)\}$ has Hausdorff dimension at most $m - (s-\alpha)p$, and Proposition 4.1 follows.

Let $F \in B_p^{s,\infty}$. Then

$$(4.2)\qquad \forall j, \quad \sum_k |C_{j,k}|^p \, 2^{(ps + \frac{mp}{2} - m)j} \le C.$$

Let d be such that $0 < d \le n$ and $B_{j,k}$ be the ball centered on $k2^{-j}$ and of size

$$\operatorname{diam}(B_{j,k}) \;=\; |C_{j,k}|^{p/d} 2^{\alpha j} j^{-2/d},$$

where α is such that

$$-d\alpha + ps + \frac{mp}{2} - m \;=\; 0.$$

Then (4.2) can be rewritten as

$$\forall j, \quad \sum_k (\operatorname{diam} B_{j,k})^d \le \frac{c}{j^2}. \tag{4.3}$$

Let $A_j = \bigcup_k B_{j,k}$. Equation (4.3) implies that the d-measure of $A = \limsup A_j$ is 0. If $x \notin \limsup A_j$, $\exists\, j_0,\ \forall j \ge 0,\ \forall k,\ x \notin B_{j,k}$ so that

$$|x - k2^{-j}| \ge C|C_{j,k}|^{p/d}\, 2^{\alpha j} j^{-2/d}.$$

Hence

$$\forall j \ge j_0, \quad |C_{j,k}| \le C2^{-(m/2+s-m/p)j}|x - k2^{-j}|^{d/p} j^{2/p}$$

and thus $F \in C_p^{s-m-d/p\,,-d/p}(x)$ (because (4.1) automatically holds for $j \le j_0$). Hence Proposition 4.1 follows.

One can wonder if similar bounds (or equalities) hold for dimensions of strong α-singularities. This problem is important for the following reasons. Recall that the multifractal formalism was introduced for the study of turbulence. In [6], Caffarelli, Kohn, and Nirenberg obtained a bound on the dimension of (possible) singularities in Navier–Stokes equations that is actually a bound on the packing dimension of "strong α-singularities" following the definition that we gave (with $\alpha = 0$).

Another reason to obtain bounds for dimensions of strong singularities is that when global regularity conditions (which imply that F is continuous) no longer hold, no result such as Proposition 4.1 can be proved. Even in the strict framework of self-similar functions, we will see in Part II that no such bounds exist. Since for applications we clearly want to be able to consider unbounded functions (for instance, the velocity of a turbulent fluid may be unbounded), it is important to obtain some positive results in that case.

Our purpose is to prove that if F belongs to $W^{s,p}$, given $\alpha < s$, the set of points x where F has a strong α-singularity has a small packing dimension. We first recall the definition of the packing dimension of a subset of $\mathbb{R}^m$ (see [12]).

Let $J > 0$ and Λ_J be the set of dyadic cubes of size 2^{-J} which contain a point of E. Define

$$m_d(E) \;=\; \lim_{J\to+\infty} \sum_{\lambda\in\Lambda_J} 2^{-dJ} \;=\; \Lambda_j^\sharp\, 2^{-dJ}$$

(where $\Lambda_j^\sharp$ denotes the cardinality of Λ_j) and

$$\operatorname{mes}_d(E) \;=\; \inf_{E\subset\cup E_n} \sum_n m_d\,(E_n).$$

The *box dimension* of E is the value of d for which $m_d\,(E)$ falls from $+\infty$ to 0. This dimension is also called the potential dimension by some physicists. It is the only one that is numerically easy to compute because it does not involve optimal coverings.

The *packing dimension* of E is the value of d for which $\mathrm{mes}_d(E)$ falls from $+\infty$ to 0. It is clearly no larger than the box dimension.

Proposition 4.2. *Let $F \in W^{s,p}(\mathbb{R}^m)$ and α be such that $-m < \alpha \le 1$. The packing dimension of the strong α-singularities of F is bounded by $m-(s-\alpha)p$ so that if $D(\alpha)$ is the packing dimension of strong α-singularities and $-m < \alpha \le 1$, then*

$$D(\alpha) \le \inf_p (m - \eta(p) + \alpha p). \tag{4.4}$$

Such a result is in many cases more satisfactory than Proposition 4.1 since we do not have to make the assumption of a minimal Hölder regularity of F. Actually, the numerical estimation of the upper bound for $D(\alpha)$ when $\alpha = 0$ using (4.4) could be a way to check whether a stronger result than the one obtained by Caffarelli, Kohn, and Nirenberg in [6] holds.

Of course, a way to avoid the problem of unbounded functions could be to consider indefinite integrals or perhaps iterated indefinite integrals of the velocity, but such quantities would have no direct physical interpretation.

We first describe the functional setting that we use. We will give bounds on the packing dimension of strong α-singularities in the Sobolev spaces $W^{s,p}$. Recall that (see [1])

(4.5)

$$\text{if } \ 0 < s < 1, \quad f \in W^{s,p} \ \Leftrightarrow \ f \in L^p \quad \text{and} \quad \int\!\!\int \frac{|f(x+t) - f(x)|^p}{|t|^{m+sp}}\, dx\, dt \le +\infty.$$

For $s \ge 1$, these spaces can be defined as follows. First, if $0 < s < 2$, they can be defined by replacing $|f(x+t) - f(x)|$ by $|f(x+t) + f(x-t) - 2f(x)|$ in (4.5), and if $\alpha \ge 2$, $f \in W^{s,p} \Leftrightarrow f \in L^p$ and $\forall i = 1, \dots, n$, $\partial f/\partial x_i \in W^{s-1,p}$ (see [1]).

The fact that these spaces are defined by a condition on the L^p-modulus of continuity $\omega_p(t) = \|f(\cdot + t) - f(\cdot)\|_p$ will yield an easy direct estimate on the packing dimension of the strong α-singularities. (The intuitive idea is that if x_0 is such a singularity, the contribution for x close to x_0 to the integral $\int_{x\in\mathbb{R}^m} |f(x+t) - f(x)|^p\, dx$ is large.) The spaces $L^{p,s}$ and $W^{s,p}$ are closely related since (see [1]) $W^{s,2} = L^{2,s}$ and $L^{p,s} \subset W^{s,p'}$ if $p > p'$ and $W^{s,p} \subset L^{p',s}$ if $p > p'$. Thus the bound of $D(\alpha)$ given by Theorem 1.4 is a consequence of Proposition 4.2 which we now prove. Define $E_{l,m}$ as the set of points x_0 such that (1.2) holds with

$$2^{-l} \le C < 2 \cdot 2^{-l} \quad \text{and} \quad 2^{-n} \le C' < 2 \cdot 2^{-n}.$$

The set of strong α-singularities of F is $\bigcup_{l,n} E_{l,n}$. Let l and n be fixed. Let Λ_j be the set of dyadic cubes of size 2^{-j} such that $\Lambda_j \cap E_{l,n} \ne \emptyset$. If $\lambda \in \Lambda_j$, there exist $A_j, B_j \subset 3\lambda$ such that (1.2) holds (where 3λ is the cube that has the same center as λ and is three times larger). We restrict the integral (4.5) to $x \in 3\lambda$, $x + t \in 3\lambda$. The integral on this set is thus bounded from below by

$$2^{-2l} 2^{-2mj} \frac{(2^{-n} 2^{-\alpha j})^p}{(2^{-j})^{m+sp}}.$$

If we sum up for all $\lambda \in \Lambda_j$, each integral is taken at most 4^m times. Thus

$$\Lambda_j^\sharp \, 2^{-2l} \, 2^{-np} \, 2^{-j[\alpha p + m - sp]} \le 4^m \|f\|^p_{W^{s,p}}$$

and thus if $d > \alpha p + m - sp$, $d - \text{mes}(E_{l,m}) = 0$ so that $d - \text{mes}(\bigcup_{l,n} E_{l,n}) = 0$. Hence Proposition 4.2 follows.

We now check that if F is a function of one real variable, the box dimension of the graph of F is exactly $2 - \eta(1)$ if $\eta(1)$ is between 0 and 1. This is a straightforward consequence of the following result (see [10] or [13]).

Proposition 4.3. *Suppose* $0 < \gamma < 1$ *and* $F : [0, 1] \to \mathbb{R}$ *is continuous. Then the box dimension of the graph of* F *is exactly* $2 - \gamma$ *if and only if*

$$F \in \bigcap_{\alpha < \gamma} B_1^{\alpha,\infty} \Big\backslash \bigcup_{\beta > \gamma} B_1^{\beta,\infty}.$$

Thus the result holds because $\eta(p) = \sup\{s : F \in B_p^{s/p,\infty}\}$.

5. The wavelet-maxima method. Our purpose in this section is to show that the wavelet-maxima method can yield a function $\theta(q)$ which is much smaller than $\eta(q) - m$ so that in general the multifractal formalism cannot hold using this method. Via our counterexamples, we will show how to slightly modify its definition so that $\theta(q) = \eta(q) - m$. Our specific study of the wavelet-maxima method is justified by its numerical importance. Arneodo, Bacry, and Muzy compared the three numerical methods in cases where the Hölder spectrum is known analytically (self-similar functions, Riemann's function), and they clearly showed (in a personal communication) that the wavelet-maxima method is the most accurate.

The reason why the wavelet-maxima method may fail is easy to understand intuitively if we relate it to the wavelet-transform integral method. The two quantities $\int_{\mathbb{R}^m} |C(a, b)|^q db$ and $a \sum_{\ell \in \mathcal{L}(a)} \sup_{(b,a') \in \ell} |C(a', b)|^q$ have the same order of magnitude if the spacing between the maxima is approximately a since then the second term is a Riemann sum of the first term. Thus the counterexamples that we will construct will have maxima with spacing much smaller than a, and if we slightly modify the wavelet-maxima method by imposing the restriction that we select only one maximum (or, say, C maxima) in an interval of length a, then the multifractal formalism will hold.

In order to give some insight into the pitfalls of the wavelet-maxima method, we begin by describing an example where the maxima accumulate in certain regions. Not surprisingly, this example involves chirps.

Lemma 5.1. *Suppose that* ψ *is compactly supported on* $[0, l]$, *has a vanishing integral and* m *first vanishing moments, and satisfies*

$$\exists \epsilon > 0 \quad \psi(x) = x^m \quad \forall x \in [0, \epsilon].$$

(This is the case, for instance, if ψ *is a spline.) There exists a function* F *that is compactly supported and arbitrarily smooth and a sequence* $a_n \to 0$ *such that for all values of* n, *the wavelet transform* $C(a_n, b)$ *has infinite maxima.*

We first construct F such that this property holds for a small interval of values of the dilation parameter a. The general case will be obtained by a superposition argument. Let

$$F(x) = x^k \sin\left(\frac{1}{x^l}\right) \phi(x),$$

where ϕ is C^∞ except at the origin and supported on $[0, 1]$, $\phi(x) = 1$ $\forall x \in [0, 1/2]$, and ϕ is such that the integral and the first m moments of F vanish. After dilating

ψ, we can suppose that it is equal to x^m on the interval $[0,1]$. Then if $x \leq 1/4$ and $a \in [1/2,1]$,

$$\begin{aligned}\frac{1}{a}\int F(t)\psi\left(\frac{x-t}{a}\right)dt &= \frac{1}{a}\int_x^1 F(t)\left(\frac{x-t}{a}\right)^m dt\\ &= -\frac{1}{a}\int_0^x F(t)\left(\frac{x-t}{a}\right)^m dt = -\frac{1}{a}\int_0^x t^k\left(\frac{x-t}{a}\right)^m \sin(t^{-l})dt\end{aligned}$$

Integrating m times by parts, we obtain either

$$\int F(t)\psi(x-t)dt = a^{-m-1}x^{k+m(l+1)}\sin\frac{1}{x^l} + o(x^{k+m(l+1)})$$

or

$$\int F(t)\psi(x-t)dt = a^{-m-1}x^{k+m(l+1)}\cos\frac{1}{x^l} + o(x^{k+m(l+1)})$$

depending on the parity of m. In all cases, the wavelet transform of F has for $a \in [1/2,1]$ an infinity of lines of maxima. The general case is obtained by considering the function

$$G(x) = \sum_{j=0}^{\infty} 2^{-mj}F(2^j(x-l)),$$

where l is larger than the size of the support of ψ.

This example also shows that one should be careful when using the wavelet-maxima method since the superposition of a small smooth function can completely perturbate the lines of maxima.

We now show that the two functions $\theta(q)$ and $\eta(q)-1$ can differ dramatically so that even in cases where the multifractal formalism holds when using the wavelet integral method, it may prove wrong when using the wavelet-maxima method. To this end, we will construct a smooth function F (so that $\eta(p)$ will take the maximal value that is compatible with the smoothness of the wavelet) such that $\theta(q) = -\infty\ \forall q$. This example will use a wavelet with one vanishing moment. However, we will show how to modify it in order to deal with wavelets with a given number of vanishing moments. We will also show in Part II that F can be a self-similar function (which will provide a case where the multifractal formalism holds using the wavelet integral method and does not hold using the wavelet-maxima method).

Proposition 5.2. *Let ψ be even and compactly supported* (*say on* $[-1,1]$) *and satisfy*

$$\int \psi(x)dx = 0 \quad \textit{and} \quad \int x\psi(x)dx = 1.$$

There exists a C^∞ compactly supported function F such that $\theta(q) = -\infty\ \forall q > 0$.

Proof. The idea of the proof is to construct a function g whose wavelet transform is equal to, say, 1 on an interval and to perturbate it by adding another function whose wavelet transform is extremely small but oscillates extremely fast, thus creating a huge number of new maxima which take values close to 1.

Let g be a C^∞ odd function supported by $[-3,3]$ such that $g(x)=1$ on $[1,2]$. Let

$$h_j(x) = 2^{-j^2}g(2^{j+4}(x-8)) + 2^{-j^4}\sin(2^{j^3}\pi x)\phi(2^jx),$$

where ϕ is a C^∞ function supported on $[1/2, 1]$ that verifies $\phi(x+3/4) = \phi(3/4-x)$ and $\forall x \in [9/16, 15/16]$, $\phi(x) = 1$. Let F be the indefinite integral of $\sum_{j\geq 0} h_j(x)$. Since h_j has a vanishing integral, F is C^∞ and compactly supported. Let G be the indefinite integral of g. F and the series $\sum_{j\geq 0} 2^{-j^2}2^{-j-4}G(2^{j+4}(x-8))$ will have the same function η. (Here the calculation will yield $\eta(p) = p$ because this series is a C^∞ function and the wavelet used will have only one vanishing moment.)

Note that

$$\frac{1}{a}\int \sin(\omega x)\psi\left(\frac{x-b}{a}\right)dx \sin(\omega b)\hat{\psi}(\omega a).$$

(Here $\omega = 2^{j^3}$.) For a given value of j, we choose a in the interval $[1/100.2^{-j}, 1/10.2^{-j}]$ such that $\hat{\psi}(\omega a)$ does not vanish (which is possible since $\hat{\psi}(\omega a)$ is an analytic function of a).

Integrating by parts, one checks that on an interval of length at least $2^{-j-4}5/16$, the wavelet transform of $2^{-j^2}2^{-j-4}G(2^{j+4}(x-8))$ takes a constant value equal to 2^{-j^2}. Thus on the same interval, the wavelet transform of F is $2^{-j^2} + 2^{-j^4}\sin(2^{j^3}b)\hat{\psi}(2^{j^3}a)$. Thus it has about $2^{-j-4}2^{j^3}$ maxima, and

$$\sum_{\max}|C(a,b)|^q \sim 2^{-j-4}2^{j^3}2^{-j^2q}.$$

Since j can be chosen arbitrarily large, the result is proved. □

Note that we could have chosen a wavelet with a given number of vanishing moments. In that case, we would have integrated g not once but the corresponding number of times. The important fact is that the wavelet transform of G should locally be constant. The reader will also easily check that we could have imposed a given function η for F.

6. Counterexamples to the multifractal formalism. We define $\mathcal{C}$ as the class of functions that can be written as the supremum of a countable set of functions of the form $c1_{[a,b]}(x)$ (where we can have $a = b$). Thus Riemann-integrable functions belong to $\mathcal{C}$, but so do, for instance, the indicatrix function of the rationals (but not the indicatrix function of the irrationals).

Proposition 6.1. *Let $d(s) :]0, +\infty[\to [0, m]$ be a function in $\mathcal{C}$. There exist two continuous functions G_1 and $G_2 : \mathbb{R}^m \to \mathbb{R}$ that share the same function $\eta(q)$ such that $d(s)$ is the Hölder spectrum of G_1 while G_2 is C^∞ except at the origin, so its spectrum vanishes everywhere.*

We construct these functions when the space dimension is $m = 1$. The generalization to the multidimensional case is straightforward.

We first construct G_1 when $d(s) = cs1_{a,b}(s)$, where $0 < a \leq b < \infty$ and $cb \leq 1$. We will actually use three other parameters α, β, and γ, where $a = \gamma$, $b = \beta\gamma$, and $c = 1/(\alpha\beta\gamma)$ so that $\gamma > 0$, $\beta \geq 1$, and $\alpha \geq 1$. We thus define $G_1 = F^{(\alpha,\beta,\gamma)}$. The general case will be obtained using a simple "superposition" procedure of the $F^{(\alpha,\beta,\gamma)}$.

We will explicitly construct G_1 by defining its coefficients on an orthonormal wavelet basis. The function G_2 will then be obtained by just moving at each scale the location of the nonvanishing wavelet coefficients of G_1. We use an orthonormal wavelet basis in the Schwartz class (see [25]), and the functions

$$\psi_{j,k}(x) = 2^{j/2}\psi(2^jx - k), \quad j, k \in \mathbf{Z},$$

are an orthonormal basis of $L^2(\mathbb{R})$. Sometimes we will index the wavelets $\psi_{j,k}$ or the wavelet coefficients $C_{j,k}$ $(= \int F\psi_{j,k})$ by the dyadic intervals $\lambda = [k2^{-j}, (k+1)k2^{-j}]$.

Let Λ be the collection of all dyadic intervals of length at most 1. We will construct a subcollection $\Lambda(\alpha,\beta) \subset \Lambda$ and consider the following "lacunary" wavelet series:

$$F(x) = \sum_{\lambda\in\Lambda(\alpha,\beta)} 2^{-(\gamma+1/2)j}\psi_\lambda(x). \tag{6.1}$$

The construction of $\Lambda(\alpha,\beta)$ is performed as follows. Define $\Lambda(\alpha,\beta) = \bigcup_{m\geq 1} \Lambda_m^{(\alpha,\beta)}$, where $\Lambda_m^{(\alpha,\beta)}$ is the set of intervals λ or couples (j,k) such that $j = [\alpha\beta m]$ and

$$2^{-j}k = \epsilon_1 l_1 + \cdots + \epsilon_m l_m \in F_m, \quad \epsilon_1,\dots,\epsilon_m \in \{0,1\}, \quad l_n = 2^{-[\alpha n]},$$

$[x]$ is the entire part of x and thus $k = 2^{[\alpha\beta m]}(\pm l_1 \pm \cdots \pm l_m)$ is an integer since $[\alpha\beta m] \geq [\alpha n]$.

Proposition 6.2. *The function F defined by* (6.1) *belongs to the global Hölder space $C^\gamma(\mathbb{R})$ so that if $s<\gamma$, the set $E^{(s)}$ of points x_0 where $f\in\Gamma^s(x_0)$ is empty. If $\gamma\leq s\leq\beta\gamma$, the Hausdorff dimension of $E^{(s)}$ is $s/\alpha\beta\gamma$. If $s>\beta\gamma$, $E^{(s)}$ is empty.*

The characterization of the space C^γ on the wavelet coefficients is

$$|C_{j,k}| \leq C2^{-(\gamma+1/2)j}$$

(a simple rewriting of (2.2) in the orthonormal basis setting). Thus F belongs to $C^\gamma(\mathbb{R})$ and the spectrum of F vanishes for $s<\gamma$.

Lemma 6.3. *A point x_0 belongs to $E^{(s)}$ if and only if*

$$\operatorname{dist}(x_0, F_m) = \eta_m 2^{-\frac{\alpha\beta\gamma}{s}m}, \quad (F_m = \{\pm l_1 \pm l_2 \pm \cdots \pm l_m\}) \tag{6.2}$$

with

$$\liminf_{m\to\infty} \eta_m 2^{-m\epsilon} = 0 \quad \textit{for any } \epsilon > 0 \tag{6.3}$$

and

$$\liminf_{m\to\infty} \eta_m 2^{m\epsilon} = +\infty \quad \textit{for any } \epsilon > 0. \tag{6.4}$$

Proof. If F is $C^s(x_0)$, the rewriting of (2.3) yields

$$|C_{j,k}| \leq C2^{-(s+1/2)j}(1+|2^jx_0-k|)^s. \tag{6.5}$$

Conversely, from (2.3), we deduce that if (6.5) holds and if F is $C^\epsilon(\mathbb{R})$ for an $\epsilon>0$, then there exists a polynomial P such that

$$|F(x)-P(x-x_0)| \leq C|x-x_0|^s \log\left(\frac{1}{|x-x_0|}\right).$$

Thus we see that F is $C^{s-\epsilon}(x_0)$ $\forall\epsilon>0$ if $\forall\epsilon>0$, $\forall\lambda\in\Lambda(\alpha,\beta)$,

$$2^{-(\gamma+1/2)j} \leq C2^{-(s-\epsilon+1/2)j}(1+|2^jx_0-k|)^{s-\epsilon} = C2^{-j/2}(2^{-j}+\operatorname{dist}(x_0,\lambda))^{s-\epsilon}.$$

Conversely, if $\exists\lambda\in\Lambda(\alpha,\beta)$ corresponding to arbitrary large values of j such that

$$2^{-(\gamma+1/2)j} \geq C2^{-j/2}(2^{-j}+\operatorname{dist}(x_0,\lambda))^{s+\epsilon},$$

F does not belong to $C^{s+\epsilon}(x_0)$ $\forall\epsilon > 0$. These two conditions can be written as

$$\limsup_{\lambda\in\Lambda(\alpha,\beta)} 2^{-\gamma j}(2^{-j} + \operatorname{dist}(x_0,\lambda))^{-s-\epsilon} = +\infty \quad \text{for any } \epsilon > 0 \tag{6.6}$$

and

$$\limsup_{\lambda\in\Lambda(\alpha,\beta)} 2^{-\gamma j}(2^{-j} + \operatorname{dist}(x_0,\lambda))^{-s+\epsilon} < \infty \quad \text{for any } \epsilon > 0. \tag{6.7}$$

Condition (6.6) can also be written as

$$2^{-j} + \operatorname{dist}(x_0,\lambda) = \eta(\lambda)2^{-\frac{\gamma}{s+\epsilon}j},$$

where $\liminf \eta(\lambda) = 0$. Since $s \geq \gamma$, $2^{-j} = o(2^{-\frac{\gamma}{s+\epsilon}j})$ and the only condition to be checked is

$$\operatorname{dist}(x_0,\lambda) = \eta(\lambda)2^{-\frac{\gamma}{s+\epsilon}j}.$$

Since $\lambda \in \Lambda_m^{(\lambda,\beta)}$, this condition is equivalent to (6.3).

The same proof shows that (6.7) becomes (6.4). Hence we have Lemma 6.3.

We now define a compact K_α and sets $E_{\alpha,\delta}$, K_α will be composed of the limit points of the F_m, and the $E_{\alpha,\delta}$'s will be subsets of K_α.

Let K_α be the compact set of the sums $\sum_1^\infty \epsilon_j l_j$, where $\epsilon_j = \pm 1$. Another equivalent definition is

$$K_\alpha = \bigcap_1^\infty (F_m + [-\lambda_m, \lambda_m]),$$

where

$$\lambda_m = l_{m+1} + l_{m+2} + \cdots.$$

Note that the sets $G_m = F_m + [-\lambda_m, \lambda_m]$ form a decreasing sequence of compact sets.

Let $G_m^{(\beta)}$ be defined by $G_m^{(\beta)} = F_m + [-\lambda_m^\beta, \lambda_m^\beta]$ and let $E_{\alpha,\beta}$ be the set of points that belong to infinite $G_m^{(\beta)}$'s. Since $\beta \geq 1$, $G_m^{(\beta)} \subset G_m$ so that $E_{\alpha,\beta} \subset K_\alpha$ and, of course, $E_{\alpha,\beta} = K_\alpha$ if $\beta = 1$.

The idea of the construction that we made is as follows. We have placed "large" wavelet coefficients on F_m so that on these sets the function F is exactly Γ^γ, but at points which are at a certain distance on F_m (measured by their belonging to certain $G_m^{(\beta)}$'s), these "large" wavelet coefficients create "weaker" singularities (corresponding to an exponent larger than γ).

Lemma 6.4. *If $\gamma \leq s < \beta\gamma$, then* (6.3) *is equivalent to $x \in \bigcap_{\delta<\frac{\beta\gamma}{s}} E_{\alpha,\delta}$, while if $s \geq \beta\gamma$, it is equivalent to $x \in K_\alpha$. Condition* (6.4) *is equivalent to $x \notin \bigcup_{\delta>\frac{\beta\gamma}{s}} E_{\alpha,\delta}$, while if $s > \beta\gamma$, it is equivalent to $x \notin K_\alpha$.*

Proof. If (6.3) holds and if $\delta < \beta\gamma/s$, let us check that $x \in E_{\alpha,\delta}$. To this end, we choose $\epsilon > 0$ such that $\delta < \beta\gamma/s - \epsilon$. Then

$$\operatorname{dist}(x_0, F_m) = \eta_m 2^{-\frac{\alpha\beta\gamma}{s}m} = o(2^{-(\frac{\alpha\beta\gamma}{s}-\epsilon)m})$$

so that $\operatorname{dist}(x_0, F_m) = o(l_m^\delta) \leq \lambda_m^\delta$ (because $\lambda_m \sim l_m$) for infinite values of m. Thus $x \in E_{\alpha,\delta}$.

Conversely, if $x \in E_{\alpha,\delta}$, $\operatorname{dist}(x, F_m) \le \lambda_m^\delta$ so that $\operatorname{dist}(x, F_m) \le C2^{-\alpha\delta m}$ for infinite values of m. If $\delta > \beta\gamma/s - \epsilon$, we get (6.3). When $s \ge \beta\gamma$, we observe that if $\eta_m > 0$ is an arbitrary sequence such that $\liminf \eta_m = 0$ and if

$$x \in \bigcap_{m \ge 1} F_m + [-\eta_m, \eta_m],$$

then $x \in K_\alpha$. This is because K_α is a compact set, and if $x \notin K_\alpha$, then $\operatorname{dist}(x, K_\alpha) = \eta > 0$ so that $\operatorname{dist}(x, F_m) \ge \eta$; hence we have a contradiction. Condition (6.3) is thus equivalent to $x \in K_\alpha$ as soon as $s \ge \beta\gamma$. The proof of the second part of the lemma is similar.

LEMMA 6.5. *The Hausdorff dimension of $E_{\alpha,\beta}$ is $1/\alpha\beta$. If $\gamma \le s \le \beta\gamma$, the Hausdorff dimension of $E^{(s)}$ is $s/\alpha\beta\gamma$. If $s > \beta\gamma$, the set $E^{(s)}$ is empty.*

The set $E_{\alpha,\beta}$ is defined by

$$E_{\alpha,\beta} = \bigcap_{m \ge 1} E_{\alpha,\beta}^{(m)} \quad \text{where } E_{\alpha,\beta}^{(m)} = G_m^{(\beta)} \cup G_{m+1}^{(\beta)} \cup \cdots \text{ and } G_m^{(\beta)} = F_m + [-\lambda_m^\beta, \lambda_m^\beta].$$

For any $\epsilon > 0$, we can cover $E_{\alpha,\beta}$ by the intervals I_q that appear in $G_n^{(\beta)}$, $n \ge m$. For a fixed n, there are 2^n such intervals of length $\sim 2^{-\alpha n\beta}$ so that if $d > 1/\alpha\beta$, $\sum |I_q|^d \le C$, where C does not depend on ϵ. Thus the Hausdorff dimension of $E_{\alpha,\beta}$ is bounded by $1/\alpha\beta$.

Now suppose that $\gamma \le s \le \beta\gamma$. Then

$$E^{(s)} = \left(\bigcap_{\delta < \frac{\beta\gamma}{s}} E_{\alpha,\delta} \right) \Bigg\backslash \left(\bigcup_{\delta > \frac{\beta\gamma}{s}} E_{\alpha,\delta} \right) \qquad \text{if } \gamma \le s < \beta\gamma,$$

while if $s = \beta\gamma$,

$$E^{(s)} = K_\alpha \Bigg\backslash \left(\bigcup_{\delta > 1} E_{\alpha,\delta} \right).$$

Checking is done the same way in both cases, so we suppose that $\gamma \le s < \beta\gamma$. Thus $E^{(s)} \subset E_{\alpha,\delta}$ for all $\delta < \beta\gamma/s$ so that $\dim(E^{(s)}) \le s/\alpha\beta\gamma$. Hence we have the two upper bounds for the Hausdorff dimensions in Lemma 6.5.

In order to obtain the lower bounds, we use a standard procedure. We construct a probability measure μ that is supported on $E_{\alpha,\beta}$ and has certain "scalings."

We now construct this measure.

Let $m_1 < m_2 < \cdots$ be an increasing sequence of integers that tends to ∞ quickly enough that for any $n \ge 1$, $m_{n+1} \ge \exp(m_n)$, and now let

$$K_{(\alpha,\beta)} = \bigcap_{n \ge 1} \tilde{G}_{m_n}^{(\beta)} \tag{6.8}$$

with

$$\tilde{G}_m^{(\beta)} = F_m + [-2^{-[\alpha\beta m]}, 2^{-[\alpha\beta m]}]. \tag{6.9}$$

This means that $\tilde{G}_m^{(\beta)}$ is a finite union of dyadic intervals, and the dyadic intervals that form $\tilde{G}_{m+1}^{(\beta)}$ will either be disjoint of those composing $\tilde{G}_m^{(\beta)}$ or included in them (just because they are dyadic intervals of smaller length). We have $[\alpha\beta m] \geq \beta[\alpha m]$, and the set $\tilde{G}_m^{(\beta)}$ is included in $G_m^{(\beta)}$ so that $K_{(\alpha,\beta)} \in E_{\alpha,\beta}$.

Let N_n be the number of intervals of length $2.2^{-[\alpha\beta m_n]}$ that can be found in $H_n = \tilde{G}_{m_1}^{(\beta)} \cap \cdots \cap \tilde{G}_{m_n}^{(\beta)}$, and let μ_n be the probability measure which on each of these N_n intervals takes the value $2^{[\alpha\beta m_n]}(2N_n)^{-1}dx$. We can easily check that $\mu_n \rightharpoonup \mu$ when $n \to \infty$, where $\mu = \mu_{(\alpha,\beta)}$ is supported by $K_{(\alpha,\beta)}$.

LEMMA 6.6. *There exists C such that $\forall I$ of length $|I| \leq 1/2$,*

$$\mu(I) \leq C|I|^{1/\alpha\beta} \log \frac{1}{|I|}. \tag{6.10}$$

Proof. We first estimate N_n. H_n is composed of N_n intervals of length $2^{-[\alpha\beta m_n]}$. When constructing H_{n+1}, we split each of these intervals into $2^{m_{n+1}-\beta m_n+\epsilon_n}$ intervals, where $|\epsilon_n| \leq 2$. Thus $N_{n+1} = N_n 2^{m_{n+1}-\beta m_n+\epsilon_n}$.

Now let I be an interval and define n by $2^{-\alpha\beta m_n} \leq |I| < 2^{-\alpha\beta m_{n-1}}$.

Consider the two cases $2^{-\alpha\beta m_n} \leq |I| < 2^{-\alpha m_n}$ and $2^{-\alpha m_n} \leq |I| < 2^{-\alpha\beta m_{n-1}}$. In the first one, I intersects at most two of the intervals that compose H_n so that

$$\mu(I) \leq CN_n^{-1} \leq C' 2^{-m_n+O(m_{n-1})} \leq C|I|^{1/\alpha\beta} \log(|I|)$$

since $m_n \geq \exp(m_{n-1})$. In the second case, suppose that $|I| \sim 2^{-\alpha j}$. Thus $\beta m_{n-1} \leq j \leq m_n$. I meets at most 2^{m_n-j} intervals so that $\mu(I) \leq 2^{m_n-j}/N_n$, but $N_n = N_{n-1}2^{m_n-\beta m_{n-1}+\epsilon_n}$. Thus

$$\begin{aligned}\mu(I) &\leq \frac{2^{-j}2^{\beta m_{n-1}-\epsilon_n}}{N_{n-1}} \leq C|I|^{1/\alpha\beta}2^{j/\beta}2^{-j}2^{\beta m_{n-1}}2^{-m_{n-1}+O(m_{n-2})}\\ &\leq C|I|^{1/\alpha\beta}2^{\frac{(\beta-1)}{\beta}(\beta m_{n-1}-j)+O(m_{n-2})}\end{aligned}$$

so that $\mu(I) \leq C|I|^{1/\alpha\beta}\log(|I|)$. Hence we have Lemma 6.6. □

We now prove the lower bounds in Lemma 6.5. We use the following slight modification of Hausdorff measure. Let $A \subset \mathbb{R}^m$ and R_ε be the set of all coverings of A by sets of diameter at most ε. Let

$$M(\varepsilon, d) \;=\; \inf_{r\in R_\varepsilon} \sum_{A_i \in r} (\operatorname{diam} A_i)^d \log\left(\frac{1}{(\operatorname{diam} A_i)}\right)$$

and let

$$d - \operatorname{mes}(A) \;=\; \limsup_{\varepsilon\to 0}\; M(\varepsilon, d)$$

be this "modified" d-dimensional Hausdorff measure. Of course, this modification does not change the Hausdorff dimension of A, which is

$$D \;=\; \inf\{d : d - \operatorname{mes}(A) = 0\} =\; \sup\,\{d : d - \operatorname{mes}(A) = +\infty\}.$$

We conclude with the following classical proposition (cf. [12]).

PROPOSITION 6.7. *Let $\mathcal{H}^s$ be the modified Hausdorff measure of dimension s. Let μ be a probability measure on $\mathbb{R}^m$, $F \in \mathbb{R}^m$. If $\limsup_{r\to 0} \mu(B(x,r))/r^s \log(1/r) < C \;\forall x \in F$,*

$$\mathcal{H}^s(F) \geq \frac{\mu(F)}{C}.$$

The first lower bound in Lemma 6.5 is thus a consequence of Lemma 6.6 and Proposition 6.7. The $\mathcal{H}^{1/\alpha\beta}$ measure of $E_{\alpha,\beta}$ is strictly positive, and thus the Hausdorff dimension of $E_{\alpha,\beta}$ is at least $1/\alpha\beta$.

We show that $\dim(E^{(s)}) \geq s/\alpha\beta\gamma$. Let μ be the probability measure $\mu_{\alpha,\beta\gamma/s}$. We check that

$$E^{(s)} \supset E_{\alpha,\beta\gamma/s} \Bigg\backslash \left(\bigcup_{\delta > \beta\gamma/s} E_{\alpha,\delta} \right) \tag{6.11}$$

and

$$\mu(E_{\alpha,\delta}) = 0 \quad \text{for any } \delta > \frac{\beta\gamma}{s};$$

since the union of these sets can be written as a countable union, the measure of their union vanishes so that the measure of $E^{(s)}$ is the same as the measure of $E_{\alpha,\beta\gamma/s}$, which is strictly positive. Hence we have the last point of Lemma 6.5.

We now prove the general case in Proposition 6.1.

Let $E_1, E_2, \ldots$ be disjoint subsets of $\mathbb{R}$ and suppose that $E_k \subset [a_k, b_k]$, where the $[a_k, b_k]$'s are disjoint. Let d_k be the Hausdorff dimension of E_k. Then the Hausdorff dimension of $\bigcup_{k\geq 1} E_k$ is $\sup(d_k)$.

We return to the function $F_{(\alpha,\beta,\gamma)}$. Clearly, $F_{(\alpha,\beta,\gamma)}$ has fast decay and is C^∞ outside of a compact set. After replacing $F_{(\alpha,\beta,\gamma)}(x)$ by $F_{(\alpha,\beta,\gamma)}(px+q)$, we can, without changing the spectrum of $F_{(\alpha,\beta,\gamma)}$, suppose that it is C^∞ outside any given interval $[a,b]$. Let $F_k(x) = f_{(\alpha_k,\beta_k,\gamma_k)}(x)$ be a sequence of functions as in Proposition 6.2 and consider the corresponding spectra $d_k(s)$. We can suppose that the singular supports of the $F_k(x)$'s are included in $[2^{-k-1}, 2^{-k}]$. (The singular support of a function is the closure of the set where this function is not C^∞.) We can also replace F_k by $\epsilon_k F_k$, where $\epsilon_k > 0$ tends to 0. Then let $G_1 = \sum_0^\infty \epsilon_k F_k$, and $d(s)$ is the supremum of the $d_k(s)$'s. The function G_1 thus constructed satisfies the requirements of Proposition 6.1, since we can easily check that a supremum of a countable set of functions of the form $ax1_{[b,c]}(x)$ is also a supremum of functions of the form $a1_{[b,c]}(x)$.

The construction of G_2 is now very easy. We remark that at each level j, the number of nonvanishing wavelet coefficients of $F_{(\alpha,\beta,\gamma)}$ is $o(2^j)$. Thus the same property holds for G_1 itself if we have chosen the contraction factors p (defined above) to be large enough. We now consider a function G_2 that has at each level j the same nonvanishing wavelet coefficients as G_1 but situated at different dyadic intervals. We group them in the smallest possible interval I_j centered at the origin. Thus the quantity (4.2) is the same for G_1 and G_2 so that these two functions share the same $B_p^{s,\infty}$ norm and hence the same function η. Nonetheless, if $x \neq 0$, there are a finite number of nonvanishing wavelet coefficients in a certain interval centered at x because the length of I_j tends to 0. Thus F_2 is C^∞ at x.

We now check that G_1 and G_2 are counterexamples to the following problem raised in [9]: Is η or ζ the Legendre transform of $m - d(\alpha)$?

Consider the function F defined by (6.1). At each level $j = [\alpha\beta m]$, it has 2^m wavelet coefficients equal to $2^{-(\gamma+1/2)j}$ so that for this j,

$$\left(\sum_k |C_{j,k}|^p \right)^{1/p} \sim 2^{(-(\gamma+1/2)+1/p\alpha\beta)j}$$

so that

$$\|F\|_{B_p^{s,\infty}} \sim 2^{js}2^{j(\frac{1}{2}-\frac{1}{p})}\left(\sum_k |C_{j,k}|^p\right)^{1/p} \sim 2^{j(s-\gamma+\frac{c\gamma}{p}-\frac{1}{p})}$$

and $\eta(p) = ap + 1 - ca$.

Thus $\eta(p)$ is linear and does not depend on b so that it clearly can be the Legendre transform of neither $cs1_{[a,b]}(s)$ (when $a \neq b$) nor the function 0. Thus in general, neither F_1 nor F_2 satisfies that η or ζ is the Legendre transform of its spectrum.

7. Acknowledgments. The author is thankful to Alain Arneodo, Emmanuel Bacry, Benoit Mandelbrot, and Yves Meyer for many enlightening discussions.

MULTIFRACTAL FORMALISM FOR FUNCTIONS PART II: SELF-SIMILAR FUNCTIONS*

S. JAFFARD†

Abstract. In this paper we introduce and study the *self-similar functions.* We prove that these functions have a concave spectrum (increasing and then decreasing) and that the different formulas that were proposed for the multifractal formalism allow us to determine either the whole increasing part of their spectrum or a part of it. One of these methods (the wavelet-maxima method) yields their complete spectrum.

Key words. multifractal formalism, self-similarity, wavelet transform

1. Introduction.

We proved in Part I that the multifractal formalism always yields an upper bound for the Hölder spectrum. Hence a very natural and important question arises: When does it yield the exact spectrum? Partial results exist for multifractal measures (especially when multinomial or for invariant measures of dynamical systems; see [6] and [8]). Hence we have similar results for the functions that are indefinite integrals of these measures. Apart from these functions, no general results hold. A few examples have been worked out: the scaling functions ϕ that appear in wavelet constructions [12], Riemann's nondifferentiable function [20], and the "peano-type" function of Polya [21]. These three examples exhibit a common feature: their graphs follow locally some self-similarity conditions. This is explicitly stated below in (2.7) for Riemann's function. The recursive definition of Polya's function is an exact self-similarity condition, and this is also the case for the scaling equation of the ϕ functions.

We can thus infer that the multifractal formalism probably holds if the function considered exhibits some kind of self-similarity. Of course, this assertion is very vague, and we are now far from guessing what is the weakest form of local self-similarity that implies the validity of the multifractal formalism. Our purpose is to verify it for a case study, i.e., under some restrictive assumptions for the self-similarity conditions. These assumptions are listed in Definition 2.1 below. In our opinion, this partial result is interesting for two reasons: 1) it is the first proof of the validity of the multifractal formalism for a several-parameter family of functions different from indefinite integrals of measures; 2) we also expect the methods we introduce to extend to more general settings. There is already some evidence for this. Since the first preprint version of this paper, Daubechies showed that some of the results concerning scaling functions can be deduced from our study [11]. Slimane showed that our restricive conditions concerning the contractions S_i in Definition 2.1 can be weakened [4].

2. Basic properties of self-similar functions.

In this section, we recall the definition of self-similar functions, give some examples, and derive their basic properties.

In the following two sections, we obtain the exact regularity of these functions at any point when the functions considered have uniform minimal regularity.

In section 4, we deduce these functions' Hölder spectra in the aforementioned case.

In section 5, we prove the validity of the multifractal formalism.

In section 6, we study the wavelet-maxima method. We show that after a slight modification, this method yields the complete spectrum, including the part where the infimum in the Legendre transform is obtained for negative values of q.

In section 7, we consider the more general case of unbounded self-similar functions.

We first recall the definition of self-similarity that was established in Part I.

Definition 2.1. *A function $F : \mathbb{R}^m \to \mathbb{R}$ is self-similar (of order $k \in \mathbb{R}^+$) if the following three conditions hold:*

- *There exists a bounded open set Ω and $S_1, \dots, S_d$ contractive similitudes such that*

$$S_i(\Omega) \subset \Omega, \tag{2.1}$$

$$S_i(\Omega) \cap S_j(\Omega) = \emptyset \quad \text{if } i \neq j. \tag{2.2}$$

(The S_i's are the product of an isometry with the mapping $x \to \mu_i x$, where $\mu_i < 1$.)

- *There exists a C^k function g such that g and its derivatives of order less than k have fast decay and F satisfies*

$$F(x) = \sum_{i=1}^{d} \lambda_i F(S_i^{-1}(x)) + g(x), \tag{2.3}$$

where the λ_i's are real or complex numbers.

- *The function F is not uniformly C^k in a certain closed subset of Ω.*

The first condition was first introduced by Hutchinson (in [17]) in order to study self-similar sets; it is called the "open-set condition." A stronger condition is sometimes required, namely,

$$S_i(\bar{\Omega}) \cap S_j(\bar{\Omega}) = \emptyset \quad \text{if } i \neq j; \tag{2.4}$$

this is called the "separated open-set condition."

Concerning the last point of the definition, if k is an integer, the condition must be understood as follows. Once restricted to a closed subset A of Ω, the derivatives of order $k-1$ of F do not belong to the Zygmund class. Thus for any $k \in \mathbb{R}^+$, this condition is equivalent to the existence of sequences $a_n \to 0$, $b_n \in A$, and $C_n \to \infty$ such that

$$|C(a_n, b_n)| \geq C_n a_n^k. \tag{2.5}$$

(This condition is a straightforward consequence of the wavelet characterization of the spaces $C^s(\mathbb{R}^m)$ that we recall below and of the localization of the wavelets.)

We will see that solutions of (2.3) need not necessarily be functions but can be distributions.

Recall the following notations introduced in Part I. Let

$$\tilde{Z}(a, q) = \int_{\mathbb{R}^m} |C(a, b)|^q db.$$

Then

$$\eta(q) = \liminf \frac{\log \tilde{Z}(a,q)}{\log a}.$$

Let

$$\alpha_{\min} = \inf_{i=1,\dots,d} \left(\frac{\log \lambda_i}{\log \mu_i} \right), \qquad \alpha_{\max} = \sup_{i=1,\dots,d} \left(\frac{\log \lambda_i}{\log \mu_i} \right).$$

We use this notation because $\alpha_{\min}$ will turn out to be the smallest pointwise Hölder regularity exponent of F and $\alpha_{\max}$ will be the largest (lower than k). Let τ be the function defined by

$$\sum_{i=1}^{d} \lambda_i^a \mu_i^{-\tau(a)} = 1.$$

The results concerning the multifractal formalism for self-similar functions are summed up in the following theorems.

THEOREM 2.2. *Suppose that F is self-similar. If $\alpha_{\min} > 0$, the function $d(\alpha)$ vanishes outside the interval $[\alpha_{\min}, \alpha_{\max}] \cup [k, +\infty)$ and is analytic and concave on $[\alpha_{\min}, \alpha_{\max}]$. Its maximal value $d_{\max}$ satisfies*

$$\sum \mu_i^{d_{\max}} = 1.$$

Let α_0 be the value for which this maximum is attained. First, suppose that g is C^∞. If $\alpha \le \alpha_0$, $d(\alpha)$ can be obtained by computing the Legendre transform of $\eta(q) - m$.

If g is only C^k, let p_0 be defined by $\eta(p_0) = kp_0$ and let $\alpha_1 < \alpha_0$ be the value of the inverse Legendre transform of $\eta(q) - m$ at p_0. If $\alpha \le \alpha_1$, $d(\alpha)$ can be obtained by computing the Legendre transform of $\eta(q) - m$.

Without any assumption on $\alpha_{\min}$, if $\sum |\lambda_j| \mu_j^m < 1$, the same results hold if we replace $d(\alpha)$ with $D'(\alpha)$, the packing dimension of the wavelet α-singularities (or by $D(\alpha)$, if g and the λ_i's are positive, and furthermore if the separated open-set condition holds).

The corresponding results concerning the *wavelet-maxima method* will be stated and proved in section 6 (see Theorem 2.3).

Before beginning our study of self-similar functions, we consider a few examples.

(1) *Indefinite integrals of multinomial measures in dimension* 1.

Let μ be a probability measure supported by $[0,1]$ and suppose that for any interval I,

$$\forall i = 1, \dots, d, \quad \mu(S_i(I)) = \lambda_i \mu(I)$$

with $\sum \lambda = D1i = 1$, the S_i's as above, and $\Omega = (0,1)$. Let

$$F(x) = \left(\int_0^x d\mu \right) - x \quad \forall x \in [0,1].$$

F vanishes at 0 and 1, and is smooth outside the intervals $S_i([0,1])$. One immediately checks that F is continuous and

$$\forall x \in S_i([0,1]), \quad F(x) = \lambda_i F(S_i^{-1}(x)) + g_i(x)$$

with g_i linear. Thus F is self-similar.

For any probability measure μ on $\mathbb{R}$, the scaling index of μ at x_0 is the supremum of all values of α such that

$$\exists C > 0, \forall \varepsilon > 0, \quad \mu([x_0 - \varepsilon, x_0 + \varepsilon]) \leq C\varepsilon^{\alpha}.$$

We can easily check that μ has a scaling index α at x_0 if and only if its indefinite integral F defined by $F(x) = \mu([0, x])$ is C^{α} at x_0 (see [2] or [19]). This property allowed Arneodo, Bacry, and Muzy [2] to determine the Hölder spectrum of the indefinite integrals of multinomial measures when the separated open-set condition holds. This remark shows that when F is the indefinite integral of a one-dimensional measure, some results derived in this paper are a consequence of similar results concerning measures (for $\alpha \in [0, 1]$) obtained by Brown, Michon, and Peyrière in [6]. Thus we are particularly interested in the case of functions that are not in bounded variation (BV), in which case Theorem 2.2 cannot be derived from corresponding results for measures.

(2) *Some self-similar fractal sets.* Consider, for instance, the example of the Van Koch set. Since it is a curve, it can be parametrized (in infinite ways) as the image of a mapping $t \to (x(t), y(t))$ from $[0, 1]$ to $\mathbb{R}^2$. This curve has dimension $\log 4/\log 3$ and a corresponding finite nonzero Hausdorff measure. Therefore, a *canonical* parametrization maps intervals of same length on sets of equal Hausdorff measure. The reader will immediately check that with *this* parametrization the Van Koch function is self-similar. Another example is supplied by Polya's function, a continuous mapping defined on $[0, 1]$ whose graph fills the area of a triangle. However, the lack of regularity of the function g in this case requires a specific treatment, and we plan to study the local regularity of this function in a forthcoming paper.

(3) *Lacunary trigonometric series and Riesz products.* Let

$$F_{\alpha}(x) = \sum_{j=0}^{\infty} 2^{-\alpha j} \sin 2\pi 2^j x$$

for $x \in [0, 1]$ and $0 < \alpha \leq 1$. Define

$$\begin{aligned} g(x) &= \sin 2\pi x \quad \text{if } \ x \in [0,1] \\ &= 0 \quad \text{otherwise.} \end{aligned}$$

Obviously,

$$F_{\alpha}(x) = 2^{-\alpha} F_{\alpha}(2x) + 2^{-\alpha} F_{\alpha}(2x - 1) + g(x)$$

so that the F_{α}'s are self-similar.

Another example is very similar. Consider the Riesz products

$$F_{\alpha,k}(x) = \prod_{j=1}^{\infty} (1 + 2^{-\alpha j} \sin(k^j x)),$$

where $0 < \alpha < 1$ and $k \in \mathbb{N}$, $k \geq 2$. It is a simple exercise to check that $\log(F_{\alpha,k}(x))$ is self-similar (the function g being $C^{\inf(2\alpha,1)}$). Since $F_{\alpha,k}(x)$ is bounded from above and below by strictly positive constants, $F_{\alpha,k}(x)$ and its logarithm share the same function η and the same spectrum so that the results that will be proved for self-similar functions will also hold for the Riesz products $F_{\alpha,k}(x)$.

(4) *Several dimension examples.* In dimension 1, the "geometry" contained in the transforms S_i is poor. In several dimensions, this is sometimes no longer the case. Consider two examples. First, if

$$\Omega = [-1,1]^2, \quad \text{let } i,j \in \left\{\frac{1}{2}, -\frac{1}{2}\right\}, \quad \text{and} \quad S_{i,j}(x) = \frac{1}{2}x + (i,j).$$

The $S_{i,j}$'s map the square Ω on its four subsquares of half size. If the homothety had a ratio smaller than 1/2, by iterating the $S_{i,j}$'s, we would get a kind of two-dimensional Cantor set. There exist more "exotic" examples. For instance, if

$$S_1^{-1} = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}, \qquad S_2^{-1} = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix} + (1,0),$$

the S_i's map a "fractal dragon" on their two self-similar components (see [9] or [16]).

In order to understand the scope and limitations of the model given by self-similar functions, it is interesting to mention a few classical examples of functions that, though not self-similar in the sense that we gave, satisfy functional equations that have similarities with (2.3).

First, the scaling function of the function φ used in the construction of orthonormal wavelet bases satisfies (see [10] or [12])

$$\varphi(x) = \sum a_k \varphi(2x-k),$$

but condition (2.2) does not hold except for some nonsmooth functions φ, such as characteristic functions of sets, in which case there exist examples similar to the fractal dragon that we mentioned above (see [9] or [16]). In [12], Daubechies and Lagarias recently proved that a converse formula to the multifractal formalism holds for these functions (i.e., the function $\eta(p)$ is the Legendre transform of $d(\alpha)$).

Our second example is the Brownian bridge on $[0,1]$. It satisfies

$$B(t) = \frac{1}{\sqrt{2}}B_1(2t) + \frac{1}{\sqrt{2}}B_2(2t-1) + \xi\Lambda(x), \tag{2.6}$$

where B_1 and B_2 are two Brownian bridges that have the same law as B, ξ is a Gaussian, $\Lambda(x) = \sup(x, 1-x)$ on $[0,1]$, and the three terms of the right-hand side of (2.6) are independent. We are in a situation where (2.3) holds "in law." Actually, the self-similar processes studied in, for instance, [3] also verify (2.3) "in law." We will not recall the definition of these processes here but only mention that in dimension 1, they coincide with the fractional Brownian motions. The reader can easily check that the results that we give below easily extend to this probabilistic setting. However, such results would be poor for the following reason. Direct methods yield sharper results for the the pointwise regularity of these processes and from a "multifractal point of view," the spectrum of these processes is not interesting since it vanishes everywhere except at one point.

Our last example is *Riemann's nondifferentiable function*

$$\Phi(x) = \sum_1^\infty \frac{1}{n^2}\sin(\pi n^2 x),$$

which was shown by Duistermaat in [13] to satisfy some functional equations similar to (2.3). For instance

$$\Phi(1+x) = \frac{\pi i}{12} - \frac{x}{2} + e^{i\pi/4}x^{3/2}\Big(4\Phi\Big(\frac{-1}{4x}\Big) - \Phi\Big(\frac{-1}{x}\Big)\Big) + \xi(x), \tag{2.7}$$

where ξ is a smooth function. Also, using the periodicity of Φ, a whole collection of similar equations can be derived. We are in a situation close to (2.3) but where the S_i's are not linear. (See [20] for an extension of the multifractal formalism to this case.)

We now determine the sense in which (2.3) has solutions, and we examine some basic regularity properties of these solutions. They will depend upon the assumptions that we make on the λ_i.

Iterating (2.3), we obtain for any N that

$$\begin{aligned} F(x) = & \sum_{n=0}^{N-1} \sum_{(i_1,\ldots,i_n)} \lambda_{i_1} \cdots \lambda_{i_n} g\big(S_{i_n}^{-1} \ldots S_{i_1}^{-1}(x)\big) \\ & + \sum_{(i_1,\ldots,i_N)} \lambda_{i_1} \cdots \lambda_{i_n} F\big(S_{i_N}^{-1} \cdots S_{i_1}^{-1}(x)\big)\,, \end{aligned} \tag{2.8}$$

so a (formal) solution of (2.3) is given by

$$F(x) = \sum_{n=0}^{\infty} \sum_{(i_1,\ldots,i_n)} \lambda_{i_1} \cdots \lambda_{i_n} g\big(S_{i_n}^{-1} \cdots S_{i_1}^{-1}(x)\big)\,. \tag{2.9}$$

Here F is written as a superposition of similar structures at different scales, reminiscent of some possible models of turbulence [5], [15], [26]. This formula also looks like a wavelet decomposition (except that g has no cancellation), and our proof of Proposition 3.2 in the next section will be similar to classical proofs of the regularity of wavelets series; see [18] or [22].

When the (formal) series (2.9) converges in a certain function space, a solution of (2.3) exists in this space. (Actually, it is easy to check that (2.9) converges almost everywhere if the separated open-set condition holds.) We will be particularly interested in three cases: first, when (2.3) has solutions that are locally L^1 functions; second, when the solutions have some global C^α smoothness (this case is important because it is the setting where the multifractal formalism works without any modification); and third, in spaces of distributions where the series converge when we make no assumption on the λ_i's. A good setting to study this last case is supplied by the real Hardy spaces, whose definition we now recall.

Suppose that we use an orthonormal basis of wavelets indexed by dyadic cubes. We denote these wavelets by ψ_λ and the corresponding wavelet coefficients by C_λ. The *real Hardy $\mathcal{H}^p$ space* (cf. [24]) is the set of distributions whose wavelet coefficients satisfy

$$\int \Big(\sum_{j,k} |C_\lambda|^2\, 2^{nj}\, \chi_\lambda(x) \Big)^{p/2} dx < +\infty, \tag{2.10}$$

assuming that the wavelets that we use are $C^{m(p^{-1}-1)}$ and have vanishing moments up to order $m(p^{-1}-1)$. This is a direct generalization of the space L^p when $p < 1$.

Recall that

$$\alpha_{\min} = \inf_{j=1,\ldots,d} \frac{\log|\lambda_j|}{\log \mu_j} \quad \text{and} \quad \alpha_{\max} = \sup_{j=1,\ldots,d} \frac{\log|\lambda_j|}{\log \mu_j}. \tag{2.11}$$

Proposition 2.3. *Suppose that* $\sum |\lambda_j|\mu_j^m < 1$. *In this case,* (2.3) *has a unique distribution solution, which is an* L^1 *function and is given by the series* (2.9). *Furthermore, if* $0 < \alpha_{\min} < k$, *this function is* $C^{\alpha_{\min}}$.

Suppose that $\sum |\lambda_j|\mu_j^m \geq 1$; *in that case,* (2.3) *may have several distribution solutions. Let* $p < 1$ *such that* $\sum |\lambda_j|^p\mu_j^m < 1$. *If* g *is* C^k *with* $k > m(p^{-1} - 1)$ *and if the moments of* g *of order less than* k *vanish,* (2.9) *converges in the Hardy real space* $\mathcal{H}^p$ *so that* (2.3) *has at least one solution in this space of distributions.*

Furthermore, these results are optimal.

Before proving Proposition 2.3, we begin with some preliminary results concerning the geometry of the mappings S_i. If A is a subset of $\mathbb{R}^n$, we define the mapping S by

$$S(A) = \bigcup_{i=1}^{d} S_i(A)$$

and let K be the set defined by

$$K = \bigcap_{n \in \mathbb{N}} S^n(\bar{\Omega}).$$

K is called the invariant compact set of S. Its Hausdorff dimension is $d_{\max}$ (defined in Theorem 2.2). We introduce some notation. Let i be a finite sequence $i = (i_1, \dots, i_n)$. We define $x_i = S_{i_1} \cdots S_{i_n}(0)$, and if the sequence i is infinite, $x_i = \lim_{n\to\infty} x_{(i_1,\dots,i_n)}$. Similarly, let $\mu_i = \mu_{i_1} \cdots \mu_{i_n}$ and $\lambda_i = \lambda_{i_1} \cdots \lambda_{i_n}$. Thus with each sequence $i \in \{1, \dots, d\}^{\mathbb{N}}$ we associate a unique point x_i in K. This correspondence is, in general, not one to one. (Consider, for instance, the example of lacunary trigonometric series where the dyadic points are the limit of two sequences.) However, the correspondence is clearly one to one if the separated open-set condition holds.

The points of K can also be represented as the limit points of the branches of the following tree T constructed in the "time-scale half-space." The treetop is conventionally the point $(0, 1) \in \mathbb{R}^m \times \mathbb{R}^+$. This treetop is linked to the d first nodes, which are the $(S_j(0), \mu_j)$'s. This point $(S_j(0), \mu_j)$ is linked to $(S_jS_k(0),\ \mu_j\mu_k), \dots$. If $\mathbb{R}^m$ is identified to $\mathbb{R}^m \times \{0\}$, then clearly the branch indexed by a sequence $i \in \{1, \dots, d\}^{\mathbb{N}}$ approaches the point x_i (and it is the only one which does so if the mapping $i \to x_i$ is one to one). This tree is related to the wavelet transform of F more precisely in Proposition 4.1. We will show that the order of magnitude of the wavelet transform of F near (x_i, μ_i) is $|\lambda_i|$.

Definition 2.4. *Let* $x \in \mathbb{R}^m$. *A "D-branch over* x*" is a branch of the tree of length* n *that starts from the origin* $(0, 1)$, *ends at*

$$(S_{i_1} \cdots S_{i_n}(0), \mu_{i_1} \cdots \mu_{i_n}),$$

and is such that

$$|S_{i_1} \cdots S_{i_n}(0) - x| \leq D\mu_{i_1} \cdots \mu_{i_n}.$$

When $D \leq 10\mathrm{Diam}(\Omega)$, *such a branch is a "main branch over* x*."*

This requirement means that the endpoint of the branch is—in the time-scale half-space—in a certain cone of width D over x. We often identify a branch with the sequence i that indexes it.

We will need the following lemma, which estimates the number of D-branches over a point x.

Lemma 2.5. *Let $x \in K$ and let $B_{j,D}(x)$ be the set of D-branches $(i_1, \ldots, i_n)$ over x such that*

$$2^{-j} \le \mu_{i_1} \cdots \mu_{i_n} < 2.2^{-j}. \tag{2.12}$$

The cardinality of this set of branches is bounded independentely of x and j by CD^m.

Proof. We can assume that the $S_{i_1} \cdots S_{i_n}(\Omega)$'s are disjoint. If not, the open-set condition implies that the corresponding sequences $(i_1, \ldots, i_n)$ and $(i'_1, \ldots, i'_m)$ satisfy—if $n \le m$, for instance—$(i_1, \ldots, i_n) = (i'_1, \ldots, i'_n)$. (One of the branches is included in the other.) In that case, we keep the longest sequence, dividing the cardinality of $B_{j,D}(x)$ by at most an absolute constant (which depends only on the values of $\mu_1, \ldots, \mu_d$). Thus we can assume that the $S_{i_1} \cdots S_{i_n}(\Omega)$'s are disjoint and are all included in $B(x, CD2^{-j})$, so if $B_{j,D}(x)^\#$ denotes the cardinality of $B_{j,D}(x)$,

$$B_{j,D}(x)^\# 2^{-mj} \mathrm{vol}(\Omega) \le C(D.2^{-j})^m,$$

and thus $B_{j,D}(x)^\#$ is bounded by CD^m. Hence Lemma 2.5 follows. □

We now prove Proposition 2.3. Existence and uniqueness in the L^1 case are straightforward. The last term in (2.8) tends to zero in L^1, so that (2.9) is the only (possible) solution in L^1, and it is actually in L^1 because the L^1 norm of series (2.9) is bounded by

$$C \sum_{|i| \le n} |\lambda_i| \mu_i^m = C \sum_{l \le n} \left(\sum_{j=1}^{d} |\lambda_j| \mu_j^m \right)^l \le C.$$

We estimate the C^s norm of F using the Littlewood–Paley characterization of this norm. For the reader's convenience, we recall this characterization.

Let ψ be a function in the Schwartz class whose Fourier transform vanishes outside $1 \le |\xi| \le 8$ and is equal to 1 on $2 \le |\xi| \le 4$. Let $\psi_l(x) = 2^{ml}\psi(2^l x)$. A function F belongs to C^s if and only if $|F * \psi_l(x)| \le C 2^{-sl}$.

We return to Proposition 2.3. We first split F as a sum $F = \sum F_j$, where F_j is series (2.9) restricted to the indices $i \in I_j$ such that

$$2^{-j} \le \mu_i < 2.2^{-j}.$$

Let $\omega_{l,j} = F_j * \psi_l$. If $l \ge j$, because of the localization and cancellation of ψ, for any N,

$$|\omega_{l,j}(x)| \le C_N \sum_{i \in I_j} \frac{\lambda_i 2^{-k(l-j)}}{(1 + 2^j |x - x_i|)^N}.$$

Because of Lemma 2.5, as soon as $N > m$,

$$\sum_{i \in I_j} \frac{1}{(1 + 2^j |x - x_i|)^N} \le C$$

so that

$$|\omega_{l,j}(x)| \le C \sup_{i \in I_j} |\lambda_i| 2^{-k(l-j)}.$$

If $j > l$, $|\omega_{l,j}(x)| \leq C \sup |F_j(x)|$ so that $|\omega_{l,j}(x)| \leq C \sup_{i \in I_j} |\lambda_i|$. Since $\sup_{i \in I_j} |\lambda_i| \leq C 2^{-\alpha_{\min} j}$, summing up, we obtain that $|(F * \psi_l)(x)| \leq C 2^{-\alpha_{\min} l}$. Hence we have the Hölder regularity of F.

In order to show that F belongs to $\mathcal{H}^p$, first notice that the regularity and cancellation that we requested for g is consistent with the atomic definition of $\mathcal{H}^p$ so that series (2.9) can be interpreted as a "vaguelette" decomposition of F (see [24]). Thus—following [24]—the "$\mathcal{H}^p$ norm" of F_j is bounded by

$$C \left(\int \left(\sum_{i \in I_j} |\lambda_i|^2 1_{|x - x_i| \leq \mu_i}(x) \right)^{p/2} dx \right)^{1/p} = C \left(\sum_{i \in I_j} \lambda_i^p \mu_i^m \right)^{1/p}.$$

By the same argument as in the L^1 case, this quantity is exponentially decreasing with j so that F belongs to $\mathcal{H}^p$.

The optimality of Proposition 2.3 can easily be checked via some explicit examples. The optimality of the global Hölder regularity is shown by example (2) above concerning lacunary trigonometric series. We sketch how to obtain the optimality of the L^1 and $\mathcal{H}^p$ criteria.

Let g be supported on $[1, 2]$ and suppose that F satisfies

$$F(x) = \lambda F(2x) + g(x).$$

If $\int g(x)dx \neq 0$ and $\lambda \geq 2$, series (2.9) does not converge in L^1 (or in any distribution space). If g has vanishing moments and $\lambda \geq 2$, the "$\mathcal{H}^p$ norm" of F can be calculated. For instance, when g is the function ψ that generates an orthonormal basis of compactly supported wavelets, ψ is properly contracted in order to be supported on the interval $[1, 2]$.

PROPOSITION 2.6. *If x does not belong to K, F is C^k in a neighborhood of x.*

Proof. Let α be such that $|\alpha| \leq k$, and let us show that the series

$$\sum \lambda_i \partial^\alpha (g \circ S_i^{-1}(.))$$

converges uniformly in a neighborhood of x.

This series is bounded in modulus by

$$\sum \frac{|\lambda_i| \mu_i^{-|\alpha|}}{(1 + \mu_i^{-1}|x - x_i|)^N} \leq \sum_j \sum_{i \in I_j} \frac{C 2^{C'j}}{(1 + 2^j |x - x_i|)^N},$$

but since $x \notin K$, $|x - x_i| \geq C > 0$ so that

$$\sum_{i \in I_j} \frac{C}{(1 + 2^j |x - x_i|)^N} \leq C' 2^{-(N-m)j}.$$

Choosing N large enough, we obtain Proposition 2.6 when $k \in \mathbb{N}$. The verification when k is not an integer is just as easy and is thus left to the reader. □

We conclude this section with a study on the uniqueness of solutions of (2.3). First, note that (2.8) holds for any N and that outside K the second term in (2.8) tends to 0 in C^k so that any distribution solution of (2.3) outside K is a function that satisfies (2.8). Thus if (2.3) has two solutions, their difference is a distribution supported by K, which is a solution of the homogeneous equation

$$F = \sum_{j=1}^{d} \lambda_j F \circ S_j^{-1}. \tag{2.13}$$

Since such a distribution is compactly supported, it belongs to a space $L^{p,s}$ (perhaps for a negative s). Note that $\|F \circ S_j^{-1}\|_{L^{p,s}} = \mu_j^{m/p-s} \|F\|_{L^{p,s}}$. Thus (2.13) implies that

$$\|F\|_{L^{p,s}} \leq \left(\sum_{j=1}^{d} |\lambda_j| \mu_j^{m/p-s} \right) \|F\|_{L^{p,s}},$$

and it has a nonvanishing solution in $L^{p,s}$ only if $\sum_{j=1}^{d} |\lambda_j| \mu_j^{(m/p)-s} > 1$.

Suppose that $\sum_{j=1}^{d} |\lambda_j| \mu_j^{m} < 1$. For all $s < 0$, let $p_0 m/(m-s)$. Then $\sum_{j=1}^{d} |\lambda_j| \mu_j^{(m/p)-s} < 1$ if $p < p_0$ so that (2.13) has no solution in $L^{p,s}$ for $p < p_0$ (hence for any p since F is compactly supported). Hence we have the uniqueness result in Proposition 2.3.

If $\sum_{j=1}^{d} |\lambda_j| \mu_j^{(m/p)-s} > 1$, it is easy to find distributions supported by K and solutions of (2.13). A trivial example is the Dirac mass at the origin, a solution of $\delta(.) = 2^m \delta(2.)$, but multinomial measures, such as the canonical measure on the triadic Cantor set, satisfy such equations. (The self-similar measures supported on K that we construct in section 4 also satisfy such equations.) In the case where $\sum_{j=1}^{d} |\lambda_j| \mu_j^{(m/p)-s} > 1$, we thus have no unique solution of (2.3), and we call (2.9) the *fundamental solution.*

For a given branch indexed by $i = (i_1, \ldots, i_n)$, let

$$\alpha(i) = \frac{\mathrm{Log}|\lambda_i|}{\mathrm{Log}\mu_i} \tag{2.14}$$

and denote the set $B_{j,10diam(\Omega)}(x)$ by $B_j(x)$.

In the next two sections, we prove the following result, which yields the exact regularity of f at each point of K when $\alpha_{\min} > 0$. (Recall that by definition f is Γ^α at x if α is the supremum of all β such that $f \in C^\beta(x)$.)

Proposition 2.7. *Suppose that* $\alpha_{\min} > 0$. *Let* $x \in K$. *Then* F *is* $\Gamma^{\alpha(x)}$ *at* x, *where*

$$\alpha(x) = \liminf_{j \to \infty} \inf_{i \in B_j(x)} \frac{\mathrm{Log}|\lambda_i|}{\mathrm{Log}\mu_i}. \tag{2.15}$$

The lower bound for $\alpha(x)$ will be obtained in section 3, and the upper bound will be obtained in section 4. In section 5, we determine the dimension of the set where F is Γ^α for a given α.

A case of special interest is when the separated open-set condition holds. In that case, there is only one branch over x and $i \to x(i)$ is onto so that if $i = (i_1(x), \ldots, i_n(x), \ldots)$ is the only sequence such that $x_0 = x(i)$, (2.14) and (2.15) become

$$\alpha(x_0) = \liminf_{n \to \infty} \frac{\mathrm{Log}|\lambda_{i_1(x_0)}| \cdots |\lambda_{i_n(x_0)}|}{\mathrm{Log}\mu_{i_1(x_0)} \cdots \mu_{i_n(x_0)}}.$$

3. A lower bound for regularity. We will need the following lemma, which yields an estimate for the products $\lambda_{i_1}\cdots\lambda_{i_n}$ on D-branches.

LEMMA 3.1. *Let $\Lambda_j(x)=\sup_{i\in B_j(x)}|\lambda_i|$ and $L_j(x)=\sum_{l=1}^{j}\Lambda_l(x)2^{-A(j-l)}$, where $A>\alpha_{\max}$. Then*

$$\liminf_{j\to\infty}\frac{\operatorname{Log}(L_j(x))}{-j\log 2}=\liminf_{j\to\infty}\frac{\operatorname{Log}(\Lambda_j(x))}{-j\log 2}\left(=\liminf_{j\to\infty}\inf_{i\in B_j(x)}\frac{\operatorname{Log}(\lambda_i)}{\operatorname{Log}(\mu_i)}\right)$$

and $\forall x\in\mathbb{R}^m$, if $\mu_i\sim 2^{-j}$,

$$|\lambda_i|\le CL_j(1+2^j|x-x_i|)^A.$$

In this lemma, we do not make any assumptions on the λ_i's. Let us prove the first assertion. $L_j\ge\Lambda_j$, and if $n(=n(j))$ is such that $n\le j$ and $\Lambda_n(x)2^{-A(j-n)}=\sup_{l\le j}\Lambda_l(x)2^{-A(j-l)}$, then $L_n\le n\Lambda_n(x)$. $A>\alpha_{\max}$ so that $n(j)\to\infty$ when $j\to\infty$. Hence we have the first assertion.

We now prove the second assertion. First, if i is a main branch, $|\lambda_i|\le L_j$. Now suppose that i is not a main branch. Let $i=(i_1,\dots,i_n)$ and let l be the largest integer such that the subbranch $(i_1,\dots,i_l)$ is a main branch over x. Clearly, $2^l|x-x_i|\sim 10\operatorname{diam}(\Omega)$ and $\lambda_i\le 2^{A(j-l)}\Lambda_l$ (because all of the λ_j's are $<2^{\alpha_{\max}}$), so

$$|\lambda_i|\le L_j\frac{\Lambda_l}{L_j}\le L_j2^{A(j-l)}\le L_j(C2^j|x-x_i|)^A.$$

Hence Lemma 3.1 follows.

PROPOSITION 3.2. *Let $x_0\in K$. The function F is $C^\beta(x_0)$ for any $\beta<\alpha(x_0)$.*

Proof. Let $x\in K$ and $P(x-y)$ be the Taylor expansion of order $[\beta]$ of (2.9) at x. We first check that this Taylor expansion yields a convergent series.

Let α be a multiindex such that $|\alpha|<\beta$. We have to check that the series

$$\sum\frac{|\lambda_i|\mu_i^{-|\alpha|}}{(1+\mu_i^{-1}|x-x_i|)^N}\tag{3.1}$$

is convergent. We split this sum into the sets

$$I_{j,l}=\{i\in I_j\text{ and }2^l<\mu_i^{-1}|x-x_i|\le 2^{l+1}\}.$$

Because of Lemma 2.5, each term has about 2^{lm} elements, and because of Lemma 3.1, on this set $I_{j,l}$,

$$\lambda_i\le CL_j(1+2^l)^A,$$

so series (3.1) is bounded by

$$C\sum_{j,l}L_j\mu_i^{-|\alpha|}(1+2^l)^{A-N}2^{lm}\le C\sum_{j,l}2^{(|\alpha|-\beta)j}2^{l(m-N+A)}$$

(since for j large enough, $L_j\le C2^{-\beta j}$), which is bounded because N can be chosen arbitrarily large.

Let $Tg_x(x-y)$ be the Taylor expansion of g of order $[\beta]$ at point x, i.e.,

$$Tg_x(x-y)=\sum_{|\gamma|\le[\beta]}\frac{\partial^\gamma g(x)}{\gamma!}(x-y)^\gamma.$$

Let J such that $2^{-J} \leq |x-y| \leq 2.2^{-J}$. Using formula (2.8) but stopping the iteration on each branch at the first level such that $\mu_i \leq 2^{-J}$, we obtain

$$\begin{aligned}(3.2)\qquad & F(y) - P(x-y) \\ &= \sum_{j\leq J}\sum_{i\in I_j} \lambda_i \left(g(S_i^{-1}(y)) - Tg_x(S_i^{-1}(x-y))\right) \\ &\quad + \sum_{j=J}\sum_{i\in I_J} \lambda_i F(S_i^{-1}(y)) - \sum_{j>J}\sum_{i\in I_j} \lambda_i Tg_x(S_i^{-1}(x-y)).\end{aligned}$$

The third sum is bounded in modulus by

$$\begin{aligned} C & \sum_{|\gamma|\leq\beta}\sum_{j\geq J} |\lambda_i|\mu_i^{-|\gamma|}|x-y|^{|\gamma|}(1+\mu_i^{-1}|x-x_i|)^{-N} \\ &\leq C\sum_{|\gamma|\leq\beta} |x-y|^{|\gamma|}\sum_{l}\sum_{j\geq J} L_j 2^{Al}2^{|\gamma|j}2^{l(m-N)} \\ &\leq C\sum_{|\gamma|\leq\beta} |x-y|^{|\gamma|}2^{(|\gamma|-\beta)J} \leq C|x-y|^{\beta}\end{aligned}$$

(where we have again split the sum into the sets $I_{j,l}$).

Because of the localization of F, the second sum is bounded by $C\sup_{i\in I_J}|\lambda_i| \leq C2^{-\beta J}$.

We now consider the first sum in (3.2). We consider two cases. Let $D = |x-y|^{-\epsilon}$ for an arbitrarily small ϵ. First, suppose that

$$|x-x_i| \leq D2^{-j}.$$

For each j, the sum has about D^m terms, and using the mean-value theorem, the sum of the corresponding terms is bounded by

$$\begin{aligned} D^m & \sum_{j\leq J}\sum_{i} L_j(1+D)^A|x-y|^{[\beta]+1}\mu_i^{-[\beta]-1} \\ &\leq C|x-y|^{[\beta]+1}\sum_{j\leq J} 2^{-\beta j}2^{([\beta]+1)j}D^{m+A} \leq C|x-y|^{\beta}D^{m+A}.\end{aligned}$$

Hence we have the bound that we claimed if we take ϵ small enough.

Now suppose that $|x-x_i| > D2^{-j}$; then $|\lambda_i| \leq CL_j(1+2^j|x-x_i|)^A$. Applying Lemma 2.5 with $D = 2^j|x-x_i|$, the remaining sum is bounded by

$$C\sum_{|\gamma|\leq\beta}\sum_{j\leq J}\frac{L_j(1+2^j|x-x_i|)^A(1+2^j|x-x_i|)^m}{(1+2^j|x-x_i|)^N}|x-y|^{\gamma}2^{\gamma j}$$

$$\leq \sum_{|\gamma|\leq\beta}\sum_{j\leq J} 2^{-\beta j}2^{\gamma j}|x-y|^{\gamma}(1+2^j|x-x_i|)^{-N+m+A},$$

and we obtain the bound in this case since $2^j|x-x_i| > |x-y|^{-\epsilon}$. Hence Proposition 3.2 follows.

4. An upper bound of the pointwise Hölder exponent. We will bound the regularity of F at each point in K by estimating the size of the wavelet transform in a neighborhood of such a point. The wavelet transform of F satisfies a functional equation similar to (2.3), which will enable us to obtain this estimate. Let $C(a,b)$ be the wavelet transform of F and $\omega(a,b)$ be the wavelet transform of g.

PROPOSITION 4.1. *There exists $A>0$ such that $\forall x\in K$, $J\in\mathbb{N}$. There exists $j\in[J-A,J]$, a branch $b=(j_1,\dots,j_n)$ in $B_j(x)$, $a\sim 2^{-j}$, and $t\in\Omega$ such that*

$$|t-x|\le Ca \quad \textit{and} \quad |C(a,t)|\ge C\Lambda_j(x).$$

Note that in this proposition, we do not have to make any assumptions on the uniform regularity of F, and we will actually use the proposition in cases where F is unbounded. Nonetheless, let us first show that if F has some minimal uniform regularity, Proposition 2.7 follows. To this end, we first recall a relation between the regularity of F and the size of the wavelet transform given by the following results (see Part I). Suppose that $s>0$. If $F\in C^s(x_0)$,

$$|C_{a,b}(F)|\le Ca^s\left(1+\frac{|b-x_0|}{a}\right)^s. \tag{4.1}$$

Thus Proposition 4.1 together with (4.1) shows that F is not smoother than $C^{\alpha(x)}$ at x. Thus using Proposition 3.2, we will have proved Proposition 2.7.

Proof of Proposition 4.1. We first prove Proposition 4.1 with $j\in[(1-\epsilon)J,J]$ (for an arbitrarily small ϵ). Let $C(a,b)$ be the wavelet transform of F and let $\omega(a,b)$ be the wavelet transform of g. Using (2.8) but stopping the iteration on each branch when $\mu_i\sim 2^{-J}$, we obtain

$$C(a,t)=\sum_{j=1}^{J}\sum_{i\in I_j}\lambda_i\omega\left(\frac{a}{\mu_i},S_i^{-1}(t)\right)+\sum_{i\in I_J}\lambda_i\, C\left(\frac{a}{\mu_i},S_i^{-1}(t)\right). \tag{4.2}$$

Let $y\in\Omega$ be a fixed point that will be determined later. Let $x\in K$ and let $b=(j_1,\dots,j_n)$ be a branch over x. Let $t=S_{j_1}=CA\cdots S_{j_n}(y)$. Then

$$|x-t|\le C\mu_{j_1}\cdots\mu_{j_n}.$$

Hence we have the first condition of Proposition 4.1.

We want to show that on the set S_j, the main term in (4.2) corresponds to the branch b. This is intuitively clear because all terms in the first sum decay like a^k because of the smoothness of g, and since F is smooth outside Ω, all terms in the second sum decay also like a^k except precisely the one corresponding to the branch b. We make this argument more precise. We first prove the following bound for the first sum in (4.2):

$$\sum_{i\in I_j}\left|\lambda_i\omega\left(\frac{a}{\mu_i},S_i^{-1}(t)\right)\right|\le Ca^k2^{kj}L_j(t). \tag{4.3}$$

First, note that because of the smoothness and decay of g,

$$\forall N\ge 0,\quad |\omega(a,b)|\le\frac{C_Na^k}{(1+|b|)^N}.$$

Thus

$$\begin{aligned}\sum_{i\in I_j}\left|\lambda_i\omega\left(\frac{a}{\mu_i},S_i^{-1}(t)\right)\right| &\leq Ca^k\sum_{i\in I_j}\frac{|\lambda_i|}{\mu_i^k(1+|2^j(t-x_i)|)^N}\\ &\leq Ca^k2^{kj}L_j(t)\sum_{i\in I_j}\frac{1}{(1+|2^j(t-x_i)|)^{N-A}}\\ &\leq Ca^k2^{kj}L_j(t).\end{aligned}$$

Hence we have (4.3). Thus

$$\sum_{j\leq J}\sum_{i\in I_j}\left|\lambda_i\omega\left(\frac{a}{\mu_i},S_i^{-1}(t)\right)\right|\leq Ca^k\sum_{j\leq J}2^{kj}L_j(t).$$

Since $\sup(\log\lambda_i/\log\mu_i)<k$, this series grows exponentially so that the first term in (4.2) is bounded by $Ca^k2^{kJ}L_J(t)$.

We now estimate the second term in (4.2) when $i\neq b$. Recall that A is the closed subset of Ω where by assumption F is not uniformly C^k. Let $A_\epsilon=A+B(0,\epsilon)$, where ϵ is a constant small enough that $A_\epsilon\subset\Omega$. Thus outside A_ϵ,

$$|C(a,b)|\leq C\frac{a^k}{(1+|b|)^N}$$

so that

$$C\left(\frac{a}{\mu_i},S_i^{-1}(t)\right)\leq C\left(\frac{a}{\mu_i}\right)^k\frac{1}{(1+2^j|t-x_i|)^N}.$$

Thus we obtain, as above,

$$\sum_{i\in I_J,\, i\neq b}\lambda_iC\left(\frac{a}{\mu_i},S_i^{-1}(t)\right)\leq Ca^k2^{kJ}L_J(t).$$

Finally, from (4.2), we get

$$\left|C(a,t)-\lambda_jC\left(\frac{a}{\mu_j},S_j^{-1}(t)\right)\right|\leq Ca^k2^{kJ}L_J(t). \tag{4.4}$$

We now estimate the term corresponding to the sequence b. Recall that the last condition in Definition 2.1 is equivalent to the existence of sequences $a_n\to0$, $b_n\in A$, and $C_n\to+\infty$ such that $|C(a_n,b_n)|\geq C_na_n^k$ so that

$$\left|\lambda_bC\left(\frac{a}{\mu_b},S_b^{-1}(t)\right)\right|\geq|\lambda_b|C_n\left(\frac{a}{\mu_b}\right)^k.$$

Recall that $\Lambda_j=\sup_{i\in B_j(x)}|\lambda_i|$. Choosing a branch for which this supremum (taken on a finite number of terms) is attained, we get for this branch that

$$\left|\lambda_bC\left(\frac{a}{\mu_b},S_b^{-1}(t)\right)\right|\geq\Lambda_J(x)C_n2^{kJ}a^k$$

so that

$$|C(a,t)| = 2^{kJ}a^k[C_n\Lambda_J(t) + R],$$

where $|R| \leq CL_J(t)$. We choose n such that $C_n \geq 2C$, which determines a value of $a_n = a/\mu_b$. If

$$\Lambda_j(t) \geq \frac{1}{2}L_J(t),$$

the proposition is proved with $j = J$. Otherwise, since

$$L_J(t) = \Lambda_J + 2^{-A}\Lambda_{J-1} + 2^{-2A}\Lambda_{J-2} + \cdots,$$

one of the terms $2^{-lA}\Lambda_{J-l}$ must be large. More precisely, there exists l such that

$$2^{-lA}\Lambda_{J-l} \geq \frac{1}{10l^2}\Lambda_J. \tag{4.5}$$

(If several values of l satisfy (4.5), we choose the smallest.) We can choose the corresponding branch in Proposition 4.1, and since $l = o(J)$, this implies the irregularity of F at x. We found points in the "cone above x" where the wavelet transform is large. The statement of Proposition 4.1 is more precise because we will need precise estimates on the wavelet transform everywhere in order to estimate the integrals of the wavelet transform needed in the multifractal formalism. We have to check that we can choose $l \leq C$. We first prove that $l \leq \epsilon J$. We have $\Lambda_{J-l} \leq 2^{-\alpha_{\min}(J-l)}$ and $\Lambda_J \geq 2^{-\alpha_{\max}J}$ so that if (4.5) holds,

$$2^{-lA}2^{-\alpha_{\min}(J-l)} \geq \frac{1}{10l^2}2^{-\alpha_{\max}J},$$

which implies that

$$l \leq \left(\frac{\alpha_{\max} - \alpha_{\min}}{A - \alpha_{\min}}\right)J.$$

Choosing A large enough, we have $l \leq \epsilon J$ for ϵ arbitrarily small. For this branch b,

$$|C(a,t)| \geq \frac{1}{2}\lambda_b(x)C\left(\frac{a}{\mu_b}, S_b^{-1}(t)\right) \tag{4.6}$$

and $C(a/\mu_b, S_b^{-1}(t)) \sim 1$. Hence we have Proposition 4.1 when $j \in [(1-\epsilon)J, J]$. We now want to prove that the proposition holds for $j \in [J-A, J]$.

Suppose that t is a point inside Ω such that the $S_i(t)$'s do not approach the boundary of Ω. We know that

$$C(a,t) = \omega(a,t) + \sum_{j=1}^{d}\lambda_j C\left(\frac{a}{\mu_j}, S_j^{-1}(t)\right),$$

but $|\omega(a,t)| \leq C_1a^k$ and outside of a certain neighborhood of Ω, $|C(a,t')| \leq C_2a^k$. Let

$$i = (i_1, \ldots i_n) \quad \text{and} \quad i' = (i_1, \ldots i_n, i_{n+1}).$$

Thus if t and r are such that $|C(\mu_i,t)-r\lambda_i|\le e$, then

$$\begin{aligned}|C(\mu_{i'},S_{i'}(t))-r\lambda_{i'}|&\left|\omega(\mu_{i'},S_{i'}(t))+\sum_j^d\lambda_jC\left(\frac{\mu_{i'}}{\mu_j},S_j^{-1}(t)\right)-r\lambda_{i'}\right|\\ &\le C_1(\mu_{i'})^k+\sum_{j\ne i_{n+1}}\lambda_jC\left(\frac{\mu_{i'}}{\mu_j}\right)^k+\lambda_{i_{n+1}}|r\lambda_i-C(\mu_i,t)|\\ &\le\left(C_1+C\sum_{j\ne i_{n+1}}\frac{\lambda_j}{(\mu_j)^k}\right)\mu_{i'}^k+e\lambda_{i+1}\le C\mu_{i'}^k+e\lambda_{i+1}.\end{aligned}$$

We start with a branch i such that $r\sim 1$ and $e=0$, which is possible because of the first part of the proof. After one iteration, we obtain an error of $C\mu_i^k$; after two iterations, we get an error of $C\mu_i^k\lambda_{i+1}+C\mu_{i+1}^k,\ldots$; and after j iterations, the error is

$$C\mu_i^k\left(\frac{\lambda_j}{\lambda_i}+\mu_i\frac{\lambda_j}{\lambda_{i+1}}+\cdots\right)\sim C\mu_i^k\frac{\lambda_j}{\lambda_i}$$

so that $|C(\mu_j,t')-r\lambda_j|\le C'\mu_i^k(\lambda_j/\lambda_i)\le\epsilon\lambda_j$, where t' is on the subtree deduced from t. Thus $C(\mu_j,t')\sim r\lambda_j$. Hence Proposition 4.1 follows.

Note that Propositions 3.2 and 4.1 show that the wavelet transform of F is "large" near the tree T, and thus the ramifications of this tree of wavelet maxima reflect the "dynamics" of self-similarity as stated by Arneodo, Bacry, and Muzy in [2].

It is remarkable that these results do not depend on the function g. If g were replaced by another function, the new F would have the same regularity at every point. Only the global smoothness of g is important. It defines a value beyond which one can no longer calculate the regularity of F.

5. Determination of the Hölder spectrum. In this section, we prove that for $\alpha<k$, the Hölder spectrum of a self-similar function is the Legendre transform of the function τ defined by

$$\sum_{i=1}^d\lambda_i^a\mu_i^{-\tau(a)}=1.$$

PROPOSITION 5.1. *Let $\alpha<k$ and define $d(\alpha)$ as the Hausdorff dimension of the set of points x where F is $\Gamma^\alpha(x)$. Then $d(\alpha)$ is given on $[0,k)$ by*

$$d(\alpha)=\left(\inf_a a\alpha-\tau(a)\right). \tag{5.1}$$

We will need the following proposition (Proposition 4.9 in [25]) in the proof of Proposition 5.1.

PROPOSITION 5.2. *Let $\mathcal{H}^s$ be the Hausdorff measure of dimension s. Let μ be a probability measure on $\mathbb{R}^m$, $F\subset\mathbb{R}^m$, and C be such that $0<C<+\infty$. Then*

- *if* $\limsup_{r\to 0}\mu(B(x,r))/r^s<C\ \forall x\in F,\ \mathcal{H}^s(F)\ge\mu(F)/C$;
- *If* $\limsup_{r\to 0}\mu(B(x,r))/r^s>C\ \forall x\in F,\ \mathcal{H}^s(F)\le 2^s/C$.

Proof of Proposition 5.1. Let $a\in\mathbb{R}$, $b=-\tau(a)$, and $P_i=\lambda_i^a\mu_i^b$. Thus $\sum P_i=1$. We first consider on K a probability measure ν such that

$$\forall(i_1,\ldots,i_n),\quad \nu(S_{i_1}\cdots S_{i_n}(K))=P_{i_1}\cdots P_{i_n}. \tag{5.2}$$

The construction of such a measure by induction is straightforward (see, for instance, [17]). Let $x \in K$, $s > 0$ and $r > 0$ and consider the set $B_j(x)$, where $2^{-j} \leq r < 2.2^{-j}$. Then

$$\frac{\nu(B_r(x))}{r^s} = \sum_{i \in B_j(x)} \frac{\lambda_i^a \mu_i^b}{\mu_i^s} \sim \sup_{i \in B_j(x)} \left(\lambda_i \, \mu_i^{\frac{b-s}{a}} \right)^a$$

(because the number of branches over x in $B_j(x)$ is bounded by an absolute constant).

Suppose that

$$\frac{b-s}{a} < -\alpha(x).$$

Then $\limsup_{r \to 0} \nu(B_r(x))/r^s \to +\infty$ so that, using Proposition 5.2, $\mathcal{H}^s(\Gamma^\alpha) = 0$. Thus $d(\alpha) \leq b + a\alpha$ so that $d(\alpha) \leq -\tau(a) + a\alpha \ \forall a \in \mathbb{R}$.

In order to prove Proposition 5.1, we have to show that the infimum is reached. Using Proposition 5.2, it is sufficient to find a and b such that $\nu(\Gamma^\alpha) > 0$.

Suppose that a and b are solutions of the following system

$$(5.3) \qquad \left.\begin{aligned} \sum_{i=1}^d \lambda_i^a \mu_i^b = 1, \\ \frac{\sum P_i \mathrm{Log}\lambda_i}{\sum P_i \mathrm{Log}\mu_i} = \alpha, \end{aligned}\right\}$$

where $P_i = \lambda_i^a \mu_i^b$. (In Lemma 5.3, we will determine the values of α for which this system has a solution.)

If $(i_1, \dots, i_n)$ is a branch over x, let $(n_j)_{j=1,\dots,d}$ be the proportion of $j's$ in the sequence $i_1, \dots, i_n$ and let F be the subset of K composed of the points x such that

$$(5.4) \qquad n_j \to P_j$$

(meaning here that $\forall \varepsilon > 0$, $\exists n : \forall m, \geq n$, if $(i_1, \dots, i_m)$ is a branch over x, then $|n_j - P_j| \leq \varepsilon \ \forall j = 1, \dots, d$ for this branch).

If $x \in F$, then

$$\liminf_{j \to \infty} \inf_{i \in B_j(x)} \frac{\mathrm{Log}\lambda_i}{\mathrm{Log}\mu_i} = \lim \frac{\mathrm{Log}\lambda_i}{\mathrm{Log}\mu_i} = \frac{\sum P_j \mathrm{Log}\lambda_j}{\sum P_j \mathrm{Log}\mu_j} = \alpha$$

so that $F \subset \Gamma^\alpha$.

Let ν be the corresponding probability defined by (5.2). We can associate with ν another probability P defined on $\{1, \dots, d\}^{\mathbb{N}}$ as follows. If $i = (i_1, \dots, i_n)$ and I_i is the subset of $\{1, \dots, d\}^{\mathbb{N}}$ of all of the sequences starting with $(i_1, \dots, i_n)$, then

$$P(I_i) = P_{i_1} \dots P_{i_n}.$$

With probability P, the i_n's are a sequence of i.i.d. random variables. The strong law of large numbers implies that with probability 1, $n_j \to P_j$ for a sequence $i \in \{1, \dots, d\}^{\mathbb{N}}$. Clearly, ν is the image of the probability P by the application $x(i)$. We want to show that on K, ν-almost everywhere $n_j \to P_j$. It would be obvious if $x(i)$ were one to one.

First, note that if $(i_1, \ldots, i_n)$ is a branch over x, so is $(i_1, \ldots, i_{n-1})$. Now suppose that (5.4) fails. For n arbitrarily large, we can find a branch over x such that

$$|n_j - P_j| \geq \varepsilon. \tag{5.5}$$

Consider such a sequence of branches over x for $n \to \infty$. Since at a scale r there are at most N branches over x, (following Lemma 2.5) such branches for which (5.4) fails can be grouped into at most N sets of increasing branches. Among these, at least one, $\tilde{b}_x$, has infinite length.

We call a branch of infinite length i such that $x = x(i)$ a *principal branch over* x. Because of Lemma 2.5, for each x, there are at most N such branches. Clearly, $\tilde{b}_x$ is a principal branch over x.

Consider the event $\{x$ is such that (5.4) fails$\}$. It is included in the event $\{\exists b$ principal branch over x such that (5.5) holds$\}$. Since the probability for one given branch is 0, the probability that (5.5) holds for at least one of the (at most) N principal branches over x is also 0 such that for probability ν, almost every point of K is such that (5.4) holds. Thus $\nu(F) = 1$, and since $F \subset \Gamma^\alpha, \nu(\Gamma^\alpha)1$. We can now apply Proposition 5.2. Hence we have the first part of Proposition 5.1.

LEMMA 5.3. *Suppose that* $\alpha_{\min} < \alpha_{\max}$. *System* (5.3) *has a solution if and only if*

$$\alpha_{\min} < \alpha < \alpha_{\max}. \tag{5.6}$$

If $\alpha_{\min} = \alpha_{\max}$, *the only solution is* $\alpha = \alpha_{\min} = \alpha_{\max}$.

Proof. One can easily check that if $a_1, \ldots, a_d,\ b_1, \ldots, b_d > 0$, and the P_i's are weights (i.e., $0 < P_i$ and $\sum P_i = 1$), then

$$\inf\left(\frac{a_i}{b_i}\right) \neq \sup\left(\frac{a_i}{b_i}\right) \implies \inf\left(\frac{a_i}{b_i}\right) < \frac{\sum P_i a_i}{\sum P_i b_i} < \sup\left(\frac{a_i}{b_i}\right)$$

so that (5.6) is necessary. Now suppose that this holds. Since $\sum \lambda_i^a \mu_i^{-\tau(a)} = 1$, $\forall i, \tau(a) \leq a\text{Log}\lambda_i/\text{Log}\mu_i$. If $a \to +\infty$, $\tau(a) \leq a\ \alpha_{\min}$ so that if j is such that $\text{Log}\lambda_j/\text{Log}\mu_j > \alpha_{\min}$, then $\lambda_j^a \mu_j^{-\tau(a)} \to 0$. Thus if $\alpha_{\min}$ is reached for i in a subset $J \subset \{1, \ldots, d\}$, then $\sum_{i \in J} \lambda_i^a \mu_i^{-\tau(a)} \to 1$, but $\sum_{i \in J} \lambda_i^a \mu_i^{-\tau(a)} = \sum_{i \in J} e^{\text{Log}\mu_i(a\alpha_{\min} - \tau(a))}$ so that $\tau(a)/a \to \alpha_{\min}$. Thus all of the $P_i \to 0$ except for $i \in J$ so that $\sum P_i \text{Log}\lambda_i / \sum P_i \text{Log}\mu_i \to \alpha_{\min}$.

If $a \to -\infty$, $\tau(a) \leq a\alpha_{\max}$ and the same argument yields $\sum P_i\text{Log}\lambda_i / \sum P_i \text{Log}\mu_i \to \alpha_{\max}$. By continuity, $\sum P_i \text{Log}\lambda_i / \sum P_i \text{Log}\mu_i$ takes all values between $\alpha_{\min}$ and $\alpha_{\max}$.

Notice that if $\alpha_{\min} = \alpha_{\max} = \alpha_0$, then $\alpha = \alpha_0$ is the only possible value for which (5.3) has a solution.

6. Proof of the multifractal formalism. Now that we have determined the spectrum of a self-similar function, we will prove the multifractal formalism for these functions. First, we will do so for the wavelet-transform integral method. We recall the formulas that are used. We compute

$$\tilde{Z}(a, q) = \int_{\mathbb{R}^m} |C(a, b)|^q db.$$

Let

$$\eta(q) = \liminf \frac{\log \tilde{Z}(a, q)}{\log a}. \tag{6.1}$$

The Hölder spectrum is computed using the formula

$$d(\alpha) = \inf_q (q\alpha - \eta(q) + m). \tag{6.2}$$

In order to estimate $\tilde{Z}(a,q)$ for self-similar functions, we first have to estimate $C(a,b)$ everywhere. Let

$$\begin{cases} i &= (i_1, \ldots, i_n), \\ \Omega_i &= S_{i_1} \cdots S_{i_n}(\Omega), \\ B_i &= \Omega_i + B(0,a), \\ C_i &= B_{(i_1,\ldots,i_{n-1})} - B_{(i_1,\ldots,i_n)}. \end{cases}$$

If $a \le \mu_i$, $\mathrm{Vol}(B_i) \sim (\mu_i)^m$ and $\mathrm{Vol}(C_i) \le C(\mu_i)^m$. Inequality (4.6) shows that there exists one point $b \in B_i$ and an a such that $C2^{-j} \le a \le 2^{-j}$ for which the order of magnitude of $C(a,b)$ is Λ_n. We show that this order of magnitude holds on a ball of size $\sim a$. To this end, we bound $C(a,b)$ in B_i (and also in C_i, which will be useful later).

LEMMA 6.1. *Let $a > 0$ and B_i be such that $a \sim \mu_i$. Then if $b \in B_i$,*

$$|C(a,b)| \le CL_i,$$

and if $a \le \mu_{i_1} \cdots \mu_{i_n}$, then if $b \in C_i$,

$$|C(a,b)| \le CL_i \left(\frac{a}{\mu_i}\right)^k.$$

Lemma 6.1 is derived from (2.8) exactly as in the beginning of the proof of Proposition 2.7. We leave the details to the reader.

We return to the estimation of $C(a,b)$. In order to prove that it keeps the same order of magnitude in a ball of size $\sim a$, we bound $\bigtriangledown_b C(a,b)$ and $\partial_a C(a,b)$. Let $\partial_b C(a,b)$ be a partial derivative of $C(a,b)$ in a certain direction $b_0 \in \mathbb{R}^m$. Clearly,

$$\partial_b C(a,b) = \frac{1}{a}\tilde{C}(a,b),$$

where $\tilde{C}(a,b)$ is a wavelet transform using the wavelet $\partial\psi$.

The bound given by Lemma 6.1 for $C(a,b)$ holds for $\tilde{C}(a,b)$ so that

$$|\partial_b C(a,b)| \le \frac{C}{a} L_i.$$

Since at a certain point of B_i, $C(a,b)$ is of the order of magnitude of L_i, this is also the case on a ball of size $\sim a$.

If we now differentiate the wavelet transform with respect to the variable a, the same procedure yields

$$\partial_a C(a,b) = \frac{1}{a}\tilde{C}(a,b),$$

where $\tilde{C}(a,b)$ is a wavelet transform using the wavelet $\psi(x) - x.\bigtriangledown\psi(x)$, so that $C(a,b)$ is of the order of magnitude of L_i on a ball of size $\sim a$ in the time-scale half-space.

Furthermore, on C_i,

$$|C(a,b)| \leq C\frac{a^k \lambda_i}{(\mu_i)^k}. \tag{6.3}$$

Let A_j be the interval $[2^{-(j+A)}, 2^{-j}]$. For each branch i such that $\mu_i \sim 2^{-j}$, Proposition 4.1 shows that there exists a ball of radius at least $C2^{-j}$ in the time-scale half-space located near x_i and in scale in the interval A_j, where $|C(a,b)| \geq C\lambda_i$. Thus

$$\begin{aligned} C\sum_{\mu_i \sim 2^{-j}} 2^{-j(m+1)}\lambda_i^q &\leq \int_{A_j\times\mathbb{R}^m} |C(a,b)|^q da\, db \\ &\leq C'\sum_{\mu_i\sim 2^{-j}} 2^{-j(m+1)}\lambda_i^q + O\left(2^{-j}\sum_{\mu_i\geq 2^{-j}} \frac{2^{-kqj}\lambda_i^q}{\mu_i^{qk-m}}\right) \end{aligned}$$

so that

$$\begin{aligned} C\sum_{2^{-j}\leq\mu_i<2.2^{-j}} \mu_i^m\lambda_i^q &\leq 2^j\int_{A_j\times\mathbb{R}^m} |C(a,b)|^q da\, db \\ &\leq C'\left[\sum_{2^{-j}\leq\mu_i<2.2^{-j}} \mu_i^m\lambda_i^q + O\left(\sum_{\mu_i\geq 2^{-j}} \frac{2^{-kqj}\lambda_i^q}{\mu_i^{qk-m}}\right)\right]. \end{aligned} \tag{6.4}$$

We first estimate the term

$$\sum_{2^{-j}\leq\mu_i<2.2^{-j}} \mu_i^m\lambda_i^q. \tag{6.5}$$

The reader should notice that in the following estimation, we do not have to assume that q is positive. This remark will be useful in section 7.

Recall that $\tau(q)$ is such that

$$\sum_{j=1}^d \mu_j^{-\tau(q)}\lambda_j^q = 1. \tag{6.6}$$

Thus

$$\sum_{2^{-j}\leq\mu_i<2.2^{-j}} \mu_i^m\lambda_i^q \sim 2^{-(m+\tau(q))j}\sum_{2^{-j}\leq\mu_i<2.2^{-j}} \mu_i^{-\tau(q)}\lambda_i^q.$$

Let

$$F(j) = \sum_{2^{-j}\leq\mu_i<2.2^{-j}} \mu_i^{-\tau(q)}\lambda_i^q.$$

From (6.6), we get

$$\sum_{|i|=N} \mu_i^{-\tau(q)}\lambda_i^q = \left(\sum_{j=1}^d \mu_j^{-\tau(q)}\lambda_j^q\right)^N = 1$$

so that

$$\sum_{|i|\leq N_0} \mu_i^{-\tau(q)} \lambda_i^q = N_0. \tag{6.7}$$

Clearly,

$$\sum_{j=1}^{J} F(j) = \sum_{\mu_i \geq 2^{-J}} \mu_i^{-\tau(q)} \lambda_i^q. \tag{6.8}$$

After permuting the indexation of the S_i's, we can assume that $\mu_1 = \inf \mu_i$ and $\mu_d = \sup \mu_i$.

The right-hand side of (6.8) contains all of the terms of length N if $\mu_1^N \geq 2^{-J}$ and no terms of length M if $\mu_d^M \leq 2^{-J}$. Thus from (6.7) and (6.8), we get

$$N \leq \sum_{j=1}^{J} F(j) \leq M,$$

which can be written as

$$J \frac{\mathrm{Log} 2}{\mathrm{Log}(\frac{1}{\mu_1})} \leq \sum_{j=1}^{J} F(j) \leq J \frac{\mathrm{Log} 2}{\mathrm{Log}(\frac{1}{\mu_d})}$$

so that there exist $C_1, C_2 > 0$ such that

$$\left.\begin{aligned} \limsup \frac{F(j)}{j} &\leq C_1, \\ \limsup F(j) &\geq C_2. \end{aligned}\right\} \tag{6.9}$$

Thus

$$\limsup \frac{1}{j} 2^{(m+\tau(q))j} \sum_{2^{-j} \leq \mu_i < 2.2^{-j}} \mu_i^m \lambda_i^q \leq C$$

and

$$\limsup 2^{(m+\tau(q))j} \sum_{2^{-j} \leq \mu_i < 2.2^{-j}} \mu_i^m \lambda_i^q \geq C'.$$

Now consider the term

$$\sum_{\mu_i \geq 2^{-j}} \frac{2^{-kqj} \lambda_i^q}{\mu_i^{qk-m}}.$$

This is bounded by

$$C 2^{-kqj} \sum_{\mu_i \geq 2^{-j}} \lambda_i^q \mu_i^{m-qk}. \tag{6.10}$$

We split this sum into bands B_l defined by $2^{-l-1} \leq \mu_i < 2^{-l}$. Using (6.7), we get

$$C2^{-kqj} \sum_{\mu_i \in B_l} \lambda_i^q \mu_i^{m-qk} \leq C2^{-kqj} 2^{-l(m-kq+\tau(q))} \sum_{\mu_i \in B_l} \lambda_i^q \mu_i^{-\tau(q)}$$

$$\leq C2^{-kqj} 2^{-l(m-kq+\tau(q))}.$$

Now suppose that q is such that $m - kq + \tau(q) \leq 0$. Equation (6.10) is bounded by

$$C2^{-kqj} 2^{-(m-kq+\tau(q))j} \leq C2^{-(m+\tau(q))j},$$

and using (6.4) and (6.9), we obtain the followingproposition.

Proposition 6.2. *Suppose that F is self-similar and let q be such that*

$$\tau(q) \leq kq - m. \tag{6.11}$$

Then

$$\limsup_{a \to 0} a^{-m-\tau(q)} \int |C(a,b)|^q db \geq C > 0 \tag{6.12}$$

$$\limsup_{a \to 0} \frac{a^{-m-\tau(q)}}{|\log a|} \int |C(a,b)|^q db \leq C' < +\infty. \tag{6.13}$$

This result together with Proposition 2.7 proves the multifractal formalism for the wavelet-integral method.

The multifractal formalism is also valid for the structure function method since we showed in Part I that $\zeta(q) = \eta(q)$ for $q > 1$. However, the restriction $q > 1$ shows that it might not yield the whole left-hand side of the spectrum but a smaller part corresponding to the region where the infimum in the Legendre transform formula is attained for $q > 1$.

Note that if k can be chosen arbitrarily large (when g is C^∞), condition (6.11) reduces to $q \geq 0$. We consider the case of negative values of q in the next section.

7. The wavelet-box method.

In this section, we first show some pitfalls of the wavelet-maxima method and then show that a slight modification allows us to obtain the spectrum even for its decreasing part.

Let us first briefly recall the principles of the wavelet-maxima method. Consider for a given $a' > 0$ the local maxima of the function $b \to C(a', b)$. Generically, they belong to a line of maxima $b = l(a)$ defined in a small left-neighborhood $[a'', a']$ of a' by the following condition: $b \to C(a,b)$ has a local maximum for $b = l(a)$. The wavelet-transform maxima method requires first the computation of

$$Z(a,q) = \sum_l \sup_{b=l(a)} |C(a,b)|^q,$$

where l is a line of maxima of the wavelet transform defined on $[a'', a']$, and the sum is taken on all lines of local maxima defined in a left-neighborhood $[a'', a']$ of a'. We then define

$$\theta(q) = \liminf \frac{\log Z(a,q)}{\log a}.$$

The counterexamples concerning the wavelet-maxima method that were given in Part I easily adapt to the self-similar case. Suppose, for instance, that g is one of these counterexamples supported by the interval $[3,4]$. (We can make this assumption because they are compactly supported and these properties still hold after a contraction and a translation.) Then

$$F(x) = \sum 2^{-\alpha j} F(2^j x),$$

where $\alpha > 0$ is self-similar and yields a similar counterexample. Nonetheless, we will see that we can adapt the wavelet-maxima method so that it yields results as good as and even better than the other methods. To this end, we introduce a slight variant, the *wavelet-box method*.

Let C be a parameter larger than 1. The wavelet-box method consists of dividing $\mathbb{R}^m$ into cubes of length C and, for each cube included in Ω, keeping only the largest local maximum (if there is one on each of these cubes). Clearly, this procedure has the advantage of not taking into account accumulations of lines of local maxima, on which the counterexamples of Part I were based. We still use the notation $\theta(q)$, which will avoid confusion with the wavelet-maxima method.

THEOREM 7.1. *Under the same hypotheses as Theorem* 2.2*, the wavelet-box method yields the increasing part of the spectrum of self-similar functions. Furthermore, if* $d_{\max} = m$ *or, equivalently, if* $\overline{\cup S_i(\Omega)} = \overline{\Omega}$*, the wavelet-box method yields the whole spectrum of self-similar functions, provided that we keep only the largest maximum of a box of size* Ca *for a constant* C *large enough, i.e.,* $d(\alpha)$ *can be obtained by computing the Legendre transform of* $\theta(q) - m$*.*

With regard to the increasing part of the spectrum (corresponding to $p \geq 0$), the theorem is a consequence of the wavelet-integral method because of the following lemma.

LEMMA 7.2. *The two quantities*

$$\int |C(a,b)|^q db \quad \textit{and} \quad a^m \sum_{\max} |C(a,b)|^q$$

are of the same order of magnitude if the sum is computed as in the wavlet box method.

This result is quite straightforward since we estimated $\int |C(a,b)|^q db$ precisely by computing its order of magnitude near the wavelet maxima. We showed that its value is about λ_i^q near the tree T and smaller far from the tree. This shows that there exists at least one maximum near each point of the tree. The estimation of $a^m \sum_{\max} |C(a,b)|^q$ then follows exactly the estimation performed in Proposition 6.2. Thus, in that case, the verification of the fractal formalism reduces to the verification for the integral formula, and the multifractal formalism holds when using the two-wavelet methods. Note that for positive q's we do not have to restrict the sum to cubes included in Ω, which is interesting if we do not have a priori knowledge on Ω.

Before proving Theorem 2.3 for the decreasing part of the spectrum, we make some general remarks.

Consider again the case $q < 0$ but for the quantity $\sum_{\max} |C(a,b)|^q$. An important difference from the exact computations of [2] appears. Recall that the authors of [2] were interested in the case where F is the indefinite integral of a multinomial measure supported by a Cantor set. In this case, the wavelet maxima are situated on the "tree over the Cantor set" since F is piecewise constant outside this set, so, for a small enough, the wavelet transform vanishes there. Thus in this case, the last term of (6.4) vanishes, and the same proof as above shows that Proposition 6.2 will hold for $q < 0$ (with the same restriction concerning the distance between the maxima).

In the general case that we consider in this paper, F is a C^k function outside K for which we do not have special information (since g is C^k but arbitrary). Thus there may be extremely small wavelet maxima "far away" (on the scale of a) from K (i.e., at a distance $\gg a$). Thus no formula involving negative values of q can work reasonably. We present an example of this phenomenon.

First, note that if $\Omega \neq K$, it is easy to construct examples where g and thus F will be locally constant so that $F(x+h) - F(x)$ will vanish on an open subset for h small enough, as does $C(a,b)$ for a small enough. Thus $\zeta(q)$ and $\eta(q)$ take the value $+\infty$ for negative values of p so that in all generality, computing $\zeta(q)$ and $\eta(q)$ for negative values of p does not make sense. The same problem appears for formulas involving wavelet maxima. Of course, in the regions where $C(a,b)$ vanishes, there are no more maxima. However, it is easy to construct g with lines of very small maxima as follows.

Let ψ be a C^{k+2} function with moments of order $k+1$ vanishing and supported by $[3/2, 2]$, and let

$$h(x) = \sum_{j \geq 0} 2^{-2kj} \psi(2^{2j}x).$$

This is supported by $[0,2]$, and if ψ is the analyzing wavelet and $a = 2^{-j}$, $C(a,b)$ vanishes outside the interval $|b| \leq 2^{-j}/2$ (if $|b| \leq 2^{-j}/8$), but $C(a,0) = C2^{-kj}$. Thus $C(a,b)$ has a line of maxima that goes through the interval $|b| \leq 2^{-j}/2$ and the supremum on this line is of the order of magnitude of 2^{-kj}. Now suppose that $F = g$ in a neighborhood of 0 (which we can always assume if $\Omega \neq K$). Then $Z(a,q)$ is larger than Ca^{-kq}. We see that no bound of $Z(a,q)$ can be found independent of k. If the multifractal formalism held, since $d(\alpha)$ is independent of k, the order of magnitude of $Z(a,q)$ would be as well. Hence we have a contradiction.

We make one final remark on Theorem 2. First, suppose that g is C^∞. If $\alpha \leq \alpha_0$, the infimum in the Legendre transform is obtained for $q > 0$ (because $\tau(0) = -d_{\max}$ and τ is convex and increasing). In that case, we cannot directly calculate $d(\alpha)$ up to α_0 since we cannot use a C^∞ wavelet with all vanishing moments, but following [1], this can be done using a sequence of increasingly smoother wavelets and determining increasingly larger parts of the spectrum. The case where g is C^k is still easier to check.

We now want to show that using the wavelet-box method, we can recover the left part of the spectrum corresponding to negative values of q when

$$\overline{\cup S^j(\Omega)} = \Omega.$$

(This implies that there exists no region where F is smooth.) The validity of this condition can actually be checked on the part of the spectrum computed for $q > 0$ since at the maximum (the case where $q = 0$) $d(\alpha) = d_{\max}$, which satisfies

$$\sum \mu_j^{d_{\max}} = 1.$$

However, the condition $\overline{\cup S^j(\Omega)} = \Omega$ can be rewritten $\sum \mu_j^m = 1$ since $\mathrm{Vol}(\Omega_j) = \mu_j^m \mathrm{Vol}(\Omega)$. Thus $\overline{\cup S^j(\Omega)} = \Omega$ is equivalent to $d_{\max} = m$, which is easy to check.

In this case, the tree T leaves no void in the region of the upper half-plane above Ω. (By this we mean that for any (a,b) in this region, we can find a point of the tree in a domain $[a/C, Ca] \times [b - Ca, b + Ca]$); however, after perhaps increasing the constant C, we can also find a point $(\mu_i, S^i(t))$ where the order of magnitude of the wavelet transform of F is λ_i. Thus if we modify the wavelet-maxima method by imposing the condition that we first take the largest local maximum on the box $[a/C, Ca] \times [b - Ca, b + Ca]$ (which amounts to considering a kind of maximal function), we see that for a given scale a,

$$\sum_{\max} |C(a,b)|^q \sim \sum_{a \sim \mu_i} |\lambda_i|^q.$$

Returning to the estimation of (6.5), we see that

$$\limsup_{a \to 0} a^{-\tau(q)} \sum_{\max} |C(a,b)|^q db \geq C > 0,$$

$$\limsup_{a \to 0} \frac{a^{-\tau(q)}}{|\log a|} \sum_{\max} |C(a,b)|^q db \leq C' < +\infty.$$

Hence we have the multifractal formalism in that case.

Note that the constant C in the definition of the wavelet-box method must be chosen "large enough" depending on the self-similar function that is analyzed.

8. Unbounded self-similar functions. Thus far, we made the assumption $\alpha_{\min} > 0$ (which is equivalent to $|\lambda_j| < 1 \; \forall j = 1, \ldots, d$). This implied that $F \in C^{\alpha_{\min}}$. Thus we were interested only in Hölder exponents larger than $\alpha > 0$. However, we would like to consider negative exponents, which, as mentioned before, should be pertinent in some applications. We have already discussed the definition of negative exponents in Part I. We will now show that the multifractal formalism holds using a slightly different definition for the Hölder spectrum. We suppose that

$$\sum_{i=1}^{d} |\lambda_i| |\mu_i|^m < 1 \tag{8.1}$$

so that a function F that satisfies (2.3) belongs to L^1. Condition (8.1) can clearly give rise to unbounded functions. In fact, the following result holds.

LEMMA 8.1. *Suppose that one of the λ_j's satisfies $|\lambda_j| > 1$ and that g does not vanish identically. Then $\forall x \in K$, F is unbounded in any neighborhood of x so that $d(\alpha) = 0 \; \forall \alpha$.*

Proof. First, note that a straightforward estimation yields that if $F \in L^\infty$, then $|C(a,b)| \leq C$ so that if F is bounded in a neighborhood of x $|C(a,b)| \leq C$ if b is in a (perhaps) smaller neighborhood of x.

Let $x \in K$ and $i = (i_1, \ldots, i_n, \ldots)$ such that $x = x(i)$. Let j be such that $|\lambda_j| > 1$. Then we fix an n and define $i' = (i_1, \ldots, i_n, j, j, \ldots) = (i'_1, \ldots)$. Proposition 4.1 shows that there exists an x_0 such that if $b_l = S^{i'_1} \cdots S^{i'_l}(x_0)$ and $a_l = \mu_{i'_1} \cdots \mu_{i'_l}$, $|C(a_l, b_l)| \sim |\lambda_{i'_1} \ldots \lambda_{i'_l}|$ and is thus unbounded. If n is large enough and $l \geq n$, the points b_l are arbitrarily close to x so that F is unbounded in any neighborhood of x. Hence we have Lemma 8.1.

In this case, the Hölder spectrum of F for $\alpha > -n$ is trivial: $d(\alpha) = 0 \; \forall \alpha > -n$.

Note that if $\sup |\lambda_j| = 1$, F can be either unbounded or bounded depending on the specific values taken by the function g, as shown by the following example.

Suppose that F satisfies

$$F(x) = F(2x) + g(x)$$

and suppose that g is Lipschitz. If g is positive and does not vanish at 0, F is unbounded, whereas if $g(0) = 0$, F is bounded.

Lemma 8.1 suggests that if F is unbounded, the spectrum defined by the Hausdorff dimension of α-singularities is not the right quantity to consider, but we should instead compute the packing dimension of strong singularities.

We now suppose that the separated open-set condition holds and that g and the λ_j's are positive. We prove Theorem 2.2 in that case.

Let $x \in K$ and $i = (i_1, \dots, i_n, \dots)$ be the (unique) branch over x. We define two subsets A_1 and A_2 of $B(x, \mu_i)$ as follows. First, let Ω' be a set where $g(x) \geq C > 0$. Suppose that $\lambda_1 > 1$ and let $i' = (i_1, \dots, i_n, 1, \dots, 1)$, where the number p of ones will be made precise later. Since

$$F(y) = \sum \lambda_i g(S_i^{-1}(y)),$$

if $y \in S^{i'}(\Omega)$, $F(y) \geq C_1 \lambda_i \lambda_1^p$. $S^{i'}(\Omega)$ is the set A_1. If $\operatorname{dist}(y, K) \geq \mu_i/2$, $F(y) \leq C_2 \lambda_i$. A_2 is the set of points of $B(x, \mu_i)$ such that $\operatorname{dist}(y, K) \geq \mu_i/2$.

We choose p such that $C_1 \lambda_1^p \geq 2C_2$. The volumes of A_1 and A_2 are $\sim \mu_i^m$ (because of the separated open-set condition). Thus if

$$\beta(x) = \limsup \frac{\log |\lambda_{i_1}(x)| \cdots |\lambda_{i_N}(x)|}{\log \mu_{i_1}(x) \cdots \mu_{i_N}(x)}, \tag{8.2}$$

F has a strong singularity of order $\beta(x)$ at x. Furthermore, the order of magnitude of F on a subset of $B(x, C\mu_{i_1}(x) \cdots \mu_{i_N}(x))$ of size comparable to the size of this ball is exactly $\mu_{i_1}(x) \cdots \mu_{i_N}(x)$ so that if $\beta(x)$ is negative, the order of the strong singularity at x is not higher than $\beta(x)$. Hence we have the first part of the following proposition. (The last part is a direct consequence of Proposition 4.1.)

PROPOSITION 8.2. *If the separated open-set condition holds, if g and the λ_j's are positive, and if* (8.1) *holds, F has a "strong singularity" of order $\beta(x)$ at x but no strong singularity of higher order. Furthermore, without any assumption on g, the S_i's or the λ_i's, F has a "wavelet singularity" of order $\beta(x)$ at x.*

It would be interesting to prove this proposition without the assumption of the separated open-set condition. It clearly holds if $K \neq \Omega$ (i.e., if $\sum \mu_i^m \neq 1$) because in that case the choice that we made for the y's is still possible.

The case where $K = \Omega$ is perhaps less interesting for applications since f is then nowhere locally bounded (by Lemma 7.2), which is usually not realistic for "physical" functions. Actually, in the case of three-dimensional turbulence, the singularities seem to concentrate on a set of dimension < 3 (see [1] or [23]).

We now determine the packing dimension of the strong α-singularities of F.

PROPOSITION 8.3. *Under the same assumptions, the packing dimension of the strong α-singularities of f is given by $D(\alpha) = \inf(a\alpha - \tau(a))$.*

We already know that $D(\alpha) \leq \inf(a\alpha - \tau(a))$, so we have to prove only the lower bound. We will use the following result (see [14] or [25]).

PROPOSITION 8.4. *Let H^s be the packing measure of dimension s. Let μ be a probability measure on $\mathbb{R}^m$, $F \in \mathbb{R}^m$, and C be such that $0 < C < +\infty$.*

If $\liminf_{r \to 0} \mu(B_r(x))/r^s < C \ \forall\, x \in F$, $H^s(F) \geq \mu(F)/C$.

The proof of Proposition 8.3 follows the proof of Proposition 5.1 since we can take exactly the same measure μ and the same set F. It is now easy to check that the multifractal formalism holds in this setting because the proof of Proposition 6.2 actually holds without any change.

We conclude this paper with the proof of the following corollary, which shows that the multifractal formalism holds in a more general setting.

COROLLARY 8.5. *Let A be a pseudodifferential elliptic operator of order s whose symbol σ satisfies*

$$\forall\alpha,\ \beta,\quad |\partial_x^\alpha \partial_\xi^\beta \sigma(x,\xi)| \le C(\alpha,\beta)(1+|\xi|)^{s-\beta}.$$

Suppose that h is a self-similar function that satisfies

$$h(x) = \sum_{i=1}^{d} \lambda_i h(S_i^{-1}(x)) + g(x),$$

and if s is negative, suppose further that the moments of g of order at most $|s|$ vanish.

Let $F = A(h)$. If $F \in C^\epsilon(\mathbb{R}^m)$ for an $\epsilon > 0$, then its spectrum is a concave function whose increasing part is given by

$$d(\alpha) = \inf_q(\alpha q - \eta(q) + m).$$

Proof. Following a result of Calderón and Zygmund [7], A can be written $\tilde{A}(-\Delta)^{m/2}$ (up to a regularizing operator), where $\tilde{A}$ and $\tilde{A}^{-1}$ are Calderón–Zygmund operators. Clearly, $(-\Delta)^{m/2}h$ is a self-similar function if $m \ge 0$ and also if $m < 0$ and g has the corresponding number of vanishing moments. Thus the multifractal formalism holds for F because Calderón–Zygmund operators are continuous on the Besov spaces so that $(-\Delta)^{m/2}h$ and F share the same function η. Since these operators are also continuous on the two-microlocal spaces (see [18]), $(-\Delta)^{m/2}h$ and F have the same Hölder regularity at each point (perhaps up to a logarithmic correction).

STABILITY AND ORTHONORMALITY OF MULTIVARIATE REFINABLE FUNCTIONS*

W. LAWTON†, S. L. LEE‡, AND ZUOWEI SHEN‡

Abstract. This paper characterizes the stability and orthonormality of the shifts of a multidimensional (M, c) refinable function ϕ in terms of the eigenvalues and eigenvectors of the transition operator $W_{c_{\text{au}}}$ defined by the autocorrelation c_{au} of its refinement mask c, where M is an arbitrary dilation matrix. Another consequence is that if the shifts of ϕ form a Riesz basis, then $W_{c_{\text{au}}}$ has a unique eigenvector of eigenvalue 1, and all of its other eigenvalues lie inside the unit circle. The general theory is applied to two-dimensional nonseparable (M, c) refinable functions whose masks are constructed from Daubechies' conjugate quadrature filters.

1. Introduction.

In this paper, we present a complete characterization of the stability and orthonormality of the shifts of a refinable function in terms of the refinement mask by analyzing the simplicity of eigenvalue 1 of the transition operator.

Denote by $\ell^1(\mathbf{Z^d})$ and $\ell^2(\mathbf{Z^d})$ the spaces of absolutely summable and modulus-square-summable complex-valued sequences defined on $\mathbf{Z^d}$, respectively. Let $M \in \mathbf{Z^{d\times d}}$ be a $d\times d$ integer matrix with eigenvalues of modulus > 1 and with $|\det M| = m > 1$. Let $c \in \ell^1(\mathbf{Z^d})$ and $\phi : \mathbf{R^d} \to \mathbf{C}$ be a complex-valued function. The equation

$$\phi(x) = \sum_{q\in\mathbf{Z^d}} mc(q)\phi(Mx - q) \tag{1.1}$$

is called a *refinement equation*. The matrix M is called a *dilation matrix*. The sequence c is called a *refinement mask*, and the function ϕ is called an (M, c) *refinable function* or (M, c) *scaling function*. We assume that $\int \phi(x)dx = 1$.

Denote by $L^1(\mathbf{R^d})$ and $L^2(\mathbf{R^d})$ the spaces of Lebesque-integrable and modulus-square-integrable functions defined on $\mathbf{R^d}$, respectively. The class of all tempered distributions on $\mathbf{R^d}$ will be denoted by $\mathcal{S}'$. The dilation operator M associated with the dilation matrix M is defined for all functions ϕ by $M\phi(x) := \phi(Mx),\ x \in \mathbf{R^d}$. This can be extended to all distributions $\phi \in \mathcal{S}'$ by defining

$$\langle M\phi, f\rangle := \frac{1}{m}\langle \phi, M^{-1}f\rangle \quad \text{for all } f \in \mathcal{S},$$

where $\mathcal{S}$ denotes the class of all infinitely differentiable functions with rapid decay at infinity. Similarly, the shift operator $T^p\phi(x) := \phi(x - p),\ p \in \mathbf{Z^d}$, for functions may be extended to distributions by

$$\langle T^p\phi, f\rangle := \langle \phi, T^{-p}f\rangle \quad \text{for all } f \in \mathcal{S}.$$

The refinement equation (1.1) may now be extended to include distributions $\phi \in \mathcal{S}'$ by writing

$$\phi = \sum_{q\in\mathbf{Z^d}} mc(q) M T^q \phi. \tag{1.2}$$

A distribution ϕ that satisfies (1.2) is called an (M, c) *refinable distribution.*

The Fourier transform of a sequence $a \in \ell^1(\mathbf{Z^d})$ will be denoted by $\widehat{a}$ and is defined by

$$\widehat{a}(u) := \sum_{p\in\mathbf{Z^2}} a(p) e^{-ipu},$$

where $i \equiv \sqrt{-1}$. Note that $\widehat{a}(u)$ is a complex-valued 2π-periodic continuous function on $\mathbf{R^d}$ and thus is defined on the d-dimensional torus $\mathbf{T^d}$. For a finitely supported sequence $(a_j)_{j\in\mathbf{Z^d}}$ with support in $[0, N-1]^d$, we define N as its *length.*

For any continuous function f defined on $\mathbf{R^d}$, we shall denote by $f_|$ the sequence $(f(p))_{p\in\mathbf{Z^d}}$, which is the restriction of f to $\mathbf{Z^d}$.

The Fourier transform of a function $f \in L^1(\mathbf{R^d})$ is

$$\widehat{f}(u) := \int_{\mathbf{R^d}} f(x) e^{-ixu} dx.$$

This maps $\mathcal{S}$ onto itself and extends to all tempered distributions $\mathcal{S}'$ by duality.

We shall assume throughout this paper that c is a finitely supported sequence that satisfies

$$\sum_{p\in\mathbf{Z^d}} c(p) = 1. \tag{1.3}$$

Then there exists a compactly supported (M, c) refinable distribution ϕ, unique up to a constant multiple, such that its Fourier transform admits the infinite-product representation

$$\widehat{\phi}(u) = \widehat{\phi}(0) \prod_{j=1}^{\infty} \widehat{c}\left((M^T)^{-j} u\right), \quad u \in \mathbf{R^d} \tag{1.4}$$

(see [11]). Henceforth, we assume that $\widehat{\phi}(0) = 1$.

An (M, c) refinable function $\phi \in L^2(\mathbf{R^d})$ is *stable* if $\{\phi(x-p)\}_{p\in\mathbf{Z^d}}$ is a Riesz basis of its closed linear span. It is *orthonormal* if $\{\phi(x-p)\}_{p\in\mathbf{Z^d}}$ is an orthonormal basis of its closed linear span.

For an (M, c) refinable function $\phi \in L^2(\mathbf{R})$, define

$$\phi_{\mathrm{au}}(x) := \int_{\mathbf{R^d}} \phi(x-t)\overline{\phi(-t)}\, dt, \quad x \in \mathbf{R^d}, \tag{1.5}$$

and

$$c_{\mathrm{au}}(p) := \sum_{q\in\mathbf{Z^d}} c(p-q)\overline{c(-q)}, \quad p \in \mathbf{Z^d}. \tag{1.6}$$

Then ϕ_{au} is a continuous (M, c_{au}) refinable function. The function ϕ_{au} is called the *autocorrelation* of ϕ and the sequence c_{au} is called the *autocorrelation* of c.

A necessary condition for an (M, c) refinable function ϕ to be orthonormal is that the refinement mask c satisfies the conditions

$$mc_{\mathrm{au}}(Mp) = \delta(p), \quad p \in \mathbf{Z^d}, \tag{1.7}$$

and

$$\sum_{q \in \mathbf{Z^d}} c(q) = 1, \tag{1.8}$$

where $\delta(p) = 1$ for $p = 0$ and $\delta(p) = 0$ otherwise. A sequence c that satisfies (1.7) and (1.8) is called a *conjugate quadrature filter* with respect to the dilation matrix M (M-CQF). Note that (1.8) implies that

$$\sum_{q \in \mathbf{Z^d}} c_{\mathrm{au}}(q) = 1. \tag{1.9}$$

For a dilation matrix M and any finitely supported refinement mask c, we define the (M, c) *subdivision operator* $S_c : \ell^2(\mathbf{Z^d}) \to \ell^2(\mathbf{Z^d})$ by

$$(S_c b)(p) := \sum_{q \in \mathbf{Z^d}} mc(p - Mq) b(q), \quad b \in \ell^1(\mathbf{Z^d}). \tag{1.10}$$

For the case $M = 2I$, this operator has been studied extensively in [1]. The adjoint of $S_{\tilde{c}}$, where $\tilde{c}(p) := \overline{c(-p)},\ p \in \mathbf{Z^d}$, is the (M, c) *transition operator*, which shall be denoted by W_c. Thus the operator $W_c : \ell^2(\mathbf{Z^d}) \to \ell^2(\mathbf{Z^d})$ is defined by

$$(W_c b)(p) = \sum_{q \in \mathbf{Z^d}} mc(Mp - q) b(q), \quad b \in \ell^2(\mathbf{Z^d}). \tag{1.11}$$

We remark that the transition operator $W_{c_{\mathrm{au}}}$ corresponding to the autocorrelation c_{au} of c is called the *wavelet-Galerkin operator* in [18].

Note that if c is conjugate symmetric, i.e., $c = \tilde{c}$, then $S_c = S_{\tilde{c}}$, and W_c is the adjoint of the subdivision operator S_c. For our purposes, we shall restrict the transition operator to the space $\ell^1(\mathbf{Z^d})$. If ϕ is an (M, c) refinable continuous function, where c is finitely supported, then ϕ is compactly supported, and the sequence $\phi_|$ is an eigenvector of W_c in $\ell^1(\mathbf{Z^d})$ of eigenvalue 1. If c is an M-CQF, then $\phi_{c_{\mathrm{au}}|} = \delta$, which is an eigenvector of $W_{c_{\mathrm{au}}}$ of eigenvalue 1.

The definition in (1.11) shows that if the refinement mask c is supported in $[0, N-1]^d$ and if $M = 2I$, then $W_{C_{\mathrm{au}}}$ maps sequences supported on $[-N+1, N-1]^d$ into sequences supported on $[-N+1, N-1]^d$. For a general dilation matrix M, a more detailed discussion in section 4 leads to the fact that $W_{c_{\mathrm{au}}}$ has a finite-dimensional invariant subspace that consists of sequences on a finite set. The operator $W_{c_{\mathrm{au}}}$ (respectively, W_c) restricted to any of its finite-dimensional invariant subspaces will be called a *restricted transition operator*.

The eigenvalues of $W_{C_{\mathrm{au}}}$ hold the key to many important properties of the refinable function, for instance, stability, regularity, and the convergence of the cascade algorithm (see [17], [5], [9], [8], [22], and [23]). The first indication of this role appeared in [17] and [18], where it was shown that for $d = 1$ and $M = (2)$, i.e., in one dimension with dyadic scaling, if ϕ is a $(2, c)$ refinable function, then ϕ is orthonormal if and only if 1 is a simple eigenvalue of the transition operator $W_{c_{\mathrm{au}}}$.

The object of this note is to investigate further the relationship between stability and orthonormality of an (M, c) refinable function on one hand and the eigenvalues of the corresponding transition operator $W_{c_{\mathrm{au}}}$ on the other in the multivariate setting with an arbitrary dilation matrix. In particular, we give a multidimensional extension of the results in [17] on the characterization of the orthonormality of the refinable function. We further show that an (M, c) refinable function ϕ is stable if and only if the transition operator $W_{c_{\mathrm{au}}}$ has a unique eigenvector of eigenvalue 1, whose Fourier transform does not vanish on the torus. This is given in Theorem 2.5, where Theorem 2.3 plays a key role in the proof. Another consequence of Theorem 2.3 is the fact that if the shifts of an (M, c) refinable function ϕ form a Riesz basis, then the sequence $\phi_{c_{\mathrm{au}}|}$ is the unique eigenvector of $W_{c_{\mathrm{au}}}$ corresponding to the eigenvalue 1, and all of the other eigenvalues of $W_{c_{\mathrm{au}}}$ lie inside the unit circle. Section 3 deals with M-CQFs. In particular, it is shown that for an M-CQF, the corresponding (M, c) refinable function belongs to $L^2(\mathbf{R^d})$, and further characterizations of orthonormality are also given. Restricted transition operators are studied in more detail in section 4. It is shown that checking for stability and orthonormality is reduced to checking whether 1 is a simple eigenvalue of a finite-order matrix, which is generated from the refinement mask of ϕ. The general theory is applied to the construction of nonseparable conjugate quadrature filters (M-CQFs) and the corresponding refinable functions from the one-dimensional CQFs of Daubechies.

Another approach to the characterization of stability and orthonormality of a refinable function ϕ with finitely supported refinement mask c makes use of the zero set of the Fourier transform of c. A detailed discussion for the univariate case can be found in [2] and [12]. In one dimension, both approaches characterize the stability and orthonormality of a refinable function ϕ in terms of its refinement mask c using the equivalent characterization of the Fourier transform of ϕ. We prefer the eigenvalue approach for the following reasons. First, as pointed out in [7], for a specified finitely supported mask, it is easier to check for stability and orthonormality of the corresponding refinable function using the eigenvalue characterization. In this case, the problem of checking for stability and orthonormality is reduced to the simple routine of checking whether 1 is a simple eigenvalue of a finite-order matrix. Second, the analysis of the zero set of the Fourier transform of the refinement mask relies on the fact that a univariate polynomial has a finite number of zeros. This no longer holds for multivariate polynomials. However, it is possible to extend the corresponding univariate results to higher dimensions by imposng the condition that a certain multivariate polynomial has a finite number of zeros, as suggested by [11].

It is of particular interest to construct compactly supported wavelets from a compactly supported refinable function and its mask. In the univariate case, with dyadic scaling ($M = (2)$), the construction is simple. For a general integer dilation $M = (m)$, an algorithmic approach in the construction of compactly supported wavelets from a given refinable function ϕ and its refinement mask is given in [16]. The problem of wavelet construction from an (M, c) refinable function ϕ and its refinement mask is much more challenging in higher dimensions. However, in dimensions no greater than 3 and $M = 2I$, a method is given in [20] and [21] under a mild condition on the refinement mask c. In this case, compactly supported wavelets can be constructed based solely on c.

2. Stability and orthonormality of refinable functions.

Let $c : \mathbf{Z^d} \to \mathbf{C}$ be a finitely supported sequence satisfying (1.3) and let M be a dilation matrix. This section studies the relationship between stability and orthonormality of the (M, c)

refinable function ϕ on one hand and the spectral properties of the corresponding transition operator W_c on the other. Recall that the sequence $\phi_|$ is an eigenvector of W_c of eigenvalue 1. We shall first establish a result relating the spectrum of W_c and the nonvanishing of the Fourier transform of $\phi_|$ and then deduce results on stability and orthonormality of ϕ.

LEMMA 2.1. *Suppose that c is a finitely supported sequence satisfying $\widehat{c}(0) = 1$. Let ϕ be a continuous (M, c) refinable function and $b \in \ell^1(\mathbf{Z^d})$. Then for any integer $N \geq 1$ and for any $r \in \mathbf{Z^d}$,*

$$\sum_{p\in\mathbf{Z^d}} b(p)\phi\left(r - M^{-N}p\right) = \left(W_c^N(b * \phi_|)\right)(r). \tag{2.1}$$

Proof. The proof is by induction on N. For $N = 1$, applying the refinement equation (1.1) gives

$$\begin{aligned}\sum_{p\in\mathbf{Z^d}} b(p)\phi\left(r - M^{-1}p\right) &= \sum_{p,q\in\mathbf{Z^d}} mb(p)c(q)\phi_|\left(Mr - p - q\right)\\ &= \sum_{q\in\mathbf{Z^d}} mc(q)b * \phi_|(Mr - q)\\ &= \left(W_c(b * \phi_|)\right)(r).\end{aligned}$$

If (2.1) holds for N, then

$$\begin{aligned}\left(W_c^{N+1}(b * \phi_|)\right)(r) &= \sum_{q\in\mathbf{Z^d}} mc(Mr - q)\left(W_c^N(b * \phi_|)\right)\\ &= \sum_{q\in\mathbf{Z^d}} mc(Mr - q)\sum_{p\in\mathbf{Z^d}} b(p)\phi\left(q - M^{-N}p\right).\end{aligned} \tag{2.2}$$

Interchanging the order of summation on the sum in (2.2) followed by a change of index, it can be written as

$$\sum_{p\in\mathbf{Z^d}} b(p)\sum_{k\in\mathbf{Z^d}} mc(k)\phi\left(M(r - M^{-N-1}p) - k\right) = \sum_{p\in\mathbf{Z^d}} b(p)\phi\left(r - M^{-N-1}p\right).$$

The result now follows by induction. □

COROLLARY 2.2. *Suppose that c is a finitely supported sequence satisfying $\widehat{c}(0) = 1$ and ϕ is a continuous (M, c) refinable function. Then $\phi_|$ is the unique eigenvector of W_c in $\ell^1(\mathbf{Z^d}) * \phi_|$ of eigenvalue 1.*

Proof. Suppose that $b * \phi_|,\ b \in \ell^1(\mathbf{Z^d})$, is another eigenvector of W_c of eigenvalue 1. Then (2.1) gives

$$\sum_{p\in\mathbf{Z^d}} b(p)\phi\left(r - M^{-N}p\right) = \left(W_c^N(b * \phi_|)\right)(r) = b * \phi_|(r)$$

for all integers $N \geq 0$ and $r \in \mathbf{Z^d}$. Letting $N \to \infty$, we have

$$\left(\sum_{p\in\mathbf{Z^d}} b(p)\right)\phi(r) = b * \phi_|(r),$$

which is equivalent to

$$\left(\sum_{p\in\mathbf{Z^d}} b(p)\right)\widehat{\phi_|}(u) = \widehat{b}(u)\widehat{\phi_|}(u), \quad u\in\mathbf{R^d}.$$

Since $\widehat{\phi_|}$ does not vanish on a set of positive measure, it follows that $\widehat{b}(u)$ is a constant. Equivalently, $b=\alpha\delta$ for some $\alpha\in\mathbf{C}$. Hence $b*\phi_| = \alpha\phi_|$. □

Remark 1. In general, if $\widehat{\phi_|}$ can be factored as

$$\widehat{\phi_|}(u) = \widehat{h}(u)\widehat{g}(u),$$

where $\widehat{g}(u)\neq 0$ for all $u\in\mathbf{R^d}$ and $g\in\ell^1(\mathbf{Z})$, then it follows from Corollary 2.2 and Wiener's theorem that $\phi_|$ is the unique eigenvector of W_c in $h*\ell^1(\mathbf{Z})$ of eigenvalue 1.

THEOREM 2.3. *Suppose that c is a finitely supported sequence satisfying $\widehat{c}(0)=1$ and ϕ is a continuous (M,c) refinable function. If*

$$\widehat{\phi_|}(u) := \sum_{p\in\mathbf{Z^d}} \phi(p)e^{-ipu} \neq 0, \quad u\in\mathbf{R^d}, \tag{2.3}$$

then $\phi_|$ is the unique eigenvector of W_c in $\ell^1(\mathbf{Z^d})$ of eigenvalue 1, *and all of the other eigenvalues of W_c lie inside the unit circle.*

Further, 1 *is a simple eigenvalue of any restricted W_c.*

Proof. Suppose that (2.3) holds, and let

$$1/\widehat{\phi_|}(u) =: \sum_{p\in\mathbf{Z^d}} w(p)e^{-ipu}, \quad u\in\mathbf{R^d}.$$

Since $1/\widehat{\phi_|}(u)$ is smooth, it follows that $w\in\ell^1(\mathbf{Z^d})$. Hence $\ell^1(\mathbf{Z^d})*\phi_| = \ell^1(\mathbf{Z^d})$, and Corollary 2.2 implies that $\phi_|$ is the unique eigenvector of W_c in $\ell^1(\mathbf{Z})$ of eigenvalue 1.

Now let $\lambda\neq 1$ be an eigenvalue of W_c and let $v\in\ell^1(\mathbf{Z^d})$ be the corresponding eigenvector. Equation (2.1) gives

$$\lambda^N v(r) = (W_c^N v)(r) = (W_c^N v*w*\phi_|)(r) = \sum_{p\in\mathbf{Z}} (v*w)(p)\phi\left(r-M^{-N}p\right). \tag{2.4}$$

The limit as $N\to\infty$ of the sum on the right of (2.4) exists and is equal to

$$\left(\sum_p v*w(p)\right)\phi(r), \quad r\in\mathbf{Z^d}.$$

Therefore, if $\lambda\neq 1$, then necessarily $|\lambda|<1$. Further, $\sum_p v*w(p)=0$.

If 1 is not a simple eigenvalue of a restricted transition operator W_c, then it must be a degenerate eigenvalue with only one eigenvector, say b. In this case, there exists a vector b_1 such that $W_c b_1 = b_1 + b$, which implies that $W_c^N b_1 = b_1 + Nb$ for all integers $N\geq 1$. Again, (2.4) gives

$$b_1(r) + Nb(r) = (W_c^N b_1)(r) = \sum_{p\in\mathbf{Z}} (b_1*w)(p)\phi\left(r-M^{-N}p\right)$$

for all $N \geq 1$, which is impossible. □

A function $\phi \in L^2(\mathbf{R^d})$ is stable if $\{\phi(\cdot - p)\}_{p \in \mathbf{Z^d}}$ is a Riesz basis of its closed linear span. Recall that $\{\phi(\cdot - p)\}_{p \in \mathbf{Z}}$ is a Riesz basis if and only if there exist constants $0 < C_1 \leq C_2 < \infty$ such that

$$C_1 \leq \sum_{q \in \mathbf{Z^d}} |\hat{\phi}(u + 2\pi q)|^2 \leq C_2 \quad \text{for almost all } u \in \mathbf{R^d}. \tag{2.5}$$

If $\phi_{\mathrm{au}|} \in \ell^1(\mathbf{Z^d})$, the Poisson summation formula leads to the characterization that ϕ is stable if and only if

$$C_1 \leq \sum_p \phi_{\mathrm{au}}(p) e^{-ipu} \leq C_2, \quad u \in \mathbf{R^d}. \tag{2.6}$$

Corollary 2.4. *Suppose that c is a finitely supported sequence satisfying $\widehat{c}(0) = 1$ and that ϕ is a stable (M, c) refinable function. Then $\phi_{\mathrm{au}|}$ is the unique eigenvector in $\ell^1(\mathbf{Z^d})$ of $W_{c_{\mathrm{au}}}$ corresponding to the eigenvalue 1, and all of the other eigenvalues of $W_{c_{\mathrm{au}}}$ lie inside the unit circle.*

Corollary 2.4 follows directly from Theorem 2.3 and equation (2.6). In one dimension with dyadic scaling, Cohen and Daubechies [3] proved that for a stable $(2, c)$ refinable function ϕ, the eigenvalues of the corresponding transition operator $W_{c_{\mathrm{au}}}$ restricted to its invariant subspace of finite sequences with zero mean lie inside the unit circle. Their result was extended to higher dimensions with dilation matrix $M = 2I$ by Long and Chen [14]. We note that in one dimension, the result of Cohen and Daubechies was also improved upon by Hervé [10].

The following theorem gives a characterization of the stability of an (M, c) refinable function. A similar result in one dimension with dilation $M = (2)$ was obtained in [5].

Theorem 2.5. *Suppose that c is a finitely supported sequence that satisfies $\widehat{c}(0) = 1$. An (M, c) refinable function ϕ is stable if and only if $W_{c_{\mathrm{au}}}$ has a unique eigenvector of eigenvalue 1 whose Fourier transform does not vanish.*

Further, 1 is a simple eigenvalue of any restricted $W_{c_{\mathrm{au}}}$.

Proof. If ϕ is stable, then condition (2.3) of Proposition 2.3 is satisfied for ϕ_{au}. Hence $W_{c_{\mathrm{au}}}$ has a unique eigenvector $\phi_{\mathrm{au}|}$ of eigenvalue 1 that has a nonvanishing Fourier transform.

Conversely, since $\phi_{\mathrm{au}|} \in \ell^1(\mathbf{Z^d})$ is an eigenvector of $W_{c_{\mathrm{au}}}$ with eigenvalue 1 and since such an eigenvector is unique and has a nonvanishing Fourier transform, it follows from (2.6) that the (M, c) refinable function ϕ is stable. □

An (M, c) refinable function $\phi \in L^2(\mathbf{R^d})$ is *interpolatory* if ϕ is continuous and satisfies

$$\phi(p) = \delta(p), \quad p \in \mathbf{Z^d}. \tag{2.7}$$

Theorem 2.6. *Suppose that c is a finitely supported sequence that satisfies $\widehat{c}(0) = 1$. A necessary and sufficient condition for a continuous (M, c) refinable function ϕ to be interpolatory is that the sequence δ is the unique eigenvector of W_c of eigenvalue 1.*

Further, 1 is a simple eigenvalue of any restricted $W_{c_{\mathrm{au}}}$.

Proof. Since ϕ is (M, c) refinable, the corresponding sequence $\phi_|$ is an eigenvector of W_c in $\ell^1(\mathbf{Z^d})$ with eigenvalue 1. If δ is the unique eigenvector of eigenvalue 1, then

$$\phi(p) = \delta(p), \quad p \in \mathbf{Z^d},$$

i.e., ϕ is interpolatory.

Conversely, if ϕ is interpolatory, then obviously $\phi_| = \delta$ is an eigenvector of W_c in $\ell^1(\mathbf{Z^d})$ with eigenvalue 1. Since

$$\sum_{p\in\mathbf{Z^d}} \phi(p)e^{-ipu} = 1 \quad \text{for all } u \in \mathbf{R^d}$$

does not vanish, by Theorem 2.3, δ is the unique eigenvector of eigenvalue 1. □

Clearly, $\phi \in L^2(\mathbf{R^d})$ is an orthonormal (M,c) refinable function if and only if ϕ_{au} is an interpolatory (M, c_{au}) refinable function.

Corollary 2.7. *Suppose that c is a finitely supported sequence that satisfies $\widehat{c}(0) = 1$. An (M,c) refinable function ϕ is orthonormal if and only if the sequence δ is the unique eigenvector of $W_{c_{\text{au}}}$ of eigenvalue* 1.

Further, 1 *is a simple eigenvalue of any restricted $W_{c_{\text{au}}}$.*

Combining this corollary with Theorem 2.5, we have the following proposition.

Proposition 2.8. *Suppose that c is a finitely supported sequence satisfying $\widehat{c}(0) = 1$ and that $\phi \in L^2(\mathbf{R^d})$ is (M,c) refinable. Then the following are equivalent:*

(i) *ϕ is orthonormal*;

(ii) *c is an M-CQF and ϕ is stable*;

(iii) *c is an M-CQF and $\widehat{\phi_{\text{au}|}}(u) \neq 0, u \in \mathbf{R^d}$.*

If c is an M-CQF, Corollary 2.7 says that the simplicity of the eigenvalue 1 of any restricted transition operator $W_{c_{\text{au}}}$ is equivalent to the orthonormality of the refinable function ϕ. On the other hand, Theorem 2.5 states that the stability of the refinable function ϕ is equivalent to the simplicity of the eigenvalue 1 of any restricted transition operator $W_{c_{\text{au}}}$ and the nonvanishing of the Fourier transform of the corresponding eigenvector. It will be shown in an example below that the simplicity of the eigenvalue 1 of a restricted $W_{c_{\text{au}}}$ does not imply the existence of an eigenvector with nonvanishing Fourier transform. This shows that the conditions in Theorem 2.5 are not superfluous. In fact, it will be interesting to know whether the simplicity of the eigenvalue 1 of a restricted transition operator together with the additional condition

$$\sum_k |\widehat{c}(u + (M^T)^{-1}2\pi\gamma_k)|^2 > 0 \tag{2.8}$$

would imply the nonvanishing of the Fourier transform of the corresponding eigenvector.

The following examples show that the simplicity of eigenvalue 1 together with (2.8) do not imply the nonvanishing of the Fourier transform of the corresponding eigenvector. In particular, they show that the converse of Theorem 2.3 is false even under the assumption in (2.8).

Example 1. Let c be the sequence

$$\left\{\ldots, 0, \frac{1}{4}, \frac{1}{2}, \frac{1}{4}, \frac{1}{4}, \frac{1}{2}, \frac{1}{4}, 0, \ldots\right\},$$

where $c(0) = 1/4$, $c(1) = 1/2, \ldots$. It is straightforward to check that the sequence $a = \{\ldots, 0, 1, 2, 2, 2, 1, 0, \ldots\}$, where $a(0) = 1$, $a(1) = 2, \ldots$, is the unique eigenvector for W_c of eigenvalue 1 and that the Fourier transform of a is $(1 + e^{iu})(1 + e^{iu} + e^{i2u})$, which vanishes at -1.

We shall show that there is a compactly supported continuous $(2,c)$ refinable function ϕ such that

$$\phi(n) = a(n), \quad n \in \mathbf{Z}, \tag{2.9}$$

and the Fourier transform $\widehat{c}(u)$ of the mask c satisfies

$$|\widehat{c}(u)|^2 + |\widehat{c}(u+\pi)|^2 > 0 \quad \text{for all } u \in \mathbf{R}. \tag{2.10}$$

The Fourier transform of c can be written as

$$\widehat{c}(u) = \widehat{b}(u)(1 - e^{iu} + e^{i2u}) = \widehat{b}(u)(e^{iu} + \omega)(e^{iu} + \omega^2), \tag{2.11}$$

where

$$b(u) = \frac{1}{4}(1 + e^{iu})^3$$

is the Fourier transform of the mask

$$b = \left\{ \dots, 0, \frac{1}{4}, \frac{3}{4}, \frac{3}{4}, \frac{1}{4}, 0, \dots \right\}$$

with $b(0) = 1/4,\ b(1) = 3/4, \dots$, and $\omega \neq 1$ is a cube root of unity. All of the roots of $\widehat{c}$ lie on the unit circle, and they are precisely $-1, -1, -1, -\omega$, and $-\omega^2$. Since no root is the negative of another root, $|\widehat{c}(u)|^2 + |\widehat{c}(u+\pi)|^2 > 0$ for all real u. Thus the mask c satisfies (2.10).

Note that the sequence b is exactly the mask for the $(2,b)$ refinable quadratic B-spline g obtained by convolving the characteristic function $\chi_{[0,1)}$ with itself three times. Let

$$\phi(x) = g(x) + g(x-1) + g(x-2), \quad x \in \mathbf{R}. \tag{2.12}$$

Then the Fourier transform of ϕ is

$$\widehat{\phi}(u) = \widehat{g}(u)(e^{iu} - \omega)(e^{iu} - \omega^2) = \widehat{g}(u)(1 + e^{iu} + e^{i2u}). \tag{2.13}$$

Since the set of roots of $(1-z)^3(1+z+z^2)$ is closed under the mapping $z \to z^2$, $\phi(x)$ is $(2,a)$ refinable by Theorem 2.1 of [15]. The function ϕ is not stable since ω and ω^2 are zeros of $1 + z + z^2$. With a suitable normalization of g, we have

$$\phi_| = \{\dots, 0, 1, 2, 2, 2, 1, 0, \dots\},$$

which is (2.9).

Example 2. Let c and ϕ be as in Example 1. Then

$$c_{\text{au}} = \{\dots, 0, 1, 4, 6, 6, 9, 12, 9, 6, 6, 4, 1, 0, \dots\}.$$

The sequence $\phi_{\text{au}|}$ is an eigenvector of $W_{c_{\text{au}}}$ of eigenvalue 1. The 11×11 linear system satisfied by the eigenvectors for $W_{c_{\text{au}}}$ corresponding to the eigenvalue 1 has rank 10. (Here $W_{c_{\text{au}}}$ is restricted to sequences supported on $[-5,5]$, which form an invariant subspace containing all finitely supported eigenvectors.) Hence $\phi_|$ is the unique eigenvector of $W_{c_{\text{au}}}$ of eigenvalue 1.

In summary, this example gives a $(2,c)$ refinable function which is not stable, but $W_{c_{\text{au}}}$ has a simple eigenvalue 1 and the mask c satisfies

$$|\widehat{c}(u)|^2 + |\widehat{c}(u+\pi)|^2 > 0 \quad \text{for all } u.$$

3. Multivariate CQF. Let M be an integer dilation matrix and $c : \mathbf{Z^d} \to \mathbf{C}$ be a finitely supported sequence that satisfies (1.3). Hence there is a unique compactly supported (M, c) refinable distribution ϕ, normalized so that $\widehat{\phi}(0) = 1$. Assuming that c is an M-CQF, we are interested in knowing when $\phi \in L^2(\mathbf{R^d})$ and obtaining further characterizations of orthonormality.

We first consider the cascade algorithm for the computation of the compactly supported (M, c) refinable distribution. Let $\phi^{(0)}$ be the indicator function of any fundamental region for $\mathbf{Z^d} \subset \mathbf{R^d}$. (Thus $\widehat{\phi^{(0)}}$ is continuous at 0 and $\widehat{\phi^{(0)}}(0) = 1$.) Starting from $\phi^{(0)}$, define a sequence of functions $\phi^{(n)}$ by

$$\phi^{(n)}(x) := \sum_{p \in Z^d} mc(p)\phi^{(n-1)}(Mx - p), \quad n = 1, 2, \ldots. \tag{3.1}$$

Then

$$\widehat{\phi^{(n)}}(u) = \widehat{\phi^{(0)}}\left((M^T)^{-n}u\right) \prod_{j=1}^{n} \left(\widehat{c}\left((M^T)^{-j}u\right)\right), \quad u \in \mathbf{R^d}. \tag{3.2}$$

The sequence $\widehat{\phi^{(n)}} \to \widehat{\phi}$ uniformly on compact subsets as $n \to \infty$, where

$$\widehat{\phi}(u) = \prod_{j=1}^{\infty} \widehat{c}\left((M^T)^{-j}u\right), \quad u \in \mathbf{R^d}, \tag{3.3}$$

since c satisfies (1.3). Further, $\widehat{\phi}$ is continuous at the origin and $\widehat{\phi}(0) = 1$.

It is clear that $\phi^{(n)} \in L^2(\mathbf{R^d})$ and is compactly supported. Next, we prove that $\|\phi^{(n)}\| = 1$ for all $n = 0, 1, \ldots$. Note that if c is an M-CQF, then (1.7) and (1.11) imply that δ is an eigenvector of $W_{c_{\mathrm{au}}}$ of eigenvalue 1. Since $\phi^{(0)}_{\mathrm{au}\,|} = \delta$ and $\phi^{(n)}_{\mathrm{au}\,|} = W_{c_{\mathrm{au}}} \phi^{(n-1)}_{\mathrm{au}\,|}$, we have $\phi^{(n)}_{\mathrm{au}\,|} = \delta$. Hence $\|\phi^{(n)}\| = 1$ for all $n = 0, 1, \ldots$.

PROPOSITION 3.1. *If c is an M-CQF, then $\phi^{(n)}$ defined by* (3.1) *converges weakly to the (M, c) refinable function $\phi \in L^2(\mathbf{R^d})$.*

If, in addition, $\|\phi\| = 1$, then $\phi^{(n)}$ converges strongly in $L^2(\mathbf{R^d})$ to ϕ.

Proof. First, note that if c is an M-CQF, then $||\phi^{(n)}|| = 1$ for all $n \geq 0$. Therefore, $\{\phi^{(n)}\}$ has a subsequence which converges weakly to $\varphi \in L^2(\mathbf{R^d})$. Since weak convergence is stronger than convergence in distribution, we have $\varphi = \phi$, and hence $\phi \in L^2(\mathbf{R^d})$.

Next, we show that the sequence $\phi^{(n)}$ itself converges weakly to ϕ. If $\phi^{(n)}$ does not converge weakly to ϕ, then there exists a subsequence $\phi^{(n_i)}$ which converges weakly to a function in $L^2(\mathbf{R^d})$ other than ϕ. This contradicts the fact that $\phi^{(n_i)}$ converges to ϕ in distribution.

In addition, if $\|\phi\| = 1$, then $\|\phi^{(n)}\| \to \|\phi\|$. With this, weak convergence of $\phi^{(n)} \to \phi$ implies strong convergence. □

Remark 2. For a general finitely supported mask c, a similar proof shows that the corresponding (M, c) refinable distribution ϕ belongs to $L^2(\mathbf{R^d})$ if the ℓ^2 operator norm $\|W_{c_{\mathrm{au}}}\| \leq 1$.

Since ϕ is compactly supported, if $\phi \in L^2(\mathbf{R^d})$, then $\phi \in L^1(\mathbf{R^d})$. Hence $\widehat{\phi}(u) \to 0$ as $|u| \to \infty$. If ϕ is refinable, then for any $p \in 2\pi\mathbf{Z^d}/\{\mathbf{0}\}$,

$$\widehat{\phi}((M^T)^n p) = \widehat{\phi}(p) \prod_{j=1}^{n} \widehat{c}(((M^T)^{n-j})p) = \widehat{\phi}(p).$$

Letting $n \to \infty$ implies that $\widehat{\phi}(p) = 0$ for $p \in 2\pi\mathbf{Z^d}/\{\mathbf{0}\}$. This means that ϕ satisfies the Strang–Fix condition of order 1. By the Poisson summation formula, this condition is equivalent to the shifts of ϕ forming a partition of unity, i.e.,

$$\sum_{p\in\mathbf{Z^d}} \phi(x-p) = 1, \quad x \in \mathbf{R^d}. \tag{3.4}$$

Proposition 3.2. *Let M be a dilation matrix, c be an M-CQF, and ϕ be the unique (M,c) refinable function normalized such that $\widehat{\phi}(0) = 1$. The following are equivalent:*

(i) *δ is the unique eigenvector of $W_{c_{\mathrm{au}}}$ of eigenvalue* 1;

(ii) *the shifts of ϕ are orthonormal*;

(iii) *the shifts of ϕ are orthogonal.*

Proof. The equivalence of (i) and (ii) is given in Corollary 2.7. We need only to show that (iii) implies (ii). If (iii) holds, multiplying both sides of (3.4) by ϕ and integrating term by term, the orthogonality of the shifts of ϕ and the fact that $\int \phi(x) = 1$ give $\|\phi\|^2 = 1$. □

As a consequence of Propositions 3.1 and 3.2, the cascade algorithm converges strongly if the corresponding (M,c) refinable function ϕ is orthonormal, a result which coincides with the well-known fact that the stability of an (M,c) refinable L^2 function implies strong convergence of the cascade algorithm.

4. Restricted transition operators. We now discuss how to restrict the transition operator to a finite-dimensional subspace. For a dilation matrix M and a finitely supported refinement mask c, a subset $D \subset \mathbf{Z^d}$ is called an *invariant support set* for the transition operator W_c if the following are satisfied:

(i) D is finite;

(ii) for all sequences b with support in D, the support of $W_c b$ is also in D; and

(iii) the support of every finitely supported eigenvector of W_c that corresponds to a nonzero eigenvalue is contained in D.

Such a finite invariant support set D for W_c always exists. To construct D, choose a vector norm $\|\cdot\|$ on $\mathbf{R^d}$ and a number $0 < \alpha < 1$ such that for all $x \in \mathbf{R^d}$,

$$||M^{-1}x|| \le (1-\alpha)||x||.$$

This is possible because the spectral radius $\rho(M^{-1}) < 1$. Now choose

$$r \ge r_{\text{min}} := \frac{(1-\alpha)}{\alpha} \max_{c(p)\neq 0} \|p\|$$

and define

$$D_r = \{p \in \mathbf{Z^d} : ||\mathbf{p}|| \le \mathrm{r}\}.$$

Clearly, D_r is an invariant support set for W_c. Further, if a sequence b is supported in D_s with $s > r$, then $W_c b$ is supported in D_t, where $t = \alpha r + (1-\alpha)s$. Therefore, D_r contains the support of every compactly supported eigenvector of W_c. Further, any compactly supported eigenvector of W_c is also an eigenvector of the restricted operator $W_c|_{\ell(D_r)}$, where $\ell(D_r)$ is the space of all sequences supported on D_r. One may construct the disk D_r to be arbitrary close to the minimal size by using a vector norm so that the corresponding operator norm $\|M^{-1}\|$ is sufficiently closed to $\rho(M^{-1})$ and by choosing $r = r_{\text{min}}$.

For the case where $M = 2I$ with refinement mask c supported in $[0, N-1]^d$, the support of ϕ is in $[0, N-1]^d$ and that of ϕ_{au} is contained in $[-N+1, N-1]^d$. A mimimal invariant support set for the corresponding transition operator $W_{c_{\mathrm{au}}}$ is $[-N+1, N-1]^d$.

For a dilation matrix M and a finitely supported mask c, let Ω be an invariant support set of $W_{c_{\mathrm{au}}}$, and $\ell(\Omega)$ be the space of all sequences supported on Ω. Then the transition operator $W_{c_{\mathrm{au}}}$ restricted to $\ell(\Omega)$ is represented by the matrix

$$A := (m\ c_{\mathrm{au}}(Mp - q))_{p,q\in\Omega}\ , \tag{4.1}$$

and $\phi_{\mathrm{au}|}$ is an eigenvector of A of eigenvalue 1.

Theorem 4.1. *Suppose that c is a finitely supported sequence satisfying $\widehat{c}(0) = 1$ and that $\phi \in L^2(\mathbf{R^d})$ is the compactly supported (M, c) refinable function. Then ϕ is stable if and only if*

(i) *there is an eigenvector corresponding to the eigenvalue 1 of matrix A defined by (4.1) whose Fourier transform does not vanish, and*

(ii) *1 is a simple eigenvalue of A.*

Proof. Conditions (i) and (ii) together with the fact that $\phi_{\mathrm{au}|}$ is an eigenvector of A of eigenvalue 1 imply that $\phi_{\mathrm{au}|}$ has a nonvanishing Fourier transform. Hence conditions (i) and (ii) imply that ϕ is stable.

On the other hand, if ϕ is stable, then $\phi_{\mathrm{au}|}$ is an eigenvector of A of eigenvalue 1 whose Fourier transform does not vanish; hence condition (i) holds. To show condition (ii), assume that 1 is not a simple eigenvalue of A. Then there exists an eigenvector a of A of eigenvalue 1, and a is not a scalar multiple of the eigenvector $\phi_{\mathrm{au}|}$. Since the transition operator $W_{c_{\mathrm{au}}}$ maps $\ell(\Omega)$ into $\ell(\Omega)$, the vector a is an eigenvector in $\ell^1(\mathbf{Z})$ of the transition operator $W_{c_{\mathrm{au}}}$ of eigenvalue 1. This contradicts Theorem 2.5. □

A similar argument using Theorem 2.6 and Corollary 2.7, respectively, leads to the following results.

Proposition 4.2. *Let c be a finitely supported sequence that satisfies $\widehat{c}(0) = 1$, ϕ be the (M, c) refinable function, and D be an invariant support set of W_c, and suppose that ϕ is continuous. Then ϕ is interpolatory if and only if the sequence δ is a unique eigenvector of the matrix*

$$C := (m\ c(Mp - q))_{p,q\in D}$$

of simple eigenvalue 1.

Proposition 4.3. *Suppose that c is a finitely supported sequence satisfying $\widehat{c}(0) = 1$ and that ϕ is the (M, c) refinable function in $L^2(\mathbf{R^d})$. Then ϕ is orthonormal if and only if the sequence δ is a unique eigenvector of the matrix A defined by (4.1) of simple eigenvalue 1.*

This proposition shows that the problem of checking whether ϕ has orthonormal shifts simply amounts to checking whether 1 is a simple eigenvalue of the matrix A. Similarly, checking whether ϕ is stable reduces to checking whether 1 is a simple eigenvalue of the matrix A and whether the Fourier transform of the corresponding eigenvector vanishes on the torus.

In the case where $d = 2, 3$ and $M = 2I$, if ϕ has orthonormal shifts and the refinement mask c satisfies

$$\overline{\widehat{c}(u)} = e^{ip_0\cdot y}\widehat{c}(u)$$

for some $p_0 \in \mathbf{Z^d}$, then it was shown in [20] and [21] that compactly supported orthonormal wavelets can easily be constructed from c and ϕ. Interested readers should consult [20] and [21] for details.

5. Construction of admissible refinement masks. This section constructs three 2×2 dilation matrices M with $|\det(M)| = 2$ and an infinite family of two-dimensional finitely supported masks c and shows that the corresponding (M, c) refinable functions ϕ are orthonormal. The refinable functions ϕ are constructed so that the set of points satisfying the condition $\{u : \widehat{\phi}(u) \neq 0\}$ contains a connected open set that contains a fundamental domain for $2\pi\mathbf{Z^2} \subset \mathbf{R^2}$. This implies that $(\widehat{\phi_{\text{au}|}})(u) > 0$; hence by Corollary 2.7, ϕ has orthonormal shifts.

Up to a similarity transformation and multiplication by matrices that represent reflection about the origin and reflection about the x_1 axis, there are only three distinct 2×2 integer dilation matrices whose determinant equals 2 or -2. They are

$$M_1 = \begin{pmatrix} 0 & -2 \\ 1 & 0 \end{pmatrix}, \quad \text{which has eigenvalues } \pm i\sqrt{2},$$

$$M_2 = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}, \quad \text{which has eigenvalues } 1 \pm i,$$

and

$$M_3 = \begin{pmatrix} 0 & -2 \\ 1 & 1 \end{pmatrix}, \quad \text{which has eigenvalues } \frac{(1 \pm i\sqrt{7})}{2}.$$

We shall now construct refinement masks $c : \mathbf{Z}^2 \to \mathbf{C}$ which generate nonseparable orthonormal refinable functions and wavelets for dilation matrices M_1, M_2, and M_3.

For a given one-dimensional sequence b, we define the *induced two-dimensional mask* $c : \mathbf{Z^2} \to \mathbf{C}$ by

$$c\begin{pmatrix} m \\ n \end{pmatrix} = b(m)\delta(n), \quad (m, n)^T \in \mathbf{Z^2}. \tag{5.1}$$

LEMMA 5.1. *Let $Z_{\widehat{b}}$ denote the set of real zeros of $\widehat{b}$. Then the zero set $Z_{\widehat{c}}$ of the Fourier transform of the induced mask c is given by*

$$Z_{\widehat{c}} = \left\{(u_1, u_2)^T : u_1 \in Z_{\widehat{b}},\ u_2 \in R\right\}. \tag{5.2}$$

Proof. From (5.1),

$$\widehat{c}((u_1, u_2)^T) = \widehat{b}(u_1), \quad (u_1, u_2)^T \in \mathbf{R^2},$$

which gives (5.2). □

LEMMA 5.2. *Let b and c be as above. Let M be a 2×2 dilation matrix, and let ϕ be the unique (M, c) refinable distribution. Then the zero set $Z_{\widehat{\phi}}$ of the Fourier transform of ϕ satisfies*

$$Z_{\widehat{\phi}} = \bigcup_{j \geq 1} (M^T)^j Z_{\widehat{c}}. \tag{5.3}$$

Proof. The assertion follows from the infinite-product representation of $\widehat{\phi}$. □

Let $\mathcal{L}_1$ and $\mathcal{L}_2$ be the lines $x_1 = \pi$ and $x_1 = -\pi$ in $\mathbf{R^2}$, respectively. For any 2×2 dilation matrix M and the corresponding (M, c) refinable function ϕ, the set K

is defined as the closure of the largest connected subset of $\mathbf{R^2}$ containing the origin and consisting of points where the Fourier transform $\widehat{\phi}$ is nonzero.

Lemma 5.3. *Let b be a one-dimensional mask and let c be the induced two-dimensional mask. Suppose that the zero set of $\hat{b}$ satisfies*

$$Z_{\widehat{b}} = \{(2n+1)\pi : n \in \mathbf{Z}\}. \tag{5.4}$$

Then K is bounded by a subset of lines $(M^T)^k \mathcal{L}_j,\ k \geq 1,\ j = 1, 2.$

Proof. The assertion follows from Lemmas 5.1 and 5.2. □

Remark 3. The refinement masks b used by Daubechies in [6] to construct orthonormal refinable functions of one variable are CQFs, and the zero set of $\widehat{b}$ satisfies condition (5.4).

For the three dilation matrices $M_n,\ n = 1, 2, 3$, the set K can be computed explicitly if the zero set of $\hat{b}$ satisfies condition (5.4). In each case, the set K is a polygon whose vertices are the columns of the matrix V_n, where

$$V_1 = \begin{pmatrix} 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix},$$

$$V_2 = \begin{pmatrix} 0 & 1 & \frac{3}{2} & 0 & -1 & -\frac{3}{2} \\ \\ 1 & 1 & \frac{1}{2} & -1 & -1 & -\frac{1}{2} \end{pmatrix},$$

$$V_3 = \begin{pmatrix} \frac{2}{3} & \frac{4}{3} & -\frac{2}{3} & -\frac{4}{3} \\ \\ \frac{5}{3} & \frac{1}{3} & -\frac{5}{3} & -\frac{1}{3} \end{pmatrix}.$$

Theorem 5.4. *Suppose that b is a one-dimensional mask satisfying the zero condition* (5.4)*, and let c be the two-dimensional induced mask. Then for $M = M_n$, $n = 1, 2, 3$, the symbol $\widehat{\phi_{\mathrm{au}|}}(u)$ is positive. Further, if b is a CQF, then c is also an M-CQF, and the corresponding (M, c) refinable function is orthonormal.*

Proof. It is straightforward to check that for each of the three dilation matrices $M_n,\ n = 1, 2, 3$, the interior of K contains the closure of a fundamental domain for $\mathbf{Z^2} \subset \mathbf{R^2}$. Therefore, the symbol $\widehat{\phi_{\mathrm{au}|}}(u) > 0$.

If b is a CQF, then c is an M-CQF because the intersection of $M\mathbf{Z^2}$ with the lattice points on the x_1-axis is exactly the set of even integers. Since the symbol is positive, by Corollary 2.7, the integer shifts of ϕ are orthonormal. □

We note that the results of Theorem 5.4 for the dilation matrix M_2 have been obtained by Cohen and Daubechies [4].

Remark 4. The fact that $\widehat{\phi_{\mathrm{au}|}}(u) > 0$ implies orthonormality was first proved in [19]. However, the proof in that paper was based on the Lebesque dominated convergence theorem and special properties of scaling tiles and was quite complicated. In [19], the refinable functions produced above were also constructed and mesh plots of some of these functions were produced. However, the report did not examine the zero set of $\widehat{\phi}$ and therefore did not actually prove that the refinable functions constructed had orthonormal shifts.

Remark 5. For each of the dilation matrices $M_n, n = 1, 2, 3$ and the mask induced by the Daubechies length-4 coefficients b, we computed an invariant support set for the transition operator $W_{c_{\mathrm{au}}}$, and we computed the eigenvalues of the corresponding restricted transition operator. There are 49, 63, and 39 nonzero eigenvalues (counted with multiplicity) corresponding to M_1, M_2, and M_3, respectively, and the eigenvalue

1 is simple in all cases. All of the eigenvalues have modulus ≤ 1 and several—but not all—of these eigenvalues are negative-integer powers of the eigenvalues of the corresponding dilation matrix. This is significant because the degree of smoothness of the refinable function implies the existence of a finite number of such eigenvalues. The corresponding eigenvectors can be constructed from the derivatives of the refinable function in the directions of the eigenvectors of the dilation matrix. The degree of smoothness of the refinable function also implies the existence of a continuous spectrum for the unrestricted transition operator that includes a continuous family of eigenvectors constructed from fractional derivative and integral operators. The discrete spectrum of the transition operator can easily be shown to coincide with the spectrum of the restricted transition operator. The significance of discrete eigenvalues that do not correspond to negative integer powers of the eigenvalues of the dilation matrices will be discussed in a subsequent paper.

Remark 6. The existence of negative-integer powers of the eigenvalues of the dilation matrix in the spectrum of $W_{c_{\mathrm{au}}}$ is not sufficient for regularity of the corresponding refinable function. Indeed, the (M_2, c) refinable function ϕ constructed from the Daubechies length-4 sequence is not continuous [24, Example 5.2], and none of the longer filters leads to C^1 solutions [4, Theorem 4.2].

Remark 7. Let V_0 be the closed shift-invariant subspace generated by ϕ and let

$$V_k := \{f(M^k\cdot) : f \in V_0\}.$$

Then $\{V_k\}$ forms a multiresolution analysis of $L^2(\mathbf{R}^\mathbf{d})$ by Remark 2.6 of [13]. We further remark that the construction of the corresponding wavelet for ϕ and c is straightforward since $|\det M| = 2$.

Acknowledgment. We thank an anonymous referee for Remark 6 and for some relevant references.

BOLTZMANN EQUATION WITH INFINITE ENERGY: RENORMALIZED SOLUTIONS AND DISTRIBUTIONAL SOLUTIONS FOR SMALL INITIAL DATA AND INITIAL DATA CLOSE TO A MAXWELLIAN*

S. MISCHLER† AND B. PERTHAME‡

Abstract. We prove new existence results for the Boltzmann equation with an initial data with infinite energy. In the framework of renormalized solutions we assume $(|x|^\alpha + |x-v|^2)\, f_0 \in L^1$ instead of $(|x|^2+|v|^2)\, f_0 \in L^1$, and we show new a priori estimates. In the framework of distributional solutions we treat small initial data compared to a Maxwellian of the type $\exp(-|x-v|^2/2)$. We also treat initial data close enough to such a Maxwellian. Hence, our theory does not require that the initial data decrease in both variables x and v.

Key words. Boltzmann equation, moments lemma, renormalized solution, distributional solution, small initial data, initial data close to a Maxwellian, dispersive effects

1. Introduction.

This paper is devoted to the existence proof of solutions to the Boltzmann equation in the case of initial data with infinite energy. We prove global existence of renormalized solutions and distributional solutions either for small initial data compared to the local Maxwellian $\exp(-|x-v|^2/2)$ or for initial data close to that particular local Maxwellian. Hence, we generalize the classical theories to initial data which do not decay in all the directions of the phase space. They may have infinite mass and energy.

More precisely, we consider the Boltzmann equation which describes the statistical evolution of a moderately rarefied gas. In this model, the gas is described by the kinetic density $f(t,x,v) \geq 0$ of particles which at time $t \in [0,+\infty[$, at the point $x \in \mathbb{R}^N$, move with velocity $v \in \mathbb{R}^N$, where N is an integer ≥ 1. This kinetic density satisfies the Boltzmann equation

$$(1.1)\quad \begin{cases} \dfrac{\partial f}{\partial t} + v\cdot\nabla_x f = Q(f,f) = Q^+(f,f) - Q^-(f,f) \qquad \text{on} \quad]0,+\infty[\times\mathbb{R}^N\times\mathbb{R}^N, \\ f(0,x,v) = f_0(x,v) \qquad\quad \text{on} \quad \mathbb{R}^N\times\mathbb{R}^N. \end{cases}$$

We refer to Cercignani [C], Cercignani, Illner, and Pulvirenti [C,I,P], DiPerna and Lions [DP,L1] and to their references for a detailed presentation of the physical meaning and the notion of renormalized solution of such an equation; we will recall this definition in section 3.

Here, Q is a quadratic collision operator, acting only on velocities, and is defined by

$$(1.2)\qquad Q^+(\varphi,\varphi)(v) = \int_{v_\star\in\mathbb{R}^N}\int_{\omega\in S^{N-1}} \varphi'\,\varphi'_\star\, B(v-v_\star,\omega)\,d\omega dv_\star,$$

$$Q^-(\varphi,\varphi) = \varphi\, L(\varphi), \tag{1.3}$$

where

$$L(\varphi) = A *_v \varphi \quad \text{ and } \quad A(z) = \int_{S^{N-1}} B(z,\omega)\, d\omega. \tag{1.4}$$

As usual, we denote, in order to shorten notation, $\varphi = \varphi(v)$, $\varphi_\star = \varphi(v_\star)$, $\varphi' = \varphi(v')$, and $\varphi'_\star = \varphi(v'_\star)$. The post-collisional velocities v' and $v'_\star$ are obtained from the pre-collisional velocities v and $v_\star$ and the unit vector ω thanks to

$$\begin{cases} v' = v - \langle v - v_\star, \omega\rangle \omega, \\ v'_\star = v_\star + \langle v - v_\star, \omega\rangle \omega. \end{cases} \tag{1.5}$$

Here and everywhere below, we denote indifferently by $a{\cdot}b$ or $\langle a, b\rangle$ the usual scalar product of $a, b \in \mathbb{R}^N$. Equations (1.5) are just a parametrization of the conservation of the impulsion and the kinetic energy during the collisions

$$\begin{cases} v' + v'_\star = v + v_\star, \\ |v'|^2 + |v'_\star|^2 = |v|^2 + |v_\star|^2. \end{cases} \tag{1.6}$$

The collision kernel B that enters the bilinear operator Q is a given function on $\mathbb{R}^N \times S^{N-1}$. We will always assume that

$$B \geq 0\,, \quad B(z,\omega) \text{ depends only on } |z| \text{ and } |\langle z,\omega\rangle| \tag{1.7}$$

and the so-called Grad [Gr] angular cut-off assumption

$$B \in L^1_{\rm loc}(\mathbb{R}^N \times S^{N-1}). \tag{1.8}$$

Renormalized solutions for the Boltzmann equation have been introduced and developed by DiPerna and Lions [DP,L1], [DP,L2], [L1], [L2], [L3], [L4]. They have proved stability results and the existence of global solutions for initial data with finite mass, energy, and entropy

$$\iint_{\mathbb{R}^N\times\mathbb{R}^N} f_0(x,v)\Big(1 + |x|^\alpha + |v|^2 + |\log f_0(x,v)|\Big)\, dvdx < +\infty, \tag{1.9}$$

for some $\alpha > 0$. In [L4], existence is extended to initial data which are bounded perturbations of particular solutions, such as pure Maxwellian.

In this work we do not assume bounded energy anymore. Due to dispersion effects (see Perthame [P1]), the assumption (1.9) can be replaced, for instance, by

$$\Gamma_\alpha = \iint_{\mathbb{R}^N\times\mathbb{R}^N} f_0(x,v)\Big(1 + |x|^\alpha + |x-v|^2 + |\log f_0(x,v)|\Big)\, dvdx < +\infty, \tag{1.10}$$

for some $\alpha > 0$. Using the fact that $\int_{\mathbb{R}^N}\int_{\mathbb{R}^N} f(t,x,v)\, |x-(1+t)\, v|^2\, dvdx$ is independant of t, we prove velocity moment bounds which give us enough a priori estimates to apply the stability result of renormalized solutions. Notice that for the Vlasov–Poisson system also, one can build solutions with infinite energy. It is enough to assume $f_0 \in L^1 \cap L^\infty$ and $|x|^2 f_0 \in L^1$ (see [P1]). Notice also that our assumption on f_0 implies that $(1+|x|^\alpha+|v|^\alpha+|\log f_0(x,v)|)\, f_0 \in L^1$. But the existence of renormalized solutions under this only assumption is open. Also, the time decay for solutions built with only the assumption (1.10) is an open question. Under the assumption (1.9), an answer is given in [P1].

On the other hand, existence, uniqueness, and time decay of the global distributional solution have been studied by many authors. The recent theory was initiated by Illner and Shinbrot [I,S] (see also [K,S]). Much progress has been made [Ba,D,G], [B,P,T], [B,T], [H], [Pa] and most general assumptions are due to [T]. They deal with small initial data with respect to a reference function $\varphi(v)\,h(x)$. The functions φ and h can have Maxwellian decay or, in the latest works, polynomial decay, which allow initial data with infinite mass; see [T]. Other existence results have been obtained for initial data close to a local Maxwellian. These theories rely on dispersive effects in the whole space.

Using the same idea as above, namely, that $|x-(1+t)\,v|^2$ solves the free transport equation and a is collisional invariant, we construct global upper and lower Maxwellian solutions of the Boltzmann equation. By the standard maximum principle this proves existence results. The new fact here is the decay assumption only on the direction $x-v$ instead of both directions x and v. We can deal with two situations: small initial data compared to the Maxwellian $\exp(-|x-v|^2/2)$ for general kernel Q or initial data close to such a Maxwellian for Maxwellian molecules. These solutions have infinite energy; nevertheless, we can prove that energy becomes locally finite: particles with high energy go away very fast despite the collisions.

The outline of the paper is the following. In the second section we establish new estimates for a classical solution of the Boltzmann equation. We prove velocity moment bounds and a local energy bound in some cases when the initial data does not satisfy energy bound. We use appropriate multiplicators in the spirit of Perthame [P2] and Lions and Perthame [L,P]. In the third section we use these estimates in order to prove the existence of renormalized solutions to the Boltzmann equation in an infinite energy case. In the fourth section we prove the existence of the global classical solution for small initial data with infinite mass and energy. In the fifth section we deal with initial data close to a local Maxwellian.

2. A priori estimates. In this section we prove new estimates for a classical solution f to the Boltzmann equation. In order to rigorously establish our result, we assume that f is of class C^1 and has compact support in space and velocity variables for every fixed time t. We assume that the collision kernel B just satisfies (1.7) and (1.8). It is classical to prove by change of variables and thanks to the symmetry property (1.7) that, for all test functions ψ in $L^\infty_{\text{loc}}(\mathbb{R}^N)$, we have the following equality:

(2.1)
$$\begin{aligned}&\int_{\mathbb{R}^N} Q(f,f)\psi dv\\ &= \frac{1}{4}\int_{v\in\mathbb{R}^N}\int_{v_\star\in\mathbb{R}^N}\int_{\omega\in S^{N-1}} B(v-v_\star,\omega)(f'\,f'_\star - f\,f_\star)(\psi+\psi_\star-\psi'-\psi'_\star)\,d\omega dv_\star dv.\end{aligned}$$

This implies that 1, v, and $|v|^2$ are collisional invariant; indeed, taking $\psi=1$, $(v_i)_{1\le i\le N}$, $|v|^2$ in (2.1), and using equation (1.6), we have

$$\int_{\mathbb{R}^N} Q(f,f)\begin{pmatrix}1\\ v\\ |v|^2\end{pmatrix} dv = 0 \quad \forall\, t,\, x\in[0,+\infty)\times\mathbb{R}^N. \tag{2.2}$$

Lemma 1. *For all time $t \geq 0$, the solution f satisfies*

$$\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)|x-(t+1)\,v|^2\,dvdx = \iint_{\mathbb{R}^N\times\mathbb{R}^N} f_0(x,v)|x-v|^2\,dvdx. \tag{2.3}$$

Proof of Lemma 1. We just multiply the Boltzmann equation (1.1) by $|x-(t+1)\,v|^2$:

$$\left(\frac{\partial}{\partial t}+v\cdot\nabla_x\right)(f\,|x-(t+1)\,v|^2) = Q(f,f)\,|x-(t+1)\,v|^2.$$

Then, we integrate the previous equation in velocity and space variables, and because $|x-(t+1)\,v|^2$ is a collisional invariant, the right-hand side vanishes and we obtain the result. □

Lemma 2. *Let α be a given real number in $(0,2)$; then the solution f satisfies for every $t \geq 0$:*

$$\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)(1+|x|^2)^{\alpha/2}\,dvdx \leq e^{\alpha\,t}\iint_{\mathbb{R}^N\times\mathbb{R}^N} f_0(x,v)\Big((1+|x|^2)^{\alpha/2}+|x-v|^2\Big)\,dvdx. \tag{2.4}$$

Proof of Lemma 2. We multiply the Boltzmann equation (1.1) by $(1+|x|^2)^{\alpha/2}$ and because $(1+|x|^2)^{\alpha/2}$ is a collisional invariant, we get after integration

$$\frac{d}{dt}\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)(1+|x|^2)^{\alpha/2}\,dvdx = \alpha\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)\,v\cdot x\,(1+|x|^2)^{\alpha/2-1}\,dvdx.$$

Next, using

$$2|v\cdot x| \leq |v|^2+|x|^2 \leq \left(1+\frac{1}{(1+t)^2}\right)|x|^2+\frac{1}{(1+t)^2}|x-(t+1)\,v|^2,$$

we get

$$\begin{aligned}&\frac{d}{dt}\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)(1+|x|^2)^{\alpha/2}\,dvdx\\ &\quad\leq \alpha\left(\frac{1}{2}+\frac{1}{2(1+t)^2}\right)\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)\frac{|x|^2}{1+|x|^2}(1+|x|^2)^{\alpha/2}\,dvdx\\ &\qquad\qquad+\frac{\alpha}{2(1+t)^2}\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)\frac{|x-(t+1)\,v|^2}{(1+|x|^2)^{1-\alpha/2}}\,dvdx\\ &\quad\leq \alpha\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)(1+|x|^2)^{\alpha/2}\,dvdx+\alpha\iint_{\mathbb{R}^N\times\mathbb{R}^N} f_0(x,v)|x-v|^2\,dvdx.\end{aligned}$$

We conclude the proof thanks to the Gronwall lemma. □

Lemma 3. *Let $\alpha \in (0,2)$; if Γ_α is finite (see (1.10)), there exists a constant $C_T = C(T,\alpha,\Gamma_\alpha)$ such that*

$$\sup_{[0,T]}\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)\Big(1+|x|^\alpha+|v|^\alpha+|\log f(t,x,v)|\Big)\,dvdx \leq C_T, \tag{2.5}$$

$$\int_0^T\iint_{\mathbb{R}^N\times\mathbb{R}^N} e(f)\,dvdxdt \leq C_T, \tag{2.6}$$

where

$$e(f)=\iint_{\mathbb{R}^N\times S^{N-1}} B(v-v_\star,\omega)(f'\,f'_\star-f\,f_\star)\log\frac{f'\,f'_\star}{f\,f_\star}\,d\omega dv_\star. \tag{2.7}$$

Proof of Lemma 3. We compute

$$\begin{aligned}&\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)|v|^\alpha\,dvdx \le \iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)\frac{1}{(1+t)^\alpha}\Big(|x|+|x-(t+1)\,v|\Big)^\alpha\,dvdx\\ &\le C\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)\Big((1+|x|^2)^{\alpha/2}+|x-(t+1)\,v|^2\Big)\,dvdx,\end{aligned}$$

which is bounded by $C_T\,\Gamma_\alpha$ thanks to Lemmas 1 and 2.

The entropy estimate is classically deduced from the bound (2.6) and we skip it (see [DP,L1] for the case $\alpha=2$). □

LEMMA 4. *For every T, there exists a constant C_T such that the solution f satisfies*

$$\int_0^T\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)\frac{|v|^2}{(1+|x|^2)^{3/2}}\,dvdxdt\le C_T\,\Gamma_1. \tag{2.8}$$

Proof of Lemma 4. We multiply (1.1) by $\dfrac{x\cdot v}{(1+|x|^2)^{1/2}}$, and we compute

$$v\cdot\nabla_x\Big(\frac{x\cdot v}{(1+|x|^2)^{1/2}}\Big)=\frac{|v|^2}{(1+|x|^2)^{3/2}}+\frac{|v|^2|x|^2(1-\frac{x}{|x|}\cdot\frac{v}{|v|})}{(1+|x|^2)^{3/2}}.$$

We remark that the second right-hand term is nonnegative, and thus we get

$$\begin{aligned}&\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(T,x,v)\frac{x\cdot v}{(1+|x|^2)^{1/2}}\,dvdx-\iint_{\mathbb{R}^N\times\mathbb{R}^N} f_0(x,v)\frac{x\cdot v}{(1+|x|^2)^{1/2}}\,dvdx\\ &\ge\int_0^T\iint_{\mathbb{R}^N\times\mathbb{R}^N} f(t,x,v)\frac{|v|^2}{(1+|x|^2)^{3/2}}\,dvdxdt.\end{aligned}$$

This ends the proof because the two left-hand side terms are bounded by $C_T\,\Gamma_1$ thanks to Lemma 3.

3. Renormalized solution. In this section we show how the previous estimates can be used to prove an existence result of a renormalized solution to the Boltzmann equation for some initial data with infinite energy. DiPerna and Lions [DP,L1] have introduced the concept of renormalized solution. A function $f\in C([0,+\infty[;L^1(\mathbb{R}^N\times\mathbb{R}^N))$ is a renormalized solution of the Boltzmann equation if

$$\frac{Q^\pm(f,f)}{1+f}\in L^1_{\mathrm{loc}}([0,+\infty[\times\mathbb{R}^N\times\mathbb{R}^N), \tag{3.1}$$

$$\frac{\partial}{\partial t}\log(1+f)+v\cdot\nabla_x\log(1+f)=\frac{Q(f,f)}{1+f}\quad\text{in}\quad\mathcal{D}'([0,\infty[\times\mathbb{R}^N\times\mathbb{R}^N). \tag{3.2}$$

They have proved a stability result that we mimic here in order to prove our existence result.

In this section we assume, following [DP,L1], that for a given $\bar{\alpha} \in (0,1)$ or $\bar{\alpha} = 2$

$$\frac{1}{1+|z|^{\bar{\alpha}}} \int_{B_R} A(v-z)\,dv \underset{|z|\to+\infty}{\longrightarrow} 0 \quad \forall R \in]0,+\infty[, \tag{3.3}$$

where $B_R = \{v \in \mathbb{R}^N; |v| < R\}$.

THEOREM 1. *Let f_0 be an initial data such that in* (1.10), $\Gamma_\alpha(f_0) < +\infty$ *for a given $\alpha \in (0,1]$ and B such that* (1.7), (1.8), *and* (3.3) *hold with $\bar{\alpha} = \alpha$ if $\alpha < 1$ and with $\bar{\alpha} = 2$ if $\alpha = 1$. Then there exists a global renormalized solution f of the Boltzmann equation with initial data f_0, and* (2.5), (2.6), *and* (2.8) *hold.*

Proof of Theorem 1. We split the proof in two steps.

Step 1. A regularized problem.

For $\lambda > 1$ we define the following cross-section:

$$B_\lambda(v,v_\star,\omega) = \frac{\lambda}{\text{meas}(S^{N-1})} \wedge B(v-v_\star,\omega)\cdot \mathcal{X}_\lambda(v,v_\star,\omega) \tag{3.4}$$

$$\text{where } \mathcal{X}_\lambda(v,v_\star,\omega) = \begin{cases} 1 & \text{if } v, v_\star, v' \text{ and } v'_\star \text{ belong to } B(0,\lambda), \\ 0 & \text{elsewhere,} \end{cases}$$

so that

$$0 \le A_\lambda(v,v_\star) = \int_{S^{N-1}} B_\lambda(v,v_\star,\omega)\,d\omega \le \lambda. \tag{3.5}$$

We set $q_\lambda(\varphi) = r_\lambda(\int_{\mathbb{R}^N} \varphi\,dv)$, where r_λ is a smooth function such that $r_\lambda = 1$ if $t < \frac{\lambda}{2}$, $r_\lambda \le \frac{\lambda}{t}$ for every t.

Let $(\rho_\epsilon(x,v))_{\epsilon>0}$ be a sequence of mollifiers, with $\text{supp}\,\rho_\epsilon \subset B(0,1)$ for all ϵ, and let

$$\phi_\lambda = \left(f_0(x,v)\, 1_{\left\{|v|<\frac{\lambda}{2}\right\}} 1_{\left\{|x|<\frac{\lambda}{2}\right\}}\right) \star \rho_{\frac{1}{\lambda}}. \tag{3.6}$$

We are looking for a solution to the regularized problem

$$\begin{cases} \dfrac{\partial f_\lambda}{\partial t} + v\cdot\nabla_x f_\lambda = q_\lambda(f_\lambda)\, Q_\lambda(f_\lambda,f_\lambda), \\ f_\lambda(0,x,v) = \phi_\lambda(x,v), \end{cases} \tag{3.7}$$

where Q_λ is defined from B_λ in the same way that Q from B in (1.2) to (1.4). We remark that this collisional term has a linear growth at infinity.

In order to prove the existence of a solution we set

$$\mathcal{A} = \{\varphi \ge 0, \quad \varphi \in L^\infty([0,T]\times\mathbb{R}^N\times\mathbb{R}^N), \quad \text{supp}\,\varphi(t,.) \subset B_{(1+t)\lambda}\times B_\lambda\},$$

which is a complete set for the uniform norm. Next, we define the map $\varphi \in \mathcal{A} \longmapsto \Lambda(\varphi) = \psi$ as the solution of

$$\begin{cases} \dot{\psi}^\# + \lambda\psi^\# = q_\lambda(\varphi)^\#\, Q^+_\lambda(\varphi,\varphi)^\# + \big(\lambda - q_\lambda(\varphi)^\#\, L_\lambda(\varphi)^\#\big)\varphi^\#, \\ \psi^\#(0,x,v) = \phi_\lambda(x,v), \end{cases} \tag{3.8}$$

where we denote $R^{\#}(t,x,v) = R(t,x+t\,v,v)$. It is obvious that Λ maps $\mathcal{A}$ into $\mathcal{A}$ and is Lipschitz continuous for the uniform norm. Then the Cauchy–Lipschitz theorem and the Gronwall lemma imply the existence of a unique global solution f_λ of the equation (3.7), which falls in $\mathcal{A}$ and is smooth.

Step 2. Passing to the limit.

Lemmas 3 and 4 applied to the sequence of regularized solution f_λ imply that f_λ satisfies the bounds (2.5), (2.6), and (2.8) uniformly in λ. Then the stability results for renormalized solution of DiPerna and Lions [DP,L1], [DP,L2], [L3] adapt here and allow us to conclude. □

4. Distributional solution for small initial data. We use the same idea in the theory of distributional solution, and more precisely for solutions satisfying $Q(f,f) \in L^\infty$. The proof we present here is adapted from [L2], and we refer to [B,P,T] for a general presentation of the method as well as a very sharp assumption, which, however, is different from ours.

Theorem 2. *Let f_0 satisfy, for some a, b, $C_0 > 0$ and x_0, $v_0 \in \mathbb{R}^N$,*

$$0 \le f_0(x,v) \le \hat{f}_0(x,v) := \frac{C_0}{6} \exp\left(-\frac{1}{2}\left|\frac{x-x_0}{a} - \frac{v-v_0}{b}\right|^2\right). \tag{4.1}$$

We assume that $A \in L^{p'}(\mathbb{R}^N)$ for some $p' \in (\frac{N}{N-1}, +\infty]$, and we have

$$C_0\, b^{\frac{N}{p}-1}\, a < \kappa := \frac{N-p}{p\,\|A\|_{p'}} \left(\frac{p}{2\pi}\right)^{\frac{N}{2p}}. \tag{4.2}$$

Then there exists a solution $f \in L^\infty((0,+\infty)\times\mathbb{R}^N_x\times\mathbb{R}^N_v)$ to the Boltzmann equation (1.1) *in $\mathcal{D}'([0,\infty[\,\times\mathbb{R}^N\times\mathbb{R}^N)$, such that*

$$0 \le f(t,x,v) \le \frac{C(t)}{6} \exp\left(-\frac{1}{2}\left|\frac{x-x_0-v\,t}{a} - \frac{v-v_0}{b}\right|^2\right), \tag{4.3}$$

where $C(t)(\ge 0)$ is uniformly bounded; more precisely,

$$\frac{1}{C(t)} = \frac{1}{C_0} - \frac{b^{\frac{N}{p}-1}\,a}{\kappa} + \frac{a}{\kappa}\left(\frac{1}{b}+\frac{t}{a}\right)^{1-\frac{N}{p}}. \tag{4.4}$$

Also, $Q^\pm(f,f) \in L^\infty((0,T)\times\mathbb{R}^N\times\mathbb{R}^N)$.

Proof of Theorem 2. We set

$$\hat{f} = C(t)\exp\left(-\frac{1}{2}\left|\frac{x-x_0-v\,t}{a} - \frac{v-v_0}{b}\right|^2\right),$$

where $C(t) \ge 0$ will be determined in such a way that we have

$$\dot{C}C^{-1}\hat{f} \ge Q^+(\hat{f},\hat{f}) \quad \text{on} \quad [0,\infty[\,\times\mathbb{R}^N\times\mathbb{R}^N. \tag{4.5}$$

We remark that $\hat{f}$ is, for all $x \in \mathbb{R}^N$ and $t \ge 0$, a Maxwellian in v, and thus $Q^+(\hat{f},\hat{f}) \equiv Q^-(\hat{f},\hat{f}) = \hat{f}\cdot A \star_v \hat{f}$.

Therefore, (4.5) holds if we have

$$\dot{C} \ge C^2 \sup_{(x,v)\in\mathbb{R}^{2N}} \left\{ A \star_v \exp\left(-\frac{1}{2}\left|\frac{x-x_0-v\,t}{a} - \frac{v-v_0}{b}\right|^2\right)\right\}.$$

Next we observe that we have on $\mathbb{R}^{2N}$, thanks to a Hölder inequality with p and p' such that $\frac{1}{p}+\frac{1}{p'}=1$ (which implies $\frac{N}{p}>1$),

$$\begin{aligned}
&A\star_v \exp\left(-\frac{1}{2}\left|\frac{x-x_0-v\,t}{a}-\frac{v-v_0}{b}\right|^2\right)\\
&\qquad\qquad\le \|A\|_{p'}\left(\int_{\mathbb{R}^N}\exp\left(-p\left|\frac{x-x_0}{a}+\frac{v_0}{b}-\left(\frac{1}{b}+\frac{t}{a}\right)v\right|^2\right)dv\right)^{1/p}\\
&\qquad\qquad\le \|A\|_{p'}\left(\frac{2\pi}{p}\right)^{\frac{N}{2p}}\left(\frac{1}{b}+\frac{t}{a}\right)^{-\frac{N}{p}} =: \lambda(t).
\end{aligned}$$

Therefore, we choose $C\in C^1([0,\infty[)$ such that $C(0)=C_0$ and solves the ordinary differential equation

$$\dot{C}=\frac{C^2}{\kappa}\frac{1}{\frac{N}{p}-1}\left(\frac{1}{b}+\frac{t}{a}\right)^{-\frac{N}{p}}. \tag{4.6}$$

The solution to (4.6) is given by (4.4) and is a global solution if the condition (4.2) holds.

In such a way, we have constructed, dividing $\hat{f}$ by 6, an upper solution $\hat{f}$ of the Boltzmann equation in the following sense:

$$\begin{cases}\dfrac{\partial}{\partial t}\hat{f}+v\cdot\nabla_x\hat{f}\ge 6\,\hat{\lambda}(t)\,\hat{f}\ge 6\,Q^{\pm}(\hat{f},\hat{f}) \quad \text{in} \quad \mathcal{D}'([0,\infty[\times\mathbb{R}^N\times\mathbb{R}^N),\\ \hat{f}(t=0,.)=\hat{f}_0,\end{cases} \tag{4.7}$$

where $\hat{\lambda}(t)=C(t)\,\lambda(t)$.

In order to prove the existence result, we define a suitable function space where we will do a classical Banach fixed point theorem. Let $\mathcal{B}$ be the space

$$\mathcal{B}=\left\{\varphi\in L^\infty([0,T]\times\mathbb{R}^N\times\mathbb{R}^N);\ 0\le\varphi(t,x,v)\le\hat{f}(t,x,v)\right\}, \tag{4.8}$$

and we define the map $\varphi\in\mathcal{B}\longmapsto\Lambda(\varphi)=\psi$ by

$$\begin{cases}\dfrac{\partial}{\partial t}\psi+v\cdot\nabla_x\psi+\hat{\lambda}(t)\,\psi=Q^+(\varphi,\varphi)+(\hat{\lambda}(t)-L(\varphi))\varphi,\\ \psi(t=0,.)=f_0.\end{cases} \tag{4.9}$$

The norm defined in $\mathcal{B}$ is the following:

$$\|\varphi\|=\operatorname*{ess\,sup}_{t\in[0,T]\,x\in\mathbb{R}^N\,v\in\mathbb{R}^N}\frac{|\varphi(t,x,v)|}{\hat{f}(t,x,v)}.$$

The function space $\mathcal{B}$ is, with the previous norm, a Banach space. The global existence and uniqueness of the solution of the Boltzmann equation is assured if the following conditions hold:

$$\forall\varphi\in\mathcal{B};\quad \Lambda\varphi\in\mathcal{B}, \tag{4.10}$$

$$\forall\varphi_1,\varphi_2\in\mathcal{B};\quad \|\Lambda\varphi_2-\Lambda\varphi_1\|\le\frac{5}{6}\,\|\varphi_2-\varphi_1\|. \tag{4.11}$$

First, we show (4.10). For all $\varphi \in \mathcal{B}$ we have

$$\begin{aligned}\frac{\partial}{\partial t}\psi + v \cdot \nabla_x \psi + \hat{\lambda}(t)\,\psi &= Q^+(\varphi,\varphi) + (\hat{\lambda}(t) - L(\varphi))\varphi,\\ &\le Q^+(\hat{f},\hat{f}) + \hat{\lambda}(t)\,\hat{f},\\ &\le \frac{\partial}{\partial t}\hat{f} + v \cdot \nabla_x \hat{f} + \hat{\lambda}(t)\hat{f}.\end{aligned}$$

Thus $\psi \le \hat{f}$. On the other hand, $\psi \ge 0$ is clear since the source term in (4.9) is nonnegative thanks to the definition of $\hat{\lambda}(t)$.

We pass to (4.11). For all $\varphi_1, \varphi_2 \in \mathcal{B}$ the following equality holds:

$$\begin{aligned}\left(\frac{\partial}{\partial t} + v \cdot \nabla_x + \hat{\lambda}(t)\right)(\psi_2 - \psi_1) &= Q^+(\varphi_2, \varphi_2 - \varphi_1) + Q^+(\varphi_2 - \varphi_1, \varphi_1)\\ &\quad + \hat{\lambda}(t)(\varphi_2 - \varphi_1) - L(\varphi_2)(\varphi_2 - \varphi_1) - (L(\varphi_2) - L(\varphi_1))\varphi_1.\end{aligned}\tag{4.12}$$

Denoting by $\mathcal{C}(t,x,v)$ the right-hand side term, equation (4.13) writes

$$(\psi_2 - \psi_1)^{\#}(t,x,v) = \int_0^t \mathcal{C}^{\#}(s,x,v)e - \int_s^t \hat{\lambda}(\sigma)\,d\sigma\,ds.$$

Next, multiplying and dividing all terms of the right-hand side by $\hat{f}^{\#}$ and using the definition of the norm and (4.7) yield

$$\begin{aligned}|\psi_2 - \psi_1|^{\#}(t,x,v) &\le (2\,\|\varphi_1\| + 2\,\|\varphi_2\| + 1)\,\|\varphi_1 - \varphi_2\| \int_0^t \hat{\lambda}(s)\,\hat{f}^{\#}(s,x,v)\,ds\\ &\le \frac{5}{6}\,\|\varphi_1 - \varphi_2\|\,\hat{f}^{\#}(t,x,v),\end{aligned}$$

and thus (4.11) holds. □

Remarks 1. We can examine in which sense the initial data is small. Of course, for a given Maxwellian profile (a, b, x_0, and v_0 fixed) f_0 has to be small enough for the uniform norm with respect to $\exp\bigl(-\frac{1}{2}\bigl|\frac{x-x_0}{a} - \frac{v-v_0}{b}\bigr|^2\bigr)$, but depending on a and b, $\|f_0\|_\infty$, can be as large as we wish.

Next, at the macroscopic level, the global mass is always infinite. Also, the macroscopic functions associated with the Maxwellian distribution are

$$\begin{aligned}\rho_0(t,x) &= \bar{\rho}_0 = (2\,\pi)^{\frac{N}{2}}\,b^N\,\frac{C_0}{6},\\ u_0(t,x) &= v_0 + \frac{b}{a}\,(x - x_0),\\ T_0(t,x) &= b^2.\end{aligned}$$

Thus, we see that we can take the uniform norm of f_0, ρ_0, and T_0 arbitrarily large if we choose $\frac{a}{b}$ small enough such that (4.2) holds. In that case the quantity

$$\sup_{v \in \mathbb{R}^N} \int_{x \in \mathbb{R}^N} f_0(x,v)\,dx \le \bar{\rho}_0\,\bigl(\frac{a}{b}\bigr)^N$$

is small; in particular, f_0 is small in $L^1(B_R \times B_R)$ for all fixed $R > 0$.

Remarks 2. We also recover the classical time decay. From (4.2) and (4.4), $C(t)$ is uniformly bounded (by some constant C_∞), and an explicit computation of $\hat{f}$ gives

$$\rho(t,x) \le \frac{C_\infty}{(\frac{1}{b}+\frac{t}{a})^N},$$
$$\rho(t,x)\,(|u(t,x)|^2+T(t,x)) \le \frac{C_\infty}{(\frac{1}{b}+\frac{t}{a})^{N+2}}.$$

5. Distributional solution for an initial data close to a local Maxwellian.

In this section we show how the idea developed in the previous section can be used to prove the existence of a global distributional solution for an initial data close to a local Maxwellian. We consider the simple case when the reference Maxwellian is $\xi_0(x,v)=\exp(-\frac{|x-v|^2}{2})$ and the cross-section B is of Maxwellian type; precisely, we assume that

$$B(z,\omega)=B\left(\left|\frac{z}{|z|}\cdot\omega\right|\right) \qquad \text{and} \qquad A(z)\equiv(2\,\pi)^{-\frac{N}{2}}. \tag{5.1}$$

Again, this gives a variant of classical results [B,P,T], [K,S] that requires global decay in both directions x and v.

THEOREM 3. *Let f_0 be an initial data which satisfies, for some ϵ, $C_0>0$,*

$$(1-\epsilon)\,C_0\,\xi_0(x,v) \le f_0(x,v) \le (1+\epsilon)\,C_0\,\xi_0(x,v). \tag{5.2}$$

If ϵ is small enough, there exists a distributional solution $f\in L^\infty((0,+\infty)\times\mathbb{R}^N_x\times\mathbb{R}^N_v)$ of the Boltzmann equation (1.1) *in the sense of distribution. Moreover, $Q^\pm(f,f)\in L^\infty((0,+\infty)\times\mathbb{R}^N\times\mathbb{R}^N)$.*

Proof of Theorem 3. *Step* 1. We first build two functions $g_0(t,x,v)=c(t)\,\xi(t,x,v)$ and $G_0(t,x,v)=C(t)\,\xi(t,x,v)$, where $\xi(t,x,v)=\exp(-\frac{|x-v\,(1+t)|^2}{2})$ and $0\le c(t)\le C(t)$ will be determined in such a way that we have

$$\begin{cases} \dfrac{\partial}{\partial t}g_0+v\cdot\nabla_x g_0+L(G_0)\,g_0=Q^+(g_0,g_0),\\ \dfrac{\partial}{\partial t}G_0+v\cdot\nabla_x G_0+L(g_0)\,G_0=Q^+(G_0,G_0),\\ g_0(t=0,.)=(1-\epsilon)\,C_0\,\xi_0, \quad G_0(t=0,.)=(1+\epsilon)\,C_0\,\xi_0. \end{cases} \tag{5.3}$$

To do so, since ξ is a Maxwellian in v and thanks to assumption (5.1), we easily compute

$$Q^+(\xi,\xi)=\xi\,L(\xi)=\frac{\xi}{(1+t)^N}. \tag{5.4}$$

Hence, the equations (5.3) are equivalent to the system of ODEs

$$\begin{cases} \dot{c}+\dfrac{C\,c}{(1+t)^N}=\dfrac{c^2}{(1+t)^N},\\ \dot{C}+\dfrac{c\,C}{(1+t)^N}=\dfrac{C^2}{(1+t)^N},\\ c(0)=(1-\epsilon)\,C_0, \quad C(0)=(1+\epsilon)\,C_0. \end{cases} \tag{5.5}$$

In order to prove the existence of global nonnegative solutions c and C for (5.5), we set $y = C - c$ and $z = C + c$, and (5.5) is equivalent to

$$\begin{cases} \dot{y} = \dfrac{y\,z}{(1+t)^N}, \quad \dot{z} = \dfrac{y^2}{(1+t)^N}, \\ y(0) = 2\,\epsilon\,C_0, \quad z(0) = 2\,C_0. \end{cases} \tag{5.6}$$

It is enough to prove an a priori bound for y. Eliminating z, the system (5.6) reduces to

$$\dot{y} = \frac{y}{(1+t)^N}\Big(2\,C_0 + \int_0^t \frac{y^2(s)\,ds}{(1+s)^N}\Big). \tag{5.7}$$

First, we remark that since $\dot{y} \geq 0$ we have

$$\dot{y} \leq 2\,C_0 \frac{y}{(1+t)^N} + \frac{y^3}{(1+s)^{2N-1}}. \tag{5.8}$$

Next, we consider the simple equation

$$\dot{Y} = (2\,C_0 + 1)\frac{Y}{(1+t)^N}, \quad Y(0) = y(0), \tag{5.9}$$

which has a global solution satisfying $Y(t) \leq 1$ if

$$\epsilon \leq \frac{1}{2\,C_0}\exp\big(2\,C_0\,(1-N)\big). \tag{5.10}$$

Now, by a comparison principle, we get $y(t) \leq Y(t)$ for all $t \geq 0$. This ends the proof of the existence of g_0 and G_0.

Step 2. Following the classical Kaniel and Shinbrot iterative scheme [K,S], we define the sequences $(g_n)_{n\in\mathbb{N}}$ and $(G_n)_{n\in\mathbb{N}}$ as

$$\begin{cases} \dfrac{\partial}{\partial t} g_n + v\cdot\nabla_x g_n + L(G_{n-1})\,g_n = Q^+(g_{n-1}, g_{n-1}), \\ \dfrac{\partial}{\partial t} G_n + v\cdot\nabla_x G_n + L(g_{n-1})\,G_n = Q^+(G_{n-1}, G_{n-1}), \\ g_n(t=0,.) = G_n(t=0,.) = f_0. \end{cases} \tag{5.11}$$

As in [K,S] we obtain, by a comparison principle, that g_n, G_n satisfy

$$0 \leq g_0(t) \leq g_1(t) \leq \cdots \leq g_n(t) \leq \cdots \leq G_n(t) \leq \cdots \leq G_1(t) \leq G_0(t). \tag{5.12}$$

Therefore, g_n and G_n are monotone sequences and converge pointwise to limits denoted by $\bar{g}$ and $\bar{G}$. We may pass to the limit, in the distributional sense, in (5.11), and we obtain

$$\begin{cases} \dfrac{\partial}{\partial t} \bar{g} + v\cdot\nabla_x \bar{g} + L(\bar{G})\,\bar{g} = Q^+(\bar{g}, \bar{g}), \\ \dfrac{\partial}{\partial t} \bar{G} + v\cdot\nabla_x \bar{G} + L(\bar{g})\,\bar{G} = Q^+(\bar{G}, \bar{G}), \\ \bar{g}(t=0,.) = \bar{G}(t=0,.) = f_0. \end{cases} \tag{5.13}$$

It remains to show that $\bar{G} = \bar{g}$. We remark that thanks to (5.12) we already know that $\bar{G} \geq \bar{g}$. To prove the other inequality, notice that

$$\begin{cases} \dfrac{\partial}{\partial t}(\bar{G}-\bar{g}) + v\cdot\nabla_x(\bar{G}-\bar{g}) + (\bar{G}-\bar{g})\,L(\bar{G}) \\ \qquad\qquad = Q^+(\bar{G}-\bar{g},\bar{G}) + Q^+(\bar{g},\bar{G}-\bar{g}) + \bar{G}\,L(\bar{G}-\bar{g}), \\ (\bar{G}-\bar{g})(t=0,.) = 0. \end{cases} \tag{5.14}$$

As before, we define the norm relative to ξ for all φ by

$$\|\varphi\|_t = \operatorname*{ess\,sup}_{s\in[0,t]\; x\in\mathbb{R}^N\; v\in\mathbb{R}^N} \frac{|\varphi(s,x,v)|}{\xi(s,x,v)}.$$

Using $\dot{\xi}^{\#} = 0$, the equation (5.14) gives

$$\Big(\frac{\bar{G}-\bar{g}}{\xi}\Big)^{\#}(t,x,v) \leq \int_0^t \frac{1}{\xi^{\#}}\big(Q^+(\bar{G}-\bar{g},\bar{G}) + Q^+(\bar{g},\bar{G}-\bar{g}) + \bar{G}\,L(\bar{G}-\bar{g})\big)^{\#}(s,x,v)\,ds. \tag{5.15}$$

Again, multiplying and dividing the collision terms by ξ and using (5.4) we deduce from (5.15) the following inequality:

$$\Big(\frac{\bar{G}-\bar{g}}{\xi}\Big)^{\#}(t,x,v) \leq 3\int_0^t \|\bar{G}\|_s\,\|\bar{G}-\bar{g}\|_s\,L(\xi)^{\#}\,ds$$

so that

$$\|\bar{G}-\bar{g}\|_T \leq 3\int_0^T \frac{C(t)}{(1+t)^N}\,\|\bar{G}-\bar{g}\|_t\,dt \qquad \text{for all } T>0.$$

Thanks to the Gronwall lemma we prove that $\bar{G} = \bar{g}$ is a distributional solution of the Boltzmann equation. $\square$

CLASSICAL SOLUTIONS OF MULTIDIMENSIONAL HELE–SHAW MODELS [*]

JOACHIM ESCHER[†] AND GIERI SIMONETT[‡]

Abstract. Existence and uniqueness of classical solutions for the multidimensional expanding Hele–Shaw problem are proved.

Key words. classical solutions, Hele–Shaw model, moving boundary problem, maximal regularity

1. The problem.

We are concerned with a class of moving boundary problems for bounded domains in $\mathbb{R}^n$, which comprise in particular the so-called single phase Hele–Shaw problem. In order to describe precisely the involved geometry, let Ω be a bounded domain in $\mathbb{R}^n$ and assume that its boundary $\partial\Omega$ is of class C^∞. Moreover, assume that $\partial\Omega$ consists of two disjoint nonempty components J and Γ. Later on, we will model over the exterior component Γ a moving interface, whereas the interior component J describes a fixed portion of the boundary. Let ν denote the outer unit normal field over Γ and fix $\alpha \in (0,1)$. Given $a > 0$, set

$$\mathcal{U} := \{\rho \in C^{2+\alpha}(\Gamma)\,;\, \|\rho\|_{C^1(\Gamma)} < a\}.$$

For each $\rho \in \mathcal{U}$ define the map

$$\theta_\rho := id_\Gamma + \rho\nu$$

and let $\Gamma_\rho := \operatorname{im}(\theta_\rho)$ denote its image. Obviously, θ_ρ is a $C^{2+\alpha}$ diffeomorphism mapping Γ onto Γ_ρ, provided $a > 0$ is chosen sufficiently small. In addition, we assume that $a > 0$ is small enough such that Γ_ρ and J are disjoint for each $\rho \in \mathcal{U}$. Let Ω_ρ denote the domain in $\mathbb{R}^n$ being diffeomorphic to Ω and whose boundary is given by J and Γ_ρ. To describe the evolution of the hypersurface Γ_ρ, fix $T > 0$ and set $I := [0, T]$. Then each map $\rho : I \to \mathcal{U}$ defines a collection of domains $\Omega_{\rho(t)},\ t \in I$. For later purposes it is convenient to introduce the following generalized parabolic cylinder:

$$\Omega_{\rho,T} := \big\{(x,t) \in \mathbb{R}^n \times [0,T]\,;\, x \in \Omega_{\rho(t)}\big\} = \bigcup_{t\in I}\big(\Omega_{\rho(t)} \times \{t\}\big)$$

and, correspondingly,

$$\Gamma_{\rho,T} := \big\{(x,t) \in \mathbb{R}^n \times [0,T]\,;\, x \in \Gamma_{\rho(t)}\big\} = \bigcup_{t\in I}\big(\Gamma_{\rho(t)} \times \{t\}\big).$$

Observe that $\Omega_{0,T}$ is just the standard parabolic cylinder $\Omega \times [0,T]$. Similarly, $\Gamma_{0,T} = \Gamma \times [0,T]$. For the sake of completeness, we write $J_T := J \times [0,T]$.

Now let $\rho_0 \in \mathcal{U}$ be given. Moreover, pick $b \in C(J)$ and $\delta \in \{0,1\}$. Then we consider the *moving boundary problem* of determining a pair (u,ρ) satisfying the following set of equations:

$$(1.1)_{\rho_0} \qquad \begin{aligned} \Delta u &= 0 \quad &&\text{in} \quad \Omega_{\rho,T}, \\ u &= 0 \quad &&\text{on} \quad \Gamma_{\rho,T}, \\ (1-\delta)u + \delta(\nabla u|\nu_J) &= b \quad &&\text{on} \quad J_T, \\ \partial_t N_\rho - (\nabla u|\nabla N_\rho) &= 0 \quad &&\text{on} \quad \Gamma_{\rho,T}, \\ \rho(0,\cdot) &= \rho_0 \quad &&\text{on} \quad \Gamma. \end{aligned}$$

Here, Δ and ∇ stand for the Laplacian and the gradient, respectively, in the Euclidean metric. The outer unit normal field over J is denoted by ν_J. The parameter δ is introduced to label the boundary condition on the fixed boundary J (where $\delta = 0$ corresponds to a Dirichlet boundary condition and $\delta = 1$ corresponds to a Neumann condition). Moreover, N_ρ is a defining function for Γ_ρ, i.e., $\Gamma_\rho = N_\rho^{-1}(0)$, $\rho \in \mathcal{U}$. A precise definition of N_ρ is given in section 2.

The set of equations in (1.1) express that the free boundary moves with normal velocity given by the normal derivative of a harmonic function which vanishes on the boundary. More precisely, the motion of the free boundary is governed by $V = -\frac{\partial u}{\partial \nu}$, where the function u satisfies the first three equations in (1.1). Here, V is the normal velocity taken to be positive for expanding hypersurfaces and ν is the outer unit normal field on the moving boundary.

Assume now that $n = 2$, $\delta = 1$, and $b > 0$. Then problem $(1.1)_{\rho_0}$ represents the classical formulation of the expanding two-dimensional Hele–Shaw flow; see Crank [5], Elliott and Ockendon [10], Elliott and Janovsky [9], DiBenedetto and Friedman [7], and Richardson [21]. In this model, u has the meaning of the pressure in an incompressible viscous fluid blob Ω_ρ. Since b is positive, further fluid is injected through the fixed boundary J at the rate b. Hence, the blob is advancing in time, modelled by the moving boundary Γ_ρ. Some authors (see Fasano and Primicerio [15] or Steinbach and Weinelt [22]) consider the above model in the case of prescribed pressure on the fixed boundary, i.e., with the inhomogeneous Dirichlet boundary condition $u = b$ on J. This boundary condition corresponds to the case $\delta = 0$ in $(1.1)_{\rho_0}$. In our model, we cover both cases and we prove the existence of a unique *classical* solution (u,ρ) for the general problem $(1.1)_{\rho_0}$; see the main result below. As pointed out in [5], [8], [9], [10], [16], and [22], there are further applications of $(1.1)_{\rho_0}$ to different multidimensional moving boundary problems. We mention the electrochemical machining problem, the one-phase Stefan problem with zero specific heat, the flow of viscous fluid through porous media, and the injection moulding process. These models make sense in higher space dimensions and under general boundary conditions on the fixed boundary J.

To clearly state our result, we need some definitions. Given an open subset U of $\mathbb{R}^m$, let $h^s(U)$ denote the little Hölder space of order $s > 0$, a closed subspace of the usual Hölder space $BUC^s(U)$; see section 2 for a precise definition. Throughout this paper we fix $\alpha \in (0,1)$ and we define

$$\mathcal{V} := h^{2+\alpha}(\Gamma) \cap \mathcal{U}.$$

Moreover, we need the anisotropic function spaces $Ch^{0,s}(\Omega_{\rho,T})$ consisting of all $u : \Omega_{\rho,T} \to \mathbb{R}$ such that, given $(x,t) \in \Omega_{\rho,T}$, the function $u(\cdot,t)$ belongs to $h^s(\Omega_{\rho(t)})$ and the function $u(x,\cdot)$ belongs to $C([0,T])$. A pair (u,ρ) is called a *classical Hölder solution* of (1.1) if

$$(u,\rho) \in Ch^{0,2+\alpha}(\Omega_{\rho,T}) \times \big(C([0,T),\mathcal{V}) \cap C^1([0,T),h^{1+\alpha}(\Gamma))\big)$$

and if (u,ρ) satisfies the equations in (1.1) pointwise. Our main result now reads as follows.

THEOREM 1.1. *Assume that $b \in h^{2+\alpha-\delta}(J)$ is nonnegative and not identically equal to zero. Then, given any initial value $\rho_0 \in \mathcal{V}$, there exist $T > 0$ and a unique classical solution (u,ρ) of $(1.1)_{\rho_0}$ on $[0,T]$. Moreover, the moving boundary $\rho : (0,T) \to \mathcal{V}$ is analytic in the time variable.*

It should be emphasized that Theorem 1.1 guarantees a unique classical solution to problem (1.1) for each $C^{2+\alpha}$ initial hypersurface Γ_{ρ_0} which is close to Γ in the sense that ρ_0 belongs to $\mathcal{V}$.

In Elliott [8] and Elliott and Janovsky [9], a variational inequality approach for problem $(1.1)_{\rho_0}$ is developed, and the existence and uniqueness of global weak solutions are proved. However, as stated in the Conclusion of [9] (see p. 106), the existence of classical solutions left an open problem.

Our approach to problem $(1.1)_{\rho_0}$ proposed in this paper is of a different nature. Indeed, transforming the original problem on a fixed domain, we are looking for classical solutions from the very beginning. After a natural reduction of the transformed equations, we are led to an evolution equation for the moving boundary involving a nonlinear and nonlocal pseudodifferential operator of first order. The main result for this pseudodifferential operator can be summarized by the fact that it depends smoothly on the unknown and that the corresponding linearized operator is a nicely behaving operator; i.e., it generates a strongly continuous analytic semigroup on an appropriate subspace of Hölder continuous functions, provided $b \geq 0$ and $b \neq 0$. This generation property of the linearization makes it possible to use the general results of the theory of maximal regularity, due to Da Prato and Grisvard [6], and to construct a unique classical solution of the nonlinear problem. The same technique has been applied to moving boundary problems arising in gravity flows of incompressible fluids through porous media; see [12] and [13].

There is a one-dimensional version of problem $(1.1)_{\rho_0}$; see the work of Fasano and Primicerio [14], [15]. Since the geometry of one-dimensional moving boundary problems is considerably easier to handle, classical solutions are well known to exist in this case.

For two-dimensional simply connected domains and for initial data belonging to an appropriate Gevrey class, Reissig [20] recently proved the existence of analytic solutions to a Hele–Shaw model with a point source.

Let $\rho_0 \in \mathcal{V}$ be given and assume that $b \in h^{2+\alpha-\delta}(J) \setminus \{0\}$ is nonnegative. Moreover, let (u,ρ) denote the classical solution of $(1.1)_{\rho_0}$ constructed in Theorem 1. Then, given $t \in [0,T]$, the pressure $u(\cdot,t) \in h^{2+\alpha}(\Omega_{\rho(t)})$ is the unique solution in $h^{2+\alpha}(\Omega_{\rho(t)})$ of the following elliptic boundary value problem:

$$\Delta u = 0 \quad \text{in} \quad \Omega_{\rho(t)}, \quad u = 0 \quad \text{on} \quad \Gamma_{\rho(t)}, \quad (1-\delta)u + \delta(\nabla u | \nu_J) = b \quad \text{on} \quad J.$$

Hence the strong maximum principle implies that the pressure $u(\cdot,t)$ is strictly positive in $\Omega_{\rho(t)}$. This property is crucial for our approach; see step (b) in the proof of Theorem 4.2.

From a mathematical and a physical point of view, problem $(1.1)_{\rho_0}$ also makes sense for negative b. However, in this so-called ill-posed case, the problem has a completely different feature, as pointed out by Elliott and Ockendon [10] based on numerical investigations, by DiBenedetto and Friedman [7] proving so-called fingering, and by Fasano and Primicerio [15] establishing blow-up and nonexistence results for one-dimensional problems. Our results are also optimal in this sense, since we guarantee the existence of classical solutions in the well-posed case $b \geq 0$, $b \neq 0$, and we *prove* that the linearized reduced problem for the moving boundary is ill-posed in the sense of Hadamard for $b \leq 0$, $b \neq 0$; see Remark 5.3.

2. The transformed problem.

In this section we transform the original problem into a problem on a fixed domain, and we introduce a nonlinear, nonlocal pseudo-differential operator Φ of an appropriate reduced problem for the moving boundary Γ_ρ. In addition, we provide a useful representation of the Fréchet derivative of Φ.

Let us first introduce some function spaces which we will need in what follows. Assume that U is an open subset of $\mathbb{R}^m$. Given $k \in \mathbb{N} \cup \{\infty\}$, let $C^k(U)$ denote the space of all $f : U \to \mathbb{R}$ having continuous derivatives up to order k. The closed subspace of $C^k(U)$ consisting of all maps from U into $\mathbb{R}$ which have bounded and uniformly continuous derivatives up to order k is denoted by $BUC^k(U)$. Given $\alpha \in (0,1)$, the space $BUC^{k+\alpha}(U)$ stands for all $f \in BUC^k(U)$ having uniformly α-Hölder continuous derivatives of order k. In addition, $C^\omega(U)$ denotes the subspace of all real analytic functions on U.

Furthermore, we write $\mathcal{S}(\mathbb{R}^m)$ for the Schwartz space, i.e., the Fréchet space of all rapidly decreasing smooth functions on $\mathbb{R}^m$.

Next let r_U denote the restriction operator with respect to U, i.e., $r_U u := u|U$ for $u \in BUC(U)$. Then the *little Hölder spaces* $h^s(U)$, $s \geq 0$, are defined as

$$h^s(U) := \text{closure of } \ r_U\big(\mathcal{S}(\mathbb{R}^m)\big) \ \text{ in } \ BUC^s(U).$$

Finally, assume that M is an m-dimensional (sufficiently) smooth submanifold of $\mathbb{R}^n$. Then the spaces $BUC^s(M)$ and $h^s(M)$, $s \geq 0$, are defined as usual by means of a smooth atlas for M; see [24].

It is useful to write Γ_ρ as a 0-level set of an appropriate function. For this, pick $a_0 \in (0, \operatorname{dist}(\Gamma, J))$ and let

$$\mathcal{N} : \Gamma \times (-a_0, a_0) \to \mathbb{R}^n, \qquad \mathcal{N}(x, \lambda) := x + \lambda\nu(x).$$

If $a_0 > 0$ is small enough, we have that

$$\mathcal{N} \in \operatorname{Diff}^\infty(\Gamma \times (-a_0, a_0), \mathcal{R}),$$

where $\mathcal{R} := \operatorname{im}(\mathcal{N})$. It is convenient to decompose the inverse of $\mathcal{N}$ into $\mathcal{N}^{-1} = (X, \Lambda)$, where

$$X \in BUC^\infty(\mathcal{R}, \Gamma) \qquad \text{and} \qquad \Lambda \in BUC^\infty(\mathcal{R}, (-a_0, a_0)).$$

Note that $X(y)$ is the nearest point on Γ to y and that $\Lambda(y)$ is the signed distance from y to Γ (that is, to $X(y)$). The neighborhood $\mathcal{R}$ consists of those points with distance less than a_0 to Γ. Given $\rho \in \mathcal{V}$, now define

$$N_\rho : \mathcal{R} \to \mathbb{R}, \qquad N_\rho(y) := \Lambda(y) - \rho(X(y)).$$

Then it is not difficult to verify that $\Gamma_\rho = N_\rho^{-1}(0)$. Therefore, the gradient ∇N_ρ is perpendicular to Γ_ρ, and ∇N_ρ points outward since $N_\rho(y) < 0$ if $y \in \Omega_\rho$. So it follows that the outer unit normal field ν on Γ_ρ is given by $\nu = \frac{\nabla N_\rho}{|\nabla N_\rho|}$. Let $\rho \in C^1([0,T], h^{1+\alpha}(\Gamma))$ be given and set

$$N_\rho(y,t) := \Lambda(y) - \rho(X(y),t), \qquad y \in \mathcal{R}, \quad t \in [0,T].$$

Then

$$V(y,t) := -\frac{\partial_t N_\rho(y,t)}{|\nabla N_\rho(y,t)|} = \frac{\partial_t \rho(X(y),t)}{|\nabla N_\rho(y,t)|}, \qquad y \in \Gamma_{\rho(t)}, \quad t \in [0,T],$$

is the normal velocity of the moving hypersurfaces $\Gamma_{\rho(t)}$ in the direction of the outer normal field. Hence the fourth equation in (1.1) can be rewritten as $-\frac{\partial_t N_\rho}{|\nabla N_\rho|} = -(\nabla u|\nu)$, which shows that the motion of the hypersurfaces $\Gamma_{\rho(t)}$ is governed by $V = -\frac{\partial u}{\partial \nu}$.

Next we introduce an appropriate extension of θ_ρ to $\mathbb{R}^n$. For this we assume that $a \in (0, a_0/4)$, and we fix a $\varphi \in C^\infty(\mathbb{R}, [0,1])$ such that

$$\varphi(\lambda) = \begin{cases} 1 & \text{if} \quad |\lambda| \le a, \\ 0 & \text{if} \quad |\lambda| \ge 3a \end{cases}$$

and such that $\sup |\partial \varphi(\lambda)| < 1/a$. Then we define for each $\rho \in \mathcal{V}$ the map

$$\Theta_\rho(y) := \begin{cases} \mathcal{N}\big(X(y), \Lambda(y) + \varphi(\Lambda(y))\rho(X(y))\big) & \text{if} \quad y \in \mathcal{R}, \\ y & \text{if} \quad y \notin \mathcal{R}. \end{cases}$$

Note that $[\lambda \mapsto \lambda + \varphi(\lambda)\rho]$ is strictly increasing since $|\partial\varphi(\lambda)\rho| < 1$. Then it is not difficult to verify that

$$\Theta_\rho \in \mathrm{Diff}^{\,2+\alpha}(\mathbb{R}^n, \mathbb{R}^n) \cap \mathrm{Diff}^{\,2+\alpha}(\Omega, \Omega_\rho) \quad \text{and} \quad \Theta_\rho | \Gamma = \theta_\rho.$$

Moreover, we observe that there exists an open neighborhood U of J such that

$$\Theta_\rho | U = id_U. \tag{2.1}$$

It should be mentioned that the above diffeomorphism was first introduced by Hanzawa [18] to transform multidimensional Stefan problems to fixed domains. In the following we use the same symbol θ_ρ for both diffeomorphisms θ_ρ and Θ_ρ. The pull-back operator induced by θ_ρ is given as

$$\theta^* u := \theta^*_\rho u := u \circ \theta_\rho \quad \text{for} \quad u \in BUC(\Omega_\rho).$$

Similarly, the corresponding push-forward operator is defined as

$$\theta_* v := \theta^\rho_* v := v \circ \theta_\rho^{-1} \quad \text{for} \quad v \in BUC(\Omega).$$

Lemma 2.1. *Given $\rho \in \mathcal{V}$ and $k \in \{1, 2\}$, we have*

$$\theta^*_\rho \in \mathrm{Isom}(h^{k+\alpha}(\Omega_\rho), h^{k+\alpha}(\Omega)) \cap \mathrm{Isom}(h^{k+\alpha}(\Gamma_\rho), h^{k+\alpha}(\Gamma))$$

with $[\theta_\rho^*]^{-1} = \theta_*^\rho$.

Proof. Let $\rho \in \mathcal{V}$ and $k \in \{1, 2\}$ be given. It follows from the mean value theorem that

$$\theta_\rho^* \in \mathrm{Isom}(BUC^{k+\alpha}(\Omega_\rho), BUC^{k+\alpha}(\Omega)).$$

Hence, to prove the first assertion, it suffices to show that $\theta_\rho^* u$ belongs to the space $h^{k+\alpha}(\Omega)$, whenever u belongs to $h^{k+\alpha}(\Omega_\rho)$. But this is an easy consequence of the following known characterization of little Hölder spaces: a function $u \in BUC^{k+\alpha}(\Omega)$ belongs to $h^{k+\alpha}(\Omega)$ iff

$$\lim_{\tau\to 0^+} \sup_{0<|x-y|\le\tau} \frac{|\partial^\beta u(x) - \partial^\beta u(y)|}{\tau^\alpha} = 0, \qquad \beta \in \mathbb{N}^n,\ |\beta| = k.$$

This can be seen by means of local coordinate charts along the lines of Lemma 2.7 and Remark 2.8 in [19]; see also [3]. The second assertion follows analogously. ∎

Given $\rho \in \mathcal{V}$, we now introduce the following transformed differential operators, acting linearly on $BUC^2(\Omega)$:

$$\begin{aligned} &A(\rho)v := -\theta_\rho^*\big(\Delta(\theta_*^\rho v)\big), \qquad B(\rho)v := \gamma\theta_\rho^*(\nabla(\theta_*^\rho v)|\nabla N_\rho), \\ &Cv := (1-\delta)\gamma_J v + \delta(\gamma_J \nabla v|\nu_J), \end{aligned}$$

where γ and γ_J denote the trace operators with respect to Γ and J, respectively. Assume now that (u, ρ) is a classical Hölder solution of $(1.1)_{\rho_0}$. Then it is not difficult to see that $v := [t \mapsto \theta_{\rho(t)}^* u(t, \cdot)]$ belongs to $C([0, T], h^{2+\alpha}(\Omega))$ and that the pair (v, ρ) satisfies the following equations:

$$(2.2)_{\rho_0} \qquad \begin{aligned} A(\rho)v &= 0 \quad \text{in} \quad \Omega_{0,T}, \\ v &= 0 \quad \text{on} \quad \Gamma_{0,T}, \\ Cv &= b \quad \text{on} \quad J_T, \\ \partial_t\rho + B(\rho)v &= 0 \quad \text{on} \quad \Gamma_{0,T}, \\ \rho(0, \cdot) &= \rho_0 \quad \text{on} \quad \Gamma. \end{aligned}$$

A pair (v, ρ) is called a *classical Hölder solution* of $(2.2)_{\rho_0}$ if

$$\begin{aligned} &v \in C([0, T], h^{2+\alpha}(\Omega)), \\ &\rho \in C([0, T], \mathcal{V}) \cap C^1([0, T], h^{1+\alpha}(\Gamma)) \end{aligned}$$

and if (v, ρ) satisfies the equations in $(2.2)_{\rho_0}$ pointwise. The following lemma is an obvious consequence of Lemma 2.1 and (2.1).

LEMMA 2.2. *Let* $\rho_0 \in \mathcal{V}$ *be given.*

(a) *If* (u, ρ) *is a classical Hölder solution of* $(1.1)_{\rho_0}$, *then* $(\theta_\rho^* u, \rho)$ *is a classical Hölder solution of* $(2.2)_{\rho_0}$.

(b) *If* (v, ρ) *is a classical Hölder solution of* $(2.2)_{\rho_0}$, *then* $(\theta_*^\rho v, \rho)$ *is a classical Hölder solution of* $(1.1)_{\rho_0}$.

In the next two lemmas we collect some results for elliptic boundary value problems in little Hölder spaces. We shall use these results in sections 3 and 4.

Lemma 2.3.

$$(A, B) \in C^{\omega}(\mathcal{V}, \mathcal{L}(h^{2+\alpha}(\Omega), h^{\alpha}(\Omega) \times h^{1+\alpha}(\Gamma))).$$

Proof. Let η denote the standard Euclidean metric on $\mathbb{R}^m$ and let $\theta^*\eta$ be the Riemannian metric on $\overline{\Omega}$ induced by the diffeomorphism θ_ρ, i.e.,

$$\theta_\rho^*\eta|_x(\xi, \zeta) := \eta|_{\theta_\rho(x)}(T_x\theta_\rho\xi, T_x\theta_\rho\zeta)$$

for $x \in \overline{\Omega}$ and ξ, $\zeta \in T_x(\overline{\Omega})$. Then $A(\rho)$ and $B(\rho)$ are just the Laplace–Beltrami operator and the outer normal derivative of $(\Omega, \theta_\rho^*\eta)$. Since the metric $\theta_\rho^*\eta$ depends analytically on $\rho \in \mathcal{V}$, the assertion follows easily. □

Lemma 2.4. *Let $\rho \in \mathcal{V}$ be given. Then for each*

$$(f, g, h) \in h^{\alpha}(\Omega) \times h^{2+\alpha}(\Gamma) \times h^{2+\alpha-\delta}(J)$$

there exists a unique classical solution $v := V(\rho)(f, g, h)$ in $h^{2+\alpha}(\Omega)$ of

$$A(\rho)v = f \quad \textit{in} \quad \Omega, \qquad v = g \quad \textit{on} \quad \Gamma, \qquad Cv = h \quad \textit{on} \quad J.$$

Moreover, there exists a positive constant $C := C(\rho)$ such that

$$\|V(\rho)(f, g, h)\|_{2+\alpha,\Omega} \le C\big(\|f\|_{\alpha,\Omega} + \|g\|_{2+\alpha,\Gamma} + \|h\|_{2+\alpha-\delta,J}\big).$$

Proof. (a) It follows from the proof of Lemma 2.3 and by construction that A is a uniformly elliptic operator having α-Hölder continuous coefficients and that C is a normal boundary operator with regular coefficients too. Hence we conclude from Theorem 7.3 and Remark 2 on p. 669 in [1] that, given any compact subset K of $\mathcal{V}$, there exists a positive constant $C := C(K)$ such that

$$\|v\|_{2+\alpha,\Omega} \le C\big(\|A(\rho)v\|_{\alpha,\Omega} + \|\gamma v\|_{2+\alpha,\Gamma} + \|Cv\|_{2+\alpha-\delta,J}\big)$$

for all $v \in h^{2+\alpha}(\Omega)$ and all $\rho \in K$.

(b) Observe that $\big(A(0), \gamma, C\big)$ is a regular elliptic boundary value problem with constant coefficients on a smooth domain. Hence it follows from formula (3) on p. 236 in [24] that

$$\big(A(0), \gamma, C\big) \in \mathrm{Isom}(h^{2+\alpha}(\Omega), h^{\alpha}(\Omega) \times h^{2+\alpha}(\Gamma) \times h^{2+\alpha-\delta}(J)).$$

Now let $\rho \in \mathcal{V}$ be given and set $K := \{t\rho\,;\, t \in [0, 1]\}$. Then K is a compact subset of $\mathcal{V}$, and therefore it follows from (a) and the continuity method (see Theorem 5.2 in [17]) that

$$\big(A(\rho), \gamma, C\big) \in \mathrm{Isom}(h^{2+\alpha}(\Omega), h^{\alpha}(\Omega) \times h^{2+\alpha}(\Gamma) \times h^{2+\alpha-\delta}(J)).$$

This completes our argumentation. □

Let us now introduce the natural decomposition $V = S \oplus T \oplus R$ of the above solution operator by setting

$$\begin{aligned} S(\rho) &:= V(\rho)(\cdot, 0, 0) \in \mathcal{L}(h^{\alpha}(\Omega), h^{2+\alpha}(\Omega)), \\ T(\rho) &:= V(\rho)(0, \cdot, 0) \in \mathcal{L}(h^{2+\alpha}(\Gamma), h^{2+\alpha}(\Omega)), \\ R(\rho) &:= V(\rho)(0, 0, \cdot) \in \mathcal{L}(h^{2+\alpha-\delta}(J), h^{2+\alpha}(\Omega)). \end{aligned}$$

Given $v \in BUC^1(\Omega)$, let $\partial_\nu v$ denote the directional derivative with respect to the outer unit normal on Γ, i.e., $\partial_\nu v := \gamma(\nabla v|\nu)$. Using this notation it follows from the strong maximum principle that

$$\partial_\nu(R(\rho)b) < 0, \tag{2.3}$$

provided $b \in h^{2+\alpha-\delta}(J) \setminus \{0\}$ with $b \geq 0$.

Throughout the remainder of this paper we fix

$$b \in h^{2+\alpha-\delta}(J) \setminus \{0\} \quad \text{with} \quad b \geq 0 \tag{2.4}$$

and we set

$$\Phi(\rho) := B(\rho)R(\rho)b \quad \text{for} \quad \rho \in \mathcal{V}.$$

It follows from Lemma 2.3 and the definition of R that Φ maps $\mathcal{V}$ into $h^{1+\alpha}(\Gamma)$. Given $\rho_0 \in \mathcal{V}$, we now consider the nonlinear evolution equation in $h^{1+\alpha}(\Gamma)$ for the operator Φ:

$$\partial_t \rho + \Phi(\rho) = 0, \qquad \rho(0) = \rho_0. \tag{2.5}$$

A function $\rho : I = [0,T] \to h^{1+\alpha}(\Gamma)$ is called a *classical Hölder solution* of (2.5) if

$$\rho \in C(I, \mathcal{V}) \cap C^1(I, h^{1+\alpha}(\Gamma))$$

and if ρ satisfies (2.5) pointwise on I. Using this notation it is now easy to state the following *reduction* of the transformed problem (2.2).

LEMMA 2.5. *Let $\rho_0 \in \mathcal{V}$ be given.*

(a) *If ρ is a classical Hölder solution of* (2.5)*, then the pair $(R(\rho)b, \rho)$ is a classical Hölder solution of* (2.2)*.*

(b) *Suppose that (v, ρ) is a classical Hölder solution of* (2.2)*. Then ρ is a classical Hölder solution of* (2.5)*.*

Proof. This follows immediately from the definition of $R(\rho)$. □

In order to treat the nonlinear evolution equation (2.5), we first show that $\Phi(\rho)$ depends smoothly on $\rho \in \mathcal{V}$ and we provide an appropriate representation of the Fréchet derivative $\partial\Phi(\rho)$ of Φ at $\rho \in \mathcal{V}$. For this we introduce for each $\rho \in \mathcal{V}$ the following linear operators:

$$\begin{aligned} K &:= K(\rho) := -\partial A(\rho)[\cdot, R(\rho)b] \in \mathcal{L}(h^{2+\alpha}(\Gamma), h^\alpha(\Omega)), \\ M &:= M(\rho) := \partial B(\rho)[\cdot, R(\rho)b] \in \mathcal{L}(h^{2+\alpha}(\Gamma), h^{1+\alpha}(\Gamma)). \end{aligned}$$

Here, the notation $\partial A(\rho)[h,v]$ stands for

$$\partial A(\rho)[h,v] = \frac{\partial}{\partial\varepsilon}\bigg|_{\varepsilon=0} A(\rho + \varepsilon h)v, \qquad h \in h^{2+\alpha}(\Gamma),\ v \in h^{2+\alpha}(\Omega).$$

LEMMA 2.6. $\Phi \in C^\omega(\mathcal{V}, h^{1+\alpha}(\Gamma))$ *with*

$$\partial\Phi(\rho) = B(\rho)S(\rho)K(\rho) + M(\rho)$$

for each $\rho \in \mathcal{V}$.

Proof. (a) Due to Lemma 2.3, it suffices to show that

$$[\rho \mapsto R(\rho)b] \in C^\omega(\mathcal{V}, h^{2+\alpha}(\Omega)) \quad \text{with} \quad \partial(R(\rho)b) = S(\rho)K(\rho).$$

(b) Recall that $\mathcal{V}$ is an open subset of $h^{2+\alpha}$. Let γ denote the trace operator with respect to Γ and let

$$F(\rho, v) := (A(\rho)v, \gamma v, Cv - b), \qquad (\rho, v) \in \mathcal{V} \times h^{2+\alpha}(\Omega).$$

Then it follows from Lemma 2.3 that

$$F \in C^\omega\big(\mathcal{V} \times h^{2+\alpha}(\Omega), h^\alpha(\Omega) \times h^{2+\alpha}(\Gamma) \times h^{2+\alpha-\delta}(J)\big).$$

Moreover, given $(\rho, v) \in \mathcal{V} \times h^{2+\alpha}(\Omega)$, we have that

$$\partial_2 F(\rho, v)w = (A(\rho)w, \gamma w, Cw) \quad \text{and} \quad \partial_1 F(\rho, v)h = (\partial A(\rho)[h, v], 0, 0)$$

for $w \in h^{2+\alpha}(\Omega)$ and $h \in h^{2+\alpha}(\Gamma)$. Now the assertion follows from Lemma 2.4 and the implicit function theorem. □

The next two sections are devoted to the study of the linearization $\partial\Phi(\rho)$ of Φ. We will see that it is a nicely behaving operator; i.e., we will prove that $-\partial\Phi(\rho)$ generates a strongly continuous analytic semigroup on $h^{1+\alpha}(\Gamma)$.

3. Localizations. Given $\kappa \in (0, a]$, let $\mathcal{R}_\kappa := \mathcal{N}(\Gamma \times (-\kappa, 0])$. Then there exists $m := m_\kappa \in \mathbb{N}$ and an atlas $\{(U_l, \varphi_l) \,;\, 1 \le l \le m\}$ of $\mathcal{R}_\kappa$ such that $\operatorname{diam}(U_l) < 2\kappa$ for all $l \in \{1, \dots, m\}$. Let

$$s_l \in C^\infty((-\delta, \delta)^{n-1}, U_l), \quad l \in \{1, \dots, m\},$$

be a parameterization of $U_l \cap \Gamma$. Furthermore, let $P := (-\delta, \delta)^{n-1}$ and $Q := P \times [0, \delta)$ and define

$$\mu_l : Q \to U_l, \qquad (\omega, r) \mapsto s_l(\omega) - r\nu(s_l(\omega)).$$

Without loss of generality, we may assume that $\delta = \kappa$ and that $\mu_l := \varphi_l^{-1}$ for $1 \le l \le m$. The additional parameter κ is introduced to control the size of the chart domain U_l. This fact will be used in section 5 to prove a perturbation result; cf. Lemma 5.1. Finally, to further economize our notation, we set $\mu := \mu_l$, $U := U_l$ and we let

$$\mu^* u := u \circ \mu, \quad u \in C(U_l) \quad \text{and} \quad \mu_* v := v \circ \mu^{-1}, \quad v \in C(Q)$$

denote the pull-back and push-forward operators, respectively, induced by μ. Given $l \in \{1, \dots, m\}$, we define *local representations* $\mathcal{A} := \mathcal{A}_l$ and $\mathcal{B} := \mathcal{B}_l$ of A and B with respect to (Q, μ_l) by setting

$$\mathcal{A}(\mu^*\rho)\mu^* = \mu^* A(\rho) \quad \text{and} \quad \mathcal{B}(\mu^*\rho)\mu^* = \mu^* B(\rho), \quad \rho \in \mathcal{V},$$

respectively. To determine the coefficients of $\mathcal{A}$ and $\mathcal{B}$, let

$$\hat\rho := \hat\rho_l := \mu_l^* \rho, \quad \rho \in \mathcal{V}$$

and put $d(\omega, r) := \hat\rho(\omega) - r$ for $(\omega, r) \in Q$. In addition, we use the notation

$$\partial_j := \partial_{\omega_j}, \quad 1 \le j \le n-1, \qquad \partial_n := \partial_r.$$

Given $1 \leq j,\, k \leq n-1$, define

$$w_{jk} := (\partial_j s|\partial_k s) + d\big((\partial_j \mu^* \nu|\partial_k s) + (\partial_k \mu^* \nu|\partial_j s)\big) + d^2(\partial_j \mu^* \nu|\partial_k \mu^* \nu).$$

Clearly, $[w_{jk}]$ is symmetric. In addition, observe that $[(\partial_j s|\partial_k s)]$ is uniformly positive definite on P and that $\sup|d(\omega,r)| \leq 2a$. Hence we may assume also that $[w_{jk}]$ is uniformly positive definite on Q, provided $a>0$ is small enough. Let w denote the inverse of $[w_{jk}]$ and let w^{jk} be the components of w. Finally, set

$$D(\omega,r) := \begin{pmatrix} \nabla\hat{\rho}\otimes\nabla\hat{\rho} & \nabla\hat{\rho} \\ (\nabla\hat{\rho})^T & 1 \end{pmatrix}, \quad (\omega,r)\in Q,$$

and let

$$g_{jk} := g^l_{jk}(\rho) := (\partial_j \mu^* \theta_\rho|\partial_k \mu^* \theta_\rho), \quad 1 \leq j,\, k \leq n,$$

denote the components of the metric tensor with respect to (Q,μ). Note that

$$\mu^*\theta_\rho(\omega,r) = \theta_\rho(\mu(\omega,r)) = s(\omega) + d(\omega,r)\nu(s(\omega))$$

since $\varphi \equiv 1$ on $\mu(Q)$. In addition, observe that $d(w,r) = \hat{\rho}(\omega) - r$ is the function $-N_\rho$ in local coordinates. Using the orthogonality relations $(\partial_j s|\nu) = 0$ and $(\partial_j \nu|\nu) = 0$, direct calculations yield the formulas

$$[g_{jk}] = \begin{pmatrix} w^{-1} & 0 \\ 0 & 0 \end{pmatrix} + D \tag{3.1}$$

and

$$[g^{jk}] = \begin{pmatrix} w & -w\nabla\hat{\rho} \\ -(w\nabla\hat{\rho})^T & 1 + (w\nabla\hat{\rho}|\nabla\hat{\rho}) \end{pmatrix}, \tag{3.2}$$

where $[g^{jk}]$ is the inverse of $[g_{jk}]$. From (3.1), (3.2), and the well-known formula (which essentially is Cramer's rule)

$$g_{nn} = \det{[g_{jk}]_{1\leq j,k\leq n}} \cdot \det{[g^{jk}]_{1\leq j,k\leq n-1}},$$

one then deduces that

$$G := \sqrt{\det{[g_{jk}]_{1\leq j,k\leq n}}} = \sqrt{\det w^{-1}}. \tag{3.3}$$

Finally, let W denote the uniformly elliptic second-order differential operator acting on $C^2(P)$ which is induced by w, i.e.,

$$W\sigma := -\sum_{j,k=1}^{n-1} w^{jk}\partial_j\partial_k\sigma, \qquad \sigma\in C^2(P).$$

In the next lemma, we use the following notation: given $\widetilde{a} \in C^\infty(Q\times\mathbb{R}\times\mathbb{R}^{n-1},\mathbb{R})$ and $\sigma\in C^1(P)$, let $a(\sigma,\nabla\sigma)$ denote the Nemitskii operator induced by $\widetilde{a}$, i.e.,

$$a(\sigma,\nabla\sigma)(\omega,r) := \widetilde{a}((\omega,r),\sigma(\omega),\nabla\sigma(\omega)), \qquad (\omega,r)\in Q.$$

Lemma 3.1. *There exist*

$$\widetilde{a}_{jk},\ \widetilde{a}_j,\ \widetilde{b}_j \in C^\infty(Q\times(-a,a)\times\mathbb{R}^{n-1},\mathbb{R}),\qquad 1\le j,\ k\le n,$$

such that

$$\begin{aligned}&[\widetilde{a}_{jk}] \quad \textit{is symmetric and uniformly positive definite,}\\ &\widetilde{b}_n \quad \textit{is uniformly positive}\end{aligned}\tag{3.4}$$

on compact subsets of $\overline{Q}\times(-a,a)\times\mathbb{R}^{n-1}$ *and such that*

$$\begin{aligned}\mathcal{A}(\hat\rho)&=-\sum_{j,k=1}^n a_{jk}(\hat\rho,\nabla\hat\rho)\partial_j\partial_k+\sum_{j=1}^n a_j(\hat\rho,\nabla\hat\rho)\partial_j+(W\hat\rho)\partial_n,\\ \mathcal{B}(\hat\rho)&=-\sum_{j=1}^n b_j(\hat\rho,\nabla\hat\rho)\partial_j.\end{aligned}\tag{3.5}$$

Proof. Recall that $A(\rho)$ and $B(\rho)$ are just the Laplace–Beltrami operator of $(\Omega,\theta_\rho^*\eta)$ and the outer normal derivative on Γ of $(\overline{\Omega},\theta_\rho^*\eta)$, respectively, where η denotes the standard Euclidean metric on $\mathbb{R}^m$; see the proof of Lemma 2.3. Hence assertion (3.4) is obvious, since $(\mathcal{A},\mathcal{B})$ is a representation of (A,B) in local coordinates. The explicit decomposition of the coefficient of ∂_n of $\mathcal{A}$ follows from (3.2). $\square$

We close this section by determining the local representations of $K(\rho)$ and $M(\rho)$ according to the parameterization (Q,μ). In order to do this, we introduce

$$\begin{aligned}\mathcal{K}&:=\mathcal{K}(\rho):=-\partial\mathcal{A}(\hat\rho)[\cdot,\mu^*(R(\rho)b)]\in\mathcal{L}(h^{2+\alpha}(P),h^\alpha(\mathring{Q})),\\ \mathcal{M}&:=\mathcal{M}(\rho):=\partial\mathcal{B}(\hat\rho)[\cdot,\mu^*(R(\rho)b)]\in\mathcal{L}(h^{2+\alpha}(P),h^{1+\alpha}(P))\end{aligned}$$

for each $\rho\in\mathcal{V}$.

Lemma 3.2. *Given* $\rho\in\mathcal{V}$, *we have*

$$\mu^*K(\rho)=\mathcal{K}(\rho)\mu^*\qquad\textit{and}\qquad\mu^*M(\rho)=\mathcal{M}(\rho)\mu^*.$$

Proof. Fix $\rho\in\mathcal{V}$. To shorten our notation, we write $v:=R(\rho)b$ and $\hat h:=\mu^*h$ for $h\in h^{2+\alpha}(\Gamma)$. Then we have

$$\begin{aligned}\mu^*K(\rho)h=\mu^*\partial A(\rho)[h,v]&=\mu^*A(\rho+h)v-\mu^*A(\rho)v+o(h)\\ &=\mathcal{A}(\hat\rho+\hat h)\mu^*v-\mathcal{A}(\hat\rho)\mu^*v+o(\hat h)\\ &=\partial\mathcal{A}(\hat\rho)[\hat h,\mu^*v]\\ &=\mathcal{K}(\rho)\mu^*h\end{aligned}$$

as $h\to0$ in $h^{2+\alpha}(\Gamma\cap U_l)$. The second assertion can be proved analogously. $\square$

Lemma 3.3. *There exist*

$$\widetilde{k}_j,\ \widetilde{m}_j\in C^\infty(Q\times(-a,a)\times\mathbb{R}^{n-1},\mathbb{R}),\quad j=0,\dots,n-1,$$

such that

$$\begin{aligned}\mathcal{K}h&=-\partial_n[\mu^*(R(\rho)b)]Wh+\sum_{j=1}^{n-1}k_j(\hat\rho,\nabla\hat\rho)\partial_jh+k_0(\hat\rho,\nabla\hat\rho)h,\\ \mathcal{M}h&=\sum_{j=1}^{n-1}m_j(\hat\rho,\nabla\hat\rho)\partial_jh+m_0(\hat\rho,\nabla\hat\rho)h\end{aligned}$$

for each $h \in h^{2+\alpha}(P)$. Here again, k_j and m_j denote the Nemitskii operators induced by $\widetilde{k}_j$ and $\widetilde{m}_j$, respectively.

Proof. The above assertions follow easily from Lemma 3.1. □

4. Fourier multiplier operators. In this section we are concerned with linear differential operators having constant coefficients, obtained by freezing the local representation $(\mathcal{A}, \mathcal{B})$ of (A, B) at $\rho \in \mathcal{V}$ and at $0 \in Q$. These operators are used to associate a Fourier multiplier operator $\mathcal{G}_1$ to the Fréchet derivative $\partial\Phi(\rho)$ of Φ at ρ.

Throughout this section we fix $\rho \in \mathcal{V}$ and $l \in \{1, \ldots, m_\kappa\}$. Of course, all operators appearing in this section will depend on the choice (ρ, l). However, we will suppress this dependence throughout this section. Let $\mathrm{H}^n = \mathbb{R}^{n-1} \times (0,1)$ denote the truncated half-space in $\mathbb{R}^n$, and let γ_0 denote the restriction operator from H^n to $\mathbb{R}^{n-1} \times \{0\} \equiv \mathbb{R}^{n-1}$. Moreover, we set

$$a^0_{jk} := a_{jk}(\hat{\rho})(0), \qquad b^0_j := b_j(\hat{\rho})(0), \qquad 1 \le j,\ k \le n, \tag{4.1}$$

and we define the following linear differential operators with constant coefficients:

$$\mathcal{A}_0 := -\sum_{j,k=1}^{n} a^0_{jk}\partial_j\partial_k, \qquad \mathcal{B}_0 := -\sum_{j=1}^{n} b^0_j \gamma_0 \partial_j.$$

Furthermore, let

$$\vec{a} := (a^0_{1n}, \ldots, a^0_{(n-1)n}), \qquad a_0 := \sum_{j,k=1}^{n-1} a^0_{jk}\xi^j\xi^k, \quad \xi \in \mathbb{R}^{n-1},$$

and define for fixed $\xi \in \mathbb{R}^{n-1}$ the following parameter-dependent quadratic polynomial:

$$q_\xi(z) := 1 + a_0(\xi) + 2i(\vec{a}|\xi)z - a^0_{nn}z^2, \quad z \in \mathbb{C}.$$

Since the matrix $[a^0_{jk}]$ is positive definite, it follows that, given $\xi \in \mathbb{R}^{n-1}$, there exists exactly one root $\lambda(\xi)$ of $q_\xi(\cdot)$ with positive real part, which is given by

$$\lambda(\xi) = \frac{i(\vec{a}|\xi)}{a^0_{nn}} + \frac{1}{a^0_{nn}}\sqrt{a^0_{nn}(1 + a_0(\xi)) - (\vec{a}|\xi)^2}.$$

Finally, we set

$$\vec{b} := (b^0_1, \ldots, b^0_{n-1}), \qquad \vec{m} := (m^0_1, \ldots, m^0_{n-1}).$$

In the following, $\mathcal{F}$ and $\mathcal{F}^{-1}$ denote the Fourier transform and the inverse Fourier transform, respectively, in $\mathbb{R}^{n-1}$. We are now ready to introduce the following Fourier multiplier operators, acting on functions defined on $\mathbb{R}^{n-1}$.

$$\mathcal{T}_0 g(x,y) := [\mathcal{F}^{-1}e^{-\lambda(\cdot)y}\mathcal{F}g](x), \tag{4.2}$$

where $g \in h^{2+\alpha}(\mathbb{R}^{n-1})$ and $(x,y) \in \mathrm{H}^n$. Moreover,

$$\mathcal{S}_0 h(x,y) := \left[\mathcal{F}^{-1}(1 - e^{-\lambda(\cdot)y})\frac{1}{1 + a_0(\cdot)}\,\mathcal{F}h\right](x), \tag{4.3}$$

for $h \in h^{\alpha}(\mathbb{R}^{n-1})$ and $(x,y) \in \mathrm{H}^n$. Then it can be shown that

$$\begin{aligned} &\mathcal{T}_0 \in \mathcal{L}(h^{2+\alpha}(\mathbb{R}^{n-1}), h^{2+\alpha}(\mathrm{H}^n)),\\ &\mathcal{S}_0 \in \mathcal{L}(h^{\alpha}(\mathbb{R}^{n-1}), h^{2+\alpha}(\mathrm{H}^n)); \end{aligned} \tag{4.4}$$

see Appendices A and B in [12]. Next note that the function $u = \mathcal{T}_0 g$ solves the elliptic boundary value problem

$$(1+\mathcal{A}_0)u = 0 \quad \text{in} \quad \mathrm{H}^n, \qquad \gamma_0 u = g \quad \text{on} \quad \mathbb{R}^{n-1},$$

whereas $v = \mathcal{S}_0 h$ is a solution of

$$(1+\mathcal{A}_0)v = h \quad \text{in} \quad \mathrm{H}^n, \qquad \gamma_0 v = 0 \quad \text{on} \quad \mathbb{R}^{n-1},$$

where we use the same notation for the extended function $\tilde{h}(x,y) := h(x)$, $(x,y) \in \mathrm{H}^n = \mathbb{R}^{n-1} \times (0,1)$. In addition, we define

$$\begin{aligned} &k^0 := \big(\partial_n[\mu^*(R(\rho)b)]\big)(0),\\ &w_0^{jk} := w^{jk}(0), \qquad 1 \le j,k \le n-1. \end{aligned} \tag{4.5}$$

Note that $\big(\partial_n[\mu^*(R(\rho)b)]\big)(0) = -\big(\partial_\nu[R(\rho)b]\big)(\mu(0))$. Hence, it follows from (2.3) that k^0 is positive. Given $h \in h^{2+\alpha}(\mathbb{R}^{n-1})$, let

$$(\mathcal{K}_0 h)(x) := -k^0 \left[1 - \sum_{j,k=1}^{n-1} w_0^{jk} \partial_j \partial_k\right] h(x), \quad x \in \mathbb{R}^{n-1}. \tag{4.6}$$

It is then obvious that

$$\mathcal{K}_0 \in \mathcal{L}(h^{2+\alpha}(\mathbb{R}^{n-1}), h^{\alpha}(\mathbb{R}^{n-1})). \tag{4.7}$$

Similarly, we set $m_j^0 := m_j(\hat{\rho})(0)$ and define

$$\mathcal{M}_0 h := \sum_{j=1}^{n-1} m_j^0 \partial_j h, \qquad h \in h^{2+\alpha}(\mathbb{R}^{n-1}).$$

Now let $t \in [0,1]$ be given and set

$$\mathcal{G}_t := t(\mathcal{B}_0 \mathcal{S}_0 \mathcal{K}_0 + \mathcal{M}_0) + (1-t)\mathcal{B}_0 \mathcal{T}_0.$$

Observe that $\mathcal{G}_t \in \mathcal{L}(h^{2+\alpha}(\mathbb{R}^{n-1}), h^{1+\alpha}(\mathbb{R}^{n-1}))$ for $t \in [0,1]$, as (4.4) and (4.7) show. Since $\mathcal{K}_0$ and $\mathcal{M}_0$ are the principal parts of $\mathcal{K}$ and $\mathcal{M}$, respectively, with coefficients fixed at $\rho \in \mathcal{V}$ and at $0 \in Q$, the operator $\mathcal{G}_1$ may be considered as the constant coefficient operator of the principal part of $\partial\Phi(\rho)$. The operator BT is called the *Dirichlet–Neumann* operator. Hence $\mathcal{G}_0$ is the constant coefficient version of the localization $\mathcal{BT}$ of BT; see also [11]. We should mention that we slightly modified the concepts and notations as introduced in [11] and [12]. However, an inspection of the proofs given in [12] show that formula (4.4) can be proved in the same way by using Fourier multiplier results in Hölder spaces; see [12, App. A.]. We can now prove the following result.

LEMMA 4.1. *Given $t \in [0,1]$, the operator $\mathcal{G}_t$ is a Fourier multiplier operator with symbol g_t; i.e., $\mathcal{G}_t = \mathcal{F}^{-1} g_t \mathcal{F}$ where*

$$g_t(\xi) := b_n^0 \lambda(\xi) \left\{ (1-t) + t k^0 \, \frac{(1 + w_0^{jk} \xi_j \xi_k)}{1 + a_0(\xi)} \right\} + i \big\{ ((t-1)\vec{b} + t\vec{m} | \xi) \big\}$$

for all $\xi \in \mathbb{R}^{n-1}$.

Proof. (a) In a first step we provide a representation of $\mathcal{S}_0 \mathcal{K}_0$. It is an immediate consequence of (4.6) that the Fourier transform of $\mathcal{K}_0 h$ is given by

$$(\mathcal{F}\mathcal{K}_0 h)(\xi) = -k^0 \, (1 + w_0^{jk} \xi_j \xi_k)(\mathcal{F}h)(\xi)$$

for $h \in h^{2+\alpha}(\mathbb{R}^{n-1})$ and $\xi \in \mathbb{R}^{n-1}$. Now it follows from (4.3) that

$$(\mathcal{F}S_0\mathcal{K}_0 h)(\xi, y) = -(1 - e^{-\lambda(\xi) y}) k^0 \, \frac{(1 + w_0^{jk} \xi_j \xi_k)}{1 + a_0(\xi)} (\mathcal{F}h)(\xi), \tag{4.8}$$

where $\xi \in \mathbb{R}^{n-1}$ and $y \in (0,1)$.

(b) Observe that $\gamma_0 \partial_j u = \partial_j \gamma_0 u$ for $u \in h^{2+\alpha}(\mathrm{H}^n)$ and $j = 1, \ldots, n-1$. Hence (4.8) yields

$$\mathcal{B}_0 \mathcal{S}_0 \mathcal{K}_0 h = \mathcal{F}^{-1} \left[b_n^0 \lambda(\xi) k^0 \, \frac{(1 + w_0^{jk} \xi_j \xi_k)}{1 + a_0(\xi)} \mathcal{F}h \right]. \tag{4.9}$$

From formula (4.2) we infer that

$$b_j^0 \gamma_0 \partial_j \mathcal{T}_0 = \mathcal{F}^{-1}[\xi \mapsto i b_j^0 \xi_j] \mathcal{F}, \qquad j = 1, \ldots, n-1,$$

and

$$b_n^0 \gamma_0 \partial_n \mathcal{T}_0 = -\mathcal{F}^{-1} b_n^0 \lambda(\cdot) \mathcal{F}.$$

Hence we find that

$$\mathcal{B}_0 \mathcal{T}_0 = \mathcal{F}^{-1}[\xi \mapsto b_n^0 \lambda(\xi) - i(\vec{b}|\xi)] \mathcal{F}. \tag{4.10}$$

Finally, it is clear that

$$\mathcal{M}_0 = \mathcal{F}^{-1}[\xi \mapsto i(\vec{m}|\xi)] \mathcal{F}. \tag{4.11}$$

Combining (4.9)–(4.11), we get the assertion. □

As a first consequence of Lemma 4.1, we show that $-\mathcal{G}_t$ generates for each $t \in [0,1]$ a strongly continuous analytic semigroup on $h^{1+\alpha}(\mathbb{R}^{n-1})$. To make this precise we need a few definitions. To begin with, assume that $\alpha_* > 0$, $\sigma > 0$ and let

$$\begin{aligned} \mathcal{E}ll\mathcal{S}_\sigma^\infty(\alpha_*) := \big\{ & a \in C^\infty(\mathbb{R}^{n-1} \times (0,\infty)) \,;\, a \text{ is positively homogeneous} \\ & \text{of degree } \sigma, \text{ all derivatives of } a \text{ are bounded on } |\xi|^2 + \mu^2 = 1, \\ & \text{and } \operatorname{Re} a(\xi,\mu) \geq \alpha_* (|\xi|^2 + \mu^2)^{\sigma/2},\ (\xi,\mu) \in \mathbb{R}^{n-1} \times (0,\infty) \big\}. \end{aligned}$$

Given two Banach spaces E_0 and E_1 such that E_1 is continuously and densely embedded in E_0, let $\mathcal{H}(E_1, E_0)$ denote the set of all $A \in \mathcal{L}(E_1, E_0)$ such that $-A$, considered as an unbounded operator in E_0, generates a strongly continuous analytic semigroup on E_0. It is known (see Remark I.1.2.1(a) in [2]) that $A \in \mathcal{L}(E_1, E_0)$ belongs to $\mathcal{H}(E_1, E_0)$ if there exist positive constants C and λ_* such that

$$\begin{aligned} &\lambda_* + A \in \mathrm{Isom}(E_1, E_0), \\ &|\lambda|\,\|x\|_{E_0} + \|x\|_{E_1} \leq C\|(\lambda + A)x\|_{E_0}, \quad x \in E_1,\ \lambda \in [\mathrm{Re}\, z \geq \lambda_*]. \end{aligned} \tag{4.12}$$

THEOREM 4.2. *Suppose that* (2.3) *holds. Then*

$$\mathcal{G}_t \in \mathcal{H}(h^{2+\alpha}(\mathbb{R}^{n-1}), h^{1+\alpha}(\mathbb{R}^{n-1})), \qquad t \in [0,1].$$

Proof. (a) Basically, the idea is to use Lemma 4.1 together with appropriate results on Fourier multipliers to verify the generation property of $\mathcal{G}_t$. Having this intention, it is well known that homogeneous symbols are much easier to handle. Hence, in a first step we introduce a parameter-dependent version of the symbol g_t, which is positively homogeneous of degree 1. Given $(\xi, \mu) \in \mathbb{R}^{n-1} \times (0, \infty)$, let

$$\lambda(\xi, \mu) := \frac{i(\vec{a}|\xi)}{a_{nn}^0} + \frac{1}{a_{nn}^0}\sqrt{a_{nn}^0(\mu^2 + a_0(\xi)) - (\vec{a}|\xi)^2}$$

and $r(\xi, \mu) := \mathrm{Re}(\lambda(\xi, \mu))$. Then we set

$$\widetilde{g}_t(\xi, \mu) := b_n^0 \lambda(\xi, \mu)\left\{(1-t) + tk^0\,\frac{(\mu^2 + w_0^{jk}\xi_j\xi_k)}{\mu^2 + a_0(\xi)}\right\} + i\{((t-1)\vec{b} + t\vec{m}|\xi)\},$$

for $(\xi, \mu) \in \mathbb{R}^{n-1} \times (0, \infty)$ and $t \in [0,1]$. Obviously, $\widetilde{g}_t(\cdot, 1) = g_t$. Moreover, it is clear that $\widetilde{g}_t \in C^\infty(\mathbb{R}^{n-1} \times (0,\infty), \mathbb{C})$ and that each $\widetilde{g}_t$ is positively homogeneous of degree 1. In addition, it is easily verified that all derivatives of a are bounded on $|\xi|^2 + \mu^2 = 1$.

(b) Observe that $k^0 > 0$, thanks to assumption (2.4) and (2.3). In addition, we know from (3.4) and (3.5) that $a_{nn}^0 > 0$ and $b_n^0 > 0$. Furthermore, there exist positive constants K and r_* such that

$$\mu^2 + a_0(\xi) \leq K(\mu^2 + |\xi|^2), \qquad r(\xi, \mu) \geq r_*\sqrt{\mu^2 + |\xi|^2}$$

for all $(\xi, \mu) \in \mathbb{R}^{n-1} \times (0, \infty)$. The first estimate follows immediately from the definition of a_0. The second one is a consequence of the ellipticity of $[a_{jk}]_{1 \leq j,k \leq n}$. Finally, recall that w is uniformly positive definite; see section 3. Hence there is a positive constant $w_* > 0$ such that $(\mu^2 + w_0^{jk}\xi_j\xi_k) \geq w_*(\mu^2 + |\xi|^2)$ for all $(\xi, \mu) \in \mathbb{R}^{n-1} \times (0, \infty)$. This leads to an estimate

$$\begin{aligned} \mathrm{Re}\,\widetilde{g}_t(\xi, \mu) =&\ b_n^0 r(\xi, \mu)\left\{(1-t) + tk^0\,\frac{(\mu^2 + w_0^{jk}\xi_j\xi_k)}{\mu^2 + a_0(\xi)}\right\} \\ \geq&\ b_n^0 r_*\sqrt{\mu^2 + |\xi|^2}\left\{(1-t) + tk^0\,\frac{w_*(\mu^2 + |\xi|^2)}{K(\mu^2 + |\xi|^2)}\right\} \\ \geq&\ b_n^0 r_*\sqrt{\mu^2 + |\xi|^2}\{(1-t) + tk_*\}, \end{aligned}$$

where $k_* := k^0 K^{-1} w_* > 0$. Now, letting

$$\alpha_* := r_* b_n^0 \min\{1, k_*\} > 0,$$

we find that $\widetilde{g}_t \in \mathcal{E}ll\mathcal{S}_1^\infty(\alpha_*)$ for all $t \in [0,1]$. Now the assertion is implied by a general result due to Amann, which in particular states that given $a \in \mathcal{E}ll\mathcal{S}_1^\infty(\alpha_*)$ and $\mu_0 > 0$; it follows that $a(\cdot, \mu_0) \in \mathcal{H}(h^{2+\alpha}(\mathbb{R}^{n-1}), h^{1+\alpha}(\mathbb{R}^{n-1}))$; see [3]. □

5. Perturbations. In this section we prove that, given $\rho \in \mathcal{V}$, the linearization $-\partial\Phi(\rho)$ of $-\Phi$ at ρ generates a strongly continuous analytic semigroup on $h^{1+\alpha}(\Gamma)$. The main technical tool is a perturbation result contained in Lemma 5.1. To state this result we need some preparation. First let

$$\partial\Phi_t(\rho) := t\partial\Phi(\rho) + (1-t)B(\rho)T(\rho)$$

for $\rho \in \mathcal{V}$ and $t \in [0,1]$. Obviously, $\partial\Phi_t(\rho)$ is a convex combination connecting $\partial\Phi(\rho)$ and the Dirichlet–Neumann operator $B(\rho)T(\rho)$; see [11].

Next, given $\kappa \in (0,a]$, choose smooth test functions $\psi_l \in \mathcal{D}(U_l)$ such that $\{(U_l,\psi_l)\ ;\ 1 \le l \le m_\kappa\}$ is a partition of unity on $\mathcal{R}_\kappa$; see section 3 for the definition of $\mathcal{R}_\kappa$. Call such a family $\{(U_l,\psi_l)\ ;\ 1 \le l \le m_\kappa\}$ a (finite) *localization sequence* for $\mathcal{R}_\kappa$. Moreover, we fix $\hat{x}_l \in \Gamma$ such that $\hat{x}_l \in U_l$, $l = 1,\dots,m_\kappa$. We may further assume that $\mu_l(0) = \hat{x}_l$ for $l = 1,\dots,m_\kappa$.

To economize our notation, the symbols $|\cdot|_s$ and $\|\cdot\|_s$ are exclusively used for the norms in $h^s(\mathbb{R}^{n-1})$ and $h^s(\Gamma)$, respectively.

Finally, throughout this section we fix $\rho \in \mathcal{V}$ and $\beta \in (0,\alpha)$.

LEMMA 5.1. *Given $\varepsilon > 0$, there exists $\kappa \in (0,a]$, a localization sequence $\{(U_l,\psi_l);$ $1 \le l \le m_\kappa\}$ for $\mathcal{R}_\kappa$, and a positive constant $C := C(\rho,\varepsilon,\kappa)$ such that*

$$|\mu_l^*(\psi_l\partial\Phi_t(\rho)h) - \mathcal{G}_t(\rho,l)\mu_l^*(\psi_l h)|_{1+\alpha} \le \varepsilon|\mu_l^*(\psi_l h)|_{2+\alpha} + C\|h\|_{2+\beta}$$

for all $h \in h^{2+\alpha}(\Gamma)$, $l \in \{1,\dots,m_\kappa\}$, and $t \in [0,1]$.

Proof. (a) We fix $\rho \in \mathcal{V}$, $l \in \{1,\dots,m_\kappa\}$ and suppress the pair (ρ,l) in our notation. Moreover, given $\varepsilon > 0$ and $\beta \in (0,\alpha)$, we only show explicitly the existence of a positive constant C such that

$$|\mu^*(\psi BSKh) - \mathcal{B}_0\mathcal{S}_0\mathcal{K}_0\mu^*(\psi h)|_{1+\alpha} \le \varepsilon|\mu^*(\psi h)|_{2+\alpha} + C\|h\|_{2+\beta}$$

for all $h \in h^{2+\alpha}(\Gamma)$. The remaining two terms

$$|\mu^*(\psi BTh) - \mathcal{B}_0\mathcal{T}_0\mu^*(\psi h)|_{1+\alpha}, \qquad |\mu^*(\psi Mh) - \mathcal{M}_0\mu^*(\psi h)|_{1+\alpha}$$

can be estimated similarly (and are even easier to handle). Our argumentation follows the proof of Lemma 6.1 in [12] and uses in particular obvious generalizations of Lemmas 6.5, 6.6, and 6.7 in [12] to the n-dimensional case.

(b) Choose a smooth test-function $\chi \in \mathcal{D}(U)$ such that $\chi|\mathrm{supp}(\psi) = 1$. Then we have

$$\mu^*\psi BSK - \mathcal{B}_0\mathcal{S}_0\mathcal{K}_0\mu^*\psi = \mu^*\chi BSK\psi - \mathcal{B}_0\mathcal{S}_0\mathcal{K}_0\mu^*\chi\psi - \mu^*\chi[BSK,\psi],$$

where ψ and χ also denote the linear operators induced by pointwise multiplication by ψ and χ, respectively, and where $[A,B] := AB - BA$ denotes the commutator of A and B. It follows, essentially from Leibniz' rule (see Lemma 6.5(b) in [12]), that there exists a positive constant C such that

$$\|[BSK,\psi]h\|_{1+\alpha} \le C\|h\|_{2+\beta}, \qquad h \in h^{2+\alpha}(\Gamma).$$

Hence, it suffices to estimate the operator

$$\mu^*\chi BSK - \mathcal{B}_0\mathcal{S}_0\mathcal{K}_0\mu^*\chi.$$

In addition, we split that operator in the following way:

$$\mu^*\chi BSK - \mathcal{B}_0\mathcal{S}_0\mathcal{K}_0\mu^*\chi = \mu^*\chi BSK - \mathcal{B}_0\mu^*\chi SK + \mathcal{B}_0\{\mu^*\chi S - \mathcal{S}_0\mu^*\chi\}K + \mathcal{B}_0\mathcal{S}_0\{\mu^*\chi K - \mathcal{K}_0\mu^*\chi\}. \tag{5.1}$$

(c) Let us start with the first term $\mu^*\chi BSK - \mathcal{B}_0\mu^*\chi SK$. Again, by Leibniz' rule, the commutator $[\mu^*\chi, \mathcal{B}_0]$ can be estimated as

$$|[\mu^*\chi, \mathcal{B}_0]u|_{1+\alpha} \le C|u|_{1+\alpha,H^n}, \qquad u \in h^{2+\alpha}(\mathrm{H}^n). \tag{5.2}$$

Thus we are left to control the operator $\mu^*\chi B - (\mu^*\chi)\mathcal{B}_0\mu^*$. By the definition of $\mathcal{B}$ we get the formula

$$\mu^*\chi B - (\mu^*\chi)\mathcal{B}_0\mu^* = (\mu^*\chi)\{\mathcal{B} - \mathcal{B}_0\}\mu^*. \tag{5.3}$$

But, as in [12, Lemma 6.7(a)], we find positive constants C and C_κ such that

$$\begin{aligned} |(\mu^*\chi)\{1 + \mathcal{A}_0 - \mathcal{A}\}(\mu^* v)|_{\alpha,H^n} &+ |(\mu^*\chi)\{\mathcal{B} - \mathcal{B}_0\}(\mu^* v)|_{1+\alpha} \\ &\le C\kappa^{1-\alpha}\|v\|_{2+\alpha,\Omega} + C_\kappa\|v\|_{1+\alpha,\Omega} \end{aligned} \tag{5.4}$$

for all $v \in h^{2+\alpha}(\Omega)$. Finally, observe that

$$S \in \mathcal{L}(h^\gamma(\Omega), h^{2+\gamma}(\Omega)), \qquad K \in \mathcal{L}(h^{2+\gamma}(\Gamma), h^\gamma(\Omega)) \tag{5.5}$$

for $\gamma \in [\beta, \alpha]$ and that

$$\mu^* \in \mathrm{Diff}^\infty(h^{2+\alpha}(\Gamma \cap U), h^{2+\alpha}(P)). \tag{5.6}$$

Combining (5.2)–(5.6), we can find a $\kappa_1 \in (0, a]$ and a positive constant C such that

$$|\mu^*(\chi BSKg) - \mathcal{B}_0\mu^*(\chi SKg)|_{1+\alpha} \le \frac{\varepsilon}{3}|\mu^* g|_{2+\alpha} + C\|g\|_{2+\beta} \tag{5.7}$$

for all $g \in h^{2+\alpha}(\Gamma \cap U)$.

(d) In a next step we estimate the operator $\mu^*\chi S - \mathcal{S}_0\mu^*\chi$. To achieve this, we use the representation

$$\mu^*\chi S - \mathcal{S}_0\mu^*\chi = \mathcal{S}_0\big\{[\mathcal{A}_0, \mu^*\chi]\mu^* S + (\mu^*\chi)\{1 + \mathcal{A}_0 - \mathcal{A}\}\mu^* S\big\}, \tag{5.8}$$

which follows from Lemma 6.6 in [12]. Again, the operator $[\mathcal{A}_0, \mu^*\chi]$ is of lower order in the sense that there exists a positive constant C such that

$$|[\mathcal{A}_0, \mu^*\chi]u|_{\alpha,\mathring{Q}} \le C|u|_{1+\alpha,\mathring{Q}}, \qquad u \in h^{1+\alpha}(\mathring{Q}). \tag{5.9}$$

Hence, it follows from (5.4), (5.5), (5.6), (5.8), and (5.9) that there is a $\kappa_2 \in (0, a]$ such that

$$|\mathcal{B}_0\big\{\mu^*(\chi SKg) - \mathcal{S}_0\mu^*(\chi Kg)\big\}|_{1+\alpha} \le \frac{\varepsilon}{3}|\mu^* g|_{2+\alpha} + C\|g\|_{2+\beta} \tag{5.10}$$

for all $g \in h^{2+\alpha}(\Gamma \cap U)$.

(e) From Lemma 3.2 we know that

$$\mu^*\chi K - \mathcal{K}_0\mu^*\chi = (\mu^*\chi)\{\mathcal{K} - \mathcal{K}_0\}\mu^* + [\mu^*\chi, \mathcal{K}_0]\mu^*.$$

But here again, it follows from Leibniz' rule that there is a $C > 0$ such that

$$|[\mu^*\chi, \mathcal{K}_0]\mu^* g|_{\alpha,H^n} \leq C\|g\|_{1+\alpha}, \qquad g \in h^{2+\alpha}(\Gamma \cap U). \tag{5.11}$$

Finally, we infer from Lemma 6.7(b) in [12] that there are positive constants C and C_κ such that

$$|(\mu^*\chi)\{\mathcal{K} - \mathcal{K}_0\}g|_{\alpha,H^n} \leq \kappa^{1-\alpha}C|\mu^* g|_{2+\alpha} + C_\kappa\|g\|_{1+\alpha} \tag{5.12}$$

for all $g \in h^{2+\alpha}(\Gamma \cap U)$. Since $\mathcal{B}_0\mathcal{S}_0 \in \mathcal{L}(h^\alpha(\mathrm{H}^n), h^{1+\alpha}(\Gamma))$, we conclude from (5.11) and (5.12) that there is a $\kappa_3 \in (0, a]$ and a $C > 0$ such that

$$|\mathcal{B}_0\mathcal{S}_0\big\{\mu^*\chi K - \mathcal{K}_0\mu^*\chi\big\}g|_{1+\alpha} \leq \frac{\varepsilon}{3}|\mu^* g|_{2+\alpha} + C\|g\|_{2+\beta} \tag{5.13}$$

for all $g \in h^{2+\alpha}(\Gamma \cap U)$. Now, letting $\kappa := \min\{\kappa_1, \kappa_2, \kappa_3\}$, the assertion follows from (5.7), (5.10), and (5.13). □

THEOREM 5.2. *We have*

$$\partial\Phi_t(\rho) \in \mathcal{H}(h^{2+\alpha}(\Gamma), h^{1+\alpha}(\Gamma)), \qquad \rho \in \mathcal{V}, \quad t \in [0,1].$$

Proof. (a) In a first step we provide a parameter-dependent a priori estimate for $\partial\Phi_t(\rho)$. To begin with, we know from Theorem 4.2 that there are positive constants λ_1 and C_1, independent of $\kappa \in (0, a]$ and $l \in \{1, \dots, m_\kappa\}$, such that

$$|g|_{2+\alpha} + |\lambda||g|_{1+\alpha} \leq C_1|(\lambda + \mathcal{G}_t(\rho, l))g|_{1+\alpha} \tag{5.14}$$

for all $g \in h^{2+\alpha}(\mathbb{R}^{n-1})$, $\lambda \in [\operatorname{Re} z \geq \lambda_1]$, and $l \in \{1, \dots, m_\kappa\}$. Furthermore, Lemma 5.1 guarantees the existence of positive constants κ, C_2, and a localization sequence $\{(U_l, \psi_l)\,;\, 1 \leq l \leq m_\kappa\}$ such that

$$|\mu_l^*\big(\psi_l\partial\Phi_t(\rho)h\big) - \mathcal{G}_t(\rho, l)\mu_l^*(\psi_l h)|_{1+\alpha} \leq \frac{1}{2C_1}|\mu_l^*(\psi_l h)|_{2+\alpha} + C_2\|h\|_{2+\beta}$$

for all $h \in h^{2+\alpha}(\Gamma)$, $l \in \{1, \dots, m_\kappa\}$, and $t \in [0,1]$. Consequently, it follows from (5.14) that

$$\begin{aligned} |\mu_l^*(\psi_l h)|_{2+\alpha} &+ |\lambda||\mu_l^*(\psi_l h)|_{1+\alpha} \\ &\leq 2C_1\big\{|\mu_l^*\big(\psi_l(\lambda + \partial\Phi_t(\rho))h\big)|_{1+\alpha} + C_2\|h\|_{2+\beta}\big\} \end{aligned} \tag{5.15}$$

for all $h \in h^{2+\alpha}(\Gamma)$, $\lambda \in [\operatorname{Re} z \geq \lambda_1]$, $l \in \{1, \dots, m_\kappa\}$, and $t \in [0,1]$. Next observe that

$$\big[h \mapsto \max_{1 \leq l \leq m_\kappa} |\mu_l^*(\psi_l h)|_{k+\alpha}\big]$$

defines an equivalent norm on $h^{k+\alpha}(\Gamma)$, $k = 1, 2$, due to the fact that the family $\{(U_l, \psi_l)\,;\, 1 \leq l \leq m_\kappa\}$ is a localization sequence for $\mathcal{R}_\kappa$; see [24]. Hence (5.15) implies the existence of a positive constant C such that

$$\|h\|_{2+\alpha} + |\lambda|\|h\|_{1+\alpha} \leq \frac{C}{2}\|(\lambda + \partial\Phi_t(\rho))h\|_{1+\alpha} + C\|h\|_{2+\beta} \tag{5.16}$$

for all $h \in h^{2+\alpha}(\Gamma)$, $\lambda \in [\operatorname{Re} z \geq \lambda_1]$, and $t \in [0,1]$.

Finally, let $(\cdot,\cdot)^0_{\theta,\infty}$ denote the continuous interpolation functor of Da Prato and Grisvard; see [6]. It is known that

$$h^{2+\beta}(\Gamma) = \big(h^{1+\alpha}(\Gamma), h^{2+\alpha}(\Gamma)\big)^0_{1-\alpha+\beta,\infty}. \tag{5.17}$$

Hence there exists a positive constant C_3 such that

$$\|h\|_{2+\beta} \le \frac{1}{2C}\|h\|_{2+\alpha} + C_3\|h\|_{1+\alpha}, \qquad h \in h^{2+\alpha}(\Gamma).$$

Now we conclude from (5.17) that

$$\|h\|_{2+\alpha} + |\lambda|\|h\|_{1+\alpha} \le C\|(\lambda + \partial\Phi_t(\rho))h\|_{1+\alpha} \tag{5.18}$$

for all $h \in h^{2+\alpha}(\Gamma)$, $\lambda \in [\operatorname{Re} z \ge \lambda_*]$, and $t \in [0,1]$, where we have set $\lambda_* := 2\max\{\lambda_1, CC_3\}$.

(b) In view of (4.12) and (5.18), it remains to prove that $\partial\Phi_t(\rho)$ is surjective for each $t \in [0,1]$. Moreover, since the estimate (5.18) is uniform in $t \in [0,1]$, a well-known homotopy argument (see Theorem 5.2 in [17]) implies that it is sufficient to prove that $\partial\Phi_0(\rho)$ is onto. Thus, let $g \in h^{1+\alpha}(\Gamma)$ be given. Then we find, as in the proof of Lemma 2.4, a unique $v \in h^{2+\alpha}(\Omega)$ such that

$$\big(A(\rho), \lambda_*\gamma + B(\rho), C\big)v = (0, g, 0). \tag{5.19}$$

The first and the third components of this identity imply that

$$T(\rho)\gamma v = \big(A(\rho), \gamma, B(\rho)\big)^{-1}(0, \gamma v, 0) = v;$$

see section 2 for the definition of the operator $T(\rho)$. Now, putting $h := \gamma v \in h^{2+\alpha}(\Gamma)$, the second component of (5.19) gives

$$\big(\lambda_* + B(\rho)T(\rho)\big)h = \big(\lambda_*\gamma + B(\rho)\big)v = g,$$

which completes our argumentation. □

Remark 5.3. Let $\rho \in \mathcal{V}$ be given. Then the proofs of Theorems 4.2 and 5.2 show that $-\partial\Phi(\rho)$ does not generate a strongly continuous semigroup on $h^{1+\alpha}(\Gamma)$ if $b \in h^{2+\alpha-\delta}(J)\backslash\{0\}$ is nonpositive. Hence, for such b, the linearized evolution equation for the moving boundary

$$\partial_t\sigma + \partial\Phi(\rho)\sigma = 0, \qquad \sigma(0) = \sigma_0$$

is not well posed in $h^{1+\alpha}(\Gamma)$ in the sense of Hadamard.

Proof of Theorem 1. Let $\rho_0 \in \mathcal{V}$ be given. Thanks to Lemmas 2.2 and 2.5 we only have to prove the existence and uniqueness of a classical Hölder solution of (2.5). To show this, fix $\beta \in (0,\alpha)$. Then it follows from Theorem 5.2 that

$$\partial\Phi(\rho) \in \mathcal{H}(h^{2+\gamma}(\Gamma), h^{1+\gamma}(\Gamma)), \quad \rho \in \mathcal{V},\ \gamma \in [\beta,\alpha].$$

From this and the known fact that little Hölder spaces are stable under continuous interpolation one finds that

$$\partial\Phi(\rho) \in \mathcal{M}_1(h^{2+\alpha}(\Gamma), h^{1+\alpha}(\Gamma)), \qquad \rho \in \mathcal{V}, \tag{5.20}$$

where $\mathcal{M}_1(E_1, E_0)$ denotes the class of all operators in $\mathcal{L}(E_1, E_0)$, having the property of maximal regularity in the sense of Da Prato and Grisvard [6]; see also [4] and [23]. The assertions now follow from Theorem 2.7 in [4].

Acknowledgments. The authors would like to thank Sigurd Angenent for helpful suggestions leading to an improvement of preliminary results. In addition, we thank the referee for carefully reading the manuscript and for suggesting some improvements.

A DEGENERATE PARABOLIC-HYPERBOLIC SYSTEM MODELING THE SPREADING OF SURFACTANTS*

MICHAEL RENARDY[†]

Abstract. We consider the initial-boundary value problem for a coupled parabolic-hyperbolic system for which the parabolic part degenerates. The problem arises in studying the spreading of surfactants on thin films, and the degeneracy occurs if either the surfactant concentration or the film height vanishes. Both cases will be considered. If the film height vanishes, the front does not advance. If, on the other hand, the surfactant concentration vanishes, then solutions with stationary or moving fronts are possible.

Key words. surfactant spreading, degenerate parabolic equations, parabolic-hyperbolic systems

AMS subject classifications. 35K65, 35Q35, 76D45

PII. S0036141096299120

1. Introduction.

We consider the spreading of a surfactant on a thin fluid film. The equations modeling this problem were introduced in [3], motivated by an application involving the medical treatment of premature infants. It is assumed that the flow in the film is driven entirely by the shear stress resulting from surface tension gradients, and that the surfactant is advected with the flow. Under these assumptions, the equations of motion, in dimensionless form, are [3]

$$h_t + \operatorname{div}\left(\frac{h^2}{2}\nabla\sigma(\Gamma)\right) = 0,$$

$$\Gamma_t + \operatorname{div}\left(h\Gamma\nabla\sigma(\Gamma)\right) = 0. \tag{1}$$

Here h is the film thickness, Γ is the surfactant concentration, and σ is the concentration-dependent surface tension coefficient. For a surfactant, $\sigma'(\Gamma) < 0$.

From a mathematical point of view, equations (1) form a parabolic-hyperbolic system. Even in the absence of molecular diffusion of the surfactant, there is an effective diffusion associated with the spreading of surfactant by the self-induced flow. This diffusion, however, is present only if both h and Γ are positive, and hence the parabolic part of the equation degenerates if either h or Γ vanishes. If molecular diffusion is added, this degeneracy is removed.

In earlier work [6], we have studied the case of positive molecular diffusion, where the parabolic equation is nondegenerate. The well-posedness of initial and initial-boundary value problems was established. In addition, it was shown that shocks associated with the hyperbolic part of the equation can develop from smooth data in finite time. For this result, it is essential that molecular diffusion be present; if it is zero, then hyperbolic shocks are impossible. The fronts which will arise in this paper are fundamentally different from hyperbolic shocks, even though they also involve

A part of this research was carried out while the author was visiting the Isaac Newton Institute, University of Cambridge.

jumps in h and Γ_x; they are associated with the parabolic part of the problem, rather than the hyperbolic part.

Throughout this paper, we shall be concerned with "smooth" solutions. Although there is an extensive literature on degenerate parabolic equations (see [4] for an overview), results guaranteeing the existence of smooth solutions seem to be known only in one space dimension [1], [2], [5]. We therefore consider only the one-dimensional case of (1):

$$h_t + \frac{1}{2}(h^2\sigma(\Gamma)_x)_x = 0,$$

$$\Gamma_t + (h\Gamma\sigma(\Gamma)_x)_x = 0. \tag{2}$$

We seek solutions for $t > 0$, on the interval $0 < x < \phi(t)$, where $\phi(t)$ is an unknown free boundary. We have initial conditions

$$\phi(0) = 1,\ h(x,0) = h_0(x),\ \Gamma(x,0) = \Gamma_0(x). \tag{3}$$

It is understood that h_0 and Γ_0 are strictly positive except at the right end point, where either $h_0(1) = 0$ or $\Gamma_0(1) = 0$. In the first case, $\phi(t) = 1$ for $t > 0$, while in the second case, $\phi(t)$ has to be determined as part of the problem, subject to the condition

$$\Gamma(\phi(t), t) = 0. \tag{4}$$

At the left end point we shall impose, for simplicity, a no-flux condition,

$$\Gamma_x(0,t) = 0. \tag{5}$$

Following the lead of [6], we make the transformation $h = \Gamma^{1/2}p$. This leads to the new set of equations

$$p_t - \frac{1}{4}\Gamma^{-1/2}\Gamma_x p^2\sigma(\Gamma)_x + \frac{1}{2}\Gamma^{1/2}pp_x\sigma(\Gamma)_x = 0,$$

$$\Gamma_t + (p\Gamma^{3/2}\sigma(\Gamma)_x)_x = 0. \tag{6}$$

The effect of the transformation is an uncoupling of the hyperbolic and parabolic parts of the equation; note that the equation for p in (6) contains no second derivatives of Γ and can be viewed as a first-order hyperbolic equation for p when Γ is given.

2. Fronts with vanishing film thickness. In this section, we consider solutions for which $\phi(t) = 1$ for all t and $h(1) = p(1) = 0$. In (6), we substitute $p(x,t) = (1-x)q(x,t)$, leading to the new set of equations:

$$q_t - \frac{1}{4}(1-x)\Gamma^{-1/2}\Gamma_x q^2\sigma(\Gamma)_x - \frac{1}{2}\Gamma^{1/2}q^2\sigma(\Gamma)_x$$

$$+\frac{1}{2}(1-x)\Gamma^{1/2}\sigma(\Gamma)_x qq_x = 0,$$

$$\Gamma_t + ((1-x)q\Gamma^{3/2}\sigma(\Gamma)_x)_x = 0. \tag{7}$$

To complement these equations, we have the initial conditions

$$\Gamma(x,0)=\Gamma_0(x), \qquad q(x,0)=q_0(x), \tag{8}$$

and we assume that Γ_0 and q_0 are smooth and strictly positive. In addition, we have the boundary condition

$$\Gamma_x(0,t)=0; \tag{9}$$

no boundary condition is needed at $x=1$.

To solve (7)–(9), we employ the iteration

$$q_t^{n+1}-\frac{1}{4}(1-x)(\Gamma^n)^{-1/2}\Gamma_x^n(q^n)^2\sigma(\Gamma^n)_x-\frac{1}{2}(\Gamma^n)^{1/2}(q^n)^2\sigma(\Gamma^n)_x$$

$$+\frac{1}{2}(1-x)(\Gamma^n)^{1/2}\sigma(\Gamma^n)_x q^n q_x^{n+1}=0,$$

$$\Gamma_t^{n+1}+((1-x)q^n(\Gamma^n)^{3/2}\sigma'(\Gamma^n)\Gamma_x^{n+1})_x=0. \tag{10}$$

To formulate results, we need to define some function spaces. Let

$$X_k=\{u\,|\,u\in H^{k-1}(0,1),\ (1-x)u^{(k)}\in L^2(0,1)\}. \tag{11}$$

Moreover, we define $\|\cdot\|_{k,p,l}$ as the norm of a function in $W^{l,p}((0,T);X_k)$. Let Z_M be the set of all (q,Γ) such that

$$q\in\bigcap_{i=1}^{k+1}W^{k+1-i,\infty}((0,T);X_i)\cap H^{k+1}((0,T),X_0),$$

$$\Gamma\in\bigcap_{i=2}^{k+2}H^{k+2-i}((0,T);X_i)\cap H^{k+1}((0,T),X_0),$$

$$\|q\|_{0,2,k+1}+\sum_{i=1}^{k+1}\|q\|_{i,\infty,k-i+1}+\|\Gamma\|_{0,2,k+1}+\sum_{i=2}^{k+2}\|\Gamma\|_{i,2,k+2-i}\le M,$$

$$q(x,0)=q_0(x),\quad \Gamma(x,0)=\Gamma_0(x),\quad \Gamma_x(0,t)=0,$$

$$\text{The time derivatives of } q \text{ and } \Gamma \text{ up to order } k$$

$$\text{satisfy the appropriate initial condition.} \tag{12}$$

By the latter condition, we mean that the initial values of time derivatives agree with those which can be derived from the equations (7) and initial conditions (8).

The solution will be constructed as a fixed point of the iteration (10) via the contraction mapping theorem. Let $\mathcal{S}$ denote the mapping $(q^n,\Gamma^n)\mapsto(q^{n+1},\Gamma^{n+1})$, which is defined by (10) in conjunction with the initial condition (8) and boundary condition (9).

LEMMA 2.1. *Assume that Γ_0 and q_0 are strictly positive and sufficiently smooth, that the function $\Gamma \mapsto \sigma(\Gamma)$ is smooth, and that $\sigma' < 0$. Moreover, assume $k \geq 2$. Finally, assume that $\Gamma_0'(0) = 0$ and that the initial values for all time derivatives of Γ up to order $k-1$ are also compatible with the boundary condition* (9). *If M is chosen sufficiently large, and T is sufficiently small relative to M, then $\mathcal{S}$ maps Z_M into itself.*

Remark. In stating the result, we have been deliberately vague about the required smoothness of the initial data. Basically, the smoothness required of the initial data is the same as is recovered by the solution. However, this involves time derivatives of q and Γ as well as the functions themselves, and the initial values of time derivatives depend on q_0 and Γ_0 in a very complicated fashion. Hence a precise smoothness condition on q_0 and Γ_0 would be very awkward to state.

We now sketch the proof of the lemma. The first equation of (10) has the simple form

$$q_t^{n+1} + g^n q_x^{n+1} + f^n = 0; \tag{13}$$

i.e., it is simply a first-order hyperbolic equation. Since g^n vanishes at both end points, no boundary conditions are required. A simple energy estimate yields that

$$\int_0^1 (q^{n+1}(x,t))^2\,dx = \int_0^1 q_0(x)^2\,dx + \frac{1}{2}\int_0^t \int_0^1 g_x^n(x,\tau)(q^{n+1}(x,\tau))^2\,dx\,d\tau$$

$$- \int_0^t \int_0^1 f^n(x,\tau) q^{n+1}(x,\tau)\,dx\,d\tau. \tag{14}$$

This yields a bound for the L^2-norm of q^{n+1}. In a similar fashion, we can obtain a bound for the L^2-norm of $(1-x)q^{n+1}$, if we first multiply (13) by $(1-x)$. We can obtain analogous bounds for spatial and temporal derivatives of q^{n+1} by taking derivatives of (12); note that the initial values of any derivative of q^{n+1} or Γ^{n+1} depend only on q_0 and Γ_0. In this fashion, we recursively obtain an estimate of the form

$$\sum_{i=1}^{k+1} \|q\|_{i,\infty,k-i+1} \leq C\left(\sum_{i=1}^{k+1} \|f\|_{i,1,k-i+1} + \sum_{i=1}^{k} \|g\|_{i,1,k-i} \sum_{i=1}^{k+1} \|q\|_{i,\infty,k-i+1}\right) + C_0, \tag{15}$$

where C_0 depends only on the initial conditions. We can bound the right-hand side of (15) by

$$C\sqrt{T}\left(\sum_{i=1}^{k+1} \|f\|_{i,2,k-i+1} + \sum_{i=1}^{k} \|g\|_{i,2,k-i} \sum_{i=1}^{k+1} \|q\|_{i,\infty,k-i+1}\right) + C_0, \tag{16}$$

and by using this and choosing T sufficiently small, we finally obtain a bound of the form

$$\sum_{i=1}^{k+1} \|q\|_{i,\infty,k-i+1} \leq C\sqrt{T} \sum_{i=1}^{k+1} \|f\|_{i,2,k-i+1} + C_0. \tag{17}$$

Finally, we can get a bound on the $(k+1)$st time derivative of q from the equation itself, and we find that $\|q\|_{0,2,k+1}$ is also bounded by an expression of the form (17).

The second equation of (10) has the form

$$\Gamma_t^{n+1} + (s^n \Gamma_x^{n+1})_x = 0; \tag{18}$$

since we also need to consider time derivatives of this equation, we look at the more general form

$$\Gamma_t + (s\Gamma_x)_x = v, \tag{19}$$

with given s and v. Here s is negative and proportional to $1-x$ as $x \to 1$. We multiply (19) with $(s\Gamma_x)_x$ and integrate. After an integration by parts this yields

$$-\frac{1}{2}\int_0^1 s(x,t)\Gamma_x(x,t)^2\,dx + \frac{1}{2}\int_0^1 s(x,0)\Gamma_0'(0)^2\,dx + \frac{1}{2}\int_0^t\int_0^1 s_t(x,\tau)\Gamma_x(x,\tau)^2\,dx\,d\tau$$

$$+\int_0^t\int_0^1 [(s(x,\tau)\Gamma_x(x,\tau))_x]^2\,dx\,d\tau = \int_0^t\int_0^1 v(x,\tau)(s(x,\tau)\Gamma_x(x,\tau))_x\,dx\,d\tau. \tag{20}$$

Noting that

$$\|\Gamma_x\|_{L^2(0,1)} \le C\|(1-x)\Gamma_x\|_{H^1(0,1)}, \tag{21}$$

we can use (20) to get a bound on $\|\Gamma\|_{2,2,0}$ in terms of v and s:

$$\|\Gamma\|_{2,2,0} \le C\|v\|_{L^2((0,T)\times(0,1))} + C_0. \tag{22}$$

We use this bound on the second equation of (10) and its first k time derivatives. After estimating time derivatives of Γ^{n+1}, we can get bounds for spatial derivatives by exploiting the equation and (21).

The lemma follows by combining the estimates sketched above. We omit the tedious but straightforward details.

On Z_M, we now define a distance function by using a weaker norm than that in (12):

$$d((q,\Gamma),(\tilde{q},\tilde{\Gamma})) = \|q-\tilde{q}\|_{0,2,k} + \sum_{i=1}^{k}\|q-\tilde{q}\|_{i,\infty,k-i} + \|\Gamma-\tilde{\Gamma}\|_{0,2,k}$$

$$+\sum_{i=2}^{k+1}\|\Gamma-\tilde{\Gamma}\|_{i,2,k+1-i}. \tag{23}$$

We now consider two equations of the form (10) and estimate the difference of the solutions. By using the a priori bounds already established in Lemma 2.1 and using similar estimates as above, one can show the following.

Lemma 2.2. *Let the assumptions be as in Lemma* 2.1. *If T is sufficiently small relative to M, then $\mathcal{S}$ is a contraction in Z_M with the metric defined by d.*

Since Z_M with the metric d is a complete metric space, the mapping $\mathcal{S}$ has a unique fixed point, which is the solution we seek.

3. Stationary fronts with vanishing concentration. We now consider the case where $\Gamma = 0$ at $x = 1$, and $h \neq 0$. For this situation, we substitute $\Gamma(x,t) = (1-x)^2\Phi(x,t)$, $p(x,t) = (1-x)^{-1}q(x,t)$. This leads to the equations

$$q_t + \sigma'((1-x)^2\Phi)\left(-\frac{1}{4}\Phi^{-1/2}q^2(1-x)^2\Phi_x^2 + \frac{3}{2}\Phi^{1/2}\Phi_x q^2(1-x) - 2\Phi^{3/2}q^2\right.$$
$$\left.+\frac{1}{2}\Phi^{1/2}\Phi_x(1-x)^2 qq_x - \Phi^{3/2}(1-x)qq_x\right) = 0,$$
$$\Phi_t - 3q\Phi^{3/2}\sigma'((1-x)^2\Phi)((1-x)\Phi_x - 2\Phi)$$
$$+(1-x)[q\Phi^{3/2}\sigma'((1-x)^2\Phi)((1-x)\Phi_x - 2\Phi)]_x = 0. \tag{24}$$

We note that for $x = 1$, we obtain the system of ODEs

$$\dot{q} = 2\Phi^{3/2}q^2\sigma'(0), \qquad \dot{\Phi} = -6q\Phi^{5/2}\sigma'(0). \tag{25}$$

We find from this that $q^3\Phi$ is constant; i.e., q is a multiple of $\Phi^{-1/3}$. Note that $\sigma'(0)$ is negative, and q and Φ are positive quantities. If we prescribe any strictly positive initial data, then (25) will lead to finite time blow up of $\Phi(1)$. Hence solutions with a stationary front can only exist for a finite time, and eventually the front will begin to advance. This behavior is well known for the porous media equation.

We can transform (24) to a nondegenerate parabolic-hyperbolic system on an infinite interval by using the substitution $1 - x = \exp(-y)$ so that y ranges from 0 to ∞. Note that

$$(1-x)\frac{\partial}{\partial x} = \frac{\partial}{\partial y}, \tag{26}$$

so the transformation indeed leads to a nondegenerate parabolic equation. A local time existence result for smooth solutions of the nondegenerate system can then be established along the lines of [6]. The issue remains whether a solution which is "smooth" as a function of y is also smooth in terms of the original variable x. From (26), we see that, for instance, Γ_x is in L^2 if $\Gamma_y \exp(y/2)$ is in L^2. Hence smoothness with respect to x translates into exponential decay with respect to y. Similarly, higher order smoothness means that the solution has an asymptotic expansion in powers of $\exp(-y)$, with sufficiently rapid decay of the remainder. It is easy to adapt the analysis of [6] to exponentially weighted spaces and thus obtain an existence result for solutions which are smooth in x. It should be stressed, however, that solutions will decay exponentially with respect to y only if such exponential decay is already present in the initial data (i.e., q_0 and Γ_0 exponentially approach a constant as $y \to \infty$). No exponential decay in y (and hence no smoothness in x) is created by the differential equation.

4. Advancing fronts with vanishing concentration. We now consider an advancing front at the location $x = \phi(t)$. We first transform the problem to a fixed domain. Since we impose a no-flux condition at $x = 0$, the total amount of surfactant,

$$M_\Gamma = \int_0^{\phi(t)} \Gamma(x,t)\,dx, \tag{27}$$

remains constant. We now set

$$y^2 = M_\Gamma - \int_0^x \Gamma(z,t)\,dz, \tag{28}$$

and we use y as an independent variable in place of x. Note that y ranges over the fixed interval $[0, \sqrt{M_\Gamma}]$, and the front is now at $y = 0$. We find

$$\frac{\partial y}{\partial x} = -\frac{\Gamma}{2y},$$

$$\frac{\partial y}{\partial t} = -\frac{1}{2y}\int_0^x \Gamma_t(z,t)\,dz = \frac{1}{2y}p\Gamma^{3/2}\sigma(\Gamma)_x = -\frac{1}{4y^2}\Gamma^{5/2}p\sigma(\Gamma)_y. \tag{29}$$

Using these relationships, we can evaluate derivatives using the chain rule:

$$\frac{\partial f}{\partial x} = \frac{\partial f}{\partial y}\frac{\partial y}{\partial x}, \qquad \frac{\partial f}{\partial t} = \frac{\partial f}{\partial t} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial t}. \tag{30}$$

In a slight abuse of notation, $\partial/\partial t$ denotes a time derivative for fixed x on the left-hand side, and a time derivative for fixed y on the right-hand side, of the last equation.

By using (30) in (6), we derive the new set of equations

$$p_t - \frac{1}{8y^2}\Gamma^{5/2}\sigma'(\Gamma)pp_y\Gamma_y - \frac{1}{16y^2}\Gamma^{3/2}\sigma'(\Gamma)p^2\Gamma_y^2 = 0,$$

$$\Gamma_t - \frac{1}{4y^2}\Gamma^{5/2}\sigma'(\Gamma)p\Gamma_y^2 + \frac{\Gamma}{2y}\left[\frac{1}{2y}\Gamma^{5/2}\sigma'(\Gamma)p\Gamma_y\right]_y = 0. \tag{31}$$

At an advancing front, we expect Γ to be proportional to $\phi(t) - x$, and hence proportional to y, while h approaches a finite limit, which makes p proportional to $y^{-1/2}$. We therefore substitute $p = y^{-1/2}q$, $\Gamma = y\Phi$, leading to the new equations

$$q_t - \frac{1}{16}\sigma'(y\Phi)\Phi^{5/2}q^2\Phi_y - \frac{1}{8}\sigma'(y\Phi)\Phi^{7/2}qq_y$$

$$-\frac{y}{8}\sigma'(y\Phi)\Phi^{5/2}qq_y\Phi_y - \frac{y}{16}\sigma'(y\Phi)\Phi^{3/2}q^2\Phi_y^2 = 0,$$

$$\Phi_t - \frac{1}{4}\sigma'(y\Phi)\Phi^{7/2}q\Phi_y - \frac{y}{4}\sigma'(y\Phi)\Phi^{5/2}q\Phi_y^2$$

$$+\frac{\Phi}{4}[\sigma'(y\Phi)\Phi^{5/2}q(y\Phi_y + \Phi)]_y = 0. \tag{32}$$

To complete the specification of the problem, we have initial conditions for Φ and q, which can be derived from (3):

$$\Phi(y,0) = \Phi_0(y), \qquad q(y,0) = q_0(y). \tag{33}$$

The no-flux boundary condition assumes the form

$$\Phi(\sqrt{M_\Gamma},t) + \sqrt{M_\Gamma}\Phi_y(\sqrt{M_\Gamma},t) = 0. \tag{34}$$

In addition, we need a boundary condition for the hyperbolic part of the equation at $y = 0$. To obtain such a boundary condition, we need to consider jump relations across the front. Suppose for simplicity that the front propagates into a film of uniform thickness so that $h = h_*$ ahead of the front. From (2), we find the Rankine–Hugoniot condition

$$-\phi'(t)[h] + \frac{1}{2}\sigma'(0)[h^2\Gamma_x] = 0. \tag{35}$$

Here $[\cdot]$ denotes the amount by which a quantity jumps across the front. The speed of the front is the speed with which the surfactant spreads, i.e.,

$$\phi'(t) = \sigma'(0)h\Gamma_x. \tag{36}$$

With h and Γ_x denoting values behind the front, (35) and (36) yield

$$-h\Gamma_x(h - h_*) + \frac{1}{2}h^2\Gamma_x = 0, \tag{37}$$

which simplifies to

$$h = \Phi^{1/2}q = 2h_*. \tag{38}$$

This is the boundary condition which we prescribe at $y = 0$. By evaluating (32) at $y = 0$, we obtain

$$q_t(0) - \frac{1}{16}\sigma'(0)\Phi^{5/2}(0)q^2(0)\Phi_y(0) - \frac{1}{8}\sigma'(0)\Phi^{7/2}q(0)q_y(0) = 0,$$

$$\Phi_t(0) + \frac{7}{8}\sigma'(0)\Phi^{7/2}(0)q(0)\Phi_y(0) + \frac{1}{4}\sigma'(0)\Phi^{9/2}q_y(0) + \frac{1}{4}\sigma''(0)\Phi^{11/2}q(0) = 0. \tag{39}$$

Moreover, (38) implies

$$\frac{1}{2}q\Phi_t + \Phi q_t = 0. \tag{40}$$

By combining (40) and (39), we find the simple condition

$$\Phi_y(0,t) + \frac{1}{3}\frac{\sigma''(0)\Phi^2(0,t)}{\sigma'(0)} = 0. \tag{41}$$

Although (32) is very similar to (7), we cannot use the same iteration. The crucial difference is that q_x in the second equation of (7) appears only in conjunction with a factor $1 - x$, while q_y in the second equation of (32) appears also without a factor y. It is basically for this reason that we need a different iteration and different estimates. To set up an iterative solution for (32), we first apply the operation

$$\frac{\partial}{\partial t} - \frac{1}{8}\sigma'(y\Phi)\Phi^{7/2}q\frac{\partial}{\partial y} - \frac{y}{8}\sigma'(y\Phi)\Phi^{5/2}\Phi_y q\frac{\partial}{\partial y} \tag{42}$$

to the second equation of (32) and then use the first equation of (32) to eliminate terms involving second derivatives of q and terms involving q_t. This yields an equation of the following form:

$$\Phi_{tt} + \Phi_{yt}\left(\frac{1}{2}\sigma'(y\Phi)\Phi^{7/2}q + yQ_1\right) - \Phi_{yy}\left(\frac{1}{16}(\sigma'(y\Phi))^2\Phi^7q^2 + yQ_2\right)$$

$$+\frac{1}{4}\sigma'(y\Phi)\Phi^{7/2}q(y\Phi_y)_{yt}-\frac{1}{32}(\sigma'(y\Phi))^2\Phi^7q^2(y\Phi_y)_{yy}$$

$$-\frac{y}{8}(\sigma'(y\Phi))^2\Phi^6q^2\Phi_y(y\Phi_y)_{yy}+Q_3=0, \tag{43}$$

where the Q_i are of the form

$$Q_i=Q_i(y,\Phi,q,\Phi_t,\Phi_y,q_y). \tag{44}$$

The iterative construction of solutions now proceeds as follows. We first determine a new iterate q^{n+1} from (32):

$$q_t^{n+1}-\frac{1}{16}\sigma'(y\Phi^n)(\Phi^n)^{5/2}(q^n)^2\Phi_y^n-\frac{1}{8}\sigma'(y\Phi^n)(\Phi^n)^{7/2}q^nq_y^{n+1}$$

$$-\frac{y}{8}\sigma'(y\Phi^n)(\Phi^n)^{5/2}q^nq_y^{n+1}\Phi_y^n-\frac{y}{16}\sigma'(y\Phi^n)(\Phi^n)^{3/2}(q^n)^2(\Phi_y^n)^2=0, \tag{45}$$

subject to the prescribed initial condition and the boundary condition

$$(\Phi^n)^{1/2}q^{n+1}=2h^* \tag{46}$$

at $y=0$. Then we determine a new iterate for Φ from (43) in the form

$$\Phi_{tt}^{n+1}+\Phi_{yt}^{n+1}\left(\frac{1}{2}\sigma'(y\Phi^n)(\Phi^n)^{7/2}q^n+yQ_1^n\right)-\Phi_{yy}^{n+1}\left(\frac{1}{16}(\sigma'(y\Phi^n))^2(\Phi^n)^7(q^n)^2+yQ_2^n\right)$$

$$+\frac{1}{4}\sigma'(y\Phi^n)(\Phi^n)^{7/2}q^n(y\Phi_y^{n+1})_{yt}-\frac{1}{32}(\sigma'(y\Phi^n))^2(\Phi^n)^7(q^n)^2(y\Phi_y^{n+1})_{yy}$$

$$-\frac{y}{32}(\sigma'(y\Phi^n))^2(\Phi^n)^6(q^n)^2\Phi_y^n(y\Phi_y^{n+1})_{yy}+Q_3^n=0, \tag{47}$$

where

$$Q_i^n=Q_i(y,\Phi^n,q^n,\Phi_t^n,\Phi_y^n,q_y^{n+1}). \tag{48}$$

To solve (47), we need initial conditions and the boundary conditions (34) and (41); the latter is implemented in the form

$$\Phi_y^{n+1}(0,t)+\frac{1}{3}\frac{\sigma''(0)(\Phi^n)^2(0,t)}{\sigma'(0)}=0. \tag{49}$$

At each step of the iteration, we must therefore first solve (45), which is simply a first-order hyperbolic PDE. Then one has to solve (47). Before stating a formal result, we outline the basic energy estimate which is used to deal with (47). We represent the equation in the schematic form

$$\Phi_{tt}-(a+yQ_1)\Phi_{yt}-(b+yQ_2)\Phi_{yy}-c(y\Phi_y)_{yt}-d(y\Phi_y)_{yy}+Q_3=0. \tag{50}$$

Moreover, we have the boundary conditions

$$\Phi_y(0,t)=f(t),\qquad \Phi(\sqrt{M_\Gamma},t)+\sqrt{M_\Gamma}\Phi_y(\sqrt{M_\Gamma},t)=0. \tag{51}$$

We note that $d(\sqrt{M_\Gamma}, t) = 0$; the energy estimates will make frequent use of this fact. To obtain the basic energy estimate, we multiply (50) by $\Phi_t + d\Phi_y/c$ and integrate. This yields

$$\sum_{i=1}^{11} A_i = 0. \tag{52}$$

In the following listing of the A_i, it is understood that all integrals over y are from 0 to $\sqrt{M_\Gamma}$.

$$A_1 = \int_0^t \int \Phi_{tt}\Phi_t \, dy \, d\tau = \frac{1}{2}\int \Phi_t^2(y,t)\, dy - \frac{1}{2}\int \Phi_t(y,0)^2 \, dy, \tag{53}$$

$$A_2 = -\int_0^t \int (a + yQ_1)\Phi_{yt}\Phi_t \, dy \, d\tau = \frac{1}{2}\int_0^t a(0,\tau)\Phi_t^2(0,\tau)\, d\tau$$

$$-\frac{1}{2}\int_0^t (a(\sqrt{M_\Gamma},\tau) + \sqrt{M_\Gamma}Q_1(\sqrt{M_\Gamma},\tau))\Phi_t^2(\sqrt{M_\Gamma},\tau)\, d\tau$$

$$+\frac{1}{2}\int_0^t \int (a + yQ_1)_y \Phi_t^2 \, dy \, d\tau, \tag{54}$$

$$A_3 = -\int_0^t \int (b + yQ_2)\Phi_{yy}\Phi_t \, dy \, d\tau = \int_0^t \int (b + yQ_2)\Phi_y \Phi_{yt} \, dy \, d\tau$$

$$+\int_0^t \int (b + yQ_2)_y \Phi_y \Phi_t \, dy \, d\tau + \int_0^t b(0,\tau) f(\tau)\Phi_t(0,\tau)\, d\tau$$

$$-\int_0^t (b(\sqrt{M_\Gamma},\tau) + \sqrt{M_\Gamma}Q_2(\sqrt{M_\Gamma},\tau))\Phi_y(\sqrt{M_\Gamma},\tau)\Phi_t(\sqrt{M_\Gamma},\tau)\, d\tau$$

$$= \frac{1}{2}\int (b(y,t) + yQ_2(y,t))\Phi_y^2(y,t)\, dy - \frac{1}{2}\int (b(y,0) + yQ_2(y,0))\Phi_y^2(y,0)\, dy$$

$$-\frac{1}{2}\int_0^t \int (b + yQ_2)_t \Phi_y^2(y,\tau)\, dy \, d\tau + \int_0^t \int (b + yQ_2)_y \Phi_y \Phi_t \, dy \, d\tau$$

$$+\int_0^t \frac{1}{\sqrt{M_\Gamma}}(b(\sqrt{M_\Gamma},\tau) + \sqrt{M_\Gamma}Q_2(\sqrt{M_\Gamma},\tau))\Phi(\sqrt{M_\Gamma},\tau)\Phi_t(\sqrt{M_\Gamma},\tau)\, d\tau$$

$$+\int_0^t b(0,\tau) f(\tau)\Phi_t(0,\tau)\, d\tau, \tag{55}$$

$$A_4 = \int_0^t \int \frac{d}{c}\Phi_{tt}\Phi_y \, dy \, d\tau = \int \frac{d}{c}(y,t)\Phi_t(y,t)\Phi_y(y,t)\, dy - \int \frac{d}{c}(y,0)\Phi_t(y,0)\Phi_y(y,0)\, dy$$

$$-\int_0^t \int \left(\frac{d}{c}\right)_t \Phi_t\Phi_y \, dy \, d\tau - \int_0^t \int \frac{d}{c}\Phi_t\Phi_{yt}\, dy\, d\tau$$

$$= \int \frac{d}{c}(y,t)\Phi_t(y,t)\Phi_y(y,t)\, dy - \int \frac{d}{c}(y,0)\Phi_t(y,0)\Phi_y(y,0)\, dy$$

$$-\int_0^t \int \left(\frac{d}{c}\right)_t \Phi_t\Phi_y \, dy\, d\tau + \frac{1}{2}\int_0^t \frac{d}{c}(0,\tau)\Phi_t^2(0,\tau)\, d\tau + \frac{1}{2}\int_0^t \int \left(\frac{d}{c}\right)_y \Phi_t^2(y,\tau)\, dy\, d\tau, \tag{56}$$

$$A_5 = -\int_0^t \int (a + yQ_1)\frac{d}{c}\Phi_y\Phi_{yt}\, dy\, d\tau = -\frac{1}{2}\int (a+yQ_1)(y,t)\frac{d}{c}(y,t)\Phi_y^2(y,t)\, dy$$

$$+\frac{1}{2}\int (a+yQ_1)(y,0)\frac{d}{c}(y,0)\Phi_y^2(y,0)\, dy + \frac{1}{2}\int_0^t \int \left[(a+yQ_1)\frac{d}{c}\right]_t \Phi_y^2\, dy\, d\tau, \tag{57}$$

$$A_6 = -\int_0^t \int (b + yQ_2)\frac{d}{c}\Phi_y\Phi_{yy}\, dy\, d\tau = \frac{1}{2}\int_0^t \frac{bd}{c}(0,\tau)\Phi_y^2(0,\tau)\, d\tau$$

$$+\frac{1}{2}\int_0^t \int \left[(b+yQ_2)\frac{d}{c}\right]_y \Phi_y^2\, dy\, d\tau, \tag{58}$$

$$A_7 = -\int_0^t \int c(y\Phi_y)_{yt}\Phi_t\, dy\, d\tau = \int_0^t \int cy\Phi_{yt}^2\, dy\, d\tau + \int_0^t \int c_y y\Phi_{yt}\Phi_t\, dy\, d\tau$$

$$+\int_0^t c(\sqrt{M_\Gamma},\tau)\Phi_t^2(\sqrt{M_\Gamma},\tau)\, d\tau, \tag{59}$$

$$A_8 = -\int_0^t \int d(y\Phi_y)_{yy}\Phi_t\, dy\, d\tau = \int_0^t \int dy\Phi_{yy}\Phi_{yt}\, dy\, d\tau$$

$$+\frac{1}{2}\int d(y,t)\Phi_y^2(y,t)\, dy - \frac{1}{2}\int d(y,0)\Phi_y^2(y,0)\, dy + \int_0^t \int d_y(y\Phi_y)_y\Phi_t\, dy\, d\tau$$

$$+\int_0^t d(0,\tau)f(\tau)\Phi_t(0,\tau)\, d\tau - \frac{1}{2}\int_0^t \int d_t\Phi_y^2\, dy\, d\tau, \tag{60}$$

$$A_9 = -\int_0^t \int d(y\Phi_y)_{yt}\Phi_y\, dy\, d\tau = \int_0^t \int dy\Phi_{yt}\Phi_{yy}\, dy\, d\tau$$

$$+\int_0^t \int d_y y \Phi_{yt} \Phi_y \, dy \, d\tau, \tag{61}$$

$$A_{10} = -\int_0^t \int \frac{d^2}{c} (y\Phi_y)_{yy} \Phi_y \, dy \, d\tau = \int_0^t \int \frac{d^2}{c} y \Phi_{yy}^2 \, dy \, d\tau$$

$$+\int_0^t \int \frac{d^2}{c} \Phi_y \Phi_{yy} \, dy \, d\tau + \int_0^t \int (\frac{d^2}{c})_y (y\Phi_y)_y \Phi_y \, dy \, d\tau$$

$$+\int_0^t \frac{d^2(0,\tau)}{c(0,\tau)} f^2(0,\tau) \, d\tau, \tag{62}$$

$$A_{11} = \int_0^t \int Q_3 \left(\Phi_t + \frac{d}{c} \Phi_y \right) dy \, d\tau. \tag{63}$$

For reasons which will become clear later, we split up Q_3 in the form $Q_3 = A + B_y$. We can then transform (63) further as follows:

$$A_{11} = \int_0^t \int A \left(\Phi_t + \frac{d}{c} \Phi_y \right) dy \, d\tau + \int_0^t \int \left(B_t + \frac{d}{c} B_y \right) \Phi_y \, dy \, d\tau$$

$$+\int_0^t B(\sqrt{M_\Gamma}, \tau) \Phi_t(\sqrt{M_\Gamma}, \tau) \, d\tau - \int_0^t B(0,\tau)\Phi_t(0,\tau) \, d\tau$$

$$-\int B(y,t)\Phi_y(y,t) \, dy + \int B(y,0)\Phi_y(y,0) \, dy. \tag{64}$$

From $\sum A_i$, we can extract the following quadratic terms:

$$\int \frac{1}{2} \Phi_t^2(y,t) + \left(\frac{d}{c} + O(y) \right) \Phi_t \Phi_y(y,t) + \left(\frac{b}{2} - \frac{ad}{2c} + \frac{d}{2} + O(y) \right) \Phi_y^2(y,t) \, dy, \tag{65}$$

$$\int_0^t \int cy \Phi_{yt}^2 + 2dy \Phi_{yy} \Phi_{tt} + \frac{d^2}{c} y \Phi_{yy}^2 \, dy \, d\tau$$

$$= \int_0^t \int cy \left(\Phi_{yt} + \frac{d}{c} \Phi_{yy} \right)^2 dy \, d\tau. \tag{66}$$

From (47), we find that, at $y = 0$,

$$\frac{d}{c} = -\frac{1}{8} \sigma'(0) (\Phi^n)^{7/2} q^n, \tag{67}$$

$$\frac{b}{2} - \frac{ad}{2c} + \frac{d}{2} = \frac{1}{64} \sigma'(0)^2 (\Phi^n)^7 (q^n)^2. \tag{68}$$

As a consequence, the quadratic expression in (65) is positive at least for small y. An additional positive contribution to the energy equation is given by

$$\int_0^t \left(\frac{1}{2}a(0,\tau)+\frac{d(0,\tau)}{2c(0,\tau)}\right)\Phi_t^2(0,\tau)\,d\tau. \tag{69}$$

Most of the remaining terms in the energy identity can be estimated in a fairly straightforward fashion. In A_7 through A_{10}, there are terms involving the product of a second and first derivative of Φ; these terms can be integrated by parts in an analogous fashion as we did for A_1 through A_6; in doing so, we obtain terms involving second derivatives of c and d. We also note that

$$\int_p^{\sqrt{M_\Gamma}} \Phi_y^2(y,t)\,dy \tag{70}$$

for $p>0$ can be estimated in terms of

$$\int_{p(0)}^{\sqrt{M_\Gamma}} \Phi_y^2(0,t)\,dy \tag{71}$$

and

$$\sqrt{t}\int_0^t\int_{p(\tau)}^{\sqrt{M_\Gamma}}\left(\Phi_{yt}+\frac{d}{c}\Phi_{yy}\right)^2(y,\tau)\,dy\,d\tau, \tag{72}$$

where $p(\tau)$ is defined by

$$p'(\tau)=d(p(\tau),\tau)/c(p(\tau),\tau), \qquad p(t)=p. \tag{73}$$

Moreover,

$$\int_0^t \Phi_t^2(\sqrt{M_\Gamma},\tau)\,d\tau \tag{74}$$

has a bound of the form

$$\epsilon\int_0^t\int y\left(\Phi_{yt}+\frac{d}{c}\Phi_{yy}\right)^2 dy\,d\tau + C(\epsilon)\int_0^t\int \Phi_t^2+\Phi_y^2\,dy\,d\tau, \tag{75}$$

where ϵ can be chosen arbitrarily small. By using these estimates, one finds, for sufficiently small t, a bound of the form

$$\begin{aligned}&\|\Phi_t\|_{L^\infty((0,t);L^2)}+\|\Phi_y\|_{L^\infty((0,t);L^2)}+\|\sqrt{y}\left(\Phi_{yt}+\frac{d}{c}\Phi_{yy}\right)\|_{L^2((0,t);L^2)}\\ &+\|\Phi_t(0,\cdot)\|_{L^2(0,t)}\le C\left(\|A\|_{L^1((0,t);L^2)}+\|B\|_{L^\infty((0,t),L^2)}+\left\|B_t+\frac{d}{c}B_y\right\|_{L^1((0,t);L^2)}\right)+C_0.\end{aligned} \tag{76}$$

Here C_0 depends only on the initial data, and C depends only on t and on the coefficients and their derivatives up to second order.

We can use the energy estimate to establish the existence of a solution to (50) and (51). For this purpose, we use a Galerkin approximation. Let ψ_m be a basis for $H^1(0, \sqrt{M_\Gamma})$. We then determine an approximate solution Φ_N as follows:

$$(\Phi_N)_t + \frac{d}{c}(\Phi_N)_y = \sum_{m=1}^{N} \alpha_m(t)\psi_m(y), \tag{77}$$

with initial condition

$$\Phi_N(y,0) = \Phi(y,0) \tag{78}$$

and boundary condition

$$(\Phi_N)_y(0,t) = f(t). \tag{79}$$

The α_m are determined from the equations

$$\begin{aligned}
&\int [(\Phi_N)_{tt} - (a+yQ_1)(\Phi_N)_{yt} + (b+yQ_2)_y(\Phi_N)_y + c_y y(\Phi_N)_{yt} - d_{yy}y(\Phi_N)_y]\psi_m\,dy \\
&\quad + \int [(b+yQ_2)(\Phi_N)_y + c(y(\Phi_N)_y)_t + d(y(\Phi_N)_y)_y - d_y y(\Phi_N)_y](\psi_m)_y\,dy \\
&\quad + \psi_m(\sqrt{M_\Gamma})\left[\frac{b+yQ_2}{\sqrt{M_\Gamma}}\Phi_N + c(\Phi_N)_t - d_y\Phi_N\right](\sqrt{M_\Gamma},t) \\
&\quad + \psi_m(0)[b(0,t)f(t) + d(0,t)f(t)] = 0,
\end{aligned} \tag{80}$$

which simply become a set of first-order integrodifferential equations. The initial condition is

$$\sum_{m=1}^{N} \alpha_m(0)\psi_m(y) = \Pi_N\left[\Phi_t(y,0) + \frac{d}{c}\Phi_y(y,0)\right]. \tag{81}$$

Here Π_N is the orthogonal projection in $L^2(0, \sqrt{M_\Gamma})$. We can now repeat the energy estimates above for the discretized system. This leads to a priori estimates which, in the usual fashion, allow us to extract a weakly convergent subsequence from the Φ_N. The limit is the solution we seek.

To obtain higher regularity of solutions to (50), we need to consider time derivatives of the equation. We shall now demonstrate how to obtain a problem of the same form as (50), with Φ_t in place of Φ. Differentiation of (50) with respect to time leads to

$$\begin{aligned}
&\Phi_{ttt} - (a+yQ_1)\Phi_{ytt} - (b+yQ_2)\Phi_{yyt} - c(y\Phi_{yt})_{yt} - d(y\Phi_{yt})_{yy} \\
&\quad -(a+yQ_1)_t\Phi_{yt} - (b+yQ_2)\Phi_{yy} - c_t(y\Phi_y)_{yt} - d_t(y\Phi_y)_{yy} + (Q_3)_t = 0.
\end{aligned} \tag{82}$$

This is indeed of the same form as (50), if we can treat the second line as a new forcing term. The first term presents no problem. To deal with the term involving

Φ_{yy}, we consider (50) as a first-order hyperbolic equation for Φ_{yy} for given Φ_{yt} and Φ_{tt}; this allows us to bound Φ_{yy} in terms of Φ_{yt}, Φ_{tt}, and the initial data. We next use (50) to express $y\Phi_{yyt}$ in terms of $y\Phi_{yyy}$ and second derivatives of Φ; this allows us to eliminate the term $c_t y\Phi_{yyt}$ in (82). Finally, we need to deal with the term $d_t(y\Phi_y)_{yy}$. We write this term as

$$d_t(y\Phi_y)_{yy} = (d_t(y\Phi_y)_y)_y - d_{yt}(y\Phi_y)_y. \tag{83}$$

The second contribution is easily dealt with, and the first is of the form B_y, where (50) can be used to express $B_t + \frac{d}{c}B_y$ in terms of second derivatives of Φ. After the transformations just outlined, (82) is now of the same form as (50) and analogous energy estimates can be applied, with Φ_t in place of Φ.

We are now ready to state an existence result for the initial-boundary value problem consisting of (32)–(34) and (38). To define the function spaces, let $\|\cdot\|_{k,p,l}$ denote the norm in $W^{l,p}((0,T);H^k(0,\sqrt{M_\Gamma}))$. We define Z_M as the set of all (q,Φ) such that

$$q \in \bigcap_{i=0}^{k} W^{k-i,\infty}((0,T);H^i(0,\sqrt{M_\Gamma})),$$

$$\Phi \in \bigcap_{i=0}^{k+1} W^{k+1-i,\infty}((0,T);H^i(0,\sqrt{M_\Gamma})),$$

$$\sum_{i=0}^{k} \|q\|_{i,\infty,k-i} + \sum_{i=0}^{k+1} \|\Phi\|_{i,\infty,k+1-i} \le M,$$

q and its first $k-1$ time derivatives satisfy the appropriate initial conditions,

Φ and its first k time derivatives satisfy the appropriate initial conditions,

$$\Phi \text{ satisfies (34).} \tag{84}$$

By $\mathcal{S}$ we denote the mapping from (q^n,Φ^n) to (q^{n+1},Φ^{n+1}) under the iteration defined above.

The existence of solutions now follows from the following theorem.

THEOREM 4.1. *Let $k \ge 3$, and assume Φ_0 and q_0 are strictly positive, sufficiently smooth, and compatible with the boundary conditions. Moreover, assume that the initial values for time derivatives of Φ and q up to orders $k-1$ and, respectively, k are compatible with the boundary conditions* (38) *and that the initial values for time derivatives of Φ up to order $k-1$ are compatible with* (34) *and* (41). *Finally, assume that the function $\Gamma \to \sigma(\Gamma)$ is smooth and $\sigma' < 0$. If M is chosen sufficiently large and T is sufficiently small relative to M, then $\mathcal{S}$ is a contraction in Z_M under the metric defined by*

$$d((q,\Phi),(\tilde{q},\tilde{\Phi})) = \sum_{i=0}^{k-1} \|q-\tilde{q}\|_{i,\infty,k-1-i} + \sum_{i=0}^{k} \|\Phi-\tilde{\Phi}\|_{i,\infty,k-i}. \tag{85}$$

The proof follows from the energy estimates given above, and we shall only sketch an outline. At each step of the iteration, we must first solve the first-order hyperbolic equation (45). An energy estimate for this equation gives a bound for $\|q^{n+1}\|_{0,\infty,0}$. To get bounds on derivatives of q^{n+1}, we differentiate (45) with respect to t and y and repeat the energy estimate. Note that boundary values for spatial derivatives of q^{n+1} at $y = 0$ can be obtained from the equation (45). We then apply the energy estimates from above to (47) and its time derivatives. In doing so, we take advantage of (64) in dealing with terms involving the highest derivatives of q^{n+1}. This yields bounds for $\|\Phi^{n+1}\|_{0,\infty,1} + \|\Phi^{n+1}\|_{1,\infty,0}$ and analogous bounds for time derivatives of Φ^{n+1}. Once time derivatives have been estimated, it is easy to get bounds on spatial derivatives from (47), which can be regarded as a first-order hyperbolic equation for Φ_{yy}, once Φ_{tt} and Φ_{yt} are known. The result now follows by putting together the bounds obtained in this fashion.

SYMMETRIES AND DECAY OF THE GENERALIZED KADOMTSEV–PETVIASHVILI SOLITARY WAVES*

ANNE DE BOUARD† AND JEAN-CLAUDE SAUT†

Abstract. We prove that the solitary waves of the generalized Kadomtsev–Petviashvili equations, when they exist, are cylindrical with respect to the transverse variables and decay with an optimal algebraic rate.

Key words. Kadomtsev–Petviashvili equations, solitary waves, symmetry, decay

AMS subject classifications. 35B40, 35B99, 35Q53

1. Introduction.

This paper is a continuation of a previous work [5] where we proved existence and nonexistence results for solitary waves of the generalized Kadomtsev–Petviashvili (KP) equations

$$(1.1)\qquad \begin{cases} u_t + u^p u_x + u_{xxx} - v_y = 0, \quad u = u(x,y,t),\ (x,y) \in \mathbb{R}^2,\ t > 0, \\ v_x = u_y \end{cases}$$

in the two-dimensional case, and

$$(1.2)\qquad \begin{cases} u_t + u^p u_x + u_{xxx} - v_y - w_z = 0, \quad u = u(x,y,z,t),\ (x,y,z) \in \mathbb{R}^3,\ t > 0, \\ v_x = u_y, \\ w_x = u_z \end{cases}$$

in the three-dimensional case.

In (1.1) (resp., (1.2)), x is the direction of propagation while y (resp., (y,z)) are the transverse variables.

Throughout the paper, we will assume that $p = m/n$, m and n are relatively prime, and n is odd, so that we can define u^p for any real-valued function u.

By solitary wave, we mean (see [5]) a solution of (1.1) (resp., (1.2)) of the type $u(x-ct,y)$ (resp., $u(x-ct,y,z)$), where $c > 0$, and $u \in Y$, with

$$Y = \text{closure of the space } \partial_x(C_0^\infty(\mathbb{R}^d)),\ d = 2,3, \text{ for the norm}$$
$$\|\partial_x\varphi\|_Y = \left(\|\nabla\varphi\|_{L^2}^2 + \left\|\partial_x^2\varphi\right\|_{L^2}^2\right)^{1/2}.$$

We are thus considering "localized" solutions to the systems

$$(1.3)\qquad \begin{cases} -cu_x + u^p u_x + u_{xxx} - v_y = 0, \\ v_x = u_y, \end{cases}$$

$$(1.4)\qquad \begin{cases} -cu_x + u^p u_x + u_{xxx} - v_y - w_z = 0, \\ v_x = u_y, \\ w_x = u_z. \end{cases}$$

Note that we may assume $c = 1$ by the simple scale change $\tilde{u}(x, x') = c^{-1/p} u(\frac{x}{\sqrt{c}}, \frac{x'}{c})$, where $x' = y$ (resp., $x' = (y, z)$). Obviously, (1.3), (1.4) imply that u must solve the equation in $\mathbb{R}^d$, $d = 2, 3$,

$$-\Delta u + \partial_x^4 u + \frac{1}{p+1}(u^{p+1})_{xx} = 0, \tag{1.5}$$

where $\Delta = \partial_x^2 + \partial_y^2$ (resp., $\partial_x^2 + \partial_y^2 + \partial_z^2$).

In order to state the results of the present paper we summarize below (and complete slightly) some relevant facts proved in [5] (see also [14] for an existence proof in the two-dimensional case).

THEOREM 1.1.

(i) *The system* (1.1) *(resp.,* (1.2)*) has a nontrivial solitary wave if and only if* $1 \le p < 4$ *(resp.,* $1 \le p < \frac{4}{3}$*).*

(ii) *Any solitary wave* u *is continuous and tends to zero at infinity. In the case where* p *is an integer,*

$$u \in H^\infty(\mathbb{R}^d) = \bigcap_{k \ge 0} H^k(\mathbb{R}^d), \quad d = 2, 3.$$

Proof. We refer to [5], except for (ii), when $3 < p < 4$ (resp., $1 < p < \frac{4}{3}$), which was not considered there. Note that (ii), when $1 < p < 3$, $p \ne 2$, is contained in the proof of Theorem 4.1 in [5].

First we treat the case $d = 2$, and $3 < p < 4$.

As in the proof of Lemma 4.1 in [5], we get from (1.5)

$$\hat{u}(\xi_1, \xi_2) = \frac{\xi_1^2}{|\xi|^2 + \xi_1^4} \hat{g}(\xi_1, \xi_2), \tag{1.6}$$

where $g = -\frac{1}{p+1} u^{p+1}$ and $\hat{f}$ denotes the Fourier transform of f with respect to (x, y).

We will use a reiteration argument. Since $Y \subset L^6(\mathbb{R}^2)$, $g \in L^{6/(p+1)}$. By Lizorkin's theorem [11], $u, u_y, u_{xx} \in L^{6/(p+1)}$ and from [3, Thm. 10.2] we deduce that $u \in L^{p_1}(\mathbb{R}^2)$, $\frac{p+1}{6} - \frac{1}{p_1} = \frac{2}{3}$, that is, $p_1 = \frac{6}{p-3}$. Assume by induction that $u \in L^{p_n}(\mathbb{R}^2)$ with $p_n \ge p_{n-1} \ge p_0 = 6 > \frac{3p}{2}$ (since $p < 4$). Then, $g \in L^{p_n/(p+1)}(\mathbb{R}^2)$, which yields by Lizorkin's theorem $u, u_y, u_{xx} \in L^{p_n/(p+1)}(\mathbb{R}^2)$ and, again by [3], $u \in L^{p_{n+1}}(\mathbb{R}^2)$, where $\frac{p+1}{p_n} - \frac{1}{p_{n+1}} = \frac{2}{3}$ (or $p_{n+1} = +\infty$ if $\frac{p+1}{p_n} < \frac{2}{3}$). Moreover, $\frac{1}{p_{n+1}} - \frac{1}{p_n} = \frac{p}{p_n} - \frac{2}{3} < 0$, and therefore

$$p_{n+1} > p_n \ge p_0 > \frac{3p}{2}.$$

Finally, either p_n converges to a finite value, or it reaches $+\infty$. The only possible finite limit being $\frac{3p}{2}$, p_n necessarily reaches $+\infty$ in a finite number of steps. Moreover, since for any n, $u, u_y, u_{xx} \in L^{p_n/(p+1)}(\mathbb{R}^2)$, one has $\nabla u \in L^q(\mathbb{R}^2)$, $\forall\ q < +\infty$ and by the Sobolev embedding theorem, $u(x, y) \to 0$ as $x^2 + y^2 \to +\infty$.

The proof for $d = 3$, $1 < p < \frac{4}{3}$ follows the same lines. One starts with $u \in L^{p_0}(\mathbb{R}^3)$, ($p_0 = \frac{10}{3}$), $g \in L^{p_0/(p+1)}(\mathbb{R}^3)$, $u, u_y, u_z, u_{xx} \in L^{p_0/(p+1)}(\mathbb{R}^3)$, which implies by Lizorkin's theorem $u \in L^{p_1}(\mathbb{R}^3)$, $\frac{p+1}{p_0} - \frac{1}{p_1} = \frac{2}{5}$. At the nth stage we obtain $\frac{p+1}{p_n} - \frac{1}{p_{n+1}} = \frac{2}{5}$, and one proves again (using $p < \frac{4}{3}$) that p_n must reach $+\infty$ in a finite number of steps. ∎

Let us now describe the content of the present paper. In the second section we prove that the solitary waves constructed in [5] (see Theorem 1.1 above) are cylindrically symmetric, that is, radially symmetric with respect to the transverse coordinates, up to a translation of the origin. Actually, we give alternate variational characterizations of the solitary waves, and we adapt an argument of Lopes [12] to prove the symmetry.

In section 3, we establish sharp (algebraic) decay rates for *any* solitary wave u of (1.1) (resp., (1.2)), namely, $r^2 u \in L^\infty(\mathbb{R}^2)$ (resp., $r^\delta u \in L^2(\mathbb{R}^3)$, $\forall\ \delta,\ 0 < \delta < \frac{3}{2}$), where $r^2 = x^2 + y^2$ (resp., $x^2 + y^2 + z^2$). The sharpness of this decay rate is put on the fore by the lump solitary wave of the KP I equation ((1.1) with $p = 1$) which decays exactly as $\frac{1}{r^2}$ at infinity, and by the fact that for "general"p's, a nontrivial solitary wave does not belong to $L^1(\mathbb{R}^d)$. Actually, our decay estimates are obtained for any solution in Y of the equation (1.5).

The method is reminiscent of that of Bona and Li [4], though we consider here a "nonsmooth" and multidimensional situation. It consists of a careful analysis of the decay properties of solutions to the convolution equation equivalent to (1.6).

In section 4 we indicate briefly how similar results can be obtained for equations having higher dispersion in x.

Finally, we present in an Appendix a global unique continuation theorem which is a key ingredient in proving the symmetry of the solitary wave (see section 2).

2. Symmetry properties of the ground states. In this section, we prove that any ground state solution of (1.3) (resp., (1.4)) is cylindrically symmetric, in the sense that it has radial symmetry with respect to transverse coordinates, up to a translation of the origin. We recall that by transverse coordinates x', we mean coordinates which are transverse to the direction of propagation, that is, $x' = y$ in the two-dimensional case (1.3) and $x' = (y, z)$ in the three-dimensional case (1.4).

A ground state is a solitary wave which minimizes the action

$$S(u) = E(u) + \frac{c}{2}\int_{\mathbb{R}^d} |u|^2, \quad d = 2 \text{ or } 3$$

among all the nonzero solutions of (1.3) (resp. (1.4)), where c is the velocity of the solitary wave and E is the energy, defined for $u \in Y$ by

$$E(u) = \frac{1}{2}\int_{\mathbb{R}^2} \left(u_x^2 + \left(D_x^{-1} u_y\right)^2\right) dxdy - \frac{1}{(p+1)(p+2)}\int_{\mathbb{R}^2} u^{p+2} dxdy$$

if $d = 2$, and

$$\begin{aligned} E(u) = {} & \frac{1}{2}\int_{\mathbb{R}^3} \left(u_x^2 + \left(D_x^{-1} u_y\right)^2 + \left(D_x^{-1} u_z\right)^2\right) dxdydz \\ & - \frac{1}{(p+1)(p+2)}\int_{\mathbb{R}^3} u^{p+2} dxdydz \ \text{ if } d = 3. \end{aligned}$$

Note (see [5]) that $D_x^{-1} u_y$ is well defined for $u \in Y$, as the unique element $v \in L^2(\mathbb{R}^d)$ such that $v_x = u_y$. An analogous definition holds for $D_x^{-1} u_z$ if $d = 3$.

Note also that both $E(u)$ and $\int_{\mathbb{R}^d} |u|^2$ are conserved quantities for equations (1.1) and (1.2); i.e., if $u(t)$ is a solution of (1.1) or (1.2), then $E(u(t))$ and $\int_{\mathbb{R}^d} |u(t)|^2$ do not depend on t (see, for example, [13]).

In [5], we proved, for p satisfying the conditions of Theorem 1.1, the existence of nontrivial solutions of equation (1.3) (resp., (1.4)), by considering the minimization problem

$$I_\lambda = \inf\left\{\int_{\mathbb{R}^2}\left[u_x^2 + cu^2 + \left(D_x^{-1}u_y\right)^2\right],\ u\in Y,\ \int_{\mathbb{R}^2} u^{p+2} = \lambda\right\}$$

$$\left(\text{resp., } I_\lambda = \inf\left\{\int_{\mathbb{R}^3}\left[u_x^2 + cu^2 + \left(D_x^{-1}u_y\right)^2 + \left(D_x^{-1}u_z\right)^2\right],\ u\in Y,\ \int_{\mathbb{R}^3} u^{p+2} = \lambda\right\}\right).$$

More precisely, with an appropriate choice of λ, if u^* is a minimum of I_λ, then u^* is a solution of the following equations (depending on whether $d=2$ or 3) in $Y'(\mathbb{R}^d)$ (the dual space of Y in the $L^2(\mathbb{R}^d)$ duality):

$$-u_{xx} + cu + D_x^{-2}u_{yy} = \frac{u^{p+1}}{p+1},\ \text{if } d=2, \tag{2.1}$$

$$-u_{xx} + cu + D_x^{-2}u_{yy} + D_x^{-2}u_{zz} = \frac{u^{p+1}}{p+1},\ \text{if } d=3, \tag{2.2}$$

so that u^* satisfies equation (1.3) if $d=2$ and (1.4) if $d=3$, in $\mathcal{D}'(\mathbb{R}^d)$.

The next lemma shows that the solutions u^* obtained in this way are exactly the ground states of equation (1.3) (resp., (1.4)) and also gives two other characterizations of those solutions, which will appear to be useful in proving the symmetry property.

In order to state the lemma, we define

$$K(u) = \frac{1}{2}\int_{\mathbb{R}^2}\left[cu^2 + \left(D_x^{-1}u_y\right)^2\right] - \frac{1}{(p+1)(p+2)}\int_{\mathbb{R}^2} u^{p+2},\ \text{if } d=2 \tag{2.3}$$

and

$$\begin{aligned} K(u) = &\frac{1}{2}\int_{\mathbb{R}^3}\left[cu^2 + \left(D_x^{-1}u_y\right)^2 + \left(D_x^{-1}u_z\right)^2\right] + \frac{1}{6}\int_{\mathbb{R}^3} u_x^2 \\ &- \frac{1}{(p+1)(p+2)}\int_{\mathbb{R}^3} u^{p+2},\ \text{if } d=3. \end{aligned} \tag{2.4}$$

Lemma 2.1. *Let $d=3$; then there is a real positive numberλ^* such that for $u^*\in Y$, the following assertions are equivalent:*

(i) $\int (u^*)^{p+2} = \lambda^*$ *and u^* is a minimum of I_{λ^*},*

(ii) *u^* is a ground state,*

(iii) $K(u^*) = 0$ *and* $\int (u_x^*)^2 = \inf\left\{\int u_x^2,\ u\in Y,\ u\neq 0,\ K(u)=0\right\}$,

(iv) $K(u^*) = 0 = \inf\left\{K(u),\ u\in Y,\ \int u_x^2 = \int (u_x^*)^2\right\}$.

Let $d=2$; then there is a real positive λ^* such that (i)–(iv) *are equivalent modulo a scale change. More precisely,* (i) *and* (ii) *are equivalent and imply* (iii) *and* (iv), *which are also equivalent; conversely, if u^* satisfies* (iii) *or* (iv), *then there is a positive μ such that $u^*(\frac{\cdot}{\mu})$ is a ground state of equation* (1.3).

Proof. To prove Lemma 2.1, we use techniques which are standard for the bound states of nonlinear Schrödinger equations (see, for example, [6]).

Let u be a minimum of I_λ; then there is a positive Lagrange parameter θ_λ such that u satisfies

$$-u_{xx} + cu + D_x^{-2}u_{yy} = \theta_\lambda\frac{u^{p+1}}{p+1},\ \text{if } d=2,\ \text{or}$$

$$-u_{xx} + cu + D_x^{-2} u_{yy} + D_x^{-2} u_{zz} = \theta_\lambda \frac{u^{p+1}}{p+1}, \text{ if } d = 3.$$

Multiplying these equations by u and integrating by parts yields $I_\lambda = \frac{\theta_\lambda}{p+1} \int u^{p+2} = \frac{\lambda \theta_\lambda}{p+1}$ for each positive λ. Since $I_\lambda = \lambda^{2/(p+2)} I_1$, we get $\theta_\lambda = 1$ by choosing $\lambda = \lambda^* = [(p+1)I_1]^{(p+2)/p}$.

Let us now prove that Lemma 2.1 holds with this choice of λ.

(i)$\Longrightarrow$(iii): Assume that u^* satisfies (i). Let $u \in Y$ with $u \neq 0$ and $K(u) = 0$; let $u_\mu = u\left(\frac{\cdot}{\mu}\right)$, with $\mu = \left(\frac{\int (u^*)^{p+2}}{\int u^{p+2}}\right)^{1/d}$ (note that $K(u) = 0$ implies $\int u^{p+2} > 0$ unless $u = 0$), so that $\int u_\mu^{p+2} = \int (u^*)^{p+2}$, and

$$K(u_\mu) = \left(\frac{1}{2} - \frac{1}{d}\right) \mu^{d-2}(1 - \mu^2) \int u_x^2. \tag{2.5}$$

Since u^* is a minimum of I_{λ^*}, we have $K(u^*) = 0$ (see (2.8) and (2.11) in [5] if $d = 2$ and (2.13)–(2.16) in [5] if $d = 3$]) and, on the other hand,

$$\begin{aligned} K(u^*) + \frac{1}{d} \int (u_x^*)^2 + \frac{1}{(p+1)(p+2)} \int (u^*)^{p+2} \\ \leq K(u_\mu) + \frac{1}{d} \int (u_\mu)_x^2 + \frac{1}{(p+1)(p+2)} \int (u_\mu)^{p+2}; \end{aligned}$$

this implies

$$\frac{1}{d} \int (u_x^*)^2 \leq \frac{\mu^{d-2}}{2} \left(1 - \frac{d-2}{d} \mu^2\right) \int u_x^2 \leq \frac{1}{d} \int u_x^2,$$

and (iii) holds.

(iii)$\Longrightarrow$(ii) (modulo a scale change): if u^* satisfies (iii), then there is a Lagrange parameter θ such that u^* solves the Euler–Lagrange equation

$$cu + D_x^{-2} u_{yy} - \frac{u^{p+1}}{p+1} = \theta u_{xx} \text{ if } d = 2, \text{ and}$$

$$cu + D_x^{-2} u_{yy} + D_x^{-2} u_{zz} - \frac{u^{p+1}}{p+1} = \left(\frac{1}{3} + \theta\right) u_{xx} \text{ if } d = 3.$$

It is easily seen, by multiplying these equations by u^*, integrating by parts, and using $K(u) = 0$, that θ is positive. Hence, setting $u_\mu = u^*(\frac{\cdot}{\mu})$, with $\mu = \frac{1}{\sqrt{\theta}}$ if $d = 2$ (resp., $\mu = 1/\sqrt{\frac{1}{3} + \theta}$ if $d = 3$), u_μ satisfies equation (2.1) (resp., (2.2)).

If $d = 3$, then by (2.5), $K(u_\mu) = \frac{1}{6} \mu (1 - \mu^2) \int (u_x^*)^2$, but since any solution of (2.2) satisfies $K(u) = 0$, this implies $\mu = 1$, i.e., $\theta = \frac{2}{3}$.

Now, the identity $S(u) = K(u) + \frac{1}{d} \int u_x^2$ shows that if u is a solution of (1.3) (resp., (1.4)), then

$$S(u) = \frac{1}{d} \int u_x^2 \geq \frac{1}{d} \int (u_x^*)^2 = \frac{1}{d} \int (u_\mu)_x^2 = S(u_\mu);$$

hence u_μ is a ground state.

(ii) $\Longrightarrow$(i): By the computations in [5, section 2], one has, for any solution u of equation (1.3) (resp., (1.4)), $K(u) = 0$ and

$$\int_{\mathbb{R}^2} \left(u_x^2 + cu^2 + D_x^{-1}u_y^2\right) = \left(1 + \frac{2}{p}\right) \int_{\mathbb{R}^2} u_x^2$$

$$\left(\text{resp., } \int_{\mathbb{R}^3} (u_x^2 + cu^2 + (D_x^{-1}u_y)^2 + (D_x^{-1}u_z)^2 = \left(\frac{4}{3p} + \frac{2}{3}\right) \int_{\mathbb{R}^3} u_x^2\right).$$

Hence if u^* is a ground state, u^* minimizes both $\int u_x^2$ and $\int_{\mathbb{R}^2}(u_x^2 + cu^2 + (D_x^{-1}u_y)^2)$ (resp., $\int_{\mathbb{R}^3}(u_x^2 + cu^2 + (D_x^{-1}u_y)^2 + (D_x^{-1}u_z)^2)$) among all the solutions of (1.3) (resp. (1.4)). Let $\lambda = \int_{\mathbb{R}^d} u^{p+2}$ and $\tilde{u}$ be a minimum of I_λ. Then

$$I_\lambda = \int_{\mathbb{R}^d} \left(\tilde{u}_x^2 + c\tilde{u}^2 + (D_x^{-1}\tilde{u}_y)^2\right) \le \int_{\mathbb{R}^d} \left((u_x^*)^2 + c(u^*)^2 + (D_x^{-1}u_y^*)^2\right)$$

and there is a positive θ such that

$$c\tilde{u} + D_x^{-2}\tilde{u}_{yy} - \tilde{u}_{xx} = \theta \frac{\tilde{u}^{p+1}}{p+1}.$$

Using the equations satisfied by $\tilde{u}$ and u^*, the preceding inequality is written as

$$I_\lambda = \frac{\theta\lambda}{p+1} \le \frac{\lambda}{p+1};$$

hence $\theta \le 1$.

On the other hand, $\bar{u} = \theta^p \tilde{u}$ satisfies equation (1.3) (resp., (1.4)), and since u^* is a ground state,

$$\begin{aligned}\int_{\mathbb{R}^d} \left((u_x^*)^2 + c(u^*)^2 + (D_x^{-1}u_y^*)^2\right) &\le \int_{\mathbb{R}^d} \left(\bar{u}_x^2 + c\bar{u}^2 + (D_x^{-1}\bar{u}_y)^2\right) \\ &\le \theta^{2p} \int_{\mathbb{R}^d} \left(\tilde{u}_x^2 + c\tilde{u}^2 + (D_x^{-1}\tilde{u}_y)^2\right)\end{aligned}$$

so that $\theta \ge 1$.

Hence $u^* = \tilde{u}$ is a minimum of I_λ with $\lambda = \lambda^*$.

(iii)$\Longleftrightarrow$(iv): Assume that (iii) holds; let $u \in Y$ with $\int_{\mathbb{R}^d} u_x^2 = \int_{\mathbb{R}^d} (u_x^*)^2$. Note that $K(\eta u) > 0$ for $\eta > 0$ sufficiently small, so that if $K(u) < 0$, then there is an $\eta_0 \in (0, 1)$ such that $K(\eta_0 u) = 0$; then setting $\tilde{u} = \eta_0 u$, one has $\tilde{u} \in Y$, $K(\tilde{u}) = 0$ and $\int_{\mathbb{R}^d} (\tilde{u}_x)^2 < \int_{\mathbb{R}^d} u_x^2 = \int_{\mathbb{R}^d} (u_x^*)^2$, which contradicts (iii), and shows that u^* satisfies (iv) since $K(u^*) = 0$.

On the opposite, assume that u^* satisfies (iv) and let $u \in Y$ with $K(u) = 0$, $u \ne 0$. Then $K(\eta u) < 0$ for $\eta > 1$, so if $\int u_x^2 < \int (u_x^*)^2$, one can find $\eta_0 > 1$ with $\int (\eta_0 u)_x^2 = \int (u_x^*)^2$ and $K(\eta_0 u) < 0$, contradicting (iv). Hence $\int u_x^2 \ge \int (u_x^*)^2$ and (iii) holds. This ends the proof of Lemma 2.1. ☐

We now state and prove our theorem concerning the symmetry properties of the ground state solutions of equation (1.3) (resp., (1.4)).

THEOREM 2.1. *Let $x' = y \in \mathbb{R}$ if $d = 2$ and $x' = (y, z) \in \mathbb{R}^2$ if $d = 3$; then, up to a translation of the origin of coordinates in x', any ground state u^* is radial in x'; that is, u^* only depends on x and $|x'|$.*

Proof of Theorem 2.1. We use an argument of Lopes [12].

Case $d = 2$. Choose $b \in \mathbb{R}$, in order that if $\Delta = \{(x, y) \in \mathbb{R}^2, y = b\}$, then

$$\int_{\Delta^+} (u_x^*)^2 = \int_{\Delta^-} (u_x^*)^2 = \frac{1}{2} \int_{\mathbb{R}^2} (u_x^*)^2 ,$$

where Δ^+ and Δ^- are the half-planes delimited by Δ. Let u^+ be defined by $u^+ = u^*$ in Δ^+ and u^+ be symmetric with respect to Δ. Then $u^+ \in Y$; indeed, if $\varphi \in L^2_{\text{loc}}$ is such that $\varphi_x = u^*$ and $\varphi_y = D_x^{-1} u_y^*$, and if

$$\varphi^+(x, y) = \begin{cases} \varphi(x, y) & \text{if } y > b, \\ \varphi(x, 2b - y) & \text{if } y < b, \end{cases}$$

then $\varphi_x^+ = u^+$ and $\int_{\mathbb{R}^2} \left(\varphi_y^+\right)^2 = 2 \int_{\Delta^+} \varphi_y^2 < +\infty$. Since there is a sequence $\varphi_n \in \mathcal{C}_0^\infty(\mathbb{R}^2)$ such that $(\varphi_n)_x$ converges to $\varphi_x = u^*$ in Y, $D_x^{-1} u_y^+ = \varphi_y^+$. Moreover, $\int_{\mathbb{R}^2} \left(u_x^+\right)^2 = \int_{\mathbb{R}^2} \left(u_x^*\right)^2$. In the same way, if $u^- = u^*$ in Δ^- and u^- is symmetric with respect to Δ, then $u^- \in Y$ and $\int_{\mathbb{R}^2} \left(u_x^-\right)^2 = \int_{\mathbb{R}^2} \left(u_x^*\right)^2$. Hence it follows from Lemma 2.1 (iv) that $K(u^+) \geq 0$ and $K(u^-) \geq 0$.

But one easily checks that

$$K(u^+) + K(u^-) = 2K(u^*) = 0$$

so that u^+ and u^- both satisfy assertion (iv) of Lemma 2.1; it results from this last lemma that u^+ and u^- are ground states of equation (1.3); thus u^+, u^-, and u^* satisfy

$$-u_{xxxx} + u_{xx} + u_{yy} = \left(\frac{u^{p+1}}{p+1} \right)_{xx} \quad \text{in } \mathbb{R}^2.$$

At last, since $u^+ = u^*$ in Δ^+ and $u^- = u^*$ in Δ^-, the unique continuation principle (see the appendix) applied to $u^+ - u^*$ (resp., $u^- - u^*$) tells us that $u^+ = u^- = u^*$, and u^* is symmetric with respect to Δ.

Case $d = 3$. Consider any plane Π parallel to the x axis; then there is a (unique) plane $\tilde{\Pi}$ parallel to Π such that

$$\int_{\tilde{\Pi}^+} (u_x^*)^2 = \int_{\tilde{\Pi}^-} (u_x^*)^2 = \frac{1}{2} \int_{\mathbb{R}^2} (u_x^*)^2 .$$

One can then show, exactly as in dimension 2 (by using the unique continuation principle stated in the appendix) that u^* is symmetric with respect to $\tilde{\Pi}$. It follows that, after a change of origin of transverse coordinates, u^* is symmetric with respect to the coordinate planes containing the x-axis.

It remains to show, using the arguments in [12] or [7], that u^* is symmetric with respect to any plane containing the x-axis. Suppose this is not the case, and let Π be a plane containing the x-axis such that u^* is not symmetric with respect to Π. Let $\tilde{\Pi}$ be parallel to Π such that u^* is symmetric with respect to $\tilde{\Pi}$; then one can construct as in [12] or [7] a sequence (C_n) of cylinders where C_0 is delimited by $\tilde{\Pi}$ and the planes of coordinates containing the x-axis, and the other cylinders are obtained by successive reflexions with respect to the three planes delimiting C_0. For each n, one has $\int_{C_n} (u^*)^2 = \int_{C_0} (u^*)^2$, and there is a subsequence of (C_n) consisting of disjoint cylinders; since u^* is square integrable, this implies $u^* = 0$ on C_0; hence, $u^* = 0$ on each C_n, but, then, $u^* = 0$ everywhere, since $\cup_{n \in \mathbb{N}} C_n = \mathbb{R}^3$.

This ends the proof of Theorem 2.1. □

3. Algebraic decay of the solitary waves. To start, we give an optimal result for the decay of the solitary wave in the two-dimensional case.

THEOREM 3.1. *Any nontrivial solitary wave of* (1.1) *satisfies*

$$r^2 u \in L^\infty(\mathbb{R}^2), \quad r^2 = x^2 + y^2. \tag{3.1}$$

Remark 3.1. Theorem 3.1 is sharp in two ways. First, the lump solution of the KP I equation ((1.1) with $p = 1$), namely,

$$u(x-ct,y) = \frac{8c\left(1 - \frac{c}{3}(x-ct)^2 + \frac{c^2}{3}y^2\right)}{\left(1 + \frac{c}{3}(x-ct)^2 + \frac{c^2}{3}y^2\right)^2}, \tag{3.2}$$

shows that in the two-dimensional case one cannot expect a decay rate better than r^{-2}. On the other hand (and this is valid for $d = 2, 3$), writing

$$-(p+1)\hat{u}(\xi_1, \xi_\perp) = \frac{\xi_1^2}{|\xi|^2 + \xi_1^4}\widehat{u^{p+1}}(\xi_1, \xi_\perp), \quad \xi_\perp = \xi_2 \text{ (resp., } (\xi_2, \xi_3)) \tag{3.3}$$

shows that u cannot belong to $L^1(\mathbb{R}^d)$, when $p = \frac{m}{n}$, m odd. (Since $\xi \mapsto \frac{\xi_1^2}{|\xi|^2+\xi_1^4}$ is not continuous at the origin, this would lead to the absurd conclusion that $\int_{\mathbb{R}^d} u^{p+1} = 0$.) So, in this case, if the solitary wave decays with an algebraic rate $r^{-\alpha}$, then necessarily $\alpha \leq d$.

Proof of Theorem 3.1. To prove (3.1), we start with a simple integral decay estimate and then use the convolution equation equivalent to (1.6).

LEMMA 3.1. *Any solitary wave of* (1.1) *satisfies*

$$\int_{\mathbb{R}^2} \left(x^2 + y^2\right)\left(|\nabla u|^2 + u_{xx}^2\right) dxdy < +\infty. \tag{3.4}$$

Proof of Lemma 3.1. Let $\chi_0 \in \mathcal{C}_0^\infty(\mathbb{R})$, $0 \leq \chi_0 \leq 1$, $\chi_0(t) = 1$ if $0 \leq |t| \leq 1$, $\chi_0(t) = 0$, $|t| \geq 2$. We set $\chi_j(x) = \chi_0\left(\frac{x^2}{j^2}\right)$, $j = 1, 2, \ldots.$ We multiply (1.5) by $\chi_j(x)x^2u$ and integrate over $\mathbb{R}^2$. Using several integrations by parts, the terms in (1.5) are computed as follows.

$$\begin{aligned}
-\int_{\mathbb{R}^2} u_{xx}\chi_j(x)x^2u &= 2\int_{\mathbb{R}^2} x\chi_j(x)uu_x + \int_{\mathbb{R}^2} \chi_j'(x)x^2uu_x + \int_{\mathbb{R}^2} x^2\chi_j(x)u_x^2 \\
&= \int_{\mathbb{R}^2} x^2\chi_j(x)u_x^2 - \int_{\mathbb{R}^2} \chi_j(x)u^2 - \int_{\mathbb{R}^2} \left(2x\chi_j'(x) + \frac{1}{2}\chi_j''(x)\right)u^2,
\end{aligned}$$

$$-\int_{\mathbb{R}^2} u_{yy}x^2\chi_j(x)u = \int_{\mathbb{R}^2} x^2\chi_j(x)u_y^2,$$

$$\begin{aligned}\int_{\mathbb{R}^2} x^2\chi_j(x)uu_{xxxx} &= \int_{\mathbb{R}^2}(x^2u\chi_j(x))_{xx}u_{xx}\\ &= \int_{\mathbb{R}^2}(2\chi_j(x)+4x\chi_j'(x)+x^2\chi_j''(x))uu_{xx}\\ &+ \int_{\mathbb{R}^2}(4x\chi_j(x)+2x^2\chi_j'(x))u_xu_{xx}+\int_{\mathbb{R}^2} x^2\chi_j(x)u_{xx}^2\\ &= \int_{\mathbb{R}^2} x^2\chi_j(x)u_{xx}^2-4\int_{\mathbb{R}^2}\chi_j(x)u_x^2-2\int_{\mathbb{R}^2}(4x\chi_j'(x)+x^2\chi_j''(x))u_x^2\\ &+\int_{\mathbb{R}^2}\left(6\chi_j''(x)+4x\chi_j'''(x)+\frac{1}{2}x^2\chi_j^{(4)}(x)\right)u^2,\end{aligned}$$

$$\begin{aligned}\int_{\mathbb{R}^2} x^2\chi_j(x)u\left(u^{p+1}\right)_{xx} &= 2\frac{p+1}{p+2}\int_{\mathbb{R}^2}\chi_j(x)u^{p+2}-(p+1)\int_{\mathbb{R}^2}x^2\chi_j(x)u^pu_x^2\\ &+\frac{p+1}{p+2}\int_{\mathbb{R}^2}(x^2\chi_j''(x)+4x\chi_j'(x))u^{p+2}.\end{aligned}$$

Finally, we arrive at

$$\begin{aligned}\int_{\mathbb{R}^2} x^2\chi_j(x)\left(|\nabla u|^2+u_{xx}^2\right) &= \int_{\mathbb{R}^2}\chi_j(x)\left[u^2+4u_x^2-\frac{2}{p+2}u^{p+2}\right]\\ &+\int_{\mathbb{R}^2}x^2\chi_j(x)u_x^2u^p+2\int_{\mathbb{R}^2}(4x\chi_j'(x)+x^2\chi_j''(x))u_x^2\\ &-\frac{1}{p+2}\int_{\mathbb{R}^2}(4x\chi_j'(x)+x^2\chi_j''(x))u^{p+2}\\ &+\int_{\mathbb{R}^2}\left(2x\chi_j'(x)+\frac{1}{2}x^2\chi_j''(x)-6\chi_j''(x)-4x\chi_j'''(x)-\frac{1}{2}x^2\chi_j^{(4)}(x)\right)u^2.\end{aligned} \tag{3.5}$$

In a similar fashion, we multiply (1.5) by $\chi_j(y)y^2u$ and integrate over $\mathbb{R}^2$ to get, successively,

$$-\int_{\mathbb{R}^2} y^2u_{xx}\chi_j(y)u=\int_{\mathbb{R}^2}y^2\chi_j(y)u_x^2,$$

$$\begin{aligned}-\int_{\mathbb{R}^2} y^2\chi_j(y)u_{yy}u &= \int_{\mathbb{R}^2}y^2\chi_j(y)u_y^2-\int_{\mathbb{R}^2}\chi_j(y)u^2\\ &-\int_{\mathbb{R}^2}\left(2y\chi_j'(y)+\frac{1}{2}y^2\chi_j''(y)\right)u^2,\end{aligned}$$

$$\int_{\mathbb{R}^2} y^2\chi_j(y)u_{xxxx}u=\int_{\mathbb{R}^2}y^2\chi_j(y)u_{xx}^2,$$

$$\frac{1}{p+1}\int_{\mathbb{R}^2}\chi_j(y)\left(u^{p+1}\right)_{xx}y^2u=-\int_{\mathbb{R}^2}u_x^2\chi_j(y)y^2u^p.$$

Adding these inequalities yields

$$\begin{aligned}\int_{\mathbb{R}^2} y^2\chi_j(y)\left(|\nabla u|^2+u_{xx}^2\right) &= \int_{\mathbb{R}^2}\chi_j(y)u^2+\int_{\mathbb{R}^2} y^2\chi_j(y)u^p u_x^2\\ &\quad+\int_{\mathbb{R}^2}\left(2y\chi_j'(y)+\frac{1}{2}y^2\chi_j''(y)\right)u^2.\end{aligned}\tag{3.6}$$

Finally, (3.5) and (3.6) imply

$$\begin{aligned}&\int_{\mathbb{R}^2}\left[x^2\chi_j(x)+y^2\chi_j(y)\right]\left(|\nabla u|^2+u_{xx}^2\right)\\ &=4\int_{\mathbb{R}^2}\chi_j(x)u_x^2+\int_{\mathbb{R}^2}\left[\chi_j(x)+\chi_j(y)\right]u^2-\frac{2}{p+2}\int_{\mathbb{R}^2}\chi_j(x)u^{p+2}\\ &+\int_{\mathbb{R}^2}\left[x^2\chi_j(x)+y^2\chi_j(y)\right]u_x^2u^p\\ &+\int_{\mathbb{R}^2}\left[2x\chi_j'(x)+2y\chi_j'(y)+\frac{1}{2}x^2\chi_j''(x)+\frac{1}{2}y^2\chi_j''(y)\right]u^2\\ &-\int_{\mathbb{R}^2}\left[6\chi_j''(x)+4x\chi_j'''(x)+\frac{1}{2}x^2\chi_j^{(4)}(x)\right]u^2\\ &+2\int_{\mathbb{R}^2}\left[4x\chi_j'(x)+x^2\chi_j''(x)\right]u_x^2-\frac{1}{p+2}\int_{\mathbb{R}^2}\left[4x\chi_j'(x)+x^2\chi_j''(x)\right]u^{p+2}.\end{aligned}\tag{3.7}$$

Let us consider the right-hand side of (3.7). The first three terms tend, as $j\to+\infty$, to $2\int_{\mathbb{R}^2}\left[2u_x^2+u^2-\frac{1}{p+2}u^{p+2}\right]$ by Lebesgue's theorem. The terms involving derivatives of χ_j tend to zero, again by Lebesgue's theorem and the properties of χ_j.

On the other hand, since $u\to0$ as $r\to+\infty$, there exists $R>0$ such that $r\geq R$ implies $|u^p|\leq\frac{1}{2}$. Thus

$$\int_{\mathbb{R}^2}\left[x^2\chi_j(x)+y^2\chi_j(y)\right]u_x^2u^p\leq C(R)+\frac{1}{2}\int_{\mathbb{R}^2}\left[x^2\chi_j(x)+y^2\chi_j(y)\right]u_x^2,$$

and finally, (3.7) implies that

$$\int_{\mathbb{R}^2}\left[x^2\chi_j(x)+y^2\chi_j(y)\right]\left(|\nabla u|^2+u_{xx}^2\right)$$

is uniformly bounded in j. Our claim follows from Fatou's lemma. □

As we mentioned previously, our analysis of the decay of the solitary wave is based on the convolution equation

$$u=ih*(u^pu_x),\tag{3.8}$$

where

$$\hat{h}(\xi_1,\xi_2)=\frac{\xi_1}{|\xi|^2+\xi_1^4},\quad |\xi|^2=\xi_1^2+\xi_2^2.$$

Lemma 3.2. *There exists a constant $C>0$ such that*

$$|h(x,y)|\leq\frac{C}{r},\quad\forall\ (x,y)\in\mathbb{R}^2\ \text{ where } r=(x^2+y^2)^{1/2}.$$

Proof. We have

$$h(x,y)=\int_{\mathbb{R}^2}\frac{\xi_1}{\xi_1^2+\xi_2^2+\xi_1^4}e^{ix\xi_1+iy\xi_2}d\xi_1 d\xi_2;$$

writing

$$\frac{\xi_1}{\xi_1^2+\xi_2^2+\xi_1^4}=\frac{1}{\xi_1^2\left(1+\xi_1^2\right)\left(\frac{\xi_2^2}{a^2}+1\right)},\quad a^2=\xi_1^2+\xi_1^4,$$

the integral is transformed under the change of variable $\xi_2=a\xi_2'$ into

$$\int_{\mathbb{R}^2}\frac{\text{sgn }\xi_1}{\sqrt{1+\xi_1^2}}\left[\int_{\mathbb{R}^2}\frac{e^{iy|\xi_1|\left(1+\xi_1^2\right)^{1/2}\xi_2'}}{1+\xi_2'^2}d\xi_2'\right]e^{ix\xi_1}d\xi_1;$$

hence, since $\mathcal{F}\left(\frac{1}{1+\xi^2}\right)(y)=e^{-|y|}$,

$$h(x,y)=\int_{-\infty}^{\infty}\frac{\text{sgn }\xi}{\left(1+\xi^2\right)^{1/2}}e^{-|y||\xi|\left(1+\xi^2\right)^{1/2}}e^{ix\xi}\ d\xi.$$

Let us consider first the case $y\neq 0$. Let

$$\begin{aligned}h_1(x,y)&=\int_0^{\infty}\frac{1}{\left(1+\xi^2\right)^{1/2}}e^{-|y|\xi\left(1+\xi^2\right)^{1/2}}e^{ix\xi}d\xi\\&=\int_0^{\infty}\frac{1}{\left(1+\xi^2\right)^{1/2}K'(\xi)}\frac{d}{d\xi}\left[e^{K(\xi)}\right]d\xi,\end{aligned}$$

with $K(\xi)=ix\xi-|y|\xi\left(1+\xi^2\right)^{1/2}$. Thus

$$\begin{aligned}h_1(x,y)&=\left[\frac{e^{K(\xi)}}{ix\left(1+\xi^2\right)^{1/2}-|y|\left(1+2\xi^2\right)}\right]_0^{\infty}-\int_0^{\infty}\frac{d}{d\xi}\left[\frac{1}{\left(1+\xi^2\right)^{1/2}K'(\xi)}\right]e^{K(\xi)}d\xi\\&=\frac{1}{|y|-ix}-\int_0^{\infty}\frac{ix\xi-4|y|\xi\left(1+\xi^2\right)^{1/2}}{\left(1+\xi^2\right)^{1/2}\left[ix\left(1+\xi^2\right)^{1/2}-|y|\left(1+2\xi^2\right)\right]^2}e^{K(\xi)}d\xi\\&\equiv\frac{1}{|y|-ix}-\int_0^{\infty}F(\xi)e^{K(\xi)}d\xi.\end{aligned}$$

Now,

$$\begin{aligned}|F(\xi)|^2&=\frac{x^2\xi^2+16y^2\xi^2\left(1+\xi^2\right)}{\left(1+\xi^2\right)\left[x^2\left(1+\xi^2\right)+y^2\left(1+2\xi^2\right)^2\right]^2}\\&\leq\frac{16}{\left(1+\xi^2\right)\left[x^2\left(1+\xi^2\right)+y^2\left(1+2\xi^2\right)^2\right]}\\&\leq\frac{16}{\left(1+\xi^2\right)^2\left(x^2+y^2\right)},\end{aligned}$$

and (since $e^{K(\xi)} \leq 1$)

$$\left| \int_0^\infty F(\xi) e^{K(\xi)} d\xi \right| \leq \frac{4}{r} \int_0^\infty \frac{d\xi}{1+\xi^2} \leq \frac{C}{r}.$$

Finally,

$$|h_1(x,y)| \leq \frac{1}{||y| - ix|} + \frac{C}{r} = \frac{C+1}{r}, \quad \text{if } y \neq 0.$$

In a similar fashion, one proves that

$$h_2(x,y) = -\int_{-\infty}^0 \frac{1}{\left(1+\xi^2\right)^{1/2}} e^{|y|\xi\left(1+\xi^2\right)^{1/2}} e^{ix\xi} d\xi$$

satisfies

$$|h_2(x,y)| \leq \frac{1}{||y| + ix|} + \frac{C}{r} = \frac{C+1}{r} \quad \text{if } y \neq 0.$$

It remains to consider the case where $y = 0$:

$$h(x,0) = \int_{-\infty}^\infty \frac{\operatorname{sgn} \xi}{\left(1+\xi^2\right)^{1/2}} e^{ix\xi} d\xi = \mathcal{F}\left(\frac{\operatorname{sgn} \xi}{\left(1+\xi^2\right)^{1/2}} \right)(x).$$

Let us check that $xh(x,0)$ is a bounded function. Actually,

$$\frac{d}{d\xi}\left(\frac{\operatorname{sgn} \xi}{\left(1+\xi^2\right)^{1/2}} \right) = \frac{1}{\left(1+\xi^2\right)^{1/2}} \delta + g = \delta + g,$$

where δ is the Dirac mass and $g \in L^1(\mathbb{R})$; thus $xh(x,0) = 1 + \mathcal{F}_x^{-1} g \in L^\infty(\mathbb{R})$. □

We prove now a (nonoptimal) pointwise decay estimate on u.

LEMMA 3.3. $ru \in L^\infty(\mathbb{R}^2)$.

Proof. From (3.8) we obtain

$$\begin{aligned} |r(x,y)u(x,y)| \leq{}& C \int_{\mathbb{R}^2} |h(x-x',y-y')r(x-x',y-y')|\, |u^p u_x(x',y')|\, dx'dy' \\ &+ C \int_{\mathbb{R}^2} |h(x-x',y-y')|\, |r(x',y')u^p u_x(x',y')|\, dx'dy'. \end{aligned} \tag{3.9}$$

By Young's inequality (using Lemma 3.2 and $u^p u_x \in L^1(\mathbb{R}^2)$), the first term in the right-hand side of (3.9) belongs to $L^\infty(\mathbb{R}^2)$. On the other hand, as it is easily checked, $\hat{h} \in L^q(\mathbb{R}^2)$, $1 < q < 2$, so that $h \in L^s(\mathbb{R}^2)$, $2 < s < \infty$. Applying Young's inequality, the second term in the right-hand side of (3.9) is bounded by $C \left\| ru_x \right\|_{L^2} \|h\|_{L^s} \|u\|^p_{L^{2ps/(s-2)}}$ for any s, $2 < s < \infty$, and the result follows from Lemma 3.1. □

We continue the proof of Theorem 3.1. We write

$$u = -\frac{1}{p+1} k * u^{p+1} \text{ where } \hat{k}(\xi_1,\xi_2) = \frac{\xi_1^2}{|\xi|^2 + \xi_1^4}. \tag{3.10}$$

LEMMA 3.4. $\hat{k} \in H^s(\mathbb{R}^2)$, *for any* s, $0 \leq s < 1$.

Proof. First we prove that $\hat{k} \in L^2(\mathbb{R}^2)$. Actually,

$$\int_{\mathbb{R}^2} \frac{\xi_1^4}{\left(|\xi|^2+\xi_1^4\right)^2} d\xi_1 d\xi_2 = \int_{\mathbb{R}} \frac{1}{\left(1+\xi_1^2\right)^2} \left[\int_{\mathbb{R}} \frac{d\xi_2}{\left[1+\frac{\xi_2^2}{\xi_1^2(1+\xi_1^2)}\right]^2} \right] d\xi_1$$

$$= \int_{\mathbb{R}} \frac{|\xi_1|}{\left(1+\xi_1^2\right)^{3/2}} d\xi_1 \int_{\mathbb{R}} \frac{d\xi_2}{\left(1+\xi_2^2\right)^2} < +\infty.$$

On the other hand, one easily checks that $|\nabla \hat{k}(\xi_1, \xi_2)| \le C|\hat{h}(\xi_1, \xi_2)|$, and we already noticed that $\hat{h} \in L^q(\mathbb{R}^2)$, for any q such that $1 < q < 2$. Thus $\partial_{\xi_1}\hat{k}, \partial_{\xi_2}\hat{k} \in L^q(\mathbb{R}^2)$, $1 < q < 2$; that is, $\hat{k}$ belongs to the homogeneous Sobolev space $\dot{H}^1_q(\mathbb{R}^2)$. By Bergh and Löfstrom ([2] Thm. 6.5.1), $\dot{H}^1_q(\mathbb{R}^2) \subset \dot{H}^s_2(\mathbb{R}^2)$ for $s = 2(1-\frac{1}{q})$; i.e., $\hat{k} \in \dot{H}^2_s$ for any $s \in [0, 1)$. Finally, $\hat{k} \in H^s(\mathbb{R}^2)$, $0 \le s < 1$. □

Now we prove an (optimal) integral decay estimate on u.

Lemma 3.5. *For any* δ, $0 \le \delta < 1$, one has

$$r^\delta u \in L^2(\mathbb{R}^2), \tag{3.11}$$

$$r^{1+\delta}\nabla u, \quad r^{1+\delta}u_{xx} \in L^2(\mathbb{R}^2). \tag{3.12}$$

Proof of Lemma 3.5. Coming back to (3.10), we estimate for $\delta > 0$

$$\left|\left(1+r^2\right)^{\delta/2} u\right| \le C \left|\left[\left(1+r^2\right)^{\delta/2} k\right] * u^{p+1}\right| + C \left|\left[\left(1+r^2\right)^{\delta/2} u^{p+1}\right] * k\right|. \tag{3.13}$$

Thanks to Lemma 3.4, we have for any $0 \le \delta < 1$,

$$\left\|\left(1+r^2\right)^{\delta/2} k * u^{p+1}\right\|_{L^2} \le C \left\|\hat{k}\right\|_{H^\delta} \|u\|^{p+1}_{L^{p+1}} \le C.$$

Observe now that $k \in L^q(\mathbb{R}^2)$, $\forall\ q,\ 1 < q \le 2$. In fact,

$$\|k\|_{L^q} \le \left\|\left(1+r^2\right)^{s/2} k\right\|_{L^2} \left\|\frac{1}{\left(1+r^2\right)^{s/2}}\right\|_{L^\alpha}, \quad \frac{1}{q} = \frac{1}{2} + \frac{1}{\alpha}, \tag{3.14}$$

so $q \in (1, 2] \iff \alpha \in (2, +\infty]$.

For a given $q \in (1, 2]$ one can choose $s \in [0, 1)$ such that $s\alpha > 2$ and (3.14) implies our claims. Thus

$$\left\|\left(1+r^2\right)^{\delta/2} u^{p+1} * k\right\|_{L^2} \le C \left\|\left(1+r^2\right)^{\delta/2} u^{p+1}\right\|_{L^\beta} \|k\|_{L^q},$$
$$\frac{1}{q} + \frac{1}{\beta} = \frac{3}{2}, \quad q \in (1, 2), \quad \beta \in (1, 2).$$

But $\left(1+r^2\right)^{\delta/2} u^{p+1} \in L^\beta(\mathbb{R}^2)$ if and only if

$$r^{\delta/(p+1)} u \in L^{\beta(p+1)}(\mathbb{R}^2). \tag{3.15}$$

On the other hand,

$$\int_{\mathbb{R}^2} r^\alpha |u|^\gamma \le \left\|r^\alpha u^{\gamma-2}\right\|_{L^\infty} \|u\|^2_{L^2} \le \left\|r^{\frac{\alpha}{\gamma-2}} u\right\|^{\gamma-2}_{L^\infty} \|u\|^2_{L^2}$$
$$\le C\|u\|^2_{L^2},$$

provided $\alpha \leq \gamma - 2$, by Lemma 3.3. In particular, $r^{(\gamma-2)/\gamma} u \in L^\gamma(\mathbb{R}^2)$, $2 \leq \gamma \leq +\infty$. Let $\gamma = \beta(p+1)$. For any $\delta \in (0,1)$ one can choose $\beta \in (1,2)$ such that

$$\frac{\delta}{p+1} \leq \frac{\gamma - 2}{\gamma}, \quad \text{i.e., } \delta \leq p + 1 - \frac{2}{\beta}, \text{ since } p \geq 1.$$

This proves that $r^\delta u \in L^2(\mathbb{R}^2)$, $0 < \delta < 1$.

Let us check briefly that $r^{1+\delta} \nabla u$, $r^{1+\delta} u_{xx} \in L^2(\mathbb{R}^2)$ for any δ, $0 < \delta < 1$. The proof is very similar to that of Lemma 3.1 and we shall sketch it formally, without the truncation argument. We multiply successively (1.5) by $|x|^{2(1+\delta)} u$, $|y|^{2(1+\delta)} u$, to get after several integrations by parts

$$\begin{aligned} &\int_{\mathbb{R}^2} \left(|x|^{2+2\delta} + |y|^{2+2\delta}\right) \left(|\nabla u|^2 + u_{xx}^2\right) \\ &\quad = (1+2\delta)(2+2\delta) \int_{\mathbb{R}^2} |x|^{2\delta} u_x^2 - (1+2\delta)(2+2\delta) \int_{\mathbb{R}^2} |x|^{2\delta} u u_{xx} \\ &\quad + (1+2\delta)(1+\delta) \int_{\mathbb{R}^2} (|x|^{2\delta} + |y|^{2\delta}) u^2 + \int_{\mathbb{R}^2} \left(|x|^{2+2\delta} + |y|^{2+2\delta}\right) u^p u_x^2 \\ &\quad - \frac{1}{p+2}(1+2\delta)(2+2\delta) \int_{\mathbb{R}^2} |x|^{2\delta} |u|^{p+2}. \end{aligned} \tag{3.16}$$

Consider the right-hand side in (3.16). The first three integrals are bounded by Lemma 3.1 and the fact that $r^\delta u \in L^2(\mathbb{R}^2)$. The last one is bounded by $C\|u\|_{L^\infty}^p \left\|r^\delta u\right\|_{L^2}^2$. Finally,

$$\begin{aligned} &\int \left(|x|^{2+2\delta} + |y|^{2+2\delta}\right) \left|u^p u_x^2\right| \\ &\quad \leq C + \frac{1}{2} \int \left(|x|^{2+2\delta} + |y|^{2+2\delta}\right) u_x^2 \end{aligned}$$

for $r \geq R$, R large enough since $u \to 0$ as $r \to +\infty$. □

We now need a decay estimate on k (see (3.10)).

Lemma 3.6.

$$r^2 k \in L^\infty(\mathbb{R}^2). \tag{3.17}$$

Proof of Lemma 3.6. By definition,

$$k(x,y) = \int_{\mathbb{R}^2} \frac{\xi_1^2}{\xi_1^2 + \xi_2^2 + \xi_1^4} e^{ix\xi_1 + iy\xi_2} d\xi_1 d\xi_2.$$

As in the proof of Lemma 3.2, we find

$$k(x,y) = \int_{-\infty}^{\infty} \frac{|\xi|}{\left(1+\xi^2\right)^{1/2}} e^{-|y||\xi|\left(1+\xi^2\right)^{1/2} e^{ix\xi}} d\xi.$$

Consider first the case where $y \neq 0$ and $\xi \geq 0$:

$$k_1(x,y) = \int_0^\infty \frac{\xi}{\left(1+\xi^2\right)^{1/2}} \frac{1}{K'(\xi)} \frac{d}{d\xi} \left[e^{K(\xi)}\right] d\xi,$$

$$K(\xi) = ix\xi - |y|\xi \left(1+\xi^2\right)^{1/2}.$$

By integration by parts,

$$\begin{aligned} k_1(x,y) &= -\int_0^\infty \frac{d}{d\xi}\left[\frac{\xi}{(1+\xi^2)^{1/2}\,K'(\xi)}\right] e^{K(\xi)} d\xi \\ &= -\int_0^\infty \frac{e^{K(\xi)}}{ix\,(1+\xi^2)^{1/2} - |y|\,(1+2\xi^2)} d\xi \\ &+ \int_0^\infty \frac{\xi^2\left[ix - 4|y|\left(1+\xi^2\right)^{1/2}\right] e^{K(\xi)}}{(1+\xi^2)^{1/2}\left[ix\,(1+\xi^2)^{1/2} - |y|\,(1+2\xi^2)\right]^2} d\xi \\ &= I_1 + I_2. \end{aligned}$$

We integrate I_1 by parts to get

$$I_1 = -\left[\frac{e^{K(\xi)}\left(1+\xi^2\right)^{1/2}}{\left[ix\,(1+\xi^2)^{1/2} - |y|\,(1+2\xi^2)\right]^2}\right]_0^\infty + \int_0^\infty \frac{d}{d\xi} H_1(\xi) e^{K(\xi)} d\xi$$

where

$$H_1(\xi) = \frac{\left(1+\xi^2\right)^{1/2}}{\left[ix\,(1+\xi^2)^{1/2} - |y|\,(1+2\xi^2)\right]^2},$$

$$I_1 = \frac{1}{(ix-|y|)^2} + \int_0^\infty \frac{d}{d\xi} H_1(\xi) e^{K(\xi)} d\xi. \tag{3.18}$$

One finds that

$$\begin{aligned} \frac{d}{d\xi} H_1(\xi) &= \frac{\xi}{(1+\xi^2)^{1/2}} \frac{1}{\left[ix\,(1+\xi^2)^{1/2} - |y|\,(1+2\xi^2)\right]^2} \\ &- 2\frac{ix\xi - 4|y|\xi\left(1+\xi^2\right)^{1/2}}{\left[ix\,(1+\xi^2)^{1/2} - |y|\,(1+2\xi^2)\right]^3} = F_1 + F_2. \end{aligned}$$

Obviously,

$$\begin{aligned} |F_1(\xi)|^2 &\le \frac{1}{(1+\xi^2)^2\,(x^2+y^2)^2}, \\ |F_2(\xi)|^2 &\le \frac{64}{\left[x^2\,(1+\xi^2) + y^2\,(1+2\xi^2)^2\right]^2} \le \frac{64}{(1+\xi^2)^2\,(x^2+y^2)^2}. \end{aligned}$$

Finally,

$$|I_1| \le \frac{9\pi+2}{2(x^2+y^2)}. \tag{3.19}$$

We now turn to I_2. By integration by parts,

$$I_2 = -\int_0^\infty \frac{d}{d\xi}\left[H_2(\xi)\right] e^{K(\xi)} d\xi$$

where

$$H_2(\xi) = \frac{\xi^2 \left[ix - 4|y| \left(1+\xi^2\right)^{1/2}\right]}{\left[ix\left(1+\xi^2\right)^{1/2} - |y|\left(1+2\xi^2\right)\right]^3},$$

$$\begin{aligned} H_2'(\xi) = {} & \frac{2\xi\left[ix\left(1+\xi^2\right)^{1/2} - 2|y|\left(2+3\xi^2\right)\right]}{\left(1+\xi^2\right)^{1/2}\left[ix\left(1+\xi^2\right)^{1/2} - |y|\left(1+2\xi^2\right)\right]^3} \\ & - \frac{3\xi^3\left[ix - 4|y|\left(1+\xi^2\right)^{1/2}\right]^2}{\left(1+\xi^2\right)^{1/2}\left[ix\left(1+\xi^2\right)^{1/2} - |y|\left(1+2\xi^2\right)\right]^4} = G_1(\xi) + G_2(\xi). \end{aligned}$$

One easily checks that

$$\begin{aligned} |G_1(\xi)|^2 &\le \frac{64}{\left[x^2\left(1+\xi^2\right) + y^2\left(1+2\xi^2\right)^2\right]^2} \le \frac{64}{\left(1+\xi^2\right)^2\left(x^2+y^2\right)^2}, \\ |G_2(\xi)|^2 &\le \frac{9 \times 16^2}{\left(1+\xi^2\right)^2\left(x^2+y^2\right)^2}, \end{aligned}$$

and

$$|I_2| \le \frac{28\pi}{x^2+y^2}. \tag{3.20}$$

This leads to the estimate

$$|k_1(x,y)| \le \frac{C}{x^2+y^2}, \quad \text{if } y \neq 0. \tag{3.21}$$

In a similar way one obtains

$$|k_2(x,y)| \le \frac{C}{x^2+y^2} \quad \text{for } y \neq 0, \tag{3.22}$$

where

$$k_2(x,y) = -\int_{-\infty}^{0} \frac{\xi}{\left(1+\xi^2\right)^{1/2}} e^{|y|\xi\left(1+\xi^2\right)^{1/2} + ix\xi} d\xi.$$

It remains to consider the case where $y = 0$. But

$$k(x,0) = \int_{-\infty}^{\infty} \frac{|\xi|}{\left(1+\xi^2\right)^{1/2}} e^{ix\xi} d\xi,$$

and showing that $x^2 k(x,0)$ is bounded amounts to proving that $\mathcal{F}_x^{-1}[\frac{d^2}{d\xi^2}R(\xi)] \in L^\infty(\mathbb{R})$, where $R(\xi) = \frac{|\xi|}{(1+\xi^2)^{1/2}}$. A simple computation shows that

$$R''(\xi) = 2\delta\left(1+\xi^2\right)^{-1/2} + g(\xi) = 2\delta + g(\xi),$$

where $g \in L^1(\mathbb{R})$; this proves our claim. The proof of Lemma 3.6 is complete. □

We are now ready to prove (3.1). From (3.10) one has

(3.23)
$$\begin{aligned}\left|r^2(x,y)u(x,y)\right| \leq C &\left|\int_{\mathbb{R}^2} r^2(x-x',y-y')k(x-x',y-y')u^{p+1}(x',y')dx'dy'\right| \\ &+ C\left|\int_{\mathbb{R}^2} k(x-x',y-y')r^2(x',y')u^{p+1}(x',y')dx'dy'\right|.\end{aligned}$$

By Lemma 3.6 and the fact that $u \in L^q(\mathbb{R}^2)$, $q \geq 2$, the first term in the right-hand side of (3.23) is bounded independently of x and y. The second term is majorized by $\|k\|_{L^q}\left\|r^2u^{p+1}\right\|_{L^{q'}}$, $\frac{1}{q}+\frac{1}{q'}=1$. Recall that $k \in L^q(\mathbb{R}^2)$, $1<q\leq 2$ (see the proof of Lemma 3.5).

If $p>1$, we write

$$\left\|r^2u^{p+1}\right\|_{L^{q'}} \leq \|ru\|^2_{L^\infty}\left(\int_{\mathbb{R}^2} u^{q'(p-1)}\right)^{1/q'},$$

which is finite for some $q' \geq 2$.

The case $p=1$ needs a different argument. One has $|\nabla(ru)| \leq r|\nabla u| + |u|$. Let $s \in (1,2)$. Then, for $\varepsilon > 0$ small,

$$\int_{\mathbb{R}^2} r^s|\nabla u|^s = \int_{\mathbb{R}^2} r^s|\nabla u|^{\frac{2s}{4-\varepsilon}}|\nabla u|^{\frac{s(2-\varepsilon)}{4-\varepsilon}},$$

and by the Hölder inequality

$$\begin{aligned}\int_{\mathbb{R}^2} r^s|\nabla u|^s &\leq \left(\int_{\mathbb{R}^2} r^{4-\varepsilon}|\nabla u|^2\right)^{\frac{s}{4-\varepsilon}}\left(\int_{\mathbb{R}^2}|\nabla u|^{\frac{s(2-\varepsilon)}{4-\varepsilon-s}}\right)^{\frac{4-\varepsilon-s}{4-\varepsilon}} \\ &\leq C\left(\int_{\mathbb{R}^2}|\nabla u|^{\frac{s(2-\varepsilon)}{4-\varepsilon-s}}\right)^{\frac{4-\varepsilon-s}{4-\varepsilon}},\end{aligned}$$

by Lemma 3.5. For, say, $s=2-\varepsilon$, one has $\frac{s(2-\varepsilon)}{4-\varepsilon-s}<2$. On the other hand, $u, \nabla u \in L^q(\mathbb{R}^2)$, $1<q\leq 2$, as is easily checked from the identity $u=-k*\frac{u^2}{2}$ and the fact that $k \in L^q(\mathbb{R}^2)$, $1<q\leq 2$. Finally, $\nabla(ru) \in L^{2-\varepsilon}(\mathbb{R}^2)$, and by the Sobolev embedding theorem, $ru \in L^{\frac{2(2-\varepsilon)}{\varepsilon}}(\mathbb{R}^2)$, i.e., $r^2u^2 \in L^{q'}$, $q'=\frac{2-\varepsilon}{\varepsilon}>2$ for ε sufficiently small, and this proves that $r^2u \in L^\infty(\mathbb{R}^2)$. □

In the three-dimensional case we have the slightly less precise result, which follows.

Theorem 3.2. *Any nontrivial solitary wave of* (1.2) *satisfies*

$$r^\delta u \in L^2(\mathbb{R}^3)\ \forall\ \delta, 0 \leq \delta < 3/2,\quad r=(x^2+y^2+z^2)^{1/2}. \tag{3.24}$$

Proof. As in Lemma 3.1, one first proves that any solitary wave of (1.2) satisfies

$$\int_{\mathbb{R}^3}(x^2+y^2+z^2)(|\nabla u|^2+u^2_{xx})dxdydz < +\infty. \tag{3.25}$$

We still use (3.8), now with

$$\hat{h}(\xi_1,\xi_2,\xi_3)=\frac{\xi_1}{|\xi|^2+\xi_1^4},\quad |\xi|^2=\xi_1^2+\xi_2^2+\xi_3^2.$$

The following lemma is the counterpart of Lemma 3.2.

LEMMA 3.7.

$$rh \in L^q(\mathbb{R}^3), \quad 3 < q < 5, \quad r = (x^2+y^2+z^2)^{1/2}.$$

Proof. It suffices to prove that $\nabla_\xi \hat{h} \in L^{q'}(\mathbb{R}^3)$, $\frac{5}{4} < q' < \frac{3}{2}$. Since $\left|\nabla_\xi \hat{h}\right| \leq \frac{C}{|\xi|^2+\xi_1^4} = g(\xi)$, we are reduced to proving that $g \in L^{q'}(\mathbb{R}^3)$, $\frac{5}{4} < q' < \frac{3}{2}$. One finds readily that

$$\begin{aligned}\int_{\mathbb{R}^3} \frac{d\xi}{(|\xi|^2+\xi_1^4)^{q'}} &= \int_{\mathbb{R}} \frac{1}{|\xi_1|^{2q'}(1+\xi_1^2)^{q'}} \left[\int_{\mathbb{R}^2} \frac{d\xi_1 d\xi_2}{\left(1+\frac{\xi_2^2+\xi_3^2}{\xi_1^2\left(1+\xi_1^2\right)}\right)^{q'}}\right] d\xi_1 \\ &= \int_{\mathbb{R}} \frac{d\xi_1}{|\xi_1|^{2(q'-1)}(1+\xi_1^2)^{q'-1}} \int_{\mathbb{R}^2} \frac{d\xi_2 d\xi_3}{(1+\xi_2^2+\xi_3^2)^{q'}}.\end{aligned}$$

The first integral in the right-hand side is finite if and only if $\frac{5}{4} < q' < \frac{3}{2}$, and the second one, if and only if $q' > 1$. □

LEMMA 3.8.

$$ru \in L^\infty(\mathbb{R}^3).$$

Proof. From (3.8) we derive

$$|ru| \leq C\,|[rh] * u^p u_x| + C\,|h * [u^p r u_x]|\,.$$

By Young's inequality and Lemma 3.7, we have

$$\|(rh) * u^p u_x\|_{L^\infty} \leq \|rh\|_{L^4} \|u\|_{L^{4p}}^p \|u_x\|_{L^2} < +\infty.$$

On the other hand, it is easily seen that $\hat{h}$, hence h, belongs to $L^2(\mathbb{R}^3)$, and Young's inequality, together with (3.25), implies

$$\|h * u^p r u_x\|_{L^\infty} \leq \|h\|_{L^2} \|ru_x\|_{L^2} \|u\|_{L^\infty}^p < +\infty. \qquad \square$$

We now use equation (3.10), still valid in dimension 3, if we set

$$\hat{k}(\xi_1,\xi_2,\xi_3) = \frac{\xi_1^2}{|\xi|^2+\xi_1^4}.$$

LEMMA 3.9. *$\hat{k}$ belongs to the homogeneous Sobolev space $\dot{H}_2^s(\mathbb{R}^3)$, for any s with $\frac{7}{10} < s < \frac{3}{2}$.*

Proof. One checks easily that the second derivatives of $\hat{k}$ are bounded by $\frac{C}{|\xi|^2+\xi_1^4}$. Thus (see the proof of Lemma 3.7) $\partial^2_{\xi_i\xi_j}\hat{k} \in L^q(\mathbb{R}^3)$, $i,j = 1,2,3$, $\frac{5}{4} < q < \frac{3}{2}$; that is, $\hat{k}$ belongs to the homogeneous Sobolev space $\dot{H}_q^2(\mathbb{R}^3)$. Again from [2], we infer that $\dot{H}_q^2(\mathbb{R}^3) \subset \dot{H}_2^s(\mathbb{R}^3)$ for $s = \frac{7}{2} - \frac{3}{q}$, i.e., $\frac{11}{10} < s < \frac{3}{2}$.

On the other hand, a simple computation also shows that the first derivatives of $\hat{k}$ are bounded by $C|\hat{h}|$ and, by using the same argument as in the proof of Lemma 3.7, it is easily seen that $\hat{h} \in L^q(\mathbb{R}^3)$, $\frac{5}{3} < q < 2$; hence, reproducing the above reasoning yields $\hat{k} \in \dot{H}^1_q(\mathbb{R}^3) \subset \dot{H}^s_2(\mathbb{R}^3)$ for $s = \frac{5}{2} - \frac{3}{q}$ and $\frac{5}{3} < q < 2$, i.e., $\frac{7}{10} < s < 1$. The lemma follows by interpolation. □

We are now in position to conclude the proof of Theorem 3.2. We use the pointwise estimate (3.13). For any δ with $\frac{7}{10} < \delta < \frac{3}{2}$, one obtains, thanks to Lemma 3.9,

$$\left\|(r^\delta k) * u^{p+1}\right\|_{L^2} \leq C \left\|\hat{k}\right\|_{\dot{H}^\delta_2} \|u\|^{p+1}_{L^{p+1}} < +\infty. \tag{3.26}$$

On the other hand, denoting by $\mathcal{F}$ the Fourier transform,

$$\begin{aligned} \left\|k * (r^\delta u^{p+1})\right\|_{L^2} &= \left\|\mathcal{F}(k * r^\delta u^{p+1})\right\|_{L^2} = \left\|\hat{k}\mathcal{F}(r^\delta u^{p+1})\right\|_{L^2} \\ &\leq C \left\|r^\delta u^{p+1}\right\|_{L^2} \end{aligned} \tag{3.27}$$

since $\hat{k} \in L^\infty(\mathbb{R}^3)$. But

$$\left|\int_{\mathbb{R}^3} r^{2\delta} u^{2(p+1)}\right| \leq \|ru\|^{2\delta}_{L^\infty} \int_{\mathbb{R}^3} |u|^{p+2(1-\delta)}.$$

Now, $u \in L^q(\mathbb{R}^3)$ for any $q > 1$, as can be checked from (3.10) and the fact that (by Lizorkin's Theorem [11]), $\hat{k}$ is a Fourier multiplier in L^q, $1 < q < \infty$ (see [5]). Since $p \geq 1$, we conclude that $r^\delta u^{p+1} \in L^2(\mathbb{R}^3)$ for any $\delta < 1$. Together with (3.26), this implies that

$$r^\delta u \in L^2(\mathbb{R}^3), \quad \frac{7}{10} < \delta < 1. \tag{3.28}$$

Let us finally prove that (3.28) is also true for $\delta < \frac{3}{2}$. Let $\delta = \frac{3}{2} - \frac{\varepsilon}{2}$, $\varepsilon > 0$ small. Then

$$\left|\int_{\mathbb{R}^3} r^{2\delta} u^{2(p+1)}\right| \leq \left\|r^{1-\varepsilon} u\right\|_{L^2} \|ru\|^2_{L^\infty} \left\|u^{2p-1}\right\|_{L^2},$$

and the right-hand side is finite by (3.28) and Lemma 3.8. □

Remarks 3.2.

1. One proves similarly to (3.12) that $r^{1+\delta}\nabla u$, $r^{1+\delta}u_{xx} \in L^2(\mathbb{R}^3)$ for any δ, $0 \leq \delta < \frac{3}{2}$.

2. We do not know whether or not $r^3 u \in L^\infty(\mathbb{R}^3)$. Note that the assertion corresponding to (3.17) (that is, $r^3 k \in L^\infty(\mathbb{R}^3)$) is not true.

3. It is worth noting that all the results of sections 2 and 3, as those of [5], are valid mutatis mutandi for the BBM version of the generalized KP equations considered here, namely, when the u_{xxx} term in (1.1) or (1.2) is replaced by $-u_{xxt}$.

4. An extension. A natural question is whether or not the results in Chapter 3 are modified by adding to (1.1) or (1.2) a higher order dispersive term in x. Essentially, they are not. To keep this paper short we will restrict ourselves to the two-dimensional and three-dimensional versions of a fifth-order KdV equation introduced by Abramyan and Stepanyants [1] and Karpman and Belashov [9], [10].

$$\begin{cases} u_t + u^p u_x + u_{xxx} + \delta u_{xxxxx} - v_y = 0, \\ v_x = u_y \end{cases} \tag{4.1}$$

in the 2-dimensional case and

$$\begin{cases} u_t + u^p u_x + u_{xxx} + \delta u_{xxxxx} - v_y - w_z = 0, \\ v_x = u_y, \quad w_x = u_z \end{cases} \tag{4.2}$$

in the 3-dimensional case.

A solitary wave of (4.1) (resp., (4.2)) is a solution of the form $u(x - ct, y)$ (resp., $u(x - ct, y, z)$) where $c > 0$ and $u \in Z = \{u \in Y,\ \partial_x^2 u \in L^2(\mathbb{R}^d)\}$, $d = 2, 3$.

In [5], we proved that when $\delta = -1$ (which we will assume from now on), (4.1) (resp., (4.2)) has a nontrivial solitary wave for arbitrary p's (resp., $1 \le p < \frac{8}{3}$), which belongs to $H^\infty(\mathbb{R}^d)$, $d = 2, 3$, when p is an integer.

Concerning the properties of such solitary waves, we have the following theorem.

THEOREM 4.1.

(i) *The solitary waves of* (4.1) *satisfy*

$$r^2 u \in L^\infty(\mathbb{R}^2), \quad r^2 = x^2 + y^2.$$

(ii) *The solitary waves of* (4.2) *satisfy*

$$r^\delta u \in L^2(\mathbb{R}^3), \quad r^2 = x^2 + y^2 + z^2, \ \textit{for any } \delta,\ 0 \le \delta < \frac{3}{2}.$$

The proof of Theorem 4.1 follows, with some technical differences, the corresponding ones in sections 2 and 3 and will be omitted. Note that the decay estimates are sharp (Remark 3.1 is still valid in this context); they are essentially imposed by the singularity of $\hat{k}$ at 0, namely, $\hat{k}(\xi) \sim \frac{\xi_1^2}{|\xi|^2}$.

Appendix. We state here the unique continuation result we have used in section 2. We consider first the two-dimensional situation.

THEOREM A.1. *Let $a, b, c \in L^\infty(\mathbb{R}^2)$ and u satisfy*

$$u, u_y, u_{xy}, u_{xx}, u_{xxx} \in L^2(\mathbb{R}^2), \tag{A.1}$$

$$u_{yy} - u_{xxxx} = a(x,y)u + b(x,y)u_x + c(x,y)u_{xx} \ \textit{in } \mathbb{R}^2. \tag{A.2}$$

Then, if u vanishes on a half-plane Π in $\mathbb{R}^2$, it vanishes everywhere in $\mathbb{R}^2$.

Proof. If the line delimiting Π is not characteristic (that is, not parallel to the x-axis), the result is an easy consequence of Isakov's unique continuation theorem [8]. If $\partial\Pi$ is parallel to the x-axis (which is the case we need in section 2), we have to use a different (global) argument which we only sketch here. It suffices obviously to prove that if u satisfying (A.1) and (A.2) is such that $u \equiv 0$ on $\{(x,y), y \le 0\}$ then it vanishes on $\Pi_T = \{(x,y), 0 \le y \le T\}$ for any $T > 0$.

We write (A.2) as

$$\frac{\partial v}{\partial y} - Av = -v + au + bu_x + cu_{xx}, \tag{A.3}$$

where

$$v = u_y - u_{xx},$$

$$A = I - \frac{\partial^2}{\partial x^2}.$$

A is a self-adjoint operator from $V = H^1(\mathbb{R})$ to $H^{-1}(\mathbb{R})$, which satisfies the hypothesis of Proposition II.1 in [15]. In order to apply the backward uniqueness result (Theorem II.1) of [15] (note that the "time" variable y is reversed in our problem), proving that v vanishes on Π_T, it suffices that the right-hand side of (A.3) defines an operator $B(y) \in L^2_y(0, T, \mathcal{L}(H^1_x(\mathbb{R}), L^2_x(\mathbb{R})))$. This is easily checked by using (A.1) and the fact that u solves the heat equation in Π_T

$$\begin{cases} u_y - u_{xx} = v, \\ u(x, 0) = 0. \end{cases} \tag{A.4}$$

Then, by the uniqueness of the Cauchy problem (A.4), u vanishes on Π_T.

For the three-dimensional situation we state the following theorem.

THEOREM A.2. *Let $a, b, c \in L^\infty(\mathbb{R}^3)$ and u satisfy*

$$u, u_y, u_z, u_{xy}, u_{xz}, u_{yz}, u_{yy}, u_{zz}, u_{xxx}, u_{xxy}, u_{xxz} \in L^2(\mathbb{R}^3), \tag{A.5}$$

$$u_{yy} + u_{zz} - u_{xxxx} = a(x, y, z)u + b(x, y, z)u_x + c(x, y, z)u_{xx}. \tag{A.6}$$

Then, if u vanishes on one side of a hyperplane H, it vanishes everywhere in $\mathbb{R}^3$.

Proof. Again, if H is not characteristic (that is, not parallel to the x-axis) the result follows from Isakov's theorem [8]. If H is parallel to the x-axis (which is the case of interest in section 2), we use a global argument. First, by the invariance of $\partial_y^2 + \partial_z^2$ by rotations in the (y, z) plane, it suffices to consider the case where H is parallel to a plane of coordinates containing the x-axis; for instance, $H = \{(x, y, z), y = 0\}$. Let us assume that u vanishes on $\{(x, y, z), y \leq 0\}$ and let us prove that u vanishes on

$$\Pi_T = \{(x, y, z), 0 \leq y \leq T\}$$

for any $T > 0$. We factorize (A.6) as

$$\frac{\partial v}{\partial y} - \mathcal{A}v = -v + au + bu_x + cu_{xx}, \tag{A.7}$$

where

$$v = u_y + Au, \mathcal{A} = I + A,$$

A being the operator (in $\mathbb{R}^2$) defined in Fourier variables by

$$\widehat{Au}(\xi_1, \xi_3) = (\xi_3^2 + \xi_1^4)^{1/2} \widehat{u}(\xi_1, \xi_3).$$

Obviously, A is a self-adjoint operator, continuous from V into V', where

$$V = \{v \in L^2(\mathbb{R}^2), v_x \in L^2(\mathbb{R}^2), |\xi_3|^{1/2}\widehat{v} \in L^2(\mathbb{R}^2)\}.$$

Again, it is easily checked that the hypothesis of Theorem II.1 in [15] is satisfied, yielding $v \equiv 0$ on Π_T and, therefore, $u \equiv 0$ on Π_T.

Acknowledgment. We thank Thierry Colin, who suggested that we use [12] to obtain the symmetry of the solitary waves.

A NOTE ON A TWO-POINT BOUNDARY VALUE PROBLEM ARISING FROM A LIQUID METAL FLOW*

YONGDONG SHI†, QINDE ZHOU†, AND YONG LI†

Abstract. A two-point boundary value problem with a positive parameter Q arising in the study of surface-tension–induced flows of a liquid metal or semiconductor is studied. On the basis of the upper–lower solution method and Schauder's fixed-point theorem, it is proved that when $0 \leq Q \leq 13.213$, the problem admits a solution. This improves a recent result where $0 \leq Q < 1$.

Key words. two-point boundary value problem, the upper–lower solution method, Schauder's fixed-point theorem

AMS subject classification. 34B

PII. S0036141095290252

1. Introduction.

Consider the following nonautonomous two-point boundary value problem (BVP) on [0,1]:

$$\begin{cases} \left[x\left(\frac{f'}{x}\right)'\right]' + Q\left[f\left(\frac{f'}{x}\right)' - x\left(\frac{f'}{x}\right)^2\right] = \beta x, & \text{(1.1a)} \\ f(0) = f(1) = \left(\frac{f'}{x}\right)'\Big|_{x=0} = \left(\frac{f'}{x}\right)'\Big|_{x=1} - 1 = 0, & \text{(1.1b)} \end{cases}$$

where $' = d/dx$. This problem arises in the study of surface-tension–induced flows of a liquid metal or semiconductor in a cylindrical floating zone of length $2L$ and radius R. Here the parameter $Q = 2L^3R^{-3}(\text{Re})$, Re is the Reynolds number, and β is a constant to determine.

Numerical solutions of (1.1) have been found [1] for $0 \leq Q \leq 32.7$ and $Q \geq 1749$. However, a theoretical proof of the existence of solutions of (1.1) has been done only for $0 \leq Q < 1$ in [2]. Hence, there is still a large gap between numerical experiments and theoretical results. In the present paper, on the basis of the upper–lower solution method and Schauder's fixed-point theorem, we prove the existence of solutions for (1.1) with $0 \leq Q \leq 13.213$. Thereby we greatly improve the existing results [2].

Our main result is the following.

THEOREM 1. *For* $0 \leq Q \leq 13.213$, *there exists a constant* β *such that* (1.1) *admits a solution* $f = f(x)$ *satisfying, on* $(0, 1)$,

$$-0.039064 \leq f(x) \leq 0, \quad -0.089647 \leq f'(x) \leq \frac{1}{3}, \quad -0.388320 \leq f''(x) \leq \frac{4}{3}.$$

2. A technical treatment of (1.1).

We observe that in (1.1), (1.1a) is a third-order equation with an unknown constant β, while the boundary value condition (1.1b) contains four equalities. Hence, following [2], we make the following technical treatment of (1.1).

[*] Received by the editors August 11, 1995; accepted for publication (in revised form) April 11, 1996.

http://www.siam.org/journals/sima/28-5/29025.html

[†] Department of Mathematics, Jilin University, Changchun 130023, People's Republic of China (math@mail.jlu.edu.cn).

Differentiating (1.1a) with respect to x, we obtain

$$\begin{cases} \left[\left(\frac{f'}{x}\right)'\right]'' + \left[\frac{1+Qf}{x}\right]\left(\frac{f'}{x}\right)'' - \left[\frac{1+Q(xf)'}{x^2}\right]\left(\frac{f'}{x}\right)' = 0, & \text{(2.1a)} \\ f(0) = f(1) = \left(\frac{f'}{x}\right)'\Big|_{x=0} = \left(\frac{f'}{x}\right)'\Big|_{x=1} - 1 = 0. & \text{(2.1b)} \end{cases}$$

Let $(f'/x)' = g$. Then (2.1) has the form

$$\begin{cases} g'' + \left[\frac{1+Qf}{x}\right] g' - \left[\frac{1+Q(xf)'}{x^2}\right] g = 0, & \text{(2.2a)} \\ g(0) = g(1) - 1 = 0. & \text{(2.2b)} \end{cases}$$

To prove the existence of solutions for (1.1), we reduce it to a problem of finding a fixed point. On the basis of the differential inequality technique, to construct upper and lower solutions of (2.2), we consider the following set:

$$D = \{f | f \in C^1[0,1], f(0) = f(1) = 0, h(x) \le f(x) \le 0, \\ m(x) \le f'(x) \le n(x)\},$$

where

$$h(x) = \frac{(25)^2}{3219} x^2 (x^{\frac{37}{25}} - 1), \qquad n(x) = \frac{1}{3} x^4,$$

$$m(x) = 25x \left(\frac{1}{126} x^{\frac{126}{25}} - \frac{1}{87} x^{\frac{87}{25}} + \frac{1}{37} x^{\frac{37}{25}} - \frac{50}{3219} \right).$$

For any $f \in D$, if (1) eq. (2.2) has a unique solution $g(x)$ and (2) the problem

$$\begin{cases} \left(\frac{f^{*\prime}}{x}\right)' = g, & \text{(2.3a)} \\ f^*(0) = f^*(1) = 0 & \text{(2.3b)} \end{cases}$$

also has a unique solution $f^*(x)$, then we may define an operator

$$T : f \longmapsto f^*, f \in D,$$

where f^* is the solution of (2.3). Thus, given $Q \in [0, 13.213]$, if we can prove that (3) T has a fixed point, namely, there exists $f \in D$ such that $Tf = f$, then f is a solution of (2.1). Integrating (2.1a) from 1 to x and using (2.1b), we obtain (1.1a) at once; here $\beta = [(\frac{f'}{x})'' + \frac{1+Qf}{x}(\frac{f'}{x})' - Q(\frac{f'}{x})^2]\big|_{x=1}$. Therefore, f must be the solution of (1.1).

In the following, we shall carry out the above three processes, respectively.

3. The solution of the problem (2.2). We consider the boundary value problem on $[x_1, x_2]$

$$y'' = a(x)y' + b(x)y, \tag{3.1a}$$

$$y(x_1) = A_1, y(x_2) = A_2, \tag{3.1b}$$

where $a(x), b(x) \in C^1[x_1, x_2]$ and $b(x) > 0$.

LEMMA 1. *Suppose that there exist functions* $\overline{\omega}(x), \underline{\omega}(x) \in C^2[x_1, x_2]$ *such that for* $x_1 \leq x \leq x_2$,

$$\begin{aligned}&\underline{\omega}(x) \leq \overline{\omega}(x),\\&\overline{\omega}''(x) \leq a(x)\overline{\omega}'(x) + b(x)\overline{\omega}(x),\\&\underline{\omega}''(x) \geq a(x)\underline{\omega}'(x) + b(x)\underline{\omega}(x),\end{aligned}$$

and

$$\underline{\omega}(x_i) \leq A_i \leq \overline{\omega}(x_i), \qquad i = 1, 2.$$

Then the problem (3.1) *has a unique solution* $y = y(x)$, *and*

$$\underline{\omega}(x) \leq y(x) \leq \overline{\omega}(x), \qquad x_1 \leq x \leq x_2.$$

Moreover, there exists a positive number N *which depends only on interval* $[x_1, x_2]$ *and the function pairs* $\overline{\omega}(x), \underline{\omega}(x)$ *such that*

$$|y'(x)| \leq N, \qquad x_1 \leq x \leq x_2.$$

Since $b(x) > 0$, we use the maximal value principle, it is easy to prove the uniqueness of solutions of (3.1), and other aspects of Lemma 1 are generalizations of Nagumo's theorem (see [3, Thm. 1.5.1]).

THEOREM 2. *Assume* $f \in D$ *and* $0 \leq Q \leq 13.213$. *Then the boundary value problem* (2.2) *has a unique solution* $g = g(x)$.

Proof. Notice for $f \in D, x \in (0, 1]$, we have

$$\begin{aligned}\frac{1 + Q(xf)'}{x^2} = \frac{1}{x^2}[1 + Q(xf' + f)] &\geq \frac{1}{x^2}[1 + Q(xm(x) + h(x))]\\&= \frac{1}{x^2}[1 + QF(x)],\end{aligned}$$

where

$$F(x) = xm(x) + h(x) = 25x^2\left(\frac{1}{126}x^{\frac{126}{25}} - \frac{1}{87}x^{\frac{87}{25}} + \frac{112}{3219}x^{\frac{37}{25}} - \frac{75}{3219}\right).$$

By a simple argument, we show that $F(x)$ is decreasing on $[0, c]$ and increasing on $[c, 1]$, where $c = 0.565711027\ldots$. Hence $F(x)$ takes a minimum at $x = c$, i.e.,

$$\min_{x\in[0,1]} F(x) = F(c) = -0.0756773788\cdots \geq -0.075678.$$

Therefore, for $0 \leq Q \leq 13.213$, we have

$$\frac{1 + Q(xf)'}{x^2} > 0, \qquad x \in (0, 1]. \tag{3.2}$$

For any positive integer $n \geq 2$, consider the boundary value problem

$$\begin{cases} g'' = -\left[\dfrac{1 + Qf}{x}\right]g' + \left[\dfrac{1 + Q(xf)'}{x^2}\right]g, & \text{(3.3a)}\\ g(\frac{1}{n}) = 0, \qquad g(1) = 1. & \text{(3.3b)}\end{cases}$$

We set $\underline{\omega}(x) \equiv 0$, $\overline{\omega}(x) = x^\alpha$, where $\alpha > 0$ is sufficiently small, so that

$$\alpha^2 + \alpha Q f \leq 1 + Q(xf)'.$$

Then

$$\begin{aligned}\overline{\omega}''(x) &\leq -\left[\frac{1+Qf}{x}\right]\overline{\omega}'(x) + \left[\frac{1+Q(xf)'}{x^2}\right]\overline{\omega}(x),\\ \underline{\omega}''(x) &\geq -\left[\frac{1+Qf}{x}\right]\underline{\omega}'(x) + \left[\frac{1+Q(xf)'}{x^2}\right]\underline{\omega}(x)\end{aligned}$$

for all $x \in [\frac{1}{n}, 1]$, $n \geq 2$, $\underline{\omega}(1) = 0 < 1 = \overline{\omega}(1)$, and $\underline{\omega}(\frac{1}{n}) = 0 < \frac{1}{n^\alpha} = \overline{\omega}(\frac{1}{n})$. By Lemma 1, we obtain that (3.3) has only one solution, $g_n = g_n(x)$, which satisfies

$$0 \leq g_n(x) \leq x^\alpha, \qquad x \in \left[\frac{1}{n}, 1\right].$$

Since $g_n(x), n = 2, 3, \ldots$ are all solutions of (3.3a) and $o \leq g_n(x) \leq x^\alpha, x \in [\frac{1}{2}, 1]$, applying the part related to the estimate of the derivative in Lemma 1, we have that $\{g_n'(x)\}$ is uniformly bounded on $[\frac{1}{2}, 1]$ and hence that $\{g_n'(1)\}$ is bounded. Without loss of generality, we let $\{g_n'(1)\} \to \alpha_0$ as $n \to \infty$.

We consider the solution of (3.3a) satisfying the initial conditions $g(1) = 1$, $g'(1) = \alpha_0$. Obviously, it exists on $[0, 1]$ and satisfies

$$0 \leq g(x) \leq x^\alpha;$$

namely, $g(x)$ is the solution of (2.2). The uniqueness of the solution is easy to obtain by (3.2). The proof of the theorem is completed.

To prove Theorem 1, we give the bound of $g(x)$ and $g'(x)$ on $[0, 1]$.

THEOREM 3. *For $f \in D$, $0 \leq Q \leq 13.213$, the solution $g(x)$ of* (2.2) *satisfies*

(3.4) (i) $g(x) > 0,\ \ g'(x) > 0, 0 < x < 1,$

(3.5) (ii) $\lim_{x \to 0+} x g'(x) = 0,$

(3.6) (iii) $x^{\frac{51}{25}} \leq g(x) \leq x^{\frac{12}{25}},$

(3.7) (iv) $\dfrac{12}{25} x^{\frac{51}{25}} \leq x g'(x) \leq \dfrac{51}{25} x^{\frac{12}{25}}.$

Proof. (i) Since $1+Q(xf)' > 0$, $x \in [0, 1]$, we see easily that $g(x) > 0$, $g'(x) \geq 0$ on $(0, 1)$ by the maximal value principle. Next we assert that $g'(x) \neq 0$ for any $x \in (0, 1)$. If not, then there exists $x_0 \in (0, 1)$ such that $g'(x_0) = 0$. We have $g''(x_0) > 0$ from (2.2a), namely, $g(x)$ takes a minimum at $x = x_0$. Hence $g(x)$ must have a maximum at some $x_1 \in (0, x_0)$. This is impossible because we have $g''(x_1) > 0$ from (2.2a), a contradiction.

(ii) Rewrite (2.2a) as follows:

$$x(xg')' = -Qfg' + [1 + Q(xf)']g.$$

Owing to $0 \leq x \leq 1$, $f \leq 0$, $1 + Q(xf)' > 0$, and $g > 0$, we have $x(xg')' > 0$; i.e., $(xg')' > 0$, and hence xg' is increasing on $(0, 1)$. Using (3.4), we obtain $xg' > 0$ for $x \in (0, 1)$, and therefore $\lim_{x \to 0+} xg'(x)$ exists and $\lim_{x \to 0+} xg'(x) \geq 0$. If there exists $\alpha > 0$ such that $\lim_{x \to 0+} xg'(x) = \alpha$, then for $\frac{\alpha}{2}$, there is a $\delta > 0$ so that

$\frac{\alpha}{2} < xg'(x) < g'(1)$ for $x \in (0, \delta)$, or $\frac{\alpha}{2x} < g'(x) < \frac{1}{x}g'(1)$. Integrating it from x to δ, we have

$$\frac{\alpha}{2} \ln \frac{\delta}{x} < g(\delta) - g(x) < g'(1) \ln \frac{\delta}{x}.$$

This means $g(x) \to -\infty$ as $x \to 0+$, contradicting $g(0) = 0$. Thus $\lim_{x\to 0+} xg'(x) = 0$.

(iii) Equation (2.2a) can be converted to the following form:

$$(x^2g')' - (xg)' - Q(xfg)' = -2Qxfg'.$$

Integrating the above equation from 0 to x, using (3.5) and $g(0) = 0$, we obtain

$$g' = \left[\frac{1+Qf}{x}\right] g - \frac{2Q}{x^2} \int_0^x tfg'\, dt, \qquad 0 < x < 1.$$

Hence, as $-0.039064 \le f(x) \le 0$, $g'(x) \ge 0$, and $0 \le Q \le 13.213$, we have $Qf > -\frac{13}{25}$. This implies

$$\begin{aligned} \frac{12}{25x}\, g(x) \le g'(x) \quad &\le \frac{1}{x}\, g(x) + \frac{26}{25x} \int_0^x g'\, dt \\ &= \frac{51}{25x}\, g(x). \end{aligned} \tag{3.8}$$

We integrate (3.8) from 1 to x and obtain (3.6).

(iv) We combine (3.6) with (3.8) and yield (3.7).

The theorem is proved.

4. The solution of boundary value problem (2.3). Integrating (2.3a) from 0 to x and using (2.3b), we see

$$f^{*\prime}(x) = kx + x \int_0^x g(t)\, dt \tag{4.1}$$

and

$$f^*(x) = \frac{1}{2}kx^2 + \int_0^x \left(s \int_0^s g(t)\, dt \right) ds, \tag{4.2}$$

where $k = -2\int_0^1 (s \int_0^s g(t)\, dt)\, ds$. By Theorem 2, we know that $g(x)$ exists and is unique, so (2.3) has a unique solution $f^* = f^*(x)$ on $[0, 1]$.

In the following, we estimate the bound of f^* and $f^{*\prime}$.

Since

$$k = -2 \int_0^1 \left(s \int_0^s g(t)\, dt \right) ds = -2 \int_0^1 \left(g(t) \int_t^1 s\, ds \right) dt = -\int_0^1 (1 - t^2) g(t)\, dt,$$

(4.1) and (4.2) become

$$f^{*\prime}(x) = -x \int_0^1 (1 - t^2) g(t)\, dt + x \int_0^x g(t)\, dt, \tag{4.3}$$

$$f^*(x) = -\frac{1}{2}x^2 \int_0^1 (1 - t^2) g(t)\, dt + \frac{1}{2} \int_0^x (x^2 - t^2) g(t)\, dt. \tag{4.4}$$

From (4.3), we have

$$\begin{aligned} f^{*\prime}(x) &= -x\int_0^x (1-t^2)g(t)\,dt - x\int_x^1 (1-t^2)g(t)\,dt + x\int_0^x g(t)\,dt \\ &= -x\int_x^1 (1-t^2)g(t)\,dt + x\int_0^x t^2 g(t)\,dt. \end{aligned}$$

By (3.4) and (3.6), we have the following inequalities:

$$\begin{aligned} f^{*\prime}(x) &\le x\int_0^x t^2\,dt = \frac{1}{3}x^4 = n(x) \le \frac{1}{3}, \\ f^{*\prime}(x) &\ge -x\int_x^1 (1-t^2)t^{\frac{12}{25}}\,dt + x\int_0^x t^2 t^{\frac{51}{25}}\,dt \\ &= 25x\left(\frac{1}{126}x^{\frac{126}{25}} - \frac{1}{87}x^{\frac{87}{25}} + \frac{1}{37}x^{\frac{37}{25}} - \frac{50}{3219}\right) \\ &= m(x) \ge -0.089647. \end{aligned}$$

From (4.4), it follows that

$$f^*(x) = \frac{1}{2}(x^2-1)\int_0^x t^2 g(t)\,dt - \frac{1}{2}x^2\int_x^1 (1-t^2)g(t)\,dt.$$

By (3.4) and (3.6), we obtain

$$\begin{aligned} 0 \ge f^*(x) &\ge \frac{1}{2}(x^2-1)\int_0^x t^2 t^{\frac{12}{25}}\,dt - \frac{1}{2}x^2\int_x^1 (1-t^2)t^{\frac{12}{25}}\,dt \\ &= \frac{(25)^2}{3219}x^2(x^{\frac{37}{25}}-1) \\ &= h(x) \ge -\left(\frac{25}{87}\right)^2\left(\frac{50}{87}\right)^{\frac{50}{37}} \ge -0.039064. \end{aligned}$$

Using similar arguments, we have

$$-0.388320 \le f^{*\prime\prime}(x) \le \frac{4}{3}.$$

In summary, we get the following inequalities:

$$-0.039064 \le f^*(x) \le 0,$$

$$-0.089647 \le f^{*\prime}(x) \le \frac{1}{3},$$

$$-0.388320 \le f^{*\prime\prime}(x) \le \frac{4}{3}.$$

5. *T* has a fixed point. We define the norm on $C^1[0,1]$ by

$$||f|| := \max|f| + \max|f'|, \qquad x \in [0,1].$$

Then $C^1[0,1]$ is a Banach space. It is easy to check that D in section 2 is a nonempty, closed, bounded, convex subset of $C^1[0,1]$. By sections 3 and 4, we see that T is well defined and $TD \subseteq D$. In addition, T maps a bounded subset of D into a compact subset of D. (For details, see [2].)

Now we prove that the operator T is continuous.

By the definition of T and (4.2), we only need prove that for any given $f_0 \in D$ and any $\varepsilon > 0$, there exists $\delta > 0$ such that as $||f - f_0|| < \delta$ and $f \in D$,

$$\max_{x\in[0,1]} |g(x) - g_0(x)| < \varepsilon, \tag{5.1}$$

where g and g_0 are solutions of (5.2) and (5.3), respectively:

$$\begin{cases} g'' + \left[\dfrac{1+Qf}{x}\right] g' - \left[\dfrac{1+Q(xf)'}{x^2}\right] g = 0, \\ g(0) = g(1) = 0, \qquad x \in [0,1]. \end{cases} \tag{5.2}$$

$$\begin{cases} g'' + \left[\dfrac{1+Qf_0}{x}\right] g' - \left[\dfrac{1+Q(xf_0)'}{x^2}\right] g = 0, \\ g(0) = g(1) = 0, \qquad x \in [0,1]. \end{cases} \tag{5.3}$$

Let $p(x) = g(x) - g_0(x)$. Then by (5.2) and (5.3), we have

$$\begin{aligned} L[p] &= p'' + [1+Qf_0]\, p' - \left[\frac{1+Q(xf_0)'}{x^2}\right] p \\ &= -\left(\tfrac{Q}{x^2}\right)[(f-f_0)(xg'-g) - (f'-f_0')xg] \\ &= -G(x), \end{aligned} \tag{5.4}$$

with $p(0) = p(1) = 0$. For any $0 \le x \le \varepsilon$, $f \in D$, and $0 \le Q \le 13.213$, by using (3.6) we obtain

$$|p(x)| = |g(x) - g_0(x)| \le 2x^{\frac{12}{25}} \le 2\varepsilon^{\frac{12}{25}} = \varepsilon_1. \tag{5.5}$$

For $x \in [\varepsilon, 1]$, $||f - f_0|| \to 0$, and $0 \le Q \le 13.213$, we claim that $|p(x)| < \varepsilon_1$.

Set

$$\varepsilon^* = (1 - 0.075678Q)\varepsilon_1. \tag{5.6}$$

If $||f - f_0||$ is sufficiently small, $x \in [\varepsilon, 1]$, and $0 \le Q \le 13.213$, then, by (3.6) and (3.7), we have

$$\begin{aligned} |G(x)| &\le \tfrac{Q}{\varepsilon^2}[\max\{|xg'| + |xg| + |g|\}]||f - f_0|| \\ &\le \tfrac{Q}{\varepsilon^2}(\tfrac{51}{25} + 1 + 1)||f - f_0|| \\ &= \tfrac{101Q}{25\varepsilon^2}||f - f_0|| < \varepsilon^*. \end{aligned} \tag{5.7}$$

For fixed f_0, let p be a solution of (5.4) with the boundary conditions $|p(\varepsilon)| \le \varepsilon_1$ and $p(1) = 0$. By (5.7), we have

$$L[p] - \varepsilon^* \le L[p] + F(x) \le L[p] + \varepsilon^*, \qquad \varepsilon \le x \le 1. \tag{5.8}$$

Let $p^{\pm}$ be solutions of the following problems:

$$\begin{cases} L[p] \pm \varepsilon^* = 0, \\ p^{\pm}(1) = 0, \qquad p^{\pm}(\varepsilon) = p(\varepsilon). \end{cases}$$

Then, using the comparison theorem, we show that

$$p^-(x) \le p(x) \le p^+(x), \qquad x \in [\varepsilon, 1].$$

Now we prove that for any $x \in [\varepsilon, 1]$, there is $p^+(\varepsilon) \le \varepsilon_1$. In fact, we see that $p^+(x) \le \varepsilon_1$ as $|p(\varepsilon)| \le \varepsilon_1$. If not, then there exists a point $x_+ \in (\varepsilon, 1)$ such that $p^+(x_+) > \varepsilon_1$. By $p^+(\varepsilon) = p(\varepsilon) \le \varepsilon_1$, there must be a point $y_+ \in (\varepsilon, 1)$ such that $p^+(x)$ takes maximum at y_+, namely,

$$p^+(y_+) > \varepsilon_1, \quad {p^+}'(y_+) = 0, \quad {p^+}''(y_+) < 0.$$

But by (5.6) and (5.9), we see that the following holds:

$$\begin{aligned} {p^+}''(y_+) + \varepsilon^* &= \left[\frac{1 + Qf_0(y_+) + Qf_0'(y_+)y_+}{y_+^2}\right] p^+(y_+) \\ &> (1 - 0.075678Q)\varepsilon_1. \end{aligned}$$

Hence, using (5.6), we get

$${p^+}''(y_+) > (1 - 0.075678Q)\varepsilon_1 - \varepsilon^* = 0,$$

a contradiction. For $x \in [\varepsilon, 1]$ and $|p(\varepsilon)| \le \varepsilon_1$, we argue similarly and obtain $p^-(x) \ge -\varepsilon_1$. Thus, when $x \in [\varepsilon, 1]$ and $|p(\varepsilon)| \le \varepsilon_1$, there exists $|p(x)| \le \varepsilon_1$.

Therefore, for any given $\varepsilon > 0$, if we choose

$$\delta = \frac{\varepsilon^*}{\frac{101Q}{25\varepsilon^2}},$$

where ε^* satisfies (5.6), then for $f \in D$, $\max_{x\in[0,1]} |g(x) - g_0(x)| = \varepsilon_1 = 2\varepsilon^{\frac{12}{25}}$ as $||f - f_0|| < \delta$, and the continuity of T is proved.

To sum up, we see that the operator T satisfies the conditions of Schauder's fixed-point theorem [4], and thus T has at least one fixed point in D.

By sections 2, 3, 4, and 5, Theorem 1 is proved.

Acknowledgment. The authors thank the referees for their valuable suggestions.

STABILITY OF TRAVELLING MULTIPLE-FRONT (MULTIPLE-BACK) WAVE SOLUTIONS OF THE FITZHUGH–NAGUMO EQUATIONS*

SHUNSAKU NII†

Abstract. Consideration is devoted to travelling multiple-front (back) wave solutions of the FitzHugh–Nagumo equations of bistable type. In particular, stability of the 1-front (back) wave is proven. In the proof, the eigenvalue problem for the 1-front wave bifurcating from coexisting simple front and back waves is regarded as a bifurcation problem for projectivized eigenvalue equations, rather than treated as a linear eigenvalue problem for each fixed wave.

Key words. travelling wave, eigenvalue problem, bifurcation

1. Introduction.

The following system is called the FitzHugh–Nagumo equations:

$$\begin{cases} u_t &= u_{xx} + f(u) - w, \\ w_t &= \varepsilon(u - \gamma w), \end{cases} \tag{1.1}$$

where $x, t \in \mathbb{R}$ and $u(x,t), w(x,t) \in \mathbb{R}$, and $1 \gg \varepsilon > 0, \gamma > 0$ are parameters. In this system, the nonlinear term $f(u)$ is assumed to be a smooth cubic-like function of u satisfying the conditions below.

$$\begin{gathered} f(0) = f(a) = f(1) = 0, \\ f'(0) < 0, \quad f'(1) < 0, \\ f(u) \begin{cases} > 0 & \text{if} \quad u \in (-\infty, 0) \cup (a, 1), \\ < 0 & \text{if} \quad u \in (0, a) \cup (1, +\infty), \end{cases} \\ \textstyle\int_0^1 f(u)du > 0, \end{gathered} \tag{1.2}$$

where $0 < a < 1$ is a constant.

In this paper we shall restrict our attention to large $\gamma > 0$ so that the system (1.1) has three spatially homogeneous stationary solutions $(u, w) \equiv (u_1, w_1) := (0, 0)$, $(u_\dagger, w_\dagger)$, and (u_2, w_2). Here u_* and w_* ($* = 1, 2$ or $\dagger$) are constants which satisfy

$$\begin{gathered} \begin{cases} f(u_*) - w_* &= 0 \\ u_* - \gamma w_* &= 0, \end{cases} \quad * = 1, 2 \text{ or } \dagger \\ 0 = u_1 < u_\dagger < u_2 < 1. \end{gathered} \tag{1.3}$$

(See Figure 1.1.)

The system (1.1) has spatial solutions called travelling waves which are explained below.

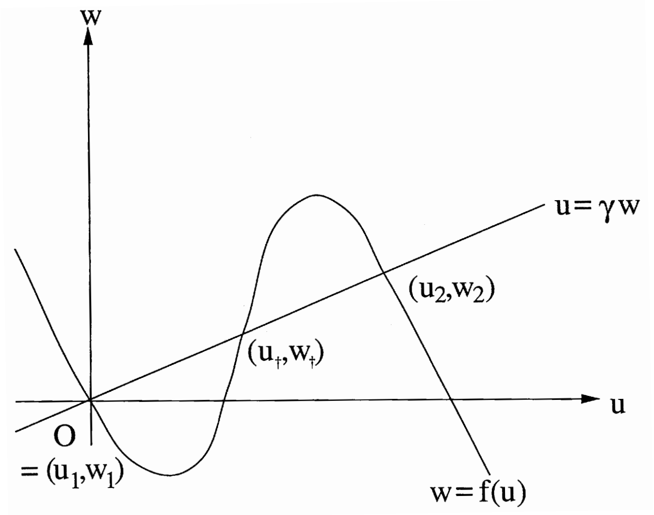

FIG. 1.1. *The nullclines of equations* (1.1).

Let $\xi = x + ct$ be a moving frame for some constant $c > 0$; then in the (ξ, t) coordinate, (1.1) is expressed as

$$\left\{ \begin{array}{ll} u_t & = u_{\xi\xi} - cu_\xi + f(u) - w, \\ w_t & = -cw_\xi + \varepsilon(u - \gamma w). \end{array} \right. \tag{1.4}$$

A travelling wave solution $(u(x,t), w(x,t)) = (u(\xi), w(\xi))$ of (1.1) at velocity c is a steady state solution of (1.4); i.e., $(u(\xi), w(\xi))$ satisfies the equations

$$\left\{ \begin{array}{rl} u_{\xi\xi} - cu_\xi + f(u) - w & = 0, \\ -cw_\xi + \varepsilon(u - \gamma w) & = 0. \end{array} \right. \tag{1.5}$$

Often, (1.5) is treated in the form of first-order equations,

$$\left\{ \begin{array}{ll} u' & = v, \\ v' & = cv - f(u) + w \qquad (' = \frac{d}{d\xi}), \\ w' & = \frac{\varepsilon}{c}(u - \gamma w). \end{array} \right. \tag{1.6}$$

This system shall be simply written as

$$z' = X(z; \mu), \tag{1.7}$$

where $z = (u, v, w)$ and $\mu = (\gamma, c; \varepsilon)$. $a_1 := (u_1, 0, w_1) = (0, 0, 0)$ and $a_2 := (u_2, 0, w_2)$ are equilibria of (1.6).

It is well known that (1.6) has a heteroclinic solution $z_1^*(\xi)$ from a_1 to a_2 ($z_2^*(\xi)$ from a_2 to a_1) for certain parameter values. This solution corresponds to a travelling wave of (1.1), which satisfies

$$\lim_{\xi \to -\infty} z_1^*(\xi) = a_1, \qquad \lim_{\xi \to +\infty} z_1^*(\xi) = a_2 \tag{1.8}$$

$$\left(\lim_{\xi \to -\infty} z_2^*(\xi) = a_2, \lim_{\xi \to +\infty} z_2^*(\xi) = a_1, \text{ respectively} \right). \tag{1.9}$$

This wave is called travelling front, or simple front, in the terminology in Deng [7] (travelling back or simple back, respectively). Deng [7] proved that for certain parameter values, the system (1.6) has heteroclinic solutions z_1^* and z_2^* simultaneously, forming what is called a heteroclinic loop. Furthermore, there is a sequence of N-heteroclinic solutions from a_1 to a_2 (from a_2 to a_1) which correspond to travelling waves called N-fronts (N-backs, respectively) bifurcating from the heteroclinic loop, together with homoclinic solutions to a_1 and a_2 which correspond to travelling pulses (simple impulses, in Deng's terminology). Here a heteroclinic solution from a_1 to a_2 (from a_2 to a_1) which rounds N times and a half in some tubular neighborhood of the heteroclinic loop is referred to as an N-heteroclinic solution from a_1 to a_2 (from a_2 to a_1). (See Figure 1.2.)

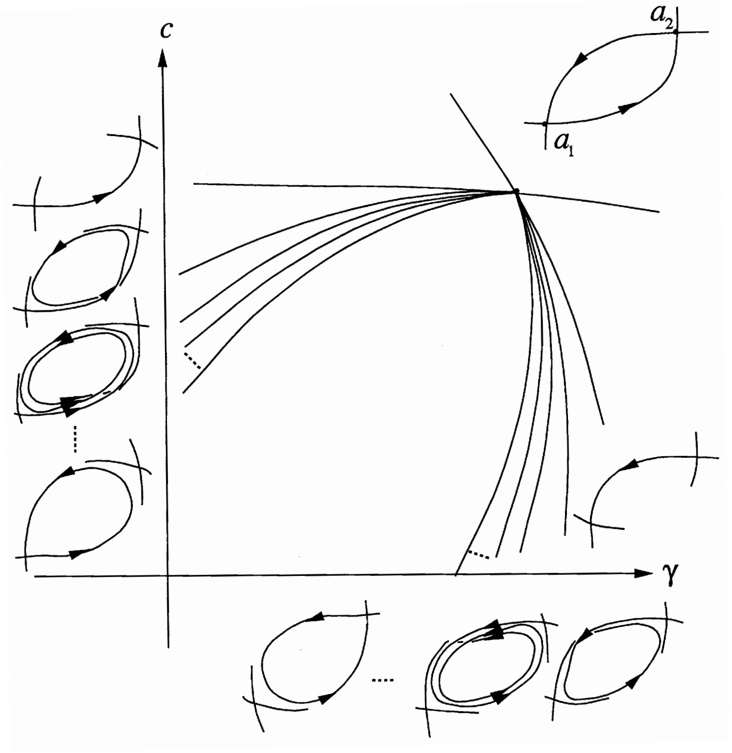

FIG. 1.2. *The bifurcation diagram of N-heteroclinic solutions of the system* (1.6).

We are concerned with the stability of these travelling waves. The eigenvalue problem for (1.4) along the travelling wave under study is often investigated to determine the stability of the wave, as stability for the linear problem implies the same for the full nonlinear problem. See Evans [8].

The linear stability is established as follows. Consider the linearization of (1.4) along the travelling wave $(u(\xi), v(\xi))$ that is under consideration:

$$(1.10) \qquad \begin{cases} P_t &= P_{\xi\xi} - cP_\xi + Df\,(u(\xi))\,P - R, \\ R_t &= -cR_\xi + \varepsilon(P - \gamma R). \end{cases}$$

The right-hand side of (1.10) defines a densely defined closed operator

$$L\begin{pmatrix} P \\ R \end{pmatrix} := \begin{pmatrix} P_{\xi\xi} - cP_\xi + Df\,(u(\xi))\,P - R \\ -cR_\xi + \varepsilon(P - \gamma R) \end{pmatrix} \tag{1.11}$$

on the space $BU(\mathbb{R}, \mathbb{R}^2) := \big\{\phi\colon \mathbb{R} \to \mathbb{R}^2 |\text{ bounded uniformly continuous}\big\}$ with supremum norm. Then, the following fact is well known (Evans [8], Bates and Jones [5]).

Fact. *Let $\sigma(L)$ be the spectrum of L; then the travelling wave $(u(\xi), v(\xi))$ is stable if the conditions below are satisfied.*

1. *There exist $\beta < 0$ so that $\sigma(L) \setminus \{0\} \subset \{\lambda | Re\lambda < \beta\}$.*
2. *0 is a simple eigenvalue.*

Remark 1.1.

1. *L has as an eigenvalue 0 corresponding to spatial translation of the wave.*
2. *Concerning a wave that connects stable steady states, there exists $\beta < 0$ so that $\sigma(L) \cap \{\lambda | \mathrm{Re}\lambda > \beta\}$ consists only of eigenvalues with finite multiplicity.* (*See Jones* [11] *for FitzHugh–Nagumo equations, Henry* [10] *for general cases.*)

Thus we prove the stability of a given wave by showing that zero is a simple eigenvalue of L and that there is no other eigenvalue with zero or positive real part.

The stability of the simple front (back) was proven by Yanagida [17] by showing that the critical eigenvalue was only simple at the origin. The stability of simple impulses can be verified in the same manner as in Jones [11] or Yanagida [16], in which the problem was treated as a singular limit problem for ε when γ was not large, or by applying Nii [12] when it is regarded as a bifurcation problem. In this case the operator L for a simple impulse possesses two critical eigenvalues; one is at the origin, and the sign of the other determines stability. Either way, the Evans function explained below plays a conclusive role.

The eigenvalue problem

$$\begin{cases} P_{\xi\xi} - cP_\xi + Df\,(u(\xi))\,P - R &= \lambda P, \\ \quad -cR_\xi + \varepsilon(P - \gamma R) &= \lambda R \end{cases} \tag{1.12}$$

can be regarded as a system of second-order linear ordinary differential equations. This system shall also be treated in the form of a first-order system,

$$\begin{cases} P' &= Q, \\ Q' &= cQ - Df\,(u(\xi))\,P + \lambda P + R \\ R' &= \frac{\varepsilon}{c}(P - \gamma R) - \frac{\lambda}{c}R, \end{cases} \qquad \left(\ ' = \tfrac{d}{d\xi}\right), \tag{1.13}$$

or simply

$$p' = A\,(u(\xi);\lambda)\,p, \tag{1.14}$$

where $p = (P, Q, R)$ and

$$A\,(u(\xi);\lambda) = \begin{pmatrix} 0 & 1 & 0 \\ \lambda - Df\,(u(\xi)) & c & 1 \\ \frac{\varepsilon}{c} & 0 & -\frac{1}{c}(\varepsilon\gamma + \lambda) \end{pmatrix}.$$

For $\mathrm{Re}\lambda > \beta$ the matrices

$$A_\pm(\lambda) := A(a_{i_\pm};\lambda) = \begin{pmatrix} 0 & 1 & 0 \\ \lambda - Df(a_{i_\pm}) & c & 1 \\ \frac{\varepsilon}{c} & 0 & -\frac{1}{c}(\varepsilon\gamma + \lambda) \end{pmatrix}$$

in both ends ($\xi \to \pm\infty$) of (1.13) have one unstable eigenvalue and two stable ones, where we assume that $\lim_{\xi\to\pm\infty}(u(\xi), w(\xi)) = a_{i_\pm}$. This means (1.13) has one solution $p_1(\xi;\lambda)$ which is bounded as $\xi \to -\infty$ up to multiplication of a nonzero constant and two independent solutions $p_2(\xi;\lambda), p_3(\xi;\lambda)$ which are bounded as $\xi \to +\infty$ up to a nontrivial linear combination of them.

The Evans function $E\mathrm{v}(\lambda)$ is defined as

$$E\mathrm{v}(\lambda) = \det\left(p_1(\xi;\lambda)p_2(\xi;\lambda)p_3(\xi;\lambda)\right)\big|_{\xi=0}. \tag{1.15}$$

Here, as we are working on small ε, $p_1(\xi;\lambda)$, $p_2(\xi,\lambda)$, and $p_3(\xi,\lambda)$ can be chosen so that they depend analytically on λ, and $E\mathrm{v}(\lambda)$ can be defined as an analytic function of λ. By definition, $E\mathrm{v}(\lambda)$ vanishes if and only if $p_1(\xi;\lambda)$, $p_2(\xi;\lambda)$, and $p_3(\xi;\lambda)$ are linearly dependent. This is equivalent to existence of a bounded solution of (1.13), which means that the λ is an eigenvalue of L. If $E\mathrm{v}(\lambda)$ is normalized so that $E\mathrm{v}(\lambda) > 0$ for large $\lambda \in \mathbb{R}$, the sign of $\frac{dE\mathrm{v}}{d\lambda}\big|_{\lambda=0}$ determines the sign of the eigenvalue other than zero. This sign is determined by the geometric structure of the single impulse or corresponding homoclinic orbit. In fact, it is positive and the sign of the eigenvalue is negative. Thus the impulse is stable. In the case of N-front (back) waves, we know that there are $2N+1$ critical eigenvalues near the origin by an argument similar to those in Alexander and Jones [2] or Nii [12]. However, we can only know by an argument similar to that used above that the number of the eigenvalues with positive real part is even. Consequently, we need more analysis to determine their stability.

In this paper, we deal with this eigenvalue problem as a "full" bifurcation problem.

Consider the coupled system of (1.6) and (1.13):

$$\left\{\begin{array}{ll} z' & = X(z;\mu), \\ p' & = A(z;\lambda,\mu)p. \end{array}\right. \tag{1.16}$$

This system on $\mathbb{R}^3 \times \mathbb{C}^3$ induces a system on $\mathbb{R}^3 \times \mathbb{CP}^2$:

$$\left\{\begin{array}{ll} z' & = X(z;\mu), \\ \hat{p}' & = Y(z,\hat{p};\lambda,\mu) \end{array}\right. \tag{1.17}$$

as it is linear in p-component.

Let $e_{i,1}(\lambda)$ ($i = 1, 2$) be an eigenvector associated with the unstable eigenvalue of $A(a_i;\lambda)$ and $e_{i,2}(\lambda)$ and $e_{i,3}(\lambda)$ be eigenvectors associated with the stable eigenvalues. Furthermore, we assume that $e_{i,2}(\lambda)$ belongs to the eigenspace corresponding to the principal stable eigenvalue, which is the stable eigenvalue with its real part larger than the other. The points in $\mathbb{CP}^2$ representing eigenspaces spanned by $e_{i,j}(\lambda)$ shall be denoted as $\hat{e}_{i,j}(\lambda)$. Then for each $i = 1, 2$, $\{a_i\} \times \mathbb{CP}^2$ is an invariant set of (1.17), which consists of equilibria $(a_i, \hat{e}_{i,j}(\lambda))$ ($j = 1, 2, 3$) and heteroclinic orbits between them. For the parameter value μ at which (1.6) has a heteroclinic solution from a_{i_-} to a_{i_+}, the system (1.17) should have a heteroclinic solution from $\left(a_{i_-}, \hat{e}_{i_-,1}(\lambda)\right)$ to $\left(a_{i_+}, \hat{e}_{i_+,j}(\lambda)\right)$ for some j depending on λ. For generic λ this solution should be from $\left(a_{i_-}, \hat{e}_{i_-,1}(\lambda)\right)$ to $\left(a_{i_+}, \hat{e}_{i_+,1}(\lambda)\right)$, because $\left(a_{i_+}, \hat{e}_{i_+,1}(\lambda)\right)$ is an attracting equilibrium in the invariant set $\{a_{i_+}\} \times \mathbb{CP}^2$ and the complementary repeller consists of $\left(a_{i_+}, \hat{e}_{i_+,2}(\lambda)\right)$, $\left(a_{i_+}, \hat{e}_{i_+,3}(\lambda)\right)$, and the heteroclinic orbits from $\left(a_{i_+}, \hat{e}_{i_+,3}(\lambda)\right)$ to $\left(a_{i_+}, \hat{e}_{i_+,3}(\lambda)\right)$. In fact, the existence of the solution from $\left(a_{i_-}, \hat{e}_{i_-,1}(\lambda)\right)$ to $\left(a_{i_+}, \hat{e}_{i_+,2}(\lambda)\right)$ or $\left(a_{i_+}, \hat{e}_{i_+,3}(\lambda)\right)$ means that λ is an eigenvalue of L and vice versa.

Let μ_0 be a parameter value at which (1.6) has a heteroclinic loop consisting of heteroclinic solutions $z_1^*(\xi)$ from a_1 to a_2 and $z_2^*(\xi)$ from a_2 to a_1. Then, for

$(\lambda, \mu) = (0, \mu_0)$, (1.17) has heteroclinic solutions from $(a_1, \hat{e}_{1,1}(0))$ to $(a_2, \hat{e}_{2,2}(0))$ and from $(a_2, \hat{e}_{2,1}(0))$ to $(a_1, \hat{e}_{1,2}(0))$ simultaneously. We interpret the eigenvalue problem associated with an N-front wave which corresponds to an N-heteroclinic solution from a_{i_-} to a_{i_+} as a bifurcation problem of finding an N-heteroclinic solution of (1.17) from $\big(a_{i_-}, \hat{e}_{i_-,1}(\lambda)\big)$ to $\big(a_{i_+}, \hat{e}_{i_+,2}(\lambda)\big)$ or $\big(a_{i_+}, \hat{e}_{i_+,3}(\lambda)\big)$.

The purpose of this paper is to prove the following theorem about the stability of the travelling 1-front (back) wave solutions of (1.1), with the strategy explained above. The stability of N-fronts for $N \geq 2$ shall be proven in the forthcoming paper using a topological method (Nii [13]).

THEOREM. *Assume that the system* (1.6) *is C^r-diffeomorphic* ($r \geq 2$) *to linear systems in some neighborhoods of equilibria a_i and ε is small; then the travelling* 1*-front* (*back*) *wave solution of FitzHugh–Nagumo equations* (1.1) *bifurcating from simple front and back travelling wave solutions is stable.*

REMARK 1.2. *The assumption that the system is diffeomorphic to linear systems shall also be discussed for strictly cubic nonlinearity.*

REMARK 1.3. *Recently, Sandstede* [15] *proved stability of N-fronts* (*backs*) *for all $N \geq 1$ by Lin's method.*

2. Existence of travelling N-front wave solutions. In this section we briefly summarize the result in Deng [7] concerning the existence of travelling N-front (back) wave solutions of (1.1) and give analysis of the parameter dependence of the 1-heteroclinic orbit of (1.6) around equilibria.

PROPOSITION 2.1 (Deng [7]). *There exists a small ε_0 and two smooth functions $\gamma(\varepsilon)$ and $\delta(\varepsilon)$ for $0 \leq \varepsilon \leq \varepsilon_0$ such that the following is satisfied for all $0 < \varepsilon < \varepsilon_0$.*

1. *On the relevant (γ, c) parameter space there are two smooth curves $c = c_{i,0}(\gamma)$* ($i = 1, 2$) *defined on the interval $|\gamma - \gamma(\varepsilon)| < \delta(\varepsilon)$ such that* (1.1) *has a simple front wave of speed $c_{1,0}(\gamma)$ and a simple back wave of speed $c_{2,0}(\gamma)$.*
2. *There is a sequence $\{c_{1,N}(\gamma)\}_{N=1}^{\infty}$ of smooth curves of the left half-interval $0 < \gamma(\varepsilon) - \gamma < \delta(\varepsilon)$ such that* (1.1) *has an N-front wave of speed $c_{1,N}(\gamma)$ for γ in this half-interval for every $N = 1, 2, \ldots$. Similarly, there is a sequence $\{c_{2,N}(\gamma)\}_{N=1}^{\infty}$ of smooth curves of the right half-interval $0 < \gamma - \gamma(\varepsilon) < \delta(\varepsilon)$ such that* (1.1) *has an N-back wave of speed $c_{2,N}(\gamma)$ for γ in this half-interval for every $N = 1, 2, \ldots$.*
3. *There is a smooth curve $c_{1,\infty}(\gamma)$ of the left half-interval $0 < \gamma(\varepsilon) - \gamma < \delta(\varepsilon)$ such that* (1.1) *has an impulse wave to a_1 with speed $c_{1,\infty}(\gamma)$. Similarly, there is a smooth curve $c_{2,\infty}(\gamma)$ of the right half-interval $0 < \gamma - \gamma(\varepsilon) < \delta(\varepsilon)$ such that* (1.1) *has an impulse wave to a_2 with speed $c_{2,\infty}(\gamma)$.*
4. *The simple front and back wave curves $c_{i,0}(\gamma)$ intersect transversely at $\gamma(\varepsilon)$. The intersection point $(\gamma(\varepsilon), c(\varepsilon))$ is smooth in ε. At $\varepsilon = 0$, $c(0) > 0$. Moreover, the sequence $\{c_{i,N}(\gamma)\}$ is monotone decreasing in $N = 1, 2, \ldots$ and converges to the corresponding impulse curve $c_{i,\infty}(\gamma)$ as $N \to \infty$ for each $i = 1, 2$ and fixed $\varepsilon > 0$ and γ.*

(*See Figure* 2.1.)

REMARK 2.1. *This result is proven in Deng* [7] *for cubic nonlinearity $f(u) = u(u-a)(1-u)$ for* (1.1)*; the proof given there, however, is valid for $f(u)$, which is not necessarily cubic. The condition $0 < a < \frac{1}{2}$ in* [7] *corresponds to the condition $\int_0^1 f(u)du > 0$ in this paper.*

We need more detailed information about the heteroclinic orbit of (1.6) corresponding to the 1-front wave around equilibria.

In what follows, we assume that the system (1.6) is linear in some small neigh-

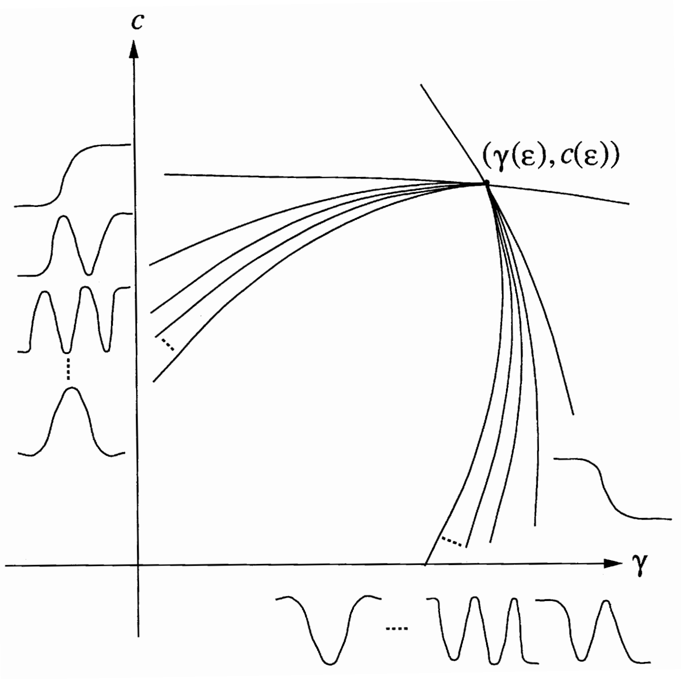

FIG. 2.1. *The bifurcation diagram of the travelling* N*-front (back) wave solutions.*

borhood of equilibria a_i $(i = 1, 2)$. This assumption can be satisfied for strictly cubic nonlinearity for suitable parameter values. In fact, the following holds.

PROPOSITION 2.2. *Let* $f(u) = u(u - a)(1 - u)$*; then there are uncountably many pairs of* (a, ε) $(0 < a < \frac{1}{2}, 0 < \varepsilon < \varepsilon_0)$ *such that for all* r *there is a neighborhood* N *of* $(\gamma(\varepsilon), c(\varepsilon))$ *in the* γ*–*c *plane depending on* a, ε, *and* r *which has the following property. There are small neighborhoods of equilibria* a_i *in which* (1.6) *can be transformed into a linear system by a local* C^r*-coordinate change in the neighborhoods.*

The proof shall be given in the Appendix.

Through suitable local coordinate changes, let us assume that in some neighborhood of each equilibrium a_i the system (1.6) is expressed in the form

$$z_i' = D_i(\mu)z_i, \tag{2.1}$$

where $z_i = (z_i^{(1)}, z_i^{(2)}, z_i^{(3)})$ and

$$D_i(\mu) = \begin{pmatrix} \lambda_{i,u}(\mu) & 0 & 0 \\ 0 & -\lambda_{i,s}(\mu) & 0 \\ 0 & 0 & -\lambda_{i,ss}(\mu) \end{pmatrix},$$

with $-\lambda_{i,ss}(\mu) < -\lambda_{i,s}(\mu) < 0 < \lambda_{i,u}(\mu)$. Moreover, the cube $\max_{k=1,2,3} |z_i^{(k)}| \leq 1$ is assumed to be in each neighborhood, and the orientation of axes is chosen so that $\{z_i | z_i^{(1)} > 0, z_i^{(2)} = 0, z_i^{(3)} = 0\} \subset \{z_i^*(\xi) | \xi \in \mathbb{R}\}$ and $\{z_i | z_i^{(1)} = 0, z_i^{(2)} > 0, z_i^{(3)} = 0\} \subset \{z_j^*(\xi) | \xi \in \mathbb{R}\}$ $(i \neq j)$ holds for $(\gamma, c) = (\gamma(\varepsilon), c(\varepsilon))$.

With this coordinate in z and through a suitable analytic transformation in the p component, (1.16) is written as

$$\left\{ \begin{aligned} z_i' &= D_i(\mu)z_i, \\ p_i' &= A_i(\lambda, \mu)p_i \end{aligned} \right. \tag{2.2}$$

for small $|\lambda|$, where $p_i = (p_i^{(1)}, p_i^{(2)}, p_i^{(3)})$ and

$$A_i(\lambda,\mu) = \begin{pmatrix} \nu_{i,u}(\lambda,\mu) & 0 & 0 \\ 0 & -\nu_{i,s}(\lambda,\mu) & 0 \\ 0 & 0 & -\nu_{i,ss}(\lambda,\mu) \end{pmatrix},$$

with $\nu_{i,*}(0,\mu) = \lambda_{i,*}(\mu)$ $(* = u, s, ss)$. The projectivized version of this system shall be denoted by

$$\tag{2.3} \begin{cases} z_i' &= D_i(\mu) z_i, \\ \hat{p}_i' &= \hat{A}_i(\hat{p}_i; \lambda, \mu). \end{cases}$$

A solution of (2.2) with initial condition $(z_i, p_i) = (\delta, 1, \bar{\delta}, p^{(1)}, p^{(2)}, p^{(3)})$ $(0 < \delta, \bar{\delta} < 1)$ hits $(1, \delta^{\Lambda_{i,s}}, \bar{\delta}\delta^{\Lambda_{i,ss}}, p^{(1)}\delta^{-(\nu_{i,u}/\lambda_{i,u})}, p^{(2)}\delta^{\nu_{i,s}/\lambda_{i,u}}, p^{(3)}\delta^{\nu_{i,ss}/\lambda_{i,u}})$, where $\Lambda_{i,s} = \frac{\lambda_{i,s}}{\lambda_{i,u}}$ and $\Lambda_{i,ss} = \frac{\lambda_{i,ss}}{\lambda_{i,u}}$. As for (2.3), we employ inhomogeneous coordinates on $\mathbb{CP}^2$. More precisely, the initial point $(z_i, \hat{p}_i) = (\delta, 1, \bar{\delta}, [p_i^{(1)} : p_i^{(2)} : p^{(3)}])$ in homogeneous coordinates shall be expressed as $(\delta, 1, \bar{\delta}, \frac{p_i^{(1)}}{p_i^{(2)}}, \frac{p_i^{(3)}}{p_i^{(2)}})$, whereas the end point $(1, \delta^{\Lambda_{i,s}}, \bar{\delta}\delta^{\Lambda_{i,ss}}, [p_i^{(1)}\delta^{-(\nu_{i,u}/\lambda_{i,u})} : p_i^{(2)}\delta^{\nu_{i,s}/\lambda_{i,u}} : p_i^{(3)}\delta^{\nu_{i,ss}/\lambda_{i,u}}])$ shall be denoted by $(1, \delta^{\Lambda_{i,s}}, \bar{\delta}\delta^{\Lambda_{i,ss}}, \frac{p^{(2)}}{p^{(1)}}\delta^{1+\hat{\Lambda}_{i,s}}, \frac{p^{(3)}}{p^{(1)}}\delta^{1+\hat{\Lambda}_{i,ss}})$. Notice that the two expressions above are based on different coordinates for the $\mathbb{CP}^2$ component. Here, $\hat{\Lambda}_{i,s} = \frac{\nu_{i,s}+\nu_{i,u}-\lambda_{i,u}}{\lambda_{i,u}}$ and $\hat{\Lambda}_{i,ss} = \frac{\nu_{i,ss}+\nu_{i,u}-\lambda_{i,u}}{\lambda_{i,u}}$, which coincide with $\Lambda_{i,s}$ and $\Lambda_{i,ss}$ for $\lambda = 0$, and thus $\Lambda_{i,s} < \Lambda_{i,ss}$ and $0 < \Lambda_{i,s} < 1$ for small λ for small ε. We restate this calculation as a lemma.

LEMMA 2.1. *The solution of* (2.3) *with initial condition* $(z, \frac{p_i^{(1)}}{p_i^{(2)}}, \frac{p_i^{(3)}}{p_i^{(2)}}) = (\delta, 1, \bar{\delta}, \pi_1, \pi_3)$ *reaches* $(z, \frac{p_i^{(2)}}{p_i^{(1)}}, \frac{p_i^{(3)}}{p_i^{(1)}}) = (1, \delta^{\Lambda_{i,s}}, \bar{\delta}\delta^{\Lambda_{i,ss}}, \frac{1}{\pi_1}\delta^{1+\hat{\Lambda}_{i,s}}, \frac{\pi_3}{\pi_1}\delta^{1+\hat{\Lambda}_{i,ss}})$.

Next, we consider connections between a_1 and a_2.

Let $\Sigma_{i,s}$ and $\Sigma_{i,u}$ be the local sections near a_i defined as

$$\tag{2.4} \begin{aligned} \Sigma_{i,s} &:= \left\{ z_i^{(2)} = 1, \max\{|z_i^{(1)}|, |z_i^{(3)}|\} \leq 1 \right\}, \\ \Sigma_{i,u} &:= \left\{ z_i^{(1)} = 1, \max\{|z_i^{(2)}|, |z_i^{(3)}|\} \leq 1 \right\}, \end{aligned}$$

and let

$$\tag{2.5} \begin{aligned} \Pi_i &: \Sigma_{i,s} \to \Sigma_{i,u} : (z_i^{(2)}, z_i^{(3)}) = \left(\Pi_i^{(2)}(z_i^{(1)}, z_i^{(3)}), \Pi_i^{(3)}(z_i^{(1)}, z_i^{(3)}) \right), \\ \Pi_{i,j} &: \Sigma_{i,u} \to \Sigma_{j,s} : (z_j^{(1)}, z_j^{(3)}) = \left(\Pi_{i,j}^{(1)}(z_i^{(2)}, z_i^{(3)}), \Pi_{i,j}^{(3)}(z_i^{(2)}, z_i^{(3)}) \right) \end{aligned}$$

be the Poincaré maps between them, where $(i,j) = (1,2)$ or $(2,1)$. (See Figure 2.2.)

By Proposition 2.1, the system (1.6) has heteroclinic solutions $z_1^*(\xi)$ from a_1 to a_2 and $z_2^*(\xi)$ from a_2 to a_1 for $\mu = (\gamma(\varepsilon), c(\varepsilon); \varepsilon)$, which means

$$\tag{2.6} \Pi_{i,j}^{(1)}(0, 0; \gamma(\varepsilon), c(\varepsilon); \varepsilon) = 0 \qquad \text{for } (i,j) = (1,2), (2,1).$$

The twisting condition of the heteroclinic loop in Deng [6], [7] is equivalent to the inequality

$$\tag{2.7} \frac{\partial \Pi_{i,j}^{(1)}}{\partial z_i^{(2)}}(0, 0; \gamma(\varepsilon), c(\varepsilon); \varepsilon) < 0.$$

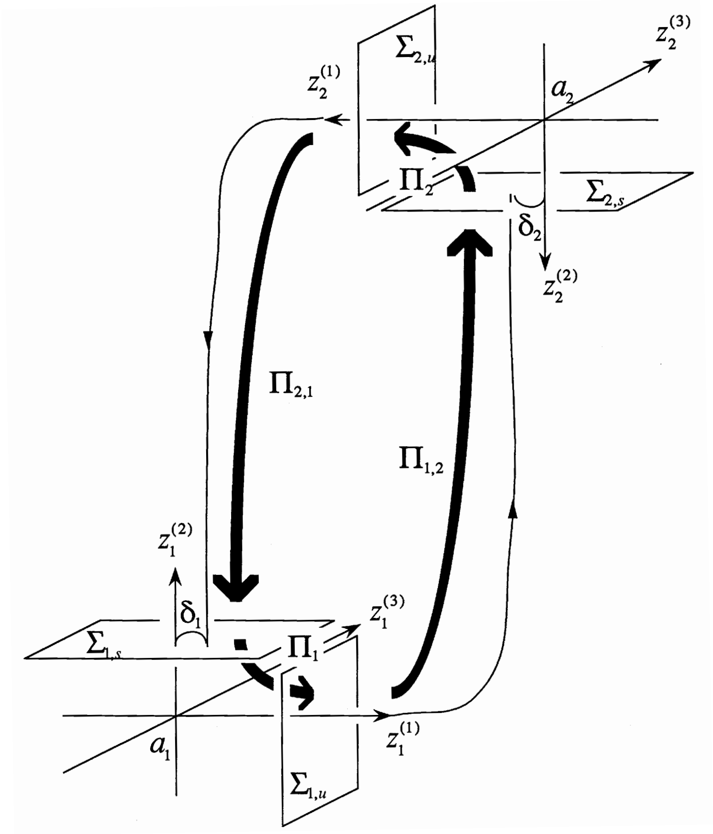

FIG. 2.2. *The local sections and Poincaré maps.*

The following transversality condition was also proven in Deng [7]:

$$\left(\frac{\partial \Pi^{(1)}_{i,j}}{\partial \gamma}(0,0), \frac{\partial \Pi^{(1)}_{i,j}}{\partial c}(0,0)\right) \neq (0,0) \qquad ((i,j) = (1,2) \text{ or } (2,1), \quad \varepsilon > 0)\,. \tag{2.8}$$

Moreover, $(\frac{\partial \Pi^{(1)}_{1,2}}{\partial \gamma}(0,0), \frac{\partial \Pi^{(1)}_{1,2}}{\partial c}(0,0))$ and $(\frac{\partial \Pi^{(1)}_{2,1}}{\partial \gamma}(0,0), \frac{\partial \Pi^{(1)}_{2,1}}{\partial c}(0,0))$ are linearly independent, and thus we can employ $(\Pi^{(1)}_{1,2}(0,0), \Pi^{(1)}_{2,1}(0,0))$ as parameters instead of (γ, c) near $(\gamma, c) = (\gamma(\varepsilon), c(\varepsilon))$. In what follows, we shall write $(\Pi^{(1)}_{2,1}(0,0), \Pi^{(1)}_{1,2}(0,0)) = (\delta_1, \delta_2)$ and regard $\varepsilon > 0$ as a fixed constant. Then, for z_i and δ_i small, Π_i and $\Pi_{i,j}$ are written as

$$\left(\Pi_i^{(2)}(z_i^{(1)}, z_i^{(3)}), \Pi_i^{(3)}(z_i^{(1)}, z_i^{(3)})\right) = \left(\left\{z_i^{(1)}\right\}^{\Lambda_{i,s}}, z_i^{(3)}\left\{z_i^{(1)}\right\}^{\Lambda_{i,ss}}\right) \tag{2.9}$$

and

$$\begin{pmatrix} \Pi^{(1)}_{i,j}(z_i^{(2)}, z_i^{(3)}; \delta_1, \delta_2) \\ \Pi^{(3)}_{i,j}(z_i^{(2)}, z_i^{(3)}; \delta_1, \delta_2) \end{pmatrix} = \begin{pmatrix} d_j^{(1)} z_i^{(2)} + \bar{d}_j^{(1)} z_i^{(3)} + \delta_j \\ d_j^{(3)} z_i^{(2)} + \bar{d}_j^{(3)} z_i^{(3)} + e_j^1 \delta_1 + e_j^2 \delta_2 \end{pmatrix} \tag{2.10}$$

$$+(\text{higher order terms}),$$

where $d_j^{(k)} = \frac{\partial \Pi_{i,j}^{(k)}}{\partial z_i^{(2)}}(0,0;0,0)$, $\bar{d}_j^{(k)} = \frac{\partial \Pi_{i,j}^{(k)}}{\partial z_i^{(3)}}(0,0;0,0)$, and $e_j^l = \frac{\partial \Pi_{i,j}^{(3)}}{\partial \delta_l}(0,0;0,0)$.

The existence of a 1-heteroclinic solution from a_1 to a_2 is expressed as

$$\begin{gathered} \Pi_{1,2}^{(1)}(0,0) > 0,\ \Pi_{2,1}^{(1)} \circ \Pi_2 \circ \Pi_{1,2}(0,0) > 0, \\ \Pi_{1,2}^{(1)} \circ \Pi_1 \circ \Pi_{2,1} \circ \Pi_2 \circ \Pi_{1,2}(0,0) = 0. \end{gathered} \tag{2.11}$$

Put $(\delta_1^{(1)}, \delta_1^{(3)}) := \Pi_{2,1} \circ \Pi_2 \circ \Pi_{1,2}(0,0)$; then

$$\Pi_1(\delta_1^{(1)}, \delta_1^{(3)}) = \left(\left\{ \delta_1^{(1)} \right\}^{\Lambda_{1,s}}, \delta_1^{(3)} \left\{ \delta_1^{(1)} \right\}^{\Lambda_{1,ss}} \right) \tag{2.12}$$

and

$$\begin{aligned} \Pi_{1,2}^{(1)} \circ \Pi_1 \left(\delta_1^{(1)}, \delta_1^{(3)} \right) = \ & \left\{ \delta_1^{(1)} \right\}^{\Lambda_{1,s}} \left(d_2^{(1)} + \bar{d}_2^{(1)} \delta_1^{(3)} \left\{ \delta_1^{(1)} \right\}^{\Lambda_{1,ss} - \Lambda_{1,s}} \right) \\ & + o \left(\left\{ \delta_1^{(1)} \right\}^{\Lambda_{1,s}} \right) + \delta_2 + o\left(\delta_2\right), \end{aligned} \tag{2.13}$$

so the last equation of (2.11) is

$$\begin{aligned} \left\{ \delta_1^{(1)} \right\}^{\Lambda_{1,s}} & \left(d_2^{(1)} + \bar{d}_2^{(1)} \delta_1^{(3)} \left\{ \delta_1^{(1)} \right\}^{\Lambda_{1,ss} - \Lambda_{1,s}} \right) \\ & + o \left(\left\{ \delta_1^{(1)} \right\}^{\Lambda_{1,s}} \right) + \delta_2 + o\left(\delta_2\right) = 0. \end{aligned} \tag{2.14}$$

By (2.10) we have the following expressions:

$$\begin{aligned} \delta_1^{(1)} & = d_1^{(1)} \delta_2^{\Lambda_{2,s}} + \bar{d}_1^{(1)} \left(e_2^1 \delta_1 + e_2^2 \delta_2 \right) \delta_2^{\Lambda_{2,ss}} + \delta_1 \\ & \qquad + \text{higher order terms}, \\ \delta_1^{(3)} & = d_1^{(3)} \delta_2^{\Lambda_{2,s}} + \bar{d}_1^{(3)} \left(e_2^1 \delta_1 + e_2^2 \delta_2 \right) \delta_2^{\Lambda_{2,ss}} + e_1^1 \delta_1 + e_1^2 \delta_2 \\ & \qquad + \text{higher order terms}. \end{aligned} \tag{2.15}$$

Here, the bifurcation curve $\{(\gamma, c_{1,1}(\gamma))\}$ is expressed as $\delta_1 = \mathrm{het}_1(\delta_2)$ with a smooth function $\mathrm{het}_1\colon (0, \Delta_2) \to (0, \Delta_1)$ in the (δ_1, δ_2)-coordinates for some $(\Delta_1, \Delta_2 > 0)$, and this function satisfies

$$\lim_{\delta_2 \downarrow 0} \mathrm{het}_1(\delta_2) = 0. \tag{2.16}$$

Therefore, $\delta_1^{(1)}, \delta_2^{(1)} \to 0$ as $\delta_2 \to 0$. Then, (2.14) means

$$\frac{\left\{ \delta_1^{(1)} \right\}^{\Lambda_{1,s}}}{\delta_2} (1 + o(1)) + \frac{1}{d_2^{(1)}} = o(1) \qquad (\delta_2 \to 0), \tag{2.17}$$

i.e.,

$$\frac{\left\{ \delta_1^{(1)} \right\}^{\Lambda_{1,s}}}{\delta_2} \to \frac{1}{-d_2^{(1)}} \quad \text{as} \quad \delta_2 \to 0. \tag{2.18}$$

Thus the following holds.

LEMMA 2.2.

$$\delta_1^{(1)} = \left(\frac{\delta_2}{-d_2^{(1)}} \right)^{\frac{1}{\Lambda_{1,s}}} + o\left(\delta_2^{\frac{1}{\Lambda_{1,s}}} \right). \tag{2.19}$$

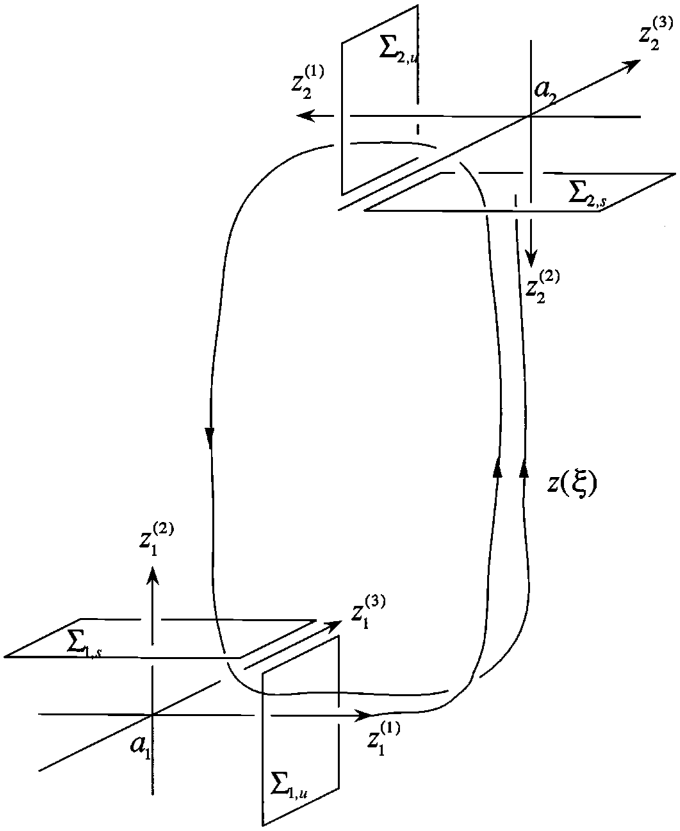

FIG. 3.1. *The orbit of* $z(\xi;\gamma,c)$.

3. λ-dependence of the eigenvalue system.

In this section, we investigate λ-dependence of the eigenvalue system (1.17).

Let us assume that the system (1.6) has a heteroclinic orbit from a_i to a_j $(i \neq j)$ for $(\gamma, c) = (\gamma_0, c_0)$, and let $z_i(\xi;\gamma_0,c_0) = (u(\xi;\gamma_0,c_0), v(\xi;\gamma_0,c_0), w(\xi;\gamma_0,c_0))$ be the solution with initial condition $z_i(0;\gamma_0,c_0) \in \Sigma_{j,s}$, or equivalently, $\{z_i(0;\gamma_0,c_0)\} = \Sigma_{j,s} \cap W^u(a_i,\gamma_0,c_0)$, where $W^u(a_i,\gamma_0,c_0)$ is the unstable manifold of the equilibrium a_i. Similarly, let $z(\xi;\gamma,c)$ be the solution of (1.6) with initial condition $\{z(0;\gamma,c)\} = \Sigma_{j,s} \cap W^u(a_i,\gamma,c)$ for (γ,c) near (γ_0,c_0); then $z(\xi;\gamma,c)$ is smooth in γ and c and coincides with $z_i(\xi;\gamma_0,c_0)$ for $(\gamma,c) = (\gamma_0,c_0)$. (See Figure 3.1.)

By differentiating (1.6) in c at $(\gamma,c) = (\gamma_0,c_0)$, $\frac{\partial z_i}{\partial c} =: z_{ic} = (u_c, v_c, w_c)$ satisfies

$$\left\{\begin{array}{ll} u_c' & = v_c, \\ v_c' & = v - c_0 v_c - Df\,(u(\xi))\, u_c + w_c, \\ w_c' & = \frac{\varepsilon}{c_0}(u_c - \gamma_0 w_c) - \frac{1}{c_0} w', \end{array}\right. \tag{3.1}$$

where $(u,v,w) = (u(\xi;\gamma_0,c_0), v(\xi;\gamma_0,c_0), w(\xi;\gamma_0,c_0))$ and $w' = \frac{dw}{d\xi}$.

Next consider the restriction of (1.16) to $\mathbb{R}^3 \times \mathbb{R}^3$ for $(\gamma,c) = (\gamma_0,c_0)$. The equilibrium $(a_i,0)$ of (1.16) has two-dimensional unstable manifold $\tilde{W}^u(a_i,\lambda,\gamma_0,c_0)$, and $\tilde{W}^u(a_i,\lambda,\gamma_0,c_0) \cap \left(\{z_i(0,\gamma_0,c_0)\} \times \mathbb{R}^3\right)$ is a one-dimensional subspace of $\mathbb{R}^3$. For $\lambda = 0$, $(z(0;\gamma_0,c_0), z_\xi(0;\gamma_0,c_0)) \in \tilde{W}^u(a_i,0,\gamma_0,c_0) \cap \left(\{z(0,\gamma_0,c_0)\} \times \mathbb{R}^3\right)$, where $z_\xi =$

$\frac{dz}{d\xi}$. Let $(z(\xi;\gamma_0,c_0),p_i(\xi;\lambda,\gamma_0,c_0))$ be the solution of (1.16) with initial condition

$$(z(0),p(0)) = \tilde{W}^u(a_i,\lambda,\gamma_0,c_0) \cap \left(\{z(0,\gamma_0,c_0)\} \times \mathbb{R}^3\right) \cap \{|p| = |z_\xi(0)|\}\,;$$

then $p_i(\xi;\lambda,\gamma_0,c_0)$ coincides with $z_\xi(\xi;\gamma_0,c_0)$ for $\lambda = 0$ and is smooth in small λ. This $p_i(\xi;\lambda,\gamma_0,c_0)$ satisfies (1.13), and by differentiating (1.13) with respect to λ at $\lambda = 0$, $\frac{\partial p_i}{\partial \lambda} =: p_{i\lambda} = (P_\lambda, Q_\lambda, R_\lambda)$ satisfies the following equations:

$$\text{(3.2)} \qquad \left\{ \begin{array}{ll} P'_\lambda & = Q_\lambda, \\ Q'_\lambda & = c_0 Q_\lambda - Df\left(u(\xi)\right) P_\lambda + R_\lambda + P, \\ R'_\lambda & = \frac{\varepsilon}{c_0}(P_\lambda - \gamma_0 R_\lambda) - \frac{1}{c_0} R', \end{array} \right.$$

where $(P,Q,R) = p_i(\xi;0,\gamma_0,c_0) = z_\xi(\xi;\gamma_0,c_0) = (u',v',w')$. Subtracting (3.1) from (3.2), we have

$$\text{(3.3)} \qquad \left\{ \begin{array}{ll} (P_\lambda - u_c)' & = (Q_\lambda - v_c), \\ (Q_\lambda - v_c)' & = c_0(Q_\lambda - v_c) - Df\left(u(\xi)\right)(P_\lambda - u_c) + (R_\lambda - w_c), \\ (R_\lambda - w_c)' & = \frac{\varepsilon}{c_0}\left((P_\lambda - u_c) - \gamma_0(R_\lambda - w_c)\right), \end{array} \right.$$

as $P = u' = v$ and $R = w'$. That is, $p_{i\lambda}(\xi;0,\gamma_0,c_0) - z_c(\xi;\gamma_0,c_0)$ satisfies the eigenvalue equations (1.13) for $\lambda = 0$. Because $p_{i\lambda}, z_c \to 0$ as $\xi \to -\infty$, we have the next lemma.

LEMMA 3.1. *There exists a constant α so that*

$$p_{i\lambda}(\xi;0,\gamma_0,c_0) = z_c(\xi;\gamma_0,c_0) + \alpha z_{i\xi}(\xi;\gamma_0,c_0).$$

Similarly, let $(z_i(\xi;\gamma_0,c_0),q_i(\xi;\lambda,\gamma_0,c_0))$ be the solution of (2.2) (see (1.16)) with initial condition

$$(z(0),q(0)) = \tilde{W}^s(a_j,\lambda,\gamma_0,c_0) \cap \left(\{z_i(0,\gamma_0,c_0)\} \times \mathbb{R}^3\right) \cap \left\{p_j^{(2)} = z_{i\xi}^{(2)}(0), p_j^{(3)} = z_{i\xi}^{(3)}(0)\right\},$$

where $\tilde{W}^s(a_j,\lambda,\gamma_0,c_0)$ is the stable manifold of the equilibrium $(a_j,0)$ of (2.2) and the p_i component of (2.2) is written as $p_i = (p_i^{(1)},p_i^{(2)},p_i^{(3)}) \in \mathbb{R}^3$. Then $q_i(\xi;\lambda,\gamma_0,c_0)$ coincides with $z_{i\xi}(\xi;\gamma_0,c_0)$ for $\lambda = 0$ and is smooth in small λ. Through a similar argument as above, we have the following as $z(\xi;\gamma,c)$ with initial condition $z(0;\gamma,c) \equiv z_i(0;\gamma_0,c_0)$ in the z_j coordinate of (2.2) is a smooth extension of $z_i(\xi;\gamma_0,c_0)$ in the stable manifold $W^s(a_j,\gamma,c)$.

LEMMA 3.2.

$$(z_i(\xi;\gamma_0,c_0),q_{i\lambda}(\xi;0,\gamma_0,c_0)) \in \tilde{W}^s(a_j,0,\gamma_0,c_0).$$

From now on, we consider the projectivized version of eigenvalue systems (1.17) and (2.3).

At first we only consider real λ and consider the system (1.17) as the system on $\mathbb{R}^3 \times \mathbb{RP}^2$. Let $\hat{\Sigma}_{i,s}$ and $\hat{\Sigma}_{i,u}$ be local sections defined by $\hat{\Sigma}_{i,s} := \Sigma_{i,s} \times \mathbb{RP}^2$, $\hat{\Sigma}_{i,u} := \Sigma_{i,u} \times \mathbb{RP}^2$, and let

$$\text{(3.4)} \qquad \begin{array}{ll} \hat{\Pi}_i & : \hat{\Sigma}_{i,s} \to \hat{\Sigma}_{i,u} \\ & : (z_i^{(2)}, z_i^{(3)}, \frac{p_i^{(2)}}{p_i^{(1)}}, \frac{p_i^{(3)}}{p_i^{(1)}}) = \left(\Pi_i^{(2)}(z_i), \Pi_i^{(3)}(z_i), \hat{\Pi}_i^{(2)}(z_i,p_i), \hat{\Pi}_i^{(3)}(z_i,p_i)\right), \\ \hat{\Pi}_{i,j} & : \hat{\Sigma}_{i,u} \to \hat{\Sigma}_{j,s} \\ & : (z_j^{(1)}, z_j^{(3)}, \frac{p_j^{(1)}}{p_j^{(2)}}, \frac{p_j^{(3)}}{p_j^{(2)}}) = \left(\Pi_{i,j}^{(1)}(z_i), \Pi_{i,j}^{(3)}(z_i), \hat{\Pi}_{i,j}^{(1)}(z_i,p_i), \hat{\Pi}_{i,j}^{(3)}(z_i,p_i)\right) \end{array}$$

be Poincaré maps between them. Then, from Lemma 2.1,

$$\begin{aligned}&\hat{\Pi}_i(z_i^{(1)}, z_i^{(3)}, \pi_1, \pi_3)\\ &= \left(\left\{z_i^{(1)}\right\}^{\Lambda_{i,s}}, z_i^{(3)}\left\{z_i(1)\right\}^{\Lambda_{i,ss}}, \tfrac{1}{\pi_1}\left\{z_i^{(1)}\right\}^{1+\hat{\Lambda}_{i,s}}, \tfrac{\pi_3}{\pi_1}\left\{z_i^{(1)}\right\}^{1+\hat{\Lambda}_{i,ss}}\right).\end{aligned} \tag{3.5}$$

As for $\hat{\Pi}_{i,j}$, the following holds.

Lemma 3.3.

$$\hat{\Pi}_{i,j}^{(1)}(0,0;0) = 0, \quad \frac{\partial \hat{\Pi}_{i,j}^{(1)}}{\partial \pi_2}(0,0;0) > 0, \quad \textit{and} \quad \frac{\partial \hat{\Pi}_{i,j}^{(1)}}{\partial \lambda}(0,0;0) > 0, \tag{3.6}$$

where $(z_i, \pi; \lambda) = (z_i^{(2)}, z_i^{(3)}, \pi_2 = \frac{p_i^{(2)}}{p_i^{(1)}}, \pi_3 = \frac{p_i^{(3)}}{p_i^{(1)}}; \lambda)$.

Proof. The first equality is obvious from the definition. As for the second inequality, it is easy to see that

$$\frac{\partial \hat{\Pi}_{i,j}^{(1)}}{\partial \pi_2}(0,0;0) = -\frac{\lambda_{i,u}}{\lambda_{j,s}} \frac{\partial \Pi_{i,j}^{(1)}}{\partial z_i^{(2)}}(0,0);$$

thus the inequality follows from inequality (2.7).

A proof of the last inequality shall be given below.

Let

$$p_i(\xi, \lambda, \gamma_0, c_0) = \left(p_i^{(1)}(\xi,\lambda), p_i^{(2)}(\xi,\lambda), p_i^{(3)}(\xi,\lambda)\right)$$

and

$$q_i(\xi, \lambda, \gamma_0, c_0) = \left(q_i^{(1)}(\xi,\lambda), q_i^{(2)}(\xi,\lambda), q_i^{(3)}(\xi,\lambda)\right).$$

Then,

$$\frac{\partial p_i^{(1)}}{\partial \lambda}(0,\lambda) = z_{ic}^{(1)}, \tag{3.7}$$

from Lemma 3.1, as $z_{i\xi}^{(1)}(0) = 0$. Thus,

$$\begin{aligned}\frac{\partial \hat{\Pi}_{i,j}^{(1)}}{\partial \lambda}(0,0;0) &= \frac{\partial}{\partial \lambda}\left\{\frac{p_i^{(1)}(0,\lambda)}{p_i^{(2)}(0,\lambda)}\right\}\Bigg|_{\lambda=0}\\ &= \frac{p_{i\lambda}^{(1)}}{p_i^{(2)}}\Bigg|_{\lambda=0} - \frac{p_i^{(1)}p_{i\lambda}^{(2)}}{\left\{p_i^{(2)}\right\}^2}\Bigg|_{\lambda=0}\\ &= \frac{z_{ic}^{(1)}(0)}{p_i^{(2)}(0,0)} \qquad (\text{as } p_i^{(1)}(0,0) = 0)\\ &= -\frac{z_{ic}^{(1)}(0)}{\lambda_{j,s}} \qquad (\text{as } p_i^{(2)}(0,0) = z_{i\xi}^{(2)}(0) = -\lambda_{i,s}).\end{aligned} \tag{3.8}$$

The last expression is not zero from the transversality condition (2.8) and the fact that the bifurcation curve is expressed as the graph of a smooth function $c_{1,1}(\gamma)$. Moreover, the bifurcation diagram (Figure 1.2) shows that it is positive. □

4. The eigenvalue equation. With $\hat{\Pi}_i$ and $\hat{\Pi}_{i,j}$, the condition for λ being an eigenvalue is expressed as follows.

LEMMA 4.1.

$$E(\lambda) := \hat{\Pi}_{1,2}^{(1)} \circ \hat{\Pi}_1 \circ \hat{\Pi}_{2,1} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;\lambda) = 0 \tag{4.1}$$

if and only if λ is an eigenvalue of the linearization operator L along the travelling 1-front wave solution corresponding to the 1-heteroclinic solution from a_1 to a_2.

Proof. $E(\lambda)$ corresponds to the $p^{(1)}$ component of the intersection $\tilde{W}^u(a_1,\lambda,\gamma,c) \cap \hat{\Sigma}_{2,s}$, and this is zero if and only if $\tilde{W}^u(a_1,\lambda,\gamma,c) \subset \tilde{W}^s(a_2,\lambda,\gamma,c)$. Thus $E(\lambda) = 0$ if and only if (1.16) has a bounded solution for the p component along the 1-heteroclinic solution for the z component. This means the lemma holds. □

Let us calculate the leading terms of $E(\lambda)$. For later use, let $\tilde{\lambda} = \frac{\lambda}{\delta_2}$ and expand $E(\lambda)$ in $\tilde{\lambda}$.

First, notice that $\hat{\Pi}_{1,2}^{(1)}(0,0;0) = -\frac{\delta_2}{\Lambda_{2,s}}$, as $\Pi_{1,2}^{(1)}(0,0) = \delta_2$ and $\hat{\Pi}_{1,2}(0,0;0)$ corresponds to the tangent vector for the 1-heteroclinic solution $z_1(\xi)$ at $z_1(\xi) \in \Sigma_{2,s}$. Similarly, $\hat{\Pi}_{1,2}^{(3)}(0,0;0) = f\delta_2 + O(\delta^2)$, where $f = \frac{\partial \hat{\Pi}_{1,2}^{(3)}}{\partial \delta_2}(0,0;0)$. Thus

$$\begin{pmatrix} \hat{\Pi}_{1,2}^{(1)}(0,0;\delta_2\tilde{\lambda}) \\ \hat{\Pi}_{1,2}^{(3)}(0,0;\delta_2\tilde{\lambda}) \end{pmatrix} = \begin{pmatrix} c_2^{(1)}\delta_2\tilde{\lambda} - \frac{\delta_2}{\Lambda_{2,s}} + O(\delta_2^2\tilde{\lambda}^2) \\ f\delta_2 + c_2^{(3)}\delta_2\tilde{\lambda} + O(\delta_2^2, \delta_2^2\tilde{\lambda}^2) \end{pmatrix} \tag{4.2}$$

where $c_j^{(k)} = \frac{\partial \hat{\Pi}_{i,j}^{(k)}}{\partial \lambda}(0,0;0)$. Then,

$$\begin{pmatrix} \hat{\Pi}_2^{(2)} \circ \hat{\Pi}_{1,2}(0,0;\delta_2\tilde{\lambda}) \\ \hat{\Pi}_2^{(3)} \circ \hat{\Pi}_{1,2}(0,0;\delta_2\tilde{\lambda}) \end{pmatrix} = \begin{pmatrix} \frac{\delta_2^{\hat{\Lambda}_{2,s}}}{c_2^{(1)}\tilde{\lambda} - \frac{1}{\Lambda_{2,s}} + O(\delta_2\tilde{\lambda}^2)} \\ \frac{c_2^{(3)}\tilde{\lambda} + f + O(\delta_2, \delta_2\tilde{\lambda}^2)}{c_2^{(1)}\tilde{\lambda} - \frac{1}{\Lambda_{2,s}} + O(\delta_2\tilde{\lambda}^2)}\delta_2^{1+\hat{\Lambda}_{2,ss}} \end{pmatrix}. \tag{4.3}$$

Similarly,

$$\hat{\Pi}_{2,1}^{(1)} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;0) = -\frac{\delta_1^{(1)}}{\Lambda_{1,s}}, \tag{4.4}$$

$$\begin{aligned} &\hat{\Pi}_{2,1}^{(1)} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;\delta_2\tilde{\lambda}) \\ &= -\frac{\delta_1^{(1)}}{\Lambda_{1,s}} + c_1^{(1)}\tilde{\lambda} + \hat{d}_1^{(1)}\left\{\hat{\Pi}_2^{(2)} \circ \hat{\Pi}_{1,2}(0,0;\delta_2\tilde{\lambda}) - \hat{\Pi}_2^{(2)} \circ \hat{\Pi}_{1,2}(0,0;0)\right\} \\ &\qquad + \hat{e}_1^{(1)}\left\{\hat{\Pi}_2^{(3)} \circ \hat{\Pi}_{1,2}(0,0;\delta_2\tilde{\lambda}) - \hat{\Pi}_2^{(3)} \circ \hat{\Pi}_{1,2}(0,0;0)\right\} \\ &\qquad + O(\delta_2^2\tilde{\lambda}^2, \delta^{2\hat{\Lambda}_{2,s}}, \delta_2^{2+2\hat{\Lambda}_{2,ss}}, \delta_2^{1+\hat{\Lambda}_{2,s}}\tilde{\lambda}, \delta_2^{2+\Lambda_{2,ss}}\tilde{\lambda}) \\ &= -\frac{1}{\Lambda_{1,s}}\left(\frac{\delta_2}{-d_2^{(1)}}\right)^{\frac{1}{\Lambda_{1,s}}} + c_1^{(1)}\delta_2\tilde{\lambda} + \frac{\hat{d}_1^{(1)}\delta_2^{\hat{\Lambda}_{2,s}}}{c_2^{(1)}\tilde{\lambda} - \frac{1}{\Lambda_{2,s}} + O(\delta_2\tilde{\lambda}^2)} + \hat{d}_1^{(1)}\Lambda_{2,s}\delta_2^{\Lambda_{2,s}} \\ &\qquad + O\left(\delta_2^{\min\{2\hat{\Lambda}_{2,s},1\}}\right), \end{aligned} \tag{4.5}$$

where $\hat{d}_j^{(k)} = \frac{\partial \hat{\Pi}_{i,j}^{(k)}}{\partial \pi_2}(0,0;0)$ and $\hat{e}_j^{(k)} = \frac{\partial \hat{\Pi}_{i,j}^{(k)}}{\partial \pi_3}(0,0;0)$, and

$$\hat{\Pi}_{2,1}^{(3)} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;0) = o(1) \qquad (\delta_2 \to 0), \tag{4.6}$$

$$\hat{\Pi}^{(3)}_{2,1} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;\delta_2\tilde{\lambda}) = o(1) \qquad (\delta_2 \to 0). \tag{4.7}$$

This means the following.

$$\begin{aligned}
&\hat{\Pi}^{(1)}_1 \circ \hat{\Pi}_{2,1} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;\delta_2\tilde{\lambda}) \\
&= \frac{\left\{\delta_1^{(1)}\right\}^{1+\hat{\Lambda}_{1,s}}}{-\frac{1}{\Lambda_{1,s}}\left(\frac{\delta_2}{-d_2^{(1)}}\right)^{\frac{1}{\Lambda_{1,s}}} + c_1^{(1)}\delta_2\tilde{\lambda} + \frac{\hat{d}_1^{(1)}\delta_2^{\hat{\Lambda}_{2,s}}}{c_2^{(1)}\tilde{\lambda} - \frac{1}{\Lambda_{2,s}} + O(\delta_2\tilde{\lambda}^2)} + \hat{d}_1^{(1)}\Lambda_{2,s}\delta_2^{\Lambda_{2,s}} + O\left(\delta_2^{\min\{2\hat{\Lambda}_{2,s},1\}}\right)} \\
&= \frac{\left(c_2^{(1)}\tilde{\lambda} - \frac{1}{\Lambda_{2,s}} + O(\delta_2\tilde{\lambda}^2)\right)\left\{\left(\frac{\delta_2}{-d_2^{(1)}}\right)^{\frac{1}{\Lambda_{1,s}}} + O\left(\delta_2^{\frac{1}{\Lambda_{1,s}}+\Delta}\right)\right\}^{1+\hat{\Lambda}_{1,s}}}{\left\{c_1^{(1)}\delta_2\tilde{\lambda} + \hat{d}_1^{(1)}\Lambda_{2,s}\delta_2^{\Lambda_{2,s}} + O\left(\delta_2^{\min\{2\hat{\Lambda}_{2,s},1\}}\right)\right\}\left(c_2^{(1)}\tilde{\lambda} - \frac{1}{\Lambda_{2,s}} + O(\delta_2\tilde{\lambda}^2)\right) + \hat{d}_1^{(1)}\delta_2^{\hat{\Lambda}_{2,s}}} \\
&= \frac{\left(c_2^{(1)}\tilde{\lambda} - \frac{1}{\Lambda_{2,s}} + o(1)\right)\left(\frac{1}{-d_2^{(1)}}\right)^{\frac{1+\hat{\Lambda}_{1,s}}{\Lambda_{1,s}}}\delta_2^{\frac{1+\hat{\Lambda}_{1,s}}{\Lambda_{1,s}}-\Lambda_{2,s}}(1+o(1))}{\left\{\hat{d}_1^{(1)}\Lambda_{2,s}+o(1)\right\}\left(c_2^{(1)}\tilde{\lambda} - \frac{1}{\Lambda_{2,s}} + o(1)\right) + \hat{d}_1^{(1)}} \qquad \text{as } \delta_2 \to 0.
\end{aligned} \tag{4.8}$$

Finally,

$$\begin{aligned}
E(\delta_2\tilde{\lambda}) = {} & c_2^{(1)}\delta_2\tilde{\lambda} \\
& + \hat{d}_2^{(1)}\left(\hat{\Pi}^{(1)}_1 \circ \hat{\Pi}_{2,1} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;\delta_2\tilde{\lambda}) - \hat{\Pi}^{(1)}_1 \circ \hat{\Pi}_{2,1} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;0)\right) \\
& + \hat{e}_2^{(1)}\left(\hat{\Pi}^{(3)}_1 \circ \hat{\Pi}_{2,1} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;\delta_2\tilde{\lambda}) - \hat{\Pi}^{(3)}_1 \circ \hat{\Pi}_{2,1} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;0)\right) \\
& + O\left(\delta_2^2\right) \\
= {} & c_2^{(1)}\delta_2\tilde{\lambda} \\
& + \hat{d}_2^{(1)}\frac{\left(c_2^{(1)}\tilde{\lambda} - \frac{1}{\Lambda_{2,s}} + o(1)\right)\left(\frac{1}{-d_2^{(1)}}\right)^{\frac{1+\hat{\Lambda}_{1,s}}{\Lambda_{1,s}}}\delta_2^{\frac{1+\hat{\Lambda}_{1,s}}{\Lambda_{1,s}}-\Lambda_{2,s}}(1+o(1))}{\left\{\hat{d}_1^{(1)}\Lambda_{2,s}+o(1)\right\}\left(c_2^{(1)}\tilde{\lambda} - \frac{1}{\Lambda_{2,s}} + o(1)\right) + \hat{d}_1^{(1)}} \\
& + \hat{d}_2^{(1)}\frac{\Lambda_{1,s}\delta_2}{-d_2^{(1)}} \\
& + \hat{e}_2^{(1)}\hat{\Pi}^{(3)}_{2,1} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;\delta_2\tilde{\lambda}) \\
& \times \frac{\left(c_2^{(1)}\tilde{\lambda} - \frac{1}{\Lambda_{2,s}} + o(1)\right)\left(\frac{1}{-d_2^{(1)}}\right)^{\frac{1+\hat{\Lambda}_{1,ss}}{\Lambda_{1,s}}}\delta_2^{\frac{1+\hat{\Lambda}_{1,ss}}{\Lambda_{1,s}}-\Lambda_{2,s}}(1+o(1))}{\left\{\hat{d}_1^{(1)}\Lambda_{2,s}+o(1)\right\}\left(c_2^{(1)}\tilde{\lambda} - \frac{1}{\Lambda_{2,s}} + o(1)\right) + \hat{d}_1^{(1)}} \\
& + \hat{e}_2^{(1)}\Lambda_{1,s}\left(\frac{\delta_2}{-d_2^{(1)}}\right)^{1+\frac{\hat{\Lambda}_{1,ss}-\hat{\Lambda}_{1,s}}{\Lambda_{1,s}}}(1+o(1)) \\
& + O\left(\delta_2^2\right)
\end{aligned} \tag{4.9}$$

as $E(0) = 0$ and

$$\begin{aligned} &\hat{\Pi}_1^{(3)} \circ \hat{\Pi}_{2,1} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;*) \\ &= \hat{\Pi}_{2,1}^{(3)} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;*) \times \hat{\Pi}_1^{(1)} \circ \hat{\Pi}_{2,1} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;*) \\ &\times \left(\delta_1^{(1)}\right)^{\hat{\Lambda}_{1,ss} - \hat{\Lambda}_{1,s}} . \end{aligned} \tag{4.10}$$

5. Proof of the theorem.

In this section we prove the following theorem.

THEOREM. *Assume that the system* (1.6) *is* C^r*-diffeomorphic* ($r \geq 2$) *to linear systems in some neighborhoods of equilibria* a_i*, and* ε *is small; then the travelling* 1*-front* (*back*) *wave solution of FitzHugh–Nagumo equations* (1.1) *bifurcating from simple front and back travelling wave solutions is stable.*

We give the proof for the 1-front wave; the proof for the 1-back wave is similar.

First, let L be the linearization operator with respect to the 1-front wave solution $z_1(\xi)$; then we have the following for spectrum $\sigma(L)$ of L.

PROPOSITION 5.1. *For some negative constant* β,

$$\sharp\left(\sigma(L) \cap \{\lambda | Re\lambda > \beta\}\right) = 3, \tag{5.1}$$

counting their multiplicity.

Proof. Let $z_1^*(\xi)$ be the simple front wave and $z_2^*(\xi)$ be the simple back wave, and let L_i ($i = 1, 2$) be the linearization operator with respect to them. Then it is well known (see Evans [8] or Jones [11]) that there exists a negative constant β so that $\sigma(L) \cap \{\lambda | \mathrm{Re}\lambda > \beta\}$ and $\sigma(L_i) \cap \{\lambda | \mathrm{Re}\lambda > \beta\}$ consist of isolated eigenvalues with finite multiplicity. Moreover, this β can be chosen so that $\sigma(L_i) \cap \{\lambda | \mathrm{Re}\lambda > \beta\} = \{0\}$ holds (see Yanagida [17]). Thus, simply applying the additive formula for eigenvalues (see Alexander and Jones [2] or Nii [12]), we conclude that $\sharp\left(\sigma(L) \cap \{\lambda | \mathrm{Re}\lambda > \beta\}\right) = 3$ for the 1-front wave. □

PROPOSITION 5.2. *L has even eigenvalues with positive real part.*

Proof. First, we remark that if L has an eigenvalue which is not real, then L also has an eigenvalue which is complex conjugate to it.

Let $E\mathrm{v}(\lambda)$ be the Evans function for the 1-front wave $z_1(\xi)$; *i.e.,*

$$E\mathrm{v}(\lambda) = \det\left(p_1(\xi;\lambda) p_2(\xi;\lambda) p_3(\xi;\lambda)\right)\big|_{\xi=0},$$

where $p_1(\xi;\lambda)$ is a solution of (1.13) along $z_1(\xi)$ which is bounded as $\xi \to -\infty$, and $p_2(\xi;\lambda)$ and $p_3(\xi;\lambda)$ are solutions which are bounded as $\xi \to +\infty$. This function is analytic in λ and vanishes at the eigenvalues of L, and each order of each vanishing point is equal to the multiplicity of the eigenvalue. See Alexander, Gardner, and Jones [1] for more detail. If we choose p_1 and p_2 so that $p_1(\xi;0) = p_2(\xi;0) = z_{1\xi}(\xi)$ then, by Lemmas 3.1 and 3.2, the derivative of $E\mathrm{v}(\lambda)$ with respect to λ at $\lambda = 0$ is expressed as follows:

$$\begin{aligned} \tfrac{\partial E\mathrm{v}}{\partial \lambda}(0) &= \det\left(\left(p_{1\lambda}(\xi;0) - p_{2\lambda}(\xi;0)\right) z_{1\xi}(\xi) p_3(\xi;0)\right)\big|_{\xi=0} \\ &= \det\left(z_{1c}(\xi) z_{1\xi}(\xi) p_3(\xi;0)\right)\big|_{\xi=0}. \end{aligned} \tag{5.2}$$

The same expression holds for the Evans function $E\mathrm{v}^*(\lambda)$ corresponding to the simple front $z_1^*(\xi)$. Moreover, $z_1(\xi)$ and $z_1^*(\xi)$ can be taken so that $z_{1c}(0)$ and $z_{1c}^*(0)$, $z_{1\xi}(0)$ and $z_{1\xi}^*(0)$, and $p_3(0;\lambda)$ for both cases coincide in the limit of $(\gamma, c) \to (\gamma_0, c_0)$. Thus the signs of $\frac{\partial E\mathrm{v}}{\partial \lambda}(0)$ and $\frac{\partial E\mathrm{v}^*}{\partial \lambda}(0)$ agree.

Here if $E\mathrm{v}$ and $E\mathrm{v}^*$ are normalized so that they are positive for large λ, then $\frac{\partial E\mathrm{v}^*}{\partial\lambda}(0) > 0$ because the simple front is stable (Yanagida [17]) and $E\mathrm{v}^*(\lambda)$ does not vanish for $\lambda > 0$. This means $\frac{\partial E\mathrm{v}}{\partial\lambda}(0) > 0$, so $E\mathrm{v}(\lambda) = 0$ for even $\lambda > 0$; thus the proposition holds. □

By the propositions above, for proof of the stability, it suffices to find one eigenvalue with negative real part which is near 0. This is achieved by proving existence of a negative solution of (4.1).

First, the right-hand side of (4.3) tends to zero as δ_2 tends to zero, provided that $\tilde{\lambda}$ is negative. Similarly, the last expression of (4.8) converges to zero uniformly in $\tilde{\lambda} < -\tilde{\lambda}_0$ for arbitrary small $\tilde{\lambda}_0 > 0$, and at the same time

$$\hat{\Pi}_1^{(1)} \circ \hat{\Pi}_{2,1} \circ \hat{\Pi}_2 \circ \hat{\Pi}_{1,2}(0,0;0) \to 0 \qquad (\delta_2 \to 0). \tag{5.3}$$

Therefore, the expansion (4.5) and (4.8) is valid for $\tilde{\lambda} < -\tilde{\lambda}_0$ when δ_2 tends to zero.

Here, (4.9) implies

$$E(\delta_2\tilde{\lambda}) = c_2^{(1)}\delta_2\tilde{\lambda} + \hat{d}_2^{(1)}\frac{\Lambda_{1,s}\delta_2}{-d_2^{(1)}} + o(\delta_2) \qquad (\delta_2 \to 0). \tag{5.4}$$

Thus

$$\frac{1}{\delta_2}E(\delta_2\tilde{\lambda}) \to c_2^{(1)}\tilde{\lambda} - \frac{\hat{d}_2^{(1)}}{d_2^{(1)}}\Lambda_{1,s} \quad \text{as} \quad \delta_2 \to 0. \tag{5.5}$$

This means $\frac{1}{\delta_2}E(\delta_2\tilde{\lambda}) = 0$ has a solution $\tilde{\lambda} = \hat{d}_2^{(1)}\Lambda_{1,s}/d_2^{(1)}c_2^{(1)} + O(\delta_2)$ for small $\delta_2 > 0$; i.e., $E(\lambda) = 0$ has a solution $\lambda = (\hat{d}_2^{(1)}\Lambda_{1,s}/d_2^{(1)}c_2^{(1)})\delta_2 + o(\delta_2)$. By the inequality (2.7) and Lemma 3.3, $c_2^{(1)} > 0$, $d_2^{(1)} < 0$, and $\hat{d}_2^{(1)} > 0$, so this solution is negative. As a result, the 1-front wave solution is stable by the argument above. This completes the proof of the theorem.

Appendix. Proof of Proposition 2.2. Let $\mathcal{V}(n)$ be the vector space of germs of the C^∞-vector fields at 0 in $\mathbb{R}^n$ and let $\mathcal{E}(n)$ be the algebra of C^∞-germs of functions on $\mathbb{R}^n$ at 0. The maximal ideal of $\mathcal{E}(n)$ generated by arbitrary C^∞-functions $f_1, \dots, f_k$ shall be denoted by $\mathcal{M}(f_1, \dots, f_k)$, and a subspace $\mathcal{V}(n; s)$ of $\mathcal{V}(n+s)$ shall be defined by

$$\mathcal{V}(n;s) = \mathcal{M}(x_1, \dots, x_n)\mathrm{span}\left\{\frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_n}\right\}. \tag{A.1}$$

For the sake of convenience we write the coordinate of $\mathbb{R}^{n+s}$ as $x_1, \dots, x_n, y_1, \dots, y_s$. The vector field $\mathrm{pr}_1 \circ X(x, y)$ is expressed as X_y for a given vector field $X \in \mathcal{V}(n; s)$, where pr_1 is the projection onto the first n coordinates. Hence $X_y \in \mathcal{V}(n)$ for every $y \in \mathbb{R}^s$ sufficiently small.

Let $\lambda_1(y), \dots, \lambda_n(y)$ be the eigenvalues of $DX_y(0)$ and assume that $\mathrm{Re}\lambda_i > 0$ for $i = 1, \dots, p$ and $\mathrm{Re}\lambda_i < 0$ for $i = p+1, \dots, n$.

We introduce two constants depending on eigenvalues:

$$\begin{aligned} A_+ &= \frac{\max\limits_{p+1\le i\le n} |\mathrm{Re}\lambda_i(0)|}{\min\limits_{1\le i\le p} |\mathrm{Re}\lambda_i(0)|}, \\ A_- &= \frac{\max\limits_{1\le i\le p} |\mathrm{Re}\lambda_i(0)|}{\min\limits_{p+1\le i\le n} |\mathrm{Re}\lambda_i(0)|}, \end{aligned} \tag{A.2}$$

and let $k_\pm$ be two integers which satisfy the condition below for some integer r:

$$k_\pm > r(1 + A_\pm). \tag{A.3}$$

Then, the following holds.

PROPOSITION A.1 (Rychlic [14]). *Let $X \in \mathcal{V}(n; s)$ and $k = k_+ + k_-$, and let X' be the Taylor expansion of X of degree $k - 1$. Then X and X' are C^r-equivalent.*

By this proposition X can be linearized through a C^r-coordinate change if the Taylor expansion of X vanishes up to degree $k - 1$.

Here, by the Poincaré–Dulac theorem (see, for example, Arnol'd [4]), this can be achieved through polynomial transformation provided that $\{\lambda_1(y), \dots, \lambda_n(y)\}$ satisfies nonresonant condition up to order $k-1$. Thus the proof of the Proposition 2.2 amounts to the proof the following lemma.

LEMMA A.1. *There are uncountably many pairs of (a, ε) $(0 < a < \frac{1}{2}, 0 < \varepsilon < \varepsilon_0)$ such that for all $k > 0$, $\{\lambda_{i,u}(\mu), -\lambda_{i,s}(\mu), -\lambda_{i,ss}(\mu)\}$ satisfies a nonresonant condition up to order k for $\mu = (\gamma(\varepsilon), c(\varepsilon), \varepsilon)$ and $(i = 1, 2)$.*

Proof. The bifurcation point $(\gamma(\varepsilon), c(\varepsilon))$ in the γ–c plane is smooth in ε and thus $\lambda_{i,u}(\gamma(\varepsilon), c(\varepsilon), \varepsilon), -\lambda_{i,s}(\gamma(\varepsilon), c(\varepsilon), \varepsilon), -\lambda_{i,ss}(\gamma(\varepsilon), c(\varepsilon), \varepsilon)$ $(i = 1, 2)$ are also smooth in ε. Moreover, $\lambda_{i,u}(\gamma(0), c(0), 0) = \frac{1}{\sqrt{2}}$, $-\lambda_{i,s}(\gamma(0), c(0), 0) = 0$, $-\lambda_{i,ss}(\gamma(0), c(0), 0) = -\sqrt{2}a$ $(i = 1, 2)$, and $-\lambda_{i,s}(\gamma(\varepsilon), c(\varepsilon), \varepsilon) < 0$ for small $\varepsilon > 0$.

Notice that the system (1.6) is symmetric with respect to the coordinate change

$$(u, v, w) \mapsto \left(-u + \frac{2(a+1)}{3}, -v, -w + \frac{2(2-a)(1-2a)(a+1)}{27}\right) \tag{A.4}$$

for $\gamma = \frac{9}{(2-a)(1-2a)} = \gamma(0)$ for any $\varepsilon > 0$. Then $\gamma(\varepsilon) = \gamma(0)$ for $\varepsilon > 0$ as $(\gamma(\varepsilon), c(\varepsilon))$ is the only parameter value at which $z_1^*(\xi)$ and $z_2^*(\xi)$ coexist. Thus $\lambda_{1,u} = \lambda_{2,u}$, $-\lambda_{1,s} = -\lambda_{2,s}$, and $-\lambda_{1,ss} = -\lambda_{2,ss}$ holds for $(\gamma(\varepsilon), c(\varepsilon))$ because of the symmetry.

For each $m = (m_u, m_s, m_{ss}) \in \mathbb{Z}^3$ $(m_* \geq 0,\ m_u + m_s + m_{ss} \geq 2)$, let I_m^u be a union of intervals such that $\varepsilon \in I_m^u$ if and only if

$$\lambda_{i,u} = m_u \lambda_{i,u} + m_s(-\lambda_{i,s}) + m_{ss}(-\lambda_{i,ss}). \tag{A.5}$$

Similarly, $\varepsilon \in I_m^s$ if and only if

$$-\lambda_{i,s} = m_u \lambda_{i,u} + m_s(-\lambda_{i,s}) + m_{ss}(-\lambda_{i,ss}) \tag{A.6}$$

and $\varepsilon \in I_m^{ss}$ if and only if

$$-\lambda_{i,ss} = m_u \lambda_{i,u} + m_s(-\lambda_{i,s}) + m_{ss}(-\lambda_{i,ss}) \tag{A.7}$$

for $\varepsilon \geq 0$. Then $I_m^* = \coprod_j I_m^{*(j)}$ $(* = u, s, ss)$, where $I_m^{*(j)}$ is a closed interval, and if $\mathrm{int}(I_m^{*(j)}) \neq \emptyset$ and $\mathrm{int}(I_{m'}^{*(j')}) \neq \emptyset$ then $I_m^{*(j)} \cap I_{m'}^{*(j')} = \emptyset$ because $\lambda_{i,u}$, $-\lambda_{i,s}$, and $-\lambda_{i,ss}$ are smooth in ε.

At $\varepsilon = 0$, the only resonances are of the form

$$-\lambda_{i,s}(\gamma(0), c(0), 0) = m\{-\lambda_{i,s}(\gamma(0), c(0), 0)\} \qquad (m \geq 2); \tag{A.8}$$

i.e., $-\lambda_{i,s}(\gamma(0), c(0), 0) = 0$ if a is irrational. This means there is no interval with $0 \in I_m^{*(j)}$ and $\mathrm{int}(I_m^{*(j)}) \neq \emptyset$. Thus, for each fixed irrational a, there exist infinitely many ε such that none of (A.5), (A.6), or (A.7) holds for any $m = (m_u, m_s, m_{ss})$. This completes the proof. □

ON THE ASYMPTOTIC SOLUTION OF LAMINAR CHANNEL FLOW WITH LARGE SUCTION*

CHUNQING LU†

Abstract. The equation considered is

$$\epsilon f^{iv} = ff''' - f'f'',$$

with boundary conditions

$$f(0) = f''(0) = 0, f(1) = 1, f'(1) = 0.$$

When $0 < \epsilon \ll 1$, the boundary value problem corresponds to the laminar flow of a viscous fluid through a porous channel under large suction. It is known that there are three solutions in this case: two of them are monotone increasing (types I and II), and the third is nonmonotone (type III). Let $(1-\Delta)$ be the turning point of $f(\eta)$ in (0, 1). This paper presents a rigorous proof of the asymptotic behavior of type III solutions, which is

$$f(\eta) \sim \kappa \sin \frac{\pi\eta}{1-\Delta}, \quad \text{where} \quad \kappa \sim \frac{1-\Delta}{\pi\Delta} \text{ and } \frac{\Delta}{\epsilon} e^{\Delta/\epsilon} \sim \frac{1}{2e\pi^9\epsilon^8},$$

uniformly on $[0, 1-\Delta]$ as $\epsilon \to 0^+$, and provides detailed information at the turning point.

Key words. laminar flow, turning point, exponential terms

1. Introduction.

Assuming that the fluid is incompressible and is injected or sucked through the walls of a rectangular channel, Berman [1], in 1953, reduced the boundary value problem for the Navier–Stokes equations to a nonlinear fourth-order ordinary differential equation

$$\epsilon f^{iv} = ff''' - f'f''. \tag{1.1}$$

If the flow is assumed to be symmetric, then f is an odd function and the boundary conditions

$$f(0) = f''(0) = 0, \tag{1.2}$$
$$f'(1) = 0, f(1) = 1 \tag{1.3}$$

are imposed, where $f(\eta)$ is the unknown function related to the stream function and η is the normalized transverse coordinate ($\eta = \pm 1$ are the walls). The parameter ϵ equals $\frac{1}{R}$ where R is the Reynolds number of the flow. The case $\epsilon < 0$ corresponds to the injection problem arising in transpiration cooling, and $\epsilon > 0$ to the suction problem for the isotope separation.

The boundary value problem (1.1)–(1.2)–(1.3) admits at least three solutions, which were classified as type I, the increasing concave down function, type II, the increasing function with a reflection point, and type III, the nonmonotone function with a turning point [12]. Here the turning point, denoted by $z_\epsilon = 1-\Delta_\epsilon$, is defined as

the value of $\eta \in (0,1)$ at which the solution vanishes. There have been many published numerical results and formally asymptotic analyses [2], [3], [8], [10], [11], [13], [14], [15]; see [7] and the references listed there. The existence of the three solutions for sufficiently small $\epsilon > 0$ can be found in [4]. As far as rigorous asymptotic results, Hastings, Lu, and MacGillivray studied the behavior of type I and type II solutions as $|R| \to \infty$ in [4] and [6], and McLeod proved the asymptotic formula of $f'''(0)$ for type I and type II solutions [9]. As for type III solutions, Robinson [12], Zaturska, Drazin, and Banks [16], and MacGillivray and Lu [7] presented formal asymptotic results in different ways. But from the rigorous analysis point of view, only very little was known about type III solutions. This paper presents a rigorous proof of the asymptotic formula for type III solutions of (1.1)–(1.2)–(1.3) as $\epsilon \to 0^+$.

The paper is organized as follows. Section 2 contains the main result of the paper. In section 3, we study the function $g(\eta, \epsilon) \equiv \frac{f(\eta,\epsilon)}{f'(0,\epsilon)}$ for $\eta \in [0, z_\epsilon]$, which turns out to behave like a sine function on that interval. This implies that the investigation of $f'(0, \epsilon)$ is crucial. In section 4, another rescaled function $u(t, \epsilon^*) = f(z_\epsilon + \Delta_\epsilon t)$, where $t = \frac{\eta - z_\epsilon}{\Delta_\epsilon}$ and $\epsilon^* = \frac{\epsilon}{\Delta_\epsilon}$, is introduced. Using the boundary conditions at $t = 1$ ($\eta = 1$) and $t = 0$ ($\eta = z_\epsilon$), we prove that as $\epsilon \to 0^+$, (1) $\epsilon^* \to 0^+$, (2) $|f'(0, \epsilon)|\Delta_\epsilon \to 1$, and (3) the limit function of $u(t, \epsilon^*)$ for $t \in [0, 1]$ is linear. Since $u'''(0) \sim \Delta_\epsilon^2 \pi^2$, it is necessary to approximate $u'''(0)$ in order to find the asymptotic value for $f'(0, \epsilon)$. In section 5, we prove the asymptotic behavior of $u(t)$ for $t > 0$, including the boundary layer on the right side, as well as one asymptotic formula linking $u'''(0)$ and $u^{iv}(0)$. In section 6, we return to the left side of the turning point and prove, with the results from section 1, another asymptotic formula linking $u'''(0)$ and $u^{iv}(0)$. In section 7, the leading terms for $u'''(0)$, $u^{iv}(0)$, and $u''(0)$ are determined. These and the asymptotic formula of $u'(0)$ given in section 5 completely provide the asymptotic behavior of the solution at the turning point. The asymptotic relation between Δ_ϵ and ϵ is finally determined at the end of section 7.

Since some previous rigorous results on the nonmonotone solutions are applied repeatedly, they should be listed here.

(I) $f^{iv}(\eta) < 0$ for all $\eta \in (0, 1]$.

(II) For any given sufficiently small $\epsilon > 0$, a type III solution exists, which means that there exists a pair $\alpha < 0$ and $\beta > 0$ depending on ϵ such that the initial value problem of (1.1) with (1.2) and $f'(0) = \alpha, f'''(0) = \beta$ has a solution satisfying (1.3).

(III) Let $z_\epsilon \equiv 1 - \Delta_\epsilon$ be the turning point of the solution, and y_ϵ the reflection point of $f(\eta)$. Then, $y_\epsilon > z_\epsilon$, and hence, $f'' > 0$ in $(0, y_\epsilon\ )$ and $f'' < 0$ in $(y_\epsilon, 1)$. Also, $f'(z_\epsilon) > 0, f''(z_\epsilon) > 0$, $z_\epsilon \to 1$, and $y_\epsilon \to 1$ as $\epsilon \to 0^+$.

(IV) As $\epsilon \to 0^+$, $\alpha \to -\infty$, $f(\eta) \to -\infty$, and $f''(\eta) \to \infty$ for each $\eta \in (0, 1)$.

Proofs of (I)–(IV) can be found in [4] and [7]. Since a type III solution exists for only sufficiently small $\epsilon > 0$, throughout the rest of the paper the expression $\epsilon \to 0$ means $\epsilon \to 0^+$. Also, for briefness, the dependence on ϵ is often dropped, such as $f(\eta, \epsilon) \equiv f(\eta)$, $g(\eta, \tilde{\epsilon}) \equiv g(\eta), h(\eta, \tilde{\epsilon}) \equiv h(\eta), \Delta_\epsilon \equiv \Delta$, $u(t, \epsilon^*) \equiv u(t)$, and so on, except for cases where the appearance of ϵ is necessary.

2. Main result.

The main result of the paper is stated in the following theorem.

THEOREM 2.1. *As $\epsilon \to 0^+$, the nonmonotone solution $f(\eta, \epsilon)$ of* (1.1)–(1.2)–(1.3) *satisfies*

$$f(\eta, \epsilon) \sim -\frac{1 - \Delta}{\pi\Delta} \sin \frac{\pi\eta}{1 - \Delta}$$

uniformly on $[0, 1-\Delta]$, *where* $f(1-\Delta, \epsilon) = 0$, *and* Δ *satisfies*

$$\frac{\Delta}{\epsilon} e^{\frac{\Delta}{\epsilon}} \sim \frac{1}{2e\pi^9\epsilon^8}.$$

Note from Theorem 2.1 that the domain of validity for the asymptotic solution includes the moving right endpoint of the interval. The uniform convergence on the closed moving interval, which is needed in the paper, is defined in the same way that one defines uniform convergence for a fixed closed interval [5]. The theorem, of course, implies that the asymptotic formula for $f(\eta, \epsilon)$ holds not only uniformly on any compact subinterval of $[0, 1-\Delta)$, but also at the turning point $\eta = 1-\Delta$. Let $\phi(\eta, \epsilon) \equiv \frac{1-\Delta}{\pi\Delta} \sin \frac{\pi\eta}{1-\Delta}$. The first asymptotic formula of the theorem means that $\lim_{\epsilon\to 0} \frac{f(\eta,\epsilon)}{\phi(\eta,\epsilon)} = 1$ uniformly for $\eta \in [0, 1-\Delta]$. Since $f(0, \epsilon) = h\,(0, \epsilon) = 0$ for all ϵ, the ratio $\frac{f(\eta,\epsilon)}{\phi(\eta,\epsilon)}$ evaluated at $\eta = 0$ is defined, as usual, by $\lim_{\eta\to 0^+} \frac{f(\eta,\epsilon)}{\phi(\eta,\epsilon)}$, and hence is equal to $\frac{f'(0,\epsilon)}{\phi'(0,\epsilon)}$. Similarly, at $\eta = 1-\Delta$, the ratio is defined as $\lim_{\eta\to(1-\Delta)^-} \frac{f(\eta,\epsilon)}{\phi(\eta,\epsilon)} = \frac{f'(1-\Delta,\epsilon)}{\phi'(1-\Delta,\epsilon)}$.

The theorem is a consequence of Theorems 3.1, 4.1, and 4.5 in the remainder of the paper.

3. Approximation on $[0, z_\epsilon]$. Because of the unboundedness of the solution and the singularity of the boundary value problem, it is necessary to rescale the solution $f(\eta)$. Since $f'(0) = \alpha \to -\infty$ as $\epsilon \to 0$, we first introduce

$$g(\eta) \equiv \frac{f(\eta)}{|\alpha|} \quad \text{and } \tilde{\epsilon} \equiv \frac{\epsilon}{|\alpha|}.$$

Equation (1.1) then takes the form

$$\tilde{\epsilon} g^{iv} = gg''' - g'g'', \tag{3.1}$$

with initial conditions

$$g(0) = g''(0) = 0, \quad g'(0) = -1, \quad g'''(0) = \frac{\beta}{|\alpha|}. \tag{3.2}$$

It is clear that the process $\epsilon \to 0$ implies $\tilde{\epsilon} \to 0$. In this section, the following theorem will be proved.

THEOREM 3.1. *Let* $h(\eta) = -\frac{\sin(\pi\eta/(1-\Delta))}{\pi/(1-\Delta)}$. *Then* $\frac{f(\eta)}{|\alpha|} - h \to 0$ *in* C^4 *on* $[0, 1-\Delta]$, *and* $\frac{f(\eta)}{|\alpha|} \sim h$ *uniformly on* $[0, 1-\Delta]$ *as* $\tilde{\epsilon} \to 0$.

The proof of Theorem 3.1 consists of Lemmas 3.3, 3.5, 3.7, 3.8, and 3.10–3.12.

Throughout the paper the following two propositions are applied repeatedly.

PROPOSITION 3.2. *Let* $\{y(x, s)\}$ *be a sequence of* C^1 *functions defined on* $[a, b]$ *with* $a = a(s), b = b(s)$, *and* $[a, b] \subseteq [c, d]$ *for all* $s \in (0, 1)$ *where* s *is a parameter. Assume that* $y(x, s)$ *is uniformly bounded on* $[a, b]$. *Then,* (1) *if* $y'(x, s)$ *is nonnegative and concave down on* $[a, b]$ *for all* s, *then* $y'(x, s)$ *is uniformly bounded on* $[a, b]$; (2) *if* $y'(x, s)$ *is nonpositive and concave up on* $[a, b]$ *for all* s, *then* $y'(x, s)$ *is uniformly bounded on* $[a, b]$.

Proof. We only give a proof of (1), since the proof of (2) is similar. Suppose, for contradiction, that the sequence $\{y'(x, s)\}$ is not uniformly bounded. Then there would be a subsequence of $\{s\}$, say $\{s_n\}$, and a sequence $\{x_n\} \subseteq [a, b]$ such that

$y'(x_n,s_n)=\max\{y'(x,s_n)\}\to\infty$ as $n\to\infty$. Without loss of generality, one can assume $x_n\to p\in[c,d]$ as $n\to\infty$. Then the concavity of y' leads to, for sufficiently large integer n, either $y'(x,s_n)>\frac{y'(x_n,s_n)-y'(a,s_n)}{x_n-a}(x-a)+y'(a,s_n)$ for $x\in(a,x_n)$ if $p\neq a$, or $y'(x,s_n)>\frac{y'(x_n,s_n)-y'(b,s_n)}{b-x_n}(b-x)+y'(b,s_n)$ for $x\in(x_n,b)$ if $p=a$. In the former case, integrating the first inequality over (a,x_n), we see that $y(x_n,\epsilon_n)$ becomes unbounded as $n\to\infty$. Similarly, in the latter case $y(b,s_n)$ becomes unbounded as $n\to\infty$. These contradict the uniform boundedness of $\{y(x,\epsilon)\}$. □

Lemma 3.3. *For any given positive $\delta\ll 1$, $g-(-(\sin\frac{\pi\eta}{z_\epsilon}/\frac{\pi}{z_\epsilon}))\to 0$ in C^1 on $[0,1-\delta]$ and in C^2 on $[\delta,1-\delta]$ as $\tilde{\epsilon}\to 0$.*

Proof. Noting that $g''>0$ on $(0,z_\epsilon)$, $g'(0)=-1$, and $g'>0$ on $[z_\epsilon,1)$, one sees that $g'>-1$; hence $g\geq-\eta$ for $\eta\in(0,z_\epsilon)$, and $0\leq g\leq\frac{1}{|\alpha|}$ for $\eta\in[z_\epsilon,1]$. Thus, $g(\eta)$ is uniformly bounded on $[0,1]$ as $\tilde{\epsilon}\to 0$. Let a positive number $\delta\ll 1$ be fixed. Since $g''>0$ on $[0,z_\epsilon]$ (in particular, on $[1-\delta,1-\frac{\delta}{2}]$), $g'(1-\delta)$ must be bounded as $\tilde{\epsilon}\to 0$; otherwise, $g(1-\frac{\delta}{2})$ would be unbounded. Using the boundedness of g' and the concavity of g'' ($g^{iv}<0$), we conclude that g'' is uniformly bounded on $[0,1-\delta]$ by Proposition 3.2. Applying the property $g^{iv}<0$, we obtain that g''' is uniformly bounded on $[\delta,1-\delta]$ (otherwise, g'' would not be bounded uniformly on $[\frac{\delta}{2},\delta]$).

Now, let us consider any sequence $\{\tilde{\epsilon}_n\}$ of $\tilde{\epsilon}$ with $\tilde{\epsilon}_n\to 0$. Since g,g', and g'' are all uniformly bounded on $[0,1-\delta]$, the Arzela–Ascoli theorem can be applied to conclude that there exist a subsequence, again denoted by $\{g(\eta,\tilde{\epsilon}_n)\}$, and a function $\tilde{h}(\eta)$ such that $g(\eta,\tilde{\epsilon}_n)\to\tilde{h}(\eta)$ in $C^1_{[0,1-\delta]}$ and $g''(\eta,\tilde{\epsilon}_n)\to\tilde{h}''(\eta)$ uniformly on $[\delta,1-\delta]$ as $n\to\infty$. Our first goal is to show $\tilde{h}(\eta)=-\frac{\sin(\pi\eta)}{\pi}$.

An integration of (3.1) with respect to η yields

$$\tilde{\epsilon}g'''=gg''-(g')^2+1+\tilde{\epsilon}\tilde{\beta}, \tag{3.3}$$

where $\tilde{\beta}=\frac{\beta}{|\alpha|}>0$. Applying the uniform boundedness of g''' on $[\delta,1-\delta]$, together with the Arzela–Ascoli theorem, one sees that $g''(\eta,\tilde{\epsilon}_n)\to\tilde{h}''(\eta)$ on that interval and $\tilde{h}$ satisfies

$$\tilde{h}\tilde{h}''-(\tilde{h}')^2+c=0, \tag{3.4}$$

where $c=\lim_{\tilde{\epsilon}\to 0}(1+\tilde{\epsilon}\tilde{\beta})\geq 1$ is a constant. Since δ is arbitrarily given, we see that $\tilde{h}(\eta)$ is defined in $(0,1)$. From (3.4),

$$\tilde{h}''=\frac{(\tilde{h}')^2-c}{\tilde{h}}.$$

Then $\tilde{h}'''$ is well defined for any $\eta\in(0,1)$. A differentiation of (3.4) shows

$$\tilde{h}\tilde{h}'''-\tilde{h}'\tilde{h}''=0, \tag{3.5}$$

for $\eta\in(0,1)$. Solving (3.5) for $\eta\in[\delta,1-\delta]$, one obtains $\tilde{h}''=A\tilde{h}$ which is valid for any $\eta\in[\delta,1-\delta]$, where A is a constant independent of δ. Thus, $\tilde{h}''$ is well defined at $\eta=0$ and $\tilde{h}''(0)=0$. It then follows from (3.4) that $c=1$. All possible solutions of equation $\tilde{h}''=A\tilde{h}$ with $\tilde{h}(0)=0,\tilde{h}'(0)=-1$ are

$$\tilde{h}(\eta)=-\tilde{h},\quad \tilde{h}(\eta)=-\frac{\sin(a\eta)}{a},\quad \tilde{h}(\eta)=-\frac{\sinh(a\eta)}{a},$$

where $a=\sqrt{|A|}>0$ is a constant. Considering the fact that $\tilde{h}''$ must have the same concavity as g'' does, we may eliminate the third possibility. Suppose $\tilde{h}=-\eta$.

Then, $g' \approx -1, g'' \approx 0$ in $[\delta, 1-\delta]$. Applying the mean value theorem on $(\delta, 1-\delta)$, we see that $g''' \approx 0$ for some $\eta_0 < 1-\delta$. Since $g'(1) = 0$ and $g'(1-\delta) \approx -1$, there exists an $\eta_1 \in (1-\delta, 1)$ such that $g''(\eta_1) \approx \frac{1}{\delta}$ by the mean value theorem. Hence, $g'''(\eta_2) = \frac{g''(\eta_1)-g''(1-\delta)}{\eta_1-(1-\delta)} > \frac{1}{2\delta^2}$ for some $\eta_2 \in (1-\delta, \eta_1)$. This implies that $g^{iv} > 0$ for some $\eta < 1$, a contradiction. Therefore, $\tilde{h}(\eta) = -\frac{\sin(a\eta)}{a}$. Next, we claim $a = \pi$. Recall that $\tilde{h}$ is the limit function of a subsequence of $\{g(\eta, \tilde{\epsilon})\}$ on $[0, 1-\delta]$ and that the value of a does not depend upon the choice of δ. It is then observed that $a \leq \pi$; otherwise, $g(1-\Delta) < 0$ for sufficiently small $\tilde{\epsilon}$, a contradiction. Similarly, it is impossible to have $a < \pi$. Thus, $a = \pi$.

Summarizing the above discussion, we have shown that any sequence $\{g(\eta, \tilde{\epsilon}_n)\}$ has a subsequence converging to $\tilde{h}$ in C^1 on $[0, 1-\delta]$ and in C^2 on $[\delta, 1-\delta]$ for any given positive $\delta \ll 1$. Since $g(1-\Delta) = 0$ and $\frac{\sin(\pi\eta)}{\pi} / \frac{\sin[\pi\eta/(1-\Delta)]}{\pi/(1-\Delta)} \to 1$ uniformly on $[0, 1-\Delta]$ as $\Delta \to 0$, we can set the limit function $h(\eta) = h(\eta, \tilde{\epsilon}) = -\frac{\sin[\pi\eta/(1-\Delta)]}{\pi/(1-\Delta)}$ for the purpose of asymptotic analysis. Since $\{g(\eta, \tilde{\epsilon}_n)\}$ is arbitrarily chosen, we conclude that $g - h \to 0$ in $C^1_{[0,1-\delta]}$ and $C^2_{[\delta,1-\delta]}$ as $\tilde{\epsilon} \to 0$. The proof of Lemma 3.3 is complete. □

PROPOSITION 3.4. *Let $g(\eta, \tilde{\epsilon})$ be a solution of* (3.1) *and $k \geq 2$ be an integer. If $g, g', g'', ..., g^{(k+1)}$ are all uniformly bounded on any compact subinterval $[0, 1-\delta]$ of $[0, 1)$, then there exists a unique C^k function $\tilde{h}(\eta)$ defined on $[0, 1)$ such that $g \to \tilde{h}$ in $C^k_{[0,1-\delta]}$ as $\tilde{\epsilon} \to 0$.*

Proof. If $k = 2$, the proof of the proposition is similar to that of Lemma 3.3. For $k > 2$, a simple application of mathematical induction derives the proposition. □

At this moment, Lemma 3.3 does not automatically imply $g \sim h(\eta)$ (hence $f(\eta, \epsilon) \sim \alpha \frac{\sin[\pi\eta/(1-\Delta)]}{\pi/(1-\Delta)}$) uniformly on any compact subinterval of $[0, 1-\Delta)$. This is because, from the proof of Lemma 3.3, the choice of the convergent subsequences may depend on δ. Therefore, to obtain the desired asymptotic result, more work is needed.

An interesting question arising from Proposition 3.4 is this: what is the largest number that k may assume? In other words, how close are g and h? An inspection of g and h at $\eta = 0$ shows that $g^v(0) = 0$ and $h^v(0) \approx -\pi^4$. Therefore, $k \leq 4$. In fact, we can prove the maximum value of k is 4. To do so, we need the uniform boundedness of higher derivatives of $g(\eta)$ on [0,1 − Δ].

LEMMA 3.5. *g''' is uniformly bounded and $g - h \to 0$ in C^2 on $[0, 1-\delta]$ for any given positive $\delta \ll 1$.*

Proof. We first prove that $g^v < 0$ as long as $g' < 0$ and $g''' > 0$; i.e., g''' is positive and concave down as long as $g' < 0$, so Proposition 3.2 can be applied. Since $g' \to -\cos \pi\eta$ on $[0, 1-\delta]$ uniformly as $\tilde{\epsilon} \to 0$, g' and h' must have the same concavity for sufficiently small $\tilde{\epsilon} > 0$. Noting that h''' has exactly one zero, $\eta = \frac{1-\Delta}{2}$, which is the reflection point of the function h', we see that g' must have a unique reflection point $\eta_3 \to \frac{1}{2}$ as $\tilde{\epsilon} \to 0$. Also, g' is concave up for $\eta < \eta_3$ and concave down for $\eta > \eta_3$. The uniqueness of η_3 follows from $g^{iv} < 0$. Differentiating (3.1) with respect to η once yields

$$\tilde{\epsilon} g^v = g g^{iv} - (g'')^2, \tag{3.6}$$

which can be rewritten as

$$\left(e^{-\frac{1}{\tilde{\epsilon}} \int g(s)ds} g^{iv}\right)' = -\frac{1}{\tilde{\epsilon}} (g'')^2 e^{-\frac{1}{\tilde{\epsilon}} \int g(s)ds}. \tag{3.7}$$

Integrating (3.7) and multiplying the exponential function on both sides leads to

$$g^{iv}(\eta) = -\frac{1}{\tilde{\epsilon}}\int_0^\eta (g''(s))^2 e^{\frac{1}{\tilde{\epsilon}}\int_s^\eta g(r)dr}ds. \tag{3.8}$$

Differentiating (3.1) with respect to η twice gives

$$\tilde{\epsilon}g^{vi} = gg^v + g'g^{iv} - 2g''g''', \tag{3.9}$$

from which

$$g^v(\eta) = \frac{1}{\tilde{\epsilon}}\int_0^\eta (g'g^{iv} - 2g''g''')e^{\frac{1}{\tilde{\epsilon}}\int_s^\eta g(r)dr}ds. \tag{3.10}$$

The same technique applied to (3.1) shows

$$g'''(\eta) = -\frac{1}{\tilde{\epsilon}}\int_0^\eta g'g''e^{\frac{1}{\tilde{\epsilon}}\int_s^\eta g(r)dr}ds + g'''(0)e^{\frac{1}{\tilde{\epsilon}}\int_0^\eta g(s)ds}. \tag{3.11}$$

In order to determine the sign of g^{iv} with (3.10), we use (3.8) and (3.11) to estimate

$$\begin{aligned} &g'g^{iv} - 2g''g''' \\ &\quad < \frac{1}{\tilde{\epsilon}}\left(-g'(\eta)\int_0^\eta (g'')^2 e^{\frac{1}{\tilde{\epsilon}}\int_s^\eta gdr}ds + 2g''(\eta)\int_0^\eta g'g''e^{\frac{1}{\tilde{\epsilon}}\int_s^\eta gdr}ds\right), \end{aligned} \tag{3.12}$$

since $g'' > 0$ for $\eta \in (0, 1-\delta)$ and $g'''(0) > 0$. Let $\eta < \min\{\eta_3, \eta_1\}$, where η_1 is the zero point of g', which also approaches $\frac{1}{2}$ as $\tilde{\epsilon} \to 0$. Since $g' < 0$, $g'' > 0$, and $g''' > 0$,

$$\begin{aligned} g''(\eta)\int_0^\eta g'g''e^{\frac{1}{\tilde{\epsilon}}\int_s^\eta gdr}ds &< \int_0^\eta g'(g'')^2 e^{\frac{1}{\tilde{\epsilon}}\int_s^\eta gdr}ds \\ &< g'(\eta)\int_0^\eta (g'')^2 e^{\frac{1}{\tilde{\epsilon}}\int_s^\eta gdr}ds. \end{aligned} \tag{3.13}$$

Applying (3.13) in (3.12), we have

$$g'g^{iv} - 2g''g''' < \frac{1}{\tilde{\epsilon}}g'(\eta)\int_0^\eta (g'')^2 e^{\frac{1}{\tilde{\epsilon}}\int_s^\eta gdr}ds < 0. \tag{3.14}$$

From (3.14) and (3.10), we see that $g^v < 0$ as long as $g''' > 0$ and $g' < 0$.

Since g''' is concave down and g'' is uniformly bounded on $[0, \frac{1}{2} - \sigma]$, the function g''' is uniformly bounded on $[0, \frac{1}{2} - \sigma]$, by Proposition 3.2, where $0 < \sigma \ll 1$. By Proposition 3.4, the second conclusion holds. $\square$

COROLLARY 3.6. *As* $\tilde{\epsilon} \to 0$, $g \sim h$ *uniformly on* $[0, 1-\delta]$ *for any given positive* $\delta \ll 1$.

Proof. For the given δ, $g(\eta)$ and $h(\eta)$ are nonzero on the interval $[\delta, 1-\delta]$; then, from the convergence of g on $[0, 1-\delta]$, we see that $g \sim h$ on $[\delta, 1-\delta]$, namely, $\lim \frac{g}{h} = 1$ uniformly on $[\delta, 1-\delta]$ as $\tilde{\epsilon} \to 0$. Since $g' - h' \to 0$ uniformly on $[0, \delta]$ (from Lemma 3.5), we see that $\lim \frac{g}{h} = 1$ for $\eta \in (0, \delta]$ uniformly. Therefore, $g \sim h$ on $[0, 1-\delta]$. $\square$

One of our goals in this section is to see how close g and h can be on $[0, 1-\delta]$. The result is given in Lemma 3.8, whose proof depends on Lemma 3.7.

LEMMA 3.7. *For any given positive* $\delta \ll 1$, $g''' - h''' \to 0$ *uniformly on* $[0, 1-\delta]$, *and* $g'' \sim h''$ *on* $[0, 1-\delta]$ *for sufficiently small* $\tilde{\epsilon} > 0$.

Proof. First, we prove that $g^{iv}(\eta)$ is uniformly bounded on $[0, 1-\delta]$. By Corollary 3.6, for a fixed positive $\sigma \ll 1$, the inequality

$$-\frac{1+\sigma}{\pi}\sin\pi\eta \le g(\eta) \le -\frac{1-\sigma}{\pi}\sin\pi\eta \tag{3.15}$$

holds for sufficiently small $\tilde{\epsilon} > 0$. From (3.15) and (3.8),

$$\begin{aligned} |g^{iv}| &\le \frac{\pi^2}{1-\Delta}\int_0^\eta \frac{(g'')^2}{\sin\pi s} d(e^{-\frac{1-\sigma}{\tilde{\epsilon}\pi}\int_s^\eta \sin\pi t dt}) \\ &= \frac{\pi^2}{1-\sigma}\frac{(g''(\xi))^2}{\sin\pi\xi}\left[1-e^{\frac{1-\sigma}{\tilde{\epsilon}\pi^2}(\cos\pi\eta-1)}\right] \\ &\le \frac{\pi^2}{1-\sigma}\frac{(g''(\xi))^2}{\sin\pi\xi}, \end{aligned} \tag{3.16}$$

where $\xi \in (0, \eta)$. Rewriting (3.16) as

$$|g^{iv}| \le \frac{\pi^2}{1-\sigma}g''(\xi)\frac{g''(\xi)}{\xi}\frac{\xi}{\sin\pi\xi},$$

one sees that g^{iv} is bounded because g'' and $g''(\xi)/\xi$ are bounded. Here, the boundedness of $g''(\xi)/\xi$ follows from that of g''' on $[0, 1-\delta]$. Then, the first conclusion of Lemma 3.7 follows from Proposition 3.4 since g, g', g'', g''', and g^{iv} are all uniformly bounded on $[0, 1-\delta]$.

To prove the second conclusion of Lemma 3.7, we use contradiction. If $\frac{g''}{h''}$ does not converge to 1 uniformly on $[0, 1-\delta]$, then there would be sequences $\{\tilde{\epsilon}_n\}$ and $\{\eta_n\}$ with $\tilde{\epsilon}_n \to 0$ and $\{\eta_n\} \subseteq [0, 1-\delta]$ such that $|\frac{g''(\eta_n)}{h''(\eta_n)} - 1| > \sigma$ for some constant $\sigma > 0$ and for all n. In addition, we can assume $\eta_n \to x \in [0, 1-\delta]$. Since $\delta > 0$ is fixed and $g''(1-\delta)h''(1-\delta) \ne 0$, the only possibility is $x = 0$. This is also impossible, for otherwise, it would imply the divergence of $(g''' - h''')$ at $\eta = 0$. □

An immediate consequence from Lemma 3.7 is that $g'''(0) = \tilde{\beta} \to \pi^2$ as $\tilde{\epsilon} \to 0$. This shows the relationship between $f'(0)$ and $f'''(0)$: $\frac{f'''(0)}{f'(0)} \to -\pi^2$ as $\tilde{\epsilon} \to 0$. With Lemma 3.7 and the expression of g^{iv} in (3.8), we can now prove the following lemma.

Lemma 3.8. *For any sufficiently small* $\delta > 0, g - h \to 0$ *in* C^4 *on* $[0, 1-\delta]$, *and* $g \sim h, g'' \sim h''$ *uniformly on* $[0, 1-\delta]$, *and* $g^{iv} \sim h^{iv}$ *uniformly on* $[\delta, 1-\delta]$.

Proof. Substituting the asymptotic formulas for g and g'' in (3.8), we obtain, by integration by parts,

(3.17)

$$g^{iv}(\eta) \sim -\left(\frac{\pi}{1-\Delta}\right)^3\left(\sin\frac{\pi\eta}{1-\Delta} + \frac{\pi}{1-\Delta}\int_0^\eta \cos\frac{\pi s}{1-\Delta}e^{\frac{(1-\sigma)^2}{\tilde{\epsilon}\pi^2}(\cos\frac{\pi\eta}{1-\Delta} - \cos\frac{\pi s}{1-\Delta})}ds\right)$$

uniformly on $[0, 1-\delta]$. Since

$$\int_0^{1-\delta}\left|\cos\frac{\pi s}{1-\Delta}\right|e^{\frac{(1-\sigma)^2}{\tilde{\epsilon}\pi^2}(\cos\frac{\pi\eta}{1-\Delta} - \cos\frac{\pi s}{1-\Delta})}ds \to 0$$

as $\tilde{\epsilon} \to 0$ by the dominated convergence theorem, we see that $g^{iv} \to h^{iv}$ uniformly on $[0, 1-\delta]$. In addition, it follows from (3.17) that $g^{iv} \sim h^{iv}$ uniformly on $[\delta, 1-\delta]$. □

Remark 1. It is false that $g^{iv} \sim h^{iv}$ uniformly on $[0, 1-\delta]$, for otherwise, if $\frac{g^{iv}(\eta,\tilde{\epsilon})}{h^{iv}(\eta,\tilde{\epsilon})} \to 1$ as $\tilde{\epsilon} \to 0$ uniformly on $[0, 1-\delta]$, then $\frac{g^{v}(0,\tilde{\epsilon})}{h^{v}(0,\epsilon)} \to 1$, a contradiction. In fact, for sufficiently small η the integral term in (3.18) is the leading term. Also, we cannot say that $g' \sim h', g''' \sim h'''$ on the interval because they do not vanish at the same points. Most importantly, we cannot have $g'' \sim h''$ at $\eta = 1-\Delta$ either, because $h'' = 0$ while $g'' \neq 0$ at $1-\Delta$.

Next, we extend the results of Lemma 3.8 from $[0, 1-\delta]$ to $[0, 1-\Delta]$.

The following proposition is a generalization of Proposition 3.4, which is applied to prove Theorem 3.1. Let $t_2 \equiv y_\epsilon$ denote the zero point of g'' in $(0,1)$. Then, $t_2 > 1-\Delta$, $g''(\eta) > 0$ for $\eta \in (0, t_2)$, and $t_2 \to 1$ as $\tilde{\epsilon} \to 0$, which is one of the previous results listed in section 1.

Proposition 3.9. *Suppose that* $\theta = \theta_{\tilde{\epsilon}} \in [1-\Delta, t_2]$ *and that* g, g', g'', g''',*and* g^{iv} *are all uniformly bounded on* $[0, \theta]$. *Then, as* $\tilde{\epsilon} \to 0$, *all* $g-h, g'-h', g''-h''$, *and* $g'''-h'''$ *converge to* 0 *uniformly on* $[0, \theta]$.

Remark 2. The uniform convergence on this "moving interval" is required for proving Lemma 6.1.

Proof. First, we see from (3.3) that $g'(\theta) \to 1$ since $g(\theta) \to 0$. Hence, $g''(\theta) \to 0$ from (3.1). By Lemmas 3.3, 3.5, 3.7, and 3.8, we see that only interval $[1-\delta, \theta]$ needs to be considered where $0 < \delta \ll 1$ is fixed.

Suppose, on the contrary, that the proposition is false for $g-h$. Then, there is a positive number σ and two sequences $\{\tilde{\epsilon}_n\}$ and $\{\eta_n\}, n = 1, 2, 3, ...$, such that $\eta_n \le \theta(n) (= \theta_{\tilde{\epsilon}_n}), |g(\eta_n, \tilde{\epsilon}_n) - h(\eta_n, \tilde{\epsilon}_n)| > \sigma$ for all n, and $\eta_n - \theta(n) \to 0$ as $n \to \infty$. Noting that $h(\theta) \to 0$ as $n \to \infty$ and $g \ge 0$ for $\eta \ge 1-\Delta$, we see that $g(\eta_n, \epsilon_n) > \frac{\delta}{2}$, and hence,

$$g'(\xi_n, \tilde{\epsilon}_n) = \frac{g(\eta_n, \tilde{\epsilon}_n) - g(\theta(n), \tilde{\epsilon}_n)}{\eta_n - \theta(n)} > \frac{\sigma}{3(\eta_n - \theta(n))},$$

which implies that g' is unbounded, a contradiction. The case $g''-h'' \to 0$ is handled the same way. To see $g'-h' \to 0$ uniformly on $[0, \theta]$, we assume, for contradiction, that $|g'(\eta_n, \tilde{\epsilon}_n) - h'(\eta_n, \tilde{\epsilon}_n)| > \sigma$ for $n = 1, 2, 3, ...$ and $\eta_n - \theta(n) \to 0$. Then, $g'(\eta_n)$ is either greater than $1 + \frac{\sigma}{2}$ or less than $1 - \frac{\sigma}{2}$. Choose $\delta = \frac{\sigma}{M}$ with $M > 4B$, where B is an upper bound for g'' on $[0, \theta]$. In the former case, there is a point $\xi_n \in (1-\delta, \eta_n)$ with $g''(\xi_n) > \frac{1+\sigma/2-g'(1-\delta)}{\eta_n-(1-\delta)} > \frac{\sigma}{2(\eta_n-1+\sigma/M)} > \frac{M}{3} > B$, a contradiction. Here, we have applied $g'(1-\delta) \approx h'(1-\delta) \approx 1-\delta$ by Lemma 3.8. The latter case is impossible, because $g'' > 0$. Similarly, $g'''-h''' \to 0$ uniformly on $[0, \theta]$, which implies $g'''(\theta) \to -\pi^2$. □

It is clear that we need to show the uniform boundedness of g, g', g'', g''', and g^{iv} on $[0, 1-\Delta]$ so that Proposition 3.9 can be applied.

Lemma 3.10. g, g', *and* g'' *are uniformly bounded on* $[0, 1-\Delta]$, $g^{(k)} - h^{(k)} \to 0$ *for* $k = 0, 1$, *and* $g(\eta) \sim -\frac{\sin[\pi\eta/(1-\Delta)]}{\pi/(1-\Delta)}$ *uniformly on* $[0, 1-\Delta]$ *as* $\tilde{\epsilon} \to 0$.

Proof. Recall that g is uniformly bounded and $g' > -\eta$ on $[0,1]$, and that $g'' > 0$ on $[0, 1-\Delta]$. Again, we assume a positive number $\delta \ll 1$ to be fixed. Since the convergence preserves the concavity of the solutions, $g''' < 0$ on $[\frac{1}{2}+\delta, 1-\delta]$, and hence, on $[\frac{1}{2}+\delta, 1]$. Then g' is concave down on $[\frac{1}{2}+\delta, 1-\Delta]$, which implies that g' must be bounded on the interval by Proposition 3.2. Furthermore, the concavity of g'' and the boundedness of g' on $[0, 1-\Delta]$ yield that g'' is bounded on $[0, 1-\Delta]$. The uniform convergence of g and g' follows from the proof of Proposition 3.9 because only the uniform boundedness of g'' is needed.

To prove the last conclusion of the lemma, we use contradiction again. Suppose it is false. Then, similar to above, there would be two sequences $\{\eta_n\}$ and $\{\tilde{\epsilon}_n\}$ such that as $n \to \infty$, $\eta_n - (1-\Delta) \to 0, \tilde{\epsilon}_n \to 0$, and $|\frac{g(\eta_n,\tilde{\epsilon}_n)}{h(\eta_n,\tilde{\epsilon}_n)} - 1| > \sigma$ for some $\sigma > 0$. Then,

$$\left|\frac{[g(\eta_n,\tilde{\epsilon}_n) - g(1-\Delta,\tilde{\epsilon}_n)]/(\eta_n - 1 + \Delta)}{[h(\eta_n,\tilde{\epsilon}_n) - h(1-\Delta,\tilde{\epsilon}_n)]/(\eta_n - 1 + \Delta)} - 1\right| > \sigma. \tag{3.18}$$

Applying the mean value theorem on both the numerator and denominator in (3.18), we see that for each n, there exist two numbers ξ_n and ζ_n such that

$$\left|\frac{g'(\xi_n,\tilde{\epsilon}_n)}{h'(\zeta_n,\tilde{\epsilon}_n)} - 1\right| > \sigma,$$

which implies either $g'(\xi_n,\tilde{\epsilon}_n) > 1 + \frac{\sigma}{2}$ or $g'(\xi_n,\tilde{\epsilon}_n) < 1 - \frac{\sigma}{2}$ since $h'(\zeta_n,\tilde{\epsilon}_n) \approx 1$. This would lead to g'' being unbounded, a contradiction. $\square$

By Lemma 3.7, $g'''(0) \to \pi^2$. It suffices to prove the uniform boundedness of g^{iv} on $[0, 1-\Delta]$ in order to get the uniform boundedness for g''' on $[0, 1-\Delta]$. Let $0 < \delta \ll 1$ be fixed. Since $h^v > 0$ on $[\frac{1}{2}+\delta, 1-\delta]$ and the convergence preserves the monotonicity, $g^v \geq 0$ on $[\frac{1}{2}+\delta, 1-\delta]$. From (3.6), we see $g^v(1-\Delta) < 0$ since $g''(1-\Delta) \neq 0$. It is then observed that g^v must have a zero in $[1-\delta, 1-\Delta)$. Let $t_5 = t_5(\tilde{\epsilon})$ denote the first zero of g^v in $[1-\delta, 1-\Delta)$. The structure of the function g^{iv} is given by the following lemma.

Lemma 3.11. *$g^v, g^{vi} \leq 0$ on $[t_5, 1-\Delta]$. Also, g''' and g^{iv} are uniformly bounded on $[0, 1-\Delta]$, and $g^{iv}(1-\Delta) \to 0$ as $\tilde{\epsilon} \to 0$.*

Proof. Since $g^v(1-\delta) \geq 0$ and t_5 is the first zero of g^v in $[1-\delta, 1-\Delta)$, we see that $g^{vi}(t_5) \leq 0$, and $g^{iv}(t_5) \geq g^{iv}(1-\delta)$ for sufficiently small $\delta > 0$. Hence, g^{iv} is uniformly bounded on $[0, t_5]$ because $g^{iv}(1-\delta)$ is uniformly bounded by Lemma 3.8. Therefore, g''', g'', and g' are all uniformly bounded on $[0, t_5]$. Next, we claim that $g^{vi}(\eta) \leq 0$ for $\eta \in [t_5, 1-\Delta]$. To see this, we assume that there is a first zero point t_6 of g^{vi} in $(t_5, 1-\Delta)$. Then, it suffices to prove $g^{vii}(t_6) < 0$, which is given as follows.

Differentiating (3.9) with respect to η once yields

$$\tilde{\epsilon} g^{vii} = g g^{vi} + 2g' g^v - g'' g^{iv} - 2(g''')^2. \tag{3.19}$$

From (3.9), we see at $\eta = t_6$, $g g^v + g' g^{iv} - 2g'' g''' = 0$, and therefore,

$$g^{iv} = \frac{2g'' g''' - g g^v}{g'}. \tag{3.20}$$

Substituting (3.20) into (3.19) leads to

$$\tilde{\epsilon} g^{vii} = \frac{[2(g')^2 + g g'']g^v - 2g'''[(g'')^2 + g' g''']}{g'} \tag{3.21}$$

at $\eta = t_6$. Since $g'' > 0$, $g'(1-\delta) \approx 1$, and $g'(1-\Delta) \to 1$, it must be that $g'(t_6) \approx 1$. Also, since $g''(1-\delta) \approx 0$, $g''' < 0$, and $g'' > 0$ for $\eta > 1-\delta$, we see $g''(t_6) \approx 0$. Thus, the first term in the numerator of (3.21) is negative because $g^v(t_6) < 0$, and the second term is approximately equal to $-2[g'''(t_6)]^2$ because $g'''(1-\delta) \approx -\pi^2(1-\delta)$ and $g^{iv} < 0$. This shows

$$\tilde{\epsilon} g^{vii}(t_6) < -[g'''(t_6)]^2 < 0.$$

Now, the picture is clear: $g^v > 0$ on $[\frac{1}{2}+\delta, t_5)$ and $g^v < 0, g^{vi} < 0$ on the interval $(t_5, 1-\Delta]$, in which g^{iv} reaches its local maximum at t_5 and then decreases. So, the bounds of $|g^{iv}|$ on $[1-\delta, 1-\Delta]$ are determined by the two ending points of the interval. By Lemma 3.8, $g^{iv}(1-\delta) \approx -\pi^3 \sin \pi(1-\delta)$. Since $t_5 > 1-\delta$, $g^{iv}(t_5) > g^{iv}(1-\delta)$, and $\delta > 0$ is arbitrarily chosen, it follows that $t_5 \to 1$ and $g^{iv}(t_5) \to 0$ as $\tilde{\epsilon} \to 0$. Therefore, to show the uniform boundedness of g^{iv} on $[0, 1-\Delta]$, we only need to prove the boundedness of $g^{iv}(1-\Delta)$. In fact, we can prove more: $g^{iv}(1-\Delta) \to 0$ as $\tilde{\epsilon} \to 0$. Suppose it is not so. Then, there exists a subsequence of $\{\tilde{\epsilon}\}$, denoted by $\{\tilde{\epsilon}_n\}, n = 1, 2, ...$, such that $g^{iv}(1-\Delta) < -\sigma$ for all $\tilde{\epsilon}_n$. From (3.1),

$$g^{iv}(1-\Delta) = \frac{-g'(1-\Delta)g''(1-\Delta)}{\tilde{\epsilon}_n}, \tag{3.22}$$

and from (3.6),

$$g^v(1-\Delta) = \frac{-[g''(1-\Delta)]^2}{\tilde{\epsilon}_n}. \tag{3.23}$$

Since $g^{vi} < 0$ and $g^{iv}(t_5) < 0$, we see from (3.22) that

$$g^v(1-\Delta) < \frac{g^{iv}(1-\Delta) - g^{iv}(t_5)}{1-\Delta-t_5} < \frac{-g'(1-\Delta)g''(1-\Delta)}{(1-\Delta-t_5)\tilde{\epsilon}_n}, \tag{3.24}$$

which, from (3.23), implies

$$\frac{-[g''(1-\Delta)]^2}{\tilde{\epsilon}_n} < \frac{-g'(1-\Delta)g''(1-\Delta)}{(1-\Delta-t_5)\tilde{\epsilon}_n}.$$

It turns out that

$$g''(1-\Delta) > \frac{g'(1-\Delta)}{1-\Delta-t_5},$$

which leads to $g''(1-\Delta)$ being unbounded, a contradiction of Lemma 3.10. The proof of Lemma 3.11 is complete. □

LEMMA 3.12. *As $\tilde{\epsilon} \to 0, g - h \to 0$ in C^4 and $g \sim h$ uniformly on $[0, 1-\Delta]$. In particular, at $\eta = 1-\Delta$, $g' \to 1, g'' \to 0, g''' \to -\pi^2$, and $g^{iv} \to 0$, as $\tilde{\epsilon} \to 0$.*

Proof. Let $1-\Delta = \theta$, and apply Lemmas 3.10 and 3.11 and Proposition 3.9. Then, $g \sim h$ uniformly on $[0, 1-\Delta]$, and the convergence holds up to C^3 on that interval. To prove the C^4 convergence, we apply the information about $g^{iv}(\eta)$ for $\eta \in [1-\delta, 1-\Delta]$ obtained in the proof of Lemma 3.11: the extreme values of g^{iv} on $[1-\delta, 1-\Delta]$ are determined at the two ending points. Since $g^{iv}(1-\delta) - h^{iv}(1-\delta) \to 0$ and $g^{iv}(1-\Delta) \to 0$, the uniform convergence of $g^{iv} - h^{iv}$ on $[1-\delta, 1-\Delta]$ follows. □

The proof of Theorem 3.1 is complete.

Our goal is to find the asymptotic behavior of the functions $f(\eta)$. It is seen from Theorem 3.1 that $f'(0)$ and Δ are to be determined. To do so, we first study the relation between these two quantities in the next section.

4. Relations among $\epsilon, \Delta_\epsilon$, and $f'(0, \epsilon)$.

To study the asymptotic behavior of the solution at the turning point, it is convenient to introduce a new independent variable

$$t \equiv \frac{\eta - z_\epsilon}{\Delta},$$

and define $f(\eta) = f(z_\epsilon + \Delta t) \equiv u(t)$ and $\epsilon^* \equiv \frac{\epsilon}{\Delta}$. Then, the turning point is $t = 0$, and $u = |\alpha| g$, $u' = |\alpha|\Delta g'$, $u'' = |\alpha|\Delta^2 g''$, $u''' = |\alpha|\Delta^3 g'''$, $u^{iv} = |\alpha|\Delta^4 g^{iv}$. The original equation (3.1), in terms of u and t, takes the form

$$\epsilon^* u^{iv} = uu''' - u'u''. \tag{4.1}$$

Lemma 3.12 applied to $u(t)$ at $t = 0$ implies that as $\epsilon \to 0, u - \frac{1-\Delta}{\pi} \sin \frac{\pi \Delta t}{1-\Delta} \to 0$ in $C^{iv}_{[-\frac{1-\Delta}{\Delta}, 0]}$, and

$$\frac{u'(0)}{|\alpha|\Delta} \to 1, \quad \frac{u''(0)}{|\alpha|\Delta^2} \to 0, \quad \frac{u'''(0)}{|\alpha|\Delta^3} \to -\pi^2, \quad \frac{u^{iv}(0)}{|\alpha|\Delta^4} \to 0. \tag{4.2}$$

The boundary conditions (1.3) now become

$$u(1) = 1, \qquad u'(1) = 0. \tag{4.3}$$

In addition, from the preliminary results listed in section 1, we see that $u^{iv}(t) < 0$ on $[-\frac{1-\Delta}{\Delta}, 1]$, and that $u(t) \geq 0, u'(t) \geq 0$ on $[0,1]$. Also, $u''(0) > 0$ for all $\epsilon^* > 0$. From (3.6), $u^v(t) < 0$ for $t \in [0,1]$. In this section we prove the following theorem.

THEOREM 4.1. *As $\epsilon \to 0$, the following conclusions hold:* (1) $\epsilon^* \to 0$, (2) $f'(0,\epsilon) \sim -\frac{1}{\Delta}$, *and* (3) $u(t, \epsilon^*) \sim t$ *uniformly on* $[0,1]$.

The proof of Theorem 4.1 consists of Lemmas 4.2, 4.3, and 4.4.

LEMMA 4.2. *There exists a positive number l such that $l \leq |\alpha|\Delta < 2$ for all $\epsilon > 0$.*

Proof. Since $u'''(0) < 0$ and $u^{iv} < 0$, we see $u''' < 0$ on $[0,1]$. An application of the concavity of $u'(t)$ for $t > 0$ shows $u'(t) \geq u'(0)(1-t)$ for $t \in [0,1]$. An integration of this inequality yields $u(1) \geq \frac{1}{2} u'(0)$. From (3.3), $g'(z_\epsilon) = \frac{f'(z_\epsilon)}{|\alpha|} = \frac{u'(0)}{|\alpha|\Delta} > \sqrt{1 + \tilde{\epsilon}\tilde{\beta}} > 1$ because $g'''(z_\epsilon) < 0$. Thus, $u'(0) > |\alpha|\Delta$, and hence, $|\alpha|\Delta < 2$. Since $u(t)$ is uniformly bounded on $[0,1]$ for all $\epsilon > 0$ and $u'(t) \geq 0$, $u'''(t) < 0$ on $[0,1]$, Proposition 3.2 can be applied. This concludes that u' is uniformly bounded above by a positive number $\frac{1}{l}$. The proof of Lemma 4.2 is complete. □

Since the behavior of the function $g(\eta)$ at the turning point has been found, we can now prove $\frac{\epsilon}{\Delta} \to 0$ as $\epsilon \to 0$, which was a crucial working assumption in [7], using (4.2) and Lemma 4.2.

LEMMA 4.3. $\epsilon^* \to 0$ *as* $\epsilon \to 0$.

Proof. Suppose not. Then, there would be a sequence $\{\epsilon_n^*\}, n = 1, 2, ...,$ such that either $\epsilon_n^* \to \infty$ or $\epsilon_n^* \to c > 0$ as $n \to \infty$. In the former case,

$$u^{iv} = \lambda_n (uu''' - u'u''), \tag{4.4}$$

where $\lambda_n = \frac{1}{\epsilon_n^*} \to 0$ as $n \to \infty$. Let $u_n \equiv u(t, \epsilon_n^*)$ be solutions of (4.4). By Lemma 4.2, one can assume that $u_n'(0) \to \gamma$ where $\gamma > 0$ is a constant. Then, $u_n''(0) = o(\Delta)$ and $u'''(0) = O\left(\Delta^2\right)$. Using the theorem that solutions continuously depend on initial conditions and parameters, we see $u_n(t) \approx \gamma t$ (since the limit equation $u^{iv} = 0$ with $u'(0) = \gamma, u(0) = u''(0) = u'''(0) = 0$ has the unique solution $u(t) = \gamma t$). This contradicts the boundary condition of $u(t)$ at $t = 1$. If $\epsilon_n^* \to \frac{1}{b} > 0$ and $u_n'(0) \to \mu \geq \frac{1}{l} > 0$ as $n \to \infty$, then $\lambda_n = \frac{1}{\epsilon_n^*} \to b > 0$. Since the limit equation

$$u^{iv} = b(uu''' - u'u'') \tag{4.5}$$

with the initial condition $u'(0) = \mu$, $u(0) = u''(0) = u'''(0) = 0$ has a unique solution $u(t) = \mu t$, we see $u_n(t) \approx \mu t$, again, a contradiction. Therefore, Lemma 4.3 holds. $\square$

Applying Lemma 4.3 and the information about $u(t)$ for $t \in [0, 1]$, we find the asymptotic behavior of $u(t)$ on $[0, 1-\delta]$ and the asymptotic relation between $\alpha \equiv f'(0)$ and Δ as follows.

Lemma 4.4. *As $\epsilon^* \to 0$, $|\alpha|\Delta \to 1$, $u(t) - t \to 0$ in $C^3_{[0,1-\delta]}$ for any given positive $\delta \ll 1$, and $u(t) \sim t$ uniformly on $[0, 1]$.*

Proof. From the proof of Lemma 4.2, $u'(t)$ is uniformly bounded on $[0, 1]$. Since $u''(0) = o(\Delta)$ and $u''' < 0$, we see that u'' is uniformly bounded on $[0, 1-\delta]$; otherwise u' would be unbounded on $[0, 1 - \frac{\delta}{2}]$. Similarly, u''' and u^{iv} are uniformly bounded on $[0, 1 - \delta]$ because $u^{iv}, u^{v} < 0$ for $t \in [0, 1]$. Then, applying an argument similar to the proof of Lemma 3.3 (mainly, an application of the Arzela–Ascoli theorem), we conclude that there exists a function $w(t)$ such that $u(t) \to w(t)$ in $C_{[0,1]}$ and in $C^3_{[0,1-\delta]}$ as $\epsilon^* \to 0$, and that $w(t)$ is neither the sine function nor the hyperbolic sine function because their fourth derivatives are positive. It turns out that $w(t) = t$. Then, the fact that $u(1) = 1$ forces $u'(0) \sim |\alpha|\Delta \to 1$. Furthermore, we claim that

$$\frac{u(t, \epsilon^*)}{t} \to 1$$

uniformly on $[0, 1]$. Suppose, on the contrary, that there exists a number $\sigma > 0$ and two sequences $\{\epsilon^*_n\}$ and $\{t_n\}$ with $\epsilon^*_n \to 0$ and $t_n \to 0$ as $n \to \infty$, such that $|\frac{u(t_n,\epsilon^*_n)}{t_n} - 1| > \sigma$ for all $n = 1, 2, 3, ...$ Then, by the mean value theorem, $|u'(\xi_n, \epsilon^*_n) - 1| > \sigma$ for all $n = 1, 2, 3, ...$ This contradicts the proved C^3 convergence. $\square$

The proof of Theorem 4.1 is complete.

By Lemma 4.4, $u'''(0) \sim -\Delta^2\pi^2$ as $\epsilon \to 0$. Therefore, we will be focusing on the approximation of $u'''(0)$ in order to find the asymptotic formula of Δ.

In the rest of the paper, the asymptotic behavior of the solution at the boundary layer $t = 1$ and at the turning point $t = 0$ is analyzed. The result is the following theorem.

Theorem 4.5. *As $\epsilon^* \to 0$,*

$$u''(1) \sim \frac{1}{\epsilon^*}, \quad u'''(1) \sim -\frac{1}{\epsilon^{*2}}, \quad u^{iv}(1) \sim -\frac{1}{\epsilon^{*3}}, \tag{4.6}$$

$$u'(0) = 1 + \epsilon^* + o(\epsilon^*), \tag{4.7}$$

$$u'''(0) \sim -(2e\pi)^{-\frac{1}{4}}\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{4\epsilon^*}}, \tag{4.8}$$

and

$$u^{iv}(0) \sim -\pi\sqrt{e}\epsilon^{*-3}e^{-\frac{1}{2\epsilon^*}}, \qquad u''(0) \sim \pi\sqrt{e}\epsilon^{*-2}e^{-\frac{1}{2\epsilon^*}}, \tag{4.9}$$

where ϵ^* satisfies

$$\pi^2\Delta^2 \sim (2e\pi)^{-\frac{1}{4}}\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{4\epsilon^*}}. \tag{4.10}$$

The proof of Theorem 4.5 is given in the remaining three sections. The first part of section 5 contains proofs of (4.6) and (4.7). Formulas (4.8), (4.9), and (4.10) are proved in the second part of section 5, and sections 6 and 7.

5. On $u(t)$ for $t \geq 0$. Differentiate (4.1) with respect to t once to get

$$\epsilon^* u^v = uu^{iv} - (u'')^2 .$$

Then, as in (3.7),

$$\left(u^{iv} e^{-\frac{1}{\epsilon^*}\int u(s)ds}\right)' = -\frac{1}{\epsilon^*}(u'')^2 e^{-\frac{1}{\epsilon^*}\int u(s)ds}, \tag{5.1}$$

which shows that the function $u^{iv}(t)e^{-\frac{1}{\epsilon^*}\int^t u(s)ds}$ is negative decreasing. Thus, for $t \in [0,1]$,

$$\left|u^{iv}(t)\right| \leq |u^{iv}(1)|e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds}. \tag{5.2}$$

Therefore, to get the asymptotic behavior of $u(t)$ in a region including the right boundary layer, we need to estimate $u^{iv}(1)$.

LEMMA 5.1. *As $\epsilon^* \to 0$,*

$$u''(1) \sim -\frac{1}{\epsilon^*}, \quad u'''(1) \sim -\frac{1}{\epsilon^{*2}}, \quad u^{iv}(1) \sim -\frac{1}{\epsilon^{*3}}.$$

Proof. Successively integrating (4.1) yields

$$\epsilon^* u''' = uu'' - (u')^2 + [u'(0)]^2 + \epsilon^* u'''(0), \tag{5.3}$$

and

$$\epsilon^* u'' = uu' - 2\int_0^t (u')^2 ds + \{[u'(0)]^2 + \epsilon^* u'''(0)\}t + \epsilon^* u''(0). \tag{5.4}$$

Since $\lim_{\epsilon^* \to 0} u'(t) = 1$ pointwise in $[0,1)$ and $u'''(0) \sim -\pi^2\Delta^2 \to 0, u''(0) = o(\Delta)$ as $\epsilon^* \to 0$, we see from (5.4) that $\epsilon^* u''(1) + 1 \to 0$, by the dominated convergence theorem. This implies $u''(1) \sim -\frac{1}{\epsilon^*}$. It then follows from (5.3) and (4.1) that $u'''(1) \sim -\frac{1}{\epsilon^{*2}}$ and $u^{iv}(1) \sim -\frac{1}{\epsilon^{*3}}$ as $\epsilon^* \to 0$. $\square$

The asymptotic behavior of $u(t)$ for $t > 0$ in the outer region has been given by Lemma 4.4 already. The asymptotic formulas for u'' and u on the interval including the right boundary layer are presented in Lemma 5.3, whose proof requires Lemma 5.2.

LEMMA 5.2. *For sufficiently small $\epsilon^* > 0$,*

$$|u'''(0)| \leq 2e^{16}\epsilon^{*-\frac{7}{4}} e^{-\frac{1}{2\epsilon^*}\int_0^1 u(s)ds}.$$

Proof. Since $u^v < 0$ for $t > 0$, $u^{iv}(t) \leq u^{iv}(0)$ for $t \in [0,1]$. Thus, $u'''(t) \leq u^{iv}(0)\,t + u'''(0)$ and $u''(t) \leq \frac{1}{2}u^{iv}(0)t^2 + u'''(0)t + u''(0)$ for $t \in [0,1]$. Let $a > 0$ be the zero of u''. It follows from the last inequality that

$$\frac{1}{2}u^{iv}(0)a^2 + u'''(0)a + u''(0) \geq 0. \tag{5.5}$$

Note from (4.1) that $u''(0) = \frac{-\epsilon^* u^{iv}(0)}{u'(0)}$, and substitute this equation into (5.5) to get

$$\frac{1}{2}u^{iv}(0)u'(0)a^2 - \epsilon^* u^{iv}(0) \geq \frac{1}{2}u^{iv}(0)u'(0)a^2 + u'(0)u'''(0)a - \epsilon^* u^{iv}(0) \geq 0.$$

Then, $a^2 < \frac{2\epsilon^*}{u'(0)}$, and hence, $a < 2\sqrt{\epsilon^*}$ for sufficiently small ϵ^* since $u'(0) \to 1$ as $\epsilon^* \to 0$. Thus $u'', u''', u^{iv} < 0$ for $t > a$. Since u'' is concave down, $u''(t) < u'''(a)(t-a)$ for $t \geq a$. On the other hand, integrating (5.1) and solving the resulting equation produces for any $t \in [-\frac{1-\Delta}{\Delta}, 1]$

$$u^{iv}(t) = -\frac{1}{\epsilon^*}\int_0^t [u''(s)]^2 e^{\frac{1}{\epsilon^*}\int_s^t u(r)dr} + u^{iv}(0)e^{\frac{1}{\epsilon^*}\int_0^t u(r)dr}. \tag{5.6}$$

Since $u^{iv}(0) < 0$,

$$\begin{aligned} |u^{iv}(t)| &> \frac{1}{\epsilon^*}e^{\frac{1}{\epsilon^*}\int_0^t u(s)ds}\int_a^t (u''(s))^2 e^{-\frac{1}{\epsilon^*}\int_0^s u(r)dr}ds \\ &\geq \frac{1}{\epsilon^*}e^{\frac{1}{\epsilon^*}\int_0^t u(s)ds}[u'''(a)]^2\int_{a+\delta_1}^{a+\delta_2}(s-a)^2 e^{-\frac{1}{\epsilon^*}\int_0^s u(r)dr}ds \\ &\geq \frac{1}{\epsilon^*}e^{\frac{1}{\epsilon^*}\int_0^t u(s)ds}[u'''(a)]^2(\delta_2-\delta_1)\delta_1^2 e^{-\frac{1}{\epsilon^*}\int_0^{a+\delta_2} u(r)dr} \end{aligned} \tag{5.7}$$

for any two δ_1 and δ_2 with $t > \delta_2 > \delta_1 > 0$, which implies

$$|u'''(a)|^2 \leq \frac{\epsilon^*|u^{iv}(t)|}{(\delta_2-\delta_1)\delta_1^2}e^{-\frac{1}{\epsilon^*}\int_{a+\delta_2}^t u(s)ds}. \tag{5.8}$$

Setting $t = 1, \delta_1 = \sqrt{\epsilon^*}, \delta_2 = 2\delta_1$ in (5.8), we have, for sufficiently small $\epsilon^* > 0$,

$$|u'''(a)|^2 \leq e^{-\frac{1}{\epsilon^*}\int_0^1 u(s)ds}\frac{|u^{iv}(1)|}{\sqrt{\epsilon^*}}e^{\frac{1}{\epsilon^*}\int_0^{a+2\sqrt{\epsilon^*}} u(s)ds}. \tag{5.9}$$

Since $a < 2\sqrt{\epsilon^*}$, $u(s) \leq 2s$, and $|u^{iv}(1)| \leq \frac{2}{\epsilon^*}$ for sufficiently small $\epsilon^* > 0$, we see from (5.9) that

$$|u'''(0)| \leq 2e^{16}\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{2\epsilon^*}\int_0^1 u(s)ds}. \tag{5.10}$$

This completes the proof of the lemma. □

LEMMA 5.3. *For any given* $0 < \delta \ll 1$, *as* $\epsilon^* \to 0$,

$$u(t) \sim u(\delta) + u'(\delta)(t-\delta) + \frac{\epsilon^{*4}u^{iv}(1)}{u^4(t)}e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds}, \tag{5.11}$$

$$u''(t) \sim u''(\delta) + u'''(\delta)(t-\delta) + \frac{\epsilon^{*2}u^{iv}(1)}{u^2(t)}e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds} \tag{5.12}$$

uniformly on $[\delta, 1]$.

Proof. Since $|u^{iv}(1)| \leq 2\epsilon^{*-3}$, we see from (5.2) that

$$|u^{iv}(t)| \leq 2{\epsilon^*}^{-3}e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds} \tag{5.13}$$

for all $t \in [0, 1]$. Integrating (5.13) from 0 to t and applying Lemma 5.2, we find that

$$\begin{aligned} |u'''(t)| &\leq |u'''(0)| + 2{\epsilon^*}^{-3}\int_0^{\frac{1}{4}} e^{-\frac{1}{\epsilon^*}\int_x^1 u(s)ds}dx \\ &\leq |u'''(0)| + 2{\epsilon^*}^{-3}e^{-\frac{1}{\epsilon^*}\int_{\frac{1}{4}}^1 u(s)ds} \\ &\leq Q\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{2\epsilon^*}\int_0^1 u(s)ds} \end{aligned} \tag{5.14}$$

for $t \le \frac{1}{4}$, where $Q = 2e^{16} + 1$, and that

$$\begin{aligned} |u'''(t)| &= |u'''(0)| + 4\epsilon^{*-3}\left(\int_0^{\frac{1}{4}} + \int_{\frac{1}{4}}^{t}\right) e^{-\frac{1}{\epsilon^*}\int_x^1 u(s)ds}dx \\ &\le Q_1\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{2\epsilon^*}\int_0^1 u(s)ds} + 4\epsilon^{*-3}\int_{\frac{1}{4}}^{t} e^{-\frac{1}{\epsilon^*}\int_x^1 u(s)ds}dx \\ &\le Q_1\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{2\epsilon^*}\int_0^1 u(s)ds} + N_1\epsilon^{*-2}e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds} \qquad (5.15) \end{aligned}$$

for $t > \frac{1}{4}$, where $N_1 > 0$ is a constant and $Q_1 = 1+Q$. Here, the method of integration by parts has been utilized when we estimate the leading term of $\int_{\frac{1}{4}}^{t} e^{-\frac{1}{\epsilon^*}\int_x^1 u(s)ds}dx$. Similarly, integrating (5.14) and (5.15) from 0 to t, respectively, we find that

$$|u''(t)| \le |u''(0)| + Q\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{2\epsilon^*}\int_0^1 u(s)ds}$$

for $t \le \frac{1}{4}$, and

$$|u''(t)| \le |u''(0)| + Q_1\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{2\epsilon^*}\int_0^1 u(s)ds} + N_2\epsilon^{*-1}e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds} \qquad (5.16)$$

for $t > \frac{1}{4}$, where $N_2 > 0$ is a constant. Since $u''(0) = -\epsilon^* u^{iv}(0)$, we see from (5.2) and Lemma 5.1 that

$$\begin{aligned} |u''(t)| &\le 2{\epsilon^*}^{-2}e^{-\frac{1}{\epsilon^*}\int_0^1 u(s)ds} + Q\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{2\epsilon^*}\int_0^1 u(s)ds} \\ &< M_1\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{2\epsilon^*}\int_0^1 u(s)ds} \qquad (5.17) \end{aligned}$$

for $t \le \frac{1}{4}$, and

$$|u''(t)| \le Q_1\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{2\epsilon^*}\int_0^1 u(s)ds} + N_2\epsilon^{*-1}e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds} \qquad (5.18)$$

for $t > \frac{1}{4}$. Thus, for all $t \in [0,1]$, the inequality (5.18) holds.

An integration of (5.1) from t to 1 gives

$$u^{iv}(1) - u^{iv}(t)e^{-\frac{1}{\epsilon^*}\int_1^t u(s)ds} = -\frac{1}{\epsilon^*}\int_t^1 (u'')^2 e^{-\frac{1}{\epsilon^*}\int_1^t u(s)ds}dt,$$

which implies

$$u^{iv}(t) = \left(u^{iv}(1) - \frac{1}{\epsilon^*}\int_t^1 (u'')^2 e^{\frac{1}{\epsilon^*}\int_r^1 u(s)ds}dr\right)e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds}. \qquad (5.19)$$

Substituting (5.18) into (5.19), we obtain

$$\begin{aligned} |u^{iv}(t) - u^{iv}(1)e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds}| &\le \frac{2}{\epsilon^*}\Bigg(\int_t^1 [Q_1^2\epsilon^{*-\frac{7}{2}}e^{-\frac{1}{\epsilon^*}\int_0^1 u(s)ds} \\ &\quad + N_2^2\epsilon^{*-2}e^{-\frac{2}{\epsilon^*}\int_x^1 u(s)ds}]e^{\frac{1}{\epsilon^*}\int_x^1 u(s)ds}dx\Bigg)e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds} \\ &\le 2Q_1^2\epsilon^{*-\frac{9}{2}}e^{-\frac{1}{\epsilon^*}\int_0^1 u(s)ds} \qquad (5.20) \\ &\quad + 2N_2^2\epsilon^{*-3}e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds}\int_t^1 e^{-\frac{1}{\epsilon^*}\int_x^1 u(s)ds}dx. \end{aligned}$$

Again, using integration by parts on the second term on the right-hand side of (5.20), we find that for any $t \in [\delta, 1]$,

$$\left| u^{iv}(t) - u^{iv}(1) e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds} \right| \leq 2Q_1^2 \epsilon^{*-\frac{9}{2}} e^{-\frac{1}{\epsilon^*}\int_0^1 u(s)ds} + N_3 \epsilon^{*-2} e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds}, \tag{5.21}$$

where N_3 is a constant depending only on δ. An integration of (5.21) over (δ, t), where $0 < \delta \ll 1$ is fixed, shows that for $t \in [\delta, 1]$,

$$u'''(t) = u'''(\delta) + \frac{\epsilon^* u^{iv}(1)}{u(t)} e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds} (1 + O(\epsilon^*)) + R(t, \epsilon^*), \tag{5.22}$$

where $R(t, \epsilon^*)$ is an exponentially small term. Successively integrating (5.22) over $[\delta, t]$ yields

$$\begin{aligned} u''(t) = {} & u''(\delta) + u'''(\delta)(t - \delta) \\ & + \frac{\epsilon^{*2} u^{iv}(1)}{u^2(t)} e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds} (1 + O(\epsilon^*)) + R_2(t, \epsilon^*), \end{aligned} \tag{5.23}$$

and

$$\begin{aligned} u(t) = {} & u(\delta) + u'(\delta)(t - \delta) + u''(\delta)\frac{(t-\delta)^2}{2} + \frac{u'''(\delta)(t-\delta)^3}{3} \\ & + \frac{\epsilon^{*4} u^{iv}(1)}{u^4(t)} e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds} (1 + O(\epsilon^*)) + R_0(t, \epsilon^*), \end{aligned} \tag{5.24}$$

where R_0 and R_2 are exponentially small terms. Since $u''(\delta)$ and $u'''(\delta)$ are of smaller order than that of $e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds}$ for the fixed $\delta < \frac{1}{4}$, from (5.17) and (5.14), Lemma 5.3 follows immediately. $\square$

COROLLARY 5.4. *For sufficiently small* $\epsilon^* > 0$,

$$u'(0) = 1 + \epsilon^* + o(\epsilon^*)$$

and

$$\frac{1}{\epsilon^*}\int_0^1 u(s)ds = \frac{1}{2\epsilon^*} + \frac{1}{2} + O(\epsilon^*).$$

Proof. Applying Lemma 5.3 for $t = 1$, one finds from (5.11) that for a fixed positive $\delta \ll 1$,

$$1 \sim u(\delta) + u'(\delta)(1 - \delta) + \epsilon^{*4} u^{iv}(1). \tag{5.25}$$

Since $u'(\delta) = u'(0) + u''(\xi_1)\delta$ and $u(\delta) = u'(0)\delta + u''(\xi_2)\frac{\delta^2}{2}$, where $\xi_i \in (0, \delta)$ and $u''(\xi_i)$ is exponentially small for $i = 1, 2$ from (5.17), we see that

$$1 \sim u'(0) + \epsilon^{*4} u^{iv}(1),$$

which implies the first conclusion of the corollary. To obtain the second conclusion, we integrate (5.11) over $[\delta, t]$. Then,

$$\int_\delta^t u(s)ds \sim u(\delta)\,(t - \delta) + u'(\delta)\frac{(t-\delta)^2}{2} + \frac{\epsilon^5 u^{iv}(1)}{u^5(t)} e^{-\frac{1}{\epsilon^*}\int_t^1 u(s)ds} (1 + O(\epsilon^*)).$$

Since $u'(\delta) \sim u'(0)$ and $u(s) \sim u'(0)s$ for $s \in [0, \delta]$,

$$\int_0^t u(s)ds = \left(\int_0^\delta + \int_\delta^t\right) uds \sim \frac{1}{2}\{[u'(0)\delta]^2 + [2u'(0)\delta(t-\delta) + u'(0)(t-\delta)]^2\} + O(\epsilon^{*2})$$

for any $t > \delta$. Thus, for all $t \in [\delta, 1]$,

$$\int_0^t u(s)ds \sim \frac{1}{2}(1+\epsilon^*)t^2 + O(\epsilon^{*2}) \tag{5.26}$$

and

$$\frac{1}{\epsilon^*}\int_0^1 u(s)ds \sim \frac{1}{2\epsilon^*} + \frac{1}{2} + O(\epsilon^*). \tag{5.27}$$

In addition, if $0 \le t \le \delta$, then $u'(t) \sim 1+\epsilon^*$, and hence, $u(t) \sim (1+\epsilon^*)t$. Therefore, (5.26) still holds for $t \in [0, \delta)$. □

The investigation of the asymptotic behavior of $u(t)$ on $(0, 1]$, and, in particular, at the right boundary layer, is complete. This enables us to prove the first asymptotic formula linking $u^{iv}(0)$ and $u'''(0)$ given in the following lemma.

LEMMA 5.5. As $\epsilon^* \to 0$, $u^{iv}(0) \sim [u'''(0)]^2\sqrt{\frac{\pi\epsilon^*}{2}} - \epsilon^{*-3}e^{-(\frac{1}{2}+\frac{1}{2\epsilon^*})}$.

Proof. Evaluating (5.6) at $t = 1$, we obtain

$$u^{iv}(1) = -\frac{1}{\epsilon^*}\int_0^t [u''(s)]^2 e^{\frac{1}{\epsilon^*}\int_s^1 u(r)dr} + u^{iv}(0)e^{\frac{1}{\epsilon^*}\int_0^1 u(r)dr}. \tag{5.28}$$

From (5.28) and (5.27), and by Lemma 5.1,

$$-\frac{1}{\epsilon^{*3}} \sim -\frac{1}{\epsilon^*}\int_0^\delta [u''(s)]^2 e^{\frac{1}{\epsilon^*}\int_s^1 u(r)dr} - \frac{1}{\epsilon^*}\int_\delta^1 [u''(s)]^2 e^{\frac{1}{\epsilon^*}\int_s^1 u(r)dr} + u^{iv}(0)e^{\frac{1}{2\epsilon^*}+\frac{1}{2}+O(\epsilon^*)}, \tag{5.29}$$

where $0 < \delta \ll 1$ is fixed. Substituting (5.23) into the second term on the right-hand side of (5.29), we find

$$\begin{aligned}\frac{1}{\epsilon^*}\int_\delta^1 [u''(s)]^2 e^{\frac{1}{\epsilon^*}\int_s^1 u(r)dr} &\sim \frac{1}{\epsilon^*}\int_\delta^1 \{u''(\delta) + u'''(\delta)(s-\delta)\}^2 e^{\frac{1}{\epsilon^*}\int_s^1 u(r)dr} ds \\ &+ \frac{1}{\epsilon^*}\int_\delta^1 \frac{\epsilon^{*4}(u^{iv}(1))^2}{u^4(s)} e^{-\frac{1}{\epsilon^*}\int_s^1 u(r)dr} ds,\end{aligned} \tag{5.30}$$

where the cross product terms in the expansion of $[u(s)]^2$ disappeared because they are negligible, for example, for the fixed δ,

$$\frac{1}{\epsilon^*}\int_\delta^1 \frac{\epsilon^{*2}u^{iv}(1)}{u^2(s)} e^{-\frac{1}{\epsilon^*}\int_s^1 u(r)dr} ds \sim -\frac{1}{\epsilon^{*2}}\int_\delta^1 \frac{1}{u^2(s)} e^{-\frac{1}{\epsilon^*}\int_s^1 u(r)dr} ds = O(\epsilon^{*-2}).$$

Similarly, the last term on the right-hand side of (5.30) is negligible. Thus,

$$\begin{aligned}-\frac{1}{\epsilon^{*3}} \sim &- \frac{1}{\epsilon^*}\int_0^\delta [u''(s)]^2 e^{\frac{1}{\epsilon^*}\int_s^1 u(r)dr} ds \\ &- \frac{1}{\epsilon^*}\int_\delta^1 [u''(\delta) + u'''(\delta)(s-\delta)]^2 e^{\frac{1}{\epsilon^*}\int_s^1 u(r)dr} ds \\ &+ u^{iv}(0)e^{\frac{1}{2\epsilon^*}+\frac{1}{2}+O(\epsilon^*)}.\end{aligned} \tag{5.31}$$

Apply Taylor's theorem to get $u''(s) = u''(0) + u'''(0)s + u^{iv}(x)\frac{s^2}{2}$ where $x \in (0, s)$. From (5.13), and since $u''(0) \sim \epsilon^* u^{iv}(0)$, the first integral in (5.31) admits

$$-\frac{1}{\epsilon^*}\int_0^\delta [u''(s)]^2 e^{\frac{1}{\epsilon^*}\int_s^1 u(r)dr} ds \sim -\frac{1}{\epsilon^*}[u'''(0)]^2 \int_0^\delta s^2 e^{\frac{1}{\epsilon^*}\int_s^1 u(r)dr} ds.$$

Here, the terms having the fourth derivative $u^{iv}(x)$ are neglected because they are of smaller order than ϵ^{*-3}. Similarly, since $u''(\delta) = u''(0) + u'''(0)\delta + u^{iv}(b)\delta^2/2$ and $u'''(\delta) = u'''(0) + u^{iv}(c)\delta$ where b, $c \in (0, \delta)$,

$$\begin{aligned}&\frac{1}{\epsilon^*}\int_\delta^1 [u''(\delta) + u'''(\delta)(s-\delta)]^2 e^{\frac{1}{\epsilon^*}\int_s^1 u(r)dr} ds \\ &\sim \frac{1}{\epsilon^*}[u'''(0)]^2 \int_\delta^1 s^2 e^{\frac{1}{\epsilon^*}\int_s^1 u(r)dr} ds.\end{aligned}$$

Finally,

$$\begin{aligned}-\frac{1}{\epsilon^{*3}} &\sim -\frac{[u'''(0)]^2}{\epsilon^*} e^{\frac{1}{\epsilon^*}\int_0^1 u(r)dr} \int_0^1 s^2 e^{-\frac{1}{\epsilon^*}\int_0^s u(r)dr} ds + u^{iv}(0) e^{\frac{1}{2\epsilon^*}+\frac{1}{2}+O(\epsilon^*)} \\ &\sim -\frac{[u'''(0)]^2}{\epsilon^*} e^{\frac{1}{2\epsilon^*}+\frac{1}{2}} \int_0^1 s^2 e^{-(\frac{1}{2\epsilon^*}+\frac{1}{2})s^2} ds + u^{iv}(0) e^{\frac{1}{2\epsilon^*}+\frac{1}{2}}. \qquad (5.32)\end{aligned}$$

Make a substitution $x = (\frac{1}{2\epsilon^*} + \frac{1}{2})s^2$ in the integral of (5.32). Then,

$$\int_0^1 s^2 e^{-(\frac{1}{2\epsilon^*}+\frac{1}{2})s^2} ds = \frac{1}{2}\left(\frac{2\epsilon^*}{1+\epsilon^*}\right)^{\frac{3}{2}} \int_0^{\frac{1+\epsilon^*}{2\epsilon^*}} x^{\frac{1}{2}} e^{-x} dx \sim \sqrt{2}\left(\frac{\epsilon^*}{1+\epsilon^*}\right)^{3/2} \Gamma\left(\frac{3}{2}\right),$$

and hence,

$$-\frac{1}{\epsilon^{*3}} \sim -\left\{\epsilon^{*-1}\sqrt{2}\left(\frac{\epsilon^*}{1+\epsilon^*}\right)^{3/2}\Gamma\left(\frac{3}{2}\right)[u'''(0)]^2 - u^{iv}(0)\right\} e^{\frac{1}{2}+\frac{1}{2\epsilon^*}},$$

from which the lemma follows. □

Our goal is to determine the asymptotic value of $u'''(0)$. Therefore, another asymptotic formula linking $u'''(0)$ and $u^{iv}(0)$ is needed. Since Lemma 5.5 is obtained using only information about $u(t)$ for $t \geq 0$, we must return to the left side of the turning point in section 6 to find how these two quantities are related for $t \leq 0$.

6. On $u(t)$ for $t \leq 0$. For convenience, we rewrite Lemma 3.12 as the following in terms of the function $u(t)$.

LEMMA 6.1. $\Delta u(t) - (-\frac{1-\Delta}{\pi}\sin\frac{\pi\Delta t}{1-\Delta}) \to 0$ in C^4 and $|u^{(k)}(t)| = O(\Delta^{k-1})$ for $k = 1, 2, 3, 4$ on $[-\frac{1-\Delta}{\Delta}, 0]$, and $u(t) \sim -\frac{1-\Delta}{\Delta\pi}\sin\frac{\pi\Delta t}{1-\Delta}$ uniformly on $[-\frac{1-\Delta}{\Delta}, 0]$.

From (5.6),

$$u^{iv}(0) = u^{iv}(-M)e^{-\frac{1}{\epsilon^*}\int_0^{-M} u(r)dr} + \frac{1}{\epsilon^*}\int_0^{-M} [u''(s)]^2 e^{-\frac{1}{\epsilon^*}\int_0^s u(r)dr} ds \qquad (6.1)$$

for any $M \in [0, \frac{1-\Delta}{\Delta}]$. To determine the leading term of $u^{iv}(0)$, we must find an asymptotic formula for the integrals of $u(r)$ in (6.1).

Lemma 6.2. *As* $\epsilon^* \to 0$,

$$\int_0^r u(t)dt \sim 2\left(\frac{1-\Delta}{\Delta\pi}\right)^2 \sin^2\frac{\pi\Delta r}{2(1-\Delta)}, \tag{6.2}$$

and

$$\int_0^r [u(s)]^2 e^{-\frac{1}{\epsilon^*}\int_0^s u(t)dt} \sim \sqrt{\frac{\pi}{2}}\epsilon^{*\frac{3}{2}}[u'''(0)]^2 \tag{6.3}$$

uniformly for all $r \in [-\frac{1-\Delta}{\Delta}, -\rho]$ *where* $\rho > 0$ *is a constant.*

Proof. Recall from section 1 that $g(\eta) \sim h(\eta) = -\frac{1-\Delta}{\pi}\sin\frac{\pi\eta}{1-\Delta}$ uniformly on $[0, 1-\Delta]$ as $\tilde{\epsilon} \to 0$. Hence,

$$\int_{1-\Delta}^{\tau} g(\eta)d\eta \sim \int_{1-\Delta}^{\tau} h(\eta)d\eta = \left(\frac{1-\Delta}{\pi}\right)^2\left(1+\cos\frac{\pi\tau}{1-\Delta}\right) \tag{6.4}$$

uniformly for $\tau \in [0, 1-\Delta]$. Let $\eta = 1-\Delta+\Delta t$ and $r = (\tau - 1 + \Delta)/\Delta$. If follows that

$$\frac{\Delta}{|\alpha|}\int_0^r u(t)dt \sim 2\left(\frac{1-\Delta}{\pi}\right)^2 \sin^2\frac{\pi\Delta r}{2(1-\Delta)},$$

which implies (6.2) by Lemma 4.4. To prove the asymptotic formula (6.3), we directly apply the definition. For any given $\sigma > 0$, from (6.2), there exists an ϵ_0^* such that if $\epsilon^* < \epsilon_0^*$, then for all $r \in [-\frac{1-\Delta}{\Delta}, 0]$,

$$e^{-\frac{2(1+\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2\sin^2\frac{\pi\Delta r}{2(1-\Delta)}} \le e^{-\frac{1}{\epsilon^*}\int_0^r u(t)dt} \le e^{-\frac{2(1-\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2\sin^2\frac{\pi\Delta r}{2(1-\Delta)}}, \tag{6.5}$$

and

$$\begin{aligned}\int_0^{|r|}(u'')^2 e^{-\frac{2(1+\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2\sin^2\frac{\pi\Delta s}{2(1-\Delta)}}ds &\le \int_0^{|r|}(u'')^2 e^{-\int_0^s\frac{u(t)}{\epsilon^*}dt}ds\\ &\le \int_0^{|r|}(u'')^2 e^{-\frac{2(1-\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2\sin^2\frac{\pi\Delta s}{2(1-\Delta)}}ds. \end{aligned}\tag{6.6}$$

Set an $r \ge \rho$. A substitution of the expression $u''(s) = u''(0) + u'''(0)s + u^{iv}(\xi)s^2/2$, where $\xi \in (0, s)$ depending on s, into the right integral of (6.6) leads to

$$\begin{aligned}&\int_0^{|r|}(u'')^2 e^{-\frac{2(1-\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2\sin^2\frac{\pi\Delta s}{2(1-\Delta)}}ds\\ &\quad\sim [u'''(0)]^2\int_0^{|r|}s^2 e^{-\frac{2(1-\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2\sin^2\frac{\pi\Delta s}{2(1-\Delta)}}ds,\end{aligned}\tag{6.7}$$

for all $\epsilon^* < \epsilon_1^*$, where $\epsilon_1^* \in (0, \epsilon_0^*)$ depending only on ρ and σ. The terms including $u''(0)$ and $u^{iv}(z)$ in the resulting expansion are neglected because $u^{iv}(t)| = \Delta^3|g^{iv}| = O(\Delta^3) \ll |u'''(0)|$, $u''(0) \sim -\epsilon^* u^{iv}(0) = o(\Delta^3) \ll |u'''(0)|$. To see that ϵ_1^* is independent of r, we rewrite the integral on the right-hand side of (6.7) as

$$\begin{aligned}&\int_0^{|r|}s^2 e^{-\frac{2(1-\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2\sin^2\frac{\pi\Delta s}{2(1-\Delta)}}ds\\ &\quad= \left\{\int_0^{\rho} + \int_{\rho}^{|r|}\right\} s^2 e^{-\frac{2(1-\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2\sin^2\frac{\pi\Delta s}{2(1-\Delta)}}ds.\end{aligned}\tag{6.8}$$

Since $\frac{2}{\pi} \le \sin\theta \le \theta$ for all $\theta \in (0, \frac{\pi}{2})$,

$$\int_\rho^{|r|} s^2 e^{-\frac{2(1-\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2 \sin^2 \frac{\pi\Delta s}{2(1-\Delta)}} ds \le \int_\rho^{|r|} s^2 e^{-\frac{2(1-\sigma)}{\epsilon^*\pi^2}s^2} ds = M_1 {\epsilon^*}^{\frac{3}{2}} \int_{k_2(\rho,\epsilon^*)}^{k_1(r,\epsilon^*)} x^{\frac{1}{2}} e^{-x} dx,$$

where $k_1(\epsilon^*) = \frac{2(1-\sigma)}{\epsilon^*\pi^2} r^2 \to \infty$, $k_2(\epsilon^*) = \frac{2(1-\sigma)}{\epsilon^*\pi^2}\rho^2 \to \infty$, and $M_1 = 2^{-\frac{5}{2}}\pi^3(1-\sigma)^{-\frac{3}{2}}$. This shows that the second integral on the right-hand side of (6.8) is of order $o({\epsilon^*}^{\frac{3}{2}})$ for all $r \in [-\frac{1-\Delta}{\Delta}, -\rho]$ as $\epsilon^* \to 0$. On the other hand, noting from Lemma 5.2 that Δ is exponentially small as $\epsilon^* \to 0$, we see that

$$\frac{2(1-\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2 \sin^2 \frac{\pi\Delta s}{2(1-\Delta)} \sim \frac{(1-\sigma)\, s^2}{2\epsilon^*}$$

uniformly on $[0, \rho]$, and

$$\begin{aligned} \int_0^\rho s^2 e^{-\frac{2(1-\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2 \sin^2 \frac{\pi\Delta s}{2(1-\Delta)}} ds &\sim \int_0^\rho s^2 e^{-\frac{(1-\sigma)s^2}{2\epsilon^*}} ds \\ &= \sqrt{2}\left(\frac{\epsilon^*}{1-\sigma}\right)^{\frac{3}{2}} \int_0^{\frac{\rho^2(1-\sigma)}{2\epsilon^*}} x^{\frac{1}{2}} e^{-x} dx \\ &\sim \sqrt{2}\left(\frac{\epsilon^*}{1-\sigma}\right)^{\frac{3}{2}} \Gamma\left(\frac{3}{2}\right), \end{aligned} \tag{6.9}$$

which implies that the first integral on the right-hand side of (6.8) contributes the leading term for (6.7). This also proves

$$\int_0^{|r|} [u''(s)]^2 e^{-\frac{2(1-\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2 \sin^2 \frac{\pi\Delta s}{2(1-\Delta)}} ds \sim \sqrt{2}\left(\frac{\epsilon^*}{1-\sigma}\right)^{\frac{3}{2}} \Gamma\left(\frac{3}{2}\right). \tag{6.10}$$

Similarly,

$$\int_0^{|r|} [u''(s)]^2 e^{-\frac{2(1+\sigma)}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2 \sin^2 \frac{\pi\Delta s}{2(1-\Delta)}} ds \sim \sqrt{2}\left(\frac{\epsilon^*}{1+\sigma}\right)^{\frac{3}{2}} \Gamma\left(\frac{3}{2}\right). \tag{6.11}$$

From (6.6) and these last two formulas, we conclude that for the given $\sigma > 0$, there is an $\epsilon_1^* > 0$ such that

$$\sqrt{2}\left(\frac{\epsilon^*}{1+2\sigma}\right)^{\frac{3}{2}} \Gamma\left(\frac{3}{2}\right) < \int_0^{|r|} (u'')^2 e^{-\int_0^s \frac{u(t)}{\epsilon^*} dt} ds < \sqrt{2}\left(\frac{\epsilon^*}{1-2\sigma}\right)^{\frac{3}{2}} \Gamma\left(\frac{3}{2}\right).$$

Therefore, (6.3) holds, and the proof of Lemma 6.2 is complete. □

We can now prove the second asymptotic relation between $u'''(0)$ and $u^{iv}(0)$ as follows.

LEMMA 6.3. *As* $\epsilon^* \to 0, u^{iv}(0) \sim -\sqrt{\frac{\pi\epsilon^*}{2}}[u'''(0)]^2$.

Proof. Set $M = \frac{1-\Delta}{\Delta}$ in (6.1). By Lemma 6.2,

$$u^{iv}(0) \sim u^{iv}(-M) e^{-\frac{1}{\epsilon^*}\int_0^{-M} u(r)dr} - \frac{[u'''(0)]^2}{\epsilon^*}\sqrt{2}{\epsilon^*}^{\frac{3}{2}}\Gamma\left(\frac{3}{2}\right). \tag{6.12}$$

From (6.5), we see that for $\epsilon^* < \epsilon_1^*$, where ϵ_1^* is given in the proof of Lemma 6.2,

$$|u^{iv}(-M)| e^{-\frac{1}{\epsilon^*}\int_0^{-M} u(r)dr} \le |u^{iv}(-M)| e^{-\frac{1-\sigma}{\epsilon^*}\left(\frac{1-\Delta}{\Delta\pi}\right)^2}.$$

Since $u^{iv}(-M) = O(\Delta^3), u'''(0) \sim \pi^2\Delta^2$, and Δ is exponentially small, the second term on the right-hand side of (6.12) provides the leading term for $u^{iv}(0)$, i.e.,

$$u^{iv}(0) \sim -\frac{[u'''(0)]^2}{\epsilon^*}\sqrt{2}\epsilon^{*\frac{3}{2}}\Gamma\left(\frac{3}{2}\right). \tag{6.13}$$

The proof of Lemma 6.3 is complete. □

7. At the turning point. The two asymptotic formulas linking $u'''(0)$ and $u^{iv}(0)$ have been determined in sections 5 and 6. In this final section, we combine them to determine the asymptotic values of these two quantities. The asymptotic value of Δ_ϵ is then determined in terms of the original parameter ϵ, which will complete the proof of the main result of the paper.

LEMMA 7.1. *As* $\epsilon^* \to 0$,

$$u'''(0) \sim -(2e\pi)^{-\frac{1}{4}}\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{4\epsilon^*}}$$

and

$$u^{iv}(0) \sim -\pi\sqrt{e}\epsilon^{*-3}e^{-\frac{1}{2\epsilon^*}}, \qquad u''(0) \sim \pi\sqrt{e}\epsilon^{*-2}e^{-\frac{1}{2\epsilon^*}}.$$

Proof. From Lemmas 5.5 and 6.3,

$$-[u'''(0)]^2\sqrt{\frac{\pi\epsilon^*}{2}} \sim [u'''(0)]^2\sqrt{\frac{\pi\epsilon^*}{2}} - \epsilon^{*-3}e^{-(\frac{1}{2}+\frac{1}{2\epsilon^*})}.$$

Then

$$u'''(0) \sim -(2e\pi)^{-\frac{1}{4}}\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{4\epsilon^*}}.$$

A simple application of Lemma 6.3 gives the asymptotic formula of $u^{iv}(0)$. The asymptotic formula of $u''(0)$ follows from $\epsilon^* u^{iv}(0) = -u'(0)u''(0)$. □

Recall from Corollary 5.4 of section 5 that $u'(0) \sim 1 + \epsilon^*$ as $\epsilon^* \to 0$. This and Lemma 7.1 provide the complete information on $u(t)$, and therefore, on $f(\eta, \epsilon)$ at the turning point.

Since also $u'''(0) \sim -\pi^2\Delta^2$ and $\epsilon^* = \frac{\epsilon}{\Delta}$, we have

$$\pi^2\Delta^2 \sim (2e\pi)^{-\frac{1}{4}}\epsilon^{*-\frac{7}{4}}e^{-\frac{1}{4\epsilon^*}}.$$

It turns out that Δ satisfies

$$\frac{\Delta}{\epsilon}e^{\frac{\Delta}{\epsilon}} \sim \frac{1}{2e\pi^9\epsilon^8}. \tag{7.1}$$

This completes the proof of Theorem 4.5. Thus, from Theorem 3.1,

$$f(\eta) \sim \frac{\sin\frac{\pi\eta}{1-\Delta}}{\frac{\pi\Delta}{1-\Delta}}$$

uniformly on $[0, 1-\Delta]$. The proof of Theorem 2.1 is complete.

Remark 3. The proved asymptotic relation (7.1) between ϵ and Δ is not exactly the same as the formula formally obtained in [7]. Therefore, the formal asymptotic technique used in [7] needs to be modified. This will be given in another paper.

Acknowledgment. The author thanks Professor J. B. McLeod for showing him the details of [9].

FREE BOUNDARY FLUID SYSTEMS IN A SEMIGROUP APPROACH AND OSCILLATORY BEHAVIOR[*]

BEN SCHWEIZER[†]

Abstract. We consider the free boundary problem of a liquid drop with viscosity and surface tension. We study the linearized equations with semigroup methods to get existence results for the nonlinear problem. The spectrum of the generator is computed. Large surface tension creates nonreal eigenvalues, and an exterior force results in a Hopf bifurcation. The methods are used to study wind-generated surface waves.

Key words. Hopf bifurcation, viscous fluid, free boundary

1. Introduction.

We consider two examples of a finite mass of viscous fluid with a free boundary. In contrast to the case of a fixed domain, the fluid is capable of showing damped oscillations. Due to surface tension the surface area carries potential energy, and oscillations correspond to an exchange of energy between its kinetic and its potential form. The time-dependent problem has parabolic and hyperbolic features, and Beale calls it "mixed in character." The work at hand contributes to the study of this dynamical system.

We assume the system to be close to a stationary solution. The theory is written down for an almost spherical liquid drop but applies also to water in a container with periodic lateral boundaries. We rewrite the equations in semigroup form; the study of the generator reveals some nonstandard properties regarding the choice of function spaces, the spectrum, and the resolvent.

In sections 2–4 we derive an existence theory using the language of semigroup theory and maximal regularity results. In sections 5–7 we study qualitative properties of the spectrum of the generator, such as nonreal or (with an external forcing) imaginary eigenvalues. The two parts interact: the existence theory allows the proof of a Hopf bifurcation in two examples.

The existence theory begins with a proof that the spectrum of the generator consists of eigenvalues and is contained in a sector of the complex plane. Therefore, a natural idea is to apply the semigroup theory for sectorial operators. But the analysis of the resolvent shows that the problem does not fit into this framework: the estimates are valid only on a subspace. On the other hand, due to the kinematic boundary condition, the nonlinearity is always contained in the same subspace. We show that the methods of semigroup theory can be adapted and derive an existence result for the linear problem in section 3 and for the nonlinear problem in section 4. The solutions provide differentiable flows on a Banach manifold. This will be the setting to prove a Hopf bifurcation in section 6.

This research was done in part while the author visited the Courant Institute for Mathematical Sciences, New York, supported by the Deutsche Forschungsgemeinschaft.

Regarding other works, we wish to mention first Beale [2], who studied infinite domains. He derives the resolvent estimate with the help of Fourier transforms. His proof is considerably longer than ours, since the infinite domain corresponds to a continuous spectrum.

Concerning finite domains, we refer to the numerous works of Solonnikov, who gave the first existence result. He derives estimates with methods from potential theory, after having transformed the equations in a half-space [15]. We mention a related article on Hopf bifurcation in a two-phase fluid system by Renardy and Joseph [13]. In their more physical model the transversal crossing of eigenvalues appears as an assumption. They do not treat the initial value problem. For a more geometric approach, see Bemelmans [4] and Wagner [17].

In the second part of this article we prove qualitative properties of the spectrum. We describe the basic idea for the case where we have only one physical parameter, a nondimensional surface tension β. We are interested in how an eigenvalue λ of the operator $\mathcal{L}_\beta$ depends on β. We do this indirectly. For some function $\tilde{\beta}$ every complex number λ is an eigenvalue of the operator $\mathcal{L}_{\tilde{\beta}(\lambda)}$. The study of the function $\tilde{\beta}$ on the real axis gives us insight into the behavior of $\lambda(\beta)$.

In section 5, we see that for vanishing surface tension the spectrum of $\mathcal{L}$ consists of both the Stokes eigenvalues in a fixed domain and the interfacial eigenvalue 0. For a fixed interfacial eigenmode with increasing β, the first two eigenvalues move towards each other and must leave the real axis, while the other eigenvalues remain trapped in fixed intervals.

We use the same general idea in two examples with an exterior force. In section 6, we assume that the liquid drop experiences negative damping. We can count the eigenvalues inside a ball and prove that if the force reaches a critical strength a pair of eigenvalues crosses transversally the imaginary axis. Using the existence results, we can prove a Hopf bifurcation.

In section 7 we apply the idea to a model for the generation of water waves by wind. A strong wind leads to a Hopf bifurcation. We also gain insight into the shape of the eigenfunctions for strong wind: two of them show the structure of an ideal fluid; the other, approximate Stokes eigenfunctions. There are works (e.g., [10], [11]) that give asymptotic formulas for the eigenvalues for a vanishing exterior force. Our results confirm their qualitative properties and provide additional mathematical insight and proofs.

2. The liquid-drop equations.

We first collect the nonlinear equations describing a liquid drop. Let Ω be the subdomain of $\mathbb{R}^3$ occupied by liquid. The velocity field and the pressure within the liquid drop are denoted by u and p, respectively. The exterior normal vector of $\partial\Omega$ is denoted by n^Ω; tangential vectors are denoted by τ_i^Ω. We use the dimensionless viscosity ν.

The surface tension will become important. The physical quantity is a number $\beta > 0$: if the surface has a mean curvature $H(\eta)$, then the surface tension creates a pressure $2\beta H(\eta)$.

We introduce the strain-tensor

$$(S_u)_{ij} = \frac{1}{2}(\partial_i u_j + \partial_j u_i)$$

and the product $(S_u) : (S_w) := \sum_{i,j} (S_u)_{ij}(S_w)_{ij}$, and we define additionally

$$S_u^n := n \cdot S_u \cdot n.$$

We deal with a free boundary problem. The unknown functions are not only u and p but also the domain Ω. We assume small perturbations of the unit sphere and parametrize the surface of the liquid drop with a function $\eta : S^2 \to \mathbb{R}$. The domain occupied by liquid is

$$\Omega(t) = \{r\xi \in \mathbb{R}^3 | \, \xi \in S^2, 0 \leq r < 1 + \eta(\xi)\}.$$

The velocity field is a function

$$u(t, .) : \Omega(t) \to \mathbb{R}^3.$$

In the interior, the following Navier–Stokes equations hold:

$$\partial_t u + (u \cdot \nabla)u - \nu\Delta u + \nabla p = 0, \tag{1}$$
$$\nabla \cdot u = 0. \tag{2}$$

The boundary conditions are the geometric condition that η always parametrizes the surface, the additional pressure created by surface tension, the condition of vanishing tangential stress, plus initial conditions:

$$\partial_t \eta + (\partial_\varphi \eta)u_\varphi + (\partial_\vartheta \eta)u_\vartheta = u_r, \tag{3}$$
$$p - 2\nu n^\Omega \cdot S_u \cdot n^\Omega = 2\beta \; H(\eta), \tag{4}$$
$$\tau_i^\Omega \cdot S_u \cdot n^\Omega = 0, \tag{5}$$
$$(u, \eta)(t = 0) = (u_0, \eta_0). \tag{6}$$

Equation (3) can be derived by considering a particle at the boundary with position $(r(t), \varphi(t), \vartheta(t))$ in spherical coordinates using $\eta(t, \varphi(t), \vartheta(t)) = r(t)$.

We will return to these nonlinear equations in section 4. We now give the linearization of the problem in $u = 0$, $\eta = 0$. We replace the domain Ω by the unit ball B^3. n^Ω and τ_i^Ω are replaced by the normal and tangential vectors of the unit sphere, $n(\xi) = \xi$ and τ_i. The radial velocity will now be written as $u_n|_\partial = n \cdot u|_\partial$.

The linearization of the mean curvature of $\partial\Omega = \{\xi(1 + \eta(\xi))| \, \xi \in S^2\}$ is denoted by $-\frac{1}{2}\underline{\Delta}\eta$. With the Laplace–Beltrami operator of the sphere Δ_B, there holds

$$\underline{\Delta} = \Delta_B + 2 \cdot id.$$

The linearized equations are

$$\begin{aligned} u : B^3 \to \mathbb{R}^3, \quad p : B^3 \to \mathbb{R}, &\quad \eta : S^2 \to \mathbb{R}, \\ \frac{d}{dt}u - \nu\Delta u + \nabla p &= 0, \\ \nabla \cdot u &= 0, \\ \frac{d}{dt}\eta &= u_n|_\partial, \\ (-p + 2\nu S_u^n)|_\partial &= \beta\underline{\Delta}\eta, \\ (\tau_i \cdot S_u \cdot n)|_\partial &= 0. \end{aligned}$$

In the equation for the pressure, we omitted the constant pressure induced by the surface tension of the unit sphere.

Before we start the analysis of the linearized liquid-drop equations, we collect some facts concerning the Stokes equation. We write $H^r = H^{r,2}$ for Sobolev spaces.

If the domain is the unit ball $B = B^3$, we often omit this argument: $H^r = H^r(B^3)$. The Stokes operator $A : (u, p) \mapsto (-\nu\Delta u + \nabla p, \nabla \cdot u)$ is elliptic in the sense of Agmon, Douglis, and Nirenberg [1] with any of the boundary conditions

$$\begin{aligned} & u|_\partial = 0, \\ \text{or} \quad & u_n|_\partial = 0, \quad \tau \cdot S_u|_\partial \cdot n = 0, \\ \text{or} \quad & (p - 2\nu S_u^n)|_\partial = 0, \quad \tau \cdot S_u|_\partial \cdot n = 0. \end{aligned}$$

Solutions to inhomogeneous boundary data have maximal regularity.

We introduce the operator

$$\mathcal{H} : H^{r-1/2}(S^2) \to H^r(B^3),$$

which maps a function to its harmonic extension.

We will use integration by parts in the following form.

LEMMA 2.1. *For smooth functions $u, w : B^3 \to \mathbb{R}^3$ with $\nabla \cdot u = \nabla \cdot w = 0$ and $\tau \cdot S_u \cdot n = 0$,*

$$2 \int_B S_u : S_w = \int_B \{-\Delta u + \nabla \mathcal{H}(2S_u^n)\} \cdot w.$$

We now return to the liquid-drop equations. Our aim is to write the linear liquid-drop equations in the form $\frac{d}{dt}x + \mathcal{L}x = 0$ and to satisfy the boundary conditions by the choice of appropriate function spaces.

We start by rewriting the boundary condition for the pressure. The pressure p is a harmonic function; therefore

$$p = \mathcal{H}(2\nu S_u^n|_\partial) - \mathcal{H}(\beta \underline{\Delta} \eta).$$

The physical quantities volume, momentum, and angular momentum are conserved. We use this fact in the definition of the function spaces.

The following point of view is useful: the first eigenspace of Δ_B corresponds to constant functions $\Phi(x) = a$; the second eigenspace, to translations $\Phi(x) = b \cdot x$. The physical conditions imply that the projection of η onto the first two eigenspaces of Δ_B vanishes.

DEFINITION 2.2. *Define the Hilbert spaces*

$$\begin{aligned} Y^r &:= \left\{ u \in H^r(B^3)^3 | \nabla \cdot u = 0; \int_{B^3} u = 0; \int_{B^3} u \wedge \gamma = 0 \; \forall \gamma \in \mathbb{R}^3 \right\}, \\ X^r &:= \left\{ (u, \eta) \in Y^r \times H^{r+1-1/2}(S^2) | \int_{S^2} \eta = 0; \int_{S^2} n \cdot \eta = 0 \right\}, \\ \tilde{X}^r &:= \{(u, \eta) \in X^r | n \cdot S_u(z) \cdot \tau|_\partial = 0 \; \forall \tau \in T_z S^2\}, \end{aligned}$$

and the operator

$$\mathcal{L} : X^r \to X^r, \qquad \tilde{X}^r \supset \mathcal{D}(\mathcal{L}) \supset \tilde{X}^{r+2}$$

by

$$\mathcal{L} \begin{pmatrix} u \\ \eta \end{pmatrix} := \begin{pmatrix} -\nu\Delta u + \nabla \mathcal{H}(2\nu S_u^n|_\partial) - \nabla \mathcal{H}(\beta \underline{\Delta} \eta) \\ -u_n|_\partial \end{pmatrix}.$$

Easy calculations show that $\mathcal{L}$ maps to X: the liquid drop does not start to move its center of mass, it does not start to rotate, and it keeps its volume.

The linearized liquid-drop equation reads

$$\frac{d}{dt}x + \mathcal{L}x = 0, \quad x \in \tilde{X}. \tag{7}$$

In the case of a pure rotation the integral $\int_B |S_u|^2$ vanishes without u being a constant. But in our function spaces a Korn inequality holds: there exists a constant C_K such that for all $u \in Y$

$$\frac{1}{C_K}\|Du\|^2_{L^2} \le 2\nu \int_{B^3} |S_u|^2 \le C_K \|Du\|^2_{L^2}. \tag{8}$$

See, e.g., [16]. Here $\|Du\|_{L^2}$ may be replaced by $\|u\|_{H^1}$ because the mean of u vanishes.

DEFINITION 2.3 (energy norms). *For functions $u, v : B^3 \to \mathbb{R}^3$ and $\eta, \sigma : S^2 \to \mathbb{R}$ we define*

$$\begin{aligned} \langle u, v\rangle_E &:= \int_B \bar{u}\cdot v, \\ \langle \eta, \sigma\rangle_E &:= \beta \int_S (-\underline{\Delta}\bar{\eta})\cdot \sigma, \\ \left\langle \begin{pmatrix} u \\ \eta \end{pmatrix}, \begin{pmatrix} v \\ \sigma \end{pmatrix} \right\rangle_E &:= \langle u, v\rangle_E + \langle \eta, \sigma\rangle_E. \end{aligned}$$

The corresponding norms are denoted by $\|.\|_E$.

LEMMA 2.4 (position of eigenvalues of $\mathcal{L}$). *Let $(u, \eta) \in \tilde{X}^2$ be an eigenvector of $\mathcal{L}$ with eigenvalue μ. Then*

$$\begin{aligned} \mathrm{Re}(\mu)\|(u,\eta)\|^2_E &= 2\nu \int_B |S_u|^2, \\ \mathrm{Im}(\mu)\|(u,\eta)\|^2_E &= 2\beta \mathrm{Im}\left(\int_S u_n|_\partial \underline{\Delta}\bar{\eta}\right). \end{aligned}$$

In the case of $\mathrm{Im}(\mu) \neq 0$ the following energy equality holds:

$$\|u\|^2_E = \|\eta\|^2_E = \frac{1}{2}\|(u,\eta)\|^2_E.$$

Proof.

$$\begin{aligned} \mu \left\| \begin{pmatrix} u \\ \eta \end{pmatrix} \right\|^2_E &= \left\langle \begin{pmatrix} u \\ \eta \end{pmatrix}, \mathcal{L}\begin{pmatrix} u \\ \eta \end{pmatrix} \right\rangle_E \\ &= \left\langle \begin{pmatrix} u \\ \eta \end{pmatrix}, \begin{pmatrix} -\nu\Delta u + \nabla\mathcal{H}(2\nu S^n_u) - \nabla\mathcal{H}(\beta\underline{\Delta}\eta) \\ -u_n|_\partial \end{pmatrix} \right\rangle_E \\ &= \int_B \{\bar{u}\cdot(-\nu\Delta u + \nabla\mathcal{H}(2\nu S^n_u))\} \\ &\quad - \int_B \bar{u}\nabla\mathcal{H}(\beta\underline{\Delta}\eta) - \beta\int_S (-\underline{\Delta}\bar{\eta})(u_n)|_\partial \\ &= 2\nu\int_B |S_u|^2 + \beta\int_S \{u_n|_\partial \underline{\Delta}\bar{\eta} - \bar{u}_n|_\partial \underline{\Delta}\eta\}. \end{aligned}$$

This implies the assertion on the real and the imaginary part of μ.

To prove the energy equality we use the second part of the eigenvalue equation, $-u_n|_\partial = \mu\eta$:

$$\begin{aligned}\mathrm{Im}(\mu)\left\|\begin{pmatrix} u \\ \eta \end{pmatrix}\right\|_E^2 &= 2\beta \mathrm{Im}\left(\int_S u_n|_\partial \underline{\Delta}\bar{\eta}\right)\\ &= 2\mathrm{Im}(\mu)\|\eta\|_E^2. \qquad \square\end{aligned}$$

Using the properties of the Stokes operator one easily proves the following lemma for $\beta \neq 0$.

Lemma 2.5. *The operator $\mathcal{L}^{-1} : X^r \to \tilde{X}^{r+1}$ is bounded.*

We point out that $\mathcal{L}^{-1} : X^0 \to \tilde{X}^2$ is not bounded: let (u, η) solve $\mathcal{L}(u, \eta) = (0, g)$. A bound for $\|u\|_{H^2}$ would imply $g = u_n|_\partial \in H^{3/2,2}(S^2)$. But a priori, only $g \in H^{1/2,2}(S^2)$ holds.

The Lumer–Phillips theorem implies the following lemma.

Lemma 2.6. *$\mathcal{L}$ generates a C^0-semigroup in the space X_E corresponding to the energy norms.*

We want to split X into a direct sum of $\mathcal{L}$-invariant subspaces $(X_n)_{n\in\mathbb{N}}$ according to spherical harmonics. The functions $\{\psi_{n,k}|n \in \mathbb{N}, k \in \{-n, ..., n\}\}$ shall span Ψ_n, the nth eigenspace of the Laplace–Beltrami operator of S^2. We denote the corresponding eigenvalue by $\Lambda_n > 0$ and the eigenvalue of $-\underline{\Delta}$ by $\underline{\Lambda_n} = \Lambda_n - 2$. Let ν be the normal vector, ∇_T the tangential gradient, and $\nabla_T^\perp = \nu \wedge \nabla$ the orthogonal tangential gradient.

A vector field is in X_n if on any sphere of radius r the function can be represented by $\psi_{n,k}\, \nu$, $\nabla_T \psi_{n,k}$, and $\nabla_T^\perp \psi_{n,k}$, $k \in \{-n, ..., n\}$.

Proposition 2.7. *The spectrum of $\mathcal{L}$ consists only of eigenvalues which are contained in a sector*

$$S_C := \{\mu| \quad |\mathrm{Im}(\mu)| < C\mathrm{Re}(\mu)\}. \tag{9}$$

Proof. By Lemma 2.5, $\mathcal{L}$ has a compact resolvent and therefore a pure point spectrum. We prove that eigenvalues are contained in a sector S_C. Let μ be an eigenvalue with eigenvector $(u, \eta) \in \tilde{X}_k$. If $\mathrm{Im}(\mu) = 0$, then μ is contained in any sector S_C. We can therefore assume $\mathrm{Im}(\mu) \neq 0$.

We use Lemma 2.4 and the fact that u depends on the radius r like $e^{\sqrt{\underline{\Lambda_k}+|\mu|}\ r}$.

$$\begin{aligned}|\mathrm{Im}(\mu)| \ \left\|\begin{pmatrix} u \\ \eta \end{pmatrix}\right\|_E^2 &= 2\beta\left|\mathrm{Im}\left(\int_S u_n|_\partial \underline{\Delta}\bar{\eta}\right)\right|\\ &\leq \beta\int_S |\underline{\Delta}\eta|^2 + \beta\int_S |u_n|_\partial|^2\\ &\leq |\underline{\Lambda_k}|\|\eta\|_E^2 + \beta C_T\sqrt{\underline{\Lambda_k} + |\mu|}\ \|u\|_{L^2(B)}^2.\end{aligned}$$

Therefore,

$$|\mathrm{Im}(\mu)| \leq C_1|\underline{\Lambda_k}| + \beta C_2 \mathrm{Re}(\mu).$$

Using Lemma 2.4 and the Korn inequality yields

$$\mathrm{Re}(\mu)\left\|\begin{pmatrix} u \\ \eta \end{pmatrix}\right\|_E^2 = 2\nu\int_B |S_u|^2$$

$$\geq \frac{1}{C_K}\|\nabla_T u\|_{L^2}^2$$
$$\geq \frac{1}{2C_K}|\underline{\Lambda_k}|\left\|\begin{pmatrix} u \\ \eta \end{pmatrix}\right\|_E^2 .$$

The assertion follows with the constant $C = 2C_1C_K + \beta C_2$. □

3. An estimate for resolvents and the time-dependent problem. In this section we collect estimates for the resolvent. A first type of estimate concerns solutions (u,η) of $(\lambda - \mathcal{L})(u,\eta) = (f,0)$. Such estimates are known in similar contexts [2], [13]. We indicate how they can be derived more easily in our case of only one fluid in a compact domain.

As a corollary, we get a second type of estimate concerning the resolvent on the full space: we show that $\mathcal{L}$ is a sectorial operator.

To solve nonlinear equations, it will be necessary to increase the regularity of the function spaces. In this section we use $X = X^r$ and $\tilde{X}^{++} = \tilde{X}^{2+r}$ with $r = 0$ or $r = 2$.

Theorem 3.1. *There exists $C_R > 0$ such that solutions $(u,\eta) \in \tilde{X}^{++}$ of*

$$(\lambda - \mathcal{L})\begin{pmatrix} u \\ \eta \end{pmatrix} = \begin{pmatrix} f \\ 0 \end{pmatrix}$$

with $\lambda \in \mathbb{C} \setminus S_C$ satisfy the regularity

$$\|(u,\eta)\|_{X^{++}} \leq C_R\|(f,0)\|_X \tag{10}$$

and the resolvents estimate

$$\|(u,\eta)\|_X \leq C_R\frac{1}{|\lambda|}\|(f,0)\|_X . \tag{11}$$

Proof. We indicate the ideas of the proof. One writes the equation as

$$\lambda u + \nu\Delta u - \nabla\mathcal{H}(2\nu S_u^n) - \frac{1}{\lambda}\nabla\mathcal{H}(\beta\underline{\Delta}u_n|_\partial) = f. \tag{12}$$

Testing with $\Delta_B\bar{u}$ and taking real and imaginary parts shows that $\beta\frac{1}{|\lambda|}\int_{S^2}|\underline{\Delta}u_n|_\partial|^2$ and $\|u\|_{H^2}^2$ can be estimated by $\|f\|_{L^2}$ and $|\lambda|^2\|u\|_{L^2}^2$.

Testing (12) with $\bar{u}$ and taking the imaginary part yields

$$|\lambda|^2\|u\|_{L^2}^2 \leq \beta\int_{S^2}\bar{u}_n\underline{\Delta}u_n + \mathrm{const}\|f\|_{L^2}|\lambda|\|u\|_{L^2}$$
$$\leq \beta C_c\|u\|_{L^2}^{1/2}\|u\|_{H^2}^{3/2} + \mathrm{const}\|f\|_{L^2}^2 + \frac{1}{2}|\lambda|^2\|u\|_{L^2}^2 .$$

This yields the estimates for u. Equation (12) provides the estimates for η. □

Corollary 3.2. *$\mathcal{L}$ is a sectorial operator on $X^{r+2}, r \geq 0$. The spectrum $\sigma(\mathcal{L})$ is contained in a sector S_C, and with a constant $M > 0$, for every $\lambda \in \mathbb{C} \setminus S_C$,*

$$(\lambda - \mathcal{L})\begin{pmatrix} u \\ \eta \end{pmatrix} = \begin{pmatrix} f \\ g \end{pmatrix} \quad\Rightarrow\quad \left\|\begin{pmatrix} u \\ \eta \end{pmatrix}\right\|_{X^{r+2}} \leq \frac{M}{|\lambda|}\left\|\begin{pmatrix} f \\ g \end{pmatrix}\right\|_{X^{r+2}} .$$

Proof. Instead of (12),

$$\lambda u + \nu \Delta u - \nabla \mathcal{H}(2\nu S_u^n) - \frac{1}{\lambda} \nabla \mathcal{H}(\beta \underline{\Delta} u_n|_\partial) = f - \frac{1}{\lambda} \nabla \mathcal{H}(\beta \underline{\Delta} g|_\partial). \tag{13}$$

For $f = 0$ Theorem 3.1 yields

$$\begin{aligned} \|(u,\eta)\|_{X^{r+2}} + |\lambda| \, \|(u,\eta)\|_{X^r} &\leq \text{const} \frac{1}{|\lambda|} \|g\|_{H^{r+3-1/2}(S^2)} \\ &\leq \text{const} \frac{1}{|\lambda|} \|(0,g)\|_{X^{r+2}}. \qquad \square \end{aligned}$$

The preceding corollary verifies one of the assumptions in the Hopf bifurcation theorem of [5]; nevertheless, that theorem cannot be applied since it assumes the nonlinearity to be of lower order.

Using Theorem 3.1 we can solve the initial value problem with the ideas of semigroup theory. Unlike in other approaches, this will provide a time-t map for the nonlinear evolution system. In particular, this tool allows an elementary proof of a Hopf bifurcation theorem.

Definition 3.3. *Let $I := [0,T]$ be a fixed time interval, $T > 0$. We introduce the spaces*

$$Z := C^\alpha(I, X),$$

$$\tilde{Z}^{++} := C^{1,\alpha}(I, X) \cap C^\alpha(I, \tilde{X}^{++}).$$

For the regularity of the initial values we define

$$D_{\mathcal{L},\alpha} := \{x \in X | \quad \|x\|_{K,\alpha} := \|t \mapsto e^{-t\mathcal{L}} x\|_{Z^{++}} < \infty\}.$$

As in the semigroup theory, we choose a path of integration Γ in the complex plane containing S_C and write functions in $\mathcal{L}$ as integrals over Γ. Following the standard lines we get the special semigroup estimates

$$\|e^{-t\mathcal{L}}(f,0)\|_X + \|t\mathcal{L}e^{-t\mathcal{L}}(f,0)\|_X + \|(t\mathcal{L})^2 e^{-t\mathcal{L}}(f,0)\|_X \leq C\|(f,0)\|_X,$$
$$\|\mathcal{L}^{-1}e^{-t\mathcal{L}}(f,0)\|_{X^{++}} + \|te^{-t\mathcal{L}}(f,0)\|_{X^{++}} + \|t^2\mathcal{L}e^{-t\mathcal{L}}(f,0)\|_{X^{++}} \leq C\|(f,0)\|_X.$$

We can now prove a result of maximal regularity, i.e., solutions of $\partial_t x + \mathcal{L}x = F$ are in Z^{++} if F is in Z. The underlying idea is taken from [6], which proves a regularity result in the case when the resolvent of the generator has optimal regularity properties.

Theorem 3.4. *Let $F \in Z = C^\alpha(I, X)$ be of the form $F = \begin{pmatrix} f \\ 0 \end{pmatrix}$ and let $x_0 \in \tilde{X}^{++}$ satisfy the compatibility condition*

$$x_0 - \mathcal{L}^{-1}F(0) \in D_{\mathcal{L},\alpha}.$$

Then the equation

$$\partial_t x + \mathcal{L}x = \begin{pmatrix} f \\ 0 \end{pmatrix},$$
$$x(0) = x_0$$

has a unique solution $x \in \tilde{Z}^{++}$ *bounded by*

$$\|x\|_{Z^{++}} \leq C_1(T, M, \alpha)\{\|x_0\|_{X^{++}} + \|x_0 - \mathcal{L}^{-1}F(0)\|_{K,\alpha} + \|F\|_Z\}.$$

The compatibility condition is always satisfied:

$$\|x(t) - \mathcal{L}^{-1}F(t)\|_{K,\alpha} \leq C_2(T, M, \alpha) \cdot \{\|x_0\|_{X^{++}} + \|x_0 - \mathcal{L}^{-1}F(0)\|_{K,\alpha} + \|F\|_Z\}.$$

Proof. One proves that $x(.)$ is in $C^\alpha(I, X^{++})$ by decomposing $x(t)$ as

$$\begin{aligned} x(t) &= e^{-t\mathcal{L}}x_0 + \int_0^t e^{-(t-s)\mathcal{L}}F(s)ds \\ &= e^{-t\mathcal{L}}(x_0 - \mathcal{L}^{-1}F(0)) + e^{-t\mathcal{L}}\mathcal{L}^{-1}(F(0) - F(t)) \\ &\quad + \int_0^t e^{-(t-s)\mathcal{L}}(F(s) - F(t))ds + \mathcal{L}^{-1}F(t). \end{aligned}$$

The first term is in $C^\alpha(I, X^{++})$ by the compatibility condition; for the other terms we can use the special semigroup estimates. The compatibility condition in t is proved in a similar manner. □

We complete our analysis of the nonstationary equation with a remark about the size of the space $D_{\mathcal{L},\alpha}$. The preceding theorem shows that it contains all functions $(u(t), \eta(t))$ that can be reached with solutions starting from 0. It furthermore contains all smooth functions with appropriate boundary data. By writing $e^{-t\mathcal{L}}x_0 - x_0$ as a complex integral one proves, for $X = X^r$,

$$\{x_0 \in \tilde{X} | \mathcal{L}x_0 \in \tilde{X}^{r+4}\} \subset D_{\mathcal{L},\alpha}.$$

Concerning the time-dependent problem, we finally remark that the equations for the center of mass and rotations can now be solved with one additional integration.

4. The nonlinear liquid-drop equation. We now consider the full free boundary problem. We will need high orders of regularity and set $X = X^2, X^{++} = X^4$. In this section we do not impose the conditions of vanishing momentum and vanishing angular momentum and extend $\mathcal{L}^{-1}$ trivially.

The transformation of the equations (1)–(6) to a fixed domain is done in the standard way, as in Beale [2]. Using the operator $\mathcal{L}$, the transformed equations read

(14) $$\partial_t \begin{pmatrix} v \\ \eta \end{pmatrix} + \mathcal{L}\begin{pmatrix} v \\ \eta \end{pmatrix} = \begin{pmatrix} F(v,\eta) \\ 0 \end{pmatrix}$$

with the boundary condition

(15) $$\tau_i \cdot S_v \cdot n = G_i(v, \eta).$$

In the case $r \geq 1$,

$$F : X^{r+2} \to H^r(B^3)^3,\ F(0,0) = 0,\ DF \text{ exists, and } DF(0,0) = 0,$$

$$G : X^{r+2} \to H^{r+1-\frac{1}{2}}(S^2)^2,\ G(0,0) = 0,\ DG \text{ exists, and } DG(0,0) = 0.$$

We solve the time-dependent problem by means of an iteration. The boundary condition (15) is satisfied with the help of a function Φ.

Definition 4.1. *For functions g_i we define a vector field $\Phi(g) : B^3 \to \mathbb{R}^3$ which has the correct boundary values. With the help of the Stokes operator A we define $\Phi(g) : B^3 \to \mathbb{R}^3$ as the solution of*

$$\begin{aligned} A\Phi(g) &= 0 \textit{ in } B^3,\\ \Phi_n(g) &= 0 \textit{ on } S^2,\\ \tau_i \cdot S_{\Phi(g)} \cdot n &= g_i \textit{ on } S^2. \end{aligned}$$

We consider new variables, namely,

$$\tilde{x} = x - \begin{pmatrix} \Phi(G(x)) \\ 0 \end{pmatrix} \tag{16}$$

with inverse $x = \xi(\tilde{x})$. The boundary condition (15) is satisfied if we construct $\tilde{x} \in \tilde{X}$. In the $\tilde{x}$-variable the equations read

$$(\partial_t + \mathcal{L})\tilde{x} = \begin{pmatrix} \tilde{F}(\tilde{x}) \\ 0 \end{pmatrix} := \begin{pmatrix} F \circ \xi(\tilde{x}) \\ 0 \end{pmatrix} - (\partial_t + \mathcal{L}) \begin{pmatrix} \Phi \circ G \circ \xi(\tilde{x}) \\ 0 \end{pmatrix},$$

$$\tilde{x}(0) = \xi^{-1}(x_0) = x_0 - (\Phi \circ G(x_0), 0). \tag{17}$$

We remark that we have a vanishing second component in the right-hand side.

In the following, we impose the conditions that initial values satisfy (5) and that the formal time derivative at 0 has the appropriate regularity.

Definition 4.2. *x_0 satisfies the nonlinear compatibility conditions in X^{++} if*

$$\tilde{x}_0 := x_0 - \begin{pmatrix} \Phi(G(x_0)) \\ 0 \end{pmatrix} \in \tilde{X}^{++}, \tag{18}$$

$$z := \tilde{x}_0 - \mathcal{L}^{-1}(\tilde{F}(\tilde{x}_0), 0) \in D_{\mathcal{L},\alpha}. \tag{19}$$

Before we state the theorem of local existence and uniqueness, we investigate the compatibility conditions in more detail. The following proposition states that the permitted small initial values form a Banach manifold. We will use this fact to prove a Hopf bifurcation; the idea is taken from Koch [9].

Proposition 4.3. *There exists $U = B_\varepsilon(0) \subset D_{\mathcal{L},\alpha}$ and a mapping $\zeta : U \to X^{++}$ such that every $x_0 = \zeta(z)$ satisfies the nonlinear compatibility conditions with small norms. We denote the manifold $\zeta(U)$ by $\mathcal{M}$. ζ can be constructed with $D\zeta(0) = id$.*

Proof. We only have to invert the equation (19) with $x_0 \in \tilde{X}^{++}$. We use the contraction mapping principle for the map

$$\tilde{X}^{++} \ni \tilde{x}_0 \mapsto z + \mathcal{L}^{-1}(\tilde{F}(\tilde{x}_0), 0) \in \tilde{X}^{++}.$$

This yields the fixed point $\tilde{x}_0 = \tilde{\zeta}(z)$. We define $\zeta := \xi \circ \tilde{\zeta}$. □

Theorem 4.4. *According to small initial values x_0 satisfying the compatibility conditions, i.e.,*

$$x_0 = \zeta(z) \in \mathcal{M}, \quad \|z\|_{K,\alpha} \textit{ small},$$

there exists a unique small solution of the nonlinear liquid-drop equation in

$$Z^{++} = C^{1,\alpha}(I, X^2) \cap C^\alpha(I, X^4).$$

As a map on the Banach manifold $\mathcal{M}$, the flow is differentiable.

Proof. We construct the solution with the help of an iteration map $T : \tilde{Z}^{++} \to \tilde{Z}^{++}$. Let $(v, \sigma) \in \tilde{Z}^{++}$ be given. We define $\tilde{f} = \tilde{F}(v, \sigma)$ and solve

$$(\partial_t + \mathcal{L})\tilde{x} = (\tilde{f}, 0),$$

$$\tilde{x}(0) = x_0 - (\Phi \circ G(x_0), 0) = \tilde{\zeta}(z)$$

for $\tilde{x} \in \tilde{Z}^{++}$ with the help of Theorem 3.4. Because of $DF(0,0) = 0$ and $DG(0,0) = 0$, the solution operator is contracting in a small ball $B_\varepsilon(0) \subset Z^{++}$ and there exists a unique fixed point $\tilde{x}$. The function $\xi(\tilde{x})$ is a solution of the nonlinear equation.

We have to take care that in the iteration the right-hand side is contained in the function space. The condition of vanishing divergence can be assured with the usual projection. This yields an additional pressure that vanishes at the boundary.

It remains to show the differentiability of the flow $x_0 \mapsto x(t)$ on the manifold, i.e., the differentiability of

$$\begin{aligned}\Phi_t : \bar{x}_0 \mapsto & \zeta^{-1} x(t) = x(t) - \mathcal{L}^{-1}\tilde{F}(x(t)) \quad \text{with} \\ & \bar{x}_0 = \zeta^{-1}(x_0) = x_0 - \mathcal{L}^{-1}\tilde{F}(x_0) = \bar{x}_0.\end{aligned}$$

We omit the straightforward calculation, proving that the derivative of Φ_t can be written as

$$D\Phi_t : \bar{w}_0 \mapsto (id - \mathcal{L}^{-1} \circ D\tilde{F}|_{x(t)})w(t),$$

where $w(.)$ solves

$$(\partial_t + \mathcal{L})w(.) = D\tilde{F}|_{x(.)} \cdot w(.),$$

$$w(0) = w_0 = (id - \mathcal{L}^{-1} \circ D\tilde{F}|_{x(t)})^{-1}\bar{w}_0. \qquad \square$$

5. The spectrum of $\mathcal{L}$. The eigenvalues of $\mathcal{L}$ can be calculated explicitly for $\beta = 0$. We investigate the movement of the eigenvalues in the complex plane as $\beta \to \infty$. We prove the qualitative behavior that has been observed numerically (compare [3]).

We will make fundamental use of the fact that the liquid-drop problem has an $O(3)$ symmetry, in other words, that $\mathcal{L}$ is $O(3)$-equivariant. The group action will be denoted by $*$. We use the decomposition $X = \bigoplus X_n$, and we describe the spectrum on X_n for $n \geq 2$.

The nth eigenspace of Δ_B, Ψ_n has the standard basis $(\psi_{n,-n}, ..., \psi_{n,n})$ with

$$\psi_{n,k}(\theta, \varphi) = P_{n,k}(cos(\theta))e^{ik\varphi}.$$

The function $\Phi_0 := \psi_{n,0}$ has an isotropy subgroup Γ isomorphic to $O(2)$. Any function $\psi : S^2 \to \mathbb{R}$ can be Γ-symmetrized by

$$\bar{\psi}(\xi) := \fint_\Gamma \gamma * \psi(\xi) d\gamma.$$

The same can be done with functions $v : B^3 \to \mathbb{R}^3$.

In this and the following section we consider only eigenfunctions $(u, \eta) \in X_n$ with $\eta = \Phi_0$. This is no restriction since every eigenfunction can be projected and symmetrized such that the second component is a multiple of Φ_0.

We make constant use of the following observation: given an eigenvalue z of $\mathcal{L}$, we can construct the eigenfunction (u, Φ_0) as the solution of a Stokes problem.

Definition 5.1. *By A_N we denote the Stokes operator in the space of functions with vanishing normal component at the boundary. The eigenvalues of A_N are denoted by $\{\kappa_j\}_{j\in\mathbb{N}}$. The corresponding eigenfunctions with symmetry Γ are denoted by $\{u_j\}_{j\in\mathbb{N}}$; and the pressure, by $\{p_j\}_{j\in\mathbb{N}}$. Their signs are determined in* (24).

For $z \in \mathbb{C} \setminus \{\kappa_j | j \in \mathbb{N}\}$ we define $(\tilde{u}(z), \tilde{p}(z))$ as the unique solution of the system

$$\begin{aligned} z\tilde{u}(z) + \nu\Delta\tilde{u}(z) - \nabla\tilde{p}(z) &= 0,\\ \nabla\cdot\tilde{u}(z) &= 0,\\ \tau\cdot S_{\tilde{u}(z)}|_\partial\cdot n &= 0,\\ \tilde{u}_n(z)|_\partial &= -z\Phi_0. \end{aligned} \tag{20}$$

The solution has the same symmetry as Φ_0, i.e., Γ. In particular, $(\tilde{p}(z) - 2\nu S^n_{\tilde{u}(z)})|_\partial$ has the symmetry Γ and is a multiple of Φ_0. We define $\tilde{r}(z) \in \mathbb{C}$ by

$$(\tilde{p}(z) - 2\nu n\cdot S_{\tilde{u}(z)}\cdot n)|_\partial =: \tilde{r}(z)\Phi_0. \tag{21}$$

We remark that $z \in \mathbb{R}$ implies $\tilde{r}(z) \in \mathbb{R}$.

Any $z \in \mathbb{C} \setminus \{\kappa_j | j \in \mathbb{N}\}$ is an eigenvalue of $\mathcal{L}$ with eigenfunction $(\tilde{u}(z), \Phi_0)$ if it satisfies

$$\tilde{r}(z) = \underline{\Lambda_k}\beta. \tag{22}$$

We remark that the functions $\tilde{u}(z)$ and $\tilde{p}(z)$ can be computed explicitly in terms of Bessel functions; this can be used to analyze the function $\tilde{r}(z)$ numerically. In the following, $\|.\|$ denotes the L^2-norm.

Proposition 5.2 (properties of $\tilde{u}(z)$). *$\tilde{u}(z)$ is a differentiable family of functions for $z \in \mathbb{C} \setminus \{\kappa_j | j \in \mathbb{N}\}$. In κ_j,*

$$\|\tilde{u}(z)\| \to \infty \quad \textit{for} \quad z \to \kappa_j. \tag{23}$$

The rescaled functions approximate the Stokes eigenfunctions

$$u_j = \lim_{\mathbb{R}\ni z\nearrow\kappa_j} \frac{\tilde{u}(z)}{\|\tilde{u}(z)\|} = \lim_{\mathbb{R}\ni z\searrow\kappa_j} \frac{-\tilde{u}(z)}{\|\tilde{u}(z)\|}. \tag{24}$$

Furthermore,

$$\|\tilde{u}(z)\| \to \infty \quad \textit{for} \quad |z| \to \infty. \tag{25}$$

Proof. We define a family of functions $(u(z), p(z))$ which depends smoothly on z in a neighborhood of κ_j by solving

$$\begin{aligned} zu(z) + \nu\Delta u(z) - \nabla p(z) &= 0,\\ \nabla\cdot u &= 0,\\ \tau\cdot S_{u(z)}\cdot n|_\partial = 0, \quad (p(z) - 2\nu S^n_{u(z)})|_\partial &= \Phi_0. \end{aligned}$$

The solution is unique; therefore, $u(\kappa_j)$ is a multiple of u_j. With the notation

$$u_n(z)|_\partial =: s(z)\Phi_0,$$

$s(.)$ is continuous and $s(\kappa_j) = 0$. (23) is proved by observing

$$\tilde{u}(z) = \frac{-z}{s(z)} u(z).$$

(24) is proved by showing that the function $s(.)|_{\mathbb{R}}$ changes sign in κ_j.

Assume $\partial_z s(\kappa_j) = 0$. Then $v := \partial_z u(\kappa_j), q := \partial_z p(\kappa_j)$ satisfies the boundary conditions

$$\tau \cdot S_v|_\partial \cdot n = 0, \quad v_n|_\partial = 0, \quad (q - 2\nu S_v^n)|_\partial = 0.$$

Additionally,

$$\kappa_j v + \nu \Delta v - \nabla q = -u(\kappa_j).$$

Multiplying with $u(\kappa_j)$ and integrating yields $0 = -\|u(\kappa_j)\|^2$—a contradiction.

(25) can be proved directly. As the solution of the Stokes system (20), $\tilde{u}$ satisfies an estimate

$$\|\tilde{u}(z)\|_{H^2} \leq C_S \, \{|z| \, \|\tilde{u}(z)\|_{L^2} + |z| \, \|\Phi_0\|_{H^{3/2}(S^2)}\}.$$

We now use $\tilde{u}_n(z)|_\partial = -z\Phi_0$, a trace formula, and an interpolation to calculate

$$\begin{aligned} |z|^2 \|\Phi_0\|^2_{L^2(S^2)} &= \|\tilde{u}_n(z)|_\partial\|^2_{L^2(S^2)} \\ &\leq C_T \|\tilde{u}(z)\|^2_{H^1} \\ &\leq C_T C_c \|\tilde{u}(z)\|_{L^2} \|\tilde{u}(z)\|_{H^2} \\ &\leq C_T C_c C_S \|\tilde{u}(z)\|_{L^2} \{|z| \|\tilde{u}(z)\|_{L^2} + |z| \|\Phi_0\|_{H^{3/2}(S^2)}\}. \end{aligned}$$

This yields $\|\tilde{u}(z)\|^2_{L^2} \geq \text{const} \cdot |z|$, and the proposition is proved. □

PROPOSITION 5.3 (properties of $\tilde{r}(z)$). *The function $\tilde{r}(z)$ satisfies*

$$\begin{aligned} &\tilde{r}(z) \to 0 \text{ for } \mathbb{R} \ni z \searrow 0, \\ &\tilde{r}(z) \to -\infty \text{ for } \mathbb{R} \ni z \nearrow \kappa_j, \\ &\tilde{r}(z) \to +\infty \text{ for } \mathbb{R} \ni z \searrow \kappa_j. \end{aligned} \tag{26}$$

$\tilde{r}(z)$ is positive for small $z > 0$,

$$\partial_z \tilde{r}(0) > 0. \tag{27}$$

Between κ_j and κ_{j+1}, there is at most one turning point. Critical values of $\tilde{r}(z)$ are positive.

Proof. The assertion of (26) for $z \to 0$ is trivial. u_j satisfies

$$u_j = \lim_{z \nearrow \kappa_j} \frac{\tilde{u}(z)}{\|\tilde{u}(z)\|}.$$

We test the eigenvalue equation of u_j with $v := \frac{\tilde{u}(\kappa_j - \varepsilon)}{\|\tilde{u}(\kappa_j - \varepsilon)\|}$ to get

$$\begin{aligned} 0 &= \langle (\kappa_j - A) u_j, v \rangle \\ &= \langle u_j, (\kappa_j - A) v \rangle - \int_S (p_j - 2\nu S^n_{u_j})|_\partial v_n|_\partial \\ &= \varepsilon \, \langle u_j, v \rangle - \int_S (p_j - 2\nu S^n_{u_j})|_\partial v_n|_\partial. \end{aligned}$$

By (24) the first term is positive for small $|\varepsilon|$; the second has the sign of $\tilde{r}(\kappa_j - |\varepsilon|)$.

To prove (27) we consider the functions $v := \partial_z \tilde{u}(0)$, $q = \partial_z \tilde{p}(0)$. They solve

$$\nu \Delta v - \nabla q = 0,$$

$$\tau \cdot S_v|_\partial \cdot n = 0, \quad v_n|_\partial = -\Phi_0, \quad (q - 2\nu S_v^n)|_\partial = \partial_z \tilde{r}(0)\Phi_0.$$

Multiplying this equation with v yields

$$-\int_{B^3} |S_v|^2 + \partial_z \tilde{r}(0)\|\Phi_0\|^2 = 0,$$

which proves (27).

We claim that turning points of $\tilde{r}(z), z \in \mathbb{R}$, are the critical points of $\|\tilde{u}(z)\|$, $z \in \mathbb{R}$. We consider the functions $v(z) := \partial_z \tilde{u}(z)$, $q(z) := \partial_z \tilde{p}(z)$, which solve

$$\begin{aligned} &\tilde{u}(z) + z v(z) + \nu \Delta v(z) - \nabla q(z) = 0, \\ &\tau \cdot S_{v(z)}|_\partial \cdot n = 0, \quad v_n(z)|_\partial = -\Phi_0, \\ &(q(z) - 2\nu S^n_{v(z)})|_\partial = \partial_z \tilde{r}(z)\Phi_0. \end{aligned} \tag{28}$$

Multiplying (28) by $\tilde{u}(z)$ yields

$$\|\tilde{u}(z)\|^2 + z\partial_z \tilde{r}(z)\|\Phi_0\|^2 - \tilde{r}(z)\|\Phi_0\|^2 = 0, \tag{29}$$

and differentiating gives

$$\partial_z \|\tilde{u}(z)\|^2 + z\partial_z^2 \tilde{r}(z)\|\Phi_0\|^2 = 0. \tag{30}$$

Consider $w := \partial_z^2 \tilde{u}(z_0)$, $r := \partial_z^2 \tilde{p}(z_0)$, which solve

$$\begin{aligned} &2v + \kappa_j w + \nu \Delta w - \nabla r = 0, \\ &\tau \cdot S_w|_\partial \cdot n = 0, \quad w_n|_\partial = 0, \\ &(r - 2\nu S^n_w)|_\partial = \partial_z^2 \tilde{r}(z_0)\Phi_0. \end{aligned} \tag{31}$$

Multiplying (31) with v yields

$$2\|v\|^2 - \langle \tilde{u}(z_0), w\rangle + \partial_z^2 \tilde{r}(z_0)\|\Phi_0\|^2 = 0. \tag{32}$$

Assume there is more than one point with $\partial_z^2 \tilde{r} = 0$. By (30) they coincide with critical points of $\|\tilde{u}(z)\|$. At least one of them satisfies $\partial_z^2 \|\tilde{u}(z)\|^2 \leq 0$. This contradicts equation (32), which implies

$$\partial_z^2 \|\tilde{u}(z)\|^2 = 2\,\langle \tilde{u}(z_0), w\rangle + 2\|v\|^2 = 6\|v\|^2 > 0.$$

The last assertion of the proposition follows from (29). □

We denote the Stokes operator with boundary condition $(p - 2\nu S^n_u)|_\partial = 0$ by A_S and the eigenvalues of A_S by $\{\rho_j\}_{j\in\mathbb{N}}$.

THEOREM 5.4 (the spectrum of $\mathcal{L}$ in dependence of β). *It holds that*

$$\rho_0 < \kappa_0 < \rho_1 < \cdots < \rho_j < \kappa_j < \cdots .$$

For $\beta = 0$ all the eigenvalues of $\mathcal{L}_\beta$ are real. Denoting them by $(\mu_j)_{j\in\mathbb{N}}$,

$$\mu_0 = 0, \quad \mu_{j+1} = \rho_j.$$

For small β the eigenvalues stay real. With increasing β the first eigenvalue moves to the right while the other eigenvalues move to the left. For some $\beta_0 > 0$ the first two eigenvalues merge and leave the real axis.

Given a radius k there exists $\beta_k > 0$ such that for $\beta > \beta_k$ the following is true. The norm of nonreal eigenvalues of $\mathcal{L}_\beta$ is larger than k. Every interval $[\kappa_j, \kappa_{j+1}]$ with $\kappa_{j+1} < k$ contains one and only one eigenvalue $\mu(\beta)$ of $\mathcal{L}_\beta$. This eigenvalue satisfies

$$\mu(\beta) \searrow \kappa_j \textit{ for } \beta \to \infty.$$

Proof. The numbers $\rho_j, j \in \mathbb{N}$ are the zeros of $\tilde{r}(z)$. The shape of $\tilde{r}$ implies the assertion on the position of the Stokes eigenvalues. For $\beta = 0$ we can compute a complete set of eigenfunctions in X_k: $\mu_0 = 0$ with eigenfunction $(0, \Phi_0)$ and $\mu_{j+1} = \rho_j$ with eigenfunctions $(\tilde{u}(\rho_j), \Phi_0)$. By the shape of $\tilde{r}(z)$ and (22) the first two eigenvalues meet at the maximum of $\tilde{r}$ and must leave the real axis. Eigenfunctions $(u(\beta), \Phi_0)$ of $\mathcal{L}_\beta$ with nonreal eigenvalues $\mu(\beta)$ satisfy the energy equality

$$\|u\|_{L^2} = \beta \underline{\Lambda_k} \|\Phi_0\|^2_{L^2(S^2)}.$$

Therefore, nonreal eigenvalues cannot stay bounded for $\beta \to \infty$. The shape of $\tilde{r}$ together with (22) prescribes the movement of the real eigenvalues as stated. The theorem is proved. □

REMARK 5.5. *Eigenvalues leave the real axis with an infinite speed. The qualitative shape of $\tilde{r}_\nu(z)$ is independent of the viscosity ν:*

$$\tilde{r}_{\alpha\nu}(\alpha z) = \alpha^2 \tilde{r}_\nu(z).$$

Proof. Eigenvalues leave the real axis in a critical point z_0 of $\tilde{r}$, an analytic function in $\mathbb{C} \setminus \{\kappa_j | j \in \mathbb{N}\}$. It holds that $\frac{\partial \mathrm{Re}(\tilde{r}(z_0))}{\partial \mathrm{Im} z} = 0$, and (22) implies

$$\underline{\Lambda_k} = \frac{\partial \mathrm{Re}(\tilde{r}(z(\beta)))}{\partial \beta} = \frac{\partial \mathrm{Re}(\tilde{r}(z))}{\partial z} \frac{\partial z}{\partial \beta}.$$

The speed of $z(\beta)$ gets infinite.

The statement on the shape of $\tilde{r}_\nu(z)$ is proved by multiplying the equation for $\tilde{u}$ by α^2:

$$\begin{aligned} (\alpha z)(\alpha u) + (\alpha\nu)\Delta(\alpha u) - \nabla(\alpha^2 p) &= 0, \\ (\alpha u)_n|_\partial &= -(\alpha z)\Phi_0, \\ (\alpha^2 p - 2(\alpha\nu) S^n_{\alpha u})|_\partial &= \alpha^2 \tilde{r}_\nu(z). \end{aligned}$$

By definition of $\tilde{r}$ the last line coincides with $\tilde{r}_{\alpha\nu}(\alpha z)$. □

6. A Hopf bifurcation for liquid drops. In this section we show how our analysis can be used to study the effect of an exterior force. In the previous section, we achieved a complete picture of the spectrum of $\mathcal{L}$. On a fixed subspace X_k, the spectrum consists of a countable number of eigenvalues that correspond to eigenvalues of the Stokes operator and two additional eigenvalues (interfacial eigenvalues) that are real for small surface tension and nonreal for large surface tension.

Starting from this situation, a Hopf bifurcation can occur if an exterior force moves the additional eigenvalues across the imaginary axis. We prove this behavior in the case of a force that preserves symmetry. A more physical force will not preserve symmetry; we study that case in section 7.

In this section we assume that the force acts on the surface and that its strength depends linearly on the position and the speed of the boundary. The symmetric force has only two parts; the one proportional to η acts as the surface tension, and we restrict our analysis to a force proportional to $\partial_t \eta(x,t) = u_n|_\partial$. We introduce the real number λ for its strength and have the boundary condition

$$(p - \nu S_u^n)|_\partial + \beta \underline{\Delta} \eta = \lambda u_n|_\partial.$$

We write the linear equations again as

$$\frac{d}{dt} x + \mathcal{L}_\lambda x = 0, \qquad x \in \tilde{X},$$

now with the operator

$$\mathcal{L}_\lambda \begin{pmatrix} u \\ \eta \end{pmatrix} := \begin{pmatrix} -\nu \Delta u + \nabla \mathcal{H}(2\nu S_u^n) - \nabla \mathcal{H}(\beta \underline{\Delta} \eta) - \nabla \mathcal{H}(\lambda u_n|_\partial) \\ -u_n|_\partial \end{pmatrix}.$$

This operator is a lower order perturbation of $\mathcal{L}$; its spectrum consists of eigenvalues and we have the local existence results as before. The following analogue of Lemma 2.4 holds.

LEMMA 6.1. *Let $(u, \eta) \in \tilde{X}^2$ be an eigenvector of $\mathcal{L}_\lambda$ with eigenvalue μ. Then*

$$\begin{aligned} \operatorname{Re}(\mu) \|(u,\eta)\|_E^2 &= 2\nu \left(\int_B |S_u|^2 \right) - \lambda |\mu|^2 \|\eta\|^2_{L^2(S^2)}, \\ \operatorname{Im}(\mu) \|(u,\eta)\|_E^2 &= 2\beta \operatorname{Im} \left(\int_S u_n|_\partial \underline{\Delta} \overline{\eta} \right). \end{aligned} \tag{33}$$

In the case of nonreal eigenvalues, $\operatorname{Im}(\mu) \neq 0$*, the following energy equality holds:*

$$\|u\|_E^2 = \|\eta\|_E^2 = \frac{1}{2} \|(u,\eta)\|_E^2. \tag{34}$$

Proof. This lemma is proved as Lemma 2.4. □

We again want to get a global picture of the position of eigenvalues, now in dependence of the parameter λ. There are two important differences from the previous section:

— the eigenvalues may have a negative real part and

— the energy equality for eigenvectors implies that nonreal eigenvalues are bounded independent of λ.

For any $z \in \mathbb{R}_+ \setminus \{\kappa_j | j \in \mathbb{N}\}$ we have defined the function $\tilde{u}(z)$. The pair $(\tilde{u}(z), \Phi_0)$ is an eigenfunction of $\mathcal{L}_{\tilde{\lambda}}$, with $\tilde{\lambda}(z)$ defined by

$$\tilde{r}(z)\Phi_0 = (\tilde{p}(z) - 2\nu S^n_{\tilde{u}(z)})|_\partial = \beta \underline{\Lambda_k} \Phi_0 + \tilde{\lambda}(z) z \Phi_0. \tag{35}$$

PROPOSITION 6.2 (properties of $\tilde{\lambda}(z)$). *There exists a constant $\lambda_0 > 0$ such that*

$$|\lambda| > \lambda_0 \Rightarrow \textit{all eigenvalues of } \mathcal{L}_\lambda \textit{are real}, \tag{36}$$

$$\tilde{\lambda}(z) \to -\infty \ for \ \mathbb{R} \ni z \to 0, \tag{37}$$

$$\tilde{\lambda}(z) \to -\infty \ for \ \mathbb{R} \ni z \nearrow \kappa_j, \tag{38}$$

$$\tilde{\lambda}(z) \to +\infty \ for \ \mathbb{R} \ni z \searrow \kappa_j. \tag{39}$$

Proof. Equation (33) implies, for nonreal eigenvalues, $|\lambda| \to \infty \Rightarrow \int |S_u|^2 \to \infty$ or $|\mu| \to \infty$ or $|\mu| \to 0$. Therefore, $|\mu| \to \infty$ or $|\mu| \to 0$. (25) implies $\|u\| \to \infty$ or $\|u\| \to 0$. This contradicts (34). (37)–(39) follow from $\tilde{\lambda}(z) = \frac{1}{z}(\tilde{r}(z) - \beta \underline{\Lambda_k})$. □

THEOREM 6.3 (the spectrum of $\mathcal{L}$ in dependence of λ). *For $\lambda < -\lambda_0$, all eigenvalues of $\mathcal{L}_\lambda$ are real. Denoting the ordered sequence of them by $(\mu_j(\lambda))_{j\in\mathbb{N}}$, they satisfy*

$$\begin{aligned}
&0 < \mu_0(\lambda) < \mu_1(\lambda) < \kappa_0, \qquad \kappa_j < \mu_{j+2} < \kappa_{j+1},\\
&\mu_0(\lambda) \searrow 0 \textit{ for } \lambda \to -\infty \quad \textit{and}\\
&\mu_{j+2}(\lambda) \nearrow \kappa_{j+1} \textit{ for } \lambda \to -\infty.
\end{aligned}$$

For $\lambda > \lambda_0$ the ordered eigenvalues satisfy

$$\begin{aligned}
&\mu_0(\lambda), \mu_1(\lambda) < 0, \qquad \kappa_j < \mu_{j+2} < \kappa_{j+1},\\
&\mu_{j+2}(\lambda) \searrow \kappa_j \textit{ for } \lambda \to \infty.
\end{aligned}$$

In a point $\bar{\lambda} \in [-\lambda_0, \lambda_0]$, a pair of conjugate complex eigenvalues crosses the imaginary axis transversally. The imaginary axis can be crossed only from right to left.

Proof. Proposition 6.2 implies the assertion for the position of positive real eigenvalues for $|\lambda| \to \infty$. We have to prove the existence of the pair of negative eigenvalues. We do this by counting eigenvalues. (25), together with the energy equality (34), implies that nonreal eigenvalues are bounded independent of λ. Let κ_J be larger than this bound. We restrict ourselves to the $J+2$ eigenvalues of $\mathcal{L}_{-\lambda_0}$ with norm smaller than κ_J.

For $\lambda \to +\infty$ (and, in particular, $\lambda > \lambda_0$) there are J eigenvalues with positive real part and norm less than κ_J. The two remaining eigenvalues must be negative.

To count the eigenvalues, we used the fact that geometric and algebraic multiplicity coincide for $|\lambda| \to \infty$. We now prove this fact.

Assumption. There exist normed functions (u, η), (v, σ) satisfying

$$\mathcal{L}\begin{pmatrix} u \\ \eta \end{pmatrix} = \mu \begin{pmatrix} u \\ \eta \end{pmatrix}, \ \mathcal{L}\begin{pmatrix} v \\ \sigma \end{pmatrix} = \mu \begin{pmatrix} v \\ \sigma \end{pmatrix} + \alpha \begin{pmatrix} u \\ \eta \end{pmatrix}, \quad v \perp u.$$

Let p denote the pressure function corresponding to u. We know $(u, \eta) \to (u_j, 0)$ for $\lambda \to \infty$. We define $(v_0, \sigma_0) = \lim_{\lambda\to\infty}(v, \sigma)$. It holds that

$$-\nu\Delta v + \nabla\mathcal{H}(2\nu S_v^n) - \nabla\mathcal{H}(\beta\underline{\Delta}\sigma + \lambda v_n|_\partial) = \mu v + \alpha u, \tag{40}$$

$$-v_n = \mu\sigma + \alpha\eta. \tag{41}$$

To prove that α is bounded we multiply (40) by u_j and integrate to get

$$\begin{aligned}
\alpha \langle u, u_j\rangle &= \langle -\mu v - \nu\Delta v + \nabla\mathcal{H}(2\nu S_v^n) - \nabla\mathcal{H}(\beta\underline{\Delta}\sigma + \lambda v_n|_\partial), u_j\rangle\\
&= \langle v, (A_N - \mu)u_j\rangle + \int_{S^2} v_n(p_j - 2\nu S_{u_j}^n)\\
&= (\kappa_j - \mu)\langle v, u_j\rangle + \int_{S^2} v_n(p_j - 2\nu S_{u_j}^n).
\end{aligned}$$

Using $\eta \to 0$, this implies that α is bounded. Equation (40) implies $(v_0)_n = 0$, and we get, from equation (41), $\sigma_0 = 0$. With $\alpha_0 := \lim \alpha$,

$$(A_N - \kappa_j)v_0 = \alpha_0 u_j,$$

a contradiction to the simplicity of the Stokes eigenvalues.

We now derive explicit equations for the velocity of eigenvalues. We consider a differentiable family of eigenvalues $\mu(\lambda) \in \mathbb{C} \setminus \mathbb{R}$ with eigenfunctions $(u(\lambda), \Phi_0)$.

We first need an equation for $\mathrm{Im}\langle u, \partial_\lambda u\rangle$. We multiply the eigenvalue equation by $\partial_\lambda u$ to get, with the help of $\partial_\lambda u_n|_\partial = -\partial_\lambda \mu(\lambda)\Phi_0$,

$$\langle \mu(\lambda)u(\lambda), \partial_\lambda u(\lambda)\rangle = 2\nu \int_{B^3} S_u : S_{\partial_\lambda \bar{u}} - (\beta \underline{\Lambda_k} + \lambda\mu(\lambda))\partial_\lambda \bar{\mu}(\lambda)\|\Phi_0\|_{L^2}^2.$$

Taking the real part and using Lemma 6.1 yields

$$\begin{aligned}
\mathrm{Re}\,\langle \mu u, \partial_\lambda u\rangle &= \frac{1}{2}\partial_\lambda\left(2\nu\int_{B^3} S_{u(\lambda)} : S_{\bar{u}(\lambda)}\right)\\
&\quad -\beta\underline{\Lambda_k}\|\Phi_0\|_{L^2}^2 \mathrm{Re}(\partial_\lambda \mu(\lambda)) - \lambda\frac{1}{2}\partial_\lambda|\mu(\lambda)|^2\|\Phi_0\|_{L^2}^2\\
&= \frac{1}{2}\partial_\lambda\{\mathrm{Re}(\mu(\lambda))2\beta\underline{\Lambda_k}\|\Phi_0\|_{L^2}^2 + \lambda|\mu(\lambda)|^2\|\Phi_0\|_{L^2}^2\}\\
&\quad -\beta\underline{\Lambda_k}\|\Phi_0\|_{L^2}^2 \mathrm{Re}(\partial_\lambda \mu(\lambda)) - \lambda\frac{1}{2}\partial_\lambda|\mu(\lambda)|^2\|\Phi_0\|_{L^2}^2\\
&= \frac{1}{2}|\mu(\lambda)|^2\|\Phi_0\|_{L^2}^2.
\end{aligned}$$

Using $\mathrm{Re}\,\langle u, \partial_\lambda u\rangle = 0$, we arrive at

$$\mathrm{Im}\,\langle u, \partial_\lambda u\rangle\,\mathrm{Im}(\mu) = -\frac{1}{2}|\mu(\lambda)|^2\|\Phi_0\|_{L^2}^2. \tag{42}$$

Now we differentiate the eigenvalue equation with respect to λ, multiply with $\partial_\lambda u$, and take the imaginary part:

$$\begin{aligned}
0 &= \mathrm{Im}\,\langle \partial_\lambda(-\mu u), \partial_\lambda u\rangle + \mathrm{Im}\,\langle -\nu\Delta\partial_\lambda u + \nabla\partial_\lambda p, \partial_\lambda u\rangle\\
&= -\mathrm{Re}(\partial_\lambda\mu)\mathrm{Im}\,\langle u, \partial_\lambda u\rangle - \mathrm{Im}(\mu)\|\partial_\lambda u\|^2 - \mathrm{Im}\{\partial_\lambda(\beta\underline{\Lambda_k} + \lambda\mu)\partial_\lambda\bar{\mu}\}\|\Phi_0\|_{L^2}^2.
\end{aligned}$$

Multiplying with $2\mathrm{Im}(\mu)$ and inserting (42) yields

$$\mathrm{Re}(\partial_\lambda\mu)|\mu|^2\|\Phi_0\|_{L^2}^2 - 2|\mathrm{Im}(\mu)|^2\|\partial_\lambda u\|^2 = 2\mathrm{Im}(\mu)\mathrm{Im}(\mu\partial_\lambda\bar{\mu})\|\Phi_0\|_{L^2}^2.$$

On the imaginary axis, $\mathrm{Re}(\mu) = 0$, this formula simplifies to

$$-\mathrm{Re}(\partial_\lambda\mu)\|\Phi_0\|_{L^2}^2 = 2\|\partial_\lambda u\|^2.$$

It proves transversality and the direction of the crossing. □

The above results lead to a Hopf bifurcation. Due to the restricted regularity, one has to avoid the implicit function theorem in the proof and use degree theory. It allows us to replace the assumption of transversality by the following. The eigenvalue cannot follow the imaginary axis, i.e.,

$$\mu(\bar{\lambda}) \in i\mathbb{R} \Rightarrow \forall\varepsilon > 0 : \mathrm{Re}(\mu(\bar{\lambda} - \varepsilon)) > 0, \qquad \mathrm{Re}(\mu(\bar{\lambda} + \varepsilon)) < 0. \tag{43}$$

Theorem 6.4. *For fixed wave number k_0, there exists a critical value for λ such that a pair of eigenvalues $\mu^\pm$ of $\mathcal{L}_\lambda$ are purely imaginary. Assume that there is no resonance, i.e., the eigenvalues for different k are no integer multiples of μ^+. Then* *a Hopf bifurcation occurs and there exists a continuous branch of $O(2)$-symmetric, periodic solutions of the nonlinear equations.*

Proof. In Proposition 4.3 we parametrized small initial values for the nonlinear equation over $U = B_\varepsilon(0) \subset D_{\mathcal{L},\alpha}$ with a mapping $\zeta : U \to X^4$. We want to restrict ourselves to functions of the prescribed symmetry group $\Gamma \simeq O(2)$. We parametrize small compatible initial values with symmetry Γ over $V := U \cap Fix(\Gamma)$ with a map $\zeta_\Gamma : V \to Fix(\Gamma) \subset X^4$ and consider the flow

$$\Phi : V \times \mathbb{R} \times \mathbb{R} \ni (z, t, \lambda) \mapsto \zeta_\Gamma^{-1} x(t) - z \in V.$$

Here $x(t)$ is the solution of the nonlinear equation with parameter λ to the initial value $\zeta_\Gamma(z)$. We used the fact that the nonlinear equation preserves the Γ-symmetry. We want to solve $\Phi(z, t, \lambda) = z$ with nontrivial z. The linearization of Φ in $(0, \bar{t} = \frac{2\pi}{\mathrm{Im}(\mu_0(\bar{\lambda}))}, \bar{\lambda})$ is

$$D_z\Phi : V \to V, \quad z \mapsto e^{-\mathcal{L}_{\bar{\lambda}}\bar{t}} z,$$

and the kernel of $D_z\Phi(., \bar{t}, \bar{\lambda}) - id$ is two-dimensional. One can perform a Liapunov–Schmidt reduction and solve the bifurcation equation with degree theory. □

7. Water waves generated by wind.

We analyze a simple two-dimensional model for a wind-generated instability of a water surface. The wind changes the pressure along the surface. We assume that the pressure profile follows the sinusoidal profile of the surface and is shifted by an angle ϕ. Measurements of Elliott [7] justify this assumption and give the value of 135° for ϕ.

We mention the two major simplifications of this model: it neglects the tangential stress, and we linearize about the zero-solution instead of assuming an underlying shear flow. The method could be extended, but the desirable further development would be a two-phase model to explore the dependence of the force of the wave number. For qualitative studies we refer to [12] and references therein.

With a surface elevation η we write the additional pressure as $e^{i\phi}\beta^*\eta$. This is equivalent to saying that we treat the complex surface tension $\beta + e^{i\phi}\beta^*\Lambda_k^{-1}$. We fix the direction of the wind by setting $0 < \phi < \pi$. The eigenvalue equations are

$$\lambda u + \nu\Delta u - \nabla p = 0, \tag{44}$$

$$\nabla \cdot u = 0, \tag{45}$$

$$u_n|_\partial = -\lambda\eta, \tag{46}$$

$$(p - 2\nu S_u^n)|_\partial = -\beta\underline{\Delta}\eta + e^{i\phi}\beta^*\eta. \tag{47}$$

Every eigenspace is (at least) two-dimensional due to the equivariance under translations. Choosing $\eta(x) = \Phi_0(x) = e^{ikx}$, we select one of the eigenfunctions. On the other hand, a positive β^* destroys the symmetry of reflections $x \mapsto -x$. The conjugate complex of an eigenvalue need not be an eigenvalue for the same η.

Lemma 7.1. *For positive β^* there is precisely one eigenvalue with positive imaginary part. The other eigenvalues are below the real axis and have a positive real part.*

Proof. As in section 5 we can write the eigenvalue equation as

$$\tilde{r}(z) = \underline{\Lambda_k}\beta + e^{i\phi}\beta^*. \tag{48}$$

The proof of the lemma is based on the study of $\tilde{r}$ in Proposition 5.3.

For $\beta^* = 0$ we consider two cases.

Case 1. The surface tension is above its critical value. Then there are two nonreal eigenvalues with multiplicity 2. Due to the reflection symmetry, they can both be represented with an eigenfunction with $\eta(x) = \Phi_0(x)$.

The function $\tilde{r} : \mathbb{R} \to \mathbb{R}$ was shown to have a negative derivative in the real eigenvalues. Since the function $\tilde{r}$ is analytic in a neighborhood of the eigenvalue and β^* acts like an imaginary component of the surface tension, we conclude that for small, positive β^* the eigenvalues get a negative imaginary part.

Case 2. The surface tension is below its critical value. Then the derivative of $\tilde{r} : \mathbb{R} \to \mathbb{R}$ is positive in the first eigenvalue, negative in all other eigenvalues. The same reasoning as before proves that for small positive β^* the first eigenvalue gets a positive imaginary part, and the other eigenvalues get a negative imaginary part.

In both cases a return to the real axis is not possible for finite β^* since real eigenvalues correspond to real surface tension or $\beta^* = 0$.

We derive an equation for λ by testing the eigenvalue equation with (u, η) in the energy space and using the integration by parts:

$$\begin{aligned}\int (-\nu \Delta u + \nabla p)\bar{u} &= 2\nu \int |S_u|^2 + \int_\partial (p - 2\nu S_u^n)\bar{u}_n \\ &= 2\nu \int |S_u|^2 - \int_\partial (-\beta \underline{\Delta} \eta + e^{i\phi}\beta^* \eta)\bar{\lambda}\bar{\eta}.\end{aligned}$$

In analogy to Lemma 2.4, we get

$$\lambda\{\|u\|^2 + \|\eta\|_E^2\} = 2\nu \int |S_u|^2 + 2i\mathrm{Im}\lambda \|\eta\|_E^2 - e^{i\phi}\beta^*\bar{\lambda}\|\eta\|_{L^2}^2. \tag{49}$$

Taking the real part of this equation, we get

$$\mathrm{Re}\lambda = 0 \Rightarrow 0 < \mathrm{Re}(e^{-i\phi}\lambda) \Rightarrow \mathrm{Im}(\lambda) > 0.$$

This proves that the eigenvalues with negative imaginary part cannot cross the imaginary axis. □

The only eigenvalue that can create an instability is the one with positive imaginary part, further denoted by λ^+. We turn to an analysis of this eigenvalue.

We know that for eigenvalues λ in a compact subset of $\mathbb{C} - \{\kappa_j | j \in \mathbb{N}\}$ the corresponding values of $\beta^* = e^{-i\phi}(\tilde{r}(\lambda) - \Lambda_k \beta)$ are finite. Therefore, for $\beta^* \to \infty$,

$$\begin{aligned}\exists j :&\quad \lambda^+(\beta^*) \to \kappa_j \\ \text{or}&\quad |\lambda^+(\beta^*)| \to \infty.\end{aligned}$$

We take the imaginary part of (49) and get

$$\mathrm{Im}\lambda^+\{\|u\|^2 - \|\eta\|_E^2\} = -\beta^*\mathrm{Im}(e^{i\phi}\bar{\lambda}^+)\|\eta\|_{L^2}^2. \tag{50}$$

Assume that $\mathrm{Im}(\lambda^+)$ stays bounded. Then we know $|\mathrm{Re}(\lambda^+)| \to \infty$. The left-hand side of (50) is bounded from below. We conclude that $\mathrm{Re}(\lambda^+) \to -\infty$.

The eigenvalue must cross the imaginary axis, by the following lemma.

Lemma 7.2. *An eigenvalue* λ *with* $|\mathrm{Im}\lambda| \to \infty$ *or* $\mathrm{Re}(\lambda) \to -\infty$ *as* $\beta^* \to \infty$ *satisfies*

$$\arg(\lambda) \to \frac{\phi \pm \pi}{2} \quad \textit{for } \beta^* \to \infty.$$

Proof. To prove this proposition we use the explicit formulas for eigenfunctions. We introduce

$$v = u - \frac{1}{\lambda}\nabla p, \tag{51}$$

which solves $\lambda v + \nu\Delta v = 0$. With constants $A = (A_1, A_2), B = (B_1, B_2), P$, and Q we write

$$\begin{aligned} p(x,y) &= Pe^{ky}e^{ikx} + Qe^{-ky}e^{ikx},\\ v(x,y) &= Ae^{\mu y}e^{ikx} + Be^{-\mu y}e^{ikx},\\ \mu^2 &= k^2 - \frac{\lambda}{\nu}, \end{aligned}$$

where we take μ as the root with positive real part, $\mathrm{Re}\mu \to \infty$.

The incompressibility reads

$$ikA_1 + \mu A_2 = 0, \qquad ikB_1 - \mu B_2 = 0. \tag{52}$$

We get an equation for P and Q if we construct

$$\begin{aligned} 0 &= iku_1(-h) + \mu u_2(-h)\\ &= \frac{k^2}{\lambda}(Pe^{-kh} + Qe^{kh}) - \frac{k\mu}{\lambda}(Pe^{-kh} - Qe^{kh}), \end{aligned}$$

which proves that $|Q/P|$ is bounded, and then

$$\left(1 - \frac{Q}{P}e^{2kh}\right) = \frac{1}{P}(P - Qe^{2kh}) \to 0. \tag{53}$$

Using $u(x,-h) = 0$, this implies

$$\frac{B_1}{|A_1| + |P|} \to 0 \qquad \text{and} \qquad \frac{B_2}{|A_2| + |P|} \to 0 \qquad \text{exponentially in } \mu.$$

We use the boundary condition of vanishing tangential stress,

$$0 = A_1\mu - B_1\mu + A_2 ik + B_2 ik + \frac{2ik^2}{\lambda}(P - Q),$$

to conclude that

$$\frac{A_1\mu\lambda}{ik^2(P - Q)} \to -1. \tag{54}$$

The boundary condition for the normal stress reads

$$0 = (P + Q) - 2\nu(A_2 - B_2)\mu - \frac{2\nu}{\lambda}k^2(P + Q) - \beta\Lambda_k - e^{i\phi}\beta^*.$$

Collecting the dominant terms yields

$$\frac{P + Q}{\beta^*} \to e^{i\phi}. \tag{55}$$

The kinematic boundary equation is

$$A_2 + B_2 + \frac{k}{\lambda}(P - Q) = -\lambda.$$

Using (54), this implies

$$\frac{k}{\lambda^2}(P - Q) \to -1. \tag{56}$$

Combining (53), (55), and (56) gives

$$\frac{\lambda^2}{e^{i\phi}\beta^*} \to -k\frac{1 - e^{-2kh}}{1 + e^{-2kh}}. \qquad \square \tag{57}$$

Remark 7.3. *The basic idea in the above proof was to show that the dominating term in the stress equation is the pressure. In this sense the following formal calculation for infinite height and vanishing viscosity is justified:*

$$\Delta p = 0, \quad p|_\partial = e^{i\phi}\beta^*\eta, \quad u = \frac{1}{\lambda}\nabla p,$$

$$-\lambda\eta = u_n|_\partial = \frac{1}{\lambda}\partial_n p = \frac{k}{\lambda}e^{i\phi}\beta^*\eta.$$

Remark 7.4. *To reduce the formula to the case of vanishing wind but variable surface tension T, one can insert $\beta^* = \Lambda_k T = k^2 T$ to get the asymptotic formula*

$$(-i\lambda)^2 = Tk^3\frac{1 - e^{-2kh}}{1 + e^{-2kh}}. \tag{58}$$

Formulas that include the viscous effect and give a similar expression for the real part of λ can be found in [11].

In this example it is not easy to prove transversality of the crossing. On the other hand, we can easily verify property (43). If the eigenvalue followed the imaginary axis then $e^{-i\phi}\tilde{r}(z)$ were real on an interval of the imaginary axis. By analyticity, it would be real on the whole of the imaginary axis, which contradicts the last lemma.

With the proof of the last section we arrived at the following theorem.

Theorem 7.5. *Assuming the nonresonance condition, for some critical value of β^* a Hopf bifurcation occurs and periodic solutions of the nonlinear evolution equations exist.*

We remark that the constructed solution is a propagating wave but not necessarily a travelling wave.

A SEMIGROUP APPROACH TO FRAGMENTATION MODELS*

D. J. McLAUGHLIN†, W. LAMB†, AND A. C. McBRIDE†

Abstract. An initial-value problem modelling fragmentation processes, where particles split into two or more pieces, is studied using the theory of linear semigroups. The existence and uniqueness of nonnegative, mass-conserving solutions are established.

Key words. semigroup theory, fragmentation equation

AMS subject classifications. 35F10, 45K05, 47D06, 47N20, 80A30

PII. S0036141095291701

1. Introduction. There are two main descriptions of coagulation and fragmentation processes, a "continuous" integral version and a "discrete" summation version. In the continuous version it is assumed that the number of particles is large enough to justify the use of a density function $u(x,t)$; $u(x,t)dx$ is then the average number of particles with mass in the interval $(x, x+dx)$ at time t. (This average and all other averages are calculated with respect to a unit volume.)

This paper is the first in a series of planned papers reporting our investigation of the continuous coagulation and multiple-fragmentation equation, namely,

$$\begin{aligned}\frac{\partial}{\partial t}u(x,t)=&\frac{1}{2}\int_0^x K(x-y,y,t)u(x-y,t)u(y,t)\,dy-u(x,t)\int_0^\infty K(x,y,t)u(y,t)\,dy\\ &+\int_x^\infty \gamma(y,x,t)u(y,t)\,dy-u(x,t)\int_0^x \frac{y}{x}\gamma(x,y,t)\,dy, \quad \text{a.e. } x>0,\ t>0,\end{aligned}\tag{1}$$

via semigroup and evolution system techniques.

In the first instance we shall deal simply with the pure fragmentation equation ($K \equiv 0$) for time-independent kernels $\gamma(x,y,t) = \gamma(x,y)$, for all $t > 0$. Therefore, we consider the equation

$$\frac{\partial}{\partial t}u(x,t) = \int_x^\infty \gamma(y,x)u(y,t)\,dy-u(x,t)\int_0^x \frac{y}{x}\gamma(x,y)\,dy, \quad \text{a.e. } x>0,\ t>0.\tag{2}$$

Future papers will extend this work to the coagulation and fragmentation equation (1) for both time-independent and time-dependent kernels. We begin by discussing the interpretation of the terms on the right-hand side of (2) and delay comment on the terms involved in (1) until the need arises.

Equation (2) models fragmentation processes in which particles may split into more than two pieces. Hence we refer to the latter as the multiple-fragmentation equation. When all of the fragmenting particles in the system each produce only two particles, the binary fragmentation equation,

$$\frac{\partial}{\partial t}u(x,t) = \int_0^\infty F(x,y)u(x+y,t)\,dy-\frac{1}{2}u(x,t)\int_0^x F(x-y,y)\,dy,\tag{3}$$

provides an alternative description. As expected, (3) is a special case of (2), obtained by setting

$$\gamma(x,y) = F(x-y,y), \quad 0 \le y \le x < \infty, \tag{4}$$

where $F(x,y)$ is symmetric; i.e., $F(x,y) = F(y,x)$ for all $x, y \ge 0$. Using the substitution $y' = x - y$ and the symmetry of F, it is not difficult to show that

$$\int_0^x \frac{y}{x} F(x-y,y)\,dy = \frac{1}{2}\int_0^x F(x-y,y)\,dy.$$

We develop our theory in terms of the multiple-fragmentation model (2) but note that, as a consequence of the foregoing discussion, our results immediately carry over to the binary-fragmentation model (3).

The multiple-fragmentation kernel $\gamma(x,y)$, $0 \le y \le x < \infty$, is the formation rate of particles of mass y due to the fragmentation of particles of mass x. We assume that $\gamma(x,y)u(x,t)\,dx\,dy\,dt$ is the average number of particles of mass in the range $(y, y+dy)$ created from the break-up of particles of mass in $(x, x+dx)$ during the time interval $(t, t+dt)$. The interpretation of the binary-fragmentation kernel $F(x,y)$ is slightly different. The binary-fragmentation kernel $F(x,y)$ is the rate at which particles of mass $x+y$ fragment to produce particles of mass x and of mass y. However, we can interpret the binary-fragmentation kernel $F(x-y,y)$ in terms of the multiple-fragmentation kernel $\gamma(x,y)$ using (4).

Note that $a : (0,\infty) \to [0,\infty)$ defined by

$$a(x) = \int_0^x \frac{y}{x}\gamma(x,y)\,dy, \qquad x > 0, \tag{5}$$

is the overall rate of break-up of an x-particle. The factor y/x is introduced so that each resulting fragment is counted once only. By writing $\gamma(x,y) = a(x)b(y,x)$ we obtain precisely the derivation of the fragmentation terms by Ziff and McGrady [20], where $a(x)$ is the overall break-up rate and $b(y,x)$ is the distribution of products formed from a particle of mass x splitting.

Thus the terms on the right-hand side of (2) represent, respectively, a gain in particles of mass x as a result of the break-up of larger particles of mass y $(x \le y < \infty)$ and a loss of particles of mass x because they have broken up into smaller pieces of mass y $(0 \le y \le x)$. Equation (2) is formulated so that the total mass of the particles is formally conserved. Thus $\frac{\partial u}{\partial t}(x,t)$ equals the sum of the two terms described above.

Many authors have already contributed to the study of existence and uniqueness theorems for the various coagulation and fragmentation models. Aizenman and Bak [1] consider the case when both K and F are constant. The semigroup and fixed point mapping techniques used in [1] form the basis of our work. Melzak [13, 14] deals with certain bounded time-independent kernels by assuming solutions are of the form $u(x,t) = \Sigma_{k=0}^{\infty} a_k(x)t^k$ and extends the results to time-dependent kernels via Cauchy–Peano approximations. The pure coagulation equation ($\gamma \equiv 0$ or $F \equiv 0$) and the pure fragmentation equation ($K \equiv 0$) have also received attention. Stewart [18, 19] deals simultaneously with unbounded coagulation and unbounded fragmentation kernels satisfying the growth conditions

$$\begin{aligned} K(x,y) &\le C_1[(1+x)^\alpha + (1+y)^\alpha] \quad (x,\, y > 0,\ 0 < \alpha < 1), \\ F(x,y) &\le C_2(1+x+y)^\beta \qquad (x,\, y > 0,\ 0 < \beta < 1). \end{aligned}$$

For physical reasons, solutions are required to satisfy

$$\int_0^\infty xu(x,t)\,dx = \int_0^\infty xf(x)\,dx \qquad \text{for all } t \ge 0,$$

where f is the initial mass distribution of particles. This corresponds to mass conservation. The semigroup approach that we adopt here will be seen to lead to unique, mass-conserving solutions; the possibility of adapting this approach to cater to other, non-mass-conserving, solutions is a topic for future research. Although we shall concentrate on models derived from (1) and use the theory of semigroups, other approaches have been adopted which rely on different formulations. One instance is [4], where Filippov discusses multiple fragmentation via the theory of Markov processes. The equations used involve expectations of masses, based on the probability of a particle of a certain size splitting. Filippov obtains explicit solutions in particular cases and also considers the possibility of mass loss or "disintegration."

2. A reformulation of the problem. To apply the theory of semigroups of linear operators we must recast (2), subject to the initial mass distribution

$$u(x,0) = f(x), \quad \text{a.e. } x > 0, \tag{6}$$

as an abstract Cauchy problem (ACP). For each fixed $t \geq 0$, we define a function $u_{(t)}\colon (0,\infty) \to \mathbf{R}$ of the "mass" variable x by $u_{(t)}(x) = u(x,t)$, for a.e. $x > 0,\ t \geq 0$. Hence we can define a vector-valued function $\tilde{u}$,

$$\tilde{u}(t) = u_{(t)}, \quad t \geq 0, \tag{7}$$

from $[0,\infty)$ into an appropriate class of functions X.

For our purposes X will be a Banach space so that $d\tilde{u}/dt$ can be interpreted as the strong derivative of the vector-valued function $\tilde{u}$. As we are interested in mass-conserving solutions, a natural space to work in is the $L_{1,-1}$-space of equivalence classes of measurable, real-valued functions ϕ such that

$$\|\phi\|_{1,-1} = \int_0^\infty x|\phi(x)|\,dx < \infty.$$

Note that this is a Banach space of type L [6, pp. 69–70] enabling us to reinterpret (2) as follows. The left-hand side, $\partial u/\partial t$, can be thought of as the derivative with respect to t of the function $\tilde{u} : [0,\infty) \to L_{1,-1}$ defined by (7). For fixed $t > 0$, we can write the right-hand side of (2) as $A\tilde{u}(t)$, where the operator $A : L_{1,-1} \supseteq D_{\max}(A) \to L_{1,-1}$ is defined on its maximal domain $D_{\max}(A)$ by

$$[A\phi](x) = \int_x^\infty \gamma(y,x)\phi(y)dy - \phi(x)\int_0^x \frac{y}{x}\gamma(x,y)\,dy, \quad \phi \in D_{\max}(A). \tag{8}$$

The initial condition (6) becomes $\tilde{u}(0) = f$.

Hence the pure fragmentation equation (2), subject to the initial mass distribution (6), can be recast as the ACP

$$\begin{aligned} \frac{d}{dt}u(t) &= Au(t), \quad t > 0, \\ u(0) &= f. \end{aligned} \tag{9}$$

(For ease of notation we have omitted the tilde.)

As indicated, we follow closely the approach used in [1]. However, instead of working in the subspaces $\mathcal{L}_n$ $(n > 0)$ defined by

$$\mathcal{L}_n = \{\phi \in L_{1,-1}\colon \phi \equiv 0 \text{ on } [n,\infty)\}, \tag{10}$$

we make use of the projection operators P_n $(n > 0)$ on $L_{1,-1}$ defined by

$$(P_n\phi)(x) = \begin{cases} \phi(x), & 0 < x < n, \\ 0, & x \geq n. \end{cases} \tag{11}$$

Details of a subspace approach adopted in the preliminary stages of our work can be found in [10, 11, 12]. The results contained therein are summarized in [8].

Throughout this paper we assume that the fragmentation kernel $\gamma(x, y)$ satisfies the following hypotheses:

(H1) $\gamma(x, y)$ is a nonnegative function on $(0, \infty) \times (0, \infty)$;

(H2) $\gamma(x, y) = 0$ whenever $y > x$;

(H3) the function $a\colon (0, \infty) \to [0, \infty)$ defined by (5) is such that $a(x) \leq C_n$ for all $x \in (0, n]$, $n > 0$, where the sequence $\{c_n\}$ may be unbounded.

3. The truncated problem. The truncated problem consists of finding a solution to the truncated ACP

$$\begin{aligned} \frac{d}{dt}u(t) &= A_n u(t), \quad t > 0, \\ u(0) &= f, \end{aligned} \tag{12}$$

where A_n is used to denote AP_n. Therefore, for $\phi \in L_{1,-1}$,

$$(A_n\phi)(x) = \begin{cases} \int_x^n \gamma(y, x)\phi(y)\,dy - \phi(x)\int_0^x \dfrac{y}{x}\gamma(x, y)\,dy, & 0 < x < n, \\ 0, & x \geq n. \end{cases}$$

We can write this as

$$(A_n\phi)(x) = \begin{cases} \int_x^n \gamma(y, x)\phi(y)\,dy - a(x)\phi(x), & 0 < x < n, \\ 0, & x \geq n, \end{cases} \tag{13}$$

where $a : (0, \infty) \to [0, \infty)$ is defined by (5).

LEMMA 3.1. *The operator A_n, given by* (13), *generates a C_0-semigroup $\{S_n(t)\}_{t\geq 0}$ on $L_{1,-1}$. Furthermore, for all $t \geq 0$,*

(i) $S_n(t) = I + \sum_{i=1}^{\infty} \frac{(tA)^i}{i!} P_n$;

(ii) *for $m > 0$ the space $\mathcal{L}_m$ defined by* (10) *is invariant under $S_n(t)$;*

(iii) *$S_n(t)\phi \geq 0$ whenever $\phi \geq 0$, i.e., the operators are nonnegative;*

(iv) *$\|S_n(t)\phi\|_{1,-1} = \|\phi\|_{1,-1}$, i.e., $\{S_n(t)\}_{t\geq 0}$ is a C_0-semigroup of isometries;*

(v) *$\int_0^\infty x[S_n(t)\phi](x)\,dx = \int_0^\infty x\phi(x)\,dx$, i.e., mass is conserved.*

Proof. Using Fubini's theorem we can show that for all $\phi \in L_{1,-1}$,

$$\|A_n\phi\|_{1,-1} = \int_0^\infty x|(A_n\phi)(x)|\,dx = \int_0^n x|(A_n\phi)(x)|\,dx \leq 2C_n\,\|\phi\|_{1,-1},$$

by (5) and (H3). Therefore A_n is a bounded operator on $L_{1,-1}$ and as such generates a uniformly (and hence strongly) continuous semigroup.

(i) The usual power series definition is used to define $S_n(t) = \exp(tA_n)$. By induction, $(A_n)^i = (AP_n)^i = A^i P_n$ for $i = 1, 2, \ldots$, from which the result follows.

(ii) We note that

$$A_n\phi = \begin{cases} A_m\phi, & \text{if } m \leq n, \\ A_n\phi, & \text{if } m > n, \end{cases}$$

and $A_n : L_{1,-1} \to \mathcal{L}_n$. The result follows from (i).

(iii) We can write $A_n\phi = B_{1,n}\phi + B_{2,n}\phi$ where

$$(B_{1,n}\phi)(x) = \begin{cases} \int_x^n \gamma(y,x)\phi(y)\,dy, & \text{if } x < n, \\ 0, & \text{if } x \geq n, \end{cases}$$

and

$$(B_{2,n}\phi)(x) = \begin{cases} -a(x)\phi(x), & \text{if } x < n, \\ 0, & \text{if } x \geq n. \end{cases} \tag{14}$$

From the calculations for $\|A_n\phi\|_{1,-1}$, we can show that the operators $B_{i,n}$ $(i = 1, 2)$ are bounded separately on $L_{1,-1}$ and hence generate C$_0$-semigroups on $L_{1,-1}$.

(a) The operator $B_{1,n}$ generates the C$_0$-semigroup, $T_{1,n}(t) = \exp(tB_{1,n})$, $t \geq 0$, where again the usual power series is used to define the exponential. Since $B_{1,n}$ is nonnegative, the semigroup $\{T_{1,n}(t)\}_{t\geq 0}$ is nonnegative. Moreover, $\{T_{1,n}(t)\}_{t\geq 0}$ is of class C$(1, \omega_{1,n})$, for some $\omega_{1,n} > 0$.

(b) Consider $B_{2,n}$ defined by (14) and let $\phi \in L_{1,-1}$. Then

$$(\lambda I - B_{2,n})\phi = 0 \Rightarrow \phi(x)[\lambda + a(x)] = 0 \qquad \text{for a.e. } x > 0.$$

Since $\gamma(x, y)$ is nonnegative, it follows that $a(x)$ is nonnegative and hence that $[\lambda + a(x)] \geq \lambda > 0$ for all $\lambda > 0$. We deduce that for all $\lambda > 0$, $(\lambda I - B_{2,n})$ is injective. To find the resolvent operator $R(\lambda, B_{2,n})$, let $\psi \in L_{1,-1}$. Then

$$\begin{aligned} (\lambda I - B_{2,n})\phi = \psi &\Rightarrow \lambda\phi(x) + a(x)\phi(x) = \psi(x) \quad \text{a.e.} \\ &\Rightarrow \phi(x) = \frac{\psi(x)}{[\lambda + a(x)]} \quad \text{a.e.} \end{aligned}$$

and ϕ belongs to $L_{1,-1}$ since $|\phi(x)| \leq \frac{1}{\lambda}|\psi(x)|$ for all $\lambda > 0$. Hence $B_{2,n}$ generates a contraction semigroup (that is, of class C$(1, 0)$), by the Hille–Yosida theorem. If $\psi \geq 0$, then $\phi(x) = R(\lambda, B_{2,n})\psi(x) \geq 0$ almost everywhere. Therefore, $R(\lambda, B_{2,n})$ is nonnegative and $B_{2,n}$, like $B_{1,n}$, generates a nonnegative semigroup, which we call $\{T_{2,n}(t)\}_{t\geq 0}$.

(c) From part (a) and the Hille–Yosida theorem, the resolvent set of $B_{1,n}$ contains the set $\{\lambda\colon \lambda > \omega_{1,n}\}$ and for all such λ, $\|R(\lambda, B_{1,n})\|_{1,-1} \leq 1/(\lambda - \omega_{1,n})$. Likewise, from (b), the resolvent set of $B_{2,n}$ contains the set $\{\lambda\colon \lambda > 0\}$ and for all such λ, $\|R(\lambda, B_{2,n})\|_{1,-1} \leq 1/\lambda$. By [15, Cor. 5.5, pp. 92–93], A_n generates a C$_0(1, \omega_{1,n})$-semigroup, $\{S_n(t)\}_{t\geq 0}$ say, where

$$[S_n(t)]\phi = \lim_{m\to\infty} \left[T_{1,n}\left(\frac{t}{m}\right) T_{2,n}\left(\frac{t}{m}\right)\right]^m \phi, \quad \text{for all } \phi \in L_{1,-1},$$

and the limit is uniform on bounded time intervals. The terms in the sequence are nonnegative since $T_{1,n}(t)$ and $T_{2,n}(t)$ are nonnegative. By [16, Cor. 5.11, p. 72] there exists a subsequence $\{m_k\}_{k=1}^{\infty}$ such that we have pointwise convergence almost everywhere. We deduce that the limit (and hence the semigroup generated by A_n) is nonnegative.

(iv) Assume $\phi \geq 0$ and $\phi \in \bigcup_m \mathcal{L}_m$. Then $\phi \in \mathcal{L}_m$ for some fixed $m > 0$.

Since $S_n(t)$ is nonnegative and $S_n(t)\phi \in \mathcal{L}_m$ by part (ii),

$$\begin{aligned} \frac{d}{dt}\|S_n(t)\phi\|_{1,-1} &= \frac{d}{dt}\int_0^m x[S_n(t)\phi](x)\,dx \\ &= \int_0^m x\frac{d}{dt}[S_n(t)\phi](x)\,dx \end{aligned}$$

$$
\begin{aligned}
&= \int_0^m x[A_n S_n(t)\phi](x)dx \\
&= \int_0^n x[A_n S_n(t)\phi](x)\,dx \quad (\text{since } A_n\colon L_{1,-1} \to \mathcal{L}_n) \\
&= \int_0^n \int_0^y \frac{x}{y}\gamma(y,x)\,dx\, y[S_n(t)\phi](y)dy - \int_0^n xa(x)[S_n(t)\phi](x)\,dx \\
&= 0 \quad (\text{by } (5)).
\end{aligned}
$$

It follows that $\|S_n(t)\phi\|_{1,-1} = \|\phi\|_{1,-1}$ for all $\phi \in \mathcal{L}_m$, $\phi \geq 0$. Since the operators $\{S_n(t)\}_{t\geq 0}$ are linear and nonnegative, we can use the decomposition of ϕ into positive and negative parts to extend this result to all $\phi \in \mathcal{L}_m$. Then, since $\bigcup_m \mathcal{L}_m$ is dense in $L_{1,-1}$, we can extend again to all $\phi \in L_{1,-1}$ by the continuity of $S_n(t)$.

(v) Since $S_n(t)$ is a nonnegative isometry, we can use positive and negative parts once more and hence remove the $|.|$-sign from the result of part (iv). □

Theorem 3.2. *The truncated problem* (12) *has a unique, strongly continuously differentiable, nonnegative, mass-conserving solution for all initial data $f \in L_{1,-1}$. The solution is given by $u(t) = S_n(t)f$, $t \geq 0$.*

Proof. This follows by Lemma 3.1 and [15, Thm. 1.3, pp. 102–103]. □

4. The limit semigroup.

In this section we show that the strong limit as $n \to \infty$ of the semigroups $\{S_n(t)\}_{t\geq 0}$, obtained in the previous section, exists and inherits the appropriate properties from $\{S_n(t)\}_{t\geq 0}$.

Lemma 4.1.

(i) *The operator $S(t)$ defined by*

$$S(t)\phi = \operatorname*{s-lim}_{n\to\infty} S_n(t)\phi, \qquad \phi \in L_{1,-1}, \tag{15}$$

exists for all $t \geq 0$ and $\{S(t)\}_{t\geq 0}$ forms a nonnegative, C_0-semigroup of isometries on $L_{1,-1}$.

(ii) *For each $t \geq 0$, the operator $S(t)$ satisfies*

$$\int_0^\infty x[S(t)\phi](x)dx = \int_0^\infty x\phi(x)dx, \quad \textit{for all } \phi \in L_{1,-1}.$$

(iii) *For all $t \geq 0$ and $m > 0$, $S(t)P_m\phi = S_m(t)\phi + P_m\phi - \phi$.*

(iv) *The spaces $\mathcal{L}_m$ $(m > 0)$ and $\bigcup_m \mathcal{L}_m$, where $\mathcal{L}_m$ is defined by* (10), *are invariant under $S(t)$.*

Proof. Let $\phi \in L_{1,-1}$.

(i) and (ii). Assume without loss of generality that $n \geq m$. Using Lemma 3.1(i), we can show that

$$S_n(t)P_m\phi = S_m(t)\phi + P_m\phi - \phi. \tag{16}$$

It is then not difficult to show that $\{S_n(t)\phi\}_{n>0}$ is a Cauchy sequence in $L_{1,-1}$ and hence the limit, which is uniform in t, exists, and $S(t)$ maps $L_{1,-1}$ into $L_{1,-1}$.

We can show that $S(t)$ inherits the properties of $S_n(t)$. For example, by definition,

$$S(t+s)\phi = \operatorname*{s-lim}_{n\to\infty} S_n(t+s)\phi = \operatorname*{s-lim}_{n\to\infty} S_n(t)S_n(s)\phi.$$

Consider

$$
\begin{aligned}
&\|S_n(t)S_n(s)\phi - S(t)S(s)\phi\|_{1,-1} \\
&\leq \|S_n(t)\{S_n(s)\phi - S(s)\phi\}\|_{1,-1} + \|\{S_n(t) - S(t)\}S(s)\phi\|_{1,-1} \\
&= \|\{S_n(s)\phi - S(s)\phi\}\|_{1,-1} + \|\{S_n(t) - S(t)\}\{S(s)\phi\}\|_{1,-1} \\
&\qquad\qquad (\text{since } \{S_n(t)\} \text{ is a semigroup of isometries on } L_{1,-1}) \\
&\to 0 \ (\text{by the definition of } S(t),\ t \geq 0).
\end{aligned}
$$

Hence $S(t+s)\phi = S(t)S(s)\phi$ for all $\phi \in L_{1,-1}$, and so $S(t+s) = S(t)S(s)$.

Similarly, we can prove that $S(0) = I$ and s-$\lim_{t\to 0^+} S(t)\phi = \phi$. The latter result involves interchanging two limits. This is permissible since the limit in (15) exists uniformly in t. We can also show that for each $t \geq 0$, $S(t)$ is a nonnegative isometry which satisfies the condition in part (ii). (See [9, pp. 48–51] for details.)

(iii) We let $n \to \infty$ in (16) to obtain the result.

(iv) From part (iii), $S(t)\phi = S_m(t)\phi$ for all $\phi \in \mathcal{L}_m$. By Lemma 3.1(ii), we note that $S_m(t) : \mathcal{L}_m \to \mathcal{L}_m$ is invariant under $S_m(t)$, and so $\mathcal{L}_m$ $(m > 0)$ and $\bigcup_m \mathcal{L}_m$ are invariant under $S(t)$. □

5. The infinitesimal generator of the limit semigroup. The infinitesimal generator, $\boldsymbol{\mathcal{A}}$, of the limit semigroup, $\{S(t)\}_{t\geq 0}$, is not necessarily the same as the operator A defined by (8). The limit semigroup gives rise to a solution $u(t) = S(t)f,\ t \geq 0$, of the ACP

$$\begin{aligned} \frac{d}{dt}u(t) &= \boldsymbol{\mathcal{A}}u(t), \quad t > 0, \\ u(0) &= f, \end{aligned} \tag{17}$$

for $\boldsymbol{\mathcal{A}}$, but this solution u need not be a solution of our original ACP (9) for A. In this section, we show that $\boldsymbol{\mathcal{A}}$ and A coincide on a dense domain. We begin by defining two spaces that we shall require in the following analysis.

Definition 5.1. *Let the function a and the operators A and P_n be defined by* (5), (8), *and* (11), *respectively. We define the space $\mathcal{D}_a$ by*

$$\mathcal{D}_a = \left\{\phi \in L_{1,-1}\colon \int_0^\infty xa(x)|\phi(x)|\,dx < \infty\right\} \tag{18}$$

and the space $\mathbf{D}$ *by*

$$\mathbf{D} = \{\phi \in L_{1,-1}\colon \underset{n\to\infty}{\text{s-lim}}\, AP_n\phi \text{ exists in } L_{1,-1}\}. \tag{19}$$

Lemma 5.2.

(i) *For all $\phi \in \mathbf{D}$, $\underset{n\to\infty}{\text{s-lim}}\, AP_n\phi = A\phi$.*

(ii) *Let $\mathcal{L}_m$ be defined by* (10). *Then $\bigcup_m \mathcal{L}_m \subseteq \mathcal{D}_a \subseteq \mathbf{D}$.*

Proof.

(i) Let $\phi \in \mathbf{D}$. Then s-$\lim_{n\to\infty} AP_n\phi$ exists and equals ψ, say. Since $AP_n\phi \to \psi$ in $L_{1,-1}$, there exists a subsequence such that $[AP_{n_k}\phi](x) \to \psi(x)$ a.e. Now

$$[AP_{n_k}\phi](x) = \begin{cases} \int_x^{n_k} \gamma(y,x)\phi(y)dy - a(x)\phi(x), & \text{if } x < n_k, \\ 0, & \text{if } x \geq n_k, \end{cases}$$

and so $\lim_{n_k\to\infty}[AP_{n_k}\phi](x) = [A\phi](x)$. The pointwise limit is unique. Thus $\psi \equiv A\phi$ and s-$\lim_{n\to\infty} AP_n\phi = A\phi$, for all $\phi \in \mathbf{D}$.

(ii) Let $\phi \in \bigcup_m \mathcal{L}_m$. Then $\phi \in \mathcal{L}_m$ for some m and

$$\begin{aligned} \int_0^\infty xa(x)|\phi(x)|dx &\leq \sup_{x\in[0,m]} a(x) \int_0^m x|\phi(x)|dx \\ &< \infty \qquad \text{(since } a \text{ satisfies (H3))}. \end{aligned}$$

Hence $\phi \in \mathcal{D}_a$ and so $\bigcup_m \mathcal{L}_m \subseteq \mathcal{D}_a$.

Now let $\phi \in \mathcal{D}_a$. Using Fubini's theorem, we can show that

$$\|A\phi\|_{1,-1} \leq 2\int_0^\infty xa(x)|\phi(x)|\,dx < \infty,$$

and so

$$\begin{aligned}\|A\phi - AP_n\phi\|_{1,-1} &\leq 2\int_0^\infty xa(x)|\phi(x) - (P_n\phi)(x)|\,dx\\ &\to 0 \qquad \text{as } n \to \infty.\end{aligned}$$

Therefore, for $\phi \in \mathcal{D}_a$, s-$\lim_{n\to\infty} AP_n\phi$ exists and equals $A\phi$. Hence $\mathcal{D}_a \subseteq \mathbf{D}$. □

THEOREM 5.3. *Let $\boldsymbol{\mathcal{A}}$ be the generator of the limit semigroup $\{S(t)\}_{t\geq 0}$ and let A be the operator defined by* (8).

(i) *The operators $\boldsymbol{\mathcal{A}}$ and A are equivalent on the space $\bigcup_m \mathcal{L}_m$, where $\mathcal{L}_m$ is given by* (10). *Moreover, $\bigcup_m \mathcal{L}_m$ is a core for $\boldsymbol{\mathcal{A}}$, i.e.,*

$$\boldsymbol{\mathcal{A}} = \overline{\boldsymbol{\mathcal{A}}|_{\bigcup_m \mathcal{L}_m}}.$$

(ii) *The generator $\boldsymbol{\mathcal{A}}$ and the operator A coincide on $\mathbf{D}$.*

(iii) *The spaces $\mathcal{D}_a$ and $\mathbf{D}$ are also cores for $\boldsymbol{\mathcal{A}}$. So*

$$\boldsymbol{\mathcal{A}} = \overline{\boldsymbol{\mathcal{A}}|_{\bigcup_m \mathcal{L}_m}} = \overline{\boldsymbol{\mathcal{A}}|_{\mathcal{D}_a}} = \overline{\boldsymbol{\mathcal{A}}|_{\mathbf{D}}}.$$

(iv) *The family $\{S(t)\}_{t\geq 0}$ is the unique C_0-semigroup such that $\boldsymbol{\mathcal{A}}\phi = A\phi$ for all $\phi \in \mathbf{D}$, and $S(t)\mathcal{L}_m \subset \mathcal{L}_m$ for all $m > 0$, $t \geq 0$.*

Proof.

(i) From Lemma 4.1(iii), $S(t)\phi = S_m(t)\phi$ for all $\phi \in \mathcal{L}_m$, $m > 0$. By definition, for all $\phi \in \mathcal{L}_m$, $m > 0$,

$$\begin{aligned}\boldsymbol{\mathcal{A}}\phi &= \operatorname*{s-lim}_{t\to 0^+} \frac{S(t)\phi - \phi}{t}\\ &= \operatorname*{s-lim}_{t\to 0^+} \frac{S_m(t)\phi - \phi}{t}\\ &= AP_m\phi \quad \text{(since } AP_m \text{ generates } \{S_m(t)\}_{t\geq 0} \text{ by Lemma 3.1)}\\ &= A\phi.\end{aligned}$$

Hence $\boldsymbol{\mathcal{A}} = A$ on $\bigcup_m \mathcal{L}_m$.

Now, $\bigcup_m \mathcal{L}_m$ is a dense subspace of $L_{1,-1}$, $\bigcup_m \mathcal{L}_m \subseteq \mathcal{D}(\boldsymbol{\mathcal{A}})$, and (by Lemma 4.1(iv)) $S(t) : \bigcup_m \mathcal{L}_m \to \bigcup_m \mathcal{L}_m$. Applying the core theorem [17, Thm. X.49, pp. 241–242], we obtain the required result.

(ii) Let $\phi \in \mathbf{D}$. Then s-$\lim_{n\to\infty} AP_n\phi$ exists and equals $A\phi$ (by Lemma 5.2(i)). Since $P_n\phi \in \mathcal{L}_n$, by part (i), we note that

$$\operatorname*{s-lim}_{n\to\infty} \boldsymbol{\mathcal{A}}P_n\phi = \operatorname*{s-lim}_{n\to\infty} AP_n\phi = A\phi.$$

Therefore we have that $P_n\phi \to \phi$ and $\boldsymbol{\mathcal{A}}P_n\phi \to A\phi$, as $n \to \infty$. Since the generator $\boldsymbol{\mathcal{A}}$ is closed, we deduce that $\mathbf{D} \subseteq \mathcal{D}(\boldsymbol{\mathcal{A}})$ and $\boldsymbol{\mathcal{A}} \equiv A$ on $\mathbf{D}$.

(iii) Let $G(\boldsymbol{\mathcal{A}})$ denote the graph of $\boldsymbol{\mathcal{A}}$. Then

$$\overline{G(\boldsymbol{\mathcal{A}}|_{\mathbf{D}})} \subseteq \overline{G(\boldsymbol{\mathcal{A}})} = G(\boldsymbol{\mathcal{A}}),$$

since $\mathbf{D} \subseteq \mathcal{D}(\boldsymbol{\mathcal{A}})$. However, because $\mathbf{D} \supseteq \bigcup_m \mathcal{L}_m$, we obtain

$$\overline{G(\boldsymbol{\mathcal{A}}|_{\mathbf{D}})} \supseteq \overline{G(\boldsymbol{\mathcal{A}}|_{\bigcup_m \mathcal{L}_m})} = G(\boldsymbol{\mathcal{A}})$$

by part (i). Thus $G(\boldsymbol{\mathcal{A}}) = \overline{G(\boldsymbol{\mathcal{A}}|_{\mathbf{D}})}$. By the definition of closure, $\overline{G(\boldsymbol{\mathcal{A}}|_{\mathbf{D}})} = G(\overline{\boldsymbol{\mathcal{A}}|_{\mathbf{D}}})$, and so $\boldsymbol{\mathcal{A}} = \overline{\boldsymbol{\mathcal{A}}|_{\mathbf{D}}}$. Hence $\mathbf{D}$ is a core for $\boldsymbol{\mathcal{A}}$. A similar argument holds for $\mathcal{D}_a$, since $\bigcup_m \mathcal{L}_m \subseteq \mathcal{D}_a \subseteq \mathbf{D} \subseteq \mathcal{D}(\boldsymbol{\mathcal{A}})$.

(iv) By [15, Thm. 2.6, p. 6], $\{S(t)\}_{t\geq 0}$ is the unique semigroup generated by $\boldsymbol{\mathcal{A}}$. Suppose there exists another generator $\mathcal{B}$, which gives rise to the C$_0$-semigroup $\{T(t)\}_{t\geq 0}$, such that $\mathcal{B} \neq \boldsymbol{\mathcal{A}}$, $\mathcal{B} = A$ on $\mathbf{D}$, and $T(t)\mathcal{L}_m \subseteq \mathcal{L}_m$, for all $m > 0$, $t \geq 0$. By the core theorem applied to $\mathcal{B}$ and $\bigcup_m \mathcal{L}_m$, we obtain

$$\mathcal{B} = \overline{\mathcal{B}|_{\bigcup_m \mathcal{L}_m}}.$$

Since $\bigcup_m \mathcal{L}_m \subseteq \mathbf{D}$, by the above assumptions on $\mathcal{B}$, we note that $\mathcal{B}\phi = A\phi = \boldsymbol{\mathcal{A}}\phi$ for all $\phi \in \bigcup_m \mathcal{L}_m$. So

$$\mathcal{B} = \overline{\boldsymbol{\mathcal{A}}|_{\bigcup_m \mathcal{L}_m}} = \boldsymbol{\mathcal{A}}.$$

This is a contradiction. Thus $\{S(t)\}_{t\geq 0}$ is the only semigroup that leaves $\mathcal{L}_m$ $(m > 0)$ invariant and whose generator $\boldsymbol{\mathcal{A}}$ coincides with the operator A on $\mathbf{D}$. □

We have shown that the generator $\boldsymbol{\mathcal{A}}$ and the operator A, defined by (8), coincide on the dense space $\mathbf{D}$. Ideally we would like $\boldsymbol{\mathcal{A}}$ and A to coincide on $\mathcal{D}(\boldsymbol{\mathcal{A}})$ so that if we considered A to be defined on $\mathcal{D}(\boldsymbol{\mathcal{A}})$ instead of on its maximal domain the ACPs (9) and (17) would become the same problem and for suitable initial data, $u(t) = S(t)f$, $t \geq 0$, would be the solution. However, so far, we have been unable to determine the precise nature of $\mathcal{D}(\boldsymbol{\mathcal{A}})$ and whether $\mathcal{D}(\boldsymbol{\mathcal{A}}) \subseteq D_{\max}(A)$ without imposing extra conditions on the fragmentation kernel $\gamma(x, y)$, as in the next theorem.

Theorem 5.4. *Let X be a Banach space of functions on $(0, \infty)$ with the property that strong convergence in X implies pointwise convergence almost everywhere. In addition to the hypotheses* (H1)–(H3), *let the fragmentation kernel $\gamma(x, y)$ be such that the operator A defined by* (8) *is a bounded operator from $L_{1,-1}$ into X. Then the operator A coincides with the infinitesimal generator, $\boldsymbol{\mathcal{A}}$, of the limit semigroup on the domain, $\mathcal{D}(\boldsymbol{\mathcal{A}})$, of the generator. Hence $\boldsymbol{\mathcal{A}}$ is a restriction of A.*

Proof. Let $\phi \in \mathcal{D}(\boldsymbol{\mathcal{A}})$. Since $\mathbf{D}$ is a core for $\boldsymbol{\mathcal{A}}$, there exists a sequence $\{\phi_n\} \subseteq \mathbf{D}$ such that $\|\phi_n - \phi\|_{1,-1} \to 0$ and $\|\boldsymbol{\mathcal{A}}\phi_n - \boldsymbol{\mathcal{A}}\phi\|_{1,-1} \to 0$ as $n \to \infty$. Hence there exists a subsequence $\{\phi_{n_k}\}$ such that $[\boldsymbol{\mathcal{A}}\phi_{n_k}](x) = [A\phi_{n_k}](x) \to [\boldsymbol{\mathcal{A}}\phi](x)$ for a.e. $x > 0$, as $n_k \to \infty$, where we have used the fact that $\boldsymbol{\mathcal{A}} \equiv A$ on $\mathbf{D}$.

Since $A \in B(L_{1,-1}, X)$,

$$A\phi = \operatorname*{s-lim}_{n_k\to\infty} A\phi_{n_k},$$

where the strong limit is with respect to the norm on X. By the assumptions on X, there exists a subsequence of the subsequence (which we also denote by ϕ_{n_k}) such that $[A\phi_{n_k}](x) \to [A\phi](x)$ for a.e. $x > 0$, as $n_k \to \infty$. Since the pointwise limit is unique, $\boldsymbol{\mathcal{A}} \equiv A$ on $\mathcal{D}(\boldsymbol{\mathcal{A}})$, and hence $\boldsymbol{\mathcal{A}} = A|_{\mathcal{D}(\boldsymbol{\mathcal{A}})}$. □

Sufficient conditions on γ for the above theorem to be applicable are now given.

Example 5.5. *Using the generalized Young's inequality* [5, pp. 13–14]*, it is not difficult to show that for fragmentation kernels γ satisfying*

$$\int_x^\infty \frac{1}{y}\gamma(y, x)\, dy \leq C, \qquad \textit{for all } x > 0,$$

and

$$\int_0^y \frac{1}{y}\gamma(y, x)\, dx \leq C, \qquad \textit{for all } y > 0,$$

for some constant $C > 0$, the operator $A \in B(L_{1,-1}, L_1)$. An example of such a γ is $\gamma(y, x) = x/y$. Note that the above conditions imply that (H3) *is valid.*

THEOREM 5.6. *Let the fragmentation kernel γ satisfy* (H1) *and* (H2) *and be such that*

$$\gamma(x, y) \leq C x^{\beta-1} \Psi\left(\frac{y}{x}\right), \tag{20}$$

where $\beta > 0$ and the function Ψ is such that

$$\int_0^1 t^{1-\beta} \Psi(t)\, dt = C' < \infty. \tag{21}$$

Then $A \in B(L_{1,-1}, L_{1,\beta-1})$, where $L_{1,\beta-1}$ is defined as in [7, p. 2].

Proof. From (8) and (5), the operator A can be expressed as the sum $B_1 + B_2$, where for $\phi \in D_{\max}(A)$ and $x > 0$,

$$(B_1\phi)(x) = \int_x^\infty \gamma(y, x)\phi(y)\, dy \quad \text{and} \quad (B_2\phi)(x) = -a(x)\phi(x).$$

We consider $\|B_1\phi\|_{1,-1}$ and $\|B_2\phi\|_{1,-1}$ separately. The result follows from the estimates (20) and (21) on making a suitable substitution or changing the order of integration, as appropriate. □

EXAMPLE 5.7. *The following examples are special cases of the above theorem.*

(i) *Let $\Psi(t) = t^\lambda$ and $\beta = 2\lambda + 1$ so that $\gamma(x, y) \leq C(xy)^\lambda$. If $-\frac{1}{2} < \lambda < 1$ then $A \in B(L_{1,-1}, L_{1,2\lambda})$. In particular, choosing $\lambda = 0$, we see that $A \in B(L_{1,-1}, L_{1,0})$ whenever $\gamma(x, y) \leq C$ for some constant $C < \infty$. Also, when $\gamma(x, y) = (xy)^\lambda$, the operator B_1 (defined above) reduces to $x^{2\lambda+1} K_1^{-\lambda-1,1}\phi$ where $K_1^{-\lambda-1,1}$ is an Erdélyi–Kober operator; see* [7, p. 39].

(ii) *Let $\Psi(t) = (1 - t)^{\alpha-1}$ $(0 < \alpha < 2)$ and $\beta = \alpha$. Then $\gamma(x, y) \leq C(x - y)^{\alpha-1}$ and $A \in B(L_{1,-1}, L_{1,\alpha-1})$. If $\gamma(x, y) = \frac{1}{\Gamma(\alpha)}(x - y)^{\alpha-1}$, then the operator B_1 is the Weyl fractional integral K_1^α of order α; see* [7, p. 36].

6. Existence and uniqueness results. We investigate the existence and uniqueness of solutions to the ACP (17) for $\boldsymbol{\mathcal{A}}$ and the ACP (9) for A. We also consider the ACP

$$\begin{aligned} \frac{d}{dt}u(t) &= \boldsymbol{\mathcal{A}}u(t) + q(t), \quad t > 0, \\ u(0) &= f, \end{aligned} \tag{22}$$

where q is a vector-valued function. The inhomogeneous term $q(t)$ can be interpreted as arising from a source term $q(x, t)$ being introduced on the right-hand side of the pure fragmentation equation (2).

THEOREM 6.1. *Let $f \in \mathcal{D}(\boldsymbol{\mathcal{A}})$, $f \geq 0$. Then the ACP* (17) *has a unique, strongly differentiable, nonnegative, mass-conserving solution given by $u(t) = S(t)f$ for all $t \geq 0$.*

Proof. The result follows by [15, Thm. 1.3, pp. 102–103] and Lemma 4.1(i), (ii) since, by definition, $\boldsymbol{\mathcal{A}}$ generates $\{S(t)\}_{t\geq 0}$. □

COROLLARY 6.2. *Suppose that one or both of the following conditions is valid:*

(i) *the generator $\boldsymbol{\mathcal{A}}$ coincides with A on $\mathcal{D}(\boldsymbol{\mathcal{A}})$;*

(ii) *$f \in \mathbf{D}$ and is such that $S(t)f \in \mathbf{D}$ for all $t \geq 0$.*

Then Theorem 6.1 *is also valid for the ACP* (9).

Proof. This is an immediate consequence of the previous theorem since, respectively,

(i) $u(t) \in \mathcal{D}(\boldsymbol{\mathcal{A}})$ for all time and $\boldsymbol{\mathcal{A}} \equiv A$ on $\mathcal{D}(\boldsymbol{\mathcal{A}})$;

(ii) $u(t) \in \mathbf{D}$ for all time and $\boldsymbol{\mathcal{A}} \equiv A$ on $\mathbf{D}$ (by Theorem 5.3(ii)). □

Note. For arbitrary initial data $f \in \mathbf{D}$, there is no guarantee that $S(t)f \in \mathbf{D}$ for all time. Consequently, for such data, we can only assert that the ACP (9) has at most one strongly differentiable, nonnegative, mass-conserving solution given by $u(t) = S(t)f,\ t \geq 0$.

COROLLARY 6.3. *Let $f \in \bigcup_m \mathcal{L}_m,\ f \geq 0$. Then there exists a unique strongly differentiable, nonnegative, mass-conserving solution to the ACP* (9) *such that $u(t) \in \bigcup_m \mathcal{L}_m$ for all $t \geq 0$. This strong solution is given by $u(t) = S(t)f,\ t \geq 0$.*

Proof. By Lemma 4.1(iv), $\bigcup_m \mathcal{L}_m$ is invariant under $S(t)$. The result follows from Corollary 6.2 since $\bigcup_m \mathcal{L}_m \subseteq \mathbf{D}$. □

The above analysis established the existence and uniqueness of a C_0-semigroup $\{S(t)\}_{t\geq 0}$ with infinitesimal generator $\boldsymbol{\mathcal{A}}$ that coincides with the operator A on a dense set $\mathbf{D}$, such that $\mathcal{L}_m$ is invariant under $S(t),\ t \geq 0$. This C_0-semigroup gives rise to a strong solution of the ACP (17) for $\boldsymbol{\mathcal{A}}$. However, in general, we do not have a precise form for $\boldsymbol{\mathcal{A}}$, and so it is difficult to interpret (meaningfully) the abstract problem we are actually solving. In certain circumstances (see Theorem 5.4) $\boldsymbol{\mathcal{A}}$ is a restriction of the operator A defined by (8), and so, by taking A to be defined on the set $\mathcal{D}(\boldsymbol{\mathcal{A}})$ instead of its maximal domain, results relating to the ACP (17) are also valid for the ACP (9).

In the remainder of this section, we state results for the ACPs (17) and (22), involving the "abstract" operator $\boldsymbol{\mathcal{A}}$. We note that in certain cases these results apply to the operator A and hence to the abstract formulation of the pure fragmentation equation (2) with a source term $q(x,t)$.

DEFINITION 6.4. *Fix $T < \infty$. A function $u \in C([0,T],X)$ is a weak solution of* (22) *on $[0,T]$ if for every $v \in \mathcal{D}(\boldsymbol{\mathcal{A}}^*)$ the function $\langle u(t), v\rangle$ is absolutely continuous on $[0,T]$ and*

$$\frac{d}{dt}\langle u(t), v\rangle = \langle u(t), \boldsymbol{\mathcal{A}}^* v\rangle + \langle q(t), v\rangle, \quad \textit{for almost all } t \in [0,T],$$

and $u(0) = f$.

THEOREM 6.5 (existence and uniqueness of a weak solution). *Let the initial data $f \in L_{1,-1},\ f \geq 0$.*

(i) *The ACP* (17) *has a unique weak solution u satisfying $u(0) = f$. The weak solution is given by $u(t) = S(t)f,\ t \geq 0$, is nonnegative, and conserves mass.*

(ii) *For each fixed $T > 0$, if $q \in L_1([0,T), L_{1,-1})$, then the ACP* (22) *has a unique weak solution u on $[0,T]$ satisfying $u(0) = f$. This weak solution is given by*

$$u(t) = S(t)f + \int_0^t S(t-s)q(s)\,ds, \quad t \in [0,T].$$

If $q \geq 0$, then the weak solution to (22) *is nonnegative.*

Proof. The existence and uniqueness results follow immediately from [3], since $\boldsymbol{\mathcal{A}}$ generates the C_0-semigroup $\{S(t)\}_{t\geq 0}$. The weak solution of the ACP (17) is nonnegative and mass conserving because the operators $S(t),\ t \geq 0$, are nonnegative isometries. Likewise, the weak solution of (22) on $[0,T]$ is nonnegative whenever $q \geq 0$. □

7. Existence and uniqueness of solutions to the pure fragmentation equation. We consider the implications on the original rate equation (2) of having existence and uniqueness of solutions to the ACP (17). We also compare our definition of a solution with that adopted in [18, 19]. This enables us to make comparisons between the existence and uniqueness results obtained here and those obtained in [18, 19] under a different set of hypotheses.

THEOREM 7.1. *Let γ satisfy* (H1)–(H3) *and let $f \in \bigcup_m \mathcal{L}_m$, $f \geq 0$. Then there exists a function u, measurable on the product set $(0,\infty) \times [0,\infty)$, such that*

(i) *$u(x,t) \geq 0$ for all $t \geq 0$ and a.e. $x > 0$;*

(ii) *$u(x,0) = f(x)$ for a.e. $x > 0$;*

(iii) *for each fixed $t \geq 0$, $\int_0^\infty xu(x,t)\,dx < \infty$;*

(iv) *$\int_0^\infty xu(x,t)\,dx = \int_0^\infty xf(x)\,dx$ for all $t \geq 0$;*

(v) *$u(x,t)$ satisfies the pure fragmentation equation* (2) *almost everywhere.*

Proof. By Corollary 6.3, the ACP (17) has a strongly continuously differentiable solution $u(t)$, $t \geq 0$. By [6, Thm. 3.4.2, pp. 70–71], since $L_{1,-1}$ is of type L, there exists a function u measurable on the product set $(0,\infty) \times [0,\infty)$ such that

(a) $u(x,t)$ is absolutely continuous for each $x \in (0,\infty)$ and $u(x,t) = [u(t)](x)$ for each $t \geq 0$;

(b) $\frac{\partial}{\partial t}u(x,t)$ exists a.e. in $(0,\infty)\times[0,\infty)$ and $\frac{\partial}{\partial t}u(x,t) = \left[\frac{d}{dt}u(t)\right](x)$ for all $t \geq 0$. Now,

$$\left[\frac{d}{dt}u(t)\right](x) = [\boldsymbol{\mathcal{A}}u(t)](x) = [Au(t)](x)$$

since $u(t) \in \bigcup_m \mathcal{L}_m$ (Corollary 6.3) and $\boldsymbol{\mathcal{A}} \equiv A$ on $\mathbf{D} \supseteq \bigcup_m \mathcal{L}_m$ (Theorem 5.3(ii)). By definition, for $t > 0$,

$$\begin{aligned}[Au(t)](x) &= \int_x^\infty \gamma(y,x)[u(t)](y)dy - [u(t)](x)\int_0^x \frac{y}{x}\gamma(x,y)\,dy\\ &= \int_x^\infty \gamma(y,x)u(y,t)dy - u(x,t)\int_0^x \frac{y}{x}\gamma(x,y)\,dy.\end{aligned}$$

Thus

$$\frac{\partial}{\partial t}u(x,t) = \int_x^\infty \gamma(y,x)u(y,t)dy - u(x,t)\int_0^x \frac{y}{x}\gamma(x,y)\,dy, \quad \text{a.e. } x > 0,\ t > 0;$$

i.e., $u(x,t)$ satisfies (2) almost everywhere.

On setting $u(x,t) = [u(t)](x)$, for a.e. $x > 0$, $t \geq 0$, parts (i)–(iv) follow immediately from the corresponding properties of $u(t)$. □

COROLLARY 7.2. *Let $f \in \bigcup_m \mathcal{L}_m$, $f \geq 0$, and let u be a solution of the pure fragmentation equation* (2) *in the sense described in Theorem* 7.1. *Then this is the only such solution which is also a solution in the strong sense, i.e., such that the vector-valued function u defined by $u(t) = u(.,t)$, $t \geq 0$, is a strong solution of the ACP* (17).

Proof. This is a direct consequence of the uniqueness of the strong solution for $f \in \bigcup_m \mathcal{L}_m$ (Corollary 6.3). □

The additional requirement that a solution of the pure fragmentation equation (2) should also satisfy the equation in a strong sense provides one means of uniquely identifying a solution to (2) for initial data $f \in \bigcup_m \mathcal{L}_m$. For arbitrary initial data $f \in L_{1,-1}$, $f \geq 0$, we have the existence and uniqueness of a weak solution to the ACP (17) (but not so, in general, for the ACP (9)) given by $u(t) = S(t)f$, $t \geq 0$. Note that for all $t \geq 0$,

$$S(t)f = \operatorname*{s-lim}_{n\to\infty} S(t)P_n f.$$

Therefore, the solution u is a limit of solutions $\{u_n\}$, given by

$$u_n(t) = S(t)P_n f, \qquad t \geq 0,$$

which satisfy the ACP (17) strongly (since $P_n f \in \bigcup_m \mathcal{L}_m \subseteq \mathcal{D}(\boldsymbol{\mathcal{A}})$). We now show that for arbitrary initial data $f \in L_{1,-1}, f \geq 0$, the function $u(x,t) = [u(t)](x),\ x > 0,\ t \geq 0$, satisfies an integral version of the pure fragmentation equation (2).

THEOREM 7.3. *Let the initial data $f \in L_{1,-1},\ f \geq 0$. Then the function $u\colon (0,\infty) \times [0,\infty) \to \mathbf{R}$ defined by $u(x,t) = [S(t)f](x),\ x > 0,\ t \geq 0$ satisfies*

$$u(x,t) = f(x) + \int_0^t \int_x^\infty \gamma(y,x) u(y,\sigma)\, dy\, d\sigma - \int_0^t a(x) u(x,\sigma)\, d\sigma \tag{23}$$

for all $t \geq 0$ and a.e. $x > 0$. Moreover, u is nonnegative and

$$\int_0^\infty x u(x,t)\, dx = \int_0^\infty x f(x)\, dx \quad \textit{for all } t \geq 0.$$

Proof. Let $u_n(t) = S(t)P_n f$ and $u(t) = S(t)f$. By [6, pp. 69–71], for each fixed $t \geq 0$, we can write $[u_{n_k}(t)](x) = u_{n_k}(x,t)$ and $[u(t)](x) = u(x,t)$, where the scalar-valued functions u_{n_k} and u appearing on the right-hand sides are measurable on the product set $(0,\infty) \times [0,\infty)$. Since $u_n(t) \to u(t)$ strongly in $L_{1,-1}$ uniformly with respect to t, for each fixed $t \geq 0$ there exists a subsequence $\{n_k\}$ independent of t such that

$$u_{n_k}(x,t) \to u(x,t) \qquad \text{as } n_k \to \infty \quad \text{for a.e. } x > 0,$$

where the set of measure zero may depend on t. However, the uniform convergence of the sequence $\{u_{n_k}(t)\}$ in $L_{1,-1}$ also means that

$$\int_0^T \int_0^\infty x |u_{n_k}(x,t) - u(x,t)|\, dx\, dt \to 0 \qquad \text{as } n_k \to \infty$$

for each finite $T > 0$, and from this we deduce that there exists a subsequence of the subsequence, which we also denote by $\{u_{n_k}(t)\}$, such that

$$u_{n_k}(x,t) \to u(x,t) \qquad \text{as } n_k \to \infty \quad \text{for a.e. } (x,t) \in (0,\infty) \times [0,T].$$

By Theorem 7.1, because $P_{n_k} f \in \mathcal{L}_{n_k} \subset \bigcup_m \mathcal{L}_m$, we deduce that $u_{n_k}(x,t)$ satisfies

$$u_{n_k}(x,t) = (P_{n_k} f)(x) + \int_0^t \int_x^\infty \gamma(y,x) u_{n_k}(y,\sigma)\, dy\, d\sigma - a(x) \int_0^t u_{n_k}(x,\sigma)\, d\sigma \tag{24}$$

for each fixed $t \geq 0$ and a.e. $x > 0$. Note that $u_{n_k}(x,t) = 0$ for $x \geq n_k$, since $\mathcal{L}_{n_k}$ is invariant under $S(t)$ (by Lemma 4.1(iv)).

Taking limits as $n_k \to \infty$ on both sides of (24), we get

$$u(x,t) = f(x) + \lim_{n_k \to \infty} \left\{ \int_0^t \int_x^\infty \gamma(y,x) u_{n_k}(y,\sigma) dy d\sigma - a(x) \int_0^t u_{n_k}(x,\sigma) d\sigma \right\} \tag{25}$$

for each fixed $t \geq 0$ and a.e. $x > 0$, where we know that the limit on the right exists because the limit on the left exists.

Now fix $t \geq 0$. For almost all fixed $x > 0$, we can show that the sequence $\{a(x) u_{n_k}(x, \,.\,)\}$ is monotonic increasing, is bounded above by the $L_1[0,t]$-function $a(x)u(x, \,.\,)$, and converges pointwise a.e. on $[0,t]$ to $a(x)u(x,\sigma)$. By the Lebesgue dominated convergence theorem, for each fixed $t \geq 0$ and almost all fixed $x > 0$,

$$\lim_{n_k \to \infty} \int_0^t a(x) u_{n_k}(x,\sigma)\, d\sigma = \int_0^t a(x) u(x,\sigma)\, d\sigma.$$

Returning to (25), we know now that $\lim_{n_k\to\infty}\int_0^t\int_x^\infty \gamma(y,x)u_{n_k}(y,\sigma)\,dy\,d\sigma$ exists for each fixed $t \geq 0$ and almost all fixed $x > 0$. For fixed $y \in (x,\infty)$ and $\sigma \in [0,t]$, the sequence $\{\gamma(y,x)u_{n_k}(y,\sigma)\}$ is monotonic and converges a.e. on $(x,\infty)\times[0,t]$ to $\gamma(y,x)u(y,\sigma)$. Hence, by the Fubini–Tonelli–Hobson theorem and the Levi theorem for sequences of Lebesgue integrable functions [2, Thm. 10.24, pp. 267–268 and p. 407],

$$\lim_{n_k\to\infty}\int_0^t\int_x^\infty \gamma(y,x)u_{n_k}(y,\sigma)\,dy\,d\sigma = \int_0^t\int_x^\infty \gamma(y,x)u(y,\sigma)\,dy\,d\sigma.$$

We have thus shown that u satisfies (19). The nonnegativity and mass conservation follow from Lemma 4.1(i)–(ii). □

COROLLARY 7.4. *There is only one solution u of the integral version of the rate equation* (19) *such that the vector-valued function $u(t)$ defined by $u(t) = u(.,t)$, $t \geq 0$, is a weak solution of the ACP* (17). *This solution is given by*

$$u(x,t) = [S(t)f](x), \quad \textit{for a.e. } x > 0,\ t \geq 0.$$

Proof. This follows since the weak solution is unique (Theorem 6.5). □

COROLLARY 7.5. *The solution u of the integral version* (23) *satisfies the pure fragmentation equation* (2) *for a.e. $t > 0$, $x > 0$ and satisfies the initial condition $u(x,0) = f(x)$.*

Proof. Since $u(x,t)$ satisfies (23) for all $t \geq 0$ and a.e. $x > 0$, $u(x,.)$ is absolutely continuous on $[0,\infty)$ and so $u(x,t)$ satisfies (2) for a.e. $t > 0$, $x > 0$. □

Remark 7.6.

1. We are able to obtain existence and uniqueness results for the pure fragmentation equation (2) regardless of whether or not the abstract problems for $\boldsymbol{\mathcal{A}}$ and A coincide.

2. In [1], although use is made of the pointwise solution $u(x,t) = [u(t)](x)$, $x > 0$, $t \geq 0$, no justification is provided. The above discussion makes this step rigorous.

3. Comparisons can now be made with Stewart's existence and uniqueness results [18, 19] (see section 1) for the case of pure fragmentation ($K \equiv 0$). Under the hypotheses (H1)–(H3) on the fragmentation kernel, we have established the existence of a solution $u(x,t) = [S(t)f](x)$, $x > 0$, $t \geq 0$, which is also a solution in the sense described in [18]. By restricting our solution of (2) to satisfy (9) in a weak sense, we obtain uniqueness without imposing further conditions on the kernels (compare with [19]). Thus, in the pure fragmentation case, our results extend those in [18, 19]. However, it should be noted that unbounded fragmentation and unbounded coagulation are dealt with simultaneously in [18], and so it is possible that the same approach applied separately to the pure fragmentation equation would lead to less restrictive conditions on the fragmentation kernel.

AN EXISTENCE AND UNIQUENESS RESULT FOR A COAGULATION AND MULTIPLE-FRAGMENTATION EQUATION*

D. J. McLAUGHLIN†, W. LAMB†, AND A. C. McBRIDE†

Abstract. Prior knowledge regarding the existence and uniqueness of nonnegative, mass-conserving solutions to a multiple-fragmentation equation is utilized to study a combined coagulation and fragmentation model. The coagulation and fragmentation equation is first recast as an abstract integral equation involving the solution operator associated with the fragmentation part. A contraction mapping argument is then used to prove the existence and uniqueness of a local solution. Detailed investigation of the related iteration scheme yields nonnegativity and mass conservation. The solution is shown to be global.

Key words. semigroup theory, coagulation, multiple fragmentation, contraction mapping

1. Introduction.

In this paper, we continue our investigation of the continuous coagulation and multiple-fragmentation equation,

$$\begin{aligned}\frac{\partial}{\partial t}u(x,t) &= \frac{1}{2}\int_0^x K(x-y,y)u(x-y,t)u(y,t)\,dy - u(x,t)\int_0^\infty K(x,y)u(y,t)\,dy\\ &\quad + \int_x^\infty \gamma(y,x)u(y,t)\,dy - u(x,t)\int_0^x \frac{y}{x}\gamma(x,y)\,dy, \quad \text{a.e. } x>0,\ t>0, \qquad (1)\end{aligned}$$

for time-independent kernels γ and K. Results obtained in our earlier paper [5] for the pure fragmentation equation ($K \equiv 0$) are now extended to models where coagulation is also taken into account. Future papers will deal with time-dependent kernels.

We recall that the fragmentation kernel $\gamma(x,y)$ represents the rate at which particles of mass y are produced from fragmenting particles of mass x. This formulation of the fragmentation kernel allows for particles splitting into more than two pieces, yet incorporates the special case of binary fragmentation. The latter case can be described by a symmetric fragmentation kernel $F(x,y)$, obtained from γ by setting $F(x,y) = \gamma(x+y,y)$ for $x, y \geq 0$.

The coagulation kernel $K(x,y)$ is the rate at which particles of mass x coalesce with particles of mass y. We introduce this kernel by assuming that the average number of coalescences between particles having mass in $(x, x+dx)$ and those having mass in $(y, y+dy)$ is $K(x,y)u(x,t)u(y,t)\,dx\,dy\,dt$ during the time interval $(t, t+dt)$. We assume this kernel is symmetric since the rate at which a particle of mass x coalesces with a particle of mass y is the same as that for a particle of mass y coalescing with one of mass x.

The first term on the right-hand side of equation (1) represents the increase in the number of particles of mass x as the result of particles of mass $x-y$ and mass y ($y \leq x$) merging to form a particle of mass x. The factor 1/2 takes into account

that either a particle of mass $x-y$ coalesces with one of mass y or vice versa. The second term accounts for the loss of particles of mass x because they have coalesced with particles of mass y, $y \geq 0$. The remaining terms are attributed to fragmentation and arise as described in [5].

Again, the first step is to recast the rate equation, subject to the initial mass distribution $u(x,0) = f(x)$, as an abstract Cauchy problem (ACP). Arguing as in [5], we arrive at the ACP

$$\begin{aligned} \frac{d}{dt}u(t) &= Au(t) + Nu(t), \quad t > 0, \\ u(0) &= f, \end{aligned} \tag{2}$$

where the linear fragmentation operator A and the nonlinear coagulation operator N are defined on suitable domains by

$$[A\phi](x) = \int_x^\infty \gamma(y,x)\phi(y)\,dy - \phi(x)\int_0^x \frac{y}{x}\gamma(x,y)\,dy \tag{3}$$

and

$$[N\phi](x) = \frac{1}{2}\int_0^x K(x-y,y)\phi(x-y)\phi(y)\,dy - \phi(x)\int_0^\infty K(x,y)\phi(y)\,dy, \tag{4}$$

respectively. By treating the initial-value problem (2) as a nonlinear perturbation of the linear ACP

$$\begin{aligned} \frac{d}{dt}u(t) &= Au(t), \quad t > 0, \\ u(0) &= f, \end{aligned} \tag{5}$$

which corresponds to the pure fragmentation equation ($K \equiv 0$), we are able to make use of the results obtained in [5].

We recall from [5] that, for suitable $f \in L_{1,-1}$, the ACP (5) has a strong solution

$$u(t) = S(t)f, \qquad t \geq 0,$$

in the weighted L_1-space

$$L_{1,-1} = \left\{ \phi : \|\phi\|_{1,-1} = \int_0^\infty x|\phi(x)|\,dx < \infty \right\}.$$

The solution operators

$$\{S(t)\}_{t\geq 0} \tag{6}$$

form a nonnegative, C$_0$-semigroup of isometries on $L_{1,-1}$. Moreover, if f is any function in $L_{1,-1}$ with $f \geq 0$, then

$$u(x,t) = [S(t)f](x) \qquad \text{for all } t \geq 0, \text{ a.e. } x > 0, \tag{7}$$

is a nonnegative solution of the integral version of the fragmentation equation,

$$u(x,t) = f(x) + \int_0^t \int_x^\infty \gamma(y,x)u(y,\sigma)\,dy\,d\sigma - \int_0^t \int_0^x \frac{y}{x}\gamma(x,y)\,dy\,u(x,\sigma)\,d\sigma,$$

and satisfies

$$\int_0^\infty xu(x,t)\,dx = \int_0^\infty xf(x)\,dx \qquad \text{for all } t \geq 0. \tag{8}$$

These results are valid provided that the fragmentation kernel γ satisfies the following hypotheses:

(H1) $\gamma(x,y)$ is a nonnegative function on $(0,\infty)\times(0,\infty)$;

(H2) $\gamma(x,y) = 0$ whenever $y > x$;

(H3) the function $a : (0,\infty) \to [0,\infty)$ defined by

$$a(x) = \int_0^x \frac{y}{x}\gamma(x,y)\,dy, \qquad x > 0, \tag{9}$$

is such that $a(x) \leq C_n$ for all $x \in (0,n],\ n > 0$.

Connections between the operator A, defined by (3), and the infinitesimal generator, $\boldsymbol{\mathcal{A}}$, of the semigroup $\{S(t)\}_{t\geq 0}$ on $L_{1,-1}$ are also given in [5]. For example, A and $\boldsymbol{\mathcal{A}}$ coincide on the subspace $\bigcup_m \mathcal{L}_m$, where

$$\mathcal{L}_m = \{\phi \in L_{1,-1} : \phi \equiv 0 \text{ on } [m,\infty)\}. \tag{10}$$

Although our treatment of (5) was carried out in the space $L_{1,-1}$, we now choose the Banach space X defined by

$$X = \{\phi \in L_{1,-1} \cap L_1 \colon |||\phi||| = \|\phi\|_1 + \|\phi\|_{1,-1} < \infty\} \tag{11}$$

for our analysis of the full equation (2). This space provides a more convenient setting for establishing that the nonlinear coagulation operator N is locally Lipschitz. We obtain the local existence and uniqueness of a mild solution of (2) via a contraction mapping argument. Then, by applying [2, Thm. 2.6, pp. 90–91], we show that the solution is global.

In the first instance, the work presented here extends the results of Aizenman and Bak [1] for constant coagulation and fragmentation kernels to bounded coagulation and bounded, unsymmetric fragmentation kernels. However, in order to prove that the solutions are nonnegative, it has been necessary to restrict attention to constant coagulation kernels and bounded, unsymmetric fragmentation kernels.

Throughout, the following hypotheses are imposed on the kernels K and γ, with the further restriction, K constant, being added only as it is required.

The fragmentation kernel γ satisfies (H1), (H2), and

(H3)$'$ $\gamma \in L^\infty((0,\infty)\times(0,\infty))$.

The coagulation kernel K satisfies the following hypotheses:

(H4) $K(x,y)$ is a nonnegative function on $(0,\infty)\times(0,\infty)$;

(H5) K is symmetric, i.e., $K(x,y) = K(y,x)$ for all $x,y \in (0,\infty)$;

(H6) $K \in L^\infty((0,\infty)\times(0,\infty))$.

As a consequence of (H3)$'$ and (H6), for all $\Omega \subseteq (0,\infty)\times(0,\infty)$,

$$\operatorname*{ess\,sup}_{(x,y)\in\Omega} |\gamma(x,y)| \leq \frac{2}{3}C_F < \infty \qquad \text{where } \frac{2}{3}C_F = \|\gamma(x,y)\|_\infty \tag{12}$$

and

$$\operatorname*{ess\,sup}_{(x,y)\in\Omega} |K(x,y)| \leq C_K < \infty \qquad \text{where } C_K = \|K(x,y)\|_\infty.$$

(The factor 2/3 is chosen for its convenience in later calculations.) We note that hypothesis (H3) is automatically satisfied since

$$a(x) := \int_0^x \frac{y}{x}\gamma(x,y)\,dy \leq \frac{1}{3}C_F x \leq \frac{1}{3}C_F n \quad \text{for all } x \in (0,n].$$

Therefore, the analysis in [5] is also valid for fragmentation kernels γ satisfying (H1), (H2), and (H3)$'$. Also, it follows by [5, Thm. 5.6 and Ex. 5.7(i)] that whenever the fragmentation kernel γ satisfies (H3)$'$, the generator $\boldsymbol{\mathcal{A}}$ of the semigroup $\{S(t)\}_{t\geq 0}$ on $L_{1,-1}$ is a restriction of the operator A.

2. The pure fragmentation semigroup on X.

We begin by showing that the pure fragmentation semigroup $\{S(t)\}_{t\geq 0}$ introduced in (6) also forms a C$_0$-semigroup on X. We need only verify that

$$\lim_{t\to 0^+} |||S(t)\phi - \phi||| = 0 \qquad \text{for all } \phi \in X,$$

since $S(t+s) = S(t)S(s)$ for all $t,\ s \geq 0$, and $S(0) = I$ hold automatically.

Theorem 2.1. *For each $t \geq 0$, let $S(t)$ be the operator introduced in* (6). *Then $\{S(t)\}_{t\geq 0}$ forms a C_0-semigroup on X and*

$$|||S(t)\phi||| \leq (1 + tC_F)\,|||\phi||| \ \textit{ for all } \phi \in X. \tag{13}$$

Proof. Let $\phi \in \bigcup_m \mathcal{L}_m$, where $\mathcal{L}_m$ is defined by (10). By [5, Cor. 6.3], $S(t)\phi$ is a strong solution of the ACP (5) with initial data $f = \phi$, and hence

$$S(t)\phi = \phi + \int_0^t AS(\tau)\phi\,d\tau. \tag{14}$$

By Fubini's theorem and (H3)$'$, $\|[A\psi]\|_1 \leq C_F\,\|\psi\|_{1,-1}$ for all $\psi \in X$. Since the operators $\{S(t)\}_{t\geq 0}$ form a C$_0$-semigroup of isometries on $L_{1,-1}$ (by [5, Lem. 4.1]), it is then not difficult to show that for all $\phi \in \bigcup_m \mathcal{L}_m$,

$$|||S(t)\phi||| = \|S(t)\phi\|_1 + \|S(t)\phi\|_{1,-1} \leq |||\phi||| + \int_0^t \|[AS(\tau)\phi]\|_1\,d\tau \leq (1 + C_F t)\,|||\phi|||\,.$$

The latter result extends to all $\phi \in X$, since for each fixed $t \geq 0$, $S(t)$ is a bounded operator on X.

From (14), we also obtain that $\|S(t)\phi - \phi\|_1 \leq C_F t\,\|\phi\|_{1,-1}$ for $\phi \in \bigcup_m \mathcal{L}_m$. Therefore, for all $\phi \in \bigcup_m \mathcal{L}_m \subseteq X$, we deduce that $S(t)\phi \to \phi$ with respect to the $|||.|||$-norm as $t \to 0^+$. This result extends to all $\phi \in X$ by continuity since $\bigcup_m \mathcal{L}_m$ is dense in X and, for all $t \leq 1$, $\|S(t)\|_{B(X)} \leq (1 + C_F)$. □

It should be noted that the infinitesimal generator, $\mathbf{A}$, of $\{S(t)\}_{t\geq 0}$ on X is not necessarily the same as the infinitesimal generator, $\boldsymbol{\mathcal{A}}$, of $\{S(t)\}_{t\geq 0}$ on $L_{1,-1}$ because now

$$\operatorname*{s-lim}_{t\to 0^+} \frac{S(t)\phi - \phi}{t} \tag{15}$$

is with respect to the $|||.|||$-norm instead of with respect to the $\|.\|_{1,-1}$-norm. However, it is possible to prove that $\mathbf{A}$ is a restriction of $\boldsymbol{\mathcal{A}}$.

THEOREM 2.2. *Let* $\mathbf{A}$ *denote the generator of the semigroup* $\{S(t)\}_{t\geq 0}$ *on* X, *and let* $\boldsymbol{\mathcal{A}}$ *denote the generator of* $\{S(t)\}_{t\geq 0}$ *on* $L_{1,-1}$. *Then* $\mathbf{A}$ *is a restriction of* $\boldsymbol{\mathcal{A}}$ *and hence is also a restriction of the operator* A *defined by* (3).

Proof. Let $\phi \in \mathcal{D}(\mathbf{A})$. By definition, the limit (15) with respect to the $|||.|||$-norm exists and equals $\mathbf{A}\phi$. Hence the limit (15) with respect to the $\|.\|_{1,-1}$-norm exists and equals $\mathbf{A}\phi$. The latter implies that $\phi \in \mathcal{D}(\boldsymbol{\mathcal{A}})$ and $\boldsymbol{\mathcal{A}}\phi = \mathbf{A}\phi$. Thus $\mathbf{A}$ is a restriction of $\boldsymbol{\mathcal{A}}$, which in turn is a restriction of A by our earlier discussion. □

The previous result shows that we may write $\mathbf{A}\phi = A\phi$ for all $\phi \in \mathcal{D}(\mathbf{A})$. Moreover, the operator A restricted to $\mathcal{D}(\mathbf{A})$ generates the semigroup $\{S(t)\}_{t\geq 0}$ on X.

3. Existence and uniqueness of solutions to the coagulation and fragmentation equation.

Our first step is to establish that the operator N which appears in the inhomogeneous term $Nu(t)$ on the right-hand side of (2) is locally Lipschitz on X.

LEMMA 3.1. *Let the coagulation kernel* K *satisfy* (H4)–(H6). *Then the operator* $N : X \to X$ *defined by* (4) *is continuous and satisfies the Lipschitz condition*

$$|||N\phi - N\psi||| \leq 2C_K\,(|||\phi||| + |||\psi|||)\,|||\phi - \psi||| \tag{16}$$

whenever $\phi,\ \psi \in X$, *i.e.,* N *is locally Lipschitz on* X.

Proof. The proof is not difficult and makes use of Fubini's Theorem, (H6), and the simple result that $\|\phi\|_1 \leq |||\phi|||$ and $\|\phi\|_{1,-1} \leq |||\phi|||$ for all $\phi \in X$. See [4, Lem. 4.3, pp. 76–77] for details. □

To obtain the local existence and uniqueness of a mild solution to the initial-value problem (2), we use a contraction mapping argument in the Banach space $Y_{b,T}$ defined by

$$Y_{b,T} = \{y \in C([0,T], X) : |||y|||_\infty < b\}, \tag{17}$$

where

$$|||y|||_\infty = \sup_{t\in[0,T]} |||y(t)|||\,.$$

For given initial data $f \in X$, the constant b is chosen such that $|||f||| < b$, and then T is chosen sufficiently small in order to satisfy the inequalities that arise in subsequent proofs.

THEOREM 3.2. *Let* $f \in X$. *For a suitable choice of* T *and* b, *the map* $u \to W_f u$ *defined by*

$$[W_f u](t) = S(t)f + \int_0^t S(t-\sigma)N(u(\sigma))\,d\sigma, \quad t \in [0,T], \tag{18}$$

has a unique fixed point $\tilde{u}$ *in the space* $Y_{b,T}$ *defined by* (17). *Moreover,* $\tilde{u}(0) = f$.

Proof.

(i) Our first step is to prove that $W_f(Y_{b,T}) \subseteq Y_{b,T}$. Let $u \in Y_{b,T}$. Then, for all $t \in [0,T]$, $N(u(t)) \in X$ and

$$|||N(u(t)))||| \leq 2C_K\,|||u(t)|||^2 \leq 2C_K b^2 < \infty,$$

by (16) with $\phi = u(t)$ and $\psi \equiv 0$. Therefore, using (13), we obtain

$$|||[W_f u](t)||| \leq |||f||| + TC_F b + \left(T + \frac{T^2}{2}C_F\right)2C_K b^2. \tag{19}$$

Since the right-hand side of (19) is finite, $[W_f u](t) \in X$ for all $t \in [0,T]$. Now let $t_1, t_2 \in [0,T]$ with $t_1 = t_2 + t,\ t > 0$. Then

$$\begin{aligned}&|||[W_f u](t_1) - [W_f u](t_2)|||\\ &\le |||(S(t)-I)S(t_2)f||| + \int_{t_2}^{t_1} |||S(t_1 - t_2)S(t_2 - \sigma)N(u(\sigma))|||\, d\sigma\\ &\qquad\qquad + \int_0^{t_2} |||(S(t) - I)S(t_2 - \sigma)N(u(\sigma))|||\, d\sigma.\end{aligned}$$

Since $S(t)$ is strongly continuous on X (by Theorem 2.1), we deduce that $W_f u \in C([0,T], X)$. Moreover, using (19) and choosing T sufficiently small, we arrive at

$$|||W_f u|||_\infty \le |||f||| + TC_F b + \left(T + \frac{T^2}{2} C_F\right) 2C_K b^2 < b.$$

(Note that such a choice of T is possible by continuity since the strict inequality holds for $T = 0$ and hence for T sufficiently close to zero.) Hence $|||W_f u|||_\infty < b$, and so $W_f u \in Y_{b,T}$ whenever $u \in Y_{b,T}$.

(ii) We now show that the map $u \to W_f u$ is a contraction mapping on $Y_{b,T}$. Let $u, v \in Y_{b,T}$. By (13), (16), and (18),

$$\begin{aligned}|||W_f u - W_f v|||_\infty &\le \sup_{t \in [0,T]} 4C_K b \int_0^t (1 + (t-\sigma)C_F)\, |||u(\sigma) - v(\sigma)|||\, d\sigma\\ &\le 4C_K b \left(T + \frac{T^2}{2} C_F\right) |||u - v|||_\infty .\end{aligned}$$

We now choose T sufficiently small so that, in addition to the previous requirement on T,

$$|||W_f u - W_f v|||_\infty \le \lambda\, |||u - v|||_\infty \quad \text{for some constant } \lambda \in (0,1);$$

i.e., we choose T such that

$$4C_K b \left(T + \frac{T^2}{2} C_F\right) \le \lambda$$

is also valid. Then, by the contraction mapping principle, there exists a unique fixed point $\tilde{u} \in Y_{b,T}$. Finally, we note that $\tilde{u}(0) = [W_f \tilde{u}](0) = f$. □

THEOREM 3.3. *Let u be the unique fixed point of the map $u \to W_f u$ obtained in Theorem 3.2. Then*

$$\int_0^\infty x[u(t)](x)\, dx = \int_0^\infty x f(x)\, dx \qquad \textit{for all } t \in [0,T].$$

Proof. By definition,

$$u(t) = S(t)f + \int_0^t S(t-\sigma)N(u(\sigma))\, d\sigma, \qquad 0 \le t \le T.$$

Therefore, by (7) and (8) (see [5, Lem. 4.1(ii)]),

$$\int_0^\infty x[u(t)](x)\, dx = \int_0^\infty x f(x)\, dx + I(t),$$

where

$$I(t) = \int_0^\infty x \left[\int_0^t S(t-\sigma) N(u(\sigma))\, d\sigma \right](x)\, dx.$$

Thus, it remains to prove that $I(t) = 0$ for all $t \in [0, T]$.

It follows from Theorem 2.1 and Lemma 3.1 that $N(u(.))$ and $S(t-.)N(u(.))$ are strongly continuous on X. Since X is a Banach space of type L [3, pp. 69–71], we note that

$$\left[\int_0^t S(t-\sigma) N(u(\sigma))\, d\sigma \right](x) = \int_0^t \left[S(t-\sigma) N(u(\sigma)) \right](x)\, d\sigma.$$

By Fubini's theorem, (7), and (8),

$$I(t) = \int_0^t \int_0^\infty x[N(u(\sigma))](x)\, dx\, d\sigma.$$

By interchanging orders of integration and making a change of variable $x' = x - y$ on the left-hand side, it is not difficult to show that

$$\frac{1}{2} \int_0^\infty \int_0^x xK(x-y,y)\phi(x-y)\phi(y)\, dy\, dx = \int_0^\infty x\phi(x) \int_0^\infty K(x,y)\phi(y)\, dy\, dx,$$

and so from (4),

$$\int_0^\infty x[N(u(\sigma))](x)\, dx = 0, \qquad 0 \le \sigma \le t \le T. \qquad \square$$

THEOREM 3.4 (existence and uniqueness of a mild solution). *Let $f \in X$. Then there exists $T \in (0, \infty]$ such that for $t \in [0, T)$ equation* (2) *has a unique mild solution with $u(0) = f$ and $u(t) \in X$ for all $t \in [0, T)$. The maximal T, $\widehat{T}$, with this property is finite only if* $\lim_{t \to \widehat{T}^-} |||u(t)||| = \infty$.

Proof. The mild solution of equation (2) on $[0, T]$ is given by the unique fixed point of the map $u \to W_f u$ obtained in Theorem 3.2. The result follows directly from [2, Thm. 2.6, pp. 90–91]. $\square$

COROLLARY 3.5. *Let u be the mild solution of* (2) *on* $[0, \widehat{T})$. *Then*

$$\int_0^\infty x[u(t)](x)\, dx = \int_0^\infty xf(x)\, dx \qquad \textit{for all } t \in [0, \widehat{T}).$$

Proof. The result follows from Theorems 3.3 and 3.4. $\square$

4. A nonnegative solution to the coagulation and fragmentation equation. In this section we prove that the mild solution obtained in Theorem 3.4 is nonnegative whenever the initial data f is nonnegative. This result is analogous to that given in [1] for the case of constant fragmentation kernels and is established by a similar argument. However, as the justification provided in [1] is somewhat incomplete, we feel it is desirable to include more detail here.

We now assume that the coagulation kernel K satisfies

(H7) $K(x, y) = C_K > 0$ for all $(x, y) \in (0, \infty) \times (0, \infty)$, in which case (H4)–(H6) are immediately satisfied. The operator N defined by (4) now reduces to

$$[N\phi](x) = \frac{C_K}{2}\int_0^x \phi(x-y)\phi(y)\,dy - C_K\phi(x)\int_0^\infty \phi(y)\,dy, \tag{20}$$

and the map $u(t) \to [W_f u](t)$, defined by (18), becomes

$$u(t) \to S(t)f + \int_0^t S(t-\sigma)\left\{\frac{C_K}{2}\int_0^{\cdot}[u(\sigma)](.-y)[u(\sigma)](y)\,dy \right. \\ \left. -C_K[u(\sigma)]\int_0^\infty [u(\sigma)](y)\,dy\right\}d\sigma. \tag{21}$$

In the previous section we proved, via a contraction mapping argument on the space $Y_{b,T}$ (defined by (17)), that the map $u \to W_f u$ has a unique fixed point $\tilde{u} \in Y_{b,T}$. The contraction mapping theorem also tells us that for any initial estimate $u_{(1)} \in Y_{b,T}$, the successive approximations $u_{(n+1)} = W_f u_{(n)}$ $(n = 1, 2, \dots)$ converge to $\tilde{u}$.

We assume that $\tilde{u}$ is known and consider the successive approximation scheme

$$u_{(n+1)}(t) = S(t)f + \int_0^t S(t-\sigma)\left\{\frac{C_K}{2}\int_0^{\cdot}[\tilde{u}(\sigma)](.-y)[\tilde{u}(\sigma)](y)\,dy \right. \\ \left. + C_K\left(-\int_0^\infty [\tilde{u}(\sigma)](y)\,dy\right)u_{(n)}(\sigma)\right\}d\sigma, \tag{22}$$

$n = 1, 2, \dots$, with a suitable $u_{(1)}(t)$. Notice that we substitute into only one term. We note that $\tilde{u}$ is a fixed point of the associated map

$$\phi(t) \to S(t)f + \int_0^t S(t-\sigma)\left\{\frac{C_K}{2}\int_0^{\cdot}[\tilde{u}(\sigma)](.-y)[\tilde{u}(\sigma)](y)\,dy \right. \\ \left. + C_K\left(-\int_0^\infty [\tilde{u}(\sigma)](y)\,dy\right)\phi(\sigma)\right\}d\sigma. \tag{23}$$

We can show that the map (23) is also a contraction mapping on the space $Y_{b,T}$, and so $\tilde{u}$ is the unique fixed point in $Y_{b,T}$. From the contraction mapping principle applied to the map (23) we obtain that the successive approximations (22) converge to $\tilde{u}$.

We now use the successive approximation scheme (22) to prove that $\tilde{u}$ is nonnegative. We begin by introducing some additional notation to ease computation.

NOTATION 4.1. *Let $\{S(t)\}_{t\geq 0}$ be the C_0-semigroup on X introduced in* (6). *Let $\tilde{u}$ be the unique fixed point of the map $u \to W_f u$ (defined by* (21)*) and suppose that $\tilde{u}$ is known. Then we define*

(i) *$h\colon [0,T] \to X$ by $h(t) := S(t)f$, $t \in [0,T]$;*

(ii) *$g\colon (t,\sigma) \to g(t,\sigma) \in X$, $0 \leq \sigma \leq t \leq T$, by*

$$g(t,\sigma) := S(t-\sigma)\left[\frac{C_K}{2}\int_0^{\cdot}[\tilde{u}(\sigma)](.-y)[\tilde{u}(\sigma)](y)\,dy\right] = S(t-\sigma)\mathcal{N}_1(\tilde{u}(\sigma)),$$

where $\mathcal{N}_1$ is defined for $\phi \in X$ by

$$(\mathcal{N}_1\phi)(x) := \frac{C_K}{2}\int_0^x \phi(x-y)\phi(y)\,dy, \qquad \text{a.e. } x > 0; \tag{24}$$

(iii) *$\xi\colon [0,T] \to \mathbf{R}$ by $\xi(t) := -C_K\int_0^\infty [\tilde{u}(t)](y)\,dy$;*

(iv) $\beta\colon [0,T]\times[0,T]\to \mathbf{R}$ *by* $\beta(t,\sigma) := \int_\sigma^t \xi(\tau)\,d\tau$*;*

(v) $\alpha : [0,T] \to \mathbf{R}$ *by* $\alpha(t) := \beta(t,0)$*.*

On using the above notation, we can write the successive approximation scheme (22) as

$$u_{(n+1)}(t) = h(t) + \int_0^t g(t,\sigma)\,d\sigma + \int_0^t \xi(\sigma)S(t-\sigma)u_{(n)}(\sigma)\,d\sigma, \tag{25}$$

$n = 1, 2, \ldots$. We can take $\xi(s)$ (also $\alpha(t)$ and $\beta(t,\sigma)$) outside the operator $S(t)$, $t \geq 0$, because the operators $\{S(t)\}_{t\geq 0}$ are linear and $\xi(\sigma)$, $\alpha(t)$, and $\beta(t,\sigma)$ are real numbers.

Lemma 4.2. *For all* $0 \leq r \leq \sigma \leq t \leq T$*,*

$$S(t-\sigma)h(\sigma) = h(t) \text{ and } S(t-\sigma)g(\sigma,r) = g(t,r).$$

Proof. This follows from the semigroup properties of $\{S(t)\}_{t\geq 0}$; see [4, Lem. 4.9, p. 86] for details. □

Lemma 4.3. *For* $0 \leq \sigma \leq t \leq T$, $n \in \mathbf{N}$*,*

$$\int_\sigma^t \xi(\tau)\frac{\beta(\tau,\sigma)^n}{n!}\,d\tau = \frac{\beta(t,\sigma)^{n+1}}{(n+1)!}.$$

Proof. This is a simple proof by induction. See [4, Lem. 4.10, pp. 86–87] for details. □

Lemma 4.4. *For all* $t \in [0,T]$ *and* $n \in \mathbf{N}$*,*

$$\int_0^t \xi(\sigma)\int_0^\sigma g(t,\tau)\frac{\beta(\sigma,\tau)^n}{n!}\,d\tau\,d\sigma = \int_0^t g(t,\sigma)\frac{\beta(t,\sigma)^{n+1}}{(n+1)!}\,d\sigma.$$

Proof. This follows from Lemma 4.3 on changing the order of integration. □

Lemma 4.5. *Let* $u_{(1)}(t)$ *be defined by*

$$u_{(1)}(t) = h(t) + \int_0^t g(t,\sigma)\,d\sigma, \qquad t \in [0,T]. \tag{26}$$

Then $u_{(1)} \in Y_{b,T}$*.*

Proof. The details are similar to the proof of Theorem 3.2, part (i). See [4, Lem. 4.13, pp. 87–89] for details. □

Lemma 4.6. *Let* $u_{(1)}(t)$ *be defined by* (26)*. Then*

$$u_{(n)}(t) = \left[\sum_{i=0}^{n-1}\frac{\alpha(t)^i}{i!}\right]h(t) + \int_0^t \left[\sum_{i=0}^{n-1}\frac{\beta(t,\sigma)^i}{i!}\right]g(t,\sigma)\,d\sigma, \quad n = 1, 2, 3, \ldots,$$

is the general formula for the nth iterate of the successive approximation scheme (25)*.*

Proof. This proof by induction uses Lemma 4.3, with $\sigma = 0$, and Lemma 4.4. We note that we can take $S(t-\sigma)$ under the integral sign because it is a bounded linear operator on X. □

Lemma 4.7. *The fixed point* $\tilde{u}$ *of the map* $u \to W_f u$*, where* $W_f u$ *is given by* (21)*, also satisfies*

$$\tilde{u}(t) = [\exp \alpha(t)]h(t) + \int_0^t [\exp \beta(t,\sigma)]g(t,\sigma)\,d\sigma, \quad t \in [0,T]. \tag{27}$$

(Recall that $\alpha(t), \beta(t,\sigma)$, and $g(t,\sigma)$ depend on $\tilde{u}$.)

Proof. This follows immediately by letting $n \to \infty$ in Lemma 4.6. ◻

The mild solution $u(t)$ of (2) (with $K(x,y) = C_K$) can be obtained as the fixed point of the map $u \to W_f u$ or as the fixed point of the map (23). The above lemma suggests that this mild solution can also be obtained as a fixed point of the map $u \to Vu$ on $Y_{b,T}$ defined by

$$(28) \qquad (Vu)(t) = [\exp \alpha(t)]h(t) + \int_0^t [\exp \beta(t,\sigma)]S(t-\sigma)[\mathcal{N}_1(u(\sigma))]\, d\sigma$$

where $\mathcal{N}_1(u(\sigma))$ is given by (24). The map $u \to Vu$ is obtained from (27) by keeping $\tilde{u}$ in the definition of $\alpha(t)$ and $\beta(t,\sigma)$ but not so in the definition of $g(t,\sigma)$. Therefore, now $g(t,\sigma) = S(t-\sigma)\mathcal{N}_1(u(\sigma))$.

LEMMA 4.8. *For a suitable choice of T and b, the map $u \to Vu$ defined by* (28) *is a contraction mapping on the space $Y_{b,T}$ (defined by* (17)*) and therefore has a unique fixed point $\hat{u} \in Y_{b,T}$. Moreover, for suitable T and b, the fixed point $\hat{u}$ of the map $u \to Vu$ coincides with the fixed point $\tilde{u}$ of the map $u \to W_f u$.*

Proof. As the proof is analogous to the proof of Theorem 3.2, we provide only a brief outline. For further details see [4, Lem. 4.16, pp. 90–93].

(i) We note that for all $u \in Y_{b,T}$, $|\xi(\tau)| \le C_K\, |||\tilde{u}(\tau)||| < C_K b$. Hence, for all $t, \sigma \in [0,T]$, $\exp \beta(t,\sigma) \le \exp(C_K bT)$, and $\exp \alpha(t) \le \exp(C_K bT)$. So for all $t \in [0,T]$, we find

$$(29) \qquad |||(Vu)(t)||| \le \exp(C_K bT)\left[(1+TC_F)\, |||f||| + \left(T + \frac{T^2}{2}C_F\right) C_K b^2\right].$$

To prove $(Vu)(t)$ is a continuous function of t we let $t_1,\ t_2 \in [0,T]$, with $t_1 > t_2$, and consider

$$(30) \qquad |||(Vu)(t_1) - (Vu)(t_2)|||\,.$$

Now (30) can be shown to be bounded by

$$\begin{aligned} &|||\{\exp \alpha(t_1)\}h(t_1) - \{\exp \alpha(t_2)\}h(t_2)||| \\ &\qquad + \int_{t_2}^{t_1} \exp \beta(t_1,\sigma)\, |||S(t_1-t_2)S(t_2-\sigma)\mathcal{N}_1(u(\sigma))|||\, d\sigma \\ &\qquad\qquad - \int_0^{t_2} |||\{\exp \beta(t_1,\sigma)S(t_1-t_2) - \exp \beta(t_2,\sigma)\}S(t_2-\sigma)\mathcal{N}_1(u(\sigma))|||\, d\sigma, \end{aligned}$$

and since

$$|||\exp \beta(t_1,t_2)S(t_1-t_2)f - f||| \to 0 \text{ as } t_1 \to t_2^+,$$

for any $f \in X$, the required continuity of $(Vu)(t)$ follows.

(ii) Using (29) and choosing T appropriately, we obtain

$$|||(Vu)(t)||| \le \exp(C_K bT)(1+TC_F)\, |||f||| + \exp(C_K bT)\left(T + \frac{T^2}{2}C_F\right) C_K b^2 < b$$

for all $t \in [0,T]$, and so $V(Y_{b,T}) \subseteq Y_{b,T}$.

(iii) We can show that for $u, v \in Y_{b,T}$, $\lambda \in (0,1)$,

$$|||(Vu)(t) - (Vv)(t)||| \leq 2C_K b \exp(C_K bT) \left(T + \frac{T^2}{2} C_F\right) |||u - v|||_\infty \leq \lambda \, |||u - v|||_\infty ,$$

provided T is such that

$$2C_K b \exp(C_K bT) \left(T + \frac{T^2}{2} C_F\right) \leq \lambda.$$

(iv) We recall that the map $u \to Vu$ is obtained from (27) by replacing $\tilde{u}$ by u in the definition of $g(t, \sigma)$. Therefore $\tilde{u}$ is a fixed point of $u \to Vu$. Since the fixed point of the map $u \to Vu$ in the space $Y_{b,T}$ is unique, it follows that $\tilde{u} \equiv \hat{u}$. □

The above lemma enables us to state that, for a suitable choice of T and any $u_{(1)} \in Y_{b,T}$, the successive approximations $u_{(n+1)} = Vu_{(n)}$ converge to the fixed point of the map $u \to W_f u$.

Theorem 4.9 (nonnegative solution). *The mild solution u of* (2) *on* $[0, T]$ *is nonnegative whenever the initial data $f \in X$ is nonnegative.*

Proof. From the above discussion and Theorem 3.4, the mild solution u can be found from the nonnegative preserving iterations $u_{(n+1)} = Vu_{(n)}$, $u_{(1)} = f$. □

5. A global solution. By Theorem 3.4, we have the existence and uniqueness of a global mild solution, u, unless there exists a $\widehat{T} < \infty$, such that

$$\lim_{t \to \widehat{T}^-} |||u(t)||| = \infty.$$

We shall prove that there is no such finite $\widehat{T}$ and so establish that there exists a unique, global, nonnegative, mild solution to the ACP formulation (2) of the full coagulation and fragmentation equation (1) with K constant and γ bounded.

Let u be the mild solution of (2) on $[0, \widehat{T})$ and consider the functions M_i $(i = 0, 1)$ defined by

$$M_i(t) = \int_0^\infty x^i [u(t)](x) \, dx, \quad t \in [0, \widehat{T}). \tag{31}$$

For nonnegative $u(t)$,

$$|||u(t)||| = M_0(t) + M_1(t).$$

By Corollary 3.5,

$$M_1(t) = \int_0^\infty x f(x) \, dx \qquad \text{for all } t \in [0, \widehat{T}),$$

and so it follows that

$$\lim_{t \to \widehat{T}^-} |||u(t)||| = \infty \qquad \text{only if} \qquad \lim_{t \to \widehat{T}^-} M_0(t) = \infty. \tag{32}$$

To prove that $\lim_{t \to \widehat{T}^-} M_0(t) = \infty$ cannot hold for any finite $\widehat{T}$, we make use of the following proposition.

PROPOSITION 5.1. *Let $u(t)$ be the mild solution of* (2) *on* $[0, \widehat{T})$. *Then* $u(x,t) = [u(t)](x)$ *satisfies*

$$\begin{aligned} u(x,t) =& f(x) + \int_0^t \left\{ \int_x^\infty \gamma(y,x)u(y,\sigma)\,dy - u(x,\sigma)\int_0^x \frac{y}{x}\gamma(x,y)\,dy \right. \\ &\left. + \frac{1}{2}\int_0^x K(x-y,y)u(x-y,\sigma)u(y,\sigma)\,dy - u(x,\sigma)\int_0^\infty K(x,y)u(y,\sigma)dy \right\} d\sigma \end{aligned}$$

for all $t \in [0, \widehat{T})$, *a.e.* $x > 0$.

Proof. The argument is somewhat involved because we must consider a truncated version of the full equation, even though this step was not necessary to prove existence and uniqueness of a local solution. We postpone this proof until the end of section 6. □

THEOREM 5.2. *Let* $M_0(t)$ *be defined by* (31) *(with* $i = 0$*) and suppose that for all* $t \in [0, \widehat{T})$, $u(t) \geq 0$. *Then*

$$M_0(t) \leq \int_0^\infty f(x)\,dx + \frac{2}{3}tC_F \int_0^\infty xf(x)\,dx.$$

Proof. For all $t \in [0, \widehat{T})$, by Proposition 5.1 and repeated use of Fubini's theorem,

$$\begin{aligned} \int_0^\infty [u(t)](x)\,dx &= \int_0^\infty f(x)\,dx + \int_0^t \left[-\frac{1}{2}\int_0^\infty \int_0^\infty K(x,y)u(y,\sigma)u(x,\sigma)\,dy\,dx \right. \\ &\qquad \left. + \int_0^\infty \int_0^x \left(1 - \frac{y}{x}\right)\gamma(x,y)\,dy\,u(x,\sigma)\,dx \right] d\sigma \\ &\leq \int_0^\infty f(x)\,dx + \int_0^t \int_0^\infty \int_0^x \gamma(x,y)\,dy\,u(x,\sigma)\,dx\,d\sigma \\ &\qquad \text{(since } u(\sigma) \geq 0 \text{ for all } \sigma \in [0,t],\ t \in [0,\widehat{T})\ \text{)} \\ &\leq \int_0^\infty f(x)\,dx + \int_0^t \int_0^\infty \frac{2}{3}C_F x u(x,\sigma)\,dx\,d\sigma \quad \text{(by (12))} \\ &= \int_0^\infty f(x)\,dx + \frac{2}{3}tC_F \int_0^\infty xf(x)\,dx. \qquad \square \end{aligned}$$

COROLLARY 5.3. *There does not exist a finite* $\widehat{T}$ *such that*

$$\lim_{t \to \widehat{T}^-} |||u(t)||| = \infty.$$

Proof. This follows immediately from Theorem 5.2 and (32). □

Thus, by the above discussion, we have established the following theorem.

THEOREM 5.4. *Let the fragmentation kernel* γ *satisfy* (H1), (H2), *and* (H3)′, *and let the coagulation kernel* K *satisfy* (H7). *Then the ACP* (2) *has a unique, global, nonnegative, mass-conserving mild solution.*

We remark that Proposition 5.1 enables us to relate the mild solution of the ACP (2) to a solution of the coagulation and fragmentation equation (1).

THEOREM 5.5. *Let* γ *and* K *be as in Theorem* 5.4. *Then the coagulation and fragmentation equation* (1) *has a nonnegative mass-conserving solution* u *given by*

$$u(x,t) = [u(t)](x) \qquad \text{for a.e. } (x,t) \in (0,\infty) \times [0,\infty),$$

where $u(t)$ $(t \geq 0)$ is the unique mild solution of the ACP (2) *obtained in Theorem* 5.4. *Moreover, this is the only solution of* (1) *such that the vector-valued function $u(.,t)$, $t \geq 0$, is a mild solution of the ACP* (2).

Proof. By Proposition 5.1, the scalar-valued function u, constructed via

$$u(x,t) = [u(t)](x) \qquad \text{for all } t \geq 0 \text{ and a.e. } x \in (0,\infty),$$

is absolutely continuous and satisfies (1) for a.e. $(x,t) \in (0,\infty) \times [0,\infty)$. The scalar-valued function inherits the nonnegativity and mass conservation from the vector-valued function. Uniqueness of the mild solution of (2) implies the uniqueness statement in the theorem. $\square$

6. A truncated coagulation and fragmentation equation. We now investigate a truncated version of the full coagulation and fragmentation equation (1) and an associated truncated version of the ACP (2). The truncated coagulation and fragmentation equation is given by

(33)
$$\frac{\partial}{\partial t}u(x,t) = \begin{cases} \frac{1}{2}\int_0^x K(x-y,y)u(x-y,t)u(y,t)dy - u(x,t)\int_0^{m-x} K(x,y)u(y,t)dy \\ \qquad + \int_x^m \gamma(y,x)u(y,t)dy - a(x)u(x,t), & \text{for a.e. } x < m, \\ \\ 0, & \text{for a.e. } x \geq m, \end{cases}$$

where a is defined by (9). We make use of the projection operator P_m $(m > 0)$ on X defined by

$$(P_m\phi)(x) = \begin{cases} \phi(x), & 0 < x < m, \\ 0, & x \geq m. \end{cases}$$

We seek a sequence $\{u_m(t)\}_{m>0}$ of approximating solutions satisfying the truncated ACP,

$$\begin{aligned} \frac{d}{dt}u_m(t) &= A_m u_m(t) + N_m u_m(t), \quad t > 0, \\ u_m(0) &= f_m, \end{aligned} \tag{34}$$

where $A_m \equiv AP_m$ and where

(35)
$$(N_m\phi)(x) = \begin{cases} \frac{1}{2}\int_0^x K(x-y,y)\phi(x-y)\phi(y)dy - \phi(x)\int_0^{m-x} K(x,y)\phi(y)dy, & x<m, \\ 0, & x \geq m. \end{cases}$$

Note that $N_m\phi \not\equiv NP_m\phi$. The initial data f_m for the truncated problem is chosen so that $|||f_m - f||| \to 0$ as $m \to \infty$, where f is the initial data for the nontruncated problem in X. At this point, we do not state the form that f_m takes, but note that f_m could equal $P_m f$.

For each fixed $m > 0$, a mild solution u_m of (34) satisfies the integral equation

$$u_m(t) = S_m(t)f_m + \int_0^t S_m(t-s)N_m(u_m(s))\,ds, \quad t \geq 0, \tag{36}$$

where $\{S_m(t)\}_{t\geq 0}$ is the linear semigroup generated by A_m on the space X defined by (11). So, we consider the map $u \to W_{m,f_m}u$ where, for each fixed $t \in [0,T]$,

$$[W_{m,f_m}u](t) = S_m(t)f_m + \int_0^t S_m(t-s)[(N_m u)(s)]\,ds. \tag{37}$$

(Compare (37) with the definition of $W_f u$ given by (18).) By repeating the argument used for the map $u \to W_f u$ in sections 2 and 3, we can prove the existence and uniqueness of a mild solution of (34). The appropriate norm estimates for the truncated operators are stated in the next two lemmas.

Lemma 6.1. *Let $\{S(t)\}_{t\geq 0}$ and $\{S_m(t)\}_{t\geq 0}$ be the linear semigroups generated by A and A_m, respectively, on X. Then for all $m > 0$, $t \geq 0$, and $\phi \in X$,*

(i) $S_m(t)\phi = (I - P_m)\phi + S(t)P_m\phi$;

(ii) $|||S_m(t)\phi||| \leq (1 + tC_F)\,|||\phi|||$;

(iii) $|||S(t)\phi - S_m(t)\phi||| \leq (2 + tC_F)\,|||\phi|||$.

Proof. Part (i) is a rewrite of [5, Lem. 4.1(iii)]. For parts (ii) and (iii), we use (12) in conjunction with part (i). □

Lemma 6.2. *The operator $N_m\colon X \to X$, defined by* (35), *is continuous and satisfies the Lipschitz condition*

$$|||N_m\phi - N_m\psi||| \leq 2C_K\,(|||\phi||| + |||\psi|||)\,|||\phi - \psi||| \tag{38}$$

whenever ϕ, $\psi \in X$. (Compare (38) *with the inequality* (16) *for N.)*

Proof. The proof is almost identical to that for Lemma 3.1. See [4, Lem. 4.24, pp. 99–100] for details. □

The next theorem is analogous to the combined results of Theorems 3.2 and 3.4.

Theorem 6.3. *For each fixed $m > 0$, let $f_m \in X$. Then, for a suitable choice of T and b, the map $u \to W_{m,f_m}u$ has a unique fixed point u_m in the space $Y_{b,T}$ defined by* (17), *where now the choice of b is such that $b > \max(|||f_m|||\,, |||f|||)$. Furthermore, there exists $T \in (0, \infty]$ such that the ACP* (34) *has a unique mild solution $u_m(t) \in X$ for all $t \in [0, T)$. The maximal T, $\widehat{T}$, with this property is finite only if $\lim_{t\to\widehat{T}^-} |||u_m(t)||| = \infty$.*

Proof. The argument follows from that outlined in the proof of Theorem 3.2 for the fixed point of the map $u \to W_f u$. We replace u, $S(t)$, Nu, and $W_f u$ by u_m, $S_m(t)$, $N_m u_m$, and $W_{m,f_m}u$, respectively. Note that $S_m(t)$ is uniformly continuous with respect to the $|||.|||$-norm since the generator A_m of $\{S_m(t)\}_{t\geq 0}$ is a bounded linear operator on X. □

Remark 6.4. The truncated data f_m is chosen such that $f_m \to f$ in X. Therefore, there exists $b > 0$ such that $b > \max(|||f_m|||\,, |||f|||)$ for all $m > 0$, and it may be assumed that the choice of b and T in the above theorem coincides with the choice of b and T in Theorem 3.2. Thus the contraction constant $\lambda \in (0, 1)$ such that

$$|||W_{m,f_m}u - W_{m,f_m}v||| \leq \lambda\,|||u - v|||$$

is independent of m.

Corollary 6.5. *The mild solution u_m of* (34) *obtained in Theorem* 6.3 *is also a strong solution.*

Proof. Note that A_m is a bounded operator on X. Also, $S_m(t - .)N_m(u_m(.))$ can be shown to be strongly continuous. Therefore, differentiating the integral equation (36), we see that the mild solution also satisfies (34) in a strong sense. □

Corollary 6.6. *Let $u_m(x, t) = [u_m(t)](x)$ for a.e. $x > 0$, $t \in [0, T]$. Then for all $t > 0$, $u_m(\,.\,,\,.\,)$ satisfies the truncated coagulation and fragmentation equation* (33) *a.e. and $u_m(x, 0) = f_m(x)$ a.e.*

Proof. By Corollary 6.5, $u_m(t)$ is a strong solution of (34). The proof now follows along similar lines to the proof of [5, Thm. 7.1]. Since X is a Banach space of type L

[3, pp. 69–70], for $t \in (0,T]$ and a.e. $x \in (0,\infty)$,

$$\frac{\partial}{\partial t}u_m(x,t) = \left[\frac{d}{dt}u_m(t)\right](x) = [A_m u_m(t)](x) + [N_m u_m(t)](x),$$

and the right-hand side of the latter equals the right-hand side of (33), as required. ☐

We can use this pointwise version of the solution to the truncated problem to prove Proposition 5.1. We shall require the following two lemmas.

Lemma 6.7. *Let $\phi \in X$ and let the operators N and N_m be defined by* (4) *and* (35)*, respectively. Then*

$$|||N_m\phi - N\phi||| \to 0, \qquad \text{as } m \to \infty.$$

Proof. Let $v_m(x) = (N_m\phi)(x) - (N\phi)(x)$, $x > 0$. For a given $x > 0$, we can always choose m sufficiently large so that

$$v_m(x) = \phi(x)\int_{m-x}^{\infty} K(x,y)\phi(y)\,dy.$$

Since $K(x,y) \le C_K$ and $\phi \in X \subseteq L_1$, it follows that $v_m(x) \to 0$ for a.e. $x > 0$ as $m \to \infty$. Also, for all $x > 0$,

$$|(1+x)v_m(x)| \le C_K\,|||\phi|||\,(1+x)|\phi(x)| + \frac{C_K}{2}(1+x)\int_0^x |\phi(x-y)||\phi(y)|\,dy,$$

and the right-hand side is an integrable function over $(0,\infty)$. By the Lebesgue dominated convergence theorem,

$$\int_0^\infty (1+x)|v_m(x)|\,dx \to \int_0^\infty (1+x).0\,dx = 0 \quad \text{as } m \to \infty;$$

i.e., $|||N_m u - Nu||| \to 0$ as $m \to \infty$. ☐

Lemma 6.8. *Let $f_m \in \mathcal{L}_m$. For a suitable choice of T and b, let u be the mild solution of* (2) *on $[0,T]$, and let u_m be the mild solution of* (34) *on the same time-interval. Then, for all $t \in [0,T]$,*

$$|||u_m(t) - u(t)||| \to 0 \qquad \textit{whenever} \qquad |||f_m - f||| \to 0,$$

and the convergence is uniform in t.

Proof. We choose T so that the contraction mapping principle can be applied simultaneously to the maps $u \to W_f u$ and $u \to W_{m,f_m}u$ on the space $Y_{b,T}$ defined by (17). (See Theorems 3.2 and 6.3.) Such a choice of T is possible by Remark 6.4. The contraction mapping principle tells us that

$$|||W^k_{m,f_m}u - u_m|||_\infty \to 0 \qquad \text{as } k \to \infty,$$

since the mild solution $u \in Y_{b,T}$ is a suitable choice for the initial estimate. Using a telescoping series we obtain

$$|||u_m - u|||_\infty \le \sum_{k=0}^{\infty} \lambda^k\,|||W_{m,f_m}u - u|||_\infty$$

where the contraction constant $\lambda < 1$ is independent of m (Remark 6.4). Hence

$$|||u_m - u|||_\infty \leq (1-\lambda)^{-1} \, |||W_{m,f_m} u - u|||_\infty .$$

Now

$$\begin{aligned} &|||[W_{m,f_m} u](t) - u(t)||| \\ &\leq |||S_m(t) f_m - S(t) f||| + \int_0^t |||S_m(t-s)[N_m(u(s))] - S(t-s)[N(u(s))]||| \, ds \\ &= |||S(t)[f_m - f]||| + \int_0^t |||S(t-s)[N_m(u(s)) - N(u(s))]||| \, ds, \end{aligned}$$

since for all $t \in [0,T]$, $N_m(u(t)) \in \mathcal{L}_m$ (see (35)) and $S(t)\phi = S_m(t)\phi$ whenever $\phi \in \mathcal{L}_m$ (from Lemma 6.1(i)). Therefore, by (12),

$$|||W_{m,f_m} u - u|||_\infty \leq (1+TC_F) \, |||f_m - f||| + (1+TC_F) \int_0^T |||N_m(u(s)) - N(u(s))||| \, ds.$$

By the bounded convergence theorem and Lemma 6.7,

$$\int_0^T |||N_m(u(s)) - N(u(s))||| \, ds \to 0 \quad \text{as} \quad m \to \infty.$$

Hence, finally, as $m \to \infty$,

$$|||u_m - u|||_\infty \to 0 \quad \text{whenever} \quad |||f_m - f||| \to 0. \qquad \square$$

Proof of Proposition 5.1. The idea behind this proof is similar to that of [5, Thm. 7.3]. We know that the solution $u_m(t)$ of the truncated problem converges strongly in X, uniformly with respect to $t \in [0,T]$, to the solution $u(t)$ of the full equation whenever the truncated data $f_m \in \bigcup_n \mathcal{L}_n$ converges strongly to f. Therefore, repeating the argument used in the proof of [5, Thm. 7.3], we obtain the existence of a subsequence $\{m_k\}$ such that whenever $f_{m_k} \to f$ strongly in X as $m_k \to \infty$, $u_{m_k}(x,t) \to u(x,t)$ for all $t \in [0,T]$ and a.e. $x \in (0,\infty)$, and also for a.e. $(x,t) \in (0,\infty) \times (0,\infty)$.

By Corollary 6.6, $u_{m_k}(x,t)$ satisfies (33) and hence satisfies the integral equation obtained by integrating both sides of (33) over $s \in [0,t]$. As before, we take limits as $k \to \infty$ on both sides of this integrated version of (33) to obtain the corresponding integral equation satisfied by $u(x,t)$.

We choose $f_m = P_m f$ so that $f_{m_k}(x) \to f(x)$ for a.e. $x > 0$. Applying the above procedure we find that

$$\begin{aligned} u(x,t) = f(x) + \lim_{m_k \to \infty} \Big\{ &\int_0^t \int_x^\infty \gamma(y,x) u_{m_k}(y,\sigma) dy d\sigma - \int_0^t a(x) u_{m_k}(x,\sigma) d\sigma \\ &+ \frac{1}{2} \int_0^t \int_0^x K(x-y,y) u_{m_k}(x-y,\sigma) u_{m_k}(y,\sigma) dy d\sigma \\ &- \int_0^t u_{m_k}(x,\sigma) \int_0^{m_k - x} K(x,y) u_{m_k}(y,\sigma) dy d\sigma \Big\}. \end{aligned} \tag{39}$$

(i) Since $u_{m_k}(t) \to u(t)$ uniformly in t, $\int_0^t u_{m_k}(\sigma)\, d\sigma \to \int_0^t u(\sigma)\, d\sigma$ in X. Therefore, there exists a subsequence of $\{m_k\}$ which we also denote by $\{m_k\}$, such that

$$\left[\int_0^t u_{m_k}(\sigma)\, d\sigma\right](x) \to \left[\int_0^t u(\sigma)\, d\sigma\right](x) \quad \text{for a.e. } x > 0.$$

We deduce that $\int_0^t u_{m_k}(x,\sigma)\,d\sigma \to \int_0^t u(x,\sigma)\,d\sigma$ since X is a Banach space of type L, and so for a.e. $x \in (0,\infty)$, $\int_0^t a(x)u_{m_k}(x,\sigma)\,d\sigma \to \int_0^t a(x)u(x,\sigma)\,d\sigma$ as $m_k \to \infty$.

(ii) We can show that, for each fixed $\sigma \in [0,t]$, $g_{m_k}(\sigma) \to g(\sigma)$ strongly in X, where

$$[g_{m_k}(\sigma)](x) = \int_0^x K(x-y,y)u_{m_k}(x-y,\sigma)u_{m_k}(y,\sigma)dy,$$

and likewise for $[g(\sigma)](x)$, with u_{m_k} replaced by u. For each $m_k > 0$, $|||g_{m_k}(\sigma)||| \leq 2C_K b^2$. Thus, by the Lebesgue dominated convergence theorem for Bochner integrable functions [3, Thm. 3.7.9, p. 83], $\int_0^t g_{m_k}(\sigma)\,d\sigma \to \int_0^t g(\sigma)\,d\sigma$ in X. Again, there exists a subsequence of $\{m_k\}$ such that

$$\int_0^t [g_{m_k}(\sigma)](x)\,d\sigma \to \int_0^t [g(\sigma)](x)\,d\sigma.$$

Thus

$$\int_0^t\!\!\int_0^x K(x-y,y)u_{m_k}(x-y,\sigma)u_{m_k}(y,\sigma)\,dy\,d\sigma \to \int_0^t\!\!\int_0^x K(x-y,y)u(x-y,\sigma)u(y,\sigma)\,dy\,d\sigma.$$

(iii) In a similar manner to part (ii), we can show that

$$\int_0^t u_{m_k}(x,\sigma)\int_0^{m_k-x} K(x,y)u_{m_k}(y,\sigma)\,dy\,d\sigma \to \int_0^t u(x,\sigma)\int_0^\infty K(x,y)u(y,\sigma)\,dy\,d\sigma.$$

(iv) Substituting parts (i)–(iii) into (39), we know that

$$\lim_{m_k\to\infty}\int_0^t\int_x^\infty \gamma(y,x)u_{m_k}(y,\sigma)\,dy\,d\sigma$$

exists in $\mathbf{R}$. We can show that

$$\lim_{m_k\to\infty}\int_x^\infty \gamma(y,x)u_{m_k}(y,\sigma)\,dy = \int_x^\infty \gamma(y,x)u(y,\sigma)\ dy,$$

and that

$$\left|\int_x^\infty \gamma(y,x)u_{m_k}(y,\sigma)dy\right| \leq \tfrac{2}{3}C_F b.$$

Hence, by the Lebesgue dominated convergence theorem,

$$\int_0^t\int_x^\infty \gamma(y,x)u_{m_k}(y,\sigma)dyd\sigma \to \int_0^t\int_x^\infty \gamma(y,x)u(y,\sigma)dyd\sigma$$

as $m_k \to \infty$.

Substituting (i)–(iv) into (39), we complete the proof of Proposition 5.1. □

We conclude by commenting on the difficulty of proving the nonnegativity of the solution of the truncated system. If we attempt to follow the steps carried out in section 4, then we must first modify the definitions given in Notation 4.1. In particular, Notation 4.1(iii) is replaced by

$$\xi\colon (0,m)\times[0,T] \to \mathbf{R}$$

defined by $\xi(x,t) := -C_K \int_0^{m-x} [\tilde{u}_m(t)](y)\,dy$.

The problem we now face is that the function ξ depends on x as well as t. This means that

$$\big(S(t-\sigma)[\xi(\,.\,,\sigma)\tilde{u}_m(\sigma)]\big)(\,.\,) \neq \xi(\,.\,,\sigma)\big(S(t-\sigma)[\tilde{u}_m(\sigma)]\big)(\,.\,),$$

and so we cannot perform the step leading to (25). Had we been able to carry out this interchange, the result would have followed immediately from the results of Lemmas 4.2–4.8 and Theorem 4.9, after appropriate changes had also been made to the definitions of h, g, β, and α. It should, however, be noted that in their analysis of the truncated full equation for constant kernels, Aizenman and Bak [1] state that the solution to the truncated full equation can be shown to be nonnegative by the same argument as that used for the nontruncated equation; unfortunately, no details are supplied.

INVERSE BACKSCATTERING FOR THE ACOUSTIC EQUATION [*]

PLAMEN STEFANOV[†] AND GUNTHER UHLMANN[‡]

Abstract. In this paper, we consider the inverse backscattering problem for the acoustic equation. The problem is to determine the sound speed of a medium by measuring the response to sound waves in the backscattering direction, i.e., by measuring the echoes. We prove that one can uniquely identify the sound speed from this information if it is a priori close to the constant sound speed.

Key words. backscattering, inverse problems, acoustic equation

1. Introduction and statement of the results.

Consider the acoustic wave equation

$$(\partial_t^2 - c^2(x)\Delta)u = 0, \qquad (t,x) \in \mathbf{R}\times\mathbf{R}^3, \tag{1.1}$$

which describes the propagation of sound waves in an inhomogeneous medium with sound speed $c(x)$. We assume throughout the paper that $0 < c(x)$, $x \in \mathbf{R}^3$, and that for some $\rho > 0$ we have

$$c(x) = 1 \qquad \text{for } |x| \geq \rho. \tag{1.2}$$

The scattering kernel measures, roughly speaking, the effect of the inhomogeneity on an incident plane wave of the form $\delta(t - x\cdot\theta)$ with $\theta \in S^2$. More precisely, assume that $c \in C^2(\mathbf{R}^3)$ and let $u(t,x,\theta)$ be the solution of the Cauchy problem

$$\left\{\begin{array}{rcll} (\partial_t^2 - c^2(x)\Delta)u &=& 0, & (t,x)\in\mathbf{R}\times\mathbf{R}^3,\\ u|_{t\ll 0} &=& \delta(t - x\cdot\theta). & \end{array}\right. \tag{1.3}$$

We have that

$$u = \partial_t^3 w,$$

where $w(t,x,\theta)$ solves

$$\left\{\begin{array}{rcll} (\partial_t^2 - c^2(x)\Delta)w &=& 0, & (t,x)\in\mathbf{R}\times\mathbf{R}^3,\\ w|_{t\ll 0} &=& h_2(t - x\cdot\theta), & \end{array}\right.$$

with $h_2(s) = s^2/2$ for $s \geq 0$, and $h_2(s) = 0$ otherwise. We write

$$w = h_2(t - x\cdot\theta) + w_{\text{sc}}.$$

In the Lax–Phillips theory of scattering [L-P] (see also [C-S], [P]) the *asymptotic wave profile* $w_{\mathrm{sc}}^{\#}$ of w_{sc} is defined by

$$w_{\mathrm{sc}}^{\#}(s,\omega,\theta) = \lim_{t\to\infty}(t+s)\partial_t w_{\mathrm{sc}}(t,(t+s)\omega,\theta),$$

where the limit exists in $L^2(\mathbf{R}_s \times S^2_\omega)$ for any $\theta \in S^2$. Then the *scattering kernel* is given by

$$S(s,\omega,\theta) = -\frac{1}{2\pi}\partial_s^3 w_{\mathrm{sc}}^{\#}(s,\omega,\theta).$$

We note that the scattering kernel S is closely connected with the Schwartz kernel of the scattering operator $\mathcal{S}$. In fact, $S(s'-s,\omega',\omega)$ is the Schwartz kernel of $\mathcal{R}(\mathcal{S}-I)\mathcal{R}^{-1}$, $\mathcal{R}$ being the Lax–Phillips translation representation [L-P] (see section 2).

The inverse backscattering problem consists in the determination of $c(x)$ from $S(s,-\theta,\theta)$, that is, roughly speaking, whether we can determine the sound speed by measuring the echoes produced by an incident plane wave in the direction θ. In this paper we show that measuring the echoes is enough to recover the sound speed if it is a priori close to a constant.

Theorem 1.1. *Let S_j be the scattering kernel associated with the sound speed c_j, $j=1,2$, satisfying* (1.2). *Assume further that $c_j \in W^{10,\infty}(\mathbf{R}^3)$. There exists $\varepsilon > 0$ such that if*

$$S_1(s,-\theta,\theta) = S_2(s,-\theta,\theta) \qquad \textit{for all } s\in\mathbf{R},\ \theta\in S^2,$$

and if

$$\|c_j - 1\|_{W^{10,\infty}(\mathbf{R}^3)} < \varepsilon, \qquad j=1,2,$$

then we have $c_1 = c_2$.

Guillemin proved in [G] that for the case considered here (and in more general situations) $\mathcal{S}$ is a Fourier integral operator, and he computed its symbol and canonical relation. In particular, $S(s,-\theta,\theta)$ makes sense and is a smooth function of θ with distributional values in the s-variable.

In the stationary approach to scattering, one considers the formal Fourier transform of (1.1):

$$\left(-\Delta + \lambda^2(1-c^{-2}(x)) - \lambda^2\right) v(x,\lambda) = 0. \tag{1.4}$$

Notice that one can consider (1.4) as a Schrödinger equation with potential

$$q(x) = \lambda^2(1-c^{-2}(x)).$$

However, this is not very useful for the study of the inverse backscattering problem, since we must consider high frequencies as well. The inverse scattering problem at a fixed energy has been solved in dimension $n \geq 3$ by Novikov [N]. This problem is in fact closely related to the inverse problem of determining a potential q from its associated Dirichlet to Neumann map. The latter problem was solved in [S-U]. For an account of this relationship, see, for instance, [U].

Given any $\theta\in S^2$, there are solutions of (1.4) of the form

$$v(x,\theta,\lambda) = e^{i\lambda x\cdot\theta} + \frac{e^{i\lambda|x|}}{|x|}a(\lambda,\omega,\theta) + o(|x|^{-1}), \qquad \text{as } |x|\to\infty, \tag{1.5}$$

where $\omega = x/|x|$. The function a is called the *scattering amplitude*. The relation between a and S is very simple:

$$\frac{i\lambda}{2\pi} a(\lambda, \omega, \theta) = \int e^{-is\lambda} S(s, \omega, \theta)\, ds.$$

Theorem 1.1 therefore has Theorem 1.2 as an immediate corollary.

THEOREM 1.2. *Let c_j, $j = 1, 2$, be as in Theorem* 1.1. *Let a_j denote the scattering amplitude associated with c_j, $j = 1, 2$. There exists $\varepsilon > 0$ such that if*

$$a_1(\lambda, -\theta, \theta) = a_2(\lambda, -\theta, \theta)$$

and if

$$\|c_j - 1\|_{W^{10,\infty}(\mathbf{R}^3)} < \varepsilon, \qquad j = 1, 2,$$

then $c_1 = c_2$.

The high-frequency asymptotics of the scattering amplitude have been considered in [G] and [V]. We do not know of any result for the inverse backscattering problem for the acoustic equation. The inverse backscattering problem for the Schrödinger equation has been studied in the papers [E-R], [B-L-M], [G-U], [M], [St II].

The structure of the paper is as follows. In section 2 we consider some preliminaries and prove Proposition 2.1, which gives a relation between $S_1 - S_2$ and $c_1^{-2} - c_2^{-2}$. In section 3 we construct the singular solution of (1.3). In section 4 we prove Theorem 1.1 by combining the results of section 3 and inverting a generalized Radon transform.

2. Preliminaries.

In this section we introduce the scattering kernel $S(s, \omega, \theta)$, and in Proposition 2.1, we prove a formula for the difference $S_1 - S_2$, where S_j, $j = 1, 2$, are related to two sound speeds $c_j \in C^2$ satisfying (1.2). A formula of a similar type related to a potential perturbation of the wave equation was first obtained in [St I].

The natural energy space for equation (1.1) is the completion $\mathcal{H}$ of $C_0^\infty(\mathbf{R}^3) \times C_0^\infty(\mathbf{R}^3)$ with respect to the energy norm

$$\|f\|_{\mathcal{H}}^2 = \frac{1}{2} \int \left(|\nabla f_1|^2 + c^{-2}(x) |f_2|^2 \right) dx, \qquad f = [f_1, f_2].$$

Throughout this paper we will denote two-dimensional vector functions ${}^t(f_1, f_2)$ by $[f_1, f_2]$. Then $\mathcal{H}$ is a Hilbert space and equation (1.1) is equivalent to

$$\partial_t u = -iAu, \qquad \text{with} \quad u = [u_1, u_2], \quad A = i \begin{pmatrix} 0 & I \\ c^2\Delta & 0 \end{pmatrix}; \tag{2.1}$$

i.e., if u solves (2.1), then $u_2 = \partial_t u_1$, $(\partial_t^2 - c^2\Delta)u_1 = 0$. Here I stands for the identity map. It is easy to see that A extends to a self-adjoint operator in $\mathcal{H}$; therefore, the solution to (2.1) is given by $u = e^{-itA} f =: U(t) f$, where $f = u|_{t=0}$. By Stone's theorem $U(t)$ forms a strongly continuous group of unitary operators in $\mathcal{H}$. Setting $c = 1$, we get the unperturbed group $U_0(t)$ in $\mathcal{H}_0$ related to the unperturbed wave equation $(\partial_t^2 - \Delta)u = 0$. The scattering operator $\mathcal{S}$ is then defined by $\mathcal{S} = W_-^{-1} W_+$, where the wave operators $W_\pm$ are defined as the strong limits $W_\pm = \text{s-lim}_{t \to \pm} U(t) U_0(-t)$. It is well known that the wave operators exist as bounded operators and moreover, $\mathcal{S}$ is also well defined as a bounded operator in $\mathcal{H}_0$ [L-P], [R-S].

As in the Introduction, we consider the scattering solution $u(t,x,\theta)$ as the solution to the following Cauchy problem:

$$\left\{\begin{array}{rcll} (\partial_t^2 - c^2\Delta)u &=& 0, & \text{in } \mathbf{R}_t \times \mathbf{R}_x^3,\\ u|_{t\ll 0} &=& \delta(t - x\cdot\theta). & \end{array}\right. \tag{2.2}$$

Here $\theta \in S^2$ is a parameter giving the direction of the incident plane wave in (2.2). The initial condition above can be replaced by $u|_{t=-\rho} = \delta(-\rho - x\cdot\theta)$, $u_t|_{t=-\rho} = \delta'(-\rho - x\cdot\theta)$. The standard way of constructing a solution of (2.2) is the following. Set $h_j(t) = t^j/j!$ for $t \ge 0$, and $h_j(t) = 0$ otherwise. Then $h_j' = h_{j-1}$, $j \ge 1$, and h_0 is the Heaviside function. If we replace the Dirac delta function δ in (2.2) by h_2, we get initial data $[h_2(-\rho - x\cdot\theta), h_1(-\rho - x\cdot\theta)]$ for $t = -\rho$, that belong locally to $\mathcal{H}$ and even to $D(A)$. As in the Introduction, consider the problem

$$\left\{\begin{array}{rcll} (\partial_t^2 - c^2\Delta)w &=& 0 & \text{in } \mathbf{R}_t \times \mathbf{R}_x^3,\\ w|_{t\ll 0} &=& h_2(t - x\cdot\theta). & \end{array}\right. \tag{2.3}$$

Then $w = h_2(t - x\cdot\theta) + w_{\text{sc}}$, where $(\partial_t^2 - c^2\Delta)w_{\text{sc}} = -(1-c^2)h_0(t - x\cdot\theta)$ and $w_{\text{sc}}|_{t\ll 0} = 0$. Therefore,

$$[w_{\text{sc}}, \partial_t w_{\text{sc}}] = -\int_{-\infty}^{t} U(t-s)(1-c^2)[0, h_0(s - x\cdot\theta)]\,ds. \tag{2.4}$$

Here $1-c^2$ has compact support; thus $(1-c^2)[0, h_0(s-x\cdot\theta)] \in \mathcal{H}$. Having constructed a solution to (2.3) we can now solve (2.2) by setting

$$u(t,x,\theta) = \partial_t^3 w(t,x,\theta). \tag{2.5}$$

Following Lax and Phillips [L-P] (see also [C-S]), as in the Introduction, we define the *asymptotic wave profile* $w_{\text{sc}}^{\#}$ of w_{sc} by

$$w_{\text{sc}}^{\#}(s,\omega,\theta) = \lim_{t\to\infty}(t+s)\partial_t w_{\text{sc}}(t,(t+s)\omega,\theta). \tag{2.6}$$

The limit exists in $L^2(\mathbf{R}_s \times S_\omega^2)$ for any θ [L-P], [C-S]. Then we define the scattering kernel S by

$$S(s,\omega,\theta) = -\frac{1}{2\pi}\partial_s^3 w_{\text{sc}}^{\#}(s,\omega,\theta). \tag{2.7}$$

In some sense S satisfies the asymptotics

$$\partial_t u(t,x,\theta) = \delta'(t - x\cdot\theta) - \frac{2\pi}{|x|}S\left(|x| - t, \frac{x}{|x|}, \theta\right) + o\left(\frac{1}{|x|}\right), \qquad \text{as } t, |x| \to \infty.$$

The formula above is a time-dependent analogue of the definition (1.5) of the scattering amplitude via the asymptotics of the solution v of the Lipmann–Schwinger equation for large x.

It turns out that S is closely related to the distribution kernel of the scattering operator $\mathcal{S}$. Denote by $(Rf)(s,\omega) = \int f(x)\delta(s - x\cdot\omega)dx$ the Radon transform of f and consider the operator $\mathcal{R}$ (the Lax and Phillips translation representation) defined by $\mathcal{R}[f_1,f_2] = \frac{1}{4\pi}(-\partial_s^2 Rf_1 + \partial_s Rf_2)$. Then $\mathcal{R}$ is a unitary map $\mathcal{R} : \mathcal{H}_0 \to L^2(\mathbf{R}\times S^2)$.

A well-known fact from the Lax–Phillips theory is that $S(s'-s,w',w)$ is the Schwartz kernel of $\mathcal{R}(\mathcal{S}-I)\mathcal{R}^{-1}$ (see [L-P], [C-S], [P]); i.e., in a distribution sense, we have

$$\left(\mathcal{R}(\mathcal{S}-I)\mathcal{R}^{-1}k\right)(s',\omega') = \int_{\mathbf{R}\times S^2} S(s'-s,\omega',\omega)k(s,\omega)\,ds\,d\omega. \tag{2.8}$$

Next we will derive a formula for $S_1 - S_2$, where S_j is related to c_j, $j=1,2$. Let us first notice that $(2\pi)^{-1}[u(\pm t\pm s,x,\pm\theta),\partial_t u(\pm t\pm s,x,\pm\theta)]$ is the distribution kernel of $U(t)W_\pm\mathcal{R}^{-1}$; i.e., for any $k\in C_0^\infty(\mathbf{R}\times S^2)$ in a distribution sense we have

$$U(t)W_\pm\mathcal{R}^{-1}k = \frac{1}{2\pi}\int_{\mathbf{R}\times S^2}\Big[u(\pm t\pm s,x,\pm\theta),\partial_t u(\pm t\pm s,x,\pm\theta)\Big]k(s,\theta)\,ds\,d\theta. \tag{2.9}$$

Indeed, denote $f=\mathcal{R}^{-1}k$ and consider W_+. Then $U(t)W_+\mathcal{R}^{-1}k = U(t+T)U_0(-T)f$ for some fixed $T>0$ depending on $\operatorname{supp} k$. Denote $[v,\partial_t v] = U(t+T)U_0(-T)f$ and denote also the right-hand side of (2.9) by $[\tilde v,\partial_t\tilde v]$. Both v and $\tilde v$ solve (1.1). Next, for $t<-T$, we have $[v,\partial_t v]=U_0(t)f$. On the other hand, for $t\ll 0$ we get for $\tilde v$

$$[\tilde v,\partial_t\tilde v] = \frac{1}{2\pi}\int_{\mathbf{R}\times S^2}\Big[\delta(t+s-x\cdot\theta),\delta'(t+s-x\cdot\theta)\Big]k(s,\theta)\,ds\,d\theta = U_0(t)f$$

by the inversion formula for $\mathcal{R}$ (see [L-P]). Therefore, v and $\tilde v$ have the same initial data and must coincide. This proves (2.9) for W_+. The proof for W_- is similar.

PROPOSITION 2.1. *Let $S_j(s,\omega,\theta)$ be the scattering kernel related to $c_j(x)\in C^2$, $j=1,2$. Then*

$$(S_1-S_2)(s,\omega,\theta) = \frac{1}{8\pi^2}\partial_s^3\iint(c_1^{-2}-c_2^{-2})u_1(t,x,\theta)u_2(-s-t,x,-\omega)\,dt\,dx,$$

where u_j are the scattering solutions related to c_j, $j=1,2$, and the integral is to be considered in a distribution sense.

Proof. Denote by $U_j(t)$, $j=1,2$, the propagators related to c_j. Consider the function $F(t)=U_2(T+t)U_1(-t+T)f$, $f\in D(A_1)=D(A_2)$. Then $F'(t)=-iU_2(T+t)(A_2-A_1)U_1(-t+T)$, and from $F(T)-F(-T)=\int_{-T}^T F'(t)dt$, we get

$$(U_2(2T)-U_1(2T))f = \int_{-T}^{T}U_2(T+t)QU_1(-t+T)f\,dt, \tag{2.10}$$

where

$$Q = \begin{pmatrix} 0 & 0 \\ (c_2^2-c_1^2)\Delta & 0\end{pmatrix}.$$

Next, choose two functions $k,l\in C_0^\infty(\mathbf{R}\times S^2)$ and set $f=\mathcal{R}^{-1}k$, $g=\mathcal{R}^{-1}l$. Then, by using standard arguments from the Lax–Phillips theory, we get that

$$(\mathcal{S}_j f,g)_{\mathcal{H}_0} = \Big(U_0(-T)U_j(2T)U_0(-T)f,g\Big)_{\mathcal{H}_0}$$

with some large $T>0$ depending on $\operatorname{supp} k$, $\operatorname{supp} l$. Therefore, by (2.10),

$$\begin{aligned}((\mathcal{S}_2-\mathcal{S}_1)f,g)_{\mathcal{H}_0} &= \int_{-T}^{T}\Big(U_0(-T)U_2(T+t)QU_1(-t+T)U_0(-T)f,g\Big)_{\mathcal{H}_0}dt\\ &= \int_{-T}^{T}\Big(QU_1(-t+T)U_0(-T)f,U_2(-t-T)U_0(T)g\Big)_{\mathcal{H}_2}dt.\end{aligned} \tag{2.11}$$

Here $\mathcal{H}_j$, $j = 0, 1, 2$, are related to $c_0 = 1$, c_1, and c_2, respectively. Next, note that $U_1(-t+T)U_0(-T)f = U_1(-t)W_+^{(1)}f = U_1(-t)W_+^{(1)}\mathcal{R}^{-1}k$. Similarly, $U_2(-t-T)U_0(T)g = U_2(-t)W_-^{(2)}\mathcal{R}^{-1}l$. Using (2.9), we get from (2.11)

$$\begin{aligned}((\mathcal{S}_2 - \mathcal{S}_1)f, g)_{\mathcal{H}_0} &\\ &= \frac{1}{8\pi^2}\int_{-T}^{T}\int\dots\int (c_2^2 - c_1^2)(\Delta u_1)(-t+s_1, x, \theta_1)\partial_t u_2(t-s_2, x, -\theta_2)\\ &\qquad \times k(s_1,\theta_1)l(s_2,\theta_2)c_2^{-2}\, ds_1 d\theta_1 ds_2 d\theta_2 dx\, dt\\ &= \frac{1}{8\pi^2}\int_{-T}^{T}\int\dots\int (c_1^{-2} - c_2^{-2})\partial_{s_1}^2 u_1(-t+s_1, x, \theta_1)\partial_t u_2(t-s_2, x, -\theta_2)\\ &\qquad \times k(s_1,\theta_1)l(s_2,\theta_2)\, ds_1 d\theta_1 ds_2 d\theta_2 dx\, dt. \end{aligned} \tag{2.12}$$

Clearly, the integrand above vanishes for $|t| > T$, so we may integrate in t over the whole real line. According to (2.8),

$$\begin{aligned}((\mathcal{S}_2 - \mathcal{S}_1)f, g)_{\mathcal{H}_0} &\\ &= \int_{[\mathbf{R}\times S^2]^2} (S_2 - S_1)(s_2 - s_1, \theta_2, \theta_1)k(s_1,\theta_1)l(s_2,\theta_2)\, ds_1 d\theta_1 ds_2 d\theta_2.\end{aligned} \tag{2.13}$$

Comparing (2.12) and (2.13), we conclude that

$$\begin{aligned}(S_1 - S_2)(s_2 - s_1, \theta_2, \theta_1) &\\ &= \frac{1}{8\pi^2}\iint (c_1^{-2} - c_2^{-2})\partial_{s_1}^2 u_1(-t+s_1, x, \theta_1)\partial_t u_2(t-s_2, x, -\theta_2)\, dx\, dt.\end{aligned}$$

The right-hand side above as a function of s_1, s_2 depends merely on $s_2 - s_1$, and setting $s = s_2 - s_1$, $\tilde{t} = -t + s_1$, we complete the proof of the proposition. □

3. Singular decomposition of the scattering solution. In this section we prove that the scattering solution $u(t, x, \theta)$ admits a singular decomposition of the type $u(t, x, \theta) = \alpha(x, \theta)\delta(t - \phi(x, \theta)) + \beta(x, \theta)h_0(t - \phi(x, \theta)) + r(t, x, \theta)$, where ϕ is a suitable phase function and the remainder $r(t, \cdot, \theta)$ belongs to $H^1 \cap L^\infty$, $\partial_t r \in L^2$. Such decompositions are in principle known for that kind of problem (see, e.g., [V] for a high-frequency asymptotics of the solution v of (1.4) given by (1.5)). Our goal here is to prove estimates on the remainder which are uniform in $c(x)$ under the assumption of a finite smoothness of c. As in Theorem 1.1, we assume that c is close to $c = 1$ in the $W^{m,\infty}$ topology for some m. It turns out that in our proof we need estimates on the remainder for t belonging to a finite interval only. This fact considerably simplifies our analysis. On the other hand, in principle one could obtain estimates on the remainder for large t which are also uniform in c. This is related to the problem of finding estimates of the remainder in the high-frequency asymptotics of the solution v of (1.4) defined in (1.5) (see [V]) which are uniform in c or finding estimates on the resolvent of $c^2\Delta + \lambda^2$. The latter problems are more delicate ones. In fact, one of the main reasons for working with time-dependent methods is the advantage we get by dealing with bounded t's only.

We start with analysis of the phase function ϕ related to (1.1). We define $\phi(x, \theta)$ as the solution to the eikonal equation

$$\left\{\begin{array}{rcl} (\nabla\phi)^2 &=& c^{-2}(x),\\ \phi|_{x\cdot\theta\ll 0} &=& x\cdot\theta. \end{array}\right. \tag{3.1}$$

Throughout this section we assume that c satisfies (1.2) and that

$$\|c-1\|_{W^{m+1,\infty}} < \varepsilon \tag{3.2}$$

with some $\varepsilon > 0$ and $m \geq 2$. We need to solve (3.1) in B_ρ. Fix $\theta \in S^2$. We may assume that $\theta = {}^t(1,0,0)$. Then (3.1) can be rewritten as

$$\left\{\begin{array}{rcl} (\nabla\phi)^2 &=& c^{-2}(x), \\ \phi|_{x_1=-\rho} &=& -\rho, \\ \partial_{x_1}\phi|_{x_1=-\rho} &=& 1. \end{array}\right. \tag{3.3}$$

The Hamiltonian system associated with (3.3) is

$$\left\{\begin{array}{rclrcll} \frac{d}{ds}x &=& 2\xi, & \frac{d}{ds}\xi &=& \nabla c^{-2}, & \\ x|_{s=0} &=& {}^t(-\rho,\eta), & \xi|_{s=0} &=& {}^t(1,0,0), & \eta \in \mathbf{R}^2. \end{array}\right. \tag{3.4}$$

Notice that the solution to (3.4) in the case $c = 1$ is $x = {}^t(2s-\rho,\eta)$, $\xi = {}^t(1,0,0)$. On the other hand, for general $c(x)$, the solution of (3.4) exists for any s (see [V]).

LEMMA 3.1. *Fix $a > 0$. Then there exists $C > 0$ such that for the solution $x = x(s,\eta)$, $\xi = \xi(s,\eta)$ of* (3.4) *we have*

$$\|x - {}^t(2s-\rho,\eta)\|_{W^{m,\infty}([0,a]\times\mathbf{R}^2)} + \|\xi - {}^t(1,0,0)\|_{W^{m,\infty}([0,a]\times\mathbf{R}^2)} \leq C\varepsilon.$$

The proof of the lemma is based on a comparison theorem for ODEs and will be omitted here.

In particular, Lemma 3.1 implies that under the smallness assumption (3.2) the Hamiltonian flow is nontrapping for small ε, more precisely, $x(s,\eta) \notin B_\rho = \{x;\ |x| < \rho\}$ for $s > a$ with some $a > 0$. Moreover, the mapping ${}^t(s,\eta) \mapsto x(s,\eta)$ is a $W^{m,\infty}$-diffeomorphism on $[0,a]\times\{\eta \in \mathbf{R}^2;\ |\eta| \leq 2\rho\}$, and its range covers B_ρ, provided that ε is small enough. We will need, in fact, to work in a larger domain, so let us assume that ε and a are such that ${}^t(s,\eta) \mapsto x(s,\eta)$ maps $[0,a]\times\{\eta \in \mathbf{R}^2;\ |\eta| \leq 5\rho\}$ into a compact covering $B_{4\rho}$. The phase function ϕ solving (3.3) is defined in $B_{4\rho}$ by (see [V])

$$\phi = -\rho + 2\int c^{-2}(x)\,ds,$$

where the integration is taken over the shortest characteristics $x = x(s,\eta)$ joining the plane $x_1 = -\rho$ and x. The change of coordinates $x \mapsto {}^t(s,\eta)$ is ε-close to $x = {}^t(2s-\rho,\eta)$ in $W^{m,\infty}$, which easily implies that ϕ must be close to $\phi = x_1$. So far θ was fixed. One can also examine easily the dependence of ϕ on $\theta \in S^2$. Thus we get the following lemma.

LEMMA 3.2. *Assume that* (3.2) *holds with $\varepsilon > 0$ sufficiently small. Then there exists $C_0 > 0$ such that*

$$\|\phi(x,\theta) - x\cdot\theta\|_{W^{m,\infty}(B_{4\rho}\times S^2)} \leq C_0\varepsilon.$$

Now we are ready to prove the principal result of this section about the scattering solution $u(t,x,\theta)$ introduced in (2.2). Denote

$$T = \rho + C_0\varepsilon, \tag{3.5}$$

where C_0 is the constant in Lemma 3.2. Note that $\max\{|\phi(x,\theta)|;\ x\in B_\rho,\ \theta\in S^2\}\le T$.

PROPOSITION 3.3. *Assume that* (3.2) *holds with $m\ge 9$ and $\varepsilon>0$ sufficiently small. Then there exists a constant $C>0$, such that for $|t|<3T$, and for any $\theta\in S^2$, we have*

$$u(t,x,\theta)=\alpha(x,\theta)\delta(t-\phi(x,\theta))+\beta(x,\theta)h_0(t-\phi(x,\theta))+r(t,x,\theta),$$

where

$$\|\alpha-1\|_{W^{m-2,\infty}(B_{4\rho}\times S^2)}\le C\varepsilon,\qquad |\beta(x,\theta)|\le C\varepsilon, \tag{3.6}$$

and

$$\|r(t,\cdot,\theta)\|_{L^\infty}+\|\partial_t r(t,\cdot,\theta)\|_{L^2}\le C\varepsilon. \tag{3.7}$$

Proof. Let us look for u of the form

$$u(t,x,\theta)=\alpha(x,\theta)\delta(t-\phi(x,\theta))+\beta(x,\theta)h_0(t-\phi(x,\theta))+\gamma(x,\theta)h_1(t-\phi(x,\theta))+\tilde r(t,x,\theta).$$

Then $\alpha=1+\tilde\alpha$, β, γ solve the transport equations

$$(2\nabla\phi\cdot\nabla+\Delta\phi)\tilde\alpha=-\Delta\phi,\qquad \tilde\alpha|_{x\cdot\theta=-\rho}=0, \tag{3.8}$$

$$(2\nabla\phi\cdot\nabla+\Delta\phi)\beta=\Delta\alpha,\qquad \beta|_{x\cdot\theta=-\rho}=0, \tag{3.9}$$

$$(2\nabla\phi\cdot\nabla+\Delta\phi)\gamma=\Delta\beta,\qquad \gamma|_{x\cdot\theta=-\rho}=0, \tag{3.10}$$

while $\tilde r$ solves

$$(c^{-2}\partial_t^2-\Delta)\tilde r=(\Delta\gamma)h_1(t-\phi),\qquad \tilde r|_{t\ll 0}=0. \tag{3.11}$$

Note that we need to solve (3.8)–(3.10) in the compact $x\cdot\theta\ge-\rho$, $\phi(x,\theta)\le 3T$, $|\eta|<\rho$ ($\eta=\eta(x)$ is determined by $x=x(s,\eta)$), and for ε sufficiently small this compact is contained in $B_{4\rho}$, where ϕ is well defined. The first equation (3.8) can be solved in $B_{4\rho}$ and (3.6) follows directly from Lemma 3.2. The estimate (3.6) for α follows easily from Lemmas 3.1 and 3.2. Next, since $\Delta\alpha=O(\varepsilon)$, we get (if $m\ge 4$) (3.6) for β as well. Similarly, if $m\ge 6$, then $|\gamma|=O(\varepsilon)$ as well. Finally, for $\tilde r$ we get by (3.11)

$$[\tilde r,\partial_t\tilde r]=\int_{-\rho}^t U(t-s)[0,(\Delta\gamma)h_1(s-\phi)]\,ds.$$

We get as above that $(\Delta\gamma)h_1(s-\phi)$ is supported in $B_{4\rho}$ for $-\rho\le s\le t$, $|t|<3T$, and moreover $\|[0,(\Delta\gamma)h_1(s-\phi)]\|_{\mathcal H}\le C\varepsilon$ (if $m\ge 8$). Note that the norm in $\mathcal H$ depends on $c(x)$ but is uniformly bounded when c satisfies (3.2) with $\varepsilon<1$. So we get

$$\|[\tilde r,\partial_t\tilde r]\|_{\mathcal H}\le C(t+\rho)\varepsilon,\qquad -\rho\le t\le T \tag{3.12}$$

(and $\tilde{r} = 0$ for $t < -\rho$). Next, $[\tilde{r}, \partial_t\tilde{r}] \in D(A)$ and

$$A[\tilde{r}, \partial_t\tilde{r}] = [\partial_t\tilde{r}, c^2\Delta\tilde{r}] = \int_{-\rho}^{t} U(t-s)A[0, (\Delta\gamma)h_1(s-\phi)]\, ds$$
$$= \int_{-\rho}^{t} U(t-s)[(\Delta\gamma)h_1(s-\phi), 0]\, ds.$$

Since $\|[(\Delta\gamma)h_1(s-\phi), 0]\|_{\mathcal{H}} = O(\varepsilon)$ (here we need $m = 9$), we get as above that

$$\big\|[\partial_t\tilde{r}, c^2\Delta\tilde{r}]\big\|_{\mathcal{H}} \le C(t+\rho)\varepsilon, \qquad -\rho \le t \le T. \tag{3.13}$$

By (3.12) and (3.13),

$$\|\nabla\tilde{r}\| + \|\Delta\tilde{r}\| + \|\partial_t\tilde{r}\| + \|\nabla\partial_t\tilde{r}\| \le C\varepsilon,$$

where $\|\cdot\| = \|\cdot\|_{L^2}$. Moreover, $\tilde{r}$ is compactly supported (uniformly in $\varepsilon < 1$, $|t| < 3T$) because of the finite speed of propagation for (1.1). Therefore, by the Poincaré inequality (see, e.g., [L-P]), we get $\|\tilde{r}\| = O(\varepsilon)$ as well. Thus,

$$\|\tilde{r}\|_{H^2} + \|\partial_t\tilde{r}\|_{H^1} \le C\varepsilon.$$

By the Sobolev embedding theorem this yields $\|\tilde{r}\|_{L^\infty} + \|\partial_t\tilde{r}\|_{L^2} = O(\varepsilon)$, and combining this with (3.6), we get (3.7) for $r = \gamma h_1(t-\phi) + \tilde{r}$. □

4. Proof of Theorem 1.1. Assume that the hypotheses of Theorem 1.1 are fulfilled and denote by u_j the scattering solutions related to c_j, $j = 1, 2$. Then, by Proposition 2.1,

$$\iint q(x)u_1(t,x,\theta)u_2(s-t,x,\theta)\, dx\, dt = 0, \qquad q := c_1^{-2} - c_2^{-2} \tag{4.1}$$

for any $s \in \mathbf{R}$, $\theta \in S^2$. Let us now apply Proposition 3.3 and substitute u_j, $j = 1, 2$, in (4.1) by its singular expansion. We get

$$\begin{aligned} -\int q\alpha_1\alpha_2\delta(s-\phi_1-\phi_2)\, dx & \\ = \int q\Big[&\alpha_2\beta_1 h_0(s-\phi_1-\phi_2) + \alpha_1\beta_2 h_0(s-\phi_1-\phi_2) \\ &+ \alpha_2 r_1(s-\phi_2) + \alpha_1 r_2(s-\phi_1)\Big]\, dx \\ + \iint q\Big[&\beta_1\beta_2 h_0(t-\phi_1)h_0(s-t-\phi_2) + r_1(t)r_2(s-t) \\ &+ \beta_1 h_0(t-\phi_1)r_2(s-t) + \beta_2 h_0(s-t-\phi_2)r_1(t)\Big]\, dx\, dt. \end{aligned} \tag{4.2}$$

Here $r_1(t) = r_1(t,x,\theta)$, $\phi_1 = \phi_1(x,\theta)$, etc. Denote $\phi(x,\theta) = \phi_1(x,\theta) + \phi_2(x,\theta)$, $a(x,\theta) = \alpha_1(x,\theta) + \alpha_2(x,\theta)$. Since by Lemma 3.2, $\phi(x,\theta)$ is close to $2x\cdot\theta$ and $a(x,\theta)$ is close to 1, the left-hand side of (4.2) reminds us of the Radon transform Rq of q. Let us recall that we have the following Parseval's equality for the Radon transform $\|\partial_s Rf\|_{L^2(\mathbf{R}\times S^2)} = 4\pi\|f\|_{L^2}$. Bearing this in mind, let us differentiate (4.2) with respect to s.

$$-\partial_s \int qa\delta(s-\phi)\, dx = I_1 + I_2 + I_3 + I_4, \tag{4.3}$$

where

$$\begin{aligned} I_1 &= \int q(\alpha_2\beta_1 + \alpha_1\beta_2)\delta(s-\phi)\,dx, \\ I_2 &= \int q[\alpha_2\partial_s r_1(s-\phi_2) + \alpha_1\partial_s r_2(s-\phi_1)]\,dx, \\ I_3 &= \int q[\beta_1\beta_2 h_0(s-\phi) + \beta_1 r_2(s-\phi_1) + \beta_2 r_1(s-\phi_2)]\,dx, \\ I_4 &= \iint q r_1(t)\partial_s r_2(s-t)\,dx\,dt. \end{aligned}$$

The left-hand side of (4.3) vanishes for $|s| > 2T$ (see Lemma 3.2 and (3.5)). Therefore, so does the right-hand side above, but this is not necessarily true for each term I_j. Let us estimate the norm in $L^2([-2T,2T]\times S^2)$ of each term in (4.3). For the left-hand side in (4.3) we have

$$\begin{aligned} &\left\| \partial_s \int q(x)a(x,\theta)\delta(s-\phi(x,\theta))\,dx \right\|_{L^2([-2T,2T]\times S^2)} \\ &\qquad = (2\pi)^{-1/2} \left\| k \int e^{ik\phi(x,\theta)} a(x,\theta) q(x)\,dx \right\|_{L^2(\mathbf{R}_k \times S^2_\theta)}. \end{aligned} \tag{4.4}$$

Let us extend $\phi(x,\xi)$ and $a(x,\theta)$ for $\xi \notin S^2$ by $\phi(x,\xi) = |\xi|\phi(x,\xi/|\xi|)$ and $a(x,\xi) = a(x,\xi/|\xi|)$, respectively. Then Lemma 3.2 implies

$$\left| \partial_x^\alpha \partial_\xi^\beta (\phi(x,\xi) - 2x\cdot\xi) \right| \le C_1 \varepsilon |\xi|^{1-|\beta|} \quad \text{for } |\alpha| + |\beta| \le m,\ x \in B_{4\rho},\ \xi \neq 0. \tag{4.5}$$

Similarly, (3.6) implies

$$\left| \partial_x^\alpha \partial_\xi^\beta (a(x,\xi) - 1) \right| \le C_1 \varepsilon |\xi|^{-|\beta|} \quad \text{for } |\alpha| + |\beta| \le m-2,\ x \in B_{4\rho},\ \xi \neq 0. \tag{4.6}$$

Since q is real-valued, the square integral of the expression in the right-hand side of (4.4) over $\mathbf{R}_k \times S^2$ equals twice the square integral over $\mathbf{R}_k^+ \times S^2_\theta$. Setting $\xi = k\theta$, $k > 0$, $\theta \in S^2$, we obtain from (4.4)

$$\left\| \partial_s \int q(x)a(x,\theta)\delta(s-\phi(x,\theta))\,dx \right\|_{L^2([-2T,2T]\times S^2)} = \sqrt{2}(2\pi)^{-1/2} \|Pq\|_{L^2(\mathbf{R}^3_\xi)}, \tag{4.7}$$

where

$$(Pq)(\xi) = \int e^{i\phi(x,\xi)} a(x,\xi) q(x)\,dx. \tag{4.8}$$

Our plan is the following. First we will show that $C_1\|q\| \le \|Pq\| \le C_2\|q\|$ with some $C_1 > 0$, $C_2 > 0$ independent of ε. Next we are going to estimate the norms in $L^2([-2T,2T]\times S^2)$ of each term $I_j = I_j(s,\theta)$ in (4.3) and will show that $I_j = O(\varepsilon\|q\|)$, $j = 1,2,3,4$. Then (4.3), (4.7) would imply that $C_1\|q\| \le \|Pq\| \le C\varepsilon\|q\|$; hence $q = 0$.

Proposition 4.1. *If c_j, $j = 1,2$, satisfy (3.2) with $m = 9$ and if $\varepsilon > 0$ is sufficiently small, then $P : L^2(B_\rho) \to L^2(\mathbf{R}^3_\xi)$ is a bounded operator. Moreover, there exist two constants $C_1 > 0$, $C_2 > 0$ independent of ε (small enough), c_1, c_2, such that*

$$C_1\|f\| \le \|Pf\| \le C_2\|f\| \qquad \textit{for any } f \in L^2(B_\rho).$$

Proof. We will show that the estimate above follows from the fact that $\phi = \phi_1 + \phi_2$ is close to $2x \cdot \theta$ (see Lemma 3.2) and a is close to 1 (see 4.6). This does not necessarily imply that P (see (4.8)) is close to the Fourier transform, but one can expect that P^*P is close to cI with some constant c. We have

$$(4.9) \qquad (P^*Pf)(x) = \iint e^{-i(\phi(x,\xi)-\phi(y,\xi))} a(x,\xi)a(y,\xi)f(y)\,dy\,d\xi.$$

The phase function above admits the representation

$$\phi(x,\xi) - \phi(y,\xi) = 2(x-y)\cdot\eta(x,y,\xi),$$

where

$$(4.10) \qquad \eta(x,y,\xi) = \frac{1}{2}\int_0^1 (\nabla_x\phi)(y+t(x-y),\xi)\,dt.$$

To prove (4.10), it is enough to apply the identity $g(1) - g(0) = \int_0^1 g'(t)dt$ to the function $g(t) = \phi(y + t(x-y))$. By Lemma 3.2, $\eta(x,y,\xi)$ belongs to $W^{m-1,\infty}$ and is homogeneous with respect to ξ of order one. Moreover,

$$\left|\partial_x^\alpha \partial_y^\beta \partial_\xi^\gamma (\eta(x,y,\xi) - \xi)\right| \le C\varepsilon|\xi|^{1-|\gamma|}$$

for $|\alpha| + |\beta| + |\gamma| \le m-1$, $x \in B_{4\rho}$, $y \in B_{4\rho}$, $\xi \neq 0$. The equation $\eta = \eta(x,y,\xi)$ can be solved for ξ provided that ε is sufficiently small. The Jacobian $J := |D\eta/D\xi|$ satisfies the estimates

$$(4.11) \qquad \left|\partial_x^\alpha \partial_y^\beta \partial_\xi^\gamma (J(x,y,\xi) - 1)\right| \le C\varepsilon|\xi|^{-|\gamma|}$$

for $|\alpha| + |\beta| + |\gamma| \le m-2$, $x \in B_{4\rho}$, $y \in B_{4\rho}$, $\xi \neq 0$. Let us perform the change of variables $\xi \to \eta$ in (4.9):

$$(4.12) \qquad P^*Pf = \iint e^{-2i(x-y)\cdot\eta} b(x,y,\eta)f(y)\tilde{J}(x,y,\eta)\,dy\,d\eta,$$

where $\tilde{J}(x,y,\eta) = J^{-1}(x,y,\xi)|_{\xi=\xi(x,y,\eta)}$, $b(x,y,\eta) = a(x,\xi)a(y,\xi)|_{\xi=\xi(x,y,\eta)}$. The principal part of the integral above is

$$\iint e^{-2i(x-y)\cdot\eta} f(y)\,dy\,d\eta = \pi^3 f,$$

so from (4.12) we get

$$(4.13) \qquad \left(P^*P - \pi^3 I\right) f = \iint e^{-2i(x-y)\cdot\eta} f(y)\left((b\tilde{J})(x,y,\eta) - 1\right)\,dy\,d\eta.$$

We are going to apply Theorem A.1 (see the Appendix below) to (4.13). By (4.11), (3.6),

(4.14)
$$\left|\partial_x^\alpha \partial_y^\beta \left((b\tilde{J})(x,y,\eta) - 1\right)\right| \le C\varepsilon \quad \text{for } |\alpha| + |\beta| \le m-2,\ x \in B_{4\rho},\ y \in B_{4\rho},\ \eta \neq 0.$$

Let us extend the operator $P^*P-\pi^3I$, defined a priori on $L^2(B_\rho)$ to an operator Q in $L^2(\mathbf{R}^3)$ by (4.13) with $\tilde{J}-1$ replaced by $\chi(x)(\tilde{J}-1)\chi(y)$, where $\chi\in C_0^\infty$, $\operatorname{supp}\chi\subset B_{2\rho}$, $\chi=1$ on B_ρ. Then, if $m-2=7$, Theorem A.1 yields $\|Q\|_{\mathcal{L}(L^2(\mathbf{R}^3))}\le C\varepsilon$, which implies

$$\|P^*P-\pi^3I\|_{\mathcal{L}(L^2(B_\rho))}\le C\varepsilon.$$

Thus, for any $f\in L^2(B_\rho)$, we have

$$\big|\|Pf\|^2-\pi^3\|f\|^2\big|=\big|\big(P^*Pf-\pi^3f,f\big)\big|\le C\varepsilon\|f\|^2,$$

and this completes the proof of Proposition 4.1 for ε small enough. □

We proceed now with estimating the norms of I_j, $j=1,2,3,4$, in $L^2([-2T,2T]\times S^2)$. By (3.6) and (4.7) we get for I_1

$$\begin{aligned}\|I_1\|_{L^2([-2T,2T]\times S^2)}&\le C\varepsilon\left\|\int|q|\delta(s-\phi)\,dx\right\|_{L^2(\mathbf{R}\times S^2)}\\&\le C'\varepsilon\left\|\partial_s\int|q|\delta(s-\phi)\,dx\right\|_{L^2(\mathbf{R}\times S^2)}\\&\le C''\|P_0|q|\|\le C'''\|q\|.\end{aligned}\tag{4.15}$$

Here P_0 is the operator (4.8) with $a=1$. In order to prove (4.15), we have approximated $|q|$ with smooth functions and have used the fact that for any $f\in C^1(\mathbf{R})$ with $f=0$ outside some finite interval $[-a,a]$, we have $\|f\|_{L^2}\le C(a)\|f'\|_{L^2}$.

To estimate I_2, I_3, and I_4, observe that

$$I_2+I_3+I_4=\int K(s,\theta,x)q(x)\,dx\tag{4.16}$$

with

$$\begin{aligned}K&=\alpha_2\partial_sr_1(s-\phi_2)+\alpha_1\partial_sr_2(s-\phi_1)+\beta_1\beta_2h_0(s-\phi)\\&\quad+\beta_1r_2(s-\phi_1)+\beta_2r_1(s-\phi_2)+\int_{-\rho}^{\rho+2T}r_1(t)\partial_sr_2(s-t)\,dt.\end{aligned}\tag{4.17}$$

When $|s|<2T$ and $x\in B_\rho$, we have $|s-\phi_2|\le 3T$, $|s-\phi_1|\le 3T$. Next, in the integral term in (4.17), we have $|T|<3T$, $-\rho\le s-t\le\rho+2T<3T$. Therefore, in (4.17), the argument of $r_j(t)$, $j=1,2$, always belongs to the interval $|t|\le 3T$; thus we can apply Proposition 3.3 to get

$$\int_{B_\rho}\int_{S^2}\int_{-2T}^{2T}|K(s,\theta,x)|^2ds\,d\theta\,dx\le(C\varepsilon)^2.$$

Therefore, by (4.16), we have

$$\|I_2+I_3+I_4\|_{L^2([-2T,2T]\times S^2)}\le C\varepsilon\|q\|.\tag{4.18}$$

Combining (4.3), (4.7), (4.15), and (4.18), we get

$$\|Pq\|\le C\varepsilon\|q\|.\tag{4.19}$$

On the other hand, by Proposition 4.1, we conclude that

$$C_1\|q\| \le \|Pq\|. \tag{4.20}$$

For ε small enough (4.19) and (4.20) imply $q = 0$. The proof of Theorem 1.1 is complete.

Appendix A. An L^2 estimate. We prove here a theorem for the boundedness of $a(x,y,D)$ in $L^2(\mathbf{R}^n)$ if a is smooth of finite order. Under the assumption that $a = a(x,\xi)$ is independent of y, Theorem 18.1.11′ in [H] says that if $\int|\partial_x^\alpha a(x,\xi)|dx \le M$ for all $\xi\in\mathbf{R}^n$ and for $|\alpha|\le n+1$, then $\|a(x,D)\|_{\mathcal{L}(L^2)} \le CM$ with $C>0$ an absolute constant. Following the proof of that theorem in [H], we obtain a generalization for amplitudes a depending on y as well.

Theorem A.1. *Let A be the operator*

$$Af = (2\pi)^{-n}\iint e^{i(x-y)\cdot\xi}a(x,y,\xi)f(y)\,dy\,d\xi.$$

If

$$\int\left|\partial_x^\alpha\partial_y^\beta a(x,y,\xi)\right|\,dx\,dy \le M \qquad \textit{for } |\alpha|+|\beta|\le 2n+1,\ \xi\in\mathbf{R}^n,$$

then $\|A\|_{\mathcal{L}(L^2)} \le CM$ with $C>0$ an absolute constant.

Proof. We have

$$Af = (2\pi)^{-2n}\iint e^{ix\cdot\xi}\tilde a(x,\xi-\zeta,\xi)\hat f(\zeta)\,d\zeta\,d\xi,$$

where $\tilde a(x,\zeta,\xi) = \int e^{-i\zeta\cdot y}a(x,y,\xi)dy$. Thus

$$\begin{aligned}\widehat{Af}(\eta) := \int e^{-i\eta\cdot x}(Af)(x)\,dx &= (2\pi)^{-2n}\iiint e^{-ix\cdot(\eta-\xi)}\tilde a(x,\xi-\zeta,\xi)\hat f(\zeta)\,d\zeta\,d\xi\,dx\\ &= (2\pi)^{-2n}\iint \tilde{\tilde a}(\eta-\xi,\xi-\zeta,\xi)\hat f(\zeta)\,d\zeta\,d\xi,\end{aligned}$$

where $\tilde{\tilde a}(\eta,\zeta,\xi) = \int e^{-i\eta\cdot x}\tilde a(x,\zeta,\xi) = \int e^{-i(\eta\cdot x+\zeta\cdot y)}a(x,y,\xi)dxdy$. Therefore, $\widehat{Af} = B\hat f$, where B is an integral operator with kernel

$$b(\eta,\zeta) = (2\pi)^{-2n}\int\tilde{\tilde a}(\eta-\xi,\xi-\zeta,\xi)\,d\xi.$$

We claim that $\int|b(\eta,\zeta)|d\eta \le CM$, $\int|b(\eta,\zeta)|d\zeta \le CM$. It is well known that this implies that B is bounded with norm not exceeding CM.

$$\int|b(\eta,\zeta)|\,d\eta \le (2\pi)^{-2n}\iint|\tilde{\tilde a}(\eta-\xi,\xi-\zeta,\xi)|\,d\xi\,d\eta.$$

The assumptions of the theorem imply $|\tilde{\tilde a}(\eta,\zeta,\xi)| \le CM(1+|\eta|+|\zeta|)^{-2n-1}$. Hence

$$\begin{aligned}\int|b(\eta,\zeta)|\,d\eta &\le C'M\iint(1+|\eta-\xi|+|\xi-\zeta|)^{-2n-1}d\eta\,d\xi\\ &= C'M\iint(1+|\eta|+|\xi-\zeta|)^{-2n-1}d\eta\,d\xi\\ &= C'M\iint(1+|\eta|+|\xi|)^{-2n-1}d\eta\,d\xi\\ &= C''M<\infty.\end{aligned}$$

We treat $\int |b(\eta,\zeta)|d\zeta$ in the same way. □

A TWO-POINT PROBLEM WITH NONLINEARITY DEPENDING ONLY ON THE DERIVATIVE*

P. HABETS[†] AND L. SANCHEZ[‡]

Abstract. We study the existence and multiplicity of solutions for a two-point boundary value problem at resonance in the first eigenvalue; the nonlinearity depends only on the first derivative and has finite limits at $\pm\infty$.

Key words. resonance, bounded nonlinearity, multiple solutions

AMS subject classification. 34B15

1. Introduction and main result.

The two-point semilinear problem

$$\begin{gathered} u'' + u + g(u') = p(t), \\ u(0) = u(\pi) = 0, \end{gathered} \tag{1}$$

where g is a continuous function in $\mathbb{R}$ and p a continuous function in $[0,\pi]$, has been studied by Cañada and Drábek [3] and Kannan, Nagle, and Pothoven [4]. Related problems involving other boundary conditions are included in [3] and have also been the object of a paper by Mawhin [5].

It has been remarked (see [3], [2], and [4]) that conditions of the Landesman–Lazer type are not appropriated to yield the existence of solutions to (1). Let us denote by $\tilde{C}[0,\pi]$ the subspace of $C[0,\pi]$ consisting of functions $\tilde{u}(t)$ such that $\int_0^\pi \tilde{u}(t)\sin t\,dt = 0$. With respect to the direct sum $C[0,\pi] = \operatorname{span}\{\sin t\} \oplus \tilde{C}[0,\pi]$, every function $p \in C[0,\pi]$ has a decomposition

$$p(t) = \bar{p}\sin t + \tilde{p}(t), \quad \bar{p} \in \mathbb{R},\ \tilde{p} \in \tilde{C}[0,\pi]. \tag{2}$$

In [3] the authors have used a result of Amann, Ambrosetti, and Mancini [1] to show that, given a bounded g, the solvability of (1) can be described in terms of the decomposition of p as follows: for each $\tilde{p}$ there exists a nonempty, bounded interval $I = I(\tilde{p})$ such that (1) has a solution if and only if (2) holds with $\bar{p} \in I$. They compute the upper bound of I in a case where

$$g(-\infty) := \lim_{u\to-\infty} g(u) = g(+\infty) := \lim_{u\to+\infty} g(u).$$

On the other hand, in [4], a contraction argument is used to show that, if $g(s) = \arctan s$, (1) is solvable for p sufficiently small.

In this note, we consider a nonlinearity based on the model studied in [4], and we give a new multiplicity result which in some sense completes the picture given in [3] and [4]; in particular, we prove that there are indeed two solutions of (1) when $\bar{p} \in \overset{\circ}{I}$ and $\bar{p} \neq \frac{2}{\pi}(g(-\infty) + g(+\infty))$. We now state precisely our main result.

THEOREM 1. *Let $g : \mathbb{R} \to \mathbb{R}$ be locally Lipschitz continuous and such that the limits $g(-\infty)$ and $g(+\infty)$ exist and are finite. Let $p \in C[0,\pi]$ split according to* (2)*. Then there exist real numbers $a = a(\tilde{p}, g) \le b = b(\tilde{p}, g)$ such that*

$$l := \frac{2}{\pi}(g(-\infty) + g(+\infty)) \in [a, b]; \tag{3}$$

and problem (1) *has*

(i) *no solution if $\bar{p} \notin [a,b]$;*
(ii) *at least one solution if $\bar{p} \in (a,b)$ or $\bar{p} \in \{a,b\} \setminus \{l\}$;*
(iii) *at least two solutions if $\bar{p} \in (a,b) \setminus \{l\}$.*

2. Proof of the theorem.

We shall use the following lemma.

LEMMA 2. *Let $m \in L^1(0,a)$ and $v \in W^{2,1}(0,a)$ satisfy the conditions*
(a) *$v'' + m(t)v' + v < 0$ in $(0,a)$,*
(b) *$v(0) = v'(0) = 0$.*
Then there exists $a_1 \in (0,a)$ such that $v(a_1) < 0$.

Proof. Suppose that $v \ge 0$ in $(0,a)$. Let $M(t) = \int_0^t m(s)\,ds$. Then assumption (a) can be written

$$((\exp M(t))v')' + (\exp M(t))v < 0 \quad \text{in } (0,a),$$

and in particular $(\exp M(t))v'(t)$ is strictly decreasing in $[0,a]$. From (b) we infer that $v < 0$ in $(0,a)$, a contradiction. □

Remark. The lemma shows that in fact v takes negative values arbitrarily near $t = 0$.

Proof of the theorem. First we note that without loss of generality we can suppose $l = 0$; i.e., $g(-\infty) + g(+\infty) = 0$. (We shall henceforth add this to our hypotheses.) In fact, letting

$$h(s) := g(s) - \frac{g(-\infty) + g(+\infty)}{2} = g(s) - \frac{\pi l}{4} \quad \text{and} \quad q(t) = p(t) - \frac{\pi l}{4},$$

we obtain an equivalent problem,

$$\begin{gathered} u'' + u + h(u') = q(t), \\ u(0) = u(\pi) = 0. \end{gathered}$$

We also have $a(\tilde{p}, g) - l = a(\tilde{q}, h)$ and $b(\tilde{p}, g) - l = b(\tilde{q}, h)$.

Proof of (i) *and* (ii). The existence of a and b satisfying (i) and (ii) is proved in [3], except possibly for the fact that (1) is solvable when $\bar{p} = b > 0 = l$ or $\bar{p} = a < l = 0$. However, this follows immediately from Claim 1 in the proof of (iii) below, by a standard approximation procedure. □

Proof of (3). Before proceeding to the proof, we shall introduce some notations. Let $C_0^1[0,\pi]$ be the subspace of $C^1[0,\pi]$ consisting of those functions that vanish at $t = 0$ or $t = \pi$ and $\tilde{C}_0^1[0,\pi] = C_0^1[0,\pi] \cap \tilde{C}[0,\pi]$. These are Banach spaces with the usual C^1 norm, $\|u\| := \max(\|u\|_\infty, \|u'\|_\infty)$. Consider the projector $Q : C[0,\pi] \to \tilde{C}[0,\pi]$ defined by

$$Qu(t) = \tilde{u}(t) = u(t) - \frac{2}{\pi}\left(\int_0^\pi u(s) \sin s\,ds\right) \sin t.$$

Denote by K the (linear, compact) inverse of the differential operator $L : \tilde{C}_0^1[0,\pi] \to \tilde{C}[0,\pi]$, $u \mapsto u'' + u$, with domain $\mathrm{Dom}L = C^2[0,\pi] \cap \tilde{C}_0^1[0,\pi]$. The problem

$$\begin{gathered} \tilde{u}'' + \tilde{u} = \tilde{p} - Qg(\bar{u}\cos t + \tilde{u}'), \\ \tilde{u}(0) = \tilde{u}(\pi) = 0 \end{gathered} \tag{4}$$

can be written

$$\tilde{u} = \tilde{T}\tilde{u} := K(\tilde{p} - Qg(\bar{u}\cos t + \tilde{u}')).$$

The operator $\tilde{T} : \tilde{C}_0^1[0,\pi] \to \tilde{C}_0^1[0,\pi]$ is completely continuous and bounded, whence Schauder's theorem applies. This proves that there is a $k > 0$ so that for any given $\bar{u} \in \mathbb{R}$, the problem (4) has a solution $\tilde{u} \in \tilde{C}_0^1[0,\pi]$ with $\|\tilde{u}\| < k$. It follows that (1) has a solution $u(t) = \bar{u}\sin t + \tilde{u}(t)$, for $\bar{p}\sin t = (I - Q)g(\bar{u}\cos t + \tilde{u}')$. By Lebesgue's theorem, we have

$$\lim_{\bar{u}\to\infty} \int_0^\pi g(\bar{u}\cos s + \tilde{u}')\sin s\, ds = 0.$$

Hence, choosing $\bar{u}$ sufficiently large, we obtain numbers

$$\bar{p} := \frac{2}{\pi}\left(\int_0^\pi g(\bar{u}\cos s + \tilde{u}'(s))\sin s\, ds\right)$$

arbitrarily small such that $\bar{p} \in [a,b]$ and, going to the limit, we have $l = 0 \in [a,b]$. □

Proof of (iii). Setting $u(t) = \bar{u}\sin t + \tilde{u}(t)$, with $\bar{u} \in \mathbb{R}$ and $\tilde{u} \in \tilde{C}_0^1[0,\pi]$, it is easily seen that (1) can be rewritten as the system

$$\begin{gathered} \tilde{u} - K[\tilde{p} - Q(g(\bar{u}\cos t + \tilde{u}'))] = 0, \\ \frac{\pi}{2}\bar{p} - \int_0^\pi g(\bar{u}\cos s + \tilde{u}'(s))\sin s\, ds = 0. \end{gathered} \tag{5}$$

As a function of the pair $(\bar{u}, \tilde{u})$, the right-hand side of (5) is a compact perturbation of the identity in $\mathbb{R} \times \tilde{C}_0^1[0,\pi]$; we denote it by $T_{\bar{p}}$ to emphasize its dependence on $\bar{p}$.

We divide this proof into several steps.

Claim 1. Given $\varepsilon > 0$, there exists $R_0 > 0$ such that if u is a solution of (1) for some $\bar{p}$ with $|\bar{p}| \geq \varepsilon$, then $\|u\| < R_0$.

Proof. Assume that there exists a sequence $(\bar{p}_n)_n$ with $|\bar{p}_n| \geq \varepsilon$ and corresponding solutions u_n with $\|u_n\| \to \infty$. Split $u_n(t) = \bar{u}_n \sin t + \tilde{u}_n(t)$ according to (2). As in the above argument, it follows from (5) that the sequence $\|\tilde{u}_n\|$ is bounded. Hence $|\bar{u}_n| \to \infty$. Also, we obtain from (5)

$$\left|\int_0^\pi g(\bar{u}_n\cos s + \tilde{u}_n'(s))\sin s\, ds\right| = \frac{\pi}{2}|\bar{p}_n| \geq \frac{\pi}{2}\varepsilon,$$

and, by Lebesgue's theorem again, we reach the contradiction $0 \geq \frac{\pi}{2}\varepsilon$. □

Claim 2. Set $B_R = \{(\bar{u}, \tilde{u}) \mid u = \bar{u}\sin t + \tilde{u} \in C_0^1[0,\pi], \|u\| \leq R\}$. Given $\bar{p}_0 \neq 0$, there exists R_0 such that for every $R > R_0$,

$$\deg(T_{\bar{p}_0}, B_R, 0) = 0. \tag{6}$$

Proof. Suppose $\bar{p}_0 > 0$. As shown in Claim 1, there exists R_0 such that for all solutions u of (5) with $\bar{p} \geq \bar{p}_0$, we have $\|u\| < R_0$. On the other hand, by (i), we can fix $\bar p_1 > \bar p_0$ such that (5) (with $\bar p = \bar p_1$) has no solution at all. The homotopy and existence properties of Leray–Schauder degree allow us to conclude that for every $R > R_0$,

$$\deg(T_{\bar p_0}, B_R, 0) = \deg(T_{\bar p_1}, B_R, 0) = 0.$$

The same argument applies if $\bar p_0 < 0$. $\square$

Claim 3. If $0 < \bar p < b$ or $0 > \bar p > a$, there exists a bounded open set $\Omega \subset \mathbb{R} \times \tilde C_0^1[0,\pi]$ such that

$$|\deg(T_{\bar p}, \Omega, 0)| = 1.$$

Proof. Step 1*: Construction of the set* Ω. To fix ideas, suppose that $0 < \bar p < b$. Choose $\rho \in (\bar p, b)$. By the characterization of a and b, there exists a solution of the problem

$$\begin{gathered}\alpha'' + \alpha + g(\alpha') = \rho \sin t + \tilde p(t) > \bar p \sin t + \tilde p(t), \qquad \text{on } (0,\pi),\\ \alpha(0) = \alpha(\pi) = 0.\end{gathered} \tag{7}$$

Fix $0 < \varepsilon < \frac{\pi}{4}\bar p$. Recall that there is $k > 0$ so that any solution of (5) is such that $\|\tilde u(t)\| \le k$. Let us then choose $\bar\beta_0$ large enough so that for any $\tilde u$ with $\|\tilde u(t)\| \le k$,

$$\bar\beta_0 \sin t > \alpha(t) + \tilde u(t) \quad \text{ in } (0,\pi)$$

and

$$\begin{aligned}(I-Q)g(\bar\beta_0\cos t + \tilde u') &= \frac{2}{\pi}\left(\int_0^\pi g(\bar\beta_0 \cos s + \tilde u'(s)) \sin s\, ds\right)\sin t\\ &< \left(\bar p - \frac{4\varepsilon}{\pi}\right)\sin t.\end{aligned}$$

Next, we choose a $\tilde\beta_0$ solution of

$$\tilde u - K[\tilde p - \tilde\varepsilon - Q(g(\bar\beta_0 \cos t + \tilde u'))] = 0,$$

where $\tilde\varepsilon = Q\varepsilon = \varepsilon(1 - \frac{4}{\pi}\sin t)$. The function $\beta_0(t) := \bar\beta_0 \sin t + \tilde\beta_0(t)$ satisfies

$$\begin{aligned}\beta_0'' + \beta_0 + g(\beta_0') &= \tilde p - \tilde\varepsilon + (I-Q)g(\bar\beta_0\cos t + \tilde\beta_0')\\ &< \tilde p + \bar p \sin t - \varepsilon, \qquad\qquad 0 < t < \pi,\\ &\beta_0(0) = \beta_0(\pi) = 0,\end{aligned}$$

and therefore $\beta(t) := \beta_0(t) + \varepsilon$ is a strict upper solution of (1) such that $\beta \ge \alpha + \varepsilon$ in $[0,\pi]$.

Choose $k > 0$ so large that

$$k(\beta - \alpha) > \beta'' - \alpha'' \quad \text{in } [0,\pi]. \tag{8}$$

Then let us consider the homotopy

$$\begin{gathered}u'' + \lambda(u + g(u') - p) - (1-\lambda)\left[k\left(u - \tfrac{\alpha+\beta}{2}\right) + \tfrac{\alpha''+\beta''}{2}\right] = 0,\\ u(0) = u(\pi) = 0, \qquad\qquad 0 \le \lambda \le 1,\end{gathered} \tag{9}$$

and the bounded open subset of $\mathbb{R} \times \tilde{C}_0^1[0,\pi]$,

$$\begin{aligned}\Omega = \{(\bar{u}, \tilde{u}) \mid u = \bar{u}\sin t + \tilde{u} \in C_0^1[0,\pi], \alpha(t) < u(t) < \beta(t) \text{ in } (0,\pi), \\ \|u'\|_\infty < N,\ u'(0) > \alpha'(0) \ \text{ and } \ u'(\pi) < \alpha'(\pi)\},\end{aligned}$$

where N is a bound for derivatives of solutions u of (9) such that $\alpha \le u \le \beta$. This bound clearly exists, since g is bounded.

Step 2*: There exists no solution $u = \bar{u}\sin t + \tilde{u}$ of* (9) *such that $(\bar{u}, \tilde{u}) \in \partial\Omega$.* First, we prove that there exists no solution $u = \bar{u}\sin t + \tilde{u}$ of (9) on $\partial\Omega$ if $0 \le \lambda < 1$. Arguing by contradiction, suppose that for some $s \in [0,\pi]$ we have $u(s) = \alpha(s)$, $u'(s) = \alpha'(s)$, $u''(s) \ge \alpha''(s)$. Then we compute

$$\alpha''(s) \le u''(s) \le \lambda\alpha''(s) + (1-\lambda)\left[k\frac{\alpha(s)-\beta(s)}{2} + \frac{\alpha''(s)+\beta''(s)}{2}\right]$$

so that

$$\alpha''(s) \le k\frac{\alpha(s)-\beta(s)}{2} + \frac{\alpha''(s)+\beta''(s)}{2},$$

contradicting the choice of k in (8). An analogous computation shows that it is impossible to have $u(s) = \beta(s)$, $u'(s) = \beta'(s)$, $u''(s) \le \beta''(s)$ for some $s \in (0,\pi)$.

Next, we show that, if $\lambda = 1$, no solution $u \in \overline{\Omega}$ can satisfy $u(s) = \alpha(s)$, $u'(s) = \alpha'(s)$ or $u(s) = \beta(s)$, $u'(s) = \beta'(s)$. This is straightforward since, in case $0 < s < \pi$,

$$\alpha''(s) + \alpha(s) + g(\alpha'(s)) - p(s) > 0 > \beta''(s) + \beta(s) + g(\beta'(s)) - p(s).$$

Also, $\beta(0) = \beta(\pi) = \varepsilon > 0$. Hence, it remains to show that $u(s) = \alpha(s)$, $u'(s) = \alpha'(s)$ cannot hold with $(\bar{u}, \tilde{u}) \in \overline{\Omega}$ and $s = 0$ or $s = \pi$. Let us consider the case $s = 0$, the other being similar. If $u(0) = \alpha(0)$, $u'(0) = \alpha'(0)$, the function $v(t) := u(t) - \alpha(t)$ would satisfy $v \ge 0$ in $[0,\pi]$ and also, on account of (7),

$$v'' + v + m(t)v' = (\bar{p} - \rho)\sin t < 0 \quad \text{in } [0,\pi],$$

where $m(t) := \frac{g(u'(t)) - g(\alpha'(t))}{u'(t) - \alpha'(t)}$ if $u'(t) \ne \alpha'(t)$ and $m(t) = 0$ otherwise. Since g is locally Lipschitz continuous, the function m is (measurable and) bounded, and we obtain a contradiction with Lemma 2.

Step 3*: Proof of the claim.* Note that (9) can be written in operator form as

$$\begin{aligned}\tilde{u} - KQ[\lambda N(\bar{u},\tilde{u}) + (1-\lambda)M(\bar{u},\tilde{u})] = 0, \\ \int_0^\pi [\lambda N(\bar{u},\tilde{u})(t) + (1-\lambda)M(\bar{u},\tilde{u})(t)]\sin t\, dt = 0,\end{aligned}$$

where

$$\begin{aligned}N(\bar{u},\tilde{u})(t) = p - g(\bar{u}\cos t + \tilde{u}'(t)) \quad \text{and} \\ M(\bar{u},\tilde{u})(t) = k\left(\bar{u}\sin t + \tilde{u}(t) - \tfrac{\alpha(t)+\beta(t)}{2}\right) + \tfrac{\alpha''(t)+\beta''(t)}{2} - \bar{u}\sin t - \tilde{u}(t).\end{aligned}$$

For $\lambda = 1$, this reduces to $T_{\bar{p}} = 0$. On the other hand, for $\lambda = 0$, it is clear that this is an equation of the form $L = 0$, where L is a linear, invertible compact perturbation of the identity. We derive from (9) that its unique solution is

$$u(t) = \frac{\alpha(t)+\beta(t)}{2} - \frac{\varepsilon}{2}\frac{\cosh\sqrt{k}(t-\pi/2)}{\cosh\sqrt{k}\pi/2} = \bar{u}\sin t + \tilde{u}(t),$$

and it is clear that $(\bar{u}, \tilde{u})$ belongs to Ω. By the invariance property of Leray–Schauder degree, we easily conclude the proof of Claim 3. $\square$

Claim 4. Assertion (iii) holds.

With $0 < \bar{p} < b$ fixed, we construct Ω as in Claim 3 and $R > R_0$ given by Claim 2 so that $\Omega \subset B_R$. Then the excision property of Leray–Schauder degree implies

$$|\deg(T_{\bar{p}}, B_R \setminus \Omega, 0)| = 1.$$

The existence of a solution of (5) (with $\bar{p} = \bar{p}_0$) in $B_R \setminus \Omega$ follows. There exists another solution in Ω by Claim 3. Similarly, we conclude that there exist two solutions if $a < \bar{p} < 0$, and the proof is complete. $\square$

3. Additional results. We do not know whether the interval $[a(\tilde{p}, g), b(\tilde{p}, g)]$ is not reduced to a point for some $\tilde{p}$. However, following the idea of [4], we can give simple conditions to ensure that, at least for small $\tilde{p}$, it is in fact nondegenerate.

PROPOSITION 3. *Assume that* $g : \mathbb{R} \to \mathbb{R}$ *is of class* C^1, $g(0) = 0$, *the limits* $g(-\infty)$ *and* $g(+\infty)$ *exist, and* $g'(0) \neq 0$. *Let* $p \in C[0, \pi]$ *split according to* (2). *Then there exists* $\varepsilon > 0$ *such that, if* $\|p\|_\infty < \varepsilon$, *we have* $a(\tilde{p}, g) < 0 < b(\tilde{p}, g)$.

Proof. The mapping $\mathcal{F} : C^2[0, \pi] \cap C_0^1[0, \pi] \to C[0, \pi]$, $u \mapsto u'' + u + g(u')$ is differentiable at $u = 0$. Since the problem

$$\begin{gathered} v'' + v + cv' = 0, \\ v(0) = v(\pi) = 0, \end{gathered}$$

where c is a nonzero constant, has only the trivial solution, it follows that $\mathcal{F}'(0)$ is an isomorphism. Hence, by the inverse mapping theorem, the range of $\mathcal{F}$ contains an open ball centered at the origin, and we can conclude. $\square$

Another interesting feature of problem (1) under the assumptions of the above proposition is that for p small and $\bar{p} \neq 0 = l$, one can indeed prove the existence of two *ordered* solutions.

PROPOSITION 4. *Assume that* $g : \mathbb{R} \to \mathbb{R}$ *is of class* C^1, $g(0) = 0$, *the limits* $g(-\infty)$ *and* $g(+\infty)$ *exist, and* $g'(0) \neq 0$. *Let* $p \in C[0, \pi]$ *split according to* (2) *and* $\bar{p} \neq l = 0$. *Then there exists* $\varepsilon > 0$ *such that, if* $\|p\|_\infty < \varepsilon$, *we have two solutions* u_1 *and* u_2 *of* (1) *with*

$$u_1(t) > u_2(t), \qquad \textit{in } (0, \pi).$$

Proof. Let $\|p\|_\infty$ be so small that the corresponding solution $u_1(t)$ given by the inverse mapping theorem has the property that the solution of the linear Cauchy problem

$$v'' + v + g(u_1')v' = 0, \quad v(0) = 0,\ v'(0) = 1 \tag{10}$$

is *positive* in $(0, \pi]$. Making the change of variable $u = u_1(t) + w$ in (1), we obtain a new problem

$$w'' + w + g(u_1'(t) + w') = g(u_1'(t)), \quad w(0) = w(\pi) = 0. \tag{11}$$

For definiteness, assume $\bar{p} > 0$. Consider the solution $z(t, \lambda)$ of the Cauchy problem associated with (11):

$$z'' + z + g(u_1'(t) + z') = g(u_1'(t)), \quad z(0) = 0,\ z'(0) = \lambda.$$

Since $v(t) := \frac{\partial z}{\partial \lambda}(t,0)$ is the solution of (10), we deduce that for $\lambda < 0$ and $|\lambda|$ sufficiently small, we have $z(t,\lambda) < 0$ for every $t \in (0,\pi]$. On the other hand, substituting $z(t,\lambda) = \lambda \sin t + x(t,\lambda)$, $x(t,\lambda)$ solves the problem

$$x'' + x + g(u_1'(t) + \lambda \cos t + x') = g(u_1'(t)), \quad x(0) = x'(0) = 0.$$

As $\lambda \to -\infty$, $x(t,\lambda)$ converges uniformly in $[0,\pi]$ to the solution $\hat{x}(t)$ of

$$x'' + x + \hat{g}(t) = g(u_1'(t)), \quad x(0) = x'(0) = 0,$$

where $\hat{g}(t) = g(-\infty)$ if $0 < t < \frac{\pi}{2}$ and $\hat{g}(t) = g(+\infty)$ if $\frac{\pi}{2} < t < \pi$. Now this is given explicitly by

$$\hat{x}(t) = \int_0^t \sin(t-s)[g(u_1'(s)) - \hat{g}(s)]\, ds.$$

As $\hat{x}(\pi) = 2\bar{p} > 0$, we have $x(\pi,\lambda) > 0$ for $|\lambda|$ large. We infer that for some (negative) value of λ, $z(.,\lambda)$ is a negative solution of (11). Hence, (1) has a second solution $u_2(t)$ such that $u_2(t) < u_1(t)$ in $(0,\pi)$. □

MEASURABLE MULTIFUNCTIONS IN NONSEPARABLE BANACH SPACES [*]

DIÓMEDES BÁRCENAS[†] AND WILFREDO URBINA[‡]

Abstract. In this article we define measurable multifunctions in nonseparable Banach spaces, prove a weak compactness criterion for the selectors of multifunctions integrably bounded, characterize Banach spaces that have the Radon–Nikodym property by means of convergence of multivalued martingales, generalize some recent results on convergence of set-valued conditional expectations, and give some applications to control theory and differential inclusions.

Key words. measurable multifunctions, set-valued martingales, multiconditional expectation, Radon–Nikodym property, Kuratowski–Mosco convergence, controllability, differential inclusions

PII. S0036141095296005

1. Introduction.

Beyond being interesting by itself, the theory of measurable multifunctions has been shown to be useful in many branches of mathematics, such as convex analysis [4], mathematical economy [20], differential inclusions [13], and control theory [1].

In this paper we start with the definition of measurable multifunctions in nonseparable Banach spaces, then give a compactness criterion for the set of all measurable selections of an integrably bounded multifunction and a characterization of Banach spaces with the Radon–Nikodym property. Also, we generalize some results related to the convergence of multiconditional expectations recently obtained by Papageorgiou [23], prove a sort of continuous dependence theorem of the attainable set for a suitable infinite-dimensional linear system in terms of Kuratowski–Mosco convergence, and, finally, provide conditions for the compactness of mild trajectories of linear differential inclusions.

We want to remark that most of these results work in general Banach spaces, dropping some hypotheses like separability and reflexivity.

2. Preliminaries.

Let (Ω, Σ, μ) be a nonnegative, complete, σ-finite measure space. For a Banach space X we shall use the following notation:

$$\mathbf{P}_{f(c)}(X) = \{A \subset X : A \neq \emptyset, \text{closed (convex)}\},$$

$$\mathbf{P}_{wkc}(X) = \{A \subset X : A \neq \emptyset, \text{weakly compact, convex}\}.$$

For a nonempty subset A of X we put $|A| = \sup_{x \in A} ||x||$.

It has been standard to define *measurable multifunctions* with values in a separable Banach space as follows. Given a separable Banach space X and a measurable space

(Ω, Σ), a multifunction $\mathbf{F} : \Omega \to 2^X \backslash \{\emptyset\}$ is measurable if for each open subset U of X we have

$$\mathbf{F}^-(U) = \{\omega \in \Omega : \mathbf{F}(\omega) \cap U \neq \emptyset\} \in \Sigma.$$

In [4] the following result is proved.

THEOREM 2.1. *Let* $\mathbf{F} : \Omega \to \mathbf{P}_f(X)$ *be a measurable multifunction. If there is a nonnegative complete, σ-finite measure μ defined on Σ, the following statements are equivalent:*

(i) $\mathbf{F}$ *is measurable.*

(ii) *For every* $x \in X,\ \omega \to d(x, \mathbf{F}(\omega))$ *is measurable.*

(iii) *There is a sequence of measurable functions* $f_n : \Omega \to X$ *such that* $\mathbf{F}(\omega) = \overline{\{f_n(\omega)\}}, \forall \omega \in \Omega$ *(Castaing representation).*

(iv) $\mathbf{GrF} = \{(\omega, x) : x \in \mathbf{F}(\omega)\} \in \Sigma \times \mathbf{B}(X)$*, with* $\mathbf{B}(X)$ *the Borel σ-field of X.*

(v) $\mathbf{F}^-(C) = \{\omega \in \Omega : \mathbf{F}(\omega) \cap C \neq \emptyset\} \in \Sigma$ *for each C closed subset of X.*

We notice that the *separability condition* in the Banach space X is a very strong restriction which can be removed thanks to the Castaing representation together with the Pettis measurability criterion ([8, p. 42]). This will be done in the next section.

Given a measurable multifunction $\mathbf{F} : \Omega \to \mathbf{P}_f(X)$, a selector of $\mathbf{F}$ is a measurable function $f : \Omega \to X$ such that $f(\omega) \in \mathbf{F}(\omega)$, μ a.e.

We will denote $\mathbf{S}^1_{\mathbf{F}}$ as the collection of selectors of $\mathbf{F}$ that are Bochner integrable. Given that definition, the following result holds [19]. $\mathbf{S}^1_{\mathbf{F}} \neq \emptyset$ if and only if the function $g : \Omega \to X$ defined by

$$g(\omega) = \inf\{||x||; x \in \mathbf{F}(\omega)\}$$

is Lebesgue integrable.

By using $\mathbf{S}^1_{\mathbf{F}}$, we can define the multivalued integral

$$\int_\Omega \mathbf{F} d\mu = \left\{ \int_\Omega f d\mu : f \in \mathbf{S}^1_{\mathbf{F}} \right\}.$$

A multifunction $\mathbf{F} : \Omega \to \mathbf{P}_f(X)$ is called *integrably bounded* if there is an $f \in L^1(\mu)$ such that $|\mathbf{F}(\omega)| \leq f(\omega)$, μ. a.e.

A collection $\{\mathbf{F}_\alpha\}_{\alpha \in \Lambda}$ of measurable multifunctions is called *uniformly integrable* if

(i) $\{|\mathbf{F}_\alpha|\}_{\alpha \in \Lambda}$ is bounded in $L^1(\mu)$, and

(ii) given $\varepsilon > 0$, there is a $\delta > 0$ such that

$$\mu(E) < \delta \Rightarrow \int_E |\mathbf{F}_\alpha| d\mu < \varepsilon$$

for each $\alpha \in \Lambda$.

Given a complete probability space $(\Omega, \Sigma, \mathbf{P})$, an integrably bounded multifunction $\mathbf{F} : \Omega \to \mathbf{P}_f(X)$, and a sub-$\sigma$-field $\Sigma_0 \subset \Sigma$, we define the *multiconditional expectation of* $\mathbf{F}$ *with respect to* Σ_0 as the multifunction $\mathbf{E}^{\Sigma_0}_{\mathbf{F}} : \Omega \to \mathbf{P}_f(X)$, for which we have

$$\mathbf{S}^1_{\mathbf{E}^{\Sigma_0}_{\mathbf{F}}} = \overline{\{\mathbf{E}^{\Sigma_0}_{\mathbf{f}} : f \in \mathbf{S}^1_{\mathbf{F}}\}},$$

where the closure is taken in the norm topology of $L^1_X(\mu)$. It has been proved by Hiai and Umegaki ([15, Cor. 1.2]) that $\mathbf{E}^{\Sigma_0}_{\mathbf{F}}$ exists and is unique.

If $(\Omega, \Sigma, \mathbf{P})$ is a complete probability space, $\{\Sigma_n\}_{n\in\mathbf{N}}$ is an increasing sequence of sub-σ-fields of Σ, and $\mathbf{F}_n : \Omega \to \mathbf{P}_f(X)$ is a sequence of integrably bounded multifunctions such that for each $n \in \mathbf{N}$, $\mathbf{F}_n$ is $\mathbf{P}$-measurable with respect to Σ_n, we say that $(\mathbf{F}_n, \Sigma_n)_{n\geq 1}$ is a *set-valued martingale* if

$$\mathbf{E}^{\Sigma_n}_{\mathbf{F}_{n+1}}(\omega) = \mathbf{F}_n(\omega) \text{ a.s.}$$

In what follows we shall also need the following definition. We say that a sequence $\{\Sigma_n\}_{n\in\mathbf{N}}$ of sub-σ-fields of Σ *converges to* Σ_0 in $L^1_X(\mathbf{P})$ if for each $f \in L^1_X(\mathbf{P})$, $\mathbf{E}^{\Sigma_n}_f \to \mathbf{E}^{\Sigma_0}_f$ in the norm topology of $L^1_X(\mathbf{P})$.

Finally, following Mosco [17], for a sequence $\{A_n\}_{n\geq 1}$ contained in $2^X\backslash\{\emptyset\}$, we set

$$\begin{aligned} s - \underline{\lim} A_n &= \{x \in X : x = \lim_{n\to\infty} x_n, x_n \in A_n\} \\ &= \{x \in X : x = \lim_{n\to\infty} d(x, A_n) = 0\} \end{aligned}$$

and

$$\omega - \overline{\lim} A_n = \{\omega - \lim_{k\to\infty} x_k, x_k \in A_{n_k}$$

for some subsequence $\{A_{n_k}\}$ of $\{A_n\}\}$.

According to Papageorgiou [23], a sequence $\{A_n\}$ is said to be convergent *in the Kuratowski–Mosco sense* to a set A (that we will denote as $A_n \xrightarrow{K.M.} A$) if

$$s - \overline{\lim} A_n = \omega - \overline{\lim} A_n = A.$$

3. Measurable multifunctions. In this section we start removing separability in the definition of measurable multifunctions.

Definition 3.1. *Let X be an arbitrary Banach space and (Ω, Σ, μ) be a positive, σ-finite complete measure space. A multifunction $\mathbf{F} : \Omega \to \mathbf{P}_f(X)$ is μ-measurable if there is a sequence of μ-measurable functions $f_n : \Omega \to X$ and $N \in \Sigma$ with $\mu(N) = 0$ so that*

$$\mathbf{F}(\omega) = \overline{\{f_n(\omega)\}}, \quad \forall \omega \in \Omega\backslash N.$$

With this definition, we restate Theorem 2.1 in the following fashion.

Theorem 3.1. *Let X be a Banach space and $\mathbf{F} : \Omega \to \mathbf{P}_f(X)$ a multifunction. The following conditions are equivalent:*

(i) $\mathbf{F}$ *is measurable.*

(ii) *There is an $N \in \Sigma$ with $\mu(N) = 0$ such that $Y = [\cup_{\omega\in\Omega\backslash N}\mathbf{F}(\omega)]$, the closed subspace generated by $\cup_{\omega\in\Omega\backslash N}\mathbf{F}(\omega)$ is separable, and for each relatively open set $U \subset Y$, $\overline{\mathbf{F}}(U) \in \Sigma$.*

(iii) *There is an $N \in \Sigma$ with $\mu(N) = 0$ such that $Y = [\cup_{\omega\in\Omega\backslash N}\mathbf{F}(\omega)]$ is separable, and for each $z \in Y$, the function $g : \Omega \to R$ defined by*

$$g(\omega) = \begin{cases} 0, & \text{if } \omega \in N, \\ d(z, \mathbf{F}(\omega)), & \text{if } \omega \in \Omega\backslash N, \end{cases}$$

is μ-measurable.

(iv) *There is an* $N \in \Sigma$ *with* $\mu(N) = 0$ *such that* $Y = [\bigcup_{\omega \in \Omega\backslash N} \mathbf{F}(\omega)]$ *is separable and*

$$\mathbf{GrF} = \{(\omega, x) : x \in \mathbf{F}(\omega)\} \in \Sigma \times \mathbf{B}(Y),$$

where $\mathbf{B}(Y)$ *is the Borel* σ*-field of* Y*.*

(v) *There is an* $N \in \Sigma$ *with* $\mu(N) = 0$ *such that* $Y = \overline{[\bigcup_{\omega \in \Omega\backslash N} \mathbf{F}(\omega)]}$ *is separable and* $\mathbf{F}^{-}(C) \in \Sigma$ *for every* C *relatively closed in* Y*.*

Proof. Since it relies on the separable case, we will prove the equivalence between (i) and (ii) in order to illustrate the technique.

(i)⇒(ii) Since $\mathbf{F} : \Omega \to \mathbf{P}_f(X)$ is μ-measurable, there is a sequence of μ-measurable functions $f_n : \Omega \to X$ and there is a set $N_0 \in \Sigma$ so that $\mu(N_0) = 0$ and

$$\mathbf{F}(\omega) = \overline{\{f_n(\omega)\}}, \forall \omega \in \Omega\backslash N_0.$$

Since each f_n is μ-measurable, the Pettis μ-measurability criterion implies that for each $n \in \mathbf{N}$ there is an $N_n \in \Sigma$ such that $\mu(N_n) = 0$ and $\overline{f_n(\Omega\backslash N_n)}$ is separable.

If $N = \bigcup_{n=0}^{\infty} N_n$, then $N \in \Sigma$, $\mu(N) = 0$, and $f_n(\Omega\backslash N)$ is separable, which implies that $Y = [\bigcup_{\omega \in \Omega\backslash N} \mathbf{F}(\omega)]$ is separable.

Define $\mathbf{G} : \Omega \to \mathbf{P}_f(Y)$ by

$$\mathbf{G}(\omega) = \begin{cases} \mathbf{F}(\omega), & \text{if } \omega \in \Omega\backslash N, \\ \{0\}, & \text{if } \omega \in N, \end{cases}$$

and $g_n : \Omega \to X$ by

$$g_n(\omega) = \begin{cases} f_n(\omega), & \text{if } \omega \in \Omega\backslash N, \\ 0, & \text{if } \omega \in N. \end{cases}$$

Since μ is complete, each g_n is measurable and

$$G(\omega) = \overline{\{g_n(\omega)\}} \;\; \forall \omega \in \Omega.$$

Therefore, G is a μ-measurable multifunction. This fact, together with the separability of Y and the completeness of μ, shows that the equivalence (i)–(ii) of Theorem 2.1 holds with $\mathbf{G}$ instead of $\mathbf{F}$, and the conclusion follows.

Now suppose (ii) holds and define $\mathbf{G} : \Omega \to \mathbf{P}_f(Y)$ as before. Since Y is separable, μ is complete, and $\mathbf{G}$ is plainly μ-measurable, we get, by Theorem 2.1, that there is a sequence $\{f_n\}$ of measurable functions $f_n : \Omega \to X$ such that $\mathbf{G}(\omega) = \overline{\{f_n(\omega)\}}$ for each $\omega \in \Omega$. Since $\mathbf{G}(\omega) = \mathbf{F}(\omega), \forall \omega \in \Omega\backslash N$, then $\mathbf{F}(\omega) = \overline{\{f_n(\omega)\}}$ $\forall \omega \in \Omega\backslash N$. Thus $\mathbf{F}$ is μ-measurable. □

Now, in this case, the definitions of $\mathbf{S}^1_{\mathbf{F}}$, multiconditional expectation, set-valued martingale, and all the other notions are analogous to the separable case.

Our next goal is to give a characterization of weak compactness in $L^1_X(\mu)$ of $\mathbf{S}^1_{\mathbf{F}}$ for $\mathbf{F}$ integrably bounded.

Theorem 3.2. *Let* $\mathbf{F} : \Omega \to \mathbf{P}_{fc}(X)$ *be an integrably bounded multifunction with* μ *finite, nonnegative, and complete. Then* $\mathbf{S}^1_{\mathbf{F}}$ *is weakly compact if and only if* $\mathbf{F}(\omega)$ *is weakly compact,* μ *a.e.*

Proof. (⇐) Since the multifunction $\mathbf{F}$ is integrably bounded, $\mathbf{S}^1_{\mathbf{F}}$ is uniformly integrable. Since for almost all $\omega \in \Omega, \mathbf{F}(\omega)$ is weakly compact, the set

$$\{f : f \in \mathbf{S}^1_{\mathbf{F}}\}$$

is relatively weakly compact in X. Now consider a sequence $\{f_n\}$ in $\mathbf{S}^1_{\mathbf{F}}$. By Ülger [27] and Diestel, Ruess, and Schachermayer [7], there is a $g_n : \Omega \to X$ so that $g_n(\omega) \in c_0\{f_n(\omega), f_{n+1}(\omega), \ldots\}$ for μ (a.e.) ω and $g \in L^1_X(\mu)$ so that

$$g_n(\omega) \to g(\omega)$$

(μ a.e.) in the norm of X with $g(\omega) \in \mathbf{F}(\omega), \mu$ a.e. Consequently, $\mathbf{S}^1_{\mathbf{F}}$ is relatively weakly compact. Plainly, $\mathbf{S}^1_{\mathbf{F}}$ is a convex subset of $L^1_X(\mu)$.

Now let $f \in \overline{\mathbf{S}^1_{\mathbf{F}}}$. Then there exists a sequence $\{f_n\}_n$ in $\mathbf{S}^1_{\mathbf{F}}$ so that $\{f_n\}_n$ converges to f in the strong topology of $L^1_X(\mu)$; hence, there is a subsequence $\{f_{n_k}\}_k$ of $\{f_n\}_n$ satisfying $f_{n_k}(\omega) \to f(\omega)$, μ a.e.

Since $\{f_{n_k}\}_k \subset \mathbf{F}(\omega)$, which is convex and weakly compact (μ a.e.), hence closed in the strong topology of X, we get $f(\omega) \in \mathbf{F}(\omega)$, μ a.e. This implies that $\mathbf{S}^1_{\mathbf{F}}$ is closed and then, by convexity, weakly closed.

($\Rightarrow$) Suppose $\mathbf{F}(\omega)$ is not weakly compact (μ a.e.); then there is a measurable set A with $\mu(A) > 0$, and $\mathbf{F}(\omega)$ is not relatively weakly compact for $\omega \in A$. Since $\mathbf{F}$ is integrably bounded, $\mathbf{S}^1_{\mathbf{F}}$ coincides with the set of all measurable selectors of $\mathbf{F}$ and, again applying the Ülger–Diestel–Ruess–Schachermayer theorem, $\mathbf{S}^1_{\mathbf{F}}$ is not relatively weakly compact, which is a contradiction. So, $\mathbf{F}(\omega)$ has to be relatively weakly compact (μ a.e.) and, being closed, weakly compact, μ a.e. □

Our proof not only generalizes the proof given by Papageorgiou in [18, 19] but is more elementary than that one. In fact, Papageorgiou's proof relies on the well-known James compactness criterion [16]; our proof relies instead on the Ülger–Diestel–Ruess–Schachermayer $L^1_X(\mu)$ compactness criterion, which uses Mazur's theorem, which is more elementary than James' theorem. Furthermore, our proof is close in spirit to the theory of single-valued functions.

We end this section with a characterization of the Radon–Nikodym property (compare with Egghe [11, Thm. II.2.2.1]).

Theorem 3.3. *For a Banach space X the following statements are equivalent:*

(i) *X has the Radon–Nikodym property.*

(ii) *For every set-valued uniformly integrable martingale $\mathbf{F}_n : \Omega \to \mathbf{P}_f(X)$, there is an integrably bounded multifunction $\mathbf{F} : \Omega \to \mathbf{P}_{fc}(X)$ such that $\mathbf{E}^{\Sigma_n}_{\mathbf{F}}(\omega) = \mathbf{F}_n(\omega)$, μ a.e.*

(iii) *For every L^∞-bounded set-valued martingale $\mathbf{F}_n : \Omega \to \mathbf{P}_{fc}(X)$, there is an integrably bounded multifunction $\mathbf{F} : \Omega \to \mathbf{P}_{fc}(X)$ such that $\mathbf{E}^{\Sigma_n}_{\mathbf{F}}(\omega) = \mathbf{F}_n(\omega)$, μ a.e.*

Proof. (i) $\Rightarrow$ (ii) Since $\{\mathbf{F}_n\}_n$ is a sequence of measurable multifunctions, we can suppose, without loss of generality, that the closed subspace Y generated by $\{\bigcup_n \bigcup_{\omega\in\Omega} \mathbf{F}_n\}$ is separable. With this assumption, we have that

$$\mathbf{F}_n : \Omega \to \mathbf{P}_{fc}(Y).$$

Since the Radon–Nikodym property is hereditary for closed subspaces, the conclusion follows using Theorem 3.1 of [22].

(ii) $\Rightarrow$ (iii) It is trivial.

(iii) $\Rightarrow$ (i) If (iii) holds, it does for single-valued martingales, and this leads to the well-known classical case (see Van Dust [10]). □

4. Convergence of multiconditional expectation. In this section we generalize Theorems 3.1 and 3.2 of [23] in several directions. The first generalization is the following one.

THEOREM 4.1. *If X^* has the Radon–Nikodym property, $\mathbf{F} : \Omega \to \mathbf{P}_{fc}(X)$ is an integrably bounded multifunction and Σ_n an increasing sequence of sub-σ-fields converging to Σ_0, then*

$$\mathbf{E}_{\mathbf{F}}^{\Sigma_n}(\omega) \xrightarrow{K.M.} \mathbf{E}_{\mathbf{F}}^{\Sigma_0}(\omega),$$

μ a.e. The result is also true if X^* has the Radon–Nikodym property and (Ω, Σ, μ) has no Σ_0-atoms.

Proof. If X^* is separable, the result is Theorem 3.1 of [23]. In the general case, by Stegall's result [25], X^* has the Radon–Nikodym property only if every separable subspace of X has a separable dual. Since $\mathbf{F}$ is μ-measurable, there is an $N \in \Sigma$ such that $\mu(N) = 0$ and Y, the closed subspace generated by $\bigcup_{\omega \in \Omega \setminus N} \mathbf{F}(\omega)$, is separable. Define $\mathbf{G} : \Omega \to \mathbf{P}_f(Y)$ by

$$\mathbf{G}(\omega) = \begin{cases} \mathbf{F}(\omega), & \text{if } \omega \in \Omega \setminus N; \\ \{0\}, & \text{if } \omega \in N. \end{cases}$$

Therefore, $\mathbf{G}$ is a μ-measurable multifunction and, since X^* has the Radon–Nikodym property, Y^* is separable; so, by Theorem 3.1 of [23],

$$\mathbf{E}_{\mathbf{G}}^{\Sigma_n}(\omega) \xrightarrow{K.M.} \mathbf{E}_{\mathbf{G}}^{\Sigma_0}(\omega), \quad \mu \text{ a.e.}$$

Since $\mathbf{E}_{\mathbf{G}}^{\Sigma_n}$ is Σ_n-μ-measurable, there is a sequence $g_{n,m} : \Omega \to Y \subset X$ of Σ_n-μ-measurable functions so that $\mathbf{E}_{\mathbf{G}}^{\Sigma_n}(\omega) = \overline{\{g_{n,m}(\mu)\}}$ $\forall \omega \in \Omega$ and $\forall n \geq 0$.

Since $\mathbf{G}(\omega) = \mathbf{F}(\omega)$ (μ a.e),

$$\mathbf{E}_{\mathbf{G}}^{\Sigma_n}(\omega) = \mathbf{E}_{\mathbf{F}}^{\Sigma_n}(\omega)$$

(μ a.e.), $\forall n \geq 0$. Therefore,

$$\mathbf{E}_{\mathbf{F}}^{\Sigma_n}(\omega) \xrightarrow{K.M.} \mathbf{E}_{\mathbf{F}}^{\Sigma_0}(\omega),$$

μ a.e.

The same type of argument allows us to obtain the following result.

THEOREM 4.2. *If X^* has the Radon–Nikodym property, $\mathbf{F}_n : \Omega \to \mathbf{P}_{wkc}(X)$ is a sequence of μ-measurable multifunctions $\mathbf{F}_n(\omega) \subset \mathbf{G}(\omega)$ (μ a.e.), with $\mathbf{G} : \Omega \to \mathbf{P}_{wkc}(X)$ integrably bounded, $\mathbf{F}_n(\omega) \xrightarrow{K.M.} \mathbf{F}(\omega)$ (μ a.e.), and $\Sigma_n \to \Sigma_0$ in $L^1_X(\mu)$; then*

$$\mathbf{S}^1_{\mathbf{E}_{\mathbf{F}}^{\Sigma_n}} \xrightarrow{K.M.} \mathbf{S}^1_{\mathbf{E}_{\mathbf{F}}^{\Sigma_0}}.$$

Proof. If X^* is separable, the result is Theorem 3.2 of [23]. In the general case, since each $\mathbf{F}_n$ is measurable, there exists an $N_n \in \mathbf{N}$ such that $\mu(N_n) = 0$ and $\bigcup_{\omega \in \Omega \setminus N_n} \mathbf{F}_n(\omega)$ is separable. If $N = \bigcup_{n=1}^{\infty} N_n$, then $N \in \Sigma$, $\mu(N) = 0$, and the closed subspace Y, generated by $\bigcup_{\omega \in \Omega \setminus N} \mathbf{F}(\omega)$, is separable. The remainder of the proof follows by using the same technique applied in the previous theorem. □

Sometimes it is possible to remove the Radon–Nikodym property in Theorem 4.2. To do that we need the following lemmas.

LEMMA 4.1. *A function $\mathbf{F} : \Omega \to \mathbf{P}_f(X)$ is μ-measurable if and only if there is an $N \in \Sigma$ so that $\mu(N) = 0$, $Y = [\bigcup_{\omega \in \Omega \setminus N} \mathbf{F}(\omega)]$ is separable, and $\overline{\mathbf{F}}(B) \in \Sigma$ for each closed ball B in the relative strong topology of Y.*

Proof. It is enough to prove the converse. Let A be a nonempty closed set of Y, set $H \subset A$ dense and countable, and $\varepsilon > 0$. If $U_\varepsilon = \bigcup_{x\in H} \overline{B}(x,\varepsilon)$, then

$$\mathbf{F}^-(U_\varepsilon) = \bigcup_{x\in H} \mathbf{F}^-(\overline{B}(x,\varepsilon)),$$

which implies that $\mathbf{F}^-(U_\varepsilon) \in \Sigma$. By setting $\varepsilon = \frac{1}{n}, n \in \mathbf{N}$, we get

$$A = \bigcap_{n=1}^{\infty} U_{\frac{1}{n}},$$

and therefore $\mathbf{F}^-(A) = \bigcap_{n=1}^{\infty} \mathbf{F}^-(U_{\frac{1}{n}}) \in \Sigma$. So, by Theorem 3.1, $\mathbf{F}$ is μ-measurable. $\square$

In the separable case, the preceding lemma is equivalent to (a) and (d) of Lemma 2.1 of [14]. The elementary proof given here is inspired by [9, p. 92].

LEMMA 4.2. *Let X be a Banach space and $\mathbf{F}_n : \Omega \to \mathbf{P}_{wkc}(X)$ be a sequence of measurable multifunctions such that there is a weakly compact, convex, and separable subset of X, W such that $\mathbf{F}_n(\omega) \subset W, \forall w \in \Omega$ and $n \in \mathbf{N}$. Then $\mathbf{F}(\omega) = \overline{\lim}_n \mathbf{F}_n(\omega)$ is measurable, takes its values in $\mathbf{P}_{wkc}(X)$, and $\mathbf{F}(\omega) \subset W, \forall w \in \Omega$.*

Proof. If X is reflexive and separable, Proposition 4.3 of Hess [14] provides the proof with $\mathbf{G}(\omega) = W$. In the general case, the Davis–Fiegel–Johnson–Pelczynski factorization scheme [5] produces a separable reflexive Banach space R, a one-to-one bounded linear operator $\mathbf{J} : R \to X$, and a weakly compact convex subset K of R such that the restriction $\mathbf{J}|_K$ is a weak homeomorphism between K and W.

Now we consider the multifunctions

$$\mathbf{J}^{-1}\mathbf{F}_n : \Omega \to \mathbf{P}_{wkc}(R).$$

$\mathbf{J}^{-1}\mathbf{F}_n(\omega) \subset K$ for each $\omega \in \Omega$ and $n \in \mathbf{N}$. Furthermore, given a closed ball B in Y, the closed subspace generated by K, we have

$$B \cap \mathbf{J}^{-1}\mathbf{F}_n(\omega) \neq \emptyset \iff (B \cap K) \cap \mathbf{J}^{-1}\mathbf{F}_n(\omega) \neq \emptyset,$$

which means that it is enough to consider closed balls in K.

Let B be a closed ball in K. Then $\mathbf{J}^{-1}\mathbf{F}_n^-(B) = \mathbf{F}_n^-(\mathbf{J}(B)) \in \Sigma$; hence Lemma 4.1 implies $\mathbf{J}^{-1}\mathbf{F}_n$ μ-measurable for each $n \in \mathbf{N}$. Now, applying Proposition 4.3 of [14], we get that

$$H = \overline{\lim}_{n\to\infty} \mathbf{J}^{-1}\mathbf{F}_n$$

is a μ-measurable multifunction with values in $\mathbf{P}_{wkc}(R)$ and $H(\omega) \subset K$, $\forall \omega \in \Omega$. Since $\mathbf{F}_n = \mathbf{J}\mathbf{J}^{-1}\mathbf{F}_n$ for each $n \in \mathbf{N}$ and $\mathbf{J}|_K$ is a weak homeomorphism between K and W, we get

$$\mathbf{F}^-(B) = \mathbf{J}H^-(B) = H^-(\mathbf{J}^{-1}B) \in \Sigma,$$

and Lemma 4.1 implies that $\mathbf{F}$ is μ-measurable. $\square$

THEOREM 4.3. *Let X be a Banach space and $\mathbf{F}_n : \Omega \to \mathbf{P}_{wkc}(X)$ be a sequence of μ-measurable multifunctions. If there is a weakly compact, convex, separable subset W of X such that $\mathbf{F}_n(\omega) \subset W, \forall w \in \Omega$ and $\forall n \in \mathbf{N}$, and $\mathbf{F}_n \xrightarrow{K.M.} \mathbf{F}$, then*

$$\mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{\mathbf{F}_n}} \xrightarrow{K.M.} \mathbf{S}^1_{\mathbf{E}^{\Sigma_0}_{\mathbf{F}}}$$

whenever Σ_n *is a sequence of sub-*σ*-fields that converges to* Σ_0 *in* $L^1_X(\mu)$.

Proof. Since W is separable, the reflexive Banach space R tailored through the Davis–Fiegel–Johnson–Pelczynski factorization scheme is separable. Let K be a weakly compact subset of R so that $\mathbf{J}|_K : K \to W$ is a weak homeomorphism. From Lemma 4.2, $\mathbf{J}^{-1}\mathbf{F}_n : \Omega \to \mathbf{P}_{wkc}(R)$ is a sequence of μ-measurable multifunctions, and so, there is another μ-measurable multifunction $\mathbf{H} : \Omega \to \mathbf{P}_{wkc}(R)$ so that $\mathbf{H}(\omega) \subset K$, $\forall \omega \in \Omega$, where $H = \overline{\lim}\mathbf{J}^{-1}\mathbf{F}_n$. By taking $G \equiv K$, we can apply Theorem 4.2 of [21] in order to get

$$\omega - \overline{\lim}\,\mathbf{S}^1_{\mathbf{J}^{-1}\mathbf{F}_n} \subset \mathbf{S}^1_{\mathbf{H}}.$$

Being R-reflexive and separable, as is its dual, and from the proof of Theorem 3.2 of [23],

$$\omega - \overline{\lim}\,\mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{\mathbf{J}^{-1}\mathbf{F}_n}} \subset \mathbf{S}^1_{\mathbf{E}^{\Sigma_0}_{\mathbf{H}}}.$$

The same proof also shows that

$$\mathbf{S}^1_{\mathbf{E}^{\Sigma_0}_{\mathbf{F}}} \subset s - \underline{\lim}\,\mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{\mathbf{J}^{-1}\mathbf{F}_n}}.$$

Now, proceeding as in Diestel [6], we define a one-to-one bounded linear operator $\tilde{\mathbf{J}} : L^1_R(\mu) \to L^1_X(\mu)$ by $\tilde{\mathbf{J}}(f) = \mathbf{J} \circ f$ (it is well defined by Hille's theorem [8, p. 47]). We claim that

$$\omega - \overline{\lim}\,\tilde{\mathbf{J}}(\mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{\mathbf{J}^{-1}\mathbf{F}_n}}) \subset \mathbf{S}^1_{\mathbf{E}^{\Sigma_0}_{\mathbf{J}(\mathbf{H})}}.$$

In fact, for each

$$f_n \in \tilde{\mathbf{J}}(\mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{\mathbf{J}^{-1}\mathbf{F}_n}}),$$

there is a $g_n \in \mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{\mathbf{J}^{-1}\mathbf{F}_n}}$ such that $f_n = \mathbf{J}g_n$; so if

$$f \in \omega - \overline{\lim}\,\tilde{\mathbf{J}}(\mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{\mathbf{J}^{-1}\mathbf{F}_n}}),$$

there is an increasing sequence of positive integer numbers $\{n_k\}$ such that

$$g_{n_k} \in \mathbf{S}^1_{\mathbf{E}^{\Sigma_{n_k}}_{\mathbf{J}^{-1}\mathbf{F}_n{}_{n_k}}}$$

and $\mathbf{J}g_{n_k}$ converges to f in the weak topology of $L^1_X(\mu)$. Since

$$\mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{\mathbf{J}^{-1}\mathbf{F}_n}} \subset \{f : \Omega \to R : f \,\text{is a measurable selector of}\, \mathbf{G} \equiv \mathbf{K}\},$$

Theorem 3.2 implies that there is a μ-measurable function $g : \Omega \to K$ such that $g_{n_{k_l}}$ converges to g in the weak topology of $L^1_R(\mu)$ for some subsequence $g_{n_{k_l}}$ of g_{n_k}; so $g \in \mathbf{H}$. Hence, given $x^* \in (L^1_X(\mu))^*$, we have

$$x^* f_{n_{k_l}} = x^* \tilde{\mathbf{J}} g_{n_{k_l}} \xrightarrow{w} x^* \tilde{\mathbf{J}} g,$$

and therefore $f = \tilde{\mathbf{J}}g$ (μ a.e.), and this implies $f \in \mathbf{J}(\mathbf{H})$. But

$$\tilde{\mathbf{J}}(\mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{\mathbf{J}^{-1}\mathbf{F}_n}}) = \mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{\mathbf{F}_n}}\ \forall n \quad \text{and} \quad \tilde{\mathbf{J}}(\mathbf{S}^1_{\mathbf{E}^{\Sigma_0}_{H}}) = \mathbf{S}^1_{\mathbf{E}^{\Sigma_0}_{\mathbf{J}(\mathbf{H})}}.$$

This fact, together with the previous inclusion, gives us

$$\omega - \overline{\lim}\, \mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{\mathbf{J}^{-1}\mathbf{F}_n}} \subset \mathbf{S}^1_{\mathbf{E}^{\Sigma_0}_{\mathbf{J}(\mathbf{H})}}.$$

It remains to prove that $\mathbf{J}(\mathbf{H}) = \mathbf{F}$, since then the conclusion follows from the obtained inclusions. By hypothesis $\mathbf{F}_n \xrightarrow{K.M.} \mathbf{F}$. Hence $\omega - \overline{\lim}\, \mathbf{F}_n = \mathbf{F}$. $\mathbf{J}$ being a weak homomorphism between K and W, we get $\mathbf{H} = \mathbf{J}^{-1}\mathbf{F}$. This ends the proof. □

Our next result brings to this context an application from operator theory.

DEFINITION 4.1. *Given X, Y Banach spaces, a bounded linear operator $T : X \to Y$ is called an Asplund operator if there are a Banach space Z and bounded linear operators $T_1 : X \to Z$, $T_2 : Z \to Y$ such that Z^* has the Radon–Nikodym property and $T = T_2 \circ T_1$.*

This notion was introduced and studied by Stegall. It has shown to be useful in convex analysis [26] and control theory [2]. Here is a small contribution to the theory of measurable multifunctions.

THEOREM 4.4. *Let (Ω, Σ, μ) be a finite complete measure space, X, Y Banach spaces, and $T : X \to Y$ an Asplund operator. If $\mathbf{F}, \mathbf{F}_n : \Omega \to \mathbf{P}_{wkc}(X)$, $n \in \mathbf{N}$, are measurable multifunctions, if there is an integrably bounded multifunction $G : \Omega \to \mathbf{P}_{wkc}(X)$, such that $\mathbf{F}_n(\omega) \subset \mathbf{G}(\omega)$ (μ a.e.) $\forall n, \in \mathbf{N}$, and if $\{\Sigma_n\}$ is a sequence of sub-σ-fields that converges to Σ_0 in $L^1_X(\mu)$, then*

$$\mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{T(\mathbf{F}_n)}} \xrightarrow{K.M.} \mathbf{S}^1_{\mathbf{E}^{\Sigma_0}_{T(\mathbf{F})}}.$$

Proof. Let Z be a Banach space such that its dual Z^* has the Radon–Nikodym property and $T_1 : X \to Z$, $T_2 : Z \to Y$ bounded operators so that $T = T_2 \circ T_1$. If $W = \overline{T_1(X)}$, then Σ_n converges to Σ_0 in $L^1_W(\mu)$, and W^* has the Radon–Nikodym property. Furthermore, $T = T_3 \circ T_1$ where $T_3 = T_2|_W$. For each $n \in \mathbf{N}$, $T_1\mathbf{F}_n : \Omega \to \mathbf{P}_{wkc}(X)$ is measurable and is contained in $T_1\mathbf{G} : \Omega \to \mathbf{P}_{wkc}(X)$, which is integrably bounded. Furthermore, $T_1\mathbf{F}_n \xrightarrow{K.M.} T_1\mathbf{F}$. So by Theorem 4.3,

$$\mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{T_1(\mathbf{F}_n)}} \xrightarrow{K.M.} \mathbf{S}^1_{\mathbf{E}^{\Sigma_0}_{T_1(\mathbf{F})}}.$$

Therefore,

$$\mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{T(\mathbf{F}_n)}} = \mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{T_3 \circ T_1(\mathbf{F}_n)}} = T_3(\mathbf{S}^1_{\mathbf{E}^{\Sigma_n}_{T_1(\mathbf{F}_n)}}) \xrightarrow{K.M.} T_2(\mathbf{S}^1_{\mathbf{E}^{\Sigma_0}_{T_1(\mathbf{F})}}) = \mathbf{S}^1_{\mathbf{E}^{\Sigma_0}_{T(\mathbf{F})}}. \qquad □$$

5. An application in control theory. In this section we give some applications of the Kuratowski–Mosco convergence into optimal control theory allowing the controls to be variable in [0, T]. Therefore, in this section, μ is the Lebesgue measure in [0,T].

Given two Banach spaces U, X and a bounded linear operator $B : U \to X$, we consider the following linear systems in X:

$$\mathbf{S}_n = \begin{cases} \dot{x}(t) = Ax(t) + Bf^{(n)}(t), \\ x(0) = x_0; \end{cases}$$

$$\mathbf{S} = \begin{cases} \dot{x}(t) = Ax(t) + Bf(t), \\ x(0) = x_0, \end{cases}$$

where $f^{(n)}, f$ are μ-measurable selectors of $\mathbf{F}_n : [0,T] \to \mathbf{P}_{wkc}(U)$, $\mathbf{F} : [0,T] \to \mathbf{P}_{wkc}(U)$, where $\mathbf{F}_n$, $\mathbf{F}$ are strongly μ-measurable multifunctions and A generates a strongly continuous semigroup of bounded linear operators $\{S_t\}_{t\geq 0}$. The set $K(t)$, defined as

$$K(T) = \left\{ \mathbf{S}_T x_0 + \int_0^T \mathbf{S}_{T-s} Bf(s) ds, f \in \mathbf{S}^1_{\mathbf{F}} \right\},$$

is called the set of attainable points for the system S in the time T. Analogously, we define the set $K_n(T)$ as the set of attainable points for the system S_n in the time T (where we consider $f \in \mathbf{S}^1_{\mathbf{F}_n}$ instead).

The system S (or S_n) is controllable in time T if $0 \in K(T)$ (respectively, $0 \in K_n(T)$). Controllability criteria for these classes of systems with $\mathbf{F}$ constant can be found in [2], [3], and [24].

The aim of this section is the following result.

Theorem 5.1. *Let $\mathbf{S}_n$, $\mathbf{S}$, $\mathbf{F}_n$, and $\mathbf{F}$ be as above. If $\mathbf{F}_n \xrightarrow{K.M.} \mathbf{F}$ and there is a $\mathbf{G} : [0,T] \to \mathbf{P}_{wkc}(X)$, integrably bounded such that for each $n \in \mathbf{N}$, $\mathbf{F}_n(\omega) \subset \mathbf{G}(\omega)$, μ a.e., then $K_n(T) \xrightarrow{K.M.} K(T)$.*

Proof. Since $\mathbf{F}_n \xrightarrow{K.M.} \mathbf{F}$, then for each $t \in [0,T]$, $\mathbf{S}_t B\mathbf{F}_n \xrightarrow{K.M.} \mathbf{S}_t B\mathbf{F}$. Furthermore, $\mathbf{S}_t B\mathbf{F}_n : \Omega \to \mathbf{P}_{wkc}(U)$ and are strongly μ-measurable with $\mathbf{S}_t B\mathbf{F}_n(\omega) \subset \mathbf{S}_t B\mathbf{G}(t)$ (μ a.e.) with $\mathbf{S}_t B\mathbf{G}$ convex weakly compact-valued and integrably bounded. Now, applying Theorem 3.4 of [21], we get

$$\int_0^T \mathbf{S}_{t-s} B\mathbf{F}_n(s) ds \xrightarrow{K.M.} cl \int_0^T \mathbf{S}_{t-s} B\mathbf{F}(s) ds,$$

which implies the conclusion because $K_n(T)$ and $K(T)$ are merely translations of $\int_0^T \mathbf{S}_{t-s} B\mathbf{F}_n(s) ds$ and $\int_0^T \mathbf{S}_{t-s} B\mathbf{F}(s) ds$, respectively. □

Corollary 5.1. *Under the same hypothesis as in Theorem* 5.1, *if $\mathbf{S}_n$ is controllable at time T and $\mathbf{F}_n \xrightarrow{K.M.} \mathbf{F}$, then $\mathbf{S}$ is controllable at time T.*

Proof. The proof follows immediately from the definitions and Theorem 5.1. □

6. Some applications in differential inclusions. Now we give a set of results related to the study of compactness of the solution of certain linear systems of differential inclusions.

In this entire section, $\Omega = [a,b] \subset \mathbf{R}$, Σ is the Borel σ-field on $[a,b]$ and μ is the Lebesgue measure on $[a,b]$.

We start with an easy result that has some interesting consequences.

Proposition 6.1. *Let X be a Banach space and $K \subset L^1_X(\mu)$ be uniformly integrable. The set*

$$A = \left\{ x : [a,b] \to X : x(t) = \int_a^t f d\mu; f \in K \right\}$$

is relatively compact in the uniform topology of $C([a,b];X)$ if and only if, for each $t \in [a,b]$, $\{x(t)\}_{x\in A}$ is relatively compact in the norm topology of X.

Proof. The boundedness and equicontinuity of A follows from the uniform integrability of K, and then the conclusion follows from the Arzéla–Ascoli theorem. □

The following result is due to Fattorini [12, Thm. 3.1] for the case $a = 0$. We present a simpler proof even though we use the same ideas as Fattorini.

THEOREM 6.1. *Let K be a uniformly integrable subset of $L^1_X(\mu)$ and $\mathbf{S}_t : X \to X$ a strongly continuous semigroup that is compact for each $t0$. Then, for $0 \leq a < b < \infty$, the set*

$$A = \left\{ x : [a,b] \to X : x(t) = \int_a^t \mathbf{S}_{t-s} f d\mu; f \in K \right\}$$

is relatively compact in the uniform topology of $C([a,b];X)$.

Proof. Let us suppose first that $a = 0$. Since K is uniformly integrable in $L^1_X(\mu)$ and $\mathbf{S}_{(\cdot)}$ is uniformly bounded on [0,b], we get that $\{\mathbf{S}_{(\cdot)} f\}_{f \in K}$ is uniformly integrable in $L^1_X(\mu)$. Let $t \in [0,b]$ and δ_n be a sequence of real numbers such that $\delta_n \to t$. Notice that for each $n \in \mathbf{N}$ and $f \in L^1_X(\mu)$,

$$\begin{aligned}\int_0^t \mathbf{S}_{t-s} f(s) d\mu(s) &= \int_0^{t-\delta_n} \mathbf{S}_{t-s} f(s) d\mu(s) + \int_{t-\delta_n}^t \mathbf{S}_{t-s} f(s) d\mu(s) \\ &= \mathbf{S}_{\delta_n} \left(\int_0^{t-\delta_n} \mathbf{S}_{t-\delta_n - s} f(s) d\mu(s) \right) + \int_{t-\delta_n}^t \mathbf{S}_{t-s} f(s) d\mu(s).\end{aligned}$$

The set $\{\int_0^t \mathbf{S}_{t-s} f(s) d\mu(s)\}_{f \in K}$ is bounded in X, and by hypothesis, $\mathbf{S}_{\delta_n}$is a compact operator; therefore, $\{\int_0^{t-\delta_n} \mathbf{S}_{t-s} f(s) d\mu(s)\}_{f \in K}$ is relatively compact in X. Thus, given a sequence $\{f_k\}$ in K, we can find, by the diagonal process, a subsequence $\{f_{k_l}\}$ of $\{f_k\}$ such that

$$\left\{ \int_0^{t-\delta_n} \mathbf{S}_{t-s} f_{k_l}(s) d\mu(s) \right\}$$

is convergent in X. Now, using the uniform integrability of K, we can see that $K - K = \{f - g : f, g \in K\}$ is also uniformly integrable. Therefore, given $\varepsilon > 0$, there are $l_0, n_0 \in \mathbf{N}$ such that for each $l > l_0$,

$$\begin{aligned}\left\| \int_0^t \mathbf{S}_{t-s}(\{f_{k_l}(s) - f_{k_{l_0}}(s)) d\mu(s) \right\| &\leq \left\| \int_0^{t-\delta_{n_0}} \mathbf{S}_{t-s}(f_{k_l}(s) - f_{k_{l_0}}(s)) d\mu(s) \right\| \\ &\quad + \left\| \int_{t-\delta_{n_0}}^t \mathbf{S}_{t-s}(f_{k_l}(s) - f_{k_{l_0}}(s)) d\mu(s) \right\| < \varepsilon,\end{aligned}$$

and now the conclusion follows from the Arzéla–Ascoli theorem.

In the general case, $a \neq 0$, we identify $L^1_X([a,b],\mu)$ with $L^1_X([0,b-a],\mu)$ using the identification $f \longleftrightarrow g$ if and only if $g(s) = f(x+a)$. Let K be uniformly integrable in $L^1_X([a,b],\mu)$ and K' its image under the identification. It is easy to see that K' is uniformly integrable in $L^1_X([0,b-a],\mu)$, and therefore, applying Proposition 6.1 together with the first part of the proof, we conclude that

$$\left\{ \int_0^t \mathbf{S}_{t-a-s} g(s) d\mu(s) \right\}_{g \in K'}$$

is relatively compact in X. This means that

$$\begin{aligned}\left\{\mathbf{S}_a\left(\int_0^{t-a}\mathbf{S}_{t-a-s}g(s)d\mu(s)\right)\right\}_{g\in K'} &= \left\{\left(\int_0^{t-a}\mathbf{S}_{t-s}g(s)d\mu(s)\right)\right\}_{g\in K'}\\ &= \left\{\left(\int_a^{t}\mathbf{S}_{t-s}g(s-a)d\mu(s)\right)\right\}_{g\in K'}\\ &= \left\{\left(\int_a^{t}\mathbf{S}_{t-s}f(s)d\mu(s)\right)\right\}_{f\in K}\end{aligned}$$

is relatively compact in K. Now, by Proposition 6.1, we conclude the proof. □

Now we state the main result of this section.

THEOREM 6.2. *Let* $\mathbf{F}\to\mathbf{P}_{wkc}(X)$ *be an integrable bounded multifunction,* $\{\mathbf{S}_t\}_{t\geq 0}$ *a strongly continuous semigroup of operators in* X*, and*

$$A=\left\{x\in C([a,b];X) : x(t)=\int_a^t\mathbf{S}_{t-s}f ds\right\}_{f\in\mathbf{S}^1_{\mathbf{F}}}.$$

Then,

(i) *if* $\mathbf{S}_t$ *is compact for each* $t>0$*,* A *is compact in* $C([a,b];X)$*;*

(ii) *if there is a compact set* $K\subset X$ *such that* $\mathbf{F}(t)\subset K$*,* $\forall t\in[a,b]$*,* A *is compact in* $C([a,b];X)$*.*

Proof. (i) From Proposition 6.1, we know that A is relatively weakly compact in $C([a,b];X)$. Let x_n, x be in $C([a,b];X)$, such that $||x_n-x||_\infty\to 0$. Clearly, for each $t\in[a,b]$, $x_n(t)$ converges weakly to $x(t)$. On the other hand, there is a sequence $\{f_n\}\subset\mathbf{S}^1_{\mathbf{F}}$ such that, for each $n\in\mathbf{N}$,

$$x_n(t)=\int_a^t\mathbf{S}_{t-s}f_n(s)d\mu(s),$$

since Theorem 3.2 ensures that $\{\mathbf{S}_{t-(\cdot)}f_n(\cdot)\}_{f\in\mathbf{S}^1_{\mathbf{F}}}$ is weakly compact, there are $g\in\mathbf{S}^1_{\mathbf{F}}$ and a subsequence $\{f_{n_k}\}$ of $\{f_n\}$ such that $\mathbf{S}_{t-(\cdot)}f_{n_k}(\cdot)$ converges to $\mathbf{S}_{t-(\cdot)}g(\cdot)$ in the weak topology of $L^1_X(\mu)$. This implies that for each $t\in[a,b]$, $x_{n_k}(t)$ converges weakly to $y(t)=\int_a^t\mathbf{S}_{t-s}g(s)d\mu(s)$. Hence $x\equiv y$.

(ii) Without loss of generality, we can suppose that K is convex and separable. By Corollary 8 of [8, p. 48], we have that for each $t\in(a,b]$, $\frac{1}{t}\int_a^t f(s)ds\in K$. Set $G\equiv K$, and let $B=\{x : x(t)=\int_a^t f(s)ds\}_{f\in\mathbf{S}^1_{\mathbf{G}}}$. Then $\{x(t)\}_{x\in B}$ is relatively compact in X, and thus B is relatively compact in $C([a,b];X)$.

Let $\{f_n\}_{n=1}^\infty$ be a sequence of simple functions in $\mathbf{S}^1_{\mathbf{F}}$, write the image of f_n as

$$\mathrm{Im}f_n=\{x_{1(n)},x_{1(n)},\dots,x_{k(n)}\},$$

and define

$$A_{n_i}=\{t\in[a,b] : f_n(t)=x_i(n),\ i=1,2,\dots,k(n)\}.$$

For each $n\in\mathbf{N}$ we have that $\{A_{n_i}\}_{i=1}^{k(n)}$ is a finite partition of $[a,b]$. Since $\{\int_a^t f_n(s)d\mu(s)\}_{n\in\mathbf{N}}$ is relatively compact, then given $\varepsilon>0$ and $n_0\in\mathbf{N}$, there is a subsequence $\{f_{n_k}\}_{k,n=1}^\infty$ of $\{f_n\}_{n=1}^\infty$ such that

$$\left\|\int_a^t(f_{n_0}(s)-f_m(s))d\mu(s)\right\|<\varepsilon\quad\forall m>n_0.$$

By means of elementary operations with the sets A_{n_k}, we construct a finite partition (for each $m > n_0$) $\{B_j\}_{j=1}^{l}$ of $[a,b]$, such that each B_j is measurable and $f_k|_{B_j}$ is constant for each k and j ($1 \leq j \leq l$, $1 \leq k \leq m$). Therefore $\{\bigcup_{k,j}^{l,m} f_k(B_j)\} = \{x_1, \ldots, x_r(m)\}$ is a finite subset of X. For each $n \geq n_0$, denote by X_n the subspace generated by $\{x_1, \ldots, x_r(n)\}$ and consider the functions $\mathbf{S}_{(\cdot)}|_{X_n}$. Since each X_n is finite dimensional and $\mathbf{S}_{(\cdot)}$ is strongly continuous, we get that $\mathbf{S}_{(\cdot)}|_{X_n}$ is continuous in the uniform topology of operators on $L(X_n, X)$ and is therefore measurable. Consequently, there is a $k \in \mathbf{N}$ such that $\mathbf{S}^k : [a,b] \to L(X_n, X)$ is a simple function and

$$||\mathbf{S}^k_{(\cdot)} - \mathbf{S}|_{X_m}(\cdot)|| < \varepsilon.$$

By using Hille's theorem [8, p. 43] we have that for each $T \in L(X_m, X)$,

$$\left\|\int_a^t T(f_{n_0}(s) - f_m(s))d\mu(s)\right\| < ||T||\varepsilon$$

for $m > n_0$, and from this we conclude that $\{\int_a^b \mathbf{S}^k(f_n)ds\}_{n=1}^{\infty}$ is relatively compact in $C([a,b], X)$. By this procedure we see that

$$\begin{aligned}\left\|\int_a^t \mathbf{S}_s(f_{n_0}(s) - f_m(s))d\mu(s)\right\| &\leq \left\|\int_a^t \mathbf{S}_s(f_{n_0}(s)) - \mathbf{S}^k(f_{n_0}(s))d\mu(s)\right\| \\ &+ \left\|\int_a^t \mathbf{S}^k(f_m(s)) - \mathbf{S}^k(f_{n_0}(s))d\mu(s)\right\| \\ &+ \left\|\int_a^t \mathbf{S}_s(f_m(s) - \mathbf{S}^k(f_m(s))d\mu(s)\right\| \\ &\leq 2\varepsilon^2 M + \varepsilon||\mathbf{S}^k||,\end{aligned}$$

where $M = \sup_{x \in K}||x||$. This implies that $\{\int_a^t \mathbf{S}_{t-s}f(s)ds : \text{f simple}\}_{f \in \mathbf{S}^1_{\mathbf{G}}}$ is relatively weakly compact in X. Now using the boundedness of $\mathbf{S}_{(\cdot)}$ on $[a,b]$ and the density of simple functions on $L^1_X(\mu)$, we conclude that

$$B = \left\{x : [a,b] \to X : x(t) = \int_a^t f(t)dt\right\}_{f \in \mathbf{S}^1_{\mathbf{G}}}$$

is relatively compact in $C([a,b]; X)$, and since

$$A = \left\{x : [a,b] \to X : x(t) = \int_a^t f(t)dt\right\}_{f \in \mathbf{S}^1_{\mathbf{F}}} \subset B,$$

then A is relatively compact in $C([a,b]; X)$.

To see that A is compact, we note that for each $s \in [a,b]$, $\mathbf{S}_s\mathbf{F}(s)$ is a compact, convex set-valued multifunction, and using Theorem 3.2 as in (i), we conclude the proof. □

The hypothesis "$\mathbf{F}(s)$ contained in a compact set K for each $s \in [a,b]$" cannot be removed, as the following example illustrates.

Example. Let X be an infinite-dimensional Banch space and K a bounded, separable and convex subset of X which is not compact. Define $\mathbf{F}(s) \equiv K, \forall s \in [0,b]$, and

$\mathbf{S}_s \equiv I$, the identity in $X, \forall s \geq 0$. If $\{x_n\}_{n=1}^{\infty}$ is a sequence in K with no convergent subsequences, then for each $t \in [0, b]$, we have

$$\left\{\int_0^t \mathbf{S}_{t-s} x_k ds\right\}_{k\in\mathbf{N}} = \{tx_k\}_{k\in\mathbf{N}},$$

which is relatively compact if and only if $t = 0$. □

We end this section by illustrating how these results can be useful in the qualitative study of the trajectories of differential inclusions in Banach spaces. To do that, we start by outlining the path developed by Frankowska [13] but remove the hypothesis of *separability and reflexibility*. In that reference the following differential inclusion is considered:

$$\mathbf{S} = \begin{cases} \dot{x}(t) \in Ax(t) + \mathbf{F}(t, x), \\ x(t_0) = x_0, \end{cases}$$

where A generates a strongly continuous semigroup $\{\mathbf{S}_t\}_{t\geq 0}$ and $\mathbf{F} : [to, T] \times X \to \mathbf{P}(X)\backslash\{\emptyset\}$ is a multifunction.

In what follows, we need the following definitions.

Let $\mathbf{F} : [to, T] \times X \to \mathbf{P}_f(X)$, $t_0 \in [0, T]$. A function $x \in C([t_0, T]; X)$ is called a *mild trajectory* for the given differential inclusion if there is an $f \in L^1([t_0, T], X)$ such that

$$f(t) \in \mathbf{F}(t, x(t)), \quad \mu \text{ a.e.},$$

and

$$x(t) = \mathbf{S}_{t-t_0} x_0 + \int_{t_0}^t \mathbf{S}_{t-s} f(s) ds.$$

A function $\varphi : X \to \mathbf{P}(X)\backslash\{\emptyset\}$ is called an *L-Lipschitz* in $K \subset X$ if, for $x, y \in X$,

$$\varphi(x) \subset \varphi(y) + L||x - y||B,$$

where B is the closed unit ball of X.

With these hypotheses in hand, the following result is proposed [13, Thm. 2.7].

Let X be a reflexive (separable) Banach space and $\mathbf{F} : [t_o, T] \times X \to X$ be a multivalued function with closed and convex values. Suppose that there is a $\mathbf{k} \in L^1_{(t_0;T)}$ so that for almost every $t \in [t_0, T]$, $\mathbf{F}(t, \cdot)$ is $\mathbf{k}(t)$-Lipschitz, and for each $x \in X$, $\mathbf{F}(t, x) \subset \mathbf{k}(t)B$. If at least one of the following conditions is satisfied,

(i) the semigroup $\mathbf{S}_{(\cdot)}$ is compact;

(ii) the semigroup $\mathbf{S}_{(\cdot)}$ is uniformly continuous;

(iii) there is a compact set $K \subset X$ such that for each $(t, x) \in [t_0, T] \times X$, $\mathbf{F}(t, x) \subset \mathbf{K}$; then for each $x \in X$, the set $\Gamma_{[t_0,T]}(\xi)$ of the mild solutions of the differential inclusion with initial values $x(t_0) = \xi$ is a compact subset of $C([t_0, T]; X)$.

According to Theorem 6.2, it is clear that statements (i) and (iii) are true without any restriction on the Banach space X, while the statement (ii) fails to be true in any infinite-dimensional Banach space, as is shown in the previous example. This is so because in the process of the proof given in [13], the relative compactness of $\{x(t)\}_{x\in S(t_0,T,X)}$ is not checked before applying the Arzéla–Ascoli theorem for infinite-dimensional Banach spaces. In that sense, Theorem 6.2 not only generalizes Theorem 2.7 (i), (ii) of [13] but also gives a correct proof of these results.

However, that paper is still interesting, since it states the problem to be solved and offers other interesting results about the subject.

MONODROMY GROUPS OF SYSTEMS OF TOTAL DIFFERENTIAL EQUATIONS OF TWO VARIABLES*

TOSHIAKI YOKOYAMA†

Abstract. Fuchsian systems of ordinary differential equations that are irreducible and free from accessory parameters are classified into eight classes. Canonical systems of these classes were determined by Haraoka [SIAM J. Math. Anal., 25 (1994), pp. 1203–1226]. Among them the canonical systems of exactly four classes are extended to the completely integrable systems of total differential equations of two variables that are introduced by Yokoyama [Funkcial. Ekvac., 35 (1992), pp. 65–93]. This paper presents monodromy groups of the four systems of total differential equations. The theory for computing monodromy groups of the systems developed by Yokoyama is applied.

Key words. monodromy group, system of total differential equations, accessory parameter

AMS subject classifications. 33E30, 33C65, 34A20

Introduction. In the theory of differential equations in the complex domain the Gauss hypergeometric differential equation

$$x(1-x)\frac{d^2y}{dx^2}+\{\gamma-(\alpha+\beta+1)x\}\frac{dy}{dx}-\alpha\beta y=0 \tag{0.1}$$

is one of the most important and interesting equations, and there are many investigations and generalizations of it. The Okubo theory is one of them. Okubo recognized a system of linear ordinary differential equations of the form

$$(xI_n-T)\frac{dY}{dx}=AY, \tag{0.2}$$

where Y is an unknown n-dimensional column vector, A is an $n\times n$ matrix, T is an $n\times n$ diagonal matrix, and I_n is the identity matrix of rank n, as a generalization of the Gauss equation (0.1), and developed a global theory of the system in [4]. His theory, which seems to be an extension of Riemann's P-function method for computing a monodromy group of the Gauss equation, consists of the following three parts: (i) reduction of a single Fuchsian differential equation to the system, (ii) definition of systems free from accessory parameters, and (iii) an algorithm for computing monodromy groups for such systems. He asserted that if the system (0.2) is free from accessory parameters, then we can determine its monodromy group explicitly up to a diagonal transformation. After Okubo, the present author [10] classified the set of irreducible systems free from accessory parameters. There are eight classes of such systems. Haraoka [2] determined canonical systems of these classes: systems (I), (I*), (II), (II*), (III), (III*), (IV), and (IV*). System (I) is known to be transformed into the generalized hypergeometric equation (see [4], [5]). System (I*) is known to be transformed into the Pochhammer equation (see [1], [8]). Systems (II), (II*), (III), (III*), (IV), and (IV*) are new. In [3] Haraoka also computed monodromy groups of these six systems by following the Okubo theory. Monodromy groups of system (II*)

of rank 4 and system (II) are also computed by Sasai [6] and Sasai and Tsuchiya [7], respectively.

In [9] the present author obtained an extension of the system (0.2) and investigated its monodromy group. If the coefficient matrix A satisfies the relation

$$(A-\rho_1 I_n)(A-\rho_2 I_n)=O, \tag{0.3}$$

where ρ_1 and ρ_2 are complex numbers, then we can extend the system (0.2) to a completely integrable system of total differential equations of two variables of the form

$$dZ=\Big\{(xI_n-T)^{-1}Adx+(A-(\rho_1+\rho_2)I_n)(yI_n-T)^{-1}dy-A\frac{d(x-y)}{x-y}\Big\}Z, \tag{0.4}$$

where Z is an unknown n-dimensional column vector. Among the eight systems we can extend systems (I*), (II*), (III*), and (IV*) to obtain systems of total differential equations, which we call systems (I**), (II**), (III**), and (IV**), respectively. It is shown in [9] that the systems of partial differential equations for the Appell functions F_1 and F_2 are reduced to system (I**) of rank 3 and system (II**) of rank 4, respectively.

The purpose of this paper is to compute monodromy groups of systems (I**), (II**), (III**), and (IV**) by following the theory developed in [9]. In section 1 we review the theory of the system (0.4). In section 2 we investigate system (I**). We give generators of a monodromy group of system (I**) in Theorem 1 in section 2.1 and prove the theorem in section 2.2. We deal with the other systems in section 3. We give generators of monodromy groups of systems (II**), (III**), and (IV**) in Theorems 2, 3, and 4 in sections 3.1, 3.2, and 3.3, respectively, and we prove these theorems in section 3.4. We use the following notation throughout this paper:

$\mathbf{Z}_{<0}$: the set of negative integers.
I_k : the identity matrix of rank k, for $k\in\mathbf{N}$.
O : zero matrix of an appropriate size.
$e(\alpha):=\exp(2\pi\sqrt{-1}\,\alpha)$, for $\alpha\in\mathbf{C}$.

1. Monodromy group of the system (0.4).

We give a short review of the theory developed in [9]. In the system (0.4) we assume that

$$T=\begin{pmatrix} t_1I_{n_1} & & & \\ & t_2I_{n_2} & & \\ & & \ddots & \\ & & & t_pI_{n_p}\end{pmatrix}\quad (t_i\neq t_j\ (i\neq j),\ n_1+n_2+\cdots+n_p=n),$$

$$A=\begin{pmatrix} A_{11} & A_{12} & \cdots & A_{1p}\\ A_{21} & A_{22} & \cdots & A_{2p}\\ \vdots & \vdots & \ddots & \vdots\\ A_{p1} & A_{p2} & \cdots & A_{pp}\end{pmatrix}\sim\begin{pmatrix}\rho_1 I_{m_1} & \\ & \rho_2 I_{m_2}\end{pmatrix}\quad (m_1+m_2=n),$$

where A_{ij} is an $n_i\times n_j$ matrix and

$$A_{ii}=\begin{pmatrix}\lambda_{i,1} & & & \\ & \lambda_{i,2} & & \\ & & \ddots & \\ & & & \lambda_{i,n_i}\end{pmatrix}\quad (i=1,\dots,p),$$

together with the conditions

$$\begin{aligned} &\lambda_{i,h},\ \lambda_{i,h}-\lambda_{i,h'}\notin \mathbf{Z}\quad (i=1,\dots,p,\ \ h,h'=1,\dots,n_i,\ \ h\neq h'),\\ &\rho_1-\rho_2\notin\mathbf{Z},\\ &\rho_j\notin\mathbf{Z}_{<0}\quad (j=1,2). \end{aligned}\tag{1.1}$$

1.1. Fundamental set of solutions. We have shown the following.

PROPOSITION 1. *The system* (0.4) *is completely integrable. Namely, we have* $d\,\Omega=\Omega\wedge\Omega$, *where* Ω *denotes the coefficient* 1*-form of* (0.4)*.*

This proposition follows from the relation (0.3) and guarantees the existence of n linearly independent solutions of the system (0.4).

PROPOSITION 2. *For each* i $(i=1,\dots,p)$, *the system* (0.4) *has* n_i *solutions*

$$Z_{i,h}(x,y)=(x-t_i)^{\lambda_{i,h}}(y-t_i)^{-\rho_1-\rho_2}W_{i,h}(x,y)\quad (h=1,\dots,n_i)$$

such that

$$W_{i,h}(t_i,y)=\textit{the } (n_1+\cdots+n_{i-1}+h)\textit{th unit } n\textit{-vector}\quad (h=1,\dots,n_i)$$

and $W_{i,h}(x,y)$ $(h=1,\dots,n_i)$ *are holomorphic in* $\mathcal{D}_i\times\Delta_i$, *where* $\mathcal{D}_i$ *is an arbitrary simply connected domain in* $\mathbf{C}$ *containing* t_i *and not containing* t_k $(k\neq i)$, *and* $\Delta_i=\mathbf{C}\setminus\overline{\mathcal{D}_i}$.

We set

$$\mathcal{Z}(x,y)=\Big(Z_{1,1}(x,y)\ \cdots\ Z_{1,n_1}(x,y)\ \cdots\ Z_{p,1}(x,y)\ \cdots\ Z_{p,n_p}(x,y)\Big).$$

PROPOSITION 3.

$$\begin{aligned}&\det\mathcal{Z}(x,y)\\ &=\frac{\prod_{i=1}^{p}\prod_{h=1}^{n_i}\Gamma(\lambda_{i,h}+1)}{\prod_{j=1}^{2}\Gamma(\rho_j+1)^{m_j}}\prod_{i=1}^{p}\prod_{h=1}^{n_i}\left\{(x-t_i)^{\lambda_{i,h}}(y-t_i)^{\lambda_{i,h}-\rho_1-\rho_2}(y-x)^{-\lambda_{i,h}}\right\}\end{aligned}$$

holds. Therefore $\mathcal{Z}(x,y)$ *is a fundamental set of solutions of* (0.4)*.*

1.2. Circuit matrices. We set

$$S_p=\bigcup_{i=1}^{p}\big(\{(x,y)\mid x=t_i\}\bigcup\{(x,y)\mid y=t_i\}\big)\bigcup\{(x,y)\mid x=y\}$$

and fix a base point (x_0,y_0) in $\mathbf{C}^2\setminus S_p$. Let $\mathcal{C}_x$ be a simple closed curve on the (x,y_0)-plane ($=\{(x,y_0)\mid x\in\mathbf{C}\}$) such that the points (x_0,y_0), (y_0,y_0), (t_1,y_0), $(t_2,y_0),\dots,(t_p,y_0)$ lie on $\mathcal{C}_x$ and come in this order when we trace $\mathcal{C}_x$ in the positive direction. For each i $(i=0,1,\dots,p)$, let σ_i be a loop on the (x,y_0)-plane that starts from (x_0,y_0), goes inside $\mathcal{C}_x$, encircles (t_i,y_0) once in the positive direction, and returns inside $\mathcal{C}_x$ to (x_0,y_0), where we set $t_0=y_0$. Let $\mathcal{C}_y$ be a copy of $\mathcal{C}_x$ onto the (x_0,y)-plane ($=\{(x_0,y)\mid y\in\mathbf{C}\}$); that is, $\mathcal{C}_y$ is a curve on the (x_0,y)-plane such that the points (x_0,x_0), (x_0,y_0), (x_0,t_1), $(x_0,t_2),\dots,(x_0,t_p)$ lie on $\mathcal{C}_y$ and come in this order when we trace $\mathcal{C}_y$ in the positive direction. Let $\mathcal{L}$ be a simple curve on the (x_0,y)-plane that starts from a point located between (x_0,y_0) and (x_0,t_1) on $\mathcal{C}_y$, goes outside $\mathcal{C}_y$, and ends at (x_0,∞). For each j $(j=1,\dots,p,p+1)$, let τ_j be a loop on the (x_0,y)-plane that starts from (x_0,y_0), goes outside $\mathcal{C}_y$ not crossing $\mathcal{L}$, encircles

(x_0, t_j) once in the positive direction, and returns outside $\mathcal{C}_y$ to (x_0, y_0) not crossing $\mathcal{L}$, where we set $t_{p+1} = x_0$. Then the homotopy classes $[\sigma_i]$ $(i = 0, 1, \dots, p)$ and $[\tau_j]$ $(j = 1, \dots, p, p+1)$ generate the fundamental group $\pi_1(\mathbf{C}^2 \setminus S_p, (x_0, y_0))$.

If we continue analytically the fundamental set of solutions $\mathcal{Z}(x, y)$ along the loop σ_i (resp., τ_j), then we obtain another fundamental set of solutions $\mathcal{Z}(x, y)M_i$ (resp., $\mathcal{Z}(x, y)N_j$), where M_i (resp., N_j) is an element in $GL(n, \mathbf{C})$. We call M_i (resp., N_j) the *circuit matrix* of $\mathcal{Z}(x, y)$ along σ_i (resp., τ_j). The *monodromy group* of the system (0.4) with respect to $\mathcal{Z}(x, y)$ is a subgroup of $GL(n, \mathbf{C})$ generated by M_i $(i = 0, 1, \dots, p)$ and N_j $(j = 1, \dots, p, p+1)$, that is to say, an image of the representation

$$R : \pi_1(\mathbf{C}^2 \setminus S_p, (x_0, y_0)) \longrightarrow GL(n, \mathbf{C})$$

that is defined by

$$\mathcal{Z}(x, y)^\gamma = \mathcal{Z}(x, y) \cdot R([\gamma])$$

for any loop γ in $\mathbf{C}^2 \setminus S_p$ with the base point (x_0, y_0), where $\mathcal{Z}(x, y)^\gamma$ denotes the analytic continuation of $\mathcal{Z}(x, y)$ along the loop γ.

We have shown the following.

Proposition 4.

(i) *For $i = 1, \dots, p$, the circuit matrix M_i has the form*

$$M_i = \begin{pmatrix} I_{n_1} & & & & & & \\ & \ddots & & & & & \\ & & I_{n_{i-1}} & & & & \\ M_{i1} & \cdots & M_{i,i-1} & M_{ii} & M_{i,i+1} & \cdots & M_{ip} \\ & & & & I_{n_{i+1}} & & \\ & & & & & \ddots & \\ & & & & & & I_{n_p} \end{pmatrix},$$

where

$$M_{ii} = \begin{pmatrix} e(\lambda_{i,1}) & & & \\ & e(\lambda_{i,2}) & & \\ & & \ddots & \\ & & & e(\lambda_{i,n_i}) \end{pmatrix}.$$

(ii) *For $j = 1, \dots, p$, the circuit matrix N_j has the form*

$$N_j = \begin{pmatrix} I_{n_1} & & & N_{1j} & & & \\ & \ddots & & \vdots & & & \\ & & I_{n_{j-1}} & N_{j-1,j} & & & \\ & & & N_{jj} & & & \\ & & & N_{j+1,j} & I_{n_{j+1}} & & \\ & & & \vdots & & \ddots & \\ & & & N_{pj} & & & I_{n_p} \end{pmatrix}.$$

(iii) *The Jordan canonical form of the circuit matrix M_0 is*

$$\begin{pmatrix} e(-\rho_1)I_{m_1} & \\ & e(-\rho_2)I_{m_2} \end{pmatrix}.$$

Proposition 5. *The circuit matrices M_i $(i = 0, 1, \dots, p)$ and N_j $(j = 1, \dots, p, p + 1)$ have the following relations*:

$$M_p M_{p-1} \cdots M_1 M_0 = I_n, \tag{1.2}$$

$$N_1 N_2 \cdots N_p N_{p+1} = e(-\rho_1 - \rho_2) \cdot I_n, \tag{1.3}$$

$$N_{p+1} = M_0, \tag{1.4}$$

and

$$M_i N_j = N_j M_i \tag{1.5}$$

for $i, j = 1, \dots, p$ with $i \neq j$.

Remark. From the relations (1.2) and (1.4) it follows that the monodromy group of (0.4) is generated by M_i $(i = 1, \dots, p)$ and N_j $(j = 1, \dots, p)$.

Restricting the system (0.4) to the (x, y_0)-plane, we obtain

$$\frac{dZ}{dx} = \Big((xI_n - T)^{-1} - \frac{1}{x - y_0} I_n\Big) AZ,$$

which is transformed into the system of Okubo normal form

$$(tI_n - T')\frac{dZ}{dt} = AZ, \tag{1.6}$$

where $T' = (T - y_0 I_n)^{-1}$, by the change of the variable x for $t = (x - y_0)^{-1}$. Since the matrices M_i $(i = 1, \dots, p)$ are also circuit matrices for the system (1.6), we can determine M_i $(i = 1, \dots, p)$ explicitly up to a diagonal transformation if (1.6) is free from accessory parameters. Once the M_i's are determined, we can determine the matrices N_j $(j = 1, \dots, p)$ by the relation

$$N_{ij} = [e(-\rho_1 - \rho_2) \cdot M_{j-1} M_{j-2} \cdots M_1 M_p M_{p-1} \cdots M_j]_{ij} \tag{1.7}$$

for $i, j = 1, \dots, p$, where $[\quad]_{ij}$ denotes the (i, j)-block in the $(n_1, n_2, \dots, n_p)$-decomposition of an $n \times n$ matrix. The relation (1.7) is derived from the form of N_j and the relations (1.2)–(1.5) (see Lemma 1 in section 2.2).

2. System (I**).

Let n be an integer equal to or greater than 3, and let t_i $(i = 1, \dots, n)$ be mutually distinct points in $\mathbf{C}$. We are concerned with a representation of the fundamental group of $\mathbf{C}^2 \setminus S_n$, where

$$S_n = \bigcup_{i=1}^{n} \big(\{(x, y) \mid x = t_i\} \bigcup \{(x, y) \mid y = t_i\}\big) \bigcup \{(x, y) \mid x = y\}.$$

2.1. Monodromy group of system (I**).

Let $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_n)$ be an element in $\mathbf{C}^n$, and let ρ_1 be an element in $\mathbf{C}$. We set

$$\rho_2 = \sum_{i=1}^{n} \lambda_i - (n - 1)\rho_1 \quad \text{and} \quad \rho = (\rho_1, \rho_2).$$

System $(\mathrm{I}^{**})_{\lambda,\rho}$ (or simply (I^{**})) of rank n is the system of total differential equations

(2.1)

$$dZ = \Big\{(xI_n - T_{\mathrm{I}^*})^{-1} A_{\mathrm{I}^*} dx + (A_{\mathrm{I}^*} - (\rho_1 + \rho_2) I_n)(yI_n - T_{\mathrm{I}^*})^{-1} dy - A_{\mathrm{I}^*} \frac{d(x - y)}{x - y}\Big\} Z$$

for an unknown n-dimensional column vector Z, where

$$T_{\mathrm{I}^*} = \begin{pmatrix} t_1 & & & \\ & t_2 & & \\ & & \ddots & \\ & & & t_n \end{pmatrix} \quad \text{and} \quad A_{\mathrm{I}^*} = \begin{pmatrix} \lambda_1 & \lambda_1-\rho_1 & \cdots & \lambda_1-\rho_1 \\ \lambda_2-\rho_1 & \lambda_2 & \cdots & \lambda_2-\rho_1 \\ \vdots & \vdots & \ddots & \vdots \\ \lambda_n-\rho_1 & \lambda_n-\rho_1 & \cdots & \lambda_n \end{pmatrix}.$$

Under the condition that $\rho_1 \neq \rho_2$, the Jordan canonical form of A_{I^*} is

$$\begin{pmatrix} \rho_1 I_{n-1} & \\ & \rho_2 \end{pmatrix}$$

(see Haraoka [2, Thm. I*]). Therefore, A_{I^*} satisfies the relation

$$(A_{\mathrm{I}^*} - \rho_1 I_n)(A_{\mathrm{I}^*} - \rho_2 I_n) = O,$$

and hence the system (2.1) is completely integrable.

We assume the conditions

$$\begin{aligned} \lambda_i &\notin \mathbf{Z} \quad (i = 1, \dots, n), \\ \rho_1 - \rho_2 &\notin \mathbf{Z}, \\ \rho_j &\notin \mathbf{Z}_{<0} \quad (j = 1, 2), \end{aligned} \tag{2.2}$$

which are corresponding to (1.1). Then the system (2.1) has a fundamental set of solutions such as we state in section 1.1, which we denote by $\mathcal{Z}_{\mathrm{I}^{**}}(x, y)$.

Theorem 1. *We assume* (2.2) *and*

$$\lambda_i - \rho_1 \notin \mathbf{Z} \quad (i = 1, \dots, n).$$

There is a diagonal matrix $D \in GL(n, \mathbf{C})$ such that the monodromy group of the system (2.1) *with respect to $\mathcal{Z}_{\mathrm{I}^{**}}(x, y)D$ is generated by*

$$M_i = \begin{pmatrix} 1 & & & & & & \\ & \ddots & & & & & \\ & & 1 & & & & \\ \xi_{i1} & \cdots & \xi_{i,i-1} & e(\lambda_i) & \xi_{i,i+1} & \cdots & \xi_{in} \\ & & & & 1 & & \\ & & & & & \ddots & \\ & & & & & & 1 \end{pmatrix} \quad (i = 1, \dots, n)$$

and

$$N_j = \begin{pmatrix} 1 & & & \eta_{1j} & & & \\ & \ddots & & \vdots & & & \\ & & 1 & \eta_{j-1,j} & & & \\ & & & \eta_{jj} & & & \\ & & & \eta_{j+1,j} & 1 & & \\ & & & \vdots & & \ddots & \\ & & & \eta_{nj} & & & 1 \end{pmatrix} \quad (j = 1, \dots, n)$$

with

$$\xi_{ij} = \begin{cases} e(\lambda_j) - e(\rho_1) & \text{for } i,j = 1, \dots, n \text{ with } i < j, \\ e(\lambda_j - \rho_1) - 1 & \text{for } i,j = 1, \dots, n \text{ with } i > j, \end{cases} \tag{2.3}$$

and

(2.4)

$$\begin{aligned} \eta_{jj} &= e(\lambda_j - \rho_1 - \rho_2) && \text{for } j = 1, \dots, n, \\ \eta_{ij} &= e(\lambda_j + \lambda_{j+1} + \cdots + \lambda_{j+r-1} - r\rho_1 - \rho_2) \cdot \xi_{ij} && \text{for } i,j = 1, \dots, n \text{ with } i \neq j, \end{aligned}$$

where we have set

$$r = r(i,j) = \begin{cases} n + i - j & \text{for } i < j, \\ i - j & \text{for } i > j, \end{cases}$$

and

$$\lambda_\ell = \lambda_{\ell - n} \quad \text{for } \ell > n.$$

2.2. Proof of Theorem 1. We have only to prove (2.4), since the elements (2.3) of M_i $(i = 1, \dots, n)$ have already been evaluated by Takano and Bannai [8] and Haraoka [1]. Note that M_i $(i = 1, \dots, n)$ and N_j $(j = 1, \dots, n)$ satisfy

$$N_1 N_2 \cdots N_n = e(-\rho_1 - \rho_2) \cdot M_n M_{n-1} \cdots M_1 \tag{2.5}$$

and

$$N_j M_i = M_i N_j \tag{2.6}$$

for $i, j = 1, \dots, n$ with $i \neq j$.

Lemma 1. *For $i, j = 1, \dots, n$, we have*

$$\eta_{ij} = [e(-\rho_1 - \rho_2) \cdot M_{j-1} M_{j-2} \cdots M_1 M_n M_{n-1} \cdots M_j]_{ij},$$

where $[\quad]_{ij}$ denotes the (i,j)-element.

Proof. Combining (2.5) and (2.6) we obtain

$$N_j N_{j+1} \cdots N_n N_1 N_2 \cdots N_{j-1} = e(-\rho_1 - \rho_2) \cdot M_{j-1} M_{j-2} \cdots M_1 M_n M_{n-1} \cdots M_j.$$

By virtue of the form of the N_j's we obtain

$$[N_j N_{j+1} \cdots N_n N_1 N_2 \cdots N_{j-1}]_{ij} = \eta_{ij}.$$

Hence, we have the relation. This completes the proof. □

Proof of Theorem 1.

Step 1. We first prove (2.4) for $j = 1$ by induction on n. In the case $n = 3$ we can obtain

$$M_3M_2M_1 = \begin{pmatrix} e(\lambda_1) & * & * \\ e(\lambda_1)(e(\lambda_1-\rho_1)-1) & * & * \\ e(\lambda_1+\lambda_2-\rho_1)(e(\lambda_1-\rho_1)-1) & * & * \end{pmatrix}$$

by direct calculation. Applying Lemma 1 with $j=1$, we have

$$\begin{aligned} \eta_{11} &= e(\lambda_1-\rho_1-\rho_2), \\ \eta_{i1} &= e(\lambda_1+\lambda_{i-1}-(i-1)\rho_1-\rho_2)\cdot\xi_{i1} \quad (i=2,3), \end{aligned}$$

which shows that (2.4) is valid for $j=1$ in the case $n=3$.

We assume for induction that (2.4) is valid for $j=1$ in the case of rank $n-1$. Then, we shall prove (2.4) for $j=1$ in the case of rank n. We use the notation λ'_i, ρ'_j, M'_i, and η'_{ij} for the case of rank $n-1$ instead of λ_i, ρ_j, M_i, and η_{ij} for the case of rank n, respectively. We set

$$L = \bigl(\zeta_{ij}\bigr)_{\substack{1\le i\le n\\1\le j\le n}} = M_nM_{n-1}\cdots M_1 \quad\text{and}\quad L' = \bigl(\zeta'_{ij}\bigr)_{\substack{1\le i\le n-1\\1\le j\le n-1}} = M'_{n-1}M'_{n-2}\cdots M'_1.$$

Provided that $\lambda'_i=\lambda_i$ for $i=1,\dots,n-1$ and $\rho'_1=\rho_1$, we have

$$M_i = \left(\begin{array}{ccc|c} & M'_i & & * \\ \hline 0 & \cdots & 0 & 1 \end{array}\right)$$

for $i=1,\dots,n-1$, and hence

$$L = M_n\left(\begin{array}{ccc|c} & L' & & * \\ \hline 0 & \cdots & 0 & 1 \end{array}\right) = \left(\begin{array}{ccc|c} & & & 0 \\ & I_{n-1} & & \vdots \\ & & & 0 \\ \hline \xi_{n1} & \cdots & \xi_{n,n-1} & e(\lambda_n) \end{array}\right)\left(\begin{array}{ccc|c} & L' & & * \\ \hline 0 & \cdots & 0 & 1 \end{array}\right)$$

From this expression it follows that

$$\zeta_{i1} = \zeta'_{i1} \quad (i=1,\dots,n-1) \quad\text{and}\quad \zeta_{n1} = \sum_{k=1}^{n-1}\xi_{nk}\cdot\zeta'_{k1}.$$

Using these relations and the assumption for induction with Lemma 1, we therefore obtain

$$
\begin{aligned}
\eta_{11} &= e(-\rho_1-\rho_2)\cdot\zeta_{11} = e(-\rho_1-\rho_2)\cdot\zeta'_{11} = e(-\rho_1-\rho_2)\cdot e(\rho_1+\rho'_2)\cdot\eta'_{11}\\
&= e(\rho'_2-\rho_2)\cdot e(\lambda_1-\rho_1-\rho'_2)\\
&= e(\lambda_1-\rho_1-\rho_2),\\
\eta_{i1} &= e(-\rho_1-\rho_2)\cdot\zeta_{i1} = e(-\rho_1-\rho_2)\cdot\zeta'_{i1} = e(-\rho_1-\rho_2)\cdot e(\rho_1+\rho'_2)\cdot\eta'_{i1}\\
&= e(\rho'_2-\rho_2)\cdot e(\lambda_1+\lambda_2+\cdots+\lambda_{i-1}-(i-1)\rho_1-\rho'_2)\cdot\xi_{i1}\\
&= e(\lambda_1+\lambda_2+\cdots+\lambda_{i-1}-(i-1)\rho_1-\rho_2)\cdot\xi_{i1}\quad(i=2,\dots,n-1),\\
\eta_{n1} &= e(-\rho_1-\rho_2)\cdot\zeta_{n1} = e(-\rho_1-\rho_2)\cdot\sum_{k=1}^{n-1}\xi_{nk}\cdot e(\rho_1+\rho'_2)\cdot\eta'_{k1}\\
&= e(\rho'_2-\rho_2)\cdot\Big\{(e(\lambda_1-\rho_1)-1)\cdot e(\lambda_1-\rho_1-\rho'_2)\\
&\quad+\sum_{k=2}^{n-1}(e(\lambda_k-\rho_1)-1)\cdot e(\lambda_1+\cdots+\lambda_{k-1}-(k-1)\rho_1-\rho'_2)\cdot(e(\lambda_1-\rho_1)-1)\Big\}\\
&= e(\rho'_2-\rho_2)\cdot(e(\lambda_1-\rho_1)-1)\cdot\Big\{e(\lambda_1-\rho_1-\rho'_2)\\
&\quad+\sum_{k=2}^{n-1}\Big(e(\lambda_1+\cdots+\lambda_k-k\rho_1-\rho'_2)-e(\lambda_1+\cdots+\lambda_{k-1}-(k-1)\rho_1-\rho'_2)\Big)\Big\}\\
&= e(\rho'_2-\rho_2)\cdot(e(\lambda_1-\rho_1)-1)\cdot e(\lambda_1+\lambda_2+\cdots+\lambda_{n-1}-(n-1)\rho_1-\rho'_2)\\
&= e(\lambda_1+\lambda_2+\cdots+\lambda_{n-1}-(n-1)\rho_1-\rho_2)\cdot\xi_{n1},
\end{aligned}
$$

which shows that (2.4) is valid for $j=1$ in the case of rank n.

Step 2. We next prove (2.4) for $j=2$. We set

$$
R=\begin{pmatrix}
0 & & & e(\rho_1)\\
1 & \ddots & & \\
 & \ddots & \ddots & \\
 & & 1 & 0
\end{pmatrix}.
$$

Moreover, we set

$$
\tilde{M}_i = R^{-1}M_{i+1}R = \begin{pmatrix}
1 & & & & & \\
 & \ddots & & & & \\
\xi_{i+1,2} & \cdots & e(\lambda_{i+1}) & \cdots & \xi_{i+1,n} & e(\rho_1)\xi_{i+1,1}\\
 & & & \ddots & & \\
 & & & & \ddots & \\
 & & & & & 1
\end{pmatrix}
$$

for $i=1,2,\dots,n-1$, and

$$
\tilde{M}_n = R^{-1}M_1R = \begin{pmatrix}
1 & & & \\
 & \ddots & & \\
 & & 1 & \\
e(-\rho_1)\xi_{12} & \cdots & e(-\rho_1)\xi_{1,n-1} & e(\lambda_1)
\end{pmatrix}.
$$

Here we see that for each i ($i = 1, \dots, n$), $\tilde{M}_i$ agrees with M_i with a parameter set $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_n)$ replaced by $\tilde{\lambda} = (\lambda_2, \lambda_3, \dots, \lambda_n, \lambda_1)$. Hence, for each i ($i = 1, \dots, n$), the $(i, 1)$-element of the matrix $e(-\rho_1 - \rho_2) \cdot \tilde{M}_n \tilde{M}_{n-1} \cdots \tilde{M}_1$ is equal to η_{i1} with $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_n)$ replaced by $\tilde{\lambda} = (\lambda_2, \lambda_3, \dots, \lambda_n, \lambda_1)$, that is,

$$\begin{aligned}
&\big[e(-\rho_1 - \rho_2) \cdot \tilde{M}_n \tilde{M}_{n-1} \cdots \tilde{M}_1\big]_{i1} \\
&\quad = \begin{cases} e(\lambda_2 - \rho_1 - \rho_2) & (i = 1), \\ e(\lambda_2 + \lambda_3 + \cdots + \lambda_i - (i-1)\rho_1 - \rho_2) \cdot (e(\lambda_2 - \rho_1) - 1) & (i = 2, \dots, n). \end{cases}
\end{aligned}$$

On the other hand, by Lemma 1 with $j = 2$, we have

$$\begin{aligned}
\eta_{i2} &= \big[e(-\rho_1 - \rho_2) \cdot M_1 M_n M_{n-1} \cdots M_2\big]_{i2} \\
&= \big[e(-\rho_1 - \rho_2) \cdot R \tilde{M}_n \tilde{M}_{n-1} \cdots \tilde{M}_1 R^{-1}\big]_{i2} \\
&= \begin{cases} e(\rho_1) \cdot \big[e(-\rho_1 - \rho_2) \cdot \tilde{M}_n \tilde{M}_{n-1} \cdots \tilde{M}_1\big]_{n1} & (i = 1), \\ \big[e(-\rho_1 - \rho_2) \cdot \tilde{M}_n \tilde{M}_{n-1} \cdots \tilde{M}_1\big]_{i-1,1} & (i = 2, \dots, n). \end{cases}
\end{aligned}$$

Therefore, we obtain

$$\begin{aligned}
\eta_{12} &= e(\rho_1) \cdot e(\lambda_2 + \cdots + \lambda_n - (n-1)\rho_1 - \rho_2) \cdot (e(\lambda_2 - \rho_1) - 1) \\
&= e(\lambda_2 + \cdots + \lambda_n - (n-1)\rho_1 - \rho_2) \cdot \xi_{12}, \\
\eta_{22} &= e(\lambda_2 - \rho_1 - \rho_2), \\
\eta_{i2} &= e(\lambda_2 + \cdots + \lambda_{i-1} - (i-2)\rho_1 - \rho_2) \cdot (e(\lambda_2 - \rho_1) - 1) \\
&= e(\lambda_2 + \cdots + \lambda_{i-1} - (i-2)\rho_1 - \rho_2) \cdot \xi_{i2} \quad (i = 3, \dots, n),
\end{aligned}$$

which shows that (2.4) is valid for $j = 2$.

Step 3. For $j = 3, 4, \dots, n$, we can prove (2.4) by the same consideration as developed in Step 2 with the matrices $R^{-(j-1)} M_i R^{j-1}$ ($i = 1, \dots, n$). Thus the proof of Theorem 1 is complete. □

3. System (II**), system (III**), and system (IV**).

Let t_1, t_2, and t_3 be mutually distinct points in $\mathbf{C}$. We are concerned with representations of the fundamental group of $\mathbf{C}^2 \setminus S_3$, where

$$S_3 = \bigcup_{i=1}^{3} \big(\{(x, y) \mid x = t_i\} \bigcup \{(x, y) \mid y = t_i\}\big) \bigcup \{(x, y) \mid x = y\}.$$

3.1. Monodromy group of system (II**).

Let n be an even integer equal to or greater than 4. We set $n = 2m$ with $m \in \{2, 3, 4, \dots\}$. Let $\lambda = (\lambda_1, \dots, \lambda_m)$, $\mu = (\mu_1, \dots, \mu_{m-1})$, ν, and $\rho = (\rho_1, \rho_2)$ be elements in $\mathbf{C}^m$, $\mathbf{C}^{m-1}$, $\mathbf{C}$, and $\mathbf{C}^2$, respectively, satisfying

$$\lambda_i \neq \lambda_j, \quad \mu_i \neq \mu_j, \quad \rho_i \neq \rho_j$$

for $i \neq j$, and

$$\sum_{i=1}^{m} \lambda_i + \sum_{i=1}^{m-1} \mu_i + \nu = m\rho_1 + m\rho_2.$$

System $(\mathrm{II}^{**})_{\lambda,\mu,\nu,\rho}$ (or simply (II^{**})) of rank n is the system of total differential equations

(3.1)

$$dZ = \Big\{(xI_n - T_{\mathrm{II}^*})^{-1}A_{\mathrm{II}^*}dx + (A_{\mathrm{II}^*} - (\rho_1+\rho_2)I_n)(yI_n - T_{\mathrm{II}^*})^{-1}dy - A_{\mathrm{II}^*}\frac{d(x-y)}{x-y}\Big\}Z$$

with

$$T_{\mathrm{II}^*} = \begin{pmatrix} t_1 I_m & & \\ & t_2 I_{m-1} & \\ & & t_3 \end{pmatrix},$$

$$A_{\mathrm{II}^*} = \left(\begin{array}{ccc|cccc}
\lambda_1 & & & & & & \\
& \ddots & & & & (\alpha_{ij}) & \\
& & \lambda_m & & & & \\ \hline
& & & \mu_1 & & & \gamma_1 \\
& (\beta_{ij}) & & & \ddots & & \vdots \\
& & & & & \mu_{m-1} & \gamma_{m-1} \\
& & & \delta_1 & \cdots & \delta_{m-1} & \nu
\end{array}\right),$$

where

$$\alpha_{ij} = (\lambda_i - \rho_1)(\lambda_i - \rho_2)\cdot \prod_{k\in\{1,\dots,m\}\setminus\{i\}} \frac{\lambda_k + \mu_j - \rho_1 - \rho_2}{\lambda_i - \lambda_k}$$
$$(i = 1,\dots,m,\ \ j = 1,\dots,m-1),$$
$$\alpha_{im} = (\lambda_i - \rho_1)(\lambda_i - \rho_2)\cdot \prod_{k\in\{1,\dots,m\}\setminus\{i\}} \frac{1}{\lambda_i - \lambda_k} \quad (i = 1,\dots,m),$$
$$\beta_{ij} = \prod_{\ell\in\{1,\dots,m-1\}\setminus\{i\}} \frac{\lambda_j + \mu_\ell - \rho_1 - \rho_2}{\mu_i - \mu_\ell} \quad (i = 1,\dots,m-1,\ \ j = 1,\dots,m),$$
$$\beta_{mj} = -\prod_{\ell\in\{1,\dots,m-1\}} (\lambda_j + \mu_\ell - \rho_1 - \rho_2) \quad (j = 1,\dots,m),$$
$$\gamma_i = \prod_{\ell\in\{1,\dots,m-1\}\setminus\{i\}} \frac{1}{\mu_i - \mu_\ell} \quad (i = 1,\dots,m-1),$$
$$\delta_j = -\prod_{k\in\{1,\dots,m\}} (\lambda_k + \mu_j - \rho_1 - \rho_2) \quad (j = 1,\dots,m-1).$$

The Jordan canonical form of A_{II^*} is

$$\begin{pmatrix} \rho_1 I_m & \\ & \rho_2 I_m \end{pmatrix}$$

(see Haraoka [2, Thm. II*]). Therefore A_{II^*} satisfies the relation

$$(A_{\mathrm{II}^*} - \rho_1 I_n)(A_{\mathrm{II}^*} - \rho_2 I_n) = O,$$

and hence the system (3.1) is completely integrable.

We assume the conditions

$$
\begin{aligned}
\lambda_i,\ \lambda_i-\lambda_j &\notin \mathbf{Z} \quad (i,j=1,\dots,m,\ \ i\neq j),\\
\mu_i,\ \mu_i-\mu_j &\notin \mathbf{Z} \quad (i,j=1,\dots,m-1,\ \ i\neq j),\\
\nu &\notin \mathbf{Z},\\
\rho_1-\rho_2 &\notin \mathbf{Z},\\
\rho_j &\notin \mathbf{Z}_{<0} \quad (j=1,2),
\end{aligned}
\tag{3.2}
$$

which are corresponding to (1.1). Then the system (3.1) has a fundamental set of solutions such as we state in section 1.1, which we denote by $\mathcal{Z}_{\mathrm{II}^{**}}(x,y)$.

Theorem 2. *We assume* (3.2) *and*

$$
\begin{aligned}
\lambda_i-\rho_k &\notin \mathbf{Z} \quad (i=1,\dots,m,\ \ k=1,2),\\
\lambda_i+\mu_j-\rho_1-\rho_2 &\notin \mathbf{Z} \quad (i=1,\dots,m,\ \ j=1,\dots,m-1).
\end{aligned}
$$

There is a diagonal matrix $D\in GL(n,\mathbf{C})$ such that the monodromy group of the system (3.1) *with respect to $\mathcal{Z}_{\mathrm{II}^{**}}(x,y)D$ is generated by*

$$
\begin{aligned}
M_1 &= \begin{pmatrix} E_m(\lambda) & (\xi_{ij})_{\substack{1\le i\le m\\ 1\le j\le m}} \\ O & I_m \end{pmatrix},\\
M_2 &= \begin{pmatrix} I_m & O & O \\ (\eta_{ij})_{\substack{1\le i\le m-1\\ 1\le j\le m}} & E_{m-1}(\mu) & (\eta_{in})_{1\le i\le m-1} \\ O & O & 1 \end{pmatrix},\\
M_3 &= \begin{pmatrix} I_{n-1} & O \\ (\zeta_j)_{1\le j\le n-1} & e(\nu) \end{pmatrix},\\
N_1 &= \begin{pmatrix} E_m(\lambda-\rho_1-\rho_2) & O \\ (\theta_{ij})_{\substack{1\le i\le m\\ 1\le j\le m}} & I_m \end{pmatrix},\\
N_2 &= \begin{pmatrix} I_m & (\phi_{ij})_{\substack{1\le i\le m\\ 1\le j\le m-1}} & O \\ O & E_{m-1}(\mu-\rho_1-\rho_2) & O \\ O & (\phi_{nj})_{1\le j\le m-1} & 1 \end{pmatrix},\\
N_3 &= \begin{pmatrix} I_{n-1} & (\psi_i)_{1\le i\le n-1} \\ O & e(\nu-\rho_1-\rho_2) \end{pmatrix},
\end{aligned}
$$

where

$$
E_m(\lambda)=\begin{pmatrix} e(\lambda_1) & & \\ & \ddots & \\ & & e(\lambda_m) \end{pmatrix}, \qquad E_m(\lambda-\rho_1-\rho_2)=e(-\rho_1-\rho_2)E_m(\lambda),
$$

$$
E_{m-1}(\mu)=\begin{pmatrix} e(\mu_1) & & \\ & \ddots & \\ & & e(\mu_{m-1}) \end{pmatrix}, \qquad E_{m-1}(\mu-\rho_1-\rho_2)=e(-\rho_1-\rho_2)E_{m-1}(\mu),
$$

$$\xi_{ij} = (e(\lambda_i) - e(\rho_1))(e(\rho_2 - \lambda_i) - 1) \cdot \prod_{k \in \{1,\dots,m\} \setminus \{i\}} \frac{e(\mu_j) - e(\rho_1 + \rho_2 - \lambda_k)}{e(\rho_1 + \rho_2 - \lambda_i) - e(\rho_1 + \rho_2 - \lambda_k)}$$
$$(i = 1, \dots, m, \;\; j = 1, \dots, m-1),$$

$$\xi_{im} = (e(\lambda_i) - e(\rho_1))(e(\rho_2 - \lambda_i) - 1) \cdot \prod_{k \in \{1,\dots,m\} \setminus \{i\}} \frac{1}{e(\rho_1 + \rho_2 - \lambda_i) - e(\rho_1 + \rho_2 - \lambda_k)}$$
$$(i = 1, \dots, m),$$

$$\eta_{ij} = \prod_{\ell \in \{1,\dots,m-1\} \setminus \{i\}} \frac{e(\rho_1 + \rho_2 - \lambda_j) - e(\mu_\ell)}{e(\mu_i) - e(\mu_\ell)} \qquad (i = 1, \dots, m-1, \;\; j = 1, \dots, m),$$

$$\eta_{in} = \prod_{\ell \in \{1,\dots,m-1\} \setminus \{i\}} \frac{1}{e(\mu_i) - e(\mu_\ell)} \qquad (i = 1, \dots, m-1),$$

$$\zeta_j = e(\lambda_j + \nu - \rho_1 - \rho_2) \cdot \prod_{\ell \in \{1,\dots,m-1\}} (e(\rho_1 + \rho_2 - \lambda_j) - e(\mu_\ell)) \qquad (j = 1, \dots, m),$$

$$\zeta_{m+j} = -\frac{1}{e(\mu_j)} \cdot \prod_{k \in \{1,\dots,m\}} (e(\mu_j) - e(\rho_1 + \rho_2 - \lambda_k)) \qquad (j = 1, \dots, m-1),$$

and

$$\begin{aligned}
\theta_{ij} &= e(\lambda_j - \rho_1 - \rho_2) \cdot \eta_{ij} \qquad (i = 1, \dots, m-1, \;\; j = 1, \dots, m), \\
\theta_{mj} &= e(-\nu) \cdot \zeta_j \qquad (j = 1, \dots, m), \\
\phi_{ij} &= e(-\lambda_i) \cdot \xi_{ij} \qquad (i = 1, \dots, m, \;\; j = 1, \dots, m-1), \\
\phi_{nj} &= e(\mu_j - \rho_1 - \rho_2) \cdot \zeta_{m+j} \qquad (j = 1, \dots, m-1), \\
\psi_i &= e(\nu - \rho_1 - \rho_2) \cdot \xi_{im} \qquad (i = 1, \dots, m), \\
\psi_{m+i} &= e(-\mu_i) \cdot \eta_{in} \qquad (i = 1, \dots, m-1).
\end{aligned}$$

3.2. Monodromy group of system (III).** Let n be an odd integer equal to or greater than 5. We set $n = 2m+1$ with $m \in \{2, 3, 4, \dots\}$. Let $\lambda = (\lambda_1, \dots, \lambda_m)$, $\mu = (\mu_1, \dots, \mu_m)$, ν, and $\rho = (\rho_1, \rho_2)$ be elements in $\mathbf{C}^m$, $\mathbf{C}^m$, $\mathbf{C}$, and $\mathbf{C}^2$, respectively, satisfying

$$\lambda_i \neq \lambda_j, \quad \mu_i \neq \mu_j, \quad \rho_i \neq \rho_j$$

for $i \neq j$, and

$$\sum_{i=1}^{m} \lambda_i + \sum_{i=1}^{m} \mu_i + \nu = (m+1)\rho_1 + m\rho_2.$$

System $(\mathrm{III}^{**})_{\lambda,\mu,\nu,\rho}$ (or simply (III**)) of rank n is the system of total differential equations

(3.3)

$$dZ = \Big\{ (xI_n - T_{\mathrm{III}^*})^{-1} A_{\mathrm{III}^*} dx + (A_{\mathrm{III}^*} - (\rho_1 + \rho_2) I_n)(yI_n - T_{\mathrm{III}^*})^{-1} dy - A_{\mathrm{III}^*} \frac{d(x-y)}{x-y} \Big\} Z$$

with

$$T_{\mathrm{III}^*} = \begin{pmatrix} t_1 I_m & & \\ & t_2 & \\ & & t_3 I_m \end{pmatrix},$$

$$A_{\mathrm{III}^*} = \begin{pmatrix} \lambda_1 & & & \gamma_1 & & & \\ & \ddots & & \vdots & & (\alpha_{ij}) & \\ & & \lambda_m & \gamma_m & & & \\ \epsilon_1 & \cdots & \epsilon_m & \nu & \kappa_1 & \cdots & \kappa_m \\ & & & \delta_1 & \mu_1 & & \\ & (\beta_{ij}) & & \vdots & & \ddots & \\ & & & \delta_m & & & \mu_m \end{pmatrix},$$

where

$$\begin{aligned} \alpha_{ij} &= (\lambda_i - \rho_1) \cdot \prod_{k \in \{1,\dots,m\} \setminus \{i\}} \frac{\lambda_k + \mu_j - \rho_1 - \rho_2}{\lambda_k - \lambda_i} \quad (i,j = 1,\dots,m), \\ \beta_{ij} &= (\mu_i - \rho_1) \cdot \prod_{\ell \in \{1,\dots,m\} \setminus \{i\}} \frac{\rho_1 + \rho_2 - \lambda_j - \mu_\ell}{\mu_i - \mu_\ell} \quad (i,j = 1,\dots,m), \\ \gamma_i &= (\lambda_i - \rho_1) \cdot \prod_{k \in \{1,\dots,m\} \setminus \{i\}} \frac{1}{\lambda_k - \lambda_i} \quad (i = 1,\dots,m), \\ \delta_i &= (\mu_i - \rho_1) \cdot \prod_{\ell \in \{1,\dots,m\} \setminus \{i\}} \frac{1}{\mu_i - \mu_\ell} \quad (i = 1,\dots,m), \\ \epsilon_j &= \prod_{\ell \in \{1,\dots,m\}} (\rho_1 + \rho_2 - \lambda_j - \mu_\ell) \quad (j = 1,\dots,m), \\ \kappa_j &= -\prod_{k \in \{1,\dots,m\}} (\lambda_k + \mu_j - \rho_1 - \rho_2) \quad (j = 1,\dots,m). \end{aligned}$$

The Jordan canonical form of A_{III^*} is

$$\begin{pmatrix} \rho_1 I_{m+1} & \\ & \rho_2 I_m \end{pmatrix}$$

(see Haraoka [2, Thm. III*]). Therefore A_{III^*} satisfies the relation

$$(A_{\mathrm{III}^*} - \rho_1 I_n)(A_{\mathrm{III}^*} - \rho_2 I_n) = O,$$

and hence the system (3.3) is completely integrable.

We assume the conditions

$$\begin{aligned} \lambda_i,\ \lambda_i - \lambda_j &\notin \mathbf{Z} \quad (i,j = 1,\dots,m,\ i \neq j), \\ \mu_i,\ \mu_i - \mu_j &\notin \mathbf{Z} \quad (i,j = 1,\dots,m,\ i \neq j), \\ \nu &\notin \mathbf{Z}, \\ \rho_1 - \rho_2 &\notin \mathbf{Z}, \\ \rho_j &\notin \mathbf{Z}_{<0} \quad (j = 1,2), \end{aligned} \tag{3.4}$$

which are corresponding to (1.1). Then the system (3.3) has a fundamental set of solutions such as we state in section 1.1, which we denote by $\mathcal{Z}_{\mathrm{III}^{**}}(x,y)$.

Theorem 3. *We assume* (3.4) *and*

$$\begin{aligned} \lambda_i - \rho_1 &\notin \mathbf{Z} \quad (i = 1,\dots,m), \\ \mu_i - \rho_1 &\notin \mathbf{Z} \quad (i = 1,\dots,m), \\ \lambda_i + \mu_j - \rho_1 - \rho_2 &\notin \mathbf{Z} \quad (i,j = 1,\dots,m). \end{aligned}$$

There is a diagonal matrix $D \in GL(n, \mathbf{C})$ such that the monodromy group of the system (3.3) *with respect to $\mathcal{Z}_{\mathrm{III}^{**}}(x, y)D$ is generated by*

$$M_1 = \begin{pmatrix} E_m(\lambda) & (\xi_{ij})_{\substack{1\le i\le m\\ 0\le j\le m}} \\ O & I_{m+1} \end{pmatrix},$$

$$M_2 = \begin{pmatrix} I_m & O & O \\ (\zeta_j)_{1\le j\le m} & e(\nu) & (\zeta_{m+j})_{1\le j\le m} \\ O & O & I_m \end{pmatrix},$$

$$\xi_{ij} = (e(\lambda_i)-e(\rho_1)) \cdot \prod_{k\in\{1,\dots,m\}\setminus\{i\}} \frac{e(\mu_j-\rho_1)-e(\rho_2-\lambda_k)}{e(\rho_2-\lambda_i)-e(\rho_2-\lambda_k)} \quad (i,j=1,\dots,m),$$

$$\zeta_j = -\prod_{\ell\in\{1,\dots,m\}} (e(\rho_2-\lambda_j)-e(\mu_\ell-\rho_1)) \quad (j=1,\dots,m),$$

$$\zeta_{m+j} = e(\rho_1) \cdot \prod_{k\in\{1,\dots,m\}} (e(\mu_j-\rho_1)-e(\rho_2-\lambda_k)) \quad (j=1,\dots,m),$$

$$\eta_{ij} = (e(\mu_i-\rho_1)-1) \cdot \prod_{\ell\in\{1,\dots,m\}\setminus\{i\}} \frac{e(\rho_2-\lambda_j)-e(\mu_\ell-\rho_1)}{e(\mu_i-\rho_1)-e(\mu_\ell-\rho_1)} \quad (i,j=1,\dots,m),$$

$$\eta_{i,m+1} = (e(\rho_1-\mu_i)-1) \cdot \prod_{\ell\in\{1,\dots,m\}\setminus\{i\}} \frac{1}{e(\mu_i-\rho_1)-e(\mu_\ell-\rho_1)} \quad (i=1,\dots,m),$$

and

$$\begin{aligned}
\theta_{0j} &= e(\lambda_j - \rho_1 - \rho_2) \cdot \zeta_j \quad (j = 1, \ldots, m),\\
\theta_{ij} &= e(-\mu_i) \cdot \eta_{ij} \quad (i, j = 1, \ldots, m),\\
\psi_i &= e(-\lambda_i) \cdot \xi_{i0} \quad (i = 1, \ldots, m),\\
\psi_{m+i} &= e(\nu - \rho_1 - \rho_2) \cdot \eta_{i,m+1} \quad (i = 1, \ldots, m),\\
\phi_{ij} &= e(\mu_j - \rho_1 - \rho_2) \cdot \xi_{ij} \quad (i, j = 1, \ldots, m),\\
\phi_{m+1,j} &= e(-\nu) \cdot \zeta_{m+j} \quad (j = 1, \ldots, m).
\end{aligned}$$

3.3. Monodromy group of system (IV).** Let $\lambda = (\lambda_1, \lambda_2)$, $\mu = (\mu_1, \mu_2)$, $\nu = (\nu_1, \nu_2)$, and $\rho = (\rho_1, \rho_2)$ be elements in $\mathbf{C}^2$ satisfying

$$\lambda_1 \neq \lambda_2, \quad \mu_1 \neq \mu_2, \quad \nu_1 \neq \nu_2, \quad \rho_1 \neq \rho_2,$$

and

$$\lambda_1 + \lambda_2 + \mu_1 + \mu_2 + \nu_1 + \nu_2 = 4\rho_1 + 2\rho_2.$$

System $(\mathrm{IV}^{**})_{\lambda,\mu,\nu,\rho}$ (or simply (IV^{**})) is the system of total differential equations of rank 6

(3.5)

$$dZ = \Big\{(xI_6 - T_{\mathrm{IV}^*})^{-1} A_{\mathrm{IV}^*} dx + (A_{\mathrm{IV}^*} - (\rho_1 + \rho_2)I_6)(yI_6 - T_{\mathrm{IV}^*})^{-1} dy - A_{\mathrm{IV}^*} \frac{d(x-y)}{x-y}\Big\} Z$$

with

$$T_{\mathrm{IV}^*} = \begin{pmatrix} t_1 I_2 & & \\ & t_2 I_2 & \\ & & t_3 I_2 \end{pmatrix},$$

$$A_{\mathrm{IV}^*} = \begin{pmatrix}
\lambda_1 & & \alpha_{13} & \alpha_{14} & \alpha_{15} & \alpha_{16}\\
& \lambda_2 & \alpha_{23} & \alpha_{24} & \alpha_{25} & \alpha_{26}\\
\beta_{11} & \beta_{12} & \mu_1 & & \beta_{15} & \beta_{16}\\
\beta_{21} & \beta_{22} & & \mu_2 & \beta_{25} & \beta_{26}\\
\gamma_{11} & \gamma_{12} & \gamma_{13} & \gamma_{14} & \nu_1 & \\
\gamma_{21} & \gamma_{22} & \gamma_{23} & \gamma_{24} & & \nu_2
\end{pmatrix},$$

where

$$\begin{aligned}
\alpha_{ij} &= \frac{\lambda_i - \rho_1}{\lambda_i - \lambda_{i'}} \cdot a_{ij} \qquad \text{for } i = 1, 2 \text{ with } \{i, i'\} = \{1, 2\}, \quad j = 3, 4, 5, 6,\\
\beta_{ij} &= \frac{\mu_i - \rho_1}{\mu_i - \mu_{i'}} \cdot b_{ij} \qquad \text{for } i = 1, 2 \text{ with } \{i, i'\} = \{1, 2\}, \quad j = 1, 2, 5, 6,\\
\gamma_{ij} &= \frac{\nu_i - \rho_1}{\nu_i - \nu_{i'}} \cdot c_{ij} \qquad \text{for } i = 1, 2 \text{ with } \{i, i'\} = \{1, 2\}, \quad j = 1, 2, 3, 4,
\end{aligned}$$

$$
\begin{aligned}
a_{13} &= \lambda_1 + \mu_2 + \nu_1 - 2\rho_1 - \rho_2, & a_{14} &= \lambda_1 + \mu_1 + \nu_2 - 2\rho_1 - \rho_2,\\
a_{15} &= \lambda_2 + \mu_2 + \nu_1 - 2\rho_1 - \rho_2, & a_{16} &= \lambda_2 + \mu_1 + \nu_2 - 2\rho_1 - \rho_2,\\
a_{23} &= \lambda_2 + \mu_2 + \nu_2 - 2\rho_1 - \rho_2, & a_{24} &= \lambda_2 + \mu_1 + \nu_1 - 2\rho_1 - \rho_2,\\
a_{25} &= \lambda_2 + \mu_2 + \nu_2 - 2\rho_1 - \rho_2, & a_{26} &= \lambda_2 + \mu_1 + \nu_1 - 2\rho_1 - \rho_2,\\
b_{11} &= \lambda_2 + \mu_1 + \nu_1 - 2\rho_1 - \rho_2, & b_{12} &= \lambda_1 + \mu_1 + \nu_2 - 2\rho_1 - \rho_2,\\
b_{15} &= \lambda_1 + \mu_1 + \nu_2 - 2\rho_1 - \rho_2, & b_{16} &= \lambda_1 + \mu_2 + \nu_2 - 2\rho_1 - \rho_2,\\
b_{21} &= \lambda_2 + \mu_2 + \nu_2 - 2\rho_1 - \rho_2, & b_{22} &= \lambda_1 + \mu_2 + \nu_1 - 2\rho_1 - \rho_2,\\
b_{25} &= \lambda_1 + \mu_1 + \nu_1 - 2\rho_1 - \rho_2, & b_{26} &= \lambda_1 + \mu_2 + \nu_1 - 2\rho_1 - \rho_2,\\
c_{11} &= \lambda_1 + \mu_2 + \nu_2 - 2\rho_1 - \rho_2, & c_{12} &= \lambda_1 + \mu_2 + \nu_1 - 2\rho_1 - \rho_2,\\
c_{13} &= \lambda_1 + \mu_2 + \nu_1 - 2\rho_1 - \rho_2, & c_{14} &= \lambda_1 + \mu_2 + \nu_2 - 2\rho_1 - \rho_2,\\
c_{21} &= \lambda_1 + \mu_1 + \nu_1 - 2\rho_1 - \rho_2, & c_{22} &= \lambda_1 + \mu_1 + \nu_2 - 2\rho_1 - \rho_2,\\
c_{23} &= \lambda_1 + \mu_1 + \nu_1 - 2\rho_1 - \rho_2, & c_{24} &= \lambda_1 + \mu_1 + \nu_2 - 2\rho_1 - \rho_2.
\end{aligned}
$$

The Jordan canonical form of A_{IV^*} is

$$
\begin{pmatrix} \rho_1 I_4 & \\ & \rho_2 I_2 \end{pmatrix}
$$

(see Haraoka [2, Thm. IV*]). Therefore, A_{IV^*} satisfies the relation

$$
(A_{\mathrm{IV}^*} - \rho_1 I_n)(A_{\mathrm{IV}^*} - \rho_2 I_n) = O,
$$

and hence the system (3.5) is completely integrable.

We assume the conditions

$$
\begin{aligned}
\lambda_1,\ \lambda_2,\ \lambda_1 - \lambda_2 &\notin \mathbf{Z},\\
\mu_1,\ \mu_2,\ \mu_1 - \mu_2 &\notin \mathbf{Z},\\
\nu_1,\ \nu_2,\ \nu_1 - \nu_2 &\notin \mathbf{Z},\\
\rho_1 - \rho_2 &\notin \mathbf{Z},\\
\rho_j &\notin \mathbf{Z}_{<0} \quad (j = 1, 2),
\end{aligned}
\tag{3.6}
$$

which are corresponding to (1.1). Then the system (3.5) has a fundamental set of solutions such as we state in section 1.1, which we denote by $\mathcal{Z}_{\mathrm{IV}^{**}}(x, y)$.

THEOREM 4. *We assume* (3.6) *and*

$$
\begin{aligned}
\lambda_i - \rho_1 &\notin \mathbf{Z} \quad (i = 1, 2),\\
\mu_i - \rho_1 &\notin \mathbf{Z} \quad (i = 1, 2),\\
\nu_i - \rho_1 &\notin \mathbf{Z} \quad (i = 1, 2),\\
\lambda_i + \mu_j + \nu_k - 2\rho_1 - \rho_2 &\notin \mathbf{Z} \quad (i, j, k = 1, 2).
\end{aligned}
$$

There is a diagonal matrix $D \in GL(n, \mathbf{C})$ such that the monodromy group of the *system* (3.5) *with respect to* $\mathcal{Z}_{\mathrm{IV}^{**}}(x,y)D$ *is generated by*

$$M_1 = \begin{pmatrix} e(\lambda_1) & & \xi_{11} & \xi_{12} & \xi_{13} & \xi_{14} \\ & e(\lambda_2) & \xi_{21} & \xi_{22} & \xi_{23} & \xi_{24} \\ & & 1 & & & \\ & & & 1 & & \\ & & & & 1 & \\ & & & & & 1 \end{pmatrix},$$

$$M_2 = \begin{pmatrix} 1 & & & & & \\ & 1 & & & & \\ \eta_{11} & \eta_{12} & e(\mu_1) & & \eta_{13} & \eta_{14} \\ \eta_{21} & \eta_{22} & & e(\mu_2) & \eta_{23} & \eta_{24} \\ & & & & 1 & \\ & & & & & 1 \end{pmatrix},$$

$$M_3 = \begin{pmatrix} 1 & & & & & \\ & 1 & & & & \\ & & 1 & & & \\ & & & 1 & & \\ \zeta_{11} & \zeta_{12} & \zeta_{13} & \zeta_{14} & e(\nu_1) & \\ \zeta_{21} & \zeta_{22} & \zeta_{23} & \zeta_{24} & & e(\nu_2) \end{pmatrix},$$

$$N_1 = \begin{pmatrix} e(\lambda_1-\rho_1-\rho_2) & & & & & \\ & e(\lambda_2-\rho_1-\rho_2) & & & & \\ \theta_{11} & \theta_{12} & 1 & & & \\ \theta_{21} & \theta_{22} & & 1 & & \\ \theta_{31} & \theta_{32} & & & 1 & \\ \theta_{41} & \theta_{42} & & & & 1 \end{pmatrix},$$

$$N_2 = \begin{pmatrix} 1 & & \phi_{11} & \phi_{12} & & \\ & 1 & \phi_{21} & \phi_{22} & & \\ & & e(\mu_1-\rho_1-\rho_2) & & & \\ & & & e(\mu_2-\rho_1-\rho_2) & & \\ & & \phi_{31} & \phi_{32} & 1 & \\ & & \phi_{41} & \phi_{42} & & 1 \end{pmatrix},$$

$$N_3 = \begin{pmatrix} 1 & & & & \psi_{11} & \psi_{12} \\ & 1 & & & \psi_{21} & \psi_{22} \\ & & 1 & & \psi_{31} & \psi_{32} \\ & & & 1 & \psi_{41} & \psi_{42} \\ & & & & e(\nu_1-\rho_1-\rho_2) & \\ & & & & & e(\nu_2-\rho_1-\rho_2) \end{pmatrix},$$

where

$$\xi_{ij} = \frac{e(\lambda_i)-e(\rho_1)}{e(\lambda_i)-e(\lambda_{i'})}\cdot x_{ij} \qquad \textit{for } i=1,2 \textit{ with } \{i,i'\}=\{1,2\}, \quad j=1,\ldots,4,$$
$$\eta_{ij} = \frac{e(\mu_i)-e(\rho_1)}{e(\mu_i)-e(\mu_{i'})}\cdot y_{ij} \qquad \textit{for } i=1,2 \textit{ with } \{i,i'\}=\{1,2\}, \quad j=1,\ldots,4,$$
$$\zeta_{ij} = \frac{e(\nu_i)-e(\rho_1)}{e(\nu_i)-e(\nu_{i'})}\cdot z_{ij} \qquad \textit{for } i=1,2 \textit{ with } \{i,i'\}=\{1,2\}, \quad j=1,\ldots,4,$$

$$\begin{aligned}
x_{11} &= \frac{[211]}{e(\nu_1+2\rho_1+\rho_2)}, & x_{12} &= \frac{[111]}{e(\nu_1+2\rho_1+\rho_2)},\\
x_{13} &= -\frac{[122]}{e(\lambda_1+\mu_2+\nu_1+3\rho_1+\rho_2)}, & x_{14} &= \frac{[111]}{e(\lambda_1+\mu_1+\nu_1+3\rho_1+\rho_2)},\\
x_{21} &= \frac{[221]}{e(\nu_1+2\rho_1+\rho_2)}, & x_{22} &= \frac{[121]}{e(\nu_1+2\rho_1+\rho_2)},\\
x_{23} &= -\frac{[212]}{e(\lambda_2+\mu_1+\nu_1+3\rho_1+\rho_2)}, & x_{24} &= \frac{[221]}{e(\lambda_2+\mu_1+\nu_1+3\rho_1+\rho_2)},\\
y_{11} &= \frac{[121]}{e(\rho_1)}, & y_{12} &= \frac{[111]}{e(\rho_1)},\\
y_{13} &= \frac{[212]}{e(\lambda_2+3\rho_1+\rho_2)}, & y_{14} &= -\frac{[222]}{e(\lambda_2+3\rho_1+\rho_2)},\\
y_{21} &= \frac{[221]}{e(\rho_1)}, & y_{22} &= \frac{[211]}{e(\rho_1)},\\
y_{23} &= -\frac{[211]}{e(\lambda_1+\lambda_2+\mu_1+\nu_1+\rho_1)}, & y_{24} &= \frac{[221]}{e(\lambda_1+\lambda_2+\mu_1+\nu_1+\rho_1)},\\
z_{11} &= -e(\lambda_1+\nu_1)[221], & z_{12} &= -e(\lambda_2+\nu_1)[111],\\
z_{13} &= [221], & z_{14} &= [111],\\
z_{21} &= -\frac{e(2\rho_1+\rho_2)[121]}{e(\mu_2)}, & z_{22} &= -\frac{e(2\rho_1+\rho_2)[211]}{e(\mu_2)},\\
z_{23} &= -[211], & z_{24} &= \frac{e(2\rho_1+\rho_2)[212]}{e(\lambda_2+\mu_2+\nu_2)},
\end{aligned}$$

and

$$\begin{aligned}
\theta_{ij} &= e(\lambda_j-\rho_1-\rho_2)\cdot\eta_{ij}, & \theta_{2+i,j} &= e(-\nu_i)\cdot\zeta_{ij},\\
\phi_{ij} &= e(-\lambda_i)\cdot\xi_{ij}, & \phi_{2+i,j} &= e(\mu_j-\rho_1-\rho_2)\cdot\zeta_{i,2+j},\\
\psi_{ij} &= e(\nu_j-\rho_1-\rho_2)\cdot\xi_{i,2+j}, & \psi_{2+i,j} &= e(-\mu_i)\cdot\eta_{i,2+j}
\end{aligned}$$

for $i,j=1,2$. Here we have set

$$[ijk]=e(\lambda_i+\mu_j+\nu_k)-e(2\rho_1+\rho_2)$$

for $i,j,k=1,2$.

3.4. Proof of Theorems 2, 3, and 4. The elements of M_i $(i=1,2,3)$ have already been determined by Haraoka [3, Thms. 7, 9, and 11]. Applying the following lemma to the M_i's, we can easily evaluate the elements of N_j $(j=1,2,3)$.

LEMMA 2. *Let M_i $(i=1,2,3)$ and N_j $(j=1,2,3)$ be matrices of the form*

$$M_1=\begin{pmatrix} M_{11} & M_{12} & M_{13}\\ & I_{n_2} & \\ & & I_{n_3}\end{pmatrix}, M_2=\begin{pmatrix} I_{n_1} & & \\ M_{21} & M_{22} & M_{23}\\ & & I_{n_3}\end{pmatrix}, M_3=\begin{pmatrix} I_{n_1} & & \\ & I_{n_2} & \\ M_{31} & M_{32} & M_{33}\end{pmatrix},$$

where M_{ij} is an $n_i\times n_j$ matrix, and

$$N_1=\begin{pmatrix} N_{11} & & \\ N_{21} & I_{n_2} & \\ N_{31} & & I_{n_3}\end{pmatrix}, N_2=\begin{pmatrix} I_{n_1} & N_{12} & \\ & N_{22} & \\ & N_{32} & I_{n_3}\end{pmatrix}, N_3=\begin{pmatrix} I_{n_1} & & N_{13}\\ & I_{n_2} & N_{23}\\ & & N_{33}\end{pmatrix},$$

where N_{ij} is an $n_i \times n_j$ matrix. Let ε be an element in $\mathbf{C} \setminus \{0\}$. Suppose that M_i $(i = 1, 2, 3)$ and N_j $(j = 1, 2, 3)$ are invertible and satisfy

$$N_1N_2N_3 = \varepsilon M_3M_2M_1 \tag{3.7}$$

and

$$N_jM_i = M_iN_j \tag{3.8}$$

for $i, j = 1, 2, 3$ with $i \neq j$. Then we have

$$N_{11} = \varepsilon M_{11}, \qquad N_{21} = \varepsilon M_{21}M_{11}, \quad N_{31} = M_{33}^{-1}M_{31}, \tag{3.9}$$

$$N_{12} = M_{11}^{-1}M_{12}, \quad N_{22} = \varepsilon M_{22}, \qquad N_{32} = \varepsilon M_{32}M_{22}, \tag{3.10}$$

and

$$N_{13} = \varepsilon M_{13}M_{33}, \quad N_{23} = M_{22}^{-1}M_{23}, \quad N_{33} = \varepsilon M_{33}. \tag{3.11}$$

Proof. We prove (3.10). By direct calculation, we obtain

$$N_1N_2N_3 = \begin{pmatrix} N_{11} & * & * \\ N_{21} & * & * \\ N_{31} & * & * \end{pmatrix}$$

and

(3.12)
$$\varepsilon M_3M_2M_1 = \varepsilon \begin{pmatrix} M_{11} & M_{12} & * \\ M_{21}M_{11} & M_{21}M_{12} + M_{22} & * \\ (M_{31} + M_{32}M_{21})M_{11} & (M_{31} + M_{32}M_{21})M_{12} + M_{32}M_{22} & * \end{pmatrix}.$$

From these with the relation (3.7) we temporarily obtain

$$N_{11} = \varepsilon M_{11}, \quad N_{21} = \varepsilon M_{21}M_{11}, \quad N_{31} = \varepsilon(M_{31} + M_{32}M_{21})M_{11},$$

and hence

$$N_1^{-1} = \begin{pmatrix} \varepsilon^{-1}M_{11}^{-1} & & \\ -M_{21} & I_{n_2} & \\ -(M_{31} + M_{32}M_{21}) & & I_{n_3} \end{pmatrix}. \tag{3.13}$$

From (3.12) and (3.13) we obtain

$$\varepsilon N_1^{-1}M_3M_2M_1 = \begin{pmatrix} I_{n_1} & M_{11}^{-1}M_{12} & * \\ & \varepsilon M_{22} & * \\ & \varepsilon M_{32}M_{22} & * \end{pmatrix}.$$

On the other hand, by the relation (3.7) multiplied by N_1^{-1} from the left we have

$$\varepsilon N_1^{-1}M_3M_2M_1 = N_2N_3 = \begin{pmatrix} I_{n_1} & N_{12} & * \\ & N_{22} & * \\ & N_{32} & * \end{pmatrix}.$$

Comparing these expressions, we obtain (3.10).

Starting with the relations

$$N_2N_3N_1 = \varepsilon M_1M_3M_2 \quad \text{and} \quad N_3N_1N_2 = \varepsilon M_2M_1M_3,$$

which are derived from (3.7) with (3.8), we can prove (3.11) and (3.9), respectively, by the same consideration as above. Thus the proof is complete. $\square$

ASYMPTOTICS OF THE ZEROS OF RELATIVISTIC HERMITE POLYNOMIALS*

MATTHEW HE[†], K. PAN[‡], AND PAOLO E. RICCI[§]

Abstract. The relativistic Hermite polynomial (RHP) is a class of orthogonal polynomials associated with varying weights. We study the asymptotics of the zeros of the RHP when both degree n of polynomials and relativistic parameter N approach infinity.

Key words. Hermite polynomials, orthogonal polynomials

AMS subject classifications. 41A, 41C

PII. S003614109529642X

1. Introduction.

Relativistic Hermite polynomials (RHPs) $\{H_n^{(N)}(x)\}_{n=0}^{\infty}$ were introduced in [1] in connection with the wave functions of the quantum relativistic harmonic oscillator. It was shown in [1] that the RHP satisfies the second-order differential equation

$$\left(1+\frac{x^2}{N}\right)y_n'' - \frac{2}{N}(N+n-1)xy_n' + \frac{n}{N}(2N+n-1)y_n = 0. \tag{1.1}$$

Equation (1.1) is a particular case of a second-order hypergeometric-type equation [9]

$$\sigma(x)y'' + \tau(x)y' + \lambda y = 0, \tag{1.2}$$

where

$$\sigma(x) = \left(1+\frac{x^2}{N}\right),$$
$$\tau = -\frac{2}{N}(N+n-1)x,$$
$$\lambda = \frac{n}{N}(2N+n-1).$$

It is easy to verify that the following relation holds:

$$\lambda = -n\tau' - \frac{1}{2}n(n-1)\sigma''.$$

By solving the equation

$$[\sigma(x)\rho_n(x;N)]' = \tau(x)\rho_n(x;N),$$

one can find the symmetric factor or weight function

$$\rho_n(x;N) = \left(1+\frac{x^2}{N}\right)^{-(N+n)}, \quad N > \frac{1}{2}, \quad n = 0,1,2,\ldots,\ x \in (-\infty,\infty). \tag{1.3}$$

Using this weight function, the following orthogonality of the RHP was established in [1]:

$$\int_{-\infty}^{\infty} x^k H_n^{(N)}(x)\rho_n(x;N)dx = 0, \qquad k = 0,1,\ldots,n-1. \tag{1.4}$$

That is, $\{H_n^{(N)}(x)\}_{n=0}^{\infty}$ is a class of orthogonal polynomials with respect to a sequence of varying weight functions $\rho_n(x)$. Clearly,

$$\lim_{N\to\infty} \rho_n(x;N) = e^{-x^2}$$

and

$$\lim_{N\to\infty} H_n^{(N)}(x) = H_n(x).$$

So the relativistic Hermite polynomials become classical Hermite polynomials when the relativistic parameter $N \to \infty$.

The distributions of zeros of RHP were studied in [2]. An analytic approximation for the distribution was derived within the framework of the WKB approximation.

The asymptotics of orthogonal polynomials with respect to varying weights are closely related to constrained or weighted polynomial approximation. Logarithmic potential has been extensively used in investigating such asymptotics. We study the asymptotics of the zeros of RHP when both n and N approach ∞ by using the potential-theoretic method.

The paper is organized as follows: in order to state our main results, we shall introduce some basics from potential theory in section 2. Applying a general result from potential theory developed in [11] to our relativistic weight function, we determine the support of the equilibrium measure explicitly in section 3. In section 4, we give an explicit formula for the density function of the equilibrium measure. The asymptotics of the zeros of the RHP when both n and N approach ∞ are determined in section 5.

2. Basics of potential theory. We shall use logarithmic potentials of Borel measures. If μ is a finite Borel measure with compact support, then its logarithmic potential is defined as its convolution with the logarithmic kernel:

$$U^{\mu}(z) = \int \log\frac{1}{|z-t|}d\mu(t).$$

Let E be a closed subset of the real number line. A weight function w on E is said to be admissible if it satisfies the following three conditions:

(i) w is continuous;

(ii) $\text{Cap}\{x \in E \mid w(x) > 0\} > 0$;

(iii) $Z := \{x \in E : w(x) = 0\}$ has capacity zero; and

(iv) if E is unbounded, then $|x|w(x) \to 0$ as $|x| \to \infty$, $x \in E$.

We say that w is strongly admissible if

(i) w^q is admissible for every q, $0 < q \leq 1$;

(ii) E is regular, i.e., for all k large, $E \cap [-k,k]$ is regular with respect to the Dirichlet problem for its complement on the Riemann sphere, and

(iii) $E \backslash Z$ is interval-like.

We define $Q = Q_w$ by

$$w(x) = \exp(-Q(x)). \tag{2.1}$$

Then $Q : E \to (-\infty, \infty]$ is continuous everywhere where w is positive, i.e., Q is finite.

Let $\mathcal{M}(E)$ be the set of all positive unit Borel measures μ with support $S(\mu) := \operatorname{supp}(\mu) \subset E$ and define the weighted energy integral

$$I_w[\mu] = \iint \log \frac{1}{|z-t|w(z)w(t)} d\mu(z)d\mu(t).$$

Let

$$V_w(E) = \inf\{I_w[\mu] \mid \mu \in \mathcal{M}(E)\}.$$

Then the following properties are true (cf. [12], [10]).

(i) $V_w(E)$ is finite.

(ii) There exists a unique $\mu_E \in \mathcal{M}(E)$ such that

$$I_w(\mu_w) = V_w(E).$$

Moreover, μ_w has finite logarithmic energy.

(iii) $S(\mu_w)$ is a compact subset of E.

(iv) The inequality

$$U^{\mu_w}(z) + Q(z) \geq F_w, \quad z \in E. \tag{2.2}$$

(v) The equality

$$U^{\mu_w}(z) + Q(z) = F_w, \quad z \in S(\mu_w). \tag{2.3}$$

The measure μ_w is called the equilibrium or extremal measure in the presence of an external field, and

$$F_w = V_w(E) - \int Q d\mu_w. \tag{2.4}$$

In order to state our applications to polynomial extremal problems, we define

$$E_{n,p}(w) := \inf\{\|[w(x)]^n[x^n - P(x)]\|_{E,p} : P \in \mathcal{P}_{n-1}\},$$

where $\mathcal{P}_n$ is the set of all polynomials with degrees $\leq n$ and

$$\|f\|_{E,p} := \left(\int_E |f|^p dx\right)^{1/p},$$

$n = 1, 2, \ldots, 0 < p \leq \infty$. The extremal polynomials $T_n(x; w, p) = x^n + \cdots \in \mathcal{P}_n$ are defined by the property

$$E_{n,p}(x) = \|[w(x)]^n T_n(x; w, p)\|_{E,p}.$$

Finally, in this section, we state the following two lemmas.

Lemma 2.1 (see [6]). *Let w be strongly admissible and $0 < p \leq \infty$. Let $\{t_{n,k}\}_{k=1}^{n}$ be the zeros of $T_n(x; w, p)$. Then there exists a closed bounded interval I containing $S(\mu_w)$ and all the zeros of $T_n(x; w, p)$. Moreover,*

$$\lim_{n\to\infty} |T_n(x; w, p)|^{1/n} = \exp\left[\int \log|z - t| d\mu_w(t)\right]$$

uniformly on every compact set of the complex plane disjoint from I,

$$\lim_{n\to\infty} [E_{n,p}]^{1/n} = \exp(F_w),$$

and

$$\lim_{n\to\infty} \mu_n = \mu_w$$

in the weak-star topology, where

$$\mu_n(B) := \frac{1}{n}\#\{k : t_{n,k} \in B\}, \qquad n = 1, 2, \ldots,$$

for any Borel set B.

Lemma 2.2 (see [6]). *Let w be strongly admissible and $0 < p \leq \infty$. Suppose that $I \subset \mathbf{R}$ is a closed bounded interval containing $S(\mu_w)$. Let $\{v_{n,k}\}_{k=1}^{n}$ be a triangular scheme of points lying in I. With this scheme, let $q_n(x) = \prod_{k=1}^{n}(x - v_{n,k})$. Assume that for some p $(0 < p \leq \infty)$,*

$$\lim_{n\to\infty} \|w^n q_n\|_{E,p}^{1/n} \leq \exp(F_w).$$

Then

$$\lim_{n\to\infty} |q_n(x)|^{1/n} = \exp\left[\int \log|z - t| d\mu_w(t)\right]$$

uniformly on every compact set of the complex plane disjoint from I, and

$$\lim_{n\to\infty} \mu_n = \mu_w$$

in the weak-star topology, where

$$\mu_n(B) := \frac{1}{n}|\{k : v_{n,k} \in B\}|, \qquad n = 1, 2, \ldots,$$

for any Borel set B.

3. Support of equilibrium measure. A fundamental theorem [5] in weighted polynomial approximation asserts that every weighted polynomial $\{w^n(x)p_n(x)\}$ must assume its maximum modulus on $S(\mu)$, i.e.,

$$\|w^n(x)p_n(x)\|_E = \|w^n(x)p_n(x)\|_{S(\mu)}, \tag{3.1}$$

where $S(\mu)$ is the support of the equilibrium measure of the set E, and $\|\cdot\|_E$ is the sup norm.

In this section we determine explicitly the support of the equilibrium measure $S(\mu)$ for the weight function $\rho_n(x;N)$. To find $S(\mu)$, we shall need to directly maximize the following F-functional [5]:

$$F(a,b) = \log\left(\frac{(b-a)}{4}\right) - \frac{1}{\pi}\int_a^b \frac{Q(x)}{\sqrt{(x-a)(b-x)}}\,dx.$$

We define $w_n(x) = \rho_n^{\frac{1}{2n}}(x;N)$. Then we have

$$Q_n(x) = \log\frac{1}{w_n(x)} = \left(\frac{1}{2}+\frac{N}{2n}\right)\log\left(1+\frac{x^2}{N}\right).$$

Since $Q_n(x)$ is an even function, the F-functional can be written as follows:

$$F(a) := f(-a,a) = \log a - \frac{1}{\pi}\left(1+\frac{N}{n}\right)\int_0^a \frac{\log\left(1+\frac{t^2}{N}\right)}{\sqrt{a^2-t^2}}\,dt - \log 2.$$

By an elementary integral formula [3],

$$\int_0^1 \frac{\log(1+bx^2)}{\sqrt{1-x^2}}\,ds = \pi\log\frac{1+\sqrt{1+b}}{2}.$$

We have

$$F(a) = \log\frac{a}{2} - \left(1+\frac{N}{n}\right)\log\frac{1+\sqrt{1+\frac{a^2}{N}}}{2}.$$

It is now elementary to check that the choice of $a = a_n$, which maximizes $F(-a,a)$, is given by

$$a_n = \sqrt{\frac{n(n+2N)}{N}}. \tag{3.2}$$

Therefore, we have determined the support $[-a_n, a_n]$ of equilibrium measure corresponding to varying weight $\rho_n(x;N)$.

Furthermore, we can determine the constant F_{w_n},

$$F_{w_n} = \log\frac{a_n}{2} - \left(1+\frac{N}{n}\right)\log\frac{1+\sqrt{1+\frac{a_n^2}{N}}}{2}.$$

We note that

$$\lim_{N\to\infty} a_n = \sqrt{2n},$$

$$\lim_{n\to\infty} F_{w_n} = -\frac{1}{2}\log N,$$

which concides with the results of [8]. We remark here that, although we use a potential-theoretic approach similar to the one used in [8], our approach is more direct. We shall continue our investigation along the same direction to determine the equilibrium measure.

4. Equilibrium measure. In section 3, we determined the support $S(\mu_n) = [-a_n, a_n]$ of equilibrium measure μ_n associated with varying weight $w_n(x)$. In this section, we apply a general formula [12, p. 53] for the density function of the equilibrium measure to our weight function $w_n(x)$ and find the following theorem.

THEOREM 4.1.

$$d\mu_n(t) = g_n(t)dt = \frac{N}{n\pi}\,\frac{\sqrt{a_n^2 - t^2}}{N + t^2}\,dt, \qquad t \in S(\mu_n). \tag{4.1}$$

Proof. It was shown in [12, Lem. 5.1] that the integral equation

$$\int_{-1}^{1} \log\frac{1}{|x-t|}g(t)dt = -Q(x) + C,$$

where C is some constant, has a solution $g(t)$ of the form

$$g(t) = \frac{2}{\pi^2}\sqrt{1-t^2}\int_0^1 \frac{sQ'(s) - tQ'(t)}{(1-s^2)^{1/2}(s^2-t^2)}\,ds + \frac{D_1}{\sqrt{1-t^2}}, \tag{4.2}$$

where

$$D_1 = \frac{1}{\pi} - \frac{1}{\pi^2}\int_{-1}^{1}\frac{sQ'(s)}{\sqrt{1-s^2}}\,ds. \tag{4.3}$$

$g(t)$ is even and has total integral 1 over $[-1, 1]$. Apply (4.2) and (4.3) to

$$Q_n(a_n x) = \left(\frac{1}{2} + \frac{N}{2n}\right)\log\left(1 + \frac{a_n^2 x^2}{N}\right),$$

and we get

$$g_n(t) = \frac{N}{n\pi}\,\frac{\sqrt{a_n^2 - t^2}}{N + t^2}.$$

We note that

$$\lim_{n\to\infty} g_n(t) = \frac{\sqrt{N}}{\pi(N+t^2)}, \qquad t \in (-\infty, \infty).\square$$

5. Asymptotics of zeros. In this section, we study the zeros distribution of $H_n^{(N)}(x)$ for n, $N \to \infty$. The following lemma tells us that the support of $H_n^{(N)}(x)$ "lives" also in some compact set in L_2.

LEMMA 5.3. *For $w(x) = (1 + x^2/N)^{(-N-n)/2}$, there is a positive constant A independent of n, N, such that, for $p \in \mathcal{P}_n$,*

$$\|w(x)p(x)\|_{(-\infty,\infty),2} \le 2\|w(x)p(x)\|_{[-Aa_n, Aa_n],2}.$$

Proof. The proof can be found in [4] for the fixed weight. Here we have a varying weight, so we may proceed exactly as in Theorem 5.2 in [4] to get the lemma. □

The next theorem will discuss the location of the zeros of $H_n^{(N)}(x)$.

Theorem 5.2. *For $w(x)=(1+x^2/N)^{(-N-n)/2}$, there is a positive constant D independent of n, N, such that all the zeros of $H_n^{(N)}(x)$ lie in $[-Da_n, Da_n]$.*

Proof. Let $X_{n,N}$ denote the largest zero of $H_n^{(N)}(x)$. Suppose now that $\forall A>0$ there exist n, N such that $X_{n,N}>Aa_n$. Let

$$t_{n,N}(x) := \frac{x-Aa_n}{x-X_{n,N}} H_n^{(N)}(x).$$

Then, for $x\in[-Aa_n, Aa_n]$,

$$|t_{n,N}(x)| \le \frac{2Aa_n}{X_{n,N}-Aa_n}|H_n^{(N)}(x)|.$$

Hence, from the lemma above, we have

$$\begin{aligned}
&\|w(x)t_{n,N}(x)\|_{(-\infty,\infty),2}\\
&\quad\le\ 2\|w(x)t_{n,N}(x)\|_{[-Aa_n,Aa_n],2}\\
&\quad\le\ 2\left(\frac{2Aa_n}{X_{n,N}-Aa_{n,N}}\right)\|w(x)H_n^{(N)}(x)\|_{[-Aa_n,Aa_n],2}\\
&\quad\le\ 2\left(\frac{2Aa_n}{X_{n,N}-Aa_{n,N}}\right)\|w(x)H_n^{(N)}(x)\|_{(-\infty,\infty),2}.
\end{aligned}$$

Thus, since $H_n^{(N)}(x)$ is extremal, the inequality implies that $1\le 4Aa_n/(X_{n,N}-Aa_n)$, that is, $X_{n,N}\le 5Aa_n$. □

Now, we consider the case in which both n and N converge to ∞ with the same rate.

Theorem 5.3. *Let $N=\lambda n$ and a_n be as in (3.2), where λ is a fixed number. Then*

$$\lim_{n\to\infty}|H_n^{(N)}(a_nx)|^{\frac{1}{n}} = \exp\left[\int_{-1}^{1}\log|z-t|d\mu(t)\right]$$

locally uniformly in $\mathbf{C}\backslash[-1,1]$, where

$$d\mu(t) = \frac{\lambda(1+2\lambda)}{\pi}\quad\frac{\sqrt{1-t^2}}{\lambda^2+(1+2\lambda)t^2}\,dt.$$

Furthermore, let $\{t_{n,k}\}_{k=1}^{n}$ be the zeros of $H_n^{(N)}(a_nx)$ and B be a Borel set. Define

$$\mu_n := \frac{1}{n}|\{k : t_{n,k}\in B\}|,\qquad n=1,2,\ldots;$$

then

$$\lim_{n\to\infty}\mu_n = \mu$$

in the weak-star topology.

Proof. Let

$$w(x) = \left(1+\frac{(1+2\lambda)}{\lambda^2}x^2\right)^{-\frac{1+\lambda}{2}}.$$

Let $t_n(x) = x^n + \cdots$ be the extremal polynomial for the sup norm on $[-1, 1]$,

$$\|w(x)^n t_n(x)\| = \inf_{p_n = x^n + \cdots} \|w(x)^n p_n(x)\|,$$

and $T_n(x) = a_n^n t_n(\frac{x}{a_n})$. Notice that $a_n = \sqrt{(1 + 2\lambda)n/\lambda}$; then

$$\begin{aligned}
&\|w(x)^n H_n^{(N)}(a_n x)\|_{[-1,1],2} \\
&\quad = \left\| \left(1 + \frac{(1+2\lambda)}{\lambda^2} x^2\right)^{-\frac{1+\lambda}{2}n} H_n^{(N)}(a_n x) \right\|_{[-1,1],2} \\
&\quad = \left\| \left(1 + \frac{(1+2\lambda)}{\lambda^2} \, \frac{x^2}{a_n^2}\right)^{-\frac{1+\lambda}{2}n} H_n^{(N)}(x) \right\|_{[-a_n,a_n],2} \\
&\quad \le \left\| \left(1 + \frac{x^2}{\lambda n}\right)^{-\frac{1+\lambda}{2}n} H_n^{(N)}(x) \right\|_{(-\infty,\infty),2} \\
&\quad \le \left\| \left(1 + \frac{x^2}{\lambda n}\right)^{-\frac{1+\lambda}{2}n} T_n(x) \right\|_{(-\infty,\infty),2} \\
&\quad \le \left\| \left(1 + \frac{x^2}{\lambda n}\right)^{-\frac{1+\lambda}{2}n} T_n(x) \right\|_{-(\infty,\infty),\infty} \\
&\quad = \left\| \left(1 + \frac{x^2}{\lambda n}\right)^{-\frac{1+\lambda}{2}n} T_n(x) \right\|_{[-a_n,a_n],\infty} \\
&\quad = \left\| \left(1 + \frac{(1+2\lambda)}{\lambda^2} x^2\right)^{-\frac{1+\lambda}{2}n} T_n(a_n x) \right\|_{[-1,1],\infty} \\
&\quad = \left\| \left(1 + \frac{(1+2\lambda)}{\lambda^2} x^2\right)^{-\frac{1+\lambda}{2}n} a_n^n t_n(x) \right\|_{[-1,1],\infty}.
\end{aligned}$$

Thus we have

$$\left\| [w(x)]^n \frac{H_n(a_n x)}{a_n^n} \right\|_{[-1,1],2}^{\frac{1}{n}} \le \left\| \left(1 + \frac{(1+2\lambda)}{\lambda^2} \, x^2\right)^{-\frac{1+\lambda}{2}n} t_n(x) \right\|_{[-1,1],\infty}^{1/n}. \tag{5.1}$$

For the weight w, notice that $t_n(x)$ is the extremal for w, and from Lemma 1, we have

$$\limsup_{n\to\infty} \left\| w(x)^n \frac{H_n(a_n x)}{a_n^n} \right\|_{[-1,1],2}^{\frac{1}{n}} \le \exp(F_w).$$

Notice that $\frac{H_n(a_n x)}{a_n^n} = x^n + \cdots$ and the zeros of $H_n^{(N)}(a_n x)$ lie in $[-D, D]$. From Lemma 2, we have the proof of the theorem. □

THEOREM 5.4. *Let $N = \lambda_n n$ and a_n be as in* (3.2). *If $\lambda_n \to \infty$, then*

$$\lim_{n\to\infty} |H_n^{(N)}(a_n x)|^{\frac{1}{n}} = \exp\left[\int_{-1}^{1} \log|z - t| d\nu(t)\right]$$

locally uniformly in $\mathbf{C}\backslash[-1, 1]$, where

$$d\nu(t) = \frac{2}{\pi} \sqrt{1 - t^2} \, dt.$$

Furthermore, let the sequence of unit measures $\{\nu_n\}_{n=1}^{\infty}$ *be*

$$\nu_n := \frac{1}{n}|\{k : t_{n,k} \in B\}|, \qquad n = 1, 2, \ldots,$$

where B *is a Borel set and* $\{t_{n,k}\}_{k=1}^{n}$ *are the zeros of* $H_n^{(N)}(a_n x)$*. If* $\lambda_n \to \infty$*, then*

$$\lim_{n-\infty} \nu_n = \nu$$

in the weak-star topology.

Proof. In the proof of (5.1), it is easy to see that for any $p_n(x) = x^n + \cdots \in \mathcal{P}_n$, we have

$$\left\|\left(1 + \frac{(1+2\lambda_n)}{\lambda_n^2}x^2\right)^{-\frac{1+\lambda_n}{2}n} \frac{H_n(a_n x)}{a_n^n}\right\|_{[-1,1],2}$$

(5.2)

$$\leq \left\|\left(1 + \frac{(1+2\lambda_n)}{\lambda_n^2}x^2\right)^{-\frac{1+\lambda_n}{2}n} p_n(x)\right\|_{[-1,1],\infty}.$$

Here, we consider $w(x) = e^{-x^2}$ on $[-1,1]$; the equilibrium measure is $d\nu = \frac{2}{\pi}\sqrt{1-t^2}\,dt$ [7]. Choose $p_n(x) = T_n(x; w, \infty)$; from (5.2), we have

$$\begin{aligned}
&\left\|[w(x)]^n \frac{H_n^{(N)}(a_n x)}{a_n^n}\right\|_{[-1,1],2}\\
&= \left\|e^{-nx^2} \frac{H_n^{(N)}(a_n x)}{a_n^n}\right\|_{[-1,1],2}\\
&\leq \left\|e^{-nx^2}\left(1 + \frac{(1+2\lambda_n)}{\lambda_n^2}x^2\right)^{\frac{1+\lambda_n}{2}n}\right\|_{[-1,1],2} \left\|\left(1 + \frac{(1+2\lambda_n)}{\lambda_n^2}x^2\right)^{-\frac{1+\lambda_n}{2}n} \frac{H_n^{(N)}(a_n x)}{a_n^n}\right\|_{[-1,1],2}\\
&\leq \left\|e^{-nx^2}\left(1 + \frac{(1+2\lambda_n)}{\lambda_n^2}x^2\right)^{\frac{1+\lambda_n}{2}n}\right\|_{[-1,1],2} \left\|\left(1 + \frac{(1+2\lambda_n)}{\lambda_n^2}x^2\right)^{-\frac{1+\lambda_n}{2}n} T_n(x; w, \infty)\right\|_{[-1,1],\infty}\\
&\leq \left\|e^{-nx^2}\left(1 + \frac{(1+2\lambda_n)}{\lambda_n^2}x^2\right)^{\frac{1+\lambda_n}{2}n}\right\|_{[-1,1],2} \left\|e^{nx^2}\left(1 + \frac{(1+2\lambda_n)}{\lambda_n^2}x^2\right)^{-\frac{1+\lambda_n}{2}n}\right\|_{[-1,1],\infty}\\
&\times \left\|e^{-nx^2} T_n(x; w, \infty)\right\|_{[-1,1],\infty}.
\end{aligned}$$

Notice that, as $\lambda_n \to \infty$,

$$\lim_{n\to\infty} \left\|e^{-nx^2}\left(1 + \frac{(1+2\lambda_n)}{\lambda_n^2}x^2\right)^{\frac{1+\lambda_n}{2}n}\right\|_{[-1,1],2}^{1/n} = 1$$

and

$$\lim_{n\to\infty} \left\|e^{nx^2}\left(1 + \frac{(1+2\lambda_n)}{\lambda_n^2}x^2\right)^{-\frac{1+\lambda_n}{2}n}\right\|_{[-1,1],\infty}^{1/n} = 1;$$

then

$$\lim_{n\to\infty}\left\|[w(x)]^n\frac{H_n^{(N)}(a_nx)}{a_n^n}\right\|_{[-1,1],2}^{1/n}\le e^{F_w}.$$

From Lemma 2, this completes the proof of the theorem. □

For the case when N is fixed and $n\to\infty$, see [8].

ORTHOGONALITY OF CARDINAL B-SPLINES IN WEIGHTED SOBOLEV SPACES *

ULRICH REIF[†]

Abstract. The cardinal B-splines $B_{j,n}, j \in \mathbb{Z}$, of order n form an orthonormal sequence in the Sobolev space $H^{n-1,2}(\mathbb{R})$ endowed with the norm $\|f\|^2_{\omega(n)} := \sum_{\mu=0}^{n-1} \omega_\mu(n) \|\partial^\mu f\|^2$ for certain positive weights $\omega_\mu(n)$. These weights are specified explicitly. Further, an application to approximation theory is discussed.

Key words. B-spline, Sobolev space, orthogonality, approximation

1. Preliminaries.

In this section we shall briefly introduce some basic concepts from B-spline theory and functional analysis; see, e.g., [4], [3], [1], and [5] for an introduction to these topics.

For $m \in \mathbb{N}$ denote by $\langle \cdot, \cdot \rangle$, $\langle \cdot, \cdot \rangle_m$ the inner products and by $\| \cdot \|$, $\| \cdot \|_m$ the norms of the Hilbert spaces $L^2(\mathbb{R})$ and $H^{m,2}(\mathbb{R})$, respectively. Let $\omega := [\omega_0, \dots, \omega_m]$ be a vector of positive weights, and define the *weighted Sobolev space* $H^{m,2}_\omega(\mathbb{R})$ by providing $H^{m,2}(\mathbb{R})$ with the inner product

$$(f,g)_\omega := \sum_{\mu=0}^{m} \omega_\mu \langle \partial^\mu f, \partial^\mu g \rangle \; . \tag{1.1}$$

Evidently, the induced norm $\| \cdot \|_\omega$ is equivalent to the standard norm $\| \cdot \|_m$ obtained for $\omega_\mu = 1$,

$$\min_\mu \sqrt{\omega_\mu}\, \|f\|_m \le \|f\|_\omega \le \max_\mu \sqrt{\omega_\mu}\, \|f\|_m \; . \tag{1.2}$$

Thus, the fundamental properties of $H^{m,2}(\mathbb{R})$ extend to $H^{m,2}_\omega(\mathbb{R})$. In particular, $H^{m,2}_\omega(\mathbb{R})$ is continuously embedded into $C^k(\mathbb{R})$ for $0 \le k < m$ (see [1]); i.e., there exist constants $\Gamma(k,m,\omega)$ such that

$$\|\partial^k f\|_\infty \le \Gamma(k,m,\omega)\, \|f\|_\omega \; . \tag{1.3}$$

The *Fourier transform* $\mathcal{F} : f \mapsto \hat{f}$ and its inverse are given by

$$\hat{f}(y) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x) \exp(-ixy)\, dx \;, \quad f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \hat{f}(y) \exp(ixy)\, dy \; . \tag{1.4}$$

Strictly speaking, (1.4) is defined for functions $f \in L^1(\mathbb{R})$, but $\mathcal{F}$ can be extended to $L^2(\mathbb{R})$ by a limiting process. Now $\mathcal{F}$ is an *isometry* in $L^2(\mathbb{R})$; i.e.,

$$\langle f, g \rangle = \langle \hat{f}, \hat{g} \rangle \;, \quad \|f\| = \|\hat{f}\| \tag{1.5}$$

[†] Mathematisches Institut A, Universität Stuttgart, Pfaffenwaldring 57, 70550 Stuttgart, Germany (reif@mathematik.uni-stuttgart.de).

for all $f, g \in L^2(\mathbb{R})$. Further, if $f(x) \leq C\,(1+|x|)^{-1-\delta}$ and $\hat{f}(y) \leq C\,(1+|y|)^{-1-\delta}$ for some constants C, $\delta > 0$, then the *Poisson summation formula* holds [5, p. 252]:

$$\sum_{j\in\mathbb{Z}} f(j) = \sqrt{2\pi} \sum_{k\in\mathbb{Z}} \hat{f}(2\pi k)\ . \tag{1.6}$$

Denote by $B_{j,n,h}$ the *uniform B-spline* of order $n \in \mathbb{N}$ with knot sequence $h\mathbb{Z}$ and support $\operatorname{supp} B_{j,n,h} = h[j, j+n]$. The *cardinal B-splines* $B_{j,n} = B_{j,n,1}$ are obtained for $h = 1$. Let

$$s(y) := \begin{cases} 2\sin(y/2)/y & \text{for } y \neq 0, \\ 1 & \text{for } y = 0; \end{cases} \tag{1.7}$$

then the Fourier transforms of $B_{j,n}$ and its derivatives are given by

$$\widehat{\partial^\mu B}_{j,n}(y) = (iy)^\mu \exp(-iy(j+n/2))\, s^n(y)/\sqrt{2\pi}; \tag{1.8}$$

see [4, p. 139]. Note that

$$\partial^\mu s^n(y)\big|_{y=2k\pi} = 0 \quad \text{for} \quad k \in \mathbb{Z}\backslash\{0\}\ ,\ 0 \leq \mu < n\ . \tag{1.9}$$

Further, with B_k as the Bernoulli numbers, the Taylor expansion of $1/s$ at the origin is (see [2])

$$1/s(y) = 1 + \sum_{k=1}^{\infty} \frac{(2^{k-1}-1)B_k}{2^{2k}(2k)!}\, y^{2k}\ . \tag{1.10}$$

The *spline space* $S_{n,h} := \operatorname{span} B_{j,n,h}$ consists of linear combinations of B-splines $b := \sum_{j\in\mathbb{Z}} b_j B_{j,n,h}$. With a slight abuse of notation, b will denote both the function and the bi-infinite column vector $[b_j]_{j\in\mathbb{Z}}$ of *B-spline coefficients*.

For an even analytic function f, let $[f]_m := [f_0, \ldots, f_{m-1}]$ be the vector of the first m coefficients of the power series $f(x) = \sum_{j=0}^\infty f_j x^{2j}$. Denote by $*$ the *convolution operator* and by a^{*k} the $(k-1)$-fold convolution of a vector a with itself; i.e.,

$$* : \mathbb{R}^m \times \mathbb{R}^m \mapsto \mathbb{R}^m\ , \quad (a*b)_\nu := \sum_{\mu=0}^{\nu} a_{\nu-\mu} b_\mu, \tag{1.11}$$

$$a^{*k} := a * a^{*(k-1)}\ , \quad a^{*1} := a; \tag{1.12}$$

then

$$[fg]_m = [f]_m * [g]_m\ , \quad [f^k]_m = [f]_m^{*k}\ . \tag{1.13}$$

2. Weights providing orthonormality. The cardinal B-splines $B_{j,n}$ have compact support and a piecewise constant derivative of order $n-1$; thus $B_{j,n} \in H_\omega^{n-1,2}(\mathbb{R})$ for arbitrary ω. It is the main result of this paper that $\omega = \omega(n)$ can be chosen such that $\{B_{j,n},\ j \in \mathbb{Z}\}$ becomes an orthonormal sequence.

THEOREM 2.1. *The sequence $\{B_{j,n}, j \in \mathbb{Z}\}$ is orthonormal in $H_{\omega(n)}^{n-1,2}(\mathbb{R})$ if and only if*

$$\omega(n) := [1/s]_n^{*2n}\ . \tag{2.1}$$

In particular, $\omega_\mu(n) > 0$ *for all* $n \in \mathbb{N}$ *and* $0 \le \mu < n$.

Proof. Since $(B_{j_1,n}, B_{j_2,n})_\omega = (B_{j_2,n}, B_{j_1,n})_\omega = (B_{0,n}, B_{|j_2-j_1|,n})_\omega$, it suffices to consider inner products of type $(B_{0,n}, B_{j,n})_\omega, j \ge 0$. For $j \ge n$ the supports of $B_{0,n}$ and $B_{j,n}$ are disjoint; hence $(B_{0,n}, B_{j,n})_\omega = 0$. For $j = 0, \dots, n-1$, we obtain using (1.5) and (1.8)

$$\begin{aligned}(B_{0,n}, B_{j,n})_\omega &= \sum_{\mu=0}^{n-1} \omega_\mu \, \langle \partial^\mu B_{0,n}, \partial^\mu B_{j,n} \rangle \\ &= \sum_{\mu=0}^{n-1} \frac{\omega_\mu}{2\pi} \int_{-\infty}^{\infty} y^{2\mu} s^{2n}(y) \exp(ijy) \, dy \\ &= \sum_{\mu=0}^{n-1} (-1)^\mu \, \omega_\mu \, \partial^{2\mu} B_{0,2n}(j+n) \, . \end{aligned} \tag{2.2}$$

Define the column vector e by $e_j := \delta_{j,0}$ and the $n \times n$-matrices P, Q by

$$P_{j,\mu} := (-1)^\mu \partial^{2\mu} B_{0,2n}(j+n), \tag{2.3}$$

$$Q_{\nu,j} := \frac{2(-1)^\nu j^{2\nu}}{(2\nu)!} - \delta_{\nu,0}\delta_{j,0} \, . \tag{2.4}$$

Scaling the rows of Q appropriately yields the Vandermonde-matrix with entries $j^{2\nu}$. Thus Q is invertible, and orthonormality of $\{B_{j,n}, \, j \in \mathbb{Z}\}$ is equivalent to

$$QP\omega = Qe = e \, . \tag{2.5}$$

For computing the product matrix $R := QP$ the summation array $j = 0, \dots, n-1$ can be transformed to $\mathbb{Z}$ exploiting $B_{0,2n}(j+n) = B_{0,2n}(-j+n)$ and $\operatorname{supp} B_{0,2n} = [0, 2n]$,

$$R_{\nu,\mu} = \sum_{j=0}^{n-1} Q_{\nu,j} P_{j,\mu} = \frac{(-1)^{\nu+\mu}}{(2\nu)!} \sum_{j \in \mathbb{Z}} j^{2\nu} \partial^{2\mu} B_{0,2n}(j+n) \, . \tag{2.6}$$

So, (1.6) becomes applicable, and we obtain the following using (1.9):

$$\begin{aligned} R_{\nu,\mu} &= \frac{1}{(2\nu)!} \sum_{k \in \mathbb{Z}} \partial^{2\nu} \big(y^{2\mu} s^{2n}(y) \big)\big|_{y=2k\pi} \\ &= \frac{1}{(2\nu)!} \sum_{k \in \mathbb{Z}} \sum_{\ell=0}^{2\nu} \binom{2\nu}{\ell} \partial^\ell \big(y^{2\mu} \big)\big|_{y=2k\pi} \partial^{2\nu-\ell} \big(s^{2n}(y) \big)\big|_{y=2k\pi} \\ &= \frac{1}{(2\nu)!} \sum_{\ell=0}^{2\nu} \binom{2\nu}{\ell} \partial^\ell \big(y^{2\mu} \big)\big|_{y=0} \partial^{2\nu-\ell} \big(s^{2n}(y) \big)\big|_{y=0} \\ &= \begin{cases} 0 & \text{for } \nu < \mu, \\ \frac{1}{(2\nu-2\mu)!} \, \partial^{2(\nu-\mu)} \big(s^{2n}(y) \big)\big|_{y=0} & \text{for } \nu \ge \mu \, . \end{cases} \end{aligned} \tag{2.7}$$

Consequently, $R\omega = [s^{2n}]_n * \omega$, and setting $\omega(n) = [1/s]_n^{*2n}$ yields

$$R\omega(n) = [s^{2n}]_n * [1/s]_n^{*2n} = [s^{2n}]_n * [1/s^{2n}]_n = [1]_n = e \, . \tag{2.8}$$

The solution is positive for all $n \in \mathbb{N}$ by (1.10) and unique since $\det R = 1$. □

TABLE 2.1
Weights $\omega(n)$ for $n \leq 7$.

n	$\omega_0(n)$	$\omega_1(n)$	$\omega_2(n)$	$\omega_3(n)$	$\omega_4(n)$	$\omega_5(n)$	$\omega_6(n)$
1	1						
2	1	$\frac{1}{6}$					
3	1	$\frac{1}{4}$	$\frac{1}{30}$				
4	1	$\frac{1}{3}$	$\frac{7}{120}$	$\frac{1}{140}$			
5	1	$\frac{5}{12}$	$\frac{13}{144}$	$\frac{41}{3024}$	$\frac{1}{630}$		
6	1	$\frac{1}{2}$	$\frac{31}{240}$	$\frac{139}{6048}$	$\frac{479}{151200}$	$\frac{1}{2772}$	
7	1	$\frac{7}{12}$	$\frac{7}{40}$	$\frac{311}{8640}$	$\frac{37}{6480}$	$\frac{59}{79200}$	$\frac{1}{12012}$

Table 2.1 shows the weights $\omega(n)$ for $n \leq 7$. The result of Theorem 2.1 can be readily generalized to uniform B-splines by scaling.

COROLLARY 2.2. *The sequence $\{B_{j,n,h}, j \in \mathbb{Z}\}$ is orthonormal in $H^{n-1,2}_{\omega(n,h)}(\mathbb{R})$ if and only if*

$$\omega_\mu(n,h) := h^{2\mu-1}\omega_\mu(n)\ . \tag{2.9}$$

3. An application.

A typical application, where the orthonormality of B-splines is of advantage, is the approximation of functions by splines.

THEOREM 3.1. *For $f \in H^{n-1,2}(\mathbb{R})$, consider the approximation problem*

$$\|f-g\|_{\omega(n,h)} \to \min\ , \quad g \in S_{n,h}\ . \tag{3.1}$$

The B-spline coefficients of the solution $Q_h f = \sum_{j\in\mathbb{Z}}(Q_h f)_j B_{j,n,h}$ are given by

$$(Q_h f)_j := (f, B_{j,n,h})_{\omega(n,h)}\ . \tag{3.2}$$

Thus, the projection $Q_h := H^{n-1,2}(\mathbb{R}) \to S_{n,h}$ is local in the sense that $(Q_h f)(x)$ depends only on the restriction of f to the interval $[x-nh, x+nh]$.

Proof. The proof is trivial. □

The approximation error satisfies the following estimates.

THEOREM 3.2. *For $f \in H^{n-1,2}(\mathbb{R}) \cap H^{n,\infty}(\mathbb{R})$ and $k \in [0,\ldots,n-1]$ there exists a constant C depending only on n and k such that*

$$\|\partial^k(f-Q_h f)\|_\infty \leq C\, h^{n-k}\, \|\partial^n f\|_\infty\ . \tag{3.3}$$

Moreover, for $f \in H^{n-1,2}(\mathbb{R})$ and $0 \leq k \leq n-2$,

$$\begin{aligned} \|\partial^k(f-Q_h f)\|_\infty &\leq \Gamma(k,n-1,\omega(n,h))\|f-Q_h f\|_{\omega(n,h)} \\ &= \Gamma(k,n-1,\omega(n,h))\left(\|f\|^2_{\omega(n,h)} - \sum_{j\in\mathbb{Z}} f_j^2\right)^{1/2} \end{aligned} \tag{3.4}$$

with the constant declared in (1.3).

Proof. Let $P_h := C^n(\mathbb{R}) \mapsto S_{n,h}$ be a standard quasi interpolant of order n. Set $\Delta_h := f - P_h f$; then

$$\|\partial^k \Delta_h\|_\infty \leq C_1\, h^{n-k}\|\partial^n f\|_\infty \tag{3.5}$$

with C_1 some constant depending only on n and k (see [4, p. 229]). $S_{n,h}$ is invariant under Q_h (i.e., $Q_h P_h = P_h$), so

$$\begin{aligned} \|\partial^k(f - Q_h f)\|_\infty &= \|\partial^k(\Delta_h - Q_h\Delta_h)\|_\infty \\ &\le C_1\, h^{n-k}\|\partial^n f\|_\infty + \|\partial^k(Q_h\Delta_h)\|_\infty\ . \end{aligned} \tag{3.6}$$

Using $\int_{\mathbb{R}} \partial^\nu B_{j,n,h}(x)\,dx = h^{1-\nu}\int_{\mathbb{R}} \partial^\nu B_{0,n}(x)\,dx$, we obtain for the second summand

$$\begin{aligned} \|\partial^k Q_h\Delta_h\|_\infty &\le \sum_{j\in\mathbb{Z}} |(\Delta_h, B_{j,n,h})_{\omega(n,h)}|\;\|\partial^k B_{j,n,h}\|_\infty \\ &\le h^{-k}\,\|\partial^k B_{0,n}\|_\infty \sup_{j\in\mathbb{Z}} |(\Delta_h, B_{j,n,h})_{\omega(n,h)}| \\ &\le \|\partial^k B_{0,n}\|_\infty \sum_{\nu=0}^{n-1} h^{2\nu-k-1}\,\omega_\nu(n) \sup_{j\in\mathbb{Z}} |\langle\partial^\nu\Delta_h, \partial^\nu B_{j,n,h}\rangle| \\ &\le C_2\, h^{n-k}\,\|\partial^n f\|_\infty\ . \end{aligned} \tag{3.7}$$

The constant C_2 also depends only on n and k; thus, (3.3) holds with $C := C_1 + C_2$. (3.4) is an immediate consequence of (1.3). □

Since $Q_h f$ depends only locally on f, the domain of Q_h can be extended significantly.

Corollary 3.3. *For $f \in H^{n-1,2}_{\text{loc}}(\mathbb{R}) \cap H^{n,\infty}_{\text{loc}}(\mathbb{R})$ (i.e., $f_{|r} \in H^{n-1,2}(r) \cap H^{n,\infty}(r)$ for any compact interval $r \subset \mathbb{R}$), the operator Q_h is well defined by* (3.2)*, and in analogy to* (3.3)*, the estimate*

$$\|\partial^k(f - Q_h f)(x)\| \le C\,h^{n-k}\,\|\partial^n f_{|[x-nh,x+nh]}\|_\infty \tag{3.8}$$

holds for $0 \le k < n$.

The numerical evaluation of (3.2) can be made efficient by using the identity

$$\langle\partial^\mu f, \partial^\mu B_{j,n,h}\rangle = \begin{cases} (-1)^\mu\,\langle f, \partial^{2\mu} B_{j,n,h}\rangle & \text{if } 2\mu < n, \\ (-1)^\mu h n!\,[hj,\dots,h(j+n)]\partial^{2\mu-n} f & \text{if } 2\mu \ge n. \end{cases} \tag{3.9}$$

The benefit is that the derivatives of f have to be evaluated solely at the knots and not at the multitude of arguments required by the quadrature scheme. (3.9) is based on repeated integration by parts. In the second case, the process stops, when the B-spline has been transformed to $\partial^{n-1}B_{j,n,h}$, which is piecewise constant. Thus, the integral can be evaluated and yields the given divided difference. A more detailed proof is not very instructive in this context.

In many applications, approximation is subject to a finite number of linear constraints, say Hermite interpolation at certain points. It turns out that the solution of such a problem is simply obtained by an orthogonal projection of the unconstrained approximant $Q_h f$ on the feasible set.

Theorem 3.4. *For $f \in H^{n-1,2}(\mathbb{R})$, consider the constrained approximation problem*

$$\|f - g\|_{\omega(n,h)} \to \min\ , \quad \Lambda g = \lambda\ , \quad g \in S_{n,h}\ , \tag{3.10}$$

where Λ is a full rank matrix with k absolutely summable bi-infinite rows. The solution $Q_h^\Lambda f = \sum_{j\in\mathbb{Z}} (Q_h^\Lambda f)_j B_{j,n,h}$ is given by

$$(Q_h^\Lambda f) := (Q_h f) - \Lambda^T(\Lambda\Lambda^T)^{-1}(\Lambda\, Q_h f - \lambda)\ . \tag{3.11}$$

Proof. Note that $\Lambda\, Q_h f$ is well defined since $(Q_h f)_j$ is bounded by

$$|(Q_h f)_j| \leq \|B_{j,n,h}\|_{\omega(n,h)} \|f\|_{\omega(n,h)} = \|B_{0,n,h}\|_{\omega(n,h)} \|f\|_{\omega(n,h)} \,. \tag{3.12}$$

Introducing the vector p of Lagrange multipliers, (3.10) is equivalent to

$$Q_h^\Lambda f + \Lambda^T p = Q_h f, \tag{3.13}$$

$$\Lambda\, Q_h^\Lambda f = \lambda \,. \tag{3.14}$$

Multiplication of the first equation by Λ and substitution yields $(\Lambda\Lambda^T)p = \Lambda\, Q_h f - \lambda$. The $k \times k$-matrix $(\Lambda\Lambda^T)$ is invertible; thus (3.11) follows. □

The benefits of approximation in $H^{m,2}_{\omega(n,h)}(\mathbb{R})$ with orthonormal B-splines are evident. First, Q_h is local and can be computed explicitly and efficiently using (3.9). Second, (3.3) indicates that the approximation order of Q_h is optimal. This property is shared by a large family of quasi interpolants, but Q_h stands out due to the fact that it is the best approximation with respect to a reasonable inner product, measuring the total deviation of function values and certain derivatives. Third, (3.4) guarantees that if the approximation is good in $H^{n-1,2}_{\omega(n,h)}(\mathbb{R})$, then the maximum norm of the error is small. This feature is of particular importance in many applications, where the absolute error is required to be smaller than a given tolerance, everywhere. Fourth, constrained approximation simply splits into solving the unconstrained problem and a subsequent projection step.

Acknowledgment. The author thanks Klaus Höllig for helpful comments.

GINZBURG–LANDAU VORTICES: DYNAMICS, PINNING, AND HYSTERESIS [*]

FANG-HUA LIN[†] AND QIANG DU[‡]

Abstract. In this paper, we consider three problems related to the mathematical study of vortex phenomena in superconductivity based on the G–L models. First, we study the long-time behavior of the solutions of the time-dependent Ginzburg–Landau equations. Then we describe results concerning the pinning effect of thin regions in a variable thickness thin film. Finally, we prove the existence of vortex-like solutions to the steady state Ginzburg–Landau equations and study the hysteresis phenomenon near the lower critical field.

Key words. superconductivity, Ginzburg–Landau equations, vortex solution, long-time behavior, vortex pinning, hysteresis

1. Introduction.

Below the critical temperature T_c, the response of a superconducting material to an externally imposed magnetic field is most conveniently described by the diagram given in Figure 1, which shows the minimum energy state of the superconductor as a function of H_0, the applied magnetic field, and the dimensionless material parameter κ (known as the Ginzburg–Landau parameter). The parameter κ determines the type of superconducting material [10]. For $\kappa < \frac{1}{\sqrt{2}}$, type-I superconductors, there is a critical magnetic field H_C below which the material will be the superconducting Meissner state but above which it will be in the normal state. For $\kappa > \frac{1}{\sqrt{2}}$, type-II superconductors, there is a third state known as the mixed (or vortex) state. The vortex state consists of many normal filaments embedded in a superconducting matrix. Each of these filaments carries with it a quantized amount of magnetic flux and is circled by a vortex of superconducting current. Thus, these filaments are often know as vortex lines. One of the most challenging problems to mathematicians working on the superconductivity models is to understand vortex phenomena in type-II superconductors, which include the recently discovered high-temperature superconductors.

The transition from the normal state to the vortex state takes place by a bifurcation as the magnetic field is lowered through some critical value H_{C_2}. The critical field H_{C_1}, on the other hand, is calculated so that at this field the energy of the wholly superconducting solution becomes equal to the energy of the single vortex filament solution for infinite superconductors.

The vortex structures have been studied extensively on the mezoscale by using the well-known Ginzburg–Landau (G–L) models of superconductivity [10, 13, 14]. The existence of vortex-like solutions for the full nonlinear G–L equations has been investigated by researchers using methods ranging from asymptotic analysis to numerical

$\kappa < \frac{1}{\sqrt{2}}$ $\kappa > \frac{1}{\sqrt{2}}$

FIG. 1. *The various states of superconductors.*

simulations; however, it has not been justified by rigorous mathematical analysis. Much progress has been made in recent years [3, 20, 21] to establish a mathematical framework for a rigorous description of both the static and dynamic properties of the vortex solutions; in particular, as the coherence length tends to zero (κ goes to infinity), various results have been obtained. From a technological point of view, this is of interest since recently discovered high critical temperature superconductors are known to have large values of κ, say κ in excess of 50.

Vortex lines may move as a result of internal interactions between these filaments and external forces (due to applied fields or thermal fluctuations) acting on them. Unfortunately, such vortex motion in an applied magnetic field induces an effective electrical resistance in the material and, thus, a loss of superconductivity. Therefore, it is crucial to understand the dynamic of these vortex lines. At the same time, one is interested in studying mechanisms that can pin the vortices at a fixed location, i.e., prevent their motion. Various such mechanisms have been advanced by physicists, engineers, and material scientists. For example, normal (nonsuperconducting) impurities in an otherwise superconducting material sample are believed to provide sites at which vortices are pinned. Likewise, regions of the sample that are thin relative to other regions are also believed to provide pinning sites. These mechanisms have been introduced into the general G–L framework to derive various variants of the original G–L models of superconductivity. Numerical simulation clearly suggests the pinning effect.

In this paper, we deal with three independent problems, yet all of them are related to the study of vortex phenomena. First we study the long-time behavior of the solutions of the time-dependent G–L equations and the main result is Theorem 2.1. Then we describe results (Theorems 3.1–3.5) concerning the pinning effect of thin regions in a variable thickness thin film, based on the models developed in [6, 12], and finally, we prove the existence of vortex-like solutions to the steady state G–L equations (Lemma 4.1) and study the hysteresis phenomenon near the lower critical field.

Before addressing the above problems, we introduce the notation and the models that will be used in the paper. The starting point of our study is the phenomenological model due to Ginzburg and Landau for superconductivity in isotropic, homogeneous material samples. Let Ω be a smooth bounded domain in $\mathbb{R}^3$, occupied by the superconducting material. By ignoring the effect of the region exterior to the sample, the steady state model can be stated as a minimization problem of the free energy functional

$$\begin{aligned}\mathcal{G}(\psi, \mathbf{A}) = \int_\Omega \Bigg\{ & f_n + a|\psi|^2 + \frac{b}{2}|\psi|^4 + \frac{1}{2m_s}\left|\left(i\bar{h}\nabla + \frac{e_s}{c}\mathbf{A}\right)\psi\right|^2 \\ & + \frac{\mu_s}{8\pi}\mathbf{h}\cdot(\mathbf{h} - 2\mathbf{H}_0)\Bigg\}\, d\Omega\,, \end{aligned} \tag{1}$$

where f_n is the free energy density of the nonsuperconducting state in the absence of a magnetic field, ψ is the (complex-valued) superconducting order parameter, $\mathbf{A}$ is the magnetic vector potential, $\mathbf{h} = (1/\mu_s)\text{curl}\mathbf{A}$ is the magnetic field, $\mathbf{H}_0$ is the applied magnetic field, a and b are constants whose values depend on the temperature and such that $b > 0$, e_s is the mass of the superconducting charge carriers which is twice the electronic charge e, c is the speed of light, μ_s is the permeability, and $2\pi\bar{h}$ is Planck's constant. It can be rewritten in nondimensionalized form:

$$\mathcal{G}(\psi, \mathbf{A}) = \int_\Omega \left(\frac{1}{2}(1 - |\psi|^2)^2 + \left|\left(\frac{i}{\kappa}\nabla + \mathbf{A}\right)\psi\right|^2 + |\text{curl}\,\mathbf{A} - \mathbf{H}_0|^2\right) d\mathbf{x}, \tag{2}$$

where κ is the so-called G–L parameter.

The functional $\mathcal{G}(\psi, \mathbf{A})$ has an interesting gauge invariance property and the minimization of $\mathcal{G}$ in appropriate functional spaces gives the following system of nonlinear differential equations that are named the G–L equations:

$$\left(\frac{i}{\kappa}\nabla + \mathbf{A}\right)^2 \psi - \psi + |\psi|^2\psi = 0 \quad \text{in } \Omega, \tag{3}$$

$$\text{curl}\,\text{curl}\,\mathbf{A} = \frac{i}{2\kappa}(\psi\nabla\psi^* - \psi^*\nabla\psi) - |\psi|^2\mathbf{A} \quad \text{in } \Omega, \tag{4}$$

along with natural boundary conditions

$$\text{curl}\,\mathbf{A} \wedge \mathbf{n} = \mathbf{H}_0 \wedge \mathbf{n} \quad \text{on } \partial\Omega \tag{5}$$

and

$$\left(\frac{i}{\kappa}\nabla\psi + \mathbf{A}\psi\right)\cdot\mathbf{n} = 0 \quad \text{on } \partial\Omega, \tag{6}$$

where $\mathbf{n}$ is the exterior normal to the boundary $\partial\Omega$. The G–L vortices are represented by the zeros of the complex order parameter ψ. In section 4, we will prove the existence of vortex solutions to the above system when κ is large and the applied field is near the lower critical field.

Equations (3)–(4) are the steady state G–L equations. The time-dependent G–L model is often described by the Gorkov–Eliashberg evolution equation [17]:

$$\left\{\begin{aligned} & \eta\frac{\partial\psi}{\partial t} + i\,\eta\,\kappa\,\Phi\,\psi + \left(\frac{i}{\kappa}\,\nabla + \mathbf{A}\right)^2 \psi - \psi + |\psi|^2\,\psi = 0, \\ & \frac{\partial\mathbf{A}}{\partial t} + \nabla\Phi + \text{ curl curl } \mathbf{A} = -\frac{i}{2\kappa}\left(\psi^*\,\nabla\psi - \psi\,\nabla\psi^*\right) - \mathbf{A}|\psi|^2. \end{aligned}\right. \tag{7}$$

Here, Φ denotes the (real) scalar electric potential, η is a relaxation parameter, and ψ^* denotes the complex conjugate of ψ. For simplicity, we take $\eta = 1$ in the rest of the paper.

The system is supplemented by the initial and boundary conditions

$$\psi\,(x,0) = \psi_0(x), \quad \mathbf{A}(x,0) = \mathbf{A}_0(x), \qquad x \in \Omega; \tag{8}$$

$$\begin{cases} \left(\dfrac{i}{\kappa}\nabla + \mathbf{A}\right)\psi \cdot \mathbf{n} = 0, \\ \qquad \text{curl}\,\mathbf{A}\ \wedge\ \mathbf{n} = \mathbf{H}_0 \wedge \mathbf{n}, \\ \left(\dfrac{\partial \mathbf{A}}{\partial t} + \nabla\Phi\right)\cdot\ \mathbf{n} = \vec{E}\cdot\mathbf{n}\ =\ 0 \quad \text{on } \partial\Omega. \end{cases} \tag{9}$$

Note that (7) and (9) are gauge invariant [11], in the sense that if $(\psi,\ \mathbf{A},\ \Phi)$ is a solution, then so is $(\psi_\chi,\ \mathbf{A}_\chi,\ \Phi_\chi)$, where

$$\psi_\chi = \psi\, e^{i\,\kappa\,\chi}, \quad \mathbf{A}_\chi = \mathbf{A} + \nabla\chi, \quad \Phi_\chi = \Phi - \frac{\partial\chi}{\partial t}.$$

The dynamics of vortices can be determined from the solutions of the time-dependent equations (7)–(9). The long-time asymptotic behavior of solutions of equations (7)–(9) as $t \to \infty$ will be studied later in section 2.

For type-II superconductors, the minimizers of $\mathcal{G}$ are believed to exhibit vortex structures. Numerical experiments show that for large values of κ and moderate field strength, the number of vortices could be exceedingly large even for a small sample size in actual physical scale. Thus, resolving the vortex phenomenon by using the full G–L equations remains computationally intensive.

Various simplifications have been made to reduce the complexity. For thin films of superconducting material, a two-dimensional model has been developed [6, 12] that can account for thickness variations through an averaging process. The model is given by the following minimization problem:

$$\mathcal{G}^a_\epsilon(\psi) = \int_\Omega a(\mathbf{x})\left(|(\nabla - i\mathbf{A}_0)\psi|^2 + \frac{1}{2\epsilon^2}(1-|\psi|^2)^2\right)d\mathbf{x}, \tag{10}$$

where Ω denotes the platform of the film, $a(\mathbf{x})$ measures the relative thickness of the film, and $\mathbf{A}_0$ is a prescribed vector potential due to the normal (to film) component of the applied field. The role of the Ginzburg–Landau parameter κ is assumed by the parameter $\epsilon(\propto 1/\kappa)$.

It was proved that for fixed ϵ, the minimizers of the above problem, along with the prescribed vector potential $\mathbf{A}_0$, provide the leading order approximation to the solution of the three-dimensional problem [6]. The creation and interaction of vortices based on the above model is connected to the prescribed magnetic potential. The number of vortices cannot be prescribed a priori, independently of $\mathbf{A}_0$. To simplify the analysis further, a simpler problem, in which the number of vortices is prescribed and the magnetic potential is ignored, can be studied. By rescaling the spatial variables, one may consider the minimization of the functional

$$\mathcal{F}^a_\epsilon(\psi) = \int_\Omega a(\mathbf{x})\left(|\nabla\psi|^2 + \frac{1}{2\epsilon^2}(1-|\psi|^2)^2\right)d\mathbf{x} \tag{11}$$

with the boundary condition

$$\psi(\mathbf{x}) = g(\mathbf{x}) \quad \text{for } \mathbf{x} \in \partial\Omega, \tag{12}$$

where g is smooth with $|g(\mathbf{x})| = 1, \mathbf{x} \in \partial\Omega$. This can be viewed as a generalization of the problem studied in [3, 20] in which $a(\mathbf{x}) \equiv 1$, i.e.,

$$\mathcal{F}_\epsilon(\psi) = \int_\Omega \left(|\nabla\psi|^2 + \frac{1}{2\epsilon^2}(1 - |\psi|^2)^2 \right) d\mathbf{x}. \tag{13}$$

The pinning effect of the variable thickness will be studied in section 3 by examining the properties of minimizers of (10) and (11).

The rest of the paper is devoted to the problems we have discussed above.

2. The uniqueness of the asymptotic limit. The global existence and uniqueness (up to gauge transformations) of classical solutions of (7)–(9) have been studied by various authors, e.g., [7, 11, 28]. The dynamics of vortices (including the simpler case which ignores the magnetic field) have been studied by [15, 16, 23, 24, 25] and recently proved in [22]. In [28], the long-time behavior, in particular the existence of the global attractor, is also investigated. Here, we shall sketch the proof of the asymptotic stability result, which shows that, as $t \to \infty$, (7)–(9) has a unique asymptotic limit up to gauge transformations.

As in [11], one may choose the so-called zero electric potential gauge for system (7)–(9). To do so, one must solve

$$\frac{\partial\chi}{\partial t} = \Phi \tag{14}$$

and, at $t = 0$,

$$\Delta\chi = -\operatorname{div}\mathbf{A} \ \text{ in } \Omega \quad \text{with} \quad \nabla\chi \cdot \mathbf{n} = -\mathbf{A}\cdot\mathbf{n} \ \text{ on } \partial\Omega. \tag{15}$$

Thus, in this gauge, $\Phi \equiv 0$ and system (1) reduces to the gradient flow of the energy functional:

$$\begin{aligned} E(\psi, \mathbf{A}) = \tfrac{1}{2}\int_\Omega \Bigg[\left| \left(\frac{i}{\kappa}\nabla + \mathbf{A} \right)\psi \right|^2 + \tfrac{1}{2}\,(|\psi|^2 - 1)^2 \\ + |\operatorname{curl}\mathbf{A} - \mathbf{H}_0|^2 \Bigg] dx. \end{aligned} \tag{16}$$

The initial condition satisfies $\operatorname{div}\mathbf{A}(0) = 0$ and $\mathbf{A}(0)\cdot\mathbf{n} = 0$. Moreover, we make a physically meaningful assumption that $\|\psi(0)\|_\infty \le 1$. Let $v = (\psi, \mathbf{A})$. As shown in [11] and [28], the flow

$$\frac{dv}{dt} = -\ \text{grad}\ \ E(v), \qquad v(0) = v_0, \tag{17}$$

has a global classical solution. Let $\mathbf{V} = \mathcal{H}^2(\Omega) \times \mathbf{H}^2(\Omega)$, where $\mathcal{H}^2(\Omega)$ and $\mathbf{H}^2(\Omega)$ are spaces of functions whose components (or real and imaginary parts) are in the standard Sobolev space $H^2(\Omega)$.

Our main result concerning (17) now follows.

Theorem 2.1.

$$V_\infty = \lim_{t\to\infty} v(t) \qquad \textit{exists in } \mathbf{V}\ .$$

To describe the idea, we start with the ODE

$$\begin{cases} \dfrac{dx}{dt} &= -\text{ grad } f(x), \qquad x \in \mathbb{R}^N \\ x(0) &= x_0 \, . \end{cases} \tag{18}$$

We assume $f \in C^2(\mathbb{R}^N)$, $\nabla \mathrm{f}(0) = 0$, and x_0 is close to 0.

Case (i). If $A = \nabla^2 f(0)$ is positive definite, then $x(t) \to 0$ (at an exponential rate) as $t \to +\infty$.

This result is standard. One can calculate

$$\frac{d}{dt} |\dot{x}|^2 = -2\langle \nabla^2 f(x) \cdot \dot{x}, \ \dot{x} \rangle \leq -2\lambda \, |\dot{x}|^2 \, .$$

Here we shall assume $|x|(t) \leq \delta_0$, and $(\nabla^2 f(x)) \geq \lambda I$ whenever $|x| \leq \delta_0$. Thus $|\dot{x}(t)| \leq |\dot{x}(0)| \, e^{-\lambda t} \quad \forall t \geq 0$ and $|x(t)| \leq |x_0| + \frac{1}{\lambda}|\dot{x}(0)| = |x_0| + \frac{1}{\lambda}|\nabla f(x_0)|$. We shall always assume x_0 is so close to the origin that $|x_0| + \frac{1}{\lambda}|\nabla f(x_0)| < \delta_0$. Then the assumption $|x(t)| \leq \delta_0$ is true for all $t > 0$ and, thus, $x(t) \to 0$ at an exponential rate as $t \to +\infty$.

Case (ii). det $(A) \neq 0$. Then one has that

$$-\frac{d}{dt} \left(f(x) - f(0)\right)^{1/2} = \frac{1}{2} \, \frac{|\nabla f(x)| \ |\dot{x}|}{(f(x) - f(0))^{1/2}}, \quad \text{if } f(x) > f(0), \tag{19}$$

$$\frac{d}{dt} \left(f(0) - f(x)\right)^{1/2} = \frac{1}{2} \, \frac{|\nabla f(x)| \ |\dot{x}|}{|f(x) - f(0)|^{1/2}}, \quad \text{if } f(x) < f(0). \tag{20}$$

We obtain the following: *either* there is a $T \in (0, \infty)$ such that

$$f(x)(T) \leq f(0) - \delta_0 \qquad (\text{for some } \ \delta_0 > 0)$$

or

$$\lim_{t \to +\infty} \ x(t) = x_\infty \quad \text{ exists.}$$

Indeed, if x is close to 0, then

$$\frac{|\nabla f(x)|}{|f(x) - f(0)|^{1/2}} \ \geq \ \frac{\lambda_{\min}}{\sqrt{2\lambda_{\max}}} \ = \ C(A) > 0.$$

Here $\lambda_{\min}$ and $\lambda_{\max}$ are the minimum and maximum, respectively, eigenvalues of $(A^T A)^{1/2}$. Therefore,

$$\int_0^\infty |\dot{x}(t)| \, dt \ \leq \ \frac{2\delta_0^{\,1/2}}{C(A)}$$

by (19)–(20) whenever $f(x)(t) \geq f(0) - \delta_0$ for all $t \geq 0$. In such a case the conclusion $\lim_{t \to +\infty} x(t) = x_\infty$ follows (in fact $x_\infty = 0$) as for Case (i).

Case (iii). det $(A) = 0$ and $f(x)$ is real analytic in B_1. We have the following well-known estimate (cf. [26, 27]). There are two positive constants $\theta_0, \sigma_0 \in (0,1)$ depending on f such that

$$|f(x) - f(0)|^{\theta_0} \ \leq \ |\text{ grad } \ f(x)| \quad \text{whenever } x \in B_{\sigma_0}(0), \tag{21}$$

$\nabla f(0) = 0$. Then, as for Case (ii), one has that *either* there is a $T \in (0, \infty)$ such that

$$f(T) \le f(0) - \delta_0$$

or

$$\lim_{t \to \infty} x(t) = x_\infty \quad \text{exists.}$$

In [27], Simon considered the case

$$E(u) = \int_M F(x, u, \nabla u)\, dx, \tag{22}$$

where M is a compact manifold without boundary and

$$\begin{cases} \dot{u} & = - \text{ grad } \ E(u) \ \equiv \ \mathcal{M}(u), \\ u(0) & = \ u_0 \simeq 0, \qquad \mathcal{M}(0) = 0. \end{cases} \tag{23}$$

Here, F is assumed to be analytic in both u and ∇u for u, ∇u near $\underline{0}$.

Suppose L is elliptic, $Lv = \frac{d}{ds}|_{s=0}\, \mathcal{M}(sv)$. Then *either* there is a $T \in (0, \infty)$ such that

$$E(u(T)) \le E\,(0) - \delta_0 \quad \text{for some } \delta_0 > 0$$

or

$$u_\infty = \lim_{t \to \infty} u(t) \quad \text{exists.}$$

To apply the above idea to the time-dependent G–L equations, we need to use the following estimate given in [11] (also see [28] for similar results).

LEMMA 2.2. *Let $v = (\psi, \mathbf{A})$ be the solution of the time-dependent G–L equations* (17). *Then*

$$\int_t^T \Big[(\dot{\psi}(s), \dot{\psi}(s)) + (\dot{\mathbf{A}}(s), \dot{\mathbf{A}}(s)) \Big]\, ds + E(\psi(T), \mathbf{A}(T)) = E(\psi(t), \mathbf{A}(t)) \tag{24}$$

for any $T > t > 0$.

The following lemma will enable us to apply the above conclusion of Simon.

LEMMA 2.3. *Let $(\psi, \mathbf{A})$ satisfy*

$$\operatorname{curl} \mathbf{A} \wedge \mathbf{n} = \mathbf{H}_0 \wedge \mathbf{n}\,, \quad \mathbf{A} \cdot \mathbf{n} = 0, \quad \textit{and} \quad \nabla\psi \cdot \mathbf{n} = 0 \quad \textit{on } \partial\Omega.$$

Let $E(\psi, \mathbf{A})$ be defined by (16) *and $(\psi_*, \mathbf{A}_*)$ be a steady state solution of the G–L equations in the gauge $\operatorname{div} \mathbf{A}_* = 0$ in Ω and $\mathbf{A}_* \cdot \mathbf{n} = 0$ on $\partial\Omega$. Then there exist constants $\theta_0, \sigma_0 \in (0, 1)$ such that*

$$|E(\psi, \mathbf{A}) - E(\psi_*, \mathbf{A}_*)|^{\theta_0} \le \| \text{ grad } \ E(\psi, \mathbf{A})\|_{L^2(\Omega)} \tag{25}$$

for any $\|(\psi, \mathbf{A}) - (\psi_*, \mathbf{A}_*)\|_{C^2(\Omega)} \le \sigma_0$.

Proof. Let

$$G\,(\psi,\, \mathbf{A}) = E\,(\psi,\, \mathbf{A}) + \tfrac{1}{2} \int_\Omega \big[|\operatorname{div} \mathbf{A}|^2 \,\big] \, dx. \tag{26}$$

By assumption, since $(\psi_*, \mathbf{A}_*)$ is a steady state solution of the G–L equations in the gauge $\operatorname{div} \mathbf{A}_* = 0$ in Ω and $\mathbf{A}_* \cdot \mathbf{n} = 0$ on $\partial\Omega$, then

$$G\left(\psi_*,\, \mathbf{A}_*\right) = E\left(\psi_*,\, \mathbf{A}_*\right) \tag{27}$$

and $(\psi_*, \mathbf{A}_*)$ remains a critical point of G. By the ellipticity of grad $G(\psi, \mathbf{A})$, see [7, 11, 28], we may apply the result of [27] to conclude that there exist constants $\theta_0, \sigma_1 \in (0,1)$ such that

$$|G(\psi,\, \mathbf{A}) - G(\psi_*, \mathbf{A}_*)|^{\theta_0} \le \|\text{ grad } \quad G\left(\psi,\, \mathbf{A}\right)\|_{L^2(\Omega)} \tag{28}$$

for any $\|(\psi, \mathbf{A}) - (\psi_*, \mathbf{A}_*)\|_{C^2(\Omega)} \le \sigma_1$.

Let χ be a gauge transformation function and $\tilde{\psi} = e^{i\kappa\chi}\psi$ with $\tilde{\mathbf{A}} = \mathbf{A} + \nabla\chi$. Let us choose χ such that $\operatorname{div} \tilde{\mathbf{A}} = 0$. Simple calculation shows that

$$\frac{\partial G}{\partial \tilde{\psi}} = e^{i\kappa\chi}\frac{\partial E}{\partial \psi} \qquad \text{and} \qquad \frac{\partial G}{\partial \tilde{\mathbf{A}}} = \frac{\partial E}{\partial \mathbf{A}}.$$

So,

$$\|\text{ grad } \ E(\psi, \mathbf{A})\|_{L^2(\Omega)} = \|\text{ grad } \ G(\tilde{\psi}, \tilde{\mathbf{A}})\|_{L^2(\Omega)}\ .$$

Since $\operatorname{div} \mathbf{A}_* = 0$ for small enough σ_0, if $\|(\psi, \mathbf{A}) - (\psi_*, \mathbf{A}_*)\|_{C^2(\Omega)} \le \sigma_0$, we have $\|(\tilde{\psi}, \tilde{\mathbf{A}}) - (\psi_*, \mathbf{A}_*)\|_{C^2(\Omega)} \le \sigma_1$. Thus,

$$\begin{aligned}
|E(\psi, \mathbf{A}) - E(\psi_*, \mathbf{A}_*)|^{\theta_0} &= |E(\tilde{\psi}, \tilde{\mathbf{A}}) - G(\psi_*, \mathbf{A}_*)|^{\theta_0} \\
&= |G(\tilde{\psi}, \tilde{\mathbf{A}}) - G(\psi_*, \mathbf{A}_*)|^{\theta_0} \\
&\le \|\text{ grad } \quad G\,(\tilde{\psi},\, \tilde{\mathbf{A}})\|_{L^2(\Omega)} \\
&= \|\text{ grad } \quad E(\psi, \mathbf{A})\|_{L^2(\Omega).}
\end{aligned}$$

This proves the lemma.

We now turn to the proof of Theorem 2.1. It is important to observe that both the energy functional and inequality in Lemma 2.3 are gauge invariant.

By Lemma 2.2, given any $\epsilon > 0$, there exists a sufficiently large time t_n such that

$$\|\dot{\psi}(t_n)\|_{L^2(\Omega)} < \epsilon, \tag{29}$$

$$\|\dot{\mathbf{A}}(t_n)\|_{L^2(\Omega)} < \epsilon, \tag{30}$$

and

$$\int_{t_n}^{T} \left[\|\dot{\psi}(s)\|^2_{L^2(\Omega)} + \|\dot{\mathbf{A}}(s)\|^2_{L^2(\Omega)}\right] ds < \epsilon \quad \forall\, T > t_n. \tag{31}$$

By gauge invariance, one may define a gauge transformation function $\tilde{\chi}(t_n)$ such that $\tilde{\psi}(t_n) = e^{i\kappa\tilde{\chi}(t_n)}\psi(t_n)$ and $\tilde{\mathbf{A}}(t_n) = \mathbf{A}(t_n) + \nabla\tilde{\chi}(t_n)$ and

$$\operatorname{div} \tilde{\mathbf{A}}(t_n) = 0 \quad \text{in } \Omega,$$

$$\tilde{\mathbf{A}}(t_n) \cdot \mathbf{n} = 0 \quad \text{on } \partial\Omega\ .$$

We note that $\tilde{\psi}(t) = e^{i\kappa\tilde{\chi}(t_n)}\psi(t)$ and $\tilde{\mathbf{A}}(t) = \mathbf{A}(t) + \nabla\tilde{\chi}(t_n)$ are again solutions of the time-dependent G–L equations in the zero electric potential gauge with properly modified initial conditions and equation (24) still holds. Also,

$$\|\dot{\tilde{\psi}}(t_n)\|_{L^2(\Omega)} < \epsilon \quad \text{and} \quad \|\dot{\tilde{\mathbf{A}}}(t_n)\|_{L^2(\Omega)} < \epsilon$$

and

$$\int_{t_n}^{T} \left[\|\dot{\tilde{\psi}}(s)\|^2_{L^2(\Omega)} + \|\dot{\tilde{\mathbf{A}}}(s)\|^2_{L^2(\Omega)}\right] ds < \epsilon \quad \forall\, T > t_n$$

remain valid. To apply Lemma 2.3, we must construct solutions that are $C^2(\Omega)$ close to some steady state for some time $\tilde{t_n} \in [t_n, t_n + 1]$. To get the C^2 closeness, we use another gauge transformation $\bar{\psi}(t) = e^{i\kappa\bar{\chi}(t)}\tilde{\psi}(t)$ and $\bar{\mathbf{A}}(t) = \tilde{\mathbf{A}}(t) + \nabla\bar{\chi}(t)$, where $\bar{\chi}$ is defined by

$$\frac{\partial\bar{\chi}}{\partial t} - \Delta\bar{\chi} = \operatorname{div}\tilde{\mathbf{A}} \quad \text{in} \;\; \Omega$$

with boundary condition

$$\frac{\partial\bar{\chi}}{\partial\mathbf{n}} = -\tilde{\mathbf{A}}\cdot\mathbf{n} = 0 \quad \text{on } \partial\Omega$$

and initial condition at $t = t_n$: $\bar{\chi}(t_n) = 0$.

Note that from the G–L equations (7)–(9), we may get [11]

$$\operatorname{div}\dot{\tilde{\mathbf{A}}} = -\frac{i}{2}\kappa\left[\tilde{\psi}\frac{\partial\psi^*}{\partial t} - \tilde{\psi}^*\frac{\partial\psi}{\partial t}\right].$$

Thus, we have

$$\int_{t_n}^{t_n+1}\left[\|\dot{\tilde{\mathbf{A}}}(s)\|^2_{L^2(\Omega)}\right] ds < c\epsilon$$

for some generic constant c. From this, we may get

$$\int_{t_n}^{t_n+1}\left[\|\nabla\dot{\bar{\chi}}(s)\|^2_{L^2(\Omega)}\right] ds < c\epsilon.$$

This further implies that

$$\int_{t_n}^{t_n+1}\left[\|\Delta\bar{\chi}(s)\|^2_{L^2(\Omega)} + \|\dot{\bar{\chi}}(s)\|^2_{L^2(\Omega)}\right] ds < c\epsilon.$$

It follows that $(\bar{\psi}, \bar{\mathbf{A}})$ also satisfies estimates similar to those in equations (29)–(31). Notice that $(\bar{\psi}, \bar{\mathbf{A}})$ is a solution of the time-dependent G–L equations in the gauge $\Phi = -\operatorname{div}\mathbf{A}$ and it satisfies a parabolic system:

$$(32) \qquad \left\{ \begin{aligned} &\frac{\partial\bar{\psi}}{\partial t} - i\,\kappa\operatorname{div}\bar{\mathbf{A}}\,\bar{\psi} + \left(\frac{i}{\kappa}\nabla + \bar{\mathbf{A}}\right)^2\bar{\psi} - \bar{\psi} + |\bar{\psi}|^2\,\bar{\psi} = 0, \\ &\frac{\partial\bar{\mathbf{A}}}{\partial t} - \Delta\bar{\mathbf{A}} = -\frac{i}{2\kappa}\left(\bar{\psi}^*\,\nabla\bar{\psi} - \bar{\psi}\,\nabla\bar{\psi}^*\right) - \bar{\mathbf{A}}|\bar{\psi}|^2 \end{aligned} \right.$$

with boundary conditions

$$\operatorname{curl} \bar{\mathbf{A}} \wedge \mathbf{n} = \mathbf{H}_0 \wedge \mathbf{n} \,, \quad \bar{\mathbf{A}} \cdot \mathbf{n} = 0, \quad \text{and} \quad \nabla \bar{\psi} \cdot \mathbf{n} = 0 \quad \text{on } \partial\Omega.$$

Using standard parabolic regularity and estimates like (29)–(31) for $(\bar{\psi}, \bar{\mathbf{A}})$, we may find a small $\delta_0 > 0$ such that for all $\delta_0 < \delta < 1$, we have

$$\|\dot{\bar{\psi}}(t_n+\delta)\|_{C^2(\Omega)} < c\epsilon \quad \text{and} \quad \|\dot{\bar{\mathbf{A}}}(t_n+\delta)\|_{C^2(\Omega)} < c\epsilon$$

and

$$\|\operatorname{div} \bar{\mathbf{A}}(t_n+\delta)\|_{C^1(\Omega)} < c\epsilon$$

for some constant c. Thus, we may conclude that in $C^2(\Omega)$, $(\bar{\psi}(t_n+\delta), \bar{\mathbf{A}}(t_n+\delta))$ is close to some solution $(\bar{\psi}_\infty, \bar{\mathbf{A}}_\infty)$ of the steady state G–L equations with $\operatorname{div} \bar{\mathbf{A}}_\infty = 0$. Now, by Lemma 2.3, we get

$$\begin{aligned} &\left|E(\bar{\psi}(t_n+\delta), \bar{\mathbf{A}}(t_n+\delta)) - E(\bar{\psi}_\infty, \bar{\mathbf{A}}_\infty)\right|^{\theta_0} \\ &\quad \le \| \text{ grad } \quad E(\bar{\psi}(t_n+\delta), \bar{\mathbf{A}}(t_n+\delta))\|_{L^2(\Omega)} \,. \end{aligned}$$

Using the gauge invariance, however, this also implies that

$$\begin{aligned} &\left|E(\psi(t_n+\delta), \mathbf{A}(t_n+\delta)) - E(\bar{\psi}_\infty, \bar{\mathbf{A}}_\infty)\right|^{\theta_0} \\ &\quad \le \| \text{ grad } \quad E(\psi(t_n+\delta), \mathbf{A}(t_n+\delta))\|_{L^2(\Omega)} \,. \end{aligned}$$

Since $(\bar{\psi}(t_n+\delta), \bar{\mathbf{A}}(t_n+\delta))$ is C^2 close to $(\bar{\psi}_\infty, \bar{\mathbf{A}}_\infty)$, we have

$$\begin{aligned} &\left|E(\psi(t_n+\delta), \mathbf{A}(t_n+\delta)) - E(\bar{\psi}_\infty, \bar{\mathbf{A}}_\infty)\right| \\ &\quad = \left|E(\bar{\psi}(t_n+\delta), \bar{\mathbf{A}}(t_n+\delta)) - E(\bar{\psi}_\infty, \bar{\mathbf{A}}_\infty)\right| \\ &\quad \le c\epsilon \,. \end{aligned}$$

By the monotonicity of $E(\psi(t), \mathbf{A}(t))$, we have that for any T, there exists t_n large enough such that

$$\begin{aligned} &E(\psi(T), \mathbf{A}(T)) - E(\bar{\psi}_\infty, \bar{\mathbf{A}}_\infty) \\ &\quad \ge E(\psi(t_n+\delta), \mathbf{A}(t_n+\delta)) - E(\bar{\psi}_\infty, \bar{\mathbf{A}}_\infty) \\ &\quad \ge c\epsilon \end{aligned}$$

for some generic constant c. Using the ideas given in Case (iii) for ODEs, we conclude that

$$\int_T^\infty \left[\|\dot{\bar{\psi}}(s)\|_{L^2(\Omega)} + \|\dot{\bar{\mathbf{A}}}(s)\|_{L^2(\Omega)}\right] ds < c\epsilon.$$

Thus, we must have that

$$V_\infty = \lim_{t\to\infty} \; v(t) \quad \text{exists in } \mathbf{V}.$$

This concludes the proof of the Theorem 2.1.

3. The pinning effect of variable thickness in thin films. In the previous section, we were concerned with the dynamic properties of solutions to the time-dependent G–L equations. In this section, we focus our attention on the static case. In particular, we illustrate that the vortices may be pinned by inhomogeneities inside the material. The inhomogeneities we consider here are introduced due to the variation in thickness of the sample. During our writing, we also became aware of independent works [9, 1, 18] on the same subject; thus, we only give a brief outline here of the approach we have used.

3.1. The Dirichlet case. To present the main idea, we first ignore the magnetic potential and consider

$$\begin{aligned} &\min\{\mathcal{F}^a_\epsilon(\psi)\ ,\ \psi|_{\partial\Omega}=g\ \} \\ &\quad = \min\left\{ \int_\Omega a(\mathbf{x}) \left(\frac{1}{2}\left|\nabla\psi\right|^2 + \frac{1}{4\epsilon^2}(1-|\psi|^2)^2 \right) d\mathbf{x}\ ,\ \ \psi|_{\partial\Omega}=g\ \right\}\ . \end{aligned} \tag{33}$$

For convenience, we assume that Ω is a bounded, smooth (say Lipschitz) domain in $\mathbb{R}^2$. We may also view ψ as a map from Ω to $\mathbb{R}^2$ and g as a smooth map from $\partial\Omega$ to $\mathbf{S}^1$ with $deg(g,\partial\Omega)=d(\geq 0)$. The coefficient a is a smooth (say Lipschitz or Hölder) function from Ω to $\mathbb{R}^R$ with $0<m\leq a(\mathbf{x})\leq M$ for all $\mathbf{x}\in\bar{\Omega}$. The minimizers of functional $\mathcal{F}^a_\epsilon$ satisfy

$$\operatorname{div}\left(a(\mathbf{x})\nabla\psi(\mathbf{x})\right) + \frac{a(\mathbf{x})}{\epsilon^2}(1-|\psi(\mathbf{x})|^2)\psi(\mathbf{x}) = 0 \quad \text{in } \Omega. \tag{34}$$

First of all, let us consider the case where, in Ω, there are at least d distinct points $\mathbf{b}_1,\ldots,\mathbf{b}_d,\ldots,\mathbf{b}_k$ with $a(\mathbf{b}_j)=m, j=1,2,\ldots,k$. Moreover, we assume that each $\mathbf{b}_j$ is a strict minimum, that is, $a(\mathbf{x})>m$ for any $\mathbf{x}\neq\mathbf{b}_j$ in a small neighborhood of $\mathbf{b}_j$. We define

$$\delta_0 = \frac{1}{2}\min\{|\mathbf{b}_j-\mathbf{b}_i|, dist(\mathbf{b}_j,\partial\Omega); j\neq i\ ,\ i,j=1,\ldots,k\} > 0. \tag{35}$$

THEOREM 3.1. *Let ψ_{ϵ_n}, $\epsilon_n \searrow 0$, be a sequence of minimizers of* (33). *Then*

$$\psi_{\epsilon_n}(\mathbf{x}) \to \psi^*(\mathbf{x}) \qquad in\ C^{1,\alpha}_{\text{loc}}\left(\overline{\Omega}/\{\mathbf{b}_1,\ldots,\mathbf{b}_d\}\right), \tag{36}$$

where

$$\psi^*(\mathbf{x}) = \prod_{j=1}^{d} \frac{\mathbf{x}-\mathbf{b}_j}{|\mathbf{x}-\mathbf{b}_j|} e^{ih^*(\mathbf{x})} \qquad in\ \Omega \tag{37}$$

and $\mathbf{b}_1,\ldots,\mathbf{b}_d$ are d distinct points in Ω with

$$a(\mathbf{b}_j) = m = \min_{\mathbf{x}\in\bar{\Omega}} a(\mathbf{x})\ . \tag{38}$$

Moreover, if we write $\psi^*(\mathbf{x}) = e^{i(\Theta(\mathbf{x})+h^*(\mathbf{x}))}$, then $h^*\in H^1(\Omega)\cap C^\alpha(\bar{\Omega})$, $\psi^*=g$ on $\partial\Omega$ and

$$\operatorname{div}\ [a(\mathbf{x})(\nabla\Theta+\nabla h^*)] = 0 \qquad in\ \ \Omega/\{\mathbf{b}_1,\ldots,\mathbf{b}_d\}. \tag{39}$$

The proof of the above theorem is based on a series of estimates as similarly presented in an earlier work [20]. One first has the energy upper bound

$$\min\{\mathcal{F}_\epsilon^a(\psi),\ \ \psi|_{\partial\Omega}=g\ \}\le m\pi d\log\frac{1}{\epsilon}+C(a,g,\Omega)$$

and energy lower bound

$$\min\left\{\int_B a(\mathbf{x})\left(\frac{1}{2}|\nabla\psi|^2+\frac{1}{4\epsilon^2}(1-|\psi|^2)^2\right)d\mathbf{x},\ \ \psi|_{\partial B}=g\ ,\ |g|\le 1\right\}$$
$$\ge m\pi d\log\frac{1}{\epsilon}-C(K), \tag{40}$$

where $m=\min_{\mathbf{x}\in B}a(\mathbf{x})$ if $deg(g,\partial B)\neq 0$. Now, the class $S_g(\lambda,K)$ may be defined as in [20].

Definition 3.2. *Let Ω, g be given as before. We say a map $u:\Omega\to\mathbb{R}^2$ belongs to the class $S_g(\lambda,K)$ if*

(i) $\mathcal{F}_\epsilon(u)\le m\pi d\log\frac{1}{\epsilon}+K$.

(ii) *for any* $\mathbf{x}\in\{\mathbf{x}\in\Omega,|u(\mathbf{x})|\le\frac{1}{2}\}$, $B_{\lambda\epsilon}(\mathbf{x})\cap\Omega\subset\{|u(\mathbf{x})|\le\frac{3}{4}\}$.

Then one can show that if ψ minimizes (33), there exists some positive constants λ,K such that $\psi\in S_g(\lambda,K)$.

One may then show that there are exactly d balls, say $B_1,\dots,B_d$, with $\mathbf{x}_1^\epsilon,\dots,\mathbf{x}_d^\epsilon$ their centers, such that the corresponding $d_j=deg(u,\partial B_j)=1$ and

$$\min\{|\mathbf{x}_j^\epsilon-\mathbf{x}_k^\epsilon|,dist(\mathbf{x}_j^\epsilon,\partial\Omega);j,k=1,\dots,d,j\neq k\ \}\ge\delta_1(\lambda,K)>0.$$

After extracting a subsequence, we have

$$\mathbf{x}_j^{\epsilon_n}\to\mathbf{x}_j^*\quad\text{as }\epsilon_n\to 0.$$

The limits $\{\mathbf{x}_j^*\}$ are all different points; moreover, $a(\mathbf{x}_j^*)=m,\ j=1,2,\dots,d$. Combining with estimates away from vortices, the proof now follows similarly to that in [3, 20].

In the following, we briefly discuss the case when the number of minima is less than the degree of the boundary data. For simplicity, we focus on the case where Ω is the unit disc B in $\mathbb{R}^2$ and $g(\theta)=e^{id\theta}$ for some positive integer $d\ge 2$. Let $a(x,y)=1+r^2,r^2=x^2+y^2$. We consider

$$E_B=\min\left\{\mathcal{F}_{\epsilon,B}^a(\psi)=\int_B\left(\frac{a}{2}|\nabla\psi|^2+\frac{a}{4\epsilon^2}(1-|\psi|^2)^2\right)dxdy,\right.$$
$$\left.\psi|_{\partial\Omega}=g\right\}. \tag{41}$$

Theorem 3.3. *Let ψ_ϵ be a sequence of minimizers of* (41) *as $\epsilon\to 0$. Then all vortices of the ψ must be separated and of degree $+1$ for small enough $\epsilon>0$ and they go to the origin as $\epsilon\to 0$.*

Proof. Indeed, for any small parameter $\delta>0$ (say $\delta<1/d$), one may choose $\epsilon\le\epsilon(\delta)$ and ψ with $\psi|_{\partial\Omega}=g$ and vortices placed along $\partial B_{\delta/2}$ such that

$$E_B\le\mathcal{F}_{\epsilon,B}^a(\psi)\le\pi d(1+\delta^2)\log\frac{\delta}{\epsilon}+\pi d^2\log\frac{1}{\delta}+c_0d^2$$
$$=\pi d(1+\delta^2)\log\frac{1}{\epsilon}+\{\pi d^2-\pi d(1+\delta^2)\}\log\frac{1}{\delta}+c_0d^2\ .$$

On the other hand, if there are either vortices of degree no less than 2 or vortices outside $B_{\sqrt{\delta}}(0)$, then by [3],

$$\mathcal{F}^a_{\epsilon,B}(\psi) \geq \pi(d + d\delta)\log\frac{1}{\epsilon} + c(\delta, d)\ .$$

For $\delta > 0$ and $\epsilon \to 0$, since $\pi(d + d\delta)\log\frac{1}{\epsilon} + c(\delta, d)$, one sees that all vortices of the minimizer must go to the origin and be of degree $+1$.

The next question is for given d (say $2 \leq d \leq 5$) and $\epsilon > 0$ (but small): How close must these vortices be to the origin? We want to show that they cannot be too close.

Indeed, for a small generic constant β, if all vortices of ψ are in the β-neighborhood of the origin, then

$$\int_{B_\beta(0)} (1 + r^2)\left(\frac{1}{2}|\nabla\psi|^2 + \frac{1}{4\epsilon^2}(1 - |\psi|^2)^2\right) dxdy \geq \pi d \log\frac{\beta}{\epsilon} - c_0 d^2$$

and

$$\int_{B\setminus B_\beta(0)} (1 + r^2)\left(\frac{1}{2}|\nabla\psi|^2 + \frac{1}{4\epsilon^2}(1 - |\psi|^2)^2\right) dxdy \geq \pi d^2 \log\frac{1}{\beta}\ .$$

So,

$$\mathcal{F}^a_{\epsilon,B}(\psi) \geq \pi d \log\frac{1}{\epsilon} + \pi d(d-1)\log\frac{1}{\beta} - c_0 d^2.$$

On the other hand, by placing vortices along $\partial B_{\delta/2}(0)$, one may construct a map with energy

$$\mathcal{F}^a_{\epsilon,B}(\psi) \leq \pi d(1 + \delta^2)\log\frac{1}{\epsilon} + \pi d(d - 1 - \delta^2)\log\frac{1}{\delta} + c_0 d^2\ .$$

Comparing the two bounds, we see that not all vortices are in the δ-neighborhood of the origin if we have

$$\pi d(d-1)\log\frac{\delta}{\beta} \geq 2c_0 d^2 + \pi d\delta^2 \log\frac{1}{\epsilon}\ .$$

By taking $\beta \leq \delta^2$, this means

$$\pi d(d-1)\log\frac{1}{\delta} - \pi d\delta^2\log\frac{1}{\epsilon} \geq 2c_0 d^2\ .$$

Again, letting $\log\frac{1}{\delta} \geq 2c_0$, it is sufficient to have

$$\frac{d-1}{2}\log\frac{1}{\delta} \geq \delta^2 \log\frac{1}{\epsilon}\ ,$$

or

$$\epsilon \geq \delta^{\frac{d-1}{2\delta^2}}\ .$$

Thus, for small but positive ϵ, δ cannot be too small.

We have performed a series of numerical experiments to illustrate the pinning effect even for modest values of ϵ. The numerical methods used here are similar to

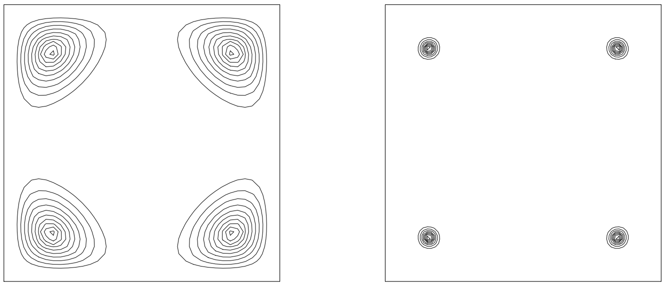

Fig. 2. *Contour plots of the magnitude of the order parameter for a model with constant thickness. The left-hand figure is for $\epsilon = .1$. The right-hand figure is for $\epsilon = .02$.*

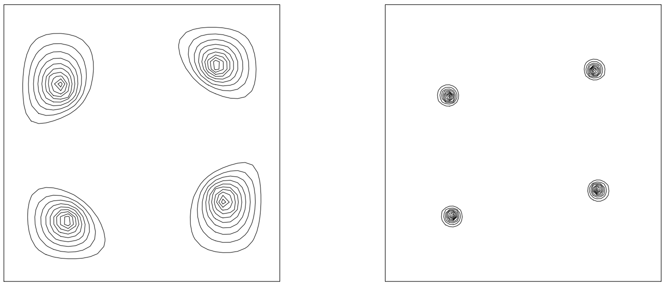

Fig. 3. *Contour plots of the magnitude of the order parameter for a model with variable thickness $a = a(x, y)$. The left-hand figure is for $\epsilon = .1$. The right-hand figure is for $\epsilon = .02$.*

those discussed in [13, 14]. For computational convenience, the unit square $[0, 1]^2$ is taken to be our sample Ω. In the first experiment, we choose the thickness function $a \equiv 1$. We solve for the minimizer of (33) by using the Dirichlet boundary conditions with $|\psi| = 1$ on the boundary. $\psi|_{\partial\Omega}$ has a winding number 4. The contour plots of the magnitude of the order parameter ψ are given in Figure 2.

Next, we choose the thickness function $a = a(x, y)$ such that it has four minima at $(0.25, 0.25), (0.75, 0.35), (0.25, 0.65), (0.75, 0.75)$ with the same minimum value. The contour plots are given in Figure 3. We see that as ϵ gets smaller, the vortices get "pinned" at the minima of a. This is the case illustrated by Theorem 3.1.

Now, we continue the numerical experiments again using the Dirichlet boundary conditions with $|\psi| = 1$ on the boundary. However, we impose the boundary condition such that $\psi|_{\partial\Omega}$ has a winding number 3. We first choose the thickness function $a = a(x, y)$ such that it has four minima at $(0.25, 0.25), (0.25, 0.65), (0.75, 0.35), (0.75, 0.75)$ with the same minimum value. The contour plots are given in Figure 4. Since the number of minima is larger than the winding number, each vortex gets pinned to a different minimum point.

Then, we change the thickness function $a = a(x, y)$ such that it has two minima at $(0.25, 0.65), (0.75, 0.35)$ with the same minimum value. The contour plots are given in Figure 5. Since the number of minima is less than the winding number, one vortex gets pinned at one minimum but the other two get attracted to another minimum with some distance still between them.

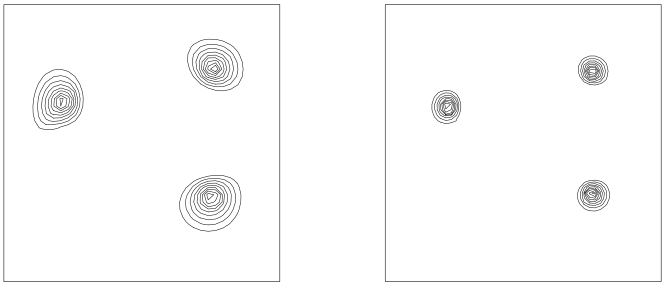

FIG. 4. *Contour plots of the magnitude of the order parameter for a model with variable thickness $a = a(x, y)$. The left-hand figure is for $\epsilon = .08$. The right-hand figure is for $\epsilon = .04$.*

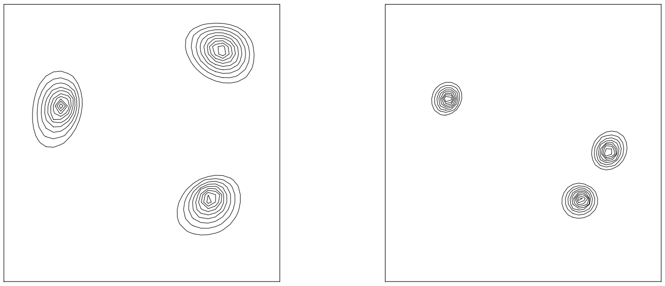

FIG. 5. *Contour plots of the magnitude of the order parameter for a model with variable thickness $a = a(x, y)$. The left-hand figure is for $\epsilon = .08$. The right-hand figure is for $\epsilon = .04$.*

For comparison purposes, we also give the pictures when choosing the thickness function $a \equiv 1$. The contour plots are given in Figure 6.

Finally, we present an experiment on the co-existence of vortex–antivortex solutions to the minimizers of (33) with constant thickness functions. This question has been rigorously studied in [22]. We again use the Dirichlet boundary conditions with $|\psi| = 1$ on the boundary. $\psi|_{\partial\Omega}$ has a winding number 0. Here, we start with a vortex state that has a vortex with winding number $+1$ on one side of the domain and a vortex with winding number -1 on the other side of the domain. We numerically follow the gradient flow of (33). The solution reaches steady state which again consists of two vortices with opposite winding numbers. The contour plots of the magnitude of the steady state solution ψ are given in Figure 7.

3.2. The Neumann problem. We now study the minimization problem with Neumann-type boundary conditions. Let $a(\mathbf{x})$ have a strict local minimum at points $\mathbf{b}_1, \ldots, \mathbf{b}_d$ with $a(\mathbf{b}_j) = m$, $j = 1, \ldots, d$. Recall that

$$\delta_0 = \frac{1}{2} \min\{|\mathbf{b}_j - \mathbf{b}_k|, dist(\mathbf{b}_j, \partial\Omega); j \neq k, \;\; j, k = 1, \ldots, d\} > 0.$$

Let $r_0 < \delta_0$, $\Omega_0 = \Omega \setminus \bigcup_{i=1}^{d} B_{r_0}(\mathbf{b}_i)$ and define

$$V = \Bigg\{ u \in H^1(\Omega) \mid \;\; |u| \geq \frac{1}{2} \;\text{ in } \Omega_0,$$

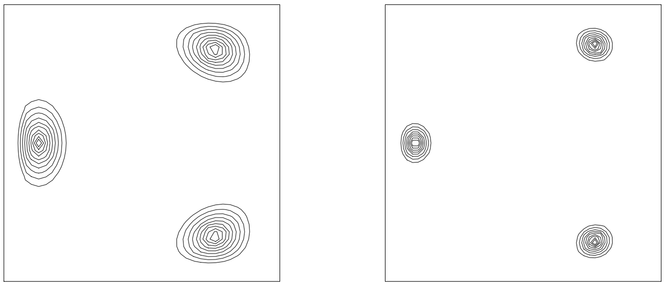

FIG. 6. *Contour plots of the magnitude of the order parameter for a model with constant thickness. The left-hand figure is for* $\epsilon = .08$. *The right-hand figure is for* $\epsilon = .04$.

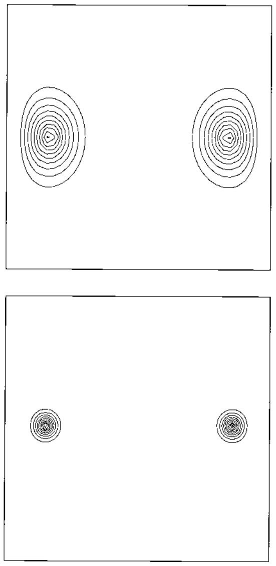

FIG. 7. *Contour plots of the magnitude of the order parameter. The top figure is for* $\epsilon = .08$. *The bottom figure is for* $\epsilon = .03$.

$$deg\left(\frac{u}{|u|}, \partial B_{r_0}(\mathbf{b}_k)\right) = 1\ ,\ 1 \le k \le d.\Big\}\ . \tag{42}$$

We consider

$$\begin{aligned} &\min\{\mathcal{F}^a_\epsilon(\psi)\ ,\ \psi \in V\ \} \\ &= \min\left\{\int_\Omega a(\mathbf{x})\left(\frac{1}{2}\left|\nabla\psi\right|^2 + \frac{1}{4\epsilon^2}(1-|\psi|^2)^2\right)d\mathbf{x}\ ,\ \ \psi \in V\ \right\}\ . \end{aligned} \tag{43}$$

It is easy to see that V is a weakly closed subset of $H^1(\Omega)$. In fact, it is also connected. For given $\epsilon > 0$, (43) has at least one minimizer, denoted by ψ_ϵ.

THEOREM 3.4. *Let* ψ_{ϵ_n}, $\epsilon_n \searrow 0$, *be a sequence of minimizers of* (43). *Then,*

$$\psi_{\epsilon_n}(\mathbf{x}) \to \psi^*(\mathbf{x}) \qquad in\ C^{1,\alpha}_{\text{loc}}\left(\overline{\Omega}/\{\mathbf{b}_1, \ldots, \mathbf{b}_d\}\right),$$

where

$$\psi^*(\mathbf{x}) = \prod_{j=1}^{d} \frac{\mathbf{x}-\mathbf{b}_j}{|\mathbf{x}-\mathbf{b}_j|} e^{ih^*(\mathbf{x})} \qquad \text{in } \Omega.$$

Moreover, if we write $\psi^*(\mathbf{x}) = e^{i(\Theta(\mathbf{x})+h^*(\mathbf{x}))}$, *then* $h^* \in H^1(\Omega) \cap C^\alpha(\bar{\Omega})$, $\frac{\partial \phi^*}{\partial n} = 0$ *on* $\partial\Omega$ *and*

$$\operatorname{div}\,[a(\mathbf{x})(\nabla\Theta + \nabla h^*)] = 0 \qquad \text{in} \quad \Omega/\{\mathbf{b}_1, \ldots, \mathbf{b}_d\}.$$

The proof follows from constructions similar to those outlined in section 3.1.

3.3. Problems with prescribed magnetic potential. Unlike bulk material, in the thin film limit, superconductors of type-I and type-II display vortex-like structure. It has been shown that the G–L functional takes the special form

$$\mathcal{F}(\psi) = \int_\Omega a(\mathbf{x}) \left(\frac{1}{2} \left| i\nabla\psi + A_0(\mathbf{x})\psi \right|^2 + (1-|\psi|^2)^2 \right) d\mathbf{x},$$

where $a(\mathbf{x})$ represents the relative thickness distribution of the thin film. Since, to leading order, the magnetic field penetrates the film uniformly, we get A_0 to be a given magnetic potential that can be prescribed by setting $\operatorname{curl} A_0(\mathbf{x}) = H$.

Numerical simulation in [6, 14] suggests that the thickness variation provides a pinning mechanism for vortices. Using techniques similar to those in section 3.1, we now provide a rigorous analysis for such phenomena in the case where κ is large while the magnetic field is weak ($H \approx \kappa^{-1}$). By a proper scaling of the free energy, we get a functional of the form

$$\mathcal{F}^a_\epsilon(\psi) = \int_\Omega a(\mathbf{x}) \left(\frac{1}{2} \left| \nabla\psi - iA_0(\mathbf{x})\psi \right|^2 + \frac{1}{4\epsilon^2}(1-|\psi|^2)^2 \right) d\mathbf{x}. \tag{44}$$

In the present form, ϵ is a small parameter measuring the relative penetration depth and the sample size. Hence, we may consider problems similar to those in section 3.1 with the functional defined above. We first consider the Dirichlet problem

$$\begin{aligned} \min\left\{\mathcal{F}^a_\epsilon(\psi)\ ,\ \psi|_{\partial\Omega} = g\ \right\} = \min\Bigg\{ \int_\Omega a(\mathbf{x}) \Bigg(& \frac{1}{2} \left| \nabla\psi - A_0(\mathbf{x})\psi \right|^2 \\ & + \frac{1}{4\epsilon^2}(1-|\psi|^2)^2 \Bigg) d\mathbf{x}\ ,\ \ \psi|_{\partial\Omega} = g\ \Bigg\}\ . \end{aligned} \tag{45}$$

For simplicity, we assume that $|g| = 1$ on $\partial\Omega$, $deg(g, \partial\Omega) = d$, and $a(\mathbf{x})$ has d distinct strict minimums at points $\mathbf{b}_1, \mathbf{b}_2, \ldots, \mathbf{b}_d$. With a proper choice of gauge, we may define

$$A_0(x,y) = \frac{1}{2}(Hy, -Hx)^T,$$

where H is the scaled applied magnetic field. We then have the following theorem.

Theorem 3.5. *Let* ψ_{ϵ_n}, $\epsilon_n \searrow 0$, *be a sequence of minimizers of* (45). *Then*

$$\psi_{\epsilon_n}(\mathbf{x}) \to \psi^*(\mathbf{x}) \qquad \text{in } C^{1,\alpha}_{\text{loc}}\left(\overline{\Omega}/\{\mathbf{b}_1, \ldots, \mathbf{b}_d\}\right),$$

where

$$\psi^*(\mathbf{x}) = \prod_{j=1}^{d} \frac{\mathbf{x}-\mathbf{b}_j}{|\mathbf{x}-\mathbf{b}_j|} e^{ih^*(\mathbf{x})} \qquad \text{in } \Omega.$$

Moreover, if we write $\psi^*(\mathbf{x}) = e^{i(\Theta(\mathbf{x})+h^*(\mathbf{x}))}$, *then* $h^* \in H^1(\Omega)\cap C^\alpha(\bar{\Omega})$, $\psi^*|_{\partial\Omega} = g$ *on* $\partial\Omega$, *and*

$$\operatorname{div}\,[a(\mathbf{x})(\nabla\Theta + \nabla h^*)] = 0 \qquad \text{in} \quad \Omega/\{\mathbf{b}_1,\ldots,\mathbf{b}_d\}.$$

Next, we may also prove similar results for the Neumann-type problems. Let V be the space defined in (42). We consider

$$\begin{aligned}\min\{\mathcal{F}_\epsilon^a(\psi)\ ,\ \psi\in V\ \} = \min\Bigg\{ \int_\Omega a(\mathbf{x}) \bigg(&\frac{1}{2}\left|\nabla\psi - A_0(\mathbf{x})\psi\right|^2 \\ &+\frac{1}{4\epsilon^2}(1-|\psi|^2)^2\bigg)\,d\mathbf{x}\ ,\quad \psi\in V\ \Bigg\}.\end{aligned} \tag{46}$$

Theorem 3.6. *Let* ψ_{ϵ_n}, $\epsilon_n \searrow 0$, *be a sequence of minimizers of* (46). *Then*

$$\psi_{\epsilon_n}(\mathbf{x}) \to \psi^*(\mathbf{x}) \qquad \text{in } C^{1,\alpha}_{\text{loc}}\left(\overline{\Omega}/\{\mathbf{b}_1,\ldots,\mathbf{b}_d\}\right),$$

where

$$\psi^*(\mathbf{x}) = \prod_{j=1}^{d} \frac{\mathbf{x}-\mathbf{b}_j}{|\mathbf{x}-\mathbf{b}_j|} e^{ih^*(\mathbf{x})} \qquad \text{in } \Omega.$$

Moreover, if we write $\psi^*(\mathbf{x}) = e^{i(\Theta(\mathbf{x})+h^*(\mathbf{x}))} = e^{i(\phi*(\mathbf{x}))}$, *then* $h^*\in H^1(\Omega)\cap C^\alpha(\bar{\Omega})$, $\frac{\partial\phi^*}{\partial n} = A_0\cdot\mathbf{n}$ *on* $\partial\Omega$ *(here,* $\mathbf{n}$ *is the outward normal of* $\partial\Omega$*), and*

$$\operatorname{div}\,[a(\mathbf{x})(\nabla\Theta + \nabla h^*)] = 0 \qquad \text{in} \quad \Omega/\{\mathbf{b}_1,\ldots,\mathbf{b}_d\}.$$

Again, the proofs of Theorems 3.3 and 3.4 are omitted due to their similarities to our earlier discussions.

4. The renormalized energy and the vortex solution of the full G–L model with applied magnetic field. With proper scaling, we focus on the following form of the G–L functional:

$$\mathcal{G}(\psi,\mathbf{A}) = \int_\Omega \left(\frac{1}{4\epsilon^2}(1-|\psi|^2)^2 + \frac{1}{2}\left|(\nabla - i\mathbf{A})\,\psi\right|^2 + \frac{1}{2}|\operatorname{curl}\mathbf{A} - H_0|^2 \right) d\mathbf{x}.$$

Let $\Omega \in \mathbb{R}^2$ be a bounded Lipshitz domain and H_0 be a constant field. In this nondimensionalization, one may view ϵ as proportional to $\frac{1}{\kappa}$ and H_0 as proportional to κ times the (nondimensionalized) applied field. Studies of the densely packed vortex state when the nondimensionalized field is near the upper critical field may be found in [4]. In the low field case, variational problems concerning the G–L functional have been considered in [5] but with boundary conditions that are not completely physical. Our discussion here is valid for the natural (physically meaningful) boundary conditions and we will borrow many useful results from [5] and [20].

4.1. The renormalized energy. Following the discussions in [20, 21, 5], we now formulate the renormalized energy: Let

$$\psi = e^{i\phi_b(\mathbf{x})} = \prod_{j=1}^{d} \frac{\mathbf{x} - \mathbf{b}_j}{|\mathbf{x} - \mathbf{b}_j|} e^{ih}$$

for some points $\mathbf{b} = (\mathbf{b}_1, \mathbf{b}_2, \ldots, \mathbf{b}_d) \in \Omega^d$ and $\frac{\partial \phi_b}{\partial \mathbf{n}} = 0$ on $\partial\Omega$. Let

$$B_\rho = \bigcup_{j=1}^{d} B_\rho(\mathbf{b}_j) \ .$$

Choose the gauge $\operatorname{div} \mathbf{A} = 0$ in Ω and $\mathbf{A} \cdot \mathbf{n} = 0$ on $\partial\Omega$. We may define ζ such that

$$\mathbf{A} = \nabla^\perp \zeta \quad \text{in } \ \Omega,$$

$$\zeta = 0 \quad \text{on } \ \partial\Omega.$$

Now, consider

$$\begin{aligned}
\mathcal{G}_\rho \ &= \int_{\Omega \setminus B_\rho} \left(\frac{1}{2} \left| \nabla \phi_b - \nabla^\perp \zeta \right|^2 + |\Delta \zeta - H_0|^2 \right) d\Omega \\
&= \int_{\Omega \setminus B_\rho} \left(\frac{1}{2} |\nabla \phi_b|^2 + \frac{1}{2} |\nabla \zeta|^2 - \nabla \phi_b \cdot \nabla^\perp \zeta + \frac{1}{2} \left| \Delta \zeta - H_0 \right|^2 \right) d\Omega \\
&:= d\pi \log \frac{1}{\rho} + W_\Omega(\mathbf{b}, H_0) + O(\rho),
\end{aligned}$$

where the last equality may be taken as the definition of the renormalized energy $W_\Omega(\mathbf{b}, H_0)$. Note

$$\begin{aligned}
-\int_{\Omega \setminus B_\rho)} \nabla \phi_b \cdot \nabla^\perp \zeta d\Omega &= \int_{\Omega \setminus B_\rho} \operatorname{div} (\zeta \cdot \nabla^\perp \phi_b) d\Omega \\
&= \sum_{j=1}^{d} 2\pi \zeta(\mathbf{b}_j) + O(\rho).
\end{aligned}$$

So,

$$\begin{aligned}
W_\Omega(\mathbf{b}, H_0) = & \int_{\Omega \setminus B_\rho} \frac{1}{2} |\nabla \phi_b|^2 d\Omega - d\pi \log \frac{1}{\rho} + \sum_{j=1}^{d} 2\pi \zeta(\mathbf{b}_j) \\
& + \int_{\Omega \setminus B_\rho} \frac{1}{2} \left(|\nabla \zeta|^2 + |\Delta \zeta - H_0|^2 \right) d\Omega + O(\rho) \\
= & \int_{\Omega \setminus B_\rho} \frac{1}{2} |\nabla \phi_b|^2 d\Omega - d\pi \log \frac{1}{\rho} + 2\pi \sum_{j=1}^{d} \zeta(\mathbf{b}_j) \\
& + \int_{\Omega \setminus B_\rho} \frac{1}{2} \left(|\nabla \zeta|^2 + |\Delta \zeta|^2 \right) d\Omega + \frac{1}{2} H_0^2 |\Omega| \\
& - \int_{\Omega \setminus B_\rho} H_0 \Delta \zeta d\Omega + O(\rho).
\end{aligned}$$

Minimizing the term involving ϕ_b, we see that ϕ_b is a multivalued harmonic function on $\Omega \setminus \{\mathbf{b}_1, \mathbf{b}_2, \ldots, \mathbf{b}_d\}$ and we may define the function $g_\Omega(\mathbf{b})$ by

$$\int_{\Omega\setminus B_\rho} \frac{1}{2}|\nabla\phi_b|^2 d\Omega - d\pi \log\frac{1}{\rho} := g_\Omega(\mathbf{b}) + O(\rho).$$

Minimizing the terms involving ζ, we can choose ζ to satisfy

$$-\Delta^2\zeta + \Delta\zeta = 2\pi\sum_{j=1}^{d}\delta_{\mathbf{b}_j} \quad \text{in } \Omega,$$

where $\delta_{\mathbf{b}_j}$ is the Dirac–Delta measure with boundary conditions

$$\zeta = 0 \quad \text{on } \partial\Omega,$$

$$\Delta\zeta = H_0 \quad \text{on } \partial\Omega.$$

So,

$$2\pi\sum_{j=1}^{d}\zeta(\mathbf{b}_j) = -\int_\Omega \left(|\nabla\zeta|^2 + |\Delta\zeta|^2\right) d\Omega + H_0\int_{\partial\Omega}\frac{\partial\zeta}{\partial n} d\Gamma\ .$$

Because H_0 is a constant, we get

$$\int_{\Omega\setminus B_\rho} H_0\Delta\zeta d\Omega = H_0\int_{\partial\Omega}\frac{\partial\zeta}{\partial n}d\Gamma + H_0 O(\rho)\ .$$

Thus,

$$W_\Omega(\mathbf{b}, H_0) = \frac{1}{2}H_0^2|\Omega| - \frac{1}{2}\int_\Omega \left(|\nabla\zeta|^2 + |\Delta\zeta|^2\right) d\Omega + H_0 O(\rho) + g_\Omega(\mathbf{b})\ .$$

Now, let us define $\zeta = \zeta_b + \zeta_{H_0}$, where

$$-\Delta^2\zeta_b + \Delta\zeta_b = 2\pi\sum_{j=1}^{d}\delta_{\mathbf{b}_j} \quad \text{in } \Omega,$$

$$\zeta_b = 0 \quad \text{on } \partial\Omega,$$

$$\Delta\zeta_b = 0 \quad \text{on } \partial\Omega,$$

and $\zeta_{H_0} = H_0\zeta_1$ with

$$-\Delta^2\zeta_1 + \Delta\zeta_1 = 0 \quad \text{in } \Omega,$$

$$\zeta_1 = 0 \quad \text{on } \partial\Omega,$$

$$\Delta\zeta_1 = 1 \quad \text{on } \partial\Omega.$$

Then

$$\int_\Omega |\nabla\zeta|^2 d\Omega = H_0^2 \int_\Omega |\nabla\zeta_1|^2 d\Omega + \int_\Omega |\nabla\zeta_b|^2 d\Omega - 2H_0 \int_\Omega \Delta\zeta_1 \zeta_b d\Omega,$$

$$\int_\Omega |\Delta\zeta|^2 d\Omega = H_0^2 \int_\Omega |\Delta\zeta_1|^2 d\Omega + \int_\Omega |\Delta\zeta_b|^2 d\Omega + 2H_0 \int_\Omega \Delta\zeta_1 \Delta\zeta_b d\Omega,$$

and

$$\begin{aligned}\int_\Omega \Delta\zeta_1(\Delta\zeta_b - \zeta_b) d\Omega &= \int_\Omega \zeta_1 \Delta(\Delta\zeta_b - \zeta_b) d\Omega \\ &= -2\pi \sum_{j=1}^d \zeta_1(\mathbf{b}_j)\ .\end{aligned}$$

So,

$$\begin{aligned}\int_\Omega \left(|\nabla\zeta|^2 + |\Delta\zeta|^2\right) d\Omega = H_0^2 \int_\Omega \left(|\nabla\zeta_1|^2 + |\Delta\zeta_1|^2\right) d\Omega \\ + \int_\Omega \left(|\nabla\zeta_b|^2 + |\Delta\zeta_b|^2\right) d\Omega - 2\pi \sum_{j=1}^d \zeta_1(\mathbf{b}_j)\ .\end{aligned}$$

Therefore,

$$W_\Omega(\mathbf{b}, H_0) = \frac{1}{2} H_0^2 C(\Omega) + 2\pi H_0 \sum_{j=1}^d \zeta_1(\mathbf{b}_j) + \tilde{g}_\Omega(\mathbf{b}) + O(\rho), \tag{47}$$

where $C(\Omega)$ is a constant and $\tilde{g}_\Omega(\mathbf{b})$ has the property

$$\tilde{g}_\Omega(\mathbf{b}) = \begin{cases} +\infty\ , & \mathbf{b}_i = \mathbf{b}_j \quad \text{for some } i \neq j\ , \\ -\infty\ , & \mathbf{b} \in \partial\Omega^d, \end{cases}$$

otherwise it is a smooth function in Ω^d.

Lemma 4.1. *$W_\Omega(\mathbf{b}, H_0)$ has a local minimum inside Ω^d whenever $H_0 \geq H_0(\Omega)$ for some constant $H_0(\Omega)$.*

Proof. Choose a small enough positive constant δ_0 and let

$$\Omega_{\delta_0} = \{x \in \Omega \mid \delta_0 \leq dist(\mathbf{x}, \partial\Omega) \leq 2\delta_0\}\ .$$

If $dist(\mathbf{b}_j, \partial\Omega) \geq \delta_0$ for all j, then $\tilde{g}_\Omega(\mathbf{b}) \geq -M(\delta_0)$, independently of H_0. On the other hand, we can choose d distinct points $\mathbf{b}_1, \mathbf{b}_2, \ldots, \mathbf{b}_d \in B_R(\mathbf{x}_0)$, where $\mathbf{x}_0$ satisfies $\zeta_1(\mathbf{x}_0) = \min_{\mathbf{x}\in\Omega} \zeta_1(\mathbf{x}) = -m_0 < 0$ such that $B_R(\mathbf{x}_0) \subset \{\mathbf{x} : dist(\mathbf{x}, \partial\Omega) \geq 2\delta_0\}$ and such that

$$\tilde{g}_\Omega(\mathbf{b}) \leq C(R)$$

for some constant $C(R)$ when R is small. Moreover,

$$\sum_{j=1}^d \zeta_1(\mathbf{b}_j) \leq -dm_0 + \tilde{C}_1 R$$

for some constant $\tilde{C}_1$. So,

$$W_\Omega(\mathbf{b}, H_0) \leq -2\pi H_0 d m_0 + C(R) + 2\pi H_0 \tilde{C}_1 R + \frac{1}{2} H_0^2 C(\Omega) \ .$$

If, however, at least one $\mathbf{b}_j$ satisfies $\mathbf{b}_j \in \Omega_{\delta_0}$, then

$$\begin{aligned} W_\Omega(\mathbf{b}, H_0) &\geq -M(\delta_0) - 2\pi H_0 \tilde{C}_2 \delta_0 - 2\pi H_0 (d-1) m_0 + \frac{1}{2} H_0^2 C(\Omega) \\ &\geq -2\pi H_0 d m_0 + C(R) + 2\pi H_0 \tilde{C}_1 R + \frac{1}{2} H_0^2 C(\Omega) \end{aligned}$$

for some constant $\tilde{C}_2$ if R, δ_0 are small enough and H_0 is large enough. Thus, $W_\Omega(\mathbf{b}, H_0)$ has a local minimum inside Ω^d whenever $H_0 > H_0(\Omega)$.

4.2. The existence of vortex solutions. Using the renormalized energy, we now study the solutions of the G–L equations (3)–(6).

THEOREM 4.2. *If $H_0 \geq H_0(\Omega)$ and $W_\Omega(\mathbf{b}, H_0)$ has a nondegenerate local minimum for some $\mathbf{b} \in \Omega^d$, then, for small ϵ, there are solutions $(\psi^\epsilon, \mathbf{A}^\epsilon)$ to the full steady state G–L equations with the gauge choice $\mathbf{A}_\epsilon = \nabla^\perp \zeta_\epsilon$ in Ω, $\mathbf{A}_\epsilon \cdot \mathbf{n} = 0$ on $\partial\Omega$ such that*

$$\psi_\epsilon(\mathbf{x}) \to \psi^*(\mathbf{x}) \quad \text{in } C^{1,\alpha}_{\text{loc}} \left(\overline{\Omega}/\{\mathbf{b}_1, \mathbf{b}_2, \ldots, \mathbf{b}_d\}\right),$$

$$\zeta_\epsilon(\mathbf{x}) \to \zeta^*(\mathbf{x}) \quad \text{in } H^2(\Omega),$$

where

$$-\Delta^2 \zeta^* + \Delta \zeta^* = 2\pi \sum_{j=1}^{d} \delta(\mathbf{b}_j) \quad \text{in } \ \Omega$$

with

$$\zeta^* = 0 \quad \text{on } \partial\Omega,$$

$$\Delta \zeta^* = H_0 \quad \text{on } \partial\Omega,$$

and

$$\psi^*(\mathbf{x}) = \prod_{j=1}^{d} \frac{\mathbf{x} - \mathbf{b}_j}{|\mathbf{x} - \mathbf{b}_j|} e^{ih^*(\mathbf{x})} \quad \text{in } \Omega.$$

Moreover, if we write $\psi^*(\mathbf{x}) = e^{i\theta_b(\mathbf{x}) + ih^*(\mathbf{x})} = e^{i\phi_b}$, then ϕ_b is a multivalued harmonic function on $\Omega \setminus \{\mathbf{b}_1, \mathbf{b}_2, \ldots, \mathbf{b}_d\}$ with $\frac{\partial \phi_b}{\partial n} = 0$ on $\partial\Omega$.

To complete the proof, we use the approach in [21]. We consider the solution of the following system:

$$\frac{\partial \psi}{\partial t} - (\nabla - i\mathbf{A})^2 \psi - \frac{1}{\epsilon^2} \psi (1 - |\psi|^2) = 0 \quad \text{in } \ \Omega, \tag{48}$$

$$\frac{\partial \mathbf{A}}{\partial t} - \Delta \mathbf{A} + \frac{i}{2} (\psi^* \nabla \psi - \psi \nabla \psi^*) + |\psi|^2 \mathbf{A} = 0 \quad \text{in } \Omega, \tag{49}$$

and

$$\operatorname{curl}\mathbf{A} = H_0 \quad \text{on } \partial\Omega, \tag{50}$$

$$(\nabla - i\mathbf{A})\psi\cdot\mathbf{n} = 0 \quad \text{on } \partial\Omega, \tag{51}$$

$$\mathbf{A}\cdot\mathbf{n} = 0 \quad \text{on } \partial\Omega \tag{52}$$

with properly defined initial conditions.

Let

$$\mathcal{E}_\epsilon(\psi,\mathbf{A}) = \frac{1}{4\epsilon^2}(1-|\psi|^2)^2 + \frac{1}{2}\left|(\nabla - i\mathbf{A})\,\psi\right|^2 + \frac{1}{2}|\operatorname{curl}\mathbf{A} - H_0|^2$$

and

$$\tilde{\mathcal{E}}_\epsilon(\psi,\mathbf{A}) = \mathcal{E}_\epsilon(\psi,\mathbf{A}) + \frac{1}{2}|\operatorname{div}\mathbf{A}|^2\ .$$

It is easy to see that (see [11], for example)

$$\int_\Omega \tilde{\mathcal{E}}_\epsilon(\psi(t),\mathbf{A}(t))d\mathbf{x} \le \int_\Omega \tilde{\mathcal{E}}_\epsilon(\psi(0),\mathbf{A}(0))d\mathbf{x}\ .$$

Assuming that the initial condition satisfies

$$\operatorname{div}\mathbf{A}(0) = 0,$$

this in turn implies

$$\int_\Omega \mathcal{E}_\epsilon(\psi(t),\mathbf{A}(t))d\mathbf{x} \le \int_\Omega \mathcal{E}_\epsilon(\psi(0),\mathbf{A}(0))d\mathbf{x}.$$

Let ρ_0 be small enough such that

$$\delta_0 = \min\{dist(\partial\Omega, \partial B_{2\rho_0}(\mathbf{b}_j)), |\mathbf{b}_j - \mathbf{b}_i|, i \ne j,\ i,j = 1,2,\ldots,d\} > 0$$

and

$$\min_{\mathbf{x}\in\partial B_{\rho_0}(\mathbf{b})} W(\mathbf{x}) \ge C(\rho_0) + W(\mathbf{b})\ .$$

Let us construct initial conditions. Let $\mathbf{A}(0) = \nabla^\perp\zeta_b$ in Ω with $\zeta_{\mathbf{b}}$ defined as before. For small ρ, let $B_\rho = \bigcup_{j=1}^d B_\rho(\mathbf{b}_j)$, and let $\psi(0) = e^{i\phi_b}$ in $\Omega\setminus B_\rho$ and extend $\psi(0)$ inside each ball $B_\rho(\mathbf{b}_j)$ by the minimizer of

$$\begin{aligned} I_\rho(\psi,\mathbf{A}) = \min\Bigg\{&\int_{B_\rho(\mathbf{b}_j)}\left(\frac{1}{2}\left|\nabla\psi - i\mathbf{A}\psi\right|^2 + \frac{1}{4\epsilon^2}(1-|\psi|^2)^2\right.\\ &\left.+\frac{1}{2}|\operatorname{curl}\mathbf{A} - H_0|^2\right)d\mathbf{x}\ |\ \ \operatorname{div}\mathbf{A} = 0 \text{ in } \Omega,\quad \mathbf{A}\cdot\mathbf{n} = 0 \text{ on } \partial\Omega,\\ &|\psi|\ |_{\partial B_\rho(\mathbf{b}_j)} = 1\ , (i\psi, (\nabla - i\mathbf{A})\psi\cdot\tau) = g \text{ on } \partial B_\rho(\mathbf{b}_j),\\ &\quad \text{and } deg(\psi, \partial B_\rho(\mathbf{b}_j)) = 1\ , j = 1,2,\ldots,d\Bigg\}, \end{aligned}$$

where τ is the unit tangent vector and $g = \nabla(\theta_b - \zeta_b) \cdot \tau$ on $\partial B_\rho(\mathbf{b}_j)$.

Using the argument in [5] and the gauge invariance, one may show that

$$I_\rho(\psi, \mathbf{A}) = \pi d \log\left(\frac{\rho}{\epsilon}\right) + \gamma d + o(1) + O(\rho).$$

Thus, we may assume

$$E_\epsilon(\psi(0), \mathbf{A}(0)) \leq d\pi \log\frac{1}{\epsilon} + W_\Omega(\mathbf{b}, H_0) + \gamma d + o(1)\ .$$

LEMMA 4.3. *The solution of* (48)–(52) *has the property, for all sufficiently small* ϵ *and for all* $t \geq 0$, *that the set* $\{\mathbf{x} \in \Omega, |\psi_\epsilon(\mathbf{x})| \leq \frac{1}{2}\}$ *is contained in a union of disjoint discs* $B_j, j = 1, 2 \dots, d$, *where*

(i) $B_j = B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)$, $\mathbf{x}_j^\epsilon \in B_{\rho_0}(\mathbf{b}_j)$, *for some small* α.

(ii) $\epsilon^\alpha \int_{\partial B_j} \mathcal{E}_\epsilon(\psi_\epsilon, \mathbf{A}_\epsilon) d\mathbf{x} \leq C(K_0)$.

Thus, $d_j = deg(\partial B_j, \psi)$ *is well defined and* $d_j = 1, j = 1, 2, \dots, d$.

Proof. Let us define

$$P = \{t \geq 0 \ \mid \ (\psi_\epsilon, \mathbf{A}_\epsilon) \text{ s.t. (i)} - \text{(ii)}\}\ .$$

Clearly, P is a closed set and by choosing the initial conditions properly, we have $0 \in P$. We now show that P is open; thus $P = [0, \infty)$. First, we have the following claim.

Claim. For any $t \in P$, there exists a $\rho^* \in (0, \rho_0)$, independent of sufficiently small ϵ, such that $\min\{dist(\mathbf{x}^\epsilon, \partial B_{\rho_0}(\mathbf{b})),\} \geq \rho^*$.

Assume that the claim is true. Then for any $t' > t$ but sufficiently close to t,

$$deg(\partial B_{\rho^*}(\mathbf{x}_j^\epsilon), \psi_\epsilon(\cdot, t')) = 1.$$

We may then follow the ideas in [21] and [5] to construct, for $\psi_\epsilon(\cdot, t')$, a new disc $\tilde{B}_j$ which satisfies (i)–(ii). Again, the center of the disc can be shown to satisfy the above claim. Thus, the lemma is proved.

Now we verify the claim. Suppose the claim is not true, there exists a sequence $\epsilon_n \searrow 0$, $t_n \nearrow t^* \in P$, such that $\mathbf{x}_i^{\epsilon_n} \to \bar{\mathbf{b}}_i \in B_{\rho_0}(\mathbf{b}_i)$ for $i = 1, 2 \dots, d$, and $\bar{\mathbf{b}}_j \in \partial B_{\rho_0}(\mathbf{b}_j)$ for some j.

We will follow constructions similar to those in [21] and [5] to show that one may replace $(\psi_\epsilon, \mathbf{A}_\epsilon)$ by $(\bar{\psi}_\epsilon, \bar{\mathbf{A}}_\epsilon)$ to satisfy

$$E(\bar{\psi}_\epsilon, \bar{\mathbf{A}}_\epsilon) \geq \pi d \log\frac{1}{\epsilon} + W_\Omega(\bar{\mathbf{b}}, H_0) + \gamma d + o(1).$$

First, let us do gauge transformation such that $\bar{\mathbf{A}}_\epsilon = \nabla^\perp \zeta_\epsilon$ with $\zeta_\epsilon = 0$ on $\partial\Omega$. Let us consider

$$\min\left\{ \int_{\Omega \setminus \bigcup_{j=1}^d B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)} \mathcal{E}_\epsilon(\bar{\psi}, \bar{\mathbf{A}}) d\mathbf{x} \ \mid \ \bar{\mathbf{A}} = \nabla^\perp \zeta \text{ in } \Omega\ ,\ deg(\bar{\psi}, \partial B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)) = 1, \right.$$

$$\left. |\bar{\psi}||_{\partial B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)} = |\psi_\epsilon||_{\partial B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)}\ , \text{ and } (i\bar{\psi}, (\nabla - i\bar{\mathbf{A}})\bar{\psi} \cdot \tau) = g_\epsilon \ \text{ on } \partial B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon) \right\},$$

where $g_\epsilon = (i\psi_\epsilon, (\nabla - i\mathbf{A}_\epsilon)\psi_\epsilon \cdot \tau)$. Note that the boundary conditions are the same gauge invariant boundary conditions considered in [5] and α satisfies property (ii) listed above.

Let $(\bar{\psi}_\epsilon, \bar{\mathbf{A}}_\epsilon)$ denote a minimizer. Let $\bar{\psi}_\epsilon = \bar{\rho}_\epsilon e^{i\bar{\phi}_\epsilon}$ and $\psi_\epsilon = \rho_\epsilon e^{i\phi_\epsilon}$ on the boundary of $\bigcup_{j=1}^d B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)$. To extend it inside the ϵ^α balls, we define a gauge transformation by

$$\Delta^2 \chi = 0 \quad \text{in } \bigcup_{j=1}^d B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)$$

with boundary conditions

$$\kappa\chi = \bar{\phi}_\epsilon - \phi_\epsilon \quad \text{ and } \quad \frac{\partial \chi}{\partial \mathbf{n}} = 0 \qquad \text{on } \bigcup_{j=1}^d \partial B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon) \ .$$

Note that χ is well defined on $\bigcup_{j=1}^d \partial B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)$. Thus, inside $\bigcup_{j=1}^d B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)$, we define

$$\bar{\psi}_\epsilon = \psi_\epsilon e^{i\kappa\chi} \quad \text{ and } \quad \bar{\mathbf{A}}_\epsilon = \mathbf{A}_\epsilon + \nabla\chi \ .$$

By the gauge invariance and the choice of the small α, we have the energy lower bound inside the ϵ^α balls:

$$\begin{aligned} \int_{\bigcup_{j=1}^d B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)} \mathcal{E}_\epsilon(\bar{\psi}_\epsilon, \bar{\mathbf{A}}_\epsilon) d\mathbf{x} &= \int_{\bigcup_{j=1}^d B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)} \mathcal{E}_\epsilon(\psi_\epsilon, \mathbf{A}_\epsilon) d\mathbf{x} \\ &\geq \pi d \log\left(\frac{\epsilon^\alpha}{\epsilon}\right) - C \end{aligned}$$

for small enough ϵ. So, we have the energy upper bound outside:

$$\int_{\Omega \setminus \bigcup_{j=1}^d B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)} \mathcal{E}_\epsilon(\bar{\psi}_\epsilon, \bar{\mathbf{A}}_\epsilon) d\mathbf{x} \leq \pi d\alpha \log\left(\frac{1}{\epsilon}\right) + C \ .$$

Using arguments similar to those in [21] and [5], we have

$$|\bar{\psi}_\epsilon| \geq \frac{1}{2} \quad \text{in } \Omega \setminus \bigcup_{j=1}^d B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon).$$

Moreover, we may modify the arguments of [21] and [5] to show that we have strong convergence of

$$\bar{\psi}_\epsilon \to e^{i\phi_{\bar{\mathbf{b}}}}$$

and

$$\bar{\mathbf{A}}_\epsilon \to \nabla^\perp \zeta_{\bar{\mathbf{b}}}$$

outside any small neighborhood of $\bar{\mathbf{b}}_j, j = 1, 2, \ldots, d$. Indeed, using the fact that $H = \operatorname{curl} \bar{\mathbf{A}}_\epsilon$ satisfies the equation

$$\operatorname{div}\left(\frac{1}{|\bar{\psi}_\epsilon|^2} \nabla H\right) = H \quad \text{in } \Omega \setminus \bigcup_{j=1}^d B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon) \ ,$$

we note that $\rho = |\bar{\psi}_\epsilon| > 1/2$ in $\Omega \setminus \bigcup_{j=1}^d B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)$ (in fact, ρ is arbitrarily close to 1 if we allow ϵ small). Therefore, we obtain from elliptic estimates that the $W^{1,p}$ norm and the C^γ norm of H are bounded locally for some $p > 2$ and $\gamma > 0$. On the other hand, from Lemma 4.1 in [21] and arguments in [21] and [5], one deduces the local strong convergence of $\bar{\psi}_\epsilon$. Then the assertion on the convergence of $\bar{\mathbf{A}}_\epsilon$ follows. We omit the details.

Next, for small δ, by strong convergence,

$$\begin{aligned} &\int_{\Omega\setminus\bigcup_{j=1}^d B_\delta(\mathbf{x}_j^\epsilon)} \mathcal{E}_\epsilon(\bar{\psi}_\epsilon, \bar{\mathbf{A}}_\epsilon)d\mathbf{x} \\ &\qquad \geq \pi d \log\left(\frac{1}{\delta}\right) + W_\Omega(\bar{\mathbf{b}}, H_0) + o(1) + O(\delta). \end{aligned} \tag{53}$$

We can also get $deg(\bar{\psi}_\epsilon, \partial B_\delta(\bar{\mathbf{b}}_j)) = 1$ for any j.

Let us write $\bar{\psi}_\epsilon = |\bar{\psi}_\epsilon| e^{i\phi_\epsilon} = \rho e^{i\theta + ih}$, where θ is the angle function inside each $B_\delta(\mathbf{x}_j^\epsilon)$ so that

$$e^{i\theta(\mathbf{x})} = \frac{\mathbf{x} - \bar{\mathbf{b}}_j}{|\mathbf{x} - \bar{\mathbf{b}}_j|} \quad \text{in } B_\delta(\mathbf{x}_j^\epsilon)\ \forall\, j.$$

We have, by gauge invariance, the energy upper bound outside the ϵ^α balls:

$$\int_{\bigcup_{j=1}^d B_\delta(\mathbf{x}_j^\epsilon)\setminus B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)} \left(|\nabla\rho|^2 + \rho^2|\nabla\theta - \nabla^\perp\zeta|^2 + |\Delta\zeta|^2\right) d\mathbf{x} \ \leq C\log\left(\frac{1}{\epsilon}\right) + K, \tag{54}$$

where $\nabla^\perp\zeta = \bar{\mathbf{A}}_\epsilon$ is the magnetic potential after a gauge transformation.

Thus, we have

$$\begin{aligned} &\int_{\bigcup_{j=1}^d B_\delta(\mathbf{x}_j^\epsilon)\setminus B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)} (1-\rho^2)|\nabla\theta - \nabla^\perp\zeta|^2 d\mathbf{x} \\ &\leq \int_{\bigcup_{j=1}^d B_\delta(\mathbf{x}_j^\epsilon)\setminus B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)} \left[2(1-\rho^2)|\nabla^\perp\zeta|^2 + 2(1-\rho^2)|\nabla\theta|^2\right] d\mathbf{x} \\ &\leq \int_{\bigcup_{j=1}^d B_\delta(\mathbf{x}_j^\epsilon)\setminus B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)} \left(\frac{1}{\epsilon}(1-\rho^2)^2 d\mathbf{x} + \epsilon|\nabla^\perp\zeta|^4\right) d\mathbf{x} + o(1) \\ &\leq C\epsilon\log\left(\frac{1}{\epsilon}\right) + \epsilon\left(\int_{\bigcup_{j=1}^d B_\delta(\mathbf{x}_j^\epsilon)\setminus B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)} |\Delta\zeta|^2 d\mathbf{x}\right)^2 + o(1) \\ &\leq C\epsilon\log\left(\frac{1}{\epsilon}\right) + C\epsilon\left(\log\left(\frac{1}{\epsilon}\right)\right)^2 + o(1) \\ &\leq o(1), \end{aligned}$$

where C is some generic constant.

This implies in particular that

$$\begin{aligned} &\int_{\bigcup_{j=1}^d B_\delta(\mathbf{x}_j^\epsilon)\setminus B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)} \mathcal{E}(\bar{\psi}_\epsilon, \bar{\mathbf{A}}_\epsilon) d\mathbf{x} \\ &\quad \geq \int_{\bigcup_{j=1}^d B_\delta(\mathbf{x}_j^\epsilon)\setminus B_{\epsilon^\alpha}(\mathbf{x}_j^\epsilon)} |\nabla\theta - \nabla^\perp\zeta|^2 d\mathbf{x} + o(1) \\ &\quad \geq \pi d\log\left(\frac{\delta}{\epsilon^\alpha}\right) + o(1). \end{aligned}$$

Therefore, by arguments in [5] and the convergence of $(\bar{\psi}_\epsilon, \bar{\mathbf{A}}_\epsilon)$, we have

$$\sum_{j=1}^{d} \int_{B_\delta(\mathbf{x}_j^\epsilon)} \mathcal{E}_\epsilon(\bar{\psi}_\epsilon, \bar{\mathbf{A}}_\epsilon)\, d\mathbf{x} \geq \pi d \log\left(\frac{\delta}{\epsilon}\right) + \gamma d + o(1) + O(\delta). \tag{55}$$

Thus, for small ϵ and small δ,

$$\int_\Omega \mathcal{E}_\epsilon(\bar{\psi}_\epsilon, \bar{\mathbf{A}}_\epsilon)\, d\mathbf{x} \geq \pi d \log\left(\frac{1}{\epsilon}\right) + W_\Omega(\bar{\mathbf{b}}, H_0) + \gamma d + o(1)\ .$$

This leads to a contradiction of the energy upper bound obtained from the energy dissipation from the energy of the initial condition since $\mathbf{b}$ is the nondegenerate local minimum of $W(\mathbf{b}, H_0)$. Hence, the claim is true.

To complete the proof of the theorem, let us use the uniform bound on the solution $(\psi^\epsilon, \mathbf{A}^\epsilon)$ as $t \to \infty$. We get a subsequence t_n such that $(\psi^\epsilon(t_n), \mathbf{A}^\epsilon(t_n)) \to (\psi^\epsilon, \mathbf{A}^\epsilon)$ as $t \to \infty$. One may then easily check that $(\psi^\epsilon, \mathbf{A}^\epsilon)$ is the critical point of the G–L functional. This proves the theorem.

Remark.

(1) One may prove, using arguments given in [5], that as $\epsilon \to 0$, the zeros of the ψ^ϵ go to the local minimum of the renormalized energy.

(2) By a more careful analysis, one may replace the assumption that the renormalized energy has a nondegenerate local minimum by simply the existence of a local minimum.

(3) One can also prove, via [19], the existence of general critical points (saddle points) of the G–L functional under similar conditions.

(4) According to the nondimensionalization used here, our theorem describes the phenomenon that the G–L system has a vortex solution for an applied field of strength on the order of $\frac{1}{\kappa}$. Recall that the standard estimates for the lower critical field are $\frac{\log(\kappa)}{\kappa}$. That is, we can prove the existence of a stable vortex state below H_{c1}.

4.3. The weak hysteresis near the lower critical field $\boldsymbol{H_{c1}}$ for type-II superconductors. We have just shown that when we decrease the applied magnetic field, there may be stable vortex states (even local energy minimizing states) even when the field strength is below the lower critical field $H_{c1}(\approx \log\kappa/\kappa)$, say, c_0/κ for some constant c_0. On the other hand, it is rather straightforward to check from the definition of $W_\Omega(\mathbf{b}, H_0)$ that there is no local minimum of the function $W_\Omega(\mathbf{b}, H_0)$ when H_0 is sufficiently small. That is, we have shown the existence of a subcooling field $0 < H_{sc} < H_{c1}$.

Let us consider another case where we gradually increase the applied field. We start, say, with a perfect superconducting state (or the *Meissner* state). It is quite possible that the Meissner state exists even when the applied field is much larger than the lower critical field H_{c1}. Indeed, if one looks for a solution to the full steady state G–L equations $(\psi, \mathbf{A})$ with $|\psi| \neq 0$, then one may write $\psi = fe^{i\chi}$ for some $f \neq 0$.

Using gauge invariance, we define $\mathbf{Q} = \mathbf{A} - \frac{1}{\kappa}\nabla\chi$, then $(f, \mathbf{Q})$ remains a solution of the steady state G–L equations which can now be written in the following form:

$$\left\{ \begin{array}{l} \frac{1}{\kappa^2}\Delta f = f^3 - f + f|\mathbf{Q}|^2 \\ -\mathrm{curl}^2\mathbf{Q} = f^2\mathbf{Q} \end{array} \right. \quad \text{in } \Omega \tag{56}$$

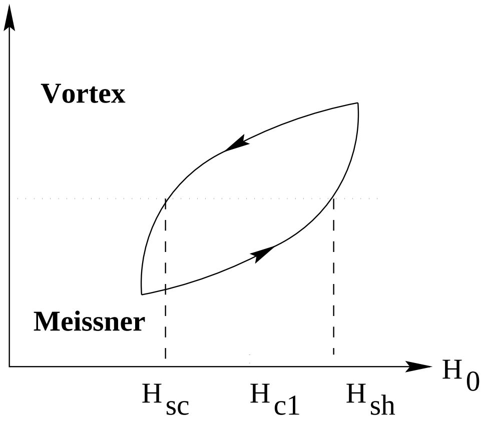

FIG. 8. *The weak hysteresis diagram for type-*II *superconductors near* H_{c1}.

with boundary conditions

$$\begin{cases} \frac{\partial f}{\partial n} = 0 \\ \mathbf{Q} \cdot \mathbf{n} = 0 \\ H = \mathrm{curl}\mathbf{Q} = H_0 \end{cases} \quad \text{on } \partial\Omega. \tag{57}$$

From the equation for $\mathbf{Q}$, we obtain

$$\begin{cases} - \quad \frac{\partial H}{\partial x_2} = f^2 Q_1 \\ \qquad \frac{\partial H}{\partial x_1} = f^2 Q_2 \end{cases} \quad \text{in } \Omega,$$

or, equivalently,

$$\mathrm{div}\left(\frac{\nabla H}{f^2}\right) = H \quad \text{in } \Omega.$$

As in [2], we let $\kappa \to \infty$ to obtain

$$f = 1 - |\mathbf{Q}|^2.$$

So, $|\nabla H|^2 = f^4(1 - f^2)$. Let $f = \rho(|\nabla H|)$. Then the equation for H becomes

$$\begin{cases} \mathrm{div}\,(\rho(\nabla H)\nabla H) = H \quad \text{in } \Omega, \\ H = \ H_0 \quad \text{on } \partial\Omega\ . \end{cases} \tag{58}$$

For $H_0 > 0$ small enough (but obviously larger than $\lim_{\kappa\to\infty} \frac{\log\kappa}{\kappa} = 0$), one can show the existence of a solution to the above equation. Moreover, such a solution is a linearly stable wholly superconducting state (Meissner state) for $0 < H_0 \le H_0^*$. The new field strength H_0^* is called the superheating field; see [2] for details.

Combining this latter result with ours given in section 4.2, a weak-hysteresis diagram of type-II superconductors near the lower critical field H_{c1} is completed (see Figure 8).

SPACE HOMOGENEOUS SOLUTIONS TO THE CAUCHY PROBLEM FOR SEMICONDUCTOR BOLTZMANN EQUATIONS[*]

A. MAJORANA[†] AND S. A. MARANO[†]

Abstract. The nonlinear Boltzmann equation for an electron gas in a semiconductor is investigated. Some meaningful properties of the collision operator are first presented. A large class of kernels is allowed. Then the global existence and uniqueness of bounded, continuous, space-independent solutions to the related Cauchy problem is performed. Finally, the conservation of mass is examined.

Key words. Boltzmann equation, semiconductor, Dirac distribution, bounded continuous solution, existence and uniqueness

1. Introduction.

A well-accepted model for the charge carrier transport in semiconductors is the Boltzmann equation for an unknown function defined in the seven-dimensional phase space spanned by time, space coordinates, and wave vector [17], [20]. This equation contains a very complicated nonlinear integral operator (the collision term). So, to avoid technical difficulties, numerous simplifying assumptions and modifications are often introduced. Although such *approximate* new Boltzmann-like models provide acceptable results in a few cases, properties of the true equation are frequently lost [11], [12], [16]. Therefore, precise information may be obtained only through the exact equation. For example, the increasing miniaturization of modern electron devices requires this accurate modeling in order to correctly describe the evolution of physical parameters. An alternative approach, which avoids the use of the Boltzmann equation, is furnished by the direct molecular simulation [10]. In this framework, techniques like Monte Carlo simulation provide detailed information about carrier transport within advanced devices, but the computational burden limits its use for many devices' engineering applications. For such reasons, great attention has recently been paid to the study of the semiconductor Boltzmann equation.

In this paper we consider the Boltzmann equation for the distribution function f of an electron gas in a semiconductor with the full collision operator $Q(f)$, which describes the interactions between the electron gas and the molecules, assumed in thermal equilibrium, of the semiconductor. We omit electron–electron collisions and hole–electron interactions, because they often are physically negligible with respect to the other interactions. This avoids both cumbersome formulas for $Q(f)$ and technical troubles that otherwise might occur (see section 4).

The main difficulty in studying the equation arises from the fact that the collision term contains integral operators of the type

$$I(f)(t,\mathsf{x},\mathsf{k}) = \int_{\mathbb{R}^3} \mathcal{G}(\mathsf{k},\mathsf{k}') f(t,\mathsf{x},\mathsf{k}')\delta(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu)\, d\mathsf{k}', \quad (t,\mathsf{x},\mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3,$$

where $\mathcal{G}$ denotes a continuous function, ε represents the particle energy, μ is a constant, and $\delta(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu)$ means the composition of the real-valued function $(\mathsf{k}, \mathsf{k}') \to \varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu$ and the Dirac distribution δ.

Usually, the distribution δ is replaced by a smooth function (we refer, for instance, to [14], [15], [18], [19]), or a simple expression of ε is employed (see, for example, [11], [16]) so that $I(f)$ may be reduced to an integral operator without distributions. However, trustable numerical results for the high-energy part of the electron distribution function can be achieved only when the correct form of ε is used [21].

We make quite general assumptions on ε, which cover all of the most common expressions considered in applications and simulations. Under such hypotheses, in sections 1 and 2, we show that the collision operator is well defined and has significant properties in the space of all bounded continuous functions. This is performed by first giving a precise meaning for and then proving some basic facts about the integral operator $I(f)$. In section 3, we examine the Boltzmann equation without external fields, since f does not depend on space coordinates. We study the related Cauchy problem and we establish the global existence and uniqueness of bounded continuous solutions. Further, we show that if the initial datum is integrable on $\mathbb{R}^3$, then the same holds for the function $\mathsf{k} \to f(t, \mathsf{k})$, $t \in \mathbb{R}_0^+$, and its integral is constant with respect to the time t. Throughout the paper, *integrable* always means Lebesgue integrable.

2. Basic equations.

The Boltzmann equation for an electron gas reads

$$\frac{\partial f}{\partial t} + \frac{1}{\hbar}\nabla_{\mathsf{k}}\varepsilon \cdot \nabla_{\mathsf{x}} f - \frac{e}{\hbar}\mathsf{E} \cdot \nabla_{\mathsf{k}} f = Q(f), \tag{2.1}$$

where the unknown function $(t, \mathsf{x}, \mathsf{k}) \to f(t, \mathsf{x}, \mathsf{k})$ represents the existence probability of an electron at the position $\mathsf{x} \in \mathbb{R}^3$, with the wave vector $\mathsf{k} \in \mathbb{R}^3$ at time $t \in \mathbb{R}_0^+$ [13], [17]. The parameters $\hbar$ and e are the Planck constant divided by 2π and the positive electric charge, respectively. The symbol ∇_{k} stands for the gradient with respect to the variables k and ∇_{x} with respect to the space coordinates x. The particle energy ε is an assigned nonnegative function defined in $\mathbb{R}^3$. In (2.1) the external force represents the electric field $(t, \mathsf{x}) \to \mathsf{E}(t, \mathsf{x})$, which satisfies a suitable Poisson equation.

We follow a semiclassical approach for the collision term $Q(f)$, so

$$Q(f) = \int_{\mathbb{R}^3} \left[S(\mathsf{k}', \mathsf{k}) f'(1 - f) - S(\mathsf{k}, \mathsf{k}') f(1 - f')\right] d\mathsf{k}' . \tag{2.2}$$

Here, for any function ϕ we use the notation $\phi' = \phi(\mathsf{k}')$. The kernel S is defined by

$$S(\mathsf{k}, \mathsf{k}') = \sum_{i=1}^{n} \mathcal{G}_i(\mathsf{k}, \mathsf{k}') \left[(n_i + 1)\delta(\varepsilon' - \varepsilon + \hbar\omega_i) + n_i \delta(\varepsilon' - \varepsilon - \hbar\omega_i)\right], \tag{2.3}$$

where n is a fixed positive integer, $\mathcal{G}_i : \mathbb{R}^3 \times \mathbb{R}^3 \to \mathbb{R}_0^+$ denotes a continuous function satisfying $\mathcal{G}_i(\mathsf{k}, \mathsf{k}') = \mathcal{G}_i(\mathsf{k}', \mathsf{k})$ for every k, $\mathsf{k}' \in \mathbb{R}^3$, and n_i and ω_i are nonnegative constants, $i = 1, 2, ..., n$. The symbol $\delta(\varepsilon' - \varepsilon \pm \hbar\omega_i)$ means the composition of the real-valued function $(\mathsf{k}, \mathsf{k}') \to \varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) \pm \hbar\omega_i$ and the Dirac distribution δ (see [8, Chapter III]).

The kernel (2.3) is rather different from the one appearing in the widely known Boltzmann equation for a perfect rarefied gas [7]. Indeed, in this case, the Dirac distributions have been ab initium eliminated in some way (we refer to [4] and [5] for a complete treatment). Consequently, the kernel of the integral term is a usual measurable function, and (2.1) can be solved in several settings, for example, Lebesgue spaces. This is not the present case. In fact, since the function ε may have many different expressions, it is not possible in general, by using a unique technique, to transform the integral operator (2.2) to an equivalent one without Dirac distributions. Moreover, the presence of distributions requires the use of functions which are at least continuous with respect to the wave vector.

We consider here the Boltzmann equation (2.1) in the simpler case when $\mathsf{E} \equiv 0$. Further, we suppose that the unknown function $(t, \mathsf{x}, \mathsf{k}) \to f(t, \mathsf{x}, \mathsf{k})$ does not depend on $\mathsf{x} \in \mathbb{R}^3$; namely, it is space homogeneous. This allows us to treat the equation with the *original expression* (2.3) *for the kernel* S.

To the best of our knowledge, no existence results concerning the complete unmodified equation (2.1) have been established. Some authors [14], [15], [19] studied the Cauchy problem for (2.1) with the full differential operator but *a different kernel*, which is usually taken to be smooth and without Dirac distributions. This choice seems to be forced by the used techniques, which require the existence of partial derivatives of S. Of course, such assumption is not satisfied by kernel (2.3). So, a new approach is probably necessary in order to get strong solutions of the full equation (2.1).

3. The collision operator. We will now make the following assumptions on the function ε:

(a$_1$) $\varepsilon : \mathbb{R}^3 \to \mathbb{R}_0^+$ *is continuous.*

(a$_2$) *There exists* $\mathsf{k}_0 \in \mathbb{R}^3$ *such that if* $D = [0, 2\pi] \times [0, \pi]$,

$$\mathsf{n} = (\sin\varphi\cos\vartheta, \sin\varphi\sin\vartheta, \cos\varphi), \quad \textit{and} \quad \eta(\rho, \vartheta, \varphi) = \varepsilon(\mathsf{k}_0 + \rho\mathsf{n}),$$

$\rho \geq 0$, $(\vartheta, \varphi) \in D$, *then*

(a$_{21}$) *the function* η *admits a continuous and positive partial derivative with respect to* ρ *for every* $(\rho, \vartheta, \varphi) \in]0, +\infty[\times D$,

(a$_{22}$) $\lim_{\rho \to 0^+} \rho^2 \left[\frac{\partial \eta(\rho, \vartheta, \varphi)}{\partial \rho} \right]^{-1} = 0$ *uniformly in* $(\vartheta, \varphi) \in D$,

(a$_{23}$) $\lim_{\rho \to +\infty} \eta(\rho, \vartheta, \varphi) = +\infty$ *uniformly in* $(\vartheta, \varphi) \in D$.

In Appendix A we list the most common expressions of ε considered in applications and simulations [3], [10]. It is easily seen that each of them satisfies hypotheses (a$_1$) and (a$_2$).

For every $f \in C^0(\mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3)$, we define

$$A(f)(t, \mathsf{x}, \mathsf{k}) = \int_{\mathbb{R}^3} S(\mathsf{k}', \mathsf{k}) f(t, \mathsf{x}, \mathsf{k}')\, d\mathsf{k}', \tag{3.1}$$

$$A^*(f)(t, \mathsf{x}, \mathsf{k}) = \int_{\mathbb{R}^3} S(\mathsf{k}, \mathsf{k}') f(t, \mathsf{x}, \mathsf{k}')\, d\mathsf{k}', \tag{3.2}$$

$$B(f)(t, \mathsf{x}, \mathsf{k}) = \int_{\mathbb{R}^3} S(\mathsf{k}, \mathsf{k}') \left[1 - f(t, \mathsf{x}, \mathsf{k}')\right] d\mathsf{k}', \tag{3.3}$$

$$\nu(\mathsf{k}) = \int_{\mathbb{R}^3} S(\mathsf{k}, \mathsf{k}')\, d\mathsf{k}',$$

$(t, \mathsf{x}, \mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3$, where the kernel S is given by (2.3). Each of the above expressions is a finite sum of terms of the kind

$$\Phi(t, \mathsf{x}, \mathsf{k}) = \int_{\mathbb{R}^3} \phi(t, \mathsf{x}, \mathsf{k}, \mathsf{k}')\delta(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu)\, d\mathsf{k}', \tag{3.4}$$

where ϕ indicates a function belonging to $C^0(\mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3)$ and μ is a real number. In Appendix B we first give a precise meaning to the right-hand side of (3.4) and then prove some technical lemmas which guarantee the following properties for Φ:

(R$_1$) $\Phi \in C^0(\mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3)$.

(R$_2$) *For every $\psi \in C^0(\mathbb{R}^3)$ with compact support,*

$$\int_{\mathbb{R}^3} \psi(\mathsf{k})\Phi(t,\mathsf{x},\mathsf{k})\,d\mathsf{k} = \int_{\mathbb{R}^3} d\mathsf{k}' \int_{\mathbb{R}^3} \psi(\mathsf{k})\phi(t,\mathsf{x},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}\,. \tag{3.5}$$

(R$_3$) *If $\phi(t,\mathsf{x},\mathsf{k},\mathsf{k}') \geq 0$ in $\mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3$ then the function $\mathsf{k} \to \Phi(t,\mathsf{x},\mathsf{k})$ is integrable on $\mathbb{R}^3$ for any $(t,\mathsf{x}) \in \mathbb{R}_0^+ \times \mathbb{R}^3$ and* (3.5) *holds for all nonnegative bounded $\psi \in C^0(\mathbb{R}^3)$.*

The aim of this section is to point out some meaningful properties of the operators $A(f)$, $B(f)$, and $Q(f)$. Throughout the paper, we suppose

$$M_A = \sup\left\{A(1)(\mathsf{k}) : \mathsf{k} \in \mathbb{R}^3\right\} < +\infty,\; M_B = \sup\left\{B(0)(\mathsf{k}) : \mathsf{k} \in \mathbb{R}^3\right\} < +\infty. \tag{3.6}$$

Since one has $B(f) = \nu - A^*(f)$, due to (2.2), we can write

$$Q(f) = (1-f)A(f) - fB(f). \tag{3.7}$$

As a consequence of (R$_1$), we immediately infer the following proposition.

PROPOSITION 3.1. *Let $f \in C^0(\mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3)$. Then $A(f)$, $B(f) \in C^0(\mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3)$. Consequently, $Q(f) \in C^0(\mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3)$. If, moreover, $0 \leq f(t,\mathsf{x},\mathsf{k}) \leq 1$ for every $(t,\mathsf{x},\mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3$, then*

$$0 \leq A(f)(t,\mathsf{x},\mathsf{k}) \leq M_A \quad \textit{and} \quad 0 \leq B(f)(t,\mathsf{x},\mathsf{k}) \leq M_B \quad \textit{in } \mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3.$$

We now come to the integrability of the function $\mathsf{k} \to Q(f)(t,\mathsf{x},\mathsf{k})$.

PROPOSITION 3.2. *Let $f \in C^0(\mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3)$ be such that the function $\mathsf{k} \to f(t,\mathsf{x},\mathsf{k})$ is integrable on $\mathbb{R}^3$ for all $(t,\mathsf{x}) \in \mathbb{R}_0^+ \times \mathbb{R}^3$ and $0 \leq f(t,\mathsf{x},\mathsf{k}) \leq 1$ in $\mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3$. Then the functions $\mathsf{k} \to A(f)(t,\mathsf{x},\mathsf{k})$ and $\mathsf{k} \to Q(f)(t,\mathsf{x},\mathsf{k})$ are integrable on $\mathbb{R}^3$ for every $(t,\mathsf{x}) \in \mathbb{R}_0^+ \times \mathbb{R}^3$. Furthermore, $\int_{\mathbb{R}^3} Q(f)(t,\mathsf{x},\mathsf{k})\,d\mathsf{k} = 0$.*

Proof. Fix $(t,\mathsf{x}) \in \mathbb{R}_0^+ \times \mathbb{R}^3$. Let $\psi_n : \mathbb{R} \to \mathbb{R}_0^+$, $n \in \mathbb{N}$, be defined by setting, for $z \in \mathbb{R}$,

$$\psi_n(z) = \begin{cases} 1 & \text{if} \quad |z| \leq n, \\ 1+n-|z| & \text{if} \quad n < |z| < n+1, \\ 0 & \text{if} \quad |z| \geq n+1. \end{cases} \tag{3.8}$$

Owing to (3.5) and Proposition 3.1, for any $n \in \mathbb{N}$ one has

$$\begin{aligned} \int_{\mathbb{R}^3} A(f)(t,\mathsf{x},\mathsf{k})\psi_n(|\mathsf{k}|)\,d\mathsf{k} &= \int_{\mathbb{R}^3} d\mathsf{k}\,\psi_n(|\mathsf{k}|) \int_{\mathbb{R}^3} S(\mathsf{k}',\mathsf{k})f(t,\mathsf{x},\mathsf{k}')\,d\mathsf{k}' \\ &= \int_{\mathbb{R}^3} d\mathsf{k}'\,f(t,\mathsf{x},\mathsf{k}') \int_{\mathbb{R}^3} S(\mathsf{k}',\mathsf{k})\psi_n(|\mathsf{k}|)\,d\mathsf{k} \leq M_A \int_{\mathbb{R}^3} f(t,\mathsf{x},\mathsf{k}')\,d\mathsf{k}'\,. \end{aligned}$$

Since $A(f)(t,\mathsf{x},\mathsf{k})\psi_n(|\mathsf{k}|) \leq A(f)(t,\mathsf{x},\mathsf{k})\psi_{n+1}(|\mathsf{k}|)$ and

$$\lim_{n\to+\infty} A(f)(t,\mathsf{x},\mathsf{k})\psi_n(|\mathsf{k}|) = A(f)(t,\mathsf{x},\mathsf{k})$$

pointwise in $\mathbb{R}^3$, the monotone convergence theorem ensures that the function $\mathsf{k} \to A(f)(t, \mathsf{x}, \mathsf{k})$ is integrable on $\mathbb{R}^3$. Moreover,

$$\int_{\mathbb{R}^3} A(f)(t,\mathsf{x},\mathsf{k})\, d\mathsf{k} \le M_A \int_{\mathbb{R}^3} f(t,\mathsf{x},\mathsf{k})\, d\mathsf{k}\,. \tag{3.9}$$

The integrability of $\mathsf{k} \to Q(f)(t,\mathsf{x},\mathsf{k})$ is an immediate consequence of (3.7) because, by Proposition 3.1, the function $B(f)$ is bounded.

Now, let $\psi \in C^0(\mathbb{R}^3)$ be nonnegative and bounded. Bearing in mind (3.7) and (R_3), we see that

$$\begin{aligned}\int_{\mathbb{R}^3} Q(f)(t,\mathsf{x},\mathsf{k})\psi(\mathsf{k})\, d\mathsf{k} &= \int_{\mathbb{R}^3} d\mathsf{k}\,(1-f(t,\mathsf{x},\mathsf{k}))\psi(\mathsf{k}) \int_{\mathbb{R}^3} S(\mathsf{k}',\mathsf{k}) f(t,\mathsf{x},\mathsf{k}')\, d\mathsf{k}' \\ &\quad - \int_{\mathbb{R}^3} d\mathsf{k}\, f(t,\mathsf{x},\mathsf{k})\psi(\mathsf{k}) \int_{\mathbb{R}^3} S(\mathsf{k},\mathsf{k}')(1-f(t,\mathsf{x},\mathsf{k}'))\, d\mathsf{k}' \\ &= \int_{\mathbb{R}^3} d\mathsf{k}'\, f(t,\mathsf{x},\mathsf{k}') \int_{\mathbb{R}^3} S(\mathsf{k}',\mathsf{k})\psi(\mathsf{k})(1-f(t,\mathsf{x},\mathsf{k}))\, d\mathsf{k} \\ &\quad - \int_{\mathbb{R}^3} d\mathsf{k}\, f(t,\mathsf{x},\mathsf{k})\psi(\mathsf{k}) \int_{\mathbb{R}^3} S(\mathsf{k},\mathsf{k}')(1-f(t,\mathsf{x},\mathsf{k}'))\, d\mathsf{k}'\,.\end{aligned}$$

Interchanging k and k' in the first of the above integrals, we infer

$$\begin{aligned}&\int_{\mathbb{R}^3} Q(f)(t,\mathsf{x},\mathsf{k})\,\psi(\mathsf{k})\, d\mathsf{k} \\ &\qquad = \int_{\mathbb{R}^3} d\mathsf{k}\, f(t,\mathsf{x},\mathsf{k}) \int_{\mathbb{R}^3} S(\mathsf{k},\mathsf{k}')(1-f(t,\mathsf{x},\mathsf{k}'))(\psi(\mathsf{k}')-\psi(\mathsf{k}))\, d\mathsf{k}'\,.\end{aligned}$$

Therefore, the proof is achieved by choosing $\psi(\mathsf{k}) = 1$, $\mathsf{k} \in \mathbb{R}^3$. □

4. Space homogeneous solutions: Existence and uniqueness.

In the case when $\mathsf{E} \equiv 0$ and the unknown function f only depends on (t, k), bearing in mind (3.7), the Boltzmann equation (2.1) becomes

$$\frac{\partial f}{\partial t} = (1-f)A(f) - fB(f). \tag{4.1}$$

We look for solutions $f : \mathbb{R}_0^+ \times \mathbb{R}^3 \to \mathbb{R}$ to (4.1) that are continuous in $\mathbb{R}_0^+ \times \mathbb{R}^3$, continuously differentiable with respect to the first variable at each point $(t,\mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3$, and, moreover, fulfill the initial condition

$$f(0,\mathsf{k}) = f_0(\mathsf{k}), \tag{4.2}$$

where $f_0 \in C^0(\mathbb{R}^3)$ and $0 \le f_0(\mathsf{k}) \le 1$ for all $\mathsf{k} \in \mathbb{R}^3$.

Theorem 4.1. *Let assumptions* (a_1) *and* (a_2), *and* (3.6) *be satisfied. Then problem* (4.1)–(4.2) *admits a unique solution f such that* $0 \le f(t,\mathsf{k}) \le 1$ *in* $\mathbb{R}_0^+ \times \mathbb{R}^3$.

Proof. We first define, for every $g \in C^0(\mathbb{R}_0^+ \times \mathbb{R}^3)$,

$$H(g)(t,\mathsf{k}) = \exp\left(\int_0^t [A(g)(r,\mathsf{k}) + B(g)(r,\mathsf{k})]\, dr\right), \quad (t,\mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3. \tag{4.3}$$

A simple computation shows that the requests on possible solutions f of (4.1)–(4.2) are equivalent to the following: $f \in C^0(\mathbb{R}_0^+ \times \mathbb{R}^3)$, $0 \le f(t,\mathsf{k}) \le 1$, and

$$f(t,\mathsf{k}) = \frac{1}{H(f)(t,\mathsf{k})}\left[f_0(\mathsf{k}) + \int_0^t H(f)(s,\mathsf{k})A(f)(s,\mathsf{k})ds\right] \tag{4.4}$$

for $(t, \mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3$.

Choose a real number α complying with

$$\alpha > \frac{1}{2} \max\left\{1, \left[M_A + (1 + M_A)(M_A + M_B)\right]^2\right\}, \tag{4.5}$$

and denote by X the real linear space of all continuous functions $g : \mathbb{R}_0^+ \times \mathbb{R}^3 \to \mathbb{R}$ such that

$$\|g\|_\alpha = \sup\left\{\exp\left(-\alpha t^2\right)|g(t, \mathsf{k})| : (t, \mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3\right\} < +\infty.$$

Arguing as in [6, pp. 2–3], we see that $(X, \|\cdot\|_\alpha)$ is a Banach space. Let

$$Z = \left\{g \in C^0(\mathbb{R}_0^+ \times \mathbb{R}^3) : 0 \le g(t, \mathsf{k}) \le 1 \text{ for every } (t, \mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3\right\}.$$

Clearly, $Z \subseteq X$. For every $g \in Z$, we define

$$T(g)(t, \mathsf{k}) = \frac{1}{H(g)(t, \mathsf{k})}\left[f_0(\mathsf{k}) + \int_0^t H(g)(s, \mathsf{k})A(g)(s, \mathsf{k})ds\right], \quad (t, \mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3.$$

The function $T(g)$ is continuous in $\mathbb{R}_0^+ \times \mathbb{R}^3$ because, by Proposition 3.1, $A(g)$, $B(g) \in C^0(\mathbb{R}_0^+ \times \mathbb{R}^3)$. Further, again owing to Proposition 3.1,

$$\begin{aligned} 0 \le T(g)(t, \mathsf{k}) &= \frac{1}{H(g)(t, \mathsf{k})}\left[f_0(\mathsf{k}) + H(g)(t, \mathsf{k}) - 1 - \int_0^t H(g)(s, \mathsf{k})B(g)(s, \mathsf{k})ds\right] \\ &\le \frac{1}{H(g)(t, \mathsf{k})}\left[f_0(\mathsf{k}) + H(g)(t, \mathsf{k}) - 1\right] \le 1 \end{aligned}$$

for every $(t, \mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3$, so $T(g) \in Z$. Hence, $T(Z) \subseteq Z$. The set Z is closed in X and, in view of (4.4), a function $f \in C^0(\mathbb{R}_0^+ \times \mathbb{R}^3)$ is a solution to problem (4.1)–(4.2) if and only if it is a fixed point of $T : Z \to Z$. Then, the proof is accomplished by showing that T is a contraction with respect to the norm $\|\cdot\|_\alpha$.

Let g, $h \in Z$. Taking into account (3.1)–(3.3), for every t, $s \in \mathbb{R}_0^+$, $t \ge s$, and every $\mathsf{k} \in \mathbb{R}^3$, one has

$$\begin{aligned} &\left|\exp\left(-\int_s^t \left[A(g)(r, \mathsf{k}) + B(g)(r, \mathsf{k})\right]dr\right) - \exp\left(-\int_s^t \left[A(h)(r, \mathsf{k}) + B(h)(r, \mathsf{k})\right]dr\right)\right| \\ &\quad \le \left|\int_s^t \left[A(g)(r, \mathsf{k}) + B(g)(r, \mathsf{k})\right]dr - \int_s^t \left[A(h)(r, \mathsf{k}) + B(h)(r, \mathsf{k})\right]dr\right| \\ &\quad = \left|\int_s^t \left[A(g - h)(r, \mathsf{k}) - A^*(g - h)(r, \mathsf{k})\right]dr\right| \\ &\quad \le (M_A + M_B)\|g - h\|_\alpha \int_s^t \exp\left(\alpha r^2\right)dr. \end{aligned}$$

Therefore, due to (4.3),

$$\left|\frac{H(g)(s, \mathsf{k})}{H(g)(t, \mathsf{k})} - \frac{H(h)(s, \mathsf{k})}{H(h)(t, \mathsf{k})}\right| \le (M_A + M_B)\|g - h\|_\alpha \int_s^t \exp\left(\alpha r^2\right)dr. \tag{4.6}$$

From this inequality, written for $s = 0$, we obtain

$$\left|\frac{f_0(\mathsf{k})}{H(g)(t, \mathsf{k})} - \frac{f_0(\mathsf{k})}{H(h)(t, \mathsf{k})}\right| \le |f_0(\mathsf{k})|(M_A + M_B)\|g - h\|_\alpha \int_0^t \exp\left(\alpha r^2\right)dr.$$

A simple computation shows that

$$\int_0^t \exp\left(\alpha r^2\right) dr \le \frac{1}{\sqrt{2\alpha}}\, \exp\left(\alpha t^2\right).$$

Consequently,

$$\left|\frac{f_0(\mathsf{k})}{H(g)(t,\mathsf{k})} - \frac{f_0(\mathsf{k})}{H(h)(t,\mathsf{k})}\right| \le \frac{M_A + M_B}{\sqrt{2\alpha}}\, \|g-h\|_\alpha \exp\left(\alpha t^2\right). \tag{4.7}$$

Next, bearing in mind (4.6), for every $(t,\mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3$ we have

$$\begin{aligned}
&\left|\frac{1}{H(g)(t,\mathsf{k})}\int_0^t H(g)(s,\mathsf{k})A(g)(s,\mathsf{k})ds - \frac{1}{H(h)(t,\mathsf{k})}\int_0^t H(h)(s,\mathsf{k})A(h)(s,\mathsf{k})ds\right| \\
&\quad \le \left|\int_0^t \frac{H(g)(s,\mathsf{k})}{H(g)(t,\mathsf{k})}A(g)(s,\mathsf{k})ds - \int_0^t \frac{H(g)(s,\mathsf{k})}{H(g)(t,\mathsf{k})}A(h)(s,\mathsf{k})ds\right| \\
&\quad + \left|\int_0^t \frac{H(g)(s,\mathsf{k})}{H(g)(t,\mathsf{k})}A(h)(s,\mathsf{k})ds - \int_0^t \frac{H(h)(s,\mathsf{k})}{H(h)(t,\mathsf{k})}A(h)(s,\mathsf{k})ds\right| \\
&\quad \le \int_0^t |A(g)(s,\mathsf{k}) - A(h)(s,\mathsf{k})|\, ds \\
&\quad + (M_A + M_B)\, \|g-h\|_\alpha \int_0^t ds \int_s^t |A(h)(s,\mathsf{k})| \exp\left(\alpha r^2\right) dr \\
&\quad \le M_A\|g-h\|_\alpha \left[\int_0^t \exp\left(\alpha s^2\right) ds + (M_A+M_B)\int_0^t ds \int_s^t \exp\left(\alpha r^2\right) dr\right] \\
&\quad \le M_A\|g-h\|_\alpha \left[\frac{1}{\sqrt{2\alpha}} \exp\left(\alpha t^2\right) + (M_A+M_B)\int_0^t dr \int_0^r \exp\left(\alpha r^2\right) ds\right] \\
&\quad = M_A\|g-h\|_\alpha \left[\frac{1}{\sqrt{2\alpha}} \exp\left(\alpha t^2\right) + (M_A+M_B)\, \frac{1}{2\alpha}\left(\exp\left(\alpha t^2\right) - 1\right)\right] \\
&\quad \le \frac{M_A\left(1 + M_A + M_B\right)}{\sqrt{2\alpha}} \|g-h\|_\alpha \exp\left(\alpha t^2\right)
\end{aligned}$$

because, by (4.5), $2\alpha > 1$. The preceding inequality, together with (4.7), gives

$$\|T(g) - T(h)\|_\alpha \le \frac{M_A + (1+M_A)\left(M_A+M_B\right)}{\sqrt{2\alpha}} \|g-h\|_\alpha.$$

Thus, the desired conclusion immediately follows from (4.5). □

Usually, one requires that the function $\mathsf{k} \to f(t,\mathsf{k})$ be integrable on $\mathbb{R}^3$. In the present setting this is achieved by assuming only that the initial datum f_0 is integrable.

THEOREM 4.2. *Let f_0 and f be as in Theorem* 4.1. *If $f_0 \in L^1(\mathbb{R}^3)$ then the function $\mathsf{k} \to f(t,\mathsf{k})$ is integrable on $\mathbb{R}^3$ for every $t \in \mathbb{R}_0^+$. Furthermore,* $\int_{\mathbb{R}^3} f(t,\mathsf{k})\, d\mathsf{k} = \int_{\mathbb{R}^3} f_0(\mathsf{k})\, d\mathsf{k}$.

Proof. Fix $\tau > 0$. We first note that if $g \in C^0(\mathbb{R}_0^+ \times \mathbb{R}^3) \cap L^1([0,\tau] \times \mathbb{R}^3)$ and $0 \le g(t,\mathsf{k}) \le 1$ for all $(t,\mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3$, then $A(g)$ is integrable on $[0,\tau] \times \mathbb{R}^3$. In fact, from Proposition 3.2 and (3.9) it follows that

$$\int_0^\tau dt \int_{\mathbb{R}^3} A(g)(t,\mathsf{k})\, d\mathsf{k} \le M_A \int_0^\tau dt \int_{\mathbb{R}^3} g(t,\mathsf{k})\, d\mathsf{k}\ .$$

Since $A(g)$ is nonnegative in $\mathbb{R}_0^+ \times \mathbb{R}^3$, the Tonelli theorem [9, p. 138] implies that $A(g) \in L^1([0,\tau] \times \mathbb{R}^3)$.

We now adopt the notation used in the proof of Theorem 4.1 and define $f_m = T(f_{m-1})$, $m \in \mathbb{N}$. Obviously, the sequence $\{f_m\}$ converges to f in Z. Moreover, we easily have

$$f_m(t,\mathsf{k}) \leq f_0(\mathsf{k}) + \int_0^t A\left(f_{m-1}\right)(s,\mathsf{k})\,ds$$

for every $m \in \mathbb{N}$, $(t,\mathsf{k}) \in \mathbb{R}_0^+ \times \mathbb{R}^3$. Since f_0 is integrable on $[0,\tau] \times \mathbb{R}^3$, the same holds for $A(f_0)$. Arguing by induction, we obtain $f_m \in L^1([0,\tau] \times \mathbb{R}^3)$ for all $m \in \mathbb{N}$ because, in view of (3.9),

$$\int_{\mathbb{R}^3} f_m(t,\mathsf{k})\,d\mathsf{k} \leq \int_{\mathbb{R}^3} f_0(\mathsf{k})\,d\mathsf{k} + M_A \int_0^t ds \int_{\mathbb{R}^3} f_{m-1}(s,\mathsf{k})\,d\mathsf{k}\ , \tag{4.8}$$

and thus

$$\int_0^\tau dt \int_{\mathbb{R}^3} f_m(t,\mathsf{k})\,d\mathsf{k} \leq \tau \left[\int_{\mathbb{R}^3} f_0(\mathsf{k})\,d\mathsf{k} + M_A \int_0^\tau ds \int_{\mathbb{R}^3} f_{m-1}(s,\mathsf{k})\,d\mathsf{k}\right].$$

It is a simple matter to see, by induction again and using inequality (4.8), that

$$\int_{\mathbb{R}^3} f_m(t,\mathsf{k})\,d\mathsf{k} \leq \exp(M_A t) \int_{\mathbb{R}^3} f_0(\mathsf{k})\,d\mathsf{k}$$

for $m \in \mathbb{N}$, $t \in \mathbb{R}_0^+$. Therefore, owing to Fatou's lemma [9, p. 129], the function $\mathsf{k} \to f(t,\mathsf{k})$ is integrable on $\mathbb{R}^3$ for every $t \in \mathbb{R}_0^+$ and f also belongs to $L^1([0,\tau] \times \mathbb{R}^3)$. From (3.7) we infer $Q(f) \in L^1([0,\tau] \times \mathbb{R}^3)$, so $\partial f/\partial t$ is integrable on $[0,\tau] \times \mathbb{R}^3$. Finally, taking into account Proposition 3.2, we get

$$\int_{\mathbb{R}^3} \frac{\partial f(t,\mathsf{k})}{\partial t}\,d\mathsf{k} = \int_{\mathbb{R}^3} Q(f)(t,\mathsf{k})\,d\mathsf{k} = 0 \quad \text{for every } t \in \mathbb{R}_0^+ .$$

Hence,

$$0 = \int_0^\tau dt \int_{\mathbb{R}^3} \frac{\partial f(t,\mathsf{k})}{\partial t}\,d\mathsf{k} = \int_{\mathbb{R}^3} d\mathsf{k} \int_0^\tau \frac{\partial f(t,\mathsf{k})}{\partial t}\,dt = \int_{\mathbb{R}^3} f(\tau,\mathsf{k})\,d\mathsf{k} - \int_{\mathbb{R}^3} f_0(\mathsf{k})\,d\mathsf{k}\ .$$

This completes the proof. □

5. Concluding remarks. We feel that it would be worthwhile to make some observations. The first concerns the presence of the term $\delta(\varepsilon' - \varepsilon \pm \hbar\omega_i)$ inside the collision operator Q. It leads to defining $Q(f)$ and, consequently, to solving problem (4.1)–(4.2) in the setting of functions $(t,\mathsf{k}) \to f(t,\mathsf{k})$ that are at least continuous with respect to the second variable. Actually, since the kernel of Q does not depend on t, the global continuity for f is quite natural.

The second remark concerns the continuity of the function $\mathcal{G}_i$ on the whole space $\mathbb{R}^3 \times \mathbb{R}^3$. In several applications and simulations, functions $\mathcal{G}_i$ defined and continuous only in a proper subset of $\mathbb{R}^3 \times \mathbb{R}^3$ are considered. In any case, $\mathcal{G}_i$ is continuous in the closed set $C = \left\{(\mathsf{k},\mathsf{k}') \in \mathbb{R}^3 \times \mathbb{R}^3 : |\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k})| = \hbar\omega_i\right\}$. By using the Tietze extension theorem [9, p. 192], we are able to find a continuous extension on the whole $\mathbb{R}^3 \times \mathbb{R}^3$. Now, in Appendix C it is shown that the integral

$$\int_{\mathbb{R}^3} \mathcal{G}_i(\mathsf{k},\mathsf{k}') f(t,\mathsf{k}') \delta(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) \pm \hbar\omega_i)\,d\mathsf{k}'$$

really can be calculated whenever we know the function $\mathcal{G}_i$ only on the set C. Hence, there is no loss of generality in assuming that $\mathcal{G}_i$ is continuous in $\mathbb{R}^3 \times \mathbb{R}^3$.

We next note that, by using hypotheses (a$_1$) and (a$_2$), the collision operator Q is reduced to an integral one, say $\tilde{Q}$, with a continuous kernel (see Appendix C). This new map naturally acts on the space of continuous functions, but it also may be considered in other function spaces. Consequently, the existence of solutions (in the relevant sense) to the full equation

$$\frac{\partial f}{\partial t} + \frac{1}{\hbar}\nabla_{\mathsf{k}}\varepsilon \cdot \nabla_{\mathsf{x}} f - \frac{e}{\hbar}\mathsf{E}\cdot\nabla_{\mathsf{k}} f = \tilde{Q}(f) \tag{5.1}$$

could be investigated in appropriate settings. Possible solutions of (5.1) do not solve, in general, the unmodified equation (2.1). Nevertheless, like in the case of the classical Boltzmann equation for a perfect rarefied gas, the study of (5.1) is of interest.

The final observation deals with the possibility of studying (2.1) as, in the right-hand side, the term describing electron–electron interactions is added to Q. In the simple parabolic case, it has the following expression [19]:

$$Q_{e-e}(f) = \int_{\mathbb{R}^3} \left[S_{e-e}(f)(\mathsf{k}',\mathsf{k})f'(1-f) - S_{e-e}(f)(\mathsf{k},\mathsf{k}')f(1-f')\right]\, d\mathsf{k}' \ , \tag{5.2}$$

where

$$\begin{aligned} S_{e-e}(f)(\mathsf{k},\mathsf{k}') &= \int_{\mathbb{R}^6} \mathcal{B}(|\mathsf{k}-\mathsf{k}'|, |\mathsf{k}-\mathsf{k}_*|) f_*(1-f'_*)\delta_\varepsilon\, \delta_{\mathsf{k}}\, d\mathsf{k}_*\ d\mathsf{k}'_*\,, \\ \delta_\varepsilon &= \delta\left(\varepsilon(\mathsf{k}) + \varepsilon(\mathsf{k}_*) - \varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}'_*)\right)\ , \\ \delta_{\mathsf{k}} &= \delta(\mathsf{k}+\mathsf{k}_* - \mathsf{k}' - \mathsf{k}'_*)\,, \end{aligned}$$

and $\mathcal{B}$ is a function satisfying suitable conditions. The operator Q_{e-e} seems to have the same form of Q, except for the kernel S_{e-e} that now depends on f. This is not completely true. In fact, $S_{e-e}(f)$ might not be defined even if $\mathcal{B}$ and f are continuous and bounded. This happens, for instance, when $\mathsf{k} = \mathsf{k}'$, in which case $\delta_\varepsilon\, \delta_{\mathsf{k}}$ becomes $\delta(\varepsilon(\mathsf{k}_*) - \varepsilon(\mathsf{k}'_*))\, \delta(\mathsf{k}_* - \mathsf{k}'_*)$.

A similar trouble occurs in the classical Boltzmann equation [4] where, to avoid the singularity, a cutoff is often introduced. The same approach may be tried in the present case. Unfortunately, several further difficulties arise whenever a general expression for ε is maintained.

Appendix A. In this appendix we list the most common expressions of the particle energy ε considered in applications and simulations [3], [10]. It is easily seen that each of them complies with assumptions (a$_1$) and (a$_2$).

$$\varepsilon(\mathsf{k}) = \frac{\hbar^2|\mathsf{k}|^2}{2m} \qquad \text{(parabolic case),}$$

$$\varepsilon(\mathsf{k}) = \varepsilon_c + \frac{\hbar^2}{2m_c}\ |\mathsf{k}-\mathsf{k}_c|^2 \qquad \text{(general parabolic case),}$$

$$\varepsilon(\mathsf{k}) = \frac{\hbar^2}{2}\left(\frac{k_1^2}{m_1} + \frac{k_2^2}{m_2} + \frac{k_3^2}{m_3}\right) \qquad \text{(ellipsoidal model),}$$

$$\varepsilon(\mathsf{k}) = \frac{\hbar^2|\mathsf{k}|^2}{2m}\,(1 - g(\vartheta,\varphi)) \qquad \text{(warped case),}$$

$$\varepsilon(\mathsf{k}) = \frac{-1 + \sqrt{1 + 2\dfrac{\alpha}{m}\hbar^2|\mathsf{k}|^2}}{2\alpha} \qquad \text{(nonparabolic case),}$$

$$\varepsilon(\mathsf{k}) = \frac{-1+\sqrt{1+2\alpha\hbar^2\left(\dfrac{k_l^2}{m_l}+\dfrac{k_t^2}{m_t}\right)}}{2\alpha} \qquad \text{(nonparabolic case)}.$$

Here, m, ε_c, m_c, k_c, m_1, m_2, m_3, α, m_l, and m_t are constant parameters. Moreover, k_1, k_2, k_3 denote the components of the vector k, and k_l, k_t are the lengths of the longitudinal and transverse projections of k with respect to an assigned direction. Finally, the function $g : [0, 2\pi] \times [0, \pi] \to \mathbb{R}$ is continuous and strictly less than one.

Appendix B. A well-known definition of the Dirac distribution δ is given by using the following family of functions with compact support [8].

Let $r \in \mathbb{R}^+$ and let $\omega_r : \mathbb{R} \to \mathbb{R}_0^+$ be the function defined by setting, for $z \in \mathbb{R}$,

$$\omega_r\,(z) = \begin{cases} \dfrac{\exp(1/2)}{K_1(1/2) - K_0(1/2)}\,\dfrac{1}{r}\,\exp\left(-\dfrac{r^2}{r^2-z^2}\right) & \text{if } |z| < r, \\ 0 & \text{otherwise,} \end{cases}$$

where K_0 and K_1 are modified Bessel functions [1], so

$$\int_{-\infty}^{+\infty} \omega_r\,(z)\; dz = 1.$$

The following lemma is an easy extension of useful facts concerning the regularization of a function [2, p. 30].

LEMMA B.1. *Let V be a nonempty subset of a real Euclidean space, let $\lambda \in C^0(\mathbb{R}^3)$, and let $\gamma \in C^0(V \times \mathbb{R}^3 \times \mathbb{R})$. Then, for every $(\mathsf{v}, \mathsf{k}) \in V \times \mathbb{R}^3$, one has*

$$\lim_{r\to 0^+} \int_{-\infty}^{+\infty} \gamma(\mathsf{v}, \mathsf{k}, u)\omega_r\,(u - \lambda(\mathsf{k}))\, du = \gamma(\mathsf{v}, \mathsf{k}, \lambda(\mathsf{k})). \tag{B.1}$$

Further, (B.1) *uniformly holds on any compact set $\Delta \subseteq V \times \mathbb{R}^3$.*

Proof. The first assertion is well known (see, for instance, [2, Lemma 2.18]). So, let us pick a compact subset Δ of $V \times \mathbb{R}^3$. Since

$$\int_{-\infty}^{+\infty} \gamma(\mathsf{v}, \mathsf{k}, u)\omega_r\,(u - \lambda(\mathsf{k}))\, du = \int_{-\infty}^{+\infty} \gamma(\mathsf{v}, \mathsf{k}, \lambda(\mathsf{k}) + s)\omega_r\,(s)\, ds, \quad (\mathsf{v}, \mathsf{k}) \in \Delta,$$

we get

$$\begin{aligned} &\left|\int_{-\infty}^{+\infty} \gamma(\mathsf{v}, \mathsf{k}, u)\omega_r\,(u - \lambda(\mathsf{k}))\, du - \gamma(\mathsf{v}, \mathsf{k}, \lambda(\mathsf{k}))\right| \\ &\quad\le \int_{-r}^{r} |\gamma(\mathsf{v}, \mathsf{k}, \lambda(\mathsf{k}) + s) - \gamma(\mathsf{v}, \mathsf{k}, \lambda(\mathsf{k}))|\,\omega_r\,(s)\, ds \\ &\quad\le \sup\left\{|\gamma(\mathsf{v}, \mathsf{k}, \lambda(\mathsf{k}) + s) - \gamma(\mathsf{v}, \mathsf{k}, \lambda(\mathsf{k}))| : (\mathsf{v}, \mathsf{k}) \in \Delta,\ |s| \le r\right\}. \end{aligned}$$

Then, by using the uniform continuity of the function $(\mathsf{v}, \mathsf{k}, s) \to \gamma(\mathsf{v}, \mathsf{k}, \lambda(\mathsf{k}) + s)$ on the compact set $\Delta \times [-r, r]$, we see that the second assertion is true too. $\square$

Throughout this appendix we denote by W a generic interval of a real Euclidean space and by p and λ two functions belonging to $C^0(W \times \mathbb{R}^3 \times \mathbb{R}^3)$ and $C^0(\mathbb{R}^3)$, respectively. For every $(\mathsf{w}, \mathsf{k}) \in W \times \mathbb{R}^3$, we define

$$\int_{\mathbb{R}^3} p(\mathsf{w}, \mathsf{k}, \mathsf{k}')\, \delta(\varepsilon(\mathsf{k}') - \lambda(\mathsf{k}))\, d\mathsf{k}' = \lim_{r\to 0^+} \int_{\mathbb{R}^3} p(\mathsf{w}, \mathsf{k}, \mathsf{k}')\omega_r\,(\varepsilon(\mathsf{k}') - \lambda(\mathsf{k}))\; d\mathsf{k}'. \tag{B.2}$$

Since, in view of (a$_{23}$), the set $\{\mathsf{k}' \in \mathbb{R}^3 : |\varepsilon(\mathsf{k}') - \lambda(\mathsf{k})| < r\}$ is bounded, the function $\mathsf{k}' \to \omega_r(\varepsilon(\mathsf{k}') - \lambda(\mathsf{k}))$ has compact support. Therefore,

$$\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\omega_r(\varepsilon(\mathsf{k}') - \lambda(\mathsf{k}))\, d\mathsf{k}' < +\infty \quad \text{for all } r > 0.$$

To prove that the right-hand side of (B.2) is a real number, we make a change of variables in the integral. Set $u_0 = \varepsilon(\mathsf{k}_0)$ and $\Omega_0 = [u_0, +\infty[\times D$. Assumption (a$_2$) guarantees that η maps $\mathbb{R}_0^+ \times D$ onto $[u_0, +\infty[$ and, for fixed (ϑ, φ), that the function $\rho \to \eta(\rho, \vartheta, \varphi)$ is strictly increasing on $\mathbb{R}_0^+$. Hence, there exists a unique function $v : \Omega_0 \to \mathbb{R}_0^+$ satisfying

$$\eta(v(u,\vartheta,\varphi),\vartheta,\varphi) = u \quad \text{for every } (u,\vartheta,\varphi) \in \Omega_0. \tag{B.3}$$

Lemma B.2. *The function v is continuous in Ω_0.*

Proof. Pick $(u,\vartheta,\varphi) \in \Omega_0$ and choose a sequence $\{(u_k,\vartheta_k,\varphi_k)\} \subseteq \Omega_0$ converging to (u,ϑ,φ). Moreover, set $\rho_k = v(u_k,\vartheta_k,\varphi_k)$, $k \in \mathbb{N}$. Making use of (B.3) and assumption (a$_{23}$), we see that $\{\rho_k\}$ is bounded. Due to the continuity of η, for any convergent subsequence $\{\rho_{r_k}\}$, one has

$$u = \lim_{k\to\infty} u_{r_k} = \lim_{k\to\infty} \eta(\rho_{r_k}, \vartheta_{r_k}, \varphi_{r_k}) = \eta\left(\lim_{k\to\infty} \rho_{r_k}, \vartheta, \varphi\right).$$

Thus, again by (B.3), $\lim_{k\to\infty} \rho_{r_k} = v(u,\vartheta,\varphi)$. This clearly forces $\lim_{k\to\infty} v(u_k,\vartheta_k,\varphi_k) = v(u,\vartheta,\varphi)$. □

The preceding proof is motivated by the fact that standard implicit function theorems cannot be applied to prove the continuity of the function v on the boundary of the set Ω_0.

Since $v(u_0,\vartheta,\varphi) = 0$, $(\vartheta,\varphi) \in D$, a continuous extension of v over $\Omega = \mathbb{R} \times D$ can be obtained by setting $v(u,\vartheta,\varphi) = 0$ for every $(u,\vartheta,\varphi) \in]-\infty, u_0[\times D$. Finally, if $(u,\vartheta,\varphi) \in \Omega$, we define

$$J(u,\vartheta,\varphi) = \begin{cases} 0 & \text{if } u \le u_0, \\ [v(u,\vartheta,\varphi)]^2 \left[\left.\dfrac{\partial \eta(\rho,\vartheta,\varphi)}{\partial \rho}\right|_{\rho = v(u,\vartheta,\varphi)} \right]^{-1} \sin\varphi & \text{otherwise.} \end{cases}$$

Lemma B.2 and hypothesis (a$_{22}$) imply $J \in C^0(\Omega)$. Moreover, we have the following lemma.

Lemma B.3. *For every $(\mathsf{w},\mathsf{k}) \in W \times \mathbb{R}^3$, one has*

$$\begin{aligned} &\lim_{r\to 0^+} \int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\omega_r(\varepsilon(\mathsf{k}') - \lambda(\mathsf{k}))\, d\mathsf{k}' \\ &\qquad = \int_D p(\mathsf{w},\mathsf{k},\mathsf{k}_0 + v(\lambda(\mathsf{k}),\vartheta,\varphi)\mathsf{n}) J(\lambda(\mathsf{k}),\vartheta,\varphi) d\vartheta\, d\varphi. \end{aligned} \tag{B.4}$$

Further, (B.4) *uniformly holds on any compact subset Δ of $W \times \mathbb{R}^3$.*

Proof. Fix $(\mathsf{w},\mathsf{k}) \in W \times \mathbb{R}^3$ and observe that

$$\begin{aligned} &\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\omega_r(\varepsilon(\mathsf{k}') - \lambda(\mathsf{k}))\, d\mathsf{k}' \\ &\quad = \int_D d\vartheta\, d\varphi\, \sin\varphi \int_0^{+\infty} p(\mathsf{w},\mathsf{k},\mathsf{k}_0 + \rho\mathsf{n})\omega_r(\varepsilon(\mathsf{k}_0 + \rho\mathsf{n}) - \lambda(\mathsf{k}))\, \rho^2 d\rho, \quad r > 0. \end{aligned}$$

Let us write $\hat{\gamma}(\mathsf{w},\mathsf{k},u,\vartheta,\varphi)$ in place of $p(\mathsf{w},\mathsf{k},\mathsf{k}_0+v(u,\vartheta,\varphi)\mathsf{n})J(u,\vartheta,\varphi)$. By making the change of variable $\rho=v(u,\vartheta,\varphi)$ in the last integral, we get

$$\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\omega_r\left(\varepsilon(\mathsf{k}')-\lambda(\mathsf{k})\right)\,d\mathsf{k}' = \int_D d\vartheta\,d\varphi \int_{u_0}^{+\infty} \hat{\gamma}(\mathsf{w},\mathsf{k},u,\vartheta,\varphi)\omega_r\left(u-\lambda(\mathsf{k})\right)du$$

and, due to the properties of the function J,

$$\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\omega_r\left(\varepsilon(\mathsf{k}')-\lambda(\mathsf{k})\right)\,d\mathsf{k}' = \int_D d\vartheta\,d\varphi \int_{-\infty}^{+\infty} \hat{\gamma}(\mathsf{w},\mathsf{k},u,\vartheta,\varphi)\,\omega_r\left(u-\lambda(\mathsf{k})\right)du.$$

Moreover, owing to Lemma B.1,

$$\text{(B.5)}\qquad \lim_{r\to 0^+}\int_{-\infty}^{+\infty} \hat{\gamma}(\mathsf{w},\mathsf{k},u,\vartheta,\varphi)\,\omega_r\left(u-\lambda(\mathsf{k})\right)du = \hat{\gamma}(\mathsf{w},\mathsf{k},\lambda(\mathsf{k}),\vartheta,\varphi)$$

uniformly in $(\vartheta,\varphi)\in D$. Hence,

$$\begin{aligned}\lim_{r\to 0^+}&\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\omega_r\left(\varepsilon(\mathsf{k}')-\lambda(\mathsf{k})\right)\,d\mathsf{k}'\\ &= \lim_{r\to 0^+}\int_D d\vartheta\,d\varphi \int_{-\infty}^{+\infty} \hat{\gamma}(\mathsf{w},\mathsf{k},u,\vartheta,\varphi)\,\omega_r\left(u-\lambda(\mathsf{k})\right)du\\ &= \int_D \hat{\gamma}(\mathsf{w},\mathsf{k},\lambda(\mathsf{k}),\vartheta,\varphi)d\vartheta\,d\varphi.\end{aligned}$$

Since, by Lemma B.1 again, (B.5) uniformly holds on $\Delta\times D$ for any compact subset Δ of $W\times\mathbb{R}^3$, the conclusion follows. □

The preceding lemma, together with (B.2), leads to

$$\text{(B.6)}\qquad \begin{aligned}&\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\lambda(\mathsf{k}))\,d\mathsf{k}'\\ &\quad= \int_D p(\mathsf{w},\mathsf{k},\mathsf{k}_0+v(\lambda(\mathsf{k}),\vartheta,\varphi)\mathsf{n})J(\lambda(\mathsf{k}),\vartheta,\varphi)\,d\vartheta\,d\varphi.\end{aligned}$$

Consequently, the continuity theorem for integrals depending on a parameter yields the following lemma.

Lemma B.4. *The function*

$$(\mathsf{w},\mathsf{k})\to\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta\left(\varepsilon(\mathsf{k}')-\lambda(\mathsf{k})\right)\,d\mathsf{k}',\quad (\mathsf{w},\mathsf{k})\in W\times\mathbb{R}^3,$$

is continuous in $W\times\mathbb{R}^3$.

We denote by $C_0^0(\mathbb{R}^3)$ the space of all functions $\psi\in C^0(\mathbb{R}^3)$ which have compact support suppψ.

Lemma B.5. *Let* $\mu\in\mathbb{R}$. *Then, for every* $\psi\in C_0^0(\mathbb{R}^3)$, $\mathsf{w}\in W$,

$$\text{(B.7)}\qquad \begin{aligned}&\int_{\mathbb{R}^3} d\mathsf{k}\,\psi(\mathsf{k})\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}'\\ &\quad= \int_{\mathbb{R}^3} d\mathsf{k}'\int_{\mathbb{R}^3} \psi(\mathsf{k})p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}\,.\end{aligned}$$

Proof. Choose $\psi \in C_0^0(\mathbb{R}^3)$ and $\mathsf{w} \in W$. By Lemma B.4, the left-hand side of (B.7) is a real number. Since, owing to Lemma B.3,

$$\lim_{r\to 0^+} \int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\omega_r\left(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu\right)\, d\mathsf{k}' = \int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu)\, d\mathsf{k}'$$

uniformly in $\{\mathsf{w}\} \times \mathrm{supp}\psi$, we get

$$\begin{aligned}\text{(B.8)} \qquad & \int_{\mathbb{R}^3} d\mathsf{k}\, \psi(\mathsf{k}) \int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu)\, d\mathsf{k}' \\ &\quad = \lim_{r\to 0^+} \int_{\mathbb{R}^3} d\mathsf{k} \int_{\mathbb{R}^3} \psi(\mathsf{k}) p(\mathsf{w},\mathsf{k},\mathsf{k}')\omega_r\left(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu\right)\, d\mathsf{k}'\,.\end{aligned}$$

For every $r > 0$ the function $(\mathsf{k},\mathsf{k}') \to \psi(\mathsf{k})p(\mathsf{w},\mathsf{k},\mathsf{k}')\omega_r\left(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu\right)$ has compact support in $\mathbb{R}^3 \times \mathbb{R}^3$ because, by assumption (a_{23}), the set

$$\left\{(\mathsf{k},\mathsf{k}') \in \mathbb{R}^3 \times \mathbb{R}^3 : \mathsf{k} \in \mathrm{supp}\psi,\ |\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu| \le r\right\}$$

is compact. Therefore, due to (B.8) and Lemma B.3 again,

$$\begin{aligned}& \int_{\mathbb{R}^3} d\mathsf{k}\, \psi(\mathsf{k}) \int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu)\, d\mathsf{k}' \\ &\quad = \lim_{r\to 0^+} \int_{\mathbb{R}^3} d\mathsf{k}' \int_{\mathbb{R}^3} \psi(\mathsf{k}) p(\mathsf{w},\mathsf{k},\mathsf{k}')\omega_r\left(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu\right)\, d\mathsf{k} \\ &\quad = \int_{\mathbb{R}^3} d\mathsf{k}' \lim_{r\to 0^+} \int_{\mathbb{R}^3} \psi(\mathsf{k}) p(\mathsf{w},\mathsf{k},\mathsf{k}')\omega_r\left(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu\right)\, d\mathsf{k} \\ &\quad = \int_{\mathbb{R}^3} d\mathsf{k}' \int_{\mathbb{R}^3} \psi(\mathsf{k}) p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu)\, d\mathsf{k}\,.\end{aligned}$$

This completes the proof. □

We note that the presence of the Dirac distribution δ prevents the establishment of (B.7) through the usual formulas on the change of order of integration. As an example, if $p(z,z') = (1 + |z||z'-1|)/(1+z^2)$, $z, z' \in \mathbb{R}$, then

$$\int_{-\infty}^{+\infty} dz \int_{-\infty}^{+\infty} p(z,z')\,\delta(z'-1)\, dz' = \int_{-\infty}^{+\infty} p(z,1)\, dz = \pi\,,$$

whereas the other iterated integral does not exist, because

$$\int_{-\infty}^{+\infty} p(z,z')\, dz = +\infty \quad \text{whenever } z' \neq 1\,.$$

Lemma B.6. *Let $\mu \in \mathbb{R}$. If $p(\mathsf{w},\mathsf{k},\mathsf{k}') \ge 0$ in $W \times \mathbb{R}^3 \times \mathbb{R}^3$ and, for any $\mathsf{w} \in W$, the function*

$$\mathsf{k} \to \int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k}) - \mu)\, d\mathsf{k}'$$

is integrable on $\mathbb{R}^3$, then (B.7) *holds for all nonnegative bounded $\psi \in C^0(\mathbb{R}^3)$.*

Proof. Pick $w \in W$ and choose a function ψ with the asserted properties. Moreover, let $\psi_n : \mathbb{R} \to \mathbb{R}_0^+$, $n \in \mathbb{N}$, be defined as in (3.8). Assumption (a_{23}) guarantees that the function $\mathsf{k} \to \psi_n(\varepsilon(\mathsf{k}))$ has compact support. Hence, by Lemma B.5,

$$\begin{aligned}\text{(B.9)}\qquad &\int_{\mathbb{R}^3} d\mathsf{k}\,\psi(\mathsf{k})\psi_n(\varepsilon(\mathsf{k}))\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}'\\ &\quad=\int_{\mathbb{R}^3} d\mathsf{k}'\int_{\mathbb{R}^3}\psi(\mathsf{k})\psi_n(\varepsilon(\mathsf{k}))p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}\end{aligned}$$

for $n \in \mathbb{N}$. Both sides of (B.9) are nonnegative and less than or equal to the real number

$$\int_{\mathbb{R}^3} d\mathsf{k}\,\psi(\mathsf{k})\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}'\,.$$

Since $\psi_n(z) \le \psi_{n+1}(z)$ for all $n \in \mathbb{N}$ and $z \in \mathbb{R}$, the sequence of functions

$$\mathsf{k} \to \psi(\mathsf{k})\psi_n(\varepsilon(\mathsf{k}))\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}'$$

is nondecreasing and pointwise convergent in $\mathbb{R}^3$ to

$$\mathsf{k} \to \psi(\mathsf{k})\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}'\,.$$

So, the monotone convergence theorem [9, p. 129] gives

$$\begin{aligned}\text{(B.10)}\qquad &\lim_{n\to\infty}\int_{\mathbb{R}^3} d\mathsf{k}\,\psi(\mathsf{k})\psi_n(\varepsilon(\mathsf{k}))\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}'\\ &\quad=\int_{\mathbb{R}^3} d\mathsf{k}\,\psi(\mathsf{k})\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}'\,.\end{aligned}$$

Making use of (B.6), it is not difficult to see that

$$\begin{aligned}&\int_{\mathbb{R}^3} d\mathsf{k}'\int_{\mathbb{R}^3}\psi(\mathsf{k})\psi_n(\varepsilon(\mathsf{k}))p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}\\ &\quad=\int_{\mathbb{R}^3} d\mathsf{k}'\,\psi_n(\varepsilon(\mathsf{k}')-\mu)\int_{\mathbb{R}^3}\psi(\mathsf{k})p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}\end{aligned}$$

for every $n \in \mathbb{N}$. This formula, together with (B.9) and (B.10), leads to

$$\begin{aligned}&\int_{\mathbb{R}^3} d\mathsf{k}\,\psi(\mathsf{k})\int_{\mathbb{R}^3} p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}'\\ &\quad=\lim_{n\to\infty}\int_{\mathbb{R}^3} d\mathsf{k}'\,\psi_n(\varepsilon(\mathsf{k}')-\mu)\int_{\mathbb{R}^3}\psi(\mathsf{k})p(\mathsf{w},\mathsf{k},\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})-\mu)\,d\mathsf{k}\,.\end{aligned}$$

Now, the same arguments used to prove (B.10) yield the conclusion. □

Appendix C. In view of (B.6), we get

$$\begin{aligned}\text{(C.1)}\qquad &\int_{\mathbb{R}^3}\mathcal{G}_i(\mathsf{k},\mathsf{k}')f(t,\mathsf{k}')\delta(\varepsilon(\mathsf{k}')-\varepsilon(\mathsf{k})\pm\hbar\omega_i)\,d\mathsf{k}'\\ &\quad=\int_D \mathcal{G}_i(\mathsf{k},\xi_\mp(\vartheta,\varphi,\mathsf{k}))f(t,\xi_\mp(\vartheta,\varphi,\mathsf{k}))J(\varepsilon(\mathsf{k})\mp\hbar\omega_i,\vartheta,\varphi)d\vartheta\,d\varphi,\end{aligned}$$

where $\xi_{\mp}(\vartheta,\varphi,\mathsf{k}) = \mathsf{k}_0 + v(\varepsilon(\mathsf{k}) \mp \hbar\omega_i, \vartheta, \varphi)\mathsf{n}$. Now $\mathsf{k}' = \xi_{\mp}(\vartheta,\varphi,\mathsf{k})$ satisfies the equation $\varepsilon(\mathsf{k}') = \varepsilon(\mathsf{k}) \mp \hbar\omega_i$ for all $(\vartheta,\varphi) \in D$, $\mathsf{k} \in \mathbb{R}^3$. In fact, recalling the definition of the function η (see hypothesis (a_2)) and (B.3), we have

$$\begin{aligned}\varepsilon(\mathsf{k}') &= \varepsilon\left(\mathsf{k}_0 + v(\varepsilon(\mathsf{k}) \mp \hbar\omega_i, \vartheta, \varphi)\mathsf{n}\right)\\ &= \eta\left(v(\varepsilon(\mathsf{k}) \mp \hbar\omega_i, \vartheta, \varphi), \vartheta, \varphi\right) = \varepsilon(\mathsf{k}) \mp \hbar\omega_i.\end{aligned}$$

Therefore, in the integral at the left-hand side of (C.1), the function $\mathcal{G}_i$ is actually evaluated for (k,k') in the set $\left\{(\mathsf{k},\mathsf{k}') \in \mathbb{R}^3 \times \mathbb{R}^3 : |\varepsilon(\mathsf{k}') - \varepsilon(\mathsf{k})| = \hbar\omega_i\right\}$.

ESTIMATES ON THE HEAT KERNEL OF PARABOLIC EQUATIONS WITH ADVECTION*

ADRIAN T. HILL†

Abstract. The paper considers heat kernels of second-order parabolic equations in $\mathbb{R}^N$, with constant uniform diffusion and advective coefficients bounded in the maximum norm. Two critical cases, corresponding to upper and lower solutions, are identified, and explicit solutions are constructed for them in terms of the error function. They are shown to bound above and below all other heat kernels satisfying the same constraints on their advective coefficients by using a method of proof which relates two heat kernels together in a way which resembles the classical parametrix construction. Sharp bounds on the corresponding parabolic solution operators in $L_1(\mathbb{R}^N)$ are obtained as a consequence.

Key words. heat kernels, non-self-adjoint operators

1. Introduction.

Upper and lower pointwise bounds on the heat kernels of second-order parabolic operators were first derived, for the general case of variable diffusion and advection coefficients in L_p spaces, by Aronson [1]. These initial qualitative estimates have more recently been sharpened, in the self-adjoint case, by Davies [2] and Fabes and Stroock [3]. For the non-self-adjoint case of equations with advection, sharper estimates have been obtained by Norris and Stroock [6].

Here, we consider the heat kernel $\Gamma(x,\,t;\,y,\,s)$ of the equation

$$Lu(x,t) \equiv \frac{\partial u}{\partial t} - \Delta\ u + a(x,\,t).\nabla u = 0, \qquad (x,\,t) \in \mathbb{R}^N \times (0,\,\infty), \tag{1.1}$$

with constant uniform diffusion, and aim to obtain sharper estimates in this physically significant special case. Our methods are classically based and, thus, we initially take a to obey assumption (A):

(A) $a(x,\,t)$ is a continuous function, Hölder continuous in x (exponent α), uniformly with respect to $(x,\,t)$ in subsets of the form $\mathbb{R}^N \times [0,\,T)$, for $T > 0$. The a_i also satisfy (1.2).

$$\text{ess. sup}_{(x,\,t)\in\mathbb{R}^N\times[0,\,\infty)}|a_i(x,\,t)| \le M_i \qquad \text{for } M_i \ge 0,\ i = 1,\,\ldots,\,N. \tag{1.2}$$

We recall that the classical heat kernel $\Gamma(x,\,t;\,y,\,s)$, $x,\,y \in \mathbb{R}^N$, $t > s \ge 0$, may be characterized as a solution of (1.1), twice continuously differentiable in space and once in time, such that

$$\lim_{t\searrow s}\int_{\mathbb{R}^N}\Gamma(x,\,t;\,y,\,s)f(y)\,dy = f(x) \tag{1.3}$$

for all continuous $f \in L_1(\mathbb{R}^N)$.

†School of Mathematical Sciences, University of Bath, BA2 7AY, United Kingdom (ath@maths.bath.ac.uk).

To derive a pointwise upper bound on $\Gamma(x,\, t;\, y, s)$ for fixed y and s, we explicitly construct a function $G_M(x-y,\, t-s)$, which is the solution of

$$\frac{\partial u}{\partial t} - \Delta u + \sum_{i=1}^{N} M_i \mathrm{sign}[x_i - y_i] \frac{\partial u}{\partial x_i} = 0, \qquad (x,\, t) \in \mathbb{R}^N \times (0,\, \infty), \tag{1.4}$$

such that

$$\lim_{t \searrow s} \int_{\mathbb{R}^N} G_M(x-y,\, t-s) f(y)\, dy = f(x) \tag{1.5}$$

for all continuous $f \in L_1(\mathbb{R}^N)$. Here, we use the convention $\mathrm{sign}[0] = 0$, and $M = [M_1,\, M_2,\, \ldots,\, M_N]^T$, where the M_i are as in (1.2).

The constructed function $G_M(x-y,\, t-s)$ also satisfies

$$\mathrm{sign}[x_i - y_i] \frac{\partial G_M}{\partial x_i} \leq 0, \qquad i = 1,\, \ldots,\, N, \tag{1.6}$$

and is, therefore, one of the solutions of the nonlinear equation

$$\frac{\partial u}{\partial t} - \Delta u - \sum_{i=1}^{N} M_i \left| \frac{\partial u}{\partial x_i} \right| = 0, \qquad (x,\, t) \in \mathbb{R}^N \times (0,\, \infty). \tag{1.7}$$

We remark that the maximality of nonsingular solutions of (1.7) has previously been considered by Pucci [7].

If one ignores the singularity at $(x,\, t) = (y,\, s)$, then intuitively $G_M(x-y,\, t-s)$ should bound $\Gamma(x,\, t;\, y, s)$ pointwise above, because it is an upper solution for (1.1), (1.3) in the sense of the comparison principle. In our main result we prove this relationship by representing Γ as the sum of G_M and a nonpositive integral term; our representation resembles, in a way, the classical parametrix construction of the heat kernel. A lower bound is similarly obtained by considering $G_{-M}(x,\, t;\, y,\, s)$, the solution of (1.4), (1.5) with $-M_i$ replacing M_i.

By appealing to the machinery of Aronson [1], this classical result is extended to the case where a obeys assumption (B):

$$a \in L_\infty[\mathbb{R}^N \times [0,\, \infty)] \text{ and } a \text{ satisfies (1.2).} \tag{B}$$

The pointwise upper limit on $\Gamma(x,\, t;\, y,\, s)$ is actually attained within the wider class of equations obeying assumption (B). This is seen from the fact that $G_M(x - y, t-s)$ satisfies (1.4) and (1.5) and is, therefore, equal to $\Theta_M(z;\, x,\, t;\, y,\, s)$, the heat kernel of

$$\frac{\partial u}{\partial t} - \Delta u + \sum_{i=1}^{N} M_i \mathrm{sign}[x_i - z_i] \frac{\partial u}{\partial x_i} = 0 \tag{1.8}$$

when $y = z$. A similar argument shows that the lower bound is also attained. Since Aronson [1] has shown that Θ_M may be pointwise approximated by the heat kernels of equations satisfying assumption (A), the upper and lower bounds given by $G_{\pm M}(x,\, t;\, y,\, s)$ are sharp (though not attained) in that case.

In section 4, we use the pointwise upper and lower bounds on $\Gamma(x,\, t;\, y,\, s)$ to deduce sharp upper and lower L_1 bounds on the solutions of (1.1) with $u(0) = u_0 \in L_1(\mathbb{R})$. In particular, we obtain

$$\|u(t)\|_1 \le \prod_{i=1}^{N} \left(2 + M_i^2 t\right) \|u_0\|_1.$$

2. Main result. For $M \in \mathbb{R}$, consider the function $g_M : \mathbb{R} \times (0,\, \infty) \to (0,\, \infty)$ given by

$$g_M(x,\, t) = \frac{1}{2\sqrt{\pi t}} \exp\left\{-\frac{(|x| - Mt)^2}{4t}\right\} + \frac{M}{4} \operatorname{erfc}\left(\frac{|x|}{2\sqrt{t}} - \frac{M\sqrt{t}}{2}\right), \tag{2.1}$$

where $\operatorname{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2}\, dt$. By direct differentiation,

$$\begin{aligned}
\frac{\partial g_M}{\partial x} &= \frac{-x}{4\sqrt{\pi t^3}} \exp\left\{-\frac{(|x| - Mt)^2}{4t}\right\},\\
\frac{\partial^2 g_M}{\partial x^2} &= \frac{1}{4\sqrt{\pi t^3}} \left(-1 + \frac{x^2}{2t} - \frac{M|x|}{2}\right) \exp\left\{-\frac{(|x| - Mt)^2}{4t}\right\},\\
\frac{\partial g_M}{\partial t} &= \frac{1}{4\sqrt{\pi t^3}} \left(-1 + \frac{x^2}{2t} + \frac{M|x|}{2}\right) \exp\left\{-\frac{(|x| - Mt)^2}{4t}\right\}.
\end{aligned} \tag{2.2}$$

Each of the right-hand sides is Lipschitz continuous. (Note that $\partial^3 g_M/\partial x^3$ is discontinuous at $x = 0$.) We deduce that g_M is a classical solution of

$$\frac{\partial u}{\partial t} - \frac{\partial^2 u}{\partial x^2} + M \operatorname{sign}[x] \frac{\partial u}{\partial x} = 0, \qquad (x,\, t) \in \mathbb{R} \times (0,\, \infty). \tag{2.3}$$

We define

$$G_M(x,\, t) = \prod_{i=1}^{N} g_{M_i}(x_i,\, t) \qquad \text{for } M \in \mathbb{R}^N. \tag{2.4}$$

By (2.2)–(2.4), $G_M(x - y,\, t)$ satisfies (1.4) and (1.6).

THEOREM 2.1. *Suppose that for some $M \in [0,\, \infty)^N$, $a(x,\, t)$ satisfies assumption* (B). *Then, for all $x,\, y \in \mathbb{R}^N$, $t > s \ge 0$,*

$$G_{-M}(x - y,\, t - s) \le \Gamma(x,\, t;\, y, s) \le G_M(x - y,\, t - s). \tag{2.5}$$

For each $y \in \mathbb{R}^N$, these bounds are attained for all $x \in \mathbb{R}^N$, $t > s \ge 0$ by the heat kernels $\Theta_{\pm M}(z;\, x,\, t;\, y,\, s)$ of (1.8) *when $y = z$.*

Remark. Aronson [1, Theorem 10, p. 679] shows that $\Gamma(x,\, t;\, y,\, s) = \tilde{\Gamma}(y,\, s;\, x,\, t)$ for $t > s \ge 0$, where $\tilde{\Gamma}$ is the heat kernel for the adjoint problem to (1.1):

$$\tilde{L}[u] \equiv \frac{\partial v}{\partial s} + \Delta v + \nabla.(a(y,\, s)v) = 0, \qquad (y,\, s) \in \mathbb{R}^N \times [0,\, t). \tag{2.6}$$

Hence, Theorem 2.1 also implies pointwise bounds for $\tilde{\Gamma}$.

3. Proof of main result.

We begin here with the following lemma.

LEMMA 3.1. *If* (1.1) *obeys assumption* (A) *for some* $M \in [0, \infty)^N$*, then*

$$\Gamma(x, t; y, s) = G(x-y, t-s) - \int_s^t \int_{\mathbb{R}^N} \Gamma(x, t; \eta, \sigma) LG(\eta - y, \sigma - s)\, d\eta d\sigma, \tag{3.1}$$

where $G(x, t)$ *is either* $G_M(x, t)$ *or* $G_{-M}(x, t)$.

Proof. The proof relies on the account given by Friedman [4, Chapter 1] of the parametrix method. Here, for $t_0 \in (s, t)$ and $D = \{z \mid |z - x| \le 1\}$, the integral on the right-hand side of (3.1) is split up as $J_1 + J_2 + J_3$, where

$$J_1 = \int_s^{t_0} \int_{\mathbb{R}^N} \Gamma(x, t; \eta, \sigma) LG(\eta - y, \sigma - s)\, d\eta d\sigma,$$

$$J_2 = \int_{t_0}^{t} \int_{\mathbb{R}^N \setminus D} \Gamma(x, t; \eta, \sigma) LG(\eta - y, \sigma - s)\, d\eta d\sigma,$$

$$J_3 = \int_{t_0}^{t} \int_{D} \Gamma(x, t; \eta, \sigma) LG(\eta - y, \sigma - s)\, d\eta d\sigma.$$

For J_1 and J_2, $\Gamma(x, t; \eta, \sigma)$ has second derivatives in x, continuous with respect to $(x, t; \eta, \sigma)$. On the other hand, for C and c, generic positive constants,

$$\begin{aligned} |LG(\eta - y, \sigma - s)| &= \left| \sum_{i=1}^N \left(a_i(\eta, \sigma) \mp M_i \text{sign}[\eta_i - y_i] \frac{\partial G}{\partial \eta_i} \right) \right| \\ &\le C \sum_{i=1}^N \left| \frac{\partial G}{\partial \eta_i} \right| \\ &\le \frac{C|\eta - y|}{(\sigma - s)^{(N+2)/2}} \exp\left(-(|\eta - y| - M(\sigma - s))^2 / 4(\sigma - s) \right) \\ &\le \frac{C}{(\sigma - s)^{3/4} |\eta - y|^{(N-1/2)}} \exp\left(-c|\eta - y|^2/(\sigma - s) \right) \end{aligned}$$

and so is absolutely integrable. Hence, differentiation in x and t commutes with integration in J_1 and J_2. (We note here that differentiation of the upper limit t in J_2 is valid, but that this yields a term which one may show to be 0.)

For J_3, we observe that for fixed y and s,

$$LG(\eta - y, \sigma - s) = \sum_{i=1}^N (a_i(\eta, \sigma) \mp M_i \text{sign}[\eta_i - y_i]) \frac{\partial G}{\partial \eta_i}(\eta - y, \sigma - s)$$

is Hölder continuous in η, uniformly for $(\eta, \sigma) \in \mathbb{R}^N \times [t_0, t]$, since (considering (2.2) and (2.4))

$$\frac{\partial G}{\partial \eta_i}(\eta - y, \sigma - s) \qquad \text{and} \qquad \text{sign}[\eta_i - y_i] \frac{\partial G}{\partial \eta_i}(\eta - y, \sigma - s)$$

are both uniformly Lipschitz continuous and assumption (A) implies that $a(\eta, \sigma)$ is uniformly Hölder continuous.

According to Friedman [4, Theorems 1.3–1.5], the first and second derivatives in x commute with integration in J_3, and

$$\frac{\partial J_3}{\partial t} = \int_{t_0}^{t} \int_D \frac{\partial \Gamma(x, t; \eta, \sigma)}{\partial t} LG(\eta - y, \sigma - s)\, d\eta d\sigma + LG(x - y, t - s).$$

The continuity of these derivatives follows from considerations similar to [4, Theorem 1.8, p. 19].

Let $J(x, t; y, s) = J_1 + J_2 + J_3$. From (2.2), (2.4) it follows that $G(x-y, t-s)$ is twice continuously differentiable in x and once in t for $x, y \in \mathbb{R}^N$ and $t > s \geq 0$. Thus, the same property holds for $G(x-y, t-s) + J(x, t; y, s)$.

Combining the above results, we deduce that

$$\begin{aligned} &LG(x-y, t-s) - L\int_s^t \int_{\mathbb{R}^N} \Gamma(x, t; \eta, \sigma) LG(\eta - y, \sigma - s)\, d\eta d\sigma \\ &\quad = LG(x-y, t-s) - LG(x-y, t-s) \\ &\quad - \int_s^t \int_{\mathbb{R}^N} L\Gamma(x, t; \eta, \sigma) LG(\eta - y, \sigma - s)\, d\eta d\sigma = 0. \end{aligned}$$

We must now prove that

$$\lim_{t \searrow s} \int_{\mathbb{R}^N} (G(x-y, t-s) + J(x, t; y, s)) f(y)\, dy = f(x) \tag{3.2}$$

for continuous $f \in L_1(\mathbb{R}^N)$. The contribution from J may be shown to be 0 by following the proof in [4, p. 20]. On the other hand, for fixed $T > 0$, it is readily shown that

$$\begin{aligned} &\left| G(x-y, t-s) - \frac{\exp(-|x-y|^2/(4(t-s)))}{(4\pi(t-s))^{N/2}} \right| \\ &\quad \leq \frac{C}{(t-s)^{(N-1)/2}} \exp\left(\frac{-c|x-y|^2}{(t-s)} \right) \\ &\quad \leq \frac{C}{(t-s)^{1/2}|x-y|^{(N-2)}} \exp\left(\frac{-c|x-y|^2}{(t-s)} \right) \end{aligned}$$

for all $(t-s) \in (0, T]$. Hence,

$$\lim_{t \searrow s} \int_{\mathbb{R}^N} \left(G(x-y, t-s) - \frac{\exp(-|x-y|^2/(4(t-s)))}{(4\pi(t-s))^{N/2}} \right) f(y)\, dy = 0,$$

so (3.2) follows from the well-known properties of the Gaussian kernel.

We deduce that $G(x-y, t-s) + J(x, t; y, s)$ satisfies the characterizing equations (1.1) and (1.3) and is, therefore, equal to $\Gamma(x, t; y, s)$. □

Proof of Theorem 2.1. We first consider (3.1) under assumption (A). It is well known that $\Gamma(x, t; \xi, \sigma) > 0$. On the other hand, for $M \in [0, \infty)^N$,

$$LG_M(x-y, t-s) = \sum_{i=1}^N (a_i(x, t) - M_i \text{sign}[x_i - y_i]) \frac{\partial G_M}{\partial x_i} \geq 0$$

by (1.2) and (1.6). So, (3.1) implies that $\Gamma(x, t; y, s) \leq G_M(x-y, t-s)$. The lower bound follows similarly.

Under conditions which include (1.1) under assumption (B), Aronson [1] defines the weak fundamental solution $\Gamma(x, t; y, s)$, which coincides with the classical heat kernel when coefficients are sufficiently smooth. He considers [1, p. 681] a sequence of classical heat kernels $\Gamma^k(x, t; y, s)$, $k \in \mathbb{N}$, for the problem

$$u_t - \Delta u + a^k(x, t) \cdot \nabla u = 0 \tag{3.3}$$

for $|x| < k$, $t > 0$, with Dirichlet boundary conditions

$$u(x,\, t) = 0, \qquad |x| = k,\ t > 0,$$

and shows that $\Gamma^k(x,\, t;\, y,\, s) \to \Gamma(x,\, t;\, y,\, s)$ pointwise, as $k \to \infty$. Here, $a^k(x,\, t)$ is an integral average of $a(x,\, t)$ formed with a smooth kernel whose support lies in $|x|^2 + t^2 < k^{-2}$. Therefore, $a^k(x,\, t)$ satisfies assumption (A).

Let $H^k(x,\, t;\, y,\, s)$ be the heat kernel of (3.3) in the extended domain $\mathbb{R}^N \times (0,\, \infty)$. Then $\Gamma^k(x,\, t;\, y,\, s) = H^k(x,\, t;\, y,\, s) + v^k(x,\, t;\, y,\, s)$ for $|x|$, $|y| \le k$, where $v^k(x,\, t;\, y,\, s)$ is the interior solution of (3.3) such that

$$v^k(x,\, t;\, y,\, s) = -H^k(x,\, t;\, y,\, s), \qquad |x| = k,\ t > 0.$$

Since H^k satisfies the upper and lower bounds (2.5), it is clear from the parabolic maximum principle [4, Chapter 2] that $v^k(x,\, t;\, y,\, s) \to 0$ pointwise, as $k \to \infty$, for fixed $(x,\, t;\, y,\, s)$. Hence, $\Gamma(x,\, t;\, y,\, s)$ satisfies (2.5).

The last part of the theorem is completed by following the argument given in the introduction. □

4. L^1 bounds. Aronson [1, section 9] shows, under conditions which include the case of (1.1) with $a(x,\, t)$ satisfying assumption (B), that if $u_0 \in L_1(\mathbb{R}^N)$, then

$$u(x,\, t) = \int_{\mathbb{R}^N} \Gamma(x,\, t;\, y,\, 0) u_0(y)\, dy \tag{4.1}$$

is the unique weak solution of the equation in $L_2[[\delta,\, T];\, L_2(\mathbb{R}^N)]$ for any $T > \delta > 0$ and that $u(x,\, t)$ also satisfies the continuity condition

$$\lim_{t \to 0} \|u(t) - u_0\|_1 = 0.$$

Here, we use the representation formula (4.1) and the pointwise bounds (2.5) on $\Gamma(x,\, t;\, y,\, 0)$ to obtain an upper bound on $\|u(t)\|_1 / \|u_0\|_1$.

Since u_0, and hence $u(t)$, may be split as the sum of nonnegative and nonpositive parts, it is sufficient to consider nonnegative u_0 for the purposes of obtaining L_1 bounds. In this case, Fubini's theorem implies that

$$\begin{aligned} \|u(t)\|_1 &= \int_{\mathbb{R}^N} \int_{\mathbb{R}^N} \Gamma(x,\, t;\, y,\, 0) u_0(y)\, dy\, dx \\ &= \int_{\mathbb{R}^N} \left(\int_{\mathbb{R}^N} \Gamma(x,\, t;\, y,\, 0)\, dx \right) u_0(y)\, dy, \qquad t > 0. \end{aligned}$$

From (2.5) we deduce that, provided u_0 is not null,

$$\inf_{y \in \mathbb{R}^N} \int_{\mathbb{R}^N} G_{-M}(x - y,\, t)\, dx \le \frac{\|u(t)\|_1}{\|u_0\|_1} \le \sup_{y \in \mathbb{R}^N} \int_{\mathbb{R}^N} G_M(x - y,\, t)\, dx.$$

That there is in fact no y dependence involved is apparent on a change of variable in the integrals, and one obtains

$$\int_{\mathbb{R}^N} G_{-M}(x,\, t)\, dx \le \frac{\|u(t)\|_1}{\|u_0\|_1} \le \int_{\mathbb{R}^N} G_M(x,\, t)\, dx. \tag{4.2}$$

Remark. Suppose that we take a sequence of smooth nonnegative initial data $u_0^k(x)$, $k \in \mathbb{N}$, for (1.8) such that $\|u_0^k\|_1 = 1$ and the support of u_0^k lies in the set

$|x-z|<k^{-1}$. Let the corresponding solution be denoted $u^k(x, t)$. Fixing $t>0$ and noting that the heat kernel $\Theta_M(z;\, x,\, t;\, y,\, 0)$ of (1.8) is equal to $G_M(x-z,\, t)$ when $y=z$, we deduce that

$$\lim_{k\to\infty}\frac{\|u^k(t)\|_1}{\|u_0^k\|_1}=\int_{\mathbb{R}^N} G_M(x,\, t)\, dx.$$

If one exchanges M_i for $-M_i$, a similar argument shows that the lower bound in (4.2) is also sharp.

The construction (2.4) of G_M implies that

$$\int_{\mathbb{R}^N} G_{\pm M}(x,\, t)\, dx=\prod_{i=1}^{N}\int_{\mathbb{R}} g_{\pm M_i}(x_i,\, t)\, dx_i. \tag{4.3}$$

A calculation using the identity [5, Formula 7.2.5, p. 299]

$$\int_x^\infty \operatorname{erfc}(t)\, dt=-x\operatorname{erfc}(x)+\frac{1}{\sqrt{\pi}}\exp(-x^2)$$

yields

$$\int_{\mathbb{R}} g_M(x,\, t)\, dx=h\left(\frac{M\sqrt{t}}{2}\right), \qquad M\in\mathbb{R},\ t\geq 0, \tag{4.4}$$

where we define

$$h(x)=\left(1+2x^2\right)\operatorname{erfc}(-x)+\frac{2x}{\sqrt{\pi}}\exp\left(-x^2\right). \tag{4.5}$$

The above analysis is summarized in the following theorem.

THEOREM 4.1. *Suppose that L obeys assumption* (B) *and that non-null initial data $u_0\in L_1(\mathbb{R})$ are given for* (1.1). *Then, if u_0 is nonnegative, the solution $u(t)$ satisfies*

$$\prod_{i=1}^{N} h\left(\frac{-M_i\sqrt{t}}{2}\right)\leq\frac{\|u(t)\|_1}{\|u_0\|_1}\leq\prod_{i=1}^{N} h\left(\frac{M_i\sqrt{t}}{2}\right). \tag{4.6}$$

For general $u_0\in L_1(\mathbb{R}^N)\setminus\{0\}$, $u(t)$ obeys the upper bound of (4.6).

For small x, the behavior of $h(x)$ is as seen in Gautschi [5, Formula 7.1.6, p. 297], where for $x\in\mathbb{R}$,

$$\begin{aligned} h(x)&=(1+2x^2)+\frac{2\exp(-x^2)}{\sqrt{\pi}}\left(x+(1+2x^2)\sum_{n=0}^{\infty}\frac{2^n}{1\cdot 3\cdots(2n+1)}x^{2n+1}\right)\\ &=1+\frac{4x}{\sqrt{\pi}}+2x^2+\frac{4x^3}{3\sqrt{\pi}}+\cdots. \end{aligned}$$

When $M_i\sqrt{t}\ll 1$ for each i, the upper bound in (4.6) grows like

$$1+\frac{2\sum_{i=1}^{N} M_i}{\sqrt{\pi}}t^{1/2}, \tag{4.7}$$

while the decay of the lower bound is found by changing the sign of the M_i's.

Using an asymptotic expansion for erfc(x) in negative powers of $|x|$ [5, Formula 7.1.23, p. 298], for $x < 0$ one obtains

$$\begin{aligned} h(x) &= -\frac{2|x|}{\sqrt{\pi}}\exp(-x^2) + (1+2x^2)\mathrm{erfc}(|x|) \\ &\sim \frac{\exp(-x^2)}{\sqrt{\pi}|x|}\left(-2x^2 + (1+2x^2)\left(1 + \sum_{n=1}^{\infty}(-1)^n \frac{1\cdot 3\cdots(2n-1)}{(2x^2)^n}\right)\right). \end{aligned}$$

(If the series is truncated, the error, $h(x)-$R.H.S., is equal to $\theta(x)$ times the first neglected term, where $\theta(x) \in (0, 1)$.) Hence, when $M_i\sqrt{t} \gg 1$ for each i, the lower bound in (4.6) decays like

$$\left(\frac{8}{\pi^{1/2}\overline{M}^3}\right)^N t^{-3N/2}\exp\left(-\sum_{i=1}^{N}\frac{M_i^2 t}{4}\right) \qquad \text{for} \quad \overline{M} \equiv \left(\prod_{i=1}^{N} M_i\right)^{1/N}. \tag{4.8}$$

Since erfc$(x)+$ erfc$(-x) = 2$, (4.5) implies that $h(x) = 2 + 4x^2 - h(-x)$. Thus, when $M_i\sqrt{t} \gg 1$ for each i, the upper bound in (4.6) may be approximated by

$$\prod_{i=1}^{N}(2 + M_i^2 t) \tag{4.9}$$

with very little error. This last result may be attributed to the fact that

$$G_M(x, t) \approx \prod_{i=1}^{N}\frac{M_i}{2} \qquad \text{for } -M_i t < x_i < M_i t,\ i = 1, 2, \ldots, N, \tag{4.10}$$

and rapidly vanishes outside this box.

Remark. Considering non-null nonnegative endpoint data $u(t) = u_0 \in L_\infty(\mathbb{R}^N)$ for the adjoint problem (2.6), a duality argument leads to the bounds

$$\prod_{i=1}^{N} h\left(\frac{-M_i\sqrt{t-s}}{2}\right) \le \frac{\|u(s)\|_\infty}{\|u_0\|_\infty} \le \prod_{i=1}^{N} h\left(\frac{M_i\sqrt{t-s}}{2}\right), \qquad s \in [0, t]. \tag{4.11}$$

Acknowledgments. The author wishes to thank Professor J. F. Toland for suggesting this problem and Dr. J. R. Norris, Dr. S. C. Harris, and Professor L. C. G. Rogers for materially helpful discussions.

SPATIAL PATTERNS DESCRIBED BY THE EXTENDED FISHER–KOLMOGOROV EQUATION: PERIODIC SOLUTIONS[*]

L. A. PELETIER[†] AND W. C. TROY[‡]

Abstract. Stationary antisymmetric single-bump periodic solutions of a fourth-order generalization of the Fisher–Kolmogorov (FK) equation are analyzed. The coefficient $\gamma > 0$ of the additional fourth-order spatial derivative is found to be a critical parameter. If $\gamma \leq \frac{1}{8}$, the family of periodic solutions is still very similar to that of the FK equation. However, if $\gamma > \frac{1}{8}$, it is possible to distinguish different families of periodic solutions and the structure of such solutions is much richer.

1. Introduction. In this paper we shall study the formation of spatially periodic patterns in bistable systems described by the *extended Fisher–Kolmogorov* (EFK) equation

$$\frac{\partial u}{\partial t} = -\gamma \frac{\partial^4 u}{\partial x^4} + \frac{\partial^2 u}{\partial x^2} + u - u^3, \qquad \gamma > 0. \tag{1.1}$$

This equation was proposed in 1987 by Coullet, Elphick, and Repaux [8] and in 1988 by Dee and van Saarloos [11] as a generalization of the classical Fisher–Kolmogorov (FK) equation

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + u - u^3, \tag{1.2}$$

which has played an important role in the studies of pattern formation in bistable systems (cf. [3, 13, 14, 16, 20, 25, 26]). The term "bistable" refers here to the fact that the uniform states $u = \pm 1$ are stable as solutions of the equation

$$\frac{du}{dt} = u - u^3.$$

The EFK equation arises in the study of singular points (so-called Lifshitz points [14]) in phase transitions and as the evolution equation in gradient systems described by the energy functional

$$I(u) = \int \left\{ \frac{\gamma}{2}(u'')^2 + \frac{\beta}{2}(u')^2 + F(u) \right\} dx, \qquad \gamma > 0,\ \beta \in \mathbf{R}, \tag{1.3}$$

where F denotes the double-well potential

$$F(u) = \frac{1}{4}(1 - u^2)^2. \tag{1.4}$$

We then obtain the EFK equation when we choose $\beta = 1$. Another important application of this equation is found in the theory of instabilities in nematic liquid crystals [5, 27].

In studies of second-order materials [10, 17, 18] one also finds the functional $I(u)$. Here $\beta < 0$. The stationary points of $I(u)$ are then equivalent to the equilibrium solutions of the Swift–Hohenberg equation

$$\frac{\partial u}{\partial t} = -\Big(1 + \frac{\partial^2}{\partial x^2}\Big)^2 u + \alpha\, u - u^3, \qquad \alpha > 0 \tag{1.5}$$

when $\alpha > 1$ through a simple scaling of x, t, and u (see, for instance, [7, 9] and the references therein).

In this paper we are interested in stationary spatial patterns which can be described by the EFK equation and in particular in *periodic patterns.* Thus, we are concerned with bounded solutions $u(x)$ of the equation

$$\gamma u^{iv} = u'' + u - u^3 \quad \text{on } \mathbf{R}. \tag{1.6}$$

Our main objectives are to determine the effect of the added higher-order gradient term and the value of the coefficient γ, on the class of possible stationary periodic patterns, and the qualitative properties of these patterns.

For convenience we recall below the types of stationary patterns that can be described by the FK equation. However, before doing so we introduce some notation. We observe that equation (1.6) has a constant of integration: if u is a solution of equation (1.6), then

$$\mathcal{E}(u) \overset{\text{def}}{=} 2\gamma u' u''' - \gamma (u'')^2 - (u')^2 + \frac{1}{2}(1-u^2)^2 \;=\; \text{constant} \;\overset{\text{def}}{=}\; \frac{\mu}{2}. \tag{1.7}$$

To eliminate arbitrary shifts, we always place the origin at a zero of u:

$$u(0) = 0 \tag{1.8}$$

whenever a zero exists.

For the special value $\gamma = 0$, equation (1.6) reduces to the stationary FK equation

$$u'' + u - u^3 = 0. \tag{1.9}$$

PROPOSITION 1.1. *The FK equation* ($\gamma = 0$) *has the following bounded stationary solutions.*

(a) *There exists a unique solution u of equation* (1.9) *(a kink), such that*

$$(u, u') \to (\pm 1, 0) \quad \text{as } x \to \pm\infty.$$

It is antisymmetric and monotone and is given explicitly by

$$u(x) = \tanh\Big(\frac{x}{\sqrt{2}}\Big).$$

This solution corresponds to the values $\gamma = 0$ and $\mu = 0$ in (1.7).

(b) *For each $\mu \in (0, 1)$, there exists a unique periodic solution u of* (1.9) *such that $u'(0) > 0$. It is* (i) *antisymmetric with respect to its zeros,* (ii) *symmetric with respect* *to the location of its maxima and its minima,* (iii) *concave where it is positive and convex where it is negative, and*

$$\text{(iv)} \qquad \max\{|u(x)| : x \in \mathbf{R}\} = \sqrt{1 - \sqrt{\mu}}.$$

(c) *There exist no bounded periodic solutions of* (1.9) *when* $\mu \notin (0, 1)$ *and no bounded solutions of* (1.9) *when* $\mu \notin [0, 1]$.

In two earlier papers [21, 24] we investigated the existence and properties of kinks of the EFK equation. They are solutions $u(x)$ of equation (1.6) which have the properties

$$(u, u', u'', u''') \to (\pm 1, 0, 0, 0) \quad \text{as } x \to \pm\infty. \tag{1.10}$$

We found that kinks exist for every $\gamma > 0$ but that their character and number change abruptly at $\gamma = \frac{1}{8}$. When $\gamma \le \frac{1}{8}$, there exists a unique odd monotone kink with the same characteristic properties as the kink of the FK equation. However, we have recently shown that for $\gamma > \frac{1}{8}$, there exists a countably infinite number of odd kinks, and none of these is monotone in its approach to ±1 as $x \to \pm\infty$ [22]. We collect these results in the following proposition.

Proposition 1.2. (a) *For each* $\gamma > 0$*, there exists an odd solution of equation* (1.6) *which satisfies* (1.10).

(b) *If* $\gamma \le \frac{1}{8}$*, there exists one and only one kink which is odd and monotone.*

(c) *If* $\gamma > \frac{1}{8}$*, there exists for every integer* $n \ge 0$ *a kink with* $2n + 1$ *zeros.*

The critical value $\gamma = \frac{1}{8}$ is related to the linearization of (1.6) around $u = 1$ or $u = -1$. For $\gamma \le \frac{1}{8}$ the corresponding eigenvalues are all real, whilst for $\gamma > \frac{1}{8}$ they are all complex.

In the present paper we investigate stationary *periodic* solutions of the EFK equation and we shall inquire how parts (b) and (c) of Proposition 1.1 generalize when we take $\gamma > 0$. We shall restrict this study to periodic solutions u which (*i*) are *odd*, (ii) are *symmetric* with respect to the location of their extrema, and (iii) have a single relative maximum between consecutive zeros. Thus, let ζ be the *first* positive zero of u'. Then we are concerned with periodic solutions of (1.6) with the following properties:

$$\begin{aligned} u(-x) &= -u(x) && \text{for } x \in \mathbf{R}, \\ u(\zeta - y) &= u(\zeta + y) && \text{for } y \in \mathbf{R}. \end{aligned} \tag{1.11}$$

We refer to solutions which satisfy (1.11) as *single-bump* periodic solutions. In this paper we shall only discuss such periodic solutions.

As we do with the FK equation we only consider solutions for which

$$\mathcal{E}(u) \ge 0 \quad \text{or} \quad \mu \ge 0.$$

We conjecture that if $\gamma > \frac{1}{8}$, there exist periodic solutions for some *negative* values of μ as well. However, we leave their analyses to a further study.

In our first result, we find that when $0 < \mu < 1$ the periodic solutions of the FK equation continue to exist for all $\gamma > 0$.

Theorem A. *Let* $0 < \mu < 1$ *and* $\gamma > 0$*. Then there exists a periodic solution* $u(x)$ *of* (1.6) *such that*

$$\max\{|u(x)| : x \in \mathbf{R}\} < 1.$$

When $\mu \geq 1$ the FK equation has no periodic solutions and we see below that this also continues to be true for all $\gamma > 0$.

Theorem B. *Let $\mu \geq 1$ and $\gamma > 0$. Then there exists no periodic solution of equation* (1.6).

When $\mu = 0$ and $\gamma > \frac{1}{8}$ the situation becomes very different from that of the FK equation. Whereas the FK equation has no periodic solutions for this value of μ, the EFK equation has two branches of periodic solutions bifurcating from the unique odd monotone kink $U(x)$ at $\gamma = \frac{1}{8}$. This is the content of the following two theorems.

Theorem C. *Let $\mu = 0$.*

(a) *If $0 < \gamma \leq \frac{1}{8}$, then there exist no periodic solutions.*

(b) *If $\gamma > \frac{1}{8}$, then there exist a periodic solution $u_1(x)$ such that*

$$\max\{|u_1(x)| : x \in \mathbf{R}\} < 1$$

and a periodic solution $u_2(x)$ such that

$$\max\{|u_2(x)| : x \in \mathbf{R}\} \in (1, \sqrt{2}).$$

Theorem D. *Let $\mu = 0$ and let $\{\gamma_i\}$ be a sequence such that*

$$\gamma_i \searrow \frac{1}{8} \quad \textit{as } i \to \infty.$$

For each $i \geq 1$, let u_i be a periodic solution corresponding to γ_i. Then

$$u_i(x) \to U(x) \quad \textit{as } i \to \infty,$$

where U is the unique odd monotone kink corresponding to $\gamma = \frac{1}{8}$. The convergence is uniform on compact intervals.

We conjecture that in addition to the single-bump periodic solutions of Theorem C, infinitely many multibump periodic solutions bifurcate from U at $\gamma = \frac{1}{8}$.

A result which is analogous to Theorem D holds for periodic solutions when $0 < \mu < 1$ and $\gamma \to 0$ (cf. Lemma 6.3). They converge to the periodic solution of the FK equation for the given value of μ.

Periodic solutions with amplitude larger than 1 continue to exist when $\gamma > \frac{1}{8}$ and $\mu > 0$ is sufficiently small. However, if either $\gamma \leq \frac{1}{8}$ or $\mu \geq \frac{4}{9}$, they cannot exist.

Theorem E. *Let $\mu \geq 0$ and $\gamma > 0$. There exist no periodic solutions $u(x)$ such that*

$$\max\{|u(x)| : x \in \mathbf{R}\} > 1$$

when one of the following conditions is satisfied:

(a) $0 < \gamma \leq \frac{1}{8}$,

(b) $\mu \geq \frac{4}{9}$.

For the global behavior of the branches of periodic solutions we obtain several bounds. We begin with a universal upper bound.

Theorem F. *Let $0 \leq \mu < 1$ and $\gamma > 0$. Then any periodic solution satisfies*

$$|u(x, \gamma)| < \sqrt{2} \quad \textit{for } x \in \mathbf{R}.$$

We also prove the following lower bound.

THEOREM G. *Let $0 \le \mu < 1$ and $\gamma > (\frac{2}{5})^4$. Then any periodic solution satisfies*

$$\max\{|u(x,\gamma)| : x \in \mathbf{R}\} > \frac{1}{50}\sqrt{\frac{1-\mu}{\log 2}}.$$

Let u be a periodic solution which satisfies (1.11). Then for its slope $u'(0)$ at the origin we prove an upper and a lower bound:

$$\frac{1}{5}\sqrt{1-\mu} < \gamma^{1/4}u'(0,\gamma) < \{8(1-\mu)\log 2\}^{1/4} \tag{1.12}$$

for $\gamma > \frac{1}{8}$ if $\mu = 0$ and for $\gamma > (\frac{2}{5})^4$ if $0 < \mu < 1$. These bounds enable us to obtain information about the behavior of periodic solutions for large values of γ. The description of their limiting behavior involves the reduced problem

$$\begin{cases} v^{iv} = v - v^3, & \text{(1.13a)} \\ v(0) = 0, \quad v''(0) = 0, & \text{(1.13b)} \\ v'(0) = \omega, \quad v'''(0) = -\dfrac{1-\mu}{4\omega} & \text{(1.13c)} \end{cases}$$

in which ω is a positive number.

THEOREM H. *Let $0 \le \mu < 1$. Suppose that $\{\gamma_i\}$ is a sequence which tends to infinity and $\{u_i\}$ is a sequence of periodic solutions which satisfy* (1.11). *Then there exist a subsequence, which we also denote by $\{\gamma_i\}$, and a periodic solution V of problem* (1.13) *such that*

$$u_i(\gamma_i^{1/4}s,\gamma_i) \to V(s) \quad \textit{as } i \to \infty$$

uniformly on compact sets.

Outline of the shooting method. We now give a brief description of the topological shooting method used to prove the existence of the families of odd periodic solutions described in Theorem A and Theorem C(b).

Since we are looking for odd solutions of (1.6), it is sufficient to consider the equation on $\mathbf{R}^+$ only and with initial conditions of the form

$$\big(u(0), u'(0), u''(0), u'''(0)\big) = (0, \alpha, 0, \beta), \tag{1.14}$$

where α and β are real. It is easily verified that a solution u of (1.6) satisfying (1.14) must be odd, and that $-u$ is also a solution. We shall see that α cannot be zero, and so we may choose α to be positive. It follows from (1.7) that

$$\beta = \frac{1}{2\alpha\gamma}\Big\{\alpha^2 - \frac{1-\mu}{2}\Big\}. \tag{1.15}$$

In Theorem A we assume that γ and μ are fixed, with $\gamma > 0$ and $0 < \mu < 1$. We are then free to vary α, our shooting parameter. We begin our analysis by showing that for each $\alpha > 0$ there exists a finite value $\xi(\alpha) > 0$, which depends continuously on α, such that

$$u'(x,\alpha) > 0 \quad \text{for } 0 < x < \xi(\alpha) \qquad \text{and} \qquad u'(\xi(\alpha),\alpha) = 0. \tag{1.16}$$

We shall show that $u'''(\xi(\alpha),\alpha) < 0$ for small values of $\alpha > 0$, that there is an $\tilde{\alpha} > 0$ for which $u'''(\xi(\tilde{\alpha}),\tilde{\alpha}) > 0$, and that

$$0 < u(\xi(\alpha),\alpha) < \sqrt{1-\sqrt{\mu}} \quad \text{for } 0 < \alpha < \tilde{\alpha}. \tag{1.17}$$

From these observations and the continuity of $\xi(\alpha)$ with respect to α we conclude that there is an intermediate value $\alpha_- \in (0, \tilde{\alpha})$ such that $u'''(\xi(\alpha_-), \alpha_-) = 0$. At $\alpha = \alpha_-$ we have

$$0 < u(\xi(\alpha_-), \alpha_-) < \sqrt{1 - \sqrt{\mu}}, \quad u'(\xi(\alpha_-), \alpha_-) = 0, \quad \text{and} \quad u'''(\xi(\alpha_-), \alpha_-) = 0,$$

and it follows from (1.7) and the definition of $\xi(\alpha_-)$ that $u''(\xi(\alpha_-), \alpha_-) < 0$. By reflecting the graph $\{(x, u(x, \alpha_-)) : 0 \leq x \leq \xi(\alpha_-)\}$ with respect to the endpoints $x = 0$ and $x = \xi(\alpha_-)$, we obtain the desired periodic solution. The details of the analysis described above are given in sections 2 and 3.

In section 5 we turn to the proof of Theorem C(b) in which we set $\mu = 0$ and restrict γ to satisfy $\gamma > \frac{1}{8}$. For $\gamma \in (0, \frac{1}{8}]$, part (a) of Theorem C states that no periodic solutions exist, and this result is proved in section 4. However, as γ passes through $\frac{1}{8}$ from below, a linearization of (1.6) around the constant solution $u = 1$ shows that the eigenvalues change from real to complex, two of the eigenvalues have positive real part and two have negative real part. Because of this change in character of the eigenvalues, Coullet, Elphick, and Repaux [8] conjectured that the range $\gamma > \frac{1}{8}$ is where one would expect to observe complex pattern formation. Such patterns could include families of periodic and aperiodic solutions, multibump heteroclinic and homoclinic orbits (kinks, respectively, solitons), and possibly chaos.

One of the main goals of our investigation of the EFK equation is to resolve this conjecture of Coullet, Elphick, and Repaux and to determine the different types of solutions that exist for the parameter regime $\mu = 0$ and $\gamma > \frac{1}{8}$. In Theorem C(b) we state our first existence result for this range of parameters. We prove that there are at least two families of periodic solutions; one of these is characterized by the fact that the relative maxima all lie *below* $u = 1$, while the relative maxima of the second family all lie *above* $u = 1$. In addition we show that both families of periodic solutions bifurcate from the odd, monotone kink (the heteroclinic orbit connecting $u = -1$ and $u = +1$) at $\gamma = \frac{1}{8}$ and continue to exist for all $\gamma > \frac{1}{8}$.

The proof of Theorem C(b) is based on the same shooting technique we used for the proof of Theorem A. Again, for each $\alpha > 0$ we find that there exists a first $\xi(\alpha) \in \mathbf{R}^+$ for which $u'(\xi(\alpha), \alpha) = 0$. In the proof of Theorem A we found that $u(\xi(\alpha), \alpha) \neq 1$ because $\mu \neq 0$. However, now we have $\mu = 0$ and indeed we find that there is a critical value $\tilde{\alpha}$ for which $u(\xi(\tilde{\alpha}), \tilde{\alpha}) = 1$. It follows from (1.6), (1.7), and uniqueness that

$$(1.18) \quad u(\xi(\tilde{\alpha}), \tilde{\alpha}) = 1, \quad u'(\xi(\tilde{\alpha}), \tilde{\alpha}) = 0, \quad u''(\xi(\tilde{\alpha}), \tilde{\alpha}) = 0, \quad \text{and} \quad u'''(\xi(\tilde{\alpha}), \tilde{\alpha}) > 0.$$

To proceed with our shooting argument we need to know that $\xi(\alpha)$ is continuous. When $u'' \neq 0$ this is an easy consequence of the implicit function theorem, but when $u'' = 0$, as it is at $\xi(\tilde{\alpha})$, this is no longer obvious and the situation is much more delicate. In Lemma 5.8 we further refine a method originally developed in [21], which uses u as an independent variable, to prove this important property.

Having established continuity of $\xi(\alpha)$ we conclude that there exists an $\alpha_- \in (0, \tilde{\alpha})$ for which $u'''(\xi(\alpha_-), \alpha_-) = 0$. As before, it follows that $u(\cdot, \alpha_-)$ is a periodic solution and by construction its relative maxima lie *below* $u = 1$.

For our second periodic solution, whose relative maxima are all greater than 1, we show that for $\alpha > \tilde{\alpha}$ sufficiently large,

$$u(\xi(\alpha), \alpha) > 1 \quad \text{and} \quad u'''(\xi(\alpha), \alpha) < 0.$$

Remembering that $u'''(\xi(\tilde{\alpha}),\tilde{\alpha}) > 0$, we conclude from the continuity of $\xi(\alpha)$ that there exists an $\alpha_+ > \tilde{\alpha}$ for which

$$u(\xi(\alpha_+),\alpha_+) > 1, \quad u'(\xi(\alpha_+),\alpha_+) = 0, \quad \text{and} \quad u'''(\xi(\alpha_+),\alpha_+) = 0.$$

Again, we conclude that $u(\cdot,\alpha_+)$ is a periodic solution, but now the construction ensures that its relative maxima lie *above* $u = 1$.

We emphasize that the key result in the proof of the existence of both families of periodic orbits is Lemma 5.8, which implies that $\xi(\alpha)$ is continuous for all $\alpha > 0$ if $\mu = 0$ and $\gamma > \frac{1}{8}$. We have recently extended this property [23] and proved that all subsequent relative maxima $\xi_i(\alpha)$ and minima $\eta_i(\alpha)$, $i = 1, 2, \ldots$, have the same continuity property. In turn this has allowed us to further refine our shooting method to establish the existence of complicated types of solutions, such as multibump heteroclinic orbits [22] and chaotic patterns [23]. The topological shooting argument developed here and extended in [22] and [23] enables one to prove chaos without having to verify the typical transversality condition (see, for instance, [12]) required by the dynamical systems approach. This verification can be very difficult.

Preliminary results suggest that the method developed here presents a framework which can be used to investigate stationary spatial patterns described by a large class of model equations, such as the Swift–Hohenberg equation (1.5), and equations describing soliton solutions in nonlinear optical fibers [1], traveling waves in a suspension bridge [19], and the deflections of an asymmetrically supported strutt:

$$u^{iv} + Pu'' + u - u^2 = 0, \qquad P \in \mathbf{R}. \tag{1.19}$$

In a series of papers [2, 6, 4] this equation has been studied by completely different (Hamiltonian) methods. Although the nonlinearity in this equation is not cubic, and the emphasis here lies on homoclinic orbits, it is interesting to compare the two different methods and the different types of results they generate. Finally, we note that in [15] a variational approach in combination with a partition of function spaces into topological subclasses has proved to be successful in analyzing equations such as (1.6) and (1.9).

2. Preliminaries. Our basic method for proving existence of odd periodic solutions is a shooting technique, so we consider the initial value problem

$$\begin{cases} \gamma u^{iv} = u'' + u - u^3, \qquad x > 0, & \text{(2.1a)} \\ u(0) = 0,\ u'(0) = \alpha,\ u''(0) = 0,\ u'''(0) = \beta. & \text{(2.1b)} \end{cases}$$

We may restrict our attention to $\alpha > 0$; if $\alpha = 0$, then (1.7) implies that $\mu = 1$ and we shall show in Lemma 2.2 that in this case no periodic solution which satisfies (1.11) can exist. Thus, if we fix $\mu \geq 0$ and $\gamma > 0$, then (1.7) yields

$$\beta = \beta(\alpha) = \frac{1}{2\gamma\alpha}\Big\{\alpha^2 - \frac{1-\mu}{2}\Big\}. \tag{2.2}$$

We seek a positive value of α such that the solution $u(x,\alpha)$ has the properties (1.11). That is,

$$u'(x,\alpha) > 0 \quad \text{for } 0 \leq x < \xi, \tag{2.3a}$$

$$u'(\xi,\alpha) = 0 \quad \text{and} \quad u'''(\xi,\alpha) = 0 \tag{2.3b}$$

for some finite $\xi = \xi(\alpha) > 0$. It is easily verified that a solution defined on $[0,\xi]$, which satisfies (2.1)–(2.3), can be extended to yield a periodic solution of period 4ξ. Thus, we define

$$\xi(\alpha) = \sup\{x > 0 : u'(\cdot,\alpha) > 0 \ \text{ on } \ [0,x)\}.$$

In this section we will show that for all values $\alpha > 0$, except those for which the corresponding solution u is a monotone kink, $\xi(\alpha)$ is finite and that u is bounded on $[0,\xi]$ with horizontal slope at ξ. Therefore, to satisfy (2.3) we must still determine $\alpha > 0$ so that

$$u'''(\xi(\alpha),\alpha) = 0.$$

At times we shall find it convenient to adopt a different formulation for the initial value problem (2.1). Since we construct periodic solutions from strictly monotone segments defined on $[0,\xi]$, we may introduce u as an independent variable, as was done in [21] for the study of kinks. Denoting the inverse function of $u(x)$ by $x(u)$, we set

$$t = u \quad \text{and} \quad z(t) = (u')^2(x(t)). \tag{2.4}$$

This yields

$$z'(t) = 2u''(x) \quad \text{and} \quad z''(t) = 2\frac{u'''(x)}{u'(x)}. \tag{2.5}$$

Hence, upon substitution into (1.7), we obtain

$$\begin{cases} zz'' = \dfrac{(z')^2}{4} + \dfrac{1}{\gamma}\{z - f_\mu(t)\}, \quad t > 0, & \text{(2.6a)} \\ z(0) = \alpha^2 \quad \text{and} \quad z'(0) = 0, & \text{(2.6b)} \end{cases}$$

where

$$f_\mu(t) = \frac{1}{2}\{(t^2-1)^2 - \mu\}. \tag{2.7}$$

We denote the solution by $z(t,\alpha)$ and write

$$\tau(\alpha) = \sup\{t > 0 : z(\cdot,\alpha) > 0 \ \text{ on } \ [0,t)\}.$$

From (2.4) and the definition of $\xi(\alpha)$ it follows that

$$\tau(\alpha) = \lim_{x\to\xi(\alpha)^-} u(x,\alpha).$$

To be assured that $z(\cdot,\alpha)$ corresponds to a periodic solution $u(\cdot,\alpha)$, we need to prove the existence of a positive α for which

$$0 < \xi(\alpha) < \infty, \quad 0 < \tau(\alpha) < \infty, \tag{2.8a}$$

and

$$\lim_{t\to\tau(\alpha)^-} z(t,\alpha) = 0, \quad \lim_{t\to\tau(\alpha)^-} \sqrt{z(t,\alpha)}z''(t,\alpha) = 0. \tag{2.8b}$$

Then (2.8), together with (2.4) and (2.5), implies that $u(\cdot,\alpha)$ satisfies (2.3) so that u is periodic.

LEMMA 2.1. *Suppose that $\mu \geq 0$ and $\gamma > 0$.*

(a) *For any $\alpha \in \mathbf{R}^+$, we have*

$$u(\xi(\alpha),\alpha) < \infty \quad \textit{and} \quad u'(\xi(\alpha),\alpha) = 0. \tag{2.9}$$

(b) *If $\mu > 0$, then*

$$\xi(\alpha) < \infty \quad \textit{for any } \alpha \in \mathbf{R}^+.$$

(c) *If $\mu = 0$, then*

$$\xi(\alpha) < \infty \quad \begin{cases} \textit{for any } \alpha \in \mathbf{R}^+ & \textit{if } \gamma > \dfrac{1}{8}, \\ \textit{for any } \alpha \in \mathbf{R}^+ \setminus \{\alpha_0\} & \textit{if } 0 < \gamma \leq \dfrac{1}{8}. \end{cases}$$

Here $\alpha_0 = U'(0)$, and U is the unique odd monotone kink found in [21].

Proof. (a) We write (2.6a) as

$$(z^{3/4})'' = \frac{3}{4\gamma}\frac{z-f}{z^{5/4}}, \tag{2.10}$$

where we have suppressed the subscript μ from f, and we define

$$\tau_0 = \sup\{t \in (0,\tau) : z' < 0 \ \text{ on } \ (0,t)\},$$

if $z' < 0$ in a right-neighborhood of the origin, and $\tau_0 = 0$ otherwise.

We distinguish two cases:

$$\text{(i)} \ \ \tau_0 = \tau \quad \text{and} \quad \text{(ii)} \ \ \tau_0 < \tau.$$

(i) In this case, $z(t) < \alpha^2$ for $0 < t < \tau$. Suppose that $\tau = \infty$ (i.e., $u(\xi(\alpha),\alpha) = \infty$). Then, since $f(t) \sim \frac{1}{2}t^4$ as $t \to \infty$, there exists a $T > 0$ such that (2.10) reduces to

$$(z^{3/4})'' < -1 \quad \text{for } t > T,$$

which implies that $\tau < \infty$, a contradiction. Thus, it must be the case that $u(\xi(\alpha),\alpha) < \infty$. If $\lim_{t\to\tau^-} z(t) > 0$, then standard theory applied to (2.6) shows that z continues to exist, with $z > 0$ on an interval $[\tau, \tau+\varepsilon)$, contradicting the definition of τ. Therefore,

$$\lim_{t\to\tau^-} z(t) = 0.$$

From this and (2.4) we conclude that $u'(\xi(\alpha),\alpha) = 0$.

(ii) We now consider the case $\tau_0 < \tau$, and again we suppose that $\tau = \infty$. At $t = \tau_0$ we have

$$z(\tau_0) > 0, \quad z'(\tau_0) = 0, \quad \text{and} \quad z''(\tau_0) \geq 0.$$

We again distinguish two cases:

$$\text{(ii}^*) \ \ 0 \leq \tau_0 < 1 \quad \text{and} \quad \text{(ii}^{**}) \ \ \tau_0 \geq 1.$$

(ii*) We claim that

$$z(t) > f(t) \quad \text{and} \quad z'(t) > 0 \quad \text{for } \tau_0 < t < \tau_0 + \varepsilon, \tag{2.11}$$

where ε is some small positive constant. If $z''(\tau_0) > 0$, this follows immediately from (2.6a). If $z''(\tau_0) = 0$, differentiation of (2.6a) yields $z'''(\tau_0) > 0$ if $\tau_0 > 0$ and $z'''(\tau_0) = 0$ if $\tau_0 = 0$. In the latter case one further differentiation of (2.6a) shows that $z^{iv}(\tau_0) > 0$. Thus, in all cases (2.11) holds.

This enables us to define

$$\tau_1 = \sup\{t > \tau_0 : z' > 0 \ \text{ on } \ (\tau_0, t)\}.$$

We shall show that

$$\tau_1 < \infty, \quad z'(\tau_1) = 0, \quad \text{and} \quad z''(\tau_1) < 0. \tag{2.12}$$

Suppose, to the contrary, that $\tau_1 = \infty$. Then, since $f(t) > 0$ for $t > \tau_+(\mu) = \sqrt{1 + \sqrt{\mu}}$, it follows from (2.10) that

$$(z^{3/4})'' < \frac{3}{4\gamma} z^{-1/4} \quad \text{for } t > \tau_+$$

or

$$y'' < \frac{3}{4\gamma} y^{-1/3} \quad \text{for } t > \tau_+, \tag{2.13}$$

where we have set $y = z^{3/4}$. If we now multiply (2.13) by $2y'$ and integrate over (τ_+, t), we find that

$$y' < \frac{3}{2\sqrt{\gamma}} \sqrt{y^{2/3} + C} \quad \text{for } t > \tau_+,$$

where C is a positive constant. Writing $w = y^{2/3} = z^{1/2}$, this inequality translates into

$$w' < \frac{1}{\sqrt{\gamma}} \sqrt{\frac{w + C}{w}} \quad \text{for } t > \tau_+.$$

Thus, since w is increasing, w' is uniformly bounded on (τ_+, ∞), so that

$$z(t) < A(1 + t)^2 \quad \text{for } t > 0 \tag{2.14}$$

for some positive constant A.

Remembering that $f(t) \sim \frac{1}{2} t^4$ as $t \to \infty$, it follows from (2.14) that $z(t) - f(t) \sim -\frac{1}{2} t^4$ as $t \to \infty$. Hence, since z is increasing, there exists a constant $K > 0$ such that

$$(z^{3/4})'' < -K(1 + t)^{3/2} \quad \text{for } t > t_1,$$

where t_1 is some sufficiently large number. Two integrations show that z cannot keep increasing indefinitely, contradicting our assumption that $\tau_1 = \infty$. Thus,

$$\tau_1 < \infty \quad \text{and} \quad z'(\tau_1) = 0.$$

To complete the proof of (2.12), in this case, we shall show that

$$\tau_1 > 1 \quad \text{and} \quad z''(\tau_1) < 0. \tag{2.15}$$

By (2.11), we can define

$$\tau^* = \sup\{t > \tau_0 : z > f \ \text{ on } \ (\tau_0, t)\}.$$

It then follows from (2.6a) that $z'' > 0$ on $(\tau_0, \tau^*]$. This implies that $\tau_1 > \tau^*$. Also, since $f' < 0$ on (0,1), it must be that $\tau_1 > 1$.

To prove the second assertion in (2.15), we need to show that $z''(\tau_1) < 0$. Suppose, to the contrary, that $z''(\tau_1) = 0$. Then, since $f' > 0$ on $(1, \infty)$, it follows that $z'''(\tau_1) < 0$, which implies that $z'' > 0$ and $z' < 0$ on a left-neighborhood of τ_1, contradicting the definition of τ_1. This completes the proof of (2.15).

It now follows from (2.6a) that $z'' < 0$ and $z' < 0$ for $t > \tau_1$ until $z = 0$ at some finite value τ. This contradicts our assumption that $\tau = \infty$. As in case (i) above it follows that $u'(\xi(\alpha), \alpha) = 0$.

(ii**) We now assume that $\tau_0 \geq 1$. The definition of τ_0 implies that $z''(\tau_0) \geq 0$. If $z''(\tau_0) > 0$, then $z' > 0$ on a right-neighborhood of τ_0 and we proceed as in the previous case. If $z''(\tau_0) = 0$, then $z'''(\tau_0) < 0$ if $\tau_0 > 1$, and it follows from (2.10) that $z'' < 0$ and $z' < 0$ to the right of τ_0 until $z = 0$ at a finite τ, a contradiction. If $\tau_0 = 1$ in this case, then $z'''(\tau_0) = 0$ as well, but $z^{iv}(\tau_0) < 0$. Again we find that $z'' < 0$ and $z' < 0$ to the right of τ_0 until $z = 0$ at a finite τ, a contradiction.

This completes the proof of part (a).

(b) Suppose, to the contrary, that there exist constants $\mu > 0$, $\alpha > 0$, and $\gamma > 0$ such that $\xi(\alpha) = \infty$. Then $u'(x) > 0$ for all $x > 0$ and by part (a), u is uniformly bounded on $\mathbf{R}^+$. Hence,

$$\lim_{x \to \infty} u(x, \alpha) \text{ exists} \overset{\text{def}}{=} \ell.$$

We distinguish three cases:

$$\text{(i)} \quad \ell > 1, \quad \text{(ii)} \quad 0 < \ell < 1, \quad \text{and} \quad \text{(iii)} \quad \ell = 1.$$

(i) Since $\ell(1 - \ell^2) < 0$ if $\ell > 1$, there exist a point $x_1 > 0$ and a constant $M > 0$ such that

$$\gamma u^{iv} - u'' < -M \quad \text{for } x > x_1.$$

When we integrate this inequality twice over (x_1, x), we obtain in turn

$$\gamma u'''(x) - u'(x) < A - Mx,$$
$$\gamma u''(x) - u(x) < Ax + B - \frac{1}{2}Mx^2,$$

where A and B are appropriate constants. Plainly, it is possible to choose $x_2 > x_1$ so large that

$$Ax + B < \frac{1}{4}Mx^2 \quad \text{for } x > x_2$$

and hence,

$$\gamma u''(x) < u(x) - \frac{1}{4}Mx^2 \quad \text{for } x > x_2.$$

Because u is uniformly bounded, this means that there exists a point $x_3 > x_2$ such that

$$\gamma u''(x) < -\frac{1}{8}Mx^2 \quad \text{for } x > x_3.$$

One more integration shows that $u'(x) \to -\infty$ as $x \to \infty$, which contradicts the assumption that $\xi(\alpha) = \infty$.

(ii) Since $\ell(1-\ell^2) > 0$ if $0 < \ell < 1$, there exist a point $y_1 > 0$ and a constant $N > 0$ such that

$$\gamma u^{iv} - u'' > N \quad \text{for } x > y_1.$$

Proceeding as in the previous case, we can find a point $y_2 > y_1$ such that

$$\gamma u''(x) > +\frac{1}{8}Nx^2 \quad \text{for } x > y_2,$$

and we conclude that $u'(x) \to \infty$ as $x \to \infty$, which contradicts the fact that u is uniformly bounded.

(iii) If $\ell = 1$, we conclude from (1.7) that there exists a point $x^* > 0$ such that

$$u'(x)u'''(x) \geq \frac{\mu}{8\gamma} > 0 \quad \text{for } x > x^*. \tag{2.16}$$

Hence, u'' has one sign on (x^*, ∞), so $\lim_{x\to\infty} u'(x) = m$ exists and $m \geq 0$. If $m > 0$, then $u(x) \to \infty$ as $x \to \infty$, violating the boundedness of u. Hence $m = 0$, so that by (2.16), $u'''(x) \to \infty$ as $x \to \infty$. Thus, $u''(x) \to \infty$, $u'(x) \to \infty$, and $u(x) \to \infty$ as $x \to \infty$, contradicting again the boundedness of u.

(c) Suppose, to the contrary, that there exist constants $\gamma > 0$ and $\alpha > 0$ such that $\xi(\alpha) = \infty$. Then $u'(x) > 0$ for all $x > 0$ and it follows as in part (b) that

$$\lim_{x\to\infty} u(x,\alpha) = 1. \tag{2.17}$$

Hence, $0 < u < 1$ for all $x > 0$, and we deduce from the differential equation that

$$\gamma u^{iv} - u'' > 0 \quad \text{for } x > 0. \tag{2.18}$$

By the maximum principle, u'' can have only one sign on $\mathbf{R}^+$, and therefore u' tends to a limit: $\lim_{x\to\infty} u'(x) = \ell_1 \geq 0$. If $\ell_1 > 0$, the solution will be unbounded on $\mathbf{R}^+$, so

$$\lim_{x\to\infty} u'(x) = 0. \tag{2.19}$$

In view of (2.18), $\lim_{x\to\infty}(\gamma u''' - u') = \ell_2$ exists, and therefore,

$$\lim_{x\to\infty} u'''(x) = \frac{\ell_2}{\gamma}.$$

Reasoning as before we find that

$$\lim_{x\to\infty} u'''(x) = 0. \tag{2.20}$$

Thus, since $\mu = 0$, it follows from (2.17)–(2.20) and the energy identity (1.7) that

$$\lim_{x\to\infty} (u, u', u'', u''') = (1,0,0,0) \qquad \text{and} \qquad u' > 0 \quad \text{on } [0,\infty). \tag{2.21}$$

If $\gamma \in (0, \frac{1}{8}]$, then (2.21) implies that $\alpha = \alpha_0$, where α_0 is the unique positive value of α for which a monotone, antisymmetric kink U exists. But this value has been excluded in the hypotheses.

If $\gamma > \frac{1}{8}$, then a linearization of (2.6a) around $u = 1$ shows that all four eigenvalues are complex with nonzero real and imaginary parts. Therefore, u cannot approach $u = 1$ monotonically, as asserted in (2.21). Thus, we have arrived at the final contradiction and Lemma 2.1 is proved.

We conclude this section with a lemma which restricts the admissible values of μ and α.

LEMMA 2.2. *Let $\gamma > 0$ and suppose that either*

$$\text{(a)} \qquad 0 \le \mu < 1 \quad \textit{and} \quad \alpha \ge \sqrt{\frac{1-\mu}{2}}$$

or

$$\text{(b)} \qquad \mu \ge 1 \quad \textit{and} \quad \alpha \ge 0.$$

Then the solution $u(\cdot, \alpha)$ of problem (2.1), (2.2) *cannot satisfy* (2.3).

Proof. Suppose, to the contrary, that there exist values of μ and α for which either (a) or (b) holds and which are such that the corresponding solution $u(x, \alpha)$ of problem (2.1), (2.2) does satisfy (2.3). We consider the two cases in succession.

(a) Observe that

$$z''(0, \alpha) = \frac{1}{\gamma\alpha^2}\Big(\alpha^2 - \frac{1-\mu}{2}\Big).$$

Thus, if $\alpha > \sqrt{\frac{1}{2}(1-\mu)}$, then $z''(0, \alpha) > 0$, and if $\alpha = \sqrt{\frac{1}{2}(1-\mu)}$, then $z''(0, \alpha) = 0$. However, in the second case $z'''(0, \alpha) > 0$. Therefore, in both cases $z'' > 0$ on an interval $(0, \delta)$.

It follows by the arguments used in the proof of part (a) of Lemma 2.1 that $z''(t) > 0$ and $z'(t) > 0$ for all $t \in (0, \tau_+(\mu)]$. In terms of the function $u(\cdot, \alpha)$ this means that there exists a point x_1 such that

$$u' > 0, \quad u'' > 0, \quad \text{and} \quad u''' > 0 \quad \text{on } (0, x_1) \qquad \text{and} \qquad u(x_1) > 1.$$

For condition (2.3b) to hold, there must be a first $x_2 > x_1$ such that

$$u''(x_2) = 0 \quad \text{and} \quad u'''(x_2) \le 0.$$

Thus, $u'' > 0$ and, hence, also $u' > 0$ on $(0, x_2)$, so that $\xi(\alpha) > x_2$. By equation (2.1a), we have $u^{iv}(x_2) < 0$, so

$$u''' < 0 \quad \text{and} \quad u'' < 0 \quad \text{on } (x_2, \xi(\alpha)].$$

In particular, $u'''(\xi(\alpha), \alpha) < 0$, which contradicts (2.3b).

(b) In this case, if $\alpha > 0$ then $z''(0, \alpha) > 0$ and we can proceed using the same arguments we used in part (a) to complete the proof. We omit the details for the sake of brevity.

If $\alpha = 0$, then by (1.7) we must have $\mu = 1$, so that $u(0) = 0$, $u'(0) = 0$, $u''(0) = 0$. If $u'''(0) = 0$ as well, then u is the trivial solution, so we must assume that $u'''(0) \neq 0$. Without loss of generality we may assume that $u'''(0) > 0$. Then $u' > 0$ and $u'' > 0$ in a right-neighborhood of the origin; hence, $z(t) > 0$ and $z'(t) > 0$ for small values of t. We may now proceed as in part (a) to show that u cannot be a periodic solution which satisfies (2.3). Theorem B is an immediate consequence of part (b) of Lemma 2.2.

3. Existence and uniqueness of periodic solutions: $0 < \mu < 1,\ \gamma > 0$. In this section we focus our attention on the parameter range $0 < \mu < 1,\ \gamma > 0$. We prove Theorem A and a uniqueness theorem for a more restricted range of values of μ, i.e., $\mu \in (0, \frac{4}{9}]$.

THEOREM 3.1. *Let $\mu \in (0,1)$ and $\gamma > 0$. Then there exists a periodic solution $u(x)$ such that*

$$\max\{|u(x)| : x \in \mathbf{R}\} < 1.$$

The proof proceeds via a sequence of lemmas.

We define the shooting set

$$\mathcal{S} = \{\hat{\alpha} > 0 : u(\xi(\alpha),\alpha) < 1,\ u''(\xi(\alpha),\alpha) < 0, \text{ and } u'''(\xi(\alpha),\alpha) < 0 \text{ for } 0 < \alpha < \hat{\alpha}\}.$$

LEMMA 3.2. *We have*

(a) $\xi \in C^1(\mathcal{S})$.

(b) *$\mathcal{S}$ is an open interval.*

(c) $$u(\xi(\alpha),\alpha) < \sqrt{1-\sqrt{\mu}} \quad \textit{if } \alpha \in \mathcal{S}.$$

Proof. (a) Let $\alpha \in \mathcal{S}$. Then, at $\xi = \xi(\alpha)$ we have

$$u'(\xi(\alpha),\alpha) = 0 \quad \text{and} \quad u''(\xi(\alpha),\alpha) < 0.$$

Hence, by the implicit function theorem, $\xi \in C^1(\mathcal{S})$.

(b) Since the inequalities in the definition of $\mathcal{S}$ are strict, the assertion follows immediately from part (a) and the continuous dependence of solutions on initial data.

Part (c) follows at once from the energy identity (1.7).

In the following lemma we show that $\mathcal{S}$ is nonempty. Define

$$\overline{\alpha} = \min\left\{\frac{\sqrt{1-\mu}}{2}, \sqrt{\frac{3(1-\mu)}{24\gamma+7}}\right\}.$$

LEMMA 3.3. $(0,\overline{\alpha}) \subset \mathcal{S}$.

Proof. Let $\alpha \in (0,\overline{\alpha})$. Observe that (1.7) implies that $u'''(0) < 0$, since $0 < \mu < 1$ and $\alpha < \overline{\alpha}$. As we increase x and as long as $u''' < 0$, it follows that $u'' < 0$, $u' < \alpha$, and $u(x) < \alpha x$. Thus, as long as $u \geq 0$ and $u''' < 0$, it follows from (2.1a) that

$$u^{iv}(x) < \frac{\alpha}{\gamma}x. \tag{3.1a}$$

We integrate this inequality three times to obtain

$$u'''(x) < \beta + \frac{\alpha}{2\gamma}x^2, \tag{3.1b}$$

$$u''(x) < \beta x + \frac{\alpha}{6\gamma}x^3, \tag{3.1c}$$

$$u'(x) < \alpha + \frac{\beta}{2}x^2 + \frac{\alpha}{24\gamma}x^4. \tag{3.1d}$$

Since we assume that $\alpha < \frac{1}{2}\sqrt{1-\mu}$, the energy identity (1.7) implies that

$$\beta < -\frac{1-\mu}{8\gamma\alpha}.$$

Hence, the right-hand sides of (3.1b) and (3.1c) are negative for $0 < x \leq 1$ and, since $\alpha < 1$, it follows that $u < 1$ on $[0, 1]$ as long as $u' \geq 0$.

On the other hand, because we have chosen $\alpha < \sqrt{\frac{3(1-\mu)}{24\gamma+7}}$, the right-hand side of (3.1d) is negative at $x = 1$. Thus, there must exist a first zero ξ of u' on $(0, 1)$, where $u < 1$, $u'' < 0$, and $u''' < 0$, so that $\alpha \in \mathcal{S}$.

Define

$$\alpha^* = \sup \mathcal{S}.$$

Lemma 3.4. *We have*

$$\alpha^* \leq \sqrt{\frac{1-\mu}{2}}.$$

Proof. It follows from (1.7) that

$$\begin{aligned} 2\gamma u' u''' &\geq (u')^2 - \frac{1}{2}\{(1-u^2)^2 - \mu\} \\ &> (u')^2 - \frac{1-\mu}{2} \quad \text{for } 0 < u < 1. \end{aligned}$$

Thus, if $\alpha^2 > (1-\mu)/2$, then $u''' > 0$, $u'' > 0$, and $u' > \alpha > 0$ as long as $0 < u \leq 1$, so that u' cannot have a first zero ξ such that $u(\xi) < 1$.

Lemma 3.5. *We have*

$$0 < u(\xi(\alpha^*), \alpha^*) < 1, \quad u''(\xi(\alpha^*), \alpha^*) < 0, \quad \textit{and} \quad u'''(\xi(\alpha^*), \alpha^*) = 0.$$

Proof. Suppose that $u(\xi(\alpha^*), \alpha^*) \geq 1$. Then by the continuous dependence of $u(\cdot, \alpha)$ on α on compact intervals, it follows that $u(\xi(\alpha), \alpha) > \sqrt{1 - \sqrt{\mu}}$ for all α in a small enough neighborhood of α^*. Since $(0, \alpha^*) \subset \mathcal{S}$, this contradicts Lemma 3.2 and we conclude that

$$u(\xi(\alpha^*), \alpha^*) < 1. \tag{3.2}$$

Thus, in the limit as α increases toward α^*, the first inequality in the definition of $\mathcal{S}$ continues to hold, and we wish to prove that the second one continues to hold as well. Suppose that the second inequality fails. It follows from the definition of ξ that $u''(\xi(\alpha^*), \alpha^*) \leq 0$. Hence, we suppose that

$$u''(\xi(\alpha^*), \alpha^*) = 0. \tag{3.3}$$

In what follows we shall write $\xi^* = \xi(\alpha^*)$ and $u^* = u(\xi^*, \alpha^*)$.

To show that (3.3) leads to a contradiction we proceed via a series of steps.

Step 1. We show that (3.3) implies that

$$u'''(\xi^*, \alpha^*) > 0. \tag{3.4}$$

Suppose that $u'''(\xi^*, \alpha^*) < 0$. Then $u'' > 0$ and $u' < 0$ in a left-neighborhood of ξ^*, contradicting the definition of ξ^*.

Next, suppose that $u'''(\xi^*, \alpha^*) = 0$. Then, since $u^* \in (0, 1)$ by (3.2), it follows from the differential equation that $u^{iv}(\xi^*, \alpha^*) > 0$, so that $u''' < 0$, $u'' > 0$, and $u' < 0$

in a left-neighborhood of ξ^*. This means that u' has a zero on $(0,\xi^*)$ contradicting again the definition of ξ^*.

Thus, if (3.3) holds, then so does (3.4).

Step 2. We show that

$$\xi(\alpha) \to \xi(\alpha^*) \quad \text{as } \alpha \to \alpha^*,\ \alpha \in \mathcal{S}. \tag{3.5}$$

First, it follows from (3.3), (3.4), and (2.1a) that

$$u'''(x,\alpha^*) > 0, \quad u''(x,\alpha^*) > 0, \quad \text{and} \quad u'(x,\alpha^*) > 0$$

for $x > \xi^*$ until $u(x_0,\alpha^*) = 1$ at a finite $x_0 > \xi(\alpha^*)$.

Next, let $\varepsilon > 0$ be small and arbitrarily chosen to satisfy

$$0 < \xi(\alpha^*) - \varepsilon < \xi(\alpha^*) < \xi(\alpha^*) + \varepsilon < x_0.$$

Since $[0,x_0]$ is compact, it follows from the definition of α^*, part (b) of Lemma 3.2, and continuity that there exists a $\delta = \delta(\varepsilon) > 0$ such that if $0 < \alpha^* - \alpha < \delta$, then $\alpha \in \mathcal{S}$,

$$u(x_0,\alpha) > \sqrt{1-\sqrt{\mu}}, \tag{3.6a}$$

and

$$u'(x_0,\alpha) > 0 \quad \text{for all } x \in [0,\xi(\alpha^*)-\varepsilon] \cup [\xi(\alpha^*)+\varepsilon, x_0]. \tag{3.6b}$$

From (3.6a), part (c) of Lemma 3.2, (3.6b), and the definition of $\xi(\alpha)$ we conclude that $\xi(\alpha) \in (\xi(\alpha^*)-\varepsilon, \xi(\alpha^*)+\varepsilon)$ if $0 < \alpha^* - \alpha < \delta$. This implies (3.5).

Step 3. The contradiction. It follows from (3.5) that

$$u'''(\xi(\alpha),\alpha) \to u'''(\xi(\alpha^*),\alpha^*) \quad \text{as } \alpha \to \alpha^*,\ \alpha \in \mathcal{S}.$$

Because $u'''(\xi(\alpha),\alpha) < 0$ for all $\alpha \in \mathcal{S}$, this implies that

$$u'''(\xi(\alpha^*),\alpha^*) \le 0,$$

which contradicts (3.4) and we conclude that (3.3) cannot hold. Thus,

$$u''(\xi(\alpha^*),\alpha^*) < 0. \tag{3.7}$$

To complete the proof we suppose that

$$u'''(\xi(\alpha^*),\alpha^*) < 0.$$

Then $\alpha^* \in \mathcal{S}$ and since $\mathcal{S}$ is open, α^* cannot be the supremum of $\mathcal{S}$. Therefore,

$$u'''(\xi(\alpha^*),\alpha^*) = 0$$

and the lemma is proved.

Corollary 3.6. *We have*

$$u(\xi(\alpha^*),\alpha^*) < \sqrt{1-\sqrt{\mu}} \quad \textit{and} \quad \alpha^* < \sqrt{\frac{1-\mu}{2}}.$$

Proof. The first inequality follows as in Lemma 3.2(c) from the energy identity (1.7). However, because we know from Lemma 3.5 that $u''(\xi^*, \alpha^*) < 0$, we now obtain strict inequality.

The second inequality is proved if we can rule out equality from Lemma 3.4. Thus, suppose that $(\alpha^*)^2 = (1-\mu)/2$. Then $u^{(i)}(0) = 0$ for $i = 2, 3, 4$ and $u^{(5)}(0) > 0$. Hence, since $u^{(i)} > 0,\ i = 2, 3, 4$ in a right-neighborhood of the origin, we conclude that $u' > 0$ as long as $u \le 1$, so that $u(\cdot, \alpha^*)$ cannot yield a periodic solution such that $u(\xi^*, \alpha^*) < 1$.

Proof of Theorem 3.1. It follows from Lemma 3.5 that the solution $u(x, \alpha^*)$ of problem (2.1) satisfies the conditions (2.3) at $\xi = \xi(\alpha^*)$ and so can be continued to yield a periodic solution with period $4\xi(\alpha^*)$.

Concerning *uniqueness*, we give the following partial result.

Lemma 3.7. *Let $\gamma > 0$ and $\frac{4}{9} \le \mu < 1$. Then there exists a unique periodic solution u which satisfies* (2.1), (2.2) *and is such that* $\max|u| < 1$.

Proof. Suppose that there are values $\gamma > 0$ and $\mu \in [\frac{4}{9}, 1)$ such that there exist two distinct periodic solutions u_1 and u_2 with $\max|u_i| < 1$ $(i = 1, 2)$. Let α_1 and α_2 be their respective slopes at $x = 0$. Since

$$\frac{d\beta}{d\alpha} = \frac{1}{2\gamma} + \frac{1-\mu}{4\gamma\alpha^2} > 0,$$

it follows that

$$\alpha_1 < \alpha_2 \quad \Rightarrow \quad u_1'''(0) < u_1'''(0) < 0.$$

Let $w = u_1 - u_2$. Then, by the mean value theorem,

$$\begin{cases} \gamma w^{iv} = w'' + (1 - 3\tilde{u}^2)w, & \text{(3.8a)} \\ w(0) = 0, \quad w'(0) < 0, \quad w''(0) = 0, \quad \text{and} \quad w'''(0) < 0, & \text{(3.8b)} \end{cases}$$

where $\tilde{u}$ is a function whose values lie between those of u_1 and u_2. Since $\frac{4}{9} \le \mu < 1$ and $\max|u_i| < \sqrt{1 - \sqrt{\mu}}$, it follows that

$$|\tilde{u}(x)| \le \frac{1}{\sqrt{3}} \quad \text{for } x \in \mathbf{R}$$

and, therefore,

$$1 - 3\tilde{u}^2(x) \ge 0 \quad \text{for } x \in \mathbf{R}.$$

Thus, we conclude from (3.8a) and (3.8b) that

$$w^{iv} < 0,\ w''' < 0,\ w'' < 0, \ \text{ and } \ w' < 0 \quad \text{for } x \in \mathbf{R}.$$

This implies that $w(x) \to -\infty$ as $x \to \infty$. Because $|w(x)| \le |u_1(x)| + |u_2(x)| \le \frac{2}{\sqrt{3}}$ for all $x \in \mathbf{R}$, this is not possible and we have a contradiction.

We conjecture that for every $\gamma > 0$ and $0 < \mu < 1$, there exists a unique periodic solution with maximum less than 1.

4. Nonexistence of periodic solutions. In this section we restrict our attention to the parameter regime

$$0 \leq \mu < 1 \quad \text{and} \quad \gamma > 0. \tag{4.1}$$

In Lemma 2.2 we already proved that no periodic solution can exist if $\mu \geq 1$ and $\gamma > 0$. We wish to determine the largest possible range of values of μ and γ in this regime in which no periodic solution exists. We emphasize again that by a periodic solution we mean a solution of problem (2.1)–(2.2) which satisfies (2.3).

In the analysis below we extend Lemma 2.2 and prove two nonexistence theorems for $0 < \gamma \leq \frac{1}{8}$. In the previous section we found that there exist periodic solutions for every $\gamma > 0$ when $0 < \mu < 1$ and that their maxima lie *below* $u = 1$. In our first nonexistence theorem we set $\mu = 0$ and show that such solutions cease to exist when $0 < \gamma \leq \frac{1}{8}$. This range of γ-values is optimal; in the next section we shall show that when $\mu = 0$ and $\gamma > \frac{1}{8}$ such periodic solutions do exist.

In section 5 it is shown that when $\mu = 0$ and $\gamma > \frac{1}{8}$, there exist periodic solutions with maxima *above* $u = 1$. In our second nonexistence theorem we shall show that when $\mu = 0$, this range of γ-values is also optimal and that no periodic solutions with maxima above $u = 1$ exist when $\gamma \leq \frac{1}{8}$.

Before proving these two theorems, we establish three technical lemmas. For this we recall that if $u(\cdot, \alpha)$ is a periodic solution, then the corresponding solution $z(\cdot, \alpha)$ of problem (2.6) has the properties

$$\lim_{t \to \tau(\alpha)^-} z(t, \alpha) = 0 \quad \text{and} \quad \lim_{t \to \tau(\alpha)^-} \sqrt{z(t, \alpha)} z''(t, \alpha) = 0, \tag{2.8b}$$

where $\tau(\alpha)$ is finite and defined by

$$\tau(\alpha) = \sup\{t > 0 : z(\cdot, \alpha) > 0 \;\text{ on }\; [0, t)\}.$$

LEMMA 4.1. *Let $0 \leq \mu < 1$ and $\gamma > 0$. If z corresponds to a periodic solution, then*

(a)
$$z(0) < \frac{1 - \mu}{2},$$

(b)
$$z'(t) < 0 \quad \textit{for } 0 < t < \tau.$$

Proof. (a) Since $z(0) = \alpha^2$, the assertion follows at once from Lemma 2.2.

(b) It follows from part (a) and (2.6a) that $z''(0) < 0$. Hence, $z' < 0$ in an interval $(0, \varepsilon)$ for some small $\varepsilon > 0$. If z' vanishes at a first $\tau_0 \in (0, \tau)$, then

$$z(\tau_0) > 0, \quad z'(\tau_0) = 0, \quad \text{and} \quad z''(\tau_0) \geq 0. \tag{4.2}$$

If $z''(\tau_0) = 0$, then $z(\tau_0) = f_\mu(\tau_0)$ by (2.6a) and a differentiation of (2.6a) yields

$$z'''(\tau_0) = -\frac{f'_\mu(\tau_0)}{\gamma z(\tau_0)} = -\frac{2\tau_0(\tau_0^2 - 1)}{\gamma\, z(\tau_0)}. \tag{4.3}$$

We shall discuss the cases (i) $\tau_0 = 1$, (ii) $\tau_0 < 1$, and (iii) $\tau_0 > 1$ in succession.

(i) $\tau_0 = 1$. It follows from (2.6a) that

$$z(\tau_0) = f_\mu(\tau_0) = -\frac{1}{2}\mu \leq 0,$$

which contradicts (4.2).

(ii) $\tau_0 < 1$. It follows from (4.3) that $z'''(\tau_0) > 0$, so that $z'' < 0$ and $z' > 0$ in a left-neighborhood $(\tau_0 - \varepsilon, \tau_0)$ of τ_0. But this contradicts the definition of τ_0.

(iii) $\tau_0 > 1$. It follows from (4.3) that $z'''(\tau_0) < 0$. Therefore, $z'' < 0$ and $z' < 0$ in a small interval $(\tau_0, \tau_0 + \varepsilon)$. When we differentiate (2.6a) and divide by $\sqrt{z}$, we obtain

$$(\sqrt{z}\, z'')' = \frac{z' - f'_\mu}{\gamma\sqrt{z}}. \tag{4.4}$$

Since $\tau_0 > 1$ and $f'_\mu > 0$ on $(1, \infty)$, it follows from (4.4) that $z'' < 0$ and $z' < 0$ on the entire interval (τ_0, τ). Integration of (4.4) over (τ_0, τ) shows that

$$\lim_{t \to \tau^-} \sqrt{z(t)}\, z''(t) = \int_{\tau_0}^{\tau} \frac{z' - f'_\mu}{\gamma\sqrt{z}}\, ds < 0,$$

contradicting (2.8b).

Thus, because (i), (ii), and (iii) lead to contradictions, we must conclude that $z''(\tau_0) > 0$. This implies by (2.6a) that $z(\tau_0) > f_\mu(\tau_0)$. Hence, $z' > 0$ in a right-neighborhood of τ_0. Because $z(\tau) = 0$, there must exist a first $\tau_1 > \tau_0$ where $z'(\tau_1) = 0$. We assert that $\tau_1 > 1$. To see this, note that (2.6a) implies that $z'' > 0$; hence, $z' > 0$ as long as $z > f_\mu$. Because $f'_\mu < 0$ on $(0, 1)$, it follows that

$$z(t) > z(\tau_0) > f_\mu(\tau_0) > f_\mu(t) \quad \text{on } \tau_0 < t \leq 1.$$

This means that $z' > 0$ on $(\tau_0, 1]$ and, hence, $\tau_1 > 1$.

At $t = \tau_1$ we have $z''(\tau_1) \leq 0$. If $z''(\tau_1) < 0$, then $z'' < 0$ and $z' < 0$ on an interval $(\tau_1, \tau_1 + \varepsilon)$. Reasoning as before, using (4.4) again, we find that $z' < 0$ on the entire interval (τ_1, τ) and that $\lim_{t \to \tau^-} \sqrt{z(t)}\, z''(t) < 0$, which contradicts (2.8b). If $z''(\tau_1) = 0$, then, as in (4.3), we find that

$$z'''(\tau_1) = -\frac{2\tau_1(\tau_1^2 - 1)}{\gamma\, z(\tau_1)} < 0.$$

Therefore, $z'' < 0$ and $z' < 0$ on a right-neighborhood of τ_1 and we can repeat the previous argument to obtain a contradiction of (2.8b).

This leads us to the conclusion that $z' < 0$ on $(0, \tau)$ and the lemma is proved.

Lemma 4.2. *Suppose that z corresponds to a periodic solution and that $f_\mu(\tau) \neq 0$. Then*

$$z''(\tau) = \lim_{t \to \tau^-} z''(t) = \frac{2}{\gamma}\left\{1 + \frac{\sqrt{\gamma}}{2}\frac{f'_\mu(\tau)}{\sqrt{f_\mu(\tau)}}\right\}. \tag{4.5}$$

Proof. Because u' and u''' both vanish as $x \to \xi^-$, or $t \to \tau^-$, it follows from l'Hôpital's rule that

$$z''(\tau) = 2\lim_{x \to \xi^-} \frac{u'''(x)}{u'(x)} = 2\lim_{x \to \xi^-} \frac{u^{iv}(x)}{u''(x)} = \frac{2}{\gamma}\left(1 + \frac{u - u^3}{u''}\right), \tag{4.6}$$

where the last term is evaluated at $x = \xi$. By the energy identity (1.7) we have

$$(u'')^2 = \frac{1}{\gamma} f_\mu(u) \quad \text{at } x = \xi,$$

so that

$$u'' = -\frac{1}{\sqrt{\gamma}}\sqrt{f_\mu(u)} \quad \text{at } x = \xi.$$

If we substitute this expression for u'' into (4.6) and remember that $u(\xi) = \tau$, the assertion follows.

Define

$$H = z\Big(z'' - \frac{1}{\gamma}\Big) - \frac{\mu}{2\gamma} \tag{4.7}$$

and

$$\tau_0 = \sup\{t \in (0, \tau) : z' < 0 \;\text{ on }\; (0, t)\}.$$

Lemma 4.3. *Let $0 \le \mu < 1$ and $0 < \gamma \le \frac{1}{8}$, and let z be the solution of problem* (2.6). *Then*

$$H(t) < 0 \quad \textit{for } 0 \le t < \tau^* = \min\{\tau_0, 1\}.$$

Proof. Observe that we can write H as

$$H = \frac{(z')^2}{4} - \frac{(t^2-1)^2}{2\gamma}. \tag{4.8}$$

Hence

$$H(0) = -\frac{1}{2\gamma} < 0$$

and it follows that $H < 0$ in a right-neighborhood of the origin. Suppose that H first vanishes at a point $t_0 \in (0, \tau^*)$. Then

$$H(t_0) = 0 \quad \text{and} \quad H'(t_0) \ge 0. \tag{4.9}$$

We deduce from (4.8), (4.9), and part (b) of Lemma 4.1 that, since $t_0 < 1$,

$$z'(t_0) = -\sqrt{\frac{2}{\gamma}}\,(1 - t_0^2). \tag{4.10}$$

For H' we differentiate (4.8) and use (4.10) to obtain

$$H'(t_0) = -(1 - t_0^2)\left\{\frac{z''}{\sqrt{2\gamma}} - \frac{2t_0}{\gamma}\right\}. \tag{4.11}$$

Since $\mu \ge 0$ and H vanishes at t_0, it follows from (4.7) and (4.9) that

$$z\Big(z'' - \frac{1}{\gamma}\Big) = \frac{\mu}{2\gamma} \ge 0 \quad \text{at } t = t_0.$$

Hence $z''(t_0) \ge \frac{1}{\gamma}$, and we conclude from (4.11) that

$$H'(t_0) \le -\frac{1}{\gamma}(1 - t_0^2)\left\{\frac{1}{\sqrt{2\gamma}} - 2t_0\right\} < 0$$

because $0 < t_0 < 1$ and $\gamma \le \frac{1}{8}$. This contradicts (4.9) and the lemma is proved.

We are now ready to prove the two nonexistence theorems for $0 < \gamma \le \frac{1}{8}$. As was explained earlier, we know that there exist periodic solutions for these values of γ when $0 < \mu < 1$ and that they do not exceed $u = 1$. In the first theorem we show that such periodic solutions no longer exist when $\mu = 0$. In the second theorem we show that if $\mu \in [0, 1)$, then there exist no periodic solutions which exceed $u = 1$.

THEOREM 4.4. *Let $\mu = 0$ and $0 < \gamma \le \frac{1}{8}$. Then there exists no periodic solution $u(x)$ such that*

$$\max\{|u(x)| : x \in \mathbf{R}\} < 1.$$

Proof. Suppose, to the contrary, that there exists a periodic solution u whose maximum is less than 1. Let z correspond to u. Then $\tau < 1$, Lemma 4.1 implies that $z' < 0$ on $(0, \tau)$, and we deduce from Lemma 4.3 that $H < 0$ on $(0, \tau)$. Thus, by (4.7),

$$z''(t) < \frac{1}{\gamma} \quad \text{for } 0 < t < \tau \tag{4.12}$$

and, in particular,

$$z''(\tau) \le \frac{1}{\gamma}.$$

From this last inequality and Lemma 4.2, we conclude that

$$f'(\tau) \le -\frac{1}{\sqrt{\gamma}}\sqrt{f(\tau)}.$$

Therefore, because of (2.7),

$$\tau \ge \frac{1}{\sqrt{8\gamma}}.$$

Since $\gamma \le \frac{1}{8}$, this means that we must have $\tau \ge 1$, a contradiction.

THEOREM 4.5. *Let $0 \le \mu < 1$ and $0 < \gamma \le \frac{1}{8}$. Then there exists no periodic solution $u(x)$ such that*

$$\max\{|u(x)| : x \in \mathbf{R}\} > 1.$$

Proof. Suppose that there exists a periodic solution u whose maximum is greater than 1. Let z correspond to u. Then $\tau > 1$. Since Lemma 4.1 implies that $z' < 0$ on $(0, \tau)$, it follows that $z'(1) < 0$.

To force a contradiction we shall show that $z'(1) > 0$. The proof of Lemma 3.4 shows that this is the case when $\alpha > \alpha_\mu = \sqrt{(1-\mu)/2}$, and by continuity this will remain so until $z'(1) = 0$ for some $\tilde{\alpha} < \alpha_\mu$. When $z'(1) = 0$, it follows from (4.8) that

$$H(1) = 0 \quad \text{and} \quad H'(1) = 0.$$

In addition,

$$H''(1) \ge \frac{1 - 8\gamma}{2\gamma^2} + \frac{\mu}{2\gamma^2 z},$$

where strict inequality holds if $\mu > 0$ and equality holds if $\mu = 0$. Thus,

$$H''(1) > 0 \quad \text{if } (\mu, \gamma) \neq \left(0, \frac{1}{8}\right),$$

in which case $H' < 0$ and $H > 0$ in a left-neighborhood of $t = 1$. Since $H < 0$ on $(0, 1)$ by Lemma 4.3, we have a contradiction.

On the other hand, if $\mu = 0$ and $\gamma = \frac{1}{8}$, then $H''(1) = 0$ and we have to consider higher derivatives. We find that

$$H'''(1) = -\frac{12}{\gamma} < 0.$$

Therefore, in this case, $H'' > 0$, $H' < 0$, and $H > 0$ in a left-neighborhood of $t = 1$ and by Lemma 4.3, we have once again arrived at a contradiction.

5. Existence of periodic solutions: $\mu = 0$, $\gamma > \frac{1}{8}$.

In the previous section we saw that if $\mu = 0$, then there are no periodic solutions for $0 < \gamma \leq \frac{1}{8}$. In this section we shall show that there do exist periodic solutions when $\gamma > \frac{1}{8}$, both with a maximum less than 1 and with a maximum greater than 1. The method of proof is similar to the one used in section 3.

THEOREM 5.1. *Let $\mu = 0$ and $\gamma > \frac{1}{8}$. Then there exists a periodic solution u such that*

$$\max\{|u(x)| : x \in \mathbf{R}\} < 1.$$

We recall from Lemma 2.1 that if $\mu = 0$ and $\gamma > \frac{1}{8}$, then

$$\xi(\alpha) < \infty \quad \text{and} \quad u'(\xi(\alpha), \alpha) = 0 \text{ for every } \ \alpha > 0.$$

Continuing as in section 3, we set

$$\mathcal{S} = \{\hat{\alpha} > 0 : u(\xi(\alpha), \alpha) < 1, \ u''(\xi(\alpha), \alpha) < 0, \text{ and } u'''(\xi(\alpha), \alpha) < 0 \text{ for } 0 < \alpha < \hat{\alpha}\}.$$

Reproducing the proofs of Lemmas 3.2–3.4, we establish the following properties of ξ and $\mathcal{S}$.

LEMMA 5.2. *Let $\mu \in [0, 1)$ and $\gamma > 0$.*

(a) *$\xi \in C^1(\mathcal{S})$.*

(b) *The set $\mathcal{S}$ is a nonempty, open interval of the form $(0, \alpha^*)$.*

(c) $$\min\left\{\frac{\sqrt{1-\mu}}{2}, \sqrt{\frac{3(1-\mu)}{24\gamma + 7}}\right\} \leq \alpha^* \leq \sqrt{\frac{1-\mu}{2}}.$$

We must still determine the properties of $u(\cdot, \alpha^*)$. This will be done in the next lemma.

LEMMA 5.3. *Let $\mu = 0$ and $\gamma > 0$. Then*

$$u(\xi(\alpha^*), \alpha^*) < 1, \quad u''(\xi(\alpha^*), \alpha^*) < 0, \quad \text{and} \quad u'''(\xi(\alpha^*), \alpha^*) = 0.$$

Proof. We first show that $u''(\xi^*, \alpha^*) < 0$, where we have written $\xi^* = \xi(\alpha^*)$.

From the definition of ξ we conclude that $u''(\xi^*, \alpha^*) \leq 0$. We claim that $u''(\xi^*, \alpha^*) < 0$. Thus, suppose to the contrary that

$$u''(\xi^*, \alpha^*) = 0. \tag{5.1}$$

Then, by the energy identity (1.7),

$$u(\xi^*, \alpha^*) = 1.$$

We assert that (5.1) implies that

$$u'''(\xi^*, \alpha^*) > 0. \tag{5.2}$$

Suppose that $u'''(\xi^*, \alpha^*) < 0$. Then $u'' > 0$ and $u' < 0$ in a left-neighborhood of ξ^*, contradicting the definition of ξ^*. On the other hand, if $u'''(\xi^*, \alpha^*) = 0$, then by uniqueness, $u(x) = 1$ for all $x \in \mathbf{R}$, a contradiction. Thus, indeed, (5.2) holds.

As in the proof of Lemma 3.5 it follows that

$$\xi(\alpha) \to \xi(\alpha^*) \quad \text{as } \alpha \to \alpha^*,\ \alpha \in \mathcal{S},$$

which means that

$$u'''(\xi(\alpha), \alpha) \to u'''(\xi(\alpha^*), \alpha^*) \quad \text{as } \alpha \to \alpha^*,\ \alpha \in \mathcal{S}.$$

Because $u'''(\xi(\alpha), \alpha) < 0$ for all $\alpha \in \mathcal{S}$, we arrive in the limit as $\alpha \to \alpha^*$ at

$$u'''(\xi(\alpha^*), \alpha^*) \leq 0, \tag{5.3}$$

which contradicts (5.2). Thus, (5.1) must be false; hence,

$$u''(\xi(\alpha^*), \alpha^*) < 0. \tag{5.4}$$

It follows from (5.4) and the energy identity (1.7) that

$$u^* = u(\xi(\alpha^*), \alpha^*) \neq 1$$

and that $\xi(\alpha)$ is continuous at $\alpha = \alpha^*$. Therefore, by the continuous dependence on initial data, if $u^* > 1$, then $u(\xi(\alpha), \alpha) > 1$ for α in a left-neighborhood of α^*. Since $(0, \alpha^*) \subset \mathcal{S}$, the definition of $\mathcal{S}$ shows that this is impossible. Thus,

$$u(\xi(\alpha^*), \alpha^*) < 1. \tag{5.5}$$

Finally, regarding u''', we must have equality in (5.3). For if

$$u'''(\xi(\alpha^*), \alpha^*) < 0,$$

then continuity implies that $\alpha^* < \sup \mathcal{S}$, a contradiction.

Thus, we have shown that the solution $u(x, \alpha^*)$ of problem (2.1) satisfies the properties (2.3) at $x = \xi(\alpha^*)$ and this yields a periodic solution of which, by (5.5), the maximum is less than 1. This completes the proof of Theorem 5.1.

In the next theorem we find periodic solutions whose maxima exceed unity.

THEOREM 5.4. *Let $\mu = 0$ and $\gamma > \frac{1}{8}$. Then there exists a periodic solution u such that*

$$\max\{|u(x)| : x \in \mathbf{R}\} > 1.$$

We now take the shooting set from those values of α for which the maximum of u *exceeds* 1. Specifically, we define

$$\mathcal{T} = \{\hat{\alpha} > 0 : u(\xi(\alpha), \alpha) > 1,\ u''(\xi(\alpha), \alpha) < 0,\ \text{and } u'''(\xi(\alpha), \alpha) < 0 \text{ for } \alpha > \hat{\alpha}\}.$$

Lemma 5.5. *We have*

$$\left(\frac{1}{\sqrt{2}},\infty\right)\subset\mathcal{T}.$$

Proof. It follows from (1.7) that

$$2\gamma u'u'''\geq (u')^2-\frac{1}{2}(1-u^2)^2.$$

Thus, if $\alpha^2>\frac{1}{2}$, then $u'''>0$, $u''>0$, and $u'>0$ as long as $0<u\leq 1$. Hence, u first reaches 1 at a finite value x_1, where

$$u'(x_1)>0,\quad u''(x_1)>0,\quad u'''(x_1)>0.$$

Therefore, at $x=\xi$ we have

$$u(\xi)>1,\quad u'(\xi)=0,\quad u''(\xi)<0, \tag{5.6}$$

where the last inequality is strict because of the energy identity (1.7). Hence, u'' has a first zero at a point $x_2\in(x_1,\xi)$. At this point we have

$$u(x_2)>1,\quad u''(x_2)=0,\quad u'''(x_2)\leq 0.$$

Since, by equation (2.1a), $u^{iv}<0$ when both $u>1$ and $u''\leq 0$, it follows that

$$u'''(\xi)<0. \tag{5.7}$$

From (5.6) and (5.7) we deduce that for any $\alpha>\frac{1}{\sqrt{2}}$,

$$u(\xi(\alpha),\alpha)>1,\quad u''(\xi(\alpha),\alpha)<1,\quad\text{and}\quad u'''(\xi(\alpha),\alpha)<0,$$

so that $(\frac{1}{\sqrt{2}},\infty)\subset\mathcal{T}$.

As with Lemma 5.2, we can prove the following properties of ξ.

Lemma 5.6. *We have*

(a) $\xi\in C^1(\mathcal{T})$,

(b) *the set $\mathcal{T}$ is an open interval of the form* (α_*,∞),

(c) $$\alpha_*\geq\alpha^*,$$

where $\alpha^*=\sup\mathcal{S}$ as defined in Lemma 5.2, *part* (b).

In the next lemma we list again the important properties of $u(\xi(\alpha),\alpha)$ at $\alpha=\alpha_*$.

Lemma 5.7. *We have*

$$u(\xi_*,\alpha_*)>1,\quad u''(\xi_*,\alpha_*)<0,\quad\textit{and}\quad u'''(\xi_*,\alpha_*)=0,$$

where we have written $\xi_*=\xi(\alpha_*)$.

Proof. From the definition of ξ we conclude that $u''(\xi_*,\alpha_*)\leq 0$. Let us first suppose that

$$u''(\xi_*,\alpha_*)=0. \tag{5.8}$$

Then, by the energy identity (1.7),

$$u(\xi_*,\alpha_*)=1.$$

We assert that (5.8) implies that

$$u'''(\xi_*, \alpha_*) > 0. \tag{5.9}$$

For if $u'''(\xi_*, \alpha_*) < 0$, then $u'' > 0$ and $u' < 0$ in a left-neighborhood of ξ_*, which contradicts the definition of ξ_*. If $u'''(\xi_*, \alpha_*) = 0$, it follows from uniqueness that $u(x) = 1$ for all $x \in \mathbf{R}$, which contradicts the condition at $x = 0$. Therefore, (5.9) holds (see also [21, Lemma 3.10]).

To complete the proof of Lemma 5.7, we need the following lemma in which we establish continuity of ξ at α_* under the above conditions.

Lemma 5.8. *Suppose that for some $\alpha_0 > 0$ we have*

$$u(\xi(\alpha_0), \alpha_0) = 1, \quad u''(\xi(\alpha_0), \alpha_0) = 0, \quad \textit{and} \quad u'''(\xi(\alpha_0), \alpha_0) > 0.$$

Then

$$\xi(\alpha) \to \xi(\alpha_0) \quad \textit{as } \alpha \to \alpha_0.$$

Accepting Lemma 5.8 for the moment, we conclude that

$$u'''(\xi(\alpha), \alpha) \to u'''(\xi(\alpha_*), \alpha_*) \text{ as } \alpha \to \alpha_*, \quad \alpha \in \mathcal{T}.$$

Because $u'''(\xi(\alpha), \alpha) < 0$ for all $\alpha \in \mathcal{T}$, it follows that

$$u'''(\xi(\alpha_*), \alpha_*) \leq 0, \tag{5.10}$$

which contradicts (5.9). Thus, (5.8) cannot be true and we conclude that

$$u''(\xi(\alpha_*), \alpha_*) < 0. \tag{5.11}$$

It follows from (5.11) and the energy identity (1.7) that

$$\textit{either} \quad u(\xi_*, \alpha_*) > 1 \quad \textit{or} \quad u(\xi_*, \alpha_*) < 1$$

and that $\xi(\alpha)$ is continuous at $\alpha = \alpha_*$. Hence, by continuous dependence on initial data, if $u(\xi_*, \alpha_*) < 1$, then $u(\xi(\alpha), \alpha) < 1$ for α in a right-neighborhood of α_*. Since $(\alpha_*, \infty) \subset \mathcal{T}$, the definition of $\mathcal{T}$ implies that this is impossible. Thus,

$$u(\xi_*, \alpha_*) > 1. \tag{5.12}$$

Finally, regarding u''', we must have equality in (5.10). For if

$$u'''(\xi(\alpha_*), \alpha_*) < 0,$$

then continuity implies that $\alpha_* > \inf \mathcal{T}$, a contradiction. Therefore,

$$u'''(\xi(\alpha_*), \alpha_*) = 0. \tag{5.13}$$

We conclude from (5.13) that the solution $u(x, \alpha_*)$ of problem (2.1) satisfies the properties (2.3) at $x = \xi(\alpha_*)$ and, thus, yields a periodic solution of which, by (5.12), the maximum is greater than 1. This completes the proof of Lemma 5.7.

The proof of Theorem 5.4 is complete once we have proved Lemma 5.8.

Proof of Lemma 5.8. Fix $\varepsilon > 0$ and small. Then by the assumptions on $u(\cdot, \alpha_0)$ there exists a $\delta > 0$ such that

$$u(\xi_0 - \varepsilon, \alpha_0) < 1 - 2\delta, \quad u(\xi_0 + \varepsilon, \alpha_0) > 1 + 2\delta, \tag{5.14a}$$

and

$$u'(x,\alpha_0) > \delta \quad \text{for all } x \in [0, \xi_0 - \varepsilon]. \tag{5.14b}$$

We wish to prove that there exists a $\nu > 0$ such that if $|\alpha - \alpha_0| < \nu$, then $u'(\cdot, \alpha)$ has a zero on $(\xi_0 - \varepsilon, \xi_0 + \varepsilon)$.

By the continuous dependence of solutions on initial data it follows from (5.14) that there exists a $\nu_1 > 0$ such that

$$u(\xi_0-\varepsilon,\alpha) < 1-\delta, \quad u(\xi_0+\varepsilon,\alpha) > 1+\delta, \text{ and } u'(x,\alpha) > 0 \text{ for all } x \in [0, \xi_0-\varepsilon] \tag{5.15}$$

if $|\alpha - \alpha_0| < \nu_1$ so that

$$\xi(\alpha) > \xi_0 - \varepsilon \quad \text{if } |\alpha - \alpha_0| < \nu_1. \tag{5.16}$$

To show that $\xi(\alpha) < \xi_0 + \varepsilon$ for α sufficiently close to α_0, it is sufficient to prove that

$$\tau(\alpha) \to \tau(\alpha_0) = 1 \quad \text{as } \alpha \to \alpha_0, \tag{5.17}$$

where we recall that $\tau(\alpha) = u(\xi(\alpha), \alpha)$. For (5.17) implies that there exists a $\nu_2 > 0$ such that

$$\tau(\alpha) < 1 + \delta \quad \text{if } |\alpha - \alpha_0| < \nu_2,$$

and, because $u' > 0$ on $(0, \xi)$, we conclude from (5.15) that

$$\xi(\alpha) < \xi_0 + \varepsilon \quad \text{if } |\alpha - \alpha_0| < \nu = \min\{\nu_1, \nu_2\}. \tag{5.18}$$

Thus, (5.15) and (5.18) yield the continuity of $\xi(\alpha)$ at α_0.

Let us now prove (5.17). Let $z_0(t) = z(t, \alpha_0)$ be the solution of problem (2.6) which corresponds to $u(x, \alpha_0)$. Then

$$z_0(t) \to 0 \quad \text{and} \quad \sqrt{z_0(t)}z_0''(t) \to A \quad \text{as } t \to 1^-,$$

where by assumption $A = 2u'''(\xi(\alpha_0), \alpha_0)$ is a positive constant. It is readily shown that this implies that the function $y_0(t) = z_0^{3/4}(t)$ has the properties

$$\frac{y_0(t)}{1-t} \to B \quad \text{and} \quad y_0'(t) \to -B \quad \text{as } t \to 1^-, \tag{5.19}$$

where $B = \frac{3}{2}\sqrt{A}$.

We can write the equation (2.6a) for z as

$$(z^{-1/4}z')' = \frac{z-f}{\gamma z^{5/4}},$$

so that, since $f(t) \geq 0$ for all $t \geq 0$, the function $y(t) = z^{3/4}(t)$ satisfies

$$y'' \leq \frac{3}{4\gamma} y^{-1/3}. \tag{5.20}$$

Fix $\rho \in (0, 1)$. Then $y_0(1 - \rho) > 0$ and it follows from the continuous dependence on initial data on $[0, \rho]$ that there exists a $\vartheta_1 > 0$ such that $\tau(\alpha) > 1 - \rho$ when $|\alpha - \alpha_0| < \vartheta_1$. Since ρ may be chosen as small as we wish, we conclude that

$$\liminf_{\alpha \to a_0} \tau(\alpha) \geq 1. \tag{5.21a}$$

It remains to prove that

$$\limsup_{\alpha\to a_0} \tau(\alpha) \le 1. \tag{5.21b}$$

Fix $\varepsilon > 0$ and $t_0 \in (0,1)$. By (5.19), it is possible to choose t_0 so close to 1 that

$$y_0'(t_0) \le -\frac{\sqrt{3}}{2}B \quad \text{and} \quad y_0(t_0) \le \frac{B}{8}\,\varepsilon.$$

By continuity we can find a constant $\vartheta_2 > 0$ so small that if $|\alpha - \alpha_0| < \vartheta_2$, then

$$y'(t_0) \le -\frac{B}{2} \quad \text{and} \quad 0 < y(t_0) \le \frac{B}{4}\varepsilon. \tag{5.22}$$

Thus, in a neighborhood of t_0 we have $y' < 0$, so that when we multiply (5.20) by y' we obtain

$$(y'^2)' \ge \frac{9}{4\gamma}(y^{2/3})'$$

for $t > t_0$ as long as $y > 0$ and $y' < 0$. This yields, upon integration over (t_0, t),

$$\begin{aligned} y'^2(t) &\ge y'^2(t_0) + \frac{9}{4\gamma}\{y^{2/3}(t) - y^{2/3}(t_0)\} \\ &\ge y'^2(t_0) - \frac{9}{4\gamma}y^{2/3}(t_0) \\ &\ge \frac{B^2}{4} - \frac{9}{4\gamma}\Big(\frac{B\varepsilon}{4}\Big)^{2/3} > \frac{B^2}{16}, \end{aligned}$$

if we choose $\varepsilon < \varepsilon_0 = \frac{1}{2}(\frac{\gamma}{3})^{3/2}B^2$. Therefore,

$$y'(t) < -\frac{B}{4} \quad \text{for } t_0 \le t \le \tau.$$

Thus, when $0 < \varepsilon < \varepsilon_0$, integration over (t_0, τ) yields

$$\tau \le t_0 + \frac{4}{B}\,y(t_0) < t_0 + \varepsilon < 1 + \varepsilon,$$

where we have used (5.22). Since ε can be chosen arbitrarily small, this proves (5.21b) and the proof of Lemma 5.8 is complete.

We conclude this section with a few observations about the existence of periodic solutions with amplitude greater than 1 when $0 < \mu < 1$.

Because the initial data, and hence the solution u of problem 2.1, depend continuously on μ, it is evident from the proof of Theorem 5.1 that there exist periodic solutions with amplitude greater than 1 when μ is sufficiently small. In the following theorem we shall show that this is no longer true when $\mu \ge \frac{4}{9}$.

THEOREM 5.9. *If $\mu \ge \frac{4}{9}$ and $\gamma > 0$ is arbitrary, then there exists no periodic solution u for which*

$$\max\{|u(x)| : x \in \mathbf{R}\} > 1.$$

Proof. Let $\mu \in (0,1)$ and suppose that z corresponds to a periodic solution such that

$$\tau = \sup\{u(x) : x \in \mathbf{R}\} > 1.$$

Then (1.7) implies that

$$\tau > \sqrt{1+\sqrt{\mu}}.$$

From Lemma 4.1(b) we know that

$$z'(t) < 0 \quad \text{and} \quad 0 < t < \tau,$$

and by multiplying equation (2.6a) by $\frac{3}{4}z^{-5/4}$ we obtain

$$(z^{3/4})'' = \frac{3}{4\gamma}\frac{z - f_\mu}{z^{5/4}} \quad \text{for } 0 < t < \tau, \tag{2.10}$$

where

$$f_\mu = \frac{1}{2}\{(1-t^2)^2 - \mu\}.$$

Let us denote the zeros of f_μ by a and b:

$$a = \sqrt{1-\sqrt{\mu}} \quad \text{and} \quad b = \sqrt{1+\sqrt{\mu}}.$$

Because $\tau > b$, we can integrate (2.10) over $(0,b)$ to obtain

$$\frac{3}{4\gamma}\Big(\int_0^a + \int_a^b\Big)\frac{z-f_\mu}{z^{5/4}}\,dt = (z^{3/4})'\Big|_0^b < 0,$$

where the inequality is clear when we remember that $z'(0) = 0$ and $z'(b) < 0$. Thus, writing

$$I_1 = \int_0^a \frac{z-f_\mu}{z^{5/4}}\,dt \quad \text{and} \quad I_2 = \int_a^b \frac{z-f_\mu}{z^{5/4}}\,dt,$$

we have

$$I_1 + I_2 < 0. \tag{5.23}$$

Recall that $z > 0$ and $z' < 0$ on $(0,\tau)$. Hence

$$I_1 > -\int_0^a \frac{f_\mu}{z^{5/4}}\,dt > -\frac{1}{z^{5/4}(a)}\int_0^a f_\mu(t)\,dt \tag{5.24}$$

and

$$I_2 = \int_a^b \frac{z+|f_\mu|}{z^{5/4}}\,dt > \frac{1}{z^{5/4}(a)}\int_a^b |f_\mu(t)|\,dt > 0, \tag{5.25}$$

because $f_\mu < 0$ on (a,b). Putting (5.24) and (5.25) into (5.23) we find that

$$-\int_0^a f_\mu(t)\,dt + \int_a^b |f_\mu(t)|\,dt < 0,$$

or, equivalently,

$$\int_0^b f_\mu(t)\,dt > 0. \tag{5.26}$$

An elementary computation shows that (5.26) holds if and only if

$$\mu < \frac{4}{9}.$$

Thus, if $\mu \geq \frac{4}{9}$, there can be no periodic solution with maxima above 1.

6. Qualitative properties. In this section we prove several qualitative properties of periodic solutions. We begin with a convexity lemma and then we establish universal global bounds for periodic solutions. This is followed by an analysis of the behavior of periodic solutions as $\gamma \to 0$ (when $0 < \mu < 1$), as $\gamma \to \frac{1}{8}$ (when $\mu = 0$), and as $\gamma \to \infty$.

We begin with a convexity property.

LEMMA 6.1. *Let $u(x)$ be a periodic solution which has a single critical point between zeros and has the symmetry properties* (1.11). *Then*

$$u''(x) < 0 \quad \textit{when } u(x) > 0.$$

Proof. By Lemma 4.1(b), if $z(t)$ is the solution of problem (2.6) which corresponds to $u(x)$, then $z'(t) < 0$ for $0 < t < \tau$, and hence,

$$u''(x) = \frac{1}{2} z'(t(x)) < 0 \quad \text{for } 0 < x < \xi.$$

Since $u''(\xi) < 0$ by the energy identity, the assertion follows.

A remarkable feature of all single-bump periodic solutions is that they are bounded by a constant which does not depend on either γ or μ. This is shown in the next lemma.

LEMMA 6.2. *Let $0 \leq \mu < 1$ and $\gamma > 0$, and let $u(x)$ be a periodic solution that has the symmetry properties* (1.11). *Then*

$$|u(x)| < \sqrt{2} \quad \textit{for } x \in (-\infty, \infty).$$

Proof. Suppose that for some $a \in \mathbf{R}$ we have $|u(a)| \geq \sqrt{2}$. Without loss of generality we may assume that u has a maximum at $x = a$. Thus, we have

$$u(a) \geq \sqrt{2}, \quad u'(a) = 0, \quad u''(a) \leq -\sqrt{\frac{1-\mu}{2\gamma}}, \quad u'''(a) = 0, \tag{6.1}$$

where the upper bound for u'' follows from the energy identity (1.7). From (1.6) we see that $u^{iv}(a) < 0$.

Thus, as x increases above a, u''' and u'' decrease. Thus, $u''' < 0$ and $u'' < 0$ as long as $u^{iv} < 0$. Furthermore,

$$u^{iv} = u'' + u - u^3 < 0 \quad \text{as long as } u > 1.$$

Thus, if

$$b = \sup\{x > a : u > 1 \ \text{ on } \ [a, x)\},$$

then

$$u(b)=1,\quad u'(b)<0,\quad u''(b)<-\sqrt{\frac{1-\mu}{2\gamma}},\quad u'''(b)<0. \tag{6.2}$$

We claim that

$$u''(x)<-\sqrt{\frac{1-\mu}{2\gamma}}\quad\text{as long as } |u|<1. \tag{6.3}$$

Suppose that (6.3) does not hold. Then u''' must have a zero at a point where $|u|<1$. Let $y>b$ be the first zero of u'''. Then by (1.7),

$$-\gamma(u'')^2-(u')^2+\frac{1}{2}(1-u^2)^2=\frac{\mu}{2}\quad\text{at } y.$$

Because of our assumption that $|u(y)|<1$,

$$\{u''(y)\}^2<\frac{1-\mu}{2\gamma}.$$

This means that

$$u''(y)>-\sqrt{\frac{1-\mu}{2\gamma}}.$$

However, since $u'''<0$ on (b,y), it follows from (6.2) that

$$u''(y)<-\sqrt{\frac{1-\mu}{2\gamma}},$$

so we have a contradiction.

Thus, (6.3) holds. In particular, we have that $u''<0$ at the first zero of u and, by (1.11), at all zeros of u. This contradicts the fact that because u is odd, $u''=0$ whenever $u=0$. Thus, we must conclude that the assertion holds.

We now turn to a discussion of the behavior of periodic solutions for values of γ close to $\gamma=0$, or $\gamma=\frac{1}{8}$ when $\mu=0$, and for large values of γ.

LEMMA 6.3. *Let $\{\gamma_i\}$ be a sequence such that*

$$\gamma_i\searrow\theta=\begin{cases}\dfrac{1}{8} & \textit{when } \mu=0\\ 0 & \textit{when } 0<\mu<1\end{cases}\qquad \textit{as } i\to\infty.$$

For each $i\geq 1$, let u_i be a periodic solution corresponding to γ_i. Then

$$u_i(x)\to U(x)\quad \textit{as } i\to\infty,\ \textit{uniformly on compact intervals},$$

where

(i) *if $\mu=0$, then U is the unique monotone symmetric kink corresponding to $\gamma=\frac{1}{8}$;*

(ii) *if $0<\mu<1$, then U is the unique periodic solution of the FK equation with energy μ.*

Proof. Let $\alpha_i=u_i'(0)$. If $0<\mu<1$, then Lemmas 3.3 and 3.4 imply that

$$\sqrt{\frac{1-\mu}{4}}\leq\alpha_i\leq\sqrt{\frac{1-\mu}{2}} \tag{6.4}$$

for i sufficiently large and $\gamma_i - \theta > 0$ sufficiently small. If $\mu = 0$, then (6.4) follows from Lemmas 5.2, 5.5, and 5.6. Hence, there exists a convergent subsequence, which we also denote by $\{\gamma_i\}$, such that

$$\alpha_i \to \hat{\alpha} \quad \text{as } i \to \infty,$$

where $\hat{\alpha}$ satisfies (6.4).

We consider the cases $\mu = 0$ and $0 < \mu < 1$ in succession.

Case I. Let $\mu = 0$ and let $\alpha_0 = U'(0)$, where U is the kink for $\gamma = \theta = \frac{1}{8}$. Suppose that $\hat{\alpha} > \alpha_0$. Then, by [21, Lemma 3.6 and Theorem 3.7],

$$u\left(\xi\left(\hat{\alpha}, \frac{1}{8}\right), \hat{\alpha}, \frac{1}{8}\right) > 1 \quad \text{and} \quad u''\left(\xi\left(\hat{\alpha}, \frac{1}{8}\right), \hat{\alpha}, \frac{1}{8}\right) < 0. \tag{6.5}$$

Since by Theorem 4.5, $u(\cdot, \hat{\alpha}, \frac{1}{8})$ cannot be a periodic solution, it also follows that

$$u'''\left(\xi\left(\hat{\alpha}, \frac{1}{8}\right), \hat{\alpha}, \frac{1}{8}\right) \neq 0. \tag{6.6}$$

The inequality in (6.5) implies that the function $\xi(\alpha, \gamma)$ is continuous at $(\hat{\alpha}, \frac{1}{8})$ so, by the continuous dependence of $u(\cdot, \alpha, \gamma)$ on α and γ, it follows that for i large enough,

$$u'''(\xi(\alpha_i, \gamma_i), \alpha_i, \gamma_i) \neq 0 \tag{6.7}$$

as well. However, since $u(\cdot, \alpha_i, \gamma_i)$ is a periodic solution for every i, we must have

$$u'''(\xi(\alpha_i, \gamma_i), \alpha_i, \gamma_i) = 0$$

for every i, which contradicts (6.7).

If $\hat{\alpha} < \alpha_0$, then by [21, Lemma 3.6 and Theorem 3.7],

$$u\left(\xi\left(\hat{\alpha}, \frac{1}{8}\right), \hat{\alpha}, \frac{1}{8}\right) < 1 \quad \text{and} \quad u''\left(\xi\left(\hat{\alpha}, \frac{1}{8}\right), \hat{\alpha}, \frac{1}{8}\right) < 0.$$

It follows from Theorem 4.4 that (6.6) holds again and, as before, we arrive at a contradiction.

Thus, for the subsequence we have $\alpha_i \to \alpha_0$ as $i \to \infty$. Because the limit is uniquely determined, it follows that the entire sequence $\{\alpha_i\}$ converges to α_0. Therefore, $u_i \to U$ uniformly on compact sets of the form $[0, L]$, $L > 0$.

Case II. Let $0 < \mu < 1$ and let $\alpha_\mu = U'(0)$, where U is the periodic solution of the FK equation with energy equal to μ. From the energy identity (1.7) in which we set $\gamma = 0$, we conclude that

$$\alpha_\mu = \sqrt{\frac{1-\mu}{2}}.$$

It follows from Corollary 3.6 that

$$\hat{\alpha} \leq \alpha_\mu.$$

In the remainder of the proof we shall show that

$$\hat{\alpha} \geq \alpha_\mu$$

as well. This proves that $\alpha_i \to \alpha_\mu$ as $i \to \infty$, and therefore $u_i \to U$ uniformly on compact sets, as asserted.

We shall show that for each $\varepsilon > 0$ there exists a $\gamma_\varepsilon > 0$ such that if $0 < \gamma < \gamma_\varepsilon$ and $u(\cdot, \alpha, \gamma)$ is a periodic solution, then $\alpha > \alpha_\mu - \varepsilon$ so

$$\liminf_{i \to \infty} \alpha_i \geq \alpha_\mu.$$

Remember that the initial conditions for u are

$$u(0) = 0, \quad u'(0) = \alpha, \quad u''(0) = 0, \quad u'''(0) = \beta(\alpha) = \frac{\alpha^2 - \alpha_\mu^2}{2\alpha\gamma}.$$

Because $\beta'(\alpha) > 0$ it follows that

$$\beta(\alpha) \leq \beta(\alpha_\mu - \varepsilon) = -\frac{\delta(\varepsilon)}{\gamma} \quad \text{for } 0 < \alpha \leq \alpha_\mu - \varepsilon,$$

where $\delta(\varepsilon) \sim \varepsilon$ as $\varepsilon \to 0$.

We now proceed as in the proof of Lemma 3.3. Because $u(0) = 0$ and $u'''(0) < 0$, it follows that $u < 1$ and $u''' < 0$ in a neighborhood of the origin. As long as these inequalities do not change it follows from the equation for u that

$$u^{iv}(x) < \frac{\alpha}{\gamma} x, \tag{6.8a}$$

$$u'''(x) < -\frac{\delta}{\gamma} + \frac{\alpha}{2\gamma} x^2, \tag{6.8b}$$

$$u''(x) < -\frac{\delta}{\gamma} x + \frac{\alpha}{6\gamma} x^3, \tag{6.8c}$$

$$u'(x) < \alpha - \frac{\delta}{2\gamma} x^2 + \frac{\alpha}{24\gamma} x^4. \tag{6.8d}$$

Set

$$x_\gamma = \gamma^{1/4}.$$

Then, when $\gamma < \gamma_1 = (2\delta/\alpha_\mu)^2$, it follows from (6.6b) that $u''' < 0$ on $(0, x_\gamma]$. Moreover, the right-hand side of (6.6d) will be negative at x_γ if $\gamma < \gamma_2 = \{12\delta/(25\alpha_\mu)\}^2$.

Thus, if we set $\gamma_\varepsilon = \min\{\gamma_1, \gamma_2\}$ and denote as usual the first zero of u' by ξ, then

$$\xi \in (0, x_{\gamma_\varepsilon}) \quad \text{and} \quad u'''(\xi) < 0 \quad \text{if } 0 < \gamma < \gamma_\varepsilon.$$

This means that if $\alpha \leq \alpha_\mu - \varepsilon$ and $\gamma \in (0, \gamma_\varepsilon)$, then $u(\cdot, \alpha, \gamma)$ cannot be a periodic solution. Therefore, if it is given that $u(\cdot, \alpha, \gamma)$ is a periodic solution, then we must conclude that $\alpha > \alpha_\mu - \varepsilon$, and the proof is complete.

To determine the behavior of periodic solutions as $\gamma \to \infty$, we first need an upper and a lower bound for the slope at the origin.

Lemma 6.4. *Let $0 \leq \mu < 1$ and $\gamma > 0$, and let $u(x)$ be a periodic solution which satisfies* (1.11). *Then*

$$u'(0) \leq \{8(1-\mu)\log 2\}^{1/4} \gamma^{-1/4} \quad \textit{for } \gamma > \theta,$$

where $\theta = 0$ if $0 < \mu < 1$ and $\theta = \frac{1}{8}$ if $\mu = 0$.

Proof. It is convenient to prove this lemma using the function $z(t)$ introduced in section 3. We then need to show that

$$z(0) \leq \{8(1-\mu)\log 2\}^{1/2}\gamma^{-1/2}. \tag{6.9}$$

It follows from (2.6a) that

$$zz'' = \frac{(z')^2}{4} + \frac{1}{\gamma}\{z - f_\mu(t)\} > -\frac{1-\mu}{2\gamma} \quad \text{for } 0 \leq t < \sqrt{2}.$$

Because $\tau < \sqrt{2}$ by Lemma 6.2, it follows that

$$z'' > -\frac{1-\mu}{2\gamma z} \quad \text{for } 0 \leq t < \tau.$$

We multiply by $z' < 0$, integrate over $(0, t)$, and obtain

$$z'(t) > -\left\{\frac{1-\mu}{\gamma}\log\frac{z(0)}{z(t)}\right\}^{1/2} \quad \text{for } 0 \leq t < \tau. \tag{6.10}$$

Let

$$t_0 = \sup\left\{t > 0 : z > \frac{1}{2}z(0) \;\text{ on }\; [0,t)\right\}.$$

Then

$$0 < t_0 < \sqrt{2} \quad \text{and} \quad \frac{z(0)}{z(t)} \leq 2 \quad \text{for } 0 \leq t \leq t_0.$$

Hence, by (6.10),

$$z'(t) > -\left(\frac{(1-\mu)\log 2}{\gamma}\right)^{1/2} \quad \text{for } 0 < t < t_0$$

and we obtain, after an integration over $(0, t_0)$,

$$z(t_0) - z(0) > -\left(\frac{(1-\mu)\log 2}{\gamma}\right)^{1/2} t_0. \tag{6.11}$$

Since $t_0 < \sqrt{2}$, this implies that

$$\frac{1}{2}z(0) < \left(\frac{(1-\mu)\log 2}{\gamma}\right)^{1/2},$$

from which (6.9) follows.

Next we establish a lower bound for $u'(0)$.

LEMMA 6.5. *We have*

$$u'(0) > \frac{1}{5}\sqrt{1-\mu}\,\gamma^{-1/4} \quad \textit{for } \gamma > \left(\frac{2}{5}\right)^4.$$

Proof. In light of the upper bound obtained in Lemma 6.3, we scale the variables and set

$$s = \frac{x}{\gamma^{1/4}} \quad \text{and} \quad v(s) = u(x). \tag{6.12}$$

We then obtain the problem

$$\begin{cases} v^{iv} = \dfrac{v''}{\sqrt{\gamma}} + v - v^3, & \text{(6.13a)} \\ v(0) = 0, \quad v''(0) = 0, & \text{(6.13b)} \\ v'(0) = \omega, \quad v'''(0) = \dfrac{1}{2\omega}\Big(\dfrac{\omega^2}{\sqrt{\gamma}} - \dfrac{1-\mu}{2}\Big) & \text{(6.13c)} \end{cases}$$

in which

$$\omega = \alpha\gamma^{1/4}$$

and we need to prove that

$$\omega > \frac{1}{5}\sqrt{1-\mu}.$$

Suppose, to the contrary, that

$$\omega \leq \frac{1}{5}\sqrt{1-\mu}.$$

Then for $\gamma > (2/5)^4$, we have

$$v'''(0) < -\frac{1-\mu}{8\omega}.$$

As long as $v > 0$ and $v''' < 0$, we have

$$v(s) < \omega s$$

and

$$v^{iv}(s) < \omega s,$$

which yields, upon integration over $(0, s)$,

$$v'''(s) < -\frac{1-\mu}{8\omega} + \frac{1}{2}\omega s^2. \tag{6.14}$$

One verifies that the right-hand side of (6.14) is negative for all $s \in [0, 1]$. Two more integrations yield

$$v'(s) < \omega - \frac{1-\mu}{16\omega}s^2 + \frac{1}{24}\omega s^4.$$

It follows that the first zero $\sigma = \sigma(\omega, \gamma)$ of v' has the properties

$$0 < \sigma < 1 \quad \text{and} \quad v'''(\sigma) < 0,$$

so v, and hence u, cannot be periodic solutions, a contradiction.

With the lower bound we now have in hand we can return to the argument used in the proof of Lemma 6.1 to obtain a lower bound for the maximum of $|u(x)|$ on $\mathbf{R}$.

LEMMA 6.6. *Let $u(x,\gamma)$ be a periodic solution. Then*

$$\max\{|u(x,\gamma)| : x \in \mathbf{R}\} > \frac{1}{50}\sqrt{\frac{1-\mu}{\log 2}} \quad \textit{if } \gamma > \left(\frac{2}{5}\right)^4.$$

Proof. If u is a periodic solution, then by Lemma 6.5,

$$z(0) > \frac{1-\mu}{25\sqrt{\gamma}} \quad \text{if } \gamma > \left(\frac{2}{5}\right)^4.$$

Therefore, by (6.11),

$$\left(\frac{(1-\mu)\log 2}{\gamma}\right)^{1/2} t_0 > \frac{1-\mu}{50\sqrt{\gamma}}.$$

This means that

$$t_0 > \frac{1}{50}\sqrt{\frac{1-\mu}{\log 2}}.$$

Now, because

$$\max\{|u(x,\gamma)| : x \in \mathbf{R}\} = \tau(\gamma) > t_0,$$

the assertion follows.

From Lemmas 6.4 and 6.5 we conclude that if u is a periodic solution which satisfies (1.11), then for γ large enough,

$$\frac{1}{8}\sqrt{1-\mu} < \omega < \{8(1-\mu)\log 2\}^{1/4}.$$

Let $\{\gamma_i\}$ be a sequence tending to infinity and let u_i be a corresponding sequence of periodic solutions, with initial slopes α_i. Let v_i and ω_i be the solutions of problem (6.13) corresponding to these periodic solutions. Then by compactness there exists a subsequence, which we also denote by $\{\omega_i\}$, which converges to a number $\omega^* < \infty$ as $i \to \infty$. Plainly, it must be the case that $v_i \to V$, uniformly on compact sets, as $i \to \infty$, where V satisfies

$$\begin{cases} V^{iv} = V - V^3, & \text{(6.15a)} \\ V(0) = 0, \quad V''(0) = 0, & \text{(6.15b)} \\ V'(0) = \omega^*, \quad V'''(0) = -\dfrac{1-\mu}{4\omega^*}. & \text{(6.15c)} \end{cases}$$

We assert that the sequence of maxima $\{\sigma_i\}$, where $\sigma_i = \sigma(\omega_i, \gamma_i)$, remains bounded:

$$\limsup_{i\to\infty} \sigma(\omega_i, \gamma_i) < \infty.$$

For if not, then there exists a subsequence along which σ_i tends to infinity. Hence,

$$V'(s) > 0 \quad \text{for } 0 \le s < \infty.$$

An argument like the one used in the proof of Lemma 2.1 shows that this is impossible. Therefore, the sequence $\{\sigma_i\}$ is bounded and there exists a subsequence which converges to some $\sigma^* < \infty$ as $i \to \infty$. Since $v_i'''(\sigma_i) = 0$ for every i, it easily follows that $V'''(\sigma^*) = 0$, so that V is a periodic solution of problem (6.15).

Thus we have the following lemma.

LEMMA 6.7. *Let* $0 \le \mu < 1$. *Suppose that* $\{\gamma_i\}$ *is a sequence which tends to infinity and* $\{u_i\}$ *is a sequence of periodic solutions which correspond to* γ_i *and which each satisfy* (1.11). *Then there exists a subsequence and a periodic solution* V *of problem* (6.15) *which also satisfies* (1.11) *such that*

$$u_i(\gamma_i^{1/4}s, \gamma_i) \to V(s) \quad \text{as } i \to \infty, \tag{6.16}$$

uniformly on compact sets.

As a by-product, the above argument yields the existence of periodic solutions V of problem (6.15) which satisfy (1.11) for every $\mu \in [0, 1)$. This result can also be proved by means of the method used in sections 3 and 5. Since the proofs are very close to those already presented, we omit them here. Summarizing, we have the following result.

THEOREM 6.8. *If* $0 \le \mu < 1$, *then problem* (6.15) *has a periodic solution* V_1 *such that*

$$\max\{|V_1(x)| : x \in \mathbf{R}\} < 1.$$

If $\mu = 0$, *then problem* (6.15) *has a periodic solution* V_2 *which satisfies* (1.11) *such that*

$$\max\{|V_2(x)| : x \in \mathbf{R}\} \in (1, \sqrt{2}).$$

STABILITY ESTIMATES IN AN INVERSE PROBLEM FOR A THREE-DIMENSIONAL HEAT EQUATION*

SERGIO VESSELLA†

Abstract. The problem of determining an insulating body D contained in a conducting one Ω is studied. If at an initial time the temperature is zero and increasing temperature is assigned on the boundary of Ω then the knowledge of the flux on a portion of $\partial\Omega$ for a finite interval of time determines D. A logarithmic stability estimate is found if some a priori assumptions are given on D.

1. Introduction.

Consider a three-dimensional heat conducting body Ω, and suppose that it contains an insulating three-dimensional body D. We want to determine D by assigning the initial temperature of Ω, the temperature on the boundary for an interval of time $[0, t_1]$, and measuring the flux of temperature on a portion Σ of $\partial\Omega$ in a subinterval of $[0, t_1]$.

Denote by $u(x, t)$ the temperature in a point x at time t and suppose that the temperature of Ω is initially zero (or, more generally, that $\Delta u(x, 0) \geq 0$). If φ is the temperature on $\partial\Omega$ then u solves the following boundary value problem:

$$\frac{\partial u}{\partial t} - \Delta u = 0 \text{ in } \left(\Omega \setminus \overline{D}\right) \times [0, t_1]\,, \tag{1}$$

$$u = \varphi \text{ on } \partial\Omega \times [0, t_1]\,, \tag{2}$$

$$\frac{\partial u}{\partial \mathbf{n}} = 0 \text{ on } \partial D \times [0, t_1]\,, \tag{3}$$

$$u\,(x, 0) = 0 \text{ for } x \in \Omega \setminus D, \tag{4}$$

where $\mathbf{n}$ denotes the unit outer normal to $\partial\,(\Omega \setminus D)$.

The problem we study consists of assigning an opportune input φ on $\partial\Omega \times [0, t_1]$ in such a way that the flux $\frac{\partial u}{\partial \mathbf{n}}$ on $\Sigma \times [t_0, t_1]$, where Σ is a nonempty open set of $\partial\Omega$, $t_0 \in (0, t_1)$, determines D.

It is simple to prove that uniqueness holds for a large class of domains D if the input φ satisfies the monotonicity condition

$$\frac{\partial\varphi\,(x, t)}{\partial t} > 0 \text{ for } (x, t) \in \partial\Omega \times [0, t_1]\,. \tag{5}$$

In fact, let $\mathcal{P}$ be the class of domains D that are C^2 and such that $\overline{D} \subset$int(Ω) and $\Omega \setminus \overline{D}$ is connected. Suppose that there exist two domains $D_1, D_2 \in \mathcal{P}$ such that

$\frac{\partial u_1}{\partial \mathbf{n}} = \frac{\partial u_2}{\partial \mathbf{n}}$ on $\Sigma \times [t_0, t_1]$. Let I be the connected component of $\overline{\Omega} \setminus (D_1 \cup D_2)$ that contains $\partial\Omega$; uniqueness for the parabolic Cauchy problem and analytic continuation in the space variables give $u_1 \equiv u_2$ in $I \times [t_0, t_1]$. Therefore, if, for instance, $D_2 \setminus D_1 \neq \emptyset$, then, by the inclusion $\partial\left((\Omega \setminus I) \setminus D_1\right) \subset (\partial I \cap \partial D_2) \cup \partial D_1$ and by the divergence theorem, we have for every $t \in (t_0, t_1)$

$$\int\limits_{(\Omega \setminus I) \setminus D_1} \frac{\partial u_1\,(x,t)}{\partial t} dx = \int\limits_{(\partial I) \cap (\partial D_2)} \frac{\partial u_1\,(x,t)}{\partial \mathbf{n}} ds = \int\limits_{(\partial I) \cap (\partial D_2)} \frac{\partial u_2\,(x,t)}{\partial \mathbf{n}} ds = 0,$$

but the maximum principle applied to $\frac{\partial u_1}{\partial t}$ yields that the first integral is strictly positive, which leads to a contradiction.

We are mainly interested in studying the stability, that is, the continuous dependence of D on the measured flux; to this purpose we assume that ∂D is connected and is locally a graphic of $\mathrm{C}^{2,\alpha}$ functions whose norms are bounded and $\operatorname{dist}(D, \partial\Omega) \geq L_0 > 0$. If this a priori information is available, (5) is satisfied and the following error bound on the measured flux of temperature holds:

$$\sup_{\Sigma \times [t_0, t_1]} \left| \frac{\partial u_1}{\partial \mathbf{n}} - \frac{\partial u_2}{\partial \mathbf{n}} \right| \leq \varepsilon.$$

Then (see Theorem 2.4)

$$\delta_{\mathcal{H}}\,(D_1, D_2) = O\left(\left| \ln \varepsilon \right|^{-s} \right),$$

where $\mathrm{D}_i, i = 1, 2$ is the domain corresponding to u_i, $\delta_{\mathcal{H}}\,(D_1, D_2)$ is the Hausdorff distance between D_1 and D_2, and s is a positive number.

We want to point out that our results can be extended simply to the case where we assign the flux of temperature, ϕ, on the boundary of Ω in the interval of time $[0, t_1]$ and we measure the temperature on Σ in a subinterval of $[0, t_1]$. If $\frac{\partial \phi}{\partial t} > 0$ and the initial temperature is zero then uniqueness and logarithmic stability remain valid.

An interesting open problem is the one where the body D is not perfectly insulating. In this case the problem that could be studied is the determination of the coefficient a in the equation $u_t - \operatorname{div}(a \nabla u) = 0$ in $\Omega \times [0, T]$, where $a = a_0 + b\chi_D$ (χ_D is the indicator function of D), a_0 and b are known positive constants, and D is the unknown to be determined, again, by a pair of Cauchy data. In [6] the authors consider the problem of determining the nonconstant function b and the domain D (in the case where a_0 is also a nonconstant function) from the whole Dirichlet-to-Neumann map.

In our opinion there is some similarity in the mathematical formulation between our problem and the problem of cracks determination. In these problems one wants to determine an unknown electrically insulating surface (or a curve in the two-dimensional version) which lies in the electrically conducting body from electrostatic measurements on the boundary. These problems are inverse problems for elliptic equations; see [1] , [2] , [3], [4] , [9], [12] , and their references.

The outline of the paper is as follows. In section 2 we begin introducing the main notations and specifying the a priori information on D and Ω; then we prove the stability result. Section 3 is an appendix where we prove some estimates used in section 2; in particular, we find (Lemma 3.1) an estimate on the analytic continuation in the space variable for solutions of the heat equation. Moreover, we prove (Lemma 3.2) an estimate from below on ∂D for positive solutions of equation (1) fulfilling condition (3).

2. Stability results. Let $x^0 \in \mathbb{R}^3$, $r > 0, A, B$ be two measurable sets in $\mathbb{R}^3$. We use the following notation:

(i) $\mathrm{B}\left(x^0, r\right) = \left\{x \in \mathbb{R}^3 \colon \left|x - x^0\right| < r\right\}$;

(ii) $|A|$ denotes the volume of A; if ∂A is smooth, $|\partial A|$ denotes the area of surface ∂A;

(iii) $\mathrm{d}\left(x^0, A\right) = \inf\limits_{x \in A} \left|x - x^0\right|$, $\mathrm{d}(A, B) = \inf\limits_{x \in A} \mathrm{d}(x, B)$;

(iv) $[A]_r = \left\{x \in \mathbb{R}^3 \colon \mathrm{d}\left(x, A\right) \leq r\right\}$; we set $[A]_0 = \overline{A}$ ($\overline{A}$ is the closure of A);

(v) $(A)_r = \left\{x \in \mathbb{R}^3 \colon \mathrm{d}\left(x, \mathbb{R}^3 \backslash A\right) \geq r\right\}$; we set $(A)_0 = A$;

(vi) $\delta_{\mathcal{H}}\left(A, B\right)$ denotes the Hausdorff distance between A and B;

(vii) $\mathrm{B}'\left(0, r\right) = \left\{x \in \mathbb{R}^2 : |x| < r\right\}$ and

$\mathrm{C}\left(0, r\right) = \left\{x \in \mathbb{R}^3 : \left(x_1, x_2\right) \in \mathrm{B}'\left(0, r\right),\ \left|x_3\right| < r\right\}$;

(viii) $K(x,t) = \begin{cases} \left(2\sqrt{\pi t}\right)^{-3} \exp\left(-\frac{|x|^2}{4t}\right) \text{ if } t > 0,\ x \in \mathbb{R}^3, \\ 0 \text{ if } t \leq 0\ x \in \mathbb{R}^3. \end{cases}$

Let α, d, h, L_0, M, be given positive numbers ($\alpha \in (0,1)$). Ω and D satisfy the a priori information listed in (6), (7).

(6) **Prior information on** Ω :

(a) *Ω is a bounded, $\mathrm{C}^{2,\alpha}$ open set in $\mathbb{R}^3$ whose boundary is connected; d is the diameter of Ω;*

(b) *for every $x \in \partial\Omega$, there exist two balls, $\mathrm{B}\left(x^0, L_0\right)$ $\mathrm{B}\left(y^0, L_0\right)$, such that $\mathrm{B}\left(x^0, L_0\right) \subset \Omega$, $\mathrm{B}\left(y^0, L_0\right) \subset \mathbb{R}^3 \setminus \overline{\Omega,}$ and $\partial\mathrm{B}\left(x^0, L_0\right)$, $\partial\mathrm{B}\left(y^0, L_0\right)$ are tangent to $\partial\Omega$ in x.*

(7) **Prior information on** D :

(a) *D is an open, bounded set in $\mathbb{R}^3$ whose boundary is connected; $\overline{D} \subset \Omega$ and* $\mathrm{d}(D, \partial\Omega) \geq L_0$;

(b) *let $y \in \partial D$ and let $\mathcal{R}$ be the rotation of coordinate that transforms the outer normal to ∂D in y in the vector $(0,0,1)$; then $\mathrm{C}(0,h) \cap \mathcal{R}\left(\partial D - y\right)$ is the graph of a function $g \in \mathrm{C}^{2,\alpha}\left(\mathrm{B}'\left(0,h\right)\right)$ with $g\left(0\right) = 0$, $\nabla g\left(0\right) = 0$, and*

(b_1) $\mathrm{C}(0,h) \cap \mathcal{R}\left(\partial D - y\right) = \left\{x \in \mathbb{R}^3 : \left(x_1, x_2\right) \in \mathrm{B}'\left(0, h\right),\ -h < x_3 < g\left(x_1, x_2\right)\right\}$,

(b_2) $\sup\limits_{\mathrm{B}'(0,h)} \left|g_{x_i x_j}\right| + h^\alpha \sup\limits_{\substack{s,t \in \mathrm{B}'(0,h) \\ s \neq t}} \frac{\left|g_{x_i x_j}(s) - g_{x_i x_j}(t)\right|}{|s-t|^\alpha} \leq M$ *for $i, j = 1, 2$.*

Note that, by denoting $L_1 = \min\left\{h, \frac{L_0}{2}, (2M)^{-1}\right\}$, the following interior and exterior sphere property hold.

Proposition 2.1. *If $r \in [0, L_1)$, then for every $x \in \partial\left[D\right]_r$ there exist two balls $B\left(x^0, L_1\right)$ and $B\left(y^0, L_1 - r\right)$ such that $B\left(x^0, L_1\right) \subset \left[D\right]_r$, $B\left(y^0, L_1 - r\right) \subset \Omega \setminus \left[D\right]_r$, and $\partial B\left(x^0, L_1\right)$, $\partial B\left(y^0, L_1 - r\right)$ are tangent to $\partial\left[D\right]_r$ in x.*

Furthermore, we have the following proposition.

Proposition 2.2. *If $r \in [0, L_1)$, then for every $x \in \Omega \setminus \overline{D}$ such that $d(x, \partial D) = r$ we have $x \in \partial\left[D\right]_r$.*

Proposition 2.3. *If $r_1, r_2 \in [0, L_1)$, then $\left(\Omega\right)_{r_1} \setminus \left[D\right]_{r_2}$ is a connected set.*

The proofs of Propositions 2.1, 2.2, and 2.3 are elementary.

Now we prove the main theorem.

THEOREM 2.4. *Let t_0, t_1 be positive numbers, and let $t_1 > t_0$. Let Ω, D_1, D_2, satisfy, respectively,* (6) *and* (7). *Let $\Sigma \subset \partial\Omega$, Σ nonempty open set of $\partial\Omega$, and $\varphi \in C^1(\partial\Omega \times [0, t_1])$, which fulfills*

$$\varphi(x, 0) = 0 \text{ for } x \in \partial\Omega \tag{8}$$

and

$$\frac{\partial\varphi}{\partial t}(x, t) > 0 \text{ for } (x, t) \in \partial\Omega \times [0, t_1], \tag{9}$$

denote $m_2 = \int\limits_{\partial\Omega} \varphi(x, t_0)\, ds$ by $m_1 = \max\limits_{\partial\Omega\times[0,t_1]} \varphi$.

Let u_j, $j = 1, 2$ satisfy

$$\frac{\partial u_j}{\partial t} - \Delta u_j = 0 \text{ in } \left(\Omega \setminus \overline{D}_j\right) \times [0, t_1], \tag{10}$$

$$u_j = \varphi \text{ on } \partial\Omega \times [0, t_1], \tag{11}$$

$$\frac{\partial u_j}{\partial \mathbf{n}} = 0 \text{ on } \partial D_j \times [0, t_1], \tag{12}$$

$$u_j(x, 0) = 0 \text{ for } x \in \Omega \setminus \overline{D}_j. \tag{13}$$

If

$$\sup_{\Sigma\times[t_0,t_1]} \left| \frac{\partial u_1}{\partial \mathbf{n}} - \frac{\partial u_2}{\partial \mathbf{n}} \right| \le \frac{m_1}{d}\varepsilon, \tag{14}$$

then there exists a nondimensional constant C, depending on $\alpha, d, h, L_0, \frac{m_2}{m_1}, M, t_0, t_1, \Sigma$, and Ω, such that

$$\delta_{\mathcal{H}}(D_1, D_2) \le Cd\left(|\ln\varepsilon|^{-\frac{1}{44}} + \varepsilon\right). \tag{15}$$

Proof. First we normalize the solutions of (10), replacing u_j with $\frac{u_j}{m_1}$ (we continue to denote $\frac{u_j}{m_1}$ with u_j).

Denote

$$u = u_1 - u_2 \text{ in } (\Omega \setminus (D_1 \cup D_2)) \times [0, t_1],$$

$$G = \left(\Omega \setminus (\Omega)_{\frac{L_0}{2}}\right) \times [0, t_1],$$

$$Q_j = \left((\Omega)_{\frac{L_0}{2}} \setminus D_j\right) \times [0, t_1].$$

By regularity estimates for parabolic equations, we have

$$\|u\|_{L^\infty(G)} + d\|\nabla_x u\|_{L^\infty(G)} + d^2\left\|D_x^2 u\right\|_{L^\infty(G)} \le E_1, \tag{16}$$

where E_1 is a nondimensional constant depending on α, L_0, Ω, and

$$\|u_j\|_{L^\infty(Q_j)} + d\|\nabla_x u_j\|_{L^\infty(Q_j)} + d^2\left\|D_x^2 u_j\right\|_{L^\infty(Q_j)} + d^3\|\nabla_x D_t u_j\|_{L^\infty(Q_j)} \le E_2, \tag{17}$$

where E_2 depends on α, d, h, L_0, M(in 16); in (17) D_x^2 denotes the matrix of second derivatives with respect to x_i, x_k). We set

$$E = \max\{E_1, E_2\}.$$

Starting from the stability estimates for the Cauchy problem for parabolic equations contained in [13, Chap. IV], estimating the constants appearing there and applying Lemma 3.1 to u_{x_k}, $k = 1, 2, 3$ yields

$$|\nabla_x u(x, t_2)| \le \frac{C_{11}}{d}(E_1 + \varepsilon)^{1-\gamma_1} \varepsilon^{\gamma_1} \text{ for } \frac{L_0}{8} \le \mathrm{d}(x, \partial\Omega) \le \frac{L_0}{2}, \tag{18}$$

where

$$t_2 = \frac{t_0 + t_1}{2},$$

$$C_{11} = C_{10}\left(\frac{\tau}{dL_0} + \frac{d^4}{\tau^{\frac{3}{2}} L_0}\right),$$

$$\tau = t_1 - t_0,$$

$$\gamma_1 = \exp - c\left(C'_{10}\left(dL_0^{-1} + d\tau^{-\frac{1}{2}}\right) + |\Omega| L_0^{-3}\right)$$

(C_{10} depends only on Σ, d, t_1; C'_{10} depends on Σ and d; and c is an absolute constant).

The proof is subdivided into two steps. In the first we prove a log–log estimate for $\delta_{\mathcal{H}}(D_1, D_2)$; in the second we prove estimate (15).

Step 1. Let $r \in \left(0, \frac{L_1}{4}\right)$. Denote by I_r the connected component of $(\Omega)_r \setminus ([D_1]_r \cup [D_2]_r)$ that contains $\partial(\Omega)_r$. By positivity of $\frac{\partial u_2}{\partial t}(x, t_2)$ in $\Omega \setminus D_2$, the inclusion $D_1 \setminus D_2 \subset (((\Omega)_r \setminus I_r) \setminus [D_2]_r) \cup ([D_2]_r \setminus D_2)$, estimate (17), and inequality (69), we have

$$\int\limits_{D_1 \setminus D_2} \frac{\partial u_2(x, t_2)}{\partial t} dx \le \int\limits_{[D_2]_r \setminus D_2} \frac{\partial u_2(x, t_2)}{\partial t} dx + \int\limits_{\left((\Omega)_r \setminus I_r\right) \setminus [D_2]_r} \frac{\partial u_2(x, t_2)}{\partial t} dx \tag{19}$$

$$\le c\frac{E_2 r d}{M L_1^3} + \int\limits_{\left((\Omega)_r \setminus I_r\right) \setminus [D_2]_r} \Delta u_2(x, t_2)\, dx.$$

By (10), (12), the divergence theorem (see [7]), the inclusion

$$\partial(((\Omega)_r \setminus I_r) \setminus [D_2]_r) \subset (\partial I_r \cap \partial [D_1]_r) \cup \partial [D_2]_r, \tag{20}$$

estimate (17), and inequality (69), we obtain

$$\int\limits_{\left((\Omega)_r \setminus I_r\right) \setminus [D_2]_r} \Delta u_2(x, t_2)\, dx \le \int\limits_{\left(\partial I_r \cap \partial [D_1]_r\right) \cup \partial [D_2]_r} \left|\frac{\partial u_2(x, t_2)}{\partial \mathbf{n}}\right| ds \tag{21}$$

$$\leq \int_{\partial I_r \cap \partial [D_1]_r} |\nabla_x u(x,t_2)|\, ds + \int_{\partial [D_2]_r} \left| \frac{\partial u_2(x,t_2)}{\partial \mathbf{n}} \right| ds + \int_{\partial [D_1]_r} \left| \frac{\partial u_1(x,t_2)}{\partial \mathbf{n}} \right| ds$$

$$\leq \frac{cd^3}{M^2 L_1^3} \left(\max_{x \in \partial I_r} |\nabla_x u(x,t_2)| + \frac{E_2 r}{d^2} \right).$$

From estimates (19) and (21) and applying inequality (66) (see Remark 3 of section 3), where u is replaced with $\frac{\partial u_2}{\partial t}$, T with t_2, T'' with t_0, and T' with $\frac{t_0+t_2}{2}$, we have

$$|D_1 \setminus D_2| \leq C_{12} d^2 \left(E_2 r + d^2 \max_{x \in \partial I_r} |\nabla_x u(x,t_2)| \right), \tag{22}$$

where C_{12} depends on $\alpha, d, h, L_0, \frac{m_2}{m_1}, M$, and τ.

Now consider the set $J = \left\{ x \in (\Omega)_r : \mathrm{d}(x, \partial\Omega) \leq \frac{L_0}{2} \right\}$. By the interior sphere property of Ω, it follows that J is connected. Furthermore, J is contained in $(\Omega)_r \setminus ([D_1]_r \cup [D_2]_r)$ and $\partial(\Omega)_r \subset J$; therefore, the inclusion $J \subset I_r$ is valid. Let $\overline{x} \in \partial I_r$, $y \in J$ such that $\mathrm{d}(y, \partial\Omega) = \frac{L_0}{4}$, and Γ be a simple curve in I_r with endpoints $\overline{x}$ and y. Γ is contained in $(\Omega)_r \setminus (D_1 \cup D_2)$, and $\mathrm{d}(\Gamma, D_j) \geq r$, $j = 1, 2$, $\mathrm{d}(\Gamma, \partial\Omega) \geq r$. We construct a chain of closed balls which are centered in Γ, have radius $\frac{r}{3}$, are tangent two by two, and are internally nonoverlapping. The first ball is centered in y; the last is at a distance less than or equal to $\frac{r}{3}$ from $\overline{x}$. If the distance is less than $\frac{r}{3}$, we add to the chain the ball of radius $\frac{r}{3}$ whose center is $\overline{x}$. The repeated use of Lemma 3.1 applied to u_{x_j}, $j = 1, 2, 3$ gives

$$|\nabla_x u(\overline{x}, t_2)| \leq 6 (1 + C_0)^{2N_r} \left(E d^{-1} + \varepsilon_1 \right)^{1 - \gamma_0^{2N_r}} \varepsilon_1^{\gamma_0^{2N_r}}, \tag{23}$$

where $C_0 = e^{\frac{L_1^2}{64 t_2}}$ and γ_0 is the exponent in the inequality (42), ε_1 is defined by

$$\varepsilon_1 = \max_{\mathrm{B}\left(y, \frac{r}{3}\right)} |\nabla_x u(x,t_2)|,$$

and

$$N_r = \frac{3^4 d^3}{4\pi r^3}.$$

By estimates (18) and (23) we obtain

$$|D_1 \setminus D_2| \leq C_{13} d^2 (E + \varepsilon) \left(r + d (1 + C_0)^{2N_r} \left(\frac{\varepsilon}{E + \varepsilon} \right)^{\gamma_1 \gamma_0^{2N_r}} \right), \tag{24}$$

where C_{13} depends on $\alpha, d, h, L_0, \frac{m_2}{m_1}, M, \tau, t_1$, and Σ.

Denoting by l the integral part of $\frac{1}{\gamma_1} \left(1 + \frac{\ln(1+C_0)}{|\ln \gamma_1|} \right)$ and ε_0 the number

$$\varepsilon_0 = E \exp\left(-\left((2l)!\right)^2 \exp\left(\frac{2 \cdot 3^4 d \left(|\ln \gamma_0| + 1 \right)}{\pi L_1} \right) \right)$$

for $\varepsilon \leq \varepsilon_0$, we can choose in (24) r given by

$$r = \frac{L_1}{4} \left(\frac{3^4 |\ln \gamma_1| \left(4 d L_1^{-1} \right)^3}{4\pi \ln \left(\left| \ln \frac{\varepsilon}{E+\varepsilon} \right| \right)^{\frac{1}{2}}} \right)^{\frac{1}{3}},$$

and we have

$$|D_1 \setminus D_2| \leq C_{14} d^3 \left(\ln \left|\ln \frac{\varepsilon}{E+\varepsilon}\right|\right)^{-\frac{1}{3}}, \tag{25}$$

where C_{14} depends on $\alpha, d, h, L_0, \frac{m_2}{m_1}, M, \tau, t_1$, Σ, and Ω. The same inequality holds for $|D_2 \setminus D_1|$.

Denote by $\sigma(\varepsilon)$ the number

$$\sigma(\varepsilon) = C_{14} \left(\ln \left|\ln \frac{\varepsilon}{E+\varepsilon}\right|\right)^{-\frac{1}{3}}$$

(here C_{14} is the same constant of estimate (25)). By Proposition 3.5 we have

$$\delta_{\mathcal{H}}(D_1, D_2) \leq 2\left(d^7 L_1^{-3} \sigma(\varepsilon)\right)^{\frac{1}{4}}. \tag{26}$$

Step 2. Let I_0 denote the connected component of $\overline{\Omega} \setminus (D_1 \cup D_2)$ that contains $\partial\Omega$. By (10), (12), inclusion (20) considered for $r = 0$, and the divergence theorem we have

$$\int\limits_{D_1 \setminus D_2} \frac{\partial u_2(x, t_2)}{\partial t} dx \leq \int\limits_{(\partial I_0 \cap \partial D_1) \setminus \partial D_2} |\nabla_x u(x, t_2)| \, ds. \tag{27}$$

Let $\overline{x} \in (\partial I_0 \cap \partial D_1) \setminus \partial D_2$. By (26), we have

$$\mathrm{d}(\overline{x}, D_2) \leq \delta(\varepsilon), \tag{28}$$

where $\delta(\varepsilon) = 2\left(d^7 L_1^{-3} \sigma(\varepsilon)\right)^{\frac{1}{4}}$.

The definition of I_0 states that $\overline{x} \in \Omega \setminus \overline{D}_2$. Let $r = d(\overline{x}_1, D_2)$. Furthermore, let ε_1 be such that $\varepsilon_1 \leq \varepsilon_0$ and $\delta(\varepsilon_1) \leq \frac{L_1}{2}$; (28) and Proposition 2.1 yield, for $\varepsilon \leq \varepsilon_1$, that $\overline{x} \in \partial [D_2]_r \cap \partial D_1$. By Proposition 2.2 we have that there exist four balls $\mathrm{B}_i^{(j)}$, $\mathrm{B}_e^{(j)}$, $j = 1, 2$, with radius $\frac{L_1}{2}$, which fulfill

(a) $\mathrm{B}_i^{(1)} \subset D_1$, $\mathrm{B}_e^{(1)} \subset \Omega \setminus \overline{D}_1$,
with $\partial \mathrm{B}_i^{(1)}$ and $\partial \mathrm{B}_e^{(1)}$ tangent to ∂D_1 in $\overline{x}$;

(b) $\mathrm{B}_i^{(2)} \subset [D_2]_r$, $\mathrm{B}_e^{(2)} \subset \Omega \setminus [D_2]_r$,
with $\partial \mathrm{B}_i^{(2)}$ and $\partial \mathrm{B}_e^{(2)}$ tangent to $\partial [D_2]_r$ in $\overline{x}$.

Note that

$$\mathrm{B}_i^{(1)} \cap \mathrm{B}_e^{(2)} \subset D_1 \setminus [D_2]_r, \tag{29}$$

$$\mathrm{B}_e^{(1)} \cap \mathrm{B}_e^{(2)} \subset \Omega \setminus \left(\overline{D}_1 \cup [D_2]_r\right). \tag{30}$$

By (29) and (30) we have

$$\left|\mathrm{B}_e^{(2)} \setminus \mathrm{B}_i^{(1)}\right| \geq \left|\mathrm{B}_e^{(2)}\right| - |D_1 \setminus [D_2]_r| \geq \frac{4\pi}{3}\left(\frac{L_1}{2}\right)^3 - d^3 \sigma(\varepsilon). \tag{31}$$

Now consider the planes $\mathcal{P}_1$ and $\mathcal{P}_2$ which are tangent in $\overline{x}$, respectively, to $\mathrm{B}_i^{(1)}$, $\mathrm{B}_e^{(1)}$ and $\mathrm{B}_i^{(2)}$, $\mathrm{B}_e^{(2)}$. $\mathrm{B}_e^{(1)} \cap \mathrm{B}_e^{(2)}$ is contained in one of the four regions in which $\mathbb{R}^3$ is divided by $\mathcal{P}_1$ and $\mathcal{P}_2$. Let $\mathcal{P}_j^+ \subset \mathcal{P}_j$, $j = 1, 2$, the half-planes that limit this region, and denote by θ, $\theta \in [0, \pi)$ the angle between $\mathcal{P}_1^+$ and $\mathcal{P}_2^+$.

By the formula

$$\left|\mathrm{B}_e^{(2)} \setminus \mathrm{B}_i^{(1)}\right| = 2\pi \left(\frac{L_1}{2}\right)^3 \left(\sin\frac{\theta}{2} - \frac{1}{3}\sin^3\frac{\theta}{2}\right) \tag{32}$$

and by (31), we have, if $\varepsilon \leq \varepsilon_2$ (where ε_2 is such that $\sigma(\varepsilon_2) \leq \frac{\pi}{100}\left(\frac{L_1}{2}\right)^3$ and $\varepsilon_2 \leq \varepsilon_1$),

$$\sin\frac{\theta}{2} - \frac{1}{3}\sin^3\frac{\theta}{2} \geq \frac{3\sqrt{3}}{8}\ .$$

Therefore, $\theta \geq \theta_0 > \frac{3}{4}\pi$. Denote $S_\theta(\overline{x})$ $=\mathrm{B}_e^{(1)}\cap\mathrm{B}_e^{(2)}$; let $\mathcal{L}$ be the plane containing the circle $\partial\mathrm{B}_e^{(1)} \cap \partial\mathrm{B}_e^{(2)}$. We can suppose, by mean of an isometry, that the center of symmetry of $S_\theta(\overline{x})$ is in the origin of coordinate, $\mathcal{L}$ is the plane $x_3 = 0$, and $\overline{x}$ belongs to x_1 axis and $\overline{x}_1 > 0$. Denote $s_0 = \frac{L_1}{8}\left(1 - \cos\frac{\theta_0}{2}\right)$. We have $\mathrm{B}(0, s_0) \subset S_\theta(\overline{x})$ and $\mathrm{d}(\mathrm{B}(0, s_0), D_j) \geq 2s_0$, $j = 1, 2$. Let $\varepsilon \leq \varepsilon_3$, where ε_3 is such that $\delta(\varepsilon_3) \leq \frac{s_0}{2}$ and $\varepsilon_3 \leq \varepsilon_2$. By (26) we have $D_1 \cup D_2 \subset [D_1]_{\frac{s_0}{2}} \subset [D_2]_{s_0}$; therefore, $\mathrm{B}(0, s_0) \subset (\Omega)_{s_0} \setminus [D_2]_{s_0}$. By Proposition 2.3, $(\Omega)_{s_0} \setminus [D_2]_{s_0}$ is connected; hence we can join every point $x \in$B$(0, s_0)$ with $y \in \Omega$ such that $\mathrm{d}(y, \partial\Omega) = \frac{L_0}{4}$. Proceeding as in the proof of (23), we obtain, by (18),

$$|\nabla_x u(x, t_2)| \leq \frac{\omega(\varepsilon)}{d} \text{ for every } x \in \mathrm{B}(0, s_0), \tag{33}$$

where

$$\omega(\varepsilon) = 12(1 + C_0)^{N_0} C_{10} (E + \varepsilon)^{1-\gamma_1\gamma_0^{2N_0}} \varepsilon^{\gamma_1\gamma_0^{2N_0}}$$

and

$$N_0 = \frac{3^4 d^3}{4\pi s_0^3}.$$

Let $\rho \in \left(0, \frac{L_1}{4}\sin\frac{\theta_0}{2}\right)$ and denote

$$x_\rho = (\overline{x}_1 - 2\rho, 0, 0),\ r = \frac{1}{2}\mathrm{d}(x_\rho, \partial S_\theta(\overline{x})).$$

Observe that

$$\frac{1}{2}\rho\sin\frac{\theta}{2} < r < \rho. \tag{34}$$

Using the Green formula for u_{x_j} in $S_\theta(\overline{x}) \times [0, t_2]$ for fix $j \in \{1, 2, 3\}$ and setting

$$f(\lambda + i\mu) = u_{x_j}(\lambda + i\mu, 0, 0, t_2), \tag{35}$$

a straightforward calculation shows that the complex analytic function f is defined in the subset of $\mathbb{C}$:

$$\Lambda = \left\{\lambda + i\mu : -s_0 \leq \lambda \leq \overline{x}_1 - 2\rho + r, |\mu| \leq \frac{1}{2}\left(\frac{L_1}{2} - \sqrt{\lambda^2 + \frac{L_1^2\cos^2\frac{\theta}{2}}{4}}\right)\right\}. \tag{36}$$

Furthermore, by (33), the following estimates follow:

$$\left|f\left(\lambda+i0\right)\right|\leq\frac{\omega\left(\varepsilon\right)}{d}\text{ for }\left|\lambda\right|\leq s_0,$$

$$\left|f\left(\lambda+i\mu\right)\right|\leq\frac{cEL_1^3e^{\frac{L_1^2}{64T}}}{r^3d}\text{ for }\lambda+i\mu\in\Lambda,$$

where c is an absolute constant.

These inequalities and estimates for analytic continuation, see [5] , give (recalling that $u_{x_j}\left(x_\rho,t_2\right)=f\left(\overline{x}_1-2\rho+i0\right)$)

$$\left|u_{x_j}\left(x_\rho,t_2\right)\right|\leq\frac{cL_1^3e^{\frac{L_1^2}{64T}}}{r^3d}\left(E+\omega\left(\varepsilon\right)\right)^{1-A_r}\left(\omega\left(\varepsilon\right)\right)^{A_r},\tag{37}$$

where

$$A_r=c_1\left(\frac{r}{L_1}\right)^{10}$$

and c, c_1 are absolute constants.

From Proposition 2.1, (17), (27), (37), and (67), we have

$$\left|D_1\setminus D_2\right|\leq C_{15}d^2\left(E+\varepsilon\right)\left(\rho+\frac{d^4}{r^3}\left(\frac{\varepsilon}{E+\varepsilon}\right)^{\gamma_2A_r}\right),\tag{38}$$

where $\gamma_2=\gamma_1\gamma_0^{2N_0}$ and C_{15} depends on $\alpha,d,h,L_0,\frac{m_2}{m_1},M,\tau,t_1,\Sigma,$ and Ω. If $\varepsilon\leq\varepsilon_4$, where $\varepsilon_4=\min\{\varepsilon_3,E\exp(-\exp\frac{2^{140}}{\gamma_2C_1})\}$, and we set in (38)

$$\rho=L_1\left|\ln\frac{\varepsilon}{E}\right|^{-\frac{1}{11}},$$

we have, recalling (34),

$$\left|D_1\setminus D_2\right|\leq C_{16}Ed^3\left|\ln\frac{\varepsilon}{E}\right|^{-\frac{1}{11}},$$

where C_{16} depends on the same data of C_{15}. The same estimate holds for $\left|D_2\setminus D_1\right|$.

Now, proceeding as in the proof of (26), we obtain

$$\delta_{\mathcal{H}}\left(D_1,D_2\right)\leq 2d\left(C_{16}E\right)^{\frac{1}{4}}\left|\ln\frac{\varepsilon}{E}\right|^{-\frac{1}{44}}.$$

Finally, by the trivial inequality $\delta_{\mathcal{H}}\left(D_1,D_2\right)\leq\frac{d}{\varepsilon_4}\varepsilon$ valid for $\varepsilon>\varepsilon_4$, we obtain (15).

Remark 1. More careful and tedious calculations in the evaluation of angle θ and of analytic continuation of f in Λ give an improvement, only concerning the epsilon dependence, in estimate (15). More precisely, (i) by inequality (31) and formula (32) we have that for every $\nu>0$ there exists $\omega_\nu>0$ ($\omega_\nu\rightarrow 0$ as $\nu\rightarrow 0$) such that if $\varepsilon\leq\omega_\nu$ then $\theta\geq\pi-\nu$; (ii) to estimate $f\left(\lambda+i\mu\right)$ in Λ we can use a more large part than really was used in the proof—in this way the exponent γ_2A_r in (38) can be replaced by $\varkappa_\nu\left(\frac{r}{R}\right)^{2+\varkappa_\nu}$, where $\varkappa_\nu\rightarrow 0$ as $\nu\rightarrow 0$, the constant C_{15} can be replaced by C_ν ($C_\nu \to \infty$ as $\nu \to 0$), and if we choose $\rho = L_1 \left|\ln \frac{\varepsilon}{E}\right|^{-\left(\frac{1+\omega_\nu}{2+\omega_\nu}\right)}$, we obtain the estimate

$$\delta_{\mathcal{H}}\left(D_1, D_2\right) = O\left(\left|\ln\varepsilon\right|^{-\frac{1}{8}+\omega_\nu}\right). \tag{39}$$

Remark 2. If in the a priori information on D, instead of ∂D, connected, we assume that $\mathbb{R}^3 \setminus \overline{D}$ is connected, $D = \bigcup_{n=1}^{N} D^{(n)}$ with $\overline{D^{(i)}} \cap \overline{D^{(j)}} = \emptyset$ for $i \neq j$, and $\partial D^{(i)}$ is connected for every $i = 1, ..., N$, then estimate (15) (and (39)) continues to hold with a different constant.

3. Appendix. In the following lemma we prove an estimate on the analytic continuation of the space variable for solutions of the heat equation.

LEMMA 3.1. *Let $\varepsilon, E, r, T > 0$. Suppose that u satisfies the equation*

$$\frac{\partial u}{\partial t} - \Delta u = 0 \textit{ in } B(0, 3r) \times [0, T].$$

Let $y \in \partial B(0, r)$. Suppose that

$$\|u\|_{L^\infty(B(0,3r)\times[0,T])} + r\left\|\nabla_x u\right\|_{L^\infty(B(0,3r)\times[0,T])} \leq E, \tag{40}$$

$$\left|u\left(x, T\right)\right| \leq \varepsilon \textit{ for } x \in B\left(y, r\right) \cap B\left(0, r\right). \tag{41}$$

The following estimate holds:

$$\left|u\left(x, T\right)\right| \leq C_0\left(E + \varepsilon\right)^{1-\gamma_0} \varepsilon^{\gamma_0} \textit{ for } x \in B\left(y, r\right) \setminus B\left(0, r\right), \tag{42}$$

where $C_0 = 240 e^{\frac{r^2}{64T}}$ and $\gamma_0 = \frac{1}{4\cosh\frac{\pi}{8}\cosh\pi}$.

Proof. The Green formula gives, for $x \in$B$(0, 3r)$,

$$u\left(x, T\right) = \int\limits_{\mathrm{B}(0,3r)} K\left(x - \xi, T\right) u\left(\xi, 0\right) d\xi \tag{43}$$

$$+ \int_0^T dt \int\limits_{\partial\mathrm{B}(0,3r)} \left(K\left(x - \xi, T - t\right)\frac{\partial u\left(\xi, t\right)}{\partial \mathbf{n}_\xi} - \frac{\partial K}{\partial \mathbf{n}_\xi}\left(x - \xi, T - t\right) u\left(\xi, t\right)\right) ds_\xi.$$

Now, let $z_k = x_k + iy_k, k = 1, 2, 3$, and consider the function $U\left(z\right)$ obtained by the formal substitution in the right-hand side of (43) of $x_k$with z_k. $U\left(z\right)$ is the complex analytic continuation of $u\left(x, T\right)$; in fact, $U\left(x_1 + i0, x_2 + i0, x_3 + i0\right) = u\left(x, T\right)$ and a simple calculation prove that for $x \in$B$(0, 3r)$, $y \in$B$(0, \frac{3r-|x|}{2})$, the Cauchy–Riemann equations $\frac{\partial U}{\partial x_k} + i\frac{\partial U}{\partial y_k} = 0$, $k = 1, 2, 3$, are valid. We continue to denote by $u\left(z, T\right)$ the function $U\left(z\right)$.

Consider $\overline{x} \in$B$(y, r) \setminus$B$(0, r)$ and denote

$$f\left(\lambda + i\mu\right) = u\left(\left(\lambda + i\mu\right)\overline{x}, T\right).$$

From (40) and (43) we have

$$\left|f\left(\lambda + i\mu\right)\right| \leq 120 E e^{\frac{r^2}{64T}} \text{ for } \lambda \in \left[0, \frac{5r}{2\left|\overline{x}\right|}\right], \mu \in \left[-\frac{r}{4\left|\overline{x}\right|}, \frac{r}{4\left|\overline{x}\right|}\right]. \tag{44}$$

Furthermore, by (41), we obtain

$$|f(\lambda+i0)| \leq \varepsilon \text{ for } \lambda \in \left[0, \frac{r}{|\overline{x}|}\right]. \tag{45}$$

By analytic continuation in the rectangle $[0, \frac{5r}{|\overline{x}|}] \times [-\frac{r}{4|\overline{x}|}, \frac{r}{4|\overline{x}|}]$ (see [5]), we have by (44) and (45) that

$$|u(\overline{x},T)| = |f(1+i0)| \leq 240 e^{\frac{r^2}{64T}} (E+\varepsilon)^{1-\gamma_0} \varepsilon^{\gamma_0},$$

where $\gamma_0 = \frac{1}{4\cosh\frac{\pi}{8}\cosh\pi}$. □

LEMMA 3.2. *Let Ω and D satisfy* (6) *and* (7), *respectively. Let u be a solution of the equation*

$$\frac{\partial u}{\partial t} - \Delta u = 0 \textit{ in } \left(\Omega \setminus \overline{D}\right) \times [0,T],$$

which is positive in $\left(\Omega \setminus \overline{D}\right) \times (0,T]$ and fulfills the condition

$$\frac{\partial u}{\partial \mathbf{n}} = 0 \textit{ on } \partial D \times [0,T].$$

The following estimate then holds:

$$\min_{x\in\partial D} u(x,T) \geq \frac{C}{L_0^4} \int_0^{T'} dt \int_{\partial\Omega} u(x,t)\, ds, \tag{46}$$

where $T' \in (0,T)$ and C is a nondimensional constant depending on $d, h, L_0, M, T, T-T'$.

The proof of this lemma is preceded by the following.

LEMMA 3.3. *Let Ω and D be as in the previous lemma. Let $x^0 \in \partial D$, $\sigma > 0$, and let v be the solution of*

$$\frac{\partial v}{\partial t} - \Delta v = 0 \textit{ in } \left(\Omega \setminus \overline{D}\right) \times [0,T,], \tag{47}$$

$$v(x,0) = K\left(x-x^0,\sigma\right) \textit{ for } x \in \Omega \setminus \overline{D}, \tag{48}$$

$$v = 0 \textit{ on } \partial\Omega \times [0,T], \tag{49}$$

$$\frac{\partial v}{\partial \mathbf{n}} = 0 \textit{ on } \partial D \times [0,T]. \tag{50}$$

For every $T' \in (0,T)$ there exist $\sigma_0 > 0$ and C_8 depending on $d, h, L_0, L_1, M, T, T-T'$ such that for $\sigma \in (0,\sigma_0)$ and $(x,t) \in \partial\Omega \times [T-T', T]$,

$$-\frac{\partial v(x,t)}{\partial \mathbf{n}} \geq \frac{1}{L_0^4} \exp -\frac{c}{C_8}\left[\left(dL_1^{-1}\right)^6 + TL_1^{-2}\right], \tag{51}$$

where c is an absolute constant and $\mathbf{n}$ is the outward normal to $\partial\Omega$.

Proof of Lemma 3. First we find an estimate from below in a point far enough from D for v. We construct v as follows: $v = w + z$, where

$$z\left(x,t\right) = K\left(x - x^0, t + \sigma\right) + \int_0^t d\eta \int_{\partial D} K\left(x - \xi, t - \eta\right) \psi\left(\xi, \eta\right) d\xi, \tag{52}$$

$\psi \in \mathrm{C}^0\left(\partial D \times [0,T]\right)$, and it is such that

$$\frac{\partial z}{\partial \mathbf{n}} = 0 \text{ on } \partial D \times [0,T]. \tag{53}$$

w is the solution of the boundary value problem (the existence of w is assured by [14, Chap. III]);

$$\frac{\partial w}{\partial t} - \Delta w = 0 \text{ in } \left(\Omega \setminus \overline{D}\right) \times [0,T],$$

$$w\left(x,0\right) = 0 \text{ for } x \in \Omega \setminus \overline{D},$$

$$w = -z \text{ on } \partial\Omega \times [0,T],$$

$$\frac{\partial w}{\partial \mathbf{n}} = 0 \text{ on } \partial D \times [0,T].$$

Condition (53) is equivalent to the integral equation

$$\psi\left(x,t\right) - \int_0^t d\eta \int_{\partial D} G\left(x,t;\xi,\eta\right) \psi\left(\xi,\eta\right) ds_\xi = F_0\left(x,t\right) \text{ for } \left(x,t\right) \in \partial D \times [0,T],$$

where

$$G\left(x,t;\xi,\eta\right) = 2\frac{\partial K}{\partial \mathbf{n}_x}\left(x - \xi, t - \eta\right) \text{ for } 0<\eta<t,\ x,\xi \in \partial D,$$

$$F_0\left(x,t\right) = -2\frac{\partial K}{\partial \mathbf{n}_x}\left(x - x^0, t + \sigma\right) \text{ for } \left(x,t\right) \in \partial D \times [0,T],$$

and $\mathbf{n}_x$ denotes unit inner normal to ∂D in x.

The continuity of F_0 gives the continuity of ψ (see [8]); furthermore,

$$\psi\left(x,t\right) = \sum_{m=0}^{\infty} F_m\left(x,t\right), \tag{54}$$

where

$$F_m\left(x,t\right) = \int_0^t d\eta \int_{\partial D} G\left(x,t;\xi,\eta\right) F_{m-1}\left(\xi,\eta\right) ds_\xi \tag{55}$$

for $m \geq 1$, $(x,t) \in \partial D \times [0,T]$.

Now for $\mu \in (0,1)$ we have

$$|G(x,t;\xi,\eta)| \leq \frac{c\left(M+h^{-1}\right)}{(t-\eta)^{\mu}\,|x-\xi|^{3-2\mu}}, \tag{56}$$

$$|F_0(x,t)| \leq \frac{c\left(M+h^{-1}\right)}{(t+\sigma)^{\mu}\,|x-x^0|^{3-2\mu}}, \tag{57}$$

where c is a constant depending on μ.

Furthermore, by a slight modification of [8, Lemma 1, p. 137], we have for $x \in \partial D$, $\xi \in \Omega \setminus D$, and $a, b \in [0,2)$,

$$\int\limits_{\partial D} \frac{ds_y}{|x-y|^{a}\,|y-\xi|^{b}} \leq \begin{cases} \frac{C_1}{|x-\xi|^{a+b-2}} \text{ if } a+b>2, \\ \\ C_2 \text{ if } a+b<2, \end{cases} \tag{58}$$

where C_1 and C_2 are constants depending on a, b, d, h, M.

Let $\mu = \frac{1}{\sqrt{3}}$ (observe that $\mu \in \left(\frac{1}{2}, \frac{2}{3}\right)$; by (55)–(58) we have

$$|F_m(x,t)| \leq \begin{cases} \frac{C_3}{d}\frac{\left(C_3 t^{1-\mu} d^{-1}|x-x^0|^{2\mu-1}\right)^m t^{-\mu}}{\Gamma((m+1)(1-\mu))|x-x^0|^{3-2\mu}} \text{ for } 2 \leq m \leq N, \\ \\ \frac{C_3}{d^{4-2\mu}}\frac{\left(C_3 t^{1-\mu} d^{2(\mu-1)}\right)^m t^{-\mu}}{\Gamma((m+1)(1-\mu))} \text{ for } m \geq N+1, \end{cases} \tag{59}$$

where N is the integral part of $\frac{3-2\mu}{2\mu-1}$ and C_3 is a constant depending on d, h, M.

Furthermore,

$$|F_0(x,t)| + |F_1(x,t)| \leq \frac{C_4}{d^{1+2\mu}}\left(\frac{T}{t+\sigma}\right)^{\mu}\frac{1}{|x-x^0|^{3-2\mu}}\ , \tag{60}$$

where C_4 depends on d, h, M, T.

By (54), (59), (60) we obtain

$$|\psi(x,t)| \leq \frac{C_4'}{d^{1+2\mu}}\left(\frac{T}{t+\sigma}\right)^{\mu}\frac{1}{|x-x^0|^{3-2\mu}}\ ; \tag{61}$$

C_4' depends on d, h, M, T.

This inequality, (52), and the maximum principle yield

$$\|w\|_{L^{\infty}((\Omega\setminus D)\times[0,T])} \leq \|z\|_{L^{\infty}(\partial\Omega\times[0,T])} \leq \frac{C_4''}{L_0^3}; \tag{62}$$

C_4'' depends on d, h, M, T.

From (52), (61), and (62) we obtain

$$v\left(x, |x-x^0|^2-\sigma\right) \geq \frac{1}{|x-x^0|^3}\left[\frac{1}{e^{1/4}\left(2\sqrt{\pi}\right)^3} - \frac{C_5\,|x-x^0|}{L_0}\right], \tag{63}$$

where C_5 depends on d, h, L_0, M, T. For such a choice of C_5, denote

$$C_6 = \min\left\{\left(2e^{1/4}\left(2\sqrt{\pi}\right)^3 C_5\right)^{-1}, \frac{L_1}{2L_0}\right\},\ C_7 = \left(2e^{1/4}\left(2\sqrt{\pi}\right)^3 C_6^3\right)^{-1}.$$

We obtain, for $x \in \left(\Omega \setminus \overline{D}\right) \cap \partial \mathrm{B}\left(x^0, C_6 L_0\right)$ and $\sigma < \frac{C_6^2 L_0^2}{2}$, the following estimate:

$$v\left(x, C_6^2 L_0 - \sigma\right) \geq \frac{C_7}{L_0^3}\ . \tag{64}$$

This estimate, the Harnack inequality, and the Hopf maximum principle give, for $T' \in (0,T)$,

$$-\frac{\partial v}{\partial \mathbf{n}}\left(x,t\right) \geq \frac{1}{L_0^4} \exp -\frac{c}{C_8}\left(\left(dL_1^{-1}\right)^6 + TL_1^{-2}\right) \text{ for } (x,t) \in \partial\Omega \times \left[T - T', T\right],$$

where $\mathbf{n}$ is the outward normal to $\partial\Omega$, c is an absolute constant,

$$C_8 = \min\left\{C_7^6, \frac{\left(T - T'\right)^{3/2}}{\left(4L_0\right)^3}\right\},$$

and C_7 is as in (64). □

Proof of Lemma 2. Let $x^0 \in \partial D$ such that

$$u\left(x^0, T\right) = \min_{x \in \partial D} u\left(x, T\right).$$

By the Green formula applied to u and $v\left(x, T - t\right)$, the positivity of u, and (51) we obtain

$$\frac{1}{2} u\left(x^0, T\right) = \lim_{\sigma \to 0^+} \int\limits_{\Omega \setminus D} u\left(x, T\right) K\left(x - x^0, \sigma\right) dx \geq \lim_{\sigma \to 0^+} \int\limits_0^T dt \int\limits_{\partial\Omega} u\left(x,t\right)\left(-\frac{\partial v}{\partial \mathbf{n}}\right)\left(x, T - t\right) ds$$

$$\geq \frac{1}{L_0^4}\left(\exp -\frac{c}{C_8}\left(\left(dL_1^{-1}\right)^6 + TL_1^{-2}\right)\right) \int\limits_0^{T'} dt \int\limits_{\partial\Omega} u\left(x,t\right) ds.$$

That is, we obtain (46). □

Remark 3. If $\|\nabla_x u\|_{L^\infty\left(\left(\Omega\right)_{L_0} \setminus D \times [0,T]\right)} \leq d^{-1}E$, $E > 0$, by (46) we have for $x \in \Omega \setminus D$ such that $\mathrm{d}(x, \partial D) \leq \frac{Cd}{L_0^4 E} \int_0^{T'} dt \int_{\partial\Omega} u ds$

$$u\left(x, T\right) \geq \frac{C}{2L_0^4} \int\limits_0^{T'} dt \int\limits_{\partial\Omega} u\left(x,t\right) ds. \tag{65}$$

Furthermore, if $T'' \in (0, T')$, using (65) where T is replaced by T' and T' by T'' and applying again the Harnack inequality, we get

$$u\left(x, T\right) \geq \frac{C_9}{L_0^4} \int\limits_0^{T''} dt \int\limits_{\partial\Omega} u\left(x,t\right) ds \text{ for } x \in \Omega \setminus D \text{ such that } \mathrm{d}\left(x, \partial\Omega\right) \geq L_0, \tag{66}$$

where C_9 depends on $d, E, h, L_0, M, T, T - T', T' - T''$.

Proposition 3.4. *Let D fulfill condition* (7), *denote* $L_2 = \min\{(2M)^{-1}, h\}$; *we have*

$$|\partial D| \leq \frac{24e^3}{M^2 L_2^3} |D| , \tag{67}$$

$$|\partial [D]_r| \leq \frac{96e^3}{M^2 L_2^3} |D| \ \textit{for } r \in (0, L_2) , \tag{68}$$

$$|[D]_r \setminus D| \leq \frac{56e^3}{M^2 L_2^3} |D| \, r. \tag{69}$$

Proof. Denote by $H(x)$ and $K(x)$, respectively, the mean and total curvature of ∂D in x. By (7) we have

$$|H(x)| \leq \min\left\{M, L_2^{-1}\right\}, \ |K(x)| \leq \min\left\{2M^2, L_2^{-2}\right\}. \tag{70}$$

Furthermore (see [10]), for $r \in (0, L_2)$, the function $\mathrm{d}(x) = \mathrm{d}(x, \partial D)$ is C^2 in $S_r = \overline{D} \setminus (D)_r$ and $|\nabla \mathrm{d}(x)| = 1$ for $x \in S_r$. By simple calculation we have

$$|\partial (D)_r| = |\partial D| + 2r \int\limits_{\partial D} H(x)\, ds + r^2 \int\limits_{\partial D} K(x)\, ds;$$

by the coarea formula we obtain

$$|S_r| = \int\limits_0^r |\{x : \mathrm{d}(x) = t\}|\, dt = r\, |\partial D| + r^2 \int\limits_{\partial D} H(x)\, ds + \frac{r^3}{3} \int\limits_{\partial D} K(x)\, ds.$$

Set $f(r) = |S_r|$. By inequality (see [11])

$$|f'(0)| \leq 12e^2 \|f\|^{\frac{2}{3}} \left(\|f'''\| + \frac{6}{L_2^3} \|f\| \right)^{\frac{1}{3}},$$

where $\|f\| = \max\limits_{[0, L_2]} |f|$, and (70) we obtain

$$|\partial D| \leq 12e^2 |D|^{\frac{2}{3}} \left(4M\, |\partial D| + \frac{6}{L_2^3} |D| \right)^{\frac{1}{3}}; \tag{71}$$

applying the arithmetic–geometric inequality to the right side of (71) we obtain (67).

From

$$|\partial [D]_r| = |\partial D| - 2r \int\limits_{\partial D} H(x)\, ds + r^2 \int\limits_{\partial D} K(x)\, ds$$

and (67) we obtain (68).

Finally, from

$$|[D]_r \setminus D| = r \left(|\partial D| - r \int\limits_{\partial D} H(x)\, ds + \frac{r^2}{3} \int\limits_{\partial D} K(x)\, ds \right)$$

and recalling (70) and (67) we have (69). □

Proposition 3.5. *Let D_1, D_2 satisfy* (7). *The following inequality then holds:*

$$\delta_{\mathcal{H}}\left(D_1, D_2\right) \leq 2dL_1^{-\frac{3}{4}} \left|D_1 \vartriangle D_2\right|^{\frac{1}{4}}. \tag{72}$$

Proof. Denote $\sigma = \left|D_1 \vartriangle D_2\right|$. First suppose that

$$\sigma \leq \frac{\pi L_1^3}{50}. \tag{73}$$

Let $x \in \overline{D}_1 \setminus D_2$. By the interior sphere property of D_1 (see Proposition 2.2), it easily follows that there exists a ball $\mathrm{B}\big(p, \frac{L_1}{2}\big)$ such that $\mathrm{B}\big(p, \frac{L_1}{2}\big) \subset D_1$ and $x \in \partial \mathrm{B}\big(p, \frac{L_1}{2}\big)$. We have

$$\left|B\left(p, \frac{L_1}{2}\right) \setminus D_2\right| \leq \left|D_1 \setminus D_2\right| \leq \sigma.$$

By (73) we have that $\mathrm{B}\big(p, \frac{L_1}{2}\big) \cap D_2$ is nonempty and there exists $y \in \partial D_2 \cap \overline{B\left(p, \frac{L_1}{2}\right)}$ such that

$$|x-y| = \mathrm{d}\left(x, \overline{D}_2 \cap \overline{B\left(p, \frac{L_1}{2}\right)}\right).$$

By the exterior sphere property of D_2, it follows that there exists a ball $\mathrm{B}(q, L_1)$ contained in $\Omega \setminus \overline{D}_2$ and tangent in y to ∂D_2. By simple geometric considerations we have that $x, y \in \overline{B\left(p, \frac{L_1}{2}\right)} \cap \overline{\mathrm{B}\left(q, L_1\right)}$. Furthermore, the inclusion $\overline{B\left(p, \frac{L_1}{2}\right)} \cap \overline{\mathrm{B}\left(q, L_1\right)} \subset \overline{D}_1 \setminus D_2$ gives

$$\left|\mathrm{B}\left(p, \frac{L_1}{2}\right) \cap \mathrm{B}\left(q, L_1\right)\right| \leq \sigma.$$

This estimate and a bound of diameter of $\mathrm{B}\big(p, \frac{L_1}{2}\big) \cap \mathrm{B}(q, L_1)$ by its volume gives

$$|x-y| \leq \text{diameter of } \left(\mathrm{B}\left(p, \frac{L_1}{2}\right) \cap \mathrm{B}\left(q, L_1\right)\right) \leq 2d\left(L_1^{-3}\sigma\right)^{\frac{1}{4}}.$$

Therefore, if $x \in \overline{D}_1 \setminus D_2$, then

$$\mathrm{d}\left(x, D_2\right) \leq 2d\left(L_1^{-3}\sigma\right)^{\frac{1}{4}}.$$

Since the same estimate is valid for $\mathrm{d}(x, D_1)$, if $x \in \overline{D}_2 \setminus D_1$, (72) holds if (73) is fulfilled. Otherwise, if (73) is not fulfilled, (72) is trivial. □

Acknowledgment. I wish to express my gratitude to Prof. Mario Primicerio, who proposed this problem to me.

GLOBAL CONVEXITY IN A THREE-DIMENSIONAL INVERSE ACOUSTIC PROBLEM[*]

MICHAEL V. KLIBANOV[†]

Abstract. We consider an inverse scattering problem (ISP) for the acoustic equation $u_{tt} = c^2(x)\Delta u, u|_{t=0} = 0, u_t|_{t=0} = \delta(x), x \in \mathbb{R}^3$. The ISP consists of the determination of the speed of sound $c(x)$ inside a bounded domain $\Omega \subset \mathbb{R}^3$ given $c(x)$ outside Ω and measurements of the amplitude $u(x,t)$ of the sound at the boundary $\partial\Omega$, $u|_{\partial\Omega} = \varphi(x,t)$. This problem is nonoverdetermined since only a single source location at $\{0\}$ is counted. Assuming regularity of the rays generated by $c(x)$ and using the *Carleman's weight functions*, we construct a cost functional J_λ. The main result is Theorem 3.1, which claims global strict convexity of J_λ on "reasonable" compact sets of solutions. Therefore, global convergence on such a set of a number of standard minimization algorithms to the unique global minimum of J_λ (i.e., solution of the ISP) is guaranteed. This in turn shows a possibility of constructions of numerical methods for this ISP which would not be affected by the problem of local minima.

Key words. inverse scattering problem, Carleman estimate, globally convex cost functional

1. Introduction.

Let $c(x)$ be the speed of sound at the point $x \in \mathbb{R}^3, c(x) \geq$ const > 0. The amplitude $u(x,t)$ of the sound waves propagating in $\mathbb{R}^3$ from the point source located at $\{0\}$ is governed by the wave equation

$$\begin{gathered} u_{tt} = c^2(x) \bigtriangleup u,\ x \in \mathbb{R}^3,\ t \in (0,T), \\ u|_{t=0} = 0,\ u_t|_{t=0} = \delta(x). \end{gathered} \tag{1.1}$$

Let $\Omega \subset \mathbb{R}^3$ be a bounded domain with a piecewise smooth boundary $\partial\Omega$ and $\{0\} \notin \overline{\Omega}$. We work with the following inverse scattering problems (ISPs).

ISP 1. *Assume that function $c(x)$ is given outside of Ω and is unknown inside of Ω. Determine $c(x)$ for $x \in \Omega$ assuming that the following function $\varphi(x,t)$ is given:*

$$u|_{\partial\Omega\times(0,T)} = \varphi(x,t).$$

Function φ can be interpreted as the result of measurements of the sound's amplitude. This problem has well-known applications in geophysics and ocean acoustics.

Solving the outer boundary value problem

$$\begin{aligned} u_{tt} &= c^2(x) \bigtriangleup u,\ \ x \in \mathbb{R}^3\backslash\Omega,\ t \in (0,T), \\ u|_{t=0} &= 0,\ u_t|_{t=0} = \delta(x), \\ u|_{\partial\Omega\times(0,T)} &= \varphi(x,t), \end{aligned}$$

one can uniquely determine function $u(x,t)$ outside of Ω. Hence, the following function $\xi(x,t)$ is given as well:

$$\frac{\partial u}{\partial n}|_{\partial\Omega\times(0,T)} = \xi(x,t).$$

Now, with the case of backscattering data in mind, we consider a more complicated ISP. Namely, let $\omega \subset \partial\Omega$ be a part of $\partial\Omega$.

ISP 2. *Assume that function $c(x)$ is given outside of Ω and is unknown inside of Ω. Determine $c(x)$ for $x \in \Omega$ assuming that the following two functions are given:*

$$u|_{\partial\Omega\times(0,T)} = \varphi(x,t), \ \ \frac{\partial u}{\partial n}|_{\omega\times(0,T)} = \xi(x,t), \ t \in (0,T). \tag{1.2}$$

As follows from our method, precise values of the function φ at $\partial\Omega\backslash\omega = \omega_1$ are not important. Rather, bounds for φ and its derivatives up to the second order are important at ω_1 in order to keep $u(x,t)$ bounded. Therefore, one can consider ISP 2 as an ISP with the *backscattering* data only.

Remarks (also, see a relevant discussion in section 5). (i) In the case of backscattering data, the function φ is usually only given at $\omega\times(0,T)$ rather than at $\partial\Omega\times(0,T)$. However, it follows from our method that one can prescribe reasonable "pseudo" values for this function at $(\partial\Omega\backslash\omega)\times(0,T)$. Given the right choice of parameters λ and ν in the Carleman's weight function (Theorem 3.1), these pseudovalues will provide very little impact on the solution $c(x)$ at the points x located far from $\partial\Omega\backslash\omega$. The real role of these pseudovalues is to provide an upper bound for the solution. In terms of estimates given below, we would not be able to obtain the "Lipshitz-like" Carleman estimate in the form of Theorem 4.1 without a boundary condition at $\partial\Omega\backslash\omega$. Rather, we would obtain a "Hölder-like" Carleman estimate. To see this, one might compare Theorem 8.3.1 in [3] with Theorem 3 in Chapter 4, section 1 in [8]. In [3], the function $u \in C_0^\infty(\Omega)$ leads to the Lipshitz-like Carleman estimate, whereas in [8], u does not have zero boundary values, which leads to a Hölder estimate. The difference between Theorem 4.1 below and Theorem 8.3.1 in [3] is that, unlike [3], we assign a single boundary condition only at $\partial\Omega\backslash\omega$.

(ii) Even in the case of backscattering data, the function $\xi(x,t)$ in (1.2) can often be computed, rather than given a priori. The following example clarifies this statement. Suppose that the function $c(x)$ is given in the half-space $\{x_3 > 0\}$ and is unknown for $\{x_3 < 0\}$. Also, let the function $\varphi(x,t) = u|_{\{x_3=0\}\times(0,T)}$ be given for all $(x,t) \in \{x_3 = 0\}\times(0,T)$. Then, function $\xi(x,t)$ can be computed for $\{x_3 = 0\}\times(0,T)$ as the solution of the corresponding boundary value problem in the half-space. Let R be a positive constant. Assume that one wants to find function $c(x)$ for $x \in \{|x| < R, \ x_3 < 0\}$ only, rather than for all $x \in \{x_3 < 0\}$. Denote

$$\Omega = \{|x| < 2R, \ x_3 < 0\}, \ \omega = \{|x| < 2R, \ x_3 = 0\}, \ \partial\Omega' = \Omega\backslash\omega.$$

Next, assign reasonable "pseudo" values for the function

$$\varphi(x,t)|_{\partial\Omega'\times(0,T)} \ = u|_{\partial\Omega'\times(0,T)}.$$

Then, given the right choice of parameters λ and ν in the Carleman's weight function in (3.2), our method should provide a good approximation for the function $c(x)$ for $x \in \{|x| < R, \ x_3 < 0\}$.

A variety of numerical methods for different versions of multidimensional coefficient ISPs including inverse acoustic problems has been developed in the past; cf. [1] and references cited therein. However, in nonlinear situations, these methods do not guarantee the absence of the local minima of cost functionals. In this paper we construct such a cost functional J_λ for the ISP 2, which is globally strictly convex on "reasonable" compact sets of solutions.

Thus, J_λ does not have local minima in the interior of such a compact set. Further, by Tikhonov's principle [9], one should assume that a solution of the ISP 2 exists and belongs to the interior of a given compact set, at least in the case of noiseless data. Hence J_λ attains its unique global minimum at an interior point of this compact set. Finally, in the case of a presence of a small-level noise in the data, convexity of J_λ implies that its unique global minimum is attained at a point which is close to the solution for the noiseless data (the corresponding result easily can be derived using the general framework of the theory of ill-posed problems [1, 9]).

Our main idea consists of the use of the *Carleman's weight functions* $\alpha^2(x)$, which are involved in the Carleman estimates for Laplace's operator (see Theorem 4.1). For this reason, we call our technique *Carleman's weight method* (CWM). The major "price" for our method is an assumption that a function associated with $u(x,t)$ has a finite number N of Fourier harmonics with respect to t for an orthonormal basis in L_2-space. That is, we work with the Galerkin approximation without proof of its convergence as $N \to \infty$. Thus, N is the regularization parameter for this ill-posed problem. Note that such an assumption is usually quite acceptable in numerical methods. In fact, all the preceding algorithms deal with some similar assumptions (implicitly or explicitly). We also note that the proof of convergence of our technique as $N \to \infty$ would almost inevitably lead to the proof of a global uniqueness theorem for this ISP. The latter, however, is a long-standing unsolved problem; cf. [7, 8].

The global convexity of cost functionals for similar 3-dimensional hyperbolic and parabolic ISPs was established by CWM in [2, 5]. However, only coefficients at the lower order derivatives were reconstructed in these references.

CWM consists of two main steps. First, by eliminating the unknown coefficient, one obtains a special boundary value problem for an elliptic system of nonlinear PDEs. Second, to solve this system, one constructs a cost functional J_λ. The presence of the Carleman's weight function in J_λ together with the Carleman estimate for Laplace's operator ensures the global strict convexity of J_λ.

In section 2, we obtain a nonlinear elliptic system convenient for treatment by CWM. In section 3, we construct the cost functional J_λ and prove its convexity. In section 4, we derive the Carleman estimate. Section 5 is devoted to discussion.

2. Nonlinear elliptic system convenient for CWM.

In this section, we use the detailed study of propagation of singularities of the hyperbolic Cauchy problem (1.1) being undertaken in the book [8]. For $x_0, x \in \mathbb{R}^3$, let $\tau(x, x_0)$ be the travel time of the sound traveling from x_0 to x. Then, function $\tau(x, x_0)$ satisfies the eikonal equation

$$|\bigtriangledown_x \tau|^2 = \frac{1}{c^2(x)}. \tag{2.1}$$

This equation generates the family of rays $L(x, x_0)$ along which the first arrival signal travels from x_0 to x. One also calls these rays *geodesic lines* generated by Riemann's matrix

$$d\tau = \frac{1}{c(x)}\sqrt{(dx_1)^2 + (dx_2)^2 + (dx_3)^2}.$$

The following functional $\tau(M)$ attains its minimum value on the geodesic line $L(x, x_0)$ (this is Fermat's principle):

$$\tau(M) = \int\limits_{M(x,x_0)} \frac{ds}{c(x)},$$

where $M(x, x_0)$ is a smooth curve connecting x_0 with x.

Regularity assumption. *In what follows, we will always assume that the family of geodesic lines is regular in $\mathbb{R}^3$; i.e., for every two points x_0, $x \in \mathbb{R}^3$, there exists a unique geodesic line $L(x, x_0)$ connecting them.*

Denote $\tau_0(x) = \tau(x, 0)$. The surface $\{t = \tau_0(x)\}$ in $\mathbb{R}^3 \times (0, T)$ defines the characteristic cone for the solution of the hyperbolic Cauchy problem (1.1). So, $u(x, t) = 0$ for $t < \tau_0(x)$. Thus, we will consider function $u(x, t)$ above this cone only. Let $G = \{(x, t) : x \in \Omega, \ \tau_0(x) \leq t \leq T\}$. Function $u(x, t)$ consists of singular and regular parts which we denote u_0 and u_1, respectively, where $u = u_0 + u_1$. CWM requires that

$$u_1(x, t) \in C^2(\overline{G}), \ \tau_0(x) \in C^2(\overline{\Omega}). \tag{2.2}$$

By [8] and to ensure (2.2), we impose somewhat excessive smoothness conditions on the function $c(x)$ (these conditions might likely be relaxed in practical computations). Theorem 4.1 of [8] can be reformulated as follows in our case.

Theorem 2.1. *Let $c(x) \geq \text{const} > 0$, $0 \notin \overline{\Omega}$, $c(x) \in C^{l+4}(\mathbb{R}^3)$, $l \geq 2s + 7$ (where $s \geq -1$ is an integer), and $H(t)$ be the Heaviside function. Then the solution of the Cauchy problem* (1.1) *has the form*

$$u(x, t) = \frac{\sigma_{-1}(x)}{\tau_0(x)} \delta(t - \tau_0(x)) + H(t) \sum_{k=0}^{s} \sigma_k(x) H_k(t^2 - \tau_0^2(x)) + v_s(x, t),$$

where

$$H_k(t) = \frac{t^k}{k!} H(t), \ k \geq 0, \ \sigma_k(x) \in C^{l-2k}(\overline{\Omega}) \text{ for } k = -1, ..., s,$$
$$\tau_0 \in C^{l+3}(\overline{\Omega}), \textit{ and } \sigma_{-1}(x) > 0 \textit{ for all } x.$$

Furthermore, $v_s(x, \tau_0(x)) = 0$; for $s \geq 1$, function $v_s(x, t)$ is continuous in $\overline{G}$ with its derivatives $\mathcal{D}_\chi^\alpha \mathcal{D}_t^\beta \mathcal{V}_s$, $\alpha = (\alpha_1, \alpha_2, \alpha_3)$, $|\alpha| + \beta \leq s - 1$.

Hence, the singular part of the function u is

$$u_0(x, t) = \frac{\sigma_{-1}(x)}{\tau_0(x)} \delta(t - \tau_0(x)), \ \ \sigma_{-1}(x) > 0, \tag{2.3}$$

and the regular part is

$$u_1(x, t) = H(t) \sum_{k=0}^{s} \sigma_k(x) H_k(t^2 - \tau_0^2(x)) + v_s(x, t).$$

Thus, to ensure that $u_1 \in C^2(\overline{G})$, we take $s = 3, \ l = 13,$ and

$$c \in C^{17}(\mathbb{R}^3). \tag{2.4}$$

Remark. Because of the singular part (2.3) in the function $u(x, t)$, functions $\tau_0(x)|_{\partial\Omega}$ and $\frac{\partial \tau_0(x)}{\partial n}|_\omega$ easily can be determined from $u(x, t)|_{\partial\Omega \times (0,T)}$ and $\frac{\partial u}{\partial n}(x, t)|_{\omega \times (0,T)}$.

Now we replace the cone $\{t = \tau_0(x)\}$ with the hyperplane $\{t = 0\}$. To do this, we introduce a new function $W(x, t)$:

$$W(x, t) = \int_0^t dz \int_0^z u(x, y + \tau_0(x)) dy. \tag{2.5}$$

Here the integral of the singular part u_0 of the function u is understood in the conventional setting as (see (2.3))

$$\int_0^z u_0(x, y + \tau_0(x))dy = \frac{\sigma_{-1}(x)}{\tau_0(x)} H(z).$$

Hence,

$$\lim_{t\to 0^+} W(x,t) = 0, \ \lim_{t\to 0^+} \frac{\partial W}{\partial t}(x,t) = \frac{\sigma_{-1}(x)}{\tau_0(x)} > 0. \tag{2.6}$$

Further, let $T_1 = T - \max\limits_{\Omega} \tau_0(x)$. We assume that $T_1 > 0$. Let $\Omega_{T_1} = \Omega \times (0, T_1)$; then

$$W \in C^2(\overline{\Omega}_{T_1}). \tag{2.7}$$

Because of (1.1), (1.2), and (1.5), function W satisfies the following conditions:

$$\triangle W - 2 \bigtriangledown (W_t) \bigtriangledown \tau_0 - W_t \triangle \tau_0 = 0 \text{ in } \Omega_{T_1}, \tag{2.8a}$$

$$W(x,0) = 0, \tag{2.8b}$$

$$W_t(x,0) > 0 \text{ in } \overline{\Omega}, \tag{2.8c}$$

$$W|_{\partial\Omega\times(0,T_1)} = \varphi_1(x,t), \ \frac{\partial W}{\partial n}|_{\omega\times(0,T_1)} = \xi_1(x,t), \tag{2.8d}$$

where functions φ_1 and ξ_1 are generated by the functions φ and ξ due to the transformation (2.5).

An inconvenience of equation (2.8a) is that highest order derivatives fall on two unknown functions rather than just a single one: $W(x,t)$ and $\tau_0(x)$. So, to obtain a *system* of the equations with respect to τ_0 and W, we take $t = 0$ in (2.8a). Then, using (2.8b) and (2.8c), we obtain

$$\triangle \tau_0 + \frac{2}{W_t(x,0)} \bigtriangledown [W_t(x,0)] \bigtriangledown \tau_0 = 0. \tag{2.9}$$

To find the Dirichlet and Neumann data for $\tau_0(x)$, we analyze singularities of functions φ and ξ in (1.2) at $t \to \tau_0^+(x)$ due to the propagation of the singularity in (2.3). Hence, the following two functions are known as well:

$$\tau_0 \mid_{\partial\Omega} = p(x), \ \frac{\partial \tau_0}{\partial n}|_{\omega} = q(x). \tag{2.10}$$

We cannot solve the nonlinear system (2.8)–(2.10) in its present form. So, we simplify this system by cutting off Fourier harmonics for $W(x,t)$ with respect to t. Let $\{a_n(t)\}_{n=1}^{\infty} \subset C^2[0, T_1]$ be an orthonormal basis in $L_2[0, T_1]$ such that $a_n(0) = 0$. Let $\{Q_n(x)\}_{n=1}^{\infty}$ be Fourier coefficients of the function $W(x,t)$ with respect to this basis,

$$Q_n(x) = \int\limits_0^{T_1} W(x,t) a_n(t) dt.$$

Choose an integer $N > 1$; we then impose the following assumption.

MAIN ASSUMPTION. *Denote*

$$v(x,t) = \sum_{n=1}^{N} a_n\ (t)\ Q_n\ (x),$$
$$\widetilde{\varphi}_1(x,t) = \sum_{n=1}^{N} a_n\ (t)\ \varphi_{1n}\ (x),$$
$$\widetilde{\xi}_1(x,t) = \sum_{n=1}^{N} a_n\ (t)\xi_{1n}(x),$$

where $\varphi_{1n}(x)$ *and* $\xi_{1n}(x)$ *are Fourier coefficients of the corresponding functions in* (2.8d)*. So, we assume that function* v *satisfies exactly the same conditions* (2.8a)–(2.8c)*,* (2.9)*, and* (2.10) *as does function* W*, whereas* (2.8d) *is replaced with*

$$v|_{\partial\Omega\times(0,T_1)} = \widetilde{\varphi}_1(x,t),\ \frac{\partial v}{\partial n}|_{\omega\times(0,T_1)} = \widetilde{\xi}_1(x,t).$$

Therefore, we arrive at the following nonlinear system of PDEs:

$$\triangle v - 2 \bigtriangledown (v_t) \bigtriangledown \tau_0 - 2v_t \triangle \tau_0 = 0, \tag{2.11a}$$

$$v(x,0) = 0, \tag{2.11b}$$

$$v_t(x,0) > 0, \tag{2.11c}$$

$$\triangle\tau_0 + \frac{2}{v_t(x,0)} \bigtriangledown [v_t(x,0)] \bigtriangledown \tau_\partial = 0, \tag{2.11d}$$

$$v|_{\partial\Omega} = \widetilde{\varphi}_1,\ \frac{\partial v}{\partial n}|_\omega = \widetilde{\xi}_1,\ \tau_0|_{\partial\Omega} = p,\ \frac{\partial \tau_0}{\partial n}|_\omega = q. \tag{2.11e}$$

Remark. Because of the finite-dimensional Fourier approximation, the existence of a solution to the system (2.8a)–(2.8d) does not necessarily imply the existence of a solution to the system (2.11a)–(2.11e). This is a major shortcoming of our main assumption, since we cannot evaluate our method as $N \to \infty$ (also, see the discussion below). However, we think that the finite-dimensional time dependence assumption is acceptable for numerical methods. In addition, Theorem 3.1 guarantees that our method finds a vector-valued function (v, τ_0), which provides a minimal discrepancy between left- and right-hand sides of (2.11a) and (2.11d), provided, of course, that a solution of the minimization problem (3.2) does exist and belongs to the interior of the set K_2 (this last assumption is very similar to the classical Tikhonov's "compact set principle"; see also the remark after the statement of Theorem 3.1).

Further, introduce vectors

$$A = \left(a_1^{'}(0), ..., a_N^{'}(0)\right),\ Q(x) = (Q_1(x), ..., Q_N(x)),$$
$$\Phi(x) = (\varphi_{11}(x), ..., \varphi_{1N}(x)),\ \text{and}\ \Psi(x) = (\xi_{11}(x), ..., \xi_{1N}(x)).$$

Let $[\ ,\ ]$ denote the dot product in $\mathbb{R}^N$. Choose an integer $n,\ 1 \leq n \leq N$, multiply both sides of (2.11a) by $a_n(t)$, and integrate it over the time interval $(0, T_1)$. We obtain the following nonlinear elliptic system of the second order:

$$\triangle Q - 2 \bigtriangledown (BQ) \cdot \bigtriangledown \tau_0 + 2BQ \frac{\bigtriangledown [A, Q] \cdot \bigtriangledown \tau_0}{[A, Q]} = 0,$$

$$\triangle \tau_0 + 2 \frac{\bigtriangledown [A, Q] \cdot \bigtriangledown \tau_0}{[A, Q]} = 0, \tag{2.12}$$

$$Q|_{\partial\Omega} = \Phi(x),\ \ \frac{\partial Q}{\partial n}|_{\omega} = \Psi(x),\ \tau_0|_{\partial\Omega} = p(x),\ \ \frac{\partial \tau_0}{\partial n}|_{\omega} = q(x),$$

where B is an $N \times N$ matrix with the elements

$$b_{nk} = \int_0^{T_1} a_n(t) a_k^{'}(t) dt;\ n, k = 1, ..., N.$$

While the form of the system (2.12) is almost what we need, it is still a bit inconvenient because of the nonzero boundary conditions. Hence, to obtain zero boundary conditions, we assume that there exists a given N-dimensional vector-valued function $F(x)$ and a given real-valued function $g(x)$ such that

$$F = [F_1, (x), ..., F_N(x)],\ F_i, g \in C^2(\overline{\Omega}),$$

$$F|_{\partial\Omega} = \Phi(x),\ \frac{\partial F}{\partial n}|_{\omega} = \Psi(x), \tag{2.13}$$

$$g|_{\partial\Omega} = p(x),\ \frac{\partial g}{\partial n}|_{\omega} = q(x).$$

Denote

$$P(x) = Q(x) - F(x),\ r(x) = \tau_0(x) - g(x).$$

Then (2.12) and (2.13) lead to

$$\triangle P - 2 \bigtriangledown (BP) \bigtriangledown (r + g) - 2 \bigtriangledown (BF) \bigtriangledown r$$

$$+2\ B(P + F)\ \frac{\bigtriangledown [A, P + F] \bigtriangledown (r + g)}{[A, P + F]} = R^{(1)}(x),$$

$$\triangle r + 2 \frac{\bigtriangledown [A, P + F] \cdot \bigtriangledown (r + g)}{[A, P + F]} = R^{(2)}(x), \tag{2.14}$$

$$P|_{\partial\Omega} = \frac{\partial P}{\partial n}|_{\omega} = 0,\ \ r|_{\partial\Omega} = \frac{\partial r}{\partial n}|_{\omega} = 0,$$

where

$$R^{(1)}(x) = -\left(\triangle F - 2 \bigtriangledown (BF) \bigtriangledown g\right),\ R^{(2)}(x) = -\triangle g. \tag{2.15}$$

So, our goal below is to solve the system (2.14), (2.15). Given the solution (P, r) of this system, one easily can reconstruct the function $\tau_0(x)$ and, therefore, $c(x)$. We also note that while zero boundary conditions for the vector (P, r) are convenient for theoretical analysis, in practical computations, one can likely work with the nonzero conditions for the vector (Q, τ_0) in (2.12).

3. Uniformly strictly convex cost functional. To solve the system (2.14) and (2.15), we introduce a weighted cost functional J_λ. As the weight function, we choose the *Carleman's weight function*, i.e., one involved in the Carleman estimate for the Laplacian operator (see Theorem 4.1).

Choose a point $x_0 \in \mathbb{R}^3 \backslash \overline{\Omega}$ such that there exists a part $\omega_1 \subseteq \omega$ for which

$$(x - x_0, n(x)) < 0 \text{ for all } x \in \omega_1$$

and

$$(x - x_0, n(x)) \geq 0 \text{ for all } x \in \partial\Omega \backslash \omega_1,$$

where $n(x)$ is the outward pointing unit normal to $\partial\Omega$ and $(\ ,\ )$ is the dot product in $\mathbb{R}^3$. Without loss of generality, we will always assume that $\Omega \subset \left\{|x - x_0| < \frac{1}{2}\right\}$. Consider functions

$$\psi(x) = |x - x_0|^2 + \frac{1}{4}, \ \ \alpha(x) = \exp\left[\lambda \psi^{-\nu}\right],$$

where λ and ν are large positive parameters to be chosen later. Because of the Carleman estimate of Theorem 4.1, we call $\alpha(x)$ *Carleman's weight function.* Let x_1 be the point on ω_1 closest to x_0. It is important for our method that Carleman's weight $\alpha(x)$ attains its maximum value at x_1 and decays exponentially in Ω with respect to the distance from x_1. The level surfaces of $\alpha(x)$ are spheres with the center at x_0.

Remark. It can be shown that if, for example, Ω is a cube, $\Omega = (1, a)^3$ with $a = \text{const} > 1$ and $\omega = \{x_3 = 1\} \cap \partial\Omega$, then one can choose $\alpha(x)$ in a simpler way as $\alpha(x) = \exp(\lambda x_3^{-\nu})$ with its level surfaces $\{x_3 = \text{const}\}$.

Let $H_0^2(\Omega)$ be the subspace of $H^2(\Omega)$ consisting of all the real-valued functions $f(x)$ satisfying the boundary conditions

$$f|_{\partial\Omega} = \left.\frac{\partial f}{\partial n}\right|_{\omega} = 0.$$

We will say that a k-dimensional vector-valued function $\beta(x)$ belongs to $H_0^2(\Omega)$ if all of its components belong to $H_0^2(\Omega)$. The same is true for any other Banach space which will be used below. For the norm $\| \cdot \|$ of such a Banach space, we define the norm of β as

$$\| \beta \| = \left[\sum_{i=1}^{k} \| \beta_i \|^2\right]^{\frac{1}{2}}.$$

Because of (2.14), denote

$$R(x) = \left(R^{(1)}(x), R^{(2)}(x)\right), \ S(x) = (P(x), r(x)),$$

$$\begin{aligned} V_1(S) = \triangle P - 2 \bigtriangledown (BP) \bigtriangledown (r + g) - 2 \bigtriangledown (BF) \bigtriangledown r \\ + 2B(P + F) \frac{\bigtriangledown [A, P + F] \bigtriangledown (r + g)}{[A, P + F]}, \end{aligned} \tag{3.1}$$

$$V_2(S) = \triangle r + 2\frac{\nabla [A, P + F] \nabla (r + g)}{[A, P + F]}, \text{ and } V(S) = (V_1(S), V_2(S)).$$

Clearly, $S \in H_0^2(\Omega)$ and $V(S)$ is an $(N+1)$-dimensional vector. Introduce the cost functional $J_\lambda(S)$ as

$$J_\lambda(S) = \int_\Omega [V(S) - R]^2 \alpha^2 dx, \tag{3.2}$$

where

$$[V(S) - R]^2 = [V(S) - R, V(S) - R]$$

is the square length of the $(N+1)$-dimensional vector $V(S) - R$. So, by (2.14) and (2.15), one should find such an $(N+1)$-dimensional vector-valued function $S = \widetilde{S} \in H_0^2(\Omega)$ that provides the minimum of the functional J_λ,

$$\min_S J_\lambda(S) = J_\lambda(\widetilde{S}).$$

First, suppose that the data F and g are given without noise and that $S^* \in H_0^2(\Omega)$ is a solution of the equation $V(S) - R = 0$. Then,

$$\min_S J_\lambda(S) = J_\lambda(S^*) = 0.$$

It also follows from the strict convexity of J_λ (Theorem 3.1) that even if functions F and g are given with noise, which is sufficiently small in the $H^2(\Omega)$-norm, then the point $\widetilde{S}$ of the unique global minimum of J_λ (on the compact set K_2 introduced below) is close to the solution S^* for the noiseless data, provided, of course, that S^* exists. The existence of S^*, however, should be assumed a priori by Tikhonov's approach to ill-posed problems; cf. [1, 9].

By Tikhonov's principle [9], we will minimize J_λ over "reasonable" compact sets introduced below.

In what follows, C will denote different positive constants depending only on Ω, ω_1, and x_0. Let $m_1 = \text{const} > 0$ and $K_1 = K_1(m_1) \subset C^2(\overline{\Omega})$ be the set of vector-valued functions (F, g) such that

$$\| (F, g) \|_{C^2(\overline{\Omega})} \leq m_1 . \tag{3.3}$$

Hence,

$$\| R \|_{C(\overline{\Omega})} \leq C m_1. \tag{3.4}$$

Likewise, we want to bound from the above C^1-norms of all vector-valued functions $S = (P, r)$ under consideration. Therefore, let m_2 and m_3 be two positive constants, $m_2 < m_3$. Then $K_2 = K_2(m_2, m_3)$ will denote a compact set of vector-valued functions $S = (P, r) \in H_0^2(\Omega) \cap H^3(\Omega)$ such that

$$[A, P + F] \geq m_2 \text{ for all } (F, g) \in K_1 \text{ and all } (P, r) \in K_2 \tag{3.5}$$

and

$$\| S \|_{H^3(\Omega)} \leq m_3. \tag{3.6}$$

Note that because of (2.11c), $[A, P+F] > 0$, which explains (3.5). Inequalities (3.5) and (3.6) imply that K_2 is a *convex* set in $H_0^2(\Omega)$. In addition, by Sobolev's embedding theorem, $K_2 \subset C^1(\overline{\Omega})$ and

$$\| S \|_{C^1(\overline{\Omega})} \leq CNm_3 \text{ for all } S \in K_2. \tag{3.7}$$

So, in working on a computational implementation of our method, one should assume, by Tikhonov's principle, that in the case of noiseless data, solution S^* of problem (2.14) does exist and belongs to the interior of K_2 [9].

The following theorem is the main result of this paper.

THEOREM 3.1. *Let Ω be a convex bounded domain, $0 \notin \overline{\Omega}$, the speed of sound $c(x) \geq \text{const} > 0$, $c(x) = \text{const}$ outside of Ω, $c(x) \in C^{17}(\mathbb{R}^3)$, the family of geodesic lines generated by $c(x)$ be regular in $\mathbb{R}^3$, and $\tau_0(x) = \tau(x,0)$ be the travel time from the source $\{0\}$ to the point x. Then there exist large positive parameters $\nu_0 = \nu_0(\Omega,\omega)$ and $\lambda_0 = \lambda_0(\Omega,\omega,N,K_1,K_2)$ such that for $\nu = \nu_0$, all $\lambda \geq \lambda_0$, and for all $(F,g) \in K_1$, the cost functional $J_\lambda(S)$ in (3.2) is uniformly strictly convex on the convex compact set $K_2 \subset H_0^2(\Omega)$. That is, for all $(F,g) \in K_1$ and $S,(S+h) \in K_2$, where $||h||_{H^2(\Omega)} < 1$, $\nu = \nu_0$, and $\lambda \geq \lambda_0$, the following inequality is valid:*

$$J_\lambda(S+h) - J_\lambda(S) - J'_\lambda(S)(h) \geq C_1 \| h \|^2_{H^2(\Omega)},$$

where J'_λ is the Frechet derivative of J_λ at the point S and C_1 is a positive constant, $C_1 = C_1(\Omega,\omega,N,\nu_0,\lambda,K_1,K_2)$, but does not depend on$S,h,F,$ and g.

Remark. There is a question, of course, on how "big" the set K_2 is. First, K_2 is a compact set in $H^2(\Omega)$, which suits the Tikhonov's principle [9] well. Second, the "size" of K_2 depends on the constants m_2 and m_3 in (3.5), (3.6). So, given m_2, the size of K_2 can be big if m_3 is a big number. The bigger the size of K_2, the larger the value of λ_0 one should use in Theorem 3.1.

Proof. In this proof, C_2 will denote different positive constants depending on the sets K_1 and K_2 only, i.e., on the constants $m_1, m_2,$ and m_3 in (3.3)–(3.6). But constants C_2 do not depend on $\lambda, \nu, S,$ and h.

The proof consists of two steps. First, using algebraic manipulations and the Cauchy–Schwarz inequality, we prove that

$$J_\lambda(S+h) - J_\lambda(S) - J'_\lambda(S)(h) \geq \frac{1}{2}\int\limits_\Omega [\triangle h]^2 \alpha^2 dx - C_2 \int\limits_\Omega \left(| \bigtriangledown h|^2 + [h]^2\right)\alpha^2 dx. \tag{3.8}$$

Second, the Carleman estimate of Theorem 4.1 implies that the first term of the right-hand side of (3.7) dominates the rest.

To establish (3.8), we evaluate $J_\lambda(S+h) - J_\lambda(S)$ and single out the derivative $J'_\lambda(S)(h)$. By (3.2),

$$J_\lambda(S+h) - J_\lambda(S) = \int\limits_\Omega [V(S+h) - V(S),\ V(S+h) + V(S) - 2R]\alpha^2 dx.$$

Let $h = (h_1, h_2)$, where h_1 and h_2 represent P and r, respectively. Then a routine algebraic analysis of (3.1) implies that

$$V_1(S+h) - V_1(S) = L_1(S,h) + G_1(S,h),$$

where L_1 and G_1 are the linear and nonlinear parts, respectively, of this difference with respect to h. Namely,

$$L_1(S,h) = \triangle h_1 - 2 \bigtriangledown (Bh_1) \bigtriangledown (r+g) - 2 \bigtriangledown (BP) \bigtriangledown h_2$$

$$+2(Bh_1)\ \frac{\bigtriangledown[A,P+F]\bigtriangledown(r+g)}{[A,P+F]}$$

$$+2B(P+F)\left\{\frac{\bigtriangledown[A,h_1]\bigtriangledown(r+g)+\bigtriangledown[A,P+F]\bigtriangledown h_2}{[A,P+F]}\right\} \tag{3.9}$$

$$-2B(P+F)\frac{\bigtriangledown[A,P+F]\bigtriangledown(r+g)}{[A,P+F]^2}[A,h_1].$$

Also, G_1 satisfies the following estimate:

$$[G_1(S,h)]\le C_2(|\bigtriangledown h|^2+[h]^2). \tag{3.10}$$

Similarly,

$$V_2(S+h)-V_2(S)=L_2(S,h)+G_2(S,h),$$

where L_2 and G_2 represent the linear and nonlinear parts, respectively, of this difference with respect to h:

$$L_2(S,h)=\triangle h_2+2\ \frac{\bigtriangledown[A,h_1]\bigtriangledown(r+g)+\bigtriangledown[A,P+F]\bigtriangledown h_2}{[A,P+F]}$$

$$-2[A,h_1]\ \frac{\bigtriangledown[A,P+F]\bigtriangledown[r+g]}{[A,P+F]^2}, \tag{3.11}$$

and

$$|G_2(S,h)|\le C_2(|\bigtriangledown h|^2+|h|^2). \tag{3.12}$$

Similarly,

$$V(S+h)+V(S)-2R=2(V(S)-R)+\triangle h+G_3(S,h), \tag{3.13}$$

where

$$[G_3(S,h)]\le C_2(|\bigtriangledown h|^2+|h|^2). \tag{3.14}$$

Again, we remark that constants C_2 are independent on S,h because of (3.7). Let $L(S,h)$ and $G(S,h)$ be $(N+1)$-dimensional vector-valued functions of the form

$$L(S,h)=(L_1(S,h),\ L_2(S,h)),\ \ G(S,h)=(G_1(S,h),\ G_2(S,h)).$$

Hence,

$$L(S,h)=\triangle h+\widetilde{L}(S,h), \tag{3.15}$$

where the linear (with respect to h) operator $\widetilde{L}$ contains only the lower order derivatives of h.

By (3.9)–(3.14),

$$J_\lambda(S+h) - J_\lambda\,(S) = \int\limits_\Omega \left[L(S,h) + G(S,h),\ 2(V(S)-R) + \triangle h + G_3(S,h)\right]\alpha^2 dx.$$

Hence,

$$J_\lambda'(S)(h) = 2\int\limits_\Omega \left[L(S,h),\ V(S)-R\right]\alpha^2 dx$$

and

$$J_\lambda(S+h) - J_\lambda(S) - J_\lambda'(S)(h) = \int\limits_\Omega \left[L(S,h), \triangle h + G_3(S,h)\right]\alpha^2 dx$$

$$+\int\limits_\Omega \left[G(S,h), 2(V(S)-R) + \triangle h + G_3(S,h)\right]\alpha^2 dx.$$

This equation together with (3.15) leads to

$$J_\lambda(S+h) - J_\lambda(S) - J_\lambda^{'}(S)(h) = \int\limits_\Omega [\triangle h]^2\alpha^2 dx + \int\limits_\Omega [\widetilde{L}(S,h), \triangle h + G_3(S,h)]\alpha^2 dx$$

$$+\int\limits_\Omega [\triangle h, G_3]\alpha^2 dx + \int\limits_\Omega [G(S,h), 2(V(S)-R) + \triangle h + G_3(S,h)]\alpha^2 dx. \tag{3.16}$$

Thus, the Cauchy–Schwarz inequality, (3.7), (3.10), (3.12), (3.14), and (3.16) immediately lead to (3.8). Further, (3.8) and the Carleman estimate (Theorem 4.1) imply that

$$J_\lambda(S+h) - J_\lambda(S) - J_\lambda'(S)(h) \geq \frac{C}{2\lambda}\sum_{i,i=1}^{3}\int\limits_\Omega \left[h_{x_ix_j}\right]^2\alpha^2 dx$$

$$+\frac{1}{2}C\lambda\int\limits_\Omega |\bigtriangledown h|^2\alpha^2 dx + \frac{1}{2}C\lambda^3\int\limits_\Omega [h]^2\alpha^2 dx - C_2\int\limits_\Omega \left(|\bigtriangledown h|^2 + [h]^2\right)\alpha^2 dx.$$

Hence, for sufficiently large $\lambda \geq \lambda_0 = \lambda_0\left(\Omega, \omega, N, K_1, K_2\right)$, we obtain

$$J_\lambda(S+h) - J_\lambda(S) - J_\lambda'(S)(h) \geq \frac{C}{2\lambda}\sum_{i,i=1}^{3}\int\limits_\Omega \left[h_{x_ix_j}\right]^2\alpha^2 dx$$

$$+C_2\lambda\int\limits_\Omega [\bigtriangledown h]^2\alpha^2 dx + C_2\lambda^3\int\limits_\Omega [h]^2\alpha^2 dx.$$

Let $\sigma = \max\limits_{\overline{\Omega}} \psi(x)$. Then, the last inequality leads to

$$J_\lambda(S+h) - J_\lambda(S) - J_\lambda'(S)(h) \geq \frac{C_2}{\lambda}\exp[2\lambda\sigma^{-\nu}] \parallel h \parallel_{H^2(\Omega)}^2 = C_1 \parallel h \parallel_{H^2(\Omega)}^2 . \qquad \square$$

Remark. A minor concern can be raised about how to keep H^3-norms of function S bounded (since $S \in K_2 \subset H^3(\Omega)$) while only the H^2-norm of h is involved in this theorem. One can argue, however, that in practical computations one could work with the finite-dimensional approximations of S, where all norms are equivalent in the finite-dimensional spaces.

4. Carleman estimate.

One can find the conventional Carleman estimates in the books [3, 4, 7]. In particular, these estimates were obtained in [3, 4] for very general differential operators, including elliptic ones. The main difference between our case and the conventional one is that we integrate over the *whole* domain Ω, Dirichlet data are given on the whole boundary $\partial\Omega$, and Neumann data are given on its *part* ω only, whereas in the conventional case, either the integration is carried out over a *part* of Ω adjacent with ω (and both Dirichlet and Neumann data are given at ω only as in [7]) or the integration is carried out over the whole domain Ω (and *both* Dirichlet and Neumann data are given at the *whole* boundary $\partial\Omega$, as in [3, 4]). This difference makes it necessary for us to carefully evaluate boundary terms arising after applying the Gaussian formula. Therefore, the major difference between our case and the conventional one lies in the method of evaluation of the boundary terms.

One of the most convenient methods of the derivation of the Carleman estimates which allows one to deal with the nonzero boundary terms is the method of [7]. So, our proof essentially follows [7]. The only two differences are in the analysis of the nonzero boundary conditions and second-order derivatives.

THEOREM 4.1. *There exist sufficiently large positive numbers λ_0, ν_0 depending only on Ω, w_1, and x_0 (see the beginning of section 3 about x_0) such that the following Carleman estimate is valid for $\nu = \nu_0$, for all $\lambda \geq \lambda_0$, and for all functions $u \in H_0^2(\Omega)$:*

$$\int\limits_{\Omega} (\triangle u)^2 \alpha^2 dx \geq \frac{C}{\lambda} \int\limits_{\Omega} \sum_{i,j=1}^{3} \left(u_{x_i x_j}\right)^2 \alpha^2 dx$$
$$+C\lambda \int\limits_{\Omega} | \bigtriangledown u|^2 \alpha^2 dx + C\lambda^3 \int\limits_{\Omega} u^2 \alpha^2 dx,$$

where the positive constant C depends on Ω, ω_1, and x_0 only.

Remark. By a slight modification of the proof of this result, we show that one can choose any $\nu \geq \nu_0$, rather that just fix $\nu = \nu_0$. This leads to an obvious slight change of Theorem 3.1.

Proof. Without loss of generality, we assume that $x_0 = 0$. Let $v(x) = u(x)\alpha(x)$; then $u = v \exp[-\lambda\psi^{-\nu}]$. Hence,

$$\begin{aligned} u_{x_i} &= (v_{x_i} + 2\lambda\nu x_i \psi^{-\nu-1} v) \exp[-\lambda\psi^{-\nu}], \\ u_{x_i x_i} &= \left\{v_{x_i x_i} + 4\lambda\nu x_i \psi^{-\nu-1} v_{x_i} \right. \\ &\quad \left. + \left(2\lambda^2\nu^2 x_i^2 \psi^{-2v-2} + \lambda\nu\psi^{-\nu-1} - \lambda\nu(\nu+1) x_i^2 \psi^{-\nu-2}\right) v\right\} \exp[-\lambda\psi^{-\nu}]. \end{aligned}$$

Hence,

$$(4.1)\ (\triangle u)^2 \psi^{\nu+1} \alpha^2 = \left[\triangle v + 4\lambda\nu\psi^{-\nu-1} \sum_{i=1}^{3} x_i v_{x_i} + 4\lambda^2\nu^2\psi^{-2\nu-2} |x|^2 (1+\gamma) v\right]^2 .$$

In what follows, $\gamma = \gamma(x, \lambda, \nu)$ will denote different $C^1(\overline{\Omega})$-functions such that

$$\lim_{\lambda,\nu\to\infty} \| \gamma(x,\lambda,\nu) \|_{C^1(\overline{\Omega})} = 0.$$

Let

$$z_1 = \triangle v,\ z_2 = 4\lambda\nu\psi^{-\nu-1}\sum_{i=1}^{3} x_i v_{x_i},$$

and

$$z_3 = 4\lambda^2\nu^2\psi^{-2\nu-2}|x|^2(1+\gamma)v. \tag{4.2}$$

Then (4.1) leads to

$$(\triangle u)^2\psi^{\nu+1}\alpha^2 = [(z_1+z_3)+z_2]^2\psi^{\nu+1} \geq 2z_2(z_1+z_3)\psi^{\nu+1}. \tag{4.3}$$

First, we estimate $2z_1z_2\psi^{\nu+1}$. Note that

$$8\lambda\nu x_i v_{x_i} \triangle v = 8\lambda\nu\sum_{j=1}^{3} v_{x_jx_j}v_{x_i}x_i$$

$$=\sum_{j=1}^{3}\frac{\partial}{\partial x_j}\left(8\lambda\nu x_i v_{x_j}v_{x_i}\right) - \sum_{j=1}^{3} 8\lambda\nu v_{x_j}v_{x_ix_j}x_i - 8\lambda\nu v_{x_i}^2$$

$$=\sum_{j=1}^{3}\frac{\partial}{\partial x_j}(8\lambda\nu x_i v_{x_j}v_{x_i}) + \frac{\partial}{\partial x_i}(-4\lambda\nu x_i|\bigtriangledown v|^2) + 4\lambda\nu|\bigtriangledown v|^2 - 8\lambda\nu v_{x_i}^2.$$

Hence,

$$8\lambda\nu x_i v_{x_i} \triangle v = 4\lambda\nu|\bigtriangledown v|^2 - 8\lambda\nu v_{x_i}^2 + \sum_{j=1}^{3}\frac{\partial}{\partial x_i}\left(8\lambda\nu x_i v_{x_j}v_{x_i}\right) + \frac{\partial}{\partial x_i}(-4\lambda\nu x_i|\bigtriangledown v|^2).$$

Therefore,

$$2z_1z_2\psi^{\nu+1} = 8\lambda\nu\sum_{i=1}^{3} x_i v_{x_i} \triangle v$$

$$= 4\lambda\nu|\bigtriangledown v|^2 + \sum_{j=1}^{3}\frac{\partial}{\partial x_j}\left(8\lambda\nu v_{x_j}\sum_{i=1}^{3} x_i v_{x_i}\right) + \sum_{i=1}^{3}\frac{\partial}{\partial x_i}(-4\lambda\nu x_i|\bigtriangledown v|^2). \tag{4.4}$$

Second, we estimate $2z_2z_3\psi^{\nu+1}$.

$$2z_2z_3\psi^{\nu+1} = 32\lambda^3\nu^3|x|^2\psi^{-2\nu-2}(1+\gamma)\sum_{i=1}^{3} x_i v_{x_i} v$$

$$=\sum_{i=1}^{3}\frac{\partial}{\partial x_i}\left[16\lambda^3\nu^3\psi^{-2\nu-2}|x|^2(1+\gamma)v^2\right] + 32\lambda^3\nu^3(\nu+1)\psi^{-2\nu-3}|x|^2(1+\gamma)v^2.$$

Therefore, (4.1)–(4.4) and the last inequality imply that

$$(\triangle u)^2\psi^{\nu+1}\alpha^2 \geq 4\lambda\nu|\bigtriangledown v|^2 + 32\lambda^3\nu^3(\nu+1)\psi^{-2\nu-3}|x|^2(1+\gamma)v^2$$

$$+\sum_{j=1}^{3}\frac{\partial}{\partial x_j}\left(8\lambda\nu v_{x_i}\sum_{i=1}^{3}x_i v_{x_i}\right)$$

$$+\sum_{i=1}^{3}\frac{\partial}{\partial x_i}[-4\lambda\nu x_i|\bigtriangledown v|^2 + 16\lambda^3\nu^3\psi^{-2\nu-2}|x|^2(1+\gamma)v^2].$$

Integrating this inequality over Ω and using the fact that $v|_{\partial\Omega}=0$, we obtain, for sufficiently large ν and λ,

$$\int\limits_{\Omega}(\triangle u)^2\psi^{\nu+1}\alpha^2 dx \geq 4\lambda\nu\int\limits_{\Omega}|\bigtriangledown v|^2 dx + 30\lambda^3\nu^3(\nu+1)\int\limits_{\Omega}\psi^{-2\nu-3}|x|^2v^2dx \tag{4.5}$$

$$+\int\limits_{\omega}\left[8\lambda\nu\frac{\partial v}{\partial n}\sum_{i=1}^{3}x_iv_{x_i} - 4\lambda\nu|x|\cos(n,x)|\bigtriangledown v|^2\right]ds.$$

Let $T(x)$ be the tangent plane to ω at the point $x \in \omega$. Introduce the local orthonormal coordinate system with the center at the point $x \in \omega$. The first two coordinate vectors of this system are $s_1(x), s_2(x) \in T(x)$, and the third one is the outward normal vector $n(x)$. Then

$$\sum_{i=1}^{3}x_iv_{x_i}|_\omega = |x|\left[\frac{\partial v}{\partial n}\cos(n,x)+\sum_{i=1}^{3}\frac{\partial v}{\partial s_k}\cos(s_k,x)\right]_\omega,$$

where $\frac{\partial}{\partial s_k}$ is the directional derivative. Because $v|_{\partial\Omega}=0$,

$$\sum_{i=1}^{3}x_iv_{x_i}\;|_\omega = |x|\cos(n,x)\frac{\partial v}{\partial n}\bigg|_\omega. \tag{4.6}$$

Further,

$$|\bigtriangledown v|^2|_\omega = \left[\left(\frac{\partial v}{\partial n}\right)^2 + \sum_{i=1}^{3}\left(\frac{\partial v}{\partial s_k}\right)^2\right]|_\omega = \left(\frac{\partial v}{\partial n}\right)^2|_\omega. \tag{4.7}$$

Hence (4.1), (4.6), and (4.7) imply that

$$\int\limits_{\omega}\left[8\lambda\nu\frac{\partial v}{\partial n}\sum_{i=1}^{3}x_iv_{x_i} - 4\lambda\nu|x|\cos(n,x)|\bigtriangledown v|^2\right]ds$$

$$= 4\lambda\nu\int\limits_{\omega}|x|\cos(n,x)\left(\frac{\partial v}{\partial n}\right)^2ds. \tag{4.8}$$

But since $\cos(n,x)\geq 0$ on $\partial\Omega\backslash\omega_1$ and $\cos(n,x)<0$ on ω_1, (4.8) leads to

$$4\lambda\nu\int\limits_{\omega}|x|\cos(n,x)\left(\frac{\partial v}{\partial n}\right)^2ds \geq 2\lambda\nu\int\limits_{\omega_1}|x|\cos(n,x)\left(\frac{\partial v}{\partial n}\right)^2ds. \tag{4.9}$$

However, since $\frac{\partial v}{\partial n}|_{\omega_1=0}$, the integral in the right-hand side of (4.9) equals zero. Hence, (4.5), (4.8), and (4.9) lead to

$$\int\limits_{\Omega}(\triangle v)^2\psi^{\nu+1}\alpha^2dx \geq C\lambda\nu\int\limits_{\Omega}|\bigtriangledown v|^2\alpha^2dx + C\lambda^3\nu^4\int\limits_{\Omega}v^2\alpha^2dx.$$

Replacing v with u and using the fact that $\nu^4 >> \nu^3$ and $\psi^{\nu+1} < 1$, we obtain

$$\int\limits_{\Omega}(\triangle u)^2\alpha^2dx \geq \int\limits_{\Omega}(\triangle u)^2\psi^{\nu+1}\alpha^2dx$$

$$\geq C\lambda\nu\int\limits_{\Omega}|\bigtriangledown u|^2\alpha^2dx + C\lambda^3\nu^4\int\limits_{\Omega}u^2\alpha^2dx. \tag{4.10}$$

The estimate (4.10), however, does not include the second-order derivatives $u_{x_ix_j}$ in its right-hand side. In order to incorporate them, we refer first to the following classical inequality for the elliptic operators in convex bounded domains Ω (cf. [6]):

$$\int\limits_{\Omega}(\triangle w)^2dx \geq C\int\limits_{\Omega}\sum_{i,j=1}^{3}(w_{x_ix_j})^2dx, \tag{4.11}$$

which is valid for all functions $w \in H^2(\Omega)$ such that $w|_{\omega} = 0$. Further, (4.1) and (4.3) imply that

$$(\triangle u)^2\psi^{\nu+1}\alpha^2 \geq [2z_2(z_1+z_3) + z_1^2 + 2z_1z_3]\psi^{\nu+1}. \tag{4.12}$$

The first bracket term of the right-hand side of (4.12) was already estimated. Below, we will estimate z_1^2 and $2z_1z_3$. To do this, we fix sufficiently large $\nu = \nu_0 = \nu_0(\Omega, \omega_1, x_0)$.

Now we estimate $2z_1z_3\psi^{\nu+1}$. Let $\nu = \nu_0$ and $\lambda \geq \lambda_0$. Similar to the above, we obtain

$$\int\limits_{\Omega}2z_1z_3\psi^{\nu+1}dx \geq -C\lambda^2\int\limits_{\Omega}|\bigtriangledown u|^2\alpha^2dx - C\lambda^3\int\limits_{\Omega}u^2\alpha^2dx. \tag{4.13}$$

Since $\psi \geq \frac{1}{4}$, then $\psi^{\nu+1} = \psi^{\nu_0+1} \geq C$. Hence, (4.11) implies that

$$\int\limits_{\Omega}z_1^2\psi^{\nu+1}dx \geq \left(\frac{1}{4}\right)^{\nu_0+1}\int\limits_{\Omega}(\triangle v)^2dx \geq C\int\limits_{\Omega}\sum_{i,j=1}^{3}(v_{x_ix_j})^2dx.$$

Replacing $v(x)$ in the latter estimate with $u(x)$, we obtain

$$\begin{aligned}\int\limits_{\Omega}z_1^2\psi^{\nu+1}dx \geq C\int\limits_{\Omega}\alpha^2\sum_{i,j=1}^{3}(u_{x_ix_j})^2dx \\ -C\lambda^2\int\limits_{\Omega}|\bigtriangledown u|^2\alpha^2dx - C\lambda^4\int\limits_{\Omega}u^2\alpha^2dx.\end{aligned} \tag{4.14}$$

Further, as we have already proven above, at least

$$\int\limits_{\Omega} 2z_2(z_1+z_3)dx \geq 0.$$

Hence, combining (4.12), (4.13), and (4.14), we obtain

$$\frac{1}{\lambda}\int\limits_{\Omega} (\triangle u)^2\alpha^2 dx \geq \frac{C}{\lambda}\int\limits_{\Omega} \alpha^2 \sum_{i,j=1}^{3} u^2_{x_i x_j} dx$$
$$-C\lambda \int\limits_{\Omega} |\bigtriangledown u|^2\alpha^2 dx - C\lambda^3 \int\limits_{\Omega} u^2\alpha^2 dx.$$

Finally, an obvious combination of the latter estimate with (4.10) leads to

$$\int\limits_{\Omega} (\triangle u)^2\alpha^2 dx \geq \frac{C}{\lambda}\int\limits_{\Omega} \alpha^2 \sum_{i,j=1}^{3} (u_{x_i x_j})^2 dx$$
$$+C\lambda \int\limits_{\Omega} |\bigtriangledown u|^2\alpha^2 dx + C\lambda^3 \int\limits_{\Omega} u^2\alpha^2 dx. \qquad \square$$

5. Discussion. Because of the exponential decay of the Carleman's weight $\alpha(x)$, the major impact in the cost functional J_λ is provided by a small neighborhood $\Omega(x_1) \subset \Omega$ of the point $x_1 \in \omega_1$ closest with x_0. Hence, the data at $\partial\Omega\backslash\omega$ are not really important for J_λ. Therefore, in fact, CWM can work with the backscattering data only. In this case, one needs the Dirichlet data on $\partial\Omega\backslash\omega$ to "bound" the solution. Hence, one does not need to know these data with good precision. By changing x_0, one can cover, by such neighborhoods, a small layer adjacent with ω. Thus, CWM can be considered as a stable layer stripping procedure: $\alpha(x)$ together with the "nonprecise" Dirichlet data at $\partial\Omega\backslash\omega$ provide a stabilization.

Since J_λ is uniformly strictly convex on K_2, then a global convergence on K_2 for a number of standard minimization techniques is guaranteed, which hopefully should lead to an effective numerical implementation(s) of this technique. The crucial point is that in such an implementation, one would not face the problem of local minima.

The major price for these attractive features of CWM consists of predetermination of the number N, which is a regularization parameter. In other words, we work with the Galerkin method without allowing $N \to \infty$. In our opinion, this is acceptable for practical computations. We also note that an increase of N could lead to nonstable algorithms; cf. [1, p. 86] for a similar conclusion. Finally, if one would be able to prove convergence of this method for $N \to \infty$, then one would almost certainly prove a global uniqueness result for this ISP, which is a long-standing problem [4, 8, 9].

THE INVERSE CONDUCTIVITY PROBLEM WITH ONE MEASUREMENT: STABILITY AND ESTIMATION OF SIZE*

HYEONBAE KANG[†], JIN KEUN SEO[‡], AND DONGWOO SHEEN[§]

Abstract. We consider the inverse problem to the refraction problem $\mathrm{div}((1+(k-1)\chi_D)\nabla u) = 0$ in Ω and $\frac{\partial u}{\partial \nu} = g$ on $\partial\Omega$. The inverse problem is to determine the size and the location of an unknown object D from the boundary measurement $\Lambda_D(g) = u|_{\partial\Omega}$. The results of this paper are twofold: stability and estimation of size of D. We first obtain upper and lower bounds of the size of D by comparing $\Lambda_D(g)$ with the Dirichlet data corresponding to the harmonic equation with the same Neumann data g. We then obtain logarithmic stability in the case of the disks. In the course of deriving the stability, we are able to compute a positive lower bound (independent of D) of the gradient of the solution u to the refraction problem with the Neumann data g satisfying some mild conditions.

1. Introduction.

Let Ω be a bounded, simply connected domain in $\mathbb{R}^n$ and let D be a subdomain compactly contained in Ω. Let $k \neq 1$ be a positive number and put $\mu = k - 1$. In this paper we consider the inverse problem to the following Neumann problem:

$$P[D,g] \quad \begin{cases} \mathrm{div}((1+\mu\chi_D)\nabla u) = 0 & \text{in } \Omega, \\ \dfrac{\partial u}{\partial \nu} = g \quad \text{on } \partial\Omega, & \displaystyle\int_{\partial\Omega} u = 0, \quad \int_{\partial\Omega} g = 0, \quad g \in L^2(\partial\Omega), \end{cases}$$

where ν is the unit outward normal vector to the boundary $\partial\Omega$. By setting

$$u^e = u|_{\Omega\setminus\overline{D}} \quad \text{and} \quad u^i = u|_D, \tag{1.1}$$

the equation $\mathrm{div}((1+\mu\chi_D)\nabla u) = 0$ may be written as

$$\Delta u^e = 0 \quad \text{in } \Omega \setminus \overline{D}, \tag{1.2}$$

$$\Delta u^i = 0 \quad \text{in } D, \tag{1.3}$$

$$u^e = u^i \quad \text{on } \partial D, \tag{1.4}$$

$$\frac{\partial u^e}{\partial \nu} = k\frac{\partial u^i}{\partial \nu} \quad \text{on } \partial D. \tag{1.5}$$

The inverse problem determines the size and the location of an unknown object D from the boundary measurement $u|_{\partial\Omega} = \Lambda_D(g)$. Practically, it determines D by applying an electric current flux g to $\partial\Omega$ and measures the corresponding electric voltage $\Lambda_D(g)$ on $\partial\Omega$.

Because of its potential of various applications, the inverse conductivity problem has been attracting much attention lately. The uniqueness of the inverse conductivity problem with one (or two) measurement has been studied in many works such as [AIP, BFS, FI, IP, KS, S]. However, there are still plenty of questions to be answered. There are also some works on the stability question [BF, FG, BFI]. The question of the stability estimate is to establish the following kind of inequality:

$$d(D_1, D_2) \leq \psi(\|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^2(\partial\Omega)}),$$

where $d(D_1, D_2)$ is a distance (e.g., the Hausdorff distance) between D_1 and D_2 and ψ is a function such that $\psi(t) \to 0$ as $t \to 0$. In the paper [BFI], Bellout, Friedman, and Isakov obtained a local stability result with $\psi(t) = Ct$ when $n = 2$ under the assumption that D_1 is a small perturbation of D_2. Without this assumption (i.e., nonlocal), however, no stability estimate for the nonmonotone case has been known.

In this paper, we obtain an estimate of the size of D (in any dimension) without a priori knowledge of the shape of D or and logarithmic stability in the case of two-dimensional disks.

We show that the size of an arbitrary subdomain D of any dimension can be calculated approximately from the boundary measurement (Theorem 3.1). More precisely, we find upper and lower bounds of D in terms of the conductivity k and the quantity $\int_{\partial\Omega}(h - \Lambda_D(g))g d\sigma$, where h is the solution of the Neumann problem $P[\emptyset, g]$, i.e., $\Delta h = 0$ in Ω and $\frac{\partial h}{\partial \nu} = g$ on $\partial\Omega$. In one dimension, where Ω is an interval and D is a subinterval of Ω, one can see via simple computations that

$$\frac{k}{k-1}\int_{\partial\Omega}(h - u) g d\sigma = \|g\|^2_{L^2(\partial\Omega)}|D|.$$

Here, $|D|$ is the Lebesgue size of D. We extend this estimation to higher dimensions in the sense of upper and lower bounds.

We then turn our attention to a theoretical study of the stability in the case of disks of dimension two. In $\mathbb{R}^2$, we suppose that the Neumann data g satisfies the following conditions:

(N1) There exists a positive number M such that $|g'(P)| > M$ if $|g(P)| < M$, $P \in \partial\Omega$. (Here, g' means the tangential derivative on $\partial\Omega$.)

(N2) $\{P \in \partial\Omega : g(P) \geq 0\}$ and $\{P \in \partial\Omega : g(P) \leq 0\}$ are nonempty connected subsets of $\partial\Omega$.

Let us call these conditions the condition (N). Condition (N1) means that g is rather steep if g is small, while (N2) means that g changes sign only twice on $\partial\Omega$. There are a lot of functions g satisfying the condition (N). For example, when Ω is a disk, $g(P) = \langle \vec{v}, \nu_P \rangle$ with a nonzero constant vector $\vec{v}$ satisfies this condition with $M = |\vec{v}|/2$.

In this paper we find a positive lower bound of $|\nabla u|$ which depends only on the conductivity k and M in (N1) when g satisfies the condition (N) (Theorem 4.1). This is one of the key observations required to derive results from this paper. Based on this observation, we prove that if D_1 and D_2 are disks and $\|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^2(\partial\Omega)}$ is small, then $|D_1 \setminus D_2|$ and $|D_2 \setminus D_1|$ are comparable (see Corollary 4.4). We then prove in Theorem 5.1 the following logarithmic stability for disks:

$$|D_1 \Delta D_2| \leq C \left|\log \|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^2(\partial\Omega)}\right|^{-1/\alpha}. \tag{1.6}$$

Here, $|D_1 \Delta D_2|$ is the measure of the symmetric difference of D_1 and D_2 and α is the number determined by the angle between ∂D_1 and ∂D_2 at the intersection points. Let us briefly explain how we obtain (1.6). Let u_j be the solution of $P[D_j, g]$ $(j = 1, 2)$. From the fact that $\|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^2(\partial\Omega)}$ is small, we can show that

$$|u_1 - u_2| \text{ is small in } D_1 \cap D_2, \tag{1.7}$$

$$|\nabla(u_1 - u_2)| \text{ is small outside } D_1 \cup D_2 \tag{1.8}$$

(see Proposition 5.2). We then derive (1.6) using the transmission condition (1.5) on ∂D. Note that in one dimension, where the uniqueness let alone the stability for the inverse conductivity problem does not hold, one can see that (1.7) does not hold while (1.8) is still true.

This paper is organized as follows. In section 2 we review the representation formula for the solution to the refraction problem in [KS]. In section 3 the size estimation of D is derived. In section 4 we prove that $|\nabla u|$ has a positive lower bound if g satisfies the condition (N) and D is a disk. The logarithmic stability of disks is derived in section 5.

The constants C appearing in estimates may vary on each occurrence. However, they are independent of the quantities to be estimated.

2. Representation of the solution to the refraction problem.

In this section we review the representation formula for the refraction problem $P[D, g]$ obtained in [KS]. Let Ω be a simply connected bounded Lipschitz domain in $\mathbb{R}^n$ and let D be a simply connected subdomain with Lipschitz boundary which is compactly contained in Ω. The single layer potential on D is defined by

$$\mathcal{S}_D f(X) = \int_{\partial D} \Gamma(X - Q) f(Q) d\sigma_Q, \qquad X \in \mathbb{R}^n,$$

where $\Gamma(X)$ is the fundamental solution of Δ:

$$\Gamma(X - Q) = \begin{cases} \dfrac{1}{2\pi} \ln|X - Q|, & n = 2, \\ \dfrac{1}{(2-n)\omega_n} |X - Q|^{2-n}, & n \geq 3, \end{cases}$$

and $d\sigma$ is the surface measure. Here ω_n is the area of the unit sphere. Let

$$\mathcal{K}_D^* f(P) = \frac{1}{\omega_n} \int_{\partial D} \frac{\langle \nu_P, P - Q \rangle}{|P - Q|^n} f(Q) d\sigma_Q$$

and $\mathcal{K}_D$ be the dual of $\mathcal{K}_D^*$. The following trace formula is well known (see [F] or [FJR]):

$$\frac{\partial}{\partial \nu} \mathcal{S}_D^{\pm} f(P) := \lim_{t \to 0^+} \langle \nu_P, \nabla \mathcal{S}_D f(P \pm t\nu_P) \rangle = \left(\pm \frac{1}{2} I + \mathcal{K}_D^* \right) f(P) \qquad (P \in \partial D). \tag{2.1}$$

Throughout this paper, $\nabla \mathcal{S}_D^+ f$ and $\nabla \mathcal{S}_D^- f$ denote the restrictions of the gradient of $\mathcal{S}_D f$ to ∂D from the exterior and interior of D, respectively.

Let $L_0^2(\partial\Omega) = \{f \in L^2(\partial\Omega) : \int_{\partial\Omega} f d\sigma = 0\}$. Then the representation formula in [KS] is as follows.

Theorem 2.1 (see [KS]). *If u is a weak solution to the Neumann problem $P[D, g]$, then there are a unique harmonic function $H \in W^{1,2}(\Omega)$ and a density function $\varphi_D \in L_0^2(\partial D)$ such that u can be expressed as*

$$u(X) = H(X) + \mathcal{S}_D \varphi_D(X) \quad \textit{for } X \in \Omega. \tag{2.2}$$

Moreover, if $f = u|_{\partial\Omega}$,

$$H(X) = \mathcal{S}_\Omega \left(-g + \frac{\partial}{\partial\nu} \mathcal{U}_\Omega^+ f|_{\partial\Omega} \right) + c_f \tag{2.3}$$

and

$$\left(\frac{k+1}{2(k-1)} I - \mathcal{K}_D^* \right) \varphi_D = \frac{\partial H}{\partial \nu}|_{\partial D} \qquad \text{on } \partial D, \tag{2.4}$$

where

$$\mathcal{U}_\Omega f(X) = \frac{1}{\omega_n} \int_{\partial\Omega} \frac{\langle Q - X, \nu_Q \rangle}{|X-Q|^n} \left(-\frac{1}{2} I + \mathcal{K}_\Omega \right)^{-1} (f - c_f)(Q) d\sigma_Q, \tag{2.5}$$

$c_f = \int_{\partial\Omega} f \eta_0 d\sigma$, *and* η_0 *is the basis of the null space of* $-\frac{1}{2}I + \mathcal{K}_\Omega^*$ *such that* $\int_{\partial\Omega} \eta_0 d\sigma = 1$.

Note that (2.5) is the solution of the exterior Dirichlet problem $\Delta u = 0$ in $\mathbb{R}^n \setminus \overline{\Omega}$ and $u = f - c_f$ on $\partial\Omega$. Moreover, φ_D satisfies

$$\varphi_D = (k-1) \frac{\partial u^i}{\partial \nu} = \frac{k-1}{k} \frac{\partial u^e}{\partial \nu}. \tag{2.6}$$

When D is a disk, it is known that

$$\mathcal{K}_D^* \varphi(P) = \frac{1}{4\pi r} \int_{\partial D} \varphi(Q) d\sigma_Q \qquad \text{for every } P \in \partial D \tag{2.7}$$

(see [KS]). Therefore, by (2.2), (2.4), and (2.6), we have

$$u = H + \frac{1}{\lambda} \mathcal{S}_D \left(\frac{\partial H}{\partial \nu} \right), \qquad \lambda = \frac{k+1}{2(k-1)}. \tag{2.8}$$

In particular, we have

$$u(X) = \left(1 - \frac{1}{2\lambda} \right) H(X) + \frac{1}{2\lambda} H(X_0), \qquad X \in D, \tag{2.9}$$

where X_0 is the center of D. In fact, by the trace formula (2.1) and (2.7), we have

$$\frac{\partial u}{\partial \nu} = \left(1 - \frac{1}{2\lambda} \right) \frac{\partial H}{\partial \nu}$$

and $u(X_0) = H(X_0)$. Equation (2.9) follows from the uniqueness of the Neumann problem.

3. Size estimations of the unknown object. In this section the domain Ω is contained in $\mathbb{R}^n$ ($n \geq 2$). Let D be a subdomain (not necessarily simply connected) of Ω. Let u_D be the solution of $P[D, g]$, and let h be the solution of $P[\emptyset, g]$, i.e., the harmonic function in Ω with the Neumann boundary data g on $\partial\Omega$ and $\int_{\partial\Omega} h d\sigma = 0$. Put $\mu = k - 1$ as before. For this section we choose the Neumann data g so that the corresponding harmonic function h satisfies

$$\inf_{x \in \Omega} |\nabla h(x)| > 0.$$

There are plenty of Neumann data g which satisfy the above condition: in any dimension, choose, for example, $g(x) = \langle \vec{v}, \nu(x) \rangle$, where $\vec{v}$ is a constant vector. In two dimensions, if g satisfies the condition (N), then the corresponding h satisfies

$$\inf_{x \in \Omega} |\nabla h(x)| > CM,$$

where C is a positive constant depending only on $\partial\Omega$ and the constant M comes from the condition (N1). (See the remark following Theorem 4.1.) The main result of this section is the following theorem.

THEOREM 3.1. *Let u_D and h be as above. Put $C_1 = (\sup_{x \in \Omega} |\nabla h(x)|)^{-2}$ and $C_2 = (\inf_{x \in \Omega} |\nabla h(x)|)^{-2}$. Let*

$$E_D(g) = \left| \int_{\partial\Omega} (h - \Lambda_D(g)) g d\sigma \right|.$$

If $k > 1$, then

$$C_1 \frac{1}{k-1} E_D(g) \le |D| \le C_2 \frac{(\sqrt{k-1}+1)^2}{k-1} E_D(g),$$

and if $0 < k < 1$, then

$$C_1 \frac{(1-\sqrt{1-k})^2}{1-k} E_D(g) \le |D| \le C_2 \frac{1}{1-k} E_D(g).$$

In particular, if $g = \langle \vec{v}, \nu(\cdot) \rangle$, where $\vec{v}$ is an unit constant vector, then $C_1 = C_2 = 1$.

Remark 3.2. Before proving Theorem 3.1, we give an explicit computation of $|D|$ which illustrates the relationship between $|D|$ and $E_D(g)$ when $\Omega = B_1(0)$ and $D = B_d(0)$ in $\mathbb{R}^2$. Here $B_r(x)$ is the disk of radius r centered at x. Let us construct the solution u_D to the refraction problem $P[D, g]$ with $g = \cos\theta$. Using the representation formula (2.8), put

$$u_D = H + \frac{1}{\lambda} \mathcal{S}_D \left(\frac{\partial H}{\partial \nu} \right), \qquad \lambda = \frac{k+1}{2(k-1)},$$

and $H(X) = \alpha x_1 = \alpha r \cos\theta$ (α is a constant to be chosen later). Then, by the trace formula (2.1) and the uniqueness of the Neumann problem, one can see that

$$\frac{1}{\lambda} \mathcal{S}_D \left(\frac{\partial H}{\partial \nu} \right) = \begin{cases} -\dfrac{k-1}{k+1} \alpha r \cos\theta & \text{if } 0 \le r \le d, \\ -\dfrac{k-1}{k+1} \dfrac{\alpha d^2}{r} \cos\theta & \text{if } d < r < 1. \end{cases}$$

Therefore,

$$u_D = \alpha \left(r - \frac{k-1}{k+1} \frac{d^2}{r} \right) \cos\theta \qquad \text{in } \Omega \setminus D.$$

If we choose $\alpha = \frac{k+1}{(k+1)+(k-1)d^2}$, then u_D is the desired solution and

$$\Lambda_D(g) = \frac{(k+1)-(k-1)d^2}{(k+1)+(k-1)d^2} \cos\theta.$$

It is easy to see that $h = r\cos\theta$ is the solution to the harmonic equation with the Neumann data g. Finally, we have

$$\int_{\partial\Omega}(h - \Lambda_D(g))gd\sigma = \frac{2(k-1)}{(k+1)+(k-1)d^2}|D|.$$

LEMMA 3.3. *Let D_j be a domain in Ω and let u_j be the solution of $P[D_j, g]$ $(j = 1, 2)$. Then*

$$\begin{aligned}\int_\Omega (1+\mu\chi_{D_1})|\nabla(u_1-u_2)|^2dx &+ \mu\int_{D_2\setminus D_1}|\nabla u_2|^2dx \\ &= \int_{\partial\Omega}(\Lambda_{D_1}(g) - \Lambda_{D_2}(g))gd\sigma + \mu\int_{D_1\setminus D_2}|\nabla u_2|^2dx.\end{aligned} \tag{3.1}$$

Proof. Since u_1 and u_2 have the same Neumann boundary data g on $\partial\Omega$,

$$\int_\Omega (1+\mu\chi_{D_1})\nabla u_1\nabla\eta dx = \int_\Omega (1+\mu\chi_{D_2})\nabla u_2\nabla\eta dx$$

and hence

$$\int_\Omega (1+\mu\chi_{D_1})\nabla(u_1-u_2)\nabla\eta dx = \mu\int_\Omega (\chi_{D_2}-\chi_{D_1})\nabla u_2\nabla\eta dx \tag{3.2}$$

for every test function $\eta \in W^{1,2}(\Omega)$. Substituting $\eta = u_1$ in (3.2) and integrating by parts, we have

$$\int_{\partial\Omega}(\Lambda_{D_1}(g) - \Lambda_{D_2}(g))gd\sigma = \mu\int_\Omega (\chi_{D_2}-\chi_{D_1})\nabla u_2\nabla u_1 dx, \tag{3.3}$$

while the substitution $\eta = u_1 - u_2$ in (3.2) yields

$$\begin{aligned}&\int_\Omega (1+\mu\chi_{D_1})|\nabla(u_1-u_2)|^2dx \\ &\quad = \mu\int_\Omega (\chi_{D_1}-\chi_{D_2})|\nabla u_2|^2dx + \mu\int_\Omega (\chi_{D_2}-\chi_{D_1})\nabla u_2\nabla u_1 dx.\end{aligned} \tag{3.4}$$

Then Lemma 3.3 follows from (3.3) and (3.4). □

Proof of Theorem 3.1. Note that (3.1) holds even when one of $D_j, j = 1, 2$, is an empty set. Therefore, formula (3.1) with $D_1 = D$ and $D_2 = \emptyset$ leads to

$$\int_\Omega (1+\mu\chi_D)|\nabla(u_D-h)|^2dx - \mu\int_D|\nabla h|^2dx = -\int_{\partial\Omega}(h-\Lambda_D(g))gd\sigma, \tag{3.5}$$

and with $D_1 = \emptyset$ and $D_2 = D$ it leads to

$$\int_\Omega |\nabla(u_D-h)|^2dx + \mu\int_D|\nabla u_D|^2dx = \int_{\partial\Omega}(h-\Lambda_D(g))gd\sigma. \tag{3.6}$$

Suppose first that $k > 1$, i.e., $\mu > 0$. Notice that by (3.6),

$$\int_{\partial\Omega}(h-\Lambda_D(g))gd\sigma > 0.$$

It then follows from (3.5) that

$$\int_{\partial\Omega}(h-\Lambda_D(g))gd\sigma \le \mu\int_D |\nabla h|^2 dx \le \frac{1}{C_1}\mu|D|.$$

On the other hand, by (3.6), we have for any positive ϵ

$$\begin{aligned} |D| &\le C_2\int_D |\nabla h|^2 dx \\ &\le C_2\left[(1+\epsilon)\int_D |\nabla(u_D-h)|^2dx + \left(1+\frac{1}{\epsilon}\right)\int_D |\nabla u_D|^2 dx\right] \\ &\le C_2\alpha(\epsilon;\mu)\int_{\partial\Omega}(h-\Lambda_D(g))gd\sigma, \end{aligned}$$

where $\alpha(\epsilon;\mu) = 1+\epsilon+\mu^{-1}(1+\epsilon^{-1})$. $\alpha(\epsilon;\mu)$ has its minimum value when $\epsilon = \frac{1}{\sqrt{\mu}}$, and in this case we have

$$|D| \le C_2\frac{(\sqrt{\mu}+1)^2}{\mu}\int_{\partial\Omega}(h-\Lambda_D(g))gd\sigma.$$

We now suppose that $k<1$. Then $-1<\mu<0$. It readily follows from (3.5) that

$$\int_{\partial\Omega}(h-\Lambda_D(g))gd\sigma < 0.$$

We then have from (3.5) that

$$|D| \le C_2\int_D |\nabla h|^2 dx \le C_2\frac{1}{-\mu}\int_{\partial\Omega}(\Lambda_D(g)-h)g\,d\sigma.$$

From (3.6), we see that

$$\int_{\partial\Omega}(\Lambda_D(g)-h)gd\sigma \le -\mu\int_D |\nabla u_D|^2 dx.$$

For every $\epsilon>0$, we obtain from (3.6) that

$$\begin{aligned} \int_D |\nabla u_D|^2 dx &\le (1+\epsilon)\int_D |\nabla(u_D-h)|^2 dx + (1+\epsilon^{-1})\int_D |\nabla h|^2 dx \\ &\le (1+\epsilon)(-\mu)\int_D |\nabla u_D|^2 dx + (1+\epsilon^{-1})\int_D |\nabla h|^2 dx, \end{aligned}$$

which implies that

$$\int_D |\nabla u_D|^2 dx \le \beta(\epsilon;\mu)\int_D |\nabla h|^2 dx,$$

where $\beta(\epsilon;\mu) = \frac{1+\epsilon^{-1}}{1+\mu(1+\epsilon)}$. The minimum of $\beta(\epsilon;\mu)$ with the function value being positive occurs when $\epsilon+1 = 1/\sqrt{-\mu}$, and in this case one has

$$\int_D |\nabla u_D|^2 dx \le \frac{1}{(1-\sqrt{-\mu})^2}\int_D |\nabla h|^2 dx.$$

It then follows that

$$\int_{\partial\Omega}(\Lambda_D(g)-h)gd\sigma \le \frac{-\mu}{(1-\sqrt{-\mu})^2}\int_D |\nabla h|^2 dx \le \frac{1}{C_1}\frac{-\mu}{(1-\sqrt{-\mu})^2}|D|.$$

This completes the proof. □

4. Lower bound of $|\nabla u|$. In this and the next section, D is a *disk* in $\mathbb{R}^2$. In this section, we prove that if u is the solution of $P[D, g]$ where g satisfies the condition (N), then $|\nabla u|$ has a positive lower bound independent of the disk D. We also prove that $|\nabla u|$ has an upper bound independent of D provided that D is at some distance from $\partial\Omega$.

THEOREM 4.1. *Let u be the solution of $P[D, g]$ with g satisfying the condition* (N). *There exists $C_k > 0$ depending only on the conductivity k (particularly independent of D) such that*

$$\inf_{X\in\Omega} |\nabla u(X)| > C_k M.$$

Here M is the number in the condition (N1).

Remark. The above theorem holds even when D is an empty set.

The proof of Theorem 4.1 will be based on the following lemma.

LEMMA 4.2. *Suppose that $D = B_{r_0}(X_0)$. Put $e_1 = (1, 0)$ and $e_2 = (0, 1)$ and let ν be the normal vector field to ∂D. For $j = 1, 2$, let*

$$v_j(X) = \langle e_j, X\rangle + \frac{1}{\lambda}\mathcal{S}_D(\langle e_j, \nu\rangle)(X), \qquad X \in \mathbb{R}^2.$$

Then, v_j $(j = 1, 2)$ satisfies $\operatorname{div}((1 + \mu\chi_D)\nabla v_j) = 0$ *and*

(4.1)
$$\begin{pmatrix}\nabla v_1(X)\\ \nabla v_2(X)\end{pmatrix} = \begin{cases} I - \dfrac{k-1}{k+1} I & \text{if } X \in D,\\ I + \dfrac{k-1}{k+1}\dfrac{r_0^2}{|X - X_0|^2}\begin{pmatrix}\cos 2\theta & \sin 2\theta\\ \sin 2\theta & -\cos 2\theta\end{pmatrix} & \text{if } X \in \mathbb{R}^2 \setminus \overline{D},\end{cases}$$

where I is the identity matrix and $(\sin\theta, \cos\theta) = \frac{X - X_0}{|X-X_0|}$. *In particular,*

$$\left|\begin{matrix}\nabla v_1(X)\\ \nabla v_2(X)\end{matrix}\right| = \begin{cases} \dfrac{4}{(k+1)^2} & \text{if } X \in D,\\ 1 - \left(\dfrac{k-1}{k+1}\dfrac{r_0^2}{|X-X_0|^2}\right)^2 & \text{if } X \in \mathbb{R}^2 \setminus \overline{D},\end{cases}$$

and hence the matrix $(\nabla v_1, \nabla v_2)^t$ is invertible at every point in $\mathbb{R}^2$.

Proof. That v_j satisfies $\operatorname{div}((1 + \mu\chi_D)\nabla v_j) = 0$ is proved in [KS, Lemma 3.3]. Recall that

$$\mathcal{S}_D(\langle e_j, \nu\rangle)(X) = \frac{1}{2\pi}\int_{\partial D} \log|X - Q| \frac{\langle e_j, Q - X_0\rangle}{|Q - X_0|} d\sigma_Q$$

is harmonic in $\mathbb{R}^2 \setminus \partial D$. Put $e(\theta) = X_0 + r_0(\cos\theta, \sin\theta)$. Then, $\nu(e(\theta)) = (\cos\theta, \sin\theta)$ and the tangential vector field $T(e(\theta)) = (-\sin\theta, \cos\theta)$. By the trace formula (2.1) and (2.7), we have

$$\frac{\partial}{\partial\nu}\mathcal{S}_D^{\pm}(\langle e_j, \nu\rangle)(e(\theta)) = \left(\pm\frac{1}{2}I + \mathcal{K}_D^*\right)(\langle e_j, \nu\rangle)(e(\theta)) = \pm\frac{1}{2}\langle e_j, \nu\rangle(e(\theta)). \tag{4.2}$$

It is well known (see [FJR]) that

$$\frac{\partial}{\partial T}\mathcal{S}_D^{+}(\langle e_j, \nu\rangle)(e(\theta)) = \frac{\partial}{\partial T}\mathcal{S}_D^{-}(\langle e_j, \nu\rangle)(e(\theta)). \tag{4.3}$$

It then follows from (4.2) that

$$\nabla \mathcal{S}_D(\langle e_j, \nu\rangle)(X) = -\frac{1}{2} e_j \qquad \text{if } X \in D. \tag{4.4}$$

We also have from (4.3) and (4.4) that

$$\begin{aligned}\nabla \mathcal{S}_D^+(\langle e_1, \nu\rangle)(e(\theta)) &= \langle \nabla \mathcal{S}_D^+(\langle e_1, \nu\rangle), \nu\rangle \nu(e(\theta)) + \langle \nabla \mathcal{S}_D^+(\langle e_1, \nu\rangle), T\rangle T(e(\theta))\\ &= \frac{1}{2}\cos\theta\ \nu(e(\theta)) + \frac{1}{2}\sin\theta\ T(e(\theta))\\ &= \frac{1}{2}(\cos 2\theta, \sin 2\theta).\end{aligned}$$

In the same way, we have

$$\nabla \mathcal{S}_D^+(\langle e_2, \nu\rangle)(e(\theta)) = \frac{1}{2}(\sin 2\theta, -\cos 2\theta).$$

It follows from the uniqueness of the interior and exterior Neumann problem for the harmonic equation that

$$\nabla \mathcal{S}_D(\langle e_1, \nu\rangle)(X) = \begin{cases} -\dfrac{1}{2} e_1 & \text{if } X \in D,\\[2ex] \dfrac{r_0^2}{2|X - X_0|^2}(\cos 2\theta, \sin 2\theta) & \text{if } X \in \mathbb{R}^2 \setminus \overline{D}\end{cases}$$

and

$$\nabla \mathcal{S}_D(\langle e_2, \nu\rangle)(X) = \begin{cases} -\dfrac{1}{2} e_2 & \text{if } X \in D,\\[2ex] \dfrac{r_0^2}{2|X - X_0|^2}(\sin 2\theta, -\cos 2\theta) & \text{if } X \in \mathbb{R}^2 \setminus \overline{D},\end{cases}$$

where $(\cos\theta, \sin\theta) = \frac{X - X_0}{|X - X_0|}$.

Therefore, we have (4.1) and Lemma 4.2 follows. This completes the proof. □

Proof of Theorem 4.1. For a small number $\epsilon > 0$, we can choose $Y_0 \in \Omega \setminus \partial D$ so that

$$|\nabla u(Y_0)| = (1 + \epsilon) \inf_{X \in \Omega \setminus \partial D} |\nabla u(X)|.$$

(Note that by the condition (N2) $\inf_{X \in \Omega\setminus\partial D} |\nabla u(X)| > 0$ (see [AM] or [S]).) By Lemma 4.2, we can choose (a, b) so that

$$\nabla u(Y_0) = a \nabla v_1(Y_0) + b \nabla v_2(Y_0).$$

By (4.1), there is a positive constant C_1 depending only on k such that

$$|(a, b)| \le C_1 |\nabla u(Y_0)|. \tag{4.5}$$

From (4.1) and (4.5), there is a positive constant C_0 depending only on k such that

$$\left| a\frac{\partial v_1}{\partial \nu} + b\frac{\partial v_2}{\partial \nu}\right| \le C_0 |\nabla u(Y_0)|, \tag{4.6}$$

$$\left| \left(a\frac{\partial v_1}{\partial \nu} + b\frac{\partial v_2}{\partial \nu}\right)'\right| \le C_0 |\nabla u(Y_0)| \tag{4.7}$$

for every $X \in \partial\Omega$. Here, $'$ denotes the tangential derivative on $\partial\Omega$. We will show that

$$|\nabla u(Y_0)| > \frac{M}{C_0}.$$

Suppose this is not true. Put

$$\omega(X) = u(X) - av_1(X) - bv_2(X).$$

Then ω satisfies the equation $\operatorname{div}((1+\mu\chi_D)\nabla\omega) = 0$ with the Neumann data

$$\frac{\partial\omega}{\partial\nu} = g - a\frac{\partial v_1}{\partial\nu} - b\frac{\partial v_2}{\partial\nu}.$$

Put

$$I^+ = \{P \in \partial\Omega : g(P) > M\} \quad \text{and} \quad I^- = \{P \in \partial\Omega : g(P) < -M\}.$$

Then, if $P \in \partial\Omega \setminus (I^+ \cup I^-)$, then by the condition $(N1)$, $|g'(P)| > M$ and hence

$$\left|\left(\frac{\partial\omega}{\partial\nu}\right)'(P)\right| \geq |g'(P)| - \left|\left(a\frac{\partial v_1}{\partial\nu} + b\frac{\partial v_2}{\partial\nu}\right)'(P)\right| > M - C_0\frac{M}{C_0} = 0.$$

Therefore, on the set $\partial\Omega \setminus (I^+ \cup I^-)$, $\frac{\partial w}{\partial\nu}$ is strictly monotone. On the other hand, if $P \in I^+$, then

$$\frac{\partial\omega}{\partial\nu}(P) \geq g(P) - \left|\left(a\frac{\partial v_1}{\partial\nu} + b\frac{\partial v_2}{\partial\nu}\right)'(P)\right| > M - C_0\frac{M}{C_0} = 0.$$

Likewise, if $P \in I^-$, then

$$\frac{\partial\omega}{\partial\nu}(P) < 0.$$

Put

$$\partial\Omega \setminus (I^+ \cup I^-) = \cup_{j=1}^m J_j,$$

where J_j are mutually disjoint connected arcs. Since $\frac{\partial\omega}{\partial\nu}$ is monotone on each J_j, if both endpoints of J_j lie in $\overline{I^+}$, then $\frac{\partial\omega}{\partial\nu} > 0$ on J_j. Similarly, if both endpoints of J_j lie in $\overline{I^-}$, then $\frac{\partial\omega}{\partial\nu} < 0$ on J_j. If one endpoint of J_j lies in $\overline{I^+}$ and the other endpoint lies in $\overline{I^-}$, then $\frac{\partial\omega}{\partial\nu}$ changes sign only once on J_j. Since $\{P \in \partial\Omega : g(P) \leq 0\}$ is connected by the condition (N2), we obtain that

$$\left\{P \in \partial\Omega : \frac{\partial\omega}{\partial\nu}(P) \leq 0\right\} \quad \text{is a connected subset of } \partial\Omega.$$

However, since $\nabla\omega(Y_0) = 0$,

$$\left\{P \in \partial\Omega : \frac{\partial\omega}{\partial\nu}(P) \leq 0\right\} \text{ is a disconnected subset of } \partial\Omega.$$

(For this, see [AM].) This gives a contradiction and the proof is complete. □

Although the following lemma is proved in a standard argument, we include a proof for the reader's sake.

LEMMA 4.3. *Let D be a disk in Ω such that $dist(D, \partial\Omega) > \delta$, and let u be the solution to $P[D, g]$. Then there exists $C = C(\delta, k, \Omega, \|g\|_{L^2(\partial\Omega)})$ such that*

$$\sup_{X \in D} |\nabla u(X)| < C.$$

Proof. Let H be the harmonic part of u in the representation (2.2). Then, by (2.9),

$$\nabla u(X) = \left(1 - \frac{1}{2\lambda}\right) \nabla H(X), \qquad X \in D.$$

Since $|\nabla H|$ is subharmonic and $\mathrm{dist}(D, \partial\Omega) > \delta$, we have, for $X \in D$,

$$\begin{aligned} |\nabla H(X)|^2 &\le C_\delta \int_\Omega |\nabla H|^2 dY \\ &= C_\delta \left[- \int_\Omega H \Delta H dY + \int_{\partial\Omega} H \frac{\partial H}{\partial \nu} d\sigma \right] \\ &\le C_\delta \left(\int_{\partial\Omega} \left| \frac{\partial H}{\partial \nu} \right|^2 d\sigma \right)^{1/2} \left(\int_{\partial\Omega} |H|^2 d\sigma \right)^{1/2}. \end{aligned}$$

By (2.1) and (2.3), one sees that

$$\frac{\partial H}{\partial \nu} = \Big(-\frac{1}{2} I + \mathcal{K}_\Omega^* \Big) \Big(-g + \frac{\partial}{\partial \nu} \mathcal{U}_\Omega^+ f|_{\partial\Omega} \Big).$$

Recall that $\mathcal{K}_\Omega^*$ is bounded on $L^2(\partial\Omega)$ and $\mathcal{U}_\Omega$ is bounded on $W^{1,2}(\partial\Omega)$ (see [V]). Moreover, by the Rellich identity,

$$C_1 \left\| \frac{\partial}{\partial T} \mathcal{U}_\Omega f \right\|_{L^2(\partial\Omega)} \le \left\| \frac{\partial}{\partial \nu} \mathcal{U}_\Omega^+ f \right\|_{L^2(\partial\Omega)} \le C_2 \left\| \frac{\partial}{\partial T} \mathcal{U}_\Omega f \right\|_{L^2(\partial\Omega)}$$

for some constant C_1 and C_2 (see [V]). Therefore, we have

$$\left\| \frac{\partial H}{\partial \nu} \right\|_{L^2(\partial\Omega)} \le C \left(\|g\|_{L^2(\partial\Omega)} + \|f\|_{L^2(\partial\Omega)} + \|\frac{\partial f}{\partial T}\|_{L^2(\partial\Omega)} \right).$$

Since $\int_{\partial\Omega} f d\sigma = 0$, it follows from the Poincaré inequality and the Rellich identity again that

$$\|f\|_{L^2(\partial\Omega)} \le C \left\| \frac{\partial f}{\partial T} \right\|_{L^2(\partial\Omega)} \le C \|g\|_{L^2(\partial\Omega)}.$$

It is easy to show that

$$\|H\|_{L^2(\partial\Omega)} \le C \|g\|_{L^2(\partial\Omega)}.$$

In conclusion, we have

$$|\nabla H(X)| \le C(\delta, \Omega, k) \|g\|_{L^2(\partial\Omega)}.$$

This completes the proof. □

As a consequence of Theorem 4.1 and Lemma 4.3, we have the following corollary.

COROLLARY 4.4. *Let D_1 and D_2 be disks in Ω such that dist$(D_j, \partial\Omega) > \delta, j = 1, 2$ for some δ. Then there exist constants C_1 and C_2 such that if $\|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^2(\partial\Omega)} \le \epsilon$, then*

$$C_1(|D_2 \backslash D_1| + \epsilon) \le |D_1 \backslash D_2| + \epsilon \le C_2(|D_2 \backslash D_1| + \epsilon).$$

Proof. Without loss of generality, assume that $k > 1$. By Theorem 4.1, Lemma 4.3, and identity (3.1),

$$|D_2 \setminus D_1| \le C \left(\|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^2(\partial\Omega)} + |D_1 \setminus D_2| \right).$$

Since (2.1) is symmetric in D_1 and D_2, we simply switch the roles of D_1 and D_2 to obtain the other inequality. This completes the proof. □

5. Stability of disks. In this section we prove logarithmic stability of the disk. Throughout this section let $\Omega_0 = \{X \in \Omega : \text{dist}(X, \partial\Omega) \ge \delta_0\}$ for some fixed $\delta_0 > 0$.

THEOREM 5.1. *Let D_1 and D_2 be disks in Ω_0. Suppose that*

$$|D_1 \cap D_2| \ge \mu_0 \min(|D_1|, |D_2|) \tag{5.1}$$

for some $\mu_0 > 0$. Let g be a Neumann data with the condition (N)*. Then there exists a constant C such that*

$$|D_1 \Delta D_2| \le C \left|\log \|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^2(\partial\Omega)}\right|^{-\frac{(3\pi\mu_0)^{1/3}}{\pi}}.$$

Let θ_0 be the angle between ∂D_1 and ∂D_2 at the points of the intersection $\partial D_1 \cap \partial D_2$. Then it is easy to see from elementary geometry of circles that if (5.1) holds, then

$$\theta_0 \ge (3\pi\mu_0)^{1/3}. \tag{5.2}$$

(In fact, assuming that $|D_1| \le |D_2|$, we let $\theta (\le \theta_0)$ be the angle between the tangent line to ∂D_1 at one of the intersection points and the line connecting two intersection points of ∂D_1 and ∂D_2. Then one can see $\theta - \sin\theta \ge \frac{1}{2}\mu_0\pi$.) Therefore, to each point $X \in \Omega \setminus (D_1 \cup D_2)$ there exists a cone $\Gamma(X)$ lying entirely in $\mathbb{R}^2 \setminus (D_1 \cup D_2)$ with the corner at X and the aperture θ_0. Put $\alpha = \pi/\theta_0$.

PROPOSITION 5.2. *Let μ_0 and α be as above. Then there exists a constant C such that if $\|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^2(\partial\Omega)} = \epsilon$, then*

$$\sup_{\Omega_0} |u_1 - u_2| \le C|\log\epsilon|^{-1/\alpha}, \tag{5.3}$$

$$\sup_{\Omega_0 \setminus (D_1 \cup D_2)} |\nabla(u_1^e - u_2^e)| \le C|\log\epsilon|^{-1/\alpha}, \tag{5.4}$$

$$\sup_{D_1 \cap D_2} |\nabla(u_1^i - u_2^i)| \le C\epsilon. \tag{5.5}$$

In order to prove Proposition 5.2, we need the following Lindelöf-type lemma. A similar idea has been used in [A].

Lemma 5.3. *Let z_0 and θ_0 be fixed and let*

$$\Gamma = z_0 + \left\{ re^{i\theta} : 0 < r < 2\rho,\ \theta_0 < \theta < \theta_0 + \frac{\pi}{\alpha} \right\}$$

for some $1 \le \alpha$ and $\rho > 0$. Suppose that ϕ is a holomorphic function in Γ satisfying

$$\begin{cases} \sup\limits_{z \in \Gamma, |z - z_0| \le 2\rho} (|\phi(z)| + |\phi'(z)|) \le L, \\ |\phi(z)| \le \epsilon \quad \text{for all } z \in \Gamma \cap \{\rho \le |z - z_0| \le 2\rho\}. \end{cases}$$

Then there exists C depending only on L such that if $0 \le r < \rho$, then

$$|\phi(z_0 + re^{i\theta})| \le C\epsilon^{(r/\rho)^\alpha \sin \alpha\theta} |\log \epsilon|^{(-1 + (r/\rho)^\alpha)/\alpha}. \tag{5.6}$$

In particular,

$$|\phi(z_0 + re^{i\frac{\pi}{2\alpha}})| \le C\epsilon^{(r/\rho)^\alpha} |\log \epsilon|^{(-1 + (r/\rho)^\alpha)/\alpha}, \tag{5.7}$$

and

$$|\phi(0)| \le C |\log \epsilon|^{-1/\alpha}. \tag{5.8}$$

Proof. Without loss of generality, we may assume that $z_0 = 0$, $\theta_0 = 0$, $\rho = 1$, and $L = 1$. Put $\mathcal{S} = \{re^{i\theta} : 0 < r < 1,\ 0 < \theta < \frac{\pi}{\alpha}\}$. Suppose that w is the harmonic function in Γ with the boundary condition

$$w = 1 \text{ on } \overline{\mathcal{S}} \cap \{|z| = 1\} \quad \text{and} \quad w = 0 \text{ on } \partial\mathcal{S} \setminus \{|z| = 1\}.$$

It follows from the maximum principle that

$$r^\alpha \sin(\alpha\theta) \le w(re^{i\theta}) \le r^\alpha.$$

Note that

$$\log |\phi(z)| \le w(z) \log \epsilon + (1 - w(z)) \log M \quad \text{for all } z \in \partial\mathcal{S},$$

where $M = \sup_{z \in \mathcal{S}} |\phi(z)| \le 1$. By the maximum principle,

$$|\phi(z)| \le \epsilon^{w(z)} M^{1 - w(z)}, \quad z \in \mathcal{S}. \tag{5.9}$$

By the hypothesis, we have

$$|\phi(0)| \le |\phi(re^{i\frac{\pi}{2\alpha}})| + \int_0^r |\phi'(se^{i\frac{\pi}{2\alpha}})| ds \le |\phi(re^{i\frac{\pi}{2\alpha}})| + r,$$

and hence

$$|\phi(0)| \le \epsilon^{r^\alpha} + r \quad \text{for all } 0 < r < 1.$$

By choosing $r^\alpha = \frac{\log |\log \epsilon|}{|\log \epsilon|}$, we get

$$|\phi(0)| \le C |\log \epsilon|^{-1/\alpha}.$$

For any point $z \in \partial\Gamma$ with $|z| \le 1$, we can repeat the above argument with the subsector $\mathcal{S}_z \subset \Gamma$ with the corner at z and congruent to $\mathcal{S}$ to obtain

$$|\phi(z)| \le C|\log \epsilon|^{-1/\alpha}.$$

Therefore,

$$M \le C|\log \epsilon|^{-1/\alpha}.$$

The desired estimates follow from (5.9) and the proof is complete. □

Proof of Proposition 5.2. By the representation formula (2.8), $u_j = H_j + \mathcal{S}_j\varphi_j$ $(j = 1, 2)$, where $\varphi_j = \frac{1}{\lambda}\frac{\partial H_j}{\partial \nu}|_{\partial D_j}$. If we put $f_j = \Lambda_{D_1}(g)$, it follows from (2.3) and a standard argument (see [V]) that

$$\begin{aligned}\|H_1 - H_2\|_{L^2(\partial\Omega)} &= \left\| S_\Omega \left(\frac{\partial}{\partial\nu} U_\Omega(\Lambda_{D_1}(g) - \Lambda_{D_2}(g)) \right) \right\|_{L^2(\partial\Omega)} + C|c_{f_1} - c_{f_2}| \\ &\le C(\|U_\Omega(\Lambda_{D_1}(g) - \Lambda_{D_2}(g))\|_{L^2(\partial\Omega)} + \epsilon) \\ &\le C(\|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^2(\partial\Omega)} + \epsilon) \\ &\le C\epsilon,\end{aligned}$$

where C depends only on the Lipschitz character of $\partial\Omega$. By standard interior estimates, we have

$$\|H_1 - H_2\|_{L^\infty(\Omega_0)} + \|\nabla(H_1 - H_2)\|_{L^\infty(\Omega_0)} \le C\epsilon. \tag{5.10}$$

So, to prove (5.3), it suffices to show that

$$\|\mathcal{S}_1\varphi_1 - \mathcal{S}_2\varphi_2\|_{L^\infty(\Omega_0)} \le C|\log \epsilon|^{-1/\alpha}. \tag{5.11}$$

Set $W = \mathcal{S}_1\varphi_1 - \mathcal{S}_2\varphi_2$. Then $W \in C(\mathbb{R}^2)$ and it is easy to check that W satisfies the following:

$$\Delta W = 0 \quad \text{in } \mathbb{R}^2 \setminus (\partial D_1 \cup \partial D_2), \tag{5.12}$$

$$\|W\|_{L^2(\partial\Omega)} \le \|H_1 - H_2\|_{L^2(\partial\Omega)} + \|u_1 - u_2\|_{L^2(\partial\Omega)} \le C\epsilon, \tag{5.13}$$

$$|W(X)| + |X||\nabla W(X)| = O(|X|^{-1}) \quad \text{as } |X| \to \infty. \tag{5.14}$$

By the representation formulas (2.8) and (2.9) for the disk, we have

$$|\nabla W(X)| = \frac{1}{2|\lambda|}|\nabla(H_1 - H_2)(X)| \le C\epsilon \quad \text{for every } X \in D_1 \cap D_2. \tag{5.15}$$

Equation (5.5) follows from (5.10) and (5.15). We also have from (2.3) that

$$\sup_{\mathbb{R}^2 \setminus \overline{D_1 \cup D_2}} (|W| + |\nabla W| + |\nabla\nabla W|) \le C(\|H_1\|_{L^2(\Omega)} + \|H_2\|_{L^2(\Omega)}) \le C. \tag{5.16}$$

Since

$$\int_{\mathbb{R}^2 \setminus \Omega} |\nabla W|^2 \le \int_{\partial\Omega} |W||\nabla W| \le C\epsilon$$

by (5.12)–(5.14), we have from the standard interior estimate that

$$\sup_{\{X \in \mathbb{R}^2 : \text{dist}(X,\Omega) \ge 1\}} (|W(X)| + |\nabla W(X)|) \le C\epsilon. \tag{5.17}$$

Therefore, (5.11) follows from the maximum principle, (5.12), (5.15), and the following inequality, still to be proved:

$$\sup_{P\in\partial(D_1\cup D_2)} |W(P)| \le C|\log\epsilon|^{-1/\alpha}. \tag{5.18}$$

To prove (5.18), for each $P \in \partial(D_1 \cup D_2)$, let $\Gamma(P)$ be a cone lying entirely in $\mathbb{R}^2 \setminus D_1 \cup D_2$ with the corner at P and the aperture greater than θ_0 given in (5.2). Let P_1 be a point in $\Gamma(P)$ such that the line joining P and P_1 bisects $\Gamma(P)$ and $\mathrm{dist}(P_1, \Omega) \ge 1$. We claim that

$$|\nabla W(tP + (1-t)P_1)| \le C\epsilon^{t^\alpha}|\log\epsilon|^{(-1+t^\alpha)/\alpha}, \qquad 0 < t < 1. \tag{5.19}$$

In fact, $\phi := W_x - iW_y$ is a holomorphic function in the cone $\Gamma(P)$, $\|\phi\|_{C^1} \le C$ on the bounded subset of $\Gamma(P)$ by (5.16), and, by (5.17),

$$\sup_{X\in\Gamma(P),\mathrm{dist}(X,\Omega)\ge 1} |\phi(X)| \le C\epsilon. \tag{5.20}$$

Thus (5.19) follows from (5.7). By (5.17) and (5.19) we have

$$\begin{aligned}
|W(P)| &\le |W(P_1)| + \int_0^1 \left|\frac{\partial}{\partial t}W(tP + (1-t)P_1)\right| dt \\
&\le C\epsilon + |P - P_1| \int_0^1 |\nabla W(tP + (1-t)P_1)| dt \\
&\le C\epsilon + |\log\epsilon|^{-1/\alpha} \int_0^1 \epsilon^{t^\alpha}|\log\epsilon|^{t^\alpha/\alpha} dt \\
&\le C|\log\epsilon|^{-1/\alpha}.
\end{aligned}$$

This proves (5.18).

Equation (5.8) also says that

$$\sup_{P\in\partial(D_1\cup D_2)} |\phi(P)| \le C|\log\epsilon|^{-1/\alpha}. \tag{5.21}$$

Thus, (5.4) follows from (5.20), (5.21), and the maximum principle. This completes the proof. □

Proof of Theorem 5.1. Put $\|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^2(\partial\Omega)} = \epsilon$. Then it follows from (5.4) and the transmission condition (1.5) that

$$\begin{aligned}
\frac{\partial}{\partial\nu}(u_1^i - u_2^e) &= \frac{\partial u_1^i}{\partial\nu} - \frac{\partial u_1^e}{\partial\nu} + \frac{\partial}{\partial\nu}(u_1^e - u_2^e) \\
&= (1-k)\frac{\partial u_1^i}{\partial\nu} + O(|\log\epsilon|^{-1/\alpha}) \quad \text{on } \partial D_1 \setminus D_2.
\end{aligned} \tag{5.22}$$

We also have from (5.5) and (1.5) that

$$\begin{aligned}
\frac{\partial}{\partial\nu}(u_1^i - u_2^e) &= \frac{\partial u_1^i}{\partial\nu} - k\frac{\partial u_1^i}{\partial\nu} + k\frac{\partial}{\partial\nu}(u_1^i - u_2^i) \\
&= (1-k)\frac{\partial u_1^i}{\partial\nu} + O(\epsilon) \quad \text{on } \partial D_2 \cap D_1,
\end{aligned} \tag{5.23}$$

where ν is the outward normal vector on $\partial(D_1 \setminus D_2)$. By the Green theorem, we have

$$\int_{D_1\setminus D_2} |\nabla(u_1-u_2)|^2 dx = \int_{\partial(D_1\setminus D_2)} \frac{\partial}{\partial\nu}(u_1^i - u_2^e)(u_1-u_2)d\sigma. \tag{5.24}$$

Thus by (5.3), (5.22), and (5.23),

$$\int_{D_1\setminus D_2} |\nabla(u_1-u_2)|^2 dx = (1-k)\int_{\partial(D_1\setminus D_2)} \frac{\partial u_1^i}{\partial\nu}(u_1-u_2)d\sigma + O(|\log\epsilon|^{-2/\alpha}).$$

Integrating by parts and using (5.22) and (5.23) again, we have

$$\begin{aligned}
&\int_{D_1\setminus D_2} |\nabla(u_1-u_2)|^2 dx \\
&= (1-k)\int_{\partial(D_1\setminus D_2)} u_1\frac{\partial}{\partial\nu}(u_1^i - u_2^e)d\sigma + O(|\log\epsilon|^{-2/\alpha}) \\
&= (1-k)^2\int_{\partial(D_1\setminus D_2)} u_1\frac{\partial u_1^i}{\partial\nu}d\sigma + O(|\log\epsilon|^{-1/\alpha}) \\
&= (1-k)^2\int_{D_1\setminus D_2} |\nabla u_1|^2 dx + O(|\log\epsilon|^{-1/\alpha}).
\end{aligned}$$

By interchanging the role of u_1 and u_2 and adding up, we have

$$\begin{aligned}
&\int_{D_1\setminus D_2} |\nabla u_1|^2 dx + \int_{D_2\setminus D_1} |\nabla u_2|^2 dx \\
&\qquad = \frac{1}{(1-k)^2}\int_{D_1\triangle D_2} |\nabla(u_1-u_2)|^2 dx + O(|\log\epsilon|^{-1/\alpha}).
\end{aligned} \tag{5.25}$$

On the other hand, (5.3) and (5.24) show that

$$\int_{D_1\Delta D_2} |\nabla(u_1-u_2)|^2 dx \le C|\log\epsilon|^{-1/\alpha}.$$

Therefore,

$$\int_{D_1\setminus D_2} |\nabla u_1|^2 dx + \int_{D_2\setminus D_1} |\nabla u_2|^2 dx = O(|\log\epsilon|^{-1/\alpha}).$$

Since $|\nabla u_1|$ and $|\nabla u_2|$ have a lower bound by Theorem 4.1, we have Theorem 5.1. This completes the proof. □

Remark. One of the main ingredients in obtaining the stability result of this paper is the estimate of the lower bound of the solution of $P[D,g]$ (see Theorem 4.1). It would be interesting to see if the same result holds in three dimensions.

ASYMPTOTIC BEHAVIOR OF SOLUTIONS OF TWO-DIMENSIONAL PERIODIC SCATTERING PROBLEMS IN ELECTROMAGNETICS[*]

URVE KANGRO[†] AND ROY NICOLAIDES[†]

Abstract. In this paper, two-dimensional electromagnetic scattering problems with a time-periodic incident field are considered. In the case of a perfect conductor scatterer with the presence of an artificial boundary, the existence of a time-periodic solution is proved. For arbitrary initial conditions, asymptotic behavior of solutions is characterized. The asymptotic solution can be represented as the time-periodic solution of the periodically forced scattering problem plus a stationary field. The source of the stationary field is explained, and equations describing it are obtained.

Key words. Maxwell equations, periodic solutions, magnetic offset, electric offset, artificial boundary

1. Introduction.

For solving scattering problems with a time-periodic incident field, the periodic solution is often obtained by introducing an artificial boundary (to limit the domain of computations), choosing arbitrary initial conditions and time-marching Maxwell's curl equations to a periodic state (see [2], [8]). One might expect that as time increases, the solution approaches the solution of the periodically forced scattering problem (the existence of which is proved in section 5). Actually, the difference between these two solutions approaches a steady state, which in general may be nonzero. For the transverse magnetic problem, the electric field is shown to converge to the expected periodic solution, while the magnetic field may have a spurious stationary component; for the transverse electric problem the situation is the opposite. We present here, with complete proofs, the results in case of the transverse magnetic problem, including the equations and the boundary conditions describing the stationary field. The transverse electric problem is briefly discussed in section 10.

Information about the spurious fields is important in practical computations since the computed fields often will be incorrect. To obtain the correct solution of the periodically forced scattering problem, some form of postprocessing is often used. In [6] we discuss some alternatives to postprocessing which enable us to get rid of the spurious stationary fields and at the same time increase the rate of convergence of the numerical methods used. The algorithms in [6] rely on the theorems presented here.

A related problem is considered in [1]. There, authors discuss the decay of solutions for a scatterer with homogeneous boundary conditions and a first-order radiation condition applied at a finite distance from the scatterer. We will solve a similar problem (see sections 6–9), but our method differs somewhat from that of [1]. For instance, we treat Lipschitz boundaries. Also, we do not require some physical compatibility conditions (e.g., the divergence condition) to be satisfied, because they might be difficult to enforce in actual calculations.

Classical work on the decay of solutions in the acoustic case (in an exterior domain) can be found in [5, Chapter 5].

2. The transverse magnetic problem. Let the scatterer be an infinitely long cylindrical perfect conductor with the axis parallel to the z-axis. We assume that the incoming field has an $\mathbf{E}$-component in the z-direction and an $\mathbf{H}$-component on the xy-plane, both independent of z. Then the scattered field satisfies the same conditions. The corresponding two-dimensional problem is called the transverse magnetic problem.

Let Γ_S be the boundary of the scatterer (on xy-plane), and let Γ be the artificial boundary. We denote the domain between these boundaries by Ω; $\mathbf{n}$ denotes the unit outer normal to Ω. Let $\mathbf{E}_i$ be the incoming electric field. Maxwell's equations for the scattered field are

$$\left\{\begin{array}{lcl} \varepsilon\dfrac{\partial \mathbf{E}}{\partial t} & = & \mathbf{curl}\ \mathbf{H} \\ \mu\dfrac{\partial \mathbf{H}}{\partial t} & = & -\mathbf{curl}\,\mathbf{E} \end{array}\right. \quad \text{in } \Omega, \tag{1}$$

with the boundary conditions

$$\begin{array}{ll} \mathbf{E} = -\mathbf{E}_i & \text{on } \Gamma_S, \\ \mathbf{E} - c\mu\mathbf{H}\times\mathbf{n} = 0 & \text{on } \Gamma, \end{array} \tag{2}$$

and the initial conditions

$$\mathbf{E}(\mathbf{x},0) = \mathbf{E}_0(\mathbf{x}), \quad \mathbf{H}(\mathbf{x},0) = \mathbf{H}_0(\mathbf{x}) \tag{3}$$

(here $\mathbf{x} = (x,y)$). We ignore the divergence conditions, since they are automatically satisfied if the initial conditions are divergence-free. Otherwise, the (nonzero) divergence is preserved in the evolution by equations (1). Since it causes no difficulties in the analysis, we prefer not to make additional assumptions about the initial conditions.

We assume that the incident field can be written in the form $\mathbf{E}_i(\mathbf{x},t) = e^{i\omega t}\widetilde{\mathbf{E}}_i(\mathbf{x})$. The initial conditions for the physical problem typically are not known, and only the periodic solution of (1), (2) of the form $\mathbf{E}(\mathbf{x},t) = e^{i\omega t}\widetilde{\mathbf{E}}(\mathbf{x})$, $\mathbf{H}(\mathbf{x},t) = e^{i\omega t}\widetilde{\mathbf{H}}(\mathbf{x})$ is of interest. To obtain the periodic solution, arbitrary initial conditions are often used, and the problem is solved on a time interval long enough to make the solution close to a periodic function. We will show below that the limiting solution, while time periodic, is generally not of the form $\mathbf{E}(\mathbf{x},t) = e^{i\omega t}\widetilde{\mathbf{E}}(\mathbf{x})$, $\mathbf{H}(\mathbf{x},t) = e^{i\omega t}\widetilde{\mathbf{H}}(\mathbf{x})$ but contains an additional static magnetic field, which is caused by "incorrect" (not satisfying certain compatibility conditions) initial conditions.

3. Preliminaries. In this section we will introduce the function spaces and a Green's formula needed later. All functions in the following are complex valued. Define the spaces

$$H^1_{0_S}(\Omega) = \{v \in H^1(\Omega) \mid v|_{\Gamma_S} = 0\}$$

equipped with the norm $|v|_1 = \|\nabla v\|_{L^2}$ (by Poincaré's inequality it is equivalent to the usual H^1-norm) and

$$H_{\mathbf{curl}}(\Omega) = \{\mathbf{u} \in L^2(\Omega)^2 \mid \mathbf{curl}\ \mathbf{u} \in L^2(\Omega)\}$$

with the norm

$$\|\mathbf{u}\|^2_{\mathbf{curl}} = \|\mathbf{u}\|^2_{L^2} + \|\mathbf{curl}\,\mathbf{u}\|^2_{L^2}.$$

We treat the functions with values in $\mathbf{C}^2$ as taking values in $\mathbf{C}^3$ where the third component is zero and the functions with values in $\mathbf{C}$ as having the first two components as zero. If Ω is bounded and the boundary of Ω is Lipschitz continuous, then the unit outer normal $\mathbf{n}$ to its boundary is defined almost everywhere; for $\mathbf{u} \in H_{\mathbf{curl}}(\Omega)$ the trace on the boundary of Ω of $\mathbf{u} \times \mathbf{n}$ is well defined and belongs to $H^{-1/2}(\Gamma \bigcup \Gamma_S)^2$; for $\mathbf{u} \in L^2(\Omega)^2$ with div $\mathbf{u} \in \text{Ł}^2(\Omega)$, the trace of $\mathbf{u} \cdot \mathbf{n}$ is in $H^{-1/2}(\Gamma \bigcup \Gamma_S)$ (see [3] for the trace theorems). The following Green's formula holds:

$$\int_\Omega (\mathbf{u} \cdot \mathbf{curl}\,\mathbf{v} - \mathbf{curl}\,\mathbf{u} \cdot \mathbf{v}) = \langle \mathbf{u} \times \mathbf{n}, \mathbf{v} \rangle_\Gamma \quad \forall \mathbf{u} \in H_{\mathbf{curl}}(\Omega) \text{ and } \forall \mathbf{v} \in H^1_{0_S}(\Omega), \tag{4}$$

where by the dot product on the left-hand side we mean the scalar product in the complex vector space and $\langle \cdot, \cdot \rangle_\Gamma$, defined in $H^{-1/2}(\Gamma) \times H^{1/2}(\Gamma)$, is the extension of the $L^2(\Gamma)$-scalar product in the sense that for $w \in L^2(\Gamma)$ we have

$$\langle w, v \rangle_\Gamma = \int_\Gamma w\overline{v} \quad \forall v \in H^{1/2}(\Gamma).$$

In $H^{1/2}(\Gamma)$ we will use the norm

$$\|\mathbf{f}\|_{H^{1/2}(\Gamma)} = \inf_{\mathbf{u} \in H^1_{0_S}(\Omega),\ \mathbf{u}|_\Gamma = \mathbf{f}} |\mathbf{u}|_1,$$

and in $H^{-1/2}(\Gamma)$ we will use the corresponding dual norm.

4. The main result. In the subsequent sections we will prove the following theorem.

THEOREM 4.1. *Assume that Ω is a bounded multiply-connected domain with a Lipschitz-continuous boundary. Let Γ be the exterior part of the boundary and let Γ_S be the interior boundary (which may consist of several pieces). Assume that the incident field $\mathbf{E}_i$ can be written in the form*

$$\mathbf{E}_i(\mathbf{x}, t) = e^{i\omega t}\widetilde{\mathbf{E}}_i(\mathbf{x}),$$

with $\widetilde{\mathbf{E}}_i \in H^2(\Omega)$ and real ω; the initial conditions satisfy $\mathbf{E}_0 \in L^2(\Omega)$ and $\mathbf{H}_0 \in L^2(\Omega)^2$. Then the solutions $\mathbf{E}$, $\mathbf{H}$ of (1)–(3) *satisfy*

$$\left.\begin{array}{l} \|\mathbf{H}(t,\cdot) - e^{i\omega t}\widetilde{\mathbf{H}}(\cdot) - \mathbf{H}^*(\cdot)\|_{L^2} \to 0 \\ \|\mathbf{E}(t,\cdot) - e^{i\omega t}\widetilde{\mathbf{E}}(\cdot)\|_{L^2} \to 0 \end{array}\right. \qquad \textit{as } t \to \infty,$$

where $e^{i\omega t}\widetilde{\mathbf{E}}(\mathbf{x})$, $e^{i\omega t}\widetilde{\mathbf{H}}(\mathbf{x})$ are unique solutions of this form of (1), (2) *(ignoring the initial conditions) and $\mathbf{H}^*$ is the unique solution of*

$$\begin{cases} \mathbf{curl}\,\mathbf{H}^* = 0, \quad \text{div } \mathbf{H}^* = \text{div } \mathbf{H}_0 & \textit{in } \Omega, \\ \mathbf{H}^* \times \mathbf{n} = 0 & \textit{on } \Gamma, \\ \mathbf{H}^* \cdot \mathbf{n} = \mathbf{H}_0 \cdot \mathbf{n} - \dfrac{1}{i\omega\mu}\mathbf{curl}\,\widetilde{\mathbf{E}}_i \cdot \mathbf{n} & \textit{on } \Gamma_S, \\ \displaystyle\int_{\Sigma_j} \mathbf{H}^* \cdot \mathbf{n} = \int_{\Sigma_j} \left(\mathbf{H}_0 \cdot \mathbf{n} - \frac{1}{i\omega\mu}\mathbf{curl}\,\widetilde{\mathbf{E}}_i \cdot \mathbf{n} \right), & j = 1, \ldots, k-1, \end{cases} \tag{5}$$

where k is the number of connectivity components of Γ_S and Σ_j, $j = 1, \dots, k-1$ are smooth lines in Ω joining the different connectivity components of Γ_S such that $\Gamma_S \cup \left(\cup_{j=1}^{k-1} \Sigma_j\right)$ is connected.

Remark. Under the assumptions of Theorem 4.1, the solution of (1)–(3) satisfies $(\mathbf{E}, \mathbf{H}) \in C([0,\infty); L^2(\Omega) \times L^2(\Omega)^2)$; it solves the integrated (in t) form of the equations (1), (2), (3), i.e., $\int_0^t \mathbf{E} \in H^1(\Omega)$, $\int_0^t \mathbf{H} \in H_{\mathbf{curl}}(\Omega)$, and

$$\varepsilon \mathbf{E} = \varepsilon \mathbf{E}_0 + \mathbf{curl} \int_0^t \mathbf{H} \ , \qquad \mu \mathbf{H} = \mu \mathbf{H}_0 - \mathbf{curl} \int_0^t \mathbf{E} \ .$$

Under the additional assumptions on initial conditions $\mathbf{E}_0 \in H^1(\Omega)$, $\mathbf{H}_0 \in H_{\mathbf{curl}}(\Omega)$ with $\mathbf{E}_0 = -\widetilde{\mathbf{E}}_i$ on Γ_S, and $\mathbf{E}_0 - \mathbf{H}_0 \times \mathbf{n} = 0$ on Γ, we have the classical solution of (1)–(3), $(\mathbf{E}, \mathbf{H}) \in C^1([0,\infty); L^2(\Omega) \times L^2(\Omega)^2) \bigcap C([0,\infty); H^1(\Omega) \times H_{\mathbf{curl}}(\Omega))$.

Idea of proof. First we show the existence of a periodic solution of (1), (2) in the form $e^{i\omega t}\widetilde{\mathbf{E}}(\mathbf{x})$, $e^{i\omega t}\widetilde{\mathbf{H}}(\mathbf{x})$. Then consider the equations for the differences

$$\mathbf{E}_d(\mathbf{x}, t) = \mathbf{E}(\mathbf{x}, t) - e^{i\omega t}\widetilde{\mathbf{E}}(\mathbf{x}), \quad \mathbf{H}_d(\mathbf{x}, t) = \mathbf{H}(\mathbf{x}, t) - e^{i\omega t}\widetilde{\mathbf{H}}(\mathbf{x}).$$

We can set up the problem in the semigroup framework and, using the fact that the electromagnetic energy is nonincreasing along the solutions, show that the solutions of (1)–(3) with the initial conditions $(\mathbf{E}_0 - \widetilde{\mathbf{E}}, \mathbf{H}_0 - \widetilde{\mathbf{H}})$ (considered as functions of t) stay inside a compact subset of $L^2(\Omega) \times L^2(\Omega)^2$. Then every sequence $(\mathbf{E}_d(t_n), \mathbf{H}_d(t_n))_{n=1}^{\infty}$ with $t_n \to \infty$ as $n \to \infty$ must have at least one accumulation point. We show that the set of all those accumulation points (the ω-limit set) consists of only one point $(0, \mathbf{H}^*)$, where $\mathbf{H}^*$ satisfies (5).

5. Existence of a periodic solution.

In this section we will prove the following result.

THEOREM 5.1. *Assume that Ω and $\mathbf{E}_i$ are as in Theorem 4.1. Then Maxwell's equations (1) together with the boundary conditions (2) have a unique time-periodic solution of the form*

$$\mathbf{E}(\mathbf{x}, t) = e^{i\omega t}\widetilde{\mathbf{E}}(\mathbf{x}), \quad \mathbf{H}(\mathbf{x}, t) = e^{i\omega t}\widetilde{\mathbf{H}}(\mathbf{x}), \tag{6}$$

where $\widetilde{\mathbf{E}} \in H^1(\Omega)$ and $\widetilde{\mathbf{H}} \in H_{\mathbf{curl}}(\Omega)$ with div $\widetilde{\mathbf{H}} = 0$.

Proof. Substituting (6) into (1), (2), eliminating $\widetilde{\mathbf{H}}$ from the equations, and dividing everything by $e^{i\omega t}$, we get the following equations for $\widetilde{\mathbf{E}}$ (note that $\mathbf{curl}\,\widetilde{\mathbf{E}} \times \mathbf{n} = \partial\widetilde{\mathbf{E}}/\partial\mathbf{n}$):

$$\begin{cases} \triangle\widetilde{\mathbf{E}} + \dfrac{\omega^2}{c^2}\widetilde{\mathbf{E}} = 0 & \text{in } \Omega, \\ \widetilde{\mathbf{E}} = -\widetilde{\mathbf{E}}_i & \text{on } \Gamma_S, \\ \dfrac{i\omega}{c}\widetilde{\mathbf{E}} + \dfrac{\partial\widetilde{\mathbf{E}}}{\partial\mathbf{n}} = 0 & \text{on } \Gamma, \end{cases} \tag{7}$$

where $c = 1/\sqrt{\varepsilon\mu}$ is the speed of light.

Since the inhomogeneous Dirichlet condition on Γ_S is not easy to handle directly, we transform the problem into a more suitable form. Let ψ be a function in $H^2(\Omega)$ satisfying $\psi = -\widetilde{\mathbf{E}}_i$ on Γ_S and $\psi \equiv 0$ in a neighborhood of Γ. Put $f = -\triangle\psi - (\omega^2/c^2)\psi$.

Then $u = \widetilde{\mathbf{E}} - \psi$ satisfies

$$\begin{cases} \triangle u + \dfrac{\omega^2}{c^2} u = f & \text{in } \Omega, \\ u = 0 & \text{on } \Gamma_S, \\ \dfrac{i\omega}{c} u + \dfrac{\partial u}{\partial \mathbf{n}} = 0 & \text{on } \Gamma. \end{cases} \tag{8}$$

To show the existence of the solution for these equations, we will first use the Lax–Milgram lemma for the equations without the term $(\omega^2/c^2)u$ to define a compact operator B (the inverse of $\triangle$ with the above boundary conditions) and then use the Fredholm alternative to invert $B + \lambda I$. Therefore, let us consider the equations

$$\begin{cases} \triangle u = g & \text{in } \Omega, \\ u = 0 & \text{on } \Gamma_S, \\ \dfrac{i\omega}{c} u + \dfrac{\partial u}{\partial \mathbf{n}} = 0 & \text{on } \Gamma, \end{cases} \tag{9}$$

with $g \in L^2(\Omega)$. The corresponding weak form asks us to find $u \in H^1_{0_S}(\Omega)$ such that

$$\int_\Omega \nabla u \cdot \nabla v + \frac{i\omega}{c} \int_\Gamma u \cdot v = -\int_\Omega g \cdot v \quad \forall v \in H^1_{0_S}(\Omega).$$

By the Lax–Milgram lemma (for complex Hilbert spaces) for any $g \in L^2(\Omega)$, there exists a unique weak solution u_g; it satisfies $|u_g|_1 \leq \|g\|_{L^2}$. Define a linear continuous operator $B : L^2(\Omega) \to L^2(\Omega)$ by $Bg = u_g$. Since B maps bounded sets of $L^2(\Omega)$ into bounded sets of $H^1_{0_S}(\Omega)$, B is a compact operator in $L^2(\Omega)$.

Now the equations (8) are equivalent to $u + (\omega^2/c^2)Bu = Bf$. By the Fredholm alternative, this equation is uniquely solvable for any right-hand side if and only if the corresponding homogeneous equation $u + (\omega^2/c^2)Bu = 0$ has only the zero solution. The weak form for the homogeneous equation asks us to find $u \in H^1_{0_S}(\Omega)$ such that

$$\int_\Omega \nabla u \cdot \nabla v - \frac{\omega^2}{c^2} \int_\Omega u \cdot v + \frac{i\omega}{c} \int_\Gamma u \cdot v = 0 \quad \forall v \in H^1_{0_S}(\Omega).$$

Substituting $v = u$ in the weak form, we find that $\int_\Gamma |u|^2 = 0$; hence $u = 0$ on Γ (recall that the dot product means the scalar product in a complex vector space). So u is a weak solution of

$$\begin{cases} \triangle u + \dfrac{\omega^2}{c^2} u = 0 & \text{in } \Omega, \\ u = 0 & \text{on } \Gamma_S, \\ u = 0, \quad \dfrac{\partial u}{\partial \mathbf{n}} = 0 & \text{on } \Gamma. \end{cases} \tag{10}$$

The conditions on Γ imply that the extension of u by zero outside Ω and across Γ is also a solution of $\triangle u + (\omega^2/c^2)u = 0$ in the sense of distributions in a larger domain. Since the eigenfunctions of the Laplacian are (real) analytic (see [4, p. 92]), it follows that u must be identically zero.

From above, it follows that (8) is uniquely solvable for any f. Let u be the solution of (8) with $f = \triangle\psi - (\omega^2/c^2)\psi$. Note that $u \in H^1_{0_S}(\Omega)$. Then $\widetilde{\mathbf{E}} = \psi + u$

is the solution of (7) with $\widetilde{\mathbf{E}} \in H^1(\Omega)$ and $\triangle\widetilde{\mathbf{E}} \in L^2(\Omega)$. Put $\widetilde{\mathbf{H}} = -(1/i\omega\mu)\mathbf{curl}\,\widetilde{\mathbf{E}}$. Then $\mathbf{curl}\,\widetilde{\mathbf{H}} \in L^2(\Omega)$ and $\operatorname{div}\widetilde{\mathbf{H}} = 0$, so $\widetilde{\mathbf{H}} \in H_{\mathbf{curl}}(\Omega)$. It is easy to see that

$$\mathbf{E}(\mathbf{x}, t) = e^{i\omega t}\widetilde{\mathbf{E}}(\mathbf{x}), \quad \mathbf{H}(\mathbf{x}, t) = e^{i\omega t}\widetilde{\mathbf{H}}(\mathbf{x})$$

satisfy Maxwell's equations (1) and the boundary conditions (2). Clearly, the solution is unique. □

6. Semigroup formulation. We will continue the proof of Theorem 4.1. In this section we will prove that the problem for the difference between the solution of (1), (2), (3) and the periodic solution $e^{i\omega t}\widetilde{\mathbf{E}}(\mathbf{x})$, $e^{i\omega t}\widetilde{\mathbf{H}}(\mathbf{x})$ can be set up in the semigroup framework. This will give us the existence and uniqueness of the solution as well as the smoothness mentioned in the remark after Theorem 4.1. In the subsequent sections we are going to use the standard tools in the semigroup theory for studying the asymptotic behavior of the solutions.

We are going to work in the state space

$$X = \{(\mathbf{E}, \mathbf{H}) \in L^2(\Omega) \times L^2(\Omega)^2\}$$

equipped with the norm

$$\|(\mathbf{E}, \mathbf{H})\|_X^2 = \varepsilon\|\mathbf{E}\|_{L^2}^2 + \mu\|\mathbf{H}\|_{L^2}^2,$$

where the corresponding inner product X is a Hilbert space. Define the operator $A : \mathcal{D}(A) \to X$ by

$$\mathcal{D}(A) = \{(\mathbf{E}, \mathbf{H}) \in H^1_{0_S}(\Omega) \times H_{\mathbf{curl}}(\Omega) \mid \mathbf{E} - c\mu\mathbf{H} \times \mathbf{n}|_\Gamma = 0\},$$

$$A(\mathbf{E}, \mathbf{H}) = \left(\frac{1}{\varepsilon}\mathbf{curl}\,\mathbf{H}, -\frac{1}{\mu}\mathbf{curl}\,\mathbf{E}\right).$$

We can write the problem for the differences

$$\mathbf{E}_d(t) = \mathbf{E}(\cdot, t) - e^{i\omega t}\widetilde{\mathbf{E}}, \quad \mathbf{H}_d(t) = \mathbf{H}(\cdot, t) - e^{i\omega t}\widetilde{\mathbf{H}}$$

(considered as functions of t with values in X) in the form

$$\text{(11)} \qquad \begin{cases} (\dot{\mathbf{E}}_d, \dot{\mathbf{H}}_d) = A(\mathbf{E}_d, \mathbf{H}_d), \\ \mathbf{E}_d(0) = \mathbf{E}_0 - \widetilde{\mathbf{E}}, \quad \mathbf{H}_d(0) = \mathbf{H}_0 - \widetilde{\mathbf{H}}. \end{cases}$$

We want to show that A generates a C_0-contraction semigroup. For this we will use the Lumer–Phillips theorem for Hilbert spaces (see [7]): *Let X be a Hilbert space*; *let $A : \mathcal{D}(A) \to X$ be a linear operator satisfying*

(i) *Re*$\langle Au, u\rangle_X \le 0$ *for all* $u \in \mathcal{D}(A)$,

(ii) $I - A$ *is surjective.*

Then A generates a linear C_0-contraction semigroup.

The first condition (energy estimate) follows from Green's formula (4):

$$\begin{aligned} \text{Re } \langle A(\mathbf{E}, \mathbf{H}), (\mathbf{E}, \mathbf{H})\rangle_X &= \text{Re} \int_\Omega \mathbf{curl}\,\mathbf{H} \cdot \mathbf{E} - \mathbf{curl}\,\mathbf{E} \cdot \mathbf{H} \\ &= -\text{Re } \langle \mathbf{H} \times \mathbf{n}, \mathbf{E}\rangle_\Gamma \\ &= -\frac{1}{c\mu}\int_\Gamma |\mathbf{E}|^2 \quad \forall(\mathbf{E}, \mathbf{H}) \in \mathcal{D}(A). \end{aligned}$$

The second condition needs more work. We have to show that for any $(\mathbf{f},\mathbf{g}) \in X$ we can find $(\mathbf{E},\mathbf{H}) \in \mathcal{D}(A)$ such that

$$\begin{cases} \mathbf{E} - \dfrac{1}{\varepsilon}\mathbf{curl}\,\mathbf{H} = \mathbf{f}, \\ \mathbf{H} + \dfrac{1}{\mu}\mathbf{curl}\,\mathbf{E} = \mathbf{g}. \end{cases}$$

Formally, by eliminating $\mathbf{H}$ we get the following equations for $\mathbf{E}$:

$$\begin{cases} \mathbf{E} + c^2\mathbf{curl}\,\mathbf{curl}\,\mathbf{E} = \mathbf{f} + \dfrac{1}{\varepsilon}\mathbf{curl}\,\mathbf{g} & \text{in } \Omega, \\ \mathbf{E} = 0 & \text{on } \Gamma_S, \\ \mathbf{E} + c\,\mathbf{curl}\,\mathbf{E} \times \mathbf{n} = c\mu\,\mathbf{g} \times \mathbf{n} & \text{on } \Gamma. \end{cases}$$

The corresponding weak form asks us to find $\mathbf{E} \in H^1_{0_S}(\Omega)$ such that

$$(12)\int_\Omega \mathbf{E}\cdot\mathbf{v} + c^2\mathbf{curl}\,\mathbf{E}\cdot\mathbf{curl}\,\mathbf{v} + c\,\langle \mathbf{E},\mathbf{v}\rangle_\Gamma = \int_\Omega \mathbf{f}\cdot\mathbf{v} + \frac{1}{\varepsilon}\mathbf{g}\cdot\mathbf{curl}\,\mathbf{v} \quad \forall \mathbf{v} \in H^1_{0_S}(\Omega).$$

Clearly, the assumptions of the Lax–Milgram lemma are satisfied, so there is a solution of (12), $\mathbf{E} \in H^1_{0_S}(\Omega)$. Put $\mathbf{H} = \mathbf{g} - (1/\mu)\ \mathbf{curl}\,\mathbf{E}$. Then $\mathbf{H} \in L^2(\Omega)^2$ and

$$\mathbf{E} - \frac{1}{\varepsilon}\mathbf{curl}\,\mathbf{H} = \mathbf{E} + c^2\mathbf{curl}\,\mathbf{curl}\,\mathbf{E} - \frac{1}{\varepsilon}\mathbf{curl}\,\mathbf{g} = \mathbf{f},$$

hence $\mathbf{H} \in H_{\mathbf{curl}}(\Omega)$. Checking the outer boundary condition, for any $\mathbf{v} \in H^1_{0_S}(\Omega)$ we have

$$\begin{aligned} \langle \mathbf{E} - c\mu\mathbf{H} \times \mathbf{n}, \mathbf{v}\rangle_\Gamma &= \int_\Gamma \mathbf{E}\cdot\mathbf{v}\ + c\mu\int_\Omega \mathbf{curl}\,\mathbf{H}\cdot\mathbf{v} - \mathbf{H}\cdot\mathbf{curl}\,\mathbf{v} \\ &= \int_\Gamma \mathbf{E}\cdot\mathbf{v}\ + c\mu\int_\Omega \varepsilon(\mathbf{E}-\mathbf{f})\cdot\mathbf{v} \\ &\quad -c\mu\int_\Omega \left(\mathbf{g} - \frac{1}{\mu}\mathbf{curl}\,\mathbf{E}\right)\cdot\mathbf{curl}\,\mathbf{v} = 0 \end{aligned}$$

by (12). Consequently, $I - A$ is surjective. From the Lumer–Phillips theorem it follows that A generates a C_0-contraction semigroup $\{T(t) \mid t \geq 0\}$ with $\|T(t)\| \leq 1\ \forall t \geq 0$.

7. Compactness of the orbits. In this section we show that for $(\mathbf{E}^0,\mathbf{H}^0) \in \mathcal{D}(A)$ the solution of (11) stays inside a compact set of X for all $t \geq 0$.

Let $(\mathbf{E}^0,\mathbf{H}^0)$ be given. The orbit through $(\mathbf{E}^0,\mathbf{H}^0)$ is

$$\gamma(\mathbf{E}^0,\mathbf{H}^0) = \{T(t)(\mathbf{E}^0,\mathbf{H}^0) \mid t \geq 0\}.$$

Equip $\mathcal{D}(A)$ with the graph norm

$$\|(\mathbf{E},\mathbf{H})\|_A = \|(\mathbf{E},\mathbf{H})\|_X + \|A(\mathbf{E},\mathbf{H})\|_X.$$

Note that the graph norm is equivalent to the norm in $H^1(\Omega) \times H_{\mathbf{curl}}(\Omega)$. In the following and also in the next section we shall assume that $(\mathbf{E}^0,\mathbf{H}^0) \in \mathcal{D}(A)$. We will remove this assumption in section 9.

Since $\{T(t) \mid t \geq 0\}$ is a contraction semigroup and A commutes with $T(t)$ on $\mathcal{D}(A)$, we have for every $(\mathbf{E}, \mathbf{H}) \in \gamma(\mathbf{E}^0, \mathbf{H}^0)$,

$$\begin{aligned}\|(\mathbf{E}, \mathbf{H})\|_A &= \|T(t)(\mathbf{E}^0, \mathbf{H}^0)\|_X + \|AT(t)(\mathbf{E}^0, \mathbf{H}^0)\|_X \\ &\leq \|(\mathbf{E}^0, \mathbf{H}^0)\|_X + \|A(\mathbf{E}^0, \mathbf{H}^0)\|_X = \|(\mathbf{E}^0, \mathbf{H}^0)\|_A.\end{aligned}$$

Consequently, $\gamma(\mathbf{E}^0, \mathbf{H}^0)$ is bounded in $H^1(\Omega) \times H_{\mathbf{curl}}(\Omega)$.

It is enough to show that the projections of $\gamma(\mathbf{E}^0, \mathbf{H}^0)$ onto $\mathbf{E}$- and $\mathbf{H}$-components have compact closures in $L^2(\Omega)$ and $L^2(\Omega)^2$, respectively. Since the $\mathbf{E}$-component stays bounded in $H^1(\Omega)$ and $H^1(\Omega)$ is compactly embedded into $L^2(\Omega)$, the first compactness is immediate. To show the compactness of $\mathrm{proj}_{\mathbf{H}}\gamma(\mathbf{E}^0, \mathbf{H}^0)$, we note that $\mathbf{E} = 0$ on Γ_S implies that

$$\mathbf{curl}\,\mathbf{E} \cdot \mathbf{n} = 0 \quad \text{on } \Gamma_S, \quad \int_{\Sigma_j} \mathbf{curl}\,\mathbf{E} \cdot \mathbf{n} = 0, \quad j = 1, \ldots, k-1,$$

and

$$\frac{d}{dt}\mathrm{div}\ \mathbf{H}(t) = 0 \ \Rightarrow \ \mathrm{div}\ \mathbf{H}(t) = \mathrm{div}\ \mathbf{H}^0.$$

Hence the normal trace of $\mathbf{H} - \mathbf{H}^0$ to Γ_S and to Σ_j makes sense, and

$$(\mathbf{H}(t) - \mathbf{H}^0) \cdot \mathbf{n} = -\frac{1}{\mu}\int_0^t \mathbf{curl}\,\mathbf{E}(\tau) \cdot \mathbf{n}\, d\tau = 0 \quad \text{on } \Gamma_S \tag{13}$$

and

$$\int_{\Sigma_j} (\mathbf{H}(t) - \mathbf{H}^0) \cdot \mathbf{n} = 0, \quad j = 1, \ldots, k-1. \tag{14}$$

Also, on Γ,

$$(\mathbf{H} - \mathbf{H}^0) \times \mathbf{n} = \frac{1}{c\mu}(\mathbf{E} - \mathbf{E}^0) \in H^{1/2}(\Gamma),$$

so the trace of $(\mathbf{H} - \mathbf{H}^0) \times \mathbf{n}$ on Γ is bounded in $H^{1/2}(\Gamma)$. Now let

$$\begin{aligned}S = \{\mathbf{G} \in H_{\mathbf{curl}}(\Omega) | \|\mathbf{G}\|_{\mathbf{curl}} \leq C, \ \|\mathbf{G} \times \mathbf{n}\|_{H^{1/2}(\Gamma)} \leq C, \ \mathrm{div}\ \mathbf{G} = 0 \text{ in } \Omega, \\ \mathbf{G} \cdot \mathbf{n} = 0 \text{ on } \Gamma_S, \ \int_{\Sigma_j} \mathbf{G} \cdot \mathbf{n} = 0, \ j = 1, \ldots, k-1\}.\end{aligned}$$

Note that $\mathbf{H} - \mathbf{H}^0 \in S$. We want to show that S is compact in $L^2(\Omega)^2$.

Suppose $\{\mathbf{G}_k\}_{k=1}^{\infty} \subset S$ is such that $\mathbf{G}_k \rightharpoonup \mathbf{G}$ (weakly) in $H_{\mathbf{curl}}(\Omega)$ as $k \to \infty$. We will show that there is a subsequence $\{\mathbf{G}_{k_l}\}_{l=1}^{\infty}$ such that $\mathbf{G}_{k_l} \to \mathbf{G}$ in $L^2(\Omega)^2$. Indeed, since div $\mathbf{G}_k = 0$ and $\mathbf{G}_k \cdot \mathbf{n} = 0$ on Γ_S, we can choose $\Phi_k \in H^1(\Omega)$ such that $\mathbf{G}_k = \mathbf{curl}\,\Phi_k$. To fix the arbitrary constant in Φ_k, we can require that $\Phi_k = 0$ on Γ_S (since $\mathbf{curl}\,\Phi_k \cdot \mathbf{n} = 0$, Φ_k is constant on each piece of Γ_S; the constants on different pieces of Γ_S must be equal because $\int_{\Sigma_j} \mathbf{curl}\,\Phi \cdot \mathbf{n} = 0$, $j = 1, \ldots, k-1$). The sequence $\{\Phi_k\}_{k=1}^{\infty}$ is bounded in $H^1(\Omega)$ (because $|\Phi_k|_1 = \|\mathbf{G}_k\|_{L^2}$), so there is a subsequence $\{\Phi_{k_l}\}_{l=1}^{\infty}$ converging weakly in $H^1(\Omega)$; the limit Φ of this sequence satisfies $\mathbf{curl}\,\Phi = \mathbf{G}$. Now we have

- $\Phi_{k_l} \to \Phi$ in $L^2(\Omega)$,
- $\Phi_{k_l}|_\Gamma \rightharpoonup \Phi|_\Gamma$ in $H^{1/2}(\Gamma)$,
- $\mathbf{G}_{k_l} \times \mathbf{n} \to \mathbf{G} \times \mathbf{n}$ in $H^{-1/2}(\Gamma)$ (because $H^{1/2}(\Gamma) \hookrightarrow\hookrightarrow H^{-1/2}(\Gamma)$).

Hence by Green's formula (4),

$$\begin{aligned}\int_\Omega \mathbf{G}_{k_l}^2 &= \int_\Omega \mathbf{G}_{k_l} \cdot \mathbf{curl}\ \Phi_{k_l}\\ &= \int_\Omega \mathbf{curl}\,\mathbf{G}_{k_l} \cdot \Phi_{k_l} + \langle \mathbf{G}_{k_l} \times \mathbf{n}, \Phi_{k_l}\rangle_\Gamma + \langle \mathbf{G}_{k_l} \times \mathbf{n}, \Phi_{k_l}\rangle_{\Gamma_S}\\ &\to \int_\Omega \mathbf{curl}\,\mathbf{G} \cdot \Phi + \langle \mathbf{G} \times \mathbf{n}, \Phi\rangle_\Gamma\\ &= \int_\Omega \mathbf{G} \cdot \mathbf{curl}\ \Phi = \int_\Omega \mathbf{G}^2.\end{aligned}$$

Since $\mathbf{G}_{k_l} \rightharpoonup \mathbf{G}$ in $L^2(\Omega)$ and $\|\mathbf{G}_{k_l}\|_{L^2(\Omega)} \to \|\mathbf{G}|_{L^2\Omega)}$ as $l \to \infty$, we have $\mathbf{G}_{k_l} \to \mathbf{G}$ in $L^2(\Omega)$. This implies that the closure of $\mathrm{proj}_\mathbf{H}\gamma(\mathbf{E}^0, \mathbf{H}^0)$ is compact in $L^2(\Omega)^2$. Consequently, the closure of the orbit $\gamma(\mathbf{E}^0, \mathbf{H}^0)$ is compact in X.

8. The $\boldsymbol{\omega}$-limit set. We will study the ω-limit set of $(\mathbf{E}^0, \mathbf{H}^0) \in \mathcal{D}(A)$ and show that it consists of only one point $(0, \mathbf{H}^*)$, where $\mathbf{H}^*$ satisfies (5).

First let us give the definition of the ω-limit set. Let $(\mathbf{E}^0, \mathbf{H}^0) \in X$ be given. The ω-limit set of $(\mathbf{E}^0, \mathbf{H}^0)$, denoted by $\omega(\mathbf{E}^0, \mathbf{H}^0)$, is the set of all $\chi \in X$ such that there exists a sequence of positive times $\{t_n\}_{n=1}^\infty$ with $t_n \to \infty$ as $n \to \infty$ such that $T(t_n)(\mathbf{E}^0, \mathbf{H}^0) \to \chi$ in X.

It is easy to see that if the closure of the orbit through $(\mathbf{E}^0, \mathbf{H}^0)$ is compact, then the ω-limit set $\omega(\mathbf{E}^0, \mathbf{H}^0)$ is nonempty, compact, connected, and invariant (i.e., $T(t)\omega(\mathbf{E}^0, \mathbf{H}^0) \subset \omega(\mathbf{E}^0, \mathbf{H}^0)$ for all $t \geq 0$). Moreover,

$$\mathrm{dist}(T(t)(\mathbf{E}^0, \mathbf{H}^0), \omega(\mathbf{E}^0, \mathbf{H}^0)) \to 0 \text{ as } t \to \infty.$$

Define $V : X \to \mathbb{R}$ by

$$V(\mathbf{E}, \mathbf{H}) = \frac{1}{2}\|(\mathbf{E}, \mathbf{H})\|_X^2.$$

($V(\mathbf{E}, \mathbf{H})$ is the electromagnetic energy.) Since the semigroup is contractive, V is a Liapunov function (nonincreasing along the solutions). Since every element of $\omega(\mathbf{E}^0, \mathbf{H}^0)$ is a limit point of a sequence of the form $T(t_n)(\mathbf{E}^0, \mathbf{H}^0)$, with $t_n \to \infty$ as $n \to \infty$, V must be constant on $\omega(\mathbf{E}^0, \mathbf{H}^0)$. For $(\mathbf{E}^0, \mathbf{H}^0) \in \mathcal{D}(A)$ we can compute

$$\begin{aligned}\frac{d}{dt}V(T(t)(\mathbf{E}^0, \mathbf{H}^0)) &= \mathrm{Re}\ \langle \dot{T}(t)(\mathbf{E}^0, \mathbf{H}^0), T(t)(\mathbf{E}^0, \mathbf{H}^0)\rangle_X\\ &= \mathrm{Re}\ \langle A(\mathbf{E}(t), \mathbf{H}(t)), (\mathbf{E}(t), \mathbf{H}(t))\rangle_X = -\frac{1}{c\mu}\int_\Gamma |\mathbf{E}(t)|^2,\end{aligned}$$

where $(\mathbf{E}(t), \mathbf{H}(t)) = T(t)(\mathbf{E}^0, \mathbf{H}^0)$.

Let $(\mathbf{E}_0^*, \mathbf{H}_0^*) \in \omega(\mathbf{E}^0, \mathbf{H}^0)$ be given. Then $(\mathbf{E}_0^*, \mathbf{H}_0^*) \in \mathcal{D}(A)$ (since $(\mathbf{E}_0^*, \mathbf{H}_0^*)$ is a limit in X of a sequence in $\mathcal{D}(A)$, bounded in the graph norm; there is in $\mathcal{D}(A)$ a weakly convergent subsequence; by the uniqueness of the limit it must converge to $(\mathbf{E}_0^*, \mathbf{H}_0^*)$). Put $(\mathbf{E}^*(t), \mathbf{H}^*(t)) = T(t)(\mathbf{E}_0^*, \mathbf{H}_0^*)$. Since $\omega(\mathbf{E}^0, \mathbf{H}^0)$ is invariant and V is constant on

$\omega(\mathbf{E}^0, \mathbf{H}^0)$, we get that $V(\mathbf{E}^*(t), \mathbf{H}^*(t))$ is constant. Hence $(d/dt)V(\mathbf{E}^*(t), \mathbf{H}^*(t)) = 0$, but this implies that $\mathbf{E}^*(t) = 0$ on Γ for all $t \geq 0$. So $(\mathbf{E}^*(t), \mathbf{H}^*(t))$ are solutions of

$$\tag{15} \begin{cases} \dot{\mathbf{E}}^*(t) = \dfrac{1}{\varepsilon}\mathbf{curl}\,\mathbf{H}^*(t), & \\ \dot{\mathbf{H}}^*(t) = -\dfrac{1}{\mu}\mathbf{curl}\,\mathbf{E}^*(t), & \\ \mathbf{E}^*(t) = 0 & \text{on } \Gamma_S, \\ \mathbf{E}^*(t) = 0, \quad \mathbf{H}^*(t) \times \mathbf{n} = 0 & \text{on } \Gamma, \\ \mathbf{E}^*(0) = \mathbf{E}_0^*, \quad \mathbf{H}^*(0) = \mathbf{H}_0^*. & \end{cases}$$

This system is overdetermined (too many boundary conditions on Γ). We will show that the only $\mathbf{E}^*$ that can satisfy these equations is zero.

Let $\mathbf{u}_k$, $k = 1, 2, \ldots$ be the orthonormal basis of $L^2(\Omega)$ consisting of the eigenfunctions of $-\triangle$ with Dirichlet boundary conditions. Let λ_k, $k = 1, 2, \ldots$ be the corresponding eigenvalues. Expand $\mathbf{E}^*(t)$ in the basis of the eigenfunctions:

$$\mathbf{E}^*(t) = \sum_{k=1}^{\infty} c_k(t)\,\mathbf{u}_k.$$

We will show that $c_k(t) \equiv 0$ for all $k = 1, 2, \ldots$. By taking the inner product of the first equation of (15) with $\mathbf{u}_k$, we get

$$\begin{aligned} \dot{c}_k(t) &= \frac{1}{\varepsilon}\int_\Omega \mathbf{curl}\,\mathbf{H}^*(t) \cdot \mathbf{u}_k = \frac{1}{\varepsilon}\int_\Omega \mathbf{H}^*(t) \cdot \mathbf{curl}\,\mathbf{u}_k \\ &= \frac{1}{\varepsilon}\int_\Omega \mathbf{H}_0^* \cdot \mathbf{curl}\,\mathbf{u}_k - c^2 \int_\Omega \int_0^t \mathbf{curl}\,\mathbf{E}^*(\tau) \cdot \mathbf{curl}\,\mathbf{u}_k \, d\tau \\ &= \frac{1}{\varepsilon}\int_\Omega \mathbf{H}_0^* \cdot \mathbf{curl}\,\mathbf{u}_k - c^2\lambda_k \int_0^t c_k(\tau) d\tau, \end{aligned}$$

so $\ddot{c}_k(t) = -c^2\lambda_k c_k(t)$ and

$$c_k(t) = a_k e^{ic\sqrt{\lambda_k}t} + a_{-k}e^{-ic\sqrt{\lambda_k}t}, \quad k = 1, 2, \ldots.$$

Denote $\gamma_k = c\sqrt{\lambda_k}$, $\gamma_{-k} = -c\sqrt{\lambda_k}$, and $\mathbf{u}_{-k} = \mathbf{u}_k$ for $k = 1, 2, \ldots$. Then we can write

$$\mathbf{E}^*(t) = \sum_{k \neq 0} a_k e^{i\gamma_k t}\mathbf{u}_k.$$

The series is convergent in $H^1(\Omega)$; hence the series $\sum_{k\neq 0} \lambda_k |a_k|^2$ also converges. Now

$$\begin{aligned} \mathbf{H}^*(t) &= \mathbf{H}_0^* - \frac{1}{\mu}\int_0^t \mathbf{curl}\,\mathbf{E}^*(\tau) d\tau \\ &= \mathbf{H}_0^* - \frac{1}{\mu}\int_0^t \sum_{k\neq 0} a_k e^{i\gamma_k \tau}\mathbf{curl}\ \mathbf{u}_k \, d\tau \\ &= \mathbf{H}_0^* - \frac{1}{\mu}\sum_{k\neq 0} \frac{a_k}{i\gamma_k}(e^{i\gamma_k t} - 1)\mathbf{curl}\ \mathbf{u}_k. \end{aligned}$$

Since $\mathbf{curl}\,\mathbf{curl}\,\mathbf{u}_k = -\triangle \mathbf{u}_k = \lambda_k \mathbf{u}_k$ and the series $\sum_{k\neq 0} \lambda_k |a_k|^2$ is convergent, the series for $\mathbf{H}^*(t)$ converges in $H_{\mathbf{curl}}(\Omega)$, uniformly in t. So we can calculate the tangential traces on Γ term by term: for any $\mathbf{v} \in H^{1/2}(\Gamma)$ we have

$$0 = \langle \mathbf{H}^*(t) \times \mathbf{n}, \mathbf{v}\rangle_\Gamma = \langle \mathbf{H}_0^* \times \mathbf{n}, \mathbf{v}\rangle_\Gamma - \frac{1}{\mu}\sum_{k\neq 0} \frac{a_k}{i\gamma_k}(e^{i\gamma_k t} - 1)\langle \mathbf{curl}\ \mathbf{u}_k \times \mathbf{n}, \mathbf{v}\rangle_\Gamma .$$

This can be written in the form $\sum_{k\neq 0} b_k e^{i\gamma_k t} =$ const, where we have denoted $b_k = (a_k/\gamma_k)\langle \mathbf{curl}\ \mathbf{u}_k \times \mathbf{n}, \mathbf{v}\rangle_\Gamma$. Note that the convergence of the series is uniform in t. Multiplying the series by $e^{-i\gamma_l t}$ and taking the mean value over $[0,\infty)$, we get (without loss of generality we can assume all γ_k are different)

$$0 = \lim_{T\to\infty} \frac{1}{T}\int_0^T \sum_{k\neq 0} b_k e^{i\gamma_k t} e^{-i\gamma_l t} dt = b_l + \lim_{T\to\infty} \frac{1}{T} \sum_{k\neq 0, k\neq l} \frac{e^{i(\gamma_k - \gamma_l)T} - 1}{i(\gamma_k - \gamma_l)} = b_l .$$

Thus for every k either $a_k = 0$ or $\langle \mathbf{curl}\, \mathbf{u}_k \times \mathbf{n}, \mathbf{v}\rangle_\Gamma = 0$ $\forall \mathbf{v} \in H^{1/2}(\Gamma)$, but the latter implies that $\partial \mathbf{u}_k/\partial \mathbf{n} = 0$ in $H^{-1/2}(\Gamma)$, which contradicts (10) having only the zero solution. Consequently, $a_k = 0$ for all $k \neq 0$; i.e., $\mathbf{E}^*(t) \equiv 0$.

For $\mathbf{H}^*$ we get from (15) first that $\mathbf{H}^*$ is independent of t, and it satisfies

$$\begin{cases} \mathbf{curl}\, \mathbf{H}^* = 0, \\ \mathbf{H}^* \times \mathbf{n} = 0 \quad \text{on } \Gamma. \end{cases} \tag{16}$$

These equations do not determine $\mathbf{H}^*$ uniquely. To get additional equations for $\mathbf{H}^*$, we note that along the orbits

$$\begin{aligned} &\text{div } (\mathbf{H}(t) - \mathbf{H}^0) = 0 && \text{in } \Omega, \\ &(\mathbf{H}(t) - \mathbf{H}^0)\cdot \mathbf{n} = 0 && \text{on } \Gamma_S, \\ &\textstyle\int_{\Sigma_j} (\mathbf{H}(t) - \mathbf{H}^0)\cdot \mathbf{n} = 0, && j = 1,\dots,k-1 \end{aligned} \tag{17}$$

(see (13) and (14)). Since $\mathbf{H}^*$ is the L^2-limit of a sequence in the form $\mathbf{H}(t_n)$ with $t_n \to \infty$ as $n \to \infty$, we get that div $\mathbf{H}^* = 0$. Using the continuity of the trace operator for the normal component from $\{\mathbf{H} \in L^2(\Omega)^2 \,|\, \text{div } \mathbf{H} = 0\}$ to $H^{-1/2}(\Gamma_S)$ and to $H^{-1/2}(\Sigma_j)$, we see that $\mathbf{H}^*$ must also satisfy conditions (17). Now recall that

$$\mathbf{H}^0 = \mathbf{H}_0 - \widetilde{\mathbf{H}} = \mathbf{H}_0 + \frac{1}{i\omega\mu}\mathbf{curl}\, \widetilde{\mathbf{E}}.$$

Since

$$\mathbf{curl}\, \widetilde{\mathbf{E}} \cdot \mathbf{n} = -\mathbf{curl}\, \widetilde{\mathbf{E}}_i \cdot \mathbf{n} \qquad \text{on } \Gamma_S$$

and

$$\int_{\Sigma_j} \mathbf{curl}\, \widetilde{\mathbf{E}} \cdot \mathbf{n} = -\int_{\Sigma_j} \mathbf{curl}\, \widetilde{\mathbf{E}}_i \cdot \mathbf{n}, \qquad j = 1,\dots,k-1,$$

we have

$$(\mathbf{H}^* - \mathbf{H}_0)\cdot \mathbf{n} = -\frac{1}{i\omega\mu}\mathbf{curl}\, \widetilde{\mathbf{E}}_i \cdot \mathbf{n} \qquad \text{on } \Gamma_S$$

and

$$\int_{\Sigma_j} (\mathbf{H}^* - \mathbf{H}_0)\cdot \mathbf{n} = -\frac{1}{i\omega\mu}\int_{\Sigma_j} \mathbf{curl}\, \widetilde{\mathbf{E}}_i \cdot \mathbf{n},$$

which together with (16) gives us (5). Uniqueness of the solution can be shown using the vector potential: the difference between two solutions is $\mathbf{curl}\,\Phi$ for some $\Phi \in H^1_{0_S}(\Omega)$ (note that the conditions on the cuts are needed to find the potential in $H^1_{0_S}(\Omega)$). From the divergence condition we get $\triangle\Phi = 0$ and on the outer boundary Γ we have $\partial\Phi/\partial\mathbf{n} = 0$, hence $\Phi \equiv 0$.

9. General data. In the last two sections we worked under the assumptions that the initial data for the problem for the differences satisfy $(\mathbf{E}^0, \mathbf{H}^0) \in \mathcal{D}(A)$. We want to use the results for problem (11) with $(\mathbf{E}^0, \mathbf{H}^0) = (\mathbf{E}_0 - \widetilde{\mathbf{E}}, \mathbf{H}_0 - \widetilde{\mathbf{H}})$, but even for $(\mathbf{E}_0, \mathbf{H}_0) = (0, 0)$ (which is often the case in practice), we have $(\mathbf{E}^0, \mathbf{H}^0) \notin \mathcal{D}(A)$ since the boundary conditions and the initial conditions are inconsistent. So we must allow $(\mathbf{E}^0, \mathbf{H}^0) \in X$.

Let $(\mathbf{E}^0, \mathbf{H}^0) \in X$ be given. Choose a sequence $(\mathbf{E}^0_k, \mathbf{H}^0_k)^\infty_{k=1}$ in $\mathcal{D}(A)$ such that $(\mathbf{E}^0_k, \mathbf{H}^0_k) \to (\mathbf{E}^0, \mathbf{H}^0)$ in X. Let $\mathbf{H}^*_k$, $k = 1, 2, \ldots$ be the corresponding steady state solutions. Since $T(t)$ is a contraction semigroup, the sequence $(\mathbf{H}^*_k)^\infty_{k=1}$ is a Cauchy sequence in X. Since $\mathbf{curl}\,\mathbf{H}^*_k = 0$, $(\mathbf{H}^*_k)^\infty_{k=1}$ converges in $H_{\mathbf{curl}}(\Omega)$. Let the limit of the sequence be $\mathbf{H}^*$. Then $\mathbf{curl}\,\mathbf{H}^* = 0$, div $\mathbf{H}^* = 0$, and since the corresponding trace operators are continuous in $H_{\mathbf{curl}}(\Omega)$, $\mathbf{H}^*$ also satisfies the boundary conditions in (5). Now for any $k \in \mathbb{N}$ and $t \geq 0$ we have

$$\begin{aligned}\|(\mathbf{E}(t), \mathbf{H}(t) - \mathbf{H}^*)\|_X \leq{}& \|T(t)(\mathbf{E}^0 - \mathbf{E}^0_k, \mathbf{H}^0 - \mathbf{H}^0_k)\|_X \\ &+ \|T(t)(\mathbf{E}^0_k, \mathbf{H}^0_k) - (0, \mathbf{H}^*_k)\|_X + \|\mathbf{H}^*_k - \mathbf{H}^*\|_{L^2(\Omega)}.\end{aligned}$$

By choosing k large we can make the first and the last term arbitrarily small, and for t large the second term is also small. So the results remain true for initial data in X.

This completes the proof of Theorem 4.1.

10. The transverse electric problem. Consider the transverse electric problem; where the scatterer is, as before, an infinitely long cylindrical perfect conductor with the axis parallel to the z-axis but where the incidence field has an $\mathbf{E}$-component in the xy-plane and an $\mathbf{H}$-component on the z-direction. The corresponding scattering problem is

$$\left\{\begin{array}{rcl} \varepsilon\dfrac{\partial\mathbf{E}}{\partial t} &=& \mathbf{curl}\,\mathbf{H} \\ \mu\dfrac{\partial\mathbf{H}}{\partial t} &=& -\mathbf{curl}\ \mathbf{E} \end{array}\right. \quad \text{in } \Omega, \tag{18}$$

with the boundary conditions

$$\begin{array}{ll} \mathbf{E} \times \mathbf{n} = -\mathbf{E}_i \times \mathbf{n} & \text{on } \Gamma_S, \\ \mathbf{E} \times \mathbf{n} + c\mu\mathbf{H} = 0 & \text{on } \Gamma, \end{array} \tag{19}$$

and the initial conditions

$$\mathbf{E}(\mathbf{x}, 0) = \mathbf{E}_0(\mathbf{x}), \quad \mathbf{H}(\mathbf{x}, 0) = \mathbf{H}_0(\mathbf{x}). \tag{20}$$

In this case one can prove the following theorem.

THEOREM 10.1. *Assume that Ω is a bounded multiply-connected domain with a Lipschitz-continuous boundary. Let Γ be the exterior part of the boundary, and let Γ_S be the interior boundary. Assume that the incident field $\mathbf{E}_i$ can be written in the form*

$$\mathbf{E}_i(\mathbf{x}, t) = e^{i\omega t}\widetilde{\mathbf{E}}_i(\mathbf{x}),$$

with $\widetilde{\mathbf{E}}_i \times \mathbf{n} \in H^{-1/2}(\Gamma_S)$ *and real* ω, *and the initial conditions satisfy* $\mathbf{E}_0 \in L^2(\Omega)^2$, $\mathbf{H}_0 \in L^2(\Omega)$. *Then the solutions* $\mathbf{E}$, $\mathbf{H}$ *of* (18)–(20) *satisfy*

$$\left.\begin{array}{l}\|\mathbf{H}(t,\cdot) - e^{i\omega t}\widetilde{\mathbf{H}}(\cdot)\|_{L^2} \to 0 \\ \|\mathbf{E}(t,\cdot) - e^{i\omega t}\widetilde{\mathbf{E}}(\cdot) - \mathbf{E}^*(\cdot)\|_{L^2} \to 0\end{array}\right. \qquad \text{as } t \to \infty,$$

where $e^{i\omega t}\widetilde{\mathbf{E}}(\mathbf{x})$, $e^{i\omega t}\widetilde{\mathbf{H}}(\mathbf{x})$ *are unique solutions of this form of* (18), (19) *(ignoring the initial conditions), and* $\mathbf{E}^*$ *is the unique solution of*

$$(21) \qquad \begin{cases} \mathbf{curl}\,\mathbf{E}^* = 0, \quad \operatorname{div}\mathbf{E}^* = \operatorname{div}\mathbf{E}_0 & \text{in } \Omega, \\ \mathbf{E}^* \times \mathbf{n} = 0 & \text{on } \Gamma \text{ and on } \Gamma_S, \\ \displaystyle\int_{\Gamma_{S_j}} \mathbf{E}^* \cdot \mathbf{n} = \int_{\Gamma_{S_j}} \mathbf{E}_0 \cdot \mathbf{n}, & j = 1, \dots k, \end{cases}$$

where Γ_{S_j}, $j = 1, \dots k$ *are the connectivity components of* Γ_S.

The idea of proof of the theorem and most of the proof itself are the same (interchanging the roles of $\mathbf{E}$ and $\mathbf{H}$ and using Neumann instead of Dirichlet conditions on Γ_S) as in the case of the transverse magnetic problem, so we will not present it here.

11. Conclusions.

We have shown that the solutions of electromagnetic scattering problems with the incident field of the form $\mathbf{E}_i(\mathbf{x}, t) = e^{i\omega t}\widetilde{\mathbf{E}}_i(\mathbf{x})$ do not always converge to the time-periodic solution of the form $e^{i\omega t}\widetilde{\mathbf{E}}(\mathbf{x})$, $e^{i\omega t}\widetilde{\mathbf{H}}(\mathbf{x})$. Instead, in case of the transverse magnetic problem there may be a magnetic offset and in case of the transverse electric problem it is possible to have an electric offset. From the equations describing the offset fields ((5) and (21), respectively) we see that if we want the spurious stationary fields to be zero, we have to have additional compatibility conditions on the data. Namely, we have

$$(22) \qquad \operatorname{div}\mathbf{H}_0 = 0 \text{ in } \Omega,$$

$$(23) \qquad \mathbf{H}_0 \cdot \mathbf{n} - \frac{1}{i\omega\mu}\mathbf{curl}\,\widetilde{\mathbf{E}}_i \cdot \mathbf{n} = 0 \text{ on } \Gamma_S,$$

$$(24) \qquad \int_{\Sigma_j} \left(\mathbf{H}_0 \cdot \mathbf{n} - \frac{1}{i\omega\mu}\mathbf{curl}\,\widetilde{\mathbf{E}}_i \cdot \mathbf{n}\right) = 0, \; j = 1, \dots, k-1$$

for the transverse magnetic problem and

$$(25) \qquad \operatorname{div}\mathbf{E}_0 = 0 \text{ in } \Omega,$$

$$(26) \qquad \int_{\Gamma_{S_j}} \mathbf{E}_0 \cdot \mathbf{n} = 0, \; j = 1, \dots k$$

for the transverse electric problem. Condition (23) reflects the requirement that the normal component of the total magnetic field is zero on Γ_S at time $t = 0$ (we can interpret $-\frac{1}{i\omega\mu}e^{i\omega t}\mathbf{curl}\,\widetilde{\mathbf{E}}_i$ as the incident magnetic field at time $t = 0$). If this is not satisfied, then we have a static magnetic field inside the body, which "causes" an additional static magnetic field outside. Condition (24) requires the magnetic flux through surfaces between the scatterers to be zero. Nonzero magnetic flux corresponds to the possibility of currents flowing parallel to the z-axis in the opposite directions in different scatterers (note that the artificial boundary condition implies that the sum of all such currents must be zero in the steady state). Condition (26) means that the total charge on the scatterer(s) must be zero at time $t = 0$. The total charge remains constant in time, and it is this charge which is responsible for the electric offset field.

In practical calculations, it may not be advantageous to impose the compatibility conditions, especially (23), on the initial data. Some alternative methods to eliminate the offset fields are discussed in [6].

For the three-dimensional scattering calculations, similar results are true. Both the electric and magnetic offset may be present, and for simply connected scatterers the equations (5) and (21) describing the offset fields are still true, as well as the compatibility conditions (23) and (26). The main idea of the proof is similar, but one needs additional results about the compactness properties of the spaces related with the operators div and **curl**.

DISCONTINUOUS SOLUTIONS OF A HAMILTON–JACOBI EQUATION WITH INFINITE SPEED OF PROPAGATION[*]

FABIO CAMILLI[†] AND ANTONIO SICONOLFI[†]

Abstract. We consider the Cauchy problem

$$\begin{aligned} u_t - \langle A(x)\nabla u, \nabla u\rangle^{\frac{1}{2}} = 0 \quad & \text{in } \mathbb{R}^N \times (0,+\infty),\\ u = u_0 \quad & \text{in } \mathbb{R}^N \times \{t=0\}, \end{aligned}$$

where $A(x)$ is a positive locally Lipschitz map from $\mathbb{R}^N$ to the space of symmetric matrices. Since no growth condition on A is assumed, pathological phenomena can occur. We study the problem in the framework of discontinuous viscosity solutions and we get some comparison results and a representation formula for the minimal solution of the problem.

Key words. Hamilton–Jacobi equations, discontinuous viscosity solution, Riemannian distance, infinite speed of propagation, canonical solutions

AMS subject classifications. 35F20, 49L25, 35C99

1. Introduction.

In this paper we study a Hamilton–Jacobi equation of the type

$$u_t + H(x, \nabla u) = 0 \qquad \text{in } \mathbb{R}^N \times (0,+\infty) \tag{1.1}$$

with the initial condition

$$u = u_0 \qquad \text{in } \mathbb{R}^N \times \{t=0\}, \tag{1.2}$$

where H is a map from $\mathbb{R}^N \times \mathbb{R}^N$ to $\mathbb{R}$ and $u_0 : \mathbb{R}^N \to \mathbb{R} \cup \{+\infty\}$ is an upper semicontinuous function.

Problem (1.1), (1.2) has been extensively studied in the framework of viscosity solutions theory; see [9], [8], [19]. To get a comparison result for solutions of (1.1), it is often assumed that on H there is a linear growth condition in x. This hypothesis yields a bounded domain of dependence of the solution from the initial datum and therefore the comparison can be carried out into a compact set of $\mathbb{R}^N \times [0,+\infty)$. Roughly speaking, this is like assuming that the first-order PDE (1.1) has the finite propagation speed property.

Here we consider a case where no growth condition on H with respect to x is assumed. More precisely, we take the Hamiltonian as

$$H(x,p) = -\langle A(x)p, p\rangle^{\frac{1}{2}},$$

where A is a locally Lipschitz continuous positive map from $\mathbb{R}^N$ to the space of the symmetric matrices. By means of some examples (see section 8) we show that certain new phenomena can occur in this case. First of all, a solution can be discontinuous

even starting from a smooth initial datum. To deal with discontinuous viscosity solutions we follow the approach of Barron and Jensen, see [4], [3], exploiting the concavity of H in p, see [17] for an application of this theory to a degenerate problem. Other phenomena are the blow-up of solutions (see Example 8.1) and the lack of uniqueness (see Example 8.2 and Proposition 7.1).

We exhibit a representation formula (see section 5) for a *canonical solution* of problem (1.1), (1.2). To do this we associate to the map A a distance d in $\mathbb{R}^N$ whose properties are described in section 3. The crucial point is that the space $(\mathbb{R}^N, d)$ may not be complete; actually the completeness of this metric is equivalent to the finite propagation speed property for equation (1.1). All the pathologies described above depend on the lack of completeness of $(\mathbb{R}^N, d)$. It is worth noting that the usual condition of linear growth of H in x implies that $(\mathbb{R}^N, d)$ is complete, but the converse is not true as we show in Example 8.3.

One idea essential to the study of the canonical solution is to prove that it is the limit in a suitable weak sense of a sequence of solutions of some approximate problems (see sections 4 and 5).

In section 7 we get some comparison principles which give as a consequence a minimality property of the canonical solution. To prove this we follow the general outline of the analogous results in [4]; we enlarge the set of the test functions as already done in [20] (see Propositions 2.1 and 2.4) and we make use of an explicit locally Lipschitz test function which is constructed in section 6.

Using the comparison principles we are also able to prove that every solution can be represented locally in $\mathbb{R}^N \times (0, +\infty)$ by a formula similar to that of the canonical solution. Furthermore we show that problem (1.1), (1.2) is uniquely solvable once a growth condition at infinity (on the solution) is also prescribed. This is similar to what happens in the parabolic case.

2. Preliminary results.

We now give some notation that we will use in what follows. For any $x = (x^1, \dots, x^N), y = (y^1, \dots, y^N) \in \mathbb{R}^N$, $\mathcal{O} \subset \mathbb{R}^N$ and $r > 0$, we set

$$\langle zx, y\rangle = \sum_{i=1}^{N} x^i y^i, \qquad |x| = \langle x, x\rangle^{\frac{1}{2}},$$

$$B^E(x, r) = \{z \in \mathbb{R}^N : |z - x| < r\}, \qquad d^E(x, \mathcal{O}) = \inf\{|y - x| : y \in \mathcal{O}\}.$$

Let $\mathcal{S}^N$ denote the algebra of the $N \times N$ symmetric matrices endowed with the norm $\|B\| = \max_{|x|=1}\langle Bx, x\rangle$ and the standard order (i.e., for $B, C \in \mathcal{S}^N$, $B \leq C$ if and only if $\langle Bx, x\rangle \leq \langle Cx, x\rangle$ for all $x \in \mathbb{R}^N$). A matrix B is called positive (nonnegative) if $B > 0$ ($B \geq 0$). If $B \geq 0$, then $B^{\frac{1}{2}}$ is the nonnegative matrix verifying $B^{\frac{1}{2}} B^{\frac{1}{2}} = B$. For any $x \in \mathbb{R}^N$, we write $x \otimes x$ for the symmetric matrix with entries $x^i x^j$ for $i, j = 1, \dots, N$. Finally, given $\alpha, \beta \in \mathbb{R}$, $\alpha \wedge \beta$ ($\alpha \vee \beta$) stands for $\min\{\alpha, \beta\}$ ($\max\{\alpha, \beta\}$).

Let us introduce the Cauchy problem we will study:

$$u_t - \langle A(x)\nabla u, \nabla u\rangle^{\frac{1}{2}} = 0 \qquad \text{in } \mathbb{R}^N \times (0, +\infty), \tag{2.1}$$

$$u = u_0 \qquad \text{in } \mathbb{R}^N \times \{t = 0\}, \tag{2.2}$$

where

$$A : \mathbb{R}^N \to \mathcal{S}^N \text{ is locally Lipschitz continuous}, \tag{2.3}$$

$$A(x) > 0 \qquad \text{for all } x \in \mathbb{R}^N, \tag{2.4}$$

and

$$u_0 \in X_0 = \left\{ v : \mathbb{R}^N \to \mathbb{R} \cup \{+\infty\} : \ v \text{ is upper semicontinuous} \right\}.$$

From now on we set $H(x,p) = -\langle A(x)p, p\rangle^{\frac{1}{2}}$.

We seek solutions in the functional space

$$X = \left\{ u : \mathbb{R}^N \times [0,+\infty) \to \mathbb{R} \cup \{+\infty\} : \ u \text{ is upper semicontinuous} \right\}.$$

Definition 2.1. *Given an upper semicontinuous (u.s.c.) function $\phi : \mathbb{R}^N \times (0,+\infty) \to \mathbb{R}$ and $(x_0,t_0) \in \mathbb{R}^N \times (0,+\infty)$, we say that a continuous function ψ is supertangent to ϕ at (x_0,t_0) if (x_0,t_0) is a point of local maximum of $\phi - \psi$.*

Definition 2.2. *A function $u \in X$ is said to be a (viscosity) solution of* (2.1) *if for any $(x_0,t_0) \in \mathbb{R}^N \times (0,+\infty)$, $M \in \mathbb{R}$, and for any function $\psi \in C^1(\mathbb{R}^N \times (0,+\infty))$ supertangent to $u \wedge M$ at (x_0,t_0), the following equality holds:*

$$\psi_t(x_0,t_0) + H\left(x_0, \nabla\psi(x_0,t_0)\right) = 0. \tag{2.5}$$

The definition of supersolution (subsolution) is given replacing the equality sign in (2.5) by $\geq$ (resp., $\leq$). As for the initial condition (2.2), it is understood that it has to be taken in the following sense:

$$u_0(x) = \sup\left\{ \limsup_{\varepsilon\to 0} u(x_\varepsilon, t_\varepsilon) : (x_\varepsilon, t_\varepsilon) \ \to (x,0), \ t_\varepsilon > 0 \right\}. \tag{2.6}$$

Exploiting the positive homogeneity of $H(x,p)$ in p, we get the following characterization.

Proposition 2.1.

(i) *A function u is a solution of* (2.1) *if and only if for any (x_0,t_0), $\alpha \leq u(x_0,t_0)$ and for any C^1 function ψ which has a local minimum on the set $\{(x,t) : u(x,t) \geq \alpha\}$ at (x_0,t_0), equality* (2.5) *holds.*

(ii) *A similar equivalence is true for supersolutions and subsolutions.*

Proof. To show that the condition given in the statement implies that u is a solution of (2.1), it is sufficient to note that if $M \in \mathbb{R}$ and ψ is a C^1 supertangent to $u \wedge M$ at (x_0,t_0), then (x_0,t_0) is a point of local minimum of ψ on $\{u \wedge M \geq u(x_0,t_0) \wedge M\} = \{u \geq u(x_0,t_0) \wedge M\}$.

To prove the converse, we use the fact that, due to the positive homogeneity of H in p, (2.1) belongs to the class of geometric equations (see [5], [13], [14]). Then a basic property of such equations permits us to assert that if u is a solution of (2.1), (2.5) holds for any supertangent to $\theta \circ (u \wedge M)$, $M \in \mathbb{R}$ and θ a continuous nondecreasing function.

Now let $\overline{\psi}$ be a C^1 function which attains a local minimum on $\{u \geq \overline{\alpha}\}$ at (x_0,t_0) for a given $\overline{\alpha} \in \mathbb{R}$. Then this point is also a local minimum on $\{u \wedge \overline{M} \geq \overline{\alpha}\}$ for any $\overline{M} \geq \overline{\alpha}$. We refer to Lemma 3.1 of [20] to construct a continuous nondecreasing function $\overline{\theta}$ such that $\overline{\theta} \circ (u \wedge \overline{M})$ permits $\overline{\psi}$ to be a supertangent at (x_0,t_0). This ends the proof of part (i). Minor modifications of the above argument also give the assertion (ii). □

The next step is to enlarge the set of test functions for equation (2.1) in such a way as to include the locally Lipschitz ones. We use an approximation argument by means of *inf convolution.*

Let us recall some properties of the (Clarke) generalized gradient that we will use later (see [6] for a general treatment).

Proposition 2.2. *Let $\phi : \mathbb{R}^N \times [0,+\infty) \to \mathbb{R}$ be a locally Lipschitz continuous function and denote by $\partial\phi(z,t)$ its generalized gradient. Then we have the following:*

(i) *The multifunction $(z,t) \to \partial\phi(z,t)$ is u.s.c.; i.e., for any (z_0,t_0), $(z_n,t_n) \to (z_0,t_0)$, $(q_n,s_n) \in \partial\phi(z_n,t_n)$ with (q_n,s_n) converging to (q,s), one has $(q,s) \in \partial\phi(z_0,t_0)$.*

(ii) *If ϕ attains a local extremum at (z_0,t_0), then $(0,0) \in \partial\phi(z_0,t_0)$.*

(iii) *If ϕ is semiconcave, then*

$$\partial\phi(z,t) = \big\{(q,s) : \textit{there exists } \overline{\phi}\ C^1\textit{-supertangent} \\ \textit{to } \phi \textit{ at } (z,t) \textit{ with } (\nabla\overline{\phi}(z,t), \overline{\phi}_t(z,t)) = (q,s)\big\}.$$

(iv)

$$\partial\phi(z,t) = \mathrm{co}\Big\{ \lim_{n\to\infty} (\nabla\phi(z_n,t_n), \phi_t(z_n,t_n)) : \\ \phi \textit{ is differentiable at } (z_n,t_n) \textit{ and } (z_n,t_n) \to (z,t)\Big\},$$

where co *means convex hull.*

The following proposition summarizes some properties of the inf convolution. We refer to [12], [18] for definitions and basic properties.

Proposition 2.3. *Let $\phi : \mathbb{R}^N \times [0,+\infty) \to \mathbb{R}$ be continuous. For $\lambda > 0$ define*

$$\phi_\lambda(z,t) = \inf_{y,s} \left\{ \phi(y,s) + \frac{\lambda}{2}(|y-z|^2 + |t-s|^2) \right\}. \tag{2.7}$$

Then

(i) *ϕ_λ is semiconcave.*

(ii) *if $(\overline{y},\overline{s})$ realizes the infimum in* (2.7), *then $\lambda(\overline{y}-z, \overline{s}-t) \in \partial\phi_\lambda(z,t)$.*

Proposition 2.4. *Let $(x_0,t_0) \in \mathbb{R}^N \times (0,+\infty)$, $\alpha \in \mathbb{R}$, and ψ be a locally Lipschitz function which attains a local minimum on $\{u \geq \alpha\}$ at (x_0,t_0). Then, if u is a solution of* (2.1), *there exists $(p,s) \in \partial\psi(x_0,t_0)$ such that*

$$s + H(x_0,p) = 0. \tag{2.8}$$

If instead u is a supersolution (subsolution), then

$$s + H(x_0,p) \geq 0 \quad (\leq 0). \tag{2.9}$$

Proof. Suppose first that u is a solution. Regularize ψ using inf convolution by defining the sequence

$$\psi_n(x,t) = \inf_{y,s} \Big\{ \psi(y,s) + \frac{n}{2}(|x-y|^2 + |t-s|^2) \Big\} \tag{2.10}$$

which converges to ψ uniformly on compact subsets of $\mathbb{R}^N \times (0,+\infty)$. Note that the addition to ψ of $-\beta(|x-x_0|^2+|t-t_0|^2)$, $\beta > 0$, does not affect the generalized gradient at (x_0,t_0). Therefore we can suppose without loss of generality that the minimum (x_0,t_0) is strict. Hence straightforward arguments provide a sequence (x_n,t_n) of local minima of ψ_n on the closed set $\{u \geq \alpha\}$ converging, up to a subsequence, to (x_0,t_0).

Now denote by (y_n,r_n) a point satisfying

$$\psi_n(x_n,t_n) = \psi(y_n,r_n) + \frac{n}{2}(|x_n-y_n|^2 + |t_n-r_n|^2)$$

and set

$$p_n = n(y_n - x_n), \qquad s_n = n(r_n - t_n). \tag{2.11}$$

Observe that

$$(p_n, s_n) \in \partial\psi_n(x_n, t_n) \cap \partial\psi(y_n, r_n) \tag{2.12}$$

according to Proposition 2.2(ii) and Proposition 2.3(ii). Exploiting Proposition 2.3(i), Proposition 2.2(iii), and Proposition 2.1, from (2.12) we get

$$s_n + H(x_n, p_n) = 0. \tag{2.13}$$

Moreover, (y_n, r_n) is convergent to (x_0, t_0) and the sequence (p_n, s_n) is bounded by (2.12) and so is convergent up to a subsequence. Denoting the limit by (p, s), we obtain, by Proposition 2.2(i),

$$(p, s) \in \partial\psi(x_0, t_0)$$

and so (2.8) follows letting $n \to +\infty$ in (2.13). Suitable modifications of the above argument also give (2.9). □

We conclude this section with two remarks.

Remark 2.1. Note that since H is nonpositive and because of (2.6), any solution u is nondecreasing for $t \in [0, +\infty)$.

Remark 2.2. If u is a subsolution of (2.1) and ψ is a test function as in Proposition 2.4 (which attains a local minimum at (x_0, t_0) on the intersection $\{u \geq \alpha\} \cap (\mathbb{R}^N \times (0, t_0])$, $\alpha \in \mathbb{R}$), then (2.9) still holds; see [5]. In this case even if u is a solution, one cannot expect equality (2.8) but only (2.9).

3. Properties of the distance function.

Here, starting from any given continuous map from $\mathbb{R}^N$ to $\mathcal{S}^N$ with nonnegative values, we define a distance on $\mathbb{R}^N$. This construction will allow us to give a representation of a *canonical* solution of (2.1), (2.2) as well as of some approximated problems we will introduce in the next section.

Definition 3.1. *Given a continuous map $C : \mathbb{R}^N \to \mathcal{S}^N$ with $C(x) \geq 0$, a continuous piecewise C^1 curve $\xi : [0, T] \to \mathbb{R}^N$ is said to be C-admissible if*

$$\dot\xi(t) \otimes \dot\xi(t) \leq C(\xi(t)) \qquad \textit{a.e. in } [0, T]. \tag{3.1}$$

We set for $x, y \in \mathbb{R}^N$,

$$\begin{aligned} d_C(x, y) = \inf\{T : &\text{ there exists a } \xi\ C\text{-admissible} \\ &\text{with } \xi(0) = x,\ \xi(T) = y\} \end{aligned} \tag{3.2}$$

with the convention that $d_C(x, y) = +\infty$ if there are no C-admissible paths joining x to y. It is an exercise to verify that d_C is a distance on $\mathbb{R}^N$, possibly infinite. Moreover, d_C turns $\mathbb{R}^N$ into a length space in the sense of [15].

We consider the distance d_A associated to the map $A(x)$ which appears in (2.1). Thanks to (2.4), d_Δ is a finite distance. We will hereafter write d instead of d_A and set $B(x, r) = \{y \in \mathbb{R}^N : d(x, y) < r\}$ for any $r > 0$, $x \in \mathbb{R}^N$.

Proposition 3.1.

(i) *d is topologically equivalent to the Euclidean distance.*

(ii) *For any $x \in \mathbb{R}^N$, the set $\{r > 0 : B(x, r)$ is relatively compact$\}$ is a nonempty, open interval.*

(iii) *The metric space* $(\mathbb{R}^N, d)$ *is complete if and only if for every* $x \in \mathbb{R}^N, r > 0$, *the ball* $B(x,r)$ *is relatively compact.*

Note that, because of (i), the expression relatively compact in (ii) and (iii) is not ambiguous.

Proof. We first show that for every x_0, r, the Euclidean ball $B^E(x_0,r)$ is open in the topology induced by d. More precisely we set for every $x \in B^E(x_0,r)$, $T_x = d^E(x, \partial B^E(x_0,r))$, where ∂ denotes the boundary in the Euclidean topology and we claim that

$$B\left(x, \frac{T_x}{M}\right) \subset B^E(x_0,r) \tag{3.3}$$

for any M satisfying

$$A(x) \leq M^2 I, \qquad x \in B^E(x_0,r). \tag{3.4}$$

If (3.3) is not true, we can find $x \in B^E(x_0,r)$, $T > 0$, and an A-admissible path ξ joining $x = \xi(0)$ to a point $\xi(T) \in \partial B^E(x_0,r)$ such that

$$T < \frac{T_x}{M} \tag{3.5}$$

and

$$\xi([0,T)) \subset B^E(x_0,r). \tag{3.6}$$

The last formula, together with (3.4), gives

$$|\dot{\xi}(t)| \leq M \qquad \text{a.e. in [0,T]}.$$

Then we get

$$T_x \leq |x - \xi(T)| \leq \int_0^T |\dot{\xi}(t)| dt \leq MT,$$

which contradicts (3.5).

We conclude the proof of (i) by proving that, for any x_0, r, $B(x_0,r)$ is open in the Euclidean topology. According to the positivity of A (see (2.4)) for any $x \in B(x_0,r)$ and $\delta > 0$, we can choose a positive number $m_\delta = m_\delta(x)$ such that

$$A(y) \geq m_\delta^2 I, \qquad y \in B^E(x,\delta). \tag{3.7}$$

If $y \in B^E(x,\delta)$, then the path ξ defined via

$$\xi(t) = x + m_\delta \frac{y-x}{|y-x|} t, \qquad t \in [0, |y-x|/m_\delta],$$

is A-admissible thanks to the relation

$$\dot{\xi}(t) \otimes \dot{\xi}(t) = m_\delta^2 \left(\frac{y-x}{|y-x|} \otimes \frac{y-x}{|y-x|}\right) \leq m_\delta^2 I \leq A(\xi(t))$$

which holds by (3.7). Hence

$$B^E(x,\delta) \subset B\left(x, \frac{\delta}{m_\delta}\right). \tag{3.8}$$

Since m_δ is nondecreasing with respect to δ, we can select $\overline{\delta}$ so that

$$\frac{\overline{\delta}}{m_{\overline{\delta}}} < r - d(x, x_0). \tag{3.9}$$

Finally we use (3.8), (3.9) to find

$$B^E(x, \overline{\delta}) \subset B(x, r - d(x, x_0)) \subset B(x_0, r),$$

which ends the proof of (i).

Now fix $x \in \mathbb{R}^N$ and denote by I_x the set that appears in (ii). Exploiting (i) and the local compactness of the Euclidean topology, we see that I_x is nonempty. Moreover I_x is obviously an interval. Hence we will prove (ii), once we show that for any given $\delta \in I_x$, there exists $\delta' > \delta$ belonging to I_x. To do this, choose $r > 0$ such that

$$B(x, \delta) \subset B^E\left(x, \frac{r}{2}\right). \tag{3.10}$$

Set $\mathcal{K} = \partial B^E(x, r)$ and define

$$f(y) = d(y, \mathcal{K}) = \inf_{\mathcal{K}} d(y, z)$$

for any $y \in \mathbb{R}^N$. The function f is continuous by (i), so taking into account that $\delta \in I_x$ and (3.10), we have that

$$\sigma = \inf_{B(x,\delta)} \{f\}$$

is positive. Therefore $B(x, \delta + \sigma) \subset B^E(x, r)$, so $\delta + \sigma \in I_x$, which proves (ii).

It is easy to see that the relative compactness of the balls implies the completeness of d. The converse follows from a general theorem for locally compact length space (see [15, Chapter 1]). □

For any $x \in \mathbb{R}^N$, let us denote by $d(x, \infty)$ the supremum of the set $\{r > 0 : B(x, r)$ is relatively compact$\}$. This notation is justified by the fact that whenever $d(x, \infty)$ is finite, it is the smallest radius for which the ball (for the distance d) centered in x becomes unbounded with respect to the Euclidean distance. The completeness of $(\mathbb{R}^N, d)$ is clearly equivalent to $d(x, \infty)$ being infinite for every x. On the other hand, $(\mathbb{R}^N, d)$ is not complete if and only if $d(x, \infty) < +\infty$ for every x.

LEMMA 3.1. *Assume that $(\mathbb{R}^N, d)$ is not complete and let x_0 be any point of $\mathbb{R}^N$. Every sequence contained in $B(x_0, d(x_0, \infty))$ has a subsequence which is fundamental with respect to d.*

Proof. The argument of Theorem 1.10 in [15] easily can be adapted to verify our Lemma 3.1. □

LEMMA 3.2. *Let $x_0, y_0 \in \mathbb{R}^N$ and $r > 0$ such that $\overline{B(x_0, r)}$ is compact and $y_0 \notin \overline{B(x_0, r)}$. Then there exist $z_0, z \in \partial B(x_0, r)$ such that*

$$d(y_0, z_0) = d(x_0, y_0) - r, \tag{3.11}$$

$$d(z, \infty) = d(x, \infty) - r. \tag{3.12}$$

Proof. To show (3.11) we consider, for every $n \in \mathbb{N}$, an A-admissible curve ξ_n verifying $\xi_n(0) = x_0$, $\xi_n(d(x_0, y_0) + \frac{1}{n}) = y_0$ and denote by z_n a point belonging to the intersection of this curve with $\partial B(x_0, r)$. We have

$$d(x_0, y_0) - r \leq d(z_n, y_0) \leq d(x_0, y_0) + \frac{1}{n} - r. \tag{3.13}$$

From (3.13) we see that every z_0, limit point of z_n, satisfies (3.11).

We turn to the proof of (3.12). If $(\mathbb{R}^N, d)$ is complete, then (3.12) is obvious for any z. If $(\mathbb{R}^N, d)$ is not complete, consider a sequence y_n contained in $B(x_0, d(x_0, \infty))$ such that $|y_n| \to +\infty$. By Lemma 3.1, y_n is fundamental for d up to a subsequence. We denote by z_n, for any n, an element of $\partial B(x_0, r)$ satisfying

$$d(z_n, y_n) = d(x_0, y_n) - r < d(x_0, \infty) - r. \tag{3.14}$$

Such a point exists by virtue of (3.11). We can assume without loss of generality that z_n converges to a limit z. Taking into account the properties of y_n and (3.14), we have

$$\begin{aligned} d(z_n, y_m) &\leq d(z_n, y_n) + d(y_n, y_m) \\ &< d(x_0, \infty) - r + \varepsilon \end{aligned} \tag{3.15}$$

for any given $\varepsilon > 0$ and n, m sufficiently large. Letting $n \to +\infty$ in (3.15), we find that the inequality

$$d(z, y_m) < d(x_0, \infty) - r + \varepsilon \tag{3.16}$$

holds for m sufficiently large. Since $|y_m| \to +\infty$, (3.16) implies that $B(z, d(x_0, \infty) - r + \varepsilon)$ is noncompact, so $d(z, \infty) \leq d(x, \infty) - r + \varepsilon$, which gives the assertion since ε is arbitrary. □

Let us stress that our assumptions on A do not exclude the possibility that $(\mathbb{R}^N, d)$ is not complete. We shall prove later that this fact is the cause of the pathologies in the analysis of problem (2.1). To emphasize this, we now show that as a consequence of Proposition 3.1 the growth conditions in x usually assumed on the Hamiltonian (see, for example, [2]) lead to the completeness of $(\mathbb{R}^N, d)$.

Corollary 3.1. *Assume that there exist positive constants α, β such that*

$$|H(x, p)| \leq (\alpha|x| + \beta)|p| \qquad \textit{for every } x, p. \tag{3.17}$$

Then $(\mathbb{R}^N, d)$ is complete.

Proof. Condition (3.17) implies that

$$\|A^{\frac{1}{2}}(x)\| \leq \alpha|x| + \beta, \qquad x \in \mathbb{R}^N.$$

So, if ξ is an A-admissible path, we find

$$|\dot{\xi}(t)| \leq \alpha|\xi(t)| + \beta \qquad \text{for a.e. } t. \tag{3.18}$$

Given $x_0 \in \mathbb{R}^N$, $r > 0$, by Gronwall's inequality, (3.17), and (3.2), we obtain

$$|x| \leq (|x_0| + \beta r)e^{\alpha r}$$

for every $x \in B(x_0, r)$. This shows that $B(x_0, r)$ is relatively compact, so the assertion follows according to Proposition 3.1(iii). □

The converse of the previous corollary is not true as we will show in Example 8.3.

4. Approximation by complete metrics. In this section we approximate A by a sequence of maps $A_n : \mathbb{R}^N \to \mathcal{S}^N$ with compact support. Moreover, we study the distances d_n associated to A_n and define functions w_n which we will prove in the next section to be convergent in a suitable sense to a solution of (2.1), (2.2).

To simplify notation, from now on $\mathcal{O}_n$ will stand for $B^E(0, 2n)$ for every $n \in \mathbb{N}$.

Proposition 4.1. *There exists a sequence of maps A_n from $\mathbb{R}^N$ to $\mathcal{S}^N$ verifying*

$$A_n(x) > 0 \quad \textit{for } x \in \mathcal{O}_n, \qquad A_n = 0 \quad \textit{for } x \in \mathbb{R}^N \setminus \mathcal{O}_n, \tag{4.1}$$

$$A_n \leq A, \tag{4.2}$$

$$A_n,\ A_n^{\frac{1}{2}} \in C^\infty(\mathbb{R}^N, \mathcal{S}^N), \tag{4.3}$$

$$A_n \textit{ converges to } A \textit{ uniformly on compact subsets of } \mathbb{R}^N. \tag{4.4}$$

Proof. Regularize the elements of $A(x)$ via mollification to obtain a sequence $C_n(x)$, with $C_n : \mathbb{R}^N \to \mathcal{S}^N$ smooth, which converges to A uniformly on compact subsets of $\mathbb{R}^N$. Set

$$M_n = \max_{\overline{\mathcal{O}}_n} \|A(x)\|,$$
$$m_n = \min_{\overline{\mathcal{O}}_n} \|A(x)\|,$$

and denote by ε_n a positive sequence verifying

$$\varepsilon_n < \frac{1}{n}\left(\frac{m_n}{M_n}\right) \wedge m_n, \tag{4.5}$$

where M_n/m_n is well defined because m_n is strictly positive by (2.4). From the convergence of C_n, it follows that we can find a subsequence, still denoted by C_n, which verifies

$$A(x) - \varepsilon_n I \leq C_n(x) \leq A(x) + \varepsilon_n I, \qquad x \in \overline{\mathcal{O}}_n. \tag{4.6}$$

Consequently we have

$$C_n(x) > 0, \qquad x \in \overline{\mathcal{O}}_n, \tag{4.7}$$

$$\|C_n(x)\| \leq 2M_n, \qquad x \in \overline{\mathcal{O}}_n. \tag{4.8}$$

Setting $\gamma_n = m_n/(m_n + \varepsilon_n)$ and using (4.5), (4.6), and (4.8), we get for any $x \in \overline{\mathcal{O}}_n$ the following inequalities:

$$\gamma_n C_n(x) \leq \gamma_n A(x) + \varepsilon_n \gamma_n I \leq \frac{m_n}{m_n + \varepsilon_n} A(x) + \frac{\varepsilon_n}{m_n + \varepsilon_n} A(x) = A(x) \tag{4.9}$$

and

$$\begin{aligned} \|\gamma_n C_n(x) - A(x)\| &\leq |\gamma_n - 1| \|C_n(x)\| + \|A(x) - C_n(x)\| \\ &\leq 2\frac{\varepsilon_n}{m_n + \varepsilon_n} M_n + \varepsilon_n \leq \frac{1}{n}\frac{m_n}{M_n}\frac{1}{m_n} 2M_n + \varepsilon_n \leq \frac{3}{n}. \end{aligned} \tag{4.10}$$

Now we consider a C^∞ cut-off function λ defined in $[0, +\infty)$ with the following properties:

$$\lambda(t) = 1, \quad t \in [0, 1]; \qquad 0 < \lambda(t) < 1, \quad t \in [1, 4]; \qquad \lambda(t) = 0, \quad t \in [4, \infty).$$

Further, we set, for any $t \in \mathbb{R}^+$, $x \in \mathbb{R}^N$, $\mu_n(t) = \lambda^2(\frac{t}{n^2})$, and $A_n(x) = \mu_n(|x|^2)\gamma_n C_n(x)$. By (4.7) and (4.9), A_n satisfies (4.1) and (4.2).

To obtain (4.3), note that since C_n is strictly positive, $C_n^{\frac{1}{2}}$ is smooth and the same is true for $A_n^{\frac{1}{2}}(x) = \lambda(\frac{|x|^2}{n^2})\sqrt{\gamma_n} C_n^{\frac{1}{2}}(x)$.

To prove (4.4), observe that, since any compact subset $\mathcal{K} \subset \mathbb{R}^N$ is contained in $B^E(0, n)$ for n sufficiently large, from (4.10) it follows for such n that

$$\max_{\mathcal{K}} \|A_n(x) - A(x)\| \leq \max_{\overline{\mathcal{O}}_n} \|\gamma_n C_n(x) - A(x)\| \leq \frac{3}{n}$$

which ends the proof. □

In connection with the maps A_n, we can define distances d_n as in the previous section, namely, via (3.1) and (3.2) with C replaced by A_n. We set for any $x \in \mathbb{R}^N$ and $r > 0$, $B_n(x, r) = \{y : d_n(x, y) < r\}$.

PROPOSITION 4.2.

(i) *For any* $x_0 \in \mathbb{R}^N \setminus \mathcal{O}_n$, $r > 0$,

$$B_n(x_0, r) = \{x_0\} \tag{4.11}$$

or, equivalently, $d_n(x_0, y) = +\infty$ *if* $y \neq x_0$.

(ii) d_n *is the distance induced on* $\mathcal{O}_n$ *by the Riemannian metric* g_n *defined via*

$$g_n(x) = A_n^{-1}(x), \qquad x \in \mathcal{O}_n. \tag{4.12}$$

Proof. If $x_0 \in \mathbb{R}^N \setminus \overline{\mathcal{O}}_n$, assertion (i) is clear. Consider $x_0 \in \partial\mathcal{O}_n$ and suppose that there exists $y_0 \in \overline{\mathcal{O}}_n$, $T > 0$, and an A_n-admissible path such that $\xi(0) = x_0$, $\xi(T) = y_0$. We have

$$|\dot{\xi}(t)|^4 \leq \langle A_n(\xi(t))\dot{\xi}(t), \dot{\xi}(t)\rangle$$

for a.e. $t \in [0, T]$, so

$$|\dot{\xi}(t)| \leq \|A_n^{\frac{1}{2}}(\xi(t))\| \qquad \text{for a.e. } t. \tag{4.13}$$

Since $A_n^{\frac{1}{2}}$ is smooth, we can select $L > 0$ verifying

$$\|A_n^{\frac{1}{2}}(x) - A_n^{\frac{1}{2}}(y)\| \leq L|x - y| \qquad \text{for any } x, y \in \overline{\mathcal{O}}_n. \tag{4.14}$$

So using (4.13) and (4.14), we get

$$|y - x_0| = |\xi(T) - \xi(0)| \leq L \int_0^T |\xi(t) - x_0| dt,$$

which implies $y_0 = x_0$ by Gronwall's inequality, concluding the proof of (i).

To establish (ii), fix n and, for any $x \in \mathcal{O}_n$, $b \in T_{\mathcal{O}_n}(x) = \mathbb{R}^N$, set

$$\|b\|_x = \langle g_n(x)b, b\rangle. \tag{4.15}$$

The previous formula gives the norm induced by the Riemannian metric (4.12) on $T_{\mathcal{O}_n}(x)$. We claim that

$$\|b\|_x \leq 1 \quad \text{if and only if} \quad b \otimes b \leq A_n(x). \tag{4.16}$$

Assume $\|b\|_x \leq 1$. By the Hölder inequality,

$$\langle A_n(x)a, b\rangle^2 \leq \langle A_n(x)a, a\rangle\langle A_n(x)b, b\rangle \qquad \text{for } a \in \mathbb{R}^N.$$

We deduce

$$\begin{aligned}\langle (b \otimes b - A_n(x))a, a\rangle &= \langle b, a\rangle^2 - \langle A_n(x)a, a\rangle \\ &\leq \|b\|_x\langle A_n(x)a, a\rangle - \langle A_n(x)a, a\rangle \leq 0.\end{aligned}$$

Conversely, let $b \otimes b \leq A_n(x)$. Then

$$0 \geq \langle (b \otimes b - A_n(x))a, a\rangle = \|b\|_x^2 - \|b\|_x,$$

which completes the proof of the claim. Now let us name g_n-admissible any continuous piecewise C^1 curve contained in $\mathcal{O}_n$ which satisfies

$$\|\dot\xi(t)\|_{\xi(t)} \leq 1 \qquad \text{for a.e. } t$$

and recall that the Riemannian distance between $x, y \in \mathcal{O}_n$ is given by

$$\begin{aligned}d_{g_n}(x, y) = \inf\{T &: \text{there exists } \xi \\ &g_n\text{-admissible with } \xi(0) = x,\ \xi(T) = y\}.\end{aligned} \tag{4.17}$$

We observe that an A_n-admissible curve which joins two points of $\mathcal{O}_n$ is contained in $\mathcal{O}_n$ thanks to (i). Hence (4.16) permits us to assert that any curve joining points in $\mathcal{O}_n$ is A_n-admissible if and only if it is g_n-admissible. This together with (3.2) and (4.17) ends the proof. □

Remark 4.1. It is easily seen that the distances d_n are not topologically equivalent to the Euclidean distance. Nevertheless, by Proposition 4.2(ii) this equivalence holds restricted to $\mathcal{O}_n$. Hence, for any $x_0 \in \mathcal{O}_n$, the function $x \to d(x, x_0)$ is continuous in $\mathcal{O}_n$ (with respect to the Euclidean topology). We can also immediately verify that $\mathbb{R}^N$, with the metric given by d_n, is complete and that for any x, r, the balls $B_n(x, r)$ are relatively compact (in the Euclidean topology).

From now on we will consider only the Euclidean topology on $\mathbb{R}^N$. We set, for any $(x, t) \in \mathbb{R}^N \times [0, +\infty)$,

$$w_n(x, t) = \sup_{B_n(x,t)}\{u_0\} = \max_{\overline{B_n(x,t)}}\{u_0\}. \tag{4.18}$$

Proposition 4.3.

(i) *For any* $x \in \mathbb{R}^N$, $w_n(x, 0) = u_0(x)$.

(ii) $w_n \in X$.

Proof. Part (i) of the assertion follows directly from (4.18). To prove (ii), fix n and observe that, by Proposition 4.2(i) and (4.18), it follows that $w_n(x, t) = u_0(x)$ for any $(x, t) \in (\mathbb{R}^N \setminus \overline{\mathcal{O}}_n) \times [0, +\infty)$. Thus w_n is u.s.c. in this set because u_0 is u.s.c. Now let $(x, t) \in \overline{\mathcal{O}}_n \times [0, +\infty)$ and (x_k, t_k) be any sequence converging to this point. Then for every k, we can select y_k satisfying

$$y_k \in \overline{B_n(x_k, t_k)}, \qquad u_0(y_k) = w_n(x_k, t_k).$$

We claim that if $x \in \partial\mathcal{O}_n$, then y_k converges to x. In view of Proposition 4.2(i), we can suppose $\{y_k\}$, $\{x_k\} \subset \mathcal{O}_n$. Let $\sigma > 0$ and k be so large that $t_k < t + \sigma$.

Consider an A_n-admissible path ξ_k and $s_k \le t+\sigma$ such that $\xi_k(0) = x_k$, $\xi_k(s_k) = y_k$. Employing (4.13), (4.14) we get for any $t \in [0, s_k]$,

$$|\dot{\xi}_k(t)| \le \|A_n^{\frac{1}{2}}(\xi_k(t))\| \le L\|\xi_k(t) - x_k\| + \|A_n^{\frac{1}{2}}(x_k)\|.$$

Hence

$$|y_k - x_k| \le L \int_0^{s_k} |\xi_k(t) - x_k| dt + L(t_0 + \sigma)\|A_n^{\frac{1}{2}}(x_k)\|,$$

and by Gronwall's inequality we obtain

$$|y_k - x_k| \le L(t_0 + \sigma)\|A_n^{\frac{1}{2}}(x_k)\| \exp(L(t_0 + \sigma)).$$

So taking into account that x_k and $\|A_n^{\frac{1}{2}}(x_k)\|$ converge to x and 0, respectively, the claim follows. Therefore w_n is u.s.c. for $(x,t) \in \partial\mathcal{O}_n \times [0,+\infty)$.

Finally, let $x \in \mathcal{O}_n$. If n is sufficiently large, we have that $y_k \in \mathcal{O}_n$ and

$$d_n(y_k, x_0) \le t_k + d_n(y_k, x) \le t + \sigma \tag{4.19}$$

for any $\sigma > 0$. We can assume without loss of generality that y_k converge to a point $y_0 \in \mathcal{O}_n$ so that using (4.19) and the continuity of $y \to d_n(y,x)$, we find

$$d_n(x, y_0) = \lim_k d_n(x, y_k) \le t.$$

Hence $w_n(x,t) \ge u_0(y_0) \ge \limsup_k u_0(y_k) = \limsup_k w_n(x_k, t_k)$, which also gives the assertion in this case. □

5. Truncated problems.

We set, for any n, $(x,p) \in \mathbb{R}^N \times \mathbb{R}^N$,

$$H_n(x,p) = -\langle A_n(x)p, p\rangle^{\frac{1}{2}} \tag{5.1}$$

and we consider the equation

$$u_t(x,t) + H_n(x, \nabla u(x,t)) = 0. \tag{5.2}$$

Our aim is to show that the function w_n defined in (4.18) is a solution of (5.2), (2.2) in the sense of Definition 2.2.

We start by recalling some elementary facts from Riemannian geometry that we will apply to the Riemannian manifolds $(\mathcal{O}_n, g_n)$. In the next proposition $(\mathcal{M}, g)$ is a Riemannian manifold, d_g is the distance associated to g, and $B_g(x,r) = \{y : d_g(x,y) < r\}$ for $x \in \mathcal{M}$, $r > 0$. By a minimizing geodesic we mean a curve $\xi : [0,T] \to \mathcal{M}$ satisfying $d_g(\xi(t), \xi(s)) = |t - s|$ for every $t, s \in [0,T]$. For such a geodesic, the Riemannian norm of $\dot{\xi}(t)$ equals 1 for any t.

PROPOSITION 5.1. *Let $x_0 \in \mathcal{M}$. There exists $\delta_0 = \delta(x_0) > 0$ such that if $\delta \in (0, \delta_0)$, then*

(i) *any two points of $B_g(x_0, 3\delta)$ can be joined by a unique minimizing geodesic.*

(ii) *d_g^2 is differentiable in $B_g(x_0, 3\delta) \times B_g(x_0, 3\delta)$.*

(iii) *for any $y_0 \in \overline{B_g(x_0, \delta)}$ and $z_0 \in \overline{B_g(y_0, \delta)}$, $z_0 \ne y_0$, denoting by ξ the minimizing geodesic joining y_0 to z_0 with $\xi(0) = y_0$, $\xi(T) = z_0$, we have that $\dot{\xi}(T)$ is equal to the Riemannian gradient at z_0 of the function $z \to d_g(y_0, z)$.*

Proof. See [16, vol. 1], and [7] for verification of this proposition. □

Part (iii) of the previous proposition is a version of the classical Gauss lemma. Recall that, as proved in Proposition 4.2(ii), one has $d_n = d_{g_n}$ in $\mathcal{O}_n$.

COROLLARY 5.1. *Let* $x \in \mathcal{O}_n$, $\delta_0 > 0$ *be as in Proposition* 5.1 *with* $(\mathcal{M}, g) = (\mathcal{O}_n, g_n)$, $y_0 \in \overline{B_n(x_0, \delta)}$ *with* $0 < \delta < \delta_0$. *If* $f : \mathcal{O}_n \to \mathbb{R}$ *is a differentiable function which attains a local minimum on* $\overline{B_n(y_0, \delta)}$ *at a point* $z_0 \neq y_0$, *then*

$$\nabla f(z_0)\dot{\xi}(T) = H_n(z_0, \nabla f(z_0)), \tag{5.3}$$

where ξ *is the minimal geodesic joining* y_0 *to* z_0 *with* $\xi(0) = y_0$, $\xi(T) = z_0$.

Proof. For any $y \in \mathcal{O}_n$, denote by $\langle \cdot, \cdot \rangle_y$ and $\| \cdot \|_y$, respectively, the inner product and the norm induced by g_n on $T_{\mathcal{O}_n}(y)$. We claim that

$$\dot{\xi}(T) = A_n(z_0)\nabla_2 d_n(y_0, z_0), \tag{5.4}$$

where $\nabla_2 d_n(y_0, z_0)$ is the Euclidean gradient of the function $z \to d_n(y_0, z)$ at z_0 and this function is differentiable by virtue of Proposition 5.1(ii). To prove the claim we observe that

$$\langle A_n(z_0)\nabla_2 d_n(y_0, z_0), b\rangle_z = \langle \nabla_2 d_n(y_0, z_0), b\rangle$$

for any $b \in \mathbb{R}^N$. This equality is equivalent to $A_n(z_0)\nabla_2 d_n(y_0, z_0)$ being the Riemannian gradient of $z \to d_n(y_0, z)$ at z_0. Hence we conclude by using Proposition 5.1(iii).

Since z_0 is a local minimum of f on $\overline{B_n(y_0, \delta)}$ we know that

$$\nabla f(z_0) = \lambda \nabla_2 d_n(y_0, z_0) \qquad \text{for some } \lambda \leq 0.$$

Therefore, noting that by (5.4)

$$1 = \|\dot{\xi}(T)\|^2_{z_0} = \langle A_n(z_0)\nabla_2 d_n(y_0, z_0), \nabla_2 d_n(y_0, z_0)\rangle,$$

we find

$$\begin{aligned}\langle \nabla f(z_0), \dot{\xi}(T)\rangle &= \lambda \langle A_n(z_0)\nabla_2 d_n(y_0, z_0), \nabla_2 d_n(y_0, z_0)\rangle^{\frac{1}{2}} \\ &= -\langle A_n(z_0)\lambda\nabla_2 d_n(y_0, z_0), \lambda\nabla_2 d_n(y_0, z_0)\rangle^{\frac{1}{2}} = H_n\left(z_0, \nabla f(z_0)\right). \qquad \square\end{aligned}$$

LEMMA 5.1. w_n *is a solution of equation* (5.2).

Proof. Since $w_n(x_0, t_0) \wedge M = \max_{\overline{B_n(x_0, t_0)}}\{u_0 \wedge M\}$ for any $(x_0, t_0) \in \mathbb{R}^N \times (0, +\infty)$, $M \in \mathbb{R}$, we need to consider only the case where w_n is finite and show that for any ψ, C^1 supertangent to w_n at (x_0, t_0), we have

$$\psi_t(x_0, t_0) + H_n(x_0, \nabla\psi(x_0, t_0)) = 0. \tag{5.5}$$

If $x_0 \in \mathbb{R}^N \setminus \mathcal{O}_n$, then $H_n(x_0, \nabla\psi(x_0, t_0)) = 0$ and the function $t \to w_n(x_0, t)$ is identically equal to $u_0(x_0)$, which gives $\psi_t(x_0, t_0) = 0$ and, consequently, (5.5).

Now we claim that for any $(x, t) \in \mathcal{O}_n \times (0, +\infty)$, $\sigma \in (0, t)$,

$$w_n(x, t) = \max_{\overline{B_n(x,\sigma)}} \{w_n(\cdot, t - \sigma)\}. \tag{5.6}$$

In fact since $\overline{B_n(y, t - \sigma)} \subset \overline{B_n(x, t)}$ for every $y \in B_n(x, \sigma)$, we see that

$$w_n(x, t) \geq \max_{\overline{B_n(x,\sigma)}} \{w_n(\cdot, t - \sigma)\}. \tag{5.7}$$

Moreover we can find z_0, z_1 verifying $u_0(z_1) = w_n(x,t)$, $d(z_0,x) \leq \sigma$, $d(z_0,z_1) \leq t-\sigma$ from which we deduce

$$w_n(x,t) = w_n(z_0, t-\sigma); \tag{5.8}$$

this equality together with (5.7) yields (5.6).

Fix $(x_0,t_0) \in \mathcal{O}_n \times (0,+\infty)$, $\delta \in (0, t_0 \wedge \delta_0)$, where δ_0 is as in Proposition 5.1 applied to $(\mathcal{O}_n, g_n)$ and select, using (5.6), $y_0 \in \overline{B_n(x,\delta)}$ such that

$$w_n(x_0,t_0) = w_n(y_0, t_0-\delta). \tag{5.9}$$

We can always assume that the C^1 supertangent ψ verifies $\psi(x_0,t_0) = w_n(x_0,t_0)$ and $\psi(x,t) \geq w_n(x,t)$ in $B_n(x_0, 3\delta) \times (t_0-\delta, t_0+\delta)$. We have, for any $x \in \overline{B_n(y_0,\delta)}$,

$$\begin{aligned}\psi(x,t_0) \geq w_n(x,t_0) &= \max_{\overline{B_n(x,\delta)}} \{w_n(\cdot, t_0-\delta)\} \\ &\geq w_n(y_0,t_0-\delta) = w_n(x_0,t_0) = \psi(x_0,t_0)\end{aligned}$$

so that

$$\psi(x_0,t_0) = \min_{\overline{B_n(y_0,\delta)}} \{\psi(\cdot, t_0)\}. \tag{5.10}$$

If $x_0 = y_0$, then by (5.10)

$$\nabla\psi(x_0,t_0) = 0. \tag{5.11}$$

Moreover because the function $t \to w_n(x_0,t)$ is nondecreasing by (4.18) and constant in $[t_0-\delta, t_0]$ by (5.9), we get

$$\psi_t(x_0,t_0) = 0. \tag{5.12}$$

This equality and (5.11) give (5.5).

If $x_0 \neq y_0$, let $d_n(x_0,y_0) = \rho \leq \delta$ and denote by ξ the minimizing geodesic joining y_0 to x_0 with $\xi(0) = y_0$ and $\xi(\rho) = x_0$. The path ξ can be extended to an interval $[0,\rho')$, $\rho' > \rho$, with the property

$$d_n(\xi(t), y_0) = t, \qquad t \in [0,\rho'). \tag{5.13}$$

Set $f(t) = \psi(\xi(t), t+t_0-\rho)$ and employ (5.6), (5.13), and (5.9) to find for t close to ρ,

$$\begin{aligned}f(t) \geq w_n(\xi(t), t+t_0-\delta) &= \max_{\overline{B_n(\xi(t),t)}} \{w_n(\cdot, t_0-\delta)\} \\ &\geq w_n(y_0,t_0-\delta) = w_n(x_0,t_0) = f(\rho).\end{aligned}$$

Hence

$$\frac{df}{dt}(\rho) = \nabla\psi(x_0,t_0)\cdot\dot{\xi}(\rho) + \psi_t(x_0,t_0) = 0.$$

By this equality, (5.10), and Corollary 5.1, we get (5.5) and conclude the proof. □

Now we show that the sequence w_n converges in a suitable sense to a function w defined via

$$w(x,t) = \inf_{\varepsilon>0} \sup_{B(x,t+\varepsilon)} \{u_0\}. \tag{5.14}$$

This result along with stability properties of viscosity solutions will imply that w is a solution of (2.1).

Definition 5.1. *Given a sequence ϕ_n of functions from $\mathbb{R}^N \times [0,+\infty) \to \mathbb{R} \cup \{+\infty\}$ and $\phi : \mathbb{R}^N \times [0,+\infty) \to \mathbb{R} \cup \{+\infty\}$, we say that $\phi = \limsup^*_n \phi_n$ in $\mathbb{R}^N \times [0,+\infty)$ if for any $(z,t) \in \mathbb{R}^N \times [0,+\infty)$,*

$$\phi(z,t) = \sup\left\{\limsup_n \phi_n(z_n,t_n) : (z_n,t_n) \to (z,t)\right\}.$$

Proposition 5.2. *Let $\phi = \limsup^*_n \phi_n$ in $\mathbb{R}^N \times [0,+\infty)$. One has that*

(i) *ϕ is u.s.c.*

(ii) *$\phi \wedge M = \limsup^*_n(\phi_n \wedge M)$ in $\mathbb{R}^N \times [0,+\infty)$ for any $M \in \mathbb{R}$.*

(iii) *If $\overline{\phi} : \mathbb{R}^N \times [0,+\infty) \to \mathbb{R} \cup \{+\infty\}$ is u.s.c. and $\overline{\phi} \geq \phi_n$ on $\mathbb{R}^N \times [0,+\infty)$ for every $n \in \mathbb{N}$, then $\overline{\phi} \geq \phi$.*

Proof. For verification of Proposition 5.2, see [11], where the previous limit is called $\Gamma - \limsup$. □

Lemma 5.2. *$w = \limsup^*_n w_n$ in $\mathbb{R}^N \times [0,+\infty)$.*

Proof. The proof is based on the inclusions

$$B_n(x_n,t_n) \subset B(x_0,t_0+\delta), \tag{5.15}$$

$$B\left(x_0, t_0 + \frac{\delta}{2}\right) \subset B_n(x_0,(1+\delta)(t_0+\delta)), \tag{5.16}$$

which we claim are true for any $(x_0,t_0) \in \mathbb{R}^N \times [0,+\infty)$, (x_n,t_n) converging to this point, $\delta > 0$, and n sufficiently large.

To obtain the first one choose n such that $d(x_n,x_0) < \frac{\delta}{2}$, $t_n < t_0 + \frac{\delta}{2}$ and note that, by this last inequality, for any $y \in B_n(x_n,t_n)$, there exists an A_n-admissible path ξ with $\xi(0) = x_n$, $\xi(t_0 + \frac{\delta}{2}) = y$. Furthermore, ξ is A-admissible since $A_n \leq A$; therefore,

$$d(x_0,y) \leq d(x_0,x_n) + d(x_n,y) < t_0 + \delta,$$

which is (5.15).

Now choose $z \in B(x_0, t_0 + \frac{\delta}{2})$ and an A-admissible path ζ verifying $\zeta(0) = x_0$, $\zeta(t_0+\delta) = z$. Since this curve is continuous we find

$$\zeta([0,t_0+\delta]) \subset B^E(0,r) \tag{5.17}$$

for a suitable $r > 0$. Exploiting the fact that A_n converges to A uniformly on compact subsets, we also have

$$A(x) \leq (1+\delta)^2 A_n(x), \qquad x \in B^E(0,r) \tag{5.18}$$

for n sufficiently large. By (5.17) and (5.18) the path $\overline{\zeta}(s) = \zeta(\frac{s}{1+\delta})$ satisfies

$$\begin{aligned}\dot{\overline{\zeta}}(s) \otimes \dot{\overline{\zeta}}(s) &= \frac{1}{(1+\delta)^2}\left(\dot{\zeta}\left(\frac{s}{1+\delta}\right) \otimes \dot{\zeta}\frac{s}{1+\delta}\right) \\ &\leq \frac{1}{(1+\delta)^2} A\left(\zeta\left(\frac{s}{1+\delta}\right)\right) \leq A_n(\overline{\zeta}(s))\end{aligned}$$

for a.e. $s \in [0,(1+\delta)(t_0+\delta)]$ and, obviously, $\overline{\zeta}(0) = x_0$, $\overline{\zeta}((1+\delta)(t_0+\delta)) = z$. Therefore $d_n(x_0,z) \le (1+\delta)(t_0+\delta)$, so (5.16) follows.

The relation (5.15) implies

$$w_n(x_n,t_n) \le \sup_{B(x_0,t_0+\delta)} \{u_0\} \le w(x_0,t_0+\delta)$$

for any given $\delta > 0$ and n sufficiently large. Therefore, taking into account that w is u.s.c., we have

$$w(x_0,t_0) \ge \limsup_{\delta\to 0} w(x_0,t_0+\delta) \ge \limsup_n w_n(x_n,t_n).$$

To end the proof we construct a sequence (z_n,s_n) converging to (x_0,t_0) such that

$$\limsup_n w_n(z_n,s_n) \ge w(x_0,t_0). \tag{5.19}$$

Suppose first that $w(x_0,t_0) < +\infty$ and fix $\delta > 0$. For any $\sigma > 0$ we can select by (5.14) a point $z_0 \in B(x_0,t_0+\frac{\delta}{2})$ satisfying

$$u_0(z_0) \ge \sup_{B(x_0,t_0+\frac{\delta}{2})} \{u_0\} - \sigma \ge w(x_0,t_0) - \sigma.$$

From this and (5.16) we obtain

$$w_n(x_0,(1+\delta)(t_0+\delta)) \ge u_0(z_0) \ge w(x_0,t_0) - \sigma.$$

Hence

$$\liminf_n w_n(x_0,(1+\delta)(t_0+\delta)) \ge w(x_0,t_0). \tag{5.20}$$

Then we choose δ_h converging to zero and set $t_h = (1+\delta_h)(t_0+\delta_h)$. By (5.20), there exists a subsequence w_{k_h} of w_n such that

$$w_{k_h}(x_0,t_h) \ge w(x_0,t_0) - \frac{1}{h}. \tag{5.21}$$

If we define

$$\begin{aligned} z_n &= x_0 \qquad \text{for any } n,\\ s_n &= t_h \qquad \text{for } k_h \le n < k_{h+1}, \end{aligned}$$

from the fact that $w_{k_h}(z_{k_h},s_{k_h}) = w_{k_h}(x_0,t_h)$ is a subsequence of $w_n(z_n,s_n)$ and by using (5.21), we get (5.19).

In the case where $w(x_0,t_0) = +\infty$, it is possible to argue as above to discover that $\lim_n w_n(x_0,(1+\delta)(t_0+\delta)) = +\infty$ for every $\delta > 0$. So, denoting by δ_n any sequence converging to zero and setting $s_n = (1+\delta_n)(t_0+\delta_n)$, $z_n = x_0$, we find that (5.19) holds. □

Remark 5.1. It is worth noting that, as easily seen in Example 8.1, the sequence w_n may not in general converge pointwisely to w. If instead $(\mathbb{R}^N,d)$ is complete, then the convergence of w_n to w is uniform on compact sets of $\mathbb{R}^N$.

THEOREM 5.1. *w is a solution of* (2.1), (2.2).

Proof. $w \in X$ thanks to Proposition 5.2(i). To prove that w is a solution of equation (2.1), we only need to show that H_n converges to H uniformly on a compact subset of $\mathbb{R}^N \times \mathbb{R}^N$, since in this case the assertion is a consequence of Lemmata 5.1, 5.2 and well-known stability results for viscosity solutions (see [2]). To get the convergence of H_n, let $\mathcal{K}$ be a compact subset of $\mathbb{R}^N \times \mathbb{R}^N$ and $m > 0$ verifying $A \geq m^2 I$ in $\mathcal{K}_1 = \{x : (x,p) \in \mathcal{K} \text{ for some } p\}$ and $|p| \leq \frac{1}{m}$ in $\mathcal{K}_2 = \{p : (x,p) \in \mathcal{K} \text{ for some } x\}$. Then for any $(x,p) \in \mathcal{K}$, we have

$$|H_n(x,p) - H(x,p)| \leq \frac{1}{m^2} \max_{\mathcal{K}_1} \|A_n(x) - A(x)\|$$

and we conclude by employing the uniform convergence of A_n to A on $\mathcal{K}_1$.

We must still prove that

$$w(x,0) = u_0(x) \qquad \text{for every } x \in \mathbb{R}^N. \tag{5.22}$$

The inequality $w(x,0) \geq u_0(x)$ is clear from (5.14). For any fixed x, according to Proposition 3.1(ii), we have that $B(x,\varepsilon)$ is relatively compact for $\varepsilon > 0$ sufficiently small and so for such ε there exists $x_\varepsilon \in \overline{B(x,\varepsilon)}$ satisfying

$$u_0(x_\varepsilon) = \sup_{B(x,\varepsilon)} \{u_0\}.$$

Therefore, by (5.14), $w(x,0) = \lim_{\varepsilon\to 0} u_0(x_\varepsilon)$ and since $u_0 \in X_0$, we get $w(x,0) \leq u_0(x)$. The equality (5.22) is therefore proved. □

In what follows we will refer to w as the canonical solution of problem (2.1), (2.2).

We conclude this section pointing out an immediate consequence of Lemma 5.2 and of Proposition 5.2(iii) that we will use in the comparison results of section 6.

COROLLARY 5.2. *Let u be a solution of* (2.1), (2.2) *and assume that $u \geq w_n$ on $\mathbb{R}^N \times [0,+\infty)$ for every $n \in \mathbb{N}$. Then $u \geq w$.*

6. Construction of a test function.

We consider a solution u of (2.1) and for any $\alpha \in \mathbb{R}$, the level sets

$$\Gamma_\alpha(t) = \{x : u(x,t) \geq \alpha\}, \qquad t \in [0,+\infty),$$

which are closed since $u \in X$, possibly empty. We set

$$J_\alpha = \{t \geq 0 : \Gamma_\alpha(t) \neq \emptyset\}$$

and define on $\mathbb{R}^N \times J_\alpha$ the function

$$v_\alpha : (x,t) \to -d^E(x, \Gamma_\alpha(t)).$$

The purpose of this section is to show that v_α is locally Lipschitz and verifies with its generalized gradient a certain differential inequality related to equation (2.1). These properties will be crucial for the proof of the comparison results of the next section.

We fix $\alpha \in \mathbb{R}$ and we write in this section for simplicity Γ, J, v instead of Γ_α, J_α, v_α, respectively. We start with two lemmata.

LEMMA 6.1.

(i) *If J is not empty, then $J \setminus \{0\}$ is a open unbounded interval.*

(ii) *Let $\mathcal{H}$ be a compact set of $\mathbb{R}^N$ and define $J_{\mathcal{H}} = \{t > 0 : \Gamma(t) \cap \mathcal{H} \neq \emptyset\}$. If $J_{\mathcal{H}}$ is not empty, then it is a closed unbounded interval. Moreover if $\bar{t} = \min\{J_{\mathcal{H}}\}$ is positive, then $\Gamma(\bar{t}) \cap \mathcal{H} \subset \partial\mathcal{H}$.*

Proof. If J is not empty, then it is an unbounded interval by the monotonicity of u; see Remark 2.1. To show that $J \setminus \{0\}$ is open we argue by contradiction and assume that J has a minimum t_0 strictly positive. Then (x_0, t_0) is a minimum of the function $\psi : (x,t) \to t$ on $\{u \geq \alpha\}$ for every $x_0 \in \Gamma(t_0)$. This implies by Proposition 2.1 that equality (2.5) holds, which is impossible because of the definition of ψ.

Now we prove (ii). Clearly $J_{\mathcal{H}}$ is an unbounded interval. To show that it is closed, set $\bar{t} = \inf J_{\mathcal{H}}$ and denote by t_n a sequence of $J_{\mathcal{H}}$ converging to $\bar{t}$. Hence there exist $x_n \in \mathcal{H}$ which verify $u(x_n, t_n) \geq \alpha$. Moreover the sequence x_n converges, up to a subsequence, to a point $\overline{x} \in \mathcal{H}$. Since u is u.s.c. one has $u(\overline{x}, \bar{t}) \geq \alpha$, which gives $\bar{t} \in J_{\mathcal{H}}$. Finally if $\bar{t} > 0$ and $\Gamma(\bar{t}) \cap \mathcal{H}^\circ \neq \emptyset$, we repeat the argument of the first part to get a contradiction. This ends the proof. □

LEMMA 6.2.

(i) *v is u.s.c. in $\mathbb{R}^N \times J$.*

(ii) *For any $(x_0, t_0) \in \mathbb{R}^N \times J$, $t_0 > 0$, and ψ C^1-supertangent to v at (x_0, t_0), one has*

$$|\nabla \psi(x_0, t_0)| \leq 1. \tag{6.1}$$

Proof. Fix $(x_0, t_0) \in \mathbb{R}^N \times J$ and let (x_n, t_n) be a sequence in $\mathbb{R}^N \times J$ converging to (x_0, t_0) such that $\lim_n v(x_n, t_n)$ exists. This limit is then finite because by employing the monotonicity of u, we can choose $\varepsilon > 0$ verifying $(t_0 - \varepsilon) \in J$ and $|v(x_n, t_n)| \leq |v(x_0, t_0 - \varepsilon)| + \varepsilon$ for n sufficiently large. Because $\Gamma(t_n)$ is a closed nonempty set, there exists, for every n, $y_n \in \Gamma(t_n)$ satisfying

$$-|y_n - x_n| = v(x_n, t_n). \tag{6.2}$$

Hence the sequence y_n is bounded and so convergent, up to a subsequence, to a point y_0 which belongs to $\Gamma(t_0)$ by the upper semicontinuity of u. Therefore taking into account (6.2), we have

$$\lim_n v(x_n, t_n) = -|x_0 - y_0| \leq v(x, t),$$

and this proves (i).

The inequality (6.1) follows from the fact that $x \to v(x,t)$ is Lipschitz continuous with Lipschitz constant 1 for every t (see [1]). □

PROPOSITION 6.1.

(i) *v is locally Lipschitz in $\mathbb{R}^N \times J$.*

(ii) *For any compact set $\mathcal{K}$ of $\mathbb{R}^N \times (J \setminus \{0\})$, there exists a positive constant $L = L(\mathcal{K})$ such that*

$$s + H(x, p) \geq Lv(x, t) \tag{6.3}$$

for every $(x,t) \in \mathcal{K}$, $(p, s) \in \partial v(x,t)$.

Proof. As a first step let us show that for any $(x_0, t_0) \in \mathbb{R}^N \times J$, $t_0 > 0$, ψ C^1-supertangent to v at this point, one has

$$\psi_t(x_0, t_0) + H(z_0, \nabla \psi(x_0, t_0)) = 0, \tag{6.4}$$

where z_0 is any element of $\Gamma(t_0)$ satisfying

$$|z_0 - x_0| = -v(x_0, t_0). \tag{6.5}$$

In fact set $\beta = v(x_0,t_0)$, $b = x_0 - z_0$, $\overline{\psi}(x,t) = \psi(x+b,t)$ and note that ψ attains a local minimum at (x_0,t_0) on the set $\{v \geq \beta\}$. Then denote by U a neighborhood of (x_0,t_0) such that the inequality $\psi(x,t) \geq \psi(x_0,t_0)$ holds for every $(x,t) \in U \cap \{v \geq \beta\}$ and write $\widetilde{U} = \{(z,t) : (z+b,t) \in U\}$. If $(z,t) \in \widetilde{U} \cap \{u \geq \alpha\}$, then $(z+b,t) \in U \cap \{v \geq \beta\}$ since $|b| = -\beta$. So we obtain $\overline{\psi}(z,t) \geq \overline{\psi}(z_0,t_0)$ which shows that (z_0,t_0) is a local minimum point of $\overline{\psi}$ on $\{u \geq \alpha\}$. Therefore by Proposition 2.1 we find

$$\overline{\psi}_t(z_0,t_0) + H(z_0, \nabla\overline{\psi}(z_0,t_0)) = 0$$

and (6.4) follows.

We turn now to the proof of (i). Let $\mathcal{K}$ be a compact subset of $\mathbb{R}^N \times J$. We can assume without loss of generality that $\mathcal{K} = \mathcal{H} \times I$, where $\mathcal{H}$ and I are a compact domain of $\mathbb{R}^N$ and a compact interval contained in J, respectively. Set $t_1 = \min I$, $m = \min_{\mathcal{H}}\{v(\cdot,t_1)\}$. Since, by the monotonicity of v, $m = \min_{\mathcal{K}}\{v\}$, we have that if $(x_0,t_0) \in \mathcal{K}$ and z_0 verifies (6.5), then $z_0 \in \widetilde{\mathcal{H}} = \{x : d^E(x,\mathcal{H}) \leq -m\}$ which is a compact set. From this, (6.4), and Lemma 6.2(ii) we get for $t_0 > 0$,

$$|\psi_t(x_0,t_0)| \leq M \tag{6.6}$$

for any positive constant M satisfying

$$\|A(x)\| \leq M^2, \qquad x \in \widetilde{\mathcal{H}}.$$

Since the inequality (6.6) holds for any $(x_0,t_0) \in \mathcal{K}$, $t_0 > 0$, and any ψ C^1 supertangent to v at (x_0,t_0), we discover that (see [4], [10]) for every $x \in \mathcal{H}$, the function $t \to v(x,t)$ is Lipschitz continuous in I with Lipschitz constant less than or equal to M. Then we get the assertion (i) recalling that v is also Lipschitz continuous in x with Lipschitz constant independent of t.

To prove (ii) let $\mathcal{K}$ be a compact subset of $\mathbb{R}^n \times (J \setminus \{0\})$ and let $\mathcal{H}$, $\widetilde{\mathcal{H}}$, and I be as above. We first select two positive constants $\widetilde{L}$, $\widetilde{m}$ satisfying

$$\begin{gathered}\|A(x) - A(y)\| \leq \widetilde{L}|x-y|,\\ A(x) \geq \widetilde{m}^2 I\end{gathered}$$

for any $x, y \in \widetilde{\mathcal{H}}$. Then we compute for any $p \neq 0$, $x, y \in \widetilde{\mathcal{H}}$,

$$\begin{aligned}|H(x,p) - H(y,p)| &\leq \frac{\|A(x)-A(y)\||p|^2}{\langle A(x)p,p\rangle^{\frac{1}{2}} + \langle A(y)p,p\rangle^{\frac{1}{2}}}\\ &\leq \frac{\widetilde{L}}{\widetilde{m}}|x-y|\,|p|.\end{aligned} \tag{6.7}$$

Set $L = \widetilde{L}/\widetilde{m}$, recall Lemma 6.2, and use (6.7) in (6.4) to find for $(x_0,t_0) \in \mathcal{K}$,

$$\begin{aligned}&\psi_t(x_0,t_0) + H(x_0, \nabla\ psi(x_0,t_0))\\ &\quad \geq -L|\nabla\psi(x_0,t_0)||x_0 - z_0| = Lv(x_0,t_0).\end{aligned} \tag{6.8}$$

If, in particular, v is differentiable at (x_0,t_0), from (6.8) we get

$$v_t(x_0,t_0) + H(x_0, \nabla v(x_0,t_0)) \geq Lv(x_0,t_0). \tag{6.9}$$

Hence we obtain (6.3) by using Proposition 2.2(iv) and the fact that H is concave in p. □

7. Comparison results.

We start by proving a maximum principle for equation (2.1). Given two solutions u_1, u_2 of (2.1), we will put by convention $u_1(x,t) - u_2(x,t) = 0$ whenever u_1 and u_2 are both infinite at (x,t).

THEOREM 7.1. *Let $\mathcal{H}$ be a bounded set of $\mathbb{R}^N$ and I be any interval with minimum equal to* 0*. If u_1 and u_2 are solutions of* (2.1), (2.2), *then*

$$\sup_{\mathcal{H}\times I}\{|u_1 - u_2|\} = \sup_{\partial\mathcal{H}\times I}\{|u_1 - u_2|\}. \tag{7.1}$$

Proof. We argue by contradiction and assume that there exists $(x_0, t_0) \in \mathcal{H}^\circ \times I$ and two positive constants α, β satisfying

$$\alpha - \beta > \sup_{\partial\mathcal{H}\times I}\{|u_1 - u_2|\}, \tag{7.2}$$

$$u_1(x_0, t_0) \geq \alpha > \beta > u_2(x_0, t_0). \tag{7.3}$$

We define

$$\Gamma_1(t) = \{x : u_1(x,t) \geq \alpha\},$$
$$\Gamma_2(t) = \{x : u_2(x,t) \geq \beta\},$$

and

$$J_i = \{t \geq 0 : \Gamma_i(t) \cap \overline{\mathcal{H}} \neq \emptyset\}, \qquad i = 1, 2.$$

By Lemma 6.1, J_1 has a minimum that we denote by t_1. We wish to show that

$$[t_1, t_0] \subset J_2. \tag{7.4}$$

In fact if $t_1 = 0$, then for any $x \in \Gamma_1(t_1) \cap \overline{\mathcal{H}}$, one has

$$u_2(x, t_1) = u_1(x, t_1) \geq \alpha > \beta$$

which gives $t_1 \in J_2$ and so (7.4).

If $t_1 > 0$, then by Lemma 6.1(ii), $\Gamma_1(t_1) \cap \overline{\mathcal{H}} \subset \partial\mathcal{H}$. This implies

$$\Gamma_1(t_1) \cap \overline{\mathcal{H}} \subset \Gamma_2(t_1); \tag{7.5}$$

otherwise, for any $x \in (\Gamma_1(t_1) \cap \overline{\mathcal{H}}) \setminus (\Gamma_2(t_1))$, we should have

$$u_1(x,t) - u_2(x,t) > \alpha - \beta$$

which is impossible by (7.2). From (7.5) we immediately get (7.4). Now set $\mathcal{K} = \overline{\mathcal{H}} \times [t_1, t_0]$ and for any $(x,t) \in \mathcal{K}$,

$$v(x,t) = -d^E(x, \Gamma_2(t)).$$

By (7.4) we can use Proposition 6.1 to deduce that v is Lipschitz in $\mathcal{K}$. We fix $\lambda > L$, where L is as in formula (6.3) and define $\overline{v}(x,t) = e^{-\lambda t} v(x,t)$ for any $(x,t) \in \mathcal{K}$. From (6.3) and the positive homogeneity of H in p, we get

$$s + H(x,p) \geq (L - \lambda)\overline{v}(x,t) \geq 0 \tag{7.6}$$

for any $(x,t) \in \mathcal{K}$, $t > 0$, $(p,s) \in \partial\overline{v}(x,t)$. Now choose $(\overline{x},\overline{t}) \in \{u_1 \geq \alpha\} \cap \mathcal{K}$ such that

$$\overline{v}(\overline{x},\overline{t}) = \min_{\{u_1 \geq \alpha\}\cap\mathcal{K}} \{\overline{v}\}. \tag{7.7}$$

Since, by the definition of $\overline{v}$ and (7.3), $\overline{v}(x_0,t_0) < 0$ and $\overline{v}(\overline{x},\overline{t}) \leq \overline{v}(x_0,t_0)$, we find

$$\overline{v}(\overline{x},\overline{t}) < 0. \tag{7.8}$$

Keeping in mind the definition of $\overline{v}$, from (7.8) we deduce

$$u_2(\overline{x},\overline{t}) < \beta$$

and, consequently,

$$\overline{x} \in \mathcal{H}^\circ, \tag{7.9}$$

because otherwise, from the inequality $u_1(\overline{x},\overline{t}) - u_2(\overline{x},\overline{t}) > \alpha - \beta$, we should get a contradiction of (7.2).

We claim that

$$\overline{t} > t_1. \tag{7.10}$$

In fact if $t_1 = 0$, $t_1 = \overline{t}$ is impossible since this should imply $u_1(\overline{x},\overline{t}) = u_2(\overline{x},\overline{t})$. If instead $t_1 > 0$, then the equality $\overline{t} = t_1$ contradicts (7.9) by Lemma 6.1(ii). Thanks to (7.7), (7.9), and (7.10) we see that $(\overline{x},\overline{t})$ is a point of local minimum of $\overline{v}$ on $\{u_1 \geq \alpha\} \cap \mathbb{R}^N \times (t_1,t_0]$. Hence by Proposition 2.4 and Remark 2.2, we get the existence of $(\overline{p},\overline{s}) \in \partial\overline{v}(\overline{x},\overline{t})$ verifying

$$\overline{s} + H(\overline{x},\overline{p}) \leq 0.$$

This contradicts (7.6) if we take into account (7.8) and the inequality $\lambda > L$. □

The argument of the previous proof gives the following corollary.

COROLLARY 7.1. *Let u_1, u_2 be two solutions of* (2.1) *and I be an interval with minimum equal to* 0. *If $u_1(x,0) \leq u_2(x,0)$ for every $x \in \mathbb{R}^N$, then either*

$$u_1 \leq u_2 \qquad \text{in } \mathbb{R}^N \times I$$

or

$$\liminf_{R\to+\infty} \sup_{\partial B^E(0,R)\times I} \{u_1 - u_2\} > 0.$$

Proof. If there exists $(x_0,t_0) \in \mathbb{R}^N \times I$ such that $u_1(x_0,t_0) > u_2(x_0,t_0)$, use the argument of Theorem 7.1 to show that

$$\sup_{\partial B^E(0,R)\times I} \{u_1 - u_2\} \geq u_1(x_0,t_0) - u_2(x_0,t_0)$$

if $R \geq |x_0|$. This proves the assertion. □

The next result yields the minimality of the canonical solution among the solutions of (2.1), (2.2).

THEOREM 7.2. *The canonical solution w is the minimal solution of* (2.1), (2.2).

Proof. In view of Corollary 5.2 it is enough to prove that if u is a solution of (2.1), (2.2), then for any n,

$$u \geq w_n \qquad \text{in } \mathbb{R}^N \times (0, +\infty), \tag{7.11}$$

where w_n are the functions defined in (4.18). Note that w_n is a subsolution of (2.1), (2.2) by (4.2). So if (7.11) is not true, using Corollary 7.1 one has that there exists $\overline{n}$ such that

$$\liminf_{R \to +\infty} \sup_{\partial B^E(0,R) \times [0,+\infty)} \{w_{\overline{n}} - u\} > 0. \tag{7.12}$$

For R sufficiently large, $\partial B^E(0,R) \subset \mathbb{R}^N \setminus \mathcal{O}_{\overline{n}}$ and $w_{\overline{n}}(x,t) = u_0(x)$ for every $(x,t) \in (\mathbb{R}^N \setminus \mathcal{O}_{\overline{n}}) \times [0, +\infty)$ by virtue of Proposition 4.2(i) and (4.18). This contradicts (7.12) since u is nondecreasing. □

Using Corollary 7.1 and Theorem 7.2 we establish that problem (2.1), (2.2) is uniquely solvable when the solutions are required to satisfy a certain growth condition at infinity.

Corollary 7.2. *Let I be any interval with minimum equal to* 0 *and u be a solution of* (2.1), (2.2). *If*

$$\liminf_{R \to +\infty} \sup_{\partial B^E(0,R) \times I} (u - w) \leq 0, \tag{7.13}$$

then $u = w$ in $\mathbb{R}^N \times I$.

We now give a characterization for solutions of equation (2.1).

Theorem 7.3. *A function $u \in X$ is a solution of* (2.1) *if and only if one has*

$$u(x_0, t_0 + s) = \max_{\overline{B(x_0,s)}} \{u(\cdot, t_0)\} \tag{7.14}$$

for any $(x_0, t_0) \in \mathbb{R}^N \times [0, +\infty)$, $s < d(x_0, \infty)$.

Proof. Let x_0, t_0, s, and u be as in the statement above and denote by $\widetilde{w}$ the canonical solution of (2.1) with initial datum $x \to u(x, t_0)$, i.e., the function given by the formula (4.18) with u_0 replaced by $u(\cdot, t_0)$. We claim that

$$\widetilde{w}(x_0, s) = \max_{\overline{B(x_0,s)}} \{u(\cdot, t_0)\}. \tag{7.15}$$

In fact from the definition of $\widetilde{w}$, the upper semicontinuity of u_0, and the compactness of $\overline{B(x_0, s + \frac{1}{n})}$ for n sufficiently large, we see that

$$\widetilde{w}(x_0, s) = \lim_n \max_{\overline{B(x_0,s+\frac{1}{n})}} \{u(\cdot, t_0)\} \geq \max_{\overline{B(x_0,s)}} \{u(\cdot, t_0)\}. \tag{7.16}$$

We select x_n verifying

$$\begin{aligned} x_n &\in \overline{B\left(x_0, s + \frac{1}{n}\right)}, \\ u(x_n, t_0) &= \max_{\overline{B(x_0,s+\frac{1}{n})}} \{u(\cdot, t_0)\}. \end{aligned} \tag{7.17}$$

If $\widetilde{x}$ is a limit point of x_n, we have

$$\widetilde{x} \in \overline{B(x_0, s)}.$$

Taking (7.16) into account,

$$\max_{\overline{B(x_0,s)}}\{u(\cdot,t_0)\} \geq u(\widetilde{x},t_0) \geq \widetilde{w}(x_0,s) \geq \max_{\overline{B(x_0,s)}}\{u(\cdot,t_0)\}. \tag{7.18}$$

The claim implies that a function $u \in X$ satisfying (7.14) is solution of (2.1).

Conversely let u be a solution of (2.1). According to (7.15), equality (7.14) is equivalent to

$$u(x_0,t_0+s) = \widetilde{w}(x_0,s) \qquad \text{for } s < d(x_0,\infty). \tag{7.19}$$

If (7.19) is not true, by Theorem 7.2 there exists $\widetilde{t} \in (0, d(x_0,\infty))$ such that

$$u(x_0,t_0+\widetilde{t}) > \widetilde{w}(x_0,\widetilde{t}). \tag{7.20}$$

We define a function $\overline{u}_0 \in X_0$ via

$$\overline{u}_0 = \begin{cases} u(\cdot,t_0) & \text{in } B(x_0,\overline{t}), \\ u(\cdot,t_0) \vee \alpha & \text{in } \mathbb{R}^N \setminus B(x_0,\overline{t}), \end{cases} \tag{7.21}$$

where $\alpha = u(x_0,t_0+\widetilde{t})$ and $\widetilde{t} < \overline{t} < d(x_0,\infty)$ and denote by $\overline{w}$ the canonical solution of (2.1) with initial datum $\overline{u}_0$.

Now we observe that by (7.21),

$$u(x,t_0) \leq \overline{u}_0(x) = \overline{w}(x,0) \qquad \text{for every } x \tag{7.22}$$

and using (7.15), (7.20), and (7.21) we see that

$$\overline{w}(x_0,\widetilde{t}) = \widetilde{w}(x_0,\widetilde{t}) < u(x_0,t_0+\widetilde{t}) = \alpha. \tag{7.23}$$

Taking (7.22), (7.23) into account and applying Corollary 7.1 to $\overline{u}(x,t) = u(x,t_0+t) \wedge \alpha$ and $\overline{w}$, which are solutions of (2.1), we get

$$\liminf_{R\to+\infty} \sup_{\partial B^E(0,R)\times[0,+\infty)} \{\overline{u} - \overline{w}\} > 0.$$

This is impossible since

$$\overline{u} \leq \alpha \qquad \text{in } \mathbb{R}^N \times [0,+\infty)$$

and

$$\overline{w}(x,t) \geq \overline{u}_0(x) \geq \alpha \qquad \text{for any } (x,t) \in (\mathbb{R}^N \setminus B(x_0,\overline{t})) \times [0,+\infty). \qquad \square$$

The previous theorem has the following interpretation: As long as the ball $B(x_0,s)$ is relatively compact, every solution of (2.1) in the interval $[t_0,t_0+s]$ can be represented with a formula analogous to that of the canonical solution.

Remark 7.1. From Theorem 7.3 it easily follows that if the initial data satisfy

$$\lim_{|x|\to+\infty} u_0(x) = +\infty,$$

then the solution of (2.1),(2.2) is unique.

Moreover if $(\mathbb{R}^N, d)$ is complete, then every solution starting from a continuous u_0 is continuous in $\mathbb{R}^N \times [0,+\infty)$.

In the final part of the section we will prove that the uniqueness of solutions of (2.1), (2.2) for any initial datum is the equivalent of the metric space $(\mathbb{R}^N, d)$ being complete.

PROPOSITION 7.1. *If* $(\mathbb{R}^N, d)$ *is not complete, then*

$$u(x,t) = t - d(x,\infty), \qquad (x,t) \in \mathbb{R}^N \times (0,+\infty) \tag{7.24}$$

is a noncanonical solution of equation (2.1).

Proof. We have for any $x_0, y_0 \in \mathbb{R}^N$,

$$d(x_0,\infty) \leq d(x_0,y_0) + d(y_0,\infty), \tag{7.25}$$

so u is locally Lipschitz with respect to the Euclidean distance. By (7.25) we get

$$u(x_0, t+t_0) = -d(x_0,\infty) + t + t_0 \geq -d(y,\infty) + t_0$$

for any $t_0, t > 0$, $y \in \overline{B(x_0,t)}$. By Lemma 3.2 we know that if $t < d(x_0,\infty)$, there exists $z \in \partial B(x_0,t)$ such that

$$u(x_0, t+t_0) = -d(z,\infty) + t_0.$$

Therefore u satisfies (7.14) and is a solution of (2.1) according to Theorem 7.3. □

From the previous proposition and Theorem 7.3 we obtain the following corollary.

COROLLARY 7.3. *Problem* (2.1), (2.2) *is uniquely solvable for any initial datum if and only if the metric space* $(\mathbb{R}^N, d)$ *is complete.*

8. Examples. The first two examples illustrate the pathologies which can occur in problem (2.1), (2.2). As we explained before these phenomena depend on the lack of completeness of the distance associated to A.

The first example shows that the canonical solution can be discontinuous and infinite even starting from a smooth initial datum.

Example 8.1. Set $N = 2$ and put in (2.1), (2.2),

$$A(x_1,x_2) = \begin{bmatrix} x_1^4 + 1 & -x_1^2 \\ -x_1^2 & 1 \end{bmatrix}$$

and

$$u_0(x_1,x_2) = -x_1^2 x_2.$$

As usual let us denote by w the canonical solution and by x_0 the point $(1,1)$. We have the following assertions.

PROPOSITION 8.1.

(i) $w(x_0, 1-\delta) \leq 0$ *for every* $1 > \delta > 0$.

(ii) $w(x_0, 1) = +\infty$.

Proof. Consider any A-admissible path $\xi(t) = (\xi_1(t), \xi_2(t))$, which, by definition, verifies

$$\langle (\dot\xi(t) \otimes \dot\xi(t)) b, b\rangle \leq \langle A(\xi(t)) b, b\rangle \quad \text{a.e.} \tag{8.1}$$

for any $b \in \mathbb{R}^2$. Then put $b = (0, \dot\xi_2(t))$ in (8.1) to find

$$|\dot\xi_2(t)| \leq 1 \qquad \text{a.e.} \tag{8.2}$$

The last inequality implies in particular that

$$B(x_0, 1-\delta) \subset \{x_2 \geq 0\} \qquad \text{for every } 1 > \delta > 0,$$

which is equivalent to assertion (i).

Now fix $\varepsilon > 0$ and let $\sigma = \sigma(\varepsilon) > 0$ be such that $d(x_0, \widetilde{x}) < \varepsilon$ if $\widetilde{x} = (1, 1-\sigma)$. The path $\xi(t) = (\frac{1}{1-t}, 1-\sigma-t)$ is A-admissible as it can be seen by a direct calculation. Therefore $\xi(t) \in B(\widetilde{x}_0, 1) \subset B(x_0, 1+\varepsilon)$ for $t \in [0,1)$ and letting $t \to 1$, we discover that

$$\sup_{B(x_0, 1+\varepsilon)} \{u_0\} = +\infty.$$

Since $\varepsilon > 0$ is arbitrary, this gives (ii). □

The second example concerns the lack of uniqueness for solutions of (2.1), (2.2).

Example 8.2. Set $N = 1$, $u_0 \equiv 0$, and

$$A(x) = \begin{cases} 1 & \text{if } x \leq 1, \\ x^6 & \text{if } x \geq 1. \end{cases}$$

The distance d associated to A coincides with the Euclidean distance in $(-\infty, 1)$. If $x, y \in [1, +\infty)$ and $y \geq x$, then $\zeta(t) = \sqrt{\frac{x^2}{1-2tx^2}}$, $t \in [0, \frac{|x^2-y^2|}{2x^2y^2}]$ is A-admissible and it is the minimal path joining x to y. Therefore we have

$$d(x,y) = \begin{cases} |x-y| & \text{if } x, y \in (-\infty, 1), \\ \frac{|x^2-y^2|}{2x^2y^2} & \text{if } x, y \in [1, +\infty), \\ 1 - x + \frac{y^2-1}{2y^2} & \text{if } x \in (-\infty, 1),\ y \in [1, +\infty). \end{cases}$$

The number $d(x, \infty)$ defined in section 2 is given by

$$d(x, \infty) = \begin{cases} \frac{3}{2} - x, & x \in (-\infty, 1), \\ \frac{1}{2x^2}, & x \in [1, +\infty). \end{cases}$$

A family u_α, $\alpha \geq 0$, of solutions of (2.1), (2.2) with $u_0 \equiv 0$ is defined via (see Proposition 7.1)

$$u_\alpha(x,t) = \max\{\alpha t - \alpha d(x, \infty), 0\}.$$

For $\alpha > 0$ these solutions are not canonical.

Finally we show that even if the Hamiltonian H has superlinear growth in x, then the distance induced can be complete. That is, the converse of Corollary 3.1 is not true.

Example 8.3. Set $N = 2$,

$$A(x_1, x_2) = \begin{bmatrix} 1 & 0 \\ 0 & f(x_1) \end{bmatrix},$$

where f is any strictly positive locally Lipschitz function from $\mathbb{R}$ to $\mathbb{R}$. If ξ is an A-admissible path starting from $x_0 = (x_1^0, x_2^0)$, it is easy to see that

$$|\dot{\xi}(t)|^2 \leq \max\{f(x_1) : x_1 \in [x_1^0 + t, x_1^0 - t]\} + 1 \qquad \text{a.e.}$$

Hence for any radius r, there exists a positive constant $M(x_0, r)$ such that

$$B(x_0, r) \subset B^E(x_0, M(x_0, r)r).$$

This inclusion shows that $B(x_0, r)$ is relatively compact and, consequently (see Proposition 3.1(iii)), the distance d is complete.

STIFF SYSTEMS OF HYPERBOLIC CONSERVATION LAWS: CONVERGENCE AND ERROR ESTIMATES*

A. KURGANOV† AND E. TADMOR†‡

Abstract. We are concerned with 2×2 nonlinear relaxation systems of conservation laws of the form $u_t + f(u)_x = -\frac{1}{\delta}S(u,v)$, $v_t = \frac{1}{\delta}S(u,v)$ which are coupled through the stiff source term $\frac{1}{\delta}S(u,v)$. Such systems arise as prototype models for combustion, adsorption, etc. Here we study the convergence of $(u,v) \equiv (u^\delta, v^\delta)$ to its equilibrium state, $(\bar{u},\bar{v})$, governed by the limiting equations, $\bar{u}_t + \bar{v}_t + f(\bar{u})_x = 0$, $S(\bar{u},\bar{v}) = 0$. In particular, we provide sharp convergence rate estimates as the relaxation parameter $\delta \downarrow 0$. The novelty of our approach is the use of a weak $W^{-1}(L^1)$-measure of the error, which allows us to obtain sharp error estimates. It is shown that the error consists of an initial contribution of size $||S(u_0^\delta, v_0^\delta)||_{L^1}$, together with accumulated relaxation error of order $\mathcal{O}(\delta)$. The sharpness of our results is found to be in complete agreement with the numerical experiments reported in [Schroll, Tveito, and Winther, *SIAM J. Numer. Anal.*, 34 (1997), pp. 1152–1166].

1. Introduction.

We are concerned with one-dimensional systems of conservation laws which are coupled through a stiff source term. The purpose of this paper is to study a convergence rate of such systems to their equilibrium solutions as the stiff relaxation parameter tends to zero.

Our system takes the form

$$u_t + f(u)_x = -\frac{1}{\delta}S(u,v), \tag{1.1}$$

$$v_t = \frac{1}{\delta}S(u,v), \tag{1.2}$$

where $\delta > 0$ is the small relaxation parameter. The stiff source term, $S(u,v)$, and the convective flux, $f(u)$, are assumed to be smooth functions. We consider the Cauchy problem associated with (1.1)–(1.2), subject to periodic or compactly supported initial data

$$u(x,0) = u_0(x), \quad v(x,0) = v_0(x). \tag{1.3}$$

Here $u(x,t) := u^\delta(x,t)$, $v(x,t) := v^\delta(x,t)$ is the unique entropy solution of (1.1)–(1.3), which can be realized as the vanishing viscosity limit $u^\delta = \lim_{\nu\downarrow 0} u^{\delta,\nu}$, $v^\delta = \lim_{\nu\downarrow 0} v^{\delta,\nu}$, where $(u^{\delta,\nu}, v^{\delta,\nu})$ is the solution of the regularized viscosity system

$$u_t^{\delta,\nu} + f(u^{\delta,\nu})_x = -\frac{1}{\delta}S(u^{\delta,\nu}, v^{\delta,\nu}) + \nu u_{xx}^{\delta,\nu}\ , \tag{1.4}$$

$$v_t^{\delta,\nu} = \frac{1}{\delta}S(u^{\delta,\nu}, v^{\delta,\nu}). \tag{1.5}$$

‡ Department of Mathematics, University of California at Los Angeles, Los Angeles, CA 90095 (tadmor@math.ucla.edu).

This regularized system, with fixed $\delta > 0$ (and $\nu > 0$), admits a unique, global (and, respectively, classical) solution. Indeed, such a solution can be constructed, for example, by fixed point iterations which alternate between the solution of the ODE (1.5) for v and the viscous conservation law—with v-dependent source term (1.4) for u. Moreover, by the maximum principle, e.g., [PW], the solution constructed admits a global uniform bound in view of our monotonicity assumption specified in section 2, $-S_u, S_v \leq 0$. Finally, by standard arguments (which we omit), there exists a constant, *independent* of ν, $C_\delta = \exp\{2(|S_u| + |S_v|)t/\delta\}$, such that

$$\begin{aligned}&\|u_1^\delta(\cdot,t) - u_2^\delta(\cdot,t)\|_{L^1} + \|v_1^\delta(\cdot,t) - v_2^\delta(\cdot,t)\|_{L^1}\\ &\quad\leq C_\delta\left[\|u_1^\delta(\cdot,0) - u_2^\delta(\cdot,0)\|_{L^1} + \|v_1^\delta(\cdot,0) - v_2^\delta(\cdot,0)\|_{L^1}\right].\end{aligned}$$

Consequently, the uniqueness of the viscous solution, $u^{\delta,\nu}$, and hence the uniqueness of its entropy limit BV-solution, u^δ, then follow. We refer to, e.g., [HW], [Lu], and [Le] for further discussions on the existence and uniqueness for various related models of the above type.

Once we identify the unique entropy solution, (u^δ, v^δ), we seek its equilibrium state as $\delta \downarrow 0$, $(\bar{u}, \bar{v})$. Formally, our equilibrium solution is governed by the limit system obtained by letting $\delta \downarrow 0$ in (1.1)–(1.2),

$$(\bar{u} + \bar{v})_t + f(\bar{u})_x = 0, \tag{1.6}$$

$$S(\bar{u}, \bar{v}) = 0. \tag{1.7}$$

To obtain the limiting equation (1.6), add (1.2) to (1.1); to obtain the constraint equation (1.7), multiply (1.2) by δ and pass to the formal limit as $\delta \to 0$.

The two main questions that we address in this paper are concerned with the convergence of the entropy solution (u^δ, v^δ) to its expected equilibrium state $(\bar{u}, \bar{v})$.

Convergence. We prove the convergence to the expected limits

$$\bar{u} = \lim_{\delta,\nu\downarrow 0} u^{\delta,\nu}, \qquad \bar{v} = \lim_{\delta,\nu\downarrow 0} v^{\delta,\nu}. \tag{1.8}$$

Moreover, we provide the following.

Error estimates. We estimate the convergence rate as $\nu \to 0$ and, in particular, as $\delta \to 0$.

Assume that $S_v \neq 0$ so we can solve the constraint equation (1.7) and obtain its solution in the explicit form

$$\bar{v} = v(\bar{u}). \tag{1.9}$$

Inserted into (1.6), we obtain that $\bar{u}$ is governed by the limiting equation

$$[\bar{u} + v(\bar{u})]_t + f(\bar{u})_x = 0. \tag{1.10}$$

Equivalently, if we denote $\bar{w} = \bar{w}(\bar{u}) := \bar{u} + v(\bar{u})$ and let its inverse[1] $\bar{u} = \bar{u}(\bar{w})$, then we conclude that the limiting equation (1.10) can be rewritten as a single conservation law, expressed in terms of the combined flux $F(\bar{w}) := f(\bar{u}(\bar{w}))$,

$$\bar{w}_t + F(\bar{w})_x = 0. \tag{1.11}$$

[1] The inverse exists since by our monotonicity assumption in section 2 below, $v'(u) = -S_u/S_v > -1$.

We obtain our convergence results under the assumptions of convexity—both $f(\cdot)$ and $F(\cdot)$ and the monotonicity of $S(u,v)$. In addition, we assume that we start with "prepared" initial data, in the sense that $u_0 \equiv u_0^\delta$ and $v_0 \equiv v_0^\delta$ approach their equilibrium state (1.7) as $\delta \downarrow 0$, i.e.,

$$||S(u_0^\delta(x), v_0^\delta(x))||_{L^1(x)} \xrightarrow{\delta\to 0} 0.$$

Specifically, we let $\epsilon = \epsilon(\delta) \downarrow 0$ denote the vanishing *initial error*

$$||S(u_0^\delta(x), v_0^\delta(x))||_{L^1(x)} \sim \epsilon(\delta) \downarrow 0. \tag{1.12}$$

Equipped with these assumptions, we formulate in section 2 our main results, which we summarize here in the following theorem.

THEOREM 1.1 (main theorem). *Consider the system* (1.3)–(1.5) *subject to* $W^2(L^1)$-*"prepared" initial data,* (1.12). *Then* $(u^{\delta,\nu}, v^{\delta,\nu})$ *converges to* $(\bar{u},\bar{v})$ *as* $\nu \to 0$, $\delta \to 0$, *and the following error estimate holds* $\forall p$, $1 \le p \le \infty$*:*

$$||u^{\delta,\nu}(\cdot,t) - \bar{u}(\cdot,t)||_{W^s(L^p(x))} \le \text{Const}_T \cdot \big(\epsilon(\delta) + \delta + \nu\big)^{\frac{1-sp}{2p}}, \quad -1 \le s \le \frac{1}{p}\ . \tag{1.13}$$

Thus, (1.13) reflects three sources for error accumulation: the initial error of size $\epsilon(\delta)$, the relaxation error of order δ, and the vanishing viscosity of order ν. For example, in the inviscid case ($\nu = 0$) and with "canonically prepared" initial data such that $\epsilon(\delta) \sim \delta$, we set $(s,p) = (0,1)$ in (1.13) to conclude an L^1-convergence rate of order $\mathcal{O}(\sqrt{\delta})$; in fact, in Corollary 2.3 below we extend this L^1-estimate to the v-variable, stating that

$$||u^\delta(\cdot,t) - \bar{u}(\cdot,t)||_{L^1} + \|v^\delta(\cdot,t) - \bar{v}(\cdot,t)\|_{L^1} = \mathcal{O}(\sqrt{\delta}). \tag{1.14}$$

The two-step proof of the main theorem is presented in sections 3 (stability) and 4 (consistency).

We close this introduction with three prototype examples.

Example 1: *Combustion.* We consider a combustion model proposed by Majda [Ma]. This model was consequently studied in [Le], [TY], and [Lu]. It takes the form

$$\begin{aligned} u_t + f(u)_x &= \frac{1}{\delta}A(u)v + \nu u_{xx}, \\ v_t &= -\frac{1}{\delta}A(u)v. \end{aligned} \tag{1.15}$$

Here $u \equiv u^{\delta,\nu}$ is a lumped variable representing some features of density, velocity, and temperature, while $v \equiv v^{\delta,\nu} \ge 0$ represents the mass fraction of unburnt gas in a simplified kinetics scheme; $\frac{1}{\delta}$ is the rate of reaction and the parameter $\nu > 0$ is a lumped parameter representing the effects of diffusion and heat conduction.

In this model, $S(u,v) = -A(u)v$ and our convexity and monotonicity assumptions (2.1)–(2.3) below hold, provided that

$$A'(u) < 0, \ A(u) \ge \eta > 0; \quad f''(u) \ge \alpha > 0. \tag{1.16}$$

The limiting equation (1.10) in this example reads

$$\bar{u}_t + f(\bar{u})_x = 0,$$

and hence $u^{\delta,\nu} - \bar{u}$ satisfies the error estimate (1.13).

Example 2: *Adsorption.* We consider the following stiff system:

$$\begin{aligned} u_t + f(u)_x &= -\frac{1}{\delta}(A(u) - v), \\ v_t &= \frac{1}{\delta}(A(u) - v). \end{aligned} \tag{1.17}$$

In this example $u \equiv u^\delta$ denotes the density of some species contained in a fluid flowing through a fixed bed, and $v \equiv v^\delta$ denotes the density of the species adsorbed on the material in the bed; $\delta > 0$ is referred to as the relaxation time. Different forms of adsorption functions, $A(u)$, are discussed in [STW], [TW1], [TW2], and the references therein.

The source term associated with this adsorption model, $S(u,v) = A(u) - v$, yields a limiting equation of the form

$$[\bar{u} + A(\bar{u})]_t + f(\bar{u})_x = 0.$$

Under the monotonicity assumption and convexity condition (consult (2.1)–(2.3)),

$$A'(u) \geq 0, \quad \left[\frac{f'(u)}{1 + A'(u)}\right]' \geq \alpha > 0. \tag{1.18}$$

We conclude the error estimate (1.13) with $\nu = 0$. In particular, for "canonically prepared" initial data such that $||A(u_0^\delta) - v_0^\delta||_{L^1} = \mathcal{O}(\delta)$, (1.14) yields a convergence rate of order $\mathcal{O}(\sqrt{\delta})$.

In this context it is interesting to contrast our above error estimates with those of [STW]. In [STW], Schroll, Tveito, and Winther studied the error estimates for the adsorption model (1.17) subject to "canonically prepared" initial data, $||A(u_0^\delta) - v_0^\delta||_{L^1} = \mathcal{O}(\delta)$, and concluded an L^1-convergence rate of order $\mathcal{O}(\delta^{\frac{1}{3}})$. Their reported numerical experiments, however, indicate a faster convergence rate of order $\mathcal{O}(\sqrt{\delta})$. Our results, e.g., (1.14), apply to their numerical experiments and confirm this optimal $\mathcal{O}(\sqrt{\delta})$ convergence rate. It should be pointed that the $\mathcal{O}(\delta^{\frac{1}{3}})$ error estimate in [STW] was derived by interpolation between L^2- and L^1-error bounds. It is here that we take advantage of our *sharper* interpolation between the *weaker* $\mathcal{O}(\delta)$ *Lip*$'$- and the $\mathcal{O}(1)$ BV-bounds. This enables us to improve over [STW] in both simplicity and generality and conclude with the sharper estimate of order $\mathcal{O}(\sqrt{\delta})$.

Example 3: *Relaxation.* Let us consider the following semilinear stiff system (see, e.g., [JX], [Li]):

$$\begin{aligned} u_t + v_x &= 0, \\ v_t + au_x &= \frac{1}{\delta}S(u,v), \end{aligned} \tag{1.19}$$

where $S(u,v) := f(u) - v$ and a is given positive number. The limiting equation, with $v(u) = f(u)$, is then

$$\bar{u}_t + f(\bar{u})_x = 0.$$

To study this system we rewrite it in the form of (1.1)–(1.2) by means of two changes of variables. First, we define the characteristic variables $w := \sqrt{a}\,u + v$, $z :=$

$\sqrt{a}\,u - v$. The system (1.19) then takes the form

$$\begin{aligned} z_t - \sqrt{a}\,z_x &= -\frac{1}{\delta}S(z,w), \\ w_t + \sqrt{a}\,w_x &= \frac{1}{\delta}S(z,w), \end{aligned} \tag{1.20}$$

with $S(z,w) = S(u(z,w), v(z,w))$. Next, we make the second change of variables, $x' := x - \sqrt{a}\,t$, obtaining

$$\begin{aligned} z_t - 2\sqrt{a}\,z_{x'} &= -\frac{1}{\delta}S(z,w), \\ w_t &= \frac{1}{\delta}S(z,w). \end{aligned} \tag{1.21}$$

In this model, the flux is linear and hence our first convexity assumption, (2.2), holds. The second one, (2.3), is satisfied for convex f's. In addition, the monotonicity of S, $S_z \geq 0, S_w \leq -\eta < 0$, amounts (in terms of S_u and S_v) to the inequalities

$$S_v \leq -\eta < 0, \quad S_v\sqrt{a} \leq S_u \leq -S_v\sqrt{a}.$$

Thus, $S(u,v) = f(u) - v$ should satisfy Liu's *subcharacteristic* condition (e.g., [Li]),

$$-\sqrt{a} \leq f'(u) \leq \sqrt{a}.$$

In this case, our main theorem with $p = 1$, for example, yields

$$||u^\delta - \bar{u}||_{W^s(L^1)} = \text{Const} \cdot \Big(||f(u_0^\delta) - v_0^\delta||_{L^1} + \delta\Big)^{\frac{1-s}{2}}, \quad -1 \leq s \leq 1.$$

2. Statement of main results. We seek the behavior of the solution of regularized system (1.4)–(1.5) towards the limit solution as $\delta \to 0$, as well as $\nu \to 0$. Throughout this section we make the following two main assumptions.

Monotonicity. $S(u,v)$ is monotonic with respect to u and strictly monotonic with respect to v,

$$S_u(u,v) \geq 0, \quad S_v(u,v) \leq -\eta < 0. \tag{2.1}$$

Convexity. $f(\cdot)$ is convex and $F(\cdot)$ is a strictly convex function,

$$f''(u) \geq 0, \tag{2.2}$$

$$F''(w) \geq \alpha > 0 \Longleftrightarrow \left(\frac{f'(\bar{u})}{1 + v'(\bar{u})}\right)' \geq \alpha > 0. \tag{2.3}$$

Remark. Our first assumption of monotonicity guarantees, by the classical maximum principle (see, e.g., [PW]), the L^∞-boundedness of $(u^{\delta,\nu}, v^{\delta,\nu})$ (proof is left to the reader).

Equipped with the two assumptions above, we now turn to the main result of this paper. To this end, our error estimate is formulated in terms of the *weak Lip'*-(semi)norm, $||\cdot||_{Lip'}$, and the dual of the *Lip*-norm given by

$$||\phi||_{Lip'} := \sup_{\psi}[(\phi - \hat{\phi_0}, \psi)/||\psi||_{W^{1,\infty}}], \quad \hat{\phi_0} := \int\limits_{supp\phi} \phi.$$

Thus, the *Lip*′-size of regular ϕ's (with bounded average over their finite support) amounts to their $W^{-1}(L^1)$-size or, equivalently, the L^1-size of their *primitive.* As we shall see, such weak (semi)norm has the advantage of providing us with *sharp* error estimates which, in turn, will be converted into strong ones.

THEOREM 2.1. *Consider the system* (1.3)–(1.5) *subject to* $W^2(L^1)$-*"prepared" initial data,* (1.12). *Then* $(u^{\delta,\epsilon}, v^{\delta,\epsilon})$ *converges to* $(\bar{u}, \bar{v})$ *as* $\delta \to 0$, $\nu \to 0$, *and the following error estimate holds:*

$$||u^{\delta,\nu}(\cdot,T) - \bar{u}(\cdot,T)||_{Lip'(x)} \leq \text{Const}_T \cdot \big(\epsilon(\delta) + \delta + \nu\big). \tag{2.4}$$

Let us consider the particular inviscid case, where $\nu = 0$. Then the entropy solution of the stiff system (1.1)–(1.2), (u^δ, v^δ), converges as $\delta \to 0$ to its equilibrium solution, $(\bar{u}, \bar{v})$, and we obtain the asserted convergence rate in terms of the initial error $\epsilon(\delta)$ and the vanishing relaxation parameter δ:

$$||u^{\delta}(\cdot,T) - \bar{u}(\cdot,T)||_{Lip'(x)} \leq \text{Const}_T \cdot \big(\epsilon(\delta) + \delta\big). \tag{2.5}$$

Remarks. 1. Our assumption of "prepared" initial data means that at the initial moment, $||S(u_0^\delta, v_0^\delta)||_{L^1} \overset{\delta\to 0}{\longrightarrow} 0$. In section 4 we will show that, in fact, $||S(u^{\delta,\nu}, v^{\delta,\nu})||_{L^1} \overset{\delta\to 0}{\longrightarrow} 0$ for all $t > 0$.

2. What about "nonprepared" initial data? In this case the initial layer formed persists in time; i.e., the initial error propagates and prevents convergence of $u^{\delta,\nu}, v^{\delta,\nu}$ to their equilibrium state.

The proof of the main theorem will be given in sections 3 and 4. To obtain this result we utilize the framework of Tadmor and Nessyahu [Ta], [NT]. To this end, we need the two ingredients of *consistency* and *stability.* Here, *consistency*—evaluated in terms of the *Lip*′-norm—measures by how much the approximate pair $(u^{\delta,\nu}, v(u^{\delta,\nu}))$ fails to satisfy the limiting equation (1.10); *stability* requires the *Lip*$^+$-stability [2] of $u^{\delta,\nu}$; that is, we seek a one-sided Lipschitz continuity (OSLC) of the viscosity solution $u^{\delta,\nu}$,

$$\|u^{\delta,\nu}(\cdot,t)\|_{Lip^+(x)} := \sup_x \,[u_x^{\delta,\nu}(x,t)]_+ \leq C_t \cdot \|u^{\delta,\nu}(\cdot,0)\|_{Lip^+(x)}. \tag{2.6}$$

By interpolation between the (weak) *Lip*′-error estimate (2.4) and the (strong) *BV*-boundedness of the error (which follows from the *Lip*$^+$-boundedness due to (2.6)), we are able to convert the weak error estimate stated in Theorem 2.1 into a *strong* one. As in [NT], we conclude with the following corollary.

COROLLARY 2.2 (global estimate). *Consider the inviscid problem* (1.1)–(1.3), (1.12). *Then the following convergence rate estimate holds:*

$$||u^{\delta}(x,T) - \bar{u}(x,T)||_{L^p} \leq \text{Const}_T \cdot (\epsilon(\delta) + \delta)^{\frac{1}{2p}}, \qquad 1 \leq p \leq \infty. \tag{2.7}$$

Remark. The above-mentioned L^p-estimates in (2.7) are, in fact, particular cases of the more general error estimate in the $W^s(L^p)$-norm

$$||u^{\delta}(x,T) - \bar{u}(x,T)||_{W^s(L^p)} \leq \text{Const}_T \cdot (\epsilon(\delta) + \delta)^{\frac{1-sp}{2p}}, \qquad -1 \leq s \leq \frac{1}{p}\ . \tag{2.8}$$

[2] Here $||\phi||_{Lip^+} := ess\sup_{x\neq y}\left[\frac{\phi(x)-\phi(y)}{x-y}\right]_+$, where, as usual, $(\cdot)_+$ denotes the "positive part of." For convenience we shall use the equivalent definition of the *Lip*$^+$ norm: $||\phi||_{Lip^+} := \sup_x\,[\phi'(x)]_+$, where the derivative of ϕ is taken in the distribution sense.

The special cases, $(s,p)=(-1,1)$ and $s=0$, correspond, respectively, to the weak *Lip*′-estimate (Theorem 2.1) and the global L^p-estimate (Corollary 2.2).

Taking $p=1$ in (2.7), we obtain, in particular, the L^1-error estimate, which reads

$$||u^\delta(x,T)-\bar{u}(x,T)||_{L^1} \leq \text{Const}_T \cdot \sqrt{\epsilon(\delta)+\delta}. \tag{2.9}$$

In this L^1-framework, we are able to extend the last estimate and obtain the same $\mathcal{O}(\sqrt{\epsilon(\delta)+\delta})$ convergence rate of v^δ towards $\bar{v}$. This brings us to the following corollary.

COROLLARY 2.3 (L^1-error estimate). *Consider the system* (1.1)–(1.3) *subject to "prepared" initial data,* (1.12)*. Then we have*

$$||u^\delta(x,T)-\bar{u}(x,T)||_{L^1}+||v^\delta(x,T)-\bar{v}(x,T)||_{L^1} \leq \text{Const}_T \cdot \sqrt{\epsilon(\delta)+\delta}. \tag{2.10}$$

In particular, for "canonically prepared" initial data, $||S(u_0^\delta,v_0^\delta)||_{L^1}=\epsilon(\delta)\sim\delta$, *we obtain a convergence rate of order* $\sqrt{\delta}$,

$$||u^\delta(x,T)-\bar{u}(x,T)||_{L^1}+||v^\delta(x,T)-\bar{v}(x,T)||_{L^1} \leq \text{Const}_T \cdot \sqrt{\delta}. \tag{2.11}$$

Proof. We first note that due to the strict monotonicity of $S(u,v)$ with respect to its second argument and the L^∞-bound of $u^\delta, v^\delta, \bar{u}$, and $\bar{v}$, we have

$$\begin{aligned} |v^\delta-\bar{v}| &= |v^\delta-v(u^\delta)+v(u^\delta)-\bar{v}| \leq |v^\delta-v(v^\delta)|+|v(v^\delta)-\bar{v}| \\ &= |v'(\tilde{u})|\cdot|u^\delta-\bar{u}|+\left|\frac{S(u^\delta,v^\delta)-S(u^\delta,v(u^\delta))}{S_v(u^\delta,\tilde{v})}\right| \sim |u^\delta-\bar{u}|+|S(u^\delta,v^\delta)|. \end{aligned}$$

Here $\tilde{u}$ and $\tilde{v}$ are appropriate midvalues, $\tilde{u}=\theta_1 u^\delta+(1-\theta_1)\bar{u}$, $\tilde{v}=\theta_2 v^\delta+(1-\theta_2)\bar{v}$. And we now obtain the desired estimate, (2.10),

$$\begin{aligned} ||v^\delta(x,T)-\bar{v}(x,T)||_{L^1} &\leq \text{Const}_T\cdot(||u^\delta(x,T)-\bar{u}(x,T)||_{L^1} \\ &\quad +||S(u^\delta(x,T),v^\delta(x,T))||_{L^1}) \\ &= \mathcal{O}(\sqrt{\epsilon(\delta)+\delta})+\mathcal{O}(\epsilon(\delta)+\delta)=\mathcal{O}(\sqrt{\epsilon(\delta)+\delta}). \end{aligned} \tag{2.12}$$

Indeed, the first $\mathcal{O}(\sqrt{\bullet})$-upperbound on the right is due to (2.9); the second upperbound, $||S(u^\delta(x,T),v^\delta(x,T))||_{L^1}=\mathcal{O}(\epsilon(\delta)+\delta)$, is outlined in section 4 below. □

Finally, arguing along the lines of [NT; Corollary 2.4], we also obtain the *pointwise* convergence towards the equilibrium solution away from discontinuities.

COROLLARY 2.4 (local estimate). *Consider the inviscid problem* (1.1)–(1.3), (1.12)*. Then the following estimate holds:*

$$|u^\delta(x,T)-\bar{u}(x,T)| \leq \text{Const}_{x,T}\cdot(\epsilon(\delta)+\delta)^{\frac{1}{3}} . \tag{2.13}$$

Here, $\text{Const}_{x,T}$ *is a constant which measures the local smoothness of* $u(\cdot,T)$ *in the small neighborhood of* x,

$$\text{Const}_{x,T} \sim 1+\max_{|y-x|<\sqrt[3]{\delta}}|\bar{u}_x(y,T)|.$$

.

3. *Lip*$^+$-stability estimate. We now turn to the proof of our main theorem. We begin with the *Lip*$^+$-stability of the solution of (1.4)–(1.5).

Assertion 3.1. *Consider the system* (1.4), (1.5) *subject to Lip*$^+$*-bounded initial data* (1.3). *Then there exists a constant (which may depend on the initial data) such that*

$$||u^{\delta,\nu}(\cdot,T)||_{Lip^+(x)} \leq \text{Const.} \tag{3.1}$$

Proof. The proof is based on the maximum principle for $(u_x^{\delta,\nu})_+$.

Differentiation of (1.4) and (1.5) with respect to x implies

$$(u_x^{\delta,\nu})_t + f''(u^{\delta,\nu})(u_x^{\delta,\nu})^2 + f'(u^{\delta,\nu})(u_x^{\delta,\nu})_x = -\frac{1}{\delta}[S_u u_x^{\delta,\nu} + S_v v_x^{\delta,\nu}] + \nu(u_x^{\delta,\nu})_{xx}, \tag{3.2}$$

$$(v_x^{\delta,\nu})_t = \frac{1}{\delta}[S_u u_x^{\delta,\nu} + S_v v_x^{\delta,\nu}]. \tag{3.3}$$

We now multiply (3.2) by $\frac{1+sgn(u_x^{\delta,\nu})}{2}$; using the monotonicity of $S(u,v)$ and convexity of $f(u)$ we obtain the following inequalities:

$$\begin{aligned}&[(u_x^{\delta,\nu})_+]_t + f'(u^{\delta,\nu}) \cdot [(u_x^{\delta,\nu})_+]_x \\ &\qquad \leq -\frac{1}{\delta}\left[S_u(u_x^{\delta,\nu})_+ + S_v v_x^{\delta,\nu}\left(\frac{1+sgn(u_x^{\delta,\nu})}{2}\right)\right] + \nu[(u_x^{\delta,\nu})_+]_{xx},\end{aligned} \tag{3.4}$$

$$(v_x^{\delta,\nu})_t \leq \frac{1}{\delta}[S_u(u_x^{\delta,\nu})_+ + S_v v_x^{\delta,\nu}]. \tag{3.5}$$

By solving the second inequality, we find (with $S_v(\tau) := S_v(x,\tau) \equiv S_v(u^{\delta,\nu}(x,\tau), v^{\delta,\nu}(x,\tau))$ and $B(t) := \int_0^t S_v(\tau)d\tau$) that

$$v_x^{\delta,\nu}(t) \leq e^{\frac{B(t)}{\delta}} v_x^{\delta,\nu}(0) + \frac{1}{\delta}\int_0^t e^{\frac{B(t)-B(\tau)}{\delta}} S_u(\tau)(u_x^{\delta,\nu}(\tau))_+ d\tau. \tag{3.6}$$

Plugging this into (3.4) and denoting $m(t) = \max_x (u_x^{\delta,\nu}(x,t))_+$, we end up with

$$\dot{m}(t) \leq -\frac{S_u(t)}{\delta}m(t) - \frac{S_v(t)}{\delta}e^{\frac{B(t)}{\delta}}(v_x^{\delta,\nu}(0))_+ - \frac{S_v(t)}{\delta^2}\int_0^t e^{\frac{B(t)-B(\tau)}{\delta}} S_u(\tau)m(\tau)d\tau. \tag{3.7}$$

The first and the third terms in the right-hand side of (3.7) add up to a perfect derivative, modulo extra terms which are differentiated along the characteristics where $u_{xx}^{\delta,v}(x(t),t) = 0$ so that

$$\dot{m}(t) \leq \left(-e^{\frac{B(t)}{\delta}}(v_x^{\delta,\nu}(0))_+\right)_t - \frac{1}{\delta}\left(\int_0^t e^{\frac{B(t)-B(\tau)}{\delta}} S_u(\tau)m(\tau)d\tau\right)_t + k(t). \tag{3.8}$$

Here the constant $k(t)$ (depending on the convexity constant of F in (2.3), α) is an upperbound on the extra terms differentiated along the characteristics, e.g., $\partial_x B(x,t)\dot{x}e^{B(t)/\delta}(u_x^{\delta,v}(0))_+/\delta \dots$. Integration of (3.8) over $(0,T)$ yields

$$m(T) \leq m(0) + (v_x^{\delta,\nu}(0))_+\left[1 - e^{\frac{B(T)}{\delta}}\right] - \frac{1}{\delta}\int_0^T e^{\frac{B(T)-B(\tau)}{\delta}} S_u(\tau)m(\tau)d\tau + \int_0^T k(\tau)d\tau. \tag{3.9}$$

In view of the positivity of S_u, we obtain that

$$(u_x^{\delta,\nu}(x,T))_+ \leq (u_x^{\delta,\nu}(x,0))_+ + (v_x^{\delta,\nu}(x,0))_+ + K_T, \quad K_T = \int_0^T k(\tau)d\tau,$$

and the assertion follows with $\text{Const} = ||u^{\delta,\nu}(\cdot,0)||_{Lip^+(x)} + ||v^{\delta,\nu}(\cdot,0)||_{Lip^+(x)} + K_T$. □

We close this section by noting that the proof of Assertion 3.1 is based on the straightforward, formal maximum principle for the positive part of $u^{\delta,\nu}$; alternatively, it could be justified, for example, by L^p iterations in (3.4).

4. *Lip*'-consistency and proof of the main result. In this section we prove the promised error estimate (2.4) in the Lip'-norm. According to the results of [Ta], [NT], the error $||u^{\delta,\nu} - \bar{u}||_{Lip'}$ is upper bounded by the truncation error

$$\left|\left|[u^{\delta,\nu} + v(u^{\delta,\nu})]_t + f(u^{\delta,\nu})_x\right|\right|_{Lip'(x,t)}. \tag{4.1}$$

This quantity measures by how much $u^{\delta,\nu}$ fails to satisfy the limiting equation (1.10). To complete this proof we have to show, therefore, that the truncation error is of order $\mathcal{O}(\epsilon(\delta) + \delta + \nu)$. We proceed as follows.

Adding the two components of the regularized system (1.5) to (1.4), we obtain that

$$u_t^{\delta,\nu} + v_t^{\delta,\nu} + f(u^{\delta,\nu})_x = \nu u_{xx}^{\delta,\nu},$$

which we rewrite as

$$\begin{aligned}*[u^{\delta,\nu} + v(u^{\delta,\nu})]_t + f(u^{\delta,\nu})_x &= u_t^{\delta,\nu} + v_t^{\delta,\nu} + f(u^{\delta,\nu})_x \\ &+[v(u^{\delta,\nu}) - v^{\delta,\nu}]_t = \nu u_{xx}^{\delta,\nu} + [v(u^{\delta,\nu}) - v^{\delta,\nu}]_t.\end{aligned}$$

It is here that we take advantage of the *weak* Lip'-norm introduced earlier in section 2: by measuring the L^1-size of its primitive, the right-hand side of the last equality tells us that the truncation error in (4.1) does not exceed

$$\begin{aligned}&||\nu u_{xx}^{\delta,\nu} + [v(u^{\delta,\nu}) - v^{\delta,\nu}]_t||_{Lip'(x,t)} \\ &\qquad \leq \text{Const}_T \cdot \left[\nu ||u_x^{\delta,\nu}||_{L^1(x,t)} + ||v(u^{\delta,\nu}) - v^{\delta,\nu}||_{L^1(x,t)}\right] \\ &\qquad =: \text{Const}_T \cdot \left[\ I + II\ \right].\end{aligned} \tag{4.2}$$

We proceed with estimating the two terms on the right. First, since $u^{\delta,\nu}$ is Lip^+-bounded, (3.1), it has a bounded variation, $||u_x^{\delta,\nu}||_{L^1(x,t)} \leq C_K$ (where C_K may depend on the Lip^+-bound, K, and the finite support of $u^{\delta,\nu}$) and, therefore, $I \leq \mathcal{O}(\nu)$. Next, we find that the second term, II, is of order

$$II \equiv ||v(u^{\delta,\nu}) - v^{\delta,\nu}||_{L^1(x,t)} \sim ||S(u^{\delta,\nu}, v^{\delta,\nu})||_{L^1(x,t)}. \tag{4.3}$$

Indeed, since $0 < \eta \leq -S_v \leq \text{Const}$, we have

$$\frac{1}{\eta} \leq \frac{|v(u^{\delta,\nu}) - v^{\delta,\nu}|}{|S(u^{\delta,\nu}, v(u^{\delta,\nu})) - S(u^{\delta,\nu}, v^{\delta,\nu})|} \leq \text{Const}$$

and, hence, $|v(u^{\delta,\nu}) - v^{\delta,\nu}| \sim |S(u^{\delta,\nu}, v(u^{\delta,\nu})) - S(u^{\delta,\nu}, v^{\delta,\nu})| = |S(u^{\delta,\nu}, v^{\delta,\nu})|$, and (4.3) follows. Returning to (4.2) we find that

$$\begin{aligned} ||\nu u^{\delta,\nu}_{xx} + [v(u^{\delta,\nu}) - v^{\delta,\nu}]_t||_{Lip'(x,t)} &\leq \text{Const}_T \cdot \Big[\ I + II\ \Big] \\ &\leq \text{Const}_T \cdot \Big[\nu + ||S(u^{\delta,\nu}, v^{\delta,\nu})||_{L^1(x,t)}\Big]. \end{aligned} \tag{4.4}$$

To conclude with the promised $\mathcal{O}(\epsilon(\delta) + \delta + \nu)$-bound, it remains to prove that $||S(u^{\delta,\nu}, v^{\delta,\nu})||_{L^1(x,t)}$—or, utilizing (4.3), that $\delta||v^{\delta,\nu}_t(\cdot,t)||_{L^1(x)}$ is of order $\mathcal{O}(\epsilon(\delta)+\delta)$,

$$||S(u^{\delta,\nu}(\cdot,t), v^{\delta,\nu}(\cdot,t))||_{L^1(x)} \equiv \delta||v^{\delta,\nu}_t(\cdot,t)||_{L^1(x)} = \mathcal{O}(\epsilon(\delta) + \delta). \tag{4.5}$$

To achieve such an estimate, we differentiate (1.4) with respect to t, multiply by $sgn(u^{\delta,\nu}_t)$, and obtain

$$\begin{aligned} |u^{\delta,\nu}_t|_t + (f'(u^{\delta,\nu})u^{\delta,\nu}_t)_x sgn(u^{\delta,\nu}_t) = -\frac{1}{\delta}\Big(S_u|u^{\delta,\nu}_t| + S_v|v^{\delta,\nu}_t|sgn(u^{\delta,\nu}_t)sgn(v^{\delta,\nu}_t)\Big) \\ +\epsilon(u^{\delta,\nu}_t)_{xx} sgn(u^{\delta,\nu}_t). \end{aligned} \tag{4.6}$$

The same treatment of equation (1.5) yields

$$|v^{\delta,\nu}_t|_t = \frac{1}{\delta}\Big(S_u|u^{\delta,\nu}_t|sgn(u^{\delta,\nu}_t)sgn(v^{\delta,\nu}_t) + S_v|v^{\delta,\nu}_t|\Big). \tag{4.7}$$

Next, we integrate the following equations with respect to x:

$$\frac{d}{dt}||u^{\delta,\nu}_t||_{L^1(x)} \leq -\frac{1}{\delta}\left(\int\limits_x S_u|u^{\delta,\nu}_t|dx + \int\limits_x S_v|v^{\delta,\nu}_t|sgn(u^{\delta,\nu}_t)sgn(v^{\delta,\nu}_t)dx\right), \tag{4.8}$$

$$\frac{d}{dt}||v^{\delta,\nu}_t||_{L^1(x)} \leq \frac{1}{\delta}\left(\int\limits_x S_u|u^{\delta,\nu}_t|sgn(u^{\delta,\nu}_t)sgn(v^{\delta,\nu}_t)dx + \int\limits_x S_v|v^{\delta,\nu}_t|dx\right). \tag{4.9}$$

Finally, we add up (4.8) and (4.9), obtaining

$$\begin{aligned} \frac{d}{dt}\Big[||u^{\delta,\nu}_t||_{L^1(x)} + ||v^{\delta,\nu}_t||_{L^1(x)}\Big] \leq \frac{1}{\delta}\Bigg[&\int\limits_x S_u|u^{\delta,\nu}_t|\Big(sgn(u^{\delta,\nu}_t)sgn(v^{\delta,\nu}_t) - 1\Big)dx \\ &+ \int\limits_x S_v|v^{\delta,\nu}_t|\Big(1 - sgn(u^{\delta,\nu}_t)sgn(v^{\delta,\nu}_t)\Big)dx\Bigg] \leq 0. \end{aligned}$$

It follows that

$$||u^{\delta,\nu}_t(\cdot,t)||_{L^1(x)} + ||v^{\delta,\nu}_t(\cdot,t)||_{L^1(x)} \leq ||u^{\delta,\nu}_t(\cdot,0)||_{L^1(x)} + ||v^{\delta,\nu}_t(\cdot,0)||_{L^1(x)} \tag{4.10}$$

and, in particular,

$$\delta||v^{\delta,\nu}_t(\cdot,t)||_{L^1(x)} \leq \delta||u^{\delta,\nu}_t(\cdot,0)||_{L^1(x)} + \delta||v^{\delta,\nu}_t(\cdot,0)||_{L^1(x)}.$$

To conclude this proof, we show that the upper bound on the right does not exceed the promised $\mathcal{O}(\epsilon(\delta)+\delta)$. Indeed, by equations (1.4)–(1.5), $u^{\delta,\nu}_t = -v^{\delta,\nu}_t - f(u^{\delta,\nu})_x + \nu u^{\delta,\nu}_{xx}$, and hence

$$\begin{aligned} \delta||u^{\delta,\nu}_t(\cdot,0)||_{L^1(x)} + \delta||v^{\delta,\nu}_t(\cdot,0)||_{L^1(x)} \leq{}& 2||S(u^{\delta,\nu}(\cdot,0), v^{\delta,\nu}(\cdot,0))||_{L^1(x)} \\ &+\delta||f(u^{\delta,\nu}(\cdot,0))_x||_{L^1(x)} + \delta\nu||u^{\delta,\nu}_{xx}(\cdot,0)||_{L^1(x)}. \end{aligned}$$

The three terms on the right are upper-bounded by $\mathcal{O}(\epsilon(\delta)+\delta)$ since, by our assumption of the "prepared" initial data (1.12), $||S(u^{\delta,\nu}(\cdot,0),v^{\delta,\nu}(\cdot,0))||_{L^1(x)}=\mathcal{O}(\epsilon(\delta))$; the BV-boundedness of $u^{\delta,\nu}$ yields $\delta||f(u^{\delta,\nu}(\cdot,0))_x||_{L^1(x)}=\mathcal{O}(\delta)$ and, finally, since the initial data are assumed to be in $W^2(L^1)$, then $\delta\nu||u^{\delta,\nu}_{xx}(\cdot,0)||_{L^1(x)}=\mathcal{O}(\delta\nu)<<\mathcal{O}(\delta)$. This completes the proof of Theorem 2.1. □

Remark. We close by noting that the $W^2(L^1)$-regularity of initial data used in the last stage of the proof can be relaxed. In fact, it is sufficient to assume $||u_{0x}||_{L^1}+\nu||u_{0xx}||_{L^1}\leq$ Const.

Note added in proof. We thank Professor R. Natalini for pointing out a gap in the previous version of the proof of Assertion 3.1. Details will appear elsewhere.

DYNAMICS AND CONDENSATION OF COMPLEX SINGULARITIES FOR BURGERS' EQUATION I[*]

DAVID SENOUF[†]

Dedicated to Sophia de Rosnay

Abstract. Spatial analyticity properties of the solution to Burgers' equation with a generic initial data are presented, following the work of Bessis and Fournier [*Research Reports in Physics: Nonlinear Physics*, Springer-Verlag, Berlin, Heidelberg, 1990, pp. 252–257]. The positive viscosity solution is a meromorphic function with a countable set of conjugate poles confined to the imaginary axis. Their motion is governed by an infinite-dimensional Calogero dynamical system (CDS). The inviscid solution is a three-sheeted Riemann surface with three branch-point singularities.

Exact pole locations are found independent of the viscosity at the inviscid shock time t_*. For $t \neq t_*$, the time evolution of the poles is obtained numerically by solving a truncated version of the CDS. A Runge–Kutta scheme is used together with a "multipole" algorithm to deal with the computationally intensive nonlinear interaction of the poles. Additionally, for $t \leq t_*$, the small viscosity behavior of the poles is shown to be a perturbation of the conjugate inviscid branch-point singularities $\pm x_s(t)$. The numerical pole dynamics also provide the width of the analyticity strip which remains uniformly bounded away from zero, agreeing with asymptotic predictions.

For small $\nu > 0$ and $t \geq t_*$, different saddle-point approximations of the solution are found within and outside the caustics $x = \pm x_s(t)$. The transition between the two regimes at $x = \pm x_s(t)$ is described by a uniform asymptotic expansion involving the Pearcey integral. The solution is computed for small viscosity using pole dynamics, finite differences (method of lines), and asymptotic methods (saddle-point method); numerical agreement is established.

1. Introduction.

In this article we investigate the spatial analyticity properties of a solution to Burgers' equation (hereafter referred to as "BE"):

$$\frac{\partial u}{\partial t} + u\,\frac{\partial u}{\partial x} = \nu\,\frac{\partial^2 u}{\partial x^2}, \qquad x \in \mathbb{R},\ t > 0,\ \nu \geq 0, \tag{1.1}$$

where the parameter ν is a viscosity coefficient and $u = u_\nu(x,t)$ represents the velocity field of a fluid particle at position x in space and time t. BE is a model for the statistical theory of turbulence [9, 10] which can be thought of as a simplified one-dimensional scalar analog of the Navier–Stokes equations of fluid dynamics. Although it does not exhibit the complexity of the Navier–Stokes equations, it does illustrate the interaction between a nonlinear first-order convective term and a second-order diffusive one. This feature, which is shared with the Navier–Stokes equations, may help us to understand the questions of regularity of so complicated a system. Although Burgers' model is not a good model for turbulence because it does not exhibit any chaotic behavior, there are other important applications besides the Ising model

analogy presented by Bessis and Fournier in [7]. A partial list of such applications can be found in the introduction of the work by She, Aurell, and Frisch in [30].

There are many tools which can be used to evaluate domains of analyticity of solutions to nonlinear PDEs: Painlevé expansions, Padé approximants, pole dynamics, spectral methods, the abstract Cauchy–Kowalewski theorem, and, more generally, methods involving analytic norms.

The work of Bardos and Benachour [5] was pioneering because it used complex analytic techniques (analytic norms) to describe domains of regularity for equations of fluid dynamics: Bardos and Benachour showed that the loss of analyticity for the incompressible Euler equations in $\mathbb{R}^n$ follows from a blowup in the vorticity $\omega = \nabla \times u$, in analogy with the blowup of the solution of the inviscid BE ($\nu = 0$), which is driven by the blowup of the gradient of the solution $\partial u/\partial x$.

Another method which also involves analytic norms is the abstract Cauchy–Kowalewski theorem. A concise and improved version of the original work of Nirenberg [27] can be found in [11]. One of the limitations of this method is that it cannot deal with parabolic PDEs. An interesting combination of Painlevé expansions and the abstract Cauchy–Kowalewski theorem applied to BE can be found in [23].

As far as spectral methods are concerned, we only mention the works of Sulem, Sulem, and Frisch [35] and Fournier and Frisch [19], both of which deal with BE. Reference [35] focuses on the numerical implementation of spectral methods to evaluate the widths of analyticity strips of solutions to nonlinear PDEs. Reference [19] focuses on spectral methods applied to the deterministic and statistical BE. More references can be found in both of these works.

The method of pole dynamics originated with Kruskal's work [26], followed by Calogero [13] and the Choodnovskys [16], who developed a mathematical tool for what was to become a very powerful method to solve nonlinear PDEs. Indeed, they showed that a very large class of nonlinear evolution equations has an associated/equivalent N-body problem/formulation. This method consists in inserting into the PDE a pole expansion of the solution (a Mittag–Leffler expansion where the complex spatial poles are time dependent). Compatibility conditions are found in the form of a dynamical system for these poles; this dynamical system is referred to as the Calogero dynamical system (CDS for short).

In [20], Frisch and Morf describe complex time singularities for nonlinear PDEs as well as make a first attempt to describe spatial singularities for BE through pole dynamics. In [20, section 4], a list of other references which use pole dynamics can be found. In [19], Fournier and Frisch devoted greater attention to (real time) complex spatial singularities for the inviscid BE from a deterministic and a statistical point of view. In the meantime, Thual, Frisch, and Hénon [36] used pole dynamics to compute the stationary pole distribution and stationary solution of a Sivashinsky-type flame-front propagation pseudo-differential equation. From the work of Fournier and Frisch [19], Bessis and Fournier [6, 7] went on to analyze the spatial analytic properties for both the inviscid and viscous deterministic case using a generic initial data. Kimura [25] has described complex space and time pole positions for the BE with periodic initial data by straightforwardly solving for the roots of the Cole–Hopf variable.

In [6, 7], Bessis and Fournier studied the analytical properties of the solution to the BE with a cubic initial data, namely,

$$u(x,0) = u_0(x) = 4x^3 - x/t_*, \qquad x \in \mathbb{R}, \tag{1.2}$$

and t_* is a fixed positive parameter corresponding to the first blowup time of the solution to the inviscid equation. This work stemmed from the observation [19] that the large wavenumber asymptotic expansion of the Fourier transform of the inviscid solution was degenerate at the shock time t_*; it was even incorrect beyond t_*. Thus, Bessis and Fournier sought for an explanation using complex analytic methods. They showed that the inviscid shock could be interpreted as a permutation of the two sides of the "physical Riemann sheet." As far as the viscous case is concerned, Bessis and Fournier showed that the poles were confined to the imaginary axis and that they satisfied a CDS. Additionally, they presented a "limiting" pole density which characterized the process of pole condensation as $\nu \to 0^+$.

The inviscid equation $u_t + u\,u_x = 0$ is a simple hyperbolic quasi-linear PDE. Its solution develops a cube root singularity at the origin at the time $t = -(\inf_x u_0'(x))^{-1} > 0$, which, for (1.2), equals t_*. This is known to be a generic singularity for the inviscid BE. It is due to the coalescence at the origin ($x = 0$) of two complex conjugate branch points $\pm x_s(t)$ of order two. Thus, the cubic initial data is considered generic due to the local cube root shape of the shock of the inviscid solution at $t = t_*$ and the associated cube root singularity (for further details, see [32, App. A] and [7, 12, 19]). Another compelling reason for which a cubic polynomial is used is that its solution can be completely analyzed for both $\nu > 0$ and $\nu = 0$, unlike a higher-order polynomial of the form $u_0(x) = 2nx^{2n-1} - x/t_*$ (see [32, App. D]).

For $t > t_*$, the inviscid solution has three real values within the real interval $(-x_s, x_s)$, and in the real complement $(-x_s, x_s)^c$ it has one real value and two complex values (see [32, App. C] and [12]). By extending (for all $t > 0$) the domain of the spatial variable x and the range of the solution u into the complex plane, Bessis and Fournier have shown in [6, 7] that the analytic structure (topology) of the inviscid solution is a three-sheeted Riemann surface with three branch points. One is at infinity, and the other two come down the imaginary axis as a conjugate pair and coalesce at the origin at the shock time t_* to form a third-order branch point. The inviscid shock in the real plane is interpreted as the permutation of the physical Riemann sheets which make up the Riemann surface. More precisely, it appears to be the connecting path between the two sides of the physical Riemann sheet which are separated by nonphysical ones (see [6] for more details).

In this work, we propose to correct and extend the results of Bessis and Fournier in [7] by using complex analytic methods and asymptotic methods (including spectral methods). Most important, we show how to use pole dynamics to determine the evolution of the domain of regularity of the solution to BE. This method can be adapted to a wide range of nonlinear PDEs.

The positive viscosity solution ($\nu > 0$) is a meromorphic function with a countable set of conjugate pairs of simple poles for all $t > 0$. These poles move towards the origin along the imaginary axis, then turn around after a finite time and start moving away from the origin (see [32, Figs. 1.1, 1.2]). In the same way that the dynamics of the branch points of the inviscid solution help in understanding the formation of a shock in the real (physical) plane, we intend to illustrate the preservation of regularity of the viscous solution by further analyzing the dynamics of the simple poles. In turn, this will shed some light on the interaction between the nonlinear convective term and the diffusive one present in the (viscous) BE. Furthermore, we clarify the limiting process which describes the vanishing viscosity limit by focusing on the small ν asymptotic behavior of the poles. As $\nu \to 0^+$, the poles condense on the imaginary axis, yielding an asymptotic pole density. The inviscid limit can be recovered by introducing an integral representation of the Mittag–Leffler expansion which involves this density.

These results are presented in [32].

We focus on BE with the same cubic initial data (1.2) used by Bessis and Fournier, whose choice will be clarified. It should be noted, however, that the method of pole dynamics used in this article is adaptable to a large class of one-dimensional evolution equations (cf. [13, 16, 36]). The main difficulty in adapting this method to equations with spatial derivatives of order higher than two is that it may translate into additional algebraic conditions. Thus, one may have to solve a differential-algebraic system of equations (DAE). Additionally, the choice of the initial data need not be fixed and is actually the focus of current research in the case of BE with random initial data. Much attention has recently been devoted to this problem (see, for example, [4, 19, 26, 30, 34]). A final note on the generality of the method: the pole expansion and pole dynamics which are derived for BE are valid for any meromorphic solution to BE and as such correct the pole expansion previously derived for BE.

In part I, we describe exact and asymptotic properties of the positive viscosity solution, its pole locations, and their dynamics.

In section 2, the solution is explicitly given by the Cole–Hopf transform for $\nu > 0$. From a careful analysis of the Cole–Hopf variable, the solution is expressed in terms of its polar singularities by means of a Mittag–Leffler (pole) expansion. A correction to the infinite dimensional CDS derived by Bessis and Fournier which governs the time evolution of the poles is found by replacing the pole expansion of the solution into the PDE. This system represents compatibility conditions for the existence of such a pole expansion.

In section 3, from the integral representation obtained via the Cole–Hopf analysis and by means of the saddle-point method, we derive an asymptotic formula for the solution $u_\nu(x,t)$ for small ν. However, for $t \geq t_*$, there is a degeneracy in the asymptotic formula at the caustic $x = \pm x_s(t)$ where two saddle points coalesce; thus, we derive both the regular saddle-point analysis within and outside the caustic and a uniformly valid expansion via Pearcey's integral, which correctly describes the transition between the two regions. The asymptotic behavior of the solution at the caustic $u_\nu(x_s(t),t)$ is obtained from the Pearcey representation and is shown to match the behavior obtained from the classical saddle-point analysis.

In section 4, we analyze the pole locations: at the inviscid shock time t_* we use the Cole–Hopf variable to approximate the poles. Highly accurate asymptotic formulas of a related Fourier integral derived in [31] enable us to obtain almost exact pole locations independent of the viscosity. At other times ($t \neq t_*$), when no such formula can be obtained, we derive weaker asymptotic results: for small $\nu > 0$ and $0 < t \leq t_*$, we show that the poles are a perturbation of the inviscid branch-point singularities of the form $\beta_k(t,\nu) = |x_s(t)| + \mathcal{O}((k\nu)^{3/4})$. For $t > t_*$, their asymptotic behavior no longer depends on the inviscid branch-point singularities, and it is given by $\beta_k(t,\nu) = \mathcal{O}((k\nu)^{3/4})$. Similarly, we also show that for large k, fixed ν, and all $t > 0$, we have $\beta_k(t,\nu) = \mathcal{O}((k\nu)^{3/4})$.

In section 5, we analyze the time evolution of the poles more explicitly since their actual location for $t \neq t_*$ has not been described. The method consists in numerically solving a truncated version of the CDS. The "initial data" which is adjoined to this truncated system is generated by the exact pole locations found in section 4. A Runge–Kutta–Fehlberg 4–5 time marching scheme is used in combination with the "multipole" algorithm designed by Greengard and Rokhlin [21]. This multipole algorithm reduces the computational complexity of the nonlinear interaction of the poles in the Calogero ODE system from $\mathcal{O}(N^2)$ to $\mathcal{O}(N \log N)$ particles (poles), thereby allowing us to carry out very large simulations with up to $N = 50,000$ poles. The closed-form solution to a two-pair pole dynamics is obtained and serves as a test case for the multipole simulation. The poles $\pm\beta_k(t,\nu)$ are confined to the imaginary axis and move towards the origin until a time $t = t_u(k)$, $k \in \mathbb{N}^*$; this is the time at which they turn around and move away from the origin. These turn-around times $t_u(k)$ decrease as k increases: $t_u(1) > t_u(2) > \cdots > t_u(n) > \cdots > 0$. Moreover, $t_u(1)$ occurs before t_* for $\nu \gtrapprox .01$ and after t_* for $\nu \lessapprox .01$. Another worthwhile feature is that t_u increases with decreasing ν, in accordance with the fact that the time at which the solution starts decaying increases with decreasing ν.

From this procedure, the evolution of the width of the analyticity strip is shown to remain uniformly bounded away from zero, agreeing with the asymptotic predictions and the well-known fact that BE with analytic initial data has a smooth solution for all times as long as $\nu > 0$ (in agreement with the results of Sulem, Sulem, and Frisch in [35]).

Finally, the solution is computed for small viscosity using pole dynamics, finite differences, and asymptotic methods (saddle-point analysis), and numerical agreement is established. The difference scheme we use is the method of lines consisting of the same Runge–Kutta–Fehlberg 4–5 scheme in time combined with central differencing in space. The solution is reconstructed from the pole positions and the Mittag–Leffler (pole) expansion of the solution.

In part II [32], the zero-viscosity limit of the solution is obtained via a process of pole condensation. It is shown that the asymptotic density of poles, which describes their condensation on the imaginary axis, can be obtained as the weak limit of a discrete Borel measure (analogously to the zero-dispersion limit of the spectral measure in the KdV problem). The analytic structure of the inviscid solution, which is a three-sheeted Riemann surface with three branch-point singularities, is recovered. The continuum limit of the pole expansion of the solution and the CDS for the poles is a system of two integro-differential equations which form a new representation of the solution to the inviscid BE. This formalism clarifies the relation between pole dynamics and branch-cut dynamics. A large wave number asymptotic expansion of the Fourier transform of the inviscid solution uniformly valid in a neighborhood of the shock time is described in terms of the Airy function. This provides a clarification of the degeneracy presented by Fournier and Frisch in [19]. In [33], this methodology is adapted to the dispersive case $\nu \in i\mathbb{R}$.

2. Integral representation, pole expansion, and pole dynamics for $\nu > 0$.

2.1. The Cole–Hopf solution and Mittag–Leffler expansion.

The Cole–Hopf solution to the initial value problem (1.1)–(1.2) can be represented by a Mittag–Leffler expansion as follows.

THEOREM 2.1. *For all $\nu, t, t_* > 0$, the solution to BE with initial data $u_0(x) = 4x^3 - x/t_*$ is*

$$u_\nu(x,t) = \frac{x}{t} - 2\nu\,\partial_x \log\bigl(E_\nu(x,t)\bigr),$$
$$E_\nu(x,t) = \int_{-\infty}^{\infty} \exp\left\{\frac{1}{2\nu}\left(\frac{x}{t}y + \alpha y^2 - y^4\right)\right\} dy,$$

where $2\alpha = 1/t_* - 1/t \in \mathbb{R}$. For fixed ν, t, $E_\nu(x,t)$ is an even entire function of x of order $4/3$ with countably many simple zeros which come in pure imaginary opposite *and conjugate pairs. Moreover, $E_\nu(x,t)$ has the infinite product representation*

$$E_\nu(x,t) = \mathcal{C}_\nu(t) \prod_{n=1}^{\infty} \left(1 + \frac{x^2}{\beta_n^2(t,\nu)}\right), \quad \sum_{n=1}^{\infty} \frac{1}{\beta_n} = +\infty, \quad \sum_{n=1}^{\infty} \frac{1}{\beta_n^2} < +\infty,$$
$$\mathcal{C}_\nu(t) = \frac{\sqrt{\alpha}}{2}\, e^{\frac{\alpha^2}{16\nu}} K_{1/4}\left(\frac{\alpha^2}{16\nu}\right), \quad \mathcal{C}_\nu(t_*) = \nu^{1/4} 2^{-3/4} \Gamma(1/4),$$

where $K_q(z)$ is the modified Bessel function of the second kind. Thus, the solution $u_\nu(x,t)$ has an alternate representation in terms of a Mittag–Leffler (pole) expansion

$$u_\nu(x,t) = \frac{x}{t} - \sum_{n=1}^{\infty} \frac{4\nu x}{x^2 + \beta_n^2(t,\nu)} = \frac{x}{t} - 2\nu \sum_{\substack{n=-\infty \\ n\neq 0}}^{\infty} \frac{1}{x - i\beta_n(t,\nu)},$$

which converges uniformly on compact sets for x away from the poles $a_n = \pm i\beta_n$.

Proof. The solution to system (1.1) is constructed using the Cole–Hopf nonlinear transform $u = -2\nu\, \partial_x \log(\phi_\nu)$ [17, 22], which was first introduced by Forsyth (cf. [18, section 207, p. 100]). This nonlinear dependent variable transformation maps BE into the diffusion equation for $\phi_\nu(x,t)$ with corresponding initial data $\phi_0(x) = \exp\{-\frac{1}{2\nu}\int_0^x u_0(y)dy\}$. The solution is therefore represented by means of a convolution:

$$\begin{aligned} \phi_\nu(x,t) &= (K_\nu * \phi_o)(x,t) \\ &= (4\pi\nu t)^{-1/2} \int_{-\infty}^{\infty} \exp\left\{-\frac{(x-y)^2}{4\nu t} - \frac{1}{2\nu}\int_0^y u_0(\eta)d\eta\right\} dy \\ &= K_\nu(x,t) E_\nu(x,t), \end{aligned}$$

where

$$K_\nu(x,t) = K(x,\nu t) = (4\pi\nu t)^{-1/2} \exp\left(-x^2/4\nu t\right)$$

is the fundamental solution of the diffusion equation and

$$E_\nu(x,t) = \int_{-\infty}^{\infty} \exp\left\{\frac{1}{2\nu}\int_0^y \left(\frac{x}{t} - \frac{\eta}{t} - u_0(\eta)\right) d\eta\right\} dy. \tag{2.1a}$$

Since $\partial_x \log\big(K_\nu(x,t)\big) = -x/2\nu t$, the solution of the original problem is given by

$$u_\nu(x,t) = \frac{x}{t} - 2\nu\, \partial_x \log\big(E_\nu(x,t)\big). \tag{2.1b}$$

For $u_0(x) = 4x^3 - x/t_*$, $\nu, t > 0$, we obtain the following solution:

$$E_\nu(x,t) = \int_{-\infty}^{\infty} \exp\left\{\frac{1}{2\nu}\left(\frac{x}{t}y + \alpha y^2 - y^4\right)\right\} dy, \qquad \alpha = \frac{t - t_*}{2tt_*} \in \mathbb{R}. \tag{2.2}$$

It is clear that E_ν is an even, real analytic function of x and therefore satisfies the conjugacy relation $E_\nu(\overline{x},t) = \overline{E_\nu(x,t)}$ (the analyticity of E_ν can be verified using Morera's theorem). The positive order λ of an entire function $f(z)$ is defined as $\lambda = \limsup_{r\to+\infty} \log\log M(r)/\log r$, where $M(r) = \max_{|z|=r}|f(z)|$. For a fixed time $t > 0$, the order of E_ν is the smallest number $\lambda \in \mathbb{R}_+$ such that

$M_\nu(r) = \max_{|x|=r} |E_\nu(x,t)| \leq \exp(r^{\lambda+\epsilon})$ for any $\epsilon > 0$ as soon as r is sufficiently large. From the asymptotic behavior of E_ν for $|x| = r \to +\infty$, we find in (4.4) that $M_\nu(r) = \mathcal{O}(r^{1/3}\exp(-\kappa(t)\, r^{4/3}/2\nu))$, where $\kappa(t)/2\nu$ is the "type" of the entire function E_ν. Thus, it is clear that its order is $\lambda = 4/3$. It is known that entire functions of fractional order have infinitely many zeros (see [3, 8]); thus, E_ν has infinitely many zeros that come in opposite and conjugate pairs. Since the fractional order of the entire function E_ν is also the exponent of convergence of its zeros a_n (see again [3, 8]), we have

$$\sum_{n=1}^{\infty} \frac{1}{|a_n|^{\lambda+\epsilon}} < +\infty \ \forall \epsilon > 0. \tag{2.3}$$

Using a Hadamard decomposition, we construct the solution u_ν by factorization of the zeros of E_ν. The canonical infinite product expansion of E_ν is (see [3])

$$E_\nu(x,t) = \mathcal{C}x^m e^{g(x)} \prod_{n=1}^{\infty} \left(1 - \frac{x}{a_n}\right) e^{x/a_n + \frac{1}{2}(x/a_n)^2 + \cdots + \frac{1}{p}(x/a_n)^p},$$

where $g(x)$ is a polynomial of degree q. The integer $h = \max(p,q)$, which is called the genus of the product representation of the entire function E_ν, satisfies the bound $h \leq \lambda \leq h+1 \Rightarrow h = 1 \Rightarrow p,q \leq 1$. Moreover, since E_ν is an even function of x, we must have $q = \deg g(x) = 0$, and therefore $p = 1$ (since $p+1 > \lambda$, $p \in \mathbb{N}$). Since $\mathcal{C} = \mathcal{C}_\nu(t) = E_\nu(0,t) \neq 0$ (see (2.6a)), we must also set $m = 0$, so the canonical product must be of the form

$$E_\nu(x,t) = \mathcal{C}_\nu(t) \prod_{n=1}^{\infty} \left(1 - \frac{x}{a_n}\right) e^{x/a_n}, \quad \sum_{n=1}^{\infty} \frac{1}{|a_n|} = +\infty, \quad \sum_{n=1}^{\infty} \frac{1}{|a_n|^2} < +\infty.$$

Due to the even parity of E_ν, its zeros come in opposite pairs $x = \pm a_n$; thus, the product representation reduces to the simple form

$$E_\nu(x,t) = \mathcal{C}_\nu(t) \prod_{n=1}^{\infty} \left(1 - \frac{x^2}{a_n^2}\right).$$

In [29], Pólya showed that functions of the form

$$\int_{-\infty}^{\infty} e^{-at^{4n} + bt^{2n} + iyt} dt \qquad n \geq 1,\ a > 0,\ b \in \mathbb{R} \tag{2.4}$$

have only real zeros. Using this property, it is straightforward to show that the zeros of E_ν come in pure imaginary conjugate pairs; thus, we let $a_n = i\beta_n$, $\beta_n > 0$ and obtain an infinite product expansion of E_ν valid for all $t, \nu > 0$:

$$E_\nu(x,t) = \mathcal{C}_\nu(t) \prod_{n=1}^{\infty} \left(1 + \frac{x^2}{\beta_n^2(t,\nu)}\right), \quad \sum_{n=1}^{\infty} \frac{1}{\beta_n} = +\infty, \quad \sum_{n=1}^{\infty} \frac{1}{\beta_n^2} < +\infty, \tag{2.5}$$

where $\mathcal{C}_\nu(t)$ is a constant depending on t which can be found explicitly: let $K_q(z)$ be the modified Bessel function of the second kind; then

$$\mathcal{C}_\nu(t) = E_\nu(0,t) = \int_{-\infty}^{\infty} e^{(\alpha y^2 - y^4)/2\nu}\, dy = \frac{\sqrt{\alpha}}{2}\, e^{\frac{\alpha^2}{16\nu}}\, K_{1/4}\left(\frac{\alpha^2}{16\nu}\right), \tag{2.6a}$$

$$\mathcal{C}_\nu(t_*) = E_\nu(0,t_*) = \int_{-\infty}^{\infty} e^{-y^4/2\nu}\, dy = \nu^{1/4} 2^{-3/4}\Gamma(1/4), \tag{2.6b}$$

with $K_{1/4}(z) = \mathcal{O}(z^{-1/4})$ as $z \to 0$. After logarithmic differentiation of E_ν and by using (2.1b) and (2.5), the spatially singular part of the solution being the ratio of two entire functions is meromorphic. Thus, we obtain a Mittag–Leffler expansion of the solution which we refer to as the pole expansion:

$$u_\nu(x,t) = \frac{x}{t} - \sum_{n=1}^{\infty} \frac{4\nu x}{x^2 + \beta_n^2(t,\nu)} = \frac{x}{t} - 2\nu \sum_{\substack{n=-\infty \\ n\neq 0}}^{\infty} \frac{1}{x - i\beta_n(t,\nu)}. \tag{2.7}$$

In the second sum, we have adopted the convention that $\beta_{-n} = -\beta_n$. Furthermore, it must be understood as a symmetric (convergent) sum of the form

$$\sum_{\substack{n=-\infty \\ n\neq 0}}^{\infty} \frac{1}{x - i\beta_n(t,\nu)} = \sum_{n\in\mathbb{N}^*} \left(\frac{1}{x - i\beta_n(t,\nu)} + \frac{1}{x + i\beta_n(t,\nu)} \right).$$

Since $\sum_n \beta_n^{-2} < \infty$ for any fixed $t, \nu > 0$, the series defining u_ν in (2.7) converges absolutely and uniformly on any strip $0 < \beta_k < \delta_k \leq |\Im x| \leq \delta_{k+1} < \beta_{k+1}$, $k \in \mathbb{N}^* = \mathbb{N}\backslash\{0\}$. Therefore, u_ν is analytic in the strip $|\Im x| < \beta_1$ where $i\beta_1$ is the first ordered pole on the imaginary axis. From (2.7), u_ν conserves the odd parity of the initial data as expected from the PDE: $u_\nu(-x,t) = -u_\nu(x,t)$. In order for this pole expansion to make sense, the behavior of the spatially singular part of the expansion should be unbounded as $t \to 0^+$ in order to balance with the term x/t. □

2.2. CDS for the poles $\boldsymbol{\beta_n(t,\nu)}$. We describe the time evolution of the poles $\beta_n(t,\nu)$ according to an infinite dimensional dynamical system which is found as a compatibility condition for the existence of the pole expansion (2.7). We prove the following property.

Property 2.2. *The imaginary part $\beta_n = \beta_n(t,\nu) : \mathbb{R}_+ \times \mathbb{R}_+ \to \mathbb{R}_+$ of the simple poles $x = \pm i\beta_n$ of $u_\nu(x,t)$ satisfy the Calogero-type infinite-dimensional dynamical system*

$$\dot{\beta}_n = \frac{\beta_n}{t} + \frac{\nu}{\beta_n} - 4\nu\beta_n \sum_{\substack{l=1 \\ l\neq n}}^{\infty} \frac{1}{\beta_l^2 - \beta_n^2} \ \forall n \in \mathbb{N}^*.$$

Adopting the convention that $\beta_{-n} = -\beta_n$, we have a symmetric formulation:

$$\dot{\beta}_n = \frac{\beta_n}{t} - 2\nu \sum_{\substack{l=-\infty \\ l\neq n,0}}^{\infty} \frac{1}{\beta_l - \beta_n} \ \forall n \in \mathbb{Z}^*.$$

Moreover, the variables $\gamma_n(t,\nu) = \beta_n^2(t,\nu)/\nu$ satisfying $\sum_n \gamma_n^{-1} < +\infty$ are the solution to the ν-independent infinite system of ODEs:

$$\frac{\dot{\gamma}_n}{2} = \frac{\gamma_n}{t} + 1 - 4\gamma_n \sum_{\substack{l=1 \\ l\neq n}}^{\infty} \frac{1}{\gamma_l - \gamma_n} \ \forall n \in \mathbb{N}^*.$$

Proof. The usual pole expansion that is sought in [1, pp. 203–209] and [13, 16, 20] is of the form

$$u_\nu = \sum_{n=1}^{N} \frac{2\nu}{x - i\beta_n}. \tag{2.8}$$

However, as $N \to +\infty$ this series diverges for any fixed x, t, ν. Since we know that the representation (2.7) converges away from the poles (since $\sum_n \beta_n^{-2} < \infty$ from (2.5)) instead of using (2.8), we replace the full Mittag–Leffler/pole expansion (2.7) in the PDE (1.1). The extension from a finite pole expansion to an infinite one is easily made (cf. [16, section 3]). We obtain an infinite system of ODEs which govern the motion of the poles $\beta_n(t,\nu)$ as they evolve with time for $t > 0$. We introduce the following notations:

$$\dot{\beta}_n = \frac{d\beta_n}{dt}, \qquad \sum_n = \sum_{n=1}^{\infty}, \qquad \sum_l = \sum_{l=1}^{\infty}, \qquad \sum_{l\neq n} = \sum_{\substack{l=1 \\ l\neq n}}^{\infty}.$$

Using partial fraction expansion we have the following property.

PROPERTY 2.3. *Let $x \notin \{i\beta_n \in i\mathbb{R}$ for all $n \in \mathbb{Z}^*\}$ and $l \neq n$; then*

$$\text{(2.9a)} \qquad \frac{1}{(x^2+\beta_n^2)(x^2+\beta_l^2)} = \frac{1}{\beta_n^2-\beta_l^2}\cdot\left(\frac{1}{x^2+\beta_l^2} - \frac{1}{x^2+\beta_n^2}\right)$$

$$\text{(2.9b)} \qquad \begin{aligned} \frac{1}{(x^2+\beta_n^2)(x^2+\beta_l^2)^2} = \frac{1}{(\beta_l^2-\beta_n^2)^2}&\cdot\left(\frac{1}{x^2+\beta_n^2} - \frac{1}{x^2+\beta_l^2}\right) \\ &+ \frac{1}{\beta_n^2-\beta_l^2}\cdot\frac{1}{(x^2+\beta_l^2)^2}. \end{aligned}$$

Due to obvious symmetries, we also have

$$\text{(2.10)} \qquad \sum_n\sum_{l\neq n}\frac{1}{(\beta_n^2-\beta_l^2)^2}\cdot\left(\frac{1}{x^2+\beta_n^2} - \frac{1}{x^2+\beta_l^2}\right) = 0.$$

Thus, combining (2.9b) and (2.10), we obtain Property 2.4.

PROPERTY 2.4. *Let $x \notin \{i\beta_n \in i\mathbb{R}$ for all $n \in \mathbb{Z}^*\}$; then*

$$\begin{aligned} \sum_n\sum_{l\neq n}\frac{1}{(x^2+\beta_n^2)}\cdot\frac{1}{(x^2+\beta_l^2)^2} &= \sum_n\sum_{l\neq n}\frac{1}{\beta_n^2-\beta_l^2}\cdot\frac{1}{(x^2+\beta_l^2)^2} \\ &= \sum_n\sum_{l\neq n}\frac{1}{\beta_l^2-\beta_n^2}\cdot\frac{1}{(x^2+\beta_n^2)^2}. \end{aligned}$$

After replacing the pole expansion (2.7) into the original PDE (1.1), canceling the terms $\pm x/t^2$, regrouping terms together in powers of $(x^2+\beta_n^2)^{-1}$, dividing by $8\nu x$, and appealing to both equation (2.9a) of Properties 2.3 and 2.4, Property 2.2 is proved. Note that in [7], the pole interaction in the dynamical system was incorrectly stated as a divergent semi-infinite sum of the form

$$\dot{\beta}_n = \frac{\beta_n}{t} - 2\nu\sum_{\substack{l\geq 1 \\ l\neq n}}\frac{1}{\beta_l-\beta_n}.$$

Due to the generality of the integral representation (2.1a,b) of solutions to an initial value problem (IVP) for BE, it is important to see that the pole representation

(2.7) and pole dynamics of Property 2.2 are special cases of the general representation for a meromorphic solution to BE.

PROPERTY 2.5. *Let $\mathcal{I} \subseteq \mathbb{Z}$ be a set of indices, either finite or countable, and let $\{a_n(t,\nu), n \in \mathcal{I}\}$ be a finite or countable set of time-dependent pole locations. Then any meromorphic solution with poles $\{a_n(t,\nu), n \in \mathcal{I}\}$ must have the following pole representation/pole dynamics:*

$$\textit{Pole representation:}\quad u_\nu(x,t) = \frac{x}{t} - 2\nu \sum_{n\in\mathcal{I}} \frac{1}{x - a_n(t,\nu)},$$

$$\textit{Pole dynamics:}\quad \dot{a}_n = \frac{a_n}{t} - 2\nu \sum_{\substack{l\in\mathcal{I}\\ l\neq n}} \frac{1}{a_n - a_l} \qquad \forall n \in \mathcal{I}.$$

Moreover, if the initial data is odd, then the poles must come in opposite pairs $\{a_{\pm n}(t,\nu), n \in \mathcal{I} \subseteq \mathbb{Z}^* = \mathbb{Z}\backslash\{0\} \mid a_{-n} = -a_n\}$. In this case, the pole representation is fully symmetric.

3. Asymptotic analysis of $u_\nu(x,t)$ as $\nu \to 0^+$, $t > t_*$.

When $\nu \to 0^+$, we evaluate the asymptotic behavior of E_ν using the saddle-point method. The caustic $x = x_s(t)$ corresponds to the envelope of the characteristics of the inviscid Burgers solution and is also determined by the following system of equations:

$$\left\{ \begin{array}{l} 0 = w_z(z,x) = x/t + 2\alpha z - 4z^3, \\ 0 = w_{zz}(z,x) = 2\alpha - 12z^2, \end{array} \right. \tag{3.1}$$

where

$$w(z,x) = \int_0^z \left(\frac{x}{t} - \frac{\eta}{t} - u_0(\eta) \right) d\eta \tag{3.2}$$

is the phase function of the integrand in the definition of $E_\nu(x,t)$. This system represents the conditions for the phase function w to have saddle points of multiplicity two, thereby yielding a curve in the (x,t) plane on which two saddle points of multiplicity one coalesce into a saddle point of multiplicity two. From the second equation in (3.1), we find $z_{caustic}(t) = \pm\sqrt{\alpha/6}$; from the first, we have

$$x = x_{caustic} = t\big(4z_{caustic}(t)^3 - 2\alpha z_{caustic}(t)\big) = \mp t \left(\frac{2\alpha}{3}\right)^{3/2} = \mp x_s(t), \tag{3.3}$$

where $x_s(t) = (3t_*)^{-3/2}(t-t_*)^{3/2}t^{-1/2}$ is the second-order branch point of the inviscid solution described in [32, App. C]. We find that all three saddle points may be relevant within the caustic $|x| < |x_s(t)| - \delta/2$, where $\delta > 0$. For a discussion on such caustics, cf. [24, 28]. When $t > t_*$, $x \in \big(-\infty, -x_s(t) - \delta/2\big) \cup \big(x_s(t) + \delta/2, \infty\big)$, $\nu \to 0^+$, the same analysis holds and one recovers the characteristic solution outside the caustic consisting of only one relevant saddle point. The transition from within the caustic to outside is not uniform as the asymptotic behavior at the caustic $x = \pm x_s(t)$ is degenerate (two saddle points have coalesced). The transitionary regime from one relevant saddle point to two at and around the caustic is therefore described by means of the Pearcey integral which allows for a uniformly valid description.

3.1. Inner expansion: $x \in \big(-x_s(t)+\delta/2,\ x_s(t)-\delta/2\big)$, $\delta > 0$, $t > t_*$. In the analysis that follows, we are only concerned with the dominant behavior of E_ν; thus, we only retain the first term:

$$E_\nu(x,t) = \sum_{s=0,1,2} \sqrt{\frac{-4\pi\nu}{w_{zz}(z_s,x)}} \exp\left(\frac{w(z_s,x)}{2\nu}\right)\Big(1+\mathcal{O}(\nu)\Big), \tag{3.4}$$

as $\nu \to 0^+$, with

$$w_z\big(z_s(x,t),x\big) = 0, \quad w_{zz}\big(z_s(x,t),x\big) = 2\alpha - 12z_s^2. \tag{3.5}$$

Since

$$0 = \frac{z_s}{4} w_z\big(z_s,x\big) = \frac{xz_s}{4t} + \frac{\alpha}{2}z_s^2 - z_s^4,$$

we have that

$$w\big(z_s(x,t),x\big) = \frac{x}{t}z_s + \alpha z_s^2 - z_s^4 = \frac{3}{4}\frac{x}{t}z_s + \frac{\alpha}{2}z_s^2. \tag{3.6}$$

The values of the saddle points $z_s = z_s(x,t)$ of (3.4) are determined by the three roots of the first equation in system (3.1), i.e., the first equation of (3.5). They are, specifically,

$$\begin{cases} z_0 = \omega\,\mathcal{A} + \omega^2\,\mathcal{B}, \\ z_1 = \omega^2\,\mathcal{A} + \omega\,\mathcal{B}, \\ z_2 = \mathcal{A} + \mathcal{B}, \end{cases} \tag{3.7}$$

where $w = e^{2\pi i/3}$ is a cube root of unity and

$$\begin{cases} \mathcal{A}(x,t) = (8t)^{-1/3} \cdot \sqrt[3]{x + \sqrt{x^2 - x_s^2}}, \\ \mathcal{B}(x,t) = (8t)^{-1/3} \cdot \sqrt[3]{x - \sqrt{x^2 - x_s^2}}. \end{cases} \tag{3.8}$$

Note that all three saddle points are real when $x, x_s \in \mathbb{R}$ and the discriminant $\Delta = x^2 - x_s^2 < 0$, that is, $|x| < |x_s(t)|$. In this case, $\mathcal{A} = \overline{\mathcal{B}}$ (see [32, App. B]). Therefore, we have $z_s \in \mathbb{R}$, $w(z_s,x) \in \mathbb{R}$, and $w_{zz}(z_s,x) = 2\alpha - 12z_s^2 \in \mathbb{R}$. Hence, all three terms in the summation signs may be relevant. Note, however, that the expansion derived for E_ν is only valid within $|x| < |x_s|$, and in order to get an expansion uniformly valid across $x = \pm x_s$ one needs to derive a uniform expansion as presented in section 3.3. The dominant behavior of the solution $u_\nu(x,t)$ is found from the Cole–Hopf representation, so within the caustic $|x| < |x_s| - \delta/2$ we have

$$\begin{aligned} \frac{U_\nu(x,t)}{t} &= 2\nu\,\partial_x \log\big(E_\nu(x,t)\big) \\ &= 2\nu\,\partial_x \log\left(\sum_{s=0,1,2}\sqrt{\frac{-4\pi\nu}{w_{zz}(z_s,x)}}e^{\frac{w(z_s,x)}{2\nu}}\big(1+\mathcal{O}(\nu)\big)\right) \\ &= 2\nu\,\frac{\sum_{s=0,1,2}\partial_x\left(\sqrt{\frac{-4\pi\nu}{w_{zz}(z_s,x)}}e^{\frac{w(z_s,x)}{2\nu}}\right)}{\sum_{s=0,1,2}\sqrt{\frac{-4\pi\nu}{w_{zz}(z_s,x)}}e^{\frac{w(z_s,x)}{2\nu}}} + \mathcal{O}(\nu^2). \end{aligned}$$

Since $w(z_s,x)\in\mathbb{R}$, $\nu>0$, and

$$\frac{\partial w}{\partial x}(z_s,x)=\frac{z_s}{t}, \tag{3.9}$$

we find

$$U_\nu(x,t)=\frac{\sum_{s=0,1,2} z_s\cdot e^{\frac{w(z_s,x)}{2\nu}}/\sqrt{w_{zz}(z_s,x)}}{\sum_{s=0,1,2} e^{\frac{w(z_s,x)}{2\nu}}/\sqrt{w_{zz}(z_s,x)}}+\mathcal{O}(\nu). \tag{3.10}$$

The x-differentiation of the asymptotic formula of $E_\nu(x,t)$ is justified due to the analytic dependency in x. Often one of the three saddle points is such that $w(z_s,x)<0$, and as such, its contribution is exponentially smaller than either of the other two. In terms of the numerical computation that will be carried out in section 5, leaving this term in (3.1) does not affect the value of u_ν. Thus, we can simplify expression (3.10) to a two-term asymptotic expansion that is similar to the one in [38, section 4.2]. Clearly, the further away we are from the caustic, the more dominant one of the saddle points becomes. However, since there is a point where the dominance of one over the other changes (i.e., where they are equally relevant), we must leave both in the asymptotic formula. Note also that $w_{zz}(z_s,x)\to\infty$ as $x\to x_s$, which is characteristic of the degeneracy of the asymptotic formula (3.10) at the caustic $x=x_s$.

PROPERTY 3.1. *For $x\in\big(-x_s(t)+\delta/2,x_s(t)-\delta/2\big)$, $\delta>0$, $t>t_*$, the inner expansion of the solution to BE as $\nu\to0^+$ is given by*

$$u_\nu(x,t)=\frac{x}{t}-\frac{U_\nu(x,t)}{t},$$
$$U_\nu(x,t)=\frac{\sum_{\{s:w(z_s,x)>0\}} z_s\cdot e^{\frac{w(z_s,x)}{2\nu}}/\sqrt{w_{zz}(z_s,x)}}{\sum_{\{s:w(z_s,x)>0\}} e^{\frac{w(z_s,x)}{2\nu}}/\sqrt{w_{zz}(z_s,x)}}+\mathcal{O}(\nu).$$

3.2. Outer expansion: $x\in\big(-x_s(t)-\delta/2,x_s(t)+\delta/2\big)^c$, $\delta>0$, $t>t_*$.

The inviscid limit is found in a straightforward manner in this case: only one saddle point is relevant, so the asymptotic limit derived in section 3.1 reduces to

$$U_\nu(x,t)=U(x,t)+\mathcal{O}(\nu)\qquad\text{as }\nu\to0^+,$$

where $U(x,t)=z_{s*}(x,t)$ is the spatially singular part of the inviscid solution (see [32, App. C]). The particular saddle point z_{s*} that is chosen at every x is the one for which $w(z_{s*},x)=\max_{s=0,1,2}w(z_s,x)$. Hence, we have the following property outside of the caustic.

PROPERTY 3.2. *Let $\delta>0$, $t>t_*$, and define $z_{s*}(x,t)$ by*

$$w(z_{s*},x)=\max_{s=0,1,2}w(z_s,x).$$

Then for $x\in\big(-x_s(t)-\delta/2,x_s(t)+\delta/2\big)^c$, the solution to BE is given by

$$u_\nu(x,t)=\frac{x}{t}-\frac{U_\nu(x,t)}{t}=\frac{x}{t}-\frac{U(x,t)}{t}+\mathcal{O}(\nu)\qquad\textit{as }\nu\to0^+,$$

where $U(x,t)=z_{s*}(x,t)$ is the Lagrangian characteristic variable of the inviscid solution.

3.3. Uniform asymptotic expansion as $\nu \to 0^+$ in a neighborhood of the caustics $x = \pm x_s(t)$ for $t > t_*$ via Pearcey's integral. Following the notation of Kaminski in [24], we introduce the Pearcey integral from which one can derive a uniform asymptotic expansion with two coalescing saddle points (see [15]): let

$$P(X,Y) = \int_{-\infty}^{+\infty} e^{i\left(v^4/4 + Xv^2/2 + Yv\right)}\,dv \tag{3.11}$$

denote the Pearcey integral. Introducing the change of variable

$$y \to (-i\nu/2)^{1/4}\,v = (\nu/2)^{1/4}\,e^{3\pi i/8}\,v$$

and deforming the path of integration back to the real axis using Jordan's lemma, we can express $E_\nu(x,t)$ as

$$\begin{aligned} E_\nu(x,t) &= \int_{-\infty}^{+\infty} \exp\left\{\frac{1}{2\nu}\left(\frac{x}{t}y + \alpha y^2 - y^4\right)\right\} dy \\ &= \left(\frac{-i\nu}{2}\right)^{1/4} \int_{-\infty}^{+\infty} \exp\left\{ i\left(\frac{v^4}{4} + \frac{\alpha e^{i\pi/4}}{\sqrt{2\nu}}\frac{v^2}{2} + \frac{xe^{-i\pi/8}}{2t}\left(\frac{1}{2\nu^3}\right)^{1/4} v\right)\right\} dv \\ &= \left(\frac{-i\nu}{2}\right)^{1/4} P\left(X = \frac{\alpha e^{i\pi/4}}{\sqrt{2\nu}}, Y = \frac{xe^{-i\pi/8}}{2t}\left(\frac{1}{2\nu^3}\right)^{1/4}\right). \end{aligned} \tag{3.12}$$

Clearly, a small ν asymptotic of E_ν is equivalent to a combined asymptotic expansion of the Pearcey integral as $|X|, |Y| \to +\infty$. The caustic of $P(X,Y)$ and the corresponding caustic of $E_\nu(x,t)$ is given by

$$Y = \frac{2}{\sqrt{27}}(-X)^{3/2} \Longleftrightarrow x = \pm x_s(t) \in \mathbb{R} \quad \text{for } t > t_*. \tag{3.13}$$

Hence, the uniform asymptotic behavior of E_ν in a neighborhood of the caustic is found from the one of $P(-X, (2/\sqrt{27} - \tau)X^{3/2})$ as $X \to +\infty$, where $\tau = 0$ at the caustic and $\tau \neq 0$ away from it (see [24]). This amounts to a uniformly valid expansion in the interval $|x \pm x_s(t)| \leq |\delta_\pm(\tau;t)|$, where $\delta_\pm(\tau) = \delta_\pm(\tau;t) = \mp\sqrt{27}x_s(t)\cdot\tau/2 \in \mathbb{R}$. This expansion is also valid outside of this interval, however the region of interest is a neighborhood of the caustic. Indeed one only needs to use the asymptotic expansion of the Airy function and its derivative to find the results obtained in sections 3.1 and 3.2. From (3.12) we have that

$$\begin{aligned} U_\nu(x,t) &= t\cdot 2\nu\,\partial_x \log\bigl(E_\nu(x,t)\bigr) \\ &= t\cdot 2\nu\,\partial_x \log\left[P\left(X(\nu;t) = \frac{\alpha e^{i\pi/4}}{\sqrt{2\nu}}, Y(\nu;x,t) = \frac{xe^{-i\pi/8}}{2t}\left(\frac{1}{2\nu^3}\right)^{1/4}\right)\right]. \end{aligned}$$

Let

$$X = X(\nu;t), \qquad Y = Y(\nu;x,t) = Y(\nu; x = \pm x_s(t) - \delta_\pm(\tau;t), t),$$

where $\delta_\pm(\tau;t) \to 0^\mp$ as $\tau \to 0^\pm$, so that

$$\begin{aligned} U_\nu\Bigl(x = \pm x_s(t) - \delta_\pm(\tau;t), t\Bigr) &= t\cdot 2\nu\,\partial_x \log P(X,Y) \\ &= -t\cdot 2\nu\,\partial_\tau \log\Bigl(P\left(-X, (2/\sqrt{27} - \tau)X^{3/2}\right)\Bigr) \Big/ \frac{\partial \delta_\pm}{\partial\tau}\,. \end{aligned}$$

Let $P(\tau) = P\left(-X, (2/\sqrt{27} - \tau)X^{3/2}\right)$. Then, since $\partial\delta_\pm/\partial\tau = \mp\sqrt{27}x_s(t)/2$, we have

$$U_\nu\Big(x = \pm x_s(t) - \delta_\pm(\tau; t), t\Big) = \pm\frac{4\nu t}{\sqrt{27}x_s(t)}\frac{P_\tau(\tau)}{P(\tau)}.$$

Let

$$Ai(z) = \frac{1}{2\pi i}\int_{-i\infty}^{i\infty} e^{v^3/3 - zv}\, dv$$

stand for the Airy function (cf. [2]); then the following property is found in [24].

Property 3.3. *The uniform asymptotic expansion of* $P(-X, (\frac{2}{\sqrt{27}} - \tau)X^{3/2})$ *as* $X \to +\infty$ *in a neighborhood of* $\tau = 0$ *is given by*

$$P\left(-X, \left(\frac{2}{\sqrt{27}} - \tau\right)X^{3/2}\right) = \Bigg[e^{iX^2[f(v_2)+f(v_3)]/2}\Bigg\{p_0(\tau)\frac{2\pi}{X^{1/6}}Ai(-X^{4/3}\zeta(\tau))$$
$$+q_0(\tau)\frac{2\pi}{iX^{5/6}}Ai'(-X^{4/3}\zeta(\tau))\Bigg\} + e^{iX^2 f(v_1)}\left(\frac{\pi}{3v_1^2 - 1}\right)^{1/2}\frac{1+i}{X^{1/2}}\Bigg]\left(1 + \mathcal{O}\left(\frac{1}{X^2}\right)\right),$$

with

$$p_0(\tau) = 3^{-1/6}(1 + \mathcal{O}(\tau)), \quad q_0(\tau) = -\frac{3^{-5/6}}{2}(1 + \mathcal{O}(\tau)), \quad \zeta(\tau) = 3^{-1/6}\tau(1 + \mathcal{O}(\tau)),$$

and

$$f(v) = f(v;\tau) = \frac{v^4}{4} - \frac{v^2}{2} + \left(\frac{2}{\sqrt{27}} - \tau\right)v,$$

and the $v_i, i = 1, 2, 3$ *are the saddle points of* $f(v;\tau)$ *determined by the equation* $f_v(v_i;\tau) = 0$*, so* $f(v_i;\tau) = -v_i^2/4 + (2/\sqrt{27} - \tau)3v_i/4$*. The* v_i*'s are, specifically,*

$$v_1(\tau) = -\frac{2}{\sqrt{3}}\sin\left(\frac{\pi}{3} + \phi(\tau)\right), v_2(\tau) = \frac{2}{\sqrt{3}}\sin(\phi(\tau)), v_3(\tau) = \frac{2}{\sqrt{3}}\sin\left(\frac{\pi}{3} - \phi(\tau)\right),$$

where

$$\phi = \phi(\tau) = \frac{1}{3}\arcsin\left(1 - \tau\sqrt{27}/2\right), \quad \tau \in \mathbb{R}, \quad |\phi| \le \frac{\pi}{6}.$$

In order to derive the uniform asymptotic expansion of the derivative P_τ, one can differentiate termwise the expression in Property 3.3 due to the analytic dependency of $P(X, Y)$ in both its arguments X, Y (see [24] and [37, p. 52]). Therefore, since

$$X = \frac{\alpha e^{i\pi/4}}{\sqrt{2\nu}} \Rightarrow \frac{iX^2}{2} = -\frac{\alpha^2}{4\nu} \Rightarrow X^{-2} = \mathcal{O}(\nu)$$

and

$$\frac{\partial f}{\partial\tau}(v_i;\tau) = -v_i, \quad \frac{\partial f}{\partial v}(v_i;\tau) = 0 \quad \Rightarrow \quad \frac{df}{d\tau}(v_i(\tau);\tau) = -v_i(\tau),$$

and using the fact that $2\alpha/3 = (x_s/t)^{2/3}$, the next property is proved.

Property 3.4. *Let $\delta_\pm(\tau;t) = \mp\sqrt{27}x_s(t)\cdot\tau/2$. Then the uniform asymptotic expansion as $\nu \to 0^+$ of $U_\nu(x = \pm x_s(t) - \delta_\pm(\tau;t), t)$ in a neighborhood of the caustic $x = \pm x_s(t)$ is*

$$\begin{aligned}U_\nu\Big(x = \pm x_s(t) - \delta_\pm(\tau;t), t\Big) = \pm\,\frac{\sqrt{3}}{2}\left(\frac{x_s(t)}{t}\right)^{1/3} &\times \Bigg[[v_2+v_3]e^{-\frac{\alpha^2}{4\nu}[f(v_2)+f(v_3)]}\\ \times\left\{p_0(\tau)\frac{2\pi}{X^{1/6}}Ai(-X^{4/3}\zeta(\tau)) + q_0(\tau)\frac{2\pi}{iX^{5/6}}Ai'(-X^{4/3}\zeta(\tau))\right\}&\\ +2v_1\,e^{-\frac{\alpha^2}{4\nu}2f(v_1)}\left(\frac{\pi}{3v_1^2-1}\right)^{1/2}\frac{1+i}{X^{1/2}}\Bigg]&\\ \Bigg/\Bigg[e^{-\frac{\alpha^2}{4\nu}[f(v_2)+f(v_3)]}\left\{p_0(\tau)\frac{2\pi}{X^{1/6}}Ai(-X^{4/3}\zeta(\tau)) + q_0(\tau)\frac{2\pi}{iX^{5/6}}Ai'(-X^{4/3}\zeta(\tau))\right\}&\\ +e^{-\frac{\alpha^2}{4\nu}2f(v_1)}\left(\frac{\pi}{3v_1^2-1}\right)^{1/2}\frac{1+i}{X^{1/2}}\Bigg] + \mathcal{O}(\nu) \qquad \textit{as } \nu \to 0^+.&\end{aligned}$$

3.3.1. Behavior at the caustics $x = \pm x_s(t)$.

At the caustics $x = \pm x_s(t)$, $\tau = 0$, $\phi(0) = \pi/6$, $v_1(0) = -2/\sqrt{3}$, and $v_2(0) = v_3(0) = 1/\sqrt{3}$. Moreover, $f(v_i;0) = -v_i^2/4 + v_i/2\sqrt{3}$, so $f(v_2;0) = f(v_3;0) = -2/3$ and $f(v_1;0) = 1/12$. Since $f(v_2;0) < 0$ and $f(v_1;0) > 0$, the dominant term as $\nu \to 0^+$ in both the numerator and denominator of U_ν is obviously the one containing the exponentially increasing factor $\exp(-\frac{\alpha^2}{4\nu}[f(v_2) + f(v_3)])$. Therefore, the dominant behavior of $U_\nu(\pm x_s(t), t)$ reduces to the simple form

$$\begin{aligned}U_\nu(\pm x_s(t), t) &= \pm\frac{\sqrt{3}}{2}\left(\frac{x_s(t)}{t}\right)^{1/3}\cdot(v_2(0) + v_3(0)) + \mathcal{O}(\nu)\\ &= \pm\left(\frac{x_s(t)}{t}\right)^{1/3} + \mathcal{O}(\nu) \quad \text{as } \nu \to 0^+.\end{aligned}$$

Thus, since $u_\nu(x,t) = x/t - U_\nu(x,t)/t$ and from the odd parity of u_ν, we have the following property.

Property 3.5. *The asymptotic behavior of the solution $u_\nu(x,t)$ as $\nu \to 0^+$ at the caustic $x = \pm x_s(t)$ for $t > t_*$ is*

$$u_\nu(\pm x_s(t), t) = \pm\frac{x_s(t)}{t} \mp \frac{1}{t}\left(\frac{x_s(t)}{t}\right)^{1/3} + \mathcal{O}(\nu).$$

This matches the solution found from a classical saddle-point analysis obtained by combining (3.2) and (3.7): when $x = x_s(t)$, both saddle points z_0, z_1 coalesce into $z_s = (x_s(t)/t)^{1/3}$. From the asymptotic formula

$$u_\nu(x,t) = \frac{x}{t} - \frac{z_s(x,t)}{t} + \mathcal{O}(\nu)$$

derived in section 3.2, Property 3.5 is verified. Note that this expression is valid only for $t \geq t_* + \varepsilon$, $\varepsilon > 0$.

4. Pole locations.

4.1. Exact pole location at $t = t_*$. From the integral representation (2.2), a Taylor expansion about $x = 0$ can be obtained when $t = t_*$.

Property 4.1. *Let*

$$\mathcal{S}_\nu(z) = \nu^{1/4}\, 2^{-3/4} \sum_{n=0}^{\infty} (-1)^n \frac{\Gamma(\frac{2n+1}{4})}{\Gamma(2n+1)}\, z^{2n}, \qquad |z| < +\infty,$$

which converges absolutely and uniformly on compact sets for z. Then

$$E_\nu(x, t_*) = \mathcal{S}_\nu\left(\frac{ix}{4t_*}(2\nu)^{-3/4}\right), \qquad |x| < +\infty.$$

Let $x = i\beta$, $\beta \in \mathbb{R}$, $|\beta| < +\infty$; then if we introduce the scaling

$$\beta = \beta(t_*, \nu) = 4t_*(2\nu\mu)^{3/4}, \tag{4.1}$$

we have

$$E_\nu\left(i \cdot 4t_*(2\nu\mu)^{3/4}, t_*\right) = \mathcal{S}_\nu\left(\mu^{3/4}\right). \tag{4.2}$$

Following this scaling, we transform the integral representation of $E_\nu(i\beta, t_*)$ to simplify its analysis. At the inviscid shock time t_*,

$$E_\nu(i\beta, t_*) = \int_{-\infty}^{\infty} \exp\left\{\frac{1}{2\nu}\left(\frac{i\beta}{t_*}y - y^4\right)\right\} dy,$$

and the change of variable

$$y \to \left(\frac{\beta}{4t_*}\right)^{1/3} z \tag{4.3}$$

introduces the scaling factor (4.1) between the imaginary part β_n of the zeros a_n and the viscosity ν. This allows us to express $E_\nu(i\beta, t_*)$ in terms of a new function $F(\mu)$, which has the advantage that its saddle points are fixed to the unit disc (thereby making the asymptotic analysis simpler):

$$E_\nu(i\beta, t_*) = \left(\frac{\beta}{4t_*}\right)^{1/3} F\left(\frac{1}{2\nu}\left(\frac{\beta}{4t_*}\right)^{4/3}\right), \quad F(\mu) = \int_{-\infty}^{\infty} e^{\mu(4iz - z^4)} dz. \tag{4.4}$$

Once the zeros $\{\mu_k\}_{k=1}^{\infty}$ of $F(\mu)$ are found (independent of ν), the poles $\pm a_k(t_*, \nu) = \pm i\beta_k(t_*, \nu)$ of $u_\nu(x, t_*)$ are given by the relation

$$\beta_k(t_*, \nu) = 4t_*(2\nu\mu_k)^{3/4} \quad \forall \nu > 0, \tag{4.5}$$

which was introduced in (4.1). It is important to see that this relation is valid regardless of whether ν is small or β is large. Thus, if we can describe the μ_k's accurately, then the pole locations are known with great precision at t_* (independent of ν). Furthermore, the expansion of $E_\nu(i\beta, t_*)$ as $\nu \to 0^+$ or as $\beta \to +\infty$ is determined by that of $F(\mu)$ as $\mu \to +\infty$. The following theorem is proved in [31].

Theorem 4.2. *The asymptotic expansion of $F(\mu) = \int_{-\infty}^{\infty} e^{\mu(4iz - z^4)} dz$ as $\mu \to +\infty$ centered about the sector $|\arg \mu| < \pi/2$ is*

$$F(\mu) = \sqrt{\frac{2\pi}{3\mu}} e^{-\frac{3}{2}\mu}\left[\cos\left(3\frac{\sqrt{3}}{2}\mu - \frac{\pi}{6}\right) + \mathcal{O}\left(\frac{1}{\mu}\right)\right] \quad \text{as } \mu \to +\infty.$$

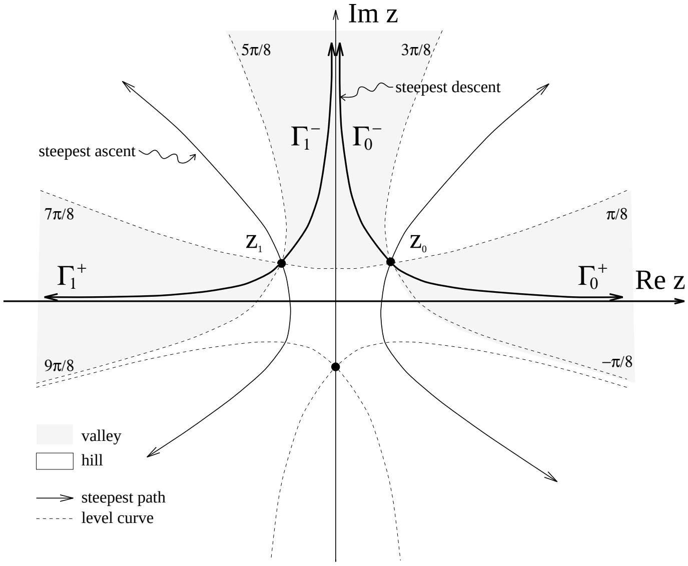

FIG. 4.1. *Hills, valleys, level curves, and steepest paths of the saddle points* $z_0 = e^{i\pi/6}$, $z_1 = e^{i5\pi/6}$ *relevant to the expansion of* $F(\mu) = \int_{-\infty}^{\infty} e^{\mu(4iz-z^4)}dz$ *as* $\mu \to +\infty$.

Moreover, the kth ordered positive zero μ_k *of* $F(\mu)$ *for* $k \geq 1$ *is given by*

$$\mu_k^{(0)} = \frac{2\pi}{3\sqrt{3}}(k - 1/3), \qquad \mu_k = \mathcal{G}\left(\mu_k^{(0)}\right) + \mathcal{O}\left(\frac{1}{k^6}\right) \quad \textit{as } k \to +\infty,$$
$$\mathcal{G}(\mu) = \mu + \frac{7}{432\mu}\left(1 - \frac{1}{6\mu}\left(1 + \frac{7}{72\mu}\left(1 - \frac{5}{12\mu}\left(1 + \frac{53143}{18900\mu}\right)\right)\right)\right).$$

In addition to this asymptotic description, the first nine values of μ_k are computed numerically in [31] and are listed in section 5. The accuracy of this asymptotic approximation is discussed in [31]; the necessity for such high accuracy will be apparent in section 5. Combining (4.5) and Theorem 4.2, the pole locations at $t = t_*$ are given by the simple form in Property 4.3.

PROPERTY 4.3. *For all* $\nu > 0$,

$$\beta_k(t_*, \nu) = 4t_* \left(\frac{4\nu\pi}{3\sqrt{3}}\right)^{3/4} \cdot \left((k - 1/3)^{3/4} + \mathcal{O}(1/k^{3/4})\right)$$

as $k \to +\infty$.

4.2. Asymptotic analysis of the pole locations $\beta_k(t, \nu)$ as $\nu \to 0^+$ for fixed k and $t \neq t_*$. The saddle-point analysis of $E_\nu(i\beta, t)$ as $\nu \to 0^+$ in the case $t \neq t_*$ is very similar to the one that is described in [31]. There are, again, two equally relevant saddle points which come in a symmetric pair. Note that in this case, their positions are time dependent, and the steepest descent paths are very similar to those displayed in Fig. 4.1, except that the saddle points are either closer together or further apart depending on whether $t < t_*$ or $t > t_*$.

Let $w(z, i\beta) = i\beta z/t + \alpha z^2 - z^4$; $2\alpha = 1/t_* - 1/t < 0$ for $0 < t < t_*$. The saddle points $z_s(\beta;t)$ are the roots of

$$0 = \frac{\partial w}{\partial z}(z, i\beta) = \frac{\beta}{t} i + 2\alpha z - 4z^3. \tag{4.6}$$

Throughout the remainder of the analysis, we write $(\beta;t)$ (as in $z_s(\beta;t)$) to denote that t is to be considered as a parameter. We let $z = -iu$; then u satisfies a cubic equation with real coefficients, namely,

$$u^3 + \frac{\alpha}{2}u - \frac{\beta}{4t} = 0.$$

In order to have some cancellation in the expansion of E_ν to obtain zeros, we need two equally relevant saddle points. Let $x_s(t) = t(2\alpha/3)^{3/2} = i\,(3t_*)^{-3/2}(t_* - t)^{3/2}t^{-1/2}$. Then for $t < t_*$, we find that two of the saddle points come in conjugate pairs only when $|\beta| > |x_s(t)|$, where $\beta = \pm|x_s(t)|$ is the boundary of analyticity of the inviscid solution up to $t = t_*$ (see [32, App. C]). From Cardan's formula for the roots of a cubic polynomial (see [32, App. B]), we find

$$\begin{cases} u_0 = \omega\mathcal{A} + \omega^2\mathcal{B} = -\frac{1}{2}\left(\mathcal{A}+\mathcal{B}\right) + i\frac{\sqrt{3}}{2}\left(\mathcal{A}-\mathcal{B}\right), \\ u_1 = \overline{u_0} = \omega^2\mathcal{A} + \omega\mathcal{B} = -\frac{1}{2}\left(\mathcal{A}+\mathcal{B}\right) - i\frac{\sqrt{3}}{2}\left(\mathcal{A}-\mathcal{B}\right), \\ u_2 = \mathcal{A}+\mathcal{B}, \end{cases} \tag{4.7}$$

where $\omega = e^{2\pi i/3}$. Since $x_s^2 = -|x_s^2| < 0$ for $t < t_*$, we find

$$\begin{aligned} &\begin{cases} \mathcal{A}(\beta;t) = (8t)^{-1/3}\ \sqrt[3]{\beta + \sqrt{\beta^2 + x_s^2}} > 0 \\ \mathcal{B}(\beta;t) = (8t)^{-1/3}\ \sqrt[3]{\beta - \sqrt{\beta^2 + x_s^2}} > 0 \end{cases} && \text{for } \boldsymbol{\beta > |x_s(t)|}, \\ &\begin{cases} \mathcal{A}(\beta;t) = -\,(8t)^{-1/3}\ \sqrt[3]{-\beta + \sqrt{\beta^2 + x_s^2}} < 0 \\ \mathcal{B}(\beta;t) = -\,(8t)^{-1/3}\ \sqrt[3]{-\beta - \sqrt{\beta^2 + x_s^2}} < 0 \end{cases} && \text{for } \boldsymbol{\beta < -|x_s(t)|}, \end{aligned} \tag{4.8}$$

so

$$z_s(-\beta;t) = -z_s(\beta;t). \tag{4.9}$$

Here we are taking the real positive branches of the square roots and cube roots in $\mathcal{A}$ and $\mathcal{B}$. We have also used the relation

$$|x_s\,(t)\,| = t\left(\frac{2|\alpha|}{3}\right)^{3/2} = t\left(-\frac{2\alpha}{3}\right)^{3/2} > 0, \tag{4.10}$$

where we are taking the positive branch of $z^{3/2}$ for $z > 0$. Moreover, when choosing the branches of the rational functions $\mathcal{A}$ and $\mathcal{B}$, one must make sure that they satisfy the relation $\mathcal{A}\cdot\mathcal{B} = -\alpha/6 > 0$ (see [32, App. B]). In terms of the original variable $z = -iu$, after separation of the real and imaginary parts, we have

$$\begin{cases} z_0 = \frac{\sqrt{3}}{2}(\mathcal{A}-\mathcal{B}) + \frac{i}{2}(\mathcal{A}+\mathcal{B}), \\ z_1 = -\overline{z_0} = \frac{\sqrt{3}}{2}(\mathcal{B}-\mathcal{A}) + \frac{i}{2}(\mathcal{A}+\mathcal{B}), \\ z_2 = -i(\mathcal{A}+\mathcal{B}). \end{cases} \tag{4.11}$$

Since we are only looking at values of $|\beta| > |x_s|$, the steepest paths and level curves look almost like the case $t = t_*$ described in Fig. 4.1 except that the saddle points have moved closer together, yet preserve the symmetry of Fig. 4.1. The path deformation is justified in the same way (see [31] for more details). The saddle points come in symmetric pairs that satisfy $z_0 = -\overline{z_1}$ for all $t > 0$. We have

$$0 = \frac{\partial w}{\partial z}\big(z_s(\beta;t), i\beta\big) = \frac{\beta}{t} i + 2\alpha z_s - 4z_s^3, \tag{4.12a}$$

$$0 = \frac{1}{4} z_s \frac{\partial w}{\partial z}\big(z_s(\beta;t), i\beta\big) = \frac{i\beta}{4t} z_s + \frac{\alpha}{2} z_s^2 - z_s^4, \tag{4.12b}$$

$$w\big(z_s(\beta;t), i\beta\big) = \frac{i\beta}{t} z_s + \alpha z_s^2 - z_s^4. \tag{4.12c}$$

Equation (4.12a) gives (4.12b), which combined with (4.12c) gives

$$w\big(z_s(\beta;t), i\beta\big) = \frac{3i\beta}{4t} z_s + \frac{\alpha}{2} z_s^2. \tag{4.13}$$

Since for $s = 0, 1$

$$z_s(\beta;t) = (-1)^s \frac{\sqrt{3}}{2}(\mathcal{A} - \mathcal{B}) + \frac{i}{2}(\mathcal{A} + \mathcal{B}), \tag{4.14a}$$

$$w_{zz}(z_s, i\beta) = 2\alpha - 12z_s^2, \quad w(z_0, i\beta) = \overline{w(z_1, i\beta)}, \tag{4.14b}$$

so

$$\Re\, w\big(z_s(\beta;t), i\beta\big) = \frac{\alpha}{4}(\mathcal{A}^2 + \mathcal{B}^2) - \frac{3\beta}{8t}(\mathcal{A} + \mathcal{B}) - \frac{\alpha^2}{6}, \tag{4.15a}$$

$$\Im\, w\big(z_s(\beta;t), i\beta\big) = (-1)^s \frac{\sqrt{3}}{8} \cdot (\mathcal{A} - \mathcal{B}) \cdot (3\beta/t + 2\alpha(\mathcal{A} + \mathcal{B}))\,, \tag{4.15b}$$

$$\theta(z_s(\beta;t), t) = \arg(-w_{zz}(z_s, i\beta)) = (-1)^s \arg(6z_0^2 - \alpha). \tag{4.15c}$$

Using a standard steepest descents analysis (see [31, 39] for example), we find that

$$E_\nu(i\beta, t) = \sum_{s=0,1} \sqrt{\frac{-4\pi\nu}{w_{zz}(z_s, i\beta)}} e^{w(z_s, i\beta)/2\nu} \left(1 + \mathcal{O}(\nu)\right) \quad \text{as } \nu \to 0^+.$$

We can further simplify the expansion using the actual value of $\sqrt{6z_s^2 - \alpha}$. Indeed, since $z_s(\beta;t) = (-1)^s \frac{\sqrt{3}}{2}(\mathcal{A} - \mathcal{B}) + \frac{i}{2}(\mathcal{A} + \mathcal{B}) = e^{i\pi/6}\mathcal{A} + e^{i5\pi/6}\mathcal{B}$ and $\mathcal{A} \cdot \mathcal{B} = -\alpha/6$,

$$6z_s^2 - \alpha = 3\sqrt{(\mathcal{A}^2 + \mathcal{B}^2 - \alpha)^2 + 3(\mathcal{A}^2 - \mathcal{B}^2)}\, e^{i\theta(z_s(\beta;t),t)}, \tag{4.16a}$$

$$\theta(z_s(\beta;t), t) = \arg(6z_s^2 - \alpha) = (-1)^s \tan^{-1}\left(\sqrt{3} \cdot \frac{\mathcal{A}^2 - \mathcal{B}^2}{\mathcal{A}^2 + \mathcal{B}^2 + \alpha/3}\right), \tag{4.16b}$$

where in (4.16b) we are taking the branch of $\tan^{-1} x$ for which $|\tan^{-1} x| < \pi/2$. Reproducing a similar analysis for $t > t_*$, we have the following result.

THEOREM 4.4. *The asymptotic expansion of $E_\nu(i\beta, t)$ as $\nu \to 0^+$ is*

$$E_\nu(i\beta, t) = \sqrt{\frac{2\pi\nu}{|6z_s^2 - \alpha|}} \exp\left\{\frac{1}{2\nu} \Re\, w\big(z_s(\beta;t), i\beta\big)\right\} \times \left[\cos\Big(\frac{1}{2\nu} \Im\, w\big(z_0(\beta;t), i\beta\big) - \frac{1}{2}\theta(z_0(\beta;t), t)\Big) + \mathcal{O}\left(\nu\right)\right],$$

where

$$z_s(\beta;t) = (-1)^s \frac{\sqrt{3}}{2}(\mathcal{A}-\mathcal{B}) + \frac{i}{2}(\mathcal{A}+\mathcal{B}) \qquad \textit{for } s = 0, 1,$$

and $\mathcal{A}$ *and* $\mathcal{B}$ *are given by*

$$\mathcal{A}(\beta;t) = (8t)^{-1/3}\ \sqrt[3]{\beta + \sqrt{\beta^2 + x_s^2}}$$
$$\mathcal{B}(\beta;t) = \begin{cases} 0 < t < t_* & (8t)^{-1/3}\ \sqrt[3]{\beta - \sqrt{\beta^2 + x_s^2}} > 0 \qquad \beta > |x_s|, \\ t > t_* & -(8t)^{-1/3}\ \sqrt[3]{-\beta + \sqrt{\beta^2 + x_s^2}} < 0 \qquad \beta > 0. \end{cases}$$

For $\beta < 0$, $z_s(\beta;t)$ is defined by the odd parity condition $z_s(\beta;t) = -z_s(-\beta;t)$. Letting $t \to t_*$ in Theorem 4.4, we obtain $\theta(z_s(\beta;t_*), t_*) = (-1)^s \pi/3$, and

$$\Re\, w\big(z_s(\beta;t_*), i\beta\big) = -\frac{3}{2}\left(\frac{\beta}{4t_*}\right)^{4/3},$$
$$\Im\, w\big(z_s(\beta;t_*), i\beta\big) = (-1)^s \frac{3\sqrt{3}}{2}\left(\frac{\beta}{4t_*}\right)^{4/3}.$$

For small ν, the poles β_k are approximated by the roots of the equation

$$\frac{1}{2\nu}\Im\, w\big(z_0(\beta;t), i\beta\big) - \frac{1}{2}\theta(z_0(\beta;t), t) = \left(k - \frac{1}{2}\right)\pi, \quad k \in \mathbb{N}^*, \tag{4.17}$$

with the convention that $\beta_{-k} \equiv -\beta_k$. Since $|\theta(z_0(\beta_k;t),t)| < \pi$ for all $\beta_k \in \mathbb{R}$, the limiting behavior of the poles is given by $\Im\, w\big(z_0(\beta;t), i\beta\big) = 0$. Recall from (4.15b) that

$$\Im w_s = \Im\, w\big(z_s(\beta;t), i\beta\big) = (-1)^s \frac{\sqrt{3}}{8} \cdot (\mathcal{A}-\mathcal{B}) \cdot (3\beta/t + 2\alpha(\mathcal{A}+\mathcal{B})),$$

so

$$\Im w_s = 0 \Leftrightarrow \begin{cases} \text{either } \mathcal{A} = \mathcal{B} \text{ or} \\ 3\beta/t + 2\alpha(\mathcal{A}+\mathcal{B}) = 0. \end{cases} \tag{4.18}$$

For $0 < t \le t_*$, $\alpha \le 0$: if $\beta \ge |x_s|$ then $\mathcal{A} > 0$, $\mathcal{B} > 0$; if $\beta \le |x_s|$ then $\mathcal{A} < 0$, $\mathcal{B} < 0$. We rewrite the second equation as $(\mathcal{A}+\mathcal{B})^3 = -\left(3\beta/2\alpha t\right)^3$, which, after expanding the left-hand side and using the fact that $\mathcal{A}\cdot\mathcal{B} = -\alpha/6$, reduces to $\beta = \pm|x_s(t)|$. The same conclusion is reached from the first equation $\mathcal{A} = \mathcal{B}$. Thus, for $0 < t \le t_*$, $\Im w_s = 0$ only if $\beta = \pm|x_s|$. Let $\hat{\beta} \ll \beta$. Then, re-substituting $\beta = |x_s(t)| + \hat{\beta}$ into the expansion for $E_\nu(i\beta, t)$ in Theorem 4.4 and reproducing an analysis which is similar to the one described in [31] (i.e., inverting the asymptotic series expansion), we find that the error term is $\mathcal{O}((k\nu)^{3/4})$ as $\nu \to 0^+$ for fixed k. Thus, we can write that $\beta_{\pm k}(t,\nu) = \pm|x_s| + \mathcal{O}((k\nu)^{3/4})$ as $\nu \to 0^+$ for fixed k. Similarly, for $t \ge t_*$, $\alpha \ge 0$, $\beta > 0 \Rightarrow \mathcal{A}-\mathcal{B} > 0$ and $\beta < 0 \Rightarrow \mathcal{A}-\mathcal{B} < 0$; hence, $\Im w_s = 0 \Leftrightarrow \beta = 0$ as a result of setting $3\beta/t + 2\alpha(\mathcal{A}+\mathcal{B}) = 0$. Since $\Im x_s(t) = 0$ for $t \ge t_*$, we have proved the following (see Fig. 5.12).

Corollary 4.5. *For all* $t > 0$ *and fixed* k, *the asymptotic behavior of the poles* $x = \pm a_k(t,\nu) = \pm i\beta_k(t,\nu)$ *is given by*

$$\beta_k(t,\nu) = \Im x_s(t) + \mathcal{O}((k\nu)^{3/4}) \qquad \textit{as } \nu \to 0^+.$$

Since $\Im x_s(t) = 0$ *for* $t \geq t_*$,

$$\beta_k(t,\nu) = \mathcal{O}((k\nu)^{3/4}) \qquad \textit{as } \nu \to 0^+$$

for fixed k. *Of particular interest is the modulus of the first ordered pole* $\beta_1(t,\nu)$ *which governs the time evolution of the width of the analyticity strip of the viscous solution.*

Following the exact same steps in the proof of Corollary 4.5, one can show the following corollary.

COROLLARY 4.6. *For all* $t > 0$ *and fixed* ν, *the asymptotic behavior of the poles* $x = \pm a_k(t,\nu) = \pm i\beta_k(t,\nu)$ *is*

$$\beta_k(t,\nu) = \mathcal{O}((k\nu)^{3/4}) \qquad \textit{as } k \to +\infty.$$

5. Numerics.

5.1. Finite difference approximation, asymptotic approximation, and pole expansion. We present a numerical scheme which enables us to solve (1.1) for moderately small values of ν. The procedure is sometimes referred to as the method of lines and consists in using a centered difference operator in space while time-marching with a Runge–Kutta scheme. The method is implemented on the interval $I = [0, 1/2]$ with boundary conditions

$$u_\nu(0,t) = u_\nu(1/2,t) = 0. \tag{5.1}$$

The boundary condition $u_\nu(1/2,t) = 0$ is chosen to be consistent with the value of the inviscid solution $u(1/2,t) = 0$. Thus, we can expect the difference approximation to be consistent with the initial (boundary) value problem for small ν. Two different initial conditions are also used:

$$u(x,0) = u_\nu(x,0) = 4x^3 - \frac{x}{t_*}, \tag{5.2a}$$

$$u_\nu(x,t_*) = \frac{x}{t_*} - \sum_{n=1}^{\infty} \frac{4\nu x}{x^2 + \beta_n^2(t_*,\nu)}. \tag{5.2b}$$

Throughout the numerics we use the parameter value $t_* = 1$. If the second condition is used, then the pole positions at $t = t_*$ are specified by the asymptotic estimate presented in Theorem 4.2. This estimate is used for all values of μ_n for $10 \leq n \leq N$:

$$\begin{cases} \beta_n(t_*,\nu) = 4t_*(2\nu\mu_n)^{3/4}, \\ \mu_n = G(\mu_n^{(0)}), \quad \mu_n^{(0)} = \frac{2\pi}{3\sqrt{3}}(n - 1/3), \quad n \geq 10, \\ G(\mu) = \mu + \frac{7}{432\mu}\left(1 - \frac{1}{6\mu}\left(1 + \frac{7}{72\mu}\left(1 - \frac{5}{12\mu}\left(1 + \frac{53143}{18900\mu}\right)\right)\right)\right). \end{cases} \tag{5.3}$$

For $1 \leq n \leq 9$, we use the numerical values found in [31, Table 3], under the column "Numerical roots":

$$\mu_1 = 0.8221037147, \quad \mu_2 = 2.0226889660, \quad \mu_3 = 3.2292915284, \tag{5.4}$$

$$\mu_4 = 4.4372464748, \quad \mu_5 = 5.6457167459, \quad \mu_6 = 6.8544374340, \tag{5.5}$$

$$\mu_7 = 8.0632985369, \quad \mu_8 = 9.2722462225, \quad \mu_9 = 10.4812510479. \tag{5.6}$$

Let

$$\begin{aligned} &u_j = u_\nu(j * \Delta x, t), \quad Ev_j = v_{j+1}, \quad E^p v_j = v_{j+p}, \\ &D_+ = (E - E^0)/\Delta x, \quad D_- = (E^0 - E^{-1})/\Delta x, \quad D_0 = (D_+ + D_-)/2. \end{aligned}$$

One then solves the system of $N_x - 1$ equations using a Runge–Kutta 4–5 scheme (which we refer to as RK45):

$$\begin{cases} du_j/dt = -D_0(u_j^2/2) + \nu D_+ D_- u_j, \quad j = 1, \dots, N_x - 1, \\ u_{j=0} = u_\nu(0,t) = 0, \quad u_{j=N_x} = u_\nu(1/2,t) = 0, \end{cases} \tag{5.7}$$

where N_x is the number of gridpoints (and gridfunctions) and $N_x * \Delta x = 1/2$. Typically, the mesh size we use is $\Delta x = .25 \times 10^{-2}$ and $N_x = 200$ gridpoints. The time stepping restrictions depend on the size of ν and on how far in time one wants to go. For example, if the final time is $t = t_* = 1$, whether $\nu = 10^{-2}$ or $\nu = 10^{-3}$ it suffices to use $\Delta t = .25 \times 10^{-2}$, $N_t = 400$ RK45 steps. However, for $\nu = 10^{-2}$, if one wants to go as far as $t = 2$, for reasons of stability one needs to use a smaller time step such as $\Delta t = 10^{-3}$, $N_t = 2,000$. The domain of integration is $(x,t) \in [0, 1/2] \times [0, T]$, where $T = 1$ or $T = 2$. Then, due to the odd parity of the solution, we reflect symmetrically for $x \in [-1/2, 0]$ according to the rule $u_\nu(-x,t) = -u_\nu(x,t)$. This finite difference scheme is used in order to compare the predictions obtained from the pole expansion and the pole dynamics in section 5.2.

5.2. Numerical pole dynamics.

We investigate the motion of the simple poles of $u_\nu(x,t)$ by solving the truncated CDS and by starting with initial data for the poles at $t = t_*$. The poles of $u_\nu(x,t)$ are located at $\pm a_n(t,\nu) = \pm i\sqrt{\nu\gamma_n(t,\nu)}$, where the variables $\gamma_n(t,\nu) > 0$ satisfy the system (cf. Property 2.2)

$$\begin{cases} \dfrac{\dot{\gamma}_n}{2} = \dfrac{\gamma_n}{t} + 1 - 4\,\gamma_n \sum_{l \neq n} \dfrac{1}{\gamma_l - \gamma_n} \\ \gamma_n(t_*,\nu) = (4t_*)^2\,(2\mu_n)^{3/2}\,\sqrt{\nu} \end{cases} \quad \forall n \in \mathbb{N}. \tag{5.8}$$

In order to solve this system we use the asymptotic estimate for μ_n presented in (5.3) and the numerical values of (5.5). We are mainly interested in describing the motion of the first pole $a_1(t,\nu) = i\beta_1(t,\nu) \in i\mathbb{R}$; this amounts to describing the time evolution of the width of the strip of analyticity of the solution $u_\nu(t,x)$. The imaginary part of the poles $\beta_n(t,\nu)$ is recovered using the relation $\beta_n(t,\nu) = \sqrt{\nu\gamma_n(t,\nu)}$. We plot the evolution of $\beta_n(t,\nu), n = 1, \dots, 4$ for different values of ν. We use N poles in the computations, i.e., β_1 through β_N where $N \times 10^{-4}$ varies from $.1, .5, 1, 2.5, 5$. That is, we consider the truncated system

$$\begin{cases} \dfrac{\dot{\gamma}_n}{2} = \dfrac{\gamma_n}{t} + 1 - 4\gamma_n \sum_{\substack{l=1 \\ l \neq n}}^{N} \dfrac{1}{\gamma_l - \gamma_n} \\ \gamma_n(t_*,\nu) = (4t_*)^2(2\mu_n)^{3/2}\sqrt{\nu} \end{cases} \quad \forall n = 1, \dots, N.$$

In order to accelerate the computation of the slowly converging pole expansions which require $\mathcal{O}(N^2)$ operations

$$\sum_{\substack{l=1 \\ l \neq n}}^{N} \frac{1}{\gamma_l - \gamma_n} \qquad \forall n = 1, \dots, N, \tag{5.9}$$

we use a multipole algorithm developed and implemented by Greengard and Rokhlin [14, 21] which reduces the computational complexity to $\mathcal{O}(N \log N)$. A fourth/fifth-order Runge–Kutta–Fehlberg scheme with automatic step-size control is used (the same one that is used for the finite difference scheme/method of lines computations of the previous section). Since the initial data is specified at $t = t_* = 1$, we can solve the system forward and backwards in time starting from $t = 1$. The typical bound on the relative error in the computation is $10^{-8} < |(x_4 - x_5)/x_5| < 10^{-4}$, where x_4 and x_5 are, respectively, the 4th- and 5th-order estimates of $\gamma_1(t,\nu)$. Once this error criterion is met, we recover the pole location via the relation $a_n(t,\nu) = i\sqrt{\nu\gamma_n(t,\nu)}$. The justification of the numerics is the most difficult aspect of this simulation because one must justify the convergence of the method as both the number of poles increases and the time step is refined. The time-step control is automatically determined by the local relative tolerance (LRT $= |(x_4 - x_5)/x_5|$) test on the 4th- and 5th-order approximations of the first ordered pole (the one closest to the origin). Thus, one cannot fix the time stepping; rather, one can have a subtle control on it by reducing this tolerance. Typically, we fix the number of poles to $N = 50,000$ and vary the tolerance on the successive intervals $10^{-10} < LRT < 10^{-6}$, $10^{-8} < LRT < 10^{-4}$, and $10^{-6} < LRT < 10^{-2}$. Then we fix the tolerance at the highest reasonable level $10^{-8} < LRT < 10^{-4}$ and vary the number of poles where $N \times 10^{-4}$ is either $.1, .5, 1, 2.5$, or 5. We see that the time step barely affects the convergence of the method. Thus, the main difficulty in this procedure arises from the slow convergence of the pole interaction (5.9) that is present in the CDS.

5.2.1. Exact solution for the two-pair pole-dynamics test. In order to verify the accuracy of the numerical pole dynamics, we implement the numerical method described in the previous section for the case where there are only four poles (two pairs). In this case, one can explicitly solve the resulting system as follows: let $a_n = i\beta_n$. That is, replace β_n by $-ia_n$ in Property 2.2 so that the two pairs of poles $\{(-a_1, a_1), (-a_2, a_2)\}$ and $\{(-\kappa_1, \kappa_1), (-\kappa_2, \kappa_2)\}$ satisfy, under the transformation $\kappa_n = a_n^2/\nu$, the equivalent systems

$$\left\{\begin{array}{l} \dot{a}_1 = a_1/t - \nu/a_1 - 4\nu a_1/(a_1^2 - a_2^2), \\ \dot{a}_2 = a_2/t - \nu/a_2 + 4\nu a_2/(a_1^2 - a_2^2), \end{array}\right. \Longleftrightarrow \left\{\begin{array}{l} \dot{\kappa}_1/2 = \kappa_1/t - 1 - 4\kappa_1/(\kappa_1 - \kappa_2), \\ \dot{\kappa}_2/2 = \kappa_2/t - 1 + 4\kappa_2/(\kappa_1 - \kappa_2). \end{array}\right.$$

Introduce a set of new variables $\{\Theta_1,\Theta_2\}$ defined by

$$\left\{\begin{array}{l} \Theta_1 = \kappa_1 + \kappa_2, \\ \Theta_2 = \kappa_1 - \kappa_2, \end{array}\right. \Longleftrightarrow \left\{\begin{array}{l} \kappa_1 = (\Theta_1 + \Theta_2)/2, \\ \kappa_1 = (\Theta_1 - \Theta_2)/2. \end{array}\right.$$

Then it is easy to show that $\{\Theta_1,\Theta_2\}$ satisfy the coupled system of nonlinear ODEs

$$\left\{\begin{array}{l} \dot{\Theta}_1 - 2\Theta_1/t = -12, \\ \dot{\Theta}_2 - 2\Theta_2/t = -8\Theta_1/\Theta_2. \end{array}\right. \tag{5.10}$$

We further introduce a new variable denoted by $\phi_2 = \Theta_2^2$ which in turn satisfies the linear ODE

$$\dot{\phi}_2 - 4\phi_2/t = -16\Theta_1. \tag{5.11}$$

We use as initial data the position of the poles $a_1(t_*,\nu) = i\beta_1(t_*,\nu)$ and $a_2(t_*,\nu) = i\beta_1(t_*,\nu)$, where $\beta_1(t_*,\nu)$ and $\beta_2(t_*,\nu)$ are given in (5.3) and (5.4). Thus, we have

$$\left\{\begin{array}{l} \Theta_1^* = \Theta_1(t_*,\nu) = \kappa_1(t_*,\nu) + \kappa_2(t_*,\nu) = a_1^2(t_*,\nu)/\nu + a_2^2(t_*,\nu)/\nu, \\ \phi_2^* = \phi_2(t_*,\nu) = \Theta_2^2(t_*,\nu) = (a_1^2(t_*,\nu)/\nu - a_2^2(t_*,\nu)/\nu)^2. \end{array}\right. \tag{5.12}$$

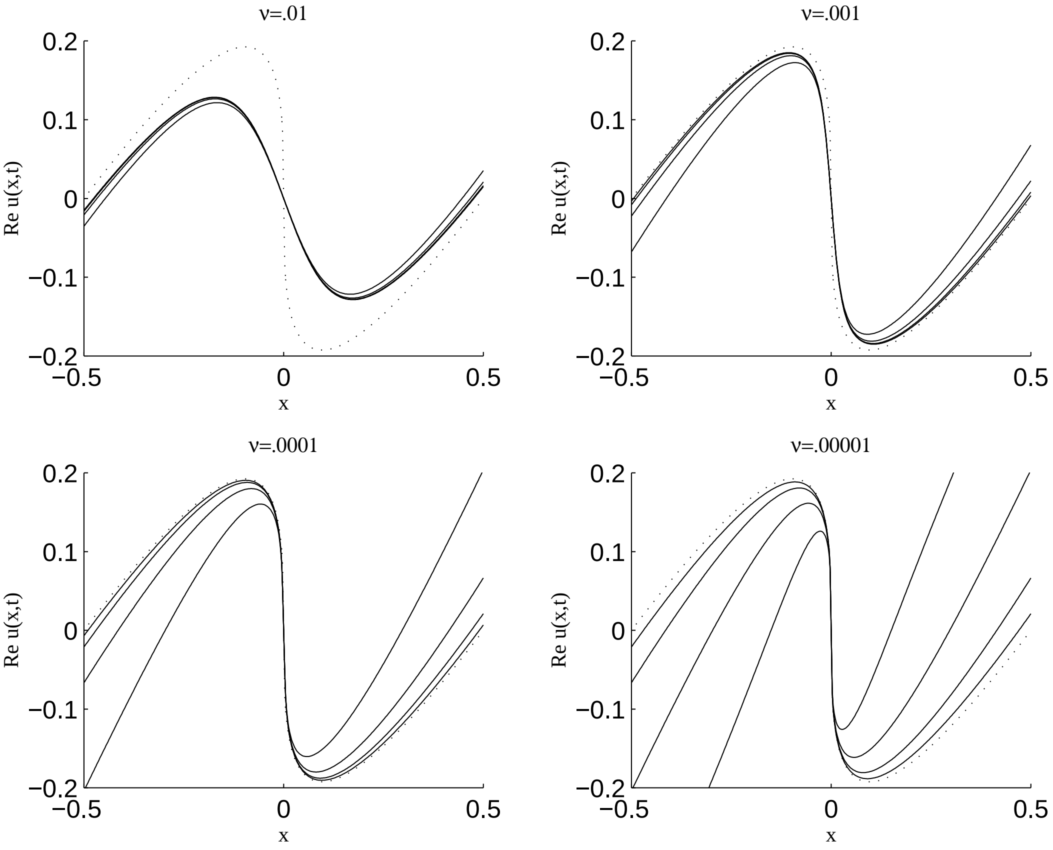

FIG. 5.1. *Convergence of the pole expansion as $N \rightarrow +\infty$ of the solution $u_\nu(x,t_*) = x/t_* - \Sigma_{n=1}^{N} 4\nu x/(x^2+\beta_n^2(t_*,\nu))$ with varying number of poles ranging from $N = 10^3, 10^4, 10^5, 10^6$ poles for $\nu = 10^{-2}, 10^{-3}, 10^{-4}, 10^{-5}$. The dotted curve is computed from the inviscid solution at $t = t_* = 1$ by $u(x,t_*) = x/t_* - (x/4t_*)^{1/3}$. For $\nu = 10^{-2}$, the inviscid solution and the pole expansion $u_\nu(x,t_*)$ do not agree because the viscosity is large enough that the solution has started decaying earlier (see comments on the turn-around time of the poles and their relation to the decay of the solution).*

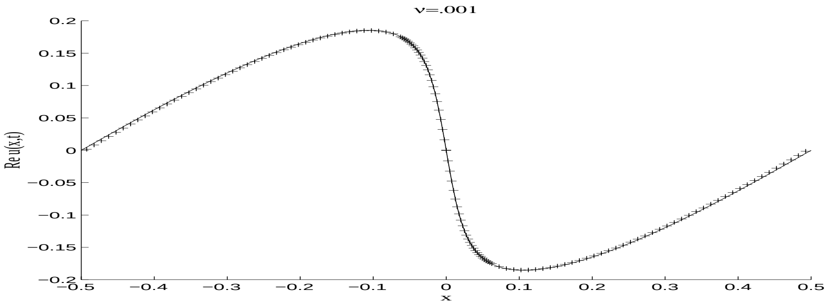

FIG. 5.2. *Comparison of the solution reconstruction at $t = t_* = 1$ from the pole expansion $u_\nu(x,t_*) = x/t_* - \Sigma_{n=1}^{N} 4\nu x/(x^2+\beta_n^2(t_*,\nu))$ with $N = 10^6$ poles and the finite difference scheme (method of lines) for $\nu = 10^{-3}$. Mesh size: $N_x = 200$ points, $\Delta x = .25 * 10^{-2}$, $N_t = 400$ RK45 time steps with $\Delta t = .25 * 10^{-2}$. Pole expansion (+) at $t = 1$ overlaps finite difference approximation in solid curve.*

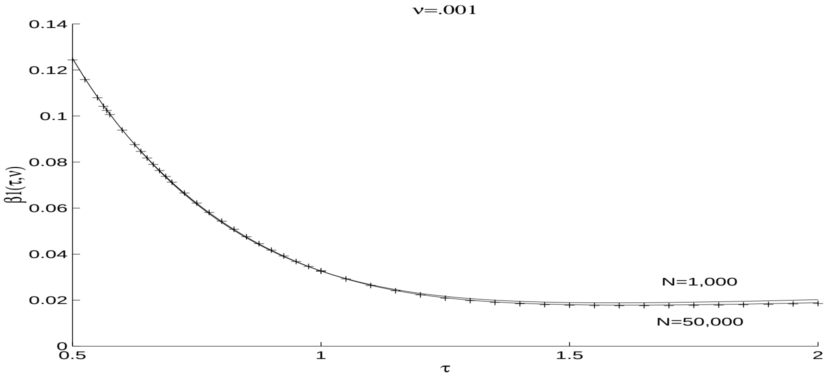

FIG. 5.9. *Closeup of Fig.* 5.8 *for* $t \in [1, 2]$.

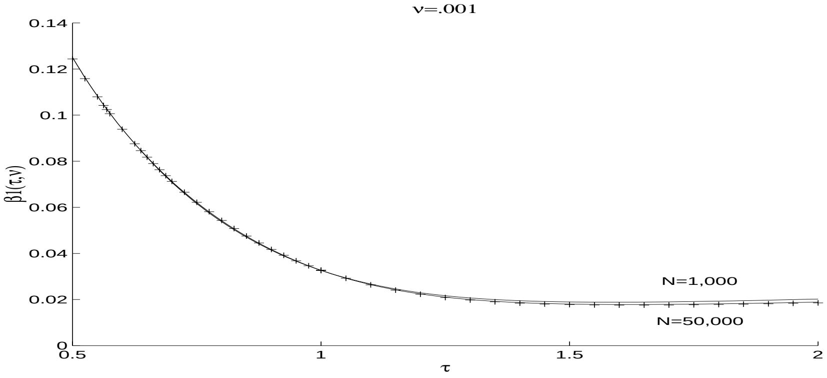

FIG. 5.10. $\beta_1(t, \nu)$ *vs.* t. *Comparison of pole number simulations for* $\nu = 10^{-3}$ *and* $N = .1, .5, 1, 2.5, 5 \times 10^4$ *poles. (+):* $N = 5 \times 10^4$ *poles; (solid):* $N = .1, .5, 1, 2.5 \times 10^4$ *poles. Differences appear more clearly in the closeup in Fig.* 5.11.

Solving the IVP consisting of the first equation in system (5.10) and equations (5.11) and (5.12), we find that

$$\left\{ \begin{array}{l} \Theta_1(t,\nu) = (t/t_*)^2 \Theta_1^* - 12t(t-t_*)/t_*, \\ \phi_2(t,\nu) = (t/t_*)^4 \left(\phi_2^* - 16t_*(t-t_*)(t\Theta_1^* - 6tt_* + 6t_*^2)/t^2\right). \end{array} \right. \tag{5.13}$$

Taking $t_* = 1$, $\nu = .001$, we use (5.13), a straightforward numerical integration scheme using RK45 and RK45 together with the multipole algorithm in which we set to zero all coefficients pertaining to $a_n, n \geq 3$. We find common values for all three methods at $t = 1.25$:

$$\left\{ \begin{array}{l} a_1(t = 1.25, \nu = .001) = 0.0408023705 * i, \\ a_2(t = 1.25, \nu = .001) = 0.1009178717 * i. \end{array} \right. \tag{5.14}$$

Computing the differences between the exact values of a_1 and a_2 and the predictions obtained from the Runge–Kutta schemes (with and without the multipole algorithm), we find that these predictions are of the order of $\mathcal{O}(10^{-10})$, which is consistent with the expected 4th-order accuracy of such numerical schemes.

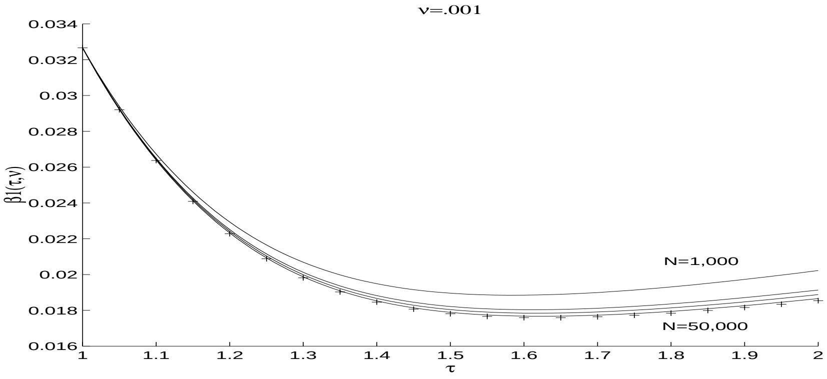

FIG. 5.11. *Closeup of Fig.* 5.10 *for* $t \in [1, 2]$. *Turn-around time at* $t_u \approx 1.62$.

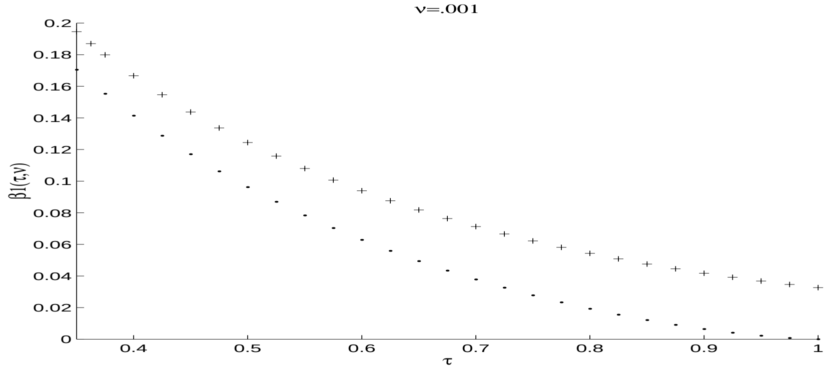

FIG. 5.12. *Comparison of the time evolutions of* $\beta_1(t, \nu = 10^{-3})$ (+) *and* $x_s(t)$ (.) *for* $t \in [.35, t_* = 1]$. *The pole dynamics are the same as Fig.* 5.8 *with* $N = 5 \times 10^4$ *poles. This illustrates the asymptotic relation* $\beta_1(t, \nu) = \Im x_s(t) + \mathcal{O}(\nu^{3/4})$ *as* $\nu \to 0^+$ *when* $t \leq t_*$ *(see Corollary* 4.5*).*

5.3. Figures, descriptions, and comparisons. In Fig. 5.1, we illustrate the "slow" convergence of the pole expansion as the viscosity decreases. In particular, for $\nu = 10^{-4}$ and 10^{-5}, we can compare the inviscid solution given by (see [32, App. C])

$$u(x, t_*) = \frac{x}{t_*} - \left(\frac{x}{4t_*}\right)^{1/3} \tag{5.15}$$

to the pole expansion and expect good agreement between the two. For ν very small, we see that even for a very large number of poles ($N = 10^6$) the tails of the pole expansion still do not match the true solution, which is expected to be very close to the inviscid one. In each of these figures there are five curves, four of which are computed from the pole expansion for an increasing number of poles $N = 10^3, 10^4, 10^5, 10^6$. The fifth (dotted curve) is the inviscid solution at t_*.

In Figs. 5.2 and 5.3 we present comparisons between the finite difference scheme and the pole expansion ($N = 10^6$ poles) at the fixed time t_*. For the finite difference scheme, we use $N_x = 200$ points, $\Delta x = .25 * 10^{-2}$, $N_t = 400$ RK45 steps with $\Delta t = .25 * 10^{-2}$.

In Figs. 5.4 and 5.5 we present comparisons between the finite difference scheme

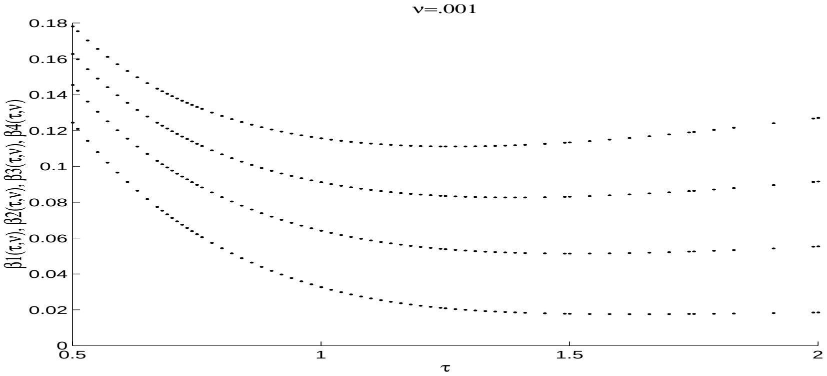

FIG. 5.13. $\beta_j(t,\nu)$ *vs.* t *for* $j = 1,\dots,4$. $\nu = 10^{-3}$ *and* $N = 5\times 10^4$ *poles. Same parameters as in Fig.* 5.8. *Turn-around times at* $t_u \approx 1.62$, $t_u \approx 1.51$, $t_u \approx 1.39$, $t_u \approx 1.27$ *for* $\beta_j(t,\nu), j = 1,\dots,4$.

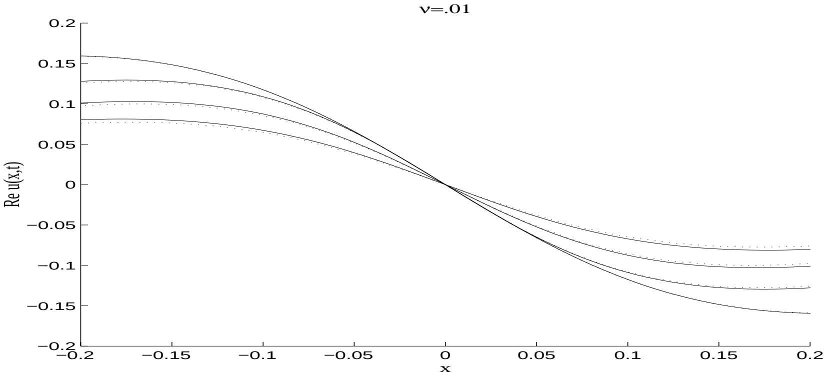

FIG. 5.17. *Closeup of Fig.* 5.6 *in* $[-.2, .2]$.

and the saddle-point approximation at the successive times $t = 1, 1.5, 2$. The mesh size is the same as the one for Figs. 5.2 and 5.3. One can observe that the saddle-point approximation overshoots the true value of the solution which is best captured by the difference scheme. This overshoot is due to the degeneracy of the saddle-point formula at the caustic and the inaccuracies around it. The correct behavior in a neighborhood of this caustic can be correctly described only by the uniform asymptotic expansion of section 3.3.

In Figs. 5.6 and 5.7, we compare the difference method and the pole dynamics for $\nu = 10^{-3}$ with $N = 50{,}000$ poles at the times $t = .5, 1, 1.5, 2$. The pole dynamics are run forward and backward in time starting from $t = t_* = 1$ until $t = .5$ and $t = 2$. The solution is then reconstructed from the pole expansion and the pole locations at these specific times and is compared to the finite difference approximations with mesh size $N_x = 200$ points, $\Delta x = .25 * 10^{-2}$, $N_t = 2{,}000$ RK45 time steps with $\Delta t = 10^{-3}$. The agreement between the finite difference and the pole dynamics close to the shock region is very good as opposed to the tails. Since the pole dynamics simulation involved only $50{,}000$ poles in Fig. 5.6, the mismatch in the tail is characteristic of the slow convergence of the pole expansion in the tails that are displayed in Fig. 5.1 for

$\nu = 10^{-3}$. There is also a small source of error in the difference scheme where the boundary condition at $x = 1/2$ is set to the inviscid value ($u(1/2, t) = 0$). This error in the difference approximation increases for larger ν. Thus, the discrepancy observed in the tails of the solution in Fig. 5.16 is more likely to arise from errors in the difference scheme than the pole dynamics. Indeed, it suffices to look at the convergence of the pole expansion at $t = t_*$ in Fig. 5.1, $\nu = 10^{-2}$, to establish confidence in the pole dynamics.

However, one can notice that regardless of the size of ν (whether $\nu = 10^{-2}$ or 10^{-3}), within the shock region of width $\mathcal{O}(\nu)$, the agreement between the pole dynamics and the difference approximation is very good (see Figs. 5.3, 5.17). This shows that the dynamics of the first few poles is accurately captured by the pole dynamics. This also becomes apparent when comparing the simulations done with varying number of poles (see Figs. 5.10 and 5.11). Finally, it should be noted that increasing the step-size of the time increment (in a reasonable way) in the pole dynamics barely affects the computations (see Figs. 5.8 and 5.9).

We plot the evolution of the first four (ordered) poles on the imaginary axis ($\beta_k, k = 1, \dots, 4$) and focus on the "turn-around" times t_u and the position of the first ordered pole β_1, which determines the width of the analyticity strip. One can see that the behavior of the pole β_1 displayed in Figs. 5.8 and 5.14 is qualitatively similar to the one obtained by Sulem, Sulem, and Frisch in [35, section III-B, Fig. 3] using spectral methods for the initial data $u_0(x) = \sin(x)$ with $\nu = .05$. The most important feature in the behavior of the first ordered pole is clearly the fact that it turns around before crossing the real axis, thus preserving the uniform analyticity of the viscous solution within the strip $|\Im x| \leq \delta_1 < \beta_1$, where $\beta_1(t, \nu) > 0$ for all $t > 0$. Moreover, it is interesting to note that the poles $\pm\beta_k(t, \nu)$ are confined to the imaginary axis and move towards the origin until a time $t = t_u(k)$, $k \in \mathbb{Z}^*$; this is the time at which they turn around and move away from the origin. These turn-around times $t_u(k)$ decrease as k increases: $t_u(1) > t_u(2) > \cdots > t_u(n) > \cdots > 0$. Moreover, $t_u(1)$ occurs before t_* for $\nu \gtrapprox .01$ and after t_* for $\nu \lessapprox .01$. Thus, the last pole to turn around is the first ordered pole β_1, i.e., the one closest to the real axis. For $\nu = 10^{-3}$, the turn-around times for $\beta_j, j = 1, \dots, 4$ are at $t \approx 1.62, 1.51, 1.39, 1.27$, respectively. For $\nu = 10^{-2}$, the turn-around times for $\beta_j, j = 1, \dots, 4$ are at $t \approx 1.05, .55, .425, .325$, respectively. Thus, comparing Figs. 5.13 and 5.15, one can see that the turn-around times $t_u(k)$ increase with decreasing ν. That is, one can relate the time of initial decay of the solution to the turn-around times $t_u(k)$ by comparing the evolution of the poles (see Figs. 5.13, 5.15) to the corresponding evolution of the solution (see Figs. 5.6, 5.16).

DYNAMICS AND CONDENSATION OF COMPLEX SINGULARITIES FOR BURGERS' EQUATION II*

DAVID SENOUF†

Abstract. The zero-viscosity limit of a meromorphic solution to Burgers' equation (BE) is found via an integral representation of the Mittag–Leffler expansion of the solution involving a "polar" measure. The weak zero-viscosity limit of this Borel measure (analogously to the zero-dispersion limit of the spectral measure in the Korteweg–de Vries (KdV) problem) corresponds to the asymptotic density of poles which characterizes their condensation on the imaginary axis. The resulting integral representation of the inviscid solution is computed by residues and is shown to match the characteristic solution up to the inviscid shock time t_*. The continuum limit of the Mittag–Leffler expansion and the Calogero dynamical system (CDS) (which describes the time evolution of the poles) is a system of two integro-differential equations which provide a new representation of the solution to the inviscid BE. For $t \leq t_*$, a uniform asymptotic expansion of the Fourier transform of the inviscid solution is obtained, thereby providing the analyticity properties of the inviscid solution.

Key words. partial differential equations, zero-viscosity limit, pole condensation

1. Introduction.

In this article we continue the investigation from part I [18] of the spatial analyticity properties of a solution to Burgers' equation (hereafter referred to as "BE"):

$$\frac{\partial u}{\partial t} + u\,\frac{\partial u}{\partial x} = \nu\,\frac{\partial^2 u}{\partial x^2}, \qquad x \in \mathbb{R},\ t > 0,\ \nu \geq 0. \tag{1.1}$$

Previous work concerning the analyticity properties of BE can be found in [3, 4, 13, 14, 18, 20].

We focus on a particular initial value problem (IVP) for (1.1) which was introduced by Fournier and Frisch [13] and further studied by Bessis and Fournier in [3, 4]. In this problem, the initial condition is given by

$$u(x,0) = u_0(x) = 4x^3 - x/t_*, \qquad x \in \mathbb{R}, \tag{1.2}$$

where t_* is a fixed positive parameter. This initial value is chosen for its generic property, which is due to the type of singularity occurring in the inviscid solution ($\nu = 0$) at the shock time $t = -\left(\inf_x u_0'(x)\right)^{-1} = t_*$ (cf. Appendix A for more details).

It was shown in part I that all meromorphic solutions to BE with an odd initial data must have a symmetric pole expansion of the form

$$u_\nu(x,t) = \frac{x}{t} - 2\nu \sum_{n\in\mathcal{I}} \frac{1}{x - a_n(t,\nu)}, \tag{1.3}$$

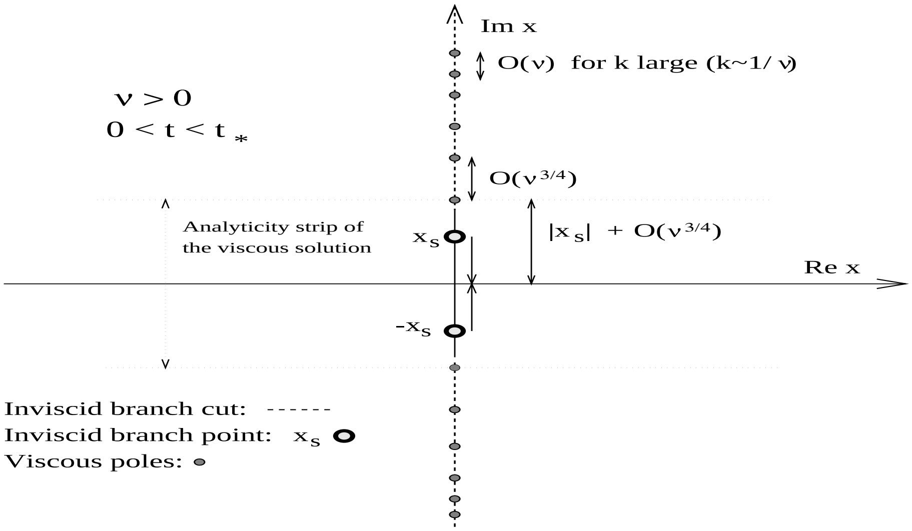

FIG. 1.1. *Inviscid branch points, branch cuts, and viscous poles for $\nu > 0$ and $0 < t < t_*$. The poles are located above the inviscid branch-point singularities according to the asymptotic formula $\beta_k(t, \nu) = \Im x_s(t) + \mathcal{O}(\nu^{3/4})$ as $\nu \to 0^+$ for k fixed. The distance separating two successive poles is asymptotically given by $\Delta\beta_k = \mathcal{O}(\nu)$ as $\nu \to 0^+$ for k large ($k \sim 1/\nu$).*

where $\mathcal{I} \subseteq \mathbb{Z}$ is a finite or countable symmetric set (i.e., if $a_n \in \mathcal{I}, a_{-n} = -a_n \in \mathcal{I}$). Moreover, the poles $\{a_n(t, \nu)\}_{n \in \mathcal{I}}$ must satisfy a Calogero-type dynamical system [8] (hereafter referred to as "CDS") of the form

$$\frac{da_n}{dt} = \frac{a_n}{t} - 2\nu \sum_{\substack{l \in \mathcal{I} \\ l \neq n}} \frac{1}{a_n - a_l} \qquad \forall n \in \mathcal{I} \subseteq \mathbb{Z}. \tag{1.4}$$

The solution to the IVP (1.1)–(1.2) is the meromorphic function

$$u_\nu(x, t) = \frac{x}{t} - 2\nu \sum_{\substack{n=-\infty \\ n \neq 0}}^{\infty} \frac{1}{x - i\beta_n(t, \nu)} = \frac{x}{t} - 2\nu \sum_{n=1}^{\infty} \frac{2x}{x^2 + \beta_n^2(t, \nu)}, \tag{1.5}$$

where $\{\pm i\beta_n\}_{n \in \mathbb{Z}^*}$ is a countable set of pure imaginary conjugate poles (the zeros of the Cole–Hopf variable) satisfying $\beta_{-n} = -\beta_n$. The motion of these poles on the imaginary axis is governed by an infinite-dimensional CDS:

$$\dot{\beta}_n = \frac{\beta_n}{t} - 2\nu \sum_{\substack{l=-\infty \\ l \neq n,0}}^{\infty} \frac{1}{\beta_l - \beta_n} = \frac{\beta_n}{t} + \frac{\nu}{\beta_n} - 2\nu \sum_{\substack{l=1 \\ l \neq n}}^{\infty} \frac{2\beta_n}{\beta_l^2 - \beta_n^2} \quad \forall n \in \mathbb{Z}^*. \tag{1.6}$$

Numerical simulations of the evolution of these poles and the solution for small viscosity are described in [18]. For more details on the derivation of (1.5) and (1.6), see the companion article [18, section 2]. As $\nu \to 0^+$, these poles condense on the imaginary axis for all $t > 0$. The asymptotic distance between two successive poles as $\nu \to 0^+$ is proportional to ν when the index of these poles grows like $k \sim 1/\nu$ (see Fig. 1.1). This condensation phenomenon is captured by an asymptotic density of poles (also referred to as the limiting pole density in the work of Bessis and Fournier

FIG. 1.2. *Inviscid branch points, branch cuts, and viscous poles for $\nu > 0$ and $t > t_*$. The inviscid branch points have coalesced at $t = t_*$ at the origin and are now moving away from each other on the real axis. However, the poles are fixed to the imaginary axis and are asymptotically given by $\beta_k(t, \nu) = \mathcal{O}(\nu^{3/4})$ as $\nu \to 0^+$ and $\Delta\beta_k = \mathcal{O}(\nu)$ as $\nu \to 0^+$ for k large ($k \sim 1/\nu$). They turn around and move away from the origin at a time $t_u > t_*$ if ν is small enough (if $\nu \gtrapprox .01$, $t_u < t_*$).*

[4]). We show that this density depends directly on the relevant saddle points of the small ν asymptotic expansion of the component $E_\nu(x,t)$ which carries the zeros of the Cole–Hopf variable. From the Cole–Hopf transformation, we find that

$$u_\nu(x,t) = \frac{x}{t} - 2\nu\,\partial_x \log\bigl(E_\nu(x,t)\bigr), \quad E_\nu(x,t) = \int_{-\infty}^{\infty} e^{w(z,x)/2\nu}\,dz,$$

where $w(z,x)$ is the phase function defined by

$$w(z,x) = \int_0^z \left(\frac{x}{t} - \frac{\eta}{t} - u_0(\eta)\right) d\eta.$$

The saddle points $z_s(\beta,t)$ of the phase function $w(z,x)$ are implicitly given by

$$0 = w_z(z_s, i\beta) = \frac{i\beta}{t} - \frac{z_s}{t} - u_0(z_s).$$

Let $\sigma(\beta;t)$ be a cumulative distribution function corresponding to the integral of the asymptotic density of poles (which we will define later). That is, $\sigma(\beta;t)$ counts the number of poles contained within the interval $[0,\beta]$. Then it is shown that

$$\sigma(\beta;t) = \frac{\Im w(z_s, i\beta)}{\pi},$$

and then the asymptotic pole locations are implicitly given by the equation

$$\frac{\sigma(\beta;t)}{2\nu} = k - 1/2, \qquad k \to +\infty.$$

We show that the asymptotic density of poles defined by Bessis and Fournier in [3, 4] as

$$\rho(\beta;t) = \lim_{\substack{n\to\infty \\ \nu\to 0^+}} \left.\frac{2\nu}{\Delta\beta_n(t,\nu)}\right|_{\beta_n=\beta}$$

is given by

$$\rho(\beta;t) = \frac{d}{d\beta}\sigma(\beta;t) = \frac{1}{\pi t}\,\Re z_s^+(\beta;t),$$

where $z_s^+(\beta;t)$ is the relevant saddle point with a positive real part in the expansion of $E_\nu(i\beta,t)$ as $\nu \to 0^+$. This density is explicitly calculated for all $t > 0$ using Cardan's formula. The Mittag–Leffler expansion (1.5) has an integral representation which is valid away from the imaginary axis. It can be expressed as the integral of a continuous function against the distributional derivative of a nonnegative regular finite Borel measure defined for $|\beta| \le \beta_{\max} < +\infty$ as

$$\sigma_\nu(\beta;\beta_{\max},t) = \int_{-\beta_{\max}}^{\beta} 2\nu \sum_{k=1}^{N_\nu} \left[\delta\left(\xi - \beta_k(t,\nu)\right) + \delta\left(\xi + \beta_k(t,\nu)\right)\right] d\xi,$$

where

$$N_\nu(\beta_{\max}) = \sup_{0<\delta\le t\le t_*} \left[\frac{\sigma(\beta_{\max};t)}{2\nu}\right] < +\infty. \tag{1.7}$$

The "polar" measure $\sigma_\nu(\beta;\beta_{\max},t)$ is analogous to the spectral measure in the KdV problem (cf. [12, 15]). The zero-viscosity limit of the pole expansion is found by taking the weak limit of $d\sigma_\nu(\beta;\beta_{\max},t)/d\beta$ which approximates the asymptotic density of poles. Thus, we show that for $\beta \in [-\beta_{\max},\beta_{\max}]$, $0 < \beta_{\max} < +\infty$,

$$\rho(\beta;t) \equiv \text{w-}\lim_{\nu\to 0^+} \frac{d\sigma_\nu}{d\beta}(\beta;\beta_{\max},t),$$

where w-$\lim_{\nu\to 0^+}$ denotes the weak limit of measures. The limiting integral representation of the solution is given by the nonparametric form

$$u(x,t) = \frac{x}{t} - \int_{-\infty}^{\infty} \frac{\rho(\beta;t)}{x - i\beta}\, d\beta = \frac{x}{t} - x\int_{-\infty}^{\infty} \frac{\rho(\beta;t)}{x^2+\beta^2}\, d\beta.$$

This representation is computed via residues, and the analytic structure of the inviscid solution is explicitly recovered up to t_*.

We also show that the continuum limit of the pair of equations consisting of the pole expansion (1.5) and the dynamical system (1.6) is the system of two integro-differential equations in parametric form:

$$\begin{aligned}\frac{\partial f}{\partial t}(\zeta,t) &= \frac{f(\zeta,t)}{t} - P.V.\int_{-\infty}^{\infty} \frac{d\zeta'}{f(\zeta,t) - f(\zeta',t)} \\ &= \frac{f(\zeta,t)}{t} - f(\zeta,t)\, P.V.\int_{-\infty}^{\infty} \frac{d\zeta'}{f^2(\zeta,t) - f^2(\zeta',t)}\end{aligned}$$

and

$$u(x,t) = \frac{x}{t} - \int_{-\infty}^{\infty} \frac{d\zeta'}{x - f(\zeta',t)} = \frac{x}{t} - x\int_{-\infty}^{\infty} \frac{d\zeta'}{x^2 - f^2(\zeta',t)},$$

in which the spatial branch cuts are defined by the condition $x \neq f(\zeta, t)$ for each fixed $t > 0$. This 2×2 system is shown to be equivalent to the characteristic equations of the inviscid BE.

The equivalence between the parametric and nonparametric form of the integral representation of the inviscid solution is obtained by introducing a simple change of variable $i\beta = f(\zeta, t)$ in the parametric equations. From this analysis, we clarify the relation between the pole positions and their asymptotic density. We show for $t = t_*$ that the pole positions can be recovered from the asymptotic density by choosing the right discretization on the "continuum" curve on which this density lies.

Furthermore, the analyticity properties of the inviscid solution can be analyzed by describing the asymptotic behavior of its Fourier transform (see [13, 20]). We find a uniform asymptotic expansion as $k \to +\infty$ of the Fourier transform of the inviscid solution, clarifying the seemingly discontinuous change of behavior of $\hat{u}(k,t)$ at t_* presented in [13]. This discontinuity in the asymptotic behavior is a direct consequence of the coalescence of the two second-order branch points $\pm x_s(t)$ into a third-order branch point at the origin $x_s(t_*) = 0$. We show that as $k \to +\infty$, $\hat{u}(k,t) = \mathcal{C}_0 \cdot (tk)^{-4/3}\mathrm{Ai}[(-3ikx_s(t)/2)^{2/3}]\left(1 + \mathcal{O}\left(k^{-1}\right)\right)$. From the (uniform) asymptotic expansion of the Airy function we find that $\hat{u}(k,t) \sim \mathcal{C}_1(t) \cdot (t_* - t)^{-1/4}\, k^{-3/2} \exp(-k|x_s(t)|)$ for $0 < t < t_*$ and $\hat{u}(k, t_*) \sim \mathcal{C}_2 \cdot (t_* k)^{-4/3}$, where $\mathcal{C}_0, \mathcal{C}_1(t), \mathcal{C}_2$ are appropriate numerical constants.

2. Polar measure, integral representation, and inviscid limit.

In [18], the solution to the IVP (1.1)–(1.2) is constructed in the following property.

PROPERTY 2.1. *Let $2\alpha = 1/t_* - 1/t$ for $\nu, t, t_* > 0$; then*

$$\begin{aligned} u_\nu(x,t) &= \frac{x}{t} - 2\nu\, \partial_x \log\bigl(E_\nu(x,t)\bigr), \\ E_\nu(x,t) &= \int_{-\infty}^{\infty} \exp\left\{\frac{1}{2\nu}\left(\frac{x}{t}y + \alpha y^2 - y^4\right)\right\} dy. \end{aligned}$$

Furthermore, $u_\nu(x,t)$ has a Mittag–Leffler (pole) representation:

$$u_\nu(x,t) = \frac{x}{t} - 2\nu \sum_{n=1}^{\infty} \frac{2x}{x^2 + \beta_n^2(t,\nu)},$$

which converges uniformly on compact sets for x away from the poles $x = \pm i\beta_n$.

From the integral representation of the solution one can describe the behavior of the solution as the viscosity tends to zero: using a saddle-point analysis, we have shown in [18, section 4.2] that the dominant behavior of $E_\nu(i\beta, t)$ as $\nu \to 0^+$ or as $\beta \to +\infty$ is given by an asymptotic relation of the form

$$\begin{aligned} &\sqrt{\frac{|6z_0(\beta;t)^2 - \alpha|}{2\pi\nu}}\ \exp\left\{-\frac{1}{2\nu}\Re w\bigl(z_0(\beta;t), i\beta\bigr)\right\} E_\nu(i\beta,t) \\ &\qquad = \cos\left(\frac{\Im w(z_0(\beta;t), i\beta)}{2\nu} - \frac{\theta(z_0(\beta;t),t)}{2}\right) + \mathcal{O}\left(\frac{\nu}{\beta^{4/3}}\right), \end{aligned}$$

where

$$\begin{aligned} w(z, i\beta) &= \int_0^z (i\beta/t - \eta/t - u_0(\eta))\, d\eta = i\beta z/t + \alpha z^2 - z^4, \\ \theta(z,t) &= \arg(\partial_z^2 w) = \arg(6z^2 - \alpha), \quad -\pi \le \theta(z,t) < \pi, \end{aligned}$$

and $z_s(\beta;t)$ is implicitly defined by

$$0 = w_z(z_s(\beta;t), i\beta) = \frac{i\beta}{4t} + \frac{\alpha}{2}z_s - z_s^3, \qquad s = 0, 1, 2. \tag{2.1}$$

Solving (2.1) using Cardan's formula (see Appendix B) and separating real and imaginary parts, we find that

$$\begin{cases} z_0 = \frac{\sqrt{3}}{2}(\mathcal{A} - \mathcal{B}) + \frac{i}{2}(\mathcal{A} + \mathcal{B}), \\ z_1 = -\overline{z_0} = \frac{\sqrt{3}}{2}(\mathcal{B} - \mathcal{A}) + \frac{i}{2}(\mathcal{A} + \mathcal{B}), \\ z_2 = -i(\mathcal{A} + \mathcal{B}), \end{cases} \tag{2.2}$$

where for $\beta > |x_s(t)|$,

$$\begin{cases} \mathcal{A}(\beta;t) = (8t)^{-1/3} \sqrt[3]{\beta + \sqrt{\beta^2 + x_s^2}} > 0, \\ \mathcal{B}(\beta;t) = (8t)^{-1/3} \sqrt[3]{\beta - \sqrt{\beta^2 + x_s^2}} > 0. \end{cases} \tag{2.3}$$

For $\beta < -|x_s(t)|$, $\mathcal{A}$ and $\mathcal{B}$ are defined by the odd parity condition $\mathcal{A}(-\beta;t) = -\mathcal{A}(\beta;t)$ and $\mathcal{B}(-\beta;t) = -\mathcal{B}(\beta;t)$ so that

$$z_s(-\beta;t) = -z_s(\beta;t). \tag{2.4}$$

For small ν (fixed k) or for large β (large k, fixed ν), the poles β_k are approximated by the roots of the equation

$$\frac{\sigma(\beta;t)}{2\nu} - \frac{1}{2\pi}\theta(z_0(\beta;t), t) = k - \frac{1}{2}, \quad k \in \mathbb{N}^*, \tag{2.5}$$

with the convention that $\beta_{-k} \equiv -\beta_k$. Clearly, since $|\theta| \leq \pi$, the contribution of θ is negligible compared with that of σ. Thus, we approximate (2.5) by

$$\frac{\sigma(\beta;t)}{2\nu} \approx k - \frac{1}{2}, \quad k \in \mathbb{N}^*. \tag{2.6}$$

Choose a parameter $\beta_{\max} < +\infty$, and then choose $N_\nu(\beta_{\max})$ as follows: let Int$[x]$ denote the integer part of x with half-integers rounded down, and fix $\nu > 0$. Then for any $\delta > 0$ and compact set $[\delta, t_*]$, define N_ν by

$$N_\nu(\beta_{\max}) = \sup_{0<\delta \leq t \leq t_*} \left[\frac{\sigma(\beta_{\max};t)}{2\nu}\right] < +\infty. \tag{2.7}$$

The $\beta_k(t,\nu)$ are ordered as follows:

$$0 \leq |x_s(t)| < \beta_1(t,\nu) < \cdots < \beta_k(t,\nu) < \cdots < \beta_{N_\nu} < +\infty \tag{2.8}$$

for $1 < k < N_\nu$. For negative indices, the ordering of the β_{-k}'s is the reverse of that given in (2.8).

Let $U_\nu^{\beta_{\max}}(x,t)$ be the N_νth partial sum of $U_\nu(x,t)$:

$$\begin{aligned} U_\nu^{\beta_{\max}}(x,t) = x - t\, u_\nu^{\beta_{\max}}(x,t) &= t \cdot 2x \cdot \sum_{n=1}^{N_\nu} \frac{2\nu}{x^2 + \beta_n^2} \\ &= t \cdot 2\nu \sum_{n=1}^{N_\nu} \left(\frac{1}{x - i\beta_n} + \frac{1}{x + i\beta_n}\right). \end{aligned} \tag{2.9}$$

Let $U_\nu(x,t)$ be the spatially singular part of the viscous solution defined by

$$U_\nu(x,t) = x - t\,u_\nu(x,t) = t \cdot 2x \sum_{n=1}^{\infty} \frac{2\nu}{x^2 + \beta_n^2(t,\nu)}, \tag{2.10}$$

and let the remainder $R_\nu^{\beta_{\max}}(x,t)$ be defined by

$$R_\nu^{\beta_{\max}}(x,t) = U_\nu(x,t) - U_\nu^{\beta_{\max}}(x,t) = t \cdot 2x \sum_{n=N_\nu+1}^{\infty} \frac{2\nu}{x^2 + \beta_n^2(t,\nu)}.$$

Let $\delta(\beta)$ denote the usual Dirac measure, and define the density $\sigma_\nu(\beta;\beta_{\max},t)$ with support in $[-\beta_{\max},\beta_{\max}]$ by

$$\sigma_\nu(\beta;\beta_{\max},t) = \int_{-\beta_{\max}}^{\beta} 2\nu \sum_{k=1}^{N_\nu} \left[\delta\left(\xi - \beta_k(t,\nu)\right) + \delta\left(\xi + \beta_k(t,\nu)\right)\right] d\xi. \tag{2.11}$$

Since the poles β_n are ordered according to (2.8), this insures that (2.11) is nonnegative and vanishes outside $[-\beta_{\max},\beta_{\max}]$. Moreover, once $\beta_{\max}$ has been chosen, $\sigma_\nu(\beta;\beta_{\max},t)$ is uniformly bounded for $0 < \delta \le t \le t_*$ by $2\nu N_\nu$. Thus, from the definition (2.7) of N_ν, $\sigma_\nu(\beta;\beta_{\max},t)$ is uniformly bounded in ν, and thus is a regular finite Borel measure. Since

$$\begin{aligned} d\sigma_\nu(\beta;\beta_{\max},t) &= 2\nu \sum_{k=1}^{N_\nu} \left[\delta\left(\beta - \beta_k(t,\nu)\right) + \delta\left(\beta + \beta_k(t,\nu)\right)\right] d\beta \\ &= 2\nu \sum_{\substack{k=-N_\nu \\ k\neq 0}}^{N_\nu} \delta\left(\beta - \beta_k(t,\nu)\right) d\beta, \end{aligned} \tag{2.12}$$

the measure $d\sigma_\nu(\beta;\beta_{\max},t)$ consists of a sum of delta functions with weight (height) 2ν decreasing as $\nu \to 0^+$. The density of these delta functions increases like $1/\Delta\beta_k = \mathcal{O}(1/\nu)$ as $\nu \to 0^+$ for $k \sim 1/\nu$. Since the measure $d\sigma_\nu$ is odd ($d\sigma_\nu(-\beta;\beta_{\max},t) = -d\sigma_\nu(\beta;\beta_{\max},t)$), we can represent $U_\nu^{\beta_{\max}}(x,t)$ as

$$U_\nu^{\beta_{\max}}(x,t) = t \cdot \int_{-\infty}^{\infty} \frac{d\sigma_\nu(\beta;\beta_{\max},t)}{x - i\beta} = t \cdot 2x \int_0^{\infty} \frac{d\sigma_\nu(\beta;\beta_{\max},t)}{x^2+\beta^2}, \tag{2.13}$$

where the last integral should be understood as

$$\int_0^{\infty} \frac{d\sigma_\nu(\beta;\beta_{\max},t)}{x^2+\beta^2} \equiv \frac{1}{2}\int_{-\infty}^{\infty} \frac{d\sigma_\nu(\beta;\beta_{\max},t)}{x^2+\beta^2}. \tag{2.14}$$

Since the measure $d\sigma_\nu(\beta;\beta_{\max},t)$ has support in the compact interval $[-\beta_{\max},\beta_{\max}]$, we have proved the following property.

Property 2.2. *$U_\nu^{\beta_{\max}}(x,t)$ has an integral representation for $x \notin [-i\beta_{\max}, i\beta_{\max}]$ given by*

$$U_\nu^{\beta_{\max}}(x,t) = t \cdot \int_{-\beta_{\max}}^{\beta_{\max}} \frac{d\sigma_\nu(\beta;\beta_{\max},t)}{x - i\beta} = t \cdot x \int_{-\beta_{\max}}^{\beta_{\max}} \frac{d\sigma_\nu(\beta;\beta_{\max},t)}{x^2+\beta^2}.$$

Now that we have established the validity of the integral representation of Property 2.2, we use this to derive an integral representation of the inviscid solution: we introduce the asymptotic pole density $\rho(\beta;t)$, which also corresponds to the asymptotic distribution of the zeros of E_ν. We define it in relation to the limiting measure $\sigma(\beta;t)$ as follows.

DEFINITION 2.1. *For $\beta \in [-\beta_{\max}, \beta_{\max}]$, the cumulative distribution function $\sigma(\beta;t)$ represents the number of poles within the interval $[0,\beta] \subset [0,\beta_{\max}]$.*

$$\sigma(\beta;t) = \int_0^\beta \rho(\zeta;t)\,d\zeta = \frac{1}{\pi}\Im w(z_s(\beta;t), i\beta).$$

It follows directly from the definition (2.5) of the zeros $\pm i\beta_k(t,\nu)$ of $E_\nu(x,t)$ and from Definition 2.1 of the asymptotic density of the zeros that

$$\lim_{\nu\to 0^+} \sum_{k=1}^{N_\nu} \frac{2\nu}{x^2+\beta_k^2(t,\nu)} = \int_{-\beta_{\max}}^{\beta_{\max}} \frac{\rho(\beta;t)}{x^2+\beta^2}\,d\beta = \frac{U^{\beta_{\max}}(x,t)}{tx} \tag{2.15}$$

for a fixed $\delta > 0$ and $0 < \delta \le t \le t_*$. Thus, we have that

$$|U^{\beta_{\max}}(x,t) - U_\nu^{\beta_{\max}}(x,t)| = t\,|x| \cdot \left| \int_{-\beta_{\max}}^{\beta_{\max}} \frac{d\sigma - d\sigma_\nu}{x^2+\beta^2} \right| < \epsilon/3 \tag{2.16}$$

for ν small enough on compact sets for x and t away from the branch cuts defined by $(-i\infty, -i|x_s|] \cup [i|x_s|, +i\infty)$ (for a similar argument see, for example, [12]). Thus the convergence of the measure $d\sigma_\nu$ to $d\sigma$ is described in the following way.

PROPERTY 2.3. *For $\beta \in [-\beta_{\max}, \beta_{\max}]$ and $0 < \delta \le t \le t_*$, the sequence of distributions $d\sigma_\nu(\beta;\beta_{\max},t)$ converges weakly to $d\sigma(\beta;t)$:*

$$\text{w-}\lim_{\nu\to 0^+} d\sigma_\nu(\beta;\beta_{\max},t) = d\sigma(\beta;t) = \rho(\beta;t)\,d\beta = \frac{1}{\pi}\Im dw(z_s(\beta;t), i\beta).$$

This measure is analogous to the spectral measure introduced in [12, 15]. Here w-$\lim_{\nu\to 0^+}$ stands for a limit in the sense of weak convergence of measures; that is, w-$\lim_{\nu\to 0^+} d\mu_\nu(\beta) = d\mu(\beta)$ if

$$\lim_{\nu\to 0^+} (\phi, d\mu_\nu) = (\phi, d\mu) = \int_{-\beta_{\max}}^{\beta_{\max}} \phi(\beta)\,d\mu(\beta)$$

for every continuous function ϕ in $[-\beta_{\max}, \beta_{\max}]$. Note that we suspect the convergence

$$\lim_{\nu\to 0^+} U_\nu^{\beta_{\max}}(x,t) = U^{\beta_{\max}}(x,t) \tag{2.17}$$

to hold uniformly over compact sets for t and x away from the branch cuts.

From the definition of the limiting function $U(x,t)$

$$U(x,t) = t \cdot x \int_{-\infty}^{\infty} \frac{\rho(\beta;t)}{x^2+\beta^2}\,d\beta,$$

the remainder $R^{\beta_{\max}}(x,t)$, defined for $x \notin (-i\infty, -i\beta_{\max}] \cup [i\beta_{\max}, i\infty)$ as

$$R^{\beta_{\max}}(x,t) = U^{\beta_{\max}}(x,t) - U(x,t) = t \cdot 2x \cdot \int_{|\beta|\ge\beta_{\max}} \frac{\rho(\beta;t)}{x^2+\beta^2}\,d\beta, \tag{2.18}$$

can be shown to go to zero as $\beta_{\max} \to +\infty$ independently of ν: fix an $R > 0$ such that $|x| \leq R < \beta_{\max}$, then $|x^2 + \beta^2| \geq \beta^2 - R^2$. Let $\theta > 1$ be a fixed parameter; then for $\beta > \beta_{\max} > \sqrt{\theta/(\theta-1)}R$, we have $1/(\beta^2 - R^2) < \theta/\beta^2$. Then since $\rho(\beta; t) = \mathcal{O}(\beta^{1/3})$ as $\beta \to +\infty$ (see Theorem 3.1), we can estimate (2.18) as $\beta_{\max} \to +\infty$ as follows:

$$\begin{aligned}\left|\int_{|\beta|\geq\beta_{\max}} \frac{\rho(\beta;t)}{x^2+\beta^2}\,d\beta\right| &\leq \mathcal{C}(t)\int_{|\beta|\geq\beta_{\max}} \frac{\beta^{1/3}}{\beta^2 - R^2}\,d\beta \\ &\leq \theta\cdot\mathcal{C}(t)\cdot\int_{|\beta|\geq\beta_{\max}} \frac{d\beta}{\beta^{5/3}} = \mathcal{O}(\beta_{\max}^{-2/3}).\end{aligned}$$

Therefore, on compact sets for x and t,

$$|U^{\beta_{\max}}(x,t) - U(x,t)| < \epsilon/3 \tag{2.19}$$

for $\beta_{\max}$ large enough independent of ν.

The last estimate concerns

$$\begin{aligned}|R_\nu^{\beta_{\max}}(x,t)| &= |U_\nu^{\beta_{\max}}(x,t) - U_\nu(x,t)| \\ &= t\,|2x|\left|\sum_{n=N_\nu+1}^{\infty} \frac{2\nu}{x^2+\beta_n^2(t,\nu)}\right|.\end{aligned} \tag{2.20}$$

In [18, section 4.2], it is shown that $\beta_n(t,\nu) = \mathcal{O}\left((n\nu)^{3/4}\right)$ as $n \to +\infty$ for fixed $\nu > 0$. Therefore, let $y_n(t,\nu) = \mathcal{C}n\nu$, where $\mathcal{C}$ is an appropriate asymptotic constant which depends on t (see (5.1) for such a representation). This assumption also can be justified by combining (5.1) and the fact that the order $\lambda = 4/3$ of the entire function E_ν is also the order of convergence of its zeros (see [18, section 2.1]). Then since $N_\nu(\beta_{\max}) = \sup_{0<\delta\leq t\leq t_*} \operatorname{Int}[\sigma(\beta_{\max};t)/2\nu]$, following a similar argument as in the proof of (2.19), we may estimate (2.20) as

$$\begin{aligned}|U_\nu^{\beta_{\max}}(x,t) - U_\nu(x,t)| &\leq t\,|2x|\left|\sum_{n=N_\nu+1}^{\infty} \frac{2\nu}{x^2+y_n^{3/2}}\right| \\ &\leq t\,|2x|\,\mathcal{C}_1\left|\int_{\beta_{\max}}^{+\infty} \frac{dy}{x^2+y^{3/2}}\right| = \mathcal{O}(\beta_{\max}^{-1/2})\end{aligned}$$

as $\beta_{\max} \to +\infty$, uniform in ν on compact sets for $t \in [\delta, t_*]$ and x away from the branch cuts. Choosing $\beta_{\max}$ large enough so that $|U(x,t) - U^{\beta_{\max}}(x,t)| < \epsilon/3$ and $|U_\nu^{\beta_{\max}}(x,t) - U_\nu(x,t)| < \epsilon/3$ independent of ν and then choosing ν small enough in such a way that $|U^{\beta_{\max}}(x,t) - U_\nu^{\beta_{\max}}(x,t)| < \epsilon/3$, we finally have

$$\begin{aligned}|U_\nu(x,t) - U(x,t)| \leq{}& |U(x,t) - U^{\beta_{\max}}(x,t)| \\ &+ |U^{\beta_{\max}}(x,t) - U_\nu^{\beta_{\max}}(x,t)| + |U_\nu^{\beta_{\max}}(x,t) - U_\nu(x,t)| < \epsilon.\end{aligned}$$

Using the fact that $\rho(\beta; t) = 0$ for $|x| < |x_s(t)|$ when $0 < t \leq t_*$, we have proved the following theorem.

THEOREM 2.4. *For $\delta > 0$, $t \in [\delta, t_*]$; on compact sets for x away from the branch cuts defined by $(-i\infty, -i|x_s|] \cup [i|x_s|, +i\infty)$, we have*

$$\lim_{\nu\to 0^+} U_\nu(x,t) = t\cdot 2x\int_{|x_s(t)|}^{\infty} \frac{\rho(\beta;t)}{x^2+\beta^2}\,d\beta.$$

3. Asymptotic density of poles. Now that we have defined the asymptotic density of poles, we proceed with its explicit computation for the different time intervals $(0, t_*)$, $t = t_*$ and $(t_*, +\infty)$. As in section 2, let w-$\lim_{\nu\to 0^+}$ denote a weak limit in the sense of weak convergence of measures. Then we prove the following.

THEOREM 3.1. it For $0 < \beta_{\max} < +\infty$, *the asymptotic density of poles* $\rho(\beta; t)$: $[-\beta_{\max}, \beta_{\max}] \times \mathbb{R}_+ \to \mathbb{R}_+$ *is a positive even function of* β *defined by*

$$\rho(\beta;t) \equiv \text{w-}\lim_{\nu\to 0^+} \frac{d\sigma_\nu}{d\beta}(\beta;\beta_{\max},t) = \frac{d\sigma}{d\beta}(\beta;t) = \frac{1}{\pi t}\,\Re z_s^+(\beta;t),$$

where $z_s^+(\beta;t)$ *is the saddle point with positive real part which is relevant to the asymptotic expansion of* $E_\nu(i\beta, t)$ *as* $\nu \to 0^+$. *This saddle point is determined by the implicit equation*

$$\frac{\partial w}{\partial z}\big(z_s(\beta;t), i\beta\big) = \frac{i\beta}{t} - \frac{z_s(\beta;t)}{t} - u_0\big(z_s(\beta;t)\big) = 0.$$

Let $\pm x_s(t) = \pm i\,(3t_*)^{-3/2}(t_* - t)^{3/2}t^{-1/2}$ *be the second-order branch points of the inviscid solution arising from the initial data* $u_0(x) = 4x^3 - x/t_*$. *For* $t > t_*$ *and for* $t < t_*$, $|\beta| > |x_s|$,

$$\rho(\beta;t) = \frac{2^{2/3}\sqrt{3}}{\pi}(4t)^{-4/3}\left\{\sqrt[3]{|\beta| + \sqrt{\beta^2 + x_s^2}} - \sqrt[3]{|\beta| - \sqrt{\beta^2 + x_s^2}}\right\}.$$

For $t < t_*$, $|\beta| < |x_s|$,

$$\rho(\beta;t) = 0.$$

For $t = t_*$,

$$\rho(\beta;t_*) = \frac{2\sqrt{3}}{\pi}(4t_*)^{-4/3}|\beta|^{1/3}.$$

For $t > t_*$, $\beta = 0$,

$$\rho(0;t) = \lim_{\substack{\beta\to 0\\ t>t_*}} \rho(\beta;t) = \frac{1}{2\pi}(t - t_*)^{1/2}t^{-3/2}t_*^{-1/2}.$$

Proof. In [3, 4], Bessis and Fournier introduced a limiting density of poles which characterizes the process of condensation of poles on the imaginary axis as the viscosity $\nu \to 0^+$. They defined it in [3] in the following way:

$$\rho(\beta;t) \equiv \lim_{\substack{n\to\infty\\ \nu\to 0^+}} \left.\frac{2\nu}{\Delta\beta_n(t,\nu)}\right|_{\beta_n=\beta} : \mathbb{R} \times \mathbb{R}_+ \to \mathbb{R}_+,$$

with $\Delta\beta_n(t,\nu) = \beta_{n+1}(t,\nu) - \beta_n(t,\nu) > 0$, where $n \in \mathbb{Z}\backslash\{0\} = \{\pm 1, \pm 2, \dots\}$, with the convention that $\beta_{-n} = -\beta_n$. Since

$$\frac{\partial w}{\partial \beta}\big(z_s(\beta;t), i\beta\big) = \frac{i}{t}\,z_s(\beta;t), \tag{3.1a}$$

$$\frac{\partial w}{\partial z}\big(z_s(\beta;t), i\beta\big) = \frac{i\beta}{t} - \frac{z_s(\beta;t)}{t} - u_0\big(z_s(\beta;t)\big) = 0. \tag{3.1b}$$

From Property 2.3 we find that the density is given by

$$\rho(\beta;t) = \frac{1}{\pi}\Im\frac{dw}{d\beta}\big(z_s(\beta;t), i\beta\big) = \frac{1}{\pi t}\,\Re z_s^+(\beta;t), \tag{3.2}$$

where $z_s^+(\beta;t)$ is the relevant saddle point with positive real part. Since $z_s(-\beta;t) = -z_s(\beta;t)$, in order to have $\rho(-\beta;t) = \rho(\beta;t) > 0$, we must take in both cases ($\beta > 0$ and $\beta < 0$) the saddle point with positive real part. That is, we must take z_0 for $\beta > 0$ and z_1 for $\beta < 0$ since they are related by $z_0(-\beta;t) = -z_0(\beta;t) = \overline{z_1}(\beta;t)$ and $z_1(-\beta;t) = -z_1(\beta;t) = \overline{z_0}(\beta;t)$ (see [18, section 4.2]). With this choice of saddle points, the asymptotic density defined in (3.2) is positive whether $\beta > 0$ or $\beta < 0$. Note that if we let $x = i\beta$, $x_0 = x_0(x,t) = z_s(\beta;t)$, then the inviscid solution is $u(x,t) = u_0(x_0(x,t),t)$, where $x - x_0 - t\,u_0(x_0) = 0$ (see Appendix C). Combining (2.2) and (3.2), we immediately have an expression for the density as a function of β and t:

$$\rho(\beta;t) = \frac{\sqrt{3}}{2\pi t}(\mathcal{A}(\beta;t) - \mathcal{B}(\beta;t)), \tag{3.3}$$

with $\mathcal{A}(\beta;t)$ and $\mathcal{B}(\beta;t)$ defined in (2.3).

We can now describe the various cases $t = t_*$, $0 < t < t_*$, $t > t_*$, and $x = 0, t > t_*$:

(i) $t = t_*$:

$$\rho(\beta;t_*) = \frac{1}{\pi t_*}\Re z_s(\beta;t_*) = \frac{\sqrt{3}}{2\pi t_*}\left(\frac{\beta}{4t_*}\right)^{1/3} = \frac{2\sqrt{3}}{\pi}(4t_*)^{-4/3}|\beta|^{1/3}. \tag{3.4}$$

In the last step of (3.4), we replace $\beta^{1/3}$ by $|\beta|^{1/3}$ to allow for both $\beta > 0$ and $\beta < 0$. Note that we can obtain (3.4) by taking the limit as $t \to t_*$ in (3.7) or (3.8). It is interesting to see that this density is the only one which explicitly can be computed from the formula introduced by Bessis and Fournier:

$$\rho(\beta;t) = \lim_{\substack{n\to\infty \\ \nu\to 0^+}} \left.\frac{2\nu}{\Delta\beta_n(t,\nu)}\right|_{\beta_n=\beta}. \tag{3.5}$$

The explicit pole positions $\beta_k(t_*,\nu)$ are given in part I by

$$\beta_k(t_*,\nu) = 4t_*\left(\frac{2\nu}{3\sqrt{3}}\right)^{3/4}\cdot\Big((k-1/3)^{3/4} + \mathcal{O}(1/k^{3/4})\Big) \tag{3.6}$$

as $k \to +\infty$ for all ν. Combining (3.5) with (3.6), one recovers (3.4).

(ii) $0 < t < t_*$: the density is zero for $|\beta| \le |x_s|$ and for $|\beta| > |x_s|$;

$$\rho(\beta;t) = \frac{2^{2/3}\sqrt{3}}{\pi}(4t)^{-4/3}\left\{\sqrt[3]{|\beta| + \sqrt{\beta^2 + x_s^2}} - \sqrt[3]{|\beta| - \sqrt{\beta^2 + x_s^2}}\right\}. \tag{3.7}$$

The behavior of $\rho(\beta;t)$ in a neighborhood of $\beta = \pm|x_s|$, ($|\beta| > |x_s|$) is

$$\rho(\beta;t) = \frac{t^{-4/3}}{\sqrt{6}\pi}\frac{\sqrt{|\beta| - |x_s|}}{|x_s|^{1/6}} + \mathcal{O}\Big(\big(|\beta| - |x_s|\big)^{3/2}\Big),$$

as mentioned in [3].

(iii) $t > t_*$: $\forall \beta \in \mathbb{R}$,

$$\rho(\beta;t) = \frac{2^{2/3}\sqrt{3}}{\pi}(4t)^{-4/3}\left\{\sqrt[3]{\beta+\sqrt{\beta^2+x_s^2}}+\sqrt[3]{-\beta+\sqrt{\beta^2+x_s^2}}\right\}. \tag{3.8}$$

(iv) $x = 0, t \geq t_*$: an interesting case occurs at the origin for $t > t_*$, as was pointed out by Bessis and Fournier in [3, 4]. The inviscid solution $u(0,t)$ at the shock is given by the asymptotic density of poles $\rho(0;t)$ (see (3.12)). If we look at the solution at the origin ($\beta \to 0$), $z_s(0;t)$ is the solution to

$$-\frac{z_s(0;t)}{t} = u_0(z_s(0;t)).$$

When $u_0(x) = 4x^3 - x/t_*$,

$$-\frac{z_s(0;t)}{t} = 4z_s(0;t)^3 - \frac{z_s(0;t)}{t_*}.$$

The nonzero pair of opposite saddle points are, therefore,

$$z_s^{\pm}(0;t) = \pm\frac{1}{2}\sqrt{\frac{t-t_*}{tt_*}} = \pm\sqrt{\frac{\alpha}{2}} \geq 0 \qquad \text{when } \ t \geq t_*.$$

The corresponding density is easily found to be

$$\rho(0;t) = \frac{1}{\pi t}\,\Re z_s^+(0;t) = \begin{cases} \frac{1}{2\pi}(t-t_*)^{1/2}t^{-3/2}t_*^{-1/2} & t > t_*, \\ 0 & t \leq t_*. \end{cases} \tag{3.9}$$

This could have been found by letting $\beta \to 0$ in (3.8). Moreover, it makes sense that the density $\rho(0;t)$ is null when $t < t_*$ since all the poles β_n are located above the inviscid branch points x_s on the imaginary axis, and $|x_s| > 0$.

3.1. Residue computation of the integral representation of the inviscid limit for $t = t_*$.

Since $x_s(t_*) = 0$, we have

$$\int_0^\infty \frac{z^{1/3}}{x^2+z^2}\,dz = \frac{\pi}{\sqrt{3}\,x^{2/3}}. \tag{3.10}$$

Combining (3.4) and (3.10), we recover the inviscid solution at $t = t_*$:

$$u(x,t_*) = \lim_{\nu\to 0^+} u_\nu(x,t_*) = \frac{x}{t_*} - \left(\frac{x}{4t_*^4}\right)^{1/3} = \frac{x}{t_*} - \frac{U(x,t_*)}{t_*}. \tag{3.11}$$

For $0 < t < t_*$, a similar computation can be done using the double keyhole contour of integration displayed in Fig. 3.1.

For $t \geq t_*$, there is an interesting special case: since $z_s(0;t) \in \mathbb{R}$ for $t \geq t_*$, $\rho(0;t) = z_s(0;t)/\pi t$. Thus the inviscid solution at the origin (shock) for $t > t_*$ is given by (see (4.4b))

$$u(0,t) = \frac{u(0^-,t) - u(0^+,t)}{2} = \pi\rho(0;t) = \frac{1}{2}\,(t-t_*)^{1/2}t^{-3/2}\,t_*^{-1/2}, \tag{3.12}$$

i.e., the solution at the shock satisfies the jump condition (see (C.6), (4.4b), Fig. C.1, and [3, 16]):

$$u(0^{\mp},t) = \pm\frac{1}{2}\,(t-t_*)^{1/2}t^{-3/2}t_*^{-1/2}. \tag{3.13}$$

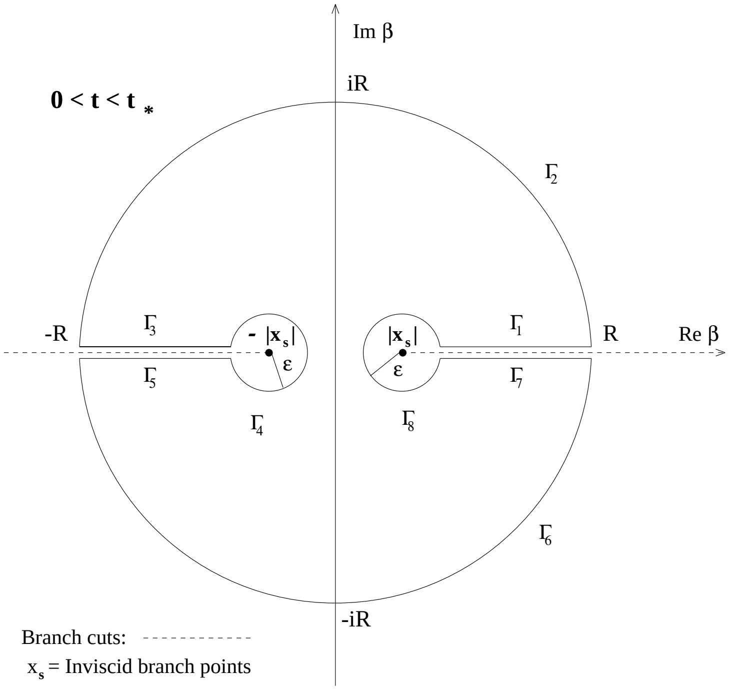

FIG. 3.1. *Contour of integration for the inviscid limit for $t < t_*$.*

Although this result was stated by Bessis and Fournier and can be derived by taking $\lim_{\beta\to 0} \rho(\beta;t)$, it is mentioned here to verify the validity formula $\rho(\beta;t) = (\pi t)^{-1}\,\Re z_s^+(\beta;t)$, where $z_s^+(\beta;t)$ is the saddle point relevant to the asymptotic expansion with a positive real part.

As a final remark, we would like to point out that this procedure which consists in recovering the analytic structure of the inviscid solution via the limiting pole density and the pole expansion is no longer possible when $t > t_*$ and $x \neq 0$. Indeed, in this case we are faced with the same (apparent) paradox that is present in the asymptotic expansion of the (spatial) Fourier transform of the inviscid solution (see section 6 and also [3]). Thus the only way to recover the inviscid solution for $t > t_*$ and $x \neq 0$ using the limiting pole density is by extending the solution obtained for $t < t_*$ to $t > t_*$.

4. Analytic extension of the integral representation of the inviscid solution on the imaginary axis. Let

$$u(x,t) = \frac{x}{t} - 2x\int_0^\infty \frac{\rho(\beta;t)}{x^2+\beta^2}\,d\beta = \frac{x}{t} - \int_{-\infty}^{\infty} \frac{\rho(\beta;t)}{x-i\beta}\,d\beta, \tag{4.1a}$$

$$\tilde{u}(y,t) = \frac{y}{t} + 2y\,P.V.\int_0^\infty \frac{\rho(\beta;t)}{y^2-\beta^2}\,d\beta = \frac{y}{t} + P.V.\int_{-\infty}^{\infty} \frac{\rho(\beta;t)}{y-\beta}\,d\beta. \tag{4.1b}$$

Then one can show that $\rho(y;t)$ is a density function which satisfies the conservation equation

$$\rho_t + (\rho\,\tilde{u})_y = 0. \tag{4.2}$$

Indeed, one only needs to verify that $u(x,t)$ defined by (4.1a) satisfies the inviscid BE $u_t + uu_x = 0$ under the assumption that (4.2) holds. Since u has branch cuts on

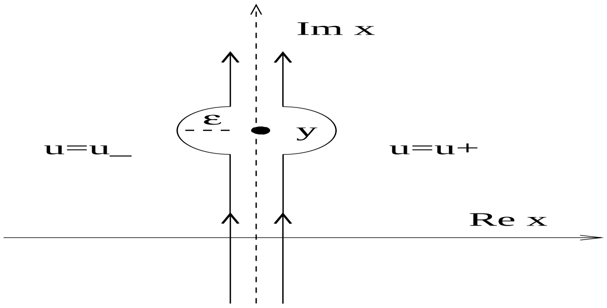

FIG. 4.1. *Analytic continuation of the integral representation of the inviscid solution on the imaginary axis.*

the imaginary axis for $t < t_*$, $\tilde{u}$ has branch cuts for y real (i.e., also on the imaginary axis); one can analytically continue u on the imaginary axis using the paths displayed in Fig. 4.1. Define the solution on the left (u_-) and right (u_+) of the imaginary axis by

$$u_\pm(iy,t) = \lim_{x\to 0^\pm} u(z = x+iy,t). \tag{4.3}$$

The discontinuity at $x = 0$ characterizes the shock solution. Thus we find that

$$\begin{aligned} u_+(iy,t) &= \frac{iy}{t} - P.V.\int_{-\infty}^{\infty} \frac{\rho(\beta;t)}{iy-i\beta}\,d\beta - \frac{\rho(y;t)}{i}\overbrace{\left(-\frac{1}{2}\oint_{|y-\beta|=\epsilon}\frac{d\beta}{y-\beta}\right)}^{\pi i} \\ &= i\left\{\frac{y}{t} + \int_{-\infty}^{\infty}\frac{\rho(\beta;t)}{y-\beta}\,d\beta + i\pi\rho(y;t)\right\}. \end{aligned}$$

Similarly, we have that

$$u_-(iy,t) = i\left\{\frac{y}{t} + \int_{-\infty}^{\infty}\frac{\rho(\beta;t)}{y-\beta}\,d\beta - i\pi\rho(y;t)\right\}.$$

Therefore,

$$\tilde{u}(y,t) = \frac{1}{2i}(u_+(iy,t) + u_-(iy,t)), \tag{4.4a}$$

$$\rho(y;t) = \frac{1}{2\pi}(u_-(iy,t) - u_+(iy,t)). \tag{4.4b}$$

Since $u_\pm$ are real on the real axis, it is clear that they satisfy the symmetry relations

$$\begin{aligned} u_\pm(\overline{x},t) &= \overline{u_\pm(x,t)}, \\ u_-(-x,t) &= -u_+(x,t), \end{aligned}$$

and therefore

$$u_\pm(iy,t) = \overline{u_\pm(-iy,t)} = -\overline{u_\mp(iy,t)}.$$

From this we have

$$\tilde{u}(y,t) = \Im u_+(iy,t), \tag{4.5a}$$

$$\rho(y;t) = -\frac{1}{\pi}\Re u_+(iy,t) = \frac{1}{\pi}\Re u_-(iy,t), \tag{4.5b}$$

and the symmetry relations

$$\tilde{u}(-y,t) = -\tilde{u}(y,t),$$
$$\rho(-y;t) = \rho(y;t).$$

Thus we have the following property.

PROPERTY 4.1.

$$u_{\pm}(iy,t) = \mp\pi\rho(y;t) + i\,\tilde{u}(y,t). \tag{4.6}$$

5. Continuum limit of the pole expansion and the CDS. Let $a_n(t,\nu) = i\beta_n(t,\nu)$, and define the complex map $\mathcal{F}(\zeta,\nu,t)$ as

$$a_n(t,\nu) = \mathcal{F}(\zeta_n^\nu = \nu n, \nu, t) : \mathbb{Z}^* \times \mathbb{R}_+^2 \to i\,\mathbb{R}_+, \quad a_{-n} = -a_n. \tag{5.1}$$

Reformulating the Mittag–Leffler expansion of u_ν (1.5) and the CDS (1.6) in terms of a_n, we have

$$u_\nu(x,t) = \frac{x}{t} - 2\nu \sum_{\substack{l=-\infty \\ l\neq 0}}^{\infty} \frac{1}{x-a_l}, \tag{5.2a}$$

$$\dot{a}_n = \frac{a_n}{t} - 2\nu \sum_{\substack{l=-\infty \\ l\neq n,0}}^{\infty} \frac{1}{a_n - a_l} \quad \forall n \in \mathbb{Z}^*. \tag{5.2b}$$

Both symmetric sums (5.2a, b) should be understood as

$$\sum_{\substack{l=-\infty \\ l\neq n,0}}^{\infty} \frac{1}{a_n - a_l} = \frac{1}{2a_n} + 2a_n \sum_{\substack{l=1 \\ l\neq n}}^{\infty} \frac{1}{a_n^2 - a_l^2} = \frac{1}{2a_n} + a_n \sum_{\substack{l=-\infty \\ l\neq 0,\pm n}}^{\infty} \frac{1}{a_n^2 - a_l^2}$$

and

$$\sum_{\substack{l=-\infty \\ l\neq 0}}^{\infty} \frac{1}{x-a_l} = 2x \sum_{l=1}^{\infty} \frac{1}{x^2 - a_l^2} = x \sum_{\substack{l=-\infty \\ l\neq 0}}^{\infty} \frac{1}{x^2 - a_l^2}.$$

At t_*, we have (cf. [18, section 4.1])

$$\begin{aligned} a_n(t_*,\nu) &= \mathcal{F}(\zeta_n^\nu = \nu n, \nu, t_*) = i \cdot 4t_*\,(2\nu\mu_n)^{3/4} \\ &= i \cdot 4t_*\,(2\nu(c_{-1}n + c_0 + c_1/n + \cdots))^{3/4} \\ &= i \cdot 4t_*\,\left(c_{-1}(2\nu n) + c_0 2\nu + c_1(2\nu)^2/(2\nu n) + \cdots)\right)^{3/4}. \end{aligned}$$

Introduce the map

$$f(\zeta,t) = \mathcal{F}(\zeta,0,t) : \mathbb{R}\times\mathbb{R}_+ \to i\,\mathbb{R}_+, \qquad f(-\zeta,t) = -f(\zeta,t), \tag{5.3}$$

where the continuous variable ζ corresponds to a position on the real axis which can be thought of as a variable obtained by simultaneously letting $\nu \to 0^+$ and $n \to +\infty$. Assume that

$$a_n(t,\nu) = \mathcal{F}(n\nu,\nu,t) = f(n\nu,t) + e_n(\nu,t), \tag{5.4}$$

in which $e_n(\nu, t)$ is a small error term that goes to 0 as $\nu \to 0^+$. Thus, formally we have

$$\begin{aligned} 2\nu \sum_{\ell \neq n} \frac{1}{a_n(t,\nu) - a_\ell(t,\nu)} &\simeq 2\nu \sum_{\ell \neq n} \frac{1}{f(n\nu, t) - f(\ell\nu, t)} \\ &\xrightarrow{\nu \to 0^+} P.V. \int_{-\infty}^{\infty} \frac{d\zeta'}{f(\zeta, t) - f(\zeta', t)}. \end{aligned} \tag{5.5}$$

Moreover, this approximation shows that representation (5.4) is valid for all time if it is true at $t = t_*$. A rigorous analysis of approximation (5.5) has been performed in the context of vortex sheets in [10]. It is then clear that the pair of equations (5.2a, b) satisfy the following property.

PROPERTY 5.1. *The continuum limit of the CDS and the pole expansion is the parametric system of integro-differential equations defined for any x such that $\forall \zeta \in \mathbb{R}$, $x \neq f(\zeta, t)$, by*

$$\begin{aligned} u(x,t) &= \frac{x}{t} - \int_{-\infty}^{\infty} \frac{d\zeta'}{x - f(\zeta', t)}, \\ \frac{\partial f}{\partial t}(\zeta, t) &= \frac{f(\zeta, t)}{t} - P.V. \int_{-\infty}^{\infty} \frac{d\zeta'}{f(\zeta, t) - f(\zeta', t)}. \end{aligned}$$

This property also can be expressed as

$$\frac{\partial f}{\partial t}(\zeta, t) = \frac{f(\zeta, t)}{t} - f(\zeta, t)\, P.V. \int_{-\infty}^{\infty} \frac{d\zeta'}{f^2(\zeta, t) - f^2(\zeta', t)} \tag{5.6}$$

and

$$u(x,t) = \frac{x}{t} - x \int_{-\infty}^{\infty} \frac{d\zeta'}{x^2 - f^2(\zeta', t)}, \qquad x \neq f(\zeta, t). \tag{5.7}$$

Equation (5.7) defines the branch cuts of the inviscid solution as the set of complex x-points for which $x = f(\zeta, t)$, while equation (5.6) defines the dynamics of these branch cuts.

Since the poles are located on the imaginary axis, one can make the additional assumption that $f(\zeta, t) = i\, g(\zeta, t)$, where $g(\zeta, t) : \mathbb{R} \times \mathbb{R}_+ \to \mathbb{R}$. Then from (5.7) we find

$$u(x,t) = \frac{x}{t} - 2x \int_{0}^{\infty} \frac{d\zeta'}{x^2 + g^2(\zeta', t)}, \qquad x \neq i\, g(\zeta, t). \tag{5.8}$$

We then define the density function $\rho(z, t)$ as

$$\rho(z, t) = \frac{1}{g_\zeta(\zeta, t)}, \tag{5.9}$$

where $z = g(\zeta, t)$. Then $d\zeta' = \rho(z', t)\, dz'$ and we introduce this change of variable in (5.8) to obtain

$$u(x,t) = \frac{x}{t} - 2x \int_{0}^{\infty} \frac{\rho(z; t)}{x^2 + z^2}\, dz.$$

As a converse to the procedure of section 3, case (i) $t = t_*$, the pole positions at t_* can be recovered from the cumulative distribution function σ (see Definition 2.1):

$$\sigma(\beta; \beta_{\max}, t) = \int_0^{\beta} \rho(\xi; t)\, d\xi \quad \text{for } |\beta| \leq \beta_{\max} \tag{5.10}$$

and, in particular, for $t = t_*$, $\rho(\beta; t_*) = \frac{2\sqrt{3}}{\pi}(4t_*)^{-4/3}|\beta|^{1/3}$, so

$$\begin{aligned}\sigma(\beta; \beta_{\max}, t_*) &= \int_0^{\beta_*} \frac{2\sqrt{3}}{\pi}(4t_*)^{-4/3}\xi^{1/3}\, d\xi \\ &= \left(\frac{2\pi}{3\sqrt{3}}\right)^{-1} \left(\frac{\beta_*}{4t_*}\right)^{4/3}.\end{aligned}$$

Inverting this relation in terms of β_*, we find that

$$\beta_* = 4t_* \left(\frac{2\pi}{3\sqrt{3}}\sigma_*\right)^{3/4}. \tag{5.11}$$

In order to recover the correct discretization, it suffices to choose

$$\sigma_* = \sigma_n(t_*, \nu) = 2\nu\mu_n \left(\frac{2\pi}{3\sqrt{3}}\right)^{-1}, \tag{5.12}$$

where $\mu_n = \frac{2\pi}{3\sqrt{3}}(n - \frac{1}{3}) + \mathcal{O}(1/n)$ as $n \to +\infty$ (see [18, section 4.1]). Therefore,

$$\sigma_* = 2\nu(n - 1/3) + \mathcal{O}(1/n) \quad \text{as } n \to +\infty, \tag{5.13}$$

and

$$\beta_* = \beta_n(t_*, \nu) = 4t_* \left(2\nu\mu_n\right)^{3/4}. \tag{5.14}$$

Similar computations can be found in [21].

6. Uniform asymptotic expansion in $(0, t_*]$ of the spatial Fourier transform of the inviscid solution $\hat{u}(k, t)$ as $k \to +\infty$.

The analyticity properties of the inviscid solution also can be analyzed by describing the asymptotic behavior of its Fourier transform (see [13, 20]). We find a uniform asymptotic expansion as $k \to +\infty$ of the Fourier transform of the inviscid solution in a neighborhood of $t = t_*$, where two second-order branch points $\pm x_s(t)$ coalesce into a third-order branch point at the origin $x_s(t_*) = 0$. Thus, we clarify the seemingly discontinuous change of behavior of $\hat{u}(k, t)$ at t_* presented in [13]. This result is resumed in the following theorem.

THEOREM 6.1. *The uniform asymptotic expansion of the Fourier transform of the inviscid solution for* $0 < t \leq t_*$ *is*

$$\hat{u}(k, t) = \mathcal{C}_0 \cdot (tk)^{-4/3} Ai\left[(-3ikx_s(t)/2)^{2/3}\right]\left(1 + \mathcal{O}\left(k^{-1}\right)\right) \quad \textit{as } k \to +\infty.$$

Thus from the asymptotic property of the Airy function and its value at the origin $Ai(0)$ *we have*

$$\hat{u}(k, t) \sim \begin{cases} \mathcal{C}_1(t) \cdot (t_* - t)^{-1/4}\, k^{-3/2}\, e^{-k\,|x_s(t)|} & 0 < t < t_* \\ \mathcal{C}_2 \cdot (t_* k)^{-4/3} & t = t_* \end{cases} \quad \textit{as } k \to +\infty.$$

Proof. In [13], Fournier and Frisch derive the asymptotic behavior of the inviscid solution via the so-called Fourier–Lagrangian (F–L) representation, which is valid up to the time where the relation $x(x_0,t) = x_0 + tu_0(x_0)$ is invertible, i.e., up to $t_* = -(\inf_{x_0} u_0'(x_0))^{-1}$. There is a discontinuous change in the behavior of $\hat{u}(k,t)$ in $k^{-3/2}\exp(-k|x_s(t)|)$ before t_* to $(t_*k)^{-4/3}$ at t_*, which arises from the fact that the two saddle points of multiplicity 1 for $0 < t < t_*$ coalesce at the origin to form a saddle point of multiplicity 2 at $t = t_*$. The F–L representation is found by changing variables from the Eulerian coordinate to the Lagrangian coordinate, followed by an integration by parts:

$$\begin{aligned}\hat{u}(k,t) &= \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} e^{-ikx}u(x,t)\,dx = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} e^{-ikx(x_0,t)}u_0(x_0)\frac{\partial x}{\partial x_0}dx_0\\ &= \frac{1}{\sqrt{2\pi}ik}\int_{-\infty}^{\infty} e^{-ikx(x_0,t)}u_0'(x_0)\,dx_0 \qquad (k\neq 0).\end{aligned}$$

For $u_0(x) = 4x^3 - x/t_*$, $x(x_0,t) = 4tx_0^3 + x_0(1-t/t_*)$, we find

$$\hat{u}(k,t) = \frac{1}{\sqrt{2\pi}ik}\int_{-\infty}^{\infty}\exp\left\{-12ikt\left(\frac{x_0^3}{3} - \frac{\alpha}{6}\,x_0\right)\right\}u_0'(x_0)\,dx_0,$$

where $2\alpha = 1/t_* - 1/t$. Let $\lambda = -12ikt$; then we are interested in finding the behavior of $\hat{u}(k,t)$ as $k\to+\infty$, that is, the behavior as $\lambda\to\infty$ of the integral

$$\int_{-\infty}^{\infty}\exp\left\{\lambda\left(\frac{x_0^3}{3} - \frac{\alpha}{6}\,x_0\right)\right\}u_0'(x_0)\,dx_0. \tag{6.1}$$

The saddle points of the integrand occur when $\partial x/\partial x_0 = 0$; thus

$$x_0 = x_0^{\pm}(t) = \pm\sqrt{\frac{\alpha}{6}} = \pm\sqrt[3]{\frac{x_s(t)}{8t}} \Rightarrow x\left(x_0^{\pm}(t)\right) = \pm x_s(t).$$

At $t = t_*$, $x_0^{\pm}(t_*) = 0$, and the two saddle points of multiplicity 1 have coalesced into a saddle point of multiplicity 2 at the origin. Let

$$f(x_0) = \frac{x(x_0,t)}{12t} = \frac{x_0^3}{3} - \frac{\alpha}{6}\,x_0,$$

and recall that $x_s(t) = t(2\alpha/3)^{3/2}$ (see (C.4)). Then

$$f(x_0^{\pm}(t)) = -\frac{2}{3}x_0^{\pm}(t)^3 = \mp\frac{x_s(t)}{12t}.$$

We introduce the coefficients

$$\begin{aligned}\zeta^{3/2} &= \frac{3}{4}\left(f(x_0^-(t)) - f(x_0^+(t))\right) = \frac{3}{2}f(x_0^-(t)) = \frac{x_s(t)}{8t},\\ \eta &= \frac{1}{2}\left(f(x_0^-(t)) + f(x_0^+(t))\right) = 0,\end{aligned}$$

which arise in the construction of a uniform asymptotic expansion of an integral with two coalescing saddle points. The integral defined in (6.1) is already in a format appropriate for such a derivation. Indeed, it is an integral of the form

$$I(\lambda;\zeta,\eta) = \int_{\mathcal{C}}\exp\left\{\lambda\left(u^3/3 - \zeta u + \eta\right)\right\}\phi_0(u)\,du,$$

where $\lambda \to \infty$. Thus the 1–1 analytic transformation $x_0 \leftrightarrow u$ given by the equation $f(x_0) = u^3/3 - \zeta u + \eta$ is simply the identity $x_0 \equiv u$. Therefore, the time-uniform asymptotic expansion of the spatial Fourier transform of the solution $\hat{u}(k,t)$ is immediately found in terms of the Airy function and its derivative (cf. [11, 23, section VII-4]). Let

$$a_0 = \frac{1}{2}\left[u_0'(\zeta^{1/2}) + u_0'(-\zeta^{1/2})\right], \qquad b_0 = \frac{1}{2\zeta^{1/2}}\left[u_0'(\zeta^{1/2}) - u_0'(-\zeta^{1/2})\right],$$

then

$$\hat{u}(k,t) = \frac{e^{-\lambda\eta}}{\sqrt{2\pi}ik} \cdot 2\pi i \left[\frac{\mathrm{Ai}\left[\lambda^{2/3}\zeta\right]}{\lambda^{1/3}}(a_0 + \mathcal{O}(1/\lambda)) + \frac{\mathrm{Ai}'\left[\lambda^{2/3}\zeta\right]}{\lambda^{2/3}}(b_0 + \mathcal{O}(1/\lambda))\right]$$

as $\lambda(k) = -12ikt \to \infty$. Since $\eta = 0$, $\zeta^{3/2} = x_s(t)/8t$, $\zeta^{1/2} = x_0^+(t)$, $u_0'(x_0) = 12x_0^2 - 1/t_*$, $a_0 = u_0'(x_0^\pm(t)) = 1/t$, $b_0 = 0$, and we obtain the asymptotic behavior of $\hat{u}(k,t)$ as $k \to +\infty$ uniform in a compact interval containing $t = t_*$:

$$\hat{u}(k,t) = \mathcal{C}_0 \cdot (tk)^{-4/3}\mathrm{Ai}\left[(-3ikx_s(t)/2)^{2/3}\right]\left(1 + \mathcal{O}\left(k^{-1}\right)\right) \quad \text{as } k \to +\infty, \tag{6.2}$$

where $\mathcal{C}_0$ is an appropriate numerical constant. Note that (6.2) can be obtained without recourse to this method by a classical asymptotic analysis in which one would express the expansion in terms of the Airy function. We choose this derivation due to the simplicity of its construction. For $0 < t < t_*$, using the fact that

$$\mathrm{Ai}(z) = \frac{e^{-\frac{2}{3}z^{3/2}}}{2\sqrt{\pi}z^{1/4}}\left(1 + \mathcal{O}\left(z^{-3/2}\right)\right) \quad \text{as } z \to \infty \text{ in } |\arg z| < \pi$$

and for $t = t_*$, and by evaluating $\mathrm{Ai}(0) = 3^{-2/3}/\Gamma(2/3)$, we obtain the asymptotic behavior of $\hat{u}(k,t)$ as $k \to +\infty$ for $0 < t \le t_*$ described in the second part of Theorem 6.1, in which $\mathcal{C}_1(t)$ is a constant depending on t and $\mathcal{C}_2$ is a numerical constant. These expansions are consistent with the fact that the Fourier transform of an analytic function with a branch-point singularity at $x_s = \Re x_s + i\Im y_s$ of the form (cf. [20])

$$v(z) \sim (z - x_s)^\mu, \qquad \mu \notin \mathbb{Z},$$

has an asymptotic behavior of the form

$$\hat{v}(k) \sim k^{-(\mu+1)}e^{-k\Im x_s}e^{ik\Re x_s} \quad \text{as } k \to +\infty.$$

Note that the expansion for $t > t_*$ obtained from (6.2) yields the incorrect behavior $|\hat{u}(k,t)| \sim \mathcal{C}_1(t) \cdot (t - t_*)^{-1/4}\, k^{-3/2}$, which is valid only for moderate wave numbers of the form $1 \ll k \le 1/|x_s|$. This is due to the fact that the formal F–L representation is no longer valid beyond t_*. The correct behavior after t_* of the form $|\hat{u}_I(k,t)| \sim \mathcal{C}_3(t) \cdot (t - t_*)^{1/2}k^{-1}$ for $k > 1/|x_s|$ which reflects the presence of a shock then must be obtained by following the work of Fournier and Frisch in [13]. The two expansions agree when $k \simeq 1/|x_s|$, giving a behavior of the form $|\hat{u}(k,t)|, |\hat{u}_I(k,t)| \sim \mathcal{C}_4(t) \cdot (t - t_*)^2$ for t close to t_* (see [13]).

Appendix A. On the generic nature of the initial data. Caflisch et al. characterize geometrically generic singularities for nonlinear hyperbolic systems in [9] in the following way: given a PDE and its initial data, a singularity is generic if, under perturbation of the "initial data," the singularity is of one of the stable types, namely, a fold corresponding to a square-root branch point in z for each t or a cusp corresponding to a cube root branch point which occurs when the two square root branch points collide. They show that these are the only stable singularity types for the inviscid BE. Loosely, they define stability as the property that under perturbation of the initial data, the perturbed solution will have the same singularity type as the original problem, i.e., either a fold or a cusp. Note that the formation of a cube root singularity must stem from a "tangential" collision of the square root branch points, i.e., one where the branch points travel at the same characteristic speed. In case of a "nontangential" collision of square root branch points travelling at different characteristic speeds, the resulting singularity remains a square root branch point. For more details see [9].

Fournier and Frisch characterized generic singularities and corresponding generic initial data for the inviscid BE in [13]. This description is based on a local analysis of the singularity and takes into account the Gallilean invariance of the PDE and its invariance under translation of the reference frame. This was reformulated in Bessis and Fournier's first paper [4].

Appendix B. Cardan's formula. The roots of a cubic polynomial are given by the well-known formula of Cardan (cf. [1, section 3.8.2]). We state this formula to clarify the choices that are made in choosing the branches of the algebraic functions which define the saddle points in the expansions: let λ, a, b, $c \in \mathbb{C}$; then the roots of the equation

$$\lambda^3 + a\lambda^2 + b\lambda + c = 0 \tag{B.1}$$

are obtained by setting

$$A = a/3, \quad B = b/3, \quad \alpha = A^2 - B, \quad \zeta = 2A^3 - 3AB + c.$$

Let $\lambda = x - A$. Then (B.1) becomes

$$x^3 - 3\alpha x + \zeta = 0. \tag{B.2}$$

Let $\omega = e^{2\pi i/3}$ be a cube root of unity; then the three roots of (B.2) are

$$\left\{\begin{array}{l} x_0 = \omega\mathcal{A} + \omega^2\mathcal{B}, \\ x_1 = \omega^2\mathcal{A} + \omega\mathcal{B}, \\ x_2 = \mathcal{A} + \mathcal{B}, \end{array}\right. \qquad \text{where} \qquad \left\{\begin{array}{l} \Delta = (\zeta/2)^2 - \alpha^3, \\ \mathcal{A} = \sqrt[3]{-\zeta/2 + \sqrt{\Delta}}, \\ \mathcal{B} = \sqrt[3]{-\zeta/2 - \sqrt{\Delta}}. \end{array}\right. \tag{B.3}$$

After choosing a branch for $\mathcal{A}$, one must choose the corresponding branch for $\mathcal{B}$ so that $\mathcal{A} \cdot \mathcal{B} = \alpha^3$. If α and ζ are real, then there are three possibilities depending on the sign of the real discriminant Δ:

(i) $\Delta < 0: \ \mathcal{A}, \mathcal{B} \in \mathbb{C}, \ \mathcal{A} = \overline{\mathcal{B}}, x_0, x_1, x_2 \in \mathbb{R}$;
(ii) $\Delta = 0: \ \mathcal{A} = \mathcal{B} \in \mathbb{R}, \ x_0 = x_1 = -\frac{x_2}{2} \in \mathbb{R}$;
(iii) $\Delta > 0: \ \mathcal{A}, \mathcal{B} \in \mathbb{R}, x_0 = \overline{x_1} \in \mathbb{C}, \ x_2 \in \mathbb{R}$.

Case (iii), which yields two conjugate roots, is the only instance when we can expect to have two equally relevant saddle points, thus allowing for some cancellation in the asymptotic expansion. The relevant roots x_0 and x_1, after separation of real and imaginary parts, are given by

$$x_0 = \overline{x_1} = -\frac{1}{2}(\mathcal{A} + \mathcal{B}) + i\frac{\sqrt{3}}{2}(\mathcal{A} - \mathcal{B}). \tag{B.4}$$

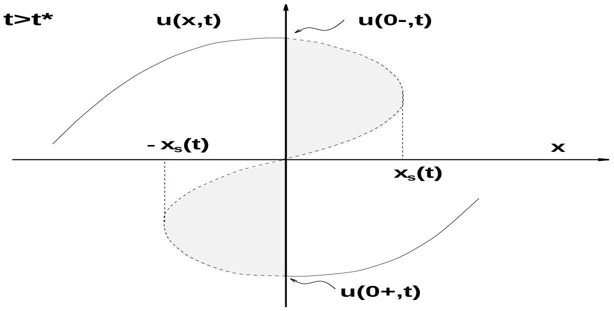

FIG. C.1. *Shock, multivaluedness, branch points, and Maxwell's equal area rule for* $t > t_*$.

Appendix C. Inviscid solution ($\nu = 0$). The inviscid BE states that the velocity of a fluid particle is conserved along certain trajectories, namely, the characteristic lines

$$\dot{x} = \frac{dx}{dt}(t) = u(x(t), t) \tag{C.1}$$

in the (x, t) plane. The implicit solution obtained by the method of characteristics reflects the conservation of the velocity along these special curves:

$$\begin{cases} u = u(x,t) = u_0(x_0(x,t)), \\ x = x_0 + t\, u_0(x_0(x,t)). \end{cases} \tag{C.2}$$

A fluid particle originally at a (Lagrangian) position x_0 in space will be at a new (Eulerian) position x after a certain time t with the same velocity along this line. Let $U = x_0$. Then, substituting $u_0(x) = 4x^3 - x/t_*$ in (C.2), we find that U satisfies the cubic equation

$$U^3 - \frac{\alpha}{2}U - \frac{x}{4t} = 0, \qquad \alpha = \frac{t - t_*}{2tt_*}. \tag{C.3}$$

This defines a three-sheeted Riemann surface for the solution with a third-order branch point at infinity and two opposite second-order branch points at $\pm x_s(t)$ defined by

$$x_s(t) = t\,(2\alpha/3)^{3/2} = i\,(3t_*)^{-3/2}(t_* - t)^{3/2}t^{-1/2}. \tag{C.4}$$

The envelope of the characteristic lines is the branch point since $0 = \frac{\partial x}{\partial x_0} \Rightarrow x\left(x_0^{\pm}(t)\right) = \pm x_s(t)$. The solution is therefore

$$U(x,t) = \begin{cases} (8t)^{-1/3}\left\{\sqrt[3]{x + \sqrt{x^2 - x_s^2}} + \sqrt[3]{x - \sqrt{x^2 - x_s^2}}\right\} & t \neq t_*, \\ \sqrt[3]{\frac{x}{4t_*}} & t = t_*. \end{cases} \tag{C.5}$$

Note the particular (real) values of $u(x,t)$ at the shock at $x = 0$ already found in (3.13):

$$u(0^{\pm}, t) = -U(0^{\pm}, t)/t = \begin{cases} \mp\frac{1}{2}\,(t - t_*)^{1/2}t^{-3/2}t_*^{-1/2} & t \geq t_*, \\ 0 & t < t_*. \end{cases} \tag{C.6}$$

The topology of the three-sheeted Riemann surface given by (C.5) and the interpretation of the shock as the permutation of two Riemann sheets has been fully explained by Bessis and Fournier in [3].

Appendix D. Generalization of the initial data to $u_0(x) = 2nx^{2n-1} - x/t_*$, $n \geq 2$. Although the inviscid singularity resulting from a polynomial of arbitrary odd order of the form $u_0(x) = 2nx^{2n-1} - x/t_*$, $n \in \mathbb{N}$, $n \geq 2$, is no longer generic (see [13, p. 707]), it is still interesting to describe the behavior of the inviscid solution and the related asymptotic density of poles. We first describe the inviscid solution and its branch points: substituting $u_0(x)$ in (C.2), we find that U is a root of the polynomial of degree $2n-1$. Let

$$\alpha_n(t) = \frac{t - t_*}{ntt_*} \quad \text{and} \quad P_n(U) = U^{2n-1} - \frac{\alpha_n(t)}{2}\,U - \frac{x}{2nt} = 0.$$

Let $U_s(t)$ satisfy

$$0 = \frac{\partial x}{\partial U}(U_s(t)) = P_n'(U_s(t)) \Longrightarrow U_s(t) = \left(\frac{\alpha_n(t)/2}{2n-1}\right)^{1/(2n-2)}.$$

The $2n-2$ branch points of the inviscid solution are then given by

$$x_s(t) = x(U_s(t)) = 2ntU_s\left(U_s^{2n-2} - \alpha_n(t)/2\right) = \mathcal{C}_n \cdot (t - t_*)^{\frac{2n-1}{2n-2}} \cdot t_*^{-\frac{2n-1}{2n-2}} \cdot t^{-\frac{1}{2n-2}},$$

where $\mathcal{C}_n = -(2n-2)(2n-1)^{\frac{2n-1}{2n-2}}(2n)^{-\frac{1}{2n-2}}$. Notice that the $2n-2$ branch points coalesce at the origin at t_*. Since $U(0^{\pm}, t) = \pm\pi t\rho(0; t) = \pm(\alpha_n(t)/2)^{\frac{1}{2n-2}}$ (cf. (3.9)), the (real) value of the inviscid solution at the origin (shock) is given by

$$u(0^{\pm}, t) = -U(0^{\pm}, t)/t = \mp\pi\rho(0; t) = \begin{cases} \mp(t - t_*)^{\frac{1}{2n-2}}(2nt_*)^{\frac{-1}{2n-2}}t^{-\frac{2n-1}{2n-2}} & t \geq t_*, \\ 0 & t < t_*. \end{cases}$$

The limiting pole density and inviscid limit are obtained using results from [17], where it is shown that the relevant saddle points in the asymptotic analysis of $E_\nu(i\beta, t_*)$ are

$$z_0(\beta; t_*) = \exp\left(\frac{i\pi}{4n-2}\right)\left(\frac{\beta}{2nt_*}\right)^{\frac{1}{2n-1}}, \quad z_1 = -\overline{z_0}.$$

Since

$$\rho(\beta; t_*) = \frac{\Re z_0(\beta; t_*)}{\pi t_*}$$

and further results in [17] concern the asymptotic behavior of the zeros $\mu_{k,n}$ of $\mathcal{F}_n(\mu) = \int_{-\infty}^{\infty} e^{\mu(2niz - z^{2n})}dz$, we have the following result.

Property D.1. *For any integer $n \geq 2$, the density of poles at the shock time t_* arising from the initial data $u_0(x) = 2nx^{2n-1} - x/t_*$ is*

$$\rho(\beta; t_*) = \frac{1}{\pi}\cos\left(\frac{\pi}{4n-2}\right)\left(\frac{\beta}{2nt_*^{2n}}\right)^{\frac{1}{2n-1}}.$$

The density at the origin ($z = 0$) *is*

$$\rho(0;t) = \begin{cases} \frac{1}{\pi t}\left(\frac{t-t_*}{2ntt_*}\right)^{\frac{1}{2n-2}} & t > t_*, \\ 0 & t \leq t_*. \end{cases}$$

Moreover at t_*, *the* k*th ordered pole of the solution for* $\nu > 0$ *is located at*

$$a_{k,n}(t_*, \nu) = i \cdot 2nt_* \left(2\nu\mu_{k,n}\right)^{\frac{2n-1}{2n}},$$

where the positive coefficients $\mu_{k,n}$ *are asymptotically given by*

$$\mu_{k,n} = \frac{\pi}{4n-2}\sec\left(\frac{\pi}{4n-2}\right)\left(\frac{n-1}{2n-1} + 1 + 2k\right) + \mathcal{O}\left(\frac{1}{k}\right) \quad \text{as } k \to +\infty.$$

Higher order approximations of $\mu_{k,n}$ are provided in [17]. At $t = t_*$, the inviscid solution can be found via the complex-valued limiting pole density $\rho(\beta; t_*)$ and the pole expansion as in (3.11) or via the characteristic equation as in Appendix C. The resulting singularity is a branch point of order $2n-1$, which arises from the coalescence of $n-1$ pair(s) of conjugate branch points of order $2n-2$ (see [13, p. 707]):

$$u(x, t_*) = \frac{x}{t_*} - \left(\frac{x}{2nt_*^{2n}}\right)^{\frac{1}{2n-1}}.$$
