ON THE MELTING OF ICE BALLS[*]

MIGUEL A. HERRERO[†] AND JUAN J. L. VELÁZQUEZ[†]

Abstract. We consider here the problem of describing the melting of an ice ball surrounded by water. The corresponding mathematical model consists of the Stefan problem with radial symmetry. We obtain asymptotic expansions for the radius of the melting ball which turn out to be of a different nature according to the cases $N \geq 3$ and $N = 2$, N being the space dimension. The methods employed combine matched asymptotic expansion techniques, a priori estimates, and topological results.

Key words. Stefan problem, asymptotic behavior, matched asymptotic expansions, a priori estimates

1. Introduction.

This paper is concerned with radial solutions of the following Stefan problem. To find functions $\theta(r,t)$ and $R(t)$ such that

$$\theta_t = \theta_{rr} + \left(\frac{N-1}{r}\right)\theta_r \quad \text{for } r > R(t) \quad \text{and} \quad t > 0 \tag{1.1a}$$

$$\theta(r,0) = \theta_0(r) \quad \text{for } r > R(0), \tag{1.1b}$$

$$\theta(r,t) = 0 \quad \text{if } r \leq R(t) \quad \text{and} \quad t > 0, \tag{1.1c}$$

$$\theta_r(R(t),t) = -\dot{R}(t) \quad \text{if } t > 0. \tag{1.1d}$$

Here $r = |x|$, $x \in \mathbb{R}^N$, and $N \geq 2$. As it stands, (1.1) is a model for describing the melting of a ball of ice surrounded by water. $\theta(r,t)$ denotes the temperature of the medium, which is assumed to be zero at the ice phase. We do not require $\theta_0(r)$ to be positive for every $r > R(0)$, so that the existence of regions where water is initially undercooled is not ruled out.

In view of classical results, one expects that under fairly general circumstances (for instance, if $\theta_0(r)$ is nonnegative or if undercooling does not affect the dynamics of the problem much) the ice ball will entirely melt at some finite time $t = T < \infty$. We shall address the following here.

Question. What is the speed at which ice balls collapse? In other words, what is the asymptotic behavior of $R(t)$ as $t \uparrow T$?

We shall show in what follows that there is a countable family of possible behaviors for $R(t)$ as the melting time $t = T$ is approached. To describe our results, it will be convenient to consider separately the cases $N = 2$ and $N \geq 3$. In the bidimensional situation we prove the following theorem.

Theorem 1.1. *Assume that $N = 2$. For any $T > 0$, there exist solutions of* (1.1) *such that the corresponding interfaces behave as $t \uparrow T$ in one of the following ways:*

$$R(t) = B(T-t)^{\frac{1}{2}} e^{-\frac{\sqrt{2}}{2}|\log(T-t)|^{\frac{1}{2}}} |\log(T-t)|^{\frac{1}{4\sqrt{\log(T-t)}}-\frac{1}{4}} \cdot (1+o(1)), \tag{1.2}$$

where B is a fixed positive constant, or

$$R(t) = C(T-t)^{\frac{l}{2}} |\log(T-t)|^{-\frac{l}{2(l-1)}} (1+o(1)), \tag{1.3}$$

where C is an arbitrary positive constant and l is any integer such that $l \geq 2$.

Concerning the case of higher dimensions, we obtain the following theorem.

Theorem 1.2. *Assume that $N \geq 3$. For any $T > 0$, there exist solutions of* (1.1) *such that the corresponding interfaces behave as $t \uparrow T$ in one of the following ways:*

$$R(t) = B_N (T-t)^{\frac{1}{2}} |\log(T-t)|^{-\frac{1}{N-2}} (1+o(1)), \tag{1.4}$$

where B_N is a fixed positive constant depending on the dimension N,

$$\textit{or} \qquad R(t) = C(T-t)^{\frac{l}{2}} (1+o(1)), \tag{1.5}$$

where C is an arbitrary positive constant and l is any integer number such that $l \geq 2$.

Let us remark briefly on Theorems 1.1 and 1.2. To begin with, we do not preclude here the existence of other possible types of shrinking spheres besides those described in (1.2)–(1.5), although it seems very unlikely in view of the arguments leading to the proofs of these results. As a matter of fact, we expect (1.2) and (1.4) to provide the generic asymptotics for the case of the classical, not undercooled, Stefan problem. However, no proof of such a statement is given here. It will be apparent from the proofs that (1.3) and (1.5) correspond to problems with small undercooling, i.e., problems where temperature changes sign somewhere for any $t < T$.

We next observe that (1.2)–(1.5) imply that the ice radii $R(t)$ are such that

$$R(t) \ll (T-t)^{\frac{1}{2}} \quad \text{as } t \uparrow T,$$

and the contracting rates are therefore faster than those corresponding to the natural scales of the problem under consideration. In particular, the solutions obtained are not self-similar.

It is worth pointing out that our approach here allows us to obtain further information on the structure of the solutions involved. For instance, asymptotic expansions for the predicted water temperature near the melting ice ball can be obtained as $t \uparrow T$. The corresponding result reads as follows.

Theorem 1.3. *Assume first that $N = 2$. Then the solutions referred to in Theorem* 1.1 *are such that the following expansions hold:*

If (1.2) *occurs, then*

$$\theta(x,T) = D\ e^{-2|\log|x||^{\frac{1}{2}}} |2\log|x||^{\frac{1}{2\sqrt{2|\log|x||}}} (1+o(1)) \quad \textit{as } x \downarrow 0, \tag{1.6}$$

where D is a fixed positive constant.

If (1.3) *occurs, then*

$$\theta(x,T) = D_1 |x|^{2l-2} (|\log|x||)^{-\frac{1}{l-1}} (1+o(1)) \quad \textit{as } x \downarrow 0 \tag{1.7}$$

for some positive constant D_1.

Now suppose that $N \geq 3$. *Then the solutions referred to in Theorem* 1.2 *are such that the following expansions hold:*

If (1.4) *occurs, then*

$$\theta(x,T) = K_N(\log|x|)^{-\frac{2}{N-2}}(1+o(1)) \quad \textit{as } x \downarrow 0, \tag{1.8}$$

where K_N *is a fixed positive constant depending on the dimension* N.

If (1.5) *occurs, then*

$$\theta(x,T) = K_1|x|^{2l-2}(1+o(1)) \quad \textit{as } x \downarrow 0 \tag{1.9}$$

for some positive constant K_1.

Concerning previous related work, it is well known that for $N = 1$ the asymptotic shape of the vanishing ice phase is a space-time wedge which has its tip at $t = T$. We refer for such a case to the paper [AK], where disappearance of one of the phases in a one-dimensional, two-phase Stefan problem is studied by means of functional analysis methods. A different approach, based on matched asymptotics expansion techniques has been developed in [RSP] and [SW].

For instance, in [SW] a formal analysis of (1.1) with (1.1d) replaced by

$$\theta_r(R(t),t) = -\Lambda\dot{R}(t) \quad \text{for } t > 0 \tag{1.10}$$

is performed in the limit $\Lambda \to \infty$. In particular a boundary layer is then identified where an expansion similar to (1.2) and (1.4) takes place. The reader is referred to [DH], [HD1], [HD2], and [S] for related work, as well as to [R] and [M] for a general outline of results concerning Stefan problems.

We conclude this introduction by describing the plan of the paper. Some preliminary material is gathered in section 2. Section 3 is then devoted to deriving the results in Theorems 1.1–1.3 by means of matched asymptotic expansion techniques in a way which we believe to be conceptually simpler than the study done in [RSP], [SW] for (1.1a)–(1.1c) and (1.10). Besides its heuristic interest, this formal method detects a number of previously unnoticed patterns and provides the basic lines along which a rigorous proof is subsequently implemented. The arguments in section 3 are made rigorous in sections 4 to 7. To be precise, the sought-for solutions are obtained by means of a topological fixed point argument. This is a classical approach in the literature on partial differential equations (PDEs) which, to mention but a few examples, has been used recently to analyze singularity patterns arising in parabolic equations in the works [B1], [B2], [AV], and [HV3], among others. The basic aspects of our topological method are presented in section 4.

Sections 5 and 6 are then devoted to providing the various estimates required to yield (1.2) in Theorem 1.1 and (1.6) in Theorem 1.3. Once this has been achieved, we conclude by sketching in section 7 those modifications required to obtain (1.3)–(1.5) as well as (1.7)–(1.9).

2. Preliminaries.

Let $(\theta(r,t),\, R(t))$ be a solution of (1.1). It will be convenient for our purposes to introduce a new variable $u(r,t)$ given by

$$u(r,t) = \int_{R(t)}^{r} \xi^{1-N}d\xi \int_{R(t)}^{\xi} s^{N-1}(\theta(s,t)+1)\,ds \quad \text{if } r > R(t), \tag{2.1a}$$

$$u(r,t) = 0 \quad \text{if } r \leq R(t). \tag{2.1b}$$

We then readily see that $u(r,t)$ satisfies

$$u_t = u_{rr} + \left(\frac{N-1}{r}\right) u_r - H(u) \quad \text{for } x \in \mathbb{R}^N, \quad t > 0, \tag{2.2a}$$

where $H(u)$ is the standard Heaviside function; i.e., $H(u) = 1$ whenever $u > 0$ and $H(u) = 0$ otherwise. Equation (2.2a) is to be complemented with the initial condition

$$u(r,0) = \int_{R(0)}^{r} \xi^{1-N} d\xi \int_{R(0)}^{\xi} s^{N-1}(\theta(s,0)+1)\, ds. \tag{2.2b}$$

For ease of notation, we shall often use the symbols Δ and ∇ instead of their radial counterparts when dealing with (2.2a) and related equations. Further, we introduce self-similar variables as follows:

$$u(r,t) = (T-t)\Phi(y,\tau), \quad y = r(T-t)^{-\frac{1}{2}}, \quad \tau = -\log(T-t); \tag{2.3}$$

we define a rescaled free boundary $\varepsilon(\tau)$ given by

$$\varepsilon(\tau) = R(t)e^{\frac{\tau}{2}} \equiv R(t)(T-t)^{-\frac{1}{2}}. \tag{2.4}$$

It is then readily seen that Φ satisfies the following equation:

$$\begin{aligned} \Phi_\tau &= \Phi_{yy} + \left(\frac{N-1}{y} - \frac{y}{2}\right)\Phi_y - H(\Phi) \\ &\equiv \Delta\Phi - \frac{1}{2}y\nabla\Phi + \Phi - (1-\chi_\varepsilon) \\ &\equiv A\Phi - (1-\chi_\varepsilon), \end{aligned} \tag{2.5}$$

where $\chi_\varepsilon(y) = 1$ for $y < \varepsilon(\tau)$ and $\chi_\varepsilon(y) = 0$ otherwise. The linear operator A will play a key role in our approach. Consider the weighted space

$$L^2_{w,r}(\mathbb{R}^+) = \left\{ f \in L^2_{\text{loc}}(\mathbb{R}^+) : \|f\|^2 = \int_0^\infty y^{N-1}|f(y)|^2 e^{\frac{-y^2}{4}}\, dy < \infty \right\}.$$

Clearly $L^2_{w,r}(\mathbb{R}^+)$ is a Hilbert space when endowed with the norm

$$\|f\|^2 = \langle f, f\rangle = \int_0^\infty y^{N-1}|f(y)|^2 e^{\frac{-y^2}{4}}\, dy,$$

where we have used the symbol $\langle\ ,\ \rangle$ to denote the corresponding scalar product. For any positive integer k, one may then define the Hilbert spaces $H^k_{w,r}(\mathbb{R}^+)$ in a straightforward way. By classical spectral theory, one then has that the radial operator A in (2.5) is self-adjoint in $L^2_{w,r}(\mathbb{R}^+)$ with domain $D(A) = H^2_{w,r}(\mathbb{R}^+)$. Furthermore, the eigenvalues of A consist of the sequence

$$\lambda_k = 1-k, \quad k = 0,1,2,\ldots. \tag{2.6a}$$

The corresponding eigenfunctions can be written in the form

$$\varphi_k(y) = \begin{cases} c_k L_k\left(\frac{y^2}{4}\right) & \text{if } N = 2, \quad k = 0,1,2,\ldots, \\ c_{k,N} L_k^{\frac{N-2}{N}}\left(\frac{y^2}{4}\right) & \text{if } N \geq 3, \quad k = 0,1,2,\ldots, \end{cases} \tag{2.6b}$$

where $L_k(x)$ (resp. $L_k^{(N-2)/N}(x)$) denotes the standard kth Laguerre polynomial (resp. the modified $L_k^{\alpha}(x)$ Laguerre polynomial with $\alpha = \frac{N-2}{N}$), cf., for instance, [L] and [MF] for a review of properties of such functions. The normalization constants c_k and $c_{k,N}$ in (2.6b) are selected so that

$$\|\varphi_k\| = 1 \quad \text{for any } k. \tag{2.6c}$$

By classical results (cf., for instance, [MF]), we readily see that

$$c_{k,N}^2 = \frac{\Gamma(\frac{N}{2})\Gamma(k+1)}{2^N \left(\Gamma\left(\frac{N-2}{2}+k+1\right)\right)^2 \pi^{\frac{N}{2}}}, \tag{2.7a}$$

$$c_k^2 = \frac{1}{4\pi\Gamma(k+1)}. \tag{2.7b}$$

The following a priori bound on solutions of (2.5) is important for our purposes:

$$\Phi(y,\tau) \le C(y^2+1) \quad \text{for some } C>0 \text{ and any } y>0, \tau>0. \tag{2.8}$$

Estimate (2.8) can be obtained, for instance, from the Bernstein-type bound

$$|\nabla\Phi(y,\tau)| \le C \quad \text{for any } y \text{ and any } \tau > 0,$$

which holds for solutions of (2.5) under rather loose assumptions on their initial values (cf., for instance, [HV1] for a related result). Arguing as in [HV2], we may deduce from (2.8) the following convergence result:

$$\begin{aligned} &\Phi(y,t) \to \frac{y^2}{4} \quad \text{as } t \to \infty, \\ &\text{uniformly on sets } y \le M < \infty. \end{aligned} \tag{2.9}$$

Since (2.9) plays an important role in what follows, we shall briefly sketch here the main ideas in its proof and refer to [HV2] for details. To begin with, an energy argument like that in [GK] shows that

$$\Phi(y,\tau) \to \Phi^*(y) \quad \tau \to \infty$$

uniformly on compact sets of $|y|$, where Φ^* is a stationary solution of (2.5). Arguing as in Lemma 4.3 of [HV2], we see that either $\lim_{\tau\to\infty} \varepsilon(\tau) = 0$ or $\lim_{\tau\to\infty} \varepsilon(\tau) = 1$. The second case would allow for a possible stationary solution $\Phi^*(y) = 1$, which would in turn yield that $\Phi(0,\tau) > 0$ for $\tau \gg 1$. This in particular implies that the ice ball has already disappeared for some time $t < T$, which is a contradiction. On the other hand, the case $\lim_{\tau\to\infty} \varepsilon(r) = 0$ gives rise to two possible stationary solutions satisfying (2.8), namely

$$\Phi^*(y) = 0, \qquad \Phi^*(y) = \frac{y^2}{4}.$$

To rule out the first possibility, we argue by contradiction as follows. Assume that $\lim_{\tau\to\infty} \Phi(y,r) = 0$ uniformly on sets $|y| \le R < \infty$. Then for fixed $A > 0$ and $\varepsilon > 0$ we may select $\tau \gg 1$ so that $\Phi(y,\tau) \le \varepsilon$ for $\tau \ge \tau_0$ and $|y| \le A$. A quick glance at equation (2.5) reveals then that $\Phi(y,\tau)$ is at most of order $O(\varepsilon e^{\tau-\tau_0})$ for $\tau > \tau_0$

at distances $y \sim Ae^{(\tau-\tau_0)/2}$. As a matter of fact, this estimate is readily suggested by dropping the absorption term $H(\Phi)$ in (2.5) and then checking how bounds on initial values propagate along characteristics for the resulting equation. In terms of the variable $u(x,t)$, one is thus led to a bound of the type

$$u(x,t) \le \varepsilon x^2 \quad \text{for} \quad x \le \delta, \quad t_0 < t < T, \tag{2.10}$$

where $\delta = \delta(\varepsilon) > 0$ is a small (but fixed) positive number and t_0 is close enough to T. On the other hand, our assumption $\Phi^*(y) = 0$ carries into

$$u(x,t_0) \le \varepsilon(T-t_0) \quad \text{for } x \le A. \tag{2.11}$$

From (2.10) and (2.11), a barrier argument as the one in [EK] or [HV1] yields that $u(x,T) = 0$ for some $x > 0$, thus contradicting the assumption that the ice ball collapses exactly at $t = T$. This concludes the proof.

3. The formal argument.

This section is devoted to showing how to obtain the asymptotic results in Theorems 1.1 and 1.2 by means of formal perturbative methods. While the approach to be described is a nonrigorous one, it is in our opinion the crux of this work. The reason for this statement is that these heuristic methods not only provide deep insight into what to expect but also mark the path along which a rigorous argument can be implemented. This last task will be postponed until sections 4–7.

For definiteness, we shall consider first the case $N = 2$ and remark then about the differences which arise for $N \ge 3$. Our starting point is the convergence result (2.9). Bearing it in mind, we set

$$\psi(y,\tau) = \Phi(y,\tau) - \frac{y^2}{4} \tag{3.1}$$

so that the function $\psi(y,\tau)$ satisfies

$$\psi_\tau = A\psi + \chi_{\varepsilon(\tau)}. \tag{3.2}$$

We now introduce the following ansatz concerning the effect of the term $\chi_{\varepsilon(\tau)}$ in (3.2).

Assumption 3.1. For $|y| \gg \varepsilon(\tau)$ and $\tau \gg 1$, we may replace (3.2) by

$$\psi_\tau = A\psi + \gamma\varepsilon(\tau)^2\delta(y), \tag{3.3}$$

where constant γ is uniquely determined by imposing that

$$\int_{\mathbb{R}^2} \chi_{\varepsilon(\tau)} dy = \gamma\varepsilon(\tau)^2 \int_{\mathbb{R}^2} \delta(y) dy \quad \text{(i.e., } \gamma = \pi). \tag{3.4}$$

We next proceed to derive (1.2) in Theorem 1.1. To this end, we set

$$\Psi(y,\tau) = \sum_{k=0}^{\infty} a_k(\tau)\varphi_k(y) \equiv a_0(\tau)\varphi_0(y) + a_1(\tau)\varphi_1(y) + Q(y,\tau). \tag{3.5}$$

The first two Fourier coefficients would then satisfy

$$\dot{a}_0 = a_0 + \gamma\varepsilon(\tau)^2\langle\varphi_0, \delta(y)\rangle \quad \text{for } \tau \gg 1, \tag{3.6a}$$

$$\dot{a}_1 = \gamma\varepsilon(\tau)^2\langle\varphi_1, \delta(y)\rangle \quad \text{for } \tau \gg 1, \tag{3.6b}$$

whereas the remainder term $Q(y,\tau)$ is such that

$$Q_\tau = AQ + \gamma\varepsilon(\tau)^2 \left(\delta(y) - \sum_{k=0}^{1} \langle\varphi_k, \delta(y)\rangle\varphi_k \right), \tag{3.6c}$$

$$\langle Q, \varphi_k \rangle = 0 \quad \text{for } k = 0, 1. \tag{3.6d}$$

We now introduce the following assumption.

Assumption 3.2. The leading term in (3.5) as $\tau \gg 1$ is $a_1(\tau)\varphi_1(y)$; i.e., evolution in time of $\psi(y, \tau)$ is driven by the eigenfunction corresponding to zero eigenvalue. Moreover, one then expects

$$|\dot{\varepsilon}(\tau)| \ll \varepsilon(\tau) \quad \text{as } \tau \to \infty, \tag{3.7a}$$

$$Q(y, \tau) \sim \gamma \varepsilon(\tau)^2 F(y) \quad \text{as } \tau \to \infty \tag{3.7b}$$

for a suitable function $F(y)$. It then turns out that $F(y)$ satisfies

$$AF + \left(\delta(y) - \sum_{k=0}^{1} \langle \varphi_k, \delta(y) \rangle \varphi_k \right) = 0, \tag{3.8a}$$

$$\langle F, \varphi_k \rangle = 0 \quad \text{for } k = 0, 1. \tag{3.8b}$$

We may now integrate (3.8a) and (3.8b) to obtain

$$F(y) = -\frac{1}{2\pi} \log y + B + O(y^2 |\log y|) \quad \text{for } \varepsilon(\tau) \ll y \le 1, \tag{3.9}$$

where constant B is detemined by the orthogonality conditions (3.8b). On the other hand, since we expect $\lim_{\tau \to \infty} a_k(\tau) = 0$ for $k = 0, 1$, we obtain from (3.6) that

$$a_k(\tau) \sim -\gamma \varphi_k(0) \int_\tau^\infty \varepsilon(s)^2 e^{(1-k)(\tau - s)} ds \quad \text{for } \tau \gg 1, \quad k = 0, 1. \tag{3.10}$$

Putting together (3.5), (3.9), and (3.10), we arrive at

$$\Phi(y, \tau \sim \frac{y^2}{4} - \gamma \sum_{k=0}^{1} \varphi_k(0)\varphi_k(y) \int_\tau^\infty \varepsilon(s)^2 e^{(1-k)(\tau - s)} ds + \gamma \varepsilon(\tau)^2 \left(B - \frac{1}{2\pi} \log y \right) \tag{3.11}$$

whenever

$$\varepsilon(\tau) \ll y \le C \quad \text{with } C > 0 \text{ and } \tau \gg 1.$$

Formula (3.11) provides an outer expansion for $\Phi(y, \tau)$ in regions sufficiently far from the free boundary. To analyze the set where $y \sim \varepsilon(\tau)$, we change variables as follows:

$$\Phi(y, \tau) = (\varepsilon(\tau))^2 w(\xi, \tau), \quad \xi = \frac{y}{\varepsilon(\tau)}. \tag{3.12}$$

Substituting (3.12) into (2.5) readily gives

$$\varepsilon \dot{\varepsilon} w - \dot{\varepsilon} \varepsilon \xi w_\xi + \varepsilon^2 w_\tau = \Delta w - \frac{\xi^2}{2} \xi w_\xi + \varepsilon^2 w - \tilde{\chi}, \tag{3.13}$$

where now $\Delta w = w_{\xi\xi} + \frac{w_\xi}{\xi}$ and $\tilde{\chi}(\xi) = 1$ whenever $\xi > 1$ and is zero elsewhere. After comparing the order of magnitude of the different terms in (3.13), we are led to guess that as $\tau \to \infty$, $w(\xi, \tau) \sim \bar{w}(\xi)$, where $\bar{w}(\xi)$ is the solution of

$$w_{\xi\xi} + \frac{w_\xi}{\xi} = 1 \quad \text{for } \xi > 1, \tag{3.14}$$

$$w(1) = w_\xi(1) = 0;$$

i.e.,

$$\bar{w}(\xi) = \frac{\xi^2}{4} - \frac{1}{2}\log\xi - \frac{1}{4} \quad \text{for } \xi > 1. \tag{3.15}$$

In view of (3.12) and (3.15), we expect that

$$\Phi(y, \tau) \sim \varepsilon^2(\tau)\bar{w}\left(\frac{y}{\varepsilon(\tau)}\right) = \frac{y^2}{4} - \frac{\varepsilon(\tau)^2}{2}\log\left(\frac{y}{\varepsilon(\tau)}\right) - \frac{\varepsilon(\tau)^2}{4} \tag{3.16}$$

for $y \sim \varepsilon(\tau)$ and $\tau \gg 1$.

Matching the inner and outer expansions (3.16) and (3.11), we obtain as a matching condition

$$B\varepsilon(\tau)^2 - \gamma\sum_{k=0}^{1}\varphi_k(0)^2\int_\tau^\infty \varepsilon(s)^2 e^{(1-k)(\tau-s)}ds = \frac{\varepsilon(\tau)^2}{2}\log\varepsilon(\tau) - \frac{\varepsilon(\tau)^2}{4}. \tag{3.17}$$

This is the basic integral equation that determines the position of the rescaled free boundary $\varepsilon(\tau)$. Actually, we claim that (3.17) yields

$$\varepsilon(\tau) \sim Ke^{-\frac{\sqrt{2\tau}}{2}}\tau^{\frac{1}{4\sqrt{\tau}}-\frac{1}{4}} \cdot (1 + o(1)) \quad \text{as } \tau \to \infty, \tag{3.18}$$

where $K = e^{4B}$.

Taking into account (2.4), one readily checks that (3.18) gives (1.2) in Theorem 1.1. For the convenience of the reader we shall briefly sketch the way in which (3.18) can be derived from (3.17). We first observe that a dominated balance argument shows that the leading terms in (3.17) satisfy

$$\frac{\varepsilon(\tau)^2}{4}\log(\varepsilon(\tau)^2) \sim -\gamma\varphi_1(0)^2\int_\tau^\infty \varepsilon(s)^2 ds = -\frac{1}{4}\int_\tau^\infty \varepsilon(s)^2 ds. \tag{3.19}$$

Now set

$$G(\tau) = \int_\tau^\infty \varepsilon(s)^2 ds.$$

Then

$$G(\tau) = -\varepsilon(r)^2,$$

and it follows from (3.19) that

$$\log(\varepsilon(\tau)^2) \sim \log G(\tau) - \log(-\log G(\tau)), \tag{3.20}$$

where here and henceforth all asymptotic equivalences are understood to hold for $r \gg 1$. Hence

$$\varepsilon^2(\log G(\tau) - \log(-\log G(\tau))) \sim -G(\tau)$$

which in turn yields

$$G^{-1}\dot{G}\log G\left(1 - \frac{\log(-\log G)}{\log G} + \cdots\right) = 1,$$

and we obtain after integration

$$\frac{1}{2}(\log G)^2 = \tau\left(1 + \frac{\log(-\log G)}{\log G} + \cdots\right) + C$$

for some constant C. To the first term, the equality above gives $|\log G| \sim (2\tau)^{1/2}$, whence

$$G(\tau) \sim e^{-\sqrt{2\tau}} \quad \text{as } \tau \to \infty \tag{3.21}$$

up to some algebraic factor. From (3.21) and our choice of G, we deduce that

$$\int_\tau^\infty e^{\tau-s}\varepsilon(s)^2 ds \sim \varepsilon(\tau)^2. \tag{3.22}$$

it then follows from (3.22) and (3.17) that

$$\varepsilon(\tau)^2\log(\varepsilon(\tau)^2) = -G(\tau) + 4B\varepsilon(r)^2 + \cdots,$$

whence

$$\frac{\dot{G}}{G}(\log G - \log(-\log G) + 4B + \cdots) = 1.$$

Taking into account (3.21), we then see that

$$\begin{aligned}\frac{1}{2}\frac{d}{d\tau}((\log G)^2) &= \left(1 + \frac{1}{2\sqrt{\tau}}\left(\log\sqrt{2} + \frac{1}{2}\log\tau\right) + \frac{4B}{\sqrt{2\tau}} + \cdots\right)^{-1} \\ &= 1 - \frac{1}{2\sqrt{2}}\frac{\log\tau}{\sqrt{\tau}} - \frac{(\log\sqrt{2} + 4B)}{\sqrt{2\tau}} + \cdots.\end{aligned}$$

Setting $\alpha = \sqrt{2}(\log\sqrt{2} + 4B)$, we obtain

$$\frac{1}{2}(\log G)^2 = \tau - \frac{\tau^{\frac{1}{2}}}{\sqrt{2}}\log\tau - \alpha\tau^{\frac{1}{2}} + \cdots$$

which at once yields

$$G(\tau) \sim K_0 e^{-\sqrt{2\tau}}\tau^{\frac{1}{2\sqrt{\tau}}} \quad \text{with } K_0 = \sqrt{2}e^{4B}. \tag{3.23}$$

Plugging (3.23) and (3.20) into (3.19) and (3.18) follows.

We next set out to describe the way in which (1.3)–(1.5) are obtained. For the ease of presentation, we shall merely sketch the points that give rise to the different behaviors involved. To begin with, we continue to suppose that $N = 2$ and that Assumption 3.1 is in force. We now recast (3.5) in the form

$$\psi(y,\tau) = \sum_{k=0}^{\infty} a_k(\tau)\varphi_k(y) = \sum_{k=0}^{l} a_k(\tau)\varphi_k(y) + Q(y,\tau). \tag{3.24}$$

It is readily seen that formulas (3.6) read in this case as

$$\dot{a}_k = (1-k)a_k + \gamma\varepsilon(\tau)^2\langle\varphi_k, \delta(y)\rangle \quad \text{for } \tau \gg 1, \quad k = 0, 1, \ldots, l, \tag{3.25a}$$

$$Q_\tau = AQ + \gamma\varepsilon(\tau)^2\left(\delta(y) - \sum_{k=0}^{l}\langle\varphi_k, \delta(y)\rangle\varphi_k\right), \tag{3.25b}$$

$$\langle Q, \varphi_k\rangle = 0 \quad \text{for } k = 0, 1, \ldots, l. \tag{3.25c}$$

We now replace Assumption 3.2 by the following.

Assumption 3.3. The leading term in (3.24) as $\tau \gg 1$ is $a_l(\tau)\varphi_l(y)$; i.e., evolution in time of $\psi(y,\tau)$ is driven by the eigenfunction corresponding to the lth eigenvalue. Moreover, one then expects

$$\frac{d}{d\tau}(\varepsilon^2(\tau)) \sim (1-l)\varepsilon^2(\tau) \quad \text{as } \tau \to \infty, \tag{3.26a}$$

$$Q(y,\tau) \sim \gamma\varepsilon(\tau)^2 F(y) \quad \text{as } \tau \to \infty, \tag{3.26b}$$

where $F(y)$ satisfies

$$A_l F + \left(\delta(y) - \sum_{k=0}^{l}\langle\varphi_k, \delta(y)\rangle\varphi_k\right) = 0, k = 0, 1, \ldots, l, \tag{3.27a}$$

$$\langle F, \varphi_k\rangle = 0 \quad \text{for } k = 0, 1, \ldots, l \tag{3.27b}$$

and the operator A_l is given by

$$A_l F \equiv F_{yy} + \left(\frac{1}{y} - \frac{y}{2}\right)F_y + lF. \tag{3.27c}$$

Integrating (3.27), we obtain

$$F(y) = -\frac{1}{2\pi}\log y + \cdots \quad \text{for } \varepsilon(\tau) \ll y \ll 1. \tag{3.28}$$

We point out that no further details on the expansion (3.28) are required to derive the sought-for result (1.3). Arguing as before, we now obtain the following outer expansion for $\Phi(y,\tau)$:

$$\Phi(y,\tau) \sim \frac{y^2}{4} - \gamma\varphi_l(0)^2\int_\tau^\infty \varepsilon(s)^2 e^{(1-l)(\tau-s)}ds + \varepsilon(\tau)^2\left(-\frac{1}{2\pi}\log y + O(1)\right) \tag{3.29}$$

whenever $\varepsilon(\tau) \ll y \ll 1$ and $\tau \gg 1$. The inner expansion for $\Phi(y,\tau)$ is exactly that already obtained in (3.16). From (3.29) and (3.16), we deduce the matching condition

$$-\gamma\varphi_l(0)^2 \int_\tau^\infty \varepsilon(s)^2 e^{(1-l)(\tau-s)}ds = \frac{1}{2}\varepsilon^2(\tau)\log\varepsilon(\tau), \tag{3.30}$$

which yields now the following asymptotic behavior for $\varepsilon(\tau)$:

$$\varepsilon(\tau) \sim Ce^{(\frac{1-l}{2})\tau}\tau^{-\frac{1}{l-1}} \quad \text{as } \tau \to \infty \tag{3.31}$$

for some positive constant C.

Estimate (3.31) can be obtained from (3.30) by means of an argument similar to that leading from (3.17) to (3.18). Indeed, setting $\tau(s) = \varepsilon^2(s)e^{-(1-l)s}$ and observing that $4\gamma\varphi_l(0)^2 = 1$ (cf. (2.8)), we may rewrite (3.20) in the form

$$-\int_\tau^\infty r(s)ds = r(\tau)\log(\varepsilon^2(\tau)) = r(\tau)\left((1-l)\tau + \log(r(\tau))\right).$$

Hence

$$\frac{1}{l-1}\int_\tau^\infty r(s)ds = r(\tau)\left(r + O(\log(r(\tau)))\right) \quad \text{for } \tau \gg 1,$$

which can be integrated to yield $r(\tau) = Cr^{-l/(l-1)}$, whence

$$\varepsilon^2(\tau) = Ce^{(1-l)\tau}\tau^{-\frac{l}{l-1}},$$

and (1.3) follows.

We conclude this section by sketching the formal derivation of (1.4) and (1.5) in Theorem 1.2. Consider first the case of (1.4). From Assumptions 3.1 and 3.2 (with $\varepsilon^2(\tau)$ replaced by $\varepsilon^N(\tau)$ where appropriate), we obtain the following outer expansion for $\Phi(y,\tau)$:

$$\Phi(y,\tau) \sim \frac{y^2}{2N} - \gamma\sum_{k=0}^{l}\varphi_k^2(0)\int_\tau^\infty \varepsilon^N(s)e^{(1-k)(\tau-s)}ds + O\left(\frac{\varepsilon^N(\tau)}{y^{N-2}}\right) \tag{3.32}$$

whenever $\varepsilon(\tau) \ll y \ll 1$ and $\tau \gg 1$. The corresponding inner expansion is also obtained in the form

$$\Phi(y,\tau) = \varepsilon^2(\tau)w(\xi,\tau) \quad \text{with } \xi = \frac{y}{\varepsilon(\tau)},$$

where $w(\xi,\tau) \sim \bar{w}(\xi)$ for large τ and $\bar{w}$ solves

$$\bar{w}_{\xi\xi} + \left(\frac{N-1}{\xi}\right)\bar{w}_\xi = 1 \quad \text{for } \xi > 1,$$

$$\bar{w}(1) = \bar{w}_\xi(1) = 0$$

(compare with (3.14)). This now yields

$$\bar{w}(\xi) = \frac{\xi^2}{2N} - \frac{1}{2(N-2)} + \frac{\xi^{2-N}}{N(N-2)},$$

whereupon the following inner expansion for Φ follows:

$$\Phi(y,\tau) \sim \frac{y^2}{2N} - \frac{\varepsilon^2(\tau)}{2(N-2)} + \frac{1}{N(N-2)}\left(\frac{\varepsilon(\tau)}{y}\right)^{N-2} \quad \text{for } y \sim \varepsilon(\tau) \text{ and } \tau \gg 1. \tag{3.33}$$

Matching (3.32) and (3.33) gives the following equation for $\varepsilon(\tau)$:

$$\gamma \sum_{k=0}^{1} \varphi_k(0)^2 \int_{\tau}^{\infty} \varepsilon(s)^N e^{(1-k)(\tau-s)} ds = \frac{\varepsilon(\tau)^2}{2(N-2)}, \tag{3.34}$$

which yields $\varepsilon(\tau) \sim C\tau^{-1/(N-2)}$ and hence (1.4). Finally, (1.5) is obtained by guessing an outer expansion of the form

$$\Phi(y,\tau) \sim \frac{y^2}{2N} - \alpha e^{(1-l)\tau}\varphi_l(y). \tag{3.35}$$

This follows by neglecting the term $\chi_{\varepsilon(\tau)}$ in (3.2) and assuming that the lth mode dominates in the Fourier expansion for $\psi(y,\tau)$. Matching (3.35) with (3.33), (1.5) follows.

4. The topological argument. In this section we shall describe the basic approach towards a rigorous derivation of Theorems 1.1–1.3. For simplicity, we shall concentrate on the case where $N = 2$ and (1.2) holds and remark briefly on the remaining situations afterwards.

4.1. Obtaining (1.2) in Theorem 1.1. Let us define $\bar{\varepsilon}(\tau)$ as follows:

$$\bar{\varepsilon}(\tau) = Ke^{-\frac{\sqrt{2\tau}}{2}}\tau^{\frac{1}{4\sqrt{\tau}}-\frac{1}{4}}, \quad K \text{ given in (3.18).} \tag{4.1}$$

In another words, $\bar{\varepsilon}(\tau)$ is the leading part in the expected asymptotic behavior of the rescaled free boundary in this case. Fix now τ_0, τ_1 with $\tau_1 \geq \tau_0 \gg 1$ and consider functions $\varepsilon(\tau)$ such that the following estimates hold for some choice of $M > 1$.

$$\sup\left\{|\varepsilon(\tau) - \bar{\varepsilon}(s)|, \text{ where } \tau, s \in [\tau_0,\tau_1] \text{ and } |\tau - s| < \frac{1}{\tau}\right\} < M\varepsilon(\tau)\tau^{-\frac{3}{2}}, \tag{4.2a}$$

$$\frac{\bar{\varepsilon}(\tau)}{M} < \varepsilon(\tau) < M\bar{\varepsilon}(\tau) \quad \text{for } \tau \in [\tau_0,\tau_1]. \tag{4.2b}$$

We next recall that if $\Phi(y,\tau)$ is a (rescaled) solution of our problem (cf. (2.3)), then $\psi(y,\tau)$ given in (3.1) solves

$$\psi_\tau = A\psi + \chi_{\varepsilon(\tau)} \quad \text{for } y \in \mathbb{R}, \quad \tau > \tau_0, \tag{4.3a}$$

$$\psi(y,\tau_0) = \psi_0(y) \quad \text{at } \tau = \tau_0, \tag{4.3b}$$

where A is the linear operator in (2.5). We want to pick $\psi_0(y)$ above in a particular manner. Namely, we take

$$\psi_0(y) = \alpha_0\tilde{\varphi}_0(y) + \alpha_1\tilde{\varphi}_1(y) + \gamma\bar{\varepsilon}(\tau_0)^2 F(y), \tag{4.4}$$

where $F(y)$ is as in (3.9), and α_0, α_1, $\tilde{\varphi}_0$, and $\tilde{\varphi}_1$ will be selected presently. As a matter of fact, for $j = 0, 1$ functions $\tilde{\varphi}_j(y)$ will coincide with the eigenfunctions $\varphi_j(y)$ given in (2.6) for, say, $y \geq (\bar{\varepsilon}(\tau_0))^{1/2}$. The main point in selecting $\psi_0(y)$ in (4.4) is that we want it to match with the inner expansion (3.16) (with $\varepsilon(\tau)$ replaced by $\bar{\varepsilon}(\tau_0)$ there) at distances $y \sim \bar{\varepsilon}(\tau_0)^{1/2}$. This amounts essentially to imposing

$$\begin{aligned} &\alpha_0\varphi_0(0) + \alpha_1\varphi_1(y) + \gamma\bar{\varepsilon}(\tau_0)^2\left(-\frac{1}{2\pi}\log y + B + \cdots\right) \\ &\quad = \frac{\bar{\varepsilon}(\tau_0)^2}{2}\log\bar{\varepsilon}(\tau_0) - \frac{\bar{\varepsilon}(\tau_0)^2}{2}\log y - \frac{\bar{\varepsilon}(\tau_0)^2}{4}, \end{aligned}$$

whence

$$\alpha_0\varphi_0 + \alpha_1\varphi_0(0) + \left(B + \frac{1}{4}\right)\gamma\bar{\varepsilon}(\tau_0)^2 = \frac{\bar{\varepsilon}(\tau_0)^2}{2}\log\bar{\varepsilon}(\tau_0) \tag{4.5}$$

so that

$$|\alpha_0| + |\alpha_1| = O(\bar{\varepsilon}(\tau_0)^2|\log\bar{\varepsilon}(\tau_0)|). \tag{4.6}$$

We have yet to determine what kind of modification is to be performed on the φ_k's near the origin for $k = 0, 1$. To ascertain this point, we observe that if no change were done at all, we would have that

$$\psi_0(y) \sim -\frac{\gamma\bar{\varepsilon}(\tau_0)^2}{2\pi}\log y \quad \text{as } y \to 0.$$

To remove such singularity, we just redefine the φ_k's near $y = 0$ as follows:

$$\alpha_0\tilde{\varphi}_0 + \alpha_1\tilde{\varphi}_1(y) = \frac{\gamma\bar{\varepsilon}(\tau_0)^2}{2\pi} + o(\bar{\varepsilon}(\tau)^2\log y) \quad \text{as } y \to 0. \tag{4.7}$$

Notice that relations (4.4)–(4.7) are compatible and allow for many possible choices of α_k, $\tilde{\varphi}_k$ for $k = 0.1$. Bearing in mind our previous arguments, we now introduce the following notation:

(4.8)

> Let τ_0, τ_1 be such that $\tau_1 \geq \tau_0 \gg 1$, and let μ be a given number such that $0 < \mu \leq 1$. We shall say that a solution $\psi(y,\tau)$ of (4.3a) which is defined for $\tau_0 \leq \tau \leq \tau_1$ belongs to the class $A(\tau_0, \tau_1, \mu)$ if there exists a constant M such that $|\psi(y,\tau)| < M(1 + y^2)$ for $y \in \mathbb{R}$ and $\tau \in [\tau_0, \tau_1]$ and conditions (4.2) are satisfied with M replaced by $M\mu$ there.

We shall say that $\psi(y,\tau) \in \overline{\mathcal{A}(\tau_0, \tau_1, \mu)}$ if it satisfies those conditions describing membership in the class $\mathcal{A}(\tau_0, \tau_s, \mu)$ when strict inequalities are replaced by the symbol $\leq$.

For $k = 0, 1$, let us now define

$$l_k(\alpha_0, \alpha_1; \tau) = \langle\psi(y, \tau; \alpha_0, \alpha_1), \varphi_k\rangle + \int_\tau^\infty e^{(1-k)(\tau - s)}\langle\chi_{\bar{\varepsilon}}, \varphi_k\rangle ds, \tag{4.9}$$

where $\psi(y, \tau; \alpha_0, \alpha_1)$ is the solution of (4.3a) such that $\psi(y, \tau_0; \alpha_0, \alpha_1) = \psi_0(y)$, $\psi_0(y)$ being a function satisfying (4.4)–(4.7) above.

The following result is a crucial ingredient in the proof of (1.2) in Theorem 1.1.

PROPOSITION 4.1. *Assume that $M > 0$ is large enough and let $\psi(y,\tau)$ be the solution of* (4.3)*, where $\psi(y,\tau_0) \equiv \psi_0(y)$ is such that* (4.4)–(4.7) *hold. Suppose also that*

$$\psi(y,\tau) \in \overline{\mathcal{A}(\tau_0,\tau_1,1)} \tag{4.10}$$

for some τ_1, τ_0 so that $\tau_1 > \tau_0 \gg 1$. Then if

$$l_k(\alpha_0,\alpha_1,\tau_1) = 0 \quad \textit{for } k = 0,1 \tag{4.11}$$

(*cf.* (4.9) *above*)*, one has that*

$$\psi(y,\tau) \in \mathcal{A}\left(\tau_0,\tau_1,\frac{1}{2}\right).$$

We shall prove Proposition 4.1 in sections 5 and 6, which contain most of the technical aspects of this paper. To keep the flow of the main arguments here, we will assume that the proposition holds true and continue with the derivation of (1.2). Let $\alpha = (\alpha_0,\alpha_1)$ be any pair of real numbers and set $l(\alpha_0,\alpha_1;\tau) = (l_0(\alpha_0,\alpha_1;\tau), l_1(\alpha_0,\alpha_1;\tau))$, where for $k = 0,1, l_k$ is defined as the right-hand side of (4.9). Let τ_1, τ_0 be such that $\tau_1 \geq \tau_0$ and define $\mathcal{U}(\tau_0,\tau_1) \subset \mathbb{R}^2$ as the open set consisting of all points $(\alpha_0,\alpha_1) \in \mathbb{R}^2$ such that the corresponding solution $\psi(y,\tau)$ of (4.3)–(4.8) satisfies that $\psi(y,\tau) \in \mathcal{A}(\tau_0,\tau_1,1)$. From our previous arguments, it follows that we may select an initial value $\psi(y,\tau_0) = \psi_0(y)$ in (4.3b) so that

$$\psi(y,\tau_0) \in \mathcal{A}\left(\tau_0,\tau_0,\frac{1}{2}\right)$$

and there exists a unique solution of $l(\alpha_0,\alpha_1,\tau_0) = 0$. Indeed, by (4.9) one has that

$$l_k(\alpha_0,\alpha_1;\tau_0) = \alpha_k + \delta(\alpha,\tau_0)(|\alpha_0| + |\alpha_1|) + O(\bar{\varepsilon}(\tau_0)^2) \quad \text{for } k = 0,1,$$

where $\delta(\alpha,\tau_0) \to 0$ as $\tau_0 \to \infty$, uniformly for $|\alpha| = |\alpha_0| + |\alpha_1|$ bounded, and the last term on the right above may be assumed to be independent on α. On the other hand, we may always suppose $l = (l_0,l_1)$ to be differentiable with respect to α_0,α_1 by means of a suitable choice of the initial value $\psi_0(y)$. We shall assume henceforth that $\varphi_0(y)$ satisfies such a condition. It then turns out that for $k = 0,1$ equation $l_k(\alpha_0,\alpha_1;\tau_0) = 0$ has a unique solution α_k such that

$$\alpha_k = O(\bar{\varepsilon}(\tau_0)^2).$$

As a matter of fact, one then has that

$$d(l,\mathcal{U}(\tau_0,\tau_0);0) = 1,$$

where for $\tau \geq \tau_0$, $d(l,\mathcal{U}(\tau_0,\tau);0)$ denotes the topological degree of the mapping l in the set $\mathcal{U}(\tau_0,\tau)$ at the value zero.

Now assume that $\mathcal{U}(\tau_0,\tau) \neq \phi$ for any $\tau \in [\tau_0,\tau_1]$ with $\tau_1 > 0$ and denote by $\partial\mathcal{U}(\tau_0,\tau)$ the boundary of the open set $\mathcal{U}(\tau_0,\tau)$. We notice that if $l \neq 0$ on $U(\partial\mathcal{U}(\tau_0,\tau))$ for $\tau_0 \leq \tau \leq \tau_1$, the $d(l,\mathcal{U}(\tau_0,\tau);0) = d(l,\mathcal{U}(\tau_0,\tau_0);0)$ for any such τ. It then follows from standard continuous dependence results that

$$\mathcal{U}(\tau_0,\tau_1) \neq \phi$$

and

$$d(l,\mathcal{U}(\tau_0,\tau_1);0)=1$$

for any $\tau_1>\tau_0$ such that $(\tau_1-\tau_0)$ is sufficiently small. We next claim that

$$d(l,\mathcal{U}(\tau_0,\tau);0)=1 \tag{4.12a}$$

for any $\tau>\tau_0$ as far as

$$\mathcal{U}(\tau_0,\tau)\neq\phi. \tag{4.12b}$$

Indeed, suppose that there exists a first time $\tau>\tau_0$ when (4.12a) fails but (4.12b) holds true. In view of our previous remark, there must be a point $\beta=(\beta_0,\beta_1)\in\partial\mathcal{U}(\tau_0,\tau)$, where $l(\beta)=0$, and clearly $\psi(y,\tau;\beta_0,\beta_1)\in\overline{\mathcal{A}(\tau_0,\tau;1)}$. We then use Proposition 4.1 to deduce that $\beta\in\mathcal{U}(\tau_0,\tau)$, which is a contradiction.

We further observe that

$$\mathcal{U}(\tau_0,\tau)\neq\phi\quad\text{for any }\tau>\tau_0, \tag{4.13}$$

$$\text{provided that }\tau_0\gg 1.$$

To check (4.13), we define $\tau^*=\sup\{\tau:\mathcal{U}(\tau_0,\tau)\neq\phi\}$. We already know that $\tau^*>\tau_0$. Assume now that $\tau^*<\infty$. By (4.12), we may select a sequence of times $\{\tau_n\}$ increasing to τ^* and a sequence $\{\alpha_n\}=\{(\alpha_{0n},\alpha_{1n})\}$ such that $l(\alpha_{0n},\alpha_{1n};\tau_n)=0$ and $\alpha_n\in\mathcal{U}(\tau_0,\tau_n)$. Since $\mathcal{U}(\tau_0,\tau_{n+1})\subset\mathcal{U}(\tau_0,\tau_n)$, one has that $\{\alpha_n\}$ is bounded. Therefore, a subsequence (still denoted by $\{\alpha_n\}$) exists which converges to some point $\alpha^*=(\alpha_0^*,\alpha_1^*)$. It then turns out that $l(\alpha_0^*,\alpha_1^*;\tau^*)=0$ and hence by Proposition 4.1 the corresponding function $\psi(y,\tau;\alpha_0^*,\alpha_1^*)$ remains at the interior of $\mathcal{A}(\tau_0,\tau^*;1)$; this is the point where restriction $\tau_0\gg 1$ needs to be imposed on (4.13). By continuous dependence results, ψ would also remain at the interior of $\mathcal{A}(\tau_0,\tau^*+\delta;1)$ for some $\delta>0$, thus contradicting the definition of τ^*.

We are now prepared to detail the argument leading to the existence of the solutions referred to in Theorems 1.1 and 1.3. Take a sequence $\{\tau_n\}$ such that $\tau_1>\tau_0$ and $\lim_{n\to\infty}\tau_n=\infty$. For any such n, $\mathcal{U}(\tau_0,\tau_n)\neq\phi$, and we may select $\alpha_n=(\alpha_{0n},\alpha_{1n})$ such that $l(\alpha_{0n},\alpha_{1n};\tau_n\}=0$.

Let $\psi_n(y,\tau)\equiv\psi_n(y,\tau;\alpha_{0n},\alpha_{1n})$ be the solution of (4.3a) with initial value $\psi_n(y,\tau_0)=\psi_0(y;\alpha_{0n},\alpha_{1n})$ satisfying (4.4)–(4.8). By Proposition 4.1, we have that $\psi_n(y,\tau)\in\mathcal{A}(\tau_0,\tau_n;\frac{1}{2})$. Since the sequence $\{\alpha_n\}$ is bounded, there exists a subsequence (still denoted by $\{\alpha_n\}$) and a value $\bar\alpha=(\bar\alpha_0,\bar\alpha_1)$ such that $\lim_{n\to\infty}\alpha_n=\bar\alpha\in\mathcal{U}(\tau_0,\tau_0)$. It then turns out that function $\psi(y,\tau;\bar\alpha_0,\bar\alpha_1)$, solution of (4.3a) with initial value $\psi(y,\tau_0;\bar\alpha_0,\bar\alpha_1)$, provides a sought-for solution satisfying (1.2), and the proof is concluded under our current assumptions.

4.2. The remaining cases. To derive (1.3) in Theorem 1.1, we just repeat our previous argument with the following modifications. First we replace $\bar\varepsilon(\tau)$ in (4.1) by

$$\bar\varepsilon(\tau)=Ce^{(1-l)\tau}\tau^{-\frac{1}{l-1}},$$

where, as in the statement of the theorem, l is any number larger than or equal to two and C is any positive constant. Instead of making use of (4.4), we now define $\psi_0(y)$ by

$$\psi_0(y)=\sum_{k=0}^{l}\alpha_k\tilde\varphi_k(y)-\frac{C}{2\pi}\log y$$

and replace condition (4.11) in Proposition 4.1 by

$$l_k(\alpha_0, \alpha_1, \ldots, \alpha_0; \tau_1) = 0 \quad \text{for } k = 0, 1, \ldots, l,$$

where the l_k's are defined as in (4.9), except that here we allow l_k to depend on all parameters $\alpha_0, \alpha_1, \ldots, \alpha_l$.

The cases corresponding to dimensions $N \geq 3$ are similar. For instance, to obtain (1.4) (resp. (1.5)), we define $\bar{\varepsilon}(\tau)$ as follows:

$$\bar{\varepsilon}(\tau) = B\tau^{-\frac{1}{N-2}} \quad (\text{resp. } \bar{\varepsilon}(\tau) = Ce^{(1-\frac{l}{2})\tau}),$$

where $B > 0$ is a fixed constant which depends on N and can be determined from (3.34) and C is any given constant. We now have to redefine the φ_k's near $y = 0$ in order to remove singularities of the type $y^{-(N-2)}$ instead of logarithmic ones. A straightforward modification of the previous approach yields then the desired results.

5. Derivation of (1.2): Analysis of the outer region. We now set out to provide the details required to justify the picture given in sections 3 and 4. To this end, we shall concentrate on proving Proposition 4.1 to highlight those modifications required to obtain (1.3)–(1.5). From now on we shall thus assume that $N = 2$ and start by considering solutions to the equation satisfied by $\psi(y, \tau)$ given in (3.2); i.e.,

$$\psi_\tau = A\psi + \chi_{\varepsilon(\tau)} \quad \text{for } \tau > \tau_0, y \in \mathbb{R} \tag{5.1}$$

with initial condition (4.3b), where $\psi_0(y)$ satisfies (4.4)–(4.8) and operator A is given in (2.5). We shall compare solutions to (5.1) and (4.3b) with those to the auxiliary equation

$$W_\tau = AW + \gamma\varepsilon(\tau)^2\delta(y) \quad \text{for } \tau > \tau_0, y \in \mathbb{R} \tag{5.2}$$

with the same initial condition at $\tau = \tau_0$. Solutions of (5.1) can be represented in the form

$$\psi(y, \tau) = a_0(\tau)\varphi_0(y) + a_1(\tau)\varphi_1(y) + E(y, \tau), \tag{5.3}$$

where $E(y, \tau)$ satisfies

$$E_\tau = \Delta E - \frac{1}{2}y\nabla E + E + (\chi_{\varepsilon(\tau)} - \langle\varphi_0, \chi_{\varepsilon(\tau)}\rangle\varphi_0 - \langle\varphi_1\chi_{\varepsilon(\tau)}\rangle\varphi_1) \tag{5.4}$$

and $\langle E, \varphi_k\rangle = 0$ for $k = 0, 1$. Bearing in mind (5.2), we shall also consider solutions $Q(y, \tau)$ to the equation

$$\begin{aligned} Q_\tau = \Delta Q - \frac{1}{2}y\nabla Q + Q \\ + \gamma\varepsilon(\tau)^2(\delta(y) - \langle\varphi_0, \delta(y)\rangle\varphi_0 - \langle\varphi_1, \delta(y)\rangle\varphi_1) \end{aligned} \tag{5.5}$$

such that $\langle Q, \varphi_k\rangle = 0$ for $k = 0, 1$. We then have the following lemma.

LEMMA 5.1. *Let $\tau_0 > 0$ be fixed. Then the solution $Q(y, \tau_0)$ of (5.5) which is defined for $\tau > \tau_0$ and satisfies $Q_0(y, \tau_0) = 0$ is given by*

$$Q_0(y, \tau) = \gamma \int_{\tau_0}^{\tau} K(y, \tau - s)e^{\tau - s}\varepsilon(s)^2 ds, \tag{5.6a}$$

where

$$\begin{aligned}K(y,\tau) &= (4\pi(1-e^{-\tau}))^{-1}\left(\exp\left(-\frac{y^2e^{-\tau}}{4(1-e^{-\tau})}\right)\right.\\ &\left.-\sum_{j=0}^{1}\varphi_j\left\langle\varphi_j,\exp\left(-\frac{y^2e^{-\tau}}{4(1-e^{-\tau})}\right)\right\rangle\right).\end{aligned}\tag{5.6b}$$

Proof. For convenience, we shall dispense with the subscript in $Q_0(y,\tau)$. Differentiating three times with respect to the y variables in (5.5) yields

$$\begin{aligned}\frac{\partial}{\partial\tau}Q_{i,j,k} &= \Delta Q_{i,j,k}-\frac{1}{2}y\nabla Q_{i,j,k}-\frac{1}{2}Q_{i,j,k}+\gamma\varepsilon(\tau)^2(\delta(y))_{i,j,k}\\ &= A_*Q_{i,j,k}-\frac{1}{2}Q_{i,j,k}+\gamma\varepsilon(\tau)^2(\delta(y))_{i,j,k}\end{aligned}$$

in an appropriate weak sense. Using a variation of constants formula in the equation above and denoting by S_* the semigroup generated by A_*, we obtain that

$$\begin{aligned}Q_{i,j,k}(y,\tau) &= \gamma\int_{\tau_0}^{\tau}e^{-(\frac{\tau-s}{2})}S_*(\tau-s)\left(\varepsilon(s)^2\frac{\partial^3(\delta(\xi))}{\partial\xi_i\partial\xi_j\partial\xi_k}\right)ds = -\gamma\int_{\tau_0}^{\tau}e^{-\frac{(\tau-s)}{2}}\varepsilon(s)^2\\ &\cdot\int_{\mathbb{R}^2}\frac{\partial^3}{\partial\xi_i\partial\xi_j\partial\xi_k}\left((4\pi(1-e^{-(\tau-s)}))^{-1}\exp\left(-\frac{(ye^{-(\frac{\tau-s}{2})}-\xi)^2}{4(1-e^{-(\tau-s)})}\delta(\xi)\right)d\xi\right)ds\\ &= \gamma\frac{\partial^3}{\partial y_i\partial y_j\partial j_k}\int_{\tau_0}^{\tau}e^{\tau-s}\varepsilon(s)^2\left((4\pi(1-e^{-(\tau-s)}))^{-1}\exp\left(-\frac{(ye^{-(\frac{\tau-s}{2})})^2}{4(1-e^{-(\tau-s)})}\right)\right)ds.\end{aligned}$$

Integrating now three times with respect to the y variables and imposing $\langle Q_1\varphi_0\rangle = \langle Q_1\varphi_1\rangle = 0$, the result follows. □

We shall elaborate a bit on the formulas in (5.6). To begin with, we observe that

$$\left\langle\varphi_0,\exp\left(-\frac{y^2e^{-(\tau-s)}}{4(1-e^{-(\tau-s)})}\right)\right\rangle = C(1-e^{-(\tau-s)})\quad\text{for some } C>0,\tag{5.7a}$$

$$\left\langle\varphi_1,\exp\left(-\frac{y^2e^{-(\tau-s)}}{4(1-e^{-(\tau-s)})}\right)\right\rangle = (a_0+a_1(1-e^{-(\tau-s)}))(1-e^{-(\tau-s)})\tag{5.7b}$$

for some constants a_0 and a_1. To check (5.7a), we simply notice that

$$\begin{aligned}\left\langle\varphi_0,\exp\left(-\frac{y^2e^{-(\tau-s)}}{4(1-e^{-(\tau-s)})}\right)\right\rangle &= c_0\int_{\mathbb{R}^2}\exp\left(-\frac{y^2}{4}-\frac{y^2e^{-(\tau-s)}}{4(1-e^{-(\tau-s)})}\right)dy\\ &= c_0(1-e^{-(\tau-s)})\int_{\mathbb{R}^2}e^{-r^2}dr,\end{aligned}$$

where c_0 is given in (2.6b). The proof of (5.7b) is similar and will therefore be omitted.

Assume now that $\tau>\tau_0+1$. We may then split the integral term in (5.6a) in the form

$$Q_0(y,\tau) = \int_{\tau_0}^{\tau-1}(\;)+\int_{\tau-1}^{\tau}(\;)\equiv Q_{0,1}(y,\tau)+Q_{0,2}(y,\tau).\tag{5.8}$$

To estimate $Q_{0,2}$, we proceed to examine the quantity

$$J \equiv \gamma \int_{\tau-1}^{\tau} (4\pi(1-e^{-(\tau-s)}))^{-1} \exp\left((\tau-s) - \frac{y^2 e^{-(\tau-s)}}{4(1-e^{-(\tau-s)})}\right) \varepsilon^2(s)ds. \tag{5.9}$$

Setting $\eta = y^2 e^{-(\tau-s)}(4(1-e^{-(\tau-s)}))^{-1}$, it follows that $e^{\tau-s} = 1+\frac{y^2}{4\eta}$ and $d\eta = 4^{-1}y^2 e^{-(\tau-s)}(1-e^{-(\tau-s)})^{-2}ds$. If we now write $f(y) = e\theta(y)$ with $\theta(y) = y^2e^{-1}(4(1-e^{-1}))^{-1}$, we easily see that

$$J = \frac{\gamma}{\pi}\int_{\theta(y)}^{\infty} \varepsilon(s)^2 \left(1+\frac{y^2}{4\eta}\right)^2 y^{-2}e^{-\eta}d\eta = \frac{\gamma}{4\pi}\int_{f(y)}^{\infty} \varepsilon(s)^2\left(1+\frac{y^2}{4\eta}\right)e^{-\eta}\eta^{-1}d\eta,$$

where $s = \tau - \log(1+\frac{y^2}{4\eta})$.

Now we shall pay attention to the term $S(\tau-\tau_0)Q(y,\tau_0)$, where $Q(y,\tau_0)$ is given by

$$\begin{aligned} Q(y,\tau_0) &= \gamma\bar{\varepsilon}(\tau_0)^2F(y) + \sum_{j=0}^{1}\alpha_j\left(\tilde{\varphi}_j - \sum_{k=0}^{1}\varphi_k\langle\varphi_k,\tilde{\varphi}_j\rangle\right) \\ &\equiv \gamma\bar{\varepsilon}(\tau_0)^2F(y) + R(y), \end{aligned} \tag{5.10}$$

where α_j, φ_j, and $\tilde{\varphi}_j$ are as in (4.4). Notice that $\langle Q(\cdot,\tau_0),\varphi_k\rangle = 0$ for $k = 0, 1$. Moreover, one has that

$$R(y) = \sum_{j=0}^{1}\alpha_j(\tilde{\varphi}_j - \varphi_j) + \sum_{j=0}^{1}\alpha_j\left(\sum_{k=0}^{1}\varphi_k(\delta_{j,k} - \langle\varphi_k,\tilde{\varphi}_j\rangle)\right),$$

where, as customary, $\delta_{j,k} = 1$ if $j = k$ and $\delta_{j,k} = 0$ otherwise. In view of (4.4)–(4.7), it holds that

$$|R(y)| \le C\left(\bar{\varepsilon}(\tau_0)^2\left|\log\left(\frac{y}{\bar{\varepsilon}(\tau_0)}\right)\right|\chi_{[y\le\bar{\varepsilon}(\tau_0)^{1/2}]} + \bar{\varepsilon}(\tau_0)^3\tau_0(1+y^2)\right).$$

Using the explicit kernel for the semigroup $S(\tau)$, we then derive

$$|S(\tau-\tau_0)R| \le C\bar{\varepsilon}(\tau_0)^3\tau_0^{\frac{3}{2}}(1+y^2) \quad \text{for } \tau_0 \le \tau \le \tau_0+1 \text{ and } y \ge \bar{\varepsilon}(\tau_0)^{\frac{1}{4}}. \tag{5.11a}$$

On the other hand, by regularizing properties of $S(\tau)$, we obtain

$$\begin{aligned} &|S(\tau-\tau_0)R| \le C\bar{\varepsilon}(\tau)^{3-\chi}(1+y^2) \quad \text{for } \tau \ge \tau_0+1, \\ &\qquad y \ge \bar{\varepsilon}(\tau_0)^{\frac{1}{4}}, \quad \text{and some } \chi \in (0,1). \end{aligned} \tag{5.11b}$$

Summing up, we have obtained the following lemma.

Lemma 5.2. *Let $\tau^* = \max\{\tau_0, \tau-1\}$ and let $Q(y,\tau)$ be the solution of (5.5) for $\tau > \tau_0$ such that $Q(y,\tau_0)$ is given by (5.10). We then have that*

$$\begin{aligned} Q(y,\tau) = {} & \gamma\bar{\varepsilon}(\tau_0)^2S(\tau-\tau_0)F(y) + \gamma\int_{\tau_0}^{\tau^*}K(y,\tau-s)e^{\tau-s}\varepsilon(s)^2ds \\ & + \gamma\int_{\tau^*}^{\tau}(A_1+A_2(1-e^{-(\tau-s)}))e^{\tau-s}\varepsilon(s)^2ds + \frac{\gamma}{\pi}\int_{\Sigma}^{\infty}\varepsilon(s)^2e^{-\eta}\eta^{-1}d\eta \\ & + \frac{\gamma}{\pi}\int_{\Sigma}^{\infty}\varepsilon(s)^2e^{-y}\eta^2(4\eta^2)^{-1}d\eta + O\left(\frac{\bar{\varepsilon}(\tau)^2}{\tau}\right)(1+y^2) \end{aligned} \tag{5.12}$$

in regions where $y \geq \bar{\varepsilon}(\tau_0)^{1/4}$ *and* $\tau > \tau_0$. *Here* A_1, A_2 *are some positive constants,* $\sum = y^2(4(e^\beta - 1))^{-1}$, *where* $\beta = \max\{\tau_0, \tau - 1\}$ *and in the last two integrals above,* $s = \tau - \log(1 + \frac{y^2}{4\eta})$.

We now proceed to estimate the difference $(E - Q)$, where E and Q are solutions of (5.4) and (5.5), respectively. To this end, we set

$$Z = E - Q, \quad g = \chi_{\varepsilon(\tau)} - \gamma\varepsilon(\tau)^2\delta(y) \tag{5.13}$$

so that Z satisfies

$$\begin{aligned} Z_\tau &= \Delta Z - \frac{1}{2}\eta\nabla Z + Z + (g - \langle\varphi_0, g\rangle\varphi_0 - \langle\varphi_1, g\rangle\varphi_1) \\ &\equiv AZ + (g - \langle\varphi_0, g\rangle\varphi_0 - \langle\varphi_1, g\rangle\varphi_1) \equiv AZ + h(y, \tau) \end{aligned} \tag{5.14a}$$

We shall consider equation (5.14a) for values $\tau > \tau_0 \gg 1$. At $\tau = \tau_0$, we impose $E(y, \tau_0) = Q(y, \tau_0)$ so that

$$Z(y, \tau_0) = 0. \tag{5.14b}$$

We then have that the solution to (5.14) can be written in the form

$$Z(y, \tau) = \int_{\tau_0}^{\tau} S(\tau - s)h(\cdot, s)ds \equiv \int_{\tau_0}^{\tau} L(y, \tau - s; s)ds, \tag{5.15a}$$

where

$$\begin{aligned} L(y, \tau - s; s) &= (4\pi(1 - e^{-(\tau - s)}))^{-1} \\ &\cdot \int_{\mathbb{R}^2} \exp\left(-\frac{(ye^{-(\frac{\tau - s}{2})} - \xi)^2}{4(1 - e^{-(\tau - s)})}\right) h(\xi, s)d\xi. \end{aligned} \tag{5.15b}$$

Without loss of generality, we may assume $\tau > \tau_0 + 1$. We then split Z in the form

$$Z(y, \tau) = \int_{\tau_0}^{\tau - 1} L\,ds + \int_{\tau - 1}^{\tau} L\,ds. \tag{5.16}$$

Then the following lemma holds.

Lemma 5.3. *There exists* $C > 0$ *such that*

$$\int_{\tau_0}^{\tau - 1} |L|ds \leq C\int_{\tau_0}^{\tau - 1} e^{-(\tau - s)}\varepsilon(s)^4 ds \tag{5.17}$$

uniformly on bounded sets $|y| \leq R < \infty$.

Proof. To begin with, we observe that

$$\begin{aligned} |\langle\varphi_0, g(\cdot, s)\rangle| &= \left|\int_{\mathbb{R}^2} \varphi_0(\chi_{\varepsilon(s)} - \gamma\varepsilon(s)^2\delta(y))e^{-y^2/4}dy\right| \\ &= \left|\int_{|y| \leq \varepsilon(s)} \varphi_0(e^{-y^2/4} - 1)dy\right| \leq C\int_{|y| \leq \varphi(s)} r^2 dr \leq C\varepsilon(s)^4 \end{aligned}$$

and a similar bound is easily obtained for $|\langle\varphi_1, g\rangle|$. We thus have that

$$|\langle\varphi_0, g(\cdot,s)\rangle| + |\langle\varphi_1, g(\cdot,s)\rangle| \le C\varepsilon(s)^4 \tag{5.18}$$

for some $C > 0$.

Recalling that $\tau - s \ge 1$ under our current assumptions, we now consider the term

$$I = \int_{\tau_0}^{\tau-1} (4\pi(1-e^{-(\tau-1)}))^{-1} \int_{\mathbb{R}^2} \exp\left(-\frac{(ye^{-(\frac{\tau-s}{2})}-\xi)^2}{4(1-e^{-(\tau-s)})}\right) g(\xi,s)ds$$

$$\equiv \int_{\tau_0}^{\tau-1} S(\tau-s)g(\cdot,s)ds \equiv \int_{\tau_0}^{\tau-1} S\left(\frac{1}{2}\right) S\left(\tau-s-\frac{3}{4}\right) S\left(\frac{1}{4}\right) g(\cdot,s)ds. \tag{5.19}$$

We claim that

$$\left\| S\left(\frac{1}{4}\right) g(\cdot,s)\right\| \le C\varepsilon(s)^4 \quad \text{for some } C > 0. \tag{5.20}$$

Let us assume (5.20) for the moment and continue. One then may use classical regularizing effects to derive that

$$\left\| S\left(\tau-s-\frac{3}{4}\right)\left(S\left(\frac{1}{4}\right) g(\cdot,s)\right)\right\| \le Ce^{-(\tau-s)}\varepsilon(s)^4. \tag{5.21}$$

Finally, a standard Sobolev imbedding yields

$$\left| S\left(\frac{1}{2}\right)\left(S\left(\tau-s-\frac{3}{4}\right) S\left(\frac{1}{4}\right) g(\cdot,s)\right)\right| \le Ce^{-(\tau-s)}\varepsilon(s)^4. \tag{5.22}$$

Putting together (5.18)–(5.22), estimate (5.17) follows. The proof will thus be complete as soon as (5.20) has been obtained. To derive this last result, we make use of a duality argument. Let $\varphi(y)$ be any radial function in $L^2(\mathbb{R})$, and consider the integral

$$J = \int_{\mathbb{R}^2} g(\xi,s)\left(\int_{\mathbb{R}^2} e^{-(y-\xi)^2}\varphi(y)dy\right)d\xi \equiv \int_{\mathbb{R}^2} g(\xi,s)G(\xi)d\xi.$$

Recalling the arguments leading to (5.18), one readily sees that

$$\begin{aligned}\int_{\mathbb{R}^2} g(\xi,s)G(\xi)d\xi &= \int_{\mathbb{R}^2} (\chi_{\varepsilon(s)} - \gamma\varepsilon(s)^2\delta(y))G(\xi)d\xi \\ &= \int_{|y|\le\varepsilon(s)} (G(\xi)-G(0))d\xi \le C\varepsilon(s)^4,\end{aligned}$$

whereupon (5.20) follows. □

Our next result reads as follows.

Lemma 5.4. *There exists $C > 0$ such that*

$$\int_{\tau-1}^{\tau} |L(y,\tau-s;s)|ds \le C\left(\int_{\tau-1}^{\tau} \varepsilon(s)^4 ds + |y|\int_0^1 \varepsilon(\tau-s)^3 s^{-2} e^{-\frac{Cy^2}{s}} ds\right). \tag{5.23}$$

Proof. Set

$$w(y,\tau-s;\xi)=\exp\left(-\frac{(ye^{-(\frac{\tau-s}{2})}-\xi)^2}{4(1-e^{-(\tau-s)})}\right). \tag{5.24a}$$

We can then readily check that

$$\int_{\tau-1}^{\tau}L(y,\tau-s;s)ds=\int_{\tau-1}^{\tau}(4\pi(1-e^{-(\tau-s)}))^{-1}e^{\tau-s}M(y,\tau-s)ds, \tag{5.24b}$$

where

$$\begin{aligned} M(y,\tau-s)=\int_{\mathbb{R}^2}&(w(y,\tau-s;\xi)-\langle\varphi_0,w(y,\tau-s;\xi)\rangle\varphi_0\\ &-\langle\varphi_1,w(y,\tau-s;\xi)\rangle\varphi_1)g(\xi,s)d\xi. \end{aligned} \tag{5.24c}$$

$$\frac{y^2}{4}+\frac{(ye^{-(\frac{\tau-s}{2})}-\xi)^2}{4(1-e^{-(\tau-s)})}=\frac{1}{4(1-e^{-(\tau-s)})}\left((y-\xi e^{-(\frac{\tau-s}{2})})^2+\xi^2(1-e^{-(\tau-s)})\right).$$

A quick computation then reveals that

$$\langle\varphi_0,w(y,\tau-s;\xi)\rangle\le Ce^{-\frac{y^2}{4}}(1-e^{-(\tau-s)}),$$

and a similar result holds when we replace φ_0 by φ_1 above. Recalling the argument leading to (5.18), we then have that

$$\int_{\mathbb{R}^2}|(\langle\varphi_0,w\rangle\varphi_0+\langle\varphi_1,w\rangle\varphi_1)|\,|g(\cdot,s)|ds\le C(1-e^{-(\tau-s)})\varepsilon(s)^4. \tag{5.25}$$

Now consider the integral

$$J\equiv\int_{\tau-1}^{\tau}(4\pi(1-e^{-(\tau-s)}))^{-1}e^{\tau-s}\left(\int_{\mathbb{R}^2}w(y,\tau-s;\xi)g(\xi,s)d\xi\right)ds. \tag{5.26}$$

Since $\int_{\mathbb{R}^2}g(\xi,s)d\xi=0$, it holds that

$$J=\int_{\tau-1}(4\pi(1-e^{-(\tau-s)}))^{-1}e^{\tau-s}\left(\int_{\mathbb{R}^2}(w(y,\tau-s;\xi)-w(y,\tau-s;0))g(\xi,s)d\xi\right)ds,$$

whence

$$\begin{aligned} |J|\le C\textstyle\int_{\tau-1}^{\tau}&(4\pi(1-e^{-1(\tau-s)}))^{-1}\\ &\cdot\left(\int_{|\xi|\le\varepsilon(s)}|w(y,\tau-s;\xi)-w(y,\tau-s;0)|d\xi\right)ds. \end{aligned} \tag{5.27}$$

We now observe that for any real numbers a and b,

$$|e^{-a^2}-e^{-(a-b)^2}|\le Ce^{-a^2/2}|a|\,|b|\quad\text{for some } C>0. \tag{5.28}$$

To check (5.28), we consider first the case where $|a|\ge|b|$. Then if $|a|\,|b|\le 1$, we have that $|1-e^{2ab-b^2}|\le C|a|\,|b|$, whereas if $|a|\,|b|>1$, $|e^{-a^2}-e^{-(a-b)^2}|\le$

$Ce^{-a^2/2} \leq Ce^{-a^2/2}|a|\,|b|$. When $|a| < |b|$, we simply select $\mu > 0$ large enough and observe that if $|a|\,|b| < \mu$, then $|1 - e^{2ab-b^2}| \leq C|a|\,|b|$ for some $C = C(\mu) > 0$, whereas for $|a|\,|b| > \mu$ one has that $2ab - b^2 \geq -\frac{b^2}{2}$ and hence $|1 - e^{2ab-b^2}| \leq C|a|\,|b|$. Having shown that (5.28) holds, we now take advantage of that inequality (with $a = ye^{-\frac{(\tau-s)}{2}}(4(1 - e^{-(\tau-s)}))^{-\frac{1}{2}}$ and $b = \xi(4(1 - e^{-(\tau-s)})^{\frac{1}{2}})$ and (5.27) to show that

$$|J| \leq C\int_{\tau-1}^{\tau}(1 - e^{-(\tau-s)})^{-1}\int_{|\xi|\leq\varepsilon(s)}(1 - e^{-(\tau-s)})^{-1}w(y,\tau - s;0)|y||\xi|d\xi$$

$$\leq C\int_{\tau-1}^{\tau}(1 - e^{-s})^2\varepsilon(s)^3|y|\exp\left(-\frac{y^2e^{-s}}{(1 - e^{-s})}\right)ds \leq C|y|\int_0^1\varepsilon(\tau - s)^3 s^{-2}e^{-\frac{Cy^2}{s}}ds. \tag{5.29}$$

Putting together (5.25) and (5.29), the result follows. □

For latter reference, we summarize the results obtained in Lemmas 5.2–5.4 as follows.

COROLLARY 5.5. *Let $E(y,\tau)$, $Q(y,\tau)$ be functions such that* (i) $E(y,\tau_0) = Q(y,\tau_0)$ *and* (ii) E *and* Q *solve, respectively,* (5.4) *and* (5.5) *for* $\tau > \tau_0$. *Assume also that* (4.2) *holds. Then for any $R > 0$, there exists $C > 0$ such that*

$$|E(y,\tau) - Q(y,\tau)| \leq C\left(\frac{\varepsilon(\tau)^3}{y}\right) \tag{5.30}$$

whenever $\bar{\varepsilon}(\tau_0)^{\frac{1}{4}} \leq y \leq R$ *and* $\tau > \tau_0$

Proof. The proof follows from (5.17), (5.23), and the bounds (4.2). □

6. Derivation of (1.2): Analysis of the inner region.

Let $\sigma(\tau)$ be a function to be discussed later (cf. (6.9)). We now fix $\bar{\tau} \gg 1$ and define

$$\xi = \frac{y}{\sigma(\bar{\tau})}; \qquad w(\xi,\tau) = (\sigma(\bar{\tau}))^{-2}\Phi(\sigma(\bar{\tau})\xi,\tau), \tag{6.1}$$

where $\Phi(y,\tau)$ is given in (2.3). A quick computation reveals that $w(\xi,\tau)$ satisfies

$$(\sigma(\bar{\tau}))^2 w_\tau = \Delta w - H(w) + (\sigma(\bar{\tau}))^2\left(w - \frac{\xi\nabla w}{2}\right), \tag{6.2}$$

where the operators Δ and ∇ are now written with respect to the inner space variable ξ. When determining the asymptotics of solutions of (6.2), a key role is played by the stationary equation

$$\Delta\nu = H(\nu). \tag{6.3}$$

For any $\lambda > 0$, a radial solution of (6.3) is given by $\nu_\lambda(\xi) = \lambda^2\bar{\nu}(\frac{\xi}{\lambda})$, where

$$\bar{\nu}(r) = \frac{r^2}{4} - \frac{1}{4} - \frac{1}{2}\log r. \tag{6.4}$$

We can readily check that the radial, nontrivial solution of (6.3) which satisfies $\nu(\xi) = 0$ for $\xi \leq \lambda$ and $\nu(\lambda) = \nu'(\lambda) = 0$ is given by

$$\nu_\lambda(\xi) = \frac{\xi^2}{4} - \frac{\lambda^2}{2}\log\left(\frac{\xi}{\lambda}\right) - \frac{\lambda^2}{4} \quad \text{for } \xi > \lambda. \tag{6.5}$$

It will be convenient to compare the functions $\nu_\lambda(\xi)$ given in (6.5) with the stationary solution of (6.2) that takes off at $\xi = \lambda$. The corresponding result reads as follows.

Lemma 6.1. *Let* $\tilde{w}_\lambda(\xi) \equiv \tilde{w}_\lambda(\xi;\bar{\tau})$ *be the stationary solution of* (6.2) *such that* $\tilde{w}_\lambda(\lambda) = \tilde{w}'_\lambda(\lambda) = 0$ *and* $\tilde{w}_\lambda(\xi) > 0$ *for* $\xi > \lambda > 0$. *Then there holds*

$$\tilde{w}_\lambda(\xi) = \nu_\lambda(\xi) + O(\sigma^2\lambda^2 \log\lambda) \quad \textit{for } \xi \le 1. \tag{6.6}$$

Proof. We set $\tilde{w}_\lambda = \nu_\lambda + \varphi$. A quick check reveals that φ solves

$$\varphi'' + \frac{\varphi'}{\xi} + \sigma^2\left(\varphi - \frac{\xi\varphi'}{2} - \frac{\lambda^2}{2}\log\frac{\xi}{\lambda} - \frac{\lambda^2}{4}\right) = 0,$$
$$\varphi(\lambda) = \varphi'(\lambda) = 0.$$

Consider first the case where ξ is close to λ. Standard ordinary differential equation (ODE) arguments yield that, in such a region

$$\varphi(\xi) \sim C\sigma^2\lambda^2\xi^2 \log\frac{\xi}{\lambda} \quad \text{for some real } C. \tag{6.7}$$

When $\lambda \ll \xi \le 1$, we introduce a new variable $\eta = \frac{\xi}{\lambda}$. Setting $\dot{\varphi} = \frac{d\varphi}{d\eta}$, we readily check that φ satisfies

$$\ddot{\varphi} + \frac{\dot{\varphi}}{\eta} + \sigma^2\lambda^2\left(\varphi - \frac{\eta\dot{\varphi}}{2}\right) = \frac{\sigma^2\lambda^4}{2}\log\eta + \frac{\sigma^2\lambda^2}{4}.$$

A dominated balance argument shows that the third term on the left is negligible with respect to the remaining ones. This in turn implies that $\varphi(\eta) \sim K^2\sigma^2\lambda^4\eta^2\log\eta$. Back to the original variables, we have derived

$$\varphi(\xi) \sim K\sigma^2\lambda^2\xi^2 \log\frac{\xi}{\lambda} \quad \text{for } \lambda \ll \xi \le 1. \tag{6.8}$$

Matching (6.7) and (6.8), we obtain $C = K$ and (6.6) follows. □

Let us now define

$$\sigma(\tau) = (\varepsilon(\tau))^\theta, \quad \text{where } \theta \text{ is a positive and small number}, 0 < \theta < \frac{1}{4}, \tag{6.9}$$

$$W(\tau) = \frac{1}{4} + \frac{1}{(\sigma(\bar{\tau}))^2}\left(a_0(\tau)\varphi_0 + a_1(\tau)\varphi_1(\sigma(\bar{\tau})) + E(\sigma(\bar{\tau}),\tau)\right), \tag{6.10}$$

where a_0, a_1, and E are as in (5.3), and

$$\lambda(\tau) = \frac{\varepsilon(\tau)}{\sigma(\tau)}. \tag{6.11}$$

We shall prove the following lemma.

Lemma 6.2. *Assume that conditions* (4.2) *and* (4.11) *hold. Then there exists a constant* $C > 0$ *such that*

$$|W(\tau) - W(\bar{\tau})| \le \frac{C}{\tau}\left(\frac{\varepsilon(\bar{\tau})}{\sigma(\bar{\tau})}\right)^2, \tag{6.12}$$

provided that $|\tau - \bar{\tau}| \le \frac{1}{\tau}$ *and* $\bar{\tau} \ge \tau_0 \gg 1$.

Proof. We set

$$\begin{aligned} W(\tau)-W(\bar\tau) &= \varphi_0(\sigma(\bar\tau))^{-2}(a_0(\tau)-a_0(\bar\tau))+\varphi_1(\sigma(\bar\tau))^{-2}(a_1(\tau)-a_1(\bar\tau)) \\ &\quad + (\sigma(\bar\tau))^{-2}(E(\sigma(\bar\tau),\tau)-E(\sigma(\bar\tau),\bar\tau)) \equiv W_1+W_2+W_3. \end{aligned} \tag{6.13}$$

Terms W_1 and W_2 in (6.13) are easily dealt with. For instance, since $\psi(y,\tau)$ satisfies (5.1), one sees that if $\tau>\bar\tau$,

$$\begin{aligned} W_2 &= \varphi_1(\sigma(\bar\tau))(\sigma(\bar\tau))^{-2}\int_{\bar\tau}^{\tau}\langle\chi_\varepsilon(s),\varphi_1\rangle ds \\ &= \varphi_1(\sigma(\bar\tau))(\sigma(\bar\tau))^{-2}\int_{\bar\tau}^{\tau}\int_{|y|\le\varepsilon(s)}\varphi_1(y)e^{-\frac{y^2}{4}}dyds; \end{aligned}$$

hence

$$|W_2|\le\frac{C|\tau-\bar\tau|}{(\sigma(\bar\tau))^2}((\varepsilon(s)-\varepsilon(\bar\tau))^2+\varepsilon(\bar\tau)^2)\le\frac{C}{\tau}\left(\frac{\varepsilon(\bar\tau)}{\sigma(\bar\tau)}\right)^2\left(1+\frac{M^2}{\tau^3}\right),$$

where (4.2) has been used to obtain the last inequality above. A similar bound for W_1 is obtained by means of (4.11). To estimate W_3, we first observe that

$$|Q(\sigma(\bar\tau),\tau)-Q(\sigma(\bar\tau),\bar\tau)|\le C\frac{\bar\varepsilon(\tau)^2}{\tau}\quad\text{for } |\tau-\bar\tau|\le\frac{1}{\tau}. \tag{6.14}$$

To obtain (6.14), we consider first the case where $|\tau_0-\bar\tau|\le\frac{1}{\tau_0}$. Setting

$$D(y)=\delta(y)-\sum_{k=0}^{1}\langle\varphi_k,\delta(y)\rangle\varphi_k(y)$$

it then turns out that

$$\begin{aligned} Q(y,\tau) &= \gamma\varepsilon(\tau_0)^2S(\tau-\tau_0)F(y)+\gamma\int_{\tau_0}^{\tau}S(\tau-s)(\varepsilon(s)^2D)ds \\ &= \gamma\varepsilon(\tau_0)^2S(\tau-\tau_0)F(y)+\gamma\int_{\tau_0}^{\tau}S(\tau-s)(\varepsilon(\tau_0)^2D)ds \\ &\quad+\gamma\int_{\tau_0}^{\tau}S(\tau-s)((\varepsilon(s)^2-\varepsilon(\tau_0)^2)D)ds \\ &= \gamma\varepsilon(\tau_0)^2F(y)+O(\varepsilon(\tau)^2\tau^{-\frac{3}{2}}|\log y|) \end{aligned}$$

for $|y|$ small, whereupon (6.14) follows. On the other hand, by (5.30) we have that

$$|E(\sigma(\bar\tau),\tau)-E(\sigma(\bar\tau),\bar\tau)|\le C\frac{\varepsilon(\tau)^2}{\tau}|Q(\sigma(\bar\tau,\tau))-Q(\sigma(\bar\tau),\bar\tau)|. \tag{6.15}$$

We thus obtain from (6.14) and (6.15) that

$$|W_3|\le C\left(\frac{\varepsilon(\tau)^2}{\tau}\right)\quad\text{for } |\tau_0-\bar\tau|\le\frac{1}{\tau_0}\ \text{ and }\ \bar\tau\ge\tau_0\gg1,$$

and putting together the bounds obtained for W_i $(i = 1, 2, 3)$ the proof is concluded in this case.

When $|\tau_0 - \bar{\tau}| > \frac{1}{\tau_0}$, we make use of (5.12) to check that (6.14) continues to hold. This is done by comparing the different terms appearing in the right-hand side of (5.12) when evaluated at $(\sigma(\bar{\tau}), \tau)$ and $(\sigma(\bar{\tau}), \bar{\tau})$, respectively. A typical argument in this direction goes as follows. For $i = 1, 2$ set $\sum_i = (\delta(\bar{\tau}))^2(4(e^{\beta_i} - 1))^{-1}$, where $\beta_i = \max\{\tau_i - 1, \tau_0\}$, and let us write $s_i = \tau_i - \log(1 - (\delta(\bar{\tau}))^2/4\eta)$. Then, if $|s_1 - s_2| \leq \frac{1}{\bar{\tau}}$, we have that

$$\begin{aligned}
&\left| \int_{\Sigma_1}^{\infty} \varepsilon(s_1)^2 e^{-\eta}\eta^{-1} d\eta - \textstyle\int_{\Sigma_2}^{\infty} \varepsilon(s_2)^2 e^{-\eta}\eta^{-1} d\eta \right| \\
&\quad \leq \int_{\Sigma_1}^{\infty} |\varepsilon(s_1) + \varepsilon(s_2)||\varepsilon(s_1) - \varepsilon(s_2)| e^{-\eta}\eta^{-1} d\eta + \int_{\Sigma_1}^{\Sigma_2} \varepsilon(s_2)^2 e^{-\eta}\eta^{-1} d\eta \\
&\quad \leq \ CM(\bar{\varepsilon}(\tau))^2 \tau^{-\frac{3}{2}} |\log \Sigma_1| + C(\bar{\varepsilon}(\tau))^2(\delta(\bar{\tau}))^2 |\log \Sigma_1| \\
&\quad \leq \ CM\theta \frac{(\bar{\varepsilon}(\tau))^2}{\tau},
\end{aligned}$$

where $\theta > 0$ can be selected arbitrarily small as $\tau_0 \to \infty$, and we have assumed for definiteness that $\Sigma_1 < \Sigma_2$. We omit further details. □

A key result in this section is the following.

LEMMA 6.3. *Under the assumptions of Lemma* 6.2*, there exists a constant* $C > 0$ *such that*

$$|W(\tau) - \nu_{\lambda(\tau)}(1)| \leq \frac{C}{\tau} \left(\frac{\varepsilon(\bar{\tau})}{\sigma(\bar{\tau})} \right)^2 \tag{6.16}$$

provided that $|\tau - \bar{\tau}| \leq \frac{1}{\tau}$*, where* ν_λ *is given in* (6.5) *and* $\bar{\tau} \geq \tau_0 \gg 1$.

Proof. We shall argue by contradiction and therefore assume that for any $K > 0$ there exists $\bar{\tau} \gg 1$ and $\tilde{\tau} \in (\bar{\tau} - \frac{1}{\tau}, \bar{\tau} + \frac{1}{\bar{\tau}})$ such that

$$|W(\tilde{\tau}) - \nu_{\lambda(\tilde{\tau})}(1)| > \frac{K}{\tilde{\tau}} \left(\frac{\varepsilon(\bar{\tau})}{\sigma(\bar{\tau})} \right)^2. \tag{6.17}$$

Now let τ be any time in the interval $(\bar{\tau} - \frac{1}{\bar{\bar{\tau}}}, \bar{\tau} + \frac{1}{\tilde{\bar{\tau}}})$. In view of (6.12) and (6.17), it holds that

$$|W(\tau) - \nu_{\lambda(\tilde{\tau})}(1)| > \frac{K}{2\tilde{\tau}} \left(\frac{\varepsilon(\tilde{\tau})}{\sigma(\tilde{\tau})} \right)^2. \tag{6.18a}$$

Assume for definiteness that

$$|W(\tau) - \nu_{\lambda(\tilde{\tau})}(1)| = \upsilon_{\lambda(\tilde{\tau})}(1) - W(\tau). \tag{6.18b}$$

We now claim the following:

$$\begin{aligned} &\text{There exists } \mu > 0 \quad \text{such that if} \quad \lambda_0(\tilde{\tau}) = \lambda(\tilde{\tau})(1 + \mu(\tilde{\tau})^{-\frac{3}{2}}), \\ &\qquad\qquad\qquad\qquad \text{then} \quad \nu_{\lambda_0}(1) > W(\tau). \end{aligned} \tag{6.19}$$

To check (6.19), we observe that since $\tilde{\tau} \gg 1$,

$$\begin{aligned}
\nu_{\lambda_0}(1) &= \frac{1}{4} + \frac{\lambda_0^2}{2}\log\lambda_0 - \frac{\lambda_0^2}{4} \\
&\sim \frac{1}{4} + \frac{\lambda^2}{2}\left(1+\mu(\tilde{\tau})^{-\frac{3}{2}}\right)^2 \log\lambda_0 - \frac{\lambda_0^2}{4} \\
&\sim \frac{1}{4} + \frac{\lambda(\tilde{\tau})^2}{2}\left(1+2\mu(\tilde{\tau})^{-\frac{3}{2}}\right)\left(\log\lambda(\tilde{\tau}) + \log\left(1+\mu(\tilde{\tau})^{-\frac{3}{2}}\right)\right) \\
&\quad - \frac{\lambda(\tilde{\tau})^2}{4}\left(1+2\mu(\tilde{\tau})^{-\frac{3}{2}}\right) = \frac{1}{4} + \frac{\lambda(\tilde{\tau})^2}{2}\log\lambda(\tilde{\tau}) \\
&\quad + \mu\lambda(\tilde{\tau})^2(\tilde{\tau})^{-\frac{3}{2}}\log\lambda(\tilde{\tau}) - \frac{\lambda(\tilde{\tau})^2}{4} \qquad (6.20)
\end{aligned}$$

whereas by (6.18),

$$W(\tau) < \nu_{\lambda(\tilde{\tau})}(1) - \frac{K}{2\tilde{\tau}}\left(\frac{\varepsilon(\tilde{\tau})}{\sigma(\tilde{\tau})}\right)^2 = \frac{1}{4} + \frac{\lambda(\tilde{\tau})^2}{2}\log\lambda(\tilde{\tau}) - \frac{\lambda(\tilde{\tau})^2}{4} - \frac{K}{2\tilde{\tau}}\lambda(\tilde{\tau})^2. \tag{6.21}$$

From (6.20) and (6.21), it follows that (6.19) holds provided that

$$\frac{K}{2\tilde{\tau}} > \frac{\mu}{\tilde{\tau}^{\frac{3}{2}}}|\log\lambda(\tilde{\tau})|,$$

and this last inequality is satisfied by selecting $\mu > 0$ small enough since

$$\tau^{-\frac{3}{2}}\log\lambda(\tau) \sim (1-\theta)\tau^{-1} \quad \text{as } \tau \to \infty.$$

We now set

$$z(\xi,\tau) = (w(\xi,\tau) - \tilde{w}_{\lambda_0}(\xi))_+, \quad \text{where } s_+ = \max\{s,0\}.$$

Since $(H(s)-H(t))(s-t)^{-1} \geq 0$ whenever $s \neq t$, we can readily check that z satisfies

$$z_\tau \leq (\sigma(\tilde{\tau}))^{-2}\Delta z + \left(z - \frac{\xi\nabla z}{2}\right) \quad \text{for } \tau > \tilde{\tau} - \frac{1}{\tilde{\tau}}, \quad 0 < \xi < 1, \tag{6.22a}$$

whereas by (6.19),

$$z = 0 \quad \text{when } \xi = 0, 1 \text{ and } \tau > \tilde{\tau} - \frac{1}{\tilde{\tau}} \tag{6.22b}$$

and

$$z = O\left(\frac{1}{\sigma(\tilde{\tau})^2}\right) \quad \text{at } \tau = \tilde{\tau} - \frac{1}{\tilde{\tau}}. \tag{6.22c}$$

By classic parabolic theory, it follows from (6.22) that

$$z(\xi,\tau) \leq A(\sigma(\tilde{\tau}))^{-2}\exp\left(-\frac{A(\tau-\tilde{\tau})}{(\sigma(\tilde{\tau})^2}\right) \quad \text{in } Q,$$

where

$$Q = \left\{ (\xi, \tau) : |\xi| \le 1, \quad \tau \in \left(\bar{\tau} - \frac{1}{\tilde{\tau}}, \tilde{\tau} + \frac{1}{\tilde{\tau}} \right) \right\}.$$

In particular, $w(\xi,\tau) \sim \tilde{w}_{\lambda_0}(\xi)$ at $\tau = \tilde{\tau}$. Recalling (6.6) (with σ, λ replaced by $\sigma(\tilde{\tau})$, $\lambda_0(\tilde{\tau})$, respectively), we see that the (rescaled) free boundary of $w(\xi,\tilde{\tau})$ is very close to $\lambda_0(\tilde{\tau})$ and in particular is larger than $\lambda(\tilde{\tau})$, which is a contradiction. The case where (6.18b) is replaced by $|W(\tau) - \nu_{\lambda(\tilde{\tau})}(1)| = W(\tau) - \nu_{\lambda(\tilde{\tau})}(1)$ is similar and will be omitted. □

We now point out the following consequence of Lemmas 6.2 and 6.3.

Corollary 6.4. *There holds*

$$|\varepsilon(\tau) - \varepsilon(\tilde{\tau})| \le C\tau^{-\frac{3}{2}}\varepsilon(\tilde{\tau}) \quad \textit{for some } C > 0 \tag{6.23}$$

whenever $|\tau - \tilde{\tau}| < \frac{1}{\tau}$ *and* $\tilde{\tau} \ge \tau_0 \gg 1$.

Proof. From (6.12) and (6.16) we readily see that

$$|\nu_{\lambda(\tau)}(1) - \nu_{\lambda(\tilde{\tau})}(1)| \le \frac{2C}{\tau}(\lambda(\tilde{\tau}))^2 \quad \text{for } |\tau - \tilde{\tau}| < \frac{1}{\tau}$$

and the result follows at once in view of the explicit formula (6.5). □

We shall conclude the proof of (1.2) by means of a careful analysis of (6.16), which can be thought of as an integral equation for the unknown rescaled free boundary $\varepsilon(\tau)$. Assume now that (4.2) holds. Then in view of (5.3), (5.30), and (6.16), we have that

$$\left| a_0(\tau)\varphi_0 + a_1(\tau)\varphi_1(0) + Q(y,\tau) - \frac{\varepsilon^2(\tau)}{2}\log\left(\frac{\varepsilon(\tau)}{\sigma(\tilde{\tau})}\right) + \frac{\varepsilon(\tau)^2}{4} \right| = O\left(\frac{\varepsilon(\tau)^2}{\tau}\right). \tag{6.24}$$

Note that the error involved in replacing $\varphi_1(y)$ by $\varphi_1(0)$ is already accounted for in the right-hand side of (6.24). We now take advantage of (5.12) to estimate $Q(y,\tau)$ in (6.24). Recalling (6.23), we have that for $(z(\tau))^0 \le y \le 1$ and Σ as in (5.12),

$$\begin{aligned} &\left| \int_\Sigma^\infty \varepsilon(s)^2 e^{-\eta}\eta^{-1}d\eta - \varepsilon(\tau)^2 \int_\Sigma^\infty e^{-\eta}\eta^{-1}d\eta \right| \\ &\le C\bar{\varepsilon}(\tau)^2\tau^{-\frac{1}{2}} \int_\Sigma^\infty e^{-\eta}\eta^{-1}d\eta \\ &\le C\bar{\varepsilon}(\tau)^2\tau^{-\frac{1}{2}}(1 - |\log\Sigma|)e^{-\Sigma} \le C\bar{\varepsilon}(\tau)^2\tau^{-\frac{1}{2}}. \end{aligned} \tag{6.25a}$$

Notice that (6.23) provides a factor $\tau^{-\frac{3}{2}}$ in the right-hand side of the first inequality above in sets where $|s - \tau| < \frac{1}{\tau}$. Extending such a bound to the interval $|s - \tau| \le 1$ required by our choice of Σ yields then the final factor $\tau^{-\frac{1}{2}}$. A similar argument gives

$$\left| \int_\Sigma^\infty \varepsilon(s)^2\eta^2 e^{-\eta}(4\eta^2)^{-1}d\eta - \varepsilon(\tau)^2 \int_\Sigma^\infty \eta^2 e^{-\eta}(4\eta^2)^{-1}d\eta \right| \le C\bar{\varepsilon}(\tau)^2\tau^{-\frac{1}{2}} \tag{6.25b}$$

and

$$\begin{aligned} &\left| \int_{\tau-1}^\tau (A_1 + A_2(1 - e^{-(\tau-s)}))e^{\tau-s}\varepsilon(s)^2 ds \right. \\ &\left. \quad - (\varepsilon(\tau))^2 \int_{\tau-1}^\tau (A_1 + A_2(1 - e^{-(\tau-1)}))e^{\tau-s}ds \right| \le C\bar{\varepsilon}(\tau)^2\tau^{-\frac{1}{2}}. \end{aligned} \tag{6.25c}$$

Recalling (5.12), we have obtained the following estimate:

$$\tag{6.26} \begin{aligned} &\left| Q(y,\tau) - \gamma - \varepsilon(\tau_0)^2 S(\tau-\tau_0)F(y) - \gamma\varepsilon(\tau_0)^2 \int_{\tau_0}^{\tau} S(\tau-s)\left(\delta(y) - \sum_{k=0}^{1}\langle\varphi_k, \delta(y)\rangle\varphi_k\right) ds \right| \\ &\leq C(\bar{\varepsilon}(\tau))^2 \tau^{-\frac{1}{2}}. \end{aligned}$$

Keeping in mind the definition of $F(y)$ (cf. (3.8)), we see that

$$S(\tau-\tau_0)F(y) + \int_{\tau_0}^{\tau} S(\tau-s)\left(\delta(y) - \sum_{k=0}^{1}\langle\varphi_k, \delta(y)\rangle\varphi_k\right) ds = F(y).$$

It then turns out that (6.26) can be recast in the form

$$\begin{aligned} &|Q(y,\tau) - \gamma\varepsilon(\tau)^2 F(y) - \gamma(\varepsilon(\tilde{\tau})^2 - \varepsilon(\tau)^2) S(\tau-\tau_0)F(y)| \\ &\leq C\bar{\varepsilon}(\tau)^2\tau^{-\frac{1}{2}} \quad \text{for } (\bar{\varepsilon}(\tau))^\theta \leq y \leq 1. \end{aligned}$$

Since the term $S(\tau-\tau_0)F(y)$ decays exponentially on sets where $|y|$ is bounded, we may take advantage again of (6.23) to obtain that

$$\tag{6.27} |Q(y,\tau) - \gamma\varepsilon(\tau)^2 F(y)| \leq C\bar{\varepsilon}(\tau)^2\tau^{-\frac{1}{2}} \quad \text{whenever } (\bar{\varepsilon}(\tau))^\theta \leq y \leq 1.$$

Using now the explicit representation for $F(y)$ (cf. (3.9)), we deduce from (6.24) and (6.27) that

$$\tag{6.28} \left| a_0(\tau)\varphi_0 + a_1(\tau)\varphi_1(0) + \left(B\gamma + \frac{1}{4}\right)\varepsilon(\tau)^2 - \frac{\varepsilon(\tau)^2}{2}\log\varepsilon(\tau) \right| \leq C\bar{\varepsilon}(\tau)^2\tau^{-\frac{1}{2}}.$$

Let us now define $\varepsilon^*(\tau)$ as follows

$$\varepsilon^*(\tau) = \begin{cases} \varepsilon(\tau) & \text{if } \tau_0 \leq \tau \leq \tau_1, \\ \bar{\varepsilon}(\tau) & \text{if } \tau \geq \tau_1. \end{cases}$$

We next observe that if (4.11) is satisfied there holds

$$a_k(\tau) = -\int_{\tau}^{\infty} e^{\lambda_k(\tau-s)}\langle\chi_{\varepsilon^*(\tau)}, \varphi_k\rangle ds.$$

Substituting this into (6.28), we finally arrive at

$$\tag{6.29} \begin{aligned} &\left| \left(B\gamma + \frac{1}{4}\right)\varepsilon^*(\tau)^2 - \frac{\varepsilon^*(\tau)^2}{2}\log\varepsilon^*(\tau) \right. \\ &\left. - \sum_{k=0}^{1}\varphi_k(0)\int_{\tau}^{\infty} e^{(1-k)(\tau-s)}\langle\chi_{\varepsilon^*(s)}, \varphi_k\rangle ds \right| \\ &= 0(\varepsilon^*(\tau)^2\tau^{-1/2}) \quad \text{for } \tau \gg 1. \end{aligned}$$

This is essentially the integral equation that has been studied in detail in section 3 (cf. the argument following (3.17)). In view of our previous analysis in section 3, we may summarize our discussion in the following.

LEMMA 6.5. *Assume that* (4.2) *and* (4.11) *hold. We then have that*

$$\varepsilon(\tau) = \bar{\varepsilon}(\tau)(1 + o(1)) \quad \textit{for } \tau \gg 1 \tag{6.30}$$

uniformly on $\tau_0 \le \tau \le \tau_1$.

End of the proof for Proposition 4.1. Having obtained (6.30) under assumption (4.11), it merely remains to show that condition $|\psi(y,\tau)| < M(1+y^2)$ in (4.8) holds for some constant M which is independent of the size of the interval $[\tau_0, \tau_1]$. To check this point, we argue as follows. We have just seen that

$$\psi(y,\tau) \sim a_0(\tau)\varphi_0 + a_1(\tau)\varphi_1(y) + O(\varepsilon(\tau)^2) \quad \text{for } \tau \gg 1 \text{ and } y = O(1). \tag{6.31}$$

We now claim that we may formally differentiate twice with respect to y in both sides of (6.31) and the corresponding expansion still holds. To wit, we set $z(y,\tau) = \psi(y,\tau) - a_1(\tau)\varphi_1(y)$ and remark that in regions where $y = O(1)$, one has that $z = O(\varepsilon^2(\tau))$ and satisfies

$$Lz = 0(\varepsilon^2(\tau)\varphi_1(y)),$$

where L denotes the parabolic operator in (5.1). It then follows that for $\tau \ge \tau_0 \gg 1$

$$z(y,\tau) = \exp\left(\int_{\tau_0}^{\tau} D(s)ds\right)\varphi_1(y) \quad \text{with } D(s) = O(\varepsilon(s)^2)$$

whereupon the desired bound for ψ follows. □

Proof of (1.6) *in Theorem* 1.3. It has been shown above that

$$\psi_{yy}(y,\tau) \sim Ca_1(\tau) + O(\varepsilon^2(\tau)) \quad \text{with } C = \frac{d^2}{dy^2}(\varphi_1(y)) \tag{6.32}$$

for, say, $y = O(1)$ and $\tau \gg 1$. Since $\theta(r,t) = \psi_{yy} + \frac{\psi_y}{y} = Ca_1(\tau)$ for some $C_1 > 0$, it follows that, setting $r = Ae^{-\tau/2}$ with $A > 0$,

$$\theta(r,T) \sim C_1 a_1 \left(-2\log\frac{r}{A}\right)(1 + o(1)) \quad \text{as } \tau \to 0. \tag{6.33}$$

Since

$$a_1(\tau) \sim \frac{\varepsilon^2(\tau)\log\varepsilon(\tau)}{2} \quad \text{as } \tau \to \infty,$$

the result follows at once from (6.33) and (3.18). □

$$f(x,T) \sim Ca_1\left(-2\log\frac{x}{A}\right)(1 + o(1)) \quad \text{as } x \to 0. \tag{6.34}$$

Since $a_1(\tau) \sim \frac{1}{2}\varepsilon^2(\tau)\log\varepsilon(\tau)$ as $\tau \to \infty$, the result follows at once from (6.34) and (3.18). □

7. The remaining cases. In this final section we shall merely sketch those modifications of the arguments developed in sections 4–6 which are required to obtain (1.3)–(1.5) and (1.7)–(1.9), thus concluding the proofs of Theorems 1.1–1.3.

7.1. Obtaining (1.3) in Theorem 1.1. In the topological argument described in section 4, we must replace $\bar{\varepsilon}(\tau)$ in (4.1) by

$$\bar{\varepsilon}(\tau) = Ce^{(1-\frac{l}{2})\tau}\tau^{-1/l-1},$$

where C is an arbitrary constant and l is an integer such that $l \geq 2$. We then substitute (4.2a) by

$$\sup\left\{|\varepsilon(\tau) - \bar{\varepsilon}(s)|, \text{where } \tau, s \in [\tau_0, \tau_1] \text{ and } |\tau - s| < \frac{1}{\tau}\right\} < M\bar{\varepsilon}(\tau)\tau^{-1},$$

which can be rephrased in an informal way as requiring that $|\frac{d}{d\tau}\bar{\varepsilon}(\tau)| < M\bar{\varepsilon}(\tau)$. Condition (4.2b) is then kept as before. As for (4.11), it is to be replaced by

$$a_k(\tau) = -\int_\tau^\infty e^{(1-\frac{k}{2})(\tau-s)}\langle \chi_{\bar{\varepsilon}(s)}, \varphi_k\rangle ds$$

for $k = 0, 1, 2, \ldots, l$.

With these modifications in mind, the analogue of Proposition 4.1 is readily stated. To analyze the outer region in this case, one writes $\psi(y, \tau)$ in the form

$$\psi(y,\tau) = \sum_{k=0}^{l-1} a_k(\tau)\varphi_k(y) + a_l(\tau)\varphi_l(y) + E(y,\tau). \tag{7.1}$$

The term $E(y, \tau)$ in (7.1) will be approximated as before by $Q(y, \tau)$, where Q satisfies now (3.25b) instead of (5.5). The solution of such an equation for $\tau > \tau_0$ such that $Q(y, \tau_0) = 0$ is given by

$$Q_0(y,\tau) = \gamma\int_{\tau_0}^{\tau} K_l(y, \tau - s)e^{\tau-s}\varepsilon(s)^2 ds, \tag{7.2a}$$

where

$$K_l(y,\tau) = (4\pi(1-e^{-\tau}))^{-1}\left(\exp\left(-\frac{y^2e^{-\tau}}{4(1-e^{-\tau})}\right) - \sum_{k=0}^{l}\varphi_k\left\langle\varphi_k, \exp\left(-\frac{y^2e^{-\tau}}{4(1-e^{-\tau})}\right)\right\rangle\right). \tag{7.2b}$$

Notice that $|K_l(y, \tau)| \leq Ce^{-l\tau}$ uniformly on sets $|y| \leq R < \infty$ when $\tau \geq 1$. Arguing as for Lemma 5.2, we then obtain the corresponding version of that result in our case. This last is obtained by making a few modifications in (5.12):

(a) Replace $S(\tau)$ by $S_l(\tau)$ there, where $S_l(\tau)$ is the semigroup associated to operator A_l in (3.27c).

(b) Replace $F(y)$ given in (3.8) by the corresponding solution of (3.27).

(c) Substitute $K(y, \tau)$ by $K_l(y, \tau)$ given in (7.2b).

(d) Replace the factor $(A_1 + A_2(1 - e^{-(\tau-1)}))$ in the integral where it appears in (5.12) by $(A_1 + A_2(1 - e^{-(\tau-1)}) + \cdots + A_l(1 - e^{-(\tau-s)}))$.

The analysis of the inner region is then performed as in section 6. The integral equation (6.16) is now to be replaced by

$$|W(\tau) - \nu_{\lambda(\tau)}(1)| \leq C\varepsilon(\tau)^2,$$

provided that $|\tau - \bar{\tau}| \leq \frac{1}{\tau}, \bar{\tau} \gg 1$.

Arguing as in section 6, we then arrive at an integral equation which is similar to (3.30). We shall omit further details.

7.2. The case where $N \geq 3$: End of the proof of Theorem 1.2. We first describe the main steps toward obtaining (1.4). To begin with, we replace $\bar{\varepsilon}(\tau)$ in (4.1) by

$$\bar{\varepsilon}(\tau) = C\tau^{-\frac{1}{N-2}}, \quad C > 0,$$

and replace (4.2a) by

$$|\varepsilon(\tau) - \bar{\varepsilon}(s)| < M\bar{\varepsilon}(s)\tau^{-(1-\theta)} \quad \text{for some } 0 < \theta \ll 1$$

whenever $|\tau - s| \leq \tau^{\theta}$.

The main novelty now with respect to the previous cases is that we may estimate directly the error term $E(y,\tau)$ in (5.3) to obtain

$$|E(y,\tau)| \leq C\bar{\varepsilon}(\tau)^N(1 + y^{-(N-2)}) \quad \text{for } \tau \gg 1$$

uniformly on sets $y \leq R < \infty$. We are thus led to a version of the integral equation (6.16) which reads now as follows:

$$|W(\tau) - \nu_{\lambda(\tau)}(1)| \leq C\bar{\varepsilon}(\tau)^2\tau^{-(1-\theta)} \quad \text{for } |\tau - \bar{\tau}| \leq \tau^{\theta}, \bar{\tau} \gg 1,$$

whence the statement in Lemma 6.5 follows in this case.

Finally, (1.5) corresponds to the situation where $\chi_{\varepsilon(\tau)}$ can be asymptotically neglected in (5.1), so that the analysis sketched at the end of section 3 can be carried out in a straightforward way.

7.3. End of the proof of Theorem 1.3. To obtain (1.7), we can argue as in the last part of section 6 to obtain that

$$\psi(y,\tau) \sim a_l(\tau)\varphi_l(y) \quad \text{for } y = O(1) \text{ and } \tau \gg 1,$$

where the expansion above also holds when differentiated twice with respect to y. In view of (6.33), one then has that at points $x = Ae^{-\tau/2}$,

$$\theta(x,T) \sim a_l\left(-2\log\frac{x}{A}\right)A^{2l-2} = a_l\left(-2\log\frac{x}{A}\right)|x|^{2l-2}e^{(l-1)\tau},$$

whence (1.7) follows in view of (3.30) and (3.31).

As to (1.8), we make use of (3.33) and (3.34) to observe that

$$\psi_{yy}(y,\tau) \sim C\tau^{-\frac{2}{N-2}} \quad \text{for } y = O(1) \text{ and } \tau \gg 1.$$

This readily gives that for $x = Ae^{-\tau/2}$

$$\theta(x,T) \sim C(|\log|x||)^{-\frac{2}{N-2}} \quad \text{as } x \downarrow 0.$$

Finally, to obtain (1.9) we merely recall that, in view of (3.35), one has that for $x = Ae^{-\tau/2}$

$$\psi_{yy}(A,\tau) \sim e^{(1-l)\tau}A^{2l-2},$$

whereupon $\theta(x,T)$ is shown to be such that

$$\theta(x,T) \sim C|x|^{2l-2} \quad \text{as } x \downarrow 0.$$

SELF-SIMILAR SOLUTIONS OF BARENBLATT'S MODEL FOR TURBULENCE*

JOSEPHUS HULSHOF[†]

Abstract. In this paper, we consider Barenblatt's k–ϵ model for turbulence. For the case of equal diffusion coefficients α and β, Barenblatt found explicit compactly supported self-similar solutions. From these, we obtain compactly supported solutions for $\alpha \neq \beta$ by transforming the equations into a four-dimensional quadratic system and verifying a transversality condition for a saddle-point connection. This involves the Poincaré transformation as well as classical properties of the hypergeometric equation and its solutions.

Key words. turbulence, compactly supported similarity solutions, quadratic systems, critical points at infinity, Poincaré transformation, saddle-point connections, transversality

Introduction. In this paper, we consider the system

$$\text{(KE)} \quad \begin{cases} k_t = \alpha\Big(\dfrac{k^2}{\varepsilon} k_x\Big)_x - \varepsilon, \\ \varepsilon_t = \beta\Big(\dfrac{k^2}{\varepsilon}\varepsilon_x\Big)_x - \gamma\dfrac{\varepsilon^2}{k}. \end{cases}$$

Here α, β, and γ are positive parameters and k and ε are unknown nonnegative functions of x (space) and t (time). This system is called the k–ε model and describes the evolution of turbulent bursts [B] (see also [LS], [HP], and [KV]); k stands for the turbulent energy density and ε is the dissipation rate of turbulent energy. In applications, α and β are usually different [LMRS, HL]. The model is also refered to in the literature as the b–ε model, which is, in fact, the original notation due to Kolmogorov ($k = b$) [K, P, MY]. We note that (KE) is a coupled system of two quasilinear diffusion-absorption equations. The diffusion coefficients may, depending on k and ε, become degenerate (very small) or singular (very large), and the second absorption term is also singular.

The only results that have been rigorously established so far are for the case where $\alpha = \beta$: for $\gamma > 3/2$, a family of explicit self-similar compactly supported "source-type" solutions was found by Barenblatt et al. [BGL], and for $\gamma > 1$, an existence result for solutions to the Cauchy problem was proved by Bertsch, Dal Passo, and Kersner [BdPK1, BdPK2], who also showed that for $\gamma > 3/2$, the self-similar solutions describe the intermediate asymptotics of these solutions.

This paper is concerned with the existence of compactly supported self-similar solutions when $\alpha \neq \beta$. Let us recall that the Barenblatt solutions are obtained by

substituting

$$k = \frac{A^2}{t^{2\mu}} f(\zeta), \qquad \varepsilon = \frac{A^2}{t^{2\mu+1}} g(\zeta), \qquad \zeta = \frac{x}{At^{1-\mu}}, \tag{0.1}$$

where $A > 0$ is a free-scaling parameter and where we restrict our attention to the case where $0 < \mu < 1$. Thus we look at profiles which decay and spread out as time evolves.

The equations for f and g are

$$\begin{cases} \alpha\Big(\dfrac{f^2}{g} f'\Big)' + (1-\mu)\zeta f' + 2\mu f - g = 0; & (0.2) \\ \beta\Big(\dfrac{f^2}{g} g'\Big)' + (1-\mu)\zeta g' + (1+2\mu)g - \gamma\dfrac{g^2}{f} = 0. & (0.3) \end{cases}$$

If we assume that

$$g(\zeta) = \kappa f(\zeta), \tag{0.4}$$

equations (0.2) and (0.3) can be reduced to one single equation if and only if

$$\alpha = \beta, \qquad \kappa = \frac{1}{\gamma - 1}, \tag{0.5}$$

the resulting equation for f being

$$\frac{\alpha}{\kappa}(ff')' + (1-\mu)\zeta f' + (2\mu - \kappa) f = 0. \tag{0.6}$$

Finally, if also

$$\mu = \frac{\kappa + 1}{3}, \quad 0 < \mu < 1, \tag{0.7}$$

equation (0.6) can be written as

$$\frac{3\alpha}{\kappa(2-\kappa)}(ff')' + (\zeta f)' = 0, \tag{0.8}$$

which has compactly supported nonnegative solutions

$$f(\zeta) = \left(C - \frac{\kappa(2-\kappa)}{6\alpha}\zeta^2\right)_+, \quad C > 0, \tag{0.9}$$

if and only if

$$0 < \kappa < 2. \tag{0.10}$$

Note that (0.5), (0.7), and (0.10) imply that $\gamma > \frac{3}{2}$.

We observe that (0.9) corresponds to the well-known Barenblatt profile for the porous-medium equation (denoted by (PME)) $u_t = (u^m)_{xx}$ with $m = 2$. In fact, substitution of $\varepsilon = \kappa k$ together with (0.5) reduces the full system (KE) to (PME).

Just as in the case of the (PME) (see, e.g., [A]), we see that at the boundary of the support of the solutions, the fluxes vanish, i.e.,

$$\frac{f^2}{g}f' \to 0 \quad \text{and} \quad \frac{f^2}{g}g' \to 0. \tag{0.11}$$

The main result of this paper is a perturbation of the explicit family of compactly supported similarity solutions above, yielding a similar family of solutions for $\gamma > 3/2$ and α close to β. This is an important and strong indication that the PDE results mentioned above for $\alpha = \beta$ are not isolated but really a first step towards a full theory for (KE).

THEOREM. *There exists an open neighborhood $\mathcal{O}$ of the set*

$$\left\{(\alpha,\beta,\gamma):\ \alpha=\beta>0,\ \gamma>\frac{3}{2}\right\}$$

such that for every $(\alpha,\beta,\gamma)\in\mathcal{O}$, there is precisely one $0<\mu<1$ for which equations (0.2) and (0.3) have a solution pair (f,g) with f and g symmetric and positive on $(-1,1)$ and

$$f(\zeta)\to 0,\quad g(\zeta)\to 0,\quad \frac{f(\zeta)}{g(\zeta)}f'(\zeta)\to-\alpha(1-\mu),\quad \frac{f(\zeta)^2}{g(\zeta)^2}g'(\zeta)\to-\beta(1-\mu) \tag{0.12}$$

as $\zeta\uparrow 1$. Moreover, if we write

$$\kappa=\frac{g(0)}{f(0)},\qquad \lambda=\frac{\alpha}{\beta}, \tag{0.13}$$

then in $\lambda=1$,

$$\kappa=\frac{1}{\gamma-1},\qquad \frac{d\mu}{d\lambda}=0,\qquad \frac{d\kappa}{d\lambda}=\frac{\kappa(2-\kappa)}{\kappa+1}\left(\kappa-1+\frac{2}{B_\kappa}\right). \tag{0.14}$$

Here B_κ is defined by

$$B_\kappa=\frac{\Gamma(\frac{1}{2})}{\Gamma(a)\Gamma(b)},\qquad a+b=\frac{3}{2},\qquad ab=\frac{3}{2(2-\kappa)}. \tag{0.15}$$

In order to perform the perturbation argument, we adapt the methods in [H] and introduce

$$t=\log\zeta,\quad x=\frac{\zeta f'}{f},\quad y=\frac{\zeta g'}{g},\quad z=\zeta^2\frac{g}{\alpha f^2},\quad u=\frac{g}{f}, \tag{0.16}$$

which transforms the two coupled nonautonomous second-order equations (0.2) and (0.3) into the four-dimensional first-order quadratic autonomous system

$$\text{(Q)}\quad\begin{cases}\dfrac{dx}{dt}=x(1-3x+y)-z(x(1-\mu)+2\mu-u);\\[2mm] \dfrac{dy}{dt}=y(1-2x)-\lambda z(y(1-\mu)+2\mu+1-\gamma u);\\[2mm] \dfrac{dz}{dt}=z(2+y-2x);\\[2mm] \dfrac{du}{dt}=u(y-x).\end{cases}$$

In section 1, we investigate this system. We find that symmetric profiles (f, g) correspond to the two-dimensional "fast" unstable manifold $\mathcal{F}$ of the positive u-axis and that the profiles satisfying the so-called interface condition as $0 < \zeta \uparrow \zeta^* < \infty$ are contained in the two-dimensional stable manifold $\mathcal{S}$ of a critical point at infinity on the line with direction vector

$$\begin{pmatrix} -(1-\mu) \\ -\lambda(1-\mu) \\ 1 \\ 0 \end{pmatrix}. \tag{0.17}$$

This involves the Poincaré transformation of (Q) and is carried out with the help of Maple. As a byproduct here, we find that it is necessary to assume that

$$\alpha \leq 2\beta \tag{0.18}$$

because otherwise $\mathcal{S}$ is one dimensional and contained in "infinity."

It follows from the analysis in section 1 that the compactly supported profiles we are looking for correspond to intersections of $\mathcal{F}$ and $\mathcal{S}$. In particular, and just as in [H], the explicit solutions above correspond to an orbit which is simply the straight line

$$x = y = -(1-\mu)z, \quad u = \kappa. \tag{0.19}$$

In section 2, we show that in the full $(x, y, z, u, \alpha, \beta, \gamma, \mu)$-space, the intersection of $\mathcal{F}$ and $\mathcal{S}$ is transversal at (0.19), thus obtaining our perturbation result. The dynamical-systems methods we use here were applied earlier in [AV] and [HV] to two-dimensional systems that come from scalar diffusion equations. However, in our case, the computations in which the hypergeometric function, the Gauss formula, and the Kummer relations appear [L] are much more involved, and again it is thanks to the help of Maple that we were able to pull through.

1. The quadratic system. In this section, we examine system (Q) in relation to the boundary conditions imposed on f and g. We note that every solution of (0.2)–(0.3) is mapped into an orbit of (Q) and that scaling with the parameter A in (0.1) corresponds to a shift in t.

By standard ODE theory [CL], there exists for every $p, q > 0$ a unique local solution (f, g) of (0.2)–(0.3) satisfying the initial conditions

$$f(0) = p, \quad g(0) = q, \quad f'(0) = 0, \quad g'(0) = 0. \tag{1.1}$$

This provides us with a two-parameter family of local solutions of (0.2)–(0.3). For the corresponding solution curve $S(t) = (x(t), y(t), z(t), u(t))$, we find

$$\lim_{t \downarrow -\infty} x(t)e^{-2t} = \lim_{\zeta \downarrow 0} \frac{f'(\zeta)}{\zeta f(\zeta)} = \frac{f''(0)}{f(0)} = \frac{1}{\alpha}(q - 2\mu p)\frac{q}{p^3}. \tag{1.2}$$

Here we have used (0.2) to compute $f''(0)$. Similarly, we find

$$\lim_{t \downarrow -\infty} y(t)e^{-2t} = \frac{1}{\beta}(\gamma q - (2\mu + 1)p)\frac{q}{p^3}, \qquad \lim_{t \downarrow -\infty} z(t)e^{-2t} = \lim_{\zeta \downarrow 0} \frac{g(\zeta)}{f(\zeta)^2} = \frac{\alpha q}{p^2}, \tag{1.3}$$

and, using l'Hôpital's rule,

$$\begin{aligned}
&\lim_{t\downarrow-\infty}\left(u(t)-\frac{q}{p}\right)e^{-2t}=\lim_{\zeta\downarrow 0}\frac{pg(\zeta)-qf(\zeta)}{p\zeta^2 f(\zeta)}=\lim_{\zeta\downarrow 0}\frac{pg'(\zeta)-qf'(\zeta)}{2p\zeta f(\zeta)+p\zeta^2 f'(\zeta)}\\
&=\lim_{\zeta\downarrow 0}\frac{pg''(\zeta)-qf''(\zeta)}{2pf(\zeta)+4p\zeta f'(\zeta)+p\zeta^2 f''(\zeta)}=\frac{q^2}{2p^4}\left(\frac{1}{\beta}(\gamma q-(2\mu+1)p)-\frac{1}{\alpha}(q-2\mu p)\right).
\end{aligned} \tag{1.4}$$

Thus $S(t)$ comes out of the point $(x,y,z,u)=(0,0,0,q/p)$ on the positive u-axis into the (invariant) open "quadrant" $O^+=\{z>0,u>0\}$ along an eigenvector corresponding to the eigenvalue 2 of the linearization of (Q) around $(0,0,0,q/p)$, which is

$$\begin{pmatrix}1 & 0 & -(2\mu-\kappa) & 0\\ 0 & 1 & -\lambda(2\mu+1-\gamma\kappa) & 0\\ 0 & 0 & 2 & 0\\ 0 & 0 & 0 & 0\end{pmatrix}. \tag{1.5}$$

Here

$$\kappa=\frac{q}{p},\qquad \lambda=\frac{\alpha}{\beta}. \tag{1.6}$$

Clearly, the positive symmetric solution pairs (f,g) are mapped into the "fast unstable manifold" of the u-axis, the sheet of integral curves tangent to the eigenvector of 2. Note that the ratio κ determines the orbit.

Next, we consider solutions of (0.2)–(0.3) with $f(\zeta)\to 0$ and $g(\zeta)\to 0$ and satisfying the no-flux condition (0.11) as $\zeta\uparrow 1$. This cannot be viewed as an initial- (or final-) boundary value problem in such a straightforward manner as above, and therefore we turn to the quadratic system. Any such solution with both components decreasing to zero as $\zeta\uparrow 1$ is mapped into an orbit which escapes to infinity in finite time. Indeed, all of the other orbits contain solutions $S(t)=(x(t),y(t),z(t),u(t))$ which persist as $t\uparrow\infty$, and it is easy to see that the corresponding solutions (f,g) are positive in $\zeta=1$. Thus we look for orbits escaping to infinity in finite time with $x<0$, $y<0$, $z>0$, and $u>0$. This means that x and y cannot both be bounded.

For the study of the unbounded orbits, we use the Poincaré transformation to determine the critical points at infinity. Rewriting (Q) as

$$\text{(Q)}\quad\begin{cases}\dot{x}_1=P_1(x_1,x_2,x_3,x_4);\\ \dot{x}_2=P_2(x_1,x_2,x_3,x_4);\\ \dot{x}_3=P_3(x_1,x_2,x_3,x_4);\\ \dot{x}_4=P_4(x_1,x_2,x_3,x_4),\end{cases}$$

where $(x_1,x_2,x_3,x_4)=(x,y,z,u)$ and dots denote differentiation with respect to t, we introduce the new coordinates X_1,X_2,X_3,X_4, and V as follows:

$$x_i=\frac{X_i}{V}\quad(i=1,2,3,4),\qquad X_1^2+X_2^2+X_3^2+X_4^2+V^2=1. \tag{1.7}$$

This transforms (Q) into an autonomous polynomial system of five first-order differential equations for X_1,X_2,X_3,X_4, and V, which leaves the 4-sphere $S^4=\{X_1^2+X_2^2+X_3^2+X_4^2+V^2=1\}$ invariant.

Differentiating (1.7), we have

$$V\dot{V}+\sum_{j=1}^{4}X_j\dot{X}_j=0 \tag{1.8}$$

and

$$\dot{X}_iV-X_i\dot{V}=P_i^*, \tag{1.9}$$

where

$$P_i^*(X_1,X_2,X_3,X_4,V)=V^2P_i(x_1,x_2,x_3,x_4). \tag{1.10}$$

Thus the P_i^*'s are homogeneous polynomials of degree 2. Combining (1.8) and (1.9), we obtain

$$V\left(V^2+\sum_{j=1}^{4}X_j^2\right)\dot{V}=-V\sum_{j=1}^{4}X_jP_j^* \tag{1.11}$$

and, with (1.8) again,

$$\begin{aligned} V\left(V^2+\sum_{j=1}^{4}X_j^2\right)\dot{X}_i &= \left(V^2+\sum_{j=1}^{4}X_j^2\right)P_i^*+X_i\left(V^2+\sum_{j=1}^{4}X_j^2\right)\dot{V} \\ &= V^2P_i^*+\sum_{j=1}^{4}X_j(X_jP_i^*-X_iP_j^*). \end{aligned} \tag{1.12}$$

Thus integral curves of (Q) correspond to integral curves with $V>0$ on S^4 of the system

$$(\tilde{\mathrm{Q}})\quad\begin{cases} X_i'=V^2P_i^*+\sum_{j=1}^{4}X_j(X_jP_i^*-X_iP_j^*) \quad (i=1,2,3,4); \\ V'=-V\sum_{j=1}^{4}X_jP_j^*. \end{cases}$$

Here we have absorbed the factor

$$V\left(V^2+\sum_{j=1}^{4}X_j^2\right)$$

in the derivative.

Unbounded solutions of (Q) correspond to solutions of $(\tilde{\mathrm{Q}})$ which approach the invariant set $S^4\cap\{V=0\}$. The critical points "at infinity" of (Q) are by definition the critical points of $(\tilde{\mathrm{Q}})$ on $S^4\cap\{V=0\}$, which in turn are the solutions of

$$\begin{cases} \sum_{j=1}^{4}X_j(X_jP_i^*-X_iP_j^*)=0 \quad (i=1,2,3,4); & (1.13) \\ X_1^2+X_2^2+X_3^2+X_4^2+V^2=1. & (1.14) \end{cases}$$

Note that we have five equations for four unknowns. It is implicit in the Poincaré transformation that these equations are dependent.

Using Maple and again writing X, Y, Z, and U for X_1, X_2, X_3, and X_4, we find that (1.13) is equivalent to

$$\begin{cases} \bigl(Y^3 + (\lambda - 1)(1-\mu)Y^2Z - \gamma\lambda YZU - (1 - \mu Z^3 - (1-\mu)ZU^2\bigr)X \\ \qquad\qquad + ZU(Z^2 + Y^2 + U^2) + (Y^2 + 2U^2 + Z^2)X^2 = 0, \\ \bigl(XY - Y^2 - (1-\mu)(\lambda - 1)YZ + \gamma\lambda ZU\bigr)X^2 - (U^2 + ZU)XY \\ \qquad - (U^2 + Z^2)Y^2 - \lambda(1-\mu)(Z^2 + U^2)YZ + \gamma\lambda ZU(U^2 + Z^2) = 0, \\ Z\bigl(X^3 + (1-\mu)ZX^2 - (ZU + U^2)X + Y^3 + \lambda(1-\mu)Y^2Z - \gamma\lambda YZU\bigr) = 0, \\ U\bigl(2X^3 + (1-\mu)X^2Z + (Y^2 + Z^2 - ZU)X + Y^3 + \lambda(1-\mu)Y^2Z - \gamma\lambda YZU\bigr) = 0, \end{cases}$$

which at first sight looks too complicated to evaluate. However, if we multiply the third equation by Z and the fourth equation by U, subtraction gives

$$XZU(X^2 + Y^2 + Z^2 + U^2) = XZU = 0, \tag{1.15}$$

which reduces the system. Also, if we substitute $X = 0$ in the first equation, we obtain

$$ZU(Y^2 + Z^2 + U^2) = ZU = 0. \tag{1.16}$$

Thus all the solutions of (1.13)–(1.14) have either $Z = 0$ or $U = 0$ or have both. This allows us to solve (1.13)–(1.14) explicitly, either by hand or by again using Maple. The solutions (X, Y, Z, U) with $Z \geq 0$ and $U \geq 0$ are

$$(\pm 1, 0, 0, 0), \quad (0, \pm 1, 0, 0), \quad (0, 0, 1, 0), \quad (0, 0, 0, 1), \quad \left(\pm\sqrt{\frac{1}{2}}, \pm\sqrt{\frac{1}{2}}, 0, 0\right),$$

$$\left(\frac{-(1-\mu)}{\sqrt{1 + (1-\mu)^2}}, 0, \frac{1}{\sqrt{1 + (1-\mu)^2}}, 0\right), \quad \left(0, \frac{-\lambda(1-\mu)}{\sqrt{1 + \lambda^2(1-\mu)^2}}, \frac{1}{\sqrt{1 + \lambda^2(1-\mu)^2}}, 0\right),$$

and, last but not least,

$$P = \left(\frac{-(1-\mu)}{\sqrt{1 + (1+\lambda^2)(1-\mu)^2}}, \frac{-\lambda(1-\mu)}{\sqrt{1 + (1+\lambda^2)(1-\mu)^2}}, \frac{1}{\sqrt{1 + (1+\lambda^2)(1-\mu)^2}}, 0\right). \tag{1.17}$$

Solution curves of ($\tilde{\mathrm{Q}}$) going into P from $S^4 \cap \{V > 0\}$ correspond to solution curves of (Q) with

$$\frac{x}{z} \to -(1-\mu), \qquad \frac{y}{z} \to -\lambda(1-\mu), \qquad \frac{u}{z} \to 0 \tag{1.18}$$

so that in view of the equation for z,

$$\frac{d}{dt}\frac{1}{z(t)} \to (\lambda - 2)(1-\mu). \tag{1.19}$$

Thus if $\lambda < 2$, these orbits reach infinity in a finite time t^* with none of the functions $x(t)$, $y(t)$, and $z(t)$ integrable near t^*. (Note that $\lambda > 2$ is impossible, as the linearization of ($\tilde{\mathrm{Q}}$) around P will confirm.) Since

$$\int x(t)dt = \int \frac{f'(\zeta)}{f(\zeta)}d\zeta, \qquad \int y(t)dt = \int \frac{g'(\zeta)}{g(\zeta)}d\zeta, \tag{1.20}$$

it follows that

$$f(\zeta^*) = g(\zeta^*) = 0, \quad \zeta^* = e^{t^*}. \tag{1.21}$$

From (1.18), we also have
(1.22)

$$\frac{f(\zeta)}{g(\zeta)} f'(\zeta) = \frac{\alpha x(t)}{z(t)} e^t \to -\alpha(1-\mu)\zeta^*, \qquad \frac{f(\zeta)^2}{g(\zeta)^2} g'(\zeta) = \frac{\alpha y(t)}{z(t)} e^t \to -\beta(1-\mu)\zeta^*$$

so that condition (0.11) is satisfied at ζ^*. We shall call (1.22) the interface conditions for f and g.

The linearization of ($\tilde{\mathrm{Q}}$) around P has eigenvalues

$$-\frac{1-\mu}{\sqrt{1+(1+\lambda^2)(1-\mu)^2}}, \qquad -\frac{(1-\mu)(2-\lambda)}{\sqrt{1+(1+\lambda^2)(1-\mu)^2}}, \qquad 0,$$

$$\frac{1-\mu}{\sqrt{1+(1+\lambda^2)(1-\mu)^2}}, \qquad \frac{\lambda(1-\mu)}{\sqrt{1+(1+\lambda^2)(1-\mu)^2}},$$

i.e., up to a (positive if $\mu < 1$) multiple, simply

$$-1, \quad -(2-\lambda), \quad 0, \quad 1, \quad \lambda.$$

We note that zero is always an eigenvalue with eigenvector perpendicular to S^4. Since we only consider the flow on S^4, this eigenvector is irrelevant.

The only eigenvector with a nonzero V-component is the one corresponding to the eigenvalue which changes sign when λ crosses the value 2. Consequently, we may distinguish between two cases.

$0 < \lambda < 2$: The stable and unstable manifolds both have dimension two. The stable manifold contains a one-parameter family of solutions satisfying the interface conditions.

$\lambda > 2$: The stable manifold has dimension one and the unstable manifold dimension three. The stable manifold is contained in $\{V = 0\}$, implying that there are no orbits going into P coming from $\{V > 0\}$.

2. Transversality of the connection. In this section, we show that the explicit compactly supported solution which exists for

$$\alpha = \beta, \qquad \mu = \frac{\gamma}{3(\gamma-1)}, \qquad \gamma > \frac{3}{2}, \tag{2.1}$$

can be used to obtain a compactly supported solution for $\alpha \neq \beta$. Throughout this section, the value of $\gamma > 3/2$ is fixed. Condition (2.1) follows from (0.5) and (0.7).

The orbit of (Q) corresponding to the exact solutions in the introduction is the straight line (0.19), and it belongs to an analytic family of solution curves of the form

$$x = X(z;\kappa,\mu,\lambda), \qquad y = Y(z;\kappa,\mu,\lambda), \qquad u = U(z;\kappa,\mu,\lambda), \tag{2.2}$$

which are defined as the images under (0.16) of the symmetric solutions to (0.2)–(0.3), and together form the "fast unstable manifold" $\mathcal{F}$ of the u-axis. In particular, we have

$$X(0;\kappa,\mu,\lambda) = 0, \qquad Y(0;\kappa,\mu,\lambda) = 0, \qquad U(0;\kappa,\mu,\lambda) = \kappa = \frac{1}{\gamma-1}. \tag{2.3}$$

Thus we can use z and κ as a coordinate system on $\mathcal{F}$. Note that the analyticity of (2.2) excludes the other "slow" orbits coming out of the u-axis.

On the other hand, we have that at infinity the orbit (0.19) goes into the critical point P given by (1.17). Thus (0.19) also belongs to the stable manifold $\mathcal{S}$ of P. In the previous section, we have seen that $\mathcal{S}$ contains the similarity profiles satisfying the interface conditions and that its dimension is two. It can be written as a family of solutions of the form

$$x = X^*(z; c, \mu, \lambda), \qquad y = Y^*(z; c, \mu, \lambda), \qquad u = U^*(z; c, \mu, \lambda). \tag{2.4}$$

Here z and c are the parameters which can be used as a coordinate system on $\mathcal{S}$. We note that c is really given by the proof of the stable-manifold theorem and corresponds to a suitable smooth curve in the linearized stable manifold [Pe].

Both $\mathcal{F}$ and $\mathcal{S}$ are two dimensional. The straight line (0.19) lies in the intersection of $\mathcal{F}$ and $\mathcal{S}$. Since we are working in a four-dimensional space, the set of parameters for which this intersection is a curve should generically be a set of codimension one. To show that this is really the case in the vincinity of the exact solution above, we apply the implicit-function theorem to the following set of equations:

$$X(z; \kappa, \mu, \lambda) - X^*(z; c, \mu, \lambda) = 0; \tag{2.5}$$

$$Y(z; \kappa, \mu, \lambda) - Y^*(z; c, \mu, \lambda) = 0; \tag{2.6}$$

$$U(z; \kappa, \mu, \lambda) - U^*(z; c, \mu, \lambda) = 0. \tag{2.7}$$

Here the value of z can be taken fixed because the flow leaves $\mathcal{F}$ and $\mathcal{S}$ invariant.

In order to conclude that the solution set of (2.5)–(2.7) is of the form

$$\kappa = \kappa(\lambda), \qquad \mu = \mu(\lambda), \qquad c = c(\lambda), \tag{2.8}$$

we have to show that the matrix containing the partial derivatives of the left-hand sides with respect to κ, μ, and c has a nonzero determinant.

The functions $X(z)$, $Y(z)$, $U(z)$, $X^*(z)$, $Y^*(z)$, and $U^*(z)$ are solutions of the three-dimensional nonautonomous system obtained from (Q) by taking z as a new independent variable:

$$(\mathrm{Q}^*) \quad \begin{cases} \dfrac{dx}{dz} = \dfrac{x(1-3x+y) - z(x(1-\mu)+2\mu-u)}{z(2+y-2x)}; \\ \dfrac{dy}{dz} = \dfrac{y(1-2x) - \lambda z(y(1-\mu)+2\mu+1-\gamma u)}{z(2+y-2x)}; \\ \dfrac{du}{dz} = \dfrac{u(y-x)}{z(2+y-2x)}. \end{cases}$$

It follows from the proof of the stable-manifold theorem that we can compute the derivatives of these functions by differentiating (Q*) with respect to the parameters and solving the resulting equations under the appropiate boundary conditons.

Writing (Q*) as

$$\frac{d\xi}{dz} = H(\xi) = H(\xi; \mu, \lambda), \quad \xi(z) = (x(z), y(z), u(z)), \tag{2.9}$$

we have for the variation $d\xi(z) = (dx(z), dy(z), du(z))$ of ξ the equation

$$\frac{d}{dz} d\xi - \frac{\partial H}{\partial \xi} d\xi = dH = \frac{\partial H}{\partial \mu} d\mu + \frac{\partial H}{\partial \lambda} d\lambda. \tag{2.10}$$

In (2.10), the derivatives of H have to be evaluated at

$$x = y = -(1-\mu)z, \quad u = \kappa, \quad \mu = \frac{\kappa+1}{3}, \quad \gamma = \frac{\kappa+1}{\kappa}, \quad \lambda = 1. \tag{2.11}$$

Using Maple again, we find

$$\frac{\partial H}{\partial \xi} = \begin{pmatrix} \frac{1}{2z} + \frac{3}{2} \frac{2-\kappa}{6+(2-\kappa)z} & 0 & \frac{3}{6+(2-\kappa)z} \\ 0 & \frac{1}{2z} + \frac{3}{2} \frac{2-\kappa}{6+(2-\kappa)z} & \frac{3(\kappa+1)}{\kappa(6+(2-\kappa)z)} \\ \frac{-\kappa}{2z} + \frac{2-\kappa}{2} \frac{\kappa}{6+(2-\kappa)z} & \frac{\kappa}{2z} - \frac{2-\kappa}{2} \frac{\kappa}{6+(2-\kappa)z} & 0 \end{pmatrix}, \tag{2.12}$$

while

$$\frac{\partial H}{\partial \mu} = \begin{pmatrix} -1 \\ -1 \\ 0 \end{pmatrix}, \qquad \frac{\partial H}{\partial \lambda} = \begin{pmatrix} 0 \\ \frac{2-\kappa}{3} - \frac{3(2-\kappa)}{6+(2-\kappa)z} \\ 0 \end{pmatrix}. \tag{2.13}$$

In what follows, we shall compute the general solution of (2.9)–(2.13) explicitly in terms of hypergeometric functions. To do so we transform (2.9)–(2.13) by

$$w = \frac{(2-\kappa)z}{6+(2-\kappa)z}, \qquad z = \frac{6w}{(2-\kappa)(1-w)},$$

$$G(w) = dx(z), \qquad J(w) = dx(z) - dy(z), \qquad F(w) = du(z) \tag{2.14}$$

into

$$\begin{pmatrix} G'(w) \\ J'(w) \\ F'(w) \end{pmatrix} = \begin{pmatrix} \frac{1}{2w} + \frac{2}{1-w} & 0 & \frac{3}{2-\kappa} \frac{1}{1-w} \\ 0 & \frac{1}{2w} + \frac{2}{1-w} & -\frac{1}{\kappa} \frac{3}{2-\kappa} \frac{1}{1-w} \\ 0 & -\frac{\kappa}{2w} & 0 \end{pmatrix} \begin{pmatrix} G(w) \\ J(w) \\ F(w) \end{pmatrix}$$

$$- \frac{6}{2-\kappa} \frac{1}{(1-w)^2} \begin{pmatrix} d\mu \\ 0 \\ 0 \end{pmatrix} + \frac{1-3w}{(1-w)^2} \begin{pmatrix} 0 \\ d\lambda \\ 0 \end{pmatrix}. \tag{2.15}$$

For $F(w)$, this yields

$$w(1-w) \frac{d^2}{dw^2} F(w) + \left(\frac{1}{2} - \frac{5}{2} w \right) \frac{d}{dw} F(w) - \frac{3}{2(2-\kappa)} F(w) = \frac{\kappa(3w-1)}{2(1-w)} d\lambda, \tag{2.16}$$

which has an explicit particular solution, namely,

$$\kappa(2-\kappa) \left(1 - \frac{2}{\kappa+1} \frac{1}{1-w} \right) d\lambda. \tag{2.17}$$

The homogeneous part of (2.16) is the standard hypergeometric equation

$$w(1-w) f''(w) + (c - (1+a+b)w) f'(w) - ab f(w) = 0 \tag{2.18}$$

with parameters a, b, and c given by

$$a+b=\frac{3}{2}, \qquad ab=\frac{3}{2(2-\kappa)}, \qquad \text{and} \quad c=\frac{1}{2}. \tag{2.19}$$

The general solution of (2.18) is given by

$$f(w)=C_1F_1(w)+C_2F_2(w), \tag{2.20}$$

where

$$F_1(w)=F\left(a,b;\frac{1}{2};w\right)=\frac{1}{1-w}F\left(\frac{1}{2}-a,\frac{1}{2}-b;\frac{1}{2};w\right) \tag{2.21}$$

and

$$F_2(w)=w^{\frac{1}{2}}F\left(\frac{1}{2}+a,\frac{1}{2}+b;\frac{3}{2};w\right)=\frac{w^{\frac{1}{2}}}{1-w}F\left(1-a,1-b;\frac{3}{2};w\right). \tag{2.22}$$

Consequently, the general solution of the homogeneous part of (2.15) is given by

$$\begin{pmatrix} G_{\text{hom}}(w) \\ J_{\text{hom}}(w) \\ F_{\text{hom}}(w) \end{pmatrix} = C_1\begin{pmatrix} 2wF_1'(w) \\ -\frac{2w}{\kappa}F_1'(w) \\ F_1(w) \end{pmatrix} + C_2\begin{pmatrix} 2wF_2'(w) \\ -\frac{2w}{\kappa}F_2'(w) \\ F_2(w) \end{pmatrix} + C_3\begin{pmatrix} \frac{w^{\frac{1}{2}}}{(1-w)^2} \\ 0 \\ 0 \end{pmatrix}. \tag{2.23}$$

The hypergeometric part in (2.23) can be derived from the special form of the matrix in (2.15).

A particular solution of (2.15) is

$$\begin{pmatrix} G_p(w) \\ J_p(w) \\ F_p(w) \end{pmatrix} = \begin{pmatrix} \frac{2\kappa w}{(1-w)^2}(3\frac{\kappa-1}{\kappa+1}-w) \\ \frac{4(2-\kappa)}{\kappa+1}\frac{w}{(1-w)^2} \\ \kappa(2-\kappa)(1-\frac{2}{\kappa+1}\frac{1}{1-w}) \end{pmatrix} d\lambda + \begin{pmatrix} \frac{-12}{2-\kappa}\frac{w}{(1-w)^2} \\ 0 \\ 0 \end{pmatrix} d\mu. \tag{2.24}$$

Thus the general solution of (2.15) is the sum of (2.23) and (2.24).

We can now write the partial derivatives of (2.2) for (2.11). The analyticity near $z=0$ combined with (2.3) implies that we have to take

$$C_2=C_3=0, \quad C_1+\kappa(2-\kappa)\frac{\kappa-1}{\kappa+1}d\lambda=d\kappa \tag{2.25}$$

so that

$$\begin{pmatrix} \frac{\partial X}{\partial \kappa} & \frac{\partial X}{\partial \mu} & \frac{\partial X}{\partial \lambda} \\ \frac{\partial (X-Y)}{\partial \kappa} & \frac{\partial (X-Y)}{\partial \mu} & \frac{\partial (X-Y)}{\partial \lambda} \\ \frac{\partial U}{\partial \kappa} & \frac{\partial U}{\partial \mu} & \frac{\partial U}{\partial \lambda} \end{pmatrix} = \tag{2.26}$$

$$\begin{pmatrix} 2wF'(a,b;\frac{1}{2};w) & \frac{-12}{2-\kappa}\frac{w}{(1-w)^2} & \frac{2\kappa w}{(1-w)^2}(3\frac{\kappa-1}{\kappa+1}-w)+2\kappa(2-\kappa)\frac{1-\kappa}{\kappa+1}wF'(a,b;\frac{1}{2};w) \\ -\frac{2w}{\kappa}F'(a,b;\frac{1}{2};w) & 0 & \frac{4(2-\kappa)}{\kappa+1}\frac{w}{(1-w)^2}-2(2-\kappa)\frac{1-\kappa}{\kappa+1}wF'(a,b;\frac{1}{2};w) \\ F(a,b;\frac{1}{2};w) & 0 & \kappa(2-\kappa)(1-\frac{2}{\kappa+1}\frac{1}{1-w})+\kappa(2-\kappa)\frac{1-\kappa}{\kappa+1}F(a,b;\frac{1}{2};w) \end{pmatrix}.$$

Next, we compute the partial derivatives of (2.4). The boundary conditions are now at $z = \infty$ and follow from (1.17), which implies that

$$\frac{dx(z)}{z} \to d\mu, \quad \frac{dy(z)}{z} \to d\mu - \frac{2-\kappa}{3} d\lambda, \quad \frac{du(z)}{z} \to 0 \quad \text{as } z \to \infty, \tag{2.27}$$

equivalent (recall (2.14)) to

$$\lim_{w\uparrow 1}(1-w)G(w) = \frac{6}{2-\kappa} d\mu, \qquad \lim_{w\uparrow 1}(1-w)J(w) = 2d\lambda, \qquad \lim_{w\uparrow 1}(1-w)F(w) = 0. \tag{2.28}$$

In order to choose the constants C_1, C_2, and C_3 accordingly, we need the asymptotic expansions of (2.23)–(2.24) as $w \uparrow 1$. At first glance, the reader may want to skip these calculations and proceed directly to (2.47).

We note that Gauss's formula implies that

$$\lim_{w\uparrow 1}(1-w)F_1(w) = B_\kappa = \frac{\Gamma(\frac{1}{2})}{\Gamma(a)\Gamma(b)}, \qquad \lim_{w\uparrow 1}(1-w)F_2(w) = A_\kappa = \frac{\Gamma(\frac{3}{2})}{\Gamma(\frac{1}{2}+a)\Gamma(\frac{1}{2}+b)}, \tag{2.29}$$

i.e.,

$$F_1(w) = \frac{B_\kappa}{1-w} + o\left(\frac{1}{1-w}\right), \qquad F_2(w) = \frac{A_\kappa}{1-w} + o\left(\frac{1}{1-w}\right) \quad \text{as } w \uparrow 1. \tag{2.30}$$

For the corresponding first components of the homogeneous solution, we find

$$\begin{aligned} 2wF_1'(w) &= 2w\frac{ab}{\frac{1}{2}}F\left(a+1, b+1; \frac{3}{2}; w\right) = \frac{6}{2-\kappa}\frac{w}{(1-w)^2}F\left(\frac{1}{2}-a, \frac{1}{2}-b; \frac{3}{2}; w\right) \\ &= \frac{6}{2-\kappa}\frac{w}{(1-w)^2} \\ &\quad \times \left(\frac{\Gamma(\frac{3}{2})\Gamma(2)}{\Gamma(a+1)\Gamma(b+1)} - \frac{(\frac{1}{2}-a)(\frac{1}{2}-b)}{\frac{3}{2}}\frac{\Gamma(\frac{5}{2})\Gamma(1)}{\Gamma(a+1)\Gamma(b+1)}(1-w) \right. \\ &\qquad\qquad \left. + o(1-w)\right) \\ &= 2B_\kappa\left(\frac{1}{(1-w)^2} - \frac{w}{(1-w)^2}\right)\left(1 + \left(\frac{1}{2} - \frac{3}{2(2-\kappa)}\right)(1-w) + o(1-w)\right) \\ &= B_\kappa\left(\frac{2}{(1-w)^2} - \left(1 + \frac{3}{2-\kappa}\right)\frac{1}{1-w} + o(\frac{1}{1-w})\right) \quad \text{as } w \uparrow 1. \end{aligned} \tag{2.31}$$

In this computation, we have used the Gauss relation for both $F(1/2 - a, 1/2 - b; 3/2; w)$ and its derivative. Similarly, we have

$$\begin{aligned} 2wF_2'(w) &= w^{\frac{1}{2}}F\left(\frac{1}{2}+a, \frac{1}{2}+b; \frac{3}{2}; w\right) + 2w^{\frac{3}{2}}\frac{(\frac{1}{2}+a)(\frac{1}{2}+b)}{\frac{3}{2}}F\left(\frac{3}{2}+a, \frac{3}{2}+b; \frac{5}{2}; w\right) \\ &= F_2(w) + 2w^{\frac{3}{2}}\frac{(\frac{1}{2}+a)(\frac{1}{2}+b)}{\frac{3}{2}}\frac{1}{(1-w)^2}F\left(1-a, 1-b; \frac{5}{2}; w\right) \\ &= F_2(w) + \frac{2w^{\frac{3}{2}}}{(1-w)^2} \end{aligned} \tag{2.32}$$

$$\begin{aligned}
&\times \frac{(\frac{1}{2}+a)(\frac{1}{2}+b)}{\frac{3}{2}}\Bigg(\frac{\Gamma(\frac{5}{2})\Gamma(2)}{\Gamma(\frac{3}{2}+a)\Gamma(\frac{3}{2}+b)} - \frac{(1-a)(1-b)}{\frac{5}{2}}\frac{\Gamma(\frac{7}{2})\Gamma(1)}{\Gamma(\frac{3}{2}+a)\Gamma(\frac{3}{2}+b)}(1-w) \\
&\qquad + o(1-w)\Bigg) \\
&\quad = F_2(w) + \frac{2w^{\frac{3}{2}}}{(1-w)^2}A_\kappa\left(1+\left(\frac{1}{2}-\frac{3}{2(2-\kappa)}\right)(1-w)+o(1-w)\right) \\
&\quad = \frac{A_\kappa}{1-w} + o\left(\frac{1}{1-w}\right) \\
&+ \frac{2}{(1-w)^2}\left(1-\frac{3}{2}(1-w)+o(1-w)\right)A_\kappa\Bigg(1+\left(\frac{1}{2}-\frac{3}{2(2-\kappa)}\right)(1-w) \\
&\qquad + o(1-w)\Bigg) \\
&\quad = A_\kappa\left(\frac{2}{(1-w)^2}-\left(1+\frac{3}{2-\kappa}\right)\frac{1}{1-w}+o\left(\frac{1}{1-w}\right)\right) \quad \text{as } w\uparrow 1.
\end{aligned}$$

For the first component corresponding to C_3, we have

$$\text{(2.33)} \qquad \frac{w^{\frac{1}{2}}}{(1-w)^2} = \frac{1}{(1-w)^2} - \frac{1}{2}\frac{1}{1-w} + o\left(\frac{1}{1-w}\right) \quad \text{as } w\uparrow 1.$$

For the particular solution corresponding to $d\lambda$, the third component is

$$\text{(2.34)} \quad \kappa(2-\kappa)\left(1-\frac{2}{\kappa+1}\frac{1}{1-w}\right) = -\frac{2\kappa(2-\kappa)}{\kappa+1}\frac{1}{1-w} + o\left(\frac{1}{1-w}\right) \quad \text{as } w\uparrow 1,$$

the second component is

(2.35)

$$\frac{4(2-\kappa)}{\kappa+1}\frac{w}{(1-w)^2} = \frac{4(2-\kappa)}{\kappa+1}\frac{1}{(1-w)^2} - \frac{4(2-\kappa)}{\kappa+1}\frac{1}{1-w} + o\left(\frac{1}{1-w}\right) \quad \text{as } w\uparrow 1,$$

and the first component is

(2.36)

$$\frac{2\kappa w}{(1-w)^2}\left(3\frac{\kappa-1}{\kappa+1}-w\right) = \frac{4\kappa(\kappa-2)}{\kappa+1}\frac{1}{(1-w)^2} + \frac{2\kappa(5-\kappa)}{\kappa+1}\frac{1}{1-w} + o\left(\frac{1}{1-w}\right) \quad \text{as } w\uparrow 1.$$

Finally, for the first component of the particular solution for $d\mu$,

$$\text{(2.37)} \quad -\frac{12}{2-\kappa}\frac{w}{(1-w)^2} = -\frac{12}{2-\kappa}\frac{1}{(1-w)^2} + \frac{12}{2-\kappa}\frac{1}{1-w} + o\left(\frac{1}{1-w}\right) \quad \text{as } w\uparrow 1.$$

Now that we have all of the asymptotic expansions as $w\uparrow 1$, we have to choose the constants in such a way that (2.28) is satisfied. First, we look at the third component,

$$\text{(2.38)} \quad \begin{aligned}
F(w) &= C_1F_1(w) + C_2F_2(w) + \kappa(2-\kappa)\left(1-\frac{2}{\kappa+1}\frac{1}{1-w}\right)d\lambda \\
&= \left(C_1B_\kappa + C_2A_\kappa - \frac{2\kappa(2-\kappa)}{\kappa+1}d\lambda\right)\frac{1}{1-w} + o\left(\frac{1}{1-w}\right) \quad \text{as } w\uparrow 1,
\end{aligned}$$

which forces us to take

$$C_1B_\kappa + C_2A_\kappa - \frac{2\kappa(2-\kappa)}{\kappa+1}d\lambda = 0. \tag{2.39}$$

Then by the Kummer relation,

$$2A_\kappa F_1(w) - 2B_\kappa F_2(w) = F(a,b;2;w), \tag{2.40}$$

$$F(w) = \kappa(2-\kappa)\left(\frac{1}{B_\kappa}\frac{2}{\kappa+1}F\left(a,b;\frac{1}{2};w\right) - \frac{2}{\kappa+1}\frac{1}{1-w} + 1\right)d\lambda + CF(a,b;2;w), \tag{2.41}$$

where $C = -C_2/(2B_\kappa)$.

For the second component, we then obviously have that the terms with $(1-w)^{-2}$ disappear and that

$$\begin{aligned} J(w) &= -\frac{2w}{\kappa}F'(w) = -C_1\frac{2w}{\kappa}F_1'(w) - C_2\frac{2w}{\kappa}F_2'(w)\frac{4(2-\kappa)}{\kappa+1}\frac{w}{(1-w)^2}d\lambda \\ &= \left(\frac{1}{\kappa}(C_1B_\kappa + C_2A_\kappa)\left(1+\frac{3}{2-\kappa}\right) - \frac{4(2-\kappa)}{\kappa+1}d\lambda\right)\frac{1}{1-w} + o\left(\frac{1}{1-w}\right) \\ &= \frac{2}{1-w}d\lambda + o\left(\frac{1}{1-w}\right) \quad \text{as } w \uparrow 1, \end{aligned} \tag{2.42}$$

which agrees with (2.28) and therefore gives no further restriction on the constants C_1, C_2, and C_3. Thus

$$J(w) = \frac{4(2-\kappa)w}{\kappa+1}\left(-\frac{1}{B_\kappa}F'\left(a,b;\frac{1}{2};w\right) + \frac{1}{(1-w)^2}\right)d\lambda - \frac{2Cw}{\kappa}F'(a,b;2;w), \tag{2.43}$$

Finally, for the first component, using (2.39) again,

$$\begin{aligned} G(w) &= 2wC_1F_1'(w) + 2wC_2F_2'(w) + C_3\frac{w^{\frac{1}{2}}}{(1-w)^2} \\ &\qquad + \frac{2\kappa w}{(1-w)^2}\left(3\frac{\kappa-1}{\kappa+1} - w\right)d\lambda - \frac{12}{2-\kappa}\frac{w}{(1-w)^2}d\mu \\ &= \left(C_3 - \frac{12}{2-\kappa}d\mu\right)\frac{1}{(1-w)^2} + \left(\frac{12}{2-\kappa}d\mu - \frac{1}{2}C_3\right)\frac{1}{1-w} + o\left(\frac{1}{1-w}\right) \quad \text{as } w \uparrow 1 \end{aligned} \tag{2.44}$$

so that

$$C_3 = \frac{12}{2-\kappa}d\mu \tag{2.45}$$

ensures that (2.28) holds. Thus

$$\begin{aligned} G(w) = &\left(\frac{4\kappa(2-\kappa)w}{(\kappa+1)B_\kappa}F'\left(a,b;\frac{1}{2};w\right) + \frac{2\kappa w}{(1-w)^2}\left(3\frac{\kappa-1}{\kappa+1} - w\right)\right)d\lambda \\ &+ 2CwF'(a,b;2;w) + \frac{12}{2-\kappa}\frac{w^{\frac{1}{2}}-w}{(1-w)^2}d\mu. \end{aligned} \tag{2.46}$$

From (2.41), (2.43), and (2.46), we then have for an appropiate choice of the coordinate c in (2.4) that

$$\begin{pmatrix} \frac{\partial X^*}{\partial c} & \frac{\partial X^*}{\partial \mu} & \frac{\partial X^*}{\partial \lambda} \\ \frac{\partial (X^*-Y^*)}{\partial c} & \frac{\partial (X^*-Y^*)}{\partial \mu} & \frac{\partial (X^*-Y^*)}{\partial \lambda} \\ \frac{\partial U^*}{\partial c} & \frac{\partial U^*}{\partial \mu} & \frac{\partial U^*}{\partial \lambda} \end{pmatrix} \tag{2.47}$$

$$= \begin{pmatrix} 2wF'(a,b;2;w) & \frac{12}{2-\kappa}\frac{w^{\frac{1}{2}}-w}{(1-w)^2} & \frac{2\kappa w}{(1-w)^2}(3\frac{\kappa-1}{\kappa+1}-w) + \frac{4\kappa(2-\kappa)w}{(\kappa+1)B_\kappa}F'(a,b;\frac{1}{2};w) \\ -\frac{2w}{\kappa}F'(a,b;2;w) & 0 & \frac{4(2-\kappa)}{\kappa+1}\frac{w}{(1-w)^2} - \frac{4(2-\kappa)w}{(\kappa+1)B_\kappa}F'(a,b;\frac{1}{2};w) \\ F(a,b;2;w) & 0 & \kappa(2-\kappa)(1-\frac{2}{\kappa+1}\frac{1}{1-w}) + \frac{2\kappa(2-\kappa)}{(\kappa+1)B_\kappa}F(a,b;\frac{1}{2};w) \end{pmatrix}.$$

Writing (2.5)–(2.7) as

$$\mathcal{F}(z;c,\kappa,\mu,\lambda) = \begin{pmatrix} X - X^* \\ X - X^* - Y + Y^* \\ U - U^* \end{pmatrix} = 0,$$

it follows that $\partial\mathcal{F}/\partial(c,\kappa,\mu,\lambda) =$

$$\begin{pmatrix} -2wF'(a,b;2;w) & 2wF'(a,b;\frac{1}{2};w) & -\frac{12}{2-\kappa}\frac{w^{\frac{1}{2}}}{(1-w)^2} & \frac{2\kappa(2-\kappa)}{\kappa+1}\beta_\kappa wF'(a,b;\frac{1}{2};w) \\ \frac{2w}{\kappa}F'(a,b;2;w) & -\frac{2w}{\kappa}F'(a,b;\frac{1}{2};w) & 0 & -\frac{2(2-\kappa)}{\kappa+1}\beta_\kappa wF'(a,b;\frac{1}{2};w) \\ -F(a,b;2;w) & F(a,b;\frac{1}{2};w) & 0 & \frac{\kappa(2-\kappa)}{\kappa+1}\beta_\kappa F(a,b;\frac{1}{2};w) \end{pmatrix}, \tag{2.48}$$

where

$$\beta_\kappa = 1 - \kappa - \frac{2}{B_\kappa}. \tag{2.49}$$

Clearly, the first three columns in this matrix have maximal rank for any $0 < w < 1$ because the Wronskian of the two hypergeometric functions $F(a,b;1/2;w)$ and $F(a,b;2;w)$ is nonzero. It follows that we can write the solution set of (2.5-7) in the form (2.8) with

$$\begin{pmatrix} -2wF'(a,b;2;w) & 2wF'(a,b;\frac{1}{2};w) & -\frac{12}{2-\kappa}\frac{w^{\frac{1}{2}}}{(1-w)^2} \\ \frac{2w}{\kappa}F'(a,b;2;w) & -\frac{2w}{\kappa}F'(a,b;\frac{1}{2};w) & 0 \\ -F(a,b;2;w) & F(a,b;\frac{1}{2};w) & 0 \end{pmatrix} \begin{pmatrix} \frac{dc}{d\lambda} \\ \frac{d\kappa}{d\lambda} \\ \frac{d\mu}{d\lambda} \end{pmatrix}$$

$$= -\begin{pmatrix} \frac{2\kappa(2-\kappa)}{\kappa+1}\beta_\kappa wF'(a,b;\frac{1}{2};w) \\ -\frac{2(2-\kappa)}{\kappa+1}\beta_\kappa wF'(a,b;\frac{1}{2};w) \\ \frac{\kappa(2-\kappa)}{\kappa+1}\beta_\kappa F(a,b;\frac{1}{2};w) \end{pmatrix}, \tag{2.50}$$

whence, using Cramer's rule,

$$\frac{dc}{d\lambda} = \frac{d\mu}{d\lambda} = 0, \qquad \frac{d\kappa}{d\lambda} = \frac{\kappa(2-\kappa)}{\kappa+1}\left(\kappa - 1 + \frac{2}{B_\kappa}\right). \tag{2.51}$$

Acknowledgments. I would like to thank G. I. Barenblatt, M. Bertsch, and L. A. Peletier for their encouragement, S. B. Angenent, G. Marí Beffa, F. Beukers, and

E. M. Opdam for fruitful discussions about special functions, the makers of Maple for making it all possible, and finally D. G. Aronson and J. L. Vazquez for [AV].

ON UNIQUENESS OF RECOVERY OF THE DISCONTINUOUS CONDUCTIVITY COEFFICIENT OF A PARABOLIC EQUATION[*]

ALAEDDIN ELAYYAN[†] AND VICTOR ISAKOV[‡]

Abstract. We prove uniqueness of a discontinuous principal coefficient of a second-order parabolic equation of the form $a_0 + \chi(Q^*)b$ with known smooth a_0 and unknown $b = b(x)$ from all possible lateral boundary measurements of solutions of this equation. In the proofs, we make use of singular solutions of parabolic equations.

Key words. partial differential equations, inverse problems

AMS subject classification. 35R30

Introduction. We consider the problem of recovery of the coefficient a of the parabolic equation

$$u_t - \operatorname{div}(a\nabla u) = 0 \quad \text{in } Q = \Omega \times (0, T)$$

with the initial and boundary conditions

$$u = 0 \quad \text{on } \Omega \times \{0\}, \qquad u = g \quad \text{on } \partial\Omega \times [0, T]$$

when $\partial u/\partial\nu$ is given for all (regular) g. Here Ω is a bounded domain in $\mathbb{R}^n$, $2 \le n$, with the boundary $\partial\Omega \in C^2$. In this paper, we prove uniqueness of discontinuous $a = a_0 + \chi(Q^*)b$, where $\chi(Q^*)$ is the indicator function of an open set $Q^* \subset Q$ with the Lipschitz lateral boundary $\partial_x Q^*$ changing with time and $a_0 = a_0(x)$ and $b = b(x)$ are, respectively, given and unknown $C^2(\bar{\Omega})$-functions. For elliptic equations, uniqueness was proven by Kohn and Vogelius [8] (piecewise-analytic a) and Isakov [5] (Lipschitz Q^* and smooth b). Also for elliptic equations, when one is making use of only one set of u, $\partial u/\partial\nu$ on $\partial\Omega$, some partial global uniqueness results for Q^* were obtained by Friedman and Isakov [4]. Regarding parabolic equations, we can refer only to Bellout's study [2] of local stability in the inverse problem. This inverse parabolic problem is fundamental for groundwater search [12] in particular and important for many engineering applications.

We introduce some notation. For standard notation, we refer to Friedman [3] and Ladyzhenskaja, Solonnikov, and Ural'ceva [9].

For an open set Q in the layer $\mathbb{R}^n \times (0, T)$, the lateral boundary $\partial_x Q$ is the x-boundary that is the closure of the set $\partial Q|\{t = 0 \text{ or } t = T\}$. We say that Q is x-Lipschitz if its x-boundary is locally the graph of a function $x_j = \gamma(x_1, \ldots, x_{j-1}, x_{j+1}, \ldots, x_n, t)$ that is Lipschitz.

1. Statement of results. Let Γ_0 be $\partial\Omega \cup B_0$ for some ball B_0 centered at a point of $\partial\Omega$.

We are interested in finding an open set Q_j and a function b_j entering the parabolic initial-boundary value problem

$$(u_j)_t - \operatorname{div}(a_j \nabla u_j) = 0 \quad \text{in } Q, \tag{1.1}$$

$$u_j = g \quad \text{on } S = \partial\Omega \times (0,T), \tag{1.2}$$

$$u = 0 \quad \text{on } \Omega \times \{0\}, \tag{1.3}$$

where

$$a_j = a_0 + \chi(Q_j) b_j > \epsilon > 0, \quad b_j \neq 0 \text{ on } \partial Q_j. \tag{1.4}$$

It is well known that for any $g \in C^{2,1}(\bar{S})$, $g = g_t = g_{tt} = 0$ on $\partial\Omega \times \{0\}$, there is a unique (generalized) solution u_j of this problem and $u_j \in C^{\lambda}(\bar{Q})$ for some $\lambda \in (0,1)$, $\nabla_x u_j \in L_2(Q)$, and $\in C(\bar{Q}\backslash\bar{Q}_j)$. For this and for other results about the direct parabolic problem (1.1)–(1.4), we refer to Friedman [3] and Ladyzhenskaja, Solonnikov, and Ural'ceva [9, pp. 153, 204, and 227].

Our main result is the following theorem.

THEOREM 1.1. *Suppose Q_1 and Q_2 are open x-Lipschitz sets, $Q_j \subset \Omega \times (-T, 2T)$, and*

$$\text{the sets } (Q\backslash\overline{Q}_j) \cap \{t = \tau\} \text{ are connected} \quad \text{when } 0 < \tau < T. \tag{1.5}$$

If solutions u_j to the initial-boundary value problems (1.1), (1.2), *and* (1.3) *satisfy the equality*

$$\partial u_1/\partial\nu = \partial u_2/\partial\nu \quad \text{on } \Gamma_0 \times (0,T) \quad (\nu \text{ is a normal}) \tag{1.6}$$

for all $g \in C^2(\partial\Omega \times [0,T])$ with $\operatorname{supp} g \subset \Gamma_0 \times (0,T)$, then

$$a_1 = a_2 \quad \text{on } Q. \tag{1.7}$$

This result guarantees uniqueness of reconstruction of Q_j from all possible lateral measurements for an arbitrary $T > 0$.

The paper is organized as follows. In section 2, we will show that if equality (1.6) is valid for all Dirichlet boundary data, g implies certain integral relations which can be interpreted as orthogonality relations. To prove uniqueness in section 4, we will modify an approach from [5] (the use of singular solutions with the pole in those orthogonality relations) to obtain a contradiction when the pole converges to the boundary of one of the domains Q_j. To show that some integrals in these relations are bounded while one of them is not, we will use estimates of integrals of singular solutions given in section 3, which is the most technically difficult part of the paper.

2. Orthogonality relations. In this section, we assume that the conditions of Theorem 1.1 are satisfied and obtain some auxiliary relations which will be used in its proof.

Denote by Q_{3t} the connected component of the open set $\Omega\backslash(\overline{Q}_{1t} \cup \overline{Q}_{2t})$ whose boundary contains Γ_0. Here $Q_{j\theta}$ is $Q_j \cap \{t = \theta\}$, $j = 1, 2$. Let $Q_3 = \cup\, Q_{3t}$ over $0 < t < T$ and let $Q_4 = Q\backslash\overline{Q}_3$.

Lemma 2.1.

$$\int_{Q_1} b_1 \nabla v_1 \cdot \nabla u_2^* \, dx\, dt = \int_{Q_2} b_2 \nabla v_1 \cdot \nabla u_2^* \, dx\, dt \tag{2.1}$$

for all solutions v_1 to equation (1.1) ($j = 1$) *near $\bar{Q}_4$ that are* 0 *when $t < 0$ and solutions u_2^* to the adjoint equation $(u_2^*)_t +$* $\operatorname{div}(a_2\nabla u_2^*) = 0$ *near $\bar{Q}_4$ that are* 0 *when $t > T$.*

Proof. From well-known results about regularity of solutions to the parabolic initial-boundary value problem (1.1)–(1.3), it follows that u_j is in $C^{2,1}(Q_3)$ and in $H^{2,1}(Q_5)$, where $Q_5 = V \times (0,T)$ and V is a vicinity of $\partial\Omega$ in Ω. Due to conditions (1.2) and (1.5), both u_1 and u_2 have the same Cauchy data on $\Gamma_0 \times (0,T)$ and satisfy the same parabolic equation in Q_3; thus from uniqueness of continuation for second-order parabolic equations (see, e.g., [7, Corollary 1.2.4]), we conclude that $u_1 = u_2$ on Q_3. Letting $u = u_2 - u_1$ and subtracting the equations (1.1) with $j = 1$ from those with $j = 2$, we get

$$\operatorname{div}((a_0 + b_2\chi(Q_2))\nabla u) - u_t = \operatorname{div}((b_1\chi(Q_1) - b_2\chi(Q_2))\nabla u_1) \quad \text{in } Q. \tag{2.2}$$

Now using the definition of a weak solution to the parabolic equation under consideration, we obtain

$$\int_Q ((a_0 + b_2\chi(Q_2))\nabla u \cdot \nabla\psi + u_t\psi) = \int_Q (b_1\chi(Q_1) - b_2\chi(Q_2))\nabla u_1 \cdot \nabla\psi \tag{2.3}$$

for any function ψ from $H_0^{1,1}(Q)$. Since u and $\chi(Q_j)$ are zero outside $\overline{Q}_4 \cap \{t < T\}$, this relation remains valid for any function ψ from $H^{1,1}(Q_6)$ (where Q_6 is an arbitrary vicinity of Q_4) that is 0 when $t > T$.

If $\psi = u_2^*$ is an $H^{1,1}(Q_6)$ solution to the adjoint equation from Lemma 2.1, then integrating the left side of (2.3) by parts with respect to t and using the definition of a weak solution to this adjoint equation with the test function u (which is zero outside $Q_4 \cap \{t < T\}$), we conclude that the left side in (2.3) is zero. Thus we have relation (2.1) with u_1 instead of v_1.

Now by using the Runge property, we extend equality (2.1) onto all v_1 solving equation (1.1) with $j = 1$ near $\overline{Q}_4$ and satisfying the initial condition (1.3). Denote the space of such v_1 by X. It is sufficient to prove that solutions u_1 to the initial-boundary value problem (1.1)–(1.3) with $j = 1$ (for various g supported in $\Gamma_0 \times (0,T)$) approximate in $L_2(Q_4)$ any solution from X. We denote the space of solutions to (1.1)–(1.3) (with various g) by X_1. Indeed, let $v_1 \in X$. Then we can approximate it similarly by solutions from X in $L_2(Q_7)$, where Q_7 is a Lipschitz domain containing Q_4 with $\operatorname{dist}(\partial_x Q_7, Q_4) > 0$. From the well-known interior Schauder-type estimates for parabolic equations, it follows that these solutions from X_1 will approximate v_1 in $H^{1,0}(Q_4)$.

To prove L_2 approximation in view of the Hahn–Banach theorem, it is sufficient to show that if f from the dual space $L_2(Q_4)$ is orthogonal to X_1, then f is orthogonal to X.

Let Ω_0 be a bounded domain with C^2-boundary such that $\Omega \subset \Omega_0$, $\Omega \neq \Omega_0$, and $\partial\Omega \backslash \Gamma_0$ belong to $\partial\Omega_0$. Let $K(x,t;y,s)$ be the Green function to the first initial value problem for the operator $\partial_t + \operatorname{div}(a_1\nabla)$ in $Q_0 \times (0,T)$. Let f be orthogonal to X_1. The Green potential

$$U(x,t;f) = \int_{Q_4} fK(x,t;\;) \tag{2.4}$$

is equal to zero on $Q_0\backslash\overline{Q}_4$ because the function $u_1 = K(x,t;\ )$ belongs to X_1 if $(x,t) \in Q_0\backslash\overline{Q}_4$. Since supp $f \subset \overline{Q}_4$, this potential is a solution to the equation $-\mathrm{div}(a_0\nabla u) = u_t$ on $Q_0\backslash\overline{Q}_4$. The coefficient a_0 belongs to $C^1(\overline{Q}_0)$, so this equation has the property of unique continuation. Therefore, $U(\ ;f) = 0$ on $Q_0\backslash\overline{Q}_4$. Now let $v \in X$; then v is a solution to the homogeneous equation near $Q_5 \cup \partial_x Q_5$, where Q_5 is an open set with C^∞ lateral boundary and $\mathrm{dist}(\partial_x Q_5, \partial_x Q_4) > 0$. Using the representation of v by a single layer potential, we obtain

$$v(y,s) = \int_{\partial_x Q_5} gK(\ ;y,s)d\Gamma$$

for some $g \in C(\partial_x Q_5)$. By using this representation, (2.4), and Fubini's theorem, we obtain

$$\int_{Q_4} fv = \int_{\partial_x Q_5} gU(\ ;f) = 0$$

because $U(\ ;f) = 0$ on $\partial_x Q_5$. Accordingly, relation (2.1) is valid for any v_1 satisfying the conditions of Lemma 2.1.

The proof is complete.

Assume that

$$Q_1 \neq Q_2. \tag{2.5}$$

Then we may assume that Q_1 is not contained in Q_2. Hence, using condition (1.5) of Theorem 1.1 on Q_j, we conclude that there is a point $(x_0,t_0) \in \partial Q_1\backslash\overline{Q}_2$ such that $(x_0,t_0) \in \partial_x Q_3$. By considering $g = 0$ for $t < t_0$ and using the translations $t \to t - t_0$ and $x \to x - x_0$, we can reduce the general case to $t_0 = 0$ and $x_0 = 0$. We can choose a ball $B \subset \mathbb{R}^n$ centered at 0 and a cylinder $Z = B \times (0,\tau)$ such that $\overline{B} \subset \Omega$, $\overline{Z}$ does not intersect $\overline{Q}_2$, and $(\partial_x Q_1) \cap \overline{Z}$ is a Lipschitz surface. Due to well-known variants of the Whitney extension theorem, there is a $C^2(\overline{Q}_1 \cup \overline{Z})$-function a_3 that coincides with a_1 on Q_1. Extend a_3 onto $Q\backslash(\overline{Q}_1 \cup \overline{Z})$ as a_0.

Lemma 2.2. *Under the conditions of Lemma* 2.1*,*

$$\int_{Q_1} b_1\nabla u_3 \cdot \nabla u_2^* = \int_{Q_2} b_2\nabla u_3 \cdot \nabla u_2^*$$

for any solution u_3 to the equation $\mathrm{div}(a_3\nabla u_3) - (u_3)_t = 0$ *near $\overline{Q}_4$ which is* 0 *when* $t < 0$ *and for any solution u_2^* from Lemma* 2.1*.*

Proof. Consider u_3 and let Q_8 be an open set with C^∞-boundary $\partial_x Q_8$ and that contains Q_4 with $\mathrm{dist}(\partial_x Q_8, Q_4) > 0$ such that u_3 is a solution to the equation $\mathrm{div}(a_3\nabla u_3) - (u_3)_t = 0$ near $\overline{Q}_8$.

Introduce a sequence of open sets Q_{4k} such that (i) $Q_{4k}\backslash Z = Q_4\backslash Z$ and (ii) the (Hausdorff) distance from ∂Q_{4k} to $\partial_x Q_4$ is less than $1/k$ and $\partial_x Q_{4k} \cap Z$ does not intersect $\overline{Q}_4$. Define a coefficient a_{3k} as a_3 on $Q_8\backslash(Q_{4k}\backslash Q_4)$ and as a_0 on $Q_{4k}\backslash Q_4$. Since $\partial Q_4 \cap Z$ is a Lipschitz surface, we have

$$\mathrm{meas}_n\{a_{3k} \neq a_3\} \to 0 \quad \text{as } k \to +\infty. \tag{2.6}$$

Let u_{3k} be solutions to the initial-boundary value problems

$$\mathrm{div}(a_{3k}\nabla u_{3k}) - (u_{3k})_t = 0 \quad \text{in } Q_8, \qquad u_{3k} = u_3 \quad \text{on } \partial_x Q_8, \qquad u_{3k} = 0 \quad \text{on } Q_8 \cap \{t = 0\}.$$

Since $u_{3k} = a_0 + \chi(Q_1)b_1$ near $\overline{Q}_1$, relation (2.1) is valid for any $u_1 = u_{3k}$. The difference $u_k = u_{3k} - u_3$ satisfies the equation

$$\operatorname{div}(a_{3k}\nabla u_k) - (u_k)_t = \operatorname{div}((a_3 - a_{3k})\nabla u_3) \quad \text{in } Q_8,$$

and $u_k = 0$ on $\partial Q_8 \cap \{t < T\}$ because u_{3k} and u_3 coincide on the lateral boundary of Q_8 and when $t = 0$. From the definition of a weak solution to this initial-boundary value problem with the test function u_k, we have

$$\int_{Q_8} a_{3k}\nabla u_k \cdot \nabla u_k + \int_{Q_8 \cap \ \{t=T\}} \frac{u_k^2}{2} = \int_{Q_8} (a_3 - a_{3k})\nabla u_3 \cdot \nabla u_k.$$

According to the assumptions, $\epsilon < a_{3k}$ for certain positive ϵ. Using this inequality, dropping the second integral in the left side, and bounding the right side by the inequality $x \cdot y \leq \epsilon^{-1}/2|x|^2 + \epsilon/2|y|^2$, we obtain

$$\int_{Q_8} \epsilon|\nabla u_k|^2 \leq C(\epsilon)\int_{Q_8} |a_3 - a_{3k}|^2|\nabla u_3|^2 + \frac{\epsilon}{2}\int_{Q_8} |\nabla u_k|^2.$$

Since ∇u_3 belongs to $L_2(Q_8)$, we conclude from (2.6) that the first integral in the right side tends to 0. Therefore, ∇u_k converges to 0 in $L_2(Q_8)$. Putting $u_1 = u_{3k} = u_3 + u_k$ into relation (2.1) and letting $k \to \infty$, we complete the proof of Lemma 2.2.

3. Estimates of integrals of singular solutions. We will make use of solutions u_3 and u_2^* with singularities outside Q_4. Solutions of elliptic equations of second order with arbitrary power singularities were constructed by Alessandrini [1]; we do not know of similar results for parabolic equations. To simplify obtaining bounds on the integrals of such solutions, we introduce new variables. We can assume that the direction e_n of the x_n-axis coincides with the interior unit normal to $\partial_x Q_1 \cap \{t = 0\}$. According to our assumptions, $\partial_x Q_1$ near the origin is the graph of a Lipschitz function $x_n = q_1(x_1, \ldots, x_{n-1}, t)$ which can be assumed to be defined and Lipschitz on the whole $\mathbb{R}^n$. The substitution

$$x_k = x_k^*, \quad k = 1, \ldots, n-1, \qquad x_n = x_n^* + q_1(x_1^*, \ldots, x_{n-1}^*, t), \quad t = t^*$$

transforms the equations (1.1) into similar equations with additional first-order differentiation with respect to x_n^* multiplied by a Lipschitz function of t. The domains Q_j are transformed onto domains with similar properties and with the additional property that the points $(0, t), 0 < t < T$, belong to $\partial_x Q_1$. Since the (hyper)plane $\{x_n^* = 0\}$ is tangent to this surface at the origin, we can find a cone $\mathcal{C} = \{|x^*/|x^*| - e_n| < \theta$, $|x^*| < \epsilon\}$ such that the cylinder $\mathcal{C} \times (0, T)$ is inside Q_1. Henceforth, we drop the sign $*$.

Let K^+ be the fundamental solution of the Cauchy problem for the forward parabolic equation $\operatorname{div}(a_3\nabla u_3) - (u_3)_t = 0$ in $*$-coordinates. Let K^- be the fundamental solution of the backward Cauchy problem for the backward parabolic equation $\operatorname{div}(a_2\nabla u_2) + u_{2t} = 0$ in these coordinates. It is known that

$$K^+ = K_1^+ + K_0^+, \qquad K^- = K_1^- + K_0^-, \tag{3.1}$$

where K_1^+ and K_1^- are the principal parts of K^+ and K^- (parametrices) and K_0^+

and K_0^- are the remainders. The principal parts are

$$K_1^+(x,t;y,\tau) = \frac{C}{(a_3(y)(t-\tau))^{n/2}} \exp\left(-\frac{|x-y|^2}{4a_3(y)(t-\tau)}\right), \tag{3.2}$$
$$K_1^-(x,t;y,\tau) = \frac{C}{(a_0(y)(\tau-t))^{n/2}} \exp\left(-\frac{|x-y|^2}{4a_0(y)(\tau-t)}\right).$$

From the known bounds of fundamental solutions of parabolic equations [9, p. 377], we have

$$|\nabla_x K_0^+(x,t;y,\tau)| \le C(t-\tau)^{-n/2} \exp\left(-\frac{|x-y|^2}{(C(t-\tau))}\right), \tag{3.3}$$
$$|\nabla_x K_0^-(x,t;y,\tau)| \le C(\tau-t)^{-n/2} \exp\left(-\frac{|x-y|^2}{(C(\tau-t))}\right).$$

When $(y,0)$ and (y,τ) are outside $\overline{Q}_1$, the functions $K^+(\ ;y,0)$ and $K^-(\ ;y,\tau)$ are (x,t)-solutions to the homogeneous parabolic equations with bounded measurable coefficients satisfying zero initial and final conditions. Using Lemma 2.2 with $u_3 = K^+(\ ;y,0)$ and $u_2^* = K^-(\ ;y,\tau)$, we get

$$\begin{aligned} &\int_{Q_1\cap Z} b_1 \nabla_x K^+(\ ;y,0)\cdot\nabla_x K^-(\ ;y,\tau) \\ &\quad = -\int_{Q_1\setminus Z} b_1 \nabla_x K^+(\ ;y,0)\cdot\nabla_x K^-(\ ;y,\tau) \\ &\quad\quad + \int_{Q_2} b_2 \nabla_x K^+(\ ;y,0)\cdot\nabla_x K^-(\ ;y,\tau). \end{aligned} \tag{3.4}$$

From the estimates in (3.3) and similar estimates for $\nabla_x K_1^+$ and $\nabla_x K_1^-$, we conclude that the integrands are bounded by an integrable function uniformly with respect to y outside Q_1. By the Lebesgue dominated-convergence theorem, we may let $y \to 0$ and replace y in (3.4) by 0. Using representation (3.1), we obtain from (3.4) that

$$|I_1| \le |I_2| + |I_3|, \tag{3.5}$$

where

$$I_1 = \int_{Q_1\cap Z} b_1 \nabla_x K_1^+(\ ;0,0)\cdot\nabla_x K_1^-(\ ;0,\tau)$$

is formed from the principal parts of K and the remainders are collected in

$$I_2 = -\int_{Q_1\setminus Z} b_1 \nabla_x K^+(\ ;0,0)\cdot\nabla K^-(\ ;0,\tau) + \int_{Q_2} b_2 \nabla_x K^+(\ ;0,0)\cdot\nabla_x K^-(\ ;0,\tau)$$

and

$$\begin{aligned} I_3 = \int_{Q_1\cap Z} b_1 (&\nabla_x K_1^+(\ ;0,0)\cdot\nabla K_0^-(\ ;0,\tau) + \nabla_x K_0^+(\ ;0,0)\cdot\nabla_x K_1^-(\ ;0,\tau) \\ &+ \nabla_x K_0^+(\ ;0,0)\cdot\nabla K_0^-(\ ;y,\tau)). \end{aligned}$$

In the following three lemmas, I_1 is bounded from below and I_2 and I_3 is bounded from above.

LEMMA 3.1.

$$|I_1| \geq C^{-1}\tau^{-n}\int_0^{\epsilon}\rho^{n-1}e^{-4p^2/(m\tau)}d\rho,$$

where $m = \inf(a_3, a_0)$ *over* Q.

Proof. Using the fact that $b_1(0) \neq 0$ and choosing ϵ in the definition of $\mathcal{C}$ to be sufficiently small, we obtain

$$\begin{aligned}|I_1| \geq\ & C^{-1}\int_{\mathcal{C}\times(0,\tau)}\nabla_x K_1^+(x,t;0,0)\cdot\nabla_x K_1^-(x,t;0,\tau)\\ =\ & C^{-1}\int_0^{\tau}\int_{\mathcal{C}}t^{-n/2-1}\exp\left(-\frac{|x|^2}{a_3(x)t}\right)x\cdot(\tau-t)^{-n/2-1}\exp\left(\frac{|x|^2}{a_0(x)(\tau-t)}\right)x\,dx\,dt\\ \geq\ & C^{-1}\int_{\mathcal{C}}\int_0^{\tau/2}|x|^2((\tau-t)t)^{-n/2-1}\exp\left(-\frac{|x|^2\tau}{mt(\tau-t)}\right)dt\,dx.\end{aligned}$$

Using the inequality

$$\frac{1}{t\tau} \leq \frac{1}{t(\tau-t)} \leq \frac{2}{t\tau} \quad \text{when } 0 < t < \frac{\tau}{2}, \tag{3.6}$$

we bound from below the integral shown above by

$$\begin{aligned}C^{-1}&\int_{\mathcal{C}}\int_0^{\tau/2}|x|^2\frac{1}{(t\tau)^{n/2+1}}\exp\left(-\frac{2|x|^2}{mt}\right)dt\,dx\\ &= \frac{1}{C\tau^{n/2+1}}\int_{\mathcal{C}}|x|^{2-n}\int_{\frac{4|x|^2}{m\tau}}^{\infty}w^{n/2-1}e^{-w}dw\,dx,\end{aligned}$$

where we substituted $w = 2|x|^2/mt$.

The function $w^{n/2-1}$ is increasing, so replacing it by its minimal value at $w = 4|x|^2/(m\tau)$, we bound the last integral from below by

$$\int_{\mathcal{C}}\tau^{1-n/2}\left(\int_{(4|x|^2/(m\tau),\infty)}e^{-w}dw\right)dx = C^{-1}\tau^{1-n/2}\int_{(0,\epsilon)}\rho^{n-1}e^{-4\rho^2/(m\tau)}d\rho.$$

The proof is complete.

LEMMA 3.2.

$$|I_2| \leq C\tau^{-n/2+1}\epsilon^{-2}e^{-\epsilon^2/(M\tau)},$$

where M *depends only on* $\sup(a_3, a_0)$ *over* Q.

Proof. I_2 consists of two integrals. The first one is bounded by

$$\begin{aligned}C&\int_{\epsilon<|x|<R,0<t<\tau}|\nabla_x K^+(\ ;0,0)\cdot\nabla_x K^-(\ ;0,\tau)|\\ \leq\ & C\int_{\epsilon<|x|<R}\int_0^{\tau/2}\frac{1}{((\tau-t)t)^{n/2+1/2}}\exp\left(-\frac{|x|^2\tau}{Mt(\tau-t)}\right)dt\,dx.\end{aligned}$$

The bound on $|\nabla_x K^+ \cdot \nabla_x K^-|$ follows from the direct differentiation of (3.2), the inequality

$$|x|(t-\tau)^{-n/2-1} \exp\left(-\frac{|x|^2}{4(t-\tau)}\right) \leq C(t-\tau)^{-n/2-1/2} \exp\left(-\frac{|x|^2}{8(t-\tau)}\right),$$

and the bounds in (3.3).

Applying inequality (3.6) as above, we bound the last integral by

$$\frac{C}{\tau^{n/2+1/2}} \int_{\epsilon<|x|<R} \int_0^{\tau/2} \frac{1}{t^{n/2+1/2}} \exp\left(-\frac{|x|^2}{Mt}\right) dt\, dx$$
$$\leq \frac{C}{\tau^{n/2+1/2}} \int_{\epsilon<|x|<R} |x|^{1-n} \int_{\frac{2|x|^2}{M\tau}}^{\infty} w^{n/2-1} w^{-1/2} e^{-w} dw\, dx$$

when we use the substitution $w = |x|^2/(Mt)$. The function $w^{-1/2}$ is decreasing. Replacing it by its value at $2|x|^2/(M\tau)$, we increase the integral, and we also use the inequality $w^{n/2-1}e^{-w} \leq Ce^{-w/2}$ and calculate the resulting integral with respect to w. Then the last integral will be less than

$$C\tau^{-n/2} \int_{\epsilon<|x|<R} |x|^{-n} \exp(-|x|^2/(M\tau)) dx$$
$$\leq C\tau^{-n/2} \int_{(\epsilon,\infty)} \rho^{-2} \rho \exp(-\rho^2/(M\tau)) d\rho$$

when we use the polar coordinates in $\mathbb{R}^n$. Replacing ρ^{-2} by its maximal value at ϵ and calculating the remaining integral with respect to ρ, we complete the bounding of the integral over $Q_1 \backslash Z$.

A similar argument works for the integral over Q_2.

The proof is complete.

Lemma 3.3.

$$|I_3| \leq C\epsilon\tau^{-n/2},$$

where M depends only on the upper bounds of $|a_3|$, $|a_0|$.

Proof. We bound the integral of the first of the three functions, forming I_3 as defined after (3.5).

As follows from (3.2), (3.3), and the argument in Lemma 3.2, replacing $|x|$ by some power of $(t-\tau)$, the absolute value of this integral is less than

$$C \int_{|x|<\epsilon} \int_{(0,\tau/2)} ((\tau-t)t)^{-n/2} t^{-1/2} \exp(-|x|^2\tau/(Mt(\tau-t)) dt\, dx$$
$$\leq C \int_{|x|<\epsilon} \int_{(0,\tau/2)} (\tau t)^{-n/2} t^{-1/2} \exp(-|x|^2/(Mt)) dt\, dx,$$

where we used inequality (3.6). Substituting $w = |x|^2/(Mt)$ in the inner integral yields

$$C\tau^{-n/2} \int_{|x|<\epsilon} |x|^{1-n} \int_{(2|x|^2/(M\tau),\infty)} w^{n/2-3/2} e^{-w} dw\, dx \leq C\tau^{-n/2} \int_{|x|<\epsilon} |x|^{1-n} dx.$$

Using the polar coordinates, we bound the last integral by $C\epsilon$.

The other terms can be bounded in a similar way. The proof is complete.

4. Proof of Theorem 1.1. Now we will complete the proof of Theorem 1.1. Let

$$\epsilon^2 = E\tau, \tag{4.1}$$

where (large) E will be chosen later.

First, we bound I_1 from below. From Lemma 3.1, substituting $w = 4\rho^2/(m\tau)$ in the integral and using condition (4.1), we obtain

$$|I_1| \geq C^{-1}\tau^{-n/2} \int_{(0,4E/m)} w^{n/2-1} e^{-w} dw \geq C^{-1}\tau^{-n/2} \tag{4.2}$$

provided $E > m$.

From (3.5), Lemmas 3.1–3.3, (4.1), and (4.2), it follows that

$$C^{-1}\tau^{-n/2} \leq C(\tau^{-n/2+1}\epsilon^{-2} \exp(-E/M) + \tau^{-n/2}\epsilon).$$

Using (4.1) again and multiplying both sides by $C\tau^{n/2}$, we obtain

$$1 \leq CE^{-1} \exp(-E/M) + C\epsilon \leq CE^{-1} + C\epsilon.$$

Let $\tau < 1$. Choose E so large that $E^{-1} < 1/(4C)$ and $\epsilon < 1/(4C)$; then the right side is smaller than $1/2$. We have a contradiction.

This contradiction shows that $Q_1 = Q_2$.

The next step of the proof is to show that

$$b_1 = b_2 \quad \text{on } \partial_x Q_1. \tag{4.3}$$

As in the proof for Q_j, we assume the opposite. Then we can assume that the origin $0 \in \partial_x Q_1$ and $b_1(0) < b_2(0)$. By continuity, $b_1(0) - b_2(0) > C^{-1}$ for some C on a certain ball B centered at the origin. Let $Z = B \times (0, T)$. Extend a_2 from Q_2 onto $\mathbb{R}^n$ as a C^2-function $a_4 > 0$. By repeating the proof of Lemma 3.2, we obtain the following orthogonality relation:

$$\int_{Q_1} (b_1 - b_2)\nabla u_3 \cdot \nabla u_4^* = 0 \tag{4.4}$$

for all solutions u_3 to the equation $\operatorname{div}(a_3 \nabla u_3) - u_{3t} = 0$ near Q_4 which are zero when $t < 0$ and for all solutions u_4^* to the adjoint equation $\operatorname{div}(a_4 \nabla u_4) + u_{4t} = 0$ near Q_4 which are zero when $t > T$. Let K^+ be a fundamental solution to the forward Cauchy problem for the first equation and K^- be the fundamental solution to the backward Cauchy problem for the adjoint equation with the coefficient a_4. Using the representation (3.1) of these fundamental solutions and splitting Q_1 into $Q_1 \cap Z$ and its complement, as in section 3, we obtain from (4.4) the inequality

$$|I_4| \leq |I_5| + |I_6|, \tag{4.5}$$

where

$$I_4 = \int_{Q_1 \cap Z} (b_1 - b_2) \nabla_x K_1^+ \cdot \nabla_x K_1^-$$

is related to the supposedly singular part and

$$I_5 = \int_{Q_1 \setminus Z} (b_1 - b_2) \nabla K^+ \cdot \nabla K^-,$$

$$I_6 = \int_{Q_1} (b_1 - b_2) \nabla K_0^+ \cdot \nabla K_0^{-2}.$$

It is easy to see that Lemmas 3.1, 3.2, and 3.3 are valid for I_4, I_5, and I_6, respectively. Therefore, as in the proof above, we arrive at the contradiction that $Q_1 = Q_2$.

This shows that the assumption about b_1 and b_2 is wrong and that $b_1 = b_2$ on $\partial_x Q_1$.

Let Ω_0 be the intersection of all $Q_{1\theta}$ over $0 < \theta < T$. Since b_1 and b_2 do not depend on t and are equal on $\partial_x Q_1$, they coincide on $Q_{1\theta} \setminus \Omega_0$. Letting $Q_0 = \Omega \times (0, T)$, we obtain from (4.4) the relation

$$\int_{Q_0} (b_1 - b_2) \nabla u_3 \cdot \nabla u_4^* = 0$$

for all u_3 and u_4^* in (4.4). As in the proof of Lemma 3.2, this implies that

$$\int_{Q_0} (b_1 - b_2) \nabla u_6 \cdot \nabla u_6^* = 0 \tag{4.6}$$

for solutions u_5 to the equation $\operatorname{div}((a_0 + b_1 \chi(Q_0)) \nabla u_5) - u_{5t} = 0$ near Q_0 which are zero when $t < 0$ and for solutions to the adjoint equation $\operatorname{div}((a_0 + b_2 \chi(Q_0)) \nabla u_6^*) - u_{6t}^* = 0$ near Q_0 which are zero when $t < T$.

Observe that by choosing T small, we can guarantee that Ω_0 is a Lipschitz domain. Indeed, for any point of $\partial_x Q_1 \cap \{t = 0\}$, there is a neighborhood where Q_1 is the subgraph of the Lipschitz function $x_j < q_j(x_1, \dots, x_{j-1}, x_{j+1}, \dots, x_n, t)$. We can cover the compact set $\partial_x Q_1 \cap \{t = 0\}$ by a finite number of such neighborhoods. Then there is T_1 such that $\partial_x Q_1 \cap \{t < T_1\}$ is contained in the union of these neighborhoods. Let $T = T_1$; then Ω_0 is Lipschitz because locally (in the corresponding neighborhood) its boundary is given by the equation $x_j = \inf q_j(x_1, \dots, x_{j-1}, x_{j+1}, \dots, x_n, t)$ over $t \in (0, T)$, and the inf of a family of uniformly Lipschitz functions is a Lipschitz function.

Now we will show that the equations for u_5 and u_6 have the same lateral Dirichlet-to-Neumann maps. Let u_5 and u_6 be a solution to these equations with zero initial conditions and the same lateral Dirichlet data. By subtracting these equations and letting $u = u_0 - u_5$, we obtain

$$\operatorname{div}((a_0 + b_2 \chi(Q_0)) \nabla u) = \operatorname{div}((b_1 - b_2) \chi(Q_0) \nabla u_5) \quad \text{in } Q.$$

From the definition of a weak solution of this equation, we have

$$\int_{\partial\Omega \times (0,T)} a_0 u_\nu \psi - \int_Q ((a_0 + b_2 \chi(Q_0)) \nabla u \cdot \nabla \psi - \int_Q u_t \psi = - \int_{Q_0} (b_1 - b_2) \nabla u_5 \cdot \nabla \psi$$

for any function $\psi \in H^{1,1}(Q)$. Using $\psi = u_6^*$, integrating by parts in the third integral of the left side, and again using the definition of a weak solution to the equation $\operatorname{div}((a_0 + b_2 \chi(Q_0)) \nabla u_6^*) + u_{6t}^* = 0$ with the test function u which is zero on

$\partial Q \cap \{t < T\}$, we conclude that the sum of the second and third integrals in the left side is zero. The right side is zero due to (4.6). Thus the first integral in the left side is zero. Since the lateral Dirichlet data $\psi = u_6^*$ can be any function in $C_0^\infty(\partial\Omega \times (0,T))$, we get $u_\nu = 0$ on $\partial\Omega \times (0,T)$. Therefore, $u_{5\nu} = u_{6\nu}$ on the lateral boundary, which means that we have the same lateral Dirichlet-to-Neumann maps.

Take as the Dirichlet data g a function which does not depend on t when $t > \tau$. Since the coefficients of the equations $\operatorname{div}((a_0 + b_j\chi(Q_0)\nabla u_j) - u_{jt} = 0$ are time independent, the solution $u_j(x,t)$ of the initial-boundary value problems on $\Omega \times (0,\infty)$ will be analytic with respect to $t > \tau$. They have the same Cauchy data on $\partial\Omega \times (0,T)$; therefore, as above, by uniqueness in the lateral Cauchy problem, $u_5 = u_6$ on $(\Omega\backslash\Omega_0) \times (0,T)$. By uniqueness of the analytic continuation, they are equal also on $(\Omega\backslash\Omega_0) \times (0,\infty)$. Now we modify the argument of [6] and consider the Laplace transforms

$$U_j(x,s) = \int_{(0,\infty)} e^{-st} u_j(x,t)\, dt.$$

They solve the following Dirichlet problems:

$$\operatorname{div}((a_0 + b_j\chi(\Omega_0))\nabla U_j) - sU_j = 0 \quad \text{in } \Omega, \qquad U_j = G \quad \text{on } \partial\Omega, \tag{4.7}$$

and $U_5 = U_6$ on $\Omega\backslash\Omega_0$. Letting $\tau \to 0$ we obtain $G(x,s) = g_0(x)s^{-1}$, where $g_0(x) = g(x,t)$ when $t > \tau$. Applying the results of [5] and [11] on identification of elliptic equations, we conclude that $b_1 = b_2$ on Ω_0. In fact, this result is obtained in [5] when $n \geq 3$, but the recent global uniqueness theorem of Nachman [10] extends it to $n = 2$.

The proof is complete.

THE EXISTENCE OF TRAVELLING WAVE SOLUTIONS OF A GENERALIZED PHASE-FIELD MODEL[*]

P. W. BATES[†], P. C. FIFE[‡], R. A. GARDNER[§], AND C. K. R. T. JONES[¶]

Abstract. This paper establishes the existence and, in certain cases, the uniqueness of travelling wave solutions of both second-order and higher-order phase-field systems. These solutions describe the propagation of planar solidification fronts into a hypercooled liquid. The equations are scaled in the usual way so that the relaxation time is $\alpha\varepsilon^2$, where ε is a nondimensional measure of the interfacial thickness. The equations for the transition layer separating the two phases form a system identical to that for the travelling-wave problem, in which the temperature is strongly coupled with the order parameter. Thus there is no longer a well-defined temperature at the inteface, as is the case in the more frequently studied situation in which the liquid phase is undercooled but not hypercooled.

For phase-field systems of two second-order equations, we prove a general existence theorem based upon topological methods. A second, constructive proof based upon invariant-manifold methods is also given when the parameter α is either sufficiently small or sufficiently large. In either regime, it is also proved that the wave and the wave velocity are globally unique.

Analogous results are also obtained for generalized phase-field systems in which the order parameter solves a higher-order differential equation. In this paper, the higher-order tems occur as a singular peturbation of the standard (isotropic) second-order equation. The higher-order terms are useful in modelling anisotropic interfacial motion.

Key words. travelling waves, phase-field equations, hypercooling

1. Introduction.

The phase-field system,

$$\begin{aligned}(u + \lambda W(\varphi))_t &= \nabla^2 u,\\ \alpha\varepsilon^2\varphi_t &= \varepsilon^2\Lambda\varphi + F(\varphi, u),\end{aligned}$$

is a well-established model for describing the behavior of phase fronts in materials that are undergoing a transition between the liquid and solid phase (see, e.g., [2, 9, 8, 3, 4]). Here u is nondimensional temperature, φ is an order parameter, $u + \lambda W(\varphi)$ is the energy density, Λ is an elliptic partial differential operator, ε is a length scale associated with the interfacial thickness and also serves as a nondimensional surface tension, and α is $O(1)$ with respect to ε. The functions W and F are characterized precisely in the next section; however, we note here that the assumptions about W include the cases in which W is either a linear or a quadratic function and that F is a bistable function. The nonnegative parameter λ is included for convenience in the analysis to

follow. In [1], the term λW is denoted simply by w. One advantage of phase-field equations over sharp interface models is that they incorporate both equations for the field variables away from the interface and the proper interface conditions within a single system. In addition, they are computationally advantageous.

We shall employ the usual measure of degree of undercooling $\Delta = (\hat{c}/\ell)(T_m - T_-)$, where $\hat{c}$, ℓ, T_m, and T_- are the specific heat, latent heat at $T = T_-$, melting temperature, and temperature of the undercooled melt. In dimensionless variables, the value $\Delta = 1$ is the threshold beyond which the melt is hypercooled (see the discussion following Hypothesis 2 in section 2). A frequently studied problem is that of describing the advance of a solid into a supercooled liquid for which $\Delta < 1$ (see, e.g., [4, 8]). Then at locations away from the interface, the temperature of the solid being formed is approximately the melting temperature T_m, and there can be no planar front moving with constant velocity (it will decelerate). The analogous problem for a hypercooled medium, in which $\Delta > 1$, has received less attention. In this case, the solidification front advances more rapidly into the liquid and can have constant speed. The existence of these travelling fronts within the framework of the phase field models is the principal aim of this paper.

The asymptotic analysis of the phase-field equations in this regime is performed in a companion paper [1], in which matched asymptotic expansions of the solution for small ε are constructed. In contrast to the case where $\Delta < 1$, it turns out that with hypercooling, both the order parameter *and* the temperature are discontinuous at the transition layer (phase interface) in the limit as $\epsilon \to 0$. This implies that the "inner" equations within the transition layer will be significantly more difficult to solve than in the case where $\Delta < 1$ since the travelling wave equations which give the fine structure of the solution in the interface now consist of a system in which the temperature equation is coupled with the equation for the order parameter. When $\Delta < 1$, temperature is constant to lowest order in the transition layer, and the resulting connection problem is a scalar ODE for φ. In this connection, it should be noted that the existence of travelling waves in the case where $\Delta > 1$ was proved by Caginalp and Nishiura [5] for a variant of the phase-field equations, used in other papers as well, in which the function F takes the form $F(\varphi, u) = F_o(\varphi) + \varepsilon u$. In the connection problem for this model, as in the present paper, u is not almost constant in the layer so that the travelling wave problem consists of a system rather than a scalar equation. However, the problem is simplified considerably by the fact that the second equation in the system (which contains the function F) is coupled only weakly to the variable u, allowing the use of a perturbative argument. In this variant model, ε has a different meaning and, most importantly, different physical assumptions are made. See [1] for a comparison of the two versions.

We shall prove several theorems on the existence and the uniqueness of travelling plane wave solutions to the phase-field system in the hypercooled regime. As shown in [1], the system for plane waves is precisely the set of "inner" equations for the transition layer.

The first model we consider is the standard isotropic phase-field system in one space variable x, in which $\Lambda = \partial^2/\partial x^2$. If $\xi = x/\varepsilon - ct/\varepsilon^2$ and u and φ are solutions of the PDEs that depend only upon ξ, then u and φ satisfy the travelling wave ODEs

$$-c(\dot{u} + \lambda \dot{W}(\varphi)) = \ddot{u},$$
$$-c\alpha\dot{\varphi} = \ddot{\varphi} + F(\varphi, u).$$

We first formulate and prove a theorem, Theorem 2.1, on the existence of heteroclinic solutions for this system using the Conley index. The theorem is quite general, requiring only geometric constraints on the nonlinearities in the equations (see Hypotheses 1–5 in section 2 below). The price for such generality is that the proof supplies relatively little information about the qualitative properties of the profile and the wave speed. It is not difficult to see that the components of the profile can exhibit a rich variety of different qualitative forms, depending on the parameters and the nonlinearities in the equations. In section 6, we present numerical results giving some of the wave profiles that can be observed.

In the asymptotics in [1], it is important to have more information about the wave and the associated wave velocity c. In particular, it is important to know that the wave speed is unique and that it depends smoothly on parameters in the equations. In section 4, we give a second proof of the existence of the profile when the parameter α is either small or large under weaker geometric constaints than those required in Theorem 2.1. The proof, which is constructive and relies upon invariant-manifold machinery, provides the local uniqueness of the wave and the wave velocity as well as their differentiable dependence on parameters. If, in addition, the more stringent constraints of Theorem 2.1 are satisfied, it is shown that the wave and the wave velocity are globally unique relative to all possible wave solutions in the isolating region constructed in section 3 and all negative values of the wave-velocity parameter.

In section 5, we consider phase-field equations where the operator Λ is a higher-order differential operator. Equations of this type are obtained by retaining higher-order terms of up to some arbitrarily prescribed order in the Ginzburg–Landau formalism used to express the self-interaction term in the free-energy functional as a differential operator. The retention of higher-order terms provides a natural way of introducing anisotropy into the equations; see [1] for a detailed derivation. The resulting travelling wave system for the inner equations at a point on the interface is

$$\begin{aligned} -c(\dot{u} + \lambda \dot{W}(\varphi)) &= \ddot{u}, \\ -c\alpha\dot{\varphi} &= \Lambda(\theta)\varphi + F(\varphi, u), \end{aligned}$$

where the vector parameter θ consists of the angles that the outward normal to the interface at this point makes with the coordinate axes (see [1]). Specifically, the operator $\Lambda(\theta)$ has the form

$$\Lambda(\theta) = \sum_{i=1}^{m} \mu^{2i-2} b_i(\theta) d^{2i}/d\xi^{2i},$$

where m is odd and the coefficients $b_i(\theta)$ are smooth positive functions of θ. In [1], it is shown that if the interaction function in the free-energy functional possesses anisotropy of order $2m$, then terms in the differential equations of order at least $2m$ must be retained in order to observe the required degree of anisotropy in solutions of the truncated equations. Also, we remark that m should be odd if Λ is to be elliptic.

The parameter μ has physical significance as the ratio of two microscopic characteristic lengths [1]. We assume that μ is small enough since the existence proof entails perturbing off the case where $\mu = 0$. This generalizes earlier work on the existence of travelling waves for the scalar problem (wherein u is constant) in the sixth-order case [11]. The results in [11] are generalized to scalar equations of arbitrarily high order in [1]. The scalar equation arises as the inner $O(1)$ approximation when the relaxation time for the phase variable, which we have denoted by $\alpha\varepsilon^2$, is assumed to be $O(\varepsilon)$ rather than the $O(\varepsilon^2)$.

In section 5, we obtain a global existence result similar to Theorem 2.1 for the higher-order connection problem under the assumption that μ is sufficiently small. We also give a constructive proof which again implies the uniqueness of the wave speed c and its differentiable dependence $c = c(\theta)$ on the parameter θ under the additional assumption that α is either small or large. This last result is needed in [1] in the asymptotic description of anisotropic interfacial motion in hypercooled solidification. In particular, the asymptotics in [1] lead to a Hamilton–Jacobi-type equation for the interface. The Hamiltonian is essentially the wave speed c of the above connection problem as a function $c = c(\theta, s)$ of the angles θ and, in the event that the initial data are in the two phases, position s along the interface.

The proofs of some of the main theorems are somewhat lengthy and technical. Readers seeking an overview of the results obtained here should first read section 2, wherein the basic structural hypotheses are formulated, and then proceed to the statement of Theorems 4.2 and 4.3 in section 4, wherein the two asymptotic limits of the wave for small and large α are described. Further qualititative understanding of the structure of various waves that appear can be obtained from the numerical results presented in section 6.

2. A global result. In this section we formulate the general travelling plane wave problem for the second-order system described in the introduction. Take the far-field liquid temperature $u_- < 0$ and the phase variable there, φ_-, to be such that the state (φ_-, u_-) lies on the equilibrium curve $F(\varphi, u) = 0$ on the right-hand ascending branch (see Figure 1). Here the right equilibrium branch is associated with the liquid phase. Note that with this convention, large φ is associated with the liquid phase while small φ along the left branch of equlibria is associated with the solid phase. Hence here φ is more appropriately thought of as a disorder parameter rather than an order parameter.

A solution of the second-order travelling wave system which is asymptotic to the state (φ_-, u_-) at $\xi = -\infty$ satisfies the system of ODEs

$$\begin{aligned} \dot{u} &= -cg(\varphi, u), \\ \dot{\varphi} &= \psi, \\ \dot{\psi} &= -c\alpha\psi - F(\varphi, u), \end{aligned} \tag{1}$$

where $c < 0$ is the wave speed, $\alpha > 0$, and

$$g(\varphi, u) = u - u_- + \lambda(W(\varphi) - W(\varphi_-)).$$

$W(\varphi)$ is a function which is either monotone decreasing or concave (see [8]). In particular, we could assume for simplicity that $W(\varphi) = A\varphi - B\varphi^2$ with $A, B \geq 0$. Additional hypotheses concerning W are formulated below.

We shall consider functions F and W which, in addition to the above, satisfy the following hypotheses.

HYPOTHESIS 1.

1. *F is a C^1 function which is "bistable" in φ for each fixed u in some interval $-u_m < u < u_m$, i.e., for each such u, $F(\varphi, u)$ has precisely three roots,*

$$h_\ell(u) < h_*(u) < h_r(u).$$

2. *$\int_{h_\ell(u)}^{h_r(u)} F(\varphi, u)\, d\varphi$ has the same sign as u and vanishes if and only if $u = 0$.*
3. *$\frac{\partial F}{\partial \varphi}(h_{\ell,r}(u), u) < 0$ for $-u_m < u < u_m$, and $\frac{\partial F}{\partial u}(\varphi, u) > 0$.*

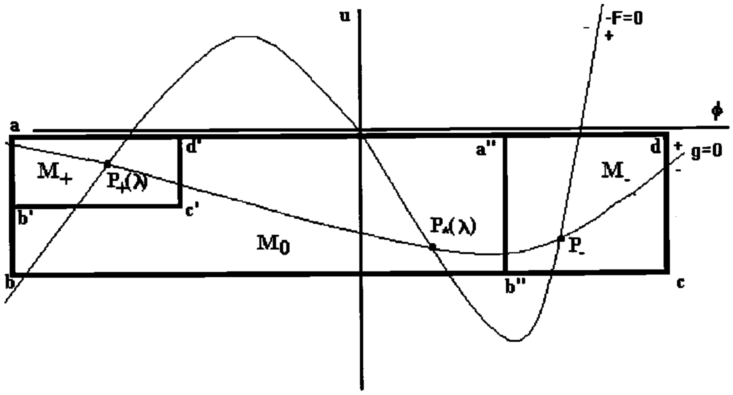

FIG. 1. *Null sets of F and g, and the boxes M_0 and $M_\pm$.*

For example, the function $F = \varphi - \varphi^3 + u$ is easily seen to satisfy each of the conditions in Hypothesis 1, as does the function $F = (1-\varphi)(\varphi + a(u))(\varphi+1)$, where $a(u)$ is a monotone increasing function with $a(0) = 0$. We remark that these conditions include the class of thermodynamically consistent phase-field equations of Fife and Penrose [8]. Since the far field at $-\infty$ is assumed to be in the liquid phase, it is appropriate to consider only waves with negative speeds c since hypercooling should produce solidification fronts propagating from the solid into the liquid. The above hypothesis is consistent with this physical requirement.

The parameter u_- is regarded as a free parameter in the range $-u_m < u_- < 0$ and the parameter φ_- is then determined by the equation $\varphi_- = h_r(u_-)$. The point $P_- = (u_-, \varphi_-, 0)$ is therefore a rest point of (1) which lies along the right branch of $F = 0$. We next impose some additional hypotheses on the null sets $F = 0$ and $g = 0$ that are needed to ensure the existence of the wave. These hypotheses can be seen to be fulfilled through a judicious choice of the remaining parameter λ. In the following, λ is allowed to vary over some interval of the form $0 \le \lambda \le \lambda_0$.

HYPOTHESIS 2 (hypercooling). *The null clines $F = 0$ and $g = 0$ of the nonlinearities in* (1) *are as depicted in Figure* 1. *More precisely, there exists $\lambda_0 > 0$ such that for $\lambda \in [0, \lambda_0]$, the equations in* (1) *admit exactly three rest points,*

$$\begin{aligned} P_- &= (u_-, \varphi_-, 0), \\ P_*(\lambda) &= (u_*(\lambda), \varphi_*(\lambda), 0), \\ P_+(\lambda) &= (u_+(\lambda), \varphi_+(\lambda), 0), \end{aligned}$$

where $\varphi_+(\lambda) = h_\ell(u_+(\lambda))$, $\varphi_- = h_r(u_-)$, and $\varphi_*(\lambda) = h_*(u_*(\lambda))$. Furthermore, we assume that

$$u_- < u_+ < 0.$$

It follows from the above that the coordinates of $P_*(\lambda)$ and $P_\pm(\lambda)$ are implicit functions of the temperature u_-. Hence the only undetermined parameter is the wave speed c.

From Figure 1, it can be seen that it is possible for the temperature $u_+(\lambda)$ to be positive at the rest point $P_+(\lambda)$ associated with the solid phase. This is clearly a nonphysical state. The temperature u_s of the solid phase should therefore be defined as $u_s = \min\{u_+(\lambda), 0\}$. In the more typical solidification process (supercooling), the temperature u_s of the solid at the interface is zero. The last condition in Hypothesis 2 requires that the temperature in the solid phase be strictly negative, which can be taken as the definition of hypercooling.

It is easily seen that hypercooling can also be defined in terms of the parameter Δ mentioned in the introduction. In our dimensionless variables, the latent heat is

$$\ell = \lambda(W(\varphi_-) - W(\varphi_s)) > 0 \quad (\varphi_s = h_\ell(u_s))$$

so that the parameter Δ is $-u_-/\ell$. It then follows that $u_+/\ell = -\Delta + 1$ so that hypercooled solidification occurs when $\Delta > 1$ and the transition to hypercooling occurs when $\Delta = 1$. The problem in which Δ is near unity is interesting. Some numerical experiments in this parameter range are presented in section 6.

With a slight abuse of notation we shall also use $P_\pm$ and P_* to denote the points $(\varphi_\pm, u_\pm)$ and (φ_*, u_*) in the (φ, u) plane, and we shall usually suppress their dependence on λ. We remark that the (physical) condition $u_- < u_+ < 0$ in Hypothesis 2 implicitly places some constraints on W and λ.

Hypothesis 3. *There exists a rectangle M_0 in the (φ, u) plane with edges parallel to the coordinate axes and with vertices at $a, b, c,$ and d as depicted in Figure* 1 *such that for each $\lambda \in [0, \lambda_0]$,*

$$\begin{aligned} -F < 0 \quad &\textit{along } \bar{ab}; \quad -F > 0 \quad \textit{along } \bar{cd}; \\ g < 0 \quad &\textit{along } \bar{bc}; \quad\;\;\; g > 0 \quad \textit{along } \bar{ad}. \end{aligned}$$

Hypothesis 4. *For each $\lambda \in [0, \lambda_0]$, there exist nested families of rectangles $M_\pm(\tau)$, $0 \le \tau \le 1$, such that* (i) $M_\pm(0) = P_\pm$, (ii) *$M_\pm(\sigma) \subset M_\pm(\tau)$ for $\sigma \le \tau$, and* (iii) *$M_\pm(\tau)$ has edges parallel to the coordinate axes and such that for $\tau > 0$, the null cline $g = 0$ intersects $\partial M_\pm(\tau)$ only along the vertical edges and the null cline $F = 0$ intersects $\partial M_\pm(\tau)$ only along the horizontal edges. Furthermore, if $M_\pm = M_\pm(1)$, then the vertices a, b', c', and d' of M_+ and the vertices a'', b'', c, and d of M_- are as depicted in Figure* 1.

It is easily seen that Hypotheses 2–4 will be satisfied whenever λ_0 is sufficiently close to zero since in that case, the rectangles M_0 and $M_\pm$ can be chosen to be thin in the vertical dimension.

Next, let (φ_w, u_w) be the point along $\{g = 0\} \cap M_0$ for which u is minimal. It follows from (i) and (ii) of Hypothesis 1 that if $r(\varphi) = -F(\varphi, u_w)$, then $r(\varphi)$ has three distinct roots at

$$\hat{\varphi}_- = h_r(u_w), \qquad \hat{\varphi}_* = h_*(u_w), \qquad \hat{\varphi}_+ = h_\ell(u_w).$$

Let $R'(\varphi) = r(\varphi)$ with $R(\hat{\varphi}_+) = 0$. It follows from Hypothesis 1 that $R(\varphi)$ is as depicted in Figure 2.

Hypothesis 5. *With λ_0 set in accordance with the previous hypotheses, let*

$$\begin{aligned} \varphi_r^+ &= h_r(u_+(\lambda)), \\ \varphi_*^+ &= h_*(u_+(\lambda)); \end{aligned}$$

assume for each $\lambda \in [0, \lambda_0]$ that

$$R(\varphi_*^+) > R(\varphi_r^+).$$

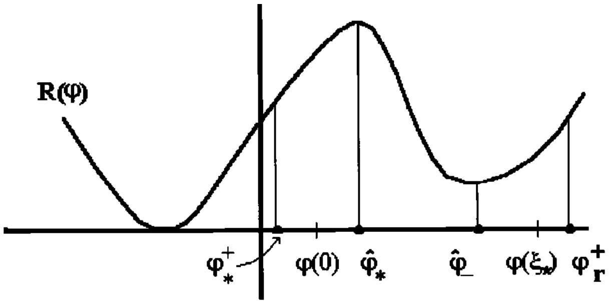

FIG. 2. *The primitive $R(\varphi)$ of $-F(\varphi, u_w)$.*

If λ_0 is near zero, $g = 0$ is nearly a horizontal line; and the rectangles M_0 and $M_\pm$ of Hypotheses 3 and 4 can be chosen to be arbitrarily thin in the vertical dimension. It then follows that $u_+(\lambda)$ is close to u_- so that $h_*(u_+(\lambda))$ will be near $\hat{\varphi}_*$ and $h_\ell(u_+(\lambda))$ will be near $\hat{\varphi}_+$. From Figure 2, we see that R has a local maximum at $\hat{\varphi}_*$ and an adjacent local minimum at $\hat{\varphi}_+$, and it therefore follows that for $\lambda \in [0, \lambda_0]$, Hypothesis 5 will always be satisfied for small λ_0.

Remark. Hypotheses 1 and 2 are natural and necessary conditions for the existence of a hypercooled phase front. It turns out that in the asymptotic regimes of either large or small α, they are also sufficient; see section 4. Hypotheses 3 and 4 are more restrictive, but they are still quite reasonable requirements for a global theory. Hypothesis 5 is somewhat more artificial. It is used below to rule out certain internal tangencies in the construction of an isolating region N in the phase space of the wave. These tangencies occur when the φ component has a local minimum when (φ, u) is exterior to the rectangle M_-. The waves that we construct therefore have monotone φ components whenever (φ, u) is exterior to this region. This is in itself a rather artificial requirement, which accounts for the artificiality of the hypothesis.

It should be noted, however, that Hypotheses 1–5 provide global geometric conditions on the nonlinearities in the equations and will hold in regimes other than in the essentially decoupled regime in which λ is assumed to be small. In particular, it should be noted that all of the above hypotheses are independent of the parameter α. In section 4, we show that for large α, the u-component of the profile is monotone increasing while the φ component has a single local maximum. On the other hand, for small α, the φ-component is monotone decreasing while the u-component is either monotone increasing (if $g = 0$ is monotone) or has a single local minimum (if $g = 0$ has a local minimum). Theorem 2.1 can be viewed as a global continuation of these two asymptotic regimes, each of which is quite far from the scalar bistable travelling wave problem. Some illustrative numerical calculations are presented in section 6.

THEOREM 2.1. *Under the above hypotheses, there exists a solution of* (1) *connecting the rest point P_- at $-\infty$ to the rest point P_+ at $+\infty$ for some wave speed $c < 0$. The solution satisfies the following bounds:*

$$u_w \le u(\xi) \le u_+,$$

$$\varphi(\xi) \ge \phi_+.$$

Furthermore, if φ_m is the value of φ in the left vertical edge of M_- and if $\varphi_{**} = \min\{\varphi_m, \varphi_w\}$, then there exist unique values $\xi_m \le \xi_{**}$ such that $\varphi(\xi_m) = \varphi_m$,

$\varphi(\xi_{**}) = \varphi_{**}$, *and*

$$\dot{\varphi}(\xi) < 0 \quad (\xi \geq \xi_m),$$

$$\dot{u}(\xi) > 0 \quad (\xi \geq \xi_{**}).$$

3. Proof of Theorem 2.1. The proof employs a topological invariant called the *Conley connection index*, which is a variant of the Conley index whose formulation permits it to detect codimension-one connections, i.e., connections between rest points P_- and P_+ for which the unstable manifold of the former and the stable manifold of the latter have dimensions adding up to that of the total state space. In this situation, any intersection of such manifolds is necessarily nontransverse, and in order to detect connections topologically, it is necessary to augment the flow with a trivial parameter flow; in this case, we include the wave velocity parameter c as a new dependent variable. The "nontriviality" of the index then forces the existence of a connecting orbit for at least one value of the wave-speed parameter. A detailed discussion of the connection index can be found in Conley and Gardner [6]; see also [10].

The main analytical construction consists of finding a certain neighborhood N in the unaugmented phase space which contains both rest points in its interior and which is isolating for each c in some interval of wave speeds $c_0 \leq c \leq c_1$. Furthermore, it is required that at the extreme parameter values c_0 and c_1, there are *no* orbits connecting P_- to P_+. The construction of the neighborhood N given here closely parallels that of the example of competitive diffusion equations studied in [6] with one important difference. In [6], both components of the wave are monotone for all parameter values for which it exists. Here, however, either component may sometimes be nonmonotone, and the neighborhood N in which we expect to locate the connection must be revised accordingly. In this regard, the construction is closer in spirit to a paper on travelling wave solutions of predator–prey systems [10], where nonmonotone behavior is also encountered.

The isolating neighborhood N will be a region of the form

$$N = N_0 \cup N_- \cup N_+ \setminus N_*(\varepsilon),$$

where $N_\pm$ are neighborhoods of the rest points $P_\pm$ of the form

$$N_\pm = M_\pm \times \{\psi : |\psi| < K\},$$

N_0 is the region

$$N_0 = M_0 \times \{\psi : -K \leq \psi \leq 0\},$$

where K is a large positive constant, and $N_*(\varepsilon)$ is a small ε neighborhood of P_*. The regions $M_\pm$ and M_0 are as in Hypotheses 4 and 3, respectively. It should be noted that these regions need to vary with the parameters.

In order to show that N is isolating, we need to verify that $S(N) \cap \partial(N)$ is empty for $c_1 \leq c \leq c_0$, where $S(N)$ denotes the set of points on solutions of (1) which remain in N for all time and, furthermore, that $S(N) = \{P_-, P_+\}$ for $c = c_0, c_1$. In order to achieve this last condition, we shall choose c_1 to be a large negative constant and c_0 to be negative and close to zero.

We begin by proving a lemma which characterizes the possible solutions in $S(N)$. For convenience, we shall denote system (1) in vector form as

$$\dot{x} = f(x, c),$$

where $x = (u, \varphi, \psi)$ and c is the wave-speed parameter. Also, we shall denote the resulting flow by $x \cdot \xi$.

LEMMA 3.1. *For all $c < 0$, $S(N)$ consists of the rest-point set $P_\pm$ interior to N and orbits in N (if any) which connect P_- at $\xi = -\infty$ to P_+ at $\xi = +\infty$.*

Proof. We first show that the only orbits which remain in the neighborhoods $N_\pm$ for all time are the rest points $P_\pm$. Suppose, for example, that there is a nonconstant orbit $x \cdot \xi \in N_-$ for all ξ. Let

$$N_\tau = M_-(\tau) \times \{\psi : |\psi| < K\},$$

where $M_-(\tau)$ is as in Hypothesis 4, and set

$$\tau_0 = \inf\{\tau \in (0, 1] : x \cdot \xi \in N_-(\tau) \text{ for all } \xi\}.$$

Since $x \cdot \xi \in N_-(1)$ for all ξ and is nonconstant, it follows that $0 < \tau_0 \leq 1$. By the minimal property of τ_0, it follows that $x_1 = x \cdot \xi \in \partial N_-(\tau_0)$ for some ξ. It follows immediately from Hypothesis 4 that if (φ_1, u_1) lies in a horizontal edge of $M_-(\tau_0)$, then $\dot{u} \neq 0$ at this point so that the orbit would have to exit $N_-(\tau_0)$ in one time direction. If (φ_1, u_1) lies in a vertical edge, then if $\psi_1 \neq 0$, the solution again leaves $N_-(\tau_0)$ in one direction, while if $\psi_1 = 0$, then by Hypotheses 1 and 4, $\ddot{\varphi}(\xi)$ is positive on the right vertical edge and negative on the left vertical edge. In either case, the solution remains outside $N_-(\tau_0)$ in both time directions. Thus in all cases, the solution would exit $N_-(\tau)$ for some τ larger than but near τ_0, contradicting the defining condition for τ_0. Finally, since (φ, u) lies in M_- for all ξ, there exists L such that $|u|$ and $|\varphi|$ are uniformly bounded by L. It then easily follows from standard regularity theory for parabolic equations that there exists $K = K(L)$ such that $|\psi| < K$ for solutions for which (φ, u) lie in M_-. If K is sufficiently large, it therefore follows that $|\psi_1| < K$. Thus in all cases, we see that the only solution which can remain in N_- for all time is the constant solution P_-. The proof for N_+ is the same and will be omitted.

Now suppose that $x \in S(N)$ and that it is not a rest point. The argument above shows that

$$x \cdot \xi \in N_0 \setminus (N_- \cup N_+ \cup N_*(\varepsilon))$$

for some ξ. In the region N_0, $\varphi(\xi)$ is a monotone decreasing function. If the solution were to remain in N_0 for all ξ, it would then follow that $\varphi(\xi)$ would tend to distinct limits at $\pm\infty$. The first equation in (1) can then be viewed as an asymptotically autonomous scalar equation for u, from which it easily follows that $u(\xi)$ tends to limits at $\pm\infty$ as well. Similarly, it easily follows from the second equation in (1) that $\psi(\xi)$ tends to zero at $\pm\infty$. The only way that this can occur is if the forward and backward limits are rest points of (1); however, the only rest points of (1) in N are $P_\pm$. It therefore follows that $x \cdot \xi$ enters N_- in some backward time $\xi = \xi_-$ and that it enters N_+ in some forward time $\xi = \xi_+$.

We now claim that $x \cdot \xi$ remains in N_- (resp. N_+) for $\xi < \xi_-$ (resp. for $\xi > \xi_+$). For example, if, after having entered N_+ at ξ_+, it were to exit this set at some $\xi_* > \xi_+$, it would have to do so by having (φ, u) cross the lower edge or the right edge of M_+, i.e., an edge interior to M_0. If it were to cross the right edge, then $\psi(\xi_*) \geq 0$. If ψ were positive at this point, this would persist for $\xi > \xi_*$ as the orbit enters the region, N_0; however, in this region, ψ is nonpositive, yielding a contradiction. Also, $\psi(\xi_*)$ cannot vanish since by Hypothesis 3, we have that at such a point, $\ddot{\varphi}(\xi_*) = -F > 0$ so that $x \cdot \xi$ would be exterior to N_+ for all ξ near ξ_*, again yielding a contradiction.

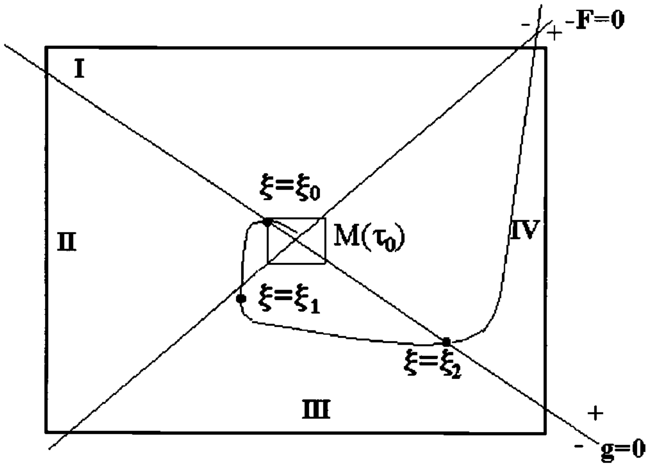

FIG. 3. *Behavior in M_+.*

If the orbit were to cross back into N_+ through the lower edge of M_+, by the above reasoning, $\dot{\varphi}$ would have to remain negative along the forward half-orbit, while $\dot{u}$ would have to remain negative (see Figure 1). This is because $g = 0$ has a negative slope here so that the monotonicity of both components must persist along the forward half-orbit. Such a solution must eventually exit N by having (φ, u) exit M_0 through the left or bottom edge.

The argument that $x \cdot \xi$ remains in N_- for $\xi \le \xi_-$ is proved by a similar, simpler argument. It will therefore be omitted.

We have now demonstrated that $\omega(x \cdot \xi) \subset N_+$ and that $\alpha(x \cdot \xi) \subset N_-$. However, the argument in the first paragraph of the proof of this lemma shows that the only way that this can occur is if $\omega(x \cdot \xi) = \{P_+\}$ and $\alpha(x \cdot \xi) = \{P_-\}$, completing the proof.

LEMMA 3.2. 1. *Suppose that $x \cdot \xi \in S(N)$ is a nonconstant orbit for system* (1). *Let u_w be the minimal value of u along $\{g = 0\} \cap M_0$; then $u_w \le u(\xi) \le u_+(\lambda)$ and $\varphi(\xi) > \varphi_+(\lambda)$ for all ξ.* 2. *Let the left vertical edge of the rectangle M_- be $\varphi = \varphi_m$, let the point where $g = 0$ has its minimum be (φ_w, u_w), and let $\varphi_{**} = \min\{\varphi_m, \varphi_w\}$. Then there exist unique points $\xi_m \le \xi_{**}$ such that $\varphi(\xi_m) = \varphi_m$ and $\varphi(\xi_{**}) = \varphi_{**}$. Furthermore, $\psi(\xi) \le 0$ for $\xi > \xi_m$ and $\dot{u}(\xi) > 0$ for $\xi > \xi_{**}$.*

Proof. 1. If $\lambda = 0$, then the solutions in $S(N)$ have constant u-component, in which case the bounds for u are obvious. Suppose then that $\lambda > 0$. The lower bound u_w for u is obvious since $\dot{u} < 0$ whenever $u < u_w$. Next, let S be the supremum of $u(\xi)$ and assume that $S > u_+$. Since $u(\xi)$ tends to limits $u_\pm < S$ at $\pm\infty$, it follows that $S = u(\xi_0)$ for some finite ξ_0 and that $\dot{u}(\xi_0) = 0$. It then follows that (φ, u) lies in the portion of the null cline $\{g = 0\}$ inside M_+ for which $u > u_+$ at $\xi = \xi_0$ (see Figure 3). We therefore also have that $\varphi(\xi_0) < \varphi_+$.

The region M_+ is composed of four wedge-shaped regions bounded by the null clines $F = 0$ and $g = 0$ and the edges of M_+, which we have denoted by I, II, III, and IV in Figure 3. At ξ_0, (φ, u) must lie on the boundary of I and II. Let τ_0 be the (unique) value of $\tau \in (0, 1)$ such that

$$(\varphi(\xi_0), u(\xi_0)) \in \partial M_+(\tau_0),$$

where $M_+(\tau)$ is the family of rectangles about P_+ defined in Hypothesis 4. Since

$S = u(\xi_0)$ is a maximum, it follows that $\ddot{u}(\xi_0) \leq 0$. However, from the first equation in (1), we see that $\ddot{u}(\xi_0) = -c\lambda W'(\varphi(\xi_0))\psi(\xi_0)$; since $-cW'(\varphi) > 0$ for $(\varphi, u) \in M_+$, it follows that $\psi(\xi_0) \leq 0$. However, if $\psi(\xi_0) = 0$, then $\dot{\psi}(\xi_0) = -F(\varphi(\xi_0), u(\xi_0)) < 0$ so that $u^{\cdots}(\xi_0) < 0$, contradicting the maximality of S for $\xi < \xi_0$. We therefore have that $\psi(\xi_0) < 0$, and the solution must therefore behave as indicated in Figure 3, i.e., (φ, u) must exit $M(\tau_0)$ in the forward time direction by moving from region I to region II. Note that both components are now decreasing monotonically with ξ.

We next claim that there exists $\xi_1 > \xi_0$ such that φ has a local minimum at ξ_1. This follows from our previous observation that $\varphi(\xi_0) < \varphi_+$ and that $x \cdot \xi \in S(N)$, so φ must have a minimum at some finite value of $\xi > \xi_0$. We assume that ξ_1 is the smallest such point. It follows that $\ddot{\varphi}(\xi_1) = -F \geq 0$ so that the point (φ, u) must lie either on the left boundary of region III or in its interior at ξ_1. In the former case, we see that $\varphi^{\cdots}(\xi_1)$ is positive since $F_u > 0$, contradicting the minimality of ξ_1. Hence the solution must lie interior to III so that $\ddot{\varphi}(\xi_1) > 0$ and thus φ has a strict local minimum at ξ_1 and $\dot{\varphi} > 0$ for $\xi > \xi_1$. Note that (φ, u) remains outside the rectangle $M_+(\tau_0)$ on the interval $\xi_0 < \xi \leq \xi_1$ and that $u(\xi_1)$ is smaller than the smallest value of u for all points in this rectangle.

For $\xi > \xi_1$ but not too large, it follows that u must continue to decrease and φ must continue to increase with ξ. Clearly, this monotonicity cannot persist for all ξ since $u(\xi_1) < u_+$, and by the previous lemma, the solution must tend to P_+ at $+\infty$. The only way that this can occur is for (φ, u) to cross $g = 0$ at a time $\xi = \xi_2$ by crossing from region III into region IV. Furthermore, φ must remain monotone increasing since (φ, u) remains below $F = 0$ on this interval.

Finally, we have that at some $\xi = \xi_2 > \xi_1$, (φ, u) lies on $g = 0$, defining the common boundary of III and IV; furthermore, it is still exterior to the rectangle $M_+(\tau_0)$. We now observe that both φ and u must continue to increase while the solution remains in region IV since $\dot{u} > 0$ and $\ddot{\varphi} > 0$ in this region. Since the orbit ultimately tends to P_+, this monotonicity cannot persist for all $\xi \geq \xi_2$, and so the orbit must cross into region I from region IV through their common boundary at some time $\xi_3 > \xi_2$. However, by monotonicity, we again have that (φ, u) remains exterior to $M(\tau_0)$ for $\xi_2 \leq \xi \leq \xi_3$. Thus at $\xi = \xi_3$, u attains a value larger than $S = u(\xi_0)$, yielding a contradiction.

It is also easily proved that $\varphi(\xi) > \varphi_+$ for all ξ. Let m be the infimum of $\varphi(\xi)$ and suppose that $m < \varphi_+$. There exists (finite) ξ_0 such that $m = \varphi(\xi_0)$, and at this point, ψ must vanish. It easily follows that (φ, u) lies in region III of M_+ so that $\dot{u}(\xi_0) < 0$ and φ has a strict local minimum here. Since the solution is assumed to lie in $S(N)$, arguments similar to those in the preceding paragraphs show that (φ, u) must eventually cross from region III to region IV and finally from region IV to region I in the forward time direction, contradicting the upper bound $u \leq u_+$ obtained above.

2. Since the orbit is a connection from P_- to P_+, there exists some $\xi = \xi_m$ such that $\varphi(\xi_m) = \varphi_m$; we assume that ξ_m is the largest value of ξ where this occurs so that $\varphi(\xi) < \varphi_m$ for $\xi > \xi_m$. It follows that $\psi(\xi_m) \leq 0$. If $\psi(\xi_m) = 0$, then $\dot{\psi}(\xi_m) = -F < 0$ since $\varphi = \varphi_m$ here. However, we would then have that φ has a strict local maximum at ξ_m so that $\psi(\xi) > 0$ and $\varphi(\xi) < \varphi_m$ for $\xi < \xi_m$. Such solutions exit N in the backward time direction. Thus $\psi(\xi_m) < 0$. If $\varphi(\xi_1) = \varphi_m$ for some $\xi_1 < \xi_m$, then assuming that ξ_1 is the largest such value less than ξ_m, we would have that $\psi(\xi_1)$ that either $\psi(\xi_1) > 0$ or $\psi(\xi_1) = 0$. Both conditions imply that the solution leaves N in the backwards direction so that ξ_m is unique.

For $\xi > \xi_m$, the solution enters the region $N \setminus (N_- \cup N_+)$ and thus $\psi(\xi) \leq 0$

for $\xi \geq \xi_m$ up to the first time $\xi = \xi_0 > \xi_m$ that the solution enters N_+, and the only possibilities are that (φ, u) enters M_+ through either region III or IV. However, if it crosses into region III at some $\xi \geq \xi_0$, then $u < u_+$, and the only way that u can begin to increase is for φ to have a local minimum at some $\xi_1 > \xi_0$ so that the solution crosses from region III into region IV for some $\xi_2 > \xi_1$. However, φ must continue to increase for as long as the solution remains in region IV, so as in part 1 of the proof, u must eventually attain values that exceed u_+—a contradiction. The only possibility is that (φ, u) enters region IV with $\dot{u} > 0$ and $\dot{\varphi} < 0$. If this monotonicity does not persist for all $\xi > \xi_0$, then φ must have a strict local minimum at some $\xi_1 > \xi_0$. For $\xi > \xi_1$, either the solution exits M_+ with $\psi > 0$ so that $x \cdot \xi$ leaves $S(N)$ or the solution remains in M_+, in which case it must cross from region IV into region I. In either case, we obtain a contradiction. We have therefore shown that ψ remains nonpositive along the entire forward half-orbit, $\xi \geq \xi_m$.

It follows from the nonpositivity of ψ for $\xi \geq \xi_m$ that $\varphi(\xi)$ is strictly monotone decreasing on this interval since if this were not the case, $\psi(\xi)$ would necessarily vanish identically on some interval. It would then follow that the orbit in question is a rest point, contrary to our assumption. It therefore follows that there exists a unique value $\xi = \xi_{**} \geq \xi_m$ such that $\varphi(\xi_{**}) = \varphi_{**}$, where $\varphi_{**} = \min\{\varphi_m, \varphi_w\}$.

We claim that $\dot{u}(\xi) > 0$ for all $\xi > \xi_{**}$. Since $\dot{\varphi} \leq 0$ for $\xi \leq \xi_{**}$, it follows that (φ, u) lies above $g = 0$ at ξ_{**} since otherwise (φ, u) would enter and remain in the region below $g = 0$ for $\xi > \xi_{**}$, and u would therefore have to decrease for all larger ξ since $g = 0$ is a monotone decreasing function of φ here; this is a contradiction. If the claim that $\dot{u} > 0$ for all $\xi \geq \xi_{**}$ were false, the point (φ, u) would have to cross the null set $g = 0$ at some $\xi_1 > \xi_{**}$. Since $\psi \leq 0$ for $\xi > \xi_m$, the φ component must decrease monotonically for all such ξ. The tangent vector to (φ, u) must therefore point into the left half-plane. Furthermore, we have that $\dot{u}(\xi_1) = 0$ so that the tangent to (φ, u) is the vector $(\psi(\xi_1), 0)$ with $\psi(\xi_1) \leq 0$. If ψ is strictly negative at this point, the solution enters the region below $g = 0$. Since φ is monotone decreasing for all $\xi \geq \xi_1$ and $g = 0$ is a monotone decreasing function of φ for $\varphi \leq \varphi_w$, it follows that (φ, u) can never cross $g = 0$ in the forward direction, and u would therefore have to monotonically decrease to a limit strictly less than u_+ at $+\infty$—a contradiction. If $\psi(\xi_1) = 0$, then we must have that $F(\varphi, u) \neq 0$ at ξ_1; otherwise, $x \cdot \xi_1$ would coincide with the rest point P_*, which is impossible. Since the solution is exterior to $N_\pm$ at this point, we must have that ψ is nonpositive near ξ_1 so that the only remaining alternative is that $-F < 0$ at this point. However, the argument now proceeds as when $\psi(\xi_1) < 0$, and the solution must still eventually leave N in the forward direction. Hence we must have that $\dot{u} > 0$ for all $\xi > \xi_{**}$.

Lemma 3.3. *There exists (large) $K > 0$ and (small) $\varepsilon > 0$ such that $S(N) \cap \partial(N)$ is empty for all $c < 0$.*

Proof. Suppose that $x \in S(N) \cap \partial N$. The boundary of N consists of the union of the following subsets:

B_1: $(\varphi, u) \in \partial M_0$ and $\psi \leq 0$;
B_2: $\psi = -K$ and $(\varphi, u) \in M_0$, or $\psi = +K$ and $(\varphi, u) \in M_\pm$;
B_3: $\psi \geq 0$ and $(\varphi, u) \in \partial M_\pm$;
B_4: $\psi = 0$ and $(\varphi, u) \in M_0 \setminus (M_+ \cup M_-)$;
B_5: $x \in \partial N_*(\varepsilon)$.

1. Suppose that $x \in B_1$. If (φ, u) lies in either horizontal edge of M_0, then $\dot{u} \neq 0$ so that the solution immediately exits N in one time direction. Next, suppose that (φ, u) lies in a vertical edge of M_0. If $\psi < 0$, then the solution immediately exits N in one

time direction. Suppose then that $\psi = 0$ at this point so that $\ddot{\varphi} = \dot{\psi} = -F(\varphi, u)$. If (φ, u) lies in the left (resp. right) edge of M_0, then $-F(\varphi, u) < 0$ (resp. $-F(\varphi, u) > 0$) so that φ has a local maximum (resp. minimum). Thus in both cases, the solution immediately exits N in both time directions.

2. Suppose that $x \in B_2$ so that $|\psi| = K$. If $x \in S(N)$ and if

$$\Phi(x,t) = \varphi(x - ct), \qquad U(x,t) = u(x - ct),$$

then Φ is a solution of the scalar parabolic equation

$$\Phi_t = \Phi_{xx} + F(\Phi, U).$$

Since the last term is a uniformly bounded, smooth function of (x, t), it follows from the $(1 + \delta)$ Schauder estimates for scalar, linear parabolic equations that Φ_x is uniformly bounded on finite time intervals so that $\Phi_x(x, 1)$ is a uniformly bounded function of x. However, $\dot{\varphi}(x) = \Phi_x(x + c, 1)$ so that $|\psi|$ is uniformly bounded from above by some constant K which depends only on the uniform bound for $F(\varphi, u)$ for $(\varphi, u) \in M_0$. In particular, K is independent of the wave speed c. It follows that for such K, if $|\psi| = K$, then $x \notin S(N)$.

3. Suppose that $x \in B_3$. If (φ, u) lies in the horizontal edges of M_-, then by Hypothesis 3, $\dot{u} \neq 0$ so that the solution immediately exits N in one time direction. If (φ, u) lies on the right vertical edge of M_- and $\psi > 0$, then (φ, u) exits M_0, and hence N, in forward time. If $\psi > 0$ with (φ, u) in the left vertical edge of M_-, then (φ, u) enters $M_0 \setminus (M_- \cup M_+)$ in forward time with $\psi > 0$; such solutions also leave N. Finally, if (φ, u) lies in a vertical edge of M_- with $\psi = 0$, then by Hypothesis 3, the solution exits N in both time directions.

Next, suppose that $(\varphi, u) \in \partial M_+$ with $\psi \geq 0$. The argument that the solution leaves N in at least one time direction is the same as in the case for $(\varphi, u) \in M_-$, with the exception of the points (φ, u) in the lower horizontal edge of M_+ when $\psi = 0$ since the latter edge is interior to M_0. However, at such a point, we have that $\dot{u} < 0$ with $\varphi < \varphi_{**}$; by Lemma 3.2, the solution through such a point cannot lie in $S(N)$.

4. Suppose that $x \in B_4$ so that $\psi = 0$ and $(\varphi, u) \in M_0 \setminus (M_- \cup M_+)$. If $F(\varphi, u) \neq 0$, then $\dot{\psi} = -F(\varphi, u)$ is nonvanishing so that ψ becomes positive in one time direction while $(\varphi, u) \notin (M_- \cup M_+)$; such solutions cannot lie in $S(N)$. We therefore have that $F = 0$ at such points. Since $(\varphi, u) \notin M_\pm$, it follows that (φ, u) must lie in either the middle branch of $F = 0$ or the portion of the left branch outside M_+. However, in the latter case, $\varphi < \varphi_+$, which is impossible by Lemma 3.2. Hence (φ, u) must lie in the middle branch of $F = 0$. If (φ, u) lies strictly below $g = 0$ at x, then $\dot{u} < 0$ and $\ddot{\psi} = -F_u \dot{u} > 0$ so that $\psi > 0$ for small ξ and the solution leaves N in both directions. Furthermore, if $g(\varphi, u) = 0$, then $x = P_*$ which is exterior to N—also a contradiction. Hence we must have that (φ, u) lies strictly above $g = 0$ at x.

By part 2 of Lemma 3.2, $\psi(\xi)$ remains nonpositive along the backward orbit segment $x \cdot [\xi_m, 0]$, beyond which point the orbit enters N_-. Furthermore, by an argument in the previous paragraph, $\psi < 0$ on this interval whenever $F(\varphi, u) \neq 0$. If $\psi = 0$ at some $\xi < \xi_m$, let ξ_* be the largest value of $\xi \leq \xi_m$ for which $\psi = 0$; if $\psi < 0$ for all $\xi < \xi_m$, let $\xi_* = -\infty$. Let $\varphi_r^+ = h_r(u_+(\lambda))$. We claim that $\varphi(\xi_*) \in [\varphi_-, \varphi_r^+]$. The upper bound follows immediately from the estimate $u(\xi) \leq u_+(\lambda)$ of Lemma 3.2. We next obtain the lower bound for $\varphi(\xi_*)$. In the event that $\xi_* = -\infty$, we have that $\varphi(\xi_*) = \varphi_-$. Assume then that ξ_* is finite and that $\varphi(\xi_*) < \varphi_-$. A contradiction will be obtained in each of two separate cases, (a) and (b), below.

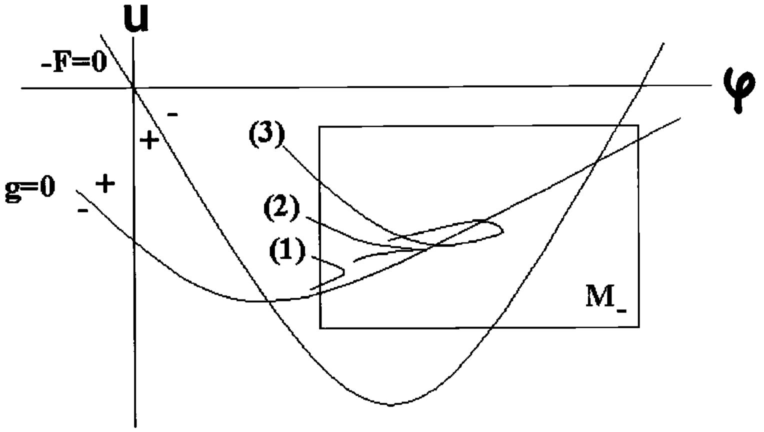

FIG. 4. *Possible behavior of the backwards orbit with* $\psi(0) = 0$.

(a) Suppose that the graph of $g = 0$ is a monotone decreasing function of φ in the range $\varphi_+ \le \varphi \le \varphi_-$. We claim that (φ, u) lies strictly above $g = 0$ on the interval $[\xi_*, 0]$. As noted above, this condition holds at $\xi = 0$. If the claim is false, let $\xi_1 \in [\xi_*, 0]$ be the largest ξ in this interval for which $g(\varphi, u) = 0$. If $\psi = 0$ at ξ_1, then by the conditions above, we must have that $F = 0$ as well, in which case x must be a rest point, and the only possibility is that $x = P_*$. However, P_* is exterior to N. Hence we must have that $\psi < 0$ at ξ_1, in which case the tangent vector to (φ, u) is $(\psi(\xi_1), 0)$. Since we have assumed that $\varphi < \varphi_-$ at ξ_*, it follows by monotonicity that $\varphi(\xi_1) < \varphi_-$ as well, and since $g = 0$ is a monotone decreasing curve, this contradicts the maximality of ξ_1. Thus $g(\varphi, u) > 0$ on $[\xi_*, 0]$. If $\varphi(\xi_*) < \varphi_-$, then by the monotonicity of $g = 0$, it follows that $\varphi(\xi_*)$ is a strict local maximum so that the solution would then necessarily exit N in the backwards direction by leaving N_- while $\psi > 0$. It therefore follows that that $\varphi(\xi_*) > \varphi_-$.

(b) Next, suppose that $g = 0$ has its local minimum at the point (φ_w, u_w) with $\varphi_w \in (\varphi_+, \varphi_-)$. By the definition of ξ_*, we have that $\varphi(\xi_*) > \varphi_m$. There are three distinct possibilities, as depicted in Figure 4. In case 1, the point (φ, u) lies above $g = 0$ at ξ_*. Since $\ddot{\varphi} = -F < 0$ at this point, φ must have a local maximum at this point and $\psi > 0$ for $\xi < \xi_*$. It now follows that the orbit cannot cross the monotone increasing portion of $g = 0$ for $\xi < \xi_*$. It follows that (φ, u) must remain in the region $-F < 0$ for as long as the backward orbit remains in N_-, and it follows that in this region, ψ must remain strictly positive. Thus φ decreases for $\xi < \xi_*$ until the solution leaves N_-. At this point, ψ is still positive, and the solution therefore exits N in the backward direction.

The other two possibilities are depicted by the orbits labelled 2 and 3 in Figure 4. In the former case, (φ, u) lies on $g = 0$ at ξ_* and the curve has a cusp at this point. However, the orbit still exits in the backward time direction. The argument is the same as for orbit 1. In the last case, case 3, (φ, u) lies below $g = 0$ at ξ_*. In this case, the positivity of ψ is again preserved for $\xi < \xi_*$ and the curve (φ, u) must cross $g = 0$ again before leaving N_-. As before, the orbit is seen to leave N in the backward direction since the orbit leaves N_- while $\psi > 0$.

We have now established the claim that $\varphi(\xi_*) \in [\varphi_-, \varphi_r^+]$. Since $\hat{\varphi}_- \le \varphi_-$, we then have that

$$\hat{\varphi}_- \leq \varphi(\xi_*) \leq \varphi_r^+,$$

where $\hat{\varphi}_- = h_r(u_w)$ and $\varphi_r^+ = h_r(u^+)$ are as in Hypothesis 5. Also, since $\varphi(0)$ lies on the middle branch of $F = 0$ and $u(0) < u_+(\lambda)$, it follows that

$$\varphi_*^+ \leq \varphi(0) \leq \hat{\varphi}_*$$

so that by Hypothesis 5, $R(\varphi(0)) > R(\varphi(\xi_*))$ (see also Figure 2). By Lemma 3.2, we have that $u(\xi) \geq u_w$, and by Hypothesis 1, we have that $F_u > 0$; it therefore follows that

$$\begin{aligned} \ddot{\varphi} &= -\alpha c\dot{\varphi} - F(\varphi, u) \\ &\leq -\alpha c\dot{\varphi} - F(\varphi, u_w). \end{aligned}$$

Since $\dot{\varphi} \leq 0$ on $[\xi_*, 0]$ and vanishes at the endpoints, we may multiply the above by $\dot{\varphi}$ on this interval and integrate to obtain

$$\begin{aligned} 0 &= \int_{\xi_*}^{0} (\dot{\varphi}(\xi)^2/2)^{\cdot} \, d\xi \\ &\geq -c\alpha \int_{\xi_*}^{0} \dot{\varphi}^2 \, d\xi + R(\varphi(0)) - R(\varphi(\xi_*)), \end{aligned}$$

where $R(\varphi)$ is an antiderivative of $-F(\varphi, u_w)$. We have by Hypothesis 5 and the negativity of c that both quantities in the last term of the above inequality are positive, yielding a contradiction. Thus $B_4 \cap S(N)$ is empty.

5. Finally, suppose that $x_\varepsilon \in B_5$ lies in $S(N)$ for a sequence ε tending to zero. Since each such orbit is a connection from P_- to P_+, there exists $\xi_\varepsilon > 0$ such that $(\varphi, u)(-\xi_\varepsilon)$ lies in the left vertical edge of M_- and is hence uniformly bounded away from the rest points. Let $y_\varepsilon = x_\varepsilon \cdot (-\xi_\varepsilon)$; by passing to a suitable subsequence, it can be assumed that y_ε converges to a limit $\bar{y}$. Furthermore, since x_ε converges to the rest point at P_*, it follows that $\xi_\varepsilon \to +\infty$. Since $\psi < 0$ whenever $(\varphi, u) \in M_0 \setminus (M_- \cup M_+)$, it follows that the orbit $\bar{y} \cdot \xi$ must remain in the region $\varphi \geq \varphi_*$ for all positive ξ, and since φ is monotone along the forward half-orbit, the solution must be a connection between P_- and P_*. It also follows, as in case 4, that the orbit must lie in the region above $g = 0$ as long as (φ, u) is exterior to M_-. Set $\xi_* = -\infty$ if $\psi < 0$ along the entire orbit; otherwise, set ξ_* to be the maximal $\xi < +\infty$ where ψ vanishes. As in case 4, it follows that $\varphi(\xi_*) \in [\varphi_-, \varphi_r^+]$. The proof is the same as the previous case and it will therefore be omitted.

A contradiction is obtained as before by replacing u with u_w in the $\dot{\psi}$ equation, multiplying by $\dot{\psi}$, and integrating over the interval $[\xi_*, +\infty)$. This completes the proof of the lemma.

We now have an isolating region N for negative wave speeds c which contains precisely two rest points, P_- and $P_+(\lambda)$. Furthermore, the only nonconstant solutions in N are connections between these two rest points. In order to complete the proof of Theorem 2.1, we need to use N to construct connection triples for the system augmented with the parameter flow $\dot{c} = 0$. In particular, an interval $I = [c_1, c_0]$ must be determined such that $S(N) = \{P_-, P_+(\lambda)\}$ when $c = c_0, c_1$. The interval I must be large enough to contain the wave speed $c < 0$ for which the connecting orbit occurs;

in this case, that means choosing $|c_1|$ sufficiently large and $c_0 < 0$ sufficiently close to zero.

LEMMA 3.4. (a) *There exits $c_0 < 0$ such that $S(N) = \{P_-, P_+(\lambda)\}$ for all $c \in [c_0, 0)$.* (b) *There exists $c_1 \ll 0$ such that $S(N) = \{P_-, P_+(\lambda)\}$ for all $c < c_1$.*

Proof. (a) When $c = 0$, u is constant and negative. Let $U = \max\{u_+(\lambda) : 0 \leq \lambda \leq \lambda_0\}$ so that $u \in [u_w, U]$ for $0 \leq \lambda \leq \lambda_0$. For u in this range, the (φ, ψ) equations form a one-parameter family of Hamiltonian "fisheye" systems which are all topologically equivalent, which have an orbit homoclinic to the rest point P_-, and which encircle P_*. In particular, for such a u, there is never an orbit running from a rest point on the right branch, $\varphi = h_r(u)$, to the corresponding rest point on the left branch, $\varphi = h_\ell(u)$, of $F = 0$. Let V be a small tubular neighborhood of the two curves of rest points,

$$(u, \varphi, \psi) = (u, h_{r,\ell}(u), 0),$$

of the $c = 0$ system. It then follows that at $c = 0$, there exists $T > 0$ such that if $x \in N \setminus V$, then at least one of $x \cdot (\pm T)$ is not in N. It then follows from standard continuous-dependence theorems for flows that at least one of $x \cdot (\pm T)$ is not in N for all sufficiently small $c < 0$ and $x \in N \setminus V$. However, any connecting orbit from P_- to P_+ necessarily enters the region $N \setminus V$ at some point. Hence there are no P_--to-P_+ connections for sufficiently small c.

(b) Let $\delta = c^{-1}$ and

$$U(\varphi) = u_- + \lambda(W(\varphi) - W(\varphi_-));$$

since N is a compact region, it follows that for any solution (u, φ, ψ) in $S(N)$, we have that $u(\xi) = U(\varphi(\xi)) + O(\delta)$ for sufficiently small δ. It therefore follows that such solutions have (φ, ψ) components which satisfy the system

$$\begin{aligned} \dot{\varphi} &= \psi, \\ \dot{\psi} &= -\alpha c \psi - F(\varphi, U(\varphi)) + O(\delta). \end{aligned}$$

Next, let $\gamma = \dot{\psi}$; then (γ, φ) satisfies the system

$$\begin{aligned} \delta\dot{\gamma} &= -\alpha\gamma + O(\delta), \\ \dot{\varphi} &= -\delta(F(\varphi, U(\varphi)) + O(\delta) + \gamma)/\alpha. \end{aligned}$$

It follows that $|\gamma|$ must remain $O(\delta)$ along bounded solutions so that after rescaling time, the φ component must satisfy the scalar equation

$$\dot{\varphi} = F(\varphi, U(\varphi)) + O(\delta).$$

Now the function $F(\varphi, U(\varphi))$ is qualitatively a cubic with attracting rest points at $\varphi_\pm$ and a repelling rest point at φ_*. It is therefore possible to find positively invariant neighborhoods of the first two rest points for all sufficiently small δ. It follows that there are no P_--to-P_+ connections for sufficiently large $|c|$. This completes the proof of the lemma.

The proof of Theorem 2.1 is now easily completed. Since N is isolating for all c in the interval $I = [c_1, c_0]$, it follows that a connection triple (S_-, S_+, S) is determined by the augmented flow

$$\begin{aligned} \dot{x} &= f(x, c), \\ \dot{c} &= 0, \end{aligned}$$

where $S_{\pm} = \{P_{\pm}\}\times I$, and $S = S(N\times I)$ for the augmented flow (see [6]). Furthermore, by our hypotheses, these connection triples are all related by continuation for $\lambda \in [0, \lambda_0]$ so that the connection index $\bar{h}$ of the triple is independent of λ. At $\lambda = 0$, the equations nearly decouple since the u equation

$$\dot{u} = -c(u - u_-)$$

is independent of φ. The above equation is linear with a repelling rest point at $u = u_-$ so that $u \equiv u_-$ is its only bounded solution. Thus at $\lambda = 0$, $u = u_-$ along solutions in S. Next, replace u in the argument of F in the $\dot{\psi}$ equation by

$$\sigma u_- + (1 - \sigma)u.$$

By the previous remark, the invariant set isolated by $N \times I$ is independent of $\sigma \in [0, 1]$ so that the triples isolated by $N \times I$ are all related by continuation for such σ. At $\sigma = 1$, the equations completely decouple—

$$\begin{aligned}
\dot{u} &= -c(u - u_-),\\
\dot{\varphi} &= \psi,\\
\dot{\psi} &= -c\alpha\psi - F(\varphi, u_-),
\end{aligned}$$

—and by the product formula for the connection index (see [6]), we have that $\bar{h}$ is the smash product of the connection index for the (φ, ψ) system with a 1-sphere. Since the index of the latter system is the homotopy type $[\bar{0}]$ of a point (see the appendix in [6]), it follows that $\bar{h} = [\bar{0}] \wedge \Sigma^1 = [\bar{0}]$. It therefore follows that $S(N)$ contains more than the two rest points P_- and P_+ for some $c \in I$, and by Lemma 3.2, the nonconstant solution in N must be the desired connecting orbit.

4. Singular limits I: Small and large $\boldsymbol{\alpha}$. In this section, we examine two asymptotic regimes wherein the parameter α is either small or large. For both regimes, we obtain two classes of results: a local theory in the neighborhood of certain reduced problems, wherein the existence of a wave and its uniqueness relative to some neighborhood of the reduced wave are obtained, and a global result concerning the asymptotic behavior as $\alpha \to 0$ and uniqueness relative to all possible wave speeds and all possible wave solutions in the isolating region N constructed in the previous section. In each case, the local analysis, which is based upon geometric singular perturbation theory, holds under substantially weakened hypotheses, wherein only Hypotheses 1 and 2 are required. The global theory draws upon several results in the preceding section, and therefore all five hypotheses need to be satisfied in this case.

Let $\theta = \alpha c$; system (1) can then be written as

$$\begin{aligned}
\dot{u} &= -cg(\varphi, u),\\
\dot{\varphi} &= \psi,\\
\dot{\psi} &= -\theta\psi - F(\varphi, u).
\end{aligned} \tag{2}$$

The system therefore has two independent parameters c and θ related to the wave speed. The following lemma obtains a region in parameter space for which connecting solutions can exist. This is needed to establish the global uniqueness of the wave and the wave velocity since invariant-manifold methods only provide local information about uniqueness in a neighborhood of the singular limit. We remark that if we do not impose some particular ansatz for the asymptotic limit, c is an arbitrary negative parameter so that even if α is assumed to be small, θ is also an arbitrary negative parameter.

LEMMA 4.1. *There exists $\theta_0 < 0$ such that there are no solutions of* (2) *in the isolating region N which connect P_- to P_+ for* any *$c \leq 0$ and $\theta \in [\theta_0, 0]$.*

Proof. For large c, we expect that $g = 0$ along bounded solutions of (2). Hence we set

$$U(\varphi) = u_- - \lambda(W(\varphi) - W(\varphi_-)),$$
$$h(\varphi) = F(\varphi, U(\varphi))$$

and consider the reduced problem

$$\begin{aligned} \dot{\varphi} &= \psi, \\ \dot{\psi} &= -\theta\psi - h(\varphi), \\ u(\xi) &= U(\varphi(\xi)). \end{aligned} \tag{3}$$

It follows from Hypotheses 1 and 2 that $h(\varphi)$ has three distinct roots $p_+ < p_* < p_-$. Furthermore, if $H'(\varphi) = h(\varphi)$, then it follows from Hypothesis 1 and, in particular, from $F_u < 0 \in M_0$ that $H(p_-) < H(p_+)$. In this manner, we see that (3) has a unique connection from p_- to p_+ which occurs for a unique negative value of $\theta = \theta_R < 0$. It is well known that this connection occurs as the transverse intersection of the center-unstable manifold of $(p_-, 0, 0)$ with the center-stable manifold of $(p_+, 0, 0)$ after appending the parameter flow $\dot{\theta} = 0$ to (3).

Next, rescale ξ to $y = |c|\xi$ and set $\delta = 1/|c|$; system (3) then takes the form

$$\begin{aligned} u' &= g(\varphi, u), \\ \varphi' &= \delta\psi, \\ \psi' &= \delta(-\theta\psi - F(\varphi, u)), \\ \theta' &= 0. \end{aligned} \tag{4}$$

Let $\mathcal{M}_0 = \{(U(\varphi), \varphi, \psi, \theta)\}$ so that $\mathcal{M}_0$ is a manifold of rest points of (4) when $\delta = 0$. Furthermore, since $g_u = 1$, $\mathcal{M}_0$ is normally hyperbolic in the sense of Fenichel [7]. It follows that $\mathcal{M}_0$ perturbs smoothly for small δ to an invariant manifold $\mathcal{M}_\delta$, where the flow on the perturbed manifold is given by (3) with $U(\varphi)$ replaced by $U(\varphi) + O(\delta)$. It immediately follows that a connection exists for small delta and that the wave speed $\theta = \theta_R + O(\delta)$. Furthermore, given any $\eta > 0$, let V_η be an η neighborhood (in $\mathbf{R}^4$) of $\mathcal{M}_0$. Since the p_--to-p_+ connection occurs as a transverse intersection of invariant manifolds of the augmented equations at $\delta = 0$, it follows that for sufficiently small η, there exists $\delta_1 > 0$ such that the connection lies in V_η for $0 \leq \delta \leq \delta_1$ and that the connecting solution is unique relative to this neighborhood.

Let $c_1 = -1/\delta_1$ and let $\theta \in (\theta_1, 0)$, where $\theta_1 = \theta_R/2$. Also, set η as in the previous paragraph. Now suppose that we have a connecting solution of (2) in the isolating neighborhood N of Theorem 2.1 for some $c \leq c_1$ and $\theta \in [\theta_1, 0]$. Changing to the scaling in (4), we find that $(u - U)' = g(\varphi, u) + O(\delta)$ so that when $u = U \pm \eta$, $(u - U)'$ has the same sign as $g(\varphi, U(\varphi) \pm \eta)$. It follows from this that V_η is a positively invariant set for (4) for sufficiently small δ so that if $|u - U(\varphi)| \geq \eta$ at some point along the solution, then this condition persists for all ξ in the forward time direction. It follows that u must be unbounded along such a solution, leading to a contradiction. Thus we must have that *all* connecting solutions relative to N lie interior to V_η for such c. Hence the only possible connecting solution in N is the one lying near the invariant manifold $\mathcal{M}_0$. However, for c in the specified range, the wave speed θ of such a connection must approximate $\theta_R = 2\theta_1$ to within $O(\delta)$; hence the set of connections relative to N is empty for $c \le c_1$ and $\theta \in [\theta_1, 0]$.

Next, set $c = 0$ in (2) so that (φ, ψ) solve the last two equations with u constant. By Lemma 3.2, solutions in $S(N)$ satisfy $u \in [u_w, u_+] = I_u$. For each fixed u in this range, (2) has three distinct rest points $p_\pm(u)$ and $p_*(u)$, and there is a connecting solution from $p_-(u)$ to $p_+(u)$ which exists at some unique $\theta = \theta(u)$, where the continuous function $\theta(u)$ is strictly negative on I_u. Let $\theta_2 < 0$ be greater than the minimum of $\theta(u)$ over I_u so that $\theta_2 < 0$. The phase plane of (2) at $c = 0$ for each $u \in I_u$ consists of the two saddles at $p_\pm$ and either an unstable node or a spiral at p_*. For $\theta \le \theta_2$, there are no connecting orbits from p_- to p_+. For such a θ, it immediately follows that one of the following hold for every nonconstant solution in N: φ becomes unbounded in at least one time direction or ψ becomes positive at some point where $\varphi < \varphi_m$, where φ_m is as in Lemma 3.2. In either case, such solutions exit N in finite time. It follows from regular perturbation theory that there exists $c_2 < 0$ such that $S(N) = \{P_\pm\}$ for $c \in [c_2, 0]$ and $\theta \in [\theta_2, 0]$.

If $c_2 < c_1$ we are done. Suppose then that $c_1 < c_2$. Finally, set $\theta = 0$ in (2) and suppose that $c \in [c_1, c_2]$. It follows from Lemma 3.1 that nonconstant solutions in $S(N)$ are connections from P_- to P_+. Furthermore, by Lemma 3.2, we have that $u(\xi) \le u_+$ along any such solution, and by Hypothesis 1, we have that $F(\varphi(\xi), u(\xi)) \le F(\varphi(\xi), u_+)$. Also, by Lemma 3.2, we have that $\psi < 0$ on a (maximal) interval of the form $(\xi_0, +\infty)$, where $\xi_0 \ge -\infty$. Thus if ξ_0 is finite, then $\psi = 0$ at this point. It follows from the above for $\xi \in (\xi_0, +\infty)$ that

$$\dot{\varphi}\ddot{\varphi} \le -F(\varphi, u_+)\dot{\varphi}.$$

Let H(φ) be an antiderivative of $-F(\varphi, u_+)$; by Hypothesis 1, we have that $H(\varphi_+) < H(\varphi)$ for all $\varphi > \varphi_+$ since $u_+ < 0$. Integration of this inequality on the interval $(\xi_0, +\infty)$ yields the inequality

$$0 \le H(\varphi_+) - H(\varphi(\xi_0)),$$

and by the conditions above, the quantity on the right is negative, yielding a contradiction. Thus there are no connecting orbits when $\theta = 0$ and $c \in [c_1, c_2]$. It immediately follows from regular peturbation theory that there exists $\theta_3 < 0$ such that the set of connections is empty for $\theta \in [\theta_3, 0]$ and $c \in [c_1, c_2]$.

The proof is completed by taking θ_0 to be the (negative) maximum of θ_i, $i = 1, 2, 3$.

We can now prove the main theorems addressing the asymptotic behavior of the connecting solutions of (1) for small and large α. We first consider the case of small α and, accordingly, write (4) in the equivalent form,

$$\begin{aligned} u' &= -\theta g(\varphi, u), \\ \varphi' &= \alpha\psi, \\ \psi' &= \alpha(-\theta\psi - F(\varphi, u)), \\ \theta' &= 0, \end{aligned} \tag{5}$$

where "prime" is $\frac{d}{dy}$ with $y = \alpha^{-1}\xi$.

THEOREM 4.2. (a) *Suppose that Hypotheses* 1 *and* 2 *are satisfied. There exists* $\alpha_0 > 0$ *such that for* $\alpha \in (0, \alpha_0)$ *and* $c = \alpha\theta$*, there exists a solution* $(u(y, \alpha)$, $\varphi(y, \alpha)$,

$\psi(y,\alpha)$, $\theta(\alpha)$) of (5) *which is near the connecting solution $(\varphi_R(\xi),\psi_R(\xi),\theta_R)$ of the reduced equation* (3) *in the sense that the perturbed solution satisfies the estimates*

$$\begin{aligned} u(\alpha^{-1}\xi,\alpha) &= U(\varphi_R(\xi)) + O(\alpha), \\ \varphi(\alpha^{-1}\xi,\alpha) &= \varphi_R(\xi) + O(\alpha), \\ \psi(\alpha^{-1}\xi,\alpha) &= \psi_R(\xi) + O(\alpha), \\ \theta(\alpha) &= \theta_R + O(\alpha) \end{aligned}$$

modulo a phase shift in ξ. The perturbed solution is unique relative to some neighborhood of the reduced solution (in its four-dimensional phase space), and it depends smoothly on parameters in the equations.

(b) *Suppose that all five hypotheses in section* 2 *are satisfied. Then the perturbed solution obtained in* (a) *is unique relative to all possible solutions in the isolating region N constructed in section* 3 *and all negative wave speeds $c < 0$.*

Proof. (a) Clearly, the parameter α in (5) plays the same role as the parameter δ in (4). An invariant manifold $\mathcal{M}_\alpha$ of the perturbed equations can be constructed near the invariant manifold $\mathcal{M}_0$ of (3) as in the proof of Lemma 4.1, and the proof of part (a) follows as in the previous lemma by transversality.

It was also proved in Lemma 4.1 that in this regime, all connecting solutions in N of (4) lie in the η-neighborhood V_η of $\mathcal{M}_0$. Furthermore, by the same lemma, it follows that such connections exist only for $\theta < \theta_0 < 0$, which is in the range of parameter values for which the manifold $\mathcal{M}_0$ will be normally hyperbolic for (5) with $\alpha = 0$. Hence any such connection must lie in the manifold $\mathcal{M}_\alpha$ for sufficiently small α, and it must therefore coincide with the unique solution in this invariant manifold.

The second result concerns asymptotic behavior as α tends to $+\infty$. We shall see that the wave is resolved into an inner and an outer layer, which makes the analysis more complicated than the previous limit $\alpha = 0$, where the wave is contained entirely in the slow manifold $\mathcal{M}_\alpha$. Set $1/\alpha = \delta$ so that (1) can be written as

$$\begin{aligned} \dot{u} &= -\delta\theta g(\varphi,u), \\ \dot{\varphi} &= \psi, \\ \dot{\psi} &= -\theta\psi - F(\varphi,u) \end{aligned} \tag{6}$$

and also in rescaled form as

$$\begin{aligned} u' &= -\theta g(\varphi,u), \\ \delta\varphi' &= \psi, \\ \delta\psi' &= -\theta\psi - F(\varphi,u), \end{aligned} \tag{7}$$

where $' = \frac{d}{dy}$ and $y = \delta\xi$. As $\delta \to 0$, a matched asymptotic expansion of the solution is constructed in the usual way. The transition layer is the solution $(u_+, \varphi_F(\xi), \psi_F(\xi), \theta_F)$ of (7) at $\delta = 0$ connecting $\varphi_- = h_r(u_+)$ to $\varphi_+ = h_\ell(u_+)$. This connection exists for some unique value $\theta_F < 0$ of θ. The construction of the fast singular limit again only requires Hypotheses 1 and 2. The slow outer layer is the solution $(u_S(y), h_\ell(u_S(y)), 0, \theta_F)$, where $u_S(y)$ is the solution of

$$u' = -\theta_F g(h_\ell(u),u)$$

satisfying $u_S(0) = u_+$. The singular solution Γ is defined to be the union of all points on the fast layer (for all ξ) with the union of points along the backward slow layer (for $y \leq 0$). Note that θ is included as a dependent variable in the phase space of the wave.

THEOREM 4.3. (a) *Suppose that Hyptotheses* 1–5 *are satisfied. Given* $\eta > 0$, *let* $V_\eta(\Gamma)$ *be an* η*-neighborhood of* Γ. *There exists* $\delta_0 > 0$ *such that for* $\delta < \delta_0$, $S(N \times \{c < 0\}) \subset V_\eta(\Gamma)$, *where* $S(N \times \{c < 0\})$ *denotes the isolated invariant set of* (6) *augmented with the parameter flow* $\dot{\theta} = 0$ *and where* N *is the isolating neighborhood constructed in section* 3.

(b) *Suppose that Hypotheses* 1 *and* 2 *are satisfied. For sufficiently small* η *and* δ, *the perturbed solution in* $V_\eta(\Gamma)$ *is uniquely determined as the transverse intersection of the center-unstable manifold of* P_- *with the center-stable manifold of* P_+ *for the equations in* (6) *augmented with* $\dot{\theta} = 0$. *The connecting solution is a smooth function of* δ *for small* δ, *and in particular, the wave speed* c *has an expansion of the form*

$$c(\delta) = \delta(\theta_F + O(\delta)).$$

Proof. (a) We first obtain another a priori estimate for the scaled wave speed θ. To this end, set $\rho = \dot{\psi}$ and replace ψ with ρ in (6). The $\dot{\psi}$ equation is then replaced by

$$\dot{\rho} = -\theta\rho + F_\varphi(\rho + F)/\theta + F_u(\delta\theta g).$$

If the solution is assumed to lie in $S(N)$, then g and the partials of F are bounded independently of θ and δ. It follows that the ρ equation is of the form

$$\dot{\rho} = (-\theta + O(1/\theta))(\rho + O(\delta)) + O(1/\theta).$$

In order for ρ to remain uniformly bounded, it follows that $|\rho| \leq K(1/|\theta|^2 + \delta)$ for some K independent of both θ and δ. However, the φ equation can be expressed as

$$-\theta\dot{\varphi} = F(\varphi, u) + \rho;$$

for large $|\theta|$ and small δ, it follows that a neighborhood of the right branch $\varphi = h_r(u)$ of $F = 0$ will be positively invariant relative to N. It is therefore impossible to have a connecting orbit from P_- to P_+ for such a θ and δ. There therefore exist $\delta_0 > 0$ and $\theta_1 < 0$ such that when $\delta < \delta_0$, the scaled wave speed θ of any connection in N must lie in the interval $[\theta_1, 0]$. Combining this with the result of Lemma 4.1 shows that $\theta \in [\theta_1, \theta_0]$.

Let $I = [\theta_1, \theta_0]$ and suppose that $\eta > 0$ is given and that

$$(x, \theta) \in (N \times I) \setminus V_\eta(\Gamma).$$

We must show that the solution through this point must leave N in at least one time direction provided that δ is sufficiently small. If this were not the case, the solution through this point would have to be a connecting orbit by Lemma 3.1. We will first show that the wave speed θ of any such connection must approximate the wave speed θ_F of the inner reduced solution. To this end, parametrize the orbit so that $\varphi(0) = \varphi_m$, where φ_m is as in Lemma 3.2. For small δ, the solution is well approximated by setting $\delta = 0$ in (6), in which we set $u \equiv u(0)$. In order for the solution to remain in N, it must approximate the saddle–saddle connection of (6) when $\delta = 0$ on finite ξ intervals. It follows that θ must be near the wave speed $\theta(u(0))$ of the saddle–saddle connection for the $\delta = 0$ system. If $u(0) \leq u_+ - \eta$, then there exists $\xi_0 < 0$ such that the solution is in a small neighborhood of the left slow manifold $\varphi = h_\ell(u(0))$ at ξ_0. It follows from the monotonicity properties of solutions in N that the solution must then remain near the left slow manifold for *all* $\xi \leq \xi_0$. However, since $u(0)$ is strictly less than u_+, it follows that $\dot{u} < 0$ for all $\xi \leq \xi_0$ so that the solution must eventually leave N by having (φ, u) exit M_0 through the bottom of the rectangle. It therefore follows that $u(0)$ must lie within η of u_+ and thus that the wave speed θ must be of order η from θ_F

The proof of (a) is now completed by following the flow through each point in $N \setminus V_\eta(\Gamma)$ and showing that the solution leaves N in at least one time direction. The details of the argument are similar to those used above to show that the wave speed is near θ_F, and we shall only provide a brief outline. Solutions in $S(N)$ for small δ remain outside the middle slow manifold $\varphi = h_*(u)$ since we see from (6) that this is a repelling rest point at $\delta = 0$ so that for small δ, we can construct a negatively invariant region about it. Therefore, a solution through such a point cannot get to P_- in backward time. We now argue as in the previous paragraph that a solution in $S(N)$ must have exactly one transition layer in which it jumps from the right slow manifold to the left slow manifold by approximating the saddle–saddle connection of (6) when $\delta = 0$. Combining these remarks with the estimates for θ and u in the transition layer, it follows that $S(N \times I) \subset V_\eta(\Gamma)$.

(b) By (a), it suffices to describe the wave in the neighborhood $V_\eta(\Gamma)$. To this end, augment (6) with the parameter flow $\dot{\theta} = 0$, let W_δ^{cs} be the center-stable manifold of P_+, and let W_δ^{cu} be the center-unstable manifold of P_- for the augmented flow with $\delta > 0$. Thus W_δ^{cs} is two dimensional and W_δ^{cu} is three dimensional. We note that W_δ^{cs} is foliated by the collection of one-dimensional stable manifolds of P_+ for each θ. Similarly, W_δ^{cu} is foliated by the two-dimensional unstable manifolds of P_- for each θ. These manifolds therefore have limiting configurations W_0^{cs} and W_0^{cu}, respectively, that can be calculated as $\delta \to 0$. The former consists of the collection of one-dimensional stable manifolds $M_s(\theta)$ of P_+ for (6) at $\delta = 0$ for each θ. The latter consists of the two-dimensional center-unstable manifold $M_{cu}(\theta)$ of the continuum of rest points $\varphi = h_r(u)$ for (6) (without the θ equation) for each θ. The tangent space to $M_{cu}(\theta)$ at each one of these rest points consists of a vector tangent to the right slow manifold and a vector in the strongly unstable direction.

The manifolds W_0^{cs} and W_0^{cu} intersect along Γ. We now describe their tangent spaces T^{cs} and T^{cu} at a point Q which lies on the fast layer and close to the "corner point" $P = (u_+, h_r(u_+), 0, \theta_F)$ of the singular limit. The former tangent space at Q consists of a vector $(0, p, q, 0)$, which is close to the strongly unstable direction at the right corner P of Γ, and another vector of the form $(0, r, s, 1)$, where the vectors (p, q) and (r, s) are independent. This is a consequence of the well-known fact that for the scalar bistable travelling wave problem, the saddle–saddle connection occurs as the transverse intersection of center-unstable and center-stable manifolds for the equations augmented with $\dot{\theta} = 0$. The tangent space T^{cu} is spanned by the vectors v_1, v_2, and v_3, where

$$\begin{aligned} v_1 &= (1, h_r'(u_+), 0, 0), \\ v_2 &= (0, p, q, 0), \\ v_3 &= (0, 0, 0, 1). \end{aligned}$$

It immediately follows that these manifolds intersect transversely at Q and therefore everywhere along Γ; thus the perturbed manifolds W_δ^{cs} and W_δ^{cu} also intersect transversely for small δ. The uniqueness of the wave in $V_\eta(\Gamma)$ as well as the differentiable dependence of the wave speed θ on δ immediately follow from this.

The following corollary summarizes the estimates obtained above on the possible wave speeds c for all possible parameter values of α. These estimates are used in [1] to compare the results obtained here from phase-field models with other models of hypercooled solidification.

COROLLARY 4.4. *Under Hypotheses* 1–5*, the wave speed c of any connecting solution of the travelling wave equations in* (1) *which lies interior to the region N constructed in section* 3 *satisfies an estimate of the form*

$$T_0/\alpha < c < T_1/\alpha$$

for some constants $T_0 < T_1 < 0$ depending only on N and for all parameter values $\alpha > 0$.

Proof. The upper bound for c is exactly the result proved in Lemma 4.1 with $T_0 = \theta_0$. A lower bound for c, $\theta_1/\alpha < 0$ also follows from the proof of Lemma 4.1 and Theorem 4.2 for $0 < \alpha < \alpha_0$ for some $\alpha_0 > 0$ since for such an α, the theorem implies that the scaled wave speed $\theta = c\alpha$ must approximate that of the singular limit. The lower bound for c in the parameter range $\alpha > 1/\delta_0$ is proved in a similar manner at the beginning of Theorem 4.3. Finally, in the parameter range $1/\delta_0 < \alpha < \alpha_1$, the estimate follows from the upper and lower bounds for c obtained in Lemma 3.4, which implicitly assumes that α lies in a compact set bounded away from $\alpha = 0$. Combining the estimates above provides the stated result for all $\alpha > 0$.

Remarks. (i) The asymptotics for small α indicate that in this regime, the φ component of the profile should be monotone decreasing in ξ while the u component will either be monotone increasing (in the event that $\{g = 0\}$ is monotone in M_0) or have a unique local minimum at some point. On the other hand, the asymptotics for large α predict that the u-component will be monotone increasing and that the φ-component will have a unique local maximum in this regime. Thus the profile is capable of exhibiting a rich variety of qualitative properties. It is therefore quite plausible that some additional hypotheses are essential in the proof of the global result (Theorem 2.1) linking these two asymptotic regimes.

(ii) Asymptotic expansions to any desired order of accuracy can be obtained in the usual way for both asymptotic regimes. In particular, we derive the first few terms of the expansion for the transition layer in the large α regime. To this end, we expand the solution in powers of δ:

$$\begin{aligned} u &= u_+ + \delta u_1(\xi) + \cdots, \\ \phi &= \varphi_0(\xi) + \delta\varphi_1(\xi) + \cdots, \\ \theta &= \theta_0 + \delta\theta_1 + \cdots, \end{aligned}$$

where $\psi = \varphi'$ has a similar expansion. The zeroth-order terms satisfy the second-order equation

$$\varphi'' + \theta_0\varphi' + F(\varphi_0, u_+) = 0$$

and are determined by taking $\varphi_0(\xi), \theta_0$ to be the solution connecting φ_+ at $+\infty$ to $\varphi_r = h_r(u_+)$ at $-\infty$. In particular, $\theta_0 = \theta_F$. The first-order asymptotics are then determined by the equations

$$\begin{aligned} u_1' &= -\theta_0\gamma(\varphi_+ - \varphi_0(\xi)), \\ \varphi_1'' + \theta_0\varphi_1' + F_\varphi\varphi_1 &= -F_u u_1 - \theta_1\varphi_0', \end{aligned}$$

where the partials of F are evaluated at $(\varphi_0(\xi), u_+)$. The kernel of the adjoint of the linear operator on the left side of the second equation is $\varphi^* = \varphi_0' e^{\theta_0 \xi}$. First, u_1 is determined by integrating the first equation,

$$u_1 = -\theta_0 \gamma \int_\xi^\infty (\varphi_+ - \varphi_0(s)) ds.$$

Since φ_0 decays exponentially to φ_+ (resp. φ_r) at $+\infty$ (resp. $-\infty$), it follows that $u_1(\xi)$ decays exponentially to zero at $+\infty$ and that $u_1(\xi)/\xi$ is asymptotic to $\varphi_+ - \varphi_r$, i.e., u_1 is linear at $-\infty$. It then follows that the integrals in the expression

$$\theta_1 = \frac{-\int_{-\infty}^\infty F_u(\varphi_0(s), u_+) u_1(s) \varphi^*(s)\, ds}{\int_{-\infty}^\infty \varphi^*(s) \varphi_0'(s)\, ds}$$

converge. Hence the first-order asymptotics are completely determined. Clearly, this procedure can now be continued to determine the terms in the asymptotic series to any desired order.

5. Singular limits II: Perturbation by higher-order equations. We finally consider the singular perturbation problem discussed in the introduction,

$$\begin{aligned} \dot u &= -cg(\varphi, u), \\ \dot\varphi_1 &= \varphi_2, \\ \dot\varphi_2 &= \varphi_3, \\ \mu\dot\varphi_3 &= \varphi_4, \\ &\vdots \\ \mu\dot\varphi_{2m-1} &= \varphi_{2m}, \\ \mu\dot\varphi_{2m} &= H(\varphi, u), \end{aligned} \tag{8}$$

where φ now denotes the vector with components φ_i and

$$H(\varphi, u) = -\left(\sum_{n=1}^{m-1} b_n \varphi_{2n+1} + \alpha c \varphi_2 + F(\varphi_1, u)\right) / b_m.$$

We shall fix the parameters in the nonlinearities and α and investigate the behavior of the above system for small μ. Let $\varphi_s = (u, \varphi_1, \varphi_2)$ denote the slow components and $\varphi_f = (\varphi_3, \ldots, \varphi_{2m})$ denote the fast components. We shall locate orbits connecting the rest point $\tilde P_- = (P_-, 0)$ to the rest point $\tilde P_+ = (P_+, 0)$.

The fast–slow structure of the system is more easily seen after the change of independent variables $\xi \to y$, where $y = \mu^{-1}\xi$, and of dependent variables $\varphi_f \to \zeta_f$, where

$$\begin{aligned} \zeta_3 &= \varphi_3 + (c\alpha\varphi_2 + F(\varphi_1, u))/b_2, \\ \zeta_j &= \varphi_j, \quad j = 4, \ldots, 2m. \end{aligned}$$

In the new variables, system (8) can be expressed as

$$\begin{aligned} u' &= -\mu c g(\varphi_1, u), \\ \varphi_1' &= \mu \varphi_2, \end{aligned} \tag{9}$$

$$\begin{aligned}
b_2\varphi_2' &= \mu(-\alpha c\varphi_2 - F(\varphi_1,u) + b_2\zeta_3),\\
\zeta_3' &= \zeta_4 + \mu V(\varphi_s,\zeta_f),\\
\zeta_4' &= \zeta_5,\\
&\vdots\\
\zeta_{2m}' &= -\left(\sum_{n=1}^{m} b_n\zeta_{2n+1}\right)/b_m,
\end{aligned}$$

where V is a smooth function of its arguments, whose precise form is not important here. Formally setting $\mu = 0$, we see that (9) is a singular perturbation of problem (1). This is more easily seen by changing back to the slow (ξ) scaling to obtain

$$\begin{aligned}
\dot{u} &= -cg(\varphi_1,u),\\
\dot{\varphi}_1 &= \varphi_2,\\
b_2\dot{\varphi}_2 &= (-\alpha c\varphi_2 - F(\varphi_1,u) + b_2\zeta_3),\\
\mu\dot{\zeta}_3 &= \zeta_4 + \mu V(\varphi_s,\varphi_f),\\
&\vdots\\
\mu\zeta_{2m} &= -\left(\sum_{n=1}^{m} b_n\zeta_{2n+1}\right)/b_{2m}.
\end{aligned}\tag{10}$$

Note that at $\mu = 0$, the ζ_f equations in (9) form a linear system that is decoupled from φ_s; let J be the coefficient matrix of this $(2m-2)$-dimensional system. It was proved in Lemma 7.1 in [1] that this matrix is always hyperbolic when the coefficients b_n are determined as in [1] by the various moments of the interaction function generating the phase-field model. In particular, J has $(m-1)$ eigenvalues with positive real part and $(m-1)$ eigenvalues with negative real part.

THEOREM 5.1. (a) *Let $V_\eta = \{\zeta_f : |\zeta_f| \le \eta\}$. There exists $\eta > 0$ and $\mu_0 = \mu_0(\eta)$ such that $\tilde{N} = N \times V_\eta$ is an isolating neighborhood for* (9) *for all $\mu \in (0,\mu_0)$ and all $c \in [c_1,c_0]$, where N is the isolating region of Theorem* 2.1 *and c_1 and c_0 are as Lemma* 3.4. *Furthermore, the set of connections from $\tilde{P}_-$ to $\tilde{P}_+$ is empty for $c = c_1, c_0$.*

(b) *The Conley connection index for* (9) *on $\tilde{N} \times [c_1,c_0]$ is the homotopy type of a point so that there exists a connection from $\tilde{P}_-$ to $\tilde{P}_+$ for some $c \in [c_1,c_0]$ and for each $\mu \in (0,\mu_-]$.*

Proof. (a) The boundary of $\tilde{N}$ is $(\partial N \times V_\eta) \cup (N \times \partial V_\eta)$. First, suppose that $\varphi_s \in \partial N$. Since N is a compact isolating region for (1) for each $c \in [c_1,c_0]$, there exists $T > 0$ and $\delta > 0$ such that if N_δ is a δ-neighborhood of N in $\mathbf{R}^3$, then for each $x \in \partial N$, there exists $\xi \in [-T,T]$ such that $x \cdot \xi \in \mathbf{R}^3 \setminus N_\delta$, i.e., the solution through x lies at a distance of at least δ from N at some time ξ that is uniformly bounded from above and below. Now suppose that $(\varphi_s,\zeta_f) \in S(\tilde{N})$ so that $|\zeta_f(\xi)| \le \eta$ for all ξ. It then follows that there exists $K > 0$ such that if $\varphi_s \in \partial N$, then the solution of (10) through (φ_s,ζ_f) satisfies

$$|\varphi_s(\xi) - x(\xi)| \le KT\eta,$$

where $x(\xi)$ is the solution of (1) through φ_s. Now choose η so that $KT\eta \le \delta$. It then follows that such a solution must leave $\tilde{N}$ in time $|\xi| \le T$ so that the solution could not lie in $S(\tilde{N})$.

With η fixed as above, we claim that if $(\varphi_s, \zeta_f) \in N \times \partial V_\eta$, then the solution of (9) through this point exits $\tilde{N}$ in finite time provided that μ is sufficiently small. If this were not the case, the solution would lie in $S(\tilde{N})$ and therefore be uniformly bounded. It follows that the perturbation $\mu V(\varphi_s, \zeta_f)$ in the ζ_3 equation is uniformly of order μ. It therefore follows that if $\bar{\zeta}$ solves $\bar{\zeta}' = J\bar{\zeta}$ with the same initial data as $\zeta_f(y)$, then there exists a constant $K > 0$ depending only on $P > 0$ such that

$$|\bar{\zeta}(y) - \zeta_f(y)| \leq KP\mu$$

for $|y| \leq P$. Since the matrix J is hyperbolic, the neighborhood V_η isolates the origin for the linear flow $\bar{\zeta}' = J\bar{\zeta}$; thus there exists $\varepsilon > 0$ and $P > 0$ such that $\bar{\zeta}(y) \notin V_{\eta+\varepsilon}$ for some $y \in [-P, P]$ whenever $\bar{\zeta}(0) \in \partial V_\eta$. Now choose μ_0 so that $KP\mu_0 < \varepsilon$; it then follows that solutions of (9) which initially lie in $N \times \partial V_\eta$ exit $\tilde{N}$ in time y with $|y| \leq P$. Thus $\tilde{N}$ is isolating for (9) for $\mu \in (0, \mu_0]$.

We next show that the set of connecting orbits from $\tilde{P}_-$ to $\tilde{P}_+$ is empty when $c = c_0, c_1$ for sufficiently small μ. As noted earlier, the matrix J is hyperbolic so that the slow subspace $\{(\varphi_s, 0)\}$ is normally hyperbolic when $\mu = 0$. We may therefore apply Fenichel's theorem [7] to obtain a smooth invariant manifold $\mathcal{M}_\mu = (\varphi_s, \zeta_f(\varphi_s))$, where $\zeta_f(\varphi_s) = O(\mu)$ over compact subsets of the slow subspace. Furthermore, since the rest points $P_\pm$ are hyperbolic for the slow reduced system (1), it follows that the rest points $\tilde{P}_\pm$ are hyperbolic relative to the flow in $\mathcal{M}_\mu$ so that they have stable and unstable manifolds in $\mathcal{M}_\mu$ that closely approximate the stable and unstable manifolds $W_\pm^{u,s}$ of $P_\pm$ of the reduced system (1) for small μ. Furthermore, $\tilde{P}_\pm$ are hyperbolic rest points of (9) so that $\tilde{P}_-$ has an unstable manifold $\tilde{W}_-^u$ and $\tilde{P}_+$ has a stable manifold $\tilde{W}_+^s$ in the full space. By the hyperbolicity of J, these manifolds closely approximate the product manifolds $W_-^u \times U_f$ and $W_+^s \times S_f$, where U_f and S_f are the unstable and stable subspaces of J. By Lemma 3.4, W_-^u and W_+^s do not intersect in N at $c = c_1, c_0$; it follows that $\tilde{W}_-^u$ and $\tilde{W}_+^s$ do not intersect in $\tilde{N}$ for sufficiently small μ for $c = c_1,\ c_0$.

(b) By part (a), the neighborhood $\tilde{N}$ can be used to define a family of connection triples $(\tilde{S}_-, \tilde{S}_+, \tilde{S})$ for system (9) augmented with $c' = 0$ and for all sufficiently small μ. This is achieved by defining $\tilde{S} = S(\tilde{N} \times [c_1, c_0])$ with an analogous definition for $\tilde{S}_\pm$ with N replaced by suitable neighborhoods of the two rest points. The key fact used in part (a) was that the coupling terms $b_2\zeta_3$ and $\mu V(\varphi_s, \zeta_f)$ linking the fast and slow subsystems in (9) are small provided the solution remains in $\tilde{N}$. We now introduce a homotopy of (9) by replacing $b_2\zeta_3$ by $\pi b_2\zeta_3$ and $\mu V(\varphi_s, \zeta_f)$ by $\pi\mu V(\varphi_s, \zeta_f)$, where the homotopy parameter $\pi \in [0, 1]$. Clearly, this only improves the estimates in part (a) so that $\tilde{N}$ generates connection triples $(\tilde{S}_-(\pi), \tilde{S}_+(\pi), \tilde{S}(\pi))$ that are all related by continuation. The connection index $\bar{h}(\pi)$ is therefore independent of π. It immediately follows from the product structure of the system at $\pi = 0$ and the product formula for $\bar{h}$ that $\bar{h}(0)$ is the product of $\bar{h}$ for the three-dimensional slow system (1) with an $(m-1)$-sphere Σ^{m-1}. By the proof of Theorem 2.1, the former index is $[\bar{0}]$, the homotopy type of a point; thus $\bar{h}(1) = \bar{h}(0) = [\bar{0}] \wedge \Sigma^{m-1} = [\bar{0}]$. Since this index is different from the "trivial" index $\Sigma^m \wedge \Sigma^{m+1}$, it follows that $S(\tilde{N})$ contains more than the two rest points $\tilde{P}_\pm$ for some $c \in [c_1, c_0]$. However, any solution which remains in $\tilde{N}$ for all ξ must lie in the invariant manifold $\mathcal{M}_\mu$. As in Lemma 3.1, it follows that any such solution must be a connecting orbit from $\tilde{P}_-$ to $\tilde{P}_+$.

As before, finer information about the wave can be obtained when α is either small or large. The following theorem is the natural generalization of the invariant-manifolds approach used by Gardner and Jones in [11] for the (scalar) higher-order phase-field equation in which the temperature is constant.

THEOREM 5.2. *Let the heteroclinic solution of* (1) *obtained when α is either small or large be denoted by*

$$(u_r(\xi,\alpha),\varphi_r(\xi,\alpha),\psi_r(\xi,\alpha),c_r(\alpha)).$$

For fixed α, there exists μ_0 such that for $\mu \in (0,\mu_0]$, the solution of (10) (*augmented with* $c'=0$) *is unique and can be expanded in a series of the form*

$$\begin{aligned}\varphi_s(\xi,\mu) &= (u_r(\xi,\alpha),\varphi_r(\xi,\alpha),\psi_r(\xi,\alpha)) + O(\mu),\\ \zeta_f(\xi,\mu) &= O(\mu),\\ c(\mu) &= c_r(\alpha) + O(\mu).\end{aligned}$$

Proof. The proof in either case is similar to those using Fenichel's theorem in the previous section. We shall therefore only give a brief outline in the case of small $\delta = 1/\alpha$. Let $c = \delta\theta$ and $\alpha c = \theta$ in (9) and augment this system with the parameter flow $\theta' = 0$. The augmented system has a four-dimensional manifold of rest points $\mathcal{M}_0$ at $\mu = 0$, namely, $\zeta_f = 0$, and by the hyperbolicity of the matrix J proved in Lemma 7.1 of [1], this manifold is normally hyperbolic. By [7], there exists a smooth invariant manifold $\mathcal{M}_\mu$ of the augmented system for small μ, and the flow on $\mathcal{M}_\mu$ is of the form

$$\begin{aligned}\theta' &= 0,\\ u' &= -\delta\theta g(\varphi_1,u) + O(\mu),\\ \varphi_1' &= \varphi_2 + O(\mu),\\ \varphi_2' &= -\theta\varphi_2 - F(\varphi_1,u) + O(\mu).\end{aligned}\tag{11}$$

In Theorem 4.3, it was proved that at $\mu = 0$, the above system has a connecting solution from P_- to P_+ for some θ and for small δ which lies in the transverse intersection of the center-unstable manifold of the former rest point and the center-stable manifold of the latter. It is easily seen from (8) that the perturbed system has the same rest points (with $\zeta_f = 0$) so that (11) has rest points P_- and P_+ with invariant manifolds W^{cu} and W^{cs} which smoothly approximate those of the reduced equations with $\mu = 0$. Since the reduced manifolds intersect transversely, this intersection must persist for small μ.

We note that all that was used in the above argument was the normal hyperbolicity of $\mathcal{M}_0$ and the transverse intersection of the two invariant manifolds of the reduced flow. The same argument therefore applies to the small α regime as well.

6. Numerical results.

We conclude with the results of some numerical experiments involving the second-order phase-field system

$$\begin{aligned}(u + \lambda\varphi - a\varphi^2)_t &= u_{xx},\\ \alpha\varepsilon^2\varphi_t &= \varepsilon^2\varphi_{xx} + b(\varphi - \varphi^3) + u\end{aligned}$$

in one space-variable x on a large finite interval $[-50, 50]$ with homogeneous Neumann boundary conditions and step-function initial data

$$(\varphi(x,0),u(x,0)) = \begin{cases} \varphi_-, & x < 20,\\ \varphi_+(\lambda), & x > 20.\end{cases}$$

Note that the equations are parameterized in a slightly different manner than the system described in the introduction. In particular, we take $W(\varphi) = \varphi - B\varphi^2$ in the equations described in the introduction; then those equations are equivalent to the above with $a = \lambda B$. In most situations, the interval above was large enough that the boundary did not appear to affect the transient behavior of the solution on time intervals large enough for travelling waves to be observed. The equations were integrated numerically with the MOL1D package which is based on the method of lines and a GEAR program to solve the associated system of ODEs. Solutions were calculated on several different meshes to check for accuracy. In all but one case (Figure 9 below), a mesh of 300 points appeared to be fine enough to give reliable results in that the wave speeds and profiles calculated on different grids matched to a high degree of accuracy.

Experiments were performed in broad ranges of the various parameters. In the following, the null sets of the nonlinearities, $F = 0$ and $g = 0$, the u-component, and the φ-component of the solution are depicted in the first, second, and third figures of each sequence. To begin with, parameters were set so as to be consistent with the hypotheses of Theorem 2.1 to test both the theorem and the numerical code. In Figure 5, $\lambda = .06$ and $a = 0$ so that $g = 0$ is close to a horizontal line and the wave is close to the scalar wave with constant u. Note that both components of the solution are monotone. In Figure 6, λ was increased so that the hypotheses of Theorem 2.1 fail to be satisfied. For example, it can be seen from Figure 6a that it is impossible to construct a rectangle M_0 which intersects $F = 0$ and $g = 0$ in the manner required in Hypothesis 3; it is also impossible to construct the rectangle M_- about P_-. However, travelling waves were still observed in the solution, indicating that the hypotheses of Theorem 2.1, while sufficient, are far from necessary conditions for the existence of the profile. The nonlinearities in Figure 7 are still consistent with the hypotheses of Theorem 2.1; however, $W(\varphi)$ is quadratic. Note that the u-component now has a local minimum while φ is still monotone decreasing. This type of profile was predicted by the asymptotic results of Theorem 4.2 with small α, although α in this particular experiment was $O(1)$. In Figure 8, the coefficient of the quadratic term in W was sufficiently increased so that it is again impossible to construct the rectangles M_0 and $M_\pm$ as required in Hypotheses 3 and 4 of Theorem 2.1. Nevertheless, the system still supports travelling waves.

Finally, in Figure 9, we illustrate another interesting limiting regime in which u_+ is near zero. In this case, the solution has a structure similar to that of the solutions constructed in Theorem 4.3, in which φ has a transition layer and the temperature u is monotone and has a “corner” near the point where the phase variable has a transition layer. This is a different singular limit problem than that of Theorem 4.3, wherein $\delta = 1/\alpha$ was assumed to be small. Here the small parameter is the scaled wave speed θ in (6), which is determined by the heteroclinic solution of the last two equations in (6) when the temperature is the constant $u = u_+$. This singular limit problem does not fit immediately into the framework of Theorem 4.3, and it requires a separate analysis. Nevertheless, it seems likely that an existence theorem along the lines of Theorem 4.3 could be obtained for small $u_+ < 0$.

It is interesting to note that we were forced to consider a much finer spatial mesh in order to observe the waves in Figure 9. Coarser meshes seemed to give rise to Hopf bifurcations in the form of periodic hot spots appearing in the temperature profile. This must be regarded as a numerical artifact since the phenomenon disappeared with mesh refinement.

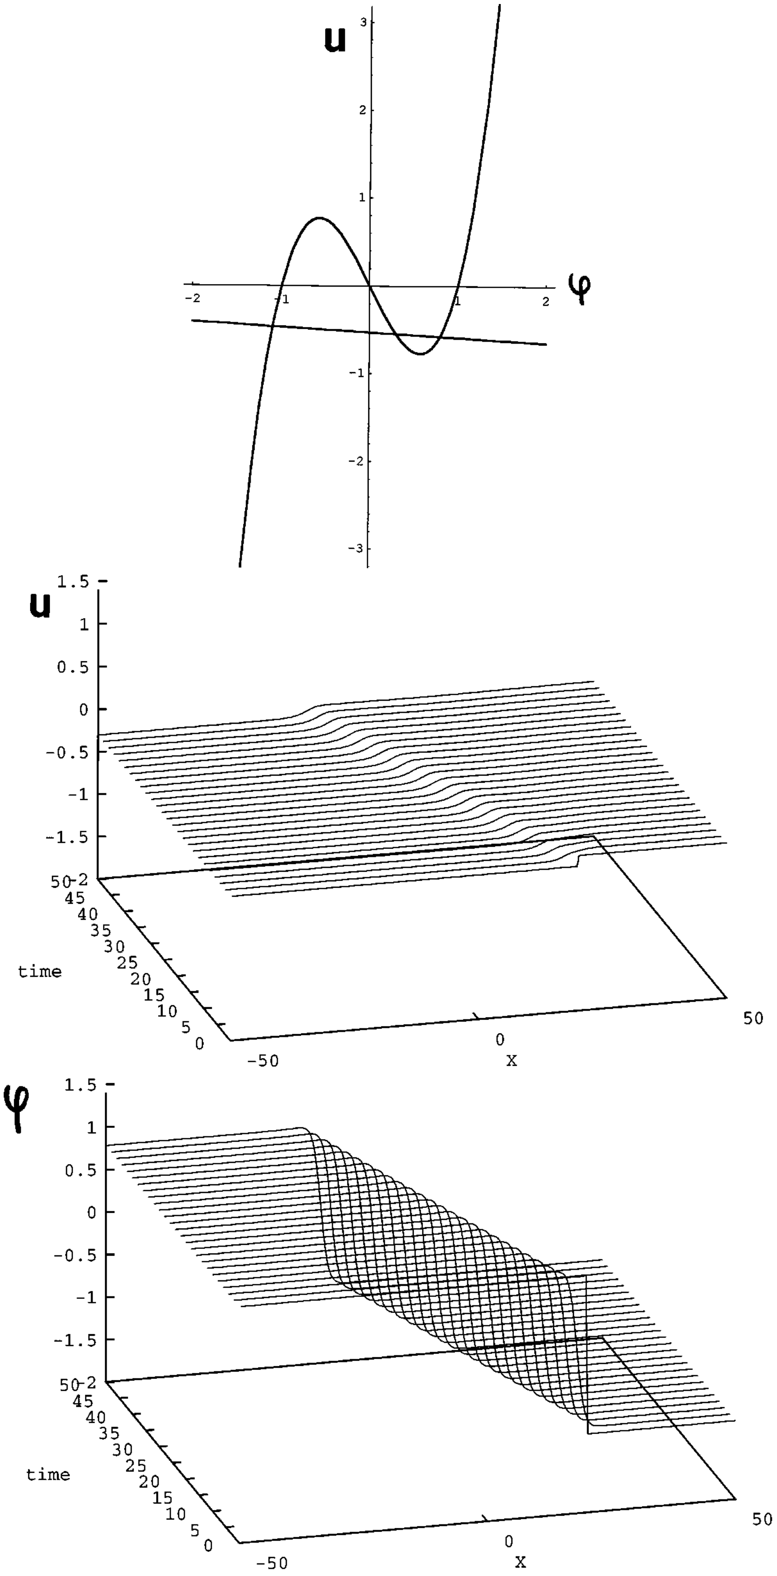

FIG. 5. $(\varphi, u)_- = (.8, -.29)$, $(\varphi, u)_+ = (-1.1, -.23)$, $\lambda = .06$, $a = 0$, $b = 2$, $\varepsilon = 1$, $\alpha = 1$.

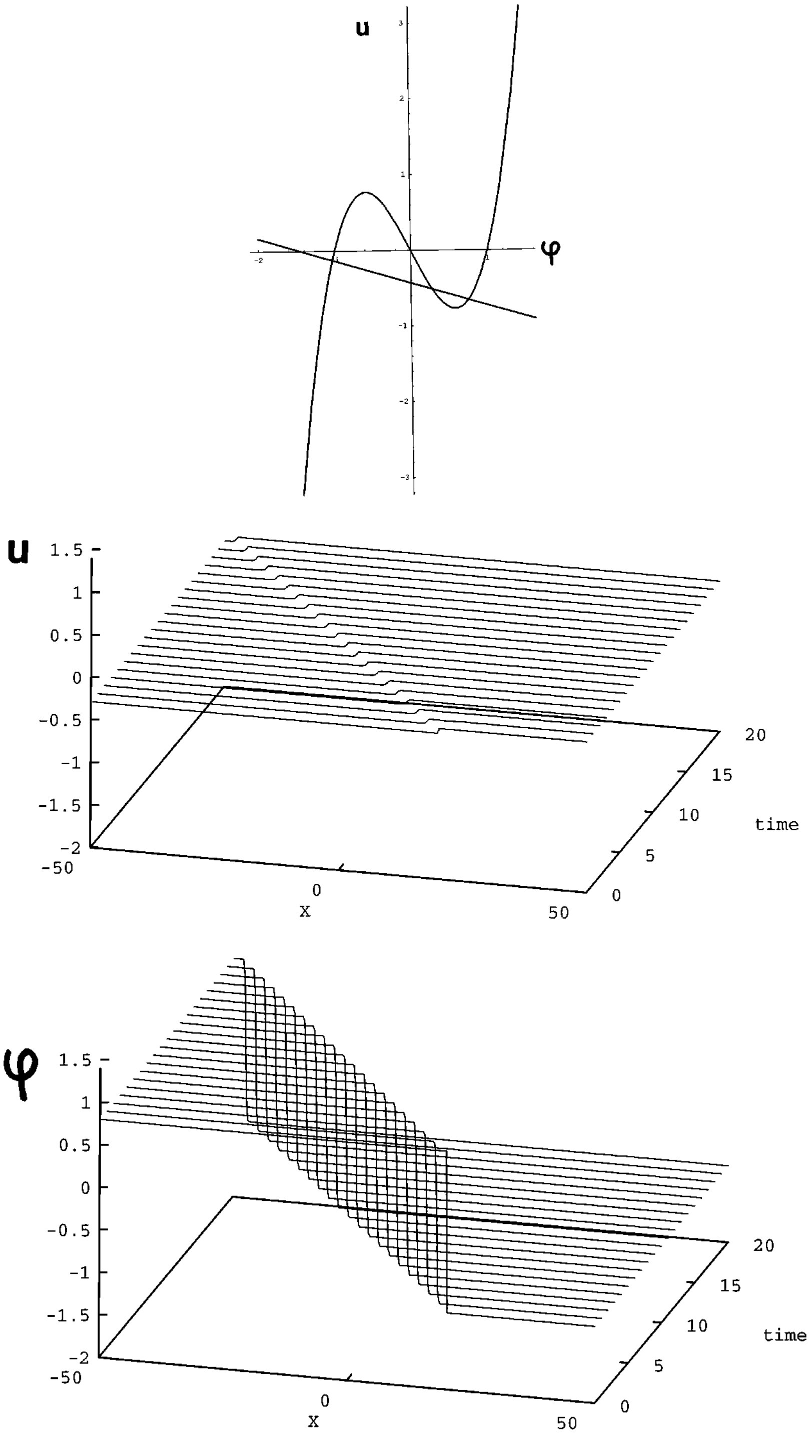

FIG. 6. $(\varphi, u)_- = (.75, -.66)$, $(\varphi, u)_+ = (-1.03, -.06)$, $\lambda = .3$, $a = 0$, $b = 2$, $\varepsilon = 1$, $\alpha = 1$.

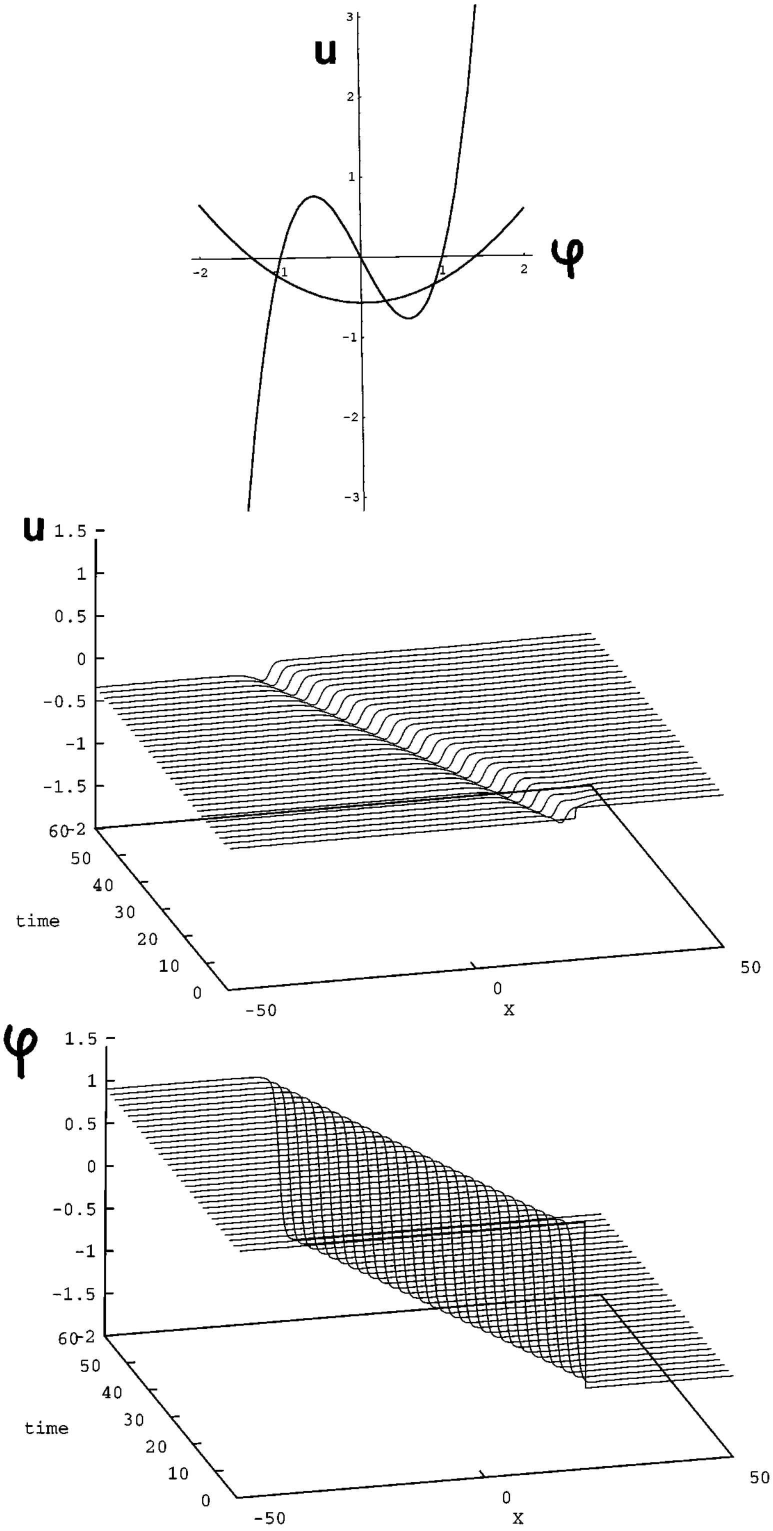

FIG. 7. $(\varphi, u)_- = (.9, -.34)$, $(\varphi, u)_+ = (-1.05, -.21)$, $\lambda = .02$, $a = .3$, $b = 2$, $\varepsilon = 1$, $\alpha = 1$.

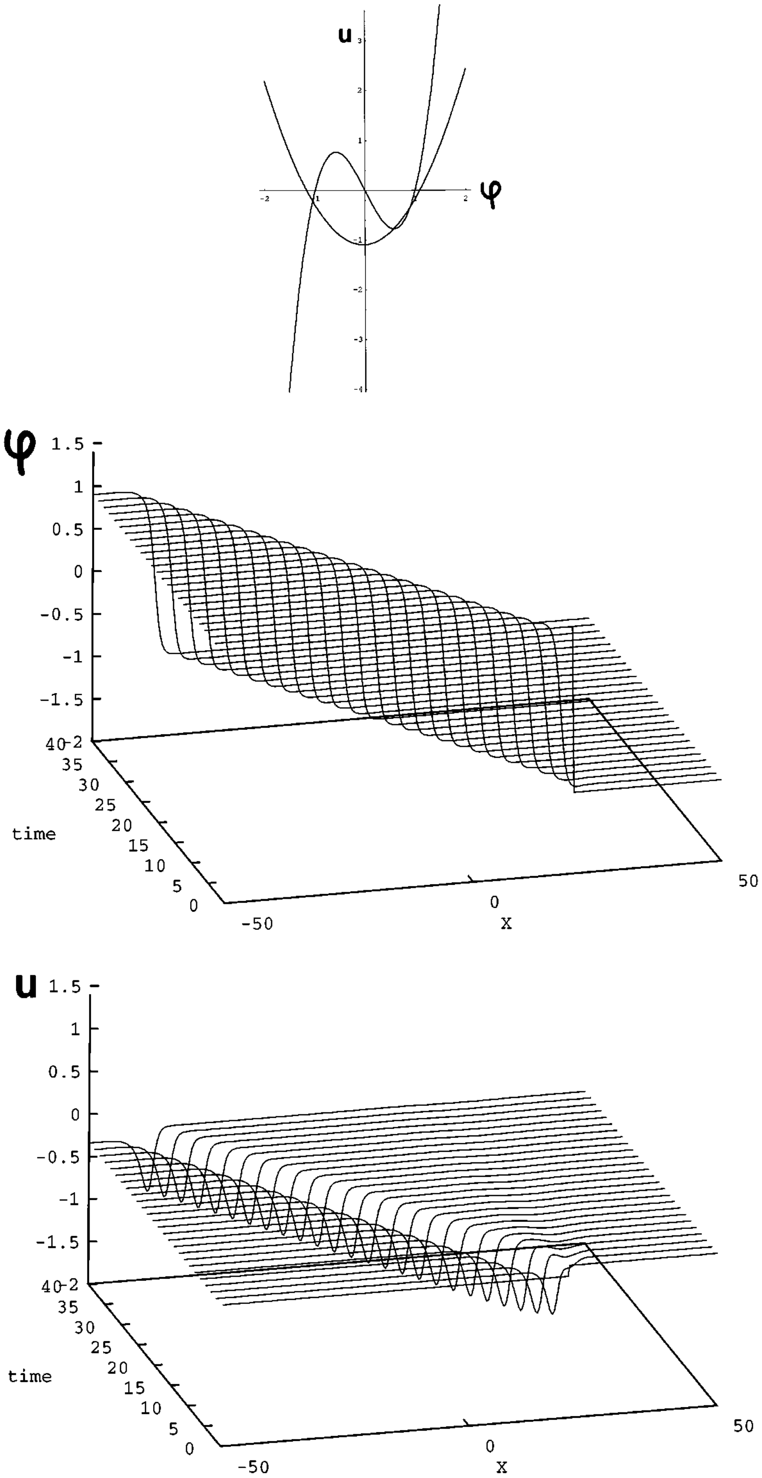

FIG. 8. $(\varphi, u)_- = (.9, -.34)$, $(\varphi, u)_+ = (-1.05, -.21)$, $\lambda = -.06$, $a = .85$, $b = 2$, $\varepsilon = 1$, $\alpha = 1$.

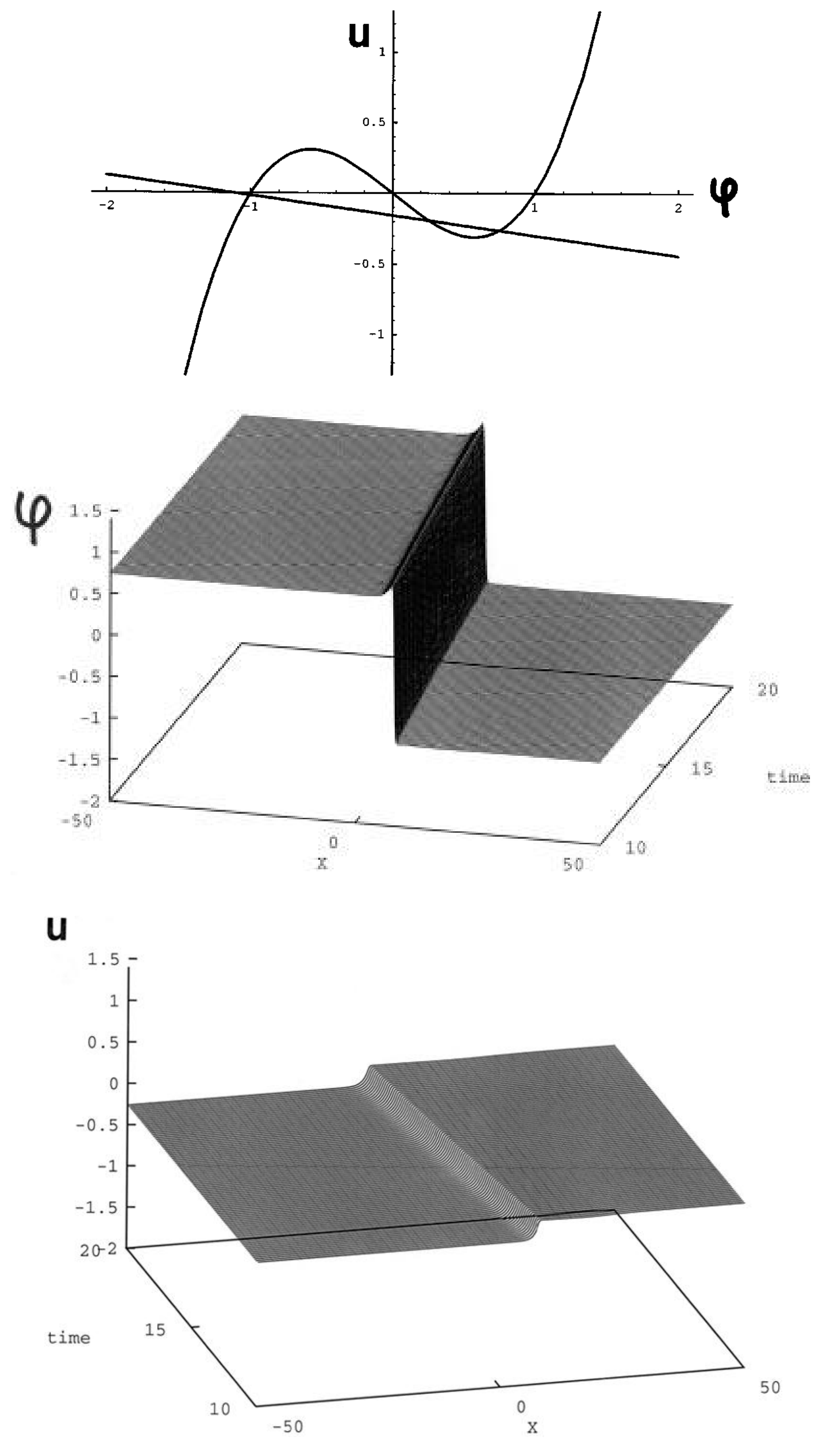

FIG. 9. $(\varphi, u)- = (.75 - .66)$, $(\varphi, u)_+ = (-1.01, -.008)$, $\lambda = .14$, $b = .8$, $a = 0$, $b = .8$, $1/\varepsilon^2 = 55$, $\alpha = 1$.

We also attempted to calculate the singular solutions of Theorem 4.3 with α large and u_+ negative and bounded away from zero. The numerical solutions did not produce travelling wave profiles consistent with the singular limit structure of Theorem 4.3. The temperature profile appeared more like the solution of a linear diffusion equation with step-function initial data, while the phase variable appeared to have a nearly stationary transition layer. In particular, the numerical solutions did not appear to converge to travelling waves. Whether the source of this is numerical or whether it points to some underlying instability of the travelling wave profiles of Theorem 4.3 is at this point unclear.

COMPRESSIBLE NAVIER–STOKES EQUATIONS IN A BOUNDED DOMAIN WITH INFLOW BOUNDARY CONDITION[*]

JAE RYONG KWEON[†] AND R. BRUCE KELLOGG[‡]

Abstract. In this paper, we study the barotropic compressible Navier–Stokes equations in a bounded plane domain Ω. Nonzero velocities are prescribed on the boundary of Ω, and the density is prescribed on that part of the boundary corresponding to entering velocity. This causes a weak singularity in the solution at the junction of incoming and outgoing flows. We prove the existence of the solution $(\mathbf{u}, p)$ of the system

$$\begin{cases} -\mu\Delta\mathbf{u} - \nu\nabla\mathrm{div}\,\mathbf{u} + \rho(p)(\mathbf{u}\cdot\nabla)\mathbf{u} + \nabla p = 0 \quad \text{in } \Omega, \\ \mathrm{div}(\rho\mathbf{u}) = 0 \quad \text{in } \Omega, \\ \mathbf{u} = \mathbf{u}_0(x,y) \quad \text{on } \Gamma, \\ p = p_0(x,y) \quad \text{on } \Gamma_{\mathrm{in}} \end{cases}$$

in the Sobolev space $H^{2,q} \times H^{1,q}(2 < q < 3)$. The proof follows from an analysis of the linearized problem and a fixed-point argument.

1. Introduction and main results.

The steady-state barotropic compressible Navier–Stokes equations are a system of PDEs of mixed type; the momentum equations form an elliptic subsystem in the velocity components, and the continuity equation is a hyperbolic equation in the density. Because, as a rule, the flow is zero on the boundary of a region, boundary value problems for the Navier–Stokes system are generally considered with the condition that the velocity components vanish on the boundary of the region. It is at least of mathematical interest and possibly of physical interest to consider boundary value problems in which the velocity components assume specified nonzero values on the boundary. Since the velocity field gives the characteristic directions for the continuity equation, values of the density must be specified on those portions of the boundary where the specified velocity vector points into the region. In this paper, we shall discuss the resulting boundary value problem in a special case. Particular attention will be paid to the boundary points where the velocity vector is tangent to the boundary since these give rise to singularities in the solution. We study the system

$$\begin{cases} -\mu\Delta\mathbf{u} - \nu\nabla\mathrm{div}\,\mathbf{u} + \rho(p)(\mathbf{u}\cdot\nabla)\mathbf{u} + \nabla p = 0 \quad \text{in } \Omega, \\ \mathrm{div}(\rho\mathbf{u}) = 0 \quad \text{in } \Omega, \\ \mathbf{u} = \mathbf{u}_0(x,y) \quad \text{on } \Gamma, \\ p = p_0(x,y) \quad \text{on } \Gamma_{\mathrm{in}}. \end{cases} \tag{1.1}$$

Here Ω is a bounded open set in R^2 with smooth boundary Γ, $\mathbf{u} = [u, v]$ is the velocity vector, p is the pressure, $\rho = \rho(p)$ is the density, μ is the viscosity constant, and ν

is the bulk viscosity constant. We assume that $\mu > 0$ and $\nu > -\mu$. The functions $\mathbf{u}_0(x, y)$ and $p_0(x, y)$ that give the boundary data are assumed to be smooth functions on the closure of Ω. The incoming and outgoing portions of the boundary, Γ_{in} and Γ_{out}, are defined by

$$\begin{aligned}\Gamma_{\text{in}} &= \{(x, y) \in \Gamma : \mathbf{u}_0 \cdot \mathbf{n} < 0\},\\ \Gamma_{\text{out}} &= \{(x, y) \in \Gamma : \mathbf{u}_0 \cdot \mathbf{n} \geq 0\},\end{aligned}$$

where $\mathbf{n} = [n_1, n_2]$ denotes the unit outward-pointing normal to Γ. In fact, to make the construction simpler, we assume throughout the paper that $v_0(x, y) \equiv 0$, $u_0(x, y) \geq C_0 > 0$.

Let $\Gamma_* \subset \Gamma$ be the set of the points at which $\mathbf{u}_0 \cdot \mathbf{n}$ is zero. We shall further simplify the situation by imposing the following condition.

Condition A. Γ_* consists of two points (x_*, y_*) and (x^*, y^*).

Again, Condition A is not essential for our results but serves to remove unessential details. With Condition A, the boundary Γ is divided into two connected arcs, the arc Γ_{in} for which $\mathbf{u}_0 \cdot \mathbf{n} < 0$ and the arc Γ_{out} for which $\mathbf{u}_0 \cdot \mathbf{n} \geq 0$. There are two increasing functions $\delta_{\pm}(y)$, defined for $y_* \leq y \leq y^*$, such that

$$\begin{aligned}\Gamma_{\text{in}} &= \{(\delta_-(y), y) \in \Gamma : y_* \leq y \leq y^*\},\\ \Gamma_{\text{out}} &= \{(\delta_+(y), y) \in \Gamma : y_* \leq y \leq y^*\},\\ \Omega &= \{(x, y) : \delta_-(y) < x < \delta_+(y), y_* \leq y \leq y^*\}.\end{aligned}$$

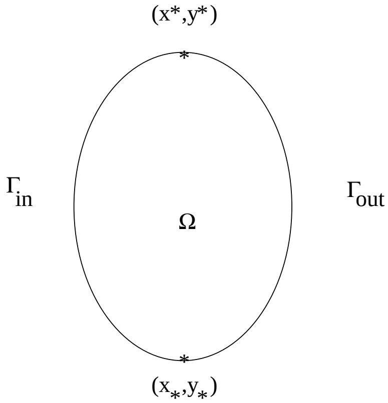

FIG. 1

(See Figure 1.) On Γ_{in}, we have

$$\mathbf{n}(\delta_-(y), y) = \frac{1}{\sqrt{1 + \delta_-'(y)^2}}[-1, \delta_-'(y)]. \tag{1.2}$$

Also, in a neighborhood of (x^*, y^*), Γ is the graph of a function $y = \epsilon_+(x)$, and in a neighborhood of (x_*, y_*), Γ is the graph of a function $y = \epsilon_-(x)$. Near (x^*, y^*) or (x_*, y_*), we have

$$\mathbf{n}(x, \epsilon_{\pm}(x)) = \frac{1}{\sqrt{1 + \epsilon_{\pm}'(x)^2}}[-\epsilon_{\pm}'(x), \pm 1].$$

Near these two points, we define $\mu(x) = (\mathbf{u}_0 \cdot \mathbf{n})(x, \epsilon(x))$, where ϵ denotes ϵ_- or ϵ_+. For simplicity, we will use ϵ to stand for ϵ_- or ϵ_+, respectively.

We will also use the following nondegeneracy assumption.

Condition B. $\mu'(x_*) \neq 0$ and $\mu'(x^*) \neq 0$.

With our assumptions, Condition B is equivalent to the condition that Γ has nonzero curvature at (x_*, y_*) and (x^*, y^*).

We define the distance from Γ_* to any point on the boundary Γ_{in}:

$$d(y) \equiv \min\left\{\sqrt{(y-y^*)^2 + (\delta_-(y) - x^*)^2}, \sqrt{(y-y_*)^2 + (\delta_-(y) - x_*)^2}\right\}. \tag{1.3}$$

Remark. Assume that Condition B holds. Then there are positive constants C_1 and C_2 such that

$$C_1 d(y) \leq \min\{|y-y^*|^{\frac{1}{2}}, |y-y_*|^{\frac{1}{2}}\} \leq C_2 d(y). \tag{1.4}$$

Proof. If $y = \epsilon(x)$, then $x = \delta_-(y)$ by the description of the boundary Γ_{in}. Thus $y - y^* = \epsilon'(\xi)(x - x^*)$ for some $\xi \in (x, x^*)$. Since $\mu(x^*) = 0$ and $\mu'(x^*) \neq 0$, we get

$$\epsilon'(\xi) = \int_{x^*}^{\xi} \epsilon''(s)ds \sim C(\xi - x^*) \quad \text{near } x^*.$$

Hence $y - y^* \sim C(x - x^*)^2 = C(\delta_-(y) - x^*)^2$ near x^* and for some C. However, $d(y) = |\delta_-(y) - x^*|\sqrt{1 + \epsilon'(\xi)^2}$ for some ξ. Thus we easily get $C_1 d(y) \leq \sqrt{y^* - y} \leq C_2 d(y)$ for some positive constants C_1 and C_2, and similarly for $\mu'(x_*) \neq 0$. □

The following lemma describes the behavior of the singularity near Γ_*.

LEMMA 1.1. *Let $\mathbf{u}_0 = [u_0, 0]$ be a given smooth vector field with $u_0 \geq C_0 > 0$. Assume that Condition* B *holds. Then there exist positive numbers m and M such that $md(y) \leq |\mu(\delta_-(y))| \leq Md(y)$ near Γ_*.*

Proof. Let y be near y^*, and let $x = \delta_-(y)$, so $y = \epsilon(x)$. Since $\mu(x^*) = 0$,

$$\begin{aligned}\mu(\delta_-(y)) &= (\mathbf{u}_0 \cdot \mathbf{n})(\delta_-(y), \epsilon(\delta_-(y))) \\ &= (\mu \circ \delta_-)'(\zeta)(\delta_-(y) - x^*)\end{aligned}$$

for some ζ with $y \leq \zeta \leq y^*$. Since $(\mu \circ \delta_-)'(y)$ is continuous in y and $\mu'(\delta_-(y^*)) > 0$, there are positive numbers m_1 and M_1 such that $m_1 \leq \mu'(\delta_-(y)) \leq M_1$ near y^*. However, by (1.3), $d(y) = |\delta_-(y) - x^*|\sqrt{\epsilon'(\delta_-(\zeta))^2 + 1}$ for some $\zeta \in [\bar{y}, y^*]$. Hence

$$\mu(\delta_-(y)) = \frac{(\mu \circ \delta_-)'(\zeta)}{\sqrt{1 + \epsilon'(\delta_-(\zeta))^2}} d(y)$$

for some $\zeta \in [\bar{y}, y^*]$. Now if $\epsilon'(x)$ is bounded near $x = x^*$, then

$$m \leq \frac{(\mu \circ \delta_-)'(\zeta)}{\sqrt{1 + \epsilon'(\delta_-(\zeta))^2}} \leq M \quad \text{near } y^*$$

for some positive constants m and M. A similar argument holds in a neighborhood of (x_*, y_*). □

As an example, let $\mathbf{u}_0$=(1, 0) and consider the domain $\Omega = \{(x,y) \in R^2 : |y| < 1 - x^2, \ -1 < x < 1\}$. Then if $y \geq 0$, $\delta_-(y) = -\sqrt{1-y}$, $\epsilon_+(x) = 1 - x^2$, and $y = \epsilon_+(\delta_-(y))$. Now (0, 1) is the singularity point. Hence $d(y) = \sqrt{(1-y)^2 + \delta_-(y)^2}$ and $|\mathbf{u}_0 \cdot \mathbf{n}| = 2\sqrt{1-y} = 2d(y)/\sqrt{2-y}$, where $\mathbf{n} = (2x, 1)$. Hence $d(y)/3 \leq |(\mu \circ \delta_-)(y)| \leq d(y)$, and similarly for $y < 0$.

We now explain our reason for taking $\mathbf{u}_0$ in the form $\mathbf{u}_0 = [u_0, 0]$. Let $\mathbf{u}_0 = [u_0, v_0]$ with v_0 not necessarily 0 be a given smooth vector field on the closure of Ω with $u_0 \geq C_0 > 0$—say $\mathbf{u}_0 \in C^\infty(\bar{\Omega})$. Consider the function $k(x, \bar{y})$ generated by the vector $\mathbf{u}_0$ and defined by the following first-order ODE: for each fixed $\bar{y}$,

$$\begin{aligned} k_x(x,\bar{y}) &= u_0^{-1} v_0(x, k(x,\bar{y})), \\ k(\delta_-(\bar{y}), \bar{y}) &= \bar{y}. \end{aligned} \tag{1.5}$$

We also consider the streamlines generated by this function, that is, the points $(x, k(x, \bar{y}))$. The solution k of (1.5) is given as follows: setting $U_0 = u_0^{-1} v_0$,

$$k(x,\bar{y}) = \int_{\delta_-(\bar{y})}^{x} U_0(s, k(s,\bar{y}))ds + \bar{y} \quad \text{for all x.} \tag{1.6}$$

Here we can observe that the function $k(x, \bar{y})$ is strictly increasing in $\bar{y}$. Now we set $y = k(x, \bar{y})$. Thus $\bar{y} = \psi(x, y)$ for some function ψ. Hence equation (1.6) can be written as

$$y = \int_{\delta_-(\psi(x,y))}^{x} U_0(s, k(s, \psi(x,y)))ds + \psi(x,y). \tag{1.7}$$

Now we want to compute the first and second derivatives of $\delta_-(\psi(x, y))$. First, we have

$$\nabla \delta_-(\psi(x,y)) = \delta'_-(\psi(x,y)) \nabla \psi(x,y), \tag{1.8}$$

$$\nabla^2 \delta_-(\psi(x,y)) = \delta''_-(\psi(x,y))(\nabla\psi)^2 + \delta'_-(\psi(x,y))\nabla^2\psi. \tag{1.9}$$

We compute $\nabla\psi(x, y)$. Differentiating both sides of (1.7) with respect to x and y, respectively, we get

$$\psi_x(x,y) = (\mathbf{u}_0 \cdot \mathbf{n})^{-1} \left\{ -v_0 - u_0 \int_{\delta_-(\psi(x,y)}^{x} \frac{\partial}{\partial x}[U_0(s, k(s, \psi(x,y)))]\mathrm{ds} \right\}, \tag{1.10}$$

$$\psi_y(x,y) = (\mathbf{u}_0 \cdot \mathbf{n})^{-1} \left\{ v_0 - u_0 \int_{\delta_-(\psi(x,y)}^{x} \frac{\partial}{\partial y}[U_0(s, k(s, \psi(x,y)))]\mathrm{ds} \right\}, \tag{1.11}$$

where $\mathbf{n}$ is the unit normal vector defined in (1.2). Since $\mathbf{u}_0 \cdot \mathbf{n}$ is zero at the points of Γ_*, ψ_x and ψ_y have singularities there. If $v_0 = 0$, $\delta'_-(y)$ is ∞ on Γ_* . In either case, the behavior of the singularities will be the same, and there is no mathematical difference between the two cases. According to this observation, throughout this paper, we choose $\mathbf{u}_0 = [u_0, 0]$ with $u_0 > 0$. With this condition, the flow enters the region from the left. Around Γ_*, the streamlines in Ω are almost parallel to the vector $\mathbf{u}_0$ because $\mathbf{u}|_\Gamma = \mathbf{u}_0$.

In this paper, we obtain the following main results. The proofs are given in section 2.

THEOREM 1.1. *Suppose that* $\mathbf{u}_0 \in H^{2,q}(\Omega)$, $p_0 \in H^{1,q}(\Omega)$, *and* $2 < q < 3$. *Then there is a constant* μ^* *depending on* $\|\mathbf{u}_0\|_{2,q} + \|p_0\|_{1,q}$ *such that if* $\mu \geq \mu^*$, *then problem* (1.1) *has a unique solution* $(u, v, p) \in H^{2,q} \times H^{2,q} \times H^{1,q}$ *with the following estimate:*

$$\|u - u_0\|_{2,q} + \|v\|_{2,q} + \|p - p_0\|_{1,q} \leq C_1,$$

where $C_1 = C(\Omega, \mu, \nu, C_0, \mu^*, |\kappa_0|_{1,\infty}, |\tau|_{1,\infty}, |\rho|_\infty, |\bar{\rho}|_\infty)$.

The condition that μ is large means that the Reynolds number of the flow is small, so the flow in this domain is a laminar flow.

The next theorem does not have a restriction on μ. Instead, it is required that the functions $\mathbf{u}_0$ and p_0 are almost constant. The proof of Theorem 1.2 is also given in section 2.

THEOREM 1.2. *Let $\mathbf{u}_0 \in H^{2,q}$, $p_0 \in H^{1,q}$, and $2 < q < 3$. For any constant C_1, there is a constant C_2 such that if $\|\mathbf{u}_0\|_{2,q} + \|p_0\|_{1,q} \le C_1$ and $\|\nabla \mathbf{u}_0\|_{1,q} + \|\nabla p_0\|_{1,q} \le C_2$, then there is a unique solution $(u, v, p) \in H^{2,q} \times H^{2,q} \times H^{1,q}$ of system* (1.1) *with the inequality*

$$\|u - u_0\|_{2,q} + \|v\|_{2,q} + \|p - p_0\|_{1,q} \le C_3,$$

where $C_3 = C(\Omega, \mu, \nu, C_0, C_1, C_2, \|\kappa_0\|_{1,q}, |\rho|_\infty, |\tau|_{1,\infty}, |\bar{\rho}|_\infty)$.

The proof of the theorems above consist of formulating problem (1.1) as a mapping on a certain Banach space in such a way that the solution to (1.1) is a fixed point of the mapping. The Schauder fixed-point theory is then used to establish the existence of a fixed point. We use the Banach space of pairs $(\mathbf{u}, p) \in (H^{2,q}(\Omega))^2 \times H^{1,q}$. The index q is chosen in the open interval $(2, 3)$. We choose $q > 2$ so that the Sobolev imbedding theorem can be applied to guarantee that the density $\rho(p)$ is well defined. We require that $q < 3$ to handle the singularities in the solution that occur on Γ_*.

In our analysis, it is convenient to use the deviation from the boundary values as dependent variables. We therefore define new dependent variables $\bar{\mathbf{u}} = \mathbf{u} - \mathbf{u}_0$ and $\bar{p} = p - p_0$. We then obtain for the first equation in (1.1) that

$$-\mu\Delta(\bar{\mathbf{u}} + \mathbf{u}_0) - \nu\nabla \mathrm{div}(\bar{\mathbf{u}} + \mathbf{u}_0) + \rho[(\bar{\mathbf{u}} + \mathbf{u}_0) \cdot \nabla](\bar{\mathbf{u}} + \mathbf{u}_0) + \nabla(\bar{p} + p_0) = 0,$$

and rearranging this equation, we get

$$-\mu\Delta\bar{\mathbf{u}} - \nu\nabla \mathrm{div}\, \bar{\mathbf{u}} + \nabla\bar{p} + \rho\{[(\bar{\mathbf{u}} + \mathbf{u}_0) \cdot \nabla]\bar{\mathbf{u}} + (\bar{\mathbf{u}} \cdot \nabla)\mathbf{u}_0\} = \mathbf{f}, \tag{1.12}$$

where $\mathbf{f} = \mu\Delta\mathbf{u}_0 + \nu\nabla \mathrm{div}\, \mathbf{u}_0 - \nabla p_0 - \rho(\mathbf{u}_0 \cdot \nabla)\mathbf{u}_0$. By the relation $\rho = \rho(p)$, $\mathrm{div}(\rho\mathbf{u}) = \rho(p)\mathrm{div}\mathbf{u} + \rho^{'}(p)\mathbf{u} \cdot \nabla p = 0$, and $\kappa(p)\mathrm{div}\, \mathbf{u} + \mathbf{u} \cdot \nabla p = 0$, where $\kappa(p) = \rho(p)\rho^{'}(p)^{-1}$. Hence the second equation in (1.1) becomes

$$\kappa(\bar{p} + p_0)\mathrm{div}\, \bar{\mathbf{u}} + (\bar{\mathbf{u}} + \mathbf{u}_0) \cdot \nabla p + \bar{\mathbf{u}} \cdot \nabla p_0 = g, \tag{1.13}$$

where $g = -\kappa(\bar{p} + p_0)\mathrm{div}\, \mathbf{u}_0 - \mathbf{u}_0 \cdot \nabla p_0$. Here we define $\tau(p)$ and $\bar{\rho}(p)$ as follows:

$$\tau(p) \equiv \frac{\kappa(p) - \kappa(p_0)}{p - p_0} \quad \text{for } p \ne p_0, \quad \tau(p_0) = \kappa'(p_0), \tag{1.14}$$

$$\bar{\rho}(p) \equiv \frac{\rho(p) - \rho(p_0)}{p - p_0} \quad \text{for } p \ne p_0, \quad \bar{\rho}(p_0) = \rho'(p_0). \tag{1.15}$$

Thus $\kappa(p) = \kappa(p_0) + \tau(p)(p - p_0)$ and $\rho(p) = \rho(p_0) + \bar{\rho}(p)(p - p_0)$. Now we join (1.12) and (1.13) and replace $\bar{\mathbf{u}}$ and $\bar{p}$ by $\mathbf{u}$ and p for convenience. Then we get

$$\left\{\begin{array}{l} -\mu\Delta\mathbf{u} - \nu\nabla \mathrm{div}\, \mathbf{u} + \nabla p + \rho\{[(\mathbf{u} + \mathbf{u}_0) \cdot \nabla]\mathbf{u} + (\mathbf{u} \cdot \nabla)\mathbf{u}_0\} = \mathbf{f} \quad \text{in } \Omega, \\ \kappa(p + p_0)\mathrm{div}\, \mathbf{u} + (\mathbf{u} + \mathbf{u}_0) \cdot \nabla p + \mathbf{u} \cdot \nabla p_0 = g \quad \text{in } \Omega, \\ \mathbf{u} = 0 \quad \text{on } \partial\Omega, \\ p = 0 \quad \text{on } \Gamma_{\text{in}}, \end{array}\right. \tag{1.16}$$

where $\mathbf{f}$ and g are defined above and $\rho = \rho(p + p_0)$.

In order to solve the nonlinear problem (1.16), we shall rephrase it as a fixed-point problem. Let $\mathbf{w}$ be a given vector field with $\mathbf{w} = 0$ on Γ, and let η be a given function with $\eta = 0$ on Γ_{in}. Let

$$\mathbf{F}(\mathbf{w}, \eta) = \mathbf{f} - \rho[(\mathbf{w} \cdot \nabla)\mathbf{w} + (\mathbf{w} \cdot \nabla)\mathbf{u}_0] - \bar{\rho}\eta(\mathbf{u}_0 \cdot \nabla)\mathbf{w}, \tag{1.17}$$

$$G(\mathbf{w}, \eta) = g - \tau\eta \operatorname{div} \mathbf{w} - \mathbf{w} \cdot \nabla p_0, \tag{1.18}$$

where $\rho = \rho(\eta + p_0), \bar{\rho} = \bar{\rho}(\eta + p_0)$, and $\tau = \tau(\eta + p_0)$. Let $\kappa_0 = \kappa(p_0)$ and $\rho_0 = \rho(p_0)$, and let U and V be given functions. Consider the linear problem

$$\begin{cases} -\mu\Delta\mathbf{u} - \nu\nabla \operatorname{div} \mathbf{u} + \rho_0(\mathbf{u}_0 \cdot \nabla)\mathbf{u} + \nabla p = \mathbf{F} \quad \text{in } \Omega, \\ \kappa_0 \operatorname{div} \mathbf{u} + U p_x + V p_y = G \quad \text{in } \Omega, \\ \mathbf{u} = 0 \quad \text{on } \partial\Omega, \\ p = 0 \quad \text{on } \Gamma_{\text{in}}. \end{cases} \tag{1.19}$$

System (1.19) is a linear system of equations which is somewhat more complicated than the Stokes system. The complications are the presence of the convection term in the first equation of (1.19) and, more importantly, the presence of the pressure p terms in the second equation of (1.19). We shall call (1.19) a compressible Stokes system. If this system has a solution for $\mathbf{F} = \mathbf{F}(\mathbf{w}, \eta)$, $G = G(\mathbf{w}, \eta)$, $U = w_1 + u_0$, and $V = w_2$, we may consider the solution as defining a map $(\mathbf{w}, \eta) \longrightarrow (\mathbf{u}, p)$. If it happens that this map has a fixed point $(\mathbf{u}, p)$, then system (1.19) becomes (1.16). Hence to solve (1.16), it suffices to find a fixed point of this map.

Throughout this paper, we will assume that

$$U \geq C_0 > 0 \tag{1.20}$$

for some constant C_0.

In this paper, we will use the following spaces and norms:

$$\begin{aligned}
\|u\|_0 &\equiv \left\{ \int_\Omega |u(\mathrm{x})|^2 \mathrm{dx} \right\}^{1/2} \quad \text{and} \quad \|u\|_{0,q} \equiv \left\{ \int_\Omega |u(\mathrm{x})|^q \mathrm{dx} \right\}^{1/q}, \\
L^2(\Omega) &= \{u : \|u\|_0 < \infty\} \;\; \text{and} \;\; L^q(\Omega) = \{u : \|u\|_{0,q} < \infty\}, \\
\|u\|_k &\equiv \sum_{j=0}^k \|\nabla^j u\|_0, \qquad \|u\|_{k,q} \equiv \sum_{j=0}^k \|\nabla^j u\|_{j,q}, \\
H^k(\Omega) &\equiv \{u \in L^2(\Omega) : \|u\|_k < \infty\}, \\
H_0^k(\Omega) &\equiv \{u \in H^k(\Omega) : u = 0 \text{ on } \partial\Omega\}, \\
H^{k,q}(\Omega) &\equiv \{u \in L^q(\Omega) : \|u\|_{k,q} < \infty\}, \\
H_0^{k,q}(\Omega) &\equiv \{u \in H^{k,q}(\Omega) : u = 0 \text{ on } \partial\Omega\}, \\
\|u\|_{-1} &\equiv \sup\{\langle u, v\rangle : v \in H_0^1(\Omega), \|v\|_1 = 1\}, \\
\|u\|_{-1,q} &\equiv \sup\{\langle u, v\rangle : v \in H_0^{1,q'}(\Omega), \|v\|_{1,q'} = 1, \; 1/q + 1/q' = 1\}, \\
|u|_{0,\infty} &\equiv \sup\{|u(\mathrm{x})| : \mathrm{x} \in \Omega\}, \\
|u|_{k,\infty} &\equiv \sum_{j=0}^k |\nabla^j u|_{0,\infty}.
\end{aligned}$$

In our proofs, C denotes a generic constant depending on certain quantities. We shall make this dependence explicitly—for example, writing $C(\Omega)$ if C depends only on Ω (for example, in the Sobolev inequalities) or $C(\Omega, u_0, C_0)$ if C depends on Ω, u_0, and C_0, and so on.

2. Large viscosity and constant ambient flows. In this section, we prove the theorems stated above. We start with some lemmas. In these lemma, the functions $\delta_-(y)$ and $d(y)$, which were defined in section 1, are regarded as functions on Ω which are independent of x.

LEMMA 2.1. *Let q be given with $2 < q < 3$. Then δ'_-, $d^2\delta''_- \in \text{\L}^q(\Omega)$.*

Proof. Since the behavior of $\delta'_-(y)$ is like that of $(\delta_-(y) - x^*)/(y - y^*)$ near x^* and $d(y) = |\delta_-(y) - x^*|\sqrt{\epsilon'(\xi)^2 + 1}$ for $\bar{x} \le \xi \le x^*$, using Condition B,

$$\int_{\delta_-(y)}^{x^*} |\delta'_-(y)|^q \mathrm{dx} \le C|y - y^*|^{\frac{1-q}{2}} \quad \text{for some constant } C.$$

Integrating both sides of above inequality with respect to y in a neighborhood of y^*, we have $\delta'_-(y) \in L^q(\Omega)$ for $q < 3$. A similar argument holds near y_*. From the relation $y = \epsilon(x), x = \delta_-(y)$, $\delta''_-(y) = -\epsilon''(\delta_-(y))\delta'_-(y)^3$. A similar argument shows that $d(y)^2\delta''_-(y) \in L^q(\Omega)$. □

In order to study the linear system (1.19), we first consider the continuity equation

$$\begin{aligned} p_x(x,y) + U^{-1}V(x,y)p_y(x,y) &= \hat{H}(x,y) \quad \text{in } \Omega, \\ p(\delta_-(y), y) &= 0, \end{aligned} \tag{2.1}$$

where U and V are given and $\hat{H} = U^{-1}H$. To solve the continuity equation, consider for each fixed $\bar{y}$,

$$\begin{aligned} p_x(x, h(x,\bar{y})) + U^{-1}V(x, h(x,\bar{y}))p_y(x, h(x,\bar{y})) &= \hat{H}(x, h(x,\bar{y})) \quad \text{in } \Omega, \\ p(\delta_-(\bar{y}), \bar{y}) &= 0, \end{aligned} \tag{2.2}$$

where $h(x,\bar{y})$ is the solution of the following first-order ODE: for each $\bar{y}$,

$$\begin{aligned} h_x(x,\bar{y}) &= U^{-1}V(x, h(x,\bar{y})) \quad \text{in } \Omega, \\ h(\delta_-(\bar{y}), \bar{y}) &= \bar{y}. \end{aligned} \tag{2.3}$$

The solution $h(x,\bar{y})$ of (2.3) is given by

$$h(x,\bar{y}) = \int_{\delta_-(\bar{y})}^{x} U^{-1}V(s, h(s,\bar{y}))ds + \bar{y}. \tag{2.4}$$

Now we set $y = h(x,\bar{y})$. Then $\bar{y} = \varphi(x,y)$ for some function φ since $h(x,\bar{y})$ is increasing in $\bar{y}$. Thus

$$y = \int_{\delta_-(\varphi(x,y)}^{x} U^{-1}V(s, h(s, \varphi(x,y)))ds + \varphi(x,y). \tag{2.5}$$

Differentiating both sides of (2.5) with respect to x and y, respectively, and using $U^{-1}V = 0$ on Γ, we get

$$\varphi_x(x,y) = -U^{-1}V(x,y) - \int_{\delta_-(\varphi(x,y))}^{x} \frac{\partial}{\partial x}[U^{-1}V(s, h(s, \varphi(x,y)))]ds, \tag{2.6}$$

$$\varphi_y(x,y) = 1 - \int_{\delta_-(\varphi(x,y))}^{x} \frac{\partial}{\partial y}[U^{-1}V(s, h(s, \varphi(x,y)))]ds. \tag{2.7}$$

LEMMA 2.2. *Let h and φ be given as above. Then $\|h\|_{2,q}$, $\|\varphi\|_{2,q}$, and $\|\nabla(\delta_- \circ \varphi)\|_{0,q}$ are bounded by a constant of the form $C(\Omega, \|U\|_{2,q}, \|V\|_{2,q}, C_0)$.*

Proof. The proof follows from the formulas above, in particular, Lemma 2.1, (2.6), (2.7), and the fact that $V = 0$ on Γ. □

Now using (2.2) $\sim$ (2.5), the solution of (2.1) is given by

$$p(x,y) = \int_{\delta_-(\varphi(x,y))}^{x} \hat{H}(s, h(s, \varphi(x,y)))ds, \tag{2.8}$$

where $\hat{H} \equiv U^{-1}H$.

LEMMA 2.3. *If $2 < q < 3$, then the solution p of (2.1), given by (2.8), satisfies the following inequality:*

$$\|p\|_{1,q} \leq C\|H\|_{1,q}, \tag{2.9}$$

where $C = C(\Omega, \|U\|_{2,q}, \|V\|_{2,q}, C_0)$.

Proof. Differentiating both sides of (2.8) with respect to y, we get

$$p_y(x,y) = \int_{\delta_-(\varphi(x,y))}^{x} \frac{\partial}{\partial y}\hat{H}(s, h(s, \varphi(x,y)))ds - \hat{H}(\delta_-(\varphi(x,y)), \varphi(x,y))\frac{\partial \delta_-(\varphi(x,y))}{\partial y},$$

and for simplicity, writing $\varphi(x,y)$ as φ, we have

$$\begin{aligned} |p_y(x,y)|^q &\leq C\left\{\left[\int_{\delta_-(\varphi(x,y))}^{x} \left|\frac{\partial}{\partial y}\hat{H}(s, h(s, \varphi(x,y)))\right| ds\right]^q + |\hat{H}(\delta_-(\varphi), \varphi)|^q \left|\frac{\partial \delta_-(\varphi)}{\partial y}\right|^q\right\} \\ &\leq C\left\{\int_{\delta_-(\varphi(x,y))}^{x} \left|\frac{\partial}{\partial y}\hat{H}(s, h(s, \varphi(x,y)))\right|^q ds + \left|\hat{H}\right|_\infty^q \left|\frac{\partial \delta_-(\varphi)}{\partial y}\right|^q\right\}, \end{aligned} \tag{2.10}$$

where we used $(a+b)^q \leq 2^{q-1}(a^q + b^q)$ in the first inequality and Hölder's inequality in the second inequality and C depends on Ω. Next, integrating both sides of (2.10) with respect to x from $\delta_-(y)$ to $\delta_+(y)$,

$$\begin{aligned} \int_{\delta_-(y)}^{\delta_+(y)} |p_y(x,y)|^q dx &\leq C\int_{\delta_-(y)}^{\delta_+(y)} \int_{\delta_-(\varphi(x,y))}^{x} \left|\frac{\partial}{\partial y}\hat{H}(s, h(s, \varphi(x,y)))\right|^q dsdx (\equiv A(y)) \\ &\quad + C|\hat{H}|_\infty^q \int_{\delta_-(y)}^{\delta_+(y)} \left|\frac{\partial \delta_-(\varphi)}{\partial y}\right|^q dx (\equiv B(y)). \end{aligned} \tag{2.11}$$

Integrating $A(y)$ and changing the variables of integration, we get

$$\begin{aligned} \int_{y_*}^{y^*} A(y)dy &= C\int_{y_*}^{y^*} \int_{\delta_-(y)}^{\delta_+(y)} \left\{\int_{\delta_-(\varphi(x,y))}^{x} \left|\frac{\partial}{\partial y}\hat{H}(s, h(s, \varphi(x,y)))\right|^q ds\right\} dxdy \\ &\leq C(\|U\|_{2,q}, \|V\|_{2,q}, \Omega)\int_\Omega |\hat{H}_y(x,y)|^q \mathrm{dx}. \end{aligned} \tag{2.12}$$

In order to estimate $B(y)$ in (2.11), we observe that $\partial(\delta_- \circ \varphi)/\partial y$ is close to $\delta'_-(y)$ near Γ. Then we have

$$\int_{y=y_*}^{y^*} \int_{\delta_-(y)}^{\delta_+(y)} \left|\frac{\partial \delta_-(\varphi(x,y))}{\partial y}\right|^q dxdy \leq C\|\delta'_-(y)\|_{0,q} < \infty, \tag{2.13}$$

where $C = C(\Omega, \|U\|_{2,q}, \|V\|_{2,q}, C_0)$ and we have used Lemma 2.1. Since $q > 2$, by the Sobolev embedding theorem, $H^{1,q}(\Omega) \subseteq C^0(\Omega)$,

$$|\hat{H}|_\infty^q \leq C\|\hat{H}\|_{1,q}^q \quad \text{for some constant } C. \tag{2.14}$$

Combining (2.11)–(2.14), we get $\|p_y\|_q^q \leq C\|\hat{H}\|_{1,q}^q$ for some constants C. Similarly, applying the same procedure for p_x, we get $\|p_x\|_q^q \leq C\|\hat{H}\|_{1,q}^q$. Furthermore, we can easily get the L^q-estimate for $p(x, y)$. Thus, since $\hat{H} = U^{-1}H$, the result follows. □

Consider the following elliptic boundary value problem:

$$\begin{aligned} -\mu\Delta\mathbf{u} - \nu\nabla\mathrm{div}\,\mathbf{u} + \rho_0(\mathbf{u}_0 \cdot \nabla)\mathbf{u} &= \bar{\mathbf{F}} \quad \text{in } \Omega, \\ \mathbf{u} &= 0 \quad \text{on } \Gamma. \end{aligned} \tag{2.15}$$

Remark. The ellipticity of the operator follows from the inequalities satisfied by μ and ν. For simplicity, we set $\bar{\mu} = (\mu + \nu)/\mu$.

Lemma 2.4. *Assume that $|\nabla(\rho_0\mathbf{u}_0)|_\infty$ is small enough. Then there is a unique weak solution $\mathbf{u}$ of* (2.15) *with* (i) $\mu\|\mathbf{u}\|_1 \leq C_1\|\bar{\mathbf{F}}\|_0$, *where $C_1 = C(\bar{\mu}, |\nabla(\rho_0\mathbf{u}_0)|_\infty)$. Furthermore, the solution $\mathbf{u}$ of* (2.15) *satisfies* (ii) $\mu\|\mathbf{u}\|_{k,q} \leq C_2\|\bar{\mathbf{F}}\|_{k-2,q}$, *where $C_2 = C(\Omega, \bar{\mu}, \mathbf{u}_0, \rho_0, k)$, k is an integer ≥ 1, $1 < q < \infty$, C_2 is bounded provided that $\bar{\mu}$ ranges over a compact subset of* $(0, \infty)$, *and μ is bounded away from zero. Also, the solution $\mathbf{u}$ of* (2.15) *satisfies* (ii) *with the small condition of $|\rho_0|_{k-2,\infty}$ $(k \geq 2)$.*

Proof. First, let $\bar{\mathbf{u}} = \mu\mathbf{u}$ and consider the modified equation of (2.15); $-\Delta\bar{\mathbf{u}} - (\bar{\mu} - 1)\nabla\mathrm{div}\bar{\mathbf{u}} + \mu^{-1}\rho_0(\mathbf{u}_0 \cdot \nabla)\bar{\mathbf{u}} = \bar{\mathbf{F}}$ in Ω and $\bar{\mathbf{u}} = 0$ on Γ. Next, we multiply both sides by $\bar{\mathbf{u}}$ and integrate by parts. Using the inequalities satisfied by μ and $\bar{\mu}$ and the smallness assumption on $|\nabla(\rho_0\mathbf{u}_0)|_\infty$ (or the condition that μ is large enough), we easily get (i). The existence of a weak solution $\bar{\mathbf{u}} \in H_0^1$ to (i) then follows from the Lax–Milgram lemma. From the standard L^q theory of elliptic equations (see [2]) applied to the modified version of (2.15), we obtain

$$\|\bar{\mathbf{u}}\|_{k,q} \leq \mu^{-1}C(\bar{\mu})|\rho_0\mathbf{u}_0|_{k-2,\infty}\|\bar{\mathbf{u}}\|_{k-1,q} + C(\bar{\mu})\|\bar{\mathbf{F}}\|_{k-2,q}.$$

This inequality holds uniformly if $\bar{\mu}$ ranges over a compact subset of $(0, \infty)$. Suppose that $|\nabla(\rho_0\mathbf{u}_0)|_\infty$ is small enough so that (i) holds. A standard argument by contradiction then establishes (ii). □

The next theorem gives a solution to the linear system (1.19).

Theorem 2.1. *Suppose that $U \geq C_0$. Assume that $|\nabla(\rho_0\mathbf{u}_0)|_\infty$ is small enough. Assume that $\|\kappa_0\|_{1,q}$ is sufficiently small or μ is large enough. Then there exists a unique solution $(\mathbf{u}, p) \in H_0^{2,q} \times H^{1,q}$ of system* (1.19) *with the following a priori estimate:*

$$\mu\|\mathbf{u}\|_{2,q} + \|p\|_{1,q} \leq C(\|\mathbf{F}\|_{0,q} + \|G\|_{1,q}), \tag{2.16}$$

where $C = C(\Omega, \|U\|_{2,q}, \|V\|_{2,q}, C_0, \bar{\mu}, \|\kappa_0\|_{1,q}, \mathbf{u}_0, \rho_0)$.

Proof. Let $\mathbf{w} \in H_0^{2,q}$ be given, and consider the following problem:

$$\begin{cases} -\mu\Delta\mathbf{u} - \nu\nabla\mathrm{div}\,\mathbf{u} + \rho_0(\mathbf{u}_0 \cdot \nabla)\mathbf{u} + \nabla p = \mathbf{F} \quad \text{in } \Omega, \\ Up_x + Vp_y = G - \kappa_0\mathrm{div}\,\mathbf{w} \quad \text{in } \Omega, \\ \mathbf{u} = 0 \quad \text{on } \partial\Omega, \\ p = 0 \quad \text{on } \Gamma_{\text{in}}. \end{cases} \tag{2.17}$$

Using Lemma 2.3 with $H = G - \kappa_0\mathrm{div}\,\mathbf{w}$, we find that the solution p in (2.1) exists and satifies

$$\|p\|_{1,q} \leq C(\|\kappa_0\|_{1,q}\|\mathbf{w}\|_{2,q} + \|G\|_{1,q}), \tag{2.18}$$

where $C = C(\Omega, \|U\|_{2,q}, \|V\|_{2,q}, C_0)$. However, by (2.8) with $H = G - \kappa_0 \operatorname{div} \mathbf{w}$, the solution p of the continuity equation (2.17) is uniquely determined, and using this solution p and Lemma 2.4, the problem

$$\begin{aligned} -\mu\Delta\mathbf{u} - \nu\nabla\operatorname{div}\mathbf{u} + \rho_0(\mathbf{u}_0\cdot\nabla)\mathbf{u} + \nabla p &= \mathbf{F} \quad \text{in } \Omega, \\ \mathbf{u} &= 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{2.19}$$

has a unique solution $\mathbf{u} \in H^{2,q}(\Omega) \cap H_0^{1,q}(\Omega)$ and satisfies the inequality

$$\mu\|\mathbf{u}\|_{2,q} \leq C(\|\nabla p\|_{0,q} + \|\mathbf{F}\|_{0,q}), \tag{2.20}$$

where $C = C(\Omega, \bar{\mu}, \rho_0, \mathbf{u}_0, q)$. Here we combine (2.18) and (2.20) and get

$$\mu\|\mathbf{u}\|_{2,q} + \|p\|_{1,q} \leq C(\|\kappa_0\|_{1,q}\|\mathbf{w}\|_{2,q} + \|\mathbf{F}\|_{0,q} + \|G\|_{1,q}), \tag{2.21}$$

where $C = C(\Omega, \|U\|_{2,q}, \|V\|_{2,q}, C_0, \bar{\mu}, \rho_0, \mathbf{u}_0, q)$. At this point, we call attention to the linear map $(\mathbf{F}, G, U, V, \mathbf{w}) \longmapsto (\mathbf{u}, p)$ defined by (2.17). If $(\mathbf{u}^*, p^*)$ is the solution corresponding to the data $(\mathbf{F}, G, U, V, \mathbf{w}^*)$, it follows that $(\mathbf{u}-\mathbf{u}^*, p-p^*)$ is the solution corresponding to the data $(0, 0, 0, 0, \mathbf{w} - \mathbf{w}^*)$. Now using (2.21), we get

$$\mu\|\mathbf{u} - \mathbf{u}^*\|_{2,q} + \|p - p^*\|_{1,q} \leq C\|\kappa_0\|_{1,q}\|\mathbf{w} - \mathbf{w}^*\|_{2,q},$$

where $C = C(\Omega, \|U\|_{2,q}, \|V\|_{2,q}, C_0, \bar{\mu}, |\rho_0|_\infty, |\mathbf{u}_0|_\infty, q)$. Thus we have

$$\mu\|\mathbf{u} - \mathbf{u}^*\|_{2,q} \leq C\|\kappa_0\|_{1,q}\|\mathbf{w} - \mathbf{w}^*\|_{2,q}.$$

Hence for fixed $\mathbf{F}$, G, U, and V, if $\mu =$ large or $\|\kappa_0\|_{1,q} =$ small, then the map $\mathbf{w} \longmapsto \mathbf{u}$ is a contraction in the topology of $H_0^{2,q}$, i.e., $\|\mathbf{u}-\mathbf{u}^*\|_{2,q} \leq (1/2)\|\mathbf{w}-\mathbf{w}^*\|_{2,q}$ and it has a unique fixed point $\mathbf{u} = \mathbf{w}$. Thus using this fixed point $\mathbf{u}$, p is uniquely determined by the continuity equation in (2.17) and (2.8). Hence $(\mathbf{u}, p)$ is the desired solution of (1.19). Again, if μ is large or $\|\kappa_0\|_{1,q}$ is small, we get (2.16) by (2.21). □

We give an example of a solution to (1.19) that emphasizes that the restriction on the regularity of the solution $(\mathbf{u}, p)$ of (1.19) in Theorem 2.1 comes from the geometry of $\partial\Omega$, not the regularity of the data. For example, let Ω be the unit disk and let $\mu = 1$, $\nu = 0$, $\mathbf{u}_0 = [1, 0]$, $\kappa_0 = 1$, $U = 1$, and $V = 0$. Let $[u, v, p]$ be defined by

$$\begin{aligned} u(x,y) &= 1 - x^2 - y^2, \\ v(x,y) &= \chi(y)[(1-y^2)^{3/2} - |x|^3], \\ p(x,y) &= 3\chi(y)(x-1)[(1-y^2)^{1/2} + x]. \end{aligned}$$

Here $\chi(y)$ is a smooth function which is $\equiv 1$ near $y = 1$ and $\equiv 0$ near $y = -1$. It is easily seen that $v \in H^{2,q}(\Omega)$ and $p \in H^{1,q}(\Omega)$ for $q < 3$. Also, $u = v = 0$ on Γ and $p = 0$ on Γ_{in}. For y near 1, $f_1 = -\Delta u + u_x + p_x = 3(1-y^2)^{1/2} + 4x + 1 \in H^{1,q}(\Omega)$ and $f_2 = -\Delta v + v_x + p_y = 3(y-y^2-xy)(1-y^2)^{-1/2} + 3(1-y^2)^{1/2} + 6|x| - 3x|x|$. The first term in this formula for f_2 may be written $3y(1-y)(1-y^2)^{-1/2} - 3xy(1-y^2)^{-1/2} \in H^{1,q}(\Omega)$. It may be seen that $|x| \in H^{1,q}(\Omega)$ and $x|x| \in H^{1,q}(\Omega)$. Hence $f_2 \in H^{1,q}(\Omega)$. Finally, $g = u_x + v_y + p_x = 3(1-y)(1-y^2)^{1/2} + 4x - 3 \in H^{2,q}(\Omega)$. Summarizing the computation above, $f_1 \in H^{1,q}(\Omega), f_2 \in H^{1,q}(\Omega)$, and $g \in H^{2,q}(\Omega)$. Hence (u, v, p) satisfies (1.19) with data of sufficient regularity to permit u, v, and p to have more regularity than they have. The singularity of the solution at (x^*, y^*) blocks further regularity in the solution.

Recall that in (1.12) and (1.13), we defined $\mathbf{f} = \mu\Delta\mathbf{u}_0 + \nu\nabla\mathrm{div}\,\mathbf{u}_0 - \nabla p_0 - \rho(\mathbf{u}_0 \cdot \nabla)\mathbf{u}_0$ and $g = -\kappa(\eta + p_0)\mathrm{div}\,\mathbf{u}_0 - \mathbf{u}_0 \cdot \nabla p_0$. Hence we get

$$\|\mathbf{f}\|_{0,q} + \|g\|_{1,q} \le C(\|\nabla\mathbf{u}_0\|_{1,q} + \|\nabla p_0\|_{1,q}). \tag{2.22}$$

Let us set $M \equiv \|\nabla\mathbf{u}_0\|_{1,q} + \|\nabla p_0\|_{1,q}$. In order to solve system (1.16), we use both the linear system (1.19) with $U = w_1 + u_0$ and $V = w_2$ and (2.16). Before doing this, we need the following lemma.

LEMMA 2.5. *Let* $\mathbf{w} \in H_0^{2,q}$ *and* $\eta \in H^{1,q}$. *Let* $\mathbf{F} = \mathbf{F}(\mathbf{w}, \eta)$ *and* $G = G(\mathbf{w}, \eta)$ *be given by* (1.17) *and* (1.18). *Let* $U = w_1 + u_0$ *and* $V = w_2$. *Then the solution* $(\mathbf{u}, p) \in H_0^{2,q} \times H^{1,q}$ *of system* (1.19) *that is given by Theorem* 2.1 *satisfies the inequality*

$$\|\mathbf{u}\|_{2,q} + \mu^{-1}\|p\|_{1,q} \le C(\|\mathbf{w}\|_{2,q} + \mu^{-1}\|\eta\|_{1,q})^2 + \frac{CM}{\mu}\|\mathbf{w}\|_{1,q} + \frac{CM}{\mu}, \tag{2.23}$$

where $C = C(\Omega, \bar{\mu}, \|\mathbf{w}\|_{2,q}, \|\mathbf{u}_0\|_{2,q}, C_0, |\kappa_0|_{1,\infty}, |\tau|_{1,\infty}, |\rho|_\infty, |\bar{\rho}|_\infty)$.

Proof. Using formula (1.17) for $\mathbf{F}(\mathbf{w}, \eta)$ and the Sobolev embedding $H^{1,q} \subseteq C^0$,

$$\begin{aligned} \|\mathbf{F}(\mathbf{w}, \eta)\|_{0,q} &\le C(\|\mathbf{f}\|_{0,q} + \|\mathbf{w} \cdot \nabla\mathbf{w}\|_{0,q} + \|\nabla\mathbf{w}\|_{0,q}|\eta|_\infty + \|\mathbf{w} \cdot \nabla\mathbf{u}_0\|_{0,q}) \\ &\le C(\|\mathbf{w}\|_{1,q} + \|\eta\|_{1,q} + \|\nabla\mathbf{u}_0\|_{1,q})\|\mathbf{w}\|_{1,q} + C\|\mathbf{f}\|_{0,q}, \end{aligned} \tag{2.24}$$

where $C = C(\Omega, |\rho|_\infty, |\bar{\rho}|_\infty)$. Next, using (1.18), we estimate $\|G(\mathbf{w}, \eta)\|_{1,q}$ and get

$$\|G\|_{1,q} \le C(\|\tau\eta\mathrm{div}\,\mathbf{w}\|_{1,q} + \|\mathbf{w} \cdot \nabla p_0\|_{1,q} + \|g\|_{1,q}), \tag{2.25}$$

$$\begin{aligned} \|\nabla(\eta\mathrm{div}\,\mathbf{w})\|_{0,q} &\le C(\|\nabla\eta\mathrm{div}\,\mathbf{w}\|_{0,q} + \|\eta\nabla\mathrm{div}\,\mathbf{w}\|_{0,q}) \\ &\le C(|\mathrm{div}\,\mathbf{w}|_\infty\|\nabla\eta\|_{0,q} + |\eta|_\infty\|\mathbf{w}\|_{2,q}), \end{aligned} \tag{2.26}$$

$$\|\eta\mathrm{div}\,\mathbf{w}\|_{0,q} \le |\mathrm{div}\,\mathbf{w}|_\infty\|\eta\|_{0,q}. \tag{2.27}$$

Hence, using the inequality $\|\mathbf{w} \cdot \nabla p_0\| \le C\|\nabla p_0\|_{1,q}\|\mathbf{w}\|_{1,q}$,

$$\|G\|_{1,q} \le C(\|\mathbf{w}\|_{2,q}\|\eta\|_{1,q} + \|\nabla p_0\|_{1,q}\|\mathbf{w}\|_{1,q} + \|g\|_{1,q}). \tag{2.28}$$

Finally, combining (2.24) and (2.28), we have

$$\begin{aligned} \|\mathbf{F}(\mathbf{w}, \eta)\|_{0,q} + \|G(\mathbf{w}, \eta)\|_{1,q} &\le C(\|\mathbf{w}\|_{2,q}\|\eta\|_{1,q} + \|\mathbf{w}\|_{1,q}^2 + M\|\mathbf{w}\|_{1,q}) \\ &\quad + C(\|\mathbf{f}\|_{0,q} + \|g\|_{1,q}), \end{aligned} \tag{2.29}$$

where $C = C(\Omega, |\tau|_{1,\infty}, |\rho|_\infty, |\bar{\rho}|_\infty)$. Recalling that $U = w_1 + u_0$ and $V = w_2$, recalling $\mathbf{f}$ and g from (1.12) and (1.13), combining (2.16) and (2.29), then dividing the resulting inequality by μ, and finally using $2\alpha\beta \le (\alpha+\beta)^2$, we get the required inequality. □

We now construct a fixed-point map. To do this, we let $\sigma = \mu^{-1}p$ and $\pi = \mu^{-1}\eta$. Then the linear sytem (1.19) becomes

$$\begin{cases} -\Delta\mathbf{u} - \mu^{-1}\nu\nabla\mathrm{div}\,\mathbf{u} + \mu^{-1}\rho_0(\mathbf{u}_0 \cdot \nabla)\mathbf{u} + \nabla\sigma = \mu^{-1}\mathbf{F}(\mathbf{w}, \mu\pi) \quad \text{in } \Omega, \\ \kappa_0\mathrm{div}\,\mathbf{u} + \mu(U\sigma_x + V\sigma_y) = G(\mathbf{w}, \mu\pi) \quad \text{in } \Omega, \\ \mathbf{u} = 0 \quad \text{on } \partial\Omega, \\ \sigma = 0 \quad \text{on } \Gamma_{\mathrm{in}}, \end{cases} \tag{2.30}$$

where $U = w_1 + u_0$ and $V = w_2$.

The existence of the solution $(\mathbf{u}, \sigma)$ of (2.30) is guaranteed by Theorem 2.1. For fixed $\mathbf{f}$ and g, define the map $T : (\mathbf{w}, \pi) \longrightarrow (\mathbf{F}(\mathbf{w}, \mu\pi), G(\mathbf{w}, \mu\pi)) \longrightarrow (\mathbf{u}, \sigma)$, where $(\mathbf{u}, \sigma)$ is the solution of (2.30). We want to prove that the map T is a contraction in some ball B in the topology of $H_0^{1,q} \times H^{0,q}$ if μ is sufficiently large or $\|\kappa_0\|_{1,q}$ is small enough. Choose a ball

$$B \equiv \{(\mathbf{w}, \pi) \in H_0^{2,q} \times H^{1,q} : \|\mathbf{w}\|_{2,q} + \|\pi\|_{1,q} \le A\}, \tag{2.31}$$

where $A \le 1$ will be chosen later.

Lemma 2.6. *Let the constants M and C be given in* (2.22) *and* (2.23)*, respectively. Assume that $\mu^{-1}M \le A/3C$ and $A \le 1/3C$. Then we have $T(B) \subset B$.*

Proof. Let $(\mathbf{w}, \pi) \in B$. Then $\|\mathbf{w}\|_{2,q} + \|\pi\|_{1,q} \le A$. Now from (2.23), we get

$$\begin{aligned}\|\mathbf{u}\|_{2,q} + \|\sigma\|_{1,q} &\le CA^2 + \frac{CM}{\mu}A + \frac{A}{3}\\ &\le \frac{A}{3} + \frac{A^2}{3} + \frac{A}{3}\\ &\le A.\end{aligned}$$

Thus the result follows. □

Remark. If A is small, and if μ is large enough or M is small enough, then we get Lemma 2.6. Thus Lemma 2.6 covers both cases.

Lemma 2.7. *Assume that M and $\|\kappa_0\|_{1,q}$ are small enough or μ is large enough. Then for fixed $\mathbf{f}$ and g, the map $T : B \longrightarrow B$ is a contraction in the topology of $H_0^{1,q} \times H^{0,q}$ if A is small.*

Proof. Consider $(\mathbf{u}, \sigma) = T(\mathbf{w}, \pi)$ and $(\mathbf{u}^*, \sigma^*) = T(\mathbf{w}^*, \pi^*)$ and set $\mathbf{F} = \mathbf{F}(\mathbf{w}, \mu\pi)$, $\mathbf{F}^* = \mathbf{F}(\mathbf{w}^*, \mu\pi^*)$, $G = G(\mathbf{w}, \mu\pi)$, and $G^* = G(\mathbf{w}^*, \mu\pi^*)$. Then from (2.30), we get

$$\begin{cases} -\Delta(\mathbf{u}-\mathbf{u}^*) - \mu^{-1}\nu\nabla\mathrm{div}(\mathbf{u}-\mathbf{u}^*) + \mu^{-1}\rho_0(\mathbf{u}_0\cdot\nabla)(\mathbf{u}-\mathbf{u}^*)\\ \qquad\qquad + \nabla(\sigma-\sigma^*) = \mu^{-1}(\mathbf{F}-\mathbf{F}^*) \quad \text{in } \Omega,\\ (\mathbf{w}^*+\mathbf{u}_0)\cdot\nabla(\sigma-\sigma^*)\\ \qquad = \mu^{-1}[G-G^*-\kappa_0\mathrm{div}(\mathbf{u}-\mathbf{u}^*)] - \mu^{-1}(\mathbf{w}-\mathbf{w}^*)\cdot\nabla p \quad \text{in } \Omega,\\ \mathbf{u}-\mathbf{u}^* = 0 \quad \text{on } \partial\Omega,\\ \sigma-\sigma^* = 0 \quad \text{on } \Gamma_{\text{in}}. \end{cases} \tag{2.32}$$

Let h be the solution of

$$\begin{aligned} h_x(x,\bar{y}) &= U^{*-1}V^*(x, h(x,\bar{y})),\\ h(\delta_-(\bar{y}),\bar{y}) &= \bar{y}. \end{aligned} \tag{2.33}$$

Applying the same procedures as in (2.3), (2.4), (2.5), and (2.8) to the continuity equation above, we can get

$$(\sigma-\sigma^*)(x,y) = \int_{\delta_-(\varphi(x,y))}^{x} B(s, h(s,\varphi(x,y)))ds, \tag{2.34}$$

where $B \equiv \mu^{-1}U^{*-1}[(G-G^*) - \kappa_0\mathrm{div}(\mathbf{u}-\mathbf{u}^*) - (\mathbf{w}-\mathbf{w}^*)\cdot\nabla p]$, $U^* = w_1^* + u_0$. However,

$$\begin{aligned}\mu^{-1}(\mathbf{F}-\mathbf{F}^*) = &-\rho'(\xi)[(\mathbf{w}\cdot\nabla)\mathbf{w} + (\mathbf{w}\cdot\nabla)\mathbf{u}_0](\pi-\pi^*)\\ &+ \rho\mu^{-1}\{[(\mathbf{w}-\mathbf{w}^*)\cdot\nabla]\mathbf{w} + (\mathbf{w}^*\cdot\nabla)(\mathbf{w}-\mathbf{w}^*) + [(\mathbf{w}-\mathbf{w}^*)\cdot\nabla]\mathbf{u}_0\}\\ &- [\bar{\rho}'(\xi)\eta(\mathbf{u}_0\cdot\nabla)\mathbf{w} + \bar{\rho}(\mathbf{u}_0\cdot\nabla)\mathbf{w}](\pi-\pi^*) - \bar{\rho}\pi^*(\mathbf{u}_0\cdot\nabla)(\mathbf{w}-\mathbf{w}^*),\end{aligned}$$

where we used the mean-value property for ρ and $\bar{\rho}$ and where ξ is between π and π^*. Hence

$$\begin{aligned}\|\mu^{-1}(\mathbf{F}-\mathbf{F}^*)\|_{0,q} &\leq C(\|\mathbf{w}\|_{2,q}^2+\|\mathbf{w}\|_{2,q}\|\eta\|_{1,q}\\ &\quad+\|\mathbf{w}\|_{2,q}+|\nabla\mathbf{u}_0|_{0,\infty}\|\mathbf{w}\|_{2,q})\|\pi-\pi^*\|_{0,q}\\ &\quad+C(\|\mathbf{w}\|_{2,q}+\|\mathbf{w}^*\|_{1,q}+\|\pi^*\|_{1,q}+\mu^{-1}|\nabla\mathbf{u}_0|_{\infty})\|\mathbf{w}-\mathbf{w}^*\|_{1,q}\\ &\leq CA(\|\mathbf{w}-\mathbf{w}^*\|_{1,q}+\|\pi-\pi^*\|_{0,q}) \quad \text{if } \mu^{-1}M\leq A, \end{aligned} \tag{2.35}$$

where $C = C(A,\mu,|\rho'|_{\infty},|\bar{\rho}|_{1,\infty})$ and $M = \|\nabla\mathbf{u}_0\|_{1,q}+\|\nabla p_0\|_{1,q}$. Next, setting $\tau^* = \tau(\eta^*+p_0)$,

$$\begin{aligned}\mu^{-1}(G-G^*) &= -\mu^{-1}[\tau\eta\mathrm{div}\,\mathbf{w}-\tau^*\eta^*\mathrm{div}\mathbf{w}^*+(\mathbf{w}-\mathbf{w}^*)\cdot\nabla p_0]\\ &= -[\tau(\eta+p_0)+\tau'(\xi)\eta^*](\pi-\pi^*)\mathrm{div}\,\mathbf{w}-[\tau\pi^*\mathrm{div}(\mathbf{w}-\mathbf{w}^*)\\ &\qquad+\mu^{-1}(\mathbf{w}-\mathbf{w}^*)\cdot\nabla p_0]. \end{aligned} \tag{2.36}$$

Now

$$\begin{aligned}\|\sigma-\sigma^*\|_{0,q} &\leq C\|B\|_{0,q}\\ &\leq C\left(\left\|\frac{G-G^*}{\mu}\right\|_{0,q}+\frac{|\kappa_0|_{\infty}}{\mu}\|\mathrm{div}(\mathbf{u}-\mathbf{u}^*)\|_{0,q}+\mu^{-1}|\mathbf{w}-\mathbf{w}^*|_{\infty}\|\nabla p\|_{0,q}\right)\\ &\leq C\left(\left\|\frac{G-G^*}{\mu}\right\|_{0,q}+\frac{\|\kappa_0\|_{1,q}}{\mu}\|\mathbf{u}-\mathbf{u}^*\|_{1,q}+\mu^{-1}\|\mathbf{w}-\mathbf{w}^*\|_{1,q}\|\nabla p\|_{0,q}\right), \end{aligned}$$

where we used the Sobolev embedding $H^{1,q}\subseteq C^0$ and $C = C(\Omega, C_0, A)$. From Lemma 2.6, we get $\mu^{-1}\|\nabla p\|_{0,q}\leq A$, and using (2.36),

$$\|\mu^{-1}(G-G^*)\|_{0,q}\leq C|\mathrm{div}\,\mathbf{w}|_{\infty}\|\pi-\pi^*\|_{0,q}+C(\|\pi^*\|_{1,q}+\mu^{-1}\|\nabla p_0\|_{1,q})\|\mathbf{w}-\mathbf{w}^*\|_{1,q},$$

where $C = C(\mu,|\tau|_{1,\infty},A,|\kappa|_{\infty})$. Thus if $\mu^{-1}M\leq A$ and $|\mathrm{div}\,\mathbf{w}|_{\infty}\leq CA$,

$$\begin{aligned}\|\sigma-\sigma^*\|_{0,q} &\leq C\mu^{-1}\|\kappa_0\|_{1,q}\|\mathbf{u}-\mathbf{u}^*\|_{1,q}\\ &\quad+CA(\|\mathbf{w}-\mathbf{w}^*\|_{1,q}+\|\pi-\pi^*|_{0,q}), \end{aligned} \tag{2.37}$$

where $C = C(\Omega, C_0, A, |\tau|_{1,\infty}, |\kappa|_{\infty})$. From the momentum equation, standard elliptic theory, Lemma 2.4, (2.35), (2.37), and the assumption that μ is large or $\|\kappa_0\|_{1,q}$ is small enough, we get

$$\begin{aligned}\|\mathbf{u}-\mathbf{u}^*\|_{1,q} &\leq C(\|\nabla(\sigma-\sigma^*)\|_{-1,q}+\|\mu^{-1}(\mathbf{F}-\mathbf{F}^*)\|_{0,q})\\ &\leq C(\|\sigma-\sigma^*\|_{0,q}+\|\mu^{-1}(\mathbf{F}-\mathbf{F}^*)\|_{0,q})\\ &\leq CA(\|\mathbf{w}-\mathbf{w}^*\|_{1,q}+\|\pi-\pi^*\|_{0,q}), \end{aligned} \tag{2.38}$$

where $C = C(\Omega, C_0, A, |\tau|_{1,\infty}, |\kappa|_{\infty})$. Combining (2.37) and (2.38), we get

$$\|\mathbf{u}-\mathbf{u}^*\|_{1,q}+\|\sigma-\sigma^*\|_{0,q}\leq CA(\|\mathbf{w}-\mathbf{w}^*\|_{1,q}+\|\pi-\pi^*|_{0,q}), \tag{2.39}$$

where C depends on the same quantity as in (2.38). Hence if $A\leq 1/2C$, we get the inequality

$$\|\mathbf{u}-\mathbf{u}^*\|_{1,q}+\|\sigma-\sigma^*\|_{0,q}\leq \frac{1}{2}(\|\mathbf{w}-\mathbf{w}^*\|_{1,q}+\|\sigma-\sigma^*\|_{0,q}). \tag{2.40}$$

This means that $T : B \longrightarrow B$, defined by $T(\mathbf{w}, \pi) = (\mathbf{u}, \sigma)$, is a contraction in the topology of $H^{1,q} \times H^{0,q}$. $\square$

Recall that $\mathbf{u} = \bar{\mathbf{u}} = \mathbf{u} - \mathbf{u}_0$ and $p = \bar{p} = p - p_0$. Combining all of the previous lemma series and theorems, we obtain a result for the existence and regularity of the solution $(\mathbf{u}, p)$ for problem (1.1) in the case of large viscosity.

THEOREM 2.2. *Suppose that* $\mathbf{u}_0 \in H^{2,q}(\Omega)$, $p_0 \in H^{1,q}(\Omega)$. *Then there is a constant* μ^* *depending on* $\|\mathbf{u}_0\|_{2,q} + \|p_0\|_{1,q}$ *such that if* $\mu \geq \mu^*$, *then problem* (1.16) *has a unique solution* $(u, v, p) \in H^{2,q} \times H^{2,q} \times H^{1,q}$ *with the following estimate:*

$$\|u - u_0\|_{2,q} + \|v\|_{2,q} + \|\sigma - \sigma_0\|_{1,q} \leq C_1, \tag{2.41}$$

where $C_1 = C(\Omega, \mu, \nu, \mu^*, C_0, |\kappa_0|_{1,\infty}, |\tau|_{1,\infty}, |\rho|_\infty, |\bar{\rho}|_\infty)$, $\sigma = \mu^{-1}p$, *and* $\sigma_0 = \mu^{-1}p_0$.

Proof. The ball B defined by (2.31) is a compact convex subset of $H_0^{1,q} \times H^{0,q}$. From Lemma 2.6, $T(B) \subset B$. From Lemma 2.7, the map T is continuous from B to $H_0^{1,q} \times H^{0,q}$. Since the continuous image of a compact set is compact, $T(B)$ is compact in $H_0^{1,q} \times H^{0,q}$. Hence by the Schauder fixed-point theorem, there is a unique $(\mathbf{u}, \sigma) \in B$ with $T(\mathbf{u}, \sigma) = (\mathbf{u}, \sigma)$. Now we combine the previous lemma series and theorems to get our main result. Let $(\mathbf{w}, \pi) \in B$, defined by (2.31). Then $\|\mathbf{w}\|_{2,q} + \|\pi\|_{1,q} \leq A$ and the constant C in (2.23) becomes $C = C(\Omega, \mu, \nu, A, \|\mathbf{u}_0\|_{2,q}, C_0, |\kappa_0|_{1,\infty}, |\tau|_{1,\infty}, |\rho|_\infty, |\bar{\rho}|_\infty)$. Let us denote this constant by C_3. However, the map T has a unique fixed point $(\mathbf{u}, \sigma) \in B$ with $\mathbf{u} = \mathbf{w}$ and $\sigma = \pi$. Therefore, if $\mathbf{u}_0 \in H^{2,q}$, $p_0 \in H^{1,q}$, $3C_3M/A \leq \mu^* \leq \mu$, and $\mu^{-1}C_3M \leq 1/3$, then using (2.23), the solution $(\mathbf{u}, \sigma)$ of system (1.16) satisfies the following inequality:

$$\|\mathbf{u}\|_{2,q} + \|\sigma\|_{1,q} \leq C_1, \tag{2.42}$$

where $C_1 = C(\Omega, \mu, \nu, \mu^*, C_0, |\kappa_0|_{1,\infty}, |\tau|_{1,\infty}, |\rho|_\infty, |\bar{\rho}|_\infty)$. $\square$

In Theorem 2.2, we have found the solution $(\mathbf{u}, p)$ of the nonlinear system (1.16) with the condition $\mu =$ large. This means that the Reynolds number is small and so the flows in this domain are laminar flows. The flows have a small perturbation around the ambient flows.

Next, combining the lemmas and theorems above, we obtain a result for the existence and regularity of the solution $(\mathbf{u}, p)$ of problem (1.1) in the case of nearly constant ambient flow.

THEOREM 2.3. *Let* $\mathbf{u}_0 \in H^{2,q}(\Omega)$, $p_0 \in H^{1,q}(\Omega)$, *and* $2 < q < 3$. *For any constant* C_1, *there is a constant* C_2 *such that if* $\|\mathbf{u}_0\|_{2,q} + \|p_0\|_{1,q} \leq C_1$ *and* $\|\nabla \mathbf{u}_0\|_{1,q} + \|\nabla p_0\|_{1,q} \leq C_2$, *then there is a unique solution* $(u, v, p) \in H_0^{2,q} \times H_0^{2,q} \times H^{1,q}$ *of system* (1.1) *with the following estimate:*

$$\|u - u_0\|_{2,q} + \|v\|_{2,q} + \|p - p_0\|_{1,q} \leq C_3, \tag{2.43}$$

where $C_3 = C(\Omega, \mu, \nu, C_0, C_1, C_2, |\rho|_\infty, |\bar{\rho}|_\infty, |\tau|_{1,\infty})$.

Proof. The existence of the solution (u, v, p) of (1.1) easily follows from the similar procedures in the proof of Theorem 2.2. Furthermore, inequality (2.43) can be obtained by using the same methods in the proof of Theorem 2.2. $\square$

THE RIEMANN PROBLEM FOR AN INHOMOGENEOUS CONSERVATION LAW WITHOUT CONVEXITY*

CARLO SINESTRARI†

Abstract. The paper studies the Riemann problem for a conservation law with a source term and a nonconvex flux-function. The complete solution is provided in the case when the flux has one inflection point and the Riemann states are stationary states of the source term. For small times, the structure of the solutions is similar to the homogeneous case. As the time increases, the size of the shocks may decrease under the action of the source, while rarefaction waves tend to traveling waves. It is also proved that if the flux has more than one inflection point, there may be shocks vanishing in finite time, in contrast to the case when the flux is convex.

Key words. hyperbolic conservation laws, source term, Riemann problem, entropy solutions, extinction of shocks

1. Introduction.

Equations of the form

$$\partial_t u(x,t) + \partial_x f(u(x,t)) = g(x,u(x,t)), \quad x \in \mathbb{R}, \quad t \geq 0, \tag{1.1}$$

are usually called *conservation laws with source* or *inhomogeneous conservation laws* and arise in various physical applications. For example, the case $g(x,u) = c(x)h(u)$ with $h, h' \neq 0$ and c with compact support was considered by Liu and Li [13], [12] as a model for transonic nozzle flow. Also, the equation

$$\partial_t u + h(u)\partial_x u = h_0 - h(u),$$

with h a cubic polinomial and h_0 a constant, was studied by some authors (e.g., Knight and Peterson [9], Murray [17], and Bonilla [2]) as a model for the so-called Gunn effect in semiconductor physics. The interesting feature of the behavior of the solutions in these cases is the appearance of new types of asymptotic states that are different from the shock, rarefaction, and N-waves which are familiar from the case where $g = 0$ (see, e.g., [11]). For instance, in the study of nozzle flow, there appears a new family of stationary waves connecting two states at $x = \pm\infty$.

In a different direction, several researchers, including Dafermos [4], Natalini and Tesei [18], Lyberopoulos [14], [16], Fan and Hale [6], [7], and the author [20], [21], have investigated the properties of (1.1) as a general equation without referring to a specific physical application, the goal being to catalog, at least for the case where $g = g(u)$, the possible structure and asymptotic profiles of solutions. All these papers concern the case of a convex f.

In contrast, the case of a nonconvex f has been considered only in the above-mentioned papers [12], [9], [17], and [2], which deal with particular models, and in the study by Lyberopoulos [15] of periodic solutions in the presence of a linear source. Thus we are still far from having a complete description of the general case. This is

because the geometric structure of the solutions when f changes convexity is much more complicated due to the presence of contact discontinuities, and there is a larger variety of asymptotic states.

In this paper, we intend to provide another step toward the understanding of the properties of the solutions of (1.1) with a general nonconvex f and a nonlinear source term g depending on u alone. The analysis is focused on Riemann initial data

$$u(x,0) = \begin{cases} u_l, & x < 0, \\ \\ u_r, & x > 0. \end{cases} \tag{1.2}$$

The importance of Riemann problems is well known in the study of homogeneous conservation laws, $g = 0$. They admit self-similar solutions which represent the time asymptotic state of any reasonable data asymptotic to u_l and u_r at $x = \mp\infty$. When $g \neq 0$, there are also many reasons to study Riemann problems. First, although the solutions are no longer self-similar, it is still possible to compute them explicitly, and this shows how the source term affects the evolution of discontinuities. Moreover, we still expect a study of the asymptotic states of the Riemann data to provide useful information about the large-time behavior of more general solutions.

In the main part of the paper, we restrict ourselves to the case when u_l and u_r are consecutive simple zeros of g and f has exactly one inflection point between u_l and u_r. Of course, the case when u_l and u_r are zeros of g is the most relevant for the study of the asymptotic behavior because for general Riemann data, the left and right state of the solution converge to stationary states of the source term. We explicitly construct the solution of problem (1.1)–(1.2). Our techniques are partly similar to those used by Ballou in [1] to find solutions to homogeneous conservation laws with piecewise-constant initial data. The results can be roughly described as follows. The solution is piecewise smooth, and for small times, it is close to the solution of the homogeneous problem. As time increases, the amplitude of the shock waves may decrease under the action of the source term, and in some cases, it tends to zero. On the other hand, rarefaction waves evolve and converge to traveling waves. Thus the asymptotic profile of the solution is given by a traveling wave, in some cases discontinuous, and can be found by solving a first-order ordinary differential equation. The statements about the asymptotic behavior are given in section 2, while the construction of the solution is done in sections 4 and 5.

Cases when f has a finite number of inflection points and g has a finite number of simple zeros could be handled by the same techniques; the results would be similar and we would again find an asymptotic state given by a superposition of shock waves and traveling waves. However, there is an interesting behavior arising when f has more than one inflection point, namely the extinction of a shock wave in finite time. Such a behavior is analyzed in the last section of the paper. It is shown that the solution of (1.1)–(1.2) may be discontinuous up to a certain time $T^* > 0$ and then become continuous. Such a property was never observed before for solutions of equation (1.1) and is the opposite of what one usually expects for this type of equation, namely the breakdown of classical solutions and the appearance of discontinuities. In this case, a crucial role is played by the source as well as the nonconvexity of f. In fact, if f is convex (see [3]) or if f has one inflection point and $g \equiv 0$ (see [5]), it has been proved that shock waves cannot vanish in finite time, and so the solution can no longer be regular after the formation of singularities.

The results above suggest what the behavior of solutions would be in more general cases. Assume, for instance, that the initial value u_0 is equal to u_l and u_r for $x < -L$

and $x > L$, respectively, and that it is equal to some function of bounded variation in $[-L, L]$. Then we still expect the solution to converge to a superposition of possibly discontinuous traveling waves. This supposition is supported by the results in the convex case (see [21]), where the solutions corresponding to initial data with compact support exhibit a behavior of this kind. Also, a similar property has been obtained in [12] and [13] in the case of nozzle flow. There the asymptotic states are given by a superposition of rarefaction, shock, and stationary waves; this is because the source term has compact support with respect to the x variable and thus the solutions behave as in the homogeneous case outside a compact interval.

2. Statement of the main results. Let us set $u_m := \min\{u_l, u_r\}$, $u_M := \max\{u_l, u_r\}$. In sections 4 and 5, we find the solution of the Cauchy problem (1.1)–(1.2) under the following assumptions.

(H1) $f \in C^2([u_m, u_M])$ and $g \in C^1([u_m, u_M])$.

(H2) There exists $\bar{u} \in \,]u_m, u_M[$ such that

$$f''(u) < 0 \quad \text{for } u \in \,]u_m, \bar{u}[\,,$$

$$f''(u) > 0 \quad \text{for } u \in \,]\bar{u}, u_M[\,.$$

(H3) $g(u_m) = g(u_M) = 0$, $g(u) > 0$ for $u \in \,]u_m, u_M[$, $g'(u_m) \neq 0$, and $g'(u_M) \neq 0$.

The case when f is convex in $[u_m, \bar{u}]$ and concave in $[\bar{u}, u_M]$ can be reduced to our case by taking $-x$ instead of x as spatial coordinate. Similarly, if g is negative in $]u_m, u_M[$, we can take $-u$ as unknown function. In order to exclude trivial cases, we also assume the following.

(H4) The shock wave connecting u_l and u_r does not satisfy the entropy admissibility criterion (see [19]), i.e.,

$$\frac{f(u_l) - f(u_r)}{u_l - u_r} < f'(u_r).$$

The full expression of the solution is lengthy, but its asymptotic state can be found in a simple way. In fact, it turns out that the solution is asymptotic to a possibly discontinuous traveling-wave solution of (1.1). We first give the result in the case where $u_l < u_r$.

Theorem 2.1. *Assume that hypotheses* (H1)–(H4) *hold and that $u_l < u_r$. Let $\hat{v}$ be the unique value in $]\bar{u}, u_r[$ such that*

$$f'(\hat{v}) = \frac{f(u_l) - f(\hat{v})}{u_l - \hat{v}}$$

and let $\phi : [0, \infty[\,\to [\hat{v}, u_r[$ be defined by

$$\int_{\hat{v}}^{\phi(\xi)} \frac{f'(v) - f'(\hat{v})}{g(v)}\, dv = \xi \quad \textit{for } \xi \geq 0.$$

Then the solution of problem (1.1)–(1.2) *satisfies*

$$u(x,t) = \begin{cases} u_l, & x < f'(\hat{v})t, \\ \phi(x - f'(\hat{v})t) + o(1), & x > f'(\hat{v})t. \end{cases}$$

Here and in the following, we denote by $o(1)$ an error term converging to zero as $t \to \infty$ uniformly in x. Observe that ϕ solves the ordinary differential problem

$$\begin{cases} \phi'(\xi) = \dfrac{g(\phi(\xi))}{f'(\phi(\xi)) - f'(\hat{v})}, & \xi > 0, \\ \lim\limits_{\xi \to 0^+} \phi(\xi) = \hat{v}, \end{cases}$$

and so $\phi(x - f'(\hat{v})t)$ is a traveling-wave solution of equation (1.1).

For the reader's convenience, we recall the results in the homogeneous case (see [8]).

THEOREM 2.2. *Assume that hypotheses* (H1), (H2), *and* (H4) *hold, that* $g \equiv 0$, *and that* $u_l < u_r$. *Then the solution of problem* (1.1)–(1.2) *is*

$$u(x,t) = \begin{cases} u_l, & x < f'(\hat{v})t, \\ h\left(\dfrac{x}{t}\right), & f'(\hat{v})t < x \leq f'(u_r)t, \\ u_r, & x > f'(u_r)t, \end{cases}$$

where $\hat{v}$ *is defined as in Theorem* 2.1 *and* $h : [f'(\hat{v}), f'(u_r)] \to [\hat{v}, u_r]$ *is the inverse of* f'.

Thus in the homogeneous case, the solution is given by a shock wave connecting u_l and $\hat{v}$ and a rarefaction wave connecting $\hat{v}$ and v_r. In the presence of the source term, the rarefaction wave asymptotically becomes a traveling wave, while the size of the shock wave remains unchanged.

Let us now turn to the case $u_l > u_r$.

THEOREM 2.3. *Assume that hypotheses* (H1)–(H4) *hold and that* $u_l > u_r$. *Let* u *be the solution of problem* (1.1)–(1.2).

(i) *Suppose* $f'(u_l) = f'(u_r)$. *Let*

$$L = \int_{u_r}^{u_l} \frac{f'(u_r) - f'(v)}{g(v)} \, dv$$

and let $\psi : [-L, 0] \to [u_r, u_l]$ *be defined by*

$$\int_{u_r}^{\psi(\xi)} \frac{f'(v) - f'(u_r)}{g(v)} \, dv = \xi \tag{2.1}$$

for $\xi \in [-L, 0]$. *Then*

$$u(x,t) = \begin{cases} u_l, & x < f'(u_r)t - L, \\ \psi(x - f'(u_r)t) + o(1), & f'(u_r)t - L \leq x \leq f'(u_r)t, \\ u_r, & x > f'(u_r)t. \end{cases}$$

(ii) *Suppose* $f'(u_l) > f'(u_r)$. *Denote by* $\bar{w}$ *the unique value in* $]\bar{u}, u_l[$ *which satisfies*

$$\frac{f(u_l) - f(\bar{w})}{u_l - \bar{w}} = f'(u_r)$$

and set

$$L = \int_{u_r}^{\bar{w}} \frac{f'(u_r) - f'(v)}{g(v)}\, dv.$$

Let $\psi : [-L, 0] \to [u_r, \bar{w}]$ *be defined by* (2.1) *for all* $\xi \in [-L, 0]$. *Then there exists a function* $\gamma : [0, \infty[\ \to \mathrm{I\!R}$ *such that*

$$\lim_{t\to\infty} \gamma(t) - f'(u_r)t = -L, \qquad \lim_{t\to\infty} \gamma'(t) = f'(u_r),$$

$$u(x,t) = \begin{cases} u_l, & x < \gamma(t), \\ \psi(x - f'(u_r)t) + o(1), & \gamma(t) < x \le f'(u_r)t, \\ u_r, & x > f'(u_r)t. \end{cases}$$

(iii) *Suppose* $f'(u_l) < f'(u_r)$. *Let* $\psi :]-\infty, 0] \to [u_r, u_l[$ *be defined by equality* (2.1) *for all* $\xi \le 0$. *Then*

$$u(x,t) = \begin{cases} \psi(x - f'(u_r)t) + o(1), & x \le f'(u_r)t, \\ u_r, & x > f'(u_r)t. \end{cases}$$

In the homogeneous case, there is the following result (see [8]).

THEOREM 2.4. *Suppose that assumptions* (H1), (H2), *and* (H4) *hold, that* $g \equiv 0$, *and that* $u_l > u_r$. *Then the solution of problem* (1.1)–(1.2) *is*

$$u(x,t) = \begin{cases} u_l, & x < f'(\hat{w})t, \\ j\left(\dfrac{x}{t}\right), & f'(\hat{w})t < x \le f'(u_r)t, \\ u_r, & x > f'(u_r)t, \end{cases}$$

where $\hat{w} \in\ ]u_r, \hat{u}[$ *is the unique value satisfying*

$$f'(\hat{w}) = \frac{f(u_l) - f(\hat{w})}{u_l - \hat{w}}$$

and $j : [f'(\hat{w}), f'(u_r)] \to [u_r, \hat{w}]$ *is the inverse of* f'.

If we look back at Theorem 2.3, we do not find in the asymptotic profile of the solution the shock wave $x = f'(\hat{w})t$ connecting the states u_l and $\hat{w}$, which appears in the homogeneous case. In section 5, we will see that if $g \neq 0$, there is still a shock wave connecting initially the states u_l and $\hat{w}$, but its amplitude decreases with time. The left state remains u_l, but the right state increases monotonically and tends to $\bar{w}$ in case (ii) and to u_l in cases (i) and (iii). Thus in cases (i) and (iii), the amplitude of the shock tends to zero and the asymptotic profile of the solution is continuous. Like the function ϕ of the case where $u_l > u_r$, the function ψ of Theorem 2.3 solves the differential equation which yields the traveling-wave solutions of (1.1).

In section 6, we consider a case where f has two inflection points, and we show that the solution has a shock which vanishes in finite time, as mentioned in section 1. The result that we obtain is the following.

Theorem 2.5. *Let assumptions* (H1) *and* (H3) *hold. Suppose, in addition, that* $u_l < u_r$ *and that* f *satisfies the following properties.*

(H5) *There exist* $\bar{u}_1$ *and* $\bar{u}_2$ *such that*

$$f''(u) > 0 \quad \textit{for } u \in \,]u_l, \bar{u}_1[\,,$$

$$f''(u) < 0 \quad \textit{for } u \in \,]\bar{u}_1, \bar{u}_2[\,,$$

$$f''(u) > 0 \quad \textit{for } u \in \,]\bar{u}_2, u_r[\,.$$

(H6) *There exist* $\hat{v}_1 \in \,]u_l, \bar{u}_1[$ *and* $\hat{v}_2 \in \,]\bar{u}_2, u_r[$ *such that*

$$f'(\hat{v}_1) = f'(\hat{v}_2) = \frac{f(\hat{v}_2) - f(\hat{v}_1)}{\hat{v}_2 - \hat{v}_1}.$$

(H7) $f'(u_l) < f'(\bar{u}_2)$.

Then the solution of problem (1.1)–(1.2) *has the following property: there exists* $T^* > 0$ *such that* $u(\cdot, t)$ *is discontinuous for any* $t < T^*$*, while it is continuous for any* $t > T^*$.

Example. Let us define $u_l = -2$, $u_r = 2$, $f(u) = (u^2 - 1)^2$, and $g(u) = 4 - u^2$. Then the assumptions of Theorem 2.5 are satisfied with

$$\bar{u}_1 = -\frac{1}{\sqrt{3}}, \qquad \bar{u}_2 = \frac{1}{\sqrt{3}}, \qquad \hat{v}_1 = -1, \qquad \hat{v}_2 = 1.$$

3. Preliminaries. It is well known (see, for instance, [10]) that under our assumptions, problem (1.1)–(1.2) possesses a unique solution in the class of the so-called *entropy solutions*, taking values in $[u_m, u_M]$. For our purposes, is enough to recall the following characterization of piecewise-smooth entropy solutions (see [8]). It is convenient to use the notation

$$\sigma(u,v) = \begin{cases} \dfrac{f(u) - f(v)}{u - v} & \text{if } u \neq v, \\[2ex] f'(u) & \text{if } u = v \end{cases} \tag{3.1}$$

for $u, v \in [u_m, u_M]$.

Theorem 3.1. *Suppose that* $u : \mathbb{R} \times \mathbb{R}_+ \to \mathbb{R}$ *is of class* C^1 *in the complement of a finite number of smooth curves* $x = \gamma_1(t), \ldots, x = \gamma_k(t)$ *which intersect themselves at most at a finite number of points, and suppose that the one-sided limits of* u *exist along* $\gamma_1, \ldots, \gamma_k$. *Then* u *is an entropy solution of problem* (1.1)–(1.2) *if and only if the following hold.*

(i) *Equalities* (1.1) *and* (1.2) *are satisfied in the classical sense in the complement of the curves* γ_i.

(ii) *Along each curve* γ_i*, the function* u *satisfies the* Rankine–Hugoniot jump condition

$$\gamma_i'(t)[u_l(t) - u_r(t)] = [f(u_l(t)) - f(u_r(t))] \quad \forall\, t > 0 \tag{3.2}$$

and the Oleinik admissibility condition

$$\begin{gathered} \sigma(u_l(t), v) \geq \sigma(u_l(t), u_r(t)) \geq \sigma(u_r(t), v) \\ \forall\, t > 0, \quad \forall\, v \in [\min\{u_l(t), u_r(t)\}, \max\{u_l(t), u_r(t)\}]. \end{gathered} \tag{3.3}$$

Here we have set

$$u_l(t) = \lim_{x \to \gamma_i(t)^-} u(x,t),$$

$$u_r(t) = \lim_{x \to \gamma_i(t)^+} u(x,t).$$

Remark 3.2. The two inequalities in (3.3) are equivalent since $\sigma(u_l(t), u_r(t))$ is a convex combination of $\sigma(u_l(t), v)$ and $\sigma(u_r(t), v)$.

To find the entropy solution of problem (1.1)–(1.2), we will construct suitable piecewise-smooth functions and then check that they satisfy conditions (i) and (ii) of Theorem 3.1. To this end, it is useful to introduce some auxiliary functions.

Definition 3.3. *For any $v \in [u_m, u_M]$, let $W(v,\cdot)$ denote the solution of*

$$\begin{cases} \partial_t W(v,t) = g(W(v,t)), \quad t \in \mathbb{R}, \\ W(v,0) = v. \end{cases} \tag{3.4}$$

For $v \in [u_m, u_M]$ and $t \geq 0$, let us also set

$$F_+(v,t) = \int_0^t f'(W(v,s))\,ds, \tag{3.5}$$

$$F(v,t) = \int_0^t f'(W(v,-s))\,ds. \tag{3.6}$$

The following result motivates the definition of W, F, and F_+ and collects some useful properties of such functions.

Lemma 3.4.

(i) *Given $u_o \in [u_m, u_M]$ and $x_o \in \mathbb{R}$, the functions*

$$\begin{cases} x(t) = x_o + F_+(u_o, t), \\ u(t) = W(u_o, t), \end{cases} \qquad t \geq 0, \tag{3.7}$$

are the solution of the characteristic system *associated with equation* (1.1)*,*

$$\begin{cases} x'(t) = f'(u(t)), \\ u'(t) = g(u(t)) \end{cases} \tag{3.8}$$

with initial data $x(0) = x_o$, $u(0) = u_o$. Similarly, given $\bar{u} \in [u_m, u_M]$ and $(\bar{x}, \bar{t}) \in \mathbb{R} \times \mathbb{R}_+$, the functions

$$\begin{cases} x(t) = \bar{x} - F(\bar{u}, \bar{t} - t), \\ u(t) = W(\bar{u}, t - \bar{t}), \end{cases} \qquad t \in [0, \bar{t}], \tag{3.9}$$

are the solution of system (3.8) *with terminal conditions $x(\bar{t}) = \bar{x}$, $u(\bar{t}) = \bar{u}$.*

(ii) *If $v = u_l$ or $v = u_r$, then $W(v,t) \equiv v$ and $F_+(v,t) = F(v,t) = f'(v)t$.*

(iii) *If $v \neq u_l, u_r$, then $W(v,\cdot)$ is strictly increasing and F and F_+ satisfy*

$$F(v,t) = F_+(W(v,-t),t). \tag{3.10}$$

(iv) *F is of class C^1 and satisfies*

$$\partial_t F(v,t) = f'(W(v,-t)), \tag{3.11}$$

$$\partial_v F(v,t) = \frac{f'(v) - f'(W(v,-t))}{g(v)} \quad (v \neq u_l, u_r). \tag{3.12}$$

(v) *Let A be an open subset of $\mathbb{R} \times \mathbb{R}_+$, and let $\tilde{u} \in C^1(A)$ satisfy*

$$F(\tilde{u}(x,t),t) = x \quad \textit{for any } (x,t) \in A. \tag{3.13}$$

Then $\tilde{u}$ solves equation (1.1) *in A.*

Proof. Properties (i) to (iii) are easy consequences of the definition and of assumption (H3) as well as equality (3.11). Let us check (3.12). For $v \neq u_l, u_r$, we have

$$\begin{aligned}\partial_v W(v,t) &= \exp\left(\int_0^t g'(W(v,s))ds\right)\\ &= \exp\left(\int_v^{W(v,t)} \frac{g'(w)}{g(w)}dw\right) = \frac{g(W(v,t))}{g(v)},\end{aligned}$$

$$\begin{aligned}\partial_v F(v,t) &= \int_0^t f''(W(v,-s))\frac{g(W(v,-s))}{g(v)}\,ds\\ &= -\frac{1}{g(v)}\int_0^t \frac{d}{ds}f'(W(v,-s))ds\\ &= \frac{f'(v) - f'(W(v,-t))}{g(v)}.\end{aligned}$$

To verify that property (v) holds, let us first observe that by equalities (3.11) and (3.12),

$$\partial_t F(v,t) + g(v)\partial_v F(v,t) = f'(v). \tag{3.14}$$

Differentiating (3.13), we obtain

$$\partial_v F\,\partial_x \tilde{u} = 1, \qquad \partial_v F\,\partial_t \tilde{u} + \partial_t F = 0.$$

Thus

$$\begin{aligned}0 &= \partial_x \tilde{u}\,(\partial_v F\,\partial_t \tilde{u} + \partial_t F) = \partial_t \tilde{u} + \partial_x \tilde{u}\,\partial_t F\\ &= \partial_t \tilde{u} + f'(\tilde{u})\partial_x \tilde{u} - g(\tilde{u}). \qquad \square\end{aligned}$$

Remark 3.5. Some comments about equality (3.13) are in order. Since we are considering Riemann initial data with a discontinuity which is not entropy admissible, we expect the solution to exhibit a fan of characteristics starting from the origin. Let us therefore consider a solution $\tilde{u}$ of (1.1) and assume that the backward characteristic from a given point (x,t) ends up at the origin. By (3.9), the value $\tilde{u}(x,t)$ satisfies equality (3.13). Thus such an equality characterizes the solutions defined by a fan of characteristics centered at the origin.

This fact is well known for the case where $g \equiv 0$. In fact, defining the functions W and F as above, we obtain $W(v,t) = v$ and $F(v,t) = f'(v)t$. Therefore, (3.13) becomes

$$f'(\tilde{u}(x,t)) = \frac{x}{t},$$

which is the equality that characterizes the rarefaction waves centered at the origin. This equality is usually derived by exploiting the self-similarity of the Riemann problem under the transformation $(x,t) \to (\lambda x, \lambda t)$ for $\lambda > 0$ rather than the method of characteristics. Such rescaling arguments, however, cannot be applied to the general inhomogeneous case.

In the following sections, we will use equality (3.13) to define $\tilde{u}$. This is equivalent to finding the inverse of F with respect to the variable v. The problem is that $\partial_v F$ is not of constant sign by (3.12) and (H2). Therefore, equality (3.13) in general defines a multivalued function, and every time, we have to select the branch of $\tilde{u}$ which fits to our purposes. This is a major complication due to the nonconvexity of f when we want to study equation (1.1) with the method of characteristics. Let us also observe that in the homogeneous case, the values of v for which $\partial_v F(v,t) = 0$ are the zeros of f'' and do not depend on t. In our case, because of the presence of the source term, these values vary with time (and so do the restrictions to be imposed on the range of $\tilde{u}$ in order to obtain a single-valued function from (3.13)).

4. The case where $u_l < u_r$.

Throughout this section, we assume that properties (H1)–(H4) hold and that $u_l < u_r$.

LEMMA 4.1. *There exists a unique $\hat{v} \in \,]\bar{u}, u_r[$ such that*

$$f'(\hat{v}) = \sigma(u_l, \hat{v}). \tag{4.1}$$

Moreover, the function $v \to \sigma(u_l, v)$ is decreasing for $v \in [u_l, \hat{v}]$.

Proof. By assumptions (H2) and (H4), we have

$$f'(\bar{u}) < \sigma(u_l, \bar{u}), \qquad f'(u_r) > \sigma(u_l, u_r).$$

Therefore, $f'(v) = \sigma(u_l, v)$ for some $v \in \,]\bar{u}, u_r[$. Denote by $\hat{v}$ the smallest of the values satisfying this equality. Then for any $v > \hat{v}$,

$$\begin{aligned}\sigma(u_l, v) &= (v - u_l)^{-1}\left(\int_{u_l}^{\hat{v}} f'(w)dw + \int_{\hat{v}}^{v} f'(w)dw\right)\\ &= (v - u_l)^{-1}\left((\hat{v} - u_l)f'(\hat{v}) + \int_{\hat{v}}^{v} f'(w)dw\right) < f'(v)\end{aligned}$$

because, by (H2), f' is increasing in $[\bar{u}, u_r]$. It follows that there is a unique value that satisfies (4.1).

Differentiating σ, we obtain

$$\partial_v \sigma(u_l, v) = \frac{f'(v) - \sigma(u_l, v)}{v - u_l}.$$

Since we have $f'(v) < \sigma(u_l, v)$ for any $v \in \,]u_l, \hat{v}[\,$, we deduce that $\sigma(u_l, \cdot)$ is decreasing in $[u_l, \hat{v}]$. ☐

DEFINITION 4.2. *Let $\hat{v}$ be the value given by Lemma* 4.1.

(i) *For any (x, t) with $t > 0$ and $x \in [F_+(\hat{v}, t), f'(u_r)t]$, let $\tilde{u}(x, t) \in [W(\hat{v}, t), u_r]$ be defined by*

$$F(\tilde{u}(x, t), t) = x.$$

(ii) *Let $\phi : [0, \infty[\,\to [\hat{v}, u_r[$ be defined by*

$$\int_{\hat{v}}^{\phi(\xi)} \frac{f'(v) - f'(\hat{v})}{g(v)}\, dv = \xi \quad \textit{for } \xi \geq 0.$$

LEMMA 4.3.

(i) *$\tilde{u}$ is well defined, of class C^1, and solves equation* (1.1) *in the interior of its domain of definition.*

(ii) *ϕ is well defined, belongs to $C([0, \infty[\,) \cap C^2(\,]0, \infty[\,)$, and satisfies*

$$\begin{cases} \phi' = \dfrac{g(\phi)}{f'(\phi) - f'(\hat{v})} & \textit{in }]0, \infty[, \\[2ex] \phi(0) = \hat{v}. \end{cases} \tag{4.2}$$

(iii) *For any $t > 0$, we have*

$$\tilde{u}(F_+(\hat{v}, t), t) = \phi(F_+(\hat{v}, t) - f'(\hat{v})t) = W(\hat{v}, t),$$

$$\tilde{u}(f'(u_r)t, t) = u_r.$$

Proof. (i) Let us fix $t > 0$ and $v \in [W(\hat{v}, t), u_r]$. Then by assumption (H3) and the definition of W,

$$u_r \geq v > W(v, -t) \geq \hat{v}.$$

Since $\hat{v} > \bar{u}$ and f' is increasing in $[\bar{u}, u_r]$ by assumption (H2), we have

$$f'(v) > f'(W(v, -t)).$$

Therefore, by (3.12),

$$\partial_v F(v, t) > 0 \quad \forall\, v \in [W(\hat{v}, t), u_r[.$$

Since, by Lemma 3.4(ii)–(iii), $F(W(\hat{v}, t), t) = F_+(\hat{v}, t)$ and $F(u_r, t) = f'(u_r)t$, we obtain that $\tilde{u}$ is well defined, of class C^1, and satisfies

$$\tilde{u}(F_+(\hat{v}, t), t) = W(\hat{v}, t), \tag{4.3}$$

$$\tilde{u}(f'(u_r)t, t) = u_r. \tag{4.4}$$

Furthermore, by Lemma 3.4(v), $\tilde{u}$ satisfies equation (1.1).

(ii) It follows from the definition and from assumptions (H2) and (H3).

(iii) By Definition 3.3,

$$F_+(\hat{v},t) - f'(\hat{v})t = \int_0^t [f'(W(\hat{v},s)) - f'(\hat{v})]\,ds$$
$$= \int_{\hat{v}}^{W(\hat{v},t)} \frac{f'(w) - f'(\hat{v})}{g(w)}\,dw.$$

Therefore,

$$W(\hat{v},t) = \phi(F_+(\hat{v},t) - f'(\hat{v})t).$$

We conclude (4.4) from (4.3). □

Theorem 4.4. *Let assumptions* (H1)–(H4) *be satisfied and let* $u_l < u_r$. *Then the solution of problem* (1.1)–(1.2) *is*

$$(4.5)\qquad u(x,t) = \begin{cases} u_l, & x < f'(\hat{v})t, \\ \phi(x - f'(\hat{v})t), & f'(\hat{v})t < x < F_+(\hat{v},t), \\ \tilde{u}(x,t), & F_+(\hat{v},t) \le x \le f'(u_r)t, \\ u_r, & x > f'(u_r)t, \end{cases}$$

where $\hat{v}$, $\tilde{u}$, *and* ϕ *are defined as in Lemma* 4.1 *and Definition* 4.2.

Proof. It is easily checked that the function defined by (4.5) satisfies the hypotheses of Theorem 3.1. In fact, by Lemma 4.3(i)–(ii) and by assumption (H3), u is a classical solution of equation (1.1) in each of the four regions which appear in (4.5). By Lemma 4.3(iii), u is continuous along the curves $x = F_+(\hat{v},t)$ and $x = f'(u_r)t$. Finally, Lemma 4.1 implies that conditions (3.2) and (3.3) are satisfied along the line of discontinuity $x = f'(\hat{v})t$ (see also Remark 3.2). □

Proof of Theorem 2.1. Let us fix $t > 0$ and $x > F_+(\hat{v},t)$. By Lemma 4.3(iii),

$$u_r > \phi(x - f'(\hat{v})t) > \phi(F_+(\hat{v},t) - f'(\hat{v})t) = W(\hat{v},t).$$

On the other hand, by Theorem 4.4 and Definition 4.2,

$$u_r \ge u(x,t) \ge W(\hat{v},t).$$

It follows that

$$|u(x,t) - \phi(x - f'(\hat{v})t)| \le u_r - W(\hat{v},t) \quad \forall\, t > 0, \quad x > F_+(\hat{v},t).$$

Since, by assumption (H3), $W(\hat{v},t) \to u_r$ as $t \to \infty$, the conclusion follows. □

5. The case where $u_l > u_r$. Throughout this section, we assume that properties (H1)–(H4) hold and that $u_l > u_r$. The following result is analogous to Lemma 4.1.

Lemma 5.1. *There exists a unique* $\hat{w} \in \,]u_r, \bar{u}[$ *such that*

$$(5.1)\qquad f'(\hat{w}) = \sigma(\hat{w}, u_l).$$

Moreover, the function $v \to \sigma(v, u_l)$ *is increasing for* $v \in [\hat{w}, u_l]$.

As observed in Remark 3.5, it is useful to find the values for which $\partial_v F(v,t) = 0$. This is done in the next lemma.

LEMMA 5.2. *For fixed $t > 0$, there exists a unique value $v^* = v^*(t) \in \,]\bar{u}, u_l[$ such that*

$$f'(v^*) = f'(W(v^*, -t)). \tag{5.2}$$

The function $t \to v^*(t)$ is strictly increasing for $t > 0$ and satisfies

$$\lim_{t\to 0} v^*(t) = \bar{u}, \tag{5.3}$$

$$\lim_{t\to\infty} v^*(t) = \begin{cases} u_l & \text{if } f'(u_r) \geq f'(u_l), \\ \bar{v} & \text{if } f'(u_r) < f'(u_l), \end{cases} \tag{5.4}$$

where $\bar{v}$ is the unique value in $]u_r, u_l[$ satisfying $f'(\bar{v}) = f'(u_r)$. Moreover,

$$\text{sgn}\partial_v F(v,t) = \text{sgn}[v - v^*(t)] \tag{5.5}$$

for any $t > 0$ and $v \in \,]u_r, u_l[$.

Proof. Let us fix $t > 0$. Since g is positive, we have by (3.4) that $v > W(v, -t)$ for any $v \in \,]u_r, u_l[\,$. Using property (H2), we obtain that

$$f'(v) < f'(W(v,-t)) \quad \text{for any } v \in \,]u_r, \bar{u}], \tag{5.6}$$

$$f'(v) > f'(W(v,-t)) \quad \text{for any } v \in [W(\bar{u}, t), u_l[\,. \tag{5.7}$$

Therefore, there exists at least one value v^* for which equality (5.2) holds. Moreover, any such v^* satisfies

$$v^* \in \,]\bar{u}, W(\bar{u}, t)[, \quad W(v^*, -t) \in \,]W(\bar{u}, -t), \bar{u}[\,. \tag{5.8}$$

Since $f'(v)$ is decreasing for $v \in [W(\bar{u}, -t), \bar{u}]$ and increasing for $v \in [\bar{u}, W(\bar{u}, t)]$, the value v^* satisfying (5.2) is unique. From inequalities (5.6) and (5.7), it follows that

$$\text{sgn}[f'(v) - f'(W(v,-t))] = \text{sgn}[v - v^*]. \tag{5.9}$$

This implies (5.5) by Lemma 3.4(iv) and assumption (H3).

Let us now take $t_2 > t_1 > 0$. We have

$$W(v^*(t_1), -t_2) < W(v^*(t_1), -t_1) < \bar{u}.$$

Since $f'(v)$ is decreasing for $v \leq \bar{u}$, we obtain

$$f'(W(v^*(t_1), -t_2)) > f'(W(v^*(t_1), -t_1)) = f'(v^*(t_1)),$$

which implies by (5.9) that $v^*(t_2) > v^*(t_1)$. Hence v^* is strictly increasing. In a similar way, it is checked that $W(v^*(t), -t)$ is a decreasing function of t.

Property (5.3) follows from (5.8) since $W(\bar{u}, 0) = \bar{u}$. To prove (5.4), let us observe that by the definition of W,

$$\int_{W(v^*(t),-t)}^{v^*(t)} \frac{dv}{g(v)} = t. \tag{5.10}$$

Let us denote by v_∞ and w_∞ the limits of $v^*(t)$ and $W(v^*(t),-t)$ as $t \to \infty$. By relations (5.2), (5.8), and (5.10), these values satisfy

$$f'(w_\infty) = f'(v_\infty), \tag{5.11}$$

$$u_r \leq w_\infty < v_\infty \leq u_l, \tag{5.12}$$

$$\int_{w_\infty}^{v_\infty} \frac{dv}{g(v)} = \infty. \tag{5.13}$$

From (5.12) and (5.13), we deduce that either $w_\infty = u_r$ or $v_\infty = u_l$. Then equality (5.11) and assumption (H2) yield (5.4). ∎

Definition 5.3. *For any $t > 0$ and $x \in [F(v^*(t),t), f'(u_r)t]$, let $\tilde{u}(x,t) \in [u_r, v^*(t)]$ be defined by*

$$F(\tilde{u}(x,t),t) = x. \tag{5.14}$$

Remark 5.4. In this paper, we sometimes denote different functions with the same symbol because they play the same role in the problem that is being considered (in this case, the function $\tilde{u}$; see Definition 4.2). However, there is no ambiguity since each of these functions appears only in the section where it has been introduced.

Lemma 5.5. *$\tilde{u}$ is well defined. It is of class C^1 and satisfies equation* (1.1) *in the interior of its domain of definition. Furthermore,*

$$\tilde{u}(f'(u_r)t,t) = u_r \quad \forall\, t > 0. \tag{5.15}$$

Proof. By Lemma 3.4(ii), we have $F(u_r,t) = f'(u_r)t$. Equality (5.5) ensures that $F(\cdot,t)$ is strictly decreasing in $[u_r, v^*(t)]$. Therefore, $\tilde{u}$ is well defined and satisfies (5.15). From Lemma 3.4(v), it follows that $\tilde{u}$ solves equation (1.1). ∎

Lemma 5.6. *There exists $\gamma \in C^1([0,\infty[)$ with the following properties.*

$$\gamma(0) = 0, \qquad \gamma'(0) = f'(\hat{w}), \tag{5.16}$$

$$\gamma(t) \in \,]F(v^*(t),t), F(\hat{w},t)[\quad \forall t > 0, \tag{5.17}$$

$$\tilde{u}(\gamma(t),t) \in \,]\hat{w}, v^*(t)[\quad \forall t > 0, \tag{5.18}$$

$$\gamma'(t) = \sigma(\tilde{u}(\gamma(t),t), u_l) \quad \forall t > 0, \tag{5.19}$$

$$\tilde{u}(\gamma(\cdot),\cdot) \text{ is increasing in }]0,\infty[\,, \tag{5.20}$$

$$\lim_{t\to 0} \tilde{u}(\gamma(t),t) = \hat{w}, \tag{5.21}$$

$$\lim_{t\to\infty} \tilde{u}(\gamma(t),t) = \begin{cases} u_l & \text{if } f'(u_r) \geq f'(u_l), \\ \bar{w} & \text{if } f'(u_r) < f'(u_l), \end{cases} \tag{5.22}$$

where $\bar{w} \in]\hat{w}, u_l[$ *is the unique value satisfying* $f'(u_r) = \sigma(u_l, \bar{w})$.

Remark 5.7. In analogy with the homogeneous case (see Theorem 2.4), we want to show that the states u_l and u_r can be connected by a shock wave followed by a rarefaction wave. The shock curve is given by $x = \gamma(t)$, where γ is the function whose existence we are going to prove, while the rarefaction wave is given by the function $\tilde{u}$. According to condition (3.2), the speed of γ is given by (5.19). In order to stay within the domain of definition of $\tilde{u}$, we must have $\gamma(t) \geq F(v^*(t), t)$. On the other hand, we cannot have $\gamma(t) > F(\hat{w}, t)$; otherwise, $\tilde{u}(\gamma(t), t))$ would assume a value smaller than $\hat{w}$, which could not be connected to u_l by an admissible shock. This motivates the restrictions in (5.17). We also notice that by property (5.16), for small times, $\gamma(t)$ is close to $f'(\hat{w})t$, which is the position of the shock in the homogeneous case.

Proof of Lemma 5.6. To simplify notation, we set

$$\chi_1(t) = F(v^*(t), t),$$

$$\chi_2(t) = F(\hat{w}, t),$$

$$h(x, t) = \sigma(\tilde{u}(x, t), u_l).$$

We have to show that there exists $\gamma \in C^1([0, \infty[)$ such that $\chi_1(t) < \gamma(t) < \chi_2(t)$ for any $t > 0$ and

$$\begin{cases} \gamma'(t) = h(\gamma(t), t) \quad \forall\, t > 0, \\ \gamma(0) = 0. \end{cases} \tag{5.23}$$

Let us observe that by equalities (3.11), (3.12), (5.1), (5.2), and (5.14),

$$\chi_1'(t) = f'(v^*(t)), \qquad \chi_2'(t) = f'(W(\hat{w}, -t)), \tag{5.24}$$

$$h(\chi_1(t), t) = \sigma(v^*(t), u_l), \qquad h(\chi_2(t), t) = f'(\hat{w}). \tag{5.25}$$

We recall that by Lemmas 5.1 and 5.2,

$$u_r < \hat{w} < \bar{u} < v^*(t) < u_l \quad \forall\, t > 0.$$

From assumption (H2) and inequalities (5.24) and (5.25), we deduce

$$\chi_1'(t) < h(\chi_1(t), t), \qquad \chi_2'(t) > h(\chi_2(t), t) \quad \forall\, t > 0. \tag{5.26}$$

We now consider equation (5.23). Since $\chi_1(0) = \chi_2(0) = 0$ and h is not defined at $(0, 0)$, we will prove the existence of a solution by an approximation procedure. We first observe that by (5.24), (5.3), and (H2), we have

$$\chi_1'(t) < f'(\hat{w})$$

for t small. On the other hand, since $W(\hat{w}, \cdot)$ is increasing, we obtain by the same relations that

$$\chi_2'(t) > f'(\hat{w})$$

for any $t > 0$. It follows that for $n \in \mathbb{N}$ large enough,

$$\chi_1\left(\frac{1}{n}\right) < \frac{f'(\hat{w})}{n} < \chi_2\left(\frac{1}{n}\right).$$

Define γ_n to be the solution of

$$\begin{cases} \gamma_n'(t) = h(\gamma_n(t), t) & \text{for } t \geq \dfrac{1}{n} \\ \gamma_n\left(\dfrac{1}{n}\right) = \dfrac{f'(\hat{w})}{n}. \end{cases}$$

The inequalities in (5.26) show that γ_n is well defined for $t \in [1/n, \infty[$ and satisfies $\chi_1 < \gamma_n < \chi_2$. Since, by Lemma 5.1 and Definition 5.3,

$$h(x,t) > \sigma(\hat{w}, u_l) = f'(\hat{w}) \quad \forall\, x \in [\chi_1(t), \chi_2(t)[\,,$$

we also have

$$\gamma_n(t) > f'(\hat{w})t \quad \forall\, t > \frac{1}{n}.$$

It follows that

$$\max\{\chi_1(t), f'(\hat{w})t\} < \gamma_n(t) < \gamma_{n+1}(t) < \chi_2(t)$$

for any n, $t > 1/n$. Thus if we define

$$\gamma(t) = \begin{cases} \lim\limits_{n\to\infty} \gamma_n(t) & \text{if } t > 0, \\ 0 & \text{if } t = 0, \end{cases}$$

it is easily seen that γ satisfies (5.17) and (5.19). (The strict inequality in (5.17) follows from (5.26).) Property (5.18) is equivalent to (5.17) by Definition 5.3. We have also obtained that

$$\gamma(t) > f'(\hat{w})t \quad \text{for any } t > 0. \tag{5.27}$$

Let us now fix $v' \in]\hat{w}, \bar{u}]$. Since, by Lemma 3.4(iv),

$$\lim_{t\to 0} \partial_t F(v', t) = f'(v') < f'(\hat{w}),$$

there exists $\varepsilon = \varepsilon(v')$ such that

$$F(v', t) < f'(\hat{w})t \quad \forall\, t < \varepsilon.$$

By the definition of $\tilde{u}$ and of χ_2, this implies

$$\tilde{u}(x,t) \in [\hat{w}, v'[\quad \forall\, t < \varepsilon, \quad x \in [f'(\hat{w})t, \chi_2(t)].$$

Since v' can be chosen arbitrarily close to $\hat{w}$, we obtain

$$\lim_{\substack{(x,t)\to(0,0) \\ f'(\hat{w})t \leq x \leq \chi_2(t)}} \tilde{u}(x,t) = \hat{w},$$

$$\lim_{\substack{(x,t)\to(0,0)\\ f'(\hat{w})t\le x\le \chi_2(t)}} h(x,t) = \sigma(\hat{w},u_l) = f'(\hat{w}).$$

From (5.17) and (5.27), we deduce that

$$\lim_{t\to 0} \tilde{u}(\gamma(t),t) = \hat{w}, \qquad \lim_{t\to 0} \gamma'(t) = f'(\hat{w}).$$

Thus we have proved properties (5.16) and (5.21).

For simplicity, let us set

$$\alpha(t) = \tilde{u}(\gamma(t),t).$$

To show that (5.20) holds, let us first observe that by (5.14) and (5.5),

$$\text{sgn}\,[\alpha(t) - v] = \text{sgn}\,[F(v,t) - \gamma(t)] \tag{5.28}$$

for any $t > 0$ and $v \in [u_r, v^*(t)]$. Suppose that $\alpha(\cdot)$ is not increasing. Then there exist $t_2 > t_1 > 0$ such that $\alpha(t_2) < \alpha(t_1)$. If we fix $v_0 \in]\alpha(t_2), \alpha(t_1)[$, we deduce by (5.28) that there exists $t_3 \in]t_1, t_2[$ such that

$$\alpha(t_3) = v_0, \qquad \gamma'(t_3) \ge \partial_t F(v_0, t_3). \tag{5.29}$$

Since $\alpha(t_1) > v_0 > \hat{w} = \alpha(0)$, we also obtain that there exists $t_4 \in]0, t_1[$ such that

$$\alpha(t_4) = v_0, \qquad \gamma'(t_4) \le \partial_t F(v_0, t_4). \tag{5.30}$$

From relations (3.11), (5.29), and (5.30), we deduce

$$f'(W(v_0), -t_4) \ge f'(W(v_0), -t_3). \tag{5.31}$$

Since $t_4 < t_3$, we have $W(v_0, -t_4) > W(v_0, -t_3)$. Moreover, by inclusions (5.18) and (5.8), $W(v_0, -t_4) < W(v^*(t_4), -t_4) < \bar{u}$. However, f' is decreasing in $[u_r, \bar{u}]$, and thus we find a contradiction to (5.31). This proves that $\alpha(\cdot)$ is increasing.

It remains to prove (5.22). Let us denote by w_∞ the limit of $\alpha(t)$ as $t \to \infty$. By (5.19), we have

$$\lim_{t\to\infty} \gamma'(t) = \sigma(w_\infty, u_l). \tag{5.32}$$

Suppose that $f'(u_r) \ge f'(u_l)$ and $w_\infty < u_l$. Then by (3.11) and Lemma 5.1,

$$\lim_{t\to\infty} \partial_t F(v,t) = \lim_{t\to\infty} f'(W(v,-t)) = f'(u_r) \ge f'(u_l) > \sigma(w_\infty, u_l)$$

for any $v < u_l$. By (5.32), this implies that

$$\gamma(t) < F(v,t) \quad \forall\, t \gg 0.$$

By (5.28), we obtain

$$\alpha(t) > v \quad \forall\, t \gg 0.$$

If we choose $v > w_\infty$, we find a contradiction to the definition of w_∞. Thus relation (5.22) is proved in the case $f'(u_r) \ge f'(u_l)$.

Let us now suppose that $f'(u_r) < f'(u_l)$. In this case, Lemma 5.2 asserts that $\lim_{t\to\infty} v^*(t) < u_l$. Then from (5.18), we obtain that $w_\infty < u_l$. By the same argument used in the case where $f'(u_r) \geq f'(u_l)$, we find a contradiction unless

$$f'(u_r) = \sigma(w_\infty, u_l).$$

By Lemma 5.1, there exists only one value $w_\infty \in]\hat{w}, u_l[$ satisfying the above equality. The proof is complete. ◻

THEOREM 5.8. *Suppose that assumptions* (H1)–(H4) *are satisfied and that* $u_l > u_r$. *Let* $\tilde{u}$ *be defined as in Definition* 5.3. *Then the function* γ *given by Lemma* 5.6 *is unique and the solution of problem* (1.1)–(1.2) *is*

$$u(x,t) = \begin{cases} u_l, & x < \gamma(t), \\ \tilde{u}(x,t), & \gamma(t) < x \leq f'(u_r)t, \\ u_r, & x > f'(u_r)t. \end{cases} \tag{5.33}$$

Proof. By Lemma 5.5 and assumption (H3), u is a classical solution of equation (1.1) in each of the three regions defined above. It is continuous on the line $x = f'(u_r)t$ by virtue of (5.15). Furthermore, from (5.19), (5.18), and Lemma 5.1, it follows that along the curve $x = \gamma(t)$, conditions (3.2) and (3.3) are satisfied. We conclude by Theorem 3.1 that u is the solution of our problem. The uniqueness of γ follows from the uniqueness of u. ◻

Proof of Theorem 2.3.

Step 1. We have

$$\lim_{t\to\infty} \gamma(t) - f'(u_r)t = \begin{cases} -L & \text{in cases (i) and (ii)}, \\ -\infty & \text{in case (iii)}. \end{cases} \tag{5.34}$$

Let us first prove this property for cases (i) and (ii). From the proof of Lemma 5.2, it follows that

$$\lim_{t\to\infty} W(v^*(t), -t) = u_r. \tag{5.35}$$

For simplicity, we set $\alpha(t) := \tilde{u}(\gamma(t), t)$, $\omega(t) := W(\alpha(t), -t)$. By (5.18),

$$u_r < \omega(t) < W(v^*(t), -t).$$

Therefore,

$$\lim_{t\to\infty} \omega(t) = u_r. \tag{5.36}$$

On the other hand, by (5.22),

$$\lim_{t\to\infty} \alpha(t) = \begin{cases} u_l & \text{if } f'(u_r) = f'(u_l), \\ \bar{w} & \text{if } f'(u_r) < f'(u_l). \end{cases} \tag{5.37}$$

From (5.14), (3.4), and (3.6), we deduce that

$$\gamma(t) - f'(u_r)t = F(\alpha(t), t) - f'(u_r)t$$

$$= \int_0^t [f'(W(\alpha(t), -s)) - f'(u_r)]ds \tag{5.38}$$

$$= \int_{\omega(t)}^{\alpha(t)} \frac{f'(v) - f'(u_r)}{g(v)}\, dv.$$

By letting $t \to \infty$ and taking into account relations (5.36) and (5.37), we prove the first part of (5.34). Let us also observe that by (5.20), equality (5.38) implies that

$$\gamma(t) > f'(u_r)t - L \quad \forall\, t > 0. \tag{5.39}$$

To prove (5.34) in case (iii) it suffices to observe that by (5.19) and (5.22),

$$\lim_{t\to\infty} \gamma'(t) = f'(u_l) < f'(u_r).$$

Step 2. Let us fix $\xi \in\,]-L, 0]$ (in cases (i) or (ii)) or $\xi \in\,]-\infty, 0]$ (in case (iii)) and define

$$\lambda(t) = \lambda_\xi(t) = \tilde{u}(f'(u_r)t + \xi, t).$$

Then $\lambda(\cdot)$ is decreasing and

$$\lim_{t\to\infty} \lambda(t) = \psi(\xi).$$

Let us first show that λ is well defined for t large enough. From Step 1 and (5.17), we deduce that

$$F(v^*(t), t) < \gamma(t) < f'(u_r)t + \xi \le f'(u_r)t \quad \forall\, t \gg 0,$$

and therefore $\tilde{u}$ is defined at $(f'(u_r)t + \xi, t)$. Next, we observe that by the definition of $\tilde{u}$,

$$F(\lambda(t), t) - f'(u_r)t \equiv \xi. \tag{5.40}$$

Differentiating this equality with respect to t, we obtain by (3.11) that

$$\partial_v F(\lambda(t), t)\lambda'(t) + f'(W(\lambda(t), -t)) - f'(u_r) \equiv 0. \tag{5.41}$$

Since $\lambda(t) \in [u_r, v^*(t)[$, we obtain from (3.12), (5.5), (5.8), and (H2) that

$$\partial_v F(\lambda(t), t) < 0, \qquad f'(W(\lambda(t), -t)) \le f'(u_r).$$

Thus equality (5.41) implies that $\lambda(\cdot)$ is decreasing. Let us denote by λ_∞ its limit as $t \to \infty$. From (5.40), (3.4), and (3.6), we deduce that

$$\begin{aligned} \xi &= \int_0^t [f'(W(\lambda(t), -s)) - f'(u_r)]\, ds \\ &= \int_{W(\lambda(t), -t)}^{\lambda(t)} \frac{f'(v) - f'(u_r)}{g(v)}\, dv \\ &\overset{t\to\infty}{\longrightarrow} \int_{u_r}^{\lambda_\infty} \frac{f'(v) - f'(u_r)}{g(v)}\, dv. \end{aligned}$$

Thus $\lambda_\infty = \psi(\xi)$.

Step 3. $\sup\{|\tilde{u}(x,t) - \psi(x - f'(u_r)t)| \;:\; x \in [\gamma(t), f'(u_r)t]\} \to 0$ as $t \to \infty$. It is convenient to set

$$\bar{z} = \lim_{t\to\infty} \alpha(t) = \begin{cases} u_l & \text{in cases (i) and (iii)}, \\ \bar{w} & \text{in case (ii)}. \end{cases}$$

For fixed $\varepsilon \in \,]0, \bar{z} - u_r[$, let us define

$$\xi_\varepsilon = \int_{u_r}^{\bar{z}-\varepsilon} \frac{f'(v) - f'(u_r)}{g(v)}\, dv.$$

By Step 1, we have

$$\gamma(t) < f'(u_r)t - \xi_\varepsilon \quad \forall\, t \gg 0.$$

By Step 2, we can apply Dini's theorem to obtain

$$\lim_{t\to\infty} \tilde{u}(\xi + f'(u_r)t, t) = \psi(\xi), \tag{5.42}$$

uniformly for $\xi \in [\xi_\varepsilon, 0]$. Let us now fix T such that

$$\tilde{u}(\xi_\varepsilon + f'(u_r)t, t) - \psi(\xi_\varepsilon) < \varepsilon \quad \forall\, t \geq T.$$

Then, since $\tilde{u}(\cdot, t)$ and $\psi(\cdot)$ are both decreasing and since inequality (5.39) holds, we obtain for $\xi \in [\gamma(t) - f'(u_r)t, \xi_\varepsilon]$ and $t \geq T$ that

$$\psi(\xi) \in [\bar{z} - \varepsilon, \bar{z}], \qquad \tilde{u}(\xi + f'(u_r)t, t) \in [\bar{z} - 2\varepsilon, \alpha(t)]. \tag{5.43}$$

Step 3 then follows from relations (5.42) and (5.43). From Steps 1 and 3 and from Theorem 5.8, it is easy to deduce Theorem 2.3. □

6. Extinction of shocks in finite time. In the previous sections, we have considered the case when f has a single inflection point between u_l and u_r and g has constant sign. It is possible to treat more complicated situations with a similar procedure and obtain an asymptotic profile for the solution consisting of a suitable number of shock waves and traveling waves. An interesting new property arising when f has more than one inflection point is that the discontinuities present in the solution may vanish in finite time. In this section, we give an example of such a behavior.

We assume that $u_l < u_r$ and that f and g satisfy hypotheses (H1), (H3), (H5), (H6), and (H7).

LEMMA 6.1. *For any $v \in [\hat{v}_1, \bar{u}_2]$, there exists a unique $\eta = \eta(v) \in [\bar{u}_2, \hat{v}_2]$ such that*

$$f'(\eta) = \sigma(v, \eta). \tag{6.1}$$

The function $v \to \eta(v)$ is continuous, differentiable in $]\hat{v}_1, \bar{u}_2[$, and strictly decreasing, and it satisfies $\eta(\hat{v}_1) = \hat{v}_2$ and $\eta(\bar{u}_2) = \bar{u}_2$. Furthermore,

$$\sigma(v, \eta(v)) > \sigma(w, \eta(v)) \quad \forall\, v, w \;:\; \hat{v}_1 \leq v < w < \eta(v), \tag{6.2}$$

$$f'(v) > f'(\eta(v)) \quad \forall\, v \in \,]\hat{v}_1, \bar{u}_2[\,. \tag{6.3}$$

Proof. From assumptions (H5) and (H6), we deduce

$$f'(w) > f'(\bar{u}_2) \quad \forall w \in [\hat{v}_1, \hat{v}_2] \setminus \{\bar{u}_2\}. \tag{6.4}$$

Therefore,

$$\sigma(v, \bar{u}_2) = \frac{1}{\bar{u}_2 - v} \int_v^{\bar{u}_2} f'(w)dw > f'(\bar{u}_2) \quad \forall v \in [\hat{v}_1, \bar{u}_2[\,. \tag{6.5}$$

From (H5) and (H6), it also follows that there exists $\hat{v}_3 \in \,]\bar{u}_1, \bar{u}_2[$ such that

$$f'(\hat{v}_1) = f'(\hat{v}_2) = f'(\hat{v}_3), \tag{6.6}$$

$$\operatorname{sgn}[f'(v) - f'(\hat{v}_3)] = \operatorname{sgn}[\hat{v}_3 - v] \quad \forall\, v \in \,]\hat{v}_1, \hat{v}_2[\,. \tag{6.7}$$

The last equality implies that

$$\sigma(v, \hat{v}_2) < f'(\hat{v}_3) \quad \forall\, v \in [\hat{v}_3, \hat{v}_2[\,. \tag{6.8}$$

For any $v \in \,]\hat{v}_1, \hat{v}_3]$, we obtain by (H6), (6.6), and (6.7) that

$$\begin{aligned} \sigma(v, \hat{v}_2) &= \frac{1}{\hat{v}_2 - v} \left[(\hat{v}_2 - \hat{v}_1)\sigma(\hat{v}_1, \hat{v}_2) - \int_{\hat{v}_1}^{v} f'(w)dw \right] \\ &< \frac{1}{\hat{v}_2 - v} [(\hat{v}_2 - \hat{v}_1)f'(\hat{v}_3) - (v - \hat{v}_1)f'(\hat{v}_3)] = f'(\hat{v}_3). \end{aligned} \tag{6.9}$$

Inequalities (6.8), (6.9), and (6.6) yield

$$\sigma(v, \hat{v}_2) < f'(\hat{v}_2) \quad \forall\, v \in \,]\hat{v}_1, \hat{v}_2[\,. \tag{6.10}$$

From (6.5) and (6.10), we deduce that for any $v \in \,]\hat{v}_1, \bar{u}_2[$, there exists a value $\eta \in \,]\bar{u}_2, \hat{v}_2[$ such that (6.1) is satisfied. If $v = \hat{v}_1$ (resp. $v = \bar{u}_2$), then (6.1) holds with $\eta = \hat{v}_2$ (resp. $\eta = \bar{u}_2$). The uniqueness of η is checked analogously to the uniqueness of $\hat{v}$ in Lemma 4.1.

Let us now prove inequality (6.3). We observe that for any $v \in \,]\hat{v}_1, \bar{u}_2[\,$,

$$\hat{v}_3 < \bar{u}_2 < \eta(v) < \hat{v}_2. \tag{6.11}$$

Therefore, if $v \leq \hat{v}_3$, (6.3) follows from (6.7). Let us then consider the case where $v > \hat{v}_3$. If we define

$$M = \max\{f'(w) \,:\, w \in [v, \eta(v)]\},$$

we have

$$f'(\eta(v)) = \sigma(v, \eta(v)) = \frac{1}{\eta(v) - v} \int_v^{\eta(v)} f'(w)dw < M. \tag{6.12}$$

Since we are assuming $v > \hat{v}_3$, we deduce from (6.11) and (H5) that

$$M = \max\{f'(v), f'(\eta(v))\},$$

which implies (6.3) by virtue of (6.12).

Let us now define

$$H(v,w) = f'(w) - \sigma(v,w) \quad \text{for } (v,w) \in [\hat{v}_1, \bar{u}_2] \times [\bar{u}_2, \hat{v}_2].$$

Then $H(v,w) = 0$ if and only if $w = \eta(v)$. For any $v \in]\hat{v}_1, \bar{u}_2[$, we have by (6.1), (6.3) and (H5) that

$$H_v(v, \eta(v)) = \frac{f'(v) - \sigma(v, \eta(v))}{\eta(v) - v} > 0, \qquad H_w(v, \eta(v)) = f''(\eta(v)) > 0.$$

It follows that $v \to \eta(v)$ is differentiable and decreasing.

It remains to prove inequality (6.2). To this end, let us fix $v \in [\hat{v}_1, \bar{u}_2[$ and define

$$K(w) = f(w) - f(\eta(v)) - f'(\eta(v))(w - \eta(v)) \quad (w \in [v, \eta(v)]).$$

By (H5), (H6), (6.1), and (6.3), we have

$$K(v) = K(\eta(v)) = 0,$$

$$K'(v) = f'(v) - f'(\eta(v)) > 0 \quad \text{if } v > \hat{v}_1,$$

$$K'(v) = 0, \qquad K''(v) > 0, \quad \text{if } v = \hat{v}_1,$$

$$K'(\eta(v)) = 0 \qquad K''(\eta(v)) > 0.$$

It follows that the two endpoints $w = v$ and $w = \eta(v)$ are local minima for $K(\cdot)$. Suppose that $K(w) \leq 0$ for some $w \in]v, \eta(v)[$. Then there would exist at least three critical points for $K(\cdot)$ in $]v, \eta(v)[$. However, the derivative of K is $K'(w) = f'(w) - f'(\eta(v))$ and can vanish at at most one value of this interval by (H5) and (H6). The contradiction proves that $K(w)$ is positive for any $w \in]v, \eta(v)[$. Thus we conclude that

$$\sigma(v, \eta(v)) - \sigma(w, \eta(v)) = -\frac{K(w)}{w - \eta(v)} > 0$$

for any $w \in]v, \eta(v)[$. The proof is complete. □

Definition 6.2. *Let $t^* > 0$ be the value such that*

$$f'(W(\bar{u}_2, -t^*)) = f'(\bar{u}_2). \tag{6.13}$$

Let $v^* : [0, t^*] \to [\bar{u}_1, \bar{u}_2]$ be defined by $v^*(0) = \bar{u}_1$ and by the equality

$$f'(W(v^*(t), -t)) = f'(v^*(t)) \quad \forall\, t \in]0, t^*] \tag{6.14}$$

(see Remark 5.4). For $t > t^*$, let us set

$$v^*(t) = W(\bar{u}_2, t - t^*). \tag{6.15}$$

Given (x,t) with $t \geq 0$ and $x \in [f'(u_l)t, F(v^*(t), t)]$, let $\tilde{u}_1(x,t) \in [u_l, v^*(t)]$ be defined by

$$F(\tilde{u}_1(x,t), t) = x. \tag{6.16}$$

Similarly, given (x,t) *with* $t \geq 0$ *and* $x \in [F_+(\hat{v}_2,t), f'(u_r)t]$, *let* $\tilde{u}_2(x,t) \in [W(\hat{v}_2,t), u_r]$ *be defined by*

$$F(\tilde{u}_2(x,t),t) = x. \tag{6.17}$$

LEMMA 6.3. *The quantities introduced above are well defined. The function* v^* *is continuous, while* $\tilde{u}_1$ *and* $\tilde{u}_2$ *are classical solutions of equation* (1.1) *in the interior of their domain of definition and satisfy*

$$\tilde{u}_1(f'(u_l)t,t) = u_l, \tag{6.18}$$

$$\tilde{u}_2(F_+(\hat{v}_2,t),t) = W(\hat{v}_2,t), \qquad \tilde{u}_2(f'(u_r)t,t) = u_r. \tag{6.19}$$

Proof. By assumptions (H5) and (H7), there exists a unique value $w^* \in]u_l, \bar{u}_2[$ satisfying

$$f'(w^*) = f'(\bar{u}_2).$$

Since $W(\bar{u}_2, -t)$ decreases monotonically from $\bar{u}_2$ to u_l as t runs the interval $[0,\infty[$, there exists a unique value t^* for which

$$W(\bar{u}_2, -t^*) = w^*. \tag{6.20}$$

This is also the unique value which satisfies (6.13).

Following the proof of Lemma 5.2, we obtain that equality (6.14) defines v^* uniquely and that v^* is continuous at $t = 0$. From (6.13), (6.14), and (6.15), it follows that v^* is continuous at $t = t^*$ and that $v^*(t^*) = \bar{u}_2$.

To show that $\tilde{u}_1$ and $\tilde{u}_2$ are well defined, we need to prove

$$\partial_v F(v,t) > 0 \quad \forall\, t > 0, \quad \forall\, v \in]u_l, v^*(t)[\cup]W(\hat{v}_2,t), u_r[. \tag{6.21}$$

By (3.12) and (H3), this is equivalent to

$$f'(v) > f'(W(v,-t)) \quad \forall\, t > 0, \quad \forall\, v \in]u_l, v^*(t)[; \tag{6.22}$$

$$f'(W(v,t)) > f'(v) \quad \forall\, t > 0, \quad \forall\, v \in]\hat{v}_2, u_r[. \tag{6.23}$$

Inequality (6.23) follows from assumption (H5), while (6.22) follows from the definition of v^* for $t \leq t^*$. If $t > t^*$ then by (6.15) and (6.20),

$$W(v^*(t), -t) = W(\bar{u}_2, -t^*) = w^* \quad \forall\, t \geq t^*. \tag{6.24}$$

Let us now take $v \in]u_l, v^*(t)[$. If $v \leq \bar{u}_1$, then (6.22) is a consequence of assumption (H5). Otherwise, by (6.24) and (H5), we have

$$f'(v) \geq f'(\bar{u}_2) = f'(w^*) = f'(W(v^*(t), -t)) > f'(W(v,-t)).$$

Thus $\tilde{u}_1$ and $\tilde{u}_2$ are well defined. The other properties follow from the definition and from Lemma 3.4(v). □

LEMMA 6.4. *There exists a function* $\gamma \in C^1([0,T^*])$ *with* $T^* > t^*$ *which satisfies the following properties:*

$$\gamma(0) = 0, \qquad \gamma'(0) = f'(\hat{v}_1), \tag{6.25}$$

$$\gamma(t) \in \,]F(\hat{v}_1,t), F(v^*(t),t)[\quad \forall\, t \in \,]0,t^*], \tag{6.26}$$

$$\gamma(t) \in \,]F(\hat{v}_1,t), F(\bar{u}_2,t)[\quad \forall\, t \in [t^*,T^*[\,, \tag{6.27}$$

$$\gamma(T^*) = F(\bar{u}_2,T^*), \qquad \gamma'(T^*) = f'(\bar{u}_2), \tag{6.28}$$

$$\gamma'(t) = f'(\eta(\tilde{u}_1(\gamma(t),t))) \quad \forall\, t \in \,]0,T^*]. \tag{6.29}$$

Furthermore, if we set

$$\alpha(t) = \tilde{u}_1(\gamma(t),t), \qquad \omega(t) = \eta(\alpha(t)) \quad \textit{for } t \in \,]0,T^*], \tag{6.30}$$

we have

$$\alpha(t) \in \,]\hat{v}_1, \min\{\bar{u}_2, v^*(t)\}[\quad \forall\, t \in \,]0,T^*[\,. \tag{6.31}$$

$$\lim_{t\to 0} \alpha(t) = \hat{v}_1, \qquad \lim_{t\to 0} \omega(t) = \hat{v}_2, \tag{6.32}$$

$$\alpha(\cdot) \textit{ is increasing,} \qquad \omega(\cdot) \textit{ is decreasing.} \tag{6.33}$$

Remark 6.5. As in section 5, the curve γ we are dealing with will turn out to be a curve of discontinuity of the solution u of our problem. We will show that $u = \tilde{u}_1$ on the left of γ and that γ is a *right contact*, i.e., its speed is equal to the characteristic speed of u on the right. By Lemma 6.1, this means that the limit from the right of $u(\cdot,t)$ at a point $\gamma(t)$ is equal to $\eta(\tilde{u}_1(\gamma(t),t))$. Thus condition (3.2) yields equality (6.29). Observe that at time T^*, we have by (6.28) and the definition of $\tilde{u}$ that

$$u(\gamma(T^*)^-,T^*) = \tilde{u}_1(\gamma(T^*),T^*) = \bar{u}_2 = \eta(\bar{u}_2) = u(\gamma(T^*)^+,T^*).$$

Thus $u(\cdot,t)$ is no longer discontinuous across γ.

Proof of Lemma 6.4. To simplify notation, we set

$$\chi_1(t) = F(\hat{v}_1,t),$$

$$\chi_2(t) = \begin{cases} F(v^*(t),t) & \text{for } t \in [0,t^*], \\ F(\bar{u}_2,t) & \text{for } t \in [t^*,\infty[\,, \end{cases}$$

$$h(x,t) = f'(\eta(\tilde{u}_1(x,t)) \quad \text{for } t > 0,\ x \in [\chi_1(t),\chi_2(t)].$$

Then by assumptions (H5) and (H6), Definition 6.2, and Lemmas 3.4(iv) and 6.1, we have

$$h(\chi_1(t),t) = f'(\hat{v}_1) > f'(W(\hat{v}_1,-t)) = \chi_1'(t) \quad \forall\, t > 0, \tag{6.34}$$

$$h(\chi_2(t),t) = f'(\eta(v^*(t),t)) < f'(v^*(t)) = \chi_2'(t) \quad \forall\, t \in \,]0,t^*[\,, \tag{6.35}$$

$$h(x,t) < f'(\hat{v}_2) = f'(\hat{v}_1) \quad \forall t \in]0,t^*[\,,\ \forall x \in]\chi_1(t),\chi_2(t)[\,. \tag{6.36}$$

Following the proof of Lemma 5.6, we find $\gamma \in C^1([0,t^*])$ which satisfies properties (6.25), (6.26), (6.32), and (6.29) for $t \in]0,t^*]$. Then we continue with γ as a solution of (6.29) in the maximal interval $[t^*,T^*[$ where (6.27) is satisfied. If T^* is finite, we can define by continuity the value of γ at T^* because γ' is uniformly bounded by (6.29).

We can exclude that $T^* = \infty$. In fact, we have

$$\lim_{t\to\infty} \chi_2'(t) = \lim_{t\to\infty} f'(W(\bar{u}_2,-t)) = f'(u_l).$$

On the other hand, since η takes values in $[\bar{u}_2,\hat{v}_2]$, we have by (H5) and (H7) that

$$\gamma'(t) \geq f'(\bar{u}_2) > f'(u_l) \quad \forall\, t < T^*.$$

Thus inequality (6.27) cannot hold for arbitrarily large t, and T^* must be finite. By (6.34), we can also exclude that $\gamma(T^*) = \chi_1(T^*)$. Therefore equalities (6.28) are satisfied.

Inclusion (6.31) follows from (6.26) and (6.27), while (6.33) is proved by the same argument used for (5.20) in the proof of Lemma 5.6. □

We define γ after T^* by setting

$$\gamma(t) = \gamma(T^*) + F_+(\bar{u}_2, t-T^*) \quad \text{for } t > T^*. \tag{6.37}$$

Then by (6.28) and Definition 3.3,

$$\gamma(t) = F(\bar{u}_2,T^*) + F_+(\bar{u}_2,t-T^*) = F(W(\bar{u}_2,t-T^*),t),$$

and by (6.16), we obtain

$$\tilde{u}_1(\gamma(t),t) = W(\bar{u}_2,t-T^*) \quad \forall\, t > T^*. \tag{6.38}$$

The next result states that the region lying between the curves $x = \gamma(t)$ and $x = F_+(\hat{v}_2,t)$ is covered univalently by the characteristics emanating from γ. Therefore, it is possible to define in this region a function $\hat{u}$ which assumes the desired values along γ and solves equation (1.1).

Lemma 6.6. *For any (x,t) with $t > 0$ and $x \in [\gamma(t),F_+(\hat{v}_2,t)]$, there exists a unique value $\tau = \tau(x,t) \in [0,\min\{t,T^*\}]$ such that*

$$x = \gamma(\tau) + F_+(\omega(\tau),t-\tau). \tag{6.39}$$

Proof. For fixed $t > 0$, define

$$y(\tau) = \gamma(\tau) + F_+(\omega(\tau),t-\tau) \quad \text{for } \tau \in [0,\min\{t,T^*\}].$$

Then by (6.32) and (6.37),

$$y(0) = F_+(\hat{v}_2,t), \qquad y(\min\{t,T^*\}) = \gamma(t).$$

We only need to prove that $y(\cdot)$ is strictly decreasing. Since f is convex in $[\bar{u}_2,u_r]$, we have $\partial_v F_+(v,s) > 0$ for any $v \in [\bar{u}_2,u_r]$ and $s > 0$. Furthermore, by (6.33), $\omega' \leq 0$. Thus by (6.29) and (3.5), we conclude

$$\begin{aligned} y'(\tau) &= \gamma'(\tau) + \partial_v F_+(\omega(\tau),t-\tau)\,\omega'(\tau) - \partial_t F_+(\omega(\tau),t-\tau) \\ &\leq f'(\omega(\tau)) - f'(W(\omega(\tau),t-\tau)) < 0. \qquad \square \end{aligned}$$

Definition 6.7. *For any $t > 0$ and $x \in [\gamma(t), F_+(\hat{v}_2, t)]$, set*

$$\hat{u}(x,t) = W(\omega(\tau(x,t)), t - \tau(x,t)), \tag{6.40}$$

where ω and τ are defined as in Lemmas 6.4 *and* 6.6.

Lemma 6.8. *The function $\hat{u}$ introduced above is a classical solution of equation* (1.1) *in the interior of its domain of definition. Moreover, it satisfies*

$$\hat{u}(\gamma(t), t) = \begin{cases} \omega(t) & \text{if } t \in [0, T^*], \\ W(\bar{u}_2, t - T^*) & \text{if } t \in [T^*, \infty[\,, \end{cases} \tag{6.41}$$

$$\hat{u}(F_+(\hat{v}_2, t)) = W(\hat{v}_2, t). \tag{6.42}$$

Proof. By (6.39), (6.40), and (3.10), we have

$$\begin{aligned} x - \gamma(\tau(x,t)) &= F_+(\omega(\tau(x,t)), t - \tau(x,t)) \\ &= F(W(\omega(\tau(x,t)), t - \tau(x,t)), t - \tau(x,t)) \\ &= F(\hat{u}(x,t), t - \tau(x,t)). \end{aligned} \tag{6.43}$$

Furthermore, by (6.29), (3.11), and (6.40),

$$\begin{aligned} \gamma'(\tau(x,t)) &= f'(\omega(\tau(x,t))) \\ &= f'(W(\hat{u}(x,t), \tau(x,t) - t)) \\ &= \partial_t F(\hat{u}(x,t), t - \tau(x,t)). \end{aligned}$$

Thus if we differentiate (6.43), we obtain

$$1 = \partial_v F \, \partial_x \hat{u}, \qquad 0 = \partial_v F \, \partial_t \hat{u} + \partial_t F.$$

Following the proof of Lemma 3.4(v), we can conclude that $\hat{u}$ solves equation (1.1). Equalities (6.41) and (6.42) follow from the definition of $\hat{u}$. □

Theorem 6.9. *Let assumptions* (H1), (H3), *and* (H5)–(H7) *be satisfied and let $\tilde{u}_1$, $\tilde{u}_2$, and $\hat{u}$ be defined as in Definitions* 6.2 *and* 6.7. *Then the function γ given by Lemma* 6.4 *is unique, and the solution of problem* (1.1)–(1.2) *is*

$$u(x,t) = \begin{cases} u_l, & x < f'(u_l)t, \\ \tilde{u}_1(x,t), & f'(u_l)t < x < \gamma(t), \\ \hat{u}(x,t), & \gamma(t) < x < F_+(\hat{v}_2, t), \\ \tilde{u}_2(x,t), & F_+(\hat{v}_2, t) < x < f'(u_r)t, \\ u_r, & x > f'(u_r)t. \end{cases} \tag{6.44}$$

Furthermore, $u(\cdot, t)$ is discontinuous at $\gamma(t)$ for $t < T^*$, while it is continuous everywhere for $t \geq T^*$ (T^* has been introduced in Lemma 6.4).

Proof. The function u is a classical solution of equation (1.1) in each of the five regions defined above by virtue of assumption (H3) and Lemmas 6.3 and 6.8. By equalities (6.18), (6.19), and (6.42), we deduce that u is continuous along the curves $x = f'(u_l)t$, $x = f'(u_r)t$, and $x = F_+(\hat{v}_2, t)$, while (6.38) and (6.41) imply the continuity along γ for $t \geq T^*$. By Lemmas 6.1, 6.4, and 6.8, γ is a curve of discontinuity which satisfies conditions (3.2) and (3.3) for $t < T^*$. Finally, the uniqueness of γ follows from the uniqueness of u. $\square$

From the previous theorem, it is possible to deduce the following asymptotic representation for u. We omit the proof, which is similar to the proof of Theorem 2.3.

THEOREM 6.10. *Under assumptions* (H1), (H3), *and* (H5)–(H7), *the solution of problem* (1.1)–(1.2) *satisfies*

$$u(x,t) = \begin{cases} u_l & \text{for } x < f'(u_l)t, \\ \\ \phi(x - f'(u_l)t) + o(1) & \text{for } x > f'(u_l)t, \end{cases} \tag{6.45}$$

where $\phi : [0, \infty[\to [u_l, u_r[$ *is defined by*

$$\int_{u_l}^{\phi(\xi)} \frac{f'(v) - f'(u_l)}{g(v)}\, dv = \xi \quad \text{for any } \xi \geq 0.$$

Acknowledgments. The author wishes to thank the referees for their helpful suggestions.

ON THE RATE OF CONVERGENCE TO EQUILIBRIUM FOR A SYSTEM OF CONSERVATION LAWS WITH A RELAXATION TERM*

ASLAK TVEITO[†] AND RAGNAR WINTHER[†]

Abstract. We analyze a simple system of conservation laws with a strong relaxation term. Well-posedness of the Cauchy problem in the framework of bounded-total-variation (BV) solutions is proved. Furthermore, we prove that the solutions converge towards the solution of an equilibrium model as the relaxation time $\delta > 0$ tends to zero. Finally, we show that the difference between an equilibrium solution ($\delta = 0$) and a nonequilibrium solution ($\delta > 0$) measured in L^1 is bounded by $O(\delta^{1/3})$.

Key words. hyperbolic conservation laws, relaxation terms, nonequilibrium, rate of convergence

1. Introduction.

The purpose of this paper is to study the following system of conservation laws:

$$(u+v)_t + f(u)_x = 0, \qquad (1.1)$$
$$\delta v_t = A(u) - v.$$

Here f and A are given functions, u and v are the unknowns and $\delta > 0$ is referred to as the relaxation time. The function $A(u)$ will throughout this paper be assumed to be an increasing function of u. Further assumptions on the model will be given in section 2.

We will be concerned in particular with the convergence of $(u, v) = (u_\delta, v_\delta)$ as δ tends to zero. In the limit of zero relaxation time, a scalar conservation law of the form

$$(w + A(w))_t + f(w)_x = 0 \qquad (1.2)$$

is obtained. Systems of the form (1.1) are usually referred to as "nonequilibrium" models, whereas (1.2) is the "equilibrium" model. The main result of this paper is that for proper conditions on the initial data, the solutions of the nonequilibrium model tend to the solution of the equilibrium model in L^1 with a deviation bounded by $O(\delta^{1/3})$.

System (1.1) arises in chromatography and is discussed in [19, 20, 28]. In this framework, u denotes the density of some species contained in a fluid flowing through a fixed bed and v denotes the density of the species adsorbed on the material in the bed. The right-hand side of the second equation models the adsorption. Different forms of adsorption functions A are discussed by, e.g., Bear and Bachmat [1, Chapter 6].

The equilibrium assumption in chromatography states that the rate of the chemical reaction is so large that the reaction can be considered as instantaneous compared to the time scales of other effects. We prove that for initial data close to equilibrium

and for small relaxation times δ, the equilibrium model provides good approximations of the nonequilibrium solutions. One should, however, be cautious. In [24], the system in a radial geometry is considered as a model for near-well reservoir simulation. Their results indicate the equilibrium model is inadequate for the analysis of this problem.

A nice introduction to systems of conservation laws with relaxation terms can be found in Whitham's book [28], where such models arising in, e.g., chromatography, traffic modeling, water waves, and gas dynamics are discussed. For applications in chromatography, a detailed discussion is provided in the books of Rhee, Aris, and Amundson [19, 20]. Systems consisting of one conservation equation and one equation with a relaxation term have been studied by several authors; cf. [2, 5, 6, 7, 12, 13, 15, 17, 18, 21, 24, 25, 27]. Much of this research is motivated by combustion theory and especially by Majda's model [15]. The question of well-posedness of this system is discussed by Teng and Ying [25] and Levy [12], and computational studies of the system are presented by Colella, Majda, and Roytburd [5] and Pember [17, 18].

The so-called subcharacteristic condition plays a central role in systems with relaxation terms. Consider system (1.1) above and let $\lambda_1 = 0$ and $\lambda_2 = f'$ denote the characteristic speeds. Similarly, $\lambda^* = f'/(1 + A')$ denotes the characteristic speed of (1.2). Then the subcharacteristic condition states that $\lambda_1 \leq \lambda^* \leq \lambda_2$, which due to the monotonicity of A is satisfied for our models. It turns out that the subcharacteristic condition is necessary for the stability of the nonequilibrium model. This issue is analyzed using linearization by Whitham [28, Chapter 10], for "small waves" by Liu [13], for a linear model by LeVeque and Wang [11], and finally by Chen and Liu [2]. In the latter paper, Chen and Liu actually prove convergence of solutions of the nonequilibrium towards the solution of an equilibrium model for two different systems. Their results are based on the theory of compensated compactness. Generalizations of their results are given in the recent paper by Chen, Levermore, and Liu [3]. Also, Schochet [21] proves convergence of a family of nonequilibrium solutions to the solution of an equilibrium model. He studies the refined traffic model, introduced by Whitham [28], which consists of a standard conservation law for the density of cars and a nonequilibrium model for the velocity.

The plan of this paper is as follows. We begin in section 2 by giving precise assumptions on system (1.1) and the initial data. Furthermore, we state the main results of the paper. Section 3 is devoted to the analysis of a finite-difference scheme approximating system (1.1). The results of section 3 are used in section 4, where we demonstrate existence, uniqueness, and stability of solutions of (1.1). We should mention here that the well-posedness of (1.1) was proved by both Levy [12] and Teng and Ying [25]. Their estimates, however, depend on the relaxation time, and since we will study the convergence of solutions of (1.1) as $\delta \to 0$, we need δ independent estimates.

In section 5, we introduce an auxiliary system where small diffusion terms are present. This auxiliary system enables us to prove in section 6 that the solution of (1.1) tends to the solution of (1.2) in L^1 with a deviation bounded by $O(\delta^{1/3})$.

Remarks. (1) The results obtained in this paper could without too much difficulty be generalized to yield slightly more general systems than those covered by (1.1). For clarity, however, we have chosen to analyze a model that is as simple as possible in order to avoid messy details containing no essential new insights.

(2) We do not know if the convergence estimate of the form $O(\delta^{1/3})$ is optimal. However, computational experiments that we have done seem to indicate that if an estimate of the form $O(\delta^{\gamma})$ is sought, then the optimal value of γ is somewhere in the

interval $[1/4, 1/2]$; see also section 6 of [22].

2. Preliminaries and statement of the main results. The purpose of this paper is to study how well solutions of the scalar conservation law

$$(w + A(w))_t + f(w)_x = 0 \tag{2.1}$$

approximate the corresponding solutions of the system

$$\begin{aligned} (u+v)_t + f(u)_x &= 0, \\ \delta v_t &= A(u) - v \end{aligned} \tag{2.2}$$

for small positive values of the relaxation time δ, i.e., $\delta \in (0, 1]$. The explicit dependence of the solution (u, v) on δ will usually be suppressed. We will assume that $f = f(u)$ is a smooth function satisfying $f(0) = 0$ and that

$$f'(u) \geq 0 \quad \text{for } u \in [0, 1].$$

The function $A = A(u)$ will be assumed to satisfy the requirements

$$\begin{gathered} A(0) = 0, \qquad A(1) = 1, \\ A'(u) \geq 0, \\ |A''(u)| \leq \alpha < 1 \end{gathered} \tag{2.3}$$

for all relevant values of u. We shall consider solutions of (2.2) in the state space

$$\mathcal{S} = [0, 1] \times [0, 1]$$

and solutions of (2.1) in $[0, 1]$.

In equilibrium, we have $v = A(u)$, and system (2.2) degenerates to the scalar equation (2.1). In order to study the deviation from equilibrium in the nonequilibrium model, we introduce an auxiliary variable defined by

$$p = A(u) - v.$$

The initial conditions (u^0, v^0) for system (2.2) are supposed to satisfy the following:

$$\begin{array}{rc} \text{(i)} & (u^0(x), v^0(x)) \in \mathcal{S} \quad \forall x \in \mathcal{R}, \\ \text{(ii)} & \mathrm{TV}(u^0) + \mathrm{TV}(v^0) \leq M, \\ \text{(iii)} & \|p^0\|_1 = \|A(u^0) - v^0\|_1 \leq M\delta, \\ \text{(iv)} & u^0(\pm\infty), v^0(\pm\infty) = 0. \end{array} \tag{2.4}$$

Here and in the rest of this paper, M denotes a generic finite constant independent of δ. The L^1-norm is denoted by $\|\cdot\|_1$ and $\mathrm{TV}(\cdot)$ denotes the total variation, defined by

$$\mathrm{TV}(z) = \sup_{h \neq 0} \int_{\mathcal{R}} \frac{|z(x+h) - z(x)|}{|h|} dx.$$

Furthermore, $\mathrm{BV} = \mathrm{BV}(\mathcal{R})$ denotes the subspace of L^1_{loc} consisting of functions with bounded total variation.

Note that (iii) above assures that the initial conditions are close to equilibrium. This is a natural assumption since we primarily want to analyze the convergence towards the solutions of the equilibrium model in (2.1). However, we shall also indicate that if (iii) is not satisfied initially, an initial layer will appear and $\|p(t)\|_1 = O(\delta)$ will be reached at an exponential rate.

What we mean by an entropy solution of the scalar equation (2.1) is well known, but let us define a similar concept for (2.2). For any $T > 0$, we let $\mathcal{D}_+(T)$ denote the set of all nonnegative C^∞-functions with compact support in $\mathcal{R} \times [0, T]$.

DEFINITION 1. *Let* (u^0, v^0) *satisfying* (2.4) *be the given initial data. Then* (u, v) *is called an* entropy solution of system (2.2) *if the following requirements are satisfied:*

1. $(u, v) \in \mathcal{S}\ \forall (x, t) \in \mathcal{R} \times \mathcal{R}_0^+$;
2. $\mathrm{TV}(u(\cdot, t)), \mathrm{TV}(v(\cdot, t)) \le M\ \forall t \in \mathcal{R}_0^+$;
3. $\|u(\cdot, t) - u(\cdot, \tau)\|_1 + \|v(\cdot, t) - v(\cdot, \tau)\|_1 \le M|t - \tau|\ \forall t, \tau \in \mathcal{R}_0^+$;
4. *For any* $(k, q) \in \mathcal{S}$ *and any* $\varphi, \psi \in \mathcal{D}_+(T)$*, where* $T > 0$ *is arbitrary,*

$$\begin{aligned}
&\int_0^T \int_{\mathcal{R}} [|u - k|\varphi_t + |f(u) - f(k)|\varphi_x + |v - q|\psi_t] dx\, dt \\
&\quad + \int_{\mathcal{R}} [|u^0 - k|\varphi(x, 0) + |v^0 - q|\psi(x, 0)] dx \\
&\quad - \int_{\mathcal{R}} [|u(x, T) - k|\varphi(x, T) + |v(x, T) - q|\psi(x, T)] dx \\
&\quad \ge \frac{1}{\delta} \int_0^T \int_{\mathcal{R}} [\sigma(u - k)\varphi - \sigma(v - q)\psi](A(u) - v) dx\, dt,
\end{aligned} \tag{2.5}$$

where σ *denotes the sign function.*

Remark. Let us again mention that the existence of entropy solutions of systems of the form of (2.2) has previously been proved by Levy [12] and Teng and Ying [25]. The reason for us to redo the existence part here is that we shall need δ-independent estimates when we consider the convergence of (u_δ, v_δ) as $\delta \to 0$. Such estimates are not provided by [12, 25].

Existence of an entropy solution satisfying the requirements of Definition 1 will be proved using a finite-difference scheme. We note that existence could also be proved using the parabolic regularizations discussed below, but the problem of computing solutions of systems of the form of (2.2) is important, and hence we find it desirable to prove existence by demonstrating convergence of a numerical scheme. An error estimate for the scheme is derived in [22].

Our scheme for analyzing system (1.1) is straightforward and semiimplicit:

$$\begin{aligned}
\frac{(u_j^{n+1} + v_j^{n+1}) - (u_j^n + v_j^n)}{\Delta t} + \frac{f(u_j^n) - f(u_{j-1}^n)}{\Delta x} &= 0 \\
\frac{\delta(v_j^{n+1} - v_j^n)}{\Delta t} &= A(u_j^{n+1}) - v_j^{n+1}
\end{aligned} \tag{2.6}$$

Here u_j^n denotes an approximation of $u(x, t)$ over the grid block

$$B_j^n = [x_{j-1/2}, x_{j+1/2}) \times [t_n, t_{n+1}),$$

where $x_j = j\Delta x$ and $t_n = n\Delta t$. Furthermore, Δt and Δx denote the step lengths in the t and x directions, respectively. Similarly, v_j^n approximates v on B_j^n. The scheme is initialized by setting

$$u_j^0 = \frac{1}{\Delta x}\int_{x_{j-1/2}}^{x_{j+1/2}} u^0(x)\,dx \quad \text{and} \quad v_j^0 = \frac{1}{\Delta x}\int_{x_{j-1/2}}^{x_{j+1/2}} v^0(x)\,dx. \tag{2.7}$$

Throughout the paper, we will assume that the grid parameters satisfy the Courant–Friedrichs–Lewy (CFL) condition

$$\mu f'(u) \le 1 \tag{2.8}$$

for all $u \in [0,1]$, where $\mu = \Delta t/\Delta x$. It is interesting from a computational point of view to note that this condition is independent of the relaxation time δ; thus very small relaxation times do not force us to use equally small time steps.

For a grid function u, the discrete total variation is defined by

$$\mathrm{TV}(u) = \sum_{j\in\mathcal{Z}} |u_j - u_{j-1}|,$$

and $\|\cdot\|_1$ denotes the discrete L^1-norm defined by

$$\|u\|_1 = \Delta x \sum_{j\in\mathcal{Z}} |u_j|.$$

In order to study the deviation from equilibrium in the nonequilibrium system, we define

$$p_j^n = A(u_j^n) - v_j^n.$$

We consider initial data satisfying

$$\begin{array}{rc} \text{(i)} & (u_j^0, v_j^0) \in S \quad \text{for all } j \in \mathcal{Z}, \\ \text{(ii)} & \mathrm{TV}(u^0) + \mathrm{TV}(v^0) \le M, \\ \text{(iii)} & \|p^0\|_1 \le M\delta, \\ \text{(iv)} & (u_{-\infty}^0, v_{-\infty}^0) = (u_\infty^0, v_\infty^0) = 0, \end{array} \tag{2.9}$$

where M is a finite constant independent of the grid parameters and the relaxation time. Note that (2.9) is simply a discrete version of (2.4).

Based on the results of the scheme, a family of approximate solutions is defined by setting

$$(u_\Delta, v_\Delta)(x,t) = (u_j^n, v_j^n) \qquad \text{for } (x,t) \in B_j^n \quad \forall (j,n) \in \mathcal{Z} \times \mathcal{Z}^+.$$

By using the properties of the scheme presented above, the following theorem will be proved in section 4.

THEOREM 2.1. *Let (u^0, v^0) be initial data satisfying* (2.4) *and let (u_j^0, v_j^0) be the corresponding discrete initial values generated by* (2.7)*. Then as Δx and Δt tend to zero, the family $\{(u_\Delta, v_\Delta)\}$ of approximate solutions generated by the finite-difference scheme described above converges in $(L^1_{\mathrm{loc}}(\mathcal{R}\times\mathcal{R}_0^+))^2$ towards a pair of functions (u,v). Furthermore, the limit (u,v) is a unique entropy solution satisfying the requirements of Definition* 1.

The entropy solution (u,v) satisfies

$$\|p(\cdot,t)\|_1 = \|A(u) - v\|_1 \le M\delta \quad \text{for} \quad t \ge 0,$$

where M is a finite constant not depending on δ. If $(\bar{u}^0, \bar{v}^0)$ is another pair of initial data satisfying (2.4)*, there is a unique entropy solution $(\bar{u}, \bar{v})$ such that*

$$\|u(\cdot,t) - \bar{u}(\cdot,t)\|_1 + \|v(\cdot,t) - \bar{v}(\cdot,t)\|_1 \leq \|u^0 - \bar{u}^0\|_1 + \|v^0 - \bar{v}^0\|_1 \quad \text{for} \;\; t \geq 0. \qquad \square$$

Since our existence theorem is based on estimates independent of δ, we could by appealing to Helly's theorem prove convergence of a subsequence in L^1_{loc} of $(u,v) = (u_\delta, v_\delta)$ as $\delta \to 0$. However, we want more than convergence—we are also interested in the rate of convergence. In order to analyze this issue, we are lead to study a parabolic regularization of the system

$$\begin{aligned} u^\epsilon_t + f(u^\epsilon)_x &= \frac{1}{\delta}(v^\epsilon - A(u^\epsilon)) + \epsilon u^\epsilon_{xx}, \\ v^\epsilon_t &= \frac{1}{\delta}(A(u^\epsilon) - v^\epsilon) + \epsilon v^\epsilon_{xx}. \end{aligned} \tag{2.10}$$

The properties of this system are analyzed in section 5. In section 6, we begin by proving that (cf. Lemma 6.1)

$$\|u^\epsilon(\cdot,t) - u(\cdot,t)\|_1 + \|v^\epsilon(\cdot,t) - v(\cdot,t)\|_1 \leq M\epsilon^{1/2}, \tag{2.11}$$

where (u^ϵ, v^ϵ) solves the regularized problem and (u,v) solves (2.2). Then we introduce a regularized equilibrium model of the form

$$(w^\epsilon + A(w^\epsilon))_t + f(w^\epsilon)_x = \epsilon(w^\epsilon + A(w^\epsilon))_{xx}. \tag{2.12}$$

For this scalar equation, it is well known (cf. Kuznetsov [10]) that

$$\|w - w^\epsilon\|_1 \leq M\epsilon^{1/2}, \tag{2.13}$$

where w solves (2.1) and w^ϵ solves (2.12). Furthermore, we prove (cf. Lemma 6.2) that

$$\|u^\epsilon - w^\epsilon\|_1 \leq \frac{M\delta}{\epsilon}, \tag{2.14}$$

where δ is the relaxation time and ϵ is the diffusion coefficient. Collecting these results, we observe that

$$\|u - w\|_1 \leq \|u - u^\epsilon\|_1 + \|u^\epsilon - w^\epsilon\|_1 + \|w^\epsilon - w\|_1 \leq M\left(\epsilon^{1/2} + \frac{\delta}{\epsilon} + \epsilon^{1/2}\right).$$

Hence, by choosing $\epsilon = \delta^{2/3}$, we obtain the following result.

THEOREM 2.2. *Let (u^0, v^0) be a pair of initial data satisfying* (2.4)*, and let $w^0 = u^0$. Then for any finite $T > 0$, there is a finite constant M such that*

$$\|u(\cdot,t) - w(\cdot,t)\|_1 \leq M\delta^{1/3} \quad \textit{for all} \;\; 0 \leq t \leq T.$$

Here (u,v) and w are solutions of (2.2) *and* (2.1)*, respectively.* □

The rest of this paper is devoted to the proof of Theorems 2.1 and 2.2.

Remark. Heuristic arguments, e.g., by a Chapman–Enskog expansion, indicate a rate of 1/2 rather than 1/3 in Theorem 2.2, but we have not been able to give rigorous arguments for such an improved rate. Neither have we been able to prove that 1/3 is optimal. In estimates (2.11), (2.13), and (2.14) leading to this rate, the first and second results are sharp but estimate (2.14) is probably not sharp. Our attempts at improving this estimate have not been successful.

3. Bounds on the approximate solutions. In this section, we will study the properties of the finite-difference scheme in (2.6) approximating the solutions of (2.2). In fact, the existence of an entropy solution of the system is proved by demonstrating convergence of the family of approximate solutions generated by the finite-difference scheme. We start by considering the standard estimates needed to prove the existence of a bounded-total-variation (BV) solution: an L^∞-bound, a bound on the total variation, and finally an L^1-continuity estimate in time. With these bounds, independent of the mesh size and the relaxation time δ, the existence of a weak solution can be demonstrated; cf., e.g., Smoller [23].

We also show that if the initial data is close to equilibrium, the discrete solution remains close to equilibrium for all time. Finally, we show that the finite difference solutions satisfy a discrete entropy inequality. This latter property enables us to prove the existence of an entropy solution satisfying the requirements of Definition 1.

The finite-difference approximations have the following properties.

LEMMA 3.1. *Suppose that the initial data* (u^0, v^0) *satisfy* (2.9) *and that the grid parameters* Δt *and* Δx *satisfy the CFL condition* (2.8). *Then for any* $\delta > 0$, *there is a finite constant* M *independent of* δ, Δt, *and* Δx *such that*

$$\begin{aligned}
&\text{I.} && (u_j^n, v_j^n) \in \mathcal{S} \quad \textit{for all } (j,n) \in \mathcal{Z} \times \mathcal{Z}^+,\\
&\text{II.} && \mathrm{TV}(u^n) + \mathrm{TV}(v^n) \le \mathrm{TV}(u^0) + \mathrm{TV}(v^0),\\
&\text{III.} && \|p^n\|_1 \le M\delta,\\
&\text{IV.} && \|u^n - u^m\|_1 + \|v^n - v^m\|_1 \le M|n-m|\Delta t,\\
&\text{V.} && \|u^n - \bar{u}^n\|_1 + \|v^n - \bar{v}^n\|_1 \le \|u^0 - \bar{u}^0\|_1 + \|v^0 - \bar{v}^0\|_1,
\end{aligned}$$

where $(\bar{u}^n, \bar{v}^n)$ *is a discrete solution based on initial data* $(\bar{u}^0, \bar{v}^0)$ *satisfying* (2.9). □

Note that since the entropy solution will inherit the properties of the approximate solutions, it will satisfy a maximum principle (I), be TV stable (II), be close to equilibrium (III), be L^1-continuous in time (IV), and be stable in L^1 (V).

The next subsections are devoted to the proof of Lemma 3.1.

3.1. Proof of I: Maximum principle. For a fixed pair of (j,n), we let $(u,v) = (u_j^{n+1}, v_j^{n+1})$, $(\bar{u}, \bar{v}) = (u_j^n, v_j^n)$, and $(u^L, v^L) = (u_{j-1}^n, v_{j-1}^n)$. Then by (2.6), we get the equations

$$\begin{aligned}
u + v &= \bar{u} + \bar{v} - \frac{\Delta t}{\Delta x}(f(\bar{u}) - f(u^L),\\
(\delta + \Delta t)v &- \Delta t A(u) = \delta \bar{v}.
\end{aligned} \tag{3.1}$$

Let us first verify that (3.1) has a unique solution (u,v) for any given $(\bar{u}, \bar{v}, u^L, v^L)$. Denote by r_1 and r_2 the two right-hand sides such that

$$v = r_1 - u,$$

and thus the single equation

$$K(u) \equiv \Delta t A(u) + (\delta + \Delta t)u + r_2 - r_1(\delta + \Delta t) = 0$$

determines u. Since K is monotone and $K(\pm\infty) = \pm\infty$, it is clear that (u,v) is uniquely determined by (3.1).

Next, we assume that $0 \le \bar{u}, \bar{v}, u^L, v^L \le 1$, and we want to prove that this implies

$$0 \le u, v \le 1, \tag{3.2}$$

which, in fact, proves part I of Lemma 3.1. In order to prove (3.2), we consider u and v as functions of u^L, $\bar{u}$, and $\bar{v}$, i.e.,

$$u = u(u^L, \bar{u}, \bar{v}) \quad \text{and} \quad v = u(u^L, \bar{u}, \bar{v}).$$

Now we want to show that u and v are monotone in all arguments, and we start by considering $\frac{\partial u}{\partial \bar{v}}$ and $\frac{\partial v}{\partial \bar{v}}$. From the first equation of (3.1), we get

$$\frac{\partial u}{\partial \bar{v}} + \frac{\partial v}{\partial \bar{v}} = 1, \tag{3.3}$$

and the second equation gives

$$(\delta + \Delta t)\frac{\partial v}{\partial \bar{v}} - \Delta t A'(u)\frac{\partial u}{\partial \bar{v}} = \delta;$$

hence

$$\frac{\partial v}{\partial \bar{v}} = \frac{\delta + \Delta t A'(u)}{\delta + \Delta t + \Delta t A'(u)} \in (0,1),$$

and then by (3.3), $\frac{\partial u}{\partial \bar{v}} \in (0,1)$ and we conclude that

$$\frac{\partial u}{\partial \bar{v}}, \frac{\partial v}{\partial \bar{v}} > 0. \tag{3.4}$$

Similarly, by differentiating (3.1) with respect to $\bar{u}$, we get

$$\frac{\partial u}{\partial \bar{u}} + \frac{\partial v}{\partial \bar{u}} = 1 - \mu f'(\bar{u}) \tag{3.5}$$

and

$$(\delta + \Delta t)\frac{\partial v}{\partial \bar{u}} - \Delta t A'(u)\frac{\partial u}{\partial \bar{u}} = 0;$$

hence

$$\frac{\partial v}{\partial \bar{u}} = \frac{\Delta t A'(u)}{\delta + \Delta t + \Delta t A'(u)}(1 - \mu f'(\bar{u})) \equiv \omega(1 - \mu f'(\bar{u})), \tag{3.6}$$

where $\omega \in [0,1)$. Now (3.5) gives

$$\frac{\partial u}{\partial \bar{u}} = (1 - \mu f'(\bar{u}))(1 - \omega),$$

and then by the CFL condition (2.8), we can conclude that

$$\frac{\partial u}{\partial \bar{u}}, \frac{\partial v}{\partial \bar{u}} \geq 0. \tag{3.7}$$

Finally, by differentiating (3.1) with respect to u^L, we get

$$\frac{\partial u}{\partial u^L} + \frac{\partial v}{\partial u^L} = \mu f'(u^L)$$

and

$$(\delta + \Delta t)\frac{\partial v}{\partial u^L} - \Delta t A'(u)\frac{\partial u}{\partial u^L} = 0;$$

hence

$$\frac{\partial v}{\partial u^L} = \frac{\Delta t A'(u)}{\delta + \Delta t + \Delta t A'(u)} \mu f'(u^L) \equiv \bar{\omega} \mu f'(u^L), \tag{3.8}$$

where $\bar{\omega} \in [0, 1)$ and

$$\frac{\partial u}{\partial u^L} = \mu f'(u^L)(1 - \bar{\omega}) \tag{3.9}$$

Now (3.8) and (3.9) give

$$\frac{\partial u}{\partial u^L}, \frac{\partial v}{\partial u^L} \geq 0. \tag{3.10}$$

By using the monotonicity properties (3.4), (3.7), and (3.10) of $u = u(u^L, \bar{u}, \bar{v})$ and $v = v(u^L, \bar{u}, \bar{v})$, we have

$$u(0, 0, 0) \leq u(u^L, \bar{u}, \bar{v}) \leq u(1, 1, 1)$$

and

$$v(0, 0, 0) \leq v(u^L, \bar{u}, \bar{v}) \leq v(1, 1, 1).$$

It is easily seen that $u(0, 0, 0) = v(0, 0, 0) = 0$ and $u(1, 1, 1) = v(1, 1, 1) = 1$, and then the maximum principle I of the lemma follows by induction.

3.2. Proof of II: The total-variation estimate. Recall that the total variation of $\{u_j^n\}$ at time $t = n\Delta t$ is defined by

$$\text{TV}(u^n) = \sum_j |u_{j+1}^n - u_j^n|.$$

In order to prove the TV bound, it is convenient to introduce the following notation:

$$U_j^n = u_{j+1}^n - u_j^n$$

and

$$V_j^n = v_{j+1}^n - v_j^n.$$

Then by rewriting the scheme in (2.6) in the form

$$\begin{aligned} u_j^{n+1} &= u_j^n - \mu(f(u_j^n) - f(u_{j-1}^n)) - \frac{\Delta t}{\delta}(A(u_j^{n+1}) - v_j^{n+1}), \\ v_j^{n+1} &= v_j^n + \frac{\Delta t}{\delta}(A(u_j^{n+1}) - v_j^{n+1}), \end{aligned} \tag{3.11}$$

we get

(3.12)

$$U_j^{n+1} = U_j^n - \mu f'(\tilde{u}_{j+1/2}^n) U_j^n + \mu f'(\tilde{u}_{j-1/2}^n) U_{j-1}^n - \frac{\Delta t}{\delta} A'(\hat{u}_{j+1/2}^{n+1}) U_j^{n+1} + \frac{\Delta t}{\delta} V_j^{n+1},$$

$$V_j^{n+1} = V_j^n + \frac{\Delta t}{\delta} A'(\hat{u}_{j+1/2}^{n+1}) U_j^{n+1} - \frac{\Delta t}{\delta} V_j^{n+1}. \tag{3.13}$$

Here $\tilde{u}^n_{j+1/2}$ satisfies

$$f(u^n_{j+1}) - f(u^n_j) = f'(\tilde{u}^n_{j+1/2})U^n_j \tag{3.14}$$

and $\hat{u}^n_{j+1/2}$ satisfies

$$A(u^n_{j+1}) - A(u^n_j) = A'(\hat{u}^n_{j+1/2})U^n_j. \tag{3.15}$$

We multiply (3.12) by $\sigma(U^{n+1}_j)$ and (3.13) by $\sigma(V^{n+1}_j)$ (recall that σ denotes the sign function), and get

$$\begin{aligned}
&|U^{n+1}_j| \\
&\quad\le (1 - \mu f'(\tilde{u}^n_{j+1/2})|U^n_j| + \mu f'(\tilde{u}^n_{j-1/2})|U^n_{j-1}| - \frac{\Delta t}{\delta} A'(\hat{u}^{n+1}_{j+1/2})|U^{n+1}_j| + \frac{\Delta t}{\delta}|V^{n+1}_j|,\\
&|V^{n+1}_j| \le |V^n_j| + \frac{\Delta t}{\delta} A'(\hat{u}^{n+1}_{j+1/2})|U^{n+1}_j| - \frac{\Delta t}{\delta}|V^{n+1}_j|.
\end{aligned}$$

By adding these inequalities, we get

$$\sum_j |U^{n+1}_j| + \sum_j |V^{n+1}_j| \le \sum_j |U^n_j| + \sum_j |V^n_j|,$$

and thus

$$\mathrm{TV}(u^n) + \mathrm{TV}(v^n) \le \mathrm{TV}(u^0) + \mathrm{TV}(v^0)$$

by induction.

3.3. Proof of III: Deviation from equilibrium. Note that $p = A(u) - v$ measures the deviation from equilibrium in the nonequilibrium model. Part III of Lemma 3.1 states that if we give initial data close to equilibrium for the nonequilibrium model, the solution will remain close to equilibrium for all time. To prove this, we begin by noting that

$$p^{n+1}_j - p^n_j = A'(\hat{u}^{n+1}_j)(u^{n+1}_j - u^n_j) - (v^{n+1}_j - v^n_j),$$

where $\hat{u}^{n+1}_j$ satisfies

$$A(u^{n+1}_j) - A(u^n_j) = A'(\hat{u}^{n+1}_j)(u^{n+1}_j - u^n_j).$$

Then, using the scheme in (3.11), we get

$$p^{n+1}_j = p^n_j - \mu A'(\hat{u}^{n+1}_j) f'(\tilde{u}^n_{j-1/2})(u^n_j - u^n_{j-1}) - \frac{\Delta t}{\delta}(1 + A'(\hat{u}^{n+1}_j))p^{n+1}_j, \tag{3.16}$$

where $\tilde{u}^n_{j-1/2}$ satisfies (3.14). Multiplying this equation by $\sigma(p^{n+1}_j)$, we obtain

$$|p^{n+1}_j| \le |p^n_j| + \mu M |u^n_j - u^n_{j-1}| - \frac{\Delta t}{\delta}|p^{n+1}_j|,$$

where M is a finite constant independent of Δx, Δt, and δ and where we have used the fact that

$$A'(u) \ge 0$$

for all $u \in [0,1]$; cf. (2.3). Since the total variation of u^n is bounded, we have

$$\|p^{n+1}\|_1 \leq \|p^n\|_1 + \tilde{M}\Delta t - \frac{\Delta t}{\delta}\|p^{n+1}\|_1, \tag{3.17}$$

where again $\tilde{M}$ is another finite constant independent of Δx, Δt, and δ. From (3.17), we get

$$\|p^n\|_1 \leq \tilde{M}\delta \tag{3.18}$$

provided that the estimate holds for $n = 0$. This concludes the proof of part III of the lemma.

Remark. As mentioned above, our interest in this paper is solutions which are close to equilibrium. For this purpose, estimate (3.18) is exactly what we need. It should be mentioned, however, that some further insight could be gained from (3.17). In fact, by assuming that Δt is sufficiently small, i.e., $\Delta t \leq$ constant δ, inequality (3.17) implies that

$$\|p^n\|_1 \leq M_1\delta + e^{-M_2 t_n/\delta}\|p^0\|_1, \tag{3.19}$$

where M_1 and M_2 are finite constants independent of δ, Δt, and Δx. Hence, for any initial data of bounded variation lying in the state spaces, the nonequilibrium discrete solution approaches a state close to equilibrium at an exponential rate.

3.4. Proof of IV: L^1-continuity in time. By using the property of p_j^n derived above, the L^1-continuity in time is easily verified. Consider the scheme in (3.14) and (3.15) using the definition of p_j^n:

$$\begin{aligned} u_j^{n+1} &= u_j^n - \mu(f(u_j^n) - f(u_{j-1}^n)) - \frac{\Delta t}{\delta}p_j^{n+1}, \\ v_j^{n+1} &= v_j^n + \frac{\Delta t}{\delta}p_j^{n+1}. \end{aligned} \tag{3.20}$$

Now

$$\|u^{n+1} - u^n\|_1 + \|v^{n+1} - v^n\|_1 \leq M\Delta t \sum_j |u_j^n - u_{j-1}^n| + \frac{\Delta t}{\delta}\|p^{n+1}\|_1,$$

where M is a finite constant independent of Δx, Δt, and δ. Thus, using parts I, II, and III of Lemma 3.1, we get

$$\|u^{n+1} - u^n\|_1 + \|v^{n+1} - v^n\|_1 = O(\Delta t),$$

and then IV follows using the triangle inequality.

3.5. Proof of V: Stability in L^1. The proof of the L^1-stability is quite similar to the proof of the TV bound and is therefore omitted.

3.6. The discrete entropy inequalities. Finally, we would like to show that the solutions of the difference scheme in (2.6) satisfy an entropy inequality.

LEMMA 3.2. *Suppose that (u_j^0, v_j^0) satisfies (2.9), and let $\phi, \psi \in \mathcal{D}_+(T)$ for some $T > 0$. Furthermore, let N be a positive integer such that $t_N \leq T$, and let E :*

$[0,1] \to \mathcal{R}$ be a convex C^∞ entropy function with an associated entropy flux F, i.e., $F : [0,1] \to \mathcal{R}$ satisfies $F' = E'f'$. Then the following inequalities hold:

$$\begin{aligned} &\Delta t \sum_{n=0}^{N-1} \Delta x \sum_{j\in\mathcal{Z}} \left(\frac{\phi(x_j,t_{n+1}) - \phi(x_j,t_n)}{\Delta t} E(u_j^{n+1}) + \frac{\phi(x_{j+1},t_n) - \phi(x_j,t_n)}{\Delta x} F(u_j^n) \right) \\ &\qquad + \Delta x \sum_{j\in\mathcal{Z}} \left(E(u_j^0)\phi(x_j,0) - E(u_j^N)\phi(x_j,t_N) \right) \qquad (3.21) \\ &\qquad \geq \left(\frac{\Delta t}{\delta}\right) \sum_{n=0}^{N-1} (\Delta x) \sum_{j\in\mathcal{Z}} E'(u_j^{n+1})\phi(x_j,t_n)(A(u_j^{n+1}) - v_j^{n+1}) \end{aligned}$$

and

$$\begin{aligned} &\Delta t \sum_{n=0}^{N-1} \Delta x \sum_{j\in\mathcal{Z}} \left(\frac{\psi(x_j,t_{n+1}) - \psi(x_j,t_n)}{\Delta t} E(v_j^{n+1}) \right) \\ &\qquad + \Delta x \sum_{j\in\mathcal{Z}} \left(E(v_j^0)\psi(x_j,0) - E(v_j^N)\psi(x_j,t_N) \right) \qquad (3.22) \\ &\qquad \geq -\left(\frac{\Delta t}{\delta}\right) \sum_{n=0}^{N-1} (\Delta x) \sum_{j\in\mathcal{Z}} E'(v_j^{n+1})\psi(x_j,t_n)(A(u_j^{n+1}) - v_j^{n+1}). \end{aligned}$$

Proof. It will be sufficient to establish inequality (3.21) since (3.22) will follow by completely similar arguments. From the difference scheme in (2.6), we observe that

$$\begin{aligned} u_j^{n+1} - k = u_j^n - k - \mu(f(u_j^n) - f(k)) + \mu(f(u_{j-1}^n) - f(k)) \\ - \left(\frac{\Delta t}{\delta}\right)(A(u_j^{n+1}) - v_j^{n+1}) \end{aligned} \qquad (3.23)$$

for any $k \in [0,1]$. By multiplying this equality by $\sigma(u_j^{n+1} - k)$ and observing that the CFL condition (2.8) implies that

$$|u_j^n - k - \mu(f(u_j^n) - f(k))| = |u_j^n - k| - \mu|f(u_j^n) - f(k)|,$$

we obtain

$$\begin{aligned} |u_j^{n+1} - k| \leq |u_j^n - k| - \mu|f(u_j^n) - f(k)| + \mu|f(u_{j-1}^n) - f(k)| \\ - \left(\frac{\Delta t}{\delta}\right) \sigma(u_j^{n+1} - k)(A(u_j^{n+1}) - v_j^{n+1}). \end{aligned}$$

If we multiply this final inequality by $\phi(x_j,t_n)$, sum over $0 \leq n \leq N-1$ and $j \in \mathcal{Z}$, and apply summation by parts with respect to time and space, the following inequality appears:

$$\begin{aligned} &\Delta t \sum_{n=0}^{N-1} \Delta x \sum_{j\in\mathcal{Z}} \left(\frac{\phi(x_j,t_{n+1}) - \phi(x_j,t_n)}{\Delta t} |u_j^{n+1} - k| \right. \\ &\qquad \left. + \frac{\phi(x_{j+1},t_n) - \phi(x_j,t_n)}{\Delta x} |f(u_j^n) - f(k)| \right) \qquad (3.24) \\ &\qquad + \Delta x \sum_{j\in\mathcal{Z}} \left(|u_j^0 - k|\phi(x_j,0) - |u_j^N - k|\phi(x_j,t_N) \right) \qquad (3.25) \end{aligned}$$

$$\geq \left(\frac{\Delta t}{\delta}\right) \sum_{n=0}^{N-1} (\Delta x) \sum_{j \in \mathcal{Z}} \sigma(u_j^{n+1} - k)\phi(x_j, t_n)(A(u_j^{n+1}) - v_j^{n+1}).$$

Now let $E_m : I \to \mathcal{R}$ be a convex piecewise-linear function of the form

$$E_m(u) = \beta_0(u - k_0) + \sum_{i=1}^{m} \beta_i |u - k_i|, \tag{3.26}$$

where $\beta_i \geq 0$ for $i = 1, 2, \ldots, m$, and let F_m be the corresponding flux given by

$$F_m(u) = \beta_0(f(u) - f(k_0)) + \sum_{i=1}^{m} \beta_i |f(u) - f(k_i)|.$$

Observe that $F_m'(u) = E_m'(u)f'(u)$ and that equality (3.23) and inequality (3.25) imply that the desired inequality (3.21) holds if the smooth functions E and F are replaced by the polygonal functions E_m and F_m. However, for any smooth convex function E, we can choose E_m of the form of (3.26) such that E_m and E_m' converge uniformly on $[0, 1]$ as $m \to \infty$ to E and E', respectively, and hence we obtain (3.21). □

4. Properties of the entropy solutions.

4. Properties of the entropy solutions. In this section, we shall conclude the proof of Theorem 2.1. The properties of the entropy solutions of system (2.2) will be derived from the corresponding properties derived for the finite-difference scheme in (2.6) above. First, we will establish the existence of entropy solutions for (2.2) by a limit argument. Thereafter, uniqueness and continuous dependence with respect to the initial data in L^1 are proved. From a proper application of Helly's theorem, the following lemma can be derived by standard arguments from parts I–IV of Lemma 3.1 (cf. [16] or [23, Chapter 16]).

LEMMA 4.1. *Suppose that (u^0, v^0) satisfies the requirements in (2.4) above. Then as the mesh parameters Δx and Δt tend to zero, there is a subsequence $\{(u_\Delta, v_\Delta)\}$ of the family of approximate solutions generated by (2.6) that converges in $(L^1_{\text{loc}}(\mathcal{R} \times \mathcal{R}_0^+))^2$ to a pair of functions (u, v). Furthermore, $u(\cdot, t), v(\cdot, t) \in \text{BV}$ for all $t \geq 0$, $(u(x, t), v(x, t)) \in \mathcal{S}$ for $(x, t) \in \mathcal{R} \times \mathcal{R}_0^+$, and the estimates*

$$\text{TV}(u(\cdot, t)) + \text{TV}(v(\cdot, t)) \leq \text{TV}(u^0) + \text{TV}(v^0), \tag{4.1}$$

$$\|p(\cdot, t)\|_1 \leq M\delta, \tag{4.2}$$

$$\|u(\cdot, t) - u(\cdot, \tau)\|_1 + \|v(\cdot, t) - v(\cdot, \tau)\|_1 \leq M|t - \tau| \tag{4.3}$$

hold, where $p(\cdot, t) = A(u(\cdot, t)) - v(\cdot, t)$ and M is independent of t and δ. □

Since the discrete solutions satisfy the entropy inequalities (3.21) and (3.22), we also easily derive that the limit (u, v) is an entropy solution of (2.2).

LEMMA 4.2. *Assume that (u^0, v^0) satisfies the requirements in (2.4), and let (u, v) be the pair of functions constructed in Lemma 4.1. Then (u, v) is an entropy solution of (2.2).*

Proof. We have to show that (u, v) satisfy the variational inequality (2.5) for any $\varphi, \psi \in \mathcal{D}_+(T)$ and $(k, q) \in \mathcal{S}$. However, by letting $\Delta t, \Delta x \to 0$ in (3.21), it follows that for any smooth entropy/entropy flux pair (E, F),

$$\int_0^T \int_{\mathcal{R}} [E(u)\varphi_t + F(u)\varphi_x] dx\, dt$$

$$\begin{aligned} &+\int_{\mathcal{R}}[E(u^0)\varphi(x,0)-E(u(x,T))\varphi(x,T)]dx \\ &\geq \frac{1}{\delta}\int_0^T\int_{\mathcal{R}}E'(u)\varphi(A(u)-v)dx\,dt. \end{aligned} \tag{4.4}$$

Hence, by choosing a sequence of smooth entropy/entropy flux pairs (E_θ, F_θ) such that as $\theta \to 0$,

$$E_\theta(u) \to |u-k| \quad \text{and} \quad E'_\theta \to \sigma(u-k)$$

pointwise, the dominated-convergence theorem implies that

$$\begin{aligned} &\int_0^T\int_{\mathcal{R}}[|u-k|\varphi_t + |f(u)-f(k)|\varphi_x]dx\,dt \\ &\qquad +\int_{\mathcal{R}}[|u^0-k|\varphi(x,0)-|u(x,T)-k|\varphi(x,T)]dx \\ &\qquad \geq \frac{1}{\delta}\int_0^T\int_{\mathcal{R}}\sigma(u-k)\varphi(A(u)-v)dx\,dt \end{aligned}$$

for all $k \in [0,1]$ and $\varphi \in \mathcal{D}_+(T)$. The rest of the desired inequality (2.5) can be derived from (3.22) by similar arguments. □

In order to show that the entropy solutions are unique, we will use arguments inspired by Kruzkov [9], Kuznetsov [10], and Lucier [14]. For any $\theta \in (0,1]$, we introduce the mollifier function ω_θ on $\mathcal{R}$ given by

$$\omega_\theta(x) = \frac{1}{\theta}\Omega\left(\frac{x}{\theta}\right),$$

where $\Omega : \mathcal{R} \to \mathcal{R}$ is a nonnegative, symmetric C^∞-function with support in $[-1,1]$ and satisfying

$$\int_{\mathcal{R}}\Omega(x)dx = 1.$$

Hence

$$\int_{\mathcal{R}}\omega_\theta(x)dx = 1$$

and $\operatorname{supp}(\omega_\theta) \subset [-\theta,\theta]$. Furthermore, we define a smooth approximation σ_θ of the sign function σ by

$$\sigma_\theta(x) = -1 + 2\int_{-\infty}^x \omega_\theta(y)dy$$

and a smooth approximation μ_θ of the absolute-value function by

$$\mu_\theta(x) = \theta + \int_{-\theta}^x \sigma_\theta(y)dy.$$

We observe that ${\mu_\theta}' = \sigma_\theta$ and ${\sigma_\theta}' = 2\omega_\theta$. Also,

$$\begin{aligned} \sigma_\theta(x) &= \sigma(x) \quad \text{for } |x| \geq \theta, \\ \mu_\theta(x) &= |x| \quad \text{for } |x| \geq \theta, \end{aligned}$$

and

$$|\mu_\theta(x) - |x|| \le \theta \quad \text{for all } x \in \mathcal{R}.$$

The next result shows that the entropy solutions of (2.2) are unique and depend continuously, independently of δ, on the initial data in L^1.

LEMMA 4.3. *Let (u, v) and $(\bar{u}, \bar{v})$ be two entropy solutions of* (2.2) *with initial data (u^0, v^0) and $(\bar{u}^0, \bar{v}^0)$, respectively, satisfying the requirements in* (2.4). *Then*

$$\|u(\cdot, t) - \bar{u}(\cdot, t)\|_1 + \|v(\cdot, t) - \bar{v}(\cdot, t)\|_1 \le \|u^0 - \bar{u}^0\|_1 + \|v^0 - \bar{v}^0\|_1 \quad \text{for all } t \ge 0.$$

Proof. The result follows by generalizing Kuznetsov's argument in [10] for scalar conservation laws. Let $T > 0$ be given and choose $(k, q) = (\bar{u}(y, \tau), \bar{v}(y, \tau))$ and $\varphi(x, t) = \psi(x, t) = \omega_\theta(x - y)\omega_\theta(t - \tau)$ in (2.5) for the solution (u, v). Integrating the result over $\mathcal{R} \times [0, T]$ with respect to y and τ, we obtain

(4.5)
$$\begin{aligned}
&\int_0^T \int_{\mathcal{R}} \int_0^T \int_{\mathcal{R}} (|u - \bar{u}| + |v - \bar{v}|)\omega_\theta{}'(t - \tau)\omega_\theta(x - y) dx\, dt\, dy\, d\tau \\
&\quad + \int_0^T \int_{\mathcal{R}} \int_0^T \int_{\mathcal{R}} |f(u) - f(\bar{u})| \omega_\theta(t - \tau)\omega_\theta{}'(x - y) dx\, dt\, dy\, d\tau \\
&\quad + \int_0^T \int_{\mathcal{R}} \int_{\mathcal{R}} [|u^0(x) - \bar{u}| + |v^0(x, t) - \bar{v}|]\omega_\theta(\tau)\omega_\theta(x - y) dx\, dy\, d\tau \\
&\quad - \int_0^T \int_{\mathcal{R}} \int_{\mathcal{R}} [|u(x, T) - \bar{u}| + |v(x, T) - \bar{v}|]\omega_\theta(T - \tau)\omega_\theta(x - y) dx\, dy\, d\tau \\
&\ge \frac{1}{\delta} \int_0^T \int_{\mathcal{R}} \int_0^T \int_{\mathcal{R}} (\sigma(u - \bar{u}) - \sigma(v - \bar{v}))(A(u) - v)\omega_\theta(x - y)\omega_\theta(t - \tau) dx\, dt\, dy\, d\tau,
\end{aligned}$$

where $u = u(x, t)$, $v = v(x, t)$, $\bar{u} = \bar{u}(y, \tau)$, and $\bar{v} = \bar{v}(y, \tau)$. By performing a similar operation on inequality (2.5) for the solution $(\bar{u}, \bar{v})$, but where we reverse the role of the variables (x, t) and (y, τ), and by adding the inequality obtained to (4.5), we observe that the terms which contain derivatives will cancel out. Hence we obtain an inequality of the form

(4.6)
$$\begin{aligned}
&R(\theta) - L(\theta) \\
&\quad \ge \frac{1}{\delta} \int_0^T \int_{\mathcal{R}} \int_0^T \int_{\mathcal{R}} (\sigma(u - \bar{u}) - \sigma(v - \bar{v}))(A(u) - A(\bar{u}) \\
&\qquad - (v - \bar{v}))\omega_\theta(x - y)\omega_\theta(t - \tau) dx\, dt\, dy\, d\tau,
\end{aligned}$$

where

$$\begin{aligned}
R(\theta) = &\int_0^T \int_{\mathcal{R}} \int_{\mathcal{R}} (|u^0(x) - \bar{u}| + |v^0(x) - \bar{v}|)\omega_\theta(x - y)\omega_\theta(\tau) dx\, dy\, d\tau \\
&+ \int_0^T \int_{\mathcal{R}} \int_{\mathcal{R}} (|u - \bar{u}^0(y)| + |v - \bar{v}^0(y)|)\omega_\theta(x - y)\omega_\theta(t) dx\, dy\, dt
\end{aligned}$$

and

$$\begin{aligned}
L(\theta) = &\int_0^T \int_{\mathcal{R}} \int_{\mathcal{R}} (|u(x, T) - \bar{u}| + |v(x, T) - \bar{v}|)\omega_\theta(T - \tau)\omega_\theta(x - y) dx\, dy\, d\tau \\
&+ \int_0^T \int_{\mathcal{R}} \int_{\mathcal{R}} (|u - \bar{u}(y, T)| + |v - \bar{v}(y, T)|)\omega_\theta(T - t)\omega_\theta(x - y) dx\, dy\, dt.
\end{aligned}$$

Due to the monotonicity of $A = A(u)$ (cf. (2.3)), the integrand on the right-hand side of (4.6) is nonnegative, and thus we get

$$L(\theta) \leq R(\theta). \tag{4.7}$$

By using the properties in (4.1) and (4.3) for both pairs of solutions, it follows easily (cf., e.g., [26]) that

$$|R(\theta) - (\|u^0 - \bar{u}^0\|_1 + \|v^0 - \bar{v}^0\|_1)| \leq M\theta$$

and

$$|L(\theta) - (\|u(\cdot, T) - \bar{u}(\cdot, T)\|_1 + \|v(\cdot, T) - \bar{v}(\cdot, T)\|_1)| \leq M\theta,$$

where M is independent of θ. Thus the desired result follows from (4.7) by letting $\theta \to 0$. □

Remarks. (1) Note that Lemmas 4.1, 4.2, and 4.3 prove Theorem 2.1. In particular, the uniqueness result of Lemma 4.3 implies that the complete sequence $\{(u_\Delta, v_\Delta)\}$ converges towards (u, v).

(2) In the proof of Theorem 2.1, we have not used the assumption on A'' given in (2.3).

(3) The stability result of Lemma 4.3 could also be proved by appealing to the similar property of the discrete scheme; cf. part V of Lemma 3.1. However, in order to prove both stability *and uniqueness* of the entropy solution, the argument presented above is needed.

5. A regularized model. The purpose of the final two sections of this paper is to analyze the convergence as δ tends to zero of the solutions of the model in (2.2) to the corresponding solutions of the equilibrium model given in (2.1). The main purpose of the discussion is to establish that the difference between these solutions, measured in the L^1-norm, is bounded by $O(\delta^{1/3})$.

In order to study this convergence, a regularized model is introduced. For any $\epsilon, \delta \in (0, 1]$, consider the pure initial-value problem

$$\begin{aligned} u_t^\epsilon + f(u^\epsilon)_x &= -\frac{1}{\delta}(A(u^\epsilon) - v^\epsilon) + \epsilon u_{xx}^\epsilon, \\ v_t^\epsilon &= \frac{1}{\delta}(A(u^\epsilon) - v^\epsilon) + \epsilon v_{xx}^\epsilon, \\ u^\epsilon(x, 0) = u^{\epsilon,0}(x), &\qquad v^\epsilon(x, 0) = v^{\epsilon,0}(x), \end{aligned} \tag{5.1}$$

where f and A are the given functions of u satisfying (2.3).

Since system (5.1) contains proper diffusion terms, the solutions will in general be smooth functions of x and t. In order to state a suitable regularity result for the system, we let $H^m(\mathcal{R})$, $m \geq 0$, denote the L^2-based Sobolev spaces of order m on $\mathcal{R}$ and we let $H^\infty(\mathcal{R}) = \bigcap_{m \geq 0} H^m(\mathcal{R})$.

Hence $H^\infty(\mathcal{R})$ consists of all C^∞-functions with the property that any derivative is in $L^2(\mathcal{R})$. In particular, if $u \in H^\infty(\mathcal{R})$, then

$$\frac{\partial^j}{\partial x^j} u(x) \to 0 \quad \text{as } x \to \pm\infty \tag{5.2}$$

for any $j \geq 0$.

In order to avoid technical difficulties with respect to smoothness, we will simply assume that the initial functions $u^{\epsilon,0}$ and $v^{\epsilon,0}$ of (5.1) are in $H^\infty(\mathcal{R})$. The following regularity result can then be established.

Lemma 5.1. *Assume that* $(u^{\epsilon,0}(x), v^{\epsilon,0}(x)) \in \mathcal{S}$ *for all* $x \in \mathcal{R}$ *and that* $u^{\epsilon,0}, v^{\epsilon,0} \in H^\infty(\mathcal{R})$. *Then there exists a unique classical solution* (u^ϵ, v^ϵ) *of* (5.1) *such that*

$$\frac{\partial^j u^\epsilon}{\partial t^j}(\cdot, t),\ \frac{\partial^j v^\epsilon}{\partial t^j}(\cdot, t) \in H^\infty(\mathcal{R})$$

for all $t \geq 0$ *and integers* $j \geq 0$. *Furthermore,*

$$(u^\epsilon(x,t), v^\epsilon(x,t)) \in \mathcal{S}$$

for all $x \in \mathcal{R}$ *and* $t \geq 0$. □

The regularity part of this lemma is rather standard and a proof can be found, for example, in [8] (cf. Chapter 5 of [8]), while the invariant region part follows from the assumptions on A and the result of Chueh, Conley, and Smoller [4], (cf. Theorem 4.4. of [4]).

In section 3, independently of the relaxation parameter δ and the discretization parameters Δx and Δt, we derived bounds for the total variation of the solution of the discrete scheme (2.6). We will need similar bounds for the solution of the regularized model (5.1), i.e., TV bounds independent of the parameters ϵ and δ. We observe that if $u \in H^\infty(\mathcal{R})$, then $u \in \mathrm{BV}$ if and only if $u_x \in L^1(\mathcal{R})$. Note that for these functions, $\mathrm{TV}(u) = \|u_x\|_1$.

Lemma 5.2. *Assume that* $(u^{\epsilon,0}(x), v^{\epsilon,0}(x)) \in \mathcal{S}$ *for all* $x \in \mathcal{R}$ *and that* $u^{\epsilon,0}, v^{\epsilon,0} \in H^\infty(\mathcal{R}) \bigcap \mathrm{BV}$. *If* (u^ϵ, v^ϵ) *is the solution of* (5.1), *then* $u^\epsilon(\cdot,t), v^\epsilon(\cdot,t) \in H^\infty(\mathcal{R}) \bigcap \mathrm{BV}$ *for all* $t \geq 0$ *and*

$$\|u_x^\epsilon(\cdot,t)\|_1 + \|v_x^\epsilon(\cdot,t)\|_1 \leq \|u_x^{\epsilon,0}\|_1 + \|v_x^{\epsilon,0}\|_1. \tag{5.3}$$

Furthermore, if the initial data is chosen such that $u_t^\epsilon(\cdot,0), v_t^\epsilon(\cdot,0) \in L^1(\mathcal{R})$, *then* $u_t^\epsilon(\cdot,t), v_t^\epsilon(\cdot,t) \in L^1(\mathcal{R})$ *for all* $t \geq 0$ *and*

$$\|u_t^\epsilon(\cdot,t)\|_1 + \|v_t^\epsilon(\cdot,t)\|_1 \leq \|u_t^\epsilon(\cdot,0)\|_1 + \|v_t^\epsilon(\cdot,0)\|_1. \tag{5.4}$$

Proof. For notational convenience, we will throughout this proof denote the solution of (5.1) by (u, v), i.e., the explicit dependence on the regularization parameter ϵ is suppressed. Let $\mu_\theta : \mathcal{R} \to \mathcal{R}$, $\theta \in (0,1]$, be the smooth approximation of the absolute-value function introduced in section 4. Hence ${\mu_\theta}' = \sigma_\theta$, where σ_θ is the smooth approximation of the sign function, while

$${\mu_\theta}'' = {\sigma_\theta}' = 2\omega_\theta.$$

Now consider system (5.1) and differentiate both equations with respect to x. We then obtain the following system:

$$\begin{aligned}(u_x)_t + (f'(u)u_x)_x &= -\frac{1}{\delta}(A'(u)u_x - v_x) + \epsilon(u_x)_{xx},\\ (v_x)_t &= \frac{1}{\delta}(A'(u)u_x - v_x) + \epsilon(v_x)_{xx}.\end{aligned} \tag{5.5}$$

Furthermore, multiply the first equation of (5.5) by $\sigma_\theta(u_x)$ and the second equation by $\sigma_\theta(v_x)$ and integrate over $(-M, M) \times (0, T)$ for $M, T > 0$. If we add the results from the two equations, we obtain

$$\tag{5.6}\begin{aligned}&\int_{-M}^{M}(\mu_\theta(u_x(x,T))+\mu_\theta(v_x(x,T)))dx+\int_0^T\int_{-M}^{M}(f'(u)u_x)_x\sigma_\theta(u_x)dx\ dt\\&=\int_{-M}^{M}(\mu_\theta(u_x^0(x))+\mu_\theta(v_x^0(x)))dx-\frac{1}{\delta}\int_0^T\int_{-M}^{M}(A'(u)u_x-v_x)(\sigma_\theta(u_x)-\sigma_\theta(v_x))dx\ dt\\&\qquad+\epsilon\int_0^T\int_{-M}^{M}(u_{xxx}\sigma_\theta(u_x)+v_{xxx}\sigma_\theta(v_x))dx\ dt.\end{aligned}$$

We observe that since $|\sigma_\theta(r)|\le 1$ and since $\sigma_\theta(r)\to\sigma(r)$ for all $r\in\mathcal{R}$, it follows from the dominated-convergence theorem that

$$\tag{5.7}\begin{aligned}\lim_{\theta\to 0}-\int_0^T\int_{-M}^{M}&(A'(u)u_x-v_x)(\sigma_\theta(u_x)-\sigma_\theta(v_x))dx\ dt\\&=-\int_0^T\int_{-M}^{M}(A'(u)u_x-v_x)(\sigma(u_x)-\sigma(v_x))dx\ dt\le 0.\end{aligned}$$

By using integration by parts with respect to x, we derive

$$\begin{aligned}&\int_0^T\int_{-M}^{M}(f'(u)u_x)_x\sigma_\theta(u_x)dx\ dt\\&\quad=\int_0^T[f'(u)u_x\sigma_\theta(u_x)]\mid_{x=-M}^{M}dt-2\int_0^T\int_{-M}^{M}f'(u)u_xu_{xx}\omega_\theta(u_x)dx\ dt.\end{aligned}$$

Since $r\omega_\theta(r)$ is uniformly bounded and since for any $r\in\mathcal{R}$, $\lim_{\theta\to 0}r\omega_\theta(r)=0$, it follows again from the dominated-convergence theorem that

$$\lim_{\theta\to 0}\int_0^T\int_{-M}^{M}f'(u)u_xu_{xx}\omega_\theta(u_x)dx\ dt=0.$$

Hence (5.2) implies that

$$\tag{5.8}\lim_{M\to\infty}\lim_{\theta\to 0}\int_0^T\int_{-M}^{M}(f'(u)u_x)_x\sigma_\theta(u_x)dx\ dt=0.$$

Finally, we observe that integration by parts with respect to x implies that

$$\int_0^T\int_{-M}^{M}(u_x)_{xx}\sigma_\theta(u_x)dx\ dt=\int_0^T u_{xx}\sigma_\theta(u_x)\mid_{x=-M}^{M}dt-2\int_0^T\int_{-M}^{M}u_{xx}^2\omega_\theta(u_x)dx\ dt.$$

Since $\omega_\theta(r)\ge 0$ and by treating the v term in the same way, we therefore obtain

$$\lim_{M\to\infty}\limsup_{\theta\to 0}\epsilon\int_0^T\int_{-M}^{M}((u_x)_{xx}\sigma_\theta(u_x)+(v_x)_{xx}\sigma_\theta(v_x))dx\ dt\le 0.$$

Together with (5.6), (5.7), and (5.8), this implies that

$$\lim_{M\to\infty}\int_{-M}^{M}(|u_x(x,T)|+|v_x(x,T)|)dx\le\|u_x^0\|_1+\|v_x^0\|_1,$$

and hence $u(\cdot,T), v(\cdot,T) \in \mathrm{BV}$ and (5.3) holds. Inequality (5.4) can be derived by a completely analogous argument by differentiating system (5.1) with respect to t instead of x. The details of this derivation are therefore omitted. □

As above, we need to measure the deviation from equilibrium,

$$p^\epsilon = A(u^\epsilon) - v^\epsilon.$$

LEMMA 5.3. *Assume that the initial data $u^{\epsilon,0}$ and $v^{\epsilon,0}$ of* (5.1) *satisfy all of the assumptions given in Lemma* 5.2. *Furthermore, assume that $\|p^\epsilon(\cdot,0)\|_1 \le M_0\delta$ and $\|p^\epsilon_x(\cdot,0)\|_1 \le M_0\delta/\epsilon$, where M_0 is independent of ϵ and δ. Then there is a constant M, independent of ϵ and δ, such that*

$$\|p^\epsilon(\cdot,t)\|_1 \le M\delta \tag{5.9}$$

and

$$\|p^\epsilon_x(\cdot,t)\|_1 \le \frac{M\delta}{\epsilon} \tag{5.10}$$

for all $t \ge 0$.

Proof. As above, we suppress the explicit dependence of ϵ throughout the proof. From the definition of the function p and from (5.1), it follows that

$$p_t = A'(u)u_t - v_t = A'(u)\left(\epsilon u_{xx} - \frac{1}{\delta}p - f(u)_x\right) - \epsilon v_{xx} - \frac{1}{\delta}p.$$

Since

$$p_{xx} = A'(u)u_{xx} + A''(u){u_x}^2 - v_{xx},$$

the expression above can be written as follows:

$$p_t = \epsilon p_{xx} - \frac{1}{\delta}(1 + A'(u))p - \epsilon A''(u){u_x}^2 - A'(u)f(u)_x. \tag{5.11}$$

Observe that if we multiply the first equation of (5.1) by $u(x,t)$ and integrate with respect to x, we obtain

$$\epsilon\int_{\mathcal{R}} {u_x}^2(x,t)dx \le \frac{1}{\delta}\int_{\mathcal{R}} |p(x,t)||u(x,t)|dx + \int_{\mathcal{R}} |u_t(x,t)||u(x,t)|dx.$$

Hence the results of Lemmas 5.1 and 5.2 imply that there is a constant M, independent of ϵ, δ, and t, such that

$$\epsilon\int_{\mathcal{R}} {u_x}^2(x,t)dx \le \frac{\|p(\cdot,t)\|_1}{\delta} + M.$$

If we multiply (5.11) by $\sigma_\theta(p)$, integrate with respect to x, and let θ tend to zero, we obtain

$$\frac{d}{dt}\|p(\cdot,t)\|_1 \le M - \frac{1-\alpha}{\delta}\|p(\cdot,t)\|_1,$$

where $0 \le \alpha < 1$ (cf. (2.3)). Gronwall's lemma therefore implies that

$$\begin{aligned}
&\|p(\cdot,t)\|_1 \\
&\quad \le \exp\left(-\frac{(1-\alpha)t}{\delta}\right)\|p(\cdot,0)\|_1 + \left(\frac{M\delta}{(1-\alpha)}\right)\left(1 - \exp\left(-\frac{(1-\alpha)t}{\delta}\right)\right) \\
&\quad \le \|p(\cdot,0)\|_1 + \frac{M\delta}{1-\alpha}.
\end{aligned}$$

We have therefore established (5.9).

In order to derive (5.10), we differentiate (5.11) with respect to x and obtain the equation

$$(p_x)_t = \epsilon(p_x)_{xx} - \frac{1}{\delta}(1 + A'(u))p_x + R, \tag{5.12}$$

where $R = R(x,t)$ is given by

$$\begin{aligned} R = &-\epsilon(A'''(u){u_x}^3 + 2A''(u)u_x u_{xx}) \\ &- \frac{1}{\delta}A''(u)u_x p - A''(u)f'(u){u_x}^2 - A'(u)(f'(u)u_{xx} - f''(u){u_x}^2). \end{aligned}$$

Now observe that $\|u_t(\cdot,t)\|_1, \|u_x(\cdot,t)\|_1$, and $(1/\delta)\|p(\cdot,t)\|_1$ are bounded independently of ϵ, δ, and t. Hence the first equation of (5.1) implies that $\epsilon\|u_{xx}\|_1$ admits a similar bound, and since

$$\lim_{x\to\pm\infty} u_x(x,t) = 0,$$

we obtain

$$\|u_x(\cdot,t)\|_\infty \le \frac{M}{\epsilon}, \tag{5.13}$$

where M is independent of ϵ, δ, and t. However, from (5.13) and the earlier bounds (5.3) and (5.9), we derive that

$$\|R(\cdot,t)\|_1 \le \frac{M}{\epsilon} \tag{5.14}$$

for all $t \ge 0$. Arguing as we did above, we therefore obtain from (5.12) that

$$\frac{d}{dt}\|p_x(\cdot,t)\|_1 \le \frac{M}{\epsilon} - \frac{1}{\delta}\|p_x(\cdot,t)\|_1,$$

and hence (5.10) follows from Gronwall's lemma. □

6. The rate of convergence. The purpose of this final section of the paper is to complete the proof of Theorem 2.2. Let (u,v) be the entropy solution of (2.2) with initial data (u^0,v^0). As in Theorem 2.1, we assume that the initial data satisfy the requirements in (2.4), i.e., $(u^0(x),v^0(x)) \in \mathcal{S}$ for $x \in \mathcal{R}$, $u^0, v^0 \in \mathrm{BV}$, and

$$\lim_{x\to\pm\infty} u^0(x) = \lim_{x\to\pm\infty} v^0(x) = 0$$

and that

$$\|p^0\|_1 = \|A(u^0) - v^0\|_1 \le M\delta,$$

where M is independent of δ. Furthermore, let w be the entropy solution of the equilibrium model (2.1) with $w(x,0) = u^0(x)$.

Our goal is to show that

$$\|u(\cdot,t) - w(\cdot,t)\|_1 \le M\delta^{1/3} \quad \text{for } 0 \le t \le T, \tag{6.1}$$

where M is independent of δ.

In order to establish the desired estimate (6.1), we shall rely on properties of the regularized model (5.1). Throughout this section, we assume that $\delta \leq \epsilon$. In fact, at the end of this section, we will choose $\epsilon = \delta^{2/3}$.

Let $\{u^{\epsilon,0}\}$ be a sequence of functions in $H^\infty(\mathcal{R})$ such that

$$\begin{gathered}\|u^{\epsilon,0} - u^0\|_1 \leq M\epsilon,\\ \mathrm{TV}(u^{\epsilon,0}) \leq \mathrm{TV}(u^0),\\ \|u^{\epsilon,0}_{xx}\|_1 \leq \frac{M}{\epsilon},\end{gathered} \tag{6.2}$$

where the constant M is independent of ϵ and δ. Such a sequence can be constructed by a standard averaging procedure using the mollifier function ω_ϵ. Furthermore, let

$$v^{\epsilon,0} = A(u^{\epsilon,0}); \tag{6.3}$$

then $p^{\epsilon,0} \equiv 0$ and

$$\begin{gathered}(u^{\epsilon,0}(x), v^{\epsilon,0}(x)) \in \mathcal{S} \quad \text{for all } x \in \mathcal{R},\\ \|v^{\epsilon,0} - v^0\|_1 \leq M\epsilon,\\ \mathrm{TV}(v^{\epsilon,0}) \leq M,\\ \|v^{\epsilon,0}_{xx}\|_1 \leq \frac{M}{\epsilon}.\end{gathered} \tag{6.4}$$

Let (u^ϵ, v^ϵ) denote the solution of system (5.1) corresponding to the initial data $(u^{\epsilon,0}, v^{\epsilon,0})$. We observe that (6.2) and (6.4) imply that $\|u^\epsilon_t(\cdot,0)\|_1$ and $\|v^\epsilon_t(\cdot,0)\|_1$ are bounded independently of ϵ and δ. Hence the initial data $(u^{\epsilon,0}, v^{\epsilon,0})$ satisfy all of the assumption of the Lemmas 5.1–5.3.

LEMMA 6.1. *Let u^0, v^0, $\{u^{\epsilon,0}\}$, and $\{v^{\epsilon,0}\}$ satisfy* (2.4), (6.2), *and* (6.3). *Then for any $T > 0$, there is a constant M, independent of ϵ and δ, such that*

$$\|u^\epsilon(\cdot,t) - u(\cdot,t)\|_1 + \|v^\epsilon(\cdot,t) - v(\cdot,t)\|_1 \leq M\epsilon^{1/2} \quad \textit{for } 0 \leq t \leq T.$$

Proof. The proof is based on the characterization in (2.5) of the entropy solution of (2.2) and a corresponding variational inequality for the regularized system (5.1). We first observe that for any $(k,q) \in \mathcal{S}$, the following system holds

$$\begin{gathered}(u^\epsilon - k)_t + (f(u^\epsilon) - f(k))_x = -\frac{1}{\delta}(A(u^\epsilon) - v^\epsilon) + \epsilon u^\epsilon_{xx},\\ (v^\epsilon - q)_t = \frac{1}{\delta}(A(u^\epsilon) - v^\epsilon) + \epsilon v^\epsilon_{xx}.\end{gathered} \tag{6.5}$$

Let $\varphi, \psi \in \mathcal{D}_+(T)$. For any $\theta \in (0,1)$, multiply the first equation of (6.5) by $\sigma_\theta(u^\epsilon - k)\varphi$ and the second equation by $\sigma_\theta(v^\epsilon - k)\psi$, add the two equations, and integrate over $\mathcal{R} \times (0,T)$. We then obtain

$$\begin{aligned}\int_0^T \int_{\mathcal{R}} &[\mu_\theta(u^\epsilon - k)\varphi_t + F_\theta(u^\epsilon, k)\varphi_x + \mu_\theta(v^\epsilon - q)\psi_t] dx\, dt\\ &+ \int_{\mathcal{R}} [\mu_\theta(u^{\epsilon,0}(x) - k)\varphi(x,0) + \mu_\theta(v^{\epsilon,0}(x) - q)\psi(x,0)] dx\\ &- \int_{\mathcal{R}} [\mu_\theta(u^\epsilon(x,T) - k)\varphi(x,T) + \mu_\theta(v^\epsilon(x,T) - q)\psi(x,T)] dx\end{aligned} \tag{6.6}$$

$$= \frac{1}{\delta}\int_0^T\int_{\mathcal{R}} (\sigma_\theta(u^\epsilon - k)\varphi - \sigma_\theta(v^\epsilon - q)\psi)(A(u^\epsilon) - v^\epsilon)dx\ dt$$
$$- \epsilon\int_0^T\int_{\mathcal{R}} [\sigma_\theta(u^\epsilon - k)\varphi u^\epsilon_{xx} + \sigma_\theta(v^\epsilon - q)\psi v^\epsilon_{xx}]dx\ dt,$$

where the flux function $F_\theta(u, k)$ satisfies

$$\frac{dF_\theta(u,k)}{du} = \sigma_\theta(u-k)f'(u), \quad F_\theta(k,k) = 0.$$

We observe that

$$\begin{aligned} -\epsilon&\int_0^T\int_{\mathcal{R}} \sigma_\theta(u^\epsilon - k)u^\epsilon_{xx}\varphi dx\ dt \\ &= -\epsilon\int_0^T\int_{\mathcal{R}} (\sigma_\theta(u^\epsilon - k)u^\epsilon_x)_x\varphi dx\ dt + 2\epsilon\int_0^T\int_{\mathcal{R}} \omega_\theta(u^\epsilon - k)(u^\epsilon_x)^2\varphi dx\ dt \\ &\geq \epsilon\int_0^T\int_{\mathcal{R}} \sigma_\theta(u^\epsilon - k)u^\epsilon_x\varphi_x dx\ dt \end{aligned}$$

and that a similar inequality can be derived for the corresponding v term. By letting $\theta \to 0$ in (6.6), we therefore obtain that for any $(k, q) \in \mathcal{S}$ and any $\varphi, \psi \in \mathcal{D}_+(T)$, the following inequality holds:

$$\begin{aligned} &\int_0^T\int_{\mathcal{R}} [|u^\epsilon - k|\varphi_t + |f(u^\epsilon) - f(k)|\varphi_x + |v^\epsilon - q|\psi_t]dx\ dt \\ &\qquad + \int_{\mathcal{R}} [|u^{\epsilon,0} - k|\varphi(x,0) + |v^{\epsilon,0} - q|\psi(x,0)]dx \\ &\qquad - \int_{\mathcal{R}} [|u^\epsilon(x,T) - k|\varphi(x,T) + |v^\epsilon(x,T) - q|\psi(x,T)]dx \\ &\quad \geq \frac{1}{\delta}\int_0^T\int_{\mathcal{R}} (\sigma(u^\epsilon - k)\varphi - \sigma(v^\epsilon - q)\psi)(A(u^\epsilon) - v^\epsilon)dx\ dt \\ &\qquad + \epsilon\int_0^T\int_{\mathcal{R}} [\sigma(u^\epsilon - k)\varphi_x u^\epsilon_x + \sigma(v^\epsilon - q)\psi_x v^\epsilon_x]dx\ dt. \end{aligned} \tag{6.7}$$

This variational inequality should be compared with the characterization (2.5) of the entropy solution of (2.2).

Now let $k = u(y,\tau),\ q = v(y,\tau)$, and $\varphi(x,t) = \psi(x,t) = \omega_\theta(x-y)\omega_\theta(t-\tau)$ in (6.7), where $(y,\tau) \in \mathcal{R} \times (0,T)$ is fixed, and integrate the result over $\mathcal{R} \times (0,T)$ with respect to y and τ. Consider (2.5) similarly, but use (y,τ) as integration variables instead of x and t. Then take $k = u^\epsilon(x,t),\ q = v^\epsilon(y,\tau)$, and

$$\varphi(y,\tau) = \psi(y,\tau) = \omega_\theta(x-y)\omega_\theta(t-\tau).$$

If we add the two inequalities, we then obtain

$$L(\epsilon,\theta) \leq R(\epsilon,\theta) - \frac{1}{\delta}I_1(\epsilon,\theta) - \epsilon I_2(\epsilon,\theta). \tag{6.8}$$

Here

$$L(\epsilon,\theta) = \int_0^T\int_{\mathcal{R}}\int_{\mathcal{R}} (|u^\epsilon(x,T) - u| + |v^\epsilon(x,T) - v|)\omega_\theta(x-y)\omega_\theta(T-\tau)dx\ dy\ d\tau$$

$$
\begin{aligned}
&+\int_0^T\int_{\mathcal{R}}\int_{\mathcal{R}}(|u^\epsilon-u(y,T)|+|v^\epsilon-v(y,T)|)\omega_\theta(x-y)\omega_\theta(T-t)dx\;dy\;dt,\\
R(\epsilon,\theta)=&\int_0^T\int_{\mathcal{R}}\int_{\mathcal{R}}(|u^{\epsilon,0}(x)-u|+|v^{\epsilon,0}(x)-v|)\omega_\theta(x-y)\omega_\theta(T)dx\;dy\;d\tau\\
&+\int_0^T\int_{\mathcal{R}}\int_{\mathcal{R}}(|u^\epsilon-u^0(y)|+|v^\epsilon-v^0(y)|)\omega_\theta(x-y)\omega_\theta(t)dx\;dy\;dt,\\
I_1(\epsilon,\theta)=&\int_0^T\int_{\mathcal{R}}\int_0^T\int_{\mathcal{R}}[(\sigma(u^\epsilon-u))(A(u^\epsilon)-A(u))+|v^\epsilon-v|]dx\;dt\;dy\;d\tau,\\
I_2(\epsilon,\theta)=&\int_0^T\int_{\mathcal{R}}\int_0^T\int_{\mathcal{R}}[(\sigma(u^\epsilon-u)u^\epsilon_x+\sigma(v^\epsilon-v)v^\epsilon_x)\omega_\theta{}'(x-y)\omega_\theta(t-\tau)]dx\;dt\;dy\;d\tau,
\end{aligned}
$$

where $u^\epsilon=u^\epsilon(x,t)$, $v^\epsilon=v^\epsilon(x,t)$, $u=u(y,\tau)$, and $v=v(y,\tau)$.

From the total-variation bounds and the L^1-continuity properties of the solutions (u^ϵ,v^ϵ) and (u,v), we obtain by a standard argument (cf., e.g., [26]) that there is a constant M, independent of ϵ, δ, and θ, such that

$$
\begin{aligned}
&|L(\epsilon,\theta)-\|u^\epsilon(\cdot,T)-u(\cdot,T)\|_1+\|v^\epsilon(\cdot,T)-v(\cdot,T)\|_1|\le M\theta,\\
&|R(\epsilon,\theta)-\|u^{\epsilon,0}-u^0\|_1+\|v^{\epsilon,0}-v^0\|_1|\le M\theta.
\end{aligned}
\tag{6.9}
$$

Furthermore, the monotonicity property of A implies that $I_1(\epsilon,\theta)\ge 0$. Finally, from the properties of (u^ϵ,v^ϵ), we obtain that

$$
|I_2(\epsilon,\theta)|\le T\sup_{0\le t\le T}(\|u^\epsilon_x(\cdot,t)\|_1+\|v^\epsilon_x(\cdot,t)\|_1)\int_{\mathcal{R}}|\omega_\theta{}'(y)|dy\le\frac{M}{\theta}.
$$

Hence, together with (6.2), (6.4), (6.8), and (6.9), this implies that

$$
\|u^\epsilon(\cdot,T)-u(\cdot,T)\|_1+\|v^\epsilon(\cdot,T)-v(\cdot,T)\|_1\le M\left(\epsilon+\theta+\frac{\epsilon}{\theta}\right).
$$

The desired result now follows by choosing $\theta=\epsilon^{1/2}$. □

In addition to the system studied above, we shall also need a regularized version of the equilibrium model. Consider the pure initial-value problem

$$
\begin{aligned}
(w^\epsilon+A(w^\epsilon))_t+f(w^\epsilon)_x&=\epsilon(w^\epsilon+A(w^\epsilon))_{xx},\\
w^\epsilon(x,0)&=u^{\epsilon,0}(x),
\end{aligned}
\tag{6.10}
$$

where $\{u^{\epsilon,0}\}\subset H^\infty(\mathcal{R})$ denotes the initial functions introduced at the beginning of this section. From the properties of $\{u^{\epsilon,0}\}$ and u^0 given above, it follows from the standard theory for scalar equations (cf., e.g., [10]) that for any $T>0$, there is a constant M, independent of ϵ, such that

$$
\|w(\cdot,t)-w^\epsilon(\cdot,t)\|_1\le M\epsilon^{1/2}\quad\text{for } 0\le t\le T.
\tag{6.11}
$$

Hence, if we write the error $u-w$ in the form

$$
u-w=(u-u^\epsilon)+(u^\epsilon-w^\epsilon)+(w^\epsilon-w),
$$

it remains to estimate the term $u^\epsilon-w^\epsilon$. In order to estimate this final error term, we shall rely on properties of system (5.1) derived in the previous section and on well-known properties of scalar diffusion equations of the form of (6.10). Consider a scalar equation of the form

$$\begin{aligned}(z + A(z))_t + f(z)_x &= \epsilon(z + A(z))_{xx} + G, \\ z(x, 0) &= z^0(x),\end{aligned} \tag{6.12}$$

where $z^0 = z^0(x)$ represents the initial function and $G = G(x, t)$ is a given source term. It is well known that if the data z^0 and G are smooth, then problem (6.12) has a unique smooth solution. Furthermore, if z and $\hat{z}$ denote two solutions of (6.12) with data (z^0, G) and $(\hat{z}^0, \hat{G})$, respectively, then we have the estimate

$$\|z(\cdot, t) - \hat{z}(\cdot, t)\|_1 \leq M_A \left(\|z^0 - \hat{z}^0\|_1 + \int_0^t \|G - \hat{G}\|_1 ds \right), \tag{6.13}$$

where the constant M_A only depends on the function A. In fact, this estimate can easily be proved by using arguments similar to those used in the proofs of Lemmas 5.2 and 5.3. Using this property of equation (6.12) and the properties of system (5.1) derived in section 5, we now establish the following estimate.

LEMMA 6.2. *Let $\{u^{\epsilon,0}\}$ and $\{v^{\epsilon,0}\}$ satisfy the requirements of Lemma* 6.1. *Then for any $T > 0$, there is a constant M, independent of ϵ and δ, such that*

$$\|u^\epsilon(\cdot, t) - w^\epsilon(\cdot, t)\|_1 \leq \frac{M\delta}{\epsilon} \quad \textit{for } 0 \leq t \leq T.$$

Proof. First, we consider system (5.1), and as above, we let

$$p^\epsilon = A(u^\epsilon) - v^\epsilon.$$

By adding the two equations of (5.1), we obtain

$$(u^\epsilon + v^\epsilon)_t + f(u^\epsilon)_x = \epsilon(u^\epsilon + v^\epsilon)_{xx}$$

or

$$(u^\epsilon + A(u^\epsilon) - p^\epsilon)_t + f(u^\epsilon)_x = \epsilon(u^\epsilon + A(u^\epsilon) - p^\epsilon)_{xx}. \tag{6.14}$$

Introduce a new function $z^\epsilon(x, t)$ defined by

$$z^\epsilon + A(z^\epsilon) = u^\epsilon + A(u^\epsilon) - p^\epsilon. \tag{6.15}$$

Then the differential equation (6.14) can be written in the form of (6.12), i.e.,

$$(z^\epsilon + A(z^\epsilon))_t + f(z^\epsilon)_x = \epsilon(z^\epsilon + A(z^\epsilon))_{xx} + G, \tag{6.16}$$

where

$$G = f(z^\epsilon)_x - f(u^\epsilon)_x.$$

From the monotonicity property of A, it follows that

$$|z^\epsilon(x, t) - u^\epsilon(x, t)| \leq |p^\epsilon(x, t)|.$$

Hence it follows from (6.2) and Lemma 5.3 that

$$\|z^\epsilon(\cdot, t) - u^\epsilon(\cdot, t)\|_1 \leq M\delta, \quad 0 \leq t \leq T. \tag{6.17}$$

By differentiating (6.15) with respect to x, we obtain

$$z_x^\epsilon - u_x^\epsilon + A'(z_x^\epsilon)(z_x^\epsilon - u_x^\epsilon) = (A'(u^\epsilon) - A'(z^\epsilon))u_x^\epsilon - p_x^\epsilon,$$

and this implies that

$$\|z_x^\epsilon(\cdot,t) - u_x^\epsilon(\cdot,t)\|_1 \leq M_A \|u^\epsilon(\cdot,t) - z^\epsilon(\cdot,t)\|_1 \|u_x^\epsilon(\cdot,t)\|_\infty + \|p_x^\epsilon(\cdot,t)\|_1.$$

From estimates (5.10), (5.13), (6.2), and (6.17), we therefore have

$$\|z_x^\epsilon(\cdot,t) - u_x^\epsilon(\cdot,t)\|_1 \leq \frac{M\delta}{\epsilon} \quad \text{for } 0 \leq t \leq T, \tag{6.18}$$

where M is independent of ϵ and δ. Now observe that the source term G introduced above can be represented in the form

$$G = f'(z^\epsilon)(z_x^\epsilon - u_x^\epsilon) + (f'(z^\epsilon) - f'(u^\epsilon))u_x^\epsilon,$$

and since $\|u_x^\epsilon(\cdot,t)\|_1$ is uniformly bounded on $[0,T]$ and since

$$\|z^\epsilon(\cdot,t) - u^\epsilon(\cdot,t)\|_\infty \leq \|z_x^\epsilon(\cdot,t) - u_x^\epsilon(\cdot,t)\|_1,$$

it follows from (6.18) that

$$\|G(\cdot,t)\|_1 \leq \frac{M\delta}{\epsilon} \quad \text{for } 0 \leq t \leq T. \tag{6.19}$$

Hence the stability estimate (6.13) implies that for $0 \leq t \leq T$,

$$\|z^\epsilon(\cdot,t) - w^\epsilon(\cdot,t)\|_1 \leq M\left(\|z^\epsilon(\cdot,0) - u^{\epsilon,0}\|_1 + \frac{\delta}{\epsilon}\right) \leq \frac{M\delta}{\epsilon}. \tag{6.20}$$

The desired estimate now follows from (6.17), (6.20), and the triangle inequality. □

Proof of Theorem 2.2. We can now easily complete the proof of Theorem 2.2. By writing

$$u - w = (u - u^\epsilon) + (u^\epsilon - w^\epsilon) + (w^\epsilon - w),$$

we obtain from Lemmas 6.1 and 6.2 and estimate (6.11) that for $0 \leq t \leq T$,

$$\|u(\cdot,t) - w(\cdot,t)\|_1 \leq M\left(\epsilon^{1/2} + \frac{\delta}{\epsilon}\right).$$

By choosing $\epsilon = \delta^{2/3}$, the desired estimate follows. □

ISOCHRONOUS CENTERS IN PLANAR POLYNOMIAL SYSTEMS[*]

C. J. CHRISTOPHER[†] AND J. DEVLIN[‡]

Abstract. Two algorithms are given for finding conditions for a critical point to be an isochronous center. The first is based on a systematic search for a transformation to the simple harmonic oscillator and as an example is used to find conditions for an isochronous center in the Kukles system; the second algorithm is specific to systems with homogeneous nonlinearities and is based on a connection with an Abel differential equation. General properties of systems with isochronous centers are also considered and results on Liénard and Hamiltonian systems are deduced; a close connection is demonstrated between isochronous centers and complex centers.

Key words. polynomial systems, centers, isochronous centers

1. Introduction.

Consider the planar system

$$\dot{x} = P(x, y), \qquad \dot{y} = Q(x, y), \tag{1.1}$$

where P and Q are polynomials in x and y and the dot denotes differentiation with respect to time. Suppose that (1.1) has a center and define a period function T by taking a semitransversal through the center with some parametrization $\mathbf{x}(s)$; $T(s)$ is then the time taken for the trajectory starting at $\mathbf{x}(s)$ to return to $\mathbf{x}(s)$.

We are interested in the case when the period function is constant; the center is then said to be *isochronous.* Probably the first nonlinear example of isochronous oscillations is Huygen's pendulum, in which the bob is constrained to follow a cycloidal path; the period of the motion is then independent of the amplitude [12]. Recently, Needham [18] has demonstrated the existence of an isochronous center in a system arising in telecommunications theory—it is of interest to note that this system hence has the property that small changes in the initial conditions can alter the amplitude of an oscillation but not its frequency.

Questions relating to the period function have been studied by a number of authors. One motivation is a connection between solutions of certain second-order boundary value problems and properties of the period function for related systems (1.1): the range of values of the period determines the range of initial conditions for which the second-order problem has a solution [5, 21]. Also, in the study of subharmonic bifurcations of periodically forced Hamiltonian systems, a nondegeneracy condition is that the period function of the unperturbed system be locally strictly monotone [8]—monotonicity conditions have hence been of special interest [4]. In particular, quadratic Hamiltonian systems and Lotka–Volterra systems are both known to have monotone period functions [10, 23]. We note that in both these applications, isochronicity represents the worst possible case.

To fully understand the properties of the period function in a class of systems, it is necessary to consider the bifurcation of critical points of the period. This question has been studied by Chicone and Jacobs [6]. Suppose that the system

$$\dot{x} = -y + P_\lambda(x, y), \qquad \dot{y} = x + Q_\lambda(x, y)$$

has a center at the origin for all λ. If $T(x; \lambda)$ is the period of the solution through the point $(x, 0)$, then T is written as

$$T(x; \lambda) = 2\pi + a_0(\lambda)x + a_1(\lambda)x^2 + \cdots.$$

If $a_i(\lambda^*) = 0$ for $i = 0, \ldots, n$ and $a_{n+1}(\lambda^*) \neq 0$, then it is shown that at most n zeros of T_x bifurcate out of the origin of the system with $\lambda = \lambda^*$ when λ is perturbed. However, if $a_i(\lambda^*) = 0$ for all i so that the origin is isochronous, then it is necessary to determine the ideal generated by the $a_i(\lambda)$; this is obviously a much more difficult problem. Thus a complete analysis of these bifurcations for a class of systems requires the identification of the subclass of systems with an isochronous center.

Isochronous centers also play an important part in another paper of Chicone and Jacobs [7]. In this paper, they look at the bifurcation of limit cycles from periodic orbits around a center. Since the method used requires knowledge of the period function, it is natural to first investigate bifurcation from isochronous centers; it is shown that at most three limit cycles can bifurcate from a quadratic isochronous center.

Necessary and sufficient conditions for quadratic systems to have an isochronous center at the origin were found by Loud [14], and conditions for systems in which P and Q are cubic polynomials without quadratic terms were obtained by Pleshkan [19]. The system $d^2x/dy^2 + g(x) = 0$ was considered by Urabe [22]: the only case which yields an isochronous center is the simple harmonic oscillator $g(x) = k^2x$. Apart from these cases, knowledge of polynomial systems with isochronous centers is slight.

In this paper, we first consider some general properties of polynomial systems with isochronous centers; these allow us to prove, for example, that a polynomial Liénard system with an isochronous center has no other critical point. We then go on to present an algorithm for obtaining necessary conditions for a point to be an isochronous center, based on a systematic search for a transformation to the simple harmonic oscillator. This is similar to the Liapunov function method which has been applied with much success to the problem of determining necessary conditions for a center [3]. This approach to isochronous centers seems to have been used first by Pleshkan in his work on cubic systems [19]. We illustrate our method by applying it to the system

$$\dot{x} = y, \qquad \dot{y} = -x + ax^2 + bxy + cy^2 + dx^3 + ex^2y + fxy^2 + gy^3 \tag{1.2}$$

and obtaining necessary conditions for the origin to be an isochronous center. To complement this work on necessary conditions, we give some simple sufficient conditions for the existence of an isochronous center. We show that the conditions obtained for (1.2) are sufficient, thus completely solving the problem for this system. We end by examining systems with homogeneous nonlinearities in some detail; we give an alternative algorithm for this special case based on a transformation to an Abel equation and we give a new class of systems with isochronous centers.

2. Some general results. In this section, we present several results of a general nature. We first give a definition of what we mean by a center.

Definition 2.1. *We say that a critical point of system* (1.1) *is a* center *if there is a deleted neighborhood of the point which consists entirely of closed trajectories surrounding that point. The center is said to be* nondegenerate *if the linearized vector field at the point has two nonzero eigenvalues and* isochronous *if its associated period function is constant.*

Remark. It can be shown [20] that by an affine transformation, a polynomial system with a nondegenerate center can be brought to the form

$$\dot{x} = -\lambda y + p(x,y), \qquad \dot{y} = \lambda x + q(x,y), \tag{2.1}$$

where p and q are polynomials with all terms of degree at least two and $\lambda \neq 0$.

Theorem 2.2. *An isochronous center is nondegenerate.*

Proof. Suppose that the origin of (1.1) is a degenerate center. If the linear terms vanish, we have

$$\dot{r} = f(\theta)r^2 + O(r^3), \qquad \dot{\theta} = g(\theta)r + O(r^2),$$

where f and g are homogeneous cubic polynomials in $\cos\theta$ and $\sin\theta$. Then for any $\delta > 0$, there are trajectories sufficiently close to the origin along which $|\dot{\theta}| < \delta$. Thus there are periodic solutions of arbitrarily large period.

Now suppose that the system has degenerate linear terms. If the flow is not to be area contracting or expanding, then the divergence of the vector field must vanish at the critical point. Thus both eigenvalues vanish and an affine transformation brings the system to the form

$$\dot{x} = ky + O(x^2+y^2), \qquad \dot{y} = O(x^2+y^2).$$

Furthermore, since scaling time by a constant will have no effect on isochronicity, we can take $k = -1$. Thus, in polar coordinates,

$$\dot{r} = r\cos\theta\sin\theta + O(r^2), \qquad \dot{\theta} = \sin^2\theta + O(r).$$

Given $\delta > 0$, there exist trajectories sufficiently close to the origin along which $\dot{\theta} < \sin^2\theta + \delta^2$. Near the origin along the positive y-axis, trajectories cross into the first quadrant. Thus trajectories go around the origin in an anticlockwise direction. Ignoring any contribution to the period by parts of the trajectory where $\dot{\theta} < 0$, we find that the period is at least

$$\int_0^{2\pi} \frac{d\theta}{\sin^2\theta + \delta^2} = \frac{2\pi}{\delta(1+\delta^2)^{1/2}}.$$

Thus we can choose δ small enough to give a contradiction.

Theorem 2.3. *An isochronous period annulus cannot have any finite critical point on its boundary except for an isochronous center.*

Proof. Suppose that we have a critical point on the boundary of an isochronous period annulus D of period T; then given a neighborhood U of the point, there is a smaller neighborhood V such that any trajectory in V will take at least time $2T$ to pass out of U. Hence any trajectory passing through $V \cap D$ will remain in $U \cap D$ for all time. Since these trajectories are closed curves, the critical point must be a center.

Corollary 2.4. *If D is an isochronous period annulus, then any trajectory in $\partial\overline{D}$ is unbounded as t increases and as t decreases.*

Although these results might appear simple, they can reveal a surprising amount of information. For example, if the polynomial Liénard system

$$\dot{x} = y - f(x), \qquad \dot{y} = -g(x)$$

has an isochronous center, then either $f \equiv 0$ or g is of odd degree and there are no other critical points. (In fact, if $f \equiv 0$ then $g = k^2 x$ by the result of Urabe [22].) This is a consequence of the following more general result.

Theorem 2.5. *Suppose that*

(1) *$Q(x,y) = q(x)$, where q has more than one zero* (*counting multiplicity*);

(2) *if the zeros of $q(x)$ are x_i and $P(x,y)$ is of degree n in y, then the coefficient of y^n in $P(x,y)$ is never zero for* $\min\{x_i\} \le x \le \max\{x_i\}$;

(3) *if $P(x,y)$ is of degree m in x, then the coefficient of x^m in $P(x,y)$ is never zero.*

Then system (1.1) *cannot have an isochronous center.*

Proof. Suppose that there is an isochronous center at the point (x_0, y_0) so that $q(x_0) = 0$. Since the linearization of (1.1) at this point is

$$\dot{x} = P_x(x_0,y_0)x + P_y(x_0,y_0)y, \qquad \dot{y} = q'(x_0)x,$$

we have $q'(x_0) \neq 0$ by Theorem 2.2. Hence condition (1) implies the existence of $x_1 \neq x_0$ such that $q(x_1) = 0$.

Let the period annulus of the isochronous center be D. If there is a trajectory in $\overline{D}$ which intersects the line $x = x_1$, then there is a trajectory in $\overline{D}$ which touches the line at a point where $\dot{x} = 0$. But $\dot{y} = 0$ on $x = x_1$, so $\overline{D}$ contains a critical point other than (x_0, y_0), contradicting Theorem 2.3. Hence $\overline{D}$ cannot intersect the line $x = x_1$ for any $x_1 \neq x_0$ such that $q(x_1) = 0$.

Now suppose that there exist x_1 and x_2 with $q(x_1) = q(x_2) = 0$ and $x_1 < x_0 < x_2$. Then $\overline{D}$ is entirely contained in the strip $(x_1, x_2) \times \mathbf{R}$. Now by (1) and (2), there exists $M > 0$ such that

$$\left|\frac{dy}{dx}\right| = \left|\frac{q(x)}{P(x,y)}\right|$$

is bounded in $[x_1, x_2] \times \{(-\infty, -M) \cup (M, \infty)\}$, so no solution can become unbounded in the strip $(x_1, x_2) \times \mathbf{R}$. But $\overline{D}$ is unbounded by Corollary 2.4—a contradiction. It follows that if the zeros of $q(x)$ are x_i, then either $x_0 = \max\{x_i\}$ or $x_0 = \min\{x_i\}$. We consider the case $x_0 = \max\{x_i\}$; the other case is similar.

Let $x_1 < x_0$ be such that $q(x_1) = 0$ and $q(x) \neq 0$ for $x \in (x_1, x_0)$. Then $\partial\overline{D}$ has points in the strip $(x_1, x_0) \times \mathbf{R}$. But $\partial\overline{D}$ is bounded in this strip, as above, and does not intersect the line $x = x_1$. So ∂D passes through points (x_0, y_-) and (x_0, y_+) where $y_- < y_0 < y_+$. Now $\dot{y}$ is single-signed for $x \in (x_1, x_0)$ and for $x > x_0$. So $\partial\overline{D} \subset (x_1, \infty) \times (y_-, y_+)$. Since D is unbounded, for arbitrarily large x there exists $y \in (y_-, y_+)$ such that $P(x,y) = 0$. But this contradicts (3), so we obtain the required result—(1.1) cannot have an isochronous center.

We also have the following result precluding the existence of an isochronous center.

Theorem 2.6. *Suppose that p and q are not both identically zero and that* (2.1) *has no critical points at infinity. Then the origin cannot be an isochronous center.*

Proof. If the origin is an isochronous center with period annulus D, then the trajectory through any finite point in $\partial\overline{D}$ is unbounded by Corollary 2.4. This is impossible if there are no critical points at infinity; so $\overline{D}$ fills the plane and for any

$R > 0$ there are periodic solutions entirely contained in the region $r > R$. But for any $M > 0$, $|\dot{\theta}| > M$ for r sufficiently large, and there are solutions of arbitrarily small period—a contradiction.

COROLLARY 2.7. *Suppose that the Hamiltonian system*

$$\dot{x} = -H_y, \qquad \dot{y} = H_x \tag{2.2}$$

of degree $n \geq 2$ has an isochronous center. If $H = H_0 + H_1 + \cdots + H_{n+1}$, where H_i is a homogeneous polynomial in x and y of degree i, then H_{n+1} has a repeated real linear factor.

Proof. Corollary 2.4 and Theorem 2.6 together imply that either the line at infinity is composed entirely of critical points or there exists a critical point at infinity with a hyperbolic sector. For system (2.2), the first of these is impossible, while a necessary condition for the second is that H_{n+1} have a repeated real linear factor.

We shall show later (Theorem 5.6) that if $H_3 \equiv \cdots \equiv H_n \equiv 0$, then the origin of (2.2) cannot be an isochronous center.

It sometimes helps to think of (1.1) as a complex system—we thus allow x and y to take complex values; however, we shall keep time t real, thus avoiding the difficulty of solution curves becoming solution surfaces. The resulting complex system will be denoted $(1.1)^*$.

DEFINITION 2.8. *We say that a critical point of the complex system* $(1.1)^*$ *is a* center *if there is a deleted neighborhood of the point in* $\mathbf{C}^2$ *which consists entirely of closed trajectories.*

THEOREM 2.9. *A critical point of the real system* (1.1) *is isochronous if and only if it is a center for system* $(1.1)^*$.

Proof. ($\Longrightarrow$) Let $(\phi(t;x,y), \psi(t;x,y))$ be the solution of $(1.1)^*$ passing through the point $(x,y) \in \mathbf{C}^2$ at time $t = 0$. It is well known that ϕ and ψ are holomorphic within their maximal interval of existence. Suppose that the origin is an isochronous center for (1.1) with period T and take a sufficiently small deleted neighborhood of the origin $A \subset \mathbf{C}^2$ so that for all $(x,y) \in A$, $\phi(t;x,y)$ and $\psi(t;x,y)$ exist for $0 \leq t \leq T$. Consider a point $(x,y) \in \mathbf{R}^2 \cap A$. Clearly, there is a product neighborhood of (x,y) in A; call this $U \times V$. First, fix $v \in V \cap \mathbf{R}$ and consider $\phi(T;u,v) - u$. This is a holomorphic function of u vanishing on the line $U \cap \mathbf{R}$ and hence identically zero on U. Now consider $\phi(T;u,v) - u$ with $u \in U$ fixed. This is a holomorphic function of v vanishing on the line $V \cap \mathbf{R}$ and hence identically zero on V. Hence $\phi(T;u,v) - u$ vanishes for all $(u,v) \in U \times V$. A similar result holds for $\psi(T,u,v) - v$. The result follows by analytic continuation throughout the deleted neighborhood.

($\Longleftarrow$) It is clear that (1.1) has a center if $(1.1)^*$ has one, so it only remains to prove isochronicity. Take $\phi(t;x,y)$, $\psi(t;x,y)$, U, and V as before. Fix $v \in V$ and consider the period $T(u)$ of the trajectory through (u,v) for $u \in U$. Since the function $T(u)$ is smooth, it must have level curves in U. (Otherwise, both partial derivatives vanish throughout U and the result holds trivially.) Take one of these curves, say $T(u) = c$; then the functions $\phi(c;u,v) - u$ and $\psi(c;u,v) - v$ vanish on this curve and hence on the whole of U. Thus the period function is constant for fixed v. Similarly, the period function is constant for fixed u and the result follows.

3. An algorithm. From (2.1) and Theorem 2.4, we can bring system (1.1) with an isochronous center to the form

$$\dot{x} = -y + O(x^2 + y^2), \qquad \dot{y} = x + O(x^2 + y^2) \tag{3.1}$$

by an affine transformation and a scaling of time by a constant. Furthermore, it can be shown [20] that there is an analytic change of coordinates $X = x + F(x, y)$, $Y = y + G(x, y)$, which brings (3.1) to the form

$$\dot{X} = -Yf(X^2 + Y^2), \qquad \dot{Y} = Xf(X^2 + Y^2),$$

where f is analytic and $f(0) = 1$. If the center is to be isochronous, then f must be constant [7]; so

$$\dot{X} = -Y, \qquad \dot{Y} = X. \tag{3.2}$$

Thus there is an analytic function $H(x, y)$ of the form $x + F(x, y)$ such that

$$\frac{d^2H}{dt^2} + H = 0. \tag{3.3}$$

Conversely, if there exists such a function $H(x, y)$ for a given system (3.1), then, taking $X = H$ and $Y = -dH/dt$, we obtain an analytic change of coordinates bringing (3.1) to the form (3.2). The search for such a function provides the basis for our algorithm.

From (3.2), we can find an analytic first integral of the system

$$\Phi(x, y) = X^2 + Y^2 = x^2 + y^2 + O(x^2 + y^2)$$

such that $d\Phi/dt = 0$; and it is easy to verify that if H is a solution of (3.3), then

$$\left(aH + b\frac{dH}{dt}\right)\Phi^n = (ax - by)(x^2 + y^2)^n + O((x^2 + y^2)^{n+1}) \tag{3.4}$$

is also a solution of (3.3) for any constants a and b and for any positive integer n. Hence if we write $H = \sum_k H_k$, where $\deg(H_k) = k$ and $H_1 = x$, then by the linearity of (3.3), we have two degrees of freedom in the choice of H_k for each odd $k \geq 3$.

We wish therefore to solve the following problem: find necessary and sufficient conditions for the existence of an analytic function $H(x, y) = x + O(x^2 + y^2)$ such that

$$P^2H_{xx} + 2PQH_{xy} + Q^2H_{yy} + (P_xP + P_yQ)H_x + (Q_xP + Q_yQ)H_y + H = 0. \tag{3.5}$$

We proceed by determining successive terms in the expansion of H. Suppose that the polynomials H_j have been found for $j \leq k - 1$. Equating the terms of degree k in (3.5), we have

$$y^2H_{kxx} - 2xyH_{kxy} + x^2H_{kyy} + (1 - k)H_k = G, \tag{3.6}$$

where G is a homogeneous polynomial of degree k whose coefficients are polynomials in the coefficients of $H_j (j \leq k - 1)$. Consider the linear operator

$$y^2\frac{\partial^2}{\partial x^2} - 2xy\frac{\partial^2}{\partial x \partial y} + x^2\frac{\partial^2}{\partial y^2} + (1 - k) \tag{3.7}$$

acting on the space of monomials of degree k. To find the rank of this operator, we consider (3.7) under the change of variables $z = x + iy$, $\overline{z} = x - iy$, which gives

$$-z^2\frac{\partial^2}{\partial z^2} + 2z\overline{z}\frac{\partial^2}{\partial z \partial \overline{z}} - \overline{z}^2\frac{\partial^2}{\partial \overline{z}^2} + (1 - k). \tag{3.8}$$

It is easy to see that (3.8) has eigenfunctions $z^r\overline{z}^s(r+s=k)$ with eigenvalues $1-(r-s)^2$. Hence for the real case (3.7), we have eigenfunctions $az^r\overline{z}^s+\overline{a}z^s\overline{z}^r$ with eigenvalues $1-(r-s)^2$. Thus when k is even, the operator is of full rank and there is a unique H_k which satisfies equation (3.6). When k is odd, the operator has nullity two and the kernel consists of functions of the form

$$(a+ib)z^{(k-1)/2}\overline{z}^{(k+1)/2}+(a-ib)z^{(k+1)/2}\overline{z}^{(k-1)/2}=2(ax+by)(x^2+y^2)^{(k-1)/2}.$$

This corresponds to the degrees of freedom (3.4) in our choice of H. Without loss of generality, therefore, we can specify that for odd k the coefficients of xy^{k-1} and y^k in H_k vanish. Hence in order to solve (3.6), we will have two consistency conditions imposed on the coefficients of G corresponding to the coefficients of $z(z\overline{z})^{(k-1)/2}$ and $\overline{z}(z\overline{z})^{(k-1)/2}$ vanishing. These will be our necessary conditions for the existence of an isochronous center. Thus solving equation (3.6) for each k, we obtain an infinite number of conditions.

Pleshkan [19] has shown that the infinite set of conditions produced is also sufficient, but in practice it is simpler to prove that the conditions obtained are sufficient by other means; some sufficient conditions are given in the next section. It is easy to see by induction that the conditions will be polynomial equations in the coefficients of P and Q, which can be reduced to a finite number by Hilbert's basis theorem.

On experimenting with different classes of systems, we found that the method seems to work most effectively when the center conditions are derived first and then assimilated into the algorithm. This is indeed the method of Pleshkan. However, we shall now give an example where the center conditions have to be derived alongside those for isochronicity since the complete center conditions are unknown at present.

The Kukles system

$$\text{(3.9)} \qquad \dot{x}=y, \qquad \dot{y}=-x+ax^2+bxy+cy^2+dx^3+ex^2y+fxy^2+gy^3$$

has been the subject of a number of recent investigations (see [9, 13, 16, 17], for example). Although the general problem of finding complete conditions for (3.9) to have a center at the origin remains unsolved, the extra conditions imposed by seeking an isochronous center allow the problem to be solved completely. We are also able to find necessary and sufficient conditions for the complex system (3.9)* to have an isochronous center at the origin.

The first six pairs of conditions for the origin of (3.9) to be an isochronous center were calculated as described above. The calculations were performed using the computer algebra system REDUCE. For an isochronous center, it is necessary that all twelve polynomials vanish. The zero-set of the polynomials can be obtained in its simplest form using REDUCE's Groebner basis procedure; however, to avoid unnecessary computation time, REDUCE was first used interactively to simplify the polynomials, as follows:

The first two conditions are

$$bc+ab+e+3g=0, \qquad 4c^2+10ac+10a^2+b^2+9d+3f=0.$$

Hence we can substitute for the variables e and f. One of the next pairs of conditions now gives

(3.10)

$$(17c^3+48ac^2+45a^2c+2b^2c+10a^3+ab^2)b+6(c-a)bd+(15c^2+42ac+15a^2+3b^2)g=0.$$

We first suppose that $(c-a)b \neq 0$. Since the transformation

$$x \mapsto \frac{x}{k}, \qquad y \mapsto \frac{y}{k} \tag{3.11}$$

preserves the form of the system, we can suppose that $c - a = 1$. If we also take $g = \lambda b$, then (3.10) gives

$$d = -\frac{[(72a^2 + 72a + 3b^2 + 15)\lambda + 120a^3 + 192a^2 + 99a + 3ab^2 + 2b^2 + 17]}{6}.$$

If a Groebner basis is now calculated for the remaining nine polynomials, we find that we must have $a = -1/2$ and $b^2 + 1 = 0$ for a common zero. This is obviously not a real solution; however, if we consider (3.9) as a complex equation with a real time parameter, we obtain a system of the following form after rescaling to compensate for the transformation (3.11):

$$\dot{x} = y, \qquad \dot{y} = -x + \mu(x \pm iy)^2 + \nu(x \pm iy)^3, \tag{3.12}$$

where μ and ν are complex coefficients.

We next consider the case $b = 0$. If a Groebner basis is now calculated for the remaining ten conditions (that is, including (3.10)), then a common zero only occurs when $a = c = 0$ and $d^2 + g^2 = 0$. The system is then of the form (3.12) with $\mu = 0$. Finally, when $a = c$ and $b \neq 0$, a Groebner basis calculation yields $a = c = 0$ and $d = -b^2/9$, and the system is

$$\dot{x} = y, \qquad \dot{y} = -x + bxy - \frac{b^2x^3}{9}. \tag{3.13}$$

This has an isochronous center at the origin since the system

$$\dot{X} = Y + \frac{b(X^2 - Y^2)}{6}, \qquad \dot{Y} = -X + \frac{bXY}{3},$$

which has an isochronous center at the origin by Theorem 4.4, can be transformed to (3.13) by the substitution $x = X$, $y = Y + b(X^2 - Y^2)/6$.

We have thus proved the following result.

THEOREM 3.1. *The real system* (3.9) *has an isochronous center at the origin if and only if it is of the form* (3.13).

The results on necessary conditions for an isochronous center which we have derived above can easily be carried over to the corresponding complex Kukles system $(3.9)^*$, the coefficients now being complex. We thus obtain systems (3.12) and $(3.13)^*$ as necessary for an isochronous center. System $(3.13)^*$ has an isochronous center as in Theorem 2.8. We will show in the next section that system (3.12) has an isochronous center. Thus we have the following result.

THEOREM 3.2. *The complex system* $(3.9)^*$ *has an isochronous center at the origin if and only if it is of the form* (3.12) *or* $(3.13)^*$.

4. Sufficient conditions for an isochronous center. The algorithm of the previous section provides necessary conditions for an isochronous center. In this section, we shall give some simple sufficient conditions.

Consider a polynomial system of the form

$$\dot{x} = -y + p(x,y), \qquad \dot{y} = x + q(x,y), \tag{4.1}$$

where p and q do not contain linear terms. We first look at the apparently trivial case

$$\dot{\theta} = \frac{d(\tan^{-1}(y/x))}{dt} = 1.$$

That is, $xq(x, y) - yp(x, y) = 0$. This will hold if and only if the system is of the form

$$\dot{x} = -y + xf(x, y), \qquad \dot{y} = x + yf(x, y) \tag{4.2}$$

for some polynomial f with $f(0, 0) = 0$. Clearly, if such a system has a center at the origin, then it is isochronous. It only remains therefore to find conditions for system (4.2) to have a center at the origin; however, this is a nontrivial problem.

In polar coordinates, we have

$$\frac{dr}{d\theta} = \sum_{i=1}^{m} r^{i+1} f_i(\cos\theta, \sin\theta), \tag{4.3}$$

where $f = \sum_i f_i$, $\deg(f_i) = i$. We can now use Devlin [11] to obtain necessary conditions for a center in terms of integrals of the functions f_i; for example, if $f_i \equiv 0$ $(i = 1, \dots, j)$, then

$$\int_0^{2\pi} f_{j+1} d\theta = 0, \qquad \int_0^{2\pi} f_{j+2} d\theta = 0.$$

We can also give the following sufficient condition for an isochronous center.

Theorem 4.1. *If there exist a 2π-periodic function $\sigma(\theta)$ and functions $A_i(\sigma)$ such that $f_i(\cos\theta, \sin\theta) = A_i(\sigma) d\sigma/d\theta$, then system* (4.2) *has an isochronous center at the origin.*

Proof. Let $R(t; R_0, t_0)$ be the solution of the initial value problem

$$\frac{dR}{dt} = \sum_{i=1}^{m} A_i(t) R^{i+1}, \qquad R(t_0) = R_0.$$

Then the solution of (4.2) with $r(0) = r_0$ is $r(\theta) = R(\sigma(\theta);\ r_0,\ \sigma(0))$; clearly, this solution is 2π-periodic for r_0 sufficiently small.

How comprehensive is this center condition for (4.2)? It is easily verified that Theorem 4.1 includes the well-known symmetry condition for a center. If f is quadratic, then it follows from the proof of Theorem 5.2 of [2] that the condition is necessary as well as sufficient. The condition is also necessary if f is homogeneous; this follows from the next result.

Corollary 4.2. *If f is homogeneous, then the origin is an isochronous center for system* (4.2) *if and only if*

$$\int_0^{2\pi} f(\cos\theta, \sin\theta) d\theta = 0.$$

Proof. The sufficiency follows from Theorem 4.1, taking $\sigma(\theta) = \int_0^\theta f(\cos s, \sin s) ds$. The necessity follows from the fact that, as above, $\int_0^{2\pi} f_{j+1}$ must vanish.

In general, however, the condition of Theorem 4.1 is not sufficient for the origin of (4.2) to be an isochronous center: in [1], there is given an equation of the form (4.3) with $m = 2$, $\deg(f_1) = 3$, and $\deg(f_2) = 6$ for which all solutions in a neighborhood of the origin are 2π-periodic but this condition is not satisfied. Setting $\xi = r^3$ in this example, we obtain a counterexample with the f_i of the correct degree.

We now consider systems of the form (1.1) satisfying the Cauchy–Riemann equations

$$P_x = Q_y, \qquad P_y = -Q_x. \tag{4.4}$$

Thus $P + iQ$ is an analytic function of the complex variable $z = x + iy$, and system (1.1) can be written in the form

$$\dot{z} = f(z). \tag{4.5}$$

We shall say that (1.1) is a *Cauchy–Riemann system.*

THEOREM 4.3. *System* (4.5) *has an isochronous center at* $z_0 = x_0+iy_0$ *if and only if* $f(z_0) = 0$ *and* $f'(z_0)$ *is nonzero and purely imaginary. The period is* $|2\pi/f'(z_0)|$.

Proof. There is a critical point at z_0 if and only if $f(z_0) = 0$. Suppose that we have an isochronous center at z_0. From Theorem 2.4, we must have $f'(z_0) \neq 0$. Furthermore, we also need $\mathrm{Re}(f'(z_0)) = 0$; otherwise, the divergence of the vector field at z_0 will not vanish.

Conversely, suppose that the above conditions are satisfied. Let z_1 be a point in a neighborhood of z_0. We define the contour integral

$$R(z) = \int_{z_1}^{z} \frac{dz}{f(z)}.$$

From Cauchy's integral formula, as z moves once around z_0, the value of $R(z)$ increases by $2\pi i/f'(z_0)$. Thus $H(z) = \exp(f'(z_0)R(z))$ is a well-defined holomorphic function in a neighborhood of z_0. But $d^2H(z)/dt^2 = f'(z_0)^2H(z)$ and $f'(z_0)^2$ is a negative real number. So $z \mapsto H(z)$ defines an analytic change of coordinates to the simple harmonic oscillator and z_0 is an isochronous center. The period follows from elementary considerations.

COROLLARY 4.4. *A sufficient condition for system* (1.1) *to have an isochronous center at a point* p *is that it satisfy the Cauchy–Riemann equations* (4.4) *and* $P(p) = Q(p) = P_x(p) = 0$, *and* $P_y(p) \neq 0$.

Remark. The relation of the Cauchy–Riemann equations to isochronicity seems to have been noticed first by Pleshkan [19].

COROLLARY 4.5. *Consider system* (4.1) *with* p *and* q *homogeneous polynomials of degree* n *satisfying the Cauchy–Riemann equations. Then the origin is an isochronous center of period* 2π. *There are exactly* $n-1$ *other critical points and these are all isochronous centers of period* $2\pi/(n-1)$.

Proof. From the hypothesis, the system can be written in the form

$$\dot{z} = f(z) = iz + az^n$$

for some $a \in \mathbf{C}\backslash\{0\}$. Since $f'(0) = i$, the origin is an isochronous center of period 2π. Apart from the origin, there are $n-1$ other critical points, corresponding to roots of the equation $z^{n-1} = -i/a$. At these points, $f'(z) = i + naz^{n-1} = -(n-1)i$. The result follows from Theorem 4.3.

We now use Theorem 4.3 to give a class of complex systems with isochronous centers at the origin; this class includes the complex Kukles system (3.12).

THEOREM 4.6. *The origin is an isochronous center for the complex system*

$$\dot{x} = y + p(x \pm iy), \qquad \dot{y} = -x + q(x \pm iy), \tag*{(4.6)$^{\pm}$}$$

where p *and* q *are polynomials with complex coefficients and with all terms of degree two or more.*

Proof. It suffices to show that the origin is an isochronous center for $(4.6)^+$: if we transform $(4.6)^-$ by $y \mapsto -y$ and $t \mapsto -t$, we obtain a system of the form $(4.6)^+$. Let

$$u = x + iy = [\mathrm{Re}(x) - \mathrm{Im}(y)] + i[\mathrm{Im}(x) + \mathrm{Re}(y)],$$

$$v = x - iy = [\mathrm{Re}(x) + \mathrm{Im}(y)] + i[\mathrm{Im}(x) - \mathrm{Re}(y)].$$

Then

$$\dot{u} = -iu + f(u), \qquad \dot{v} = iv + g(u), \tag{4.7}$$

where $f = p + iq$, $g = p - iq$. By Theorem 4.3, $u(t)$ is 2π-periodic for $|u(0)|$ sufficiently small. Hence we only need to prove that $v(t)$ is 2π-periodic. But from (4.7),

$$v(t) = e^{it}\left[v(0) + \int_0^t e^{-is} g(u(s))ds\right],$$

so it suffices to show that

$$\int_0^{2\pi} e^{-is} g(u(s))ds = 0. \tag{4.8}$$

For this, more information on the solutions u is required.

Following the proof of Theorem 4.3, we set $H(u) = u \exp \int_0^u \gamma(\xi) d\xi$, where

$$\frac{1}{(-iu + f(u))} = i\left(\frac{1}{u} + \gamma(u)\right).$$

Then $dH(u)/dt = -iH(u)$, so $H(u(t)) = H(u(0))e^{-it}$. But $H(u) = u + O(u^2)$ as $u \to 0$, so the inverse function H^{-1} exists in a neighborhood of the origin and $H^{-1}(\xi) = \xi + O(\xi^2)$ as $\xi \to 0$. Hence

$$u(t) = H^{-1}(H(u(0))e^{-it}) = H(u(0))e^{-it} + \sum_{j=2}^{\infty} h_j e^{-ijt}.$$

Since $g(u)$ is a polynomial, equation (4.8) follows for $|u(0)|$ sufficiently small.

5. Systems with homogeneous nonlinearities. We now consider systems of the form

$$\dot{x} = y + p(x, y), \qquad \dot{y} = -x + q(x, y), \tag{5.1}$$

where p and q are homogeneous polynomials of degree n. We shall derive an alternative algorithm to find conditions for the origin of this system to be an isochronous center. Expressing the system in polar coordinates, we have

$$\dot{r} = f(\theta)r^n, \qquad \dot{\theta} = -1 + g(\theta)r^{n-1}, \tag{5.2}$$

where f and g are homogenous polynomials of degree $n+1$ in $\cos\theta$ and $\sin\theta$. We now take

$$\rho = \frac{r^{n-1}}{1 - r^{n-1}g(\theta)} \tag{5.3}$$

to bring the system to the Abel equation

$$\frac{d\rho}{d\theta} = -(n-1)f(\theta)g(\theta)\rho^3 + (g'(\theta) - (n-1)f(\theta))\rho^2. \tag{5.4}$$

There is much literature on the relationship between equations (5.1) and (5.4); many of the results can be found in the survey paper [15]. We shall write $\rho(\theta; c)$ for the solution of (5.4) with starting point c at $\theta = 0$. Clearly, periodic solutions of (5.1) sufficiently close to the origin are transformed to 2π-periodic solutions of (5.4).

THEOREM 5.1. *System* (5.1) *has an isochronous center at the origin if and only if, for the corresponding system* (5.4),

$$\rho(2\pi; c) = c, \qquad \int_0^{2\pi} g(\theta)\rho(\theta; c) = 0 \tag{5.5}$$

for all sufficiently small $c > 0$.

Proof. The first condition is that for a center, so we need only consider the period. Since $\dot\theta = -1 + gr^{n-1} = -1/(1 + g\rho)$, the period of the solution of (5.2) which is transformed to $\rho(\theta; c)$ is

$$\int_0^{2\pi} (1 + g(\theta)\rho(\theta; c))d\theta = 2\pi + \int_0^{2\pi} g(\theta)\rho(\theta; c)d\theta.$$

The result follows.

As in [2, 11], we write $\rho(\theta; c) = \sum_{i=1}^{\infty} a_i(\theta)c^i$ with $a_1(0) = 1$ and $a_i(0) = 0$ for $i > 1$. Hence from Theorem 5.1, we have an isochronous center if and only if, for all $i \geq 1$,

$$a_i(2\pi) = a_i(0), \qquad \int_0^{2\pi} g(\theta)a_i(\theta)d\theta = 0. \tag{5.6}$$

A formula to calculate the coefficients $a_i(\theta)$ is known [11]: if l, r, and σ_i are operators $C[0, 2\pi] \to C[0, 2\pi]$ defined by

$$(lh)(\theta) = -(n-1)\int_0^{\theta} f(s)g(s)h(s)ds, \qquad (rh)(\theta) = \int_0^{\theta} [g'(s) - (n-1)f(s)]h(s)ds,$$
$$(\sigma_0 h)(\theta) \equiv 0, \qquad (\sigma_1 h)(\theta) = h(\theta),$$
$$\sigma_i = (i-2)\sigma_{i-2}l + (i-1)\sigma_{i-1}r, \quad i \geq 2,$$

then $a_i(\theta) = (\sigma_i 1)(\theta)$, where 1 is the constant function $1(\theta) \equiv 1$. This together with (5.6) provides an alternative algorithm to that given in section 3. As an example of this formulation, we give the first few necessary conditions explicitly.

COROLLARY 5.2. *If system* (5.1) *has an isochronous center at the origin, then the following conditions hold:*

(A)

$$\int_0^{2\pi} g(\theta)d\theta = 0;$$

(B)

$$\int_0^{2\pi} f(\theta)d\theta = 0;$$

(C)

$$\int_0^{2\pi} g\left[g-(n-1)\int_0^{\theta} f\right] d\theta = 0;$$

(D)

$$\int_0^{2\pi} f(\theta)g(\theta)d\theta = 0;$$

$$\text{(E)}\qquad (n-1)\int_0^{2\pi} g\left[\int_0^{\theta} fg\right] d\theta - \int_0^{2\pi} g\left[g-(n-1)\int_0^{\theta} f\right]^2 d\theta = 0;$$

(F)

$$\int_0^{2\pi} fg\left[g-(n-1)\int_0^{\theta} f\right] d\theta = 0;$$

(G)

$$\int_0^{2\pi} fg\left[g-(n-1)\int_0^{\theta} f\right]^2 d\theta = 0;$$

$$\text{(H)}\quad (n-1)\int_0^{2\pi} [g'-(n-1)f]\cdot\left[\int_0^{\theta} fg\right]^2 d\theta - 2\int_0^{2\pi} fg\left[g-(n-1)\int_0^{\theta} f\right]^3 d\theta = 0.$$

Condition (5.5) is sufficient as well as necessary, and we now give an example where it is used to prove isochronicity.

THEOREM 5.3. *Suppose that there exist a positive integer l with $2l \le n$ and polynomials $U(x,y)$ and $V(x,y)$ such that*

$$xp+yq=(x^2+y^2)^lU, \qquad xq-yp=(x^2+y^2)^lV,$$

$$(n-1)U_x=(n+1-2l)V_y, \qquad (n-1)U_y=-(n+1-2l)V_x.$$

Then the origin is an isochronous center for system (5.1).

Proof. Let $m=n+1-2l$. Then U and V are homogeneous polynomials of degree m and $(n-1)U+imV$ is a holomorphic function of the complex variable $z=x+iy$; so

$$(n-1)U+imV+(a+ib)z^m=r^m(m\sigma-i\sigma'),$$

where $\sigma(\theta)=(a\cos(m\theta)-b\sin(m\theta))/m$. Thus

$$f(\theta)=\frac{U}{r^m}=\frac{m\sigma}{(n-1)}, \qquad g(\theta)=\frac{V}{r^m}=-\frac{\sigma'}{m}, \tag{5.7}$$

and the Abel equation (5.4) reduces to $d\rho/d\theta=\rho^3\sigma\sigma'$. This has solution

$$\rho(\theta;c)=(c^{-2}+\sigma(0)^2-\sigma(\theta)^2)^{-1/2}$$

and since $g(\theta)=-\sigma'/m$, condition (5.5) holds.

Using (5.7), it is straightforward to verify that the conditions of the theorem are satisfied if and only if

$$\dot z=-iz+z^l\bar z^{l-1}\frac{[(n-l)(a+ib)z^m+(1-l)(a-ib)\bar z^m]}{m(n-1)}.$$

(Note that for $l = 1$ this reduces to a Cauchy–Riemann system.) For $z \in \mathbf{C}\backslash\{0\}$, we make the change of variables $w = z(z\bar{z})^{(l-1)/m}$. This gives the system

$$\dot{w} = -iw + \frac{(a+ib)w^{m+1}}{m};$$

by Corollary 4.5, all critical points of this system are isochronous centers. Hence we have the following result.

Corollary 5.4. *If the conditions of Theorem* 5.3 *are satisfied, then every critical point of the system is an isochronous center.*

A similar property holds for quadratic and cubic systems.

Theorem 5.5. *If a polynomial system with quadratic or cubic homogeneous nonlinearities has an isochronous center at the origin, then every critical point of the system is an isochronous center.*

Proof. For the quadratic case, the classification of isochronous centers is given by Loud [14]: the origin is an isochronous center if and only if the system can be brought to the form

$$\dot{x} = -y + Bxy, \qquad \dot{y} = x + Dx^2 + Fy^2$$

with $(D/B, F/B) = (-1/2, 1/2)$, $(0,1)$, $(0,1/4)$, or $(-1/2, 2)$. The first of these yields a Cauchy–Riemann system and so is covered by Corollary 4.5. The second and third have no other critical points, and the fourth has a symmetry $x \mapsto 2/B - x$ so that the other critical point $(2/B, 0)$ is also an isochronous center.

The cubic case was examined by Pleshkan [19], who gave the following condition: the origin is an isochronous center if and only if the system can be brought to one of the following forms:

$$(1) \quad \begin{cases} \dot{x} = -y - ax^3 - 3bx^2y + 3axy^2 + by^3, \\ \dot{y} = x + bx^3 - 3ax^2y - 3bxy^2 + ay^3, \end{cases}$$

$$(2) \quad \begin{cases} \dot{x} = -y - ax^3 + bx^2y + axy^2, \\ \dot{y} = x - ax^2y + bxy^2 + ay^3, \end{cases}$$

$$(3) \quad \begin{cases} \dot{x} = -y + 3ax^2y, \\ \dot{y} = x - 2ax^3 + 9axy^2. \end{cases}$$

The first of these is a Cauchy–Riemann system, while for the second $\dot{\theta} = 1$; the result thus holds for these two cases. In the third case, if $a \leq 0$ then there are no other critical points, so we take $a > 0$. Since the system is symmetric about the y-axis, we only need to consider the critical point at $((2a)^{-1/2}, 0)$. The change of coordinates

$$X = \frac{1}{2} - \left(\frac{a}{2}\right)^{1/2} x, \qquad Y = \frac{1}{2}\left(\frac{a}{2}\right)^{1/2} y$$

brings this point to the origin, and the system becomes

$$\dot{X} = -Y(1 - 12P), \qquad \dot{Y} = (P + 18Y^2)P',$$

where $P = X - X^2$. In a neighborhood of the origin, define

$$u = (1 - 12P)^{-3/2}PP', \qquad v = Y(1 - 12P)^{-3/2};$$

this brings the system to the form $\dot{u} = -v$, $\dot{v} = u$, so the critical point is indeed an isochronous center.

Finally, we consider Hamiltonian systems

$$\dot{x} = -H_y, \qquad \dot{y} = H_x \tag{5.8}$$

with homogeneous nonlinearities. If the origin is an isochronous center, then by Theorem 2.2 and by scaling time by a constant, we can suppose the Hamiltonian H to be of the form $H = (x^2 + y^2)/2 + h(x, y)$, where h is homogeneous. Under these conditions, we can improve on Corollary 2.7.

THEOREM 5.6. *The Hamiltonian system* (5.8) *with* $H = (x^2+y^2)/2+h(x, y)$ *has an isochronous center at the origin if and only if* $h \equiv 0$.

Proof. Clearly, if $h \equiv 0$, then the origin is an isochronous center. For the converse, we suppose that the origin is an isochronous center and that $h \not\equiv 0$ and consider trajectories in the period annulus, that is, the level curves $H = c$ as c increases from zero. By Corollary 2.4, there are level curves in the period annulus with points arbitrarily far from the origin. Write $H = r^2/2 + g(\theta)r^n$, where g is a homogeneous polynomial in $\cos\theta$ and $\sin\theta$ of degree n. The distance of the curve $H = c$ from the origin achieves its maximum on the ray $\theta = \theta_0$ where $g(\theta)$ achieves its minimum. By Corollary 5.2, $g(\theta)$ changes sign and so $g(\theta_0) < 0$. Hence there is a critical point on the ray $\theta = \theta_0$ at the point where

$$r = (-ng(\theta_0))^{-1/(n-2)}.$$

Thus it is not possible for there to be points in the period annulus arbitrarily far from the origin—a contradiction.

Acknowledgment. Both authors wish to thank the Science and Engineering Research Council for its funding of this research.

EFFECTIVE REDUCIBILITY OF QUASI-PERIODIC LINEAR EQUATIONS CLOSE TO CONSTANT COEFFICIENTS*

ÀNGEL JORBA†, RAFAEL RAMÍREZ-ROS†, AND JORDI VILLANUEVA†

Abstract. Let us consider the differential equation

$$\dot{x} = (A + \varepsilon Q(t, \varepsilon))x, \quad |\varepsilon| \leq \varepsilon_0,$$

where A is an elliptic constant matrix and Q depends on time in a quasi-periodic (and analytic) way. It is also assumed that the eigenvalues of A and the basic frequencies of Q satisfy a diophantine condition. Then it is proved that this system can be reduced to

$$\dot{y} = (A^*(\varepsilon) + \varepsilon R^*(t, \varepsilon))y, \quad |\varepsilon| \leq \varepsilon_0,$$

where R^* is exponentially small in ε, and the linear change of variables that performs such a reduction is also quasi-periodic with the same basic frequencies as Q. The results are illustrated and discussed in a practical example.

Key words. quasi-periodic Floquet theorem, quasi-periodic perturbations, reducibility of linear equations

1. Introduction.

The well-known Floquet theorem states that any linear periodic system $\dot{x} = A(t)x$ can be reduced to constant coefficients $\dot{y} = By$ by means of a periodic change of variables. Moreover, this change of variables can be taken over $\mathbb{C}$ with the same period as $A(t)$.

A natural extension is to consider the case in which the matrix $A(t)$ depends on time in a quasi-periodic way. Before beginning the discussion of this issue, let us recall the definition and basic properties of quasi-periodic functions.

DEFINITION 1.1. *A function f is a* quasi-periodic function *with a vector of basic frequencies $\omega = (\omega_1, \ldots, \omega_r)$ if $f(t) = F(\theta_1, \ldots, \theta_r)$, where F is 2π periodic in all its arguments and $\theta_j = \omega_j t$ for $j = 1, \ldots, r$. Moreover, f is called* analytic *on a strip of width ρ if F is analytical on an open set containing $|\operatorname{Im} \theta_j| \leq \rho$ for $j = 1, \ldots, r$.*

It is also known that an analytic quasi-periodic function $f(t)$ on a strip of width ρ has Fourier coefficients defined by

$$f_k = \frac{1}{(2\pi)^r} \int_{\mathbb{T}^r} F(\theta_1, \ldots, \theta_r) e^{-(k,\theta)\sqrt{-1}} \, d\theta$$

such that f can be expanded as

$$f(t) = \sum_{k \in \mathbb{Z}^r} f_k e^{(k,\omega)\sqrt{-1}t}$$

for all t such that $|\operatorname{Im} t| \leq \rho / \|\omega\|_\infty$. We denote by $\|f\|_\rho$ the norm

$$\|f\|_\rho = \sum_{k \in \mathbb{Z}^r} |f_k| e^{|k|\rho},$$

and it is not difficult to check that it is well defined for any analytical quasi-periodic function defined on a strip of width ρ. Finally, to define an analytic quasi-periodic matrix, we note that all of these definitions hold when f is a matrix-valued function. In this case, to define $\|f\|_\rho$, we use the infinity norm (which will be denoted by $|\cdot|_\infty$) for the matrices f_k.

With these definitions and properties, let us return to the problem of the reducibility of a linear quasi-periodic equation $\dot{x} = \widehat{A}(t)x$ to constant coefficients. The approach of this paper is to assume that the system is close to constant coefficients, that is, $\widehat{A}(t) = A + \varepsilon Q(t, \varepsilon)$, where ε is small. This case has already been considered in many papers (see [2], [8], and [9] among others), and the results can be summarized as follows. Let λ_i be the eigenvalues of A and let $\alpha_{ij} = \lambda_i - \lambda_j$ for $i \neq j$. Then if all the values $\operatorname{Re}\alpha_{ij}$ are different from zero, the reduction can be performed for $|\varepsilon| < \varepsilon_0$, ε_0 sufficiently small (see [2]). If some of the $\operatorname{Re}\alpha_{ij}$ are zero (this happens, for instance, if A is elliptic, that is, if all the λ_i are on the imaginary axis), more hypotheses are needed—usually these are (i) a diophantine condition involving the α_{ij} and the basic frequencies of $Q(t, \varepsilon)$ and (ii) to assume a nondegeneracy condition with respect to ε on the corresponding $\alpha_{ij}(\varepsilon)$ of the matrix $A + \varepsilon\overline{Q}(\varepsilon)$ ($\overline{Q}(\varepsilon)$ denotes the average of $Q(t, \varepsilon)$). This allows to prove (see [9] for details) that there exists a Cantorian set $\mathcal{E}$ such that the reduction can be performed for all $\varepsilon \in \mathcal{E}$. Moreover, the relative measure of the set $[0, \varepsilon_0] \setminus \mathcal{E}$ in $[0, \varepsilon_0]$ is exponentially small in ε_0.

Our purpose here is somewhat different. Instead of looking for a total reduction to constant coefficients (this seems to lead us to eliminate a dense set of values of ε; see [8] or [9]), we try to minimize the quasi-periodic part without taking out any value of ε. The result obtained is that the quasi-periodic part can be made exponentially small. Since all of the proof is constructive (and can be carried out with a finite number of steps), it can be applied to practical examples in order to perform an “effective” reduction: if ε is small enough, the remainder will be so small that, for practical purposes, it can be taken equal to zero. The error produced with this dropping can be easily bounded by means of the Gronwall lemma. Finally, we want to stress that we have also eliminated the nondegeneracy hypothesis of previous papers [8], [9].

Before finishing this introduction, we want to mention a similar result obtained when the dynamics of the system is slow: $\dot{x} = \varepsilon(A + \varepsilon Q(t, \varepsilon))x$. This case is contained in [14], which is an extension of [12]. The result obtained is also that the quasi-periodic part can be made exponentially small in ε. Total reducibility has been also considered in this case: in [15], it is stated that the reduction can be performed except for a set of values of ε of measure exponentially small.

There are many other results for the reducibility problem. For instance, in the case of the Schrödinger equation with quasi-periodic potential, we mention [3], [4], [5], [10], [11], and [13]. Another classical and remarkable paper is [7], where the general case (that is, without asking to be close to constant coefficients) is considered. Finally, classical results for quasi-periodic systems can be found in [6].

In order to simplify reading, the paper has been divided as follows. Section 2 contains the exposition (without technical details) of the main ideas and methodology, section 3 contains the main theorem, sections 4 and 5 are devoted to the proofs and, finally, section 6 contains an example to show how these results can be applied to a concrete problem.

2. The method. The method used is based on the same inductive scheme as [8]. Let us write our equation as

$$\dot{x} = (A + \varepsilon Q(t, \varepsilon))x, \tag{1}$$

where A is an elliptic $d \times d$ matrix and $Q(t,\varepsilon)$ is quasi-periodic with $\omega = (\omega_1, \dots, \omega_r)$ as vector of basic frequencies and analytic on a strip of width ρ. First of all, let us rewrite this equation as

$$\dot{x} = (A_0(\varepsilon) + \varepsilon \widetilde{Q}(t,\varepsilon))x,$$

where $A_0(\varepsilon) = A + \overline{Q}(\varepsilon)$ and $\widetilde{Q}(t,\varepsilon) = Q(t,\varepsilon) - \overline{Q}(\varepsilon)$. Now let us assume that we are able to find a quasi-periodic $d \times d$ matrix P (with the same basic frequencies as Q) verifying

$$\dot{P} = A_0(\varepsilon)P - PA_0(\varepsilon) + \widetilde{Q}(t,\varepsilon) \tag{2}$$

such that $\|\varepsilon P(t,\varepsilon)\|_\sigma < 1$ for some $\sigma > 0$. In this case, it is not difficult to check that the change of variables $x = (I + \varepsilon P(t,\varepsilon))y$ transforms equation (1) into

$$\dot{y} = (A_0(\varepsilon) + \varepsilon^2 (I + \varepsilon P(t,\varepsilon))^{-1} \widetilde{Q}(t,\varepsilon) P(t,\varepsilon))y. \tag{3}$$

Since this equation is similar to (1) but with ε^2 instead of ε, the inductive scheme seems clear: average the quasi-periodic part of (3) and restart this process. The main difficulty that appears in this process comes from equation (2) because the solution contains the denominators $\lambda_i(\varepsilon) - \lambda_j(\varepsilon) + \sqrt{-1}(k,\omega)$, $1 \le i,\, j \le d$, where $\lambda_i(\varepsilon)$ are the eigenvalues of $A_0(\varepsilon)$. (This is shown in the proof of Lemma 4.2.) This divisor appears in the kth Fourier coefficient of P. Note that if the values $\lambda_i(\varepsilon) - \lambda_j(\varepsilon)$ are outside the imaginary axis, the (modulus of the) divisor can be bounded from below, making it easy to prove the convergence. On the other hand, the value $\lambda_i(\varepsilon) - \lambda_j(\varepsilon) + \sqrt{-1}(k,\omega)$ can be arbitrarily small, giving rise to convergence problems.

2.1. Avoiding the small divisors. Let us begin by assuming that the eigenvalues λ_i of the original unperturbed matrix A (see equation (1)) and the basic frequencies of Q satisfy the diophantine condition

$$|\lambda_i - \lambda_j + \sqrt{-1}(k,\omega)| \ge \frac{c}{|k|^\gamma} \quad \forall\, k \in \mathbb{Z}^r \setminus \{0\}, \tag{4}$$

where $|k| = |k_1| + \cdots + |k_r|$. Note that, in principle, we cannot guarantee that this condition holds in equation (2) because the eigenvalues of $A_0(\varepsilon)$ have been changed with respect to the ones of A (by an amount of $\mathcal{O}(\varepsilon)$) and some of the divisors can be very small or even zero.

The key point is to realize that as the eigenvalues of A move by an amount of $\mathcal{O}(\varepsilon)$ at most, the quantities $\lambda_i(\varepsilon) - \lambda_j(\varepsilon)$ are contained in a (complex) ball $B_{i,j}(\varepsilon)$ centered in $\lambda_i - \lambda_j$ and with radius $\mathcal{O}(\varepsilon)$. Since the center of the ball satisfies condition (4), the values (k,ω) cannot be inside that ball if $|k|$ is less than some value $M(\varepsilon)$. This implies that it is possible to cancel all of the harmonics such that $0 < |k| < M(\varepsilon)$ because they do not produce small divisors. (Note that we can have resonances only when (k,ω) is inside $B_{i,j}(\varepsilon)$.) The harmonics with $|k| \ge M(\varepsilon)$ are exponentially small in $M(\varepsilon)$ (when $M(\varepsilon) \to \infty$), that is, exponentially small in ε (when $\varepsilon \to 0$), so we do not need to eliminate them.

The idea of considering only frequencies less than some threshold M has already been applied in other contexts (see, for instance, [1]).

2.2. The iterative scheme. To apply the considerations above, we define, as before, $A_0(\varepsilon) = A + \varepsilon\overline{Q}(\varepsilon)$, $\widetilde{Q}(t,\varepsilon) = Q(t,\varepsilon) - \overline{Q}(\varepsilon)$ and we split $\widetilde{Q}(t,\varepsilon)$ into the sum of two matrices $Q_0(t,\varepsilon)$ and $R_0(t,\varepsilon)$: $Q_0(t,\varepsilon)$ contains the harmonics $Q_k e^{(k,\omega)\sqrt{-1}t}$

with $|k| < M(\varepsilon)$ and $R_0(t,\varepsilon)$ contains those with $|k| \geq M(\varepsilon)$. Therefore, (1) can be rewritten as

$$\dot{x} = (A_0(\varepsilon) + \varepsilon Q_0(t,\varepsilon) + \varepsilon R_0(t,\varepsilon))x. \tag{5}$$

Now the idea is to cancel $Q_0(t,\varepsilon)$ and to leave $R_0(t,\varepsilon)$. (It is already exponentially small with ε.) Therefore, we compute P_0 such that

$$\dot{P}_0 = A_0(\varepsilon)P_0 - P_0A_0(\varepsilon) + Q_0(t,\varepsilon).$$

Then the change $x = (I + \varepsilon P_0(t,\varepsilon))y$ gives

$$\dot{y} = \left[A_0 + \varepsilon^2(I+\varepsilon P_0)^{-1}Q_0P_0 + \varepsilon(I+\varepsilon P_0)^{-1}R_0(I+\varepsilon P_0)\right]y.$$

This equation can be rewritten to be like (5) to repeat the process. Note that the size of the harmonics with $0 < |k| < M(\varepsilon)$ has been squared. As we will see in the proofs, this is enough to guarantee convergence of those terms to zero. Thus the final equation has a purely quasi-periodic part that is exponentially small with ε.

2.3. Remarks. It is interesting to note that it is enough to apply a finite number of steps of the inductive process. We do not need to completely cancel the harmonics with $0 < |k| < M(\varepsilon)$, but we can stop the process when they are of the same size as those of R. (From the proof, it can be seen that the number of steps needed to achieve this is of order $|\ln|\varepsilon||$.) This allows us to (with the help of a computer) apply this procedure on a practical example.

Another remarkable point concerns the diophantine condition. Note that we need the condition only up to a finite order ($M(\varepsilon)$, which is of order $(1/|\varepsilon|)^{1/\gamma}$, as we shall see in the proofs). This means that in a practical example when the perturbing frequencies are known with finite precision, the diophantine condition can be easily checked.

3. The theorem. In what follows, $\mathcal{Q}_d(\rho,\omega)$ stands for the set of analytic quasi-periodic $d \times d$ matrices on a strip of width ρ and that have ω as their vector of basic frequencies. Moreover, i will denote $\sqrt{-1}$.

THEOREM 3.1. *Consider the equation $\dot{x} = (A + \varepsilon Q(t,\varepsilon))x$, $|\varepsilon| \leq \varepsilon_0$, $x \in \mathbb{R}^d$, where we have the following hypotheses:*

1. *A is a constant $d \times d$ matrix with different eigenvalues $\lambda_1, \dots, \lambda_d$.*
2. *$Q(\cdot,\varepsilon) \in \mathcal{Q}_d(\rho,\omega)$ with $\|Q(\cdot,\varepsilon)\|_\rho \leq q$ $\forall |\varepsilon| \leq \varepsilon_0$, for some $\omega \in \mathbb{R}^r$, and where $q, \rho > 0$.*
3. *The vector ω satisfies the diophantine conditions*

$$|\lambda_j - \lambda_\ell + i(k,\omega)| \geq \frac{c}{|k|^\gamma} \quad \forall\, k \in \mathbb{Z}^r \setminus \{0\} \quad \forall\, j,\, \ell \in \{1,\dots,d\} \tag{6}$$

for some constants $c > 0$ and $\gamma > r - 1$. As usual, $|k| = |k_1| + \cdots + |k_r|$.

Then there exist positive constants ε^*, a^*, r^*, and m such that for all ε, $|\varepsilon| \leq \varepsilon^*$, the initial equation can be transformed into

$$\dot{y} = (A^*(\varepsilon) + \varepsilon R^*(t,\varepsilon))y, \tag{7}$$

where

1. *A^* is a constant matrix with $|A^*(\varepsilon) - A|_\infty \leq a^*|\varepsilon|$ and*
2. *$R^*(\cdot,\varepsilon) \in \mathcal{Q}_d(\rho,\omega)$ and $\|R^*(\cdot,\varepsilon)\|_{\rho-\delta} \leq r^* \exp(-(m/|\varepsilon|)^{1/\gamma}\delta)$ $\forall\, \delta \in\,]0,\rho]$.*

Furthermore, the quasi-periodic change of variables that performs this transformation is also an element of $\mathcal{Q}_d(\rho, \omega)$. Finally, a general explicit computation of ε^*, a^*, r^*, and m is possible:

$$\varepsilon^* = \min\left(\varepsilon_0, \frac{\alpha}{eq\beta(3d-1)}\right), \qquad a^* = \frac{eq\beta^2}{e-1}, \qquad r^* = ea^*, \qquad m = \frac{c}{10eq\beta}$$

where $e = \exp(1)$, $\alpha = \min_{j\neq\ell}(|\lambda_j - \lambda_\ell|)$, and β is the condition number of a regular matrix S such that $S^{-1}AS$ is diagonal, that is, $\beta = C(S) = |S^{-1}|_\infty |S|_\infty$.

Remark 3.1. For fixed values of $\lambda_1, \ldots, \lambda_d$ and γ, hypothesis 3 is not satisfied for any $c > 0$ only for a set of values of ω of zero measure if $\gamma > r - 1$.

Remark 3.2. In case the eigenvalues of the perturbed matrices move on balls of radius $\mathcal{O}(\varepsilon^p)$ (that is, if the nondegeneracy hypothesis needed in [8] or [9] is not satisfied), it is not difficult to show that the bound of the exponential can be improved: $\|R^*(\cdot, \varepsilon)\|_{\rho-\delta} \leq r^* \exp(-(m/|\varepsilon|)^{p/\gamma}\delta)$. The proof is very similar but uses $M(\varepsilon) = (m/|\varepsilon|)^{p/\gamma}$ instead of $(m/|\varepsilon|)^{1/\gamma}$.

Remark 3.2 seems to show that this nondegeneracy hypothesis is not necessary, and it is only used for technical reasons. In fact, the results seem to be better when this hypothesis is not satisfied.

Remark 3.3. If the unperturbed matrix A has multiple eigenvalues (that is, if hypothesis 1 is not satisfied), the theorem is still true, but the exponent of ε in the exponential of the remainder is slightly worse. This happens because the (small) divisors are now raised to a power that increases with the multiplicity of the eigenvalues. The proof is not included since it does not introduce new ideas and the technical details are rather tedious.

Remark 3.4. The values of ε^*, a^*, r^*, and m given in the theorem are rather pessimistic. In the proof, we have used simple (but rough) bounds instead of cumbersome but more accurate ones. If one is interested in realistic bounds for a given problem, the best thing to do is to rewrite the proof for that particular case. We have done this in section 6 where, with the help of a computer program, we have applied some steps of the method to an example. This allows us to obtain not only better bounds but also (numerically) the reduced matrix as well as the corresponding change of variables.

4. Lemmas.

We will use some lemmas to simplify the proof of Theorem 3.1.

4.1. Basic lemmas.

LEMMA 4.1. *Let $Q(t) = \sum_{k\in\mathbb{Z}^r} Q_k e^{i(k,\omega)t}$ be an element of $\mathcal{Q}_d(\rho, \omega)$ and $M > 0$. Let us define $\overline{Q} = Q_0$, $\widetilde{Q}(t) = Q(t) - Q_0$,*

$$Q_{\geq M}(t) = \sum_{\substack{k\in\mathbb{Z}^r \\ |k|\geq M}} Q_k e^{i(k,\omega)t},$$

and $\widetilde{Q}_{<M} = \widetilde{Q} - Q_{\geq M}$. Then we have the bounds

1. $|\overline{Q}|_\infty$, $\|\widetilde{Q}\|_\rho$, $\|\widetilde{Q}_{<M}\|_\rho \leq \|Q\|_\rho$ *and*
2. $\|Q_{\geq M}\|_{\rho-\delta} \leq \|Q\|_\rho e^{-M\delta}$ $\forall\, \delta \in\,]0, \rho]$.

Proof. The proof follows immediately. □

The next lemma is used to control the variation of the eigenvalues of a perturbed diagonal matrix.

LEMMA 4.2. *Let D be a $d\times d$ diagonal matrix with different eigenvalues $\lambda_1, \ldots, \lambda_d$ and $\alpha = \min_{j\neq\ell}(|\lambda_j - \lambda_\ell|)$. Then if A verifies $|A - D|_\infty \leq b \leq \alpha/(3d-1)$, the following conditions hold:*

1. *A has different eigenvalues $\mu_1, \dots, \mu_d$ and $|\lambda_j - \mu_j| \le b$ if $j = 1, \dots, d$.*

2. *There exists a regular matrix S such that $S^{-1}AS = D^* = \operatorname{diag}(\mu_1, \dots, \mu_d)$ satisfying $C(S) \le 2$.*

Proof. The proof is contained in [8]. □

LEMMA 4.3. *Let $(q_n)_n$, $(a_n)_n$, and $(r_n)_n$ be sequences defined by*

$$q_{n+1} = q_n^2, \qquad a_{n+1} = a_n + q_{n+1}, \qquad r_{n+1} = \frac{2+q_n}{2-q_n} r_n + q_{n+1}$$

with initial values $q_0 = a_0 = r_0 = e^{-1}$. Then $(q_n)_n$ is decreasing to zero and $(a_n)_n$ and $(r_n)_n$ are increasing and convergent to some values a_∞ and r_∞, respectively, with $a_\infty < 1/(e-1)$ and $r_\infty < e/(e-1)$.

Proof. It is immediate that q_n goes to zero quadratically, and this implies that a_n is convergent to the value a_∞:

$$a_\infty = \sum_{j=0}^{\infty} q_j < \sum_{j=1}^{\infty} e^{-j} = \frac{1}{e-1}.$$

Then

$$r_n \le p \left(r_0 + \sum_{j=1}^{n} q_j \right) \le p a_\infty,$$

where $p = \prod_{j=0}^{\infty} (2+q_j)/(2-q_j)$. This product is convergent. In fact,

$$\ln p = \sum_{j=0}^{\infty} \left[\ln\left(1 + \frac{q_j}{2}\right) - \ln\left(1 - \frac{q_j}{2}\right) \right] \le \frac{3}{2} a_\infty \le \frac{3}{2(e-1)} < 1,$$

and so $p < e$, where we have used the fact that $\ln(1+x) \le x$ and $-\ln(1-x) \le 2x$ for $x \in (0, 1/2)$. □

4.2. The inductive lemma. The next lemma is used to perform a step of the inductive procedure.

Before stating the result, let us introduce some notation. Let D and α be as in Lemma 4.2 and let ε^*, q^*, L, and $M(\varepsilon)$ be positive constants. We consider the equation at the step n of the iterative process:

$$\dot{x}_n = (A_n(\varepsilon) + \varepsilon Q_n(t,\varepsilon) + \varepsilon R_n(t,\varepsilon)) x_n, \quad |\varepsilon| \le \varepsilon^*, \tag{8}$$

where $Q_n(\cdot,\varepsilon)$, $R_n(\cdot,\varepsilon) \in \mathcal{Q}_d(\rho,\omega)$ and $\overline{Q}_n(\varepsilon) = Q_n(\cdot,\varepsilon)_{\ge M(\varepsilon)} = 0$. We assume that for some a_n, q_n, $r_n \ge 0$ and $|\varepsilon| < \varepsilon^*$, the following bounds hold:

$$|A_n(\varepsilon) - D| \le q^* a_n |\varepsilon|, \qquad \|Q_n(\cdot,\varepsilon)\|_\rho \le q^* q_n, \qquad \|R_n(\cdot,\varepsilon)\|_{\rho-\delta} \le q^* r_n e^{-M(\varepsilon)\delta},$$

where δ is such that $0 < \delta \le \rho$. (The constant q^* has been introduced to simplify the proof of the theorem later on.) We want to see if it is possible to apply a step of the iterative process to equation (8) to obtain

$$\dot{x}_{n+1} = (A_{n+1}(\varepsilon) + \varepsilon Q_{n+1}(t,\varepsilon) + \varepsilon R_{n+1}(t,\varepsilon)) x_{n+1}, \quad |\varepsilon| \le \varepsilon^*, \tag{9}$$

such that $Q_{n+1}(\cdot,\varepsilon)$, $R_{n+1}(\cdot,\varepsilon) \in \mathcal{Q}_d(\rho,\omega)$ and $\overline{Q}_{n+1}(\varepsilon) = Q_{n+1}(\cdot,\varepsilon)_{\ge M(\varepsilon)} = 0$. We also want to relate the bounds a_{n+1}, q_{n+1}, and r_{n+1} of the terms of this equation with the corresponding bounds of equation (8).

LEMMA 4.4. *Let $\lambda_1^{(n)}(\varepsilon), \dots, \lambda_d^{(n)}(\varepsilon)$ be the eigenvalues of $A_n(\varepsilon)$. Under the previous notation, if*

1. *$L \geq 8q^*$, $\varepsilon^* \leq \alpha/q^*(3d-1)$,*
2. *$a_n \leq 1$, $q_n \leq e^{-1}$, and*
3. *the condition*

$$|\lambda_j^{(n)}(\varepsilon) - \lambda_\ell^{(n)}(\varepsilon) + i(k,\omega)| \geq L|\varepsilon|, \quad |\varepsilon| \leq \varepsilon^*,$$

is satisfied for all j and ℓ and for all $k \in \mathbb{Z}^r$ such that $0 < |k| < M(\varepsilon)$, then equation (8) can be transformed into (9) and

$$q_{n+1} = q_n^2, \qquad a_{n+1} = a_n + q_{n+1}, \qquad r_{n+1} = \frac{2+q_n}{2-q_n} r_n + q_{n+1}\,.$$

The quasi-periodic change of variables that performs this transformation is

$$x_n = (I + \varepsilon P_n(t,\varepsilon))x_{n+1}, \tag{10}$$

where $P_n(\cdot,\varepsilon)$ is the (only) solution of

$$\dot{P}_n = A_n(\varepsilon)P_n - P_n A_n(\varepsilon) + Q_n(t,\varepsilon), \quad \overline{P}_n = 0, \tag{11}$$

that belongs to $\mathcal{Q}_d(\rho,\omega)$. Moreover, $\|\varepsilon P_n(\cdot,\varepsilon)\|_\rho \leq q_n/2 < 1/2$.

Remark 4.1. A_n, Q_n, R_n, P_n, M, and $\lambda_j^{(n)}$ depend on ε but, for simplicity, we will not write this explicitly.

Proof of Lemma 4.4. Let us begin by studying the solutions of (11). Let S_n be the matrix found in Lemma 4.2 with $S_n^{-1}A_nS_n = D_n = \operatorname{diag}(\lambda_1^{(n)},\ldots,\lambda_d^{(n)})$ and $C(S_n) \leq 2$. This lemma can be applied because

$$|A_n - D|_\infty \leq q^* a_n|\varepsilon| \leq q^*\varepsilon^* \leq \frac{\alpha}{3d-1} \quad \forall\, |\varepsilon| \leq \varepsilon^*.$$

Making the change of variables $P_n = S_nX_nS_n^{-1}$ and defining $Y_n = S_n^{-1}Q_nS_n$, equation (11) becomes

$$\dot{X}_n = D_nX_n - X_nD_n + Y_n, \quad \overline{Y}_n = 0.$$

Since D_n is a diagonal matrix, we can handle this equation as d^2 unidimensional equations, which can be easily solved by expanding in Fourier series. If $X_n = (x_{\ell j,n})$ and $Y_n = (y_{\ell j,n})$ with

$$x_{\ell j,n}(t) = \sum_{\substack{k\in\mathbb{Z}^r\\0<|k|<M}} x_{\ell j,n}^k e^{i(k,\omega)t}, \qquad y_{\ell j,n}(t) = \sum_{\substack{k\in\mathbb{Z}^r\\0<|k|<M}} y_{\ell j,n}^k e^{i(k,\omega)t},$$

the coefficients must be

$$x_{\ell j,n}^k = \frac{y_{\ell j,n}^k}{\lambda_j^{(n)} - \lambda_\ell^{(n)} + i(k,\omega)},$$

and by hypothesis 3, they can be bounded by $|x_{\ell j,n}^k| \leq (L|\varepsilon|)^{-1}|y_{\ell j,n}^k|$, which implies

$$\begin{aligned}\|P_n\|_\rho &\leq C(S_n)\|X_n\|_\rho \leq C(S_n)(L|\varepsilon|)^{-1}\|Y_n\|_\rho \leq C(S_n)^2(L|\varepsilon|)^{-1}\|Q_n\|_\rho\\ &\leq 4(L|\varepsilon|)^{-1}q^*q_n \leq |\varepsilon|^{-1}\frac{q_n}{2}.\end{aligned}$$

Hence $\|\varepsilon P_n\|_\rho \leq q_n/2 < 1/2$. Thus $I + \varepsilon P_n$ is invertible and

$$\|(I + \varepsilon P_n)^{-1}\|_\rho \leq \frac{1}{1 - \|\varepsilon P_n\|_\rho} < 2.$$

Now applying the change of (10) to (8) and defining $Q_n^* = \varepsilon(I+\varepsilon P_n)^{-1} Q_n P_n$, $A_{n+1} = A_n + \varepsilon \overline{Q_n^*}$, $Q_{n+1} = (\widetilde{Q_n^*})_{<M}$, and $R_{n+1} = (I + \varepsilon P_n)^{-1} R_n (I + \varepsilon P_n) + (Q_n^*)_{\geq M}$, it is easy to derive equation (9). Finally, we use Lemma 4.1 to bound the terms of this equation:

$$\begin{aligned}
\|Q_n^*\|_\rho &\leq \|(I + \varepsilon P_n)^{-1}\|_\rho \|Q_n\|_\rho \|\varepsilon P_n\|_\rho \leq \|Q_n\|_\rho q_n \leq q^* q_n^2 = q^* q_{n+1},\\
\|Q_{n+1}\|_\rho &\leq \|Q_n^*\|_\rho \leq q^* q_{n+1},\\
|A_{n+1} - D|_\infty &\leq |A_n - D|_\infty + |\varepsilon \overline{Q_n^*}|_\infty \leq q^*(a_n + q_{n+1})|\varepsilon| = q^* a_{n+1}|\varepsilon|,\\
\|R_{n+1}\|_{\rho-\delta} &\leq \frac{1 + \|\varepsilon P_n\|_\rho}{1 - \|\varepsilon P_n\|_\rho} \|R_n\|_{\rho-\delta} + \|(Q_n^*)_{\geq M}\|_{\rho-\delta}\\
&\leq \left(\frac{1 + q_n/2}{1 - q_n/2} r_n + q_{n+1} \right) q^* e^{-M\delta} = q^* r_{n+1} e^{-M\delta} \quad \forall\, \delta \in \,]0, \rho],
\end{aligned}$$

and the proof is complete. □

5. Proof of Theorem 3.1. Let S be a regular matrix such that $S^{-1}AS = D = \operatorname{diag}(\lambda_1, \ldots, \lambda_d)$. We define ε^*, α, β, and m as in Theorem 3.1. We also define $q^* = e\beta q$, $M = M(\varepsilon) = (m/|\varepsilon|)^{1/\gamma}$, and $L = 8q^*$.

The (constant) change $x = Sx_0$ transforms the initial equation into

$$\dot{x}_0 = (D + \varepsilon Q^*(t, \varepsilon)) x_0, \tag{12}$$

where $Q^* = S^{-1}QS$ and so $\|Q^*\|_\rho \leq e^{-1} q^*$ for $|\varepsilon| \leq \varepsilon^*$. We split equation (12) as follows:

$$\dot{x} = (A_0 + \varepsilon Q_0(t) + \varepsilon R_0(t)) x_0,$$

where $A_0 = D + \varepsilon \overline{Q^*}$, $Q_0 = \widetilde{Q^*}_{<M}$, and $R_0 = Q^*_{\geq M}$. Using Lemma 4.1, it is easy to see that

$$|A_0 - D|_\infty \leq q^* a_0 |\varepsilon|, \qquad \|Q_0\|_\rho \leq q^* q_0, \qquad \|R_0\|_{\rho-\delta} \leq q^* r_0 e^{-M\delta}$$

$\forall\, \delta \in \,]0, \rho]$ and $|\varepsilon| \leq \varepsilon^*$ if $a_0 = q_0 = r_0 = e^{-1}$.

We will show that in all of the steps, the hypotheses of Lemma 4.4 are satisfied. Since hypothesis 1 and 2 are easy to check, we focus on hypothesis 3.

Now since $a_n \leq 1$, $|\varepsilon| \leq \varepsilon^*$, and $|A_n - D|_\infty \leq q^*|\varepsilon| \leq \alpha/(3d-1)$, Lemma 4.2 gives that

$$|\alpha_{j\ell}^{(n)} - \alpha_{j\ell}| < 2q^*|\varepsilon| \quad \forall\, j,\, \ell,\ |\varepsilon| \leq \varepsilon^*,$$

where $\alpha_{j\ell} = \lambda_j - \lambda_\ell$ and $\alpha_{j\ell}^{(n)} = \lambda_j^{(n)} - \lambda_\ell^{(n)}$, where $\lambda_1^{(n)}, \ldots, \lambda_d^{(n)}$ are the eigenvalues of $A_n(\varepsilon)$.

Using hypothesis 3 of Theorem 3.1, we obtain that if $k \in \mathbb{Z}^r$ and $0 < |k| < M(\varepsilon)$,

$$\begin{aligned}
|\alpha_{j\ell}^{(n)} + i(k, \omega)| &\geq |\alpha_{j\ell} + i(k, \omega)| - |\alpha_{j\ell}^{(n)} - \alpha_{j\ell}| > \frac{c}{|k|^\gamma} - 2q^*|\varepsilon|\\
&> \left(\frac{c}{m} - 2q^* \right) |\varepsilon| = L|\varepsilon|,
\end{aligned}$$

and hypothesis 3 of Lemma 4.4 is verified.

Consequently, the iterative process can be carried out and Lemma 4.3 ensures the convergence of the process. The composition of all of the changes $I + \varepsilon P_n$ is convergent because $\|I + \varepsilon P_n\|_\rho \leq 1 + q_n/2$. Then the final equation is

$$\dot{x}_\infty = (A_\infty(\varepsilon) + \varepsilon R_\infty(t, \varepsilon))x_\infty, \quad |\varepsilon| \leq \varepsilon^*, \tag{13}$$

where $|A_\infty(\varepsilon) - D|_\infty \leq q^* a_\infty |\varepsilon| \leq (e\beta/(e-1))q|\varepsilon|$ and

$$\|R_\infty(\cdot, \varepsilon)\|_{\rho-\delta} \leq q^* r_\infty e^{-M(\varepsilon)\delta} \leq \frac{e^2\beta}{e-1} q \exp\left\{-\left(\frac{m}{|\varepsilon|}\right)^{1/\gamma} \delta\right\} \quad \forall\, \delta \in]0, \rho].$$

To complete the proof, the change $x_\infty = S^{-1}y$ transforms equation (13) into equation (7) with the bounds that we were looking for.

6. An example. The results of this paper can be applied in many ways according to the kind of problem we are interested in. Let us illustrate this with the help of an example.

Let us consider the equation

$$\ddot{x} + (1 + \varepsilon q(t))x = 0, \tag{14}$$

where $q(t) = \cos(\omega_1 t) + \cos(\omega_2 t)$ with $\omega_1 = \sqrt{2}$ and $\omega_2 = \sqrt{3}$. Defining y as $\dot{x}$, we can rewrite (14) as

$$\begin{pmatrix} \dot{x} \\ \dot{y} \end{pmatrix} = \left[\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} + \varepsilon \begin{pmatrix} 0 & 0 \\ -q(t) & 0 \end{pmatrix}\right] \begin{pmatrix} x \\ y \end{pmatrix}. \tag{15}$$

Since $\lambda_{1,2} = \pm i$, the diophantine condition (6) is satisfied for $\gamma = 1$ (because the frequencies are quadratic irrationals). The value of c will be discussed later. For the sake of simplicity, let us take $\rho = 2$ and $\delta = 1$. This implies that $q = \|Q\|_\rho = 2e^2$. It is not difficult to derive $\beta = 2$ and, finally, $\varepsilon^* = 4.9787\ldots \times 10^{-3}$ and $r^* = 2.5419\ldots \times 10^2$.

The value of c might be calculated for all $k = (k_1, k_2)$, but better (larger) values can be used since we need to consider $|k|$ only up to a finite order. For instance, an easy computation shows that for $|k| \leq 125$, c is 0.149. If $|k| = 126$, then c must be at most 0.013 due to the quasi resonance produced by $k = (70, -56)$. In the range $126 \leq |k| \leq 10^5$, there are no more relevant resonances, so the value $c = 0.013$ suffices.

To begin our discussion, let us suppose that the value of ε in (15) is $\varepsilon = 2 \times 10^{-6}$. If we take $c = 0.149$, we obtain that $m = 1.8545\ldots \times 10^{-4}$ and $M = 93$. (Recall that the process cancels frequencies such that $|k| < M(\varepsilon)$.) If the value of M had been larger than 125, we would have used the value $c = 0.013$ instead. Therefore, we can reduce the system to constant coefficients with a remainder R^* such that $\|R^*\|_{\rho-1} < 10^{-37}$.

If the given value of ε is smaller—for instance, $\varepsilon = 10^{-7}$—the computed value of M if $c = 0.149$ is 1855, so $c = 0.013$ must be used. This produces $M = 162$ and $\|R^*\|_{\rho-1} < 10^{-67}$. A value of $\varepsilon = 5 \times 10^{-8}$ implies that $M = 324$ and $\|R^*\|_{\rho-1} < 10^{-138}$. The computation of the reduced matrix as well as the quasi-periodic change of variables will be discussed below.

Another interesting problem is the study of reducibility for a value of ε larger than the ε^* given above. Let us continue working with the same equation but with $\varepsilon = 0.1$ as our example.

To increase the value of ε^*, one may try to rewrite the proof using optimal bounds at each step. This has not been done here in order to get an easy, clean, and short proof. Instead of doing this, we think that it is much better to rewrite the proof for our example using no bounds but exact values. This will produce the best results for this problem.

For that purpose, we have implemented the algorithm used in the proof of the theorem as a C program for a (given) fixed value of ε. The program computes and performs a finite number of the changes of variables used to prove the theorem. As a result, the reduced system (including the remainder) as well as the final change of variables are written.

To simplify and make the program more efficient, all of the coefficients have been stored as double-precision variables. During all of the operations, all of the coefficients less than 10^{-20} have been dropped in order to control the size of the Fourier series that appears during the process. Of course, this introduces some (small) numerical error in the results.[1]

After four changes of variables, (15) is transformed into

$$\begin{pmatrix} \dot{x} \\ \dot{y} \end{pmatrix} = \left[\begin{pmatrix} 0.0 & b_{12} \\ b_{21} & 0.0 \end{pmatrix} + R(t) \right] \begin{pmatrix} x \\ y \end{pmatrix}, \tag{16}$$

where $b_{12} = 1.000000366251255$ and $b_{21} = -0.992421151834871$. The remainder R is very small: the largest coefficient it contains is less than 10^{-16}. Note that the accuracy (relative error) of this remainder is very poor due to the use of double-precision arithmetic (15–16 digits) for the coefficients. During the computations, M has not been given a value. Instead, we have tried to cancel all the frequencies with amplitude larger than 10^{-16}. (It turns out from the computations that all of these frequencies satisfy $|k| \leq 20$.) It is also possible to obtain a better accuracy in the result, using a multiple-precision arithmetic.

Finally, to check the software, we have tabulated a solution of (16) for a timespan of 10 time units. We have transformed this table by means of the (quasi-periodic) change of variables given by the program. Then we have taken the first point of the transformed table as initial condition of (15) to produce (by means of numerical integration) a new table. The differences between these two tables are less than 10^{-13}, as expected.

Therefore, for practical purposes, this is an "effective" Floquet theorem in the sense that it allows to compute the reduced matrix as well as the change of variables with the usual accuracy used in numerical computations.

Acknowledgments. The authors want to thank C. Bonet and C. Simó for fruitful discussions and remarks.

FUNCTION NORMS AND FRACTAL DIMENSION*

CLAUDE TRICOT†

Abstract. Using functional norms $L^\alpha(f)$, we introduce a two-parameter norm family $\mathcal{L}^{(\alpha,\beta)}(f)$ by performing sections on the definition domain of f. These norms are used on the difference function $f(x)-f(y)$ to obtain the operators $\mathrm{S}_\tau^{(\alpha,\beta)}(f)$ which measure the irregularity of f. The order of growth of $\mathrm{S}_\tau^{(\alpha,\beta)}(f)$ at 0 determines an irregularity index $\Delta^{(\alpha,\beta)}(f)$. In particular, $\Delta^{(\infty,1)}(f)$ is the fractal dimension of the graph of f. We investigate the value of $\Delta^{(\alpha,\beta)}(f)$ for the series $f(x) = \sum_{n=0}^{\infty} 2^{-nH} g(2^n x + \phi_n)$, where $0 < H < 1$, (ϕ_n) is a real-number sequence, and g is a continuous periodic function of period 1.

Key words. norm, fractal dimension, functional norm, oscillation, irregular function

1. Introduction.

In signal analysis, typical data sets can be represented by irregular functions. There are many ways to give a mathematical meaning to the word "irregular." For example, we can say that a function is irregular if it is nowhere differentiable. However, this criterion does not allow us to compare the irregularities of two functions. We can define the *irregularity degree* of a function f defined in a domain D of R^N by evaluating the fractal dimension of its graph G_f. For this evaluation, the procedure described in [11] has been used in many further studies of profiles or surfaces [4, 10]. It consists of calculating for every $x \in D$ and every $\tau > 0$ the *oscillation* of f over the ball $B_\tau(x)$, that is, the difference betwen the supremum and minimum of $f(y)$ for $\|x - y\| \leq \tau$. The arithmetic mean of these oscillations over D is a function of τ, called the *τ-variation* V_τ of f. When τ tends to 0, the order of growth of V_τ is directly related to the graph dimension (in the sense of Minkowski and Bouligand), which we denote by $\mathrm{Dim}(G_f)$.

Many functions other than V_τ may be used to characterize the irregularity of f. As a general rule, we first perform a *local analysis* of the irregularity on the ball $B_\tau(x)$ and then use an averaging process over D to obtain some *global* measure. A number of researchers prefer to discard the oscillation measurements since the extremal values of a signal may be too sensitive to errors in the data acquisition. They may instead choose an average of the differences $|f(x) - f(y)|$ in the neighborhood of x. If we choose, for example, to perform a quadratic mean both locally (over $B_\tau(x)$) and globally (over D), we obtain the *standard deviation* of $|f(x) - f(y)|$ over the whole definition domain, that is, $\mathcal{D}_\tau = \{(x, y) \in R^{2N} \,/\, x \in \mathrm{D},\, \|x-y\| \leq \tau\}$. In this analysis, the behavior of the function

$$\sqrt{\frac{1}{(2\tau)^N \,\mathrm{Vol}_N(\mathrm{D})} \int_{\mathrm{D}} \left(\int_{B_\tau(x)} |f(x) - f(y)|^2 \, dy \right) dx}$$

at $\tau = 0$ is used to characterize the irregularity of f.

One of our aims is to gather various such irregularity functions into the same family and to find their relationships. To achieve this goal, the seminorms L^α, $\alpha \geq 1$, are introduced in section 2. By using cross-sections of the definition domain D of f, we show in section 3 how to construct a doubly indexed family $\mathcal{L}^{(\alpha,\beta)}$ of seminorms for $\alpha \in [1, +\infty]$ and $\beta \in [1, +\infty]$. Then in section 4, we define our general irregularity functions $\mathrm{S}_\tau^{(\alpha,\beta)}(f)$. For example,

$$\mathrm{S}_\tau^{(\alpha,\alpha)}(f) = \left(\frac{1}{\mathrm{Vol}_{2N}(\mathcal{D}_\tau)} \int_{\mathcal{D}_\tau} |f(x) - f(y)|^\alpha \, dy \, dx \right)^{\frac{1}{\alpha}}.$$

The case where $\alpha = \beta = 2$ corresponds to the standard deviation. Another example is

$$\mathrm{S}_\tau^{(\infty,1)}(f) = \frac{1}{\mathrm{Vol}_N(\mathrm{D})} \int_{\mathrm{D}} \left(\sup_{y \in B_\tau(x)} |f(x) - f(y)| \right) dx,$$

a function equivalent to the variation of f. Also,

$$\mathrm{S}_\tau^{(\infty,\infty)}(f) = \sup_{(x,y) \in \mathcal{D}_\tau} |f(x) - f(y)|$$

is the maximum oscillation of f over D.

We study the main properties of the operators $\mathrm{S}_\tau^{(\alpha,\beta)}$ and show that they are continuous and increasing with respect to each of the variables α and β. For each of them, we introduce in section 5 an *irregularity index* as follows:

$$\Delta^{(\alpha,\beta)}(f) = \limsup_{\tau \to 0} \left(N + 1 - \frac{\log \mathrm{S}_\tau^{(\alpha,\beta)}(f)}{\log \tau} \right).$$

The special case $\Delta^{(\infty,1)}(f)$ gives the dimension of the graph of f, but all of these indices are interesting in themselves for the characterization of irregularities. For differentiable functions, they all have the same value N. For many *fractal* functions, they still take a common value larger than N. However, they are not identical in general since for some f, the irregularity functions $\mathrm{S}_\tau^{(\alpha,\beta)}(f)$ are not equivalent near 0. We show that $\Delta^{(\alpha,\beta)}(f)$ as a function of α and β is increasing on $[1, +\infty] \times [1, +\infty]$ and continuous on $[1, +\infty) \times [1, +\infty)$. Finally, in section 6, we study a well-known family of nowhere-differentiable functions defined by the series

$$f(x) = \sum_{n=0}^{+\infty} 2^{-nH} g(2^n x + \phi_n),$$

where $0 < H < 1$, $\phi_n \in R$, and g is continuous and periodic with period 1. To simplify the arguments, we consider only the functions g that verify the extra property

$$g(x) + g\left(x + \frac{1}{2}\right) = \text{constant}.$$

Particular cases of such functions f are the Weierstrass and the Knopp–Takagi functions. We give the conditions on g so that our irregularity indices $\Delta^{(\alpha,\beta)}(f)$ all take the same value $2 - H$ (for the same subject in a slightly different setting, see, e.g., [8, 1]).

We also show that for other fuctions g, the indices may take a common value different from $2-H$ or even take values that depend on the pair (α, β).

One application of this paper consists of providing approximations of the dimension $\mathrm{Dim}(G_f)$ using other indices that may be more robust numerically. However, our aim is really to exhibit a full range of irregularity indices and to show their relationships in order to give the necessary theoretical support to their experimental utilization.

2. $(\boldsymbol{\alpha})$ seminorms.

2.1. Definitions. Let D be a measurable set in R^N, $N \geq 2$, and $\mathrm{Vol}_N(\mathrm{D})$ be its N-dimensional Lebesgue measure. We assume that $0 < \mathrm{Vol}_N(\mathrm{D}) < +\infty$. Let $\mathcal{M}_b(\mathrm{D})$ be the set of all bounded, measurable functions $f : \mathrm{D} \longrightarrow R$. For each $f \in \mathcal{M}_b(\mathrm{D})$ and for each $\alpha > 0$, let us define the following multiple integral:

$$L^\alpha(f;\mathrm{D}) = \left(\frac{1}{\mathrm{Vol}_N(\mathrm{D})}\int_{\mathrm{D}} |f(x)|^\alpha \, dx\right)^{1/\alpha}, \tag{1}$$

where $x = (x_1, \ldots, x_N)$. If $\alpha \geq 1$, L^α is a *seminorm* on $\mathcal{M}_b(\mathrm{D})$. The extra term $1/\mathrm{Vol}_N(\mathrm{D})$ constitutes a slight change with respect to the classical seminorm definition. Its introduction allows us to consider L^α as an *average* and implies that $L^\alpha(f;\mathrm{D})$ is increasing with respect to α (see Theorem 2.1 below), a crucial property in this paper.

We complete (1) with the standard definition of the seminorm L^∞, the *essential supremum* of f over its definition domain:

$$L^\infty(f;\mathrm{D}) = \operatorname{ess\,sup}_{x\in\mathrm{D}}|f(x)|. \tag{2}$$

For fixed D and f, $L^\alpha(f;\mathrm{D})$ may be considered as a function of the variable α defined on $]0,+\infty]$, the set of positive, nonzero, real numbers completed with $+\infty$. This will allow us in section 2.3 to consider the continuity of L^α at $+\infty$.

2.2. Seminorms on the cross-sections. Let $N \geq 2$. We may also define the (α) seminorms of f when restricted to a cross-section of D by a hyperplane.

Given $k < N$ and $t = (t_1, \ldots, t_k)$, a point of the projection of D on R^k, we denote by

$$\mathrm{D}^{(t)} = \mathrm{D} \cap \{\{t\} \times R^{N-k}\} \tag{3}$$

the cross-section of D by the hyperplane of equations $x_1 = t_1, \ldots, x_k = t_k$. Let us consider $\mathrm{D}^{(t)}$ as a subset of R^{N-k} and assume that $0 < \mathrm{Vol}_{N-k}(\mathrm{D}^{(t)}) < +\infty$. Then for all $\alpha > 0$, we define

$$L^\alpha(f;\mathrm{D}^{(t)}) = \left(\frac{1}{\mathrm{Vol}_{N-k}(\mathrm{D}^{(t)})}\int_{\mathrm{D}^{(t)}} |f(x)|^\alpha \, dx_{k+1}\cdots dx_N\right)^{1/\alpha}, \tag{4}$$

where $x = (t_1, \ldots, t_k, x_{k+1}, \ldots, x_N)$. Also,

$$L^\infty(f;\mathrm{D}^{(t)}) = \operatorname{ess\,sup}_{x\in\mathrm{D}^{(t)}}|f(x)|. \tag{5}$$

2.3. Properties. Let us enumerate some fundamental properties of the operator $L^\alpha(f;\mathrm{D})$. They are verified by $L^\alpha(f;\mathrm{D}^{(t)})$ as well. The first three characterize a seminorm.

Theorem 2.1. *The operators L^α have the following properties:*

1. $L^\alpha(f;\mathrm{D}) = 0 \iff f(x) = 0$ *almost everywhere on* D.
2. *For every a,* $L^\alpha(a\,f;\mathrm{D}) = |a|\,L^\alpha(f;\mathrm{D})$.
3. *If f_1, $f_2 \in \mathcal{M}_b(\mathrm{D})$ and $\alpha \in [1,+\infty]$, then*

$$L^\alpha(f_1+f_2;\mathrm{D}) \le L^\alpha(f_1;\mathrm{D}) + L^\alpha(f_2;\mathrm{D}). \tag{6}$$

This is the triangular inequality *associated with the Minkowski inequality for finite sums.*

4. *If f_1, $f_2 \in \mathcal{M}_b(\mathrm{D})$ and if $f_1(x) \le f_2(x)$ almost everywhere on* D*, then*

$$L^\alpha(f_1;\mathrm{D}) \le L^\alpha(f_2;\mathrm{D}). \tag{7}$$

5. *Fix $f \in \mathcal{M}_b(\mathrm{D})$. Then $L^\alpha(f;\mathrm{D})$ is a continuous, increasing function of α on $]0,+\infty]$.*
6. *For all α, $\beta \in]0,+\infty]$,*

$$L^\alpha(|f|^\beta;\mathrm{D}) = (L^{\alpha\beta}(f;\mathrm{D}))^\beta. \tag{8}$$

7. *For all $\alpha \in]0,+\infty]$, $\beta \in]0,+\infty]$, and $\beta \le \alpha$,*

$$L^\beta(f;\mathrm{D}) \le L^\alpha(f;\mathrm{D}) \le (L^\beta(f;\mathrm{D}))^{\frac{\beta}{\alpha}}(L^\infty(f;\mathrm{D}))^{1-\frac{\beta}{\alpha}}. \tag{9}$$

The proof of formula (9) uses the inequality

$$\int_\mathrm{D} |f(x)|^\alpha\,dx \le \left(\int_\mathrm{D} |f(x)|^\beta\,dx\right) \operatorname{ess\,sup}_\mathrm{D}|f(x)|^{\alpha-\beta},$$

which is true when $\beta \le \alpha$. The proof of the other properties uses classical arguments and they are left to the reader.

3. $(\boldsymbol{\alpha},\boldsymbol{\beta})$ seminorms.

3.1. Definitions. Let k be an integer, $1 \le k < N$, and D be a measurable subset of R^N with the following two properties:

(i) $0 < \mathrm{Vol}_N(\mathrm{D}) < +\infty$.
(ii) If E is the orthogonal projection of D over R^k, then for all $t \in E$,

$$0 < \mathrm{Vol}_{N-k}(\mathrm{D}^{(t)}) < +\infty.$$

The cross-section $\mathrm{D}^{(t)}$ is defined in section 2.2. We remark that $\mathrm{Vol}_k(E) > 0$. An example of such a set D is any bounded, open set in R^N. Another example will be presented in section 4.1. The two conditions above allow us to calculate the seminorms of f over all cross-sections of D using formula (4).

Given $f \in \mathcal{M}_b(\mathrm{D})$, we may evaluate $L^\alpha(f;\mathrm{D}^{(t)})$ for all $t \in E$. The result is a function of t. We may evaluate the seminorm of this function as well. We finally obtain two-parameter operators as follows:

$$\mathcal{L}^{(\alpha,\beta)}(f;\mathrm{D}) = L^\beta(L^\alpha(f;\mathrm{D}^{(t)});E), \tag{10}$$

where $(\alpha,\beta) \in]0,+\infty] \times]0,+\infty]$. As a particular case,

$$\mathcal{L}^{(\infty,\infty)}(f;\mathrm{D}) = L^\infty(f;\mathrm{D}) = \operatorname{ess\,sup}_\mathrm{D}|f(x)|. \tag{11}$$

3.2. Properties. The following is a direct consequence of Theorem 2.1.

THEOREM 3.1. *The operators $\mathcal{L}^{(\alpha,\beta)}$ have the following properties:*

1. $\mathcal{L}^{(\alpha,\beta)}(f;\mathrm{D}) = 0 \iff f(x) = 0$ *almost everywhere on* D.
2. *For all a,* $\mathcal{L}^{(\alpha,\beta)}(a\, f;\mathrm{D}) = |a|\,\mathcal{L}^{(\alpha,\beta)}(f;\mathrm{D})$.
3. *If f_1, $f_2 \in \mathcal{M}_b(\mathrm{D})$ and $\alpha \in [1,+\infty]$, $\beta \in [1,+\infty]$, then*

$$\mathcal{L}^{(\alpha,\beta)}(f_1+f_2;\mathrm{D}) \le \mathcal{L}^{(\alpha,\beta)}(f_1;\mathrm{D}) + \mathcal{L}^{(\alpha,\beta)}(f_2;\mathrm{D}). \tag{12}$$

These three properties prove that $\mathcal{L}^{(\alpha,\beta)}$ is a seminorm for $(\alpha,\beta) \in [1,+\infty] \times [1,+\infty]$.

4. *If $f \in \mathcal{M}_b(\mathrm{D})$ is fixed, then $\mathcal{L}^{(\alpha,\beta)}(f;\mathrm{D})$ is a continuous, increasing function of α and β on $]0,+\infty] \times]0,+\infty]$.*
5. *Let us fix* D *and $f \in \mathcal{M}_b(\mathrm{D})$ and write*

$$\mathcal{L}^{(\alpha,\beta)}(f;\mathrm{D}) = \mathcal{L}^{(\alpha,\beta)}, \qquad \mathcal{L}^{(\infty,\infty)}(f;\mathrm{D}) = \|f\|$$

for simplicity. Given real numbers α, β, γ, and δ in $]0,+\infty)$, we seek relationships between $\mathcal{L}^{(\alpha,\beta)}$ and $\mathcal{L}^{(\gamma,\delta)}$. Here are some inequalities:

If $\gamma \le \alpha$,

$$\mathcal{L}^{(\gamma,\beta)} \le \mathcal{L}^{(\alpha,\beta)} \le \left(\mathcal{L}^{(\gamma,\frac{\beta\gamma}{\alpha})}\right)^{\frac{\gamma}{\alpha}} \|f\|^{1-\frac{\gamma}{\alpha}}. \tag{13}$$

If $\delta \le \beta$,

$$\mathcal{L}^{(\alpha,\delta)} \le \mathcal{L}^{(\alpha,\beta)} \le \left(\mathcal{L}^{(\alpha,\delta)}\right)^{\frac{\delta}{\beta}} \|f\|^{1-\frac{\delta}{\beta}}. \tag{14}$$

If $\gamma \le \alpha$ and $\delta \le \beta$,

$$\mathcal{L}^{(\gamma,\delta)} \le \mathcal{L}^{(\alpha,\beta)} \le \left(\mathcal{L}^{(\gamma,\frac{\gamma\delta}{\alpha})}\right)^{\frac{\gamma\delta}{\alpha\beta}} \|f\|^{1-\frac{\gamma\delta}{\alpha\beta}}. \tag{15}$$

Finally, if $\gamma \le \alpha$ and $\beta \le \delta$,

$$\mathcal{L}^{(\gamma,\delta)} \le \left(\mathcal{L}^{(\alpha,\beta)}\right)^{\frac{\beta}{\delta}} \|f\|^{1-\frac{\beta}{\delta}} \le \left(\mathcal{L}^{(\gamma,\frac{\gamma\delta}{\alpha})}\right)^{\frac{\beta\gamma}{\alpha\delta}} \|f\|^{1-\frac{\beta\gamma}{\alpha\delta}}. \tag{16}$$

Inequalities corresponding to the cases where $\alpha \le \gamma$, $\delta \le \beta$ and $\alpha \le \gamma$, $\beta \le \delta$ are deduced from (15) and (16) by a change of variables.

6. *For a fixed $f \in \mathcal{M}_b(\mathrm{D})$, $\mathcal{L}^{(\alpha,\beta)}(f;\mathrm{D})$ is continuous on $]0,+\infty] \times]0,+\infty]$.*

Proof. Let us prove (13). The first inequality comes from the monotonicity of $\mathcal{L}^{(\alpha,\beta)}$. The second is obtained by using (9). For all $t \in E$,

$$L^{\alpha}(f;\mathrm{D}^{(t)}) \le (L^{\gamma}(f;\mathrm{D}^{(t)}))^{\frac{\gamma}{\alpha}} (L^{\infty}(f;\mathrm{D}^{(t)}))^{1-\frac{\gamma}{\alpha}}.$$

Also, $L^{\infty}(f;\mathrm{D}^{(t)}) \le \|f\|$. Now using the seminorm L^{β}, we get

$$L^{\beta}(L^{\alpha}(f;\mathrm{D}^{(t)});E) \le L^{\beta}((L^{\gamma}(f;\mathrm{D}^{(t)}))^{\frac{\gamma}{\alpha}};E)\,\|f\|^{1-\frac{\gamma}{\alpha}}.$$

From (8), the right-hand side member of the above equation is simply

$$L^{\frac{\beta\gamma}{\alpha}}(L^{\gamma}(f;\mathrm{D}^{(t)});E)^{\frac{\gamma}{\alpha}}\,\|f\|^{1-\frac{\gamma}{\alpha}}.$$

Hence we have formula (13).

For (14), use (9). For all $g \in \mathcal{M}_b(E)$,

$$L^\delta(g;E) \leq L^\beta(g;E) \leq (L^\delta(g;E))^{\frac{\delta}{\beta}} (L^\infty(g;E))^{1-\frac{\delta}{\beta}}.$$

Then replace $g(t)$ by $L^\alpha(f;\mathrm{D}^{(t)}))$.

Formulas (15) and (16) are obtained from (13) and (14). We may notice that formulas (13)–(16) are all consequences of (9). We could get other formulas by instead using the Hölder inequality for integrals.

For the continuity of $\mathcal{L}^{(\alpha,\beta)}(f;\mathrm{D})$, $\alpha < \infty$, use (13) to get

$$\mathcal{L}^{(\gamma,\beta)} \leq \mathcal{L}^{(\alpha,\beta)} \leq (\mathcal{L}^{(\gamma,\beta)})^{\frac{\gamma}{\alpha}} \|f\|^{1-\frac{\gamma}{\alpha}}. \tag{17}$$

This implies that

$$\lim_{\gamma\to\alpha,\gamma<\alpha} \mathcal{L}^{(\gamma,\beta)} = \mathcal{L}^{(\alpha,\beta)}.$$

This helps us to prove continuity on the left of α and on the right of γ.

Finally, use the Lebesgue convergence theorem to prove continuity at $\alpha = \infty$.

The other elements of the proof are left to the reader. □

4. Norms for the difference function.

4.1. Difference function. Given a measurable subset $\mathrm{D} \subset R^N$ and a nonconstant function $f \in \mathcal{M}_b(\mathrm{D})$, the *difference function* is defined as

$$F(x,y) = f(x) - f(y). \tag{18}$$

Its definition domain is $\mathrm{D} \times \mathrm{D} \subset R^{2N}$, but we are only interested in values of F for x and y close to each other. Only these values can help measure the irregularity of f.

Here are some notations:

If $x = (x_1, \dots, x_N)$ is in R^N, then $\|x\| = \max_{1\leq i\leq N} |x_i|$ is the *norm of the maximum* of x.

τ_0 is a fixed real number > 0 and τ is a parameter in $]0, \tau_0]$.

$B_\tau(x)$ is the ball of center x and radius τ:

$$B_\tau(x) = \{y \,/\, \|x-y\| \leq \tau\}.$$

Its volume is $(2\tau)^N$.

D is a compact subset of R^N such that $\mathrm{Vol}_N(\mathrm{D}) > 0$.

$\mathrm{D}(\tau)$ is the τ-*Minkowski sausage* of D, the compact set

$$\mathrm{D}(\tau) = \cup_{x\in\mathrm{D}} B_\tau(x)$$

of all points in R^N at a distance $\leq \tau$ from D.

$\mathcal{D}_\tau$ is the compact set

$$\mathcal{D}_\tau = \{(x,y) \in R^{2N} \,/\, x \in \mathrm{D},\, \|x-y\| \leq \tau\}. \tag{19}$$

It is included in $\mathrm{D} \times \mathrm{D}(\tau)$. For all $x \in \mathrm{D}$, its x-cross-section is $\mathrm{D}_\tau^{(x)}$ (see equation (3)), identified here with $B_\tau(x)$. We may write

$$\mathcal{D}_\tau = \cup_{x\in\mathrm{D}} \{x\} \times B_\tau(x).$$

This set verifies the two conditions stated in section 3.1. It is therefore possible to calculate the operators $\mathcal{L}^{(\alpha,\beta)}$ of a function defined on $\mathcal{D}_\tau$.

$\mathcal{C}(\mathrm{D})$ is the set of all continuous functions defined on D. Then $\mathcal{C}(\mathrm{D}) \subset \mathcal{M}_b(\mathrm{D})$.

Henceforth, let us assume that the function f is in $\mathcal{C}(\mathrm{D}(\tau_0))$. Therefore, $F \in \mathcal{C}(\mathcal{D}_\tau)$ for all $\tau \leq \tau_0$. The continuity assumption helps us to simplify the vocabulary. For example, the seminorm $\operatorname{ess\,sup}(f)$ is the same as the *norm* $\sup(f)$. The seminorms L^α, $\alpha \geq 1$, and $\mathcal{L}^{(\alpha,\beta)}$, $(\alpha,\beta) \in [1,+\infty] \times [1,+\infty]$, become norms as well.

One method for measuring the *local* irregularity of f consists of evaluating the (α) norm of the difference function $F(x,y)$ over the cross-section $\mathcal{D}_\tau^{(x)}$. The result is a function of x since the local irregularity may vary on D. We get a *global* measure of the irregularity by calculating the (β) norm of this function. The final result is denoted by $\mathrm{S}_\tau^{(\alpha,\beta)}(f)$, or $\mathrm{S}_\tau^{(\alpha,\beta)}$ when there is no ambiguity. For all $(\alpha,\beta) \in]0,+\infty] \times]0,+\infty]$, we have

$$\mathrm{S}_\tau^{(\alpha,\beta)}(f) = \mathcal{L}^{(\alpha,\beta)}(F;\mathcal{D}_\tau) = L^\beta(L^\alpha(F;\mathcal{D}_\tau^{(x)});\mathrm{D}). \tag{20}$$

When $0 < \alpha < +\infty$ and $0 < \beta < +\infty$, this gives

$$\mathrm{S}_\tau^{(\alpha,\beta)}(f) = \left(\frac{1}{(2\tau)^{\frac{N\beta}{\alpha}} \operatorname{Vol}_N(\mathrm{D})} \int_{\mathrm{D}} \left(\int_{B_\tau(x)} |f(x)-f(y)|^\alpha \, dy \right)^{\frac{\beta}{\alpha}} dx \right)^{\frac{1}{\beta}}. \tag{21}$$

4.2. Particular cases.

1. If $\alpha = 1$ and $\beta = 1$,

$$\mathrm{S}_\tau^{(1,1)}(f) = \frac{1}{\operatorname{Vol}_N(\mathrm{D})\,(2\tau)^N} \int_{\mathrm{D}} \int_{B_\tau(x)} |f(x)-f(y)| \, dy\, dx. \tag{22}$$

This is the arithmetic mean of all values $|f(x)-f(y)|$ over $\mathcal{D}_\tau$.

2. If $\alpha = 1$ and $\beta = \infty$,

$$\mathrm{S}_\tau^{(1,\infty)}(f) = (2\tau)^{-N} \sup_{x\in\mathrm{D}} \left(\int_{B_\tau(x)} |f(x)-f(y)| \, dy \right). \tag{23}$$

In this formula, the local arithmetic mean of values $|f(x)-f(y)|$ is evaluated first; then the supremum is taken over x.

3. If $\alpha = \infty$ and $\beta = 1$,

$$\mathrm{S}_\tau^{(\infty,1)}(f) = \frac{1}{\operatorname{Vol}_N(\mathrm{D})} \int_{\mathrm{D}} \left(\sup_{y\in B_\tau(x)} |f(x)-f(y)| \right) dx. \tag{24}$$

For every x, the largest distance between $f(x)$ and $f(y)$ is calculated for y near x. This gives an evaluation of the *oscillation* of f at x. Then the arithmetic mean of oscillations is taken over D. The usual definition for the τ-oscillations of f at x is as follows:

$$\operatorname{osc}_\tau(f;x) = \sup\left\{ f(y) - f(y') \,/\, \|x-y\| \leq \tau,\ \|x-y'\| \leq \tau \right\}.$$

Using the triangle inequality, we get

$$\frac{1}{2}\operatorname{osc}_\tau(f;x) \leq \sup_{y\in B_\tau(x)} |f(x)-f(y)| \leq \operatorname{osc}_\tau(f;x). \tag{25}$$

The integral of τ-oscillations has been studied in [11, 3, 4] and in a number of subsequent publications under the name of the *τ-variation* of f:

$$V_\tau(f) = \int_{\mathrm{D}} \operatorname{osc}_\tau(f;x)\,dx. \tag{26}$$

From (24), (25), and (26), we deduce that $\mathrm{S}_\tau^{(\infty,1)}(f)$ is equivalent as τ tends to 0 to the τ-variation:

$$\frac{1}{2\mathrm{Vol}_N(\mathrm{D})}\,V_\tau(f) \leq \mathrm{S}_\tau^{(\infty,1)}(f) \leq \frac{1}{\mathrm{Vol}_N(\mathrm{D})}\,V_\tau(f). \tag{27}$$

We will see (equation (42)) how the order of growth to 0 of V_τ is directly related to the *fractal dimension* of the graph of f. The same relationship stands for $\mathrm{S}_\tau^{(\infty,1)}$.

4. If $\alpha = \beta = +\infty$,

$$\begin{aligned}\mathrm{S}_\tau^{(\infty,\infty)}(f) &= \sup_{x\in\mathrm{D}}\left(\sup_{y\in B_\tau(x)} |f(x)-f(y)|\right)\\ &= \sup_{(x,y)\in\mathcal{D}_\tau} |f(x)-f(y)|.\end{aligned} \tag{28}$$

This is the maximum τ-oscillation of f over D.

5. If $0 < \alpha = \beta < +\infty$,

$$\mathrm{S}_\tau^{(\alpha,\alpha)}(f) = \left(\frac{1}{\mathrm{Vol}_{2N}(\mathcal{D}_\tau)}\int_{\mathcal{D}_\tau} |f(x)-f(y)|^\alpha\,dy\,dx\right)^{\frac{1}{\alpha}}. \tag{29}$$

This may be written as

$$\mathrm{S}_\tau^{(\alpha,\alpha)}(f) = L^\alpha(F;\mathcal{D}_\tau). \tag{30}$$

Formula (29) is a continuous form of the discrete Kolmogorov means

$$\left[\frac{2}{n(n+1)}\sum_{1\leq j<i}^{n} |x_i - x_j|^\alpha\right]^{\frac{1}{\alpha}},$$

where $x_1,\dots,x_n$ are n real numbers. These mean values lead to the notion of *transfinite diameter* (in the sense of Pólya and Szegö). For a full account of these diameters, see [6].

When $\alpha = 2$, formula (29) is a *standard deviation* between $f(x)$ and $f(y)$ values over the domain $\mathcal{D}_\tau$.

4.3. Properties. Recall that f belongs to $\mathcal{C}(\mathrm{D}(\tau_0))$, $\alpha \in \,]0,+\infty]$, and $\beta \in \,]0,+\infty]$. Properties 1–5 of $\mathrm{S}_\tau^{(\alpha,\beta)}$ come directly from those of $\mathcal{L}^{(\alpha,\beta)}$ (section 3.2). We will give a proof only for property 6. In the particular case of the variation V_τ, properties 1–3 (which characterize a norm) can be found in [12].

THEOREM 4.1. *The operators* $\mathrm{S}_\tau^{(\alpha,\beta)}$ *have the following properties:*

1. $\mathrm{S}_\tau^{(\alpha,\beta)}(f) = 0 \iff f$ *is constant over* D.
2. *For all a,* $\mathrm{S}_\tau^{(\alpha,\beta)}(a\,f) = |a|\,\mathrm{S}_\tau^{(\alpha,\beta)}(f)$.
3. *If* $f_1,\ f_2 \in \mathcal{C}(\mathrm{D}(\tau_0))$, $\alpha \in [1,+\infty]$, *and* $\beta \in [1,+\infty]$, *then*

$$\mathrm{S}_\tau^{(\alpha,\beta)}(f_1+f_2) \leq \mathrm{S}_\tau^{(\alpha,\beta)}(f_1) + \mathrm{S}_\tau^{(\alpha,\beta)}(f_2). \tag{31}$$

4. *Let us fix* $f \in \mathcal{C}(\mathrm{D}(\tau_0))$. $\mathrm{S}_\tau^{(\alpha,\beta)}(f)$ *is an increasing and continuous function with respect to the variables* α *and* β *over* $]0,+\infty]$.

5. *Inequalities* (13)–(16) *are still true if we replace* $\mathcal{L}^{(\alpha,\beta)}$ *by* $\mathrm{S}_\tau^{(\alpha,\beta)}(f)$ *and* $\|f\|$ *by* $\mathrm{S}_\tau^{(\infty,\infty)}$. *We do not present these new formulas.*

6. *For all* $(\alpha,\beta) \in]0,+\infty] \times]0,+\infty]$,

$$\lim_{\tau\to 0} \mathrm{S}_\tau^{(\alpha,\beta)}(f) = 0. \tag{32}$$

Proof. Since f is uniformly continuous over the compact set $\mathrm{D}(\tau_0)$, the function $\sup_{\mathcal{D}_\tau} |f(x) - f(y)|$ tends to 0 with τ. Hence (32) is true for $\alpha = \beta = +\infty$. When α and β are real numbers, use the inequality $\mathrm{S}_\tau^{(\alpha,\beta)}(f) \leq \mathrm{S}_\tau^{(\infty,\infty)}(f)$. □

4.4. Behavior in the neighborhood of 0. When τ tends to 0, the order of growth of $\mathrm{S}_\tau^{(\alpha,\beta)}(f)$ depends on f, α and β. If the domain D is convex, and $\alpha \geq 1$, $\beta \geq 1$, then we may show that this function does not tend to 0 faster than τ.

THEOREM 4.2. *Let* D *be a compact, convex subset of* R^N, $\tau_0 > 0$ *be a real number, and* f *be defined, continuous on* $\mathrm{D}(\tau_0)$, *and nonconstant on* D. *We can find a constant* $c > 0$ (*depending only on* D *and* f) *such that for all* $(\alpha,\beta) \in [1,+\infty] \times [1,+\infty]$,

$$\liminf_{\tau\to 0} \frac{1}{\tau} \mathrm{S}_\tau^{(\alpha,\beta)}(f) \geq c. \tag{33}$$

Since $\mathrm{S}_\tau^{(\alpha,\beta)}(f)$ is increasing with respect to α and β (property 4 of Theorem 4.1), it suffices to verify (33) when $\alpha = \beta = 1$.

Since f is uniformly continuous over the compact set $\mathrm{D}(\tau_0)$, for all $\epsilon > 0$, there exists $\tau_1(\epsilon) > 0$, smaller than τ_0, such that

$$\tau \leq \tau_1(\epsilon) \Longrightarrow \forall x \in \mathrm{D},\, \forall y \in B_\tau(x) \,:\, |f(x) - f(y)| \leq \epsilon. \tag{34}$$

To prove the theorem, we will find two real numbers $c_1 > 0$ and c_2 such that

$$\tau \leq \tau_1(\epsilon) \Longrightarrow \int_{\mathcal{D}_\tau} |f(x) - f(y)|\, dx\, dy \geq (c_1 - \epsilon\, c_2)\, \tau^{N+1}. \tag{35}$$

Using (22), the constant c of formula (33) is then equal to

$$c = \frac{c_1}{2^N \operatorname{Vol}_N(\mathrm{D})}.$$

The cases where $N = 1$ and $N \geq 2$ are studied separately.

Proof for $N = 1$. D is a closed interval $[a,b]$ on the line and f is defined and continuous on $[a - \tau_0, b + \tau_0]$. Let

$$c_1 = \sup_{x\in[a,b]} f(x) - \inf_{x\in[a,b]} f(x).$$

This number is strictly positive. There exist two points $y_1 < y_2$ of $[a,b]$ such that

$$|f(y_1) - f(y_2)| = c_1.$$

We can write

$$\int_{\mathcal{D}_\tau} |f(x) - f(y)|\, dx\, dy = \int_{-\tau}^{\tau} \left(\int_a^b |f(x) - f(x+u)|\, dx \right) du,$$

where

$$\int_a^b |f(x)-f(x+u)|\,dx \geq \left|\int_{y_1}^{y_2} (f(x)-f(x+u))\,dx\right|$$
$$= \left|\int_{y_1}^{y_1+u} f(x)\,dx - \int_{y_2}^{y_2+u} f(x)\,dx\right|.$$

Since the inequality $|\int_{y_1}^{y_1+u} f(x)\,dx - u\,f(y_1)| \leq u\,\epsilon$ is also valid near y_2, we get

$$\int_a^b |f(x)-f(x+u)|\,dx \geq u(c_1 - 2\,\epsilon). \tag{36}$$

Finally, by integrating with respect to u on $[-\tau,\tau]$,

$$\int_{\mathcal{D}_\tau} |f(x)-f(y)|\,dx\,dy \geq (c_1 - 2\,\epsilon)\tau^2.$$

This is formula (35), with $N=1$, $c_1 = \sup_{x\in[a,b]} f(x) - \inf_{x\in[a,b]} f(x)$, and $c_2 = 2$. The constant c of Theorem 4.2 is

$$c = \frac{1}{2(b-a)}\left(\sup_{x\in[a,b]} f(x) - \inf_{x\in[a,b]} f(x)\right). \qquad \square$$

Proof for $N \geq 2$. Let us use the Euclidean norm, defined as

$$\|(x_1,\ldots,x_N\|_2 = \sqrt{x_1^2+\cdots+x_N^2}.$$

The Euclidean ball of center x and radius τ is denoted by $B_\tau^{(2)}(x)$. When $x \in \mathrm{D}$, this ball is included in $\mathrm{D}(\tau)$. To obtain (35), it suffices to find c_1 and c_2 such that

$$\tau \leq \tau_1(\epsilon) \Longrightarrow \int_{\mathrm{D}} \int_{B_\tau^{(2)}(0)} |f(x)-f(x+u)|\,du\,dx \geq (c_1 - \epsilon\,c_2)\,\tau^{N+1} \tag{37}$$

with $\tau_1(\epsilon)$ as in (34).

For any u in R^N, let us use the spherical coordinates $u=(\rho,\theta)$, where $\rho = \|u\|_2 \geq 0$ and $\theta = (\theta_1,\ldots,\theta_{N-1})$ belongs to a Cartesian product of intervals denoted by Θ. The Jacobian of the change of coordinates from Cartesian to spherical is $J(\theta) = \rho^{N-1}\,a(\theta)$ with $a(\theta) > 0$ almost everywhere on Θ. The integral $\int_\Theta a(\theta)\,d\theta$ is equal to $2^{N-1}\pi$. It is the $(N-1)$-dimensional volume of the boundary of the unit ball $B_1^{(2)}(0)$. Define

$$I(u) = \int_{\mathrm{D}} |f(x)-f(x+u)|\,dx.$$

The proof is in two parts:

(a) We will first show that there exist two positive functions $c_1(\theta)$ and $c_2(\theta)$ defined on Θ such that

$$\int_\Theta c_1(\theta)\,a(\theta)\,d\theta > 0, \qquad \int_\Theta c_2(\theta)\,a(\theta)\,d\theta < +\infty, \tag{38}$$

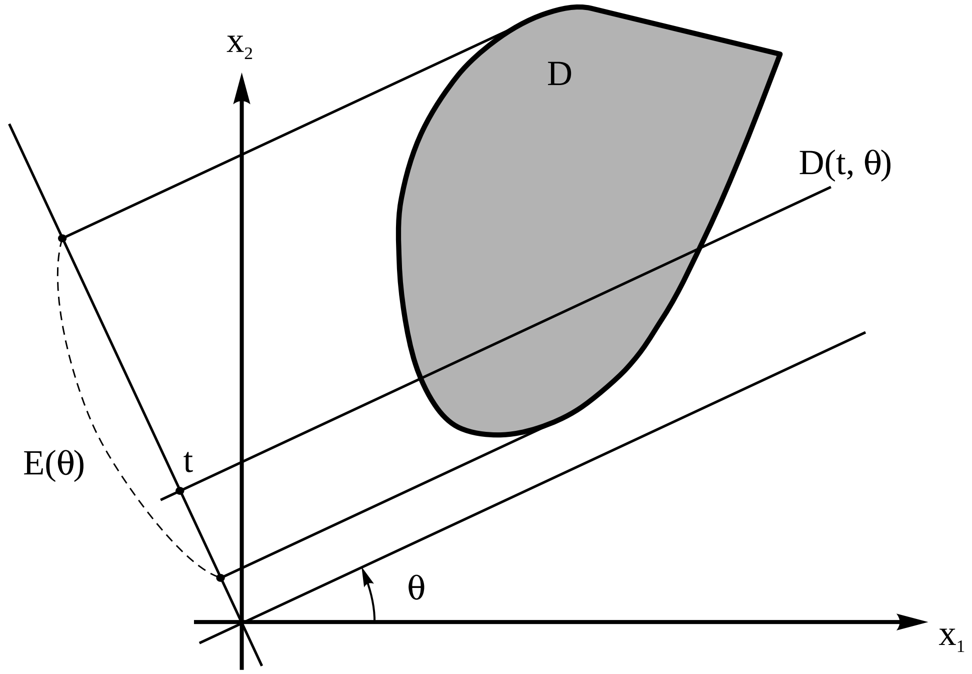

FIG. 1. *The projection $E(\theta)$ and the line $D(t,\theta)$ in the case where $N=2$.*

and for all $u = (\rho, \theta)$,

$$I(u) \geq \rho(c_1(\theta) - \epsilon\, c_2(\theta)). \tag{39}$$

Let us fix u, such that $\rho \neq 0$. Let us denote the following:

$P(\theta)$ is the hyperplane passing through 0 perpendicular to u.

$E(\theta)$ is the orthogonal projection of D over $P(\theta)$.

For all $t \in E(\theta)$, $D(t,\theta)$ is the line passing through t, parallel to u. Since D is convex, the intersection of the line with D is a segment. (See Figure 1.)

$c(t,\theta) = \sup_{x\in \mathrm{D}\cap D(t,\theta)} f(x) - \inf_{x\in \mathrm{D}\cap D(t,\theta)} f(x)$ is the total oscillation of f on $\mathrm{D}\cap D(t,\theta)$. It is a continuous function of (t,θ).

Using a linear, orthogonal change of variables, we can use the case where $N=1$ and (36) to get

$$\int_{D(t,\theta)} |f(x) - f(x+u)|\, dx \geq \rho(c(t,\theta) - 2\epsilon).$$

Integrating with respect to t over $E(\theta)$,

$$I(u) \geq \rho\left(\int_{E(\theta)} c(t,\theta)\, dt - 2\,\epsilon\, \mathrm{Vol}_{N-1}(E(\theta))\right).$$

This proves (39) with

$$c_1(\theta) = \int_{E(\theta)} c(t,\theta)\, dt \tag{40}$$

and

$$c_2(\theta) = 2\,\mathrm{Vol}_{N-1}(E(\theta)).$$

Let us now verify the inequalities in (38). Since f is nonconstant over D, there exists a pair (t_0, θ_0) such that $c(t_0, \theta_0) > 0$. By continuity, $c(t, \theta)$ is strictly positive in a neighborhood of (t_0, θ_0). Also, $a(\theta)$ is positive, continuous, and almost everywhere nonzero. This implies

$$\int_\Theta \int_{E(\theta)} c(t,\theta)\, a(\theta)\, dt\, d\theta > 0.$$

Hence the first inequality stands. The second follows from the boundedness of D.

(b) Now we use (39) to prove (37)

$$\begin{aligned}\int_{\mathrm{D}} \int_{B_\tau^{(2)}(0)} &|f(x) - f(x+u)|\, du\, dx \\ &\geq \int_{B_\tau^{(2)}(0)} \rho(c_1(\theta) - \epsilon\, c_2(\theta))\, J(\theta)\, d\theta\, d\rho \\ &= \int_0^\tau \rho^N\, d\rho \int_\Theta (c_1(\theta) - \epsilon\, c_2(\theta))\, a(\theta)\, d\theta \\ &= \frac{\tau^{N+1}}{N+1} \left(\int_\Theta c_1(\theta)\, a(\theta)\, d\theta - \epsilon \int_\Theta c_2(\theta)\, a(\theta)\, d\theta \right).\end{aligned}$$

To obtain (37), it suffices to choose

$$c_1 = \frac{1}{N+1} \int_\Theta c_1(\theta)\, a(\theta)\, d\theta, \qquad c_2 = \frac{1}{N+1} \int_\Theta c_2(\theta)\, a(\theta)\, d\theta.$$

From (38), we know that $c_1 > 0$ and $c_2 < +\infty$. The constant c of Theorem 4.2 is

$$c = \frac{1}{(N+1)2^N \mathrm{Vol}_N(\mathrm{D})} \int_\Theta \int_{E(\theta)} c(t,\theta)\, a(\theta)\, dt\, d\theta. \qquad \square \tag{41}$$

5. Critical exponents.

5.1. Orders of growth to 0. We keep the notations of section 4. Let us consider a nonconstant function f in $\mathcal{C}(\mathrm{D}(\tau_0))$. Its graph G_f over D is

$$G_f = \{(x, f(x)) \,/\, x \in \mathrm{D}\} \subset R^{N+1}.$$

When the variation $V_\tau(f)$ tends slowly to 0, G_f shows some irregularities at all scales. Such a graph may be called a *fractal* in a weak sense [12]. Let us denote by $\mathrm{Dim}(G_f)$ the fractal dimension. It is a global *irregularity index* which is in direct relationship with the order of growth of $V_\tau(f)$ near 0 [11]. We get

$$\mathrm{Dim}(G_f) = \limsup_{\tau \to 0} \left(N + 1 - \frac{\log V_\tau(f)}{\log \tau} \right). \tag{42}$$

Using (27), this formula is still true after replacing $V_\tau(f)$ by $\mathrm{S}_\tau^{(\infty,1)}(f)$. Analoguously, any of the functions $\mathrm{S}_\tau^{(\alpha,\beta)}(f)$ can measure the irregularity of f in a certain sense and gives raise to an irregularity index as follows:

$$\Delta^{(\alpha,\beta)}(f) = \limsup_{\tau \to 0} \left(N + 1 - \frac{\log \mathrm{S}_\tau^{(\alpha,\beta)}(f)}{\log \tau} \right). \tag{43}$$

In this formula, $\mathrm{S}_\tau^{(\alpha,\beta)}(f)$ tends to 0 with τ (see (32)).

5.2. Properties. The properties of operators $\mathrm{S}_\tau^{(\alpha,\beta)}$ have the following consequences:

THEOREM 5.1. *Let* D *be a compact, convex subset of* R^N. *The indices* $\Delta^{(\alpha,\beta)}$ *have the following properties:*

1. *For all* $(\alpha,\beta) \in [1,+\infty] \times [1,+\infty]$,

$$N \le \Delta^{(\alpha,\beta)}(f) \le N+1. \tag{44}$$

2. $\Delta^{(\alpha,\beta)}(f)$ *is increasing with respect to each of the variables* α *and* β.

3. *Here are some relationships between* $\Delta^{(\alpha,\beta)}(f)$ *and* $\Delta^{(\gamma,\delta)}(f)$ *for all strictly positive real numbers* α, β, γ, *and* δ:

If $\gamma \le \alpha$,

$$\Delta^{(\gamma,\beta)}(f) \le \Delta^{(\alpha,\beta)}(f) \le \frac{\gamma}{\alpha}\Delta^{(\gamma,\frac{\beta\gamma}{\alpha})}(f) + \left(1-\frac{\gamma}{\alpha}\right)\Delta^{(\infty,\infty)}(f). \tag{45}$$

If $\delta \le \beta$,

$$\Delta^{(\alpha,\delta)}(f) \le \Delta^{(\alpha,\beta)}(f) \le \frac{\delta}{\beta}\Delta^{(\alpha,\delta)}(f) + \left(1-\frac{\delta}{\beta}\right)\Delta^{(\infty,\infty)}(f). \tag{46}$$

If $\gamma \le \alpha$ *and* $\delta \le \beta$,

$$\Delta^{(\gamma,\delta)}(f) \le \Delta^{(\alpha,\beta)}(f) \le \frac{\gamma\delta}{\alpha\beta}\Delta^{(\gamma,\frac{\gamma\delta}{\alpha})}(f) + \left(1-\frac{\gamma\delta}{\alpha\beta}\right)\Delta^{(\infty,\infty)}(f). \tag{47}$$

Finally, if $\gamma \le \alpha$ *and* $\beta \le \delta$,

$$\begin{aligned}\Delta^{(\gamma,\delta)}(f) &\le \frac{\beta}{\delta}\Delta^{(\alpha,\beta)}(f) + \left(1-\frac{\beta}{\delta}\right)\Delta^{(\infty,\infty)}(f)\\ &\le \frac{\beta\gamma}{\alpha\delta}\Delta^{(\gamma,\frac{\gamma\delta}{\alpha})}(f) + \left(1-\frac{\beta\gamma}{\alpha\delta}\right)\Delta^{(\infty,\infty)}(f).\end{aligned} \tag{48}$$

4. *If* α, β, γ, *and* δ *belong to* $[1,+\infty)$,

$$|\Delta^{(\alpha,\beta)}(f) - \Delta^{(\gamma,\delta)}(f)| \le 1 - \frac{\min\{\alpha,\gamma\}\min\{\beta,\delta\}}{\max\{\alpha,\gamma\}\max\{\beta,\delta\}}. \tag{49}$$

In particular, this shows that $\Delta^{(\alpha,\beta)}(f)$ *is continuous with respect to the two variables* α *and* β *over* $[1,+\infty) \times [1,+\infty)$.

Proof.

(a) Let us verify (44). The right-hand side inequality comes from (32). Formula (33) implies

$$\liminf\left(N+1-\frac{\log \mathrm{S}_\tau^{(\alpha,\beta)}(f)}{\log\tau}\right) \ge \lim\left(N-\frac{\log c}{\log\tau}\right) = N.$$

Therefore, $\Delta^{(\alpha,\beta)}(f) \ge N$.

(b) Since $\mathrm{S}_\tau^{(\alpha,\beta)}$ is increasing, so is $\Delta^{(\alpha,\beta)}$.

(c) Formulas (45)–(48) can be obtained from (13)–(16). Let us assume that $\tau < 1$. Formula (13) gives

$$-\frac{\log \mathrm{S}_\tau^{(\gamma,\beta)}}{\log\tau} \le -\frac{\log \mathrm{S}_\tau^{(\alpha,\beta)}}{\log\tau} \le \frac{\gamma}{\alpha}\left(-\frac{\log \mathrm{S}_\tau^{(\gamma,\frac{\beta\gamma}{\alpha})}}{\log\tau}\right) + \left(1-\frac{\gamma}{\alpha}\right)\left(-\frac{\log \mathrm{S}_\tau^{(\infty,\infty)}}{\log\tau}\right).$$

Now use the inequality

$$\limsup_{\tau\to 0}(g_1(\tau)+g_2(\tau)) \le \limsup_{\tau\to 0} g_1(\tau) + \limsup_{\tau\to 0} g_2(\tau),$$

true for any g_1 and g_2, to get (45).

(d) Formula (49) is implied by the increasing property of $\Delta^{(\alpha,\beta)}$ and by formulas (44), (47), and (48).

If $\gamma \le \alpha$ and $\delta \le \beta$, (47) implies

$$\begin{aligned} 0 \le \Delta^{(\alpha,\beta)} - \Delta^{(\gamma,\delta)} &\le \left(1-\frac{\gamma\delta}{\alpha\beta}\right)(\Delta^{(\infty,\infty)} - \Delta^{(\gamma,\delta)}) \\ &\le 1-\frac{\gamma\delta}{\alpha\beta}. \end{aligned}$$

If $\gamma \le \alpha$ and $\beta \le \delta$, (48) implies

$$\begin{aligned} 0 &\le \Delta^{(\alpha,\beta)} - \Delta^{(\gamma,\delta)} + \left(1-\frac{\beta}{\gamma}\right)(\Delta^{(\infty,\infty)} - \Delta^{(\alpha,\beta)}) \\ &\le \left(1-\frac{\beta\gamma}{\alpha\delta}\right)(\Delta^{(\infty,\infty)} - \Delta^{(\gamma,\delta)}). \end{aligned}$$

Since $\beta\gamma/\alpha\delta \le \beta/\delta$, we get

$$|\Delta^{(\alpha,\beta)} - \Delta^{(\gamma,\delta)}| \le 1-\frac{\beta\gamma}{\alpha\delta}.$$

Similar results are obtained in the other cases. □

6. The study of a nowhere-differentiable function.

6.1. A function defined as a series. Let f be defined on R as follows:

$$f(x) = \sum_{n=0}^{+\infty} 2^{-nH} g(2^n x + \phi_n), \tag{50}$$

where $0 < H < 1$, ϕ_n are real numbers, and g is continuous and periodic with periodicity 1. Then f has also period 1. In this series, amplitudes tend to 0 more slowly than the periods and hence the local oscillations of f. The convergence is absolute so that f is continuous. The phases ϕ_n are here only to help give a more "natural" look to the graph of f for a model of a rough profile, for example [2].

It is well known that such functions are nowhere differentiable and that their graph is a fractal curve. Following the choice of g, we can obtain by this method a Weierstrass function or a Knopp–Takagi function (see [7] for some historical references; see also [9]). When g shows some kind of regularity (when it is continuously differentiable, for example), the fractal dimension of G_f is $2-H$. Finding a general condition on g in order to get this particular result is a difficult task. See, for example, [8]. In this section, we will assume that g verifies one more condition to simplify the calculations of $\mathrm{S}_\tau^{(\alpha,\beta)}(f)$. Using this assumption, we will be able to establish relationships between $\Delta^{(\alpha,\beta)}(f)$ and $\Delta^{(\alpha,\beta)}(g)$, and we will show how to get a fractal dimension different from $2-H$.

6.1.1. Definition domain. Functions g and f are defined on R, but the domain D must be a compact set. We take $\mathrm{D} = [0,1]$ and

$$\mathcal{D}_\tau = \{(x,y) \in R^2 \,/\, x \in [0,1],\ \|x-y\| \leq \tau\}.$$

6.1.2. Notations. Let $f_1(\tau)$ and $f_2(\tau)$ be two positive functions defined in a neighborhood of 0 that tends to 0 with τ. We write

$$\begin{aligned} f_1 \simeq f_2 &\quad \text{if } 0 < \liminf_{\tau\to 0} \frac{f_1(\tau)}{f_2(\tau)} \leq \limsup_{\tau\to 0} \frac{f_1(\tau)}{f_2(\tau)} < +\infty,\\ f_1 \preceq f_2 &\quad \text{if } \limsup_{\tau\to 0} \frac{f_1(\tau)}{f_2(\tau)} < +\infty,\\ f_1 \prec f_2 &\quad \text{if } \lim_{\tau\to 0} \frac{f_1(\tau)}{f_2(\tau)} = 0. \end{aligned}$$

The symbols $\succeq$ and $\succ$ denote the converse relations. We recall that f_1 is *Hölderian with exponent* H at x if $|f_1(x+\tau) - f_1(x)| \preceq \tau^H$. When f_1 is defined on D, it is *uniformly Hölderian with exponent* H on D if there exists a constant C such that for all $x \in \mathrm{D}$ and $y \in \mathrm{D}$, $|f_1(x) - f_1(y)| \leq C|x-y|^H$. An equivalent condition is $\mathrm{S}_\tau^{(\infty,\infty)}(f_1) \preceq \tau^H$.

6.2. Function $g(x)$. We assume that g verifies the following condition:

There exists a constant c such that for all x,

$$g(x) + g\left(x + \frac{1}{2}\right) = c. \tag{51}$$

This constant then is equal to $g(0) + g(1/2) = 2\int_0^1 g(x)\,dx$.

Function g is therefore completely determined on the interval $[0,1/2]$. It may be extended to $]1/2,1]$ using (51) and then to R by periodicity.

6.2.1. Examples.

1. If $g(x) = \cos(2\pi x)$, f is a *Weierstrass function* (see Figure 2). Function g is continuously differentiable, and for all α and β in $[1,+\infty]$, $\mathrm{S}_\tau^{(\alpha,\beta)}(g) \simeq \tau$ in the neighborhhood of 0.

2. If $g(x) = 2x$ on $[0,1/2]$, f is a *Knopp–Takagi function* [7, 5] (see Figure 3). Function g is not everywhere differentiable but rather uniformly Hölderian with exponent 1. For all α and β in $[1,+\infty]$, $\mathrm{S}_\tau^{(\alpha,\beta)}(g) \simeq \tau$.

3. If $g(x) = x^\gamma$ on $[0,1/2]$, $0 < \gamma < 1$ (see Figure 4), the norms $\mathrm{S}_\tau^{(\alpha,\beta)}(g)$ tend to 0 at a rate depending on β. Using the relation

$$(x+\tau)^\gamma - x^\gamma \simeq \tau x^{\gamma-1}$$

when $x \neq 0$, we can show that

$$\mathrm{S}_\tau^{(\alpha,\beta)}(g) \simeq \tau^{\min\{1,\gamma+1/\beta\}}.$$

This result does not depend on α.

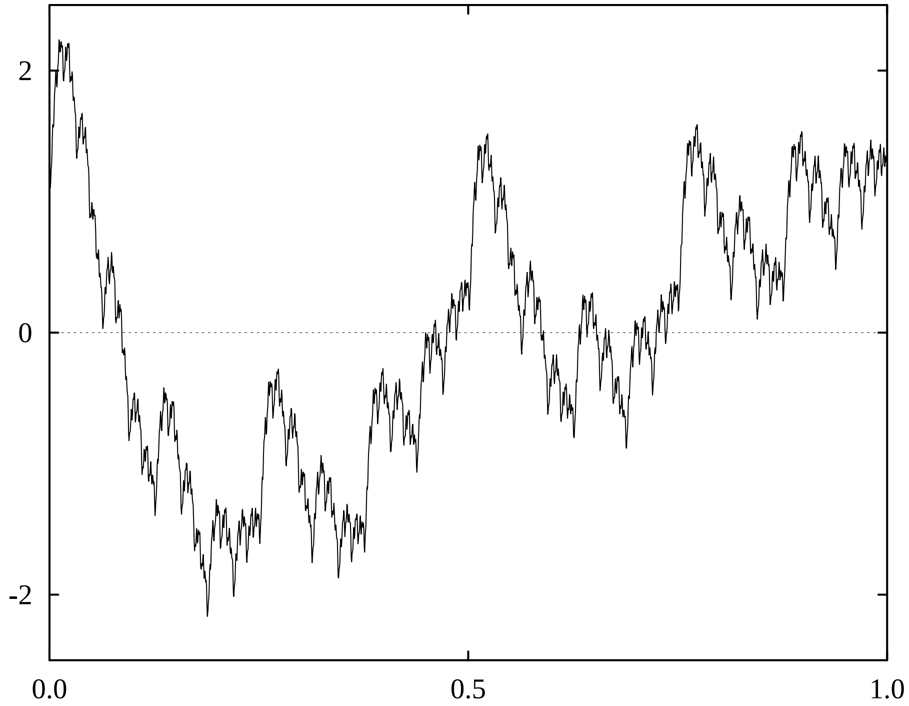

FIG. 2. *A Weierstrass function with* $g(x) = \cos(2\pi x)$*,* $H = 1/2$*, and a sequence* (ϕ_n) *of random numbers.*

6.2.2. Properties. The periodicity of g implies the following.

PROPOSITION 6.1. *For all* $k \geq 1$*,* $\alpha \in [1, +\infty]$*, and* $\beta \in [1, +\infty]$*,*

$$\mathrm{S}_\tau^{(\alpha,\beta)}(g(kx)) = \mathrm{S}_{k\tau}^{(\alpha,\beta)}(g(x)). \tag{52}$$

Proof. By continuity, it suffices to prove (52) for finite α and β. A change of variables gives

$$\mathrm{S}_\tau^{(\alpha,\beta)}(g(kx))^\beta = \frac{1}{(2k\tau)^{\frac{\beta}{\alpha}}} \frac{1}{k} \int_0^k \left(\int_{-k\tau}^{k\tau} |g(y) - g(y+v)|^\alpha \, dv \right)^{\frac{\beta}{\alpha}} dy.$$

By periodicity,

$$\mathrm{S}_\tau^{(\alpha,\beta)}(g(kx))^\beta = \frac{1}{(2k\tau)^{\frac{\beta}{\alpha}}} \int_0^1 \left(\int_{-k\tau}^{k\tau} |g(y) - g(y+v)|^\alpha \, dv \right)^{\frac{\beta}{\alpha}} dy,$$

which gives the result. □

The periodicity of g and assumption (51) imply the following.

PROPOSITION 6.2. *Assume that the constant* c *in* (51) *is* 0*. For any integer* n *and real numbers* ϕ_1 *and* ϕ_2*,*

$$\int_0^1 g(2nx + \phi_1) g(x + \phi_2) \, dx = 0. \tag{53}$$

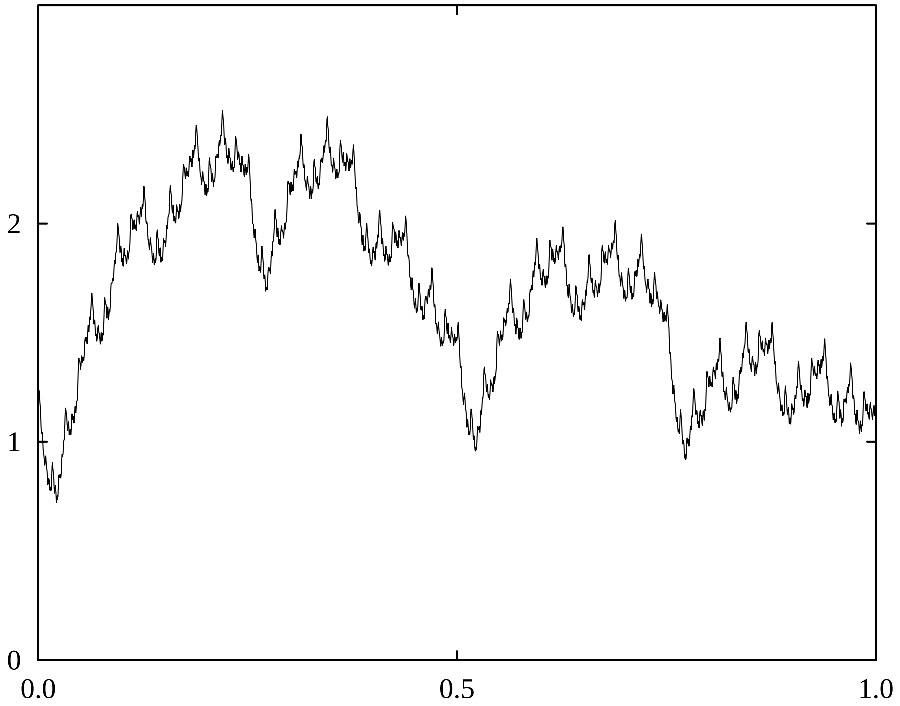

Fig. 3. *A Knopp–Takagi function with $g(x) = 2x$ on $[0, 1/2]$, $H = 1/2$, and a sequence (ϕ_n) of random numbers.*

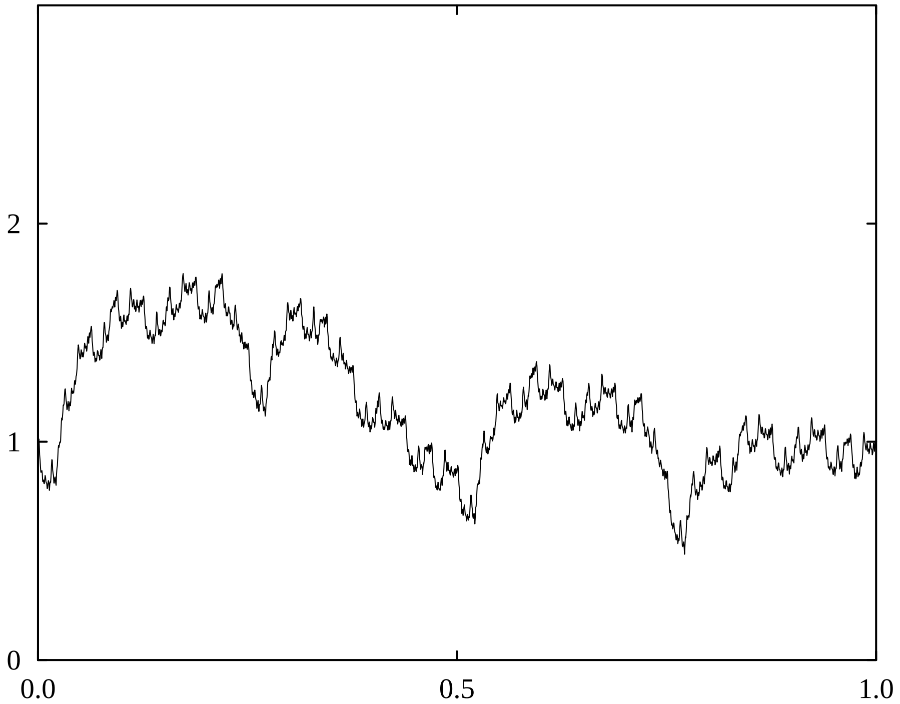

Fig. 4. *Function f obtained with $g(x) = \sqrt{x}$ on $[0, 1/2]$, $H = 1/2$, and a sequence (ϕ_n) of random numbers.*

Proof. The change of variables $x = y + 1/2$ gives

$$\int_{1/2}^{1} g(2nx+\phi_1)g(x+\phi_2)\,dx = \int_0^{1/2} g(2ny+\phi_1+n)g\left(y+\phi_2+\frac{1}{2}\right)\,dy.$$

Since $g(2ny+\phi_1+n) = g(2ny+\phi_1)$ (periodicity) and $g(y+\phi_2+1/2) = -g(y+\phi_2)$ (assumption (51)), we find

$$\int_{1/2}^{1} g(2nx+\phi_1)g(x+\phi_2)\,dx = -\int_0^{1/2} g(2nx+\phi_1)g(x+\phi_2)\,dx.$$

Hence we have the result. □

Corollary 6.3. *Let n and k be two integers, $0 < k < n$, and ϕ_1 and ϕ_2 be two real numbers. Then*

$$\int_{\mathcal{D}_\tau} (g(2^n x+\phi_1) - g(2^n y+\phi_1))(g(2^k x+\phi_2) - g(2^k y+\phi_2))\,dx\,dy = 0. \tag{54}$$

Proof. Without loss of generality, we can asume that the constant c in (51) is 0. Writing the integral as

$$\begin{aligned}\int_{-\tau}^{\tau}\Bigg[\int_0^1 &(g(2^n x+\phi_1)g(2^k x+\phi_2)\\ &- g(2^n x+\phi_1)g(2^k x+\phi_2+2^k u) - g(2^n x+\phi_1+2^n u)g(2^k x+\phi_2)\\ &+ g(2^n x+\phi_1+2^n u)g(2^k x+\phi_2+2^k u))\,dx\Bigg]du,\end{aligned}$$

we see that it suffices to verify the equality

$$\int_0^1 g(2^n x+\phi_1)g(2^k x+\phi_2)\,dx = 0.$$

This last integral can be written as

$$2^{-k}\int_0^{2^k} g(2^{n-k}y+\phi_1)g(y+\phi_2)\,dy$$

or (by periodicity)

$$\int_0^1 g(2^{n-k}y+\phi_1)g(y+\phi_2)\,dy.$$

This is equal to zero (Proposition 6.2). □

6.3. Evaluations of $\boldsymbol{\Delta}^{(\alpha,\beta)}(\boldsymbol{f})$. The previous results will be used for the following.

Theorem 6.4. *For every $\alpha \geq 1$, $\beta \geq 1$, and f as in* (50), *we have*

$$\mathrm{S}_\tau^{(\alpha,\beta)}(f) \succeq \tau^H. \tag{55}$$

Proof. It suffices to prove (55) for $\alpha = \beta = 1$. We take a function $h(x, y)$ defined on $R \times R$ such that $\sup |h| \leq 1$. Let us denote by I the integral $\int_{\mathcal{D}_\tau} |f(x) - f(y)|\, dx\, dy$. Then

$$\begin{aligned} I &\geq \int_{\mathcal{D}_\tau} |h(x, y)(f(x) - f(y))|\, dx\, dy \\ &\geq \left| \int_{\mathcal{D}_\tau} h(x, y)(f(x) - f(y))\, dx\, dy \right| \\ &= \left| \sum_0^{+\infty} 2^{-nH} \int_{\mathcal{D}_\tau} h(x, y)(g(2^n x + \phi_n) - g(2^n y + \phi_n))\, dx\, dy \right|. \end{aligned}$$

If $I_n = \int_{\mathcal{D}_\tau} h(x, y)(g(2^n x + \phi_n) - g(2^n y + \phi_n))\, dx\, dy$,

$$I \geq \sum_0^{+\infty} 2^{-nH} I_n.$$

Let k be the integer such that

$$2^{-k-1} < \tau \leq 2^{-k}$$

and

$$h(x, y) = \frac{1}{2 \sup |g|} (g(2^k x + \phi_k) - g(2^k y + \phi_k)).$$

The condition $\sup |h| \leq 1$ is fulfilled. From Corollary 6.3, $I_n = 0$ for all $n \neq k$. On the other hand,

$$\sqrt{\frac{1}{\tau} I_k} \simeq \mathrm{S}_\tau^{(2,2)}(g(2^k x + \phi_k)).$$

Periodicity implies $\mathrm{S}_\tau^{(2,2)}(g(2^k x + \phi_k)) = \mathrm{S}_\tau^{(2,2)}(g(2^k x))$. From (52), this is the value of $\mathrm{S}_{2^k \tau}^{(2,2)}(g)$. Since $2^k \tau \simeq 1$, $\mathrm{S}_{2^k \tau}^{(2,2)}(g) \simeq \mathrm{S}_1^{(2,2)}(g)$, a constant value. Therefore,

$$\sqrt{\frac{1}{\tau} I_k} \simeq 1.$$

We can deduce that $I_k \simeq \tau$. Since $2^{-kH} \simeq \tau^H$,

$$I \succeq \tau^{1+H}.$$

Finally,

$$\mathrm{S}_\tau^{(1,1)}(f) \succeq \frac{1}{\tau} I \succeq \tau^H. \qquad \square$$

COROLLARY 6.5. *Functions g and f being as before, we have for all $\alpha \geq 1$ and $\beta \geq 1$ that*

$$\Delta^{(\alpha,\beta)}(f) \geq 2 - H. \tag{56}$$

Now let us prove an inequality in the other sense.

Theorem 6.6. *If g is uniformly Hölderian with exponent* 1, *then f is uniformly Holderian with exponent H.*

Proof. Extending the Minkowski inequality to series, we write

$$\mathrm{S}_\tau^{(\infty,\infty)}(f) = \sup_{\mathcal{D}_\tau} |f(x) - f(y)| \leq \sum_0^\infty 2^{-nH}\, \mathrm{S}_\tau^{(\infty,\infty)}(g(2^n x + \phi_n)).$$

Let k be such that $2^{-k-1} < \tau \leq 2^{-k}$. Then

$$\begin{aligned} \mathrm{S}_\tau^{(\infty,\infty)}(g(2^n x + \phi_n)) &= \mathrm{S}_\tau^{(\infty,\infty)}(g(2^n x)) \quad \text{by periodicity} \\ &= \mathrm{S}_{2^n\tau}^{(\infty,\infty)}(g(x)) \quad \text{from (52)} \\ &\preceq \begin{cases} 2^n\tau & \text{if } n \leq k \text{ since } g \text{ is Hölderian,} \\ 1 & \text{if } n > k \text{ since } g \text{ is periodic.} \end{cases} \end{aligned}$$

Therefore,

$$\begin{aligned} \mathrm{S}_\tau^{(\infty,\infty)}(f) &\preceq \sum_0^k 2^{-nH} 2^n \tau + \sum_{k+1}^\infty 2^{-nH} \\ &\simeq \tau 2^{k(1-H)} + 2^{-kH} \\ &\simeq \tau^H. \qquad \square \end{aligned}$$

Corollary 6.7. *If g is uniformly Hölderian with exponent* 1, *then for all $\alpha \geq 1$ and $\beta \geq 1$,*

$$\Delta^{(\alpha,\beta)}(f) \leq 2 - H. \tag{57}$$

Notice that we have used the relation $\mathrm{S}_\tau^{(\infty,\infty)}(g) \preceq \tau$ in the proof of Theorem 6.6. Since $H < 1$, this theorem is a particular case of the following.

Theorem 6.8. *Let $\alpha \in [1,\infty]$, $\beta \in [1,\infty]$, and $\omega > 0$ be such that $\mathrm{S}_\tau^{(\alpha,\beta)}(g) \preceq \tau^\omega$. Then*

(i) *If $\omega \neq H$, $\mathrm{S}_\tau^{(\alpha,\beta)}(f) \preceq \tau^{\min\{H,\omega\}}$.*

(ii) *If $\omega = H$, $\mathrm{S}_\tau^{(\alpha,\beta)}(f) \preceq \tau^H |\log \tau|$.*

Proof. Use the inequality

$$\mathrm{S}_\tau^{(\alpha,\beta)}(f) \leq \sum_0^\infty 2^{-nH} \mathrm{S}_\tau^{(\alpha,\beta)}(g(2^n x + \phi_n)),$$

where $\mathrm{S}_\tau^{(\alpha,\beta)}(g(2^n x+\phi_n)) = \mathrm{S}_{2^n\tau}^{(\alpha,\beta)}(g) \preceq (2^n\tau)^\omega$. Let k be such that $2^{-k-1} < \tau \leq 2^{-k}$. We get

$$\sum_0^k 2^{-nH} \mathrm{S}_\tau^{(\alpha,\beta)}(g(2^n x + \phi_n)) \preceq \tau^\omega \sum_0^k 2^{n(\omega - H)}.$$

The right-hand side member has the same order of growth as

$$\begin{array}{ll} \tau^\omega 2^{k(\omega-H)} \simeq \tau^H & \text{if } \omega > H, \\ k\,\tau^\omega \simeq \tau^H |\log \tau| & \text{if } \omega = H, \\ \tau^\omega & \text{if } \omega < H. \end{array}$$

On the other hand, $\mathrm{S}^{(\alpha,\beta)}_{2^n\tau}(g) \preceq 1$ by periodicity, and

$$\sum_{k+1}^{\infty} 2^{-nH}\mathrm{S}^{(\alpha,\beta)}_{\tau}(g(2^n x+\phi_n)) \preceq \sum_{k+1}^{\infty} 2^{-nH} \simeq \tau^H.$$

Gathering these results, the proof is completed. □

Corollary 6.9. *For all $\alpha \geq 1$ and $\beta \geq 1$,*

$$\Delta^{(\alpha,\beta)}(f) \leq \max\{2-H, \Delta^{(\alpha,\beta)}(g)\}. \tag{58}$$

Proof. Let ω be such that $\Delta^{(\alpha,\beta)}(g) \leq 2-\omega$ and $\omega \neq H$. There exists $\tau_1 < 1$ such that

$$\tau \leq \tau_1 \Longrightarrow 2 - \frac{\log \mathrm{S}^{(\alpha,\beta)}_{\tau}(g)}{\log \tau} \leq 2-\omega,$$

i.e., $\mathrm{S}^{(\alpha,\beta)}_{\tau}(g) \leq \tau^{\omega}$. Theorem 6.8 implies $\mathrm{S}^{(\alpha,\beta)}_{\tau}(f) \succeq \tau^{\min\{H,\omega\}}$. Hence

$$\Delta^{(\alpha,\beta)}(f) \leq 2-\min\{H,\omega\}.$$

With ω tending to $2-\Delta^{(\alpha,\beta)}(g)$, we get (58). □

Conjecture. *Let us denote by $\delta^{(\alpha,\beta)}(f)$ the following index:*

$$\delta^{(\alpha,\beta)}(f) = \liminf_{\tau\to 0}\left(2 - \frac{\log \mathrm{S}^{(\alpha,\beta)}_{\tau}}{\log \tau}\right).$$

Then for all $\alpha \geq 1$ and $\beta \geq 1$,

$$\delta^{(\alpha,\beta)}(f) \geq \max\{2-H, \delta^{(\alpha,\beta)}(g)\}. \tag{59}$$

This formula would be the symmetric to (58).

A particular case. This conjecture is true if $\alpha=\beta=2$. To show this, we write

$$\begin{aligned}\mathrm{S}^{(2,2)}_{\tau}(f)^2 &= \sum_{0}^{\infty} 2^{-2nH}\mathrm{S}^{(2,2)}_{\tau}(g(2^n x+\phi_n))^2\\ &= \sum_{0}^{\infty} 2^{-2nH}\mathrm{S}^{(2,2)}_{2^n\tau}(g)^2.\end{aligned}$$

Let ω be such that $\delta^{(2,2)}(g) \geq 2-\omega$. Then $\mathrm{S}^{(2,2)}_{\tau}(g) \succeq \tau^{\omega}$. Let k be the integer such that $2^{-k-1} < \tau \leq 2^{-k}$. Then

$$\mathrm{S}^{(2,2)}_{\tau}(f)^2 \succeq \sum_{0}^{k} 2^{-2nH}(2^n\tau)^{2\omega}.$$

The second member of this relation has the same order of growth as

$$\begin{array}{ll}\tau^{2\omega}2^{2k(\omega-H)} \simeq \tau^{2H} & \text{if } \omega > H,\\ k\,\tau^{2\omega} \simeq \tau^{2H}|\log\tau| & \text{if } \omega = H,\\ \tau^{2\omega} & \text{if } \omega < H.\end{array}$$

Therefore,

$$\mathrm{S}_\tau^{(2,2)}(f) \succeq \begin{cases} \tau^{\min(H,\omega)} & \text{if } \omega \neq H, \\ \tau^H \sqrt{|\log \tau|} & \text{if } \omega = H. \end{cases}$$

This proves that $\delta^{(2,2)}(f) \geq 2 - \min\{H, \omega\}$. Letting ω tend to $2 - \delta^{(2,2)}(g)$, we get (59).

Remarks.

1. Corollary 6.5 confirms the conjecture.
2. Corollaries 6.5 and 6.7 prove that $\Delta^{(\alpha,\beta)}(f) = 2 - H$ for all $\alpha \geq 1$ and $\beta \geq 1$ when g is uniformly Hölderian with exponent 1.

The irregularity indices may take values different from $2 - H$. First, let us prove the following.

Proposition 6.10. *We have*

$$\Delta^{(1,1)}(f) \geq 2\Delta^{(2,2)}(g) - \Delta^{(\infty,\infty)}(g). \tag{60}$$

Proof. Using the same notations as in the proof of Theorem 6.4, recall that

$$I \geq \sum_0^{+\infty} 2^{-nH} I_n.$$

Let us choose

$$h(x, y) = \frac{g(x + \phi_0) - g(y + \phi_0)}{\mathrm{S}_\tau^{(\infty,\infty)}(g)}.$$

We get $I_n = 0$ for all $n \geq 1$, and

$$I_0 \simeq \tau \frac{\mathrm{S}_\tau^{(2,2)}(g)^2}{\mathrm{S}_\tau^{(\infty,\infty)}(g)}.$$

There exists a constant $c_1 > 0$ such that

$$\mathrm{S}_\tau^{(1,1)}(f) \geq c_1 \frac{\mathrm{S}_\tau^{(2,2)}(g)^2}{\mathrm{S}_\tau^{(\infty,\infty)}(g)},$$

which can be written as

$$2 - \frac{\log \mathrm{S}_\tau^{(1,1)}(f)}{\log \tau} \geq 2\left(2 - \frac{\log \mathrm{S}_\tau^{(2,2)}(g)}{\log \tau}\right) - \left(2 - \frac{\mathrm{S}_\tau^{(\infty,\infty)}(g)}{\log \tau}\right) - \frac{\log c_1}{\log \tau}.$$

Formula (60) is obtained by taking the lim sup on both sides of this inequality. □

Corollary 6.11. *If* $\Delta^{(2,2)}(g) = \Delta^{(\infty,\infty)}(g)$*, then for all* $\alpha \geq 1$ *and* $\beta \geq 1$*,*

$$\Delta^{(\alpha,\beta)}(f) = \max\{2 - H, \Delta^{(\infty,\infty)}(g)\}. \tag{61}$$

Proof. With this assumption, the right-hand side member of (60) is $\Delta^{(\infty,\infty)}(g)$. Then $\Delta^{(\alpha,\beta)}(f) \geq \Delta^{(1,1)}(f) \geq \Delta^{(\infty,\infty)}(g)$. The proof is completed with the help of (56) and (58). □

6.4. Some applications.

1. If $g(x) = \cos 2\pi x$, $f(x)$ is a Weierstrass function. Since $g(x)$ is differentiable, Corollaries 6.5 and 6.7 can be used, and

$$\Delta^{(\alpha,\beta)}(f) = 2 - H$$

for all $\alpha \geq 1$ and $\beta \geq 1$. The same result holds for the Knopp–Takagi function, where $g(x) = 2x$ on $[0, 1/2]$. This shows in particular that the fractal dimension of the graph of the Takagi function is $2 - H$, a result that is very easy to prove when the phases ϕ_n are all zero but more difficult otherwise. Another proof in a different context can be found in [1].

2. Let g be the Weierstrass function

$$g(x) = \sum_{0}^{\infty} 2^{-n\omega} \cos(2\pi 2^n x + \phi_n)$$

on $[0, 1/2]$. The parameter ω is in $]0, 1[$. Then $\mathrm{S}_\tau^{(\alpha,\beta)}(g) \simeq \tau^\omega$. Corollary 6.11 lets us conclude that

$$\Delta^{(\alpha,\beta)}(f) = 2 - \min(H, \omega)$$

for any $\alpha \geq 1$ and $\beta \geq 1$.

3. Let $g(x) = \sqrt{x}$ on $[0, 1/2]$. Then

$$\mathrm{S}_\tau^{(\alpha,\beta)}(g) \simeq \tau^{\min(1, \frac{1}{2} + \frac{1}{\beta})}$$

(section 6.2.1). It follows that

$$\Delta^{(\alpha,\beta)}(g) = \max\left\{1, \frac{3}{2} - \frac{1}{\beta}\right\}.$$

(i) If $\beta \leq 2$, then $\Delta^{(\alpha,\beta)}(g) = 1$. From Corollaries 6.5 and 6.7, we deduce that

$$\Delta^{(\alpha,\beta)}(f) = 2 - H$$

for all $\alpha \geq 1$. This is the value of the fractal dimension of G_f in particular.

(ii) If $\beta \geq 2$, $\Delta^{(\alpha,\beta)}(g) = 3/2 - 1/\beta$. If, for example, $H = 3/4$, then Corollary 6.9 gives

$$\Delta^{(\alpha,\beta)}(f) \leq \begin{cases} \frac{5}{4} & \text{if } 2 \leq \beta \leq 4, \\ \frac{3}{2} - \frac{1}{\beta} & \text{if } \beta \geq 4. \end{cases}$$

The equality is conjectural.

INEQUALITIES ON MATRIX-DILATED LITTLEWOOD–PALEY ENERGY FUNCTIONS AND OVERSAMPLED AFFINE OPERATORS*

CHARLES K. CHUI[†] AND XIANLIANG SHI[‡]

Abstract. Affine operators and Littlewood–Paley energy functions with matrix dilations are considered in this paper. Estimates and comparisons of the infimum and supremum measurements of these two operations are derived. These results are applied to the study of affine frames and wavelets. In particular, multivariate matrix-dilated wavelet families are characterized and a matrix-dilation oversampling theorem on preservation of frame-bound ratios is established.

Key words. matrix dilation, Littlewood–Paley, inequalities, oversampling

1. Introduction and results.

The theory of s-dimensional discrete wavelet transform is the mathematical analysis of a family

$$\{\psi_{\ell,b;j,k}\colon\ 1 \le \ell \le L, \quad j \in \mathbb{Z}, \quad k \in \mathbb{Z}^s\} \tag{1.1}$$

of functions generated by some functions $\psi_1, \dots, \psi_L$ in $L^2 := L^2(\mathbb{R}^s)$, in the sense that

$$\psi_{\ell,b;j,k}(x) := b^{s/2} |\det M|^{j/2} \psi_\ell(M^j x - kb), \tag{1.2}$$

where $b > 0$ is the (discretization) sample period and M is a nonsingular $s \times s$ matrix whose eigenvalues $\lambda_1, \dots, \lambda_s$ satisfy

$$|\lambda_\alpha| > 1, \quad \alpha = 1, \dots, s. \tag{1.3}$$

While the special case where $M = 2I_s$, where I_s denotes the s-dimensional identity matrix, is a somewhat straightforward generalization of the univariate theory, this paper is concerned with more general dilation matrices M. The objective of this paper is to establish some inequalities on the Littlewood–Paley energy functions and affine operators and to apply these results to the study of affine frames and wavelets and the boundedness of the Littlewood–Paley g-function operators.

Let us first introduce some notations. For a given family

$$\Psi := \{\psi_1, \dots, \psi_L\} \tag{1.4}$$

of functions in L^2, the operator T_b, defined by

$$(T_b f)(\mathbf{x}) := \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z},\mathbf{k}\in\mathbb{Z}^s} \langle f, \psi_{\ell,b;j,\mathbf{k}}\rangle \psi_{\ell,b;j,\mathbf{k}}(\mathbf{x}), \quad f \in L^2, \tag{1.5}$$

will be called an *affine operator*, and the infinite series

$$L_\Psi(\mathbf{x}) := \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z}} |\widehat{\psi}_\ell((M^T)^j \mathbf{x})|^2 \tag{1.6}$$

will be called the corresponding *Littlewood–Paley energy function* associated with the family Ψ. Here M^T denotes the transpose of M and the Fourier transform $\widehat{\psi}$ of ψ is defined, as usual, by

$$\widehat{\psi}(x) = \int_{\mathbb{R}^s} \psi(t) e^{-ixt} dt.$$

We will also use the standard operator norm notation $\|T\|$ for bounded linear operators T on L^2. It is clear that

$$\|T\| = \sup_{\substack{f,g\in\mathcal{D} \\ \|f\|\le 1, \|g\|\le 1}} \langle Tf, g\rangle, \tag{1.7}$$

where $\|f\|$ denotes the L^2 norm of f and $\mathcal{D}$ denotes the set of all infinitely differentiable and compactly supported functions. Let us also consider the measurement

$$\|T\|^* := \sup_{\|f\|=1} |\langle Tf, f\rangle| \tag{1.8}$$

and observe that $\|T\|^* \le \|T\|$ always holds for any bounded operator on L^2, but the two quantities are different in general. For certain operators, however, such as the affine operators in (1.5) and the Fourier multipliers defined by $\widehat{Tf} = m\widehat{f}$, $m \in L^\infty$, we do have equality.

The main contents of this paper are estimation and comparison of the quantities

$$\begin{cases} \|L_\Psi\|_* := \operatorname{ess\,inf}_{\mathbf{x}} |L_\Psi(\mathbf{x})|, \\ \|L_\Psi\|^* := \operatorname{ess\,sup}_{\mathbf{x}} |L_\Psi(\mathbf{x})|, \\ \|T_b\|_* := \inf_{\|f\|=1} |\langle T_b f, f\rangle|, \quad \text{and} \\ \|T_b\|^* \quad \text{as defined in (1.8)} \end{cases}$$

and applications of these results to the study of affine frames and wavelets.

In the one-dimensional setting with $M = (2)$, $b = 1$, and $L = 1$, we recall from Mallat and Zhong [5] that ψ is called a *dyadic wavelet* if the sequence

$$(W_j f)(x) := f * (2^j \psi(2^j \cdot))(x), \quad j \in \mathbb{Z},$$

satisfies the so-called stability condition

$$A\|f\|^2 \le \sum_{j\in\mathbb{Z}} \|W_j f\|^2 \le B\|f\|^2, \quad f \in L^2,$$

where $0 < A \le B < \infty$ are constants independent of f. This concept is instrumental to the construction of dyadic duals for the recovery of $f \in L^2$ from the sequence $W_j f$, $j \in \mathbb{Z}$. It is clear that ψ is a dyadic wavelet if and only if the corresponding Littlewood–Paley energy function L_ψ defined in (1.6) is bounded both from above and away from zero. In our earlier work [2], we also established the critera for L_ψ to have these boundedness properties, namely, $\psi \in L^2$ with $\int \psi = 0$,

$$\text{ess inf}\left\{|\widehat{\psi}(\omega)|\colon\ \frac{1}{2}a \le |\omega| \le a\right\} > 0$$

for some $a > 0$, and

$$|\psi(x)| \le \Phi(|x|), \quad x \in \mathbb{R},$$

for some nonnegative and nonincreasing function Φ on $(0, \infty)$ that satisfies

$$\Phi(0) + \int_1^\infty \Phi(x)(\ln x)^{1/2} dx < \infty.$$

However, the method used in [2] for establishing this one-variable result does not generalize to the study of the multidimensional setting with a more general dilation matrix M. In sections 2 and 3, we will establish certain upper-bound and lower-bound results in the multidimensional setting with matrix dilations. Assuming that Φ is a nonincreasing continuous function defined on $[0, \infty)$ and satisfies

$$K_\Phi := \int_{\mathbb{R}^s} \Phi(|\mathbf{x}|)\left(1 + \sqrt{\ln^+ |\mathbf{x}|}\right) d\mathbf{x} < \infty, \tag{1.9}$$

we will establish the following in section 2.

Theorem 1. *Let Φ be a nonincreasing function on $[0, \infty)$ that satisfies (1.9) and $\Psi = \{\psi_1, \dots, \psi_L\}$ be a collection of functions in L^2.*

(i) *If $\|T_b\| < \infty$, then*

$$\|L_\Psi\|^* \le \|T_b\|^* = \|T_b\|. \tag{1.10}$$

(ii) *Let Ψ satisfy*

$$|\psi_\ell(\mathbf{x})| \le \Phi(|\mathbf{x}|), \quad \ell = 1, \dots, L. \tag{1.11}$$

Then there exists some positive constant C, independent of Φ, such that

$$\|L_\Psi\|^* \le C K_\Phi^2 \tag{1.12}$$

if and only if

$$\int \psi_\ell(\mathbf{x}) d\mathbf{x} = 0, \quad \ell = 1, \dots, L. \tag{1.13}$$

Furthermore, (1.11) *cannot be replaced by the simple assumption $\psi_\ell \in L^1 \cap L^2$, $\ell = 1, \dots, L$, to ensure $\|L_\Psi\|^* < \infty$.*

For certain more specific dilation matrices M, we can even compare the quantities $\|L_\Psi\|_*$ and $\|T_b\|_*$. More precisely, the following result will be established in section 3.

Theorem 2. *Let $M = \lambda U$, where $\lambda > 1$ and U is a unitary matrix, and assume that $\|T_b\| < \infty$. Then*

$$\|L_\Psi\|_* \geq \|T_b\|_*. \tag{1.14}$$

In section 4, we will compare the values of $\|T_b\|^*$ and $\|T_b\|_*$ with those of their corresponding oversampled operators. In particular, the following result is established.

Theorem 3. *Suppose that M is any nonsingular square matrix with integer entries and with all its eigenvalues satisfying* (1.3). *Let n be any natural number that satisfies*

$$(n, |\det M|) = 1 \tag{1.15}$$

and Ψ be a finite family with corresponding affine operator T_b that satisfies $\|T_b\|^* < \infty$. Then

$$\|T_b\|_* \leq \|T_{b/n}\|_* \leq \|T_{b/n}\|^* \leq \|T_b\|^*. \tag{1.16}$$

Furthermore, (1.16) *does not hold in general without the assumption* (1.15).

Finally, we will discuss, in section 5, an application of these results to the theory of affine frames and wavelets and a study of the boundedness of Littlewood–Paley g-function operators.

2. Proof of Theorem 1.

This section is devoted to the proof of Theorem 1.

2.1. Preliminary results.

To facilitate the proof of the theorem, we need the following three lemmas. First, observe that if M satisfies (1.3), then we have for some positive $J \in \mathbb{Z}$,

$$\theta := \min_{\mathbf{x} \in \sigma} |(M^T)^J \mathbf{x}| > 1, \tag{2.1}$$

where σ denotes the unit sphere

$$\sigma := \{\mathbf{x} \in \mathbb{R}^s \colon\ |\mathbf{x}| = 1\}.$$

By (2.1), we see that σ lies in the bounded component of the complement of its image

$$M^J(\sigma) := \{\mathbf{y} = (M^T)^J \mathbf{x} \colon\ \mathbf{x} \in \sigma\}$$

under $(M^T)^J$.

The following lemma is evident.

Lemma 1. *If M satisfies* (1.3), *then for any $\mathbf{x} \in \mathbb{R}^s \backslash \{\mathbf{0}\}$, there exists some $j_0 \in \mathbb{Z}$ and $\mathbf{x}_0 \in \Omega_J(M)$ such that $M^{j_0 J}\mathbf{x}_0 = \mathbf{x}$, where*

$$\Omega_J(M) := \Omega_J(M)^0 \cup \sigma \tag{2.2}$$

and $\Omega_J(M)^0$ denotes the open region with boundary $\sigma \cup M^J(\sigma)$. Furthermore, the pair $(j_0, \mathbf{x}_0)$ is unique.

In the following, $L^2(Q)$ will denote the space of all square-integrable functions f on a measurable set Q with norm

$$\|f\|_{L^2(Q)} := \left(\int_Q |f(\mathbf{x})|^2 d\mathbf{x} \right)^{1/2}.$$

LEMMA 2. *Let Q be any measurable set in $\mathbb{R}^s$ and $\{f_j\}_{j\in\mathbb{Z}}$ be a sequence in $L^2(Q)$. Then the following two statements are equivalent:*

(i) $\|\sum_j c_j f_j\|^2_{L^2(Q)} \le B\sum_j |c_j|^2,\ \{c_j\}\in\ell^2.$

(ii) $\sum_j |\int_Q f\bar{f}_j|^2 \le B\|f\|^2_{L^2(Q)},\ f\in L^2(Q).$

The following lemma can be found in [7, p. 43].

LEMMA 3. *For any real number $\delta\notin\mathbb{Z}\cup\big(\mathbb{Z}+1/2\big)$, the identity*

$$1-e^{i\delta t}=F_1(\delta)+F_2(\delta,t)+F_3(\delta,t),\quad t\in[-\pi,\pi], \tag{2.3}$$

holds, where

$$F_1(\delta):=\left(1-\frac{\sin\pi\delta}{\pi\delta}\right),$$

$$F_2(\delta,t):=\sum_{k=1}^{\infty}\frac{(-1)^k 2\delta\sin\pi\delta}{\pi(k^2-\delta^2)}\cos kt,$$

and

$$F_3(\delta,t):=i\sum_{k=1}^{\infty}\frac{(-1)^k 2\delta\cos\pi\delta}{\pi\big(\big(k-\frac{1}{2}\big)^2-\delta^2\big)}\sin\left(k-\frac{1}{2}\right)t.$$

2.2. Proof of Theorem 1(i). Let $\|T_b\|<\infty$. Then for any f with $\|f\|=1$, we have

$$\begin{aligned}\langle T_b f,f\rangle &= \frac{b^s}{(2\pi)^{2s}}\sum_{\ell=1}^{L}\sum_{j\in\mathbb{Z},\mathbf{k}\in\mathbf{Z}^s}|\det M|^j\left|\int_{\mathbb{R}^s}\widehat{f}((M^T)^j\mathbf{x})\overline{\widehat{\psi}_\ell(\mathbf{x})}e^{ib\mathbf{kx}}d\mathbf{x}\right|^2\\ &=\sum_{\ell=1}^{L}\sum_{j\in\mathbb{Z}}\frac{|\det M|^j}{b^s}\sum_{\mathbf{k}\in\mathbf{Z}^s}\left|\frac{1}{(2\pi b^{-1})^s}\int_{[0,2\pi b^{-1}]^s}\right.\\ &\qquad\left.\left[\sum_{\mathbf{m}\in\mathbf{Z}^s}\widehat{f}((M^T)^j(\mathbf{x}+2\pi b^{-1}\mathbf{m}))\overline{\widehat{\psi}_\ell(x+2\pi b^{-1}\mathbf{m})}e^{ib\mathbf{kx}}\right]^2 d\mathbf{x}\right|.\end{aligned}$$

Therefore,

$$\begin{aligned}&\sum_{\ell=1}^{L}\sum_{j\in\mathbb{Z}}\frac{|\det M|^j}{(2\pi)^s}\int_{[0,2\pi b^{-1}]^s}\left|\sum_{\mathbf{m}\in\mathbf{Z}^s}\widehat{f}((M^T)^j(\mathbf{x}+2\pi b^{-1}\mathbf{m}))\overline{\widehat{\psi}_\ell(\mathbf{x}+2\pi b^{-1}\mathbf{m})}\right|^2 d\mathbf{x}\\ &\quad\le\|T_b\|^*.\end{aligned}$$

On the other hand, by using the notation $\mathbf{e}:=(1,\dots,1)$ and considering any $\mathbf{x}_0\in\mathbb{R}^s\backslash\{\mathbf{0}\}$, we have for any positive integer J' that

$$\begin{aligned}&\sum_{\ell=1}^{L}\sum_{j=-J'}^{J'}\frac{|\det M|^j}{(2\pi)^s}\int_{[(M^T)^{-j}\mathbf{x}_0-\pi_b^{-1}\mathbf{e},(M^T)^{-j}\mathbf{x}_0+\pi b^{-1}\mathbf{e}]}\\ &\left|\sum_{m\in\mathbf{Z}^s}\widehat{f}((M^T)^j(\mathbf{x}+2\pi b^{-1}\mathbf{m}))\overline{\widehat{\psi}_\ell(\mathbf{x}+2\pi b^{-1}\mathbf{m})}\right|^2 d\mathbf{x}\le\|T_b\|^*.\end{aligned} \tag{2.4}$$

Now if we set $\widehat{f}(\mathbf{x}) = (\pi\varepsilon^{-1})^{s/2}\chi_{[\mathbf{x}_0-\varepsilon\mathbf{e},\mathbf{x}_0+\varepsilon\mathbf{e}]}(\mathbf{x})$ in (2.4) and take the limit as $\varepsilon \to 0$ and $J' \to \infty$ consecutively, we arrive at (1.10). This completes the proof of Theorem 1(i).

2.3. Proof of Theorem 1(ii). Assume that (1.11) holds. We will first show that

$$\sum_{\ell=1}^{L}\sum_{j\in\mathbb{Z}}|\widehat{\psi}_\ell((M^T)^{Jj}\mathbf{x})|^2 \le C\left\{\int_{\mathbb{R}^s}\Phi(|\mathbf{t}|)\big(1+\sqrt{\ln^+|\mathbf{t}|}\big)d\mathbf{t}\right\}^2, \quad \mathbf{x}\neq 0. \tag{2.5}$$

Observe that since

$$\sum_{\ell=1}^{L}\sum_{j\in\mathbb{Z}}|\widehat{\psi}_\ell((M^T)^{Jj}((M^T)^{J}\mathbf{x}))|^2 = \sum_{\ell=1}^{L}\sum_{j\in\mathbb{Z}}|\widehat{\psi}_\ell((M^T)^{Jj}\mathbf{x})|^2,$$

an application of Lemma 1 shows that (2.5) is valid provided that it holds for any $\mathbf{x}\in\Omega_J(M)$. For this reason, we call $\Omega_J(M)$ a "fundamental region."

By (1.11) and (1.13), we see that

$$\begin{aligned}
|\widehat{\psi}_\ell(M^T)^{Jj}\mathbf{x})| &= \left|\int_{\mathbb{R}^s}\psi_\ell(\mathbf{t})(e^{-i\mathbf{t}(M^T)^{Jj}\mathbf{x}}-1)d\mathbf{t}\right| \\
&\le |(M^T)^{Jj}\mathbf{x}|\int_{|\mathbf{t}|\le|(M^T)^{Jj}\mathbf{x}|^{-1}}\Phi(|\mathbf{t}|)|\mathbf{t}|d\mathbf{t} + 2\int_{|\mathbf{t}|\ge|(M^T)^{Jj}\mathbf{x}|^{-1}}\Phi(|\mathbf{t}|)d\mathbf{t} \\
&=: K_{1,j}+K_{2,j},
\end{aligned}$$

and this gives

$$\begin{aligned}
P_1(\mathbf{x}) &:= \sum_{\ell=1}^{L}\sum_{j=-\infty}^{-1}|\widehat{\psi}_\ell((M^T)^{Jj}\mathbf{x})|^2 \\
&\le 2L\sum_{j=1}^{\infty}|K_{1,-j}|^2 + 2L\sum_{j=1}^{\infty}|K_{2,-j}|^2 \\
&=: 2P_{1,1}(\mathbf{x}) + 2P_{1,2}(\mathbf{x}).
\end{aligned} \tag{2.6}$$

Next, consider

$$\mu_0 := \int_{|\mathbf{t}|\le|(M^T)^{-J}\mathbf{x}|^{-1}}\Phi(|\mathbf{t}|)|\mathbf{t}|d\mathbf{t}$$

and

$$\mu_k := \int_{|(M^T)^{-Jk}\mathbf{x}|^{-1}\le|\mathbf{t}|\le|(M^T)^{-J(k+1)}\mathbf{x}|^{-1}}\Phi(|\mathbf{t}|)|\mathbf{t}|d\mathbf{t}, \quad k=1,2,\ldots.$$

Then we see that

$$\begin{aligned}
P_{1,1}(\mathbf{x}) &= L\sum_{j=1}^{\infty}|(M^T)^{-Jj}\mathbf{x}|^2(\mu_0+\cdots+\mu_{j-1})^2 \\
&\le L\left[\sum_{k=0}^{\infty}\left(\sum_{j=k+1}^{\infty}|(M^T)^{-Jj}\mathbf{x}|^2\mu_k^2\right)^{1/2}\right]^2 \\
&\le C_2\Big(\int_{\mathbb{R}^s}\Phi(|\mathbf{t}|)d\mathbf{t}\Big)^2.
\end{aligned} \tag{2.7}$$

As for $P_{1,2}(x)$, we first observe that

$$P_{1,2}(\mathbf{x}) = L\sum_{j=1}^{\infty}\left(\sum_{k=j}^{\infty}\mu_k\right)^2 \le C_3\left[\sum_{k=1}^{\infty}\left(\sum_{j=1}^{k-1}\mu_k^2\right)^{1/2}\right]^2 \tag{2.8}$$

$$\le C_4\left[\sum_{k=1}^{\infty}\sqrt{k}\int_{|(M^T)^{-Jk}\mathbf{x}|^{-1}\le|\mathbf{t}|\le|(M^T)^{-J(k+1)}\mathbf{x}|^{-1}}\Phi(|\mathbf{t}|)d\mathbf{t}\right]^2.$$

By (2.1), we see that if $\mathbf{x}\in\Omega_J(M)$ and

$$|\mathbf{t}| \ge \max(2, |(M^T)^{-Jk}\mathbf{x}|^{-1}),$$

then

$$|\mathbf{t}| \ge |(M^T)^{-Jk}\mathbf{x}|^{-1} = \frac{1}{|\mathbf{x}|}\frac{|\mathbf{x}|}{|(M^T)^{-J}\mathbf{x}|}\frac{|(M^T)^{-J}\mathbf{x}|}{|(M^T)^{-J2}\mathbf{x}|}\cdots\frac{|(M^T)^{-J(k-1)}\mathbf{x}|}{|(M^T)^{-Jk}\mathbf{x}|}$$

$$\ge \frac{\theta^k}{|\mathbf{x}|} \ge \frac{\theta^k}{\min\limits_{x\in\Omega_J(M)}|\mathbf{x}|}.$$

Hence $\sqrt{\ln|\mathbf{t}|}\ge C_5\sqrt{k}$, and it follows from (2.8) that

$$P_{1,2}(\mathbf{x}) \le C_6\left[\int_{\mathbb{R}^s}\Phi(|\mathbf{t}|)\left(1+\sqrt{\ln^+|\mathbf{t}|}\right)d\mathbf{t}\right]^2. \tag{2.9}$$

Setting (2.7) and (2.8) into (2.6), we obtain

$$P_1(\mathbf{x}) \le C_7\left[\int_{\mathbb{R}^s}\Phi(|\mathbf{t}|)\left(1+\sqrt{\ln^+|\mathbf{t}|}\right)d\mathbf{t}\right]^2. \tag{2.10}$$

Next, let us estimate the sum

$$P_2(\mathbf{x}) := \sum_{\ell=1}^{L}\sum_{j=0}^{\infty}|\widehat{\psi}_\ell((M^T)^{Jj}\mathbf{x})|^2.$$

To do so, we divide $\mathbb{R}^s$ into cubes

$$Q_{\mathbf{m}} := \mathbf{m} + Q_0, \quad \mathbf{m}\in\mathbb{Z}^s, \tag{2.11}$$

with

$$Q_{\mathbf{0}} := \{\mathbf{x}\in\mathbb{R}^s\colon\ 0\le x_\alpha<1, \quad \alpha=1,\ldots,s\}$$

and set

$$\psi_\ell(\mathbf{m};\mathbf{x}) := \psi_\ell(\mathbf{x})\chi_{Q_{\mathbf{m}}}(\mathbf{x}).$$

Then by the triangle inequality, we have

$$P_2(\mathbf{x}) \le C_8\left[\sum_{\mathbf{m}\in\mathbb{Z}^s}\sum_{\ell=1}^{L}\left(\sum_{j=0}^{\infty}|\widehat{\psi}_\ell(\mathbf{m};(M^T)^{Jj}\mathbf{x})|^2\right)^{1/2}\right]^2. \tag{2.12}$$

We claim that there exists a constant C_9 depending only on s and M such that

$$\sum_{j=0}^{\infty}\left|\int_{Q_{\mathbf{m}}} g(\mathbf{t})e^{-i\mathbf{t}(M^T)^{Jj}\mathbf{x}}d\mathbf{t}\right|^2 \le C_9\int_{Q_{\mathbf{m}}}|g(\mathbf{t})|^2 d\mathbf{t}. \tag{2.13}$$

By Lemma 2, we see that this claim is equivalent to

$$\int_{Q_{\mathbf{m}}}\left|\sum_{j=0}^{\infty} c_j e^{-i\mathbf{t}(M^T)^{Jj}\mathbf{x}}\right|^2 d\mathbf{t} \le C_9\sum_{j=0}^{\infty}|c_j|^2, \quad \{c_j\}\in \ell^2. \tag{2.14}$$

It is sufficient to prove (2.14) for $\mathbf{m}=\mathbf{0}$. For this purpose, we decompose Q_0 into 2^s equal cubes and denote by $\mathbf{a}_\alpha$, $\alpha = 0, 1, \ldots, 2^s-1$, with $\mathbf{a}_0 = 0$ the vertices of these cubes with smallest componentwise coordinates. By the Bessel inequality for trigonometric systems, it is obvious that

$$\int_{Q_{\mathbf{0}}}\left|\sum_{\alpha=0}^{2^s-1}\sum_{\mathbf{k}\in\mathbb{Z}^s} b_{\alpha,\mathbf{k}} e^{-i\mathbf{t}(\mathbf{a}_\alpha+\mathbf{k})}\right|^2 dt \le C_{10}\sum_{\alpha,\mathbf{k}}|b_{\alpha,\mathbf{k}}|^2, \quad \text{all } \{b_{\alpha,\mathbf{k}}\}\in\ell^2, \tag{2.15}$$

where the constant C_{10} depends only on s. Now consider the cubes

$$R_{\alpha,\mathbf{k}} := \frac{1}{2}Q_0 + \mathbf{a}_\alpha + \mathbf{k}.$$

Since M satisfies (1.3), we see that there exist at most

$$\lambda := \left[\ln\sqrt{s}\Big/\ln\frac{1}{|||M^{-J}|||}\right]+1$$

numbers of points of the form $(M^T)^{Jj}\mathbf{x}$ in each cube $R_{\alpha,\mathbf{k}}$, where $j\ge 0$, $\mathbf{x}\in\Omega_J(M)$ and $|||\cdot|||$ denotes the spectral norm of M. Therefore, by (2.15), we obtain

$$\int_{Q_{\mathbf{0}}}\left|\sum_{\alpha,\mathbf{k}}\ \sum_{(M^T)^{Jj}\mathbf{x}\in R_{\alpha,\mathbf{k}}} c_j e^{-i\mathbf{t}(\mathbf{a}_\alpha+\mathbf{k})}\right|^2 d\mathbf{t} \le C_{11}\sum_j |c_j|^2, \quad \{c_j\}\in\ell^2,$$

where the constant C_{11} depends only on s and M. Thus to establish (2.14), it is sufficient to prove that for any $\{c_j\}\in\ell^2$, we have

$$\int_{Q_{\mathbf{0}}}\left|\sum_{\alpha,\mathbf{k}}\ \sum_{(M^T)^{Jj}\mathbf{x}\in R_{\alpha,\mathbf{k}}} c_j e^{-i\mathbf{t}(\mathbf{a}_\alpha+\mathbf{k})}(1-e^{-i\mathbf{t}\mathbf{h}(j,\alpha,\mathbf{k},\mathbf{x})})\right|^2 d\mathbf{t} \le C_{12}\sum|c_j|^2, \tag{2.16}$$

where

$$\mathbf{h}(j,\alpha,\mathbf{k},\mathbf{x}) = (h_{j,1},h_{j,2},\ldots,h_{j,s}) := (M^T)^{Jj}\mathbf{x} - (\mathbf{a}_\alpha+\mathbf{k})$$

with

$$|h_{j,\alpha}| \le \frac{1}{4}, \quad \alpha = 1,\ldots,s. \tag{2.17}$$

From (2.3), we see that

$$\begin{aligned}1-e^{-i\mathbf{t}\mathbf{h}(j,\alpha,\mathbf{k},\mathbf{x})} &= 1-\prod_{\beta=1}^{s}\{1-F_1(h_{j,\beta})-F_2(h_{j,\beta},t_\beta)-F_3(h_{j,\beta},t_\beta)\}\\ &= \sum{}' F_1(h_{j,\beta_1})\cdots F_1(h_{j,\beta_p})F_2(h_{j,\beta_{p+1}},t_{\beta_{p+1}})\cdots F_2(h_{j,\beta_q},t_{\beta_q})\\ &\quad\times F_3(h_{j,\beta_{q+1}},t_{\beta_{q+1}})\cdots F_3(h_{j,\beta_r},t_{\beta_r}),\end{aligned}\tag{2.18}$$

where $(\beta_1,\dots,\beta_r)$ is a permutation of some subset of the set $(1,\dots,s)$ and the sum $\sum'$ is taken over all possible nonempty subsets of $(1,\dots,s)$ and their permutations. According to (2.16), we need to estimate the integral

$$\begin{aligned}I := \int_{Q_\mathbf{0}}\Bigg|&\sum_{\alpha,k}\sum_{(M^T)^{Jj}\mathbf{x}\in R_{\alpha,k}} c_j e^{-i\mathbf{t}(\mathbf{a}_\alpha+\mathbf{k})}F_1(h_{j,\beta_1})\cdots F_1(h_{j,\beta_p})\\ &\times F_2(h_{j,\beta_{p+1}},t_{\beta_{p+1}})\cdots F_2(h_{j,\beta_q},t_{\beta_q})F_3(h_{j,\beta_{q+1}},t_{\beta_{q+1}})\\ &\cdots F_3(h_{j,\beta_r},t_{\beta_r})\Bigg|^2 d\mathbf{t}.\end{aligned}$$

By the generalized Minkowskii inequality and (2.17), we see that

$$\begin{aligned}I^{1/2} \le \sum_{n_{\beta_{p+1}}=1}^{\infty}\cdots\sum_{n_{\beta_r}=1}^{\infty}&\Bigg(\int_{Q_\mathbf{0}}\Bigg|\sum_{\alpha,\mathbf{k}}\sum_{(M^T)^{Jj}\mathbf{x}\in R_{\alpha,\mathbf{k}}} c_j e^{-i\mathbf{t}(\mathbf{a}_\alpha+\mathbf{k})}\\ &\times F_1(h_{j,\beta_1})\cdots F_1(h_{j,\beta_p})\frac{(-1)^{n_{\beta_{p+1}}}2h_{j,\beta_{p+1}}\sin\pi h_{j,\beta_{p+1}}}{\pi(n_{\beta_{p+1}}^2-h_{j,\beta_{p+1}}^2)}\\ &\cdots\frac{(-1)^{n_{\beta_q}}2h_{j,\beta_q}\sin\pi h_{j,\beta_q}}{\pi(n_{\beta_q}^2-h_{j,\beta_q}^2)}\,\frac{(-1)^{n_{\beta_{q+1}}}2h_{j,\beta_{q+1}}\cos\pi h_{j,\beta_{q+1}}}{\pi\left(\left(n_{\beta_{q+1}}-\frac12\right)^2-h_{j,\beta_{q+1}}^2\right)}\\ &\cdots\frac{(-1)^{n_{\beta_r}}2h_{j,\beta_r}\cos\pi h_{j,\beta_r}}{\pi\left(\left(n_{\beta_r}-\frac12\right)^2-h_{j,\beta_r}^2\right)}\cos n_{\beta_{p+1}}t_{\beta_{p+1}}\cdots\cos n_{\beta_q}t_{\beta_q}\\ &\times\sin\left(n_{\beta_{q+1}}-\frac12\right)t_{\beta_{q+1}}\cdots\sin\left(n_{\beta_r}-\frac12\right)t_{\beta_r}\Bigg|^2 d\mathbf{t}\Bigg)^{1/2}\\ \le C_{12}&\left(1-\frac{\sin\frac{\pi}{4}}{\frac{\pi}{4}}\right)^p\left(\sum_{n=1}^{\infty}\frac{1}{\pi\left(n^2-\frac{1}{16}\right)}\right)^{q-p}\\ &\times\left(\sum_{n=1}^{\infty}\frac{1}{\pi\left(\left(n-\frac12\right)^2-\frac{1}{16}\right)}\right)^{r-q}\left(\sum_j|c_j|^2\right)^{1/2}\\ \le C_{13}&\left(\sum|c_j|^2\right)^{1/2}.\end{aligned}\tag{2.19}$$

Hence by (2.18) and (2.19), we arrive at (2.14) and then (2.13). By (2.13), we then see that

$$\begin{aligned}\sum_{j=0}^{\infty}|\widehat{\psi}_\ell(\mathbf{m};(M^T)^{Jj}\mathbf{x})|^2 &= \sum_{j=0}^{\infty}\left|\int_{Q_\mathbf{m}}\psi_\ell(\mathbf{t})e^{-i\mathbf{t}(M^T)^{Jj}\mathbf{x}}d\mathbf{t}\right|^2\\ &\le C_{15}\int_{Q_\mathbf{m}}|\psi_\ell(\mathbf{t})|^2d\mathbf{t}.\end{aligned}$$

Therefore, it follows from (1.6) that

$$P_2(\mathbf{x}) \le C_{16} \left[\sum_{\mathbf{m}\in\mathbf{Z}^s} \left(\int_{Q_\mathbf{m}} (\Phi(|\mathbf{t}|))^2 d\mathbf{t} \right)^{1/2} \right]^2 \le C_{17} \left(\int_{\mathbb{R}^s} \Phi(|\mathbf{t}|) d\mathbf{t} \right)^2 . \tag{2.20}$$

Combining (2.10) and (2.20), we obtain (2.5). It is clear that (2.5) implies (1.12).

Conversely, by the hypothesis stated in Theorem 1, the functions $\widehat{\psi}_\ell$ are continuous on $\mathbb{R}^s$. Therefore, if $\widehat{\psi}_\ell(\mathbf{0}) \ne 0$ for some ℓ, then there exists a ball $B_\varepsilon := \{\mathbf{x}\colon |\mathbf{x}| \le \varepsilon\}$ on which $|\widehat{\psi}_\ell(\mathbf{x})|^2 \ge \eta > 0$. By (1.1), for any $\mathbf{x} \in \mathbb{R}^s \backslash \{\mathbf{0}\}$, there exists a j_0 such that $(M^T)^j \mathbf{x} \in B_\varepsilon$ for all $j \le j_0$. Therefore, $L_\Psi(\mathbf{x}) = \infty$. This is a contradiction to the hypothesis and hence completes the proof of Theorem 1(ii).

2.4. Counterexamples. Finally, we will construct examples of $\psi_\ell \in L^1 \cap L^2$, $\ell = 1, \ldots, L$, each of which has zero mean, but $\|L_\Psi\|^* = \infty$. For this purpose, it is sufficient to consider $s = 1$, $L = 1$, and $M = (2)$. Denote by h the hat function with supp $h = [-1, 1]$ defined by $h(x) := 1 - |x|$ for $|x| \le 1$. Set

$$\psi(x) := \sum_{n=0}^{\infty} 4^{-n} (h(x - m_n) + h(x + m_n)),$$

with $m_n = \prod_{k=1}^{n} 2^{4^{2k}}$. Then it is evident that $\psi \in L^1 \cap L^2$ and $\int \psi = 0$. We also observe that

$$\widehat{\psi}(x) = -\frac{8i \sin^2 \frac{x}{2}}{x^2} \sum_{n=0}^{\infty} 4^{-n} \sin m_n x. \tag{2.21}$$

Next, we prove that the function

$$L_\Psi(x) = \sum_{j\in\mathbf{Z}} |\widehat{\psi}(2^j x)|^2$$

is not bounded. To do so, consider

$$P_1(x) := \sum_{j=0}^{\infty} |\widehat{\psi}(2^{-j} x)|^2 .$$

Then since $\|L_\Psi\|^* \ge \|P_1\|_{L[0,1]}$, it is sufficient to show that

$$\|P_1\|_{L[0,1]} = \infty. \tag{2.22}$$

To prove (2.22), we see that

$$\begin{aligned}
\int_0^1 |P_1(x)|dx &= C_{18}\sum_{j=0}^{\infty} 2^{3j}\int_{2^{-j}}^{2^{-j+1}} \frac{1}{2^{2j}}\left|\sum_{n=1}^{\infty} 4^{-n}\sin m_n x\right|^2 dx \\
&\geq C_{19}\int_0^1 \frac{1}{x}\left|\sum_{n=1}^{\infty} 4^{-n}\sin m_n x\right|^2 dx - O(1) \\
&\geq C_{19}\sum_{k=1}^{\infty}\int_{m_{k+1}^{-1}}^{m_k^{-1}} \frac{1}{x}\left|\sum_{n=k+1}^{\infty} 4^{-n}\sin m_n x\right|^2 dx - O(1) \\
&= C_{19}\sum_{k=1}^{\infty}\int_{1}^{m_{k+1}m_k^{-1}} \frac{1}{x}\left(\sum_{n=k+1}^{\infty} 4^{-n}\sin \frac{m_n}{m_{k+1}}x\right)^2 dx - O(1) \\
&\geq C_{19}\sum_{k=1}^{\infty}\sum_{\nu=1}^{\left[\frac{m_{k+1}}{2\pi m_k}\right]-1} \frac{1}{2(\nu+1)\pi}\int_{2\nu n}^{2(\nu+1)\pi}\left|\sum_{n=k+1}^{\infty} 4^{-n}\sin \frac{m_n}{m_{k+1}}x\right|^2 dx - O(1) \\
&= C_{19}\sum_{k=1}^{\infty}\sum_{\nu=1}^{\left[\frac{m_{k+1}}{2\pi m_k}\right]-1} \frac{1}{\nu+1}\sum_{n=k+1}^{\infty} 4^{-2n} - O(1) = \infty.
\end{aligned}$$

This completes the proof of Theorem 1. □

3. Proof of Theorem 2. To prove Theorem 2, we consider the sum

$$\begin{aligned}
I_{J'} := \sum_{\ell=1}^{L}\sum_{j=-\infty}^{-J'} \frac{|\det M|^j}{(2\pi)^s}&\int_{[(M^T)^{-j}\mathbf{x}_0-\pi b^{-1}\mathbf{e},(M^T)^{-j}\mathbf{x}_0+\pi b^{-1}\mathbf{e}]} \\
&\left|\sum_{\mathbf{m}\in\mathbb{Z}^s} \hat{f}((M^T)^j(\mathbf{x}+2\pi b^{-1}\mathbf{m}))\overline{\widehat{\psi_\ell}(\mathbf{x}+2\pi b^{-1}\mathbf{m})}\right|^2 d\mathbf{x},
\end{aligned}$$

where $\widehat{f}(\mathbf{x}) := (\pi\varepsilon^{-1})^{s/2}\chi_{[\mathbf{x}_0-\varepsilon\mathbf{e},\mathbf{x}_0+\varepsilon\mathbf{e}]}(\mathbf{x})$ as in the proof of Theorem 1(i). For any fixed $j \in \mathbb{Z}$, we decompose $\mathbb{Z}^s$ into a union of two disjoint sets

$$\mathbb{Z}^s = \mathbb{Z}_{j,1} \cup \mathbb{Z}_{j,2},$$

where $\mathbb{Z}_{j,2}$ is the set of all $\mathbf{m}$ for which the function $\hat{f}((M^T)^j(\mathbf{x}+2\pi b^{-1}\mathbf{m}))$ is equal to zero everywhere on the cube $[(M^T)^{-j}\mathbf{x}_0 - \pi b^{-1}\mathbf{e},\ (M^T)^{-j}\mathbf{x}_0 + \pi b^{-1}\mathbf{e}]$. If $|(M^T)^j\mathbf{e}| > \pi^{-1}b\varepsilon$, then the cardinality $n(\mathbb{Z}_{j,1})$ of the set $\mathbb{Z}_{j,1}$ is bounded. If $|(M^T)^j\mathbf{e}| \leq \pi^{-1}b\varepsilon$, then $n(\mathbb{Z}_{j,1}) = O(\varepsilon^s|\det M|^j)$. Thus we have

$$n(\mathbb{Z}_{j,1}) = O(\varepsilon^s|\det M|^j + 1). \tag{3.1}$$

It follows from (3.2) that the function

$$g_j(x) := \sum_{\mathbf{m}\in\mathbb{Z}^s} \chi_{[\mathbf{x}_0-\varepsilon\mathbf{e},\mathbf{x}_0+\varepsilon\mathbf{e}]}((M^T)^j(\mathbf{x}+2\pi b^{-1}\mathbf{m}))$$

is dominated by $O(\varepsilon^s|\det M|^j+1)$, where "$O$" is independent of ε and j. Hence by the Cauchy inequality, we see that

$$\begin{aligned} I_{J'} &\le \sum_{\ell=1}^{L}\sum_{j=-\infty}^{-J'}\frac{|\det M|^j}{(2\varepsilon)^s}\int_{[(M^T)^{-j}\mathbf{x}_0-\pi b^{-1}\mathbf{e},(M^T)^{-j}\mathbf{x}_0+\pi b^{-1}\mathbf{e}]} g_j(\mathbf{x}) \\ &\quad\times\sum_{\mathbf{m}\in\mathbf{Z}^s}|\widehat{\psi}_\ell(\mathbf{x}+2\pi\mathbf{m})|^2\chi_{[\mathbf{x}_0-\varepsilon\mathbf{e},\mathbf{x}_0+\varepsilon\mathbf{e}]}((M^T)^j(\mathbf{x}+2\pi b^{-1}\mathbf{m}))d\mathbf{x} \qquad (3.2)\\ &\le C_1\sum_{\ell=1}^{L}\sum_{j=-\infty}^{-J'}\int_{(M^T)^{-j}([\mathbf{x}_0-\varepsilon\mathbf{e},\mathbf{x}_0+\varepsilon\mathbf{e}])}\left\{|\widehat{\psi}_\ell(\mathbf{x})|^2+\frac{|\det M|^j}{(2\varepsilon)^s}|\widehat{\psi}_\ell(\mathbf{x})|^2\right\}d\mathbf{x}. \end{aligned}$$

Since $|||M^{-1}|||<\infty$, we may choose for any fixed $\mathbf{x}_0\neq\mathbf{0}$ and any ball $B_r:=\{\mathbf{x}\colon|\mathbf{x}|\le r\}$ some $\varepsilon_0>0$ and sufficiently large J_0 such that for any $0<\varepsilon<\varepsilon_0$ and $J'>J_0$, the sets $(M^T)^{-j}([\mathbf{x}_0-\varepsilon\mathbf{e},\mathbf{x}_0+\varepsilon\mathbf{e}])$, $-\infty<j\le -J'$, are mutually disjoint and are also disjoint with B_r. Hence for an arbitrarily given $\eta>0$, we have

$$\sum_{\ell=1}^{L}\sum_{j=-\infty}^{-J'}\int_{(M^T)^{-j}([\mathbf{x}_0-\varepsilon\mathbf{e},\mathbf{x}_0+\varepsilon\mathbf{e}])}|\widehat{\psi}_\ell(\mathbf{x})|^2d\mathbf{x}\le\eta$$

for all sufficiently large J and sufficiently small $\varepsilon>0$. Therefore, by (3.2), we get

$$\begin{aligned} I'_{J'} &:= \sum_{\ell=1}^{L}\sum_{j=-J'+1}^{\infty}\frac{|\det M|^j}{(2\pi)^s}\int_{[0,2\pi b^{-1}]^s} \qquad (3.3)\\ &\quad\left|\sum_{\mathbf{m}\in\mathbf{Z}^s}\hat{f}((M^T)^j(\mathbf{x}+2\pi b^{-1}\mathbf{m}))\overline{\widehat{\psi}_\ell(\mathbf{x}+2\pi b^{-1}\mathbf{m})}\right|^2d\mathbf{x} \\ &= \langle T_bf,f\rangle - I_{J'}\ge\|T_b\|_*-C_2\eta \\ &\quad-\frac{C_3}{(2\varepsilon)^s}\int_{[\mathbf{x}_0-\varepsilon\mathbf{e},\mathbf{x}_0+\varepsilon\mathbf{e}]}\sum_{\ell=1}^{L}\sum_{j=-\infty}^{-J'}|\widehat{\psi}_\ell((M^T)^{-j}\mathbf{x})|^2d\mathbf{x}. \end{aligned}$$

On the other hand, it is clear that for any fixed J and all sufficiently small $\varepsilon>0$, we have

$$\begin{aligned} I'_{J'} &= \sum_{\ell=1}^{L}\sum_{j=-J'+1}^{\infty}|\det M|^j\int_{(M^T)^{-j}([\mathbf{x}_0-\varepsilon\mathbf{e},\mathbf{x}_0+\varepsilon\mathbf{e}])}|\hat{f}((M^T)^j\mathbf{x})\overline{\widehat{\psi}_\ell(\mathbf{x})}|^2d\mathbf{x} \\ &= \sum_{\ell=1}^{L}\frac{1}{(2\varepsilon)^s}\int_{[\mathbf{x}_0-\varepsilon\mathbf{e},\mathbf{x}_0+\varepsilon\mathbf{e}]}\sum_{j=-J'+1}^{\infty}|\widehat{\psi}_\ell((M^T)^{-j}\mathbf{x})|^2d\mathbf{x}. \end{aligned}$$

Hence in view of the boundedness of L_Ψ, we may take $\varepsilon\to0$ in (3.3) to arrive at

$$\sum_{\ell=1}^{L}\sum_{j=-J'+1}^{\infty}|\widehat{\psi}_\ell((M^T)^{-j}\mathbf{x}_0)|^2\ge\|T_b\|_*-C_2\eta-C_3\sum_{\ell=1}^{L}\sum_{j=-\infty}^{-J'}|\widehat{\psi}_\ell((M^T)^{-j}\mathbf{x}_0)|^2 \qquad (3.4)$$

for almost all x_0. Since η is arbitrary, assertion (3.4) together with the boundedness of L_Ψ yields $\|T_b\|_*\le\|L_\Psi\|_*$. This completes the proof of Theorem 2. □

In the following, we consider the special case where $\operatorname{supp} \widehat{\psi}_\ell \subset [-\pi/b, \pi/b]^s$, $\ell = 1, 2, \dots, L$. For this case, we have

$$\begin{aligned}\langle T_b f, f\rangle &= \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z}} \frac{|\det M|^j}{(2\pi)^s} \int_{[0,2\pi b^{-1}]^s} \left| \sum_{\mathbf{m}\in\mathbb{Z}^s} \hat{f}((M^T)^j(\mathbf{x}+2\pi b^{-1}\mathbf{m}))\overline{\widehat{\psi}_\ell(\mathbf{x}+2\pi b^{-1}\mathbf{m})} \right|^2 d\mathbf{x} \\ &= \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z}} \frac{|\det M|^j}{(2\pi)^s} \int_{[0,2\pi b^{-1}]^s} \sum_{\mathbf{m}\in\mathbb{Z}^s} |\hat{f}((M^T)^j(\mathbf{x}+2\pi b^{-1}\mathbf{m}))\widehat{\psi}_\ell(\mathbf{x}+2\pi b^{-1}\mathbf{m})|^s d\mathbf{x} \\ &= \sum_{\ell=1}^{L} \frac{1}{(2\pi)^s} \int_{\mathbb{R}^s} \sum_{j\in\mathbb{Z}} |\widehat{\psi}_\ell((M^T)^{-j}\mathbf{x})|^2 |\hat{f}(\mathbf{x})|^2 d\mathbf{x}.\end{aligned}$$

This implies that

$$\|T_b\|_* = \|L_\Psi\|_* \quad \text{and} \quad \|T_b\|^* = \|L_\Psi\|^*. \tag{3.5}$$

A more general formulation can be stated as follows. Set

$$E(\psi) := \{\omega\colon\ \widehat{\psi}(\omega) = 0\},$$

and for $\mathbf{k} \in \mathbb{Z}^s$, $\ell = 1, \dots, L$, consider

$$E_{\mathbf{k}}(\psi_\ell) := \{\omega \in [-\pi/b, \pi/b]^s\colon\ \omega + 2\mathbf{k}\pi/b \in E(\psi_\ell)\}.$$

Then we have the following.

Corollary 1. *Let $\psi_\ell \in L^2$, $\ell = 1, \dots, L$, such that for each ℓ, the sets $E_{\mathbf{k}}(\psi_\ell)$, $\mathbf{k} \in \mathbb{Z}^s$, are mutually disjoint. Then* (3.5) *holds.*

4. Proof of Theorem 3.

In this section, we establish a general result which implies the multivariate (matrix-dilated) version of the so-called second oversampling theorem introduced in [3].

4.1. A preliminary result.

In order to prove Theorem 3, we first introduce some notations and establish a lemma. For a natural number $n \geq 2$, consider

$$\mathcal{B}_n := \{\mathbf{p} = (p_1, \dots, p_s)\colon\ p_\ell \in \mathbb{Z}, \quad 0 \leq p_\ell \leq n-1, \quad \ell = 1, \dots, s\}$$

and adopt the notation

$$\mathcal{B}_n^0 := \mathcal{B}_n \backslash \{\mathbf{0}\}.$$

Let $\mathbf{a} = (a_1, \dots, a_s)$ and $\mathbf{b} = (b_1, \dots, b_s)$ be two integer vectors. If $\mathbf{a}$ and $\mathbf{b}$ satisfy $a_\ell \equiv b_\ell \pmod{n}$, $\ell = 1, \dots, s$, then we write

$$\mathbf{a} \equiv \mathbf{b} \pmod{n}.$$

We have the following result.

Lemma 4. *Let M be an integer matrix with $|\det M| > 1$ and $n \geq 2$ be any natural number that satisfies* (1.15). *Then the equation*

$$M\mathbf{p} \equiv \mathbf{0} \pmod{n} \tag{4.1}$$

does not have any solution in $\mathcal{B}_n^0$.

Proof. Suppose that $\mathbf{p} = (p_1, \ldots, p_s) \in \mathcal{B}_n^0$ satisfies (4.1). Then there exists some $\mathbf{k} = (k_1, \ldots, k_s) \in \mathbb{Z}^s$ that satisfies

$$M\mathbf{p} = n\mathbf{k}.$$

Therefore, we have for some ℓ, $1 \le \ell \le s$, that

$$1 \le p_\ell \le n - 1 \tag{4.2}$$

and

$$p_\ell = \frac{n\Delta_\ell}{\det M}, \tag{4.3}$$

where

$$\Delta_\ell = \begin{vmatrix} m_{11} & \ldots & m_{1,\ell-1} & k_1 & m_{1,\ell+1} & \ldots & m_{1s} \\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\ m_{s1} & \ldots & m_{s,\ell-1} & k_s & m_{s,\ell+1} & \ldots & m_{ss} \end{vmatrix}.$$

Since $(n, |\det M|) = 1$ and p_ℓ is an integer, it follows from (4.3) that $\Delta_\ell / \det M$ must also be an integer. Hence (4.3) implies that p_ℓ / n is an integer as well. However, this is a contradiction to (4.2). □

4.2. Proof of Theorem 3. The proof of this theorem is divided into three steps.

4.2.1. Decomposition. Let $\mathbf{p}^1$ be any vector in $\mathcal{B}_n^0$ and consider the sequence of vectors

$$M^0\mathbf{p}^1 = \mathbf{p}^1, \quad M\mathbf{p}^1, \quad M^2\mathbf{p}^1, \ldots.$$

By Lemma 4, we see that to every vector $M^j\mathbf{p}^1$ in this sequence, there exists a vector $\mathbf{q}_j = (q_1^j, \ldots, q_s^j) \in \mathcal{B}_n^0$ that satisfies

$$M^j\mathbf{p}^1 \equiv \mathbf{q}_j \pmod{n}.$$

Since $\mathcal{B}_n^0$ is a finite set, there exist $0 \le j_1 < j_2$ such that

$$\mathbf{q}_{j_1} = \mathbf{q}_{j_2}. \tag{4.4}$$

If j_1 and j_2 are the smallest integers for which (4.4) holds, then j_1 must be zero. Therefore, we obtain an ordered system $\mathbf{q}_0, \mathbf{q}_1, \ldots, \mathbf{q}_{j_2}$ with $j_2 > 0$, $\mathbf{q}_0 = \mathbf{p}^1 = \mathbf{q}_{j_2}$, and $\mathbf{q}_j \ne \mathbf{q}_0$, where $0 < j < j_2$. Denote this system by $\mathcal{F}_1 = (\mathbf{p}_1^1, \ldots, \mathbf{p}_{\mu_1}^1)$, i.e., $\mathbf{p}_1^1 = \mathbf{q}_0, \mathbf{p}_2^1 = \mathbf{q}_1, \ldots, \mathbf{p}_{\mu_1}^1 = \mathbf{q}_{j_2}$. If $\mathcal{F}_1 = \mathcal{B}_n^0$, we terminate the process. Otherwise, we choose $\mathbf{p}_1^2 \in \mathcal{B}_n^0 \backslash \mathcal{F}_1$ and the same process yields the second ordered system $\mathcal{F}_2 = (\mathbf{p}_1^2, \ldots, \mathbf{p}_{\mu_2}^2)$. Continue this process until all the elements in $\mathcal{B}_n^0$ are chosen. Then we arrive at a decomposition

$$\mathcal{B}_n^0 = \mathcal{F}_1 \cup \mathcal{F}_2 \cup \cdots \cup \mathcal{F}_r,$$

which has the following two properties:

(a) $\mathcal{F}_t \cap \mathcal{F}_{t'} = \emptyset$ if $t \ne t'$.

(b) The periodic extension $\mathcal{F}_t^p$ of $\mathcal{F}_t = (\mathbf{p}_1^t, \ldots, \mathbf{p}_{\mu_t}^t)$, defined by

$$\mathcal{F}_t^p = (\ldots \mathbf{p}_{-1}^t, \mathbf{p}_0^t, \mathbf{p}_1^t, \ldots, \mathbf{p}_{\mu_t}^t, \ldots) \quad \text{and} \quad \mathbf{p}_{\mu_t^+\nu}^t = \mathbf{p}_\nu^t \quad \text{for all } \nu \in \mathbb{Z},$$

satisfies $M\mathbf{p}_j^t \equiv \mathbf{p}_{j+1}^t (\mathrm{mod}\ n)$, where $t = 1, \dots, r$, $j \in \mathbb{Z}$.

We now decompose the family of functions

$$\mathcal{S}_\ell := \{\psi_{\ell,b/n;j,\mathbf{k}}(\mathbf{x})\colon\ 1 \le \ell \le L, \quad j \in \mathbb{Z}, \quad \mathbf{k} \in \mathbb{Z}^s\}$$

into n^s subsets as follows:

$$\mathcal{S}_\ell = \mathcal{S}_{\ell,0} \cup \bigcup_{t=1}^{r} \{\mathcal{S}_{\ell,1}^t \cup \cdots \cup \mathcal{S}_{\ell,\mu_t}^t\},$$

where

$$\mathcal{S}_{\ell,0} := \{\psi_{\ell,b;j,\mathbf{k}}(\mathbf{x})\colon\ 1 \le \ell \le L, \quad j \in \mathbb{Z}, \quad \mathbf{k} \in \mathbb{Z}^s\}$$

and

$$\mathcal{S}_{\ell,\mu}^t := \left\{ |\det M|^{j/2} \psi_\ell \left(M^j \mathbf{x} - \frac{b\mathbf{p}_{j+\mu}^t}{n} - \mathbf{k}b \right)\colon\ 1 \le \ell \le L, \quad j \in \mathbb{Z}, \quad \mathbf{k} \in \mathbb{Z}^s \right\},$$

where $\mu = 1, \dots, \mu_\ell$ and $t = 1, \dots, r$. By the definition of $\|T_b\|_*$ and $\|T_b\|^*$, we see that for any f with $\|f\| = 1$, we have

$$\|T_b\|_* \le \sum_{\ell=1}^{L} \sum_{g \in \mathcal{S}_{\ell,0}} |\langle f, g \rangle|^2 \le \|T_b\|^*. \tag{4.5}$$

4.2.2. Upper bound. Let $j_0 \in \mathbb{Z}$ and consider

$$\sigma_{\ell,j_0}^{\mu,t}(f) := \sum_{j \ge j_0} \sum_{\mathbf{k}} \left| \left\langle |\det M|^{j/2} \psi_\ell \left(M^j \cdot - \frac{\mathbf{p}_{j+\mu}^t b}{n} - \mathbf{k}b \right), f \right\rangle \right|^2,$$

where $\mu = 1, \dots, \mu_t$ and $t = 1, \dots, r$. If $j \ge j_0$, then since the property (b) implies that

$$M^{j-j_0} \mathbf{p}_{j_0+\mu}^t \equiv \mathbf{p}_{j+\mu}^t \quad (\mathrm{mod}\ n),$$

for any $\mathbf{k} \in \mathbb{Z}^s$, we have a unique $\mathbf{k'} \in \mathbb{Z}^s$ such that

$$M^j \mathbf{x} - \frac{b\mathbf{p}_{j+\mu}^t}{n} - \mathbf{k}b = M^j \left(\mathbf{x} - \frac{bM^{-j_0} \mathbf{p}_{j_0+\mu}^t}{n} \right) - \mathbf{k'}b.$$

Therefore, the two collections of functions $\{M^j \mathbf{x} - b\mathbf{p}_{j+\mu}^t/n - \mathbf{k}b\colon \mathbf{k} \in \mathbb{Z}^s\}$ and $\{M^j(\mathbf{x} - bM^{-j_0}\mathbf{p}_{j_0+\mu}^t/n) - \mathbf{k}b\colon\ \mathbf{k} \in \mathbb{Z}^s\}$ are identical. It then follows for any $f \in L^2$ with $\|f\| = 1$ that

$$\begin{aligned}
\sum_{\ell=1}^{L} \sigma_{\ell,j_0}^{\mu,t}(f) &= \sum_{\ell=1}^{L} \sum_{j \ge j_0} \sum_{k \in \mathbb{Z}^s} \left| \left\langle |\det M|^{j/2} \psi_\ell \left(M^j \left(\cdot - \frac{bM^{-j_0}\mathbf{p}_{j_0+\mu}^t}{n} \right) - \mathbf{k}b \right), f \right\rangle \right|^2 \\
&= \sum_{\ell=1}^{L} \sum_{j \ge j_0} \sum_{\mathbf{k} \in \mathbb{Z}^s} \left| \left\langle |\det M|^{j/2} \psi_\ell (M^j \cdot - \mathbf{k}), f \left(\cdot + \frac{bM^{-j_0}\mathbf{p}_{j_0+\mu}^t}{n} \right) \right\rangle \right|^2 \\
&\le \|T_b\|^*.
\end{aligned}$$

Thus we obtain

$$\sum_{\ell=1}^{L} \sum_{g\in\mathcal{S}^t_{\ell,\mu}} |\langle f, g\rangle|^2 = \lim_{j_0\to-\infty} \sum_{\ell=1}^{L} \sigma^{\mu,t}_{\ell,j_0}(f) \le \|T_b\|^*. \tag{4.6}$$

Combining (4.5) and (4.6), we arrive at

$$\begin{aligned}
&\sum_{\ell=1}^{L} \sum_{j\in\mathbf{Z}} \sum_{\mathbf{k}\in\mathbf{Z}^s} |\langle f, \psi_{b/n,\ell;j,\mathbf{k}}\rangle|^2 \\
&\qquad = \sum_{\ell=1}^{L} \sum_{g\in\mathcal{S}_{\ell,0}} |\langle f, g\rangle|^2 + \sum_{\ell=1}^{L} \sum_{t=1}^{\mu} \sum_{\mu=1}^{\mu_t} \sum_{g\in\mathcal{S}^t_{\ell,\mu}} |\langle f, g\rangle|^2 \\
&\qquad \le n^s \|T_b\|^*
\end{aligned}$$

for any $f \in L^2$ with $\|f\| = 1$. Therefore, we have $\|T_{b/n}\|^* \le \|T_b\|^*$.

4.2.3. Lower bound. To establish a lower-bound estimate for $\|T_{b/n}\|_*$, it is sufficient to restrict our attention to compactly supported and bounded functions f with $\|f\| = 1$. Suppose that supp $f \subset [-K, K]^s$, $K > 0$. Set

$$\theta^{\mu,t}_{\ell,j_0}(f) := \sum_{j<j_0} \sum_{\mathbf{k}\in\mathbf{Z}^s} |\langle |\det M|^{j/2} \psi_\ell(M^j \cdot -\mathbf{k}b), f^{\mu,t}_{j_0}\rangle|^2,$$

where

$$f^{\mu,t}_{j_0}(\mathbf{x}) := f\left(\mathbf{x} + \frac{bM^{-j_0}\mathbf{p}^t_{j_0+\mu}}{n}\right). \tag{4.7}$$

Then we have

$$\begin{aligned}
\sum_{\ell=1}^{L} \sum_{g\in\mathcal{S}^t_{\ell,\mu}} |\langle f, g\rangle|^2 &= \sum_{\ell=1}^{L} \sum_{j\in\mathbf{Z}} \sum_{\mathbf{k}\in\mathbf{Z}^s} \left|\left\langle |\det M|^{j/2} \psi_\ell\left(M^j \cdot - \frac{\mathbf{p}^t_{j+\mu} b}{n} - \mathbf{k}b\right), f\right\rangle\right|^2 \\
&\ge \sum_{\ell=1}^{L} \sigma^{\mu,t}_{\ell,j_0}(f) + \sum_{\ell=1}^{L} \theta^{\mu,t}_{\ell,j_0}(f) - \sum_{\ell=1}^{L} \theta^{\mu,t}_{\ell,j_0}(f) \qquad (4.8)\\
&\ge \|T\|_* - \sum_{\ell=1}^{L} \theta^{\mu,t}_{\ell,j_0}(f).
\end{aligned}$$

We claim that

$$\lim_{j_0\to-\infty} \theta^{\mu,t}_{\ell,j_0}(f) = 0. \tag{4.9}$$

To prove (4.9), we first observe that by (4.7), supp $f^{\mu,t}_0 \subset I^{\mu,t}_{j_0}$, where

$$I^{\mu,t}_{j_0} := \left[-K\mathbf{e} - \frac{bM^{-j_0}\mathbf{p}^t_{j_0+\mu}}{n}, K\mathbf{e} - \frac{bM^{-j_0}\mathbf{p}^t_{j_0+\mu}}{n}\right].$$

Hence by the Cauchy inequality, we see that

$$\begin{aligned}|\langle|\det M|^{j/2}\psi_\ell(M^j\cdot-\mathbf{k}),f_{j_0}^{\mu,t}\rangle|^2 &\le |\det M|^j(2K)^s\|f\|_\infty\int_{I_{j_0}^{\mu,t}}|\psi_\ell(M^j\mathbf{x}-\mathbf{k}b)|^2d\mathbf{x}\\ &=(2K)^s\|f\|_\infty\int_{M^j\left(I_{j_0}^{\mu,t}\right)}|\psi_\ell(\mathbf{x}-\mathbf{k}b)|^2d\mathbf{x}.\end{aligned}$$

Thus for any positive J_0, we have

$$\begin{aligned}\theta_{\ell,j_0}^{\mu,t}(f)\le{}&(2K)^s\|f\|_\infty\sum_{j_0-J_0\le j<j_0}\sum_{\mathbf{k}\in\mathbf{Z}^s}\int_{\mathbf{k}b+M^j\left(I_{j_0}^{\mu,t}\right)}|\psi_\ell(\mathbf{x})|^2d\mathbf{x}\\ &+(2K)^s\|f\|_\infty\sum_{j\le j_0-J_0}\sum_{\mathbf{k}\in\mathbf{Z}^s}\int_{\mathbf{k}b+M^j\left(I_{j_0}^{\mu,t}\right)}|\psi_\ell(\mathbf{x})|^2d\mathbf{x}.\end{aligned}$$

On the other hand, observe that for $\mathbf{k}\neq\mathbf{k}'$ and sufficiently small j and j', we have

$$\{\mathbf{k}b+M^j(I_{j_0}^{\mu,t})\}\cap\{\mathbf{k}'b+M^{j'}(I_{j_0}^{\mu,t})\}=\emptyset.$$

If $\mathbf{k}$ is fixed, then the function

$$\sum_{j\le j_0-J_0}\chi_{\mathbf{k}b+M^j\left(I_{j_0}^{\mu,t}\right)}(\mathbf{x})$$

is bounded and

$$\lim_{J_0\to\infty}\left|\bigcup_{j\le j_0-J_0}(\mathbf{k}b+M^j(I_{j_0}^{\mu,t}))\right|=0.$$

Therefore, for any $\varepsilon>0$, since $\psi_\ell\in L^2$, we may find some positive J_0 such that for all $J'\ge J_0$,

$$\theta_{\ell,j_0}^{\mu,t}(f)\le C_1(2K)^s\|f\|_\infty\sum_{j_0-J'\le j<j_0}\sum_{\mathbf{k}\in\mathbf{Z}^s}\int_{\mathbf{k}b+M^j\left(I_{j_0}^{\mu,t}\right)}|\psi_\ell(\mathbf{x})|^2d\mathbf{x}+\varepsilon. \tag{4.10}$$

Fix $J'\ge J_0$. Then taking the limit of the quantity on the right-hand side of (4.10) as $j_0\to-\infty$, we get

$$\overline{\lim_{j_0\to\infty}}\,\theta_{\ell,j_0}^{\mu,t}(f)\le\varepsilon.$$

This establishes the claim in (4.9). Now applying (4.5), (4.8), and (4.9), we obtain

$$\begin{aligned}&\sum_{\ell=1}^{L}\sum_{j\in\mathbf{Z}}\sum_{\mathbf{k}\in\mathbf{Z}^s}|\langle f,\psi_{\ell,b/n;j,\mathbf{k}}\rangle|^2\\ &\quad=\sum_{\ell=1}^{L}\sum_{g\in\mathcal{S}_{\ell,0}}|\langle f,g\rangle|^2+\sum_{\ell=1}^{L}\sum_{t=1}^{r}\sum_{\mu=1}^{\mu_t}\sum_{g\in\mathcal{S}_{\ell,\mu}^t}|\langle f,g\rangle|^2\ge n^s\|T_b\|_*.\end{aligned}$$

That is, we have

$$\|T_{b/n}\|_*\ge\|T_b\|_*.$$

This completes the proof of (1.16).

That (1.16) does not hold in general without the assumption (1.15) follows from Remark 2 in [3; p. 45]. □

5. Applications to wavelet analysis and a study of the boundedness of g-function operators. In this section, we give some applications of Theorems 1–3 to the analysis of wavelets and affine frames and study the boundedness of the Littlewood–Paley g-function operators. In particular, a characterization of stable matrix-dilated wavelet families is given, and the second oversampling theorem for the matrix-dilated setting is established.

5.1. Matrix-dilated wavelets. Let M be an $s \times s$ real matrix that satisfies (1.3). A family $\Psi = \{\psi_1, \dots, \psi_L\} \subset L^2$ is called a *stable matrix-dilated wavelet family relative to* M if there exist two positive numbers A and B such that

$$A\|f\|^2 \leq \sum_{\ell=1}^{L} \sum_{j} \|W_{\ell,j} f\|^2 \leq B\|f\|^2, \quad f \in L^2, \tag{5.1}$$

where $W_{\ell,j} f$ is defined by

$$(W_{\ell,j} f)(\mathbf{x}) := f * (|\det M|^j \psi_\ell(M^j \cdot))(\mathbf{x}). \tag{5.2}$$

We call the constants A and B wavelet *bounds*.

Denote by $\eta_\ell(\mathbf{x})$, $\ell = 1, \dots, L$, the functions determined by

$$\hat{\eta}_\ell(\mathbf{x}) := \frac{\widehat{\psi}_\ell(\mathbf{x})}{\sum\limits_{p=1}^{L} \sum\limits_{j \in \mathbf{Z}} |\widehat{\psi}_p((M^T)^j \mathbf{x})|^2}. \tag{5.3}$$

If Ψ is a stable matrix-dilated wavelet family relative to M, then any $f \in L^2$ has a decomposition

$$f(x) = \sum_{\ell=1}^{L} \sum_{j \in \mathbf{Z}} ((W_{\ell,j} f) * \bar{\eta}_{\ell,j}^{-})(\mathbf{x}),$$

where $(W_{\ell,j} f)(\mathbf{x})$ is the integral wavelet transform of f relative to Ψ as defined in (5.2), $\eta_{\ell,j}(\mathbf{x}) := |\det M|^j \eta_\ell(M^j \mathbf{x})$ with η_ℓ given by (5.3), and $g^-(\mathbf{x})$ denotes $g(-\mathbf{x})$. For the one- and two-dimensional settings with $M = (2)$ and $M = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 2 \end{smallmatrix}\right)$, respectively, this decomposition has been studied in the framework of signal analysis by Mallat and Zhong [5] (see also [4] and [6]). It is clear that (5.1) holds if and only if the corresponding Littlewood–Paley energy function (1.6) satisfies

$$A \leq L_\Psi(x) \leq B \quad \text{a.e.}$$

Therefore, using Theorem 1, we may establish the following characterization of stable matrix-dilated wavelet families.

PROPOSITION 1. *Let M be an $s \times s$ real matrix that satisfies* (1.3), *and assume that the family $\Psi = (\psi_1, \dots, \psi_L)$ satisfies* (1.11). *Then Ψ is a stable matrix-dilated wavelet family relative to M in the sense of* (5.1) *if and only if Ψ satisfies both of the following.*

(i) $\int \psi_\ell(\mathbf{x}) d\mathbf{x} = 0, \ell = 1, \dots, L$; *and*

(ii) $L_\Psi(\mathbf{x}) > 0$ *for any* $\mathbf{x} \in \Omega_J(M)$, *where* $\Omega_J(M)$ *is defined in* (2.2).

Indeed, by Theorem 1, we see that (i) is a necessary condition for Ψ to be a stable matrix-dilated wavelet family. It is also evident that (ii) is also a necessary condition. On the other hand, if Ψ satisfies (1.11), then by the proof of Theorem 1, we see that the series $\sum_{j\in\mathbb{Z}} |\widehat{\psi}_\ell((M^T)^j\mathbf{x})|^2$ is uniformly convergent to a continuous function on $\overline{\Omega_J(M)}$. Thus (i) and (ii) imply that Ψ is a stable matrix-dilated wavelet family.

As a consequence of this proposition, we have the following criterion on stable matrix-dilated wavelet families (see [2] for the one-variable setting).

Corollary 2. *Let M be an $s \times s$ real matrix that satisfies* (1.3) *and $\Psi = (\psi_1, \dots, \psi_L)$ be a family of functions that satisfy* (1.11) *and* (1.13). *If there exists some $j_0 \in \mathbb{Z}$ such that $\widehat{\psi}(\omega) \neq 0$ on the set*

$$(M^T)^{j_0 J}\overline{\Omega_J(M)} := \{\omega\colon\ (M^T)^{-j_0 J}\omega \in \overline{\Omega_J(M)}\},$$

where $\Omega_J(M)$ is defined in (2.2), *then Ψ is a stable matrix-dilated wavelet family relative to M.*

Recall that a family (1.2) is called a *frame* with frame bounds A and B, $0 < A \leq B$, if

$$A\|f\|^2 \leq \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z},\mathbf{k}\in\mathbb{Z}^s} |\langle f, \psi_{\ell,b;j,\mathbf{k}}\rangle|^2 \leq B\|f\|^2, \quad f \in L^2. \tag{5.4}$$

If $A = B$ in (5.4), then the family (1.2) is called a *tight frame.*

By Theorems 1 and 2, we may establish the following.

Proposition 2. *Let $M = \lambda U$, where $\lambda > 1$ and U is an $s \times s$ unitary matrix. If the family* (1.2) *constitutes a frame with frame bounds A and B, then Ψ is a stable matrix-dilated wavelet family relative to M with wavelet frame bounds A and B.*

Conversely, if ψ_ℓ, $\ell = 1, \dots, L$, satisfy the condition in Corollary 1 *and Ψ is a matrix-dilated wavelet family relative to M with bounds A and B, then* (1.2) *constitutes a frame with bounds A and B.*

For the univariate setting, the first statement of this result was established in our earlier work [1].

5.2. Oversampling for frames. As a consequence Theorem 3, we have the following so-called second oversampling theorem for frames.

Proposition 3. *Let all the entries of M be integers and the condition* (1.3) *be satisfied. If the family* (1.2) *constitutes a frame with frame bounds A and B and n is a natural number that satisfies* (1.15), *then the family*

$$\{n^{-s/2}\psi_{\ell,b/n;j,\mathbf{k}}(\mathbf{x})\colon\ 1 \leq \ell \leq L, \quad j \in \mathbb{Z}, \quad \mathbf{k} \in \mathbb{Z}^s\} \tag{5.5}$$

also constitutes a frame with the same bounds. However, this conclusion does not hold in general without assumption (1.13).

This is a generalization of Theorem 4 in [3]. From this proposition, we see that if M and n satisfy the assumptions in Proposition 3 and the family (1.2) constitutes a tight frame, then the family (5.5) is a tight frame as well.

5.3. Boundedness of g-function operators. Let ψ be any square-integrable function on $\mathbb{R}^s$ with $\int \psi = 0$ and set $\psi_t(\mathbf{x}) := t^{-s}\psi(\mathbf{x}/t)$. Then the operator

$$g(f)(\mathbf{x}) := \left(\int_0^\infty |\psi_t * f(\mathbf{x})|^2 \frac{dt}{t}\right)^{1/2} \tag{5.6}$$

is called a *Littlewood–Paley g-function operator* associated with ψ. It is clear that

$$\begin{aligned}\int |g(f)(\mathbf{x})|^2 d\mathbf{x} &= \frac{1}{(2\pi)^s}\int_0^\infty \frac{dt}{t}\int_{\mathbb{R}^s} |\widehat{\psi}_t(\mathbf{x})\widehat{f}(\mathbf{x})|^2 d\mathbf{x} \\ &= \frac{1}{(2\pi)^s}\int_{\mathbb{R}^s} |\widehat{f}(\mathbf{x})|^2 \left(\sum_{j\in\mathbb{Z}}\int_{2^j}^{2^{j+1}} \frac{dt}{t}|\widehat{\psi}(t\mathbf{x})|^2\right) d\mathbf{x}.\end{aligned}$$

Hence we have

$$\int |g(f)(\mathbf{x})|^2 d\mathbf{x} \le \frac{1}{(2\pi)^s}\int_{\mathbb{R}^s} |\widehat{f}(\mathbf{x})|^2 \int_1^2 \sum_{j\in\mathbb{Z}} |\widehat{\psi}(2^{-j}t\mathbf{x})|^2 dt d\mathbf{x} \le 2\int |g(f)(\mathbf{x})|^2 d\mathbf{x}.$$

and this yield the following result.

Proposition 4. *The g-function operator* (5.6) *is bounded in L^2 if and only if the corresponding Littlewood–Paley energy function*

$$L_\psi(\mathbf{x}) := \sum_{j\in\mathbb{Z}} |\widehat{\psi}(2^j\mathbf{x})|^2$$

satisfies $\int_1^2 L_\psi(t\mathbf{x})dt \in L^\infty$.

By combining this result and Theorem 1, we obtain the following.

Proposition 5. *Let Φ be a nonincreasing function on* $[0,\infty)$ *that satisfies* (1.9) *and ψ satisfies $\int \psi = 0$ and $|\psi(\mathbf{x})| \le \Phi(|\mathbf{x}|)$, $\mathbf{x} \in \mathbb{R}^s$. Then the g-function operator associated with ψ is bounded in L^2.*

A MULTIVARIATE FORM OF HARDY'S INEQUALITY AND L_p-ERROR BOUNDS FOR MULTIVARIATE LAGRANGE INTERPOLATION SCHEMES*

SHAYNE WALDRON[†]

Abstract. The *multivariate* generalization of *Hardy's inequality*—that for $m - n/p > 0$,

$$(*) \qquad \left\| x \mapsto \int_{[\underbrace{x,\ldots,x}_{m},\Theta]} f \right\|_p \le \frac{\|f\|_p}{(m-1)!(m-n/p)_{\#\Theta}},$$

valid for $f \in L_p(\mathbb{R}^n)$ and Θ an arbitrary finite sequence of points in $\mathbb{R}^n$—is discussed.

The linear functional $f \mapsto \int_\Theta f$ was introduced by Micchelli in connection with Kergin interpolation. This functional also naturally occurs in other multivariate generalizations of Lagrange interpolation, including *Hakopian interpolation* and the *Lagrange maps* of section 5. For each of these schemes, $(*)$ implies L_p-error bounds.

We discuss why $(*)$ plays a crucial role in obtaining L_p-bounds from pointwise integral error formulas for multivariate generalizations of Lagrange interpolation.

1. Introduction.

1.1. Overview. The central result of this paper is the following inequality: for $m - n/p > 0$,

$$(1.1.1) \quad \left\| x \mapsto \int_{[\underbrace{x,\ldots,x}_{m},\Theta]} f \right\|_{L_p(\Omega)} \le \frac{1}{(m-1)!(m-n/p)_{\#\Theta}} \|f\|_{L_p(\Omega)}, \quad \forall f \in L_p(\Omega),$$

where the functional $\int_{[x,\cdots,x,\Theta]}$ is defined in Definition 2.1.1, Θ is a finite sequence of points in $\mathbb{R}^n$, and Ω is a suitable domain in $\mathbb{R}^n$. This inequality is a *multivariate* generalization of *Hardy's inequality*—that for $p > 1$,

$$(1.1.2) \qquad \left\| x \mapsto \frac{1}{x}\int_0^x f \right\|_{L_p(0,\infty)} \le \frac{p}{p-1} \|f\|_{L_p(0,\infty)}, \quad \forall f \in L_p(0,\infty).$$

Thus, we will refer to (1.1.1) as the *multivariate form of Hardy's inequality.*

*Received by the editors October 11, 1994; accepted for publication (in revised form) October 10, 1995. This work was supported by the Chebyshev professorship of Carl de Boor and was completed while at the Center for the Mathematical Sciences at the University of Wisconsin–Madison.

Our interest in (1.1.1) comes from a desire to obtain L_p-bounds from the many integral error formulas for *multivariate* generalizations of Lagrange interpolation that involve the linear functional

$$f \mapsto \int_{[\underbrace{x,\ldots,x}_{m},\Theta]} f. \tag{1.1.3}$$

The paper is structured in the following way. In the remainder of this section, the notation that we will use and the facts about Sobolev spaces that we will need are discussed. In section 2, some properties of the linear functional $f \mapsto \int_\Theta f$, and its connection with simplex splines, are given. In section 3, the multivariate form of Hardy's inequality is proved. In section 4, the multivariate form of Hardy's inequality is applied to obtain L_p-bounds for the error in the scale of mean value interpolations, which includes Kergin and Hakopian interpolation. In section 5, in a similar vein, L_p-bounds for the error in *Lagrange maps* are obtained. In section 6, we discuss why the multivariate form of Hardy's inequality is applicable to the many error formulas for multivariate Lagrange interpolation schemes and is likely to be so for others yet to be obtained.

1.2. Some notation. The discussion takes place in $\mathbb{R}^n$ with the following definitions holding throughout. The space of n-variate polynomials of degree k will be denoted by $\Pi_k(\mathbb{R}^n)$, and the space of homogeneous polynomials of degree k will be denoted by $\Pi_k^0(\mathbb{R}^n)$. The differential operator induced by $q \in \Pi_k(\mathbb{R}^n)$ will be written $q(D)$. Let $\|\cdot\|$ be the *Euclidean norm* on $\mathbb{R}^n$, and let $\Omega \subset \mathbb{R}^n$, with $\bar{\Omega}$ its closure. The letters i, j, k, l, m, n will be reserved for integers, and $1 \le p \le \infty$. We use standard multivariate notation, so, e.g., $\{\alpha : |\alpha| = k\}$ is the set of multiindices α of length k.

We find it convenient to make no distinction between the matrix $[\theta_1, \ldots, \theta_k]$ and the *k-sequence* $\theta_1, \ldots, \theta_k$ of its columns. Since $[\theta_1, \ldots, \theta_k]f$ is a standard notation for the *divided difference* of f at $\Theta = [\theta_1, \ldots, \theta_k]$, we use for the latter the nonstandard notation

$$\delta_\Theta f = \delta_{[\theta_1,\ldots,\theta_k]} f.$$

Note the special case

$$\delta_{[x]} f = f(x).$$

Similarly, to avoid any confusion, the closed interval with endpoints a and b will be denoted by $[a \,..\, b]$.

The derivative of f in the directions Θ is denoted

$$D_\Theta f := D_{\theta_1} \cdots D_{\theta_k} f.$$

The notation $\tilde{\Theta} \subset \Theta$ means that $\tilde{\Theta}$ is a subsequence of Θ, and $\Theta \backslash \tilde{\Theta}$ denotes the complementary subsequence. The subsequence consisting of the first j terms of Θ is denoted Θ_j, and

$$x - \Theta := [x - \theta_1, \ldots, x - \theta_k].$$

Thus, with $\Theta := [\theta_1, \ldots, \theta_7]$, we have, for example, that

$$D_{[x-\Theta\backslash\Theta_5, x-\theta_3]} f = D_{x-\theta_6} D_{x-\theta_7} D_{x-\theta_3} f.$$

The diameter and convex hull of a sequence Θ will be that of the corresponding set and will be denoted by $\operatorname{diam}\Theta$ and $\operatorname{conv}\Theta$, respectively.

Many of the constants in this paper involve the *shifted factorial function*

$$(a)_n := (a)(a+1)(a+2)\cdots(a+n-1) = \frac{\Gamma(a+n)}{\Gamma(a)}, \tag{1.2.1}$$

where Γ is the *gamma function.* The gamma function satisfies the relation

$$\Gamma(a+1) = a\Gamma(a), \quad \forall a > 0,$$

and has $\Gamma(1) = 1$. In particular,

$$\Gamma(n+1) = n!, \quad n = 0, 1, 2, \ldots. \tag{1.2.2}$$

Some of our calculations require the *beta integrals*

$$\int_0^1 t^{a-1}(1-t)^{b-1}\,dt = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}, \qquad a, b > 0, \tag{1.2.3}$$

and the *hypergeometric function*

$${}_2F_1\left({a, b \atop c}; x\right) := \sum_{n=0}^{\infty} \frac{(a)_n(b)_n}{n!(c)_n} x^n. \tag{1.2.4}$$

The standard reference to these is the monograph [E53].

1.3. Geometry of the domain Ω. We say that $\Omega \subset \mathbb{R}^n$ is *star-shaped with respect to S*, a set (resp. sequence) in $\mathbb{R}^n$, when Ω contains the convex hull of $S \cup \{x\}$ for any $x \in \Omega$. This condition is weaker than Ω being convex.

In our results, it will be required that $\bar{\Omega}$ be star-shaped with respect to $\Theta \in \mathbb{R}^{n\times k}$, where Ω is an open set in $\mathbb{R}^n$. This condition is required of $\bar{\Omega}$, rather than of Ω, so as to include cases where some points in Θ lie on the boundary of Ω. (See Figure 1.1.) One such example of interest is the *Lagrange* finite element given by linear interpolation at Θ, the vertices of a n-simplex; see, e.g., Ciarlet [Ci78, p. 46]. In this case, $\bar{\Omega} = \operatorname{conv}\Theta$, and none of the points of Θ are in the open simplex Ω.

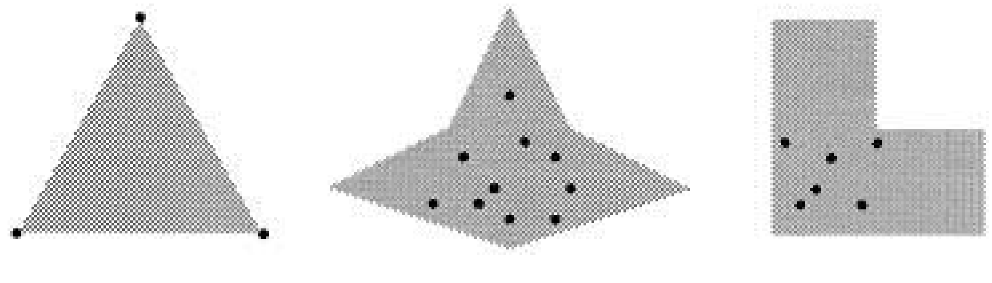

FIG. 1.1. *Examples of domains Ω (shaded) for which $\bar{\Omega}$ is star-shaped with respect to the points in Θ ($\bullet$).*

We now show that being star-shaped with respect to a finite sequence is equivalent to being star-shaped with respect to its convex hull.

PROPOSITION 1.3.1. *If* $\Omega \subset \mathbb{R}^n$ *and* $\Theta \in \mathbb{R}^{n\times k}$*, then the following are equivalent:*

(a) Ω *is star-shaped with respect to* Θ*.*

(b) Ω *is star-shaped with respect to* $\operatorname{conv}\Theta$*.*

Proof. (See Figure 1.2.) Only the implication (a) $\Longrightarrow$ (b) requires proof. Suppose (a). To obtain (b), it suffices to prove that if Ω is star-shaped with respect to points u and v, then $\operatorname{conv}\{u,v,x\} \subset \Omega$, $\forall x \in \Omega$, i.e., Ω is star-shaped with respect to $\operatorname{conv}\{u,v\}$.

Assume without loss of generality that u, v, x are affinely independent, and $z \in \operatorname{conv}\{u,v,x\}$. Let w be the point of intersection of the line through u and z with the interval $\operatorname{conv}\{x,v\}$. Since Ω is star-shaped with respect to v, we have that $w \in \Omega$. Thus, since Ω is star-shaped with respect to u, we have that $z \in \operatorname{conv}\{u,w\} \subset \Omega$. □

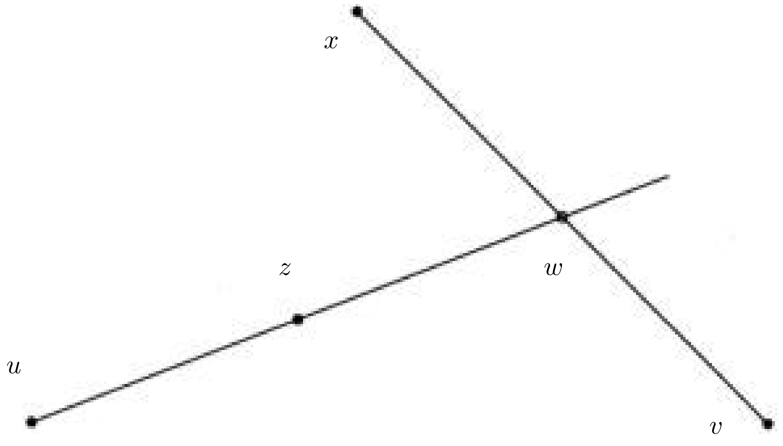

FIG. 1.2. *The proof of Proposition* 1.3.1.

This equivalence ensures that if $\bar{\Omega}$ is star-shaped with respect to Θ, then $f \in L_p(\Omega)$ is defined over the region of integration in (1.1.3) for all $x \in \Omega$.

1.4. Sobolev spaces. Let $W_p^{(k)}(\Omega)$ be the *Sobolev space* consisting of those functions defined on Ω (a bounded open set in $\mathbb{R}^n$ with a *Lipschitz* boundary) with derivatives up to order k in $L_p(\Omega)$, and equipped with the usual topology; see, e.g., Adams [Ad75]. It is convenient to include in the definition the condition that Ω have a Lipschitz boundary so that Sobolev's embedding theorem can be applied. The full statement of Sobolev's embedding theorem can be found in any text on Sobolev spaces, see, e.g., [Ad75, p. 97]; however, we will need only the following consequence of it. If $j - n/p > 0$, then

$$W_p^{(k+j)}(\Omega) \subset C^k(\bar{\Omega}).$$

To measure the size of its kth derivative, it is convenient to associate with each $f \in W_p^{(k)}(\Omega)$ the function $|D^k f| \in L_p(\Omega)$, given by the rule

$$|D^k f|(x) := \sup_{\substack{\Theta\in\mathbb{R}^{n\times k}\\ \|\theta_i\|\le 1}} |D_\Theta f(x)| = \sup_{\substack{\theta\in\mathbb{R}^n\\ \|\theta\|=1}} |D_\theta^k f(x)|, \tag{1.4.1}$$

where the derivatives $D_\Theta f$ are computed from any (fixed) choice of representatives for the partial derivatives $D^\alpha f \in L_p(\Omega)$, $|\alpha| = k$. The equality of the two suprema follows from a classical result of Banach on the norm of a symmetric multilinear map (cf. Harris [Har96]). It is also proved in Chen and Ditzian [CD90]. This definition of $|D^k f|$ is consistent with its standard univariate interpretation. From (1.4.1), it is easy to see that $|D^k f|$ is well defined and satisfies

$$|D_\Theta f| \le |D^k f| \, \|\theta_1\| \cdots \|\theta_k\| \tag{1.4.2}$$

for all $\Theta \in \mathrm{I\!R}^{n\times k}$. The inequality (1.4.2) holds a.e. To emphasize that $D_\Theta f$ and $|D^k f|$ are in $L_p(\Omega)$, we will say that (1.4.2) holds in $L_p(\Omega)$. The $L_p(\Omega)$-norm of $|D^k f|$ gives a seminorm for $f \in W_p^{(k)}(\Omega)$,

$$f \mapsto \big|f\big|_{k,p,\Omega} := \| \, |D^k f| \, \|_{L_p(\Omega)}. \tag{1.4.3}$$

Because of (1.4.2), this coordinate-independent seminorm (1.4.3) is more appropriate for the analysis that follows than other equivalent seminorms, such as

$$f \mapsto \| \, (\|D^\alpha f\|_{L_p(\Omega)} : |\alpha| = k) \, \|_p.$$

2. The linear functional $f \mapsto \int_\Theta f$.

2.1. Definitions. The construction of the maps of Kergin and Hakopian depends intimately on the following linear functional, called the *divided difference functional on* $\mathrm{I\!R}^n$ by Micchelli in [M79], and analyzed there and in [M80].

Definition 2.1.1. *For any $\Theta \in \mathrm{I\!R}^{n\times(k+1)}$, let*

$$f \mapsto \int_\Theta f := \int_0^1 \int_0^{s_1} \cdots \int_0^{s_{k-1}} f(\theta_0 + s_1(\theta_1 - \theta_0) + \cdots + s_k(\theta_k - \theta_{k-1})) \, ds_k \cdots ds_2 \, ds_1$$

with the convention that $\int_{[]} f := 0$.

In addition to Kergin and Hakopian interpolation, the linear functional $f \mapsto \int_\Theta f$ also occurs when discussing other *multivariate* generalizations of Lagrange interpolation, e.g., the *Lagrange maps* of section 5. It was used as early as 1878, when in [Ge1878], Genocchi proved the *Hermite–Genocchi formula*, namely, that for $\Theta \in \mathrm{I\!R}^{1\times(k+1)}$ and $f \in C^k(\mathrm{conv}\,\Theta)$,

$$\delta_\Theta f = \int_\Theta D^k f.$$

In this section, we outline those properties of $f \mapsto \int_\Theta f$ needed in the subsequent sections. Many of these properties are apparent from the following observation.

Observation 2.1.2. *If S is any k-simplex in $\mathrm{I\!R}^m$ and $A : \mathrm{I\!R}^m \to \mathrm{I\!R}^n$ is any affine map taking the $k+1$ vertices of S onto the $k+1$ points in Θ, then*

$$\int_\Theta f = \frac{1}{k! \, \mathrm{vol}_k(S)} \int_S f \circ A,$$

with $\mathrm{vol}_k(S)$ *the* (k*-dimensional*) *volume of* S.

With the choice

$$A : \mathbb{R}^k \to \mathbb{R}^n : (s_1, \dots, s_k) \mapsto \theta_0 + s_1(\theta_1 - \theta_0) + \cdots + s_k(\theta_k - \theta_{k-1}),$$

$$S := \{(s_1, \dots, s_k) \in \mathbb{R}^k : 0 \le s_k \le \cdots \le s_2 \le s_1 \le 1\},$$

this is simply Definition 2.1.1. The different choice

$$A : \mathbb{R}^{k+1} \to \mathbb{R}^n : (v_0, \dots, v_k) \mapsto v_0\theta_0 + \cdots + v_k\theta_k,$$

$$S := \left\{(v_0, \dots, v_k) \in \mathbb{R}^{k+1} : v_j \ge 0,\ \sum_{j=0}^{k} v_j = 1\right\}$$

shows that our definition of $\int_\Theta f$ coincides with the one used by Micchelli in [M80].

Properties 2.1.3.

(a) *The value of* $\int_\Theta f$ *does not depend on the ordering of the points in* Θ*.*

(b) *The distribution*

$$M_\Theta : C_0^\infty(\mathbb{R}^n) \to \mathbb{R} : f \mapsto k! \int_\Theta f$$

is the (normalized) simplex spline with knots Θ (*cf.* [M80])*.*

(c) *If* $f \in C(\operatorname{conv}\Theta)$*, then* $\int_\Theta f$ *is defined, and for some* $\xi \in \operatorname{conv}\Theta$*,*

$$\int_\Theta f = \frac{1}{k!} f(\xi).$$

(d) *If* $g : \mathbb{R}^s \to \mathbb{R}$ *and if* $B : \mathbb{R}^n \to \mathbb{R}^s$ *is an affine map, then*

$$\int_\Theta (g \circ B) = \int_{B\Theta} g.$$

Remark 2.1.4. Let $A|$ denote the restriction of A to the orthogonal complement of its kernel, which is a 1–1 map onto the affine hull of Θ. The simplex spline M_Θ of (b) has support $\operatorname{conv}\Theta$. It can be represented by the nonnegative bounded function

$$\operatorname{conv}\Theta \to \mathbb{R} : t \mapsto M(t|\Theta) := \frac{\operatorname{vol}_{k-d}(A^{-1}t \cap S)}{|\det(A|)| \operatorname{vol}_k(S)}, \quad d := \dim \operatorname{conv}\Theta,$$

in the sense that

$$M_\Theta f = \int_{\operatorname{conv}\Theta} M(\cdot|\Theta) f. \tag{2.1.5}$$

In particular, if the points of Θ are affinely independent, then

$$k! \int_\Theta f = \frac{1}{\operatorname{vol}_k(\operatorname{conv}\Theta)} \int_{\operatorname{conv}\Theta} f = \text{average value of } f \text{ on } \operatorname{conv}\Theta. \tag{2.1.6}$$

Thus $\int_\Theta f$ is defined (as a real number) if and only if $M(\cdot|\Theta) f \in L_1(\operatorname{conv}\Theta)$, in which case

$$\left|\int_\Theta f\right| \le \int_\Theta |f|. \tag{2.1.7}$$

If f is nonnegative on $\operatorname{conv}\Theta$, then $\int_\Theta f \in [0\mathinner{..}\infty]$ is defined (by Definition 2.1.1). Therefore, we will write (2.1.7) for all f which are defined on $\operatorname{conv}\Theta$—with the understanding that $\int_\Theta f$ is defined if and only if $\int_\Theta |f| < \infty$ or f is nonnegative. In the univariate case, that is, when $n = 1$, $M(\cdot|\Theta)$ is the (*normalized*) *B-spline* with knots Θ. For additional details about M_Θ and $M(\cdot|\Theta)$, see, e.g., Micchelli [M79].

Example 2.1.8. As a special case of (2.1.5), we have

$$\int_{[\underbrace{0,\dots,0}_{m},\ \underbrace{1,\dots,1}_{k+1-m}]} f = \frac{1}{(m-1)!(k-m)!}\int_0^1 t^{k-m}(1-t)^{m-1} f(t)\,dt.$$

Thus, by Property 2.1.3(d) with $B : t \mapsto x + t(v-x)$ and $\Theta = [0,\dots,0,1,\dots,1]$,

$$\begin{aligned}\int_{[\underbrace{x,\dots,x}_{m},\ \underbrace{v,\dots,v}_{k+1-m}]} f &= \int_{[\underbrace{0,\dots,0}_{m},\ \underbrace{1,\dots,1}_{k+1-m}]} f(x+\cdot(v-x)) \\ &= \frac{1}{(m-1)!(k-m)!}\int_0^1 t^{k-m}(1-t)^{m-1} f(x+t(v-x))\,dt.\end{aligned} \tag{2.1.9}$$

2.2. Some technical details.

Remark 2.2.1. In view of Properties 2.1.3(a),

$$\Theta \mapsto \int_\Theta f$$

could be thought of as a map defined on finite multisets in $\mathbb{R}^n$ rather than on sequences. However, adopting this definition leads to certain unnecessary complications. For example, to discuss the continuity of $\Theta \mapsto \int_\Theta f$, it would be necessary to endow the set of multisets of $k+1$ points in $\mathbb{R}^n$ with the appropriate topology. Thus, in the interest of simplicity, $\Theta \mapsto \int_\Theta f$ remains a map on sequences—but with the reader encouraged to think of it, as does the author, as a map on multisets.

Finally, by (2.1.5), we can describe the continuity of $\Theta \mapsto \int_\Theta f$ as follows.

PROPOSITION 2.2.2.

(a) *For $f \in C(\mathbb{R}^n)$, the map*

$$\mathbb{R}^{n\times(k+1)} \to \mathbb{R} : \Theta \mapsto \int_\Theta f$$

is continuous.

(b) *For $f \in L_1^{\mathrm{loc}}(\mathbb{R}^n)$, the map*

$$\{\Theta \in \mathbb{R}^{n\times(k+1)} : \operatorname{vol}_n(\operatorname{conv}\Theta) > 0\} \to \mathbb{R} : \Theta \mapsto \int_\Theta f$$

is continuous.

3. The main results: The multivariate form of Hardy's inequality and L_p-inequalities.

In this section, we prove the multivariate form of Hardy's inequality. This inequality is useful for obtaining L_p-bounds from integral error formulas for various multivariate interpolation schemes.

First, we need a technical lemma.

3.1. A lemma.

LEMMA 3.1.1. *Let m, k, be integers, and $\mu \in \mathbb{R}$. If $1 \le m \le k$ and $m+\mu > 0$, then*

$$\int_0^1 \int_0^{s_1} \cdots \int_0^{s_{k-1}} (1-s_m)^\mu \, ds_k \cdots ds_1 = \frac{1}{(m-1)!(m+\mu)_{k+1-m}}.$$

Proof. This can be proved by successively evaluating the univariate integrals. Instead, a proof using the properties of $f \mapsto \int_\Theta f$ is given.

From Definition 2.1.1, it is seen that

$$\int_0^1 \int_0^{s_1} \cdots \int_0^{s_{k-1}} (1-s_m)^\mu \, ds_k \cdots ds_1 = \int_\Theta (\cdot)^\mu,$$

where

$$\Theta := [\underbrace{1,\ldots,1}_{m}, \underbrace{0,\ldots,0}_{k+1-m}].$$

By (2.1.9), (1.2.3), and (1.2.2), it follows that

$$\begin{aligned} \int_\Theta (\cdot)^\mu &= \frac{1}{(m-1)!(k-m)!} \int_0^1 t^{k-m}(1-t)^{m-1}(1-t)^\mu \, dt \\ &= \frac{1}{(m-1)!(k-m)!} \frac{\Gamma(k-m+1)\Gamma(m+\mu)}{\Gamma(k+1+\mu)} \\ &= \frac{1}{(m-1)!(m+\mu)_{k+1-m}}. \end{aligned}$$

Here the condition that $m+\mu > 0$ is needed to ensure that the beta integral is finite. □

3.2. The multivariate form of Hardy's inequality. We now prove the multivariate form of Hardy's inequality.

THEOREM 3.2.1. *Let Θ be a nonempty finite sequence in $\mathbb{R}^n$, and let Ω be an open set in $\mathbb{R}^n$ for which $\bar{\Omega}$ is star-shaped with respect to Θ. If $m - n/p > 0$, then the rule*

$$H_{m,\Theta} f(x) := \int_{[\underbrace{x,\ldots,x}_{m},\Theta]} f \tag{3.2.2}$$

induces a positive bounded linear map $H_{m,\Theta} : L_p(\Omega) \to L_p(\Omega)$ with norm

$$\|H_{m,\Theta}\|_{L_p(\Omega)} \le \frac{1}{(m-1)!(m-n/p)_{\#\Theta}} \to \infty \qquad \text{as } m - n/p \to 0^+. \tag{3.2.3}$$

This upper bound for $\|H_{m,\Theta}\|_{L_p(\Omega)}$ is sharp when Θ involves only one point, i.e., when

$$\Theta = [v, \ldots, v],$$

and is also sharp when $p = \infty$. Furthermore, if $\Omega \subset \Omega'$, then

$$\|H_{m,\Theta}\|_{L_p(\Omega)} \le \|H_{m,\Theta}\|_{L_p(\Omega')}. \tag{3.2.4}$$

Proof. Suppose that $m - n/p > 0$. Then $m > 0$. Let $k+1 := m + \#\Theta$, and write

$$[\underbrace{x,\ldots,x}_{m},\Theta] =: [\underbrace{x,\ldots,x}_{m},\theta_m,\theta_{m+1},\ldots,\theta_k].$$

By Definition 2.1.1,

$$H_{m,\Theta}f(x) = \int_S f(A_x s)\,ds, \tag{3.2.5}$$

where $s := (s_1,\ldots,s_k)$,

$$\int_S := \int_0^1 \int_0^{s_1} \cdots \int_0^{s_{k-1}}, \qquad ds := ds_k \cdots ds_1,$$

and

$$A_x s := x + s_m(\theta_m - x) + s_{m+1}(\theta_{m+1} - \theta_m) + \cdots + s_k(\theta_k - \theta_{k-1}).$$

The domain of integration for f in (3.2.5) is $\operatorname{conv}[x,\Theta]$, which by Proposition 1.3.1 is contained (up to a set of measure zero) in Ω for any $x \in \Omega$. However, for $f \in L_p(\Omega)$, it is not clear whether the integrals in (3.2.5) converge so as to define a function $H_{m,\Theta}f$ which is in $L_p(\Omega)$ (or is even measurable for that matter).

First, suppose that f is a *nonnegative measurable function.* Then (3.2.5) defines a nonnegative measurable function $H_{m,\Theta}f$, as is now shown. The nonnegativity of $H_{m,\Theta}f$, i.e., the positiveness of the map $H_{m,\Theta}$, is obvious, and the measurability of $H_{m,\Theta}f$ is a consequence of Tonelli's theorem (see, e.g., Folland [Fo84, p. 65]) as follows.

First, we prove that the map

$$(x,s) \mapsto f(A_x s) \tag{3.2.6}$$

is measurable. Since f is measurable, the measurability of (3.2.6) is equivalent to $A^{-1}(E)$ being measurable for each $E \in \mathcal{E}$, where

$$A : (x,s) \mapsto A_x s,$$

and $\mathcal{E}$ is any family of sets that generates the Lebesgue σ-algebra. Take $\mathcal{E}$ as the Borel sets together with all the subsets F of any Borel set B of measure zero. Since A is continuous, the inverse image under A of a Borel set is a Borel set (which is measurable). For $F \subset B$, $A^{-1}(F)$ is contained within the Borel set $A^{-1}(B)$, which has zero measure (see below), and hence is measurable. For $s_m \neq 1$, the set

$$\{x : A_x s \in B\} = \frac{1}{1-s_m}(B - s_m\theta_m - s_{m+1}(\theta_{m+1}-\theta_m) - \cdots - s_k(\theta_k - \theta_{k-1})),$$

hence has zero measure, and so, by Tonelli's theorem,

$$\operatorname{meas}(A^{-1}(B)) = \int_S \operatorname{meas}(\{x : A_x s \in B\})\,ds = 0.$$

This completes the proof of the measurability of (3.2.6). Since (3.2.6) is a nonnegative measurable function, it follows from Tonelli's theorem that

$$H_{m,\Theta} : x \mapsto \int_S f(A_x s)$$

is measurable.

Apply Minkowski's inequality for integrals (see, e.g., Folland [Fo84, p. 186]) to the sum (integral) $\int_S$ of functions $x \mapsto f(A_x s)$ to obtain

$$\|H_{m,\Theta} f\|_{L_p(\Omega)} \le \int_S \|x \mapsto f(A_x s)\|_{L_p(\Omega)}\, ds. \tag{3.2.7}$$

The case where $1 \le p < \infty$. Inequality (3.2.7) can be written as

$$\|H_{m,\Theta} f\|_{L_p(\Omega)} \le \int_S \left(\int_\Omega f(A_x s)^p \, dx \right)^{1/p} ds.$$

Make the change of variables

$$y = A_x s$$

in the inner integral above. The new region of integration is contained in Ω, and $dy = (1 - s_m)^n dx$. Thus, by the change of variables formula (see, e.g., Rudin [Ru87, p. 153]), it follows that

$$\begin{aligned} \int_S \left(\int_\Omega f(A_x s)^p \, dx \right)^{1/p} ds &\le \int_S \left(\int_\Omega \frac{f(y)^p \, dy}{(1 - s_m)^n} \right)^{1/p} ds \\ &= \left(\int_S (1 - s_m)^{-n/p} \, ds \right) \|f\|_{L_p(\Omega)}. \end{aligned}$$

From Lemma 3.1.1 with $k + 1 - m = \#\Theta$ and $\mu = -n/p$, it follows that

$$\int_S (1 - s_m)^{-n/p} \, ds = \frac{1}{(m-1)!(m - n/p)_{\#\Theta}}. \tag{3.2.8}$$

The case where $p = \infty$. Since $x \mapsto A_x s$ maps sets of measure zero to sets of measure zero, it follows from (3.2.7) that

$$\|H_{m,\Theta} f\|_{L_\infty(\Omega)} \le \int_S \|f\|_{L_\infty(\Omega)} \, ds = \frac{1}{k!} \|f\|_{L_\infty(\Omega)} \tag{3.2.9}$$

with equality when f is constant. The fact that

$$\int_S ds = \frac{1}{k!},$$

used above, follows from Observation 2.1.2 or from Lemma 3.1.1 with $\mu = 0$.

So far, it has been shown that for a nonnegative measurable f, (3.2.2) defines a nonnegative measurable function which satisfies

$$\|H_{m,\Theta} f\|_{L_p(\Omega)} \le \frac{1}{(m-1)!(m - n/p)_{\#\Theta}} \|f\|_{L_p(\Omega)}. \tag{3.2.10}$$

In view of this inequality, $H_{m,\Theta}$ induces a map from the nonnegative functions in $L_p(\Omega)$ to $L_p(\Omega)$. Each $f \in L_p(\Omega)$ can be written as

$$f = f^+ - f^-,$$

a difference of nonnegative functions in $L_p(\Omega)$ (its *positive* and *negative parts*), and so (due to its linearity) $H_{m,\Theta}$ induces a map on $L_p(\Omega)$, also denoted by $H_{m,\Theta}$. Since

$$\|H_{m,\Theta}f\|_{L_p(\Omega)} \le \|H_{m,\Theta}(|f|)\|_{L_p(\Omega)}, \quad \forall f \in L_p(\Omega),$$

inequality (3.2.10) holds for all $f \in L_p(\Omega)$, which gives (3.2.3).

Next, (3.2.4) is shown. Since the restriction map

$$L_p(\Omega') \to L_p(\Omega) : f \mapsto f|_\Omega$$

is onto and $(H_{m,\Theta}f)|_\Omega$ depends only on $f|_\Omega$,

$$\begin{aligned}\|H_{m,\Theta}\|_{L_p(\Omega)} &= \sup_{f\in L_p(\Omega')} \frac{\|H_{m,\Theta}(f|_\Omega)\|_{L_p(\Omega)}}{\|f|_\Omega\|_{L_p(\Omega)}} \le \sup_{\substack{f\in L_p(\Omega')\\ f=\chi_\Omega f}} \frac{\|H_{m,\Theta}f\|_{L_p(\Omega')}}{\|f\|_{L_p(\Omega')}} \\ &\le \sup_{f\in L_p(\Omega')} \frac{\|H_{m,\Theta}f\|_{L_p(\Omega')}}{\|f\|_{L_p(\Omega')}} = \|H_{m,\Theta}\|_{L_p(\Omega')}.\end{aligned}$$

Finally, the sharpness is proved. Suppose that $\Theta = [v, \ldots, v]$. Let

$$f := \|\cdot - v\|^\alpha, \quad \alpha \in \mathbb{R}.$$

Then by (2.1.9), and (1.2.3), for $m + \alpha > 0$,

$$\begin{aligned}H_{m,\Theta}f(x) &= \frac{1}{(m-1)!(\#\Theta-1)!}\int_0^1 t^{\#\Theta-1}(1-t)^{m-1}\,\|x + t(v-x) - v\|^\alpha\,dt \\ &= \frac{1}{(m-1)!(\#\Theta-1)!}\int_0^1 t^{\#\Theta-1}(1-t)^{m-1+\alpha}\,dt\,\|x-v\|^\alpha \\ &= \frac{1}{(m-1)!(\#\Theta-1)!}\frac{\Gamma(\#\Theta)\Gamma(m+\alpha)}{\Gamma(\#\Theta+m+\alpha)}\,\|x-v\|^\alpha \\ &= \frac{1}{(m-1)!(m+\alpha)_{\#\Theta}}\,\|x-v\|^\alpha,\end{aligned}$$

so that $f := \|\cdot - v\|^\alpha$, $m + \alpha > 0$, is an eigenvector of $H_{m,\Theta}$ with eigenvalue

$$\lambda := \frac{1}{(m-1)!(m+\alpha)_{\#\Theta}}.$$

Thus

$$\begin{aligned}\|H_{m,\Theta}\|_{L_p(\Omega)} &\ge \sup\left\{\frac{1}{(m-1)!(m+\alpha)_{\#\Theta}} : \|\cdot - v\|^\alpha \in L_p(\Omega),\ \alpha + m > 0\right\} \\ &\ge \sup\left\{\frac{1}{(m-1)!(m+\alpha)_{\#\Theta}} : \alpha > -n/p\right\} \\ &= \frac{1}{(m-1)!(m-n/p)_{\#\Theta}},\end{aligned}$$

giving equality in (3.2.3). The sharpness for the case where $p = \infty$ follows from the observation that there is sharpness in inequality (3.2.9) for f constant and Ω bounded, together with inequality (3.2.4). □

Remark 3.2.11. If $\mathrm{vol}_n(\mathrm{conv}\,\Theta) > 0$, then by Remark 2.1.4, it follows that the value of $H_{m,\Theta}f(x)$ is the same for all representatives of $f \in L_p(\Omega)$. Indeed, by Proposition 2.2.2, for all $f \in L_p(\Omega)$, we have that $H_{m,\Theta}f \in C(\bar{\Omega})$, regardless of whether or not $m - n/p > 0$.

On the other hand, when $\mathrm{vol}_n(\mathrm{conv}\,\Theta) = 0$, then the function $H_{m,\Theta}f$ need not be so well behaved. For example, if $n > 1$ and Θ consists of a single point θ, then $f \in L_p(\Omega)$ can be altered on a null set so that $H_{m,\Theta}f$ takes on arbitrary preassigned values on any countable dense subset of Ω. For the details of one such construction, see the end of this section.

3.3. Special case: Hardy's inequality. In the very special case where $n = 1$, $m = 1$, and $\Theta = [0]$, we have by (2.1.6) that

$$H_{m,\Theta}f(x) = \frac{1}{x}\int_0^x f. \tag{3.3.1}$$

With the choice $\Omega = (0, \infty)$, (3.2.3) is Hardy's inequality (1.1.2). This well-known inequality was first proved by Hardy [Ha28]; see also [HLP67, section 9.8].

For a comprehensive survey of the literature connected with Hardy's inequality, see [FMP91, Chapter IV]. The only *multivariate* occurrence of Theorem 3.2.1 that the author is aware of is, implicitly, in Arcangeli and Gout [AG76] for the case when Θ consists of a single point. The bulk of the 174 references for [FMP91, Chapter IV] deal with *univariate* generalizations of Hardy's inequality—some of which are special cases of Theorem 3.2.1.

3.4. Further L_p-bounds. Next, we use Theorem 3.2.1 to give a bound particularly suited for obtaining L_p-bounds from integral error formulas, such as those given in sections 4 and 5.

THEOREM 3.4.1. *Fix $a_1, \dots, a_s \in \mathbb{R}^{k+1} \setminus 0$, where $s \geq 0$. Let $\Theta \in \mathbb{R}^{n \times k}$, and let Ω be a bounded open set in $\mathbb{R}^n$ for which $\bar{\Omega}$ is star-shaped with respect to Θ. If $m - n/p > 0$, then the rule*

$$\mathcal{L}f(x) := \int_{[\underbrace{x,\dots,x}_{m},\Theta]} \left(\prod_{j=1}^{s} D_{[x,\Theta]a_j}\right) f \tag{3.4.2}$$

induces a bounded linear map $\mathcal{L} : W_p^s(\Omega) \to L_p(\Omega)$ with

$$\|\mathcal{L}f\|_{L_p(\Omega)} \leq \left(\max_{x \in \bar{\Omega}} \prod_{j=1}^{s} \|[x,\Theta]a_j\|\right) \frac{1}{(m-1)!(m-n/p)_{\#\Theta}} \left|f\right|_{s,p,\Omega}. \tag{3.4.3}$$

In addition, when $p = \infty$, we have the pointwise estimate

$$|\mathcal{L}f(x)| \leq \frac{1}{(\#\Theta + m - 1)!}\left(\prod_{j=1}^{s} \|[x,\Theta]a_j\|\right)\left|f\right|_{s,\infty,\Omega}, \qquad a.e.\ x \in \Omega. \tag{3.4.4}$$

Proof. It follows from Theorem 3.2.1 that (3.4.2) induces a linear map $W_p^s(\Omega) \to L_p(\Omega)$. Next, (3.4.3) is proved.

Let $x \in \Omega$ and $f \in W_p^s(\Omega)$. By (1.4.2),

$$\left|\left(\prod_{j=1}^{s} D_{[x,\Theta]a_j}\right) f\right| \leq \left(\prod_{j=1}^{s} \|[x,\Theta]a_j\|\right) |D^s f| \tag{3.4.5}$$

in $L_p(\Omega)$. Here $|D^s f| \in L_p(\Omega)$ is defined by (1.4.1). Thus

$$A_x f := \left(\prod_{j=1}^{s} D_{[x,\Theta]a_j}\right) f$$

defines a bounded linear map $A_x : W_p^s(\Omega) \to L_p(\Omega)$ with

$$|A_x f| \leq K\,|D^s f| \tag{3.4.6}$$

in $L_p(\Omega)$, where

$$K := K(a_1, \ldots, a_s, \Omega) := \max_{x \in \bar{\Omega}} \prod_{j=1}^{s} \|[x,\Theta]a_j\|.$$

Notice that

$$\mathcal{L}f(x) = (H_{m,\Theta}\, A_x f)\,(x).$$

Thus, (3.4.6) and the *positiveness* of $H_{m,\Theta} : L_p(\Omega) \to L_p(\Omega)$ implies that

$$|\mathcal{L}f| \leq H_{m,\Theta}(K\,|D^s f|),$$

in $L_p(\Omega)$. Take the $L_p(\Omega)$-norm of this inequality and then apply Theorem 3.2.1 to obtain

$$\|\mathcal{L}f\|_{L_p(\Omega)} \leq \frac{1}{(m-1)!(m-n/p)_{\#\Theta}} K\,\|\,|D^s f|\,\|_{L_p(\Omega)}.$$

Since

$$\|\,|D^s f|\,\|_{L_p(\Omega)} = \bigl|f\bigr|_{s,p,\Omega},$$

this proves (3.4.3).

Similarly, from (3.4.5) and Theorem 3.2.1, we have for a.e. $x \in \Omega$ that

$$\begin{aligned} |\mathcal{L}f(x)| &\leq \left(\prod_{j=1}^{s} \|[x,\Theta]a_j\|\right) \|H_{m,\Theta}(|D^s f|)\|_{L_\infty(\Omega)} \\ &\leq \left(\prod_{j=1}^{s} \|[x,\Theta]a_j\|\right) \frac{1}{(\#\Theta + m - 1)!} \bigl|f\bigr|_{s,\infty,\Omega}, \end{aligned}$$

which is (3.4.4). □

In the special case when $s = 0$, Theorem 3.4.1 reduces to Theorem 3.2.1. Theorem 3.4.1 together with Property 2.1.3(d) can be used to obtain bounds for maps more general than (3.4.2). One such example is the *lift* of an *elementary liftable map*; see [Wa97].

3.5. An example. Finally, here is the example promised in Remark 3.2.11.

Let $n > 1$ and Θ consist of the single point θ. Suppose that $\bar{\Omega}$ is star-shaped with respect to θ, and that B is a countable dense subset of Ω. It is possible to change $f \in L_p(\Omega)$ on the intersection of Ω with the cone C with vertex θ and base B, which is a null set, so that $H_{m,[\theta]}f$, as computed from (3.2.2), takes on arbitrary preassigned values on B.

The cone C consists of the union of rays r emanating from θ and passing through a point $b \in B$. Let r be such a ray, and order the points from B lying on r as $b_1, b_2, \ldots$, so that b_i is closer to θ than b_{i+1}. By Remark 2.1.4,

$$H_{m,[\theta]} f(b_i) = \int M(\cdot | \underbrace{b_i, \ldots, b_i}_{m}, \theta)\, f$$

with the integration above being over the interval $[\theta \mathinner{\ldotp\ldotp} b_i] := \operatorname{conv}\{\theta, b_i\}$ weighted by a nonnegative polynomial. Thus, by redefining f to be an appropriate constant over each of the intervals $[\theta \mathinner{\ldotp\ldotp} b_1]$, $[b_1 \mathinner{\ldotp\ldotp} b_2]$, $[b_2 \mathinner{\ldotp\ldotp} b_3], \ldots$, one can make $H_{m,[\theta]} f(b_i)$ take on any preassigned values.

The function $H_{m,[\theta]} f$ is more than simply an interesting example. It occurs in the *multipoint Taylor error formula* for multivariate Lagrange interpolation given by Ciarlet and Raviart [CR72]. From the multipoint Taylor formula, Arcangeli and Gout [AG76] obtained L_p-bounds for multivariate Lagrange interpolation, long used by those working in finite elements, but known to few approximation theorists. For this reason, these bounds are discussed in some detail in Section 5.

4. Application: L_p-error bounds for Kergin and Hakopian interpolation. In this section, we use Theorem 3.4.1 to obtain L_p-error bounds for the *scale of mean value interpolations*, which includes the *Kergin* and *Hakopian maps*.

To describe the mean-value interpolations and the Lagrange maps of section 5, we will need the following facts about linear interpolation.

4.1. Linear interpolation. Let F be a finite-dimensional space and Λ a finite-dimensional space of linear functionals defined at least on F. We say that the corresponding *linear interpolation problem*, $\operatorname{LIP}(F, \Lambda)$ for short, is *correct* if for every g upon which Λ is defined, there is a unique $f \in F$ which agrees with g on Λ, i.e.,

$$\lambda(f) = \lambda(g), \quad \forall \lambda \in \Lambda.$$

The linear map $L : g \mapsto f$ is called the associated (*linear*) *projector* with *interpolants* F and *interpolation conditions* Λ. Each linear projector with finite-dimensional range F is the solution of a $\operatorname{LIP}(F, \Lambda)$ for some unique choice of the interpolation conditions Λ.

Notice that the correctness of $\operatorname{LIP}(F, \Lambda)$ depends only on the action of Λ on F.

4.2. The scale of mean value interpolations. Throughout this section, $\Theta \in \mathrm{I\!R}^{n \times k}$. For $0 \le m < k$, we have the *mean value interpolation*

$$\mathcal{H}_\Theta^{(m)} : \{f : f \text{ is } C^{k-m-1} \text{ on } \operatorname{conv} \Theta\} \to \Pi_{k-m-1}(\mathrm{I\!R}^n),$$

which is given by

$$\mathcal{H}_\Theta^{(m)} f(x) := m! \sum_{j=m+1}^{k} \sum_{\substack{\tilde\Theta \subset \Theta_{j-1} \\ \#\tilde\Theta = m}} \int_{\Theta_j} D_{x - \Theta_{j-1} \setminus \tilde\Theta} f.$$

$\mathcal{H}_\Theta^{(m)}$ is a linear projector with interpolants $\Pi_{k-m-1}(\mathrm{I\!R}^n)$ and interpolation conditions

$$\operatorname{span}\{f \mapsto \int_{\tilde\Theta} q(D) f : \tilde\Theta \subset \Theta,\ \#\tilde\Theta \ge m+1,\ q \in \Pi^0_{\#\tilde\Theta - m - 1}(\mathrm{I\!R}^n)\}.$$

The map $\mathcal{H}_\Theta^{(0)}$ is *Kergin's map*, and $\mathcal{H}_\Theta^{(n-1)}$ is *Hakopian's map*. The Kergin interpolant matches function values at Θ, as does the Hakopian interpolant in case Θ is in general position; however, this latter fact is not obvious. For this reason, the scale $(\mathcal{H}_\Theta^{(m)} : 0 \le m < k)$ of multivariate mean-value interpolations is thought of as a multivariate generalization of Lagrange interpolation. For more details, see [Wa97].

For the remainder of this section, Ω will be a bounded open set in $\mathbb{R}^n$ with a Lipschitz boundary. From [Wa97], we obtain the following integral error formulas for the scale of mean-value interpolations.

THEOREM 4.2.1. *Suppose that $\bar{\Omega}$ is star-shaped with respect to Θ. If $0 \le j < k-m$, $q \in \Pi_j^0(\mathbb{R}^n)$, $p > n$, and $f \in W_p^{(k-m)}(\Omega)$, then*
(4.2.2)

$$q(D)\bigl(f-\mathcal{H}_\Theta^{(m)} f\bigr)(x) = (m+j)! \sum_{i=k-m-j}^{k} \sum_{\substack{\tilde{\Theta}\subset\Theta_{i-1} \\ \#\tilde{\Theta}=m+j+i-k}} \int_{[\underbrace{x,\dots,x}_{k+1-i},\Theta_i]} D_{[x-\Theta_{i-1}\setminus\tilde{\Theta},x-\theta_i]} q(D) f.$$

This formula involves only derivatives of f of order $k-m$.

Remark 4.2.3. In [Wa97], formula (4.2.2) was proved only for $f \in C^{k-m}(\mathbb{R}^n)$, without any reference to p. We now outline how it can be extended to $f \in W_p^{(k-m)}(\Omega)$. By Sobolev's embedding theorem, the condition $p > n$ implies that

$$W_p^{(k-m)}(\Omega) \subset C^{k-m-1}(\bar{\Omega}) \subset C(\bar{\Omega}).$$

Thus $\mathcal{H}_\Theta^{(m)} f$ is defined for all $f \in W_p^{(k-m)}(\Omega)$. To extend (4.2.2) to $f \in W_p^{(k-m)}(\Omega)$, use a density argument.

4.3. L_p-bounds for the scale of mean-value interpolations. Next, we apply Theorem 3.4.1 to (4.2.2) to obtain L_p-bounds for the scale of mean-value interpolations. Let

$$h_{x,\Theta} := \sup_{\theta\in\Theta} \|x-\theta\|, \qquad h_{\Omega,\Theta} := \sup_{x\in\Omega} h_{x,\Theta} \le \operatorname{diam}\Omega.$$

THEOREM 4.3.1. *Suppose that $\bar{\Omega}$ is star-shaped with respect to Θ. If $0 \le j < k-m$, $p > n$, and $f \in W_p^{(k-m)}(\Omega)$, then*

$$\bigl|f-\mathcal{H}_\Theta^{(m)} f\bigr|_{j,p,\Omega} \le C_{n,p,j,k,m}\,(h_{\Omega,\Theta})^{k-m-j}\bigl|f\bigr|_{k-m,p,\Omega}, \tag{4.3.2}$$

where

$$C_{n,p,j,k,m} := \frac{1}{(1-n/p)_{k-m-j}}.$$

The constant $C_{n,p,j,k,m} \to \infty$ as $p \to n^+$. Additionally, if $p = \infty$, then we have the pointwise estimate that for all $x \in \bar{\Omega}$,

$$|D^j(f-\mathcal{H}_\Theta^{(m)} f)|(x) \le \frac{1}{(k-m-j)!}(h_{x,\Theta})^{k-m-j}\bigl|f\bigr|_{k-m,\infty,\Omega}.$$

Proof. Choose $q \in \Pi_j^0(\mathbb{R}^n)$ so that

$$q(D) = D_{u_1}\cdots D_{u_j},$$

where $u_1, \ldots, u_j \in \mathbb{R}^n$ with $\|u_i\| \le 1$. By Theorem 3.4.1, we have for each of the terms in (4.2.2) that

$$\Bigl\| x \mapsto \int_{[\underbrace{x,\ldots,x}_{k+1-i},\Theta_i]} D_{[x-\Theta_{i-1}\setminus\tilde{\Theta},x-\theta_i]} q(D) f \Bigr\|_{L_p(\Omega)}$$
$$\le \frac{\Gamma(k+1-i-n/p)}{\Gamma(k+1-i)\Gamma(k+1-n/p)} (h_{\Omega,\Theta})^{k-m-j} \bigl| f \bigr|_{k-m,\infty,\Omega}.$$

Notice that in the above, the constants

$$\max_{x\in\bar{\Omega}} \prod_{\theta\in[\Theta_{i-1}\setminus\tilde{\Theta},\theta_i]} \|x-\theta\|$$

were replaced by the possibly larger but far less complicated constant $(h_{\Omega,\Theta})^{k-m-j}$. This gives the first inequality with

$$C_{n,p,j,k,m} := (m+j)! \sum_{i=k-m-j}^{k} \binom{i-1}{m+j+i-k} \frac{1}{(k-i)!(k+1-i-n/p)_i}$$
$$= \frac{(k-1)!}{(k-m-j-1)!(1-n/p)} \, {}_2F_1\Bigl({-m-j,\, 1-n/p \atop 1-k} ; 1 \Bigr).$$

By the Chu–Vandermonde convolution identity:

$${}_2F_1\Bigl({-n, b \atop c} ; 1 \Bigr) = \frac{(c-b)_n}{(c)_n},$$

which is the special case $a = -n$ of equation (14) in [E53, p. 61], it follows that

$$C_{n,p,j,k,m} = \frac{1}{(1-n/p)_{k-m-j}}.$$

The second inequality, which is proved in [Wa97], follows from the pointwise estimate (3.4.4). □

By considering the special case of Taylor interpolation at a point by polynomials of degree $\le k$, we obtain the following estimate of the distance of smooth functions from Π_k.

Corollary. *Suppose that $\Omega \subset \mathbb{R}^n$ is a bounded, open, star-shaped region that has a Lipschitz boundary. Then for $p > n$ and $0 \le j \le k+1$,*

(4.3.3)
$$\operatorname{dist}_{|\cdot|_{j,p,\Omega}}(f, \Pi_k) := \inf_{g\in\Pi_k} \bigl| f - g \bigr|_{j,p,\Omega}$$
$$\le \frac{1}{(1-n/p)_{k+1-j}} (\operatorname{diam}\Omega)^{k+1-j} \bigl| f \bigr|_{k+1,p,\Omega}, \quad \forall f \in W_p^{k+1}(\Omega).$$

Note that

$$\frac{1}{(1-n/p)_{k+1-j}} \to \infty \qquad \text{as } p \to n^+.$$

That an inequality of the form of (4.3.3) holds for $j = 0$, where the constant $1/(1-n/p)_{k+1-j}$ is replaced by some unknown constant depending only on n, k, and

p, is the content of the paper by Dechevski and Quak [DQ90]. From this, they obtain the corresponding "improved" version of the Bramble–Hilbert lemma (see [BH70]).

4.4. A related result of Lai and Wang. The only related result in the literature is an L_p-bound for the error in Hakopian interpolation given by Lai and Wang [LW84]. In that paper they show the following.

THEOREM 4.4.1 ([LW84, Theorem 1]). *Let $|\alpha| \le k-n$. Then for any positive integer $\ell \le k+|\alpha|-n+1$, we have*

(4.4.2)

$$\begin{aligned} &D^\alpha(f-\mathcal{H}_\Theta^{(n-1)})(x) \\ &\quad=(|\alpha|+n-1)\sum_{\mu_1=1}^{|\alpha|+n}\sum_{i_1=1}^{n}(x-\theta_{|\alpha|+n-\mu_1+1})_{i_1}\sum_{\mu_2=1}^{\mu_1}\sum_{i_2=1}^{n}(x-\theta_{|\alpha|+n-\mu_2+2})_{i_2} \\ &\qquad\times\cdots\times\sum_{\mu_\ell=1}^{\mu_{\ell-1}}\sum_{i_\ell=1}^{n}(x-\theta_{|\alpha|+n-\mu_\ell+\ell})_{i_\ell}\int_{[\underbrace{x,\ldots,x}_{\mu_\ell},\theta_1,\ldots,\theta_{|\alpha|+n-\mu_\ell+\ell}]} D^{\alpha+\sum_{j=1}^{\ell}e^{i_j}}f \\ &\qquad-\sum_{j=|\alpha|+n-1+\ell}^{k-1}\ \sum_{|\gamma|=j-n+1} D^\alpha\omega_\gamma(x)\int_{[\theta_1,\ldots,\theta_j]} D^\gamma f. \end{aligned}$$

The above uses standard multiindex notation. The ith component of $x \in \mathbb{R}^n$ is x_i, and e^i is the ith unit vector in $\mathbb{R}^n$. To (4.4.2), Lai and Wang apply the integral form of Minkowski's inequality in the form

$$\left\| x \mapsto \int_{[\underbrace{x,\ldots,x}_{\mu},\theta_1,\ldots,\theta_{k+1-\mu}]} D^\beta f \right\|_{L_p(G)} \le C_2\, \|D^\beta f\|_{L_p(G)}, \quad \mu = 1,\ldots,|\alpha|+n, \tag{4.4.3}$$

to obtain the following.

THEOREM 4.4.4 ([LW84, Theorem 2]). *Let G be a convex set containing Θ with diameter h. If $p > n$, $|\alpha| \le k-n$, and $f \in W_p^{(k-n+1)}(G)$, then*

$$\|D^\alpha(f-\mathcal{H}_\Theta^{(n-1)}f)\|_{L_p(G)} \le C\, h^{k-n+1-|\alpha|} \max_{|\beta|=k-n+1} \|D^\beta f\|_{L_p(G)}, \tag{4.4.5}$$

where C is a constant independent of f.

Since $f \mapsto \max_{|\beta|=k+1-n} \|D^\beta f\|_{L_p(\Omega)}$ and $f \mapsto \big|f\big|_{k+1-n,p,\Omega}$ are equivalent seminorms, Theorem 4.4.4 follows from Theorem 4.3.1. Had Lai and Wang attempted to compute the C_2 of (4.4.3) using the multivariate form of Hardy's inequality, they would have obtained

$$C_2 \le \frac{1}{(\mu-1)!(\mu-n/p)_{k+1-\mu}}.$$

Thus their constant C in (4.4.5) would have the same qualitative behavior as our $C_{n,p,j,k,m}$ of (4.3.2), namely, that $C \to \infty$ as $p \to n^+$.

4.5. The behavior of $C_{n,p,j,k,m}$ as a function of its parameters. In [Wa97], it is shown that, in an appropriate sense, the constant $C_{n,p,j,k,m}$ of (4.3.2) is the best possible when $p = \infty$. The question then arises whether or not the overestimation committed in using the multivariate form of Hardy's inequality to obtain $C_{n,p,j,k,m}$ is significant for $p < \infty$. In particular, does the best possible constant C in the inequality

$$\left|f - \mathcal{H}_{\Theta}^{(m)} f\right|_{j,p,\Omega} \leq C\,(h_{\Omega,\Theta})^{k-m-j} \left|f\right|_{k-m,p,\Omega} \tag{4.5.1}$$

become unbounded as $p \to n^+$? In the univariate case, at least, the answer is *no*—the best possible constant in (4.5.1) does not become unbounded.

Before we show this, let us clarify a little the role that the condition $p > n$ plays in Theorems 4.3.1 and 4.4.4. The condition $p > n$ is necessary if these results are to be stated in terms of the Sobolev space $W_p^{(k-m)}(\Omega)$—in particular, so that $\mathcal{H}_{\Theta}^{(m)} f$ is defined for $f \in W_p^{(k-m)}(\Omega)$. However, it makes good sense to ask what the best constant C is for which (4.5.1) holds for all sufficiently smooth functions f—say, e.g., $f \in C^{k-m}(\bar{\Omega})$. The condition $p > n$ is again needed when we seek to apply the multivariate form of Hardy's inequality to the integral error formulas (4.2.2) and (4.4.2).

We now show that in the univariate case, i.e., when $n = 1$, there is a best possible constant C in (4.5.1) for all sufficiently smooth f which can be bounded independently of $1 \leq p \leq \infty$. The crucial step in the argument to follow is the use of the B-spline L_p-estimate that

$$\|M(\cdot|\Theta)\|_{L_p(\mathbb{R})} \leq \left(\frac{\#\Theta - 1}{\operatorname{diam}\Theta}\right)^{1-1/p} \tag{4.5.2}$$

when $\operatorname{diam}\Theta > 0$; see de Boor [B73].

In line with [Wa97], the univariate case of the map $\mathcal{H}_{\Theta}^{(m)}$, termed the *generalized Hermite map*, will be emphasized by writing it as $H_{\Theta}^{(m)}$. This map has the simple form

$$H_{\Theta}^{(m)} f = D^m(H_{\Theta} D^{-m} f),$$

where H_{Θ} is the *Hermite interpolator* at the points Θ and $D^{-m}f$ is any function for which $D^m(D^{-m}f) = f$.

THEOREM 4.5.3. *Let Θ be a k-sequence in the interval $[a\,.\,.\,b]$. If $1 \leq p, q \leq \infty$, $0 \leq j < k - m$, and $f \in C^{k-m}[a\,.\,.\,b]$, then*

$$\|D^j(f - H_{\Theta}^{(m)} f)\|_{L_p[a..b]} \leq \frac{(m+j)!}{(k-m-j)!}\,\frac{k^{1/q}}{k!}\,(b-a)^{k-m+\frac{1}{p}-\frac{1}{q}}\,\|D^{k-m}f\|_{L_q[a..b]}.$$

Proof. Fix $x \in [a\,.\,.\,b]$. For Θ a finite sequence in $\mathbb{R}$, let

$$\omega_{\Theta}(x) := \prod_{\theta\in\Theta}(x - \theta).$$

With this notation, replacing each occurrence in (4.2.2) of a linear functional of the form $f \mapsto \int_{\Theta} f$ by integration against a B-spline, we obtain that

$$\begin{aligned} &D^j(f - H_{\Theta}^{(m)} f)(x) \\ &\quad = (m+j)! \sum_{i=k-m-j}^{k} \sum_{\substack{\tilde{\Theta}\subset\Theta_{i-1} \\ \#\tilde{\Theta}=m+j+i-k}} \omega_{\Theta_{i-1}\backslash\tilde{\Theta}}(x)\,(x-\theta_i)\,\frac{1}{k!}\int D^{k-m} f\, M(\cdot|x,\Theta_i). \end{aligned}$$

By Hölder's inequality and (4.5.2), we have that

$$\left|\int D^{k-m} f\, M(\cdot|x,\Theta_i)\right| \le \left(\frac{k}{\operatorname{diam}[x,\Theta_i]}\right)^{1/q} \|D^{k-m}f\|_{L_q[a..b]}.$$

Since

$$\left|\frac{\omega_{\Theta_{i-1}\backslash\tilde{\Theta}}(x)\,(x-\theta_i)}{(\operatorname{diam}[x,\Theta_i])^{1/q}}\right| \le (b-a)^{k-m-1/q},$$

we obtain that

$$\begin{aligned}
&|D^j(f-H_\Theta^{(m)}f)(x)| \\
&\quad\le (m+j)! \sum_{i=k-m-j}^{k} \binom{i-1}{m+j+i-k} \frac{k^{1/q}}{k!}(b-a)^{k-m-1/q}\|D^{k-m}f\|_{L_q[a..b]} \\
&\quad= \frac{(m+j)!}{(k-m-j)!}\frac{k^{1/q}}{k!}(b-a)^{k-m-1/q}\|D^{k-m}f\|_{L_q[a..b]}.
\end{aligned}$$

Finally, take $\|\cdot\|_{L_q[a..b]}$ of both sides. □

To adapt this argument to the multivariate case, it is necessary to have the *simplex spline* analogue of the B-spline L_p-estimate (4.5.2). This is provided by Dahmen [D79], who shows that when $\operatorname{vol}_n(\operatorname{conv}\Theta) > 0$,

$$\|M(\cdot|\Theta)\|_{L_p(\mathbb{R}^n)} \le \frac{k!(k+1)!}{n!(n+1)!(n-k)!}\left(\frac{1}{\operatorname{vol}_n(\operatorname{conv}\Theta)}\right)^{1-1/p} \tag{4.5.4}$$

with $k+1 := \#\Theta$. Yet, with this in hand, it does not seem possible to apply the argument of Theorem 4.5.3 in any satifactory form.

Remark 4.5.5. Incidentally, the constant in (4.5.4) is not the best possible. Already, by using the fact that $\int M(\cdot|\Theta) = 1$ together with the case of (4.5.4) where $p=\infty$, we obtain

$$\|M(\cdot|\Theta)\|_{L_p(\mathbb{R}^n)} \le \left(\frac{k!(k+1)!}{n!(n+1)!(n-k)!}\frac{1}{\operatorname{vol}_n(\operatorname{conv}\Theta)}\right)^{1-1/p}.$$

In the univariate case this overestimates (4.5.2) by a factor of $((k+1)!/2)^{1-1/p}$.

The key step in proving (4.5.2) is the bound

$$M(\cdot|\Theta) \le \frac{k}{\operatorname{diam}\Theta}, \tag{4.5.6}$$

which follows from the partition of unity property of B-splines. Thus, a close examination of the simplex-spline analogue of the B-spline partition of unity, given recently by Dahmen, Micchelli, and Seidel [DMS92], should give tighter bounds than those of (4.5.4). However, we make no attempt here to give such an argument.

Remark 4.5.7. There are other integral error formulas for the scale of mean-value interpolations to which Theorem 3.4.1 can be applied to give L_p-bounds. These include those of Lai and Wang [LW86] (Kergin interpolation), Gao [Ga88], and Hakopian [BHS93, p. 200] (Hakopian interpolation). See [Wa97] for a discussion of the relative merits of each of these formulas.

5. Application: L_p-error bounds for multivariate Lagrange interpolation. In this section, we use Theorem 3.4.1 to obtain L_p-error bounds for *multivariate Lagrange interpolation schemes.*

5.1. Lagrange maps. A linear interpolation problem for which the space of interpolation conditions is spanned by *point evaluations* at Θ, a finite sequence in $\mathbb{R}^n$, is called a *Lagrange interpolation problem.* If P is the space of interpolants for such a problem and the problem is correct, then the associated linear projector, called the *Lagrange map*, will be denoted by $L_{P,\Theta}$. The *Lagrange form* of a Lagrange map is given by

$$L_{P,\Theta} f = \sum_{\theta \in \Theta} f(\theta) \ell_\theta. \tag{5.1.1}$$

Here (5.1.1) uniquely defines

$$\ell_\theta := \ell_{\theta,P,\Theta} \in P,$$

the *Lagrange function* for $\theta \in \Theta$. In other words, $(\delta_{[\theta]})_{\theta\in\Theta}$ is dual (biorthonormal) to $(\ell_\theta)_{\theta\in\Theta}$.

Lagrange maps into a space containing polynomials of degree k are frequently used to interpolate to scattered data; see, e.g., Alfeld [Al89]. Particular examples receiving much attention lately are maps where the interpolants include *radial basis functions* or *multivariate splines* and de Boor and Ron's *least solution* for the polynomial interpolation problem [BR90] (also see [BR92] for its generalization). In addition, there are, of course, the maps of Kergin and Hakopian.

For such maps, there is the *multipoint Taylor formula* for the error. This formula was initiated by the work of Ciarlet and Wagschal [CW71]; most of the relevant papers are in French, and it is not well known outside the area of finite elements. It is for these reasons and because our Theorem 3.4.1 implies L_p-estimates from the multipoint Taylor formula that we discuss the formula here.

5.2. The multipoint Taylor formula.

FORMULA 5.2.1 (multipoint Taylor formula; see [CR72]). *Let Θ be a finite sequence in $\mathbb{R}^n$, and let Ω be an open set in $\mathbb{R}^n$ for which $\bar\Omega$ is star-shaped with respect to Θ. If $L_{P,\Theta}$ is a Lagrange map with $\Pi_k(\mathbb{R}^n) \subset P \subset C^k(\bar\Omega)$, then for $f \in C^{k+1}(\bar\Omega)$, $q \in \Pi_k(\mathbb{R}^n)$, and $x \in \bar\Omega$, its error satisfies*

$$\big(q(D)(f - L_{P,\Theta} f)\big)(x) = -\sum_{\theta\in\Theta} \left(\int_{[\underbrace{x,\dots,x}_{k+1},\theta]} D^{k+1}_{\theta-x} f \right) (q(D)\ell_\theta)(x). \tag{5.2.2}$$

The term *multipoint Taylor formula* comes from the fact that

$$\theta \mapsto \int_{[\underbrace{x,\dots,x}_{k+1},\theta]} D^{k+1}_{\theta-x} f$$

is the error in *Taylor interpolation* of degree k at the point x, a special case of the error in Kergin interpolation. The proof of (5.2.2) further justifies the use of this term.

The region of integration in (5.2.2) consists of line segments from x to $\theta \in \Theta$ (see Figure 5.1).

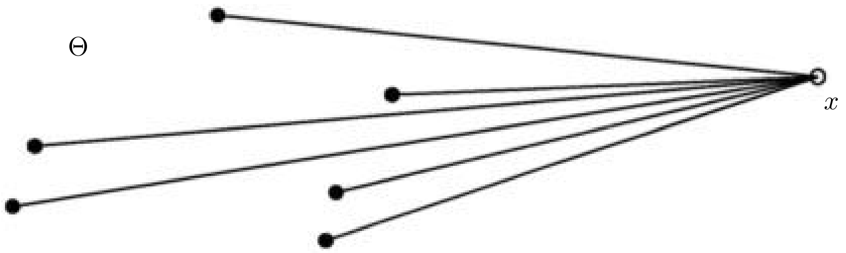

FIG. 5.1. *The region of integration in* (5.2.2) *for* Θ *consisting of six points.*

From the multipoint Taylor formula, Arcangeli and Gout [AG76] obtain L_p-bounds for the error in a Lagrange map. These bounds are precisely those obtained by applying Theorem 3.4.1 to (5.2.2). The crucial step in the argument presented in [AG76, Proposition 1-1] is the use of the multivariate form of Hardy's inequality for the map

$$x \mapsto H_{k+1,[v]}f(x) := \int_{[\underbrace{x,\ldots,x}_{k+1},v]} f. \tag{5.2.3}$$

This inequality is not explicitly stated, though the proof of their (weaker) Proposition 1–1 would imply it.

Remark 5.2.4. The key step in the proof of Proposition 1-1 in [AG76] is an application of Hölder's inequality to the splitting

$$\int_{[\underbrace{x,\ldots,x}_{k+1},v]} f = \frac{1}{k!}\int_0^1 (1-t)^{-1/q-\varepsilon}\left((1-t)^{k+1/q-\varepsilon}f(x+t(v-x))\right)dt,$$

where $\varepsilon := (k+1-n/p)/q$ and $1/p+1/q=1$, as opposed to our use of the integral form of Minkowski's inequality.

Having identified the precise role of the multivariate form of Hardy's inequality in [AG76], it is possible to use it to run through Arcangeli and Gout's calculation for a much more general class of norms, including those most often used in numerical analysis. The resulting bounds, given below, have smaller (and simpler) constants than those one might hope to obtain by applying the inequalities for similar norms to the results of [AG76].

For the remainder of this section, Ω will denote a bounded open set in $\mathbb{R}^n$ with a Lipschitz boundary, and Θ will denote a finite sequence in $\mathbb{R}^n$. Recall that

$$h_{\Omega,\Theta} = \sup_{x\in\Omega}\sup_{\theta\in\Theta}\|x-\theta\| \le \operatorname{diam}\Omega.$$

COROLLARY 5.2.5. *Suppose that $\bar{\Omega}$ is star-shaped with respect to Θ and that $L_{P,\Theta}$ is a Lagrange map with $\Pi_k(\mathbb{R}^n) \subset P \subset C^k(\Omega)$. If $k+1-n/p>0$, $g\in\Pi_k$, and $f \in W_p^{(k+1)}(\Omega)$, then*

(5.2.6)

$$\|g(D)(f-L_{P,\Theta}f)\|_{L_p(\Omega)} \le \frac{1}{k!(k+1-n/p)}\left(\sum_{\theta\in\Theta}\|g(D)\ell_\theta\|_{L_\infty(\Omega)}\right)\bigl|f\bigr|_{k+1,p,\Omega}(h_{\Omega,\Theta})^{k+1},$$

and so, in particular,

$$(5.2.7) \qquad |f - L_{P,\Theta}f|_{p,\Omega} \le \frac{1}{k!(k+1-n/p)} \Bigl(\sum_{\theta\in\Theta} |\ell_\theta|_{\infty,\Omega} \Bigr) \bigl|f\bigr|_{k+1,p,\Omega} \, (h_{\Omega,\Theta})^{k+1},$$

where $|\cdot|_{p,\Omega}$ is any seminorm on $W_p^k(\Omega)$ of the form

$$|f|_{p,\Omega} := \| \, (\|g_i(D)f\|_{L_p(\Omega)})_{i=1}^m \, \|_{\mathbb{R}^m},$$

where the $g_i \in \Pi_k(\mathbb{R}^n)$'s are fixed and $\|\cdot\|_{\mathbb{R}^m}$ is any monotone norm on $\mathbb{R}^m$.

Proof. By Sobolev's embedding theorem, the condition $k+1-n/p > 0$ implies that

$$W_p^{(k+1)}(\Omega) \subset C(\bar\Omega),$$

and so the Lagrange map $L_{P,\Theta}$ is well defined. As in Remark 4.2.3, (5.2.2) can be extended to $f \in W_p^{(k+1)}(\Omega)$. Fix $f \in W_p^{(k+1)}(\Omega)$ and $x \in \Omega$. Let $h := h_{\Omega,\Theta}$. By (1.4.2),

$$|D^{k+1}_{\theta-x}f| \le |D^{k+1}f| \, \|\theta - x\|^{k+1} \le |D^{k+1}f| \, h^{k+1}$$

in $L_p(\Omega)$. Thus, from (5.2.2), it follows that for a.e. $x \in \Omega$,

$$|(g(D)(f - L_{P,\Theta}f))(x)| \le \sum_{\theta\in\Theta} \Bigl(\int_{[\underbrace{x,\ldots,x}_{k+1},\theta]} |D^{k+1}f| \Bigr) \|g(D)\ell_\theta\|_{L_\infty(\Omega)} \, h^{k+1}.$$

To this, the condition $k+1-n/p > 0$ allows us to apply the multivariate form of Hardy's inequality to obtain (5.2.6). □

In [AG76, Theorem 1-1], (5.2.7) is proved when $|\cdot|_{p,\Omega}$ is of the form $|\cdot|_{i,p,\Omega}$ for some $0 \le i \le k$, with $h_{\Omega,\Theta}$ replaced by $\operatorname{diam}\Omega$. In that paper, some bounds on the size of the Lagrange functions ℓ_θ together with relevant applications are given. One application is bounding the error in a *finite element scheme*; also see Ciarlet [Ci78, p. 128]. Another, of interest to approximation theorists, is to estimate the distance of smooth functions from $\Pi_k(\mathbb{R}^n)$ and to give the corresponding *constructive* version of the Bramble–Hilbert lemma; see [BH70].

The condition in Corollary 5.2.5 that $k+1-n/p > 0$ plays an analogous role to the condition in Theorem 4.3.1 that $n > p$. Namely, it is required so that the results can be stated in terms of Sobolev spaces and to apply the multivariate form of Hardy's inequality. Additionally, by Theorem 4.5.3, the unboundedness of the constant in (5.2.7) as $k+1-n/p \to 0^+$ is not a true reflection of the behavior of the error in the invariate case.

With the multivariate form of Hardy's inequality in hand, it is also possible to obtain pointwise error bounds for Lagrange maps.

Corollary 5.2.8. *Suppose that $\bar\Omega$ is star-shaped with respect to Θ and that $L_{P,\Theta}$ is a Lagrange map with $\Pi_k(\mathbb{R}^n) \subset P \subset C^k(\Omega)$. With $f \in W_\infty^{(k+1)} \subset C(\bar\Omega)$ and $x \in \bar\Omega$, we have the (coordinate-independent) pointwise error bound*

$$(5.2.9) \qquad |f(x) - L_{P,\Theta}f(x)| \le \frac{1}{(k+1)!} \bigl|f\bigr|_{k+1,\infty,\Omega} \sum_{\theta\in\Theta} \|\theta - x\|^{k+1} |\ell_\theta(x)|$$

and the (coordinate-dependent) pointwise error bound

$$(5.2.10) \qquad |f(x) - L_{P,\Theta}f(x)| \le \sum_{\theta\in\Theta} \sum_{|\alpha|=k+1} \frac{1}{\alpha!} \|D^\alpha f\|_{L_\infty(\Omega)} \, |(\theta - x)^\alpha \ell_\theta(x)|.$$

Proof. The proof runs along the same lines as that for Corollary 5.2.5, except that for (5.2.10), we first expand $D_{\theta-x}^{k+1}f$ as

$$D_{\theta-x}^{k+1}f = \sum_{|\alpha|=k+1} \frac{(k+1)!}{\alpha!}(\theta-x)^\alpha D^\alpha f$$

by using the multinomial identity. □

Neither of (5.2.9) or (5.2.10) occurs in the literature. For $f \in C^{k+1}(\Omega)$, they can be obtained more simply by applying the mean-value theorem, as given by Properties 2.1.3(c), to the integrals occurring in (5.2.2).

Remark 5.2.10. The results of [AG76] have been extended in the following ways. In [Go77], Gout treats the error in certain forms of *Hermite interpolation*—that is where, in addition to function values, certain derivatives are matched at the points in Θ. In [AS84], Arcangeli and Sanchez bound the error in a Lagrange map for functions from *fractional-order* Sobolev spaces.

5.3. The error formula of Sauer and Xu. There is another error formula, one for the error in a Lagrange map with range (interpolants) $\Pi_k(\mathbb{R}^n)$, that has been given recently by Sauer and Xu; see [SX95].

Sauer and Xu order the $\dim \Pi_k(\mathbb{R}^n)$ points in Θ so that each Lagrange interpolation problem with points Θ^j (by definition, the initial segment of Θ consisting of the first $\dim \Pi_j(\mathbb{R}^n)$ terms) and interpolants $\Pi_j(\mathbb{R}^n)$ is correct for $j = 0, \ldots, k$. They consider the collection $\boldsymbol{\Psi}$ of all $(k+1)$-sequences $\Psi = [\psi_0, \ldots, \psi_k]$, which they call *paths*, with $\psi_j \in \Theta^j \backslash \Theta^{j-1}$ for all j. Given this notation, Sauer and Xu state their result in the following form.

THEOREM 5.3.1 ([SX95, Theorem 3.6]). *Suppose that $L_{P,\Theta} := L_{\Pi_k(\mathbb{R}^n),\Theta}$ is a Lagrange map and that $f \in C^{k+1}(\mathbb{R}^n)$. Then*

$$L_{P,\Theta}f(x) - f(x) = \sum_{\Psi \in \boldsymbol{\Psi}} p_\Psi(x) \int_{[x,\Psi]} D_{x-\psi_k} D_{\psi_k-\psi_{k-1}} \cdots D_{\psi_2-\psi_1} D_{\psi_1-\psi_0} f, \tag{5.3.2}$$

where $p_\Psi \in \Pi_k(\mathbb{R}^n)$ is given by

$$p_\Psi(x) := (k+1)!\, \ell_{\psi_k,\Pi_k(\mathbb{R}^n),\Theta}(x) \prod_{i=1}^{k} \ell_{\psi_i,\Pi_i(\mathbb{R}^n),\Theta^i}(\psi_{i+1}).$$

The region of integration in each term of (5.3.2) is the convex hull of x and Ψ (see Figure 5.2).

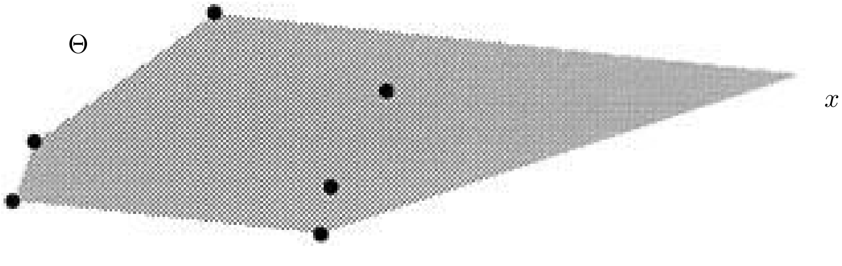

FIG. 5.2. *The region of integration in* (5.3.2) *for* Θ *consisting of six points.*

From (5.3.2), the following pointwise estimate is obtained.

COROLLARY 5.3.3 ([SX95, Corollary 3.11]). *Suppose, in addition to the hypotheses of Theorem 5.3.1, that $\bar{\Omega}$ is star-shaped with respect to Θ. Then for all $x \in \bar{\Omega}$,*

$$\begin{aligned} &|f(x) - L_{P,\Theta}f(x)| \\ &\qquad \le \frac{1}{(k+1)!} \sum_{\Psi \in \mathbf{\Psi}} \|D_{x-\psi_k} D_{\psi_k - \psi_{k-1}} \cdots D_{\psi_2 - \psi_1} D_{\psi_1 - \psi_0} f\|_{L_\infty(\Omega)} |p_\Psi(x)|. \end{aligned} \tag{5.3.4}$$

The bound (5.3.4) is of a form similar to those of (5.2.9) and (5.2.10). For a more direct comparison, we obtain from (5.2.2) the bound

$$|f(x) - L_{P,\Theta}f(x)| \le \frac{1}{(k+1)!} \sum_{\theta \in \Theta} \|D_{\theta - x}^{k+1} f\|_{L_\infty(\Omega)} |\ell_\theta(x)|. \tag{5.3.5}$$

This last bound has $\#\Theta = \sum_{j=0}^{k} \#\Theta^j$ terms, as opposed to $\#\mathbf{\Psi} = \prod_{j=0}^{k} \#\Theta^j$ for (5.3.4), and requires no ordering of Θ. For the purposes of comparison, in the bivariate case, i.e., when $n = 2$, we have that $\#\Theta = (k+2)(k+1)/2$, while $\#\mathbf{\Psi} = (k+1)!$. In addition, bounds analogous to (5.3.5) can be obtained from (5.2.2) for the derivatives of the error in $L_{P,\Theta}$.

To obtain L_p-bounds from (5.3.2), it is necessary to bound

$$x \mapsto L_{1,\Psi} f(x) := \int_{[x,\Psi]} f \tag{5.3.6}$$

in terms of $\|f\|_{L_p(\Omega)}$. This can be done by using the multivariate form of Hardy's inequality. Thus, we have the following instance of Theorem 3.4.1.

COROLLARY 5.3.7. *Suppose the hypotheses of Corollary* 5.3.3. *If $1 - n/p > 0$, then*

$$\|f - L_{P,\Theta} f\|_{L_p(\Omega)} \le \frac{1}{(1-n/p)_{k+1}} \left(\sum_{\Psi \in \mathbf{\Psi}} \|p_\Psi\|_{L_\infty(\Omega)} \right) |f|_{k+1,p,\Omega} (h_{\Omega,\Theta})^{k+1}.$$

The condition $1 - n/p > 0$ is needed so that the multivariate form of Hardy's inequality can be applied to (5.3.6). By comparison, to obtain (5.2.7) from (5.2.3), only the weaker condition that $k + 1 - n/p > 0$ was needed.

6. Other error bounds.

6.1. Discussion. Most of the integral error formulas for Lagrange maps given in the literature, including those of section 5, can be obtained from

$$f(x) - L_{P,\Theta} f(x) = \sum_{\theta \in \Theta} \left(\int_{[x]} f - \int_{[\theta]} f \right) \ell_\theta(x),$$

which is valid whenever P contains the constants, by appropriately using the identity

$$\int_{[\Theta,v]} f - \int_{[\Theta,w]} f = \int_{[\Theta,v,w]} D_{v-w} f \tag{6.1.1}$$

and integration by parts.

For example, in Gregory [Gr75] integration by parts is used to give a *Taylor-type* expansion for f. From this is obtained an integral error formula for *linear interpolation* on a triangle, i.e., when Θ consists of three affinely independent points in $\mathrm{I\!R}^2$, and the interpolants are the linear polynomials $P := \Pi_1(\mathrm{I\!R}^2)$. Such an argument is frequently referred to as a *Sard kernel theory* argument, as developed by Sard [Sa63]. The resulting formula is complicated—it has four line integrals and five area integrals. Another example is given by Hakopian [H82], who uses (6.1.1) to obtain an integral error formula for *tensor-product* Lagrange interpolation.

In view of their derivations, all of these integral error formulas involve terms which consist of a function (obtained appropriately from the Lagrange functions) multiplied by the integral of some derivative against a simplex spline. Thus it is possible to apply the multivariate form of Hardy's inequality to all such formulas (and those likely to be obtained in the future) to obtain L_p-bounds—with the caution that, as pointed out for the examples in sections 4 and 5, for small p, this may not accurately reflect the behavior of the error.

Exactly how to use (6.1.1) and integration by parts to obtain the best possible error formula for a given purpose is far from clear. In a future paper, the author considers the simplest case, that of linear interpolation on a triangle. There the formulas of Ciarlet and Wagschal [CW71], Gregory [Gr75], Sauer and Xu [SX95], and others are discussed.

Acknowledgments. The author would like to thank the referees, Carl de Boor, Shaun Cooper, and Geoff Pritchard for their considered comments and help with this paper.

BLOWUP IN REACTION-DIFFUSION SYSTEMS WITH DISSIPATION OF MASS*

MICHEL PIERRE† AND DIDIER SCHMITT†

Abstract. We prove blowup in finite time of the solutions to some reaction-diffusion systems that preserve nonnegativity and for which the total mass of the components is uniformly bounded. (These are natural properties in applications.) This is done by presenting explicit counterexamples constructed with the help of formal computation software. Several partial results of global existence had been obtained previously in the literature. Our counterexamples explain a posteriori why extra conditions are needed. Negative results are also provided as a by-product for linear parabolic equations in nondivergence form and with discontinuous coefficients and for nonlinear Hamilton–Jacobi evolution equations.

Key words. parabolic system, reaction-diffusion, global existence, blowup, parabolic equation in nondivergence form, Hamilton–Jacobi equation

1. Introduction.

We are mainly interested in global existence in time or blowup in finite time of solutions to reaction-diffusion systems of the form

$$\frac{\partial u}{\partial t} - d_1 \Delta u = f(u,v) \quad \text{on } (0,\infty)\times\Omega, \tag{1}$$

$$\frac{\partial v}{\partial t} - d_2 \Delta v = g(u,v) \quad \text{on } (0,\infty)\times\Omega \tag{2}$$

for which the following two main properties hold:

- the positivity of the solutions is preserved with time, which is equivalent to

$$\forall u, v \geq 0, \quad f(0,v) \geq 0, \qquad g(u,0) \geq 0; \tag{3}$$

- the total mass of the components u and v is nonincreasing with time, which is essentially ensured by the structure condition

$$f + g \leq 0. \tag{4}$$

Here f and g are regular functions from $[0,\infty[^2$ into $I\!R, d_1$ and d_2 are positive constants, and Ω is a smooth bounded open subset of $I\!R^N$. As usual, "good" boundary conditions should be prescribed for u and v, for instance,

$$u = 0, \qquad v = 0 \quad \text{on } \partial\Omega, \tag{5}$$

as well as initial conditions,

$$u(0,.) = u_0 \geq 0, \qquad v(0,.) = v_0 \geq 0. \tag{6}$$

† CNRS UMR 9973, INRIA-Lorraine Projet NUMATH, Laboratoire de Mathématiques, Université Henri Poincaré–Nancy I, B.P. 239, 54506 Vandoeuvre-lès-Nancy cedex, France (pierre@loria.fr, dschmitt@iecn.u-nancy.fr).

The main consequence of properties (3) and (4) is that the solutions u and v satisfy an a priori L^1-estimate uniformly in time. Indeed, integrating the sum of (1) and (2) and taking (5) into account leads to

$$\frac{\partial}{\partial t}\int_\Omega u(t)+v(t)\le\int_\Omega f+g\le 0,$$

$$\int_\Omega u(t)+v(t)\le\int_\Omega u_0+v_0. \tag{7}$$

Since u and v are nonnegative, this is a uniform estimate of their L^1-norms. It is well known that local existence of nonnegative solutions holds for the system (1), (2), (5), (6) when $u_0, v_0\in L^\infty(\Omega)$. Moreover, existence is global as soon as $u(t)$ and $v(t)$ satisfy an a priori L^∞-estimate uniformly in time.

Here the a priori estimate is only in $L^1(\Omega)$. Much work has been done to analyze how this L^1-estimate or, more generally, structure conditions like (4) help to provide global existence.

Note, for instance, that if $d_1=d_2$, summing (1) and (2) leads—thanks to (4)—to

$$\frac{\partial}{\partial t}(u+v)-d_1\Delta(u+v)\le 0,$$

and by the maximum principle,

$$||(u+v)(t)||_\infty\le||u_0+v_0||_\infty,$$

so global existence holds.

Note also that properties (3) and (4) imply global existence (for nonnegative data) for the associated ordinary differential system

$$\dot u=f(u,v),\qquad \dot v=g(u,v).$$

For the complete system with different diffusion coefficients $d_1\ne d_2$, the question is considerably more delicate. One of the main result is that, in general, if one of u or v is a priori bounded, then so is the other. This is the case if, for instance, we have the extra information

$$f\le 0. \tag{8}$$

Obviously, by the maximum principle, this implies $||u(t)||_\infty\le||u_0||_\infty$. If g is of at most polynomial growth, then global existence can be proved [2], [4], [6], [7], [8].

However, it was still an open problem to decide what happens for systems without any a priori L^∞-bound on either u or v and whether extra conditions must be added to (3) and (4). This is precisely the goal of this paper, where we prove that blowup in L^∞ may occur in finite time for these systems.

In order to better understand the question, let us discuss some explicit examples of "systems" that naturally appear in this class. We have, for instance, the following:

$$u_t-d_1\Delta u=\lambda u^3v^2-u^2v^3, \tag{9}$$

$$v_t-d_2\Delta v=-u^2v^3+u^3v^2. \tag{10}$$

Here $f+g=(\lambda-1)u^3v^2 \leq 0$ if $\lambda \in [0,1]$. If $d_1=d_2$ or, more generally, if d_1 is close to d_2, then the system (9), (10), (5), (6) has a global solution. (See the remark above when $d_1=d_2$ and see [1] and [10] in general.)

Now if d_1 and d_2 are distinct and not close to each other, the question is more serious. If $\lambda=0$, we are in the situation described above where (8) also holds. Then u is a priori uniformly bounded and global existence can be proved. The case when λ is small enough can also be taken care of similarly [10]. Now the question is open when $\lambda \in \,]0,1]$. Note that here we even have

$$f+\lambda g=(\lambda-1)u^2v^3 \leq 0, \tag{11}$$

so if $\lambda \in [0,1[$, inequalities (4) and (11) are linearly independent. This implies, for instance, an a priori L^1-bound on the nonlinear terms.

We will see here that similar systems with these properties may present blowup in L^∞.

Let us also discuss another example, which is specifically studied in [3], [9], and [10]:

$$\begin{aligned} u_t-d_1u_{xx}&=-c(x)u^\alpha v^\beta,\\ v_t-d_2v_{xx}&=c(x)u^\alpha v^\beta, \end{aligned}$$

where $c:(-1,1)\to I\!R$ is given. Here $\Omega=(-1,1)$ and f and g also depend on the space variable x and satisfy $f+g=0$.

If $c\equiv 1$, we are in the situation of (8) and global existence follows. The same holds if $c(.)$ is of constant sign. Now the situation is quite different if $c(.)$ changes sign. The following specific case is analyzed in [9]:

$$c(x)>0 \quad \text{on } (0,1), \qquad c(0)=0, \qquad c(x)<0 \quad \text{on } (-1,0).$$

It can be shown that u and v are uniformly bounded in $L^\infty_{\text{loc}}([0,\infty)\times(0,1])$ and $L^\infty_{\text{loc}}([0,\infty)\times[-1,0))$. Therefore, blowup can only occur at $x=0$ and, if so, will occur for u and v at the same time. If c(.) vanishes fast enough at 0, then no blowup occurs (see [9]). The question is still open for a general $c(.)$. However, here we present similar examples where blowup in L^∞ does happen.

It is interesting to remark that in all of our examples, although solutions blow up in $L^\infty(\Omega)$ for some T, they can be extended across T as global "weak" solutions, for instance, in the sense of distributions.

Finally, let us mention that the blowup examples described in this paper provide interesting by-products for two questions of independent interest related to the following equations:

$$\begin{cases} u_t-a(x,t)\Delta u=f & \text{on } (0,T)\times\Omega,\\ u_{|\partial\Omega}=0, \qquad u(0,.)=0, \end{cases} \tag{12}$$

where

$$0<d_1\leq a(x,t)\leq d_2, \tag{13}$$

and

$$\begin{cases} u_t-\max(d_1\Delta u, d_2\Delta u)=f & \text{on } (0,T)\times\Omega,\\ u_{|\partial\Omega}=0, \qquad u(0,.)=0. \end{cases} \tag{14}$$

We prove that problem (14) is ill-posed for $f \in L^p(Q_T)$ when p is close to 1 (although it is well-posed if $p \geq 2$). For problem (12), we prove there is no estimate of the form

$$||u(T)||_{L^1(\Omega)} \leq C||f||_{L^p(Q_T)} \tag{15}$$

with a constant C depending only on d_1, d_2, T, and Ω when p is close to 1. Here also, such estimates are valid if $p \geq 2$. Note also that (15) holds when $a(.,.)$ is continuous with C depending on its modulus of continuity. Indeed, we have an L^p-theory, and u_t and Δu are bounded in L^p. Obviously, the question here concerns a subclass of parabolic operators of nondivergence form with discontinuous coefficients.

2. The main results. We denote by B the Euclidian unit ball in $I\!R^N$, $Q_T = (0,T) \times B$, and $\Sigma_T = (0,T) \times \partial B$.

THEOREM 2.1. *There exist $f, g \in C^\infty([0,\infty)^2, I\!R)$, $d_1, d_2 > 0$, $T > 0$, u_0, $v_0 \in C^\infty(\overline{B})$, $u_0 \geq 0$, $v_0 \geq 0$, $\alpha_1, \alpha_2 \in C^\infty([0,T])$, $\lambda \in]0,1[$, and $u, v \geq 0$, classical solutions of*

$$\frac{\partial u}{\partial t} - d_1 \Delta u = f(u,v) \quad \textit{on } Q_T, \tag{16}$$

$$\frac{\partial v}{\partial t} - d_2 \Delta v = g(u,v) \quad \textit{on } Q_T, \tag{17}$$

$$u(t,x) = \alpha_1(t), \qquad v(t,x) = \alpha_2(t) \quad \textit{on } \Sigma_T, \tag{18}$$

$$u(0,x) = u_0(x), \qquad v(0,x) = v_0(x) \quad \textit{on } B \tag{19}$$

such that

$$f + g \leq 0, \qquad f + \lambda g \leq 0, \tag{20}$$

$$\exists k > 0,\, p \geq 1, \quad \forall u, v \geq 0, \qquad |f(u,v)| + |g(u,v)| \leq k(u^p + v^p + 1), \tag{21}$$

$$\forall r, s \geq 0, \quad f(0,s) \geq 0, \qquad g(r,0) \geq 0, \tag{22}$$

and

$$\lim_{t \uparrow T} ||u(t)||_{L^\infty(B)} = \lim_{t \uparrow T} ||v(t)||_{L^\infty(B)} = +\infty. \tag{23}$$

THEOREM 2.2. *There exist $\alpha, \beta > 1$, $d_1, d_2 > 0$, $T > 0, u_0$, $v_0 \in C^\infty(\overline{B})$, $u_0 \geq 0$, $v_0 \geq 0$, $\alpha_1, \alpha_2 \in C^\infty([0,T])$, $c_1, c_2 \in C^k(\overline{Q}_T)$ with $k \geq 0$, and $u, v \geq 0$, classical solutions of*

$$\frac{\partial u}{\partial t} - d_1 \Delta u = c_1(t,x) u^\alpha v^\beta \quad \textit{on } Q_T, \tag{24}$$

$$\frac{\partial v}{\partial t} - d_2 \Delta v = c_2(t,x) u^\alpha v^\beta \quad \textit{on } Q_T, \tag{25}$$

$$u(t,x) = \alpha_1(t), \qquad v(t,x) = \alpha_2(t) \quad \textit{on } \Sigma_T, \tag{26}$$

$$u(0,x) = u_0(x), \qquad v(0,x) = v_0(x) \quad \textit{on } \Omega \tag{27}$$

such that

$$c_1(x,t) + c_2(x,t) \leq 0 \quad \textit{on } Q_T \tag{28}$$

and

$$\lim_{t\uparrow T} ||u(t)||_{L^\infty(B)} = \lim_{t\uparrow T} ||v(t)||_{L^\infty(B)} = +\infty. \tag{29}$$

Remark 2.1. In both theorems, u and v satisfy

$$\frac{\partial u}{\partial t} - d_1\Delta u + \frac{\partial v}{\partial t} - d_2\Delta v \leq 0. \tag{30}$$

Together with the boundary conditions on u and v, this implies, in particular, that the L^1-norms of $u(t)$ and $v(t)$ are bounded on $(0,T)$. Actually, as will appear clearly in the examples in the next section, in both cases, there exists $p^* \in (1,\infty)$ such that

$$\forall p < p^*, \quad \sup_{t\in(0,T)} (||u(t)||_{L^p(B)} + ||v(t)||_{L^p(B)}) < \infty, \tag{31}$$

$$\forall p \geq p^*, \quad \lim_{t\uparrow T} ||u(t)||_{L^p(B)} = \lim_{t\uparrow T} ||v(t)||_{L^p(B)} = +\infty. \tag{32}$$

The proofs of both theorems will be obtained by presenting explicit solutions u and v satisfying the fundamental inequality (30). Many consequences may be derived from this together with the nonnegativity of u and v. We have already mentioned the uniform L^1-bound on u and v. It also implies (see [2] and [6]) that for all $p \in (1,\infty)$, there exists $C = C(p, T, \Omega, \alpha_1, \alpha_2, ||u_0||_\infty, ||v_0||_\infty)$ such that

$$\forall t \in (0,T), \quad ||u||_{L^p(Q_T)} \leq C||v||_{L^p(Q_T)}, \qquad ||v||_{L^p(Q_T)} \leq C||u||_{L^p(Q_T)}. \tag{33}$$

Consequently, u and v can only blow up at the same time t when (30) holds.

Remark 2.2. Another interesting consequence of (30) may be obtained by setting

$$w(t,x) := u(t,x) + v(t,x), \qquad a(t,x) = \frac{d_1u(t,x) + d_2v(t,x)}{u(t,x) + v(t,x)}. \tag{34}$$

Then (30) can be rewritten as

$$\frac{\partial w}{\partial t} - \Delta(aw) \leq 0. \tag{35}$$

Here, thanks to the positivity of u and v, we have the a priori estimate

$$0 < \min(d_1, d_2) \leq a(t,x) \leq \max(d_1, d_2). \tag{36}$$

A natural question is whether the parabolic inequality (35) implies the existence of a constant C depending only on d_1, d_2, T, α_1, and α_2 such that for p large,

$$||w||_{L^p(Q_T)} \leq C(||w_0||_\infty + 1). \tag{37}$$

By duality, this is equivalent (see the next section) to the existence of a similar constant C such that

$$||z(T)||_{L^1(Q_T)} \leq C||\theta||_{L^q(Q_T)}, \tag{38}$$

where $1/q + 1/p = 1$ and z is solution of the dual problem

$$z_t - b\Delta z = \theta \quad \text{on } Q_T, \qquad b(t) = a(T-t), \tag{39}$$

$$z(0,.) = 0, \qquad z_{|\partial\Omega} = 0. \tag{40}$$

It turns out that (38) is valid for all $q \geq 2$. Indeed, for $q = \infty$, it is an easy consequence of the maximum principle which holds for (39). For $q = 2$, we may (formally) multiply (39) by $-\Delta z$ to obtain

$$\frac{\partial}{\partial t}\frac{1}{2}\int_\Omega |\nabla z(t)|^2 + \int_\Omega b(\Delta z)^2 = -\int_\Omega \theta\Delta z.$$

Using the uniform estimate (36) and Young's inequality, we deduce that

$$\frac{1}{2}\int_\Omega |\nabla z(t)|^2 + \min(d_1, d_2)\int_0^t\int_\Omega (\Delta z)^2 \leq \frac{1}{2}\min(d_1, d_2)\int_0^t\int_\Omega (\Delta z)^2 + C\int_0^t\int_\Omega \theta^2,$$

which implies

$$\int_{Q_T} ||\Delta z||_{L^2(Q_T)} \leq C||\theta||_{L^2(Q_T)}, \tag{41}$$

where C depends only on d_1 and d_2. Therefore, estimate (38) is true for $q = 2$ (and, by interpolation, for any $q \in [2, \infty]$). We even have that z_t and Δz (and not only z itself) are bounded in $L^2(Q_T)$.

As a consequence of the counterexamples in Theorems 2.1 and 2.2, we will see that (38) is false when q is close to 1. More precisely, we have the following.

Proposition 2.3. *There exists $p \in (1, 2)$, $b_n \in C^\infty(\overline{Q}_T)$, $d_1, d_2 > 0$, $\theta_n \in C^\infty(\overline{Q}_T)$, $\theta_n \geq 0$, and $z_n \in C^\infty(\overline{Q}_T)$, the solution of*

$$\frac{\partial z_n}{\partial t} - b_n\Delta z_n = \theta_n \quad \textit{on } Q_T, \tag{42}$$

$$z_n(0,.) = 0, \qquad z_{n_{|\partial B}} = 0 \tag{43}$$

such that

$$0 < d_1 \leq b_n \leq d_2, \tag{44}$$

$$||\theta_n||_{L^p(Q_T)} = 1, \tag{45}$$

$$\lim_{n\to\infty} ||z_n||_{L^\infty(0,T;L^1(B))} = +\infty. \tag{46}$$

Finally, we mention a final consequence of independent interest for the following nonlinear Hamilton–Jacobi evolution equations.

Proposition 2.4. *There exist $p \in (1, 2)$, $d_1, d_2 > 0$, $\theta_n \in C^\infty(\overline{Q}_T)$, and $z_n \in L^2(Q_T)$ with $\Delta_{z_n}, \partial z_n/\partial t \in L^2(Q_T)$ the solution of*

$$\frac{\partial z_n}{\partial t} - \max(d_1\Delta z_n, d_2\Delta z_n) = \theta_n \quad \textit{on } Q_T, \tag{47}$$

$$z_n(0,.) = 0, \qquad z_{n_{|\partial B}} = 0 \tag{48}$$

such that

$$||\theta_n||_{L^p(Q_T)} = 1, \tag{49}$$

$$\lim_{n\to\infty} ||z_n||_{L^\infty(0,T;L^1(B))} = +\infty. \tag{50}$$

3. The proofs.

Preliminary remarks. As stated in section 2, the proofs of Theorems 2.1 and 2.2 are obtained by constructing explicit functions u and v satisfying the inequality

$$u_t - d_1\Delta u + v_t - d_2\Delta v \leq 0. \tag{51}$$

It will turn out that they are also solutions of systems of the form (16), (17) and (24), (25) with the properties listed in the statements of the theorems.

For reasons that come from a precise analysis of the problem and a guess of the possible singularities, we look a priori for functions u and v of the form

$$u(t,x) = \frac{a(T-t)+b|x|^2}{(T-t+|x|^2)^\gamma}, \qquad v(t,x) = \frac{c(T-t)+d|x|^2}{(T-t+|x|^2)^\gamma}, \tag{52}$$

where $|.|$ denotes the Euclidian norm and $a, b, c, d > 0$ and $\gamma > 1$ are to be determined so that (51) holds for some $d_1, d_2 > 0$, also to be determined. This has been done with the help of the formal computation software Maple, where the unknown coefficients can be progressively adapted “by hand” to satisfy (51). As a consequence, the solutions that we found in this way are not numerically simple.

Here we give one solution which can also be explicitly checked by direct computations. For this, we choose

$$N = 10 \text{ (for the dimension)}, \qquad \gamma = 5/4, \tag{53}$$

$$a = 1/25, \qquad b = 1, \qquad c = 11/2, \qquad d = 1/10, \tag{54}$$

$$d_1 = 1, \qquad d_2 = 1/10. \tag{55}$$

Lengthy but straightforward computations show that u and v given by (52) with the data (53)–(55) satisfy inequality (51) and, more precisely,

$$u_t - d_1\Delta u = \frac{A_1(T-t)^2 + B_1(T-t)|x|^2 + C_1|x|^4}{(T-t+|x|^2)^{\gamma+2}}, \tag{56}$$

$$v_t - d_2\Delta v = \frac{A_2(T-t)^2 + B_2(T-t)|x|^2 + C_2|x|^4}{(T-t+|x|^2)^{\gamma+2}}, \tag{57}$$

$$u_t + v_t - d_1\Delta u - d_2\Delta v = \frac{A(T-t)^2 + B(T-t)|x|^2 + C|x|^4}{(T-t+|x|^2)^{\gamma+2}}, \tag{58}$$

where

$$A_1 = -1899/100, \qquad B_1 = -323/100, \qquad C_1 = 496/100, \tag{59}$$

$$A_2 = 1194/80, \qquad B_2 = 281/80, \qquad C_2 = -427/80, \tag{60}$$

$$A = -1626/400, \qquad B = 113/400, \qquad C = -151/400. \tag{61}$$

We check that $B^2 - 4AC < 0$ so that (51) holds.

Remark. Note that other explicit solutions are also found in dimension $N = 1$. We easily show that they satisfy (24) and (25) in Theorem 2.2. However, the corresponding functions f and g of Theorem 2.1 are technically difficult to present.

TABLE 1

k	$\tilde{\lambda_k}$	$\tilde{\mu_k}$	$\tilde{\nu_k}$
0	$2^{-3} \times 3^7 \times 5^8 \times 43 \times 653$	$-2^{-2} \times 3^7 \times 5^9 \times 3023$	$-2^{-3} \times 3^9 \times 5^8 \times 239$
1	$2^{-2} \times 3^5 \times 5^8 \times 7 \times 7703$	$-2^{-4} \times 3^5 \times 5^8 \times 11 \times 20717$	$-2^{-4} \times 3^5 \times 5^8 \times 12203$
2	$-2 \times 3^5 \times 5^7 \times 19 \times 359$	$2^{-3} \times 3^4 \times 5^7 \times 29 \times 61 \times 131$	$-2^{-3} \times 3^4 \times 5^7 \times 7 \times 79 \times 173$
3	$-2^4 \times 3 \times 5^6 \times 23 \times 31 \times 397$	$3 \times 5^6 \times 409 \times 9011$	$-3^2 \times 5^6 \times 281159$
4	$-3^{-1} \times 2^7 \times 5^5 \times 61 \times 4567$	$3^{-1} \times 2^3 \times 5^8 \times 28591$	$-3^{-1} \times 2^3 \times 5^5 \times 883517$
5	$-3^{-1} \times 2^{13} \times 5^3 \times 17 \times 19^2$	$3^{-1} \times 2^6 \times 5^4 \times 59 \times 2087$	$-3^{-1} \times 2^6 \times 5^3 \times 13 \times 73 \times 179$

Proof of Theorem 2.1. We will show that u and v defined as above satisfy the conclusions of the theorem. Obviously, $u(0), v(0) \in C^\infty(\bar{B})$, $u_{|\partial B} = \alpha_1 \in C^\infty([0,T])$, $v_{|\partial B} = \alpha_2 \in C^\infty([0,T])$, and, since $\gamma > 1$,

$$\lim_{t \uparrow T} ||u(t)||_\infty = \lim_{t \uparrow T} ||v(t)||_\infty = +\infty. \tag{62}$$

More precisely, all of the L^p-norms for $p \geq 20$ blow up at $t = T$.

Now we need to determine f and g. Starting from (56) and (57), we look for polynomial functions P and Q, homogeneous and of degree 5 in u and v, such that

$$u_t - d_1 \Delta u = P(u,v), \qquad v_t - d_2 \Delta v = Q(u,v). \tag{63}$$

Formal computations lead to the following expressions, which can be checked directly by, again, lengthy but straightforward computations:

$$P(u,v) = \sum_{k=0}^{5} \lambda_k u^{5-k} v^k, \qquad Q(u,v) = \sum_{k=0}^{5} \mu_k u^{5-k} v^k \tag{64}$$

with $\lambda_k = (229)^{-5} \tilde{\lambda}_k$ and $\mu_k = (229)^{-5} \tilde{\mu}_k$ and where $\tilde{\lambda}_k$ and $\tilde{\mu}_k$ are given in Table 1.

We check that $P + Q = \sum_{k=0}^{5} \nu_k u^{5-k} v^k$, where all the $\nu_k = (229)^{-5} \tilde{\nu}_k$'s are negative so that for λ close to 1, $P + \lambda Q$ also has negative coefficients. Therefore, (20) holds for P and Q. However, P and Q do not satisfy (22). Since u and v are bounded from below on Q_T by

$$m_1 = \frac{\min(a,b)}{(T+1)^{\gamma-1}}, \qquad m_2 = \frac{\min(c,d)}{(T+1)^{\gamma-1}},$$

respectively, we can always modify P and Q on a neighborhood of $\{0\} \times [0, \infty[\, \cup \, [0, \infty[\, \times \{0\}$. Let $\varphi \in C^\infty(\mathbb{R}^2)$ be a function which is identically one on $[m_1, \infty) \times [m_2, \infty)$ and such that

$$\forall u, v \geq 0, \quad \varphi(0, v) = \varphi(u, 0) = 0.$$

We set

$$\forall u, v \geq 0, \quad f(u,v) := \varphi(u,v)P(u,v), \qquad g(u,v) := \varphi(u,v)Q(u,v).$$

Then for the same values of λ close to 1 as above,

$$f + \lambda g = \varphi(P + \lambda Q) \leq 0,$$

so (16), (17), (20), (21), and (22) are satisfied.

Proof of Theorem 2.2. We use the same functions u and v as above. We only have to prove that the expressions in (56) and (57) can be written as in (24) and (25). For this we choose $\alpha, \beta > 1$ such that

$$\alpha + \beta > (\gamma + 2)/(\gamma - 1) \tag{65}$$

and (see (52), (56), and (57))

$$c_1(t,x) := \frac{A_1(T-t)^2 + B_1(T-t)|x|^2 + C_1|x|^4}{(a(T-t) + b|x|^2)^\alpha (c(T-t) + d|x|^2)^\beta} (T - t + |x|^2)^{(\alpha+\beta)\gamma - \gamma - 2},$$

$$c_2(t,x) := \frac{A_2(T-t)^2 + B_2(T-t)|x|^2 + C_2|x|^4}{(a(T-t) + b|x|^2)^\alpha (c(T-t) + d|x|^2)^\beta} (T - t + |x|^2)^{(\alpha+\beta)\gamma - \gamma - 2}.$$

Obviously, with this choice of c_1 and c_2, relations (24) and (25) hold. The sign of $c_1 + c_2$ is the same as the sign of $A(T-t)^2 + B(T-t)|x|^2 + C|x|^4$ in (58), which has already been checked to be negative. Now, thanks to the choice of (6.5), c_1 and c_2 are at least continuous on $\overline{Q_T}$. Actually, they are C^∞ except at the point $(T, 0)$, where they tend to 0. We can make them more regular by choosing α and β even larger.

Proof of Proposition 2.3. We take u and v as in (52) and we set

$$w_n(t,x) := u\left(t - \frac{1}{n}, x\right) + v\left(t - \frac{1}{n}, x\right), \tag{66}$$

$$a_n(t,x) := \left[d_1 u\left(t - \frac{1}{n}, x\right) + d_2 v\left(t - \frac{1}{n}, x\right)\right] / w_n(t,x). \tag{67}$$

Note that

$$0 < \min(d_1, d_2) \leq a_n \leq \max(d_1, d_2).$$

By (51),

$$\frac{\partial w_n}{\partial t} - \Delta(a_n w_n) \leq 0 \quad \text{ on } Q_T. \tag{68}$$

For $\theta \in C^\infty(\overline{Q}_T)$, $\theta \geq 0$, and $b_n(t) = a_n(T-t)$, let $z \in C^\infty(\overline{Q}_T)$, $z \geq 0$ be the solution of

$$\frac{\partial z}{\partial t} - b_n \Delta z = \theta \quad \text{ on } Q_T, \tag{69}$$

$$z(0,.) = 0, \qquad z_{|\partial B} = 0. \tag{70}$$

The existence of z is classical (see, e.g., [5]). We set $\tilde{z}(t) = z(T-t)$ so that

$$-(\tilde{z}_t + a_n \Delta \tilde{z}) = \tilde{\theta}, \qquad \tilde{\theta}(t) = \theta(T-t). \tag{71}$$

Now let $\varphi \in C_0^\infty(B)$ with $0 \le \varphi \le 1$ and $\varphi \equiv 1$ on $B(0,1/2)$. Using (68)–(71), we have

$$\begin{aligned}\int_{Q_T} \tilde{\theta} w_n \varphi = \int_{Q_T} -w_n \varphi(\tilde{z}_t + a_n \Delta \tilde{z}) = \int_\Omega w_n(0)\varphi \tilde{z}(0) + \int_{Q_T} \tilde{z}(w_{n_t}\varphi - \Delta(a_n w_n \varphi))\\ = \int_\Omega w_n(0)\varphi z(T) + \int_{Q_T} \tilde{z}[\varphi(w_{n_t} - \Delta(a_n w_n)) - 2\nabla\varphi\nabla(a_n w_n) - a_n w_n \Delta\varphi].\end{aligned}$$

Since $\nabla\varphi$ and $\Delta\varphi$ are identically zero around the origin, the terms $\nabla\varphi\nabla(a_n w_n)$ and $a_n w_n \Delta\varphi$ are uniformly bounded independently of n. Also using inequality (68), we obtain

$$\begin{aligned}\int_{Q_T} \tilde{\theta} w_n \varphi &\le \int_\Omega w_n(0) z(T) + C\int_{Q_T} z\\ &\le (\|w_n(0)\|_\infty + CT)\|z\|_{L^\infty(0,T,L^1(B))}.\end{aligned} \tag{72}$$

If we had

$$\|z\|_{L^\infty(0,T,L^1(B))} \le k\|\theta\|_{L^p(Q_T)} \tag{73}$$

for some $p \in (1,2)$, some $k = k(d_1, d_2, p, T)$, and all $\theta \in C^\infty(\overline{Q}_T)$, then from (72) we would deduce by duality that for some C independent of n,

$$\|w_n\varphi\|_{L^{p'}(Q_T)} \le C.$$

This is false for p' large enough (that is, for p small enough) by the construction of u and v and the definition (66) of w_n. Therefore, the solutions of (69) and (70) do not satisfy estimate (73) (see (72)) for some p close to 1, whence the statement of Proposition 2.3 follows.

Proof of Proposition 2.4. For $\theta_n \in C^\infty(\overline{Q}_T)$, it is classical (see, e.g., [1] and [10]) that there exists a solution of (47) and (48) whose regularity is at least such that

$$z_n \in L^\infty(Q_T), \qquad z_{n_t}, \Delta z_n \in L^2(Q_T),$$

and (47) is satisfied at least a.e. $x, t \in Q_T$. We choose θ_n as in the statement of Proposition (2.3). We obviously have that

$$\max(d_1\Delta z_n, d_2\Delta z_n) \ge b_n \Delta z_n \quad \text{a.e.}$$

so that

$$\frac{\partial z_n}{\partial t} - b_n \Delta z_n \ge \theta_n.$$

By the maximum principle applied to the operator $\partial/\partial t - b_n\Delta$, this solution z_n is greater than the one defined in Proposition 2.3. As a consequence, (50) follows from (46).

HIGHER GRADIENT INTEGRABILITY OF EQUILIBRIA FOR CERTAIN RANK-ONE CONVEX INTEGRALS*

MICHAEL M. DOUGHERTY[†] AND DANIEL PHILLIPS[‡]

Abstract. In this note, we prove $L^m_{\text{loc}}(\Omega)$, $1 < m < \infty$, estimates of the gradients of equilibria $\mathcal{U} \in W^{1,p}(\Omega; \mathbb{R}^N)$ for a class of variational integrals $\int_\Omega f(D\mathcal{U})\,dx$. Our proof employs a bootstrap argument based on a result of DiBenedetto and Manfredi [*Amer. J. Math.*, 115 (1993), pp. 1107–1134].

1. Introduction and main result.

Let $\Omega \subset \mathbb{R}^n$, $n \geq 2$, be a bounded domain. For $\mathcal{U} \in W^{1,p}(\Omega; \mathbb{R}^N)$, $1 < p < \infty$, define

$$\mathcal{F}(\mathcal{U}) = \int_\Omega f(D\mathcal{U})dx, \tag{1.1}$$

where f has the form

$$f(A) = |A|^p + g(A) \tag{1.2}$$

and g is a rank-one convex function such that

$$\bigtriangledown g(A) \text{ exists} \quad \text{for all } A \in \mathcal{M}^{N\times n}, \tag{1.3}$$

$$|g(A)| \leq a|A|^q + b \tag{1.4}$$

for real numbers a, b, and $1 \leq q < p < \infty$. By the rank-one convexity of g, we mean that

$$g(\lambda A + (1-\lambda)B) \leq \lambda g(A) + (1-\lambda)g(B) \tag{1.5}$$

holds for all $0 \leq \lambda \leq 1$ and $A, B \in \mathcal{M}^{N\times n}$ with rank $\{A - B\} \leq 1$. Our result concerns equilibrium points of $\mathcal{F}$, i.e., functions $\mathcal{U} \in W^{1,p}(\Omega; \mathbb{R}^N)$ which satisfy

$$\text{div}\left(\frac{\partial f}{\partial A}(D\mathcal{U})\right) = 0 \quad \text{in } \mathcal{D}'(\Omega; \mathbb{R}^N). \tag{1.6}$$

We prove the following.

THEOREM. *Suppose $\mathcal{U} \in W^{1,p}(\Omega; \mathbb{R}^N)$, $1 < p < \infty$, is an equilibrium point of* (1.1) *and that* (1.2)–(1.4) *hold. Then for each subset $\Omega' \Subset \Omega$ and every $m \in (1, \infty)$, there exists a constant $C = C(a, b, m, p, n, N, \Omega', \Omega)$ such that*

$$\|D\mathcal{U}\|_{L^m(\Omega')} \leq C\big(1 + \|D\mathcal{U}\|_{L^p(\Omega)} + \|\mathcal{U}\|_{L^p(\Omega)}\big). \tag{1.7}$$

Remark 1. In particular, the result holds for minimizers of (1.1)–(1.5) when they exist, i.e., functions $\mathcal{U} \in W^{1,p}(\Omega; \mathbb{R}^N)$ such that $\mathcal{F}(\mathcal{U}) \leq \mathcal{F}(\mathcal{V})$ whenever $\mathcal{U} - \mathcal{V} \in W_0^{1,p}(\Omega; \mathbb{R}^N)$.

Remark 2. By the Sobolev embedding theorem, we have $\mathcal{U} \in C^\alpha(\Omega; \mathbb{R}^N)$ for all $\alpha \in (0,1)$. Previously, local Hölder continuity of minimizers for $0 < \alpha < 1$ was established in [F].

2. Background and examples. Rank-one convex functions satisfying (1.2)–(1.4) arise in optimization problems [K-S] and as approximate energies for models from nonlinear elasticity [B-P]. Such functions $f(A)$ have the feature that they can depend nonlinearly on the subdeterminants of A. For example, if we let $n = N$ and $g(A) = h(\det A)$ with h convex, then g is rank-one convex. If $p > n$ and

$$|h(d)| \leq C(|d| + 1), \tag{2.1}$$

then

$$f(A) = |A|^p + h(\det A) \tag{2.2}$$

is an example of an integrand satisfying (1.2)–(1.4). Functionals of this type but with a much more singular dependence on d are used in nonlinear elasticity theory. There one assumes $h(d) = +\infty$ for $d \leq 0$. Existence of minimizers for the singular problem is established but little is known about the minimizers themselves. One approach in studying the elasticity problem is to consider a sequence of approximate problems with

$$|h_k(d)| \leq c_k(|d| + 1) \tag{2.3}$$

and

$$h_k(d) \uparrow h(d) \quad \text{as } k \longrightarrow \infty. \tag{2.4}$$

These problems do have equilibrium points. The motivation for the present work is the investigation of gradient estimates for solutions to the approximate problem.

Prior work on estimating the gradient of solutions to such problems was done in [C-E] and [G-M]. In these papers, it was assumed that f is C^2 and

$$\lim_{|A| \to \infty} \frac{D^2(|A|^p) - D^2 f(A)}{|A|^{p-2}} = 0, \tag{2.5}$$

where $p \geq 2$. These works show that minimizers have locally bounded gradients. However, for a large class of integrands (such as (2.1)–(2.2), for instance), one must have $p > 2n$ in order for (2.5) to hold. To see this for our example, let $d \in \mathbb{R}$ such that $h''(d) > 0$ and $\lambda > 0$ and set

$$A = \operatorname{diag}[A_{11}, \ldots, A_{nn}], \tag{2.6}$$

where $A_{11} = d\lambda^{1-n}$ and $A_{ii} = \lambda$ for $2 \leq i \leq n$. Then

$$\left. \frac{\partial^2 h(\det A)}{\partial A_{11} \partial A_{11}} \right|_A = h''(d)\lambda^{2n-2}. \tag{2.7}$$

If we then consider (2.5) with $A = A(\lambda)$ and let $\lambda \longrightarrow \infty$, it follows that $p > 2n$ is required.

Thus for many examples with $n < p \leq 2n$, our theorem provides L^m estimates for the gradient of solutions for all $m < \infty$. Moreover, this information is new even for minimizers. In cases where (1.2)–(1.4) hold, our result establishes L^m estimates for equilibria in general.

3. Lemmas and proof of theorem. The proof will utilize the following lemmas.

Lemma 3.1. *Given* (1.3)–(1.5)*, there exists a constant $C < \infty$ such that*

$$|\bigtriangledown g(A)| \le C(1 + |A|^{q-1}) \tag{3.1}$$

holds for all $A \in \mathcal{M}^{N\times n}$.

Lemma 3.2. *If $\mathcal{U} \in W^{1,p}(\Omega;\mathbb{R}^N)$, $1 < p < \infty$, is an equilibrium point of* (1.1)–(1.5)*, then $\mathcal{U}$ satisfies the Euler–Lagrange equations in the weak sense:*

$$p \cdot \operatorname{div}(|D\mathcal{U}|^{p-2}D\mathcal{U}) = -\operatorname{div}(\bigtriangledown g(D\mathcal{U})). \tag{3.2}$$

That is, for each $\varphi \in W_0^{1,p}(\Omega;\mathbb{R}^N)$,

$$\int_\Omega p|D\mathcal{U}|^{p-2}\left\langle D\mathcal{U}, D\varphi\right\rangle dx = -\int_\Omega \left\langle \bigtriangledown g(D\mathcal{U}), D\varphi\right\rangle dx. \tag{3.3}$$

The first lemma can be found in [Dac, section 4.2.1.2]. The second lemma is a straightforward application of the dominated convergence theorem, (3.1), and Hölder's inequality. Our final lemma is a result of DiBenedetto and Manfredi [DB-M, Theorem 2.1] (see also Iwaniec [I, Theorem 2]).

Lemma 3.3. *Let $F \in L^p(\Omega;\mathbb{R}^{nN})$. Suppose $\mathcal{U} \in W^{1,p}(\Omega;\mathbb{R}^N)$ is a weak solution of*

$$\operatorname{div}(|D\mathcal{U}|^{p-2}D\mathcal{U}) = \operatorname{div}(|F|^{p-2}F) \quad \text{in } \Omega, \tag{3.4}$$

i.e.,

$$\int_\Omega |D\mathcal{U}|^{p-2}\langle D\mathcal{U}, D\varphi\rangle dx = \int_\Omega |F|^{p-2}\langle F, D\varphi\rangle dx \tag{3.5}$$

for all $\varphi \in W_0^{1,p}(\Omega;\mathbb{R}^N)$. Assume $d > 0$ and B_d, B_{2d}, $B_{4d} \subset \Omega$ are concentric balls of radii d, $2d$, and $4d$, respectively. Let $\eta \in C_0^\infty(B_{2d})$, $0 \le \eta \le 1$, and $\eta \equiv 1$ in B_d. If $|F| \in L^r_{\mathrm{loc}}(\Omega)$ for some $r \in [p,\infty)$, then $|D\mathcal{U}| \in L^r_{\mathrm{loc}}(\Omega)$, and for each $B_{4d} \subset \Omega$, there exists $\gamma = \gamma(n,N,p,r,d)$ such that

$$\|D(\eta\mathcal{U})\|_{L^r(\Omega)} \le \gamma\big(\|\eta F\|_{L^r(\Omega)} + \|\eta\mathcal{U}\|_{L^p(\Omega)}\big). \tag{3.6}$$

Proof of Theorem. We begin by rewriting the Euler–Lagrange equations (3.2) in the form of (3.4). We do this by taking

$$|F|^{p-2}F = -\frac{1}{p}\bigtriangledown g(D\mathcal{U}),$$

that is,

$$F = -\left(\frac{1}{p}\right)^{\frac{1}{p-1}} |\bigtriangledown g(D\mathcal{U})|^{\frac{2-p}{p-1}} \bigtriangledown g(D\mathcal{U}). \tag{3.7}$$

In particular,

$$|F| = \left(\frac{1}{p}\right)^{\frac{1}{p-1}} |\bigtriangledown g(D\mathcal{U})|^{\frac{1}{p-1}}. \tag{3.8}$$

Without loss of generality, assume $q > 1$. From (3.1), we have that

$$|\bigtriangledown g(D\mathcal{U})| \leq C(1 + |D\mathcal{U}|^{q-1}) \in L^{\frac{p}{q-1}}(\Omega). \tag{3.9}$$

Thus

$$|F| \in L^{(p-1)\cdot\frac{p}{q-1}}(\Omega). \tag{3.10}$$

By Lemma 3.3, we have

$$|D\mathcal{U}| \in L_{\text{loc}}^{p\cdot\frac{p-1}{q-1}}(\Omega), \tag{3.11}$$

and an estimate from (3.6). Note that $r \equiv p \cdot \frac{p-1}{q-1} > p$.

The other gradient estimates follow from the first by a bootstrap argument. Since we have proved that $|D\mathcal{U}| \in L_{\text{loc}}^{p\cdot(p-1)/(q-1)}(\Omega)$, we can further say that

$$|\bigtriangledown g(D\mathcal{U})| \in L_{\text{loc}}^{p\cdot\frac{p-1}{q-1}\cdot\frac{1}{q-1}}(\Omega), \tag{3.12}$$

which implies that

$$|F| \in L_{\text{loc}}^{p\cdot(\frac{p-1}{q-1})^2}(\Omega), \tag{3.13}$$

which by Lemma 3.3 gives

$$|D\mathcal{U}| \in L_{\text{loc}}^{p\cdot(\frac{p-1}{q-1})^2}(\Omega). \tag{3.14}$$

By induction, we get $|D\mathcal{U}| \in L_{\text{loc}}^{m}(\Omega)$ for each $m \in (p, \infty)$. □

THE LIMIT OF THE FULLY ANISOTROPIC DOUBLE-OBSTACLE ALLEN–CAHN EQUATION IN THE NONSMOOTH CASE*

CHARLES M. ELLIOTT[†] AND REINER SCHÄTZLE[‡]

Abstract. In this paper, we prove that solutions of the anisotropic Allen–Cahn equation in double-obstacle form with kinetic term

$$\varepsilon\beta(\nabla\varphi)\partial_t\varphi - \varepsilon\nabla A'(\nabla\varphi) - \frac{1}{\varepsilon}\varphi = \frac{\pi}{4}u \quad \text{in } [|\varphi| < 1],$$

where A is a convex function homogeneous of degree two and β depends only on the direction of $\nabla\varphi$, converge to an anisotropic mean-curvature flow

$$\beta(N)V_N = -\mathrm{tr}(B(N)D^2B(N)R) - B(N)u.$$

Here N, V_N, and R denote the normal, the normal velocity, and the second fundamental form of the interface, respectively, and $B := \sqrt{2A}$.

AMS subject classifications. 35R35, 35K22

PII. S0036141095286733

1. Introduction.

The Allen–Cahn equation

$$\varepsilon\partial_t\varphi_\varepsilon - \varepsilon\Delta\varphi_\varepsilon + \frac{1}{\varepsilon}W'(\varphi_\varepsilon) = c_W u, \tag{1}$$

where $W(t) := (t^2-1)^2$ is a double well potential and c_W is a certain constant depending only on W, was introduced by Allen and Cahn in [1] as a model for grain boundary motion. It is the L^2-gradient flow of the energy functional

$$F_\varepsilon(\varphi) := \int \frac{\varepsilon}{2}|\nabla\varphi|^2 + \frac{1}{\varepsilon}W(\varphi) - c_W u\varphi. \tag{2}$$

In its double-obstacle form (see Blowey and Elliott in [5]), the Allen–Cahn equation is replaced by a parabolic variational inequality with constraint that reads

$$\begin{gathered}\forall\eta \in \mathrm{L}^2(\mathrm{H}^{1,2}),\ |\eta| \le 1 : \\ \int \varepsilon\partial_t\varphi\ (\varphi-\eta) + \varepsilon\nabla\varphi\ (\nabla\varphi - \nabla\eta) - \frac{1}{\varepsilon}\varphi(\varphi-\eta) - \frac{\pi}{4}u(\varphi-\eta) \le 0, \\ |\varphi| \le 1.\end{gathered} \tag{3}$$

The convergence of solutions of the Allen–Cahn equation to the mean-curvature flow

$$V_N = -\kappa - u \tag{4}$$

was proved by Chen in [6], de Mottoni and Schatzmann in [10], Evans, Soner, and Souganidis in [13], and Bellettini and Paolini in [3]; in double-obstacle form, this was

* Received by the editors May 26, 1995; accepted for publication (in revised form) January 9, 1996.

proved by Chen and Elliott in [8], Nochetto, Paolini, and Verdi in [17] and Nochetto and Verdi in [18].

Anisotropy is now introduced by replacing the gradient in (2) and considering the functional

$$F_\varepsilon(\varphi) := \int \varepsilon A(\nabla\varphi) + \frac{1}{\varepsilon}W(\varphi) - c_W u\varphi, \tag{5}$$

where A is convex and homogeneous of degree two. Moreover, we do not consider the gradient flow of this functional but introduce a kinetic factor depending on $\nabla\varphi$ in front of $\partial_t\varphi$. Then the Allen–Cahn equation takes the form

$$\varepsilon\beta(\nabla\varphi)\partial_t\varphi_\varepsilon - \varepsilon\nabla A'(\nabla\varphi_\varepsilon) + \frac{1}{\varepsilon}W'(\varphi_\varepsilon) = c_W u, \tag{6}$$

where β is a positive function homogeneous of degree zero. McFadden et al. [15], Wheeler and McFadden [21], and Bellettini and Paolini [4] with $\beta = 1$ used formal asymptotics to provide the conjecture that (6) approximates the anisotropic mean-curvature flow, which reads, in two space dimensions,

$$\beta(N)V_N = -\gamma(\gamma + \gamma'')(\theta(N))\kappa - \gamma(\theta(N))u, \tag{7}$$

where γ is 2π-periodic, θ is the angle, and $\gamma(\theta(N)) := \sqrt{2A(N)}$. This conjecture was proved by the authors in [11] without the kinetic factor in the case when the evolution of the anisotropic mean-curvature flow is smooth. Moreover, it is proved there that the Hausdorff distance between the zero-level set of φ_ε, the solution of (6) in its double-obstacle form, and the interface of the flow is of order $O(\varepsilon^2)$. In the isotropic case, this bound was established by Nochetto, Paolini, and Verdi in [17].

The first difficulty that arises from (6) is how to define a weak solution for this equation. The problem is that, unless β is constant, β is discontinuous at 0. Thus far, it is not clear how to give such a definition. Instead, we consider (6) and its double-obstacle variant in the viscosity sense. For viscosity solutions see, for example, the article [9] of Crandall, Ishi, and Lions. In spite of (6) not admitting a comparison principle in the presence of a nonconstant kinetic factor, we will prove that it has a solution. This will be done by proving uniform convergence of solutions of regularized equations to (6) in section 2.

In section 4, we prove that solutions of (6) in double-obstacle form approximate the corresponding anisotropic mean-curvature flow. The existence of a level-set solution describing this flow was proved by Chen, Giga, and Goto in [7]. The approximation is then meant in the sense that φ_ε, the solution of (6) in double-obstacle form, converges to 1 (respectively, to -1) where the level-set solution is positive (respectively, negative). This is proved by constructing suitable sub- and supersolutions of (6) in double-obstacle form. The construction is similar to that given by Nochetto and Verdi in [18]. Because of the anisotropic nature of the problem, instead of the ordinary distance function, we had to use a distance function that is induced by a Finsler geometry as outlined by Bellettini and Paolini in [4]; see section 3. These sub- and supersolutions are finally compared with the solutions, yielding our result.

The convergence result determines the limit of φ_ε uniquely when the interface of the flow does not develop an interior. Otherwise—that is, in the case called *fattening*—there remains an ambiguity.

For applications, it may be easier to consider equations where the kinetic term does not have a discontinuity at 0. After completing this paper, in [12], we considered

$\beta_\varepsilon \in \mathrm{C}^0(\mathbb{R}^n)$ with $\beta_\varepsilon(p) = \beta(p)$ for $|p| \geq \varepsilon$. The corresponding Allen–Cahn equation reads

$$\varepsilon \beta_\varepsilon(\tilde{\varphi}_\varepsilon)\partial_t \tilde{\varphi}_\varepsilon - \varepsilon \nabla A'(\nabla \tilde{\varphi}_\varepsilon) + \frac{1}{\varepsilon} W(\tilde{\varphi}_\varepsilon) = c_W u.$$

In [12], we proved that the Hausdorff distance between the zero-level set of the solutions of its double-obstacle variant and the interface of the flow is of order $O(\varepsilon^2)$ when this flow is smooth.

2. Existence and comparison.

2.1. Notation. Let $\beta \in C^{0,1}_{\mathrm{loc}}(\mathbb{R}^n - \{0\})$, $A \in C^{2,1}_{\mathrm{loc}}(\mathbb{R}^n - \{0\})$, and $u \in W^{2,1}_\infty(\mathbb{R}^n \times [0,T])$ be given. We assume that β is homogeneous of degree zero and that A is homogeneous of degree two. Set $B := \sqrt{2A}$. We assume the following bounds:

$$\begin{gathered} n,\ T,\ \|\beta\|_{C^{0,1}(B_2(0)-B_{1/2}(0))},\ \|B\|_{C^{2,1}(B_2(0)-B_{1/2}(0))}, \\ \|A\|_{C^{2,1}(B_2(0)-B_{1/2}(0))},\ \|u\|_{W^{2,1}_\infty(\mathbb{R}^n\times[0,T])} \leq \Lambda, \\ \Lambda^{-1} \leq \beta(p),\ A(p),\ B(p) \leq \Lambda \quad \text{for } |p| = 1, \quad \text{and} \\ \Lambda^{-1} I \leq D^2 A. \end{gathered} \tag{8}$$

Define $F \in C^0(\mathbb{R}^n \times [0,T] \times (\mathbb{R}^n - \{0\}) \times S(n))$, where $S(n)$ denotes the set of all real, symmetric $n \times n$ matrices endowed with the usual ordering by

$$F(x,t,p,X) := -\beta(p)^{-1}\mathrm{tr}(B(p)D^2B(p)X) - \beta(p)^{-1}B(p)u(x,t). \tag{9}$$

Since B is homogeneous of degree one, it follows that F is geometric in the sense that

$$F(x,t,\lambda p, \lambda X + \sigma(p \otimes p)) = \lambda F(x,t,p,X) \quad \text{for } \lambda > 0,\ \sigma \in \mathbb{R},$$

where $\otimes$ denotes the tensor product $p \otimes q = (p_i q_j)_{i,j}$ on $\mathbb{R}^n$.

Our limit problem, the fully anisotropic mean-curvature flow, is

$$\beta(\nabla\omega)\partial_t\omega - \mathrm{tr}(B(\nabla\omega)D^2B(\nabla\omega)D^2\omega) - B(\nabla\omega)u = 0, \tag{10}$$

with the evolving interface given by $\Gamma_t := [\omega(.,t) = 0]$. Equation (10) was treated by Chen, Giga, and Goto in [7] when u was independent of space, but all of their methods apply to general u. In order to give meaning to (10), we seek a solution in the viscosity sense of

$$\partial_t\omega + F(x,t,\nabla\omega, D^2\omega) = 0.$$

Existence and comparison for (10) were proved in [7].

We recall the definition of viscosity solutions. In the following, we denote by LSC(...) and USC(...) the sets of lower semicontinuous and upper semicontinuous functions.

Definition 2.1. *Let $K \in C^0(\mathbb{R}^n \times [0,T] \times \mathbb{R} \times \mathbb{R} \times (\mathbb{R}^n - \{0\}) \times S(n))$. A function $v : Q \to \mathbb{R}$, where $\emptyset \neq Q \subseteq \mathbb{R}^n \times\ ]0,T[$ is open, is called a* viscosity subsolution *of*

$$K(x,t,v,\partial_t v, \nabla v, D^2 v) = 0 \quad \text{in } Q, \tag{11}$$

written as

$$K(x,t,v,\partial_t v, \nabla v, D^2 v) \leq 0 \quad \text{in } Q,$$

if $v \in \mathrm{USC}(Q)$ *and*

$$\forall (a,p,X) \in \mathrm{P}^{2,+}v(x,t),\ (x,t) \in Q: \qquad K_\star(x,t,v(x,t),a,p,X) \leq 0,$$

where $K_\star$ *is the* lower semicontinuous envelope of K, *that is,*

$$K_\star(x,t,r,a,p,X) \\ := \inf\{\liminf_{j\to\infty} K(x_j,t_j,r_j,a_j,p_j,X_j) \mid (x_j,t_j,r_j,a_j,p_j,X_j) \to (x,t,r,a,p,X)\}.$$

$\mathrm{P}^{2,+}$ *is the* set of superdifferentials *and is defined in the next subsection. A* supersolution *is defined analogously by considering* $K^\star$, *the upper semicontinuous envelope of* K, *and the set of subdifferentials* $\mathrm{P}^{2,-}$. v *is a* solution of (11) *when it is both a sub- and a supersolution. It is necessary to introduce the semicontinuous envelopes since* K *is not continuous when* $p = 0$.

The double-obstacle problem corresponding to (11) *is given by*

$$\max(v-1, \min(v+1, K(x,t,v,\partial_t v, \nabla v, D^2 v))) = 0 \quad \text{in } Q. \tag{12}$$

Equivalently, v *is a* subsolution of (12) *if*

$$v \in \mathrm{USC}(Q), \\ v \leq 1,$$

and

$$\forall (a,p,X) \in \mathrm{P}^{2,+}v(x,t),\ (x,t) \in Q,\ \text{with } v(x,t) > -1: \\ K_\star(x,t,v(x,t),a,p,X) \leq 0.$$

In this article, we mainly study parabolic equations and their double-obstacle problems, that is, where K is given by

$$K(x,t,v,\partial_t v, \nabla v, D^2 v) = \partial_t v + H(x,t,v,\nabla v, D^2 v).$$

Definition 2.2. *For* $v : Q \to \mathbb{R}$, *where* $\emptyset \neq Q \subseteq \mathbb{R}^n \times]0,T[$ *is open,* $(x_0,t_0) \in Q$, *we define the* sets of superdifferentials

$$\mathrm{P}^{2,+}v(x_0,t_0) := \{(a,p,X) \in \mathbb{R} \times \mathbb{R}^n \times S(n) \mid v(x,t) \leq v(x_0,t_0) \\ + a(t-t_0) + p(x-x_0) + \tfrac{1}{2}(x-x_0)^T X (x-x_0) \\ + o(|t-t_0| + |x-x_0|^2) \text{ as } t \to t_0,\ x \to x_0\},$$

and

$$\overline{\mathrm{P}}^{2,+}v(x_0,t_0) := \{(a,p,X) \in \mathbb{R} \times \mathbb{R}^n \times S(n) \mid \exists (a_j,p_j,X_j) \in \mathrm{P}^{2,+}v(x_j,t_j) : \\ (a_j,p_j,X_j) \to (a,p,X),\ (x_j,t_j) \to (x_0,t_0), v(x_j,t_j) \to v(x_0,t_0)\}.$$

The sets of subdifferentials $\mathrm{P}^{2,-}$ *and* $\overline{\mathrm{P}}^{2,-}$ *are defined analogously.*

Remark 2.3. It is seen easily that for $\varphi \in C^{2,1}(Q)$ with $v - \varphi \leq (v-\varphi)(x_0,t_0)$ in Q, the triple of derivatives $(\partial_t\varphi, \nabla\varphi, D^2\varphi)(x_0,t_0) \in \mathrm{P}^{2,+}v(x_0,t_0)$.

Conversely, for all superdifferentials $(a,p,X) \in \mathrm{P}^{2,+}v(x_0,t_0)$, there is a $\varphi \in C^{2,1}(Q)$ with $v - \varphi \leq (v-\varphi)(x_0,t_0)$ in Q and $(a,p,X) = (\partial_t\varphi, \nabla\varphi, D^2\varphi)(x_0,t_0)$. A proof of the second statement can be found in [19, section 14A].

2.2. The equation. We consider the anisotropic Allen–Cahn equation

$$\varepsilon\beta(\nabla\varphi)\partial_t\varphi - \varepsilon\nabla A'(\nabla\varphi) + \frac{1}{\varepsilon}W'(\varphi) - c_W u = 0 \quad \text{in } \mathbb{R}^n \times [0,T], \tag{13}$$

where $W(t) := (t^2-1)^2$. As already pointed out in the introduction, it is not clear how to define a weak solution of (13). Therefore, we treat (13) and its double-obstacle variant in the viscosity sense. To be precise, we define $G_\varepsilon,\ \tilde{G}_\varepsilon \in C^0(\mathbb{R}^n \times [0,T] \times \mathbb{R} \times (\mathbb{R}^n - \{0\}) \times S(n))$ by

(14)

$$G_\varepsilon(x,t,r,p,X) := -\varepsilon\beta(p)^{-1}\mathrm{tr}(D^2A(p)X) - \frac{1}{\varepsilon}\beta(p)^{-1}r - \beta(p)^{-1}\frac{\pi}{4}u(x,t)$$

and

$$\tilde{G}_\varepsilon(x,t,r,p,X) := -\varepsilon\beta(p)^{-1}\mathrm{tr}(D^2A(p)X) + \frac{1}{\varepsilon}\beta(p)^{-1}W'(r) - \beta(p)^{-1}c_W u(x,t).$$

Then in the viscosity formulation, the Allen–Cahn equation (13) reads

$$\partial_t\varphi + \frac{1}{\varepsilon}\tilde{G}_\varepsilon(.,.,\varphi,\nabla\varphi,D^2\varphi) = 0, \tag{15}$$

and its double-obstacle variant is given by

$$\max\left(\varphi - 1, \min\left(\varphi + 1, \partial_t\varphi + \frac{1}{\varepsilon}G_\varepsilon(.,.,\varphi,\nabla\varphi,D^2\varphi)\right)\right) = 0. \tag{16}$$

As already mentioned, existence and comparison for (10) were proved by Chen, Giga, and Goto in [7]. We will state these theorems without proof.

Throughout this article, we will compute on the whole of $\mathbb{R}^n$ and we will consider only space-periodic functions; therefore, we assume u and the initial data to be periodic in space. Here and in the following, *periodic* means *space periodic* and that there are n linearly independent periods.

THEOREM 2.4. *Let* $\emptyset \neq \Omega \subseteq \mathbb{R}^n$ *be open,* $0 < T \leq \Lambda,$ *and* $H \in C^0(\Omega \times [0,T] \times \mathbb{R} \times (\mathbb{R}^n - \{0\}) \times S(n))$ *satisfy*

(i) $|H(x,t,r,p,X)| \leq C(\Gamma)$ *for* $|r|,|p|,\|X\| \leq \Gamma,$

(ii) $H(x,t,r,p,X) \geq H(x,t,r,p,Y)$ *when* $X \leq Y,$

(iii) $H(x,t,r,p,X) - H(x,t,s,p,X) \geq -\Lambda(r-s)$ *when* $r \geq s,$

(iv) $|H(x,t,r,p,X) - H(y,t,r,p,X)| \leq \Lambda|x-y|(1+|p|),$ *and*

(v) $H_\star(x,t,r,0,0) = H^\star(x,t,r,0,0).$

Further, let $v \in \mathrm{USC}(\bar{\Omega} \times [0,T])$ *and* $w \in \mathrm{LSC}(\bar{\Omega} \times [0,T])$ *satisfy*

$$\partial_t v + H_\star(.,.,v,\nabla v,D^2 v) \leq 0,$$

and

$$\partial_t w + H^\star(.,.,w,\nabla w,D^2 w) \geq 0,$$

either

(a) *in* $\Omega \times]0,T[$

or

(b) *in* $\Omega \times]0,T[$ *in the double-obstacle sense.*

Next, we assume that either

(α) $\Omega = \mathbb{R}^n$ *and* v *and* w *are periodic with the same period*

or

(β) $\Omega \subset\subset \mathbb{R}^n$ *and* $v \leq w$ *on* $\partial\Omega \times [0, T[$.

Then

$$v(.,0) \leq w(.,0) \quad \textit{in } \Omega$$

implies

$$v \leq w \quad \textit{in } \Omega \times [0, T[.$$

Proof. This comparison principle was proved by Chen, Giga, and Goto in [7]. Properly, they considered H to be independent of x and they did not consider the double-obstacle problem. However, their proof applies to the general case. See also Theorem 2.12, where the ideas of [7] are applied to prove a modified comparison principle for the double-obstacle Allen–Cahn equation. ∎

THEOREM 2.5. *For periodic, continuous initial data,* (10) *has a unique solution.*

Proof. We again refer to [7]. ∎

Remark 2.6. When β is constant, one can easily check that G_ε and $\tilde{G}_\varepsilon$ of (14) satisfy the assumptions for H in Theorem 2.4. Therefore, the corresponding parabolic equations admit a comparison principle when they are considered in the viscosity sense. For nonconstant β, a comparison principle of this kind does not hold. This can be seen as follows. We take $u = 0$ and consider solutions which are constant in space. Such solutions w satisfy the ordinary differential equation

$$\varepsilon\beta^\star(t)w'(t) - \frac{1}{\varepsilon}w(t) = 0$$

and the inequality $|w(t)| < 1$, where $\beta^\star$ is any function satisfying $\inf\beta \leq \beta^\star \leq \sup\beta$. Taking $\beta^\star = \inf\beta$ and $\beta^\star = \sup\beta$, comparison is easily contradicted. Since (15) does not admit a comparison principle, the existence of solutions to (15) cannot be proved by Perron's method.

The rest of this section is devoted to proving existence of solutions to (15) and a modified comparison principle in which the sub- or supersolution in Theorem 2.4 satisfies additional conditions.

Existence is proved by approximating (15) through regularized equations. We will establish a uniform bound on the Hölder continuity of solutions of these regularized equations, hence getting a solution of (15). To carry out the limit procedure, we recall a definition of [9, section 6], which is stated below in Definition 2.7.

In section 4, we will construct sub- and supersolutions which admit the additional condition required in the modified comparison principle (Theorem 2.12). Therefore, we will be able to compare these sub- and supersolutions with a solution and conclude the desired convergence as $\varepsilon \to 0$ for these solutions.

DEFINITION 2.7. *For a family of functions* $v_\delta : Q \subseteq \mathbb{R}^N \to \mathbb{R}$, *we define*

$$v := \lim_{\delta \to 0_\star} v_\delta$$

by

$$v(z_0) := \inf\left\{\liminf_{j\to\infty} v_{\delta_j}(z_j) \mid \delta_j \to 0,\ z_j \to z_0\right\}.$$

$\lim_{\delta\to 0}{}^\star v_\delta$ *is defined analogously.*

2.3. Regularization. First, we consider (13) when $\beta \in C^\infty(\mathbb{R}^n),\ A \in C^\infty(\mathbb{R}^n)$, W' is replaced by any $f \in C^\infty(\mathbb{R}),$ and $u \in C^\infty(\mathbb{R}^n \times [0,T])$ is periodic in space. We drop the homogeneity assumptions on β and A, but we demand

$$\begin{aligned} \Lambda^{-1} &\leq \beta \leq \Lambda, \\ \Lambda^{-1} I &\leq D^2 A, \\ \Lambda^{-1}|p|^2 - \Lambda &\leq A(p), \\ \|u\|_{L^\infty(\mathbb{R}^n \times [0,T])},\ \|\nabla u\|_{L^\infty(\mathbb{R}^n \times [0,T])},\ |f(0)| &\leq \Lambda, \quad \text{and} \\ f' &\geq -\Lambda. \end{aligned} \tag{17}$$

We consider the equation

(18)

$$\partial_t \varphi - \beta(\nabla\varphi)^{-1} \operatorname{tr}(D^2 A(\nabla\varphi) D^2 \varphi) + \beta(\nabla\varphi)^{-1} f(\varphi) - \beta(\nabla\varphi)^{-1} u = 0 \quad \text{in } \mathbb{R}^n \times [0,T]$$

with periodic initial data $\varphi_0 \in C^\infty(\mathbb{R}^n)$ and

$$\|\varphi_0\|_{C^{0,1}(\mathbb{R}^n)} \leq \Lambda. \tag{19}$$

Since (18) admits a comparison principle, we conclude from (19) that a solution of (18) satisfies

$$\|\varphi\|_{L^\infty(\mathbb{R}^n \times [0,T])},\ \|\nabla\varphi\|_{L^\infty(\mathbb{R}^n \times [0,T])} \leq C(\Lambda). \tag{20}$$

With this a priori bound, we find using techniques of [14] that (18) has a unique, periodic solution $\varphi \in C^\infty(\mathbb{R}^n \times [0,T])$.

We write (18) in divergence form as

$$\beta(\nabla\varphi)\partial_t \varphi - \nabla A'(\nabla\varphi) + f(\varphi) - u = 0,$$

multiply by $\partial_t \varphi$, integrate over $K_{t_0} := K \times [0, t_0]$, where K is a periodic cell, and get

$$\int_{K_{t_0}} \beta(\nabla\varphi)|\partial_t\varphi|^2 + A'(\nabla\varphi)\partial_t\nabla\varphi + f(\varphi)\partial_t\varphi = \int_{K_{t_0}} u\partial_t\varphi. \tag{21}$$

We define $F(t) := \int_0^t (f(s) - f(0) + (\Lambda+1)s)ds$ and get $F'(t) = f(t) - f(0) + (\Lambda+1)t,\ F'(0) = 0,$ and $F'' \geq 1$. From (20) and (21), we conclude

$$\begin{aligned} \Lambda^{-1} \int_{K_{t_0}} |\partial_t\varphi|^2 &+ \int_K A(\nabla\varphi(t_0)) + F(\varphi(t_0)) \\ &\leq \int_K A(\varphi_0) + F(\varphi_0) + \int_{K_{t_0}} ((\Lambda+1)\varphi - f(0) + u)\partial_t\varphi \\ &\leq \int_K A(\nabla\varphi_0) + F(\varphi_0) + C(\Lambda)|K| + \frac{1}{2\Lambda}\int_{K_{t_0}} |\partial_t\varphi|^2. \end{aligned}$$

Assuming

$$\int_K A(\nabla\varphi_0) + F(\varphi_0) \leq \Lambda \tag{22}$$

we obtain, noting (17),

$$\begin{aligned} &\|\partial_t\varphi\|_{L^2(0,T;L^2(K))},\ \|A(\nabla\varphi)\|_{L^\infty(0,T;L^2(K))}, \\ &\|F(\varphi)\|_{L^\infty(0,T;L^1(K))},\ \|\varphi\|_{L^2(0,T;H^{1,2}(K))} \leq C(\Lambda). \end{aligned} \tag{23}$$

As in [11], the above $L^2(0,T;L^2(K))$ estimate on $\partial_t\varphi$ together with (20) yields

$$\|\varphi\|_{H^{1/n+1,1/2(n+1)}(\mathbb{R}^n\times[0,T])} \leq C(\Lambda), \tag{24}$$

where $H^{\alpha,\alpha/2}$ denotes the space of functions that are Hölder continuous of exponent α in space and exponent $\frac{\alpha}{2}$ in time.

Now we approximate β, A, and u of section 2.1 appropriately by β_δ, A_δ, $u_\delta \in \mathrm{C}^\infty$ as in (17). In the case of the smooth well, we take $f_\delta = W'$; for the double-obstacle problem, we take $f_\delta := g' + \frac{1}{\delta}h'$ with $g \geq 0$, $g'(t) = -t$ for $|t| \leq 1$, $|g''| \leq \Lambda$, $h(t) = 0$ for $|t| \leq 1$, $th'(t) > 0$ for $|t| > 1$, and $0 \leq h'' \leq \Lambda$. Taking the approximation such that $A_\delta \to A$ uniformly on compact subsets of $\mathbb{R}^n$, we have in the smooth case

$$\int_K A_\delta(\nabla\varphi_0) + F_\delta(\varphi_0) \leq C(\Lambda) \tag{25}$$

for small δ. Since $|\varphi_0| \leq 1$ is required in the double-obstacle problem, we have

$$\int_K \left(g + \frac{1}{\delta}h\right)(\varphi_0) = \int_K g(\varphi_0) \leq C(g)|K|,$$

which yields (25) as well. From (22) and (23), we conclude that (24) is satisfied for the unique solution φ_δ of (18) when (β, A, f, u) is substituted by $(\beta_\delta, A_\delta, f_\delta, u_\delta)$. Equation (18) can be considered as a viscosity equation of the form

$$\partial_t\varphi_\delta + H_\delta(.,.,\varphi_\delta, \nabla\varphi_\delta, D^2\varphi_\delta) = 0 \quad \text{in } \mathbb{R}^n \times]0,T[.$$

Choosing β_δ and A_δ as convolutions—that is, $\beta_\delta(p) := \int_{\mathbb{R}} \beta(q)\eta_\delta(p-q)dq$ and $A_\delta(p) := \int_{\mathbb{R}} A(q)\eta_\delta(p-q)dq$, where $\eta_\delta(p) := \delta^{-1}\eta(\frac{p}{\delta})$ with $\eta \in C^\infty(\mathbb{R})$, $\eta \geq 0$, and $\int \eta = 1$—it is easily seen that

$$\lim_{\delta\to 0_\star}{}^{(\star)} (\beta_\delta(p)(a + H_\delta(x,t,r,p,X))) = (\beta(p)(a + \tilde{G}_1(x,t,r,p,X)))_\star^{(\star)}$$

when the smooth well is considered and that

$$\begin{aligned} &\lim_{\delta\to 0_\star} (a + H_\delta(x,t,r,p,X)) \leq 0 \\ &\qquad \Rightarrow \max(r-1, \min(r+1, a + G_1(x,t,r,p,X)))_\star \leq 0 \end{aligned}$$

and

$$\begin{aligned} &\lim_{\delta\to 0}{}^\star (a + H_\delta(x,t,r,p,X)) \geq 0 \\ &\qquad \Rightarrow \max(r-1, \min(r+1, a + G_1(x,t,r,p,X)))^\star \geq 0 \end{aligned}$$

when the double-obstacle problem is considered. Taking a uniformly convergent subsequence, passing to the limits, and applying [9, Lemma 6.1], we obtain a solution of (15) and its double-obstacle variant. Since only an estimate of $\|\varphi_0\|_{C^{0,1}(\mathbb{R}^n)}$ was required, we have proved the following existence theorem.

Theorem 2.8. *For every periodic* $\varphi_0 \in C^{0,1}(\mathbb{R}^n)$*, there are periodic viscosity solutions* $\varphi, \tilde{\varphi} \in H^{1/(n+1),1/2(n+1)}(\mathbb{R}^n \times [0,T])$ *to the anisotropic double-obstacle Allen–Cahn and its smooth form, that is,*

$$\max\left(\varphi - 1, \min\left(\varphi + 1, \partial_t\varphi + \frac{1}{\varepsilon}G_\varepsilon(.,.,\varphi,\nabla\varphi,D^2\varphi)\right)\right) = 0 \quad \textit{in } \mathbb{R}^n\times\ ]0,T[,$$

$$\partial_t\tilde{\varphi} + \frac{1}{\varepsilon}\tilde{G}_\varepsilon(.,.,\tilde{\varphi},\nabla\tilde{\varphi},D^2\tilde{\varphi}) = 0 \quad \textit{in } \mathbb{R}^n \times]0,T[,$$

and

$$\varphi(.,0) = \tilde{\varphi}(.,0) = \varphi_0 \quad \textit{in } \mathbb{R}^n.$$

Here G_ε and $\tilde{G}_\varepsilon$ are defined in (14).

Remark 2.9. Taking $H = \frac{1}{\varepsilon} G_\varepsilon$ in Theorem 2.4, we observe that it satisfies all conditions except

$$\text{(v)} \quad G_{\varepsilon,\star}(x,t,r,0,0) = G^\star_\varepsilon(x,t,r,0,0).$$

In the next theorem, we impose an additional condition on the sub- or supersolution of Theorem 2.4 for $H = \frac{1}{\varepsilon} G_\varepsilon$ which is sufficient to establish comparison. To prove this theorem, we apply the following theorem, which is given in a more general version in [9, Theorem 8.3]. Since we apply it to the double-obstacle problem, we must state it with one detail slightly changed.

Theorem 2.10. *Let $v \in \mathrm{USC}(\mathbb{R}^n \times\,]0,T[)$ and $w \in \mathrm{LSC}(\mathbb{R}^n \times\,]0,T[)$, and define $\Phi(t,x,y) := v(x,t) - w(y,t) - \alpha|x-y|^2$, where $\alpha \geq 0$. We suppose that $\Phi(t_0,x_0,y_0) = \sup_{]0,T[\,\times \mathbb{R}^n \times \mathbb{R}^n} \Phi$, where $(t_0,x_0,y_0) \in\,]0,T[\,\times \mathbb{R}^n \times \mathbb{R}^n$. We assume that there is an $r > 0$ such that for $\Gamma > 0$, $(a,p,X) \in \mathrm{P}^{2,+}v(x,t)$,*

$$|x - x_0| + |t - t_0| + |v(x,t) - v(x_0,t_0)| \leq r \quad \textit{and} \quad |p| + \|X\| \leq \Gamma$$
$$\textit{implies } a \leq C(\Gamma);$$

likewise, for $(a,p,X) \in \mathrm{P}^{2,-}w(y,t)$,

$$|y - y_0| + |t - t_0| + |w(y,t) - w(y_0,t_0)| \leq r \quad \textit{and} \quad |p| + \|X\| \leq \Gamma$$
$$\textit{implies } a \geq -C(\Gamma).$$

Then there are $a \in \mathbb{R}$ and $X, Y \in S(n)$ such that

$$(a, 2\alpha(x_0 - y_0), X) \in \overline{\mathrm{P}}^{2,+}v(x_0,t_0),$$
$$(a, 2\alpha(x_0 - y_0), Y) \in \overline{\mathrm{P}}^{2,-}w(y_0,t_0),$$

and

$$X \leq Y.$$

Moreover, when $\alpha = 0$, we get

$$X \leq 0 \leq Y.$$

Remark 2.11. We observe that the condition about the boundedness of the time derivative of v is satisfied if v is a subsolution of a parabolic equation. In this case, it is indeed sufficient to require merely that $|v(x,t)| \leq \Gamma$, as is done in [9, Theorem 8.3]. If v is a solution of a double-obstacle problem, this bound can only be concluded if $v(x,t) > -1$. Therefore, we have to replace $|v(x,t)| \leq \Gamma$ by $|v(x,t) - v(x_0,t_0)| \leq r$ since we will apply the theorem when $v(x_0,t_0) > -1$.

Theorem 2.12. *We assume that v and w are periodic with the same period, that they are sub- and supersolutions, respectively, of*

$$\max\left(\varphi - 1, \min\left(\varphi + 1, \partial_t \varphi + \frac{1}{\varepsilon} G_\varepsilon(.,.,\varphi,\nabla\varphi,D^2\varphi)\right)\right) = 0 \quad \textit{in } \mathbb{R}^n \times\,]0,T[,$$

and that $v(.,0) \leq w(.,0)$. Moreover, we assume that for $(a,0,X) \in \overline{\mathrm{P}}^{2,-}w(x_0,t_0)$ with $(x_0,t_0) \in \mathbb{R}^n \times\,]0,T[$ and $w(x_0,t_0) < 1$,

$$(26) \qquad \limsup_{p \to 0,\ p \neq 0} \left(\varepsilon\beta^\star a - \varepsilon tr(D^2A(p)X) - \frac{1}{\varepsilon} w(x_0,t_0) - \frac{\pi}{4} u(x_0,t_0)\right) \geq 0$$

holds for any $\inf\beta \le \beta^\star \le \sup\beta$*. Then the following comparison inequality holds:*

$$v \le w \quad \textit{in } \mathbb{R}^n \times [0,T[.$$

Proof. We prove the theorem by contradiction. Suppose there is $(\bar{x},\bar{t}) \in \mathbb{R}^n \times]0,T[$ such that $v(\bar{x},\bar{t}) > w(\bar{x},\bar{t})$. Choose T_0 so that $0 < \bar{t} < T_0 < T$. We know that v and w are upper and lower semicontinuous, respectively, so periodicity implies

$$\sup_{y\in\mathbb{R}^n} (v(y,T_0) - w(y,T_0)) < \infty;$$

hence for λ large enough, we have

$$\text{(27)} \qquad \forall y \in \mathbb{R}^n\colon\ \exp(-\lambda t)(v(x,t) - w(x,t)) > \exp(-\lambda T_0)(v(y,T_0) - w(y,T_0)).$$

We assume additionally that $\lambda > C(\Lambda)\varepsilon^{-2}$.

We define

$$\tilde{v}(x,t) := \exp(-\lambda t)v(x,t)$$

and

$$\tilde{w}(x,t) := \exp(-\lambda t)w(x,t).$$

We conclude from (27) that

$$\sup_{\mathbb{R}^n\times[0,T_0]} (\tilde{v} - \tilde{w}) =: \delta > 0,$$

and, since $\tilde{v}$ and $\tilde{w}$ are upper and lower semicontinuous, respectively, that there exists $(x_0,t_0) \in \mathbb{R}^n \times [0,T_0]$ such that

$$\text{(28)} \qquad \tilde{v}(x_0,t_0) - \tilde{w}(x_0,t_0) = \sup_{\mathbb{R}^n\times[0,T_0]} (\tilde{v} - \tilde{w}),$$

and, noting that $(\tilde{v} - \tilde{w})(.,0) \le 0$, for any such (x_0,t_0),

$$\text{(29)} \qquad 0 < t_0 < T_0.$$

For proving comparison for viscosity solutions, we proceed with the standard technique of doubling the number of space variables and penalizing this doubling. We define for $\alpha > 0$ and $\eta \in \mathbb{R}^n$ the upper semicontinuous functions

$$\text{(30)} \qquad \begin{aligned} \Psi(t,x,y) &:= \tilde{v}(x,t) - \tilde{w}(y,t), \\ \Phi_\alpha(t,x,y) &:= \Psi(t,x,y) - \alpha|x-y|^2, \quad \text{and} \\ \Phi_{\alpha,\eta}(t,x,y) &:= \Psi(t,x,y) - \alpha|x-y-\eta|^2. \end{aligned}$$

We distinguish two cases and in each derive a contradiction.

Case (i). There is a $\mu > 0$ such that for all $|\eta| < \mu$ one of the maximum points (t_η, x_η, y_η) of $\Phi_{\alpha,\eta}$, that is

$$\Phi_{\alpha,\eta} \le \Phi_{\alpha,\eta}(t_\eta,x_\eta,y_\eta) \quad \text{in } [0,T_0]\times\mathbb{R}^n\times\mathbb{R}^n,$$

satisfies

$$\text{(31)} \qquad x_\eta - y_\eta = \eta.$$

We define $f(\eta) := \sup_{x-y=\eta} \Psi$ and get

$$f(\eta) \geq \Psi(t_\eta, x_\eta, y_\eta) = \Phi_{\alpha,\eta}(t_\eta, x_\eta, y_\eta) \geq \sup_{x-y=\xi} \Phi_{\alpha,\eta} = f(\xi) - \alpha|\xi - \eta|^2$$

for all $\xi,\ \eta \in U_\mu(0)$. Therefore, $f : U_\mu(0) \to \mathbb{R}$ is constant and

$$\sup_{x-y=\eta} \Psi = f(\eta) = f(0) = \sup_{x=y} \Psi = \sup_{\mathbb{R}^n \times [0,T_0]} (\tilde{v} - \tilde{w}) = \tilde{v}(x_0, t_0) - \tilde{w}(x_0, t_0)$$

by (28). This yields

$$\forall x, y \in U_{\mu/2}(x_0)\colon \quad \forall t \in [0, T_0]\colon \quad \tilde{v}(x,t) - \tilde{w}(y,t) \leq \tilde{v}(x_0,t_0) - \tilde{w}(x_0,t_0).$$

Applying Theorem 2.10 to $\Phi = \Psi$, we get

$$\begin{aligned} \exists \tilde{a},\ \tilde{X},\ \tilde{Y}\colon \quad & (\tilde{a}, 0, \tilde{X}) \in \overline{\mathrm{P}}^{2,+} v(x_0, t_0), \\ & (\tilde{a}, 0, \tilde{Y}) \in \overline{\mathrm{P}}^{2,-} w(x_0, t_0), \\ & \tilde{X} \leq 0 \leq \tilde{Y}. \end{aligned}$$

Setting $a := \tilde{a} \exp(\lambda t_0)$, $X := \tilde{X} \exp(\lambda t_0)$, and $Y = \tilde{Y} \exp(\lambda t_0)$ and noting that $\exp(\lambda(t - t_0)) v(x_0, t_0) = (1 + \lambda(t - t_0)) v(x_0, t_0) + O(|t - t_0|^2)$, we have

$$\begin{aligned} (a + \lambda v(x_0, t_0), 0, X) &\in \overline{\mathrm{P}}^{2,+} v(x_0, t_0), \\ (a + \lambda w(x_0, t_0), 0, Y) &\in \overline{\mathrm{P}}^{2,-} w(x_0, t_0), \end{aligned}$$

and

$$X \leq 0 \leq Y.$$

Furthermore, the inequality $1 \geq v(x_0, t_0) > w(x_0, t_0) \geq -1$ holds. Since v and w are sub- and supersolutions, respectively, we obtain

$$\begin{aligned} a + \lambda v(x_0, t_0) + \frac{1}{\varepsilon} G_{\varepsilon,\star}(x_0, t_0, v(x_0, t_0), 0, X) \leq 0 \quad \text{and} \\ a + \lambda w(x_0, t_0) + \frac{1}{\varepsilon} G_{\varepsilon}^{\star}(x_0, t_0, w(x_0, t_0), 0, Y) \geq 0. \end{aligned} \tag{32}$$

Using the definition of the semicontinuous envelope, we conclude from (32) that

$$\begin{aligned} 0 &\geq \liminf_{p \to 0,\ p \neq 0} \left(\varepsilon \beta(p)(a + \lambda v(x_0, t_0)) - \varepsilon \operatorname{tr}(D^2 A(p) X) - \frac{1}{\varepsilon} v(x_0, t_0) - \frac{\pi}{4} u(x_0, t_0) \right) \\ &\geq \liminf_{p \to 0,\ p \neq 0} \left(\varepsilon \beta(p)(a + \lambda v(x_0, t_0)) - \frac{1}{\varepsilon} v(x_0, t_0) - \frac{\pi}{4} u(x_0, t_0) \right) \end{aligned}$$

since $X \leq 0$. Therefore,

$$0 \geq \varepsilon \beta^\star (a + \lambda v(x_0, t_0)) - \frac{1}{\varepsilon} v(x_0, t_0) - \frac{\pi}{4} u(x_0, t_0) \tag{33}$$

for some $\inf \beta \leq \beta^\star \leq \sup \beta$. Taking this $\beta^\star$ and $(\tilde{a}, 0, \tilde{Y}) \in \overline{\mathrm{P}}^{2,-} w(x_0, t_0)$ in (26),

(34)

$$\begin{aligned} 0 &\leq \limsup_{p \to 0,\ p \neq 0} (\varepsilon \beta^\star (a + \lambda w(x_0, t_0)) - \varepsilon \operatorname{tr} \left(D^2 A(p) Y) - \frac{1}{\varepsilon} w(x_0, t_0) - \frac{\pi}{4} u(x_0, t_0) \right) \\ &\leq \varepsilon \beta^\star (a + \lambda w(x_0, t_0)) - \frac{1}{\varepsilon} w(x_0, t_0) - \frac{\pi}{4} u(x_0, t_0) \end{aligned}$$

since $Y \geq 0$. From (33) and (34), we obtain

$$0 \geq \left(\varepsilon\beta^\star\lambda - \frac{1}{\varepsilon}\right)(v(x_0,t_0) - w(x_0,t_0)) > 0,$$

which is a contradiction.

Case (ii) For all $\mu > 0$, there is an $|\eta| < \mu$ such that one of the maximum points (t_η, x_η, y_η) of $\Phi_{\alpha,\eta}$, that is,

$$\Phi_{\alpha,\eta} \leq \Phi_{\alpha,\eta}(t_\eta, x_\eta, y_\eta) \quad \text{in } [0,T_0] \times \mathbb{R}^n \times \mathbb{R}^n,$$

satisfies

$$x_\eta - y_\eta \neq \eta. \tag{35}$$

From periodicity and upper semicontinuity, we obtain for a subsequence

$$\begin{aligned} (t_\eta, x_\eta, y_\eta) \to (t_\alpha, x_\alpha, y_\alpha) \in [0,T_0] \times \mathbb{R}^n \times \mathbb{R}^n, \quad \Phi_\alpha \leq \Phi_\alpha(t_\alpha, x_\alpha, y_\alpha) \quad \text{and} \\ \tilde{v}(x_\eta, t_\eta) - \tilde{w}(y_\eta, t_\eta) \to \tilde{v}(x_\alpha, t_\alpha) - \tilde{w}(y_\alpha . t_\alpha). \end{aligned} \tag{36}$$

From [9, Proposition 3.7], for a subsequence $\alpha \to \infty$, we get

$$\begin{aligned} (t_\alpha, x_\alpha, y_\alpha) &\to (t_0, x_0, y_0) \in [0,T_0] \times \mathbb{R}^n \times \mathbb{R}^n, \quad x_0 = y_0, \\ \tilde{v}(x_\alpha, t_\alpha) - \tilde{w}(y_\alpha, t_\alpha) &\to \tilde{v}(x_0,t_0) - \tilde{w}(x_0,t_0) = \sup_{\mathbb{R}^n \times [0,T_0]} (\tilde{v} - \tilde{w}). \end{aligned} \tag{37}$$

It follows from (28) that

$$\begin{aligned} & 0 < t_0 < T_0; \\ \text{hence} \quad & 0 < t_\alpha < T_0, \quad v(x_\alpha, t_\alpha) > w(y_\alpha, t_\alpha) \quad \text{for } \alpha \text{ large} \\ \text{and} \quad & 0 < t_\eta < T_0, \quad v(x_\eta, t_\eta) > w(y_\eta, t_\eta) \quad \text{for } |\eta| \text{ small.} \end{aligned}$$

Applying Theorem 2.10 to $\Phi = \Phi_{\alpha,\eta}(.,.,. - \eta)$ yields, after multiplying with $\exp(\lambda t_0)$,

$$\begin{aligned} \exists a,\ X,\ Y\colon \quad & (a + \lambda v(x_\eta, t_\eta), p_\eta, X) \in \overline{\mathrm{P}}^{2,+} v(x_\eta, t_\eta), \\ & (a + \lambda w(y_\eta, t_\eta), p_\eta, Y) \in \overline{\mathrm{P}}^{2,-} w(y_\eta, t_\eta), \\ & X \leq Y, \\ & p_\eta = 2\alpha(x_\eta - y_\eta - \eta)\exp(\lambda t_\eta). \end{aligned}$$

It also holds that $1 \geq v(x_\eta, t_\eta) > w(y_\eta, t_\eta) \geq -1$. Since v and w are sub- and supersolutions, we obtain

$$\begin{aligned} 0 &\geq \varepsilon(a + \lambda v(x_\eta, t_\eta)) + G_\varepsilon(x_\eta, t_\eta, v(x_\eta, t_\eta), p_\eta, X) \\ &\quad - \varepsilon(a + \lambda w(y_\eta, t_\eta)) - G_\varepsilon(y_\eta, t_\eta, w(y_\eta, t_\eta), p_\eta, Y) \\ &\geq \left(\varepsilon\lambda - C(\Lambda)\frac{1}{\varepsilon}\right)(v(x_\eta, t_\eta) - w(y_\eta, t_\eta)) - C(\Lambda)|u(x_\eta, t_\eta) - u(y_\eta, t_\eta)| \\ &\to \left(\varepsilon\lambda - C(\Lambda)\frac{1}{\varepsilon}\right)(v(x_0,t_0) - w(x_0,t_0)) > 0, \end{aligned}$$

which is again a contradiction.

Therefore, $v \leq w$ in $\mathbb{R}^n \times [0,T[$. □

Remark 2.13. The conclusion of the above proposition remains true if (26) is replaced by the analogous condition for v. More precisely, instead of (26), we require for $(a, 0, X) \in \overline{\mathrm{P}}^{2,+} v(x_0, t_0)$ with $(x_0, t_0) \in \mathbb{R}^n \times]0, T[$ and $v(x_0, t_0) > -1$ that

$$\liminf_{p \to 0,\ p \neq 0} \left(\varepsilon \beta^\star a - \varepsilon \mathrm{tr}(D^2 A(p) X) - \frac{1}{\varepsilon} v(x_0, t_0) - \frac{\pi}{4} u(x_0, t_0) \right) \leq 0$$

for any $\inf \beta \leq \beta^\star \leq \sup \beta$.

This modified comparison principle is also valid for the smooth Allen–Cahn equation with obvious changes.

3. The distance function. As already pointed out in the introduction, we use a distance function that is induced by a Finsler metric for the construction of the sub- and supersolutions. This section is devoted to the presentation of some definitions and properties of the Finsler metric (see [4]) and the induced distance function. Most of these properties are known in the isotropic case; see [2]. However, Lemma 3.4 and the viscosity estimate of the time derivative of the distance function in Proposition 3.6 were not required in the isotropic case, but they will be used in section 4 for proving convergence in the anisotropic case.

3.1. The dual. We consider $\beta,\ A,\ B$, and u as in (8). As in [4], we define the dual of B,

$$B^\circ(q) := \sup\{ qp \mid B(p) \leq 1 \}. \tag{38}$$

B° is convex and homogeneous of degree one. Since $A \in \mathrm{C}^2(\mathbb{R}^{\mathrm{n}} - \{0\})$ is strictly convex, $B^\circ \in \mathrm{C}^2(\mathbb{R}^{\mathrm{n}} - \{0\})$ and satisfies

$$\begin{gathered} c_0(\Lambda) \leq B^\circ(q) \leq C(\Lambda) \quad \text{for } |q| = 1, \\ B(\nabla B^\circ(q)) = 1 \quad \text{for } q \neq 0, \\ \nabla B(\nabla B^\circ(q)) D^2 B^\circ(q) = 0 \quad \text{for } q \neq 0, \quad \text{and} \\ \|B^\circ\|_{C^2(B_2(0) - B_{1/2}(0))} \leq C(\Lambda). \end{gathered} \tag{39}$$

3.2. The distance function. We define a nonsymmetric metric d in $\mathbb{R}^n$ by

$$d(x, y) := B^\circ(x - y). \tag{40}$$

We easily obtain for $x, y, z \in \mathbb{R}^n$ that

$$\begin{gathered} d(x, z) \leq d(x, y) + d(y, z), \\ d(x + z, y + z) = d(x, y), \quad \text{and} \\ c_0(\Lambda)|x - y| \leq d(x, y) \leq C(\Lambda)|x - y|. \end{gathered} \tag{41}$$

Let $\omega \in \mathrm{LSC}(\mathbb{R}^n \times [0, T[)$ be a supersolution of

$$\begin{gathered} \beta(\nabla \omega) \partial_t \omega - \mathrm{tr}(B(\nabla \omega) D^2 B(\nabla \omega) D^2 \omega) - B(\nabla \omega) u \geq 0 \quad \text{in } \mathbb{R}^n \times]0, T[, \quad \text{or} \\ \partial_t \omega + F^\star(.,., \nabla \omega, D^2 \omega) \geq 0, \end{gathered} \tag{42}$$

where F is defined in (14). We define the distance function δ as follows:

$$\delta(x, t) := \inf_{y, \omega(y,t) \leq 0} d(x, y). \tag{43}$$

(41) implies

$$|\delta(x, t) - \delta(y, t)| \leq C(\Lambda)|x - y|. \tag{44}$$

We will prove some properties of δ; most of them are well known.

The next three lemmas were proved by Barles, Soner, and Souganidis in [2] in the isotropic case.

LEMMA 3.1. $\omega_\infty := \chi_{[\omega>0]}$ *is a supersolution of* (42).

Proof. From [7], we know that $\omega_\varepsilon := \min(1, \max(\frac{\omega}{\varepsilon}, 0))$ is a supersolution of (42). Because $\omega_\infty = \lim_{\varepsilon\to 0\star}\omega_\varepsilon$, defined in Definition 2.7, we get from [9, Lemma 6.1] that ω_∞ is a supersolution as well. □

LEMMA 3.2. *We define* $\delta^k(x,t) := \inf_{y\in\mathbb{R}^n}(k\omega_\infty(y,t) + d(x,y))$. *Then*

(i) $\delta^k = \min(\delta, k) \in \mathrm{LSC}(\mathbb{R}^n \times [0,T[)$ *and*

(ii) $\partial_t\delta^k + F^\star(.,.,\nabla\delta^k, D^2\delta^k) + C(\Lambda)|\nabla\delta^k|\delta^k \geq 0$ *in* $\mathbb{R}^n \times]0,T[$ *in the viscosity sense.*

Proof. (i) Trivially, we get

$$0 \leq \delta^k(x,t) \leq k\omega_\infty(x,t) + d(x,x) \leq k.$$

Second, if $\delta(x,t) = d(x,y)$ with $\omega(y,t) \leq 0$, then $\omega_\infty(y,t) = 0$ and

$$\delta^k(x,t) \leq d(x,y) = \delta(x,t);$$

hence

$$0 \leq \delta^k \leq \min(\delta, k).$$

Moreover, $\forall y \in \mathbb{R}^n : \ [\omega(y,t) \leq 0 \Rightarrow d(x,y) \geq \delta(x,t)]$. This yields

$$k\omega_\infty(y,t) + d(x,y) \geq \min(\delta(x,t), k);$$

hence

$$\delta^k \geq \min(\delta, k).$$

Now let $(x_j,t_j) \to (x_0,t_0) \in \mathbb{R}^n \times [0,T[$ and $\delta^k(x_j,t_j) = k\omega_\infty(y_j,t_j) + d(x_j,y_j)$. We obtain $d(x_j,y_j) \leq k$ and, for a subsequence, $y_j \to y_0$. This yields

$$\liminf_{j\to\infty} \delta^k(x_j,t_j) \geq k\omega_\infty(y_0,t_0) + d(x_0,y_0) \geq \delta^k(x_0,t_0).$$

(ii) Let $\varphi \in C^{2,1}(\mathbb{R}^n \times [0,T[)$ with $\delta^k - \varphi \geq (\delta^k - \varphi)(x_0,t_0),\ 0 < t_0 < T$, and $\delta^k(x_0,t_0) = k\omega_\infty(y_0,t_0) + d(x_0,y_0)$. Defining

$$\psi(y,t) := \varphi(y - y_0 + x_0, t), \quad \psi \in C^{2,1}(\mathbb{R}^n \times [0,T[),$$

we get, for $(y,t) \in \mathbb{R}^n \times]0,T[$ and $x := y - y_0 + x_0$,

$$\begin{aligned} k\omega_\infty(y,t) + d(x,y) - \psi(y,t) &\geq \delta^k(x,t) - \varphi(x,t) \\ &\geq \delta^k(x_0,t_0) - \varphi(x_0,t_0) = k\omega_\infty(y_0,t_0) + d(x_0,y_0) - \psi(y_0,t_0). \end{aligned} \tag{45}$$

Since $x - y = x_0 - y_0$, we get $d(x,y) = d(x_0,y_0)$, and (45) together with Lemma 3.1 yields

$$\partial_t\psi(y_0,t_0) + F^\star(y_0,t_0,\nabla\psi(y_0,t_0), D^2\psi(y_0,t_0)) \geq 0.$$

This implies

$$\begin{aligned}&\partial_t\varphi(x_0,t_0)+F^\star(x_0,t_0,\nabla\varphi(x_0,t_0),D^2\varphi(x_0,t_0))\\&\quad\geq F^\star(x_0,t_0,\nabla\varphi(x_0,t_0),D^2\varphi(x_0,t_0))-F^\star(y_0,t_0,\nabla\varphi(x_0,t_0),D^2\varphi(x_0,t_0))\\&\quad=\beta(\nabla\varphi(x_0,t_0))^{-1}B(\nabla\varphi(x_0,t_0))(u(y_0,t_0)-u(x_0,t_0))\\&\quad\geq -C(\Lambda)|\nabla\varphi(x_0,t_0)||x_0-y_0|\\&\quad\geq -C(\Lambda)|\nabla\varphi(x_0,t_0)|\delta^k(x_0,t_0)\end{aligned}$$

since $\delta^k(x_0,t_0)=k\omega_\infty(y_0,t_0)+d(x_0,y_0)\geq d(x_0,y_0)\geq c_0(\Lambda)|x_0-y_0|$. □

PROPOSITION 3.3. *δ is lower semicontinuous and is a viscosity supersolution of*

$$\partial_t\delta+F^\star(.,.,\nabla\delta,D^2\delta)+C(\Lambda)|\nabla\delta|\delta\geq 0\quad \textit{in } \mathbb{R}^n\times]0,T[.$$

Proof. Let $(x_j,t_j)\to(x_0,t_0)$ and choose $k>\delta(x_0,t_0)$. We obtain

$$\liminf_{j\to\infty}\delta(x_j,t_j)\geq\liminf_{j\to\infty}\delta^k(x_j,t_j)\geq\delta^k(x_0,t_0)=\delta(x_0,t_0),$$

where we have used the lower semicontinuity of δ^k, established in Lemma 3.2(i).

To prove that δ is a viscosity supersolution, we pass to the limit in Lemma 3.2(ii). According to [9, Lemma 6.1], viscosity supersolutions are preserved under the limit procedure defined in Definition 2.7. Hence it suffices to prove

$$\delta=\lim_{k\to\infty_\star}\delta^k. \tag{46}$$

From Lemma 3.2(i),

$$\delta=\lim_{k\to\infty}\delta^k\geq\lim_{k\to\infty_\star}\delta^k.$$

Conversely, let $(x_j,t_j)\to(x_0,t_0)$ and $k_j\to\infty$ with

$$\limsup_{j\to\infty}\delta^{k_j}(x_j,t_j)\leq\left(\lim_{k\to\infty_\star}\delta^k\right)(x_0,t_0)+\tau\leq\delta(x_0,t_0)+\tau$$

for some $\tau>0$. For j large, we get $\delta^{k_j}(x_j,t_j)<k_j$; hence

$$\delta(x_0,t_0)\leq\liminf_{j\to\infty}\delta(x_j,t_j)=\liminf_{j\to\infty}\delta^{k_j}(x_j,t_j)\leq\left(\lim_{k\to\infty_\star}\delta^k\right)(x_0,t_0)+\tau,$$

and (46) is established, concluding the proof. □

LEMMA 3.4. *For $x_0\in\mathbb{R}^n$ and $0\leq t_0\leq t_1<T$, the inequality*

$$\mu(\delta(x_0,t_1))\geq\mu(\delta(x_0,t_0))-C(\Lambda)(t_1-t_0) \tag{47}$$

holds, where $\mu(r):=\int_0^r\frac{s}{1+s}ds$.

Proof. The function μ, used below to define a subsolution for (51), appears in [7].

It suffices to prove the assertion when $\varrho:=\delta(x_0,t_0)>0$. We define $v(x,t):=\mu(\varrho)-\Gamma(t-t_0)-\mu(B^\circ(x_0-x))$ for some positive constant Γ chosen below, and we observe from Lemma 3.1 that $v\in C^{2,1}((\mathbb{R}^n-\{x_0\})\times[0,T[)$. For $x\neq x_0$, we get

$$\begin{aligned}\partial_tv(x,t)&=-\Gamma,\\\nabla v(x,t)&=\mu'(B^\circ(x_0-x))\nabla B^\circ(x_0-x)\\&=B^\circ(x_0-x)\nabla B^\circ(x_0-x)(1+B^\circ(x_0-x))^{-1},\quad\text{and}\\D^2v(x,t)&=-B^\circ(x_0-x)D^2B^\circ(x_0-x)(1+B^\circ(x_0-x))^{-1}\\&\quad-\nabla B^\circ(x_0-x)\otimes\nabla B^\circ(x_0-x)(1+B^\circ(x_0-x))^{-1}\\&\quad+B^\circ(x_0-x)\nabla B^\circ(x_0-x)\otimes\nabla B^\circ(x_0-x)(1+B^\circ(x_0-x))^{-2}.\end{aligned} \tag{48}$$

We observe that $v \in C^{1,1}(\mathbb{R}^n \times [0,T[)$ and satisfies

$$\begin{aligned} \nabla v(x_0,t) &= 0 \quad \text{and} \\ \|D^2 v(x,t)\| &\leq C(\Lambda)(1+B^\circ(x_0-x))^{-1}, \end{aligned} \tag{49}$$

where we have used (39). We conclude that for $x \neq x_0$,

$$\begin{aligned} &\partial_t v(x,t) + F(x,t,\nabla v(x,t), D^2 v(x,t)) \\ &\quad \leq -\Gamma + (1+B^\circ(x_0-x))^{-1} F(x,t,B^\circ(x_0-x)\nabla B^\circ(x_0-x), -C(\Lambda)I) \\ &\quad \leq -\Gamma + C(\Lambda)(1+B^\circ(x_0-x))^{-1} F(x,t,c_0(\Lambda)B^\circ(x_0-x)\nabla B^\circ(x_0-x), -I) \\ &\quad \leq -\Gamma + C(\Lambda) \leq 0 \end{aligned}$$

when $\Gamma \geq C(\Lambda)$. Here we have used

$$F(x,t,p,-I) \leq C(\Lambda)(1+|p|), \tag{50}$$

which can easily be derived from the definition of F and (8).

To prove that v is a subsolution of

$$\partial_t v + F_\star(.,.,\nabla v, D^2 v) \leq 0 \tag{51}$$

on the whole $\mathbb{R}^n \times]0,T[$, we consider $\psi \in C^{2,1}(\mathbb{R}^n \times\,]0,T[)$ with

$$(v-\psi) \leq (v-\psi)(x_0,s_0)$$

for some $0 < s_0 < T$. We get from (49) that

$$\nabla\psi(x_0,s_0) = \nabla v(x_0,s_0) = 0.$$

Adding $|x-x_0|^4 + |t-s_0|^2$ to ψ, we may assume $(v-\psi)(x,t) < (v-\psi)(x_0,s_0)$ for all $(x,t) \neq (x_0,s_0)$. We define $\psi_\tau(x,t) := \psi(x,t) + \tau\ x * N$ for some $N \neq 0$. As $\tau \to 0$, we get

$$(v-\psi_\tau)(.,s_0) \leq (v-\psi_\tau)(x_\tau,s_0)$$

on a neighborhood $U(x_0)$ of x_0 and $x_\tau \to x_0$. This yields

$$\nabla v(x_\tau,s_0) = \nabla\psi_\tau(x_\tau,s_0) = \nabla\psi(x_\tau,s_0) + \tau N \neq \nabla\psi(x_\tau,s_0);$$

hence $x_\tau \neq x_0$. Furthermore, we have

$$D^2\psi(x_0,s_0) \leftarrow D^2\psi_\tau(x_\tau,s_0) \geq D^2 v(x_\tau,s_0) \geq -(1+B^\circ(x_0-x_\tau))^{-1}C(\Lambda)I \to -C(\Lambda)I.$$

Using (50), we get

$$\begin{aligned} &\partial_t\psi(x_0,s_0) + F_\star(x_0,s_0,\nabla\psi(x_0,s_0), D^2\psi(x_0,s_0)) \\ &\quad \leq -\Gamma + F_\star(x_0,s_0,0,-C(\Lambda)I) \leq -\Gamma + C(\Lambda) \leq 0; \end{aligned}$$

hence (51) is established.

We define $U := \{x \in \mathbb{R}^n \mid B^\circ(x_0-x) < \varrho\}$. For $x \in U$, we see that

$$d(x_0,x) = B^\circ(x_0-x) < \varrho = \delta(x_0,t_0);$$

hence

$$\omega(x, t_0) > 0$$

and

$$v(x, t_0) \leq \mu(\varrho) \leq \mu(\varrho)\omega_\infty(x, t_0).$$

For $x \in \partial U$ and $t \in [t_0, T[$, we get $v(x, t) \leq 0 \leq \mu(\varrho)\omega_\infty(x, t)$. We conclude with the comparison principle (Theorem 2.4),

$$\forall x \in U: \quad \forall t \in [t_0, T[: \quad v(x, t) \leq \mu(\varrho)\omega_\infty(x, t). \tag{52}$$

We choose $y_0 \in [\omega(., t_1) \leq 0]$ such that $\delta(x_0, t_1) = B^\circ(x_0 - y_0)$. If $y_0 \notin U$, we see that $\delta(x_0, t_1) = B^\circ(x_0 - y_0) \geq \varrho = \delta(x_0, t_0)$ and

$$\mu(\delta(x_0, t_1)) \geq \mu(\varrho) \geq \mu(\delta(x_0, t_0)).$$

If $y_0 \in U$, we obtain from (52)

$$0 = \mu(\varrho)\omega_\infty(y_0, t_1) \geq v(y_0, t_1) = \mu(\varrho) - \Gamma(t_1 - t_0) - \mu(B^\circ(x_0 - y_0)).$$

Taking into account that $\varrho = \delta(x_0, t_0)$ and $B^\circ(x_0 - y_0) = \delta(x_0, t_1)$, (47) follows. □

Proposition 3.5. *δ is continuous from below; that is, if $(x_j, t_j) \to (x_0, t_0)$ and $t_j \leq t_0 < T$, then*

$$\delta(x_j, t_j) \to \delta(x_0, t_0).$$

Proof. Because of the already established lower semicontinuity of δ, it suffices to show

$$\limsup_{j \to \infty} \delta(x_j, t_j) \leq \delta(x_0, t_0). \tag{53}$$

From (47), we get

$$\mu(\delta(x_0, t_0)) \geq \limsup_{j \to \infty}(\mu(\delta(x_0, t_j)) - C(\Lambda)(t_0 - t_j)) = \mu\left(\limsup_{j \to \infty} \delta(x_0, t_j)\right),$$

where μ is defined in (3.4), since μ is continuous and increasing. Since μ is strictly increasing, it follows that

$$\delta(x_0, t_0) \geq \limsup_{j \to \infty} \delta(x_0, t_j),$$

which yields (53) when taking into account that $|\delta(x_j, t_j) - \delta(x_0, t_j)| \leq C(\Lambda)|x_j - x_0| \to 0$. □

Proposition 3.6. *δ is a viscosity supersolution of*

$$\begin{aligned} B(\nabla\delta) &\geq 1, & -B(\nabla\delta) &\geq -1, \\ -\nabla B(\nabla\delta) D^2\delta \nabla B(\nabla\delta) &\geq 0, & -D^2\delta &\geq -C(\Lambda)\delta^{-1} I, \end{aligned}$$

and

$$\partial_t \delta \geq -C(\Lambda)\left(1 + \frac{1}{\delta}\right)$$

in $[\delta > 0] \cap (\mathbb{R}^n \times]0, T[)$.

Proof. Let $\varphi \in C^{2,1}(\mathbb{R}^n \times]0,T[)$, $(x_0, t_0) \in \mathbb{R}^n \times]0,T[$ with $\delta(x_0,t_0) > 0$ and $(\delta - \varphi) \geq (\delta - \varphi)(x_0, t_0) = 0$ in $\mathbb{R}^n \times]0,T[$. We choose $y_0 \in [\omega(.,t_0) \leq 0]$ with

$$0 < \delta(x_0,t_0) = d(x_0,y_0) = B^\circ(x_0 - y_0);$$

note in particular that $x_0 \neq y_0$. For all $x \in \mathbb{R}^n$, we get $B^\circ(x - y_0) \geq \delta(x, t_0)$; hence

$$B^\circ(x - y_0) - \varphi(x,t_0) \geq B^\circ(x_0 - y_0) - \varphi(x_0,t_0).$$

Since $x_0 \neq y_0$ and $B^\circ \in C^2(\mathbb{R}^n - \{0\})$, we get

$$\nabla\varphi(x_0,t_0) = \nabla B^\circ(x_0 - y_0)$$

and

$$D^2\varphi(x_0,t_0) \leq D^2 B^\circ(x_0 - y_0) \leq C(\Lambda) I |x_0 - y_0|^{-1} = C(\Lambda)\delta(x_0,t_0)^{-1} I,$$

where we have used the fact that $D^2 B^\circ$ is homogeneous of degree -1. From (39), we get

$$B(\nabla\varphi(x_0,t_0)) = 1$$

and

$$-\nabla B(\nabla\varphi) D^2\varphi \nabla B(\nabla\varphi)(x_0,t_0) \geq 0.$$

From (3.4), for $0 \leq t < t_0$, we get

$$\begin{aligned}\mu(\varphi(x_0,t_0)) = \mu(\delta(x_0,t_0)) &\geq \mu(\delta(x_0,t)) - C(\Lambda)(t_0 - t)\\ &\geq \mu(\varphi(x_0,t)) - C(\Lambda)(t_0 - t),\end{aligned}$$

and

$$\begin{aligned}-C(\Lambda) \leq \frac{\mu(\varphi(x_0,t)) - \mu(\varphi(x_0,t_0))}{t - t_0} &\to \mu'(\varphi(x_0,t_0))\partial_t\varphi(x_0,t_0)\\ = \frac{\varphi(x_0,t_0)}{1 + \varphi(x_0,t_0)}\partial_t\varphi(x_0,t_0).&\end{aligned}$$

Since $\varphi(x_0,t_0) = \delta(x_0,t_0)$, this yields

$$\partial_t\varphi(x_0,t_0) \geq -C(\Lambda)(1 + \delta(x_0,t_0)^{-1}). \qquad \square$$

4. Convergence.

Remark 4.1. In this section, we construct sub- and supersolutions for the double-obstacle Allen–Cahn problem which satisfy the additional condition of the modified comparison principle (Theorem 2.12).

We consider β, A, B, and u as in (8) and ω and δ as in section 3.2.

Definition 4.2. *We define the following auxiliary functions, which appear in formal asymptotics for the double-obstacle Allen–Cahn equation:*

$$\psi_0(r) := \begin{cases} 1, & r \geq \frac{\pi}{2},\\ \sin(r), & |r| \leq \frac{\pi}{2},\\ -1, & r \leq -\frac{\pi}{2}\end{cases}$$

and

$$\psi_1(r) := \begin{cases} \dfrac{1}{2}(r\psi_0(r) - \dfrac{\pi}{2} + \psi_0'(r)), & |r| \leq \dfrac{\pi}{2}, \\ 0, & |r| \geq \dfrac{\pi}{2}. \end{cases}$$

We see that $\psi_0,\ \psi_1 \in \mathrm{C}^2([-\frac{\pi}{2}, \frac{\pi}{2}]) \cap \mathrm{C}^{1,1}(\mathbb{R})$. *Moreover,*

$$\begin{aligned} &\psi_0'' + \psi_0 = 0 \quad \textit{on} \ \left[-\frac{\pi}{2}, \frac{\pi}{2}\right] \quad \textit{and} \\ &\psi_1'' + \psi_1 = \psi_0' - \frac{\pi}{4} \quad \textit{on} \ \left[-\frac{\pi}{2}, \frac{\pi}{2}\right]. \end{aligned} \tag{54}$$

We define

$$\psi(r, v) := \psi_0(r) + \varepsilon v \psi_1(r)$$

and

$$\lambda_\varepsilon(x, t) := \frac{\delta(x, t)}{\varepsilon} - \pi - f(t),$$

where $f(t) := \alpha \exp(-\gamma^2 t)$ *with* $1 \leq \alpha,\ \gamma \leq C(\Lambda)$ *chosen below. We set* $v := u + \varepsilon g$, *where* $g(t) := \alpha\gamma \exp(-\gamma^2 t)$, *and*

$$\psi_\varepsilon := \psi(\lambda_\varepsilon, v).$$

PROPOSITION 4.3. *For* $0 < \varepsilon < \varepsilon_0(\Lambda)$, ψ_ε *is a supersolution of*

$$\max\left(\psi_\varepsilon - 1, \min\left(\psi_\varepsilon + 1, \partial_t \psi_\varepsilon + \frac{1}{\varepsilon} G_\varepsilon^\star(.,., \psi_\varepsilon, \nabla\psi_\varepsilon, D^2\psi_\varepsilon)\right)\right) \geq 0 \quad \textit{in } \mathbb{R}^n \times]0, T[. \tag{55}$$

Moreover, ψ_ε *satisfies the additional condition* (26) *of the modified comparison principle*; *that is, for* $(a, 0, X) \in \overline{\mathrm{P}}^{2,-}\psi_\varepsilon(x_0, t_0)$, $0 < t_0 < T$, *and* $\psi_\varepsilon(x_0, t_0) < 1$,

$$\limsup_{p \to 0,\ p \neq 0} \left(\varepsilon\beta^* a - \varepsilon tr(D^2 A(p) X) - \frac{1}{\varepsilon}\psi_\varepsilon(x_0, t_0) - \frac{\pi}{4} u(x_0, t_0)\right) \geq 0 \tag{56}$$

holds for any $\inf \beta \leq \beta^\star \leq \sup \beta$.

Proof. We take ε so small that $\varepsilon f,\ \varepsilon g,\ \varepsilon|f'|,\ \varepsilon|g'| \leq 1$. We have $|\psi_1(r)|,\ |\psi_1'(r)| \leq \psi_0'(r)$. For $|v| \leq C(\Lambda)$, this yields

$$\psi_r(r, v) = \psi_0'(r) + \varepsilon v \psi_1'(r) = \psi_0'(r)(1 + O_\Lambda(\varepsilon));$$

hence

$$\frac{1}{2}\psi_0'(r) \leq \psi_r(r, v) \leq 2\psi_0'(r) \tag{57}$$

when $0 < \varepsilon < \varepsilon_0(\Lambda)$. Therefore, $\psi_\varepsilon \in \mathrm{LSC}(\mathbb{R}^n \times [0, T[)$ since $\delta \in \mathrm{LSC}(\mathbb{R}^n \times [0, T[)$. Since $\psi(r, v) = -1$ for $r \leq -\frac{\pi}{2}$, we get

$$\psi_\varepsilon \geq -1.$$

Suppose $(\bar{x},\bar{t}) \in \mathbb{R}^n \times]0,T[$ is such that $\psi_\varepsilon(\bar{x},\bar{t}) < 1$. It follows that $\lambda_\varepsilon(\bar{x},\bar{t}) < \frac{\pi}{2}$. From Remark 2.3, we see that for any $(\bar{a},\bar{p},\bar{X}) \in \mathrm{P}^{2,-}\psi_\varepsilon(\bar{x},\bar{t})$, there is a $\varphi \in C^{2,1}(\mathbb{R}^n \times [0,T[)$ such that

$$(58) \qquad \begin{array}{l} (\bar{a},\bar{p},\bar{X}) = (\partial_t\varphi, \nabla\varphi, D^2\varphi)(\bar{x},\bar{t}) \quad \text{and} \\ \psi_\varepsilon - \varphi \geq (\psi_\varepsilon - \varphi)(\bar{x},\bar{t}), \end{array}$$

and, without loss of generality, $(\psi_\varepsilon - \varphi)(\bar{x},\bar{t}) = 0$ and $(\bar{x},\bar{t})$ is a strict minimum. Our aim is to prove that ψ_ε is a supersolution. By Definition 2.1, it remains to show that

$$(59) \qquad \bar{a} + \frac{1}{\varepsilon} G_\varepsilon^\star(\bar{x},\bar{t},\psi_\varepsilon(\bar{x},\bar{t}),\bar{p},\bar{X})) \geq 0.$$

We distinguish two cases.

(i) $\lambda_\varepsilon(\bar{x},\bar{t}) < -\frac{\pi}{2}$. Using the continuity from below in time of δ (see Proposition 3.5), we conclude that

$$\lambda_\varepsilon(x,t) < -\frac{\pi}{2} \quad \text{for } (x,t) \in U(\bar{x},\bar{t}) \text{ and } t \leq \bar{t},$$

and for these (x,t), it follows that $\psi_\varepsilon(x,t) = -1$. This yields

$$\bar{X} = D^2\varphi(\bar{x},\bar{t}) \leq 0, \qquad \bar{a} = \partial_t\varphi(\bar{x},\bar{t}) \geq 0,$$

and

$$\bar{p} = \nabla\varphi(\bar{x},\bar{t}) = 0.$$

For $p \neq 0$ and $\inf\beta \leq \beta^\star \leq \sup\beta$, we obtain

$$(60) \qquad \varepsilon\beta^\star\bar{a} - \varepsilon\mathrm{tr}(D^2A(p)\bar{X}) - \frac{1}{\varepsilon}\psi_\varepsilon(\bar{x},\bar{t}) - \frac{\pi}{4}u(\bar{x},\bar{t}) \geq \left(\frac{1}{\varepsilon} - C(\Lambda)\right) \geq 0$$

when $0 < \varepsilon < \varepsilon_0(\Lambda)$. Taking $\beta^\star = \beta(p)$ and letting p tend to $\bar{p} = 0$, we obtain

$$\begin{aligned} &\bar{a} + \frac{1}{\varepsilon}G_\varepsilon^\star(\bar{x},\bar{t},\psi_\varepsilon(\bar{x},\bar{t}),\bar{p},\bar{X}) \\ &\quad \geq \limsup_{p\to 0, p\neq 0}\left(\bar{a} + \frac{1}{\varepsilon}G_\varepsilon(\bar{x},\bar{t},\psi_\varepsilon(\bar{x},\bar{t}),p,\bar{X})\right) \\ &\quad = \limsup_{p\to 0, p\neq 0}\left(\bar{a} - \frac{1}{\varepsilon\beta(p)}\left(\varepsilon\mathrm{tr}(D^2A(p)\bar{X}) + \frac{1}{\varepsilon}\psi_\varepsilon(\bar{x},\bar{t}) + \frac{\pi}{4}u(\bar{x},\bar{t})\right)\right) \geq 0, \end{aligned}$$

which is (59).

(ii) $-\frac{\pi}{2} \leq \lambda_\varepsilon(\bar{x},\bar{t}) < \frac{\pi}{2}$. In the next two subsections, we will establish the existence of subsequences (x_τ,t_τ) and $\psi_\varepsilon^\tau(x_\tau,t_\tau)$ such that as $\tau \to 0$,

$$(61) \qquad \begin{array}{l} (x_\tau,t_\tau) \to (\bar{x},\bar{t}), \\ \psi_\varepsilon^\tau(x_\tau,t_\tau) \to \psi_\varepsilon(\bar{x},\bar{t}), \\ \nabla\varphi(x_\tau,t_\tau) \neq 0, \end{array}$$

and

$$R_\varepsilon^\tau := \left(\varepsilon\beta^\star\partial_t\varphi - \varepsilon\mathrm{tr}(D^2A(\nabla\varphi)D^2\varphi) - \frac{1}{\varepsilon}\psi_\varepsilon^\tau - \frac{\pi}{4}u)(x_\tau,t_\tau\right) \geq \varepsilon - \varepsilon^{-1}\varrho_\Lambda(\tau),$$

where $\inf\beta \le \beta^\star \le \sup\beta$ and $\beta^\star = \beta(\nabla\varphi(x_\tau, t_\tau))$. Furthermore, if $|\nabla\varphi(x_\tau, t_\tau)| \le \Lambda\varepsilon$, then the last inequality holds for any $\inf\beta \le \beta^\star \le \sup\beta$. Here $\varrho_\Lambda(\tau) \to 0$.

Taking $\beta^\star = \beta(\nabla\varphi(x_\tau, t_\tau))$ in the definition of R^τ_ε, we find from (61) that

$$\begin{aligned}
&\varepsilon\partial_t\varphi(\bar{x},\bar{t}) + G^\star_\varepsilon(\bar{x},\bar{t},\psi_\varepsilon(\bar{x},\bar{t}),\nabla\varphi(\bar{x},\bar{t}),D^2\varphi(\bar{x},\bar{t}))\\
&\quad \ge \limsup_{\tau\to0}(\varepsilon\partial_t\varphi(x_\tau,t_\tau) + G_\varepsilon(x_\tau,t_\tau,\psi^\tau_\varepsilon(x_\tau,t_\tau),\nabla\varphi(x_\tau,t_\tau),D^2\varphi(x_\tau,t_\tau)))\\
&\quad = \limsup_{\tau\to0}(\beta(\nabla\varphi(x_\tau,t_\tau))^{-1}R^\tau_\varepsilon) \ge 0,
\end{aligned}$$

which is (59). Thus ψ_ε is a supersolution.

We now turn to the proof of (56). First, we observe that for any $(\bar{x},\bar{t}) \in \mathbb{R}^n \times]0,T[$ with $\psi_\varepsilon(\bar{x},\bar{t}) < 1$ and φ satisfying (58) with $|\bar{p}| = |\nabla\varphi(\bar{x},\bar{t})| \le \Lambda\varepsilon$,

$$\limsup_{q\to\bar{p},q\neq0}\left(\varepsilon\beta^\star\bar{a} - \varepsilon\operatorname{tr}(D^2A(q)\bar{X}) - \frac{1}{\varepsilon}\psi_\varepsilon(\bar{x},\bar{t}) - \frac{\pi}{4}u(\bar{x},\bar{t})\right) \ge 0 \tag{62}$$

for $\inf\beta \le \beta^\star \le \sup\beta$.

To prove (62), we again distinguish two cases. In case (i), $\lambda_\varepsilon(\bar{x},\bar{t}) < -\frac{\pi}{2}$, (62) is an immediate consequence of (60). In case (ii), $-\frac{\pi}{2} \le \lambda_\varepsilon(\bar{x},\bar{t}) < -\frac{\pi}{2}$, it follows from (61), for any $\inf\beta \le \beta^\star \le \sup\beta$, that

$$\begin{aligned}
&\limsup_{q\to\bar{p},q\neq0}\left(\varepsilon\beta^\star\bar{a} - \varepsilon\operatorname{tr}(D^2A(q)\bar{X}) - \frac{1}{\varepsilon}\psi_\varepsilon(\bar{x},\bar{t}) - \frac{\pi}{4}u(\bar{x},\bar{t})\right)\\
&\quad\ge \limsup_{q\to\nabla\varphi(\bar{x},\bar{t}),q\neq0}\left(\varepsilon\beta^\star\partial_t\varphi(\bar{x},\bar{t}) - \varepsilon\operatorname{tr}(D^2A(q)D^2\varphi(\bar{x},\bar{t})) - \frac{1}{\varepsilon}\psi_\varepsilon(\bar{x},\bar{t}) - \frac{\pi}{4}u(\bar{x},\bar{t})\right)\\
&\quad\ge \limsup_{\tau\to0} R^\tau_\varepsilon \ge 0,
\end{aligned}$$

which is (62).

Now we consider $(a,0,X) \in \overline{\mathrm{P}}^{2,-}\psi_\varepsilon(x_0,t_0)$ with $\psi_\varepsilon(x_0,t_0) < 1$. From the definition of $\overline{\mathrm{P}}^{2,-}$, we get $(a_j,p_j,X_j) \in \mathrm{P}^{2,-}\psi_\varepsilon(x_j,t_j)$, which, as $j\to\infty$, satisfies

$$\begin{aligned}
(a_j,p_j,X_j) &\to (a,0,X),\\
(x_j,t_j) &\to (x_0,t_0),
\end{aligned}$$

and

$$\psi_\varepsilon(x_j,t_j) \to \psi_\varepsilon(x_0,t_0).$$

We apply (62) to $(\bar{x},\bar{t}) = (x_j,t_j)$ and obtain

$$\limsup_{q\to p_j,\ q\neq0}\left(\varepsilon\beta^\star a_j - \varepsilon\operatorname{tr}(D^2A(q)X_j) - \frac{1}{\varepsilon}\psi_\varepsilon(x_j,t_j) - \frac{\pi}{4}u(x_j,t_j)\right) \ge 0,$$

which yields the existence of $q_j \neq 0$ with $q_j \to 0$ and

$$\varepsilon\beta^\star a_j - \varepsilon\operatorname{tr}(D^2A(q_j)X_j) - \frac{1}{\varepsilon}\psi_\varepsilon(x_j,t_j) - \frac{\pi}{4}u(x_j,t_j) \ge -\frac{1}{j}.$$

From this we infer (56), concluding the proof. □

4.1. Approximation. In this section, we approximate ψ_ε by a smooth ψ_ε^τ, and we will get $(x_\tau, t_\tau) \to (\bar{x}, \bar{t})$ as in (61).

We take the notation of the preceding subsection, and we assume $-\frac{\pi}{2} \leq \lambda_\varepsilon(\bar{x}, \bar{t}) < \frac{\pi}{2}$.

From the definition of λ_ε, it follows that $\frac{\pi}{2}\varepsilon < \delta(\bar{x}, \bar{t})$, and from the lower semicontinuity of δ (see Proposition 3.3), we get

$$\begin{aligned} \delta &\geq \frac{\pi}{2}\varepsilon, \\ \lambda_\varepsilon &\geq -\pi \end{aligned} \quad \text{in } \overline{U(\bar{x}, \bar{t})} \tag{63}$$

for some neighborhood $U(\bar{x}, \bar{t})$ of $(\bar{x}, \bar{t})$. We take a Dirac sequence $\eta_\tau(r) = \tau^{-1}\eta(\frac{r}{\tau})$ for $\eta \in \mathrm{C}_0^\infty(\mathbb{R}),\ \eta \geq 0, \int \eta = 1$, and define

$$\begin{aligned} \psi_0^\tau(r) &:= \textstyle\int \psi_0(s)\eta_\tau(r-s)ds, \\ \psi_1^\tau(r) &:= \textstyle\int \psi_1(s)\eta_\tau(r-s)ds. \end{aligned}$$

We get $(\psi_0^\tau)',\ \psi_1^\tau \in \mathrm{C}_0^\infty(\mathbb{R})$, and

$$|\psi_1^\tau|,\ |(\psi_1^\tau)'| \leq C(\Lambda)(\psi_0^\tau)'. \tag{64}$$

We define

$$\psi^\tau(r, v) := \psi_0^\tau(r) + \varepsilon v \psi_1^\tau(r) + \tau r,$$

and for $|v| \leq C(\Lambda),\ 0 < \varepsilon < \varepsilon_0(\Lambda)$, we get

$$\psi_r^\tau(r, v) \geq \tau > 0. \tag{65}$$

We choose $u^\tau \in C^\infty(\mathbb{R}^n \times [0, T])$ with

$$\|u^\tau\|_{C^{2,1}(\mathbb{R} \times [0,T])} \leq C(\Lambda)$$

and

$$\|u^\tau - u\|_{L^\infty(\mathbb{R}^n \times [0,T])} \leq \varrho(\tau) \to 0 \quad \text{for } \tau \to 0.$$

We define $v^\tau := u^\tau + \varepsilon g$ and get

$$\|v^\tau\|_{C^{2,1}(\mathbb{R}^n \times [0,T])} \leq C(\Lambda).$$

We set

$$\psi_\varepsilon^\tau := \psi^\tau(\lambda_\varepsilon, v^\tau).$$

Using the above approximation properties in τ and (63), we obtain $\varrho_\Lambda(\tau) \to 0$ as $\tau \to 0$ such that

$$\begin{aligned} \psi_\varepsilon^\tau - \psi_\varepsilon \geq &-\|\psi_0^\tau - \psi_0\|_{L^\infty(\mathbb{R})} - \varepsilon\|v^\tau - v\|_{L^\infty(\mathbb{R}^n \times [0,T])}\|\psi_1^\tau\|_{L^\infty(\mathbb{R})} \\ &- \varepsilon\|v\|_{L^\infty(\mathbb{R}^n \times [0,T])}\|\psi_1^\tau - \psi_1\|_{L^\infty(\mathbb{R})} - \tau\pi \\ \geq &-\varrho_\Lambda(\tau) \end{aligned}$$

on $\overline{U(\bar{x}, \bar{t})}$ and

$$|\psi_\varepsilon^\tau(\bar{x}, \bar{t}) - \psi_\varepsilon(\bar{x}, \bar{t})| \leq \varrho_\Lambda(\tau).$$

Therefore, for small τ,

$$\begin{gathered}\exists (x_\tau, t_\tau) \in U(\bar{x}, \bar{t})\colon \quad \psi_\varepsilon^\tau - \varphi \geq (\psi_\varepsilon^\tau - \varphi)(x_\tau, t_\tau) \quad \text{on } U(\bar{x}, \bar{t}), \\ (x_\tau, t_\tau) \to (\bar{x}, \bar{t}) \quad \text{as } \tau \to 0, \quad \text{and} \\ (\psi_\varepsilon^\tau - \varphi)(x_\tau, t_\tau) =: \nu_\tau \to (\psi_\varepsilon - \varphi)(\bar{x}, \bar{t}) = 0.\end{gathered} \tag{66}$$

The last convergence yields

$$\begin{aligned}1 > \psi_\varepsilon(\bar{x}, \bar{t}) &= \lim_{\tau \to 0} \psi_\varepsilon^\tau(x_\tau, t_\tau) \\ &\geq \limsup_{\tau \to 0} \psi(\lambda_\varepsilon(x_\tau, t_\tau), v(x_\tau, t_\tau)) \geq \psi\left(\limsup_{\tau \to 0} \lambda_\varepsilon(x_\tau, t_\tau), v(\bar{x}, \bar{t})\right);\end{aligned}$$

hence

$$\lambda_\varepsilon(x_\tau, t_\tau) < \frac{\pi}{2} \quad \text{for } \tau \text{ small.} \tag{67}$$

Because of (65) and since ψ^τ is smooth, there is $\delta^\tau \in C^{2,1}(U(\bar{x}, \bar{t}))$ such that

$$\begin{gathered}\varphi(x, t) = \psi^\tau(\lambda_\varepsilon^\tau(x, t), v^\tau(x, t)) - \nu_\tau \quad \text{and} \\ \lambda_\varepsilon^\tau(x, t) = \frac{\delta^\tau(x, t)}{\varepsilon} - \pi - f(t),\end{gathered} \tag{68}$$

where ν_τ is defined in (66). For $(x, t) \in U(\bar{x}, \bar{t})$, we obtain

$$\psi^\tau(\lambda_\varepsilon, v^\tau) - \varphi(x, t) = (\psi_\varepsilon^\tau - \varphi)(x, t) \geq \nu_\tau = (\psi^\tau(\lambda_\varepsilon^\tau, v^\tau) - \varphi)(x, t),$$

and equality holds for $(x, t) = (x_\tau, t_\tau)$. From (65), we conclude

$$\begin{gathered}\delta \geq \delta^\tau \quad \text{in } U(\bar{x}, \bar{t}) \quad \text{and} \\ \delta(x_\tau, t_\tau) = \delta^\tau(x_\tau, t_\tau) \geq \frac{\pi}{2}\varepsilon,\end{gathered} \tag{69}$$

where we have used (63).

4.2. Computation. In this section, we will carry out the computations to establish the fourth line of (61). We again use the notation of the preceding sections.

We continue from (69). Observing Remark 2.3, we have that

$$(\partial_t \delta^\tau, \nabla \delta^\tau, D^2 \delta^\tau)(x_\tau, t_\tau) \in \mathrm{P}^{2,-}\delta(x_\tau, t_\tau),$$

and from the definition of supersolutions, using Proposition 3.6, we obtain

$$\begin{gathered}B(\nabla \delta^\tau(x_\tau, t_\tau)) = 1, \qquad c_0(\Lambda) \leq |\nabla \delta^\tau(x_\tau, t_\tau)| \leq C(\Lambda), \\ -\nabla B(\nabla \delta^\tau) D^2 \delta^\tau \nabla B(\nabla \delta^\tau)(x_\tau, t_\tau) \geq 0, \\ D^2 \delta^\tau(x_\tau, t_\tau) \leq C(\Lambda) \delta(x_\tau, t_\tau)^{-1} I \leq C(\Lambda) \varepsilon^{-1} I, \quad \text{and} \\ \partial_t \delta^\tau(x_\tau, t_\tau) \geq -C(\Lambda)(1 + \delta(x_\tau, t_\tau)^{-1}) \geq -C(\Lambda) \varepsilon^{-1}.\end{gathered} \tag{70}$$

Further, from Proposition 3.3, we get

$$(\beta(\nabla \delta^\tau) \partial_t \delta^\tau - \operatorname{tr}(B(\nabla \delta^\tau) D^2 B(\nabla \delta^\tau) D^2 \delta^\tau) - B(\nabla \delta^\tau) u + C(\Lambda) |\nabla \delta^\tau| \delta)(x_\tau, t_\tau) \geq 0,$$

and, since $D^2 A = B D^2 B + B' \otimes B'$, we conclude

$$(\beta(\nabla \delta^\tau) \partial_t \delta^\tau - \operatorname{tr}(D^2 A(\nabla \delta^\tau) D^2 \delta^\tau) - u + C(\Lambda) \delta)(x_\tau, t_\tau) \geq 0. \tag{71}$$

From (68), we compute

$$\nabla\varphi = \varepsilon^{-1}\psi_r^\tau \nabla\delta^\tau + \varepsilon\psi_1^\tau \nabla v^\tau = \varepsilon^{-1}\psi_r^\tau(\nabla\delta^\tau + O_\Lambda(\varepsilon^2)). \tag{72}$$

From (65) and $|\nabla\delta^\tau(x_\tau, t_\tau)| \geq c_0(\Lambda)$, we get

$$\nabla\varphi(x_\tau, t_\tau) \neq 0, \tag{73}$$

which is the third line of (61).

Differentiating again, we get

$$\begin{aligned} D^2\varphi = {}& \varepsilon^{-2}\psi_{rr}^\tau \nabla\delta^\tau \otimes \nabla\delta^\tau + \varepsilon^{-1}\psi_r^\tau D^2\delta^\tau \\ &+ (\psi_1^\tau)'(\nabla v^\tau \otimes \nabla\delta^\tau + \nabla\delta^\tau \otimes \nabla v^\tau) + \varepsilon\psi_1^\tau D^2 v^\tau \\ = {}& \varepsilon^{-2}\psi_{rr}^\tau \nabla\delta^\tau \otimes \nabla\delta^\tau + \varepsilon^{-1}\psi_r^\tau D^2\delta^\tau + O_\Lambda(1) \end{aligned} \tag{74}$$

since $|\nabla\delta^\tau(x_\tau, t_\tau)| \leq C(\Lambda)$.

Further, we obtain

$$\varepsilon\partial_t\varphi = \psi_r^\tau(\partial_t\delta^\tau - \varepsilon f') + \varepsilon^2\psi_1^\tau\partial_t v^\tau = \psi_r^\tau(\partial_t\delta^\tau - \varepsilon f' + O_\Lambda(\varepsilon^2)). \tag{75}$$

We recall the definition of R_ε^τ in (61),

$$R_\varepsilon^\tau := \left(\varepsilon\beta^\star\partial_t\varphi - \varepsilon\operatorname{tr}(D^2A(\nabla\varphi)D^2\varphi) - \frac{1}{\varepsilon}\psi_\varepsilon^\tau - \frac{\pi}{4}u\right)(x_\tau, t_\tau) \tag{76}$$

for $\inf\beta \leq \beta^\star \leq \sup\beta$ and $\beta^\star = \beta(\nabla\varphi(x_\tau, t_\tau))$ or $|\nabla\varphi(x_\tau, t_\tau)| \leq \Lambda\varepsilon$.

Using (72), (74), and (75), we get

$$\begin{aligned} R_\varepsilon^\tau \geq {}& -\varepsilon^{-1}(\psi_{rr}^\tau \nabla\delta^\tau D^2A(\nabla\varphi)\nabla\delta^\tau + \psi^\tau) \\ &+ \psi_r^\tau\beta^\star\partial_t\delta^\tau - \frac{\pi}{4}u \\ &- \psi_r^\tau\operatorname{tr}(D^2A(\nabla\varphi)D^2\delta^\tau) \\ &- \varepsilon\psi_r^\tau\beta^\star f' - C(\Lambda)\varepsilon. \end{aligned} \tag{77}$$

Using the homogeneity of A and β, (8), and (72), we obtain

$$\begin{aligned} D^2A(\nabla\varphi) &= D^2A(\nabla\delta^\tau + O_\Lambda(\varepsilon^2)) = D^2A(\nabla\delta^\tau) + O_\Lambda(\varepsilon^2), \\ \nabla\delta^\tau D^2A(\nabla\delta^\tau)\nabla\delta^\tau &= 2A(\nabla\delta^\tau) = B(\nabla\delta^\tau)^2 = 1, \quad \text{and} \\ \beta(\nabla\varphi) &= \beta(\nabla\delta^\tau + O_\Lambda(\varepsilon^2)) = \beta(\nabla\delta^\tau) + O_\Lambda(\varepsilon^2). \end{aligned} \tag{78}$$

From (77) and (78), it follows that

$$\begin{aligned} R_\varepsilon^\tau \geq {}& -\varepsilon^{-1}(\psi_{rr}^\tau + \psi^\tau) \\ &+ \psi_r^\tau(\beta^\star\partial_t\delta^\tau - \operatorname{tr}(D^2A(\nabla\varphi)D^2\delta^\tau) - u) \\ &+ \left(\psi_r^\tau - \frac{\pi}{4}\right)u \\ &- \varepsilon c_0(\Lambda)\psi_r^\tau f' - C(\Lambda)\varepsilon, \end{aligned} \tag{79}$$

where again $|\nabla\delta^\tau(x_\tau, t_\tau)| \leq C(\Lambda)$ was used.

In the following lemma, we will prove that

$$\psi_r^\tau(\beta^\star\partial_t\delta^\tau - \operatorname{tr}(D^2A(\nabla\varphi)D^2\delta^\tau) - u) \geq -C(\Lambda)(\delta + \varepsilon). \tag{80}$$

From (63) and (67), we know that $|\lambda_\varepsilon(x_\tau, t_\tau)| \leq \pi$. This yields $\delta(x_\tau, t_\tau) \leq \varepsilon(\lambda_\varepsilon(x_\tau, t_\tau) + \pi + f(t_\tau)) \leq C(\Lambda)\varepsilon(1 + f(t_\tau))$. Plugging (80) in (79), we obtain

$$
\begin{aligned}
R_\varepsilon^\tau \geq & - \varepsilon^{-1}(\psi_{rr}^\tau + \psi^\tau) \\
& + \left(\psi_r^\tau - \frac{\pi}{4}\right) u \\
& - \varepsilon \psi_r^\tau c_0(\Lambda) f' - C(\Lambda)\varepsilon(1+f) \\
\geq & -\varepsilon^{-1}(\psi_{rr}^\tau + \psi^\tau) \\
& + \left((\psi_0^\tau)' - \frac{\pi}{4}\right) u \\
& - \varepsilon(\psi_0^\tau)' c_0(\Lambda) f' - C(\Lambda)\varepsilon(1+f)
\end{aligned} \tag{81}
$$

since $|\varepsilon f'|, |\varepsilon f| \leq 1$.

Setting $r := \lambda_\varepsilon(x_\tau, t_\tau)$, we compute

$$
\begin{aligned}
&-\varepsilon^{-1}(\psi_{rr}^\tau + \psi^\tau) + \left((\psi_0^\tau)' - \frac{\pi}{4}\right) v^\tau \\
&= \int_{\mathbb{R}} \left(-\varepsilon^{-1}(\psi_0'' + \psi_0)(s) - (\psi_1'' + \psi_1)(s) v^\tau + \left(\psi_0' - \frac{\pi}{4}\right)(s) v^\tau\right) \eta_\tau(r-s)ds - \varepsilon^{-1}\tau r \\
&= \int_{|s| \geq \frac{\pi}{2}} \left(-\varepsilon^{-1}(\psi_0'' + \psi_0)(s) - (\psi_1'' + \psi_1)(s) v^\tau + \left(\psi_0' - \frac{\pi}{4}\right)(s) v^\tau\right) \eta_\tau(r-s)ds - \varepsilon^{-1}\tau r,
\end{aligned}
$$

where we have used (54). We know from (67) and the definition of η_τ that $\eta_\tau(r-s) = 0$ when $s \geq \frac{\pi}{2}$, $r = \lambda_\varepsilon(x_\tau, t_\tau)$, and τ is small since $\limsup_{\tau \to 0} \lambda_\varepsilon(x_\tau, t_\tau) < \frac{\pi}{2}$. Therefore, the term above is estimated for small τ by

$$
\begin{aligned}
&\int_{-\infty}^{-\frac{\pi}{2}} \left(-\varepsilon^{-1}(\psi_0'' + \psi_0)(s) + \left(-\psi_1'' - \psi_1 + \psi_0 - \frac{\pi}{4}\right)(s) v^\tau\right) \eta_\tau(r-s)ds - \varepsilon^{-1}\tau r \\
&\qquad \geq \int_{-\infty}^{-\frac{\pi}{2}} (\varepsilon^{-1} - C(\Lambda)) \eta_\tau(r-s)ds - \varepsilon^{-1}\tau r \\
&\qquad \geq -\varepsilon^{-1}\varrho_\Lambda(\tau).
\end{aligned}
$$

Using the above computations, we get

$$
\begin{aligned}
R_\varepsilon^\tau \geq & \left((\psi_0^\tau)' - \frac{\pi}{4}\right)(u - v^\tau) \\
& - c_0(\Lambda)\varepsilon(\psi_0^\tau)' f' - C(\Lambda)\varepsilon(1+f) - \varepsilon^{-1}\varrho_\Lambda(\tau) \\
\geq & \, \varepsilon(\psi_0^\tau)'(-c_0(\Lambda) f' - g) \\
& + \varepsilon\left(\frac{\pi}{4} g - C(\Lambda) - C(\Lambda) f\right) - \varepsilon^{-1}\varrho_\Lambda(\tau),
\end{aligned} \tag{82}
$$

where we have used $v^\tau = u^\tau + \varepsilon g$.

Since $f(t) = \alpha \exp(-\gamma^2 t)$ and $g(t) = \alpha\gamma \exp(-\gamma^2 t)$, we obtain

$$
R_\varepsilon^\tau \geq \varepsilon - \varepsilon^{-1}\varrho_\Lambda(\tau) \tag{83}
$$

when $\gamma \geq C(\Lambda)$ and $\alpha \geq \exp(\gamma^2 T)$, which is the fourth line of (61).

Proof of (80). We now prove (80), that is,

$$
\psi_r^\tau(\beta^\star \partial_t \delta^\tau - \operatorname{tr}(D^2 A(\nabla\varphi) D^2 \delta^\tau) - u) \geq -C(\Lambda)(\delta + \varepsilon).
$$

We again take the notation of the previous subsection.

Since $\psi_r^\tau > 0$, we need only consider the situation when

$$
\beta^\star \partial_t \delta^\tau - \operatorname{tr}(D^2 A(\nabla\varphi) D^2 \delta^\tau) - u \leq 0.
$$

From (70), we know

$$\partial_t \delta^\tau \geq -C(\Lambda)\varepsilon^{-1}$$

and

$$D^2\delta^\tau \leq C(\Lambda)\varepsilon^{-1} I.$$

When $\partial_t \delta^\tau \geq 0$, since $0 \leq D^2 A \leq C(\Lambda)I$, we infer

$$c_0(\Lambda)\partial_t\delta^\tau \leq \beta^\star \partial_t \delta^\tau \leq \operatorname{tr}(D^2A(\nabla\varphi)D^2\delta^\tau) + u \leq C(\Lambda)\varepsilon^{-1};$$

hence in any case,

$$|\partial_t \delta^\tau| \leq C(\Lambda)\varepsilon^{-1}.$$

Since $D^2\delta^\tau$ is symmetric, there is an orthonormal basis $\{v_1, \dots, v_n\}$ of $\mathbb{R}^n$ and $\gamma_1, \dots, \gamma_n \in \mathbb{R}$ such that

$$D^2\delta^\tau = \sum_{i=1}^n \gamma_i v_i \otimes v_i$$

and

$$\gamma_i \leq C(\Lambda)\varepsilon^{-1}.$$

We define

$$\alpha_i^\varphi := v_i^T D^2 A(\nabla\varphi) v_i$$

and

$$\alpha_i^\delta := v_i^T D^2 A(\nabla\delta^\tau) v_i.$$

We know

$$c_0(\Lambda) \leq \alpha_i^\varphi, \qquad \alpha_i^\delta \leq C(\Lambda)$$

since $c_0(\Lambda)I \leq D^2A \leq C(\Lambda)I$. From (78), we obtain $|\alpha_i^\varphi - \alpha_i^\delta| \leq C(\Lambda)\varepsilon^2$ and

$$\exp(-C(\Lambda)\varepsilon^2) \leq \frac{\alpha_i^\varphi}{\alpha_i^\delta} \leq \exp(C(\Lambda)\varepsilon^2)$$

when $0 < \varepsilon < \varepsilon_0(\Lambda)$.

We compute

$$\begin{aligned}
&\operatorname{tr}(D^2A(\nabla\varphi)D^2\delta^\tau)\\
&\quad = \sum_{i=1}^n \gamma_i\alpha_i^\varphi = \sum_{\gamma_i>0}\gamma_i\alpha_i^\varphi + \sum_{\gamma_i<0}\gamma_i\alpha_i^\varphi\\
&\quad \leq \exp(C(\Lambda)\varepsilon^2)\sum_{\gamma_i>0}\gamma_i\alpha_i^\delta + \exp(-C(\Lambda)\varepsilon^2)\sum_{\gamma_i<0}\gamma_i\alpha_i^\delta\\
&\quad \leq \exp(-C(\Lambda)\varepsilon^2)\sum_{i=1}^n\gamma_i\alpha_i^\delta + C(\Lambda)\varepsilon = \exp(-C(\Lambda)\varepsilon^2)\operatorname{tr}(D^2A(\nabla\delta^\tau)D^2\delta^\tau) + C(\Lambda)\varepsilon.
\end{aligned}$$

Multiplying by $\exp(C(\Lambda)\varepsilon^2)$ yields

$$\begin{aligned}&\mathrm{tr}(D^2A(\nabla\varphi)D^2\delta^\tau)\\&\quad\leq \mathrm{tr}(D^2A(\nabla\delta^\tau)D^2\delta^\tau)+C(\Lambda)\varepsilon+(1-\exp(C(\Lambda)\varepsilon^2))\mathrm{tr}(D^2A(\nabla\varphi)D^2\delta^\tau).\end{aligned}$$

Taking into account the fact that $\mathrm{tr}(D^2A(\nabla\varphi)D^2\delta^\tau)\geq\beta^\star\partial_t\delta^\tau-u\geq -C(\Lambda)\varepsilon^{-1}$, we obtain

$$\mathrm{tr}(D^2A(\nabla\varphi)D^2\delta^\tau)\leq \mathrm{tr}(D^2A(\nabla\delta^\tau)D^2\delta^\tau)+C(\Lambda)\varepsilon. \tag{84}$$

In the case where $\beta^\star=\beta(\nabla\varphi)$, we observe from (78) that

$$|\beta(\nabla\varphi)\partial_t\delta^\tau-\beta(\nabla\delta^\tau)\partial_t\delta^\tau|\leq C(\Lambda)\varepsilon.$$

On the other hand, when $|\nabla\varphi|\leq\Lambda\varepsilon$, we conclude from (72) that $\psi_r^\tau\leq C(\Lambda)\varepsilon^2$; hence

$$|\psi_r^\tau(\beta^\star\partial_t\delta^\tau-\beta(\nabla\delta^\tau)\partial_t\delta^\tau)|\leq C(\Lambda)\varepsilon.$$

Together with (71) and (84), we obtain

$$\begin{aligned}&\psi_r^\tau(\beta^\star\partial_t\delta^\tau-\mathrm{tr}(D^2A(\nabla\varphi)D^2\delta^\tau)-u)\\&\quad\geq\psi_r^\tau(\beta(\nabla\delta^\tau)\partial_t\delta^\tau-\mathrm{tr}(D^2A(\nabla\delta^\tau)D^2\delta^\tau)-u)-C(\Lambda)\varepsilon\\&\quad\geq -C(\Lambda)(\varepsilon+\delta),\end{aligned}$$

which concludes the proof. □

Remark 4.4. Subsolutions can be constructed in an analogous way.

With these sub- and supersolutions and the modified comparison principle (Theorem 2.12), we are now able to prove the convergence result.

We consider the following situation. Let $D\subset\mathbb{R}^n$ be an open, periodic subset with $\emptyset\neq D$, $\overline{D}\neq\mathbb{R}^n$, and define $\Gamma_0:=\partial D$. We denote by δ_0 the signed distance function of Γ_0, positive on D, induced by the metric d of section 3.2, that is,

$$\delta_0(x):=\begin{cases}\inf\limits_{y\in\Gamma_0}d(x,y) & \text{for } x\in D,\\ -\inf\limits_{y\in\Gamma_0}d(x,y) & \text{for } x\notin D.\end{cases}$$

δ_0 is periodic, bounded, and Lipschitz continuous,

$$|\nabla\delta_0|\leq C(\Lambda).$$

Since $\emptyset\neq D$, $\overline{D}\neq\mathbb{R}^n$, for Λ large enough, we have

$$\begin{aligned}|\delta_0|&\leq\Lambda,\\ \sup\delta_0&\geq\Lambda^{-1},\quad\text{and}\\ \inf\delta_0&\leq-\Lambda^{-1}.\end{aligned}$$

From Theorem 2.5, we obtain the existence of a unique periodic $\omega\in C(\mathbb{R}^n\times[0,T[)$ which solves

$$\begin{aligned}\partial_t\omega+F(.,.,\nabla\omega,D^2\omega)&=0\quad\text{in }\mathbb{R}^n\times]0,T[\quad\text{and}\\ \omega(.,0)&=\delta_0,\end{aligned}\tag{85}$$

where F is defined in section 2.1. We assume that for $0\leq t<T$,

$$\sup\omega(.,t)\geq\Lambda^{-1}$$

and

$$\inf \omega(.,t) \leq -\Lambda^{-1}.$$

From Theorem 2.8, we get a periodic viscosity solution $\varphi_\varepsilon \in C(\mathbb{R}^n \times [0,T[)$ of the double-obstacle Allen–Cahn problem,

(86)

$$\max\left(\varphi_\varepsilon - 1, \min\left(\varphi_\varepsilon + 1, \partial_t \varphi_\varepsilon + \frac{1}{\varepsilon} G_\varepsilon(.,.,\varphi_\varepsilon, \nabla\varphi_\varepsilon, D^2\varphi_\varepsilon)\right)\right) = 0 \quad \text{in } (\mathbb{R}^n \times]0,T[).$$

For the initial conditions, we assume

$$\begin{aligned} &\varphi_\varepsilon(.,0) = 1 \quad \text{for } \delta_0 \geq C(\Lambda)\varepsilon \quad \text{and} \\ &\varphi_\varepsilon(.,0) = -1 \quad \text{for } \delta_0 \leq -C(\Lambda)\varepsilon; \end{aligned} \tag{87}$$

for example, $\varphi_\varepsilon(.,0) = \varphi_{\varepsilon,0} = \max(-1, \min(1, \frac{\delta_0}{\varepsilon}))$.

The convergence theorem can now be stated.

THEOREM 4.5.

$$\varphi_\varepsilon \to 1 \quad \textit{pointwise on } [\omega > 0]$$

and

$$\varphi_\varepsilon \to -1 \quad \textit{pointwise on } [\omega < 0].$$

Moreover, this convergence is uniform on compact subsets of $[\omega > 0]$*, respectively,* $[\omega < 0]$*.*

Proof. We define $\omega_\varepsilon^+ := \omega + \Gamma\varepsilon$ for $\Gamma = C(\Lambda)$ chosen below. According to [7], ω_ε^+ is a supersolution of (42). As in section 3.2 and Definition 4.2, we define

$$\begin{aligned} \delta_\varepsilon^+(x,t) &:= \inf_{y,\ \omega_\varepsilon^+(y,t) \leq 0} d(x,y), \\ \lambda_\varepsilon^+(x,t) &:= \frac{\delta_\varepsilon^+(x,t)}{\varepsilon} - \pi - f(t), \quad \text{and} \\ \psi_\varepsilon^+ &:= \psi(\lambda_\varepsilon^+, v). \end{aligned}$$

For $0 < \varepsilon < \varepsilon_0(\Lambda)$, we claim that

$$\psi_\varepsilon^+ \geq \varphi_\varepsilon. \tag{88}$$

From Theorem 2.12 and Proposition 4.3, it suffices to verify that

$$\psi_\varepsilon^+(.,0) \geq \varphi_\varepsilon(.,0). \tag{89}$$

When $\varphi_\varepsilon(x,0) = -1$, the inequality is satisfied since $\psi_\varepsilon^+ \geq -1$.

Now we assume $\varphi_\varepsilon(x,0) > -1$. From (87), we get $\omega(x,0) = \delta_0(x) \geq -C(\Lambda)\varepsilon$ and

$$\omega_\varepsilon^+(x,0) \geq -C(\Lambda)\varepsilon + \Gamma\varepsilon \geq \frac{\Gamma}{2}\varepsilon > 0$$

when $\Gamma \geq C(\Lambda)$. Therefore, there is a $y \in [\omega_\varepsilon^+(.,0) \leq 0]$ such that $\delta_\varepsilon^+(x,0) = d(x,y) > 0$. This yields

$$\begin{aligned} \frac{\Gamma}{2}\varepsilon &\leq \omega_\varepsilon^+(x,0) - \omega_\varepsilon^+(y,0) = \omega(x,0) - \omega(y,0) \\ &= \delta_0(x) - \delta_0(y) \leq C(\Lambda)|x-y| \leq C(\Lambda)d(x,y) = C(\Lambda)\delta_\varepsilon^+(x,0). \end{aligned}$$

We conclude

$$\lambda_\varepsilon^+(x,0) = \frac{\delta_\varepsilon^+(x,0)}{\varepsilon} - \pi - \alpha \geq c_0(\Lambda)\Gamma - \pi - \alpha.$$

Since $\alpha \leq C(\Lambda)$, we can choose $\Gamma \geq C(\Lambda)$ to get

$$\lambda_\varepsilon^+(x,0) \geq \frac{\pi}{2};$$

hence

$$\psi_\varepsilon^+(x,0) = 1 \geq \varphi_\varepsilon(x,0),$$

establishing (89) and therefore (88).

We take (x_0,t_0) with $\omega(x_0,t_0) < 0$. There is $\tau > 0$ and a neighborhood $U(x_0,t_0)$ such that

$$\omega \leq -\tau \quad \text{on } U(x_0,t_0);$$

hence

$$\omega_\varepsilon^+ \leq -\frac{\tau}{2} \quad \text{on } U(x_0,t_0) \quad \text{for } 0 < \varepsilon < \varepsilon_0(\Lambda,\tau).$$

On $U(x_0,t_0)$, we have

$$\delta_\varepsilon^+ = 0;$$

hence

$$\lambda_\varepsilon^+ \leq -\pi$$

and, finally,

$$\varphi_\varepsilon \leq \psi_\varepsilon^+ = -1 \quad \text{on } U(x_0,t_0). \qquad \square$$

Remark 4.6. When $H^n([\omega = 0]) = 0$, then the limit of φ_ε is uniquely determined in $L^1(\mathbb{R}^n \times [0,T[)$ by Theorem 4.5.

When fattening occurs—that is, $H^n([\omega = 0]) > 0$—there remains an ambiguity.

Acknowledgments. We thank Maurizio Paolini and Mete Soner for several discussions related to the topic of this article.

THE ASYMPTOTIC BEHAVIOR OF THE HYPERBOLIC CONSERVATION LAWS WITH RELAXATION ON THE QUARTER-PLANE[*]

SHINYA NISHIBATA[†] AND SHIH-HSIEN YU[‡]

Abstract. The hyperbolic conservation laws with relaxation appear in many physical models such as those for gas dynamics with thermo-nonequilibrium, elasticity with memory, flood flow with friction, and traffic flow. The main concern of this article is the long-time behavior of the interaction between the relaxations and the boundary conditions. In this article, we investigate this problem for a simple model of a 2×2 system. It is proven that the solution of the system asymptotically converges to a traveling wave moving away from the boundary under suitable conditions on the boundary.

Key words. equilibrium state, subcharacteristic condition, boundary condition

1. Introduction.

The phenomena of relaxation are present in the kinetic theory of gas, e.g., the Broadwell model [1], [2], [8], [13], elasticity with memory, gas flow with thermo-nonequilibrium, water waves, etc. Liu [9] gave a 2×2 strictly hyperbolic system as a model equation for the relaxation phenomenon, where he studied the asymptotic behavior of the solution for both rarefaction waves and traveling waves. In the same paper, the validity of the Chapman–Enskog expansion was also investigated. In most of the physical situations where relaxations occur, it is inevitable to take boundary effects into account. In this paper, we would like to extend the results of Liu [9] to cases where the boundary effects are taken into consideration.

In the case of the initial value problem, the asymptotic behavior of Liu's 2×2 system is governed by an equilibrium equation. However, for the initial-boundary value problem in the first quadrant, we must consider the effect of the boundary condition. The number of boundary conditions required for the equilibrium equation is one or zero depending on whether the equilibrium characteristic speed is positive or not. For the 2×2 system, the number of the boundary conditions required is the same as the number of characteristics out of the boundary, which could be zero, one, or two depending on the directions of the characteristics. Therefore, for the 2×2 system and for the equilibrium equation, they may not require the same number of boundary conditions. In the case where the numbers are different, there might be some boundary layer appearing; cf. [8] and [15]. In [8], there are various interesting behaviors due to the boundary conditions. In this paper, we consider the case when both the 2×2 system and the equilibrium equation require one boundary condition.

Previously, Chen [3] studied the nonlinear diffusion wave for Liu's model. Nishibata [12] followed Liu's model equation to study the stability of the stationary solution for the initial-boundary problems, which is closely related to the work in this paper.

Consider the following system of two quasi-linear linear hyperbolic equations as a model of relaxation [9]:

$$\left\{\begin{array}{l} u_t + f(u,v)_x = 0 \quad \text{for } x, t > 0, \\ v_t + g(u,v)_x = h(u,v). \end{array}\right. \tag{1.1}$$

The first equation represents a conservation law for and the second equation represents a rate equation. Suppose that this system is a strictly hyperbolic; $\lambda_1(u,v) < \lambda_2(u,v)$, where λ_1 and λ_2 are the eigenvalues of the Jacobian matrix

$$\begin{pmatrix} f_u(u,v) & f_v(u,v) \\ g_u(u,v) & g_v(u,v) \end{pmatrix}.$$

In order to make the conservation law and the rate equation strongly coupled, we assume that

$$f_v(u,v) \neq 0 \quad \text{for all } (u,v) \text{ under consideration.}$$

The term $h(u,v)$ acts as the a source (or a sink) when v is less (or greater) than the equilibrium state $v_*(u)$. $h(u,v)$ often assumes the form

$$h(u,v) = \frac{v_*(u) - v}{\tilde{\tau}(u)}$$

for some positive function $\tilde{\tau}(u)$, the relaxation time. We make the general assumption

$$\frac{\partial h(u,v)}{\partial v} < 0, \quad h(u, v_*(u)) = 0,$$

for all (u,v) under consideration. We impose boundary values on u:

$$u(0,t) = u_-, \qquad u(\infty,t) = u_+, \tag{1.2}$$

where u_- and v_- are constants. Since the solution at $x = \infty$ is permanent, it is an equilibrium state:

$$v(\infty,t) = v_*(u_-). \tag{1.3}$$

When the solution is close to the equilibrium state, we often ignore the rate equation and replace the conservation law with the equilibrium equation:

$$\frac{\partial u}{\partial t} + \frac{\partial f_*(u)}{\partial x} = 0, \quad f_*(u) =: f(u, v_*(u)). \tag{1.4}$$

When $(u_-, v_*(u_-)$ and $(u_+, v_*(u_+))$ are connected by a shock wave for the system (1.1), we have the Rankine–Hugoniot relation with the shock speed σ:

$$\sigma = \frac{f_*(u_-) - f_*(u_+)}{u_- - u_+}.$$

For the stability of (1.1), we require the subcharacterisitc condition $\lambda_1 < \sigma < \lambda_2$. Here we are interested in the case $\sigma > 0$. In order to make the equilibrium equation (1.4) and system (1.1) require the same number of boundary conditions on the boundary $x = 0$, we assume the following:

$$\lambda_1(u,v) < 0 < \sigma < \lambda_2(u,v) \quad \text{for all } (u,v) \text{ under consideration.} \tag{1.5}$$

Furthermore, for simplicity, we assume that

$$f_*^{''}(u) > 0. \tag{1.6}$$

We define $\hat{u}$ as the number uniquely determined to satisfy

$$f_*'(\hat{u}) = \sigma.$$

We denote by $(\phi(x-\sigma t), \psi(x-\sigma t))$ a traveling-wave solution of the Cauchy problem of system (1.1) that connects the end states $(u_-, v_*(u_-))$ and $(u_+, v_*(u_+))$. When $|u_- - u_+|$ tends to 0, the curve $L = \{(\phi(x), \psi(x)) : x \in \mathbf{R}\}$ degenerates to the point $(\hat{u}, v_*(\hat{u}))$ by (1.6), i.e., when $|u_- - u_+|$ is sufficiently small,

$$\|\phi(x) - \hat{u}\|_\infty + \|\psi(x) - v_*(\hat{u})\|_\infty \le K_0 |u_- - u_+|. \tag{1.7}$$

where K_0 is an constant depending on $\hat{u}$ only (see [9]).

Henceforth, we normalize the traveling wave as follows:

$$\phi(0) = \hat{u}.$$

Remark. In the remainder of this paper, all of the constants depend only on $\nabla^i f(\hat{u}, \hat{v})$, $\nabla^i g(\hat{u}, \hat{v})$, and $\nabla^i h(\hat{u}, \hat{v})$ $(i = 0, 1, 2)$, where $\hat{v} = v_*(\hat{u})$ unless otherwise mentioned.

The initial conditions are chosen so that $(u(x,0), v(x,0)) = (u_0(x), v_0(x))$ with $u_0,\ v_0 \in C^3[0,\infty)$ and that the following is satisfied:

$$\begin{aligned} &\sum_{i=0}^{3} |\nabla^i (u_0(x) - \phi(x - x_0))|^2 + \sum_{i=0}^{3} |\nabla^i (v_0(x) - \psi(x - x_0))|^2 \\ &\le \begin{cases} \delta_1 |\phi(x - x_0) - u_+| & \text{if } x > x_0, \\ \delta_1 |\phi(x - x_0) - u_-| & \text{if } 0 < x < x_0, \end{cases} \end{aligned} \tag{1.8}$$

where δ_1 and x_0 are certain constants to be determined later.

Recall that we set the boundary conditions in (1.2). In addition, suppose that λ_1 and λ_2 satisfy the following condition:

$$\begin{gathered} -\lambda_2(u,v) < \lambda_1(u,v) < 0 < -\frac{(\lambda_1 + \lambda_2)}{\lambda_1 \lambda_2(u,v)} < \sigma < \lambda_2(u,v) \\ \text{for all } (u,v) \text{ under consideration} \end{gathered} \tag{1.9}$$

This additional assumption will later be necessary to estimate the rate of convergence of $v(0,t) - v_*(u_-)$ on the boundary.

We introduce the perturbations $\bar{u}$ and $\bar{v}$:

$$\begin{cases} u(x,t) = \phi(x - \sigma t - x_0) + \bar{u}(x,t), \\ v(x,t) = \phi(x - \sigma t - x_0) + \bar{v}(x,t). \end{cases} \tag{1.10}$$

Note that in the rest of this section, (ϕ, ψ) will stand for $(\phi(x-\sigma t-x_0), \psi(x-\sigma t-x_0))$ unless otherwise mentioned.

From (1.1), we have the system of differential equations for the perturbation $(\bar{u}, \bar{v})$:

$$\begin{cases} \bar{u}_t + (\nabla f \cdot (\bar{u}, \bar{v}))_x = -M(f)_x, \\ \bar{v}_t + (\nabla g \cdot (\bar{u}, \bar{v}))_x = \nabla h \cdot (\bar{u}, \bar{v}) - M(g)_x + M(h), \end{cases} \tag{1.11}$$

where $M(f) =: f(\phi+\bar{u},\psi+\bar{v}) - f - \nabla f\cdot(\bar{u},\bar{v})$ for any function f, where f, ∇f, ∇g, and ∇h are evaluated at $(\phi(x-\sigma t-x_0),\psi(x-\sigma t-x_0))$.

Remark. The function $M(f)$ is a function of higher than second order in $(\bar{u},\bar{v})$.

THEOREM 1.1 (local existence theorem). *For system* (1.1)*, there is a* $\delta_3 > 0$ *such that for any* $\sum_{i=0}^{1}\left(\|\partial_x^i(u(\cdot,0)-\hat{u})\|_\infty + \|\partial_x^i(v(\cdot,0)-v_*(\hat{u}))\|_\infty\right) \le \delta_3/2$*, there is constant* $\tau(\delta_3) > 0$ *such that the solution* (u,v) *exists in* $[0,\infty)\times[0,\tau(\delta_3))$ *and satisfies*

$$\sup_{0<t<\tau(\delta_3)}\left(\sum_{i=0}^{1}\|\partial_x^i(u(\cdot,t)-\hat{u})\|_\infty + \|\partial_x^i(v(\cdot,t)-v_*(\hat{u}))\|_\infty\right) \le \delta_3.$$

The proof is given by the standard iteration method (see [7]).

We denote

$$N(t) =: \|\phi'\|_\infty + \|\psi'\|_\infty + \mathrm{sup}_{0<\tau<t}\left(\sum_{i=0}^{1}\|\partial_x^i\bar{u}(\cdot,\tau)\|_\infty + \sum_{i=0}^{1}\|\partial_x\bar{v}(\cdot,\tau)\|_\infty\right),$$
$$t_n =: n\tau(\delta_2), \quad n\in\mathbf{N}.$$

LEMMA 1.2 (main lemma). *For given small* δ_0 *and* δ_2 *satisfying* $|u_- - u_+| < \delta_0 < \delta_2 \ll \delta_3$*, we choose* δ_1 *and* x_0 *so that* δ_1*,* $e^{-|u_- - u_+|x_0}$*, and* $\delta_1 x_0$ *are sufficiently small. Suppose that* $N(t_{n-1}) < \delta_2/2$ *holds. Then we have* $N(t_n) < \delta_2/2$*.*

Proof. See section 3.

THEOREM 1.3 (global existence theorem). *For given small* δ_0 *and* δ_2 *satisfying* $|u_- - u_+| < \delta_0 < \delta_2 \ll \delta_3$*, we choose* δ_1 *and* x_0 *to satisfy the requirement that* δ_1*,* $e^{-|u_- - u_+|x_0}$*, and* $\delta_1 x_0$ *are sufficiently small. Then the solution* $(u(x,t),v(x,t))$ *exists globally and satisfies*

$$\sup_{t>0}\Bigg(\|\phi'\|_\infty + \|\psi'\|_\infty + |u_- - u_+| + \sum_{i=0}^{1}\|\partial_x^i(u(\cdot,t)-\phi(\cdot-\sigma t-x_0))\|_\infty$$
$$+\sum_{i=0}^{1}\|\partial_x^i(v(\cdot,t)-\psi(\cdot-\sigma t-x_0))\|_\infty\Bigg) < \frac{\delta_2}{2}.$$

Proof. From Theorem 1.1 and Lemma 1.2, Theorem 1.3 follows.

THEOREM 1.4 (the convergence theorem). *Given that* $|u_- - u_+| < \delta_0 < \delta_2 \ll \delta_3$ *are small, suppose that* δ_1*,* $e^{-|u_- - u_+|x_0}$*, and* $\delta_1 x_0$ *are sufficiently small. Then there is a unique* $s_\infty < \infty$ *such that* $(u(x,t),v(x,t))$ *converges to the traveling wave* $(\phi(x-\sigma t-s_\infty),\psi(x-\sigma t-s_\infty))$ *when* t *tends to* ∞*.*

Proof. See section 3.

The difficulty in the present problem is due to the fact that the wave is moving away from the boundary, so we cannot determine the location error. In section 2, this difficulty is resolved by introducing the Riemann invariants and a suitable weight function to obtain an a priori estimate for the rate of $v(0,t) - v_*(u_-)$ converging to 0.

The same difficulty in determining the location error also arises in the initial-boundary problem for viscous conservation laws and the Cauchy problem for undercompressible flow. For the initial-boundary problems for the Burgers equation, Yu [14] and Liu and Yu [10] used the boundary gradient estimate to obtain the location error and get the asymptotic stability. In case of undercompressible flow, Zumbrum and Liu [11] used the pointwise estimate to overcome the difficulty of determining the location error.

In section 3, we introduce a sequence of the location error associated with a time sequence tending to a infinity. By using the sequence of the location error and the decreasing rate of $|v(0,t) - v_*(u_-)|$, the standard energy method can be applied to show the global existence. We also show that the solution asymptotically converges to the traveling wave.

2. Initial-boundary problem and boundary-value estimate.

2.1. Convergence of boundary value. We introduce new variables r_1 and r_2 to diagonalize the linear parts of (1.11).

Notation.

$$\begin{pmatrix} r_1 \\ r_2 \end{pmatrix} := L(x,t) \cdot \begin{pmatrix} \bar{u} \\ \bar{v} \end{pmatrix} \tag{2.1}$$

with $L(x,t) := R(x,t)^{-1}$, where

$$R(x,t) := \begin{pmatrix} -f_v & -f_v \\ f_u - \lambda_1 & f_u - \lambda_2 \end{pmatrix}.$$

Substitute the variables r_1 and r_2 into (1.1); it then follows that

$$\begin{aligned} &\begin{pmatrix} r_1 \\ r_2 \end{pmatrix}_t + \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} \begin{pmatrix} r_1 \\ r_2 \end{pmatrix}_x - L(x,t) \begin{pmatrix} 0 \\ \nabla h(\bar{u},\bar{v}) \end{pmatrix} \\ &\quad = L(x,t)_t R(x,t) \begin{pmatrix} r_1 \\ r_2 \end{pmatrix} - \begin{pmatrix} \lambda_1 & 0 \\ 0, & \lambda_2 \end{pmatrix} L(x,t) R(x,t)_x \begin{pmatrix} r_1 \\ r_2 \end{pmatrix} \\ &\qquad + L(x,t) \begin{pmatrix} 0 \\ M(h) \end{pmatrix} + L(x,t) \begin{pmatrix} -M(f)_x \\ -M(g)_x \end{pmatrix}. \end{aligned} \tag{2.2}$$

Next, we set

$$\begin{aligned} lW(x,t) &:= e^{\frac{2H\cdot(x-\sigma t)}{c_2 - c_1}}, \\ \mu(u,v) &:= f_u(u,v) - (f_v h_u h_v^{-1})(u,v), \\ H &:= h_v(\hat{u},\hat{v}) < 0, \\ c_i &=: \lambda_i(\hat{u},\hat{v}) \quad \text{with } i = 1,2, \\ b &= \frac{(c_2 - \sigma)}{(\sigma - c_1)}, \end{aligned}$$

where the variable $\mu(u,v)$ is the dynamic characteristic speed defined in [9]. From the definition of W, it follows that

$$\frac{W_x}{W} = \frac{2H}{(c_2 - c_1)}. \tag{2.3}$$

We multiply (2.2) by $W(x,t)(r_1, b\ r_2)$ and integrate it over $0 < x < \infty$. We substitute (1.7) into this integration. We then substitute (2.3) and Schwartz's inequality into this integration. Then there is a positive constant K_1 such that

(2.4)

$$\frac{d}{dt}\int_0^\infty W \cdot (r_1^2 + b\ r_2^2)(x,t)dx + ((-\lambda_1 r_1^2 - b\ \lambda_2 r_2^2) \cdot W)(0,t)$$

$$\leq \frac{-kH}{c_2 - c_1} \int_0^\infty W \cdot (r_1^2 + b\ r_2^2) dx$$
$$+ K_1 \left(N(t)(r_1^2(0,t) + b\ r_2^2(0,t)) + |u_- - u_+| \int_0^\infty W \cdot (r_1^2 + b\ r_2^2)(x,t) dx \right),$$

where

$$k = -2(c_2 - \sigma) + \sqrt{4(c_2 - \sigma)^2 + \frac{((c_2 - \sigma) + (\sigma - c_1) b)^2}{b}}.$$

Next, we compute the terms of (2.4) evaluated at $x = 0$. Substituting $x = 0$ into (1.10), it follows that

$$\bar{u}(0,t) = u_- - \phi(-x_0 - \sigma t). \tag{2.5}$$

From (2.5) and (2.1), we have that

$$-f_v\ (r_1 + r_2)(0,t) = u_- - \phi(-\sigma t - x_0). \tag{2.6}$$

From (2.6), we have that

$$r_2^2(0,t) = \left(\frac{-(u_- - \phi(-x_0 - \sigma t))}{f_v} - r_1(0,t) \right)^2. \tag{2.7}$$

Substituting (2.7) in the boundary term on the left-hand side (LHS) of (2.4), we obtain

(2.8)
$$-(\lambda_1 r_1^2 + \lambda_2 b\ r_2^2)(0,t) = -\left(\lambda_1 r_1^2 + b\ \lambda_2 \left(r_1 + \frac{(u_- - \phi(-\sigma t - x_0))}{f_v} \right)^2 \right)$$
$$> -\frac{(\lambda_1 + b\ \lambda_2) r_1^2(0,t)}{2} - K_0 \lambda_2 \left(\frac{(u_- - \phi(-x_0 - \sigma t)}{f_v} \right)^2,$$

where K_0 is a positive constant depending only on $\hat{u}$. From assumption (1.9), $-(\lambda_1 + b\lambda_2) > 0$. Hence if $N(t)K_1 \ll -(\lambda_1 + b\ \lambda_2)/8$, then the boundary term on the right-hand side (RHS) of (2.4) can be absorbed into the positive boundary term on the LHS of (2.4). Therefore, there are constants K_2 and K_1 such that

(2.9)
$$\frac{d}{dt} \int_0^\infty W(r_1^2 + b\ r_2^2) dx \leq \frac{-H(k + K_1(N(t) + |u_- - u_+|))}{c_2 - c_1} \int_0^\infty W(r_1^2 + b\ r_2^2) dx$$
$$+ K_2(\phi(x_0 - \sigma t) - u_-)^2 W(0,t).$$

Lemma 2.1.

$$d := -2c_2 + \sqrt{4(c_2 - \sigma)^2 + \frac{((c_2 - \sigma) + (\sigma - c_1) b)^2}{b}} < 0.$$

Proof. Due to an algebraic manipulation of (1.9), Lemma 2.1 follows.

LEMMA 2.2. *If $K_1(|u_- - u_+| + N(t)) < -d/4$, then for $t' \in (0,t)$,*

$$\int_0^1 \left(r_1^2(x,t') + b\ r_2^2(x,t')\right) dx \le e^{\frac{-dHt'}{(c_2-c_1)}} \int_0^\infty (r_1^2(x,0) + b\ r_2^2(x,0))W(x,0)dx$$
$$+ K_2 e^{\frac{-2H}{(c_2-c_1)}} \int_0^{t'} e^{\frac{-dH(t'-s)}{2(c_2-c_1)}} (\phi(-x_0 - \sigma s) - u_-)^2 ds. \tag{2.10}$$

Proof. From (2.9), we have that for $t' \in (0,t)$,

$$\int_0^1 (r_1^2(x,t') + b\ r_2^2(x,t'))W(1,t')dx < \int_0^\infty \left((r_1^2 + b\ r_2^2)W\right)(x,t')dx$$
$$\le e^{\frac{-H(k+K_1(N(t')+|u_- - u_+|))t'}{c_2-c_1}} \int_0^\infty \left((r_1^2 + b\ r_2^2)W)\right)(x,0)dx \tag{2.11}$$
$$+ \int_0^{t'} K_2(\phi(-\sigma s - x_0) - u_-)^2 W(0,s) e^{\frac{-H(k+K_1(N(t')+|u_- - u_+|))(t'-s)}{c_2-c_1}} ds.$$

Dividing both sides of (2.11) by $W(1,t')$ and substituting the condition $K_1(|u_- - u_+| + N(t)) < -d/4$ into (2.11), Lemma 2.2 follows.

THEOREM 2.3. *Suppose for a given $\delta_2\,(< -d/4K_1)$ that the following holds:*

$$\text{if } |u_- - u_+| + N(t) \le \delta_2, \quad |u_- - u_+| \ll 1, \quad \text{and} \quad x_0 \gg 1, \tag{2.12}$$
then there is a constant K_3 such that for $t' \in (0,t)$,

$$|v(0,t') - v_*(u_-)| \tag{2.13}$$
$$\le K_3 \left\{\delta_2^{1/2}\delta_1^{1/4} + \delta_1^{1/2}\right\} \left[(\phi(-x_0 - \sigma t') - u_-)^2 + |\phi(-x_0/2) - u_-| e^{dt'/2}\right]^{1/4}_.$$

Proof. By the condition on the initial value ((1.8)) and Lemma 2.2, we have

$$\int_0^\infty W(x,0)(\bar{u}^2(x,0) + \bar{v}^2(x,0))dx$$
$$= O(1)\delta_1 \left(\int_{[0,x_0/2]} + \int_{[x_0/2,x_0]}\right) W(x,0)|\phi(x - x_0) - u_-|^2 dx$$
$$+ O(1)\delta_1 \int_{x_0}^\infty W(x,0)|\phi(x - x_0) - u_+|^2 dx \tag{2.14}$$
$$= O(1)\delta_1 \left\{|\phi(-x_0/2) - u_-| + e^{\frac{Hx_0}{c_2-c_1}}\right\}.$$

Hence from (2.14) and Lemma 2.2, we have

$$\int_0^1 \bar{u}^2(x,t') + \bar{v}^2(x,t')dx \tag{2.15}$$
$$= O(1)\delta_1 \left\{|\phi\left(\frac{-x_0}{2}\right) - u_-| e^{dt'/2} + \left(\phi\left(\frac{-x_0 - \sigma t'}{2}\right) - u_-\right)^2\right\}.$$

From $N(t) + |u_- - u_+| < \delta_2$, we have that for $t' \in (0,t)$,

$$\int_0^1 |\bar{u}_x(x,t')|^2 + |\bar{v}_x(x,t')|^2 dx \le N(t)^2 \le \delta_2^2. \tag{2.16}$$

From (2.16) and (2.15),

$$\text{(2.17)}\quad \sup_{0\le x,x'\le 1} |v(x,t') - v(x',t')| \le K_3'\delta_2^{1/2}\delta_1^{1/4}\left[(\phi(-x_0-\sigma t') - u_-)^2 + |\phi(-x_0/2) - u_-|e^{dt'/2}\right]^{1/4},$$

and from (2.15), there is an $\bar{x} \in [0,1]$ satisfying

$$\text{(2.18)}\quad |v(\bar{x},t')| \le \left\{K_3'\delta_1\left(\left|\phi\left(-\frac{x_0}{2}\right) - u_-\right| e^{dt'/2} + \left(\phi\left(-\frac{x_0-\sigma t'}{2}\right) - u_-\right)^2\right)\right\}^{1/2},$$

where K_3' is a constant depending only on $\hat{u}$. From (2.17) and (2.18), Theorem 2.3 follows. Here note that by standard ordinary differential equation theory, the first term of the RHS of (2.13) converges to zero with an exponential rate. Hence $v(0,t)$ converges to $v_*(\hat{u})$ with an exponential rate.

2.2. The sequence of the location error. From the a priori boundary estimate Theorem 2.3, we obtain that $v(0,t)$ converges to $v_*(\hat{u})$ with an exponential rate. Once we get the rate of convergence, we can handle the boundary terms that appear in the usual energy estimate. However, we still have to deal with the asymptotic state caused by the location error, which is thus far unexamined. In order to resolve this difficulty, we introduce a sequence of the location error.

DEFINITION 2.4. *The sequence of the location error* $\{\sigma t + s_n\}_{n\in\mathbf{N}}$ *is associated with the time sequence* $\{t_n | t_n = n\tau(\delta_2),\ n \in \mathbf{N}\}$ (*cf. the comment below Theorem* 1.1). *We define* $\{s_n\}_{n\in\mathbf{N}}$ *by the following implicit equation:*

$$\text{(2.19)}\qquad \int_0^\infty u(x,t_n) - \phi(x-\sigma t_n - s_n)dx = 0.$$

Here s_n *is uniquely determined because* ϕ *is monotonic* (*see Liu* [9]).

From (2.19), we have the following identity due to the conservation laws:

$$\text{(2.20)}$$
$$\begin{aligned}
0 &= \int_0^\infty u(x,t_n) - \phi(x-s_n-\sigma t_n)dx \\
&= \int_0^\infty u(x,t_n) - \phi(x-x_0-\sigma t_n)dx + \int_0^\infty \phi(x-x_0-\sigma t_n) - \phi(x-s_n-\sigma t_n)dx \\
&= \int_0^\infty u(x,0) - \phi(x-x_0)dx + \int_0^{t_n} \frac{d}{dt}\left\{\int_0^\infty u(x,t) - \phi(x-x_0-\sigma t)dx\right\}dt \\
&\qquad + \int_0^\infty \phi(x-x_0-\sigma t_n) - \phi(x-s_n-\sigma t_n)dx \\
&= \int_0^{t_n} f(u_-, v(0,t)) - f(\phi(-x_0-\sigma t), \psi(-x_0-\sigma t))dt + \int_0^\infty u(x,0) - \phi(x-x_0)dx \\
&\qquad + \int_{x_0}^{s_n} (\phi(-\sigma t_n - s) - u_+)ds \\
&= O(1)\int_0^{t_n} |\psi(-x_0-\sigma t) - v_*(u_-)| + |v(0,t) - v_*(u_-)|dt
\end{aligned}$$

$$
\begin{aligned}
&+O(1)\left\{\int_0^{t_n}|\phi(-x_0-\sigma t)-v_*(u_-)|dt+|u_--u_+||x_0-s_n|\right\}\\
&+\int_0^\infty u(x,0)-\phi(x-x_0)dx.
\end{aligned}
$$

Hence we have that when $|u_--u_+|\ll 1$, it follows from Theorem 2.3 that

$$
|s_n-x_0|<\frac{O(1)\left(\delta_1+\delta_1^{1/4}\delta_2^{1/2}\left|\phi\left(-\frac{x_0}{4}\right)-u_-\right|\right)}{|u_--u_+|^3}. \tag{2.21}
$$

3. Proof of Lemma 1.2. We will split this section into five subsections in order to prove the main lemma. Then in the last subsection, we will show that the wave (u,v) converges to the asymptotic wave $(\phi(x-\sigma t-s_\infty),\psi(x-\sigma t-s_\infty))$, where the asymptotic location error $\sigma t+s_\infty$ is defined formally as

$$
s_\infty=\lim_{n\to\infty}s_n. \tag{3.1}
$$

The existence of the above limit will be shown at the end of this paper. In the next four subsections, we will show that

$$
N(t_n)+|u_--u_+|\le\frac{\delta_2}{2}\quad\text{for } n\in\mathbf{N} \tag{3.2}
$$

by induction.

3.1. Preliminaries for the global existence theorem (Theorem 1.3). Because of the assumption of Lemma 1.2, $N(t_0)+|u_--u_+|\le\delta_2/2$ holds for $t_0=0$. Hence we assume that the solution (u,v) exists in $[0,t_{n-1}]$ and that (3.2) holds for $n-1$. Then by the local existence theorem (Theorem 1.1), the existence of the solution (u,v) can be extended to $[0,\infty)\times[0,t_n]$, and it satisfies

$$
N(t_n)+|u_--u_+|<\delta_2.
$$

We define the function $z(x,t)$:

$$
z(x,t)=-\int_x^\infty u(y,t)-\phi(y-\sigma t-s_n)dy. \tag{3.3}
$$

Then from Theorem 2.3, we have the following for $0<t\le t_n$:

$$
\begin{aligned}
&|z(0,t)|= \\
&\frac{O(1)\left\{\delta_2^{1/2}\delta_1^{1/4}\left((\phi(-x_0-\sigma t)-u_-)^2+\left|\phi\left(-\frac{x_0}{2}\right)-u_-\right|e^{dt/2}\right)^{1/4}+|\phi(x_0-\sigma t)-u_-|\right\}}{|u_--u_+|},
\end{aligned} \tag{3.4}
$$

$$
\begin{aligned}
&|z_t(0,t)|= \\
&O(1)\left\{\delta_2^{1/2}\delta_1^{1/4}\left((\phi(-x_0-\sigma t)-u_-)^2+\left|\phi\left(-\frac{x_0}{2}\right)-u_-\right|e^{dt/2}\right)^{1/4}+|\phi(x_0-\sigma t)-u_-|\right\}.
\end{aligned} \tag{3.5}
$$

Define $\tilde u$ and $\tilde v$ as follows:

$$
u(x,t)=\phi(x-\sigma t-s_n)+\tilde u(x,t),\qquad v(x,t)=\psi(x-\sigma t-s_n)+\tilde v(x,t).
$$

$$z_x(0,t) = u_- - \phi(-\sigma t - s_n).$$

Substitute the function $z(x,t)$ in (1.1). From the conservation law in (1.1), we have that

$$\begin{aligned} &z_t + f(\phi(x-\sigma t - s_n) + z_x, \psi(x - \sigma t - s_n) + \tilde{v})) \\ &\quad - f(\phi(x-\sigma t - s_n), \psi(x-\sigma t - s_n)) = 0. \end{aligned} \tag{3.6}$$

In the next three subsections, the functions f, g, ∇f, ∇g, λ_1, λ_2, and h are evaluated at $(\phi(x-\sigma t - s_n), \psi(x - \sigma t - s_n))$ unless otherwise specified. Therefore,

$$\tilde{v}(x,t) = -f_v^{-1}(z_t + f_u z_x + Q_0(f)), \tag{3.7}$$

where $Q_0(f) = f(z_x + \phi, \tilde{v} + \psi) - f(\phi,\psi) - \nabla f(z_x, \tilde{v})$. Hence $Q_0(f) = O(1)(z_x^2 + \tilde{v}^2)$. Substitute (3.7) into the rate equation in (1.1); then it follows that

$$\begin{aligned} &z_{tt} + (\lambda_1 + \lambda_2) z_{xt} + \lambda_1 \lambda_2 z_{xx} - h_v(z_t + \mu z_x) \qquad (3.8) \\ &\quad = f_v^{-1}\left(f_{vt} + g_v f_{vx} - g_{vx}\right)(z_t + f_u z_x) + Q_0(f)(f_v^{-1} g_v f_{vx} - g_{vx} + h_v) \\ &\qquad - f_v Q_0(h) - Q_0(f)_t - g_v Q_0(f)_x + f_v Q_0(g)_x \qquad (3.9) \\ &\quad := (\text{RHS})_{3.8} \\ &\quad =: f_v^{-1}\left(f_{vt} + g_v f_{vx} - g_{vx}\right)(z_t + f_u z_x) + (\text{RHS})'_{(3.8)}. \end{aligned}$$

Without loss of generality, we may assume that

$$h_v(\hat{u}, v_*(\hat{u})) = -2 \tag{3.10}$$

by rescaling the coordinates (x,t). This condition is given simply for convenience of calculation.

3.2. Step I: The telegraph equation. Before we carry out the calculation for the nonlinear equation (1.1), we introduce the linear telegraph equation in order to arrange the nonlinear terms in (1.1). By assuming for the moment that in equation (3.8), λ_1, λ_2, and μ are all constant and the RHS is identically zero, we have

$$\begin{cases} \xi_{tt} + (c_1 + c_2)\xi_{xt} + c_1 c_2 \xi_{xx} + 2(\xi_t + \sigma \xi_x) = 0 \quad \text{for } x, t > 0, \\ c_1 < 0 < \sigma < c_2, \end{cases} \tag{3.11}$$

Integrate $(3.11)\xi + (3.11)\xi_t + (3.11)((c_1 + c_2)/2)\xi_x$ over $0 < x < \infty$, $0 < \tau < t$. We obtain that

(3.12)

$$\begin{aligned} &\int_0^\infty \left(-\frac{c_1 c_2}{2}\xi_x^2 + \frac{(\xi_t + (c_1 + c_2)\xi_x)^2}{4} + \frac{(\xi_t + 2\xi)^2}{4}\right)(x,t)dx - \frac{(c_1 + c_2)}{2}\xi^2(0,t) \\ &\qquad + \int_0^t \left(-\sigma \xi^2 - c_1 c_2 \xi_x \xi - \frac{(c_1 + c_2)}{4} c_1 c_2 \xi_x \xi_t - \frac{(c_1 + c_2)}{2}\xi_t^2\right)(0,t)d\tau \\ &\qquad + \int_0^\tau \int_0^\infty \xi_t^2 + 2\sigma \xi_x \xi_t + (\sigma(c_1 + c_2) - c_1 c_2)\xi_x^2 dx d\tau \\ &= \int_0^\infty \left(-\frac{c_1 c_2}{2}\xi_x^2 + \frac{(\xi_t + (c_1 + c_2)\xi_x)^2}{4} + \frac{(\xi_t + 2\xi)^2}{4}\right)(x,0)dx - \frac{c_1 + c_2}{2}\xi^2(0,0). \end{aligned}$$

The integrand in the double integral in (3.12) is positive due to the subcharacteristic condition. Except for the integral on the boundary ($x = 0$), all of the integrals in

(3.12) are positive. The defect of this model is that there is no lower derivative in the double integral of (3.12), which prevents us from using energy estimates. However, this defect can be resolved by adding the following two conditions due to the nonlinearity of (1.1):

$$\text{for some constant } K_4,$$

$$0 < K_4(|\phi'| + |\psi'|) < -\mu(\phi,\psi)_x, \tag{3.13}$$

$$|\mu(\phi,\psi) - \sigma| \ll 1. \tag{3.14}$$

The reasoning behind these conditions can be found in Liu [9].

3.3. Step II: Preliminaries for the energy estimate. In the following, we assume (2.12) for $t = t_n$ a priori.

Integrate (3.8)z over $0 < \tau < t_n$ and $0 < x < \infty$.

$$\begin{aligned}
&\int_0^\infty \left(z_t z + (\lambda_1+\lambda_2)z_x z - \frac{h_v}{2}z^2\right)(x,t_n)dx + \int_0^t \left(-\lambda_1\lambda_2 z z_x - h_v\mu z^2\right)(0,\tau)d\tau \\
&+ \int_0^t\int_0^\infty -z_t^2 - \underbrace{((\lambda_1+\lambda_2)z)_t\, z_x}_{B_1} \underbrace{-(\lambda_1\lambda_2 z_x)z_x}_{B_2} dxd\tau + \int_0^t\int_0^\infty (h_{vt} + h_{vx}\mu)z^2 + h_v\mu_x z^2 dxd\tau \\
&\quad = \underbrace{\int_0^t\int_0^\infty f_v^{-1}\left(f_{vt} + g_v f_{vx} - g_{vx}\right)(z_t + f_u z_x)z dxd\tau}_{B_3} \\
&\qquad + \int_0^t\int_0^\infty (\text{RHS})'_{(3.8)} z dxd\tau + \int_0^\infty \left(z_t z + (\lambda_1+\lambda_2)z_x z - \frac{h_v z^2}{2}\right)(x,0)dx.
\end{aligned} \tag{3.15}$$

First, we evaluate B_3 as follows:

If δ_2 is sufficiently small, then from (3.13) and (3.14), we have

$$(h_{vt} + h_{vx}\mu)z^2 + h_v u_x z^2 \;= (h_{vv}\phi_x + h_{vu}\psi_x)(\mu - \sigma) + h_v\mu_x z^2 > \frac{1}{2}|h_v\mu_x|z^2. \tag{3.16}$$

Next, we evaluate B_1 by the following inequality. Since the magnitude of the shock is sufficiently small (i.e., $|u_- - u_+| \ll 1$), we have

$$|\phi'| + |\psi'| \gg |\phi''| + |\psi''|. \tag{3.17}$$

Hence

$$\begin{aligned}
B_1 &= \int_0^t\int_0^\infty ((\lambda_1+\lambda_2)z)_t z_x dxd\tau \\
&= \int_0^t\int_0^\infty (\lambda_1+\lambda_2)_t z z_x + (\lambda_1+\lambda_2)z_t z_x dxd\tau \\
&= O(1)(\|\phi'\|_\infty + \|\psi'\|_\infty)\int_0^t z^2(0,\tau)d\tau \\
&\qquad + \int_0^t\int_0^\infty (\lambda_1+\lambda_2)z_t z_x dxdz + o(1)\int_0^t\int_0^\infty (|\phi'| + |\psi'|)z^2 dxd\tau.
\end{aligned} \tag{3.18}$$

Similarly to (3.18), we have

$$\begin{aligned} B_2 &= \int_0^t \int_0^\infty -(\lambda_1\lambda_2 z)_x z_x dx d\tau \\ &= o(1)\int_0^t \int_0^\infty (|\phi'|+|\psi'|)z^2 dx d\tau \\ &\qquad + O(1)(\|\phi'\|_\infty + \|\psi'\|_\infty)\int_0^t z^2(0,\tau)d\tau - \int_0^t \int_0^\infty (\lambda_1\lambda_2)z_x^2 dx d\tau. \end{aligned} \tag{3.19}$$

Also, we have

$$\begin{aligned} B_3 &= \int_0^t \int_0^\infty f_v^{-1}\left(f_{vt}+g_v f_{vx} - g_{vx}\right)(z_t + f_u z_x) z dx d\tau \\ &= O(1)(\|\phi'\|_\infty + \|\psi'\|_\infty)\left(\int_0^\infty z^2(x,t)+z^2(x,0)dx + \int_0^t z^2(0,\tau)d\tau\right) \\ &\qquad + o(1)\int_0^\tau \int_0^\infty (|\phi'|+|\psi'|)z^2(x,\tau)dx d\tau. \end{aligned} \tag{3.20}$$

Using (3.16)–(3.20), we have that

$$\begin{aligned} &\int_0^\infty \left(z_t z + (\lambda_1+\lambda_2)z z_x - \frac{h_v}{2}z^2\right)(x,t)dx \\ &\quad + \int_0^t \int_0^\infty -z_t^2 - (\lambda_1+\lambda_2)z_t z_x - \lambda_1\lambda_2 z_x^2 + \frac{1}{2}|h_v\mu_x|z^2 dx d\tau \\ &\quad + \int_0^t (-\lambda_1\lambda_2 z z_x - h_v\mu z^2)(0,\tau)d\tau + \left(\frac{c_1+c_2}{2} - O(1)\delta_0\right)z^2(0,t) \\ &= \int_0^\infty \left(z_t z + (\lambda_1+\lambda_2)z_x z - \frac{h_v}{2}z^2\right)(x,0)dx \\ &\quad + O(1)\delta_2\bigg(\int_0^t \int_0^\infty (z_t^2 + z_x^2 + z_{tt}^2 + z_{xx}^2 + z_{xt}^2)dx d\tau \\ &\quad + \int_0^t z^2(0,\tau)d\tau + \int_0^t z^2(x,t)+z^2(x,0)dx\bigg) \\ &\quad + O(1)(\|\phi'\|_\infty + \|\psi'\|_\infty)\int_0^\infty z^2(0,\tau)d\tau. \end{aligned} \tag{3.21}$$

The double integrals on the RHS of (3.21) come from the nonlinear terms in $(\text{RHS})_{(3.8)}$. Note that the double integral in (3.21) has zero-order derivatives. Next, we use condition (3.10) and integrate $(3.8)z + (3.8)z_t + (3.8)((c_1+c_2)/2)z_x$ over the intervals $0 < x < \infty$ and $0 < \tau < t$. By the same method as used to derive (3.21), we have that

$$\begin{aligned} &(1-O(1)\delta_2)\bigg(\int_0^\infty \left(-\frac{\lambda_1\lambda_2}{2}z_x^2 + \frac{(z_t+(\lambda_1+\lambda_2)z_x)^2}{2} + \frac{(z_x+2z)^2}{2}\right)(x,t)dx \\ &\quad + \int_0^t \int_0^\infty \left(z_t^2 + 2\sigma z_x z_t + (\mu(\lambda_1+\lambda_2)-\lambda_1\lambda_2)z_x^2 + \frac{h_v\mu_x}{2}z^2\right)dx d\tau\bigg) \\ &\quad - (1+O(1)\delta_2)\frac{c_1+c_2}{2}z^2(0,t) + (1-O(1)\delta_2)\frac{c_1+c_2}{2}z^2(0,0) \end{aligned} \tag{3.22}$$

$$
\begin{aligned}
&+\int_0^t \left(\sigma(1+O(1)\delta_2)z^2-\lambda_1\lambda_2 z_x z\right)_{|x=0} d\tau\\
&+\int_0^t -\left(\frac{\lambda_1+\lambda_2}{2}z_x^2-\lambda_1\lambda_2 z_x z_t\left(-\frac{c_1+c_2}{2}-O(1)\delta_2\right)z_t^2\right)_{|x=0} d\tau\\
=&\,(1+O(1)\delta_2)\int_0^\infty \left(-\frac{\lambda_1\lambda_2}{2}z_x^2+\frac{(z_t+(\lambda_1+\lambda_2)z_x)^2}{2}+\frac{(z_x+2z)^2}{2}\right)(x,0)dx\\
&+O(1)\delta_2\int_0^t\int_0^\infty z_t^2+z_x^2+z_{xx}^2+z_{xt}^2+z_{tt}^2 dxd\tau.
\end{aligned}
$$

We denote

$$x_1 := x, \qquad x_2 := t.$$

Integrate $(3.22)_i$ and $(3.22)_{ij}$ below (for $i, j = 1, 2$) over $[0, \infty) \times [0, t_n]$. We have

(3.23)

$$\int_0^t\int_0^\infty (3.8)_{x_i} z_{x_i} + (3.8)_{x_i} z_{x_i x_2} + (3.8)_{x_i} z_{x_i x_1}\frac{(c_1+c_2)}{2} dxd\tau, \tag{$(3.23)_i$}$$

$$\int_0^t\int_0^\infty (3.8)_{x_i x_j} z_{x_i x_j} + (3.8)_{x_i x_j} z_{x_i x_j x_2} + (3.8)_{x_i x_j} z_{x_i x_j x_1}\frac{(c_1+c_2)}{2} dxd\tau. \tag{$(3.23)_{ij}$}$$

For the nonlinear terms on the RHS of $(3.23)_{ij}$, there are some integrals whose integrands have some terms of the fourth derivatives as follows:

$$\int_0^t\int_0^\infty W(z_{x_1}, z_{x_2}) z_{x_i x_j x_k x_l} z_{x_i x_j x_m} dxd\tau \qquad \text{for } i, j, m, l = 0,\ 1, \tag{3.24}$$

where $\lim_{(x^2+y^2)\to 0} W(x, y)/(x^2 + y^2)^{1/2}$ exists. If $m \in \{k, l\}$, then let $m = k$. Hence

$$
\begin{aligned}
&\int_0^t\int_0^\infty W(z_{x_1}, z_{x_2}) z_{x_i x_j x_k x_l} z_{x_i x_j x_k} dxd\tau\\
&\qquad = \frac{1}{2}\int_0^t\int_0^\infty W(z_{x_1}, z_{x_2})\partial_{x_l} z^2_{x_i x_j x_k} dxd\tau = (\mathrm{RHS})_{(3.25)}.
\end{aligned} \tag{3.25}
$$

By using integration by parts and the condition $|z_{x_p}| + |z_{x_i x_j}| \le N(t) + |u_- - u_+|$ for $p = 1, 2$,

$$
\begin{aligned}
(\mathrm{RHS})_{(3.25)} = O(1)\delta_2 \Bigg(&\int_0^t\int_0^\infty \left(z^2_{x_i x_j x_1} + z^2_{x_i x_j x_2}\right) dxd\tau + \int_0^t z^2_{x_i x_j x_k}(0, \tau)d\tau\\
&+\int_0^\infty z^2_{x_i x_j x_k}(x, t)dx + \int_0^\infty z^2_{x_i x_j x_k}(x, 0)dx\Bigg).
\end{aligned}
$$

If $m \ne k, l$, then we may assume that $m = 1$ and $k = l = 2$.

(3.26)

$$\begin{aligned}
&\int_0^t\int_0^\infty W(z_{x_1},z_{x_2})z_{x_ix_jx_2x_2}z_{x_ix_jx_1}dxd\tau\\
&=\int_0^t\int_0^\infty \big(\partial_{x_2}(W(z_{x_1},z_{x_2})z_{x_ix_jx_1}z_{x_ix_jx_2})-(\partial_{x_2}W(z_{x_1},z_{x_2}))z_{x_ix_jx_1}z_{x_ix_jx_2}\big)\,dxd\tau\\
&\qquad\qquad\qquad\qquad-\int_0^t\int_0^\infty W(z_{x_1},z_{x_2})z_{x_ix_jx_2x_1}z_{x_ix_jx_2}dxd\tau\\
&=(\mathrm{RHS})_{(3.26)}.
\end{aligned}$$

The last term on the RHS of (3.26) is handled similarly to (3.25). Consequently, the order of the other terms remaining on the RHS of (3.26) is at most three.

$(3.23)_{ij}$ can be rewritten as follows using (3.25) and (3.26):

$(3.23)'_{ij}$

$$\begin{aligned}
&(1-O(1)\delta_2)\bigg(\int_0^\infty -\frac{\lambda_1\lambda_2}{2}z^2_{x_ix_jx_1}+\frac{(z_{x_ix_jx_2}+(\lambda_1+\lambda_2)z_{x_ix_jx_1})^2}{2}(x,t)dx\\
&\qquad\qquad+\int_0^\infty\frac{(z_{x_ix_jx_1}+2z_{x_ix_j})^2}{2}(x,t)dx\\
&+\int_0^t\int_0^\infty z^2_{x_ix_jx_2}+2\sigma z_{x_ix_jx_1}z_{x_ix_jx_2}+(\mu(\lambda_1+\lambda_2)-\lambda_1\lambda_2)z^2_{x_ix_jx_1}+\frac{h_v\mu_x}{2}z^2_{x_ix_j}dxd\tau\bigg)\\
&\qquad-(1+O(1)\delta_2)\frac{c_1+c_2}{2}z^2_{x_ix_j}(0,t)-(1-O(1)\delta_2)\frac{c_1+c_2}{2}z^2_{x_ix_j}(0,0)\\
&\qquad+\int_0^t\Big(\sigma(1+O(1)\delta_2)z^2_{x_ix_j}-\lambda_1\lambda_2z_{x_ix_jx_1}z_{x_ix_j}\Big)(0,t)d\tau\\
&+\underbrace{\int_0^t-\bigg(\frac{\lambda_1+\lambda_2}{2}z^2_{x_ix_jx_1}-\lambda_1\lambda_2z_{x_ix_jx_1}z_{x_ix_jx_2}+\Big(-\frac{c_1+c_2}{2}-O(1)\delta_2\Big)z^2_{x_ix_jx_2}\bigg)(0,t)d\tau}_{I_{ij}}\\
&\qquad=(1+O(1)\delta_2)\int_0^\infty\bigg(-\frac{\lambda_1\lambda_2}{2}z^2_{x_ix_jx_1}+\frac{(z_{x_ix_jx_2}+(\lambda_1+\lambda_2)z_{x_ix_jx_1})^2}{2}\\
&\qquad\qquad+\frac{(z_{x_ix_jx_1}+2z_{x_ix_j})^2}{2}\bigg)(x,0)dx\\
&\qquad+O(1)\delta_2\int_0^t\int_0^\infty\sum_{i=1}^2z^2_{x_i}+\sum_{1\le i,j\le 2}z^2_{x_ix_j}+\sum_{1\le i,j,k\le 2}z^2_{x_ix_jx_k}dxd\tau.
\end{aligned}$$

In what follows, we look for suitable positive linear combinations of (3.22), $(3.23)_i$, and $(3.23)_{ij}$ to treat the integrals on the boundary $x=0$.

3.4. Step III: The estimate of the boundary integral at $x=0$. In (3.4) and (3.5), we have already estimated the lower derivative terms, i.e., those of order zero and one on the boundary $x=0$. From (3.8) and $z_x(0,t)=u_--\phi(-\sigma t-s_n)$, we have that

$$z_{tt}(0,t)=-(1+O(1)\delta_2)\lambda_1\lambda_2z_{xx}(0,t)+O(1)|\phi'(-\sigma t-s_n)|. \tag{3.27}$$

From (3.27), all of the second derivatives on the boundary $(x=0)$ can be expressed in terms of the linear combination of $z_{tt}(0,t)$ and the lower derivatives that have been estimated in (3.4) and (3.5). Similarly, for the third derivatives at the boundary $x = 0$, we have

$$z_{xtt}(0,t) = -\sigma^2 \phi''(-\sigma t - s_n). \tag{3.28}$$

From (3.28), $(3.8)_t$, and $(3.8)_x$, we have the following:

(3.29)

$$\begin{aligned} z_{ttt}(0,t) &= -(1 + O(1)\delta_2)(\lambda_1\lambda_2 z_{xxt}(0,t) + 2z_{tt}(0,t)) + O(1)\delta_2|z_t(0,t)|, \\ (\lambda_1+\lambda_2)z_{xt}(0,t) &= -(1+O(1)\delta_2)(\lambda_1\lambda_2 z_{xxx}(0,t) - 2\sigma z_{xx}(0,t)) + O(1)\delta_2|z_t(0,t)|. \end{aligned}$$

From (3.27) and (3.29), we can express the third derivatives $z_{x_i x_j x_k}(0,t)$ in terms of $z_{ttt}(0,t)$, $z_{tt}(0,t)$, and the other terms whose rates of convergence are known.

In $(3.23)'_{12}$, look at the integral that contains the third derivatives at the boundary $x = 0$ except for the quadratic term z_{xtt}:

(3.30)

$$\begin{aligned} &\int_0^t -\lambda_1\lambda_2 z_{xtt}(0,\tau) z_{xxt}(0,\tau) - \frac{\lambda_1+\lambda_2}{4}\lambda_1\lambda_2 z_{xxt}^2(0,\tau)d\tau \quad \left[\text{let } \epsilon(t) = \frac{\lambda_1+\lambda_2}{8} > 0\right] \\ &\quad \geq \int_0^t \frac{\lambda_1\lambda_2}{\epsilon(t)} z_{xtt}^2(0,\tau) + \epsilon(t)\lambda_1\lambda_2 z_{xxt}^2(0,\tau) - \frac{\lambda_1+\lambda_2}{4}\lambda_1\lambda_2 z_{xxt}^2(0,\tau)d\tau \\ &\quad \geq \int_0^t \frac{\lambda_1\lambda_2}{\epsilon(t)} z_{xtt}^2(0,\tau) - \frac{\lambda_1+\lambda_2}{8}\lambda_1\lambda_2 z_{xxt}^2(0,\tau)d\tau \quad [\text{from (3.28)}] \\ &\quad = O(1)\int_0^t z_t^2(0,\tau)d\tau - (1+O(1)\delta_2)\frac{c_1+c_2}{8(c_1+c_2)}\int_0^t \left(\frac{1}{2}z_{ttt}^2 - \frac{9}{c_1^2c_2^2}z_{tt}^2\right)d\tau. \end{aligned}$$

Conclusion. Using the inequalities in (3.30), we can find constants $D_{ij} > 0$ such that

$$|I_{ij}(t)| \leq D_{ij}\int_0^t \sum_{i=0}^3 (z_t)^2(0,\tau)d\tau, \tag{3.31}$$

where $I_{ij}(t)$ is the integral defined at the boundary $x = 0$ in $(3.23)'_{ij}$.

In order to evaluate the integral $\int_0^t z_t t^2(0,\tau)d\tau$, we need the following lemma.

Lemma 3.1. *The following inequality holds for an arbitrary positive constant C and an arbitrary function $q(t) \in C^3[0,\infty)$:*

$$\begin{aligned} &\sqrt{C}\int_0^t q_{tt}^2(0,\tau)d\tau + C^{1/4}q_{tt}^2(0,t) - 12(C^{3/4}+C^{1/4})\left(q_t^2(0,t) + q_{tt}^2(0,0) + q_{tt}^2(0,0)\right) \\ &\quad \leq C\int_0^t q_t^2(\tau)d\tau + 10\int_0^t q_{ttt}^2(\tau)d\tau. \end{aligned}$$

Proof. By using the Schwartz inequality and integration by parts,

(3.32)

$$\begin{aligned} &\int_0^t Cq_t^2 + q_{ttt}^2 d\tau \\ &\quad > \left|\int_0^t 2\sqrt{C}q_t q_{ttt}d\tau\right| \end{aligned}$$

$$
\begin{aligned}
&= \left| 2\sqrt{C}\int_0^t \partial_t(q_{tt}q_t)d\tau - 2\sqrt{C}\int_0^t q_{tt}^2 d\tau \right| \\
&\geq 2\sqrt{C}\left(\int_0^t q_{tt}^2 d\tau - |q_t q_{tt}(t)| - |q_t q_{tt}(0)| \right) \\
&\geq 2\sqrt{C}\left(\int_0^t q_{tt}^2 d\tau - (C^{1/4}q_t^2(t) + C^{-1/4}q_{tt}^2(t)) - \Big(C^{1/4}q_t^2(0) + C^{-1/4}q_{tt}^2(0) \Big) \right).
\end{aligned}
$$

On the other hand,

$$
\begin{aligned}
(3.33) \qquad \int_0^t \sqrt{C}q_{tt}^2 + 9q_{ttt}^2 d\tau &> 6C^{1/4}\left| \int_0^t q_{tt}q_{ttt}d\tau \right| \\
&> 3C^{1/4}\left(q_{tt}^2(t) - q_{tt}^2(0) \right).
\end{aligned}
$$

The proof follows from (3.32) and (3.33).

From Lemma 3.1, we estimate the integral $\int_0^t z_{tt}(0,\tau)d\tau$ by $\int_0^t z_t^2(0,\tau)d\tau$ and $\int_0^t z_{ttt}^2(0,\tau)d\tau$. Namely, Lemma 3.1 allows us to bound $\int_0^t z_{tt}(0,\tau)d\tau$ by a positive linear combination of $\int_0^t z_t(0,\tau)d\tau$ and $\int_0^t z_{ttt}(0,\tau)d\tau$. Keeping the above calculation in mind, we complete the proof of Lemma 1.2. At first, we show that all the boundary terms can be treated precisely. To this end, we take the positive constant F_0 such that

$$
(3.34) \qquad -\frac{c_1+c_2}{8c_1c_2}F_0 > 2\sum_{1\leq i,j\leq 2} D_{ij}.
$$

Then from (3.34), (3.31), and (3.30), we have that

$$
\begin{aligned}
(3.35) \qquad &\sum_{(i,j)\neq(1,2),(2,1)} I_{ij}(t) + 2F_0 I_{12}(t) \\
&\qquad \geq -\frac{c_1+c_2}{16c_1c_2}\int_0^t z_{ttt}(0,\tau)d\tau - \sum_{(i,j)\neq(1,2),(2,1)} D_{ij}\sum_{i=0}^{2}\int_0^t (\partial_t^i z)^2(0,\tau)d\tau.
\end{aligned}
$$

From the positive linear combination in (3.35), we evaluate the integrals of the third derivatives at the boundary $x=0$. Actually, from Lemma 3.1, the integrals of the second derivatives at $x=0$ can be bounded by the third and first derivatives at the boundary. Hence for a large constant C,

$$
\begin{aligned}
(3.36) \qquad &C\int_0^t z_t^2(0,\tau)d\tau + \sum_{(i,j)\neq(1,2),(2,1)} I_{ij}(t) + 2F_0 I_{12}(t) \\
&\qquad \geq -O(1)C\int_0^t z^2(0,\tau)d\tau + \sqrt{\frac{C}{10}}\int_0^t z_{tt}^2(0,\tau)d\tau.
\end{aligned}
$$

Thus we finish the evaluation of the boundary integrals. Next, we complete the energy estimate for the following equation over the interval $(0,t]\times[0,\infty)$:

$$
(3.37) \qquad \sum_{(i,j)\neq(1,2),(2,1)} (3.23)'_{ij}z_{x_ix_j} + (3.23)'_{ij}z_{x_ix_jx_2} + \frac{c_1+c_2}{2}(3.23)'_{ij}z_{x_ix_jx_1}
$$

$$
\begin{aligned}
&+2F_0(3.23)'_{12}z_{x_1x_2}+2F_0(3.23)'_{12}z_{x_1x_2x_2}+2F_0\frac{c_1+c_2}{2}(3.23)'_{12}z_{x_1x_2x_1}\\
&+\sum_{1\le i\le 2}(3.23)_i z_{x_i}+(3.23)_i z_{x_ix_2}+\frac{c_1+c_2}{2}(3.23)_i z_{x_ix_1}\\
&+(3.23)z+(3.23)z_{x_2}+\frac{c_1+c_2}{2}(3.23)z_{x_1}.
\end{aligned}
$$

Hence by $(3.23)'_{ij}$, we have

$$
\begin{aligned}
&\int_0^\infty\left(\sum_{1\le i,j\le 2}z^2_{x_ix_j}+\sum_{1\le i\le 2}z_i^2+z^2\right)(x,t)dx+\int_0^t\int_0^\infty\sum_{i=1}^3|\nabla^i_{(x,t)}z|^2dxd\tau\\
&\quad\le O(1)\int_0^\infty\left(\sum_{1\le i,j\le 2}z^2_{x_ix_j}+\sum_{1\le i\le 2}z_i^2+z^2\right)(x,0)dx+O(1)C\int_0^t(z^2+z_t^2)(0,\tau)d\tau\\
&\quad=:(\mathrm{RHS})_{(3.38)}.
\end{aligned}
\tag{3.38}
$$

From (3.3), we have that

$$
\begin{cases}
|z(x,0)|=|(x_0-s_n)\phi'|+O(1)\delta_1|\phi(x-x_0)-u_+|/|u_--u_+| & \text{for } x>x_0,\\
|z(x,0)|=|(x_0-s_n)\phi'|+O(1)\delta_1x_0 & \text{for } 0<x<x_0.
\end{cases}
\tag{3.39}
$$

From (2.21), (3.4), and (3.5), if we choose δ_1, $e^{-|u_--u_+|x_0}$, and δ_1x_0 sufficiently small for fixed $\delta_2\ll 1$ and $|u_--u_+|\le\delta_2$, then by substituting (3.39) in (3.38), we get the a priori estimate

$$
N(t_n)+|u_--u_+|\le\frac{\delta_2}{2}.
\tag{3.40}
$$

At last, we have shown that (3.2) holds for n. This completes the proof of Lemma 1.2.

3.5. The convergence theorem (Theorem 1.4). Since we have the global existence theorem (Theorem 1.3) and (3.2) for all $n\in\mathbf{N}$, Theorem 1.4 is valid for $t=\infty$. This asserts the validity of asymptotic shock location $s_\infty+\sigma t$. Actually, replacing x_0 by s_m in (2.20), we have

$$
|s_n-s_m|\le\frac{K_4|\phi(-x_0-\sigma t_n)-\phi(-x_0-\sigma t_m)|}{|u_--u_+|^3}
$$

for some constant K_4. Hence $\{s_n\}_{n\in\mathbf{N}}$ is a Cauchy sequence, and thus $s_\infty=\lim_{n\to\infty}s_n$ exists. From the definition of $\{s_n\}_{n\in\mathbf{N}}$, we have that

$$
\lim_{t\to\infty}\int_0^\infty(u(x,0)-\phi(x-\sigma t-s_\infty))\,dx=0.
$$

Let $z_\infty(x,t):=-\int_x^\infty u(x,t)-\phi(x-\sigma t-s_\infty)dx$ and $w_\infty(x,t):=v(x,t)-\psi(x-\sigma t-s_\infty)$. From assumption (1.8) of the initial value, we obtain

$$
\int_0^\infty\sum_{j=1}^3|\partial_x^jz_\infty|^2(x,0)dx+\int_0^\infty\sum_{j=0}^2|\partial_x^jw_\infty|^2(x,0)dx
$$

arbitrarily small when we choose δ_1 and x_0 to have $\exp(-x_0|u_- - u_+|)$, where $\delta_1 x_0$ and δ_1 are sufficiently small. By the same method as used to show global existence, we have the following energy estimate:

$$\int_0^\infty \int_0^\infty \sum_{j=1}^{3} \left(|\partial_x^j z_\infty|^2 + |\partial_t^j z_\infty|^2\right)(x,\tau)dxd\tau + \int_0^\infty z_\infty^2(x,t)dx < C, \tag{3.41}$$

where C is a constant independent of t. By making use of (3.41), it follows that the solution converges to the asymptotic traveling wave $(\phi(x-\sigma t - s_\infty), \psi(x - \sigma t - s_\infty))$.

Acknowledgment. The authors would like to express their gratitude to their thesis advisor, Professor Tai-Ping Liu, for generously sharing his ideas.

A NONLINEAR GRATING PROBLEM IN DIFFRACTIVE OPTICS[*]

GANG BAO[†] AND YUNMEI CHEN[†]

Abstract. In this paper, the existence and regularity of solutions of a system of Maxwell equations in periodic structures are established. The diffraction (scattering) problem is reformulated in a bounded domain by introducing the transparent boundary conditions. An indirect approach is then used to carry out the regularity analysis. This problem arises in the modeling of the surface-enhanced second harmonic generation of nonlinear optics.

Key words. existence and regularity of solutions, Maxwell equations, second harmonic generation, nonlinear grating

1. Introduction. Consider a plane wave of frequency ω_1 incident on a grating or periodic structure ruled on some nonlinear optical material. Because of the presence of the nonlinear material, the nonlinear optical interaction gives rise to diffracted waves of frequencies ω_1 and $\omega_2 = 2\omega_1$. This process represents the simplest situation in nonlinear optics—second harmonic generation (SHG). In this paper, we study questions on the existence and regularity of solutions of the PDE that governs SHG. As a first step, we use the well-known undepleted-pump approximation, which allows us to reduce the model to a system of generalized Helmholtz equations. We are seeking a "quasi-periodic" solution at frequency ω_1 or ω_2 which satisfies the "radiation condition at infinity"; this means that near $x_2 = \pm\infty$, the solution is a linear combination of plane waves propagating away from the structure.

This work is motivated by the recent research on surface-enhanced nonlinear optical effects. One of the many important applications of nonlinear optical phenomena is a method for obtaining coherent radiation at a wavelength shorter than that of available lasers through SHG. Unfortunately, nonlinear optical effects are generally so weak that their observation requires extremely high-intensity laser beams. Recently, in the sequence of papers [13], [14], [12], a PDE model was introduced to model nonlinear SHG in periodic structures. In particular, it was shown in [13] and [14] that SHG can be greatly enhanced by using diffraction gratings or periodic structures and that the PDE model can accurately predict the field propagation. Our goal is to examine the well-posedness of the PDE model by using our variational formulation.

Our main well-posedness result is as follows: there exists a unique quasi-periodic solution of frequencies ω_1 and $\omega_2 = 2\omega_1$ of the nonlinear diffraction problem with the radiation condition for all but possibly a discrete set of parameters. The proof of this result follows in principle an earlier work of DiBenedetto, Elliott, and Friedman [6]. However, because of weaker regularity assumptions on the coefficients in our model PDE, essential modifications must be made.

Results on existence and uniqueness for Maxwell equations in linear media with

periodic structures were obtained by Chen and Friedman [5] assuming that the dielectric coefficient ϵ is a piecewise-constant function. They showed that for all but possibly a discrete number of ϵ's, there exists a unique solution to the Maxwell equations by an integral-equation approach. Little is known concerning the questions of existence and uniqueness for nonlinear Maxwell equations in periodic structures. In two simple cases where the Maxwell equations can be reduced to a system of nonlinear Helmholtz equations, existence and uniqueness results have recently been obtained in [2] and [3]. Computational results have also been obtained by using a combination of the method of finite elements and the fixed-point iteration algorithm. In this work, using a different approach, we study the well-posedness of a more complicated but linear PDE model. Its main advantage over previous results is that the current model supports a larger class of nonlinear optical materials with cubic symmetry structures. An interesting future project is to tackle the nonlinear model directly.

A good background on the linear theory of diffractive optics in grating structures may be found in Petit [11]. A brief description of the present problem along with a discussion of some other mathematical problems arising from industrial applications of diffractive optics can be found in Friedman [7, Chapter 5]. For the underlying physics of nonlinear optics, we refer the reader to the classic books of Bloembergen [4] and Shen [15].

The outline of this paper is as follows. The governing system of Maxwell equations is introduced in section 2, and it is reformulated inside a periodic "box" with boundary conditions derived from our knowledge of the fundamental solutions in linear media. We then proceed in section 3 to study the corresponding PDEs of frequencies ω_1 and $\omega_2 = 2\omega_1$ by a variational approach. The existence and regularity of solutions of the diffraction problem are established.

2. Modeling of the scattering problem. Throughout, the media are assumed to be nonmagnetic with constant magnetic permeability. For convenience, the magnetic permeability constant is assumed to be equal to unity everywhere. We also assume that no external charge or current is present in the field.

The time-harmonic Maxwell equations that govern SHG then take the form

$$\nabla \times \mathbf{E} = -\frac{i\omega}{c}\mathbf{H}, \qquad \nabla \cdot \mathbf{H} = 0, \tag{2.1}$$

$$\nabla \times \mathbf{H} = \frac{i\omega}{c}\mathbf{D}, \qquad \nabla \cdot \mathbf{D} = 0, \tag{2.2}$$

along with the constitutive equation

$$\mathbf{D} = \epsilon\mathbf{E} + 4\pi\chi^{(2)}(x,\omega) : \mathbf{E}\mathbf{E}, \tag{2.3}$$

where $\mathbf{E}$ is the electric field, $\mathbf{H}$ is the magnetic field, $\mathbf{D}$ is electric displacement, ϵ is the dielectric coefficient, c is the speed of light, ω is the angular frequency, and $\chi^{(2)}$ is the second-order nonlinear susceptibility tensor of third rank, i.e., $\chi^{(2)} : \mathbf{E}\mathbf{E}$ is a vector whose jth component is $\sum_{k,l=1}^{3} \chi^{(2)}_{jkl}\mathbf{E}_k\mathbf{E}_l$.

Remarks. The medium is said to be linear if $\mathbf{D} = \epsilon\mathbf{E}$ or $\chi^{(2)}$ vanishes. In principle, all optical media are essentially nonlinear, i.e., $\mathbf{D}$ is a nonlinear function of $\mathbf{E}$.

The physics of SHG may be described as follows: when a plane wave at frequency $\omega = \omega_1$ is incident on a nonlinear medium, because of the interaction of the incident wave and nonlinear medium, diffracted waves of frequencies $\omega = \omega_1$ and $\omega = 2\omega_1$ are generated. The fact that new frequency components are present is the most striking difference between nonlinear and linear optics. However, for most media, nonlinear optical effects are so weak that they may reasonably be ignored. In particular, the conversion of energy into the new frequency component is very small. The observation of nonlinear phenomena in the optical region can normally only be made by using high-intensity beams, say by application of a high-intensity laser.

We assume that the depletion of energy from the pump waves (at frequency $\omega = \omega_1$) may be neglected, which is the well-known undepleted-pump approximation in the literature; see [13] and [14]. Under the approximation, equation (2.3) at frequencies $\omega = \omega_1$ and $\omega = \omega_2 = 2\omega_1$, respectively, may be written as

$$\mathbf{D}(x,\omega_1) = \epsilon(x,\omega_1)\mathbf{E}(x,\omega_1), \tag{2.4}$$

$$\mathbf{D}(x,\omega_2) = \epsilon(x,\omega_2)\mathbf{E}(x,\omega_2) + 4\pi\chi^{(2)}(x,\omega_2) : \mathbf{E}(x,\omega_1)\mathbf{E}(x,\omega_1). \tag{2.5}$$

Next, we want to further reduce the nonlinear coupled system (2.1)–(2.2). Throughout the paper, all of the fields are assumed to be invariant in the x_3 direction. Here, as in the linear case, in transverse electric (TE) polarization the electric field is transversal to the (x_1, x_2)-plane and in transverse magnetic (TM) polarization the magnetic field is transversal to the (x_1, x_2)-plane. In the nonlinear case, however, the polarization is determined by group symmetry properties of $\chi^{(2)}$. In this paper, motivated by applications, we assume that the electromagnetic fields are TM polarized at frequency ω_1 and TE polarized at frequency ω_2. This polarization assumption is known to support a large class of nonlinear optical materials, for example, crystals with cubic symmetry structures.

Therefore,

$$\mathbf{H}(x,\omega_1) = u(x_1,x_2,\omega_1)\vec{x_3}, \tag{2.6}$$

$$\mathbf{E}(x,\omega_2) = v(x_1,x_2,\omega_2)\vec{x_3}. \tag{2.7}$$

For convenience, we define

$$\epsilon_j = \epsilon(x_1,x_2,\omega_j), \quad j = 1,2, \tag{2.8}$$

$$k_j = \frac{\omega_j}{c}\sqrt{\epsilon_j}, \quad \mathrm{Im} k_j \geq 0. \tag{2.9}$$

At frequency ω_1, system (2.1)–(2.2) can be simplified to

$$\nabla \cdot \left(\frac{1}{k_1^2} \nabla u \right) + u = 0. \tag{2.10}$$

Because of equation (2.2),

$$\begin{aligned} \mathbf{E}(x,\omega_1) &= \frac{c}{i\omega_1\epsilon_1} \nabla \times \mathbf{H}(x,\omega_1) \\ &= \frac{c}{i\omega_1\epsilon_1}(\partial_{x_2}u, -\partial_{x_1}u, 0). \end{aligned}$$

Hence the second harmonic field satisfies

$$\left[\triangle + k_2^2\right] v = -\frac{4\pi\omega_2^2}{c^2} \sum_{j,l=1,2,3} \chi^{(2)}_{3jl}(x,\omega_2)(\mathbf{E}(x,\omega_1))_j(\mathbf{E}(x,\omega_1))_l \tag{2.11}$$

$$= \sum_{j,l=1,2} \chi_{jl}\partial_{x_j}u\,\partial_{x_l}u, \tag{2.12}$$

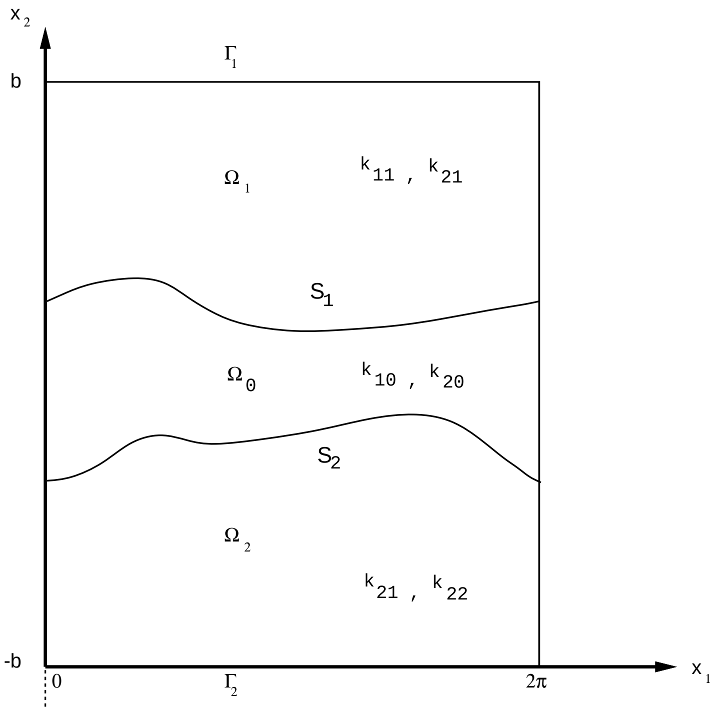

FIG. 1. *Problem geometry.*

where $\triangle$ is the usual Laplace operator and $\chi_{jl} = (-1)^{j+l}(16\pi/\epsilon_1^2)\chi^{(2)}_{3,j,l}(x,\omega_2)$.

Let us further specify the problem geometry. We assume that the medium and material are periodic in the x_1 variable of period 2π and are invariant in the x_3 variable. We may then restrict ourselves to one period in x_1, as shown in Figure 1.

We introduce the following notation:

$$\begin{aligned} \Gamma_j &= \{x_2 = (-1)^{j-1}b,\ 0 < x_1 < 2\pi\}, \qquad S_j = \{0 < x_1 < 2\pi,\ x_2 = \phi_j(x_1)\},\\ \Omega_1 &= \{0 < x_1 < 2\pi,\ \phi_1(x_1) < x_2 < b\}, \qquad \Omega_2 = \{0 < x_1 < 2\pi,\ -b < x_2 < \phi_2(x_1)\},\\ \Omega_1^+ &= \{0 < x_1 < 2\pi,\ x_2 \geq b\}, \qquad \Omega_2^+ = \{0 < x_1 < 2\pi,\ x_2 \leq -b\},\\ \Omega_0 &= \{0 < x_1 < 2\pi,\ \phi_2(x_1) < x_2 < \phi_1(x_1)\}, \qquad \Omega = \{0 < x_1 < 2\pi,\ -b < x_2 < b\}. \end{aligned}$$

Suppose that the whole space is filled with material in such a way that the “indexes of refraction” k_1 and k_2 satisfy

$$k_j(x) = \begin{cases} k_{j1} & \text{in } \Omega_1^+ \cup \bar{\Omega}_1,\\ k_{j0} & \text{in } \Omega_0,\\ k_{j2} & \text{in } \Omega_2^+ \cup \bar{\Omega}_2, \end{cases}$$

for $j = 1, 2$, where k_{j1} and k_{j2} are constants, k_{j1} are real and positive, and $\text{Re}k_{j2} > 0$ and $\text{Im}k_{j2} \geq 0$. The case $\text{Im}k_{j2} > 0$ accounts for materials which absorb energy.

Throughout, we make the following regularity assumptions on the material and geometry:

$$(2.13) \qquad k_{j0}(x) \in C^1(\Omega_0), \qquad \phi_j(x_1) \in C^{1,\gamma}(0, 2\pi) \quad \text{for some } 0 < \gamma < 1,$$

$$\chi_j \in L^\infty(\Omega) \quad \text{and} \quad \chi_j = 0 \quad \text{in } \Omega_1 \cup \Omega_2. \tag{2.14}$$

We wish to solve system (2.10)–(2.12) when an incoming plane wave

$$u_I = u_i e^{i\alpha_1 x_1 - i\beta_{11} x_2} \tag{2.15}$$

is incident on S_1 from Ω_1^+, where u_i is a real constant, $\alpha_1 = k_{11}\sin\theta$, $\beta_{11} = k_{11}\cos\theta$, and $-\pi/2 < \theta < \pi/2$ is the angle of incidence.

We are interested in "quasi-periodic" solutions (u, v), that is, solutions (u, v) such that

$$u_\alpha = u e^{-i\alpha_1 x_1} \quad \text{and} \quad v_\alpha = v e^{-i\alpha_2 x_1} \quad (\alpha_2 = k_{21}\sin\theta)$$

are 2π-periodic in the x_1 direction.

It follows from system (2.10)–(2.12) that

$$\nabla_{\alpha_1} \cdot \left(\frac{1}{k_1^2} \nabla_{\alpha_1} u_\alpha\right) + u_\alpha = 0, \tag{2.16}$$

$$\left[\triangle_{\alpha_2} + k_2^2\right] v_\alpha = \sum_{j,l=1,2} \chi_{jl}^\alpha \partial_{x_j}^{\alpha_1} u \, \partial_{x_l}^{\alpha_1} u, \tag{2.17}$$

where

$$\triangle_{\alpha_2} = \triangle + 2i\alpha_2 \partial_{x_1} - |\alpha_2|^2, \qquad \nabla_{\alpha_1} = \nabla + i(\alpha_1, 0),$$

and

$$\chi_{jl}^\alpha = \chi_{jl} e^{i(2\alpha_1 - \alpha_2)x_1}, \qquad \partial_{x_1}^{\alpha_1} = \partial_{x_1} + i\alpha_1, \qquad \partial_{x_2}^{\alpha_1} = \partial_{x_2}.$$

We next derive the transparent boundary conditions.

Expand u_α and v_α in a Fourier series:

$$u_\alpha(x_1, x_2) = \sum_{n \in Z} u_\alpha^n(x_2) e^{inx_1}, \tag{2.18}$$

$$v_\alpha(x_1, x_2) = \sum_{n \in Z} v_\alpha^n(x_2) e^{inx_1}, \tag{2.19}$$

where

$$u_\alpha^n(x_2) = \frac{1}{2\pi} \int_0^{2\pi} u_\alpha(x_1, x_2) e^{-inx_1} dx_1,$$
$$v_\alpha^n(x_2) = \frac{1}{2\pi} \int_0^{2\pi} v_\alpha(x_1, x_2) e^{-inx_1} dx_1.$$

For $j = 1, 2$, define the coefficients

$$\beta_{1j}^n(\alpha) = e^{i\gamma_{1j}/2} \left|k_{1j}^2 - (n + \alpha_1)^2\right|^{1/2}, \quad n \in Z, \tag{2.20}$$

$$\beta_{2j}^n(\alpha) = e^{i\gamma_{2j}/2} \left|k_{2j}^2 - (n + \alpha_2)^2\right|^{1/2}, \quad n \in Z, \tag{2.21}$$

where

$$\gamma_{1j} = \arg(k_{1j}^2 - (n + \alpha_1)^2), \quad 0 \le \gamma_{1j} < 2\pi$$
$$\gamma_{2j} = \arg(k_{2j}^2 - (n + \alpha_2)^2), \quad 0 \le \gamma_{2j} < 2\pi.$$

Throughout, we assume that $k_{1j}^2 \neq (n+\alpha_1)^2$ and $k_{2j}^2 \neq (n+\alpha_2)^2$ for all $n \in Z$, $j = 1, 2$; this assumption excludes the "resonant" cases, where waves can propagate along the x_1-axis. The assumption also ensures that a fundamental solution for (2.16) and (2.17) exists inside Ω_1 and Ω_2. It then follows from our knowledge of the fundamental solution (see, e.g., [5]) that inside Ω_1 and Ω_2, u_α and v_α can be expressed as a sum of plane waves: for $j = 1, 2$,

$$u_\alpha|_{\Omega_j} = \sum_{n\in Z} a_j^n e^{\pm i\beta_{1j}^n(\alpha)x_2 + inx_1}, \tag{2.22}$$

$$v_\alpha|_{\Omega_j} = \sum_{n\in Z} b_j^n e^{\pm i\beta_{2j}^n(\alpha)x_2 + inx_1}, \tag{2.23}$$

where a_j^n and b_j^n are complex scalars. Since β_{sj}^n is real for at most finitely many n's, there are only a finite number of *propagating* plane waves in the sum (2.22) and (2.23); the remaining waves are exponentially damped (or unbounded) as $|x_2| \to \infty$. We are only interested in the case where (u_α, v_α) is composed of bounded *outgoing* plane waves in Ω_1 and Ω_2 plus the incident incoming wave u_I in Ω_1. From (2.18), (2.19), (2.22), and (2.23), we have

$$u_\alpha^n(x_2) = \begin{cases} u_\alpha^n(b)e^{i\beta_{11}^n(\alpha)(x_2-b)}, & n \neq 0, \quad \text{in } \Omega_1, \\ u_\alpha^0(b)e^{i\beta_{11}(x_2-b)} + u_i e^{-i\beta_{11}x_2} - u_i e^{i\beta_{11}(x_2-2b)}, & n = 0, \quad \text{in } \Omega_1, \\ u_\alpha^n(-b)e^{-i\beta_{12}^n(\alpha)(x_2+b)} & \qquad\quad\;\; \text{in } \Omega_2 \end{cases} \tag{2.24}$$

and

$$v_\alpha^n(x_2) = \begin{cases} v_\alpha^n(b)e^{i\beta_{21}^n(\alpha)(x_2-b)} & \text{in } \Omega_1, \\ v_\alpha^n(-b)e^{-i\beta_{22}^n(\alpha)(x_2+b)} & \text{in } \Omega_2. \end{cases} \tag{2.25}$$

Let ν be the unit outward normal vector defined by

$$\nu = \begin{cases} \vec{x_2} & \text{on } \Gamma_1, \\ -\vec{x_2} & \text{on } \Gamma_2, \end{cases}$$

where $\vec{x_2}$ is the unit vector of the x_2-axis.

We can then calculate the derivative of $u_\alpha^n(x_2)$ and $v_\alpha^n(x_2)$ with respect to ν:

$$\left.\frac{\partial u_\alpha^n}{\partial \nu}\right|_{\Gamma_j} = \begin{cases} i\beta_{11}^n u_\alpha^n(b), & n \neq 0, \quad \text{on } \Gamma_1, \\ i\beta_{11} u_\alpha^0(b) - 2iu_i\beta_{11}e^{-i\beta_{11}b}, & n = 0, \quad \text{on } \Gamma_1, \\ i\beta_{12}^n u_\alpha^n(-b) & \qquad\quad\;\; \text{on } \Gamma_2 \end{cases} \tag{2.26}$$

and

$$\left.\frac{\partial v_\alpha^n}{\partial \nu}\right|_{\Gamma_j} = \begin{cases} i\beta_{21}^n(\alpha)v_\alpha^n(b) & \text{on } \Gamma_1, \\ i\beta_{22}^n(\alpha)v_\alpha^n(-b) & \text{on } \Gamma_2. \end{cases} \tag{2.27}$$

Therefore,

$$\left.\frac{\partial u_\alpha}{\partial \nu}\right|_{\Gamma_1} = \sum_{n\in Z} i\beta_{11}^n u_\alpha^n(b)e^{inx_1} - 2iu_i\beta_{11}e^{-i\beta_{11}b}, \tag{2.28}$$

$$\left.\frac{\partial u_\alpha}{\partial \nu}\right|_{\Gamma_2} = \sum_{n\in Z} i\beta_{12}^n u_\alpha^n(-b)e^{inx_1}, \tag{2.29}$$

$$\left.\frac{\partial v_\alpha}{\partial \nu}\right|_{\Gamma_1} = \sum_{n\in Z} i\beta_{21}^n v_\alpha^n(b)e^{inx_1}, \tag{2.30}$$

$$\left.\frac{\partial v_\alpha}{\partial \nu}\right|_{\Gamma_2} = \sum_{n\in Z} i\beta_{22}^n v_\alpha^n(-b)e^{inx_1}. \tag{2.31}$$

Since the fields u_α and v_α are 2π-periodic in x_1, without loss of generality, we can move the problem from $\mathbb{R}^2$ to the quotient space (cylinder) $\mathbb{R}^2/(2\pi Z \times \{0\})$. For the remainder of the paper, we shall identify Ω with the cylinder $\Omega/(2\pi Z \times \{0\})$ and do similarly for the boundaries $\Gamma_j \equiv \Gamma_j/2\pi Z$. Thus from now on, all functions defined on Ω and Γ_j are implicitly 2π-periodic in the x_1 variable.

For functions $f \in H^{1/2}(\Gamma_j)$ (the Sobolev space of complex-valued functions on the circle), define the operator T_{sj}^α by

$$(T_{sj}^\alpha f)(x_1) = \sum_{n\in Z} i\beta_{sj}^n(\alpha) f^n e^{inx_1} \tag{2.32}$$

for $s, j = 1, 2$, where $f^n = (1/2\pi)\int_0^{2\pi} f(x_1)e^{-inx_1}$ and equality is taken in the sense of distributions.

From (2.32) and the definition of $\beta_{sj}^n(\alpha)$, it is clear that T_{sj}^α is a standard pseudodifferential operator (in fact, a convolution operator) of order one.

From (2.28)–(2.31), we see that for $j = 1, 2$,

$$\begin{aligned} T_{11}^\alpha(u_\alpha|_{\Gamma_1}) &= \frac{\partial u_\alpha}{\partial \nu}|_{\Gamma_1} + 2iu_i\beta_{11}e^{-i\beta_{11}b}, \\ T_{12}^\alpha(u_\alpha|_{\Gamma_2}) &= \frac{\partial u_\alpha}{\partial \nu}|_{\Gamma_2}, \\ T_{2j}^\alpha(v_\alpha|_{\Gamma_j}) &= \frac{\partial v_\alpha}{\partial \nu}|_{\Gamma_j}, \end{aligned}$$

that is, T_{sj}^α are Dirichlet–Neumann maps. We will use the abbreviated notations $T_{1j}^\alpha u_\alpha$ and $T_{2j}^\alpha v_\alpha$ to mean $T_{1j}^\alpha(u_\alpha|_{\Gamma_j})$ and $T_{2j}^\alpha(v_\alpha|_{\Gamma_j})$, respectively.

Thus the scattering problem has been formulated as follows:

$$\nabla_{\alpha_1} \cdot \left(\frac{1}{k_1^2} \nabla_{\alpha_1} u_\alpha \right) + u_\alpha = 0 \quad \text{in } \Omega, \tag{2.33}$$

$$(\triangle_{\alpha_2} + k_2^2)v_\alpha = \sum_{j,l=1,2} \chi_{jl}^\alpha \partial_{x_j}^{\alpha_1} u_\alpha \partial_{x_l}^{\alpha_1} u_\alpha \quad \text{in } \Omega, \tag{2.34}$$

$$\left(T_{11}^\alpha - \frac{\partial}{\partial \nu} \right) u_\alpha = 2iu_i\beta_{11}e^{-i\beta_{11}b} \quad \text{on } \Gamma_1, \tag{2.35}$$

$$\left(T_{12}^\alpha - \frac{\partial}{\partial \nu} \right) u_\alpha = 0 \quad \text{on } \Gamma_2, \tag{2.36}$$

$$\left(T_{21}^\alpha - \frac{\partial}{\partial \nu} \right) v_\alpha = 0 \quad \text{on } \Gamma_1, \tag{2.37}$$

$$\left(T_{22}^\alpha - \frac{\partial}{\partial \nu} \right) v_\alpha = 0 \quad \text{on } \Gamma_2. \tag{2.38}$$

3. Existence and regularity of the scattering problem.

We are now ready to present the main result of this paper.

THEOREM 3.1. *Assume that the regularity assumptions* (2.13) *and* (2.14) *hold. Then for all but possibly a discrete set of frequencies ω, the scattering problem* (2.33)–(2.38) *admits a unique solution*

$$u_\alpha \in H^1(\Omega) \cap C^{1,\sigma}(\Omega_1^+ \cup \Gamma_1) \cap C^{1,\sigma}(\overline{\Omega}_0) \cap C^{1,\sigma}(\Omega_2^+ \cup \Gamma_2),$$

and $v_\alpha \in W^{2,p}(\Omega)$ for some $0 < \sigma < 1$ and any $1 < p < \infty$.

The proof may be given by proving Theorems 3.3 and 3.10 below.

We first establish $C^{1,\sigma}$ estimates of the pump field u_α. As in [1], we introduce a smooth 2π-periodic function u_0 supported near Γ_1 such that $u_0(x_1, b) = 0$ and $\partial_{x_2} u_0(x_1, b) = -2iu_i\beta_{11}e^{-i\beta_{11}b}$. Recall that u_i is the fixed constant given in (2.15). Then $u_\alpha - u_0$, still denoted by u_α, satisfies

$$\nabla_{\alpha_1} \cdot \left(\frac{1}{k_1^2} \nabla_{\alpha_1} u_\alpha\right) + u_\alpha = -f \quad \text{in } \Omega, \tag{3.1}$$

$$\left(T_{11}^\alpha - \frac{\partial}{\partial \nu}\right) u_\alpha = 0 \quad \text{on } \Gamma_1, \tag{3.2}$$

$$\left(T_{12}^\alpha - \frac{\partial}{\partial \nu}\right) u_\alpha = 0 \quad \text{on } \Gamma_2, \tag{3.3}$$

where

$$f = \nabla_{\alpha_1} \cdot \left(\frac{1}{k_1^2} \nabla_{\alpha_1} u_0\right).$$

By examining the variational formulation of (3.1)–(3.3), the following result holds; see [1] for the proof.

THEOREM 3.2. *Under the assumptions* (2.13) *and* (2.14)*, for all but possibly a discrete set of frequencies ω, the problem* (3.1)–(3.3) *admits a unique weak solution $u_\alpha \in H^1(\Omega)$.*

According to the standard elliptic regularity theory [9], [10], $u_\alpha \in C^\beta(\tilde{\Omega})$ for some $0 < \beta < 1$ and $||u_\alpha||_{C^\beta(\tilde{\Omega})} \le C$ with $\tilde{\Omega} \Subset \Omega$, where C depends on k_1, f, and $\text{dist}(\tilde{\Omega}, \Omega)$.

Denote $\tilde{\Omega} = \{(x_1, x_2),\ 0 < x_1 < 2\pi,\ -b_1 < x_2 < b_1\}$, where $b_1 < b$ is chosen such that $\tilde{\Omega} \subseteq \Omega \backslash \text{supp}\{u_0\}$ and $-b_1 < \phi_2(x) < \phi_1(x) < b_1\ \forall x_1 \in (0, 2\pi)$.

THEOREM 3.3. *Under the assumptions* (2.13) *and* (2.14)*, for all but possibly a discrete set of frequencies ω, the problem* (3.1)–(3.3) *admits a unique solution*

$$u_\alpha \in H^1(\Omega) \cap C^{1,\sigma}(\Omega_1^+ \cup \Gamma_1) \cap C^{1,\sigma}(\overline{\Omega}_0) \cap C^{1,\sigma}(\Omega_2^+ \cup \Gamma_2)$$

for some $0 < \sigma < 1$.

Moreover,

$$\|\nabla u_\alpha\|_{C^\sigma(\Omega_1^+ \cup \Gamma_1)} + \|\nabla u_\alpha\|_{C^\sigma(\overline{\Omega}_0)} + \|\nabla u_\alpha\|_{C^{1,\sigma}(\Omega_2^+ \cup \Gamma_2)} \le C, \tag{3.4}$$

where the constant C depends on k_1, α_1, u_i, and $\|u_\alpha\|_{C^\gamma(\tilde{\Omega})}$.

Note that near the boundary Γ_1 or Γ_2, the problem (3.1)–(3.3) becomes a Helmholtz equation with constant coefficients and smooth pseudodifferential boundary conditions. The $C^{1,\sigma}$ regularity of u_α then follows.

The standard elliptic regularity results [9] indicate the $C^{1,\sigma}$ regularity of u_α away from a tubular neighborhood of the two interfaces S_1 and S_2 due to the definition of k_1 and (2.13).

Thus it suffices to prove the regularity result in the tubular neighborhood of each interface. We shall restrict our attention to the interface S_1. The $C^{1,\sigma}$ regularity of u_α in the tubular neighborhood of S_2 can be established in the same manner; hence its proof will be omitted.

For simplicity, we shall drop the subscript of u_α. By using the definition of ∇_{α_1} and $f = 0$ away from near S_1, equation (3.1) may be rewritten as

$$\nabla \cdot \left(\frac{1}{k_1^2} \nabla u\right) + i\alpha_1 \frac{1}{k_1^2} \frac{\partial u}{\partial x_1} + i\alpha_1 \frac{\partial}{\partial x_1} \left(\frac{1}{k_1^2} u\right) + \left(1 - \alpha_1^2 \frac{1}{k_1^2}\right) u = 0. \tag{3.5}$$

For any fixed $(x_1^0, x_2^0) \in S_1$, $x_2^0 = \phi_1(x_1^0)$, and $r > 0$, denote

$$Q_r = \{(x_1, x_2), \quad |x_1 - x_1^0| < r, \quad |x_2 - x_2^0| < r\}.$$

One may choose R such that $Q_R \subset \Omega$. Consider the transformation in Q_R:

$$x_1' = x_1 - x_1^0, \quad x_2' = x_2 - \phi_1(x_1), \quad u'(x_1', x_2') = u(x_1, x_2), \quad k_1'(x_1', x_2') = k_1(x_1, x_2). \tag{3.6}$$

Using this transformation, Q_R is mapped into a set containing a neighborhood Q_{R_0} of the origin. Without loss of generality, the preimage of Q_{R_0} is assumed to contain $Q_{R/2}$. For simplicity, we shall omit the primes and set (in the new coordinate system)

$$Q_{R_0}^+ = Q_{R_0} \cap \{x_2 > 0\}, \qquad Q_{R_0}^- = Q_{R_0} \cap \{x_2 < 0\}.$$

Consider a more general model problem in Q_{R_0}:

$$\frac{\partial}{\partial x_i}\left(a_{ij}\frac{\partial u}{\partial x_j}\right) + \frac{\partial}{\partial x_j}(b_j u) + c_j\frac{\partial u}{\partial x_j} + du + f = 0. \tag{3.7}$$

Suppose that $u \in C^\gamma(Q_{R_0}) \cap H^1(Q_{R_0})$. Suppose also that the coefficients $a_{ij}, b_j \in C^\gamma(Q_{R_0}^\pm)$ and $c_j, d, f \in C(Q_{R_0}^\pm)$ have a jump at $x_2 = 0, b_j$, and a_{1j}, a_{2j} are linearly independent, and the principle part of the operator is elliptic in Q_{R_0}, i.e., there is a constant c_0 such that

$$\left|\sum a_{ij}\xi_i\bar{\xi}_j\right| \geq c_0|\xi|^2.$$

Theorem 3.4. *Under the above assumptions, the solution of* (3.7) *satisfies*

$$u \in C^{1,\sigma}(Q_{R_0/4}^\pm) \tag{3.8}$$

for some $0 < \sigma < 1$.

Before proving Theorem 3.4, we make the following remarks.

Theorem 3.4 holds with the same proof in the multidimensional case.

Theorem 3.3 may be proved by using Theorem 3.4. Actually, using the transformation (3.6), equation (3.5) becomes a special case of (3.7) with

$$\begin{aligned}
a_{11} &= \frac{1}{k_1^2}, & a_{12} = a_{21} &= -\frac{1}{k_1^2}\phi_{1x_1}, & a_{22} &= \frac{1}{k_1^2}(\phi_{1x_1}^2 + 1),\\
b_1 &= i\alpha_1\frac{1}{k_1^2}, & b_2 &= -i\alpha_1\phi_{1x_1}\frac{1}{k_1^2}, & f &= 0,\\
c_1 &= i\alpha_1\frac{1}{k_1^2}, & c_2 &= -i\alpha_1\frac{1}{k_1^2}\phi_{1x_1}, & d &= 1 - \frac{\alpha_1^2}{k_1^2}.
\end{aligned}$$

It is easy to check that according to (2.13), the regularity assumptions of Theorem 3.4 are satisfied. By Theorem 3.4, the solution of (3.7) with the above choices of the coefficients satisfies

$$\nabla u \in C^\sigma(Q_{R_0/4}^\pm)$$

for some $0 < \sigma < 1$. Theorem 3.3 then follows.

The proof of (3.8) roughly follows an approach introduced by DiBenedetto, Elliott, and Friedman in [6]. They established the same regularity as in (3.8) for the solution of

$$\frac{\partial}{\partial x_i}\left(a_{ij}\frac{\partial u}{\partial x_j}\right)+B_j\frac{\partial u}{\partial x_j}+Cu=F$$

under the assumptions that

$$a_{ij}\in C^\gamma(Q^\pm_{R_0}),\qquad |\nabla B_j|,\ C,\ F\in L^\infty_{\text{loc}}(Q_{R_0}).$$

However, in our case, since b_j and c_j have a jump across the interface $x_2=0$, the functions $\nabla B_j=\nabla(b_j+c_j)$ and $C=\partial b_j/\partial x_j+d$ may not belong to $L^\infty_{\text{loc}}(Q_{R_0})$. Thus the weak regularity assumptions on the coefficients in our case require more delicate estimates.

Also, in [6], a crucial step for the proof of Hölder continuity of $\partial_{x_1}u$ is to establish the inequality

$$\int_{Q_\rho}|\partial_{x_1}u-(\partial_{x_1}u)_\rho|^2\le CR^{2\beta}\int_{Q_R}|\nabla u|^2+C\left(\frac{\rho}{R}\right)^4\int_{Q_R}|\partial_{x_1}u-(\partial_{x_1}u)_R|^2. \tag{3.9}$$

Again due to the jump of k at $x_2=0$, we are unable to show (3.9) in our case. Fortunately, by some careful estimates, we can obtain a weaker estimate (3.18) below instead of (3.9), which also implies the Hölder continuity of $\partial_{x_1}u$.

We now present our proof of Theorem 3.4. We first assume that $b_2=0$ in equation (3.7). The general case may be reduced to the case of $b_2=0$ by considering the transformation $\tilde u=ue^{\lambda\cdot x}$, where λ_j are determined by

$$\sum_{j=1}^2 a_{ij}\lambda_j+b_i=0.$$

Consider the auxiliary problem

$$\frac{\partial}{\partial x_i}(a^0_{ij}(x_1,x_2)P_{x_j})=0\quad\text{in } Q_{R_0}, \tag{3.10}$$

$$P=u\quad\text{on } \partial Q_{R_0}, \tag{3.11}$$

where $a^0_{ij}=a_{ij}(0,0)$. Because of the jump, equation (3.10) is not an equation with constant coefficients.

Set

$$w_R=\frac{1}{|Q_R|}\int_{Q_R}wdx,\qquad w^\pm_R=\frac{1}{|Q^\pm_R|}\int_{Q^\pm_R}wdx.$$

As shown in [6], the following result holds.

LEMMA 3.5. *For any* $0<\rho<R_0/16$,

$$\int_{Q_\rho}|P_{x_1}-(P_{x_1})_\rho|^2dx\le C\left(\frac{\rho}{R_o}\right)^4\int_{Q_{R_0}}|P_{x_1}-(P_{x_1})_{R_0}|^2dx, \tag{3.12}$$

$$\int_{Q^\pm_\rho}|\nabla P-(\nabla P)^\pm_\rho|^2dx\le C\left(\frac{\rho}{R_0}\right)^4\int_{Q_{R_0}}|P_{x_1}|^2dx. \tag{3.13}$$

Returning to u, we have

$$\begin{aligned}-\frac{\partial}{\partial x_i}(a_{ij}^0(x_1,x_2)(u-P)_{x_j}) = &-\frac{\partial}{\partial x_i}((a_{ij}(x_1,x_2)-a_{ij}^0(x_1,x_2))u_{xj}) \\ &+\frac{\partial}{\partial x_1}(b_1(x_1,x_2)u)+c_j(x_1,x_2)\frac{\partial u}{\partial x_j}+d(x_1,x_2)u+f(x_1,x_2).\end{aligned} \tag{3.14}$$

Lemma 3.6. *There is a constant C that depends on $\|a_{ij}\|_{C^\gamma(Q_{R_0}^\pm)}$, $\|b_1\|_{C^\gamma(Q_{R_0}^\pm)}$, and $\|u\|_{C^\gamma(Q_{R_0})}$ such that*

$$\int_{Q_{R_0}}|\nabla(u-P)|^2 \le CR_0^{2\gamma}\int_{Q_{R_0}}|\nabla u|^2 + CR_0^{2+2\gamma}. \tag{3.15}$$

Proof. Note that $a_{ij}\in C^\gamma(Q_{R_0}^\pm)$ implies that $a_{ij}-a_{ij}^0\in C^\gamma(Q_{R_0})$.

Multiplying (3.14) by $u-P$ and integrating over Q_{R_0}, by using the ellipticity of the operator, we obtain

$$\begin{aligned}\int_{Q_{R_0}}|\nabla(u-P)|^2 \le CR_0{}^{2\gamma}\int_{Q_{R_0}}|\nabla u|^2 &+ \left|\int_{Q_{R_0}}\frac{\partial}{\partial x_j}(b_1u)(u-P)\right| \\ &+\left|\int_{Q_{R_0}}c_j\frac{\partial u}{\partial x_j}(u-P)\right|+\left|\int_{Q_{R_0}}(du+f)(u-P)\right|.\end{aligned} \tag{3.16}$$

Note that no boundary term occurs from the integration by parts since $u-P=0$ on the boundary. We next estimate the last three terms in (3.16). First,

$$\begin{aligned}\left|\int_{Q_{R_0}}c_j(x_1,x_2)\frac{\partial u}{\partial x_j}(u-P)\right| &\le \int_{Q_{R_0}}|c_j(x_1,x_2)|\left|\frac{\partial u}{\partial x_j}\right||u-P| \\ &\le CR_0^{2\gamma}\int_{Q_{R_0}}|\nabla u|^2+R_0^{-2\gamma}\int_{Q_{R_0}}|u-P|^2.\end{aligned}$$

From Poincaré's inequality,

$$\int_{Q_{R_0}}|u-P|^2 \le \frac{1}{2}R_0^2\int_{Q_{R_0}}|\nabla(u-P)|^2,$$

for $R_0^{2-2\gamma}\le 1/2$,

$$\left|\int_{Q_{R_0}}c_j(x_1,x_2)\frac{\partial u}{\partial x_j}(u-P)\right| \le CR_0^{2\gamma}\int_{Q_{R_0}}|\nabla u|^2+\frac{1}{4}\int_{Q_{R_0}}|\nabla(u-P)|^2.$$

Next,

$$\begin{aligned}\left|\int_{Q_{R_0}}(d(x_1,x_2)u+f(x_1,x_2))(u-P)\right| &\le \int_{Q_{R_0}}(|d|\,|u|+|f|)|u-P| \\ &\le CR_0^{2+2\gamma}+\frac{1}{8}\int_{Q_{R_0}}|\nabla(u-P)|^2.\end{aligned}$$

Similarly, integration by parts yields

$$\begin{aligned}\int_{Q_{R_0}} \frac{\partial}{\partial x_1}(b_1 u)(u-P) &= -\int_{Q_{R_0}} (b_1 u - (b_1 u)(0,0)) \frac{\partial (u-P)}{\partial x_1} \\ &\le C R_0^{\gamma} \int_{Q_{R_0}} |\nabla (u-P)| \\ &\le C R_0^{2+2\gamma} + \frac{1}{8}\int_{Q_{R_0}} |\nabla(u-P)|^2.\end{aligned}$$

Estimate (3.15) follows by combining the above estimates. □

The next result is an analogue of Lemma 3.5 on u.

LEMMA 3.7. *For any* $0 < \rho < \eta R$, $0 < \eta < 2^{-4}$, $R \le R_0$,

(3.17)
$$\int_{Q_\rho^{\pm}} |\nabla u - (\nabla u)_\rho^{\pm}|^2 \le C \left[R^{2\gamma} + \left(\frac{\rho}{R}\right)^4 \right] \int_{Q_R} |\nabla u|^2 + C R^{2+2\gamma},$$

(3.18)
$$\begin{aligned}\int_{Q_\rho} |\partial_{x_1} u - (\partial_{x_1} u)_\rho|^2 \le C R^{2\gamma} \int_{Q_R} |\nabla u|^2 + C\left(\frac{\rho}{R}\right)^4 \int_{Q_R} |\partial_{x_1} u - (\partial_{x_1} u)_R|^2 \\ + C R^{2+2\gamma}.\end{aligned}$$

Proof. For any $R > 0$, we decompose u on Q_{R_0} into the sum of P and $P - u$ such that P solves the auxiliary problem (3.10)–(3.11) on Q_R. By using (3.13) and (3.15), we obtain

$$\begin{aligned}\int_{Q_\rho^{\pm}} |\nabla u - (\nabla u)_\rho^{\pm}|^2 &\le \int_{Q_\rho^{\pm}} |\nabla u - \nabla P|^2 + |(\nabla u)_\rho^{\pm} - (\nabla P)_\rho^{\pm}|^2 \\ &\quad + |\nabla P - (\nabla P)_\rho^{\pm}|^2 \\ &\le 2\int_{Q_\rho^{\pm}} |\nabla u - \nabla P|^2 + \int_{Q_\rho^{\pm}} |\nabla P - (\nabla P)_\rho^{\pm}|^2 \\ &\quad + C R^{2\gamma} \int_{Q_R} |\nabla u|^2 + C R^{2+2\gamma} + C\left(\frac{\rho}{R}\right)^4 \int_{Q_R} |\partial_{x_1} P|^2.\end{aligned}$$

From a simple energy estimate of the auxiliary problem (3.10)–(3.11) on Q_R,

$$\int_{Q_R} |\nabla P|^2 \le C \int_{Q_R} |\nabla u|^2.$$

Thus

$$\int_{Q_\rho^{\pm}} |\nabla u - (\nabla u)_\rho^{\pm}|^2 \le C R^{2\gamma} \int_{Q_R} |\nabla u|^2 + C\left(\frac{\rho}{R}\right)^4 \int_{Q_R} |\nabla u|^2 + C R^{2+2\gamma}.$$

Next, from (3.12) and (3.15),

$$\begin{aligned}\int_{Q_R} |\partial_{x_1} u - (\partial_{x_1} u)_\rho|^2 &\le 2\int_{Q_\rho} |\nabla u - \nabla P|^2 + \int_{Q_\rho^{\pm}} |\nabla P - (\nabla P)_\rho|^2 \\ &\le C\left(\frac{\rho}{R}\right)^4 \int_{Q_R} |\partial_{x_1} P - (\partial_{x_1} P)_R|^2 + C R^{2\gamma} \int_{Q_R} |\nabla u|^2 \\ &\quad + C R^{2+2\gamma}. \qquad (3.19)\end{aligned}$$

Also,

$$\int_{Q_R} |\partial_{x_1} P - (\partial_{x_1} P)_R|^2 \le 2 \int_{Q_R} |\nabla(P-u)|^2 + \int_{Q_R} |\partial_{x_1} u - (\partial_{x_1} u)_R|^2. \tag{3.20}$$

Substituting (3.20) into (3.19) yields estimate (3.18). □

LEMMA 3.8. *For any $\varepsilon > 0$, there exist $R_1 \in (0, R_0)$ and $C > 0$ such that for any $0 < \rho < R < R_1$,*

$$\int_{Q_\rho} |\nabla u|^2 \le C \left(\frac{\rho}{R}\right)^{2-\varepsilon} \int_{Q_R} |\nabla u|^2 + C\rho^{2-\varepsilon}, \tag{3.21}$$

where the constants R_1 and C depend on ε.

Proof. Apply Lemma 3.7 with $\rho_i = \eta^i R$, $R < R_1$, and $R_1^{2\gamma} < \eta^4$, where $\eta < 2^{-4}$ is to be determined.

Integrating the inequality

$$|(\nabla u)^\pm_{\rho_{i+1}} - (\nabla u)^\pm_{\rho_i}|^2 \le 2|\nabla u - (\nabla u)^\pm_{\rho_i}|^2 + 2|\nabla u - (\nabla u)^\pm_{\rho_{i+1}}|^2$$

over $Q^\pm_{\rho_{i+1}}$ and dividing by $|Q^\pm_{\rho_{i+1}}|$, we get from (3.17)

$$\begin{aligned} |(\nabla u)^\pm_{\rho_{i+1}} - (\nabla u)^\pm_{\rho_i}|^2 \le{}& \frac{C}{\rho_{i+1}^2}(\rho_i^{2\gamma} + \eta^4) \int_{Q_{\rho_i}} |\nabla u|^2 + \frac{C\rho_i^{2+2\gamma}}{\rho_{i+1}^2} \\ &+ \frac{C}{\rho_{i+1}^2}(\rho_{i-1}^{2\gamma} + \eta^4) \int_{Q_{\rho_{i-1}}} |\nabla u|^2 + \frac{C\rho_{i-1}^{2+2\gamma}}{\rho_{i+1}^2}. \end{aligned} \tag{3.22}$$

Next, apply (3.17) with $R = \rho_i$, $\rho = \rho_{i+1}$:

$$\begin{aligned} \int_{Q^\pm_{\rho_{i+1}}} |\nabla u|^2 &\le \int_{Q^\pm_{\rho_{i+1}}} \left|(\nabla u)^\pm_{\rho_{i+1}}\right|^2 + C(\rho_i^{2\gamma} + \eta^4) \int_{Q_{\rho_i}} |\nabla u|^2 + C\rho_i^{2+2\gamma} \\ &\le |Q^\pm_{\rho_{i+1}}||(\nabla u)^\pm_{\rho_{i+1}}|^2 + C(\rho_i^{2\gamma} + \eta^4) \int_{Q_{\rho_i}} |\nabla u|^2 + C\rho_i^{2+2\gamma}. \end{aligned} \tag{3.23}$$

Observe that

$$\begin{aligned} \left|Q^\pm_{\rho_{i+1}}\right| \left|(\nabla u)^\pm_{\rho_i}\right|^2 &= \frac{|Q^\pm_{\rho_{i+1}}|}{|Q^\pm_{\rho_i}|^2} \left|\int_{Q^\pm_{\rho_i}} \nabla u\right|^2 \\ &\le \frac{|Q^\pm_{\rho_{i+1}}|}{|Q^\pm_{\rho_i}|} \int_{Q^\pm_{\rho_i}} |\nabla u|^2 = \eta^2 \int_{Q^\pm_{\rho_i}} |\nabla u|^2. \end{aligned} \tag{3.24}$$

From (3.22) and (3.24), we have

$$\begin{aligned} \left|Q^\pm_{\rho_{i+1}}\right| \left|(\nabla u)^\pm_{\rho_{i+1}}\right|^2 \le{}& \eta^2 \int_{Q^\pm_{\rho_i}} |\nabla u|^2 + C(\rho_i^{2\gamma} + \eta^4) \int_{Q_{\rho_i}} |\nabla u|^2 \\ &+ C\rho_i^{2+2\gamma} + C(\rho_{i-1}^{2\gamma} + \eta^4) \int_{Q_{\rho_{i-1}}} |\nabla u|^2 + C\rho_{i-1}^{2+2\gamma}. \end{aligned} \tag{3.25}$$

Substituting (3.25) into (3.23), we have

$$\begin{aligned} \int_{Q^\pm_{\rho_{i+1}}} |\nabla u|^2 \le{}& C(\eta^2 + \rho_i^{2\gamma}) \int_{Q_{\rho_i}} |\nabla u|^2 + C(\rho_{i-1}^{2\gamma} + \eta^4) \int_{Q_{\rho_{i-1}}} |\nabla u|^2 \\ &+ C\rho_i^{2+2\gamma} + C\rho_{i-1}^{2+2\gamma}. \end{aligned}$$

By the choice of ρ_i, η^i, and R_1,

$$\rho_i^{2\gamma} < \rho_{i-1}^{2\gamma} < \cdots < \rho_0^{2\gamma} = R^{2\gamma} < R_1^{2\gamma} < \eta^4,$$

we have

$$\int_{Q^\pm_{\rho_{i+1}}} |\nabla u|^2 \le C\eta^2 \int_{Q_{\rho_i}} |\nabla u|^2 + C\eta^4 \int_{Q_{\rho_{i-1}}} |\nabla u|^2 + C\rho_{i-1}^{2+2\gamma}.$$

Iterating with respect to i, we obtain

$$\begin{aligned}\int_{Q^\pm_{\rho_n}} |\nabla u|^2 &\le C\eta^{2(n-1)} \int_{Q_R} |\nabla u|^2 + C(\rho_{n-2}^{2+2\gamma} + \rho_{n-3}^{2+2\gamma}\eta^2 + \cdots + \rho_0^{2+2\gamma}\eta^{2(n-1)})\\ &\le C\eta^{2(n-1)} \int_{Q_R} |\nabla u|^2 + C\rho_0^{2+2\gamma}\\ &\le C_0\eta^{2(n-1)} \int_{Q_R} |\nabla u|^2 + CR^{2+2\gamma},\end{aligned}$$

where $C > 0$ is independent of n.

We choose η such that

$$\eta^\varepsilon = \frac{1}{C_0}.$$

Then

$$\begin{aligned}\int_{Q^\pm_{\rho_n}} |\nabla u|^2 &\le \eta^{2(n-1)-\varepsilon} \int_{Q_R} |\nabla u|^2 + CR^{2+2\gamma}\\ &\le \eta^{n(2-\varepsilon)-2+(n-1)\varepsilon} \int_{Q_R} |\nabla u|^2 + CR^{2+2\gamma}\\ &\le \left(\frac{\rho_n}{R}\right)^{(2-\varepsilon)} \eta^{(n-1)\varepsilon-2} \int_{Q_R} |\nabla u|^2 + CR^{2+2\gamma}\\ &\le C\left(\frac{\rho_n}{R}\right)^{(2-\varepsilon)} \int_{Q_R} |\nabla u|^2 + CR^{2+2\gamma}, \qquad (3.26)\end{aligned}$$

where we have used $\rho_n/R = \eta^n$ and $|\eta^{(n-1)\varepsilon-2}| \le |\eta^{-2}| \le C$; here the constant C depends on ε.

Assertion (3.21) follows by the following interpolation of (3.26). In fact, for $\rho_{k+1} < \rho < \rho_k$,

$$\begin{aligned}\int_{Q^\pm_\rho} |\nabla u|^2 \le \int_{Q^\pm_{\rho_k}} |\nabla u|^2 &\le C\left(\frac{\rho_k}{R}\right)^{2-\varepsilon} \int_{Q_R} |\nabla u|^2 + CR^{2+2\gamma}\\ &= C\left(\frac{\rho_{k+1}}{\eta R}\right)^{2-\varepsilon} \int_{Q_R} |\nabla u|^2 + CR^{2+2\gamma}\\ &\le C\left(\frac{\rho}{R}\right)^{2-\varepsilon} \int_{Q_R} |\nabla u|^2 + CR^{2+2\gamma}.\end{aligned}$$

The estimate of (3.21) follows from Campanato's lemma [8, p. 86., Lemma 2.1]. □

Lemma 3.9. *For any $0 < \rho < \tilde{R}$, where $\tilde{R} = R_1(\varepsilon)$ is determined in Lemma* 3.8 *for $\varepsilon = \gamma$,*

$$\int_{Q_\rho} |\partial_{x_1} u - (\partial_{x_1} u)_\rho|^2 \leq C \left(\frac{\rho}{R}\right)^{2+\gamma} \int_{Q_R} |\partial_{x_1} u - (\partial_{x_1} u)_R|^2 + C\rho^{2+\gamma} . \tag{3.27}$$

Proof. Combining (3.18) and (3.21), with $\rho = R$, $R = \tilde{R}$, $0 < \rho < \eta R$, and $\eta < 2^{-4}$, we have

$$\begin{aligned}\int_{Q_\rho} |\partial_{x_1} u - (\partial_{x_1} u)_\rho|^2 &\leq CR^{2\gamma} \int_{Q_R} |\nabla u|^2 + C \left(\frac{\rho}{R}\right)^4 \int_{Q_R} |\partial_{x_1} u - (\partial_{x_1} u)_R|^2 + CR^{2+2\gamma} \\ &\leq CR^{2\gamma} \left[C \left(\frac{R}{\tilde{R}}\right)^{2-\gamma} \int_{Q_{\tilde{R}}} |\nabla u|^2 + CR^{2-\gamma} \right] \\ &\quad + C \left(\frac{\rho}{R}\right)^4 \int_{Q_R} |\partial_{x_1} u - (\partial_{x_1} u)_R| + CR^{2+2\gamma} \\ &\leq CR^{2+\gamma} + C \left(\frac{\rho}{R}\right)^4 \int_{Q_R} |\partial_{x_1} u - (\partial_{x_1} u)_R|.\end{aligned}$$

Hence (3.27) follows from the Campanato lemma.

Using the same arguments as in [6], we can establish (3.27) for any sets Q_ρ and Q_R with center in $Q_{R_0/2}$ since no use has been made of the symmetry or comparative size of $Q^+_{R_0/2}$ and $Q^-_{R_0/2}$. It follows from a Campanato's result that $\partial_{x_1} u$ is Hölder continuous in $Q_{R_0/2}$. The Hölder continuity of $\partial_{x_2} u$ in $\bar{Q}^{\pm}_{R_0/4}$ may also be established by a similar procedure; see, e.g., [6].

Finally, concerning the regularity of the second harmonic field v_α, i.e., solutions of the Helmholtz equation, we have the following general regularity result.

Theorem 3.10. *Under the assumptions* (2.13) *and* (2.14)*, for all but possibly a discrete set of frequencies ω, the problem* (2.34)*,* (2.37)*,* (2.38) *admits a unique solution $v_\alpha \in W^{2,p}(\Omega)$ for $1 < p < \infty$, and the upper bound of its $W^{2,p}$ norm depends on $||\chi^\alpha_{jl}||_{L^\infty(\Omega)}$, $||u_\alpha||_{C^{1,\sigma}(\overline{\Omega_0})}$, and p.*

The proof may be given by combining the regularity results of Theorem 3.3 and the standard elliptic regularity results [9].

Acknowledgments. We thank Professor Avner Friedman for informing us the paper [6]. We also thank the referee and editor for useful comments.

A SEMILINEAR DIRAC EQUATION IN $H^s(\mathbf{R}^3)$ FOR $s > 1$[*]

M. ESCOBEDO[†] AND L. VEGA[†]

Abstract. Local and global well-posedness for the Cauchy problem associated with the nonlinear Dirac equation

$$i\frac{\partial\psi}{\partial t} + i\alpha\cdot\nabla\psi - m\beta\psi + G(\psi) = 0 \quad \text{in } \mathbf{R}^4$$

are studied in the Sobolev spaces H^s. For regular enough covariant nonlinearities that homogeneous of degree $p \geq 3$, local well-posedness in H^s is proved for $s > \frac{3}{2} - \frac{1}{p-1}$ when p is an odd integer and for $\frac{3}{2} - \frac{1}{p-1} < s < \frac{p-1}{2}$ when p is not an odd integer. If $p > 3$, global well-posedness for small initial data in $H^{s(p)}$, $s(p) = \frac{3}{2} - \frac{1}{p-1}$, is also proved. Local and global well-posedness of the Cauchy problem for the nonlinear Klein–Gordon and wave equations are also considered.

Key words. Dirac equation, well-posedness, Sobolev spaces

Introduction. In this paper, we consider the nonlinear Dirac equation

$$i\frac{\partial\psi}{\partial t} + i\alpha\cdot\nabla\psi - m\beta\psi + G(\psi) = 0 \quad \text{in } \mathbf{R}^4 \tag{0.1}$$

with the following notation:

(i) The unknown ψ is a function from $\mathbf{R}^4$ to $\mathbf{C}^4$ of the variables $(x,t) \in \mathbf{R}^4$ with $x = (x_1, x_2, x_3) \in \mathbf{R}^3$.

(ii)

$$\alpha\cdot\nabla\psi = \sum_{j=1}^{3} \alpha_j \frac{\partial\psi}{\partial x_j},$$

where $(\alpha_j)_{j=1}^3$ are 4×4 matrices defined by

$$\alpha_k = \begin{pmatrix} 0 & \sigma^k \\ \sigma^k & 0 \end{pmatrix}, \quad k = 1,2,3,$$

with

$$\sigma^1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad \sigma^2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \qquad \sigma^3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

(iii) m is a positive real number and β is the 4×4 matrix

$$\beta = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}.$$

Notice that

$$\alpha_i\alpha_j + \alpha_j\alpha_i = 2\delta_{ij}I,$$

$$\alpha_i\beta + \beta\alpha_i = 0, \qquad \beta^2 = I.$$

(iv) $G(\cdot)$ is a nonlinear function from $\mathbf{C}^4$ to $\mathbf{C}^4$.

As a simple example of nonlinearity, one can consider $G(u) = |u|^{p-1}u$, where $|\cdot|$ denotes the norm in $\mathbf{C}^4$, or, more generally, $G = (g_1, g_2, g_3, g_4)$, where each of the g_i's is a polynomial in all the components u_j of u. Nevertheless, the more interesting nonlinearities must present some particular structure in order for the equation to be invariant by the Lorentz transformations. These are the so-called covariant nonlinearities. The simplest examples are

$$G(\psi) = |\langle \beta\psi, \psi\rangle|^{\frac{p-1}{2}} \beta\psi + a|\langle \beta\psi, \alpha_5\psi\rangle|^{\frac{p-1}{2}} \alpha_5\beta\psi \quad \text{for } p \geq 1, \tag{0.2}$$

where $a \in \mathbf{C}$, $\alpha_5 = \alpha_1\alpha_2\alpha_3$, and $\langle\, ,\rangle$ denotes the Hermitian product in $\mathbf{C}^4$. The nonlinear Dirac equation has been widely used to build relativistic models of extended particles and extensively studied in the physics literature, in particular, the cubic case $p = 3$ (cf. Finkelstein et al. [8], Rañada [12], Soler [14], and Wakano [16]). Observe that the quantity $\langle\beta\psi, \psi\rangle$ has no definite sign since

$$\langle\beta\psi, \psi\rangle = \psi_1^2 + \psi_2^2 - \psi_3^2 - \psi_4^2.$$

This makes the covariant nonlinearity $G(\psi)$ defined in (0.2) less regular than the noncovariant nonlinearity with the same homogeneity $J(\psi) = |\psi|^{p-1}\psi$. For instance, if $p = 4$, $G(z)$ has less than $\frac{3}{2}$ derivatives in L^∞. We are interested in the Cauchy problem associated with (0.1),

$$\begin{cases} i\dfrac{\partial\psi}{\partial t} + i\alpha\cdot\nabla\psi - m\beta\psi + G(\psi) = 0 & \text{in } \mathbf{R}^4, \\ \psi(x,0) = \psi_0 & \text{in } \mathbf{R}^3, \end{cases} \tag{0.3}$$

in particular, the local and global well-posedness of (0.3) under the weakest possible regularity assumptions. This problem has previously been considered by several authors for different types of nonlinearities. As far as we know, the first well-known result was given by Reed in [13]. He assumed that the nonlinearity $G = (g_1, g_2, g_3, g_4)$ is such that each of the g_i's is a polynomial in all the components u_i, each of whose terms has order p with $p \geq 4$. Then he proved that for all initial data ψ_0 in $H^s(\mathbf{R}^3, \mathbf{C}^4)$ with $s > 3$ small enough, problem (0.3) has a unique solution in $\mathbf{C}(\mathbf{R}, H^3(\mathbf{R}^3, \mathbf{C}^4)) \cap \mathbf{C}^1(\mathbf{R}, H^2(\mathbf{R}^3, \mathbf{C}^4))$ such that its $L^\infty(\mathbf{R}^3, \mathbf{C}^4)$ norm decays in time like $(1+t)^{\frac{3}{2}}$. This result was improved by Dias and Figuera in [5]. They first showed the same global existence result under similar assumptions on G but for $p = 3$ and $s > 2$. Moreover, they proved a global existence result for small initial data in $H^{2+\varepsilon}$ for any $\varepsilon > 0$ and for the cubic covariant nonlinearity (0.2) with $a = 0$. They also obtained an estimate for the decay rate of the $L^\infty(\mathbf{R}^3, \mathbf{C}^4)$ norm as t goes to ∞. Later, in [10], Najman showed in particular the existence of a local solution in the cubic case for any initial data in $H^2(\mathbf{R}^N, \mathbf{C}^4)$. All of these results were far from optimal from the point of view of the local or global existence of solutions. Indeed, as is the case for the Schrödinger, Klein–Gordon, and heat equations, one would expect the following situation. Given an homogeneous nonlinearity G of degree p, there is an exponent $s(p)$ such that, on one hand, the Cauchy problem (0.3) is globally well posed in $H^{s(p)}(\mathbf{R}^3)$ for initial data small enough in the $H^{s(p)}$ norm. On the other hand, the Cauchy problem is locally well posed for any initial data in $H^s(\mathbf{R}^3)$ for $s \geq s(p)$. The value of that critical exponent $s(p)$ is given by the homogeneity of the Cauchy problem and can generally be obtained by scaling arguments.

For instance, let us consider the problem of the existence of solutions to

$$(\mathcal{P})\begin{cases} i\dfrac{\partial\psi}{\partial t}+i\alpha\cdot\nabla\psi+G(\psi)=0 \quad \text{in } \mathbf{R}^4,\\ \psi(x,0)=\psi_0 \quad \text{in } \mathbf{R}^3\end{cases}$$

with $\psi_0\in H^s(\mathbf{R}^3)$. We scale the unknown function ψ in the form

$$\forall\lambda>0,\,\forall t\in\mathbf{R},\,\forall x\in\mathbf{R}^3,\quad \psi_\lambda(t,x)=\lambda^\gamma\psi(\lambda t,\lambda x)$$

with $\gamma+s-\frac{3}{2}=0$ in such a way that, for all $\lambda>0$,

$$||\lambda^\gamma\psi_0(\lambda\cdot)||_{H^s}=\lambda^{-s}||\psi_0||_{L^2}+||\psi_0||_{\dot H^s},$$

where $\dot H^s$ is the homogeneous H^s space defined at the end of this section. Our initial problem is then equivalent to the local existence for each of the following problems:

$$(\mathcal{P}_\lambda)\begin{cases} i\dfrac{\partial\psi_\lambda}{\partial t}+i\alpha\cdot\nabla\psi_\lambda+\lambda^{(s-\frac{3}{2})(p-1)+1}G(\psi_\lambda)=0 \quad \text{in } \mathbf{R}^4,\\ \psi_l(x,0)=\lambda^\gamma\psi_0(\lambda x) \quad \text{in } \mathbf{R}^3.\end{cases}$$

Observe that, at least formally, the smaller $\lambda^{(s-\frac{3}{2})(p-1)+1}$ is, the closer the equation in $(\mathcal{P}_\lambda)$ is to the linear Dirac equation, and hence the easier it should be to find a solution of the Cauchy problem for ψ_λ in H^s and the larger the existence time of that solution should be. However, since on the other hand, the existence time of ψ_λ is an increasing function of λ, the exponent $(s-\frac{3}{2})(p-1)+1$ must be positive or, equivalently,

$$s>\frac{3}{2}-\frac{1}{p-1}.$$

We prove in Theorems I and II below that the value $\frac{3}{2}-\frac{1}{p-1}$ is actually the critical exponent as far as local and global existence are concerned. If we consider the Dirac equation with mass, $m\neq 0$, the same argument can be made if we also scale the mass from m to λm by using Sobolev spaces defined in a slightly different way with a suitable dependence on m.

If the nonlinearity G is regular enough, the local existence in $H^s(\mathbf{R}^N,\mathbf{C}^4)$ for $s>\frac{3}{2}$ is easy to prove using the Haussdorf–Young inequalities (see Lemma 1.3 below) and the Sobolev embedding $H^s(\mathbf{R}^3,\mathbf{C}^4)\subset L^\infty(\mathbf{R}^3,\mathbf{C}^4)$, which holds when $s>\frac{3}{2}$. (Of course, this will not give any decay-rate estimate on $L^\infty(\mathbf{R}^N,\mathbf{C}^4)$ as $t\to\infty$.) As we stated before, this regularity is too high for even covariant nonlinearities. On the other hand, notice that the critical value for s is $\frac{3}{2}-\frac{1}{p-1}$ and therefore smaller than $\frac{3}{2}$. This problem was partially solved in the papers of Reed [13], Dias and Figueira [5], and Moreau [9] by working in spaces involving precise decay rates in time of the spatial Sobolev norms and using the Hausdorff–Young-type inequalities of the linear Dirac group.

Here we use a slightly different argument and obtain local and global solutions under weaker regularity asumptions than in the previous works. As we will see, these are optimal in the case where $p>3$ and, except in the critical case, for $p=3$. This approach is similar to the one used by Cazenave and Weissler [4] for the Schrödinger equation or by Weissler [17] for parabolic equations. Our local results are equivalent to those obtained by Ponce and Sideris in [11] for the nonlinear wave equation. Moreover, the global results for small initial data are new even in that setting. The key idea is to obtain new sharp estimates in $L^{p-1}(\mathbf{R}, L^\infty(\mathbf{R}^N))$ for $p > 3$ (see Theorems 1.5 and 4.2). In order to state our results, let us define, for every $p \geq 1$,

$$s(p) = \max\left\{1, \frac{3}{2} - \frac{1}{p-1}\right\}. \tag{0.4}$$

Observe that if $s(p) < s$, then $\frac{1}{p-1} > \frac{3-2s}{2}$.

Theorem I. *Suppose that $G(u)$ is given by (0.2) for $p \geq 3$. Consider s such that*

$$\begin{cases} s(p) < s < \dfrac{p-1}{2} & \text{if } p > 3 \text{ and is not an odd integer,} \\ s(p) < s & \text{if } p \geq 3 \text{ is an odd integer} \end{cases} \tag{0.5}$$

and let $\gamma > 0$ be such that $\frac{1}{\gamma} \in (\frac{3-2s}{2}, \frac{1}{p-1})$. Then for every $\psi_0 \in H^s(\mathbf{R}^3, \mathbf{C}^4)$, there is a $T^* = T^*(||\psi_0||_{H^s}) > 0$ and a solution ψ to (0.3) such that

$$u \in \mathbf{C}((-T^*, T^*); H^s(\mathbf{R}^3, \mathbf{C}^4)) \cap \mathbf{C}^1((-T^*, T^*); L^2(\mathbf{R}^3, \mathbf{C}^4))$$
$$\cap L^\gamma_{\text{loc}}((-T^*, T^*); L^\infty(\mathbf{R}^3)).$$

Moreover,

(i) *this solution is unique in $L^\infty((-T, T); H^s(\mathbf{R}^3, \mathbf{C}^4)) \cap L^\gamma((-T, T); L^\infty(\mathbf{R}^3))$ for every $T < T^*$;*

(ii) *if $T^* < \infty$, then $||\psi||_{L^\gamma((-T^*,T^*);L^\infty(\mathbf{R}^3))} + ||\psi||_{L^\infty((-T^*,T^*);H^s(\mathbf{R}^3))} = \infty$;*

(iii) *there are a $T \equiv T(||\psi_0||_{H^s}) < T^*(||\psi_0||_{H^s})$ and a neighborhood V of ψ_0 in $H^s(\mathbf{R}^3, \mathbf{C}^4)$ such that for all $0 \leq s' < s$, the map $\psi_0 \longrightarrow \psi(\cdot)$ is continuous from V to $\mathbf{C}((-T, T); H^{s'}(\mathbf{R}^3, \mathbf{C}^4))$.*

Theorem II. *Suppose that G is given by (0.2), $p > 3$, and $s(p) = \frac{3}{2} - \frac{1}{p-1}$. Then for every $\psi_0 \in H^{s(p)}(\mathbf{R}^3, \mathbf{C}^4)$, there are a $T^* = T^*(\psi_0) > 0$ and a solution ψ to (0.3) such that*

$$\psi \in \mathbf{C}((-T^*, T^*); H^{s(p)}(\mathbf{R}^3, \mathbf{C}^4)) \cap \mathbf{C}^1((-T^*, T^*); L^2(\mathbf{R}^3, \mathbf{C}^4))$$
$$\cap L^{p-1}_{\text{loc}}((-T^*, T^*); L^\infty(\mathbf{R}^3)).$$

Moreover,

(i) *this solution is unique in $L^\infty((-T, T); H^{s(p)}(\mathbf{R}^3)) \cap L^{p-1}((-T, T; L^\infty(\mathbf{R}^3))$ for all $T < T^*$;*

(ii) *if $||\psi_0||_{H^{s(p)}(\mathbf{R}^3,\mathbf{C}^4)}$ is suficiently small, then $T^* = \infty$ and*

$$\psi \in L^\infty((-\infty, \infty); H^{s(p)}(\mathbf{R}^3)) \cap L^{p-1}(\mathbf{R}; L^\infty(\mathbf{R}^3)).$$

In this case,

$$\lim_{t \to \pm\infty} ||\psi(t) - W(t)\phi_\pm||_{H^{s(p)}(\mathbf{R}^3)} = 0,$$

where $\{W(t)\}_{t>0}$ stands for the linear Dirac group, $\phi_\pm \in H^{s(p)}(\mathbf{R}^3)$, and

$$\begin{cases} \phi_+ = \psi_0 - i\displaystyle\int_0^\infty W(-\tau)G(\psi)(\tau)d\tau, \\ \phi_- = \psi_0 - i\displaystyle\int_{-\infty}^0 W(-\tau)G(\psi)(\tau)d\tau; \end{cases} \tag{0.6}$$

(iii) *if* $T^* < \infty$*, then* $||\psi||_{L^{p-1}((-T^*,T^*);L^\infty(\mathbf{R}^3))} + ||\psi||_{L^\infty((-T^*,T^*);H^{s(p)}(\mathbf{R}^3))} = \infty$;

(iv) *there are a* $T \equiv T(\psi_0) < T^*(\psi_0)$ *and a neighborhood* V *of* ψ_0 *in* $H^{s(p)}(\mathbf{R}^3, \mathbf{C}^4)$ *such that the map* $\psi_0 \longrightarrow \psi$ *is continuous from* V *to* $\mathbf{C}((-T,T); H^{s'}(\mathbf{R}^3, \mathbf{C}^4))$ *for all* s' *in* $(0, s(p))$*. Finally, if* $||\psi_0||_{H^{s(p)}}$ *is small enough, this is true for* $T = \infty$*.*

Remark 1. Theorem I is true whenever the nonlinearity G satisfies $G(0) = 0$ and is in the Sobolev space $W^{s',\infty}(\mathbf{C}^4, \mathbf{C}^4)$ for some $s' > s$, i.e.,

(a) $d^k G \in L^\infty_{\mathrm{loc}}(\mathbf{C}^4, \mathbf{C}^4)$ for $k = 1, \ldots, [s']$, where $[s']$ denotes the integer part of s' and $d^k G$ denotes the kth order differential of G, and

(b) if we set $m = [s']$, then for every $R > 0$,

$$\sup_{|\xi|\le 1, |\zeta| \le 1} \frac{|d^m G(\xi) - d^m(\zeta)|}{|\xi - \zeta|^{s'-m}} = C_R < \infty.$$

On the other hand, Theorem II is true for every nonlinearity G satisfying (a) and (b) that is homogeneous of degree p. Moreover, the same arguments prove that problem (0.3) is globally well posed in $H^1(\mathbf{R}^3)$ for small initial datas if the nonlinearity G is homogeneous of degree $p = 2$ and belongs to $W^{s',\infty}(\mathbf{C}^4, \mathbf{C}^4)$ for some $s' > 1$.

Nevertheless, we observe that there exist only two possibilities in order for a function like $|\langle \beta u, u\rangle|^{\frac{p-1}{2}} \beta u$ to satisfy (a) and (b):

- either p is an odd integer, and then the function $|\langle \beta z, z\rangle|^{\frac{p-1}{2}} \beta z$ is in $\mathbf{C}^\infty$, or
- p is not an odd integer, and then it must be such that $\frac{p-1}{2} > s$.

Remark 2. When $p = 3$, i.e., in the cubic case, Theorem I shows the local existence in $H^s(\mathbf{R}^3, \mathbf{C}^4)$ for all $s > 1$. The local or global existence for the cubic case in $H^1(\mathbf{R}^3, \mathbf{C}^4)$ remains open. On the other hand, Theorem II needs $p > 3$, and therefore we cannot prove global existence, even for small initial data, for the cubic case.

Remark 3. The fact (stated in Theorems I(iii) and II(iv)) that the map $\psi_0 \longrightarrow \psi$ is, in general, only continuous with values in $\mathbf{C}((-T,T); H^{s'}(\mathbf{R}^3, \mathbf{C}^4))$ for all s' in $(0, s)$ and not in $\mathbf{C}((-T,T); H^s(\mathbf{R}^3, \mathbf{C}^4))$ is due to the lack of regularity of the general nonlinearities $G(\cdot)$ that we consider. It is nevertheless easy to check that if the nonlinearity G is regular enough, the maps $\psi_0 \longrightarrow \psi$ defined in Theorems I(iii) and II(iv) are Lipschitz from V into $\mathbf{C}((-T,T); H^s(\mathbf{R}^3, \mathbf{C}^4)) \cap L^\gamma((-T,T), L^\infty(\mathbf{R}^3)$ and $\mathbf{C}((-T,T); H^{s(p)}(\mathbf{R}^3, \mathbf{C}^4)) \cap L^{p-1}((-T,T), L^\infty(\mathbf{R}^3)$, respectively (see Remark 9 in section 3 below).

Remark 4. The size condition on the initial data in Theorem II(ii) is necessary. This follows in particular from the existence results of localized solutions to (0.1) due to Cazenave and Vazquez [3]. These authors proved the existence of solutions of the form $\psi(t,x) = \exp(-i\omega t)\phi(x)$ for any $\omega \in (0, m)$, where $\phi \in \mathbf{C}^1(\mathbf{R}^3, \mathbf{C}^4)$ is such that ϕ and $\nabla\phi$ have an exponential decay as $|x| \to \infty$ (see also Balabane et al. [1]). It is clear that these localized solutions do not belong to the space $L^{p-1}(\mathbf{R}; L^\infty(\mathbf{R}^3))$.

Remark 5. Equation (0.1) has a natural energy given by

$$E(\psi) = -\frac{i}{2} \int_{\mathbf{R}^3} \langle \alpha \cdot \nabla\psi, \beta\psi\rangle dx + \frac{m}{2} \int_{\mathbf{R}^3} \langle \psi, \beta\psi\rangle dx - \int_{\mathbf{R}^3} H(u) dx,$$

where $\nabla H(\psi) = G(\psi)$. This energy E is well defined and of class C^2 on the space $H^{\frac{1}{2}}(\mathbf{R}^3, \mathbf{C}^4)$. It was recently proved by Esteban and Sere in [7] that if $H \in \mathbf{C}^2(\mathbf{R}, \mathbf{R})$, $H(0) = 0$, and for some $\theta > 1$, $H'(x) \ge \theta H(x)$, then E has infinitely many critical points in $H^{\frac{1}{2}}(\mathbf{R}^3, \mathbf{C}^4)$. That gives infinitely many solutions of (0.1) which actually belong to $\bigcap_{2\le q<\infty} W^{1,q}(\mathbf{R}^3, \mathbf{C}^4)$. The space $H^{\frac{1}{2}}(\mathbf{R}^3, \mathbf{C}^4)$ is then the natural one for studying the steady states of (0.1). Nevertheless, it has not yet been possible to use any conservation law to obtain global solutions of (0.1).

In particular, the proof of these results requires estimates on the linear operator

$$A = -i\alpha \cdot \nabla + m\beta. \tag{0.7}$$

This is a self-adjoint operator in $L^2(\mathbf{R}^3, \mathbf{C}^4)$ with domain $H^1(\mathbf{R}^3, \mathbf{C}^4)$. Then iA generates a strongly continuous unitary group in $H^s(\mathbf{R}^3, \mathbf{C}^4)$, which we will denote $(W(t))_{t\in\mathbf{R}}$. Some of the estimates on $W(t)$ given in section 1 have already been used in the study of (0.3) (see, for instance, Dias and Figueira [5], Moreau [9], and Reed [13]).

Remark 6. As we shall see in section 4, similar arguments can be used to study the nonlinear Klein–Gordon and wave equations to obtain results on local and global existence. The estimate in $L^{p-1}(\mathbf{R}; L^\infty(\mathbf{R}^3))$ allows us to prove global existence for small initial data for the critical case established by Ponce and Sideris [11].

Throughout this paper, we will use the following notation:

1. The spaces $L^r(\mathbf{R}^3, \mathbf{C}^4)$ and $H^s(\mathbf{R}^3, \mathbf{C}^4)$ will always be denoted $L^r(\mathbf{R}^3)$ and $H^s(\mathbf{R}^3)$, respectively. Their norms will be denoted $||\cdot||_r$ and $||\cdot||_{H^s}$, respectively.

2. In section 2, we use the Besov spaces $B^s_{p,q}(\mathbf{R}^3, \mathbf{C}^4)$ and the homogeneous Besov spaces $\dot{B}^s_{p,q}(\mathbf{R}^3, \mathbf{C}^4)$ for $s > 0$, $p \geq 1$, and $q \geq 1$ reals. They will be denoted $B^s_{p,q}(\mathbf{R}^3)$ and $\dot{B}^s_{p,q}(\mathbf{R}^3)$. We refer the interested reader to the book of Triebel [15] for the definitions and main properties of these spaces. In particular, we will use the following quantities, which are proved to be equivalent to the usual norms (see [15, Theorem, p. 110]),

$$\begin{cases} ||\psi||_{B^s_{p,q}} = ||\psi||_p + ||\psi||_{\dot{B}^s_{p,q}}, \\ ||\psi||_{\dot{B}^s_{p,q}} = \left\{ \int_{\mathbf{R}^3} \dfrac{||\triangle^M_y \psi||^q_p}{|y|^{N+sq}} dy \right\}^{\frac{1}{q}}, \end{cases}$$

with the following notation: M is any integer such that $M > s$, $\triangle_y v(x) = v(x + \frac{y}{2}) - v(x - \frac{y}{2})$ for all $x \in \mathbf{R}^3$ and $y \in \mathbf{R}^3$, and $\triangle^{k+1}_y v \equiv \triangle_y(\triangle^k_y v)$ for all $k \geq 1$. (In the case where $p = q = 2$, this is a direct consequence of the Plancherel identity.)

3. We also use the functional space $L^{r_1}(\mathbf{R}; L^{r_2}(\mathbf{R}^3, \mathbf{C}^4))$ of functions ψ from $\mathbf{R}^4$ to $\mathbf{C}^4$ such that

$$||\psi||_{L^{r_1}(\mathbf{R}; L^{r_2}(\mathbf{R}^3))} \equiv \left\{ \int_{\mathbf{R}} \left(\int_{\mathbf{R}^3} |\psi(t,x)|^{r_2} dx \right)^{\frac{r_1}{r_2}} dt \right\}^{\frac{1}{r_1}} < \infty,$$

where $r_1 \geq 1$ and $r_2 \geq 1$ and where the quantity $||\psi||_{L^{r_1}(\mathbf{R}; L^{r_2}(\mathbf{R}^3))}$ defines a norm. This space will be denoted $L^{r_1}(\mathbf{R}; L^{r_2}(\mathbf{R}^3))$.

4. For $\theta > 0$ and ψ from $\mathbf{R}^4$ to $\mathbf{C}^4$, we denote by $D^\theta_x \psi$ the fractional derivative $(\widehat{D^\theta_x \psi})(\xi) = |\xi|^\theta \hat{\psi}(\xi)$. The homogeneous space $\dot{H}^s$ is defined as the set of measurable functions ψ such that $D^s_x \psi \in L^2$ and

$$||\psi||_{\dot{H}^s} \equiv ||D^s_x \psi||_{L^2}.$$

The rest of the paper is organized as follows. Section 1 covers linear estimates, section 2 covers nonlinear estimates, section 3 contains proof of our main results, and section 4 presents an extension to the Klein–Gordon and wave equations.

1. Linear estimates. Throughout this section, we denote by $\{\psi_j\}_{j\in\mathbf{Z}}$ a smooth partition of unity such that

$$\psi_j(|\xi|) = \psi\left(\frac{|\xi|}{2^j}\right) \quad \text{with supp}\psi \subset (1,2),$$

and we set $\phi_j = \psi_j^2$. For every sufficiently regular function f, we define $S_j f$ and $\tilde{S}_j f$, respectively, by

$$\begin{aligned} \widehat{\left(S_j f\right)}(\xi) &= \phi_j(|\xi|)\hat{f}(|\xi|), \\ \widehat{\left(\tilde{S}_j f\right)}(\xi) &= \psi_j(|\xi|)\hat{f}(|\xi|). \end{aligned}$$

Finally, we define the operator $e^{it\sqrt{m^2-\triangle}}$ acting on a sufficiently regular function f by

$$\mathcal{F}\left(e^{it\sqrt{m^2-\triangle}}f\right)(\xi) = e^{it\sqrt{m^2+|\xi|^2}}\hat{f}(\xi).$$

LEMMA 1.1. (a) *For all $m \geq 0$ and $t > 0$, let*

$$I_j(|x|,t,m) = \int_{\mathbf{R^3}} e^{ix\cdot\xi+it\sqrt{m^2+|\xi|^2}}\psi_j(|\xi|)d\xi \quad \forall x \in \mathbf{R}^3, \quad \forall \xi \in \mathbf{R}^3.$$

Then there is a positive constant C independent of j, t, m, and x such that for all j, t, m, and x,

$$|I_j(|x|,t,m)| \leq C\frac{2^j}{t}(2^{2j}+m^2)^{\frac{1}{2}}. \tag{1.1}$$

(b) *For every $2 \leq p < \infty$, there is a positive constant C_p independent of j, t, and m such that*

$$\begin{cases} \left\|S_j e^{it\sqrt{m^2-\triangle}}f\right\|_p \leq C|t|^{-\alpha(p)}\left\|D_x^{\alpha(p)}(m^2-\triangle)^{\frac{\alpha(p)}{2}}f\right\|_{p'}, \\ \alpha(p) = 2\left(\frac{1}{2}-\frac{1}{p}\right). \end{cases} \tag{1.2}$$

Proof. (a) By a change of variables, we trivially have

$$I_j(|x|,t,m) = \frac{1}{m^3}I_{j\lg_2 m}(|x|m, tm, 1),$$

where $\lg_2 m$ is the logatithm in base 2 of m. Hence we can restrict ourselves to the case where $1 \leq m \leq 2$. Using polar coordinates, we have

$$\begin{aligned} I_j(|x|,t,m) &= \int_0^\infty \psi_j(r)e^{it(m^2+r^2)^{\frac{1}{2}}}r^2\int_{\mathbf{S^2}} e^{ir|x|\cos\theta}\sin\theta\, d\theta \\ &= \int_0^\infty \psi_j(r)e^{it(m^2+r^2)^{\frac{1}{2}}}r\frac{\sin r|x|}{|x|}\,dr. \end{aligned}$$

We shall consider several different cases. First, assume that $|x| \leq 2^{-j+5}$. Then by integration by parts, we have

$$\begin{aligned} |I(|x|,t,m)| &= \left|\int_0^\infty \psi_j(r)\frac{\sin r|x|}{|x|}\frac{(m^2+r^2)^{\frac{1}{2}}}{itr}\frac{d}{dr}\left(e^{it(m^2+r^2)^{\frac{1}{2}}}\right)dr\right| \\ &\leq C\frac{2^j}{t}(2^{2j}+m^2)^{\frac{1}{2}}. \end{aligned}$$

Now consider $|x| > 2^{-j+5}$ and $|t\theta_m - |x|| < 3/4t\theta_m$, where $\theta_m = \sup_{2^j<r<2^{j+1}} r(m^2+r^2)^{-1/2}$. Hence $|x| > t\theta_m/4$, and the estimate immediately follows.

Finally, assume that $|x| > 2^{-j+5}$ and $|t\theta_m - |x|| \geq 3/4t\theta_m$. Then integration by parts gives us

$$\begin{aligned}\frac{1}{|x|}&\left|\int_0^\infty \psi_j(r)r\left(\tfrac{tr}{(m^2+r^2)^{1/2}} \pm |x|\right)^{-1} \tfrac{d}{dr}e^{i(t(m^2+r^2)^{\frac{1}{2}} \pm r|x|)}\,dr\right| \\ &\leq c\frac{2^j}{|x|}\sup_r\left(\frac{tr}{(m^2+r^2)^{\frac{1}{2}}} \pm |x|\right)^{-1} \\ &\leq c\frac{2^j}{|x|}(t\theta_m)^{-1} \leq c\frac{2^j}{t}(2^{2j}+m^2)^{-\frac{1}{2}}.\end{aligned}$$

(b) By definition,

$$\left|S_je^{it\sqrt{m^2-\triangle}}f\right| = \left|\int_{\mathbf{R^3}} e^{ix\cdot\xi+it\sqrt{m^2+|\xi|^2}}\phi_j(|\xi|)\hat{f}(\xi)d\xi\right|,$$

and then, using (a),

$$\left|S_je^{it\sqrt{m^2-\triangle}}f\right| \leq C||\psi_j\hat{f}||_\infty\frac{2^j(m^2+2^{2j})^{\frac{1}{2}}}{|t|} \leq C||\tilde{S}_jf||_{L^1}\frac{2^j(m^2+2^{2j})^{\frac{1}{2}}}{|t|},$$

where $\widehat{(\tilde{S}_jf)} = \psi_j\hat{f}$. Since by Plancherel's theorem we have

$$||S_je^{it\sqrt{m^2-\triangle}}f||_2 \leq C||\psi_j\hat{f}||_2,$$

by Riesz's interpolation theorem, we have, for every $2 \leq p < \infty$,

$$\begin{aligned}\left\|S_je^{it\sqrt{m^2-\triangle}}f\right\|_p &\leq C\left[\frac{2^j(m^2+2^{2j})^{\frac{1}{2}}}{|t|}\right]^{\alpha(p)}||\tilde{S}_jf||_{p'} \\ &\leq C|t|^{-\alpha(p)}\left\|D_x^{\alpha(p)}(m^2-\triangle)^{\frac{\alpha(p)}{2}}S_jf\right\|_{p'} \\ &\leq C|t|^{-\alpha(p)}\left\|D_x^{\alpha(p)}(m^2-\triangle)^{\frac{\alpha(p)}{2}}f\right\|_{p'}. \qquad \square\end{aligned}$$

LEMMA 1.2. *Let $\mathcal{K}_m(t)(f,g)$ be the solution of the initial-value problem (IVP)*

$$\text{(1.3)}\qquad \begin{cases} u_{tt} - \triangle u + m^2u = 0, & x\in\mathbf{R}^3,\quad t\in\mathbf{R},\quad m\geq 0,\\ u(x,0) = f(x), & x\in\mathbf{R}^3,\\ u_t(x,0) = g(x), & x\in\mathbf{R}^3.\end{cases}$$

Then for $2 \leq p < \infty$,

$$\text{(1.4)}\qquad \begin{aligned}||\mathcal{K}_m(t)(f,g)||_{L^p} \leq C|t|^{-\alpha(p)}\Big(&\left\|D_x^{\alpha(p)}(m^2-\Delta)^{\frac{\alpha(p)}{2}}f\right\|_{L^{p'}} \\ &+ \left\|D_x^{\alpha(p)}(m^2-\Delta)^{\frac{\alpha(p)}{2}-1}g\right\|_{L^{p'}}\Big),\end{aligned}$$

where $\alpha(p) = 2(\frac{1}{2}-\frac{1}{p})$ and C is a positive constant independent of m and t.

Proof. By the Littlewood–Paley theorem, we have, for $p \geq 2$,

$$\begin{aligned} ||\mathcal{K}_m(t)(f,g)||_{L^p} &\leq \left\| \left(\sum_{j=-\infty}^{\infty} |S_j \mathcal{K}_m(t)(f,g)|^2 \right)^{\frac{1}{2}} \right\|_{L^p} \\ &\leq \left(\sum_{j=-\infty}^{\infty} ||S_j \mathcal{K}_m(t)(f,g)||_{L^p}^2 \right)^{\frac{1}{2}}. \end{aligned} \tag{1.5}$$

Now using Lemma 1.1(b),

$$\begin{aligned} ||S_j \mathcal{K}_m(t)(f,g)||_{L^p} \leq & \, c|t|^{-\alpha(p)} \left(\left\| D_x^{\alpha(p)} (m^2 - \Delta)^{\frac{\alpha(p)}{2}} \tilde{S}_j f \right\|_{L^{p'}} \right. \\ & \left. + \left\| D_x^{\alpha(p)} (m^2 - \Delta)^{\frac{\alpha(p)}{2-1}} \tilde{S}_j g \right\|_{L^{p'}} \right). \end{aligned} \tag{1.6}$$

Then using (1.5), (1.6), and the fact that $p' \leq 2$,

$$\begin{aligned} ||\mathcal{K}_m(t)(f,g)||_{L^p} \leq c|t|^{-\alpha(p)} & \left(\left\| \left(\sum_j \left| \tilde{S}_j \left(D_x^{\alpha(p)} (m^2 - \Delta)^{\frac{\alpha(p)}{2}} f \right) \right|^2 \right)^{\frac{1}{2}} \right\|_{L^{p'}} \right. \\ & \left. + \left\| \left(\sum_j |\tilde{S}_j (D_x^{\alpha(p)} (m^2 - \Delta)^{\alpha(p)/2-1} g)|^2 \right)^{\frac{1}{2}} \right\|_{L^{p'}} \right). \end{aligned}$$

Using the Littlewood–Paley theorem again, we obtain the desired result. □

LEMMA 1.3. *Let $W(t)\psi_0$ be the solution of*

$$\begin{cases} i\dfrac{\partial \psi}{\partial t} + i\alpha \cdot \nabla \psi - m\beta\psi = 0 \quad \textit{in } \mathbf{R}^4, \\ \psi(x,0) = \psi_0 \quad \textit{in } \mathbf{R}^3. \end{cases} \tag{1.7}$$

Then for $1 < p \leq 2$, there is a positive constant C such that

$$||W(t)\psi_0||_{L^p} \leq C|t|^{-\alpha(p)} ||(D_x^{\alpha(p)} (m^2 - \Delta)^{\frac{\alpha(p)}{2}} \psi_0||_{Lp'},$$

with $\alpha(p) = 2(\frac{1}{2} - \frac{1}{p})$.

Proof. It is well known that $W(t)\psi_0$ solves the IVP (1.3) with $f = \psi_0$ and $g = -\alpha \cdot \nabla\psi_0 - im\beta\psi_0$. Therefore, the desired result follows from Lemma 1.2. □

LEMMA 1.4. *Let $a > 1$, $b > 1$, $\alpha \in (0, N)$, and $\beta \in (0, N)$ such that*

$$\left(\frac{\beta}{N} - \frac{1}{b} \right) \left(\frac{1}{a} - \frac{\alpha}{N} \right) > 0.$$

Then there is a positive constant C such that for every $u \in C^\infty$ tending to zero as $|x|$ goes to ∞, we have

$$||u||_{L^\infty(\mathbf{R}^N)} \leq C||D^\alpha u||_{L^a(\mathbf{R}^N)}^\theta ||D^\beta u||_{L^b(\mathbf{R}^N)}^{1-\theta}, \tag{1.8}$$

with

$$\theta = \frac{\dfrac{\beta}{N} - \dfrac{1}{b}}{\left(\dfrac{\beta}{N} - \dfrac{1}{b} \right) + \left(\dfrac{1}{a} - \dfrac{\alpha}{N} \right)}.$$

Proof. We first suppose that $u \in \mathcal{S}(\mathbf{R}^N)$. Assume first that $\frac{1}{a} - \frac{\alpha}{N} < 0$ and set $f = D_x^\alpha u$. Then for any $\epsilon > 0$, we have

$$\begin{aligned} u = I^\alpha f &= \int f(x-y)\varphi_1\left(\frac{|y|}{\epsilon}\right)\frac{dy}{|y|^{N-\alpha}} + \epsilon^{\alpha-N}\int f(x-y)\varphi_2\left(\frac{|y|}{\epsilon}\right)^{\alpha-N} dy \\ &= I + II, \end{aligned}$$

where $\varphi_1 \in C_0^\infty(\mathbf{R})$, $\varphi_1(r) = 1$ if $|r| \le \frac{1}{2}$, $\varphi_1(r) = 0$ if $r > 1$, and $\varphi_1 + \varphi_2 = 1$.

Hence Hölder's inequality gives

$$|I| \le C\epsilon^{\alpha - N\left(1-\frac{1}{a'}\right)}||f||_{L^a} = c\epsilon^{\alpha-\frac{N}{a}}||f||_{L^a}. \tag{1.9}$$

Set $\omega_\alpha(y) = \varphi_2(|y|)|y|^{\alpha-N}$. Hence $\hat{\omega}_\alpha(\xi) = |\xi|^{-\alpha}\psi(\xi)$ with $\psi \in \mathcal{S}(\mathbf{R^N})$. Therefore, if $\omega_\alpha^\epsilon(y) = \omega_\alpha(y/\epsilon)$, then

$$(D^{\alpha-\beta}\omega_\alpha^\epsilon)\hat{}(\xi) = \epsilon^{N+\beta-\alpha}(\epsilon|\xi|)^{-\beta}\psi(\epsilon\xi).$$

Hence

$$|D^{\alpha-\beta}\omega_\alpha^\epsilon| \le C\epsilon^{\beta-\alpha}\left(1 + \frac{|x|}{\epsilon}\right)^{\beta-N}. \tag{1.10}$$

Now

$$\begin{aligned} |II| &= \epsilon^{\alpha-N}\int D^{\beta-\alpha}fD^{\alpha-\beta}\omega_\alpha^\epsilon \\ &\le \epsilon^{\alpha-N}||D^{\beta-\alpha}f||_{L^b}||D^{\alpha-\beta}\omega_\alpha^\epsilon||_{L^{b'}} \le C\epsilon^{\beta-\frac{N}{b}}||D^{\beta-\alpha}f||_{L^b}, \end{aligned} \tag{1.11}$$

where the last inequality follows from (1.10). Choosing ϵ properly, we obtain (1.8) from (1.9) and (1.11).

If $\frac{1}{a} - \frac{\alpha}{N} > 0$, then by hypothesis, $\frac{1}{b} - \frac{\beta}{N} < 0$ and we can argue as above, using $g = D^\beta u$ instead of f.

The general case for $u \in C^\infty$ tending to zero as $|x|$ goes to ∞ follows by density. □

Theorem 1.5 (Strichartz-type estimates).

(i) *Given* $2 \le p < \infty$, $\frac{1}{q} + \frac{1}{p} = \frac{1}{2}$, *there is a positive constant* C *such that for all* $\psi_0 \in H^{\alpha(p)}(\mathbf{R}^3)$,

$$||W(\cdot)\psi_0||_{L^q(\mathbf{R};L^p(\mathbf{R}^3))} < C||D_x^{\frac{\alpha(p)}{2}}(m^2 - \triangle)^{\frac{\alpha(p)}{4}}\psi_0||_{L^2(\mathbf{R}^3)}, \tag{1.12}$$

where

$$\alpha(p) = 2\left(\frac{1}{2} - \frac{1}{p}\right). \tag{1.13}$$

(ii) *Let* s *and* p *satisfy* (0.5). *Then for all* $\gamma > p - 1$ *such that* $\frac{1}{\gamma} \in (\frac{3-2s}{2}, \frac{1}{p-1})$ *and all* $r' > \gamma$ *such that* $\frac{1}{r'} \in (\frac{3-2s}{2}, \frac{1}{\gamma})$, *there is a positive constant* C *such that for every* $T > 0$ *and all* $\psi_0 \in H^s(\mathbf{R}^3)$,

$$||W(.)\psi_0||_{L^\gamma((-T,T);L^\infty(\mathbf{R}^3))} \le C(1+m)^{\frac{1}{r'}}T^{\frac{1}{\gamma}-\frac{1}{r'}}||\psi_0||_{H^s}. \tag{1.14a}$$

(iii) *Let $p > 3$. Then there is a positive constant C such that*
(1.14b)
$$\forall \psi_0 \in H^{s(p)}(\mathbf{R}^3), \quad ||W(\cdot)\psi_0||_{L^{p-1}((-\infty,\infty);L^\infty(\mathbf{R}^3))} \le C(1+m)^{\frac{1}{p-1}}||\psi_0||_{H^{s(p)}}.$$

Proof. Part (i) follows from standard arguments and is already known; see Brenner [2] and Moreau [9]. Therefore, we only sketch its proof. By looking at the adjoint of the operator $\psi_0 \mapsto W(\cdot)\psi_0$, it is equivalent for us to prove

$$\left\| \int_{-\infty}^{\infty} D^{-\alpha(p)/2}(m^2-\Delta)^{-\alpha(p)/4}W(-t)F(\cdot,t)\,dt \right\|_{L^2} \le C||F||_{L^{q'}(\mathbf{R};L^{p'}(\mathbf{R}^3))}. \tag{1.15}$$

However,

$$\left\| \int_{-\infty}^{\infty} D^{-\alpha(p)/2}(m^2-\Delta)^{-\alpha(p)/4}W(-t)F(x,t)\,dt \right\|_{L^2}^2$$
$$= \int_{-\infty}^{\infty}\int_{\mathbf{R^3}} \overline{F(x,t)} \int_{-\infty}^{\infty} D^{-\alpha(p)}(m^2-\Delta)^{-\alpha(p)/2}W(t-\tau)F(\cdot,\tau)\,d\tau)\,dxdt,$$

and therefore it suffices to prove that

$$\begin{aligned} &\left\| \int_{-\infty}^{\infty} D^{-\alpha(p)}(m^2-\Delta)^{-\alpha(p)/2}W(t-\tau)F(\cdot,\tau)\,d\tau \right\|_{L^q(\mathbf{R};L^p(\mathbf{R}^3))} \\ &\quad \le C||F||_{L^{q'}(\mathbf{R};L^{p'}(\mathbf{R}^3))}. \end{aligned} \tag{1.16}$$

Now by Minkowski's integral inequality and Lemma (1.3), the left-hand side of (1.16) is bounded by

$$C\left\| \int_{-\infty}^{\infty} \frac{d\tau}{|t-\tau|^{\alpha(p)}}\,||F(\cdot,\tau)||_{L_x^{p'}(\mathbf{R^3})} \right\|_{L_t^q}.$$

Then part (i) follows from the Hardy–Littlewood–Sobolev theorem with exponents $\frac{1}{q} = \frac{1}{q'} - (1-\alpha(p))$.

We now prove (ii). Choose $q > 1$ such that

$$2 - s < \frac{1}{q} < \frac{1}{2} + \frac{1}{p-1}$$

and $r > 1$ such that

$$\frac{1}{2} = \frac{1}{q} - \frac{1}{r'}.$$

Observe that

$$\frac{1}{r'} = \frac{1}{q} - \frac{1}{2} < \frac{1}{\gamma}$$

and therefore $r' > \gamma$. We now define

$$\varepsilon = s + \frac{1}{q} - 2,$$

from which we have

$$2 - \frac{1}{q} + \varepsilon \equiv \frac{3}{2} - \frac{1}{r'} + \varepsilon = s,$$

and we set $\theta = \frac{3}{q'} + \varepsilon$. We then have

$$\left(\int_{-T}^{T} ||W(t)\psi_0||_\infty^\gamma dt\right)^{\frac{1}{p-1}} \leq T^{\frac{1}{\gamma} - \frac{1}{r'}} \left(\int_{-T}^{T} ||W(t)\psi_0||_\infty^{r'} dt\right)^{\frac{1}{r'}}.$$

Using Sobolev's embedding since $q'\theta > 3$ and using estimate (i), we get

$$\begin{aligned}\left(\int_{-T}^{T} ||W(t)\psi_0||_\infty^{r'} dt\right)^{\frac{1}{r'}} &\leq C \left(\int_{-T}^{T} ||D_x^\theta W(t)\psi_0||_{q'}^{r'} dt\right)^{\frac{1}{r'}} \\ &\leq C(1+m)^{\frac{\alpha(q')}{2}} ||\psi_0||_{H^{\theta+\alpha(q')}}.\end{aligned}$$

By the choice of θ and the definition $\alpha(q') \equiv \frac{2}{r'}$, we have $\theta + \alpha(q') \equiv s$, and (ii) follows.

To prove (iii), suppose that $p > 3$ and $s = s(p)$. In this case we estimate the L^∞-norm using the Gagliardo–Nirenberg-type inequality given by Lemma 1.4 with exponents

$$\begin{aligned} &a = 2, \qquad \alpha = s(p) = \frac{3}{2} - \frac{1}{p-1}, \qquad \frac{1}{b} = \frac{1}{4} - \frac{1}{2(p-1)}, \\ &\beta = 1 - \frac{2}{p-1}, \qquad \theta = \frac{p-3}{p+1}, \qquad 1 - \theta = \frac{4}{p+1}, \end{aligned}$$

we obtain

$$\begin{aligned} &||W(t)\psi_0||_{L^{p-1}((\mathbf{R});L^\infty(\mathbf{R}^3))} \\ &\quad \leq C\left(\int_{-\infty}^{\infty} ||D_x^{s(p)}W(t)\psi_0||_{L^2}^{\theta(p-1)} ||D_x^\beta W(t)\psi_0||_{L^b}^{(1-\theta)(p-1)} dt\right)^{\frac{1}{p-1}} \\ &\quad \leq C||D_x^{s(p)}W(t)\psi_0||_{L^\infty((\mathbf{R});L^2)}^\theta \left(\int_{-\infty}^{\infty} ||D_x^\beta W(t)\psi_0||_{L^b}^{(1-\theta)(p-1)} dt\right)^{\frac{1}{p-1}}. \end{aligned}$$

We now observe that the pairs $(\infty, 2)$ and $((1-\theta)(p-1), b)$ are admissible exponents; in particular,

$$\frac{1}{(1-\theta)(p-1)} + \frac{1}{b} = \frac{p+1}{4(p-1)} + \frac{1}{4} - \frac{1}{2(p-1)} = \frac{1}{2}.$$

Therefore, by (i),

$$||D_x^{s(p)}W(t)\psi_0||_{L^\infty((\mathbf{R});L^2(\mathbf{R}^3))} \leq C||D_x^{s(p)}\psi_0||_{L^2(\mathbf{R}^3)} \leq C||\psi_0||_{H^{s(p)}},$$

where we have used $\alpha(2) = 0$, and

$$\begin{aligned}\left(\int_{-\infty}^{\infty} ||D_x^\beta W(t)\psi_0||_{L^b(\mathbf{R}^3)}^{(1-\theta)(p-1)} dt\right)^{\frac{1}{p-1}} &\leq C(1+m)^{\frac{(1-\theta)\alpha(b)}{2}} ||D_x^\beta \psi_0||_{H^{\alpha(b)}}^{1-\theta} \\ &\leq C(1+m)^{\frac{1}{p-1}} ||\psi_0||_{H^{s(p)}}^{1-\theta}\end{aligned}$$

since $\beta + \alpha(b) = s(p)$. The result follows since $\alpha(b) = \frac{1}{2} + \frac{1}{p-1}$. □

Remark 7. The restriction $p > 3$ in Theorems 1.5(ii) and II comes then from the use of Sobolev's embedding when $s > s(p)$ and the Gagliardo–Nirenberg inequality when $s = s(p)$.

2. Nonlinear estimates. This section is devoted to the proof of a kind of fractional chain rule on the Besov spaces $B^s_{p,q}(\mathbf{R}^3, \mathbf{C}^4)$. Let us recall here that on these spaces we use the norm

$$\begin{cases} ||\psi||_{B^s_{p,q}} = ||\psi||_p + ||\psi||_{\dot{B}^s_{p,q}}, \\ ||\psi||_{\dot{B}^s_{p,q}} = \left\{ \int_{\mathbf{R}^4} \frac{||\triangle^M_y \psi||^q_p}{|y|^{N+sq}} dy \right\}^{\frac{1}{q}} \end{cases}$$

for any integer $M > s$ and where $\triangle_y v(\cdot) = v(\cdot + \frac{y}{2}) - v(\cdot - \frac{y}{2})$. We are mainly interested in the application of Proposition 2.1 and Corollary 2.2 below to the case where $p = q = 2$. In this case, the Plancherel identity shows that $||\cdot||_{B^s_{p,q}}$ and $||\cdot||_{\dot{B}^s_{p,q}}$ are actually equivalent to the usual norms on $B^s_{p,q}$ and $\dot{B}^s_{p,q}$, respectively.

Proposition 2.1. *Let be $s > 1$ and $m = [s]$. Suppose that a given function ϕ belongs to $W^{s',\infty}_{\text{loc}}(\mathbf{C}^4, \mathbf{C}^4)$ for some $s' \in (s, [s]+1)$ and satisfies $\phi(0) = 0$. Then for any $\psi \in B^s_{p,q}(\mathbf{R}^3, \mathbf{C}^4) \cap L^\infty(\mathbf{R}^3, \mathbf{C}^4)$, $\phi(\psi) \in B^s_{p,q}(\mathbf{R}^3, \mathbf{C}^4)$ and, moreover,*

$$\begin{aligned} ||\phi(\psi)||_{B^s_{p,q}} \leq \sup_{|z| \leq ||\psi||_\infty} |d\phi(z)|||\psi||_p + \sum_{k=1}^{[s]} \sup_{|z| \leq ||\psi||_\infty} |d^k \phi(z)|||\psi||^{k-1}_\infty ||\psi||_{\dot{B}^s_{p,q}} \\ + C(||\psi||_\infty) ||\psi||_{\dot{B}^s_{p,q}} ||\psi||^{s'-1}_\infty, \end{aligned}$$

where for every $R > 0$, the constant C_R is defined by

$$C(R) = \sup_{|\xi| \leq R, |\zeta| \leq R} \frac{|d^m G(\xi) - d^m G(\zeta)|}{|\xi - \zeta|^{s'-m}} \tag{2.1}$$

and $d^k \phi$ is the differential of order k of ϕ.

Proof. This proposition is esentially proved in Escobedo [6]. For the sake of completeness, we will give the details of the proof for the case where $s \in (1, 2)$. The general case can easily be completed by using the results in [6].

First, since $\phi(0) = 0$,

$$||\phi(\psi)||_p \leq \sup_{|z| \leq ||\psi||_\infty} |d\phi(z)|||\psi||_p.$$

We now estimate $||\phi(\psi)||_{\dot{B}^s_{p,q}}$. For this observe that

$$\triangle^2_y \phi(\psi) = \triangle_y(\triangle_y \phi(\psi))$$

and then, for every $x \in \mathbf{R}^3$,

$$\begin{aligned} \triangle_y \phi(\psi)(x) &= \phi\left(\psi\left(x + \tfrac{y}{2}\right)\right) - \phi\left(\psi\left(x - \tfrac{y}{2}\right)\right) \\ &= \int_0^1 d\phi\left(\theta\psi\left(x + \frac{y}{2}\right) + (1 - \theta\psi\left(x - \frac{y}{2}\right)\right) \triangle_y \psi(x) d\theta, \end{aligned}$$

from which we have

$$\begin{aligned}\triangle_y^2\phi(\psi)(x) &= \int_0^1 \triangle_y\left[d\phi\left(\theta\psi\left(x+\frac{y}{2}\right)+(1-\theta)\psi\left(x-\frac{y}{2}\right)\right)\triangle_y\psi(x)\right]d\theta\\ &= \int_0^1 d\phi\left(\theta\psi\left(x+\frac{y}{2}\right)+(1-\theta)\psi\left(x-\frac{y}{2}\right)\right)\triangle_y^2\psi(x)d\theta\\ &\quad+\int_0^1 \triangle_y\left(d\phi\left(\theta\psi\left(x+\frac{y}{2}\right)+(1-\theta)\psi\left(x-\frac{y}{2}\right)\right)\right)\triangle_y\psi(x)d\theta\\ &\equiv I_1+I_2.\end{aligned}$$

First, we estimate I_1, which is the easiest. Indeed, since

$$|I_1| \le \sup_{|z|\le||\psi||_\infty} |d\phi(z)||\triangle_y^2\psi|,$$

we deduce

$$\left\{\int_{\mathbf{R}^4}\frac{||I_1||_p^q}{|y|^{N+sq}}dy\right\}^{\frac{1}{q}} \le \sup_{|z|\le||\psi||_\infty}|d\phi(z)|||\psi||_{\dot{B}^s_{p,q}}.$$

Now consider I_2. Since

$$\begin{aligned}&\triangle_y\Big(d\phi\left(\theta\psi\left(x+\frac{y}{2}\right)+(1-\theta)\psi\left(x-\frac{y}{2}\right)\right)\Big)\\ &\qquad= d\phi(\theta\psi(x+y)+(1-\theta)\psi(x))-d\phi(\theta\psi(x)+(1-\theta)\psi(x-y)),\end{aligned}$$

we have, using the hypothesis on ϕ,

$$\begin{aligned}&\Big|\triangle_y\left(d\phi\left(\theta\psi\left(x+\frac{y}{2}\right)+(1-\theta)\psi\left(x-\frac{y}{2}\right)\right)\right)\Big||\triangle_y\psi|\\ &\quad\le C(||u||_\infty)|\theta\psi(x+y)+(1-\theta)\psi(x)-\theta\psi(x)-(1-\theta)\psi(x-y)|^{s'-1}|\triangle_y\psi|\\ &\quad\le C(||u||_\infty)C'_s|\triangle_y\psi|(|\psi(x+y)-\psi(x)|^{s'-1}-|\psi(x)-\psi(x-y)|^{s'-1})\\ &\quad= C(||u||_\infty)C'_s|\triangle_y\psi|(|\tau_y\triangle_y\psi(x)|^{s'-1}+|\tau_{-y}\triangle_y\psi(x)|^{s'-1}),\end{aligned}$$

where for every $x \in \mathbf{R}^3$ and $y \in \mathbf{R}^3$, $\tau_y\psi(x) = \psi(x+\frac{y}{2})$. We now take $\varepsilon > 0$ such that $s' > s + (1 - \frac{s}{s+\varepsilon})$ and define $\rho = s + \varepsilon$. Then

$$s' > s+\left(1-\frac{s}{s+\varepsilon}\right) \Longrightarrow s'-1 > s\left(1-\frac{1}{s+\varepsilon}\right) \equiv s\left(1-\frac{1}{\rho}\right) \Longrightarrow \rho's' > s.$$

Using Hölder's inequality

$$\begin{aligned}||I_2||_p &\le C(||u||_\infty)C'_s||\triangle_y\psi||_{\rho p}|||\tau_y\triangle_y\psi|^{s'-1}+|\tau_{-y}\triangle_y\psi|^{s'-1}||_{\rho' p}\\ &\le 2C(||u||_\infty)C'||\triangle_y\psi||_{\rho p}||\triangle_y\psi||^{s'-1}_{(s'-1)\rho' p},\end{aligned}$$

where C' is a constant depending only on s', p, and ρ. Again using Hölder's inequality,

$$\begin{aligned}&\left\{\int_{\mathbf{R}^4}\frac{||I_2||_p^q}{|y|^{N+sq}}dy\right\}^{\frac{1}{q}}\\ &\quad\le 2C(||u||_\infty)C'\left\{\int_{\mathbf{R}^4}\frac{||\triangle_y\psi||_{\rho p}^{\rho q}}{|y|^{N+sq}}dy\right\}^{\frac{1}{\rho q}}\left\{\int_{\mathbf{R}^4}\frac{||\triangle_y\psi||^{(s'-1)\rho' q}_{(s'-1)\rho' p}}{|y|^{N+sq}}dy\right\}^{\frac{1}{\rho' q}}.\end{aligned}$$

Since $s < r$ and $s < \rho'(s'-1)$, by the definition of the homogeneous norms that we are using,

$$\left\{ \int_{\mathbf{R}^4} \frac{||I_2||_p^q}{|y|^{N+sq}} dy \right\}^{\frac{1}{q}} \leq ||\psi||_{\dot{B}^{\frac{s}{\rho}}_{\rho p, \rho q}} ||\psi||^{(s'-1)}_{\dot{B}^{\frac{s}{(s'-1)\rho'}}_{(s'-1)\rho' p, (s'-1)\rho' q}} .$$

Finally, observe that since $\rho > 1$ and $\rho'(s'-1) > 1$, we have for any $M > s$ that

$$||\triangle_y \psi||_{\rho p}^{\rho q} = \left\{ \int_{\mathbf{R}^3} |\triangle_y^M \psi(x)|^{\rho p} dx \right\}^{\frac{q}{p}} \leq ((M+1)||\psi||_\infty^{\rho - 1})^q \left\{ \int_{\mathbf{R}^3} |\triangle_y^M \psi(x)|^p dx \right\}^{\frac{q}{p}} .$$

We easily deduce that for some positive constant C depending only on ρ, p, q, and s, we have

$$\begin{aligned} ||\psi||_{\dot{B}^{\frac{s}{\rho}}_{\rho p, \rho q}} &\leq C ||\psi||_\infty^{1 - \frac{1}{\rho}} ||\psi||^{\frac{1}{\rho}}_{\dot{B}^s_{p,q}} , \\ ||\psi||^{(s'-1)}_{\dot{B}^{\frac{s}{(s'-1)\rho'}}_{(s'-1)\rho' p, (s'-1)\rho' q}} &\leq C ||\psi||_\infty^{(s'-1) - \frac{1}{\rho'}} ||\psi||^{\frac{1}{\rho'}}_{\dot{B}^s_{p,q}} , \end{aligned}$$

and Proposition 1.2 follows. □

Corollary 2.2. *Let be $s > 1$ and $m = [s]$. Suppose that ϕ is a given homogeneous function from $\mathbf{C}^4$ to $\mathbf{C}^4$ of degree p and belongs to $W^{s',\infty}_{\text{loc}}(\mathbf{C}^4, \mathbf{C}^4)$ for some $s' > s$. Then there is a positive constant C depending only on s, s', p, and q such that for any $\psi \in B^s_{p,q}(\mathbf{R}^3, \mathbf{C}^4) \cap L^\infty(\mathbf{R}^3, \mathbf{C}^4)$, $\phi(\psi) \in B^s_{p,q}(\mathbf{R}^3, \mathbf{C}^4)$ and, moreover,*

$$||\phi(\psi)||_{B^s_{p,q}} \leq C \left[C(1) + \sup_{|z| \leq 1} |d\phi(z)| + \sum_{k=1}^{[s]} \sup_{|z| \leq 1} |d^k \phi(z)| \right] ||\psi||_{B^s_{p,q}} ||\psi||_\infty^{p-1},$$

where $C(1)$ is given by (2.1) *for $R = 1$.*

Proof. If ϕ is homogeneous of degree p, its differential of order $k < [s']$ is homegeneous of degree $p - k$. On the other hand, if $m = [s]$,

$$\begin{aligned} C(R) &= \sup_{|\xi| \leq R, |\zeta| \leq R} \frac{|d^m \phi(\xi) - d^m \phi(\zeta)|}{|\xi - \zeta|^{s' - m}} \\ &\equiv \sup_{|\xi| \leq R, |\zeta| \leq R} \frac{R^{p-1} |d^m \phi(\frac{\xi}{R}) - d^m \phi(\frac{\zeta}{R})|}{R^{s'-1} |\frac{\xi}{R} - \frac{\zeta}{R}|^{s'-m}} \\ &= R^{p - s'} \sup_{|\xi| \leq 1, |\zeta| \leq 1} \frac{|d^m \phi(\xi) - d^m \phi(\zeta)|}{|\xi - \zeta|^{s'-m}} . \end{aligned}$$

The result then follows by Proposition 2.1. □

Remark 8. If we consider the function G defined in (0.2) with $p \geq 3$ and s satisfying (0.5) or $s = s(p)$ when $p > 3$, then G is homogeneous of degree p. If $p \geq 3$ is an odd integer, G is C^∞ and then belongs to $W^{s',\infty}_{\text{loc}}(\mathbf{C}^4, \mathbf{C}^4)$ for all s'. If p is not an odd integer, then G belongs to $W^{s',\infty}_{\text{loc}}(\mathbf{C}^4, \mathbf{C}^4)$ for $s' = \frac{p-1}{2}$, which by (0.5) is greater than s. Corollary 2.2 can then be applied to $G(\psi)$, and this will be used in Lemma 3.1 below.

3. Proof of the main results. As stated in the introduction, the operator iA generates a strongly continuous unitary group in H^s, which we denote by $W(t)$. We can write then the Cauchy problem (0.3) in the following integral form:

$$\psi(t) = W(t)\psi_0 - i\int_0^t W(t-\tau)G(\psi)d\tau. \tag{3.1}$$

We assume throughout this section that G is given by (0.2) with $p \geq 3$ and that s satisfies (0.5) or $s = s(p)$ and $p > 3$.

LEMMA 3.1.

(i) *Suppose that $p > 3$. Then there is $C > 0$ such that for every $T \in (0, \infty]$ and all $\psi \in L^\infty((-T,T); H^{s(p)}(\mathbf{R}^3)) \cap L^{p-1}((-T,T); L^\infty(\mathbf{R}^3))$, we have*

$$\int_0^t W(t-\tau)G(\psi)d\tau \in L^{p-1}((-T,T); L^\infty(\mathbf{R}^3))$$

and

$$\begin{aligned}&\left\|\int_0^t W(t-\tau)G(\psi)d\tau\right\|_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}\\ &\qquad \leq C||\psi||_{L^\infty((-T,T);H^{s(p)}(\mathbf{R}^3))}||\psi||^{p-1}_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}.\end{aligned}$$

(ii) *Suppose that p and s satisfy (0.5) and assume that $\gamma > (p-1)$ is such that $s > \frac{3}{2} - \frac{1}{\gamma}$. Suppose that $\psi \in L^\infty((-T,T); H^{s(p)}(\mathbf{R}^3)) \cap L^\gamma((-T,T); L^\infty(\mathbf{R}^3))$. Then*

$$\int_0^t W(t-\tau)G(\psi)d\tau \in L^{p-1}((-T,T); L^\infty(\mathbf{R}^3))$$

and, moreover,

$$\begin{aligned}&\left\|\int_0^t W(t-\tau)G(\psi)d\tau\right\|_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}\\ &\qquad \leq CT^{\frac{1}{p-1}-\frac{1}{\gamma}}||\psi||_{L^\infty((-T,T);H^{s(p)}(\mathbf{R}^3))}||\psi||^{p-1}_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}\end{aligned}$$

for every r' such that $\frac{1}{r'} \in (2-s, \frac{1}{\gamma})$.

Proof. First, we prove (i). Using Theorem 1.5, we have

$$\begin{aligned}&\left\|\int_0^t W(t-\tau)G(\psi)(\tau)d\tau\right\|_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}\\ &\quad \leq \left\|\int_{-T}^T |W(t-\tau)G(\psi)(\tau)|d\tau\right\|_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}\\ &\quad \leq \int_{-T}^T ||W(t-\tau)G(\psi)(\tau)||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}d\tau \leq C\int_{-T}^T ||G(\psi)(\tau)||_{H^{s(p)}}d\tau,\end{aligned}$$

where in the last inequality we used Theorem 1.5(iii). Now by Corollary 2.2,

$$\int_{-T}^T ||G(\psi)(\tau)||_{H^{s(p)}}d\tau \leq C||\psi||_{L^\infty((-T,T);H^{s(p)}(\mathbf{R}^3))}\int_{-T}^T ||\psi(\tau)||^{p-1}_\infty d\tau.$$

The proof of (ii) is similar. Indeed,

$$\begin{aligned}&\left\|\int_0^t W(t-\tau)G(\psi)d\tau\right\|_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}\\&\quad\le\left\|\textstyle\int_{-T}^T |W(t-\tau)G(\psi)|d\tau\right\|_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}\\&\quad\le \textstyle\int_{-T}^T ||W(t-\tau)G(\psi)||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}d\tau\le CT^{\frac{1}{p-1}-\frac{1}{\gamma}}\int_{-T}^T ||G(\psi)||_{H^s}d\tau,\end{aligned}$$

where in the last inequality we used Theorem 1.5(ii). Again using Corollary 2.2,

$$\int_{-T}^T ||G(\psi)||_{H^s}d\tau\le C||\psi||_{L^\infty((-T,T);H^s(\mathbf{R}^3))}\int_{-T}^T ||\psi(\tau)||_\infty^{p-1}d\tau.$$

Finally, (ii) follows using Hölder's inequality since $\gamma>p-1$. □

LEMMA 3.2.

(i) *Let* $\gamma>p-1$ *and* $T\in(0,\infty]$. *If* ψ_1 *and* ψ_2 *are in* $L^\infty((0,T);L^2(\mathbf{R}^3))\cap L^\gamma((0,T);L^\infty(\mathbf{R}^3))$ *for some* $T\in\mathbf{R}$, *then*

$$\begin{aligned}&\left\|\int_0^t W(t-\tau)(G(\psi_1)-G(\psi_2))d\tau\right\|_{L^\infty((0,T);L^2(\mathbf{R}^3))}\\&\quad\le CT^{1-\frac{(p-1)}{\gamma}}||\psi_1-\psi_2||_{L^\infty((0,T);L^2(\mathbf{R}^3))}\left(||\psi_1||^{p-1}_{L^\gamma((0,T);L^\infty(\mathbf{R}^3))}+||\psi_2||^{p-1}_{L^\gamma((0,T);L^\infty(\mathbf{R}^3))}\right).\end{aligned}$$

(ii) *For every* $T\in(0,\infty]$, *if* ψ_1 *and* ψ_2 *are in* $L^\infty((-T,T);L^2(\mathbf{R}^3))\cap L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))$, *then*

$$\begin{aligned}&\left\|\int_0^t W(t-\tau)(G(\psi_1)-G(\psi_2))d\tau\right\|_{L^\infty((-T,T);L^2(\mathbf{R}^3))}\\&\quad\le C||\psi_1-\psi_2||_{L^\infty((-T,T);L^2(\mathbf{R}^3))}\left(||\psi_1||^{p-1}_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}+||\psi_2||^{p-1}_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}\right).\end{aligned}$$

Proof. We prove (i); the proof of (ii) is similar. By our linear estimates, for all $t\in(0,T)$,

$$\begin{aligned}&\left\|\int_0^t W(t-\tau)(G(\psi_1(\tau))-G(\psi_2(\tau)))d\tau\right\|_{L^2(\mathbf{R}^3)}\\&\qquad\le\int_0^t ||(G(\psi_1(\tau))-G(\psi_2(\tau)))||_{L^2(\mathbf{R}^3)}d\tau.\end{aligned}$$

Moreover, since $\frac{p-1}{2}>s>1$,

$$|G(\psi_1)-G(\psi_2)|\le C_p|\psi_1-\psi_2|(|\psi_1|^{p-1}+|\psi_2|^{p-1}),$$

from which we have, for all $t\in(0,T)$,

$$\begin{aligned}&\int_0^t ||(G(\psi_1(\tau))-G(\psi_2(\tau)))||_{L^2(\mathbf{R}^3)}d\tau\\&\quad\le C_p||\psi_1-\psi_2||_{L^\infty((0,T);L^2(\mathbf{R}^3))}\int_0^t\left(||\psi_1(\tau)||^{p-1}_{L^\infty(\mathbf{R}^3)}+||\psi_2(\tau)||^{p-1}_{L^\infty(\mathbf{R}^3)}\right)d\tau,\end{aligned}$$

and the result follows. □

LEMMA 3.3. *Let be $\psi_0 \in H^s(\mathbf{R}^3)$ and $\gamma \geq p-1$. Suppose that $\psi \in L^\gamma((-T,T);L^\infty(\mathbf{R}^3)) \cap L^\infty((-T,T);H^s(\mathbf{R}^3))$ is a solution of equation* (3.1). *Then $\psi \in \mathbf{C}([-T,T];H^s(\mathbf{R}^3))$. Furthermore, if ψ_1 and ψ_2 are two such solutions, then $\psi_1=\psi_2$.*

Proof. The first statement follows from the facts that $W(t)$ is a strongly continuous group on $H^s(\mathbf{R}^3)$ and that $G(\psi) \in L^1((-T,T);H^s(\mathbf{R}^3))$. The proof of the second statement is by now classical. We write it down for the sake of completeness following Cazenave and Weissler [4]. Suppose that $\psi_1(t) \neq \psi_2(t)$ for some $t \in (-T,T)$. Let $t_0 = \inf\{t \in (-T,T); \psi_1(t) \neq \psi_2(t)\}$. Since ψ_1 and ψ_2 are continuous, t_0 is well defined and $\psi_1(t_0)=\psi_2(t_0)$. Moreover, the functions $\phi_1(t)=\psi_1(t+t_0)$ and $\phi_2(t)=\psi_2(t+t_0)$ are two solutions of equation (3.1) on the interval $(0,T-t_0)$. Then by Lemma 3.2, for all $t \in (t_0,T)$,

$$\begin{aligned} ||\psi_1-\psi_2||_{L^\infty((t_0,t);L^2(\mathbf{R}^3))} &= \left\| \int_0^t W(t-\tau)(G(\psi_1)-G(\psi_2))d\tau \right\|_{L^\infty((t_0,t);L^2(\mathbf{R}^3))} \\ &\leq C(t-t_0)^{1-\frac{(p-1)}{\gamma}} ||\psi_1-\psi_2||_{L^\infty((t_0,t);L^2(\mathbf{R}^3))} \\ &\quad \cdot \left(||\psi_1||^{p-1}_{L^\gamma((t_0,t);L^\infty(\mathbf{R}^3))} + ||\psi_2||^{p-1}_{L^\gamma((t_0,t);L^\infty(\mathbf{R}^3))} \right). \end{aligned}$$

For $t>t_0$ but sufficiently close to t_0, it follows that

$$C(t-t_0)^{1-\frac{(p-1)}{\gamma}} \left(||\psi_1||^{p-1}_{L^\gamma((t_0,t);L^\infty(\mathbf{R}^3))} + ||\psi_2||^{p-1}_{L^\gamma((t_0,t);L^\infty(\mathbf{R}^3))} \right) < 1.$$

(Observe that even if $\gamma = p-1$, since ψ_1 and ψ_2 belong to $L^\gamma((-T,T);L^\infty(\mathbf{R}^3))$, we have that $||\psi_1||^{p-1}_{L^\gamma((t_0,t);L^\infty(\mathbf{R}^3))}$ and $||\psi_2||^{p-1}_{L^\gamma((t_0,t);L^\infty(\mathbf{R}^3))}$ tend to 0 as $t \to t_0$.) This implies that $||\psi_1-\psi_2||_{L^\infty((t_0,t);L^2(\mathbf{R}^3))}=0$, which contradicts the choice of t_0 and thus proves $\psi_1(t)=\psi_2(t)$ for all $t \in (-T,T)$. □

Proof of Theorem I. Let $\gamma > p-1$ such that $\frac{3}{2}-\frac{1}{\gamma}<s$. For $T>0$ and $M>0$, we define

$$\mathbf{X}(T,M) = \{\psi \in L^\infty((-T,T);H^s(\mathbf{R}^3)) \cap L^\gamma((-T,T);L^\infty(\mathbf{R}^3)); |||\psi||| \leq M\},$$

where

$$|||\psi||| = \sup_{t\in(-T,T)} ||\psi||_{H^s(\mathbf{R}^3)} + ||\psi||_{L^\gamma((-T,T);L^\infty(\mathbf{R}^3))}.$$

The set $\mathbf{X}(T,M)$ endowed with the metric

$$d(\psi_1,\psi_2) = ||\psi_1-\psi_2||_{L^\infty((-T,T);L^2(\mathbf{R}^3))}$$

is a complete metric space. We want to find conditions on T and M which imply that the map $\mathcal{F}$, given by

$$\mathcal{F}(\psi) = W(t)\psi_0 - i\int_0^t W(t-\tau)G(\psi)d\tau,$$

is a strict contraction on $\mathbf{X}(T,M)$. By Lemma 3.1, there are positive constants C_1 and C_2 depending only on s, p, and γ such that for all $\psi \in \mathbf{X}(T,M)$,

$$|||\mathcal{F}(\psi)||| \leq C_1||\psi_0||_{H^s(\mathbf{R}^3)} + C_2T^{1+\frac{2-p}{\gamma}-\frac{1}{r'}}M^p.$$

Then if

$$C_1||\psi_0||_{H^s(\mathbf{R}^3)} + C_2 T^{1+\frac{2-p}{\gamma}-\frac{1}{r'}} M^p \leq M, \tag{3.2}$$

$\mathcal{F}(\psi) \in \mathbf{X}(T, M)$. On the other hand, by Lemma 3.2, there is a positive constant C_3 depending only on s, p, and γ such that for all $\psi_1 \in \mathbf{X}(T, M)$ and $\psi_2 \in \mathbf{X}(T, M)$,

$$d(\mathcal{F}(\psi_1), \mathcal{F}(\psi_2)) < C_3 T^{1-\frac{(p-1)}{\gamma}} M^{p-1}.$$

Then if

$$C_3 T^{1-\frac{(p-1)}{\gamma}} M^{p-1} < 1, \tag{3.3}$$

$\mathcal{F}$ is a strict contraction. Therefore, if T and M satisfy (3.2) and (3.3), $\mathcal{F}$ is a strict contraction on $\mathbf{X}(T, M)$. Thus given any $\psi_0 \in H^s(\mathbf{R}^3)$ and any $M > C_1||\psi_0||_{H^s(\mathbf{R}^3)}$, there exists $T > 0$ depending only on $||\psi_0||_{H^s(\mathbf{R}^3)}$, s, p, γ, and M such that $\mathcal{F}$ has a unique fixed point in $\mathbf{X}(T, M)$ which is a solution of (3.1) in $L^\infty((-T, T); H^s(\mathbf{R}^3)) \cap L^\gamma((-T, T); L^\infty(\mathbf{R}^3))$.

We now call T^* the supremum of all $T > 0$ for which there exists a solution of (3.1) in $L^\infty((-T, T); H^s(\mathbf{R}^3)) \cap L^\gamma((-T, T); L^\infty(\mathbf{R}^3))$. We have proved that $T^* > 0$. Moreover, by Lemma 3.3, two such solutions coincide on the intersection of their domains of definition. We can see that if $T^* < \infty$ then no solution of (3.1) exists on $L^\infty((-T^*, T^*); H^s(\mathbf{R}^3)) \cap L^\gamma((-T^*, T^*); L^\infty(\mathbf{R}^3))$. By Lemma 3.3, if such a solution existed, it would be in $\mathbf{C}([-T^*, T^*]; H^s(\mathbf{R}^3))$. Then, however, this solution could be continued beyond T^* by solving (3.1), taking $\psi(T^*)$ as the initial value. We can then define the maximal solution ψ of (3.1) as the solution in $\mathbf{C}((-T^*, T^*); H^s(\mathbf{R}^3))$ such that for any $T \in (0, T^*)$, it belongs to $L^\infty((-T, T); H^s(\mathbf{R}^3)) \cap L^\gamma((-T, T); L^\infty(\mathbf{R}^3))$.

In order to prove the continuous dependence of the solution from the initial value, fix $T \in (0, T^*)$ and M such that (3.2) and (3.3) hold for all initial values ϕ with H^s norm less than $2||\psi_0||_{H^s(\mathbf{R}^3)}$. Then the fixed-point argument can be done in $\mathbf{X}(T, M)$ for any such ϕ. This implies that $T < T^*(\phi)$ for all of these ϕ's. Moreover, let $\psi_{0,k}$ be a sequence such that

$$||\psi_{0,k}||_{H^s(\mathbf{R}^3)} \leq 2||\psi_0||_{H^s(\mathbf{R}^3)}, \qquad ||\psi_{0,k} - \psi_0||_{H^s(\mathbf{R}^3)} \longrightarrow 0 \quad \text{as } k \longrightarrow \infty.$$

Therefore, $T < T^*(\psi_{0,k})$ and $|||\psi_k||| < M$ for all k. We now have

$$\begin{aligned} ||\psi_k - \psi||_{L^2(\mathbf{R}^3)} &\leq ||W(t)(\psi_{0,k} - \psi_0)||_{L^2(\mathbf{R}^3)} + \int_0^t ||(G(\psi_k(\tau)) - G(\psi(\tau)))||_{L^2(\mathbf{R}^3)} d\tau \\ &\leq ||W(t)(\psi_{0,k} - \psi_0)||_{L^2(\mathbf{R}^3)} \\ &\quad + C_p||\psi_k - \psi||_{L^\infty((0,T);L^2(\mathbf{R}^3))} \int_0^t \Big(||\psi_k(\tau)||^{p-1}_{L^\infty(\mathbf{R}^3)} + ||\psi(\tau)||^{p-1}_{L^\infty(\mathbf{R}^3)}\Big) d\tau \\ &\leq ||W(t)(\psi_{0,k} - \psi_0)||_{L^2(\mathbf{R}^3)} + C_3 T^{1-\frac{p-1}{\gamma}} M^{p-1} ||\psi_k - \psi||_{L^2(\mathbf{R}^3)}. \end{aligned}$$

Now using (3.3), we deduce that

$$||\psi_k - \psi||_{L^2(\mathbf{R}^3)} \leq \Big(1 - C_3 T^{1-\frac{p-1}{\gamma}} M^{p-1}\Big)^{-1} ||W(t)(\psi_{0,k} - \psi_0)||_{L^2(\mathbf{R}^3)},$$

from which we get $\psi_k \longrightarrow \psi$ in $\mathbf{C}((-T, T); L^2(\mathbf{R}^3))$. Since by construction the sequence ψ_k is bounded in $\mathbf{C}((-T, T); H^s(\mathbf{R}^3))$ and, more precisely,

$$||\psi_k(t)||_{H^s} \leq M \quad \text{for } t \in (-T, T),$$

we deduce by interpolation that

$$||\psi_k(t) - \psi(t)||_{H^{s'}} \leq C(M)||W(t)(\psi_{0,k} - \psi_0)||^{\theta}_{L^2(\mathbf{R}^3)}$$

for some $\theta \in (0,1)$, from which we get $\psi_k \longrightarrow \psi$ in $\mathbf{C}((-T,T); H^{s'}(\mathbf{R}^3))$ for all $s' \in (0,s)$.

Finally, we prove that this solution ψ belongs to $\mathbf{C}^1((-T,T); L^2(\mathbf{R}^3))$. Since $\psi \in \mathbf{C}([-T,T]; H^s(\mathbf{R}^3))$, we know that $\nabla\psi \in \mathbf{C}([-T,T]; H^{s-1}(\mathbf{R}^3))$. On the other hand, we claim that G continuously maps $\mathbf{C}([-T,T]; H^s(\mathbf{R}^3))$ into $\mathbf{C}([-T,T]; L^2(\mathbf{R}^3))$. Indeed, since G continuously maps $L^{2p}(\mathbf{R}^3)$ into $L^2(\mathbf{R}^3)$, it continuously maps $\mathbf{C}([-T,T]; L^{2p}(\mathbf{R}^3))$ into $\mathbf{C}([-T,T]; L^2(\mathbf{R}^3))$. Also, it maps $\mathbf{C}([-T,T]; H^s(\mathbf{R}^3))$ into $\mathbf{C}([-T,T]; L^{2p}(\mathbf{R}^3))$ by the Sobolev embedding theorem since $1 \leq s(p) < s \Longrightarrow 2p < \frac{6}{3-2s}$. Then differentiating then the integral equation (3.1), we obtain that ψ satisfies equation (0.1), from which we get that ψ_t is in $\mathbf{C}((-T,T); L^2(\mathbf{R}^3))$ and so ψ belongs to $\mathbf{C}^1((-T,T); L^2(\mathbf{R}^3))$. □

Remark 9. Assume that the nonlinearity G is in $W^{1+s'',\infty}_{\mathrm{loc}}(\mathbf{C}^4, \mathbf{C}^4)$ for some $s'' > s$ and is such that, for some positive constant,

$$||dG||_{W^{s'',\infty}(\mathbf{B}_r)} \leq Cr^{p-1},$$

where $\mathbf{B}_r$ is the ball in $\mathbf{C}^4$ centered at zero and of radius r. Then

$$\begin{aligned} ||\psi_k - \psi||_{H^s(\mathbf{R}^3)} &\leq ||W(t)(\psi_{0,k} - \psi_0)||_{H^s(\mathbf{R}^3)} + \int_0^t ||(G(\psi_k(\tau)) - G(\psi(\tau)))||_{H^s(\mathbf{R}^3)} d\tau \\ &\leq ||W(t)(\psi_{0,k} - \psi_0)||_{H^s(\mathbf{R}^3)} \\ &\quad + C_p||\psi_k - \psi||_{L^\infty(0,T;H^s(\mathbf{R}^3))} \int_0^t ||dG||_{W^{s'',\infty}(\mathbf{B}_{r(k,\tau)})} d\tau, \end{aligned}$$

where $r(k,\tau) = ||\psi_k(\tau)||_{L^\infty(\mathbf{R}^3)} + ||\psi(\tau)||_{L^\infty(\mathbf{R}^3)}$. Then by Theorem 1.5,

$$\begin{aligned} ||\psi_k - \psi||_{H^s(\mathbf{R}^3)} &\leq ||W(t)(\psi_{0,k} - \psi_0)||_{H^s(\mathbf{R}^3)} \\ &\quad + C'_p||\psi_k - \psi||_{L^\infty(0,T;H^s(\mathbf{R}^3))} \int_0^t \left(||\psi_k(\tau)||^{p-1}_{L^\infty(\mathbf{R}^3)} + ||\psi(\tau)||^{p-1}_{L^\infty(\mathbf{R}^3)}\right) d\tau. \end{aligned}$$

Then it is clear that for small enough T, the application $\psi_0 \to \psi$ is Lipschitz from V to $\mathbf{C}((-T,T); H^s(\mathbf{R}^3))$. Using Theorem 1.5, one can prove in a similar way that the application is Lipschitz from V to $L^\gamma((-T,T); L^\infty(\mathbf{R}^3))$.

Proof of Theorem II. First, suppose that ψ_0 is any given function of $H^{s(p)}(\mathbf{R}^3)$. In a similar way as in the proof of Theorem I, we define

$$\mathbf{X}(T,M,\psi_0) = \{\psi \in L^\infty((-T,T); H^{s(p)}(\mathbf{R}^3)) \cap L^{p-1}((-T,T); L^\infty(\mathbf{R}^3)); |||\psi||| \leq M\},$$

where

$$|||\psi||| = \sup_{t\in(-T,T)} ||\psi - \psi_0||_{H^{s(p)}(\mathbf{R}^3)} + ||\psi||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))}.$$

By choosing T sufficiently small, we can be sure that the set $\mathbf{X}(T,M,\psi_0)$ is not empty for M as small as we need. Indeed, the function $W(t)\psi_0$ is such that

$$\lim_{t\to 0} ||W(t)\psi_0 - \psi_0||_{H^{s(p)}(\mathbf{R}^3)} = 0, \tag{3.4}$$

and since by Theorem 1.5, $W(t)\psi_0 \in L^{p-1}(\mathbf{R}; L^\infty(\mathbf{R}^3))$, we also have

$$\lim_{T\to 0} ||W(t)\psi_0||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))} = 0. \tag{3.5}$$

The set $\mathbf{X}(T, M, \psi_0)$ endowed with the metric

$$d(\psi_1, \psi_2) = ||\psi_1 - \psi_2||_{L^\infty((-T,T);L^2(\mathbf{R}^3))}$$

is a complete metric space.

Now there is a positive constant C_1 such that for any $\psi \in \mathbf{X}(T, M, \psi_0)$,

$$\begin{aligned} |||\mathcal{F}(\psi)||| \leq \sup_{t\in(-T,T)} ||W(t)\psi_0 - \psi_0||_{H^{s(p)}(\mathbf{R}^3)} &+ ||W(t)\psi_0||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))} \\ &+ C_1(M + ||\psi_0||_{H^{s(p)}(\mathbf{R}^3)})M^{p-1}. \end{aligned} \tag{3.6}$$

On the other hand, by Lemma (3.2), there is a positive constant C_2 such that for every ψ_1 and ψ_2 in $\mathbf{X}(T, M, \psi_0)$, we have

$$d(\mathcal{F}(\psi_1), \mathcal{F}(\psi_2)) \leq C_2 d(\psi_1 - \psi_2)M^{p-1}. \tag{3.7}$$

Let us fix conditions on T and M in order for $\mathcal{F}$ to be a strict contraction on $\mathbf{X}(T, M, \psi_0)$. We first choose M such that

$$C_2 M^{p-1} < 1 \quad \text{and} \quad C_1(M + ||\psi_0||_{H^{s(p)}(\mathbf{R}^3)})M^{p-2} < \frac{1}{2}. \tag{3.8}$$

Then using (3.3) and (3.4), we take T small enough in order to have $\mathbf{X}(T, M, \psi_0)$ not be empty and

$$||W(t)\psi_0||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))} + \sup_{t\in(-T,T)} ||W(t)\psi_0 - \psi_0||_{H^{s(p)}(\mathbf{R}^3)} < \frac{M}{2}. \tag{3.9}$$

Under conditions (3.8) and (3.9), $\mathcal{F}$ is a strict contraction from $\mathbf{X}(T, M, \psi_0)$ into itself. This shows that for any ψ_0 in $H^{s(p)}$, there is $T \equiv T(\psi_0)$ such that $\mathcal{F}$ has a unique fixed point in $\mathbf{X}(T, M, \psi_0)$ which is a solution of (3.1) in $L^\infty((-T, T); H^{s(p)}(\mathbf{R}^3)) \cap L^{p-1}((-T, T); L^\infty(\mathbf{R}^3))$. Using Lemma 3.3 as in the proof of Theorem I, we deduce the existence of a maximal solution ψ of (3.1) in $\mathbf{C}((-T^*, T^*); H^{s(p)}(\mathbf{R}^3))$ which is unique in $L^\infty((-T, T); H^{s(p)}(\mathbf{R}^3)) \cap L^\gamma((-T, T); L^\infty(\mathbf{R}^3))$ for all $T \in (0, T^*)$.

In order to prove the continuous dependence in the same way as in Theorem I, we will show that we can find $T > 0$, $M > 0$, and a neighborhood V of ψ_0 in $H^{s(p)}(\mathbf{R}^3)$ such that the previous fixed-point argument can be done in $\mathbf{X}(T, M, \phi)$ for any $\phi \in V$. For this observe that for all $u \in \mathbf{X}(T, M, \phi)$,

$$\begin{aligned} |||\mathcal{F}(u)||| \leq & \sup_{t\in(-T,T)} ||W(t)\phi - \phi||_{H^{s(p)}(\mathbf{R}^3)} + ||W(t)\phi||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))} \\ & + C(M + ||\phi||_{H^{s(p)}(\mathbf{R}^3)})M^{p-1} \\ \leq & 2||(\phi - \psi_0)||_{H^{s(p)}(\mathbf{R}^3)} + \sup_{t\in(-T,T)} ||W(t)\psi_0 - \psi_0||_{H^{s(p)}(\mathbf{R}^3)} \\ & + ||W(t)(\phi - \psi_0)||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))} \\ & + ||W(t)\psi_0||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))} \\ & + C(M + ||(\phi - \psi_0)||_{H^{s(p)}(\mathbf{R}^3)} + ||\psi_0||_{H^{s(p)}(\mathbf{R}^3)})M^{p-1}. \end{aligned} \tag{3.10}$$

On the other hand, by Lemma 3.2., for any u and v in $\mathbf{X}(T, M, \phi)$, we have (3.7), i.e.,

$$d(\mathcal{F}(u), \mathcal{F}(v)) \leq C_3 d(u, v) M^{p-1}.$$

First, we choose M such that

$$C_3 M^{p-1} < 1 \quad \text{and} \quad C(M + 2||\psi_0||_{H^{s(p)}(\mathbf{R}^3)}) M^{p-2} < \frac{1}{2}. \tag{3.11}$$

Then we choose T such that

$$\sup_{t\in(-T,T)} ||W(t)\psi_0 - \psi_0||_{H^{s(p)}(\mathbf{R}^3)} + ||W(t)\psi_0||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))} < \frac{M}{2}. \tag{3.12}$$

Finally, in order to define the neighborhood V of ψ_0 in $H^{s(p)}$, we remark that by Theorem 1.5 there is a positive constant C such that for every $T > 0$,

$$\begin{aligned} ||W(t)(\psi_0 - \phi)||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))} &\leq ||W(t)(\psi_0 - \phi)||_{L^{p-1}(\mathbf{R};L^\infty(\mathbf{R}^3))} \\ &\leq C||\psi_0 - \phi||_{H^{s(p)}(\mathbf{R}^3)}. \end{aligned}$$

Therefore, there is δ_0 small enough such that if $||\phi - \psi_0||_{H^{s(p)}(\mathbf{R}^3)} < \delta_0$, then for all $T > 0$,

$$2||\phi - \psi_0||_{H^{s(p)}(\mathbf{R}^3)} + ||W(t)(\psi_0 - \phi)||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))} < \frac{M}{4}. \tag{3.13}$$

We then define

$$V = \{\phi \in H^{s(p)}(\mathbf{R}^3); ||\phi - \psi_0||_{H^{s(p)}(\mathbf{R}^3)} < \delta\}, \tag{3.14}$$

where

$$\delta = \min(\delta_0, ||\psi_0||_{H^{s(p)}(\mathbf{R}^3)}). \tag{3.15}$$

Then observe that if $\phi \in V$ by (3.15) and (3.11), we also have

$$\begin{aligned} C(M + ||(\phi - \psi_0)||_{H^{s(p)}(\mathbf{R}^3)} + ||\psi_0||_{H^{s(p)}(\mathbf{R}^3)})M^{p-1} &\leq C(M + 2||\psi_0||_{H^{s(p)}(\mathbf{R}^3)})M^{p-1} \\ &< \frac{M}{4}. \end{aligned}$$

It is now straightforward to check that for every $\phi \in V$, the application $\mathcal{F}$ is a strict contraction on $\mathbf{X}(T, M, \phi)$. Therefore, for all $\phi \in V$, it has a unique fixed point in $\mathbf{X}(T, M, \phi)$ which is a solution to (3.1) in $L^\infty((-T,T); H^{s(p)}(\mathbf{R}^3)) \cap L^{p-1}((-T,T); L^\infty(\mathbf{R}^3))$. If we now consider a sequence $\{\phi_k\} \subset V$ such that $\phi_k \longrightarrow \psi_0$ in $H^{s(p)}$, then as we have just seen, $T < T^*(\phi_k)$ and $||u_k||_{L^{p-1}((-T,T);L^\infty(\mathbf{R}^3))} < M$ for all k. The proof now ends as in Theorem I.

In order to prove global existence for small initial data, consider again the estimates (3.6) and (3.7). Since we take $||\psi_0||_{H^{s(p)}(\mathbf{R}^3)} < M$, we deduce from (3.6) the existence of a positive constant C' independent of T such that

$$|||\mathcal{F}(\psi)||| \leq C'||\psi_0||_{H^{s(p)}(\mathbf{R}^3)} + 2C_1 M^p. \tag{3.16}$$

Then from (3.7) and (3.16), we see that if $M > (1 + C')||\psi_0||_{H^{s(p)}(\mathbf{R}^3)}$ and M is so small that $C'||\psi_0||_{H^{s(p)}(\mathbf{R}^3)} + 2C_1 M^p < M$ and $C_2 M^{p-1} < 1$, we may carry out our fixed-point argument in the space

$$\mathbf{X}(\infty, M, \psi_0) = \{\psi \in L^\infty(\mathbf{R}; H^{s(p)}(\mathbf{R}^3)) \cap L^{p-1}(\mathbf{R}; L^\infty(\mathbf{R}^3)); |||\psi||| \leq M\}.$$

We now show the scattering result. Let ψ be the global solution with small initial data ψ_0 obtained above. Since, as we have seen, $\psi \in L^\infty(\mathbf{R}; H^{s(p)}(\mathbf{R}^3)) \cap L^{p-1}(\mathbf{R}; L^\infty(\mathbf{R}^3))$, we deduce that $\phi_\pm$ defined by (0.6) belong to $H^{s(p)}(\mathbf{R}^3)$ and that

$$||\phi_\pm||_{H^{s(p)}(\mathbf{R}^3)} \leq ||\psi_0||_{H^{s(p)}(\mathbf{R}^3)} + C|||\psi|||^p.$$

On the other hand, for all $t \in \mathbf{R}^3$,

$$W(-t)\psi(t) - \phi_+ = \int_t^\infty W(-\tau)G(\psi(\tau))d\tau$$

from which, taking norms in $H^{s(p)}(\mathbf{R}^3)$, we get

$$\begin{aligned} ||W(-t)\psi(t) - \phi_+||_{H^{s(p)}(\mathbf{R}^3)} &\leq \int_t^\infty ||W(-\tau)G(\psi(\tau))||_{H^{s(p)}(\mathbf{R}^3)} d\tau \\ &\leq C \int_t^\infty ||\psi(\tau)||_{H^{s(p)}(\mathbf{R}^3)} ||\psi(\tau)||_\infty^{p-1} d\tau \\ &\leq C \sup_{t \in \mathbf{R}} ||u||_{H^{s(p)}(\mathbf{R}^3)} \int_t^\infty ||\psi(\tau)||_\infty^{p-1} d\tau. \end{aligned}$$

Since $\psi \in L^{p-1}(\mathbf{R}; L^\infty(\mathbf{R}^3))$, we have $||\psi(\tau)||_\infty^{p-1} \in L^1(\mathbf{R})$ and therefore

$$\lim_{t \to \infty} \int_t^\infty ||\psi(\tau)||_\infty^{p-1} d\tau = 0.$$

We then deduce

$$\lim_{t \to \infty} ||\psi(t) - W(t)\phi_+||_{H^{s(p)}(\mathbf{R}^3)} \equiv \lim_{t \to \infty} ||W(-t)\psi(t) - \phi_+||_{H^{s(p)}(\mathbf{R}^3)} = 0.$$

The same proof holds for ϕ_-. □

4. Extension to the Klein–Gordon and wave equations. The arguments of the previous sections can be used to study local and global existence for the Cauchy problem associated with the nonlinear Klein–Gordon and wave equations. For the sake of simplicity, we consider equations of the form

$$\text{(4.1)} \qquad \begin{cases} u_{tt} - \triangle u + m^2 u = (Du)^\gamma, & x \in \mathbf{R}^3, \quad t \in \mathbf{R}, \quad m \geq 0, \\ u(x,0) = f(x), & x \in \mathbf{R}^3, \\ u_t(x,0) = g(x), & x \in \mathbf{R}^3, \end{cases}$$

where $Du = (\partial_t u, \nabla u)$ and γ is a multiindex of length 4 with $|\gamma| = l \in \mathbf{Z}^+$. In order to relate our results to previous ones, for the sake of brevity, let us only mention the work of Ponce and Sideris [11]. These authors considered the more general nonlinearity $G(u, \nabla u) = u^k(\nabla u)^\gamma$, where $k \in \mathbf{Z}^+$. They showed that if $l = 2$ or $l = 3$ and $2 < s \leq \frac{5}{2}$, then for every $(f, g) \in H^s(\mathbf{R}^3) \times H^{s-1}(\mathbf{R}^3)$, there exists a $T > 0$ depending on s and $||f||_{H^s} + ||g||_{H^{s-1}}$ such that (4.1) has a unique solution u satisfying, in particular,

$$\begin{cases} u \in \bigcap_{j}^{2} \mathbf{C}^j([0,T); H^{s-j}(\mathbf{R}^3)), \\ \int_0^T ||\nabla u(t,\cdot)||_{L^\infty}^2 dt < \infty. \end{cases} \tag{4.2}$$

Moreover, if no restriction is imposed on the order of the nonlinearity in ∇u, $|\gamma| = l \in \mathbf{Z}^+$, $l \geq 3$, then the previous result holds for $s > s(l) = \frac{5}{2} - \frac{1}{l-1}$.

Using arguments similar to those used in section 3, this can be improved to obtain a global existence result for small data. In particular, we prove the following theorem.

THEOREM 4.1. *Let $|\gamma| = l \in \mathbf{Z}^+$, $l > 3$, and $s(l) = \frac{5}{2} - \frac{1}{l-1}$. Then for every $(f,g) \in H^{s(l)}(\mathbf{R}^3) \times H^{s(l)-1}(\mathbf{R}^3)$, there exists a $T^* > 0$ depending on s and of (f,g) and a solution u to* (4.1) *such that*

$$\begin{cases} u \in \mathbf{C}((-T^*,T^*); H^{s(l)}(\mathbf{R}^3)) \cap \mathbf{C}^1((-T^*,T^*); L^2(\mathbf{R}^3)), \\ \nabla u \in L^{l-1}_{\text{loc}}((-T^*,T^*); L^\infty(\mathbf{R}^3)). \end{cases}$$

Moreover,

(i) *this solution is the unique solution satisfying*

$$\forall T < T^*, \quad u \in L^\infty((-T,T); H^s(\mathbf{R}^3)) \quad \text{and} \quad \nabla u \in L^{l-1}((-T,T); L^\infty(\mathbf{R}^3));$$

(ii) *if $T^* < \infty$, then $||\nabla u||_{L^{l-1}((-T^*,T^*);L^\infty(\mathbf{R}^3))} + ||u||_{L^\infty((-T^*,T^*);H^{s(l)}(\mathbf{R}^3))} = \infty$;*

(iii) *there is $T < T^*$ and a neighborhood V of (f,g) in $H^{s(l)}(\mathbf{R}^3) \times H^{s(l)-1}(\mathbf{R}^3)$ such that for all $0 \leq s' < s(l)$, the map $(f,g) \longrightarrow u$ is continuous from V to $\mathbf{C}((-T,T); H^{s'}(\mathbf{R}^3))$; and*

(iv) *if $||f||_{H^s} + ||g||_{H^{s-1}}$ is sufficiently small, then $T^* = \infty$,*

$$u \in L^\infty(\mathbf{R}; H^{s(l)}(\mathbf{R}^3)), \quad \text{and} \quad \nabla u \in L^{l-1}(\mathbf{R}; L^\infty(\mathbf{R}^3)).$$

The proof of Theorem 4.1 is based on the following linear estimates in the same way as the proofs of Theorems I and II are based on Theorem 1.5. The new inequality which allows us to obtain global results is (4.4) below.

THEOREM 4.2. *Let $\mathcal{K}_m(t)(f,g)$ be the solution of* (1.3). *Then the following hold:*

(i) *Given $2 \leq p < \infty$, $\frac{1}{p} + \frac{1}{q} = \frac{1}{2}$, and $\alpha(p) = 2(\frac{1}{2} - \frac{1}{p})$, there is a positive constant C such that*

$$\begin{aligned} &||\mathcal{K}_m\ (\cdot)(f,g)||_{L^q(\mathbf{R};L^p(\mathbf{R}^3))} \\ &\quad \leq C\left(\left\| D_x^{\frac{\alpha(p)}{2}} (m^2 - \triangle)^{\frac{\alpha(p)}{4}} f \right\|_{L^2(\mathbf{R}^3)} + \left\| D_x^{\frac{\alpha(p)}{2}} (m^2 - \triangle)^{\frac{\alpha(p)}{4} - \frac{1}{2}} g \right\|_{L^2(\mathbf{R}^3)} \right). \end{aligned} \tag{4.3}$$

(ii) *If $p = 3$ and $s(p) = \frac{3}{2} - \frac{1}{p-1}$, then there is a positive constant C such that*

$$||\mathcal{K}_m(\cdot)(f,g)||_{L^{p-1}(\mathbf{R};L^\infty(\mathbf{R}^3))} \leq C(1+m)^{\frac{1}{l-1}}(||f||_{H^{s(p)}(\mathbf{R}^3)} + ||(m^2 - \triangle)^{-\frac{1}{2}} g||_{H^{s(p)}(\mathbf{R}^3)}). \tag{4.4}$$

(iii) *Given $s > s(p)$ and $p \geq 3$ for all $\gamma > p-1$ such that $\frac{1}{\gamma} \in (\frac{3-2s}{2}, \frac{1}{p-1})$ and all $r' > \gamma$ such that $\frac{1}{r'} \in (\frac{3-2s}{2}, \frac{1}{\gamma})$, there is a positive constant C such that for all*

$T > 0$,

$$\begin{aligned}(4.5)\qquad &||\mathcal{K}_m\ (\cdot)(f,g)||_{L^\gamma(-T,T;L^\infty(\mathbf{R}^3))}\\ &\le C(1+m)^{\frac{1}{r'}}T^{\frac{1}{\gamma}-\frac{1}{r'}}(||f||_{H^s(\mathbf{R}^3)} + ||(m^2-\triangle)^{-\frac{1}{2}}g||_{H^s(\mathbf{R}^3)}).\end{aligned}$$

Proof. The proof follows from the corresponding estimates for the operators

$$(4.6)\qquad \mathcal{K}_m^{\pm}(\cdot)(f,g) = \left(e^{\pm it\sqrt{-\triangle+m^2}}f, e^{\pm it\sqrt{-\triangle+m^2}}(-\triangle+m^2)^{-\frac{1}{2}}g\right).$$

These are obtained in a similar way as in Theorem 1.5 using Lemmas 1.2 and 1.4. □

IMPLICIT TIME DISCRETIZATION AND GLOBAL EXISTENCE FOR A QUASI-LINEAR EVOLUTION EQUATION WITH NONCONVEX ENERGY*

G. FRIESECKE† AND G. DOLZMANN‡

Abstract. We establish global existence of weak solutions for the viscoelastic system $u_{tt} = Div(\frac{\partial\Phi}{\partial F}(Du) + Du_t)$ with nonconvex stored-energy function Φ. Unlike previous methods [P. Rybka, *Proc. Roy. Soc. Edinburgh Sect.* A, 121 (1992), pp. 101–138], our result does not require that $\frac{\partial\Phi}{\partial F}$ be globally Lipschitz continuous. Our approach is based on implicit time discretization and a compactness property of the discrete dynamical scheme not shared by energy-minimizing sequences and not known to be shared by approximation schemes of Galerkin type.

Key words. nonconvex functionals, evolution equations, implicit time discretization, viscoelasticity, solid–solid phase transitions

Introduction. This article is devoted to the system of partial differential equations (PDEs)

$$u_{tt} = \text{Div}\ (\sigma(Du) + Du_t), \tag{0.1}$$

where u is a mapping from an open bounded domain $\Omega \subset \mathbb{R}^n$ to $\mathbb{R}^N$ satisfying appropriate initial and boundary conditions, and $\sigma(F) = \partial\Phi(F)/\partial F$ for some "stored-energy function" $\Phi : M^{N\times n} \to \mathbb{R}$.

To establish global existence results has required considerable effort even in the case where $n = N = 1$ [GMM, Da, A, Y, AB, P]. Previous results in higher dimensions were obtained notably by Gajewski, Gröger, and Zacharias [GGZ], Clement [C], Friedman and Nečas [FN], Engler [E1], and Rybka [R]. For work on related models involving, e.g., higher gradients, thermal effects, or memory terms, see [AHNS, BBN1, BBN2, BFS, BHJPS, BN, CH, E2, FM, HZ, KH, MNS, NR, NS, SS]. The techniques employed for (0.1) in higher dimensions (Galerkin methods [GGZ, C]; Galerkin methods combined with regularity theorems on Du [FN]; semigroup methods [E1, R]; and semigroup methods combined with regularity theorems on Du [Pec]) make the standard assumption that $\Phi(F) \sim |F|^p$ $(p \geq 2)$ for large $|F|$ and, in addition, crucially rely on at least one of the following two hypotheses:

(i) the underlying energy function Φ is convex [GGZ, C, FN, E1, Pec], or

(ii) the nonlinearity σ is globally Lipschitz continuous [GGZ, R].

Here we present a new approach to the system (0.1) which allows one to establish global existence without hypotheses (i) or (ii), provided, e.g., the following natural

monotonicity condition at infinity is imposed:

$$(\sigma(\bar{F}) - \sigma(F)) \cdot (\bar{F} - F) \geq 0 \quad \text{for all } |F|, |\bar{F}| \geq R \quad \text{and some } R > 0. \tag{0.2}$$

In fact, this condition has already been proposed in the case where $n = N = 1$ by Andrews and Ball [AB], who employed it to prove global existence.

Our approach was partially inspired by recent work of Kinderlehrer and Pedregal [KP] and Demoulini [De] on measure-valued solutions to evolution equations with nonconvex energy functionals and involves two main steps: (i) implicit time discretization and minimization of an associated static problem at each time step ((2.1) and (2.2) in section 2) and (ii) passing to the limit in the nonlinear term $\sigma(Du)$. The feasibility of (i) relies on a simple but powerful observation, namely that the discretized counterpart of the damping term Du_t provides convexity of the static problem despite the stored-energy function Φ not being convex (Lemma 2.1). Achieving (ii) is based on a "propagation of regularity" property of the discrete scheme which may be interesting in its own right (Proposition 3.1 in section 3): it says, roughly, that the amount of oscillations in Du at any finite time t can be controlled by the amount of oscillations present in the initial data. In particular, we show that if a sequence of initial data $u^h|_{t=0}$ converges strongly in the Sobolev space $W^{1,2}(\Omega, \mathbb{R}^N)$, then the sequence of corresponding approximate solutions u^h converges strongly in $L^2(0, T; W^{1,2}(\Omega, \mathbb{R}^N))$ as the time stepsize h tends to zero.

This controllability of oscillations created in Du until time t is a subtle feature of the dynamics. First, it becomes false if the assumption of strong convergence of the $u^h|_{t=0}$ is dropped (see Example 2.1), reflecting the fact that the system (0.1) and its discretization do not regularize Du in time. Second, it is not shared by minimizing sequences (u^j, v^j) of the underlying Lyapunov function

$$E[u, v] = \int_\Omega \left(\Phi(Du) + \frac{1}{2}\, |v|^2 \right) dx \tag{0.3}$$

(which decreases with time along solutions $(u(t), u_t(t))$ of (0.1); see (2.7) and Theorem 4.1). The lack of convexity (or polyconvexity, quasiconvexity, ...) properties of the energy Φ often enforces the creation of finer and finer oscillations in Du (see [BJ1, BJ2, CK] and after them many others) and leads to weak and not strong convergence of minimizing sequences (u^j, v^j) whose limits $(u, 0)$ in particular fail to satisfy the corresponding equilibrium equations Div $\sigma(Du) = 0$.

Example 0.1 (see [S, SH, F]). Let $n = 2$, $N = 1$, $\Omega = (0, 1) \times (0, 1)$, $\Phi = (u_x^2 - 1)^2 + (u_y)^4$, and choose the boundary condition $u(x, y)|_{\partial\Omega} = x^2/2$. One easily sees that the infimum of $I[u] = \int_\Omega \Phi(Du)\, dx$ on the Sobolev space $W^{1,4}(\Omega)$ is zero but not attained; minimizing sequences strive to simultaneously achieve $u_x(x, y) \in \{\pm 1\}$ and $u_y \equiv 0$, which is impossible as the latter together with Poincaré's inequality implies $u(x, y) \equiv x^2/2$. In fact, every minimizing sequence converges weakly and not strongly in $W^{1,4}(\Omega)$ to $x^2/2$, which is neither a minimizer nor an equilibrium state of (0.1).

Theorem 4.1 below applies in particular to this example and shows that the initial-value problem is by contrast well posed.

The interesting but more difficult issue of controllability of oscillations created as time $t \to \infty$ will not be addressed here, but see [FM] for recent progress on a related model problem in one space dimension.

The system in question is of some physical interest as a model for the dynamics of coherent solid–solid phase transitions, a connection which has in fact motivated much of the analytical [AB, P, R] and numerical [KL1, KL2, S, SH] work on (0.1). In this context, u could either be

(i) a scalar function of one spatial variable (i.e., $n = N = 1$) so that (0.1) becomes the equation of one-dimensional nonlinear viscoelasticity $u_{tt} = \sigma(u_x)_x + u_{xxt}$ [AB, P];

(ii) a scalar function of two spatial variables (i.e., $n = 2$ and $N = 1$), with u representing the out-of-plane displacement field of an antiplane shear deformation [S, SH]; or

(iii) a mapping from $\Omega \subset \mathbb{R}^3$ to $\mathbb{R}^3$ representing the deformation of a body that occupies in a reference configuration the domain Ω [KL1, KL2, R].

In suitable units, (0.1) then corresponds to the equation of balance of linear momentum $u_{tt} = \operatorname{Div} T$, where the (Piola–Kirchhoff) stress tensor T is modeled by the constitutive assumption

$$T = \sigma(Du) + Du_t. \tag{0.4}$$

As pointed out in [AB, P, R, KL1, KL2, S, SH], lack of convexity of Φ (as admitted here) is the crucial mathematical feature allowing one to model phase transitions. Our hypotheses in particular include stored-energy functions Φ whose set of minima is a finite union of rotationally invariant "potential wells" as described in [BJ1, BJ2]. We emphasize, however, that from the point of view of the continuum theory of solid–solid phase transitions more sophisticated dissipation mechanisms should be studied which should in particular meet the fundamental requirements of balance of angular momentum and dynamic frame indifference which are violated by the linear damping term in the constitutive assumption (0.4).

1. The initial-boundary-value problem. Let $\Omega \subset \mathbb{R}^n$ be an open bounded domain not required to satisfy any regularity conditions, and consider for vector-valued functions $u : \Omega \times [0, \infty) \to \mathbb{R}^N$ the initial-boundary-value problem

$$u_{tt} = \operatorname{Div}(\sigma(Du) + Du_t) \quad \text{in } \Omega \times (0, \infty), \tag{1.1a}$$

$$u = g \quad \text{on } \partial\Omega \times [0, \infty), \tag{1.1b}$$

$$u = u_0 \quad \text{in } \Omega \times \{0\}, \tag{1.1c}$$

$$u_t = v_0 \quad \text{in } \Omega \times \{0\}, \tag{1.1d}$$

where g, u_0, and v_0 are given functions, $\sigma(A) = \partial\Phi(F)/\partial F$, and the stored-energy function Φ satisfies the following hypotheses:

(H1) $\Phi \in C^2(M^{N\times n})$.

(H2) There exist $c > 0$, $C > 0$, and $p \geq 2$ such that

$$c|F|^p - C \leq \Phi(F) \leq C(|F|^p + 1), \qquad |\sigma(F)| \leq C(|F|^{p-1} + 1).$$

(H3) There exists $K > 0$ such that $(\sigma(\bar{F}) - \sigma(F)) \cdot (\bar{F} - F) \geq -K|\bar{F} - F|^2$.

LEMMA 1.1. *If* Φ *satisfies* (H1), *then* (H3) *is satisfied provided one of the following holds:*

(i) *σ is monotone, i.e.,* $(\sigma(\bar{F}) - \sigma(F)) \cdot (\bar{F} - F)) \geq 0 \, \forall F$ *and* $\bar{F}$.

(ii) *σ is globally Lipschitz continuous.*

(iii) *σ is the sum of a monotone and a globally Lipschitz continuous function.*

(iv) *σ satisfies the Andrews–Ball condition* (0.2).

Proof. The first three assertions are obvious. To prove that (0.2) implies (H3), note first that the desired inequality is clear either if both $|F|$, $|\bar F| \le 2R$ (since $\sigma|_{B(2R,0)}$ is globally Lipschitz continuous) or if both $|F|$, $|\bar F| \ge R$. Thus we may assume $|F| < R$ and $|\bar F| > 2R$. Let $F(\lambda) := \bar F - \lambda(\bar F - F)/|\bar F - F|$, then $|F(\lambda)|$ is equal to $|\bar F| > 2R$ at $\lambda = 0$ and to $|F| < R$ at $\lambda = |\bar F - F|$. Thus there exists $\lambda_0 \in (0, |\bar F - F|)$ such that $|F(\lambda_0)| = 2R$. Writing $F(\lambda_0) = F_0$ and using $\bar F - F_0 = \lambda_0(\bar F - F)/|\bar F - F|$, we calculate

$$\begin{aligned}(\sigma(\bar F) - \sigma(F)) \cdot (\bar F - F) = \frac{|\bar F - F|}{\lambda_0}&(\sigma(\bar F) - \sigma(F_0)) \cdot (\bar F - F_0)\\ &+ (\sigma(F_0) - \sigma(F)) \cdot (\bar F - F)\\ \ge{}& 0 - K_0|F_0 - F||\bar F - F| \quad (\text{since } |F_0|, |\bar F| \ge R)\\ \ge{}& -K_0|\bar F - F|^2,\end{aligned}$$

where K_0 is the Lipschitz norm of $\sigma|_{B(2R,0)}$.

2. The discrete scheme. Let $p \ge 2$ be the growth exponent from (H2), fix boundary data $g \in W^{1,p}(\Omega, \mathbb{R}^N)$, and let $\mathcal{A} := \{u \in W^{1,p}(\Omega, \mathbb{R}^N) : u - g \in W_0^{1,p}(\Omega, \mathbb{R}^N)\}$. We define approximate solutions to (1.1) by means of the following implicit time-discretization scheme (compare in particular [De]). For a fixed time stepsize $h > 0$ and initial data $u_0^h \in \mathcal{A}$, $v_0^h \in L^2(\Omega, \mathbb{R}^N)$, define inductively

$$\begin{aligned}(2.1)\qquad u^{h,-1} &:= u_0^h - hv_0^h,\\ u^{h,0} &:= u_0^h,\\ u^{h,j} &:= \text{a minimizer on } \mathcal{A} \text{ of the functional } J^{h,j}[u] \quad (j \in \mathbb{N}),\end{aligned}$$

where $\mathbb{N} = \{1, 2, 3, \dots\}$ and

(2.2)
$$J^{h,j}[u] := \int_\Omega \left(\Phi(Du) + \frac{1}{2h}|Du - Du^{h,j-1}|^2 + \frac{1}{2h^2}|u - 2u^{h,j-1} + u^{h,j-2}|^2\right) dx.$$

Note that for $j \ge 1$, the minimizers $u^{h,j}$ satisfy the Euler–Lagrange equations

$$\begin{aligned}&\int_\Omega \left[\left(\sigma(Du^{h,j}) + \frac{1}{h}(Du^{h,j} - Du^{h,j-1})\right)\right.\\ (2.3)\qquad &\qquad \left.\cdot D\zeta + \frac{1}{h^2}(u^{h,j} - 2u^{h,j-1} + u^{h,j-2}) \cdot \zeta\right] dx = 0\\ &\forall \zeta \in C_0^\infty(\Omega, \mathbb{R}^N),\end{aligned}$$

which represent a weak, time-discretized version of (1.1a). Now construct a time-dependent function $u^h : \Omega \times [0, \infty) \to \mathbb{R}^N$ by interpreting the $u^{h,j}$ as values at time jh and by interpolating linearly

$$(2.4)\quad u^h(x,t) := (j - t/h)u^{h,j-1}(x) + (t/h - (j-1))u^{h,j}(x) \quad (t \in ((j-1)h, jh]).$$

We will eventually show that if the initial data $u_0^h \to u_0$ and $v_0^h \to v_0$ in, respectively, $W^{1,p}$ and L^2, then a subsequence of the u^h converges to a weak solution of the initial-boundary-value problem (1.1). As a first step, consider the issue of well definedness of the above scheme. There is indeed something to prove, namely the following lemma.

LEMMA 2.1. *If $h > 0$, $u^{h,j-1} \in \mathcal{A}$, and $u^{h,j-2} \in L^2(\Omega, \mathbb{R}^N)$, then $J^{h,j}$ attains its infimum on $\mathcal{A}$.*

Proof. (The important thing to note here is that the term in $J^{h,j}$ involving the discretized counterpart of Du_t provides convexity of the integrand with respect to Du, despite Φ not being convex.)

By hypothesis (H2) and the fact that $\mathcal{A}$ is a weakly closed subset of $W^{1,p}(\Omega, \mathbb{R}^N)$, the assertion follows from the direct method of the calculus of variations provided $J^{j,h}$ is weakly sequentially lower semicontinuous (wslsc) on $W^{1,p}(\Omega, \mathbb{R}^N)$. Introducing the notation

$$\tilde{\Phi}(F) := \Phi(F) + \frac{1}{2h}|F|^2$$

and rewriting

$$J^{h,j}[u] = \int_\Omega \left(\tilde{\Phi}(Du) - \frac{1}{h} Du \cdot Du^{h,j-1} + \frac{1}{2h}|Du^{h,j-1}|^2 + \frac{1}{2h^2}|u - 2u^{h,j-1} + u^{h,j-2}|^2 \right),$$

it is clear that $u \mapsto J^{h,j}[u] - \int_\Omega \tilde{\Phi}(Du)\,dx$ is wslsc. Also, by (H3)

$$(D\tilde{\Phi}(\bar{F}) - D\tilde{\Phi}(F)) \cdot (\bar{F} - F) \geq \left(-K + \frac{1}{h} \right) |\bar{F} - F|^2;$$

that is to say, $\tilde{\Phi}$ is convex for $h \leq h_0 := 1/K$. Standard theorems in the calculus of variations [D, Theorem 2.6] then yield $u \mapsto \int_\Omega \tilde{\Phi}(Du)\,dx$ wslsc on $W^{1,p}(\Omega, \mathbb{R}^N)$.

In fact the above arguments only require quasi convexity of $u \mapsto \int_\Omega \tilde{\Phi}(Du)\,dx$ and hence remain valid if the damping term Δu_t in (1.1a) is replaced by a weaker (rank-one-elliptic) term whose associated quadratic form is only rank-one convex rather than convex. See section 5.3.

To proceed, we introduce the energy functional

$$E[u,v] := \int_\Omega \left(\Phi(Du) + \frac{1}{2}|v|^2 \right) dx \quad (u \in W^{1,p}(\Omega, \mathbb{R}^N), v \in L^2(\Omega, \mathbb{R}^N)) \tag{2.5}$$

and the notation

$$v^{h,j} := \frac{1}{h}(u^{h,j} - u^{h,j-1}) \quad (h > 0, j \in \mathbb{N} \cup \{0\}). \tag{2.6}$$

The next lemma is a discrete analog of the dissipation identity

$$E[u(t), u_t(t)] + \int_0^t \int_\Omega |Du_t|^2 = E[u_0, v_0] \tag{2.7}$$

for smooth solutions of (1.1).

LEMMA 2.2 (discrete energy inequality). *Let $u^{h,j}, v^{h,j}$ be as defined in* (2.1) *and* (2.6). *Given $\epsilon \in (0,1)$ there exists $h_0(\epsilon) > 0$ such that for all $h \leq h_0$*

(2.8)
$$\sup_{j \in \mathbb{N} \cup \{0\}} E[u^{h,j}, v^{h,j}] + \sum_{j=1}^\infty h \int_\Omega \left((1-\epsilon)|Dv^{h,j}|^2 + \frac{1}{2} \left| \frac{v^{h,j} - v^{h,j-1}}{h^{1/2}} \right|^2 \right) \leq E[u_0^h, v_0^h].$$

Proof. To simplify the notation, we drop all superscript h's. By (H3), for $h \leq h_0 := 2\epsilon/K$, the mapping $F \mapsto \Phi(F) + (\epsilon/h)|F - Du^j(x)|^2$ is convex for all $x \in \Omega$. Thus

$$\begin{aligned}&\Phi(\bar{F}) + \frac{\epsilon}{h}|\bar{F} - Du^j(x)|^2 - \Big(\Phi(F) + \frac{\epsilon}{h}|F - Du^j(x)|^2\Big)\\ &\quad\leq \Big(\sigma(\bar{F}) + \frac{2\epsilon}{h}(\bar{F} - Du^j(x))\Big) \cdot (\bar{F} - F)\end{aligned}$$

for all x, F, and $\bar{F}$; hence for all $j \in \mathbb{N} \cup \{0\}$,

$$\begin{aligned}&E[u^{j+1}, v^{j+1}] - E[u^j, v^j]\\ &\quad= \int_\Omega \Big[\Phi(Du^{j+1}) + \frac{\epsilon}{h}|Du^{j+1} - Du^j|^2 - \Big(\Phi(Du^j) + \frac{\epsilon}{h}|Du^j - Du^j|^2\Big)\\ &\qquad - \frac{\epsilon}{h}|Du^{j+1} - Du^j|^2 + \frac{1}{2}(|v^{j+1}|^2 - |v^j|^2)\Big]\,dx\\ &\quad\leq \int_\Omega \Big[\Big(\sigma(Du^{j+1}) + \frac{2\epsilon}{h}(Du^{j+1} - Du^j)\Big) \cdot (Du^{j+1} - Du^j)\\ &\qquad - \frac{\epsilon}{h}|Du^{j+1} - Du^j|^2 + \frac{1}{2}(|v^{j+1}|^2 - |v^j|^2)\Big]\,dx\\ &\quad= \int_\Omega \Big[\Big(\sigma(Du^{j+1}) + \frac{1}{h}(Du^{j+1} - Du^j)\Big) \cdot (Du^{j+1} - Du^j)\\ &\qquad - \frac{1-\epsilon}{h}|Du^{j+1} - Du^j|^2 + \frac{1}{2}(|v^{j+1}|^2 - |v^j|^2)\Big]\,dx.\end{aligned}$$

Now by (H2) and the fact that $Du^j \in L^p(\Omega, M^{n\times N})$ and $\sigma(Du) \in L^{p'}(\Omega, M^{n\times N})$, where $1/p' + 1/p = 1$, $\zeta = u^{j+1} - u^j$ is admissible as a test function in the Euler–Lagrange system (2.3) for u^j. So the last expression above equals

$$\begin{aligned}&\int_\Omega \Big(-(v^{j+1} - v^j) \cdot v^{j+1} - \frac{1-\epsilon}{h}|Du^{j+1} - Du^j|^2 + \frac{1}{2}(|v^{j+1}|^2 - |v^j|^2)\Big)\,dx\\ &\quad= \int_\Omega \Big(-\frac{1-\epsilon}{h}|Du^{j+1} - Du^j|^2 - \frac{1}{2}|v^{j+1} - v^j|^2\Big)\,dx.\end{aligned}$$

Applying the above estimate successively for all $j \in \mathbb{N} \cup \{0\}$ yields the assertion.

When passing to the limit $h \to 0$, it will be important to simultaneously use two different interpolations of the $u^{h,j}$ (resp., $v^{h,j}$): the piecewise linear interpolation u^h introduced in (2.4) and a piecewise constant one taking only the values $u^{h,j}$ (and called $\tilde{u}^h$ below). While the former has the advantage of being differentiable with respect to time, it is only the latter for which the exact Euler–Lagrange system (2.3) is available for every t.

For $h > 0$ and $j \in \mathbb{N} \cup \{0\}$, we let $I_{h,j} := ((j-1)h, jh]$ and define the following functions on $\Omega \times [0, \infty)$:

$$\begin{aligned}
\tilde{u}^h(x,t) &:= u^{h,j}(x) && (t \in I_{h,j}),\\
u^h(x,t) &:= (j - \tfrac{t}{h})u^{h,j-1} + (\tfrac{t}{h} - (j-1))u^{h,j} && (t \in I_{h,j}),\\
\tilde{v}^h(x,t) &:= v^{h,j}\ (= \tfrac{1}{h}(u^{h,j} - u^{h,j-1})) && (t \in I_{h,j}),\\
v^h(x,t) &:= (j - \tfrac{t}{h})v^{h,j-1} + (\tfrac{t}{h} - (j-1))v^{h,j} && (t \in I_{h,j}),\\
\tilde{w}^h(x,t) &:= w^{h,j} (:= \tfrac{1}{h}(v^{h,j} - v^{h,j-1})) && (t \in I_{h,j}).
\end{aligned} \tag{2.9}$$

Note that

$$\partial_t u^h = \tilde{v}^h, \qquad \partial_t v^h = \tilde{w}^h \tag{2.10}$$

and that the Euler–Lagrange system (2.3) can be rewritten as

$$\int_\Omega [(\sigma(D\tilde{u}^h) + D\tilde{v}^h) \cdot D\zeta + \tilde{w}^h \cdot \zeta]\, dx = 0 \quad \forall \zeta \in C_0^\infty(\Omega, \mathbb{R}^N), \quad \forall t > 0 \tag{2.11}$$

or (integrating over time)

$$\begin{aligned}
&\int_0^T \int_\Omega [(\sigma(D\tilde{u}^h) + D\tilde{v}^h) \cdot D\zeta - v^h \cdot \zeta_t]\, dx\, dt + \int_\Omega v^h \cdot \zeta\, dx|_{t=T}\\
&\qquad - \int_\Omega v^h \cdot \zeta\, dx|_{t=0} = 0 \quad \forall T > 0,\\
&\forall \zeta \in L^1(0,T; W_0^{1,p}(\Omega, \mathbb{R}^N))\\
&\qquad \cap L^2(0,T; W^{1,2}(\Omega, \mathbb{R}^N)) \cap W^{1,1}(0,T; L^2(\Omega, \mathbb{R}^N)).
\end{aligned} \tag{2.12}$$

Notation. In the next lemma and frequently below, we will abbreviate the function spaces $X(\Omega, \mathbb{R}^N)$ and $X(\Omega, M^{N\times n})$ by X and the spaces $Y(0,T;X)$ by $Y(X)$.

LEMMA 2.3 (weak convergences from the discrete energy inequality). *Assume*

$$\sup_{h>0} E[u_0^h, v_0^h] < \infty.$$

Then after extracting suitable subsequences, we have the following convergences as $h \to 0$:

$$\begin{aligned}
u^h|_{t=0} = u_0^h &\rightharpoonup u_0 \quad \mathit{in}\, W^{1,p},\\
v^h|_{t=0} = v_0^h &\rightharpoonup v_0 \quad \mathit{in}\, L^2,
\end{aligned} \tag{2.13}$$

and for every $T > 0$,

$$\begin{aligned}
\tilde{u}^h &\overset{*}{\rightharpoonup} \tilde{u} \quad \mathit{in}\ L^\infty(W^{1,p}),\\
u^h &\overset{*}{\rightharpoonup} u \quad \mathit{in}\ L^\infty(W^{1,p}), W^{1,\infty}(L^2), W^{1,2}(W^{1,2}),\\
\tilde{v}^h &\overset{*}{\rightharpoonup} \tilde{v} \quad \mathit{in}\ L^\infty(L^2), L^2(W^{1,2}),\\
v^h &\overset{*}{\rightharpoonup} v \quad \mathit{in}\ L^\infty(L^2), L^2(W^{1,2}), W^{1,2}(W^{-1,p'}),\\
\tilde{w}^h &\overset{*}{\rightharpoonup} \tilde{w} \quad \mathit{in}\ L^2(W^{-1,p'}),\\
\sigma(D\tilde{u}^h) &\overset{*}{\rightharpoonup} \tilde{\sigma} \quad \mathit{in}\ L^\infty(L^{p'}).
\end{aligned} \tag{2.14}$$

Here $W^{-1,p'}(\Omega,\mathbb{R}^N)$ denotes the usual negative Sobolev space, i.e., the completion of $L^{p'}(\Omega,\mathbb{R}^N)$ under the norm

$$\|u\|_{W^{-1,p'}} = \sup_{\zeta\in W_0^{1,p}\setminus\{0\}} \frac{|\int_\Omega u\cdot\zeta\,dx|}{\|\zeta\|_{W^{1,p}}},$$

and we say that $u^h \overset{*}{\rightharpoonup} u$ in $L^\infty(0,T;X)$ if

$$\int_0^T \langle u^h,\zeta\rangle\,dt \to \int_0^T \langle u,\zeta\rangle\,dt \quad \forall\zeta\in L^1(0,T;X),$$

where X' denotes the dual space of X. (If X is a Banach space with separable dual X', then the dual of $L^1(0,T;X)$ is the space $L^\infty(0,T;X')$ of essentially bounded, strongly measurable functions from $(0,T)$ into X'.)

Proof. The first four assertions are immediate consequences of Lemma 2.2 and (2.10). The last statement follows from the boundedness of $D\tilde{u}^h(t)$ in L^p and (H2). Finally, to prove the fifth convergence in (2.14), note that by (2.11),

$$\|\tilde{w}^h(t)\|_{W^{-1,p'}} \le \|\sigma(D\tilde{u}^h(t))\|_{L^{p'}} + \|D\tilde{v}^h(t)\|_{L^{p'}} \quad \forall t>0.$$

Now the first term is bounded in $L^\infty(L^{p'})$ and the last term in $L^2(L^2)$, so both terms are bounded in $L^2(L^{p'})$.

The following elementary lemma shows that the weak limits of piecewise constant and piecewise linear interpolations of a function given at discrete time steps actually coincide. (For an almost identical statement, see [KP].)

LEMMA 2.4. *Let $\Omega\subset\mathbb{R}^n$ be open and let $\{w^{h,j}\}_{j\in\mathbb{N},h>0}$ be a collection of functions in $L^1_{\text{loc}}(\Omega,\mathbb{R}^N)$. Define the piecewise constant and piecewise linear interpolations $\tilde{w}^h$ and w^h (as elements of $L^1_{\text{loc}}(\Omega\times[0,\infty),\mathbb{R}^N)$ by, respectively,*

$$\tilde{w}^h(x,t) := \sum_{j=1}^\infty \chi^{h,j}(t)w^{h,j}(x),$$
$$w^h(x,t) := \sum_{j=1}^\infty \chi^{h,j}(t)\left[\left(j-\frac{t}{h}\right)w^{h,j-1}(x) + \left(\frac{t}{h}-(j-1)\right)w^{h,j}(x)\right],$$

where $\chi^{h,j} := \chi_{((j-1)h,jh)}$ denotes the characteristic function of the interval $I_{h,j} := ((j-1)h,jh]$. Suppose that

$$\begin{cases} \tilde{w}^h \rightharpoonup \tilde{w}, \\ w^h \rightharpoonup w \end{cases}$$

weakly in $L^1_{\text{loc}}(\Omega\times[0,\infty),\mathbb{R}^N)$ as $h\to 0$. Then $\tilde{w}=w$.

Proof. Clearly it is enough to check that

$$\int_0^\infty\int_\Omega w\cdot\zeta\,dx\,dt = \int_0^\infty\int_\Omega \tilde{w}\cdot\zeta\,dx\,dt \quad \forall\zeta\in C_0^\infty(\Omega\times(0,\infty),\mathbb{R}^N).$$

A simple calculation shows that for h small enough,

$$\begin{aligned}
&\int_0^\infty \int_\Omega w^h(x,t)\cdot\zeta(x,t)\,dx\,dt \\
&= \int_0^\infty \int_\Omega \sum_{j=1}^\infty \chi^{h,j}(t)\left[\left(j-\frac{t}{h}\right)w^{h,j-1}(x)+\left(\frac{t}{h}-(j-1)\right)w^{h,j}(x)\right]\cdot\zeta(x,t)\,dx\,dt \\
&= \int_0^\infty \int_\Omega \tilde{w}^h(x,t)\cdot\left(\sum_{k=1}^\infty \chi^{h,k}(t)\left[\left(j-\frac{t}{h}\right)\zeta(x,t)+\left(\frac{t}{h}-(j-1)\right)\zeta(x,t+h)\right]\right)dx\,dt.
\end{aligned}$$

Since ζ has compact support, it follows that

$$\sum_{k=1}^\infty \chi^{h,k}(t)\left[\left(j-\frac{t}{h}\right)\zeta(x,t)+\left(\frac{t}{h}-(j-1)\right)\zeta(x,t+h)\right]\to\zeta$$

uniformly on $\Omega\times[0,\infty)$, and the result is a consequence of the weak convergence of w^h and $\tilde{w}^h$.

COROLLARY 2.1. *The limits obtained in Lemma* 2.3 *satisfy* $\tilde{u}=u$ *and* $\tilde{v}=v=u_t$. *In particular,* $u\in L^\infty(W_0^{1,p})\cap W^{1,\infty}(L^2)\cap W^{1,2}(W^{1,2})\cap W^{2,2}(W^{-1,p'})$ (*so that the traces* $u|_{t=0}$ *and* $u_t|_{t=0}$ *are well defined in, respectively,* $W^{1,2}$ *and* $W^{-1,p'}$) *and*

$$\int_0^T\int_\Omega[(\tilde{\sigma}+Du_t)\cdot D\zeta-u_t\cdot\zeta_t]\,dx\,dt+\int_\Omega u_t\cdot\zeta\,dx\Big|_{t=T}-\int_\Omega u_t\cdot\zeta\,dx\Big|_{t=0}=0$$

$$\forall T>0,\qquad \forall\zeta\in L^1(W_0^{1,p})\cap L^2(W^{1,2})\cap W^{1,1}(L^2),$$

$$u|_{t=0}=u_0,$$

$$u_t|_{t=0}=v_0. \tag{2.15}$$

In order to show that u is a weak solution to (1.1), it only remains to "pass to the limit in the nonlinear term," i.e., to demonstrate that under the assumptions of Lemma 2.3, $\tilde{\sigma}=\sigma(Du)$. This is in general false.

Example 2.1. *Let* $n=N=1$, $\Phi(u_x)=(u_x^2-1)^2$, $\Omega=(0,1)$, $g(x)=x/2$, $u_0^h(x)=\int_0^x\eta(x'/h)\,dx'$, *and* $v_0^h=0$, *where* $\eta(z)=-1$ *if* $z\in(n,n+1]$ *and* $n\equiv 0$ *mod* 4, $\eta(z)=1$ *otherwise. Let* $h\in\{1/4,1/8,1/12,\ldots\}$. *Then* $u^{h,j}\equiv u_0^h$ *is a solution to the discrete scheme* (2.1) (*and its interpolations* u^h, $\tilde{u}^h$ *are solutions to the continuous problem* (1.1)). *However,* $\tilde{u}_x^h=u_x^h\equiv\eta(\cdot/h)$ *does not converge strongly in* $L^1_{\mathrm{loc}}(\Omega\times(0,T))$ *as* $h\to 0$ *and* $0=\tilde{\sigma}\neq\sigma(u_x)=\sigma(1/2)$.

3. Propagation of regularity for the discrete scheme. The fact illustrated in Example 2.1 that the limiting PDE (1.1) does not regularize Du in time was already observed in [AB, P] and is a fundamental feature of evolution equations whose underlying stored-energy functions are not convex. It implies that passage to the limit in the nonlinearity σ cannot be achieved via estimating higher spatial derivatives and appealing to compact embedding theorems—neither for the scheme (2.1) analyzed here nor for approximate solutions obtained by any other method.

Note, however, that the oscillations of u_x^h in Example 2.1 were not created by the (continuous or discretized) dynamics but were already present in the initial data.

PROPOSITION 3.1 (propagation of regularity for the deformation gradient). *Let* u_0^h *and* v_0^h *be as in Lemma* 2.3, *and let* h *be the index of the subsequence delivered* *by Lemma* 2.3 *for which the convergences* (2.13) *and* (2.14) *hold. If in addition Du_0^h converges strongly in L^2 as $h \to 0$, then both Du^h and $D\tilde{u}^h$ converge strongly in $L^2(0,T;L^2)$ as $h \to 0$ $\forall\, T > 0$. More precisely,*

$$\limsup_{h\to 0} \int_0^T \int_\Omega |Du^h - Du|^2\, dx\, dt \le \limsup_{h\to 0} \int_\Omega |Du_0^h - Du_0|^2\, dx \frac{1}{2K} e^{4KT}, \tag{3.1}$$

$$\limsup_{h\to 0} \int_0^T \int_\Omega |D\tilde{u}^h - Du|^2\, dx\, dt \le \limsup_{h\to 0} \int_\Omega |Du_0^h - Du_0|^2\, dx \frac{1}{2K} e^{4KT} \tag{3.2}$$

$\forall\, T > 0$*, with K as in* (H3).

Example 2.1 shows that the assumption that the initial data converge strongly cannot be omitted.

For the large class of stored-energy functions admitted here (see (H1)–(H3)) it seems to be unknown whether an analogue of Proposition 3.1 holds for Galerkin approximations (as used for similar systems in [BBN1]) or for approximations obtained by regularization ("viscosity method" employed for a similar system in [E2]).

Estimate (3.1) also holds for a sequence of solutions to the limit system (1.1). The proof is similar but technically simpler and is left to the interested reader.

One ingredient in the proof of Proposition 3.1 will be the following result, interesting in its own right.

Proposition 3.2 (regularization for the velocity). *Let u_0^h and v_0^h be as in Lemma* 2.3*, and let h be the index of the subsequence delivered by Lemma* 2.3 *for which the convergences* (2.13) *and* (2.14) *hold. Then* (*without assuming strong convergence for the initial data*) *v^h and $\tilde{v}^h = \partial_t u^h$ converge strongly in $L^2(0,T;L^2)$ as $h \to 0$, $\forall\, T > 0$.*

This reflects the remarkable smoothing effects of the limit system (1.1) on u_t discovered by Pego [P] in one space dimension and generalized later by Rybka [R] to several dimensions in the case of globally Lipschitz-continuous nonlinearities σ.

Before embarking upon the proof of the above results, we prepare three lemmas. The first is a well-known Aubin-type result which can, for example, be found in [L, Chapter 1, Theorem 5.1].

Lemma 3.1. *Let X_s, X, and X_w be reflexive Banach spaces such that the following inclusions hold: $X_s \hookrightarrow$ (compact) $X \hookrightarrow$ (continuous) X_w. Let p_0, $p_1 \in (1,\infty)$ and $T > 0$. Then the embedding of $L^{p_0}(0,T;X_s) \cap W^{1,p_1}(0,T;X_w)$ equipped with the norm $\|\cdot\|_{L^{p_0}(X_s)} + \|\partial_t \cdot\|_{L^{p_1}(X_w)}$ into $L^{p_0}(0,T;X)$ is compact.*

The next lemma investigates more closely the connection between the piecewise-constant and the piecewise linear interpolation of a function given at discrete time steps.

Lemma 3.2. *Let X be a Banach space and $\{w^{h,j}\}_{j\in\mathbb{N},h>0}$ a collection of elements in X. Define the piecewise constant and piecewise linear interpolations $\tilde{w}^h$ and w^h* (*as elements of $L^1_{\mathrm{loc}}([0,\infty);X)$*) *by*

$$\tilde{w}^h := w^{h,j} \quad \text{on } I_{h,j},$$

$$w^h(t) := \left(j - \frac{t}{h}\right) w^{h,j-1} + \left(\frac{t}{h} - (j-1)\right) w^{h,j} \quad \text{on } I_{h,j}$$

($j \in \mathbb{N}, I_{h,j}$ *as in Lemma* 2.4). *Assume that*

$$\sup_{j\ge 1} \|w^{h,j}\|^2 \le C_1 \tag{3.3}$$

and for some $\alpha > 0$,

$$\sum_{j=1}^{\infty} h \left\| \frac{w^{h,j} - w^{h,j-1}}{h^\alpha} \right\|^2 \leq C_2. \tag{3.4}$$

Then $\forall T > 0$ and $\forall w \in L^2(0,T;X)$ with $\sup_t \|w(t)\|^2 \leq C_1$, the following estimate holds:

$$\int_0^T \|\tilde{w}^h - w\|^2 \, dt \leq 2 \int_0^T \|w^h - w\|^2 \, dt + 4hC_1 + \frac{2}{3} h^{2\alpha} C_2.$$

Proof. For $t \in I_{h,j}$, we have by construction

$$w^h(t) - w(t) = (w^{h,j} - w(t)) - \left(j - \frac{t}{h}\right)(w^{h,j} - w^{h,j-1})$$

and thus

$$\begin{aligned} \|w^{h,j} - w(t)\|^2 &= \|(w^h(t) - w(t)) + \left(j - \frac{t}{h}\right)(w^{h,j} - w^{h,j-1})\|^2 \\ &\leq 2\|w^h(t) - w(t)\|^2 + 2\left|j - \frac{t}{h}\right|^2 \|w^{h,j} - w^{h,j-1}\|^2. \end{aligned}$$

Integrating this inequality over $I_{h,j}$ yields

$$\int_{I_{h,j}} \|w^{h,j} - w(t)\|^2 \, dt \leq 2 \int_{I_{h,j}} \|w^h(t) - w(t)\|^2 \, dt + \frac{2}{3} h \|w^{h,j} - w^{h,j-1}||^2.$$

Denoting by $J := \text{int}(\frac{T}{h})$ the largest integer less than or equal to T/h, we have $|T - Jh| \leq h$ and thus

$$\begin{aligned} \int_0^T \|\tilde{w}^h(t) - w(t)\|^2 \, dt &= \sum_{j=1}^{J} \int_{I_{h,j}} \|w^{h,j} - w(t)\|^2 \, dt + \int_{Jh}^T \|\tilde{w}^h(t) - w(t)\|^2 \, dt \\ &\leq \sum_{j=1}^{J} \left\{ 2 \int_{I_{h,j}} \|w^h(t) - w(t)\|^2 \, dt + \frac{2}{3} h \|w^{h,j} - w^{h,j-1}\|^2 \right\} + 4hC_1 \\ &\leq 2 \int_0^T \|w^h(t) - w(t)\|^2 \, dt + \frac{2}{3} h^{2\alpha} \sum_{j=1}^{\infty} h \left\| \frac{w^{h,j} - w^{h,j-1}}{h^\alpha} \right\|^2 + 4hC_1. \end{aligned}$$

This immediately implies the result.

The third (elementary and well-known) lemma will be used to estimate various "harmless" terms in the proof of Proposition 3.1.

LEMMA 3.3. *Let $\tilde{\Omega} \subseteq \mathbb{R}^m$ be open, $q \in (1, \infty)$, $\phi^h \to 0$ weakly in $L^{q'}(\tilde{\Omega})$ as $h \to 0$, and Ψ be a compact subset of $L^q(\tilde{\Omega})$. Then*

$$\sup_{\psi \in \Psi} \left| \int_\Omega \phi^h \psi \, dx \right| \to 0 \quad (h \to 0).$$

Proof of Proposition 3.2. Since $v^h \rightharpoonup v = u_t$ weakly in $L^2(W^{1,2})$ and in $W^{1,2}(W^{-1,p'})$, by Lemma 3.1, $v^h \to u_t$ strongly in $L^2(L^2)$. From this, by Lemma

3.2 with $X = L^2$, $w^{h,j} = v^{h,j}$, $w = u_t$, and $\alpha = 1/2$, we obtain $\tilde{v}^h = \partial_t u^h \to u_t$ strongly in $L^2(L^2)$. Note that hypothesis (3.4) of Lemma 3.2 is satisfied thanks to the remarkable estimate

$$\sup_{h>0} \sum_{j=1}^{\infty} h \left\| \frac{v^j - v^{j-1}}{h^{1/2}} \right\|_{L^2}^2 < \infty$$

derived in Lemma 2.2, which had not been used up until now.

Proof of Proposition 3.1. Besides (2.12), we will also need another time-integrated version of the Euler–Lagrange system (2.11) which does not require the test function ζ to be differentiable in time:

(3.5)

$$\int_0^T \int_\Omega \left[(\sigma(D\tilde{u}^h) + D\tilde{v}^h) \cdot D\zeta - \tilde{v}^h \cdot \frac{\zeta(\cdot + h) - \zeta}{h} \right] dx\, dt + \fint_{T-h}^{T} \int_\Omega \tilde{v}^h \cdot \zeta(\cdot + h)\, dx\, dt$$
$$- \fint_{-h}^{0} \int_\Omega v_0^h \cdot \zeta(\cdot + h)\, dx\, dt = 0 \quad \forall T > 0, \forall \zeta \in L^1(0, T; W_0^{1,p}).$$

Testing (3.5) with $\tilde{u}^h - u$ and (2.15) with $u^h - u$ and subtracting, we have

$$\begin{aligned}
&\int_0^t \int_\Omega [\sigma(D\tilde{u}^h) \cdot (D\tilde{u}^h - Du) - \tilde{\sigma} \cdot (Du^h - Du)]\, dx\, d\tau \\
&\quad + \int_0^t \int_\Omega [D\tilde{v}^h \cdot (D\tilde{u}^h - Du) - Du_t \cdot (Du^h - Du)]\, dx\, d\tau \\
&\quad - \int_0^t \int_\Omega \left[\tilde{v}^h \cdot \left(\tilde{v}^h(\cdot + h) - \frac{u(\cdot + h) - u}{h} \right) - u_t \cdot ((u^h)_t - u_t) \right] dx\, d\tau \\
&\quad + \int_\Omega \left[\fint_{t-h}^{1} \tilde{v}^h \cdot (\tilde{u}^h(\cdot + h) - u(\cdot + h))\, d\tau - u_t(t) \cdot (u^h(t) - u(t)) \right] dx \\
&\quad - \int_\Omega v_0^h \cdot \left[\fint_{-h}^{0} (\tilde{u}^h(\cdot + h) - u(\cdot + h))\, dt - (u_0^h - u_0) \right] dx = 0.
\end{aligned}$$

Fix $T > 0$, let $t \in (0, T)$, denote the five terms above by $T_1, \dots, T_5$, and write $\eta(h)$ for quantities tending to zero as $h \to 0$ uniformly with respect to $t \in (0, T)$.

$$\begin{aligned}
T_1 &= \int_0^t \int_\Omega [(\sigma(D\tilde{u}^h) - \sigma(Du)) \cdot (D\tilde{u}^h - Du) + \sigma(Du) \cdot\ (D\tilde{u}^h - Du) \\
&\qquad\qquad - \tilde{\sigma} \cdot (Du^h - Du)]\, dx\, d\tau \\
&\geq -K \int_0^t \int_\Omega |D\tilde{u}^h - Du|^2 - \sup_{t \in (0,T)} \left| \int_{\Omega_T} (\chi_{\Omega_t} \sigma(Du)) \cdot (D\tilde{u}^h - Du)\, dx\, d\tau \right| \\
&\quad - \sup_{t \in (0,T)} \left| \int_{\Omega_T} (\chi_{\Omega_t} \tilde{\sigma}) \cdot (Du^h - Du)\, dx\, d\tau \right| \\
&\geq -K \int_0^t \int_\Omega |D\tilde{u}^h - Du|^2 - \eta(h) \\
&\geq -2K \int_0^t \int_\Omega |Du^h - Du|^2 - \eta(h).
\end{aligned}$$

Here the first inequality follows from Lemma 1.1, the second from Lemma 3.3 (with $\tilde{\Omega} = \Omega \times (0,T) =: \Omega_T$, $p = q'$, and, e.g., $\Psi = \{\chi_{\Omega_t}\sigma(Du) : t \in [0,T]\}$, $\phi^h = D\tilde{u}^h - Du$), and the third from Lemma 3.2 (with $X = L^2$, $w^{h,j} = Du^{h,j}$, and $\alpha = 1$, noting that assumption (3.4) holds by Lemma 2.2).

$$\begin{aligned}
T_2 &= \int_0^t \int_\Omega [((Du^h)_t - Du_t) \cdot (Du^h - Du) + D\tilde{v}^h \cdot (D\tilde{u}^h - Du^h)]\, dx\, d\tau \\
&= \frac{1}{2} \int_\Omega |Du^h(t) - Du(t)|^2\, dx - \frac{1}{2} \int_\Omega |Du^h(0) - Du(0)|^2\, dx \\
&\quad + \sum_{j=1}^{\infty} \int_{I_{h,j} \cap (0,t)} \int_\Omega h(j - t/h) |Dv^{h,j}|^2 \\
&\le \frac{1}{2} \int_\Omega |Du^h(t) - Du(t)|^2\, dx - \frac{1}{2} \int_\Omega |Du^h(0) - Du(0)|^2\, dx + \frac{1}{2} h^2 \sum_{j=1}^{\infty} \int_\Omega |Dv^{h,j}|^2 \\
&= \frac{1}{2} \int_\Omega |Du^h(t) - Du(t)|^2\, dx - \frac{1}{2} \int_\Omega |Du^h(0) - Du(0)|^2\, dx + \eta(h),
\end{aligned}$$

the last equality being a consequence of Lemma 2.2.

$$\begin{aligned}
|T_3| &\le \|\tilde{v}^h\|_{L^2(L^2)} \left(\|\tilde{v}^h - u_t\|_{L^2(0,T+h;L^2)} + \left\| u_t - \frac{u - u(\cdot - h)}{h} \right\|_{L^2(h,T+h;L^2)} \right) \\
&\quad + \|u_t\|_{L^2(L^2)} \|\tilde{v}^h - v_t\|_{L^2(L^2)} \\
&= \eta(h)
\end{aligned}$$

by Proposition 3.2 and the fact that $u \in W^{1,\infty}(0, 2T; L^2)$. To estimate T_4 and T_5, we will need

$$\|\tilde{u}^h - u^h\|^2_{L^\infty(0,\infty;L^2)} = \sup_{j \in \mathbb{N}} \|u^{h,j} - u^{h,j-1}\|^2_{L^2} = h^2 \sup_{j \in \mathbb{N}} \|v^{h,j}\|^2_{L^2} = \eta(h). \tag{3.6}$$

As for T_4,

$$\begin{aligned}
|T_4| &\le \|\tilde{v}^h\|_{L^\infty(-h,T;L^2)} \|\tilde{u}^h - u\|_{L^\infty(0,T+h;L^2)} + \|u_t\|_{L^\infty(L^2)} \|u^h - u\|_{L^\infty(L^2)} \\
&\le \|\tilde{v}^h\|_{L^\infty(-h,T;L^2)} \|\tilde{u}^h - u^h\|_{L^\infty(0,T+h;L^2)} \\
&\quad + (\|\tilde{v}^h\|_{L^\infty(-h,T;L^2)} + \|u_t\|_{L^\infty(L^2)}) \|u^h - u\|_{L^\infty(0,T+h;L^2)} \\
&= \eta(h)
\end{aligned}$$

by (3.6), Proposition 3.2, and the continuous embedding $W^{1,2}(L^2) \hookrightarrow L^\infty(L^2)$. Similarly,

$$|T_5| \le \|v_0^h\|_{L^2} (\|\tilde{u}^h - u\|_{L^\infty(0,h;L^2)} + \|u_0^h - u_0\|_{L^2}) = \eta(h)$$

by the weak convergence of u_0^h to u_0 in $W^{1,p}$ and the compact embedding $W^{1,p} \hookrightarrow L^2$. Collecting terms and multiplying by two,

$$\partial_t \int_0^t \!\! \int_\Omega |Du^h - Du|^2\, dx\, dt \le \int_\Omega |Du^h(0) - Du(0)|^2\, dx + \eta(h) + 4K \int_0^t \!\! \int_\Omega |Du^h - Du|^2\, dx\, d\tau$$

and thus by Gronwall's inequality,

$$\int_0^T \int_\Omega |Du^h - Du|^2\, dx\, dt \le \left(\int_\Omega |Du^h(0) - Du(0)|^2\, dx + \eta(h) \right) \frac{1}{4K} e^{4KT}.$$

Letting $h \to 0$ gives (3.1), and (3.2) follows by appealing again to Lemma 3.2 (with $X = L^2$, $w^{h,j} = Du^{h,j}$, and $\alpha = 1$). The proof of Proposition 3.1 is complete.

4. Global existence of weak solutions and the energy inequality. We are now ready to present the main result of this article.

THEOREM 4.1 (global existence of weak solutions). *Let $\Omega \subset \mathbb{R}^n$ be open and bounded, assume Φ satisfies* (H1), (H2), *and* (H3)*; let $g \in W^{1,p}(\Omega, \mathbb{R}^N)$, and let the initial data $u_0 \in \mathcal{A} = \{u \in W^{1,p}(\Omega, \mathbb{R}^N) : u - g \in W_0^{1,p}(\Omega, \mathbb{R}^N)\}$ and $v_0 \in L^2(\Omega, \mathbb{R}^N)$. Then there exists*

$$\begin{aligned} u \in\ & L^\infty(0, \infty; \mathcal{A}) \\ & \cap W^{1,\infty}(0, \infty; L^2(\Omega, \mathbb{R}^N)) \\ & \cap W^{1,2}_{\mathrm{loc}}([0, \infty); W^{1,2}(\Omega, \mathbb{R}^N)) \\ & \cap W^{2,2}_{\mathrm{loc}}([0, \infty); W^{-1,p'}(\Omega, \mathbb{R}^N)), \end{aligned} \tag{4.1}$$

which is a weak solution of (1.1)*, i.e.,*

$$\begin{aligned} \int_0^\infty \int_\Omega [(\sigma(Du) + Du_t) \cdot D\zeta - u_t \cdot \zeta_t]\, dx\, dt = 0 \quad & \forall \zeta \in C_0^\infty(\Omega \times (0, \infty), \mathbb{R}^N) \\ u|_{t=0} = u_0&, \\ u_t|_{t=0} = v_0&, \end{aligned} \tag{4.2}$$

and satisfies the dissipation inequality

$$E[u(t), u_t(t)] - E[u_0, v_0] \le -\int_0^t \int_\Omega |Du_t|^2\, dx\, d\tau \tag{4.3}$$

for almost every $t > 0$.

Proof. Set $u_0^h \equiv v_0$, $v_0^h \equiv v_0\, \forall h$. Define $u^{h,j}$ ($j \in \mathbb{N}, h > 0$) by (2.1). Then the hypotheses of Lemma 2.4 and Proposition 3.1 are trivially satisfied, and all assertions except the energy inequality follow immediately from Lemma 2.3, Corollary 2.1, and Proposition 3.1.

The energy inequality is less immediate as the mapping

$$u \mapsto \int_\Omega \Phi(Du)\, dx$$

is not assumed to be weakly lower semicontinuous on $W^{1,p}$. The remedy here is to split Φ into $(\Phi(\cdot) + \frac{K}{2}|\cdot|^2)$ and $(-\frac{K}{2}|\cdot|^2)$ (K as in (H3)) and to use the strong convergence of $D\tilde{u}^h$ in L^2.

By Lemma 2.2, $\forall \epsilon \in (0, 1)$ there exists $h_0(\epsilon) > 0$ such that for $0 < h \le h_0(\epsilon)$ and every $t > 0$, the following inequality holds:

$$\begin{aligned} & \int_\Omega \Phi(D\tilde{u}^h)\, dx + \frac{1}{2} \int_\Omega |\tilde{v}^h(t)|^2\, dx + (1 - \epsilon) \int_0^t \int_\Omega |D\tilde{v}^h|^2\, dx\, d\tau \\ & \le \int_\Omega \Phi(Du_0)\, dx + \frac{1}{2} \int_\Omega |v_0|^2\, dx. \end{aligned}$$

Since $\tilde{v}^h(t) \to u_t$ strongly in $L^2(\Omega)$ for a.e. $t > 0$ and $D\tilde{v}^h \rightharpoonup Du_t$ weakly in $L^2(\Omega_t)$, it follows from the weak lower semicontinuity of the norm in $L^2(\Omega_t)$ that

$$\begin{aligned}(4.4)\qquad \limsup_{h\to 0} \int_\Omega \Phi(D\tilde{u}^h)\,dx + \frac{1}{2}\int_\Omega |u_t|^2\,dx + (1-\epsilon)\int_0^t \int_\Omega |Du_t|^2\,dx\,d\tau \\ \leq \int_\Omega \Phi(Du_0)\,dx + \frac{1}{2}\int_\Omega |v_0|^2\,dx \quad (\text{a.e. } t > 0).\end{aligned}$$

However, since for a.e. $t > 0$

$$\begin{cases} D\tilde{u}^h(t) \rightharpoonup Du(t)\,\text{weakly in } L^p, \\ D\tilde{u}^h(t) \to Du(t)\,\text{strongly in } L^2, \end{cases}$$

we obtain

$$\begin{aligned}\int_\Omega \Phi(Du)\,dx &= \int_\Omega \left(\Phi(Du) + \frac{K}{2}|Du|^2\right)\,dx - \int_\Omega \frac{K}{2}|Du|^2\,dx \\ &\leq \limsup_{h\to 0}\int_\Omega \left(\Phi(D\tilde{u}^h) + \frac{K}{2}|D\tilde{u}^h|^2\right)\,dx - \int_\Omega \frac{K}{2}|Du|^2\,dx \\ &\leq \limsup_{h\to 0}\int_\Omega \Phi(D\tilde{u}^h)\,dx + \limsup_{h\to 0}\int_\Omega \frac{K}{2}|Du^h|^2\,dx - \int_\Omega \frac{K}{2}|Du|^2\,dx \\ &= \limsup_{h\to 0}\int_\Omega \Phi(D\tilde{u}^h)\,dx.\end{aligned}$$

Substituting this inequality into (4.4) yields the result since $\epsilon > 0$ was arbitrary.

5. Concluding remarks.

5.1. Uniqueness in the Lipschitz continuous case. If in addition σ is globally Lipschitz continuous, weak solutions of (1.1) are unique in the function class in which we have established existence. Indeed, a simple calculation shows that if u and $\bar{u}$ are two solutions of (4.2) and lie in the space (4.1), then

$$\begin{aligned}&\partial_t \frac{1}{2}\left(\int_0^t \int_\Omega |D\bar{u} - Du|^2\,dx\,d\tau + \int_\Omega |\bar{u}(t) - u(t)|^2\,dx\right) \\ &\quad = -\int_0^t \int_\Omega (\sigma(D\bar{u}) - \sigma(Du)) \cdot (D\bar{u} - Du)\,dx\,d\tau + \int_0^t \int_\Omega |\bar{u}_t - u_t|^2\,dx\,d\tau \\ &\quad \leq (\text{Lip } \sigma)\int_0^t \int_\Omega (|D\bar{u} - Du|^2 + |\bar{u}_t - u_t|^2)\,dx\,d\tau\end{aligned}$$

and

$$\begin{aligned}&\partial_t \frac{1}{2}\int_0^t \int_\Omega |\bar{u}_t - u_t|^2\,dx\,d\tau \\ &\quad = -\int_0^t \int_\Omega [(D\bar{u}_t - Du_t)\cdot(\sigma(D\bar{u}) - \sigma(Du)) + |D\bar{u}_t - Du_t|^2]\,dx\,d\tau \\ &\quad \leq \frac{1}{4}(\text{Lip } \sigma)\int_0^t \int_\Omega |D\bar{u} - Du|^2\,dx\,d\tau.\end{aligned}$$

Adding these two inequalities and appealing to Gronwall's inequality gives $\bar{u} - u \equiv 0$. This calculation is a modest generalization of the uniqueness theorem of Rybka [R] (which applies to the same assumptions on σ and to a slightly more "regular" function space).

It would be interesting to investigate whether uniqueness remains true in the more general setting of hypotheses (H1)–(H3).

5.2. Anisotropic growth at infinity. It is easily seen that Theorem 4.1 remains true if hypothesis (H2) on Φ is replaced by the anisotropic growth condition

$$\text{(H2)}' \qquad \Phi(F) = \sum_{i=1}^{N} \Phi_i(F_i), \quad \text{where } F_i \text{ denotes the } i\text{th column of } F, \quad \text{and}$$
$$\exists C > 0, \quad c > 0, \quad p_i \geq 2 \quad \text{such that for all } i,$$
$$c|f|^{p_i} - C \leq \Phi_i(f) \leq C(|f|^{p_i} + 1)$$

and $p = \max\{p_i, \dots, p_N\}$. While of minor conceptual interest, this modification entails to the best of our knowledge the first existence proof for (1.1) in the paradigm case $n = 2$, $N = 1$, $\Phi(u_x, u_y) = (u_x^2 - 1)^2 + u_y^2$, $g = 0$ studied numerically in [S, SH].

5.3. Infinitesimal frame indifference. The following modification is mathematically a little less trivial and physically more interesting. Theorem 4.1 also remains true if the system (1.1a) is replaced by the system with weaker damping

$$u_{tt} = \text{Div } \sigma(Du) + Lu_t,$$

where L is any symmetric (rank-one-) elliptic operator in divergence form, i.e., $Lv =$ Div $A(Dv)$ with A a linear mapping from $M^{N \times n}$ to $M^{N \times n}$, $A(F) \cdot G = F \cdot A(G) \, \forall F$, $G \in M^{N \times n}$,

$$A(\xi \otimes \eta) \cdot \xi \otimes \eta \geq \lambda |\xi|^2 |\eta|^2 \quad \forall \xi \in \mathbb{R}^N \text{ and } \eta \in \mathbb{R}^n \text{ and some } \lambda > 0 \tag{5.1}$$

and with the dissipation integrand $|Du_t|^2$ in (4.3) replaced by $A(Du_t) \cdot Du_t$. (To obtain approximate solutions, instead of (2.2), one would now minimize the functional

$$J^{h,j}[u] = \int_\Omega \Bigg(\Phi(Du) + \frac{1}{2h} A(Du - Du^{h,j-1}) \cdot (Du - Du^{h,j-1}) + \frac{1}{2h^2} |u - 2u^{h,j-1} + u^{h,j-2}|^2 \Bigg) \, dx,$$

whose integrand need no longer be convex but is readily shown to be quasi convex for $h \leq \lambda / K$ thanks to Plancherel's formula, (H3), and (5.1).)

In particular, in the case $n = N = 3$ relevant for elasticity, one may take $A(F) = \frac{1}{2}(F + F^T)$, i.e., $Lu_t = \text{Div}(\frac{1}{2}(Du_t + (Du_t)^T))$. This weaker damping term no longer causes energy dissipation along infinitesimal rigid rotations $u(x,t) = u_0(x) + tBx$ $(B + B^T = 0)$ and (unlike Δu_t) fulfills the fundamental requirement of frame indifference at least infinitesimally.

Acknowledgments. We thank Stefan Müller for stimulating discussions. Also, the first author thanks Hamid Bellout for interesting comments on references [BBN1, BBN2].

STRUCTURAL STABILITY OF MORSE–SMALE GRADIENT-LIKE FLOWS UNDER DISCRETIZATIONS*

MING-CHIA LI[†]

Abstract. In this paper, we show that the qualitative property of a Morse–Smale gradient-like flow is preserved by its discretization mapping obtained via numerical methods. This means that for all sufficiently small h, there is a homeomorphism H_h conjugating the time-h map Φ^h of the flow to the discretization mapping ϕ^h. Garay [*Numer. Math.*, 72 (1996), pp. 449–479] showed this result by relying on techniques of Robbin [*Ann. Math.*, 94 (1971), pp. 447–493]. Our result sharpens and unifies that in [*Numer. Math.*, 72 (1996), pp. 449–479] by using Robinson's method in [*J. Differential Equations*, 22 (1976), pp. 28–73] of the structural stability theorem for diffeomorphisms.

We also study the problem on a manifold with boundary. Under the assumption that the manifold M is positively invariant for the flow, we show that the qualitative properties are weakly stable, which means we allow the homeomorphism H_h from M into a larger manifold M' which contains M and is of the same dimension as M.

1. Introduction.

First, we introduce some notations and definitions. Let M be a smooth manifold with distance $d(\cdot,\cdot)$ arising from the Riemannian metric. For $p \geq 0$, let $\mathrm{Diff}^p(M)$ denote the set of C^p diffeomorphisms on M with the uniformly C^p topology.

Definition 1.1. *We say that Φ^t is a C^{p+1}* Morse–Smale gradient-like flow on *M if Φ^t is a C^{p+1} flow on M and satisfies the following:* (i) *The nonwandering set $\Omega(\Phi^t)$ consists of a finite number of hyperbolic singularities; in particular, there are no closed orbits.* (ii) *The stable and unstable manifolds of singularities are transversal* (*see* [5]).

Definition 1.2. *A C^{p+1} function $\phi : \mathbb{R} \times M \to M$ is called a* discretization mapping of order p for Φ^t *if there are constants $K_1 > 0$ and $h_0 > 0$ such that $d(\Phi(h,x),\phi(h,x)) \leq K_1 h^{p+1}$ for all $h \in [0,h_0]$ and $x \in M$.*

Discretizations arise in numerical analysis. Obviously, all of the conditions above are satisfied if ϕ comes from an explicit Runge–Kutta method of order p (see [1]).

We note that for every h, Φ^h is a Morse–Smale diffeomorphism and hence it is structurally stable (see [5] or [11]). Therefore, there exists a neighborhood $\mathcal{U}_h$ of Φ^h in $\mathrm{Diff}^1(M)$ such that for any $\psi \in \mathcal{U}_h$ there is a homeomorphism H_h such that $H_h \circ \psi = \Phi^h \circ H_h$. However, the neighborhood $\mathcal{U}_h$ depends on h, so we cannot guarantee $\phi^h \in \mathcal{U}_h$ for all $h \in [0,h_0]$, although we will know $d_{C^1}(\Phi^h,\phi^h) \leq K_2 h^p$ in Lemma 2.1.

Theorem A. *Let M be a smooth compact manifold without boundary, $p \geq 2$, Φ^t be a C^{p+1} Morse–Smale gradient-like flow on M, and ϕ be a discretization mapping of order p for Φ^t. Then there is a constant $K > 0$ and for all sufficiently small h, there exists a homeomorphism H_h on M such that $H_h \circ \Phi^h(x) = \phi^h \circ H_h(x)$ and $d(H_h(x),x) \leq K h^p$ for all $x \in M$.*

*Received by the editors September 25, 1995; accepted for publication (in revised form) January 8, 1996.

[†]Department of Mathematics, Northwestern University, 2033 Sheridan Road, Evanston, IL 60208 (minka@math.nwu.edu).

Here we only need a C^{p+1} discretization mapping with $p \geq 2$ rather than C^{p+k+1}, where $p+k \geq 3$, which Garay worked with in [2].

The following corollary is an immediate result of Theorem A which gives an observation about the qualitative embedding.

Corollary. *For all sufficiently small h, the discretization mapping ϕ^h embeds in a local flow on M. In fact, if we define $\Psi_h(t,x) = H_h \circ \Phi^t \circ H_h^{-1}(x)$ for $t \in \mathbb{R}$ and $x \in M$, then for all h small enough, $\Psi_h(t,\cdot)$ is a local flow with the properties that Ψ_h is a continuous function on $\mathbb{R} \times M$ and $\Psi_h(h,x) = \phi^h(x)$.*

Theorem B. *Let M' be a smooth manifold and M be a compact subset of M' with* closure(interior(M)) $= M$. *For $p \geq 2$, let Φ^t be a C^{p+1} Morse–Smale gradient-like flow on M' such that M is positively invariant for Φ^t and the nonwandering set of Φ^t restricted to M, $\Omega(\Phi^t|_M)$, is contained in the interior of M. Let ϕ be a discretization mapping of order p for Φ^t. Then there is a constant $K > 0$ and, for all sufficiently small h, there exists a homeomorphism H_h from M to $H_h(M) \subset M'$ such that $H_h \circ \Phi^h(x) = \phi^h \circ H_h(x)$ and $d(H_h(x),x) \leq Kh^p$ for all $x \in M$. For example, take $M' = \mathbb{R}^n$ and $M = \mathbb{D}^n$, a closed disk in $\mathbb{R}^n$.*

2. Proof of Theorem A.

2. Proof of Theorem A. Throughout this section, we assume the conditions of Theorem A. Before proving the theorem, we first investigate the d_{C^1} distance between Φ^h and ϕ^h.

Lemma 2.1. *There is a constant $K_2 > 0$ such that $d_{C^1}(\Phi^h, \phi^h) \leq K_2 h^p$ for all $h \in [0, h_0]$.*

Proof. Because $d(\Phi(h,x), \phi(h,x)) \leq K_1 h^{p+1}$, $\frac{\partial^j \Phi}{\partial h^j}(0,x) = \frac{\partial^j \phi}{\partial h^j}(0,x)$ for $j = 0, 1, \ldots, p-1$. By Taylor's expansion formula with one remainder in integral form, we have

$$\Phi(h,x) - \phi(h,x) = h^p \int_0^1 \frac{(1-s)^{p-1}}{(p-1)!} \left(\frac{\partial^p \Phi}{\partial h^p}(sh,x) - \frac{\partial^p \phi}{\partial h^p}(sh,x) \right) ds.$$

Differentiating both sides with respect to x, the integrand stays uniformly bounded since $\Phi, \phi \in C^{p+1}$ and M is compact. Therefore, there is a constant $K_2 > 0$ such that $|\frac{\partial \Phi}{\partial x}(h,x) - \frac{\partial \phi}{\partial x}(h,x)| \leq K_2 h^p$ for all $h \in [0, h_0]$ and $x \in M$. □

Since $\mathrm{Diff}^1(M)$ is an open subset of $C^1(M,M)$ (see [3]), Lemma 2.1 implies that $\phi^h \in \mathrm{Diff}^1(M)$ for all h small enough.

For the proof of Theorem A, we need more definitions. For $x, y \in M$, define $d_\Phi(x,y) = \sup\{d(\Phi^s(x), \Phi^s(y)) : s \in \mathbb{R}\}$. Then $d_\Phi(x,y)$ is a metric on the manifold M. Let $\mathfrak{X}^0(M)$ be the set of continuous vector fields on M.

Definition 2.2. *We say that a vector field $v \in \mathfrak{X}^0(M)$ is* d_Φ-Lipschitz *if there is a least positive constant $\Lambda(v)$ such that $|v(x) - v(y)| \leq \Lambda(v) d_\Phi(x,y)$ for all $x, y \in M$.*

Let $\mathfrak{X}^\Phi(M)$ be the set of all d_Φ-Lipschitz vector fields on M. For $v \in \mathfrak{X}^\Phi(M)$, we define $\|v\|_\Phi = \max\{\|v\|_0, \Lambda(v)\}$. Then $(\mathfrak{X}^\Phi(M), \|v\|_\Phi)$ is a Banach space.

Definition 2.3. *A subbundle $E \subset TM$ is* d_Φ-Lipschitz *if there is a least positive constant $\Lambda(E)$ such that $|E(x) - E(y)| \leq \Lambda(E) d_\Phi(x,y)$ for all $x, y \in M$, where $|E(x) - E(y)|$ is an appropriate distance function between Euclidean spaces.*

We briefly sketch the proof as follows. Let

$$\begin{aligned} Q_h(v_x) &= T\Phi^{-h} \circ v \circ \Phi^h(x) - \exp_x^{-1} \circ \phi^{-h} \circ \exp_{\Phi^h(x)} \circ v \circ \Phi^h(x), \\ G_h(v) &= T\Phi^{-h} \circ v \circ \Phi^h - v. \end{aligned}$$

We will construct a right inverse J_h of G_h. Let

$$\Theta_h(v) = J_h Q_h(v).$$

Then we prove that Θ_h preserves vector fields of small d_Φ-Lipschitz size, is a contraction, and has a fixed point $\widetilde{v}_h$. Thus $Q_h(\widetilde{v}_h) = G_h J_h Q_h(\widetilde{v}_h) = G_h \Theta_h(\widetilde{v}_h) = G_h(\widetilde{v}_h)$ and $\exp_x^{-1} \circ \phi^{-h} \circ \exp_{\Phi^h(x)} \circ \widetilde{v}_h \circ \Phi^h(x) = \widetilde{v}_h(x)$. For all $x \in M$, define

$$H_h(x) = \exp(\widetilde{v}_h(x)).$$

Then we have $H_h \circ \Phi^h = \phi^h \circ H_h$.

We denote the nonwandering set $\Omega(\Phi^t) = \{p_1, p_2, \ldots, p_m\}$ with the order $i \le j$ if $W^u(p_i) \cap W^s(p_j) \neq \emptyset$.

Proposition 2.4 (existence of compatible stable and unstable subbundles). *There are neighborhoods U_i of p_i, $i = 1, \ldots, m$, and compatible families of stable and unstable subbundles $\{E_i^\sigma(x) \subset T_xM : x \in O(U_i)\}$, $\sigma = s, u$. That is, the following hold:*

1. (*disjointness*) *$U_i \cap U_j = \emptyset$ for $i \neq j$.*
2. (*splitting*) *$E_i^u(x) + E_i^s(x) = T_xM$ for $x \in O(U_i)$.*
3. (*extension*) *$E_i^u(p_i) = \mathbb{E}^u(p_i)$ and $E_i^s(p_i) = \mathbb{E}^s(p_i)$, where $\mathbb{E}^u(p_i) \oplus \mathbb{E}^s(p_i) = T_{p_i}M$ is the splitting for the hyperbolic singularity p_i.*
4. (*invariance*) *E_i^u and E_i^s are $T\Phi^t$-invariant.*
5. (*compatibility*) *$E_i^u(x) \supset E_j^u(x)$ and $E_i^s(x) \subset E_j^s(x)$ if $1 \le i < j$ and $x \in O^+(U_i) \cap O^-(U_j)$.*
6. (*hyperbolicity estimate*) *There is a Riemannian metric and a constant $\mu > 0$ such that $\|T\Phi^{-t} \circ v^u \circ \Phi^t\|_0 \le e^{-\mu t}\|v^u\|_0$ and $\|T\Phi^t \circ v^s \circ \Phi^{-t}\|_0 \le e^{-\mu t}\|v^s\|_0$ for $v^u \in E_i^u|_{U_i}$, $v^s \in E_i^s|_{U_i}$, and $0 \le t \le 1$.*
7. (*d_Φ-Lipschitz*) *E_i^u and E_i^s are d_Φ-Lipschitz.*

Proof. Here we give only the outline of the proof. (For details, see [7] and [8] and also compare with the treatment for diffeomorphisms in [6] and [9].) We proceed by induction. Assume that there exist compatible families of unstable subbundles $\{E_i^u(x) : x \in O(U_i)\}$ for $i = 1, \ldots, k-1$. First, we use backward induction $j = k-1, \ldots, 1$ to construct an unstable subbundle $E_k^u(x)$ for $x \in (\cup_{l=j}^{k-1} W^u(p_l)) \cap U_{D_k^s}$, which is compatible with $E_l^u(x)$ for $j \le l \le k-1$, where $U_{D_k^s}$ is a fundamental neighborhood of $W^s(p_k)$. Then by the Φ^t-invariance, we extend the unstable subbundle E_k^u over a neighborhood U_k of p_k and $O(U_k)$. □

Choose a partition of unity $\theta_1, \ldots, \theta_m$ subordinate to the cover $O(U_1), \ldots, O(U_m)$ of M, i.e., for every i, $\theta_i : M \to [0, \infty)$ is a smooth function such that $\mathrm{supp}(\theta_i) \subset O(U_i)$ and $\sum_{i=1}^m \theta_i(x) = 1$ for all $x \in M$. For $v \in \mathfrak{X}^0(M)$, we write $\theta_i v = v_i^u + v_i^s$ with $v_i^\sigma(x) \in E_i^\sigma(x)$ for $x \in O(U_i)$ and $\sigma = s, u$. Hence $\mathrm{supp}(v_i^\sigma) \subseteq \mathrm{supp}(\theta_i) \subset O(U_i)$ for $\sigma = s, u$. Define $J_h : \mathfrak{X}^0(M) \to \mathfrak{X}^0(M)$ by

$$J_h(v) = \sum_{i=1}^{m} \left(\sum_{n=1}^{\infty} T\Phi^{nh} \circ v_i^s \circ \Phi^{-nh} - \sum_{n=0}^{\infty} T\Phi^{-nh} \circ v_i^u \circ \Phi^{nh} \right).$$

First, we have to show that J_h is well defined.

Proposition 2.5. *There exist $C > 1$ and $\mu > 0$ such that $\|T\Phi^r \circ v_i^s \circ v^{-r}\|_0 \le Ce^{-\mu r}\|v_i^s\|_0$ and $\|T\Phi^{-r} \circ v_i^u \circ \Phi^r\|_0 \le Ce^{-\mu r}\|v_i^u\|_0$ for all $r \ge 0$ and all i. Then J_h is well defined, a continuous linear map, and a right inverse of G_h, i.e., $G_h J_h(v) = v$.*

Proof. There exists $t_1 > 0$ such that for all $x \in M$, the orbit of x lies in $\cup_{j=0}^m U_j$ except at most t_1 amount of the time. There exists $t_2 > 0$ such that for all i, $\mathrm{supp}(\theta_i) \subset \cup_{t=-t_2}^{t_2} \Phi^t(U_i)$. Let $t_0 = t_1 + t_2$. Then for all i and $x \in \mathrm{supp}(\theta_i)$, the forward orbit of x lies in $\cup_{j=i}^m U_j$ except at most t_0 amount of the time and the backward orbit of x lies in $\cup_{j=1}^i U_j$ except at most t_0 amount of the time. It follows that there exist $C > 1$ and $\mu > 0$ such that $\|T\Phi^r \circ v_i^s \circ \Phi^{-r}\|_0 \le Ce^{-\mu r}\|v_i^s\|_0$ and $\|T\Phi^{-r} \circ v_i^u \circ \Phi^r\|_0 \le Ce^{-\mu r}\|v_i^u\|_0$ for all $r \ge 0$ and all i. Therefore, the two infinite series defining J_h converge uniformly. Since $v \mapsto v_i^\sigma$ is continuous linear, $J_h : \mathfrak{X}^0(M) \to \mathfrak{X}^0(M)$ is continuous linear. □

In order to prove the contraction of Θ_h, we first estimate J_h and Q_h in the following two lemmas.

Lemma 2.6. *There are constants $K_5, K_6 > 0$ such that $\|J_h\|_0 \le K_5 h^{-1}$ and $\Lambda(J_h(v)) \le K_6 h^{-1}(\Lambda(v) + \|v\|_0)$ for all $v \in \mathfrak{X}^\Phi(M)$.*

Proof. From Proposition 2.5, we have that $\|T\Phi^r \circ v_i^s \circ \Phi^{-r}\|_0 \le Ce^{-\mu r}\|v_i^s\|_0$ and $\|T\Phi^{-r} \circ v_i^u \circ \Phi^r\|_0 \le Ce^{-\mu r}\|v_i^u\|_0$ for all $r \ge 0$ and all i. In particular, $\|T\Phi^{nh} \circ v_i^s \circ \Phi^{-nh}\|_0 \le Ce^{-\mu nh}\|v_i^s\|_0$ and $\|T\Phi^{-nh} \circ v_i^u \circ \Phi^{nh}\|_0 \le Ce^{-\mu nh}\|v_i^u\|_0$ for all $n \ge 0$. Therefore,

$$\begin{aligned}\|J_h\|_0 &\le \sum_{i=1}^m 2\sum_{n=0}^\infty Ce^{-\mu nh} = \sum_{i=1}^m \frac{2C}{1-e^{-\mu h}}\\ &= \sum_{i=1}^m \frac{2C}{1-(1-\mu h + O(h^2))} = \sum_{i=1}^m \frac{2C}{\mu h - O(h^2)}\\ &\le \sum_{i=1}^m \frac{4C}{\mu} h^{-1} \le K_5 h^{-1} \quad \text{for some } K_5 > 0.\end{aligned}$$

As Robinson pointed out in [7] (see also [9]), $\Lambda(T\Phi^{-r} \circ v_i^u \circ \Phi^r) \le Ce^{-\mu r}\Lambda(v_i^u) + bCre^{-\mu(r-1)}\|v_i^u\|_0$; here b is a bound on the second derivatives in local coordinates. Thus

$$\begin{aligned}\sum_{n=0}^\infty \Lambda(T\Phi^{-nh} \circ v_i^u \circ \Phi^{nh}) &\le \sum_{n=0}^\infty \Big(Ce^{-\mu nh}\Lambda(v_i^u) + bCnhe^{-\mu(nh-1)}\|v_i^u\|_0\Big)\\ &\le \frac{C}{1-e^{-\mu h}}\Lambda(v_i^u) + \frac{bChe^\mu}{(1-e^{-\mu h})^2 e^{\mu h}}\|v_i^u\|_0\\ &\le \frac{C}{1-e^{-\mu h}}\Lambda(v_i^u) + \frac{bChe^\mu}{(e^{\frac{\mu h}{2}} - e^{-\frac{\mu h}{2}})^2}\|v_i^u\|_0\\ &\le \frac{C}{\mu h - O(h^2)}\Lambda(v_i^u) + \frac{bChe^\mu}{(\mu h + O(h^3))^2}\|v_i^u\|_0.\end{aligned}$$

Similarly,

$$\sum_{n=1}^\infty \Lambda(T\Phi^{nh} \circ v_i^s \circ \Phi^{-nh}) \le \frac{C}{\mu h - O(h^2)}\Lambda(v_i^s) + \frac{bChe^\mu}{(\mu h + O(h^3))^2}\|v_i^s\|_0.$$

Therefore,

$$\begin{aligned}\Lambda(J_h(v)) &\le \sum_{i=0}^m \left(\sum_{n=1}^\infty \Lambda(T\Phi^{nh} \circ v_i^s \circ \Phi^{-nh}) + \sum_{n=0}^\infty \Lambda(T\Phi^{-nh} \circ v_i^u \circ \Phi^{nh})\right)\\ &\le K_6 h^{-1}(\Lambda(v) + \|v\|_0) \quad \text{for some } K_6 > 0. \qquad \square\end{aligned}$$

Lemma 2.7. *There exist $K_7 > 0$ and $\delta > 0$ such that for all $\|v\|_0, \|w\|_0 < \delta$,*

$$\begin{aligned}\|Q_h(0)\|_0 &\le d_{C^0}(\phi^h, \Phi^h) \quad \textit{and}\\ \|Q_h(v) - Q_h(w)\|_0 &\le \big(K_7 \max\{\|v\|_0, \|w\|_0\} + d_{C^1}(\phi^h, \Phi^h)\big)\,\|v - w\|_0.\end{aligned}$$

In particular, $\|Q_h(v)\|_0 \leq K_7\|v\|_0\|v\|_0 + d_{C^1}(\phi^h, \Phi^h)\|v\|_0 + d_{C^0}(\phi^h, \Phi^h)$.

Proof. First, $\|Q_h(0)\|_0 = \|\exp_x^{-1} \circ \phi^{-h} \circ \Phi^h(x)\|_0 = d_{C^0}(\phi^h, \Phi^h)$. Let $L_h(v_{\Phi^h(x)}) = T\Phi^{-h}(v_{\Phi^h(x)}) - \exp_x^{-1}(\phi^{-h}(\exp_{\Phi^h(x)}(v_{\Phi^h(x)})))$. Since Φ^h and ϕ^h are C^{p+1}, L_h is $C^p \subset C^2$ and so there exist $K_7 > 0$ and $\delta > 0$ such that $\|D^2L_h(v)\|_0 \leq K_7$ for all $\|v\|_0 < \delta$. By the mean-value theorem, we have for all $\|v\|_0, \|w\|_0 < \delta$,

$$\begin{aligned}
\|Q_h(v) - Q_h(w)\|_0 &= \sup_{x\in M} |L_h(v_{\Phi^h(x)}) - L_h(w_{\Phi^h(x)})| \\
&= \sup_{y\in M} |L_h(v_y) - L_h(w_y)| \\
&= \sup_{y\in M} \left| \int_0^1 DL_h(w_y + s(v_y - w_y))(v_y - w_y)ds \right| \\
&\leq \sup_{\substack{y\in M \\ |v_y^*|\leq \|v\|_0, \|w\|_0}} |DL_h(v_y^*)| \cdot |v_y - w_y| \\
&= \sup_{\substack{y\in M \\ |v_y^*|\leq \|v\|_0, \|w\|_0}} \left\{ \left| \int_0^1 D^2L_h(sv_y^*)v_y^* ds \right| + \|DL_h(0)\|_0 \right\} \|v - w\|_0 \\
&\leq \left(K_7 \max\{\|v\|_0, \|w\|_0\} + d_{C^1}(\phi^h, \Phi^h)\right) \|v - w\|_0. \qquad \square
\end{aligned}$$

Now we show that Θ_h is a contraction and has a fixed point $\widetilde{v}_h$.

PROPOSITION 2.8. *There is a positive constant K such that for all h sufficiently small, Θ_h preserves $\mathfrak{X}^0_{Kh^p}(M)$ and is a contraction on $\mathfrak{X}^0_{Kh^p}(M)$, where $\mathfrak{X}^0_{Kh^p}(M) \equiv \{v \in \mathfrak{X}^0(M) : \|v\|_0 \leq Kh^p\}$. Therefore, for all h sufficiently small, Θ_h has a unique fixed point $\widetilde{v}_h$ in $\mathfrak{X}^0_{Kh^p}(M)$.*

Proof. From the previous lemma, we have for all $\|v\|_0, \|w\|_0 < \delta$,

$$\begin{aligned}
\|\Theta_h(v) - \Theta_h(w)\|_0 &\leq \|J_h\|_0 \|Q_h(v) - Q_h(w)\|_0 \\
&\leq K_5 h^{-1} \left(K_7 \max\{\|v\|_0, \|w\|_0\} + d_{C^1}(\phi^h, \Phi^h)\right) \|v - w\|_0.
\end{aligned}$$

Choose a suitable $K > 0$ such that for all sufficiently small h and all $v, w \in \mathfrak{X}^0_{Kh^p}(M)$, $Kh^p < \delta$,

$$\begin{aligned}
\|\Theta_h(v)\|_0 &\leq \|J_h\|_0 \left(\|Q_h(v)\|_0 + \|Q_h(0)\|_0\right) \\
&\leq K_5 h^{-1} \left(K_7 \|v\|_0\|v\|_0 + d_{C^1}(\phi^h, \Phi^h)\|v\|_0 + d_{C^0}(\phi^h, \Phi^h)\right) \\
&\leq K_5 h^{-1} \left(K_7 Kh^p Kh^p + K_2 h^p Kh^p + K_1 h^{p+1}\right) \leq Kh^p
\end{aligned}$$

and

$$\|\Theta_h(v) - \Theta_h(w)\|_0 \leq K_5 h^{-1} \left(K_7 Kh^p + K_2 h^p\right) \|v - w\|_0 < \|v - w\|_0. \qquad \square$$

Thus far, we have been able to construct a topological semiconjugacy. Since $\widetilde{v}_h$ is continuous, $H_h \equiv \exp(\widetilde{v}_h)$ is continuous. Because H_h is homotopic to the identity, H_h is of degree one and hence onto (see [4]). Moreover, $d_{C^0}(H_h, id_M) = d_{C^0}(\exp(\widetilde{v}_h), id_M) = \|\widetilde{v}_h\|_0 \leq Kh^p$. Finally, we have to prove that H_h is one to one.

To this end, we estimate the d_Φ-Lipschitz sizes of $Q_h(v)$ and $\Theta_h(v)$.

LEMMA 2.9. *For $v \in \mathfrak{X}^\Phi(M)$,*

$$\begin{aligned}
\Lambda(Q_h(v)) &\leq \left(K_7\|v\|_0 + d_{C^1}(\phi^h, \Phi^h)\right)(1 + \Lambda(v)), \\
\Lambda(\Theta_h(v)) &\leq K_6 h^{-1}\{\left(K_7\|v\|_0 + d_{C^1}(\phi^h, \Phi^h)\right)(1 + \Lambda(v)) \\
&\qquad + K_7\|v\|_0\|v\|_0 + d_{C^1}(\phi^h, \Phi^h)\|v\|_0 + d_{C^0}(\phi^h, \Phi^h)\}.
\end{aligned}$$

Thus there is a constant $K_8 > 0$ such that Θ_h preserves $v \in \mathfrak{X}^0_{Kh^p}(M) \cap \mathfrak{X}^\Phi(M)$ with $\Lambda(v) \leq K_8 h^{p-1}$.

Proof.

$$\begin{aligned}|Q_h(v_x) - Q_h(v_y)| &\leq \|DL_h(v^*)\|_0 d(v \circ \Phi^{-h}(x), v \circ \Phi^{-h}(y)) \\ &\leq \left(K_7\|v\|_0 + d_{C^1}(\phi^h, \Phi^h)\right) \\ &\quad \cdot \left(d(\Phi^{-h}(x), \Phi^{-h}(y)) + |v \circ \Phi^{-h}(x) - v \circ \Phi^{-h}(y)|\right) \\ &\leq \left(K_7\|v\|_0 + d_{C^1}(\phi^h, \Phi^h)\right)(d_\Phi(x,y) + \Lambda(v) d_\Phi(x,y)) \\ &= \left(K_7\|v\|_0 + d_{C^1}(\phi^h, \Phi^h)\right)(1 + \Lambda(v)) d_\Phi(x,y).\end{aligned}$$

Then $\Lambda(Q_h(v)) \leq \left(K_7\|v\|_0 + d_{C^1}(\phi^h, \Phi^h)\right)(1 + \Lambda(v))$. Moreover,

$$\begin{aligned}\Lambda(\Theta_h(v)) &\leq \Lambda(J_h Q_h(v)) \\ &\leq K_6 h^{-1}(\Lambda(Q_h(v)) + \|Q_h(v)\|_0) \\ &\leq K_6 h^{-1}\{\left(K_7\|v\|_0 + d_{C^1}(\phi^h, \Phi^h)\right)(1 + \Lambda(v)) \\ &\quad + K_7\|v\|_0\|v\|_0 + d_{C^1}(\phi^h, \Phi^h)\|v\|_0 + d_{C^0}(\phi^h, \Phi^h)\}.\end{aligned}$$

Choose a suitable constant $K_8 > 0$ such that, for all sufficiently small h and all $v \in \mathfrak{X}^0_{Kh^p}(M) \cap \mathfrak{X}^\Phi(M)$ with $\Lambda(v) \leq K_8 h^{p-1}$,

$$\begin{aligned}\Lambda(\Theta_h(v)) &\leq K_6 h^{-1}\{(K_7 K h^p + K_2 h^p)(1 + K_8 h^{p-1}) \\ &\quad + K_7 K h^p K h^p + K_2 h^p K h^p + K_1 h^{p+1}\} \\ &\leq K_8 h^{p-1}. \qquad \square\end{aligned}$$

Furthermore, the d_Φ-Lipschitz size of the fixed point $\widetilde{v}_h$ is dominated by $K_8 h^{p-1}$.

LEMMA 2.10. *For the fixed point $\widetilde{v}_h$, we have $\widetilde{v}_h \in \mathfrak{X}^\Phi(M)$ and $\Lambda(\widetilde{v}_h) \leq K_8 h^{p-1}$.*

Proof. Let $v_h^1 = 0$ and $v_h^{n+1} = \Theta_h(v_h^n)$ for $n \in \mathbb{N}$. Since Θ_h preserves the space $\mathfrak{X}^0_{Kh^p}$ and is a contraction, $\|v_h^n\|_0 \leq Kh^p$ for all $n \in \mathbb{N}$ and $\|v_h^n - \widetilde{v}_h\|_0 \to 0$ as $n \to \infty$, where $\widetilde{v}_h$ is the fixed point of Θ_h in $\mathfrak{X}^0_{Kh^p}(M)$. Because $\Lambda(v_h^n) \leq K_8 h^{p-1}$ for all $n \in \mathbb{N}$, we have $\widetilde{v}_h \in \mathfrak{X}^\Phi(M)$ and $\Lambda(\widetilde{v}_h) \leq K_8 h^{p-1}$. $\square$

We also need the following two lemmas. The first one is an easy consequence of Gronwall's theorem (see [11]). The second one was proved by Robbin in [6, Lemma 2.3].

LEMMA 2.11. *There is a constant $L > 0$ such that $d(\Phi^s(p), \Phi^s(q)) \leq L d(p,q)$ whenever $p, q \in M, s \in [0, h_0]$.*

LEMMA 2.12. *There is a constant $\alpha > 0$ such that for $p, q \in M$ and $v \in \mathfrak{X}^0_{Kh^p}(M)$, $\alpha d(p,q) - d(\exp(v(p)), \exp(v(q))) \leq |v(p) - v(q)|$.*

Now let us prove that H_h is one to one and complete the proof of Theorem A.

PROPOSITION 2.13. *For all h sufficiently small, $H_h \equiv \exp(\widetilde{v}_h)$ is one to one.*

Proof. Suppose $H_h(x) = H_h(y)$. By the conjugacy, we have $H_h(\Phi^{kh}(x)) = \phi^{kh}(H_h(x)) = \phi^{kh}(H_h(y)) = H_h(\Phi^{kh}(y))$ for all $k \in \mathbb{Z}$. There exists $s_0 \in \mathbb{R}$ such that $d_\Phi(x,y) \leq 2d(\Phi^{s_0}(x), \Phi^{s_0}(y))$. Take $k_0 \in \mathbb{Z}$ with $k_0 h \leq s_0 < (k_0+1)h$; then $s_0 - k_0 h \in [0, h) \subset [0, h_0]$. Let $p = \Phi^{k_0 h}(x)$ and $q = \Phi^{k_0 h}(y)$. By Lemma 2.11, there is a constant L such that $d(\Phi^{s_0}(x), \Phi^{s_0}(y)) = d(\Phi^{s_0 - k_0 h}(p), \Phi^{s_0 - k_0 h}(q)) \leq L d(p,q)$. Hence $d_\Phi(p,q) = d_\Phi(x,y) \leq 2d(\Phi^{s_0}(x), \Phi^{s_0}(y)) \leq 2L d(p,q)$. By the previous lemma, there exists $\alpha > 0$ such that $\alpha d(p,q) - d(\exp(\widetilde{v}_h(p)), \exp(\widetilde{v}_h(q))) \leq |\widetilde{v}_h(p) - \widetilde{v}_h(q)|$.

Because $\Lambda(\widetilde{v}_h) \le K_8 h^{p-1}$,

$$\begin{aligned}\alpha d(p,q) - d(\exp(\widetilde{v}_h(p)), \exp(\widetilde{v}_h(q))) &\le |\widetilde{v}_h(p) - \widetilde{v}_h(q)| \\ &\le K_8 h^{p-1} d_\Phi(p,q) \le K_8 h^{p-1} 2L d(p,q).\end{aligned}$$

Therefore, $(\alpha - K_8 h^{p-1} 2L) d(p,q) \le d(H_h(p), H_h(q)) = 0$. If h is small enough such that $\alpha - K_8 h^{p-1} 2L > 0$, then $d(p,q) = 0$ and $p = q$. Thus $x = \Phi^{-k_0 h}(p) = \Phi^{-k_0 h}(q) = y$, and hence H_h is one to one. □

3. Proof of Theorem B. Because $\Omega(\Phi^t|_M) \subset \text{interior}(M)$, the singularities $\{p_i : i = 1, \dots, m\}$ are not on the boundary of M. For our convenience, we denote the boundary of M by p_0. We use induction to construct compatible families of stable and unstable subbundles. Assume that for $0 \le i \le k-1$ there exist a neighborhood U_i of p_i in M and continuous subbundles $\{E_i^\sigma(x) \subset T_x M : x \in O(U_i)\}$, $\sigma = u, s$, such that the following hold:

1. (disjointness) $U_i \cap U_j = \emptyset$ for $i \ne j$.
2. (splitting) $E_i^u(x) + E_i^s(x) = T_x M$ for $x \in O(U_i) \cap M$.
3. (boundary) $E_0^u(x) = T_x M$ and $E_0^s(x) = \{0_x\}$ for $x \in O(U_0) \cap M$.
4. (extension) For $i \ne 0$, $E_i^u(p_i) = \mathbb{E}^u(p_i)$ and $E_i^s(p_i) = \mathbb{E}^s(p_i)$, where $\mathbb{E}^u(p_i) \oplus \mathbb{E}^s(p_i) = T_{p_i} M$ is the splitting for the hyperbolic singularity p_i.
5. (invariance) E_i^u and E_i^s are $T\Phi^t$-invariant.
6. (compatibility) $E_i^u(x) \supset E_j^u(x)$ and $E_i^s(x) \subset E_j^s(x)$ if $0 \le i < j$ and $x \in O^+(U_i) \cap O^-(U_j) \cap M$.
7. (hyperbolicity estimate) There is a Riemannian metric and a constant $\mu > 0$ such that $\|T\Phi^{-t} \circ v^u \circ \Phi^t\|_0 \le e^{-\mu t} \|v^u\|_0$ and $\|T\Phi^t \circ v^s \circ \Phi^{-t}\|_0 \le e^{-\mu t} \|v^s\|_0$ for $v^u \in E_i^u|_{U_i}$, $v^s \in E_i^s|_{U_i}$, and $0 \le t \le 1$.
8. (d_Φ-Lipschitz) E_i^u and E_i^s are d_Φ-Lipschitz.

First, we use backward induction $j = k-1, \dots, 0$ to construct a unstable subbundle $E_k^u(x)$ for $x \in (\cup_{l=j}^{k-1} W^u(p_l)) \cap U_{D_k^s}$, which is compatible with $E_l^u(x)$ for $j \le l \le k-1$, where $U_{D_k^s}$ is a fundamental neighborhood of $W^s(p_k)$. When $j = 0$, the only requirements for the compatibility are $E_k^u(x) \subset E_0^u(x) = T_x M$ and $\{0_x\} = E_0^s(x) \subset E_k^s(x)$, which are easily satisfied. Then by the Φ^t-invariance, we extend the unstable subbundle E_k^u over a neighborhood U_k of p_k and $O(U_k)$ (for details, see [10]).

By shrinking U_i if necessary, we can choose a partition of unity $\theta_0, \dots, \theta_m$ subordinate to the cover $O(U_0), \dots, O(U_m)$ of M such that $\text{supp}(\theta_0) \subset M$ and $\text{supp}(\theta_i) \subset \text{interior}(M)$ for $i \ne 0$. For $v \in \mathfrak{X}^0(M)$, we write $\theta_i v = v_i^u + v_i^s$ with $v_i^\sigma(x) \in E_i^\sigma(x)$ and $\sigma = u, s$. Define $J_h : \mathfrak{X}^0(M) \to \mathfrak{X}^0(M)$ by $J_h(v_x) = \sum_{i=0}^m (\sum_{n=1}^\infty T\Phi^{nh} \circ v_i^s \circ \Phi^{-nh}(x) - \sum_{n=0}^\infty T\Phi^{-nh} \circ v_i^u \circ \Phi^{nh}(x))$. Since M is positively invariant for Φ^h, $E_0^s(x) = \{0_x\}$ for $x \in O(U_0) \cap M$, $\text{supp}(\theta_0) \subset M$, and $\text{supp}(\theta_i) \subset \text{int}(M)$ for $i \ne 0$, it follows that $J_h(v) = -\sum_{n=0}^\infty T\Phi^{-nh} \circ v_0^u \circ \Phi^{nh} + \sum_{i=1}^m (\sum_{n=1}^\infty T\Phi^{nh} \circ v_i^s \circ \Phi^{-nh} - \sum_{n=0}^\infty T\Phi^{-nh} \circ v_i^u \circ \Phi^{nh})$. By the same argument as above, we can prove that J_h is a continuous linear map and J_h is a right inverse of G_h on $\mathfrak{X}^0(M)$. Moreover, we can prove that $\Theta_h \equiv J_h Q_h$ preserves $\mathfrak{X}^0_{Kh^p}(M)$ and is a contraction on $\mathfrak{X}^0_{Kh^p}(M)$, where $\mathfrak{X}^0_{Kh^p}(M) = \{v \in \mathfrak{X}^0(M) : \|v\|_0 \le Kh^p\}$. Then there is a unique fixed point $\widetilde{v}_h \in \mathfrak{X}^0_{Kh^p}(M)$. Therefore, $H_h \equiv \exp(\widetilde{v}_h)$ is a homeomorphism from M to $H_h(M) \subset M'$.

Remark. The referee observed that Theorem B follows from Theorem A through the following argument. Find a slightly larger M and modify the vector field so that it points into M. Then form the double N and extend the vector field by the symmetry of the double. Make the vector field on the double Morse–Smale by applying the Kupka–Smale theorem on $N\backslash M$. Finally, extend the discretization to the double. However, we have presented our original proof in order to avoid discussing the double of a manifold.

Acknowledgment. The author would like to thank Professor Clark Robinson of Northwestern University for his inspiration and general introduction to this subject.

RAZUMIKHIN-TYPE THEOREMS ON EXPONENTIAL STABILITY OF NEUTRAL STOCHASTIC FUNCTIONAL DIFFERENTIAL EQUATIONS[*]

XUERONG MAO[†]

Abstract. Recently, we initiated in [*Systems Control Lett.*, 26 (1995), pp. 245–251] the study of exponential stability of neutral stochastic functional differential equations, and in this paper, we shall further our study in this area. We should emphasize that the main technique employed in this paper is the well-known Razumikhin argument and is completely different from those used in our previous paper [*Systems Control Lett.*, 26 (1995), pp. 245–251]. The results obtained in [*Systems Control Lett.*, 26 (1995), pp. 245–251] can only be applied to a certain class of neutral stochastic functional differential equations excluding neutral stochastic differential delay equations, but the results obtained in this paper are more general, and they especially can be used to deal with neutral stochastic differential delay equations. Moreover, in [*Systems Control Lett.*, 26 (1995), pp. 245–251], we only studied the exponential stability in mean square, but in this paper, we shall also study the almost sure exponential stability. It should be pointed out that although the results established in this paper are applicable to more general neutral-type equation, for a particular type of equation discussed in [*Systems Control Lett.*, 26 (1995), pp. 245–251], the results there are sharper.

Key words. exponential stability, Razumikhin-type theorem, Brownian motion, Doob martingale inequality, Borel–Cantelli lemma

1. Introduction.

Deterministic neutral functional differential equations and their stability have been studied by many authors, e.g., Haddock et al. [3], Hale and Lunel [4], and the references therein. Motivated by the chemical-engineering systems as well as the theory of aeroelasticity, Kolmanovskii and Nosov [8] introduced the neutral stochastic functional differential equations of the form

$$d[x(t) - G(x_t)] = f(t, x_t)dt + g(t, x_t)dw(t) \tag{1.1}$$

on $t \geq 0$ with initial data $x_0 = \xi \in L^2_{\mathcal{F}_0}([-\tau, 0]; R^n)$. (For notation, please see section 2 below.) Kolmanovskii and Nosov [8] not only established the theory of existence and uniqueness of the solution to (1.1) but also investigated the stability and asymptotic stability of the equations (see also Kolmanovskii and Myshkis [7]). However, the exponential stability of such equations has not been studied until recently by the author in [11]. To be more precise, let us give the definition of exponential stability.

DEFINITION 1.1. *Denote by $x(t;\xi)$ the solution of equation* (1.1). *The trivial solution of equation* (1.1) *is said to be exponentially stable in mean square if there exists a pair of positive constants γ and M such that*

$$E|x(t;\xi)|^2 \leq Me^{-\gamma t} \sup_{-\tau \leq \theta \leq 0} E|\xi(\theta)|^2, \quad t \geq 0,$$

or, equivalently,

$$\limsup_{t\to\infty} \frac{1}{t} \log E|x(t;\xi)|^2 \le -\gamma$$

for all $\xi \in L^2_{\mathcal{F}_0}([-\tau,0];R^n)$. *The trivial solution of equation* (1.1) *is said to be almost surely exponentially stable if there is a positive constant* $\bar{\gamma}$ *such that*

$$\limsup_{t\to\infty} \frac{1}{t} \log |x(t;\xi)| \le -\bar{\gamma} \quad a.s.$$

for all $\xi \in L^2_{\mathcal{F}_0}([-\tau,0];R^n)$.

In this paper, we shall further our study in this area. We should emphasize that the main technique employed in this paper is the well-known Razumikhin argument (see Razumikhin [13], [14]). To explain this technique, applying Itô's formula to $e^{\lambda t}|x(t) - G(x_t)|^2$, one may see that to have exponential stability in mean square, it would require that

$$E\Big(2(\phi(0) - G(\phi))^T f(t,\phi) + \text{trace}[g^T(t,\phi)g(t,\phi)]\Big) \le -\lambda E|\phi(0) - G(\phi)|^2 \tag{1.2}$$

for all $t \ge 0$ and *all* $\phi \in L^2_{\mathcal{F}_t}([-\tau,0];R^n)$. As a result, one would be forced to impose very severe restrictions on the functions $f(t,\phi)$ and $g(t,\phi)$. However, by the Razumikhin argument, one needs to require that (1.2) hold only for those $\phi \in L^2_{\mathcal{F}_t}([-\tau,0];R^n)$ satisfying

$$E|\phi(\theta)|^2 < qE|\phi(0) - G(\phi)|^2, \quad -\tau \le \theta \le 0,$$

but not necessarily for all ϕ, where $q > 1$ is a constant. Hence the restrictions on the functions $f(t,\phi)$ and $g(t,\phi)$ can be weakened considerably. This is the basic idea exploited in this paper.

This main technique of this paper is completely different from those used in our previous paper [11]. The results obtained in [11] can be applied only to a certain class of neutral stochastic functional differential equations excluding neutral stochastic differential delay equations, but the results obtained in this paper are much more general, and they especially can be used to deal with neutral stochastic differential delay equations. Moreover, in [11], we only studied the exponential stability in mean square, but in this paper, we shall also study the almost sure exponential stability. It should be pointed out that although the results established in this paper are applicable to more general neutral-type equations, for a particular class of equations discussed in [11], the results there are sharper. (Please see section 5 below for details.) Of course, this is not surprising because the results obtained by applying a particular technique to a particular equation are generally sharper than those obtained by using a general technique which is applicable to more general equations.

In this paper, the theory of existence and uniqueness of the solutions will first be introduced very briefly in section 2. The main results of this paper will be shown in sections 3 and 4, where several useful criteria will be established on the exponential stability in mean square as well as the almost sure exponential stability for the trivial solution of equation (1.1). In section 5, we shall compare our new results with the previous ones obtained in [11]. To show the power of the Razumikhin argument, the general results established in sections 3 and 4 will be applied to deal with the exponential stability of neutral stochastic differential delay equations in section 6 and of linear neutral stochastic functional differential equations in section 7.

2. Neutral stochastic functional differential equations. Throughout the paper, unless otherwise specified, we let $\tau > 0$ and $C([-\tau,0];R^n)$ denote the family of continuous functions φ from $[-\tau,0]$ to R^n with the norm $||\varphi|| = \sup_{-\tau\le\theta\le 0}|\varphi(\theta)|$, where $|\cdot|$ is the Euclidean norm in R^n. If A is a vector or matrix, its transpose is denoted by A^T. If A is a matrix, its norm $||A||$ is defined by $||A|| = \sup\{|Ax| : |x| = 1\}$ (without any confusion with $||\varphi||$). Moreover, let $w(t) = (w_1(t),\dots,w_m(t))^T$ be an m-dimensional Brownian motion defined on a complete probability space $(\Omega,\mathcal{F},P)$ with a natural filtration $\{\mathcal{F}_t\}_{t\ge 0}$ (i.e., $\mathcal{F}_t = \sigma\{w(s) : 0 \le s \le t\}$). For each $t \ge 0$, denote by $L^2_{\mathcal{F}_t}([-\tau,0];R^n)$ the family of all $\mathcal{F}_t$-measurable $C([-\tau,0];R^n)$-valued random variables $\phi = \{\phi(\theta) : -\tau \le \theta \le 0\}$ such that $\sup_{-\tau\le\theta\le 0} E|\phi(\theta)|^2 < \infty$. Also, define $L^2_{\mathcal{F}_\infty}([-\tau,0];R^n) = \bigcup_{t\ge 0} L^2_{\mathcal{F}_t}([-\tau,0];R^n)$. Obviously, $C([-\tau,0];R^n) \subset L^2_{\mathcal{F}_\infty}([-\tau,0];R^n)$.

Consider the n-dimensional neutral stochastic functional differential equation

$$d[x(t) - G(x_t)] = f(t,x_t)dt + g(t,x_t)dw(t) \tag{2.1}$$

on $t \ge 0$ with initial data $x_0 = \xi$. Here

$$G : C([-\tau,0];R^n) \to R^n, \qquad f : R_+ \times C([-\tau,0];R^n) \to R^n,$$
$$g : R_+ \times C([-\tau,0];R^n) \to R^{n\times m}$$

are all continuous functionals. Moreover, $x_t = \{x(t+\theta) : -\tau \le \theta \le 0\}$, which is regarded as a $C([-\tau,0];R^n)$-valued stochastic process, and $\xi = \{\xi(\theta) : -\tau \le \theta \le 0\} \in L^2_{\mathcal{F}_0}([-\tau,0];R^n)$. An $\mathcal{F}_t$-adapted process $x(t), -\tau \le t < \infty$ (let $\mathcal{F}_t = \mathcal{F}_0$ for $-\tau \le t \le 0$), is said to be a solution of equation (2.1) if it satisfies the initial condition and, moreover, for every $t \ge 0$,

$$x(t) - G(x_t) = \xi(0) - G(\xi) + \int_0^t f(s,x_s)ds + \int_0^t g(s,x_s)dw(s). \tag{2.1$'$}$$

To ensure the existence and uniqueness of the solution, one of the key hypotheses is the following:

(H) There is a constant $\kappa \in (0,1)$ such that

$$E|G(\phi_1) - G(\phi_2)|^2 \le \kappa \sup_{-\tau\le\theta\le 0} E|\phi_1(\theta) - \phi_2(\theta)|^2$$

for all $\phi_1,\phi_2 \in L^2_{\mathcal{F}_\infty}([-\tau,0];R^n)$.

In addition, we need further hypotheses on f and g. For example, f and g are uniformly Lipschitz continuous, or they are locally Lipschitz continuous and satisfy the linear-growth condition. Under these hypotheses, Kolmanovskii and Nosov [8] showed that there is a unique continuous solution to equation (2.1), and any moment, especially the second moment, of the solution is finite. Since the existence and uniqueness of the solution are not the main topic of this paper, we shall not discuss them in detail. All we need to do in this paper is assume that a unique solution exists and is continuous and that its second moment is finite. The solution will be denoted by $x(t;\xi)$.

3. Exponential stability in mean square. In this section, we will investigate the exponential stability in mean square for the solution of equation (2.1). For the general theory on stochastic stability, we refer the reader to Arnold [1], Friedman [2], Has'minskii [5], Mao [9, 10], or Mohammed [12]. For the stability purpose of this paper, we always assume that $G(0) = 0$, $f(t, 0) \equiv 0$, and $g(t, 0) \equiv 0$. Therefore, equation (2.1) admits a trivial solution $x(t; 0) \equiv 0$. The following Razumikhin-type theorem gives a sufficient condition for the exponential stability in mean square of this trivial solution.

THEOREM 3.1. *Assume that there is a constant $\kappa \in (0, 1)$ such that*

$$E|G(\phi)|^2 \le \kappa \sup_{-\tau\le\theta\le 0} E|\phi(\theta)|^2, \quad \phi \in L^2_{\mathcal{F}_\infty}([-\tau, 0]; R^n). \tag{3.1}$$

Let $q > (1 - \sqrt{\kappa})^{-2}$. Assume furthermore that there is a $\lambda > 0$ such that

$$E\Big(2(\phi(0) - G(\phi))^T f(t, \phi) + trace[g^T(t, \phi)g(t, \phi)]\Big) \le -\lambda E|\phi(0) - G(\phi)|^2 \tag{3.2}$$

for all $t \ge 0$ and those $\phi \in L^2_{\mathcal{F}_t}([-\tau, 0]; R^n)$ satisfying

$$E|\phi(\theta)|^2 < qE|\phi(0) - G(\phi)|^2, \quad -\tau \le \theta \le 0.$$

Then for all $\xi \in L^2_{\mathcal{F}_0}([-\tau, 0]; R^n)$,

$$E|x(t; \xi)|^2 \le q(1 + \sqrt{\kappa})^2 e^{-\bar{\gamma}t} \sup_{-\tau\le\theta\le 0} E|\xi(\theta)|^2, \quad t \ge 0, \tag{3.3}$$

where

$$\bar{\gamma} = \min\left\{\lambda,\ \frac{1}{\tau}\log\left[\frac{q}{(1 + \sqrt{q\kappa})^2}\right]\right\} > 0. \tag{3.4}$$

In other words, the trivial solution of equation (2.1) *is exponentially stable in mean square.*

In order to prove this theorem, let us present two useful lemmas.

LEMMA 3.2. *Let* (3.1) *hold for some $\kappa \in (0, 1)$. Then*

$$E|\phi(0) - G(\phi)|^2 \le (1 + \sqrt{k})^2 \sup_{-\tau\le\theta\le 0} E|\phi(\theta)|^2$$

for all $\phi \in L^2_{\mathcal{F}_\infty}([-\tau, 0]; R^n)$.

Proof. For any $\varepsilon > 0$,

$$\begin{aligned} E|\phi(0) - G(\phi)|^2 &\le E|\phi(0)|^2 + 2E\big(|\phi(0)||G(\phi)|\big) + E|G(\phi)|^2 \\ &\le (1 + \varepsilon)E|\phi(0)|^2 + (1 + \varepsilon^{-1})E|G(\phi)|^2 \\ &\le \big[1 + \varepsilon + \kappa(1 + \varepsilon^{-1})\big] \sup_{-\tau\le\theta\le 0} E|\phi(\theta)|^2. \end{aligned}$$

Therefore, the desired result follows by taking $\varepsilon = \sqrt{\kappa}$. The proof is complete. □

LEMMA 3.3. *Let* (3.1) *hold for some $\kappa \in (0, 1)$. Let $\rho \ge 0$ and $0 < \gamma < \tau^{-1}\log(1/\kappa)$. Let $x(t)$ be a solution of equation* (2.1). *If*

$$e^{\gamma t}E|x(t) - G(x_t)|^2 \le (1 + \sqrt{\kappa})^2 \sup_{-\tau\le\theta\le 0} E|x(\theta)|^2 \tag{3.5}$$

for all $0 \le t \le \rho$, then

$$e^{\gamma t}E|x(t)|^2 \le \frac{(1 + \sqrt{\kappa})^2}{(1 - \sqrt{\kappa e^{\gamma\tau}})^2} \sup_{-\tau\le\theta\le 0} E|x(\theta)|^2. \tag{3.6}$$

Proof. Let $\kappa e^{\gamma\tau} < \varepsilon < 1$. For $0 \le t \le \rho$, note that

$$E|x(t) - G(x_t)|^2 \ge E|x(t)|^2 - 2E\big(|x(t)||G(x_t)|\big) + E|G(x_t)|^2$$
$$\ge (1-\varepsilon)E|x(t)|^2 - (\varepsilon^{-1} - 1)E|G(x_t)|^2.$$

Hence

$$E|x(t)|^2 \le \frac{1}{1-\varepsilon} E|x(t) - G(x_t)|^2 + \frac{\kappa}{\varepsilon} \sup_{-\tau\le\theta\le 0} E|x(t+\theta)|^2.$$

By condition (3.5), we then derive that for all $0 \le t \le \rho$,

$$e^{\gamma t}E|x(t)|^2 \le \frac{1}{1-\varepsilon} \sup_{0\le t\le\rho}\Big[e^{\gamma t}E|x(t) - G(x_t)|^2\Big] + \frac{\kappa}{\varepsilon} \sup_{0\le t\le\rho}\Big[e^{\gamma t} \sup_{-\tau\le\theta\le 0} E|x(t+\theta)|^2\Big]$$
$$\le \frac{(1+\sqrt{\kappa})^2}{1-\varepsilon} \sup_{-\tau\le\theta\le 0} E|x(\theta)|^2 + \frac{\kappa e^{\gamma\tau}}{\varepsilon} \sup_{-\tau\le t\le\rho}\Big[e^{\gamma t}E|x(t)|^2\Big].$$

However, this holds for all $-\tau \le t \le 0$ as well. Therefore,

$$\sup_{-\tau\le t\le\rho}\Big[e^{\gamma t}E|x(t)|^2\Big] \le \frac{(1+\sqrt{\kappa})^2}{1-\varepsilon} \sup_{-\tau\le\theta\le 0} E|x(\theta)|^2 + \frac{\kappa e^{\gamma\tau}}{\varepsilon} \sup_{-\tau\le t\le\rho}\Big[e^{\gamma t}E|x(t)|^2\Big].$$

Since $1 > \kappa e^{\gamma\tau}/\varepsilon$, we see that

$$\sup_{-\tau\le t\le\rho}\Big[e^{\gamma t}E|x(t)|^2\Big] \le \frac{\varepsilon(1+\sqrt{\kappa})^2}{(1-\varepsilon)(\varepsilon - \kappa e^{\gamma\tau})} \sup_{-\tau\le\theta\le 0} E|x(\theta)|^2.$$

The required assertion (3.6) follows by taking $\varepsilon = \sqrt{\kappa e^{\gamma\tau}}$. The proof is complete. □

We can now begin to prove Theorem 3.1.

Proof of Theorem 3.1. First, note that $q/(1+\sqrt{q\kappa})^2 > 1$ since $q > (1-\sqrt{k})^{-2}$ and hence $\bar{\gamma} > 0$. Now fix any $\xi \in L^2_{\mathcal{F}_0}([-\tau, 0]; R^n)$ and simply write $x(t;\xi) = x(t)$. Without any loss of generality, we may assume that $\sup_{-\tau\le\theta\le 0} E|\xi(\theta)|^2 > 0$. Let $\gamma \in (0, \bar{\gamma})$ arbitrarily. It is easy to show that

$$0 < \gamma < \min\left\{\lambda,\ \frac{1}{\tau}\log\Big(\frac{1}{\kappa}\Big)\right\} \quad \text{and} \quad q > \frac{e^{\gamma\tau}}{(1-\sqrt{\kappa e^{\gamma\tau}})^2}. \tag{3.7}$$

We now claim that

$$e^{\gamma t}E|x(t) - G(x_t)|^2 \le (1+\sqrt{\kappa})^2 \sup_{-\tau\le\theta\le 0} E|\xi(\theta)|^2 \quad \text{for all } t \ge 0. \tag{3.8}$$

If so, an application of Lemma 3.3 to (3.8) yields that

$$e^{\gamma t}E|x(t)|^2 \le \frac{(1+\sqrt{\kappa})^2}{(1-\sqrt{\kappa e^{\gamma\tau}})^2} \sup_{-\tau\le\theta\le 0} E|\xi(\theta)|^2 \le q(1+\sqrt{\kappa})^2 \sup_{-\tau\le\theta\le 0} E|x(\theta)|^2$$

for all $t \ge 0$, where we have used (3.7), and the desired result (3.3) follows by letting $\gamma \to \bar{\gamma}$. The remainder of the proof is to show (3.8) by contradiction. Suppose (3.8) is not true. Then in view of Lemma 3.2, there is a $\rho \ge 0$ such that

$$e^{\gamma t}E|x(t) - G(x_t)|^2 \le e^{\gamma\rho}E|x(\rho) - G(x_\rho)|^2 = (1+\sqrt{\kappa})^2 \sup_{-\tau\le\theta\le 0} E|\xi(\theta)|^2 \tag{3.9}$$

for all $0 \le t \le \rho$ and, moreover, there is a sequence of $\{t_k\}_{k\ge 1}$ such that $t_k \downarrow \rho$ and

$$e^{\gamma t_k} E|x(t_k) - G(x_{t_k})|^2 > e^{\gamma\rho} E|x(\rho) - G(x_\rho)|^2. \tag{3.10}$$

Applying Lemma 3.3, we derive from (3.9) that

$$\begin{aligned} e^{\gamma t} E|x(t)|^2 &\le \frac{(1+\sqrt{\kappa})^2}{(1-\sqrt{\kappa e^{\gamma\tau}})^2} \sup_{-\tau\le\theta\le 0} E|x(\theta)|^2 \\ &= \frac{e^{\gamma\rho}}{(1-\sqrt{\kappa e^{\gamma\tau}})^2} E|x(\rho) - G(x_\rho)|^2 \end{aligned}$$

for all $-\tau \le t \le \rho$. Particularly,

$$E|x(\rho+\theta)|^2 \le \frac{e^{\gamma\tau}}{(1-\sqrt{\kappa e^{\gamma\tau}})^2} E|x(\rho) - G(x_\rho)|^2 < qE|x(\rho) - G(x_\rho)|^2 \tag{3.11}$$

for all $-\tau \le \theta \le 0$, where (3.7) has been used once again. By assumption (3.2), we then have

$$E\Big(2(x(\rho) - G(x_\rho))^T f(\rho, x_\rho) + \text{trace}[g^T(\rho, x_\rho) g(\rho, x_\rho)]\Big) \le -\lambda E|x(\rho) - G(x_\rho)|^2.$$

Recalling $\gamma < \lambda$, we see by the continuity of the solution and the functionals G, f, and g (this is the standing hypothesis in this paper) that for all sufficiently small $h > 0$,

$$E\Big(2(x(t) - G(x_t))^T f(t, x_t) + \text{trace}[g^T(t, x_t) g(t, x_t)]\Big) \le -\gamma E|x(t) - G(x_t)|^2$$

if $\rho \le t \le \rho + h$. Now by Itô's formula, for all sufficiently small $h > 0$,

$$\begin{aligned} &e^{\gamma(\rho+h)}\ E|x(\rho+h) - G(x_{\rho+h})|^2 - e^{\gamma\rho} E|x(\rho) - G(x_\rho)|^2 \\ &\quad = \int_\rho^{\rho+h} e^{\gamma t}\Big[\gamma E|x(t) - G(x_t)|^2 \\ &\qquad + E\Big(2(x(t) - G(x_t))^T f(t, x_t) + \text{trace}[g^T(t, x_t) g(t, x_t)]\Big)\Big] dt \\ &\quad \le 0; \end{aligned} \tag{3.12}$$

however, this contradicts (3.10), so (3.8) must hold. The proof is now complete. □

4. Almost sure exponential stability. In this section, we discuss the almost sure exponential stability for the neutral stochastic functional differential equations. It will be shown that under the linear-growth condition, the exponential stability in mean square implies the almost sure exponential stability.

THEOREM 4.1. *Let (3.1) hold for some $\kappa \in (0,1)$. Assume that there exists a positive constant $K > 0$ such that*

$$E\big(|f(t,\phi)|^2 + \text{trace}\big[g^T(t,\phi) g(t,\phi)\big]\big) \le K \sup_{-\tau\le\theta\le 0} E|\phi(\theta)|^2 \tag{4.1}$$

for all $t \ge 0$ and $\phi \in L^2_{\mathcal{F}_\infty}([-\tau, 0]; R^n)$. Assume also that the trivial solution of equation (2.1) is exponentially stable in mean square, that is, there exists a pair of positive constants γ and M such that

$$E|x(t;\xi)|^2 \le M e^{-\gamma t} \sup_{-\tau\le\theta\le 0} E|\xi(\theta)|^2, \quad t \ge 0, \tag{4.2}$$

for all $\xi \in L^2_{\mathcal{F}_0}([-\tau, 0]; R^n)$. *Then*

$$\limsup_{t\to\infty} \frac{1}{t} \log |x(t;\xi)| \le -\frac{\bar\gamma}{2} \quad a.s., \tag{4.3}$$

where $\bar\gamma = \min\{\gamma, \tau^{-1}\log(1/\kappa)\}$, *that is, the trivial solution of equation* (2.1) *is also almost surely exponentially stable. In particular, if* (3.1), (3.2), *and* (4.1) *hold, then the trivial solution of equation* (2.1) *is almost surely exponentially stable.*

To prove the theorem, we need to present another lemma which is very useful in the study of the almost sure exponential stability of neutral stochastic functional differential equations.

Lemma 4.2. *Assume that there exists a constant* $\kappa \in (0, 1)$ *such that*

$$|G(\varphi)|^2 \le \kappa \sup_{-\tau\le\theta\le 0} |\varphi(\theta)|^2, \quad \varphi \in C([-\tau, 0]; R^n). \tag{4.4}$$

Let $z : [-\tau, \infty) \to R^n$ *be a continuous function. Let* $0 < \gamma < \tau^{-1}\log(1/\kappa)$ *and* $H > 0$. *If*

$$|z(t) - G(z_t)|^2 \le He^{-\gamma t} \quad \textit{for all } t \ge 0, \tag{4.5}$$

then

$$\limsup_{t\to\infty} \frac{1}{t} \log |z(t)| \le -\frac{\gamma}{2}. \tag{4.6}$$

Proof. Choose any $\varepsilon \in (\kappa e^{\gamma\tau}, 1)$. In the same way as in the proof of Lemma 3.3, we can show that for any $T > 0$,

$$\sup_{0\le t\le T} \Big[e^{\gamma t}|z(t)|^2\Big] \le \frac{H}{1-\varepsilon} + \frac{\kappa e^{\gamma\tau}}{\varepsilon} \sup_{-\tau\le t\le T} \Big[e^{\gamma t}|z(t)|^2\Big].$$

It then follows that

$$\Big(1 - \frac{\kappa e^{\gamma\tau}}{\varepsilon}\Big) \sup_{0\le t\le T} \Big[e^{\gamma t}|z(t)|^2\Big] \le \frac{H}{1-\varepsilon} + \frac{\kappa e^{\gamma\tau}}{\varepsilon} \sup_{-\tau\le t\le 0} |z(t)|^2.$$

Consequently,

$$\limsup_{t\to\infty} \frac{1}{t} \log |z(t)| \le -\frac{\gamma}{2},$$

as required. The proof is complete. □

Proof of Theorem 4.1. First, note that condition (4.1) implies condition (4.4) since $C[-\tau; 0]; R^n) \subset L^2_{\mathcal{F}_\infty}([-\tau, 0]; R^n)$. Now fix any initial data ξ and write the solution $x(t;\xi) = x(t)$ simply. By the well-known Doob martingale inequality (cf. Karatzas and Shreve [6]), the Hölder inequality, and condition (4.2), we can easily derive that for any integer $k \ge 1$,

(4.7)

$$\begin{aligned} &E\Big(\sup_{0\le\theta\le\tau} |x(k\tau+\theta) - G(x_{k\tau+\theta})|^2\Big) \\ &\le 3E|x(k\tau) - G(x_{k\tau})|^2 + 3K(\tau+4)\int_{k\tau}^{(k+1)\tau} \Big(\sup_{-\tau\le\theta\le 0} E|x(s+\theta)|^2\Big)ds \\ &\le \Big(6M(1+\kappa)e^{-\bar\gamma(k\tau-\tau)} + 3K(\tau+4)M\int_{k\tau}^{(k+1)\tau} e^{-\bar\gamma(s-\tau)}ds\Big)\Big[\sup_{-\tau\le\theta\le 0} E|\xi(\theta)|^2\Big] \\ &\le Ce^{-\bar\gamma k\tau}, \end{aligned}$$

where $C = 3Me^{\bar{\gamma}\tau}\big[2(1+\kappa)+K(\tau+4)\big]\sup_{-\tau\le\theta\le0} E|\xi(\theta)|^2$. Let $\varepsilon \in (0, \bar{\gamma})$ be arbitrary. It then follows from (4.7) that

$$P\left(\omega : \sup_{0\le\theta\le\tau} |x(k\tau+\theta) - G(x_{k\tau+\theta})|^2 > e^{-(\bar{\gamma}-\varepsilon)k\tau}\right) \le Ce^{-\varepsilon k\tau}.$$

In view of the well-known Borel–Cantelli lemma, we see that for almost all $\omega \in \Omega$,

$$\sup_{0\le\theta\le\tau} |x(k\tau+\theta) - G(x_{k\tau+\theta})|^2 \le e^{-(\bar{\gamma}-\varepsilon)k\tau} \tag{4.8}$$

holds for all but finitely many k. Hence for all $\omega \in \Omega$ excluding a P-null set, there exists a $k_o(\omega)$ for which (4.8) holds whenever $k \ge k_o$. In other words, for almost all $\omega \in \Omega$,

$$|x(t) - G(x_t)|^2 \le e^{-(\bar{\gamma}-\varepsilon)(t-\tau)} \quad \text{if } t \ge k_o\tau.$$

However, $|x(t) - G(x_t)|^2$ is finite on $[0,\ k_o\tau]$. Therefore, for almost all $\omega \in \Omega$, there exists a finite number $H = H(\omega)$ such that

$$|x(t) - G(x_t)|^2 \le He^{-(\bar{\gamma}-\varepsilon)t} \quad \text{for all } t \ge 0.$$

An application of Lemma 4.2 now yields

$$\limsup_{t\to\infty} \frac{1}{t}\log|x(t)| \le -\frac{\bar{\gamma}-\varepsilon}{2} \quad \text{a.s.},$$

and the desired result (4.3) follows by letting $\varepsilon \to 0$. The proof is complete. □

5. Comparison with existing results.

Recently, in [11], we studied the exponential stability in mean square for a class of neutral stochastic functional differential equations using a completely different technique from the one in this paper. The aim of this section is to compare our previous results in [11] with our new results in this paper. The equation studied in [11] is of the form

$$d[x(t) - G(x_t)] = [f_1(t, x(t)) + f_2(t, x_t)]dt + g(t, x_t)dw(t) \tag{5.1}$$

on $t \ge 0$ with initial data $x_0 = \xi$, where $f_1 : R_+ \times R^n \to R^n,\ f_2 : R_+ \times C([-\tau, 0]; R^n) \to R^n$, and G and g are the same as before. Let us first state a useful result.

Theorem 5.1. *Let* (3.1) *hold. Assume that there are two positive constants* λ_1 *and* λ_2 *such that*

$$\begin{aligned} &E\Big(2(\phi(0) - G(\phi\ ))^T[f_1(t, \phi(0)) + f_2(t, \phi)] + trace[g^T(t, \phi)g(t, \phi)]\Big) \\ &\qquad \le -\lambda_1 E|\phi(0)|^2 + \lambda_2 \sup_{-\tau\le\theta\le0} E|\phi(\theta)|^2 \end{aligned} \tag{5.2}$$

for all $t \ge 0$ *and* $\phi \in L^2_{\mathcal{F}_\infty}([-\tau, 0]; R^n)$. *If*

$$0 < \kappa < \frac{1}{4} \quad \textit{and} \quad \lambda_1 > \frac{\lambda_2}{(1 - 2\sqrt{\kappa})^2}, \tag{5.3}$$

then the trivial solution of equation (5.1) *is exponentially stable in mean square.*

Proof. By condition (5.3), we can choose q such that

$$\frac{1}{\kappa} > q > \frac{1}{(1-\sqrt{\kappa})^2} \quad \text{and} \quad \lambda_1 > \frac{\lambda_2 q}{(1-\sqrt{\kappa q})^2}. \tag{5.4}$$

By defining $f(t,\varphi) = f_1(t,\varphi(0)) + f_2(t,\varphi)$ for $t \geq 0$ and $\varphi \in C([-\tau,0];R^n)$, equation (5.1) can be written as equation (2.1), so all that we need to do is verify condition (3.2). To do so, let $t \geq 0$ and $\phi \in L^2_{\mathcal{F}_t}([-\tau,0];R^n)$, satisfying

$$E|\phi(\theta)|^2 < qE|\phi(0) - G(\phi)|^2, \quad -\tau \leq \theta \leq 0.$$

Note that for any $\varepsilon > 0$,

$$-E|\phi(0)|^2 \leq -\frac{1}{1+\varepsilon}E|\phi(0) - G(\phi)|^2 + \frac{1}{\varepsilon}E|G(\phi)|^2. \tag{5.5}$$

It then follows from (5.2) and (5.5) that

$$\begin{aligned} &E\Big(2(\phi(0) - G(\phi))^T[f_1(t,\phi(0)) + f_2(t,\phi)] + \text{trace}[g^T(t,\phi)g(t,\phi)]\Big) \\ &\quad\leq -\lambda_1 E|\phi(0)|^2 + \lambda_2 \sup_{-\tau\leq\theta\leq 0} E|\phi(\theta)|^2 \\ &\quad\leq -\Big[\lambda_1\Big(\frac{1}{1+\varepsilon} - \frac{\kappa q}{\varepsilon}\Big) - \lambda_2 q\Big]E|\phi(0) - G(\phi)|^2. \end{aligned} \tag{5.6}$$

In particular, choose $\varepsilon = \sqrt{\kappa q}/(1-\sqrt{\kappa q})$ and hence

$$\Big[\lambda_1\Big(\frac{1}{1+\varepsilon} - \frac{\kappa q}{\varepsilon}\Big) - \lambda_2 q\Big] = \lambda_1(1-\sqrt{\kappa q})^2 - \lambda_2 q > 0,$$

where we have used (5.4). In other words, condition (3.2) is satisfied and hence the conclusion follows from Theorem 3.1. The proof is complete. □

To compare this result with one in our previous paper [11], let us introduce another new notation $\mathcal{W}([-\tau,0];R_+)$, which is the family of all Borel-measurable bounded nonnegative functions $\eta(\theta)$ defined on $-\tau \leq \theta \leq 0$ such that $\int_{-\tau}^0 \eta(\theta)d\theta = 1$. In [11], conditions (3.1) and (5.2) were strengthened as follows: There is a constant $\kappa \in (0,1)$ and a function $\eta_1 \in \mathcal{W}([-\tau,0];R_+)$ such that

$$|G(\varphi)|^2 \leq \kappa \int_{-\tau}^0 \eta_1(\theta)|\varphi(\theta)|^2 d\theta \quad \text{for all } \varphi \in C([-\tau,0];R^n); \tag{5.7}$$

moreover, there exists a function $\eta_2(.) \in \mathcal{W}([-\tau,0];R_+)$ and two positive constants λ_1 and λ_2 such that

$$\begin{aligned} &2(\varphi(0) - G(\varphi\ ))^T[f_1(t,\varphi(0)) + f_2(t,\varphi)] + \text{trace}[g^T(t,\varphi)g(t,\varphi)] \\ &\quad\leq -\lambda_1|\varphi(0)|^2 + \lambda_2\int_{-\tau}^0 \eta_2(\theta)|\varphi(\theta)|^2 d\theta \end{aligned} \tag{5.8}$$

for all $t \geq 0$ and $\varphi \in C([-\tau,0];R^n)$. These two conditions are indeed stronger than (3.1) and (5.2), respectively. For example, if (5.7) holds, then for any $\phi \in$

$L^2_{\mathcal{F}_\infty}([-\tau,0];R^n)$,

$$\begin{aligned} E|G(\phi)|^2 &\le \kappa \int_{-\tau}^0 \eta_1(\theta) E|\phi(\theta)|^2 d\theta \\ &\le \kappa \sup_{-\tau\le\theta\le 0} E|\phi(\theta)|^2 \int_{-\tau}^0 \eta_1(\theta) d\theta = \kappa \sup_{-\tau\le\theta\le 0} E|\phi(\theta)|^2, \end{aligned}$$

that is, (3.1) holds. However, what we gained in [11] with this price paid is the following sharper result.

Theorem 5.2 (Mao [11]). *Let* (5.7) *and* (5.8) *hold. If* $\lambda_1 > \lambda_2$ *and* $\kappa \in (0,1)$, *then the trivial solution of equation* (5.1) *is exponentially stable in mean square.*

Obviously, $\lambda_1 > \lambda_2$ and $\kappa \in (0,1)$ are much sharper than (5.3). The disadvantage of Theorem 5.2 is that (5.7) and (5.8) are somehow too restricted. For instance, Theorem 5.2 is not applicable to the case of neutral stochastic differential delay equations. However, Theorem 5.1 can be applied to deal with the delay case easily. Let us now turn to this topic.

6. Neutral stochastic differential delay equations. As an application, let us apply the theory established in the previous sections to deal with the exponential stability of neutral stochastic differential delay equations of the form

$$d[x(t) - \bar{G}(x(t-\tau))] = \bar{f}(t, x(t), x(t-\tau))dt + \bar{g}(t, x(t), x(t-\tau))dw(t) \tag{6.1}$$

on $t \ge 0$ with initial data $x_0 = \xi$, where $\bar{G} : R^n \to R^n$, $\bar{f} : R_+ \times R^n \times R^n \to R^n$, and $\bar{g} : R_+ \times R^n \times R^n \to R^{n\times m}$. As before, assume that equation (6.1) has a unique global solution denoted by $x(t;\xi)$ and, moreover, $\bar{G}(0) = 0$, $\bar{f}(t,0,0) = 0$, and $\bar{g}(t,0,0) = 0$. We now employ Theorem 5.1 to establish one useful corollary.

Corollary 6.1. *Assume that there is a constant* $\kappa \in (0,1)$ *such that*

$$|\bar{G}(x)|^2 \le \kappa |x|^2, \quad x \in R^n. \tag{6.2}$$

Assume also that there are two positive constants λ_1 *and* λ_2 *such that*

$$2(x - \bar{G}(y))^T \bar{f}(t,x,y) + \mathrm{trace}[\bar{g}^T(t,x,y)\bar{g}(t,x,y)] \le -\lambda_1 |x|^2 + \lambda_2 |y|^2 \tag{6.3}$$

for all $t \ge 0$ *and* $x, y \in R^n$. *If*

$$0 < \kappa < \frac{1}{4} \quad \textit{and} \quad \lambda_1 > \frac{\lambda_2}{(1-2\sqrt{\kappa})^2}, \tag{6.4}$$

then the trivial solution of equation (6.1) *is exponentially stable in mean square.*

This corollary follows directly from Theorem 5.1 since equation (6.1) can be written as equation (5.1) by defining

$$G(\varphi) = \bar{G}(\varphi(-\tau)), \qquad f_1(t,x) = \bar{f}(t,x,0),$$

$$f_2(t,\varphi) = -\bar{f}(t,\varphi(0),0) + \bar{f}(t,\varphi(0),\varphi(-\tau)), \qquad g(t,\varphi) = \bar{g}(t,\varphi(0),\varphi(-\tau))$$

for $t \ge 0$, $x \in R^n$ and $\varphi \in C([-\tau,0];R^n)$. Of course, we can directly apply Theorems 3.1 and 4.1 to obtain a more general result. For this purpose, let us introduce another new notation $L^2_{\mathcal{F}}(\Omega;R^n)$, which is the family of R^n-valued $\mathcal{F}$-measurable random variables X such that $E|X|^2 < \infty$.

THEOREM 6.2. *Let* (6.2) *hold with* $\kappa \in (0,1)$. *Let* $q > (1-\sqrt{\kappa})^{-2}$. *Assume that there is a constant* $\lambda > 0$ *such that*

$$E\Big(2(X-\bar{G}(Y))^T\ \bar{f}(t,X,Y) + \text{trace}[\bar{g}^T(t,X,Y)\bar{g}(t,X,Y)]\Big)$$

$$\le -\lambda E|X-\bar{G}(Y)|^2 \tag{6.5}$$

for all $t \ge 0$ *and those* $X, Y \in L^2_{\mathcal{F}}(\Omega; R^n)$ *satisfying* $E|Y|^2 < qE|X-\bar{G}(Y)|^2$. *Then the trivial solution of equation* (6.1) *is exponentially stable in mean square. Furthermore, if there is a positive constant* K *such that*

$$|\bar{f}(t,x,y)|^2 + \text{trace}[\bar{g}^T(t,x,y)\bar{g}(t,x,y)] \le K(|x|^2+|y|^2), \quad x,y \in R^n, \tag{6.6}$$

then the trivial solution of equation (6.1) *is also almost surely exponentially stable.*

This theorem follows directly from Theorems 3.1 and 4.1 since equation (6.1) can be written as equation (2.1) by defining

$$G(\varphi) = \bar{G}(\varphi(-\tau)), \qquad f(t,\varphi) = \bar{f}(t,\varphi(0),\varphi(-\tau)), \qquad g(t,\varphi) = \bar{g}(t,\varphi(0),\varphi(-\tau))$$

for $t \ge 0$ and $\varphi \in C([-\tau,0]; R^n)$.

7. Linear neutral stochastic functional differential equations. As another application, let us consider a linear neutral stochastic functional differential equation

$$d[x(t) - G(x_t)] = [-Ax(t) + B_0(x_t)]dt + \sum_{i=1}^m B_i(x_t)dw_i(t) \tag{7.1}$$

on $t \ge 0$ with initial data $x_0 = \xi$. Here A is an $n \times n$ constant matrix and

$$G(\varphi) = \int_{-\tau}^0 d\gamma(\theta)\varphi(\theta), \qquad B_i(\varphi) = \int_{-\tau}^0 d\beta_i(\theta)\varphi(\theta)$$

for $\varphi \in C([-\tau,0]; R^n)$, $0 \le i \le m$, where $\gamma(\theta) = (\gamma^{kl}(\theta))_{n\times n}$, $\beta_i(\theta) = (\beta_i^{kl}(\theta))_{n\times n}$ and all $\gamma^{kl}(\theta)$ and $\beta_i^{kl}(\theta)$ are functions of bounded variation on $-\tau \le \theta \le 0$. Let $V_{\gamma^{kl}}(\theta)$ denote the total variations of γ^{kl} on the interval $[-\tau,\theta]$ and let $V_\gamma(\theta) = ||V_{\gamma^{kl}}(\theta)||$. We can define $V_{\beta_i}(\theta)$ similarly. In particular, let

$$\hat{\gamma} = V_\gamma(0) \quad \text{and} \quad \hat{\beta}_i = V_{\beta_i}(0), \quad 0 \le i \le m.$$

Let us now impose the first assumption:

$$0 < \hat{\gamma} < \frac{1}{2}. \tag{7.2}$$

Then for any $\phi \in L^2_{\mathcal{F}_\infty}([-\tau,0]; R^n)$,

$$E|G(\varphi)|^2 \le \hat{\gamma}E\int_{-\tau}^0 dV_\gamma(\theta)|\varphi(\theta)|^2 \le \hat{\gamma}^2 \sup_{-\tau\le\theta\le0} E|\varphi(\theta)|^2. \tag{7.3}$$

In other words, (3.1) is satisfied with $\kappa = \hat{\gamma}^2$. Moreover,

$$2E\big[|\phi(0)||G(\phi)|\big] \le \frac{\hat{\gamma}}{1-2\hat{\gamma}}E|\phi(0)|^2 + \frac{1-2\hat{\gamma}}{\hat{\gamma}}E|G(\phi)|^2$$

$$\le \frac{\hat{\gamma}}{1-2\hat{\gamma}}E|\phi(0)|^2 + \hat{\gamma}(1-2\hat{\gamma}) \sup_{-\tau\le\theta\le0} E|\varphi(\theta)|^2. \tag{7.4}$$

Similarly, one can show that

$$2E\big[|\phi(0)||B_0(\phi)|\big] \le \frac{\hat{\beta}_0}{1-2\hat{\gamma}} E|\phi(0)|^2 + \hat{\beta}_0(1-2\hat{\gamma}) \sup_{-\tau\le\theta\le 0} E|\varphi(\theta)|^2, \tag{7.5}$$

$$2E\big[|G(\phi)||B_0(\phi)|\big] \le 2\hat{\gamma}\hat{\beta}_0 \sup_{-\tau\le\theta\le 0} E|\varphi(\theta)|^2, \tag{7.6}$$

and

$$\sum_{i=1}^{m} E|B_i(\phi)|^2 \le \left[\sum_{i=1}^{m} \hat{\beta}_i^2\right] \sup_{-\tau\le\theta\le 0} E|\varphi(\theta)|^2. \tag{7.7}$$

Let $\lambda_{\min}(A+A^T)$ denote the smallest eigenvalue of $A+A^T$. Using (7.4)–(7.7), we then see that

$$\begin{aligned} E&\left(2(\phi(0)-G(\phi))^T[-A\phi(0)+B_0(\phi)] + \sum_{i=1}^{m} E|B_i(\phi)|^2\right) \\ &\le -\left[\lambda_{\min}(A+A^T) - \frac{\hat{\gamma}||A||+\hat{\beta}_0}{1-2\hat{\gamma}}\right] E|\phi(0)|^2 \\ &\quad + \left[(\hat{\gamma}||A||+\hat{\beta}_0)(1-2\hat{\gamma}) + 2\hat{\gamma}\hat{\beta}_0 + \sum_{i=1}^{m} \hat{\beta}_i^2\right] \sup_{-\tau\le\theta\le 0} E|\phi(\theta)|^2. \end{aligned} \tag{7.8}$$

To close this paper, we apply Theorems 5.1 and 4.1 and conclude the following corollary.

Corollary 7.1. *Let* (7.2) *hold. If*

$$\lambda_{\min}(A+A^T) > \frac{2(\hat{\gamma}||A||+\hat{\beta}_0)}{1-2\hat{\gamma}} + \frac{1}{(1-2\hat{\gamma})^2}\left[2\hat{\gamma}\hat{\beta}_0 + \sum_{i=1}^{m} \hat{\beta}_i^2\right],$$

then the trivial solution of equation (7.1) *is exponentially stable in mean square and is also almost surely exponentially stable.*

Acknowledgment. The author would like to thank the anonymous referee for helpful suggestions.

AN EXTENSION OF THE STABILITY INDEX FOR TRAVELING-WAVE SOLUTIONS AND ITS APPLICATION TO BIFURCATIONS[*]

SHUNSAKU NII[†]

Abstract. We treat the stability index for traveling-wave solutions of one-dimensional reaction-diffusion equations due to Alexander, Gardner, and Jones [*J. Reine Angew. Math.*, 410 (1990), pp. 167–212]. An extension of the stability index which makes the index robust to perturbation is given and, using the extension, an additive formula for a gluing bifurcation of traveling waves is proven. We also consider certain heteroclinic bifurcations as an application, some specific examples of which are discussed.

Key words. traveling wave, stability index, heteroclinic bifurcation

1. Introduction.

We often encounter the following type of equations as model equations in chemistry, mathematical biology, and other areas concerning formation of spatial patterns; these kinds of equations are called reaction-diffusion equations:

$$\begin{cases} \frac{\partial u_1}{\partial t} = d_1 \Delta u_1 + f_1(u_1, \ldots, u_n), \\ \quad\vdots \\ \frac{\partial u_n}{\partial t} = d_n \Delta u_n + f_n(u_1, \ldots, u_n), \end{cases} \tag{1.1}$$

where $d_i \geq 0$ represents—as a model equation of a chemical reaction, for instance—the spatial diffusion rate of chemicals and f_i models their production.

Stable steady-state constant solutions of such systems correspond to homogeneous equilibrium states. On the other hand, pattern formations which appear in transition processes are attracting interest, and much research has been devoted to them. For systems with a one-dimensional space variable, traveling-wave solutions are especially important from this point of view. In this paper, we deal with their stability and bifurcations.

Consider a one-dimensional reaction-diffusion system

$$u_t = Bu_{xx} + F(u), \tag{1.2}$$

where $x, t \in \mathbb{R}$, $u(x,t) \in \mathbb{R}^n$, B is an $n \times n$ positive diagonal matrix, and $F\colon \mathbb{R}^n \to \mathbb{R}^n$. Set $\xi = x - \theta t$ and rewrite this equation on a moving frame (ξ, t); then we have

$$u_t = Bu_{\xi\xi} + \theta u_\xi + F(u). \tag{1.3}$$

In the x-coordinate, a steady-state solution of equation (1.3) is a solution which translates with constant velocity θ, preserving the solution's profile. This is a traveling-wave

solution of system (1.2). In this paper, we restrict our attention to the traveling waves satisfying the boundary condition

$$\lim_{x\to\pm\infty} u(x,t) = u_\pm, \tag{1.4}$$

where we assume that $u \equiv u_\pm$ are stable steady-state constant solutions of (1.2), i.e., $u(x,t) = u(\xi)$ is a solution of the ordinary differential equation.

$$Bu_{\xi\xi} + \theta u_\xi + F(u) = 0 \tag{1.5}$$

with $\lim_{\xi\to\pm\infty} u(\xi) = u_\pm$. This means that $(u(\xi), u'(\xi))$ is a heteroclinic solution connecting $(u_-, 0)$ and $(u_+, 0)$ of the first-order system

$$\begin{cases} u' = v, \\ v' = -B^{-1}F(u) - \theta B^{-1}v \end{cases} \quad ({}' = \tfrac{d}{d\xi}). \tag{1.6}$$

This kind of wave corresponds to the movement of a transition layer between two equilibrium states when u_- is different from u_+, whereas it corresponds to the propagation of a pulse when u_- equals to u_+.

The existence problem of such traveling waves or, equivalently, heteroclinic (homoclinic) orbits of (1.6) already commands a large body of literature, and it is also one of the main sources of motivation for the development of bifurcation theory for homoclinic or heteroclinic orbits of vector fields.

However, not all traveling waves correspond to observed phenomena which are described by the equations. Physical systems always suffer from noise which comes from outside the system. Therefore, waves represented by unstable solutions, which are destroyed by small perturbations of their initial conditions, cannot sustain themselves in the systems in the real world. That is why we need stability analysis; in other words, we have to know stable solutions which, even if they are perturbed slightly, recover to the original solutions as time goes on.

We usually use the technique of linear stability; that is, we linearize the equation about the wave under study and investigate whether this linearized operator on the appropriate space has no eigenvalue with a positive real part. This is because, in the context of semilinear parabolic equations, it is well known that stability for the linear problem implies the same for the nonlinear problem under an appropriate setting. Therefore, the eigenvalue problem is the main issue for the stability analysis of traveling waves. See Alexander, Gardner, and Jones [1], and for more details, see Bates and Jones [4] and Henry [9].

One way to approach the eigenvalue problem is to investigate the Evans function, which is an analytic function on the complex plane derived from the eigenvalue problem and vanishes at the eigenvalues (see Evans [6], [7], Jones [12], and Yanagida [20]). This function is the basis of the stability index due to Alexander, Gardner, and Jones [1], which is the main subject of this paper. In fact, it is an algebraically dressed refinement of the Evans function.

The aim of this paper is to determine the stability of traveling waves that are generated by certain bifurcations.

First, we present an extension of the stability index.

Consider a system depending on a parameter $\mu \in \mathbb{R}$,

$$u_t = Bu_{xx} + F(u;\mu). \tag{1.7}$$

Assume that at $\mu = 0$ this system has a traveling-wave solution $u_0(\xi)$ with velocity θ, i.e., $u_0(\xi)$ satisfies

$$Bu_{\xi\xi} + \theta u_\xi + F(u;\mu) = 0 \tag{1.8}$$

for $\xi = x - \theta t$. The stability index is defined for u_0. For $\mu \neq 0$, (1.7) generically does not have a traveling wave, so the stability index is not defined. However, equation (1.8) or the following system corresponding to it should retain some information for $\mu \approx 0$, and it is important to obtain this information when (1.8) (or (1.9)) undergoes various bifurcations:

$$\begin{cases} u' = v, \\ v' = -B^{-1}F(u;\mu) - \theta B^{-1}v \end{cases} \qquad ({}' = \tfrac{d}{d\xi}). \tag{1.9}$$

In fact, for each μ, (1.9) has a solution $(u(\xi;\mu), u'(\xi;\mu))$ that is "near" $(u_0(\xi), u_0'(\xi))$, and we can make use of this. The stability index is originally defined as the first Chern number of a certain vector bundle over the two-dimensional sphere, but we regard it as an element of the two-dimensional homotopy group of the complex projective space (Theorem 2.2). We prove that this definition has a kind of robustness; namely, we can define the index for $u(\xi;\mu)$ as an element of the relative homotopy group, and it inherits the information of the index defined for $u_0(\xi)$ (Theorem 3.1).

Next, an additive formula (Theorem 3.2) of the index of the gluing bifurcation [8] of heteroclinic orbits of (1.9) is proven as an application of the extension of the stability index.

Sometimes we see gluing bifurcations of traveling waves—two traveling waves are glued with each other at the ends of $\xi \to \pm\infty$ and a new traveling wave is produced. At first, Yanagida and Maginu [21] treated this kind of problem for pulses with oscillating tails and where the equilibrium of (1.9) with which the pulses are associated has a one-dimensional unstable manifold. In this case, the definition and calculation of the Evans function was relatively easy. Later, Alexander and Jones [2], [3] dealt with the same problem when the unstable manifold is two dimensional. In [2], an additive formula for the bifurcation is proven using cobordism. Our result provides another way of proving it.

The additive formula tells us that for a wave generated by a gluing bifurcation of two waves, the linearized operator possesses two eigenvalues near the origin; one is at the origin corresponding to the translation of the wave, so the sign of the other one determines the stability. Alexander and Jones [2] showed that the direction of the intersection of stable and unstable manifolds of equilibria of (1.9) determines the sign (Proposition 4.1). This is also a generalization of the works of Evans [7], Jones [12], Yanagida [20], and Yanagida and Maginu [21]. In those works, the geometrical meaning of direction was clear. In the general situation, however, we must define the direction properly.

Besides the additive formula, other applications of the extension based on its robustness are expected. For example, a similar index is defined in [19] to detect the existence of N-homoclinic bifurcations, and there may be some relation between these two indices.

The remainder of this paper is devoted to an application to a heteroclinic bifurcation. A generic two-parameter family of vector fields with two heteroclinic orbits in a row undergoes a gluing bifurcation that produces a heteroclinic orbit that stays in some neighborhood of the concatenation of original two heteroclinic orbits (see Kokubu [17]). This type of bifurcation is also observed in some reaction-diffusion equations. We apply the preceding argument to this kind of bifurcation. In this case, we must determine the direction of the intersections to apply to actual examples (Theorem 4.3). This is not an easy task in general situations, but we can determine the stability for the case of a heteroclinic loop. More precisely, assume that system (1.9) has two equilibria $(u_1, 0)$ and $(u_2, 0)$, and assume that for a certain parameter value, there exist two heteroclinic orbits from $(u_1, 0)$ to $(u_2, 0)$ and from $(u_2, 0)$ to $(u_1, 0)$ forming a loop called a heteroclinic loop. Then the system undergoes a gluing bifurcation, producing a homoclinic orbit with respect to $(u_1, 0)$. In this situation, we show that the stability of the traveling wave corresponding to the homoclinic orbit is determined by the bifurcation diagram (Theorem 4.4); we show the relation between bifurcation diagrams and stability in Figure 5.7. This is another main theorem of this paper.

This paper is divided into five parts. In section 2, we briefly summarize the definition of the stability index and translate it in order to treat it via our methods. In section 3, we prove that the index can be extended and give a proof of the additive formula. Sections 4 and 5 are devoted to an application to a heteroclinic bifurcation and its examples.

2. The stability index.

First, we briefly summarize the construction of stability indices for traveling-wave solutions of one-dimensional reaction-diffusion equations due to Alexander, Gardner, and Jones. For details and proofs, see [1] and the references therein.

2.1. Traveling waves and their stability.

Consider one-dimensional reaction-diffusion equations of the following form:

$$u_t = Bu_{xx} + F(u). \tag{2.1}$$

Here $u(x,t) \in \mathbb{R}^n$, $x, t \in \mathbb{R}$, B : positive diagonal $n \times n$ matrix, and $F : C^2$ with derivatives through order 2 bounded on $\mathbb{R}^n$.

We get on the moving frame (ξ, t), where $\xi = x - \theta t$ and the velocity θ is a constant. In this coordinate, (2.1) is written as follows:

$$u_t = Bu_{\xi\xi} + \theta u_\xi + F(u). \tag{2.2}$$

A traveling-wave solution of (2.1) is a stationary solution $u_0(\xi) = u_0(x - \theta t)$ of (2.2) for some θ; in other words, it is a solution of (2.1) which translates at some constant velocity θ preserving its shape.

In what follows, we assume the existence of a traveling-wave solution satisfying the following assumptions.

(T.W.) There exist $C > 0$, $a > 0$, and $u_\pm \in \mathbb{R}^n$ with $F(u_\pm) = 0$ such that

1. $|u_0(\xi) - u_+| \leq Ce^{-a\xi}$ $(\xi > 0)$,
2. $|u_0(\xi) - u_-| \leq Ce^{a\xi}$ $(\xi < 0)$, and
3. $|u_0'(\xi)| \leq Ce^{-a|\xi|}$ ($\xi \in \mathbb{R}$, where $' = \frac{d}{d\xi}$).

Next, we define stability of traveling waves.

Definition 2.1. *A traveling wave $u_0(\xi)$ is asymptotically stable relative to* (2.2) *if there exists a neighborhood N of u_0 in $BU(\mathbb{R}, \mathbb{R}^n)$ such that each solution $u(\xi, t)$ of* (2.2) *that starts in N at $t = 0$ satisfies*

$$\|u(\xi,t) - u_0(\xi + k)\|_\infty \to 0 \quad (t \to +\infty) \tag{2.3}$$

for some $k \in \mathbb{R}$ depending on $u(\xi, t)$, where $BU(\mathbb{R}, \mathbb{R}^n) = \{v : \mathbb{R} \to \mathbb{R}^n |$ bounded uniformly continuous$\}$.

Remark 2.1. If $u_0(\xi)$ is a traveling wave, then so is $u_0(\xi + k)$.

To find the stability of $u_0(\xi)$, we linearize (2.2) about $u_0(\xi)$,

$$P_t = LP := BP_{\xi\xi} + \theta P_\xi + DF(u_0(\xi))P, \tag{2.4}$$

and consider the eigenvalue problem for L:

$$LP = \lambda P. \tag{2.5}$$

In order to determine the stability of u_0, it suffices to study the eigenvalue problem (2.5) because of the following well-known fact.

Fact (see [1], [4], and [9]). *$u_0(\xi)$ is asymptotically stable if the spectrum $\sigma(L)$ of L satisfies the following:*

1. *there exists $\beta < 0$ such that $\sigma(L) \setminus \{0\} \subset \{\lambda | \mathrm{Re}\lambda < \beta\}$;*
2. *0 is a simple eigenvalue* (0 *is an eigenvalue corresponding to translation*)*.*

Here we have the following for $\sigma(L)$.

Proposition 2.1. *If $u_\pm$ are stable for* (2.1)*, then there exists a simple closed curve K and a constant $\beta < 0$ such that*

$$\sigma(L) \cap \{\lambda | \mathrm{Re}\lambda > \beta\} \subset K^\circ, \tag{2.6}$$

where K° is the interior enclosed by K. Moreover, $\sigma(L) \cap K^\circ$ consists of isolated eigenvalues with finite multiplicity.

With this proposition, we conclude that $u_0(\xi)$ is stable if L has no eigenvalue in K° other than the simple one at 0.

Henceforth, we construct an index to detect eigenvalues of L inside K°.

2.2. Construction of the stability index. The eigenvalue problem

$$(L - \lambda)P := BP_{\xi\xi} + \theta P_\xi + DF(u_0(\xi))P - \lambda P = 0, \quad P(\xi) \in \mathbb{C}^n, \tag{2.7}$$

can be taken as a second-order linear ordinary differential equation, which we write in a first-order system as follows:

$$Y' = A(\lambda, \xi)Y, \tag{2.8}$$

where

$$Y(\xi) = \begin{pmatrix} P(\xi) \\ Q(\xi) \end{pmatrix} \in \mathbb{C}^{2n}, \quad Q = P',$$

and

$$A(\lambda, \xi) = \begin{pmatrix} 0 & I \\ B^{-1}(\lambda I - DF(u_0(\xi))) & -\theta B^{-1} \end{pmatrix}.$$

For each λ, (2.8) has at least one nontrivial bounded solution up to multiplication of constants if and only if it is an eigenvalue of L, in which case the P component of such a solution is an eigenfunction of L.

We introduce a new variable τ via the relation

$$\xi = \frac{1}{\kappa} \log\left(\frac{1+\tau}{1-\tau}\right). \tag{2.9}$$

This turns (2.8) into an autonomous system on $\mathbb{C}^{2n} \times (-1, +1)$:

$$\begin{cases} Y' = A(\lambda, \tau)Y := A(\lambda, \xi(\tau))Y, \\ \tau' = \kappa(1 - \tau^2) \end{cases} \qquad (\,' = \tfrac{d}{d\xi}). \tag{2.10}$$

Letting

$$A(\lambda, \pm 1) = \begin{pmatrix} 0 & I \\ B^{-1}\left(\lambda I - DF\left(u_\pm\right)\right) & -\theta B^{-1} \end{pmatrix}, \tag{2.11}$$

we augment (2.10) into a system on $\mathbb{C}^{2n} \times [-1, +1]$, which is of class C^1 for sufficiently small $\kappa > 0$. This system is also denoted by

$$\begin{cases} Y' = A(\lambda, \tau)Y, \\ \tau' = \kappa(1 - \tau^2). \end{cases} \tag{2.12}$$

$(\mathbf{O}, -1)$ and $(\mathbf{O}, +1)$ are equilibria of (2.12). The next lemma shows that λ is an eigenvalue of L if and only if the unstable manifold $\mathbf{W}_-^u$ of $(\mathbf{O}, -1)$ and the stable manifold $\mathbf{W}_+^s$ of $(\mathbf{O}, +1)$ has a nontrivial intersection, namely, $\mathbf{W}_-^u \cap \mathbf{W}_+^s \neq \{\mathbf{O}\} \times (-1, 1)$.

Lemma 2.1. *Let $(Y(\xi), \tau(\xi))$ be a nontrivial solution of* (2.12).

1. *$Y(\xi)$ is bounded as $\xi \to -\infty$ if and only if $(Y(\xi), \tau(\xi)) \in \mathbf{W}_-^u$.*
2. *$Y(\xi)$ is bounded as $\xi \to +\infty$ if and only if $(Y(\xi), \tau(\xi)) \in \mathbf{W}_+^s$.*

Now we are at the final stage of constructing the stability index.

Proposition 2.2. *If $u_\pm$ are stable, then there is a constant $\beta < 0$ such that for all λ with* $\mathrm{Re}\lambda > \beta$, *$A(\lambda, -1)$ (resp. $A(\lambda, +1)$) have n eigenvalues with positive real parts and n with negative.*

This means that $\mathbf{W}_-^u\big|_{\mathbb{C}^{2n} \times \{\tau\}}$ and $\mathbf{W}_+^s\big|_{\mathbb{C}^{2n} \times \{\tau\}}$ are n-dimensional subspaces of $\mathbb{C}^{2n} \times \{\tau\}$. We regard them as n-dimensional vector bundles over intervals.

For each fixed λ, define a continuous map

$$\Phi_\lambda \colon [-1, 1) \to G_n(\mathbb{C}^{2n}) : \tau \mapsto \left[\mathbf{W}^u|_{\mathbb{C}^{2n} \times \{\tau\}}\right], \tag{2.13}$$

where $G_n(\mathbb{C}^{2n})$ is the Grassmannian manifold of n-dimensional subspaces in $\mathbb{C}^{2n}$.

Let $U_\pm^\lambda$ ($S_\pm^\lambda$) be the unstable (stable) subspace of $A(\lambda, \pm 1)$.

Lemma 2.2. *If λ is not an eigenvalue of L, then*

$$\Phi_\lambda(\tau) \to [U_+^\lambda] \quad (\tau \to +1) \tag{2.14}$$

locally uniformly in $G_n(\mathbb{C}^{2n})$ for $\lambda \notin \sigma(L)$.

Set

$$\mathfrak{K} := (K^\circ \times \{-1\}) \cup (K \times [-1, +1]) \cup (K^\circ \times \{+1\}) \cong \mathbb{S}^2 \tag{2.15}$$

and

$$\mathfrak{G} : \mathfrak{K} \to G_n(\mathbb{C}^{2n}) : \mathfrak{G}(\lambda, \tau) = \begin{cases} \left[U_-^\lambda\right], & \lambda \in K^\circ, \quad \tau = -1, \\ \Phi_\lambda(\tau), & \lambda \in K, \quad \tau \in (-1, 1), \\ \left[U_+^\lambda\right], & \lambda \in K^\circ, \quad \tau = +1. \end{cases} \tag{2.16}$$

By Lemma 2.2, $\mathfrak{G}$ is continuous and induces an n-dimensional vector bundle $\mathfrak{E}(K)$ over $\mathfrak{K}$.

Definition 2.2.

$$\mathfrak{E}(K) := \mathfrak{G}^*\big(\Gamma_n(\mathbb{C}^{2n})\big)\,, \tag{2.17}$$

where $\Gamma_n(\mathbb{C}^{2n})$ *is the canonical bundle over* $G_n(\mathbb{C}^{2n})$.

Alexander et al. showed that this bundle determines the stability of the traveling wave $u_0(\xi)$.

Theorem 2.1 (Alexander, Gardner, and Jones [1]). *The first Chern number* $c_1(\mathfrak{E}(K))$ *of the bundle* $\mathfrak{E}(K)$ *coincides with the number of eigenvalues of* L *in* K° *including their multiplicity.*

We modify this theorem slightly for later use.

Consider a system that (2.12) induces on $\overset{n}{\wedge}\mathbb{C}^{2n} \times [-1,+1]$,

$$\begin{cases} Y^{(n)\prime} = A^{(n)}(\lambda,\tau)Y^{(n)}, \\ \qquad \tau' = \kappa(1-\tau^2). \end{cases} \tag{2.18}$$

Here $Y^{(n)}(\xi) \in \overset{n}{\wedge}\mathbb{C}^{2n}$ and $A^{(n)} = A \otimes I \otimes \cdots \otimes I + \cdots + I \otimes I \otimes \cdots \otimes I \otimes A|_{\overset{n}{\wedge}\mathbb{C}^{2n}}$, where $\overset{n}{\wedge}\mathbb{C}^{2n}$ denotes the nth exterior power of $\mathbb{C}^{2n}$. Let $m = \binom{2n}{n} - 1$; then $\mathbb{CP}^m \cong \mathbb{P}(\overset{n}{\wedge}\mathbb{C}^{2n})$ and (2.18) defines a system of the following form on $\mathbb{CP}^m \times [-1,+1]$ since it is linear in the $Y^{(n)}$ component:

$$\begin{cases} z' = Z(z,\tau;\lambda), \\ \tau' = \kappa(1-\tau^2) \end{cases} \quad (z \in \mathbb{CP}^m). \tag{2.19}$$

Let $\tilde{U}^\lambda_\pm$ ($\tilde{S}^\lambda_\pm$) be points on $\mathbb{CP}^m$ corresponding to $\overset{n}{\wedge}U^\lambda_\pm$ ($\overset{n}{\wedge}S^\lambda_\pm$), i.e., $\tilde{U}^\lambda_\pm := \Pi(\overset{n}{\wedge}U^\lambda_\pm)$ (resp. $\tilde{S}^\lambda_\pm := \Pi(\overset{n}{\wedge}S^\lambda_\pm)$) for the projection $\Pi\colon \mathbb{C}^{m+1} \setminus \{\mathbf{O}\} \to \mathbb{CP}^m$; then $(\tilde{U}^\lambda_-, -1)$ and $(\tilde{U}^\lambda_+, +1)$ (resp. $(\tilde{S}^\lambda_-, -1)$ and $(\tilde{S}^\lambda_+, +1)$) are equilibria of (2.19). These equilibria are attractive in the invariant subspaces $\mathbb{CP}^m \times \{\tau = -1\}$ and $\mathbb{CP}^m \times \{\tau = +1\}$, which means that $(\tilde{U}^\lambda_-, -1)$ have a one-dimensional unstable direction in the whole space $\mathbb{CP}^m \times [-1,+1]$—namely, the τ direction—and $(\tilde{U}^\lambda_+, +1)$ is an attracting equilibrium. By Lemma 2.2, system (2.19) has a heteroclinic orbit from $(\tilde{U}^\lambda_-, -1)$ to $(\tilde{U}^\lambda_+, +1)$ for $\lambda \notin \sigma(L)$. This heteroclinic orbit is given by $\{(\tilde{\Phi}_\lambda(\tau), \tau)\}$, where $\tilde{\Phi}_\lambda(\tau) := \Pi(\overset{n}{\wedge}\Phi_\lambda(\tau))$. Define a map G by

$$G : \mathfrak{K} \to \mathbb{CP}^m : G(\lambda,\tau) = \begin{cases} \tilde{U}^\lambda_-, & \lambda \in K^\circ, \quad \tau = -1, \\ \tilde{\Phi}_\lambda(\tau), & \lambda \in K, \quad \tau \in (-1,1), \\ \tilde{U}^\lambda_+, & \lambda \in K^\circ, \quad \tau = +1; \end{cases} \tag{2.20}$$

then Theorem 2.1 can be restated as follows. (See Figure 2.1.)

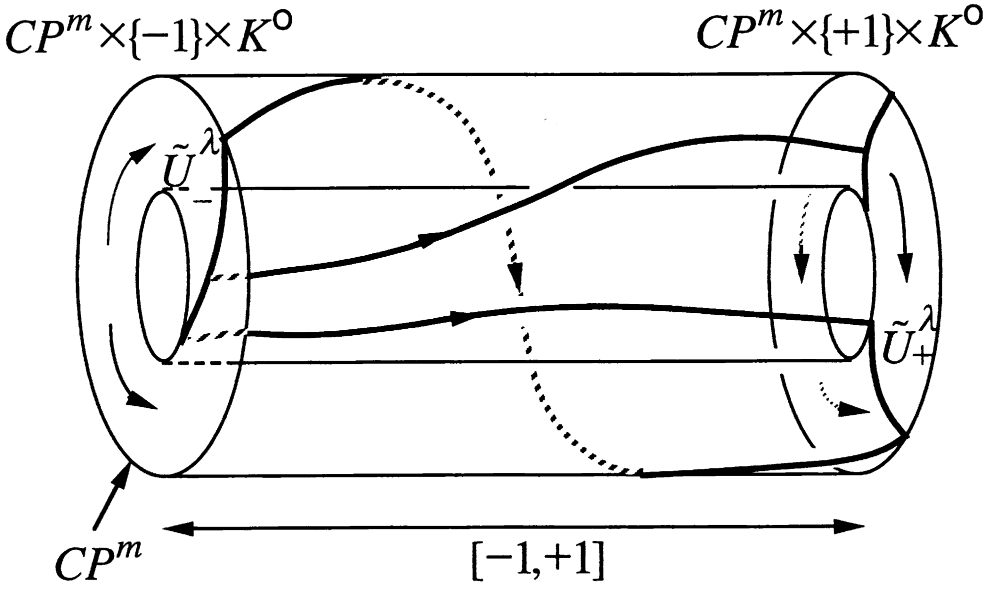
Theorem 2.2. $[G] \in \pi_2(\mathbb{CP}^m)) \cong \mathbb{Z}$ *counts the number of eigenvalues of* L *in* K°.

Proof. First, let us recall some parts of the proof of Theorem 2.1 in [1].

Let $H_- := (K^\circ \times \{-1\}) \cup (K \times I)$ and $H_+ := K^\circ \times \{+1\}$; then $H_- \cap H_+ = \mathbb{S}^1$. In [1], nonvanishing sections $\Gamma_-(\lambda,\tau)$ and $\Gamma_+(\lambda)$ of $\overset{n}{\wedge}\mathfrak{E}(K)$ over H_- and H_+ are constructed, i.e.,

(2.21)

$$\Gamma_- : H_- \to \overset{n}{\wedge}\mathbb{C}^{2n} : \Gamma_-(\lambda,\tau) \in \begin{cases} \Pi^{-1}(\tilde{U}^\lambda_-) = \overset{n}{\wedge}U^\lambda_-, & \lambda \in K^\circ, \quad \tau = -1, \\ \Pi^{-1}(\tilde{\Phi}_\lambda(\tau)) = \overset{n}{\wedge}\Phi_\lambda(\tau), & \lambda \in K, \quad \tau \in [-1,1], \end{cases}$$



$CP^m \times \{-1\} \times K^{\circ}$
$CP^m \times \{+1\} \times K^{\circ}$
$\tilde{U}_-^{\lambda}$
$\tilde{U}_+^{\lambda}$
CP^m
$[-1,+1]$

FIG. 2.1. *A schematic picture of Theorem* 2.2.

and

$$\Gamma_+ : H_+ \to \overset{n}{\wedge}\mathbb{C}^{2n} : \Gamma_+(\lambda) \in \Pi^{-1}(\tilde{U}_+^{\lambda}) = \overset{n}{\wedge} U_+^{\lambda}, \quad \lambda \in K^{\circ}, \tag{2.22}$$

where $\overset{n}{\wedge}\mathfrak{E}(K)$ is the exterior power of $\mathfrak{E}(K)$ and coincides with $G^*(\Gamma_1(\mathbb{C}^m))$. Trivializations of $\overset{n}{\wedge}\mathfrak{E}(K)$ over $H_\pm$ are defined with $\Gamma_\pm$ as

$$h_- : H_- \times \mathbb{C} \to \overset{n}{\wedge}\mathfrak{E}(K) : ((\lambda,\tau),z) \mapsto ((\lambda,\tau), z\Gamma_-(\lambda,\tau)), \tag{2.23}$$

$$h_+ : H_+ \times \mathbb{C} \to \overset{n}{\wedge}\mathfrak{E}(K) : ((\lambda,1),z) \mapsto ((\lambda,1), z\Gamma_+(\lambda)). \tag{2.24}$$

Then the map $g_E(\lambda)$ over $H_- \cap H_+$ defined by

$$h_+^{-1} \circ h_-((\lambda,1),z) = ((\lambda,1), g_E(\lambda)z) \tag{2.25}$$

can be seen as a map from $\mathbb{S}^1$ into $\mathbb{C}\setminus\{0\}$. In [1], it is shown that the homotopy class $[g_E] \in \pi_1(\mathbb{C}\setminus\{0\}) \cong \mathbb{Z}$ coincides with the number of eigenvalues of L in K°.

With $h_\pm$, we construct a map $h : \overset{n}{\wedge}\mathfrak{E}(K) \to \mathbb{C}^{m+1}$ as follows. Let N_- and N_+ be open neighborhoods of H_- and H_+ and extend $h_\pm$ over $N_\pm \times \mathbb{C}$. Urysone's lemma assures that there exist continuous functions $\alpha_\pm : N_\pm \to [0,1]$ satisfying $\alpha_\pm(\lambda,\tau) = 1$ if $(\lambda,\tau) \in H_\pm$ and $\alpha_\pm(\lambda,\tau) = 0$ if (λ,τ) is in some neighborhood of $\partial N_\pm$. Using this $\alpha_\pm$, define $h_i : \overset{n}{\wedge}\mathfrak{E}(K) \to \mathbb{C}$ $(i = 0,1)$ as

$$\begin{aligned} h_0((\lambda,\tau),v) &= \begin{cases} \alpha_-(\lambda,\tau)\cdot \pi_{h_-} \circ h_-^{-1}((\lambda,\tau),v), & (\lambda,\tau) \in N_-, \\ 0, & (\lambda,\tau) \notin N_-, \end{cases} \\ h_1((\lambda,\tau),v) &= \begin{cases} \alpha_+(\lambda,\tau)\cdot \pi_{h_+} \circ h_+^{-1}((\lambda,\tau),v), & (\lambda,\tau) \in N_+, \\ 0, & (\lambda,\tau) \notin N_+, \end{cases} \end{aligned} \tag{2.26}$$

where $\pi_{h_\pm} : H_\pm \times \mathbb{C} \to \mathbb{C}$ are projections. Then the map h is defined as

$$h : \overset{n}{\wedge}\mathfrak{E}(K) \to \mathbb{C}^{m+1} : h((\lambda,\tau),v) = (h_0((\lambda,\tau),v), h_1((\lambda,\tau),v), 0, \ldots, 0). \tag{2.27}$$

This h induces a map $\tilde{h} : \mathfrak{K} \to \mathbb{CP}^m$.

In what follows, we show that this $\tilde{h}$ is homotopic to G. First, let us assume that for any $((\lambda, \tau), v) \in \overset{n}{\wedge} \mathfrak{E}(K) \subset \mathfrak{K} \times \mathbb{C}^{m+1}$, $v \neq 0$, no negative real s satisfies $v = sh\left((\lambda, \tau), v\right)$. Under this condition,

$$h_s : \overset{n}{\wedge} \mathfrak{E}(K) \to \mathbb{C}^{m+1} : h_s((\lambda, \tau), v) := (1 - s)h((\lambda, \tau), v) + sv \tag{2.28}$$

induces a homotopy $\tilde{h}_s : \mathfrak{K} \to \mathbb{CP}^m$ with $\tilde{h}_0 = \tilde{h}$ and $\tilde{h}_1 = G$. When the assumption above is not satisfied, let $\mathbb{C}^{m+1}$ be identified with the subspace of $\mathbb{C}^{2m+2}$ as $\mathbb{C}^{m+1} \times \{0\} \subset \mathbb{C}^{m+1} \times \mathbb{C}^{m+1} = \mathbb{C}^{2m+2}$ and regard h as $h' : \overset{n}{\wedge} \mathfrak{E}(K) \to \mathbb{C}^{2m+2}$, and let h_{odd}, G', $G'_{\text{even}} : \overset{n}{\wedge} \mathfrak{E}(K) \to \mathbb{C}^{2m+2}$ be

$$\begin{aligned} h_{\text{odd}}((\lambda, \tau), v) &= (h_0((\lambda, \tau), v), 0, h_1((\lambda, \tau), v), 0, \ldots, 0), \\ G'((\lambda, \tau), v) &= (v, 0), \\ G'_{\text{even}}((\lambda, \tau), v) &= (0, v_0, 0, v_1, 0, \ldots, 0, v_m), \end{aligned} \tag{2.29}$$

where $v = (v_0, v_1, \ldots, v_m) \in \mathbb{C}^{m+1}$. Then h' and these maps induce the maps $\tilde{h}'$, $\tilde{h}_{\text{odd}}$, $\tilde{G}'$, $\tilde{G}'_{\text{even}} : \overset{n}{\wedge} \mathfrak{E}(K) \to \mathbb{CP}^{2m+1}$, and by the same argument as above,

$$\tilde{h}' \simeq \tilde{h}_{\text{odd}}, \qquad \tilde{h}_{\text{odd}} \simeq \tilde{G}'_{\text{even}}, \qquad \tilde{G}'_{\text{even}} \simeq \tilde{G}' \tag{2.30}$$

in $\mathbb{CP}^{2m+1}$. Thus $\tilde{h}'$ and $\tilde{G}'$ are homotopic in $\mathbb{CP}^{2m+1}$. Here $\mathbb{CP}^m$ can be regarded as a subspace of $\mathbb{CP}^{2m+1}$ corresponding to the inclusion $\mathbb{C}^{m+1} \hookrightarrow \mathbb{C}^{2m+2}$, and $\tilde{h} = \tilde{h}'$ and $G = \tilde{G}'$ by this identification. Thus $\tilde{h}$ is homotopic to G in $\mathbb{CP}^{2m+1}$.

Recall that $\mathbb{CP}^{2m+1}$ can be regarded as a cell complex as $\mathbb{CP}^{2m+1} = e^0 \cup e^2 \cup \cdots \cup e^{4m+2}$, where e^i $(i = 0, \ldots, 4m + 2)$ is an i-dimensional cell, and in this cell decomposition, $\mathbb{CP}^{2m+1} \setminus \mathbb{CP}^m \subset e^{m+1} \cup \cdots \cup e^{4m+2}$ consists of cells the dimension of which are equal or greater than 4. This means that the homotopy $\tilde{h} \simeq G$ can be realized in $\mathbb{CP}^m$ as $\tilde{h}, G : \mathfrak{K} \to \mathbb{CP}^m$ and $\mathfrak{K}$ is two dimensional. Thus $[\tilde{h}] = [G] \in \pi_2(\mathbb{CP}^m)$ with a natural identification corresponding to a change of base point.

The next step is to show that $[g_E] = [\tilde{h}]$ by a suitable isomorphism from $\pi_1(\mathbb{C}\setminus\{0\})$ to $\pi_2(\mathbb{CP}^m)$. The map $\tilde{h}$ can be regarded as $\tilde{h} : \mathfrak{K} \to \mathbb{CP}^1 \subset \mathbb{CP}^m$. Here again, the inclusion $\mathbb{CP}^1 \hookrightarrow \mathbb{CP}^m$ induces an isomorphism $\pi_2(\mathbb{CP}^1) \cong \pi_2(\mathbb{CP}^m)$, and by this homomorphism, $[\tilde{h}] \in \pi_2(\mathbb{CP}^m)$ is considered to be $[\tilde{h}] \in \pi_2(\mathbb{CP}^1)$. Recall that $h_+^{-1} \circ h_-((\lambda, 1), z) = ((\lambda, 1), g_E(\lambda)z)$, so if $\Gamma_-(\lambda, 1) = w(\lambda)\Gamma_+(\lambda)$ for $\lambda \in K$, $\tau = 1$, then $g_E(\lambda) = w(\lambda)$, i.e.,

$$g_E(\lambda) = \frac{h_1((\lambda, 1), v)}{h_0((\lambda, 1), v)}. \tag{2.31}$$

This means that g_E can be seen as

$$g_E : \mathbb{S}^1 \cong K \times \{+1\} \to \mathbb{CP}^1 \cong \mathbb{S}^2 : g_E(\lambda) = [h_0((\lambda, 1), v) : h_1((\lambda, 1), v)]. \tag{2.32}$$

Clearly, g_E is homotopic to some map $\bar{g} : \mathbb{S}^1 \to \mathbb{S}^1 = \big\{[1 : z] \,\big|\, |z| = 1\big\} \subset \mathbb{CP}^1$, and by suspension homomorphism, $[\bar{g}] \in \pi_1(\mathbb{S}^1)$ corresponds to $[\tilde{h}] \in \pi_2(\mathbb{CP}^1)$. Here this homomorphism is an isomorphism since $\pi_1(\mathbb{S}^1) \cong \pi_2(\mathbb{S}^2) \cong \mathbb{Z}$. Thus we get the desired result. □

Remark 2.2. We omit references to base points in the following argument because the isomorphism corresponding to a change of base points is uniquely determined by those points as $\pi_1\left(\mathbb{CP}^m\right) = 0$.

The whole arguments hold also for homology, but we employ homotopy for the sake of easier intuitive understanding.

3. An extension of the stability index.

In this section, we consider an extension of the stability index for perturbed systems and give a proof of one of our main theorems.

3.1. Perturbed systems. Consider a system of the form (2.2) with a parameter $\mu \in \mathbb{R}$:

$$u_t = Bu_{\xi\xi} + \theta(\mu)u_\xi + F(u;\mu). \tag{3.1}$$

Suppose that this system has a traveling wave $u_0(\xi)$ at $\mu = \mu_0$ that satisfies condition (T.W.). We assume without loss of generality that $F(u_\pm;\mu) = 0$ for all $\mu \in \mathbb{R}$. We also assume that $u_\pm$ are both stable for (2.1) or, in this case, for

$$u_t = Bu_{xx} + F(u;\mu). \tag{3.2}$$

We consider the equation of the stationary solutions for (3.1),

$$Bu_{\xi\xi} + \theta(\mu)u_\xi + F(u;\mu) = 0, \tag{3.3}$$

and we again write this as a first-order system,

$$\begin{cases} u' = v, \\ v' = -B^{-1}F(u;\mu) - \theta(\mu)B^{-1}v \end{cases} \qquad ('= \tfrac{d}{d\xi}). \tag{3.4}$$

Let $(u_0(\xi), u_0'(\xi))$ be the heteroclinic solution from $(u_-,0)$ to $(u_+,0)$ of (3.4) with $\mu = \mu_0$. Choose some point $(u_0^\dagger, v_0^\dagger)$ near $(u_+,0)$ on the orbit of $(u_0(\xi), u_0'(\xi))$, and take an n-dimensional plane Σ that intersects with the unstable manifold $\mathfrak{W}_-^u$ of $(u_-,0)$ transversely at $(u_0^\dagger, v_0^\dagger)$.

LEMMA 3.1. *When μ is near μ_0, $\mathfrak{W}_-^u \cap \Sigma = \big\{(u_\mu^\dagger, v_\mu^\dagger)\big\}$ (one point). Moreover, the point $(u_\mu^\dagger, v_\mu^\dagger)$ depends on μ continuously.* (*See Figure* 3.1.)

Proof. Consider (3.4) with a trivial equation $\mu' = 0$:

$$\begin{cases} u' = v, \\ v' = -B^{-1}F(u;\mu) - \theta(\mu)B^{-1}v, \\ \mu' = 0. \end{cases} \tag{3.5}$$

$S := \{(u_-,0,\mu) | \mu \in \mathbb{R}\}$ is a normally hyperbolic invariant set for (3.5), and let V^u be its unstable manifold. From the definition of Σ, V^u and $\Sigma \times \mathbb{R}$ intersect transversely at (u_0, v_0, μ_0) and, moreover, both V^u and $\Sigma \times \mathbb{R}$ are $(n+1)$-dimensional, so the intersection $V^u \cap \{\Sigma \times \mathbb{R}\}$ is a one-dimensional curve. The image under projection for (u,v) components is the curve $\{(u_\mu^\dagger, v_\mu^\dagger)\}$ parameterized by μ, and thus it is continuous. □

By translation on ξ, we can assume that $(u_0(0), u_0'(0)) = (u_0^\dagger, v_0^\dagger)$. We denote a solution that starts at $(u_\mu^\dagger, v_\mu^\dagger)$ when $\xi = 0$ by $(u(\xi;\mu), u'(\xi;\mu))$, namely, $(u(\xi;\mu_0), u'(\xi;\mu_0)) = (u_0(\xi), u_0'(\xi))$ and $u(\xi,\mu) \to u_-$ as $\xi \to -\infty$ since $(u_\mu^\dagger, v_\mu^\dagger) \in \mathfrak{W}_-^u$.

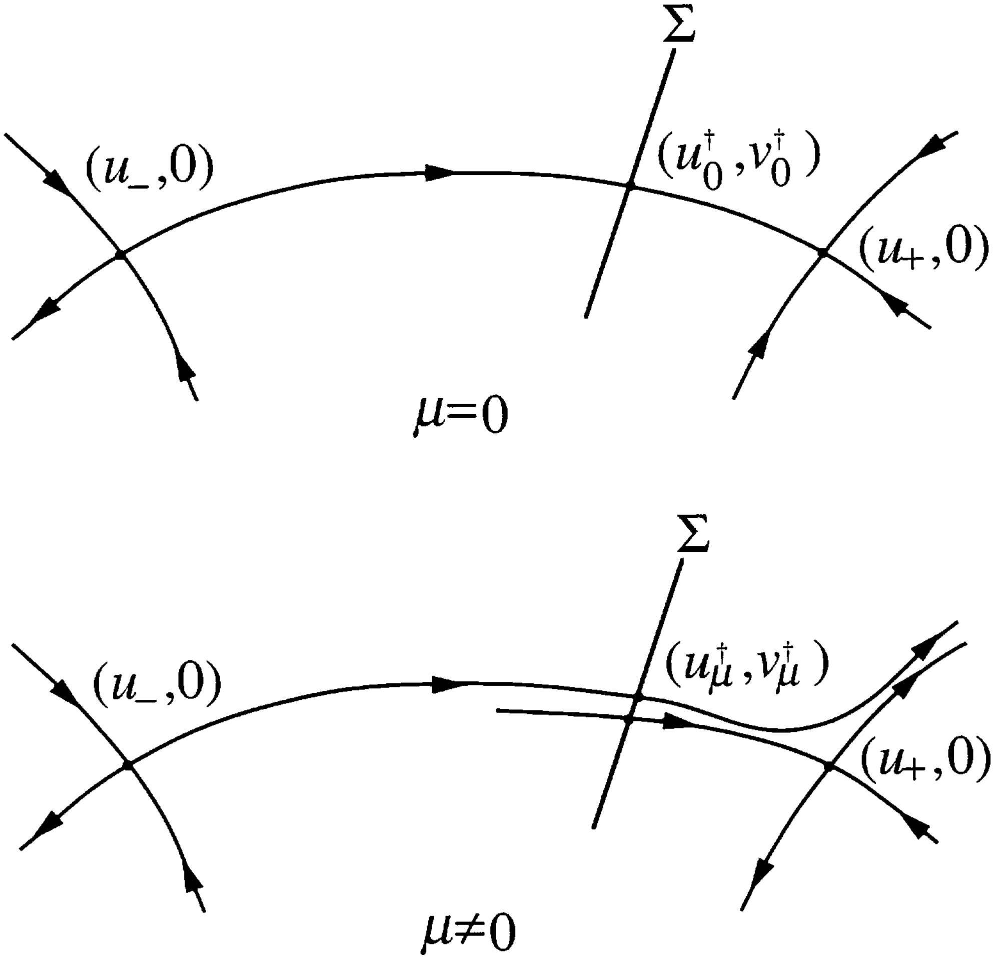
For this solution $u(\xi;\mu)$ and

$$\mathfrak{K}' = (K^\circ \times \{-1\}) \cup (K \times [-1,0]) \cong D^2,$$

we construct a map $G_-^\mu : \mathfrak{K}' \to \mathbb{CP}^m$ as follows.

Consider a system corresponding to (2.8),

$$Y' = A(\lambda, \xi; \mu)Y, \tag{3.6}$$



Σ
$(u_-,0)$
$(u_0^\dagger, v_0^\dagger)$
$(u_+,0)$
$\mu=0$
Σ
$(u_-,0)$
$(u_\mu^\dagger, v_\mu^\dagger)$
$(u_+,0)$
$\mu\neq 0$

FIG. 3.1. *The intersection point of* $\mathfrak{W}^u_-$ *and* Σ *for* μ *near* μ_0.

where

$$Y(\xi) = \begin{pmatrix} P(\xi) \\ Q(\xi) \end{pmatrix} \in \mathbb{C}^{2n}, \quad Q = P',$$

and

$$A(\lambda, \xi; \mu) = \begin{pmatrix} 0 & I \\ B^{-1}(\lambda I - DF(u(\xi;\mu))) & -\theta B^{-1} \end{pmatrix}.$$

A similar argument as before leads to a system on $\mathbb{C}^{2n} \times [-1, +1)$,

$$\begin{cases} Y' = A(\lambda, \tau; \mu) Y, \\ \tau' = \kappa(1 - \tau^2) \end{cases} \quad ({}' = \tfrac{d}{d\xi}), \tag{3.7}$$

where

$$A(\lambda, -1; \mu) = \begin{pmatrix} 0 & I \\ B^{-1}(\lambda I - DF(u_-)) & -\theta B^{-1} \end{pmatrix}.$$

Again, this equation induces a system on $\mathbb{CP}^m \times [-1, 1)$,

$$\begin{cases} z' = Z(z, \tau : \lambda; \mu), \\ \tau' = \kappa(1 - \tau^2) \end{cases} \qquad (z \in \mathbb{CP}^m). \tag{3.8}$$

We define a map G^{μ}_{-} as

$$G^{\mu}_{-} : \mathfrak{K}' \to \mathbb{CP}^m : G^{\mu}_{-}(\lambda, \tau) = \begin{cases} \tilde{U}^{\lambda}_{-}, & \lambda \in K^{\circ}, \quad \tau = -1, \\ \tilde{\Phi}^{\mu}_{\lambda}(\tau), & \lambda \in K, \quad \tau \in (-1, 0], \end{cases} \tag{3.9}$$

where $(\tilde{\Phi}^{\mu}_{\lambda}(\tau), \tau)$ is the unstable manifold of an equilibrium $(\tilde{U}^{\lambda}_{-}, -1)$ of (3.8). Obviously, this map is continuous and $G^{\mu_0}_{-} = G|_{\mathfrak{K}'}$ for G in (2.16).

Take a neighborhood N of $G((K \times [0, +1]) \cup (K^{\circ} \times \{+1\}))$ in $\mathbb{CP}^m$ satisfying $\pi_1(N) = 0$ and $\pi_2(N) = 0$. Such an N exists, for example, for K small and $(u^{\dagger}_0, v^{\dagger}_0)$ near $(u_+, 0)$.

Clearly, $G^{\mu}_{-}(\lambda, \tau)$ is also continuous in μ, so if μ is near μ_0, then

$$G^{\mu}_{-}\,(K \times \{0\}) \subset N. \tag{3.10}$$

This means that G^{μ}_{-} defines an element of the relative homotopy group $\pi_2\,(\mathbb{CP}^m, N)$.

Theorem 3.1.

$$\pi_2(\mathbb{CP}^m, N) \cong \pi_2(\mathbb{CP}^m) \cong \mathbb{Z},$$

and $[G^{\mu}_{-}] \in \pi_2(\mathbb{CP}^m, N)$ *corresponds to* $[G] \in \pi_2(\mathbb{CP}^m)$ *through the above isomorphism. Consequently,* $[G^{\mu}_{-}]$ *determines the stability of the travelling wave* $u_0(\xi)$ *at* $\mu = \mu_0$.

Proof. Consider the following exact sequence:

$$0 = \pi_2(N) \to \pi_2(\mathbb{CP}^m) \xrightarrow{p} \pi_2(\mathbb{CP}^m, N) \to \pi_1(N) = 0. \tag{3.11}$$

By the definition of N, $[G](\in \pi_2(\mathbb{CP}^m)$ corresponds to $[G^{\mu_0}_{-}]\,(\in \pi_2(\mathbb{CP}^m, N))$ through the homomorphism p. Moreover, (3.10) implies $[G^{\mu}_{-}] = [G^{\mu_0}_{-}]$ in $\pi_2\,(\mathbb{CP}^m, N)$. Here from the assumption on N, both ends of the above sequence are trivial, which implies that

$$\pi_2(\mathbb{CP}^m, N) \cong \pi_2(\mathbb{CP}^m) \cong \mathbb{Z},$$

and we get the desired result. □

Corollary 3.1. *The same argument holds for the perturbation of orbits. That is, at* $\mu = \mu_0$*, we can make a similar extension of the stability index for a solution of* (3.4) *on the unstable manifold* $\mathbf{W}^u_{-}$ *of* $(u_-, 0)$ *if it is near* $(u_0(\xi), u_0'(\xi))$. (*See Figure* 3.2.)

3.2. Additive formula for gluing bifurcation. In this section, we give a proof of an additive formula for the stability index under the gluing bifurcation of traveling waves. This theorem has been proven by Alexander and Jones [2] using cobordism invariance of the Chern number. Here we give another proof of additivity based on the above extension of the index.

Suppose system (3.1) has two traveling waves $u_1(\xi)$ and $u_2(\xi)$ when $\mu = \mu_0$ that satisfy

$$\begin{aligned} &u_1(\xi) \to u_- \quad (\xi \to -\infty), \qquad u_1(\xi) \to u_* \quad (\xi \to +\infty), \\ &u_2(\xi) \to u_* \quad (\xi \to -\infty), \qquad u_2(\xi) \to u_+ \quad (\xi \to +\infty), \end{aligned}$$

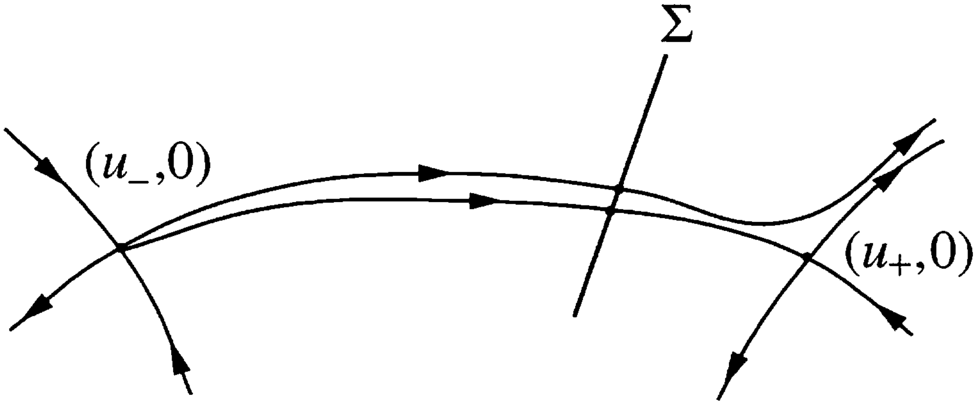


FIG. 3.2. *The case of the perturbation of an orbit.*

and (T.W.), where the stationary solutions $u_\pm$ and u_* are stable. Let $\Gamma_i = \{(u_i(\xi), u_i'(\xi))\}$ $(i = 1, 2)$ be the heteroclinic orbits of (3.4) corresponding to the traveling waves $u_i(\xi)$. Assume that system (3.4) undergoes a gluing bifurcation, that is, that the system has a heteroclinic orbit $\Gamma = \{(u(\xi), u'(\xi))\}$ from $(u_-, 0)$ to $(u_+, 0)$ for $\mu \approx \mu_0$ that stays in a tubular neighborhood of $\Gamma_1 \cup \Gamma_2$. (See Figure 3.3.)

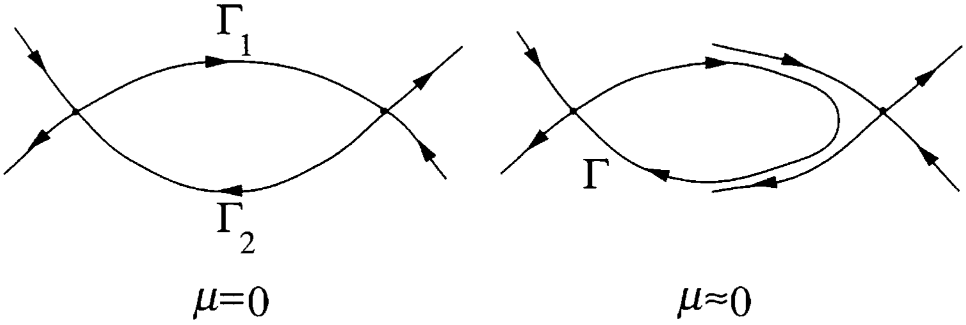

FIG. 3.3. *A gluing bifurcation.*

Fix a simple closed curve K on the complex plane $\mathbb{C}$, and let

$$G, G_i : \mathfrak{K} \to \mathbb{CP}^m, \quad i = 1, 2, \tag{3.12}$$

be the maps defined for $u(\xi)$ and $u_i(\xi)$.

In the situation above, we have the following additive formula.

THEOREM 3.2.

$$[G] = [G_1] + [G_2] \in \pi_2(\mathbb{CP}^m). \tag{3.13}$$

Proof. By definition, it holds that

$$G_1|_{(K\cup K^\circ)\times\{\tau=+1\}} = G_2|_{(K\cup K^\circ)\times\{\tau=-1\}} : K \cup K^\circ \to \mathbb{CP}^m. \tag{3.14}$$

Write this map as

$$H : K \cup K^\circ \to \mathbb{CP}^m. \tag{3.15}$$

First, let us assume that

$$\pi_1(H(K \cup K^\circ)) = 0 \quad \text{and} \quad \pi_2(H(K \cup K^\circ)) = 0. \tag{3.16}$$

Take a neighborhood N of $H(K \cup K^\circ)$ in $\mathbb{CP}^m$ that satisfies

$$\pi_1(N) = 0 \quad \text{and} \quad \pi_2(N) = 0. \tag{3.17}$$

If μ is close enough to μ_0 and as a result Γ is included in some small neighborhood of $\Gamma_1 \cup \Gamma_2$, we can assume that

$$\begin{cases} u(\xi) \approx u_1(\xi) & (\xi \leq 0), \\ u(\xi) \approx u_2(\xi) & (\xi \geq 0) \end{cases} \tag{3.18}$$

through some translations in the ξ variable. (See Figure 3.4.)

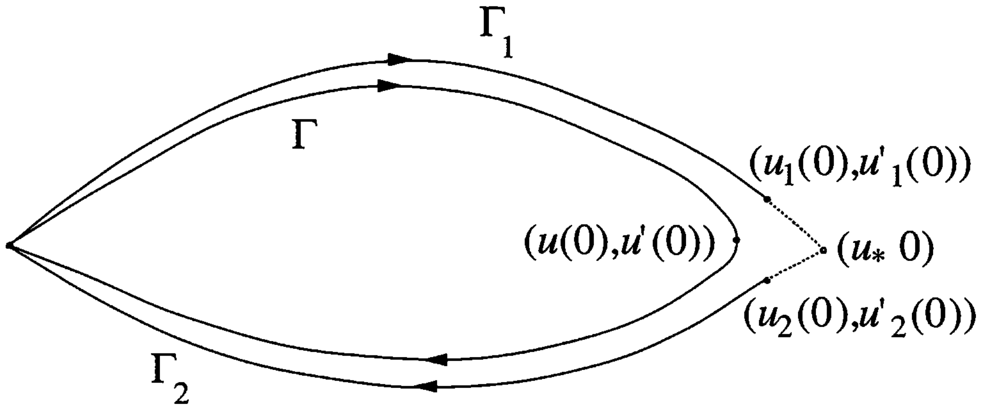

FIG. 3.4. Γ *and* $\Gamma_1 \cup \Gamma_2$.

This implies $u(0) \approx u_*$ and

$$G_1|_{K\times\{\tau=+1\}} \approx G_1|_{K\times\{\tau=0\}} \approx G|_{K\times\{\tau=0\}} \, : K \to \mathbb{CP}^m, \tag{3.19}$$

which means that

$$G(K \times \{0\}) \subset N. \tag{3.20}$$

Set

$$G_- := G|_{(K^\circ\times\{\tau=-1\})\cup(K\times[-1,0])}, \tag{3.21}$$

$$G_+ := G|_{(K\times[0,+1])\cup(K^\circ\times\{\tau=+1\})}, \tag{3.22}$$

$$G_{1-} := G_1|_{(K^\circ\times\{\tau=-1\})\cup(K\times[-1,+1])}, \tag{3.23}$$

$$G_{2+} := G_2|_{(K\times[-1,+1])\cup(K^\circ\times\{\tau=+1\})}; \tag{3.24}$$

then we have

$$G_- \simeq G_{1-} : (D^2, \partial D^2) \to (\mathbb{CP}^m, N), \tag{3.25}$$

$$G_+ \simeq G_{2+} : (D^2, \partial D^2) \to (\mathbb{CP}^m, N), \tag{3.26}$$

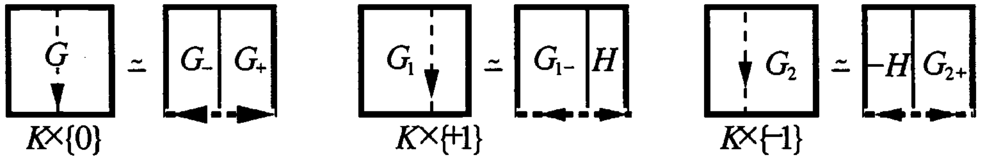

FIG. 3.5. *G, G_1, and G_2 as elements in $\pi_2(\mathbb{CP}^m, N)$.*

where $\simeq$ indicates homotopy.

Consider the following exact sequence again, where both ends are trivial:

$$0 = \pi_2(N) \to \pi_2(\mathbb{CP}^m) \xrightarrow{i} \pi_2(\mathbb{CP}^m, N) \to \pi_1(N) = 0. \tag{3.27}$$

From these definitions, we have (see Figure 3.5)

$$i([G]) = [G_-] + [G_+], \tag{3.28}$$

$$i([G_1]) = [G_{1-}] + [H], \tag{3.29}$$

$$i([G_2]) = -[H] + [G_{2+}]. \tag{3.30}$$

Here (3.25) and (3.26) imply that

$$[G_-] = [G_{1-}], \qquad [G_+] = [G_{2+}] \quad \text{in } \pi_2(\mathbb{CP}^m, N), \tag{3.31}$$

and by the definition of N, $[H] = 0$. This leads to

$$\begin{aligned} i\,([G]) &= [G_-] + [G_+] \\ &= [G_{1-}] + [G_{2+}] \\ &= i([G_1]) + i([G_2]) \quad \text{in } \pi_2(\mathbb{CP}^m, N). \end{aligned} \tag{3.32}$$

From this, we get the desired result, namely,

$$\begin{aligned} [G] &= i^{-1} \circ i([G]) \\ &= i^{-1} \circ i([G_1]) + i^{-1} \circ i\,([G_2]) \\ &= [G_1] + [G_2] \quad \text{in } \pi_2(\mathbb{CP}^m). \end{aligned} \tag{3.33}$$

For general K, divide K° into small parts; then each part satisfies condition (3.16) if the partition is fine enough, and therefore the above argument is applicable to each part. Collecting all of the parts, we get the result for K. □

4. Application.

4.1. Direct consequences of the additive formula. In this section, we consider some applications of Theorem 3.2. First, the next theorem is its direct consequence.

THEOREM 4.1. *Under the assumption of Theorem* 3.2, *$u(\xi)$ is unstable if either $u_1(\xi)$ or $u_2(\xi)$ is unstable.*

Proof. Suppose $u_1(\xi)$ is unstable, that is, the eigenvalue problem

$$(L_1 - \lambda)P := BP_{\xi\xi} + \theta P_\xi + DF(u_1(\xi))P - \lambda P \tag{4.1}$$

has an eigenvalue λ_1 with a positive real part. Take a simple closed curve $K_1 \subset \mathbb{C}$ satisfying

$$\lambda_1 \in K_1^\circ \quad \text{and} \quad K_1 \cup K_1^\circ \subset \{\lambda \in \mathbb{C} | \mathrm{Re}\lambda > 0\}. \tag{4.2}$$

By applying Theorem 3.2 to this K_1, we have an eigenvalue λ_0 inside K_1° of the eigenvalue problem

$$(L-\lambda)P := BP_{\xi\xi} + \theta P_\xi + DF(u(\xi))P - \lambda P, \tag{4.3}$$

which means that $\mathrm{Re}\lambda_0 > 0$, and hence $u(\xi)$ is unstable. (See Figure 4.1.)

The case where $u_2(\xi)$ is unstable can be treated similarly. □

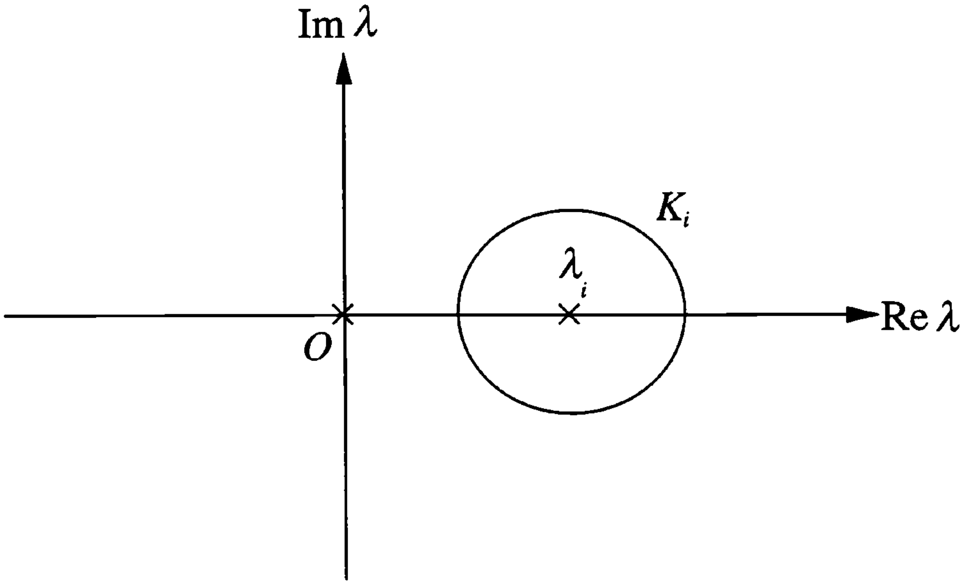

FIG. 4.1. *The eigenvalue with* $\mathrm{Re}\lambda_0 > 0$.

This theorem means that $u(\xi)$ can be stable only if both $u_1(\xi)$ and $u_2(\xi)$ are stable.

In what follows, let us suppose that both $u_1(\xi)$ and $u_2(\xi)$ are stable. In this case, Theorem 3.2 only tells us that L has two eigenvalues near the origin, and consequently we cannot decide the stability of $u(\xi)$ from this theorem alone. Actually, we have examples of both cases. (See section 5.)

4.2. Orientation index. Consider the eigenvalue problem for $\lambda \in \mathbb{R}$:

$$(L-\lambda)P := BP_{\xi\xi} + \theta P_\xi + DF(u_0(\xi))P - \lambda P = 0, \quad P(\xi) \in \mathbb{R}^n. \tag{4.4}$$

Again, we rewrite this as

$$\begin{cases} Y' = A(\lambda,\tau)Y, \\ \tau' = \kappa(1-\tau^2), \end{cases} \tag{4.5}$$

which defines a system on $\mathbb{RP}^m \times [-1,+1]$ as follows:

$$\begin{cases} z' = Z(z,\tau:\lambda), \\ \tau' = \kappa(1-\tau^2) \end{cases} \quad (z \in \mathbb{RP}^m). \tag{4.6}$$

Take $\lambda_1, \lambda_2 \in \mathbb{R}$ with $\beta < \lambda_1 < \lambda_2$, where β is as in Proposition 2.1, and assume that $\lambda_1, \lambda_2 \notin \sigma(L)$. Of course, Lemma 2.2 holds for $\lambda = \lambda_i$, $i = 1, 2$.

Set

$$\mathfrak{k} := ([\lambda_1, \lambda_2] \times \{-1\}) \cup (\{\lambda_1, \lambda_2\} \times [-1, +1]) \cup ([\lambda_1, \lambda_2] \times \{+1\}) \cong \mathbb{S}^1 \tag{4.7}$$

and let

$$g : \mathfrak{k} \to \mathbb{RP}^m \tag{4.8}$$

be defined in a similar manner as before, that is,

$$g(\lambda, \tau) = \begin{cases} \tilde{U}^{\lambda}_{-}, & \lambda \in [\lambda_1, \lambda_2], & \tau = -1, \\ \tilde{\Phi}_{\lambda}(\tau), & \lambda = \lambda_i,\ i = 1, 2, & \tau \in (-1, 1), \\ \tilde{U}^{\lambda}_{+}, & \lambda \in [\lambda_1, \lambda_2], & \tau = +1, \end{cases} \tag{4.9}$$

where $\tilde{U}^{\lambda}_{\pm}$ are the equilibria of (4.6) that correspond to the unstable subspaces $U^{\lambda}_{\pm}$ of $A(\lambda, \pm 1)$ and $(\tilde{\Phi}_{\lambda}(\tau), \tau)$ is a heteroclinic orbit connecting $(\tilde{U}^{\lambda}_{-}, -1)$ and $(\tilde{U}^{\lambda}_{+}, +1)$.

Next, for this g, we have as a part of Theorem 2.2.

THEOREM 4.2. *$[g] \in \pi_1(\mathbb{RP}^m) \cong \mathbb{Z}_2$ counts the parity of the number of eigenvalues of L on the interval $[\lambda_1, \lambda_2]$. That is, if the interval includes an odd number of eigenvalues, then $[g] = 1$, and if it includes an even number of eigenvalues, then $[g] = 0$.*

Proof. Theorem 2.1 was proven in [1] using the Evans function. First, we briefly summarize its construction.

Consider equations (2.18) and (2.19). An orbit $\{(Y(\lambda, \tau), \tau)\}_{-1<\tau<1}$ of (2.18) can be chosen so that $\Pi(Y(\lambda, \tau)) = \tilde{\Phi}_{\lambda}(\tau)$ for the projection $\Pi : \mathbb{C}^{m+1} \setminus \{\mathbf{O}\} \to \mathbb{CP}^m$ and for each τ, $Y(\lambda, \tau)$ is analytic in λ [1]. Similarly, an orbit $\{(Y^*(\lambda, \tau), \tau)\}_{-1<\tau<1}$ of (2.18) can be chosen so that $\Pi(Y^*(\lambda, \tau)) = \tilde{\Phi}^*_{\lambda}(\tau)$ and for each τ, $Y^*(\lambda, \tau)$ is analytic in λ, where $\{(\tilde{\Phi}^*_{\lambda}(\tau), \tau)\}_{-1<\tau<1}$ is the unique orbit of (2.19) satisfying

$$\lim_{\tau \to +1} (\tilde{\Phi}^*_{\lambda}(\tau), \tau) = (\tilde{S}^{\lambda}_{+}, +1). \tag{4.10}$$

Note that $Y(\lambda, \tau) \in \overset{n}{\wedge}(\mathbf{W}^u_{-}|_{\mathbb{C}^{2n} \times \{\tau\}})$ and $Y^*(\lambda, \tau) \in \overset{n}{\wedge}(\mathbf{W}^s_{+}|_{\mathbb{C}^{2n} \times \{\tau\}})$.

We define the Evans function $D(\lambda)$ as

$$D(\lambda) := Y(\lambda, 0) \wedge Y^*(\lambda, 0) \in \overset{2n}{\wedge}\mathbb{C}^{2n} \cong \mathbb{C}. \tag{4.11}$$

This function is analytic in λ, and the number of zeroes of D in K° coincides with the number of eigenvalues of L in K° including its multiplicity. For λ real, $Y(\lambda, \tau)$ and $Y^*(\lambda, \tau)$ can be taken so that they are both real analytic in λ and thus $D(\lambda)$ is real analytic.

Let $\Pi_s : \mathbb{R}^{m+1} \setminus \mathbf{O} \to \mathbb{S}^m$ and $\Pi_p : \mathbb{S}^m \to \mathbb{RP}^m$ be projections and set $\hat{\Phi}_{\lambda}(\tau) = \Pi_s(Y(\lambda, \tau))$ and $\hat{\Phi}^*_{\lambda}(\tau) = \Pi_s(Y^*(\lambda, \tau))$; then $\tilde{\Phi}_{\lambda}(\tau) = \Pi_p(\hat{\Phi}_{\lambda}(\tau))$ and $\tilde{\Phi}^*_{\lambda}(\tau) = \Pi_p(\hat{\Phi}^*_{\lambda}(\tau))$. We define $\hat{U}^{\lambda}_{\pm,i}$ and $\hat{S}^{\lambda}_{\pm,i}$ $(i = 1, 2)$ as $\Pi_p^{-1}(\tilde{U}^{\lambda}_{\pm}) = \{\hat{U}^{\lambda}_{\pm,1}, \hat{U}^{\lambda}_{\pm,2}\}$ and $\Pi_p^{-1}(\tilde{S}^{\lambda}_{\pm}) = \{\hat{S}^{\lambda}_{\pm,1}, \hat{S}^{\lambda}_{\pm,2}\}$ so that

$$\lim_{\tau \to \pm 1} \hat{\Phi}_{\lambda_1}(\tau) = \hat{U}^{\lambda_1}_{\pm,1} \quad \text{and} \quad \lim_{\tau \to \pm 1} \hat{\Phi}^*_{\lambda_1}(\tau) = \hat{S}^{\lambda_1}_{\pm,1} \tag{4.12}$$

hold. Moreover, $\hat{U}^{\lambda}_{\pm,i}$ and $\hat{S}^{\lambda}_{\pm,i}$ depend continuously on λ. Note that $\lim_{\tau \to +1} \hat{\Phi}^*_{\lambda_2}(\tau) = \hat{S}^{\lambda_2}_{+,1}$ holds by (4.10). If we consider $\hat{U}^{\lambda}_{\pm,i}, \hat{S}^{\lambda}_{\pm,i} \in \mathbb{R}^{m+1}$ by the inclusion

$\mathbb{S}^m \hookrightarrow \mathbb{R}^{m+1} = \overset{n}{\wedge}\mathbb{R}^{2n}$, the sign of $D(\lambda_1)$ coincides with that of $\hat{U}^{\lambda_1}_{+,1} \wedge \hat{S}^{\lambda_1}_{+,1}$ and thus with that of $\hat{U}^{\lambda_2}_{+,1} \wedge \hat{S}^{\lambda_2}_{+,1}$ by continuity. This means that $D(\lambda_1)D(\lambda_2) > 0$ if and only if

$$\lim_{\tau\to+1} \hat{\Phi}_{\lambda_2}(\tau) = \hat{U}^{\lambda_2}_{+,1} \tag{4.13}$$

and $D(\lambda_1)D(\lambda_2) < 0$ if and only if

$$\lim_{\tau\to+1} \hat{\Phi}_{\lambda_2}(\tau) = \hat{U}^{\lambda_2}_{+,2}. \tag{4.14}$$

In the former case, a lift $\hat{g} : \mathfrak{k} \to \mathbb{S}^m$ of $g : \mathfrak{k} \to \mathbb{RP}^m$ is expressed as

$$\hat{g}(\lambda,\tau) = \begin{cases} \hat{U}^{\lambda}_{-,1}, & \lambda \in [\lambda_1,\lambda_2], \qquad\quad \tau = -1, \\ \hat{\Phi}_{\lambda}(\tau), & \lambda = \lambda_i, \quad i = 1,2, \quad \tau \in (-1,1), \\ \hat{U}^{\lambda}_{+,1}, & \lambda \in [\lambda_1,\lambda_2], \qquad\quad \tau = +1, \end{cases} \tag{4.15}$$

and thus g is zero homotopic in $\mathbb{RP}^m$, whereas in the latter case, g cannot be lifted because $\lim_{\tau\to+1} \hat{\Phi}_{\lambda_2}(\tau) = \hat{U}^{\lambda_2}_{+,2} \neq \hat{U}^{\lambda_2}_{+,1}$, and thus g is not zero homotopic in $\mathbb{RP}^m$. This proves that $D(\lambda_1)D(\lambda_2) > 0$ if and only if $[g] = 0$ and that $D(\lambda_1)D(\lambda_2) < 0$ if and only if $[g] = 1$.

Here, since $D(\lambda)$ is a real analytic function on $[\lambda_1,\lambda_2]$, there are even zeros in $[\lambda_1,\lambda_2]$ if $D(\lambda_1)D(\lambda_2) > 0$ and odd zeros if $D(\lambda_1)D(\lambda_2) < 0$ including multiplicity. Thus the theorem holds. □

For $0 > \lambda_1$ close to 0 and λ_2 large, Alexander and Jones [2] showed that the direction of intersection of the unstable manifold of $(u_-,0)$ and the stable manifold of $(u_+,0)$ with respect to the traveling-wave speed θ determines the index $[g]$. More precisely, the sign of the derivative $\frac{dD}{d\lambda}|_{\lambda=0}$ of the Evans function $D(\lambda)$ at $\lambda = 0$ is determined as follows.

Assume that $u \equiv u_\pm$ are stationary solutions of the system and that for $\theta = \theta_0$ the system has a traveling wave. Let $X^{\theta_0}(\xi)$ be the corresponding heteroclinic solution from $(u_-,0)$ to $(u_+,0)$ at $\theta = \theta_0$ of

$$\begin{cases} u' = v, \\ v' = -B^{-1}F(u) - \theta B^{-1}v \end{cases} \qquad ({}' = \tfrac{d}{d\xi}). \tag{4.16}$$

Let $\mathfrak{W}^u_\theta$ be the unstable manifold of $(u_-,0)$ and $\mathfrak{W}^s_\theta$ be the stable manifold of $(u_+,0)$, both n-dimensional. Also, we assume that $\mathfrak{W}^u_\theta \cap \mathfrak{W}^s_\theta = \emptyset$, except for $\theta = \theta_0$. Extend $X^{\theta_0}(\xi)$ smoothly in θ to the solutions $X^\theta_u(\xi) \in \mathfrak{W}^u_\theta$ and $X^\theta_s(\xi) \in \mathfrak{W}^s_\theta$ for θ near θ_0.

For the traveling wave at $\theta = \theta_0$, define the solutions $(Y(\lambda,\tau),\tau)$ and $(Y^*(\lambda,\tau),\tau)$ of (2.18) so that $D(\lambda) > 0$ holds for large λ, and choose the vectors $V^1_u,\dots,V^{n-1}_u$ in $\mathbf{W}^u_-\big|_{\mathbb{C}^{2n}\times\{0\}}$ and $V^1_s,\dots,V^{n-1}_s$ in $\mathbf{W}^s_+\big|_{\mathbb{C}^{2n}\times\{0\}}$ so that

$$\begin{aligned} Y(0,0) &= X^{\theta_0\prime}(0) \wedge V^1_u \wedge \cdots \wedge V^{n-1}_u, \\ Y^*(0,0) &= X^{\theta_0\prime}(0) \wedge V^1_s \wedge \cdots \wedge V^{n-1}_s, \end{aligned}$$

which implies that $X^{\theta_0\prime}(0), V^1_u,\dots,V^{n-1}_u$ ($X^{\theta_0\prime}(0), V^1_s,\dots,V^{n-1}_s$) is a basis of $T_{X^{\theta_0}(0)}\mathfrak{W}^u_{\theta_0}$ (resp. $T_{X^{\theta_0}(0)}\mathfrak{W}^s_{\theta_0}$). Then we have

$$\begin{aligned} D(0) &= Y(0,0) \wedge Y^*(0,0) \\ &= \det\left(X^{\theta_0\prime}_u(0)V^1_u \cdots V^{n-1}_u X^{\theta_0\prime}_s(0)V^1_s \cdots V^{n-1}_s\right). \end{aligned}$$

Proposition 4.1 (Alexander and Jones [2]).

$$\frac{dD(\lambda)}{d\lambda}\bigg|_{\lambda=0} = \det\left(\left(\frac{dX_s^\theta(0)}{d\theta}\bigg|_{\theta=\theta_0} - \frac{dX_u^\theta(0)}{d\theta}\bigg|_{\theta=\theta_0}\right) V_u^1 \cdots V_u^{n-1} X^{\theta_0}{}'(0) V_s^1 \cdots V_s^{n-1}\right).$$

This proposition implies that the sign of $(\frac{dX_s^\theta(0)}{d\theta}|_{\theta=\theta_0} - \frac{dX_u^\theta(0)}{d\theta}|_{\theta=\theta_0})$ determines $[g]$ because if $\frac{dD}{d\lambda}(0) > 0$, then $D(\lambda_1) < 0$ for $\lambda_1 < 0$ close to 0, which means that $[g] = 1$ as $D(\lambda_2) > 0$ for λ_2 large, and if $\frac{dD}{d\lambda}(0) < 0$, then $D(\lambda_1) > 0$ for $\lambda_1 < 0$, so $[g] = 0$.

4.3. Gluing bifurcations and stability. In this section, we discuss the stability of a traveling-wave bifurcating from two traveling waves by a gluing bifurcation.

Consider an ordinary differential equation on $\mathbb{R}^{2n}$ depending on a parameter $\mu \in \mathbb{R}^k$ $(k \geq 2)$,

$$\dot{x} = f(x) + g(x;\mu) \quad (\dot{} = \tfrac{d}{dt}), \tag{4.17}$$

where f and g are smooth and $g(x;0) = 0$. Assume that (4.17) has three equilibria $\mathbf{O}_1(\mu)$, $\mathbf{O}_2(\mu)$, and $\mathbf{O}_3(\mu)$ and that the eigenvalues

$$-\eta_{n-1}^i(\mu), \dots, -\eta_1^i(\mu), -\rho^i(\mu), \nu^i(\mu), \kappa_1^i(\mu), \dots, \kappa_{n-1}^i(\mu)$$

of linearizations of F at each equilibrium satisfy

$$-\mathrm{Re}\eta_{n-1}^i(0) \leq \cdots \leq -\mathrm{Re}\eta_1^i(0) < -\rho^i(0) < 0 < \nu^i(0) < \mathrm{Re}\kappa_1^i(0) \leq \cdots \leq \mathrm{Re}\kappa_{n-1}^i(0).$$

Also, assume that for $\mu = 0$, the system

$$\dot{x} = f(x) \tag{4.18}$$

has heteroclinic orbits Γ_i of (4.18) from $\mathbf{O}_i(0)$ to $\mathbf{O}_{i+1}(0)$ $(i = 1, 2)$ simultaneously.

In what follows, we consider bifurcations of these heteroclinic orbits under the following nondegeneracy conditions.

1. For each i, the heteroclinic orbit $\Gamma_i = \{h_i(t)\}$ is tangent to the eigenspace associated with the eigenvalue $\nu^i(0)$ of linearization of f at $\mathbf{O}_i(0)$ as $t \to -\infty$ and the eigenspace associated with $-\rho^{i+1}(0)$ of $\mathbf{O}_{i+1}(0)$ as $t \to +\infty$.
2. For $\mu = 0$, the unstable manifold $\mathfrak{W}^u(\mathbf{O}_i)$ and the stable manifold $\mathfrak{W}^s(\mathbf{O}_{i+1})$ $(i = 1, 2)$ have a one-dimensional intersection, i.e., for all $p \in \Gamma_i$,

$$\dim(T_p\mathfrak{W}^u(\mathbf{O}_i) \cap T_p\mathfrak{W}^s(\mathbf{O}_{i+1})) = 1.$$

3. $\mathfrak{W}^u(\mathbf{O}_i(0))$ is transverse to the $(n+1)$-dimensional ν-stable manifold $\mathfrak{W}^{\nu,s}(\mathbf{O}_{i+1}(0))$ $(i = 1, 2)$ that is invariant and is tangent to the sum of the eigenspaces corresponding to $\nu^{i+1}(0)$, $-\rho^{i+1}(0)$, and $-\eta_j^{i+1}$ $(1 \leq j \leq n-1)$. Also, $\mathfrak{W}^s(\mathbf{O}_{i+1}(0))$ is transverse to the $(n+1)$-dimensional $(-\rho)$-unstable manifold corresponding to the eigenvalues $-\rho^i(0)$, $\nu^i(0)$, and $\kappa_k^i(0)$ $(1 \leq k \leq n-1)$.
4. For a nontrivial bounded solution $\hat{q}^i(t)$ $(i = 1, 2)$ of the linear ordinary differential equation

$$\dot{\hat{z}} = -{}^tDf(h_i(t))\hat{z} \quad (i = 1, 2), \tag{4.19}$$

the vectors given by the integrals

$$\int_{-\infty}^{+\infty} \hat{q}^i(s) \cdot \frac{\partial}{\partial\mu} g(h_i(s); 0) ds \tag{4.20}$$

are linearly independent and hence nonzero.

Remark 4.1. The bounded solution $\hat{q}^i(t)$ is unique up to multiplication by constants.

Under these conditions, we have the following result.

PROPOSITION 4.2 (Kokubu [17]). *Under conditions* 1–4 *above, there exist two hypersurfaces M_i $(i = 1, 2)$ of codimension* 1 *in a sufficiently small neighborhood of $\mu = 0$ in $\mathbb{R}^k$ so that each of M_i consists of parameter values μ for which the system has a heteroclinic orbit Γ_i. Moreover, M_1 and M_2 intersect transversely at $\mu = 0$.*

In order to investigate the existence of a heteroclinic orbit from $\mathbf{O}_1$ to $\mathbf{O}_3$, we divide our analysis into two cases:

(i) $\nu^2(0) \neq \rho^2(0)$ (the case of noncritical eigenvalues);

(ii) $\nu^2(0) = \rho^2(0)$ (the case of critical eigenvalues).

PROPOSITION 4.3 (Kokubu [17]). *Under conditions* 1–4 *and for the case of noncritical eigenvalues, there exists a hypersurface M of codimension* 1 *with the boundary*

$$\partial M = M_1 \cap M_2$$

in a sufficiently small neighborhood of $\mu = 0$ in $\mathbb{R}^k$ so that M consists of parameter values μ for which the system has a heteroclinic orbit $\Gamma = \{h(t)\}$ from O_1 to O_3. Moreover,

(a) *if $\nu^2(0) < \rho^2(0)$, then M is tangent to M_2 at $\mu = 0$, and*

(b) *if $\nu^2(0) > \rho^2(0)$, then M is tangent to M_1 at $\mu = 0$.*

For the case of critical eigenvalues, we impose a further condition as follows:

5. The set $\{\mu | \nu^2(\mu) = \rho^2(\mu)\}$ forms a surface Π in the parameter space $\mathbb{R}^k$ and is transverse to both M_1 and M_2 at $\mu = 0$.

PROPOSITION 4.4 (Kokubu [17]). *Under conditions* 1–5 *and for the case of critical eigenvalues, there exists a hypersurface M of codimension* 1 *with the boundary*

$$\partial M = M_1 \cap M_2$$

in a sufficiently small neighborhood of $\mu = 0$ in $\mathbb{R}^k$ so that M consists of parameter values μ for which the system has a heteroclinic orbit $\Gamma = \{h(t)\}$ from O_1 to O_3. Moreover, M is tangent to neither M_1 nor M_2 at $\mu = 0$ in Π.

The proofs of Propositions 4.3 and 4.4 are as follows.

We may assume that $\nu^2 < \rho^2$, for otherwise we can apply the same argument by replacing t with $-t$. Take the heteroclinic solution $h_i(t)$ so that $h_i(0)$ is near $\mathbf{O}_2$, and let Σ_i be a properly chosen $(2n-1)$-dimensional plane that passes through $h_i(0)$ and is transverse to $\dot{h}_i(0)$. Let $q^i(t)$ be a solution of the variational equation

$$\dot{z} = Df(h_i(t))z \tag{4.21}$$

along $h_i(t)$, for which the next limits exist and are nonzero, and let $q^1(t)$ point to $\mathbf{O}_3$ along the heteroclinic orbit Γ_2 in the limit of $t \to +\infty$ and $q^2(t)$ point to $\mathbf{O}_1$ along the heteroclinic orbit Γ_1 in the limit of $t \to -\infty$:

$$\lim_{t \to -\infty} |q^i(t)| e^{\rho^i(0)t}, \qquad \lim_{t \to +\infty} |q^i(t)| e^{-\nu^{i+1}(0)t}. \tag{4.22}$$

We remark that the adjoint $\hat{q}^i(t)$ of $q^i(t)$ is a nontrivial bounded solution of equation (4.19) for each i. In this situation, there are two points $x_1^u(\mu) \in \mathfrak{W}^u(\mathbf{O}_1) \cap \Sigma_1$ and $x_2^s(\mu) \in \mathfrak{W}^s(\mathbf{O}_2) \cap \Sigma_1$ depending on μ smoothly, and their difference can be expressed as

$$x_1^u - x_2^s = \alpha(\mu) q^1(0); \tag{4.23}$$

similarly, there are two points $x_2^u(\mu) \in \mathfrak{W}^u(\mathbf{O}_2) \cap \Sigma_2$ and $x_3^s(\mu) \in \mathfrak{W}^s(\mathbf{O}_3) \cap \Sigma_2$ such that

$$x_3^s - x_2^u = \beta(\mu) q^2(0). \tag{4.24}$$

The function $\alpha(\mu)$ ($\beta(\mu)$) measures the separation of $\mathfrak{W}^u(\mathbf{O}_1)$ and $\mathfrak{W}^s(\mathbf{O}_2)$ in Σ_1 ($\mathfrak{W}^u(\mathbf{O}_2)$ and $\mathfrak{W}^s(\mathbf{O}_3)$ in Σ_2). For $\alpha(\mu) > 0$ and $\beta(\mu) > 0$, $\mathfrak{W}^u(\mathbf{O}_1)$ intersects with Σ_2, and we can also find a point $\tilde{x}_1^u(\mu) \in \mathfrak{W}^u(\mathbf{O}_1) \cap \Sigma_2$ such that

$$x_3^s - \tilde{x}_1^u = \chi(\mu) q^2(0), \tag{4.25}$$

where $\chi(\mu)$ measures the separation of $\mathfrak{W}^u(\mathbf{O}_1)$ and $\mathfrak{W}^s(\mathbf{O}_3)$ in Σ_2. $\chi(\mu)$ can be extended to the parameter values for which $\alpha(\mu) = 0$ or $\beta(\mu) = 0$. Proposition 4.2 was proven by showing that

$$\frac{d}{d\mu}\alpha(0) = |q^1(0)| \int_{-\infty}^{+\infty} \hat{q}^1(s) \frac{\partial}{\partial \mu} g(h_1(s); 0) ds \tag{4.26}$$

and

$$\frac{d}{d\mu}\beta(0) = |q^2(0)| \int_{-\infty}^{+\infty} \hat{q}^2(s) \frac{\partial}{\partial \mu} g(h_2(s); 0) ds, \tag{4.27}$$

where the right-hand sides of the equations are nonzero and linearly independent. Proposition 4.3 is proved by showing that $\chi(\mu) > 0$ if $\alpha(\mu) = 0$ and $\beta(\mu) > 0$, $\chi(\mu) < 0$ if $\alpha(\mu) > 0$ and $\beta(\mu) = 0$, and $\frac{d}{d\mu}\chi(0) = \frac{d}{d\mu}\beta(0)$.

For the proof of the existence part of Proposition 4.4, take $a = \alpha(\mu)$, $b = \beta(\mu)$, and $\lambda = \rho^2(\mu)/\nu^2(\mu) - 1$ as parameters and consider in the parameter space (a, b, λ), where $\lambda \geq 0$. Then the separation $\chi = \chi(a, b, \lambda)$ is defined in this parameter space, smooth in b and λ, and Lipschitz continuous in a. For the derivative of χ with respect to b, we have $\frac{\partial \chi}{\partial b}(0) = 1$. By a modification of the implicit-function theorem, we get a unique solution $b = b(a, \lambda)$ of $\chi(a, b, \lambda) = 0$ that is smooth in λ and Lipschitz in a. A similar argument for $\lambda \leq 0$ gives a unique solution $a = a(b, \lambda)$ of $\chi(a, b, \lambda) = 0$, and these coincide for $\lambda = 0$.

For some reaction-diffusion equations, this kind of bifurcation takes place. (See the examples below.) In such cases, from the stability of the traveling waves corresponding to the heteroclinic orbits Γ_1 and Γ_2, with some information about the twisting of these orbits, we can determine the stability of the traveling wave corresponding to the heteroclinic orbit Γ. We explain this in what follows.

First, we determine $(\frac{dX_s^\theta(0)}{d\theta}|_{\theta=\theta_0} - \frac{dX_u^\theta(0)}{d\theta}|_{\theta=\theta_0})$ in Proposition 4.1 from the above conditions. For the case where $\nu^2 < \rho^2$, take $X_u^\mu(\xi) \in \mathfrak{W}_\mu^u(\mathbf{O}_1)$ of Proposition 4.1 as $X_u^\mu(0) = \tilde{x}_1^u(\mu)$ and $X_s^\mu(\xi) \in \mathfrak{W}_s^\mu(\mathbf{O}_3)$ as $X_s^\mu(0) = x_3^s(\mu)$ so that

$$X_s^\mu(0) - X_u^\mu(0) = \chi(\mu) q^2(0). \tag{4.28}$$

Then

$$\left.\frac{\partial X_s^\mu(0)}{\partial \mu}\right|_{\mu=0} - \left.\frac{\partial X_u^\mu(0)}{\partial \mu}\right|_{\mu=0} = \frac{\partial \chi}{\partial \mu}(0) q^2(0) = \frac{\partial \beta}{\partial \mu}(0) q^2(0). \tag{4.29}$$

This means that if μ includes the traveling-wave speed θ or its translation $\theta - \theta_0$ as one of the parameters, then $(\frac{dX_s^\theta(0)}{d\theta}|_{\theta=\theta_0} - \frac{dX_u^\theta(0)}{d\theta}|_{\theta=\theta_0})$ is near $\frac{\partial \beta}{\partial \theta}(0) q^2(0)$. In particular, the sign of

$$\det\left(\left(\left.\frac{dX_s^\theta(0)}{d\theta}\right|_{\theta=\theta_0}-\left.\frac{dX_u^\theta(0)}{d\theta}\right|_{\theta=\theta_0}\right)V_u^1\cdots V_u^{n-1}{X^{\theta_0}}'(0)V_s^1\cdots V_s^{n-1}\right)$$

coincides with that of

$$\det\left(\frac{\partial\beta}{\partial\theta}(0)q^2(0)V_u^1\cdots V_u^{n-1}{X^{\theta_0}}'(0)V_s^1\cdots V_s^{n-1}\right)$$

for $\mu\approx 0$ if $\frac{\partial\beta}{\partial\theta}(0)\neq 0$.

For the case where $\nu^2=\rho^2$, for $\alpha>0$ and $\beta>0$, χ is also smooth in α, although it is not necessarily smooth in α at $\mu=0$. Because $\frac{\partial\chi}{\partial\beta}=1$, $d\chi(\mu)\neq 0$ for $\mu\in M$ if $\mu\approx 0$, $\alpha>0$, and $\beta>0$, which means that $\frac{\partial\chi}{\partial\theta}\neq 0$ if the θ direction is transverse to M. From this we can easily conclude that if the sign of $\frac{\partial\chi}{\partial\theta}$ coincides with that of $\frac{\partial\chi}{\partial\beta}$ at some $\mu\in M$, then the sign of

$$\det\left(\left(\left.\frac{dX_s^\theta(0)}{d\theta}\right|_{\theta=\theta_0}-\left.\frac{dX_u^\theta(0)}{d\theta}\right|_{\theta=\theta_0}\right)V_u^1\cdots V_u^{n-1}{X^{\theta_0}}'(0)V_s^1\cdots V_s^{n-1}\right)$$

coincides with the sign of

$$\det\left(\frac{\partial\beta}{\partial\theta}(0)q^2(0)V_u^1\cdots V_u^{n-1}{X^{\theta_0}}'(0)V_s^1\cdots V_s^{n-1}\right)$$

for the same μ, and vice versa. We remark that $\chi(\mu)<0$ for μ near the α-axis and $\chi(\mu)>0$ for μ near the β-axis, so we know the sign of $\frac{\partial\chi}{\partial\theta}$ from the bifurcation diagram. We state the above argument as a theorem.

THEOREM 4.3. *Assume that system* (3.4) *associated with the existence problem of traveling waves for system* (2.1) *undergoes the bifurcation as described in Propositions* 4.3 *and* 4.4. *Then if $\nu^2<\rho^2$, we have the following equality for the derivative of the Evans function that is defined for the traveling wave corresponding to the heteroclinic orbit* Γ:

$$\operatorname{sign}\left(\left.\frac{dD(\lambda)}{d\lambda}\right|_{\lambda=0}\right)=\operatorname{sign}\left(\det\left(\frac{\partial\beta}{\partial\theta}(0)q^2(0)V_u^1\cdots V_u^{n-1}{X^{\theta_0}}'(0)V_s^1\cdots V_s^{n-1}\right)\right).$$

The same equality holds for $\nu^2=\rho^2$ if the sign of $\frac{\partial\chi}{\partial\theta}$ coincides with that of $\frac{\partial\chi}{\partial\beta}$, and if it differs, then

$$\operatorname{sign}\left(\left.\frac{dD(\lambda)}{d\lambda}\right|_{\lambda=0}\right)=-\operatorname{sign}\left(\det\left(\frac{\partial\beta}{\partial\theta}(0)q^2(0)V_u^1\cdots V_u^{n-1}{X^{\theta_0}}'(0)V_s^1\cdots V_s^{n-1}\right)\right).$$

We also obtain a similar result for $\nu^2\geq\rho^2$ by replacing $\xi(=x-\theta t)$ with $-\xi$ in system (3.4).

Of course, Theorem 4.3 is not enough to determine the stability. We must know the orientation of $(V_u^1,\dots,V_u^{n-1})$ or, equivalently, that of $(V_s^1,\dots,V_s^{n-1})$ to determine the sign of $\frac{dD}{d\lambda}(0)$. To do this, we have to use other properties of the system.

In what follows, let us assume that system (3.4) undergoes the bifurcation as in Propositions 4.3 and 4.4 with $\mathbf{O}_1=\mathbf{O}_3$. In such a case, the two heteroclinic orbits Γ_1 and Γ_2 for $\mu=0$ form a loop called a heteroclinic loop and the orbit $\Gamma=\{h(\xi)|\xi\in\mathbb{R}\}$

bifurcating from the loop is a homoclinic orbit. In this situation, the orientation of $(V_u^1, \dots, V_u^{n-1})$ with respect to the homoclinic orbit is easily determined as follows.

Let $(\hat{V}_{u,1}^0, \dots, \hat{V}_{u,1}^{n-1})$ (resp. $(\hat{V}_{s,1}^0, \dots, \hat{V}_{s,1}^{n-1})$) be a basis of the unstable (resp. stable) eigenspace of $\mathbf{O}_1$ satisfying

$$\hat{V}_{u,1}^0 = \lim_{\xi \to -\infty} \frac{h_1(\xi)}{|h_1(\xi)|}, \qquad \hat{V}_{s,1}^0 = \lim_{\xi \to +\infty} \frac{h_2(\xi)}{|h_2(\xi)|},$$

and

$$\det \left(\hat{V}_{u,1}^0 \cdots \hat{V}_{u,1}^{n-1} \hat{V}_{s,1}^0 \cdots \hat{V}_{s,1}^{n-1} \right) > 0.$$

Then $(\hat{V}_{u,1}^0, \dots, \hat{V}_{u,1}^{n-1})$ determines the orientation of the local unstable manifold of $\mathbf{O}_1$ and propagates with the orientation of the global unstable manifold $\mathfrak{W}^u(\mathbf{O}_1)$ of $\mathbf{O}_1$. Let $(\hat{V}_{u,2}^0, \dots, \hat{V}_{u,2}^{n-1})$ be a basis of the unstable eigenspace of $\mathbf{O}_2$ with

$$\hat{V}_{u,2}^0 = \lim_{\xi \to -\infty} \frac{h_2(\xi)}{|h_2(\xi)|},$$

and let

$$\hat{V}_{s,2}^0 = \lim_{\xi \to +\infty} \frac{h_1(\xi)}{|h_1(\xi)|}.$$

From assumption 2 for the heteroclinic orbit Γ_1, the tangent space $T_{h_1(\xi)}\mathfrak{W}^u(\mathbf{O}_1)$ is tangent to the space spanned by $\hat{V}_{s,2}^0, \hat{V}_{u,2}^1, \dots, \hat{V}_{u,2}^{n-1}$ in the limit of $\xi \to +\infty$. We determine the orientation of $(\hat{V}_{u,2}^1, \dots, \hat{V}_{u,2}^{n-1})$ so that the orientation of $(\hat{V}_{s,2}^0, \hat{V}_{u,2}^1, \dots, \hat{V}_{u,2}^{n-1})$ is compatible with that of $\mathfrak{W}^u(\mathbf{O}_1)$, and then the orientation of $\mathfrak{W}^u(\mathbf{O}_2)$ is naturally determined by that of $(\hat{V}_{u,2}^0, \hat{V}_{u,2}^1, \dots, \hat{V}_{u,2}^{n-1})$. Similarly, the orientation of $\mathfrak{W}^u(\mathbf{O}_2)$ again determines the orientation of the unstable eigenspace of $\mathbf{O}_1$, but this orientation is not necessarily compatible with that of $(\hat{V}_{u,1}^0, \dots, \hat{V}_{u,1}^{n-1})$, which we defined earlier.

Definition 4.1. *The heteroclinic loop that consists of* Γ_1 *and* Γ_2 *is said to be nontwisted with respect to the strong unstable direction if the above orientation is compatible with that of* $(\hat{V}_{u,1}^0, \dots, \hat{V}_{u,1}^{n-1})$ *defined at the beginning. Otherwise, it is said to be twisted with respect to the strong unstable direction.*

Twisting with respect to the strong stable direction is similarly defined.

We have another definition of twisting, which is directly related to the structure of bifurcation. (See, for example, Deng [5] and the references therein.)

Consider $q^2(\xi)$, which is the solution of the variational equation (4.21) along $h_2(\xi)$ given in the proof of Propositions 4.3 and 4.4. From the requirement for $q^2(\xi)$ (see (4.22)), we may assume that

$$\lim_{\xi \to -\infty} q^2(\xi) e^{\rho^2 \xi} = -\hat{V}_{s,2}^0$$

and

$$\lim_{\xi \to +\infty} q^2(\xi) e^{-\nu^1 \xi} = c\hat{V}_{u,1}^0$$

for some nonzero constant c.

Definition 4.2. *The heteroclinic orbit Γ_2 is nontwisted if c is positive and twisted if c is negative.*

With these two kinds of twistings, we define the sign σ of $\Gamma = \{h(\xi)\}$ as follows.

Definition 4.3. $\sigma = +1$ *if either of the following holds.*

(1) *The heteroclinic loop is nontwisted with respect to the strong unstable direction and Γ_2 is nontwisted.*

(2) *The heteroclinic loop is twisted with respect to the strong unstable direction and Γ_2 is twisted.*

Otherwise, $\sigma = -1$.

Lemma 4.1. *If either of the following is satisfied for the heteroclinic loop that consists of two heteroclinic orbits Γ_1 and Γ_2, then $\sigma = +1$; otherwise, $\sigma = -1$.*

(1) *The heteroclinic loop is nontwisted with respect to the strong stable direction and Γ_1 is nontwisted.*

(2) *The heteroclinic loop is twisted with respect to the strong stable direction and Γ_1 is twisted.*

Proof. By the definitions of the two kinds of twistings above, the heteroclinic loop consisting of two heteroclinic orbits Γ_1 and Γ_2 that is nontwisted (twisted) with respect to the strong unstable direction is nontwisted (twisted) with respect to the strong stable direction if both heteroclinic orbits Γ_1 and Γ_2 are nontwisted or both are twisted. Otherwise, the loop that is nontwisted with respect to the strong unstable direction is twisted with respect to the strong stable direction, and vice versa. The lemma clearly holds. □

Then we can determine the sign of $\frac{dD}{d\lambda}(0)$.

Theorem 4.4.

$$\operatorname{sign}\left(\left.\frac{dD(\lambda)}{d\lambda}\right|_{\lambda=0}\right) = \sigma \cdot \operatorname{sign}\left(\frac{\partial\beta}{\partial\theta}\right)$$

if $\nu^2 < \rho^2$. The same equality holds for $\nu^2 = \rho^2$ if the sign of $\frac{\partial\chi}{\partial\theta}$ coincides with that of $\frac{\partial\chi}{\partial\beta}$, and if it differs, then

$$\operatorname{sign}\left(\left.\frac{dD(\lambda)}{d\lambda}\right|_{\lambda=0}\right) = -\sigma \cdot \operatorname{sign}\left(\frac{\partial\beta}{\partial\theta}\right).$$

For the case where $\nu^2 > \rho^2$, the following holds:

$$\operatorname{sign}\left(\left.\frac{dD(\lambda)}{d\lambda}\right|_{\lambda=0}\right) = -\sigma \cdot \operatorname{sign}\left(\frac{\partial\alpha}{\partial\theta}\right).$$

The same equality holds for $\nu^2 = \rho^2$ if the sign of $\frac{\partial\chi}{\partial\theta}$ coincides with that of $\frac{\partial\chi}{\partial\alpha}$ for χ of the time-reversed system, and if it differs, then

$$\operatorname{sign}\left(\left.\frac{dD(\lambda)}{d\lambda}\right|_{\lambda=0}\right) = \sigma \cdot \operatorname{sign}\left(\frac{\partial\alpha}{\partial\theta}\right).$$

Proof. Define the orientation of the unstable manifold $\mathfrak{W}^u(\mathbf{O}_i)$ $(i = 1, 2)$ and the stable manifold $\mathfrak{W}^s(\mathbf{O}_i)$ of $\mathbf{O}_i$ continuously depending on μ by

$$\hat{V}^0_{u,1} = \lim_{\xi\to-\infty} \frac{h(\xi)}{|h(\xi)|}$$

and

$$\hat{V}^0_{s,1} = \lim_{\xi\to+\infty} \frac{h(\xi)}{|h(\xi)|}.$$

Let $V^1_u(\xi), \ldots, V^{n-1}_u(\xi)$ $(V^1_u(\xi), \ldots, V^{n-1}_u(\xi))$ be solutions of the variational equation along $h(\xi)$ such that $h'(\xi), V^1_u(\xi), \ldots, V^{n-1}_u(\xi)$ is a properly ordered basis of $T_{h(\xi)}\mathfrak{W}^u(\mathbf{O}_1)$ and $h'(\xi), V^1_s(\xi), \ldots, V^{n-1}_s(\xi)$ is a basis of $T_{h(\xi)}\mathfrak{W}^s(\mathbf{O}_1)$. Then the orientation of $\mathfrak{W}^u(\mathbf{O}_1)$ propagates along $h(\xi)$, which approaches to $\mathbf{O}_2$ once and comes back to $\mathbf{O}_1$. By definition, the orientation of $\mathfrak{W}^u(\mathbf{O}_1)$ coincides with that of $\mathfrak{W}^u(\mathbf{O}_2)$ when $h(\xi)$ is near $\mathbf{O}_2$. This implies that the orientation of $(\hat{V}^0_{u,1},\ V^1_u(\xi), \ldots, V^{n-1}_u(\xi))$ is compatible with that of $(\hat{V}^0_{u,1},\ \hat{V}^1_{u,1}, \ldots, \hat{V}^{n-1}_{u,1})$ for large ξ if and only if the heteroclinic loop is nontwisted. Therefore, the sign of

$$\det\left(\hat{V}^0_{u,1} V^1_u(\xi) \cdots V^{n-1}_u(\xi) h'(\xi) V^1_s(\xi) \cdots V^{n-1}_s(\xi)\right)$$

is positive for large ξ if the heteroclinic loop is nontwisted and negative if the heteroclinic loop is twisted. Therefore, by the definition of twisting of Γ_2, it follows that

$$\operatorname{sign}\left(\det\left(q^2(\xi)\ V^1_u(\xi) \cdots V^{n-1}_u(\xi) h'(\xi) V^1_s(\xi) \cdots V^{n-1}_s(\xi)\right)\right)$$

is positive if condition (1) or (2) of Definition 4.3 holds and negative otherwise. This proves the theorem.

By replacing ξ with $-\xi$ and taking into account Lemma 4.1 and the definition of χ (see (4.25)) in the proof of Propositions 4.3 and 4.4, we get the result for the case where $\nu^2 > \rho^2$. □

Remark 4.2.

(1) The heteroclinic loop is nontwisted with respect to the strong direction if system (3.4) has a certain symmetry for $\mu = 0$. For example, $h_2(\xi) = -h_1(\xi)$ or $h_2(\xi) = (h^u_2(\xi), h^v_2(\xi)) = (h^u_1(-\xi), -h^v_1(-\xi))$, where h^u_i denotes the u-component of h_i and h^v_i denotes the v-component of h_i. Note that a standing wave (a traveling wave with velocity $\theta = 0$) possesses the latter type of symmetry.

(2) When the dimension of system (3.4) is equal to or less than 3, the twisting of the loop is determined only by the twistings of Γ_1 and Γ_2.

Theorem 4.4 means that if σ is given, then we can determine the stability of the traveling wave corresponding to the homoclinic orbit $h(\xi)$ only from the bifurcation diagram. We summarize this in Figure 5.7.

5. Examples. In this section, we consider two examples of reaction-diffusion equations that possesses traveling waves forming a heteroclinic loop, and we study the stability of bifurcating waves by applying the theorems of this paper.

Example 1. We treat the following activator–inhibitor system:

$$\begin{cases} \varepsilon\tau u_t = \varepsilon^2 u_{xx} + f(u, v; \gamma, \nu), \\ \quad v_t = v_{xx} + g(u, v; \gamma, \nu), \end{cases} \tag{5.1}$$

where ε and τ are real positive parameters, ε is sufficiently small, and

$$\begin{cases} f(u, v; \gamma, \nu) = -u^3 + u - v, \\ g(u, v; \gamma, \nu) = u - \gamma v + \nu. \end{cases} \tag{5.2}$$

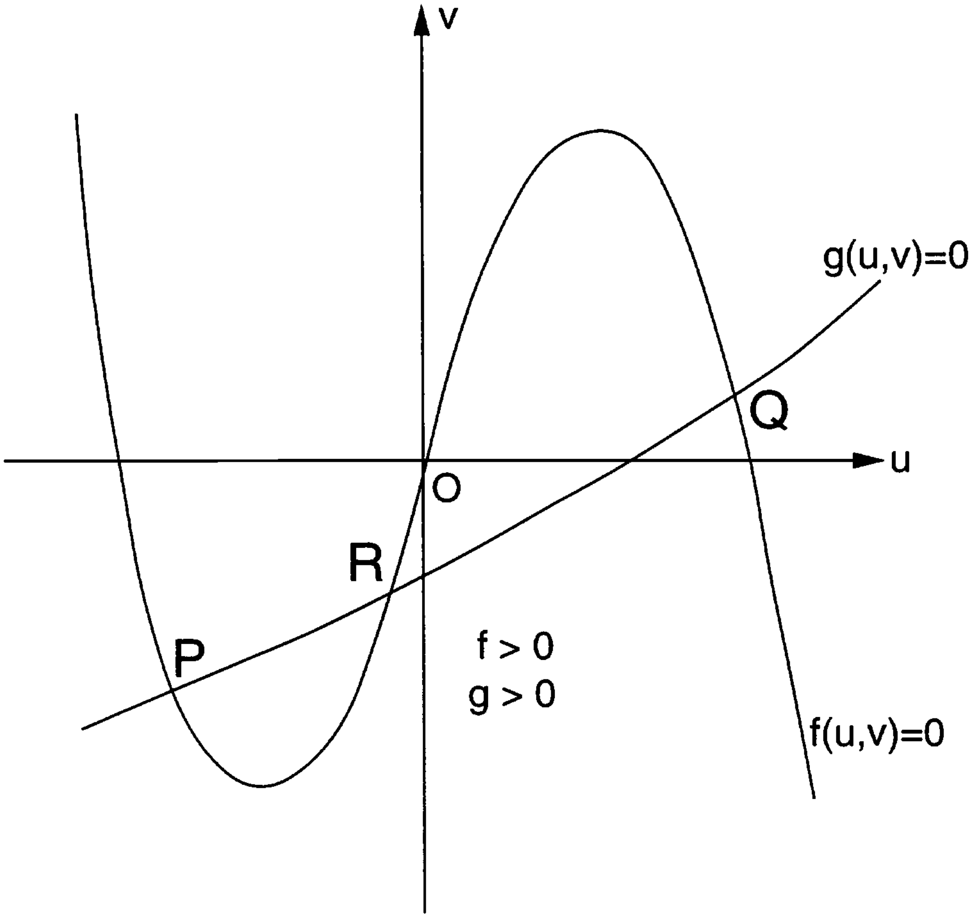

FIG. 5.1. *Nullclines of f and g in Example* 1.

The nullcline of f intersects with that of g at three points P, Q, and R, where P and Q are stable and R is an unstable constant solution of (5.1) (see Figure 5.1).

In what follows, we introduce the traveling coordinate $\xi = x - \theta t$, and we regard γ, ν, and the wave speed θ as bifurcation parameters. Consider

$$\text{(5.3)} \qquad \begin{cases} u' = \frac{1}{\varepsilon} u_1, \\ v' = v_1, \\ u_1' = -\frac{\theta\tau}{\varepsilon} u_1 - \frac{1}{\varepsilon} f(u, v; \gamma, \nu), \\ v_1' = -\theta v_1 - g(u, v; \gamma, \nu) \end{cases} \qquad ({}' = \tfrac{d}{d\xi})$$

corresponding to the existence of a traveling wave for (5.1). This system possesses heteroclinic orbits $\Gamma_1 = \{h_1(\xi; \gamma, \nu)\}$ from $(P, \mathbf{O})$ to $(Q, \mathbf{O})$ and $\Gamma_2 = \{h_2(\xi; \gamma, \nu)\}$ from $(Q, \mathbf{O})$ to $(P, \mathbf{O})$. The traveling (standing if $\theta = 0$) wave corresponding to Γ_1 is called a traveling (standing) front and Γ_2 is called a traveling (standing) back. Figure 5.2 depicts the situation in the parameter space, where M_1 corresponds to Γ_1 and M_2 corresponds to Γ_2. Notice that the thick curve shows the coexistence of both heteroclinic orbits or, in other words, the existence of what is called a heteroclinic loop.

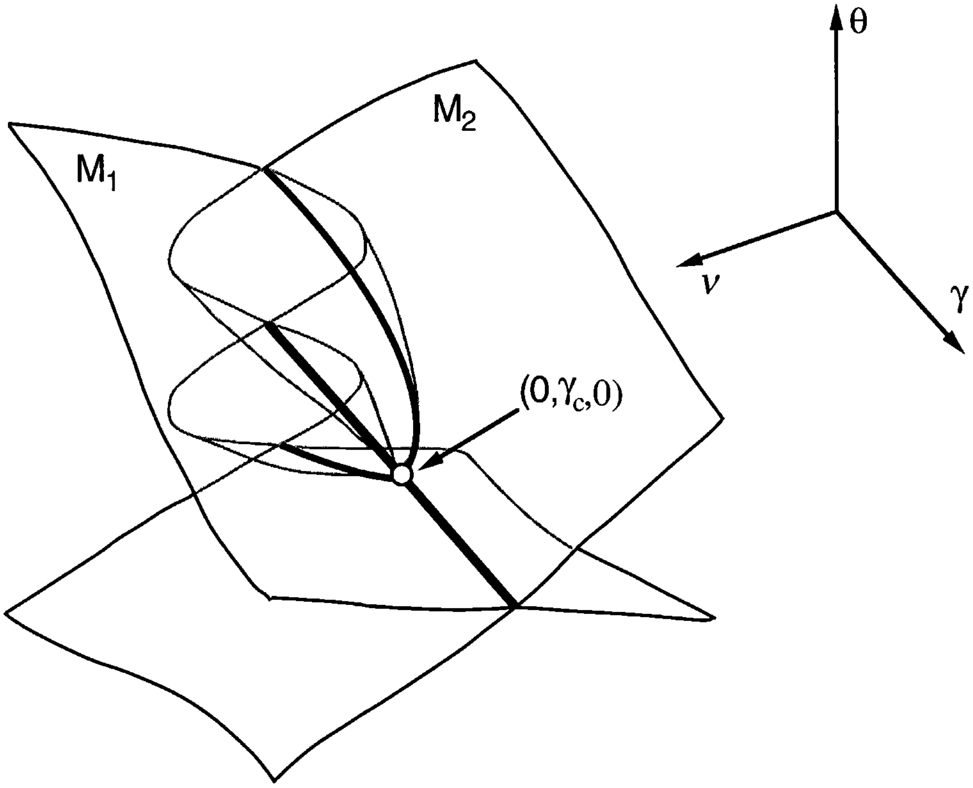

FIG. 5.2. *Bifurcation diagram of the traveling front and traveling back in Example* 1.

In Figure 5.3, bifurcation diagrams for ν and θ for fixed γ are shown.

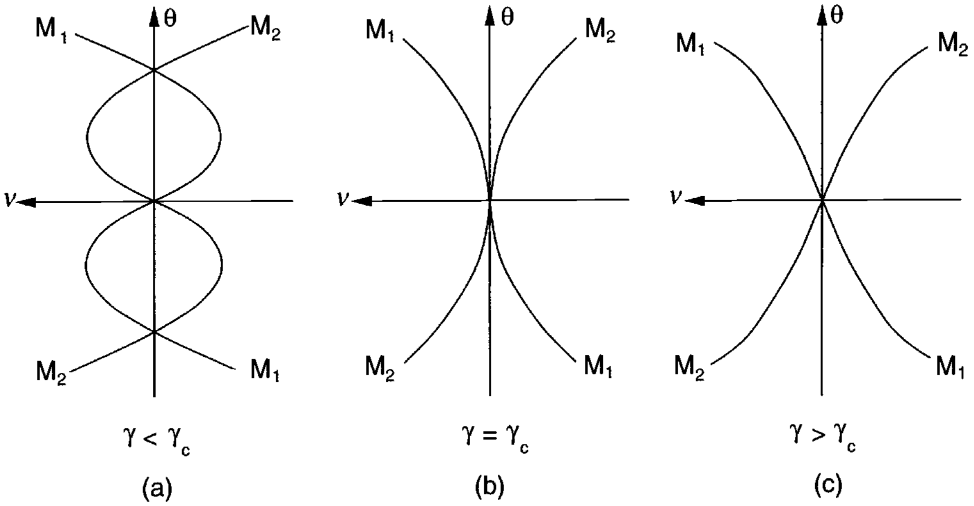

FIG. 5.3. *Bifurcation diagram of the traveling front and traveling back in Example* 1 *for fixed* γ.

Kokubu, Nishiura, and Oka [18] showed the existence of homoclinic orbits $\Gamma_P = \{h_P(\xi)\}$ associated with $(P, \mathbf{O})$ and $\Gamma_Q = \{h_Q(\xi)\}$ associated with $(Q, \mathbf{O})$ bifurcating from the heteroclinic loops; these homoclinic orbits correspond to traveling (standing) pulses. We show bifurcation diagrams in Figures 5.4 and 5.5, where M_P and M_Q correspond to these waves.

The stability and instability of fronts and backs are known. Ikeda [11] proved the stability and instability of pulses in [18] using the singular-perturbation method. In this example, we prove the stability and instability, applying the theorems in this paper without using the information in the singular limit.

First, note that the standing front and back that correspond to the heteroclinic loop for $(\gamma, \nu, \theta) = (\gamma, 0, 0)$ and $\gamma < \gamma_c$ are unstable. From Theorem 4.1, both standing pulses associated with P and Q bifurcating from the heteroclinic loop are unstable. Fronts and backs corresponding to the heteroclinic loops for other parameter values are known to be stable, and thus the pulses other than the above can be stable, and this is indeed the case. In such cases, the eigenvalue problem (2.7) for pulses has one eigenvalue near the origin other than the one at the origin, and it is real. We show that the derivative of the Evans function at the origin $\frac{dD}{d\lambda}(0)$ is positive, which means that $[g]$ in Theorem 4.2 is equal to 1 for $\lambda_1 < 0$ near 0 and λ_2 large, i.e., 0 is the only eigenvalue whose real part is equal or grater than 0. Thus the pulse is stable.

The heteroclinic orbits Γ_1 and Γ_2 are known to be nontwisted for $\nu = 0$. Notice that system (5.3) has the symmetry

$$h_2(\xi; \gamma, 0) = -h_1(\xi; \gamma, 0) \tag{5.4}$$

for the heteroclinic loop, and so it is nontwisted with respect to the strong direction (Remark 4.2). From Theorem 4.4 and the bifurcation diagram (Figure 5.5), we have

$$\operatorname{sign}\left(\frac{dD}{d\lambda}(0)\right) > 0,$$

and therefore the pulses are stable.

Example 2. Our next example is a Lotka–Volterra competition system:

$$\begin{cases} \quad u_t = u_{\xi\xi} + f(u,v), \\ \quad v_t = dv_{\xi\xi} + g(u,v), \qquad \xi \in \mathbb{R}, \quad t > 0, \\ u(0,\xi) \geq 0, \qquad v(0,\xi) \geq 0, \end{cases} \tag{5.5}$$

where

$$\begin{cases} f(u,v) = (1-u-cv)u, \\ g(u,v) = (a-bu-v)v, \end{cases} \tag{5.6}$$

and $a, b, c,$ and d are positive constants.

This system has two stable constant solutions $(u,v) \equiv (0,a)$ and $(u,v) \equiv (1,0)$ for $1/c < a < b$. Again consider the following system in search of traveling waves:

$$\begin{cases} u' = u_1, \\ v' = v_1, \\ u_1' = -\theta u_1 - (1-u-cv)u, \\ v_1' = -\frac{\theta}{d} v_1 - \frac{1}{d}(a-bu-v)v \end{cases} \qquad ({}' = \tfrac{d}{d\xi}). \tag{5.7}$$

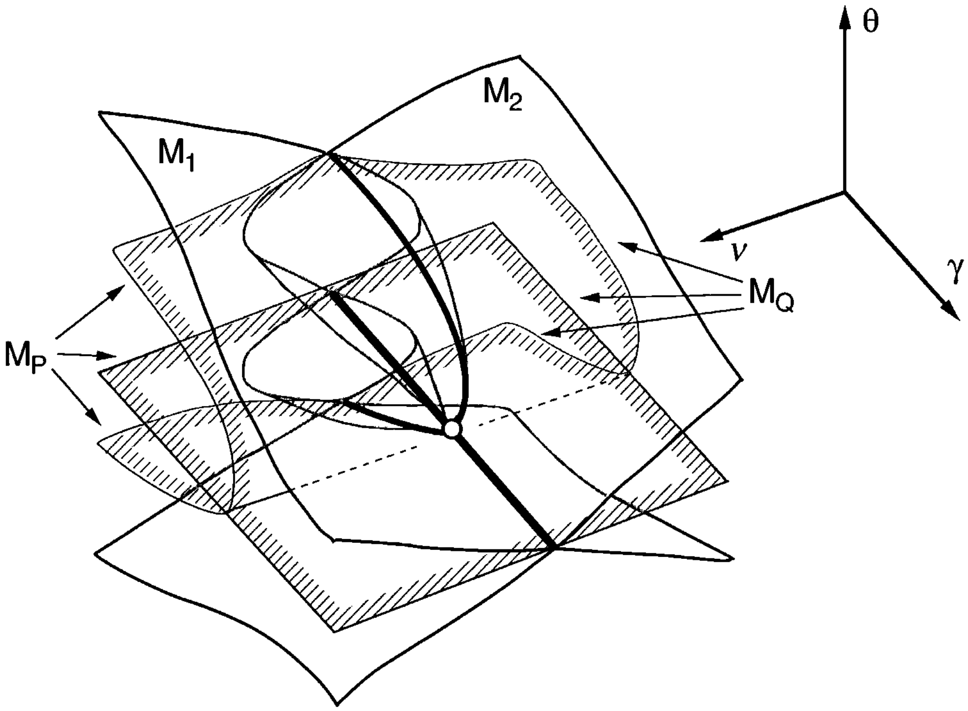

FIG. 5.4. *Bifurcation diagram of the traveling pulses in Example* 1.

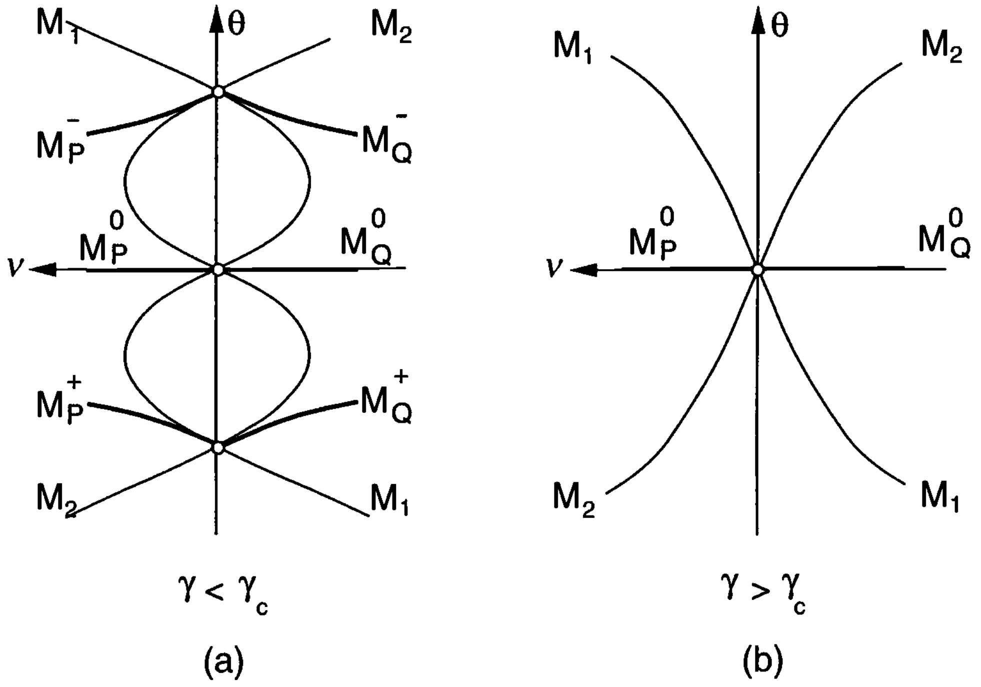

FIG. 5.5. *Bifurcation diagram of the traveling pulses in Example* 1 *for fixed* γ.

For each fixed d, there exist C^1 families $h_1(\xi; a, b, c)$ and $\theta(a, b, c)$ defined on $\mathfrak{P} = \{(a, b, c)|0 < 1/c < a < b\}$ such that h_1 is a solution of (5.7) with $\theta = \theta(a, b, c)$ satisfying

$$\lim_{\xi\to-\infty} h_1(\xi; a, b, c) = (0, a, 0, 0), \qquad \lim_{\xi\to+\infty} h_1(\xi : a, b, c) = (1, 0, 0, 0), \tag{5.8}$$

and $\theta_a(a, b, c) > 0$, $\theta_b(a, b, c) < 0$, and $\theta_c(a, b, c) > 0$. Moreover, there exists a C^1 family $a = a(b, c) \in (1/c, b)$ on $\{(b, c)|0 < 1/c < b\}$ such that $\theta(a(b, c), b, c) = 0$ holds (see Kan-on [13]). $\theta = 0$ means that this system also has symmetry, by which we can get a heteroclinic solution $h_2(\xi; a, b, c)$ satisfying

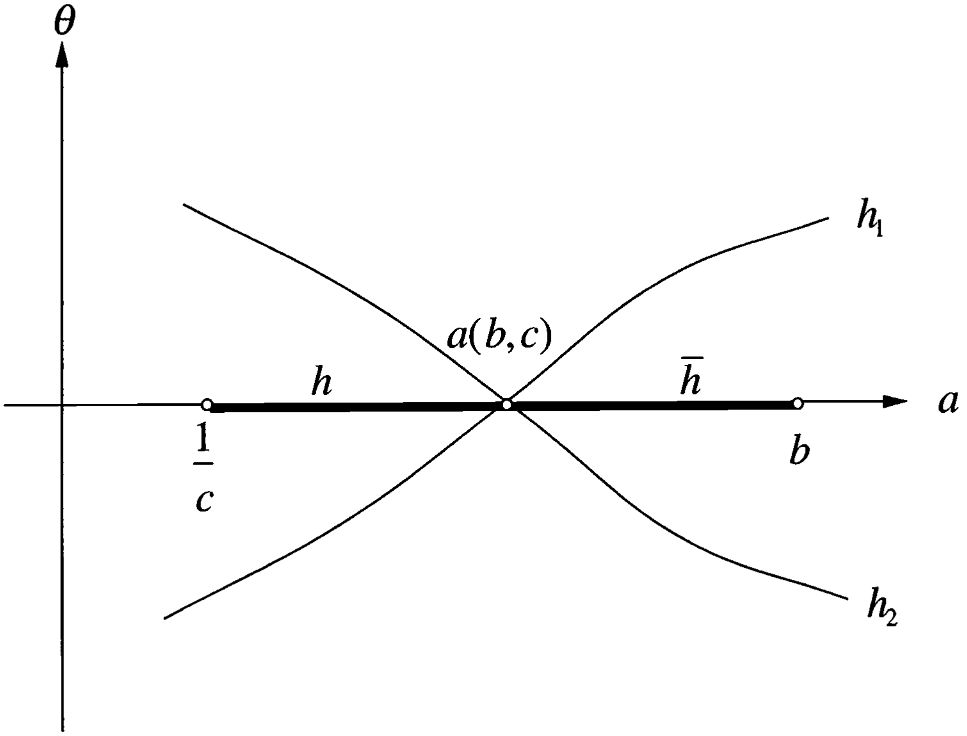

FIG. 5.6. *Bifurcation diagram in Example* 2.

$$\lim_{\xi\to-\infty} h_2(\xi; a, b, c) = (1, 0, 0, 0), \qquad \lim_{\xi\to+\infty} h_2(\xi : a, b, c) = (0, a, 0, 0) \tag{5.9}$$

by setting

(5.10)
$$h_2(\xi; a, b, c) = (h_1^1(-\xi; a, b, c), h_1^2(-\xi; a, b, c), -h_1^3(-\xi; a, b, c), -h_1^4(-\xi; a, b, c)),$$

where

$$h_1(\xi; a, b, c) = (h_1^1(\xi; a, b, c), h_1^2(\xi; a, b, c), h_1^3(\xi; a, b, c), h_1^4(\xi; a, b, c)). \tag{5.11}$$

This means that for $(\theta, a, b, c) = (0, a(b, c), b, c)$, the system possesses a nontwisted heteroclinic loop consisting of h_1 and h_2, and it is known that both h_1 and h_2 are

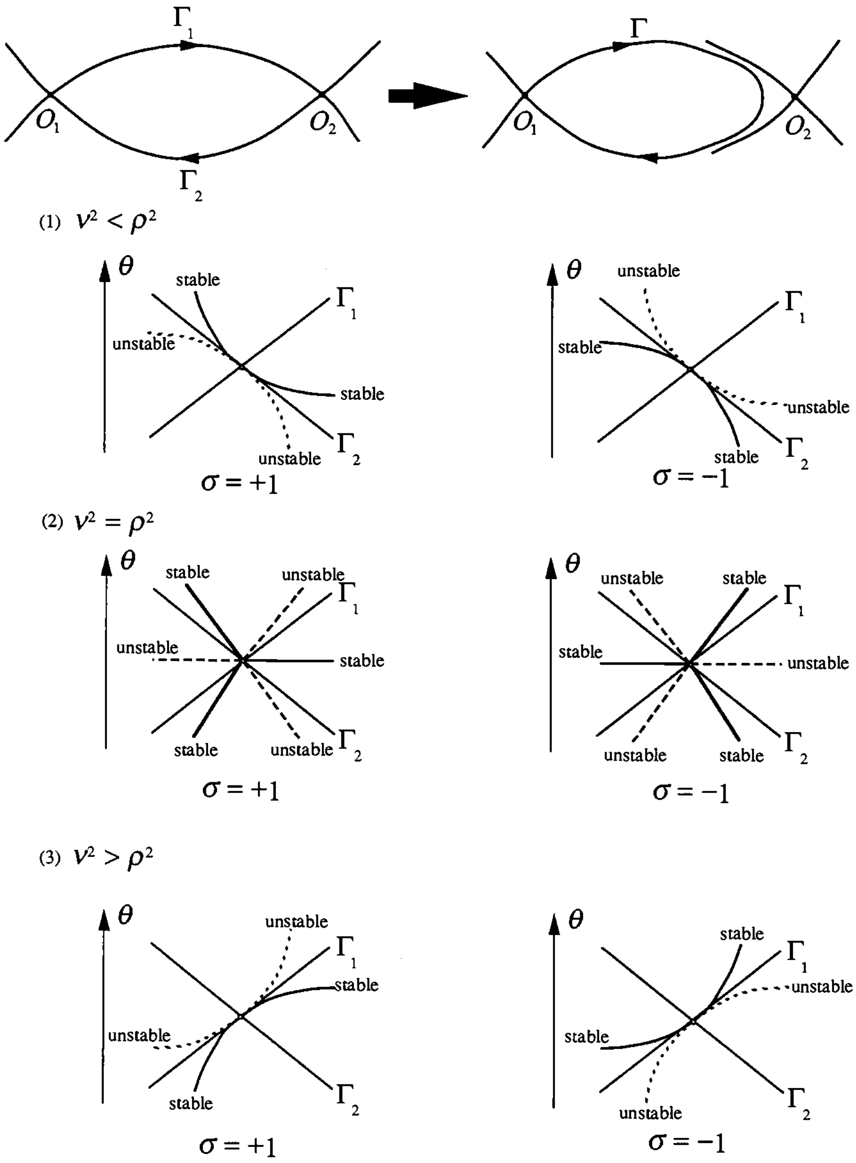

FIG. 5.7. *Stability of bifurcating pulses.*

nontwisted. Of course, system (5.7) has homoclinic orbits bifurcating from the heteroclinic loop (see Kan-on [14]). More precisely, there exists a C^1 family of solutions of (5.7) $h(\xi; a, b, c)$ ($\bar{h}(\xi; a, b, c)$) with $\theta = 0$ defined on $\mathfrak{Q} = \{(a, b, c) | 0 < 1/c < b, 1/c < a < a(b, c)\}$ ($\bar{\mathfrak{Q}} = \{(a, b, c) | 0 < 1/c < b, a(b, c) < a < b\}$) that satisfies

$$(5.12) \qquad \lim_{\xi \to \pm\infty} h(\xi; a, b, c) = (0, a, 0, 0) \qquad \left(\lim_{\xi \to \pm\infty} \bar{h}(\xi; a, b, c) = (1, 0, 0, 0) \right).$$

Again, traveling waves corresponding to the heteroclinic orbits are stable [16]. Kan-on [15] proved the instability of pulses by constructing an eigenfunction that corresponds to a positive eigenvalue.

However, by applying Theorem 4.4, we readily see from the bifurcation diagram (Figure 5.6) that the pulses are unstable.

Acknowledgments. The author expresses his sincere gratitude to Professors T. Nishida and H. Kokubu for valuable advice and encouragement. The author is also grateful to Professors H. Ikeda, C. Jones, Y. Kan-on, Y. Nishiura, and E. Yanagida for their useful comments and stimulating discussions.

SOLUTION OF A FINITE CONVOLUTION EQUATION WITH A HANKEL KERNEL BY MATRIX FACTORIZATION*

NORBERT GORENFLO† AND MATTHIAS WERNER‡

This paper is dedicated to the memory of our friend Hans-Jürgen Böttger, who worked at the Department of Mathematics at the Technical University of Berlin. He spent a great deal of time in mathematical discussions with us.

Abstract. The following problem is considered. The convolution f of a function g supported in the interval $[-1, 1]$ with the function $H_0(k|\cdot|)$ is known on $[-1, 1]$. An expression for g is searched for. It is shown that the problem of continuing the convolution f from the interval $[-1, 1]$ to the whole real axis in a consistent way is equivalent to solving a certain Hilbert boundary-value problem for two unknown functions. This Hilbert boundary-value problem differs essentially from the corresponding one from the modern theory of finite convolution equations in Sobolev spaces (cf. [B. V. Pal'cev, *Math. USSR Sb.*, 41 (1982), pp. 289–328]), which has not yet been factored, in that it is set up in the original space, not in the range of the Fourier transform operator, and it does not contain the full convolution kernel but only its asymptotics at infinity. It is shown that a factorization for this problem can be given in terms of solutions of a certain singular algebraic ordinary differential equation. This factorization leads to an integral representation of the unknown function g. Finally, the singular differential equation, which remains to be solved, is discussed. At this point, work should be continued.

Key words. convolution equations on a finite interval, factorization of matrix functions, singular differential equations

1. Introduction.

In this paper, a factorization method for solving the finite convolution equation of the first kind,

$$\int_{-1}^{1} g(y)H_0(k|x-y|)\,dy = f(x), \quad |x| \le 1, \tag{1.1}$$

is presented, where H_0 denotes the first-kind Hankel function of order zero.

In spite of a highly developed Sobolev space theory of finite convolution equations, which has been worked out during the last 15 years and is based on the equivalence of such a convolution equation with a corresponding matrix Hilbert boundary-value problem (cf. [1] and, especially, the profound paper of Pal'cev [15]), the problem of factorization of the Hilbert boundary-value problem which is assigned to equation (1.1) according to this theory remains an open question (regarding the hitherto unsatisfactory results in the attempts of solving equation (1.1) by Wiener–Hopf methods, cf. the survey of Meister [9, p. 226]). Thus the only closed-form solution of (1.1) which was known up to the present is a "classical" solution. It consists of a series representation of g in terms of the eigenfunctions of the integral operator Q,

$$QF(\alpha) = \int_0^{\pi} F(\beta)H_0(k|\cos\alpha - \cos\beta|)\,d\beta, \quad \alpha \in [0, \pi],$$

which is connected to (1.1) by the substitutions $x = \cos\alpha$, $y = \cos\beta$. The eigenfunctions of Q are the even Mathieu functions $ce_n(\cdot, k^2/4)$, $n \in N_0$; here we have used the notation in [11]. For the approach of representing the solution g of (1.1) as a series of Mathieu functions, see, e.g., [4] and [2].

In the present paper an integral representation of the solution of (1.1) in terms of the right-hand side f and solutions of a certain singular algebraic ordinary differential equation will be derived. This differential equation is of higher complexity than the standard ordinary differential equations of mathematical physics, including Mathieu's equation and the differential equation for spheroidal functions, and remains to be studied.

The solutions of the differential equation used in our approach are obtained by the factorization of a matrix Hilbert boundary-value problem for two unknown functions whose solution can be used to extend the right-hand side f of (1.1) from the interval $[-1, 1]$ to the whole real axis in a consistent way, which means that (1.1) holds for all $x \in \mathbb{R}$ (so that (1.1) can be solved by Fourier transformation).

This Hilbert problem differs essentially from the Hilbert problems occurring in the above-mentioned newer theory of finite convolution equations and, respectively, boundary-value problems for partial differential equations (cf. [1], [9], [10], [15], [16], and the references therein). Whereas the latter Hilbert problems are set up in the range of the Fourier transform operator, the Hilbert problem used in this paper is set up in the original space. Also, the coefficient matrix of the Hilbert problems considered in [1], etc., contains the symbol of the underlying convolution kernel, while the coefficient matrix of ours does not contain the full kernel $H_0(k|\cdot|)$ but is based only on its asymptotics at infinity, which causes a considerable simplification of the Hilbert problem.

We have divided the process of the solution of (1.1) in section 2 into three steps. In step 1, we establish the Hilbert problem; in step 2, we show how it can be factored by the use of solutions of an ordinary differential equation; and finally, in step 3, we give the solution of (1.1). In section 3, the ordinary differential equation on which our solution of (1.1) is founded is specified and discussed.

Our solution of (1.1) holds for arbitrary $k \neq 0$ with $\operatorname{Re} k \geq 0$ and $\operatorname{Im} k \geq 0$. On this general condition for every $p > 1$ and $f \in L^p([-1, 1])$) equation (1.1) has at most one solution: $g \in L^p([-1, 1])$. Although this special injectivity result follows from the general theory of finite convolution equations discussed above, we present a proof of it in the appendix because we need some of the formulas therein for our final solution of (1.1).

We still want to note that the factorization of the Hilbert boundary-value problem presented in this paper by solutions of an ordinary differential equation is closely related to the generalized Riemann problem examined in [3].

We also want to cite [5], where (by function-theoretic methods) finite convolution equations with simpler kernels are solved explicitly.

2. Solution of the integral equation.

To begin with, we recall that, regarding the parameter k in (1.1), we assume

$$k \neq 0, \quad \operatorname{Re} k \geq 0, \quad \text{and} \quad \operatorname{Im} k \geq 0.$$

Throughout this paper, we assume that the function g in (1.1) lies in $L^p([-1, 1])$ for some $p > 1$.

Step 1. We reformulate problem (1.1) as the problem of solving a certain Hilbert boundary-value problem for two unknown functions. With the solution of this Hilbert problem, we shall be able to express the right-hand side f in (1.1) for arguments $x \in \mathbb{R}\backslash[-1,1]$ as well.

Theorem 2.1. *If g is a solution of* (1.1), *we have*

$$\mu^-(x) + A(x)\mu^+(x) = \chi_{(-1,1)}(x) \begin{pmatrix} e^{-ikx} \displaystyle\int_{-1}^{1} g(y) H_0^{(1)}(k|x-y|)\,dy \\ e^{ikx} \displaystyle\int_{-1}^{1} g(y) H_0^{(1)}(k|x-y|)\,dy \end{pmatrix} \tag{2.1}$$

$$= \chi_{(-1,1)}(x) f(x) \begin{pmatrix} e^{-ikx} \\ e^{ikx} \end{pmatrix}, \quad x \in \mathbb{R}\backslash\{-1,1\},$$

with

$$\chi_{(-1,1)}(x) = 1 \quad \textit{for } |x| < 1, \qquad \chi_{(-1,1)}(x) = 0 \quad \textit{for } |x| > 1,$$

$$A(x) = \begin{pmatrix} 1 & -2e^{-2ikx} \\ 0 & -1 \end{pmatrix} \quad \textit{for } x < -1,$$

$$A(x) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \quad \textit{for } |x| < 1,$$

$$A(x) = \begin{pmatrix} -1 & 0 \\ -2e^{2ikx} & 1 \end{pmatrix} \quad \textit{for } x > 1,$$

$$\mu^-(x) = \frac{1}{2} \begin{pmatrix} e^{-ikx} \displaystyle\int_{-1}^{1} g(y) H_0^{(1)}(k(x-y))\,dy \\ -e^{ikx} \displaystyle\int_{-1}^{1} g(y) H_0^{(2)}(k(x-y))\,dy \end{pmatrix} \quad \textit{for } \operatorname{Im} x \le 0, \tag{2.2}$$

and

$$\mu^+(x) = \frac{1}{2} \begin{pmatrix} -e^{-ikx} \displaystyle\int_{-1}^{1} g(y) H_0^{(2)}(-k(x-y))\,dy \\ e^{ikx} \displaystyle\int_{-1}^{1} g(y) H_0^{(1)}(-k(x-y))\,dy \end{pmatrix} \quad \textit{for } \operatorname{Im} x \ge 0. \tag{2.3}$$

μ^- is holomorphic in the lower complex half-plane $\operatorname{Im} x < 0$, μ^+ is holomorphic in the upper complex half-plane $\operatorname{Im} x > 0$, and both functions are continuous up to the boundary line $\mathbb{R}$. Furthermore, we have

$$\mu^-(x) = O\left(|x|^{-\frac{1}{2}}\right) \quad \textit{and} \quad \mu^+(x) = O\left(|x|^{-\frac{1}{2}}\right), \quad |x| \to \infty. \tag{2.4}$$

Proof. The Hankel functions $H_\nu^{(1)}$ and $H_\nu^{(2)}$ of first and second kind, respectively, and order ν satisfy the following monodromic relations in $\mathbb{C}\backslash(-\infty, 0]$:

$$H_\nu^{(1)}(e^{m\pi i}z) = \frac{\sin(1-m)\nu\pi}{\sin\nu\pi} H_\nu^{(1)}(z) - e^{-\nu\pi i}\frac{\sin m\nu\pi}{\sin\nu\pi} H_\nu^{(2)}(z),$$

$$H_\nu^{(2)}(e^{m\pi i}z) = \frac{\sin(1+m)\nu\pi}{\sin\nu\pi} H_\nu^{(2)}(z) + e^{\nu\pi i}\frac{\sin m\nu\pi}{\sin\nu\pi} H_\nu^{(1)}(z),$$

$$m \in \mathbb{Z} \quad \text{(see [6, 8.476])}.$$

From these equations for $\nu = 0$ and $m = -1$, respectively, $m = 1$, we conclude that for $|y| < 1$,

$$\begin{aligned}
H_0^{(1)}(k(x-y))_- - H_0^{(2)}(-k(x-y))_+ - 2H_0^{(1)}(-k(x-y))_+ &= 0 \quad \text{for } x < -1,\\
-H_0^{(2)}(k(x-y))_- - H_0^{(1)}(-k(x-y))_+ &= 0 \quad \text{for } x < -1,\\
H_0^{(1)}(k(x-y))_- - H_0^{(2)}(-k(x-y))_+ &= 2H_0^{(1)}(k|x-y|) \quad \text{for } |x| < 1,\\
-H_0^{(2)}(k(x-y))_- + H_0^{(1)}(-k(x-y))_+ &= 2H_0^{(1)}(k|x-y|) \quad \text{for } |x| < 1,\\
H_0^{(1)}(k(x-y))_- + H_0^{(2)}(-k(x-y))_+ &= 0 \quad \text{for } x > 1,\\
-H_0^{(2)}(k(x-y))_- + 2H_0^{(2)}(-k(x-y))_+ + H_0^{(1)}(-k(x-y))_+ &= 0 \quad \text{for } x > 1.
\end{aligned}$$

Here the subscript "$-$" or "$+$" means that x approaches the real axis from the lower or, respectively, upper complex half-plane. Multiplication by $g(y)$, integration over $(-1, 1)$, and balancing with the exponential factors e^{-ikx} and e^{ikx} now yields (2.1).

From the asymptotic behavior of the Hankel functions [6, 8.451], we obtain (2.4). □

If problem (2.1) is solved, we can compute the right-hand side f in (1.1) for the values $x \in \mathbb{R}\backslash[-1, 1]$ as follows:

$$f(x) = \int_{-1}^{1} g(y) H_0(k|x-y|)\, dy = 2\begin{cases} e^{-ikx}\mu_2^+(x), & x < -1,\\ e^{ikx}\mu_1^-(x), & x > 1. \end{cases} \tag{2.5}$$

Thus f is known on the whole real axis and (1.1) can be solved by Fourier transformation.

Step 2. We derive a fundamental system for the homogeneous problem

$$\mu^-(x) + A(x)\mu^+(x) = 0, \quad x \in \mathbb{R}\backslash\{-1, 1\}. \tag{2.6}$$

To this end, the theory of Vekua for the Hilbert boundary-value problems with piecewise-continuous coefficients for several unknown functions [19, Chapter 2] is used. The piecewise-continuous coefficients are the components of the matrix A.

Throughout the following, it is assumed that $\operatorname{Im} k > 0$ because then the matrix A has definite limits for $x \to \pm\infty$. Later in this paper, we shall show that all of the results that we shall derive for the case $\operatorname{Im} k > 0$ also hold in the case $\operatorname{Im} k = 0$, i.e., $k > 0$.

The transformation of (2.6) to a Hilbert problem on a closed contour with the transformation

$$z = -\frac{ix}{x-i}$$

leads to

$$\Phi^+(z) = G(z)\Phi^-(z), \quad z \in L. \tag{2.7}$$

Here L is the boundary of the circle with radius 1/2 and center $-i/2$,

$$\Phi^+(z) = \mu^-(x), \qquad \Phi^-(z) = \mu^+(x),$$

where Φ^+ is defined inside and Φ^- is defined outside L and

$$G(z) = \begin{cases} \begin{pmatrix} 1 & 0 \\ 2e^{-\frac{2kz}{z+i}} & -1 \end{pmatrix}, & z \in a_3 \frown a_1, \\ \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, & z \in a_1 \frown a_2, \\ \begin{pmatrix} -1 & 2e^{\frac{2kz}{z+i}} \\ 0 & 1 \end{pmatrix}, & z \in a_2 \frown a_3 \end{cases}$$

with

$$a_1 = \frac{1-i}{2}, \qquad a_2 = \frac{-1-i}{2}, \quad \text{and} \quad a_3 = -i.$$

$a_p \frown a_q$ is the segment of L joining the points a_p and a_q in the mathematical positive direction. The discontinuities $z = a_1$, $z = a_2$, and $z = a_3$, respectively, of G correspond to the discontinuities $x = 1$, $x = -1$, and $x = \infty$, respectively, of A.

Problem (2.7) fulfills all the conditions in [19, Chapter 2]. With the notation therein, obviously a_1, a_2, and a_3 are all nonspecial points of (2.7) and the corresponding numbers ρ_j^σ are all equal to 0, respectively, $\pm 1/2$.

We consider the solutions Φ of (2.7) of class $h(a_1, a_2)$. This means that

$$\lim_{z\in\mathbb{C}, z\to a_1} |z-a_1|^\varepsilon \Phi(z) = 0, \qquad \lim_{z\in\mathbb{C}, z\to a_2} |z-a_2|^\varepsilon \Phi(z) = 0 \quad \text{for all } \varepsilon > 0$$

$$\text{and} \tag{2.8}$$

$$|\Phi(z)| \le c|z-a_3|^{-\alpha}, \quad z \in \mathbb{C} \text{ near } a_3, \quad \text{for some } c > 0 \text{ and } \alpha \in [0,1).$$

In the last estimate, $|\Phi(z)|$ denotes any norm of the vector $\Phi(z)$.

LEMMA 2.1. *The partial indices of the Hilbert problem* (2.7), (2.8) *are both zero.*

Proof. From [19, formula (13.49)], we obtain that the total index of (2.7) and (2.8) is zero. Thus it remains to show that both partial indices are nonnegative.

Because of (2.1), for any function f defined by a function $g \in L^p([-1,1])$ for some $p > 1$ via (1.1) with

$$\varphi^+(z) = (x(z)-i)\mu^-(x(z)), \qquad \varphi^-(z) = (x(z)-i)\mu^+(x(z))$$

and

$$b(z) = \chi_{(-1,1)}(x(z))(x(z)-i)f(x(z))(e^{-ikx(z)}, e^{ikx(z)})^T, \quad z \in L, \tag{2.9}$$

we have

$$\varphi^+(z) = G(z)\varphi^-(z) + b(z), \quad z \in L,$$

and because of (2.2), (2.3), and (2.4) the function φ belongs to the class $h(a_1, a_2)$. Furthermore, $\varphi(z)$ is vanishing for $|z| \to \infty$.

It is not hard to show that for $g \in L^p([-1,1])$, $p > 1$, the function f defined by (1.1) is Hölder continuous on $[-1,1]$. (Because of the logarithmic singularity of the function H_0, there is an analogy to the logarithmic potential in two-dimensional potential theory, whose Hölder continuity is a well-known fact.) Thus it follows (see [19, formula (14.6)]) that

$$\int_L b(z)^T [X^+(z)^T]^{-1} q(z)\, dz = 0 \tag{2.10}$$

for all vectors

$$q = (q_{-\chi_1 - 1}, q_{-\chi_2 - 1})^T,$$

where X is a fundamental matrix for (2.7) and (2.8), χ_1 and χ_2 are the partial indices of (2.7) and (2.8), and q_α is an arbitrary polynomial of degree not greater than α, $q_\alpha \equiv 0$ for $\alpha < 0$.

It remains to show that if (2.10) holds for every function b of the form (2.9), the polynomials $q_{-\chi_1-1}$ and $q_{-\chi_2-1}$ both must vanish because this implies χ_1, $\chi_2 \geq 0$. For this aim we derive a contradiction from the hypothesis $q_{-\chi_1-1} \not\equiv 0$. (The hypothesis $q_{-\chi_2-1} \not\equiv 0$ is contradicted analogously.) Hence assume $q_{-\chi_1-1} \not\equiv 0$. Because the total index $\chi_1 + \chi_2$ is zero, it follows that $q_{-\chi_2-1} \equiv 0$. Thus with

$$e_1 := (1, 0)^T \quad \text{and} \quad \varphi(z) := (e^{-ikx(z)}, e^{ikx(z)})[X^+(z)^T]^{-1} e_1,$$

(2.10) yields

$$\int_{a_1 \frown a_2} f\left(\frac{iz}{z+i}\right) \frac{q_{-\chi_1-1}(z)}{z+i} \varphi(z)\, dz = 0$$

for all functions f of the form (1.1) with $g \in L^p([-1,1])$ for arbitrary $p > 1$. Because for $p > 1$ the integral operator (1.1) is injective on $L^p([-1,1])$ (as proved in the appendix) and has the same kernel as its adjoint on $L^q([-1,1])$, $1/p + 1/q = 1$, the adjoint operator is also injective and therefore the functions f defined by (1.1) for $g \in L^p([-1,1])$ are dense in $L^p([-1,1])$ [17, corollary to Theorem 4.12]. Because of $q_{-\chi_1-1} \not\equiv 0$, it follows that φ must vanish identically on $a_1 \frown a_2$. (For the growth of $[X(z)^T]^{-1}$ near $z = a_1, a_2$, see [19, p. 97].)

With

$$\det\,(X(z))[X(z)^T]^{-1} e_1 = (-\alpha_2(z), \alpha_1(z))^T,$$

by definition of a fundamental matrix, the function $\alpha := (\alpha_1, \alpha_2)^T$ is a nonzero solution of (2.7) and (2.8) (namely, the negative of the second column of X). Furthermore, it holds that

$$e^{ikx(z)} \alpha_1^+(z) - e^{-ikx(z)} \alpha_2^+(z) = \det(X^+(z))\varphi(z) = 0, \quad z \in a_1 \frown a_2,$$

or

$$\alpha^+(z) = \alpha_1^+(z)(1, e^{2ikx(z)})^T, \quad z \in a_1 \frown a_2. \tag{2.11}$$

Because the sectionally holomorphic function α is a solution of (2.7), by virtue of (2.7), it can be continued analytically from the interior of L into the region outside of L across the segment $a_1 \frown a_2$. Note that the matrix G obviously possesses a corresponding analytic continuation; that the thus-defined function α is holomorphic in a neighborhood of $a_1 \frown a_2$ is an immediate consequence from Morera's theorem [12, p. 367]. By the analyticity of α^+ in a neighborhood of $a_1 \frown a_2$, we see by analytic continuation that (2.11) also holds inside L and therefore also on the segments $a_3 \frown a_1$ and $a_2 \frown a_3$. It follows that

$$\alpha^-(z) = G(z)^{-1}\alpha^+(z) = \alpha_1^+(z)G(z)^{-1}(1, e^{2ikx(z)})^T, \quad z \in L\backslash\{a_1, a_2, a_3\}.$$

The vector $(1, e^{2ikx(z)})^T$ is an eigenvector of the matrix $G(z)^{-1} = G(z)$ to the eigenvalue 1 on $a_3 \frown a_1 \cup a_2 \frown a_3$ and to the eigenvalue -1 on $a_1 \frown a_2$. We conclude that α_1 is a nonzero solution of class $h(a_1, a_2)$ of the simple one-dimensional Hilbert problem

$$\begin{gathered}\alpha_1^+(z) = \alpha_1^-(z) \quad \text{on } a_3 \frown a_1 \text{ and } a_2 \frown a_3\\ \text{and}\\ \alpha_1^+(z) = -\alpha_1^-(z) \quad \text{on } a_1 \frown a_2.\end{gathered} \tag{2.12}$$

Because (2.11) holds for $z \in L\backslash\{a_1, a_2, a_3\}$, we have

$$\alpha_1^+(z) = e^{\frac{2kz}{z+i}}\alpha_2^+(z), \quad z \in L\backslash\{a_1, a_2, a_3\}.$$

Because $\operatorname{Im} k > 0$, it follows that $\alpha_1^+(z)$ decays exponentially if z approaches $a_3 = -i$ along the segment $a_2 \frown a_3$. However, this is impossible for the nonzero solution α_1 of (2.12) of class $h(a_1, a_2)$ (cf. [13, formula (78, 16)]). Hence our assumption $q_{-\chi_1-1} \not\equiv 0$ leads to a contradiction. □

Next, it will be shown that the fundamental solutions of (2.7) and (2.8) fulfill a certain 2×2 system of singular algebraic differential equations. To this end, we need the following estimations for the derivatives of solutions of (2.7) and (2.8).

Lemma 2.2. *If Φ is a solution of* (2.7) *and* (2.8) *we have*

$$\begin{gathered}\lim_{z\in\mathbb{C}, z\to a_1} |z-a_1|^{1+\varepsilon}\Phi'(z) = 0, \qquad \lim_{z\in\mathbb{C}, z\to a_2} |z-a_2|^{1+\varepsilon}\Phi'(z) = 0 \quad \textit{for all } \varepsilon > 0,\\ \textit{and}\\ |\Phi'(z)| \le c|z-a_3|^{-(2+\alpha)}, \quad z \in \mathbb{C} \textit{ near } a_3,\end{gathered} \tag{2.13}$$

for α from (2.8) *and some $c > 0$.*

Proof. It is useful to consider the original problem (2.6). Therefore, let $\mu(x) = \Phi(z)$. To prove the estimate for a_1, because

$$\Phi'(z) = -\frac{1}{(z+i)^2}\mu'(x), \tag{2.14}$$

it must be shown that

$$\lim_{x_0\in\mathbb{C}, x_0\to 1} |x_0 - 1|^{1+\varepsilon}\mu'(x_0) = 0 \quad \text{for all } \varepsilon > 0. \tag{2.15}$$

For x_0 near 1, $x_0 \neq 1$, $0 < r < |x_0 - 1|$, and small $\delta > 0$, we consider the function μ on the circle $B_{r,\delta} := \{x \in \mathbb{C} |\, |x - x_0| < r + \delta\}$. If $B_{r,\delta}$ intersects the real line, we continue the sectionally holomorphic function μ analytically into the lower, respectively, upper complex half-plane ("lower" if x_0 lies in the upper half-plane; "upper" if x_0 lies in the lower half-plane) by virtue of equation (2.6). From the Cauchy integral formula we now obtain

$$\mu'(x_0) = \frac{1}{2\pi i}\int_{|x-x_0|=r} \frac{\mu(x)}{(x-x_0)^2}dx;$$

hence

$$|\mu'(x_0)| \leq \frac{\max\limits_{|x-x_0|=r} |\mu(x)|}{r}. \tag{2.16}$$

However, by (2.8),

$$\max_{|x-x_0|=r} |\mu(x)| \leq c \max_{|x-x_0|=r} |x-1|^{-\varepsilon} = c(|x_0-1|-r)^{-\varepsilon} \quad \text{for all } \varepsilon > 0.$$

Now (2.15) follows from these two inequalities if we set, e.g., $r = |x_0-1|/2$. The estimate for $\Phi'(z)$ near $z = a_2$ is obtained analogously.

Because the singularity $z = a_3 = -i$ corresponds to $x = \infty$, by virtue of (2.14), it remains to show that

$$|\mu'(x_0)| \leq c|x_0|^{\alpha} \tag{2.17}$$

if x_0 tends to infinity in the lower, respectively, upper half-plane. Without loss of generality, let $\operatorname{Im} x_0 \leq 0$. For fixed $r > 0$ and $\delta > 0$, continue the function μ analytically from the lower half-plane into the region $0 < \operatorname{Im} x < r + \delta$, $|\mathrm{Re}\ x| > 1$, across the two half-lines $(-\infty, -1)$ and $(1, \infty)$ by virtue of relation (2.6). In the same way as above, we obtain (2.16) and hence, by (2.8), also (2.17). Note that in the latter case the exponential factors $e^{\pm 2ikx}$, which occur by the process of analytic continuation, behave well for $\operatorname{Re} x \to \pm\infty$ and that the radius r is the same for all values of x_0. □

After this preparation, we can prove the following theorem. Concerning the involved theory of differential equations having singular points we refer, for example, to [8, §23] (cases $x = -1$ and $x = 1$ in what follows) and [7, Chapter XIX] (case $x = \infty$).

THEOREM 2.2. *Let X be a fundamental matrix of* (2.7) *and* (2.8)*, let V, $V(x) = X(z)$, be the corresponding fundamental matrix of* (2.6)*, and define the diagonal matrix D by*

$$D = ik \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Then the matrix-valued function Y,

$$Y(x) := V(x)^T e^{xD}, \quad e^{xD} = \begin{pmatrix} e^{ikx} & 0 \\ 0 & e^{-ikx} \end{pmatrix},$$

fulfills the first-order system of differential equations

$$(x^2-1)Y'(x) = P(x)Y(x), \tag{2.18}$$

where P is a matrix-valued function whose component functions are polynomials of degree 2 *or less.*

The points $x = -1$ and $x = 1$ are regular singular points of (2.18) *and*

$$\textit{for } x \in \{-1, 1\}, \quad \textit{the indices at } x \textit{ are } 0 \textit{ and } \frac{1}{2}. \tag{2.19}$$

Furthermore,

(2.20) (2.18) *possesses a nonzero entire solution,* *and there are solutions φ and Ψ of* (2.18) *with the asymptotics*

$$\varphi(x) \sim x^{\frac{1}{2}} e^{-ikx} c^{(1)} \quad \textit{and} \quad \Psi(x) \sim x^{\frac{1}{2}} e^{ikx} c^{(2)}, \quad |x| \to \infty, \tag{2.21}$$

such that

$$\begin{gathered} \varphi \textit{ and } \Psi \textit{ are the solutions to the index } \frac{1}{2} \\ \textit{at the points } x = -1 \textit{ and } x = 1, \textit{ respectively.} \end{gathered} \tag{2.22}$$

Here $c^{(1)}$ and $c^{(2)}$ are nonzero constant complex vectors and each of the asymptotic relations (2.21) *holds in a certain sector of the complex plane.*

Proof. By differentiating (2.6) with V instead of μ we arrive at the central relationship

$$(V^-)'(x) + DV^-(x) + A(x)[(V^+)'(x) + DV^+(x)] = 0, \quad x \in \mathbb{R}\backslash\{-1, 1\},$$

that is, $V' + DV$ is also a solution of (2.6). Hence $-(\cdot - a_3)^2 X' + DX$ is a solution of (2.7) and so is X^*,

$$X^*(z) := (z - a_1)(z - a_2)(z - a_3)^2 X'(z) - (z - a_1)(z - a_2)DX(z).$$

Because of (2.13), X^* also fulfills condition (2.8) and hence lies in the class $h(a_1, a_2)$.

Because both partial indices of problem (2.7), (2.8) are zero (Lemma 2.1), the fundamental matrix X is holomorphic in $z = \infty$ and so X' in $z = \infty$ has a zero of order at least 2. Therefore, X^* has degree 2 or less at $z = \infty$. Hence (because the partial indices of (2.7) and (2.8) are zero and X and X^* are of the same class $h(a_1, a_2)$) there exists a matrix function Q whose coefficients are polynomials of degree 2 or less in z, with

$$X^*(z) = X(z)Q(z)$$

(see [19, formula (13.47)]).

Because of

$$X^*(z) = \frac{x^2 - 1}{2(x - i)^2}[V'(x) + DV(x)],$$

with

$$R(x) := 2(x - i)^2 Q(z) = 2(x - i)^2 Q\left(-\frac{ix}{x - i}\right)$$

it follows that

$$(x^2 - 1)[V'(x) + DV(x)] = V(x)R(x).$$

The coefficients of the matrix function R are polynomials of degree 2 or less in x.

With

$$W(x) := e^{xD}V(x), \quad e^{xD} = \begin{pmatrix} e^{ikx} & 0 \\ 0 & e^{-ikx} \end{pmatrix},$$

we arrive at

$$(x^2-1)W'(x) = W(x)R(x).$$

By transposing, we now obtain (2.18), where $Y = W^T$ and $P = R^T$.

Obviously, the points $x = -1$ and $x = 1$ are regular singular points of (2.18).

With the matrix A from (2.6), we define

$$B(x) := e^{xD}A(x)e^{-xD}, \quad x \in \mathbb{R}\backslash\{-1,1\}.$$

B is constant on each of the segments $(-\infty,-1)$, $(-1,1)$, and $(1,\infty)$.

The matrix $W = e^{\cdot D}V$ fulfills

$$W^-(x) + B(x)W^+(x) = 0, \quad x \in \mathbb{R}\backslash\{-1,1\},$$

and therefore W^-, which we think is continued analytically into the upper complex half-plane through the segment $(-1,1)$ via the relation $W^-(x) = -W^+(x)$, $x\epsilon(-1,1)$, satisfies the following monodromic relation if the point $x = -1$ is encircled in the mathematical positive direction:

$$W^-(x)_{\text{new}} = \begin{pmatrix} 1 & -2 \\ 0 & -1 \end{pmatrix} W^-(x)_{\text{old}}.$$

From this it follows that the first column of the matrix solution Y^* of (2.18),

$$Y^*(x) := \left[\begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix} W^-(x)\right]^T,$$

returns to its original value and that the second column of Y^* changes sign if $x = -1$ is encircled. Therefore, the indices of (2.18) at $x = -1$ are of the form n and $m + 1/2$ for some n, $m \in \mathbb{Z}$. That $n = m = 0$ follows from the fact that the fundamental matrix V of (2.6) satisfies the estimates

$$\lim_{x\in\mathbb{C}, x\to -1} |x+1|^{\varepsilon} V(x) = 0 \quad \text{for all } \varepsilon > 0$$

and

$$|V(x)^{-1}| \leq c|x+1|^{-\alpha}, \quad x \in \mathbb{C} \text{ near } -1, \quad \text{for some } c > 0 \quad \text{and} \quad \alpha \in [0,1).$$

Here $|V(x)^{-1}|$ denotes any norm of the matrix $V(x)^{-1}$; the first estimate is a consequence of (2.8) and the second estimate holds by definition of a fundamental matrix of class $h(a_1, a_2)$ [19, p. 97].

In the same way, it can be proved that the indices of (2.18) at $x = 1$ are 0 and 1/2. The solution to the index 0 at $x = 1$ turns out to be proportional to the solution to the index 0 at $x = -1$; this shows (2.20).

Because of $\operatorname{Im} k > 0$, the matrix A of (2.6) satisfies

$$\lim_{x\to+\infty} A(x)^{-1} \lim_{x\to-\infty} A(x) = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{2.23}$$

From this, by the construction of the fundamental matrix of class $h(a_1, a_2)$ performed in [19], it can be deduced that for the fundamental matrix X of (2.7) and (2.8),

$$\lim_{z \to -i} (z+i)^{\frac{1}{2}} X(z) = X_0 \quad \text{with } \det X_0 \neq 0$$

if z approaches $-i$ within the given sectors of the complex plane. (Note that there is no logarithmic singularity near $z = -i$ because the matrix (2.23) possesses a complete set of eigenvectors to the double eigenvalue -1; the matrix X_0 is constant on each sector.) It follows that for the solution Y of (2.18),

$$Y(x) = V(x)^T e^{xD} = X(z)^T e^{xD},$$

the asymptotic relation

$$Y(x) \sim x^{\frac{1}{2}} X_0^T e^{xD}, \quad |x| \to \infty,$$

holds within the corresponding sectors. Hence (2.21) is also valid. Because the second (respectively, first) column of Y changes sign if $x = -1$ (respectively, $x = 1$) is encircled (the second column of Y is just the second column of the previously examined matrix solution Y^* of (2.18)), (2.22) is also proved. □

In section 3, an explicit expression for the polynomial matrix P is given which contains only two complex parameters whose values are still unknown.

Until now, the assumption $\operatorname{Im} k > 0$ was necessary, but now we prove the following fact.

Theorem 2.3. *All of the results obtained so far also hold in the case* $\operatorname{Im} k = 0$ *(i.e.,* $k > 0$*).*

Proof. Let $k > 0$ and $0 < \alpha < \pi/2$, and let γ be any smooth curve in the complex plane so that γ contains the segment $[-1, 1]$ as well as the set $\{\lambda e^{i\alpha} | \lambda \in \mathbb{R}, |\operatorname{Re}(\lambda e^{i\alpha})| \geq 2\}$ and that $\operatorname{Im} \gamma$ is a monotonic function of $\operatorname{Re} \gamma$. We now consider the Hilbert boundary-value problem (2.6) on the curve γ instead of $\mathbb{R}$. Again using the transformation

$$z = -\frac{ix}{x-i},$$

we obtain problem (2.7) on a closed arc L^* instead of L. Because for $k > 0$ the matrix A has definite limits for $|x| \to \infty$, $x \in \gamma$, the so-modified problem (2.7) again fulfills all the conditions in [19, Chapter 2]. Now it is not hard to see that all of the results that we have obtained so far for problem (2.6) (respectively, (2.7)) hold in exactly the same way for the modified problem (2.6) (respectively, (2.7)). We want to note that by analytic continuation from relation (2.1), it follows that

$$\mu^-(x) + A(x)\mu^+(x) = 0 \quad \text{for } x \in \gamma \backslash [-1, 1]. \qquad □$$

Step 3. We express the solution g of the original problem (1.1) in terms of the fundamental system Y of (2.18)–(2.22). Regarding the parameter k, we impose no restriction; that is, we assume $k \neq 0$, $\operatorname{Re} k \geq 0$, and $\operatorname{Im} k \geq 0$.

Theorem 2.4. *Let X be a fundamental matrix of* (2.7) *and* (2.8)*, set $V(x) = X(z)$, and define the matrix D as in Theorem* 2.2. *Consider the fundamental system Y of* (2.18)–(2.22) *specified by $Y(x) = V(x)^T e^{xD}$ for* $\operatorname{Im} x \leq 0$ *and the requirement that for* $\operatorname{Im} x \geq 0$ *the values $Y(x)$ are obtained by analytic continuation from the lower complex half-plane across the segment* $(-1, 1)$.

If f is given by (1.1), *we have*

$$f(s) = \int_{-1}^{1} f(\tau)T(s,\tau)\,d\tau \quad \textit{for all } s \in \mathbb{R}\backslash\{-1,1\}, \tag{2.24}$$

where the "transfer function" T is defined by

$$T(s,\tau) = \begin{cases} -\dfrac{1}{i\pi(s-\tau)}[Y^+(s)^T[Y(\tau)^T]^{-1}(1,1)^T]_2, & s \in (-\infty,-1), \\ \delta(s-\tau), & s \in (-1,1), \\ \dfrac{1}{i\pi(s-\tau)}[Y^-(s)^T[Y(\tau)^T]^{-1}(1,1)^T]_1, & s \in (1,\infty). \end{cases}$$

Here $[\ ]_1$ and $[\ ]_2$ denote the first and second components, respectively, of the vector within the brackets, δ is the Dirac delta distribution, and $Y^{\pm}(s)$ denotes the limit of $Y(s^*)$ if s^* approaches s from the upper or lower half-plane, respectively.

Furthermore, with

$$f\hat{}(\rho) = \int_{\mathbb{R}} f(x)e^{-i\rho x}dx,$$

the solution g of (1.1) *is given by*

$$g(x) = \frac{1}{4\pi}\int_{\mathbb{R}} \sqrt{k^2-\rho^2}\, f\hat{}(\rho)e^{i\rho x}d\rho. \tag{2.25}$$

Here the sign of the square root is specified by (A1) *in the appendix. In general, these Fourier integrals must be interpreted in the sense of tempered distributions.*

Proof. With φ^+ and φ^- defined in the formulas preceding equation (2.9) and b defined as in (2.9), it follows from (2.1) that

$$\varphi^+(z) = G(z)\varphi^-(z) + b(z)$$

for $z \in L$ (if $\operatorname{Im} k > 0$), respectively, $z \in L^*$ (if $k > 0$). Because both partial indices of (2.7) and (2.8) are zero, we have

$$\varphi(z) = \frac{1}{2\pi i}X(z)\int_{a_1\frown a_2} \frac{1}{t-z}X^+(t)^{-1}b(t)\,dt, \quad z \in \mathbb{C}$$

(see [19, formula (14.3)]). It follows that the solution μ of (2.1) is given by

$$\mu(x) = \frac{1}{2\pi i}V(x)\int_{-1}^{1}\frac{f(\tau)}{x-\tau}V^-(\tau)^{-1}(e^{-ik\tau}, e^{ik\tau})^T d\tau, \quad x \in \mathbb{C}.$$

This can be written as

$$\mu^{\mp}(x) = \pm\frac{1}{2\pi i}e^{-xD}Y(x)^T\int_{-1}^{1}\frac{f(\tau)}{x-\tau}[Y(\tau)^T]^{-1}(1,1)^T d\tau, \quad x \in \mathbb{C}.$$

(Note that for $x \in (-1,1)$, it holds that $V^+(x) = -V^-(x)$ but $Y^+(x) = Y^-(x)$ because Y has been defined by analytic continuation across $(-1,1)$.)

Together with relation (2.5), we can now express the values $f(x)$ of the right-hand side f of (1.1) for all $x \in \mathbb{R}$ as asserted in (2.24).

Formula (2.25) follows immediately from the results obtained in the appendix. □

Remark 2.1. Using (2.24), equation (2.25) can be formally written as

$$g(x) = \int_{-1}^{1} f(\tau) K(x,\tau)\, d\tau,$$

where the formal distribution kernel K is given by

$$K(x,\tau) = \frac{1}{4\pi} \int_{\mathbb{R}} \int_{\mathbb{R}} \sqrt{k^2 - \rho^2} e^{i(x-s)\rho}\, d\rho\, T(s,\tau)\, ds.$$

3. The singular differential equation. In the following theorem, we give an explicit representation of the coefficient matrix P of problem (2.18)–(2.22).

THEOREM 3.1. *There is a fundamental matrix V of* (2.6) *and* (2.8) *for which the corresponding polynomial matrix P in* (2.18) *is of the form*

(3.1)
$$P(x) = \begin{pmatrix} 0 & r - ik \\ s - ik & 0 \end{pmatrix} + \begin{pmatrix} \frac{1}{2} - \sqrt{\frac{1}{4} - rs} & 0 \\ 0 & \frac{1}{2} + \sqrt{\frac{1}{4} - rs} \end{pmatrix} x + \begin{pmatrix} 0 & ik \\ ik & 0 \end{pmatrix} x^2$$

for some r, $s \in \mathbb{C}$.

Proof. We have the identity

$$ZA(-x)Z = A(x) = A(x)^{-1}, \quad x \in \mathbb{R}, \quad \text{with } Z := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

Therefore, if V is any fundamental matrix of (2.6) and (2.8), the matrix function V^*,

$$(V^*)^{\mp}(x) := ZV^{\pm}(-x),$$

is also a fundamental matrix of (2.6) and (2.8). Because both partial indices of (2.6) and (2.8) are zero, there must be a constant matrix C with

$$ZV(-x) = V^*(x) = V(x)C.$$

From this, for the fundamental system Y of (2.18), which satisfies

$$Y(x) = V(x)^T e^{xD} \quad \text{for } \operatorname{Im} x \leq 0,$$

we derive

$$Y(x) = -C^T Y(-x) Z, \quad x \in (-1,1).$$

(Note that $V^+(x) = -V^-(x)$ for $x \in (-1,1)$) and $C = C^{-1}$ (by replacing x by $-x$ in the above equality and solving the resulting equation for $Y(x)$.) From (2.18), it now follows that

$$P(-x) = -C^T P(x) C^T. \tag{3.2}$$

We define the constant matrices P_0, P_1, and P_2 by

$$P(x) = P_0 + P_1 x + P_2 x^2.$$

Because of (2.19), we have the following:

$$\begin{gathered} P_0 - P_1 + P_2 \text{ has the eigenvalues } 0 \text{ and } -1 \\ \text{and} \\ P_0 + P_1 + P_2 \text{ has the eigenvalues } 0 \text{ and } 1. \end{gathered} \tag{3.3}$$

Furthermore, because of (2.21),

$$P_2 \text{ has the eigenvalues } -ik \text{ and } ik. \tag{3.4}$$

(From a more detailed analysis along the lines of the proof of the asymptotic relation (2.21) and the proof of the last estimate in (2.13), one can obtain an asymptotic relation not only for Y but also for Y', and so, using (2.18), one can directly deduce that $P_2 = X_0^T D (X_0^T)^{-1}$ with X_0 from the proof of (2.21). Note that the diagonal matrix D just has the entries $\pm ik$.)

If the fundamental matrix V is changed into the fundamental matrix VS, where S is any constant invertible matrix, the matrix C^T changes into $S^T C^T (S^T)^{-1}$. For that reason, because of $C = C^{-1}$, we can assume that C^T is equal to

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \text{or} \quad \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}.$$

If C^T were the first or second of these matrices, then it would follow from (3.2) that $P_2 = -P_2$ and hence that $P_2 = 0$, which would contradict (3.4). Therefore, we can assume that C^T is equal to the third of these matrices. With this form of C^T, we obtain from (3.2) that there exist $r, s, a, b, p, q \in \mathbb{C}$ with

$$P_0 = \begin{pmatrix} 0 & r - ik \\ s - ik & 0 \end{pmatrix}, \qquad P_1 = \begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}, \quad \text{and} \quad P_2 = \begin{pmatrix} 0 & p \\ q & 0 \end{pmatrix}. \tag{3.5}$$

Because of (3.4), we have $pq = -k^2$ so that for

$$U := \begin{pmatrix} 1 & 0 \\ 0 & \dfrac{p}{ik} \end{pmatrix},$$

it holds that

$$UP_2U^{-1} = \begin{pmatrix} 0 & ik \\ ik & 0 \end{pmatrix}.$$

Therefore, if we change the fundamental matrix V of (2.6) and (2.8), which led us to (3.5), into the fundamental matrix VU^T, the matrix P given by (3.5) changes into a matrix that also has the form (3.5) but, in addition, with $p = q = ik$.

With $p = q = ik$ in (3.5), it now follows from (3.3) that

$$a = \frac{1}{2} - \sqrt{\frac{1}{4} - rs} \quad \text{and} \quad b = \frac{1}{2} + \sqrt{\frac{1}{4} - rs},$$

and we have reached the form (3.1).

The last condition from (2.19) and (2.21) which must be fulfilled by the matrix P given by (3.1) is that the exponent in the power of x occurring in (2.21) before $e^{\mp ikx}$ is equal to $1/2$. However, this condition turns out to be fulfilled automatically if P is of the form (3.1), where r and s are arbitrary complex numbers. □

Remark 3.1. A change of the sign of the square root $(1/4 - rs)^{1/2}$ together with an exchange of r and s in the matrix P_0 simply corresponds to the change from the fundamental matrix V to the fundamental matrix

$$V \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

so that also a definite sign can be attached to the square root.

Remark 3.2. To construct the fundamental system $Y = V^T e^{\cdot D}$ of (2.18), the parameters r and s in (3.1) have to be determined so that the conditions (2.20) and (2.22) are fulfilled. Note that (2.22) leads to only one condition because if $\Psi = (\Psi_1, \Psi_2)^T$ is a solution of (2.18) to the index $1/2$ at $x = 1$, which fulfills (2.21), the function φ,

$$\varphi(x) = (\Psi_1(-x), -\Psi_2(-x))^T,$$

is the solution to the index $1/2$ at $x = -1$ and also fulfills (2.21). Because the columns of the fundamental system $Y = V^T e^{\cdot D}$ are proportional to Ψ, respectively, φ (as was shown in the proof of Theorem 2.2), for the solution of (1.1) it suffices to know the function Ψ. If for every value of k the parameters $r(k)$ and $s(k)$ are determined in the above manner, the function Ψ is a function of the parameters k and x:

$$\Psi = \Psi(k; x). \tag{3.6}$$

Finally, we want to derive a scalar differential equation of the second order which is equivalent to the first-order system (2.18).

COROLLARY 3.1. *If the vector y is a solution of* (2.18) *with the matrix P given by* (3.1)*, the first component y_1 of y satisfies the scalar second-order differential equation*

$$(x^2 - a^2)(x^2 - 1)y_1''(x) + p(x)y_1'(x) + q(x)y_1(x) = 0, \tag{3.7}$$

where

$$a = \sqrt{\frac{ir}{k} + 1},$$

$$p(x) = -x^3 + (2 - a^2)x,$$

and

$$q(x) = k^2x^4 + \left[ik(2ik - s)a^2 + \frac{1}{2} - \sqrt{\frac{1}{4} + ik(a^2 - 1)s}\right]x^2$$

$$+ ik(s - ik)a^4 + a^2\left(\frac{1}{2} - \sqrt{\frac{1}{4} + ik(a^2 - 1)s}\right).$$

Proof. With P given by (3.1) we solve the first of the two equations in (2.18) for the second component y_2 of y and differentiate the resulting expression to obtain an expression for y_2'. Then we compare the latter expression with the second equation in (2.18), in which y_2 has been replaced by the expression obtained earlier from the first equation in (2.18). This yields (3.7) with the asserted forms of a, p, and q. □

Remark 3.3. For $a^2 \neq 1$, of course, $-a$ and a are only apparent singular points of (3.7).

Remark 3.4. In the special case $a^2 = 1$ (i.e., $r = 0$) and

$$\sqrt{\frac{1}{4} + ik(a^2-1)s} = +\frac{1}{2},$$

(3.7) reduces to

$$(x^2-1)y_1''(x) - xy_1'(x) + (k^2x^2 - k^2 - iks)y_1(x) = 0.$$

This is the spheroidal differential equation with the indices 0 and 3/2 at $x = \pm 1$ [11], [12]. (The indices are not 0 and 1/2, which does not contradict (3.3) because the differential equation is only a differential equation for the first component y_1 of y.) Therefore, (3.7) is a generalization of this spheroidal differential equation. The parameters a and s, of course, have yet to be determined properly.

Remark 3.5. With respect to the importance of the functions $\Psi(k;\cdot)$, referred to in (3.6), for the solution of the original problem (1.1) by (2.24) and (2.25), we propose to thoroughly investigate the differential equation (2.18), (3.1), respectively, the differential equation (3.7).

4. Remarks. Our mathematical interest and examination of equation (1.1) found its origin in the employment of the second author with a doping problem in solid-state physics (diffusion through a slit).

For the connection between (1.1) and a certain mixed boundary-value problem for the Helmholtz equation, see, e.g., [2]. Because the diffusion equation can be transformed into a family of Helmholtz equations by performing a Laplace transform with respect to the time variable, the solution of (1.1) also leads to the solution of the corresponding mixed boundary-value problem for the diffusion equation.

Another application of equation (1.1), for example, arises in the problem of computing the distortion of a two-dimensional plane wave diffracted by a slit [18, p. 284].

In the future, we plan to demonstrate that the theory presented in this paper also applies to some other physical problems involving the Helmholtz equation and to derive the corresponding ordinary differential equations.

Appendix. We show that for $p > 1$ the integral operator

$$M : L^p([-1,1]) \to L^p([-1,1]), \qquad Mg(x) = \int_{-1}^{1} g(y)H_0(k|x-y|)\,dy,$$

is injective.

In the following, we define the Fourier transform $h\hat{}$ of a function h by

$$h\hat{}(\rho) = \int_{\mathbb{R}} h(x)e^{-i\rho x}dx, \quad \rho \in \mathbb{R}.$$

From the Sommerfeld–Weyl integral

$$H_0(k\sqrt{x^2+y^2}) = \frac{1}{\pi}\int_{\mathbb{R}} \frac{e^{i(\sqrt{k^2-\rho^2}x+\rho y)}}{\sqrt{k^2-\rho^2}}\,d\rho, \quad x > 0,$$

with

$$\text{(A1)} \qquad \operatorname{Im} \sqrt{k^2 - \rho^2} > 0 \quad \text{if } \operatorname{Im} k > 0,$$

respectively,

$$\sqrt{k^2 - \rho^2} > 0 \quad \text{for } |\rho| < k \quad \text{and} \quad \operatorname{Im} \sqrt{k^2 - \rho^2} > 0 \quad \text{for } |\rho| > k, \quad \text{if } \operatorname{Im} k = 0$$

(see, e.g., [12, p. 823]), by letting $x \downarrow 0$, we see that (in the sense of tempered distributions)

$$\text{(A2)} \qquad H_0(k|\cdot|)\hat{\ }(\rho) = \frac{2}{\sqrt{k^2 - \rho^2}}, \quad \rho \in \mathbb{R}.$$

Now we assume that $g \in L^p([-1,1])$ for some $p > 1$ and $Mg \equiv 0$. We have to prove that $g \equiv 0$. To this end, we assume that the functions g and $f := Mg$ are defined on the whole real line by setting $g(x) = 0$ for $|x| > 1$ and defining f by (1.1) also for $|x| > 1$. Furthermore, because

$$L^r([-1,1]) \subset L^s([-1,1]) \quad \text{for } s < r,$$

we can assume that $p < 2$. (In the following, we shall make use of the theory of the Fourier transform on $L^p(\mathbb{R})$, $p < 2$, as it is given, e.g., in [14].)

Because of (A2), the Parseval formula [14, Theorem (6.4.2)] yields

$$f(x) = \int_{\mathbb{R}} g(y) H_0(k|x-y|)\, dy = \int_{\mathbb{R}} \frac{g\hat{\ }(\rho)}{\pi\sqrt{k^2 - \rho^2}} e^{i\rho x} d\rho, \quad x \in \mathbb{R}.$$

Because $g\hat{\ }$ is continuous and bounded on $\mathbb{R}$, the function $g\hat{\ }/(k^2 - \cdot^2)^{1/2}$ lies in $L^p(\mathbb{R})$. Hence repeated use of the Parseval formula leads to

$$\int_{\mathbb{R}} \frac{|g\hat{\ }(\rho)|^2}{\sqrt{k^2 - \rho^2}}\, d\rho = \int_{\mathbb{R}} \frac{g\hat{\ }(\rho)}{\sqrt{k^2 - \rho^2}} \overline{g\hat{\ }(\rho)}\, d\rho = \pi \int_{\mathbb{R}} f(x) \overline{g(x)}\, dx = 0.$$

The last equality holds because $f(x) = 0$ for $|x| \le 1$ and $g(x) = 0$ for $|x| > 1$. Together with (A1), it now follows that $g\hat{\ } \equiv 0$ and hence $g \equiv 0$.

Acknowledgment. The first author wants to thank his father, Professor Rudolf Gorenflo of the Department of Mathematics at the Free University of Berlin, for mathematical discussions and especially for making some important literature available.

MULTIVARIABLE BIG AND LITTLE q-JACOBI POLYNOMIALS[*]

JASPER V. STOKMAN[†]

Abstract. A four-parameter family of multivariable big q-Jacobi polynomials and a three-parameter family of multivariable little q-Jacobi polynomials are introduced. For both families, full orthogonality is proved with the help of a second-order q-difference operator which is diagonalized by the multivariable polynomials. A link is made between the orthogonality measures and R. Askey's q-extensions of Selberg's multidimensional beta-integrals.

Key words. big q-Jacobi polynomials, little q-Jacobi polynomials, BC_n-type Askey–Wilson polynomials, multivariable orthogonal polynomials, q-extensions of Selberg's multidimensional beta-integrals

1. Introduction.

In the one-variable case, big (resp. little) q-Jacobi polynomials depend apart from q on (essentially) three (resp. two) parameters. The big and little q-Jacobi polynomials are orthogonal with respect to inner products which are both given by a Jackson (q-) integral over a positive weight function. The associated orthogonality measures therefore have positive weights on infinitely many discrete mass points.

The one-variable big and little q-Jacobi polynomials are q-analogues of the classical Jacobi polynomials in the sense that when q tends to 1, the big and little q-Jacobi polynomials tend (up to a possible translation and dilation of the variable) to the classical Jacobi polynomials.

The families of one-variable big and little q-Jacobi polynomials are members of the Askey–Wilson hierarchy. The Askey–Wilson hierarchy consists of families of orthogonal polynomials which are joint eigenfunctions of a second-order q-difference operator. Some families can be obtained from others by limit transitions or by specializations of parameters. This induces the hierarchy structure between the families. In this point of view, the four-parameter family of Askey–Wilson polynomials is on top of the hierarchy and the families of big (resp. little) q-Jacobi polynomials are directly below the Askey–Wilson polynomials. Suitable limit transitions are known from the Askey–Wilson polynomials to the big (resp. little) q-Jacobi polynomials (cf. [12]). Furthermore, the little q-Jacobi polynomials can be obtained from the big q-Jacobi polynomials by a suitable limit transition.

Recently, Koornwinder introduced in [11] a multivariable (BC_n-type) generalization of the family of Askey–Wilson polynomials by extending the three-parameter family of Macdonald polynomials of type (BC_n, B_n) to a five-parameter family of orthogonal polynomials. Four of these parameters play the same role as in the one-variable case, while the fifth parameter is an extra deformation parameter. The BC_n-type Askey–Wilson polynomials are again joint eigenfunctions of a second q-difference operator. Koornwinder remarked in [11] that the whole Askey–Wilson hierarchy could probably be generalized to the BC_n case as well as the limit transitions between the families.

In this paper, a four-parameter family of multivariable BC_n-type big q-Jacobi polynomials and a three-parameter family of multivariable BC_n-type little q-Jacobi polynomials are introduced which have the following properties:

(1) compared with the one-variable case, there is an extra deformation parameter involved;

(2) the multivariable big (resp. little) q-Jacobi polynomials are joint eigenfunctions of a second-order q-difference operator;

(3) the multivariable big (resp. little) q-Jacobi polynomials are mutually orthogonal with respect to an inner product, which is essentially given by a multidimensional Jackson integral over a positive weight function;

(4) in a paper by the author and Koornwinder (cf. [18]), limit transitions from multivariable Askey–Wilson polynomials to multivariable big (resp. little) q-Jacobi polynomials and from multivariable big q-Jacobi polynomials to multivariable little q-Jacobi polynomials are proved which generalize the limit transitions in the one-variable case, and it is proved that the multivariable big (resp. little) q-Jacobi polynomials are q-analogues of generalized Jacobi polynomials (see [19]) (which are related with BC_n-type Heckman–Opdam polynomials by a suitable change of variables).

This paper is organized as follows. In section 2, the definitions of big and little q-Jacobi polynomials in one variable are given. In section 3, we will consider two formal limits of the BC_n-type Askey–Wilson polynomials, which generalize the limits from Askey–Wilson polynomials to big (resp. little) q-Jacobi polynomials in the one-variable case. We will obtain two second-order q-difference operators D_B (resp. D_L), and in section 4, it will be proved that D_B and D_L are triangular with respect to the basis of monomial symmetric functions. In section 5, the multivariable big and little q-Jacobi polynomials will be introduced. We will use techniques introduced by Macdonald in [15] to prove full orthogonality of the polynomials. First, it will be proved that the big (resp. little) q-Jacobi polynomials are joint eigenfunctions of D_B (resp. D_L) by proving the self-adjointness of D_B (resp. D_L). Full orthogonality of the big (resp. little) q-Jacobi polynomials will then be a consequence of the fact that the eigenvalues are sufficiently different.

Furthermore, it will be shown in section 5 that for special values of the extra deformation parameter, the multidimensional Jackson integrals over the weight functions are essentially the q-extensions of Selberg's multidimensional beta-integrals which were introduced by Askey [3]. Askey's conjectured evaluations of these multidimensional Jackson integrals have recently been proved [6], [8], [10]. Section 6 contains some proofs which were omitted in section 5.

Notation and conventions. Throughout this paper, we work with a fixed $q \in (0,1)$. $\mathbb{N} = \{1, 2, \ldots\}$ denotes the natural numbers and $\mathbb{N}_0$ denotes the natural numbers together with 0. The convention will be used that $\prod_{i=l}^{k} a_i = 1$ if $k < l$ for $k, l \in \mathbb{N}_0$. If there is no confusion possible, the dependence on the parameters will be omitted in the formulas.

2. One variable big and little q-Jacobi polynomials.

Let $a, b \in \mathbb{R}$, $a < b$, and f be a function defined on the points $\{aq^k, bq^k \mid k \in \mathbb{N}_0\}$. Define the Jackson ($q$-) integral of f over $[a, b]$ by

$$\int_a^b f(x)\, d_qx := \int_0^b f(x)\, d_qx - \int_0^a f(x)\, d_qx,$$
$$\int_0^b f(x)\, d_qx := (1-q) \sum_{k=0}^{\infty} f(bq^k) bq^k,$$

provided that the infinite sums in the definition of the q-integral from 0 to a and in the definition of the q-integral from 0 to b are absolutely convergent. In the special case that $a = bq^{k+1}$ for some $k \in \mathbb{N}_0$, we have

$$\int_{bq^{k+1}}^{b} f(x)\, d_qx = (1-q) \sum_{m=0}^{k} f(bq^m) bq^m, \tag{2.1}$$

so we can then use (2.1) as definition of the q-integral from bq^{k+1} to b without worrying about convergence.

Define the q-shifted factorial by

$$(a;q)_b := \frac{(a;q)_\infty}{(q^b a;q)_\infty}, \qquad (a;q)_\infty := \prod_{k=0}^{\infty}(1-aq^k),$$

for $a \in \mathbb{C}$ and $b \in \mathbb{C}\backslash\mathbb{N}_0$ such that $q^b a \neq q^{-k}$ for all $k \in \mathbb{N}_0$. For $l \in \mathbb{N}_0$, we set $(a;q)_l := \prod_{k=0}^{l-1}\left(1-aq^k\right)$. Denote

$$(a_1, \ldots, a_r; q)_b := \prod_{j=1}^{r} (a_j;q)_b\,.$$

Let $c, d > 0$, $a \in (-c/dq, 1/q)$, and $b \in (-d/cq, 1/q)$ or $a = cz$ and $b = -d\bar{z}$ with $z \in \mathbb{C} \setminus \mathbb{R}$. Denote V_B^q for the set of parameters (a,b,c,d) which satisfy these conditions. Define

$$w_B(x;a,b,c,d;q) := \frac{(qx/c, -qx/d;q)_\infty}{(qax/c, -qbx/d;q)_\infty}; \tag{2.2}$$

then $w_B(x;a,b,c,d;q)$ is positive for $x \in [-d,c]$, and

$$\langle f,g\rangle_{B,1,q}^{a,b,c,d} := \int_{-d}^{c} f(x)g(x)w_B(x;a,b,c,d;q)\, d_qx, \quad f,g \in \mathbb{R}[x], \tag{2.3}$$

is a well-defined inner product on $\mathbb{R}[x]$.

Definition 2.1. *The big q-Jacobi polynomials* $\{P_m(x;a,b,c,d;q)\,|\, m \in \mathbb{N}_0\}$ *are defined by the following two conditions:*

(1) $P_m(x)$ *is a monic polynomial of degree* m *in* x*;*

(2) $\langle P_m(x), x^l\rangle_{B,1} = 0$ *if* $l < m$.

Consequently, the big q-Jacobi polynomials are mutually orthogonal with respect to $\langle\,.\,,\,.\,\rangle_{B,1}$. Explicit expressions for the big q-Jacobi polynomials are given by

$$P_m(x;a,b,c,d;q) = \frac{(qa;q)_m\,(-qad/c;q)_m}{(q^{m+1}ab;q)_m\,(qa/c)^m}\,{}_3\phi_2\left[\begin{matrix} q^{-m}, q^{m+1}ab, qxa/c \\ qa, -qad/c\end{matrix}; q, q\right],$$

with the q-hypergeometric series defined by

$${}_{r+1}\phi_r\left[\begin{matrix} a_1, \ldots, a_{r+1} \\ b_1, \ldots, b_r\end{matrix}; q, z\right] := \sum_{k=0}^{\infty} \frac{(a_1, \ldots, a_{r+1};q)_k\, z^k}{(b_1, \ldots, b_r, q;q)_k}$$

(cf. [2]).

Note that $P_m(x;a,b,c/d,1;q) = d^{-m}P_m(dx;a,b,c,d;q)$, so the big q-Jacobi polynomials depend (apart from q) essentially on a, b, and the ratio c/d. The second-order q-difference operator

$$\begin{aligned}(2.4)\quad \left(D_{1,q}^{a,b,c,d}f\right)(x) := q\left(a-\frac{c}{qx}\right)\left(b+\frac{d}{qx}\right)(f(qx)-f(x)) \\ +\left(1-\frac{c}{x}\right)\left(1+\frac{d}{x}\right)\left(f(q^{-1}x)-f(x)\right) \quad (f\in\mathbb{R}[x])\end{aligned}$$

is diagonalized by the big q-Jacobi polynomials

$$(2.5)\qquad \left(D_{1,q}^{a,b,c,d}P_m(\,.\,;a,b,c,d;q)\right)(x) = a_m^{a,b,q}P_m(x;a,b,c,d;q) \quad \forall m\in\mathbb{N}_0$$

with eigenvalues

$$(2.6)\qquad a_m^{a,b,q} := qab(q^m-1)+(q^{-m}-1).$$

Note that D_1 is self-adjoint with respect to $\langle\,.\,,\,.\,\rangle_{B,1}$ because $\{P_m(x)\,|\,m\in\mathbb{N}_0\}$ is an orthogonal basis of $\mathbb{R}[x]$ with respect to $\langle\,.\,,\,.\,\rangle_{B,1}$ which consists of eigenfunctions of D_1.

The little q-Jacobi polynomials can be introduced in a similar way. Let $0<a<1/q$ and $b<1/q$, and denote by V_L^q the set of parameters (a,b) which satisfy these conditions. Define

$$(2.7)\qquad v_L(x;a,b;q) := \frac{(qx;q)_\infty}{(qbx;q)_\infty}x^\alpha \quad (a=q^\alpha);$$

then $v_L(x;a,b;q)$ is positive for $x\in[0,1]$ and

$$(2.8)\qquad \langle f,g\rangle_{L,1,q}^{a,b} := \int_0^1 f(x)g(x)v_L(x;a,b;q)\,d_qx, \quad f,g\in\mathbb{R}[x],$$

is an inner product on $\mathbb{R}[x]$.

Definition 2.2. *The little q-Jacobi polynomials $\{p_m(x;a,b;q)\,|\,m\in\mathbb{N}_0\}$ are defined by the following two conditions:*

(1) $p_m(x)\in\mathbb{R}[x]$ *is a monic polynomial of degree m in x;*

(2) $\langle p_m(x),x^l\rangle_{L,1}=0$ *if $l<m$.*

Consequently, the little q-Jacobi polynomials are mutually orthogonal with respect to $\langle\,.\,,\,.\,\rangle_{L,1}$. Explicit expressions for the little q-Jacobi polynomials are given by

$$p_m(x;a,b;q) := \frac{(-1)^m q^{\binom{m}{2}}(qa;q)_m}{(q^{m+1}ab;q)_m}\,{}_2\phi_1\left[\begin{matrix}q^{-m},q^{m+1}ab\\ qa\end{matrix};q,qx\right]$$

(cf. [1]). The little q-Jacobi polynomials are eigenfunctions of the q-difference operator $D_{1,q}^{b,a,1,0}$ with the same eigenvalues as in the big q-Jacobi case ((2.5) and (2.6)):

$$(2.9)\qquad \left(D_{1,q}^{b,a,1,0}p_m(\,.\,;a,b;q)\right)(x) = a_m^{a,b,q}p_m(x;a,b;q) \quad \forall m\in\mathbb{N}_0,$$

so $D_{1,q}^{b,a,1,0}$ is self-adjoint with respect to $\langle\,.\,,\,.\,\rangle_{L,1,q}^{a,b}$.

Remark 2.3. In this section, we defined the one-variable big and little q-Jacobi polynomials as monic polynomials because the multivariable generalizations will be monic. However, it is more common to normalize the big and little q-Jacobi polynomials differently. The big q-Jacobi polynomials are usually defined by

$$\tilde{P}_m(x;a,b,c,d;q) = {}_3\phi_2\left[\begin{matrix} q^{-m}, q^{m+1}ab, qxa/c \\ qa, -qad/c \end{matrix}; q, q\right]$$

and the little q-Jacobi polynomials are usually defined by

$$\tilde{p}_m(x;a,b;q) = {}_2\phi_1\left[\begin{matrix} q^{-m}, q^{m+1}ab \\ qa \end{matrix}; q, qx\right].$$

For more details about the one-variable big and little q-Jacobi polynomials, see [1], [2], [7], and [13].

3. Formal limits of multivariable Askey–Wilson polynomials. Let A be the algebra of Laurent polynomials in the independent indeterminates $x_1, \ldots, x_n$. The Weyl group W corresponding to the root system of type BC_n acts in a natural way on A. Let A^W be the subalgebra of A consisting of W-invariant Laurent polynomials. Let P^+ be the partitions of length $\leq n$, so

$$P^+ := \{\lambda = (\lambda_1, \ldots, \lambda_n) \,|\, \lambda_1 \geq \cdots \geq \lambda_n \geq 0\}. \tag{3.1}$$

W acts on $\mathbb{Z}^n$ by sign changes and permutations of the coordinates. The monomials $\{\tilde{m}_\lambda \,|\, \lambda \in P^+\}$, with $\tilde{m}_\lambda := \sum_{\mu \in W\lambda} x^\mu$, form a basis of A^W. Let $a, b, c, d, t \in \mathbb{C}$ and define the weight function $\delta(x;a,b,c,d;q,t)$ by

$$\delta(x_1, \ldots, x_n) := \delta^+(x_1, \ldots, x_n)\delta^+(x_1^{-1}, \ldots, x_n^{-1}),$$

$$\delta^+(x) := \prod_{i=1}^n \frac{(x_i^2;q)_\infty}{(ax_i, bx_i, cx_i, dx_i;q)_\infty} \prod_{1\leq k<l\leq n} \frac{(x_kx_l^{-1}, x_kx_l;q)_\infty}{(tx_kx_l^{-1}, tx_kx_l;q)_\infty}.$$

Assume that $|a|, |b|, |c|, |d| \leq 1$ and that if a, b, c, and d are complex, then they appear in conjugate pairs. Assume furthermore that the pairwise products of a, b, c, and d are not equal to 1. Denote $du := du_1 \cdots du_n$ and $e^{iu} := (e^{iu_1}, \ldots, e^{iu_n})$. Suppose that $t \in (0,1)$; then

$$\langle f, g\rangle_{AW,t} := \int \cdot\cdot \int_{[-\pi,\pi]^n} f(e^{iu})\overline{g(e^{iu})}\delta(e^{iu};t)du, \quad f, g \in A^W,$$

is an Hermitian inner product on A^W. Define a partial order on P^+ in the following way: $\mu, \lambda \in P^+$. Then

$$\mu \leq \lambda \Leftrightarrow \sum_{j=1}^i \mu_j \leq \sum_{j=1}^i \lambda_j, \quad i = 1, \ldots, n. \tag{3.2}$$

Remark 3.1. For the root system $R = R^+ \cup (-R^+)$ of type BC_n, choose the positive roots R^+ by

$$R^+ = \{e_i\}_{i=1}^n \cup \{e_i \pm e_j\}_{1\leq i<j\leq n} \cup \{2e_i\}_{i=1}^n, \tag{3.3}$$

where $\{e_i\}_{i=1}^n$ is the standard orthonormal basis for $\mathbb{R}^n$, then P^+ coincides with the set of dominant weights, and $\lambda > \mu$ for $\lambda, \mu \in P^+$ iff $\lambda - \mu$ is a sum of positive roots (cf. [11]).

Definition 3.2. *Let $t \in (0,1)$. The Askey–Wilson polynomials*

$$\{Q_\lambda(x; a, b, c, d; q, t) \mid \lambda \in P^+\}$$

are defined by the following two conditions:

(1) $Q_\lambda(t) = \tilde{m}_\lambda + \sum_{\mu<\lambda;\mu\in P^+} c_{\lambda,\mu}(t)\tilde{m}_\mu$*, for certain* $c_{\lambda,\mu}(t) \in \mathbb{C}$*;*

(2) *if* $\mu < \lambda$ *and* $\mu \in P^+$*, then* $\langle Q_\lambda(t), \tilde{m}_\mu\rangle_{AW,t} = 0$.

Define a second-order q-difference operator $D_{AW,q,t}^{a,b,c,d}$ by

$$(D_{AW}f)(x) := \sum_{i=1}^n \big(\psi_i(x)(T_{q,i}f - f)(x) + \phi_i(x)\big(T_{q^{-1},i}f - f\big)(x)\big)$$

for $f \in A^W$, with

$$(T_{q,i}f)(x) := f(x_1, \ldots, x_{i-1}, qx_i, x_{i+1}, \ldots, x_n), \tag{3.4}$$

the q-shift in the ith component, and with $\psi_i(x; a, b, c, d; q, t)$ and $\phi_i(x; a, b, c, d; q, t)$ given by

$$\psi_i(x) := \frac{(1-ax_i)(1-bx_i)(1-cx_i)(1-dx_i)}{(1-x_i^2)(1-qx_i^2)} \prod_{l\neq i} \frac{(1-tx_ix_l)(1-tx_ix_l^{-1})}{(1-x_ix_l)(1-x_ix_l^{-1})}$$

$$\phi_i(x) := \psi_i(x_1^{-1}, \ldots, x_n^{-1}).$$

Koornwinder proved the following theorem in [11].

Theorem 3.3. *Let $t \in (0,1)$. Define $b_\lambda(a, b, c, d; q, t)$ for $\lambda \in P^+$ by*

$$b_\lambda := \sum_{j=1}^n \left(q^{-1}abcdt^{2n-j-1}(q^{\lambda_j} - 1) + t^{j-1}(q^{-\lambda_j} - 1)\right);$$

then $D_{AW,t}Q_\lambda(t) = b_\lambda(t)Q_\lambda(t)$ for all $\lambda \in P^+$ and $\langle Q_\lambda(t), Q_\mu(t)\rangle_{AW,t} = 0$ if $\lambda \neq \mu$.

For the one-variable case ($n = 1$), explicit expressions of the Askey–Wilson polynomials $\{Q_m(x; a, b, c, d; q) \mid m \in \mathbb{N}_0\}$ are given by

$$Q_m(x; a, b, c, d; q) = \frac{(ab, ac, ad; q)_m}{a^m\,(q^{m-1}abcd; q)_m}\,{}_4\phi_3\left[\begin{matrix} q^{-m}, q^{m-1}abcd, ax, ax^{-1} \\ ab, ac, ad \end{matrix}; q, q\right]$$

(cf. [4],[13]) and the following limit transitions hold:

$$\lim_{\epsilon\to 0}\left(\frac{\epsilon(cd)^{\frac12}}{q^{\frac12}}\right)^m Q_m\left(\frac{q^{\frac12}x}{\epsilon(cd)^{\frac12}}; \epsilon a(qd/c)^{\frac12}, \epsilon^{-1}(qc/d)^{\frac12}, -\epsilon^{-1}(qd/c)^{\frac12}, -\epsilon b(qc/d)^{\frac12}; q\right)$$
$$= P_m(x; a, b, c, d; q),$$

$$\lim_{\epsilon\to 0}\left(\frac{\epsilon}{q^{\frac12}}\right)^m Q_m\left(\frac{q^{\frac12}x}{\epsilon}; \epsilon q^{\frac12}b, \epsilon^{-1}q^{\frac12}, -q^{\frac12}, -q^{\frac12}a; q\right) = p_m(x; a, b; q).$$

(See [12, Propositions 6.1 and 6.2] and take into account that the Askey–Wilson polynomials used in those limit transitions are written as function of $(x+x^{-1})/2$ and that the polynomials used in [12] are not monic.)

The most obvious generalizations of these two limits to the n-variable case give two new second-order q-difference operators and a new set of eigenvalues.

Let $x=(x_1,\ldots,x_n)$ and denote $cx:=(cx_1,\ldots,cx_n)$ for $c\in\mathbb{C}$; then we have the following limits for the big q-Jacobi case:

$$\begin{aligned}\lim_{\epsilon\to 0}\psi_i&\left(\frac{q^{\frac12}x}{\epsilon(cd)^{\frac12}};\epsilon a(qd/c)^{\frac12},\epsilon^{-1}(qc/d)^{\frac12},-\epsilon^{-1}(qd/c)^{\frac12},-\epsilon b(qc/d)^{\frac12};q,t\right)\\&=h_i(x;a,b,c,d;q,t),\end{aligned}$$

with $h_i(x;a,b,c,d;q,t)$ given by

$$h_i(x;a,b,c,d;q,t):=qt^{n-1}\Big(a-\frac{c}{qx_i}\Big)\Big(b+\frac{d}{qx_i}\Big)\prod_{l\neq i}\frac{x_l-tx_i}{x_l-x_i},\tag{3.5}$$

$$\begin{aligned}\lim_{\epsilon\to 0}\phi_i&\left(\frac{q^{\frac12}x}{\epsilon(cd)^{\frac12}};\epsilon a(qd/c)^{\frac12},\epsilon^{-1}(qc/d)^{\frac12},-\epsilon^{-1}(qd/c)^{\frac12},-\epsilon b(qc/d)^{\frac12};q,t\right)\\&=g_i(x;c,d;q,t)\end{aligned}$$

with $g_i(x;c,d;q,t)$ given by

$$g_i(x;c,d;q,t):=\Big(1-\frac{c}{x_i}\Big)\Big(1+\frac{d}{x_i}\Big)\prod_{l\neq i}\frac{x_i-tx_l}{x_i-x_l},\tag{3.6}$$

and

$$\lim_{\epsilon\to 0}b_\lambda\left(\epsilon a(qd/c)^{\frac12},\epsilon^{-1}(qc/d)^{\frac12},-\epsilon^{-1}(qd/c)^{\frac12},-\epsilon b(qc/d)^{\frac12};q,t\right)=a_\lambda(a,b;q,t),$$

with

$$a_\lambda(a,b;q,t):=\sum_{j=1}^{n}\big(qabt^{2n-j-1}(q^{\lambda_j}-1)+t^{j-1}(q^{-\lambda_j}-1)\big).\tag{3.7}$$

For the little q-Jacobi case, we have the following limits:

$$\lim_{\epsilon\to 0}\psi_i\left(\frac{q^{\frac12}x}{\epsilon};\epsilon q^{\frac12}b,\epsilon^{-1}q^{\frac12},-q^{\frac12},-q^{\frac12}a;q,t\right)=h_i(x;b,a,1,0;q,t),$$

$$\lim_{\epsilon\to 0}\phi_i\left(\frac{q^{\frac12}x}{\epsilon};\epsilon q^{\frac12}b,\epsilon^{-1}q^{\frac12},-q^{\frac12},-q^{\frac12}a;q,t\right)=g_i(x;1,0;q,t),$$

and

$$\lim_{\epsilon\to 0}b_\lambda\left(\epsilon q^{\frac12}b,\epsilon^{-1}q^{\frac12},-q^{\frac12},-q^{\frac12}a;q,t\right)=a_\lambda(a,b;q,t).$$

Therefore, define the q-difference operator $D^{a,b,c,d}_{n,q,t}$ by

$$(D_n f)(x) := \sum_{j=1}^{n} \big(h_j(x)(T_{q,j}f - f)(x) + g_j(x)\big(T_{q^{-1},j}f - f\big)(x)\big); \tag{3.8}$$

then D_{AW} tends to $D^{a,b,c,d}_{n,q,t}$ (resp. to $D^{b,a,1,0}_{n,q,t}$) in the two limits we have just considered, and the eigenvalues $\{b_\lambda(a,b,c,d;q,t)\,|\,\lambda \in P^+\}$ tend to $\{a_\lambda(a,b;q,t)\,|\,\lambda \in P^+\}$. For $n=1$, $D^{a,b,c,d}_{1,q,t}$ and $D^{b,a,1,0}_{1,q,t}$ correspond with the second-order q-difference operators for which the one-variable big (resp. little) q-Jacobi polynomials are joint eigenfunctions ((2.4) and (2.5) (resp. (2.9))), and $\{a_m(a,b;q,t)\,|\,m \in \mathbb{N}_0\}$ is exactly the corresponding set of eigenvalues (formula (2.6)). Therefore, we denote

$$D^{a,b,c,d}_{B,q,t} := D^{a,b,c,d}_{n,q,t} \tag{3.9}$$

and

$$D^{a,b}_{L,q,t} := D^{b,a,1,0}_{n,q,t}. \tag{3.10}$$

In section 5, we will see that the multivariable big (resp. little) q-Jacobi polynomials are joint eigenfunctions of D_B (resp. D_L) with eigenvalues $\{a_\lambda\,|\,\lambda \in P^+\}$. In [18], it is shown that the formal limit transitions of the second-order q-difference operator D_{AW} that we discussed in this section can be used to prove limit transitions from multivariable Askey–Wilson polynomials to multivariable big and little q-Jacobi polynomials.

Remark 3.4. Van Diejen mentioned similar limit transitions in [5] but did not look for eigenfunctions of the newly obtained q-difference operators. In his terminology, the limit transitions correspond to sending the center of mass in an n-particle-difference Calogero–Moser system with trigonometric potentials (Hamiltonian given by D_{AW}) to infinity.

4. Triangularity of the second-order q-difference operator $D^{a,b,c,d}_{n,q,t}$.

Note that

$$\Delta(x)^{-1}(T_{t,i}\Delta)(x) = \prod_{l\neq i} \frac{x_l - tx_i}{x_l - x_i}, \tag{4.1}$$

where $\Delta(x)$ is the Vandermonde determinant $\Delta(x) := \prod_{1\le i<j\le n}(x_i - x_j)$. Therefore, we can rewrite the second-order q-difference operator D_n (given by (3.8)) in the following form:

$$(D_n f)(x) = \Delta(x)^{-1}(\tilde{D}_n f)(x), \tag{4.2}$$

with

$$(\tilde{D}_n f)(x) := \sum_{i=1}^{n} \left(\tilde{h}_i(x)(T_{q,i}f - f)(x) + \tilde{g}_i(x)\big(T_{q^{-1},i}f - f\big)(x)\right), \tag{4.3}$$

$$\tilde{h}_i(x) = q\left(a - \frac{c}{qx_i}\right)\left(b + \frac{d}{qx_i}\right)t^{n-1}(T_{t,i}\Delta)(x), \tag{4.4}$$

$$\tilde{g}_i(x) = \left(1 - \frac{c}{x_i}\right)\left(1 + \frac{d}{x_i}\right)t^{n-1}\big(T_{t^{-1},i}\Delta\big)(x). \tag{4.5}$$

Denote $\mathbb{C}[x_1,\ldots,x_n]$ for the $\mathbb{C}$-algebra of polynomials in the variables $x_1,\ldots,x_n$. We have the following result.

Lemma 4.1.

$$\tilde{D}_n\left(\mathbb{C}[x_1,\ldots,x_n]\right)\subseteq\mathbb{C}[x_1,\ldots,x_n].$$

Proof. For $f\in\mathbb{C}[x_1,\ldots,x_n]$, define the backward partial q-derivative in the ith coordinate by

$$\left(D_q^{i,-}f\right)(x):=\frac{(f-T_{q,i}f)(x)}{(1-q)x_i}.$$

Note that $D_q^{i,-}$ maps $\mathbb{C}[x_1,\ldots,x_n]$ into itself. Now it can easily be checked that

$$(\tilde{D}_nf)(x)=\sum_{j=1}^{n}\left(A_j(x)\left(T_{q^{-1},j}\left(\left(D_q^{j,-}\right)^2f\right)\right)(x)+B_j(x)\left(T_{q^{-1},j}\left(D_q^{j,-}f\right)\right)(x)\right),$$

with

$$A_j(x)=(1-q)^2q^{-2}(qax_j-c)(qbx_j+d)t^{n-1}(T_{t,j}\Delta)(x),$$

$$\begin{aligned}B_j(x)=\frac{(1-q)}{q}t^{n-1}\Bigg(&\left(x_j+(d-c)-\frac{cd}{x_j}\right)(T_{t^{-1},j}\Delta)(x)\\&-\left(q^2abx_j+(qad-qbc)-\frac{cd}{x_j}\right)(T_{t,j}\Delta)(x)\Bigg).\end{aligned}$$

The lemma follows because $\left((T_{t,j}-T_{t^{-1},j})\Delta\right)(x)\in\mathbb{C}[x_1,\ldots,x_n]$ is divisible by x_j in $\mathbb{C}[x_1,\ldots,x_n]$. □

Let S_n be the permutation group of $\{1,\ldots,n\}$. S_n acts on $\mathbb{C}[x_1,\ldots,x_n]$ by permutation of the variables $x_1,\ldots,x_n$. Denote $\mathbb{C}[x_1,\ldots,x_n]^{S_n}$ for the subalgebra (over $\mathbb{C}$) of symmetric polynomials.

For $\lambda\in P^+$, define the symmetric monomial function m_λ by $m_\lambda(x):=\sum_{\mu\in S_n\lambda}x^\mu$, with $x^\mu:=x_1^{\mu_1}\ldots x_n^{\mu_n}$ and $w\lambda:=(\lambda_{w^{-1}(1)},\ldots,\lambda_{w^{-1}(n)})$. Then $\{m_\lambda\,|\,\lambda\in P^+\}$ is a $\mathbb{C}$-basis for $\mathbb{C}[x_1,\ldots,x_n]^{S_n}$.

A second basis is given by the Schur functions $\{s_\lambda\,|\,\lambda\in P^+\}$, where

$$s_\lambda(x):=\Delta(x)^{-1}\sum_{w\in S_n}\det(w)x^{w(\lambda+\delta)},$$

where $\det(w)$ is the determinant of the linear map $w:\mathbb{R}^n\to\mathbb{R}^n$ given by $w(e_i):=e_{w(i)}$ $(i=1,\ldots,n)$ for an arbitrary basis $\{e_1,\ldots,e_n\}$ of $\mathbb{R}^n$, and where

$$\delta:=(n-1,n-2,\ldots,1,0)\in P^+. \tag{4.6}$$

Let $\lambda\in P^+$; then

$$s_\lambda=m_\lambda+\sum_{\mu<\lambda;\mu\in P^+}c_{\lambda,\mu}m_\mu \tag{4.7}$$

for certain $c_{\lambda,\mu}\in\mathbb{R}$. See [17] for more details about Schur functions.

PROPOSITION 4.2. *Let $a, b, c, d, t \in \mathbb{C}$ and $\lambda \in P^+$. Then*

$$D_n m_\lambda = a_\lambda m_\lambda + \sum_{\mu<\lambda;\mu\in P^+} d_{\lambda,\mu} m_\mu$$

for certain $d_{\lambda,\mu} \in \mathbb{C}$, with $a_\lambda = a_\lambda(a, b; q, t)$ given by (3.7). *$d_{\lambda,\mu}$ and a_λ depend polynomially on $a, b, c, d,$ and t.*

Proof. Let $e_1, \ldots, e_n$ be the standard basis of $\mathbb{R}^n$ and $\langle\, .\,,\, .\,\rangle$ be the standard inner product on $\mathbb{R}^n$. Let S_n act on $\mathbb{R}^n$ by permutation of the basis $\{e_1, \cdots, e_n\}$. Define

$$\tilde{P} := \{\lambda = (\lambda_1, \ldots, \lambda_n) \in \mathbb{Z}^n \,|\, \lambda_1 \geq \cdots \geq \lambda_n\},$$

and give $\tilde{P}$ the same partial order as P^+ (see (3.2)). For $\mu \in \mathbb{Z}^n$, define

$$J_\mu := \sum_{w\in S_n} \det(w) x^{w\mu}.$$

Then $J_\mu = 0$ unless $\mu = w(\nu + \delta)$ for certain $w \in S_n$ and $\nu \in \tilde{P}$, and in that case, we have $J_\mu = \det(w) J_{\nu+\delta}$. Write $\tilde{D}_n = \psi_+ + \psi_-$ with

$$(\psi_+ f)(x) := \sum_{j=1}^{n} \tilde{h}_j(x)(T_{q,j} f - f)(x), \qquad (\psi_- f)(x) := \sum_{j=1}^{n} \tilde{g}_j(x)(T_{q^{-1},j} f - f)(x).$$

Let $S_n^\lambda \subseteq S_n$ be the stabilizer of $\lambda \in P^+$, so $S_n^\lambda := \{w \in S_n \,|\, w\lambda = \lambda\}$. Denote $T_{q,e_i} := T_{q,i}$ and $\sigma := e_1 = (1, 0, \ldots, 0) \in \mathbb{R}^n$. Using the fact that

$$\Delta(x) = \sum_{w\in S_n} \det(w) x^{w\delta}$$

and

$$m_\lambda(x) = |S_n^\lambda|^{-1} \sum_{v\in S_n} x^{v\lambda} \quad (\lambda \in P^+),$$

we obtain, for $\lambda \in P^+$,

$$\begin{aligned}
(\psi_+ m_\lambda)(x) &= \frac{1}{(n-1)!} \sum_{u\in S_n} q t^{n-1} \left(a - \frac{c}{q} x^{-u\sigma}\right) \left(b + \frac{d}{q} x^{-u\sigma}\right) (T_{t,u\sigma}\Delta)(x) \\
&\quad \times (T_{q,u\sigma} m_\lambda - m_\lambda)(x) \\
&= \frac{1}{(n-1)!|S_n^\lambda|} \sum_{u,v,w\in S_n} q t^{n-1} \left(a - \frac{c}{q} x^{-u\sigma}\right) \left(b + \frac{d}{q} x^{-u\sigma}\right) \det(w) \\
&\quad \times t^{\langle u\sigma, w\delta\rangle} (q^{\langle u\sigma, v\lambda\rangle} - 1) x^{w\delta + v\lambda} \\
&= \frac{1}{(n-1)!|S_n^\lambda|} \sum_{u',v'\in S_n} t^{\langle \sigma, v'\delta+\delta\rangle} (q^{\langle \sigma, v'u'\lambda\rangle} - 1) \left(qab \sum_{w\in S_n} \det(w) x^{w(\delta+u'\lambda)} \right. \\
&\left. + (ad - bc) \sum_{w\in S_n} \det(w) x^{w(\delta+u'\lambda-v'^{-1}\sigma)} - \frac{cd}{q} \sum_{w\in S_n} \det(w) x^{w(\delta+u'\lambda-2v'^{-1}\sigma)} \right).
\end{aligned}$$

The third equality is obtained by the substitution of $u' = w^{-1}v$ and $v' = u^{-1}w$. Similarly, we have

$$(\psi_- m_\lambda)(x) = \frac{1}{(n-1)!|S_n^\lambda|}\sum_{u',v'\in S_n} t^{\langle\sigma,\delta-v'\delta\rangle}(q^{-\langle\sigma,v'u'\lambda\rangle}-1)\Bigg(\sum_{w\in S_n}\det(w)x^{w(\delta+u'\lambda)}$$
$$+(d-c)\sum_{w\in S_n}\det(w)x^{w(\delta+u'\lambda-v'^{-1}\sigma)} - cd\sum_{w\in S_n}\det(w)x^{w(\delta+u'\lambda-2v'^{-1}\sigma)}\Bigg).$$

Let $w,u',v'\in S_n$ and $\lambda\in P^+$; then $w(\delta+u'\lambda)\le\delta+wu'\lambda\le\delta+\lambda$, and

$$w(\delta+u'\lambda)=\delta+\lambda \Leftrightarrow w=(1) \quad\text{and}\quad u'\in S_n^\lambda.$$

Furthermore, we have $w(\delta+u'\lambda-v'^{-1}\sigma)\le\delta+wu'\lambda-wv'^{-1}\sigma<\delta+wu'\lambda\le\delta+\lambda$ and $w(\delta+u'\lambda-2v'^{-1}\sigma)<\delta+\lambda$. Thus

$$\psi_\epsilon m_\lambda = \alpha_\lambda^\epsilon J_{\lambda+\delta} + \sum_{\mu<\lambda;\mu\in\tilde{P}}\beta_{\lambda,\mu}^\epsilon J_{\mu+\delta}, \quad \epsilon=\pm,$$

with $\beta_{\mu,\lambda}^\epsilon\in\mathbb{C}$, $\alpha_\lambda^+=\sum_{i=1}^n qabt^{2n-i-1}(q^{\lambda_i}-1)$, and $\alpha_\lambda^-=\sum_{i=1}^n t^{i-1}(q^{-\lambda_i}-1)$. Lemma 4.1 implies

$$\tilde{D}_n m_\lambda = \psi_+ m_\lambda + \psi_- m_\lambda = a_\lambda J_{\lambda+\delta} + \sum_{\mu<\lambda;\mu\in P^+} c_{\lambda,\mu}J_{\mu+\delta} \quad (\lambda\in P^+)$$

for certain $c_{\lambda,\mu}\in\mathbb{C}$. Formula (4.7) gives now the triangularity property.

Finally, note that the coefficients of J_ν ($\nu\in P^+$) in the expressions for $\psi_+ m_\lambda$ and $\psi_- m_\lambda$ depend polynomially on a,b,c,d, and t. Therefore, the coefficients of $D_n m_\lambda$ with respect to the basis of monomial symmetric functions depend polynomially on a,b,c,d, and t. □

5. Multivariable big and little *q*-Jacobi polynomials. The $\mathbb{R}$-algebra of symmetric polynomials in $x_1,\dots,x_n$ will be denoted by $\mathcal{A}^{\mathcal{S}}$, so $\mathcal{A}^{\mathcal{S}}:=\mathbb{R}[x_1,\dots,x_n]^{S_n}$. We first define inner products $\langle\,.\,,\,.\,\rangle_{B,n,q,t}^{a,b,c,d}$ and $\langle\,.\,,\,.\,\rangle_{L,n,q,t}^{a,b}$ on $\mathcal{A}^{\mathcal{S}}$, which generalize the inner products $\langle\,.\,,\,.\,\rangle_{B,1}$ and $\langle\,.\,,\,.\,\rangle_{L,1}$ ((2.3) and (2.8)) to the multivariable case.

For the big q-Jacobi case, we fix some $(a,b,c,d)\in V_B^q$ unless otherwise stated (V_B^q is defined in section 2). Define a symmetric bilinear form $\langle\,.\,,\,.\,\rangle_{B,n,q,t}^{a,b,c,d}$ for $t\in(0,1)$ on $\mathcal{A}^{\mathcal{S}}$ by

$$\langle f,g\rangle_{B,t} := \sum_{j=0}^n \langle f,g\rangle_{j,B,t}, \quad f,g\in\mathcal{A}^{\mathcal{S}}, \tag{5.1}$$

with $\langle f,g\rangle_{j,B,t}$ given by the following multidimensional Jackson integral:

$$\int_{x_1=0}^{c}\int_{x_2=0}^{tx_1}\cdots\int_{x_j=0}^{tx_{j-1}}\int_{x_{j+1}=-dt^{n-j-1}}^{0}\int_{x_{j+2}=-dt^{n-j-2}}^{qt^{-1}x_{j+1}} \tag{5.2}$$
$$\cdots\int_{x_n=-d}^{qt^{-1}x_{n-1}} f(x)g(x)w_j(x;t)d_qx,$$

with $d_qx := d_qx_n \cdots d_qx_1$ and the weight function $w_j(x;a,b,c,d;q,t)$ given by

$$w_j(x;t) := d_j^\tau \left(\prod_{i=1}^{n} \frac{(qx_i/c, -qx_i/d;q)_\infty}{(qax_i/c, -qbx_i/d;q)_\infty} \right) \Delta_\tau^j(x), \tag{5.3}$$

with $t = q^\tau$ and

$$\begin{aligned} \Delta_\tau^j(x) := \Delta(x) &\left(\prod_{\substack{1 \le k < m \le n \\ k \le j}} |x_k|^{2\tau-1} \left(q^{1-\tau} \frac{x_m}{x_k}; q \right)_{2\tau-1} \right) \\ &\times \prod_{j<k<m\le n} |x_m|^{2\tau-1} \left(q^{1-\tau} \frac{x_k}{x_m}; q \right)_{2\tau-1} \end{aligned} \tag{5.4}$$

and with $d_j^\tau = d_j^\tau(c,d)$ a positive constant given by

$$d_j^\tau := \prod_{\substack{1 \le k < m \le n \\ k \le j}} |y_{mk}|^{2\tau-1} \frac{(q^{1-\tau} y_{mk}^{-1};q)_{2\tau-1}}{(q^{1-\tau} y_{mk};q)_{2\tau-1}}, \quad y_{mk} := \frac{-d}{c} q^{(n-m-k+1)\tau}. \tag{5.5}$$

In view of (2.1), we have that the measure associated with $\langle \, . \, , \, . \, \rangle_{j,B}$ has infinitely many discrete mass points given by the set

$$\begin{aligned} W_B^j := \{(x_1, \ldots, x_n) \,|\, & x_i = cq^{(i-1)\tau + k_i} \text{ if } i \le j \text{ and } 0 \le k_1 \le \cdots \le k_j, \\ & x_i = -dq^{(n-i)\tau + k_i} \text{ if } i > j \text{ and } 0 \le k_n \le \cdots \le k_{j+1}\}. \end{aligned} \tag{5.6}$$

We have that $w_j(x;t) > 0$ for all $x \in W_B^j(t)$ and all $t \in (0,1)$. Indeed, we only need to check that Δ_τ^j is positive because $(a,b,c,d) \in V_B^q$. For Δ_τ^j, it is easily checked that the terms of the form

$$\left(q^{1-\tau} x_p/x_r;q\right)_{2\tau-1} = \frac{\left(q^{1-\tau} x_p/x_r;q\right)_\infty}{\left(q^{\tau} x_p/x_r;q\right)_\infty}$$

are positive on the mass points since both the numerator and the denominator are positive on the mass points. Furthermore, note that for $x \in W_B^j$ we have the inequalities $x_1 > \cdots > x_n$, so the Vandermonde determinant $\Delta(x)$ is positive for $x \in W_B^j$. Finally, it can be shown that w_j is bounded on W_B^j (in fact, we will see in the proof of Proposition 5.5 (section 6) that $w_j(x;q^\tau)$ is uniformly bounded on the set $\{(x,\tau) \,|\, \tau \in K, x \in W_B^j(q^\tau)\}$, with K an arbitrary compact subset of $(0,\infty)$), so $\langle \, . \, , \, . \, \rangle_{B,t}$ is a well-defined positive definite inner product for all $t \in (0,1)$.

For the little q-Jacobi case, we fix $(a,b) \in V_L^q$ unless otherwise stated (V_L^q is defined in section 2). Define a symmetric bilinear form $\langle \, . \, , \, . \, \rangle_{L,n,q,t}^{a,b}$ on $\mathcal{A}^\mathcal{S}$ by

$$\langle f,g \rangle_{L,t} := \int_{x_1=0}^{1} \int_{x_2=0}^{tx_1} \cdots \int_{x_n=0}^{tx_{n-1}} f(x)g(x)v(x;t) d_qx, \quad f,g \in \mathcal{A}^\mathcal{S}, \tag{5.7}$$

with the weight function $v(x;a,b;q,t)$ given by

$$v(x;t) := \left(\prod_{i=1}^{n} \frac{(qx_i;q)_\infty}{(qbx_i;q)_\infty} x_i^\alpha \right) \Delta_\tau(x) \quad (a = q^\alpha, t = q^\tau), \tag{5.8}$$

$$\Delta_\tau(x) := \Delta(x) \prod_{1 \le i < j \le n} |x_i|^{2\tau-1} \left(q^{1-\tau} \frac{x_j}{x_i}; q \right)_{2\tau-1}. \tag{5.9}$$

The measure associated with the inner product $\langle\, .\, ,\, .\,\rangle_L$ has infinitely many discrete mass points given by the set

$$W_L := \{(x_1, \ldots, x_n) \,|\, x_i = q^{(i-1)\tau + k_i} \text{ with } 0 \leq k_1 \leq \cdots \leq k_n\}. \tag{5.10}$$

By a similar argument as in the big q-Jacobi case, we have that $v(x;t) > 0$ for all $x \in W_L(t)$ and all $t \in (0,1)$ because $(a,b) \in V_L^q$. Furthermore, $v(x)(\prod_{i=1}^n x_i^{-\alpha})$ is bounded on W_L (we will see in the proof of Proposition 5.5 (section 6) that $v(x;q^\tau)(\prod_{i=1}^n x_i^{-\alpha})$ is uniformly bounded on $\{(x,\tau) \,|\, \tau \in K, x \in W_L(q^\tau)\}$, with K an arbitrary compact subset of $(0,\infty)$), so $\langle\, .\, ,\, .\,\rangle_{L,t}$ is well defined because $\alpha > -1$ and positive definite for all $t \in (0,1)$.

Definition 5.1. *Let $t \in (0,1)$. The big q-Jacobi polynomials*

$$\{P_\lambda^B(\,.\,; a, b, c, d; q, t) \,|\, \lambda \in P^+\}$$

are defined by the following two conditions: let $\lambda \in P^+$; then

(1) $P_\lambda^B(t) = m_\lambda + \sum_{\mu < \lambda; \mu \in P^+} c_{\lambda,\mu}(t) m_\mu$ *for some* $c_{\lambda,\mu}(t) \in \mathbb{R}$*;*

(2) $\langle P_\lambda^B(t)\,,\, m_\mu\rangle_{B,t} = 0$ *if* $\mu < \lambda$, $\mu \in P^+$.

Definition 5.2. *Let $t \in (0,1)$. The little q-Jacobi polynomials*

$$\{P_\lambda^L(\,.\,; a, b; q, t) \,|\, \lambda \in P^+\}$$

are defined by the following two conditions: let $\lambda \in P^+$; then

(1) $P_\lambda^L(t) = m_\lambda + \sum_{\mu < \lambda; \mu \in P^+} d_{\lambda,\mu}(t) m_\mu$ *for some* $d_{\lambda,\mu}(t) \in \mathbb{R}$*;*

(2) $\langle\, P_\lambda^L(t), m_\mu\,\rangle_{L,t} = 0$ *if* $\mu < \lambda$, $\mu \in P^+$.

For $n = 1$, the inner products $\langle\, .\, ,\, .\,\rangle_B$ and $\langle\, .\, ,\, .\,\rangle_L$ are the same as the inner products given by (2.3) and (2.8), respectively. Thus for $n = 1$, the big (resp. little) q-Jacobi polynomials given by Definition 5.1 (resp. Definition 5.2) are exactly the one-variable big (resp. little) q-Jacobi polynomials as defined in section 2 (Definition 2.1 (resp. Definition 2.2)).

Observe that the multivariable big q-Jacobi polynomials depend (apart from q) only on a, b, t, and the ratio c/d. Indeed, let $f \in \mathcal{A}^{\mathcal{S}}$ and define $f_d \in \mathcal{A}^{\mathcal{S}}$ by $f_d(x) := f(dx)$; then

$$\langle f, g\rangle_{B,n,q,t}^{a,b,c,d} = d^{2\tau\binom{n}{2}+n} \langle f_d, g_d\rangle_{B,n,q,t}^{a,b,\frac{c}{d},1}, \quad f, g \in \mathcal{A}^{\mathcal{S}},$$

because

$$\int_0^\alpha h(u) d_q u = \alpha \int_0^1 h(\alpha u) d_q u \quad (\alpha \neq 0), \tag{5.11}$$

and $d_j^\tau(c,d) = d_j^\tau(c/d, 1)$, so $w_j(dx; a, b, c, d; q, t) = d^{2\tau\binom{n}{2}} w_j(x; a, b, c/d, 1; q, t)$. Therefore, we have that

$$d^{-|\lambda|} P_\lambda^B(dx; a, b, c, d; q, t) = P_\lambda^B\left(x; a, b, \frac{c}{d}, 1; q, t\right), \quad \lambda \in P^+,$$

where $|\lambda| := \sum_{i=1}^n \lambda_i$.

Remark 5.3. If we compare the weight functions w_j with the function w given by

$$w(x) := \left(\prod_{i=1}^n \frac{(qx_i/c, -qx_i/d; q)_\infty}{(qax_i/c, -qbx_i/d; q)_\infty}\right) \tilde{\Delta}_\tau(x), \tag{5.12}$$

with

$$\tilde{\Delta}_\tau(x) := \Delta(x) \prod_{1\le i<j\le n} \operatorname{sgn}(x_i)|x_i|^{2\tau-1}\left(q^{1-\tau}\frac{x_j}{x_i};q\right)_{2\tau-1}, \tag{5.13}$$

and $\operatorname{sgn}(x_i)=1$ if $x_i\ge 0$ and $=-1$ if $x_i<0$, then we have that

$$\Delta_\tau^j(x) = \left(\prod_{k=1}^{j}\operatorname{sgn}(x_k)^{n-k}\right)\left(\prod_{j<k<m\le n}\operatorname{sgn}(x_k)\psi_\tau\left(\frac{x_m}{x_k}\right)\right)\tilde{\Delta}_\tau(x) \tag{5.14}$$

with the function ψ_τ given by

$$\psi_\tau(z) := |z|^{2\tau-1}\frac{\left(q^{1-\tau}z^{-1};q\right)_{2\tau-1}}{\left(q^{1-\tau}z;q\right)_{2\tau-1}}. \tag{5.15}$$

ψ_τ is a quasi-constant function, i.e., $\psi_\tau(qz)=\psi_\tau(z)$, so $w_j(x)=\phi_j(x)w(x)$ for some quasi-constant function ϕ_j ($T_{q,i}\phi_j=\phi_j$ for all i). The essential difference between $w(x)$ and $w_j(x)$ on W_B^j is that $w(x)$ can have poles on W_B^j, while $w_j(x)$ has no poles on W_B^j. Therefore, one can think of $\langle\,.\,,\,.\,\rangle_B$ as q-integration over the set of mass points $\cup_{j=0}^n W_B^j$ with respect to the weight function w, whereby one should resolve the poles of w on W_B^j when q-integrating over W_B^j by slightly modifying the weight function w (i.e., multiplying w with the quasi-constant function $d_j\phi_j$). The constants d_j in the definition of $w_j(x)$ will turn out to be crucial for the self-adjointness of D_B with respect to $\langle\,.\,,\,.\,\rangle_B$. Note that

$$d_j^\tau = \prod_{\substack{1\le k<m\le n\\ k\le j}}\psi_\tau(y_{mk}),\quad \text{with } y_{mk} := \frac{-d}{c}q^{(n-m-k+1)\tau}, \tag{5.16}$$

so d_j^τ can also be expressed in terms of the quasi-constant function ψ_τ.

The inner products simplify when $\tau=k\in\mathbb{N}$. In that case, we have that $w_j(x)=w(x)$ on W_B^j for $j=0,\ldots,n$ (with $w(x)$ given by (5.12)). This follows from (5.14) and (5.16) since $\psi_k(z)=-\operatorname{sgn}(z)$. Furthermore, it holds that

$$\tilde{\Delta}_k(x) = (-1)^{k\binom{n}{2}}q^{-\binom{k}{2}\binom{n}{2}}\prod_{l=0}^{k-1}\prod_{i\ne j}(x_i-q^lx_j), \tag{5.17}$$

so $\tilde{\Delta}_k(x)$ is symmetric, and $\tilde{\Delta}_k(x)=0$ if $x_i=q^lx_j$ for certain $i\ne j$ and certain $l\in\{0,\ldots,k-1\}$. Thus when $\tau=k\in\mathbb{N}$, we have, for $f,g\in\mathcal{A}^{\mathcal{S}}$,

$$\begin{aligned}\langle f,g\rangle_{B,q^k} &= \int_{x_1=-d}^{c}\int_{x_2=-d}^{x_1}\cdots\int_{x_n=-d}^{x_{n-1}} f(x)g(x)w(x;q^k)d_qx,\\ &= \frac{1}{n!}\int_{x_1=-d}^{c}\cdots\int_{x_n=-d}^{c} f(x)g(x)w(x;q^k)d_qx,\end{aligned} \tag{5.18}$$

$$\begin{aligned}\langle f,g\rangle_{L,q^k} &= \int_{x_1=0}^{1}\int_{x_2=0}^{x_1}\cdots\int_{x_n=0}^{x_{n-1}} f(x)g(x)v(x;q^k)d_qx\\ &= \frac{1}{n!}\int_{x_1=0}^{1}\cdots\int_{x_n=0}^{1} f(x)g(x)v(x;q^k)d_qx.\end{aligned} \tag{5.19}$$

Here we have used that the weight functions $w(x;q^k)$ and $v(x;q^k)$ are zero for $x=(x_1,\dots,x_n)$ with $x_i=x_j$ for some $1\leq i\neq j\leq n$, so if $x\in\mathbb{R}^n$ contributes to the support of the orthogonality measure, then the S_n orbit of $x\in\mathbb{R}^n$ has cardinality $n!$.

Finally, we may replace $w(x;a,b,c,d;q,q^k)$ in (5.18) by $\tilde{w}(x;a,b,c,d;q,q^k)$,

$$\tilde{w}(x)=\frac{n!}{\Gamma_{q^k}(n+1)}\left(\prod_{i=1}^{n}w_B(x_i)\right)\prod_{1\leq i<j\leq n}x_i^{2k}\left(q^{1-k}\frac{x_j}{x_i};q\right)_{2k},$$

and $v(x;a,b;q,q^k)$ in (5.19) by $\tilde{v}(x;a,b;q,q^k)$,

$$\tilde{v}(x)=\frac{n!}{\Gamma_{q^k}(n+1)}\left(\prod_{i=1}^{n}v_L(x_i)\right)\prod_{1\leq i<j\leq n}x_i^{2k}\left(q^{1-k}\frac{x_j}{x_i};q\right)_{2k},$$

with the q-gamma function $\Gamma_q(a)$ $(a\notin-\mathbb{N}_0)$ defined by

$$\Gamma_q(a):=\frac{(q;q)_{a-1}}{(1-q)^{a-1}},$$

because w and v are symmetric functions such that

$$\tilde{w}(x)=\frac{n!}{\Gamma_{q^k}(n+1)}w(x)\prod_{i<j}\frac{x_i-q^kx_j}{x_i-x_j},\qquad \tilde{v}(x)=\frac{n!}{\Gamma_{q^k}(n+1)}v(x)\prod_{i<j}\frac{x_i-q^kx_j}{x_i-x_j},$$

and

$$\sum_{w\in S_n}\prod_{i<j}\frac{x_{w(i)}-q^kx_{w(j)}}{x_{w(i)}-x_{w(j)}}=\Gamma_{q^k}(n+1)$$

(cf. [8, p. 1479]).

Remark 5.4. For $t=q^k$, $k\in\mathbb{N}$, $\langle 1,1\rangle_L$ and $\langle 1,1\rangle_B$ are (up to the constant $1/\Gamma_{q^k}(n{+}1)$) the q-extensions of Selberg's multidimensional beta-integrals, introduced by Askey [3]. Askey's conjectured evaluations of these multidimensional q-integrals have recently been proved.

Let $t=q^k$, $k\in\mathbb{N}$, $a=q^\alpha$, and $b=q^\beta$; then Habsieger [8] and Kadell [10] have independently proved that

$$\langle 1,1\rangle_L=q^{k(\alpha+1)\binom{n}{2}+2k^2\binom{n}{3}}\prod_{j=1}^{n}\frac{\Gamma_q(\alpha+1+(j-1)k)\Gamma_q(\beta+1+(j-1)k)\Gamma_q(jk)}{\Gamma_q(\alpha+\beta+2+(n+j-2)k)\Gamma_q(k)},$$

and Evans [6] has proved that

$$\begin{aligned}\langle 1,1\rangle_B=&q^{k^2\binom{n}{3}-\binom{k}{2}\binom{n}{2}}\prod_{j=1}^{n}\Big(\frac{\Gamma_q(\alpha+1+(j-1)k)\Gamma_q(\beta+1+(j-1)k)\Gamma_q(jk)}{\Gamma_q(\alpha+\beta+2+(n+j-2)k)\Gamma_q(k)}\\&\times\frac{(-d/c;q)_\infty(-c/d;q)_\infty(cd)^{1+(j-1)k}}{\big((-d/c)q^{\alpha+1+(j-1)k};q\big)_\infty\big((-c/d)q^{\beta+1+(j-1)k};q\big)_\infty(c+d)}\Big).\end{aligned}$$

The inner products $\langle\,.\,,\,.\,\rangle_{B,t}$ and $\langle\,.\,,\,.\,\rangle_{L,t}$ depend continuously on $t\in(0,1)$, in the following sense.

Proposition 5.5. *Let $f, g \in \mathcal{A}^{\mathcal{S}}$.*

(1) *$\langle f, g\rangle_{B,t}$ is continuous in t for $t \in (0,1)$.*

(2) *$\langle f, g\rangle_{L,t}$ is continuous in t for $t \in (0,1)$.*

We will omit the proof of the proposition in this section because it is rather long and technical. The proof will be given in section 6 (Proposition 6.1).

Let $\lambda \in P^+$. It is clear from the proof of Proposition 4.2, that the coefficients in the expansion of the symmetric polynomial $D^{a,b,c,d}_{n,q,t} m_\lambda$ with respect to the basis of monomials $\{m_\mu \,|\, \mu \in P^+\}$ are real for $(a,b,c,d) \in V^q_B$. Therefore, $D_B m_\lambda \in \mathcal{A}^{\mathcal{S}}$. Similarly, we have that $D_L m_\lambda \in \mathcal{A}^{\mathcal{S}}$.

Theorem 5.6. *Let $t \in (0,1)$.*

(1) *$D_{B,t}$ is self-adjoint with respect to $\langle\,.\,,\,.\,\rangle_{B,t}$.*

(2) *$D_{L,t}$ is self-adjoint with respect to $\langle\,.\,,\,.\,\rangle_{L,t}$.*

The proof will be given in section 6 (Theorem 6.5). The two essential ingredients for the proof are a special version of the q-partial integration rule (Lemma 6.4) and certain functional relations for the weight functions (Proposition 6.3). Self-adjointness is then a consequence of the fact that stock terms (which come from the q-partial integration rule) are zero or cancel. In the big q-Jacobi case, the specific positive constants d_j in the weight functions w_j are crucial for the cancellation of certain stock terms.

With the aid of Propositions 4.2 and 5.5 and Theorem 5.6, it is now straightforward to proof the main theorem. The proof is similar to proofs given by Macdonald in [15] and [16] (see also the second edition of [17]), and Koornwinder in [11].

Theorem 5.7. *Let $t \in (0,1)$.*

(1) *Let $\lambda \in P^+$; then*

$$D_{B,t} P^B_\lambda(t) = a_\lambda(t) P^B_\lambda(t),$$

with a_λ given by (3.7). *For $\lambda, \mu \in P^+$, we have*

$$\langle P^B_\lambda(t), P^B_\mu(t)\rangle_{B,t} = 0 \qquad \textit{if } \lambda \neq \mu.$$

(2) *Let $\lambda \in P^+$; then*

$$D_{L,t} P^L_\lambda(t) = a_\lambda(t) P^L_\lambda(t).$$

For $\lambda, \mu \in P^+$, we have

$$\langle P^L_\lambda(t), P^L_\mu(t)\rangle_{L,t} = 0 \qquad \text{if } \lambda \neq \mu.$$

Proof. (1) Proposition 4.2 and Theorem 5.6 imply that $P^B_\lambda(t)$ is an eigenfunction of $D_{B,t}$ with eigenvalue $a_\lambda(t)$. Fix $(a,b,c,d) \in V^q_B$, fix $\mu, \lambda \in P^+$, $\mu \neq \lambda$, and fix $t \in (0,1)$ such that $a_\lambda(a,b;q,t) \neq a_\mu(a,b;q,t)$. The self-adjointness of $D_{B,t}$ then gives that $\langle P^B_\lambda(t), P^B_\mu(t)\rangle_{B,t} = 0$. Note that $a_\lambda(a,b;q,t) \in \mathbb{R}[t]$ and $a_\lambda(a,b;q,t) = a_\mu(a,b;q,t)$ as polynomials in t iff $\lambda = \mu$ because $ab \notin \{q^{-2}, q^{-3}, \ldots\}$. Therefore, (1) will be proved if we prove that $\langle P^B_\lambda(t), P^B_\mu(t)\rangle_{B,t}$ is continuous in t for $t \in (0,1)$. This follows from Proposition 5.5. The proof of (2) is similar. □

For $t = 1$, define

$$\langle f, g\rangle_{B,n,1} := \lim_{t\uparrow 1} \langle f, g\rangle_{B,n,t}, \tag{5.20}$$

$$\langle f, g\rangle_{L,n,1} := \lim_{t\uparrow 1} \langle f, g\rangle_{L,n,t} \tag{5.21}$$

for $f, g \in \mathcal{A}^{\mathcal{S}}$, provided that the limits exist. We then have the following proposition.

Proposition 5.8. *$\langle\,.\,,\,.\,\rangle_{B,n,1}$ and $\langle\,.\,,\,.\,\rangle_{L,n,1}$ (defined by (5.20) and (5.21)) are well-defined inner products on $\mathcal{A}^{\mathcal{S}}$ and are explicitly given by*

$$\langle f, g\rangle_{B,n,1} = \frac{1}{n!}\int_{x_1=-d}^{c}\cdots\int_{x_n=-d}^{c} f(x)g(x)\left(\prod_{i=1}^{n} w_B(x_i)\right) d_qx, \tag{5.22}$$

$$\langle f, g\rangle_{L,n,1} = \frac{1}{n!}\int_{x_1=0}^{1}\cdots\int_{x_n=0}^{1} f(x)g(x)\left(\prod_{i=1}^{n} v_L(x_i)\right) d_qx \tag{5.23}$$

for $f, g \in \mathcal{A}^{\mathcal{S}}$. The corresponding multivariable big and little q-Jacobi polynomials (using Definitions 5.1 and 5.2 for $t = 1$) can be given explicitly in terms of the one-variable big and little q-Jacobi polynomials by the formulas ($\lambda \in P^+$)

$$P_\lambda^B(x; a, b, c, d; q, 1) = |S_n^\lambda|^{-1}\sum_{w\in S_n}\left(\prod_{i=1}^{n} P_{\lambda_{w^{-1}(i)}}(x_i; a, b, c, d; q)\right), \tag{5.24}$$

where P_n ($n \in \mathbb{N}_0$) are the one-variable big q-Jacobi polynomials (Definition 2.1) and $|S_n^\lambda| := \#\{w \in S_n \mid w\lambda = \lambda\}$, and

$$P_\lambda^L(x; a, b; q, 1) = |S_n^\lambda|^{-1}\sum_{w\in S_n}\left(\prod_{i=1}^{n} p_{\lambda_{w^{-1}(i)}}(x_i; a, b; q)\right), \tag{5.25}$$

where p_n ($n \in \mathbb{N}_0$) are the one-variable little q-Jacobi polynomials (Definition 2.2).

Proof. Fix $j \in \{0, \ldots, n\}$. The set of mass points $W_B^j(q^\tau)$ (given by (5.6)) is in one-to-one correspondence with

$$V_j := \{p = (p_1, \ldots, p_n) \mid 0 \le p_1 \le \cdots \le p_j,\ 0 \le p_n \le \cdots \le p_{j+1}\} \tag{5.26}$$

by the formula

$$x^{(j)}(p; \tau) = \left(cq^{p_1}, \ldots, cq^{(j-1)\tau+p_j}, -dq^{(n-j-1)\tau+p_{j+1}}, \ldots, -dq^{p_n}\right) \in W_B^j(q^\tau). \tag{5.27}$$

We first calculate $\lim_{\tau\downarrow 0}\Delta_\tau^j(x^{(j)}(p;\tau))$ for fixed $p \in V_j$, where $\Delta_\tau^j(x)$ is given by (5.4).

Rewrite Δ_τ^j as $\Delta_\tau^j = \rho_\tau^j D_\tau^j$ with

$$\rho_\tau^j(x) := \prod_{\substack{1\le i<k\le n\\ i\le j}}\frac{x_i - x_k}{x_i - q^\tau x_k}\prod_{j<l<m\le n}\frac{x_m - x_l}{x_m - q^\tau x_l} \tag{5.28}$$

and

$$D_\tau^j(x) := \prod_{\substack{1\le i<k\le n\\ i\le j}} x_i^{2\tau}\left(q^{1-\tau}\frac{x_k}{x_i}; q\right)_{2\tau}\prod_{j<l<m\le n}|x_m|^{2\tau}\left(q^{1-\tau}\frac{x_l}{x_m}; q\right)_{2\tau}. \tag{5.29}$$

For $p \in V_j$ and $\tau \in (0, \infty)$, define

$$g_{ik}^{(j)}(p,\tau) := \frac{(x_i^{(j)}(p;\tau) - x_k^{(j)}(p;\tau))}{(x_i^{(j)}(p;\tau) - q^\tau x_k^{(j)}(p;\tau))}; \tag{5.30}$$

then we can write ρ_τ^j, evaluated at the mass point $x^{(j)}(p;\tau)$, as

$$\rho_\tau^j(x^{(j)}(p;\tau)) = \prod_{\substack{1\le i<k\le n\\ i\le j}} g_{ik}^{(j)}(p,\tau) \prod_{j<l<m\le n} g_{ml}^{(j)}(p,\tau). \tag{5.31}$$

Let $p \in V_j$; then for $1 \le i < k \le n$ with $i \le j$, we have

$$g_{ik}^{(j)}(p,0) := \lim_{\tau\downarrow 0} g_{ik}^{(j)}(p,\tau) = \begin{cases} 1 & \text{if } x_i^{(j)}(p;0) \neq x_k^{(j)}(p;0), \\ \dfrac{k-i}{k-i+1} & \text{if } x_i^{(j)}(p;0) = x_k^{(j)}(p;0), \end{cases} \tag{5.32}$$

and for $j < l < m \le n$, we have

$$g_{ml}^{(j)}(p,0) := \lim_{\tau\downarrow 0} g_{ml}^{(j)}(p,\tau) = \begin{cases} 1 & \text{if } x_l^{(j)}(p;0) \neq x_m^{(j)}(p;0), \\ \dfrac{m-l}{m-l+1} & \text{if } x_l^{(j)}(p;0) = x_m^{(j)}(p;0). \end{cases} \tag{5.33}$$

Thus we have $\lim_{\tau\downarrow 0} \rho_\tau^j(x^{(j)}(p;\tau)) = n(x^{(j)}(p;0))$ with $n(x)$ defined by

$$n(x) := \prod_{\{1\le l<m\le n \,|\, x_l = x_m\}} \frac{m-l}{m-l+1}.$$

Fix $x \in \mathbb{R}^n$ with $x_1 \ge \cdots \ge x_n$, and denote $m(x) := \#\{w \in S_n \,|\, wx = x\}$. Let $(\lambda_1, \ldots, \lambda_p)$ be the sequence of natural numbers such that $\lambda_1 + \cdots + \lambda_p = n$ and such that

$$x_1 = \cdots = x_{\lambda_1} > x_{\lambda_1+1} = \cdots = x_{\lambda_1+\lambda_2} > \cdots > x_{\lambda_1+\cdots+\lambda_{p-1}+1} = \cdots = x_n.$$

Then we have

$$\begin{aligned} n(x) = \prod_{i=1}^p \left(\prod_{1\le l<m\le\lambda_i} \frac{m-l}{m-l+1} \right) &= \prod_{i=1}^p \left(\prod_{r=1}^{\lambda_i-1} (\frac{r}{r+1})^{\lambda_i - r} \right) \\ &= \prod_{i=1}^p \frac{1}{\lambda_i!} = \frac{1}{m(x)}. \end{aligned}$$

It follows that $\lim_{\tau\downarrow 0} \rho_\tau^j(x^{(j)}(p;\tau)) = 1/m(x^{(j)}(p;0))$ for all $p \in V_j$. Furthermore, it is easily checked that $\lim_{\tau\downarrow 0} D_\tau^j(x^{(j)}(p;\tau)) = 1$ for all $p \in V_j$. Hence we have

$$\lim_{\tau\downarrow 0} \Delta_\tau^j(x^{(j)}(p;\tau)) = 1/m(x^{(j)}(p;0)), \quad p \in V_j.$$

Furthermore, we have $\lim_{\tau\downarrow 0} d_j^\tau = 1$ (with d_j^τ given by (5.5)), so for every $p \in V_j$,

$$\lim_{\tau\downarrow 0} w_j(x^{(j)}(p;\tau); q^\tau) = \frac{1}{m(x^{(j)}(p;0))} \prod_{i=1}^n w_B(x_i^{(j)}(p;0))$$

with $w_j(x)$ given by (5.3). Write $\langle f, g\rangle_{j,B,q^\tau}$ as a sum over $p \in V_j$ using formula (5.27); then we will see in Proposition 6.1 that we are allowed to pull the limit $\tau \downarrow 0$ through the infinite sum. Thus we obtain

$$\begin{aligned} \lim_{\tau\downarrow 0} \langle f, g\rangle_{B,q^\tau} = \sum_{j=0}^n \int_{x_1=0}^c \int_{x_2=0}^{x_2} \cdots \int_{x_j=0}^{x_{j-1}} \int_{x_{j+1}=-d}^0 \int_{x_{j+2}=-d}^{qx_{j+1}} \\ \cdots \int_{x_n=-d}^{qx_{n-1}} f(x)g(x) \frac{1}{m(x)} \left(\prod_{i=1}^n w_B(x_i) \right) d_q x. \end{aligned} \tag{5.34}$$

(5.22) now follows by symmetrizing the right-hand side of this formula. Formula (5.24) then follows directly from the orthogonality of the one-variable big q-Jacobi polynomials. The proof of the proposition for the little q-Jacobi case is similar. □

Note that Theorems 5.6 and 5.7 are still valid for $t = 1$. The two theorems are easy consequences of the corresponding results in the one-variable case. For $t = 1$, both theorems also follow by a continuity argument in t from the corresponding theorems for $t \in (0, 1)$.

Similarly, we can express the multivariable big (resp. little) q-Jacobi polynomials for $t = q$ in terms of one-variable big (resp. little) q-Jacobi polynomials.

Proposition 5.9. *For $\lambda \in P^+$, define $\tilde{\lambda} \in P^+$ by $\tilde{\lambda} := \lambda + \delta$ (δ given by* (4.6)*).*

(1) *Let $(a, b, c, d) \in V_B^q$ and $\lambda \in P^+$; then*

$$P_\lambda^B(x; a, b, c, d; q, q) = \Delta(x)^{-1} \sum_{w \in S_n} \det(w) \left(\prod_{i=1}^n P_{\tilde{\lambda}_{w^{-1}(i)}}(x_i; a, b, c, d; q) \right).$$

(2) *Let $(a, b) \in V_L^q$ and $\lambda \in P^+$; then*

$$P_\lambda^L(x; a, b; q, q) = \Delta(x)^{-1} \sum_{w \in S_n} \det(w) \left(\prod_{i=1}^n p_{\tilde{\lambda}_{w^{-1}(i)}}(x_i; a, b; q) \right).$$

Proof. The proposition follows from (4.7), (5.17), (5.18), (5.19), and the orthogonality in the one variable case. □

The families of multivariable big (resp. little) q-Jacobi polynomials for $t = 1$ and $t = q$ are more or less the trivial families since full orthogonality of the multivariable big (resp. little) q-Jacobi polynomials for $t = 1$ and $t = q$ can easily be deduced from the orthogonality in the one-variable case. From this point of view, we can think of t as an extra (continuous) deformation parameter linking these two trivial families of multivariable big (resp. little) q-Jacobi polynomials.

6. Some proofs. In this section, we give the proofs that we omitted in section 5. We start with the proof of Proposition 5.5.

Proposition 6.1. *Let $f, g \in \mathcal{A}^{\mathcal{S}}$.*

(1) *$\langle f, g \rangle_{B,t}$ is continuous in t for $t \in (0, 1]$, where for $t = 1$, the inner product is given by* (5.22).

(2) *$\langle f, g \rangle_{L,t}$ is continuous in t for $t \in (0, 1]$, where for $t = 1$, the inner product is given by* (5.23).

Proof. It is sufficient to prove continuity in τ for $\tau \in [0, \infty)$ ($t = q^\tau$). If $h(z, \tau)$ is a function such that $h(uq^k, \tau)$ is continuous in $\tau \in [0, \infty)$ for all $k \in \mathbb{N}_0$ ($u \neq 0$), then

$$\int_0^u h(z, \tau) d_q z = (1 - q) \sum_{k=0}^\infty h(uq^k, \tau) uq^k$$

will be continuous in τ if for every compact subset K of $[0, \infty)$, there exists a $\epsilon_K < 1$ such that

$$\sup_{(k,\tau) \in \mathbb{N}_0 \times K} \left| q^{k\epsilon_K} h(uq^k, \tau) \right| < \infty.$$

For $\tau \in [0, \infty)$, define

$$w_j(x; q^\tau) := d_j^\tau \left(\prod_{i=1}^n w_B(x_i) \right) \Delta_\tau^j(x), \tag{6.1}$$

where d_j^τ is given by (5.5) and $\Delta_\tau^j(x) := \rho_\tau^j(x) D_\tau^j(x)$ for $\tau \in [0,\infty)$, with $D_j(x)$ defined by (5.29) for $\tau \in [0,\infty)$ and with $\rho_\tau^j(x)$ defined by (5.28) for $\tau \in (0,\infty)$ and $\rho_0^j(x) := m(x)^{-1}$ for $\tau = 0$ (where $m(x) := \{w \in S_n \,|\, wx = x\}$). The inner product $\langle\, . \,, \, . \,\rangle_{B,n,q^\tau}$ for $\tau \in [0,\infty)$ can now be given by formulas (5.1) and (5.2) if we use the weight function $w_j(x;q^\tau)$ given by (6.1). (Indeed, w_j is exactly the weight function (5.3) for $\tau > 0$, and for $\tau = 0$ we have $D_0^j(x) = 1$ and $d_j^0 = 1$, so it then follows from formula (5.34).)

Therefore, in the big q-Jacobi case, it will be sufficient to prove that for every $K \subset [0,\infty)$ compact and all $j \in \{0,\ldots,n\}$,

$$\sup_{(p,\tau)\in V_j\times K} \left|\Delta_\tau^j(x^{(j)}(p;\tau))\right| < \infty, \quad j = 0,\ldots,n,$$

with V_j and $x^{(j)}(p;\tau)$ defined by (5.26) and (5.27), respectively. (Clearly, $d_j^\tau(c,d,q)$ is continuous in τ for $\tau \in [0,\infty)$.)

Similarly, in the little q-Jacobi case, we can take (5.7) as the definition of $\langle\, . \,, \, . \,\rangle_{L,n,q^\tau}$ for all $\tau \in [0,\infty)$ if we take the function $v(x;1) := \bigl(\prod_{i=1}^n v_L(x_i)\bigr)\Delta_0(x)$ with $\Delta_0(x) := \rho_0^n(x) D_0^n(x) = m(x)^{-1}$ as the weight function for $\tau = 0$ in (5.7).

Thus in the little q-Jacobi case, it will be sufficient to prove that for arbitrary $K \subset [0,\infty)$ compact,

$$\sup_{(p,\tau)\in V_n\times K} |\Delta_\tau(\tilde{x}(p;\tau))| < \infty$$

(where $\tilde{x}(p;\tau) := (q^{p_1}, q^{\tau+p_2}, \ldots, q^{(n-1)\tau+p_n})$) because if $-1 < \alpha < 0$, then the factor x_i^α in the weight function can be compensated by taking $\epsilon_{K,i} = -\alpha$ $(i = 1,\ldots,n)$.

We will prove that for all $j \in \{0,\ldots,n\}$ and all $K \subset [0,\infty)$ compact,

$$\sup_{(p,\tau)\in V_j\times K} |\rho_\tau^j(x^{(j)}(p;\tau))| < \infty \tag{6.2}$$

and

$$\sup_{(p,\tau)\in V_j\times K} |D_\tau^j(x^{(j)}(p;\tau))| < \infty. \tag{6.3}$$

Then we are ready because the little q-Jacobi case follows from (6.2) and (6.3) with $j = n$ and $c = 1$. We use the expression for $\rho_\tau^{(j)}$ evaluated at a specific mass point $x^{(j)}(p;\tau) \in W_B^j(q^\tau)$ as was given in the proof of Proposition 5.8 (formula (5.31)),

$$\rho_\tau^j(x^{(j)}(p;\tau)) = \prod_{\substack{1\le i<k\le n\\ i\le j}} g_{ik}^{(j)}(p,\tau) \prod_{j<l<m\le n} g_{ml}^{(j)}(p,\tau) \tag{6.4}$$

with $g_{rs}^{(j)}(p,\tau)$ defined by (5.30) for $\tau > 0$ and by (5.32) and (5.33) for $\tau = 0$.

Proof of (6.2). We look at the factors of the form $g_{rs}^{(j)}(l,\tau)$ in the expression for $\rho_\tau^j(x^{(j)}(l,\tau))$ (see (6.4)).

Case (1): $k \le j < m$. We have

$$g_{km}^{(j)}(l,\tau) = \frac{1 + (d/c)q^{(n-m-k+1)\tau} q^{l_m - l_k}}{1 + (d/c)q^{(n-m-k+2)\tau} q^{l_m - l_k}}$$

for $l \in V_j$ and $\tau \in K$. Thus $\sup_{(l,\tau)\in V_j\times K} |g_{km}^{(j)}(l,\tau)| < \infty$ because the map $\psi : [0,\infty)\times K \to \mathbb{R}$ given by

$$\psi(x,\tau) = \frac{1+(d/c)xq^{(n-m-k+1)\tau}}{1+(d/c)xq^{(n-m-k+2)\tau}}$$

is continuous, and $\lim_{x\to\infty}\psi(x,\tau) = q^{-\tau}$ uniformly for $\tau \in K$.

Case (2): $k < m \leq j$. Let $l \in V_j$ and $\tau \in K$. We have

$$g_{km}^{(j)}(l,\tau) = \frac{1-q^{(m-k)\tau}q^{l_m-l_k}}{1-q^{(m-k+1)\tau}q^{l_m-l_k}} \tag{6.5}$$

if $\tau > 0$ and $l_m \geq l_k$ or if $\tau = 0$ and $l_m > l_k$. Furthermore, we have $g_{km}^{(j)}(l,0) = (m-k)/(m-k+1)$ if $l_k = l_m$. We have to prove that $\sup_{(l,\tau)\in V_j\times K} |g_{km}^{(j)}(l,\tau)| < \infty$. First, consider the supremum over $V_j^0 \times K$, where V_j^0 is the subset of V_j defined by $V_j^0 := \{l \in V_j \,|\, l_k = l_m\}$. Since $g_{km}^{(j)}(l,\tau) = g_{km}(0,\tau)$ independently of $l \in V_j^0$, and since $g_{km}^{(j)}(0,\tau)$ is continuous in $\tau \in [0,\infty)$, we have $\sup_{(l,\tau)\in V_j^0\times K} |g_{km}^{(j)}(l,\tau)| < \infty$. Furthermore, $\sup_{(l,\tau)\in V_j^1\times K} |g_{km}^{(j)}(l,\tau)| < \infty$ with $V_j^1 := V_j\backslash V_j^0$ follows from the fact that the map $\psi_{km} : [0,q]\times K \to \mathbb{R}$ given by

$$\psi_{km}(x,\tau) := \frac{1-q^{(m-k)\tau}x}{1-q^{(m-k+1)\tau}x}$$

is continuous, and $[0,q]\times K$ is compact.

Case (3): $j < k < m$. Similar arguments as in case (2) gives uniform boundness of $g_{mk}^{(j)}(l,\tau)$ for $l \in V_j$ and $\tau \in K$.

Proof of (6.3). We examine the factors of the form $|x_r|^{2\tau}\left(q^{1-\tau}x_s/x_r;q\right)_{2\tau}$ in the expression for $D_j^\tau(x)$ for $x \in W_B^j(q^\tau)$ (see (5.29)).

Case (1): $k \leq j < m$. For $x \in W_B^j(q^\tau)$, we have $x_k = cq^{(k-1)\tau+l_k}$ and $x_m = -dq^{(n-m)\tau+l_m}$ for some $l_m, l_k \in \mathbb{N}_0$. Using the formula

$$q^{2k\tau}\left(q^{1-\tau-k}z;q\right)_{2\tau} = \frac{\left(q^\tau z^{-1};q\right)_k}{\left(q^{-\tau}z^{-1};q\right)_k}\left(q^{1-\tau}z;q\right)_{2\tau},$$

we get

$$x_k^{2\tau}\left(q^{1-\tau}\frac{x_m}{x_k};q\right)_{2\tau} = \left(cq^{(k-1)\tau}\right)^{2\tau}\frac{\left(q^{\tau-l_m}w_{km}^{-1};q\right)_{l_k}}{\left(q^{-\tau-l_m}w_{km}^{-1};q\right)_{l_k}}\left(q^{1-\tau+l_m}w_{km};q\right)_{2\tau}$$

with $w_{km} := (-d/c)q^{(n-m-k+1)\tau}$. Then

$$\left|\frac{\left(q^{\tau-l_m}w_{km}^{-1};q\right)_{l_k}}{\left(q^{-\tau-l_m}w_{km}^{-1};q\right)_{l_k}}\right| \leq 1$$

for all $l_k, l_m \in \mathbb{N}_0$ and $\tau \in K$ because

$$1-q^{-\tau-l_m+i}w_{km}^{-1} \geq 1-q^{\tau-l_m+i}w_{km}^{-1} > 0 \quad \forall\tau\in K,\ l_m\in\mathbb{N}_0,\ i\in\{0,\ldots,l_k-1\}.$$

Choose $N_K \in \mathbb{N}_0$ such that $2\tau \leq N_K$ for all $\tau \in K$. Then

$$\left|\left(q^{1-\tau+l_m}w_{km};q\right)_{2\tau}\right| \leq \left|\left(q^{1-\tau+l_m}w_{km};q\right)_{N_K}\right|,$$

and arguments similar to those in Case (2) of the proof of (6.2) show that

$$\sup_{(l_m,\tau)\in\mathbb{N}_0\times K}\left|\left(q^{1-\tau+l_m}w_{km};q\right)_{N_K}\right|<\infty.$$

Case (2): $k<m\le j$. For $x\in W_B^j(q^\tau)$, we have that $x_k=cq^{(k-1)\tau+l_k}$ and $x_m=cq^{(m-1)\tau+l_m}$ for some $l_k,l_m\in\mathbb{N}_0$ with $l_k\le l_m$, so

$$\left|x_k^{2\tau}\left(q^{1-\tau}\frac{x_m}{x_k};q\right)_{2\tau}\right|=\left(cq^{(k-1)\tau}\right)^{2\tau}q^{2l_k\tau}\left|\frac{\left(q^{1-\tau}\left(q^{(m-k)\tau+l_m-l_k}\right);q\right)_\infty}{\left(q^{1+\tau}\left(q^{(m-k)\tau+l_m-l_k}\right);q\right)_\infty}\right|.$$

We have

$$\left|\frac{\left(q^{1-\tau}\left(q^{(m-k)\tau+l_m-l_k}\right);q\right)_\infty}{\left(q^{1+\tau}\left(q^{(m-k)\tau+l_m-l_k}\right);q\right)_\infty}\right|\le 1$$

for $\tau\in K$ and $l_m,l_k\in\mathbb{N}_0$ with $l_k\le l_m$ because

$$1-q^{1+\tau}\left(q^{(m-k)\tau+l_m-l_k}\right)q^i\ge 1-q^{1-\tau}\left(q^{(m-k)\tau+l_m-l_k}\right)q^i>0$$

for all $\tau\in K$, all $l_m,l_k\in\mathbb{N}_0$ with $l_k\le l_m$, and all $i\in\mathbb{N}_0$.

Case (3): $j<k<m$. Similar arguments as in case (2) give a uniform boundedness of

$$\left||x_m|^{2\tau}\left(q^{1-\tau}\frac{x_k}{x_m};q\right)_{2\tau}\right|$$

for $\tau\in K, x_k\in\{-dq^{(n-k)\tau+l_k}\}_{l_k\in\mathbb{N}_0}, x_m\in\{-dq^{(n-m)\tau+l_m}\}_{l_m\in\mathbb{N}_0}$, $l_m\le l_k$. □

We have the following corollary.

COROLLARY 6.2. *Let $f,g\in\mathcal{A}^{\mathcal{S}}$.*

(1) $\langle D_{B,t}f,g\rangle_{B,t}$ *is continuous in t for $t\in(0,1]$.*

(2) $\langle D_{L,t}f,g\rangle_{L,t}$ *is continuous in t for $t\in(0,1]$.*

Proof. Let $\lambda\in P^+$. The coefficients in the expansion of the symmetric polynomial $D_{n,q,t}^{a,b,c,d}m_\lambda$ with respect to the basis of monomials $\{m_\mu\mid\mu\in P^+\}$ are continuous in $t\in(0,1]$ for arbitrary fixed $a,b,c,d\in\mathbb{C}$ because they depend polynomially on t (Proposition 4.2). Now apply Proposition 6.1. □

Define the forward and backward partial q-derivatives in the ith coordinate by

$$\left(D_q^{i,+}f\right)(x):=\frac{\left(T_{q^{-1},i}f-f\right)(x)}{(1-q)x_i}\quad\text{and}\quad\left(D_q^{i,-}f\right)(x):=\frac{\left(f-T_{q,i}f\right)(x)}{(1-q)x_i},\tag{6.6}$$

respectively. In the one-variable case, we will use the notation D_q^+ and D_q^-, respectively. $D_{n,q,t}^{a,b,c,d}$ can now be written in the following form:

$$(D_nf)(x)=\sum_{i=1}^n\left(p_i(x)\left(D_q^{i,-}f\right)(x)+q_i(x)\left(D_q^{i,+}f\right)(x)\right),$$

with

$$p_i(x;a,b,c,d;q,t):=\hat{h}(x_i;a,b,c,d;q)t^{n-1}\Delta(x)^{-1}\left(T_{t,i}\Delta\right)(x),$$

$$\hat{h}(y;a,b,c,d;q) := -q(1-q)y\left(a-\frac{c}{qy}\right)\left(b+\frac{d}{qy}\right)$$

and

$$q_i(x;c,d;q,t) := \hat{g}(x_i;c,d;q)t^{n-1}\Delta(x)^{-1}(T_{t^{-1},i}\Delta)(x),$$

$$\hat{g}(y;c,d;q) := (1-q)y\left(1-\frac{c}{y}\right)\left(1+\frac{d}{y}\right).$$

We have the following result.

Proposition 6.3. (1) *Let* $i \in \{1,\ldots,n\}$ *and* $j \in \{0,\ldots,n\}$*; then*

$$\begin{aligned}\big(T_{q^{-1},i}(p_i(\,.\,;a,b,c,d;q,t)w_j(\,.\,;a,b,c,d;q,t))\big)(x)\\ = -q_i(x;c,d;q,t)w_j(x;a,b,c,d;q,t).\end{aligned} \tag{6.7}$$

(2) *Let* $i \in \{1,\ldots,n\}$*; then*

$$\begin{aligned}\big(T_{q^{-1},i}(p_i(\,.\,;b,a,1,0;q,t)v(\,.\,;a,b;q,t))\big)(x)\\ = -q_i(x;1,0;q,t)v(x;a,b;q,t).\end{aligned} \tag{6.8}$$

Proof. In Remark 5.3, we saw that $w_j(x) = \phi_j(x)w(x)$ with w given by (5.12),

$$w(x;a,b,c,d;q,t) = \left(\prod_{j=1}^{n} w_B(x_j;a,b,c,d;q)\right)\tilde{\Delta}_\tau(x),$$

and with ϕ_j a quasi-constant function (w_B given by (2.2)). Thus for (1), it is sufficient to prove (6.7) with w_j replaced by w. For (2), it will be sufficient to prove (6.8) with v replaced by

$$\left(\prod_{j=1}^{n} v_L(x_j;a,b;q)\right)\tilde{\Delta}_\tau(x)$$

(with v_L given by (2.7)).

For every $i \in \{1,\ldots,n\}$, we have

$$\left(T_{q^{-1},i}\left(\frac{(T_{t,i}\Delta)}{\Delta}\tilde{\Delta}_\tau\right)\right)(x) = \frac{\left(T_{t^{-1},i}\Delta\right)(x)}{\Delta(x)}\tilde{\Delta}_\tau(x),$$

which follows from a straightforward calculation using (4.1). Thus the proposition follows from

$$\hat{h}(q^{-1}y;a,b,c,d;q)w_B(q^{-1}y;a,b,c,d;q) = -\hat{g}(y;c,d;q)w_B(y;a,b,c,d;q)$$

and

$$\hat{h}(q^{-1}y;b,a,1,0;q)v_L(q^{-1}y;a,b;q) = -\hat{g}(y;1,0;q)v_L(y;a,b;q). \qquad \square$$

The self-adjointness of D_B with respect to $\langle\,.\,,.\,\rangle_B$ and the self-adjointness of D_L with respect to $\langle\,.\,,.\,\rangle_L$ can now be proved with the help of the following special version of the q-partial integration rule. The proof is similar to the proof of the usual q-partial integration rule (cf. [13]).

Lemma 6.4. *Let $\alpha \neq 0$ and let f_i be functions in one variable ($i = 1, \dots, 4$). Suppose that f_1 and f_4 are defined on $\{\alpha q^k \mid k \in \mathbb{N}_0\}$ and that f_2 and f_3 are defined on $\{\alpha q^k \mid k \in \mathbb{N}_0 \cup \{-1\}\}$. Suppose that*

$$\lim_{k\to\infty} \left(f_1(\alpha q^{k+1}) f_2(\alpha q^k) + f_3(\alpha q^k) f_4(\alpha q^{k+1})\right)$$

exists and is equal to L. Then

$$\begin{aligned}\int_0^\alpha \left(\left(D_q^- f_1\right)(x) f_2(x) + \left(D_q^+ f_3\right)(x) f_4(x)\right) d_q x &= f_1(\alpha) f_2(q^{-1}\alpha) \\ + f_3(q^{-1}\alpha) f_4(\alpha) - L - \int_0^\alpha &\left(f_1(x)\left(D_q^+ f_2\right)(x) + f_3(x)\left(D_q^- f_4\right)(x)\right) d_q x.\end{aligned}$$

Theorem 6.5. *Let $t \in (0, 1]$.*

(i) *$D_{B,t}$ is self-adjoint with respect to $\langle\, .\, ,\, .\, \rangle_{B,t}$.*

(ii) *$D_{L,t}$ is self-adjoint with respect to $\langle\, .\, ,\, .\, \rangle_{L,t}$.*

Proof. (i) Fix $j \in \{0, \dots, n\}$. Define

$$W_j(\tau) := \{x \mid x_k = cq^{(k-1)\tau + l_k} (k \leq j), x_k = -dq^{(n-k)\tau + l_k} (k > j) \text{ and } l_k \in \mathbb{N}_0\}.$$

First, let us check that if $\tau \in (0, \infty) \setminus \cup_{p=1}^n (1/p)\mathbb{N}$, then $w_j(x; q^\tau) \neq 0$ for $x \in W_j(\tau)$ iff $x \in W_B^j(q^\tau)$.

Therefore, let $x \in W_j(\tau)$. Then $\left(q^{1-\tau} x_{k+1}/x_k; q\right)_\infty = 0$ if $1 \leq k < j$ and $l_k > l_{k+1}$, and $\left(q^{1-\tau} x_k/x_{k+1}; q\right)_\infty = 0$ if $j < k < n$ and $l_k < l_{k+1}$. Furthermore, if we assume that $\tau \in (0, \infty) \setminus \cup_{p=1}^n (1/p)\mathbb{N}$, then $(q^\tau x_m/x_k; q)_\infty \neq 0$ for $1 \leq k < m \leq j$ and $(q^\tau x_k/x_m; q)_\infty \neq 0$ for $j < k < m \leq n$. Therefore, if $\tau \in (0, \infty) \setminus \cup_{p=1}^n (1/p)\mathbb{N}$, then $\Delta_\tau^j(x) \neq 0$ for $x \in W_j(\tau)$ iff $x \in W_B^j(q^\tau)$, and so this also holds for $w_j(x; q^\tau)$.

As a consequence, we have that

$$\langle f, g\rangle_{j,B,t} = \int_{x_1=0}^{c} \cdots \int_{x_j=0}^{ct^{j-1}} \int_{x_{j+1}=-dt^{n-j-1}}^{0} \cdots \int_{x_n=-d}^{0} f(x) g(x) w_j(x; t) d_q x \tag{6.9}$$

for all $f, g \in \mathcal{A}^{\mathcal{S}}$ if $\tau \in (0, \infty) \setminus \cup_{p=1}^n (1/p)\mathbb{N}$. We will prove self-adjointness for $\tau \notin \cup_{p=1}^n (1/p)\mathbb{N}$; then Corollary 6.2 asserts self-adjointness for $\tau \in [0, \infty)$. Therefore, fix $\tau \in (0, \infty) \setminus \cup_{p=1}^n (1/p)\mathbb{N}$. We will apply Lemma 6.4 repeatedly on the right-hand side of the formula

$$\begin{aligned}\langle D_{B,t} f, g\rangle_{B,t} = \sum_{j=0}^{n} \sum_{l=1}^{n} \int_{x_1=0}^{c} \cdots \int_{x_j=0}^{ct^{j-1}} \int_{x_{j+1}=-dt^{n-j-1}}^{0} \\ \cdots \int_{x_n=-d}^{0} \left(p_l(x)\left(D_q^{l,+} f\right)(x) + q_l(x)\left(D_q^{l,-} f\right)(x)\right) g(x) w_j(x) d_q x.\end{aligned} \tag{6.10}$$

Formula (6.10) is valid because the proof of Proposition 6.1, together with the fact that $\tau \notin \cup_{p=1}^n (1/p)\mathbb{N}$, shows that the multisums in the right-hand side of (6.10) converge absolutely for each $j \in \{0, \dots, n\}$ and each $l \in \{1, \dots, n\}$. We are therefore also allowed to interchange the order of q-integration in the right-hand side of (6.10).

For $x = (x_1, \ldots, x_n)$, we denote $\hat{x}_i := (x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n)$, and we denote $\hat{x}_i(u) := (x_1, \ldots, x_{i-1}, u, x_{i+1}, \ldots, x_n)$. Define W_j^i by

$$W_j^i(\tau) := \{\hat{x}_i \,|\, x \in W_j(\tau)\}.$$

Note that $W_{i-1}^i = W_i^i$ for all $i \in \{1, \ldots, n\}$. Let $f, g \in \mathcal{A}^{\mathcal{S}}$. For $i \leq j$, we apply Lemma 6.4 on

$$\int_{x_i=0}^{ct^{i-1}} \big(p_i(x)\big(D_q^{i,-}f\big)(x) + q_i(x)\big(D_q^{i,+}f\big)(x)\big)g(x)w_j(x)d_qx_i, \tag{6.11}$$

and for $i > j$, we apply Lemma 6.4 to

$$\int_{x_i=0}^{-dt^{n-i}} \big(p_i(x)\big(D_q^{i,-}f\big)(x) + q_i(x)\big(D_q^{i,+}f\big)(x)\big)g(x)w_j(x)d_qx_i \tag{6.12}$$

with fixed $\hat{x}_i \in W_j^i$ for the variable x in the integrand of (6.11) and (6.12). Therefore, define

$$\begin{aligned} f_1^{i,j,\hat{x}_i}(y) &:= f(\hat{x}_i(y)), \qquad & f_2^{i,j,\hat{x}_i}(y) &:= p_i(\hat{x}_i(y))w_j(\hat{x}_i(y))g(\hat{x}_i(y)),\\ f_3^{i,j,\hat{x}_i}(y) &:= f(\hat{x}_i(y)), \qquad & f_4^{i,j,\hat{x}_i}(y) &:= q_i(\hat{x}_i(y))w_j(\hat{x}_i(y))g(\hat{x}_i(y)). \end{aligned}$$

Then formula (6.7) gives

$$\begin{aligned} &\int_{x_i=0}^{ct^{i-1}} \left(f_1^{i,j,\hat{x}_i}(x_i)\left(D_q^+ f_2^{i,j,\hat{x}_i}\right)(x_i) + f_3^{i,j,\hat{x}_i}(x_i)\left(D_q^- f_4^{i,j,\hat{x}_i}\right)(x_i)\right) d_qx_i\\ &\qquad = -\int_{x_i=0}^{ct^{i-1}} f(x)\big(p_i(x)\big(D_q^{i,-}g\big)(x) + q_i(x)\big(D_q^{i,+}g\big)(x)\big)w_j(x)d_qx_i \end{aligned} \tag{6.13}$$

if $i \leq j$ and

$$\begin{aligned} &\int_{x_i=0}^{-dt^{n-i}} \left(f_1^{i,j,\hat{x}_i}(x_i)\left(D_q^+ f_2^{i,j,\hat{x}_i}\right)(x_i) + f_3^{i,j,\hat{x}_i}(x_i)\left(D_q^- f_4^{i,j,\hat{x}_i}\right)(x_i)\right) d_qx_i\\ &\qquad = -\int_{x_i=0}^{-dt^{n-i}} f(x)\big(p_i(x)\big(D_q^{i,-}g\big)(x) + q_i(x)\big(D_q^{i,+}g\big)(x)\big)w_j(x)d_qx_i \end{aligned} \tag{6.14}$$

if $i > j$, with $\hat{x}_i \in W_j^i$ fixed for the variable x in the integrands. Define

$$h^{i,j,\hat{x}_i}(\gamma) := f_1^{i,j,\hat{x}_i}(\gamma)f_2^{i,j,\hat{x}_i}(q^{-1}\gamma) + f_3^{i,j,\hat{x}_i}(q^{-1}\gamma)f_4^{i,j,\hat{x}_i}(\gamma).$$

Then we will prove the following:

(1a) $h^{i,j,\hat{x}_i}(cq^{(i-1)\tau}) = 0$ if $i \leq j$ and $\hat{x}_i \in W_j^i$;

(1b) $h^{i,j,\hat{x}_i}(-dq^{(n-i)\tau}) = 0$ if $i > j$ and $\hat{x}_i \in W_j^i$;

(2a) $\lim_{l_i\to\infty} h^{i,j,\hat{x}_i}(cq^{(i-1)\tau+l_i+1}) = 0$ for $i \in \{1, \ldots, n\}, j \geq i+1$, and $\hat{x}_i \in W_j^i$;

(2b) $\lim_{l_i\to\infty} h^{i,j,\hat{x}_i}(-dq^{(n-i)\tau+l_i+1}) = 0$ for $i \in \{1, \ldots, n\}, j \leq i-2$, and $\hat{x}_i \in W_j^i$;

(2c) $\lim_{l_i\to\infty} h^{i,i,\hat{x}_i}(cq^{(i-1)\tau+l_i+1})$ and $\lim_{l_i\to\infty} h^{i,i-1,\hat{x}_i}(-dq^{(n-i)\tau+l_i+1})$ exist and have the same limit for all $i \in \{1, \ldots, n\}$ and all $\hat{x}_i \in W_i^i = W_{i-1}^i$.

Observe that if these five statements are valid, then the multisum over $\hat{x}_i \in W_i^i$ of the function

$$\hat{h}_i(\hat{x}_i) := \left(\prod_{j\neq i} |x_j|\right)\left(\lim_{l_i\to\infty} h^{i,i,\hat{x}_i}(cq^{(i-1)\tau+l_i+1})\right)$$

is absolutely convergent for $i = 1, \ldots, n$. This follows from the formula

$$\hat{h}_i(\hat{x}_i) := \left(\prod_{j\neq i} |x_j|\right)\left(\int_{x_i=0}^{ct^{i-1}} f(x)\big(p_i(x)\big(D_q^{i,-}g\big)(x) + q_i(x)\big(D_q^{i,+}g\big)(x)\big)w_i(x)d_qx_i\right.$$
$$\left. - \int_{x_i=0}^{ct^{i-1}} \big(p_i(x)\big(D_q^{i,-}f\big)(x) + q_i(x)\big(D_q^{i,+}f\big)(x)\big)g(x)w_i(x)d_qx_i\right),$$

which is a consequence of Lemma 6.4, (6.13), (1a), and (2c). The self-adjointness of $D_{B,t}$ with respect to $\langle\, .\, ,\, .\, \rangle_{B,t}$ then follows directly from this observation and these five statements, in view of Lemma 6.4, (6.10), (6.13), and (6.14).

For the proof of the five statements, we use the fact that

$$h^{i,j,\hat{x}_i}(\gamma) = \big(f(\hat{x}_i(\gamma))g(\hat{x}_i(q^{-1}\gamma)) - f(\hat{x}_i(q^{-1}\gamma))g(\hat{x}_i(\gamma))\big)\, p_i(\hat{x}_i(q^{-1}\gamma))w_j(\hat{x}_i(q^{-1}\gamma))$$

for $\gamma \in \{cq^{(i-1)\tau+l_i}\}_{l_i\in\mathbb{N}_0}$ if $i \leq j$ and for $\gamma \in \{-dq^{(n-i)\tau+l_i}\}_{l_i\in\mathbb{N}_0}$ if $i > j$ with fixed $\hat{x}_i \in W_j^i$. This formula is a consequence of (6.7).

(1a) If $i = 1$, then $w_j(\hat{x}_1(cq^{-1})) = 0$ for $j \geq i$ because $(qx_1/c;q)_\infty$ is zero when $x_1 = cq^{-1}$. If $1 < i \leq n$, then $w_j(\hat{x}_i(cq^{(i-1)\tau-1})) = 0$ if $j \geq i$ because $x_{i-1} = cq^{(i-2)\tau+l_{i-1}}$ for certain $l_{i-1} \in \mathbb{N}_0$, so $\big(q^{1-\tau}cq^{(i-1)\tau-1}/x_{i-1};q\big)_\infty = 0$.

(1b) This is similar to the proof of (1a).

(2a) If $i \in \{1, \ldots, n\}$ and $j \geq i+1$, then $x_{i+1} = cq^{i\tau+l_{i+1}}$ for certain $l_{i+1} \in \mathbb{N}_0$, so $\big(q^{1-\tau}x_{i+1}/cq^{(i-1)\tau+l_i};q\big)_\infty = 0$ if $l_i > l_{i+1}$, and therefore $w_j(\hat{x}_i(cq^{(i-1)\tau+l_i})) = 0$ if $l_i > l_{i+1}$.

(2b)This is similar to the proof of (2a).

(2c) f, g are polynomials, so

$$\frac{f(x)(T_{q^{-1},i}g)(x) - (T_{q^{-1},i}f)(x)g(x)}{x_i} \in \mathbb{R}[x_1, \ldots, x_n]$$

is continuous as a function of x_i in $x_i = 0$ for arbitrary fixed $\hat{x}_i$. It is therefore sufficient to prove that

$$\lim_{l_i\to\infty}\Big(-dq^{(n-i)\tau+l_i}p_i(\hat{x}_i(-dq^{(n-i)\tau+l_i}))w_{i-1}(\hat{x}_i(-dq^{(n-i)\tau+l_i}))\Big)$$

and

$$\lim_{l_i\to\infty}\Big(cq^{(i-1)\tau+l_i}p_i(\hat{x}_i(cq^{(i-1)\tau+l_i}))w_i(\hat{x}_i(cq^{(i-1)\tau+l_i}))\Big)$$

exist and that they have the same limit for all $\hat{x}_i \in W_i^i$ and all $i \in \{1, \ldots, n\}$. Fix $i \in \{1, \ldots, n\}$ and $\hat{x}_i \in W_i^i$. Since $x_ip_i(x)$ is continuous as a function of x_i in $x_i = 0$, it is sufficient to prove that

$$\lim_{l_i\to\infty} d_i^\tau\Delta_\tau^i(\hat{x}_i(cq^{(i-1)\tau+l_i})) \quad \text{and} \quad \lim_{l_i\to\infty} d_{i-1}^\tau\Delta_\tau^{i-1}(\hat{x}_i(-dq^{(n-i)\tau+l_i}))$$

exist and that they have the same limit. We have

$$\Delta_\tau^i(x) = \phi_i(x) \prod_{1\le k<i} (x_k - x_i)|x_k|^{2\tau-1} \left(q^{1-\tau}\frac{x_i}{x_k}; q\right)_{2\tau-1} \times \prod_{i<m\le n} (x_i - x_m)|x_i|^{2\tau-1} \left(q^{1-\tau}\frac{x_m}{x_i}; q\right)_{2\tau-1}$$

with

$$\phi_i(x) := \left(\prod_{\substack{1\le k<m\le n\\ k<i;\, m\neq i}} (x_k - x_m)|x_k|^{2\tau-1} \left(q^{1-\tau}\frac{x_m}{x_k}; q\right)_{2\tau-1} \right) \times \prod_{i<k<m\le n} (x_k - x_m)|x_m|^{2\tau-1} \left(q^{1-\tau}\frac{x_k}{x_m}; q\right)_{2\tau-1}$$

independent of x_i and

$$\Delta_\tau^{i-1}(x) = \phi_i(x) \prod_{1\le k<i} (x_k - x_i)|x_k|^{2\tau-1} \left(q^{1-\tau}\frac{x_i}{x_k}; q\right)_{2\tau-1} \times \prod_{i<m\le n} (x_i - x_m)|x_m|^{2\tau-1} \left(q^{1-\tau}\frac{x_i}{x_m}; q\right)_{2\tau-1}.$$

Therefore, it is sufficient to prove that

$$\lim_{l_i\to\infty} d_i^\tau \sigma_i(\hat{x}_i(cq^{(i-1)\tau+l_i})) \quad \text{and} \quad \lim_{l_i\to\infty} d_{i-1}^\tau \rho_i(\hat{x}_i(-dq^{(n-i)\tau+l_i}))$$

exist and that they have the same limit, with

$$\sigma_i(x) := \prod_{i<m\le n} (x_i - x_m)|x_i|^{2\tau-1} \left(q^{1-\tau}\frac{x_m}{x_i}; q\right)_{2\tau-1},$$

$$\rho_i(x) := \prod_{i<m\le n} (x_i - x_m)|x_m|^{2\tau-1} \left(q^{1-\tau}\frac{x_i}{x_m}; q\right)_{2\tau-1}.$$

Clearly,

$$\lim_{l_i\to\infty} \rho_i(\hat{x}_i(-dq^{(n-i)\tau+l_i})) = \prod_{i<m\le n} |x_m|^{2\tau},$$

and the formula

$$q^{k(2\tau-1)}\left(q^{1-\tau-k}z; q\right)_{2\tau-1} = \frac{\left(q^\tau z^{-1}; q\right)_k}{\left(q^{1-\tau}z^{-1}; q\right)_k}\left(q^{1-\tau}z; q\right)_{2\tau-1}$$

gives that

$$\lim_{l_i\to\infty} \sigma_i(\hat{x}_i(cq^{(i-1)\tau+l_i})) = \prod_{i<m\le n} |x_m|^{2\tau} \frac{(cq^{(i-1)\tau})^{2\tau-1}\left(q^{1-\tau}\left(x_m/cq^{(i-1)\tau}\right); q\right)_{2\tau-1}}{|x_m|^{2\tau-1}\left(q^{1-\tau}\left(cq^{(i-1)\tau}/x_m\right); q\right)_{2\tau-1}}.$$

Thus

$$\lim_{l_i\to\infty}\sigma_i(\hat{x}_i(cq^{(i-1)\tau+l_i}))=\frac{d_{i-1}^{\tau}}{d_i^{\tau}}\prod_{i<m\le n}|x_m|^{2\tau}$$

for $\hat{x}_i \in W_i^i$ because the function ψ_τ given by formula (5.15) is a quasi-constant function.

(ii) Fix $\tau\in(0,\infty)\setminus\cup_{p=1}^{n}(1/p)\mathbb{N}$ and $f,g\in\mathcal{A}^{\mathcal{S}}$; then a similar argument as in the proof of (i) gives that

$$\langle f,g\rangle_L=\int_{x_1=0}^{1}\cdots\int_{x_n=0}^{q^{(n-1)\tau}}f(x)g(x)v(x)d_qx,$$

and the order of q-integration may be changed because of absolute convergence. Fix $i\in\{1,\dots,n\}$ and fix $x_k\in\{q^{(k-1)\tau+l_k}\}_{l_k\in\mathbb{N}_0}(k\neq i)$. Define

$$\begin{aligned}f_1^i(x_i)&:=f(x), & f_2^i(x_i)&:=p_i(x;b,a,1,0;q,t)v(x;a,b;q,t)g(x),\\ f_3^i(x_i)&:=f(x), & f_4^i(x_i)&:=q_i(x;1,0;q,t)v(x;a,b;q,t)g(x)\end{aligned}$$

$(x=(x_1,\dots,x_{i-1},x_i,x_{i+1},\dots,x_n))$. It follows from formula (6.8) and Lemma 6.4 that the proof of (ii) is complete if the following two formulas are valid:

$$f_1^i(q^{(i-1)\tau})f_2^i(q^{(i-1)\tau-1})+f_3^i(q^{(i-1)\tau-1})f_4^i(q^{(i-1)\tau})=0, \tag{6.15}$$

$$\lim_{k\to\infty}\Big(f_1^i(q^{(i-1)\tau+k+1})f_2^i(q^{(i-1)\tau+k})+f_3^i(q^{(i-1)\tau+k})f_4^i(q^{(i-1)\tau+k+1})\Big)=0. \tag{6.16}$$

For the proof, we use the formula

$$\begin{aligned}f_1^i(\gamma)f_2^i(q^{-1}\gamma)+f_3^i(q^{-1}\gamma)f_4^i(\gamma)=\big(&f(\hat{x}_i(\gamma))g(\hat{x}_i(q^{-1}\gamma))-f(\hat{x}_i(q^{-1}\gamma))g(\hat{x}_i(\gamma))\big)\\ &\times p_i(\hat{x}_i(q^{-1}\gamma);b,a,1,0;q,t)v(\hat{x}_i(q^{-1}\gamma);a,b;q,t)\end{aligned}$$

with $\gamma\in\{q^{(i-1)\tau+l_i}\}_{l_i\in\mathbb{N}_0}$. This formula is a consequence of (6.8). The proof of (6.15) is similar to the proof of (1a), and (6.16) holds because

$$\lim_{l_i\to\infty}q^{(i-1)\tau+l_i}p_i(\hat{x}_i(q^{(i-1)\tau+l_i});b,a,1,0;q,t)v(\hat{x}_i(q^{(i-1)\tau+l_i});a,b;q,t)$$

is zero for $i=1,\dots,n-1$ because $v(\hat{x}_i(q^{(i-1)\tau+l_i});a,b;q,t)=0$ for l_i sufficiently big and is also zero if $i=n$ since

$$\lim_{l_n\to\infty}v(\hat{x}_n(q^{(n-1)\tau+l_n});a,b;q,t)\left(q^{(n-1)\tau+l_n}\right)^{-\alpha}$$

exists, and

$$\lim_{l_n\to\infty}\left(q^{(n-1)\tau+l_n}\right)^{\alpha+1}p_i(\hat{x}_n(q^{(n-1)\tau+l_n});b,a,1,0;q,t)=0$$

since $\alpha>-1$. □

Note added in proof. The evaluation formula for $\langle 1,1\rangle_{L,q^k}$ which we presented in Remark 5.4 for the special parameter values $k\in\mathbb{N}$ is in fact valid for all $k\in(0,\infty)$. This follows from a modified form of Askey, Habsieger, and Kadell's formula which has recently been proved by K. Aomoto in his preprint "On elliptic product formulas for Jackson integrals associated with reduced root systems."

APPROXIMATION FROM SHIFT-INVARIANT SPACES BY INTEGRAL OPERATORS*

JUNJIANG LEI†, RONG-QING JIA‡, AND E. W. CHENEY§

Abstract. We investigate approximation from shift-invariant spaces by using certain integral operators and discuss various applications of this approximation scheme. We assume that our integral operators commute with shift operators and that their kernel functions decay at a polynomial rate. We prove that the approximation order provided by such an integral operator is m if and only if the integral operator reproduces polynomials of degree up to $m-1$, where m is a positive integer. Using this result, we characterize the approximation order provided by a finitely generated shift-invariant space whose generators decay in a polynomial rate and have stable shifts. We also review some already well-studied approximation schemes such as projection, cardinal interpolation, and quasi-interpolation by considering them as special cases of integral operators.

Key words. approximation order, shift-invariant spaces, integral operators, quasi-interpolation

1. Introduction.

There are many ways to construct approximation schemes associated with shift-invariant spaces. Among them are cardinal interpolation (see, e.g., [3, 8]), quasi-interpolation (see, e.g., [4, 7, 18]), projection (see, e.g., [9, 14, 16, 19]), and convolution (see, e.g., [20]). In this paper, we unify these approximation schemes in a systematic fashion by viewing them all as special cases of the approximation scheme induced by an integral operator L of the form

$$(Lf)(x) = \int K(x,y)f(y)\,dy, \quad x \in \mathbb{R}^n, \tag{1.1}$$

where the kernel K is assumed to be a complex-valued measurable function on $\mathbb{R}^n \times \mathbb{R}^n$ and the convention $\int = \int_{\mathbb{R}^n}$ has been adopted. In particular, we characterize the approximation order provided by such an integral operator. We also give a characterization of the approximation order provided by a finitely generated shift-invariant space with stable generators. All of our results are valid for approximation in $L_p(\mathbb{R}^n)$, $1 \le p \le \infty$.

A linear subspace S of $L_p(\mathbb{R}^n)$ is called shift-invariant if $f \in S$ implies $f(\cdot - \nu) \in S$ for all $\nu \in \mathbb{Z}^n$. Since our main interest lies in approximation from shift-invariant spaces, it is natural to assume that the integral operator L commutes with all shift operators T_ν on $L_p(\mathbb{R}^n)$:

$$LT_\nu = T_\nu L, \quad \nu \in \mathbb{Z}^n.$$

We use T_u to denote the translation of a function f by $u \in \mathbb{R}^n$: $(T_u f)(x) = f(x-u)$, $x \in \mathbb{R}^n$. If the translation is given by a multiinteger, we call it a shift (in accordance with current parlance). It is easily seen that the commutativity described above is equivalent to the equation

$$K(x-\nu, y) = K(x, y+\nu) \quad \text{for all } \nu \in \mathbb{Z}^n \text{ and a.e. } x, y \in \mathbb{R}^n. \tag{1.2}$$

We also assume that our integral operator decays at a polynomial rate. To be precise, the kernel function K is assumed to satisfy the following two conditions:

$$\int_{\mathbb{R}^n} |K(x,\cdot)|\, dx \in L_\infty([0,1)^n) \tag{1.3}$$

and, for some nonnegative integer m,

$$\int_{\mathbb{R}^n} (1+\|y\|)^m |K(\cdot,y)|\, dy \in L_\infty([0,1)^n), \tag{1.4}$$

where the norm $\|\cdot\|$ on $\mathbb{R}^n$ is defined by

$$\|y\| := \max\{|y_1|, \ldots, |y_n|\} \quad \text{for } y = (y_1, \ldots, y_n) \in \mathbb{R}^n.$$

Conditions (1.2)–(1.4) assure that the operator L given by (1.1) is a bounded operator on $L_p(\mathbb{R}^n)$ (see Lemma 2.2). Moreover, when conditions (1.2) and (1.4) are fulfilled, we can extend the domain of the operator L to include $\Pi_m = \Pi_m(\mathbb{R}^n)$, the linear space of polynomials of (total) degree no greater than m on $\mathbb{R}^n$. We adopt the convention that $\Pi_{-1} = \{0\}$.

For $h > 0$, let σ_h be the scaling operator defined by the equation

$$\sigma_h f := f(\cdot/h).$$

If L is a linear operator on $L_p(\mathbb{R}^n)$, then we denote by L_h the operator $\sigma_h L \sigma_{1/h}$. Given a positive integer m, we say that the integral operator L provides approximation order m if for every sufficiently smooth function f in $L_p(\mathbb{R}^n)$,

$$\|L_h f - f\|_p = \mathcal{O}(h^m) \quad \text{as } h \downarrow 0.$$

Let S be a closed shift-invariant subspace of $L_p(\mathbb{R}^n)$. Then $\sigma_h(S) = \{\sigma_h f : f \in S\}$. We say that S provides approximation order m if for every sufficiently smooth function f in $L_p(\mathbb{R}^n)$,

$$\inf_{s_h \in \sigma_h(S)} \|f - s_h\|_p = \mathcal{O}(h^m) \quad \text{as } h \downarrow 0.$$

In the next two sections, we shall show that under conditions (1.2)–(1.4), the integral operator L provides approximation order m if and only if it reproduces all polynomials in Π_{m-1}. We use this result to characterize the approximation order provided by S in terms of the Strang–Fix conditions, assuming that S is generated by finitely many functions that have stable shifts and a suitable decay.

We use the standard multiindex notation as in [1]. For instance, if α and β are multiindices, then $|\alpha|$ denotes the length of α and $\alpha \le \beta$ means that α is less than or equal to β coordinatewise. For a domain D in $\mathbb{R}^n$, we denote by $\|f\|_p(D)$ the usual L_p norm of a (complex-valued) function f on D. This is simply written as $\|f\|_p$ when $D = \mathbb{R}^n$. We use $f|_E$ to denote the restriction of the function f to a subset E of its original domain. We denote by $W_p^m(\mathbb{R}^n)$ the usual Sobolev space as in [1] and by $|f|_{m,p}$ the seminorm of a function $f \in W_p^m(\mathbb{R}^n)$. We assume that all of our functions are Lebesgue measurable. We denote by $C_c(\mathbb{R}^n)$ the space of compactly supported continuous functions on $\mathbb{R}^n$ and by $C_0(\mathbb{R}^n)$ the space of continuous functions on $\mathbb{R}^n$ that vanish at infinity (see [10, p. 126]).

2. Approximation power of integral operators. In this section, we estimate the lower bound of the approximation order provided by an integral operator that commutes with shifts. In what follows, I denotes the unit cube $[0,1)^n$ in $\mathbb{R}^n$ and p is a real number such that $1 \le p \le \infty$.

THEOREM 2.1. *Let K be a kernel function satisfying conditions* (1.2)–(1.4)*, and let L be the integral operator given in* (1.1)*. If $Lq = q$ for all $q \in \Pi_{m-1}$, then*

$$\|L_h f - f\|_p \le C|f|_{m,p} h^m, \quad f \in W_p^m(\mathbb{R}^n), \tag{2.1}$$

where C is a constant independent of p, f, and h.

This result may be viewed as a generalization of the well-known Bramble–Hilbert lemma. The proof of the theorem will be given after the next two lemmas.

LEMMA 2.2. *Let K be a kernel function satisfying conditions* (1.2)–(1.4)*, and let L be the integral operator given in* (1.1)*. Let $\|L\|_p$ be the norm of L as an operator on $L_p(\mathbb{R}^n)$. Then there exists a constant M such that $\|L\|_p \le M$ for all $1 \le p \le \infty$.*

Proof. Let $k_1 := \int |K(x,\cdot)|\,dx$. Then for $y \in I$ and $\nu \in \mathbb{Z}^n$, we deduce from (1.2) that

$$k_1(y+\nu) = \int |K(x-\nu, y)|\,dx = \int |K(x,y)|\,dx.$$

This together with (1.3) implies that $k_1 \in L_\infty(\mathbb{R}^n)$. Hence for any $f \in L_1(\mathbb{R}^n)$,

$$\|Lf\|_1 \le \int\!\!\int |K(x,y)|\,|f(y)|\,dy\,dx = \int k_1(y)\,|f(y)|\,dy \le \|k_1\|_\infty \|f\|_1.$$

Similarly, the function $k_2 := \int |K(\cdot,y)|\,dy$ lies in $L_\infty(\mathbb{R}^n)$. Thus for any $f \in L_\infty(\mathbb{R}^n)$, we have $\|Lf\|_\infty \le \|k_2\|_\infty \|f\|_\infty$. Let M be the maximum of $\|k_1\|_\infty$ and $\|k_2\|_\infty$. By the Riesz–Thorin interpolation theorem (see, e.g., [10, Theorem 6.27]), we conclude that $\|Lf\|_p \le M\|f\|_p$ for all p, $1 \le p \le \infty$. □

In the next lemma, we summarize some properties of a special case of L that will be used in the proof of Theorem 2.1 and on other occasions later. Select a function χ in $C_c^\infty(\mathbb{R}^n)$ such that $\int \chi = 1$. Let

$$K(x,y) = \chi(x-y), \quad x, y \in \mathbb{R}^n.$$

For this kernel, the integral operator defined in (1.1) is the usual convolution operator $\chi *$. It is easy to verify that this kernel function satisfies conditions (1.2)–(1.4). It follows from the previous lemma that the operator $\chi *$ is bounded on $L_p(\mathbb{R}^n)$. It is clear that $\chi * f \in C^\infty(\mathbb{R}^n)$ for every locally integrable function f. Furthermore, one can verify that the operator from $L_p(\mathbb{R}^n)$ to $\ell_p(\mathbb{Z}^n)$ given by $f \mapsto (\chi * f)|_{\mathbb{Z}^n}$ is also bounded. The dilates of this operator, $\sigma_h(\chi *)\sigma_{1/h}$ for $h > 0$, are often used as an approximation tool. The convergence of this scheme as $h \downarrow 0$ stems from the fact that $\chi * 1 = 1$, i.e., the operator $\chi *$ reproduces polynomials of degree zero. To enhance approximation power, we need to choose a kernel function in such a way that the corresponding convolution operator reproduces polynomials of a higher degree. To this end, we recall the following smoothing operator J employed in [12]:

$$(Jf)(x) = \int [f(x) - \nabla_u^m f(x)]\chi(u)\, du, \quad x \in \mathbb{R}^n,$$

where m is a positive integer and ∇_u^m is the mth difference operator defined by

$$\nabla_u^m := (1 - T_u)^m, \quad u \in \mathbb{R}^n,$$

where 1 denotes the identity operator. Simple computations show that the smoothing operator J is identical to the convolution operator $\chi_m *$, where

$$\chi_m(x) := \sum_{j=1}^{m} (-1)^{j-1} j^{-n} \binom{m}{j} \chi(x/j), \quad x \in \mathbb{R}^n. \tag{2.2}$$

It is clear that χ_m satisfies all the conditions that χ does, and, moreover, $Jq = q$ for all $q \in \Pi_{m-1}$. The preceding discussion is summarized in the following lemma.

Lemma 2.3. *The operator $J = \chi_m *$ maps locally integrable functions into infinitely differentiable functions. Moreover, there is a constant C independent of p and $f \in L_p(\mathbb{R}^n)$ such that*

(a) $\|Jf\|_p \le C\|f\|_p$,

(b) $\|(Jf)|_{\mathbb{Z}^n}\|_{\ell_p} \le C\|f\|_p$,

(c) $\|Jf - f\|_p \le C|f|_{m,p}$ *for* $f \in W_p^m(\mathbb{R}^n)$, *and*

(d) $Jf = f$ *for all* $f \in \Pi_{m-1}$.

The proof of this lemma can be found in [12].

Proof of Theorem 2.1. Let $f \in W_p^m(\mathbb{R}^n)$. It suffices to show that $\|Lf - f\|_p \le C|f|_{m,p}$ since (2.1) follows from this estimate by a change of variables. Clearly,

$$\begin{aligned} \|Lf - f\|_p &\le \|Lf - LJf\|_p + \|LJf - Jf\|_p + \|Jf - f\|_p \\ &\le \{||L||_p + 1\}||f - Jf||_p + ||LJf - Jf||_p. \end{aligned} \tag{2.3}$$

By Lemma 2.2, $M := \sup_{1 \le p \le \infty} \|L\|_p < \infty$. Moreover, part (c) of Lemma 2.3 asserts that $\|Jf - f\|_p \le C|f|_{m,p}$. Consequently,

$$\{\|L\|_p + 1\}||Jf - f||_p \le (M+1)C|f|_{m,p}.$$

It thus remains to prove that

$$\|LJf - Jf\|_p \le C|f|_{m,p}. \tag{2.4}$$

Let $g := LJf - Jf$, and define $a_x(\nu) := g(x - \nu)$ for $\nu \in \mathbb{Z}^n$. Suppose $1 \le p < \infty$. Since $g \in L_p(\mathbb{R}^n)$, with $I = [0,1)^n$ we have

$$\begin{aligned} \|LJf - Jf\|_p^p = \|g\|_p^p = \int |g(x)|^p \, dx &= \sum_{\nu \in \mathbb{Z}^n} \int_{I-\nu} |g(x)|^p \, dx \\ = \sum_\nu \int_I |g(x-\nu)|^p \, dx &= \int_I \sum_\nu |g(x-\nu)|^p \, dx = \int_I ||a_x||_{\ell_p}^p \, dx. \end{aligned}$$

If $p = \infty$, then we also have

$$\|LJf - Jf\|_\infty = \sup_{x \in I} \|a_x\|_{\ell_\infty}.$$

Now it is clear that (2.4) will be established if we can show that

$$\|a_x\|_{\ell_p} \le C|f|_{m,p}, \quad x \in I, \tag{2.5}$$

for some constant C independent of f, p, and x.

Let q_z be the $(m-1)$st Taylor polynomial of Jf about $z \in \mathbb{R}^n$, and let r_z be the corresponding remainder, $Jf - q_z$. Note that for every $z \in \mathbb{R}^n$, we have $Jf(z) = q_z(z)$. Furthermore, by the assumption on L, $Lq_z = q_z$. For each $x \in I$ and $\nu \in \mathbb{Z}^n$,

$$Jf(x-\nu) = q_{x-\nu}(x-\nu) = Lq_{x-\nu}(x-\nu).$$

We therefore have

$$\begin{aligned} a_x(\nu) = g(x-\nu) &= (LJf - Jf)(x-\nu) = (LJf - q_{x-\nu})(x-\nu) \\ &= (LJf - Lq_{x-\nu})(x-\nu) = [L(Jf - q_{x-\nu})](x-\nu) \\ &= (Lr_{x-\nu})(x-\nu) = (T_\nu L r_{x-\nu})(x) = (LT_\nu r_{x-\nu})(x). \end{aligned} \tag{2.6}$$

The last step used the fact that L commutes with shifts. Next, for $x, y \in \mathbb{R}^n$ and $\nu \in \mathbb{Z}^n$, define

$$e_{x,y}(\nu) := r_{x-\nu}(y-\nu) = (T_\nu r_{x-\nu})(y).$$

Using (2.6), we can write, for each $x \in I$ and $\nu \in \mathbb{Z}^n$,

$$\begin{aligned} a_x(\nu) = (LT_\nu r_{x-\nu})(x) &= \int K(x,y)(T_\nu r_{x-\nu})(y)\,dy \\ &= \int K(x,y) r_{x-\nu}(y-\nu)\,dy = \int K(x,y) e_{x,y}(\nu)\,dy. \end{aligned} \tag{2.7}$$

To estimate $e_{x,y}(\nu)$, use the integral form of the remainder in Taylor's theorem:

$$\begin{aligned} e_{x,y}(\nu) &= r_{x-\nu}(y-\nu) = (Jf - q_{x-\nu})(y-\nu) \\ &= \int_0^1 \sum_{|\alpha|=m} \frac{m}{\alpha!}\big(D^\alpha Jf\big)\big(x-\nu+t(y-x)\big)(1-t)^{m-1}(y-x)^\alpha dt \\ &= \int_0^1 \sum_{|\alpha|=m} \frac{m}{\alpha!}(T_{-x-t(y-x)} D^\alpha Jf)(-\nu)(1-t)^{m-1}(y-x)^\alpha\,dt. \end{aligned}$$

The operators J, D^α, and T_u commute with each other. It follows that for any $x, y \in \mathbb{R}^n$ and $\nu \in \mathbb{Z}^n$,

$$|e_{x,y}(\nu)| \le m\|y-x\|^m \int_0^1 \sum_{|\alpha|=m} |(JT_{-x-t(y-x)} D^\alpha f)(-\nu)|\,dt. \tag{2.8}$$

Since $D^\alpha f \in L_p(\mathbb{R}^n)$, we can use Lemma 2.3(b) to obtain

$$\begin{aligned} \sum_{|\alpha|=m} \|(J(T_{-x-t(y-x)} D^\alpha f))|_{\mathbb{Z}^n}\|_{\ell_p} &\le C \sum_{|\alpha|=m} \|T_{-x-t(y-x)} D^\alpha f\|_{L_p(\mathbb{R}^n)} \\ &= C \sum_{|\alpha|=m} \|D^\alpha f\|_p = C|f|_{m,p}. \end{aligned} \tag{2.9}$$

Now we combine (2.8) with (2.9) and use the generalized Minkowski inequality (see, e.g., [10, p. 186]) to write

$$\tag{2.10} \begin{aligned} \|e_{x,y}\|_{\ell_p} &\leq m\|y-x\|^m \int_0^1 \sum_{|\alpha|=m} \|(JT_{-x-t(y-x)}D^\alpha f\|_{\ell_p}\, dt \\ &\leq m||y-x||^m \int_0^1 C|f|_{m,p}\, dt = mC\,\|y-x\|^m|f|_{m,p}. \end{aligned}$$

From equation (2.7), we have

$$|a_x(\nu)| \leq \int |K(x,y)|\,|e_{x,y}(\nu)|\, dy.$$

This leads to

$$\begin{aligned} \|a_x\|_{\ell_p} &\leq \int |K(x,y)|\,\|e_{x,y}\|_{\ell_p}\, dy \\ &\leq \int |K(x,y)|mC\|x-y\|^m|f|_{m,p}\, dy. \end{aligned}$$

Note that $\|x-y\| \leq 1+\|y\|$ for $x \in I$ and $y \in \mathbb{R}^n$. Hence it follows that

$$\|a_x\|_{\ell_p} \leq mC|f|_{m,p} \int (1+\|y\|)^m |K(x,y)|\, dy.$$

Taking (1.4) into account, we obtain the desired estimate (2.5), thereby completing the proof. □

We close this section by noting that when $p=\infty$, the condition that L commutes with shifts is not required (cf. [6]).

3. Upper bound. In this section, we show that the converse of Theorem 2.1 is also true. This gives an upper bound for the approximation order and hence gives a characterization of the approximation order provided by the integral operator discussed in the preceding section.

THEOREM 3.1. *Fix $m \in \mathbb{N}$ and $p \in [1,\infty]$. Let K be a kernel function satisfying conditions* (1.2) *and* (1.4)*, and let L be the integral operator given in* (1.1)*. If*

$$\tag{3.1} \|L_h f - f\|_p(I) = o(h^{m-1}) \quad \text{for all } f \in C_c^\infty(\mathbb{R}^n), \text{ as } h \downarrow 0,$$

then $Lq = q$ for all $q \in \Pi_{m-1}$.

The proof of the theorem is based on the following lemma.

LEMMA 3.2. *Fix $m \in \mathbb{N}$. Let K be a kernel function satisfying conditions* (1.2) *and* (1.4)*, and let L be the integral operator given in* (1.1)*. If*

$$\tag{3.2} \|L_h q - q\|_1(I) = o(h^{m-1}) \quad \text{for all } q \in \Pi_{m-1}, \text{ as } h \downarrow 0,$$

then $Lq = q$ for all $q \in \Pi_{m-1}$.

Proof. Our proof is motivated by the work of Lei and Jia [17]. For $-1 \leq k \leq m-1$, we shall prove that $Lq = q$ for all monomials $q(x) = x^\alpha$ with $|\alpha| = k$. This will be done by induction on k. Since $\Pi_{-1} = \{0\}$, the statement is true for $k=-1$. Suppose $0 \leq k \leq m-1$ and $Lq = q$ for all $q \in \Pi_{k-1}$. Let $q(x) = x^\alpha$, where α is some multiindex such that $|\alpha| = k$. We wish to prove $Lq = q$.

Let $h > 0$ be such that $1/h$ is an integer. Then I is the disjoint union of the cubes $h(I - \nu)$, where ν runs over the set

$$J_h := \{(\nu_1, \dots, \nu_n) \in \mathbb{Z}^n : -1/h < \nu_j \le 0 \text{ for } j = 1, \dots, n\}.$$

Thus we have

$$\|L_h q - q\|_1(I) = \sum_{\nu \in J_h} \|L_h q - q\|_1\bigl(h(I - \nu)\bigr) = h^n \sum_{\nu \in J_h} \|L\sigma_{1/h} q - \sigma_{1/h} q\|_1(I - \nu).$$

But $\sigma_{1/h} q = h^k q$; hence it follows that

$$\|L_h q - q\|_1(I) = h^{n+k} \sum_{\nu \in J_h} \|Lq - q\|_1(I - \nu). \tag{3.3}$$

By a change of variables, we obtain

$$\|Lq - q\|_1(I - \nu) = \|T_\nu L q - T_\nu q\|_1(I) = \|L(T_\nu q) - T_\nu q\|_1(I).$$

Write $T_\nu q = q + q_\nu$, where $q_\nu \in \Pi_{k-1}$. Since $Lq_\nu = q_\nu$, it follows that

$$LT_\nu q - T_\nu q = L(q + q_\nu) - (q + q_\nu) = Lq - q.$$

This shows that

$$\|Lq - q\|_1(I - \nu) = \|Lq - q\|_1(I) \quad \text{for all } \nu \in \mathbb{Z}^n. \tag{3.4}$$

Note that the number of elements in J_h is $(1/h)^n$. Therefore, (3.3) and (3.4) together give

$$\|L_h q - q\|_1(I) = h^k \|Lq - q\|_1(I).$$

Thus $\|L_h q - q\|_1(I) = o(h^{m-1})$ implies that

$$\|Lq - q\|_1(I) = o(h^{m-1-k}).$$

Since $k \le m - 1$, we conclude that $Lq - q = 0$, i.e., $Lq = q$. □

Proof of Theorem 3.1. By the Hölder inequality, with p' being the exponent conjugate to p, we have

$$\|L_h f - f\|_1(I) \le \|L_h f - f\|_p(I) \|1\|_{p'}(I) = \|L_h f - f\|_p(I).$$

Hence (3.1) implies

$$\|L_h f - f\|_1(I) = o(h^{m-1}) \quad \text{for all } f \in C_c^\infty(\mathbb{R}^n). \tag{3.5}$$

By Lemma 3.2, the theorem will be established if we can verify (3.2). For this purpose, it suffices to consider a specific function $q(x) = x^\alpha$ for $|\alpha| \le m-1$. By the C^∞-Urysohn lemma (see [10, p. 237]), there exists a function $\chi \in C_c^\infty(\mathbb{R}^n)$ such that $0 \le \chi \le 1$, $\chi = 1$ on $[-2, 2]^n$, and χ is supported on $[-3, 3]^n$. Let $f := \chi q$. Then $f \in C_c^\infty(\mathbb{R}^n)$, $f = q$ on $[-2, 2]^n$, and $|f(x)| \le |q(x)|$ for all $x \in \mathbb{R}^n$. Hence we have

$$\|L_h q - q\|_1(I) = \|L_h q - f\|_1(I) \le \|L_h(q - f)\|_1(I) + \|L_h f - f\|_1(I).$$

In view of (3.5), we only have to show that

$$\|L_h(q-f)\|_1(I) = o(h^{m-1}). \tag{3.6}$$

A point $x' \in I$ can be written as $h(x-\nu)$, where $x \in I$, $\nu \in \mathbb{Z}^n$ and $\|\nu\| \le 1/h$. We observe that

$$\begin{aligned} L_h(q-f)(x') &= L\sigma_{1/h}(q-f)(x'/h) = L\sigma_{1/h}(q-f)(x-\nu) \\ &= T_\nu L\sigma_{1/h}(q-f)(x) = LT_\nu\sigma_{1/h}(q-f)(x). \end{aligned}$$

Note that $|q(x)-f(x)| = 0$ for $\|x\| \le 2$ and $|q(x)-f(x)| \le 2|q(x)|$ for all $x \in \mathbb{R}^n$. Hence for any $h > 0$ and $x \in \mathbb{R}^n$,

$$|(LT_\nu\sigma_{1/h})(q-f)(x)| = \Big|\int K(x,y)[(T_\nu\sigma_{1/h})(q-f)](y)\,dy\Big|$$

$$\begin{aligned} &= \Big|\int K(x,y)[\sigma_{1/h}(q-f)](y-\nu)\,dy\Big| = \Big|\int K(x,y)(q-f)(hy-h\nu)\,dy\Big| \\ &= \Big|\int_{\|hy-h\nu\|>2} K(x,y)(q-f)(hy-h\nu)\,dy\Big| \le 2\int_{\|hy-h\nu\|>2} |K(x,y)||(hy-h\nu)^\alpha|\,dy. \end{aligned}$$

However, $\|hy-h\nu\| > 2$ implies that $|(hy-h\nu)^\alpha| \le \|(hy-h\nu)\|^m = h^m\|y-\nu\|^m$. Hence it follows that

$$|(LT_\nu\sigma_{1/h})(q-f)(x)| \le 2h^m \int_{\|y-\nu\|>2/h} |K(x,y)|\|y-\nu\|^m\,dy.$$

Recall that $\|\nu\| \le 1/h$. Hence $\|y-\nu\| > 2/h$ implies

$$\|y\| \ge \|y-\nu\| - \|\nu\| > 1/h \ge \|\nu\|.$$

It follows that $\|y-\nu\| \le \|\nu\| + \|y\| \le 2\|y\|$. Therefore, for $x \in I$ and $\|\nu\| \le 1/h$, we have

$$|(LT_\nu\sigma_{1/h})(q-f)(x)| \le 2h^m \int_{\|y-\nu\|>2/h} |K(x,y)|(2\|y\|)^m\,dy \le 2^{m+1}h^m M,$$

where M is a constant such that $\int |K(x,y)|\|y\|^m\,dy \le M$ for almost every $x \in I$. The existence of such a constant is guaranteed by (1.4). Consequently,

$$|L_h(q-f)(x')| \le 2^{m+1}h^m M \quad \text{for a.e. } x' \in I,$$

from which (3.6) follows at once. This completes the proof of the theorem. □

Remarks. Theorems 2.1 and 3.1 together characterize the approximation order of an integral operator with its kernel satisfying (1.2)–(1.4) by means of the degree of polynomials the operator can reproduce. Therefore, only integer approximation orders appear in our settings. Also, Theorem 3.1 remains true if the cube I in (3.1) is replaced by any nonempty open subset of $\mathbb{R}^n$.

The following corollary will play an important role in the rest of the paper.

COROLLARY 3.4. *Let S be a shift-invariant subspace of $L_p(\mathbb{R}^n)$. Let K be a kernel function satisfying conditions* (1.2)–(1.4)*, and let L be the integral operator given in* (1.1)*. Suppose that L is a projection onto S, i.e., L maps $L_p(\mathbb{R}^n)$ to S and $Lf = f$ for all $f \in S$. Then S provides approximation order m if and only if $\Pi_{m-1} \subset S$.*

Proof. If $Lq = q$ for all $q \in \Pi_{m-1}$, then by Theorem 2.1 we have

$$\|L_h f - f\|_p \le C|f|_{m,p} h^m \quad \text{for all } f \in W_p^m(\mathbb{R}^n).$$

Consequently, since $L(\sigma_{1/h} f) \in S$,

$$\inf_{s\in S} \|\sigma_h s - f\|_p \le \|\sigma_h L \sigma_{1/h} f - f\|_p = \|L_h f - f\|_p = \mathcal{O}(h^m) \quad \text{for all } f \in W_p^m(\mathbb{R}^n).$$

Hence S provides approximation order m.

For the necessity part, assume that S provides approximation order m. Consider $f \in C_c^\infty(\mathbb{R}^n)$. Then

$$\inf_{s_h \in \sigma_h(S)} \|f - s_h\|_p = \mathcal{O}(h^m).$$

But for any $s \in S$,

$$L_h(\sigma_h s) = (\sigma_h L \sigma_{1/h})(\sigma_h s) = (\sigma_h L)(s) = \sigma_h s.$$

It follows that

$$\begin{aligned} \|f - L_h f\|_p &\le \|f - \sigma_h s\|_p + \|\sigma_h s - L_h f\|_p \\ &= \|f - \sigma_h s\|_p + \|L_h(\sigma_h s - f)\|_p \\ &\le (1 + \|L\|_p)\|f - \sigma_h s\|_p. \end{aligned}$$

Here we used $\|L_h\|_p = \|L\|_p$, proved by a change of variables. From the preceding inequality, we have

$$\|L_h f - f\|_p \le (1 + \|L\|_p) \inf_{s\in S} \|f - \sigma_h s\|_p = \mathcal{O}(h^m).$$

By Theorem 3.1, $Lq = q$ for all $q \in \Pi_{m-1}$. □

4. Stable families. In this section, we study finitely generated shift-invariant spaces whose generators decay in a polynomial rate and have stable shifts.

In order to give a precise definition of "decay" for a function, we utilize a family of spaces $\mathcal{L}_m$, which originated from [13]. For $m \in \mathbb{Z}_+$, $\mathcal{L}_m$ is defined to be the space of functions f such that

$$\operatorname*{ess\,sup}_{x\in I} \sum_{\nu\in\mathbb{Z}^n} |f(x+\nu)|(1 + \|x+\nu\|)^m < \infty.$$

If $f \in \mathcal{L}_m$, then we denote by $\|f\|_{\mathcal{L}_m}$ the essential supremum in this definition. It is clear that $\mathcal{L}_m \subset L_p(\mathbb{R}^n)$ for all $1 \le p \le \infty$ and for all $m = 0, 1, 2, \ldots$. The space $\mathcal{L}_m$ is closely related to a certain Banach algebra, which we now define. Let $\mathcal{B}_m$ be the set of functions τ of the form

$$\tau(z) = \sum_{\nu\in\mathbb{Z}^n} a(\nu) z^\nu, \quad z \in \mathbb{R}^n,$$

with

$$\|\tau\|_{\mathcal{B}_m} := \sum_{\nu\in\mathbb{Z}^n} |a(\nu)|(1 + \|\nu\|)^m < \infty. \tag{4.1}$$

Here $\mathbb{R}^n$ denotes the torus in $\mathbb{C}^n$:

$$\mathbb{R}^n = \{(z_1, z_2, \dots, z_n) \ : \ z_j \in \mathbb{C} \text{ and } |z_j| = 1 \text{ for } \ j = 1, 2, \dots, n\}.$$

With the norm $\| \cdot \|_{\mathcal{B}_m}$ and the usual pointwise operations (addition and multiplication), $\mathcal{B}_m$ becomes a Banach algebra. The relationship between $\mathcal{L}_m$ and $\mathcal{B}_m$ is revealed in the next lemma. For f and g in $\mathcal{L} := \mathcal{L}_0$, define

$$[f, g](z) := \sum_{\nu \in \mathbb{Z}^n} \langle T_\nu f, g \rangle z^\nu, \quad z \in \mathbb{R}^n.$$

This series converges uniformly and absolutely. (See part (a) of the following lemma.) Here $\langle f, g \rangle := \int f(x)\bar{g}(x)\,dx$ denotes the inner product of two functions f and g on $\mathbb{R}^n$, and $\bar{g}$ means the complex conjugate of g. In the following, we use the symbol $*'$ to denote a "semidiscrete" convolution. Thus $(f*'a)(x) = \sum_{\nu \in \mathbb{Z}^n} f(x - \nu)a(\nu)$, or $f*'a = \sum_{\nu \in \mathbb{Z}^n} a(\nu) T_\nu f$.

Lemma 4.1. *Let $f, g \in \mathcal{L}_m$ and $\tau \in \mathcal{B}_m$. Write $\tau(z) = \sum_{\nu \in \mathbb{Z}^n} a(\nu) z^\nu$. Then*

(a) *$[f, g] \in \mathcal{B}_m$ and $\|[f, g]\|_{\mathcal{B}_m} \le \|f\|_{\mathcal{L}_m} \|g\|_{\mathcal{L}_m}$,*

(b) *$f*'a \in \mathcal{L}_m$ and $\|f*'a\|_{\mathcal{L}_m} \le \|f\|_{\mathcal{L}_m} \|\tau\|_{\mathcal{B}_m}$, and*

(c) *$1/\tau \in \mathcal{B}_m$ if $\tau(z) \ne 0$ for all $z \in \mathbb{R}^n$ (Wiener's lemma).*

Proof. First note that for any $v, w \in \mathbb{R}^n$,

$$1 + \|v\| \le 1 + \|v + w\| + \|w\| \le (1 + \|v + w\|)(1 + \|w\|).$$

Consequently,

$$(1 + \|v\|)^m \le (1 + \|v + w\|)^m \, (1 + \|w\|)^m. \tag{4.2}$$

Now, to show that $[f, g] \in \mathcal{B}_m$, we calculate, with the aid of inequality (4.2),

$$\begin{aligned} \sum_{\nu \in \mathbb{Z}^n} |\langle T_\nu f, g \rangle|(1 + \|\nu\|)^m &= \sum_{\nu \in \mathbb{Z}^n} \left| \int f(x - \nu)\bar{g}(x)\,dx \right| (1 + \|\nu\|)^m \\ &\le \sum_\nu \sum_\mu \int_I \big| f(x + \mu - \nu) g(x + \mu) \big| (1 + \|\nu\|)^m \,dx \\ &\le \int_I \sum_\mu \sum_\nu \big| f(x + \mu - \nu) \big| \big| g(x + \mu) \big| (1 + \|x + \mu - \nu\|)^m (1 + \|x + \mu\|)^m \,dx \\ &\le \int_I \|f\|_{\mathcal{L}_m} \|g\|_{\mathcal{L}_m} \,dx = \|f\|_{\mathcal{L}_m} \|g\|_{\mathcal{L}_m}. \end{aligned}$$

This proves part (a) of the lemma.

For part (b), we have a similar calculation:

$$\begin{aligned} &\sum_{\nu \in \mathbb{Z}^n} |(f*'a)(x + \nu)|(1 + \|x + \nu\|)^m \\ &\qquad \le \sum_\nu \sum_\mu |f(x + \nu - \mu) a(\mu)| (1 + \|x + \nu\|)^m \\ &\qquad \le \sum_\mu \sum_\nu |f(x + \nu - \mu)| |a(\mu)| (1 + \|x + \nu - \mu\|)^m (1 + \|\mu\|)^m \\ &\qquad \le \|f\|_{\mathcal{L}_m} \|\tau\|_{\mathcal{B}_m}. \end{aligned}$$

Taking the essential supremum for $x \in I$, we obtain the assertion in (b). The assertion in (c) follows immediately from Lemmas 3.2 and 3.3 of [16]. □

We now consider stability of the shifts of a finite number of functions. Let $p \in [1, \infty]$. A finite subset $\Phi = \{\phi_j\}_{j=1}^N$ of $\mathcal{L}$ is said to have L_p-stable shifts, if there are constants $A > 0$ and $B > 0$ such that for any finitely supported sequences a_j $(j = 1, \ldots, N)$,

$$A \sum_{j=1}^{N} \|a_j\|_{\ell_p} \leq \Big\| \sum_{j=1}^{N} \phi_j *' a_j \Big\|_{L_p} \leq B \sum_{j=1}^{N} \|a_j\|_{\ell_p}. \tag{4.3}$$

The above definition is equivalent to the assertion that (4.3) holds for any sequences $a_j \in \ell_p$ when $1 \leq p < \infty$ and for any $a_j \in c_0$ when $p = \infty$. (The space c_0 consists of all sequences vanishing at infinity.) Indeed, the subspace of finitely supported sequences is dense in ℓ_p $(1 \leq p < \infty)$ and dense in c_0. Furthermore, the series involved in $f *' a$ converges absolutely for any $f \in \mathcal{L}$ and $a \in \ell_p$ (cf. [13]).

Let us recall from [13] that Φ has L_p-stable shifts if and only if there are sequences $b_j \in \ell_1(\mathbb{Z}^n)$, $j = 1, \ldots, N$, such that the functions $\widetilde{\phi}_j := \phi_j *' b_j$ are dual to the functions ϕ_j in the sense that

$$\langle T_\nu \phi_j, T_\mu \widetilde{\phi}_k \rangle = \delta_{\nu\mu} \delta_{jk}, \quad j, k = 1, \ldots, N, \ \mu, \nu \in \mathbb{Z}^n, \tag{4.4}$$

where δ is the Kronecker symbol. Therefore, we may drop the affiliation L_p- from the word "stability".

Theorem 4.2. *Let $\Phi = \{\phi_1, \phi_2, \ldots, \phi_N\}$ be a subset of $\mathcal{L}$ that has stable shifts. Then $\Phi \subset \mathcal{L}_m$ if and only if $\{\widetilde{\phi}_1, \widetilde{\phi}_2, \ldots, \widetilde{\phi}_N\} \subset \mathcal{L}_m$.*

Proof. Because of the dual relationship, we need to prove only one of the two implications. Suppose that $\Phi \subset \mathcal{L}_m$. Let $\Phi(z)$ be the $N \times N$ Gramian matrix of Φ:

$$\Phi(z) := \big([\phi_j, \phi_k](z) \big)_{1 \leq j,k \leq N}, \quad z \in \mathbb{R}^n.$$

By Lemma 4.1(a), every entry of $\Phi(z)$ lies in $\mathcal{B}_m$. Since $\mathcal{B}_m$ is a Banach algebra, every minor of $\Phi(z)$, including the determinant $\det \Phi(z)$, is in $\mathcal{B}_m$. By Theorems 4.1 and 4.2 of [13], the stability of Φ implies that $\det \Phi(z) \neq 0$ for all $z \in \mathbb{R}^n$. It follows from Lemma 4.1(c) that the function $1/\det \Phi(z)$, $z \in \mathbb{R}^n$, is in $\mathcal{B}_m$. We conclude that every entry $\tau_{jk}(z)$ of the inverse matrix of the Gramian $\Phi(z)$ is in $\mathcal{B}_m$. By [13, Theorem 4.1], the dual functions of ϕ_j are given by

$$\widetilde{\phi}_j := \sum_{k=1}^{N} \phi_k *' b_{jk}, \quad j = 1, \ldots, N,$$

where b_{jk} are the sequences representing the functions τ_{jk}:

$$\tau_{jk}(z) = \sum_{\nu \in \mathbb{Z}^n} b_{jk}(\nu) z^\nu, \quad z \in \mathbb{R}^n, \ j, k = 1, \ldots, N.$$

In light of Lemma 4.1(b), $\widetilde{\phi}_j \in \mathcal{L}_m$ for $j = 1, \ldots, N$. □

5. Approximation by projection. In this section, we study the approximation order provided by projections onto some shift-invariant spaces. We employ the spaces $\mathcal{L}_m$ introduced in the preceding section.

For a finite subset $\Phi = \{\phi_j\}_{j=1}^N$ of $L_p(\mathbb{R}^n)$, we denote by $S(\Phi)_p$ the $L_p(\mathbb{R}^n)$-closure of the linear span of the functions ϕ_j $(j = 1, \ldots, N)$ and their shifts. When the generators ϕ_j have stable shifts and $p = 2$, we can use their dual functions to construct an orthogonal projection onto $S(\Phi)_2$. Since the functions in Φ and their dual functions decay sufficiently fast, we can extend the orthogonal projections to operators on $L_p(\mathbb{R}^n)$ for $1 \le p \le \infty$. These facts are formalized as follows.

Lemma 5.1. *Let $\{\phi_1, \phi_2, \ldots, \phi_N\}$ be a subset of $\mathcal{L}_m$ with stable shifts and let $\widetilde{\phi}_j$ be the dual functions* (*in the sense of* (4.4)). *Set*

$$Pf := \sum_{j=1}^{N} \sum_{\nu \in \mathbb{Z}^n} \langle f, T_\nu \widetilde{\phi}_j \rangle \, T_\nu \phi_j, \quad f \in L_p(\mathbb{R}^n),$$

$$K(x,y) := \sum_{j=1}^{N} \sum_{\nu \in \mathbb{Z}^n} \phi_j(x-\nu) \overline{\widetilde{\phi}_j}(y-\nu), \quad x, y \in \mathbb{R}^n.$$

Then the following statements are true:

(a) *P is a projection of $L_p(\mathbb{R}^n)$ onto $S(\Phi)_p$.*

(b) *For every $f \in L_p(\mathbb{R}^n)$, $(Pf)(x) = \int K(x,y) f(y)\,dy$, $x \in \mathbb{R}^n$.*

(c) *The kernel K satisfies conditions* (1.2)–(1.4).

Proof. Let S be the linear space of all functions of the form $\sum_{j=1}^{N} \phi_j *' a_j$, where a_j lies in $\ell_p(\mathbb{Z}^n)$ for $1 \le p < \infty$ and lies in $c_0(\mathbb{Z}^n)$ for $p = \infty$. Because of the stability condition in (4.3), the space S is a closed shift-invariant subspace of $L_p(\mathbb{R}^n)$. This is the smallest closed shift-invariant space containing the functions ϕ_j ($j = 1, \ldots, N$) and their shifts. Therefore, $S = S(\Phi)_p$. In other words, any function $f \in S(\Phi)_p$ has a representation of the form $\sum_{j=1}^{N} \phi_j *' a_j$. Now we see that (a) is true by virtue of the duality (4.4). The assertion in (b) comes from a straightforward calculation. It remains to verify that the kernel function K satisfies conditions (1.2)–(1.4). Condition (1.2) is obviously satisfied. From the decay properties of ϕ_j and $\widetilde{\phi}_j$, (1.3) follows easily. Indeed,

$$\operatorname*{ess\,sup}_{y \in I} \int |K(x,y)|\,dx \le \sum_{j=1}^{N} \|\phi_j\|_{L_1} \|\widetilde{\phi}_j\|_{\mathcal{L}}.$$

To verify (1.4), we use (4.2) to obtain

$$(1 + \|y\|)^m |K(x,y)| \le \sum_{j=1}^{N} \sum_{\nu \in \mathbb{Z}^n} (1 + \|y - \nu\|)^m \, |\widetilde{\phi}_j(y-\nu)| \, (1 + \|\nu\|)^m \, |\phi_j(x - \nu)|.$$

When $x \in I$, $\|\nu\| \le 1 + \|x - \nu\|$ for every $\nu \in \mathbb{Z}^n$. Consequently,

$$\begin{aligned} &\operatorname*{ess\,sup}_{x \in I} \int (1 + \|y\|)^m |K(x,y)|\,dy \\ &\qquad \le \operatorname*{ess\,sup}_{x \in I} \sum_{j=1}^{N} \sum_{\nu \in \mathbb{Z}^n} (2 + \|x - \nu\|)^m |\phi_j(x-\nu)| \int (1 + \|y\|)^m |\widetilde{\phi}_j(y)|\,dy. \end{aligned}$$

The right-hand side is finite because of the decay properties of ϕ_j and $\widetilde{\phi}_j$. □

We are now in a position to consider the approximation power of the projection operator P, which is determined by the so-called Strang–Fix conditions. Let $m \in \mathbb{N}$, $1 \le p \le \infty$, and $\Phi = \{\phi_j\}_{j=1}^{N} \subset \mathcal{L}_m$. Note that the functions ϕ_j decay fast enough so that the partial derivatives $D^\alpha \widehat{\phi}_j$ exist and are continuous for $j = 1, \ldots, N$ and

$|\alpha| \le m-1$. (Here $\widehat{\phi}$ denotes the Fourier transform of ϕ.) We say that Φ satisfies the Strang–Fix conditions of order m if there is a finite linear combination ϕ of the functions ϕ_j and their shifts such that

$$\widehat{\phi}(0) \neq 0, \tag{5.1}$$

$$D^\alpha \widehat{\phi}(2\pi\nu) = 0, \quad |\alpha| \le m-1, \quad 0 \neq \nu \in \mathbb{Z}^n. \tag{5.2}$$

THEOREM 5.2. *Let Φ be a finite subset of $\mathcal{L}_m$ that has stable shifts. Let P be the projection given in Lemma* 5.1. *Let $h > 0$ and $P_h = \sigma_h P \sigma_{1/h}$. Then*

(a) *P_h is a projection onto $\sigma_h(S(\Phi)_p)$;*

(b) *if Φ satisfies the Strang–Fix conditions of order m, then*

$$\|P_h f - f\|_p \le C|f|_{m,p} h^m, \quad f \in W_p^m(\mathbb{R}^n), \tag{5.3}$$

where C is a constant independent of f, p, and h.

Proof. To prove (a), let $s_h \in S_h$. Then $s_h = \sigma_h s$ for some $s \in S(\Phi)_p$. It follows that

$$P_h s_h = (\sigma_h P \sigma_{1/h})(\sigma_h s) = \sigma_h P s = \sigma_h s = s_h.$$

To prove (b), suppose that Φ satisfies the Strang–Fix conditions of order m. Let $q \in \Pi_{m-1}$ and write $\Phi = \{\phi_1, \phi_2, \ldots, \phi_N\}$. As is well known (see, e.g., [18]), there exist sequences a_j, $j = 1, \ldots, N$, such that

(i) $|a_j(\nu)| = \mathcal{O}(\|\nu\|^{m-1})$ as $\|\nu\| \to \infty$;

(ii) $q = \sum_{j=1}^N \phi_j *' a_j$.

Note that the growth property (i) and the decay properties of ϕ_j ensure that the series defining $\phi_j *' a_j$ are absolutely convergent for almost all x. By the duality relation (4.4), we have $a_j(\nu) = \langle q, T_\nu \widetilde{\phi}_j \rangle$. Thus

$$Pq = \sum_{j=1}^N \sum_{\nu \in \mathbb{Z}} a_j(\nu) T_\nu \phi_j = \sum_{j=1}^N \phi_j *' a_j = q.$$

Since $Pq = q$ for all $q \in \Pi_{m-1}$, Theorem 2.1 asserts that the estimate in (5.3) is valid. $\square$

The converse of the preceding theorem is also true. Therefore, we have the following characterization.

THEOREM 5.3. *Let Φ be a finite subset of $\mathcal{L}_m$ that has stable shifts. For $1 \le p \le \infty$, the shift-invariant space $S(\Phi)_p$ provides approximation order m if and only if Φ satisfies the Strang–Fix conditions of order m.*

Proof. The sufficiency follows from Theorem 5.2. To prove the necessity, we apply Lemma 5.1 and Corollary 3.4 to conclude that $Pq(x) = \int K(x,y)q(y)\,dy = q(x)$ for $x \in \mathbb{R}^n$ and $q \in \Pi_{m-1}$, where P and K are as given in Lemma 5.1. Let $q_\alpha(x) := x^\alpha/\alpha!$, $x \in \mathbb{R}^n$, and

$$\rho_\alpha := \sum_{j=1}^N \langle q_\alpha, \widetilde{\phi}_j \rangle \phi_j, \quad |\alpha| \le m-1.$$

Then $\rho_\alpha \in \operatorname{span}(\Phi)$. Since $q_\alpha(y) = \sum_{\beta\le\alpha} q_\beta(y-\xi)q_{\alpha-\beta}(\xi)$ for all $y, \xi \in \mathbb{R}^n$, we obtain by Lemma 5.1 that

$$\begin{aligned} q_\alpha(x) = Pq_\alpha(x) &= \int \sum_{j=1}^{N} \sum_{\nu\in\mathbb{Z}^n} \overline{\widetilde{\phi}}_j(y-\nu)\phi_j(x-\nu)q_\alpha(y)\,dy \\ &= \sum_{\beta\le\alpha} \sum_{\nu\in\mathbb{Z}^n} \sum_{j=1}^{N} \Big[\int \overline{\widetilde{\phi}}_j(y-\nu)q_\beta(y-\nu)\,dy\Big]\phi_j(x-\nu)q_{\alpha-\beta}(\nu), \end{aligned}$$

where $x \in \mathbb{R}^n$ and $|\alpha| \le m-1$. In short, we get $q_\alpha = \sum_{\beta\le\alpha} \rho_\beta *' q_{\alpha-\beta}$ for $|\alpha| \le m-1$, which implies that Φ satisfies the Strang–Fix conditions of order m. (Here and hereafter we use $f*'g$ for $f*'(g|_{\mathbb{Z}^n})$ when g is a continuous function on $\mathbb{R}^n$.) This implication is well known. For example, the argument used in [12] can be carried over verbatim to the present setting. □

A few remarks are in order. A characterization of the L_2-approximation order of a shift-invariant space is given in [2], where the conditions on decay and stability are not required. In [11], a characterization of the L_p-approximation order ($1 \le p \le \infty$) is established for the shift-invariant space generated by a compactly supported function ϕ with $\hat{\phi}(0) \neq 0$.

6. Quasi-interpolation and cardinal interpolation. In this section, we consider the approximation power provided by two important approximation schemes: quasi-interpolation and cardinal interpolation.

Let us first look at quasi-interpolation. A quasi-interpolant associated with a collection $\Phi = \{\phi_j\}_{j=1}^N \subset \mathcal{L}$ is a linear mapping $Q(\Phi, \Lambda)$, given by

$$Q(\Phi,\Lambda)f := \sum_{\nu\in\mathbb{Z}^n} \sum_{j=1}^{N} \lambda_j(T_{-\nu}f)\,T_\nu\phi_j, \tag{6.1}$$

where the λ_j's are linear functionals on $L_p(\mathbb{R}^n)$ and Λ is the collection of these λ_j's.

Recall that a bounded linear functional λ on $L_p(\mathbb{R}^n)$ $(1 \le p < \infty)$ has the representation

$$\lambda f = \int g(x)f(x)\,dx, \quad f \in L_p(\mathbb{R}^n),$$

where g is some function in $L_{p'}(\mathbb{R}^n)$ with $1/p' + 1/p = 1$. We say that λ is compactly supported if g is. Moreover, by the Riesz representation theorem (see, e.g., [10, p. 216]), a bounded linear functional λ on $C_0(\mathbb{R}^n)$ has the representation

$$\lambda f = \int f\,d\mu, \quad f \in C_0(\mathbb{R}^n),$$

where μ is a complex Borel measure on $\mathbb{R}^n$. We say that λ is compactly supported if there is a compact subset F of $\mathbb{R}^n$ such that $\mu(E \setminus F) = 0$ for every Borel subset E of $\mathbb{R}^n$. If this is the case, then the domain of λ can be extended to $C(\mathbb{R}^n)$.

The approximation order provided by a quasi-interpolant is closely related to the Strang–Fix conditions (see, e.g., $[3, 4, 5, 6, 7, 8, 18]$). This fact is substantiated again in the following theorem. Our primary interest here is to show that the results concerning approximation power provided by integral operators may be easily applied to quasi-interpolants.

Theorem 6.1. *Let $m \in \mathbb{N}$, $1 \le p \le \infty$, and $\Phi = \{\phi_j\}_{j=1}^N \subset \mathcal{L}_m$. Then there is a set of compactly supported bounded linear functionals $\Lambda = \{\lambda_j\}_{j=1}^N$ on $L_p(\mathbb{R}^n)$ for $1 \le p < \infty$ or on $C_0(\mathbb{R}^n)$ for $p = \infty$ such that the quasi-interpolant $Q(\Phi, \Lambda)$ provides approximation order m if and only if Φ satisfies the Strang–Fix conditions of order m.*

To prove this theorem we need the following.

Lemma 6.2. *Let A be any bounded linear operator on $L_p(\mathbb{R}^n)$ $(1 \le p \le \infty)$. Let J denote the operator $\chi_m *$, where χ_m is the function given in* (2.2). *The operator A provides approximation order m if and only if the composite operator AJ does so.*

Proof. By definition, $A_h = \sigma_h A \sigma_h^{-1}$, $J_h = \sigma_h J \sigma_h^{-1}$, and $(AJ)_h = \sigma_h (AJ) \sigma_h^{-1}$. Clearly, $(AJ)_h = A_h J_h$. We also note that by a change of variable, $\|A_h\|_p \le \|A\|_p$ for all $h > 0$, where $\|A_h\|_p$ and $\|A\|_p$ denote the operator norms of A_h and A on $L_p(\mathbb{R}^n)$. It follows that

$$\begin{aligned}\Big| \|A_h f - f\|_p - \|(AJ)_h f - f\|_p \Big| \\ &\le \|(A_h f - f) - (A_h J_h f - f)\|_p \\ &= \|A_h(f - J_h f)\|_p \le \|A\|_p \, \|f - J_h f\|_p.\end{aligned}$$

By Lemma 2.3(c), $\|f - J_h f\|_p = \mathcal{O}(h^m)$. The proof is complete. □

Proof of Theorem 6.1. To prove the sufficiency, we assume that Φ satisfies the Strang–Fix conditions of order m. Recall from [12] that there are finitely supported sequences a_j, $j = 1, \dots, N$, such that the function $\phi := \sum_{j=1}^N \phi_j *' a_j$ satisfies $\phi *' q = q$ for all $q \in \Pi_{m-1}$. Let Q be the operator given by

$$Qf := \phi *' (\chi_m * f), \quad f \in L_p(\mathbb{R}^n),$$

where χ_m is the function given in (2.2). By Lemma 2.3(d), we have $Qq = q$ for all $q \in \Pi_{m-1}$. Clearly, the operator Q can be written as a quasi-interpolant in the form (6.1) and as an integral operator in the form (1.1) with the kernel function

$$K(x, y) := \sum_{j=1}^N \sum_{\nu \in \mathbb{Z}^n} \chi_m *' a_j(\nu - y)\, \phi_j(x - \nu), \quad x, y \in \mathbb{R}^n.$$

This kernel function satisfies conditions (1.2)–(1.4) since a_j and χ_m are all compactly supported. By Theorem 2.1, we conclude that Q provides approximation order m.

To prove the necessity, we assume that $\Lambda = \{\lambda_j\}_{j=1}^N$ is a set of linear functionals as described in the theorem such that the quasi-interpolant $Q := Q(\Phi, \Lambda)$ provides approximation order m. Consider the composite operator $L := QJ$, where $J := \chi_m *$. By straightforward computation, we obtain

$$Lf(x) = \int K(x, y) f(y)\, dy, \quad x \in \mathbb{R}^n,$$

where

$$K(x, y) = \sum_{\nu \in \mathbb{Z}^n} \sum_{j=1}^N \lambda_j \big(\chi_m(\cdot + \nu - y)\big) \phi_j(x - \nu), \quad x, y \in \mathbb{R}^n.$$

Clearly, the kernel K satisfies (1.2). Moreover, since the λ_j's are bounded and compactly supported, K satisfies conditions (1.3) and (1.4). In light of Lemma 6.2, L

provides approximation order m. By Theorem 3.1, $Lq = q$ for all $q \in \Pi_{m-1}$. Consequently, $Qq = q$ for all $q \in \Pi_{m-1}$ by Lemma 2.3(d).

In order to complete the proof, we need to consider linear functionals on Π_{m-1}. Let Δ_{m-1} denote the set of multiindices β with $|\beta| \le m-1$. Let λ be a linear functional on Π_{m-1}. We claim that there exists a sequence a with support on Δ_{m-1} such that for all $\nu \in \mathbb{Z}^n$,

$$\lambda(q(\cdot + \nu)) = \sum_{\alpha \in \mathbb{Z}^n} a(\alpha) q(\nu + \alpha) \quad \text{for all } q \in \Pi_{m-1}. \tag{6.2}$$

Indeed, for each $\alpha \in \Delta_{m-1}$, we can find a unique polynomial $q_\alpha \in \Pi_{m-1}$ such that $q_\alpha(\alpha) = 1$ and $q_\alpha(\gamma) = 0$ for $\gamma \in \Delta_{m-1} \setminus \{\alpha\}$. Let $a(\alpha) := 0$ for $\alpha \in \mathbb{Z}^n \setminus \Delta_{m-1}$ and $a(\alpha) := \lambda q_\alpha$ for $\alpha \in \Delta_{m-1}$. Then for every $\gamma \in \Delta_{m-1}$, we have

$$\sum_{\alpha \in \mathbb{Z}^n} a(\alpha) q_\gamma(\alpha) = a(\gamma) = \lambda q_\gamma.$$

Since any polynomial $q \in \Pi_{m-1}$ can be represented as $\sum_{\gamma \in \Delta_{m-1}} q(\gamma) q_\gamma$, it follows that

$$\sum_{\alpha \in \mathbb{Z}^n} a(\alpha) q(\alpha) = \lambda q.$$

The above identity is true for all $q \in \Pi_{m-1}$. Thus if we replace q by $q(\cdot + \nu)$, where $\nu \in \mathbb{Z}^n$, we obtain the desired relation (6.2).

By what has been proved in the previous paragraph, for each $j = 1, \ldots, N$, we can find sequences a_j with support on Δ_{m-1} such that

$$\lambda_j(q(\cdot + \nu)) = \sum_{\alpha \in \mathbb{Z}^n} a_j(\alpha) q(\nu + \alpha) \quad \text{for all } q \in \Pi_{m-1}.$$

It follows that

$$Q(\Phi, \Lambda) q = \sum_{\nu \in \mathbb{Z}^n} q(\nu) \phi(\cdot - \nu),$$

where $\phi := \sum_{j=1}^N \phi_j *' a_j$. Therefore, $Q(\Phi, \Lambda) q = q$ for all $q \in \Pi_{m-1}$ implies that $\phi *' q = q$ for all $q \in \Pi_{m-1}$. Hence Φ satisfies the Strang–Fix conditions of order m. The proof of the theorem is complete. □

Now let us consider cardinal interpolation. Let ϕ be a continuous function in $\mathcal{L}$. To interpolate a bounded sequence b by the shifts of ϕ, we look for a bounded sequence a such that the function $\phi *' a$ agrees with b on $\mathbb{Z}^n$. This is often called "cardinal interpolation." The problem is said to be "poised" if for any bounded sequence b there exists a unique bounded sequence a for which $\phi *' a$ is a cardinal interpolant to b. Employing the same argument used in [3] and [8], we can show that cardinal interpolation with $\phi \in \mathcal{L}$ is poised if and only if the symbol of ϕ, defined by the equation

$$s_\phi(\xi) := \sum_{\nu \in \mathbb{Z}^n} \phi(\nu) e^{i\nu \cdot \xi}, \quad \xi \in \mathbb{R}^n,$$

does not vanish anywhere on $\mathbb{R}^n$. If this is the case, we define the function ψ by the rule

$$\widehat{\psi} := \widehat{\phi} / s_\phi. \tag{6.3}$$

The function ψ turns out to be well defined and to be the basic Lagrange interpolation function because

$$\psi(\nu) = \delta_{0\nu}, \quad \nu \in \mathbb{Z}^n.$$

Therefore, $\psi *'$ is the cardinal interpolation operator.

THEOREM 6.3. *Let $m > 0$ and let ϕ be a continuous function in $\mathcal{L}_m$. Assume that cardinal interpolation with ϕ is poised. Then the function ψ as defined in equation* (6.3) *belongs to $\mathcal{L}_m$. Furthermore, the following statements are equivalent:*

(a) *The cardinal interpolation operator $\psi *'$ provides L_∞-approximation order m.*

(b) *The function ϕ satisfies the Strang–Fix conditions of order m.*

(c) *The shift-invariant space $S(\phi)_p$ generated by ϕ in $L_p(\mathbb{R}^n)$ $(1 \le p \le \infty)$ provides L_p-approximation order m.*

Proof. First, we prove that (a) and (b) are equivalent. Let

$$Lf := \psi *'(\chi_m * f), \quad f \in L_\infty(\mathbb{R}^n),$$

where χ_m is the function given in (2.2). Then

$$Lf(x) = \int K(x,y) f(y)\, dy$$

with the kernel function

$$K(x,y) = \sum_{\nu \in \mathbb{Z}^n} \chi_m(\nu - y)\psi(x - \nu).$$

Clearly, K satisfies condition (1.2). Moreover, since $\psi \in \mathcal{L}_m$ and χ_m is compactly supported, K also satisfies conditions (1.3) and (1.4). By Lemma 6.2 and Theorems 2.1 and 3.1, we conclude that the cardinal interpolation operator $\psi *'$ provides L_∞-approximation order m if and only if $Lq = q$ for all $q \in \Pi_{m-1}$. The latter is equivalent to saying that $\psi *' q = q$ for all $q \in \Pi_{m-1}$. If this is true, then by the Poisson summation formula, we have $\hat{\psi}(0) = 1$ and $D^\alpha \hat{\psi}(2\beta\pi) = 0$ for $|\alpha| \le m-1$ and $\beta \in \mathbb{Z}^n \setminus \{0\}$. Since $\hat{\phi} = \hat{\psi} s_\phi$, by the Leibniz rule for differentiation, we see that ϕ satisfies the Strang–Fix conditions of order m. Conversely, if ϕ satisfies the Strang–Fix conditions of order m, then so does ψ because $\hat{\psi} = \hat{\phi}/s_\phi$. Hence for any $q \in \Pi_{m-1}$, there exists a sequence a such that $|a(\nu)| = \mathcal{O}(\|\nu\|^{m-1})$ as $\|\nu\| \to \infty$ and $q = \sum_{\nu \in \mathbb{Z}^n} a(\nu)\psi(\cdot - \nu)$. But $\psi(\nu) = \delta_{0\nu}$, so this gives $a(\nu) = q(\nu)$ for $\nu \in \mathbb{Z}^n$. In other words, $\psi *' q = q$ for all $q \in \Pi_{m-1}$. Thus conditions (a) and (b) are equivalent.

Second, we show that conditions (b) and (c) are equivalent. By the assumption, $s_\phi(\xi) \ne 0$ for all $\xi \in \mathbb{R}^n$. It follows that the shifts of ϕ are stable. Indeed, by the Poisson summation formula, we have

$$s_\phi(\xi) = \sum_{\beta \in \mathbb{Z}^n} \hat{\phi}(\xi + 2\pi\beta), \quad \xi \in \mathbb{R}^n.$$

Hence $s_\phi(\xi) \ne 0$ implies $\hat{\phi}(\xi + 2\pi\beta) \ne 0$ for at least one $\beta \in \mathbb{Z}^n$. Thus Theorem 5.3 is applicable to the present situation. The equivalence of (b) and (c) follows. ☐

Remark. After this work had been completed, we learned that Kyriazis in [15] also considered approximation by means of kernel operators. In his paper, Kyriazis obtained lower bounds for the approximation order provided by integral operators under a different set of conditions assumed for the kernel functions. However, his paper does not contain any result on the upper bound for the approximation order.

GAS DYNAMICS SYSTEM: TWO SPECIAL CASES*

FRANÇOIS BEREUX[†], ERIC BONNETIER[†], AND PHILIPPE G. LeFLOCH[†]

Abstract. We consider the compressible Euler system of conservation laws for the mass, momentum, and energy of a gas. We prove that Murat and Tartar's compensated compactness method applies to this system in two cases: either

(1) the equations of state have a special form (specifically, the Lagrangian sound speed is a function of the pressure only) that leads to the existence of a large family of entropy pairs

or

(2) the conservation law of energy is replaced by the conservation law for the specific entropy. Indeed, the latter is the physically meaningful formulation when the system is derived by relaxation from an isentropic two-phase mixture.

The paper primarily investigates the structure of the gas dynamics system and includes a complete description of the (i) mathematical entropies, (ii) decoupling properties, (iii) invariant domains after Chuey, Conley, and Smoller's theory, and (iv) Tartar's commutation relations. The existence of weak solutions in cases (1) and (2) above is deduced from the pioneering work of DiPerna.

Key words. gas dynamics, discontinuous solutions, entropy, compensated compactness method

1. Introduction.

This paper considers certain hyperbolic systems of PDEs that arise in the modeling of compressible fluid flows and multiphase mixtures. We are interested in proving the existence of entropy discontinuous solutions based on the vanishing artificial viscosity method. We recall that smooth solutions to hyperbolic conservation laws do not exist globally in time even if the initial data are smooth. Weak solutions in the sense of distributions are sought and must be further selected with the so-called entropy criterion; cf. Lax [17, 18] and Dafermos [12] for background on hyperbolic problems.

Activity concerning the existence of entropy weak solutions to systems of conservation laws with data in L^∞ was initiated in the pioneering work of DiPerna [13, 14, 15]. In particular, in [14], the existence of globally-defined-in-time, weak solutions to the isentropic Euler system was established. This system is composed of two conservation laws for the mass and momentum of the gas assuming (formally) that the specific entropy is a constant. DiPerna's proof can be viewed as one of the main success of the compensated compactness method introduced by Murat and Tartar [22, 30]. The latter is an efficient tool for studying nonlinear composite limits of weakly convergent sequences. The proof by DiPerna uses the fact that the system of isentropic gas dynamics is genuinely nonlinear in the sense of Lax and admits a large family of mathematical entropy pairs, i.e., additional conservation laws. The latter are necessary to take advantage of Tartar's commutation relations.

DiPerna's results have been extended in several directions for systems of two (and more) conservation laws. We refer to the works by Serre [26, 28, 29] and Chen et al.

We focus here on the full system of gas dynamics composed of three conservation laws of mass, momentum, and energy. Generally speaking, this system shares few properties with the isentropic system due to the lack of mathematical entropies, and it has been recognized that the compensated compactness method should fail in general [2]. In this paper, we intend to tackle this system in two *special* instances. In both cases, it will be established that the 3×3 system of gas dynamics has a very similar structure to that of the isentropic 2×2 system. Our results can therefore be viewed as a direct corollary of DiPerna's fundamental work [13, 14]. The purpose of this paper is above all to investigate the mathematical properties of the gas dynamics system. It contains a full description of the mathematical entropies, decoupling properties, bounded invariant domains, and properties of Tartar's commutation relations.

Our motivation in this paper has been to search for (necessary and) sufficient conditions that allow one to use the compensated compactness technique on the gas dynamics system. In section 2, we investigate a *special class of equations of state*—specifically, the case where the Lagrangian sound speed of the gas depends upon the pressure only. This assumption leads to many interesting properties for the Euler system. It admits a large family of mathematical entropy pairs, and Chuey, Conley, and Smoller's theory applies to obtain bounded invariant domains. It follows that under the assumption above, the system belongs to the class of rich systems introduced by Serre [27]. We prove the strong convergence of the vanishing artificial viscosity method, which implies existence of entropy weak solutions. We recall that the 3×3 system under consideration possesses two genuinely nonlinear characteristic fields and one linearly degenerate field. Observe that in our main theorem in section 2 (Theorem 2.1), all of the variables (say, density, velocity, and entropy) are proven to be L^∞ functions; furthermore, the entropy variable can propagate oscillations as expected. Note that Theorem 2.1 allows vacuum states in the solution. The system is not strictly hyperbolic at those points, and we use [14].

As this paper was completed, we learned of a result similar to our Theorem 2.1—however, in the Lagrangian framework—by Chen and Dafermos [4].

Section 3 of the paper considers a coupled set of two isentropic Euler systems that arise in the modeling of two-phase mixtures. By relaxation from this 4×4 model, a system of three conservation laws is derived. We observe that, somewhat surprisingly, and for smooth solutions only, the latter is equivalent to the gas dynamics system. However, the systems are distinct for discontinuous solutions. Instead of the classical formulation that is composed of the conservation laws of mass, momentum, and energy supplemented with the entropy inequality, we arrive at a set of conservation laws for the mass, momentum, and *specific entropy* supplemented with an *energy* inequality. In this new form, the gas dynamics system happens to share many properties with the isentropic 2×2 system. We check that the linearly degenerate characteristic field is a Temple field so that the method of Benzoni-Gavage and Serre [1] applies. We prove the existence of entropy solutions for this rather nonclassical formulation of the gas dynamics system. The key of the proof is that a uniform estimate for the total variation of the specific entropy can be derived.

For further properties of the compressible Euler equations, we refer to Bonnetier and LeFloch [2].

2. A class of equations of state.

We consider the compressible Euler system, which consists of the conservation laws for the mass, momentum, and total energy of a gas [10]:

$$\begin{aligned}\partial_t\rho + \partial_x(\rho u) &= 0,\\ \partial_t(\rho u) + \partial_x(\rho u^2 + p) &= 0,\\ \partial_t(\rho E) + \partial_x(\rho u E + pu) &= 0.\end{aligned} \tag{2.1}$$

The main unknowns are the specific density ρ, the velocity u, and the total energy E. We define the internal energy e as $e = E - u^2/2$ and the specific entropy S and the temperature $T > 0$ by the classical relation $TdS = pd(1/\rho) + de$. The equation of state yields the pressure p as a (smooth enough) function of ρ and S:

$$p = p(\rho, S) > 0, \qquad p_\rho > 0 \quad \text{for all } \rho > 0. \tag{2.2a}$$

We also make the standard assumption that

$$p_{\rho\rho} > 0 \quad \text{and} \quad p_S > 0 \quad \text{for all } \rho > 0. \tag{2.2b}$$

The Eulerian sound speed c is classically defined by

$$c^2 = p_\rho(\rho, S) = \big(p_\rho + \rho^{-2} p p_e\big)(\rho, e).$$

It will be convenient to express our results in term of the variables u, p, and S. Therefore, we set $\rho = \tilde\rho(p, S)$ and $e = \tilde e(p, S)$ with the natural constraint $\tilde e_p + p\big(1/\tilde\rho\big)_p = 0$. We introduce the specific volume $v = 1/\rho$ (we shall use the notation $v = \tilde v(p, S)$ as well) and the Lagrangian sound speed $C = \rho c$. The latter is the relevant wave speed when the mass Lagrangian coordinates are being used.

In view of (2.2), system (2.1) is strictly hyperbolic and possesses two genuinely nonlinear characteristic fields associated with the wave speeds $u \pm c$ and one linearly degenerate field associated with u. Strict hyperbolicity, however, may be lost in the vacuum where $\rho = 0$. It is well known that discontinuities form in finite time in initially smooth solutions to (2.1). We are interested in proving existence of weak solutions based on the vanishing artificial viscosity method. Therefore, we consider the following approximation:

$$\begin{aligned}\partial_t\rho^\varepsilon + \partial_x(\rho^\varepsilon u^\varepsilon) &= \varepsilon\, \partial_{xx}^2(\rho^\varepsilon),\\ \partial_t(\rho^\varepsilon u^\varepsilon) + \partial_x(\rho^\varepsilon (u^\varepsilon)^2 + p^\varepsilon) &= \varepsilon\, \partial_{xx}^2(\rho^\varepsilon u^\varepsilon),\\ \partial_t(\rho^\varepsilon E^\varepsilon) + \partial_x(\rho u^\varepsilon E^\varepsilon + p^\varepsilon u^\varepsilon) &= \varepsilon\, \partial_{xx}^2(\rho^\varepsilon E^\varepsilon).\end{aligned} \tag{2.3}$$

We shall assume that smooth solutions to (2.3) assuming a smooth initial data exist. For a proof in the isentropic case, see [14]. Initial data for u, p, and S—say, u_0, p_0, and S_0, respectively—are assumed to be given functions in $L^\infty(\mathbb{R})$ and, with obvious notation, we assume that ρ_0 and $\rho_0 E_0$ belong to $L^1(\mathbb{R})$. The entropy inequality is classically stated as

$$\partial_t(\rho S) + \partial_x(\rho u S) \le 0, \tag{2.4}$$

which, at least formally, can be checked for the limit of the $(u^\varepsilon, p^\varepsilon, S^\varepsilon)$'s as $\varepsilon \to 0$.

In this section, we consider the case where the Lagrangian sound speed is a function of the pressure, i.e.,

$$C(p, S) = C_0(p) \quad \text{or, equivalently,} \quad \rho c(p, S) = C_0(p). \tag{2.5}$$

As we prove below, (2.5) is satisfied if for some positive constants a and b,

$$\frac{1}{\tilde{\rho}(p,S)} - aS \quad \text{and} \quad \tilde{e}(p,S) - bS \quad \text{are functions of } p \text{ only.} \tag{2.6}$$

Our main result of existence and convergence is now stated.

THEOREM 2.1. *Consider the compressible Euler system* (2.1)–(2.2) *with an equation of state of the form* (2.6)*. Then we have the following uniform bounds for the approximate solutions* $(u^\varepsilon, p^\varepsilon, S^\varepsilon)$ *generated by* (2.3):

$$\begin{aligned} &0 \le p^\varepsilon(t,x), |u^\varepsilon(t,x)| \le \text{const.}\big(\|p_0\|_{L^\infty(\mathbb{R})} + \|u_0\|_{L^\infty(\mathbb{R})}\big), \\ &0 \le S^\varepsilon(t,x) \le \text{const.} \sup\nolimits_{\mathbb{R}} S_0, \end{aligned} \tag{2.7a}$$

where the constants are independent of t, x, *and* ε, *and*

$$\|\rho^\varepsilon(t)\|_{L^1(\mathbb{R})} = \|\rho_0^\varepsilon\|_{L^1(\mathbb{R})}, \qquad \|\rho^\varepsilon(t)E^\varepsilon(t)\|_{L^1(\mathbb{R})} = \|\rho_0^\varepsilon E_0\|_{L^1(\mathbb{R})}. \tag{2.7b}$$

Let us make one of the following two assumptions:

(1) *the approximations are bounded away from the vacuum, i.e.,*

$$0 < \text{const.} \le p^\varepsilon(t,x) \le \text{const.} \tag{2.8a}$$

with uniform constants;

(2) *the equation of state has the form*

$$p = k\,\rho^\gamma \quad \textit{with } \gamma > 1 \quad \textit{and} \quad k > 0. \tag{2.8b}$$

Then there is a triplet (u,p,S) *in* $L^\infty(\mathbb{R}_+ \times \mathbb{R})^3$ *with* ρ *and* ρE *in* $L^\infty(\mathbb{R}_+, L^1(\mathbb{R}))$ *and a subsequence of* $(u^\varepsilon, p^\varepsilon, S^\varepsilon)$ *such that*

$$\begin{aligned} &u^\varepsilon \to u, \qquad p^\varepsilon \to p \quad \textit{in the strong } L^q \textit{ norm for all finite } q, \\ &\rho^\varepsilon = \tilde{\rho}(p^\varepsilon, S^\varepsilon) \rightharpoonup \rho = \tilde{\rho}(p,S) \quad \textit{in the weak-}\star\ L^\infty \textit{ topology,} \end{aligned} \tag{2.9}$$

and (u,p,S) *is an entropy weak solution to* (2.1) *and* (2.4)*.*

The proof of Theorem 2.1 is based on four lemmas dealing, respectively, with

1. the mathematical entropies (Lemma 2.1),
2. a decoupling property (Lemma 2.2),
3. Tartar's equation (Lemma 2.3), and
4. the invariant regions (Lemma 2.4).

We shall state these four lemmas, give their proofs, and conclude with a proof of Theorem 2.1. First, we provide a complete description of the set of entropies. A pair (U,F) is a mathematical entropy for the system

$$\partial_t w + \partial_x f(w) = 0$$

if every smooth solution w satisfies the additional conservation law

$$\partial_t U(w) + \partial_x F(w) = 0.$$

Equivalently, the pair (U,F) should satisfy

$$\nabla F(w) = \nabla U(w) \nabla f(w). \tag{2.10}$$

We prove that (2.5) is a necessary and sufficient condition for the existence of a large family of entropies for (2.1).

Lemma 2.1. *Consider the compressible Euler system* (2.1). *Let us view C as a function of the variables* (p, S).

(1) *Suppose first that $\partial_S C$ is identically zero, so* (2.5) *holds. Then the mathematical entropies U are of the form*

$$U(u, p, S) = \rho h(S) + \rho h_1(u, p) \tag{2.11a}$$

(*with ρ viewed as a function of (p, S)*), *where h is an arbitrary function and h_1 satisfies the following wave equation:*

$$\partial^2_{uu} h_1 - \partial_p \big(C_0(p)^2 \, \partial_p h_1 \big) = 0. \tag{2.11b}$$

(2) *Suppose that $\partial_S c$ does not vanish identically on any interval. Then the mathematical entropies U are of the form*

$$U(u, p, S) = \rho h(S), \tag{2.12}$$

where h is an arbitrary function.

The existence of entropies that depend upon u for particular equations of state was discovered by Schochet [25] and Croisille and Villedieu [11]. For simplicity, we did not include the trivial entropies ρ, ρu, and ρE in case (2) of Lemma 2.1. However, the latter are recovered in case (1) by a suitable choice of h_1.

Lemma 2.2. *Assume that* (2.5) *holds. We denote by g an antiderivative of $-1/C_0(p)^2$ and by G an antiderivative of pg', i.e.,*

$$g'(p) = -\frac{1}{C_0(p)^2}, \qquad G'(p) = p g'(p).$$

Then there exist two functions $g_1 = g_1(S)$ and $g_2 = g_2(S)$, one of which is nonconstant, that satisfy

$$g_1'(S) \geq 0 \quad \text{and} \quad g_2'(S) \geq 0 \tag{2.13}$$

so that

$$\frac{1}{\rho(p, S)} = g(p) + g_1(S), \qquad e(p, S) = -G(p) + g_2(S). \tag{2.14}$$

The assumption (2.6) made in Theorem 2.1 corresponds to the choice $g_1(S) = aS$ and $g_2(S) = bS$ in (2.14). We continue our discussion with the more general assumption, i.e., (2.5). We shall return to (2.6) in the course of the proof of Theorem 2.1. Assuming (2.5), we now show that (2.1) can be formally decoupled into a system of two equations for u and p and a scalar equation for S. As explained now, the decoupling holds for smooth solutions in Lagrangian coordinates but also in a weaker sense for weak solutions in Eulerian coordinates.

For smooth solutions, system (2.1) is equivalent to

$$\begin{aligned} \partial_t p + u \partial_x p + \frac{C_0(p)^2}{\rho} \partial_x u &= 0, \\ \partial_t u + u \partial_x u + \frac{1}{\rho} \partial_x p &= 0, \\ \partial_t S + u \partial_x S &= 0. \end{aligned} \tag{2.15}$$

The decoupling becomes clear when using Lagrangian coordinates. Consider the change of variables $(t, x) \to (t, y)$ defined by

$$\partial_t y = \rho u, \qquad \partial_x y = -\rho. \tag{2.16}$$

Again, for smooth solutions, (2.15) transforms into

$$\begin{aligned} \partial_t p + C_0(p)^2 \partial_y u &= 0, \\ \partial_t u + \partial_y p &= 0, \\ \partial_t S &= 0. \end{aligned} \tag{2.17}$$

The first two equations in (2.17) can be solved independently of the last one. This is not true when (2.5) is not satisfied and C_0 depends on S as well.

Next, consider the case of discontinuous solutions. The change of variables $(t, x) \to (t, y)$ is Lipschitz continuous if ρ and u are measurable and bounded functions. We recall that the Lagrangian–Eulerian transformation preserves the notion of entropy weak solution [32]. In view of (2.14), the equations in (2.1) take the form

$$\begin{aligned} \partial_t \frac{1}{g + g_1} + \partial_x \frac{u}{g + g_1} &= 0, \\ \partial_t \frac{u}{g + g_1} + \partial_x \left(\frac{u^2}{g + g_1} + p \right) &= 0, \\ \partial_t \frac{-G(p) + g_2(S) + u^2/2}{g + g_1} + \partial_x \left(\frac{(-G(p) + g_2(S) + u^2/2)u}{g + g_1} + pu \right) &= 0. \end{aligned} \tag{2.18}$$

Passing to Lagrangian coordinates, we are left with

$$\begin{aligned} \partial_t (g(p) + g_1(S)) - \partial_y u &= 0, \\ \partial_t u + \partial_y p &= 0, \\ \partial_t \left(-G(p) + \frac{u^2}{2} + g_2(S) \right) + \partial_y (pu) &= 0, \end{aligned} \tag{2.19}$$

i.e.,

$$\begin{aligned} \partial_t g(p) - \partial_y u &= -\partial_t g_1(S), \\ \partial_t u + \partial_y p &= 0, \\ \partial_t \left(-G(p) + \frac{u^2}{2} \right) + \partial_y (pu) &= -\partial_t g_2(S). \end{aligned} \tag{2.20}$$

Observe that the right-hand side of (2.20) depends on u and p but not on S. Consider the first two equations in (2.17) and (2.20). The left-hand sides in (2.17) and (2.20) coincide (up to multiplying the first equation in (2.17) by $g'(p)$); the right-hand side of (2.17) is identically zero, whereas the right-hand side of (2.20) contains a term due to the fact that the specific entropy need not be a smooth function.

Possible oscillations in the sequence $(u_\varepsilon, p_\varepsilon, S_\varepsilon)$ are classically described by a Young measure $\nu_{t,x}$, i.e., a probability measure for almost every (t, x) such that

$$f(u_\varepsilon, p_\varepsilon, S_\varepsilon) \rightharpoonup \langle \nu_{t,x}, f \rangle \quad L^\infty \text{ weak-}\star$$

for every continuous function f. Uniform bounds on the amplitude of the $(u_\varepsilon, p_\varepsilon, S_\varepsilon)$'s are assumed for the time being (cf. Lemma 2.4 below). The following lemma is concerned with the reduction of the Young measure to a Dirac mass measure.

Lemma 2.3. *Let $\nu = \nu(u, p, S)$ be a Young measure with compact support that satisfies Tartar's commutation relations*

$$\langle \nu, U_1 F_2 - U_2 F_1 \rangle = \langle \nu, U_1 \rangle \langle \nu, F_2 \rangle - \langle \nu, U_2 \rangle \langle \nu, F_1 \rangle \tag{2.21}$$

for any (U_1, F_1) and (U_2, F_2) in the following family of entropy pairs:

$$\begin{aligned} U(u, p, S) &= \rho h(S) + \rho h_1(u, p), \\ F(u, p, S) &= \rho u h(S) + \rho u h_1(u, p) + k_1(u, p), \end{aligned} \tag{2.22}$$

where h is arbitrary, h_1 is a solution to (2.11b), *and k_1 is given by solving $k_{1,u} = C_0(p)^2 h_{1,p}$ and $k_{1,p} = h_{1,p}$. Suppose that either the closure of the support of ν contains no point with $\rho = 0$ or C_0 is defined from the equation of state* (2.8b). *Then ν is a tensor product of the form*

$$\nu(u, p, S) = \delta_{u_*} \otimes \delta_{p_*} \otimes \mu(S), \tag{2.23}$$

where u_* and p_* are constants and $\mu = \mu(S)$ is a probability measure.

Let us complete Lemma 2.3 with additional comments. We recall that Tartar obtained a reduction of the Young measure in the case of scalar equations using only one entropy function. Next, DiPerna proved a similar result for the elasticity system [13]. Following [13] and [8, 31], it is not difficult to check the following result for the 3×3 system. If the Young measure ν has a small support in the variables (u, p) about a constant state (u_*, p_*), then one extra entropy pair is enough to obtain the reduction of the Young measure to the form (2.23). Namely, one can consider the mathematical entropy

$$U(u, p, S) = \frac{u g(p)}{g(p) + g_1(S)}, \qquad F(u, p, S) = p + \frac{u^2}{2} \frac{g(p) - g_1(S)}{g(p) + g_1(S)}. \tag{2.24}$$

It remains to derive the required a priori estimates. The following result was first mentioned in [27].

Lemma 2.4. *Each domain*

$$\left\{ \pm u + \int^p \frac{dp}{C_0(p)} \leq \text{const.} \right\}$$

is an invariant domain for (2.1) *and* (2.3). *The uniform bounds*

$$\begin{aligned} &0 \leq p^\varepsilon(t, x), |u^\varepsilon(t, x)| \leq \text{const.}, \\ &0 \leq \sup_{x \in \mathbb{R}} S^\varepsilon(t, x) \leq \sup_{x \in \mathbb{R}} S^\varepsilon(0, x) \end{aligned} \tag{2.25}$$

hold for the approximate solutions $(u^\varepsilon, p^\varepsilon, S^\varepsilon)$ generated by (2.3) *with a constant independent of t, x, and ε.*

We now give the proofs of the lemmas stated above.

Proof of Lemma 2.1. It is convenient to use the Lagrangian coordinates (2.16) which transform (2.1) into

$$\begin{aligned} \partial_t u + \partial_y p &= 0, \\ \partial_t p + C(p, S)^2 \partial_y u &= 0, \\ \partial_t S &= 0. \end{aligned}$$

Searching for conservation laws of the form $\partial_t\varphi(u,p,S)+\partial_y\psi(u,p,S)=0$, we arrive at the following necessary and sufficient conditions:

$$\begin{aligned}\psi_u &= C(p,S)^2\varphi_p,\\ \psi_p &= \varphi_u,\\ \psi_S &= 0.\end{aligned}\tag{2.26}$$

Eliminating ψ in (2.26), we obtain

$$\begin{aligned}\varphi_{uu} &= \big(C(p,S)^2\varphi_p\big)_p,\\ \varphi_{uS} &= 0,\\ (C(p,S)^2\varphi_p)_S &= 0.\end{aligned}\tag{2.27}$$

First, suppose that $C=C_0(p)$. Then the third equation in (2.27) reduces to $\varphi_{pS}=0$. It follows that φ has the form

$$\varphi(u,p,S)=h(S)+h_1(u,p),$$

where h is an arbitrary function of S and h_1 is a solution to the wave equation (2.11b). The associated entropy flux ψ is obtained by integration from (2.26). We can recover the conservation laws (2.1) with suitable choices of h and h_1. We also observe that the entropy flux does not depend on S. In particular, this implies that the pair (h_1,ψ) is also an entropy pair for the 2×2 system composed of the first two equations in (2.17).

Next, consider the case that $C_S\neq 0$. Taking the u-derivative of the third equation in (2.27) and combining it with the second equation in (2.27) yields $(C^2)_S\varphi_{up}=0$. Therefore, φ can be decomposed into

$$\varphi(u,p,S)=h_2(p,S)+h_3(u).$$

From the first equation in (2.27), it follows that $h_3''(u)=\partial_p\big(C^2\partial_p h_2\big)(p,S)$, which therefore equals some constant, say α. We deduce the general form of h_2 and h_3 by integrating out the latter:

$$\varphi(u,p,S)=\frac{\alpha u^2}{2}+\beta u+\int^p\frac{\alpha p+\gamma}{C^2(p,S)}dp+h(S),$$

where α, β, and γ are arbitrary constants and h is an arbitrary function of S. Choosing the constant in a proper way, we see that the only available entropies are the specific volume, the velocity, the energy, and any function of the physical entropy S. In other words, there is no extra conservation law but

$$\partial_t S=0.$$

The above conclusions are easily rewritten in the Eulerian setting by observing that $U=\rho\varphi$, $F=\rho u\varphi+\psi$ is an entropy pair for (2.1) if (φ,ψ) is an entropy pair in the Lagrangian framework. Finally, the conditions that guarantee the convexity of the entropies are derived from straightforward computations; cf. also Harten [16] for the entropy (2.12). The proof of Lemma 2.1 is complete. ∎

Proof of Lemma 2.2. Using the specific volume $v=1/\rho$ instead of ρ, condition (2.5) reads $-p_v=C_0(p)^2$, which is readily integrated (in view of the definition of g, i.e., $g'(p) = -1/C_0(p)^2$) into $g(p) = v - g_1(S)$ for some function g_1. This leads to the expression for the density ρ in (2.14). The expression for the energy e follows immediately by integration from the constraint $\tilde{e}_p + p\tilde{v}_p = 0$. Observe that all of standard thermodynamics constraints are satisfied. In particular, we have

$$p\,dv + de = (pg_1'(S) + g_2'(S))\,dS \equiv TdS$$

with $T > 0$ if (2.13) holds and if not both of the functions g_1 and g_2 are constants. □

Proof of Lemma 2.3. First, consider relation (2.21) for the family of entropies of the form of (2.11) with $h = 0$. We observe that the latter reduces to the classical commutation relations for the isentropic system. Namely, define a two-variable Young measure $\tilde{\nu} = \tilde{\nu}(u,p)$ by the relation

$$\langle \tilde{\nu}, \theta \rangle = \frac{\langle \nu, \rho(p,S)\theta(u,p)\rangle}{\langle \nu, \rho(p,S)\rangle} \qquad \text{for every continuous } \theta.$$

For every continuous h_1 and h_2, we have

$$\begin{aligned} &\langle \nu, \rho h_1(\rho u h_2 + k_2) - \rho h_2(\rho u h_1 + k_1)\rangle \\ &\quad = \langle \nu, \rho h_1\rangle\langle \nu, (\rho u h_2 + k_2)\rangle - \langle \nu, \rho h_2\rangle\langle \nu, (\rho u h_1 + k_1)\rangle. \end{aligned} \tag{2.28}$$

Using (2.28) and choosing $h_2 = 1$ and $k_2 = 0$, we get the following relation for the new measure $\tilde{\nu}$:

$$\langle \tilde{\nu}, \rho u h_1\rangle - \langle \tilde{\nu}, (\rho u h_1 + k_1)\rangle = \langle \tilde{\nu}, h_1\rangle\langle \tilde{\nu}, u\rangle\langle \nu, \rho\rangle - \langle \nu, \rho\rangle \left\langle \tilde{\nu}, uh_1 + \frac{k_1}{\rho} \right\rangle.$$

This combined with (2.28) easily yields

$$\langle \tilde{\nu}, h_1 k_2 - k_2 h_1\rangle = \langle \tilde{\nu}, h_1\rangle\langle \tilde{\nu}, k_2\rangle - \langle \tilde{\nu}, k_2\rangle\langle \tilde{\nu}, h_1\rangle. \tag{2.29}$$

Therefore, we can apply the classical reduction theorem to $\tilde{\nu}$ and (2.29), that is, either the result in [13] in the strictly hyperbolic case (if the support of ν does not meet the vaccum) or the result in [14] if the equation of state is given by (2.8b) and a vacuum is allowed. It follows that the Young measure $\tilde{\nu}$ is either a Dirac mass in (u,p) or has its support on the vacuum line $\{p = 0\}$. We observe that we may modify the measure ν at the vacuum points to meet our purpose, and (2.23) is established. □

Proof of Lemma 2.4. Under assumption (2.5), system (2.1) admits the three Riemann invariants $\pm u + \int^p dp/C_0(p)$ and S as is clear from the decoupled formulation (2.17). The desired estimates in Lemma 2.4 are a consequence of Chuey, Conley, and Smoller's theory about bounded invariant domains for nondegenerate parabolic equations [9]. The relevant properties for each of the above functions, say $G(u,p,S) = G(\rho, \rho u, \rho E)$, are as follows:

$$\nabla_{(\rho,\rho u,\rho E)} G \text{ is a left eigenvector} \tag{2.30a}$$

of the Jacobian matrix of the conservative system (2.1), and G is a quasi-convex function, that is, for every $\xi \in \mathbb{R}^3$,

$$\xi \cdot \nabla_{(\rho,\rho u,\rho E)} G = 0 \Longrightarrow \nabla^2_{(\rho,\rho u,\rho E)} G \geq 0. \tag{2.30b}$$

These properties are easily checked for $G = \pm u + \int^p dp/C_0(p)$ or $G = S$.

Note that assumption (2.5) is not necessary to derive the a priori estimate for S^ε; cf. [3] for details. Consider for simplicity a sequence of entropy solutions to (2.1). Consider the entropy inequality associated with the entropy (2.12) for functions satisfying $h' > 0$ and $h'' > 0$. Integrating the inequality $\partial_t \rho^\varepsilon\, h(S^\varepsilon) \le 0$ with respect to the space variable, we get

$$\frac{d}{dt}\int_{\mathbb{R}} \rho^\varepsilon\, h(S^\varepsilon)\, dx \,\le 0. \tag{2.31}$$

Writing (2.31) for the family of functions $h_q(S) = S^q$ with $q \to \infty$ yields at the limit

$$\frac{d}{dt}\sup_{x\in\mathbb{R}} S^\varepsilon(t,x) \le 0,$$

at least away from the vacuum. We observe that without loss of generality the value of S can be arbitrarily modified at a point where $\rho = 0$. Namely, in the equations in (2.1) and the entropy inequalities, all of the terms containing the variable S are multiplied by ρ. The proof of Lemma 2.4 is complete. □

Proof of Theorem 2.1. In view of Lemma 2.4, there exists a Young measure to represent the composite weak-$\star$ limits of the sequence $(u^\varepsilon, p^\varepsilon, S^\varepsilon)$. In order to apply the compensated compactness method to (2.3), we recall [13] that the entropy dissipation measures corresponding to the entropies in (2.22),

$$\partial_t U(u,p,S) + \partial_x F(u,p,S),$$

remain in a compact subset of the negative Sobolev space H^{-1}_{loc}. This follows from an energy-type estimate for (2.3) and Murat's lemma [21]. Therefore, the classical div–rot lemma applies and provide us with (2.21). Lemma 2.3 shows that the Young measure is a Dirac mass in the variables (u,p) but not necessarily in S. It follows that there is a pair (u,p) and a subsequence such that $(u^\varepsilon, p^\varepsilon)$ converges strongly in all L^q $(q < \infty)$ and S^ε converges weakly. Extracting another subsequence if necessary, we can assume that ρ^ε converges weakly to some function, say ρ. We then *define* S by the relation $\tilde\rho(p,S) = \rho$. We emphasize that with the choice of variables (u,p,ρ), the conservative variables and fluxes in (2.1) are linear functions of ρ. Namely, this is obvious for the conservation laws of mass and momentum. On the other hand, for the energy equation, we observe that assumption (2.6) used with (2.14) implies

$$\rho E = \rho\left(\frac{u^2}{2} - G(p) - \frac{bg(p)}{a}\right)$$

so that the conservative variable and the flux in the conservation law of energy are linear in ρ. Note that assumption (2.6) is required in this step of the proof only. Since u^ε and p^ε converge strongly and ρ^ε converges weakly but we need to deal with *linear functions* of ρ^ε only, one can justify the passage to the limit in (2.3) and get (2.1). The proof of Theorem 2.1 is complete. □

3. Relaxed model for two-phase mixtures. Let us begin with the following system of four conservation laws $(i = 1, 2)$:

$$\begin{aligned} &\partial_t \rho_i + \partial_x(\rho_i u_i) = 0,\\ &\partial_t(\rho_i u_i) + \partial_x(\rho_i u_i^2 + p_i) = s_i\,\frac{\rho_2}{\delta}(u_1 - u_2), \end{aligned} \tag{3.1}$$

which describes a mixture of two fluids, say of gas and water bubbles. Here $s_1 = -1$ and $s_2 = 1$. The main unknowns are the mass density ρ_i and the velocity u_i of the phases $i = 1, 2$. We supplement the system with the equations of state for the pressures p_i. We shall assume that

$$p_i = \tilde{p}_i(\rho_i), \quad \frac{d\tilde{p}_i}{d\rho} > 0, \quad \frac{d^2\tilde{p}_i}{d\rho^2} > 0,$$

which ensures the hyperbolicity and genuine nonlinearity of (3.1). The internal energy $e_i = \tilde{e}_i(\rho_i)$ is defined by the relation

$$\frac{d\tilde{e}_i'}{d\rho} = \frac{\tilde{p}_i}{\rho_i^2} \tag{3.2}$$

and the total energy for phase i is $E_i = e_i + u^2/2$. In view of

$$\partial_t(\rho_i E_i) + \partial_x(\rho_i u_i E_i + p_i u_i) = s_i u_i \frac{\rho_2}{\delta}(u_1 - u_2), \tag{3.3}$$

which follows from (3.1) (at least for classical solutions), it is natural to supplement (3.1) with the entropy inequality

$$\partial_t(\rho_1 E_1 + \rho_2 E_2) + \partial_x(\rho_1 u_1 E_1 + \rho_2 u_2 E_2 + p_1 u_1 + p_2 u_2) = -\frac{\rho_2}{\delta}(u_1 - u_2)^2 \le 0. \tag{3.4}$$

This model describes a mixture of gas and liquid (or solid) dropplets. The source term in the momentum equation is called the drag force. The parameter δ can be identified with a relaxation time, i.e., the time for the small dropplets to acquire the same velocity as the one of the gas; cf. Sainsaulieu [24] for the derivation of this model from a more microscopic physical description.

Our focus here is on analyzing the zero-relaxation limiting system derived from (3.1). When $\delta \to 0$, we formally have

$$u_1 = u_2 \equiv u \quad \text{(average flow velocity)}, \tag{3.5}$$

and we are left with the 3 × 3 relaxed system

$$\begin{aligned} \partial_t \rho_i + \partial_x(\rho_i u) = 0, \quad i = 1, 2 \\ \partial_t\big((\rho_1 + \rho_2)u\big) + \partial_x\big((\rho_1 + \rho_2)u^2 + p_1 + p_2\big) = 0, \end{aligned} \tag{3.6}$$

while the entropy inequality (3.4) becomes

$$\partial_t\left(\rho_1 e_1 + \rho_2 e_2 + \frac{(\rho_1 + \rho_2)u^2}{2}\right) + \partial_x\big((\rho_1 e_1 + \rho_2 e_2)u + (p_1 + p_2)u\big) \le 0. \tag{3.7}$$

The main unknowns of the new system are taken to be ρ_1, ρ_2, and u.

At this stage it is interesting to observe that—for classical solutions—(3.6)–(3.7) coincides with the gas dynamics system studied in section 2. However, the weak solutions of both systems do not coincide. To make our point, we introduce the new variables

$$\rho = \rho_1 + \rho_2, \qquad S = \frac{\rho_2}{\rho}$$

together with the familiar notation

$$p = p_1 + p_2, \qquad e = e_1 + e_2, \qquad E = e + \frac{u^2}{2}$$

so that (3.6)–(3.7) takes the form

$$\begin{aligned} \partial_t \rho + \partial_x(\rho u) &= 0, \\ \partial_t(\rho u) + \partial_x(\rho u^2 + p) &= 0, \\ \partial_t(\rho S) + \partial_x(\rho S u) &= 0 \end{aligned} \tag{3.8}$$

and

$$\partial_t(\rho E) + \partial_x(\rho u E + pu) \leq 0. \tag{3.9}$$

For smooth solutions, (3.8) is equivalent to system (2.1). In particular, the family of mathematical entropies derived in Lemma 2.1 for (2.1) is the same for (3.8). The entropy weak solutions to both systems are distinct, however, since the classical formulation of the gas dynamic system conserves the total energy and lets the entropy decrease, while (3.8)–(3.9) conserves the entropy while decreasing the energy!

We shall prove that the new formulation (3.8)–(3.9) allows us to apply the compensated compactness method in all generality without assuming restriction (2.5) on the equation of state. For the sake of generality, we disregard special form of p that could be derived from the above relation $p = p_1 + p_2$. Consider the approximate solutions ρ^ε, u^ε, and S^ε given by solving

$$\begin{aligned} \partial_t \rho + \partial_x(\rho u) &= \varepsilon\, \partial_{xx} \rho, \\ \partial_t(\rho u) + \partial_x(\rho u^2 + p) &= \varepsilon\, \partial_{xx}(\rho u), \\ \partial_t(\rho S) + \partial_x(\rho S u) &= \varepsilon\, \partial_{xx}(\rho S) \end{aligned} \tag{3.10}$$

from the initial data ρ_0, u_0, and S_0 in L^∞. Observe that inequality (3.9) is automatically satisfied in the limit. For simplicity, we restrict ourselves to solutions that are bounded away from the vacuum. We denote by $\mathrm{BV}(\mathbb{R})$ the space of all Lebesgue-measurable, scalar-valued functions of bounded variation in one variable.

THEOREM 3.1. *Suppose that ρ^ε, u^ε, and S^ε are smooth solutions to* (3.10) *that satisfy the uniform bound*

$$\begin{gathered} 0 < \text{const.} \leq \rho^\varepsilon(t,x) \leq \text{const.}, \\ |u^\varepsilon(t,x)| \leq \text{const.}, \qquad |S^\varepsilon(t,x)| \leq \text{const.}, \end{gathered} \tag{3.11}$$

where the constants are independent of t, x, and ε. Suppose that the initial data S_0 belongs to the space $\mathrm{BV}(\mathbb{R})$. *Then there is a triplet (ρ, u, S) in $L^\infty(\mathbb{R}_+ \times \mathbb{R})^3$ and a subsequence of $(\rho^\varepsilon, u^\varepsilon, S^\varepsilon)$ so that*

$$\rho^\varepsilon \to \rho, \qquad u^\varepsilon \to u, \qquad S^\varepsilon \to S \tag{3.12}$$

in the strong L^q norm for all finite q, and (ρ, u, S) is an entropy weak solution to (3.8)–(3.9).

This convergence and existence result can be extended to the cases where either one of the conservation laws of mass, momentum, and energy is used as an "entropy inequality," while the rest of the equations are written as conservation laws (including the specific entropy). In other words, Theorem 3.1 holds for any of the following two formulations:

$$\begin{aligned} \partial_t\rho + \partial_x(\rho u) &= 0, & \partial_t\rho + \partial_x(\rho u) &\le 0,\\ \partial_t(\rho u) + \partial_x(\rho u^2 + p) &\le 0, & \partial_t(\rho u) + \partial_x(\rho u^2 + p) &= 0,\\ \partial_t(\rho E) + \partial_x(\rho u E + pu) &= 0, & \partial_t(\rho E) + \partial_x(\rho u E + pu) &= 0,\\ \partial_t(\rho S) + \partial_x(\rho S u) &= 0, & \partial_t(\rho S) + \partial_x(\rho S u) &= 0. \end{aligned} \tag{3.13}$$

Proof of Theorem 3.1. The heart of the proof is the derivation of an a priori estimate for the total variation of S^ε. A straightforward calculation using the first and third equations in (3.11) shows that S is a solution to the scalar advection-diffusion equation

$$\partial_t S^\varepsilon + V^\varepsilon\,\partial_x S^\varepsilon = \varepsilon\partial_{xx}S^\varepsilon \tag{3.14}$$

with

$$V^\varepsilon = u^\varepsilon - 2\varepsilon\partial_x(\log\rho^\varepsilon).$$

We use a classical approach to estimate the total variation of S as follows. Set $w = \partial_x S^\varepsilon$ and take $q > 1/2$. From (3.14), we deduce

$$\partial_t|w|^{2q} + \partial_x(V^\varepsilon|w|^{2q}) + (2q-1)|w|^{2q}\partial_x V^\varepsilon \le \varepsilon\partial_{xx}\left(\frac{|w|^{2q+1}}{(2q+1)}\right).$$

Letting $q \to 1/2$, we obtain

$$\partial_t|w| + \partial_x(V^\varepsilon|w|) \le \varepsilon\partial_{xx}\left(\frac{|w|^2}{2}\right).$$

Integrating the latter over $x \in \mathbb{R}$ yields an estimate for $\partial_x S^\varepsilon$:

$$\int_{\mathbb{R}} |\partial_x S^\varepsilon(t,x)|\,dx \;\le\; \int_{\mathbb{R}} |S_0'(x)|\,dx \tag{3.15}$$

when S_0 belongs to $W^{1,1}(\mathbb{R})$. The case where $S_0 \in \mathrm{BV}(\mathbb{R})$ is treated by a standard regularization process. By Helly's theorem, the sequence $\{S^\varepsilon\}$ (or a subsequence of it) converges in any L^q norm, $1 \le q < \infty$.

Next, we will apply the compensated compactness method to (3.10). We shall use functions that are entropy functions for the isentropic gas dynamics system but not for the full system; here we follow the method proposed by Benzoni-Gavage and Serre. We present the main lines of the proof and refer to [1] for details. The total variation estimate above allows us to control the nonconservative terms that arise. As before, let C denote the Lagrangian sound speed and consider the class $\mathcal{A}$ of all pairs (U,F) of the form $U = \rho h_1(u,p)$ that satisfies the wave equation (2.11b) with C_0 replaced by C, i.e.,

$$\partial^2_{uu}h_1 - \partial_p\big(C(p,S)^2\,\partial_p h_1\big) = 0 \tag{3.16}$$

for each value of S. For an entropy pair (U,F) in the class $\mathcal{A}$, it is not hard to check using (3.15) that

$$\partial_t U + \partial_x F \in \text{compact set of } H^{-1}_{\mathrm{loc}}(\mathbb{R}_+\times\mathbb{R})$$

so that the commutation equation (2.21) is satisfied by every entropy pairs in $\mathcal{A}$. From the reduction theorem of DiPerna [13] for genuinely nonlinear systems, we deduce that u^ε and p^ε converge in a strong sense. The proof of Theorem 3.1 is complete. □

Remark 3.1. Chuey, Conley, and Smoller's theory does not apply to system (3.10), and there are in general no available invariant regions. In the special case where $p = a^2 S\rho/(1-\rho)$, Peng [23] shows the existence of invariant regions for the Riemann problem and obtains global existence using the Glimm scheme.

It would be interesting to show that as the relaxation parameter δ tends to 0, the solutions of (3.1) converge strongly to a solution of the relaxed system (3.8). One can anticipate that the relaxation terms have the same effect in canceling oscillations, as we proved for the vanishing viscosity method. Rigorous convergence results were established by Chen, Levermore, and Liu [6, 7] for genuinely nonlinear 2×2 systems with relaxation. Their argument is based on the fact that from every convex entropy of the relaxed equations stems a *compatible* entropy of the full system. The scalar product of the entropy gradient with the relaxation term has a constant sign, which yields the required $H^{-1}_{\rm loc}$ compactness property.

Even though (3.1) consists of two genuinely nonlinear systems, coupled only through the lower-order source terms, a rigorous proof of convergence of the solutions $(\rho_i^\delta, u_i^\delta)_{i=1,2}$ to a solution of the relaxed system (3.8)–(3.9) seems extremely difficult. This is due mainly to the form of the relaxation terms, as we now explain.

Let us begin with the vanishing viscosity regularization for (3.1), i.e., for $i = 1, 2$,

$$\begin{aligned} &\partial_t \rho_i + \partial_x(\rho_i u_i) = \varepsilon\, \partial_{xx}\rho_i, \\ &\partial_t(\rho_i u_i) + \partial_x(\rho_i u_i^2 + p_i) = s_i\, \frac{\rho_2}{\delta}(u_1 - u_2) + \varepsilon\, \partial_{xx}(\rho_i u_i). \end{aligned} \tag{3.17}$$

We show in Proposition 3.1 below that (3.17) does not admit any invariant domain in the sense of Chuey, Conley, and Smoller. Nevertheless, assuming a uniform L^∞ bound on the solutions of (3.17), a standard energy method yields the following a priori estimate:

$$\delta^{-1/2}\|u_1^{\varepsilon,\delta} - u_2^{\varepsilon,\delta}\|_{L^2(\mathbb{R})} + \varepsilon^{1/2}\Sigma_{i=1,2}\big(\|\partial_x \rho_i^{\varepsilon,\delta}\|_{L^2(\mathbb{R})} + \|\partial_x u_i^{\varepsilon,\delta}\|_{L^2(\mathbb{R})}\big) \le \text{const.} \tag{3.18}$$

Letting δ tend to 0 first, it is easy to see that the solutions of (3.17) converge strongly in $L^2_{\rm loc}$ to a solution of (3.8)–(3.9), and Theorem 3.1 applies to the resulting 3×3 system.

On the other hand, if we let ε tend to 0 first, the desired convergence result, and therefore the existence of entropy weak solutions to (3.1) and (3.4), is a consequence of DiPerna's theorem for 2×2 genuinely nonlinear systems [14]. Furthermore, for each $\delta > 0$, these solutions satisfy the entropy inequality (3.4). On the other hand, in the terminology of [6, 7], the total energy is a compatible entropy for (3.1). It turns out that there is no other compatible entropy.

PROPOSITION 3.1.

(1) *System* (3.17) *does not admit any invariant domain in the sense of Chuey, Conley, and Smoller.*

(2) *Every entropy of* (3.17) *takes the form* $\eta_1(\rho_1, u_1) + \eta_2(\rho_2, u_2)$, *where* η_i *is an entropy for the associated subsystem*

$$\begin{aligned} &\partial_t \rho_i + \partial_x(\rho_i u_i) = 0, \\ &\partial_t(\rho_i u_i) + \partial_x(\rho_i u_i^2 + p_i) = 0. \end{aligned} \tag{3.19}$$

(3) *The only compatible entropy for* (3.17) *is the total energy* $\rho_1 E_1 + \rho_2 E_2$.

Proof. Let R_δ denote the right-hand side of (3.1). To show the first claim, observe that the invariant domains in the sense of [9] must be in the form $\pm w_i(\rho_1, \rho_1 u_1, \rho_2, \rho_2 u_2) \leq 0$, where $(w_i)_{i=1,4}$ are four Riemann invariants for (3.1). Another necessary condition is that

$$\nabla w_i \cdot R_\delta \leq 0. \tag{3.20}$$

An easy calculation shows that the Riemann invariants of (3.17) are the same as those of the subsystems and thus depend only on either (ρ_1, u_1) or (ρ_2, u_2), whereas R_δ is proportional to $u_1 - u_2$. Thus (3.20) cannot hold.

We now examine the structure of the entropy pairs $(U, F)(\rho_1, u_1, \rho_2, u_2)$ for (3.17). Eliminating the entropy flux F in condition (2.10) yields the following equations for U:

$$\begin{bmatrix} (u_1 - u_2) & -\frac{\tilde{p}_2'}{\rho_2} & \frac{\tilde{p}_1'}{\rho_1} & 0 \\ -\rho_2 & (u_1 - u_2) & 0 & -\frac{\tilde{p}_2'}{\rho_2} \\ \rho_1 & 0 & (u_1 - u_2) & \frac{\tilde{p}_1'}{\rho_1} \\ 0 & \rho_1 & -\rho_2 & (u_1 - u_2) \end{bmatrix} \begin{bmatrix} U_{\rho_1,\rho_2} \\ U_{\rho_1,u_2} \\ U_{u_1,\rho_2} \\ U_{u_1,u_2} \end{bmatrix} = 0 \tag{3.21}$$

together with

$$U_{u_i,u_i} = \frac{\tilde{p}_i'}{\rho_i} U_{\rho_i,\rho_i}, \quad i = 1, 2. \tag{3.22}$$

If $u_1 \pm (p_1')^{1/2} \neq u_2 \pm (p_2')^{1/2}$, the matrix in (3.21) is invertible and therefore

$$U_{\rho_1,\rho_2} = U_{\rho_1,u_2} = U_{u_1,\rho_2} = U_{u_1,u_2} = 0.$$

The conditions in (2.10) induce exactly the same constraints on F. Thus the entropy pairs for (3.1) have the form $(U, F) = \big(\eta_1(\rho_1, u_1) + \eta_2(\rho_2, u_2), q_1(\rho_1, u_1) + q_2(\rho_2, u_2)\big)$, where η_i satisfies (3.22), i.e., is an entropy for the ith subsystem, and q_i is the associated entropy flux. For such a pair $(U, F) = (\eta_1 + \eta_2, q_1 + q_2)$ with convex η_1 and η_2, the solutions of (3.1) obtained by the viscosity method satisfy

$$\partial_t U(\rho_1^\delta, u_1^\delta, \rho_2^\delta, u_2^\delta) + \partial_x F(\rho_1^\delta, u_1^\delta, \rho_2^\delta, u_2^\delta) \leq \nabla U \cdot R_\delta. \tag{3.23}$$

We now seek compatible entropies, i.e., pairs (U, F) for which the term on the right-hand side of (3.23) is nonpositive. In other words, we require that

$$\operatorname{sign}(u_1 - u_2)(g_1 - g_2) \leq 0 \tag{3.24}$$

for all quadruples $(\rho_1, u_1, \rho_2, u_2)$, where $g_i(\rho_i, u_i) = \eta_{i,u}(\rho_i, u_i)/\rho_i$. Condition (3.24) implies that g_i depends only on u_i, and thus

$$\eta_{i,u} = \rho_i g_i(u_i). \tag{3.25}$$

From (3.22) and the definition (3.2) of the internal energy, we obtain

$$\frac{\partial^2 \eta_i}{\partial \rho^2} = \frac{\tilde{p}_i'}{\rho_i^2} \frac{\partial^2 \eta_i}{\partial u^2} = \tilde{e}_i'' g_i''(u_i).$$

Integrating twice with respect to ρ_i, we find

$$\eta_i = \tilde{e}_i g_i'(u_i) + \rho_i h(u_i) + k(u_i)$$

for some functions h and k. From (3.25), we see that k is a constant and

$$\rho_i^{-1}\tilde{e}_i g_i''(u_i) = \rho_i^{-1}\tilde{e}_i(\rho_i) g_i''(u_i) = g_i(u_i) - h(u_i),$$

which implies that $g_i'' = 0$ since the right-hand side is independent of ρ_i. Thus g_i is a linear function of u_i, while (3.25) again implies that $h' = g_i$. We conclude that the only compatible entropies have the form

$$\eta_i = \alpha(\rho_i u_i^2/2 + e_i) + \beta\rho_i u_i + \gamma\rho_i + \zeta$$

for some constants α, β, γ, and ζ, which completes the proof of Proposition 3.1. □

THE CAUCHY PROBLEM AND THE CONTINUOUS LIMIT FOR THE MULTILAYER MODEL IN GEOPHYSICAL FLUID DYNAMICS[*]

T. COLIN[†]

Abstract. We study a multilayer model in geophysical fluid dynamics that approximately governs the large-scale motions of the atmosphere or the ocean. The model consists of n two-dimensional Euler equations which represent the evolution of n layers of liquid. These equations are written using the potential vorticity. The potential vorticity in each layer is obtained from the velocity potential of the adjacent layers. We show that the Cauchy problem for this model is globally well-posed in time for smooth initial data. In the second part of the paper, we let the number of layers tend to infinity while their thickness tends to zero. We write the system as a suitable finite-element approximation of a continuous model and show the convergence of this approximation to the classical quasi-geostrophic model.

Key words. geophysical fluid dynamics, layers model, quasi-geostrophic

1. Introduction, setting of the problem, and statement of results.

1.1. The model. Consider a fluid which is formed by the superposition of a finite number n of homogeneous layers with uniform density within each layer, the density being different from one layer to another. The multilayered quasi-geostrophic model describes concervation of potential vorticity ζ_l in each layer with the β-plane approximation. The thickness of each layer has the same value D_0, and we denote by ρ_l the density in the lth layer, $l = 1, \ldots, n$. The nondimensional model (see [9, p. 421]) reads

$$(1)\qquad \begin{cases} \left(\dfrac{\partial}{\partial t} + u_l \dfrac{\partial}{\partial x} + v_l \dfrac{\partial}{\partial y}\right) \zeta_l = -a v_l, \quad l = 1 \text{ to } n, \\ u_l = -\dfrac{\partial \psi_l}{\partial y}, \qquad v_l = \dfrac{\partial \psi_l}{\partial x}, \end{cases}$$

$$(2)\qquad \begin{cases} \zeta_1 = \Delta_{x,y}\psi_1 + f_{r1,2}(\psi_2 - \psi_1), \\ \zeta_l = \Delta_{x,y}\psi_l - f_{rl,1}(\psi_l - \psi_{l-1}) + f_{rl,2}(\psi_{l+1} - \psi_l), \quad 2 \le l \le n-1, \\ \zeta_n = \Delta_{x,y}\psi_n - f_{rn,1}(\psi_n - \psi_{n-1}), \end{cases}$$

where

$$f_{rl,1} = \frac{DF}{D_0} \frac{\rho_0}{\rho_l - \rho_{l-1}}$$

and

$$f_{rl,2} = \frac{DF}{D_0}\frac{\rho_0}{\rho_{l+1} - \rho_l}.$$

In the above equations, (u_l, v_l) is the velocity field within the lth layer. All functions depend only on the horizontal variables x and y and on the time t. The term $-av_l$ in (1) corresponds to the action of the Coriolis force in the β-plane approximation [9]. Note that the function ψ_l is in fact the physical pressure inside the lth layer; see [9, p. 421]. ρ_0 is a characteristic (constant) value for the density of the fluid and $F = f_0^2 L^2/gD$, where L (resp. D), is the characteristic horizontal (resp. vertical) scale of the fluid. f_0 is the Coriolis parameter and g is the gravitational acceleration. We introduce the following notation,

$$\beta_l = \frac{DF\rho_0}{D_0(\rho_l - \rho_{l-1})}\varepsilon^2,$$

where ε is a small (nondimensional) parameter, and we assume that

$$\frac{1}{\delta} \geq \beta_l \geq \delta \quad \text{for } l = 2, \dots, n, \tag{3}$$

where δ is a fixed positive number. Relation (3) is taken to be satisfied independently of n. The parameters $f_{rl,1}$ and $f_{rl,2}$ therefore read

$$f_{rl,1} = \frac{1}{\varepsilon^2}\beta_l, \qquad f_{rl,2} = \frac{1}{\varepsilon^2}\beta_{l+1}.$$

With this notation, system (2) takes the form

$$\begin{cases} \zeta_1 = \Delta_{x,y}\psi_1 + \dfrac{1}{\varepsilon^2}\beta_2(\psi_2 - \psi_1), \\[2ex] \zeta_l = \Delta_{x,y}\psi_l - \dfrac{1}{\varepsilon^2}\beta_l(\psi_l - \psi_{l-1}) + \dfrac{1}{\varepsilon^2}\beta_{l+1}(\psi_{l+1} - \psi_l), \quad 2 \leq l \leq n-1, \\[2ex] \zeta_n = \Delta_{x,y}\psi_n - \dfrac{1}{\varepsilon^2}\beta_n(\psi_n - \psi_{n-1}). \end{cases} \tag{4}$$

A derivation of this model and its physical meaning can be found in [9, pp. 416–422]. See also the appendix of [6].

We will use periodic boundary conditions that correspond to $(x, y) \in \mathbf{T}^2$, where $\mathbf{T}^2$ denotes the two-dimensional torus. The aim of this paper is to show that system (1)–(4) is globally well-posed for smooth initial data and to perform the limit $n \to \infty$ in a suitable sense.

The "natural" limit system is the quasi-geostrophic equation

$$\left(\frac{\partial}{\partial t} - \frac{\partial\psi}{\partial y}\frac{\partial}{\partial x} + \frac{\partial\psi}{\partial x}\frac{\partial}{\partial y}\right)\left(\Delta_{x,y}\psi + \frac{\partial}{\partial z}\left(\beta(z)\frac{\partial\psi}{\partial z}\right)\right) = -a\frac{\partial\psi}{\partial x}. \tag{5}$$

In this equation, z is a spatial variable while the function $z \mapsto \beta(z)$ is proportional to

$$\frac{1}{\dfrac{\partial\rho(z)}{\partial z}},$$

i.e., to the inverse of the square of the Brunt–Väisälä frequency (see [9, pp. 354–358]).

This system is of considerable physical interest because of the qualitative results that are readily deduced from it (see [9] and [11]). For its mathematical treatement, see [1], where the asymptotic expansion leading from some set of primitive equations to (5) is justified, and [2], where the viscous case is considered. See also [7] and [4] for analysis of models without vertical stratification.

1.2. Notation and statement of results. In section 2, we prove that for fixed n, system (1)–(4) is globally well-posed. Our result in this direction is the following (see Theorem 2.1):

Let $s > 2$ and $(\zeta_1^0, \dots, \zeta_n^0) \in (H^s(\mathbf{T}^2))^n$ be such that

$$\sum_{l=1}^{n} \int_{\mathbf{T}^2} \zeta_l^0 = 0.$$

Then there exists a unique solution $(\zeta_1, \dots, \zeta_n) \in (\mathcal{C}(\mathbf{R}^+, H^s(\mathbf{T}^2)))^n$ and $((u_1, v_1), \dots, (u_n, v_n)) \in (\mathcal{C}(\mathbf{R}^+, H^{s-1}(\mathbf{T}^2)))^{2n}$ to (1) and (4) such that $(\zeta_1, \dots, \zeta_n)(t = 0) = (\zeta_1^0, \dots, \zeta_n^0)$.

In the third section, we show how (1)–(4) may be viewed as a finite-element approximation in the vertical direction to the continuous system (5) and how the limit $n \to \infty$ can be performed. Indeed, system (4) can be viewed as a finite-element approximation in only one direction of a continuous three-dimensional elliptic equation. This leads us to introduce the functions $\Psi_1^\varepsilon(x, y, z, t)$, $\Psi_3^\varepsilon(x, y, z, t)$, and $Z_2^\varepsilon(x, y, z, t)$ below in terms of the classical basis functions. However, equation (1) is not a finite-element approximation of the corresponding continuous equation. We therefore need to introduce other auxilliary functions ($\Psi_2^\varepsilon(x, y, z, t)$ and $Z_1^\varepsilon(x, y, z, t)$) in order to write system (1)–(4) as a coherent approximation of the quasi-geostrophic model (5).

Specifically, we denote by $\phi_j^\varepsilon(z)$ the functions defined on $[0, 1]$ such that

$$\begin{aligned}
&\phi_1^\varepsilon(z) = 1 - \frac{z}{\varepsilon} \quad \text{if } 0 \le z \le \varepsilon, \quad 0 \text{ elsewhere},\\
&\phi_i^\varepsilon(z) = 1 - \frac{|z - i\varepsilon|}{\varepsilon} \quad \text{if } z \in [(i-1)\varepsilon, (i+1)\varepsilon], \quad 0 \text{ elsewhere}, \quad i = 2, \dots, n-1,\\
&\phi_n^\varepsilon(z) = 1 - \frac{1 - z}{\varepsilon} \quad \text{if } z \in [1 - \varepsilon, 1], \quad 0 \text{ elsewhere},
\end{aligned}$$

where we assume that $\varepsilon = 1/(n-1)$. We assume that there exists a smooth function $\beta(z)$ such that

$$\beta_l^\varepsilon = \frac{1}{\varepsilon} \int_{(l-2)\varepsilon}^{(l-1)\varepsilon} \beta(z) dz \quad \text{for } l = 2, \dots, n$$

and then introduce

$$\Psi_1^\varepsilon(x, y, z, t) = \sum_{l=1}^{n} \psi_l^\varepsilon(x, y, t) \phi_l^\varepsilon(z). \tag{6}$$

We also construct the piecewise-constant function $\Psi_2^\varepsilon(x, y, z, t)$, which is equal to $\psi_l^\varepsilon(x, y, t)$ on $[(l-1)\varepsilon, l\varepsilon[$ for $l = 1, \dots, n-1$, namely

$$\Psi_2^\varepsilon(x, y, z, t) = \sum_{l=1}^{n-1} \psi_l^\varepsilon(x, y, t) \mathbf{1}_{[(l-1)\varepsilon, l\varepsilon[}(z), \tag{7}$$

where $\mathbf{1}_{[a,b]}(z)$ denotes the characteristic function of $[a,b]$.

In order to solve (4), we need to consider the function Ψ_3^ε of the following form:

$$\Psi_3^\varepsilon = \sum_{i=1}^{n} f_i^\varepsilon \phi_i^\varepsilon. \tag{8}$$

Moreover, we impose the condition that Ψ_3^ε satisfies

$$\int_0^1 \Psi_3^\varepsilon(z)\phi_i^\varepsilon(z)dz = \varepsilon\psi_i^\varepsilon \quad \text{for all } i = 1, \dots, n. \tag{9}$$

Thus (9) reads

$$\int_0^1 \Psi_3^\varepsilon \phi_k^\varepsilon(z)dz = \int_0^1 \sum_{i=1}^{n} f_i^\varepsilon \phi_i^\varepsilon(z)\phi_k^\varepsilon(z)dz = \varepsilon\psi_k^\varepsilon.$$

Using the explicit values of ϕ_l^ε, we find that the coefficients (f_i^ε) are given by

$$\begin{pmatrix} \psi_1^\varepsilon \\ \cdots \\ \psi_n^\varepsilon \end{pmatrix} = B_n \begin{pmatrix} f_1^\varepsilon \\ \cdots \\ f_n^\varepsilon \end{pmatrix}, \tag{10}$$

where B_n is the $n \times n$ matrix

$$B_n = \frac{1}{6}\begin{pmatrix} 2 & 1 & 0 & & & & \\ 1 & 4 & 1 & 0 & & 0 & \\ 0 & \cdots & \cdots & \cdots & 0 & & \\ & 0 & 1 & 4 & 1 & 0 & \\ & & 0 & \cdots & \cdots & \cdots & 0 \\ & 0 & & 0 & 1 & 4 & 1 \\ & & & & 0 & 1 & 2 \end{pmatrix}.$$

In the same direction, we define the piecewise-constant function Z_1^ε by

$$Z_1^\varepsilon(x,y,z,t) = \sum_{l=1}^{n-1} \zeta_l^\varepsilon(x,y,t)\mathbf{1}_{[(l-1)\varepsilon, l\varepsilon[}(z). \tag{11}$$

We also introduce $Z_2^\varepsilon(x,y,z,t)$ defined in the same way as Ψ_3^ε:

$$Z_2^\varepsilon(x,y,z,t) = \sum_{i=1}^{n} g_i^\varepsilon \phi_i^\varepsilon, \tag{12}$$

where (g_i^ε) are given by

$$\begin{pmatrix} \zeta_1^\varepsilon \\ \cdots \\ \zeta_n^\varepsilon \end{pmatrix} = B_n \begin{pmatrix} g_1^\varepsilon \\ \cdots \\ g_n^\varepsilon \end{pmatrix}.$$

With this notation, the original system can be written exactly as follows:

$$\frac{\partial}{\partial t} Z_1^\varepsilon + \nabla \cdot ((U_2^\varepsilon, V_2^\varepsilon)(Z_1^\varepsilon + ay)) = 0, \tag{13}$$

and for all $k = 1, \dots, n$,

$$\int_0^1 Z_2^\varepsilon \phi_k^\varepsilon(z)dz = \int_0^1 \Delta_{x,y}\Psi_3^\varepsilon(z)\phi_k^\varepsilon(z)dz - \int_0^1 \beta(z)\frac{\partial \Psi_1^\varepsilon}{\partial z}\frac{\partial \phi_k^\varepsilon}{\partial z}dz, \tag{14}$$

where

$$U_2^\varepsilon = -\frac{\partial \Psi_2^\varepsilon}{\partial y} \quad \text{and} \quad V_2^\varepsilon = \frac{\partial \Psi_2^\varepsilon}{\partial x}. \tag{15}$$

The result that we obtain is as follows (for a precise statement, see Theorem 3.1):

The sequences Ψ_1^ε, Ψ_2^ε, *and* Ψ_3^ε *converge to the same limit* Ψ, *which is a solution of* (3).

2. Global existence of strong solution for fixed n.

We aim to solve (4) on the torus $\mathbf{T}^2$ with the additional restriction

$$\sum_{l=1}^n \int_{\mathbf{T}^2} \psi_l = 0.$$

We need this condition in order to ensure the uniqueness of the solution of the elliptic system (4). Indeed, this system corresponds to a discretization of a continuous problem with homogeneous Neuman boundary conditions.

One of the principal goals of this section is to prove the following result.

THEOREM 2.1. *Let* $s > 2$ *and* $(\zeta_1^0, \dots, \zeta_n^0) \in (H^s(\mathbf{T}^2))^n$ *be such that*

$$\sum_{l=1}^n \int_{\mathbf{T}^2} \zeta_l^0 = 0.$$

Then there exists a unique solution $(\zeta_1, \dots \zeta_n) \in (\mathcal{C}(\mathbf{R}^+, H^s(\mathbf{T}^2)))^n$ *and* $((u_1, v_1), \dots, (u_n, v_n)) \in (\mathcal{C}(\mathbf{R}^+, H^{s+1}(\mathbf{T}^2)))^{2n}$ *to* (1) *and* (4) *such that* $(\zeta_1, \dots, \zeta_n)(t = 0) = (\zeta_1^0, \dots, \zeta_n^0)$.

To prove this result, we use a classical energy method to obtain local-in-time existence. Then the solution is shown to extend globally using a priori estimates. The constants occurring in this section may depend on n.

2.1. Local-in-time existence.

PROPOSITION 2.2. *Let* $(\zeta_1^0, \dots, \zeta_n^0) \equiv \zeta^0 \in (H^s(\mathbf{T}^2))^n$ *with* $s > 2$ *such that* $|\zeta^0|_{(H^s)^n} \leq M$. *Then for sufficiently small* T, *there exists a unique solution* $\zeta = (\zeta_1, \dots, \zeta_n)$ *to* (1)–(4) *such that* $\zeta \in \mathcal{C}([0,T], (H^s(\mathbf{T}^2))^n)$ *and* $|\zeta|_{L^\infty([0,T],(H^s(\mathbf{T}^n))^n)} \leq 2M$.

Proof. For $\zeta \in \mathcal{C}([0,T], (H^s(\mathbf{T}^2))^n)$, we construct $\tilde\psi$ satisfying

$$\begin{cases} \zeta_1 = \Delta_{x,y}\tilde\psi_1 + \dfrac{1}{\varepsilon^2}\beta_2(\tilde\psi_2 - \tilde\psi_1), \\ \\ \zeta_l = \Delta_{x,y}\tilde\psi_l - \dfrac{1}{\varepsilon^2}\beta_l(\tilde\psi_l - \tilde\psi_{l-1}) + \dfrac{1}{\varepsilon^2}\beta_{l+1}(\tilde\psi_{l+1} - \tilde\psi_l), \quad 2 \leq l \leq n-1, \\ \\ \zeta_n = \Delta_{x,y}\tilde\psi_n - \dfrac{1}{\varepsilon^2}\beta_n(\tilde\psi_n - \tilde\psi_{n-1}). \end{cases} \tag{16}$$

Let $\tilde{u}_l = -\frac{\partial\tilde{\psi}_l}{\partial y}$ and $\tilde{v}_l = \frac{\partial\tilde{\psi}_l}{\partial x}$ and consider the solution $\tilde{\zeta}$ to

$$\begin{cases} \left(\dfrac{\partial}{\partial t} + \tilde{u}_l \dfrac{\partial}{\partial x} + \tilde{v}_l \dfrac{\partial}{\partial y}\right) \tilde{\zeta}_l = -a\tilde{v}_l, \quad l = 1 \text{ to } n, \\ \tilde{\zeta}(0) = \zeta_0. \end{cases} \tag{17}$$

We denote by $\mathcal{T}$ the mapping that carries ζ into $\tilde{\zeta}$. We want to prove that $\mathcal{T}$ is a contraction in a suitable space $\mathcal{C}(0, T, X)$ for sufficiently small T. Let us first solve the elliptic system. Introduce the operator on $\mathbf{R}^n$ whose matrix is

$$\mathcal{A}_n = -\begin{pmatrix} -\frac{\beta_2}{\varepsilon^2} & \frac{\beta_2}{\varepsilon^2} & & & 0 \\ & \cdots & \cdots & & \\ & \frac{\beta_l}{\varepsilon^2} & -\frac{\beta_l+\beta_{l+1}}{\varepsilon^2} & \frac{\beta_{l+1}}{\varepsilon^2} & \\ & & \cdots & \cdots & \\ 0 & & & \frac{\beta_n}{\varepsilon^2} & -\frac{\beta_n}{\varepsilon^2} \end{pmatrix}.$$

The matrix $\mathcal{A}_n$ is symmetric and

$$(\mathcal{A}_n X, X) = -\sum_{i=1}^{n-1} \beta_{i+1} \left(\frac{x_{i+1} - x_i}{\varepsilon}\right)^2,$$

where $X = (x_1, \ldots, x_n)$, so that—thanks to (3)—0 is a simple eigenvalue. Hence if $\zeta \in (\mathcal{C}([0,T], (H^s)))^n$, then there exists a unique $\tilde{\psi} \in (\mathcal{C}([0,T], (H^{s+2})))^n$ satisfying (16) such that $\sum_{i=1}^n \int_{\mathbf{T}^2} \psi_i dxdy = 0$ and

$$|\tilde{\psi}|_{(\mathcal{C}([0,T],(H^{s+2})))^n} \leq C|\zeta|_{(\mathcal{C}([0,T],(H^s)))^n}. \tag{18}$$

Let us now apply ∂_α^s to (17) and form the product with $\partial_\alpha^s \tilde{\zeta}_l$; an integration yields

$$\frac{\partial}{\partial t}\int_{\mathbf{T}^2} |\partial_\alpha^s \tilde{\zeta}_l|^2 + \int_{\mathbf{T}^2} \partial_\alpha^s((\tilde{u}_l, \tilde{v}_l) \cdot \nabla\tilde{\zeta}_l)\partial_\alpha^s \tilde{\zeta}_l = -a \int_{\mathbf{T}^2} \partial_\alpha^s \tilde{v}_l \partial_\alpha^s \tilde{\zeta}_l. \tag{19}$$

On the other hand, since $\frac{\partial}{\partial x}\tilde{u}_l + \frac{\partial}{\partial y}\tilde{v}_l = 0$, $\int_{\mathbf{T}^2}(\tilde{u}_l, \tilde{v}_l) \cdot \nabla\partial_\alpha^s\tilde{\zeta}_l\partial_\alpha^s\tilde{\zeta}_l = 0$ for all l, and hence (19) becomes

$$\frac{\partial}{\partial t}\int_{\mathbf{T}^2} |\partial_\alpha^s \tilde{\zeta}_l|^2 + \int_{\mathbf{T}^2} (\partial_\alpha^s \nabla((\tilde{u}_l, \tilde{v}_l)\tilde{\zeta}_l) - (\tilde{u}_l, \tilde{v}_l) \cdot \nabla\partial_\alpha^s\tilde{\zeta}_l)\partial_\alpha^s \tilde{\zeta}_l = -a \int_{\mathbf{T}^2} \partial_\alpha^s \tilde{v}_l \partial_\alpha^s \tilde{\zeta}_l. \tag{20}$$

The classical commutator estimate (see [3]) implies

$$\frac{\partial}{\partial t}\int_{\mathbf{T}^2} |\partial_\alpha^s \tilde{\zeta}_l|^2 \leq C(|(\tilde{u}_l, \tilde{v}_l)|_{H^{s+1}}|\tilde{\zeta}_l|_{L^\infty} + |\nabla(\tilde{u}_l, \tilde{v}_l)|_{L^\infty}|\tilde{\zeta}_l|_{H^s})|\tilde{\zeta}_l|_{H^s} + a|\tilde{v}_l|_{H^s}|\tilde{\zeta}_l|_{H^s}. \tag{21}$$

Furthermore, $|\tilde{\zeta}_l|_{L^\infty} \leq C|\tilde{\zeta}_l|_{H^s}$ as soon as $s > 1$ and $|\nabla(\tilde{u}_l, \tilde{v}_l)|_{L^\infty} \leq C|(\tilde{u}_l, \tilde{v}_l)|_{H^{s+1}}$. Hence equation (21) leads to

$$\frac{\partial}{\partial t}\int_{\mathbf{T}^2} |\partial_\alpha^s \tilde{\zeta}_l|^2 \leq C(|(\tilde{u}_l, \tilde{v}_l)|_{H^{s+1}}|\tilde{\zeta}_l|_{H^s}^2) + a|\tilde{v}_l|_{H^s}|\tilde{\zeta}_l|_{H^s}. \tag{22}$$

Thanks to (18), we obtain

$$\frac{\partial}{\partial t}|\tilde{\zeta}_l|^2_{H^s} \leq C_1(1+M)|\tilde{\zeta}_l|^2_{H^s} + C_2$$

if $|\zeta|_{(L^\infty(0,T,H^s))^n} \leq 2M$. This yields

$$\begin{aligned} |\tilde{\zeta}_l|^2_{H^s} &\leq e^{C_1(1+M)t}|\zeta_0|^2_{H^s} + (e^{C_1(1+M)t}-1)\frac{C_2}{C_1(1+M)} \\ &\leq e^{C_1(1+M)t}M + (e^{C_1(1+M)t}-1)\frac{C_2}{C_1(1+M)}. \end{aligned} \tag{23}$$

Choose T sufficiently small so that the right-hand side of (9) is less than or equal to $2M$. If B_M denotes the ball of radius $2M$ in $(\mathcal{C}([0,T],H^s))^n$, then for sufficiently small T,

$$\mathcal{T} \text{ maps } B_M \text{ into itself.} \tag{24}$$

We next show that $\mathcal{T}$ is a contraction in the $(\mathcal{C}([0,T],L^2))^n$ norm, provided that T is sufficiently small. Indeed, for ζ^1 and ζ^2, we have

$$|\tilde{\psi}^1 - \tilde{\psi}^2|_{(L^\infty(0,T,H^{s+2}))^n} \leq C|\zeta^1-\zeta^2|_{(L^\infty(0,T,H^s))^n}. \tag{25}$$

On the other hand,

$$\frac{\partial}{\partial t}(\tilde{\zeta}^1_l - \tilde{\zeta}^2_l) + (\tilde{u}^1_l,\tilde{v}^1_l).\nabla(\tilde{\zeta}^1_l - \tilde{\zeta}^2_l) + ((\tilde{u}^1_l,\tilde{v}^1_l) - (\tilde{u}^2_l,\tilde{v}^2_l))\cdot\nabla\tilde{\zeta}^2_l = -a(\tilde{v}^1_l - \tilde{v}^2_l). \tag{26}$$

Multiply (12) by $(\tilde{\zeta}^1_l - \tilde{\zeta}^2_l)$ and integrate to obtain

$$\begin{aligned} \tfrac{\partial}{\partial t}\textstyle\int_{\mathbf{T}^2}|\tilde{\zeta}^1_l - \tilde{\zeta}^2_l|^2 &\leq C'|\nabla\tilde{\zeta}^2_l|_{L^\infty}|\tilde{\zeta}^1_l - \tilde{\zeta}^2_l|_{L^2}|\zeta^1-\zeta^2|_{(L^2)^n} \\ &\leq C'|\tilde{\zeta}^1_l - \tilde{\zeta}^2_l|_{L^2}|\zeta^1-\zeta^2|_{(L^2)^n} \end{aligned}$$

as soon as $s>2$, where (11) has been used. We deduce that

$$|\tilde{\zeta}^1 - \tilde{\zeta}^2|_{(L^\infty(0,T,L^2))^n} \leq C'T|\zeta^1-\zeta^2|_{(L^\infty(0,T,L^2))^n}.$$

If T is such that $C'T<1$, then $\mathcal{T}$ becomes a contraction from B_R into itself and therefore it has a unique fixed point $\zeta \in (L^\infty(0,T,H^s))^n$. Since $\frac{\partial}{\partial t}\zeta \in (L^\infty(0,T,H^{s-1}))^n$, we get $\zeta \in (\mathcal{C}([0,T],H^{s-\eta}))^n$ for all $\eta>0$. We still have to prove that $\zeta \in (\mathcal{C}([0,T],H^s))^n$. To this end, we use the fact that $(u,v) \in (L^\infty(0,T,H^{s+1}))^n$ and write ζ in term of caracteristics. This concludes the proof of Proposition 2.2.

2.2. Globalization. In order to show that the solution is global, it is sufficient to prove that $|\zeta|_{(H^s)^n}(t)$ cannot tend to infinity in finite time. To do this, we use the fact that (22) can be refined by Youdovitch's techniques [12] for the two-dimensional Euler equation (see also [3] or [8]). Namely, we have $|\zeta(t)|_{(L^\infty)^n} \leq C|\zeta_0|_{(L^\infty)^n}$. It follows that $|(u,v)(t)|_{\mathcal{C}^1_*} \leq C|\zeta_0|_{(L^\infty)^n}$, where $\mathcal{C}^1_*$ denotes Zygmund's class (see [3]). Then for all $\varepsilon>0$, we obtain

$$|\nabla(u,v)(t)|_{(L^\infty)^{2n}} \leq \frac{C}{\varepsilon}|(u,v)|_{\mathcal{C}^1_*}\log\left(e + \frac{|(u,v)|_{\mathcal{C}^{1+\varepsilon}}}{|(u,v)|_{\mathcal{C}^1_*}}\right).$$

(See [3] for a proof of this inequality.) In the present context, this gives

$$\begin{aligned}|\nabla(u,v)(t)|_{(L^\infty)^{2n}} &\le C\log(e+|(u,v)|_{(H^{s+1})^n})\\ &\le C\log(e+|\zeta|_{(H^s)^n})\end{aligned}$$

as soon as $s>2$. Estimate (21) leads to

$$\frac{\partial}{\partial t}|\zeta|^2_{(H^s)^n}\le C|\zeta|^2_{(H^s)^n}\log(e+|\zeta|_{(H^s)^n}),$$

which gives $|\zeta|_{(H^s)^n}\le Ce^{Ce^t}$. Hence the solution is global.

3. Continuous stratification limit. The above results give some bounds on the solution. However, these bounds depend on the number of layers n and therefore are not directly helpful in performing the limit $n\to\infty$. Here we will derive some bounds which are independent of the number of layers and introduce functions depending of a vertical variable z.

Remark 1. The different constants occuring in this section, which we denote generically by C, *do not depend on* n.

In this section, we will use the notation introduced in section 1, especially (6)–(15).

Let $\zeta_0(x,y,z)$ be defined on $\mathbf{T}^2\times[0,1]$, let V_ε be the subspace engendered by $\{(\phi_i^\varepsilon(z)), i=1,\dots,n\}$, and let Π_ε be the projector onto V_ε in L^2. We assume that $\zeta_0(x,y,z)\in L^2\cap\mathcal{C}^0(\mathbf{T}^2\times[0,1])$ and $\zeta_0^\varepsilon=\Pi_\varepsilon\zeta_0$.

The result reads as follows.

THEOREM 3.1. *Let $\zeta_0(x,y,z)\in L^2\cap\mathcal{C}^0(\mathbf{T}^2\times[0,1])$. The following convergences hold for all $0<T<\infty$ when ε tends to* 0:

(i)

$$(U_2^\varepsilon,V_2^\varepsilon)\to(U,V)\quad \textit{in } \mathcal{C}([0,T],L^2(\mathbf{T}^2\times[0,1]))\ \textit{strongly.}$$

(ii) *Z_1^ε and Z_2^ε converge to the same limit Z in $L^p(0,T,L^2(\mathbf{T}^2\times[0,1]))$ strongly for all $p<\infty$ and in $L^\infty(0,T,L^2\cap L^\infty(\mathbf{T}^2\times[0,1]))$ weakly.*

(iii)

$$\Psi_3^\varepsilon\rightharpoonup\Psi\quad \textit{in } L^\infty(0,T,L^2(\mathbf{T}^2\times[0,1]))\ \textit{weakly.}$$

(iv)

$$\begin{aligned}\nabla^\perp\Psi_1^\varepsilon\to\nabla^\perp\Psi\quad &\textit{in } \mathcal{C}([0,T],L^2(\mathbf{T}^2\times[0,1]))\ \textit{strongly}\\ \textit{and}\quad &\textit{in } L^\infty(0,T,H^1(\mathbf{T}^2\times[0,1]))\ \textit{weakly.}\end{aligned}$$

Moreover, (U,V), Ψ, and Z satisfy

$$\frac{\partial Z}{\partial t}+\nabla\cdot((U,V)(Z+ay))=0,$$

$$U=-\frac{\partial\Psi}{\partial y}\quad \textit{and}\quad V=\frac{\partial\Psi}{\partial x},$$

and

$$Z=\Delta_{x,y}\Psi+\frac{\partial}{\partial z}\left(\beta(z)\frac{\partial\Psi}{\partial z}\right),$$

with $\frac{\partial \Psi}{\partial z} = 0$ *in* $z = 0$ *and* $z = 1$,

$$Z(t = 0) = \zeta_0.$$

We have used the classical notation $\nabla^\perp h$ for the vector field $(-\frac{\partial h}{\partial y}, \frac{\partial h}{\partial x})$. The remaining of this section is devoted to the proof of this result.

3.1. A priori estimates. We define the sequences Z_{01}^ε and Z_{02}^ε by (11) and (12). Then Z_{01}^ε and Z_{02}^ε converge to ζ_0 in $L^2(\mathbf{T}^2 \times [0, 1])$ strongly. Moreover, since the functions $\zeta_l^\varepsilon + ay$ are transporting by a measure-preserving flow in time, we have the following:

(27) the sequences Z_1^ε and Z_2^ε are bounded in $L^\infty(0, +\infty, L^2 \cap L^\infty(\mathbf{T}^2 \times [0, 1]))$;

moreover, the following equality holds:

$$|ay + \zeta_l^\varepsilon(x, y, t)|_{L^2 \cap L^\infty(\mathbf{T}^2)} = |ay + \zeta_{0l}^\varepsilon(x, y)|_{L^2 \cap L^\infty(\mathbf{T}^2)}. \tag{28}$$

Definition 3.2. *Let us introduce the space* $H_n^s(\mathbf{T^2})$ *as follows.*

$$H_n^s(\mathbf{T^2}) = \left\{ \psi = (\psi_1, \dots, \psi_n) \in (H^s(\mathbf{T^2}))^n \quad \textit{such that} \int_{\mathbf{T^2}} \sum_{i=1}^n \psi_i = 0 \quad \textit{and} \right.$$
$$\left. \frac{1}{n-1} \sum_{i=1}^n \int_{\mathbf{T^2}} |(-\Delta_{x,y})^{s/2} \psi_i|^2 + \int_{\mathbf{T^2}} \frac{1}{n-1} |(\mathcal{A}_n)^{s/2} \psi|^2 < \infty \right\},$$

where $\mathcal{A}_n$ *is the matrix introduced in section* 2.1.

The space $H_n^s(\mathbf{T^2})$ *is endowed with its natural norm.*

Remark 2. The matrix $\mathcal{A}_n$ corresponds to a discretization of the operator

$$\frac{\partial}{\partial z} \left(\beta(z) \frac{\partial \Psi}{\partial z} \right)$$

with homogeneous Neuman boundary conditions; see, for example, [10].

If we denote the lth eigenvalue of $-\frac{\partial}{\partial z}(\beta(z)\frac{\partial \Psi}{\partial z})$ by λ_l and the lth eigenvalue of $\mathcal{A}_n$ by λ_l^ε, the Min–Max principle (see [5]) implies that $\lambda_l^\varepsilon \geq \lambda_l$. Moreover, $\lambda_0 = 0$ and $\lambda_1 > 0$; hence $\mathcal{A}_n$ has 0 as simple eigenvalue, and the corresponding eigenvector is $(1, \dots, 1)$. Therefore, $((1/(n-1)) \sum_{i=1}^n \int_{\mathbf{T^2}} |(-\Delta_{x,y})^{s/2} \psi_i|^2 + \int_{\mathbf{T^2}} (1/(n-1)) |(\mathcal{A}_n)^{s/2} \psi|^2)^{1/2}$ is a norm on $H_n^s(\mathbf{T^2})$.

Lemma 3.3. *The sequence* (ψ_l^ε) *satisfies*

$$|(\psi_1^\varepsilon, \dots, \psi_n^\varepsilon)|_{L^\infty(\mathbf{R}^+, H_n^2(\mathbf{T^2}))} \leq C,$$

where the constant C *is independent of* n.

Proof. We form the scalar product of (4) with $(\Delta_{x,y} \psi_l^\varepsilon)$ and $(\mathcal{A}_n(\psi_l^\varepsilon))$ and we use the fact that (ζ_l^ε) is bounded in $L^\infty(\mathbf{R}^+, H_n^0(\mathbf{T^2}))$. This yields the result. Moreover, we obtain

$$\frac{1}{n-1} \int_{\mathbf{T^2}} |\nabla_{x,y} \mathcal{A}_n^{1/2}(\psi_l^\varepsilon)|^2 \in L^\infty(\mathbf{R}^+). \tag{29}$$

LEMMA 3.4. *The sequence* (ζ_l^ε) *satisfies*

$$\frac{1}{n-1}\sum_{l=1}^{n}|\frac{\partial\zeta_l^\varepsilon}{\partial t}|_{H^{-1}(\mathbf{T}^2)}\le K$$

and $\frac{\partial\Psi_1^\varepsilon}{\partial t}$ *is bounded in* $L^\infty(\mathbf{R}^+,H^1(\mathbf{T}^2\times[0,1]))$.

Proof. For all l, we have

$$\frac{\partial}{\partial t}\zeta_l^\varepsilon+\nabla_{x,y}\cdot(\nabla_{x,y}^\perp\psi_l^\varepsilon(\zeta_l^\varepsilon+ay))=0.$$

Furthermore,

$$\begin{aligned}|\nabla_{x,y}\cdot(\nabla_{x,y}^\perp\psi_l^\varepsilon(\zeta_l^\varepsilon+ay))|_{H^{-1}(\mathbf{T}^2)}&\le C|\psi_l^\varepsilon|_{H^1(\mathbf{T}^2)}|\zeta_l^\varepsilon|_{L^\infty(\mathbf{T}^2)}\\&\le C|\psi_l^\varepsilon|_{H^1(\mathbf{T}^2)}.\end{aligned}$$

These two last inequalities imply that

$$\left|\frac{\partial\zeta_l^\varepsilon}{\partial t}\right|_{H^{-1}(\mathbf{T}^2)}\le C|\psi_l^\varepsilon|_{H^1(\mathbf{T}^2)}.$$

The first part of the lemma then follows from (29). For the second part, differentiate (4) with respect to t and multiply it by (ψ_l^ε); we obtain that

$$\frac{\partial\psi_l^\varepsilon}{\partial t}\text{ is bounded in }L^\infty(0,T,H_n^1(\mathbf{T}^2)).$$

It then follows that $\frac{\partial\Psi_1^\varepsilon}{\partial t}$ is bounded in $L^\infty(\mathbf{R}^+,H^1(\mathbf{T}^2\times[0,1]))$ by the definition (6) of Ψ_1^ε.

LEMMA 3.5. *The sequences* Ψ_3^ε *and* Z_2^ε *are bounded in* $L^\infty(\mathbf{R}^+,L^2(\mathbf{T}^2\times[0,1]))$.

Proof. It is sufficient to show that the matrix B_n occurring in system (10) is invertible, the norm of its inverse being bounded independently of n. The matrix B_n is clearly symmetric and irreductible. Gerschgörin's theorem implies that its eigenvalues are included in the union of the disks

$$\left|\lambda-\frac{1}{3}\right|\le\frac{1}{6}\quad\text{and}\quad\left|\lambda-\frac{2}{3}\right|\le\frac{1}{3}.$$

The lemma follows.

3.2. End of the proof of Theorem 3.1. Let us consider

$$\nabla_{x,y}^\perp\Psi_1^\varepsilon=\sum_{l=1}^{n}\nabla_{x,y}^\perp\psi_l^\varepsilon(x,y,t)\phi_l^\varepsilon(z).$$

The vector field $\nabla_{x,y}^\perp\Psi_1^\varepsilon$ is bounded in $L^\infty(\mathbf{R}^+,H^1(\mathbf{T}^2\times[0,1]))$ by (29) and $\frac{\partial}{\partial t}\nabla_{x,y}^\perp\Psi_1^\varepsilon$ is bounded in $L^\infty(\mathbf{R}^+,L^2(\mathbf{T}^2\times[0,1]))$ thanks to Lemma 3.4. We can therefore extract a subsequence that converges in $\mathcal{C}([0,T],L^2(\mathbf{T}^2\times[0,1]))$ strongly and in $L^\infty(0,T,H^1(\mathbf{T}^2\times[0,1]))$ weakly for all $T<\infty$ to a vector field $\nabla_{x,y}^\perp\Psi$. Moreover, $Z_1^\varepsilon\rightharpoonup Z$ in $L^\infty(0,T,L^2\cap L^\infty)$ weakly. We will now show that the limits of the sequences Z_1^ε and Z_2^ε are the same and that this is also the case for the limits of Ψ_1^ε, Ψ_2^ε, and Ψ_3^ε.

The function Ψ_1^ε is related to a P1 finite-element approximation in the z-direction of Ψ, while Ψ_2^ε is a piecewise-constant approximation of Ψ_1^ε. It will therefore be possible to show that $\nabla_{x,y}^\perp \Psi_2^\varepsilon - \nabla_{x,y}^\perp \Psi_1^\varepsilon \rightarrow_{\varepsilon\rightarrow 0} 0$ in $L^\infty([0,T], L^2(\mathbf{T}^2\times[0,1]))$ strongly; this is related to the fact that $\nabla_{x,y}^\perp \Psi_1^\varepsilon$ is bounded in $L^\infty([0,T], H^1(\mathbf{T}^2\times[0,1]))$.

The functions Ψ_3^ε and Z_2^ε are also some piecewise-constant approximations of Ψ and Z, but these approximations are obtained versus the mass matrix B_n, and we cannot directly use the H^1 bound of Ψ_1^ε. Therefore, the convergences $\Psi_3^\varepsilon - \Psi \rightarrow 0$ and $Z_2^\varepsilon - Z \rightarrow 0$ are obtained only in $L^\infty([0,T], L^2(\mathbf{T}^2\times[0,1]))$ weakly.

These results are stated precisely in the next two propositions and proved by some explicit computations.

PROPOSITION 3.6. *The sequence $\nabla_{x,y}^\perp \Psi_2^\varepsilon$ converges to $\nabla_{x,y}^\perp \Psi$ in $\mathcal{C}([0,T], L^2(\mathbf{T}^2\times[0,1]))$ strongly.*

Proof. We compute the $L^2(\mathbf{T}^2\times[0,1])$ norm of the difference between $\nabla_{x,y}^\perp \Psi_2^\varepsilon$ and $\nabla_{x,y}^\perp \Psi_1^\varepsilon$ and get

$$\begin{aligned}
&|\nabla_{x,y}^\perp \Psi_2^\varepsilon - \nabla_{x,y}^\perp \Psi_1^\varepsilon|_{L^2(\mathbf{T}^2\times[0,1])} \\
&\quad = \int_{\mathbf{T}^2}\int_0^1 \left| \sum_{l=1}^{n} \nabla_{x,y}^\perp \psi_l^\varepsilon(x,y,t)\phi_l^\varepsilon(z) - \sum_{l=1}^{n-1} \nabla_{x,y}^\perp \psi_l^\varepsilon(x,y,t)\mathbf{1}_{[(l-1)\varepsilon,l\varepsilon[}(z)\right|^2 dxdydz.
\end{aligned}$$

Taking into account the supports of ϕ_l^ε, we obtain

$$\begin{aligned}
&\int_0^1 \left| \sum_{l=1}^{n} \nabla_{x,y}^\perp \psi_l^\varepsilon(x,y,t)\phi_l^\varepsilon(z) - \sum_{l=1}^{n-1} \nabla_{x,y}^\perp \psi_l^\varepsilon(x,y,t)\mathbf{1}_{[(l-1)\varepsilon,l\varepsilon[}(z)\right|^2 dz \\
&\quad = \int_0^1 \sum_{l=1}^{n} |\nabla_{x,y}^\perp \psi_l^\varepsilon|^2 |\phi_l^\varepsilon|^2 dz + \frac{1}{n-1}\sum_{l=1}^{n-1} |\nabla_{x,y}^\perp \psi_l^\varepsilon|^2 \\
&\quad - 2\int_0^1 \sum_{l=1}^{n-1} \nabla_{x,y}^\perp \psi_l^\varepsilon \phi_l^\varepsilon \nabla_{x,y}^\perp \psi_l^\varepsilon \mathbf{1}_{[(l-1)\varepsilon,l\varepsilon[} \\
&\quad - 2\int_0^1 \sum_{l=2}^{n-1} \nabla_{x,y}^\perp \psi_l^\varepsilon \phi_l^\varepsilon \nabla_{x,y}^\perp \psi_{l-1}^\varepsilon \mathbf{1}_{[(l-2)\varepsilon,(l-1)\varepsilon[} \\
&\quad + 2\int_0^1 \sum_{l=1}^{n-1} \nabla_{x,y}^\perp \psi_l^\varepsilon \phi_l^\varepsilon \nabla_{x,y}^\perp \psi_{l+1}^\varepsilon \phi_{l+1}^\varepsilon.
\end{aligned}$$

An explicit computation of the integrals yields

$$\begin{aligned}
&\int_0^1 \left| \sum_{l=1}^{n} \nabla_{x,y}^\perp \psi_l^\varepsilon(x,y,t)\phi_l^\varepsilon(z) - \sum_{l=1}^{n-1} \nabla_{x,y}^\perp \psi_l^\varepsilon(x,y,t)\mathbf{1}_{[(l-1)\varepsilon,l\varepsilon[}(z)\right|^2 dz \\
&\quad = \frac{2\varepsilon}{3}\sum_{l=2}^{n-2} \nabla_{x,y}^\perp \psi_l^\varepsilon \cdot (\nabla_{x,y}^\perp \psi_l^\varepsilon - \nabla_{x,y}^\perp \psi_{l-1}^\varepsilon) \qquad (30) \\
&\quad - \frac{2\varepsilon}{3}\nabla_{x,y}^\perp \psi_n^\varepsilon \cdot \nabla_{x,y}^\perp \psi_{n-1}^\varepsilon + \frac{\varepsilon}{3}|\nabla_{x,y}^\perp \psi_1^\varepsilon|^2 + \frac{\varepsilon}{3}|\nabla_{x,y}^\perp \psi_n^\varepsilon|^2.
\end{aligned}$$

Then since $(\nabla^{\perp}_{x,y}\psi^{\varepsilon}_1)_l$ is bounded in $L^{\infty}(\mathbf{R}^+, H^1_n(\mathbf{T}^2))$, we have

$$\left|\int_{\mathbf{T}^2} \frac{2\varepsilon}{3}\sum_{l=2}^{n-2} \nabla^{\perp}_{x,y}\psi^{\varepsilon}_l . (\nabla^{\perp}_{x,y}\psi^{\varepsilon}_l - \nabla^{\perp}_{x,y}\psi^{\varepsilon}_{l-1})\right| \le C\frac{2\varepsilon}{3} \underset{\varepsilon\to 0}{\longrightarrow} 0$$

in $L^{\infty}(0,T)$. We still have to deal with the following terms in (30):

$$-\frac{2\varepsilon}{3}\nabla^{\perp}_{x,y}\psi^{\varepsilon}_n . \nabla^{\perp}_{x,y}\psi^{\varepsilon}_{n-1} + \frac{\varepsilon}{3}|\nabla^{\perp}_{x,y}\psi^{\varepsilon}_1|^2 + \frac{\varepsilon}{3}|\nabla^{\perp}_{x,y}\psi^{\varepsilon}_n|^2.$$

Since $\nabla^{\perp}_{x,y}\Psi^{\varepsilon}_1$ is bounded in $L^{\infty}(\mathbf{R}^+, H^1(\mathbf{T}^2\times[0,1]))$, for almost every x and y and for all i, we have

$$|\nabla^{\perp}_{x,y}\psi^{\varepsilon}_i|^2_{L^{\infty}(0,1)} \le C|\nabla^{\perp}_{x,y}\psi^{\varepsilon}_i|^2_{H^1(0,1)}.$$

Hence

$$\int_{\mathbf{T}^2} |\nabla^{\perp}_{x,y}\psi^{\varepsilon}_i|^2 \le C|\nabla^{\perp}_{x,y}\Psi^{\varepsilon}_1|^2_{H^1((0,1)\times\mathbf{T}^2)}$$

and

$$\int_{\mathbf{T}^2}\left(-\frac{2\varepsilon}{3}\nabla^{\perp}_{x,y}\psi^{\varepsilon}_n . \nabla^{\perp}_{x,y}\psi^{\varepsilon}_{n-1} + \frac{\varepsilon}{3}|\nabla^{\perp}_{x,y}\psi^{\varepsilon}_1|^2 + \frac{\varepsilon}{3}|\nabla^{\perp}_{x,y}\psi^{\varepsilon}_n|^2\right) \underset{\varepsilon\to 0}{\longrightarrow} 0$$

in $L^{\infty}(0,T)$. Plugging this result into (30) and integrating on $\mathbf{T}^2$ conclude the proof of the proposition.

Concerning the sequences Ψ^{ε}_3 and Z^{ε}_2, we have the following result.

PROPOSITION 3.7. *The sequences Ψ^{ε}_3 and Z^{ε}_2 converge, respectively, to Ψ and Z in $L^{\infty}(0,T,L^2(\mathbf{T}^2\times[0,1]))$ weakly.*

Proof. Since the functions Ψ^{ε}_3 and Z^{ε}_2 are obtained by the same construction, it is enough to show the result for one of them. We will work with Z^{ε}_2 and show that $Z^{\varepsilon}_1 - Z^{\varepsilon}_2 \rightharpoonup 0$ in $L^{\infty}(0,T,L^2(\mathbf{T}^2\times[0,1]))$.

For any interval $[a,b]\subset[0,1]$, for fixed n, there exist two integers k_1 and k_2 such that $(k_1-1)/(n-1) < a \le k_1/(n-1)$ and $k_2/(n-1) \le b < (k_2+1)/(n-1)$. Then

$$\int_a^b (Z^{\varepsilon}_1 - Z^{\varepsilon}_2)dz = \int_a^{\frac{k_1}{n-1}} (Z^{\varepsilon}_1 - Z^{\varepsilon}_2)dz + \int_{\frac{k_1}{n-1}}^{\frac{k_2}{n-1}} (Z^{\varepsilon}_1 - Z^{\varepsilon}_2)dz + \int_{\frac{k_2}{n-1}}^{b} (Z^{\varepsilon}_1 - Z^{\varepsilon}_2)dz. \tag{31}$$

Let us compute each term of the right-hand side of (31).

(i)

$$\begin{aligned}\int_{\frac{k_1}{n-1}}^{\frac{k_2}{n-1}} (Z^{\varepsilon}_1 - Z^{\varepsilon}_2)dz &= \int_{\frac{k_1}{n-1}}^{\frac{k_2}{n-1}} \sum_{l=k_1+1}^{k_2} \zeta^{\varepsilon}_l \mathbf{1}_{[(l-1)\varepsilon, l\varepsilon[} dz - \int_{\frac{k_1}{n-1}}^{\frac{k_2}{n-1}} \sum_{l=k_1-1}^{k_2} g^{\varepsilon}_l \phi^{\varepsilon}_l dz \\ &= \varepsilon\sum_{l=k_1+1}^{k_2}\zeta^{\varepsilon}_l - g^{\varepsilon}_{k_1-1}\frac{\varepsilon}{2} - g^{\varepsilon}_{k_2}\frac{\varepsilon}{2} - \varepsilon\sum_{l=k_1}^{k_2-1} g^{\varepsilon}_l .\end{aligned}$$

Using the relationship between ζ^{ε}_l and g^{ε}_l, namely $\zeta^{\varepsilon}_l = (1/6)(g^{\varepsilon}_{l-1} + 4g^{\varepsilon}_l + g^{\varepsilon}_{l+1})$ for $1 < l < n$, we get after simplification that

$$\int_{\frac{k_1}{n-1}}^{\frac{k_2}{n-1}} (Z_1^\varepsilon - Z_2^\varepsilon)dz = \varepsilon\zeta_{k_2}^\varepsilon - \frac{\varepsilon}{3}g_{k_2}^\varepsilon - \frac{\varepsilon}{3}g_{k_2-1}^\varepsilon - \frac{\varepsilon}{2}g_{k_1-1}^\varepsilon - \frac{\varepsilon}{3}g_{k_1+1}^\varepsilon - \frac{5\varepsilon}{6}g_{k_1}^\varepsilon. \tag{32}$$

Therefore, equation (32) yields

$$\left|\int_{\frac{k_1}{n-1}}^{\frac{k_2}{n-1}} (Z_1^\varepsilon - Z_2^\varepsilon)dz\right| \leq C\sqrt{\varepsilon}\left(\varepsilon\sum_{l=1}^n g_l^{\varepsilon 2}\right)^{1/2}; \tag{33}$$

the constant C does not depend on n or $[a,b]$.

(ii) We proceed in the same way for the terms $\int_a^{k_1/(n-1)}$ and $\int_{k_2/(n-1)}^b$, and as in (33), we finally obtain

$$\left|\int_a^b (Z_1^\varepsilon - Z_2^\varepsilon)dz\right| \leq C\sqrt{\varepsilon}\left(\varepsilon\sum_{l=1}^n g_l^{\varepsilon 2}\right)^{1/2}. \tag{34}$$

Now take $\phi \in L^1(0,T,L^2(\mathbf{T}^2 \times [0,1]))$ and construct

$$\phi^N = \sum_{i=1}^N \alpha_i^N(x,y,t)\mathbf{1}_{[a_i(x,y,t),b_i(x,y,t)[}(z)$$

such that

$$|\phi - \phi^N|_{L^1(0,T,L^2(\mathbf{T}^2\times[0,1]))} \underset{N\to\infty}{\longrightarrow} 0.$$

Then

$$\begin{aligned}&\int_0^T \int_{\mathbf{T}^2}\int_0^1 (Z_1^\varepsilon - Z_2^\varepsilon)\phi dxdydzdt \\ &\quad= \int_0^T \int_{\mathbf{T}^2}\int_0^1 (Z_1^\varepsilon - Z_2^\varepsilon)(\phi - \phi^N) + \int_0^T \int_{\mathbf{T}^2}\int_0^1 (Z_1^\varepsilon - Z_2^\varepsilon)\phi^N.\end{aligned}$$

The first estimate that we have is

$$\left|\int_0^T \int_{\mathbf{T}^2}\int_0^1 (Z_1^\varepsilon - Z_2^\varepsilon)\phi\right| \leq C|\phi - \phi^N|_{L^1(0,T,L^2(\mathbf{T}^2\times[0,1]))} + \left|\int_0^T \int_{\mathbf{T}^2}\int_0^1 (Z_1^\varepsilon - Z_2^\varepsilon)\phi^N\right|.$$

Hence by (24),

$$\begin{aligned}\left|\int_0^T \int_{\mathbf{T}^2}\int_0^1 (Z_1^\varepsilon - Z_2^\varepsilon)\phi^N\right| &\leq \int_0^T \int_{\mathbf{T}^2} C\sqrt{\varepsilon}\left(\sum_{i=1}^N |\alpha_i^N(x,y,t)|\right)\left(\varepsilon\sum_{l=1}^n g_l^{\varepsilon 2}\right)^{1/2} \\ &\leq \sqrt{\varepsilon}\left|\left(\sum_{i=1}^N |\alpha_i^N(x,y,t)|\right)\right|_{L^2((0,T)\times\mathbf{T}^2)}\end{aligned}$$

since $(\varepsilon\sum_{l=1}^n g_l^{\varepsilon 2})^{1/2}$ is bounded in $L^\infty((0,T),L^2(\mathbf{T}^2))$. We therefore obtain

$$\left|\int_0^T \int_{\mathbf{T}^2}\int_0^1 (Z_1^\varepsilon - Z_2^\varepsilon)\phi\right| \leq C|\phi - \phi^N|_{L^1(0,T,L^2(\mathbf{T}^2\times[0,1]))}$$

$$+ C\sqrt{\varepsilon}\left|\left(\sum_{i=1}^{N}|\alpha_i^N(x,y,t)|\right)\right|_{L^2((0,T)\times\mathbf{T}^2)}.$$

It follows that

$$\limsup_{\varepsilon\to 0}\left|\int_0^T\int_{\mathbf{T}^2}\int_0^1(Z_1^\varepsilon - Z_2^\varepsilon)\phi\right| \le C|\phi-\phi^N|_{L^1(0,T,L^2(\mathbf{T}^2\times[0,1]))}.$$

Letting $N\to\infty$ in this expression, we obtain the result.

We can now perform the limit process on (13), (14), and (15). Thanks to Proposition 3.6, (15) directly gives

$$U = -\frac{\partial\Psi}{\partial y} \quad\text{and}\quad V = \frac{\partial\Psi}{\partial x}.$$

On the other hand, since $Z_1^\varepsilon \rightharpoonup Z$ in $L^\infty(0,T,L^2\cap L^\infty)$ weakly and since $(U_2^\varepsilon, V_2^\varepsilon)\to(U,V)$ in $L^\infty(0,T,L^2)$ strongly, we have

$$(U_2^\varepsilon,V_2^\varepsilon)(Z_1^\varepsilon + ay) \rightharpoonup (U,V)(Z+ay) \quad \text{in } \mathcal{D}',$$

and (13) gives

$$\frac{\partial Z}{\partial t} + \nabla\cdot((U,V)(Z+ay)) = 0.$$

In order to perform the limit on the elliptic equation (14), one use Proposition 3.7 and the classical result of variational approximation.

Moreover, since the L^2 norm of $Z+ay$ is conserved by the flow and since $Z_{01}^\varepsilon\to\zeta_0$ in L^2 strongly, for all t the convergences of $Z_1^\varepsilon(t)$ and $Z_2^\varepsilon(t)$ are strong in L^2; hence $Z_1^\varepsilon(t)$ and $Z_2^\varepsilon(t)$ converge to $Z(t)$ in $L^p(0,T,L^2(\mathbf{T}^2\times[0,1]))$ strongly for all $p<\infty$.

HIGHER GRADIENT INTEGRABILITY OF MINIMIZERS FOR A POLYCONVEX CASE IN TWO DIMENSIONS[*]

MICHAEL M. DOUGHERTY[†]

Abstract. Local L^p-estimates, $1 < p < \infty$, of the gradient are proved for minimizers of certain functionals whose integrands have quadratic growth in the gradient and are polyconvex "at infinity." Both variations of dependent and independent variables of the minimizers are used to derive equations from which Calderon–Zygmund theory gives the result. Hölder continuity of the minimizers will follow as a corollary.

Key words. polyconvexity, regularity theory

1. Introduction.

In this paper, local higher integrability of the gradient is proved for minimizers of certain polyconvex functionals in the calculus of variations. Specifically, let $\Omega \subset \mathbb{R}^2$ be a bounded domain. Define an energy functional $\mathcal{E}$ by

$$\mathcal{E}[\mathcal{U}] = \int_\Omega \left(\frac{1}{2} |D\mathcal{U}|^2 + h(\det D\mathcal{U}) \right) dX = \int_\Omega \gamma(D\mathcal{U})\, dX \tag{1.1}$$

for each $\mathcal{U} = (u, v) \in W^{1,2}(\Omega; \mathbb{R}^2)$, where $h \in C^1(\mathbb{R})$ is convex, $h \geq 0$, and $|h'|$ is bounded. Thus

$$\lim_{d\to\infty} h'(d) = L_+ \quad \text{and} \quad \lim_{d\to-\infty} h'(d) = -L_- \tag{1.2}$$

exist and are finite. Also assume that h is asymptotically linear in the sense that there exists $\beta > 0$ such that

$$\begin{aligned} L_+ - h'(d) &= \mathcal{O}(d^{-\beta}) \quad &&\text{as } d \to \infty, \\ -L_- - h'(d) &= \mathcal{O}(|d|^{-\beta}) \quad &&\text{as } d \to -\infty. \end{aligned} \tag{1.3}$$

The function $\mathcal{U}$ is called a *minimizer* of $\mathcal{E}$ if $\mathcal{E}(\mathcal{U}) \leq \mathcal{E}(\mathcal{W})$ whenever $\mathcal{U} - \mathcal{W} \in W_0^{1,2}(\Omega; \mathbb{R}^2)$. The main result is the following.

Theorem. *Let $\mathcal{U} \in W^{1,2}(\Omega; \mathbb{R}^2)$ be a minimizer for the functional $\mathcal{E}$ given by* (1.1) *and* (1.3)*, with $\beta > 0$. Then $|D\mathcal{U}| \in L^p_{\text{loc}}(\Omega)$ for any $p \in [1, \infty)$. Moreover, for each $p \in [1, \infty)$ and $\Omega' \subset\subset \Omega$,*

$$\|D\mathcal{U}\|_{L^p(\Omega')} \leq C\big(1 + \|\mathcal{U}\|_{L^2(\Omega)} + \|D\mathcal{U}\|_{L^2(\Omega)}\big), \tag{1.4}$$

where $C < \infty$ depends on p, Ω', Ω, and the structure of h.

The Sobolev and Morrey embedding theorems then give the following.

Corollary. *If $\mathcal{U}$ is as in the theorem, then $\mathcal{U} \in C^{0,\alpha}(\Omega; \mathbb{R}^2)$ for any $\alpha \in (0, 1)$.*

Prior work on higher integrability includes a result of Giaquinta and Giusti (see [7, Theorem 4.1] or [6, Theorem 3.1, p. 159]). Applying their work to minimizers of (1.1)

gives $|D\mathcal{U}| \in L^{2+\sigma}_{\mathrm{loc}}(\Omega)$ for some $\sigma > 0$. Their argument is based on the minimality of $\mathcal{U}$ and polynomial growth in $D\mathcal{U}$ of the integrand, but it relies neither on any convexity nor on differentiability of the integrand. A result under more stringent conditions is given by Chipot and Evans [3], who proved local Lipschitz regularity for a class of minimizers $\mathcal{U} \in W^{1,2}(\Omega; \mathbb{R}^N)$, $\Omega \subset \mathbb{R}^n$, of functionals whose Euler–Lagrange equations become linear, strongly elliptic constant-coefficient equations as $|D\mathcal{U}| \to \infty$. Their estimates arise through a blowup method. For n-dimensional cases, $n \geq 2$, where $\gamma(D\mathcal{U}) = |D\mathcal{U}|^p + h(\det D\mathcal{U})$ and $|h(\det D\mathcal{U})| \leq A + B|D\mathcal{U}|^q$, $1 \leq q < p < \infty$, Dougherty and Phillips [5] proved (1.4) by applying a result of DiBenedetto and Manfredi [4] on solutions of nonhomogeneous p-Laplace equations.

In this paper, the functional (1.1) is differentiable, but the integrand remains polyconvex at infinity. Indeed, though $h(d)$ becomes linear for large d, this term can have large oscillations for large $|D\mathcal{U}|$. The method below exploits two systems of equations derived from (1.1), these being the usual weak Euler–Lagrange equations and another system derived from variations of the independent variables. The L^p-boundedness of Riesz potentials (see [8] and [4]) yields the main result.

2. Preliminaries.

LEMMA 2.1. *Minimizers of* (1.1) *exist.*

Proof. This follows from work of Ball and Murat, who showed that $\mathcal{E}$ is sequentially weakly lower semicontinuous and thus that the integrand in (1.1) is $W^{1,2}$-quasiconvex [1, Theorem 4.5]. □

The weak Euler–Lagrange equations can be obtained from a straightforward application of the dominated-convergence theorem. Specifically, it is not hard to show that the following lemma holds (cf. [6, Chapter I]).

LEMMA 2.2. *Let $\mathcal{E}$ be as in* (1.1). *If $\mathcal{U}$ is a minimizer of $\mathcal{E}$, then the Euler–Lagrange equations hold in the weak sense:*

$$\Delta u = \bigtriangledown \cdot \big\langle -h'(d)v_y,\, h'(d)v_x \big\rangle, \tag{2.1.1}$$

$$\Delta v = \bigtriangledown \cdot \big\langle h'(d)u_y,\, -h'(d)u_x \big\rangle, \tag{2.1.2}$$

where $d = \det D\mathcal{U} = u_x v_y - u_y v_x$.

A simple density argument shows that $h(d)$ can be replaced by any function

$$\hat{h}(d) = h(d) + a \cdot d + b, \tag{2.2}$$

where a and b are arbitrary constants, without changing the set of minimizers. Indeed, it is not hard to prove the following.

LEMMA 2.3. *For any $\mathcal{U} \in W^{1,2}(\Omega; \mathbb{R}^2)$ and any $\Phi \in W^{1,2}_0(\Omega; \mathbb{R}^2)$,*

$$\int_\Omega \big(\det(D\mathcal{U} + D\Phi) - \det(D\mathcal{U})\big)\, dX = 0. \tag{2.3}$$

Choosing $a = (L_- - L_+)/2$ and adjusting b so $h \geq 0$ still holds, it can be assumed without loss of generality that $L_- = L_+ = M > 0$. Equation (1.3) can then be replaced by

$$\begin{aligned} |M - h'(d)| &\leq K|d|^{-\beta} \quad \text{for } d \geq 1, \\ |-M - h'(d)| &\leq K|d|^{-\beta} \quad \text{for } d \leq -1. \end{aligned} \tag{2.4}$$

From now on, it will also be assumed without loss of generality that $\beta \in (0, 1)$.

Next, consider equilibrium equations which arise from variations of the independent variables. For each $\Phi \in C_c^1(\Omega;\mathbb{R}^2)$, define $\mathcal{Z}_\varepsilon(X) \equiv X + \varepsilon\Phi(X)$. For $|\varepsilon|$ sufficiently small, $\mathcal{U}(\mathcal{Z}_\varepsilon) - \mathcal{U} \in W_0^{1,2}(\Omega;\mathbb{R}^2)$, and so $\mathcal{E}[\mathcal{U}] \le \mathcal{E}[\mathcal{U}(\mathcal{Z}_\varepsilon)]$. An argument similar to that given in [2, Theorem A.1] allows differentiation of $\mathcal{E}[\mathcal{U}(\mathcal{Z}_\varepsilon)]$ in ε to get the following.

Lemma 2.4. *For $\mathcal{U}$ and $\mathcal{E}$ as in the theorem, the following holds for every $\Phi \in C_c^1(\Omega;\mathbb{R}^2)$:*

$$0 = \frac{d}{d\varepsilon}\bigg|_{\varepsilon=0} \mathcal{E}[\mathcal{U}(\mathcal{Z}_\varepsilon)] = \int_\Omega \left(\frac{\partial\gamma}{\partial \mathcal{U}^i_{x_j}}(D\mathcal{U})\mathcal{U}^i_{x_k}\Phi^k_{x_j} - \gamma(D\mathcal{U})\left(\Phi^1_{x_1} + \Phi^2_{x_2}\right)\right) dX. \tag{2.5}$$

A straightforward calculation then shows this system can be written in $\mathcal{D}'(\Omega)$ as

$$\left[\frac{u_x^2 + v_x^2 - u_y^2 - v_y^2}{2} + f(d)\right]_x + [u_x u_y + v_x v_y]_y = 0, \tag{2.6.1}$$

$$[u_x u_y + v_x v_y]_x + \left[\frac{u_y^2 + v_y^2 - u_x^2 - v_x^2}{2} + f(d)\right]_y = 0, \tag{2.6.2}$$

where

$$f(d) = dh'(d) - h(d). \tag{2.7}$$

Lemma 2.5. *For $\mathcal{E}$ and $\mathcal{U}$ as in Lemma 1.1, $f \in L^{\frac{1}{1-\beta}}(\Omega)$.*

Proof. This follows from the asymptotic behavior of h. For $d \ge 1$,

$$\begin{aligned} |f(d)| &= \left|d(h'(d) - M) + dM - h(d)\right| \\ &\le \left|d(h'(d) - M)\right| + \left|\int_0^d \left(M - h'(s)\right) ds - h(0)\right| \\ &\le Kd^{1-\beta} + 2M + \int_1^d Ks^{-\beta}\, ds + |h(0)|. \end{aligned}$$

Replacing M with $-M$ gives a similar result for $d \le -1$, and so for all d,

$$|f(d)| \le C(1 + |d|)^{1-\beta}, \tag{2.8}$$

which gives

$$\|f(d)\|_{L^{\frac{1}{1-\beta}}(\Omega)} \le C\left(1 + \|D\mathcal{U}\|^{2(1-\beta)}_{L^2(\Omega)}\right) \le C\left(1 + \|D\mathcal{U}\|^2_{L^2(\Omega)}\right). \qquad \square \tag{2.9}$$

Now define the following quantities:

$$\begin{aligned} A &= \frac{u_x^2 + v_x^2 - u_y^2 - v_y^2}{2}, \\ B &= u_x u_y + v_x v_y. \end{aligned} \tag{2.10}$$

Subtracting $\partial/\partial y$ of (2.6.2) from $\partial/\partial x$ of (2.6.1) and adding $\partial/\partial x$ of (2.6.2) to $\partial/\partial y$ of (2.6.1) gives in $\mathcal{D}'(\Omega)$ the system

$$\begin{aligned} \Delta A &= -f_{xx} + f_{yy}, \\ \Delta B &= -2f_{xy}. \end{aligned} \tag{2.11}$$

The proof of the following lemma follows an argument similar to that given in [2, pp. 126–127].

LEMMA 2.6. *For $\mathcal{U}$ and $\mathcal{E}$ as in the theorem and $p \in (1,\infty)$, if $f(d) \in L^p(B_{3r})$, $B_{3r} \subset \Omega$, then $A, B \in L^p(B_r)$, where $B_r \subset B_{3r}$ are concentric. Furthermore,*

$$\|A\|_{L^p(B_r)} + \|B\|_{L^p(B_r)} \le c_{r,p} \Big(\|f\|_{L^p(B_{3r})} + \|D\mathcal{U}\|^2_{L^2(B_{3r})} \Big) . \tag{2.12}$$

Proof. Let $\eta \in C_c^\infty(B_{3r})$, with $0 \le \eta \le 1$, $\eta = 1$ on B_{2r}, $|\triangledown\eta| \le cr^{-1}$, and $|D^2\eta| \le cr^{-2}$, with c independent of r. Let $g \in C_c^\infty(B_r)$. Set

$$w(X) = \frac{1}{2\pi} \int_{B_r} \log |X - Z| g(Z)\, dZ. \tag{2.13}$$

Then

$$\begin{aligned}
\int_{B_r} Ag\, dX &= \int_{\mathbb{R}^2} A\eta\Delta w\, dX = \int_{\mathbb{R}^2} \big(A\left(\Delta(\eta w) - w\Delta\eta - 2\triangledown w\cdot\triangledown\eta\right)\big)\, dX \\
&= \int_{\mathbb{R}^2} f(d)\big(-(\eta w)_{xx} + (\eta w)_{yy}\big)\, dX + \int_{B_{3r}-B_{2r}} A\left(-w\Delta\eta - 2\triangledown w\cdot\triangledown\eta\right)\, dX \\
&= \int_{B_{3r}} f(d)\eta(-w_{xx} + w_{yy})\, dX \\
+ &\int_{B_{3r}-B_{2r}} \Big\{ f(d)(-2\eta_x w_x - \eta_{xx} w + 2\eta_y w_y + \eta_{yy} w) - Aw\Delta\eta - 2A\triangledown w\cdot\triangledown\eta \Big\}\, dX \\
&\equiv \text{(I)} + \text{(II)}.
\end{aligned}$$

Now let $1 < p < \infty$ and $q = p/(p-1)$. By the Hölder and Calderon–Zygmund inequalities, it follows that

$$\begin{aligned}
|\text{I}| &\le c_p \|f\|_{L^p(B_{3r})} \|D^2 w\|_{L^q(B_r)} \le c_p \|f\|_{L^p(B_{3r})} \|D^2 w\|_{L^q(\mathbb{R}^2)} \\
&\le c_p' \|f\|_{L^p(B_{3r})} \|g\|_{L^q(\mathbb{R}^2)} = c_p' \|f\|_{L^p(B_{3r})} \|g\|_{L^q(B_r)}.
\end{aligned} \tag{2.14}$$

To estimate (II), note first that Hölder's inequality gives

$$|w| + |\triangledown w| \le c(r,p)\, \|g\|_{L^q(B_r)} \quad \text{on } B_{3r} - B_{2r}.$$

Thus

$$\begin{aligned}
\text{(II)} &\le c'(r,p) \big\{ \|f\|_{L^1(B_{3r})} + \|A\|_{L^1(B_{3r})} \big\}\, \|g\|_{L^q(B_r)} \\
&\le c'(r,p) \big\{ \|f\|_{L^1(B_{3r})} + \|D\mathcal{U}\|^2_{L^2(B_{3r})} \big\}\, \|g\|_{L^q(B_r)}.
\end{aligned} \tag{2.15}$$

Combining (2.14) and (2.15) and taking the supremum over all $g \in C_c^\infty(B_r)$ with $\|g\|_{L^q} = 1$ gives

$$\begin{aligned}
\|A\|_{L^p(B_r)} &\le c''(r,p) \big\{ \|f\|_{L^1(B_{3r})} + \|f\|_{L^p(B_r)} + \|D\mathcal{U}\|^2_{L^2(B_{3r})} \big\} \\
&\le c'''(r,p) \big\{ \|f\|_{L^p(B_{3r})} + \|D\mathcal{U}\|^2_{L^2(B_{3r})} \big\}.
\end{aligned}$$

This proves estimate (2.12) for A, and the estimate for B follows similarly. □

Now consider the quantities $\nu_1(x), \nu_2(x) \ge 0$, defined to be the singular values of $D\mathcal{U}$, i.e., the eigenvalues of $\sqrt{D\mathcal{U}^T D\mathcal{U}}$. Thus ν_1^2 and ν_2^2 will each satisfy the characteristic equation for the matrix

$$D\mathcal{U}^T D\mathcal{U} = \begin{pmatrix} u_x^2 + v_x^2 & u_x u_y + v_x v_y \\ u_x u_y + v_x v_y & u_y^2 + v_y^2 \end{pmatrix} \tag{2.16}$$

given by

$$0 = \det \begin{pmatrix} (u_x^2+v_x^2)-\lambda & u_xu_y+v_xv_y \\ u_xu_y+v_xv_y & (u_y^2+v_y^2)-\lambda \end{pmatrix} = \lambda^2 - |D\mathcal{U}|^2\lambda + d^2. \tag{2.17}$$

Hence

$$\left(\nu_1^2-\nu_2^2\right)^2 = |D\mathcal{U}|^4 - 4d^2 = 4\left(\frac{|D\mathcal{U}|^2}{2}+|d|\right)\left(\frac{|D\mathcal{U}|^2}{2}-|d|\right), \tag{2.18}$$

$$\nu_1^2+\nu_2^2 = |D\mathcal{U}|^2. \tag{2.19}$$

This leads to the following.

Lemma 2.7. *For $\mathcal{E}$ and $\mathcal{U}$ as in Lemma* 1.1 *and for $p \in (1,\infty)$, if $f(d) \in L^p(B_{3r})$, then $\nu_1^2-\nu_2^2 \in L^p(B_r)$. In particular, the following estimates hold:*

$$\|\nu_1-\nu_2\|_{L^{2p}(B_r)} \le C\left(1+\|f\|_{L^p(B_{3r})}+\|D\mathcal{U}\|_{L^2(B_{3r})}\right); \tag{2.20}$$

$$\left\|\sqrt{\frac{|D\mathcal{U}|^2}{2}-|d|}\right\|_{L^{2p}(B_r)} \le C\left(1+\|f\|_{L^p(B_{3r})}+\|D\mathcal{U}\|_{L^2(B_{3r})}\right). \tag{2.21}$$

Proof. For almost every point $X \in \Omega$,

$$\left(D\mathcal{U}^T D\mathcal{U}\right)(X) = \mathcal{P}^T(X)\begin{pmatrix} \nu_1^2(X) & 0 \\ 0 & \nu_2^2(X)\end{pmatrix}\mathcal{P}(X)$$

for some $\mathcal{P}(X) \in SO(2)$. Thus

$$\begin{aligned}\begin{pmatrix} A & B \\ B & -A\end{pmatrix} &= D\mathcal{U}^T D\mathcal{U} - \frac{1}{2}|D\mathcal{U}|^2 I \\ &= \mathcal{P}^T\begin{pmatrix}\nu_1^2 & 0 \\ 0 & \nu_2^2\end{pmatrix}\mathcal{P} - \frac{1}{2}\begin{pmatrix}\nu_1^2+\nu_2^2 & 0 \\ 0 & \nu_1^2+\nu_2^2\end{pmatrix},\end{aligned}$$

and so

$$\begin{pmatrix}\nu_1^2-\nu_2^2 & 0 \\ 0 & \nu_2^2-\nu_1^2\end{pmatrix} = 2\,\mathcal{P}\begin{pmatrix} A & B \\ B & -A\end{pmatrix}\mathcal{P}^T \in L^p_{\text{loc}}(\Omega;\mathcal{M}^{2\times 2}), \tag{2.22}$$

with the same estimate for $\nu_1^2-\nu_2^2$ as those given by Lemma 2.6 for A and B. Since $\nu_1, \nu_2 \ge 0$ and in light of (2.18),

$$|\nu_1-\nu_2| + \sqrt{\frac{|D\mathcal{U}|^2}{2}-|d|} \le 2\sqrt{|\nu_1^2-\nu_2^2|}, \tag{2.23}$$

and estimates (2.20) and (2.21) follow. □

3. Proof of the theorem. Assume (2.4) without loss of generality. Adding $M\Delta u$ to both sides of (2.1.1) and $M\Delta v$ to both sides of (2.1.2) gives the divergence-form equations

$$\begin{aligned}\Delta u &= \frac{1}{M+1}\bigtriangledown\cdot\langle Mu_x - h'(d)v_y,\, Mu_y + h'(d)v_x\rangle \equiv \bigtriangledown\cdot F, \\ \Delta v &= \frac{1}{M+1}\bigtriangledown\cdot\langle Mv_x + h'(d)u_y,\, Mv_y - h'(d)u_x\rangle \equiv \bigtriangledown\cdot G.\end{aligned} \tag{3.1}$$

The result will follow by the L^p-boundedness of Riesz potentials if appropriate L^p-estimates for the components of F and G can be obtained for all $1 < p < \infty$ (cf. [8] and [4]). The proof utilizes a bootstrapping argument. The first step is proved for $|F|$ in detail, and $|G|$ follows similarly. The bootstrap for the next step is then outlined to complete the proof.

Let $\Omega' \subset\subset \Omega$. From the integrability of $f(d)$ given in (2.9), Lemma 2.7 gives

$$\|\nu_1 - \nu_2\|_{L^{\frac{2}{1-\beta}}(\Omega')} \leq C\left(1 + \|f(d)\|_{L^{\frac{1}{1-\beta}}(\Omega)} + \|D\mathcal{U}\|_{L^2(\Omega)}\right), \tag{3.2}$$

$$\left\|\sqrt{\frac{|D\mathcal{U}|^2}{2} - |d|}\right\|_{L^{\frac{2}{1-\beta}}(\Omega')} \leq C\left(1 + \|f(d)\|_{L^{\frac{1}{1-\beta}}(\Omega)} + \|D\mathcal{U}\|_{L^2(\Omega)}\right). \tag{3.3}$$

Set

$$\begin{aligned} S_0 &= \{X \in \Omega' : |d(X)| < 1\}, \\ S_+ &= \{X \in \Omega' : d(X) \geq 1\}, \\ S_- &= \{X \in \Omega' : d(X) \leq -1\}. \end{aligned} \tag{3.4}$$

By means of singular decomposition, there exist $\mathcal{P}(X), \mathcal{Q}(X) \in SO(2)$ such that

$$D\mathcal{U} = \mathcal{P}\begin{pmatrix} \nu_1 & 0 \\ 0 & \nu_2 \end{pmatrix}\mathcal{Q} \quad \text{on } S_+, \tag{3.5}$$

$$\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} D\mathcal{U} = \mathcal{P}\begin{pmatrix} \nu_1 & 0 \\ 0 & \nu_2 \end{pmatrix}\mathcal{Q} \quad \text{on } S_-. \tag{3.6}$$

Claim 1. *$Mu_x - h'(d)v_y \in L^{\frac{2}{1-\beta}}(S_+)$, with the estimate*

$$\|Mu_x - h'(d)v_y\|_{L^{\frac{2}{1-\beta}}(S_+)} \leq C\left(1 + \|D\mathcal{U}\|_{L^2(\Omega)}\right). \tag{3.7}$$

Proof. To prove this, first estimate

$$\begin{aligned} |Mu_x - h'(d)v_y| &= \frac{1}{2}\big|(M + h'(d))(u_x - v_y) + (M - h'(d))(u_x + v_y)\big| \\ &\leq \frac{1}{2}\Big[\big|(M + h'(d))\,(u_x - v_y)\big| + \big|(M - h'(d))\,(u_x + v_y)\big|\Big] \\ &\equiv \frac{1}{2}\big[(\mathrm{I}) + (\mathrm{II})\big]. \end{aligned} \tag{3.8}$$

There exist $\mathcal{P}, \mathcal{Q} \in SO(2)$, rotations by angles θ and ϕ, respectively, such that (3.5) holds. Thus

$$\begin{aligned}
u_x - v_y &= tr\left[\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix} D\mathcal{U}\right]\\
&= tr\left[\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\mathcal{P}\begin{pmatrix}\nu_1 & 0\\ 0 & \nu_2\end{pmatrix}\mathcal{Q}\right]\\
&= tr\left[\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\begin{pmatrix}\cos\theta & \sin\theta\\ -\sin\theta & \cos\theta\end{pmatrix}\begin{pmatrix}\nu_1 & 0\\ 0 & \nu_2\end{pmatrix}\begin{pmatrix}\cos\phi & \sin\phi\\ -\sin\phi & \cos\phi\end{pmatrix}\right] \qquad (3.9)\\
&= tr\left[\begin{pmatrix}\cos\theta & \sin\theta\\ \sin\theta & -\cos\theta\end{pmatrix}\begin{pmatrix}\nu_1\cos\phi & \nu_1\sin\phi\\ -\nu_2\sin\phi & \nu_2\cos\phi\end{pmatrix}\right]\\
&= (\nu_1-\nu_2)(\cos\theta\cos\phi+\sin\theta\sin\phi)\\
&= (\nu_1-\nu_2)\cos(\theta-\phi).
\end{aligned}$$

Still confined to S_+, since $d \geq 1$, estimate

(3.10)

$$\begin{aligned}
&(\mathrm{II}) \leq (M - h'(d))\sqrt{2}\sqrt{|D\mathcal{U}|^2} \leq K|d|^{-\beta}\left(\sqrt{2}\sqrt{|D\mathcal{U}|^2 - 2|d| + 2|d|}\right)\\
&\quad\leq 2K|d|^{-\beta}\sqrt{\frac{|D\mathcal{U}|^2}{2} - |d|} + 2K|d|^{-\beta}\sqrt{|d|} \leq 2K\sqrt{\frac{|D\mathcal{U}|^2}{2} - |d|} + 2K|d|^{\frac{1-\beta}{2}}.
\end{aligned}$$

From estimates (2.9), (2.20), and (2.21), we get

$$\begin{aligned}
\|\mathrm{I}\|_{L^{\frac{2}{1-\beta}}(S_+)} + \|\mathrm{II}\|_{L^{\frac{2}{1-\beta}}(S_+)} &\leq C\left(1 + \|f(d)\|_{L^{\frac{1}{1-\beta}}(\Omega)} + \|D\mathcal{U}\|_{L^2(\Omega)}\right)\\
&\leq C\left(1 + \|D\mathcal{U}\|_{L^2(\Omega)}\right).
\end{aligned} \qquad (3.11)$$

This completes the proof of Claim 1.

Claim 2. *$Mu_x - h'(d)v_y \in L^{\frac{2}{1-\beta}}(S_-)$, with the estimate*

$$\|Mu_x - h'(d)v_y\|_{L^{\frac{2}{1-\beta}}(S_-)} \leq C\left(1 + \|D\mathcal{U}\|_{L^2(\Omega)}\right). \qquad (3.12)$$

Proof. The proof is nearly the same as that of Claim 1, except that the respective methods for estimating (I) and (II) are reversed. In S_-, estimate

(3.13)

$$\begin{aligned}
&(\mathrm{I}) \leq (M + h'(d))\sqrt{2}\sqrt{|D\mathcal{U}|^2} \leq K|d|^{-\beta}\left(\sqrt{2}\sqrt{|D\mathcal{U}|^2 - 2|d| + 2|d|}\right)\\
&\quad\leq 2K|d|^{-\beta}\sqrt{\frac{|D\mathcal{U}|^2}{2} - |d|} + 2K|d|^{-\beta}\sqrt{|d|} \leq 2K\sqrt{\frac{|D\mathcal{U}|^2}{2} - |d|} + 2K|d|^{\frac{1-\beta}{2}}.
\end{aligned}$$

As for (II), using (3.6), compute as before

(3.14)

$$\begin{aligned}
u_x + v_y = tr\, D\mathcal{U} &= tr\left[\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}^2 D\mathcal{U}\right] = tr\left[\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\mathcal{P}\begin{pmatrix}\nu_1 & 0\\ 0 & \nu_2\end{pmatrix}\mathcal{Q}\right]\\
&= (\nu_1-\nu_2)\cos(\theta-\phi).
\end{aligned}$$

Thus

$$\|\mathrm{I}\|_{L^{\frac{2}{1-\beta}}(S_-)} + \|\mathrm{II}\|_{L^{\frac{2}{1-\beta}}(S_-)} \leq C\left(1 + \|D\mathcal{U}\|_{L^2(\Omega)}\right). \qquad (3.15)$$

Claim 3. *$Mu_y + h'(d)v_x \in L^{\frac{2}{1-\beta}}(S_+)$, along with an estimate of the form* (3.7) *for $Mu_y + h'(d)v_x$.*

Proof. As in the proofs of Claims 1 and 2, first estimate this quantity as follows:

$$\begin{aligned}|Mu_y + h'(d)v_x| &\leq \frac{1}{2}\Big[|(M + h'(d))(u_y + v_x)| + |(M - h'(d))(u_y - v_x)|\Big] \\ &\equiv \frac{1}{2}\,[(\mathrm{III}) + (\mathrm{IV})].\end{aligned} \tag{3.16}$$

Since $d \geq 1$, it follows that

$$u_y + v_x = (D\mathcal{U})_{12} + (D\mathcal{U})_{21} = \left[\left(\mathcal{P}\begin{pmatrix}\nu_1 & 0\\ 0 & \nu_2\end{pmatrix}\mathcal{Q}\right)_{12} + \left(\mathcal{P}\begin{pmatrix}\nu_1 & 0\\ 0 & \nu_2\end{pmatrix}\mathcal{Q}\right)_{21}\right].$$

Reading off these entries from the matrix

$$\mathcal{P}\begin{pmatrix}\nu_1 & 0\\ 0 & \nu_2\end{pmatrix}\mathcal{Q} = \begin{pmatrix}\cos\theta & \sin\theta\\ -\sin\theta & \cos\theta\end{pmatrix}\begin{pmatrix}\nu_1 & 0\\ 0 & \nu_2\end{pmatrix}\begin{pmatrix}\cos\phi & \sin\phi\\ -\sin\phi & \cos\phi\end{pmatrix}$$

gives

$$\begin{aligned}u_y + v_x &= (\nu_1\cos\theta\sin\phi + \nu_2\sin\theta\cos\phi - \nu_1\sin\theta\cos\phi - \nu_2\cos\theta\sin\phi) \\ &= (\nu_1 - \nu_2)(\cos\theta\sin\phi - \sin\theta\cos\phi) \\ &= (\nu_1 - \nu_2)\sin(\phi - \theta).\end{aligned} \tag{3.17}$$

The estimate for (IV) is the same as for (II) in Claim 1, and so Claim 3 is proved.

Claim 4. *$Mu_y + h'(d)v_x \in L^{\frac{2}{1-\beta}}(S_-)$, along with an estimate of form* (3.14) *for $Mu_y + h'(d)v_x$.*

Proof. Again, the proof is nearly the same as that of Claim 3, except for the reversal of the roles of (III) and (IV). The estimate for (I) from Claim 2 holds for (III) here. To estimate (IV), write

$$\begin{aligned}u_y - v_x &= \left[\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}D\mathcal{U}\right]_{12} + \left[\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}D\mathcal{U}\right]_{21} \\ &= \left\{\left[\mathcal{P}\begin{pmatrix}\nu_1 & 0\\ 0 & \nu_2\end{pmatrix}\mathcal{Q}\right]_{12} + \left[\mathcal{P}\begin{pmatrix}\nu_1 & 0\\ 0 & \nu_2\end{pmatrix}\mathcal{Q}\right]_{21}\right\} \\ &= (\nu_1 - \nu_2)\sin(\phi - \theta).\end{aligned} \tag{3.18}$$

This completes the proof of Claim 4.

Claim 5. *$D\mathcal{U} \in L^{\frac{2}{1-\beta}}(S_0)$, with an estimate*

$$\|D\mathcal{U}\|_{L^{\frac{2}{1-\beta}}(S_0)} \leq C\left(1 + \|D\mathcal{U}\|_{L^2(\Omega)}\right). \tag{3.19}$$

Proof. The estimate follows from (2.21) and the observation that the estimate $|D\mathcal{U}| \leq \sqrt{|D\mathcal{U}|^2 - 2|d|} + \sqrt{2}$ holds on S_0, and Claim 5 is proved.

We have shown so far that $\Delta u = \bigtriangledown \cdot F$, where $|F| \in L^p(\Omega')$ for $p = 2/(1-\beta)$. An argument similar to the one given above shows that $|G| \in L^p(\Omega')$ as well. Then from local estimates for Riesz potentials comes the estimate

$$\|D\mathcal{U}\|_{L^{\frac{2}{1-\beta}}(\Omega'')} \leq C\left(1 + \|\mathcal{U}\|_{L^2(\Omega)} + \|D\mathcal{U}\|_{L^2(\Omega)}\right) \tag{3.20}$$

on any subdomain $\Omega'' \subset\subset \Omega'$. Now the proof employs the bootsrapping. From (2.8), it is easy to see that

$$|f(d)| \leq C(1+|D\mathcal{U}|)^{2(1-\beta)}. \tag{3.21}$$

From (3.20), we then get

$$\|f(d)\|_{L^{\frac{1}{(1-\beta)^2}}(\Omega'')} \leq C\left(1+\|\mathcal{U}\|_{L^2(\Omega)}+\|D\mathcal{U}\|_{L^2(\Omega)}\right). \tag{3.22}$$

After passing to further subdomains, Lemmas 2.6 and 2.7 apply with $p=(1-\beta)^2$, and estimates (3.7), (3.12), (3.19), and (3.20) follow with $(1-\beta)^2$ replacing $(1-\beta)$ and with the modification that the $\|\mathcal{U}\|_{L^2(\Omega)}$ term be included in the right-hand sides of all these estimates. After m steps, $(1-\beta)$ is replaced by $(1-\beta)^m$, and the theorem follows. □

Remark. In the case where $\beta > 1$, $f(d) \in L^\infty(\Omega)$ and no bootstrap is required.

STABILITY OF GASEOUS STARS IN SPHERICALLY SYMMETRIC MOTIONS[*]

SONG-SUN LIN[†]

Abstract. We study the linearized stability of stationary solutions of gaseous stars which are in spherically symmetric and isentropic motion. If viscosity is ignored, we have following three types of problems: (EC), Euler equation with a solid core; (EP), Euler–Poisson equation without a solid core; (EPC), Euler–Poisson equation with a solid core. In Lagrangian formulation, we prove that any solution of (EC) is neutrally stable. Any solution of (EP) and (EPC) is also neutrally stable when the adiabatic index $\gamma \in (\frac{4}{3}, 2)$ and unstable for (EP) when $\gamma \in (1, \frac{4}{3})$. Moreover, for (EPC) and $\gamma \in (1, 2)$, any solution with small total mass is also neutrally stable. When viscosity is present ($\nu > 0$), the velocity disturbance on the outer surface of gas is important. For $\nu > 0$, we prove that the neutrally stable solution (when $\nu = 0$) is now stable with respect to positive-type disturbances, which include Dirichlet and Neumann boundary conditions. The solution can be unstable with respect to disturbances of some other types. The problems were studied through spectral analysis of the linearized operators with singularities at the endpoints of intervals.

Key words. stability, isentropic gas, self-gravitating, solid core, limit-point singularity

1. Introduction.

In this paper, we shall study the stability problem of gaseous stars which are in spherically symmetric and isentropic motion. The problem originated in Newtonian (nonrelativistic) astrophysical theory. A model equation for describing such motion is shown below:

$$\frac{\partial \rho}{\partial t} + v\frac{\partial \rho}{\partial r} + \rho\frac{\partial v}{\partial r} + \frac{2}{r}\rho v = 0, \tag{1.1}$$

$$\begin{aligned}\rho\left(\frac{\partial v}{\partial t} + v\frac{\partial v}{\partial r}\right) + \frac{\partial p}{\partial r} = &- \frac{\rho}{r^2}\left\{M_0 + 4\pi\delta\int_{R_0}^{r}\rho(t,s)s^2ds\right\}\\ &+ \nu\left\{\frac{\partial^2 v}{\partial r^2} + \frac{2}{r}\frac{\partial v}{\partial r} - \frac{2}{r^2}v\right\},\end{aligned} \tag{1.2}$$

$$p = A\rho^{\gamma}, \tag{1.3}$$

where $t \geq 0$ and $0 \leq R_0 < r < \infty$; see, e.g., [6, 7, 8, 9, 10, 11, 12, 13, 14, 20]. Here the unknown variable ρ is the density of the gas and v is the outward velocity. p is the pressure, A is a positive constant which is related to entropy, and $\gamma \in$ (1,2) is the adiabatic exponent.

The explanation of the physical parameters δ, M_0, R_0, and ν is as follows:

δ is the effect of self-gravitating of gas, the mutual graviational attraction among gas molecules, and is assumed to be either 0 or 1. If $\delta = 0$, we ignore the effect of self-gravitating. This may happen when the total amount of gas is relatively small. If $\delta = 1$, we then consider the self-gravitating of gas to be important.

M_0 is the total mass of the solid core surrounded by the gas. If $M_0 = 0$, then we assume that $R_0 = 0$. This is the case when there is no solid core and also no vacuum in the central part of the gaseous body. If $M_0 > 0$, we assume that there is a stationary, spherical solid core surrounded by the gas. In this case, we normalize the radius of the solid core with $R_0 = 1$. We also assume that the gas is in contact the surface of the solid core, i.e., no vacuum exists between the core and the gas. A nonslip condition is now imposed at the interface, i.e.,

$$v(t,1) = 0 \quad \text{for } t \geq 0. \tag{1.4}$$

We note that astrophysicists consider the solid core to be made of condensed gases in which there may be complicated activity that influences the surrounding gas. However, for mathematical simplicity, we will consider these condensed gases to be a solid core and ignore their influence on the surface gas.

ν is viscosity coefficient. We are mainly concered with inviscid flow, i.e., $\nu = 0$. After presenting a detailed study of inviscid flow, we will discuss the effect of viscosity on the stability of stationary solutions.

If viscosity is ignored, then according to the different combinations of parameters δ, M_0, and R_0, we have following three types of problems:

(EC): Euler equation with solid core ($\delta = 0,\ M_0 > 0,\ R_0 = 1,\ \nu = 0$);

(EP): Euler–Poisson equation without solid core ($\delta = 1$, $M_0 = 0$, $R_0 = 0$, $\nu = 0$);

(EPC): Euler–Poisson equation with solid core ($\delta = 1$, $M_0 > 0$, $R_0 = 1$, $\nu = 0$).

If viscosity is present, i.e., $\nu > 0$, then the Euler equation will be replaced by a Navier–Stokes equation and we have problems (NSC), (NSP), and (NSPC), respectively.

The stationary solution $(\overline{\rho}(r), 0)$ of (1.1)–(1.3) satisfies

$$\frac{d\overline{p}}{dr} = -\frac{\overline{\rho}}{r^2}\left\{M_0 + 4\pi\delta\int_{R_0}^{r}\overline{\rho}(s)s^2\right\}. \tag{1.5}$$

If we introduce the variable $u(r)$ and the parameter $\mu > 0$ in

$$\overline{\rho} = C_\gamma u^q \quad \text{and} \quad \mu = d_\gamma M_0,$$

where

$$q = \frac{1}{\gamma - 1}, \qquad C_\gamma = \left\{\frac{A\gamma}{4\pi(\gamma-1)}\right\}^{\frac{1}{2-\gamma}}, \quad \text{and} \quad d_\gamma = \left\{(4\pi)^{\gamma-1}\frac{\gamma-1}{A\gamma}\right\}^{\frac{1}{2-\gamma}},$$

then (1.5) and (1.4) can be studied by considering the following initial-value problems: for (EC),

$$\left.\begin{array}{l} u'' + \frac{2}{r}u' = 0, \quad r > 1, \\ u(1,\alpha,\mu) = \alpha \quad \text{and} \quad u'(1,\alpha,\mu) = -\mu \end{array}\right\}; \tag{1.6}$$

for (EP),

$$\left.\begin{array}{l} u'' + \frac{2}{r}u' + u^q = 0, \quad r > 0, \\ u(0,\alpha) = \alpha \quad \text{and} \quad u'(0,\alpha) = 0 \end{array}\right\}; \tag{1.7}$$

and for (EPC),

$$\left.\begin{array}{l} u'' + \frac{2}{r}u' + u^q = 0, \quad r > 1, \\ u(1,\alpha,\mu) = \alpha \quad \text{and} \quad u'(1,\alpha,\mu) = -\mu \end{array}\right\}. \tag{1.8}$$

Here $\alpha > 0$ is taken as a shooting parameter.

The total mass of the stationary solution u is given by

$$\tilde{M}(u) = 4\pi C_\gamma \int_{R_0}^{R} u^q(r) r^2 dr, \tag{1.9}$$

where $R \in (R_0, \infty]$ is the first zero of u, i.e.,

$$u(R) = 0 \quad \text{and} \quad u(r) > 0 \quad \text{in } (R_0, R).$$

From a physical point of view, we are only interested in a stationary solution with finite total mass.

The solution of (1.6) with finite total mass can be written explicitly as

$$u = \mu \left(\frac{1}{r} - \frac{1}{R} \right) \tag{1.10}$$

for some $R \in (1, \infty]$.

The solution of (1.7) has been studied extensively by Lane et al.; see, e.g., [1]. Their solutions include the ball type ($R < \infty$), the ground-state type ($R = +\infty$), and the singularity type, i.e., $\lim_{r \to 0^+} u(r) = \infty$.

Equation (1.8) has recently been studied in [5] and may have multiple solutions for certain μ and $\tilde{M}$ when $q > 3$.

The multiplicity results of these problems will be given in section 2.

In this paper, we mainly study the stability of stationary solutions obtained from (1.6), (1.7), and (1.8) since only the local existence and not the global-existance of the initial-value problem in (1.1)–(1.3) is known (see, e.g., [6, 7, 8, 9, 10, 11, 12, 13, 14]). We therefore need only study the linearized stability of these stationary solutions.

The linearized stability problem of the stationary solution $\overline{\rho}(r)$ will be studied in Lagrangian formulation. Indeed, equations (1.1)–(1.3) can be written in Lagrangian coordinates as

$$\rho_t + 4\pi\rho(r^2 v)_x = 0, \tag{1.11}$$

$$v_t + 4\pi r^2 p_x + \frac{1}{r^2}(M_0 + x) = 16\pi^2 \nu (r^2 \rho v_x)_x - 2\nu v (r^2 \rho)^{-1}, \tag{1.12}$$

$$r = \left\{ R_0 + \frac{3}{4\pi} \int_0^x \frac{1}{\rho(t, y)} dy \right\}^{\frac{1}{3}} \quad \text{and} \quad x = 4\pi \int_{R_0}^{r} \rho(s, t) s^2 ds,$$

where $t \geq 0$ and $x \in (0, \tilde{M})$. We assume that the perturbation of $(\overline{\rho}(x), 0)$ is in a radial direction only and write

$$\rho(t, x) = \overline{\rho}(x)\{1 + \varepsilon e^{\lambda t} \Phi(x)\} \quad \text{and} \quad v(t, x) = \varepsilon e^{\lambda t} \Psi(x) \tag{1.13}$$

in (1.11) and (1.12), where $|\varepsilon|$ is small. Let

$$\phi(x) = \int_0^x \frac{\Phi(y)}{\overline{\rho}(y)} dy.$$

Then the linear equations for Φ and Ψ can be simplified as follows:

$$(\overline{\rho}\overline{p}\phi_x)_x - \frac{1}{\pi\gamma\overline{r}^3}\overline{p}_x\phi = \frac{\lambda^2}{\gamma(4\pi\overline{r}^2)^2}\phi - \frac{\lambda\nu}{4\pi\gamma\overline{r}^2}\left\{16\pi^2\left[\overline{r}^4\overline{\rho}\left(\frac{1}{4\pi\overline{r}^2}\phi\right)_x\right]_x - \frac{2}{\overline{r}^2\overline{\rho}}\frac{1}{4\pi\overline{r}^2}\phi\right\} \tag{1.14}$$

with boundary condition

$$\phi(0) = 0, \tag{1.15}$$

where

$$\overline{r} = \left\{1 + \frac{3}{4\pi}\int_0^x \frac{1}{\overline{\rho}(y)}dy\right\}.$$

Transforming (1.14) into $\overline{r}$-coordinates and writting $\phi(x) = \psi(\overline{r})$, we obtain

$$\overline{L}\psi \equiv (\overline{r}^{-2}\overline{p}\psi')' - \frac{4}{\gamma}\overline{r}^{-3}\overline{p}'\psi = \frac{\lambda^2}{\gamma}\overline{r}^{-2}\overline{\rho}\psi - \frac{\lambda\nu}{\gamma}(\overline{r}^{-2}\psi')' \tag{1.16}$$

with $\psi(R_0) = 0$, where $\overline{p}$ is the pressure in $\overline{r}$-coordinates. Since $\overline{\rho}(R) = 0$, if $\nu = 0$, then (1.16) is singular at $\overline{r} = R$. We can prove that the singularity at R is a limit-point type and so $\overline{L}$ is self-adjoint. Therefore, λ^2 is real for any eigenvalue λ when $\nu = 0$. Now $\overline{\rho}$ is called neutrally stable if $\lambda^2 < 0$ for any eigenvalue λ and unstable if $\lambda_1^2 > 0$ for some eigenvalue λ_1. Hence if $\nu = 0$, then neutrally stable is the best we can hope for. Indeed, when $\nu = 0$, we have our stability results for ball-type solutions as follows.

THEOREM 1.1. *Assume that $\nu = 0$ and ball-type solutions have been considered. Then*

(I) *any solution of* (EC) *is neutrally stable*;

(II) *any solution of* (EP) *is neutrally stable if $q \in (1, 3)$ and unstable if $q > 3$; and*

(III) *for* (EPC), *we have the following:*

(i) *any solution is neutrally stable if $q \in (1, 3]$,*

(ii) *for any $q > 1$, $u(\cdot, \alpha, \mu)$ is neutrally stable if $\alpha \in (0, \mu]$, and*

(iii) *if $|R - 1|$ is sufficiently small, then it is neutrally stable.*

Some stability results concerning ground-state-type and singularity-type solutions are also presented in section 4.

When viscosity is present and $\lambda \notin [-\frac{\gamma}{\nu}p(R_0), 0]$, then (1.16) is regular at R. In this case, the viscosity term plays the dominant role in studying the eigenvalue problems. Now $\overline{\rho}$ is called stable if $\mathrm{Re}\lambda < 0$ for any eigenvalue λ and unstable if $\mathrm{Re}\lambda_1 > 0$ for some eigenvalue λ_1. Note that (1.16) is genuinely quadratic in λ (linear in λ^2 when $\nu = 0$) and λ is complex in general. Hence when $\nu > 0$, we may have better than the neutral stability that we have when $\nu = 0$. Since the outer surface of gas is a free surface, the velocity disturbance Ψ on it will play an important role. For example, we have stability results for (EC), (EP), and (EPC) as follows.

THEOREM 1.2. *Let u be a neutrally stable, ball-type stationary solution of* (EC), (EP), *or* (EPC) *when $\nu = 0$. Then for any $\nu > 0$, u is stable with respect to $\Psi = \psi_1 + i\psi_2$ if $\psi_j(\tilde{M})\psi_j'(\tilde{M}) \leq 0$ for both $j = 1$ and 2 on the gas surface. On the other hand, there is a positive constant κ_* depending on u such that u is unstable with respect to $\Psi = \psi_1 + i\psi_2$ if $\psi_1'(\tilde{M})/\psi_1(\tilde{M}) \geq \kappa_*$ and some ψ_2.*

The precise definition of stability with respect to the boundary disturbance Ψ is given in section 5.

The paper is organized as follows. In section 2, we recall some useful multiplicity results for stationary solutions with finite total masses. Their stabilities will be investigated in subsequent sections. In section 3, we study the linearized operators $\overline{L}$ and prove that they have limit-point-type singularities at their endpoints. We also provide a useful comparison lemma to test for stability. In section 4, we prove various stability results, which include Theorem 1.1. The solutions for other types of stability problems are also studied. In section 5, we study the effect of viscosity on stability problems and prove some results, including Theorem 1.2. In Appendix A, we study the asymptotic behavior of solutions of (1.16) at R when $\nu = 0$, which is very useful for studying ball-type solutions. In Appendix B, we recall Friedrichs' criteria for the spectrum discreteness of differential operators that have singular endpoints. These criteria are very useful in studying ground-state-type and singularity-type solutions.

2. Stationary solutions. In this section, we recall some multiplicity results for stationary solutions without interior vacuums and with finite total masses. Let $R \leq \infty$ be the first zero of solution u and $\tilde{M}(u)$ be the total mass given in (1.9). For notational simplicity, we omit the constant $4\pi C_\gamma$ in (1.9) and then define

$$M(u) = \int_{R_0}^{R} u(r)^q r^2 dr, \tag{2.1}$$

where $R_0 = 0$ for (EP) and $R_0 = 1$ for (EC) and (EPC).

Since the total mass of a gas remains constant while it is in motion and it may tend to a stationary state as time goes by, it is useful to know the numbers of stationary solutions for the same total mass. Hence we try to answer the following questions.

Questions. Given $M > 0$, how many solutions u are there for (EP) with $M(u) = M$? Given $\mu > 0$ and $M > 0$, how many solutions u are there for (EC) or (EPC) with $M(u) = M$?

Complete answers of (EC) and (EP) can be provided; see, e.g., [1]. However, (EPC) has only recently been studied and the result is complete for $1 < q \leq 3$ but partial when $q > 3$; see [5].

First, for (EC), the solution of (1.6) is given by

$$u(r, \alpha, \mu) = \alpha - \mu + \mu \frac{1}{r}. \tag{2.2}$$

If $\alpha \in (0, \mu)$, then $u(R(\alpha, \mu), \alpha, \mu) = 0$ with

$$R(\alpha, \mu) = \left(1 - \frac{\alpha}{\mu}\right)^{-1}.$$

In this case, we may write $u(\cdot, \alpha, \mu) = u_{R,\mu}$ with

$$u_{R,\mu}(r) = \mu \left(\frac{1}{r} - \frac{1}{R}\right).$$

It is clear that $M(u_{R,\mu})$ is strictly increasing in R and tends to

$$M_q^* = \begin{cases} +\infty & \text{if } 1 < q \leq 3, \\ \dfrac{1}{q-3} \cdot \mu^q & \text{if } q > 3. \end{cases}$$

If $\alpha = \mu$, then $R(\mu, \mu) = +\infty$ and

$$u(r, \mu, \mu) = \frac{\mu}{r}$$

with

$$M(u(\cdot, \mu, \mu)) = M_q^*.$$

If $\alpha > \mu$, then $M(u(\cdot, \alpha, \mu)) = \infty$, which is not of physical interest. Hence we have the following unique result for (EC).

PROPOSITION 2.1. *For any $q > 1$, $\mu > 0$, and $M \in (0, M_q^*)$, there is a unique solution $u_{R,\mu}$ for* (EC) *such that $M(u_{R,\mu}) = M$.*

Next, for (EP), we consider the initial-value problem

$$u'' + \frac{2}{r}u' + u^q = 0, \quad r > 0, \tag{2.3}$$

$$u'(0, \alpha) = 0 \quad \text{and} \quad u(0, \alpha) = \alpha > 0. \tag{2.4}$$

It is known that solutions of (2.3) have similar properties. Indeed, if $u(r)$ is a solution of (2.3), then for any $\beta > 0$,

$$u_\beta(r) = \beta^\sigma u(\beta r) \tag{2.5}$$

is also a solution, where $\sigma = \frac{2}{q-1}$. The total mass of u_β is

$$M(u_\beta) = \beta^{\frac{3-q}{q-1}} M(u). \tag{2.6}$$

The property (2.5) is related to the following classical Lane–Emden–Fowler transformations:

Let

$$r = e^{-\tau} \quad \text{and} \quad z(\tau) = r^\sigma u(r). \tag{2.7}$$

(2.3) can then be transformed into the autonomous equation

$$z'' + (2\sigma - 1)z' + \sigma(\sigma - 1)z + z^q = 0 \tag{2.8}$$

or, equivalently, the dynamic system

$$\begin{cases} z' = y, \\ y' = -\{2\sigma - 1)y + \sigma(\sigma - 1)z + z^q\}. \end{cases} \tag{2.9}$$

If $q \in (1, 3]$, then $0 = (0, 0)$ is the only equilibrium for (2.9) on the right half-plane $R_+^2 = \{(z, y) : z \geq 0\}$. If $q > 3$, then there is another equilibrium $S = (z_\sigma, 0)$, where

$$z_\sigma = \{\sigma(1 - \sigma)\}^{\frac{2}{\sigma}}. \tag{2.10}$$

0 is always a saddle point with the unstable manifold Γ, which is leaving in the direction $(1, 1 - \sigma)^t$, and the stable manifold $\tilde{\Gamma}$, which is arriving for the direction $(1, -\sigma)$, where $(a, b)^t$ is the transpose of vector (a, b) in R^2. Let

$$q^+ = 1 + \frac{2}{\sigma^+} \quad \text{and} \quad \sigma^+ = \sqrt{2} - \frac{1}{2}.$$

It is than easy to verify that $q^+ \in (3,5)$.

We now list some useful properties of the equilibrium S and system (2.9) on the phase plane R^2_+.

Proposition 2.2.

(I)

(i) *If* $q \in (3, q^+)$, *then* S *is a stable improper node.*

(ii) *If* $q = q^+$, *then* S *is a stable proper node.*

(iii) *If* $q \in (q^+, 5)$, *then* S *is stable spiral.*

(iv) *If* $q = 5$, *then* S *is a center.*

(v) *If* $q > 5$, *then* S *is an unstable spiral.*

(II)

(i) *For* $q \in (3,5)$, *the unstable manifold* Γ *of* 0 *is a heteroclinic orbit connecting* 0 *and* S. *There is no nontrivial periodic orbit on* R^2_+.

(ii) *For* $q = 5, \Gamma = \tilde{\Gamma}$, *i.e.,* Γ *is a homoclinic orbit of* 0. *The inside of* Γ *is covered by a family of concentric periodic orbits centered around* 0.

(iii) *For* $q > 5$, *the stable manifold* $\tilde{\Gamma}$ *of* 0 *is a heteroclinic orbit connecting* 0 *and* S.

The proofs are elementary and omitted; see [1] for details.

Every trajectory in the phase plane of (2.9) represents a family of self-similar solutions in (2.5). After carefully investigating the trajectories in the phase plane, we have exactly four types of solutions for (EP) with finite total mass for (EP):

(i) B-type solutions: ball-type solutions that lie on $\tilde{\Gamma}$ and appear when $q \in (1,5)$;

(ii) G-type solutions: ground-state solutions that also lie on $\tilde{\Gamma}$ and only appear when $q \geq 5$; they also have fast decay rates as $r \to +\infty$, i.e.,

$$\lim_{r \to +\infty} ru(r) \in (0,\infty); \tag{2.11}$$

(iii) SB-type solutions: ball-type solutions with a singularity at $r = 0$ that appear when $q \in (3,5)$ and are trajectories between Γ and $\tilde{\Gamma}$ that have a weak singularity, i.e., u satisfies

$$\lim_{r \to 0^+} r^\sigma u(r) \in (0,\infty); \tag{2.12}$$

(iv) SG-type solutions: ground-state solutions with a singularity at $r = 0$ that lie on Γ and satisfy (2.12); they also appear when $q \in (3,5)$;

Note that if the singularity at $r = 0$ is strong, i.e.,

$$\lim_{r \to 0^+} ru(r) > 0, \tag{2.13}$$

then u has an infinite total mass: for example, the SB-type solution when $q \in (1,3)$. If the ground-state solution has a slow-decay rate at ∞, i.e.,

$$\lim_{r \to \infty} r^\sigma u(r) > 0, \tag{2.14}$$

then u also has an infinite total mass, which includes the following cases:

(i) $q_\sigma r^{-\sigma}$ for $q > 3$; this corresponds to the equilibrium $S = (z_\sigma, 0)$;

(ii) when $q = 5$, all trajectories lie on homoclinic orbit Γ;

(iii) when $q > 5$, all trajectories spiral out from S;

With this preparation complete, we can now state our unique results for (EP).

Proposition 2.3. *For* (EP), *we have the following:*

(i) *If $q \in (1,3)$ and any $M > 0$, there is a unique—B-type—solution u such that $M(u) = M$.*

(ii) *If $q = 3$, only a special $\hat{M}$ of a stationary solution u—a B-type solution—admits.* (*All similar solutions of u also have the same total mass $\hat{M}$.*)

(iii) *If $q \in (3,5)$ and any $M > 0$, there are unique B-type, SB-type, and SG-type solutions with the same total mass M.*

(iv) *If $q = 5$ and any $M > 0$, there is a unique—G-type—solution u such that $M(u) = M$.*

(v) *If $q > 5$, there is no stationary solution with finite total mass.*

Proof. The proofs are based on the phase-plane analysis in (2.9) and the use of (2.6), and they are elementary. Thus the details are omitted. □

As for (EPC), there are two types of solutions with finite total mass:

(i) BC-type solutions: ball-type solutions with solid cores;

(ii) GC-type solutions: ground-state solutions with solid cores that satisfy (2.11).

We recall some results from [5].

Proposition 2.4. *For* (EPC), *we have the following:*

(i) *When $q \in (1,3]$, for any $\mu > 0$ and $M > 0$, there is a unique—BC-type—solution u that satisfies $M(u) = M$.*

(ii) *When $q > 3$, for any $\mu > 0$, the solution set is the disjoint union of N many connected components $C_k = \{u(\cdot, \alpha, \mu) : \alpha \in (\tilde{\alpha}_k,\, \hat{\alpha}_k)\}$, $k = 1, 2, \ldots, N$, where $N = N(\mu, q)$ is a positive integer or infinity.*

At C_k with $k \geq 2$, $M((u(\cdot, \alpha, \mu))$ tends to infinity at at least one end. At $C_1, \tilde{\alpha}_1 = 0$ and $\hat{\alpha}_1 > \mu$.

For detailed statements of Proposition 2.4(ii), see Theorems 3.5, 3.7, 3.9, and 3.13 in [5].

Remark 2.5. When there is a vaccum in the central part of the gaseous body that is also stationary, then u satisfies

$$u''(r) + \frac{2}{r}u'(r) + u^q(r) = 0, \qquad R_1 < r < R_2, \tag{2.15}$$

$$u(R_1) = 0 = u(R_2), \tag{2.16}$$

where $0 < R_1 < R_2 \leq \infty$. For any $q > 1$ and $0 < R_1 < R_2 < \infty$, Ni and Nussbaum [17] proved that there is a unique positive solution of (2.15) and (2.16). In contrast to Proposition 2.3(v), for any $q > 1$, the solution u of (2.15) and (2.16) with $R_2 < \infty$ has a finite total mass. We can then ask the following questions: Given $q > 1$ and $M > 0$, how many solutions u are there for (2.15) and (2.16) with $M(u) = M$? What is the stability of these annular-type solutions? These problems will be studied later.

3. Linearizations.

In this section, we will use a Lagrangian formulation to study the stability of the stationary solutions obtained in last section. Since we want to know the stability result when the outer surface of the gas is also perturbed, it is convenient to work in Lagrangian coordinates. We study only the inviscid flow in this section and defer study of the the viscous flow to section 5.

For notational simplicity, we replace $\bar{r}$ with r in (1.16) with $\nu = 0$. We then obtain

$$\mathcal{L}\psi = -\ell W \psi \quad \text{in } (R_0, R), \tag{3.1}$$

where

$$\mathcal{L}\psi \equiv (r^{-2}p\psi')' - \frac{4}{\gamma}r^{-3}p'\psi, \qquad W(r) \equiv \frac{\rho(r)}{\gamma r^2}, \quad \text{and} \quad \ell = -\lambda^2.$$

ψ also satisfies the boundary condition

$$\psi(R_0) = 0. \tag{3.2}$$

In terms of u, (3.1) can also be written as

$$L_0\psi \equiv \psi'' + \left\{(1+q)\frac{u'}{u} - \frac{2}{r}\right\}\psi' - \frac{4q}{r}\frac{u'}{u}\psi = -\ell(\gamma AC_\gamma^{\gamma-1})^{-1}\frac{\psi}{u}. \tag{3.3}$$

Since $u(R) = 0$, $\mathcal{L}$ is singular at R. Furthermore, $\mathcal{L}$ is also singular at $r = 0$ for (EP).

When $R < \infty$, we first study the asymptotic behavior of solution ψ of (3.1) at R. Indeed, we have the following result. (The proof is given in Appendix A.)

LEMMA 3.1. *Let $R < \infty$. If ℓ is real and ψ is a (real) solution of (3.1) in (R_0, R), then either ψ is bounded at $r = R$ or $\psi(r) = (R-r)^{-q}\hat{\psi}(r)$ for r close to R, with $\hat{\psi}(R) \neq 0$, and $\hat{\psi}$ is continuous at R. Furthermore, in the former case, ψ is C^2 at R, and in the latter case,*

$$\psi'(r) = q(R-r)^{-q-1}\hat{\psi}(R) + o((R-r)^{-q-1}) \tag{3.4}$$

as $r \to R^-$.

Similarly, if $R_0 = 0$, then either $\psi(0) \neq 0$ or $|\psi(r)| \leq Cr^3$ for r close to 0 and some $C > 0$.

To study the singularity type at R, it is convenient to remove the weight function W from right-hand side of (3.1). Indeed, if $R_0 = 1$, let $r_0 = 1$, and if $R_0 = 0$, choose any $r_0 \in (0, R)$ and fix it. Then define

$$s = s(r) = \int_{r_0}^{r} W(\tau)d\tau = \frac{1}{\gamma}\int_{r_0}^{r} \tau^{-2}\rho(\tau)d\tau \tag{3.5}$$

and

$$S_0 = \int_{r_0}^{R_0} W(\tau)d\tau \quad \text{and} \quad S = \int_{r_0}^{R} W(\tau)d\tau.$$

It is clear that $S_0 = 0$ when $R_0 = 1$ and $S_0 = -\infty$ when $R_0 = 0$. Furthermore, $W > 0$ in (R_0, R) implies that the inverse function of $s(r)$ exists. We may denote it by

$$r = r(s)$$

for $s \in (S_0, S)$. Let

$$\chi(s) = \psi(r(s)).$$

Then (3.1) is transformed into

$$\tilde{\mathcal{L}}\chi = -\ell\chi \quad \text{in } (S_0, S), \tag{3.6}$$

where

$$\tilde{\mathcal{L}}\chi = \frac{1}{\gamma}\frac{d}{ds}\left(r^{-4}p\rho\frac{d\chi}{ds}\right) - 4\frac{p'}{r\rho}\chi.$$

Let $L^2(S_0, S)$ be the complex-valued L^2-space on (S_0, S) with the standard inner product

$$(\chi, \tilde{\chi}) \equiv \int_{S_0}^{S} \overline{\chi}\tilde{\chi} ds. \tag{3.7}$$

It is clear that

$$(\chi, \tilde{\chi}) = \int_{R_0}^{R} \overline{\psi}\tilde{\psi} W(r) dr \equiv (\psi, \tilde{\psi})_w. \tag{3.8}$$

Here $(\ ,\ )_w$ defines an inner product in space $L^2_w(R_0, R)$ by (3.8).

Now we can prove $\tilde{\mathcal{L}}$ has limit-point-type singularity at S.

LEMMA 3.2. *If $S < \infty$, then $\tilde{\mathcal{L}}$ is limit-point type at S. Furthermore, for* (EP), *$\tilde{\mathcal{L}}$ is also limit-point type at $-\infty$.*

Proof. From [2], it is known that $\tilde{\mathcal{L}}$ is the limit-point-type singularity at S if we can find a solution pair $\{\ell, \chi\}$ for (3.6) in a neighborhood of S such that χ is not L^2. This can be done as follows:

Since

$$p = AC_\gamma^\gamma u^{q+1} \tag{3.9}$$

and

$$p' = A(q+1)C_\gamma^\gamma u^q u',$$

we have

$$\frac{p'(r)}{r\rho(r)} = A(q+1)C_\gamma^{\gamma-1} \frac{u'(r)}{r}. \tag{3.10}$$

Hence (3.10) implies

$$\lim_{r \to R} \frac{p'(r)}{r\rho(r)} = A(q+1)C_\gamma^{\gamma-1} \frac{u'(R)}{R}. \tag{3.11}$$

Fix $\hat{S} \in (S_0, S)$. For any real ℓ, let χ be the real solution of the following initial-value problem:

$$\tilde{\mathcal{L}}\chi = -\ell\chi \quad \text{in } (\hat{S}, S), \tag{3.12}$$

$$\chi(\hat{S}) = 0 \quad \text{and} \quad \chi'(\hat{S}) = 1. \tag{3.13}$$

Denote $\hat{R} = r(\hat{S})$. Now (3.11) implies that there exists $\ell_0 < 0$ such that

$$\ell_0 r\rho(r) - 4p'(r) \le 0 \tag{3.14}$$

in $[\hat{R}, R]$. We claim that $\chi \notin L^2(\hat{S}, S)$ if $\ell \le \ell_0$.

Indeed, if $\chi \in L^2(\hat{S}, S)$, then Lemma 3.1 and (3.8) imply that χ is bounded at S. From (3.12) and (3.13), we obtain

$$\frac{1}{\gamma} \int_{\hat{S}}^{S} r^{-4} p\rho \left(\frac{d\chi}{ds}\right)^2 ds = \ell \int_{\hat{S}}^{S} \chi^2 ds - 4 \int_{\hat{S}}^{S} \frac{p'}{r\rho} \chi^2 ds. \tag{3.15}$$

Now the left-hand side of (3.15) is positive and the right-hand side of (3.15) is nonpositive when $\ell \leq \ell_0$, a contradication. This implies that $\chi \notin L^2(\hat{S}, S)$ for $\ell \leq \ell_0$. Therefore, $\tilde{\mathcal{L}}$ is limit-point type at S.

For (EP), (3.10) and (1.7) imply that

$$\lim_{r \to 0^+} \frac{p'(r)}{r\rho(r)} = -\frac{A}{3}(q+1)C_\gamma^{\gamma-1}u^q(0). \tag{3.16}$$

Now using (3.11) and (3.16), we can choose $\ell_0 < 0$ such that (3.14) holds in $(0, \hat{R})$. Let $\psi(r) = \chi(s(r))$; then Lemma 3.1 implies either

$$\psi(0) \neq 0 \tag{3.17}$$

or

$$|\psi(r)| \leq Cr^3 \quad \text{and} \quad |\psi'(r)| \leq Cr^2 \tag{3.18}$$

for some $C > 0$. Now we can rule out the possibility of (3.18) when $\ell \leq \ell_0$. Indeed, if (3.18) holds, then

$$0 < \frac{1}{\gamma}\int_{-\infty}^{\hat{S}} r^{-4}p\rho \left(\frac{d\chi}{ds}\right)^2 ds = \int_{-\infty}^{\hat{S}} \left(\ell - \frac{4p'}{r\rho}\right)\chi^2 ds < 0,$$

a contradication.

Hence we must have (3.17) when $\ell \leq \ell_0$, i.e., $\chi \notin L^2(-\infty, \hat{S})$. Therefore, $\tilde{\mathcal{L}}$ is a limit-point-type at $-\infty$. The proof is complete. □

An immediate consequence of Lemma 3.2 is that $\tilde{\mathcal{L}}$ is self-adjoint. Indeed, we have the following result (for the proof, see [2]).

Corollary 3.3. *For* (EC) *and* (EPC)*, if $R < \infty$, let $\mathcal{D}_1$ be the set of all functions χ such that*

(i) *χ is differentiable and χ' is absolutely continuous on $[0, \hat{S}]$ for any $\hat{S} < S$,*

(ii) *χ and $\tilde{\mathcal{L}}\chi \in L^2(0, S)$, and*

(iii) *$\chi(0) = 0$.*

Then $\tilde{\mathcal{L}}$ is self-adjoint, i.e.,

$$(\tilde{\mathcal{L}}\chi, \hat{\chi}) = (\chi, \tilde{\mathcal{L}}\hat{\chi}) \tag{3.19}$$

for all χ and $\hat{\chi}$ in $\mathcal{D}_1$.

Similarly, for (EP)*, let $\mathcal{D}_0$ be the set of all functions χ such that*

(i)′ *χ is differentiable and χ' is absolutely continuous over $(-\infty, \hat{S}]$ for any $\hat{S} \in (-\infty, S)$ and*

(ii)′ *χ and $\tilde{\mathcal{L}}\chi \in L^2(-\infty, S)$.*

Then $\tilde{\mathcal{L}}$ is self-adjoint.

Furthermore, using Friedrichs' criteria, we can prove that $\tilde{\mathcal{L}}$ has only a discrete spectrum.

Theorem 3.4. *Let u be a stationary solution of* (EC), (EP), *or* (EPC) *with $R < \infty$. The spectra of $\tilde{\mathcal{L}}$ consist of sequences of strictly increasing eigenvalues $\{\ell_j\}_{j=1}$ with associated eigenfunctions $\{\chi_j\}_{j=1}^\infty$ in $\mathcal{D}_1$ (or $\mathcal{D}_0$).*

Proof. We first claim that no continuous spectrum comes out of S. Indeed, using (3.5), it can be verified that

$$s(r) = S - c_1(R-r)^{q+1} + o((R-r)^{q+1}) \tag{3.20}$$

for r close to R, where $c_1 > 0$ depends on R, $u'(R)$, and γ.

Let

$$a(s) = \frac{1}{\gamma} r^{-4} p(r)\rho(r), \qquad b(s) = \frac{4p'}{r\rho}, \quad \text{and} \quad c(s) = 1.$$

(3.20) then implies

$$a(s) = c_2(S-s)^{2-\varepsilon} + o((S-s)^{2-\varepsilon}), \tag{3.21}$$

where $\varepsilon = \frac{1}{q+1}$ and $c_2 > 0$. Let

$$h(s) = \int_0^s \frac{1}{a(\tau)} d\tau.$$

Then (3.21) implies

$$h(s) = c_3(S-s)^{\varepsilon-1} + o((S-s)^{\varepsilon-1}) \tag{3.22}$$

for s close to S, where $c_3 > 0$.

Hence (3.21) and (3.22) imply that

$$4ah^2 = c_4(S-s)^{\varepsilon} + o((S-s)^{\varepsilon}), \tag{3.23}$$

where $c_4 > 0$. (3.11) now implies that $b(s)$ is bounded at S. Therefore, (3.23) implies that

$$Z(s) = \frac{1}{c}\left\{ b + \frac{1}{4ah^2} \right\} \to +\infty \tag{3.24}$$

as $s \to S$. By Proposition B.3 in Appendix B, no continuous spectrum comes out of S, and $\tilde{\mathcal{L}}$ is totally descrete in R^1. In particular, for (EC) and (EPC), the spectrum of $\tilde{\mathcal{L}}$ is a sequence of eigenvalues $\{\ell_j\}_{j=1}^{\infty}$ such that

$$\lim_{j\to\infty} \ell_j = +\infty. \tag{3.25}$$

For (EP), we also need to prove that (3.24) holds when $s \to -\infty$. From (3.5), we have

$$s = -c_0 r^{-1} + o(r^{-1}) \tag{3.26}$$

for $r \to 0^+$, where $c_0 > 0$. Therefore,

$$a(s) = c_5 s^4 + o(s^4) \tag{3.27}$$

as $s \to -\infty$, where $c_5 > 0$. Let

$$h(s) = \int_s^0 \frac{1}{a(\tau)} d\tau.$$

Then (3.27) implies

$$h(s) = c_6(-s)^{-3} + o(s^{-3}) \tag{3.28}$$

as $s \to -\infty$, where $c_6 > 0$. Hence (3.27) and (3.28) imply

$$4ah^2 = c_7 s^{-2} + o(s^{-2})$$

as $s \to -\infty$. (3.24) then follows from last equation and (3.16). Hence no continuous spectrum comes out from $-\infty$ for (EP). The proof is complete. $\square$

From Lemma 3.4, $\tilde{\mathcal{L}}$ has only the real eigenvalue ℓ. Therefore, λ is either real or purely imaginary for any eigenvalue λ.

From these observations, we then introduce the following notion of stability.

Definition 3.5. *Let u be a ball-type stationary solution of* (EC), (EP), *or* (EPC), *and let* $\{\ell_j\}_{j=1}^{\infty}$ *be the associated eigenvalues of* $\tilde{\mathcal{L}}$ *given in Theorem* 3.4. *u is then called* neutrally stable *if* $\ell_1 > 0$ (*i.e.,* $\lambda_1 = \pm i\sqrt{\ell_1}$ *is purely imaginary*), *is called* unstable *if* $\ell_1 < 0$ (*i.e.,* $\lambda_1 = \pm\sqrt{|\ell_1|}$ *is real*), *and is called* marginally stable *if* $\ell_1 = 0$.

A similar definition can also be given for ground-state- and singularity-type solutions.

Remark 3.6. From Lemma 3.1 and Theorem 3.4, if ψ is an eigenfunction, then $\psi(R)$ is bounded. Furthermore, for (EP), $\psi(r) = O(r^3)$ as $r \to 0^+$. Moreover, the least eigenvalue ℓ_1 can be obtained by a variational method; see, e.g., [3]. Indeed, for (EC) or (EPC), we have

$$\ell_1 = \inf\left\{\frac{Q(\psi)}{I(\psi)} : \psi(1) = 0 \quad \textit{and} \quad \psi \in C^1[1,R]\right\},$$

where

$$Q(\psi) = \int_1^R \left\{r^{-2}p(r)\psi'^2(r) + \frac{4}{\gamma}r^{-3}p'(r)\psi^2(r)\right\}dr$$

and

$$I(\psi) = \frac{1}{\gamma}\int_1^R r^{-2}\rho(r)\psi^2(r)dr.$$

A similar formulation also holds for (EP) with $\psi(r) = O(r^3)$ as $r \to 0^+$.

The following comparison lemma is very useful for testing the stability of stationary solutions.

Lemma 3.7. *Let u be a BC-type stationary solution for* (EC) *or* (EPC). *Then the following hold:*

(i) *If there exists a* $\tilde{\psi} \in C^2([1,R])$ *with* $\tilde{\psi}(1) = 0$, $\tilde{\psi} > 0$ *in* $(1,R]$, *that satisfies*

$$L_0\tilde{\psi} \le 0 \ (\textit{but not} \equiv) \quad \textit{in } (1,R),$$

then u is neutrally stable.

(ii) *If there exists a* $\overline{\psi} \in C^2([1,R])$ *with* $\overline{\psi}(1) = 0$, $\overline{\psi} > 0$ *in* $(1,R]$, *that satisfies*

$$L_0\overline{\psi} \ge 0 \ (\textit{but not} \equiv) \quad \textit{in } (1,R),$$

then u is unstable.

A similar result also holds for a B-type stationary solution u for (EP) *provided the comparison function* $\tilde{\psi}$ (*or* $\overline{\psi}$) *satisfies* $\tilde{\psi}$ (*or* $\overline{\psi}$) $\in L^2_w(0,R)$ *and* $\mathcal{L}\tilde{\psi}$ (*or* $\mathcal{L}\overline{\psi}$) $\in L^2_w(0,R)$.

Proof. Let $\psi_1 > 0$ in (R_0,R) be the associated eigenfunction with respect to ℓ_1 in (3.20). If there is a $\tilde{\psi}$ that satisfies all conditions in (i), then it is easy to see that $\mathcal{L}\tilde{\psi} \le 0$ in $(1,R)$, which implies that

$$0 = \int_1^R (\tilde{\psi}\mathcal{L}\psi_1 - \psi_1\mathcal{L}\tilde{\psi})dr > -\ell_1\int_1^R W\tilde{\psi}\psi_1 dr.$$

Therefore, $\ell_1 > 0$. This proves (i). (ii) and the cases for (EP) can be proved analogously. The proof is complete. □

4. Stability results. In this section, we shall use the methods developed in the preceding section to study the stability of various stationary solutions. We begin with ball-type solutions, proceed to ground-state solutions, and finally conclude with singular solutions.

4.1. Ball-type solutions. We first introduce an auxiliary operator $\tilde{L}$, defined as

$$\tilde{L}\psi \equiv \psi'' - \frac{(q+3)}{r}\psi' + \frac{4q}{r^2}\psi. \tag{4.1}$$

$\tilde{L}$ is closed related to L_0, as can be seen from the following:

$$L_0\psi = \tilde{L}\psi + \left\{(1+q)\psi' - \frac{4q}{r}\psi\right\}\left(\frac{u'}{u} + \frac{1}{r}\right). \tag{4.2}$$

The following results for operator $\tilde{L}$ are very useful in constructing the comparison functions $\tilde{\psi}$ and $\overline{\psi}$ according to Lemma 3.7.

Lemma 4.1. *For any $q > 1$, we have $\tilde{L}(r^4) = 0$ and $\tilde{L}(r^q) = 0$. Moreover, if $q = 4$, we also have $\tilde{L}(r^4 \log r) = 0$.*

Furthermore, if we let (i) $\tilde{\psi} = r^4 - r^q$ *if $q \in (1, 4)$,* (ii) $\tilde{\psi} = r^4 \log r$ *if $q = 4$, and* (iii) $\tilde{\psi} = r^q - r^4$ *if $q \in (4, \infty)$, then we have* (a) $\tilde{L}\tilde{\psi} = 0$ *for $r > 1$,* (b) $\tilde{\psi}(1) = 0$*, and* (c) *the following:*

$$(1+q)\tilde{\psi}' - \frac{4q}{r}\tilde{\psi} > 0 \quad \textit{for} \quad r > 1. \tag{4.3}$$

Proof. The computations are straightforward, so we verify only the last inequality and omit the others. Indeed, for $q \neq 4$,

$$(1+q)(r^q - r^4)' - \frac{4q}{r}(r^q - r^4) = q(q-3)r^{q-1} - 4r^3,$$

and for $q = 4$,

$$(1+q)(r^4 \log r)' - \frac{4q}{r}(r^4 \log r) = 4r^3 \log r + 5r^3.$$

The result follows. □

Next, it is easy to verify the following lemma, so we omit the proof.

Lemma 4.2. *If $u > 0$ in $(1, R)$ and satisfies the equation*

$$u'' + \frac{2}{r}u' + f(u) = 0 \quad \textit{for } r > 1,$$

then

$$\frac{d}{dr}\left(\frac{u'}{u} + \frac{1}{r}\right) = -\frac{1}{r^2u^2}\{(ru' + u)^2 + r^2uf(u)\}.$$

In particular, if $u(\cdot, \alpha, \mu)$ is a solution of (1.6) or (1.8), then $\alpha \leq \mu$ implies

$$\left(\frac{u'}{u} + \frac{1}{r}\right) < 0 \quad \text{in } (1, R). \tag{4.4}$$

We can now establish the stability results for (EC) and (EPC) when $\alpha \leq \mu$.

THEOREM 4.3.

(i) *For any $q > 1$, $\mu > 0$, and $R > 1$, the solution $u_{R,\mu}$ of* (EC) *is neutrally stable.*

(ii) *For any $q > 1$, let $u(\cdot,\alpha,\mu)$ be the solution of* (EPC)*. Then $u(\cdot,\alpha,\mu)$ is neutrally stable if $\alpha \le \mu$.*

Proof. It is not difficult to verify $R(\alpha,\mu) < \infty$ when $\alpha \le \mu$ in (ii). Let $\tilde{\psi}$ be given as in Lemma 4.1. Then for both (i) and (ii), Lemmas 4.1 and 4.2 imply $L\tilde{\psi} < 0$ in $(1, R)$.

Thus Lemma 3.7 implies that $u_{R,\mu}$ and $u(\cdot,\alpha,\mu)$ with $0 < \alpha \le \mu$ are neutrally stable. The proof is complete. □

We can also establish other stability results for (EPC) by choosing appropriate comparison functions and applying Lemma 3.7. For example, we can prove the following theorem.

THEOREM 4.4. *For* (EPC)*, we have the following:*

(i) *If $q \in (1, 3]$, then all BC-type solutions are neutrally stable.*

(ii) *For any $q > 1$, there is $R_q > 1$ such that u is neutrally stable whenever the first zero R of u is less than R_q.*

Proof. (i) It is known that $R(\alpha,\mu) < \infty$ for any $\alpha > 0$ and $\mu > 0$ when $q \in (1, 3]$; see, e.g., [18]. Let $\tilde{\psi} = r^3 - 1$. Then $\tilde{\psi}(1) = 0$, $\tilde{\psi} > 0$ in $(0,\infty)$, and

$$L_0\tilde{\psi} = \left\{ \frac{u'}{u}(3-q)r^2 + \frac{4q}{r} \right\},$$

which is negative in $(0,\infty)$ if $q \in (1, 3]$. Thus by Lemma 3.7(i), u is neutrally stable.

(ii) Let $\tilde{\psi} = \log r$. Then $\tilde{\psi}(1) = 0$, $\tilde{\psi} > 0$ in $(1,\infty)$, and

$$L_0\tilde{\psi} = -3r^{-2} + \frac{1}{r}\frac{u'}{u}\{(1+q) - 4q\log r\}.$$

Therefore, $L_0\tilde{\psi} < 0$ in $(1, R)$ if $R \le R_q \equiv \exp(\frac{1+q}{4q})$. The result also follows from Lemma 3.7(i). The proof is complete. □

Remark 4.5. By picking a comparison function $\tilde{\psi}$ different from $\log r$ in Theorem 4.4(ii), we can also obtain another $\tilde{R}_q$, which ensures that u is neutrally stable when $R \le \tilde{R}_q$.

By choosing an appropriate comparison function, we obtain the following stability results for (EP).

THEOREM 4.6. *For* (EP)*, we have the following:*

(i) *If $q \in (1, 3)$, then any B-type solution is neutrally stable.*

(ii) *If $q = 3$, then any B-type solution is marginally stable.*

(iii) *If $q \in (3, 5)$, then any B-type solution is unstable.*

Proof. Let $\tilde{\psi} = r^3$. Then $\tilde{\psi}(0) = \tilde{\psi}'(0) = 0$ and $\tilde{\psi} > 0$ in $(0,\infty)$. Furthermore, we have

$$L_0\tilde{\psi} = (3-q)r^2\frac{u'}{u}.$$

Hence the result follows by Lemma 3.7. The proof is complete. □

Proof of Theorem 1.1. Combining the results from Theorems 4.3, 4.4, and 4.6, we obtain Theorem 1.1. □

4.2. Ground-state solutions. From section 2, we know that if a ground-state-type solution u has a finite total mass, then it is necessary that u have a fast decay rate, i.e.,

$$\lim_{r\to\infty} ru(r) = m \in (0,\infty). \tag{4.5}$$

In this section, we will prove that the linearized operator $\mathcal{L}$ associated with u has a continuous spectrum $(0,\infty)$. Therefore, u cannot be neutrally stable. In fact, it is either marginally stable or unstable.

LEMMA 4.7. *If u is a G- or GC-type solution and satisfies* (4.5)*, then the linearized operator $\mathcal{L}$ of u is discrete below* 0 *and has a continuous spectrum* $(0,\infty)$*.*

Proof. In Lemma 3.4, we have shown that no continuous spectrum comes from $r=0$ for $\mathcal{L}$ in (EP). Therefore, we need only study $\mathcal{L}$ as $r\to\infty$. We may assume that $m=1$ in (4.5). We then have

$$p(r) = \tilde{A}r^{-1-q} + o(r^{-1-q})$$

and

$$p'(r) = -(1+q)\tilde{A}r^{-q} + o(r^{-q})$$

as $r\to\infty$, where $\tilde{A} = AC_\gamma^\gamma$. As before, we have the following asymptotic expansions for the coefficients of $\mathcal{L}$ as $r\to\infty$:

$$a(r) = r^{-2}p(r) = \tilde{A}r^{-3-q} + o(r^{-3-q}),$$

$$b(r) = \frac{4}{\gamma}r^{-3}p'(r) = -4q\tilde{A}r^{-5-q} + o(r^{-5-q}),$$

and

$$c(r) = \frac{1}{\gamma}r^{-2}\rho(r) = \hat{A}r^{-2-q} + o(r^{-2-q})$$

as $r\to\infty$, where $\hat{A}>0$ is a constant. Therefore, for large fixed $\hat{r}$, we have

$$h(r) = \int_{\hat{r}}^{r} \frac{d\tau}{a(\tau)} = \{\tilde{A}(4+q)\}^{-1}r^{4+q} + o(r^{4+q})$$

as $r\to\infty$.

We claim that

$$Z(r) = \frac{1}{c(r)}\left\{b(r) + \frac{1}{4a(r)h^2(r)}\right\} \to 0 \quad \text{as } r\to\infty. \tag{4.6}$$

Indeed, it is clear that

$$4a(r)h^2(r) = 4\tilde{A}^{-1}(4+q)^{-2}r^{q+5} + o(r^{5+q}) \quad \text{as } r\to\infty.$$

Therefore, we have

$$\begin{aligned} b(r) + \frac{1}{4a(r)h^2(r)} &= \tilde{A}\left\{\frac{(4+q)^2}{4} - 4q\right\}r^{-5-q} + o(r^{-5-q}) \\ &= \frac{\tilde{A}}{4}(q-4)^2r^{-5-q} + o(r^{-5-q}). \end{aligned}$$

Hence

$$Z(r) = A^* r^{-3}(q-4)^2 + o(r^{-3})$$

for some $A^* > 0$. (4.6) follows. Now by Proposition B.3 (II)–(III) in Appendix B, the linearized operator $\mathcal{L}$ of u has a continuous spectrum $(0,\infty)$ and is descrete below 0. The proof is complete. □

An immediate consequence of Lemma 4.7 is the following theorem for ground-state-type stationary solutions.

THEOREM 4.8. *Any ground-state-type solution of* (EC), (EP), *or* (EPC) *is either marginally stable or unstable.*

4.3. Singular solutions. In this section, we will continuously apply Friedrichs' criteria to study the stability of singularity-type solutions. We know that if $q \in (3,5)$ and u is a singular solution of (EP) with finite total mass, then u has a weak singularity at $r=0$, i.e.,

$$\lim_{r\to o^+} r^\sigma u(r) = m \in (0,\infty). \tag{4.7}$$

As in section 4.2, we are interested in the limit of $Z(r)$ as $r \to 0^+$. (4.7) now implies the following expansions:

$$a(r) = r^{-2}p(r) = \tilde{A} r^{-\sigma(q+1)-2} + o(r^{-\sigma(q+1)-2}),$$

$$b(r) = \frac{4}{\gamma} r^{-3} p'(r) = -4\sigma q \tilde{A} r^{-\sigma(q+1)-4} + o(r^{-\sigma(q+1)-4}),$$

and

$$c(r) = \hat{A} r^{-2-\sigma q} + o(r^{-2-\sigma q})$$

as $r \to 0^+$ for some positive constants $\tilde{A}$ and $\hat{A}$.
Therefore,

$$h(r) = \int_0^r \frac{ds}{a(s)} = \tilde{A}^{-1}\{3+\sigma(q+1)\}^{-1} r^{\sigma(q+1)+3},$$

with $h(0)=0$.

It is straightfoward to compute

$$\begin{aligned} Z(r) &= A^* r^{-\sigma-2}\left\{\frac{1}{4}\left[3+\sigma(q+1)\right]^2 - 4\sigma q\right\} + o(r^{-\sigma-2}) \\ &= \frac{A^*}{4} r^{-\sigma-2}\{4\sigma^2+4\sigma-7\} + o(r^{-\sigma-2}) \end{aligned}$$

for some positive constant A^*.

Hence we obtain the following lemma.

LEMMA 4.9. *Let u be a singular solution of* (EP) *satisfying* (4.7). *Then we have the following:*

(i) *if* $q \in (3, q^+)$, *then* $\lim_{r\to 0^+} Z(r) = +\infty$;

(ii) *if* $q = q^+$, *then* $\lim_{r\to 0^+} Z(r) = 0$;

(iii) *if* $q \in (q^+, 5)$, *then* $\lim_{r\to 0^+} Z(r) = -\infty$;

and

$$\Omega_0 = \int_0^{\hat{r}} \left\{ \frac{c(r)}{-a(r)Z(r)} \right\}^{\frac{1}{2}} dr < \infty.$$

Therefore, by applying Theorem 4.6(iii), Lemma 4.9, and Proposition B.3, we obtain the following theorem for singularity-type solutions.

THEOREM 4.10. *For problem* (EP)*, we have the following:*

(i) *If $q \in (3, q^+)$, then any SB-type solution is unstable and has no continuous spectrum. Any SG-type solution is also unstable but has a continuous spectrum* $(0, \infty)$.

(ii) *If $q = q^+$, then any SB-type and SG-type solution is unstable and has a continuous spectrum* $(0, \infty)$.

(iii) *If $q \in (q^+, 5)$, then any SB-type and SG-type solution is unstable, and there is a sequence of pure imaginary eigenvalues $\{\lambda_k\}$ such that* $\lim_{k\to\infty} \lambda_k^2 = -\infty$.

Proof. For any $q \in (3,5)$ and for an SB-type solution u, choose $\tilde{\psi} = r^3$. Then we have

$$L\tilde{\psi} = (3-q)r^2 \frac{u'}{u} > 0.$$

Therefore, by modifying the proof of Lemma 3.5, we can prove that u is unstable. The remaining results follow from Lemma 4.9 and Proposition B.3. The details of the proof are omitted and the proof is complete. □

5. Effects of viscosity. In this section, we shall study the effect of viscosity on the stability problem of stationary solutions. From equation (1.2), it is clear that stationary solutions for inviscid flow are also solutions for viscous flow. As we have seen in the previous sections, the best possibilities for stationary solutions are neutrally stable in the inviscid case. It is known that neutral stability is very sensitive to disturbances. Therefore, we need to know what effect viscosity has on neutrally stable stationary solutions.

Since the gaseous mass is not confined from outside, its outer surface is a free surface maintained by the attraction of the core and its own gravitational forces. Presumably, the surface of the gas should be very sensitive to a direct disturbance of it. In this section, we show that this is the case, as mentioned in Theorem 1.2.

When viscosity its present, the linearized equation is

$$\mathcal{L}\psi = \lambda^2 W\psi - \lambda\nu\hat{\mathcal{L}}\psi, \tag{5.1}$$

where

$$\hat{\mathcal{L}}\psi \equiv \frac{1}{\gamma}(r^{-2}\psi')' \tag{5.2}$$

or, equivalently,

$$\left\{ r^{-2}\left(p(r) + \lambda\frac{\nu}{\gamma} \right)\psi' \right\}' - \frac{1}{\gamma}\{4r^{-3}p'(r) + \lambda^2 r^{-2}\}\psi = 0. \tag{5.3}$$

When $\nu > 0$, the eigenvlaue equation (5.1) is linear for ψ but quadratic for λ, which is different from ordinary eigenvalue problems. Indeed, if $\nu = 0$ in (5.1), then (5.1) is linear for $\ell = -\lambda^2$. Since the coefficients of $\mathcal{L}$, $\hat{\mathcal{L}}$, and W are real, it is easy to see that if $\{\lambda, \psi\}$ is a solution of (5.1), then its conjugate $\{\overline{\lambda}, \overline{\psi}\}$ is also a solution.

This property does not affect the stability, which depends on the sign of Reλ in the stationary solution.

In this section, we concentrate on the effects of viscosity and boundary disturbances. Therefore, we restrict our study to ball-type solutions which are neutrally stable. The problems of unstable stationary solutions, ground-state solutions, and singularity-type solutions will be left for future study.

We first consider (EC) and (EPC) and then continue by studying (EP).

Let

$$\lambda^* = \frac{\gamma}{\nu} P(R_0). \tag{5.4}$$

When $R_0 = 1$, we will prove that (5.1) is regular on $[1, R]$ when $\lambda \notin [-\lambda^*, 0]$. Indeed, for $\lambda \neq -\lambda^*$, let $\psi(\cdot, \lambda) = \psi(\cdot, \lambda, \nu)$ be the solution of (5.3) that satisfies the initial conditions

$$\psi(1, 0) = 0 \tag{5.5}$$

and

$$\psi'(1, \lambda) = 1. \tag{5.6}$$

We can then prove the following result.

Lemma 5.1. *Let u be a BC-type stationary solution of* (EC) *or* (EPC). *If $\lambda \notin [-\lambda^*, 0]$, then $\psi(\cdot, \lambda)$ is C^2 on $[1, R]$ and is analytic in $\lambda \in \mathbf{C} - [-\lambda^*, 0]$. Furthermore, if $\lambda \in (-\lambda^*, 0)$, then either $\psi(\cdot, \lambda)$ is bounded at $r = \hat{r}$ or $|\psi(r, \lambda)|$ grows like $|\log |r - \hat{r}||$ as $r \to \hat{r}$, where $\hat{r} \in (1, R)$ satisfies $p(\hat{r}) + \lambda \frac{\nu}{\gamma} = 0$. If $\lambda = -\lambda^*$, then any nontrivial solution ψ of* (5.3) *is unbounded in a neighborhood of $r = 1$. The case in which $\lambda = 0$ was studied in Lemma* 3.1.

Proof. Let $\lambda = \lambda_1 + i\lambda_2$ and $\psi = \psi_1 + i\psi_2$ in (5.3) and denote

$$a = r^{-2}\left(p + \lambda_1 \tfrac{\nu}{\gamma}\right), \qquad b = \lambda_2 \frac{\nu}{\gamma} r^{-2},$$

$$c = \frac{1}{\gamma}\{4r^{-3}p' + r^{-2}(\lambda_1^2 - \lambda_2^2)\}, \qquad d = \frac{2}{\gamma}\lambda_1\lambda_2 r^{-2}.$$

Then it is clear that $a^2(\hat{r}) + b^2 = 0$ for some $\hat{r} \in [1, R]$ if and only if $\lambda_2 = 0$ and $\lambda_1 \in [-\lambda^*, 0]$. In this case, $p(\hat{r}) + \lambda_1 \frac{\nu}{\gamma} = 0$.

Now (5.3) can be written as the following system of equations:

$$\begin{aligned} (a\psi_1' - b\psi_2')' &= c\psi_1 - d\psi_2, \\ (b\psi_1' + a\psi_2')' &= d\psi_1 + c\psi_2. \end{aligned} \tag{5.7}$$

For $\lambda \notin [-\lambda^*, 0]$, denote

$$\tilde{\psi}_1 = a\psi_1 - b\psi_2 \quad \text{and} \quad \tilde{\psi}_2 = b\psi_1 + a\psi_2. \tag{5.8}$$

We then have

$$\begin{aligned} \psi_1 &= (a\tilde{\psi}_1 + b\tilde{\psi}_2)(a^2 + b^2)^{-1}, \\ \psi_2 &= (-b\tilde{\psi}_1 + a\tilde{\psi}_2)(a^2 + b^2)^{-1}. \end{aligned} \tag{5.9}$$

By a straightforward but lengthy computation on (5.7), we obtain the following system of equations for $\tilde{\psi}_1$ and $\tilde{\psi}_2$:

$$\begin{aligned}\tilde{\psi}_1'' &= \tilde{A}\tilde{\psi}_1' + \tilde{B}\tilde{\psi}_1 + \tilde{C}\tilde{\psi}_2' + \tilde{D}\tilde{\psi}_2,\\ \tilde{\psi}_2'' &= \tilde{A}\tilde{\psi}_2' + \tilde{B}\tilde{\psi}_2 - \tilde{C}\tilde{\psi}_1' - \tilde{D}\tilde{\psi}_2,\end{aligned} \tag{5.10}$$

where

$$\tilde{a} = a(a^2+b^2)^{-1}, \qquad \tilde{b} = b(a^2+b^2)^{-1}, \tag{5.11}$$

and

$$\begin{aligned}\tilde{A} &= a'\tilde{a} + b'\tilde{b},\\ \tilde{B} &= (a''+c)\tilde{a} + (b''+d)\tilde{b} + a'\tilde{a}' + b'\tilde{b}',\\ \tilde{C} &= a'\tilde{b} - b'\tilde{a},\\ \tilde{D} &= (a''+c)\tilde{b} - (b''+d)\tilde{s} + a'\tilde{b}' - b'\tilde{a}'.\end{aligned} \tag{5.12}$$

Since the coefficients of (5.10) are continuous on $[1,R]$, then $\tilde{\psi}_1'$ and $\tilde{\psi}_2'$ are C^2 on $[1,R]$ and analytic in $\lambda \in \mathbf{C} - [-\lambda^*, 0]$. Hence ψ_1 and ψ_2 have the same properties as $\tilde{\psi}_1$ and $\tilde{\psi}_2$. This proves the first part of the lemma.

To study $\lambda \in (-\lambda^*, 0)$, we write (5.3) as

$$\psi'' + \left\{\frac{1}{r-\hat{r}} + g(r)\right\}\psi' + \frac{1}{r-\hat{r}}f(r)\psi = 0 \quad \text{for } r < \hat{r},$$

where g and f are analytic at $\hat{r}$. Hence $\hat{r}$ is a regular singular point. Therefore, by a standard theorem (see, e.g., [2]), this implies that ψ either is bounded at $\hat{r}$ or grows logarithmically at $\hat{r}$.

Finally, if $\lambda = -\lambda^*$, then $p(1) = \lambda^* \frac{\nu}{\gamma}$. Let $s = r-1$; then (5.3) can be written as

$$\psi'' + \left(\frac{2}{s} + g\right)\psi' + \left(\frac{c_2}{s^2} + \frac{c_1}{s} + f\right)\psi = 0 \qquad \text{for } s > 0,$$

where g and f are continuous at $s = 0$ and $c_2 > 0$.

Let

$$\mu_1 = \frac{1}{2}(-1 + \sqrt{1-4c_2}) \qquad \text{and} \qquad \mu_2 = \frac{1}{2}(-1 - \sqrt{1-4c_2}).$$

If $\mu_1 \neq \mu_2$, then ψ behaves asymptotially like s^{μ_1} or s^{μ_2} as $s \to 0^+$. If $\mu_1 = \mu_2 = -\frac{1}{2}$, then $|\psi(s)|$ behaves asymptotically like $s^{-\frac{1}{2}}$ or $s^{-\frac{1}{2}}|\log s|$ as $s \to 0^+$. In any case, ψ is unbounded at $s = 0$. The case in which $\lambda = 0$ was studied in Lemma 3.1. The proof is complete. □

Considering (1.13) and Lemma 5.1, we introduce the following notion.

DEFINITION 5.2. *For* $\lambda \notin [-\lambda^*, 0], \psi(\cdot, \lambda)$ *is called a* stable mode *if* $\text{Re}\lambda < 0$*, an* unstable mode *if* $\text{Re}\lambda > 0$*, and a* marginally stable mode *if* $\text{Re}\lambda = 0$.

In the following, we shall study the relationship between the sign of $\text{Re}\lambda$ and $\psi(R, \lambda)$, i.e., how the disturbance of the gas surface influences the stability of the stationary solution u.

Since $\psi(\cdot, \lambda)$ is C^2 in $[1,R]$ for $\lambda \notin [-\lambda^*, 0]$, $\psi(R, \lambda)$ and $\psi'(R, \lambda)$ satisfies homogeneous boundary conditions at R, i.e.,

$$a_j \psi_j'(R) + b_j \psi_j(R) = 0, \tag{5.13}$$

where $\psi_1 = \text{Re}\psi$ and $\psi_2 = \text{Im}\psi$, $a_j = a_j(\lambda)$ and $b_j = b_j(\lambda)$ are analytic in $\lambda \notin [-\lambda^*, 0]$ for $j = 1, 2$.

When $a_j \neq 0$, denote

$$\kappa_j(\lambda) = \frac{b_j(\lambda)}{a_j(\lambda)}. \tag{5.14}$$

Then (5.13) can be written as

$$\frac{\psi_j'(R)}{\psi_j(R)} = -\kappa_j. \tag{5.15}$$

When $a_j = 0$, i.e., ψ_j satisfies the Dirichlet boundary condition $\psi_j(R) = 0$, we adopt the convention $\kappa_j = +\infty$.

We can now introduce the notion of the stability of stationary solutions with respect to the boundary conditions (5.5) and (5.15) (or (5.13)).

Definition 5.3. *Let u be a BC-type stationary solution for* (EC) *or* (EPC). *Then u is called* stable *with respect to* (5.5) *and* (5.15) *if any eigenvalue λ of* (5.1), (5.5), *and* (5.15) *satisfies* $\text{Re}\lambda < 0$. *u is called* unstable *if there is an eigenvalue $\tilde{\lambda}$ of* (5.1), (5.5), *and* (5.15) *such that* $\text{Re}\tilde{\lambda} > 0$. *$u$ is called* marginally stable *if any eigenvalue λ of* (5.1), (5.5), *and* (5.15) *satisfies* $\text{Re}\lambda \leq 0$ *and equality holds for some $\tilde{\lambda}$.*

The stability problem with respect to boundary condition (5.15) can also be studied by making the following observation:

Denote

$$\mathbf{C}^+ = \{\lambda \in \mathbf{C} : \text{Re}\lambda > 0\}, \qquad \mathbf{C}^- = \{\lambda \in \mathbf{C} : \text{Re}\lambda < 0\},$$
$$\text{and} \quad \mathbf{C}^0 = \{\lambda \in \mathbf{C} : \text{Re}\lambda = 0\}.$$

For any stationary solution u and any

$$(\kappa_1, \kappa_2) \in \overline{\mathbf{R}}^2 \equiv \mathbf{R}^2 \cup \{(k_1, \infty) : \kappa_1 \in \mathbf{R}^1\} \cup \{(\infty, k_2) : \kappa_2 \in \mathbf{R}^1\} \cup \{(\infty, \infty)\},$$

denote by $\sigma(\kappa_1, \kappa_2)$ the set of eigenvalues of (5.1), (5.5), and (5.15). Then define

$$K_s = K_s(u) \equiv \{(\kappa_1, \kappa_2) : \sigma(\kappa_1, \kappa_2) \subset \mathbf{C}^-\},$$

$$K_u = K_u(u) \equiv \{(\kappa_1, \kappa_2) : \sigma(\kappa_1, \kappa_2) \cap \mathbf{C}^+ \neq \phi\},$$

and

$$K_m = K_m(u) = \{(\kappa_1, \kappa_2) : \sigma(\kappa_1, \kappa_2) \cap \mathbf{C}^+ = \phi \quad \text{and} \quad \sigma(\kappa_1, \kappa_2) \cap \mathbf{C}^0 \neq \phi\}.$$

From Lemma 5.1, we know that any one of K_s, K_u, and K_m is nonempty. Hence the stability of u with respect to a given (κ_1, κ_2) is equivalent to deciding to which set—K_s, K_u, or K_m—(κ_1, κ_2) belongs. In general, for a given u, it is not easy to completely identify K_s, K_u, and K_m. However, we shall find some subsets of K_s and K_u that will give us sufficient conditions to determine whether u is stable or unstable with respect to given (κ_1, κ_2).

We first prove the following stability result.

THEOREM 5.4. *Let u be a neutrally stable BC-type stationary solution of* (EC) *or* (EPC) *when $\nu = 0$. Then for any $\nu > 0$, we have*

$$\{(\kappa_1, \kappa_2) : \kappa_1 \geq 0, \quad \kappa_2 \geq 0\} \subset K_s(u), \tag{5.16}$$

i.e., u is stable if

$$\kappa_1 \geq 0 \quad \textit{and} \quad \kappa_2 \geq 0 \tag{5.17}$$

or, equivalently, if

$$\psi_j'(R)\psi_j(R) \leq 0 \tag{5.18}$$

for $j = 1, 2$.

Proof. Since u is assumed to be neutrally stable when $\nu = 0$, 0 is not an eigenvalue of (5.1), (5.5), and (5.15). If $\lambda \in (-\lambda^*, 0)$, then there is nothing to prove. Hence we consider the case where $\lambda \notin [-\lambda^*, 0)$ and is an eigenvalue with respect to (5.15) such that $(\kappa_1(\lambda), \kappa_2(\lambda))$ satisfies (5.17). We must prove that

$$\text{Re}\lambda < 0. \tag{5.19}$$

Indeed, multiply (5.1) by $\overline{\psi}$ and then integrate from 1 to R; λ satisfies

$$a\lambda^2 + b\lambda + c = 0, \tag{5.20}$$

where

$$a = \frac{1}{\gamma}\int_1^R r^{-2}\rho(r)(\psi_1^2 + \psi_2^2)dr > 0, \tag{5.21}$$

$$b = -\nu\int_1^R \overline{\psi}\hat{\mathcal{L}}\psi dr, \quad \text{and} \quad c = -\int_1^R \overline{\psi}\mathcal{L}\psi dr.$$

Since u is assumed to be neutrally stable when $\nu = 0$, we have $\ell_1 > 0$ in (3.1). Moreover, ψ is C^2 on $[1, R]$. Hence Remark 3.6 implies that

$$c > 0. \tag{5.22}$$

Now let

$$b = b_1 + ib_2, \tag{5.23}$$

where

$$\begin{aligned} b_1 &= -\nu\int_1^R (\psi_1\hat{\mathcal{L}}\psi_1 + \psi_2\hat{\mathcal{L}}\psi_2) \\ &= \nu\left\{\sum_{j=1}^2 \int_1^R r^{-2}(\psi_j')^2 - \sum_{j=1}^2 R^{-2}\psi_j'(R)\psi_j(R)\right\} \end{aligned}$$

and

$$\begin{aligned} b_2 &= -\nu\int_1^R (\psi_1\hat{\mathcal{L}}\psi_2 - \psi_2\hat{\mathcal{L}}\psi_1) \\ &= \frac{\nu}{\gamma}R^{-2}(\psi_2(R)\psi_1'(R) - \psi_1(R)\psi_2'(R)). \end{aligned}$$

Assumption (5.18) implies that

$$b_1 > 0. \tag{5.24}$$

Now we are going to show that the root λ of (5.20) satisfies (5.19) provided the coefficients satisfy (5.21)–(5.24). It is clear that the roots λ of (5.20) are given by

$$\lambda_{\pm} = \frac{1}{2a}\{-(b_1 + ib_2) \pm (b^2 - 4ac)^{\frac{1}{2}}\}. \tag{5.25}$$

Let

$$X = b_1^2 - b_2^2 - 4ac \quad \text{and} \quad Y = b_1 b_2.$$

Then

$$b^2 - 4ac = X + 2iY.$$

Moreover, if x and y are real numbers such that

$$(x + iy)^2 = X + iY,$$

then

$$x^2 = \frac{1}{2}\{X + (X^2 + 4Y^2)^{\frac{1}{2}}\}.$$

To show (5.19), it suffices to prove that $b_1 > |x|$, i.e.,

$$b_1^2 > x^2. \tag{5.26}$$

By (5.21) and (5.22), we have

$$2b_1^2 - X = b_1^2 + b_2^2 + 4ac > 0. \tag{5.27}$$

It is easy to check that

$$(2b_1^2 - X)^2 - (X^2 + 4Y^2) = 16ac. \tag{5.28}$$

Hence (5.26) follows from (5.21), (5.22), (5.27), and (5.28). The proof is complete. □

Next, we prove the following instability results.

LEMMA 5.5. *Let u be a neutrally stable BC-type stationary solution of* (EC) *or* (EPC) *when $\nu = 0$. For any $\nu > 0$, if λ is real and $\lambda > 0$, we have*

$$\psi(R, \lambda) > 0 \quad \textit{and} \quad \psi'(R, \lambda) > 0. \tag{5.29}$$

Furthermore, we have

$$\lim_{\lambda \to 0^+} \frac{\psi'(R, \lambda)}{\psi(R, \lambda)} = +\infty \tag{5.30}$$

and

$$\lim_{\lambda \to \infty} \frac{\psi'(R, \lambda)}{\psi(R, \lambda)} = +\infty. \tag{5.31}$$

Proof. If $\lambda > 0$, then $p(r) + \lambda\frac{\nu}{\gamma} > 0$ in $[1, R]$. Integrating (5.3) from 1 to r and using (5.5) and (5.6), we obtain

(5.32)
$$r^{-2}\left(p(r) + \lambda\frac{\nu}{\gamma}\right)\psi'(r) = \left(p(1) + \lambda\frac{\nu}{\gamma}\right) + \frac{1}{\gamma}\int_1^r \{4s^{-3}p'(s) + \lambda^2 s^{-2}\}\psi(s,\lambda)ds.$$

If λ^2 is large enough that

(5.33)
$$\lambda^2 + 4s^{-1}p'(s) \geq 0 \quad \text{in } [1, R],$$

then (5.5), (5.6), and (5.32) imply

(5.34)
$$\psi(r,\lambda) > 0 \quad \text{and} \quad \psi'(r,\lambda) > 0 \quad \text{in } [1, R].$$

In particular, (5.29) holds.

Now by applying Theorem 5.4, we claim that (5.29) also holds for any $\lambda > 0$. Otherwise, by the continuous dependence of $\psi(R,\lambda)$ with respect to λ, we have $\psi'(R,\lambda_1) = 0$ or $\psi(R,\lambda_1) = 0$ for some $\lambda_1 > 0$. Since (5.18) is satisfied by this λ_1, Theorem 5.4 implies $\lambda_1 < 0$, a contradiction. Hence (5.29) holds for any $\lambda > 0$.

To show (5.30), we note that u is neutrally stable and by Proposition A.1 in Appendix A, we have

(5.35)
$$\lim_{r\to R^-}(R-r)^q\psi(r,0) = c_0 > 0$$

and

(5.36)
$$\lim_{r\to R^-}(R-r)^{q+1}\psi'(r,0) = c_1 > 0.$$

From (5.35), (5.36), and (5.29), it is not difficult to prove that (5.30) holds. The details of the proof are omitted.

Finally, it remains to prove (5.31). If $\lambda > 0$ and is large enough, then (5.3), (5.33), and (5.34) imply that

(5.37)
$$\psi''(r,\lambda) > 0 \quad \text{in } [1, R].$$

Moreover, by (5.32), there is a positive constant c_2 that is independent on λ such that for a large λ, we have

(5.38)
$$\psi'(R,\lambda) \geq \lambda c_2 \int_r^R \psi(s,\lambda)ds$$

for $r \in [\frac{1}{2}R, R]$. Now for any $s \in [\frac{1}{2}R, R]$, write

(5.39)
$$\psi(s,\lambda) = \psi(R,\lambda) + \psi'(R,\lambda)(s-R) + \frac{1}{2}\psi''(\tilde{r},\lambda)(s-R)^2$$

for some $\tilde{r} \in (s, R)$. Subsituting (5.39) into (5.38) and using (5.37), we obtain

(5.40)
$$\psi'(R,\lambda)\left\{1 + \frac{1}{2}\lambda c_2(R-r)^2\right\} \geq \lambda c_2\psi(R,\lambda)(R-r).$$

If we choose r such that $(R-r)\lambda^{\frac{1}{2}} = 1$, then (5.40) implies that for a large λ, we have

$$\psi'(R,\lambda) \geq c_3\lambda^{\frac{1}{2}}\psi(R,\lambda),$$

where the positive constant c_3 is independent of λ. Hence (5.31) follows. The proof is complete. □

For any real $\lambda \notin [-\lambda^*, 0]$, $\psi(r,\lambda)$ is a real function, i.e., $\psi_2 = \mathrm{Im}\psi \equiv 0$. $\kappa_2(\lambda)$ is then undetermined for all real $\lambda \notin [-\lambda^*, 0]$. However, we can define $\kappa_2(\lambda)$ for these λ by going through the following limiting process.

Let λ_1 and λ_2 be real numbers such that $\lambda_1 \notin [-\lambda^*, 0]$ and $|\lambda_2| \neq 0$ and is sufficiently small. We then have

$$\psi(r, \lambda_1 + i\lambda_2) = \psi(r,\lambda_1) + i\lambda_2\frac{\partial\psi}{\partial\lambda}(r,\lambda_1) + o(|\lambda_2|^2) \tag{5.41}$$

as $\lambda_2 \to 0$. Therefore, for any real $\lambda_1 \notin [-\lambda^*, 0]$, we can define

$$\kappa_2(\lambda_1) = \frac{\partial^2\psi}{\partial r\partial\lambda}(R,\lambda_1)/\frac{\partial\psi}{\partial\lambda}(R,\lambda_1). \tag{5.42}$$

It is not difficult to prove that $\kappa_2(\lambda)$ is well defined and is continuous for $\lambda \in \mathbf{C} - [-\lambda^*, 0]$.

Now by applying Lemma 5.5, we have that following instability result.

Theorem 5.6. *Let u be a neutrally stable BC-type stationary solution of* (EC) *or* (EPC) *when $\nu = 0$. Then for any $\nu > 0$, there is a positive constant $\kappa^* = \kappa^*(\nu, u)$ such that for any $\kappa_1 < -\kappa^*$, there is a nonempty open set $U(\kappa_1, \nu, u)$ such that u is unstable with respect to* (5.5) *and* (5.15) *for (κ_1, κ_2) with $\kappa_2 \in U(\kappa_1, \nu, u)$.*

Proof. For any $\nu > 0$, let

$$\kappa^*(\nu, u) = \min\left\{\frac{\psi'(R,\lambda,\nu)}{\psi(R,\lambda,\nu)} : \lambda \in (0,\infty)\right\}.$$

By (5.30) and (5.31), we have $\kappa^*(\nu, u) > 0$. If $\kappa_1 < -\kappa^*$, then there is $\lambda_1 > 0$ such that

$$\frac{\psi'(R,\lambda_1)}{\psi(R,\lambda_1)} = -\kappa_1.$$

Let

$$U(\kappa_1,\nu,u) = \{\kappa_2 \in (-\infty,\infty] : (\kappa_1,\kappa_2) \in K_u\}.$$

Then (5.42) implies that

$$\kappa_2(\lambda_1) \in U(\kappa_1,\nu,u).$$

Thus $U(\kappa_1,\nu,u)$ is nonempty. It is clear that $U(\kappa_1,\nu,u)$ is open, and the result follows. The proof is complete. □

Proof of Theorem 1.2. Theorem 1.2 follows from Theorems 5.4 and 5.6. □

We now come to (EP). In this case, (5.3) has a singularity at $r = 0$ even for $\lambda \notin [-\lambda^*, 0)$. Therefore, we need to modify our argument to obtain a result as in Lemma 5.1. Indeed, the initial conditions (5.5) and (5.6) will be replaced with

$$r^{-2}\psi(r,\lambda) = 0 \quad \text{at } r = 0 \tag{5.43}$$

and

$$(r^{-2}\psi(r,\lambda))' = 1 \quad \text{at } r = 0. \tag{5.44}$$

We then have the following result.

LEMMA 5.7. *Let u be a B-type solution of* (EP). *Then the solution $\psi(r,\lambda)$ of* (5.3), (5.43), *and* (5.44) *exists in a neighborhood of $r = 0$ if $\lambda \neq -\lambda^* \equiv \frac{\gamma}{\nu}p(0)$. Furthermore, $\psi(\cdot,\lambda)$ has the same property as in Lemma* 5.1.

Proof. Following the same argument as in the proof of Lemma 5.1, we have equation (5.9) for $\tilde{\psi}_1$ and $\tilde{\psi}_2$ in $r > 0$. For $\lambda \neq -\lambda^*$, after a careful computation, (5.9) can be written as

$$\tilde{\psi}_1'' = \left(-\frac{2}{r} + g_1\right)\tilde{\psi}_1' + \left(\frac{2}{r^2} + f_1\right)\tilde{\psi}_1 + g_2\tilde{\psi}_2' + f_2\tilde{\psi}_2 \tag{5.45}$$

and

$$\tilde{\psi}_2'' = \left(-\frac{2}{r} + g_1\right)\tilde{\psi}_2' + \left(\frac{2}{r^2} + f_1\right)\tilde{\psi}_2 - g_2\tilde{\psi}_1' - f_2\tilde{\psi}_1, \tag{5.46}$$

where $g_j(r)$ and $rf_j(r)$ are continuous (in fact, C^2) at $r = 0$ for $j = 1, 2$. Now $r = 0$ is a regular singular point in (5.45) and (5.46). By a standard argument, we can prove that there is bounded solution $\{\tilde{\psi}_1, \tilde{\psi}_2\}$ of (5.45) and (5.46). Moreover, they satisfy

$$\begin{aligned} \tilde{\psi}_1(r) &= a_0 r + o(r), \\ \tilde{\psi}_2(r) &= b_0 r + o(r) \end{aligned} \tag{5.47}$$

as $r \to 0^+$. The details of the proof are omitted. Now the initial conditions (5.43) and (5.44) imply that a_0 and b_0 satisfy

$$a_0 = p(0) + \lambda_1\frac{\nu}{\gamma} \quad \text{and} \quad b_0 = \lambda_2\frac{\nu}{\gamma}. \tag{5.48}$$

Subsituting (5.47) into (5.9), we obtain

$$\begin{aligned} \psi_1(r) &= r^3 + o(r^3), \\ \psi_2(r) &= O(r^3) \end{aligned} \tag{5.49}$$

as $r \to 0^+$.

The other properties of $\psi(\cdot,\lambda)$ can also be obtained as in proving Lemma 5.1; the details are omitted. The proof is complete. □

By arguing as in Theorems 5.4 and 5.6, we can obtain the following stability result for problem (EP).

THEOREM 5.8. *Let u be a neutrally stable B-type stationary solution of* (EP) *when $\nu = 0$. Then for any $\nu > 0$, u is stable with respect to* (5.43) *and* (5.15) *if $\kappa_1 \geq 0$ and $\kappa_2 \geq 0$. On the other hand, there is a positive constant $\kappa^* = \kappa^*(\nu, u)$ such that for any $\kappa_1 < -\kappa^*$, there is a nonempty open set $U(\kappa_1, \nu, u)$ such that u is unstable with respect to* (5.43) *and* (5.15) *for (κ_1, κ_2) with $\kappa_2 \in U(\kappa_1, \nu, u)$.*

Proof. The proof is the same as was used for Theorems 5.4 and 5.6. Therefore, the details are omitted. □

Remark 5.9. In their recent work on (EC), Makino et al. [15, 16, 19] showed that when $\gamma > \frac{4}{3}$ and $\nu > 0$, $u_{R,\mu}$ is nonlinearly asymptotically stable with respect to small perturbations. Their result is consistent with ours.

Appendix A. Asymptotic behavior at *R*. In this section, we shall study the asymptotic behavior of a real solution ψ at R for (3.3) with real ℓ. Let

$$\tau = R - r \quad \text{and} \quad \tilde{\psi}(\tau) = \psi(r).$$

Then $\tilde{\psi}$ satisfies

$$\tilde{\psi}'' + \{(1+q)\tau^{-1} + g(\tau)\}\tilde{\psi}' + \tau^{-1} f(\tau)\tilde{\psi} = 0.$$

For simplicity, we omit the $\sim$'s and write the last equation as

$$\text{(A.1)} \qquad \psi'' + \{(1+q)\tau^{-1} + g(\tau)\}\psi' + \tau^{-1} f(\tau)\psi = 0, \quad \tau > 0,$$

where g and f are continuous at $\tau = 0$.

Then we have the following result concerning the behavior of ψ at 0.

PROPOSITION A.1. *For any $q > 1$, let ψ be a solution of* (A.1). *Then either ψ is bounded at* 0 *or*

$$\text{(A.2)} \qquad \psi(\tau) = \tau^{-q}\hat{\psi}(\tau)$$

with $\hat{\psi}$ continuous at 0 *and $\hat{\psi}(0) \neq 0$. Furthermore, in the former case, ψ is C^2 at* 0*, and in the latter case, we have*

$$\text{(A.3)} \qquad \psi'(\tau) = -q\tau^{-q-1}\hat{\psi}(0) + o(\tau^{-q-1})$$

as $\tau \to 0^+$.

Proof. If g and f are analytic in a neighborhood of $\tau = 0$, then the result is well known; see, e.g., [2]. For completeness, we provide a proof here that assumes only that g and f are continuous at $\tau = 0$. Since the proof is elementary, some details are omitted.

For $\tau > 0$, let

$$\text{(A.4)} \qquad \psi(\tau) = \tau^{-q}\omega(\tau).$$

ω then satisfies

$$\text{(A.5)} \qquad \omega'' + \{(1-q)\tau^{-1} + g\}\omega' + (f - qg)\tau^{-1}\omega = 0, \quad \tau > 0.$$

Let $G(0) = 0$ and $G'(\tau) = g(\tau)$, (A.5) can then be written as

$$\text{(A.6)} \qquad (\tau^{1-q}e^G\omega')' + \tau^{-q}e^G(f - qg)\omega = 0.$$

Fix $\tau_1 > 0$ and let $\tau_0 \in (0, \tau_1)$ be chosen later. After integrating (A.6) from τ to τ_0, we have

$$\text{(A.7)} \qquad \omega'(\tau) = \tau^{q-1}E(\tau)C_0 + \tau^{q-1}E(\tau)\int_\tau^{\tau_0} F(s)s^{-q}\omega(s)ds,$$

where

$$E(\tau) = \exp(-G(\tau)), \qquad F(\tau) = (f - qg)\exp(G(\tau)),$$
$$\text{and} \quad C_0 = \tau_0^{1-q}\omega'(\tau_1)\exp(G(\tau_1)).$$

We first claim that

$$\omega \text{ and } \omega' \text{ are bounded on } (0,\tau]. \tag{A.8}$$

Indeed, let

$$C_1 = |C_0| \max_{\tau\in[0,\tau_1]} |E(\tau)| \quad \text{and} \quad C_2 = \max_{\tau\in[0,\tau_1]} |E(\tau)| \cdot \max_{\tau\in[0,\tau_1]} |F(\tau)|.$$

Then from (A.7), we have

$$|\omega'(\tau)| \le C_1\tau^{q-1} + C_2\tau^{q-1}\int_\tau^{\tau_0} s^{-q}|\omega(s)|ds, \tag{A.9}$$

which implies that

$$|\omega'(\tau)| \le C_1\tau^{q-1} + C_3 \max_{s\in[\tau,\tau_0]} |\omega(s)|,$$

where

$$C_3 = C_2\cdot(q-1)^{-1}.$$

Now for any $\tau \in (0,\tau_0)$, substituting (A.9) into

$$\omega(\tau) = \omega(\tau_0) + \int_{\tau_1}^{\tau} \omega'(s)ds,$$

we obtain

$$|\omega(\tau)| \le |\omega(\tau_0)| + C_4 + C_3\tau_0 \max_{s\in[\tau,\tau_0]} |\omega(s)|, \tag{A.10}$$

where

$$C_4 = C_1\tau_1^q.$$

Now if we choose $C_3\tau_0 < 1$, (A.10) then implies

$$|\omega(\tau)| \le (1 - C_3\tau_0)^{-1}\{|\omega(\tau_0)| + C_4\}.$$

Hence ω is bounded on $[0,\tau_1]$. By (A.9), ω' is bounded on $[0,\tau_1]$, which also implies that ω is continuous at 0. Now if $\omega(0) \ne 0$, then (A.4) and (A.8) imply (A.3). If $\omega(0) = 0$, we shall claim that

$$|\omega(\tau)| \le C_5\tau^q \tag{A.11}$$

for some $C_5 > 0$. Indeed, $\omega(0) = 0$ and ω' bounded on $[0,\tau_1]$ implies that

$$|\omega(\tau)| \le C_6\tau. \tag{A.12}$$

Now substituting (A.12) into (A.9), we have

$$|\omega'(\tau)| \le C_7\tau^{q-1} + C_8\tau \tag{A.13}$$

for some $C_7 > 0$ and $C_8 > 0$. Substituting (A.13) into

$$\omega(\tau) = \int_0^\tau \omega'(s)ds,$$

we obtain a better estimate for ω than (A.12). After repeating the processes a finite number of times, (A.15) follows. The proof is complete. □

Appendix B. Friedrichs' criteria. In this section, we recall a useful criterion of Friedrichs [4] for studying the spectra of second-order differential operators that are self-adjoint and singular at their endpoints.

Let $J = (x-, x+) \subset \mathbf{R}^1$ be a bounded or unbounded open interval.

Let $a(x)$, $a'(x)$, $b(x)$, and $c(x)$ be continuous functions on J. Furthermore, $a(x)$ and $c(x)$ are positive on J. The eigenvalue equation

$$-(a(x)\phi'(x))' + b(x)\phi(x) = \lambda c(x)\phi(x)$$

can be written as

$$L\phi = \lambda\phi,$$

where

$$L = c^{-1}(x)\left\{-\frac{d}{dx}\left(a(x)\frac{d}{dx}\right) + b(x)\right\}.$$

Define

$$h = \left|\int \frac{dx}{a(x)} + C\right| > 0$$

in the neighborhood of $x-$ or $x+$. The constants $C = C_-$ or $C = C_+$ should be chosen such that at the endpoint, h is either zero or infinite.

$$\text{(B.1)} \qquad \text{If } h(x-) = 0 \qquad (\text{or } h(x+) = 0),$$

then we require that

$$\text{(B.2)} \qquad \phi(x-) = 0 \qquad (\text{or } \phi(x+) = 0).$$

Otherwise, we need not put conditions on ϕ at $x-$ or $x+$.

Define $X = \{\phi : J \to \mathbf{R}^1 : \phi$ is absolutely continuous and satisfies $\int_{x-}^{x+} c(x)\phi^2(x)dx < \infty$, $\int_{x-}^{x+} a(x)\phi'^2(x)dx < \infty$, and $\int_{x-}^{x+} |b(x)|\phi^2(x)dx < \infty$ and also satisfies (B.1) if (B.2) holds$\}$ and

$$(\phi, \psi) = \int_{x-}^{x+} c(x)\phi(x)\psi(x)dx.$$

Definition B.1. *The spectrum of L is called* discrete below λ_* *if for every $\lambda' < \lambda_*$ there exists at most a finite number of mutually orthogonal eigenfunctions $\phi_\lambda(x)$ associated with eigenvalue $\lambda \le \lambda'$ such that for every $\phi \in X$ such that*

$$(\phi, \phi_\lambda) = 0,$$

we have

$$(\phi, L\phi) \ge \lambda_*(\phi, \phi).$$

L is called totally discrete *if L possesses a pure point spectrum.*

Remark B.2. If the spectrum is discrete below every λ_*, then it is totally discrete.

Define

$$Z(x) = \frac{1}{c(x)}\left\{b(x) + \frac{1}{4a(x)h^2(x)}\right\}.$$

Friedrichs' criterion can then be stated as follows.

Proposition B.3.

(I) *L is totally discrete if*

$$Z(x) \to \infty \quad \text{as } x \to x- \text{ and } x \to x+.$$

(II) *L is discrete below λ_* if*

$$\liminf Z(x) \geq \lambda_* \quad \text{as } x \to x- \text{ and } x \to x+.$$

(III) *L is not discrete below λ^* if $Z(x)$ is bounded below and*

$$\limsup Z(x) < \lambda^*$$

as either $x \to x-$ or $x \to x+$.

(IV) *The spectrum of L is discrete below λ_*, unbounded below, if*

$$\liminf_{x \to x-} Z(x) \geq \lambda_*,$$

$$\lim_{x \to x+} Z(x) = -\infty,$$

and

$$\Omega = \int_{x_0}^{x+} \left\{ \frac{c(x)}{-a(x)Z(x)} \right\}^{\frac{1}{2}} dx < \infty,$$

where $x_0 < x+$ such that $Z(x) < 0$ in $(x_0, x+)$. A similar result holds if the roles of $x-$ and $x+$ are interchanged.

Acknowledgments. The author wishes to thank Professors T. P. Liu and T. Makino for several useful discussions about this work.

LONG-TIME BEHAVIOR FOR A CONVECTION-DIFFUSION EQUATION IN HIGHER DIMENSIONS[*]

MIGUEL ESCOBEDO[†] AND ENRIQUE ZUAZUA[‡]

Abstract. We study the long-time behavior of the solutions of the Cauchy problem

$$u_t - \triangle u + \frac{\partial |u|^{q-1}u}{\partial x_1} + \frac{\partial |u|^{p-1}u}{\partial x_2} = 0$$

in $\mathbf{R}^N \times (0,\infty)$ with initial data in $L^1(\mathbf{R}^N)$. We consider the range of exponents

$$1 < q < 1 + \frac{1}{N}, \qquad 1 + \frac{q}{N+1} < p.$$

We prove that nonnegative solutions with smooth initial data satisfy the entropy inequality

$$\frac{\partial u^{q-1}}{\partial x_1} \le \frac{C}{t}.$$

With the aid of this inequality, we show that, as $t \to \infty$, solutions behave like the nonnegative fundamental entropy solution of the reduced equation

$$u_t - \sum_{j=2}^{N} \frac{\partial^2 u}{\partial {x_j}^2} + \frac{\partial |u|^{q-1}u}{\partial x_1} = 0$$

of mass $\int_{\mathbf{R}^N} u(x,0)dx$, which has a self-similar structure.

Key words. parabolic scalar conservation law, convection-diffusion equation, entropy inequality, entropy solution, conservation of mass, long-time behavior, self-similarity

Introduction. In this paper, we continue the study of the long-time behavior of the solutions to some simple examples of scalar parabolic conservation laws, such as

$$u_t - \triangle u + \sum_{i=1}^{N} \frac{\partial f_i(u)}{\partial x_i} = 0 \quad \text{in } Q = \mathbf{R}^N \times (0,\infty), \tag{0.1}$$

$$u(\cdot,0) = u_0(\cdot) \quad \text{in } \mathbf{R}^N, \tag{0.2}$$

where $N \ge 1$, $f_i \in C^1([0,\infty)) \cap C^2((0,\infty))$, $f(0) = 0$, and $u_0 \in L^1(\mathbf{R}^N)$.

Solutions of (0.1)–(0.2) with L^1 initial data satisfy the following two properties:

$$\int_{\mathbf{R}^N} u(t,x)dx = \int_{\mathbf{R}^N} u_0(x)dx \quad \forall t \ge 0 \quad \text{(conservation of mass);} \tag{0.3}$$

$$\|u(t)\|_\infty \leq C\left(\int_{\mathbf{R}^N} u_0\right) t^{-\frac{N}{2}} \quad \forall t > 0 \quad (L^\infty \text{ decay}). \tag{0.4}$$

The asymptotic behavior of the solutions of (0.1)–(0.2) was studied in [EZ], [EVZ1], [EVZ2], [EVZ3], [C1], [C2], and [Z1] under one of the following conditions:

$$\text{for every } i \in \{1,\dots,N\}, \quad \text{the limits } \lim_{s\to 0} \frac{f_i(s)}{|s|^{1/N}s} \text{ exist} \tag{0.5}$$

or

$$\begin{cases} \exists q \in \left(1, 1+\dfrac{1}{N}\right) \quad \text{and} \quad j \in \{1,\dots,N\} \quad \text{such that } f_i \equiv 0 \quad \text{if } i \neq j, \\ f_j(0) = f_j'(0) = 0 \quad \text{and} \quad \text{the following limit exists:} \\ \lim\limits_{s\to 0} \dfrac{f_j''(s)}{|s|^{q-3}s}. \end{cases} \tag{0.6}$$

In these papers, three different types of asymptotic behaviors were observed: weakly nonlinear, self-similar, and strongly nonlinear. Let us briefly recall the main results obtained in these previous works.

Weakly nonlinear behavior. This case was considered in [EZ, section 6, Theorem 5], where the following result was proved. (See [Z2] for the second term of the asymptotic development.)

THEOREM 0.1. *Suppose that $f_i(s)/|s|^{1/N}s \to 0$ as $s \to 0$ for all $i = 1,\dots,N$ and assume that u solves* (0.1)–(0.2) *with $\int u_0 = M$. Then for every $r \in [1,\infty]$,*

$$\lim_{t\to\infty} t^{\frac{N}{2}(1-\frac{1}{r})} ||u(t) - MK(t)||_{L^r(\mathbf{R}^N)} = 0,$$

where $K(t,x)$ is the heat kernel in $\mathbf{R}^N$.

Self-similar behavior. It was proved in [AEZ] that if $q = 1 + 1/N$, then for every $M \in \mathbf{R}$ and every $\mathbf{C} \equiv (C_1,\dots,C_N) \in \mathbf{R}^N$, there is a unique self-similar solution $\omega_{M,\mathbf{C}}$ of the problem

$$\begin{cases} \omega_t - \triangle\omega + \sum\limits_{i=1}^{N} C_i \dfrac{\partial|\omega|^{q-1}\omega}{\partial x_i} = 0 \quad \text{for } t > 0, \quad x \in \mathbf{R}^N, \\ \omega(t,x) = t^{-N/2} g\left(\dfrac{x}{\sqrt{t}}\right); \quad \displaystyle\int g = M. \end{cases} \tag{0.7}$$

We refer to [AEZ] and [K] for further properties of the profiles g. In [EZ] (see also [Z1]), we then proved the following.

THEOREM 0.2. *Suppose that $\mathbf{f} \equiv (f_1,\dots,f_N)$ satisfies $f_i(s)/|s|^{1/N}s \to C_i$ as $s \to 0$ for all $i = 1,\dots,N$ with $\mathbf{C} = (C_1,\dots,C_N) \neq 0$, and assume that u is the solution of* (0.1)–(0.2) *with $\int_{\mathbf{R}^N} u_0 = M$. Then for every $r \in [1,\infty]$,*

$$\lim_{t\to\infty} t^{\frac{N}{2}(1-\frac{1}{r})} ||u(t) - \omega_{M,\mathbf{C}}(t)||_{L^r(\mathbf{R}^N)} = 0.$$

Strongly nonlinear behavior. It was proven in [C1] and [C2] that for every $M \in \mathbf{R}$ and $C \in \mathbf{R}$, there is a unique function $v_M \in BC((0,\infty); L^1(\mathbf{R}^N))$ which satisfies the "reduced equation"

$$v_t - \sum_{j=2}^{N} \frac{\partial^2 v}{\partial {x_j}^2} + C\frac{\partial|v|^{q-1}v}{\partial x_1} = 0 \quad \text{in } \mathcal{D}'((0,\infty)\times\mathbf{R}^N), \tag{0.8}$$

the initial conditions

$$
\begin{cases} \lim\limits_{t\to 0} \displaystyle\int_{\mathbf{R}^N} v(t,x)\phi(x)dx = M\phi(0) \quad \forall \phi \in BC(\mathbf{R}^N), \\ \forall r > 0, \quad \lim\limits_{t\to 0} \displaystyle\int_{\mathbf{R}^{N-1}} \int_{|x_1|>r} |u(t,x_1,\overline{x})| dx_1 d\overline{x} = 0 \end{cases} \tag{0.9}
$$

with $\overline{x} = (x_2, \ldots, x_N)$, and a suitable "entropy condition" (see Proposition 1.2 below for details).

By BC, we denote the set of bounded and continuous functions.

Note that equation (0.8) has a parabolic nature in the directions $\overline{x} = (x_2, \ldots, x_N)$ but a purely hyperbolic one in the direction x_1.

In [EVZ2], this uniqueness result was proved in the class of constant-sign solutions. Then the restriction on the sign was removed by Carpio [C1], [C2].

The entropy solution v_M of (0.8)–(0.9) has a self-similar structure and decays in $L^\infty(\mathbf{R}^N)$ like $t^{-(N+1)/2q}$, which is a faster decay rate than (0.4) since $1 < q < (N+1)/N$.

The following result about the asymptotic behavior of the solutions was obtained in [EVZ2] for constant-sign solutions and then extended to general solutions in [C1] and [C2].

Theorem 0.3. *Suppose that* $\mathbf{f} \equiv (f_1, \ldots, f_N)$ *satisfies* (0.6) *with* $j = 1$ *and*

$$
\lim_{s\to 0} \frac{f_1(s)}{|s|^{q-1}s} = C.
$$

Assume that u *is the solution of* (0.1)–(0.2) *with* $\int_{\mathbf{R}^N} u_0 = M$. *Then for every* $r \in [1,\infty)$,

$$
\lim_{t\to\infty} t^{\frac{N+1}{2q}(1-\frac{1}{r})} ||u(t) - v_M(t)||_{L^r(\mathbf{R}^N)} = 0,
$$

where v_M *is the fundamental entropy solution of* (0.8)–(0.9).

If we consider the simple example $f_i \equiv C_i|u|^{q_i-1}u$, condition (0.5) means that for every i, $q_i \geq 1 + 1/N$, while in the range $q \in (1, 1+1/N)$, (0.6) means that the convection is pointing in a fixed space direction.

In this paper, we consider a simple example where, in the frame of strongly nonlinear behavior, the convection is not unidirectional, namely

$$
u_t - \triangle u + \frac{\partial |u|^{q-1}u}{\partial x_1} + \frac{\partial |u|^{p-1}u}{\partial x_2} = 0 \tag{0.10}
$$

with

$$
1 < q < 1 + \frac{1}{N}, \quad q < p. \tag{0.11}
$$

Observe that the first-order, nonlinear term of (0.10) can be written as $q|u|^{q-1}\langle(1, (p/q)|u|^{p-q}, 0, \ldots, 0), \nabla u\rangle$, where $\langle\cdot,\cdot\rangle$ denotes the scalar product in $\mathbf{R}^N$. It can therefore be seen as a convection term in the nonconstant direction $(1, (p/q)|u|^{p-q}, 0, \ldots, 0)$. Since the solutions of equation (0.10) with initial data $u_0 \in L^1(\mathbf{R}^N)$ decay in L^∞ (see (0.4)), as t goes to ∞, the vector that determines the direction of convection points increasingly in the direction $(1, 0, \ldots, 0)$. One is then tempted to conclude that the solutions u of (0.10) behave like the solutions of the equation

$$
u_t - \triangle u + \frac{\partial |u|^{q-1}u}{\partial x_1} = 0 \tag{0.12}
$$

and therefore, in view of Theorem 0.3, like the fundamental entropy solution of the reduced equation

$$u_t - \sum_{j=2}^{N} \frac{\partial^2 u}{\partial {x_j}^2} + \frac{\partial |u|^{q-1} u}{\partial x_1} = 0. \tag{0.13}$$

The main result of this paper shows that this is actually true under a further restriction on p.

Main result. *Suppose that*

$$1 < q < 1 + \frac{1}{N} \quad \textit{and} \quad 1 + \frac{q}{N+1} < p. \tag{0.14}$$

Assume that u is the solution of (0.10) *with initial data u_0 in $L^1(\mathbf{R}^N)$ of mass $\int_{\mathbf{R}^N} u_0 = M$. Then for every $r \in [1, \infty)$,*

$$\lim_{t \to \infty} t^{\frac{N+1}{2q}(1-\frac{1}{r})} ||u(t) - v_M(t)||_{L^r(\mathbf{R}^N)} = 0, \tag{0.15}$$

where v_M is the fundamental entropy solution of (0.13) *of mass M.*

Note that $1 + q/(N+1) > q$ if and only if $q < 1 + 1/N$. Also notice that no sign conditions are imposed to u_0.

Assumption (0.14) is probably sharp, i.e., the long-time behavior is probably of a different nature in the range $1 < q < 1 + 1/N$ and $q < p \leq 1 + q/(N+1)$. Although we do not have a rigorous proof of this fact, it will be obvious from the scaling arguments below. (See section 5.1 for a more detailed discussion.)

Notice that an immediate corollary of our main result is that solutions of (0.10) decay like $t^{-(N+1)/2q}$ in L^∞. Obtaining this decay rate is actually the hardest part of the proof of the main result. Once the decay estimate is obtained, the proof of convergence follows from a classical scaling argument where the compactness is derived by means of the kinetic approach developped by Lions, Perthame, and Tadmor [LPT] that was adapted to the present frame by Carpio [C1], [C2].

To get such a decay estimate, we will prove an entropy inequality of the following form:

$$\frac{\partial u^{q-1}}{\partial x_1} \leq \frac{C}{t},$$

which is rather classical in the context of scalar hyperbolic conservation laws and which was proved in [EVZ1] and [EVZ2] for parabolic conservation laws of the form (0.12).

The remainder of the paper is organized as follows.

Section 1 covers previous results. Section 2 deals with the entropy estimate and decay in L^∞. Section 3 contains the proof of the main result for positive solutions, and section 4 contains the proof of the main result for general solutions. Finally, further comments are presented in section 5.

1. Previous results. Throughout this paper, we will use the following result concerning the existence, uniqueness, and a priori estimates for classical solutions to (0.11) with initial data in $L^1(\mathbf{R}^N)$. Its proof is by now very classical. For a very similar result and its detailed proof, see, for instance, [EZ].

Proposition 1.1. *For all $p > 1$ and $q > 1$ and all initial data $u_0 \in L^1(\mathbf{R}^N)$, there is a unique, classical solution $u \in \mathbf{C}((0, \infty); L^1(\mathbf{R}^N))$ of* (0.11) *and* (0.2) *such that*

$$u \in \mathbf{C}((0, \infty); W^{2,r}(\mathbf{R}^N)) \cap \mathbf{C}^1((0, \infty); L^r(\mathbf{R}^N))$$

for every $r \in (1, +\infty)$. Moreover, this solution satisfies

(1.1)
$$\begin{cases} ||u(t)||_{L^1(\mathbf{R}^N)} \leq ||u_0||_{L^1(\mathbf{R}^N)}, \\ \forall r \in [1, +\infty], \quad \exists C_r \equiv C(r, ||u_0||_{L^1(\mathbf{R}^N)}) \quad ||u(t)||_{L^r(\mathbf{R}^N)} \leq C_r t^{-\frac{N}{2}(1-\frac{1}{r})} \quad \forall t > 0, \end{cases}$$

(1.2)
$$\forall u_0 \in L^1(\mathbf{R}^N) \cap L^r(\mathbf{R}^N), \quad ||u(t)||_{L^r(\mathbf{R}^N)} \leq \left(C_r t + ||u_0||_{L^r(\mathbf{R}^N)}^{-\frac{2r}{N(r-1)}} \right)^{-\frac{N}{2}(1-\frac{1}{r})} \qquad \forall t > 0,$$

$$\forall u_0 \in L^1(\mathbf{R}^N) \cap L^\infty(\mathbf{R}^N), \quad ||u(t)||_{L^\infty(\mathbf{R}^N)} \leq ||u_0||_{L^\infty(\mathbf{R}^N)} \quad \forall t > 0. \tag{1.3}$$

Here we also state the results that we need regarding the entropy solutions of the reduced equation (0.13).

In what follows, we will use the following notation: every $x \in \mathbf{R}^N$ is written as $x = (x_1, \overline{x})$, where $\overline{x} = (x_2, \ldots, x_N) \in \mathbf{R}^{N-1}$.

Proposition 1.2 (see [EVZ2], [C1], and [C2]). *If $1 < q < 1 + 1/N$, for every $M \in \mathbf{R}$, there is a unique function $v_M \in C((0, \infty); L^1(\mathbf{R}^N))$ that satisfies*

$$v_t - \sum_{j=2}^{N} \frac{\partial^2 v}{\partial {x_j}^2} + \frac{\partial |v|^{q-1} v}{\partial x_1} = 0 \qquad \text{in } \mathcal{D}'((0, \infty) \times \mathbf{R}^N), \tag{1.4}$$

$$\begin{cases} |v - \psi|_t - \displaystyle\sum_{j=2}^{N} \frac{\partial^2 |v - \psi|}{\partial {x_j}^2} + \frac{\partial ||v|^{q-1} v - |\psi|^{q-1} \psi|}{\partial x_1} \leq \operatorname{sign}(v - \psi) \sum_{j=2}^{N} \frac{\partial^2 \psi}{\partial {x_j}^2} \\ \quad \text{in } \mathcal{D}'((0, \infty) \times \mathbf{R}^N), \quad \forall \psi = \psi(\overline{x}) \in \mathcal{D}(\mathbf{R}^{N-1}), \end{cases} \tag{1.5}$$

$$\lim_{t \to 0} \int v(t, x) \phi(x) dx = M \phi(0) \quad \forall \phi \in BC(\mathbf{R}^N), \tag{1.6}$$

$$\forall r > 0, \quad \lim_{t \to 0} \int_{\mathbf{R}^{N-1}} \int_{|x_1| > r} |v(t, x_1, \overline{x})| dx_1 d\overline{x} = 0. \tag{1.7}$$

The function v_M has the self-similar form

$$v_M(t, x) = t^{-\frac{N+1}{2q}} g_M \left(\frac{x_1}{t^\beta}, \frac{\overline{x}}{\sqrt{t}} \right), \tag{1.8}$$

where

$$\beta = \frac{N + 1 + q - Nq}{2q} \tag{1.9}$$

and $g_M \in L^1(\mathbf{R}^N) \cap L^\infty(\mathbf{R}^N)$ has compact support in the x_1 variable and decays exponentially as $|x| \to \infty$.

Inequality (1.5) is an entropy-type condition in the spirit of Kruzhkov [Kr], which deals with the fact that equation (1.4) has lost the diffusion term in the x_1 variable. A weak solution of (1.4) that also satisfies (1.6) will be called an entropy solution.

2. Entropy estimate and decay in $L^\infty(\mathbf{R}^N)$. Observe that when $1 < q < 1 + 1/N$, $q < 1 + q/(N+1) < 1 + 1/N$ and therefore hypothesis (0.14) can be written as

$$1 < q < 1 + \frac{q}{N+1} < p. \tag{2.1}$$

After the results in [EVZ2], [C1], and [C2], it is clear that in this range of parameters, problem (0.10) does not have a parabolic scaling in all the variables. In order to make this statement more precise, let us proceed as follows. If u is the solution of (0.10) given by Proposition 1.1, we define for every $\lambda > 0$

$$u_\lambda(t, x_1, \overline{x}) = \lambda^{\frac{N+1}{2q}} u(\lambda t, \lambda^\beta x_1, \sqrt{\lambda}\overline{x}), \tag{2.2}$$

where

$$\beta = \frac{N + 1 + q - Nq}{2q}. \tag{2.3}$$

The function u_λ satifies

$$\frac{\partial u_\lambda}{\partial t} - \sum_{j=2}^{N} \frac{\partial^2 u_\lambda}{\partial x_j^2} + \frac{\partial |u_\lambda|^{q-1} u_\lambda}{\partial x_1} = \lambda^{1-2\beta} \frac{\partial^2 u_\lambda}{\partial x_1^2} - \lambda^{\frac{1}{2} - \frac{(N+1)(p-1)}{2q}} \frac{\partial |u_\lambda|^{p-1} u_\lambda}{\partial x_2}, \tag{2.4}$$

$$u_\lambda(0, x) = \lambda^{\frac{N+1}{2q}} u_0(\lambda^\beta x_1, \sqrt{\lambda}\overline{x}) \quad \forall x \equiv (x_1, \overline{x}) \in \mathbf{R}^N. \tag{2.5}$$

Observe that

$$\begin{cases} \beta > \dfrac{1}{2} \Longleftrightarrow q < 1 + \dfrac{1}{N}, \\ \dfrac{1}{2} - \dfrac{N+1}{2q}(p-1) < 0 \Longleftrightarrow 1 + \dfrac{q}{N+1} < p. \end{cases} \tag{2.6}$$

The idea of the proof of the main theorem is to pass to the limit in (2.4) as $\lambda \to \infty$, using (2.6), to say that in the limit we obtain a solution U of the problem (0.13) that can be identified with v_M. The main difficulty is to obtain the appropriate a priori bounds on the family $\{u_\lambda\}$. Observe that if we want $\{u_\lambda(t)\}$ to be uniformly bounded in $L^r(\mathbf{R}^N)$ for some $r \geq 1$ and $t > 0$, we need for u the estimate

$$||u(t)||_{L^r(\mathbf{R}^N)} \leq C t^{-\frac{N+1}{2q}(1-\frac{1}{r})}. \tag{2.7}$$

One of the main tools for doing this is the entropy estimate. The following theorem, which is the main result of this section, provides those two estimates.

THEOREM 2.1. *Suppose that p and q satisfy* (2.1). *Assume that u is the solution of* (0.10) *and* (0.2) *with nonnegative initial data u_0 of mass $\int_{\mathbf{R}^N} u_0 dx = M$ such that*

$$u_0 \in L^1(\mathbf{R}^N) \cap L^\infty(\mathbf{R}^N). \tag{2.8}$$

Then there is a positive constant $C \equiv C(p, q, ||u_0||_{L^\infty(\mathbf{R}^N)}, M)$ such that

$$\left[\frac{\partial u^{q-1}}{\partial x_1}\right]^+ \leq C t^{-1} \quad \forall t > 0 \tag{2.9}$$

and

$$||u(t)||_{L^\infty(\mathbf{R}^N)} \le Ct^{-\frac{N+1}{2q}} \quad \forall t > 0. \tag{2.10}$$

Theorem 2.1 will be proved via a sequence of lemmas.

LEMMA 2.2. *Assume that the hypotheses of Theorem* 2.1 *hold. Then for some positive t_0 and some positive constant $A \equiv A(p,q)$, we have*

$$\left[\frac{\partial u^{q-1}}{\partial x_1}\right]^+ \le At^{-1} \quad \forall t \in (0, t_0) \quad \forall x \in \mathbf{R}^N. \tag{2.11}$$

Moreover, if for some positive constants C_0 and α, we have

$$u(t,x) \le C_0(1+t)^{-\alpha} \quad \forall t > 0 \quad \forall x \in \mathbf{R}^N, \tag{2.12}$$

then for every $\tau_0 > 0$, there is a positive constant $C = C(\tau_0, p, q, C_0, \alpha)$ such that

$$\left[\frac{\partial u^{q-1}}{\partial x_1}\right]^+ \le Ct^{-\sigma} \quad \forall t > \tau_0 \quad \forall x \in \mathbf{R}^N \tag{2.13}$$

with $\sigma = \min(1, 2\alpha(p-1))$.

Proof. By the comparison principle, since $u_0 \ge 0$, the solution u is strictly positive in $(0,\infty) \times \mathbf{R}^N$. Define $z = qu^{q-1}$. The equation (0.10) then reads

$$z_t - \triangle z - \gamma \frac{|\nabla z|^2}{z} + z\frac{\partial z}{\partial x_1} + q(q-1)u^{q-2}\frac{\partial u^p}{\partial x_2} = 0$$

with $\gamma = (2-q)/(q-1) > 0$. If we differentiate in x_1 and denote $w = \partial z/\partial x_1$, we have

$$\begin{aligned} &w_t - \triangle w + w^2 + \gamma\frac{|\nabla z|^2}{z^2}w + \left(z - 2\gamma\frac{w}{z}\right)\frac{\partial w}{\partial x_1} - 2\frac{\gamma}{z}\sum_{j=2}^N \frac{\partial z}{\partial x_j}\frac{\partial w}{\partial x_j} \\ &\quad + q(q-1)\frac{\partial}{\partial x_1}\left(u^{q-2}\frac{\partial u^p}{\partial x_2}\right) = 0. \end{aligned} \tag{2.14}$$

Now the last term in the left-hand side is

$$q(q-1)\frac{\partial}{\partial x_1}\left(u^{q-2}\frac{\partial u^p}{\partial x_2}\right) = C_1(p,q)z^{\frac{p-1}{q-1}}\frac{\partial w}{\partial x_2} + C_2(p,q)\frac{z^{\frac{p-1}{q-1}}}{z}w\frac{\partial z}{\partial x_2}.$$

Therefore, w satisfies

$$\begin{aligned} &w_t - \triangle w + w^2 + \gamma\frac{|\nabla z|^2}{z^2}w + \left(z - 2\gamma\frac{w}{z}\right)\frac{\partial w}{\partial x_1} \\ &\quad - 2\frac{\gamma}{z}\sum_{j=2}^N \frac{\partial z}{\partial x_j}\frac{\partial w}{\partial x_j} + C_1(p,q)z^{\frac{p-1}{q-1}}\frac{\partial w}{\partial x_2} + C_2(p,q)\frac{z^{\frac{p-1}{q-1}}}{z}w\frac{\partial z}{\partial x_2} = 0. \end{aligned} \tag{2.15}$$

This is a parabolic equation whose coefficients are not bounded in all of $(0,\infty) \times \mathbf{R}^N$ since $u(t,x)$ tends to zero as $|x| \to \infty$ at any positive time t. Nevertheless, since $u > 0$ and u is smooth for $t > 0$, $w \in L^\infty_{\text{loc}}((0,\infty) \times \mathbf{R}^N) \cap \mathbf{C}^{2,1}((0,\infty) \times \mathbf{R}^N)$.

Let us prove that for $t > 0$, $w(t) \in L^\infty(\mathbf{R}^N)$ and satisfies the estimate (2.11). To this end, consider the solution u_ε of (0.10) with initial data $u_\varepsilon(0) = u_0 + \varepsilon$ and $0 < \varepsilon < 1$. By the uniqueness of solutions and the classical parabolic regularity, we deduce that for every $t > 0$, $u_\varepsilon(t) \to u(t)$ and $\nabla u_\varepsilon(t) \to \nabla u(t)$ uniformly on any compact subset of $\mathbf{R}^N$ as $\varepsilon \to 0$.

On the other hand, since $u_0 \geq 0$, $u_\varepsilon \geq \varepsilon$. Therefore, the function $w_\varepsilon \equiv q(u_\varepsilon^{q-1})_{x_1}$ is in $L^\infty((0,T) \times \mathbf{R}^N)$ for every $\varepsilon > 0$ and $T > 0$. Moreover, it satisfies (2.15) with $z_\varepsilon = qu_\varepsilon^{q-1}$ instead of z. Therefore, multiplying the equation satisfied by w_ε by $\operatorname{sign}^+ w_\varepsilon$, using Kato's inequality, and taking into account that

$$\begin{aligned}\left| \frac{z_\varepsilon^{\frac{p-1}{q-1}}}{z_\varepsilon} w_\varepsilon^+ \frac{\partial z_\varepsilon}{\partial x_2} \right| &\leq w_\varepsilon^+ \left\{ \delta \left| \frac{\partial z_\varepsilon}{\partial x_2} \right|^2 z_\varepsilon^{-2} + \frac{1}{4\delta} z_\varepsilon^{\frac{2(p-1)}{q-1}} \right\} \\ &\leq \delta w_\varepsilon^+ \left| \frac{\partial z_\varepsilon}{\partial x_2} \right|^2 z_\varepsilon^{-2} + \delta |w_\varepsilon^+|^2 + \frac{1}{64\delta^3} z_\varepsilon^{\frac{4(p-1)}{q-1}}\end{aligned}$$

for any $\delta > 0$, by choosing $\delta > 0$ small enough, we obtain
(2.16)

$$\begin{aligned}\frac{\partial w_\varepsilon^+}{\partial t} - \triangle w_\varepsilon^+ + \frac{1}{2}(w_\varepsilon^+)^2 + \frac{\gamma}{2}\frac{|\nabla z_\varepsilon|^2}{z_\varepsilon^2} w_\varepsilon^+ + \left(z_\varepsilon - 2\gamma \frac{w_\varepsilon}{z_\varepsilon} \right) \frac{\partial w_\varepsilon^+}{\partial x_1} - 2\frac{\gamma}{z_\varepsilon} \sum_{j=2}^N \frac{\partial z_\varepsilon}{\partial x_j} \frac{\partial w_\varepsilon^+}{\partial x_j} \\ + C_1(p,q) z_\varepsilon^{\frac{p-1}{q-1}} \frac{\partial w_\varepsilon^+}{\partial x_2} \leq C(p,q) ||u_\varepsilon(t)||_{L^\infty(\mathbf{R}^N)}^{4(p-1)} \leq C(p,q)(||u_0||_{L^\infty(\mathbf{R}^N)} + 1)^{4(p-1)}\end{aligned}$$

for all $0 < \varepsilon < 1$ since $||u_\varepsilon(t)||_{L^\infty(\mathbf{R}^N)} \leq ||u_\varepsilon(0)||_{L^\infty(\mathbf{R}^N)} = ||u_0||_{L^\infty(\mathbf{R}^N)} + \varepsilon$.

Let us set $t_0 = (1/2)(||u_0||_{L^\infty(\mathbf{R}^N)} + 1)^{-2(p-1)}$ and define $W_\varepsilon(\tau; t) = A(t + \tau)^{-1}$ for every $\varepsilon > 0$, where $\tau \equiv \tau(\varepsilon)$ and $A > 0$ is independent of ε such that

(i) $A^2/2 - A \geq C(p,q)$ (with $C(p,q)$ as in the right-hand side of (2.16)),

(ii) $0 < \tau < t_0$, and

(iii) $A/\tau > ||w_\varepsilon(0)||_{L^\infty(\mathbf{R}^N)}$.

A simple calculation shows that

$$\frac{dW_\varepsilon}{dt} + \frac{1}{2}W_\varepsilon^2 = \left(\frac{A^2}{2} - A \right)(\tau + t)^{-2} \geq C(p,q)(\tau + t)^{-2} \quad \forall t > 0.$$

Now if $t \in (0, t_0)$, we have

$$(\tau + t) \leq 2t_0 = (||u_0||_{L^\infty(\mathbf{R}^N)} + 1)^{-2(p-1)}.$$

Then

$$(\tau + t)^{-2} \geq (||u_0||_{L^\infty(\mathbf{R}^N)} + 1)^{4(p-1)},$$

and so

$$\frac{dW_\varepsilon}{dt} + \frac{1}{2}W_\varepsilon^2 = \left(\frac{A^2}{2} - A \right)(\tau + t)^{-2} \geq 2C(p,q)(||u_0||_{L^\infty(\mathbf{R}^N)} + 1)^{4(p-1)} \quad \forall t \in (0, t_0).$$

Since $W_\varepsilon(0) > w_\varepsilon(0)$ by construction, by the comparison principle, we deduce that

$$w_\varepsilon^+(t,x) \leq A(t + \tau(\varepsilon))^{-1} \leq At^{-1} \quad \forall x \in \mathbf{R}^N \quad \forall t \in (0, t_0).$$

Passing to the limit as $\varepsilon \to 0$, we obtain (2.11).

In order to prove (2.13), we use the following argument. Since equation (0.10) is autonomous, for every $\tau \in (0, t_0/2)$, the function defined by $\widetilde{u}(t,x) = u(t + \tau, x)$ solves (0.10) with initial data $\widetilde{u}(0) = u(\tau)$ and satisfies (2.12). Therefore, the function $\widetilde{w} = q\partial\widetilde{u}^{q-1}/\partial x_1$ solves an equation similar to (2.15), which for the sake of brevity we call $\widetilde{(2.15)}$. In the same way, we can define $\widetilde{u}_\varepsilon$, $\widetilde{z}_\varepsilon$, and $\widetilde{w}_\varepsilon$ by $\widetilde{z}_\varepsilon(t) = z_\varepsilon(t+\tau)$ and $\widetilde{w}_\varepsilon(t) = w_\varepsilon(t+\tau)$, where $\widetilde{u}_\varepsilon$ is the solution of (0.10) with data $u(\tau)+\varepsilon$. Then

$$\begin{aligned} \frac{\partial \widetilde{w}_\varepsilon^+}{\partial t} - \triangle \widetilde{w}_\varepsilon^+ + \frac{1}{2}(\widetilde{w}_\varepsilon^+)^2 + \frac{\gamma}{2}\frac{|\nabla \widetilde{z}_\varepsilon|^2}{\widetilde{z}_\varepsilon^2}(\widetilde{w}_\varepsilon^+) + \left(\widetilde{z}_\varepsilon - 2\gamma\frac{\widetilde{w}_\varepsilon}{\widetilde{z}_\varepsilon}\right)\frac{\partial \widetilde{w}_\varepsilon^+}{\partial x_1}& \\ - 2\frac{\gamma}{\widetilde{z}_\varepsilon}\sum_{j=2}^{N} \frac{\partial \widetilde{z}_\varepsilon}{\partial x_j}\frac{\partial \widetilde{w}_\varepsilon^+}{\partial x_j} + C_1(p,q)\widetilde{z}_\varepsilon^{\frac{p-1}{q-1}}\frac{\partial \widetilde{w}_\varepsilon^+}{\partial x_2} &\le C(p,q)(||u_0||_{L^\infty(\mathbf{R}^N)}+1)^{4(p-1)}. \end{aligned}$$

Since $\widetilde{w_\varepsilon}(0) = w_\varepsilon(\tau)$ by (2.11), $\widetilde{w}_\varepsilon(0) \in L^\infty(\mathbf{R}^N)$. On the other hand, by what we have just proved, $||\widetilde{w}_\varepsilon(0)||_{L^\infty(\mathbf{R}^N)} < A\tau^{-1}$ for every $\varepsilon > 0$. By the comparison principle, we deduce that

$$\forall \varepsilon > 0, \quad \forall t > 0, \quad \forall x \in \mathbf{R}^N, \quad \widetilde{w}_\varepsilon(t,x) \le C(p,q)(||u_0||_{L^\infty(\mathbf{R}^N)}+1)^{4(p-1)}t + A\tau^{-1},$$

and so, letting $\varepsilon \to 0$, $\widetilde{w} \in L^\infty_{\text{loc}}((0,\infty); L^\infty(\mathbf{R}^N))$.

Moreover, multiplying $\widetilde{(2.15)}$ by $\text{sign}^+\widetilde{w}$ and using (2.12), we get

$$\left\{ \begin{aligned} \frac{\partial \widetilde{w}^+}{\partial t} - \triangle \widetilde{w}^+ + \frac{1}{2}(\widetilde{w}^+)^2 + \frac{\gamma}{2}\frac{|\nabla \widetilde{z}|^2}{(\widetilde{z})^2}(\widetilde{w}^+) + (\widetilde{z} - 2\gamma\frac{\widetilde{w}}{\widetilde{z}})\frac{\partial \widetilde{w}^+}{\partial x_1}& \\ - 2\frac{\gamma}{\widetilde{z}}\sum_{j=2}^{N} \frac{\partial \widetilde{z}}{\partial x_j}\frac{\partial \widetilde{w}^+}{\partial x_j} + C_1(p,q)\widetilde{z}^{\frac{p-1}{q-1}}\frac{\partial \widetilde{w}^+}{\partial x_2} &\le C(p,q)(1+t)^{-4\alpha(p-1)}. \end{aligned} \right.$$

We now consider the cases where $2\alpha(p-1) \ge 1$ and $2\alpha(p-1) < 1$ separately.

The case where $2\alpha(p-1) \ge 1$. Consider the function $W(t) = A(t+\tau_1)^{-1}$ with A such that $A^2/2 - A > C(p,q)$ and $1 > \tau_1 > 0$ such that $||\widetilde{w}(0)||_{L^\infty(\mathbf{R}^N)} < A/\tau_1$. With this choice of A and τ_1, we have

$$\frac{dW}{dt} + \frac{1}{2}W^2 = \left(\frac{A^2}{2} - A\right)(\tau_1 + t)^{-2} > C(p,q)(1+t)^{-4\alpha(p-1)}.$$

By the comparison principle, we deduce as before that

$$w^+(t+\tau, x) \equiv \widetilde{w}^+(t,x) \le A(t+\tau_1)^{-1} < At^{-1} \quad \forall t > 0 \quad \forall x \in \mathbf{R}^N.$$

The case where $2\alpha(p-1) < 1$. Define the function $W(t) = A(1+t)^{-2\alpha(p-1)}$, choosing A such that

$$A\left(\frac{A}{2} - 2\alpha(p-1)\right) \ge 2C(p,q) \quad \text{and} \quad A \equiv A(\tau) > ||\widetilde{w}(0)||_{L^\infty(\mathbf{R}^N)}.$$

Then

$$\begin{aligned} \frac{dW}{dt} + \frac{1}{2}W^2 &= A(1+t)^{-4\alpha(p-1)}\left\{\frac{A}{2} - 2\alpha(p-1)(1+t)^{2\alpha(p-1)-1}\right\} \\ &\ge A(1+t)^{-4\alpha(p-1)}\left\{\frac{A}{2} - 2\alpha(p-1)\right\} \ge 2C(p,q)(1+t)^{-4\alpha(p-1)}. \end{aligned}$$

Arguing as before, we obtain $\widetilde{w}^+(t) \le A(1+t)^{-2\alpha(p-1)}$ for all $t > 0$. This gives

$$\left[\frac{\partial u^{q-1}(t+\tau, x)}{\partial x_1}\right]^+ \le A(1+t)^{-\sigma} \quad \forall t > 0$$

and, for some $C = C(\sigma, \tau_0) > 0$, $[\partial u^{q-1}/\partial x_1]^+ \leq Ct^{-\sigma}$ for every $t > \tau_0$, and (2.13) follows. □

LEMMA 2.3. *Assume that the hypotheses of Theorem* 2.1 *are satisfied and that* (2.12) *holds. Then we have the following:*

(a) *If* $2\alpha(p-1) < 1$, *for every* $\delta > 0$, *there exists* $C \equiv C(p, q, \delta, C_0) > 0$ *such that*

$$\left\| \int_{\mathbf{R}} u(t, z, \overline{x}) dz \right\|_{L^\infty(\mathbf{R}^{N-1})} \leq Ct^{-\alpha(N-1)(p-1)+\delta} \quad \forall t > 2^{N-1}. \tag{2.17}$$

(b) *If* $2\alpha(p-1) \geq 1$, *there exists* $C \equiv C(p, q, C_0) > 0$ *such that*

$$\left\| \int_{\mathbf{R}} u(t, z, \overline{x}) dz \right\|_{L^\infty(\mathbf{R}^{N-1})} \leq Ct^{-\frac{N-1}{2}} \quad \forall t > 2^{N-1}. \tag{2.18}$$

Proof. Let us define $v(t, \overline{x}) = \int_{\mathbf{R}} u(t, z, \overline{x}) dz$. This function satisfies

$$v_t - \sum_{j=2}^{N} \frac{\partial^2 v}{\partial {x_j}^2} + \frac{\partial \int_{\mathbf{R}} u^p(t, z, \overline{x}) dz}{\partial x_2} = 0,$$

and therefore it solves the integral equation

$$v(2t, \overline{x}) = (K_{N-1}(t) * v(t))(\overline{x}) - \int_0^t \left(\frac{\partial}{\partial x_2} K_{N-1}(t-s) * \int_{\mathbf{R}} u^p(s+t, z, \cdot) dz \right) (\overline{x}) ds, \tag{2.19}$$

where K_{N-1} denotes the heat kernel in $(0, \infty) \times \mathbf{R}^{N-1}$, i.e.,

$$K_{N-1}(t, \overline{x}) = (4\pi t)^{-\frac{N-1}{2}} \exp\left(-\frac{|\overline{x}|^2}{4t} \right).$$

The following estimates are easily obtained:

$$||K_{N-1}(t)||_{L^r(\mathbf{R}^{N-1})} \leq \gamma_0 t^{-\frac{N-1}{2}(1-\frac{1}{r})},$$
$$||\nabla K_{N-1}(t)||_{L^r(\mathbf{R}^{N-1})} \leq \gamma_0 t^{-\frac{N-1}{2}(1-\frac{1}{r})-\frac{1}{2}}$$

for all $r \in [1, \infty]$ and $t > 0$ with $\gamma_0 > 0$ large enough.

Now consider any r such that

$$1 < r < \frac{N-1}{N-2} \quad \text{if } N > 2, \qquad r > 1 \quad \text{if } N = 2$$

and take $L^r(\mathbf{R}^{N-1})$ norms in (2.19). Using (2.12), we obtain

$$\begin{aligned} ||v(2t)||_{L^r(\mathbf{R}^{N-1})} &\leq \gamma_0 M t^{-\frac{N-1}{2}(1-\frac{1}{r})} \\ &\quad + \gamma_0 M C_0^{p-1} \int_0^t (t-s)^{-\frac{N-1}{2}(1-\frac{1}{r})-\frac{1}{2}} (1+s+t)^{-\alpha(p-1)} ds, \end{aligned}$$

and then

$$||v(2t)||_{L^r(\mathbf{R}^{N-1})} \leq \gamma_0 M t^{-\frac{N-1}{2}(1-\frac{1}{r})} + \frac{2r\gamma_0 M C_0^{p-1}}{r-(N-1)(r-1)} t^{-\frac{N-1}{2}(1-\frac{1}{r})+\frac{1}{2}-\alpha(p-1)}.$$

If $2\alpha(p-1) \geq 1$, $1/2 - \alpha(p-1) \leq 0$ and then

$$||v(t)||_{L^r(\mathbf{R}^{N-1})} \leq \gamma_1 t^{-\frac{N-1}{2}(1-\frac{1}{r})} \quad \forall t \geq 2 \tag{2.20}$$

with $\gamma_1 = M\gamma_0(1 + 2rC_0^{p-1}/(r - (N-1)(r-1)))$.

On the other hand, if $2\alpha(p-1) < 1$,

$$||v(t)||_{L^r(\mathbf{R}^{N-1})} \leq \gamma_1 t^{-\frac{N-1}{2}(1-\frac{1}{r})+\frac{1}{2}-\alpha(p-1)} \quad \forall t \geq 2. \tag{2.21}$$

When $N = 2$, this gives an estimate on the $L^r(\mathbf{R}^N)$ norm of $v(t)$ for every finite $r > 1$. When $N > 2$, we divide the interval $(1/(N-1), 1)$ into the intervals $(j/(N-1), (j+1)/(N-1))$, $j = 1, \ldots, N-2$. Now for any $r > (N-1)$, choose $(r_j)_{j=1}^{N-2}$ such that $1/r_j \in ((N-j-1)/(N-1), (N-j)/(N-1))$ and

$$\frac{1}{r_{N-2}} - \frac{1}{r} < \frac{1}{N-1}, \tag{2.22}$$

$$\frac{1}{r_j} - \frac{1}{r_{j+1}} < \frac{1}{N-1} \quad \forall j = 1, \ldots, N-2. \tag{2.23}$$

We can now use (2.20)–(2.21) with $r_1 \in (1, (N-1)/(N-2))$ and take the $L^{r_2}(\mathbf{R}^{N-1})$ norm in (2.19):

$$\begin{aligned} ||v(2t)||_{L^{r_2}(\mathbf{R}^{N-1})} &\leq M\gamma_0 t^{-\frac{N-1}{2}(\frac{1}{r_1}-\frac{1}{r_2})} ||v(t)||_{L^{r_1}(\mathbf{R}^{N-1})} \\ &\quad + \left\| \int_0^t \left(\frac{\partial}{\partial x_2} K_{N-1}(t-s) * \int_{\mathbf{R}} u^p(s+t, z, \cdot) dz \right) ds \right\|_{L^{r_2}(\mathbf{R}^{N-1})}. \end{aligned}$$

The last term in the right-hand side can be estimated as follows for $1/r_1 + 1/\overline{r}_1 = 1 + 1/r_2$:

$$\begin{aligned} &\left\| \int_0^t \left(\frac{\partial}{\partial x_2} K_{N-1}(t-s) * \int_{\mathbf{R}} u^p(s+t, z, \cdot) dz \right) (\overline{x}) ds \right\|_{L^{r_2}(\mathbf{R}^{N-1})} \\ &\quad \leq \int_0^t ||u(s+t)||_{L^\infty(\mathbf{R}^N)}^{p-1} \left\| \left| \frac{\partial}{\partial x_2} K_{N-1}(t-s) \right| * v(s+t) \right\|_{L^{r_2}(\mathbf{R}^{N-1})} ds \\ &\quad \leq \int_0^t ||u(s+t)||_{L^\infty(\mathbf{R}^N)}^{p-1} \left\| \frac{\partial}{\partial x_2} K_{N-1}(t-s) \right\|_{L^{\overline{r}_1}(\mathbf{R}^{N-1})} ||v(s+t)||_{L^{r_1}(\mathbf{R}^{N-1})} ds. \end{aligned}$$

First, suppose that $2\alpha(p-1) \geq 1$. Then using (2.12) and (2.20), we obtain, for all $t \geq 2$,

$$\begin{aligned} ||v(2t)||_{L^{r_2}(\mathbf{R}^{N-1})} &\leq \gamma_0 t^{-\frac{N-1}{2}(\frac{1}{r_1}-\frac{1}{r_2})} \gamma_1 t^{-\frac{N-1}{2}(1-\frac{1}{r_1})} \\ &\qquad + \gamma_0 C_0^{p-1} \gamma_1 \int_0^t (t-s)^{-\frac{N-1}{2}(\frac{1}{r_1}-\frac{1}{r_2})-\frac{1}{2}} (s+t)^{-\frac{N-1}{2}(1-\frac{1}{r_1})-\alpha(p-1)} ds \\ &= \gamma_0\gamma_1 t^{-\frac{N-1}{2}(1-\frac{1}{r_2})} \\ &\qquad + \gamma_0 C_0^{p-1} \gamma_1 \frac{2r_1 r_2}{r_1 r_2 - (N-1)(r_2 - r_1)} t^{-\frac{N-1}{2}(1-\frac{1}{r_2})+(\frac{1}{2}-\alpha(p-1))}. \end{aligned}$$

Since $2\alpha(p-1) \geq 1$, we deduce that

$$||v(t)||_{L^{r_2}(\mathbf{R}^{N-1})} \leq \gamma_2 t^{-\frac{N-1}{2}(1-\frac{1}{r_2})} \quad \forall t \geq 4 \tag{2.24}$$

with $\gamma_2 = \gamma_0\gamma_1(1 + C_0^{p-1} 2r_1 r_2/(r_1 r_2 - (N-1)(r_2 - r_1)))$.

On the other hand, suppose that $2\alpha(p-1) < 1$. Then using (2.20), we obtain, for all $t \geq 2$,

$$\begin{aligned}
||v(2t)||_{L^{r_2}(\mathbf{R}^{N-1})} &\leq \gamma_0\gamma_1 t^{-\frac{N-1}{2}(1-\frac{1}{r_2})+\frac{1}{2}-\alpha(p-1)} \\
&\quad + \gamma_0 C_0^{p-1}\gamma_1 \int_0^t (t-s)^{-\frac{N-1}{2}(\frac{1}{r_1}-\frac{1}{r_2})-\frac{1}{2}}(s+t)^{-\frac{N-1}{2}(1-\frac{1}{r_1})+\frac{1}{2}-2\alpha(p-1)}ds \\
&= \gamma_0\gamma_1 t^{-\frac{N-1}{2}(1-\frac{1}{r_2})+\frac{1}{2}-\alpha(p-1)} \\
&\quad + \gamma_0 C_0^{p-1}\gamma_1 \frac{2r_1r_2}{r_1r_2-(N-1)(r_2-r_1)} t^{-\frac{N-1}{2}(1-\frac{1}{r_2})+2(\frac{1}{2}-\alpha(p-1))}.
\end{aligned}$$

Since $2\alpha(p-1) < 1$, we deduce that

$$(2.25) \qquad ||v(t)||_{L^{r_2}(\mathbf{R}^{N-1})} \leq \gamma_2 t^{-\frac{N-1}{2}(1-\frac{1}{r_2})+2(\frac{1}{2}-\alpha(p-1))} \quad \forall t \geq 4.$$

By iteration of this argument, we obtain

$$(2.26) \qquad ||v(t)||_{L^{r_j}(\mathbf{R}^{N-1})} \leq \gamma_j t^{-\theta_j} \quad \forall t \geq 2^j$$

for $j = 1, \ldots, N-2$, where

$$\theta_j \equiv \begin{cases} \dfrac{N-1}{2}\left(1-\dfrac{1}{r_j}\right) - j\left(\dfrac{1}{2}-\alpha(p-1)\right) & \text{if } 2\alpha(p-1) < 1, \\ \dfrac{N-1}{2}\left(1-\dfrac{1}{r_j}\right) & \text{if } 2\alpha(p-1) \geq 1 \end{cases}$$

and $\gamma_j = \gamma_0\gamma_1\cdots\gamma_{j-1}(1 + C_0^{p-1}2r_{j-1}r_j/(r_{j-1}r_j - (N-1)(r_j - r_{j-1})))$. Finally, we take L^r norms in (2.19) and use (2.20)–(2.21) for $j = N-2$ and (2.22) to get

$$(2.27) \qquad ||v(t)||_{L^r(\mathbf{R}^{N-1})} \leq \gamma t^{-\theta} \quad \forall t \geq 2^{N-1},$$

where

$$\theta \equiv \begin{cases} \dfrac{N-1}{2}\left(1-\dfrac{1}{r}\right) - (N-1)\left(\dfrac{1}{2}-\alpha(p-1)\right) & \text{if } 2\alpha(p-1) < 1, \\ \dfrac{N-1}{2}\left(1-\dfrac{1}{r}\right) & \text{if } 2\alpha(p-1) \geq 1 \end{cases}$$

and $\gamma = \gamma_0\gamma_1\cdots\gamma_{N-2}(1 + C_0^{p-1}2r_{N-2}r/(r_{N-2}r - (N-1)(r - r_{N-2})))$.

The estimate in L^∞ remains to be proved. Unfortunately, we cannot let $r \to \infty$ in (2.27) since (due to (2.22)–(2.23)) when that happens, $r_j \to (N-1)/(N-j-1)$ for all $j = 1, \ldots, N-2$ and then all of the constants γ_j blow up.

We first consider the case where $2\alpha(p-1) \geq 1$. For any $r > N-1$, taking L^∞ norms in (2.19), we obtain

$$\begin{aligned}
&||v(2t)||_{L^\infty(\mathbf{R}^{N-1})} \\
&\quad \leq \gamma_0 t^{-\frac{N-1}{2r}}\gamma t^{-\frac{N-1}{2}(1-\frac{1}{r})} + \gamma_0 C_0^{p-1}\gamma \int_0^t (t-s)^{-\frac{N-1}{2r}-\frac{1}{2}}(s+t)^{-\frac{N-1}{2}(1-\frac{1}{r})-\alpha(p-1)}ds \\
&\quad \leq \gamma_0\gamma\left(1 + \frac{2rC_0^{p-1}}{r-(N-1)}\right)t^{-(N-1)/2}
\end{aligned}$$

for every $t \geq 2^{N-1}$. This concludes the proof of Lemma 2.3 when $2\alpha(p-1) \geq 1$.

Let us now consider the case where $2\alpha(p-1) < 1$. We will use the following inequality of Gagliardo and Nirenberg (see, for instance, [B, p. 195]):

$$(2.28) \qquad \forall \rho \geq 1, \quad \forall r > (N-1), \quad ||v||_{L^\infty(\mathbf{R}^{N-1})} \leq C||v||^{1-a}_{L^\rho(\mathbf{R}^{N-1})}||v||^a_{W^{1,r}(\mathbf{R}^{N-1})},$$

where

$$(2.29) \qquad a\left(\frac{1}{\rho} - \frac{1}{r} + \frac{1}{(N-1)}\right) = \frac{1}{\rho}$$

and the constant C depends only on ρ and r. We will apply (2.28) to $v(t)$ with ρ large. We then need to estimate $||v(t)||_{W^{1,r}}$ for some $r > (N-1)$. Since we have already estimated $||v(t)||_{L^r(\mathbf{R}^{N-1})}$ in (2.27), we only have to estimate $||\nabla v(t)||_{L^r(\mathbf{R}^{N-1})}$. Since by definition $v(t, \overline{x}) = \int_{\mathbf{R}} u(t, z, \overline{x})dz$, we have $\nabla v(t, \overline{x}) = \int_{\mathbf{R}} \nabla_{\overline{x}} u(t, z, \overline{x})dz$. Let us define the auxiliary function $V(t, \overline{x}) = \int_{\mathbf{R}} |\nabla_{\overline{x}} u(t, z, \overline{x})|dz$. Then, obviously,

$$\forall t > 0, \quad \forall \overline{x} \in \mathbf{R}^{N-1}, \quad |\nabla v(t, \overline{x})| \leq V(t, \overline{x}).$$

To estimate $||V(t)||_{L^r(\mathbf{R}^{N-1})}$, we note that for all $t > 0$ and $\tau > 0$,

$$u(t+\tau) = K(t) * u(\tau) - \int_0^t \frac{\partial}{\partial x_1} K(t-s) * u^q(s+\tau)ds - \int_0^t \frac{\partial}{\partial x_2} K(t-s) * u^p(s+\tau)ds.$$

Taking the gradient in the $\overline{x}$ variables and norms in $\mathbf{R}^{N-1}$ and integrating in $\mathbf{R}$ with respect to x_1, we obtain

$$\begin{aligned} V(t+\tau, \overline{x}) \leq & \int_{\mathbf{R}} (|\nabla_{\overline{x}} K(t)| * u(\tau))dx_1 \\ & + q \int_{\mathbf{R}} \int_0^t \left|\frac{\partial}{\partial x_1} K(t-s)\right| * u^{q-1} |\nabla_{\overline{x}} u(s+\tau)| ds dx_1 \\ & + p \int_{\mathbf{R}} \int_0^t \left|\frac{\partial}{\partial x_2} K(t-s)\right| * u^{p-1} |\nabla_{\overline{x}} u(s+\tau)| ds dx_1. \end{aligned}$$

If we denote by $K_1(t, x_i)$ the heat kernel in the one space variable x_i, i.e., $K_1(t, x_i) = (4\pi t)^{-1/2} \exp(-|x_i|^2/4t)$, then $K(t, x) = K_1(t, x_1) \cdots K_1(t, x_N)$ and therefore $|\nabla_{\overline{x}} K(t, x)| = K_1(t, x_1)|\nabla K_{N-1}(t, \overline{x})|$. It is then straightforward to see that $\int_{\mathbf{R}} |\nabla_{\overline{x}} K(t)| * u(\tau)dx_1 = |\nabla K_{N-1}(t)| * v(\tau)$. On the other hand,

$$\begin{aligned} & \int_{\mathbf{R}} \left|\frac{\partial}{\partial x_1} K(t-s)\right| * u^{q-1} |\nabla_{\overline{x}} u(s+\tau)| dx_1 \\ & \qquad = \int_{\mathbf{R}^{N-1}} K_{N-1}(t-s, \overline{x} - \overline{y}) \\ & \int_{\mathbf{R}} \int_{\mathbf{R}} \frac{|x_1 - y_1|}{2(t-s)} K_1(t-s, x_1 - y_1) u^{q-1}(s+\tau, y) |\nabla_{\overline{x}} u(s+\tau, y)| dy_1 dx_1 d\overline{y} \\ & \qquad \leq \left(\int_{\mathbf{R}} \frac{|z|}{2(t-s)} K_1(t-s, z)dz\right) C_0^{q-1} (s+\tau)^{-\alpha(q-1)} \\ & \int_{\mathbf{R}^{N-1}} K_{N-1}(t, \overline{x} - \overline{y}) \int_{\mathbf{R}} |\nabla_{\overline{x}} u(s+\tau, y)| dy_1 d\overline{y} \\ & \qquad \leq \frac{C(q, \tau)}{\sqrt{t-s}} K_{N-1}(t-s) * V(s+\tau) \end{aligned}$$

and

$$\begin{aligned}
&\int_{\mathbf{R}} \left|\frac{\partial}{\partial x_2} K(t-s)\right| * u^{p-1}|\nabla_{\overline{x}} u(s+\tau)|dx_1 \\
&\qquad = \int_{\mathbf{R}^{N-1}} \left|\frac{\partial}{\partial x_2} K_{N-1}(t-s, \overline{x}-\overline{y})\right| \\
&\int_{\mathbf{R}}\int_{\mathbf{R}} K_1(t-s, x_1-y_1) u^{p-1}(s+\tau, y)|\nabla_{\overline{x}} u(s+\tau, y)|dy_1 dx_1 d\overline{y} \\
&\qquad \leq C_0^{p-1}(s+\tau)^{-\alpha(p-1)} \int_{\mathbf{R}^{N-1}} \left|\frac{\partial}{\partial x_2} K_{N-1}(t-s, x-\overline{y})\right| \int_{\mathbf{R}} |\nabla_{\overline{x}} u(s+\tau, y)|dy_1 d\overline{y} \\
&\qquad \leq C(p,\tau) \left|\frac{\partial}{\partial x_2} K_{N-1}(t-s)\right| * V(s+\tau).
\end{aligned}$$

For all $t > 0$ and $\tau > 0$, we deduce that

$$||V(t+\tau)||_{L^r(\mathbf{R}^{N-1})} \leq Ct^{-\frac{1}{2}}||v(\tau)||_{L^r(\mathbf{R}^{N-1})} + C(p,q,\tau)\int_0^t (t-s)^{-\frac{1}{2}}||V(s+\tau)||_{L^r(\mathbf{R}^{N-1})}.$$

For any $\tau > 0$ fixed, if we set $g(t) = ||V(t+\tau)||_{L^r(\mathbf{R}^{N-1})}$, we can write, for every $t \in (0,1)$,

$$g(t) \leq t^{-\frac{1}{2}}||v(\tau)||_{L^r(\mathbf{R}^{N-1})} + C\int_0^t (t-s)^{-\frac{1}{2}} g(s)ds.$$

By Gronwall's lemma, we deduce that there is a positive constant $C' = C'(p,q,C_0)$ such that $g(t) \leq C'||v(\tau)||_{L^r(\mathbf{R}^{N-1})}t^{-1/2}$ for every $t \in (0,1)$. In particular, for every $\tau > 0$,

$$||\nabla v(1+\tau)||_{L^r(\mathbf{R}^{N-1})} \leq ||V(1+\tau)||_{L^r(\mathbf{R}^{N-1})} \equiv g(1) \leq C'||v(\tau)||_{L^r(\mathbf{R}^{N-1})}.$$

By (2.27), there is a positive constant Γ such that for all $t \geq 2^N$,

$$||v(t)||_{W^{1,r}(\mathbf{R}^{N-1})} \leq \Gamma t^{-\theta}. \tag{2.30}$$

We use now (2.27), (2.28), and (2.30) to obtain

$$||v(t)||_{L^\infty(\mathbf{R}^{N-1})} \leq C(\rho, r)\gamma^{1-a}\Gamma^a t^{-\Theta} \quad \forall t \geq 2^N \tag{2.31}$$

with

$$\begin{aligned}
\Theta \equiv (1-a)&\left[\frac{N-1}{2}\left(1-\frac{1}{\rho}\right) - (N-1)\left(\frac{1}{2}-\alpha(p-1)\right)\right] \\
&+ a\left[\frac{N-1}{2}\left(1-\frac{1}{r}\right) - (N-1)\left(\frac{1}{2}-\alpha(p-1)\right)\right],
\end{aligned}$$

which we can rewrite as

$$\begin{aligned}
\Theta \equiv (1-a)(N-1)\alpha(p-1) - (1-a)\frac{N-1}{2\rho} \\
+ a\left[\frac{N-1}{2}\left(1-\frac{1}{r}\right) - (N-1)\left(\frac{1}{2}-\alpha(p-1)\right)\right].
\end{aligned}$$

By (2.29), we have $a \equiv a(\rho, r) = (1 - \rho/r + \rho/(N-1))^{-1}$. Now we leave $r > N-1$ fixed and let $\rho \to \infty$. Then $a(\rho, r) \to 0$ as $\rho \to \infty$ and

$$\lim_{\rho\to\infty} \Theta = \begin{cases} (N-1)\alpha(p-1) & \text{if } 2\alpha(p-1) < 1, \\ \dfrac{N-1}{2} & \text{if } 2\alpha(p-1) \geq 1. \end{cases}$$

This completes the proof of Lemma 2.3 when $2\alpha(p-1) < 1$. □

LEMMA 2.4. *Assume that the hypotheses of Theorem* 2.1 *are satisfied and that for some positive constants l, τ_1, and C_1,*

$$\left[\frac{\partial u^{q-1}}{\partial x_1}\right]^+ \leq C_1 t^{-l} \quad \forall t > \tau_1.$$

Then for every $\overline{x} \in \mathbf{R}^{N-1}$,

$$\sup_{x_1 \in \mathbf{R}} |u(t, x_1, \overline{x})| \leq \left(\frac{q}{q-1}\right)^{\frac{1}{q}} C_1^{\frac{1}{q}} t^{-\frac{l}{q}} \left(\int_{\mathbf{R}} u(t, z, \overline{x}) dz\right)^{\frac{1}{q}} \quad \forall t > \tau_1. \tag{2.32}$$

Proof. We follow the argument of [EVZ2]. We fix a time $t > \tau_1$ and consider a point $(y_1, \overline{y}, t)$. At this point, we call $B = u^{q-1}(y_1, \overline{y}, t)$. By hypothesis, we have

$$\forall x_1 \in \left[y_1 - \frac{B}{C_1}t^l, y_1\right], \quad u^{q-1}(x_1, \overline{y}, t) \geq B - C_1\frac{(y_1 - x_1)}{t^l}$$

or, equivalently,

$$u(y_1 - z, \overline{y}, t) \geq \left(\frac{C_1}{t^l}\right)^{\frac{1}{q-1}} \left(\frac{Bt^l}{C_1} - z\right)^{\frac{1}{q-1}} \quad \forall z \in \left[0, \frac{Bt^l}{C_1}\right].$$

Integrating with respect to z on $(0, Bt^l/C_1)$ gives

$$\begin{aligned} \int_{\mathbf{R}} u(z, \overline{y}, t) dz &\geq \left(\frac{C_1}{t^l}\right)^{\frac{1}{q-1}} \int_0^{\frac{Bt^l}{C_1}} \left(\frac{Bt^l}{C_1} - z\right)^{\frac{1}{q-1}} dz \\ &= \left(\frac{C_1}{t^l}\right)^{\frac{1}{q-1}} \int_0^{\frac{Bt^l}{C_1}} s^{\frac{1}{q-1}} ds = \frac{q-1}{q} B^{\frac{q}{q-1}} \frac{t^l}{C_1} \quad \forall t > \tau_1. \end{aligned}$$

Therefore,

$$u^q(y_1, \overline{y}, t) \leq \frac{q}{q-1} C_1 t^{-l} \int_{\mathbf{R}} u(z, \overline{y}, t) dz \quad \forall t > \tau_1. \qquad \square$$

Proof of Theorem 2.1. By (2.8), applying estimates (1.1) and (1.3) of Proposition 1.1, we have that for some positive constant C_0, the solution u satisfies

$$u(t, x) \leq C_0(1+t)^{-\frac{N}{2}} \quad \forall t > 0 \quad \forall x \in \mathbf{R}^N. \tag{2.33}$$

We can then apply Lemma 2.2 with $\alpha = N/2$. Thus for every $\tau_0 > 0$, there is a positive constant $C = C(\tau_0, p, q, C_0)$ such that

$$\left[\frac{\partial u^{q-1}}{\partial x_1}\right]^+ \leq Ct^{-\sigma} \quad \forall t > \tau_0 \tag{2.34}$$

with $\sigma = \min(1, N(p-1))$.

From (2.34) and (2.11), we immediately see that if $N(p-1) \geq 1$, (2.9) is proved. Moreover, by Lemma 2.3 and, more precisely, by (2.18),

$$\int_{\mathbf{R}} u(z, \overline{y}, t)dz \leq Ct^{-\frac{N-1}{2}} \quad \forall t > 2^{N-1}$$

for some other constant $C = C(p, q, C_0)$. Then by Lemma 2.4,

$$\begin{aligned}|u(t, x_1, \overline{x})| &\leq \left(\frac{q}{q-1}\right)^{\frac{1}{q}} C^{\frac{1}{q}} t^{-\frac{1}{q}} \left(\int_{\mathbf{R}} u(t, z, \overline{x})dz\right)^{\frac{1}{q}} \\ &\leq \left(\frac{q}{q-1}\right)^{\frac{1}{q}} C^{\frac{1}{q}} t^{-\frac{1}{q}-\frac{N-1}{2q}} \quad \forall t > 2^N \quad \forall x \in \mathbf{R}^N.\end{aligned}$$

Taking into account the fact that (1.1) holds, this implies (2.10) since $(N+1)/2q > N/2$.

We can now suppose that $N(p-1) < 1$. Then $\sigma = N(p-1)$ and by Lemma 2.3, for every $\delta > 0$, there exists $C \equiv C(p, q, \delta, C_0) > 0$ such that

$$\left\|\int_{\mathbf{R}} u(t, z, \overline{x})dz\right\|_{L^\infty(\mathbf{R}^{N-1})} \leq Ct^{-\frac{N(N-1)(p-1)}{2}+\delta} \quad \forall t > 2^{N-1}. \tag{2.35}$$

We now choose δ in the following way. Since $p > 1 + q/(N+1)$, we have $(N+1)(p-1)/q > 1$. Therefore, for k large enough,

$$\frac{(p-1)^2(N+1)N}{q}\left(\frac{(N+1)(p-1)}{q}\right)^{k-1} > 2.$$

Let us set

$$k_0 = \min\left\{k \in \mathbf{N} : \frac{(p-1)^2(N+1)N}{q}\left(\frac{(N+1)(p-1)}{q}\right)^{k-1} > 2\right\}. \tag{2.36}$$

We choose δ such that

$$\begin{cases} \dfrac{(N+1)N(p-1)}{2q} - k_0\dfrac{\delta}{q} > \dfrac{(N+1)N(p-1)}{4q}, \\ \delta < \dfrac{N(N-1)(p-1) - Nq}{2}. \end{cases} \tag{2.37}$$

Now using (2.34), (2.35) (with δ defined by (2.37)), and Lemma 2.4,

$$\begin{cases} u(t, x) \leq Ct^{-\alpha_1} \quad \forall t > \tau \quad \forall x \in \mathbf{R}^N, \\ \alpha_1 = \dfrac{N(N+1)(p-1)}{2q} - \dfrac{\delta}{q} \end{cases} \tag{2.38}$$

for some $\tau > 0$. Using Lemma 2.2, this in turn gives

$$\forall \tau_0 > 0, \quad \exists C > 0 \quad \left[\frac{\partial u^{q-1}}{\partial x_1}\right]^+ \leq Ct^{-\sigma_1} \quad \forall t > \tau_0 \tag{2.39}$$

with $\tau > 0$ and $\sigma_1 = \min(1, 2\alpha_1(p-1))$. Therefore, if $2\alpha_1(p-1) \geq 1$, in view of (2.11) and (2.39), (2.9) is proved and (2.10) follows as above. On the other hand, if

$2\alpha_1(p-1) < 1$, then $\sigma_1 = 2\alpha_1(p-1)$, and then by (2.39) and (2.17), for every $\delta > 0$, there exists $C \equiv C(p, q, \delta, C_0) > 0$ such that

$$\left\| \int_{\mathbf{R}} u(t, z, \overline{x}) dz \right\|_{L^\infty(\mathbf{R}^{N-1})} \leq C t^{-\alpha_1 (N-1)(p-1)+\delta_1} \quad \forall t > 2^{N-1}. \tag{2.40}$$

We choose δ_1 to be

$$\delta_1 \equiv \delta \frac{(N+1)(p-1)}{q}. \tag{2.41}$$

Again by (2.39)–(2.41) and Lemma 2.4, we obtain

$$\begin{cases} u(t,x) \leq C t^{-\alpha_2} \quad \forall t > 0 \quad \forall x \in \mathbf{R}^N, \\ \alpha_2 = \dfrac{(N+1)(p-1)}{q} \left(\dfrac{N(N+1)(p-1)}{2q} - 2\dfrac{\delta}{q} \right). \end{cases}$$

In this way, step by step, by choosing $\delta_j = \delta_{j-1}(N+1)(p-1)/q$ we obtain a sequence of numbers

$$\alpha_k = \left[\frac{(N+1)(p-1)}{q} \right]^{k-1} \left(\frac{N(N+1)(p-1)}{2q} - k\frac{\delta}{q} \right)$$

such that if $2\alpha_{j-1}(p-1) < 1$, then

$$u(t,x) \leq C t^{-\alpha_j} \quad \forall t > 0 \quad \forall x \in \mathbf{R}^N,$$
$$\int_{\mathbf{R}} u(t, z, \overline{x}) dz \leq t^{-\alpha_{j-1}(N-1)(p-1)+\delta_{j-1}} \quad \forall t > 2^{N-1} \quad \forall x \in \mathbf{R}^N.$$

We claim that for $k = k_0$ (where k_0 is defined by (2.36)), we have $2\alpha_{k_0}(p-1) > 1$. For this observe that by the choice of δ (see (2.37)),

$$\begin{aligned} \alpha_{k_0} &= \left(\frac{N(N+1)(p-1)}{2q} - k_0 \frac{\delta}{q} \right) \left[\frac{(N+1)(p-1)}{q} \right]^{k_0 - 1} \\ &\geq \frac{N(N+1)(p-1)}{4q} \left(\frac{(N+1)(p-1)}{q} \right)^{k_0-1}, \end{aligned}$$

and so by the choice of k_0,

$$2\alpha_{k_0}(p-1) \geq \frac{(p-1)^2(N+1)N}{q} \left[\frac{(N+1)(p-1)}{q} \right]^{k_0-1} > 1.$$

Thus (2.9) and (2.10) are deduced as above. □

Corollary 2.5. *Under the hypotheses of Theorem* 2.1*, there is a positive constant C such that*

$$\frac{\partial u^q}{\partial x_1} \leq C \frac{u}{1+t} \quad \forall t > 0, \tag{2.42}$$

$$\int_{\mathbf{R}^N} \left| \frac{\partial u^q}{\partial x_1} \right| dx \leq \frac{CM}{(1+t)} \quad \forall t > 0. \tag{2.43}$$

Proof. Inequality (2.42) is a direct consequence of Theorem 2.1.

For (2.43), we use the fact that

$$\int_{\mathbf{R}^N} \frac{\partial u^q}{\partial x_1} dx = 0.$$

Then by (2.42),

$$\int_{\mathbf{R}^N} \left(\frac{\partial u^q}{\partial x_1}\right)^- dx = \int_{\mathbf{R}^N} \left(\frac{\partial u^q}{\partial x_1}\right)^+ \leq \frac{C}{1+t} \int_{\mathbf{R}^N} u dx. \qquad \square$$

3. Main result for nonnegative solutions. In this section, we prove the main result for nonnegative initial data. By the maximum principle, this means that the solution u is also nonnegative. In order to pass to the limit in (2.4) as $\lambda \to \infty$, we need some further estimates on the family $\{u_\lambda\}$ defined in (2.2).

LEMMA 3.1. *If u solves* (0.10) *and* (0.2) *and u_λ is the family of functions defined by* (2.2)*, then*

$$\begin{aligned} &\int_\tau^T \int_{\mathbf{R}^N} \left(|\nabla_{\overline{x}} u_\lambda(t,x)|^2 + \lambda^{1-2\beta} \left| \frac{\partial u_\lambda(s+\tau)}{\partial x_1} \right|^2 \right) dx dt \\ &\qquad \leq \frac{1}{2} \int_{\mathbf{R}^N} |u_\lambda(\tau,x)|^2 dx \leq C(M) \tau^{-\frac{(N+1)}{2q}} \quad \forall \lambda > 0 \end{aligned} \tag{3.1}$$

for all $T > 0$ and $\tau \in (0,T)$.

Proof. Multiplying equation (0.10) by u and integrating by parts, we get that for every $T > 0$ and $\tau \in (0,T)$,

$$\int_\tau^T \int_{\mathbf{R}^N} |\nabla u(t,x)|^2 dx dt \leq \frac{1}{2} \int_{\mathbf{R}^N} |u(\tau,x)|^2 dx \leq C(M) \tau^{-\frac{(N+1)}{2q}}.$$

The result follows from the definition of u_λ. $\square$

LEMMA 3.2. *If u solves* (0.10) *and* (0.2) *and u_λ is the family of functions defined by* (2.2)*, then for every $\tau > 0$, there is a positive constant such that*

$$||\nabla_{\overline{x}} u_\lambda(t)||_{L^1(\mathbf{R}^N)} \leq C \quad \forall t \geq \tau_0, \tag{3.2}$$

where $\nabla_{\overline{x}} u = (\partial u/\partial x_2, \dots, \partial u/\partial x_N)$.

Proof. For every λ, the function u_λ satisfies

$$\begin{aligned} u_\lambda(t+\tau) = K_\lambda(t) * u_\lambda(\tau) &- \int_0^t K_\lambda(t-s) * \left(\frac{\partial u_\lambda^q(s+\tau)}{\partial x_1} \right) ds \\ &- \lambda^{\frac{1}{2} - \frac{(N+1)(p-1)}{2q}} \int_0^t \left(\frac{\partial K_\lambda(t-s)}{\partial x_2} \right) * u_\lambda^p(s+\tau) ds, \end{aligned}$$

where $K_\lambda(t,x) = \lambda^{\beta-1/2} K(t, \lambda^{\beta-1/2} x_1, \overline{x})$. Then for every $t \in (0,1)$ and $\tau > \tau_0$,

$$\begin{aligned} &||\nabla_{\overline{x}} u_\lambda(t+\tau)||_{L^1(\mathbf{R}^N)} \\ &\quad \leq M ||\nabla_{\overline{x}} K_\lambda(t)||_{L^1(\mathbf{R}^N)} + \int_0^t ||\nabla_{\overline{x}} K_\lambda(t-s)||_{L^1(\mathbf{R}^N)} \left\| \frac{\partial u_\lambda^q(s+\tau)}{\partial x_1} \right\|_{L^1(\mathbf{R}^N)} ds \\ &\qquad + \lambda^{\frac{1}{2} - \frac{(N+1)(p-1)}{2q}} \int_0^t \left\| \frac{\partial K_\lambda(t-s)}{\partial x_2} \right\|_{L^1(\mathbf{R}^N)} ||\nabla_{\overline{x}} u_\lambda^p(s+\tau)||_{L^1(\mathbf{R}^N)} ds \\ &\quad \leq C t^{-\frac{1}{2}} + C \int_0^t (t-s)^{-\frac{1}{2}} (s+\tau)^{-1} ds \end{aligned}$$

$$+\int_0^t (t-s)^{-\frac{1}{2}}(s+\tau)^{-\frac{(N+1)(p-1)}{2q}}||\nabla_{\overline{x}} u_\lambda^p(s+\tau)||_{L^1(\mathbf{R}^N)}ds.$$

If $g(t)=||\nabla_{\overline{x}}u_\lambda(t+\tau)||_{L^1(\mathbf{R}^N)}$, we have for $t\in(0,1)$ and for all $\tau>\tau_0$ that

$$g(t)\le (C\sqrt{t}+CMt^{-\frac{1}{2}})+C\tau_0^{-\frac{(N+1)(p-1)}{2q}}\int_0^t (t-s)^{-\frac{1}{2}}g(s)ds.$$

From Gronwall's lemma, we deduce that (3.2) holds. □

LEMMA 3.3. *There is a sequence* $\{\lambda_n\}$ *and* $U\in L^\infty((0,\infty);L^1(\mathbf{R}^N))\cap L^\infty((0,\infty)\times\mathbf{R}^N)$*, a solution of* (1.4)*, satisfying the entropy condition* (1.5) *and such that*

$$\forall\varepsilon>0,\quad \forall t_2>t_1>0,\quad u_{\lambda_n}\to U\quad \text{in } \mathbf{C}([t_1,t_2];W^{-\varepsilon,2}_{\text{loc}}(\mathbf{R}^N)),$$
$$\forall r\in[1,\infty),\quad \forall t>0,\quad u_{\lambda_n}(t)\to U(t)\quad \text{in } L^r_{\text{loc}}(\mathbf{R}^N).$$

Proof. By Theorem 2.1 and Corollary 2.5, if u_0 is nonnegative and satisfies (2.8), the family u_λ defined by (2.2) satisfies

$$0<u_\lambda(t,x)\le Ct^{-\frac{N+1}{2q}}\quad \forall t>0\quad \forall x\in\mathbf{R}^N, \tag{3.3}$$

$$\frac{\partial u_\lambda^{q-1}(t)}{\partial x_1}\le Ct^{-1}\quad \text{in } (0,+\infty)\times\mathbf{R}^N, \tag{3.4}$$

$$\int_{\mathbf{R}^N}\left|\frac{\partial u_\lambda^q(t)}{\partial x_1}\right|dx\le CMt^{-1}\quad \forall t>0, \tag{3.5}$$

$$\int_{\mathbf{R}^N}\left|\frac{\partial u_\lambda^{q+r}(t)}{\partial x_1}\right|dx\le CMt^{-1-r\frac{N+1}{2q}}\quad \forall t>0. \tag{3.6}$$

The argument now follows [EVZ2]:

(i) From (3.2)–(3.3) and (3.6), we deduce that the family $\{u_\lambda^{q+r}\}$ is uniformly bounded in $L^\infty(\tau,\infty;W^{1,1}(\mathbf{R}^N))$ for every $r\ge 1$ and $\tau>0$.

(ii) From (3.1), (3.2), (3.5), and (2.4), we deduce that $\{\partial_t u_\lambda\}$ is uniformly bounded in $L^2_{\text{loc}}((0,\infty);H^{-s}_{\text{loc}}(\mathbf{R}^N))$ for some positive s.

(iii) From (i), we deduce that $\{u_\lambda\}$ is uniformly bounded in $L^\infty_{\text{loc}}((0,\infty);L^2_{\text{loc}}(\mathbf{R}^N))$.

For every bounded set Ω of $\mathbf{R}^N$, since $L^2(\Omega)$ is compactly embedded in $H^{-\varepsilon}(\Omega)$ for every $\varepsilon>0$ and $H^{-\varepsilon}(\Omega)$ is continuously embedded in $H^{-s}(\Omega)$ for every $s>\varepsilon$, we deduce from (ii), (iii), and the compactness result of [S] that

(iv) $\{u_\lambda^{q+r}\}$ is relatively compact in $\mathbf{C}([t_1,t_2];H^{-\varepsilon}(\Omega))$.

We can therefore extract a subsequence $\lambda_n\to\infty$ such that

$$u_{\lambda_n}\to U\quad \text{in } \mathbf{C}([t_1,t_2];H^{-\varepsilon}(\Omega)) \tag{3.7}$$

for every bounded domain Ω in $\mathbf{R}^N$ and every $\varepsilon<s$. Since by (i) and (3.3), we know that $\{u_\lambda(t)\}$ is relatively compact in $L^r_{\text{loc}}(\mathbf{R}^N)$ for every $1\le r<\infty$ and every $t>0$, we deduce that

$$u_{\lambda_n}(t)\to U(t)\quad \text{in } L^r_{\text{loc}}(\mathbf{R}^N). \tag{3.8}$$

Then passing to the limit in (2.4) through the sequence $\{\lambda_n\}$ in the sense of the distributions $\mathcal{D}'((0,\infty)\times\mathbf{R}^N)$, we see that U is a weak solution of (1.4). Moreover, since for every n, u_{λ_n} is a regular solution of (0.10), for any $\psi \in \mathcal{D}(\mathbf{R}^{N-1})$, $\psi = \psi(\overline{x})$, we have

$$
\begin{aligned}
&|u_{\lambda_n} - \psi|_t - \widetilde{\triangle}|u_{\lambda_n} - \psi| + \frac{\partial}{\partial x_1}|u^q_{\lambda_n} - |\psi|^{q-1}\psi| \\
&\quad \leq \operatorname{sign}(u_{\lambda_n} - \psi)\widetilde{\triangle}\psi + \lambda^{1-2\beta}\frac{\partial^2 u_{\lambda_n}}{\partial x_1^2}\operatorname{sign}(u_{\lambda_n} - \psi) - \lambda^{\frac{1}{2}-\frac{(N+1)(p-1)}{2q}}\frac{\partial|u^p_{\lambda_n} - |\psi|^{p-1}\psi|}{\partial x_2}
\end{aligned}
$$

in the sense of the distributions $\mathcal{D}'((0,\infty) \times \mathbf{R}^N)$, where $\tilde{\Delta}$ denotes the Laplacian in the variables $(x_2, \dots, x_N)$. Taking into account that

$$
\frac{\partial^2 u_{\lambda_n}}{\partial x_1^2}\operatorname{sign}(u_{\lambda_n} - \psi) \leq \frac{\partial^2 |u_{\lambda_n} - \psi|}{\partial x_1^2} + \frac{\partial^2 \psi}{\partial x_1^2}\operatorname{sign}(u_{\lambda_n} - \psi)
$$

and passing to the limit as $n \to \infty$, we obtain that U satisfies the entropy condition (1.5). Moreover, U satisfies (3.3) and (3.4). We then have that $U \in L^\infty((\tau,\infty) \times \mathbf{R}^N)$ for every $\tau > 0$, and since $||u(t)||_{L^1(\mathbf{R}^N)} = M$, we also have that $U \in L^\infty((0,\infty); L^1(\mathbf{R}^N))$ and $\int_{\mathbf{R}^N} U(t,x)dx \leq M$ $\forall t > 0$.

In order to identify U as the function v_M of Proposition 1.2, we also need to prove that U takes the initial data $M\delta$ in the sense of (1.6)–(1.7). To this end, we need the following.

Lemma 3.4. *Suppose that u is the classical solution of* (0.10) *and* (0.2) *and the family* $\{u_\lambda\}$ *is the one defined in* (2.2). (*Note that we do not assume u to be of constant sign.*) *Then for every $t_0 > 0$ and $\varepsilon > 0$, there are $k_0 > 0$ and $\lambda_0 > 0$ such that*

$$
\int_{|x_1|+|\overline{x}|\geq k_0} |u_\lambda|(t, x_1, \overline{x})dx_1 d\overline{x} \leq \varepsilon \tag{3.9}
$$

for every $t \in (0, t_0)$ and $\lambda \geq \lambda_0$.

Proof. If $N \geq 3$, we define

$$
v_\lambda(t, x_3, \dots, x_N) = \int_{\mathbf{R}^2} u_\lambda(t, x_1, x_2, x_3, \dots, x_N)dx_1 dx_2.
$$

For every $\lambda > 0$, the function v_λ satisties the $(N-2)$-dimensional linear heat equation. Since the family of initial data $\{v_\lambda(0)\}$ is an approximation of the identity in $\mathbf{R}^{N-2}$, we deduce that for every $t_2 > t_1 > 0$ and every $\varepsilon > 0$, there are $k_0 > 0$ and $\lambda_0 > 0$ such that

$$
\begin{aligned}
&\int_{|(x_3,\dots,x_N)|>k_0} v_\lambda(t, x_3, \dots, x_N)dx_3 \cdots dx_N \\
&\qquad \equiv \int_{\mathbf{R}^2}\int_{|(x_3,\dots,x_N)|>k_0} u_\lambda(t, x_3, \dots, x_N)dx_1 dx_2 dx_3 \cdots dx_N \leq \varepsilon \\
&\qquad\qquad \forall \lambda \geq \lambda_0 \quad \forall t \in (0, t_0).
\end{aligned}
$$

Therefore, in order to prove (3.9), we need only the fact that under the same conditions,

$$
\int_{|x_1|\geq k_0}\int_{\mathbf{R}^{N-1}} u_\lambda(t, x_1, \dots, x_N)dx_1 \cdots dx_N \leq \varepsilon \quad \forall \lambda \geq \lambda_0 \quad \forall t \in (0, t_0), \tag{3.10}
$$

$$
\int_{|x_2|\geq k_0}\int_{\mathbf{R}^{N-1}} u_\lambda(t, x_1, \cdots, x_N)dx_1 \cdots dx_N \leq \varepsilon \quad \forall \lambda \geq \lambda_0 \quad \forall t \in (0, t_0). \tag{3.11}
$$

Let us estimate (3.10); the bound (3.11) can be obtained in the same way. We define

$$v_\lambda(t,x_1,\overline{x}) = \int_{-\infty}^{x_1} u_\lambda(t,z,\overline{x})dz \quad \forall (x_1,\overline{x}) \in \mathbf{R}^N.$$

Then v_λ satisfies

$$\frac{\partial v_\lambda}{\partial t} - \sum_{j=2}^N \frac{\partial^2 v_\lambda}{\partial x_j^2} - \lambda^{1-2\beta}\frac{\partial^2 v_\lambda}{\partial x_1^2} - \lambda^{\frac{1}{2}-\frac{(N+1)(p-1)}{2q}} \frac{\partial}{\partial x_2}\int_{-\infty}^{x_1} |u_\lambda|^{p-1}u_\lambda dz = -|u_\lambda|^{q-1}u_\lambda \le 0.$$

Take $w_\lambda(t,x_1) = \int_{\mathbf{R}^{N-1}} v_\lambda(t,x_1,\overline{x})d\overline{x}$. The function w_λ then satisfies

$$\frac{\partial w_\lambda}{\partial t} - \lambda^{1-2\beta}\frac{\partial^2 w_\lambda}{\partial {x_1}^2} \le 0; \qquad w_\lambda(0) = \int_{\mathbf{R}^{N-1}}\int_{-\infty}^{x_1} u_\lambda(t,z,\overline{x})dzd\overline{x},$$

and it is bounded from above by the solution W_λ of the equation

$$\partial_t W_\lambda - \lambda^{1-2\beta}\frac{\partial^2 W_\lambda}{\partial x_1^2} = 0$$

with the same initial data. We have $W_\lambda(t,x_1) = (K_\lambda(t) * w_\lambda(0))(x_1)$ with $K_\lambda(t,x_1) = \lambda^{\beta-1/2}K_1(t,\lambda^{\beta-1/2}x_1)$ and where K_1 is the one-dimensional heat kernel. Let us show that for every $k_0 > 0$ and every $t > 0$,

$$\lim_{\lambda\to\infty} w_\lambda(t,-k_0) = \lim_{\lambda\to\infty}\int_{\mathbf{R}^{N-1}}\int_{-\infty}^{-k_0} u_\lambda(t,z,\overline{x})dx_1 d\overline{x} = 0. \tag{3.12}$$

By definition,

$$\begin{aligned} W_\lambda(t,-k_0) &= \lambda^{\beta-\frac{1}{2}}(4\pi t)^{-\frac{1}{2}}\int_{\mathbf{R}} \exp\left(-\frac{|z|^2}{4t\lambda^{1-2\beta}}\right) w_\lambda(0,-k_0-z)dz \\ &\le M\lambda^{\beta-\frac{1}{2}}(4\pi t)^{-\frac{1}{2}}\int_{\{|z|\ge k/2\}} \exp\left(-\frac{|z|^2}{4t\lambda^{1-2\beta}}\right)dz \\ &\quad + \lambda^{\beta-\frac{1}{2}}(4\pi t)^{-\frac{1}{2}}\int_{\{|z|<k/2\}} \exp\left(-\frac{|z|^2}{4t\lambda^{1-2\beta}}\right) w_\lambda(0,-k_0-z)dz \end{aligned}$$

and

$$\lim_{\lambda\to\infty}\int_{\{|z|\ge k/2\}} \exp\left(-\frac{|z|^2}{4t\lambda^{1-2\beta}}\right)dz = 0$$

since $1-2\beta < 0$. Moreover, by construction, we have uniformly on the set $\{|z| < k/2\}$ that

$$\begin{aligned} \lim_{\lambda\to\infty} w_\lambda(0,-k_0-z) &= \lim_{\lambda\to\infty}\int_{\mathbf{R}^{N-1}}\int_{-\infty}^{-k_0-z} u_\lambda(0,y,\overline{x})dyd\overline{x} \\ &\le \lim_{\lambda\to\infty}\int_{\mathbf{R}^{N-1}}\int_{-\infty}^{-\lambda^\beta k_0/2} u_0(y,\overline{x})dyd\overline{x} = 0, \end{aligned}$$

from which, using that $\int_{\mathbf{R}} K_\lambda(t,y)dy = 1$ for every t, we deduce that

$$\lim_{\lambda\to\infty}\int_{\{|z|<k/2\}} \exp\left(-\frac{|z|^2}{4t\lambda^{1-2\beta}}\right) w_\lambda(0,-k_0-z)dz = 0,$$

and (3.12) follows. It is easy to see that the limits above are uniform on intervals of the form $(0,t_0)$ with $t_0>0$ finite.

On the other hand, now define $w_\lambda(t,x_1)=\int_{\mathbf{R}^{N-1}}\int_{x_1}^{\infty}u_\lambda(t,z,\overline{x})dzd\overline{x}$. Then w_λ satisfies

$$\begin{aligned}\frac{\partial w_\lambda}{\partial t}-\lambda^{1-2\beta}\frac{\partial^2 w_\lambda}{\partial {x_1}^2}&=\int_{\mathbf{R}^{N-1}}|u_\lambda|^{q-1}u_\lambda d\overline{x}\\&\le Ct^{-\frac{N+1}{2q}(q-1)}\int_{\mathbf{R}^{N-1}}u_\lambda(x_1,\overline{x})d\overline{x}\equiv -Ct^{-\frac{N+1}{2q}(q-1)}\frac{\partial w_\lambda}{\partial x_1}.\end{aligned}$$

By the classical parabolic comparison principle, for every $\lambda>0$, the function w_λ is bounded from above by W_λ, the solution of

$$\begin{aligned}\frac{\partial W_\lambda}{\partial t}-\lambda^{1-2\beta}\frac{\partial^2 W_\lambda}{\partial {x_1}^2}+Ct^{-\frac{N+1}{2q}(q-1)}\frac{\partial W_\lambda}{\partial x_1}&=0,\\W_\lambda(0,x_1)=\int_{\mathbf{R}^{N-1}}\int_{x_1}^{\infty}u_\lambda(0,z,\overline{x})dzd\overline{x}&.\end{aligned}$$

Therefore, the function

$$\omega_\lambda(t,x_1)\equiv W_\lambda\left(t,x_1+\frac{C}{\beta}t^\beta\right)$$

(where, remember, β is defined in (2.3)) satisfies

$$\frac{\partial \omega_\lambda}{\partial t}-\lambda^{1-2\beta}\frac{\partial^2\omega_\lambda}{\partial {x_1}^2}=0;\qquad \omega_\lambda(0,x_1)=\int_{\mathbf{R}^{N-1}}\int_{x_1}^{\infty}u_\lambda(0,z,\overline{x})dzd\overline{x}.$$

By the same argument as before, we deduce that for every $k>0$ and for all $t_0>0$,

$$\lim_{\lambda\to\infty}\int_{\mathbf{R}^{N-1}}\int_{k}^{\infty}u_\lambda(t,z,\overline{x})dx_1d\overline{x}=0\quad\forall t\in(0,t_0).\tag{3.13}$$

From (3.12) and (3.13), we deduce (3.10). The same argument gives the estimate for (3.11), and this completes the proof of Lemma 3.4 for the case where $u_0\ge 0$. Of course the same proof holds for nonpositive initial data $u_0\le 0$.

In the general case, let

$$u_0^+=\max(0,u_0),\qquad u_0^-=\min(0,u_0)$$

so that $u_0\equiv u_0^++u_0^-$. Let v and w be the solutions of (0.10) and (0.2) with, respectively, u_0^+ and u_0^- as initial data. By the maximum principle, $w\le u\le v$ on $(0,\infty)\times\mathbf{R}^N$. Thus for every $\lambda>0$, $w_\lambda\le u_\lambda\le v_\lambda$ on $(0,\infty)\times\mathbf{R}^N$. Therefore, using (3.9) for nonpositive and nonnegative initial data, we deduce the lemma in the general case. □

We can show now that the function U takes $M\delta$ as initial data in the sense of (1.7).

Lemma 3.5. *For every function $\varphi\in BC(\mathbf{R}^N)$,*

$$\lim_{t\to 0}\int_{\mathbf{R}^N}U(t,x)\varphi(x)dx=M\varphi(0).\tag{3.14}$$

Proof. Let us prove (3.14) for $\varphi \in \mathcal{D}(\mathbf{R}^N)$ first. To this end, we multiply equation (2.4) by φ and integrate by parts on $(0,t) \times \mathbf{R}^N$. This gives

$$
\begin{aligned}
&\left| \int_{\mathbf{R}^N} u_\lambda(t,x)\varphi(x)dx - \int_{\mathbf{R}^N} u_\lambda(0,x)\varphi(x)dx \right| \\
&\quad \leq \left| \int_0^t \int_{\mathbf{R}^N} u_\lambda(s,x)\widetilde{\triangle}\varphi(x)dxds \right| + \lambda^{1-2\beta}| \int_0^t \int_{\mathbf{R}^N} u_\lambda(s,x)\frac{\partial^2\varphi}{\partial x_1^2}(x)dxds| \\
&\qquad\qquad + \left| \int_0^t \int_{\mathbf{R}^N} |u_\lambda(s,x)|^{q-1} u_\lambda(s,x)\frac{\partial\varphi}{\partial x_1}dxds \right| \\
&\qquad\qquad + \lambda^{\frac{1}{2}-\frac{(N+1)(p-1)}{2q}} \left| \int_0^t \int_{\mathbf{R}^N} |u_\lambda(s,x)|^{p-1} u_\lambda(s,x)\frac{\partial\varphi}{\partial x_2}dxds \right| \\
&\quad \leq Mt||\widetilde{\triangle}\varphi||_{L^\infty(\mathbf{R}^N)} + \lambda^{1-2\beta}t\left\| \frac{\partial^2\varphi}{\partial x_1^2} \right\|_{L^\infty(\mathbf{R}^N)} + 2\sqrt{t}\left\| \frac{\partial\varphi}{\partial x_1} \right\|_{L^\infty(\mathbf{R}^N)} \\
&\qquad + \lambda^{\frac{1}{2}-\frac{(N+1)(p-1)}{2q}} \frac{t^{1-\frac{N}{2}(p-1)}}{1-\frac{N}{2}(p-1)} \left\| \frac{\partial\varphi}{\partial x_2} \right\|_{L^\infty(\mathbf{R}^N)}.
\end{aligned}
$$

Since $\{u_\lambda(0)\}$ is an approximation of the identity, for every $\varepsilon > 0$, there is a $\tau > 0$ and $\lambda_0 > 0$ such that if $t \in (0,\tau)$ and $\lambda > \lambda_0$,

$$\left| \int_{\mathbf{R}^N} u_\lambda(t,x)\varphi(x)dx - M\varphi(0) \right| \leq \varepsilon.$$

Passing to the limit as λ_k goes to ∞, we obtain

$$\left| \int_{\mathbf{R}^N} U(t,x)\varphi(x)dx - M\varphi(0) \right| \leq \varepsilon \quad \forall t \in (0,\tau).$$

Using Lemma 3.4 and (3.14), we easily conclude the proof of Lemma 3.5. □

From Lemma 3.5, we easily deduce the following for U.

COROLLARY 3.6. *The function U satisfies $U \in \mathbf{C}((0,\infty); L^p(\mathbf{R}^N))$ for every $p \in [1,\infty)$ and $u_{\lambda_k}(t,.) \to U(t,.)$ in $L^p(\mathbf{R}^N)$ uniformly in $t \in [t_1,t_2]$ with $0 < t_1 < t_2 < \infty$. Moreover, it is an entropy solution of* (1.4)–(1.7).

We then deduce by the uniqueness of the function v_M of Proposition 1.2 that $U \equiv v_M$ and that it is the entire family u_λ which converges to v_M as $\lambda \to \infty$ uniformly in $C([t_1,t_2], L^r(\mathbf{R}^N))$ for every $r \in [1,\infty)$ and $0 < t_1 < t_2 < \infty$. As in section 2, this implies that for all such r's,

$$\lim_{\lambda\to\infty} ||u_\lambda(1,\cdot) - v_M(1,\cdot)||_{L^r(\mathbf{R}^N)} = 0. \tag{3.15}$$

By a simple change of variables, (3.15) proves the main result if the initial data $u_0 \geq 0$ satisfy (2.8).

Suppose now that we only have $u_0 \geq 0$ with $u_0 \in L^1(\mathbf{R}^N)$. By (1.1), we have that for any fixed $\tau > 0$, $u(\tau)$ satisfies (2.8). Applying the previous arguments to the function $\widetilde{u}(t) = u(t+\tau)$, we deduce the main result for nonnegative initial data $u_0 \in L^1(\mathbf{R}^N)$.

4. Proof of the main result for general initial data. In this section, we consider the solutions of (0.10) and (0.2) where the initial data u_0 may be any function of $L^1(\mathbf{R}^N)$, not necessarily positive or negative but which may change sign. Then we no longer have the entropy inequality (2.9) anymore. Regardless, since

$$\forall t > 0, \quad \forall x \in \mathbf{R}^N, \quad |u(t,x)| \leq \overline{u}(t,x),$$

where $\overline{u}$ is the solution of (0.10) with initial data $\overline{u}(0) = |u_0|$, the decay estimate (2.10) is still true. The proof follows the same lines as in the case of nonnegative initial data. The only difference is how we obtain the compactness of the family $\{u_\lambda\}$. Since we cannot use the entropy inequality, we use a general compactness result of [LPT] based on the kinetic approach and slightly modified in [C1] and [C2] to handle nonlinearities which are not of class C^2.

Proposition 4.1. *Let $\rho_\lambda \in C(0,\infty; L^1(\mathbf{R}^N)) \cap L^\infty(\mathbf{R}^N \times (0,\infty))$ be a family of solutions of*

$$\frac{\partial \rho_\lambda}{\partial t} - \lambda^{1-2\beta}\frac{\partial^2 \rho_\lambda}{\partial x_1^2} - \sum_{j=2}^{N} \frac{\partial^2 \rho_\lambda}{\partial x_j^2} + \frac{\partial |\rho_\lambda|^{q-1}\rho_\lambda}{\partial x_1} + \lambda^{\frac{1}{2}-\frac{(N+1)(p-1)}{2q}} \frac{\partial |\rho_\lambda|^{p-1}\rho_\lambda}{\partial x_2} = 0 \tag{4.1}$$

such that the following hold:

1. *For all convex functions S,*

(4.2)
$$\frac{\partial S(\rho_\lambda)}{\partial t} - \lambda^{1-2\beta}\frac{\partial^2 \eta_{11}(\rho_\lambda)}{\partial x_1^2} - \sum_{j=2}^{N} \frac{\partial^2 \eta_{jj}(\rho_\lambda)}{\partial x_j^2} + \frac{\partial \eta_1(\rho_\lambda)}{\partial x_1} + \lambda^{\frac{1}{2}-\frac{(N+1)(p-1)}{2q}} \frac{\partial \eta_2(\rho_\lambda)}{\partial x_2} \leq 0,$$

where

$$\eta_1(t) = q\int_0^t S'(s)|s|^{q-1}ds, \qquad \eta_2(t) = p\lambda^{\frac{1}{2}-\frac{(N+1)(p-1)}{2q}} \int_0^t S'(s)|s|^{p-1}ds,$$
$$\eta_{11} = \lambda^{1-2\beta}(S(t) - S(0)), \qquad \eta_{jj} = (S(t) - S(0)) \quad \forall j \in \{2, \ldots, N\}.$$

2. *ρ_λ is bounded in $L^\infty((0,\infty) \times \mathbf{R}^N) \cap L^\infty((0,\infty); L^1(\mathbf{R}^N))$ uniformly in λ.*

Then ρ_λ is relatively compact in $L^1_{\text{loc}}((0,\infty) \times \mathbf{R}^N)$.

By (2.10), the family u_λ satisfies condition 2 above. Since for every $\lambda > 0$, the function u_λ is a classical solution of the parabolic equation (4.1), it satisfies (4.2). We then deduce that u_λ is relatively compact in $L^1_{\text{loc}}((0,\infty) \times \mathbf{R}^N)$. The proof then follows the same lines as in section 3.

5. Further comments.

5.1. More general nonlinearities. With some trivial modifications in the proof, one can show that the main result is still true for the solutions of the Cauchy problem with initial data $u_0 \in L^1(\mathbf{R}^N)$ that satisfies

$$u_t - \triangle u + \sum_{i=1}^{N} \frac{\partial |u|^{r_i - 1}u}{\partial x_i} = 0 \quad \text{in } Q = \mathbf{R}^N \times (0,\infty) \tag{5.1}$$

with $\{r_i\}_{i=1}^N$ such that for some $q \in (1, 1 + 1/N)$, either $r_i = q$ or $r_i > 1 + q/(N+1)$.

Under slight modifications in the proof, the same result can be extended to small perturbations of the pure power-like case. More precisely, consider the Cauchy problem with initial data in $L^1(\mathbf{R}^N)$ associated with the equation

$$u_t - \triangle u + \sum_{i=1}^{N} \frac{\partial f_i(u)}{\partial x_i} = 0 \quad \text{in } (0,\infty) \times \mathbf{R}^N \tag{5.2}$$

with $f_i \in C^1([0,\infty)) \cap C^2((0,\infty))$, $f_i(0) = f_i'(0) = 0$. Moreover, suppose that there exist $q \in (1, 1+1/N)$, $j \in \{1, \ldots, N\}$, and $r_i > 1 + q/(N+1)$ for $i \neq j$ such that the limits

$$\lim_{s \to 0} \frac{f_j''(s)}{|s|^{q-3}s} = q(q-1)C \neq 0 \quad \text{and} \quad \lim_{s \to 0} \frac{f_i''(s)}{|s|^{r_i - 3}s}, \quad i \neq j,$$

exist. Then the main result stated in the introduction remains true for the solutions of (5.2) and (0.2), where the limiting equation is

$$u_t - \tilde{\triangle} u + C\frac{\partial |u|^{q-1}u}{\partial x_j} = 0.$$

5.2. Open problems. We cannot consider the case where one of the powers r_i is such that $q < r_i < 1 + q/(N+1)$. Even the simplest equation

$$u_t - \triangle u + \frac{\partial |u|^{q-1}u}{\partial x_1} + \frac{\partial |u|^{p-1}u}{\partial x_2} = 0$$

with $1 < q < p \leq 1 + q/(N+1)$ is out of the scope of our results.

However, looking at the scaling transformation (2.4), we see that when $p = 1 + q/(N+1)$, the nonlinearities remain invariant. Therefore, in this particular case, one expects the large-time behavior to be given by self-similar entropy solutions of the reduced equation

$$u_t - \sum_{j=2}^{N} \frac{\partial^2 u}{\partial {x_j}^2} + \frac{\partial |u|^{q-1}u}{\partial x_1} + \frac{\partial |u|^{p-1}u}{\partial x_2} = 0.$$

Note that the two nonlinearities are present. The large-time behavior is probably of a completely different nature in the range $1 < q < p < 1 + q/(N+1)$.

STABILITY AND LYAPUNOV FUNCTIONS FOR REACTION-DIFFUSION SYSTEMS[*]

W. B. FITZGIBBON[†], S. L. HOLLIS[‡], AND J. J. MORGAN[§]

Abstract. It is shown for a large class of reaction-diffusion systems with Neumann boundary conditions that in the presence of a separable Lyapunov structure, the existence of an a priori L^r estimate, uniform in time, for some $r > 0$, implies the L^∞-uniform stability of steady states. The results are applied to a general class of Lotka–Volterra systems and are seen to provide a partial answer to the global existence question for a large class of balanced systems with nonlinearities that are not bounded by any polynomial.

1. Introduction.

One of the persistent problems in the theory of systems of reaction-diffusion equations concerns the description of the qualitative effects of adding diffusion to systems of ordinary differential equations. To be more precise, if $f = (f_i)_{i=1}^m\colon \mathbb{R}^m \to \mathbb{R}^m$, then solutions to the system of ordinary differential equations

$$\begin{aligned} &\dot{u}(t) = f(u(t)), \quad t > 0,\\ &u(0) = u_0 \end{aligned} \tag{1.1}$$

determine constant solutions to the reaction-diffusion system

$$\begin{aligned} &\partial u/\partial t = D\Delta u + f(u) && \text{on } \Omega \times (0,\infty),\\ &\partial u/\partial \mathbf{n} = 0 && \text{on } \partial\Omega \times (0,\infty),\\ &u(\,\cdot\,,0) = u_0(\,\cdot\,) && \text{on } \Omega, \end{aligned} \tag{1.2}$$

where $u = (u_1, \ldots, u_m)^T$, D is a diagonal matrix with distinct entries $d_i > 0$ along the diagonal and Δ denotes the vector Laplacian. One principal question associated with these systems is whether or not global existence of solutions to (1.1) for all choices of initial data guarantees global existence of solutions to (1.2) for all choices of sufficiently smooth initial data. This question remained unresolved until the recent work of Pierre and Schmidt [19]. In that work, the authors give an example of a two-component system for which solutions to (1.1) exist globally while those to the partial differential equation blow up in finite time. Their work is related to a long-standing question pointed out by Martin in the early 1980s regarding the global existence of nonnegative solutions to two component systems of the form

$$\begin{aligned} &\partial u/\partial t = d_1\Delta u + f_1(u,v),\\ &\partial v/\partial t = d_2\Delta v + f_2(u,v) \end{aligned} \quad \text{on } \Omega \times (0,\infty), \tag{1.3}$$

where $f_1(0,v)$, $f_2(u,0) \geq 0$ for all $u, v \geq 0$ and $f_1(u,v) + f_2(u,v) \leq 0$ for all $u, v \geq 0$. These two conditions on the vector field (f_1, f_2) are referred to, respectively, as quasi positivity and balancing.

This has given rise to similar questions about more general, balanced, quasi-positive reaction-diffusion systems of the form

$$(1.4) \qquad \partial u_i/\partial t = d_i \Delta u_i + f_i(u) \quad \text{on } \Omega \times (0,\infty), \quad i = 1, \dots, m,$$

where $u = (u_1, \dots, u_m)^T$, $f_i(u) \geq 0$ whenever $u \in \mathbb{R}^m_+$ with $u_i = 0$, and $\sum_{i=1}^m f_i(u) \leq 0$ for all $u \in \mathbb{R}^m_+$. It should be noted that these balancing and quasi positivity assumptions easily imply that $f(0) = 0$ and that all solutions of the ordinary differential equation in (1.1) having nonnegative initial data exist and are bounded for all $t \geq 0$. In particular, for any $M > 0$, the region

$$\left\{ u \;\Big|\; \sum_{i=1}^n u_i \leq M, \quad u_i \geq 0 \right\}$$

is invariant for these systems; therefore, the zero solution is stable with respect to $\mathbb{R}^m_+$.

This structure is merely a simple case of a more general, separable Lyapunov structure for (1.1). Such a structure has the form $H(u) = \sum_{i=1}^m h_i(u_i)$, where H: $\mathbb{R}^m_+ \to [0,\infty)$ is a convex function that has a unique zero in $\mathbb{R}^m_+$ and whose level hypersurfaces bound invariant regions for solutions of (1.1). The existence of such an H easily guarantees the stability of the steady state z. Recent work in this vein includes [1], [5], [6], [10], [14], and [16].

The work at hand concerns the persistence of stability of steady-state solutions to (1.1) in the presence of a separable Lyapunov structure when diffusion is added to the system, that is, in the setting of (1.2) with nonnegative, continuous initial data. Questions of stability for nonlinear systems are frequently resolved via linearized stability or Lyapunov-type methods. Typically, when one attempts to lift Lyapunov functions from the setting of (1.1) to (1.2), one obtains estimates in $L_1(\Omega)$ or $L_p(\Omega)$ and not the optimal uniform $L_\infty(\Omega)$ estimates needed to obtain stability. Therefore, the central theme of our work will be the introduction of an intermediate notion of stability from $C(\overline{\Omega})$ to $L_p(\Omega)$, and the bootstrapping of $L_p(\Omega)$ estimates to $L_\infty(\Omega)$.

We should point out the phenomena of diffusion driven instabilities. It is well known that the addition of diffusion can destabilize constant steady states; see, e.g., [3] and [18]. Therefore, we shall be lead to the conclusion that the systems of ordinary differential equations which admit diffusion-driven instability do not have a Lyapunov structure of the type to be described.

Our subsequent development consists of five sections. In addition to detailing our hypotheses and outlining relevant theory, the second section introduces the central notion of stability from $C(\overline{\Omega})$ to $L_p(\Omega)$ and bootstraps this stability from $L_p(\Omega)$ to $L_\infty(\Omega)$. As such, the second section forms the theoretical basis of the paper. The third section introduces the notion of D-diffusively convex Lyapunov functionals and demonstrates the connection to the work in section 2. The fourth section is concerned with application of the theory. It begins by considering balanced two-component systems and then applies the theory to dissipative chemical systems and Lotka–Volterra systems. We conclude with some general comments and remarks.

We conclude this section with two remarks. First, our result gives a partial answer to Martin's original question. We determine that balanced, quasi-positive reaction-diffusion systems subject to homogeneous Neumann boundary conditions have global solutions for all choices of continuous, sufficiently small, nonnegative initial data. Second, we have limited our discussion to the case of homogeneous Neumann boundary conditions for the following reason. If all components of our system satisfy strictly dissipative boundary conditions, such as homogeneous Dirichlet or homogeneous Robin, then the presence of a separable Lyapunov structure along with these boundary conditions allows one to employ linearized stability arguments to obtain asymptotic stability. In the case of a mixture of homogeneous Neumann boundary conditions and dissipative conditions (as mentioned above), the arguments follow our development.

2. Preliminaries and ∞–r stability. In what follows, Ω shall be a bounded domain in $\mathbb{R}^n$ that lies locally on one side of its $C^{2+\alpha}$ boundary $\partial\Omega$. We shall always assume that the initial data $u_0 = (u_{0_1}, \ldots, u_{0_m})^T \in C(\Omega)^m$ and that the vector field $f = (f_i)_{i=1}^m$ has the property that

$$f \in C^1(\mathbb{R}^m; \mathbb{R}^m). \tag{2.1}$$

However, we make no assumptions concerning the growth rates of the individual components f_i of f. The symbol D will denote an $m \times m$ diagonal matrix with distinct entries $d_i > 0$, $i = 1$ to m, along the diagonal. We point out that all results contained herein would trivialize were we to assume that the d_i's are identical. We hope that we shall not introduce undue confusion by using the symbol "Δ" to denote both the vector and the scalar Laplacian. Equations without subscripts will typically denote vector equations and nonsubscripted scalar equations shall be specifically referred to as such.

In our general discussion, we use the notation $z_0 = (z_{0_1}, \ldots, z_{0_m})^T \in \mathbb{R}^m$ to denote an equilibrium point (or steady state) of (1.1). Namely, we have

$$f(z_0) = 0. \tag{2.2}$$

A closed subset of $M \subseteq \mathbb{R}^m$ will be called a forward invariant set for (1.2) if $u_0(x) = (u_{0_1}(x), \ldots, u_{0_m}(x))^T \in M$ for all $x \in \Omega$ implies that

$$u(x,t) = (u_1(x,t), \ldots, u_m(x,t)) \in M \tag{2.3}$$

for all $(x,t) \in \Omega \times [0, T_{\max})$. Here $[0, T_{\max})$ denotes the maximal interval of existence for solutions to the initial boundary value problem (1.2). We shall require that there exists a forward invariant set M (not necessarily bounded) for solutions to (1.2). Hence because the d_i's are assumed to be distinct, we assume that there exists a forward invariant m-cube

$$M = M_1 \times \cdots \times M_m \tag{2.4}$$

for (1.2), where each M_i, $i = 1$ to m, is a closed interval. *We point out that we have said nothing concerning the boundedness of M, and consequently we make no presuppositions concerning the global existence of solutions to* (1.2). For example, M may well be $\mathbb{R}^m_+$ (the positive orthant) or all of $\mathbb{R}^m$.

In what follows, the mild abuse of notation $v \in M$ will be used frequently to indicate that a function $v : \Omega \to \mathbb{R}^m$ has the property that $v(x) \in M$ for all $x \in \Omega$.

Our analysis will involve the standard Lebesgue spaces $L_p(\Omega)$, $p \geq 1$:

$$L_p(\Omega) = \left\{ u \;\middle|\; \int_\Omega |u|^p dx < \infty \right\}; \tag{2.5}$$

$$\|u\|_{p,\Omega} = \left(\int_\Omega |u|^p dx \right)^{1/p}. \tag{2.6}$$

We shall also want to consider the analogous spaces obtained with $0 < p < 1$. Although (2.6) does not define a norm on $L_p(\Omega)$ if $0 < p < 1$, we will use the same notation for the functional defined on $L_p(\Omega)$ by the right side of (2.6). If $p \geq 1$ and $k > 0$, then $W_p^{(k)}(\Omega)$ denotes the usual kth-order Sobolev space in $L_p(\Omega)$ and $W_p^{(2k,k)}(\Omega \times (\tau, T))$ denotes its analogue in $L_p(\Omega \times (\tau, T))$. For definitions of these spaces for both integral and nonintegral k, we refer the reader to [12].

We will need the following fractional-Sobolev-space embedding theorem of Amann [2].

Theorem 2.1. *Let $k \in \mathbb{N}$ and suppose that $\partial\Omega$ is uniformly regular of class C^k. If $0 \leq s' \leq s \leq k$ and $1 < p, q < \infty$, then $W_p^s(\Omega)$ embeds continuously in $W_q^{s'}(\Omega)$ whenever $1/p \geq 1/q$ and $s - (n/p) \geq s' - (n/q)$.*

We now introduce the notion of ∞–r stability. It will be a notion of stability with respect to M, which will allow us to consider steady states belonging to ∂M.

Definition 2.2. *Let $z_0 \in M$ be an equilibrium point of the vector field $f = (f_i)_{i=1}^m$ and let $0 < r \leq \infty$. Then z_0 is said to be uniformly ∞–r stable with respect to M if for all $\varepsilon > 0$ there exists a $\delta > 0$ such that $u_0 \in M$ and $\|u_{0_i} - z_{0_i}\|_{\infty,\Omega} < \delta$ for $i = 1$ to m imply*

(i) *a classical solution to (1.2) exists on $\Omega \times [0, \infty)$;*

(ii) *$\|u_{0_i}(\cdot\,, t) - z_{0_i}\|_{r,\Omega} < \varepsilon$ for $i = 1$ to m and $t > 0$.*

An ∞–r stable equilibrium point $z_0 \in M$ is said to be uniformly ∞–r asymptotically stable if there exists a $\delta > 0$ such that $u_0 \in M$ and $\|u_i - z_{0_i}\|_{\infty,\Omega} < \delta$ for $i = 1$ to m imply

(iii) *$\lim_{t\to\infty} \|u_i(\cdot\,, t) - z_{0_i}\|_{r,\Omega} = 0$ for $i = 1$ to m.*

The usual notions of stability with respect to M now correspond to ∞–∞ stability with respect to M as stated formally in the following definition.

Definition 2.3. *An equilibrium point $z_0 \in M$ is said to be uniformly stable with respect to M if it is uniformly ∞–∞ stable with respect to M. A stable equilibrium point $z_0 \in M$ is said to be uniformly asymptotically stable with respect to M if it is uniformly ∞–∞ asymptotically stable with respect to M.*

We shall see in what follows that the notion of ∞–r stability is intermediate and may be subsumed by the notion of stability. For a given point $v_0 \in \mathbb{R}^m$, let the symbol $C_\eta(v_0)$ denote the m-dimensional cube centered at v_0 with diameter $2\sqrt{m}\,\eta$ and $B_\delta(v_0)$ denote the m-dimensional ball of radius δ about v_0. We remark that $C_\varepsilon(v_0) \subseteq B_{\sqrt{m}\,\varepsilon}(v_0)$. The analysis that follows will require "cutoff" functions $\varphi_{\eta,v_0} \in C^\infty(\mathbb{R}^m; [0, 1])$, defined for $\eta > 0$ by

$$\begin{aligned} &\varphi_{\eta,v_0}(u) = 1 \quad \text{for } u \in C_\eta(v_0), \\ &\varphi_{\eta,v_0}(u) = 0 \quad \text{for } u \in \mathbb{R}^m \setminus C_{2\eta}(v_0). \end{aligned} \tag{2.7}$$

If $z_0 \in M$ is an equilibrium point, we truncate the vector field f by componentwise multiplication by φ_{η,z_0} for $\eta > 0$, i.e., we define $f[\eta, z_0] = (f_i[\eta, z_0])_{i=1}^m$ by

$$f_i[\eta, z_0](u) = \varphi_{\eta,z_0}(u) f_i(u). \tag{2.8}$$

Then solutions to the truncated system

$$\partial v/\partial t = D\Delta v + f[\eta, z_0](v) \quad \text{on } \Omega \times (0, \infty), \tag{2.9a}$$

$$\partial v/\partial \mathbf{n} = 0 \quad \text{on } \partial\Omega \times (0, \infty), \tag{2.9b}$$

$$v(\cdot\,, 0) = v_0 \quad \text{on } \Omega, \tag{2.9c}$$

where $v_{0_i} = \varphi_{\eta,z_0}(u_0)u_{0_i}$, exist on $\Omega \times [0, \infty)$ and are globally bounded. Moreover, it is trivial to observe that if $z_0 \in M$ is an equilibrium point of f, then z_0 is also an equilibrium point of $f[\eta, z_0]$.

We now formally state a few simple observations concerning solutions to (2.9).

LEMMA 2.4. *If $\eta > 0$, $v_0 \in C(\overline{\Omega}; C_{2\eta}(z_0))$, and $f[\eta, z_0]$ is the vector field defined via* (2.8)*, then* (2.9) *has a unique classical solution on $\Omega \times [0, \infty)$. Moreover,*

(i) *$v(\cdot, t) \in C_{2\eta}(z_0) \cap M$ for $t \geq 0$;*

(ii) *if $v(\cdot, t) \in C_\eta(z_0) \cap M$ for $0 \leq t < T$, then $v(x, t) = u(x, t)$ for $(x, t) \in \Omega \times [0, T)$, where u is the solution to* (1.2).

Proof. We observe that $M \cap C_{2\eta}(z_0)$ is a bounded invariant region for (2.9) because the vector field $f[\eta, z_0]$ is identically zero exterior to $C_{2\eta}(z_0)$ and does not point out of M. Therefore, solutions to (2.9) exist globally and remain confined to $M \cap C_{2\eta}(z_0)$ for all time [21]. Classical uniqueness theory for parabolic equations together with the observation that $f[\eta, z_0]|_{C_\eta(z_0)} = f|_{C_\eta(z_0)}$ immediately confirms the second assertion. □

LEMMA 2.5. *If z_0 is uniformly ∞–r stable for* (2.9) *with respect to M for some $r \in (0, \infty)$, then z_0 is uniformly ∞–p stable for* (2.9) *with respect to M for all $p \in (0, \infty)$. Analogous results hold for uniform ∞–r asymptotic stability.*

Proof. If $0 < p < r$, the results follow easily by the Jensen inequality and the convexity of $g(z) = |z|^{r/p}$. If $r < p$, then because $g(z) = |z - z_{0_i}|^{p-r}$ is bounded above by $(2\sqrt{m}\,\eta)^{p-r}$ on $C_{2\eta}(z_0)$ and since $v(x, t) \in C_{2\eta}(z_0)$ for all $(x, t) \in \Omega \times (0, \infty)$, we have

$$(2.10) \qquad |v_i - z_{0_i}|^p \leq (2\sqrt{m}\,\eta)^{p-r} |v_i - z_{0_i}|^r \quad \text{on } \Omega \times (0, \infty),$$

from which the desired results follow. □

The next theorem provides the foundation of our development. It states that ∞–r stability of the truncated system (2.9) guarantees ∞–∞ stability of the original system (1.2).

THEOREM 2.6. *Let $z_0 \in M$ be an equilibrium point of the vector field f. If $r > 0$ and z_0 is a uniformly ∞–r stable equilibrium point for* (2.9)*, then z_0 is a uniformly stable solution for* (1.2)*. Analogous results hold for uniformly ∞–r asymptotic stability.*

Proof. We begin by fixing $\eta > 0$. If we are able to choose $\delta > 0$ so that solutions to (2.9) have the property that $v_0 \in C_\delta(z_0)$ implies that $v(x, t) \in C_\varepsilon(z_0)$, where $\varepsilon < \eta$, then solutions to (2.9) and (1.2) coincide. Therefore, it will suffice to demonstrate that uniformly ∞–r stable solutions of (2.9) are uniformly stable solutions of (2.9).

By virtue of Lemma 2.5 with $p = 2$, we know that there exists a continuous function $\tilde{\rho}_1$ with $\tilde{\rho}_1(0) = 0$ and $\tilde{\rho}_1(s) > 0$ for $s > 0$ such that for $i = 1$ to m and $t \in [0, \infty)$,

$$(2.11) \qquad \|v_i(\cdot, t) - z_{0_i}\|_{2,\Omega} \leq \tilde{\rho}_1(\|v_0 - z_0\|_{\infty,\Omega}).$$

We shall demonstrate via an iteration scheme that there exists a continuous function ρ with $\rho(0) = 0$ and $\rho(s) > 0$ such that for $i = 1$ to m and $t \in [0, \infty)$, we have

$$(2.12) \qquad \|v_i(\cdot, t) - z_{0_i}\|_{\infty,\Omega} \leq \rho(\|v_0 - z_0\|_{\infty,\Omega}),$$

and we shall thereby obtain our desired conclusion. Toward this end, we set

$$(2.13) \qquad w(x, t) = v(x, t) - z_0$$

and multiply the ith component of (2.9a) by w_i to obtain

$$w_i \partial w_i/\partial t - w_i d_i \Delta w_i = w_i f_i[\eta, z_0](v). \tag{2.14}$$

Because $f[\eta, z_0]$ is Lipschitz, there exists an N such that integration of (2.14) on the space–time cylinder $\Omega \times (\tau, T)$ yields

$$\begin{aligned} &\frac{1}{2}\|w_i(\cdot\,, T)\|_{2,\Omega}^2 + d_i \int_\tau^T \int_\Omega |\nabla w_i|^2 dx dt \\ &\quad\le \frac{1}{2}\|w_i(\cdot\,, \tau)\|_{2,\Omega}^2 + N \sum_{k=1}^m \int_\tau^T \int_\Omega |w_i||w_k| dx dt. \end{aligned}$$

This implies that if $\tau \ge 0$ and $\tau + 1 < T < \tau + 3$, then

$$\begin{aligned} &\frac{1}{2}\|w_i(\cdot\,, T)\|_{2,\Omega}^2 + d_i \int_{\tau+1}^T \int_\Omega |\nabla w_i|^2 dx dt \\ &\quad\le \frac{1}{2}\|w_i(\cdot\,, \tau)\|_{2,\Omega}^2 + N \sum_{k=1}^m \max_{[\tau,\, \tau+3]} \int_\Omega |w_i||w_k| dx. \end{aligned} \tag{2.15}$$

After applying Young's inequality and (2.11) to the right side of (2.15) and the mean-value theorem for integrals to the t-integral on the left side, we construct an increasing sequence $\{T_{1,j}\}_{j=1}^\infty$ with

$$T_{1,1} \le 3 \quad \text{and} \quad 1 < T_{1,j+1} - T_{1,j} < 3 \quad \forall j \in \mathbb{N} \tag{2.16}$$

and a continuous function ρ_1 with $\rho_1(0) = 0$ and $\rho_1(s) > 0$ for $s > 0$ such that

$$\|w_i(\cdot\,, T_{1,j})\|_{2,\Omega}^{(1)} \le \rho_1(\|v_0 - z_0\|_{\infty,\Omega}) \quad \forall j \in \mathbb{N}. \tag{2.17}$$

Now we begin to make use of a well-known classical estimate for parabolic initial boundary value problems from Ladyženskaja, Solonnikov, and Uralćeva [12, p. 341]. More specifically, recall that if $1 < q < \infty$, $0 < \tau < T \le \tau + 3$, $\theta \in L^q(\Omega \times (\tau, T))$, $\phi_0 \in W_q^{2-2/q}(\Omega)$, and ϕ solves

$$\begin{aligned} \partial\phi/\partial t &= d_i \Delta\phi + \theta && \text{on } \Omega \times (\tau, T), \\ \partial\phi/\partial \mathbf{n} &= 0 && \text{on } \partial\Omega \times (\tau, T), \\ \phi(\cdot\,, \tau) &= \phi_0 && \text{on } \Omega, \end{aligned} \tag{2.18}$$

then there exists $c > 0$ such that

$$\|\phi\|_{q,\Omega\times(\tau,T)}^{(2,1)} \le c\Big[\|\theta\|_{q,\Omega\times(\tau,T)} + \|\phi_0\|_{q,\Omega}^{(2-2/q)}\Big], \tag{2.19}$$

where c depends only on d_i and Ω. Applying this parabolic regularity estimate with $q = 2$, we obtain a constant $c_1 > 0$ such that

$$\|w_i\|_{2,\Omega\times(T_{1,j},T_{1,j+1})}^{(2,1)} \le c_1 \Big(\|f_i[\eta, z_0](v)\|_{2,\Omega\times(T_{1,j},T_{1,j+1})} + \|w_i(\cdot\,, T_{1,j})\|_{2,\Omega}^{(1)}\Big). \tag{2.20}$$

We now claim that for every $k \in \mathbb{N}$, there exist

(i) a sequence $\{T_{k,j}\}_{j=1}^\infty$ such that $T_{k,1} \le k+2$ and $1 < T_{k,j+1} - T_{k,j} < 3$ $\forall j \in \mathbb{N}$,

(ii) a constant $c_k > 0$, and

(iii) a function $\rho_k \in C([0,\infty),[0,\infty))$ such that $\rho_k(0)=0$
such that for all $j \in \mathbb{N}$, the estimate

$$\|w_i\|^{(2,1)}_{q_k,\Omega\times(T_{k,j},T_{k,j+1})} \leq c_k\Big(\|f_i[\eta,z_0](v)\|_{q_k,\Omega\times(T_{k,j},T_{k,j+1})} + \rho_k(\|v_0-z_0\|_{\infty,\Omega})\Big) \tag{2.21}$$

is valid with $q_k = 2\big((n+2)/n\big)^{k-1}$.

To establish this claim, we begin by noting that (2.16), (2.17), and (2.20) combine to give the claim for $k=1$. We now proceed by induction on k. Suppose that the claim holds for $k=\ell\geq 1$ and consider the case where $k=\ell+1$. Since $f_i[\eta,z_0]$ is Lipschitz, we can use our hypothesis and Lemma 2.5 with $p=q_\ell$ to conclude from (2.21) that there exists a continuous function $\tilde{\rho}_\ell$ such that $\tilde{\rho}_\ell(0)=0$ and

$$\|w_i\|^{(2,1)}_{q_\ell,\Omega\times(T_{\ell,j},\,T_{\ell,j+4})} \leq \tilde{\rho}_\ell(\|v_0-z_0\|_\infty) \quad \forall j\in\mathbb{N}. \tag{2.22}$$

Note that $T_{\ell,j+4}-T_{\ell,j}>4$. Therefore, (2.22) implies the following inequalities:

$$\int_{T_{\ell,j}}^{T_{\ell,j}+1}\Big(\|w_i\|^{(2)}_{q_\ell,\Omega}\Big)^{q_\ell}dt,\ \int_{T_{\ell,j}+2}^{T_{\ell,j}+3}\Big(\|w_i\|^{(2)}_{q_\ell,\Omega}\Big)^{q_\ell}dt \leq \big[\tilde{\rho}_\ell(\|v_0-z_0\|_{\infty,\Omega})\big]^{q_\ell}. \tag{2.23}$$

Consequently, we can construct a sequence $\{T_{\ell+1,j}\}_{j=1}^\infty$ with

$$T_{\ell,k} < T_{\ell+1,2k-1} < T_{\ell,k}+1 \quad \text{and} \quad T_{\ell,k}+2 < T_{\ell+1,2k} < T_{\ell,k}+3 \tag{2.24}$$

such that

$$\|w_i(\cdot\,,T_{\ell+1,j})\|^{(2)}_{q_\ell,\Omega} \leq \tilde{\rho}_\ell(\|v_0-z_0\|_\infty) \quad \forall j\in\mathbb{N}. \tag{2.25}$$

We now apply Theorem 2.1 to conclude that $W^{(2)}_{q_\ell}(\Omega)$ imbeds continuously into $W^{(2-2/q_{\ell+1})}_{q_{\ell+1}}(\Omega)$. Therefore, there exists $\rho_{\ell+1}\in C([0,\infty),[0,\infty))$ such that $\rho_{\ell+1}(0)=0$ and

$$\|w_i(\cdot\,,T_{\ell+1,j})\|^{(2-2/q_{\ell+1})}_{q_{\ell+1},\Omega} \leq \rho_{\ell+1}(\|v_0-z_0\|_\infty) \quad \forall j\in\mathbb{N}. \tag{2.26}$$

Now by combining (2.26) with the parabolic regularity estimate in (2.19), we see that our claim is true for $k=\ell+1$, thus establishing the claim for all $k\in\mathbb{N}$.

Now with k taken such that $q_k>(n+2)/2$, we have from [12] that there exists $C>0$ such that

$$\|w\|_{\infty,\Omega\times(T_{k,j},T_{k,j+1})} \leq C\|w\|^{(1,2)}_{q_k,\Omega\times(T_{k,j},T_{k,j+1})} \quad \forall j\in\mathbb{N}.$$

Therefore, if we combine this with our claim above, we find that there exists a continuous function $\tilde{\rho}_k$ such that $\tilde{\rho}_k(0)=0$ and

$$\|w\|_{\infty,\Omega\times(T_{k,j},\,T_{k,j+1})} \leq \tilde{\rho}_k(\|v_0-z_0\|_\infty) \quad \forall j\in\mathbb{N}.$$

However, $T_{k,1}\leq k+2$, so

$$\|w\|_{\infty,\Omega\times[k+2,\infty)} \leq \tilde{\rho}_k(\|v_0-z_0\|_\infty). \tag{2.27}$$

We now recall that the operator $-d_i\Delta$ with homogeneous Neumann boundary conditions generates a nonexpansive analytic semigroup $T_i(t)$ on $C(\overline{\Omega})$; see Stewart [22]. Therefore, we have

$$\begin{aligned} w_i(t) &= T_i(t)(v_{0_i} - z_{0_i}) + \int_0^t T_i(t-s) f_i[\eta, z_0](v(\cdot\,, s))ds \\ &= T_i(t)(v_{0_i} - z_{0_i}) + \int_0^t T_i(t-s)\Big(f_i[\eta, z_0](v(\cdot\,, s)) - f_i[\eta, z_0](z_0)\Big)ds, \end{aligned}$$

which implies that

$$\|w_i(t)\|_{\infty,\Omega} \le \|v_0 - z_0\|_{\infty,\Omega} + \int_0^t K_\eta \|w(\cdot\,, s)\|_{\infty,\Omega} ds.$$

Therefore, since $\|w(\cdot\,,t)\|_{\infty,\Omega} = \max_{1\le i\le m} \|w_i(\cdot\,,t)\|_{\infty,\Omega}$, we have

$$\|w(\cdot\,,t)\|_\infty \le e^{K_\eta t}\|v_0 - z_0\|_\infty.$$

Consequently, because of (2.27) we have

$$\|w\|_{\infty,\Omega\times\mathbb{R}_+} \le \max\left\{e^{K_\eta(k+2)}\|v_0 - z_0\|_\infty,\ \tilde{\rho}_k(\|v_0 - z_0\|_\infty)\right\}. \tag{2.28}$$

Finally, since $\eta > 0$ is fixed, for any $\varepsilon \in (0, \eta)$ there exists $\delta > 0$ such that

$$\|v_0 - z_0\|_\infty < \delta \ \text{ implies } \ \|v - z_0\|_{\infty,\Omega\times\mathbb{R}_+} = \|w\|_{\infty,\Omega\times\mathbb{R}_+} < \varepsilon. \qquad \square$$

We point out that if z_0 is not a constant, we can modify the preceding arguments as follows. Suppose that $z_0 = w$ is a smooth function satisfying

$$-D\Delta w = f(w) \quad \text{on } \Omega, \tag{2.29a}$$

$$\partial w/\partial \mathbf{n} = 0 \quad \text{on } \partial\Omega \tag{2.29b}$$

In a manner similar to what was done above, the vector field may be truncated in a rectangular neighborhood containing $\{w(x) \mid x \in \Omega\}$. For $\eta > 0$, let $b_1(\eta, w)$ be an m-dimensional cube such that $w \in \text{int} b_1(\eta, w)$ with $\eta = \inf_{x\in\Omega} \operatorname{dist}(w(x), \partial b_1(\eta, w))$, and let $b_2(\eta, w)$ denote the m-cube concentric to $b_1(\eta, w)$ with twice the diameter. We mollify the characteristic function of $b_1(\eta, w)$ to produce a nonnegative function $\varphi_{\eta,w}$ such that

(i) $\varphi_{\eta,w} \in C^\infty(\mathbb{R}^m; [0, 1])$,
(ii) $\varphi_{\eta,w}(u) = 1$ if $u \in b_1(\eta, w)$, and
(iii) $\varphi_{\eta,w}(u) = 0$ if $u \in \mathbb{R}^m \setminus b_2(\eta, w)$,

and thus produce a corresponding truncated system (cf. (2.8) and (2.9)):

$$\begin{aligned} &\partial v/\partial t = D\Delta v + f[\eta, w](v) && \text{on } \Omega \times (0, \infty), \\ &\partial v/\partial \mathbf{n} = 0 && \text{on } \partial\Omega \times (0, \infty), \\ &v(\cdot\,, 0) = \varphi_{\eta,w}(u_0)u_0 && \text{on } \Omega. \end{aligned} \tag{2.30}$$

If $\mu = v - w$ and η is chosen such that $\eta > \|w\|_\infty$, we have

$$\begin{aligned} &\partial\mu_i/\partial t = d_i\Delta\mu_i + f_i[\eta, w](v) - f_i[\eta, w](w) && \text{on}\Omega \times (0, \infty), \\ &\partial\mu_i/\partial \mathbf{n} = 0 && \text{on}\partial\Omega \times (0, \infty), \\ &\mu_i(x, 0) = v_{0_i} - w_i && \text{on}\Omega. \end{aligned}$$

Then it is not difficult to establish an analogue of Lemma 2.4 and deduce that global solutions to (2.30) exist and that if they are sufficiently close to w, they satisfy (2.30). The following result concludes this section. Its proof is essentially a verbatim repetition of the one given for Theorem 2.6.

THEOREM 2.7. *Let $w \in M$ be a classical, spatially nonhomogeneous solution to the elliptic system* (2.29). *If $r > 0$ and w is a uniformly ∞–r stable steady state of* (2.30)*, then w is a uniformly stable steady-state solution of* (1.2). *Analogous results hold for uniformly ∞–r asymptotically stable solutions.*

We remark that an interesting reference pertaining to (2.29) is Matano [15].

3. *D*-diffusively convex Lyapunov functionals.

The most common tool for analyzing he local stability of equilibrium points for systems of ordinary differential equations of the form of (1.1) is the principle of linearized stability. If all the eigenvalues of the derivative of f at z_0 have negative real part, then z_0 is locally asymptotically stable. On the other hand, if any of the eigenvalues have positive real part, then the equilibrium point z_0 is unstable. These ideas carry over to the context of semilinear parabolic equations; see, e.g., [9]. In the case of nonhyperbolic equilibrium points, however, linearization methods do not apply.

Questions of nonlinear stability are frequently resolved by Lyapunov's direct method. Roughly speaking, a Lyapunov function V is a nonnegative functional which is defined and continuously differentiable in a neighborhood of a equilibrium point z_0 and is uniquely minimized in that neighborhood by z_0. If

$$\dot{V}(u) = \partial V(u) f(u) \leq 0 \tag{3.1}$$

in this neighborhood, then it follows that z_0 is a stable equilibrium point. Asymptotic stability can be deduced from conditions such as

$$\dot{V}(u) < -\alpha V(u) \tag{3.2}$$

for some $\alpha > 0$. In certain cases, a Lyapunov functional satisfying (3.1) in a neighborhood of an equilibrium point of a system of ordinary differential equations is useful in the context of the associated reaction-diffusion system. For this purpose, we introduce the notion of D-diffusively convex Lyapunov functionals for reaction-diffusion systems.

DEFINITION 3.1. *Let D be the matrix of diffusion coefficients for* (1.2) *and suppose that M is a forward invariant rectangle* (*possibly unbounded*) *for* (1.2). *If $z_0 \in M$ is an equilibrium point of f, we say that a nonnegative functional V is a D-diffusively convex Lyapunov functional around z_0 provided that the following conditions hold:*

(i) *There exists a $\xi > 0$ such that $V \in C^2(M \cap B_\xi(z_0); \mathbb{R}^+)$.*

(ii) *There exist constants $r > 0$ and $K > 0$ such that*

$$V(u) \geq K \sum_{i=1}^{m} |u_i - z_{0_i}|^r \quad \textit{for } u \in B_\xi(z_0) \cap M.$$

(iii) $V(z_0) = 0$.

(iv) *The matrix $D\partial^2 V(u)$ is positive semidefinite for $u \in B_\xi(z_0) \cap M$.* (*Here $\partial^2 V(u)$ is the Hessian matrix of V.*)

(v) $\partial V(u) f(u) \leq 0$ *for $u \in B_\xi(z_0) \cap M$.*

We remark that conditions (i)–(iii) and (v) are essentially those which define a Lyapunov functional for (1.1) around z_0 and that condition (iv) represents an additional strengthening of the concept. If the functional V is separable, i.e.,

$$V(u) = \sum_{i=1}^{n} V_i(u_i), \tag{3.3}$$

then we may ensure (iv) by assuming that $V_i''(u_i) \geq 0$. In general, however, convexity of V does not suffice for condition (iv). It is relatively straightforward to see that D-diffusively convex Lyapunov functionals guarantee the persistence of stability of equilibrium points. We have the following theorem.

THEOREM 3.2. *Let $z_0 \in M$ be an equilibrium point for the vector field f, where M is a forward invariant set for the semilinear parabolic system* (1.2). *If there exists a D-diffusively convex Lyapunov functional V for f around z_0, then z_0 is a stable steady state for* (1.2) *with respect to M. Moreover, if V also satisfies* (3.2), *then z_0 is asymptotically stable with respect to M.*

Proof. We choose $\eta > 0$ so that the cube $C_{2\eta}(z_0)$ is contained in $B_\xi(z_0)$, and we construct the truncated vector field $f[\eta, z_0]$ as in (2.8) and (2.9). If $v_0(x) \in C_{2\eta}(z_0) \cap M$ for $x \in \Omega$, it is immediately verified that

$$\partial V(v(x,t)) f(v(x,t)) = \partial V(v(x,t)) f[\eta, z_0](v(x,t)) \leq 0. \tag{3.4}$$

If we multiply the ith component of (2.9a) by $\partial V(v)/\partial v_i$, we obtain

$$(\partial V(v)/\partial v_i) \partial v_i/\partial t = d_i (\partial V(v)/\partial v_i) \Delta v_i + (\partial V(v)/\partial v_i) f_i[\eta, z_0](v). \tag{3.5}$$

If we integrate this expression on the space–time cylinder and sum the components, we observe that

$$\begin{aligned} \int_\Omega V(v(x,t))dx = &- \int_0^T \int_\Omega (\nabla v)^T D \partial^2 V(v) \nabla v dx dt \\ &+ \int_0^t \int_\Omega \partial V(v) f[\eta, z_0](v) dx + \int_\Omega V(v_0(x))dx. \end{aligned}$$

Hence by virtue of conditions (iv) and (v) in Definition 3.1, we have

$$\int_\Omega V(v(x,t))dx \leq \int_\Omega V(v_0(x))dx. \tag{3.6}$$

Using (3.6) and the coercivity of V, we get

$$\begin{aligned} K \left[\sum_{i=1}^{m} \|v_i(\cdot\,, t) - z_{0,i}\|_{r,\Omega} \right] &\leq \left[\int_\Omega V(v(x,t))dx \right]^{1/r} \\ &\leq \left[\int_\Omega V(v_0(x))dx \right]^{1/r} \\ &\leq \rho \left(\sum_{i=1}^{m} \|v_{0_i} - z_{0_i}\|_{\infty,\Omega} \right) \end{aligned} \tag{3.7}$$

for some continuous ρ with $\rho(0) = 0$ and $\rho(s) > 0$ for $s > 0$. This will ensure ∞–r stability, and from Theorem 2.6 we may conclude that z_0 is stable. Finally, in case

(3.2) holds, we take v_0 sufficiently close to z_0 to guarantee that our solution stays close to z_0 for all $t > 0$. Then we can obtain the estimate

$$\int_\Omega V(v(x,t))dx \leq e^{-\alpha t} \int_\Omega V(v_0(x))dx, \tag{3.8}$$

and from this follows the asymptotic stability assertion. □

In view of Theorem 2.7, one can naturally be lead to attempt to use D-diffusively convex Lyapunov functions to analyze the stability of spatially nonhomogeneous steady-state solutions. The following simple proposition squashes this endeavor for large classes of dynamical systems.

PROPOSITION 3.3. *Let M be a forward invariant set for* (1.2) *and let $V(v) = \sum_{i=1}^m V_i(v_i)$ be a nonnegative separable function which satisfies the defining hypotheses of Definition* 3.1, *except possibly* (ii) *and* (iii), *for all points of M. If $w = (w_1, \ldots, w_m)^T \in M$ is a solution to* (2.29), *then the following are true:*

(i) *If there exists $\alpha > 0$ such that $V_i''(v_i) > \alpha$ for all $v = (v_1, \ldots, v_m)^T \in M$, then $f(w) = 0$.*

(ii) *If $V(v) = \sum_{i=1}^m c_i v_i$, $\partial V(v) f(v) \leq 0$ and $M \subseteq \mathbb{R}_+^m$, then there exists a $k > 0$ such that $y(x) = \sum_{i=1}^m c_i d_i w_i(x) = k$ for all $x \in \Omega$, i.e., $w(x)$ belongs to a closed bounded subset of the hyperplane $\{v \mid \Sigma c_i d_i v_i = k\} \cap \mathbb{R}_+^m$.*

Proof. In the first case, we multiply the ith component of (2.29a) by $V_i'(w_i)$ to obtain

$$-d_i V_i'(w_i) \Delta w_i = V_i'(w_i) f_i(w). \tag{3.9}$$

If we sum these terms and integrate on Ω, we have

$$\sum_{i=1}^m d_i \int_\Omega V_i''(w_i) |\nabla w_i|^2 dx = \sum_{i=1}^n \int_\Omega V_i'(w_i) f_i(w) dx \leq 0. \tag{3.10}$$

Consequently,

$$\sum_{i=1}^m \alpha d_i \int_\Omega |\nabla w_i|^2 dx = 0, \tag{3.11}$$

and we may conclude that each w_i is a constant. Therefore, because $w = (w_1, \ldots, w_n)^T$ is a solution to (2.29), we must have $f_i(w) = 0$. If we follow the same train of reasoning for the second case, then we observe that $-\Delta(\Sigma c_i d_i w_i) \leq 0$. The fact that M is required to lie in $\mathbb{R}_+^m$ implies that $\Sigma d_i w_i \geq 0$, and hence we conclude from maximum principles that $\nabla(\Sigma c_i d_i w_i)$ vanishes and $\Sigma c_i d_i w_i(x) = k$ for some constant $k \geq 0$. Thus $w(x)$ lies in the hyperplane $\{v \mid \Sigma c_i d_i v_i = k\}$. The continuity of y implies that its range is closed and bounded. □

As a closing remark for this section, we point out that an additional treatment of Lyapunov theory in the context of reaction-diffusion systems can be found in [20].

4. Applications.

We begin by considering of the two-component system

$$\begin{aligned}
&\partial u/\partial t - d_1 \Delta u = -f(u,v) && \text{on } \Omega \times (0,\infty),\\
&\partial v/\partial t - d_2 \Delta v = f(u,v) && \text{on } \Omega \times (0,\infty),\\
&\partial u/\partial \mathbf{n} = \partial v/\partial \mathbf{n} = 0 && \text{on } \partial\Omega \times (0,\infty),\\
&u(\,\cdot\,,0) = u_0(\,\cdot\,), \qquad v(\,\cdot\,,0) = v_0(\,\cdot\,) && \text{on } \Omega,
\end{aligned} \tag{4.1}$$

where $f \in C^2(\mathbb{R}^2_+; \mathbb{R}_+)$ and $f(0,v) = 0$ for all $v \in \mathbb{R}_+$. Here we assume that the initial data u_0 and v_0 are continuous and nonnegative on $\overline{\Omega}$. It may be surprising that questions concerning the global existence of solutions to this system remain open. If the nonlinearity f is polynomially bounded, then it is known [10] that solutions to (4.1) exist for all time and remain uniformly bounded in the $L_\infty(\Omega)$ norm. Analogous results [8] have also have been obtained in the case where the nonlinearity is of the form

$$f(u,v) = u\varphi(v), \tag{4.2}$$

where φ need not be polynomially bounded but is required to grow less than exponentially, e.g., $\varphi(v) = e^{\sqrt{v}}$.

We are able to establish a simple result concerning the stability of the steady state $(0, \tilde{v})$ for (4.1).

PROPOSITION 4.1. *If $\tilde{v} \geq 0$, then the constant solution $(u,v) = (0,\tilde{v})$ is a stable equilibrium point for* (4.1) *with respect to $\mathbb{R}^2_+$.*

Proof. By assumption, $f(0,\tilde{v}) = 0$, and hence $(0,\tilde{v})$ is a steady-state solution of the system. In the case where $\tilde{v} = 0$, the result follows by noting that $\mathbb{R}^2_+$ is an invariant m-cube for the system, that ∞–1 stability follows from integrating each equation on the space–time cylinder and adding them to obtain the conservation law

$$\int_\Omega (u(x,t) + v(x,t))dx = \int_\Omega (u_0(x) + v_0(x))dx, \tag{4.3a}$$

and that $V = u + v$ defines a D-diffusively convex Lyapunov functional around $(0,0)$ with respect to $\mathbb{R}^2_+$. Now suppose that $\tilde{v} > 0$ and let $0 < \varepsilon < \tilde{v}$. Maximum principles demonstrate that solutions which initially lie in $M_\varepsilon = \{(u,v) \mid u \geq 0,\ v \geq \tilde{v} - \varepsilon\}$ remain so. The conservation law

$$\int_\Omega (u(x,t) + v(x,t) - (\tilde{v} - \varepsilon))dx = \int_\Omega (u_0(x) + v_0(x) - (\tilde{v} - \varepsilon))dx \tag{4.3b}$$

follows as before. Thus if the initial data are close to $(0, \tilde{v} - \varepsilon)$ in the L^∞ norm, then the solution remains close in the L^1 norm. Also, $V = u + v - (\tilde{v} - \varepsilon)$ defines a D-diffusively convex Lyapunov functional around $(0, \tilde{v} - \varepsilon)$ with respect to M_ε. Consequently, ∞–1 stability implies uniform stability with respect to M_ε. Therefore, it follows that solutions in $\mathbb{R}^m_+$ can be made to remain uniformly close to $(0, \tilde{v})$. □

We hope that we do not belabor the issue by pointing out that the system

$$\begin{aligned} \partial u/\partial t &= d_1 \Delta u - u e^{kv^\gamma}, \\ \partial v/\partial t &= d_2 \Delta v + u e^{kv^\gamma}, \end{aligned} \tag{4.4}$$

for example, with $\partial u/\partial \mathbf{n} = \partial v/\partial \mathbf{n} = 0$ on $\partial\Omega$ and any $\gamma \geq 1$ satisfies the hypotheses and hence admits $(0,\tilde{v})$ as a stable solution with respect to M as above whenever $\tilde{v} \geq 0$.

We now focus on a general class of diffusive Lotka–Volterra systems. Typically, Lotka–Volterra systems feature quadratic nonlinearities. They are intended to describe the species interaction among m-species ecological systems. Here we follow the development of Leung [13] and consider systems of the form

$$\begin{aligned} &\partial u/\partial t = D\Delta u + U(e + Pu) && \text{on } \Omega \times (0,\infty), \\ &\partial u/\partial \mathbf{n} = 0 && \text{on } \partial\Omega \times (0,\infty), \\ &u(\,\cdot\,, 0) = u_0(\,\cdot\,), && \text{on } \Omega, \end{aligned} \tag{4.5}$$

where $U = \operatorname{diag}\{u_1, \dots, u_m\}$, $e = (e_1, \dots, e_m)^T$ is a constant vector, and $P = (p_{ij})$ is an $m \times m$ matrix with constant entries. We assume that the following conditions are satisfied.

$(\mathrm{LV})_1$ There is a vector $q = (q_1, \dots, q_m)^T$, with each $q_i > 0$, that solves the linear system

$$e + Pq = 0. \tag{4.6}$$

$(\mathrm{LV})_2$ For each q satisfying (4.6) there is a diagonal matrix $A = \operatorname{diag}\{a_1, \dots, a_m\}$, with each $a_i > 0$, such that for all $w \in \mathbb{R}^m$,

$$(Aw)^T Pw = \sum_{i,j=1}^{m} a_i w_i p_{ij} w_j \leq 0. \tag{4.7}$$

Condition $(\mathrm{LV})_1$ guarantees the existence of a steady state with positive components. However, we have made no assumptions concerning the nonsingularity of the matrix P. Indeed, many Lotka–Volterra systems feature a multiplicity of positive steady states. The nonnegativity of the quadratic form (4.7) translates as weighted conservation of the interaction between the species of the system. Leung refers to this condition as admissibility.

The next lemma asserts that a well-known Lyapunov function for (4.5) provides a D-diffusively convex Lyapunov structure.

LEMMA 4.2. *There exists $\xi > 0$ such that the function V on $\mathbb{R}^m_+ \cap B_\xi(q)$ defined by*

$$V(v) = \sum_{i=1}^{m} V_i(v_i) = \sum_{i=1}^{m} \big(a_i(u_i - q_i) - a_i q_i \log(u_i/q_i)\big) \tag{4.8}$$

is D-diffusively convex on $\mathbb{R}^m_+ \cap B_\xi(q)$.

Proof. If $B_\xi(q)$ does not intersect the coordinate hyperplanes of $\mathbb{R}^m_+$, then it is clear that V is continuously differentiable and nonnegative on $B_\xi(q)$. Moreover, it is clear that $V(q) = 0$, and a careful analysis will reveal that $K > 0$, $\xi > 0$, and $r > 0$ may be chosen so that hypothesis (ii) of Definition 3.1 holds. We observe that if $u \in \mathbb{R}^m_+$, then

$$\partial V(u) f(u) = (A(u - q))^T P(u - q) = \sum_{i,j=1}^{m} a_i(u_i - q_i) P_{ij}(u_j - q_j) \leq 0. \tag{4.9}$$

The separability of V and the observation that $V_i''(v_i) = a_i q_i / v_i$ complete the proof. □

We immediately have the following result.

PROPOSITION 4.3. *If $(\mathrm{LV})_1$ and $(\mathrm{LV})_2$ are satisfied, then the steady-state solution $q = (q_1, \dots, q_m)^T$ is stable. Moreover, the semilinear elliptic system*

$$\begin{aligned} -D\Delta w &= W(e + Pw) && \text{on } \Omega, \\ \partial w/\partial \mathbf{n} &= 0 && \text{on } \partial\Omega, \end{aligned} \tag{4.10}$$

where $W = \operatorname{diag}\{w_1, \dots, w_m\}$, has no spatially nonhomogeneous positive solutions.

Proof. Because $\mathbb{R}^m_+$ is an invariant m-cube for solutions to (4.5), Lemma 4.2 and Theorem 3.2 establish the first assertion. To establish the second assertion, we let M_1

be an m-cube which contains both $w \in \mathbb{R}^m_+$ and $q \in \mathbb{R}^m_+$ and does not intersect the coordinate hyperplanes of $\mathbb{R}^M_+$, and we let M_2 be a second m-cube which contains M_1 and also does not intersect the coordinate hyperplanes. Now let $\varphi \in C^\infty(\mathbb{R}^m; \mathbb{R}_+)$ be such that $\varphi(u) = 1$ if $u \in M_1$ and $\varphi(u) = 0$ for $u \in \mathbb{R}^m \setminus M_2$. From the application of part (i) of Proposition 3.3 to the truncated system

$$\begin{aligned} -D\Delta w &= \varphi(w) W(e + Pw) \quad \text{on } \Omega, \\ \partial w/\partial \mathbf{n} &= 0 \qquad\qquad\qquad\quad\; \text{on } \partial\Omega, \end{aligned} \tag{4.11}$$

the remaining assertion follows directly. □

We mention that for $n \geq 3$, the question of global existence for (4.5) is in general unresolved. For spatial dimension one, global existence and uniform boundedness for solutions may be established by applying results in [16], and for $n = 2$, we are at least assured the existence of long-time solutions; see [17]. We mention this to underscore the point that global well-posedness theory for reaction-diffusion systems remains incomplete.

Differential equations which describe the dispersion and reaction of m chemical species are generally of the form

$$\partial u/\partial t = D\Delta u + f(u), \tag{4.12}$$

where the ith component of the dependent variable $u = (u_1, \ldots, u_m)^T$ represents the concentration density of the ith chemical species. The vector field $f = (f_i)_{i=1}^m$ is assumed to be in each component a polynomial function of the components of u and is intended to model the chemical reaction kinetics. In his study of dissipative chemical reactions [7], Gröger introduced the following hypothesis.

(G) There exists a vector $e = (e_1, \ldots, e_m)^T$ with each $e_i > 0$ such that $f(e) = 0$ and

$$\sum_{i=1}^m f_i(u) \log(u_i/e_i) \leq 0.$$

Furthermore, the quantity $\sum_{i=1}^m f_i(u) \log(u_i/e_i)$ is known to have the physical interpretation of being a suitably scaled rate of chemical dissipation, and work on the mathematical theory of reaction networks [11] confirms that many nontrivial systems satisfy this hypothesis. If the chemical species are required to remain confined to a reaction vessel for all time, the appropriate boundary conditions are given by

$$\partial u/\partial \mathbf{n} = 0 \quad \text{on } \partial\Omega \times (0, \infty). \tag{4.13}$$

Finally, a condition of the form

$$f_i(u) \geq 0 \quad \text{for all } u \in \mathbb{R}^m_+ \quad \text{with } u_i = 0 \tag{4.14}$$

together with the maximum principle ensures that $\mathbb{R}^m_+$ is a forward invariant set for (4.12). We have the following proposition.

Proposition 4.4. *We consider* (4.12) *together with the boundary conditions* (4.13). *If all the conditions describing a dissipative chemical reaction outlined above hold, then the steady state $u = e$ is uniformly stable. Moreover, the elliptic system*

$$\begin{aligned} -D\Delta w &= f(w) \quad \textit{on } \Omega, \\ \partial w/\partial \mathbf{n} &= 0 \qquad\;\; \textit{on } \partial\Omega \end{aligned} \tag{4.15}$$

has no spatially inhomogeneous positive solutions.

Proof. We define

$$V(u) = \sum_{i=1}^{m} V_i(u) = \sum_{i=1}^{m} (u_i \log(u/e_i) - u_i + e_i) \tag{4.16}$$

and verify that all of the conditions of Definition 3.1 hold locally about e. Consequently, Theorem 3.2 implies that e is uniformly stable. An argument analogous to the one of Proposition 4.3 ensures the nonexistence of positive spatially inhomogeneous steady states. □

The comments concerning the global well-posedness and boundedness of solutions to Lotka–Volterra systems also apply to this class of dissipative chemical systems.

In addition to satisfying $f(0) = 0$ and a condition of the form (4.4), many reaction-diffusion systems satisfy a linear balancing condition of the following form.

(B) There exist positive constants c_i for $i =$ to m such that for all $n \in \mathbb{R}^m_+$,

$$\sum_{i=1}^{m} c_i f_i(u) = 0.$$

In this case, an obvious generalization of Proposition 4.1 dictates the stability of the zero solution.

5. Further generalizations and concluding remarks. Our results tend to support the general hypothesis that the addition of diffusion to systems of ordinary differential equations which have D-diffusively convex Lyapunov functions does not create exotic spatial or temporal phenomena which did not originally exist. If this is indeed the case, then the presence of diffusion in these systems is irrelevant to their long-term dynamics, and any spatial phenomena produced by diffusion must be of a transient nature.

We need not have limited our consideration to diffusion mechanisms of the form $D\Delta u$. We could have allowed operators of the form

$$\sum_{j,k=1}^{n} \frac{\partial}{\partial x_k} \left(d^i_{jk}(x,t) \frac{\partial u_i}{\partial x_j} \right)$$

in each component. In this case, it is necessary to assume uniformly strong ellipticity along with smoothness conditions on coefficients and some conditions on the derivatives of the coefficients. In general, the arguments could become quite technical but should be tractable. We leave the details to the interested reader. Numerical experiments [4] with two-component systems which model exothermic chemical reactions indicate that quasi-linear diffusivities do have an effect on the intermediate dynamics of the systems.

The necessity that our forward invariant set M be an m-cube described by (2.4) is purely a consequence of assuming distinct diffusion coefficients and in no way actually enters into the preceding analysis. Other types of geometries can arise in situations where some of the diffusion coefficients are equal. As a simple example, consider a three-component model of the form

$$\begin{aligned} \partial u/\partial t - \Delta u &= -\alpha_1 f(u,v,w) && \text{on } \Omega \times (0,\infty), \\ \partial v/\partial t - \Delta v &= -\alpha_2 f(u,v,w) && \text{on } \Omega \times (0,\infty), \\ \partial w/\partial t - d\Delta w &= f(u,v,w) && \text{on } \Omega \times (0,\infty), \\ \partial u/\partial \mathbf{n} = \partial v/\partial \mathbf{n} &= \partial w/\partial \mathbf{n} = 0 && \text{on } \partial\Omega \times (0,\infty), \\ u(\,\cdot\,,0) &= u_0, \quad v(\,\cdot\,,0) = v_0, \quad w(\,\cdot\,,0) = w_0 && \text{on } \Omega, \end{aligned} \tag{5.1}$$

where $f \in C^2(\mathbb{R}^3_+;\mathbb{R}_+)$; $f(0,v,w) = f(u,0,w) = 0$ for all $u, v, w \in \mathbb{R}_+$; $\alpha_1, \alpha_2, d > 0$; and the initial data u_0, v_0, and w_0 are continuous and nonnegative on $\overline{\Omega}$. By the maximum principle, it follows that $\min_\Omega\{\alpha_1 v_0 - \alpha_2 u_0\} \le \alpha_1 v - \alpha_2 u \le \max_\Omega\{\alpha_1 v_0 - \alpha_2 u_0\}$ and $w \ge \min_\Omega w_0$. Consequently, if $z_1, z_3 \ge 0$, then the set

$$M_1 = \{(u,v,w) \mid \alpha_1 v - \alpha_2 u \le -\alpha_2 z_1, \quad v \ge 0, \quad w \ge z_3\}$$

is a forward invariant set for (5.1), and if $z_2, z_3 \ge 0$, then the set

$$M_2 = \{(u,v,w) \mid u \ge 0, \quad \alpha_1 v - \alpha_2 u \ge \alpha_1 z_2, \quad w \ge z_3\}$$

is a forward invariant set for (5.1). Now in a manner similar to the proof of Proposition 4.1, one can show that any point $(z_1, 0, z_3)$ with $z_1, z_3 \ge 0$ is stable with respect to M_1 and any point $(0, z_2, z_3)$ with $z_2, z_3 \ge 0$ is stable with respect to M_2. One can then continue to argue as in the proof of Proposition 4.1 that such equilibrium points are stable with respect to $\mathbb{R}^3_+$.

AN INVERSE PROBLEM FOR THE HYDRAULIC PROPERTIES OF POROUS MEDIA*

PAUL DuCHATEAU†

Abstract. An inverse problem is formulated to determine the two coefficients in the pressure head formulation of the porous flow equation from a simple hydraulic experiment. Integral identities are derived which relate changes in the coefficients to changes in measured outputs. These identities are used to precisely define the sense in which the experimental data are able to distinguish between different porous media. It is also shown that the mapping associating input coefficient values to output data values is explicitly invertible and that there is a related output least squares problem whose solution is the solution of the inverse problem.

Key words. inverse problems, parabolic equations, structural identification

Introduction. Flow in an unsaturated porous medium can be modeled by nonlinear partial differential equations in which the coefficients in the equation characterize the hydraulic properties of the medium. Treatment of such equations is simplified by assuming that the coefficients are functions of the unknown dependent variable only. This is equivalent to supposing the medium is homogeneous and isotropic, and in such cases it is feasible to seek coefficients which are characteristic of a specific porous medium [2, 5, 7, 10].

Since direct experimental measurement of hydraulic properties of porous media is often inconvenient, attempts have been made to obtain the properties indirectly by formulating and solving a suitable inverse problem. The goal of the indirect approach is to replace a difficult physical experiment by an inverse problem for which the input data are easy to measure and whose solution leads to the hydraulic properties of the medium. The requirement that the data be easy to measure suggests that the data should be dynamic rather than steady state and should be measured on the boundary of the physical domain [5, 12].

An obstacle to considering inverse problems involving nonlinear partial differential equations is the lack of an explicit solution for the so-called direct problem. One approach, referred to in the literature as the method of output least squares, seeks to avoid this obstacle by formulating the inverse problem as an optimization problem seeking coefficients which produce a solution for the differential equation that best matches some experimentally measured output [4, 11]. The appeal of the output least squares approach lies in the well-developed theory for dealing with optimization problems. On the other hand, it is usually not evident that the solution to the optimization problem solves the original inverse problem. In particular, the error functional may be based on data which do not uniquely determine the unknown coefficients. In [6, 8], examples are constructed which illustrate the difficulties with this approach.

This paper formulates an inverse problem to determine simultaneously the two coefficients in the pressure head formulation of the porous flow equation from a simple

hydraulic experiment. These coefficients, water capacity and hydraulic conductivity, characterize the hydraulic properties of a porous medium. Integral identities are derived which relate changes in the coefficients to changes in measured outputs. Using these identities it is possible to precisely define the sense in which the experimental data are able to distinguish between porous media. In addition it can be shown that a coefficient pair that optimizes an output least squares functional whose definition is based on the measured outputs of this inverse problem must necessarily also solve the inverse problem. Finally, the mapping associating coefficient values to output data values is shown to be explicitly invertible in a suitable class of coefficient pairs. More precisely, it is shown that if the measured data satisfy certain necessary conditions then it is possible to construct coefficients which approximately reproduce this output when used in the model equations. If the output is known to have been generated by a suitable coefficient pair, then it can be shown that the constructed coefficient pair approximates the actual coefficients.

Two experiments and the associated inverse problems are described here. In the first experiment, termed the phase one experiment, an initially saturated vertical column of soil is allowed to drain to equilibrium under gravity. Solution of the associated phase one inverse problem determines the hydraulic functions for the soil in the column over a portion of their domain. A second experiment, labeled phase two, leads to an inverse problem whose solution extends the portion of the domain over which the hydraulic functions are determined. These experiments are probably not unique but illustrate what seems to be an important feature for successful identification of unknown ingredients in partial differential equations where the ingredients are functions of the state variable only. The identification is considerably simplified if it is possible to construct an experiment where the boundary value of the state variable varies monotonically with time. In the two experiments described here, the boundary measurement of the pressure head $p(t) = h(0,t)$ is forced to behave monotonically; gravity is the driving force in phase one, and in the phase-two experiment it is the applied suction.

The organization of this paper is as follows. Section 1 establishes several essential facts about the solution of the so-called direct problem associated with the phase-one experiment and derives key integral identities for analyzing the inverse problem. Uniqueness and solvability results for the phase-one inverse problem are presented in section 2. Sections 3 and 4 repeat these procedures for the phase-two experiment.

1. The phase-one direct problem.

Consider a vertical soil column which is totally saturated and then allowed to drain under gravity. If there is no flow across the top end of the column and if the bottom end of the column is at the water table, then the capillary pressure head $h(z,t)$ can be shown to satisfy

$$
\begin{aligned}
&C(h)\partial_t h(z,t) = \partial_z(K(h)(\partial_z h(z,t) - 1)) && \text{for } 0 < z < L, \quad 0 < t < T,\\
&h(z,0) = 0 && \text{for } 0 < z < L,\\
&\partial_z h(0,t) - 1 = 0, \qquad h(L,t) = 0 && \text{for } 0 < t < T.
\end{aligned}
\tag{1.1}
$$

Here C and K denote the water capacity and hydraulic conductivity, respectively. The column is assumed to be of length L with $z = 0$ at the top of the column and $z = L$ at the bottom. For notational convenience, let $Q_T = \{(z,t)\colon\ 0 < z < L, 0 < t < T\}$.

Problem (1.1) will be called the phase-one direct problem. For suitable coefficients C and K this direct problem has a unique smooth solution [4, 9]. This solution is initially zero at each point and tends toward a steady state equal to the linear function $h(z) = z - L$, $0 < z < L$, as t tends to infinity. In point of fact, there is no finite time T at which $h(0, T)$ actually equals $-L$ but for every small positive ε there exists a finite time $T = T(\varepsilon)$ such that $h(0, T) = -L+\varepsilon$. Then as (z, t) ranges over Q_T, $h(z, t)$ takes its values in the interval $[-L + \varepsilon, 0]$ rather than in $(-L, 0)$. Recognizing this, the parameter T will nevertheless be assumed here to denote a fixed, large, positive number; the head values $h(z, t)$ will vary between zero and $-L$ during this phase of the experiment; and the ε will be omitted from subsequent discussions.

Coefficients C and K are said to be *admissible* if they satisfy

$$(1.2)\qquad \begin{aligned} &\text{(i)} \quad C\varepsilon\, \mathbb{C}(-\infty, 0] \quad \text{and} \quad 0 < c_0 \le C(h) \le c_1 \quad \text{for } h < 0,\\ &\text{(ii)} \quad K\varepsilon \text{ Piecewise}-\mathbb{C}^1(-\infty, 0] \quad \text{and} \quad 0 < k_0 \le K(h) \le k_1 \quad \text{for } h < 0. \end{aligned}$$

For each pair of admissible coefficients (C, K), the direct problem (1.1) has a unique solution $h(z, t)$ whose dependence on the coefficients will be indicated by the notation $h = \Psi_1[C, K]$. In a physical experiment in which a vertical column drains under gravity as described, it is relatively easy to measure the pressure head at the top of the column and to measure the flux or outflow at the bottom of the column. The draining of the column may be simulated by solving (1.1) for $h = \Psi_1[C, K]$, and the measured data then correspond to the computed functions

$$(1.3)\qquad p(t) = h(0, t) \quad \text{and} \quad q(t) = K(h(L, t))(\partial_z h(L, t) - 1) \quad \text{for } 0 < t < T.$$

The dependence of the outputs $p(t)$ and $q(t)$ on the coefficients C and K will be indicated by the notation $(p, q) = \Gamma \cdot \Psi_1[C, K]$. The notations $p = \Gamma_0 \cdot \Psi_1[C, K]$ and $q = \Gamma_L \cdot \Psi_1[C, K]$ indicate the association between the individual outputs and the coefficient pairs. This association defines the *coefficient-to-data mapping* for the phase-one experiment. Since the functions (p, q) are viewed as system outputs it is reasonable to expect that their properties are determined by, and must be deduced from, the equation and properties of the coefficients. These properties are of some interest in their own right, and they are essential to the analysis of the inverse problem described in subsequent sections of the paper. This first lemma characterizes the behavior of the output function $q(t)$ in the phase-one experiment.

LEMMA 1.1. *For admissible coefficients C and K, the output $q(t) = \Gamma_L \cdot \Psi_1[C, K]$ satisfies*

$$(1.4)\qquad q\varepsilon\mathbb{C}[0, T), \qquad q(0) = -K(0), \quad \text{and} \quad q(t) < 0 \quad \text{for } 0 < t < T.$$

Proof. The smoothness properties of the solution imply that $q(t)$ is continuous on $[0, T]$, and it then follows from the initial and boundary conditions that $q(0) = -K(0) \le -k_0$.

For $h = \Psi_1[C, K]$ and an arbitrary smooth function $\varphi(z, t)$,

$$(1.5)\qquad \iint_{Q_T} [\partial_t a(h(z, t)) - \partial_z(K(h)(\partial_z h(z, t) - 1))]\partial_z \varphi \, dz\, dt = 0,$$

where

$$a(h(z, t)) = \int_0^{h(z,t)} C(s)\, ds.$$

Then $\partial_t a(h(z,t)) = C(h)\partial_t h(z,t)$ and $a(h(z,0)) = 0$ for $h = \Psi_1[C,K]$. Integration by parts shows

$$\begin{aligned}\iint_{Q_T} \partial_t a(h(z,t))\partial_z\varphi\,dz\,dt &= \int_0^L a(h)\partial_z\varphi\Big|_{t=0}^{t=T} dz - \iint_{Q_T} a(h)\partial_{tz}\varphi\,dz\,dt\\ &= \iint_{Q_T} \partial_z hC(h)\partial_t\varphi\,dz\,dt - \int_0^T a(h)\partial_t\varphi\Big|_{z=0}^{z=L} dt\\ &\quad + \int_0^L a(h)\partial_z\varphi\Big|_{t=0}^{t=T} dz\end{aligned}$$

and

$$\begin{aligned}&\iint_{Q_T} [\partial_z(K(h)(\partial_z h(z,t)-1))]\partial_z\varphi\,dz\,dt\\ &\quad = \int_0^T (K(h)(\partial_z h(z,t)-1))\partial_z\varphi\Big|_{z=0}^{z=L} dt\\ &\qquad - \iint_{Q_T} (K(h)(\partial_z h(z,t)-1))\partial_{zz}\varphi\,dz\,dt.\end{aligned}$$

Then

$$\begin{aligned}&\iint_{Q_T} [(\partial_z h-1)(C(h)\partial_t\varphi + K(h)\partial_{zz}\varphi) + C(h)\partial_t\varphi]\,dz\,dt\\ &\quad = \int_0^T a(h)\partial_t\varphi + K(h)(\partial_z h-1)\partial_z\varphi\Big|_{z=0}^{z=L} dt - \int_0^L a(h)\partial_z\varphi\Big|_0^T dz.\end{aligned} \tag{1.6}$$

Now suppose $\varphi(z,t)$ solves the adjoint problem

$$\begin{aligned} C(h)\partial_t\varphi(z,t) + K(h)\partial_{zz}\varphi(z,t) &= 0 && \text{in } Q_T,\\ \varphi(z,T) &= 0, && 0 < z < L,\\ \varphi(0,t) &= 0, \qquad \partial_z\varphi(L,t) = \vartheta(t), && 0 < t < T\end{aligned}$$

for arbitrary smooth boundary input $\vartheta(t)$. Then

$$\begin{aligned} a(h(z,0)) &= 0 \quad\text{and}\quad a(h(L,t)) = 0,\\ \partial_t\varphi(0,t) &= 0 \quad\text{and}\quad \partial_z\varphi(z,T) = 0,\\ \partial_z h(0,t) - 1 &= 0,\end{aligned}$$

and it follows that (1.6) reduces to the following simple integral identity:

$$\int_0^T q(t)\vartheta(t)\,dt = \iint_{Q_T} C(h)\partial_t\varphi(z,t)\,dz\,dt.$$

Now choose the boundary input $\vartheta(t)$ in the adjoint problem such that $\vartheta(T) = 0$ and $\vartheta(t)$ is sufficiently large and positive for $0 < t < T$ that $\partial_{zz}\varphi(z,t) > 0$ on Q_T. Then $\partial_t\varphi(z,t) < 0$ on Q_T, and since $\vartheta(t)$ is otherwise arbitrary and $C(h(z,t)) \geq c_0 > 0$, it follows from the integral identity that $q(t) < 0$ almost everywhere on $[0,T]$.

Certain properties of the solution of the direct problem are needed if the integral identity arguments are to be used to analyze the inverse problem. The next lemma establishes one of these properties.

LEMMA 1.2. *For admissible coefficients $C(h)$ and $K(h)$, let $h = \Psi_1[C, K]$. Then $\partial_z h(z,t) - 1 < 0$ almost everywhere on Q_T.*

Proof. For $h = \Psi_1[C, K]$ and an arbitrary smooth function $\varphi(z,t)$, the basic integral identity (1.6) is valid. Suppose now that $\varphi(z,t)$ solves the adjoint problem

$$\begin{aligned} C(h)\partial_t\varphi(z,t) + K(h)\partial_{zz}\varphi(z,t) &= F(z,t) && \text{in } Q_T,\\ \varphi(z,T) &= 0, && 0 < z < L,\\ \varphi(0,t) = 0, \qquad \varphi(L,t) &= 0, && 0 < t < T. \end{aligned} \tag{1.7}$$

Since

$$a(h(z,0)) = 0, \quad \text{and} \quad \partial_z h(0,t) - 1 = 0$$

and

$$\partial_t\varphi(0,t) = 0, \qquad \partial_z\varphi(z,T) = 0, \quad \text{and} \quad \partial_t\varphi(L,t) = 0,$$

it follows that (1.6) reduces to

$$\iint_{Q_T} (\partial_z h - 1)F(z,t)\,dz\,dt = -\iint_{Q_T} C(h)\partial_t\varphi\,dz\,dt + \int_0^T q(t)\partial_z\varphi(L,t)\,dt. \tag{1.8}$$

If the function $F(z,t)$ appearing in the adjoint equation is nonnegative in Q_T, then the maximum principle asserts that the solution $\varphi(z,t)$ of (1.7) satisfies $\varphi(z,t) < 0$ in Q_T. If, in addition, at each z in $(0,L)$, the function $F(z,t)$ is assumed to increase so rapidly with respect to t that one has $\partial_{zz}\varphi(z,t) < 0$ in Q_T, then it is clear from the adjoint equation that $\partial_t\varphi(z,t) > 0$ in Q_T. Finally, $\varphi < 0$ in Q_T implies that $\partial_z\varphi(L,t) > 0$ for $0 < t < T$. Since $q(t)$ is already known to be negative by Lemma 1.1, it follows that the right side of (1.8) is strictly negative. $F(z,t)$ is nonnegative and increasing with t but is otherwise arbitrary; hence it follows from (1.8) that $\partial_z h(z,t) - 1 < 0$ almost everywhere in Q_T.

An additional property of the solution to the direct problem, also essential to the analysis of the inverse problem, is asserted in the following lemma.

LEMMA 1.3. *For admissible coefficients C and K, let $h = \Psi_1[C, K]$. Then $\partial_t h(z,t)$ is negative almost everywhere in Q_T.*

Proof. For $h = \Psi_1[C, K]$ and an arbitrary smooth function $\varphi(z,t)$,

$$\iint_{Q_T} [C(h)\partial_t h(z,t) - \partial_z(\partial_z b(h(z,t)) - K(h))]\partial_t\varphi\,dz\,dt = 0, \tag{1.9}$$

where

$$b(h(z,t)) = \int_0^{h(z,t)} K(s)\,ds.$$

Then integration by parts shows that

$$\begin{aligned} \iint_{Q_T} \partial_{zz} b(h(z,t))\partial_t\varphi\,dz\,dt &= \int_0^T \Big[\partial_z b(h)\partial_t\varphi + \partial_t b(h)\partial_z\varphi\Big]_{z=0}^{z=L} dt \\ &- \int_0^L \partial_z b(h)\partial_z\varphi\Big|_{t=0}^{t=T} dz - \iint_{Q_T} \partial_t b(h(z,t))\partial_{zz}\varphi\,dz\,dt \end{aligned}$$

and

$$\iint_{Q_T} \partial_z K(h(z,t))\partial_t\varphi\, dz\, dt = \int_0^T K(h)\partial_t\varphi\Big|_{z=0}^{z=L} dt - \int_0^L K(h)\partial_z\varphi\Big|_{t=0}^{t=T} dt + \iint_{Q_T} \partial_t K(h(z,t))\partial_z\varphi\, dz\, dt.$$

Then

$$\begin{aligned}&\iint_{Q_T} \partial_t h[C(h)\partial_t\varphi + K(h)\partial_{zz}\varphi + K'(h)\partial_z\varphi]\, dz\, dt\\ &= -\int_0^L K(h)(\partial_z h - 1)\partial_z\varphi\Big|_{t=0}^{t=T} dz \\ &\quad + \int_0^T \Big[(\partial_z b(h) - K(h))\partial_t\varphi + \partial_t b(h)\partial_z\varphi\Big]_{z=0}^{z=L} dt.\end{aligned} \tag{1.10}$$

If $\varphi(z,t)$ solves

$$\begin{aligned} C(h)\partial_t\varphi + K(h)\partial_{zz}\varphi + K'(h)\partial_z\varphi = F(z,t) \qquad & \text{in } Q_T,\\ \varphi(z,T) = 0, \qquad & 0 < z < L,\\ \partial_z\varphi(0,t) = 0, \qquad \partial_z\varphi(L,t) = 0, \qquad & 0 < t < T,\end{aligned} \tag{1.11}$$

then

$$\int_0^T \Big[(\partial_z b(h) - K(h))\partial_t\varphi + \partial_t b(h)\partial_z\varphi\Big]_{z=0}^{z=L} dt = \int_0^T q(t)\partial_t\varphi(L,t)\, dt$$

since $\partial_z b(h) - K(h) = K(h)(\partial_z h - 1)$ equals 0 and $q(t)$ at $z = 0$, L, respectively, and $\partial_t b(h(L,t)) = K(0)\partial_t h(L,t) = 0$. Also,

$$\int_0^L K(h)(\partial_z h - 1)\partial_z\varphi\Big|_{t=0}^{t=T} dz = -K(0)\int_0^L \partial_z\varphi(z,0)\, dz = K(0)(\varphi(0,0) - \varphi(L,0))$$

since $\partial_z\varphi(z,T) = 0$ and $\partial_z h(z,0) - 1 = -1$. Then (1.10) reduces to

$$\iint_{Q_T} \partial_t h(z,t)F(z,t)\, dz\, dt = \int_0^T q(t)\partial_t\varphi(L,t)\, dt + K(0)(\varphi(0,0) - \varphi(L,0)). \tag{1.12}$$

If $F(z,t)$ is nonnegative in Q_T, then the maximum principle applied to (1.11) asserts that $\varphi(z,t)$ can have no maximum on the interior of Q_T. Moreover, since $\partial_z\varphi = 0$ at $z = 0$, L, it follows [1, p. 261, 3] that $\varphi(z,t)$ cannot achieve a maximum at either of the boundary points $z = 0$, L. Then the maximum value of $\varphi(z,t)$ must occur at $t = T$, where $\varphi(z,T)$ is known to vanish for $0 < z < L$. It follows that $\varphi(z,t) < 0$ in Q_T. In particular, $\varphi(L,t) < 0$ for $0 < t < T$ and $\varphi(L,T) = 0$. The nonnegative, but otherwise arbitrary, function $F(z,t)$ may be chosen to grow so rapidly with respect to t near $z = L$ that $\partial_t\varphi(L,t) > 0$ for $0 < t < T$. In Lemma 1.1, $q(t)$ has been shown to be negative, so the first integral on the right side of (1.12) is strictly negative. Since F is nonnegative and increasing with t but is otherwise arbitrary, the values of F can be adjusted to cause $\varphi(0,0)-\varphi(L,0)\geq 0$. Then the right side of (1.12) is negative, and it follows that unless $\partial_t h(z,t)<0$ almost everywhere in Q_T it is possible to further adjust the nonnegative function F so that a contradiction of (1.12) is obtained.

The final lemma relating to properties of the solution to the direct problem characterizes the behavior of the output function $p(t)=h(0,t)$ during the phase-one experiment.

LEMMA 1.4. *For admissible coefficients C and K let $h(z,t)=\Psi_1[C,K]$. Then for each τ, $0<\tau\leq T$,*

$$z-L<h(z,t)<0 \quad \textit{and} \quad h(0,\tau)<h(z,t)<0 \quad \textit{for } 0<z<L, \quad 0<t<\tau.$$

In addition, $p(t)=h(0,t)=\Gamma_0\cdot\Psi_1[C,K]$ satisfies

$$p\varepsilon\mathbb{C}^1[0,T], \qquad p(0)=0, \quad \text{and} \quad p'(t)<0 \quad \text{for } 0<t<T. \tag{1.13}$$

Proof. For $h(z,t)=\Psi_1[C,K]$, let $u(z,t)=:h(z,t)-z+L$. Then for any τ, $0<\tau\leq T$, $u(z,t)$ solves

$$\begin{aligned}
C(h)\partial_t u &= \partial_z(K(h)\partial_z u) && \text{in } Q_\tau,\\
u(z,0) &= L-z, && 0<z<L,\\
\partial_z u(0,t) &= 0, \qquad u(L,t)=0, && 0<t<\tau.
\end{aligned}$$

The maximum–minimum principle implies that $0<u(z,t)<L-z$ in Q_τ for each τ in $(0,T]$; hence $z-L<h(z,t)<0$ in Q_T. Evidently, the maximum over the parabolic boundary for the function $h(z,t)$ occurs at $z=0$, where $\partial_z h(0,t)=1$, and this leads to $h(0,\tau)<h(z,t)<0$ for (z,t) in Q_τ, $0<\tau\leq T$.

To prove (1.13) choose the test function $\varphi(z,t)$ in the identity (1.10) to solve the following adjoint problem:

$$\begin{aligned}
C(h)\partial_t\varphi+K(h)\partial_{zz}\varphi+K'(h)\partial_z\varphi &= 0 && \text{in } Q_T,\\
\varphi(z,T) &= 0, && 0<z<L,\\
\partial_z\varphi(0,t) &= \vartheta(t), \qquad \varphi(L,t)=0, && 0<t<T.
\end{aligned}$$

Then (1.10) reduces to the identity

$$K(0)\int_0^L \partial_z\varphi(z,0)\,dz = -\int_0^T K(h(0,t))\partial_t h(0,t)\vartheta(t)\,dt;$$

i.e.,

$$K(0)\varphi(0,0)=\int_0^T K(h(0,t))p'(t)\vartheta(t)\,dt.$$

Choose the input $\vartheta(t)$ in the adjoint problem such that $\vartheta(T)=0$ and $\vartheta(t)<0$ for t in $[0,T)$. Then it follows from the extended maximum principle [1] that the maximum value of $\varphi(z,t)$ on the parabolic boundary of Q_T occurs at $z=0$. Evidently, $\varphi(0,t)$ is positive if $\vartheta(t)$ is negative for t in $[0,T)$; hence $\varphi(0,0)$ is positive and $K(0)\varphi(0,0)$ is positive as well. Since $\vartheta(t)$ is negative but is otherwise arbitrary, it follows from the last identity that $p'(t)$ must be negative for $0<t<T$.

Note that conditions (1.4) and (1.13) are necessary conditions for (p,q) to be a data pair generated by admissible coefficients as described by (1.3). A function pair (p,q) will be said to be an *admissible data pair* if they satisfy conditions (1.13) and

(1.4), respectively. The following theorem contains the integral identity on which the analysis of the inverse problem rests.

THEOREM 1.5. *For admissible coefficients C_j and K_j, $j = 1, 2$, let $h_j(z, t) = \Psi_1[C_j, K_j]$. For arbitrary smooth functions $\vartheta_0(t)$, $\vartheta_1(t)$, let the notation $\varphi = \Psi^*[\vartheta_0, \vartheta_1]$ indicate the solution of the following adjoint initial boundary value problem:*

$$\begin{aligned}&\alpha(z,t)\partial_t\varphi(z,t) + \beta(z,t)\partial_{zz}\varphi + \gamma(z,t)\partial_z\varphi = 0, && 0 < z < L, \quad 0 < t < \tau,\\ &\varphi(z,\tau) = 0, && 0 < z < L,\\ &\beta(0,t)\partial_z\varphi(0,t) = \vartheta_0(t), \qquad \varphi(L,t) = \vartheta_1(t), && 0 < t < \tau,\end{aligned} \tag{1.14}$$

where the coefficients α, β, γ are given by

$$\beta(z,t) = \int_0^1 K_1(h_2(z,t) + s(h_1(z,t) - h_2(z,t)))\,ds, \tag{1.15}$$

$$\alpha(z,t) = \int_0^1 C_1(h_2(z,t) + s(h_1(z,t) - h_2(z,t)))\,ds, \tag{1.16}$$

$$\gamma(z,t) = \int_0^1 K_1'(h_2(z,t) + s(h_1(z,t) - h_2(z,t)))\,ds. \tag{1.17}$$

If $(p_j, q_j) = \Gamma \cdot \Psi_1[C_j, K_j], j = 1, 2$, then increments in the inputs of $\Delta C = C_1 - C_2$, $\Delta K = K_1 - K_2$, lead to increments in output of $\Delta q = q_1 - q_2$, $\Delta p = p_1 - p_2$, and for any τ, $0 < \tau \le T$, the input and output increments are related by

$$\begin{aligned}&\int_0^\tau [\Delta q(t)\vartheta_1(t) + \Delta p(t)\vartheta_0(t)]\,dt\\ &\quad = \iint_{Q_\tau} [\Delta K(h_2)(\partial_z h_2(z,t) - 1)\partial_z\varphi + \Delta C(h_2)\varphi\partial_t h_2]\,dz\,dt.\end{aligned} \tag{1.18}$$

Proof. For admissible coefficients C_j and K_j, let $h_j(z,t) = \Psi_1[C_j, K_j]$, $j = 1, 2$. Then for an arbitrary smooth function $\varphi(z,t)$ and any $\tau, 0 < \tau \le T$,

$$\begin{aligned}&\iint_{Q_\tau} \varphi[\partial_t(a_1(h_1) - a_1(h_2)) - \partial_z(\partial_z(b_1(h_1) - b_1(h_2)) - K_1(h_1) + K_1(h_2))]\,dz\,dt\\ &\quad = -\iint_{Q_\tau} \varphi[\partial_t(a_1(h_2) - a_2(h_2)) - \partial_z(\partial_z(b_1(h_2) - b_2(h_2)) - K_1(h_2) + K_2(h_2))]\,dz\,dt.\end{aligned}$$

Integration by parts leads to

$$\begin{aligned}&-\iint_{Q_\tau} [\alpha(z,t)\partial_t\varphi + \beta(z,t)\partial_{zz}\varphi + \gamma(z,t)\partial_z\varphi]\Delta h(z,t)\,dz\,dt\\ &\qquad + \int_0^L [a_1(h_1) - a_1(h_2)]\varphi\Big|_{t=0}^{t=\tau} dz\\ &\qquad + \int_0^\tau [(b_1(h_1) - b_1(h_2))\partial_z\varphi - (\partial_z(b_1(h_1) - b_1(h_2)) - (K_1(h_1) - K_1(h_2)))\varphi]\Big|_{z=0}^{z=L} dt\\ &\quad = \int_0^\tau \Delta K(h_2)(\partial_z h_2 - 1)\varphi\Big|_{z=0}^{z=L} dt\\ &\qquad - \iint_{Q_\tau} [\Delta K(h_2)(\partial_z h_2 - 1)\partial_z\varphi + \Delta C(h_2)\partial_t h_2\varphi]\,dz\,dt,\end{aligned}$$

where $\alpha(z,t)$, $\beta(z,t)$, and $\gamma(z,t)$ are defined in (1.15), (1.16), and (1.17); i.e., recall that for any smooth function of one variable, F,

$$F(u) - F(v) = G(x)(u-v), \quad \text{where } G(x) = \int_0^1 F'(v(x) + s(u(x) - v(x)))\, ds.$$

If $\varphi(x,t)$ solves the auxiliary problem (1.14), then this expression reduces to (1.18), since in this case

$$\begin{aligned}
[a_1(h_1) - a_1(h_2)]\varphi\Big|_{t=0}^{t=\tau} &= (a_1(h_1) - a_1(h_2))\varphi(z,\tau) \\
&\quad - (a_1(z-1) - a_1(z-1))\varphi(z,0) = 0, \\
[(b_1(h_1) - b_1(h_2))\partial_z\varphi\Big|_{z=0}^{z=L} &= (b_1(0) - b_1(0))\partial_z\varphi(1,t) - (b_1(h_1) - b_1(h_2))\partial_z\varphi(0,t) \\
&= 0 - \Delta h(0,t)\beta(0,t)\partial_z\varphi_2(0,t) = -(p_1(t) - p_2(t))\vartheta_1(t), \\
[(\partial_z(b_1(h_1) - b_1(h_2)) - (K_1(h_1) &- K_1(h_2))) + \Delta K(h_2)(\partial_z h_2 - 1)]\varphi\Big|_{z=0}^{z=L} \\
&= (K_1(h_1)(\partial_z h_1 - 1) - K_2(h_2)(\partial_z h_2 - 1))\varphi\Big|_{z=0}^{z=L} \\
&= \Delta q(t)\vartheta_0(t) - 0.
\end{aligned}$$

The integral identity (1.18) provides an explicit expression relating changes in input to changes in output for the coefficient to data mapping $(p,q) = \Gamma \cdot \Psi_1[C,K]$. Note that for $\varphi = \varphi_0 = \Psi^*[\vartheta_0, 0]$, (1.18) becomes

$$(1.19) \quad \int_0^\tau \Delta p(t)\vartheta_0(t)\, dt = \iint_{Q_\tau} [\Delta K(h_2)(\partial_z h_2(z,t) - 1)\partial_z\varphi_0 + \Delta C(h_2)\varphi_0\partial_t h_2]\, dz\, dt,$$

and for $\varphi = \varphi_1 = \Psi^*[0, \vartheta_1]$, (1.18) reduces to the identity

$$(1.20) \quad \int_0^\tau \Delta q(t)\vartheta_1(t)\, dt = \iint_{Q_\tau} [\Delta K(h_2)(\partial_z h_2(z,t) - 1)\partial_z\varphi_1 + \Delta C(h_2)\varphi_1\partial_t h_2]\, dz\, dt.$$

The identity (1.18) relates changes ΔC and ΔK in the hydraulic properties of the porous medium to the corresponding changes Δp and Δq which then occur in the measured experimental output for the phase-one experiment. This identity contains information on the Jacobian of the coefficient to data mapping which associates a coefficient pair (C,K) to an output pair (p,q) in the phase-one experiment.

2. The phase-one inverse problem. For admissible coefficients C, K it was shown in Lemma 1.4 that for each t, $0 < t < T$, the solution $h = \Psi_1[C,K]$ of the phase-one direct problem assumes all values between 0, at the bottom of the column, and $p(t) = h(0,t)$ at the top of the column. Then for a fixed $t\varepsilon[0,T]$, the coefficients $C(h(z,t))$ and $K(h(z,t))$ are evaluated at all points of the interval $[p(t), 0]$ as z varies from 0 to L. As (z,t) ranges over the rectangle Q_T, $C(h(z,t))$ and $K(h(z,t))$ are evaluated at all points on the inverval $[-L, 0]$. Then the phase-one experiment explores the interval $[-L, 0]$ in the domain of the coefficients C and K, and the coefficient to data mapping $\Gamma \cdot \Psi$ carries function pairs that are defined and smooth on $[-L, 0]$ onto pairs of data functions (p,q) that are defined and continuous on $[0,T]$. The phase-one inverse problem consists of using the output pair $[p(t), q(t)\colon\ 0 \le t \le T]$ to find the coefficient pair $[C(h), K(h) : -L \le h \le 0]$. Recall that there is no finite time T at which $h(0,T)$ actually equals $-L$ but for every positive ε there exists a finite time

$T = T(\varepsilon)$ such that $h(0,T) = -L+\varepsilon$. Then the data $[p,q]$ on $[0,T]$ determine C and K on $[-L+\varepsilon, 0]$. Since the ε can be chosen to be arbitrarily small, for practical purposes of identification ε is zero; hence the ε will be omitted from subsequent discussions.

The integral identities derived in the previous section suggest a natural interpretation of the sense in which the measured output $[p,q]$ is able to distinguish between coefficient pairs $[C,K]$. It will be shown that the measured outputs p and q determine the coefficients C and K uniquely within an appropriate class of distinguishable functions. Moreover, a constructive algorithm will be defined for inverting the coefficient to data mapping in one such class. Finally, it will be shown that the inverse problem has an equivalent formulation as an output least squares optimization problem whose solution can be shown to solve the inverse problem.

Continuous functions f_1 and f_2 that are not identical on an interval $[\lambda,\rho]$ are said to be *distinguishable* on $[\lambda,\rho]$ if there exists a partition $\{\lambda = \xi_0 < \xi_1 < \cdots < \xi_n = \rho\}$ of $[\lambda,\rho]$ such that on each subinterval (ξ_{m-1},ξ_m) of the partition either

$$\text{(i)} \qquad f_1(x) = f_2(x) \quad \text{for } \xi_{m-1} \le x \le \xi_m$$

or else

$$\text{(ii)} \qquad f_2(x) \ne f_1(x) \quad \text{for } \xi_{m-1} < x < \xi_m.$$

It will be convenient for the proofs to follow if the number of subintervals in the partition is minimal. That is, subintervals on which f_1 coincides with f_2 do not occur consecutively, and consecutive subintervals (ξ_{m-1},ξ_m), (ξ_m,ξ_{m+1}), where the graphs of f_1 and f_2 do not cross, are separated by a point where f_1 equals f_2; i.e., $f_1(\xi_m) = f_2(\xi_m)$. A partition with this property will be said to be *adjusted to* the functions f_1 and f_2.

Functions that are not distinguishable need not be equal at all points of their domain. For example, the function $f_1(x) = x\sin(1/x)$ is neither distinguishable from nor identical to $f_2(x) = 0$ on $[0,1]$, since f_1 is clearly not identical to f_2 yet f_1 and f_2 are equal at infinitely many points in every neighborhood of zero. However, there exist classes of functions which are proper subsets of the continuous functions and any two functions from the class are either distinguishable on the interval of definition or else they are identical there. Analytic functions are one such class, as are the so-called polygonal functions that are continuous and piecewise linear on their interval of definition.

THEOREM 2.1. *For admissible coefficients C_j and K_j, $j = 1,2$, let $h_j(z,t) = \Psi_1[C_j,K_j]$. Let $(p_j,q_j) = \Gamma \cdot \Psi_1[C_j,K_j]$ for $j = 1,2$. If the pairs C_1,K_1 and C_2,K_2 are distinguishable on the interval $[-L,0]$ then p_1,p_2 and q_1,q_2 are not identical on $[0,T]$.*

Proof. Suppose that C_1,K_1 and C_2,K_2 are distinguishable on the interval $[-L,0]$ and $q_1 = q_2$ and $p_1 = p_2$ on $[0,T]$. It will now be shown that the two conditions are inconsistent.

Let $\{0 = \xi_0 > \xi_1 > \cdots > \xi_n = h(0,T)\}$ denote a partition of $[h(0,T),0]$ adjusted to the distinguishable functions K_1 and K_2 and let $\{0 = \xi_0 > \xi_1' > \cdots \xi_{n-1}' > \xi_n\}$ denote a (possibly different) partition of $[h(0,T),0]$ adjusted to C_1 and C_2. For the sake of discussion, suppose that $K_1(h) \ne K_2(h)$ for $\xi_0 < h < \xi_1$ and suppose $C_1(h) \ne C_2(h)$ for $\xi_0 < h < \xi_1'$. Let η_1 denote the smaller of the two numbers ξ_1 and ξ_1' and let $\tau \le T$ denote the unique value at which the monotone function $q(t)$ satisfies $q(\tau) = \eta_1$. Then $\Delta K(h) = K_1(h) - K_2(h)$ and $\Delta C(h) = C_1(h) - C_2(h)$ do not vanish at any point of the interval $(0,\eta_1)$.

Let $\varphi_1 = \Psi^*[0,\vartheta_1]$, where the input function $\vartheta_1(t)$ satisfying $\vartheta_1(\tau) = 0$ is chosen to be sufficiently large and positive for $0 < t < \tau$ that

$$\vartheta_1(t) > \varphi_1(z,t) > 0 \quad \text{and} \quad \partial_z \varphi_1(z,t) > 0 \quad \text{for } 0 < z < L, \quad 0 < t < \tau. \tag{2.1}$$

Similarly, for $\vartheta_0(t)$ satisfying $\vartheta_0(\tau) = 0$, choose ϑ_0 sufficiently large and positive for $0 < t < \tau$ that $\varphi_2 = \Psi^*[\vartheta_0, 0]$ satisfies

$$\varphi_2(z,t) < 0 \quad \text{and} \quad \partial_z \varphi_2(z,t) > 0 \quad \text{for } 0 < z < L, \quad 0 < t < \tau. \tag{2.2}$$

It follows from Lemmas 1.2 and 1.3 that $\partial_z h_2(z,t) - 1$ and $\partial_t h_2(z,t)$ are strictly negative almost everywhere on Q_τ. If $q_1 = q_2$ and $p_1 = p_2$ on $[0,T]$ then $\Delta q(t) = q_1(t) - q_2(t) = 0$ and $\Delta p(t) = p_1(t) - p_2(t) = 0$ for $0 \leq t \leq \tau$, and it follows from (1.19) and (1.20) that

$$\iint_{Q_\tau} \Delta K(h_2)(\partial_z h_2(z,t) - 1)\partial_z \varphi_1 \, dz \, dt = -\iint_{Q_\tau} \Delta C(h_2)\varphi_1 \partial_t h_2 \, dz \, dt, \tag{2.3}$$

$$\iint_{Q_\tau} [\Delta K(h_2)(\partial_z h_2(z,t) - 1)\partial_z \varphi_2 \, dz \, dt = -\iint_{Q_\tau} \Delta C(h_2)\varphi_2 \partial_t h_2 \, dz \, dt. \tag{2.4}$$

Now because of (2.1), (2.3) implies that ΔK and ΔC have opposite signs, whereas (2.4), taken with (2.2), implies ΔK and ΔC are of the same sign on $(0, \eta_1)$. It then follows that q_1, q_2 and p_1, p_2 cannot be identical on $[0,T]$ if C_1, C_2 and K_1, K_2 are distinguishable on the interval $[-L, 0]$. Only a slight modification of the argument is required to deal with alternative possibilities for ΔC and ΔK on the initial subintervals of the partitions.

Inverse problems are often reformulated as optimization problems in which an error functional based on the measured output data is to be minimized over a class of admissible inputs. Although this has the advantage of providing a means of computing a solution to the problem, it is often not evident that the solution of the optimization problem is also a solution of the inverse problem. It will be shown here that for a properly formulated error functional, any pair of admissible coefficients (C,K) that minimizes the error functional must also solve the inverse problem.

Theorem 2.2. *For a fixed pair of admissible coefficients C_0, K_0, let $(p(t; C_0, K_0)$, $q(t; C_0, K_0)) = \Gamma \cdot \Psi_1[C_0, K_0]$ denote the corresponding measured output. For an arbitrary pair of admissible coefficients C, K, let $h(z,t) = \Psi_1[C,K]$ and $(p(t; C, K)$, $q(t; C, K)) = \Gamma \cdot \Psi_1[C,K]$. Define the output least squares error functional associated to the pair (C,K) to be*

$$J[(C,K)] = \int_0^T (p(t; C,K) - p(t; C_0, K_0)^2 dt + \int_0^T (q(t; C,K) - q(t; C_0, K_0))^2 dt. \tag{2.5}$$

Then the variation of this functional is given by

$$\delta J[(C,K), (\delta C, \delta K)] = \iint_{Q_T} [\delta K(h)(\partial_z h(z,t) - 1)\partial_z \varphi + \delta C(h)\partial_t h(z,t)\varphi] \, dz \, dt, \tag{2.6}$$

where $\varphi(z,t) = \Psi^*[\vartheta_0, \vartheta_1]$ with data $\vartheta_0(t) = 2(p(t; C,K) - p(t; C_0, K_0))$ and $\vartheta_1(t) = 2(q(t; C,K) - q(t; C_0, K_0))$. Moreover, if (C,K) minimizes the functional J then $\Gamma \cdot \Psi_1[C,K] = \Gamma \cdot \Psi_1[C_0, K_0]$; i.e., (C,K) solves the inverse problem.

Proof. The variation of the functional J is easily computed to be

$$\delta J[(C,K), (\delta C, \delta K)] = \int_0^T 2(p(t; C,K) - p(t; C_0, K_0))\delta p(t) \, dt + \int_0^T 2(q(t; C,K) - q(t; C_0, K_0))\delta q(t) \, dt,$$

where δp and δq denote the differences $\delta p(t) = p(t; C+\delta C, K+\delta K) - p(t; C, K)$ and $\delta q(t) = q(t; C+\delta C, K+\delta K) - q(t; C, K)$. If φ denotes the solution of (1.14) for data $\vartheta_0(t) = 2(p(t; C, K) - p(t; C_0, K_0))$ and $\vartheta_1(t) = 2(q(t; C, K) - q(t; C_0, K_0))$, then the result (1.18) with $h_2(z,t) = \Psi_1[C, K]$ asserts that

$$\begin{aligned}\delta J[(C,K),(\delta C,\delta K)] &= \int_0^T [\vartheta_0(t)\delta p(t) + \vartheta_1(t)\delta q(t)]\,dt \\ &= \iint_{Q_T} [\delta C(h_2)\varphi\partial_t h_2 + \delta K(h_2)(\partial_z h_2 - 1)\partial_z\varphi]\,dz\,dt.\end{aligned}$$

But this is precisely (2.6).

Now if (C, K) is an admissible coefficient pair that causes the variation $\delta J[(C,K),(\delta C,\delta K)]$ to vanish for arbitrary perturbations $(\delta C, \delta K)$ of the coefficients, then it follows from (2.6) in combination with Lemmas 1.2 and 1.3 that φ and $\delta_z\varphi$ must vanish on Q_T. However, φ is the solution of the parabolic problem (1.14) and can vanish identically if and only if the data $\vartheta_0(t)$ and $\vartheta_1(t)$ are each zero. But this is to say that the computed outputs $p(t; C, K)$ and $q(t; C, K)$ agree with the measured outputs $p(t; C_0, K_0)$ and $q(t; C_0, K_0)$. Then (C, K) solves the inverse problem.

This result establishes that if the inverse problem is reformulated as an output least squares problem based on the overspecified data p and q, then a solution of the output least squares problem is truly a solution of the inverse problem.

Theorem 2.1 asserts that distinguishable coefficient pairs cannot produce pairs of data functions that are identical; i.e., the measured boundary data (p, q) determine the coefficient pair (C, K) uniquely within any subset of the admissible coefficients where functions that are indistinguishable are identical. One such subset is the set of polygonal coefficient functions constructed on a fixed partition of $[-L, 0]$.

Theorem 2.1 may be interpreted as an assertion that the coefficient to data mapping $(p, q) = \Gamma\cdot\Psi_1[C, K]$ is injective from the set of polygonal coefficients to admissible data pairs, but this is not quite sufficient to ensure invertibility. In fact, the coefficient to data mapping is separately monotone in each coefficient and a monotone mapping on a totally ordered space is invertible. Hence if the space of coefficients can be parameterized in a totally ordered fashion then the coefficient to data mapping can be inverted. Such a parameterization and inversion becomes possible due to the fact that monotonicity permits the coefficient to data mapping to be factored into a product of simpler maps.

Let p and q denote admissible data functions on an interval $[0, T]$, and let $\{0 = t_0 < \cdots < t_n = T\}$ denote a partition of $[0, T]$. The data function $p(t) = h(0, t)$ is monotone decreasing from the value 0 at $t = 0$ down to the value $p(T) = -L$ (i.e., $-L + \varepsilon$) at $t = T$. Then the data values $p_m = p(t_m)$ define a corresponding partition, $\{0 = p_0 > \cdots > p_n = -L\}$ of the interval $[-L, 0]$, which is the domain of the coefficients C, K during phase one.

Define a mapping Π_n: $\mathbb{C}[-L, 0] \longrightarrow \mathbb{R}^{n+1}$ which carries functions $K(h)$ and $C(h)$ from $\mathbb{C}[-L, 0]$ onto arrays of values $\{\kappa_m\}$ and $\{\xi_n\}$ equal to the values of the coefficients at the node points of the partition $\{p_m\colon\ m = 0, \ldots, n\}$ of their domain $[-L, 0]$; i.e.,

(2.7)
$$\Pi_n K = \{\kappa_m = K(p_m) : 0 \le m \le n\} \quad \text{and} \quad \Pi_n C = \{\xi_m = C(p_m) : 0 \le m \le n\}.$$

It will also be convenient to define a mapping P_n carrying an array of $n+1$ real values to a polygonal (continuous and piecewise-linear) function. This mapping, P_n, may be defined to have the following action on the array $\{\kappa_0, \kappa_1, \ldots, \kappa_n\}$:

$$P_n\{\kappa_m\} = \sum_{m=0}^{n} \kappa_m \Lambda_m(v), \tag{2.8}$$

where $\Lambda_m(v)$ denotes the piecewise-linear, continuous "hat functions" defined as follows on the partition $\{p_m\}$ of $[-L, 0]$: for $m = 0, 1, 2, \ldots, n$,

$$\Lambda_0(v) = 1 - v/p_1 \qquad \text{if } 0 = p_0 \le v \le p_1,$$

$$\Lambda_m(v) = \begin{cases} \dfrac{v - p_{m-1}}{p_m - p_{m-1}}, & \text{if } p_{m-1} \le v \le p_m, \\ \dfrac{p_{m+1} - v}{p_{m+1} - p_m} & \text{if } p_m \le v \le p_{m+1}, \end{cases}$$

$$\Lambda_m(v) = 0 \qquad \text{if } v < p_{m-1} \quad \text{or} \quad v > p_{m+1}.$$

For admissible coefficients C and K and a given partition $\{p_m\}$ of $[-L, 0]$, the polygonal functions $C^* = P_n\Pi_n C$ and $K^* = P_n\Pi_n K$ denote the unique polygonal approximations to C and K on the partition $\{p_m\}$; i.e., at each node point $p = p_m$, $C^*(p) = C(p)$ and $K^*(p) = K(p)$.

Similarly, for arbitrary arrays $\{\kappa_0, \kappa_1, \ldots, \kappa_n\}$ and $\{\xi_0, \ldots, \xi_n\}$ of positive parameters, (2.8) defines polygonal coefficients $K^*(v) = P_n[\kappa_0, \ldots, \kappa_n](v)$ and $C^*(v) = P_n[\xi_0, \ldots, \xi_n](v)$ on $p_n \le v \le p_0 = 0$. When these coefficients are used, the direct problem (1.1) has a unique solution $h^* = \Psi_1[C^*, K^*]$ on Q_T[9]. The corresponding data pair $(p^*, q^*) = \Gamma \cdot \Psi_1[C^*, K^*]$ is an admissible pair by the lemmas of the previous section. An algorithm can now be defined that produces arrays $\{\kappa_0, \kappa_1, \ldots, \kappa_n\}$ and $\{\xi_0, \ldots, \xi_n\}$ of parameters for which the corresponding computed output (p^*, q^*) approximates the measured data (p, q).

Assume an admissible data pair (p, q) is given on $[0, T]$. Let $\{t_m : 0 \le m \le n\}$ denote an arbitrary partition of $[0, T]$, and let $\{p_m : 0 \le m \le n\}$ denote the associated partition of $[p(T), 0]$ induced by the monotone function $p(t)$. For each k, $1 \le k \le n$, let $\varphi_k(z, t) = \Psi^*[\vartheta_k, 0]$ and $\psi_k(z, t) = \Psi^*[0, \rho_k]$ denote solutions to adjoint problems (1.14) with $\tau = t_k$. For each k, (1.14) is equivalent to a linear one-dimensional parabolic initial boundary value problem that is driven from a zero initial state by controlling the flux $\vartheta_k(t)$ at the left endpoint or by controlling the function value $\rho_k(t)$ at the right endpoint. The data functions ϑ_k and ρ_k in the adjoint problems are chosen to satisfy $\vartheta_k(t_k) = \rho_k(t_k) = 0$. In addition, $\vartheta_k(t)$, $\rho_k(t)$ can be chosen sufficiently large and positive for $0 < t < t_k$ that it follows

$$\varphi_k(z, t) < 0, \qquad \partial_z \varphi_k(z, t) > 0,$$

and

$$\psi_k(z, t) > 0, \qquad \partial_z \psi_k(z, t) > 0 \quad \text{on } Q_\tau.$$

Then the pairs $(\kappa_0, \xi_0), (\kappa_1, \xi_1), \ldots, (\kappa_n, \xi_n)$ of parameters defining the polygonal approximations for K and C are constructed, one at a time, according to the following algorithm.

Step 0. Assume $\kappa_0 = K(0)$ and $\xi_0 = C(0)$ are given. (These are the values of K and C at saturation.)

Step 1. For $\tau = t_1$, let

$$\begin{aligned} C^\sharp &= P_n[\xi_0, \xi_0, \dots, \xi_0] \quad \text{and} \quad K^\sharp = P_n[\kappa_0, \kappa_0, \dots, \kappa_0], \\ h_2(z,t) &= \Psi_1[C^\sharp, K^\sharp] \\ (p^\sharp, q^\sharp) &= \Gamma \cdot \Psi_1[C^\sharp, K^\sharp]. \end{aligned}$$

Then (κ_1, ξ_1) are given by

$$\begin{pmatrix} \kappa_1 \\ \xi_1 \end{pmatrix} = \begin{pmatrix} \kappa_0 \\ \xi_0 \end{pmatrix} + [M]^{-1} \begin{pmatrix} d_1 \\ e_1 \end{pmatrix}, \tag{2.9}$$

where the entries of the 2×2 matrix M are given by

$$\begin{aligned} M_{11} &= \iint_{Q_\tau} \Lambda_1(h_2)(\partial_z h_2 - 1)\partial_z \varphi_1 \, dz \, dt, \qquad & M_{12} &= \iint_{Q_\tau} \Lambda_1(h_2)\varphi_1 \partial_t h_2 \, dz \, dt, \\ M_{21} &= \iint_{Q_\tau} \Lambda_1(h_2)(\partial_z h_2 - 1)\partial_z \psi_1 \, dz \, dt, \qquad & M_{22} &= \iint_{Q_\tau} \Lambda_1(h_2)\psi_1 \partial_t h_2 \, dz \, dt \end{aligned} \tag{2.10}$$

and

$$d_1 = \int_0^T (q - q^\sharp)\vartheta_1(t) \, dt, \qquad e_1 = \int_0^\tau (p - p^\sharp)\rho_1(t) \, dt. \tag{2.11}$$

Then $C^*(h) = \xi_0 \Lambda_0(h) + \xi_1 \Lambda_1(h)$ and $K^*(h) = \kappa_0 \Lambda_0(h) + \kappa_1 \Lambda_1(h)$ for $p_1 \leq h \leq 0$.

Proceed in this way to generate pairs $(\kappa_1, \xi_1), \dots, (\kappa_{m-1}, \xi_{m-1})$ which define the polygonal coefficients C^* and K^* on the portion $p_{m-1} \leq h \leq 0$ of their domain. Pairs $(\kappa_i, \xi_i), i = 0, 1, \dots, m-1$, are known at this stage. To compute the next pair (ξ_m, κ_m), given the pairs (κ_i, ξ_i), $0 \leq i \leq m-1$, continue as follows:

Step m. For $\tau = t_m$, let

$$\begin{aligned} C^\sharp &= P_n[\xi_0, \xi_1, \dots, \xi_{m-1}, \dots, \xi_{m-1}] \text{ and } K^\sharp = P_n[\kappa_0, \kappa_1, \dots, \kappa_{m-1}, \dots, \kappa_{m-1}], \\ h_2(z,t) &= \Psi_1[C^\sharp, K^\sharp] \\ (p^\sharp, q^\sharp &= \Gamma \cdot \Psi_1[C^\sharp, K^\sharp]. \end{aligned}$$

Then (κ_m, ξ_m) are given by

$$\begin{pmatrix} \kappa_m \\ \xi_m \end{pmatrix} = \begin{pmatrix} \kappa_{m-1} \\ \xi_{m-1} \end{pmatrix} + [M]^{-1} \begin{pmatrix} d_{m-1} \\ e_{m-1} \end{pmatrix}, \tag{2.12}$$

where the entries of the 2×2 matrix M are given by

$$\begin{aligned} M_{11} &= \iint_{Q_\tau} \Lambda_1(h_2)(\partial_z h_2 - 1)\partial_z \varphi_m \, dz \, dt, \qquad & M_{12} &= \iint_{Q_\tau} \Lambda_1(h_2)\varphi_m \partial_t h_2 \, dz \, dt, \\ M_{21} &= \iint_{Q_\tau} \Lambda_1(h_2)(\partial_z h_2 - 1)\partial_z \psi_m \, dz \, dt, \qquad & M_{22} &= \iint_{Q_\tau} \Lambda_1(h_2)\psi_m \partial_t h_2 \, dz \, dt \end{aligned} \tag{2.13}$$

and

$$d_1 = \int_0^\tau (q - q^\sharp)\vartheta_m(t) \, dt, \qquad e_1 = \int_0^\tau (p - p^\sharp)\rho_m(t) \, dt. \tag{2.14}$$

In this way, n pairs of parameter values can be generated. It remains to be seen in what sense the polygonal coefficients based on these parameter pairs can produce computed output that approximates the measured output (p, q) used in the algorithm to find the parameters.

THEOREM 2.3. *Let* $[p(t), q(t)]$ *denote an admissible data pair on* $[0, T]$*, and let* $\{0 = t_0 < \cdots < t_n = T\}$ *denote an arbitrary partition of the interval* $[0, T]$*. Suppose that parameter pairs* $\{(\xi_0, \kappa_0), \ldots, (\xi_n, \kappa_n)\}$ *have been generated using the algorithm described previously and that* $(p^*, q^*) = \Gamma \cdot \Psi_1[C^*, K^*]$ *for* $C^* = P_n[\xi_0, \ldots, \xi_n]$ *and* $K^* = P_n[\kappa_0, \ldots, \kappa_n]$*. Then*

(a) $\int_0^{t_m}(p(t) - p^*(t))\vartheta_m(t)\,dt = \int_0^{t_m}(q(t) - q^*(t))\rho_m(t)\,dt = 0, m = 1, \ldots, n,$

(b) *if* $p, q \varepsilon \mathbb{C}^2[t_{m-1}, t_m]$ *for* $m = 1, \ldots n$*, then* $|p(t_m) - p^*(t_m)| \leq \nu\Delta t^2$ *and* $|q(t_m) - q^*(t_m)| \leq \nu\Delta t^2$ *for* $m = 1, \ldots, n$ *for a positive constant* ν *depending on* p *and* q *and* $\Delta t = \max(t_m - t_{m-1})$.

Proof. Suppose (p, q) is an admissible data pair; i.e., p and q satisfy (1.13) and (1.4), respectively. Let $\{0 = t_0 < \cdots < t_n = T\}$ denote a partition of the interval $[0, T]$, and let $\{0 = p_0 > \cdots > p_n = -L\}$ denote the corresponding partition of the interval $[-L, 0]$ induced by the monotone function, $p(t)$.

The initial parameter pair $\xi_0 = C(0)$, $\kappa_0 = K(0)$ is assumed to be known. This represents no loss of generality since these values are often known from independent experiments, or they may be determined by asymptotic estimates from the data $p(t)$, $q(t)$, [5, 6].

The computed outputs $(p^*, q^*) = \Gamma \cdot \Psi_1[C^*, K^*]$ have been generated by the polygonal coefficients $C^* = P_n[\xi_0, \ldots, \xi_n]$ and $K^* = P_n[\kappa_0, \ldots, \kappa_n]$. Let $(p^\sharp, q^\sharp)$ denote outputs computed from the coefficients $C^\sharp = P_n[\xi_0, \ldots, \xi_0]$ and $K^\sharp = P_n[\kappa_0, \ldots, \kappa_0]$, and let

$$\begin{pmatrix} \kappa_1' \\ \xi_1' \end{pmatrix} = \begin{pmatrix} \kappa_0 \\ \xi_0 \end{pmatrix} + [M]^{-1} \begin{pmatrix} d_1' \\ e_1' \end{pmatrix}, \tag{2.15}$$

where the entries of the 2×2 matrix M are given by (2.10) and

$$d_1' = \int_0^{t_1} (q - q^*)\vartheta_1(t)\,dt, \qquad e_1' = \int_0^{t_1} (p - p^*)\rho_1(t)\,dt. \tag{2.16}$$

Then it follows from (2.9), (2.11) and (2.15), (2.16) that

$$\begin{pmatrix} \kappa_1' \\ \xi_1' \end{pmatrix} = \begin{pmatrix} \kappa_0 \\ \xi_0 \end{pmatrix} + [M]^{-1} \begin{pmatrix} d_1 \\ e_1 \end{pmatrix} + [M]^{-1} \begin{pmatrix} d_1'' \\ e_1'' \end{pmatrix},$$

where

$$d_1'' = \int_0^{t_1} (q^\sharp - q^*)\vartheta_1(t)\,dt, \qquad e_1'' = \int_0^{t_1} (p^\sharp - p^*)\rho_1(t)\,dt.$$

This may be written as

$$\begin{pmatrix} \kappa_1' \\ \xi_1' \end{pmatrix} = \begin{pmatrix} \kappa_1 \\ \xi_1 \end{pmatrix} + [M]^{-1} \begin{pmatrix} d_1'' \\ e_1'' \end{pmatrix}. \tag{2.17}$$

Applying the integral identities (1.19) and (1.20) to the coefficient pairs $(C_1, K_1) = (C^\sharp, K^\sharp)$ and $(C_2, K_2) = (C^*, K^*)$ leads to

$$\begin{aligned} (\kappa_0 - \kappa_1)M_{11} + (\xi_0 - \xi_1)M_{12} &= d_1'', \\ (\kappa_0 - \kappa_1)M_{21} + (\xi_0 - \xi_1)M_{22} &= e_1''. \end{aligned}$$

That is,

$$[M]\begin{pmatrix}\kappa_0-\kappa_1\\ \xi_0-\xi_1\end{pmatrix}=\begin{pmatrix}d_1''\\ e_1''\end{pmatrix}, \tag{2.18}$$

where the entries of the 2×2 matrix M are given by (2.10) and we have used the fact that $\Delta K(v)=K^\sharp(v)-K^*(v)=\kappa_0\Lambda_0(v)+\kappa_0\Lambda_1(v)-(\kappa_0\Lambda_0(v)+\kappa_1\Lambda_1(v))=(\kappa_0-\kappa_1)\Lambda_1(v)$ and $\Delta C(v)=(\xi_0-\xi_1)\Lambda_1(v)$. Now (2.17) and (2.18) together imply that

$$\begin{pmatrix}\kappa_1'\\ \xi_1'\end{pmatrix}=\begin{pmatrix}\kappa_1\\ \xi_1\end{pmatrix}+[M]^{-1}[M]\begin{pmatrix}\kappa_0-\kappa_1\\ \xi_0-\xi_1\end{pmatrix}=\begin{pmatrix}\kappa_0\\ \xi_0\end{pmatrix},$$

and this result, taken with (2.15), implies $d_1'=e_1'=0$. However, this is result (a) in the case where $m=1$. In much the same way, one can show that (a) holds for $1<m\le n$ by letting

$$\begin{pmatrix}\kappa_m'\\ \xi_m'\end{pmatrix}=\begin{pmatrix}\kappa_{m-1}\\ \xi_{m-1}\end{pmatrix}+[M]^{-1}\begin{pmatrix}d_{m-1}'\\ e_{m-1}'\end{pmatrix}$$

and proceeding as above to show that $d_{m-1}'=e_{m-1}'=0$.

To prove (b) introduce the family of functions $\{\lambda_m(t)\}$, piecewise-linear, continuous functions on the partition $\{t_m\}$ of $[0,T]$. The family $\{\lambda_m(t)\}$ is analogous to the family $\{\Lambda_m(v)\}$ on the partition $\{p_m\}$ of $[-L,0]$. Then, with a slight abuse of notation, $P_nq(t)=[q(t_0),q(t_1),\ldots,q(t_n)]\varepsilon\mathbb{R}^{n+1}$ and

$$\Pi_nP_nq(t)=\sum_{i=0}^{n}q(t_i)\lambda_i(t),$$

where Π_nP_nq denotes the unique polygonal approximation to $q(t)$ on the partition $\{t_m\}$ of $[0,T]$.

For outputs p^* and q^* generated by the polygonal coefficients of the algorithm, use (a) in the case where $m=1$ to write

$$\int_0^{t_1}p(t)-p^*(t))\vartheta_1(t)\,dt=\int_0^{t_1}(p(t)-\Pi_nP_np(t))\vartheta_1(t)\,dt$$
$$+\int_0^{t_1}(\Pi_nP_np(t)-\Pi_nP_np^*(t))\vartheta_1(t)\,dt+\int_0^{t_1}(\Pi_nP_np^*(t)-p^*(t))\vartheta_1(t)\,dt=0.$$

On $[0,t_1]$, $\Pi_nP_np(t)-\Pi_nP_np^*(t)=(p(t_1)-p^*(t_1))\lambda_1(t)$; hence

$$|p(t_1)-p^*(t_1)|=\left|\int_0^{t_1}(p(t)-\Pi_nP_np(t))\vartheta_1(t)\,dt+\int_0^{t_1}(\Pi_nP_np^*(t)-p^*(t))\vartheta_1(t)\,dt|\right|/I_1,$$

where $I_1=\int_0^{t_1}\lambda_1(t)\vartheta_1(t)\,dt>0$. Making use of a well-known property of the trapezoidal approximation for integrals, it follows that if $p\varepsilon\mathbb{C}^2[0,t_1]$ then for η_1, a positive constant depending on $p(t)$ and $p^*(t)$,

$$|p(t_1)-p^*(t_1)|\le\eta_1(t_1-0)^3=\eta_1\Delta t_1^3.$$

Similarly, $|q(t_1)-q^*(t_1)|\le\eta_1\Delta t_1^3$ with a possibly large value of η_1.

For $m = 2$, it follows from (a) that

$$\int_{t_1}^{t_2} (\Pi_n P_n p^*(t) - \Pi_n P_n p(t))\vartheta_2(t)\,dt = \int_0^{t_2} (p(t) - \Pi_n P_n p(t))\vartheta_2(t)\,dt$$
$$+ \int_0^{t_2} (\Pi_n P_n p^*(t) - p^*(t))\vartheta_2(t)\,dt - \int_0^{t_1} (\Pi_n P_n p^*(t) - \Pi_n P_n p(t))\vartheta_2(t)\,dt.$$

Hence

$$|p(t_2) - p^*(t_2) \leq \left|\int_0^{t_2} (p(t) - \Pi_n P_n p(t))\vartheta_2(t)\,dt\right| / I_2$$
$$+ \left|\int_0^{t_2} (\Pi_n P_n p^*(t) - p^*(t))\vartheta_2(t)\,dt\right| / I_2 + \eta_1 \Delta t_1^3 \int_0^{t_2} \lambda_1(t)\vartheta_2(t)\,dt / I_2.$$

Again using the property of the trapezoidal approximation for integrals leads to

$$|p(t_2) - p^*(t_2)| \leq \eta_1 \Delta t_1^3 + \eta_2 \Delta t_2^3 + \eta_1^* \Delta t_1^3 + \eta_2^* \Delta t_2^3 + \eta_1 I_1' / I_2 \Delta t_1^3.$$

Then there exist positive constants, which we denote again by η_1 and η_2, such that

$$|p(t_2) - p^*(t_2)| \leq \eta_1 \Delta t_1^3 + \eta_2 \Delta t_2^3 \quad \text{and} \quad |q(t_2) - q^*(t_2)| \leq \eta_1 \Delta t_1^3 + \eta_2 \Delta t_2^3.$$

For each m, $1 \leq m \leq n$, one can show in this way that

$$|p(t_m) - p^*(t_m)| \leq \sum_{i=1}^{m} \eta_i \Delta t_i^3 \quad \text{and} \quad |q(t_m) - q^*(t_m)| \leq \sum_{i=1}^{m} \eta_i \Delta t_i^3.$$

Letting $\Delta t = \max\{\Delta t_i\colon 1 \leq i \leq n\}$, note that $m\Delta t \leq n\Delta t \sim T$; hence if $\eta = \max \eta_i$, then

$$|p(t_m) - p^*(t_m)| \leq (\eta n \Delta t)\Delta t^2 \quad \text{and} \quad |q(t_m) - q^*(t_m)| \leq (\eta n \Delta t)\Delta t^2.$$

Letting $\nu = \eta T$ gives part (b) of the theorem.

Theorem 2.3 shows that given any admissible data pair (p, q) it is always possible to construct a pair of polygonal coefficients C^*, K^* such that the resulting computed output $(p^*, q^*) = \Gamma \cdot \Psi_1[C^*, K^*]$ reproduces the measured output (p, q) with accuracy dependent on the mesh size for the partition $\{t_m\}$. In case it is known that the measured data (p, q) are in fact equal to $\Gamma \cdot \Psi_1[C, K]$ for some admissible coefficient pair (C, K), then the following theorem describes how (C^*, K^*) is related to (C, K).

THEOREM 2.4. *Let $(p, q) = \Gamma \cdot \Psi_1[C, K]$ for (C, K), an admissible coefficient pair, and let $\{0 = t_0 < \cdots < t_n = T\}$ denote an arbitrary partition of the interval $[0, T]$. Suppose parameter pairs $\{(\xi_0 \kappa_0), \ldots, (\xi_n, \kappa_n)\}$ have been generated using the algorithm described previously and that $(p^*, q^*) = \Gamma \cdot \Psi_1[C^*, K^*]$ for $C^* = P_n[\xi_0, \ldots, \xi_n]$ and $K^* = P_n[\kappa_0, \ldots, \kappa_n]$. If $C, K \varepsilon \mathbb{C}^2[p_i, p_{i-1}]$ for $1 \leq i \leq n$, then*

$$|\xi_i - C(p_i)| \leq \nu \Delta p \quad \text{and} \quad |\kappa_i - K(p_i)| \leq \nu \Delta p \quad \text{for } 1 \leq i \leq n,$$

for a positive constant ν depending on C and K for $\Delta p = \max\{p_{i-1} - p_i\}$.

Proof. Apply the integral identities (1.19) and (1.20) with the coefficient pairs $(C_1, K_1) = (C, K)$ and $(C_2, K_2) = (C^*, K^*)$ and $\tau = t_1$. Then with $\varphi_j = \Psi^*[\vartheta_j, 0]$

and $\psi_j = \Psi^*[0,\rho_j]$ as they were in Theorem 2.3, by part (a) of Theorem 2.3,

$$\iint_{Q_\tau} [\Delta K(h_2)(\partial_z h_2(z,t) - 1)\partial_z \varphi + \Delta C(h_2)\varphi\partial_t h_2]\, dz\, dt = 0,$$
$$\iint_{Q_\tau} [\Delta K(h_2)(\partial_z h_2(z,t) - 1)\partial_z \psi + \Delta C(h_2)\psi\partial_t h_2]\, dz\, dt = 0,$$

where $\Delta K(h) = K(h) - K^*(h)$ and $\Delta C(h) = C(h) - C^*(h)$. Now letting $\Pi_n P_n K$ and $\Pi_n P_n C$ denote the polygonal approximations to K and C on the partition $\{p_m\}$ of $[-L, 0]$ leads to

$$\begin{aligned}\iint_{Q_\tau} &(\Pi_n P_n K(h_2) - K^*(h_2))(\partial_z h_2(z,t) - 1)\partial_z \varphi\, dz\, dt \\ &+ \iint_{Q_\tau} (\Pi_n P_n C(h_2) - C^*(h_2))\varphi\partial_t h_2\, dz\, dt \\ &= \iint_{Q_\tau} (\Pi_n P_n K(h_2) - K(h_2))(\partial_z h_2(z,t) - 1)\partial_z \varphi\, dz\, dt \\ &+ \iint_{Q_\tau} (\Pi_n P_n C(h_2) - C(h_2))\varphi\partial_t h_2\, dz\, dt,\end{aligned}$$

$$\begin{aligned}\iint_{Q_\tau} &(\Pi_n P_n K(h_2) - K^*(h_2))(\partial_z h_2(z,t) - 1)\partial_z \psi\, dz\, dt \\ &+ \iint_{Q_\tau} (\Pi_n P_n C(h_2) - C^*(h_2))\psi\partial_t h_2\, dz\, dt \\ &= \iint_{Q_\tau} (\Pi_n P_n K(h_2) - K(h_2))(\partial_z h_2(z,t) - 1)\partial_z \psi\, dz\, dt \\ &+ \iint_{Q_\tau} (\Pi_n P_n C(h_2) - C(h_2))\psi\partial_t h_2\, dz\, dt.\end{aligned}$$

It follows from Lemma 1.4 that $p_1 \le u_2(z,t) \le p_0 = 0$ for $(z,t)\varepsilon Q_{t_1}$. Then

$$\begin{aligned}\Pi_n P_n K(h_2) - K^*(h_2) &= (K(p_1) - \kappa_1)\Lambda_1(u_2(z,t)), \\ \Pi_n P_n C(h_2) - C^*(h_2) &= (C(p_1) - \xi_1)\Lambda_1(u_2(z,t)) \quad \text{on } Q_{t_1}\end{aligned}$$

and for M the 2×2 matrix whose entries are given by (2.10)

$$[M]\begin{bmatrix} K(p_1) - \kappa_1 \\ C(p_1) - \xi_1 \end{bmatrix} = \begin{bmatrix} I(K,\varphi) + J(C,\varphi) \\ I(K,\varphi) + J(C,\psi) \end{bmatrix}. \tag{2.19}$$

Using the lemmas of section 1 together with a well-known property of the polygonal approximation for a smooth function, it follows that for $\tau = t_1$ there exists a positive constant ν_1 such that

$$|I(K,\varphi)| = \left| \iint_{Q_\tau} (\Pi_n P_n K(h_2) - K(h_2))(\partial_z h_2(z,t) - 1)\partial_z \varphi\, dz\, dt \right| \le \nu_1 (p_1 - p_0)^2,$$
$$|J(C,\varphi)| = \left| \iint_{Q_\tau} (\Pi_n P_n C(h_2) - C(h_2))\varphi\partial_t h_2\, dz\, dt \right| \le \nu_1 (p_1 - p_0)^2,$$

and for a larger constant, which we still denote by ν_1,

$$|I(K,\varphi)| + |J(C,\varphi)| \le \nu_1 (p_1 - p_0)^2 \quad \text{and} \quad |I(K,\psi)| + |J(C,\psi)| \le \nu_1 (P_1 - p_0)^2.$$

Then it follows from (2.19) that there exists a positive constant, denoted again by ν_1, such that

$$|K(p_1) - \kappa_1| \le \nu_1 (p_1 - p_0)^2 \quad \text{and} \quad |C(p_1) - \xi_1| \le \nu_1 (p_1 - p_0)^2.$$

Continuing in a fashion similar to what was done in the proof of Theorem 2.3, we obtain for each i, $1 \le i \le n$,

$$|K(p_i) - \kappa_i| \le \sum_{j=1}^{i} \nu_j \Delta p_j^2 \quad \text{and} \quad |C(p_i) - \xi_j| \le \sum_{j=1}^{i} \nu_j \Delta p_j^2.$$

Let Δp and ν denote the largest of the numbers Δp_j and ν_j, respectively, and note that $n\Delta p \sim L$. Then for each i, $1 \le i \le n$,

$$|K(p_i) - \kappa_i| \le L\nu\Delta p \quad \text{and} \quad |C(p_i) - \xi_i| \le L\nu\Delta p,$$

which is what was to be proven.

Theorem 2.4 asserts that for a vertical column, initially saturated and allowed to drain to equilibrium under the force of gravity, it is possible to construct polygonal functions which approximate the hydraulic functions $C(h)$, $K(h)$ on the range $-L \le h \le 0$ for a column of length L; i.e., this phase-one experiment determines the hydraulic coefficients on the range $-L \le h \le 0$ from data $\{p(t), q(t)\colon\ 0 \le t \le T\}$ measured at the top and bottom of the column. The monotonicity of the data function $p(t)$ permits the parameter pairs characterizing the polygonal functions approximating C and K to be found one at a time rather than as an ensemble. In effect, the coefficient to data mapping is factored into n mappings, each of which associates a coefficient parameter pair (ξ_i, κ_i) to a data parameter pair (p_i, q_i). Each of these factor mappings is then uniquely invertible as expressed, for example in (2.12).

It will be shown in the next section that the range over which the coefficients can be determined can be extended by applying suction to the bottom of the column in what will be referred to as phase two of the experiment.

3. The phase-two direct problem. Consider a vertical soil column, initially saturated and allowed to drain to a state of equilibrium under gravity. The column will now be drained further by applying suction. If there is no flow across the top end of the column and a suction $s(t)$ is applied to the bottom end of the column, then the capillary pressure head $h(z,t)$ can be shown to satisfy

$$\begin{aligned} &C(h)\partial_t h(z,t) = \partial_z(K(h)(\partial_z h(z,t) - 1)) && \text{for } 0 < z < L, \quad 0 < t < T, \\ &h(z,0) = z - 1 && \text{for } 0 < z < L, \\ &\partial_z h(0,t) - 1 = 0, \qquad h(L,t) = s(t) && \text{for } 0 < t < T. \end{aligned} \tag{3.1}$$

Here C and K continue to denote the water capacity and hydraulic conductivity, respectively. In fact, they are the same functions as seen previously since the phase-two experiment deals with the same soil subject, now for conditions designed to explore more of the range of the hydraulic functions C and K. The applied suction at the bottom, denoted by $s(t)$, is assumed to be smooth and monotone in time; i.e., $s(t)$ satisfies

$$s\varepsilon\mathbb{C}^1[0,T], \qquad s(0) = 0, \qquad s'(t) < 0 \quad \text{for } 0 < t < T. \tag{3.2}$$

Problem (3.1) is called the phase-two direct problem. For each pair of admissible coefficients (C, K), the direct problem (3.1) has a unique solution h whose dependence on the coefficients will be indicated by writing $h = \Psi_2[C, K]$. In the phase-two experiment, it is still relatively easy to measure the pressure head $h(0, t)$ at the top of the column and the flux or outflow, $K(h)(\partial_z h(1, t) - 1)$, at the bottom of the column. Likewise, for $h = \Psi_2[C, K]$, we can compute the functions

$$(3.3) \qquad p(t) = h(0, t) \quad \text{and} \quad q(t) = K(h)(\partial_z h(1, t) - 1) \quad \text{for } 0 < t < T.$$

The dependence of $p(t)$ and $q(t)$ on the coefficients C and K will be indicated by writing $(p, q) = \Gamma \cdot \Psi_2[C, K]$, and this association is called the *coefficient-to-data mapping* for the phase-two experiment. The functions (p, q) are viewed as output, and their properties are determined by and must be deduced from the properties of the input, particularly the suction $s(t)$. The following lemmas are the analogues of corresponding lemmas for the phase-one experiment and are needed in order to carry out the analysis of the inverse problem associated with the phase-two experiment.

LEMMA 3.1. *For admissible coefficients C and K, let $(p, q) = \Gamma \cdot \Psi[C, K]$. If $s(t)$ satisfies* (3.2), *then $q(t)$ defined in* (3.3) *satisfies*

$$(3.4) \qquad q \varepsilon \mathbb{C}[0, t], \qquad q(0) = 0, \quad \text{and} \quad q(t) < 0 \quad \text{for } 0 < t < T.$$

Proof. Let $\varphi(z, t) = s(t) + z - L$. Then $\partial_t \varphi(z, t) = s'(t)$ and $\partial_z \varphi(z, t) = 1$. Hence if $h(z, t)$ solves (3.1), it follows that $C(h)\partial_t(h - \varphi) = \partial_z(K(h)\partial_z(h - \varphi)) - C(h)s'(t)$. Then $w(z, t) = h(z, t) - \varphi(z, t)$ solves the initial boundary value problem

$$\begin{aligned} C(h)\partial_t w(z, t) - \partial_z(K(h)\partial_z w(z, t)) &= -C(h)s'(t) > 0, \\ w(z, 0) &= z - L - (z - L) = 0, \\ \partial_z w(0, t) &= \partial_z h(0, t) - \partial_z \varphi(0, t) = 0, \quad w(1, t) = s(t) - s(t) = 0. \end{aligned}$$

Then the maximum principle can be applied as in the proof of Lemma 1.1 and the conclusion follows.

LEMMA 3.2. *For admissible coefficients C and K, let $h = \Psi_2[C, K]$. If $s(t)$ satisfies* (3.2), *then $\partial_z h(z, t) - 1 < 0$ almost everywhere in Q_T.*

The proof of this and the next two lemmas are similar to the proofs of Lemmas 1.2, 1.3, and 1.4 and are omitted.

LEMMA 3.3. *For admissible coefficients C and K, let $h = \Psi_2[C, K]$. If $s(t)$ satisfies* (3.2), *then $\partial_t h(z, t) < 0$ almost everywhere in Q_T.*

LEMMA 3.4. *For admissible coefficients C and K, let $(p, q) = \Gamma \cdot \Psi_2[C, K]$. If $s(t)$ satisfies* (3.2), *then $h = \Psi_2[C, K]$ satisfies*

$$\textit{for each } \tau, 0 < \tau \le T, \quad s(\tau) + z - L < h(z, t) < z - L \quad \textit{for } 0 \le z \le L, \quad 0 \le t \le \tau$$

and $p(t) = h(0, t)$ satisfies

$$(3.5) \qquad p \varepsilon \mathbb{C}^1[0, T], \qquad p(0) = -L, \quad \textit{and} \quad p'(t) < 0 \quad \textit{for } 0 < t < T.$$

THEOREM 3.5. *For admissible coefficients C_j and K_j, $j = 1, 2$, let $h_j(z, t) = \Psi_2[C_j, K_j]$ and suppose $s(t)$ satisfies* (3.2). *Let $(p_j, q_j) = \Gamma \cdot \Psi_2[C_j, K_j]$, $j = 1, 2$. Then for any τ, $0 < \tau \le T$.*

$$(3.6) \quad \int_0^\tau \Delta p(t)\vartheta(t)\, dt = \iint_{Q_\tau} [\Delta K(h_2)(\partial_z h_2(z, t) - 1)\partial_z \varphi_1 + \Delta C(h_2)\varphi_1 \partial_t h_2]\, dz\, dt,$$

$$(3.7) \quad \int_0^\tau \Delta q(t)\rho(t)\, dt = \iint_{Q_\tau} [\Delta K(h_2)(\partial_z h_2(z, t) - 1)\partial_z \varphi_2 + \Delta C(h_2)\varphi_2 \partial_t h_2]\, dz\, dt,$$

where $\varphi_1 = \Psi^*[\vartheta, 0]$ *and* $\varphi_2 = \Psi^*[0, \rho]$, *respectively.*

The proof of this theorem is nearly identical to the proof of Theorem 1.5 and is omitted.

Note that conditions (3.4) and (3.5) are necessary conditions for (p, q) to be a data pair generated from the phase-two experiment by admissible coefficients C and K. A function pair (p, q) as defined in (1.3) will be said to be a phase-two admissible data pair if they satisfy conditions (3.4) and (3.5), respectively.

4. The phase-two inverse problem. In the phase-one experiment the data $p(t)$ and $q(t)$ measured over the interval $[0, T]$ are used to determine the coefficients C and K on the interval $[-L, 0]$. In the phase-two experiment, the coefficients are assumed to be known on $[-L, 0]$, and a new experiment is conducted, applying suction to the column and again measuring $p(t)$ and $q(t)$ for a period of time. The time interval for the phase-two experiment will also be denoted by $[0, T]$, although T in phase two does not need to have a connection to the T for phase one.

In Lemma 3.1, it was shown that $h = \Psi_2[C, K]$ satisfies $h(z, t) > s(t) + z - L$ in Q_T. Then the domain of the coefficient-to-data mapping consists of pairs of functions that are continuous on the interval $[h_*, 0]$ for $h_* = -L + s(T)$. The range of the coefficient-to-data mapping consists of pairs of functions that are continuous on $[0, T]$. Thus while the phase-one inverse problem determines the coefficients C and K on the interval $[-L, 0]$, for $s(t)$ satisfying (3.2), the phase-two inverse problem will extend knowledge of the unknown coefficients to the interval $[-L + p(T), -L]$.

The next theorems are the phase-two analogues of Theorems 2.1, 2.3, and 2.4. The proofs of these theorems are virtually the same as the proofs of the phase-one theorems and are therefore omitted.

THEOREM 4.1. *For admissible coefficients* C_j *and* K_j, $j = 1, 2$, *let* $h_j(z, t) = \Psi_2[C_j, K_j]$ *and suppose* $s(t)$ *satisfies* (3.2). *Let* $(p_j, q_j) = \Gamma \cdot \Psi_2[C_j, K_j]$, $j = 1, 2$. *If* C_1, C_2 *and* K_1, K_2 *are distinguishable on the interval* $[h_*, 0]$, *then* p_1, p_2 *and* q_1, q_2 *are not identical on* $[0, T]$.

Theorem 4.1 asserts that distinguishable coefficients cannot produce phase-two experimental data pairs that are identical. Then the coefficient pairs are uniquely determined by the data collected for the phase-two experiment. The theorem may also be interpreted as asserting that the coefficient-to-data mapping $(p, q) = \Gamma \cdot \Psi_2[C, K]$ is an injection from a class of distinguishable functions into the set of admissible data. The injectivity of this mapping implies invertibility in the sense of Theorem 2.3.

THEOREM 4.2. *Let* $[p(t), q(t)]$ *denote a phase-two admissible data pair on* $[0, T]$, *and let* $\{0 = t_0 < \cdots < t_n = T\}$ *denote an arbitrary partition of the interval* $[0, T]$. *Suppose parameter pairs* $\{(\xi_0, \kappa_0), \ldots, (\xi_n, \kappa_n)\}$ *have been generated using the algorithm described in section* 2 *(modified to apply to the phase-two experiment) and that* $(p^*, q^*) = \Gamma \cdot \Psi_1[C^*, K^*]$ *for* $C^* = P_n[\xi_0, \ldots, \xi_n]$ *and* $K^* = P_n[\kappa_0, \ldots, \kappa_n]$. *Then*

(a) $\int_0^{t_m} (p(t) - p^*(t))\vartheta_m(t)\, dt = \int_0^{t_m} (q(t) - q^*(t))\rho_m(t)\, dt = 0, m = 1, \ldots, n;$

(b) *if* $p, q \varepsilon \mathbb{C}^2[t_{m-1}, t_m]$ *for* $m = 1, \ldots n$, *then* $|p(t_m) - p^*(t_m)| \leq \nu \Delta t^2$ *and* $|q(t_m) - q^*(t_m)| \leq \nu \Delta t^2$ *for* $m = 1, \ldots, n$ *for a positive constant* ν *depending on* p *and* q *and* $\Delta t = \max(t_m - t_{m-1})$.

Note that for each m, ξ_m, κ_m represent approximations to the values $C(-1 + s_m)$ and $K(-1 + s_m)$, respectively. Thus ξ_0 and κ_0 are the last values obtained in the phase-one experiment and are therefore known for the phase-two experiment.

THEOREM 4.3. *Let* $(p, q) = \Gamma \cdot \Psi_1[C, K]$ *for* (C, K) *an admissible coefficient pair, and let* $\{0 = t_0 < \cdots < t_n = T\}$ *denote an arbitrary partition of the interval* $[0, T]$. *Suppose that parameter pairs* $\{(\xi_0, \kappa_0), \ldots, (\xi_n, \kappa_n)\}$ *have been generated using the al-*

gorithm described previously and that $(p^*, q^*) = \Gamma \cdot \Psi_1[C^*, K^*]$ *for* $C^* = P_n[\xi_0, \ldots, \xi_n]$ *and* $K^* = P_n[\kappa_0, \ldots, \kappa_n]$*. If* $C, K \varepsilon \mathbb{C}^2[p_i, p_{i-1}]$ *for* $1 \leq i \leq n$*, then*

$$|\xi_i - C(p_i)| \leq \nu \Delta p \quad \text{and} \quad |\kappa_k - K(p_i)| \leq \nu \Delta p \quad \text{for } 1 \leq i \leq n$$

for a positive constant ν *depending on* C *and* K *and for* $\Delta p = \max\{p_{i-1} - p_i\}$.

Theorem 4.3 asserts that by applying suction to one end of a vertical column of soil, it is possible to extend the interval over which the hydraulic functions C and K can be determined. The extent of the domain of determination is then limited only by the experimental capabilities of the suction apparatus.

ON CONCENTRATION OF POSITIVE BOUND STATES OF NONLINEAR SCHRÖDINGER EQUATIONS WITH COMPETING POTENTIAL FUNCTIONS[*]

XUEFENG WANG[†] AND BIN ZENG[†]

Abstract. Some nonlinear Schrödinger equations with several competing potential functions are considered. Ground states (least energy solutions) are proved to exist and concentrate at a point in the semiclassical limit. The concentration points are shown to be located on the middle ground of the competing potential functions and in some cases are given explicitly in terms of these functions. Also given is a necessary condition for location of concentration of positive bound states (solutions with higher but finite energy).

Key words. nonlinear Schrödinger equations, competing potentials, ground states, bound states, energy, semiclassical limit, concentration, existence

1. Introduction.

The simplest equation considered in this paper is the following:

$$h^2\Delta u - V(x)u + K(x)|u|^{p-1}u = 0, \quad x \in R^n, \tag{1}$$

where $1 < p < (n+2)/(n-2)^+$ ($= \infty$ if $n = 1, 2$) and $V(x)$ and $K(x)$ are positive smooth functions with $V(x)$ bounded below by a positive constant and $K(x)$ bounded. We are interested in the existence and concentration behavior of positive *ground states* of (1) and its generalization (4) (see below) in the semiclassical limit $h \to 0$. We are also interested in finding a necessary condition for location of concentration of positive *bound states* of these equations. A ground state of (1) is a solution of the equation which has the least energy,

$$\frac{1}{2}\int_{R^n}(h^2|\nabla u|^2 + V(x)u^2)\,dx - \frac{1}{p+1}\int_{R^n}K(x)|u|^{p+1}\,dx,$$

among all nontrivial solutions of (1). A bound state is a solution with finite but not necessarily least energy.

Equation (1) arises at least in the study of standing-wave solutions of the following time-dependent nonlinear Schrödinger equation:

$$ih\frac{\partial\psi}{\partial t} = -h^2\Delta\psi + V(x)\psi - K(x)|\psi|^{p-1}\psi, \quad x \in R^n.$$

It also provides standing-wave solutions of the Klein–Gorden equations. See [1] and the references therein for more background. Many authors [1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11], [13], [16], [17], [18], [19], [20] have worked on equation (1) in various forms and obtained numerous results on existence, uniqueness, and radial symmetry

of solutions. Of particular interest in this paper is the following existence result of Rabinowitz [19]: if

$$K(x) \equiv 1 \quad \text{and} \quad \liminf_{|x|\to\infty} V(x) > \inf_{x\in R^n} V(x) > 0, \tag{2}$$

then for small h, (1) has a positive ground state. Subsequently, Wang [22] addressed the concentration problem of bound states of (1). For ground states, he proved that under condition (2), any sequence of ground states contains a subsequence which concentrates at a global minimum of $V(x)$ as h tends to zero. Moreover, if we hold $V(x)$ constant instead of $K(x)$, by essentially the same proof as in [22], we can show that ground states concentrate at a global maximum of $K(x)$. When neither $V(x)$ nor $K(x)$ is constant, there would presumably be competition between $V(x)$ and $K(x)$: each would try to attract ground states to their minimum and maximum points, respectively. Now some natural questions arise: Do ground states still concentrate? If so, where? These questions are the primary motivation of this paper.

By variational techniques as developed by Rabinowitz [19] and Wang [22], we show that under certain conditions on the potential functions $V(x)$ and $K(x)$, positive ground states still exist for small h and as h approaches zero, they concentrate at a point on the "middle ground" between "valleys" of $V(x)$ and "peaks" of $K(x)$. More precisely, we prove that if

$$\frac{\liminf_{|x|\to\infty} V^{(2p+2+n-np)/(2p-2)}(x)}{\limsup_{|x|\to\infty} K^{2/(p-1)}(x)} > \inf_{x\in R^n} \frac{V^{(2p+2+n-np)/(2p-2)}(x)}{K^{2/(p-1)}(x)}, \tag{3}$$

then positive ground state solutions of (1) *exist* for small positive h and *concentrate* at a global minimum point of $g(x) := V^{(2p+2+n-np)/(2p-2)}(x)/K^{2/(p-1)}(x)$ as h approaches zero (see Corollaries 2.9 and 3.2). We remark that if (3) does not hold, even the existence is in question. However, if we know that a sequence $\{u_{h_k}\}$ of positive ground states of (1) exists with each having a local maximum point moving toward a point x_0 as $h_k \to 0$, then x_0 is a global minimum point of $g(x)$ and $\{u_{h_k}\}$ concentrates at x_0. Consequently, in the even worse scenario in which $g(x)$ does not have a minimum point, the positive ground states, if any, do not concentrate as h shrinks (they move off to infinity).

To gain further insight into the effect of potential functions on the concentration process, we also consider the following generalization of (1):

$$h^2\Delta u - V(x)u + K(x)|u|^{p-1}u + Q(x)|u|^{q-1}u = 0, \quad x \in R^n, \tag{4}$$

where $1 < q < p < (n+2)/(n-2)^+$ and $Q(x)$ is a bounded smooth function that is allowed to change its sign. When $V(\infty) = \infty$, a result in [19] implies the existence of ground states of (4) for any $h > 0$. In other cases, we cannot find any result in the literature that can be directly applied to obtain even the existence of ground states. The *ground-energy function* $C(s)$, which is defined to be the least (or ground) energy associated with

$$\Delta u - V(s)u + K(s)|u|^{p-1}u + Q(s)|u|^{q-1}u = 0, \quad x \in R^n, \tag{5}$$

where $s \in R^n$ is regarded as a parameter instead of an independent variable, plays a central role in our results and analysis. (See section 2 for the precise definition.) Let c_∞ be the ground energy associated with

$$\Delta u - V_\infty u + K_\infty |u|^{p-1}u + Q_\infty |u|^{q-1}u = 0, \quad x \in R^n,$$

where

$$V_\infty = \liminf_{|s|\to\infty} V(s), \qquad K_\infty = \limsup_{|s|\to\infty} K(s), \qquad Q_\infty = \limsup_{|s|\to\infty} Q(s).$$

We prove that if

$$c_\infty > \inf_{s\in R^n} C\,(s),$$

then for small h (4) has a positive ground state u_h and as h shrinks to zero, after passing to a subsequence u_h concentrates at a global minimum point of $C(s)$ (see Theorems 2.7 and 3.1). From this we will obtain some concrete sufficient conditions (explicitly expressed in terms of the potential functions) for the existence of positive ground states of (4) with small h—see Corollary 2.8. As will be seen, in the case of (1), $g(s)$ is just a positive constant multiple of the ground-energy function $C(s)$ (see (34)). Thus the results for (1) described above are consequences of these general results for (4). However, unlike (1), in the general case (4), we do not (and it is impossible to) have an explicit formula for $C(s)$, and hence we cannot explicitly express the location of concentration of ground states in terms of the potential functions $V(x)$, $K(x)$, and $Q(x)$.

In this paper, we also provide a necessary condition for location of concentration of positive bound states (not necessarily with least energy) of (4). We prove that a point x_0 at which a sequence of positive bound states concentrates as $h \to 0$ must be a critical point of the ground-energy function $C(s)$, provided that (5) with $s = x_0$ has at most one positive decaying solution (up to translations); in the special case (1), this means that the concentration points of positive bound states can only be critical points of $g(x) := V^{(2p+2+n-np)/(2p-2)}(x)/K^{2/(p-1)}(x)$. (See Theorem 4.1 for the precise statement as well as some specific conditions that ensure the uniqueness of aforementioned solutions of (5).) This generalizes the corresponding result in Wang [22], where the case $K(x) \equiv 1$ is considered. This is also in the converse direction of the following result of Floer, Weinstein, and Oh [6], [16], [17]: for small h, (1) with $K(x) \equiv 1$ has a positive "multibump" bound state which concentrates at any given finite set of nondegenerate critical points of $V(x)$ under the condition, say, that $V(x)$ is bounded. (See [22] for a remark on this condition.)

We mention that in Zeng's thesis [24], for equation (1), an existence result in the spirit of [6], [16], and [17] is established under a technical nondegeneracy condition. In particular, if both $V(x)$ and $K(x)$ share a common critical point x_0 (so x_0 is a critical point of $g(x)$) and if none of $(\partial^2/\partial x_i^2)g\,(x_0)$, $i = 1, 2, \ldots, n$, is zero, then for small h, (1) has a positive bound state concentrating at x_0 as $h \to 0$. In this connection, after our work was completed, we received an interesting preprint by Gui, "Existence of multi-bump solutions for nonlinear Schrödinger equations via variational method," which deals with the equation

$$h^2\Delta u - V(x)u + f(u) = 0, \quad x \in R^n. \tag{6}$$

Gui proves the existence of bound states concentrating at finitely many local (not necessarily strict) minimum points of $V(x)$. However, he does not consider the competing potential $K(x)$. Rabinowitz later informed us that, in his thesis, Thandi proved the existence of solutions of (6) with infinitely many bumps and that Del Pino and Felmer also obtained existence results similar to Gui's independently.

We remind the reader that *throughout this paper, we always make the following assumptions*:

(H_1): $V(x)$, $K(x)$, and $Q(x)$ are C^1 smooth in R^n.

(H_2): $\inf_{x\in R^n} V(x) = \overline{V} > 0$, and both $K(x)$ and $Q(x)$ are bounded in R^n, with $K(x) > 0$ and $Q(x)$ allowed to change sign.

2. Existence of ground states.

2.1. Preliminaries. We start by transforming equation (4). Let $v(x) = u(hx)$. Then equation (4) becomes

$$\Delta v(x) - V(hx)v + K(hx)|v|^{p-1}v + Q(hx)|v|^{q-1}v = 0, \quad x \in R^n. \tag{7}$$

Since equations (4) and (7) are equivalent, we shall thereafter focus on equation (7).

Let E_h be the Hilbert subspace of $v \in H^1(R^n)$ under the norm

$$\|v\|^2_{E_h} := \int_{R^n} (|\nabla v|^2 + V(hx)v^2)\, dx < +\infty.$$

Define the *energy functional* associated with (7) by

$$\begin{aligned} I_h(v) := \frac{1}{2}\int_{R^n} (|\nabla v|^2 + V(hx)v^2)\, dx - \frac{1}{p+1}\int_{R^n} K(hx)|v|^{p+1}\, dx \\ - \frac{1}{q+1}\int_{R^n} Q(hx)|v|^{q+1}\, dx \end{aligned} \tag{8}$$

for $v \in E_h$ and $h > 0$, and define the *solution manifold* of (7) by

$$\begin{aligned} M_h := \Big\{ v \in E_h\backslash\{0\} : \int_{R^n} (|\nabla v|^2 + V(hx)v^2)\, dx = \int_{R^n} K(hx)|v|^{p+1}\, dx \\ + \int_{R^n} Q(hx)|v|^{q+1}\, dx \Big\}. \end{aligned} \tag{9}$$

(Any nontrivial solution of (7) in $H^1(R^n)$ belongs to M_h; hence we have the name for M_h.) A *ground state* of (7) is defined as a solution of (7) which minimizes $I_h(v)$ on M_h. The *ground energy* associated with (7) is defined as

$$c_h := \inf_{v\in M_h} I_h(v). \tag{10}$$

By the Sobolev imbedding theorem, it is easy to see that the ground energy c_h is finite. It is also routine to show that (i) any minimizer of I_h on M_h is a solution of (7); (ii) any minimizer is of one sign and since I_h is even, we can always take it to be positive. Thus to show that (7) has a positive ground state, we only need to show that I_h has a minimizer over M_h.

We now show that these minimizers can be found through a minimax process. Let

$$\Gamma_h := \{\, \eta \in C([0,1], E_h) : \eta(0) = 0,\ \eta(1) \not\equiv 0,\ I_h(\eta(1)) \le 0\,\} \tag{11}$$

and define

$$c^*_h := \inf_{\eta\in\Gamma_h} \max_{0\le t\le 1} I_h(\eta(t)). \tag{12}$$

Thus c^*_h is the mountain-pass minimax value associated with I_h.

Define yet another minimax value,

$$c_h^{**} := \inf_{v\in E_h\backslash\{0\}} \max_{t\geq 0} I_h(tv). \tag{13}$$

Lemma 2.1. $c_h = c_h^* = c_h^{**}$.

Remark. This kind of result has already been observed [14], [19] for equations which do not include our (7) or (4) when Q is negative. From this result, we see that to show the existence of ground states of (7), we just need to prove that the minimax value given by (12) and (13) is a critical value of I_h, though we shall not strictly follow this course when proving existence in the future.

Proof. We first show that $c_h = c_h^{**}$. This will follow if we can show that for any $v \in E_h\backslash\{0\}$, the ray $R_t = \{tv : t \geq 0\}$ intersects the solution manifold M_h once and only once at $\theta v\,(\theta > 0)$, where $I_h(tv)$, $t \geq 0$, achieves its maximum. A direct computation shows that critical points of the function $f(t) := I_h(tv)$ occur at and only at the intersections of the ray R_t and M_h. It is easy to see that the ray R_t intersects M_h. Suppose this occurs first at $t = t_0 > 0$. Let

$$g(t) = At^{p-1} + Bt^{q-1}, \tag{14}$$

where $A = \int_{R^n} K(hx)|v|^{p+1}\,dx$ and $B = \int_{R^n} Q(hx)|v|^{q+1}\,dx$. Then

$$\int_{R^n} (|\nabla v|^2 + V(hx)v^2)\,dx = g(t_0).$$

On the other hand, it is elementary to show that

$$g(t) \text{ is strictly increasing on any interval where } g(t) > 0. \tag{15}$$

Thus $g(t)$ is strictly increasing for $t \geq t_0$, and hence the ray R_t intersects M_h only once. We have shown that $c_h = c_h^{**}$.

It remains to show that $c_h = c_h^*$. The inequality $c_h^* \leq c_h^{**} = c_h$ is true because for each nonzero $v \in E_h$, there exists a segment of the half-line $\{tv : t \geq 0\}$ that contains the maximum point of $I_h(tv)$ and is a path in Γ_h. Now we show that $c_h \leq c_h^*$.

By the Sobolev embedding theorem, for nonzero v with $\|v\|_{E_h}$ small,

$$\int_{R^n} (|\nabla v|^2 + V(hx)v^2)\,dx > \int_{R^n} K(hx)|v|^{p+1}\,dx + \int_{R^n} Q(hx)|v|^{q+1}\,dx. \tag{16}$$

We claim that any path $\eta(t)$ in Γ_h crosses M_h. Otherwise, by the continuity of $\eta(t)$, inequality (16) still holds true when v is replaced by each nonzero $\eta(t)$ for $t \in [0,1]$. Recall that $\eta(1)$ is nonzero. Then

$$\begin{aligned} I_h(\eta(1)) &= \frac{1}{2}\int_{R^n} (|\nabla\eta|^2 + V(hx)\eta^2)\,dx - \frac{1}{p+1}\int_{R^n} K(hx)|\eta|^{p+1}\,dx \\ &\quad - \frac{1}{q+1}\int_{R^n} Q(hx)|\eta|^{q+1}\,dx \\ &> \frac{1}{q+1}\int_{R^n} (|\nabla\eta|^2 + V(hx)\eta^2)\,dx - \frac{1}{p+1}\int_{R^n} K(hx)|\eta|^{p+1}\,dx \\ &\quad - \frac{1}{q+1}\int_{R^n} Q(hx)|\eta|^{q+1}\,dx \\ &\geq \left(\frac{1}{q+1} - \frac{1}{p+1}\right)\int_{R^n} K(hx)|\eta|^{p+1}\,dx \\ &> 0. \end{aligned}$$

The above inequality violates the definition of $\eta(1)$. Thus $\eta(t)$ crosses M_h, and hence

$$\max_{0\le t\le 1} I_h(\eta(t)) \ge \inf_{v\in M_h} I_h(v) = c_h.$$

This completes the proof of Lemma 2.1. ∎

Now we discuss the properties of the ground energy c_h given by (10). Denote c_1 by $c(V,K,Q)$. The following comparison result is similar to the one in [19].

LEMMA 2.2. *Suppose that $V_a(x)$, $V_b(x)$, $K_a(x)$, $K_b(x)$, $Q_a(x)$, and $Q_b(x)$ satisfy our* (*standing*) *conditions* (H_1) *and* (H_2). *If*

$$V_a \le V_b, \qquad K_a \ge K_b, \qquad Q_a \ge Q_b, \tag{17}$$

then

$$c\,(V_a, K_a, Q_a) \le c\,(V_b, K_b, Q_b).$$

If, in addition, one of the inequalities in (17) *is strict and $V_b(x)$, $K_b(x)$, and $Q_b(x)$ are constant functions, then*

$$c\,(V_a, K_a, Q_a) < c\,(V_b, K_b, Q_b).$$

Proof. Let I^a be the energy functional associated with $c\,(V_a,K_a,Q_a)$. Define other related notation in the obvious way. Note that $E^b \subset E^a$ and for any $v \in E^b$, $I^a(v) \le I^b(v)$. Thus by Lemma 2.1,

$$\begin{aligned} c\,(V_b, K_b, Q_b) &= \inf_{v\in E^b\setminus\{0\}} \max_{t\ge 0} I^b(tv) \ge \inf_{v\in E^a\setminus\{0\}} \max_{t\ge 0} I^a(tv) \\ &= c\,(V_a, K_a, Q_a). \end{aligned}$$

Now we prove the second assertion. Since $V_b(x)$, $K_b(x)$, and $Q_b(x)$ are constants, we have that $E^b = E^a = H^1$. Furthermore, it is well known that there exists a ground state $v_b \in H^1$ such that $c\,(V_b,K_b,Q_b) = I^b(v_b)$. (See, e.g., [19, Theorem 4.23]. We should mention that condition (f_5) in [19] is not satisfied if $Q_b < 0$, but that condition is used there to show identities like those in our Lemma 2.1.) Now we have

$$\begin{aligned} c\,(V_b, K_b, Q_b) = I^b(v_b) \ &= \ \max_{t\ge 0} I^b(tv_b) \ > \ \max_{t\ge 0} I^a(tv_b) \\ &\ge \inf_{v\in H^1\setminus\{0\}} \max_{t\ge 0} I^a(tv) \ = \ c\,(V_a, K_a, Q_a). \end{aligned}$$

Here we used Lemma 2.1. This proves Lemma 2.2. ∎

Next, we define the *ground-energy function* $C(s)$ mentioned in section 1. For each $s \in R^n$, consider

$$\Delta v(x) - V(s)v + K(s)|v|^{p-1}v + Q(s)|v|^{q-1}v = 0, \quad x \in R^n. \tag{18}$$

Let I^s be the associated energy functional, i.e.,

$$\begin{aligned} I^s(v) := \frac{1}{2}\int_{R^n} (|\nabla v|^2 + V(s)v^2)\,dx - \frac{1}{p+1}\int_{R^n} K(s)|v|^{p+1}\,dx \\ - \frac{1}{q+1}\int_{R^n} Q(s)|v|^{q+1}\,dx. \end{aligned} \tag{19}$$

Define the *ground-energy function* by

$$C\,(s) = \inf_{v \in M^s} I^s(v), \tag{20}$$

where M^s is the solution manifold of (18) defined as in (9). As mentioned in the proof of Lemma 2.1, it is well known that for each $s \in R^n$, (18) has a positive ground state $v_s(x)$ (i.e., $v_s(x)$ solves (20)). By [7], v_s is spherically symmetric about, say, the origin and is decreasing in $r = |x|$.

LEMMA 2.3.

(i) *The ground energy function $C(s)$ is locally Lipschitz continuous in $s \in R^n$.*

(ii) *Denote by $C_i^l(s)$ and $C_i^r(s)$, $i = 1, 2, 3, \ldots, n$, the left and right partial derivatives of $C(s)$ with respect to ith variable s_i, respectively. Then they always exist at all $s \in R^n$ and*

$$\begin{aligned} C_i^l(s) = \sup_{v_s \in G^s} \bigg[&\frac{1}{2}\frac{\partial V(s)}{\partial s_i} \int_{R^n} v_s^2(x)\,dx \\ &- \frac{1}{p+1}\frac{\partial K(s)}{\partial s_i} \int_{R^n} v_s^{p+1}(x)\,dx - \frac{1}{q+1}\frac{\partial Q(s)}{\partial s_i} \int_{R^n} v_s^{q+1}(x)\,dx \bigg], \end{aligned} \tag{21}$$

$$\begin{aligned} C_i^r(s) = \inf_{v_s \in G^s} \bigg[&\frac{1}{2}\frac{\partial V(s)}{\partial s_i} \int_{R^n} v_s^2(x)\,dx \\ &- \frac{1}{p+1}\frac{\partial K(s)}{\partial s_i} \int_{R^n} v_s^{p+1}(x)\,dx - \frac{1}{q+1}\frac{\partial Q(s)}{\partial s_i} \int_{R^n} v_s^{q+1}(x)\,dx \bigg], \end{aligned} \tag{22}$$

where $i = 1, 2, 3, \ldots, n$ and $G^s =$ the set of all positive (radial) ground states of (18).

(iii) *The function $C(s)$ is C^1 smooth throughout R^n in any of the following cases:* (a) $n = 1$; (b) $Q(s) \le 0$ *in* R^n; (c) $1 < q < p \le n/(n-2)$ *and* $n > 2$.

Remark. In general, by Rademacher's theorem and (i), $C(s)$ is differentiable almost everywhere in R^n. Also, if (18) has a unique positive ground state (up to translations) for each s, then $C(s)$ is C^1 smooth. Unfortunately, the uniqueness is known only in the cases listed in (iii). We point out that if (b) in part (iii) holds at a point, then all partial derivatives of $C(s)$ exist at that point.

Proof. As discussed in the proof of Lemma 2.1, for any s, $t \in R^n$, there is a unique positive constant $\theta(s,t)$ such that $\theta(s,t)v_t(x) \in M^s$. Thus

$$\begin{aligned} &\int_{R^n} (|\nabla v_t(x)|^2 + V(s)v_t^2(x))\,dx \\ &\quad = \theta^{p-1}(s,t) \int_{R^n} K(s)v_t^{p+1}(x)\,dx + \theta^{q-1}(s,t) \int_{R^n} Q(s)v_t^{q+1}(x)\,dx \end{aligned} \tag{23}$$

and $\theta(t,t) = 1$. By the implicit-function theorem, $\theta(s,t)$ is differentiable with regard to variable s.

CLAIM 2.3.1. *$\theta(s,t)$ is bounded for bounded s and t.*

To see this, we first observe that

$$\begin{aligned} C(t) = I^t(v_t) &= \left(\frac{1}{2} - \frac{1}{q+1}\right) \int_{R^n} (|\nabla v_t(x)|^2 + V(t)v_t^2(x))\,dx \\ &\quad + \left(\frac{1}{q+1} - \frac{1}{p+1}\right) \int_{R^n} K(t)v_t^{p+1}(x)\,dx \\ &= \left(\frac{1}{2} - \frac{1}{p+1}\right) \int_{R^n} K(t)v_t^{p+1}(x)\,dx \end{aligned}$$

$$+\left(\frac{1}{2}-\frac{1}{q+1}\right)\int_{R^n} Q(t)v_t^{q+1}(x)\,dx. \tag{24}$$

From this, Lemma 2.2, and the Sobolev imbedding theorem, we have that $C(t)$ and the H^1, L^{p+1}, and L^{q+1} norms of v_t are bounded for bounded t; moreover, for such a t, $C(t)$, and the L^{p+1} norm of v_t are bounded from below by a positive constant. Now from (23), we see that Claim 2.3.1 is true.

To prove (i), we first note that the gradient with respect to variable s of

$$\begin{aligned}
&I^s(\theta(s,t)v_t(x))\\
&\quad=\frac{1}{2}\theta^2(s,t)\int_{R^n}(|\nabla v_t(x)|^2+V(s)v_t^2(x))\,dx\\
&\qquad-\frac{1}{p+1}\theta^{p+1}(s,t)\int_{R^n}K(s)v_t^{p+1}(x)\,dx-\frac{1}{q+1}\theta^{q+1}(s,t)\int_{R^n}Q(s)v_t^{q+1}(x)\,dx.
\end{aligned}$$

is given by

$$\begin{aligned}
&\nabla_s I^s(\theta(s,t)v_t)\\
&\quad=\frac{1}{2}\theta^2(s,t)\nabla_s V(s)\int_{R^n}v_t^2(x)\,dx-\frac{1}{p+1}\theta^{p+1}(s,t)\nabla_s K(s)\int_{R^n}v_t^{p+1}(x)\,dx\\
&\qquad-\frac{1}{q+1}\theta^{q+1}(s,t)\nabla_s Q(s)\int_{R^n}v_t^{q+1}(x)\,dx\\
&\qquad+\nabla_s\theta(s,t)\bigg[\theta^2(s,t)\int_{R^n}(|\nabla v_t(x)|^2+V(s)v_t^2(x))\,dx\\
&\qquad\quad-\theta^{p+1}(s,t)\int_{R^n}K(s)v_t^{p+1}(x)\,dx-\theta^{q+1}(s,t)\int_{R^n}Q(s)v_t^{q+1}(x)\,dx\bigg]\Big/\theta(s,t)\\
&\quad=\frac{1}{2}\theta^2(s,t)\nabla_s V(s)\int_{R^n}v_t^2(x)\,dx-\frac{1}{p+1}\theta^{p+1}(s,t)\nabla_s K(s)\int_{R^n}v_t^{p+1}(x)\,dx\\
&\qquad-\frac{1}{q+1}\theta^{q+1}(s,t)\nabla_s Q(s)\int_{R^n}v_t^{q+1}(x)\,dx
\end{aligned}\tag{25}$$

because $\theta(s,t)v_t(x)\in M^s$. Thus by Claim 2.3.1, for any $R>0$, there exists a constant M such that

$$|\nabla_s I^s(\theta(s,t)v_t)|\le M,\quad |s|,\,|t|\le R. \tag{26}$$

From this it follows that for any $|s^1|$, $|s^2|\le R$,

$$\begin{aligned}
C(s^1)-C(s^2)&\le I^{s^1}(\theta(s^1,\,s^2)v_{s^2})-I^{s^2}(v_{s^2})\\
&=(s^1-s^2)\cdot\nabla_s I^s(\theta(s,s^2)v_{s^2}(x))\big|_{s=\xi\in[s^1,\,s^2]}\\
&\le M|s^1-s^2|,
\end{aligned}$$

where $[s^1,\,s^2]$ is the segment connecting s^1 and s^2.

Similarly, we can show

$$C(s^1)-C(s^2)\ge -M|s^1-s^2|.$$

This finishes the proof of part (i) of Lemma 2.3.

Claim 2.3.2. *For any sequence $\{s_k\}\to s_0$, there exists a subsequence* (*still denoted by $\{s_k\}$*) *such that $v_{s_k}\to w_0$ strongly in H^1, where w_0 is a positive ground state of* (18) *with $s=s_0$.*

As noted earlier, $\|v_s\|_{H^1}$ is bounded for bounded s. Therefore, by the standard elliptic regularity theory, we have, after passing to a subsequence,

$$v_{s_k} \to \text{some } w_0 \quad \text{weakly in } H^1 \text{ and strongly in } C^2_{\text{loc}}, \tag{27}$$

where $w_0 \geq 0$ satisfies (18) with $s = s_0$.

Since

$$-V(s_k)v_{s_k}(0) + K(s_k)|v_{s_k}|^{p-1}v_{s_k}(0) + Q(s_k)|v_{s_k}|^{q-1}v_{s_k}(0) = -\Delta v_{s_k}(0) \geq 0$$

(recall that $v_s(x)$ is radially decreasing), we have

$$K(s_0)|w_0|^{p-1}(0) + Q(s_0)|w_0|^{q-1}(0) \geq V(s_0) > 0.$$

Thus $w_0 \not\equiv 0$, and hence by the strong-maximum principle, $w_0(x) > 0$. Since it belongs to H^1 space, it is easy to show that $w_0(x) \to 0$ as $x \to \infty$. From this, (27), and the fact that $v_s(x)$ is radially decreasing, we obtain that for any small $\delta > 0$, there exists a constant $\rho > 0$ such that

$$|v_{s_k}(x)| < \delta \quad \text{for } |x| > \rho \quad \text{and} \quad k = 1, 2, \ldots. \tag{28}$$

Now take a sufficiently small δ such that

$$\overline{V} - \|K\|_{L^\infty}\, \delta^{p-1} - \|Q\|_{L^\infty}\, \delta^{q-1} > \frac{1}{2}\overline{V},$$

where $\overline{V} = \inf V(x)$. Then by (18) and (28), v_{s_k} is a subsolution of

$$\Delta w - \frac{1}{2}\overline{V}w = 0 \quad \text{for } |x| > \rho.$$

By the comparison principle,

$$|v_{s_k}(x)| \leq \delta \exp\{-C_1(|x| - \rho)\} \quad \text{for } |x| \geq \rho, \tag{29}$$

where C_1 is a positive constant independent of k. Moreover, by virtue of the elliptic interior estimates, the gradient of $v_{s_k}(x)$ also decays exponentially fast at ∞ uniformly with respect to k. Combining these estimates for $v_{s_k}(x)$ with (27), we deduce that $(\rho' > \rho)$

$$\|v_{s_k} - w_0\|^2_{H^1(R^n)} = \|v_{s_k} - w_0\|^2_{H^1(B_{\rho'})} + \int_{B^c_{\rho'}} (|\nabla v_{s_k} - \nabla w_0|^2 + |v_{s_k} - w_0|^2)\, dx$$

converges to zero as $k \to \infty$. From this and the continuity of $C(s)$ (already proved), it follows that w_0 is a ground state of (18) with $s = s_0$. This completes the proof of Claim 2.3.2.

Now we proceed to prove part (ii). To save notation, we assume without loss of generality that $s \in R^1$, i.e., $n = 1$. For the same reason, we shall prove (21) and (22) only at $s = 0$.

For any $v_0 \in G^0$, the set of all positive (radial) ground states of (18) with $s = 0$, and for any $r > 0$, we have

$$\begin{aligned} C(r) - C(0) &\leq I^r(\theta(r,0)v_0) \; - \; I^0(v_0) \\ &= r\nabla_s\, I^s(\theta(s,0)v_0)\big|_{s=\xi\in[0,\,r]}. \end{aligned}$$

This, (25), and the fact that $\theta(s,0) \to \theta(0,0) = 1$ as $s \to 0$ imply that

$$\limsup_{r\to 0^+} \frac{C(r)-C(0)}{r} \le \inf_{v_0 \in G^0} \left[\frac{1}{2}V'(0)\int v_0^2(x)\,dx \right.$$

$$\left. - \frac{1}{p+1}K'(0)\int v_0^{p+1}(x)\,dx - \frac{1}{q+1}Q'(0)\int v_0^{q+1}(x)\,dx\right]. \tag{30}$$

On the other hand,

$$\begin{aligned} C(r) - C(0) &\ge I^r(\theta(r,r)v_r) \;-\; I^0(\theta(0,r)v_r) \\ &= r\nabla_s\, I^s(\theta(s,r)v_r)\big|_{s=\xi\in[0,\,r]}. \end{aligned}$$

From this, Claim 2.3.2, and (25), we have

$$\liminf_{r\to 0^+} \frac{C(r)-C(0)}{r} \ge \text{ right-hand side of (30).}$$

Thus (22) is true. (21) follows similarly.

To prove part (iii), we notice that in all cases (a)–(c), we have the uniqueness (up to translations) of positive ground states of (18) (see [1] when $n = 1$ and [2], [9], and [15, Appendix C] in cases (b) and (c)), and consequently the right and left partial derivatives of $C(s)$ are equal at all s. Furthermore, by Claim 2.3.2, the partial derivatives given by (21) or (22) are continuous in s. This completes the proof of Lemma 2.3. □

Using the arguments in the proof of Lemma 2.3(i), we easily see that the following is true.

LEMMA 2.4. *If V, K, and Q are constant functions, $c(V, K, Q)$ (defined before the statement of Lemma 2.2) depends continuously on them.*

We now present an expression for $C(s)$ which, in particular, enables us to express $C(s)$ explicitly in terms of $V(s)$ and $K(s)$ in the case where $Q(s) = 0$. Substituting $v(x) = \lambda w(\mu x)$ with $\mu^2 = V(s)$, $\lambda = [V(s)/K(s)]^{1/(p-1)}$, and

$$\alpha(s) = \frac{Q(s)}{V^{\frac{p-q}{p-1}}(s)\,K^{\frac{q-1}{p-1}}(s)}, \tag{31}$$

into (18), we have

$$\Delta w(x) - w + |w|^{p-1}w + \alpha(s)|w|^{q-1}w = 0. \tag{32}$$

LEMMA 2.5. *Let $c_{\alpha(s)} := c\,(1, 1, \alpha(s))$, i.e., the ground energy associated with (32). Then $c_{\alpha(s)}$ is a decreasing function of $\alpha(s)$ and*

$$C\,(s) = \frac{V^{\frac{p+1}{p-1}-\frac{n}{2}}(s)}{K^{\frac{p+1}{p-1}-1}(s)}c_{\alpha(s)}. \tag{33}$$

In particular, if $Q(s) = 0$, then

$$C\,(s) = \left(\frac{1}{2} - \frac{1}{p+1}\right)\frac{V^{\frac{p+1}{p-1}-\frac{n}{2}}(s)}{K^{\frac{p+1}{p-1}-1}(s)}\int_{R^n} U^{p+1}(x)\,dx, \tag{34}$$

where $U(x)$ is the unique positive ground state (up to translation) of (32) with $\alpha = 0$.

Proof. The monotone property of $c_{\alpha(s)}$ follows from Lemma 2.2.

Since (18) and (32) are related as indicated above, by direct computations, we obtain (33) and (34). □

We close this subsection by a result which will be very important to the existence and concentration results.

LEMMA 2.6. *There exists positive constant $\bar{c}$ such that $c_h > \bar{c}$. On the other hand,*

$$\limsup_{h \to 0^+} c_h \le \inf_{s \in R^n} C(s).$$

Proof. By Lemma 2.2, $c_h \ge c(\inf V, \|K\|_{L^\infty}, \|Q\|_{L^\infty})$, which is positive (as can be seen from an expression like (24)).

The remaining part of lemma can be proved by choosing good test functions. See the proof of Lemma 2.2 in [22] for a similar situation. □

2.2. Existence results. Define

$$V_\infty = \liminf_{|s| \to \infty} V(s), \qquad K_\infty = \limsup_{|s| \to \infty} K(s), \qquad Q_\infty = \limsup_{|s| \to \infty} Q(s). \tag{35}$$

Let $c_\infty := c\,(V_\infty, K_\infty, Q_\infty)$. If $V_\infty = +\infty$, define $c_\infty := +\infty$ (see (33)).

THEOREM 2.7. *If*

$$c_\infty > \inf_{s \in R^n} C\,(s), \tag{36}$$

then for small $h > 0$, equation (7) (*and hence* (4)) *has a positive ground-state solution.*

Proof. By Lemma 2.1, we can find a sequence $\{u_m\}$ such that $\|u_m\|_{E_h} = 1$ and

$$\max_{t \ge 0} I_h(tu_m) \to c_h \quad \text{as } m \to \infty.$$

By [12, Theorem 4.3] and Lemma 2.1 again, there exist a sequence $\{w_m\}$ in E_h and a sequence $\{\xi_m\}$ such that

$$I_h(w_m) \to c_h,\ I_h'(w_m) \to 0 \quad \text{and} \quad \|w_m - \xi_m u_m\|_{E_h} \to 0. \tag{37}$$

(The fact that [12, Theorem 4.3] applies in situations like ours was pointed out in [19].)

CLAIM 2.7.1. *$|\xi_m|$ has a positive lower bound.*

Otherwise, since $\{u_m\}$ is bounded in E_h, we have, after passing to a subsequence if necessary, $w_m \to 0$ in E_h. Hence $I_h(w_m) \to 0 = c_h$, which contradicts Lemma 2.6. This proves Claim 2.7.1.

By (37), for large m,

$$\begin{aligned} c_h + 1 + \|w_m\|_{E_h} &\ge I_h(w_m) - \frac{1}{q+1} I_h'(w_m) w_m \\ &\ge \left(\frac{1}{2} - \frac{1}{q+1}\right) \|w_m\|_{E_h}^2. \end{aligned}$$

It follows that $\{w_m\}$ is bounded in E_h. Hence by (37), $\{\xi_m\}$ is bounded. Furthermore, along a subsequence if necessary, $w_m \to$ some w_0 weakly in E_h, strongly in

$L^{\tau}_{\mathrm{loc}}(R^n)$, $1<\tau<2n/(n-2)^+$, and almost everywhere in R^n; by (37) again, w_0 is a weak and hence classical solution of equation (7).

If $w_0 \not\equiv 0$, then $w_0 \in M_h$. By Fatou's lemma,

$$\begin{aligned}
c_h &= \lim_{m\to\infty}\left(I_h(w_m) - \frac{1}{q+1}I_h'(w_m)w_m\right)\\
&= \lim_{m\to\infty}\left[\left(\frac{1}{q+1}-\frac{1}{p+1}\right)\int_{R^n}K(hx)|w_m|^{p+1}\,dx + \left(\frac{1}{2}-\frac{1}{q+1}\right)\|w_m\|^2_{E_h}\right]\\
&\geq \left(\frac{1}{q+1}-\frac{1}{p+1}\right)\int_{R^n}K(hx)|w_0|^{p+1}\,dx + \left(\frac{1}{2}-\frac{1}{q+1}\right)\|w_0\|^2_{E_h}\\
&= I_h(w_0) \geq c_h.
\end{aligned}$$

This implies that $I_h(w_0)=c_h$ and hence $|w_0|$ is a positive ground state of (7), and we are done.

Now we show that $w_0 \not\equiv 0$ for small h. Otherwise,

$$w_m \to 0 \quad \text{in } L^{\tau}_{\mathrm{loc}}(R^n), \quad 1<\tau<\frac{2n}{(n-2)^+}. \tag{38}$$

Claim 2.7.2. *$\int_{R^n}|u_m|^{p+1}\,dx$ has a positive lower bound.*

Otherwise, by passing to a subsequence if necessary and by Hölder's inequality, we have that the L^{p+1} and L^{q+1} norms of u_m converge to 0 as $m\to\infty$. Thus this is also true for w_m by (37) and the boundedness of ξ_m. Now we are led to

$$\begin{aligned}
c_h &= \lim_{m\to\infty}\left[I_h(w_m) - \frac{1}{2}I_h'(w_m)w_m\right]\\
&= \lim_{m\to\infty}\int_{R^n}\left[\left(\frac{1}{2}-\frac{1}{p+1}\right)K(hx)|w_m|^{p+1} + \left(\frac{1}{2}-\frac{1}{q+1}\right)Q(hx)|w_m|^{q+1}\right]dx\\
&\leq \lim_{m\to\infty}\left[\left(\frac{1}{2}-\frac{1}{p+1}\right)\|K\|_{L^\infty}\int_{R^n}|w_m|^{p+1}\,dx\right.\\
&\quad \left. + \left(\frac{1}{2}-\frac{1}{q+1}\right)\|Q\|_{L^\infty}\int_{R^n}|w_m|^{q+1}\,dx\right]\\
&= 0.
\end{aligned}$$

This contradicts Lemma 2.6 and proves Claim 2.7.2.

By assumption (36) and Lemma 2.4, we can choose $\epsilon>0$ so small that

$$c^{\epsilon} := c\,(V_\infty-\epsilon, K_\infty+\epsilon, Q_\infty+\epsilon) > \inf_{s\in R^n} C\,(s) \tag{39}$$

Take a constant ρ sufficiently large such that for $|x|>\rho$,

$$V(x) > V_\infty-\epsilon,\ K(x) < K_\infty+\epsilon,\ Q(x) < Q_\infty+\epsilon. \tag{40}$$

Let M^ϵ denote the solution manifold for the equation

$$\Delta v - (V_\infty-\epsilon)v + (K_\infty+\epsilon)|v|^{p-1}v + (Q_\infty+\epsilon)|v|^{q-1}v = 0, \quad x\in R^n. \tag{41}$$

From the proof of Lemma 2.1, there exists $\alpha_m>0$ such that $\alpha_m u_m \in M^\epsilon$. It is easy to see that for some $\kappa>0$ independent of m,

$$\alpha_m^{p+1}\int_{R^n}(K_\infty+\epsilon)|u_m|^{p+1}\,dx + \alpha_m^{q+1}\int_{R^n}(Q_\infty+\epsilon)|u_m|^{q+1}\,dx$$

$$
\begin{aligned}
&= \alpha_m^2 \int_{R^n} (|\nabla u_m|^2 + (V_\infty - \epsilon)|u_m|^2)\, dx \\
&\le \kappa \alpha_m^2 \|u_m\|_{E_h}^2 \;=\; \kappa \alpha_m^2 .
\end{aligned}
$$

This and Claim 2.7.2 imply the boundedness of α_m.

Now observe that by (40),

$$
\begin{aligned}
c_h &= \lim_{m\to\infty} \max_{t\ge 0} I_h(tu_m) \\
&\ge \limsup_{m\to\infty} I_h(\alpha_m u_m) \\
&= \limsup_{m\to\infty} \Bigg[\frac{1}{2}\int_{R^n} (|\nabla(\alpha_m u_m)|^2 + V(hx)(\alpha_m u_m)^2)\, dx \\
&\qquad - \frac{1}{p+1}\int_{R^n} K(hx)|\alpha_m u_m|^{p+1}\, dx - \frac{1}{q+1}\int_{R^n} Q(hx)|\alpha_m u_m|^{q+1}\, dx \Bigg] \\
&\ge \limsup_{m\to\infty} \Bigg[\frac{1}{2}\int_{R^n} (|\nabla(\alpha_m u_m)|^2 + (V_\infty - \epsilon)(\alpha_m v_m)^2)\, dx \\
&\qquad - \frac{1}{p+1}\int_{R^n} (K_\infty + \epsilon)|\alpha_m v_m|^{p+1}\, dx - \frac{1}{q+1}\int_{R^n} (Q_\infty + \epsilon)|\alpha_m v_m|^{q+1}\, dx \\
&\qquad + \frac{1}{2}\int_{B_{\rho/h}} (V(hx) - (V_\infty - \epsilon))(\alpha_m u_m)^2\, dx \\
&\qquad - \frac{1}{p+1}\int_{B_{\rho/h}} (K(hx) - (K_\infty + \epsilon))|\alpha_m u_m|^{p+1}\, dx \\
&\qquad - \frac{1}{q+1}\int_{B_{\rho/h}} (Q(hx) - (Q_\infty + \epsilon))|\alpha_m u_m|^{q+1}\, dx \Bigg], \qquad (42)
\end{aligned}
$$

where $B_{\rho/h}$ is the ball in R^n centered at 0 with radius ρ/h.

On the other hand, by the Sobolev embedding theorem, for $1 < \tau < 2n/(n-2)^+$,

$$
\|w_m - \xi_m u_m\|_{L^\tau} \le C(n,\, \tau)\|w_m - \xi_m u_m\|_{E_h} \to 0.
$$

Therefore, by Claim 2.7.1 and (38), we have that $\|u_m\|_{L^\tau(B_{\rho/h})} \to 0$ as $m \to \infty$. This fact, together with (42) and the boundedness of α_m, implies $c_h \;\ge\; c^\epsilon$, which is impossible for small h according to Lemma 2.6 and (39). □

The following result gives several sufficient conditions for existence which are more specific than condition (36).

COROLLARY 2.8. *If one of the following hypotheses holds true, then for small h, equation* (7) (*and hence* (4)) *has a positive ground-state solution.* (*Recall that V_∞, K_∞, and Q_∞ are defined in* (35).)

1. $V_\infty = \sup_{x\in R^n} V(x)$, $K_\infty = \inf_{x\in R^n} K(x)$, *and* $Q_\infty = \inf_{x\in R^n} Q(x)$.
2. *There exists a point $s_0 \in R^n$ such that*

$$
V_\infty \ge V(s_0), \qquad K_\infty \le K(s_0), \quad \textit{and} \quad Q_\infty \le Q(s_0),
$$

with one of the above inequalities being strict.

3. *There exists a point $s_0 \in R^n$ such that*

$$
\frac{V_\infty^{(2p+2+n-np)/(2p-2)}}{K_\infty^{2/(p-1)}} \ge \frac{V^{(2p+2+n-np)/(2p-2)}(s_0)}{K^{2/(p-1)}(s_0)},
$$

$$
\frac{Q_\infty}{V_\infty^{(p-q)/(p-1)} K_\infty^{(q-1)/(p-1)}} \le \frac{Q(s_0)}{V^{(p-q)/(p-1)}(s_0)\, K^{(q-1)/(p-1)}(s_0)},
$$

with one of the above inequalities being strict.

4. $K_\infty = 0$ *and* $Q_\infty < 0$. *In this case, h need not be small.*

Remark. If $V_\infty = +\infty$, then it is already proved in [19, Theorem 1.7] that (4) has a positive ground state for every $h > 0$. See also a recent preprint by Bartsch and (Z. Q.) Wang, "Existence and multiplicity results for some superlinear elliptic problems on R^n," which weakens this condition. However, our result here is not covered by [19] or any other papers to our knowledge.

Proof. By using Lemmas 2.2 and 2.5, it is easy to verify that each of the conditions 1–3 is sufficient to guarantee that either $c_\infty > \inf_{s\in R^n} C(s)$ or $V(x)$, $K(x)$, and $Q(x)$ are all constant functions. The desired existence follows either from Theorem 2.7 or, in the case where $V(x)$, $K(x)$, and $Q(x)$ are constant functions, from [20, Theorem 4.23].

Under condition 4, note that by Lemma 2.2, $c_{\alpha(s)} \geq c(1,1,0) > 0$ if $|s|$ is sufficiently large. That is, $c_{\alpha(s)}$ has a positive lower bound. Then (33) implies that $c_\infty = +\infty$. Replacing every V_∞ in the proof of Theorem 2.7 by a large number, we see that (4) has a positive ground state for every h. □

In the particular case of equation (1), i.e., $Q(x) \equiv 0$ in equation (4), Corollary 2.8 immediately implies the following.

Corollary 2.9. *If*

$$\frac{\liminf_{|x|\to\infty} V^{(2p+2+n-np)/(2p-2)}(x)}{\limsup_{|x|\to\infty} K^{2/(p-1)}(x)} > \inf_{x\in R^n} \frac{V^{(2p+2+n-np)/(2p-2)}(x)}{K^{2/(p-1)}(x)}, \tag{43}$$

then for small h, equation (1) *has a positive ground-state solution.*

3. Concentration of ground states. In this and the following sections, v_h is always referred to a positive ground state of (7), and $u_h(x) := v_h(x/h)$ is always a positive ground state of (4). We shall always assume that they are related in this way.

Theorem 3.1. *Under condition* (36), *for every sequence* $\{h'_k\} \to 0^+$, *there exists a subsequence* $\{h_k\}$ *such that a sequence of positive ground states* $\{u_{h_k}(x)\}$ *of* (4) *concentrates at a global minimum point* x_0 *of* $C(s)$ *in the following sense: for each small positive* h_k, $u_{h_k}(x)$ *has a unique maximum point* x_k *with* $\lim_{h_k\to 0^+} x_k = x_0$; *moreover, for each positive* δ *and large* k,

$$\max_{|x-x_0|\leq\delta} u_{h_k}(x) > C_1 \tag{44}$$

and

$$u_{h_k}(x) \leq C_2 \left|\frac{x-x_k}{h_k}\right|^{\frac{1-n}{2}} \exp\left(-\overline{V}^{\frac{1}{2}}\left|\frac{x-x_k}{h_k}\right|\right) \quad \text{for } x \in R^n, \tag{45}$$

where C_1 *and* C_2 *depend only on* n, p, q, $\overline{V} := \inf V$, $\widehat{K} := \sup K$, *and* $\widehat{Q} := \sup Q$.

As an immediate consequence of this and Lemma 2.5, we have the following result.

Corollary 3.2. *Assume* (43). *For every sequence* $\{h'_k\} \to 0^+$, *there exists a subsequence* $\{h_k\}$ *such that a sequence of positive ground states* $\{u_{h_k}(x)\}$ *of* (1) *concentrates at a global minimum point* x_0 *of*

$$g(x) := \frac{V^{(2p+2+n-np)/(2p-2)}(x)}{K^{2/(p-1)}(x)}$$

in the sense specified in the statement of Theorem 3.1.

The proof of this theorem will be lengthy but will be along the main lines of the proof of the corresponding result in [22]. We shall first show that there exists a sequence of points $\{y_{h_k}\}$ in R^n such that (i) most of the "mass" of v_{h_k} is contained in a ball (of fixed size) centered at y_{h_k} and (ii) $h_k y_{h_k}$ is bounded. This will be done in Lemmas 3.3 and 3.4. Then in Lemma 3.5, we show that (i) any limit point of $h_k y_{h_k}$ is a global minimum point of the ground-energy function $C(s)$ and (ii) $w_k(x) := v_{h_k}(x + y_{h_k}) = u_{h_k}(h_k x + h_k y_{h_k})$ converges in $H^1(R^n)$. After finishing these steps, the theorem will follow from modifying the arguments in the proof of [22, Theorem 2.1] (which is from (2.15) to the end in that paper). We shall not give the details of the easy modifications.

Now we proceed to prepare the first of these lemmas. Observe that for any v on the solution manifold M_h,

$$\begin{aligned} I_h(v) = {} & \left(\frac{1}{2} - \frac{1}{q+1}\right) \int_{R^n} (|\nabla v|^2 + V(hx)v^2)\, dx \\ & + \left(\frac{1}{q+1} - \frac{1}{p+1}\right) \int_{R^n} K(hx)|v|^{p+1}\, dx. \end{aligned} \tag{46}$$

Define a *measure* μ_h by

$$\mu_h(\Omega) = \int_\Omega \left[\left(\frac{1}{2} - \frac{1}{q+1}\right)(|\nabla v_h|^2 + V(hx)v_h^2) + \left(\frac{1}{q+1} - \frac{1}{p+1}\right) K(hx)|v_h|^{p+1}\right] dx.$$

By Lemma 2.6, along a subsequence if necessary, as $h \to 0$,

$$\mu_h(R^n) = c_h \to \tilde{c} \leq \inf_{s \in R^n} C\,(s), \tag{47}$$

where $\tilde{c} \geq \bar{c} > 0$. By the concentration-compactness lemma of P. L. Lions in [11, part 1] (or see [21]), there are three possibilities:

1 (*compactness*). There exists a sequence $\{y_{h_k}\}$ that satisfies the following: for any $\epsilon > 0$, there is a $\rho > 0$ such that

$$\int_{B_\rho(y_{h_k})} d\mu_{h_k} \geq \tilde{c} - \epsilon. \tag{48}$$

2 (*vanishing*). There exists a sequence $\{h_k\}$ that tends to zero such that for all $\rho > 0$,

$$\lim_{h_k \to 0^+} \sup_{y \in R^n} \int_{B_\rho(y)} d\mu_{h_k} = 0;$$

3 (*dichotomy*). There exist a constant $\tilde{c}'$ with $0 < \tilde{c}' < \tilde{c}$, sequences $\{\rho_{h_k}\} \to \infty$ and $\{y_{h_k}\} \subset R^n$, and two nonnegative measures $\mu^1_{h_k}$ and $\mu^2_{h_k}$ such that

$$0 \leq \mu^1_{h_k} + \mu^2_{h_k} \leq \mu_{h_k},$$

$$\operatorname{supp}(\mu^1_{h_k}) \subset B_{\rho_{h_k}}(y_{h_k}), \qquad \operatorname{supp}(\mu^2_{h_k}) \subset B^c_{2\rho_{h_k}}(y_{h_k}),$$

$$\mu^1_{h_k}(R^n) \to \tilde{c}', \qquad \mu^2_{h_k}(R^n) \to \tilde{c} - \tilde{c}'.$$

LEMMA 3.3. *Neither vanishing* (2) *nor dichotomy* (3) *occurs.*

Proof.

CLAIM 3.3.1. *Vanishing* (2) *does not occur.*

Otherwise, $v_{h_k} \to 0$ in L^τ for each τ with $2 < \tau < 2n/(n-2)^+$ (see [11, part 2] or [4]). Then

$$\begin{aligned} 0 &= \lim_{k\to\infty} \left(\frac{1}{2} - \frac{1}{p+1}\right) \widehat{K} \int_{R^n} v_{h_k}^{p+1}\,dx + \left(\frac{1}{2} - \frac{1}{q+1}\right) \widehat{Q} \int_{R^n} v_{h_k}^{q+1}\,dx \\ &\geq \limsup_{k\to\infty} \left(\frac{1}{2} - \frac{1}{p+1}\right) \int_{R^n} K(h_k x) v_{h_k}^{p+1}\,dx + \left(\frac{1}{2} - \frac{1}{q+1}\right) \int_{R^n} Q(h_k x) v_{h_k}^{q+1}\,dx \\ &= \limsup_{k\to\infty} c_{h_k} \ \geq\ \bar{c}\ >\ 0. \end{aligned}$$

This contradiction proves Claim 3.3.1.

CLAIM 3.3.2. *Dichotomy* (3) *does not occur.*

Otherwise, take $\phi_h \in C_0^1(R^n)$ such that $\phi_h \equiv 1$ in $B_{\rho_h}(y_h)$, $\phi_h \equiv 0$ in $B^c_{2\rho_h}(y_h)$, and $0 \leq \phi_h \leq 1$, $|\nabla \phi_h| \leq 2/\rho_h$.

Write

$$v_h = \phi_h v_h + (1-\phi_h) v_h =: v_{1h} + v_{2h},$$

where v_{1h} and v_{2h} are defined in the last equality. Then as $h_k \to 0$,

$$\begin{aligned} I_{h_k}(v_{1h_k}) &\geq \mu_{h_k}(B_{\rho_{h_k}}(y_{h_k}))\ \geq\ \mu^1_{h_k}(B_{\rho_h}(y_{h_k})) \\ &= \mu^1_{h_k}(R^n)\ \to\ \tilde{c}' \end{aligned} \tag{49}$$

and

$$\begin{aligned} I_{h_k}(v_{2h_k}) &\geq \mu_{h_k}(B^c_{2\rho_{h_k}}(y_{h_k}))\ \geq\ \mu^2_{h_k}(B^c_{2\rho_{h_k}}(y_{h_k})) \\ &= \mu^2_{h_k}(R^n)\ \to\ \tilde{c} - \tilde{c}'. \end{aligned} \tag{50}$$

Let $\Omega_h = B_{2\rho_h}(y_h) \backslash B_{\rho_h}(y_h)$. Then

$$\begin{aligned} \left(\frac{1}{2} - \frac{1}{q+1}\right) \int_{\Omega_{h_k}} (|\nabla\ v_{h_k}|^2 + V(h_k x) v_{h_k}^2)\,dx + \left(\frac{1}{q+1} - \frac{1}{p+1}\right) \int_{\Omega_{h_k}} K(h_k x) v_{h_k}^{p+1}\,dx \\ = \mu_{h_k}(\Omega_{h_k}) \\ = \mu_{h_k}(R^n) - \mu_{h_k}(B_{\rho_{h_k}}(y_{h_k})) - \mu_{h_k}(B^c_{2\rho_{h_k}}(y_{h_k})) \\ \leq \mu_{h_k}(R^n) - \mu^1_{h_k}(R^n) - \mu^2_{h_k}(R^n) \\ \to 0. \end{aligned} \tag{51}$$

Thus by the Sobolev embedding theorem, we have

$$\int_{\Omega_{h_k}} (v_{h_k}^{p+1} + v_{h_k}^{q+1})\,dx \to 0 \quad \text{as } h_k \to 0^+.$$

Consequently,

$$\int_{R^n} K(h_k x) v_{h_k}^{p+1}\,dx = \int_{R^n} K(h_k x)(v_{1h_k} + v_{2h_k})^{p+1}\,dx$$

$$\begin{aligned}
&= \int_{B_{\rho_{h_k}}(y_{h_k})} K(h_k x) v_{1h_k}^{p+1}\, dx + \int_{\Omega_{h_k}} K(h_k x) v_{h_k}^{p+1}\, dx \\
&\quad + \int_{B^c_{2\rho_{h_k}}(y_{h_k})} K(h_k x) v_{2h_k}^{p+1}\, dx \\
&= \int_{R^n} K(h_k x) v_{1h_k}^{p+1}\, dx + \int_{R^n} K(h_k x) v_{2h_k}^{p+1}\, dx + o(1). \qquad (52)
\end{aligned}$$

Similarly,

$$\int_{R^n} Q(h_k x) v_{h_k}^{q+1}\, dx = \int_{R^n} Q(h_k x) v_{1h_k}^{q+1}\, dx + \int_{R^n} Q(h_k x) v_{2h_k}^{q+1}\, dx + o(1). \qquad (53)$$

Next, observe that

$$\begin{aligned}
\int_{R^n} (|\nabla v_{h_k}|^2 + V(h_k x) v_{h_k}^2)\, dx &= \int_{R^n} (|\nabla v_{1h_k}|^2 + V(h_k x) v_{1h_k}^2)\, dx \\
&\quad + \int_{R^n} (|\nabla v_{2h_k}|^2 + V(h_k x) v_{2h_k}^2)\, dx + J_{h_k}, \qquad (54)
\end{aligned}$$

where $J_{h_k} := 2\int_{R^n} (\nabla v_{1h_k} \cdot \nabla v_{2h_k} + V(h_k x)\, v_{1h_k} v_{2h_k})\, dx \to 0$ as $h_k \to 0$ because of (51).

Now (49)–(50) and (52)–(54) imply that

$$\begin{aligned}
\tilde{c} &= \lim_{h_k \to 0^+} I_{h_k}(v_{h_k}) \\
&= \lim_{h_k \to 0^+} (I_{h_k}(v_{1h_k}) + I_{h_k}(v_{2h_k}) + o(1)) \\
&\geq \liminf_{h_k \to 0^+} I_{h_k}(v_{1h_k}) + \liminf_{h_k \to 0^+} I_{h_k}(v_{2h_k}) \\
&\geq \tilde{c}' + (\tilde{c} - \tilde{c}') = \tilde{c}.
\end{aligned}$$

Therefore,

$$\lim_{h_k \to 0^+} I_{h_k}(v_{1h_k}) = \tilde{c}', \qquad \lim_{h_k \to 0^+} I_{h_k}(v_{2h_k}) = \tilde{c} - \tilde{c}'. \qquad (55)$$

Let

$$J^1_{h_k} := \int_{R^n} (|\nabla v_{1h_k}|^2 + V(h_k x) v_{1h_k}^2)\, dx - \int_{R^n} K(h_k x) v_{1h_k}^{p+1}\, dx - \int_{R^n} Q(h_k x) v_{1h_k}^{q+1}\, dx$$

and

$$J^2_{h_k} := \int_{R^n} (|\nabla v_{2h_k}|^2 + V(h_k x) v_{2h_k}^2)\, dx - \int_{R^n} K(h_k x) v_{2h_k}^{p+1}\, dx - \int_{R^n} Q(h_k x) |v_{2h_k}|^{q+1}\, dx.$$

By the fact that $v_h \in M_h$ and by equalities (52)–(54), we get

$$J^1_{h_k} = -J^2_{h_k} + o(1). \qquad (56)$$

Now we conclude our proof of Claim 3.3.2 by showing that (56) is not true. We discuss all three possible cases and show that each leads to a contradiction.

For simplicity of notation, let

$$A_1 := \textstyle\int_{R^n} K(h_k x) v_{1h_k}^{p+1}\, dx \quad \text{and} \quad B_1 := \int_{R^n} Q(h_k x) v_{1h_k}^{q+1}\, dx.$$

Take $\theta_1 > 0$ such that $\theta_1 v_{1h} \in M_h$. That is,

$$\theta_1^{p+1} A_1 + \theta_1^{q+1} B_1 = \theta_1^2 \int_{R^n} (|\nabla v_{1h}|^2 + V(hx) v_{1h}^2)\, dx.$$

Case 1. After passing to a subsequence, $J_{h_k}^1 \leq 0$. In this case, we have

$$\theta_1^{p-1} A_1 + \theta_1^{q-1} B_1 = \int_{R^n} (|\nabla v_{1h_k}|^2 + V(h_k x) v_{1h_k}^2)\, dx \leq A_1 + B_1.$$

Thus $\theta_1 \leq 1$ (see (15)) and hence by (55), as $h_k \to 0^+$,

$$c_{h_k} \leq I_{h_k}(\theta_1 v_{1h_k}) \leq I_{h_k}(v_{1h_k}) \to \tilde{c}' < \tilde{c}.$$

This is absurd because $c_{h_k} \to \tilde{c} > \tilde{c}'$.

Case 2. After passing to a subsequence, $J_{h_k}^2 \leq 0$. In this case, we will be led to a contradiction again as in Case 1.

Case 3. After passing to a subsequence, $J_{h_k}^1 > 0$ and $J_{h_k}^2 > 0$. From (56), it follows that $J_{h_k}^1 = o(1)$ and $J_{h_k}^2 = o(1)$. If $\theta_1 \leq 1 + o(1)$, we are done by arguments similar to those in the proof for Case 1. Now suppose that $\lim_{h_k \to 0^+} \theta_1 = \theta_0 > 1$. We claim that along a subsequence, $\lim_{h_k \to 0^+} (A_1 + B_1) > 0$. Otherwise,

$$\lim_{h_k \to 0^+} \int_{R^n} (|\nabla v_{1h_k}|^2 + V(h_k x) v_{1h_k}^2)\, dx \leq \lim_{h_k \to 0^+} J_{h_k}^1 = 0,$$

which implies that $\tilde{c}' = \lim_{h_k \to 0^+} I_{h_k}(v_{1h_k}) = 0$. This is absurd.

Now observe that

$$\begin{aligned} 0 = \lim_{h_k \to 0^+} J_{h_k}^1 &= \lim_{h_k \to 0^+} (\theta_1^{p-1} A_1 + \theta_1^{q-1} B_1 - A_1 - B_1) \\ &\geq \lim_{h_k \to 0^+} (\theta_1^{q-1} - 1)(A_1 + B_1) = (\theta_0^{q-1} - 1) \lim_{h_k \to 0^+} (A_1 + B_1) \\ &> 0. \end{aligned}$$

We are led to a contradiction again. This proves Claim 3.3.2 and Lemma 3.3. □

Henceforth in this section, the sequence $\{y_{h_k}\}$ is always referred to the one obtained in (48).

Let $w_k(x) := v_{h_k}(x + y_{h_k}) = u_{h_k}(h_k x + h_k y_{h_k})$. Then $w_k(x)$ is a positive ground state of

$$\Delta w_k - V(h_k x + h_k y_{h_k}) w_k + K(h_k x + h_k y_{h_k}) w_k^p + Q(h_k x + h_k y_{h_k}) w_k^q = 0. \tag{57}$$

LEMMA 3.4. *If* (36) *holds, then the sequence* $\{h_k y_{h_k}\}$ *is bounded as* h_k *tends to zero.*

Proof. Suppose that after passing to a subsequence, $h_k y_{h_k} \to \infty$. Since c_{h_k} is bounded, so is $w_k := w_{h_k}$ in H^1. Therefore, along a subsequence, $w_k \to$ some w_0 weakly in H^1, strongly in L^τ_{loc}, where $1 < \tau < 2n/(n-2)^+$, and almost everywhere in R^n. By the compactness condition (48), for any $\epsilon > 0$, there exists $\rho > 0$ such that

$$\left(\frac{1}{2} - \frac{1}{q+1}\right) \int_{B_\rho^c} (|\nabla w_k|^2 + \overline{V}\, w_k^2)\, dx \leq \mu_{h_k}(B_\rho^c(y_{h_k})) < \epsilon.$$

By this and the Sobolev embedding theorem, we have that

$$w_k \to w_0 \quad \text{strongly in } L^\tau, \quad 1 < \tau < \frac{2n}{(n-2)^+}. \tag{58}$$

Observe that

$$\begin{aligned}\left(\frac{1}{2}-\frac{1}{p+1}\right)&\int_{R^n}\widehat{K}w_0^{p+1}\,dx+\left(\frac{1}{2}-\frac{1}{q+1}\right)\int_{R^n}\widehat{Q}w_0^{q+1}\,dx\\&\geq \limsup_{h_k\to 0^+}\left[\left(\frac{1}{2}-\frac{1}{p+1}\right)\int_{R^n}K(h_kx+h_ky_{h_k})w_k^{p+1}\,dx\right.\\&\qquad\left.+\left(\frac{1}{2}-\frac{1}{q+1}\right)\int_{R^n}Q(h_kx+h_ky_{h_k})w_k^{q+1}\,dx\right]\\&=\limsup_{h_k\to 0^+} c_{h_k}\\&\geq \bar{c}>0.\end{aligned}$$

Thus $w_0(x)$ is a nonzero function. Choose $\epsilon>0$ such that (39) holds. By (58) and the assumption $h_ky_{h_k}\to\infty$, we have

$$\Delta w_0-\left(V_\infty-\frac{\epsilon}{2}\right)w_0+\left(K_\infty+\frac{\epsilon}{2}\right)w_0^p+\left(Q_\infty+\frac{\epsilon}{2}\right)w_0^q\geq 0\quad\text{in } H^{-1}.$$

In particular,

$$\int_{R^n}(|\nabla w_0|^2+(V_\infty-\epsilon)w_0^2)\,dx<\int_{R^n}(K_\infty+\epsilon)|w_0|^{p+1}\,dx+\int_{R^n}(Q_\infty+\epsilon)|w_0|^{p+1}\,dx$$

since $w_0\not\equiv 0$. Take $\theta>0$ such that $\theta w_0\in M^\epsilon$, the solution manifold for equation (41). Then $\theta<1$ by the above inequality. Let

$$A:=\textstyle\int_{R^n}K(h_kx+h_ky_{h_k})w_{h_k}^{p+1}\,dx\quad\text{and}\quad B:=\int_{R^n}Q(h_kx+h_ky_{h_k})w_{h_k}^{q+1}\,dx.$$

By (58) and the assumption that $h_ky_{h_k}\to\infty$, we have

$$\limsup_{h_k\to 0^+}A\leq\int_{R^n}(K_\infty+\epsilon)w_0^{p+1}\,dx\quad\text{and}\quad\limsup_{h_k\to 0^+}B\leq\int_{R^n}(Q_\infty+\epsilon)w_0^{q+1}\,dx.$$

These and (48) imply that

$$\begin{aligned}c^\epsilon&:=c\,(V_\infty-\epsilon,K_\infty+\epsilon,Q_\infty+\epsilon)\\&\leq\frac{1}{2}\theta^2\int_{R^n}(|\nabla w_0|^2+(V_\infty-\epsilon)w_0^2)\,dx\\&\quad-\frac{\theta^{p+1}}{p+1}\int_{R^n}(K_\infty+\epsilon)w_0^{p+1}\,dx-\frac{\theta^{q+1}}{q+1}\int_{R^n}(Q_\infty+\epsilon)w_0^{q+1}\,dx\\&\leq\liminf_{h_k\to 0+}\left[\frac{1}{2}\theta^2\int_{R^n}(|\nabla w_k|^2+V(h_kx+h_ky_m)w_k^2)\,dx\right.\\&\qquad-\frac{\theta^{p+1}}{p+1}\int_{R^n}K(h_kx+h_ky_m)w_k^{p+1}\,dx\\&\qquad\left.-\frac{\theta^{q+1}}{q+1}\int_{R^n}Q(h_kx+h_ky_m)w_k^{q+1}\,dx\right]\\&=\liminf_{h_k\to 0+}f(\theta),\end{aligned}$$

where $f(\theta):=(1/2)\theta^2(A+B)-(1/(p+1))\theta^{p+1}A-(1/(q+1))\theta^{q+1}B$. Noting that $A+B>0$, we can easily show that $(d/d\theta)f(\theta)=(A+B)\theta-A\theta^p-B\theta^q>0$ for $\theta\in(0,1)$. Consequently, $f(\theta)<f(1)$ for $\theta\in(0,1)$. This and Lemma 2.6 yield

$$c^\epsilon\leq\liminf_{h_k\to 0+}f(1)=\liminf_{h_k\to 0+}c_{h_k}\leq\inf_{s\in R^n}C\,(s),$$

a contradiction to (39). ∎

Now from Lemma 3.4 and its proof, we know that for any sequence $\{h'_k\} \to 0$, there exists a subsequence $\{h_k\}$ such that $\bar{x}_k := h_k y_{h_k} \to x_0$, and $w_k \to w_0$ weakly in H^1, where $w_0 \geq 0, \not\equiv 0$; moreover, (58) holds.

LEMMA 3.5. $C(x_0) = \inf_{s\in R^n} C(s)$. *Furthermore, $w_k \to w_0$ strongly in H^1.*

Proof. By (58) and the elliptic regularity theory, as $k \to \infty$, $w_k \to w_0$ in C^2_{loc} and

$$\Delta w_0 - V(x_0)w_0 + K(x_0)w_0^p + Q(x_0)w_0^q = 0, \quad x \in R^n.$$

Consequently, by (48) and (58) again,

$$\begin{aligned}
&\inf_{s\in R^n} C(s) \\
&\leq C(x_0) \\
&\leq \left(\frac{1}{2} - \frac{1}{q+1}\right)\int_{R^n} (|\nabla w_0|^2 + V(x_0)w_0^2)\,dx + \left(\frac{1}{q+1} - \frac{1}{p+1}\right)\int_{R^n} K(x_0)w_0^{p+1}\,dx \\
&\leq \liminf_{k\to\infty} \left[\left(\frac{1}{2} - \frac{1}{q+1}\right)\int_{R^n} (|\nabla w_k|^2 + V(h_k x + \bar{x}_k)w_k^2)\,dx \right.\\
&\quad \left. + \left(\frac{1}{q+1} - \frac{1}{p+1}\right)\int_{R^n} K(h_k x + \bar{x}_k)w_k^{p+1}\,dx\right] \\
&= \liminf_{k\to\infty} c_{h_k} \leq \inf_{s\in R^n} C(s).
\end{aligned}$$

This implies that $C(x_0) = \inf_{s\in R^n} C(s)$. From the above inequalities and (58), we see that

$$\lim_{k\to\infty}\int_{R^n} (|\nabla w_k|^2 + V(h_k x + \bar{x}_k)w_k^2)\,dx = \int_{R^n} (|\nabla w_0|^2 + V(x_0)w_0^2)\,dx.$$

From this and by arguments involving the application of Fatou's lemma on the complement of large balls, it is easy to show that $w_k \to w_0$ in H^1. ∎

As mentioned earlier, Theorem 3.1 follows from this lemma and the arguments in [22]. We omit the details.

Remarks. 1. Condition (36) is used in the proof of Theorem 3.1 to ensure the existence of ground states and to show the boundedness of $\{h_k y_{h_k}\}$ in Lemma 3.4. If we do not have condition (36) but know that a sequence $\{u_{h_k}\}$ of positive ground states of (4) exists with each having a local maximum point moving toward a point x_0 as $h_k \to 0$, then by modifying our proof above, it is easy to show that x_0 is a global minimum point of the ground-energy function $C(s)$ and that $\{u_{h_k}\}$ concentrates at x_0 in the sense specified in the statement of Theorem 3.1. See also [22, Theorem 2.3].

2. From this we see that in the even worse scenario where $C(s)$ does not have a minimum point, the positive ground states, if any, do not concentrate as h shrinks (they move off to infinity).

3. As pointed out in section 1, unlike (1), in the general case (4), it is impossible to have an explicit formula for $C(s)$, and hence we cannot explicitly express the location of concentration of ground states in terms of the potential functions $V(x)$, $K(x)$, and $Q(x)$. We believe that if the exponent p in (4) is close to the critical exponent $(n+2)/(n-2)^+$, then the concentration points of ground states are close to maximum points of $K(x)$, and if the other exponent q is close to 1, then these concentration points are close to minimum points of $(V(x) - Q(x))^{(2p+2+n-np)/(2p-2)}/K^{2/(p-1)}(x)$. The techniques developed in [23] may be useful in proving this.

4. Necessary condition for location of concentration. In this section, we assume that there are positive constants γ and C such that

$$|\nabla V(x)|, |\nabla K(x)|, |\nabla Q(x)| \leq C \exp(\gamma |x|). \tag{59}$$

THEOREM 4.1. *Suppose that a sequence of positive bound states $u_{h_k}(x)$ of* (4) *concentrates at a point x_0 in the following sense: for any $\epsilon > 0$, there exist positive constants ρ and N such that*

$$u_{h_k}(x) \leq \epsilon \quad \textit{for } k \geq N \quad \textit{and} \quad |x - x_0| \geq h_k \rho. \tag{60}$$

Then in any of the cases (a) $n = 1$, (b) $Q(x_0) \leq 0$ *in* R^n, *or* (c) $1 < q < p \leq n/(n-2)$ *and* $n > 2$, *the point x_0 is a critical point of the ground energy function $C(s)$: $\nabla C(x_0) = 0$. In particular, in the case of* (1) (*i.e.*, $Q \equiv 0$), $\nabla g(x_0) = 0$, *where* $g(x) = V^{(2p+2+n-np)/(2p-2)}(x)/K^{2/(p-1)}(x)$.

Remark. Each of (a)–(c) is used only to guarantee the uniqueness of positive decaying solutions of (63) below. Thus any condition that guarantees the uniqueness can be a substitute for either of (a)–(c).

Proof. We shall follow the main lines of the proof of the corresponding result in [22]. First, we show that $\{u_{h_k}\}$ is bounded in $L^\infty(R^n)$. This can be achieved by slightly modifying the argument in [22].

Next, let $w_k(x) = u_{h_k}(x_0 + h_k x)$. Then

$$\Delta w_k - V(x_0 + h_k x) w_k + K(x_0 + h_k x) w_k^p + Q(x_0 + h_k x) w_k^q = 0. \tag{61}$$

By (60), $w_k(x)$ decays to zero uniformly with respect to k. Then a simple comparison argument shows

$$w_k(x) \leq C_1 \exp(-C_2 |x|) \quad \text{for } x \in R^n, \tag{62}$$

where C_1 and C_2 are positive constants independent of k. By elliptic regularity theory, together with the boundedness of $\|w_k\|_{L^\infty}$, there exists a $w_0(x)$ in $C^2(R^n)$ such that, along a subsequence, $w_k(x)$ converges to $w_0(x)$ strongly in C^2_{loc}, satisfying (62) and

$$\Delta w_0(x) - V(x_0) w_0(x) + K(x_0) w_0^p(x) + Q(x_0) w_0^q(x) = 0. \tag{63}$$

By the maximum principle, $\max_{x \in R^n} w_k(x) \geq C_0 > 0$, where the constant C_0 is independent of k. This together with (63) implies that all the maximum points of $w_k(x)$ have to remain in a bounded domain for all k. Consequently, $\max_{x \in R^n} w_0(x) \geq C_0 > 0$, and by the strong-maximum principle, $w_0(x) > 0$. Furthermore, as mentioned in the proof of Lemma 2.3, in each of the cases (a)–(c), (63) has only one positive decaying solution (up to translation). Thus w_0 is a ground state of (63).

Multiplying (61) on both sides by $\nabla w_k(x)$ and integrating on $B_R = B_R(0)$, we have

$$\int_{B_R} \left[\Delta w_k \nabla w_k - \frac{1}{2} \nabla (V(x_0 + h_k x) w_k^2) + \frac{1}{2} h_k \nabla V(x_0 + h_k x) w_k^2 \right.$$
$$\left. + K(x_0 + h_k x) \frac{\nabla w_k^{p+1}}{p+1} + Q(x_0 + h_k x) \frac{\nabla w_k^{q+1}}{q+1} \right] dx = 0.$$

Therefore, by the divergence theorem, we have

$$h_k \int_{B_R} \left[\frac{1}{2} \nabla V(x_0 + h_k x) w_k^2 - \frac{1}{p+1} \nabla K(x_0 + h_k x) w_k^{p+1} \right.$$

$$
\begin{aligned}
&\qquad - \frac{1}{q+1}\nabla Q(x_0+h_k x) w_k^{q+1}\Big] \, dx \\
&= -\int_{B_R} \Delta w_k \nabla w_k \, dx + \int_{\partial B_R} \frac{1}{2}\Big[V(x_0+h_k x) w_k^2 \, \nu \\
&\qquad - \frac{1}{p+1} K(x_0+h_k x) w_k^{p+1} \nu - \frac{1}{q+1} Q(x_0+h_k x) w_k^{q+1} \nu \Big] \, dS \\
&= \int_{\partial B_R} \Big[-\nabla w_k \frac{\partial w_k}{\partial \nu} + \frac{|\nabla w_k|^2}{2}\nu + \frac{1}{2} V(x_0+h_k x) w_k^2 \, \nu \\
&\qquad - \frac{1}{p+1} K(x_0+h_k x) w_k^{p+1} \nu - \frac{1}{q+1} Q(x_0+h_k x) w_k^{q+1} \nu \Big] \, dS \\
&=: J_R,
\end{aligned}
$$

where ν stands for the unit outward normal to ∂B_R. Note that for each k,

$$
\begin{aligned}
\int_0^\infty |J_R| \, dR &\le \int_0^\infty dR \int_{\partial B_R} \Big[\frac{3}{2} |\nabla w_k|^2 + \frac{1}{2} V(x_0+h_k x) w_k^2 \\
&\qquad + \frac{1}{p+1} K(x_0+h_k x) w_k^{p+1} + \frac{1}{q+1} Q(x_0+h_k x) w_k^{q+1} \Big] \, dS \\
&\le \frac{3}{2} \int_{R^n} [|\nabla w_k|^2 + V(x_0+h_k x) w_k^2 + K(x_0+h_k x) w_k^{p+1} \\
&\qquad + Q(x_0+h_k x) w_k^{q+1}] \, dx,
\end{aligned}
$$

which is finite because u_{h_k} is a bound state. Consequently, there exists $R_m \to \infty$ such that $J_{R_m} \to 0$. Recall that we assume the growth condition (59) and that we have obtained estimate (62) for $w_k(x)$. By the Lebesgue dominated-convergence theorem,

$$
\begin{aligned}
&\frac{1}{2} \int_{R^n} \nabla V(x_0+h_k x) w_k^2 \, dx \\
&\qquad = \frac{1}{p+1} \int_{R^n} \nabla K(x_0+h_k x) w_k^{p+1} \, dx + \frac{1}{q+1} \int_{R^n} \nabla Q(x_0+h_k x) w_k^{q+1} \, dx.
\end{aligned}
$$

Letting $h_k \to 0$, we obtain

$$
\begin{aligned}
&\frac{1}{2} \nabla V(x_0) \int_{R^n} w_0^2(x) \, dx \\
&\qquad = \frac{1}{p+1} \nabla K(x_0) \int_{R^n} w_0^{p+1}(x) \, dx + \frac{1}{q+1} \nabla Q(x_0) \int_{R^n} w_0^{q+1}(x) \, dx. \qquad (64)
\end{aligned}
$$

Now the desired conclusion follows from Lemma 2.3 and the remark below it since w_0 is a ground state of (63). □

Note added in proof. Some of the papers mentioned in section 1 that concern the existence of concentrating bound states of (6) have already been published:

ERROR BOUNDS IN NONSMOOTH IMAGE DEBLURRING[*]

ALFRED S. CARASSO[†]

Abstract. This paper deals with image deblurring when the unknown original image is not smooth and a priori bounds on its derivatives cannot be prescribed in the inversion algorithm. A significant class of such deblurring problems occurring in medical, industrial, military, astronomical, and environmental applications is shown to be equivalent to backwards-in-time continuation in a generalized diffusion equation that may involve fractional Laplacians. The *slow-evolution-from-the-continuation-boundary* (SECB) constraint, introduced by the author in [*SIAM J. Numer. Anal.*, 31 (1994), pp. 1535–1557], is applicable to such nonsmooth image deblurring. A new analytical approach based on Fourier analysis provides sharp error estimates for SECB deblurring explicitly in terms of the constants entering the a priori constraints. It also leads to an explicit formula that expresses SECB's improvement over the classical Tikhonov–Miller method. An example from positron emission tomography (PET) imaging is used to illustrate the meaning of the SECB constraint. In this application, use of the SECB constraint reduces the L^2 norm of the Tikhonov–Miller inverse operator by almost a factor of ten.

Key words. ill-posed problems, infinitely smoothing operators, image deblurring, SECB restoration, Tikhonov–Miller restoration, nonsmooth images, PET imaging, error bounds

1. Introduction.

Explicit a priori bounds on derivatives of the unknown solutions underlie much of the analysis and numerical computation of ill-posed inverse problems in partial differential and integral equations. Mathematically, such a priori smoothness implies that solutions lie in a compact set in function space. Together with uniqueness of solutions, this leads to continuity of the inverse operator and stable numerical algorithms. On the physical side, smoothness constraints are appropriate in many problems of practical interest where solutions are known to possess relatively simple structures.

However, there are important classes of problems, notably in medical imaging, where solutions exhibit fairly complex structures, are typically not smooth, and often display singularities that may be of vital significance. In such problems, reconstruction methods that incorporate a priori smoothness assumptions on the solution are ill advised. The use of such procedures may result in visually pleasing but oversmoothed solutions in which significant diagnostic information has been eliminated.

In the absence of smoothness, error estimates that imply a *rate of convergence* as the data noise level $\epsilon \downarrow 0$ are not possible. However, error bounds valid for *fixed* small $\epsilon > 0$ that remain useful at realistic values of ϵ are possible, even when smoothness constraints are inapplicable. This was demonstrated in a recent paper [3] dealing with ill-posed continuation problems in partial differential equations. A new type of a priori constraint on solutions is introduced in [3], the so-called *slow-evolution-from-the-continuation-boundary* (SECB) constraint. The SECB constraint stabilizes

the inversion process against noise in the data, even when smoothness constraints are inapplicable. Applications include the harmonic continuation problem in the unit disc in the L^∞ norm, the spatial continuation problem for the heat equation in the L^2 norm, and the backwards-in-time continuation problem for self-adjoint parabolic equations in the L^2 norm. These three problems are canonical examples of ill-posed problems involving infinitely smoothing operators [6], [15].

This self-contained paper focuses on L^2 error bounds in *image deblurring*. An important class of image deblurring problems is shown to be equivalent to backwards-in-time continuation in a generalized diffusion equation involving fractional Laplacians. The SECB constraint can be applied to this ill-posed continuation problem. We bypass the Banach space approach used to obtain error bounds in [3] and rely instead on Fourier analysis in L^2. This method provides new and sharper estimates explicitly in terms of the constants entering the a priori constraints. It also leads to an explicit formula that expresses SECB's improvement over the classical Tikhonov–Miller method [16]. An example of a nonsmooth image from nuclear medicine illustrates the meaning of the SECB constraint and provides typical representative values for the constraint constants. This enables us to relate our analysis to real applications. Since the primary emphasis is on error bounds for the SECB method, no deblurring experiments are presented in this paper. However, such experiments are reported in [3, section 5], where the SECB approach is compared with three other image deblurring methods, using optimal values for the restoration parameters. These experiments confirm the analysis in the present paper by showing that the SECB constraint sharply reduces noise contamination.

2. Image deblurring with class-G point-spread functions.

We study a class of image restoration problems whereby the original image is reconstructed from a noisy blurred version [1], [7], [14], [21]. Following [21, Chapter 12], we consider space-invariant point-spread functions $p(x,y)$, and formulate the deblurring problem as the problem of solving the integral equation $Pg = f$, where

$$Pg \equiv \int_{R^2} p(x-u, y-v) g(u,v) du dv = f_e(x,y) + n(x,y) \equiv f(x,y). \tag{1}$$

Here $g(x,y)$ is the desired unblurred image, $f_e(x,y)$ is the blurred image that would have been recorded in the absence of noise, and $n(x,y)$ represents the cumulative effects of all noise processes that affect the final acquisition of the actual recorded image $f(x,y)$. This includes the case of *multiplicative noise*, where $n(x,y)$ is a function of $f_e(x,y)$. The noise component $n(x,y)$ is unknown but may be presumed small. Likewise, $f_e(x,y)$ is unknown. The type and intensity of the blurring caused by $p(x,y)$, together with the magnitude of $n(x,y)$, ultimately limit the quality of the restoration that can be achieved.

We denote by G the class of blurring kernels $p(x,y)$ with Fourier transform given by

$$\begin{aligned} \hat{p}(\xi,\eta) &\equiv \int_{R^2} p(x,y) e^{-2\pi i(\xi x + \eta y)} dx dy \\ &= e^{-\sum_{i=1}^{J} \alpha_i (\xi^2+\eta^2)^{\beta_i}}, \quad \alpha_i \geq 0, \quad 0 < \beta_i \leq 1. \end{aligned} \tag{2}$$

While many imaging phenomena are not described by (2), the latter encompasses highly significant applications. Thus if all α_is except one are zero, (2) reduces to

$\hat{p}(\xi,\eta) = e^{-\alpha(\xi^2+\eta^2)^\beta}$, which is the characteristic function of a Lévy "stable" probability distribution [5]. The case $\beta = 1$ corresponds to the Gaussian distribution and occurs in quite diverse contexts, including undersea imaging [27], nuclear medicine [20], [22], magnetic resonance imaging [17], computed tomography scanners [18], onboard optical seekers in cruise missiles [2], and ultrasonic imaging in nondestructive evaluation [12]. The case $\beta = 5/6$ describes long-exposure atmospheric-turbulence blurring [26]. The case $\beta = 1/2$ corresponds to the Cauchy distribution and has been used to model X-ray scattering in radiology [25]. Values of β satisfying $1/2 \leq \beta \leq 1$ characterize a wide variety of electron-optical devices [10], [11]. Such devices constitute important components in night-vision and undersea imaging systems [4], [11]. Modern biomedical imaging modalities such as II-TV fluoroscopic systems [23], selenium imaging plates [19], digital TV tomography systems [24], and radiographic screen-film systems [8], [13] are also based on electron-optical components. Methods exist for determining the values of α and β in each component electron-optical device [10]. In a typical imaging situation, several such components are commonly cascaded and used to image objects through a distorting medium such as the atmosphere or the ocean. The overall optical-transfer function is then given by (2), which is an example of an *infinitely divisible* characteristic function [5]. In many other applications, the general functional form described by (2) can be used to best-fit empirically determined optical-transfer functions by suitable choices of the parameters α_i, β_i, and J. In summary, the class G defined by (2) is worthy of analytical interest.

When the kernel of the integral operator P in (1) satisfies (2), the blurred noiseless image $f_e(x,y)$ may be identified with $u(x,y,1)$, where $u(x,y,t)$ is the unique bounded solution of the well-posed direct problem

$$\begin{aligned} &u_t = -\sum_{i=1}^{J} \gamma_i(-\Delta)^{\beta_i} u, \quad t > 0, \quad x,y \in R^2, \quad \gamma_i = \alpha_i(4\pi^2)^{-\beta_i}, \\ &u(x,y,0) = g(x,y), \end{aligned} \tag{3}$$

and $g(x,y)$ is the original unblurred image. This follows by recognizing (2) as the Fourier transform of the fundamental solution for the initial value problem (3). If all $\beta_i = 1$, (3) is the classical heat-conduction equation. For $0 < \beta_i \leq 1$, (3) represents a generalized diffusion process. The image restoration problem (1) is thus equivalent to backwards-in-time continuation of the solution of (3) from noisy data $f(x,y)$ at $t = 1$ rather than $f_e(x,y)$, where $f(x,y)$ is the blurred recorded image. The unblurred image $g(x,y)$ is the continuation at $t = 0$. For given fixed t with $0 < t < 1$, the continuation at time t represents a *partial restoration.* As $t \downarrow 0$, the partial restorations become sharper but noisier. Displaying a sequence of partial restorations at t_n as $t_n \downarrow 0$ can be helpful in identifying features which become obscured by noise at $t = 0$.

Fractional powers of the integral operator P in (1) are naturally related to the evolution equation (3). For fixed t with $0 \leq t \leq 1$, define P^t to be the convolution integral operator in $L^2(R^2)$, with kernel $p(t; x-u, y-v)$, where $p(t;x,y)$ is the inverse Fourier transform of $\exp\{-\sum_{i=1}^{J} t\alpha_i(\xi^2+\eta^2)^{\beta_i}\}$. Then $P^tP^s = P^{t+s}$ for all $s,t \geq 0$, and $P^0 = I$. The solution of (3) may be written as $u(t) = P^t g,\ 0 \leq t \leq 1$. Let $\|\ \|$ denote the $L^2(R^2)$ norm. By continuity, $\|P^t g - g\|$ is small for sufficiently small $t > 0$. Note that P is an infinitely smoothing operator.

Remark 1. The smallness of $\|P^s g - g\|$ for a given fixed $s > 0$ need not imply *any* smoothness in g. Fix $g \in L^2$, fix $s > 0$, and fix $\delta > 0$. If the α_i's are sufficiently

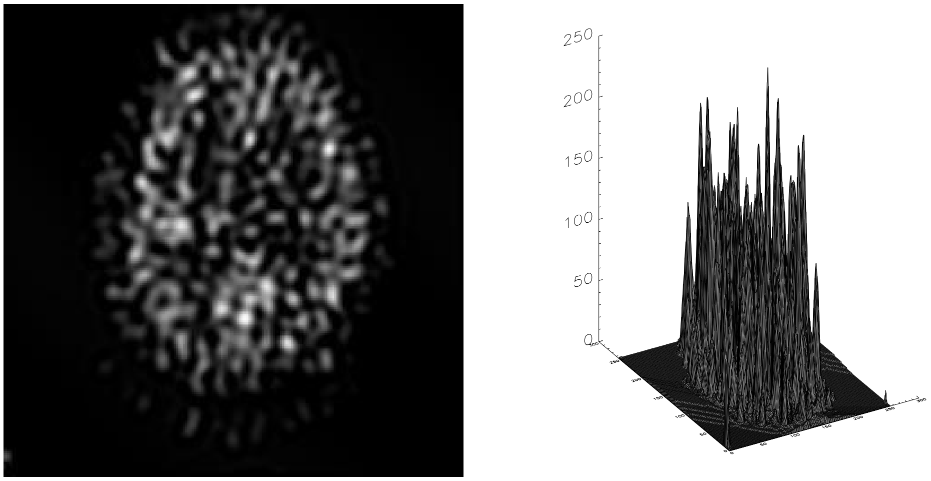

FIG. 1. *Left: PET image of transverse slice of human brain. Right: Image intensity as function of position $g(x, y)$.*

small, then

$$\int_{R^2} |\hat{g}(\xi,\eta)|^2 \left|1 - e^{-\sum_{i=1}^{J} s\alpha_i(\xi^2+\eta^2)^{\beta_i}}\right|^2 d\xi d\eta < \delta, \tag{4}$$

even if for every $q > 0$,

$$\int_{R2} (\xi^2 + \eta^2)^q |\hat{g}(\xi,\eta)|^2 d\xi d\eta = \infty. \tag{5}$$

As we will see below, the significance of the SECB constraint derives from this observation.

3. An example from nuclear medicine. The following example from positron emission tomography (PET) is helpful in motivating subsequent developments. Neuropsychiatrists have long been interested in correlating brain activity with such disorders as alcoholism, schizophrenia, dementia, Alzheimer's disease, mood disorders, and the like. PET imaging is a widely used modality in this field of research. A positron-emitting radionuclide is used to tag glucose molecules in their course through the brain. The metabolic rate of glucose is a key parameter that measures cerebral function and reflects the extent to which regions of the brain are working or failing to work. An emitted positron travels approximately 1 mm to 2 mm before colliding with an electron, resulting in an annihilating reaction in which two gamma ray photons are emitted at 180 degrees from each other. An extracranial ring of coincidence detectors, programmed to count emissions that are paired at 180 degrees, records every such positron emission. Following a coincidence, the source position can be mathematically reconstructed. This leads to an image of the distribution of the glucose tracer, which enables the radiologist to pinpoint areas of abnormal brain activity or to determine the health of cells.

A 256 × 256 PET image of a transverse slice of a human brain was obtained from the Nuclear Medicine Branch of the National Institutes of Health. That image,

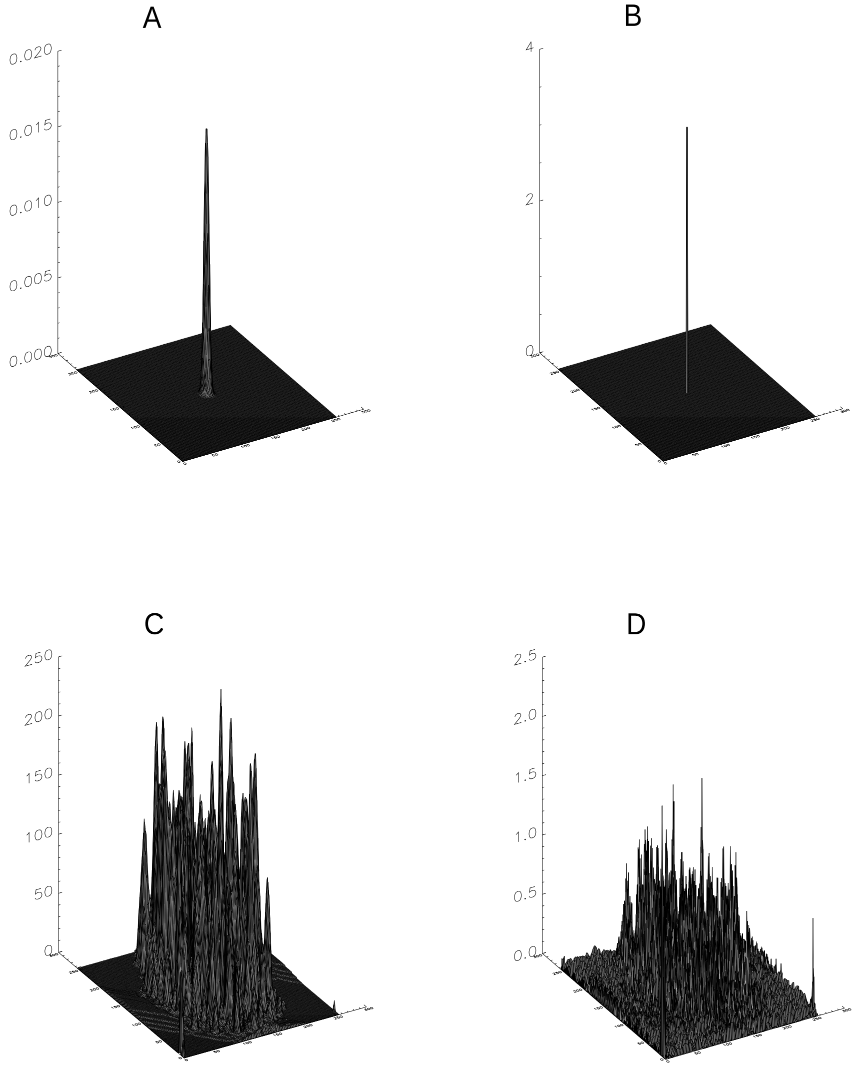

FIG. 2. (A) *The empirically determined PET-scanner Gaussian point-spread function* $p(x, y)$ *and the kernel of integral operator* P; (B) $q(x, y)$*, the* 200*th convolution root of* $p(x, y)$ *and the kernel of* $P^{0.005}$; (C) $P^{0.005}g$ *with* $g(x, y)$ *as in Fig.* 1; (D) $P^{0.005}g - g$. *The maximum intensity in* (B) *is* 200 *times that in* (A)*, while the maximum intensity in* (C) *is* 167 *times that in* (D).

displayed on the left in Fig. 1, consists of pixel values ranging from 0 to 255. The bright spots in the image represent areas of high positron emission and therefore high levels of brain activity. When the same pixel values are plotted as a function of x and y, we obtain the function $g(x, y)$ shown on the right in Fig. 1. Evidently, $g(x, y)$ is not a smooth function. Define the discrete L^2 norm of g by

$$\|g\| = \left\{ (256)^{-2} \sum_{j,k=1}^{256} g(x_j, y_k)^2 \right\}^{1/2}. \tag{6}$$

We find that $\|g\| = 40.15$. In general, owing to scattering of positrons prior to annihilation and to detector effects, reconstructed PET images are seldom as sharp as $g(x,y)$ shown in Fig. 1. Rather, a blurred image $f = Pg$ is obtained, where P is the convolution integral operator in (1), while $g(x,y)$ in Fig. 1 is the unknown original image in the deconvolution problem $Pg = f$. Some concentrated areas of moderate to high brain activity are quite often not apparent in the blurred image $f(x,y)$ but become evident only after deconvolution. Thus the mathematical problem becomes one of recovering g in Fig. 1 from some noisy blurred version f. The point-spread function associated with a given PET scanner can be determined experimentally by imaging a known point source. Typically, this empirically determined point-spread function is found to be well approximated by a Gaussian.

An example of a PET scanner Gaussian point-spread function $p(x,y)$ is shown in Fig. 2A. In Fig. 2B, $q(x,y)$, the 200th convolution root of $p(x,y)$ is shown. The function $q(x,y)$ is itself a Gaussian, one where the full width at half maximum is $\sqrt{200}$ times smaller than in $p(x,y)$. At the same time, the maximum value in $q(x,y)$ is 200 times larger than in $p(x,y)$. If P denotes the convolution operator with kernel $p(x,y)$, then $P^{0.005}$ is the operator with kernel $q(x,y)$. The function $q(x,y)$ is a good approximation of the Dirac δ-function in the following sense. The lack of smoothness of $g(x,y)$ in Fig. 1 notwithstanding, $P^{0.005}g$, shown in Fig. 2C, is almost identical to g. The difference, $(P^{0.005}g - g)$, is shown in Fig. 2D. In fact, we find that $\|P^{0.005}g - g\| = 0.123 = 0.003\|g\|$.

Let $\epsilon = 0.001\|g\| = 0.04$ represent an upper bound for the L^2 norm of the *noise* in the blurred image $f = Pg$. Smoothness constraints on the unknown sharp image g are not possible in the ill-posed deconvolution problem $Pg = f$. Instead, we have found that g satisfies the following *slow-evolution* constraint:

$$\|P^{0.005}g - g\| \le K\epsilon, \quad K \ge 3.1. \tag{7}$$

In section 6, we shall see how this constraint stabilizes the deconvolution problem $Pg = f$.

4. Error bounds in Tikhonov–Miller restoration. One of the best known techniques for regularizing ill-posed integral equations is the Tikhonov–Miller method [16]. In image deblurring [14], Tikhonov–Miller restoration is considered a canonical method. Seemingly more elaborate stochastic restoration procedures, such as Wiener filtering or maximum a posteriori (MAP) restoration [1], [14], ultimately result in mathematically similar expressions for the deblurred image. In addition, the Tikhonov–Miller method requires no a priori assumptions regarding the statistical character of the data noise.

In its simplest form, Tikhonov–Miller restoration requires an a priori bound ϵ for the L^2 norm of the *noise* in the blurred image f, together with an a priori bound M for the L^2 norm of the unblurred image g:

$$\|Pg - f\| \le \epsilon, \quad \|g\| \le M. \tag{8}$$

Here $\epsilon/M \ll 1$, and $\| \ \|$ denotes the $L^2(R^2)$ norm. It is assumed that ϵ and M are compatible with the existence of a $g(x,y) \in L^2$ satisfying (8). Tikhonov–Miller restoration [16] is defined as that unique function $g^T(x,y)$ which minimizes the functional

$$\|Ph - f\|^2 + \omega^2\|h\|^2, \quad \omega = \epsilon/M, \tag{9}$$

over all $h \in L^2(R^2)$. We have

$$g^T = [P^*P + \omega^2 I]^{-1}P^*f, \quad \omega = \epsilon/M. \tag{10}$$

Because no a priori bounds on derivatives of the unknown solution g were incorporated in (9), the best possible bound on the error in g^T is [16]

$$\|g - g^T\| \leq \sqrt{2}M, \tag{11}$$

irrespective of how small ϵ may be. See Remark 1 following Theorem 1 in [3]. The estimate in (11) cannot guarantee accuracy; in fact, appreciable noise contamination of the restored image is commonly experienced [3, section 5]. To get an error bound implying convergence as $\epsilon \downarrow 0$ in the Tikhonov–Miller method, stronger constraints need to be imposed on $g(x, y)$. Let L be an elliptic differential operator, let the unblurred image $g(x, y)$ be sufficiently smooth, and let an a priori bound $\|Lg\| \leq N$ be known. In this case, the appropriate Tikhonov–Miller functional to be minimized over all h in $L^2(R^2)$ is given by

$$\|Ph - f\|^2 + (\epsilon^2/N^2)\|Lh\|^2. \tag{12}$$

As shown in [6] and [15], an error bound of the form

$$\|g - g^T\| = O(N\{\log(N/\epsilon)\}^{-q}) \quad \text{as } \epsilon \downarrow 0 \tag{13}$$

is the best possible for (12). The value of $q > 0$ in (13) depends on the order of L and may be less than 1 if L is a fractional power Laplacian, for example. A major difficulty in connection with (12) lies in inferring a priori the correct value for N when the unknown image $g(x, y)$ is suspected of having localized singular behavior; there is the danger of underestimating N by several orders of magnitude. Moreover, while (13) implies convergence as $\epsilon \downarrow 0$, in practice, ϵ is small but *fixed*, depending as it does on the various noise processes inherent in the given imaging system. The logarithmic continuity result in (13) requires ϵ to be unrealistically small before the error bound becomes useful. Thus if $N = 1000$ and $q = 1$, we have $N\{\log(N/\epsilon)\}^{-1} \leq 10$ if and only if $\epsilon \leq 10^{-40}$. If $q = 1/2$, the requirement on ϵ is dramatically more severe.

5. SECB restoration. Like the Tikhonov–Miller method, the SECB approach requires no a priori knowledge of the statistical character of the data noise, but it does require an a priori bound ϵ for the L^2 norm of the noise in the blurred image f, together with an a priori bound M for the L^2 norm of the unblurred image g:

$$\|Pg - f\| \leq \epsilon, \quad \|g\| \leq M, \quad \epsilon/M \ll 1. \tag{14}$$

In addition, $\|P^s g - g\|$ is required to be small for some fixed s, $0 < s < 1$. This is always true by continuity if s is sufficiently small. We obtain an additional constraint on the class of solutions by requiring that s be known and not *too* small. Specifically, let ϵ and M be as above, with $\epsilon/M \ll 1$. For given K with $0 < K \ll M/\epsilon$, let s^* be defined by

$$s^* = \log\{M/(M - K\epsilon)\}/\log(M/\epsilon). \tag{15}$$

The SECB constraint requires that there exist a constant K with $0 < K \ll M/\epsilon$ such that

$$\|P^s g - g\| \leq K\epsilon, \quad s \text{ fixed}, \quad s^* < s < 1. \tag{16}$$

It is desirable (see section 6.2) that both the blurring operator P and the unblurred image $g(x, y)$ be such that (16) holds with a small $K > 0$ and a relatively large $s < 1$

so that $s/s^* \gg 1$. A large value of s/s^* reflects a priori knowledge that the given blurred image $f(x,y)$ has evolved slowly from the unknown sharp image $g(x,y)$, but it does not imply smoothness of $g(x,y)$. See (4) and (5) in Remark 1 in section 2. The four parameters $\{\epsilon,\ M,\ K,\ s\}$ constitute the a priori information in the SECB method. SECB restoration is then defined as the unique function $g^{\min}(x,y)$ which minimizes the functional

$$\|Ph - f\|^2 + \omega^2\|h\|^2 + K^{-2}\|h - P^s h\|^2, \quad \omega = \epsilon/M, \tag{17}$$

over all $h \in L^2(R^2)$. Note that SECB restoration reduces to Tikhonov–Miller restoration if $s = 0$ or $K = \infty$ in (17). When applicable, the SECB constraint produces error bounds that can be useful at realistic values of ϵ.

Remark 2. In applying the SECB constraint to an image where ϵ and M are known, a useful strategy is to first fix a small positive value of s. Since the point-spread function $p(x,y)$ is known, Fourier analysis may be used to obtain the kernel of P^s and determine how well that kernel approximates the Dirac δ-function. Prior experience with similar images, along the lines depicted in Fig. 2, may be used to arrive at an estimate for $\|P^s g - g\|$ and hence $\|P^s g - g\|/\epsilon$. The constant K in (16) is an upper bound for the latter quantity.

THEOREM 1. *Let the unblurred image $g(x,y)$ satisfy constraints* (14) *and* (16). *Let $g^{\min}(x,y)$ be the function which minimizes* (17). *Let $\omega = \epsilon/M$, and let $Q = Q(K,\omega,s)$ be the positive definite self-adjoint operator in $L^2(R^2)$ given by*

$$Q = P^*P + \omega^2 I + K^{-2}(I - P^s)^*(I - P^s). \tag{18}$$

Then $g^{\min}$ is the unique solution of $Qg^{\min} = P^*f$, and $g^{\min}$ satisfies

$$\|Pg^{\min} - f\|^2 + \omega^2\|g^{\min}\|^2 + K^{-2}\|(I - P^s)g^{\min}\|^2 \le 3\epsilon^2, \tag{19}$$

$$\|P(g - g^{\min})\|^2 + \omega^2\|g - g^{\min}\|^2 + K^{-2}\|(I - P^s)(g - g^{\min})\|^2 \le 3\epsilon^2, \tag{20}$$

$$\|g - g^{\min}\| \le \epsilon\sqrt{3}\|Q^{-1/2}\|. \tag{21}$$

Proof. Let $\mathcal{H}$ denote the Hilbert-space direct sum $L^2(R^2) \bigoplus L^2(R^2) \bigoplus L^2(R^2)$ with elements $[u,v,w]$, scalar product $([u_1,v_1,w_1],[u_2,v_2,w_2]) \equiv \langle u_1,u_2\rangle + \langle v_1,v_2\rangle + \langle w_1,w_2\rangle$, and norm $|||\ \ |||$. Let $\widetilde{P} : L^2(R^2) \mapsto \mathcal{H}$ be defined by $\widetilde{P}h = \big[Ph, \omega h, K^{-1}(I - P^s)h\big]$, and let $\widetilde{f} = [f,0,0]$. We seek to minimize $|||\widetilde{P}h - \widetilde{f}|||$ over all $h \in L^2$. The normal equation $\widetilde{P}^*\widetilde{P}g^{\min} = \widetilde{P}^*\widetilde{f}$ gives $Qg^{\min} = P^*f$, with Q as in (18). By hypothesis, $|||\widetilde{P}g - \widetilde{f}|||^2 \le 3\epsilon^2$. The minimizing element $g^{\min}$ is such that $\widetilde{P}g^{\min}$ is the orthogonal projection in $\mathcal{H}$ of $\widetilde{f}$ on the range of $\widetilde{P}$. By the Pythagorean theorem,

$$|||\widetilde{P}g^{\min} - \widetilde{f}|||^2 + |||\widetilde{P}(g - g^{\min})|||^2 = |||\widetilde{P}g - \widetilde{f}|||^2 \le 3\epsilon^2. \tag{22}$$

This gives (19) and (20). We now establish (21). From (18) and (20), we have

$$\|Q^{1/2}(g - g^{\min})\|^2 = \langle Q(g - g^{\min}), (g - g^{\min})\rangle = |||\widetilde{P}(g - g^{\min})|||^2 \le 3\epsilon^2. \tag{23}$$

Hence

$$\begin{aligned} \|g - g^{\min}\| &= \|Q^{-1/2}\ Q^{1/2}(g - g^{\min})\| \\ &\le \|Q^{-1/2}\|\|Q^{1/2}(g - g^{\min})\| \\ &\le \epsilon\sqrt{3}\|Q^{-1/2}\|. \end{aligned} \tag{24}$$

This completes the proof. ▯

6. Fourier analysis of SECB restoration. Inequality (21) in Theorem 1 reduces the problem of obtaining an error bound in SECB restoration to that of estimating $\|Q^{-1/2}(\epsilon, M, K, s)\|$. With $\hat{p}(\xi,\eta)$ as in (2), we have the following upon Fourier transforming $Q^{-1/2}h$:

$$(\widehat{Q^{-1/2}h})(\xi,\eta) = \left\{|\hat{p}(\xi,\eta)|^2 + \omega^2 + K^{-2}|1-\hat{p}^s(\xi,\eta)|^2\right\}^{-1/2}\hat{h}(\xi,\eta). \tag{25}$$

Using Parseval's theorem, $\|Q^{-1/2}h\| = \|(\widehat{Q^{-1/2}h})\|$, from which it follows that

$$\begin{aligned}\|Q^{-1/2}\| &= \sup_{\xi,\eta}\left\{|\hat{p}(\xi,\eta)|^2 + \omega^2 + K^{-2}|1-\hat{p}^s(\xi,\eta)|^2\right\}^{-1/2} \\ &= \left[\inf_{x\geq 0}\{e^{-2x}+\omega^2+K^{-2}(1-e^{-sx})^2\}\right]^{-1/2}, \quad \omega = \epsilon/M. \qquad (26)\end{aligned}$$

We now turn our attention to minimizing $\phi(x)$ on $x \geq 0$, where

$$\phi(x) = e^{-2x} + \omega^2 + K^{-2}(1-e^{-sx})^2, \quad \omega = \epsilon/M. \tag{27}$$

If $s = 0$, then $\phi(\infty) = \epsilon^2/M^2$ and $\|Q^{-1/2}\| = M/\epsilon$. In this case, we recover the Tikhonov–Miller error bound (11). More generally, the next lemma shows why we need $s > s^*$ in the SECB constraint (16).

LEMMA 1. *Let s^* be as in* (15). *If $s \leq s^*$, $M/(\epsilon\sqrt{3}) \leq \|Q^{-1/2}\| \leq (M/\epsilon)$.*

Proof. Let $x_0 = \log(M/\epsilon)$. Then $e^{-2x_0} = \omega^2$ and $1 - e^{-sx_0} \leq K\omega$ if $s \leq s^*$. Hence $\omega^2 \leq \phi(x_0) \leq 3\omega^2$ if $s \leq s^*$, and the result follows from (26). □

LEMMA 2. *Let $s > 0$. Then on $x \geq 0$, $\phi(x)$ has a unique minimum at $x = \bar{x} > 0$ where*

$$e^{-2\bar{x}} = sK^{-2}(e^{-s\bar{x}} - e^{-2s\bar{x}}). \tag{28}$$

Moreover, if $K/s > 1$,

$$\frac{2e}{1+2e}\log\left\{\frac{K}{s}\right\} \leq \bar{x} \leq \frac{1}{2-s}\log\left\{\frac{K^2}{s\left[1-(s/K)^{2es/(1+2e)}\right]}\right\}. \tag{29}$$

Proof. We have $\phi'(x) = 0$ if and only if $e^{-2x} = sK^{-2}(e^{-sx} - e^{-2sx})$. Let $\bar{x}$ be the abscissa of the unique point where the curve $y = e^{-2x}$ intersects the curve $y = sK^{-2}(e^{-sx} - e^{-2sx})$. We have $\phi''(\bar{x}) = 4e^{-2\bar{x}} - 2s^2K^{-2}e^{-s\bar{x}} + 4s^2K^{-2}e^{-2s\bar{x}}$. Using $2s^2K^{-2}e^{-s\bar{x}} = 2se^{-s\bar{x}} + 2s^2K^{-2}e^{-2s\bar{x}}$, we find that $\phi''(\bar{x}) = (4-2s)e^{-2\bar{x}} + 2s^2K^{-2}e^{-2s\bar{x}}$. Since $0 < s \leq 1$, $\phi''(\bar{x}) > 0$. Thus $\bar{x}$ is the unique minimum. Next, $e^{-2\bar{x}} = s^2K^{-2}\bar{x}(e^{-s\bar{x}} - e^{-2s\bar{x}})/s\bar{x} \leq s^2K^{-2}\bar{x}$ since $f(y) \equiv (e^{-y} - e^{-2y})/y$ is a monotone decreasing function with a maximum value of 1 at $y = 0$. If $0 < \bar{x} < 1$, then $e^{-2\bar{x}} < s^2K^{-2}$, which implies that $\bar{x} > \log(K/s)$. If $\bar{x} \geq 1$, then $\log(\bar{x})/\bar{x} \leq 1/e$ and $1 + \log(\bar{x})/2\bar{x} \leq (1+2e)/2e$. From $\bar{x}e^{2\bar{x}} \geq K^2/s^2$, we get $\bar{x}\{1 + \log(\bar{x})/2\bar{x}\} \geq \log(K/s)$. Hence $\bar{x} \geq \{2e/(1+2e)\}\log(K/s)$ if $\bar{x} \geq 1$, and the inequality remains valid if $0 < \bar{x} < 1$. To obtain the upper bound on $\bar{x}$ in (29), first observe that $1 - e^{-s\bar{x}} \geq 1 - \{s/K\}^{2es/(1+2e)}$. Hence from (28), $e^{-(2-s)\bar{x}} = sK^{-2}(1 - e^{-s\bar{x}}) \geq sK^{-2}\left[1 - \{s/K\}^{2es/(1+2e)}\right]$. The result follows upon taking logarithms. □

LEMMA 3. *If $0 < K/s \leq 2$, $\|Q^{-1/2}\| < 5$.*

Proof. From (28), $\bar{x}e^{2\bar{x}} = (K^2s^{-2})\{s\bar{x}/(e^{-s\bar{x}} - e^{-2s\bar{x}})\} \leq 4s\bar{x}/(e^{-s\bar{x}} - e^{-2s\bar{x}})$ if $K/s \leq 2$. Hence $(1/4)\bar{x}e^{(2-s)\bar{x}} \leq s\bar{x}/(1 - e^{-s\bar{x}}) \leq \bar{x}/(1 - e^{-\bar{x}})$, the last inequality resulting from the fact that $g(y) \equiv y/(1-e^{-y})$ is a monotone increasing function on $y \geq 0$, and $0 < s \leq 1$. Therefore, $e^{\bar{x}} \leq e^{(2-s)\bar{x}} \leq 4(1-e^{-\bar{x}})^{-1}$. Thus $\bar{x} \leq \log 5$, and $e^{-2\bar{x}} \geq 1/25$. The result now follows from (26). Note that from (15), $0 < K/s \leq 2$ implies $s/s^* \geq \{(M-2s\epsilon)/(2\epsilon)\}\log(M/\epsilon) \gg 1$. □

LEMMA 4. *Let $K/s > 1$, and let $x_0 \geq (1/(2-s))\log\left[K^2/s\left\{1-(s/K)^{2es/(1+2e)}\right\}\right]$. Consider the iteration*

$$x_{n+1}e^{2x_{n+1}} = K^2 s^{-2}\left\{sx_n/(e^{-sx_n} - e^{-2sx_n})\right\}, \quad n = 0, 1, 2, \ldots. \tag{30}$$

Then $0 < x_{n+1} \leq x_n \leq \cdots \leq x_1 \leq x_0$, and the sequence $\{x_n\}$ converges to $\bar{x}$.

Proof. Let $h(y) \equiv y/(e^{-y} - e^{-2y})$. Then $h(y)$ and ye^{2y} are monotone increasing functions on $y \geq 0$. Since $0 < s \leq 1$, the function xe^{2x} eventually increases faster than $K^2s^{-2}h(sx)$, and the two curves intersect at $x = \bar{x}$. In particular, $xe^{2x} \geq K^2s^{-2}h(sx)$ if $x \geq \bar{x}$. Therefore, using (29) in Lemma 2, $x_1e^{2x_1} = K^2s^{-2}h(sx_0) \leq x_0e^{2x_0}$, which implies that $x_1 \leq x_0$. Let $A_n = K^2s^{-2}h(sx_n)$ so that $x_{n+1}e^{2x_{n+1}} = A_n$. Then $x_{m+1} \leq x_m$ implies $A_{m+1} \leq A_m$. It follows that $0 < x_{n+1} \leq x_n \leq \cdots \leq x_1 \leq x_0$, and $K^2s^{-2} < A_{n+1} \leq A_n \leq \cdots \leq A_1 \leq A_0$. Therefore, x_n converges to $z > 0$, and A_n converges to $K^2s^{-2}h(sz)$, which implies $z = \bar{x}$. □

THEOREM 2. *Let $s > s^*$, let g satisfy* (14) *and* (16), *and let $g^{\min}$ be as in Theorem* 1. *If $0 < K/s \leq 2$, then $\|g - g^{\min}\| < 5\epsilon\sqrt{3}$. If $K/s > 2$, let*

$$\begin{aligned} A &= \left\{sK^{-2}\left(1 - \{s/K\}^{2es/(1+2e)}\right)\right\}^{2/(2-s)}, \\ B &= \{\epsilon/M\}^2, \\ C &= K^{-2}\left\{1 - (s/K)^{2es/(1+2e)}\right\}^2. \end{aligned} \tag{31}$$

Then

$$\|Q^{-1/2}\| \leq \{A + B + C\}^{-1/2} \tag{32}$$

and

$$\|g - g^{\min}\| \leq \epsilon\sqrt{3}\,\{A + B + C\}^{-1/2}. \tag{33}$$

Proof. If $0 < K/s \leq 2$, the result follows from Lemma 3 and (21). If $K/s > 2$, we can use the upper and lower bounds for $\bar{x}$ in Lemma 2 to estimate $\phi(\bar{x})$. We find $\phi(\bar{x}) \geq A + B + C$, where A, B, and C are as in (31). The result follows from (21) together with $\|Q^{-1/2}\| = \{\phi(\bar{x})\}^{-1/2}$. □

6.1. An example. The above analysis produces reliable error bounds in SECB restoration. In the PET imaging example of section 3, we have $M = 40.15$, $\epsilon = 0.04$, $s = 0.005$, and $K = 3.1$. This gives $K/s = 620$, $s^* = 4.47 \times 10^{-4}$, and $s/s^* = 11.2$. Lemma 2 provides upper and lower bounds for $\bar{x}$ for given K and s. From (29), we get $5.4308 \leq \bar{x} \leq 5.6045$. From (31) in Theorem 2, given ϵ, M, K, and s, we can find an upper bound for $\|Q^{-1/2}\| = \{\phi(\bar{x})\}^{-1/2} \leq \{A + B + C\}^{-1/2}$. We get $\|Q^{-1/2}\| \leq 105.87$. However, we may also use the iteration in Lemma 4 to calculate $\bar{x}$ to high accuracy. Evaluating $\phi(\bar{x})$ then provides the *exact* value for $\|Q^{-1/2}\|$ as in (26). We find $\bar{x} = 5.5902$ and $\{\phi(\bar{x})\}^{-1/2} = \|Q^{-1/2}\| = 103.14$. Evidently, the estimates provided by Lemma 2 and Theorem 2 are in close agreement with the exact values in this example.

As previously noted, SECB restoration reduces to Tikhonov–Miller restoration ((9)), if $s = 0$. The exact value for $\|Q^{-1/2}\|$ when $s = 0$ is $M/\epsilon = 1004$. The present value, $\|Q^{-1/2}\| = 103$, is about ten times smaller. This illustrates the stabilizing property of the SECB constraint. We obtain the estimate $\|g - g^{\min}\| \leq 7.15$ for the SECB image, versus $\|g - g^T\| \leq 56.78$ for the Tikhonov–Miller image.

In [3, section 2], a one-dimensional SECB deblurring example is given where $\epsilon = 10^{-3}$, $M = 10$, $K = 3$, and $s = 0.01$. In this case, $s/s^* = 307$, and $\|Q^{-1/2}\| = 56.86$. Without the SECB constraint, $\|Q^{-1/2}\| = M/\epsilon = 10^4$, which is 175 times larger.

6.2. Improvement over Tikhonov–Miller and the ratio (s/s^*). It follows from (27) that $\inf_{x \geq 0} \phi(x) > \epsilon^2/M^2$ whenever $s > 0$. Hence from (26), the SECB bound for $\|Q^{-1/2}\|$ is *always* smaller than the corresponding Tikhonov–Miller bound M/ϵ. However, as may be surmised from Lemma 1 and the above-mentioned examples, SECB's improvement over the Tikhonov–Miller value increases as the value of s/s^* increases. In the case where $K/s \leq 2$, this was noted at the end of the proof of Lemma 3. For the case where $K/s > 2$, the role played by s/s^* in the estimate of Theorem 2 may be discerned through the following analysis.

With A, B, and C as in (31), let $b = 2e/(1+2e) \approx 0.845$, and write $\{s/K\}^{bs} = \exp\{-bs\log(K/s)\} \approx 1 - bs\log(K/s)$ for small values of s such as typically enter the SECB constraint. We may likewise replace the exponent $2/(2-s)$ by unity. Then

$$(34) \qquad A \approx bs^2K^{-2}\log(K/s), \qquad C \approx b^2s^2K^{-2}\{\log(K/s)\}^2, \quad (K/s) > 2.$$

Therefore,

$$(35) \qquad (A+B+C)^{-1/2} \approx \frac{(K/s)}{[b^2\{\log(K/s)\}^2 + b\log(K/s) + \{K\epsilon/(sM)\}^2]^{1/2}}.$$

From (15), we have $s^* \approx K\epsilon/\{M\log(M/\epsilon)\}$ for $K\epsilon \ll M$. Hence

$$(36) \qquad K/s \approx (s^*/s)(M/\epsilon)\log(M/\epsilon).$$

The following result, which shows that $\|Q^{-1/2}\| \ll M/\epsilon$ whenever $s^*/s \ll 1$, is immediate from (32), (35), and (36).

THEOREM 3. *Let $K/s > 2$, let $b = 2e/(1+2e)$, and let A, B, and C be as in* (31). *For small $s > 0$, we have*

$$\|Q^{-1/2}\| \leq (A+B+C)^{-1/2}$$

$$(37) \qquad \approx \frac{(s^*/s)(M/\epsilon)\log(M/\epsilon)}{[b^2\{\log(K/s)\}^2 + b\log(K/s) + \{K\epsilon/(sM)\}^2]^{1/2}}, \quad (K/s) > 2.$$

6.3. Behavior as $\epsilon \downarrow$ o. While the SECB constraint can result in useful error bounds at realistic values of ϵ, the estimates in Theorems 2 and 3 do not imply convergence as $\epsilon \downarrow 0$. With s fixed in the SECB constraint (16), $\epsilon \downarrow 0$ implies $K \uparrow \infty$, and Lemma 2 then shows that $\bar{x} \uparrow \infty$. Thus $\phi(\bar{x}) \to 0$. However, $\epsilon\{\phi(\bar{x})\}^{-1/2}$ remains bounded, and $\|g - g^{\min}\|$ becomes small, on the order of $\|P^sg - g\|$, as $\epsilon \downarrow 0$. We have the following result.

THEOREM 4. *Let $\|g\| \leq M$. Fix $s > 0$, let $\sigma = \|P^sg - g\|$, and let $b = 2e/(1+2e)$. For each $\epsilon > 0$, let $K = \sigma/\epsilon$, let $\omega = \epsilon/M$, and let $g^{\min}$ be the unique solution of $Qg^{\min} = P^*f$, where $Q = P^*P + \omega^2I + K^{-2}(I-P^s)^*(I-P^s)$. Then*

$$(38) \qquad \|g - g^{\min}\| < \sqrt{3}\|P^sg - g\| + O\{(s\epsilon)^{sb}\} \quad \textit{as } \epsilon \downarrow 0.$$

Proof. With $K = \sigma/\epsilon$, we have from (27) that

$$\begin{aligned}\epsilon^{-2}\phi(\bar{x}) &= \epsilon^{-2}e^{-2\bar{x}} + M^{-2} + \sigma^{-2}(1-e^{-s\bar{x}})^2 \\ &> \sigma^{-2}(1-e^{-s\bar{x}})^2 > \sigma^{-2}(1-(s\epsilon/\sigma)^{sb})^2\end{aligned} \tag{39}$$

upon using (29) in Lemma 2. From Theorem 2, we have $\|g - g^{\min}\| \le \epsilon\sqrt{3}\{\phi(\bar{x})\}^{-1/2}$ for every $\epsilon > 0$. The result follows. □.

7. Summary. A priori information is essential in the analysis of ill-posed continuation problems in partial differential equations [9]. The classical approach to regularization is based on prescribed bounds on the derivatives of the unknown solution. This approach suffers from three major drawbacks. First, derivatives may fail to exist in many problems of practical interest. Second, when such derivatives exist, it may not be possible to estimate them reliably from a priori considerations. Third, when an estimate N on some Sobolev norm of the desired solution is known, the best possible error bound for the regularized solution has the form $O(N\{\log(N/\epsilon)\}^{-q})$, $q > 0$. This is the notorious *logarithmic continuity* described in Fritz John's writings on ill-posed problems. Here ϵ, the norm of the data noise, is fixed and small, but it is seldom small enough to render that error bound meaningful.

A different method of regularization was examined in this paper for continuation problems of the form $Pg = f$, where P is an infinitely smoothing integral operator with known kernel $p(x, y)$. This method does not require differentiability of the unknown solution g, yet it leads to useful error bounds at realistic values of ϵ. The method is based on the observation that in many applications where the unknown g may not be differentiable, both g and the integral operator P are sufficiently well-behaved that for some fixed small $s > 0$, P^s almost acts like the identity operator when applied to g. Thus $\|P^s g - g\|$ can be expected to be small. This idea was illustrated in Fig. 2 using an example from nuclear medicine. The SECB constraint consists of imposing the requirement that $\|P^s g - g\|/\epsilon$ be bounded by some known constant K. The constraint becomes effective when s can be chosen relatively large with K relatively small so that $s^*/s \ll 1$. In Theorem 2, error bounds were obtained for the SECB approach explicitly in terms of the constants ϵ, M, K, and s entering the a priori constraints. In Theorem 3, an explicit formula was derived that compares the L^2 norm of the SECB inverse operator to that of the Tikhonov–Miller inverse operator. The improvement was shown to be governed by the ratio s^*/s. The SECB error bound for the regularized solution may be several hundred times smaller than that for the Tikhonov–Miller method if s^*/s is sufficiently small. Image deblurring experiments reported in [3] show that substantial improvement occurs even for moderately small values of s^*/s.

EXPONENTIAL ASYMPTOTICS IN A SINGULAR LIMIT FOR n-LEVEL SCATTERING SYSTEMS[*]

ALAIN JOYE[†]

Abstract. The singular limit $\varepsilon \to 0$ of the S-matrix associated with the equation $i\varepsilon d\psi(t)/dt = H(t)\psi(t)$ is considered, where the analytic generator $H(t) \in M_n(\mathbf{C})$ is such that its spectrum is real and nondegenerate for all $t \in \mathbf{R}$. Sufficient conditions allowing us to compute asymptotic formulas for the exponentially small off-diagonal elements of the S-matrix as $\varepsilon \to 0$ are made explicit and a wide class of generators for which these conditions are verified is defined. These generators are obtained by means of generators whose spectrum exhibits eigenvalue crossings which are perturbed in such a way that these crossings turn into avoided crossings. The exponentially small asymptotic formulas which are derived are shown to be valid up to exponentially small relative error by means of a joint application of the complex Wentzel–Kramers–Brillouin (WKB) method together with superasymptotic renormalization. This paper concludes with the application of these results to the study of quantum adiabatic transitions in the time-dependent Schrödinger equation and of the semiclassical scattering properties of the multichannel stationary Schrödinger equation. The results presented here are a generalization to n-level systems, $n \geq 2$, of results previously known for two-level systems only.

Key words. singular perturbations, semiclassical and adiabatic approximations, n-level S-matrix, turning-point theory

1. Introduction.

Several problems of mathematical physics lead to the study of the scattering properties of linear ordinary differential equations in a singular limit

$$i\varepsilon\psi'(t) = H(t)\psi(t), \quad t \in \mathbf{R}, \quad \varepsilon \to 0, \tag{1.1}$$

where the prime denotes the derivative with respect to t, $\psi(t) \in \mathbf{C}^n$, and $H(t) \in M_n(\mathbf{C})$ for all t. A system described by such an equation will be called an n-level system. Let us mention, for example, the study of the adiabatic limit of the time-dependent Schrödinger equation or the semiclassical limit of the one-dimensional multichannel stationary Schrödinger equation at energies above the potential barriers, to which we will return below. When the generator $H(t)$ is well behaved at $+\infty$ and $-\infty$, the scattering properties of the problem can be described by means of a matrix naturally associated with equation (1.1), the so-called S-matrix. This matrix relates the behavior of the solution $\psi(t)$ as $t \to -\infty$ to that of $\psi(t)$ as $t \to +\infty$. Assuming that the spectrum $\sigma(t)$ of $H(t)$ is real and nondegenerate,

$$\sigma(t) = \{e_1(t) < e_2(t) < \cdots < e_n(t)\} \in \mathbf{R}, \tag{1.2}$$

the S-matrix is essentially given by the identity matrix

$$S = \mathrm{diag}(s_{11}(\varepsilon), s_{22}(\varepsilon), \ldots, s_{nn}(\varepsilon)) + \mathcal{O}(\varepsilon^\infty), \quad \text{where } s_{jj}(\varepsilon) = 1 + \mathcal{O}(\varepsilon) \text{ as } \varepsilon \to 0, \tag{1.3}$$

provided $H(t)$ is C^∞; see, e.g., [F1], [F2], and [W]. Moreover, if $H(t)$ is assumed to be analytic, it was proven in various situations that the off-diagonal elements s_{jk} of S are exponentially decreasing [FF], [W], [F1], [F2], [JKP], [JP4]:

$$s_{jk} = \mathcal{O}\left(\mathrm{e}^{-\kappa/\varepsilon}\right), \quad \forall j \neq k, \tag{1.4}$$

as $\varepsilon \to 0$. See also [JP1], [N], [M], and [Sj] for corresponding results in infinite-dimensional spaces. Since the physical information is often contained in these off-diagonal elements, it is of interest to be able to give an asymptotic formula for s_{jk} rather than a mere estimate.

For two-level systems (or systems reducible to this case (see [JP2], [J], and [MN])), the situation is now reasonably well understood, at least under generic circumstances. Indeed, a rigorous study of the S-matrix associated with (1.1) when $n = 2$ under the hypotheses loosely stated above is provided in the recent paper [JP4]. The treatment presented unifies, in particular, earlier results obtained for either the time-dependent adiabatic Schrödinger equation (see, e.g., [JP3] and the references therein) or the study of the above barrier reflexion in the semiclassical limit (see, e.g., [FF] and [O]). Further references are provided in [JP4]. As an intermediate result, the asymptotic formula

$$s_{jk} = g_{jk}\mathrm{e}^{-\Gamma_{jk}/\varepsilon}\,(1 + \mathcal{O}(\varepsilon)), \quad \varepsilon \to 0, \tag{1.5}$$

for $j \neq k \in \{1, 2\}$ with $g_{jk} \in \mathbf{C}$ and $\mathrm{Re}\Gamma_{jk} > 0$ is proven in [JP4]. As is well known, to get an asymptotic formula for s_{jk}, one has to consider (1.1) in the complex plane, in particular in the vicinity of the degeneracy points of the analytic continuations of eigenvalues $e_1(z)$ and $e_2(z)$. Provided the level lines of the multivalued function

$$\mathrm{Im}\int_0^z e_1(z') - e_2(z')dz' = \mathrm{cst}, \tag{1.6}$$

called Stokes lines, naturally associated with (1.1) behave properly in the complex plane, the so-called complex Wentzel–Kramers–Brillouin (WKB) method allows to prove (1.5). More importantly, however, it is also shown in [JP4] how to improve (1.5) to an asymptotic formula accurate up to an exponentially small relative error:

$$s_{jk} = g^*_{jk}(\varepsilon)\mathrm{e}^{-\Gamma^*_{jk}(\varepsilon)/\varepsilon}(1 + \mathcal{O}(\mathrm{e}^{-\kappa/\varepsilon})), \quad \varepsilon \to 0, \tag{1.7}$$

with $g^*_{jk}(\varepsilon) = g_{jk} + \mathcal{O}(\varepsilon)$ and $\Gamma^*_{jk}(\varepsilon) = \Gamma_{jk} + \mathcal{O}(\varepsilon^2)$. This is achieved by using a complex WKB analysis jointly with the recently developed superasymptotic theory [Be], [N], [JP2]. Note that when given a generator, the principal difficulty in justifying formulas (1.5) and (1.7) is the verification that the corresponding Stokes lines (1.6) display the proper behavior *globally* in the complex plane, which may or may not be the case [JKP]. However, this condition is always satisfied when the complex eigenvalue degeneracy is close to the real axis, as shown in [J]. See also [MN] and [R] for recent related results.

For n-level systems, with $n \geq 3$, the situation is by no means as well understood. There are some results obtained with particular generators. In [D], [CH1], [CH2], and [BE], certain elements of the S-matrix are computed if $H(t) = H^*(t)$ depends linearly on t, $H(t) = A+tB$ for some particular matrices A and B. The choices of A and B are such that all components of the solution $\psi(t)$ can be deduced from the first one and an exact integral representation of this first component can be obtained. The integral representation is analyzed by standard asymptotic techniques, and this leads to results which are valid for any $\varepsilon > 0$, as in the case for the classical Landau–Zener generator. The study of the three-level problem when $H(t) = H^*(t) \in M_3(\mathbf{R})$ is tackled in the closing section of the very interesting paper [HP]. A nonrigorous and essentially local discussion of the behavior of the level lines of $\operatorname{Im} \int_0^z e_j(z') - e_k(z')dz'$, $j \neq k = 1, 2, 3$, is provided, and it justifies in very favorable cases an asymptotic formula for some elements of the S-matrix. See also the review [So], where a nonrigorous study of (1.1) is made close to a complex degeneracy point of a group of eigenvalues by means of an exact solution to a model equation. However, no asymptotic formula for s_{jk}, $j \neq k$, can be found in the literature for general n-level systems, $n \geq 3$. This is due to the fact that the direct generalization of the method used successfully for two-level systems may lead to seemingly inextricable difficulties for $n = 3$. Indeed, with three eigenvalues, one has to consider three sets of level lines $\operatorname{Im} \int_0^z e_j(z') - e_k(z')dz'$ to deal with (1.1) in the complex plane, and the conditions that they have to fulfill in order for the limit $\varepsilon \to 0$ to be controlled may be incompatible for a given generator; see [F1], [F2], and [HP]. It should be mentioned, however, that there are specific examples in which this difficult problem can be mastered. Such a result was recently obtained in the semiclassical study [Ba] of a particular problem of resonances for which similar considerations in the complex plane are required.

The goal of this paper is to provide some general insight into the asymptotic computation of the S-matrix associated with n-level systems, $n \geq 3$, based on a generalization of the techniques which proved to be successful for two-level systems. The content of this paper is twofold. On one hand, we set up a general framework in which asymptotic formulas for the exponentially small off-diagonal coefficients can be proven. On the other hand, we actually prove such formulas for a wide class of n-level systems. In the first part of the paper, we give our definition of the S-matrix associated with equation (1.1) and make explicit the symmetries it inherits from the symmetries of $H(t)$ for $t \in \mathbf{R}$ (Proposition 2.1). We then turn to the determination of the analyticity properties of the eigenvalues and eigenvectors of $H(z)$, $z \in \mathbf{C}$, which are at the root of the asymptotic formulas that we derive later (Lemma 3.1). The next step is the formulation of sufficient conditions adapted to the scattering situation that we consider, under which a complex WKB analysis allows us to prove a formula like (1.5) (Proposition 4.1). The conditions stated are similar but not identical to those given in [JKP] or [HP]. As a final step, we show how to improve the asymptotic formula (1.5) to (1.7) by means of superasymptotic machinery (Proposition 5.2 and Lemma 5.2). We then turn to the second part of the paper, where we show that a wide class of generators fits into our framework and satisfies our conditions. These generators are obtained by perturbation of generators whose eigenvalues display degeneracies on the real axis (in the spirit of [J]). We prove that for these generators, in the absence of any symmetry of the generator $H(t)$, at least one element per column in the S-matrix can be asymptotically computed (Theorem 6.1). This is the main technical section of the paper. The major advantage of this construction is that it is sufficient to look at the behavior of the eigenvalues on the real axis to check if the conditions are satisfied. The closing section contains an application of our general results to the study of quantum adiabatic transitions in the time-dependent Schrödinger equation and of the semiclassical scattering properties of the multichannel stationary Schrödinger equation. In particular, we make explicit use of the symmetries of the S-matrix to increase the number of its elements for which an asymptotic formula holds. In the latter application, further specific symmetry properties of the S-matrix are derived (Lemma 7.1).

2. Definition and properties of the *S*-matrix. We consider the evolution equation

$$i\varepsilon\psi'(t) = H(t)\psi(t), \quad t \in \mathbf{R}, \quad \varepsilon \to 0, \tag{2.1}$$

where the prime denotes the derivative with respect to t, $\psi(t) \in \mathbf{C}^n$, and $H(t) \in M_n(\mathbf{C})$ for all t. We make some assumptions on the generator $H(t)$. The first is the usual analyticity condition in this context.

H1. *There exists a strip*

$$S_\alpha = \{z \in \mathbf{C} |\, |\mathrm{Im} z| \leq \alpha\}, \quad \alpha > 0, \tag{2.2}$$

such that $H(z)$ is analytic for all $z \in S_\alpha$.

Since we are studying scattering properties, we need sufficient decay at infinity.

H2. *There exist two nondegenerate matrices $H(+), H(-) \in M_n(\mathbf{C})$ and $a > 0$ such that*

$$\lim_{t \to \pm\infty} |t|^{1+a} \sup_{|s| \leq \alpha} \|H(t+is) - H(\pm)\| < \infty. \tag{2.3}$$

We finally give a condition which has to do with the physics behind the problem.

H3. *For $t \in \mathbf{R}$, the spectrum of $H(t)$, denoted by $\sigma(t)$, is real and nondegenerate*

$$\sigma(t) = \{e_1(t) < e_2(t) < \cdots < e_n(t)\} \subset \mathbf{R}, \tag{2.4}$$

and there exists $g > 0$ such that

$$\inf_{\substack{j \neq k \\ t \in \mathbf{R}}} |e_j(t) - e_k(t)| \geq g. \tag{2.5}$$

As a consequence of H3, for each $t \in \mathbf{R}$, there exists a complete set of projectors $P_j(t) = P_j^2(t) \in M_n(\mathbf{C})$, $j = 1, 2, \ldots, n$, such that

$$\sum_{j=1}^{n} P_j(t) \equiv \mathbf{I}, \tag{2.6}$$

$$H(t) = \sum_{j=1}^{n} e_j(t) P_j(t), \tag{2.7}$$

and there exists a basis of $\mathbf{C}^n$ of eigenvectors of $H(t)$. We determine these eigenvectors $\varphi_j(t)$, $j = 1, 2, \ldots, n$, uniquely (up to a constant) by requiring them to satisfy

$$H(t)\varphi_j(t) = e_j(t)\varphi_j(t), \tag{2.8}$$

$$P_j(t)\varphi_j'(t) \equiv 0, \quad j = 1, 2, \ldots, n. \tag{2.9}$$

Explicitly, if $\psi_j(t)$, $j = 1, 2, \ldots, n$, form a complete set of differentiable eigenvectors of $H(t)$, the eigenvectors

$$\varphi_j(t) = \mathrm{e}^{-\int_0^t \xi_j(t')dt'} \psi_j(t) \quad \text{s.t. } \varphi_j(0) = \psi_j(0) \tag{2.10}$$

with

$$\xi_j(t) = \frac{\langle \psi_j(t) | P_j(t) \psi_j'(t) \rangle}{\|\psi_j(t)\|^2}, \quad j = 1, \ldots, n, \tag{2.11}$$

verify (2.9). The fact that this choice leads to an analytic set of eigenvectors close to the real axis will be proven below. We expand the solution $\psi(t)$ along the basis just constructed, thus defining the unknown coefficients $c_j(t)$, $j = 1, 2, \ldots, n$, to be determined,

$$\psi(t) = \sum_{j=1}^{n} c_j(t) \mathrm{e}^{-i\int_0^t e_j(t')dt'/\varepsilon} \varphi_j(t). \tag{2.12}$$

The phases $\mathrm{e}^{-i\int_0^t e_j(t')dt'/\varepsilon}$ (see H3) are introduced for convenience. By inserting (2.12) into (2.1), we get the following differential equation for the $c_j(t)$'s:

$$c_j'(t) = \sum_{k=1}^{n} a_{jk}(t) \mathrm{e}^{i\Delta_{jk}(t)/\varepsilon} c_k(t), \tag{2.13}$$

where

$$\Delta_{jk}(t) = \int_0^t (e_j(t') - e_k(t'))dt' \tag{2.14}$$

and

$$a_{jk}(t) = -\frac{\langle \varphi_j(t) | P_j(t) \varphi_k'(t) \rangle}{\|\varphi_j(t)\|^2}. \tag{2.15}$$

Here $\langle \cdot | \cdot \rangle$ denotes the usual scalar product in $\mathbf{C}^n$. Our choice (2.9) implies $a_{jj}(t) \equiv 0$. It is also shown below that the $a_{jk}(t)$'s are analytic functions in a neighborhood of the real axis and that hypothesis H2 implies that they satisfy the estimate

$$\lim_{t\to\pm\infty} \sup_{j\neq k} |t|^{1+a} |a_{jk}(t)| < \infty. \tag{2.16}$$

As a consequence of this last property and of the fact that the eigenvalues are real by assumption, the following limits exist:

$$\lim_{t\to\pm\infty} c_j(t) = c_j(\pm\infty). \tag{2.17}$$

We are now able to define the associated S-matrix, $S \in M_n(\mathbf{C})$, by the identity

$$S \begin{pmatrix} c_1(-\infty) \\ c_2(-\infty) \\ \vdots \\ c_n(-\infty) \end{pmatrix} = \begin{pmatrix} c_1(+\infty) \\ c_2(+\infty) \\ \vdots \\ c_n(+\infty) \end{pmatrix}. \tag{2.18}$$

Such a relation makes sense because of the linearity of equation (2.13). It is a well-known result that under our general hypotheses, the S-matrix satisfies

$$S = \mathbf{I} + \mathcal{O}(\varepsilon). \tag{2.19}$$

Note that the jth column of the S-matrix is given by the solution of (2.13) at $t = \infty$ subjected to the initial conditions $c_k(-\infty) = \delta_{jk}$, $k = 1, 2, \ldots, n$.

In general, the S-matrix defined above has no particular properties besides that of being invertible. However, when the generator $H(t)$ satisfies some symmetry properties, the same is true for S. Since such properties are important in applications, we show below that if $H(t)$ is self-adjoint with respect to some indefinite scalar product, then S is unitary with respect to another indefinite scalar product. Let $J \in M_n(\mathbf{C})$ be an invertible self-adjoint matrix. We define an indefinite metric on $\mathbf{C}^n$ by means of the indefinite scalar product

$$(\cdot,\cdot)_J = \langle\cdot|J\cdot\rangle. \tag{2.20}$$

It is easy to check that the adjoint $A^{\#}$ of a matrix A with respect to the $(\cdot,\cdot)_J$ scalar product is given by

$$A^{\#} = J^{-1}A^*J. \tag{2.21}$$

Proposition 2.1. *Let $H(t)$ satisfy* H1 *and* H2 *and possess n distinct eigenvalues $\forall t \in \mathbf{R}$. Furthermore, assume that $H(t)$ is self-adjoint with respect to the scalar product $(\cdot,\cdot)_J$,*

$$H(t) = H^{\#}(t) = J^{-1}H^*(t)J, \quad \forall t \in \mathbf{R}, \tag{2.22}$$

and the eigenvectors $\varphi_j(0)$ of $H(0)$ satisfy

$$(\varphi_j(0), \varphi_j(0))_J = \rho_j, \quad \rho_j \in \{-1, 1\}, \quad \forall j = 1, \dots, n. \tag{2.23}$$

Then the eigenvalues of $H(t)$ are real $\forall t \in \mathbf{R}$ and the S-matrix is unitary with respect to the scalar product $(\cdot,\cdot)_R$, where $R = R^* = R^{-1}$ is the real diagonal matrix $R = \mathrm{diag}(\rho_1, \rho_2, \dots, \rho_n)$,

$$S^{\#} = RS^*R = S^{-1}. \tag{2.24}$$

Remark. The condition $(\varphi_j(0), \varphi_j(0))_J = \pm 1$ can always be satisfied by suitable renormalization provided $(\varphi_j(0), \varphi_j(0))_J \neq 0$.

The main interest of this proposition is that when the S-matrix possesses symmetries, some of its elements can be deduced from resulting identities without resorting to their actual computations.

A simple proof of Proposition 2.1 that makes use of notions discussed in the next section can be found in Appendix A. Proposition 2.1 can actually be used for the two main applications that we deal with in section 7. Note that in specific cases, further symmetry properties can be derived for the S-matrix; see section 7.

3. Analyticity properties. The generator $H(z)$ is analytic in S_α; hence the solution of the linear equation (2.1) $\psi(z)$ is analytic in S_α as well. However, the eigenvalues and eigenprojectors of $H(z)$ may have singularities in S_α. Let us recall some basic properties, the proofs of which can be found in [K]. The eigenvalues and eigenprojectors of a matrix analytic in a region of the complex plane have analytic continuations in that region with possible singularities located at points z_0, called exceptional points. In a neighborhood free of exceptional points, the eigenvalues are given by branches of analytic functions and their multiplicities are constant. One eigenvalue can therefore be analytically continued until it coincides at z_0 with one or several other eigenvalues. The set of such points defines the set of exceptional points. The eigenvalues may possess branching points at an exceptional z_0, where they are continuous, whereas the eigenprojectors are also multivalued but diverge as $z \to z_0$. Hence by hypothesis H3, the n distinct eigenvalues $e_j(t)$ defined on the real axis are

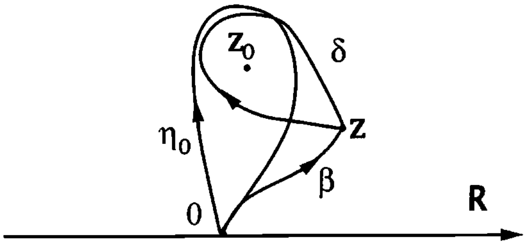

FIG. 1. *The paths β, δ, and η_0 in $S_\alpha \backslash \Omega$.*

analytic on the real axis and possess multivalued analytic continuations in S_α, with possible branching points at the set of degeneracies Ω, given by

$$\Omega = \{z_0 | \; e_j(z_0) = e_k(z_0) \quad \text{for some } k \text{ and } j \text{ and some analytic continuation}\}. \tag{3.1}$$

By assumption H2, Ω is finite, and by H3, $\Omega \cap \mathbf{R} = \emptyset$ and $\Omega = \overline{\Omega}$ due to Schwarz's principle. Similarly, the eigenprojectors $P_j(t)$ defined on the real axis are analytic on the real axis and possess multivalued analytic continuations in S_α with possible singularities at Ω. To see more precisely what happens to these multivalued functions when we turn around a point $z_0 \in \Omega$, we consider the construction described in Figure 1. Let f be a multivalued analytic function in $S_\alpha \backslash \Omega$. We denote by $f(z)$ the analytic continuation of the restriction of f around 0 along some path $\beta \in S_\alpha \backslash \Omega$ from 0 to z. Then we perform the analytic continuation of $f(z)$ along a negatively oriented loop δ based at z around a unique point $z_0 \in \Omega$, and we denote by $\widetilde{f}(z)$ the function that we get when we come back to the starting point. (If δ is positively oriented, the construction is similar.) For later purposes, we define η_0 as the negatively oriented loop homotopic to the loop based at the origin encircling z_0 obtained by following β from 0 to z, δ from z back to z, and β in the reverse sense from z back to the origin. We will keep this notation in the rest of this section. It follows from the discussion above that if we perform the analytic continuation of the set of eigenvalues $\{e_j(z)\}_{j=1}^n$, along a negatively oriented loop around $z_0 \in \Omega$, we get the set $\{\widetilde{e}_j(z)\}_{j=1}^n$ with

$$\widetilde{e}_j(z) = e_{\sigma_0(j)}(z), \quad j = 1, \dots, n, \tag{3.2}$$

where

$$\sigma_0 : \; \{1, 2, \dots, n\} \to \{1, 2, \dots, n\} \tag{3.3}$$

is a permutation that depends on η_0. Similarly, and with the same notations, we get for the analytic continuations of the projectors around z_0

$$\widetilde{P}_j(z) = P_{\sigma_0(j)}(z), \quad j = 1, \dots, n. \tag{3.4}$$

Let us consider now the eigenvectors $\varphi_j(t)$. We define $W(t)$ as the solution of

$$\begin{aligned} W'(t) &= \sum_{j=1}^n P_j'(t) P_j(t) W(t) \\ &\equiv K(t) W(t), \qquad W(0) = \mathbf{I}, \end{aligned} \tag{3.5}$$

where $t \in \mathbf{R}$. It is well known [K], [Kr] that $W(t)$ satisfies the intertwining identity

$$W(t) P_j(0) = P_j(t) W(t), \quad j = 1, 2, \dots, n, \quad \forall t \in \mathbf{R}, \tag{3.6}$$

so that if $\{\varphi_j(0)\}_{j=1}^n$ denotes a set of eigenvectors of $H(0)$, the vectors defined by

$$\varphi_j(t) = W(t)\varphi_j(0) \tag{3.7}$$

are eigenvectors of $H(t)$. Moreover, using the identity $Q(t)Q'(t)Q(t) \equiv 0$, which is true for any differentiable projector, it is easily checked that condition (2.9) is satisfied by these vectors. The generator $K(t)$ is analytic on the real axis and can be analytically continued in $S_\alpha \backslash \Omega$. Actually, $K(z)$ is single valued in $S_\alpha \backslash \Omega$. Indeed, let us consider the analytic continuation of $K(z)$ around $z_0 \in \Omega$. We get from (3.4) that

$$\widetilde{P}_j'(z) = P'_{\sigma_0(j)}(z) \tag{3.8}$$

so that

$$\begin{aligned}\widetilde{K}(z) &= \sum_{j=1}^n \widetilde{P}_j'(z)\widetilde{P}_j(z) = \sum_{j=1}^n P'_{\sigma_0(j)}(z)P_{\sigma_0(j)}(z)\\ &= \sum_{k=1}^n P_k'(z)P_k(z) = K(z).\end{aligned} \tag{3.9}$$

Consequently, $W(t)$ can be analytically continued in $S_\alpha \backslash \Omega$, where it is multivalued and satisfies both (3.5) and (3.6) with $z \in S_\alpha \backslash \Omega$ in place of $t \in \mathbf{R}$. Moreover, the relation between the analytic continuation $W(z)$ from 0 to some point $z \in S_\alpha \backslash \Omega$ and the analytic continuation $\widetilde{W}(z)$ is given by a monodromy matrix $W(\eta_0)$ such that

$$\widetilde{W}(z) = W(z)W(\eta_0), \tag{3.10}$$

where η_0 is the negatively oriented loop based at the origin which encircles only $z_0 \in \Omega$ (see Figure 1). Note also that the analytic continuation $W(z)$ is invertible in $S_\alpha \backslash \Omega$ and $W^{-1}(z)$ satisfies

$$W^{-1\prime}(z) = -W^{-1}(z)K(z), \qquad W^{-1}(0) = \mathbf{I}. \tag{3.11}$$

As a consequence, the eigenvectors (3.7) possess multivalued analytic extensions in $S_\alpha \backslash \Omega$. Indeed, it is easily seen that the analytic continuation of $\varphi_j(z)$ along a negatively oriented loop around $z_0 \in \Omega$, $\widetilde{\varphi}_j(z)$, is proportional to $\varphi_{\sigma_0(j)}(z)$. Hence we introduce the quantity $\theta_j(\eta_0) \in \mathbf{C}$ by the definition

$$\widetilde{\varphi}_j(z) = \mathrm{e}^{-i\theta_j(\eta_0)}\varphi_{\sigma_0(j)}(z), \quad j = 1, 2, \ldots, n. \tag{3.12}$$

Note that this is equivalent to $W(\eta_0)\varphi_j(0) = \mathrm{e}^{-i\theta_j(\eta_0)}\varphi_{\sigma_0(j)}(0)$ (see (3.10)). Let us consider the couplings (2.15). Using the definition (3.7), the invertibility of $W(t)$, and the identity (3.6), it is not difficult to see that we can rewrite

$$a_{jk}(t) = -\frac{\langle \varphi_j(0)|P_j(0)W(t)^{-1}K(t)W(t)\varphi_k(0)\rangle}{\|\varphi_j(0)\|^2}, \quad t \in \mathbf{R}, \tag{3.13}$$

which is analytic on the real axis and can be analytically continued in $S_\alpha \backslash \Omega$, where it is multivalued. Thus the same is true for the coefficients $c_j(t)$ which satisfy the linear differential equation (2.13), and their analytic continuations satisfy the same equation with $z \in S_\alpha \backslash \Omega$ in place of $t \in \mathbf{R}$. We now come to the main identity of this section regarding the coefficients $c_j(z)$. Let us denote by $c_j(z)$ the analytic continuation of

$c_j(0)$ from 0 to some $z \in S_\alpha \backslash \Omega$. We perform the analytic continuation of $c_j(z)$ along a negatively oriented loop around $z_0 \in \Omega$ and denote by $\widetilde{c}_j(z)$ the function that we get when we come back at the starting point z.

LEMMA 3.1. *For any $j = 1, \ldots, n$, we have*

$$\widetilde{c}_j(z) e^{-i \int_{\eta_0} e_j(u)du/\varepsilon} e^{-i\theta_j(\eta_0)} = c_{\sigma_0(j)}(z) \tag{3.14}$$

where η_0, $\theta_j(\eta_0)$ and $\sigma_0(j)$ are defined as above.

Proof. It follows from hypothesis H1 that $\psi(z)$ is analytic in S_α so that

$$\begin{aligned} &\sum_{j=1}^{n} c_j(z) \mathrm{e}^{-i \int_0^z e_j(u)du/\varepsilon} \varphi_j(z) \\ &\quad = \sum_{j=1}^{n} \widetilde{c}_j(z) \mathrm{e}^{-i \widetilde{\int_0^z e_j(u)du}/\varepsilon} \widetilde{\varphi}_j(z) \\ &\quad = \sum_{j=1}^{n} \widetilde{c}_j(z) \mathrm{e}^{-i \int_{\eta_0} e_j(u)du/\varepsilon} \mathrm{e}^{-i \int_0^z e_{\sigma_0(j)}(u)du/\varepsilon} \mathrm{e}^{-i\theta_j(\eta_0)} \varphi_{\sigma_0(j)}(z). \end{aligned} \tag{3.15}$$

We conclude by the fact that $\{\varphi_j(z)\}_{j=1}^n$ is a basis. □

Remark. It is straightforward to generalize the study of the analytic continuations around one singular point of the functions given above to the case where the analytic continuations are performed around several singular points since Ω is finite. The loop η_0 can be rewritten as a finite succession of individual loops encircling only one point of Ω so that the permutation σ_0 is given by the composition of a finite number of individual permutations. Thus the factors $\mathrm{e}^{-i\theta_j(\eta_0)}$ in (3.12) should be replaced by a product of such factors, each associated with one individual loop, and the same is true for the factors $\exp(-i \int_{\eta_0} e_j(z)dz/\varepsilon)$ in Lemma 3.1. This process is performed in the proof of Theorem 6.1.

4. Complex WKB analysis. This section is devoted to basic estimates on the coefficients $c_j(z)$ in certain domains extending to infinity in both the positive and negative directions inside the strip S_α. We first consider what happens in neighborhoods of $\pm\infty$. It follows from assumption H2 by a direct application of the Cauchy formula that (possibly by reducing α by an arbitrarily small amount)

$$\lim_{t \to \pm\infty} \sup_{|s| \leq \alpha} |t|^{1+a} \|H'(t+is)\| < \infty. \tag{4.1}$$

Hence the same is true for the single-valued matrix $K(z)$:

$$\lim_{t \to \pm\infty} \sup_{|s| \leq \alpha} |t|^{1+a} \|K(t+is)\| < \infty. \tag{4.2}$$

Let $0 < T \in \mathbf{R}$ be such that

$$\min_{z \in \Omega} \mathrm{Re} z > -T \quad \text{and} \quad \max_{z \in \Omega} \mathrm{Re} z < +T. \tag{4.3}$$

All quantities encountered so far are analytic in $S_\alpha \cap \{z||\mathrm{Re} z| > T\}$, and we denote with a "$\widetilde{\ }$" any analytic continuation in that set. As noticed earlier,

$$\widetilde{W}'(z) = K(z)\widetilde{W}(z), \quad z \in S_\alpha \cap \{z||\mathrm{Re} z| > T\} \tag{4.4}$$

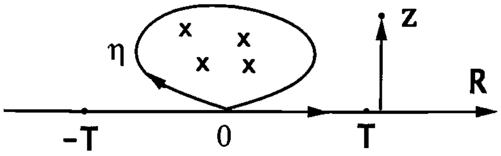

FIG. 2. *The path of integration for* $\widetilde{\Delta}_{jk}(z)$ *(the x's denote points of* Ω*).*

so that it follows from (4.2) that the limits

$$\lim_{t\to\pm\infty} \widetilde{W}(t+is) = \widetilde{W}(\pm\infty) \tag{4.5}$$

exist uniformly in $s \in]-\alpha,\alpha[$. Consequently (see (3.13)),

$$\lim_{t\to\pm\infty} |t|^{1+a} \sup_{|s|\leq\alpha} |\widetilde{a}_{jk}(t+is)| < \infty, \quad \forall j,k \in \{1,\dots,n\}. \tag{4.6}$$

Finally, for $|t| > T$, we can write

$$\begin{aligned} \mathrm{Im}\widetilde{\Delta}_{jk}(t+is) &= \mathrm{Im}\left(\int_\eta e_j(z)dz - \int_\eta e_k(z)dz\right) \\ &+ \int_0^s \mathrm{Re}(e_{\sigma(j)}(t+is') - e_{\sigma(k)}(t+is'))ds', \end{aligned} \tag{4.7}$$

where this equation is obtained by deforming the path of integration from 0 to $z = t+is$ into a loop η based at the origin, which may encircle points of Ω, followed by the real axis from 0 to Rez and a vertical path from Rez to z (see Figure 2) and σ is the corresponding permutation. Hence we have

$$\sup_{z\in S_\alpha \cap\{z||\mathrm{Re}z|>T\}} \mathrm{Im}\widetilde{\Delta}_{jk}(z) < \infty, \tag{4.8}$$

which together with (4.6) yields the existence of the limits

$$\lim_{t\to\pm\infty} \widetilde{c}_j(t+is) = \widetilde{c}_j(\pm\infty) \tag{4.9}$$

uniformly in $s \in]-\alpha,\alpha[$. We now define the domains in which useful estimates can be obtained.

DEFINITION. *Let* $j \in \{1,\dots,n\}$ *be fixed. A* dissipative domain for the index j, $D_j \subset S_\alpha \backslash \Omega$, *is such that*

$$\sup_{z\in D_j} \mathrm{Re}z = \infty, \qquad \inf_{z\in D_j} \mathrm{Re}z = -\infty \tag{4.10}$$

and is defined by the property that for any $z \in D_j$ *and any* $k \in \{1,\dots,n\}$*, there exists a path* $\gamma^k \subset D_j$ *parameterized by* $u \in]-\infty,t]$ *which links* $-\infty$ *to* z*,*

$$\lim_{u\to-\infty} \mathrm{Re}\gamma^k(u) = -\infty, \qquad \gamma^k(t) = z, \tag{4.11}$$

with

$$\sup_{z\in D_j} \sup_{u\in]-\infty,t]} \left|\frac{d}{du}\gamma^k(u)\right| < \infty, \tag{4.12}$$

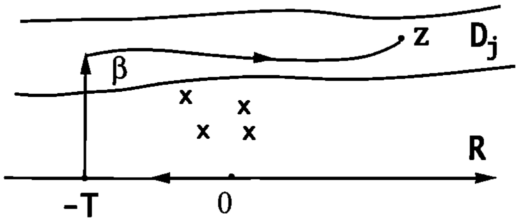

FIG. 3. *The path β along which the analytic continuation of $\Delta_{jk}(t)$ in D_j is taken.*

and satisfies the monotonicity condition

$$\text{Im}\widetilde{\Delta}_{jk}(\gamma^k(u)) \text{ is a nondecreasing function of } u \in]-\infty, t]. \tag{4.13}$$

Such a path is a dissipative path for $\{jk\}$. *Here $\widetilde{\Delta}_{jk}(z)$ is the analytic continuation of*

$$\Delta_{jk}(t) = \int_0^t (e_j(t') - e_k(t'))dt', \quad t \in \mathbf{R}, \tag{4.14}$$

in D_j along a path β described in Figure 3 going from 0 to $-T \in \mathbf{R}$ along the real axis and then vertically up or down until it reaches D_j, where $T > 0$ is chosen as in (4.3).

Let $\widetilde{c}_k(z)$, $k = 1, 2, \ldots, n$, $z \in D_j$, be the analytic continuations of $c_k(t)$ along the same path β which are solutions of the analytic continuation of (2.13) in D_j along β:

$$\widetilde{c}_k'(z) = \sum_{l=1}^{n} \widetilde{a}_{kl}(z) \mathrm{e}^{i\widetilde{\Delta}_{kl}(z)/\varepsilon} \widetilde{c}_l(z). \tag{4.15}$$

We take as initial conditions in D_j

$$\lim_{\text{Re } z \to -\infty} \widetilde{c}_k(z) = \lim_{t \to -\infty} c_k(t) = \delta_{jk}, \quad k = 1, \ldots, n, \tag{4.16}$$

and we define

$$x_k(z) = \widetilde{c}_k(z) \mathrm{e}^{i\widetilde{\Delta}_{jk}(z)/\varepsilon}, \qquad z \in D_j, \quad k = 1, \ldots, n. \tag{4.17}$$

LEMMA 4.1. *In a dissipative domain for the index j, we get the estimates*

$$\sup_{z \in D_j} |x_j(z) - 1| = \mathcal{O}(\varepsilon), \tag{4.18}$$

$$\sup_{z \in D_j} |x_k(z)| = \mathcal{O}(\varepsilon), \quad \forall k \neq j. \tag{4.19}$$

Remark. The real axis is a dissipative domain for all indices. In this case, we have $\widetilde{c}_j(t) \equiv c_j(t)$. Hence we get from the application of the lemma for all indices successively that $S = \mathbf{I} + \mathcal{O}(\varepsilon)$.

The estimates we are looking for are then just a direct corollary.

PROPOSITION 4.1. *Assume that there exists a dissipative domain D_j for the index j. Let η_j be a loop based at the origin which encircles all of the degeneracies between the real axis and D_j and let σ_j be the permutation of labels associated with η_j, in the spirit of the remark ending the previous section. The loop η_j is negatively (respectively,* *positively) oriented if D_j is above (respectively, below) the real axis. Then the solution of* (2.13) *subjected to the initial conditions $c_k(-\infty) = \delta_{jk}$ satisfies*

$$c_{\sigma_j(j)}(+\infty) = \mathrm{e}^{-i\theta_j(\eta_j)}\mathrm{e}^{-i\int_{\eta_j} e_j(z)dz/\varepsilon}\left(1 + \mathcal{O}(\varepsilon)\right), \tag{4.20}$$

$$c_{\sigma_j(k)}(+\infty) = \mathcal{O}\big(\varepsilon \mathrm{e}^{\operatorname{Im}\int_{\eta_j} e_j(z)dz/\varepsilon + h_j(e_{\sigma_j(j)}(+\infty) - e_{\sigma_j(k)}(+\infty))/\varepsilon}\big), \tag{4.21}$$

with $h_j \in [H_j^-, H_j^+]$, where $H_j^\pm$ is the maximum (respectively, minimum) imaginary part of the points at $+\infty$ in D_j:

$$H^+ = \limsup_{t\to+\infty} \sup_{s|t+is\in D_j} s, \qquad H^- = \liminf_{t\to+\infty} \inf_{s|t+is\in D_j} s. \tag{4.22}$$

Thus we see that it is possible to get the (exponentially small) asymptotic behavior of the element $s_{\sigma_j(j),j}$ of the S-matrix, provided there exists a dissipative domain for the index j. The difficult part of the problem is, of course, to prove the existence of such domains D_j, which do not necessarily exist, and to have enough of them to compute the asymptotic of the whole S-matrix. This task is the equivalent for n-level systems of studying the global behavior of the Stokes lines for two-level systems. We postpone this aspect of the problem until the next section. Note that we also get from this result an exponential bound on the elements $s_{\sigma_j(k),j}$ of the S-matrix, $k \neq j$, which may or may not be useful. If η_j encircles no point of Ω, we cannot get the asymptotic behavior of $s_{\sigma_j(j),j}$ but only get the exponential bounds. Since our main concern is asymptotic behaviors, we call the corresponding dissipative domain trivial.

Remark. In contrast with the two-level case (see [JP4]) we have to work with dissipative domains instead of working with one dissipative path for all indices. Indeed, it is not difficult to convince oneself with specific three-level cases that such a dissipative path may not exist, even when the eigenvalue degeneracies are close to the real axis. In return, we prove below the existence of dissipative domains in this situation.

Proof of Proposition 4.1. The asymptotic relation is a direct consequence of Lemma 3.1, (4.9), (4.17), and the first part of Lemma 4.1. The estimate is a consequence of the same equations, the second estimate of Lemma 4.1, and the identity, for $t > T$,

$$\begin{aligned}\operatorname{Im}\widetilde{\Delta}_{jk}(t+is) &= \operatorname{Im}\left(\int_{\eta_j} e_j(z)dz - \int_{\eta_j} e_k(z)dz\right)\\ &\quad + \int_0^s \operatorname{Re}(e_{\sigma_j(j)}(t+is') - e_{\sigma_j(k)}(t+is'))ds'.\end{aligned} \tag{4.23}$$

The path of integration from 0 to z for $\widetilde{\Delta}_{jk}(z)$ is deformed into the loop η_j followed by the real axis from 0 to Rez and a vertical path from Rez to z. It remains to take the limit $t \to +\infty$. □

Proof of Lemma 4.1. We rewrite equations (4.15) and (4.16) as an integral equation and perform an integration by parts on the exponentials:

$$\begin{aligned}\widetilde{c}_k(z) = \delta_{jk} &- i\varepsilon\sum_{l=1}^n \frac{\widetilde{a}_{kl}(z)}{\widetilde{e}_k(z) - \widetilde{e}_l(z)}\mathrm{e}^{i\widetilde{\Delta}_{kl}(z)/\varepsilon}\widetilde{c}_l(z)\\ &+ i\varepsilon\sum_{l=1}^n \int_{-\infty}^z \left(\frac{\widetilde{a}_{kl}(z')}{\widetilde{e}_k(z') - \widetilde{e}_l(z')}\right)'\mathrm{e}^{i\widetilde{\Delta}_{kl}(z')/\varepsilon}\widetilde{c}_l(z')dz'\end{aligned}$$

$$+ i\varepsilon \sum_{l,m=1}^{n} \int_{-\infty}^{z} \frac{\widetilde{a}_{kl}(z')\widetilde{a}_{lm}(z')}{\widetilde{e}_k(z') - \widetilde{e}_l(z')} \mathrm{e}^{i\widetilde{\Delta}_{km}(z')/\varepsilon} \widetilde{c}_m(z')dz'. \tag{4.24}$$

Since all eigenvalues are distinct in $S_\alpha \backslash \Omega$, the denominators are always different from 0. In terms of the functions x_k, we get

$$\begin{aligned} x_k(z) = \delta_{jk} &- i\varepsilon \sum_{l=1}^{n} \frac{\widetilde{a}_{kl}(z)}{\widetilde{e}_k(z) - \widetilde{e}_l(z)} x_l(z) \\ &+ i\varepsilon \sum_{l=1}^{n} \int_{-\infty}^{z} \left(\frac{\widetilde{a}_{kl}(z')}{\widetilde{e}_k(z') - \widetilde{e}_l(z')} \right)' \mathrm{e}^{i(\widetilde{\Delta}_{jk}(z) - \widetilde{\Delta}_{jk}(z'))/\varepsilon} x_l(z')dz' \\ &+ i\varepsilon \sum_{l,m=1}^{n} \int_{-\infty}^{z} \frac{\widetilde{a}_{kl}(z')\widetilde{a}_{lm}(z')}{\widetilde{e}_k(z') - \widetilde{e}_l(z')} \mathrm{e}^{i(\widetilde{\Delta}_{jk}(z) - \widetilde{\Delta}_{jk}(z'))/\varepsilon} x_m(z')dz'. \end{aligned} \tag{4.25}$$

We introduce the quantity

$$|||x|||_j = \sup_{\substack{z \in D_j \\ l=1,\dots,n}} |x_l(z)| \tag{4.26}$$

and consider for each k equation (4.25) along the dissipative path $\gamma^k(u)$ described in the definition of D_j such that

$$\left| \mathrm{e}^{i(\widetilde{\Delta}_{jk}(\gamma^k(t)) - \widetilde{\Delta}_{jk}(\gamma^k(u)))/\varepsilon} \right| \leq 1 \tag{4.27}$$

when $u \leq t$ along that path. Due to the integrability of the $\widetilde{a}_{kl}(z)$ at infinity and the uniform boundedness of $d\gamma^k(u)/du$, we get the estimate $|x_k(z) - \delta_{kj}| \leq \varepsilon |||x|||_j A$ for some constant A uniform in $z \in D_j$; hence $|||x|||_j \leq 1 + \varepsilon |||x|||_j A$. Consequently, for ε small enough, $|||x|||_j \leq 2$ and the result follows. □

5. Superasymptotic improvement.

All of the results above can be improved substantially by using the so-called superasymptotic renormalization method [Be], [N], [JP2]. The joint use of complex WKB analysis and superasymptotic renormalization is very powerful, as demonstrated recently in [JP4] for two-level systems, and, roughly speaking, it allows us to replace all remainders $\mathcal{O}(\varepsilon)$ by $\mathcal{O}(\mathrm{e}^{-\kappa/\varepsilon})$, where $\kappa > 0$. We briefly show how to achieve this improvement in the case of n-level systems.

Let $H(z)$ satisfy H1, H2, and H3 in S_α, and let

$$\widehat{S}_\alpha = S_\alpha \backslash \cup_{r=1,\dots,p} (J_r \cup \overline{J_r}), \tag{5.1}$$

where each J_r is an open domain containing only one point of Ω in the open upper half-plane. Hence any analytic continuation $e_j(z)$ of $e_j(t)$, $t \in \mathbf{R}$, in $\widehat{S}_\alpha$ is isolated in the spectrum of $H(z)$ so that $e_j(z)$ is analytic and multivalued in $\widehat{S}_\alpha$, and the same is true for the corresponding analytic continuation $P_j(z)$ of $P_j(t)$, $t \in \mathbf{R}$. Let σ_r be the permutation associated with the loop ζ_r based at the origin which encircles J_r once such that

$$\widetilde{e}_j(z) = e_{\sigma_r(j)}(z), \tag{5.2}$$

with the convention of section 3. The matrix $K(z)$ is analytic and single valued in $\widehat{S}_\alpha$. Consider the single-valued analytic matrix

$$H_1(z, \varepsilon) = H(z) - i\varepsilon K(z), \quad z \in \widehat{S}_\alpha. \tag{5.3}$$

For ε small enough, the spectrum of $H_1(z,\varepsilon)$ is nondegenerate $\forall z \in \widehat{S}_\alpha$ so that its eigenvalues $e_j^1(z,\varepsilon)$ and eigenprojectors $P_j^1(z,\varepsilon)$ are multivalued analytic functions in $\widehat{S}_\alpha$. Moreover, for ε small enough, the analytic continuations of $e_j^1(z,\varepsilon)$ and $P_j^1(z,\varepsilon)$ around J_r satisfy $\widetilde{e}_j^1(z) = e^1_{\sigma_r(j)}(z)$ and $\widetilde{P}_j^1(z) = P^1_{\sigma_r(j)}(z)$, as can be easily deduced from (5.2) by perturbation theory. Consequently, the matrix

$$K_1(z,\varepsilon) = \sum_{j=1}^m P_j^{1\prime}(z,\varepsilon)P_j^1(z,\varepsilon) \tag{5.4}$$

is analytic and single valued in $\widehat{S}_\alpha$. Defining the single-valued matrix

$$H_2(z,\varepsilon) = H(z) - i\varepsilon K_1(z,\varepsilon), \quad z \in \widehat{S}_\alpha, \tag{5.5}$$

we can repeat the argument for ε small enough. By induction, we set for any $q \in \mathbf{N}$

$$H_q(z,\varepsilon) = H(z) - i\varepsilon K_{q-1}(z,\varepsilon), \tag{5.6}$$

$$K_{q-1}(z,\varepsilon) = \sum_{j=1}^m P_j^{q-1\prime}(z,\varepsilon)P_j^{q-1}(z,\varepsilon), \quad z \in \widehat{S}_\alpha, \tag{5.7}$$

for ε is small enough. We have

$$H_q(z,\varepsilon) = \sum_{j=1}^m e_j^q(z,\varepsilon)P_j^q(z,\varepsilon), \tag{5.8}$$

where the eigenvalues and eigenprojections are multivalued in $\widehat{S}_\alpha$ and satisfy

$$\widetilde{e}_j^q(z,\varepsilon) = e^q_{\sigma_r(j)}(z,\varepsilon), \tag{5.9}$$

$$\widetilde{P}_j^q(z,\varepsilon) = P^q_{\sigma_r(j)}(z,\varepsilon), \quad j = 1,\dots,n, \tag{5.10}$$

with the notations of (5.2). We quote from [JP4] and [JP2] the main proposition regarding this construction.

Proposition 5.1. *Let $H(z)$ satisfy* H1, H2, *and* H3 *in S_α, and let $\widehat{S}_\alpha$ be defined as above. Then there exist constants $c > 0$ and $\varepsilon^* > 0$ and a real function $b(t)$ with $\lim_{t\to\pm\infty} |t|^{1+a}b(t) < \infty$ such that*

$$\|K_q(z,\varepsilon) - K_{q-1}(z,\varepsilon)\| \le b(\mathrm{Re}z)\varepsilon^q c^q q!, \tag{5.11}$$

$$\|K_q(z,\varepsilon)\| \le b(\mathrm{Re}z) \tag{5.12}$$

for all $z \in \widehat{S}_\alpha$, all $\varepsilon < \varepsilon^*$, and all $q \le q^*(\varepsilon) \equiv [1/\mathrm{e}c\varepsilon]$, where $[y]$ denotes the integer part of y and e *is the basis of the neperian logarithm.*

We can deduce from this that in $\widehat{S}_\alpha$

$$e_j^q(z,\varepsilon) = e_j(z) + \mathcal{O}(\varepsilon^2 b(\mathrm{Re}z)), \tag{5.13}$$

$$P_j^q(z,\varepsilon) = e_j(z) + \mathcal{O}(\varepsilon b(\mathrm{Re}z)), \quad \forall q \le q^*(\varepsilon). \tag{5.14}$$

We introduce the notation $f^{q^*(\varepsilon)} \equiv f^*$ for any quantity f^q depending on the index q, and we henceforth drop the ε in the arguments of the functions that we encounter. We define the multivalued analytic matrix $W_*(z)$ for $z \in \widehat{S}_\alpha$ by

$$W_*{}'(z) = K_*(z)W_*(z), \qquad W_*(0) = \mathbf{I}. \tag{5.15}$$

Due to the above observations and Proposition 5.1, $W_*(z)$ enjoys all of the properties that $W(z)$ does, such as

$$W_*(z)P_j^*(0) = P_j^*(z)W_*(z), \tag{5.16}$$

$$\widetilde{W}^*(z) = W_*(z)W_*(\zeta_r) \tag{5.17}$$

and, uniformly in s,

$$\lim_{t \pm \infty} W_*(t+is) = W_*(\infty). \tag{5.18}$$

Thus we define for any $z \in \widehat{S}_\alpha$ a set of eigenvectors of $H_*(z)$ by $\varphi_j^*(z) = W_*(z)\varphi_j^*(0)$, where $H_*(0)\varphi_j^*(0) = e_j^*(0)\varphi_j^*(0)$, $j = 1, \ldots, n$, that satisfy

$$\widetilde{\varphi}_j^*(0) = \exp\{-i\theta_j^*(\zeta_r)\}\varphi^*_{\sigma_r(j)}(0),$$

with $\theta_j^*(\zeta_r) = \theta(\zeta_r) + \mathcal{O}(\varepsilon) \in \mathbf{C}$. Let us expand the solution of (2.1) on this multivalued set of eigenvectors as

$$\psi(z) = \sum_{j=1}^{n} c_j^*(z) \mathrm{e}^{-i\int_0^z e_j^*(z')dz'/\varepsilon} \varphi_j^*(z). \tag{5.19}$$

Since the analyticity properties of the eigenvectors and eigenvalues of $H_*(z)$ are the same as those enjoyed by the eigenvectors and eigenvalues of $H(z)$, we get, as in Lemma 3.1,

$$\widetilde{c}_j^*(z)\mathrm{e}^{-i\int_{\zeta_r} e_j^*(u)du/\varepsilon}\mathrm{e}^{-i\theta_j^*(\zeta_r)} = c^*_{\sigma_r(j)}(z), \quad \forall z \in \widehat{S}_\alpha. \tag{5.20}$$

Substituting (5.19) in (2.1), we see that in $\widehat{S}_\alpha$ the multivalued coefficients $c_j^*(z)$ satisfy the differential equation

$$c_j^{*\prime}(z) = \sum_{k=1}^{n} a_{jk}^*(z)\mathrm{e}^{i\Delta_{jk}^*(z)/\varepsilon}c_k^*(z), \tag{5.21}$$

where

$$\Delta_{jk}^*(z) = \int_0^z e_j^*(z') - e_k^*(z')dz' \tag{5.22}$$

and

$$a_{jk}^*(z) = \frac{\langle \varphi_j^*(z)(0) | P_j^*(z)(0)W_*(z)^{-1}(K_{q^*-1}(z) - K_{q^*}(z))W_*(z)\varphi_k^*(0)\rangle}{\|\varphi_j^*(0)\|^2}; \tag{5.23}$$

compare this with (3.13). The key point of this construction is that it follows from Proposition 5.1 with $q = q^*(\varepsilon)$ that

$$|a_{jk}^*(z)| \leq 2b(\mathrm{Re}z)\mathrm{e}^{-\kappa/\varepsilon}, \quad \forall z \in \widehat{S}_\alpha, \tag{5.24}$$

where $\kappa = 1/ec > 0$, and it follows from (5.13) that

$$\mathrm{Im}\Delta_{jk}^*(z) = \mathrm{Im}\Delta_{jk}(z) + \mathcal{O}(\varepsilon^2) \tag{5.25}$$

uniformly in $z \in \widehat{S}_\alpha$. Thus we deduce from (5.24) that the limits

$$\lim_{t\to\pm\infty} c_j^*(t+is) = c_j^*(\pm\infty), \quad j = 1, \dots, n, \tag{5.26}$$

exist for any analytic continuation in $\widehat{S}_\alpha$. Moreover, along any dissipative path $\gamma^k(u)$ for $\{jk\}$, as defined above, we get from (5.25)

$$\left| \mathrm{e}^{i(\widetilde{\Delta}^*_{jk}(\gamma^k(t)) - \widetilde{\Delta}^*_{jk}(\gamma^k(u)))/\varepsilon} \right| = \mathcal{O}(1), \quad \forall u \leq t, \tag{5.27}$$

so that, reproducing the proof of Lemma 4.1, we have the following result.

LEMMA 5.1. *In a dissipative domain D_j, if $\widetilde{c}_k^*(-\infty) = c_k^*(-\infty) = \delta_{kj}$, then*

$$\widetilde{c}_j^*(z) = 1 + \mathcal{O}(e^{-\kappa/\varepsilon}), \tag{5.28}$$

$$e^{i\widetilde{\Delta}_{jk}(z)\varepsilon} \widetilde{c}_k^*(z) = \mathcal{O}(e^{-\kappa/\varepsilon}), \quad \forall k \neq j, \tag{5.29}$$

uniformly in $z \in \widehat{S}_\alpha$.

This lemma yields the following improved version of our main result.

PROPOSITION 5.2. *Under the conditions of Proposition* 4.1 *and with the same notations, if $c_k^*(-\infty) = \delta_{jk}$, then*

$$c^*_{\sigma_j(j)}(+\infty) = \mathrm{e}^{-i\theta_j^*(\eta_j)} \mathrm{e}^{-i\int_{\eta_j} e_j^*(z)dz/\varepsilon} (1 + \mathcal{O}(\mathrm{e}^{-\kappa/\varepsilon})), \tag{5.30}$$

$$c^*_{\sigma_j(k)}(+\infty) = \mathcal{O}\left(\mathrm{e}^{-\kappa/\varepsilon} \mathrm{e}^{\mathrm{Im} \int_{\eta_j} e_j(z)dz/\varepsilon + h_j(e_{\sigma_j(j)}(+\infty) - e_{\sigma_j(k)}(+\infty))/\varepsilon} \right). \tag{5.31}$$

Note that we may or may not replace $e_j(z)$ by $e_j^*(z)$ in the estimate without altering the result. It remains to make the link between the S-matrix and the $c_k^*(+\infty)$'s of the proposition explicit. We define $\beta_j^{*\pm}$ by the relations

$$\varphi_j^*(\pm\infty) = \mathrm{e}^{-i\beta_j^{*\pm}} \varphi_j(\pm\infty) \tag{5.32}$$

($H_*(z)$ and $H(z)$ coincide at $\pm\infty$). By comparison with (5.19) and (2.12), we deduce the following lemma.

LEMMA 5.2. *If $c_k(t)$ and $c_k^*(t)$ satisfy $c_k(-\infty) = c_k^*(-\infty) = \delta_{jk}$, then the element kj of the S-matrix is given by*

(5.33)

$$\begin{aligned} s_{kj} = c_k(+\infty) &= e^{-i(\beta_k^{*+} - \beta_j^{*-})} e^{-i\int_0^{+\infty} e_k^*(t') - e_k(t')dt'/\varepsilon} e^{-i\int_{-\infty}^0 e_j^*(t') - e_j(t')dt'/\varepsilon} c_k^*(+\infty) \\ &\equiv e^{-i\alpha_{kj}^*} c_k^*(+\infty), \end{aligned}$$

with $\beta_j^{*\pm} = \mathcal{O}(\varepsilon)$ and $\int_{\pm\infty}^0 e_j^*(t') - e_j(t')dt'/\varepsilon = \mathcal{O}(\varepsilon)$, i.e., $e^{-i\alpha_{kj}^*} = 1 + \mathcal{O}(\varepsilon)$.

Remarks. (i) Proposition 5.2 together with Lemma 5.2 are the main results of the first part of this paper.

(ii) As a direct consequence of these estimates on the real axis, we have

$$s_{jk} = \mathcal{O}(\mathrm{e}^{-\kappa/\varepsilon}), \quad \forall k \neq j, \tag{5.34}$$

and

$$s_{jj} = \mathrm{e}^{-i\alpha_{jj}^*}(1 + \mathcal{O}(e^{-\kappa/\varepsilon})). \tag{5.35}$$

(iii) It should be clear from the analysis performed above that all of the results obtained hold if the generator $H(z)$ in (2.1) is replaced by

$$H(z,\varepsilon) = H_0(z) + \mathcal{O}(\varepsilon b(\mathrm{Re} z)), \tag{5.36}$$

with $b(t) = \mathcal{O}(1/t^{1+a})$, provided $H_0(z)$ satisfies the hypotheses we assumed.

6. Avoided crossings. We now come to the second part of the paper, in which we prove asymptotic formulas for the off-diagonal elements of the S-matrix by means of the general setup presented above. To start with, we define a class of n-level systems for which we can prove the existence of one nontrivial dissipative domain for all indices. They are obtained by means of systems that exhibit degeneracies of eigenvalues on the real axis, hereafter called real crossings, which we perturb in such a way that these degeneracies are lifted and turn into avoided crossings on the real axis. When the perturbation is small enough, this process moves the eigenvalue degeneracies off the real axis, but they remain close to the place where the real crossings occurred. This method was used successfully in [J] to deal with two-level systems. We do not attempt to list all of the cases in which dissipative domains can be constructed by means of this technique but rather present a wide class of examples which are relevant in the theory of quantum adiabatic transitions and in the theory of multichannel semiclassical scattering, as described below.

Let $H(t,\delta) \in M_n(\mathbf{C})$ satisfy the following assumptions.

H4. *For each fixed $\delta \in [0,d]$, the matrix $H(t,\delta)$ satisfies* H1 *in a strip S_α independent of δ and $H(z,\delta)$ and $\partial/\partial z H(z,\delta)$ are continuous as a functions of two variables $(z,\delta) \in S_\alpha \times [0,d]$. Moreover, it satisfies* H2 *uniformly in $\delta \in [0,d]$, with limiting values $H(\pm,\delta)$ which are continuous functions of $\delta \in [0,d]$.*

H5. *For each $t \in \mathbf{R}$ and each $\delta \in [0,d]$, the spectrum of $H(t,\delta)$, denoted by $\sigma(t,\delta)$, consists of n real eigenvalues*

$$\sigma(t,\delta) = \{e_1(t,\delta), e_2(t,\delta), \dots, e_n(t,\delta)\} \subset \mathbf{R} \tag{6.1}$$

which are distinct when $\delta > 0$:

$$e_1(t,\delta) < e_2(t,\delta) < \cdots < e_n(t,\delta). \tag{6.2}$$

When $\delta = 0$, the functions $e_j(t,0)$ are analytic on the real axis and there exists a finite set of crossing points $\{t_1 \le t_2 \le \cdots \le t_p\} \in \mathbf{R}$, $p \ge 0$, such that the following hold:

(i) *$\forall t < t_1$,*

$$e_1(t,0) < e_2(t,0) < \cdots < e_n(t,0). \tag{6.3}$$

(ii) *$\forall j < k \in \{1,2,\dots,n\}$, there exists at most one t_r with*

$$e_j(t_r,0) - e_k(t_r,0) = 0, \tag{6.4}$$

and if such a t_r exists, we have

$$\frac{\partial}{\partial t}\left(e_j(t_r,0) - e_k(t_r,0)\right) > 0. \tag{6.5}$$

(iii) *$\forall j \in \{1,2,\dots,n\}$, the eigenvalue $e_j(t,0)$ crosses eigenvalues whose indices are all superior to j or all inferior to j.*

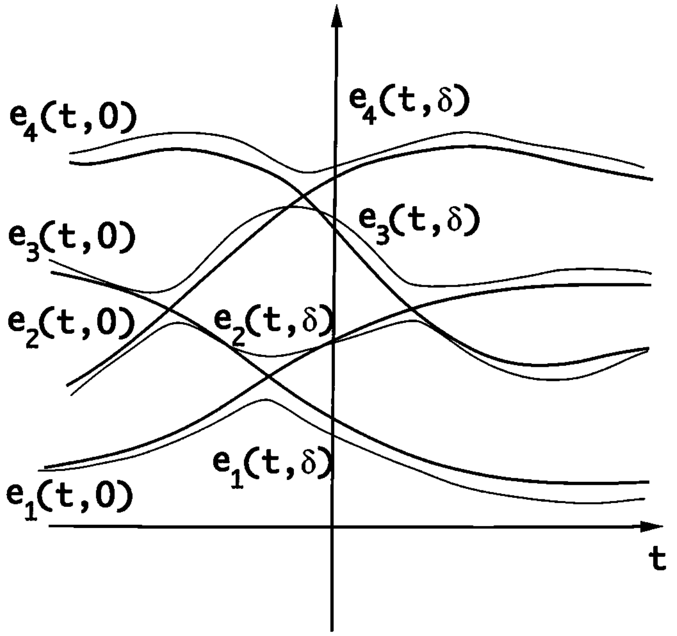

FIG. 4. *A pattern of eigenvalue crossings (bold curves) with the corresponding pattern of avoided crossings (fine curves) satisfying* H5.

Remarks. (i) The parameter δ can be understood as a coupling constant that controls the strength of the perturbation.

(ii) The eigenvalues $e_j(t,0)$ are assumed to be analytic on the real axis, because of the degeneracies on the real axis. However, if $H(t,\delta)$ is self-adjoint for any $\delta \in [0,d]$, this is true for an indexation, as follows from a theorem of Rellich; see [K].

(iii) In Figure 4, we give an example of a pattern of crossings with the corresponding pattern of avoided crossings for which the above conditions are fulfilled.

(iv) The crossings are assumed to be generic in the sense that the derivatives of $e_j - e_k$ are nonzero at the crossing t_r.

(v) The crossing points $\{t_1, t_2, \dots, t_p\}$ need not be distinct, which is important when the eigenvalues possess symmetries. However, for each $j = 1, \dots, n$, the eigenvalue $e_j(t,\delta)$ experiences avoided crossings with $e_{j+1}(t,\delta)$ and/or $e_{j-1}(t,\delta)$ at a subset of distinct points $\{t_{r_1}, \dots, t_{r_j}\} \subseteq \{t_1, t_2, \dots, t_p\}$.

We now state the main lemma of this section regarding the analyticity properties of the perturbed levels and the existence of dissipative domains for all indices in this perturbative context.

LEMMA 6.1. *Let* $H(t,\delta)$ *satisfy* H4 *and* H5. *We can choose* $\alpha > 0$ *small enough so that the following assertions are true for sufficiently small* $\delta > 0$*:*

(i) *Let* $\{t_{r_1}, \dots, t_{r_j}\}$ *be the set of avoided crossing points experienced by* $e_j(t,\delta)$, $j = 1, \dots, n$. *For each* j, *there exists a set of distinct domains* $J_r \in S_\alpha$, *where* $r \in \{r_1, \dots, r_j\}$,

$$J_r = \{z = t + is \,|\, 0 \le |t - t_r| < L, \quad 0 < g < s < \alpha'\}, \tag{6.6}$$

with L *small enough,* $\alpha' < \alpha$, *and* $g > 0$ *such that* $e_j(-\infty,\delta)$ *can be analytically* *continued in*

$$S_\alpha^j = S_\alpha \setminus \cup_{r=r_1,\ldots,r_j} (J_r \cup \overline{J_r}). \tag{6.7}$$

(ii) *Let t_r be an avoided crossing point of $e_j(t,\delta)$ with $e_k(t,\delta)$, $k = j \pm 1$. Then the analytic continuation of the restriction of $e_j(t,\delta)$ around t_r along a loop based at $t_r \in \mathbf{R}$ which encircles J_r once yields $\widetilde{e}_j(t_r,\delta)$ back at t_r with*

$$\widetilde{e}_j(t_r,\delta) = e_k(t_r,\delta). \tag{6.8}$$

(iii) *For each $j = 1,\ldots,n$, there exists a dissipative domain D_j above or below the real axis in $S_\alpha \cap \{z = t + is| \, |s| \geq \alpha'\}$. The permutation σ_j associated with these dissipative domains* (*see Proposition* 4.1) *are all given by $\sigma_j = \sigma$, where σ is the permutation that maps the index of the kth eigenvalue $e_j(\infty,0)$ numbered from the lowest one on k for all $k \in \{1,2,\cdots,n\}$.*

Remarks. (i) In part (ii), the same result is true along a loop encircling $\overline{J_r}$.

(ii) The dissipative domains D_j of part (iii) are located above (respectively, below) all of the sets J_r (respectively, $\overline{J_r}$), $r = 1,\ldots,p$.

(iii) The main interest of this lemma is that the sufficient conditions required for the existence of dissipative domains in the complex plane can be deduced from the behavior of the eigenvalues on the *real* axis.

(iv) We emphasize that more general types of avoided crossings than those described in H5 may lead to the existence of dissipative domains for *certain* indices, but we want to obtain dissipative domains for *all* indices. For example, if part (iii) of H5 is satisfied for certain indices only, then part (iii) of Lemma 6.1 is satisfied for those indices only.

(v) Note also that there are patterns of eigenvalue crossings for which there exist no dissipative domain for some indices. For example, if $e_j(t,0)$ and $e_k(t,0)$ display two crossings, it is not difficult to see from the proof of the lemma that no dissipative domains can exist for j or k.

We postpone the proof of Lemma 6.1 to the end of this section and continue with its consequences. By applying the results of the previous section, we get the following result.

THEOREM 6.1. *Let $H(t,\delta)$ satisfy* H4 *and* H5. *If $\delta > 0$ is small enough, the elements $\sigma(j)j$ of the S-matrix, with $\sigma(j)$ defined in Lemma* 6.1, *are given in the limit $\varepsilon \to 0$ for all $j = 1,\ldots,n$ by*

$$s_{\sigma(j)j} = \prod_{k=j}^{\sigma(j)\mp 1} e^{-i\theta_k(\zeta_k)} e^{-i\int_{\zeta_k} e_k(z,\delta)dz/\varepsilon} \left(1 + \mathcal{O}(\varepsilon)\right), \quad \sigma(j) \begin{cases} > j, \\ < j, \end{cases} \tag{6.9}$$

where for $\sigma(j) > j$ (respectively, $\sigma(j) < j$), ζ_k, $k = j,\ldots,\sigma(j)-1$ (respectively, $k = j,\ldots,\sigma(j)+1$), denotes a negatively (respectively, positively) oriented loop based at the origin which encircles the set J_r (respectively, $\overline{J_r}$) corresponding to the avoided crossing between $e_k(t,\delta)$ and $e_{k+1}(t,\delta)$ (respectively, $e_{k-1}(z,\delta)$) at t_r, $\int_{\zeta_k} e_k(z,\delta)dz$ denotes the integral along ζ_k of the analytic continuation of $e_k(0,\delta)$, and $\theta_k(\zeta_k)$ is the corresponding factor defined by (3.12); *see Figure* 5.

More accurately, with the notations of section 5, *we have the improved formula*

$$s_{\sigma(j)j} = e^{-i\alpha^*_{\sigma(j)j}} \prod_{k=j}^{\sigma(j)\mp 1} e^{-i\theta_k^*(\zeta_k)} e^{-i\int_{\zeta_k} e_k^*(z,\delta)dz/\varepsilon} (1 + \mathcal{O}(e^{-\kappa/\varepsilon})), \quad \sigma(j) \begin{cases} > j, \\ < j. \end{cases} \tag{6.10}$$

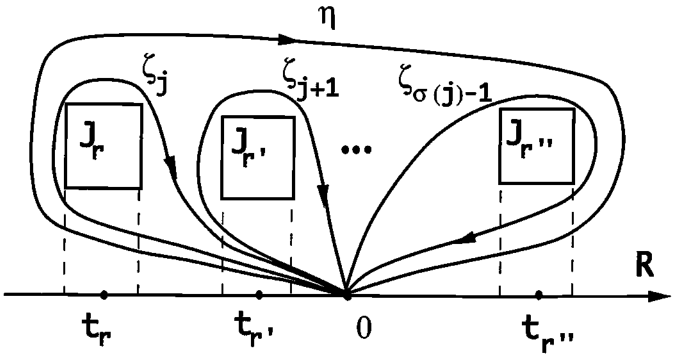

FIG. 5. *The loops η_j and ζ_k, $k = j, \dots, \sigma(j)-1$.*

The elements $\sigma(l)j$, $l \neq j$, are estimated by

$$s_{\sigma(l)j} = \mathcal{O}\left(\varepsilon e^{h(e_{\sigma(j)}(\infty,\delta)-e_{\sigma(l)}(\infty,\delta))/\varepsilon} \prod_{k=j}^{\sigma(j)\mp 1} e^{\mathrm{Im}\int_{\zeta_k} e_k(z,\delta)dz/\varepsilon}\right), \quad \sigma(j)\begin{cases} > j, \\ < j, \end{cases} \tag{6.11}$$

where h is strictly positive (*respectively, negative*) *for $\sigma(j) > j$* (*respectively, $\sigma(j) < j$*)*.*

Remarks. (i) Since the eigenvalues are continuous at the degeneracy points, we have that

$$\lim_{\delta\to 0} \mathrm{Im} \int_{\zeta_k} e_k(z,\delta)dz = 0, \quad \forall k = 1, \dots, p. \tag{6.12}$$

(ii) The remainders $\mathcal{O}(\varepsilon)$ depend on δ, but it should be possible to get estimates that are valid as both ε and δ tend to zero, in the spirit of [J], [MN], and [R].

(iii) This result shows that at least one off-diagonal element per column of the S-matrix can be computed asymptotically. However, it is often possible to get more elements by making use of the symmetries of the S-matrix. Moreover, if there exist dissipative domains that go above or below other eigenvalue degeneracies further away in the complex plane, other elements of the S-matrix can be computed.

(iv) Finally, note that all starred quantities in (6.10) depend on ε.

Proof of Theorem 6.1. The first thing to determine is whether the loops ζ_k are above or below the real axis. Since the formulas that we deduce from the complex WKB analysis are asymptotic, it suffices to choose the case that yields exponential decay of $s_{\sigma(j)j}$. It is readily checked in the proof of Lemma 6.1 below that if $\sigma(j) > j$, D_j is above the real axis and if $\sigma(j) < j$, D_j is below the real axis. Then it remains to explain how to pass from the loop η_j given in Proposition 4.1 to the set of loops ζ_k, $k = j, \dots, \sigma(j)-1$. We briefly deal with the case where $\sigma(j) > j$; the other case is similar. It follows from Lemma 6.1 that we can deform η_j into the set of loops ζ_k, each associated with one avoided crossing, as described in Figure 5. Thus we have

$$\int_{\eta_j} = \sum_{k=j}^{\sigma(j)-1} \int_{\zeta_k} \tag{6.13}$$

for the decay rate and (see (3.10))

$$W(\eta_j) = W(\zeta_{\sigma(j)-1}) \cdots W(\zeta_{j+1}) W(\zeta_j) \tag{6.14}$$

for the prefactors. Let ν_j be a negatively oriented loop based at t_r which encircles J_r as described in Lemma 6.1. Now consider the loop ζ_j associated with this avoided crossing and deform it to the path obtained by going from 0 to t_r along the real axis, from t_r to t_r along ν_j, and back from t_r to the origin along the real axis. By point (ii) of Lemma 6.1, we get

$$\widetilde{e}_j(0,\delta) = e_{j+1}(0,\delta) \tag{6.15}$$

along ζ_j, and, accordingly (see (3.12)),

$$\widetilde{\varphi}_j(0,\delta) = \mathrm{e}^{-i\theta_j(\zeta_j)}\varphi_{j+1}(0,\delta). \tag{6.16}$$

This justifies the first factor in the formula. By repeating the argument at the next avoided crossings, keeping in mind that we get $e_{j+1}(0,\delta)$ at the end of ζ_j and so on, we get the final result. The estimate on $s_{\sigma(l)j}$ is obtained by direct application of lemma 6.1. □

Proof of Lemma 6.1. In what follows, we shall denote "$\frac{\partial}{\partial t}$" by a "$\prime$." We must consider the analyticity properties of $\widetilde{e}_j(z,\delta)$ and define domains in which every point z can be reached from $-\infty$ by means of a path $\gamma(u)$, $u \in\,]-\infty,t]$, $\gamma(t) = z$ such that $\mathrm{Im}\widetilde{\Delta}_{jk}(\gamma(u),\delta)$ is nondecreasing in u for certain indices $j \neq k$ when $\delta > 0$ is fixed. Note that by Schwarz's principle, if $\gamma(u)$ is dissipative for $\{jk\}$, then $\overline{\gamma(u)}$ is dissipative for $\{kj\}$. When $\gamma(u) = \gamma_1(u) + i\gamma_2(u)$ is differentiable, saying that $\gamma(u)$ is dissipative for $\{jk\}$ is equivalent to

$$\begin{aligned}\mathrm{Re}(\widetilde{e}_j(\gamma(u),\delta) - \widetilde{e}_k(\gamma(u),\delta))\dot{\gamma}_2(u) + \mathrm{Im}(\widetilde{e}_j(\gamma(u),\delta) - \widetilde{e}_k(\gamma(u),\delta))\dot{\gamma}_1(u) \geq 0,\\ \forall u \in\,]-\infty,t],\end{aligned} \tag{6.17}$$

where "$\dot{}$" denotes the derivative with respect to u. Moreover, if the eigenvalues are analytic in a neighborhood of the real axis, we have in that neighborhood the relation

$$\mathrm{Im}(\widetilde{e}_j(t+is,\delta) - \widetilde{e}_k(t+is,\delta)) = \int_0^s \mathrm{Re}\ (\widetilde{e}'_j(t+is',\delta) - \widetilde{e}'_k(t+is',\delta))ds', \tag{6.18}$$

which is a consequence of the Cauchy–Riemann identity. We proceed as follows. We construct dissipative domains above and below the real axis when $\delta = 0$, and we show that they remain dissipative for the perturbed quantities $\widetilde{\Delta}_{jk}(z,\delta)$, provided δ is small enough. We introduce some quantities to be used in the construction. Let $C_r \subset \{1,\dots,n\}^2$ denote the set of distinct couples of indices such that the corresponding eigenvalues experience one crossing at $t = t_r$. Similarly, $N \subset \{1,\dots,n\}^2$ denotes the set of couples of indices such that the corresponding eigenvalues never cross.

Let $I_r = [t_r - L, t_r + L] \in \mathbf{R}$, $r = 1,\dots,p$, with L so small that

$$\min_{r\in\{1,\dots,p\}}\ \min_{\{jk\}\in C_r,\, j<k}\ \inf_{t\in I_r}(e'_j(t,0) - e'_k(t,0)) \equiv 4c > 0. \tag{6.19}$$

This relation defines the constant c, and we also define b by

$$\min_{r\in\{1,\dots,p\}}\ \min_{\{jk\}\in C_r,\, j<k}\ \inf_{t\in\mathbf{R}\setminus I_r}|e_j(t,0) - e_k(t,0)| \geq 4b > 0, \tag{6.20}$$

$$\min_{\{jk\}\in N,\, j<k}\ \inf_{t\in\mathbf{R}}|e_j(t,0) - e_k(t,0)| \geq 4b > 0. \tag{6.21}$$

We further introduce

$$I_r^\alpha = \{z = t + is | t \in I_r, |s| \leq \alpha\}, \quad r = 1,\dots,p. \tag{6.22}$$

Then we choose α small enough so that the only points of degeneracy of eigenvalues in S_α are on the real axis and

$$\min_{r\in\{1,\dots,p\}}\ \min_{\{jk\}\in C_r,\, j<k}\ \inf_{z\in I_r^\alpha} \mathrm{Re}(e_j'(z,0)-e_k'(z,0)) > 2c > 0 \tag{6.23}$$

$$\min_{r\in\{1,\dots,p\}}\ \min_{\{jk\}\in C_r,\, j<k}\ \inf_{z\in S_\alpha\setminus I_r^\alpha} |\mathrm{Re}(e_j(z,0)-e_k(z,0))| > 2b > 0 \tag{6.24}$$

$$\min_{\{jk\}\in N,\, j<k}\ \inf_{z\in S_\alpha} |\mathrm{Re}(e_j(z,0)-e_k(z,0))| > 2b > 0. \tag{6.25}$$

The fact that this choice is always possible is a consequence of the analyticity of $e_j(z,0)$ close to the real axis and of the fact that we can essentially work in a compact because of hypothesis H4. Let $a(t)$ be integrable on $\mathbf{R}$ and such that

$$\frac{a(t)}{2} > \max_{j<k\in\{1,\dots,n\}}\ \sup_{|s|\le\alpha} \left|\mathrm{Re}(e_j'(t+is,0)-e_k'(t+is,0))\right|. \tag{6.26}$$

It follows from H4 that such functions exist.

Let $r\in\{1,\dots,p\}$ and $\gamma_2(u)$ be a solution of

$$\begin{cases} \dot\gamma_2(u) = -\frac{\gamma_2(u)a(u)}{b}, & u\in\,]-\infty,t_r-L],\\ \dot\gamma_2(u)=0, & u\in\,]t_r-L,t_r+L[,\\ \dot\gamma_2(u) = +\frac{\gamma_2(u)a(u)}{b}, & u\in[t_r+L,\infty[, \end{cases} \tag{6.27}$$

with $\gamma_2(t_r)>0$. Then $\gamma_2(u)>0$ for any u since

$$\begin{cases} \gamma_2(u) = \gamma_2(t_r)\mathrm{e}^{-\int_{t_r-L}^{u} a(u')du'/b}, & u\in\,]-\infty,t_r-L],\\ \gamma_2(u) = \gamma_2(t_r), & u\in\,]t_r-L,t_r+L[,\\ \gamma_2(u) = \gamma_2(t_r)\mathrm{e}^{\int_{t_r+L}^{u} a(u')du'/b}, & u\in[t_r+L,\infty[, \end{cases} \tag{6.28}$$

and since $a(u)$ is integrable, the limits

$$\lim_{u\to\pm\infty}\gamma_2(u) = \gamma_2(\pm\infty) \tag{6.29}$$

exist. Moreover, we can always choose $\gamma_2(t_r)>0$ sufficiently small so that $\gamma^r(u)\equiv u+i\gamma_2(u)\in S_\alpha$ for any real u. Let us verify that this path is dissipative for all $\{jk\}\in C_r$, $j<k$. For $u\in\,]-\infty,t_r-L]$, using

$$\mathrm{Re}(e_j(z,0)-e_k(z,0)) < -2b < 0, \quad \forall z\in S_\alpha\cap\{z|\mathrm{Re}z\le t_r-L\}, \tag{6.30}$$

$$|\mathrm{Im}(e_j(t+is,0)-e_k(t+is,0))| < |s| \sup_{s'\in[0,s]} \left|\mathrm{Re}(e_j'(t+is',0)-e_k'(t+is',0))\right| \tag{6.31}$$

(see (6.18)), and the definition (6.26), we have

$$\begin{aligned} &\mathrm{Re}(e_j(\gamma^r(u),0)-e_k(\gamma^r(u),0))\dot\gamma_2(u) + \mathrm{Im}(e_j(\gamma^r(u),0)-e_k(\gamma^r(u),0))\dot\gamma_1(u)\\ &\quad = -\mathrm{Re}(e_j(\gamma^r(u),0)-e_k(\gamma^r(u),0))\frac{\gamma_2(u)a(u)}{b} + \mathrm{Im}(e_j(\gamma^r(u),0)-e_k(\gamma^r(u),0))\\ &\quad > 2\gamma_2(u)a(u) - \gamma_2(u)a(u)/2 > \gamma_2(u)a(u) > 0. \end{aligned} \tag{6.32}$$

Similarly, when $u \geq t_r + L$, using

$$\operatorname{Re}(e_j(z,0) - e_k(z,0)) > 2b > 0, \quad \forall z \in S_\alpha \cap \{z | \operatorname{Re} z \geq t_r + L\}, \tag{6.33}$$

we get

$$\begin{aligned} &\operatorname{Re}(e_j(\gamma^r(u),0) - e_k(\gamma^r(u),0))\dot{\gamma}_2(u) + \operatorname{Im}(e_1(\gamma^r(u),0) - e_k(\gamma^r(u),0))\dot{\gamma}_1(u) \\ &\quad = \operatorname{Re}(e_j(\gamma^r(u),0) - e_k(\gamma^r(u),0))\frac{\gamma_2(u)a(u)}{b} + \operatorname{Im}(e_j(\gamma^r(u),0) - e_k(\gamma^r(u),0)) \\ &\quad > 2\gamma_2(u)a(u) - \gamma_2(u)a(u)/2 > \gamma_2(u)a(u) > 0. \end{aligned} \tag{6.34}$$

Finally, for $s \in [t_r - L, t_r + L]$, we have with (6.23) that

$$\begin{aligned} \operatorname{Im}(e_j(\gamma^r(u),0) - e_k(\gamma^r(u),0)) &= \int_0^{\gamma_2(u)} \operatorname{Re}(e'_j(t'+is,0) - e'_k(t'+is,0)) \\ &\geq \gamma_2(u)2c > \gamma_2(u)c > 0. \end{aligned} \tag{6.35}$$

Thus $\gamma^r(u)$ is dissipative for all $\{jk\} \in C_r$, $j < k$. Note that the last estimate shows that it is not possible to find a dissipative path for $\{jk\} \in C_r$, $j < k$ below the real axis.

Now consider $\{jk\} \in N$, $j < k$, and let $\gamma_2^+(u)$ be a solution of

$$\dot{\gamma}_2^+(u) = -\frac{\gamma_2^+(u)a(u)}{b}, \qquad \gamma_2^+(0) > 0, \quad u \in]-\infty, +\infty[, \tag{6.36}$$

i.e.,

$$\gamma_2^+(u) = \gamma_2^+(0)\mathrm{e}^{-\int_0^u a(u')du'/b}. \tag{6.37}$$

As above, we have $\gamma_2^+(u) > 0$ for any u and we can choose $\gamma_2^+(0) > 0$ small enough so that $\gamma^+(u) \equiv u + i\gamma_2^+(u) \in S_\alpha$ for any $u \in \mathbf{R}$. Since

$$\operatorname{Re}(e_j(z,0) - e_k(z,0)) > -2b, \quad \forall z \in S_\alpha, \tag{6.38}$$

we check by a computation analogous to (6.32) that $\gamma^+(u)$ is dissipative for $\{jk\} \in N$, $j < k$. Similarly, we can verify that if $\gamma_2^-(u)$ is the solution of

$$\dot{\gamma}_2^-(u) = \frac{\gamma_2^-(u)a(u)}{b}, \qquad \gamma_2^-(0) < 0, \quad u \in]-\infty, +\infty[, \tag{6.39}$$

with $|\gamma_2^-(0)|$ small enough, the path $\gamma^-(u) \equiv u + i\gamma_2^-(u)$ below the real axis is in S_α for any $u \in \mathbf{R}$ and is dissipative for $\{jk\} \in N$, $j < k$, as well.

Finally, the complex conjugates of these paths yield dissipative paths above and below the real axis for $\{jk\} \in N$, $j > k$.

We now define the dissipative domains by means of their borders. Let $\gamma^+(u)$ and $\gamma^-(u)$, $u \in \mathbf{R}$, be two dissipative paths in S_α defined as above with $|\gamma_2^-(0)|$ sufficiently small so that $\overline{\gamma^-}$ is below γ^+. We set

$$D = \{z = t + is | 0 < -\gamma_2^-(t) \leq s \leq \gamma_2^+(t), \quad t \in \mathbf{R}\}. \tag{6.40}$$

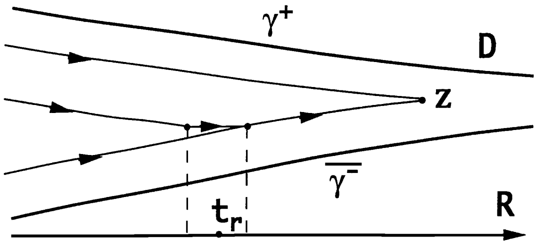

FIG. 6. *The dissipative domain D and some dissipative paths.*

Let $z \in D$, and $j \in \{1, \dots, n\}$ be fixed. By assumption H5, the set X_j of indices k such that $\{jk\} \in C_r$ for some $r \in \{1, \dots, p\}$ consists of values k that satisfy $j < k$ or it consists of values k that satisfy $j > k$. Let us assume that the first alternative takes place. Now for any $k \in \{1, \dots, n\}$, there are three cases.

(1) If $k \in X_j$, then there exists a dissipative path $\gamma^r \in D$ for $\{jk\} \in C_r$, $j < k$, constructed as above which links $-\infty$ to z. It is enough to select the initial condition $\gamma_2(t_r)$ suitably; see Figure 6.

(2) Similarly, if $j < k \notin X_j$, there exists a dissipative path $\gamma^+ \in D$ for $\{jk\}$ constructed as above which links $-\infty$ to z obtained by a suitable choice of $\gamma_2^+(0)$.

(3) Finally, if $k > j$, we can take as a dissipative path for $\{jk\}$ the path $\overline{\gamma^-} \in D$ constructed as above which links $-\infty$ to z with a suitable choice of $\gamma_2^-(0)$. Hence D is dissipative for the index j when $\delta = 0$. If j is such that the set X_j consists of points k with $k > j$, a similar argument with the complex conjugates of the above paths shows that the domain $\overline{D}$ below the real axis is dissipative for j when $\delta = 0$.

Let us show that these domains remain dissipative when $\delta > 0$ is not too large. We start by considering the analyticity properties of the perturbed eigenvalues $e_j(z, \delta)$, $\delta > 0$. Let $0 < \alpha' < \alpha$ be such that

$$I_r^{\alpha'} \cap (D \cup \overline{D}) = \emptyset, \quad \forall r = 1, \dots, p. \tag{6.41}$$

The analytic eigenvalues $e_j(z, 0)$, $j \in \{1, \dots, n\}$, are isolated in the spectrum of $H(z, 0)$ for any $z \in \widetilde{S}_\alpha$, where

$$\widetilde{S}_\alpha = S_\alpha \setminus \cup_{r=1,\dots,p} I_r^{\alpha'}. \tag{6.42}$$

For any $j = 1, \dots, n$ we get from perturbation theory [K] that the analytic continuations $\widetilde{e}_j(z, \delta)$ of $e_j(t_1 - L, \delta)$ in $\widetilde{S}_\alpha$ are all distinct in $\widetilde{S}_\alpha$, provided δ is small enough. This is due to the fact that assumption H4 implies the continuity of $H(z, \delta)$ in δ uniformly in $z \in S_\alpha$, as is easily verified. More precisely, for any fixed index j, the eigenvalue $e_j(t, \delta)$ experiences avoided crossings at the points $\{t_{r_1}, \dots, t_{r_j}\}$. We can assume without loss of generality that

$$I_k^{\alpha'} \cap I_l^{\alpha'} = \emptyset, \quad \forall k \neq l \in \{r_1, \dots, r_j\}. \tag{6.43}$$

Hence for $\delta > 0$ small enough, the analytic continuation $\widetilde{e}_j(z, \delta)$ is isolated in the spectrum of $H(z, \delta)$ uniformly in $z \in S_\alpha \setminus \cup_{r=r_1,\dots,r_j} I_r^{\alpha'}$. Since by assumption H5 there is no crossing of eigenvalues on the real axis when $\delta > 0$, there exists a $0 < g < \alpha'$ that depends on δ such that $\widetilde{e}_j(z, \delta)$ is isolated in the spectrum of $H(z, \delta)$ uniformly in $z \in S_\alpha^j$, where

$$S_\alpha^j = S_\alpha \setminus \cup_{r=r_1,\dots,r_j} (J_r \cup \overline{J_r}) \tag{6.44}$$

and

$$J_r = I_r^{\alpha'} \cap \{z|\,\mathrm{Im}z > g\}, \quad r = 1, \dots, p. \tag{6.45}$$

Hence the singularities of $\widetilde{e}_j(z,\delta)$ are located in $\cup_{r=r_1,\dots,r_j}(J_r \cup \overline{J_r})$, which yields the first assertion of the lemma.

Consider a path ν_r from $t_r - L$ to $t_r + L$ which goes above J_r, where t_r is an avoided crossing between $e_j(t,\delta)$ and $e_k(t,\delta)$, $k = j \pm 1$. By perturbation theory again, $e_j(t_r - L,\delta)$ and $e_k(t_r - L,\delta)$ tend to $e_{j'}(t_r - L, 0)$ and $e_{k'}(t_r - L, 0)$ as $\delta \to 0$ for some $j', k' \in 1, \dots, n$, whereas $e_j(t_r + L,\delta)$ and $e_k(t_r + L,\delta)$ tend to $e_{k'}(t_r + L, 0)$ and $e_{j'}(t_r + L, 0)$ as $\delta \to 0$; see Figure 4. Now the analytic continuations of the restrictions of $e_j(t,\delta)$ and $e_k(t,\delta)$ around $t_r - L$ along ν_r, $\widetilde{e}_j(z,\delta)$ and $\widetilde{e}_k(z,\delta)$ tend to the analytic functions $\widetilde{e}_{j'}(z,0) = e_{j'}(z,0)$ and $\widetilde{e}_{k'}(z,0) = e_{k'}(z,0)$ as $\delta \to 0$ for all $z \in \nu_r$. Thus we deduce that for δ small enough,

$$\widetilde{e}_j(t_r + L,\delta) \equiv e_k(t_r + L,\delta) \tag{6.46}$$

since we know that $\widetilde{e}_j(t_r + L,\delta) = e_{\sigma(j)}(t_r + L,\delta)$ for some permutation σ. Hence point (iii) of the lemma follows.

Note that the analytic continuations $\widetilde{e}_j(z,\delta)$ are single valued in $\widetilde{S}_\alpha$. Indeed, the analytic continuation of $e_j(t_r - L,\delta)$ along $\overline{\nu_r}$, denoted by $\widehat{e}_j(z,\delta)$, $\forall z \in \overline{\nu_r}$, is such that

$$\widehat{e}_j(t_r + L,\delta) = \overline{\widetilde{e}_j(t_r + L,\delta)} = \widetilde{e}_j(t_r + L,\delta) = e_k(t_r + L,\delta) \tag{6.47}$$

due to Schwarz's principle. We further require δ to be sufficiently small so that the following estimates are satisfied:

$$\min_{r\in\{1,\dots,p\}} \min_{\substack{\{jk\}\in C_r\\ j<k}} \inf_{z\in\widetilde{S}_\alpha\setminus I_r^\alpha} |\mathrm{Re}(\widetilde{e}_j(z,\delta) - \widetilde{e}_k(z,\delta))| > b > 0, \tag{6.48}$$

$$\min_{\substack{\{jk\}\in N\\ j<k}} \inf_{z\in\widetilde{S}_\alpha} |\mathrm{Re}(\widetilde{e}_j(z,\delta) - \widetilde{e}_k(z,\delta))| > b > 0, \tag{6.49}$$

$$\max_{j<k\in\{1,\dots,n\}} \sup_{\mathrm{Im}z|\; z\in\widetilde{S}_\alpha} \left|\mathrm{Re}(\widetilde{e}'_j(z,\delta) - \widetilde{e}'_k(z,\delta))\right| < a(\mathrm{Re}z), \tag{6.50}$$

and, in the compacts $\widetilde{I}_r^\alpha = I_r^\alpha \setminus I_r^{\alpha'}$,

$$\begin{aligned} &\min_{r\in\{1,\dots,p\}} \min_{\substack{\{jk\}\in C_r\\ j<k}} \inf_{z\in\widetilde{I}_r^\alpha} |\mathrm{Im}(\widetilde{e}_j(z,\delta) - \widetilde{e}_k(z,\delta))| \\ &> \frac{1}{2} \min_{r\in\{1,\dots,p\}} \min_{\substack{\{jk\}\in C_r\\ j<k}} \inf_{z\in\widetilde{I}_r^\alpha} |\mathrm{Im}(\widetilde{e}_j(z,0) - \widetilde{e}_k(z,0))| > |\mathrm{Im}z|c, \end{aligned} \tag{6.51}$$

$$\begin{aligned} &\max_{r\in\{1,\dots,p\}} \max_{j<k\in\{1,\dots,n\}} \sup_{z\in\widetilde{I}_r^\alpha} |\mathrm{Im}(\widetilde{e}_j(z,\delta) - \widetilde{e}_k(z,\delta))| \\ &< 2 \max_{r\in\{1,\dots,p\}} \max_{j<k\in\{1,\dots,n\}} \sup_{z\in\widetilde{I}_r^\alpha} |\mathrm{Im}(\widetilde{e}_j(z,0) - \widetilde{e}_k(z,0))| < |\mathrm{Im}z|a(\mathrm{Re}z). \end{aligned} \tag{6.52}$$

The simultaneous requirements (6.26) and (6.50) are made possible by the continuity properties of $H'(z,\delta)$ and the uniformity in δ of the decay at $\pm\infty$ of $H(z,\delta)$ assumed in H4 together with the fact that $a(t)$ can be replaced by a multiple of $a(t)$ if necessary to satisfy both estimates. The condition on δ is given by the first inequalities in (6.51) and (6.52), whereas the second ones are just recalls.

Then it remains to check that the paths γ^r, γ^+, and γ^- defined above satisfy the dissipativity condition (6.17) for the corresponding indices. This is not difficult since the above estimates are precisely designed to preserve inequalities such as (6.32), (6.34), and (6.35). However, it should not be forgotten that in the sets $I_r^{\alpha'}$, the eigenvalues may be singular so that (6.18) cannot be used there. Therefore, when checking that a path parameterized as above by $u \in \mathbf{R}$ is dissipative, it is necessary to consider separately the case $u \in \mathbf{R}\backslash(\cup_{r=1,\ldots,p} I_r)$, where we proceed as above with (6.48), (6.49), (6.50), and (6.18), and the case $u \in \cup_{r=1,\ldots,p} I_r$, where we use use (6.51) and (6.52) instead of (6.18) as follows. If $u \in I_r$ for r such that t_r is a crossing point for $e_j(t,0)$ and $e_k(t,0)$, we take (6.51) to estimate $\text{Im}(\widetilde{e}_{j'}(z,\delta) - \widetilde{e}_{k'}(z,\delta))$ for the corresponding indices j' and k', and if t_r is not a crossing point for $e_j(t,0)$ and $e_k(t,0)$, we use (6.52) to estimate $\text{Im}(\widetilde{e}_{j'}(z,\delta) - \widetilde{e}_{k'}(z,\delta))$. Consequently, the domains D and $\overline{D}$ defined above keep the same dissipativity properties when $\delta > 0$ is small enough.

Let us finally turn to the determination of the associated permutation σ. As noticed earlier, the eigenvalues $\widetilde{e}_j(z,\delta)$ are continuous in δ uniformly in $z \in \widetilde{S}_\alpha$. Hence, since the eigenvalues $e_j(z,0)$ are analytic in S_α, we have

$$\lim_{\delta\to 0} \widetilde{e}_j(\infty,\delta) = e_j(\infty,0) \quad j = 1,2,\ldots,n, \tag{6.53}$$

whereas along the real axis (see Figure 4), we have

$$\lim_{\delta\to 0} e_{\sigma(j)}(\infty,\delta) = e_j(\infty,0), \tag{6.54}$$

with σ defined in the lemma, from which the result follows. □

7. Applications. Let us consider the time-dependent Schrödinger equation in the adiabatic limit. The relevant equation is then (2.1), where $H(t) = H^*(t)$ is the time-dependent self-adjoint Hamiltonian. Thus we can take $J = \mathbf{I}$ in Proposition 2.1 to get

$$H(t) = H^*(t) = H^{\#}(t). \tag{7.1}$$

Since the norm of an eigenvector is positive, it remains to impose the gap hypothesis in H3 to fit in the framework, and we deduce that the S-matrix is unitary since $R = \mathbf{I}$. In this context, the elements of the S-matrix describe the transitions between the different levels between $t = -\infty$ and $t = +\infty$ in the adiabatic limit.

We now specify our concern a little further and consider a three-level system, i.e., $H(t) = H^*(t) \in M_3(\mathbf{C})$. We assume that $H(t)$ satisfies the hypotheses of Theorem 6.1 with an extra parameter δ, which we omit in the notation, and displays two avoided crossings at $t_1 < t_2$, as shown in Figure 7. The corresponding permutation σ is given by

$$\sigma(1) = 3, \qquad \sigma(2) = 1, \qquad \sigma(3) = 2. \tag{7.2}$$

By Theorem 6.1, we can compute asymptotically the elements s_{31}, s_{12}, s_{23}, and s_{jj}, $j = 1,2,3$. Using the unitarity of the S-matrix, we can get some more information. Introducing

$$\Gamma_j = \left| \text{Im} \int_{\zeta_j} e_j(z)dz \right|, \quad j = 1,2, \tag{7.3}$$

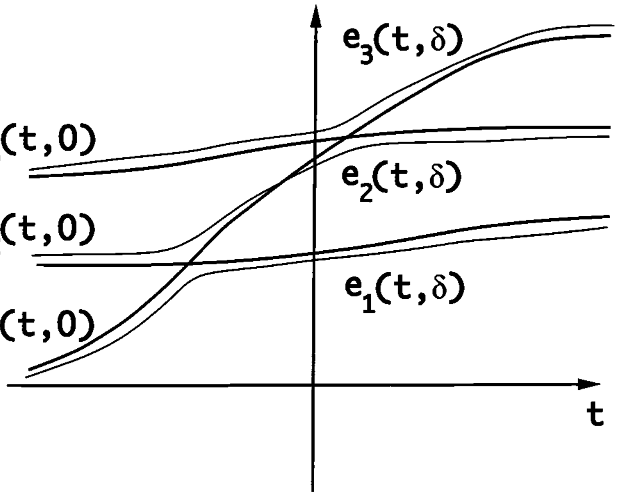

FIG. 7. *The pattern of avoided crossings in the adiabatic context.*

where ζ_j is in the upper half-plane, with the notation of section 6, it follows that

$$s_{31} = \mathcal{O}(e^{-(\Gamma_1+\Gamma_2)/\varepsilon}), \qquad s_{12} = \mathcal{O}(e^{-\Gamma_1/\varepsilon}), \qquad s_{23} = \mathcal{O}(e^{-\Gamma_2/\varepsilon}), \tag{7.4}$$

and

$$s_{jj} = 1 + \mathcal{O}(\varepsilon), \quad j = 1, 2, 3. \tag{7.5}$$

Expressing the fact that the first and second columns as well as the second and third rows are orthogonal, we deduce

$$s_{21} = -\overline{s_{12}}\frac{s_{11}}{\overline{s_{22}}}(1 + \mathcal{O}(e^{-2\Gamma_2/\varepsilon})), \tag{7.6}$$

$$s_{32} = -\overline{s_{23}}\frac{s_{33}}{\overline{s_{22}}}(1 + \mathcal{O}(e^{-2\Gamma_1/\varepsilon})). \tag{7.7}$$

Finally, the estimate in Theorem 6.1 yields

$$s_{13} = \mathcal{O}(\varepsilon e^{-|h|(e_2(\infty,\delta)-e_1(\infty,\delta))/\varepsilon} e^{-\Gamma_2/\varepsilon}) = \mathcal{O}(e^{-(\Gamma_2+\Gamma_2+K)/\varepsilon}), \tag{7.8}$$

where $K > 0$, since we have that $\Gamma_j \to 0$ as $\delta \to 0$. Hence we get

(7.9)
$$S = \begin{pmatrix} s_{11} & s_{12} & \mathcal{O}\left(e^{-(\Gamma_2+\Gamma_2+K)/\varepsilon}\right) \\ -\overline{s_{12}}\frac{s_{11}}{\overline{s_{22}}}\left(1 + \mathcal{O}\left(e^{-2\Gamma_2/\varepsilon}\right)\right) & s_{22} & s_{23} \\ s_{31} & -\overline{s_{23}}\frac{s_{33}}{\overline{s_{22}}}\left(1 + \mathcal{O}\left(e^{-2\Gamma_1/\varepsilon}\right)\right) & s_{33} \end{pmatrix},$$

where all s_{jk}'s above can be computed asymptotically up to exponentially small relative error using (6.10).

The smallest asymptotically computable element s_{31} describes the transition from $e_1(-\infty, \delta)$ to $e_3(+\infty, \delta)$. The result that we obtain for this element is in agreement with the rule of thumb that claims that the transitions take place locally at the avoided crossings and can be considered as independent. Accordingly, we can only estimate the smallest element of all, s_{13}, which describes the transition from $e_3(-\infty,\delta)$ to $e_1(+\infty,\delta)$, for which the avoided crossings are not encountered in the "right order," as discussed in [HP]. It is possible, however, to get an asymptotic expression for this element in some cases. When the unperturbed levels $e_2(z,0)$ and $e_3(z,0)$ possess a degeneracy point in S_α and when there exists a dissipative domain for the index 3 of the unperturbed eigenvalues going above this point, one can convince oneself that s_{13} can be computed asymptotically for δ small enough using the techniques presented above.

Our second application is the study of the semiclassical scattering properties of the multichannel stationary Schrödinger equation with energy above the potential barriers. The relevant equation is then

$$-\varepsilon^2\frac{d^2}{dt^2}\Phi(t)+V(t)\Phi(t)=E\Phi(t), \tag{7.10}$$

where $t\in\mathbf{R}$ is a space variable, $\Phi(t)\in\mathbf{C}^m$ is the wave function, $\varepsilon\to 0$ denotes Planck's constant, $V(t)=V^*(t)\in M_m(\mathbf{C})$ is the matrix of potentials, and the spectral parameter E is kept fixed and large enough so that

$$U(t)\equiv E-V(t)>0. \tag{7.11}$$

Introducing

$$\psi(t)=\begin{pmatrix}\Phi(t)\\ i\varepsilon\Phi(t)\end{pmatrix}\in\mathbf{C}^{2m}, \tag{7.12}$$

we cast equation (7.10) into the equivalent form (2.1) for $\psi(t)$ with the generator

$$H(t)=\begin{pmatrix}\mathbf{O} & \mathbf{I}\\ U(t) & \mathbf{O}\end{pmatrix}\in M_{2m}(\mathbf{C}). \tag{7.13}$$

It is readily verified that

$$H(t)=J^{-1}H^*(t)J, \tag{7.14}$$

with

$$J=\begin{pmatrix}\mathbf{O} & \mathbf{I}\\ \mathbf{I} & \mathbf{O}\end{pmatrix}. \tag{7.15}$$

Concerning the spectrum of $H(t)$, we should remark that if the real and positive eigenvalues of $U(t)$, $k_j^2(t)$, $j=1,\dots,m$ associated with the eigenvectors $u_j(t)\in\mathbf{C}^m$ are assumed to be distinct, i.e.,

$$0<k_1^2(t)<k_2^2(t)<\cdots<k_m^2(t), \tag{7.16}$$

then the spectrum of the generator $H(t)$ given by (7.13) consists of $2m$ real distinct eigenvalues

$$-k_m(t)<-k_{m-1}(t)<\cdots<-k_1(t)<k_1(t)<k_2(t)<\cdots<k_m(t) \tag{7.17}$$

associated with the $2m$ eigenvectors

$$\begin{aligned}\chi_j^{\pm}(t)&=\begin{pmatrix}u_j(t)\\ \pm k_j(t)u_j(t)\end{pmatrix}\in\mathbf{C}^{2m},\\ H(t)\chi_j^{\pm}(t)&=\pm k_j(t)\chi_j^{\pm}(t).\end{aligned} \tag{7.18}$$

We check that

$$(\chi_j^{\pm}(0), \chi_j^{\pm}(0))_J = \pm 2k_j(0)\|u_j(0)\| \neq 0, \quad j = 1, \ldots, m, \tag{7.19}$$

where $\|u_j(0)\|$ is computed in $\mathbf{C}^m$, so that Proposition 2.1 applies. Before dealing with its consequences, we further make explicit the structure of S. Adopting the notation suggested by (7.17) and (7.18), we write

$$H(t) = \sum_{j=1}^{m} k_j(t) P_j^{+}(t) - \sum_{j=1}^{m} k_j(t) P_j^{-}(t), \tag{7.20}$$

$$\psi(t) = \sum_{j=1}^{m} c_j^{+}(t)\varphi_j^{+}(t) \mathrm{e}^{-i\int_0^t k_j(t')dt'/\varepsilon} + \sum_{j=1}^{m} c_j^{-}(t)\varphi_j^{-}(t) \mathrm{e}^{i\int_0^t k_j(t')dt'/\varepsilon} \tag{7.21}$$

and introduce

$$\mathbf{c}^{\pm}(t) = \begin{pmatrix} c_1^{\pm}(t) \\ c_2^{\pm}(t) \\ \vdots \\ c_m^{\pm}(t) \end{pmatrix} \in \mathbf{C}^m. \tag{7.22}$$

Hence we have the block structure

$$S \begin{pmatrix} \mathbf{c}^{+}(-\infty) \\ \mathbf{c}^{-}(-\infty) \end{pmatrix} \equiv \begin{pmatrix} S_{++} & S_{+-} \\ S_{-+} & S_{--} \end{pmatrix} \begin{pmatrix} \mathbf{c}^{+}(-\infty) \\ \mathbf{c}^{-}(-\infty) \end{pmatrix} = \begin{pmatrix} \mathbf{c}^{+}(+\infty) \\ \mathbf{c}^{-}(+\infty) \end{pmatrix}, \tag{7.23}$$

where $S_{\sigma\tau} \in M_m(\mathbf{C})$, $\sigma, \tau \in \{+, -\}$.

Let us turn to the symmetry properties of S. We get from (7.19) and Proposition 2.1 that

(7.24)
$$\begin{pmatrix} S_{++} & S_{+-} \\ S_{-+} & S_{--} \end{pmatrix}^{-1} = \begin{pmatrix} \mathbf{I} & \mathbf{O} \\ \mathbf{O} & -\mathbf{I} \end{pmatrix} \begin{pmatrix} S_{++} & S_{+-} \\ S_{-+} & S_{--} \end{pmatrix}^{*} \begin{pmatrix} \mathbf{I} & \mathbf{O} \\ \mathbf{O} & -\mathbf{I} \end{pmatrix} = \begin{pmatrix} S_{++}^{*} & -S_{-+}^{*} \\ -S_{+-}^{*} & S_{--}^{*} \end{pmatrix}.$$

In terms of the blocks $S_{\sigma\tau}$, this is equivalent to

$$S_{++}S_{++}^{*} - S_{+-}S_{+-}^{*} = \mathbf{I}, \tag{7.25}$$

$$S_{++}S_{-+}^{*} - S_{+-}S_{--}^{*} = \mathbf{O}, \tag{7.26}$$

$$S_{--}S_{--}^{*} - S_{-+}S_{-+}^{*} = \mathbf{I}. \tag{7.27}$$

The block S_{++} describes the transmission coefficients associated with a wave traveling from the right and S_{-+} describes the associated reflexion coefficients. Similarly, S_{--} and S_{+-} are related to the transmission and reflexion coefficients associated with a wave incoming from the left. It should be noted that in the case of equation (7.10), another convention is often used to define an S-matrix (see, for instance, [F1]). This gives rise to a different S-matrix with a similar interpretation. However, it is not difficult to establish a one-to-one correspondence between the two definitions. If the matrix of potentials $V(t)$ is real symmetric, we have further symmetry in the S-matrix.

Lemma 7.1. *Let S given by* (7.23) *be the S-matrix associated with* (7.10) *under condition* (7.11). *If we further assume that $V(t) = \overline{V(t)}$, then taking $\varphi_j^{\pm}(0) \in \mathbf{R}^{2m}$, $j = 1, \ldots, m$, in* (7.21), *we get*

$$S_{++} = \overline{S_{--}}, \qquad S_{+-} = \overline{S_{-+}}. \tag{7.28}$$

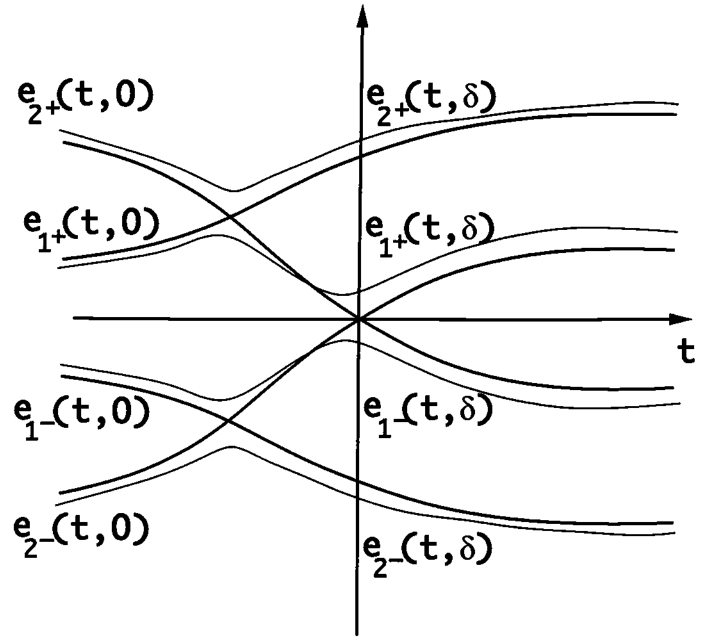

FIG. 8. *The pattern of avoided crossings in the semiclassical context.*

The corresponding results for the S-matrix defined in [F1] are derived in [MN]. The proof of this lemma can be found in Appendix B. We now consider (7.10) in the case where $U(t)=U^*(t)=\overline{U(t)}\in M_2(\mathbf{R})$, which describes a two-channel Schrödinger equation. We assume that the four-level generator $H(t)$ displays three avoided crossings at $t_1<t_2$, two of which take place at the same point t_1 because of the symmetry of the eigenvalues, as in Figure 8. By Lemma 7.1, it is enough to consider the blocks S_{++} and S_{+-}. The transitions corresponding to elements of these blocks which we can compute asymptotically are from level 1^+ to level 2^+ and from level 2^- to level 1^+. They correspond to elements s_{21}^{++} and s_{12}^{+-}, respectively. With the notation

$$\Gamma_j=\left|\operatorname{Im}\int_{\zeta_j}k_1(z)dz\right|,\quad j=1,2, \tag{7.29}$$

where ζ_j is in the upper half-plane, we have the estimates

(7.30)
$$s_{21}^{++}=\mathcal{O}(\mathrm{e}^{-\Gamma_1/\varepsilon}),\qquad s_{12}^{+-}=\mathcal{O}(\mathrm{e}^{-(\Gamma_1+\Gamma_2)/\varepsilon}),\qquad s_{jj}^{++}=1+\mathcal{O}(\varepsilon),\quad j=1,2.$$

It follows from (7.26) and Lemma 7.1 that the matrix $S_{++}S_{+-}^T$ is symmetric. Hence

$$s_{11}^{++}s_{21}^{+-}+s_{12}^{++}s_{22}^{+-}=s_{21}^{++}s_{11}^{+-}+s_{22}^{++}s_{12}^{+-}, \tag{7.31}$$

whereas we get from (7.25) that

$$s_{11}^{++}\overline{s_{21}^{++}}+s_{12}^{++}\overline{s_{22}^{++}}=s_{11}^{+-}\overline{s_{21}^{+-}}+s_{12}^{+-}\overline{s_{22}^{+-}}. \tag{7.32}$$

The only useful estimate we get with Theorem 6.1 is

$$s_{22}^{+-}=\mathcal{O}(\mathrm{e}^{-(\Gamma_1+\Gamma_2+K)/\varepsilon}),\quad K>0, \tag{7.33}$$

which together with (7.30) in (7.31) yields

$$s_{21}^{+-} = s_{21}^{++} s_{11}^{+-} / s_{11}^{++} + \mathcal{O}(\mathrm{e}^{-(\Gamma_1+\Gamma_2)/\varepsilon}). \tag{7.34}$$

Thus from (7.32) and (5.34) for s_{11}^{+-},

$$s_{12}^{++} = -\overline{s_{21}^{++}} \frac{s_{11}^{++}}{\overline{s_{22}^{++}}} (1 + \mathcal{O}(\mathrm{e}^{-\kappa/\varepsilon})), \tag{7.35}$$

with

$$0 < \kappa < \min(\Gamma_1, \Gamma_2). \tag{7.36}$$

Summarizing, we have

$$S_{++} = \begin{pmatrix} s_{11}^{++} & -\overline{s_{21}^{++}} \frac{s_{11}^{++}}{\overline{s_{22}^{++}}} \left(1 + \mathcal{O}\left(\mathrm{e}^{-\kappa/\varepsilon}\right)\right) \\ s_{21}^{++} & s_{22}^{++} \end{pmatrix} \tag{7.37}$$

and

$$S_{+-} = \begin{pmatrix} \mathcal{O}\left(\mathrm{e}^{-\kappa/\varepsilon}\right) & s_{12}^{+-} \\ \mathcal{O}\left(\mathrm{e}^{-\kappa/\varepsilon}\right) & \mathcal{O}\left(\mathrm{e}^{-(\Gamma_1+\Gamma_2+K)/\varepsilon}\right) \end{pmatrix}, \tag{7.38}$$

where all elements $s_{jk}^{\sigma\tau}$ can be asymptotically computed up to exponentially small relative corrections using (6.10). We obtain no information on the first column of S_{+-} except estimate (5.34), where (7.36) necessarily holds. However, if there exists one or several other dissipative domains for certain indices, it is then possible to get asymptotic formulas for the estimated terms.

Appendix A. Proof of Proposition 2.1. A direct consequence of the property

$$H(t) = H^{\#}(t) = J^{-1} H^*(t) J \tag{A.1}$$

is the relation $\sigma(H(t)) = \overline{\sigma(H(t))}$. Thus if $\sigma(H(0)) \subset \mathbf{R}$, then $\sigma(H(t)) \subset \mathbf{R}$ for all $t \in \mathbf{R}$ since the analytic eigenvalues are assumed to be distinct and nondegenerate for all $t \in \mathbf{R}$. Let $e_j(0)$ be the eigenvalue associated with $\varphi_j(0)$. Then due to the property $H(0) = H^{\#}(0)$,

$$(\varphi_j(0), H(0)\varphi_k(0))_J = e_k(0)(\varphi_j(0), \varphi_k(0))_J = \overline{e_j(0)}(\varphi_j(0), \varphi_k(0))_J \tag{A.2}$$

for any $j, k = 1, \ldots, n$. For $j = k$, we get from the assumption $(\varphi_j(0), \varphi_j(0))_J \neq 0$ that $e_j(0) \in \mathbf{R}$, and from the fact that the eigenvalues of $H(0)$ are distinct,

$$(\varphi_j(0), \varphi_k(0))_J = 0, \quad j \neq k. \tag{A.3}$$

The resulting reality of $e_j(t)$ for all $t \in \mathbf{R}$ and $j = 1, \ldots, n$ together with (A.1) yields

$$P_j(t) = J^{-1} P_j^*(t) J. \tag{A.4}$$

Hence using the fact that the P_j^*'s are projectors,

$$\begin{aligned} K(t) = \sum_{j=1}^{n} P_j{}'(t) P_j(t) &= \sum_{j=1}^{n} (J^{-1} P_j^*(t) J)' J^{-1} P_j^*(t) J = J^{-1} \sum_{j=1}^{n} P_j^{*\prime}(t) P_j^*(t) J \\ &= -J^{-1} \sum_{j=1}^{n} P_j^*(t) P_j^{*\prime}(t) J = -J^{-1} K^*(t) J. \end{aligned} \tag{A.5}$$

Let $\Phi, \Psi \in \mathbf{C}^n$ and $W(t)$ be defined by

$$W'(t) = K(t)W(t), \qquad W(0) = \mathbf{I} \tag{A.6}$$

(see (3.5)). Then we have

$$\begin{aligned}(W(t)\Phi, W(t)\Psi)'_J &= \langle W'(t)\Phi | JW(t)\Psi\rangle + \langle W(t)\Phi | JW'(t)\Psi\rangle \\ &= \langle K(t)W(t)\Phi | JW(t)\Psi\rangle + \langle W(t)\Phi | JK(t)W(t)\Psi\rangle \\ &= \langle W(t)\Phi | J(J^{-1}K^*(t)J + K(t))W(t)\Psi\rangle \equiv 0. \end{aligned} \tag{A.7}$$

Thus in the indefinite metric, the scalar products of the eigenvectors of $H(t)$, $\varphi_j(t) = W(t)\varphi_j(0)$ (see (3.7)), are constants:

$$(\varphi_j(t), \varphi_k(t))_J \equiv (\varphi_j(0), \varphi_k(0))_J. \tag{A.8}$$

We can then normalize the $\varphi_j(0)$ in such a way that

$$(\varphi_j(t), \varphi_k(t))_J = (\varphi_j(0), \varphi_k(0))_J = \delta_{jk}\rho_j, \tag{A.9}$$

with $\rho_j \in \{+1, -1\}$. Let $\psi(t)$ and $\chi(t)$ be two solutions of (2.1). By an argument similar to the one above using (A.1), we deduce

$$(\chi(t), \psi(t))_J \equiv (\chi(0), \psi(0))_J. \tag{A.10}$$

Inserting the decompositions

$$\psi(t) = \sum_{j=1}^{n} c_j(t) \mathrm{e}^{-i\int_0^t e_j(t')dt'/\varepsilon} \varphi_j(t), \tag{A.11}$$

$$\chi(t) = \sum_{j=1}^{n} d_j(t) \mathrm{e}^{-i\int_0^t e_j(t')dt'/\varepsilon} \varphi_j(t) \tag{A.12}$$

in this last identity yields

$$\begin{aligned}\sum_{j,k=1}^{n} \overline{d}_k(t) c_j(t) (\varphi_k(t), \varphi_j(t))_J \mathrm{e}^{i\int_0^t (e_k(t') - e_j(t'))/\varepsilon dt'} &= \sum_{j} \overline{d}_j(t)\rho_j c_j(t) \\ \equiv \sum_{j=1}^{n} \overline{d}_j(0)\rho_j c_j(0) &= \sum_{j=1}^{n} \overline{d}_j(\pm\infty)\rho_j c_j(\pm\infty). \end{aligned} \tag{A.13}$$

Since the initial conditions for the coefficients,

$$c_j(-\infty) = \delta_{jk}, \qquad d_j(-\infty) = \delta_{jl}, \tag{A.14}$$

imply

$$c_j(+\infty) = s_{jk}, \qquad d_j(+\infty) = s_{jl}, \tag{A.15}$$

introducing the matrix $R = \mathrm{diag}(\rho_1, \rho_2, \ldots, \rho_n) \in M_n(\mathbf{C})$, we get from (A.13) that

$$R = S^* R S, \tag{A.16}$$

which is equivalent to the assertion $S^{-1} = RS^*R$. □

Appendix B. Proof of Lemma 7.1. Let $G = G^* = G^{-1}$ be given in block structure by

$$G = \begin{pmatrix} \mathbf{I} & \mathbf{O} \\ \mathbf{O} & -\mathbf{I} \end{pmatrix} \in M_{2m}(\mathbf{C}) \tag{B.1}$$

and $H(t)$ be given by (7.13) with $U(t) = \overline{U(t)} = U^*(t)$. Since

$$GH(t)G = -H(t), \qquad \overline{H(t)} = H(t)\,, \tag{B.2}$$

and the eigenvalues of $H(t)$ are real, it is readily verified that

$$GP_j^{\pm}(t)G = P_j^{\mp}(t), \qquad \overline{P_j^{\pm}(t)} = P_j^{\pm}(t), \quad j = 1, \dots, m. \tag{B.3}$$

Hence

$$K(t) = \sum_{\substack{j=1 \\ \tau=\pm}}^{m} P_j^{\tau\prime}(t)P_j^{\tau}(t) = \overline{K(t)} = GK(t)G, \tag{B.4}$$

from which it follows that the solution $W(t)$ of

$$W'(t) = K(t)W(t), \qquad W(0) = \mathbf{I} \tag{B.5}$$

satisfies

$$W(t) = \overline{W(t)} = GW(t)G. \tag{B.6}$$

Since the matrix of potentials $U(0)$ is real symmetric, its eigenvectors $u_j(0)$ may be chosen real so that we can assume that

$$\varphi_j^{\pm}(0) = \begin{pmatrix} u_j(0) \\ \pm k_j(0)u_j(0) \end{pmatrix} \in \mathbf{R}^{2m}. \tag{B.7}$$

Thus it follows from the above that

$$\varphi_j^{\pm}(t) = W(t)\varphi_j^{\pm}(0) \in \mathbf{R}^{2m}, \quad \forall t \in \mathbf{R}, \tag{B.8}$$

and satisfies

$$G\varphi_j^{\pm}(t) = GW(t)GG\varphi_j^{\pm}(0) = W(t)G\varphi_j^{\pm}(0) = \varphi_j^{\mp}(t). \tag{B.9}$$

Finally, the main consequence of (B.2) is that if $\psi(t)$ is a solution of

$$i\varepsilon\psi'(t) = H(t)\psi(t), \tag{B.10}$$

then $\varphi(t) = G\overline{\psi(t)}$ is another solution, as is easily verified. Thus we can write with (7.21), (B.8), and (B.9) that

$$\begin{aligned} \varphi(t) &= \sum_{j=1}^{m} d_j^{+}(t)\varphi_j^{+}(t)\mathrm{e}^{-i\int_0^t k_j(t')dt'/\varepsilon} + \sum_{j=1}^{m} d_j^{-}(t)\varphi_j^{-}(t)\mathrm{e}^{i\int_0^t k_j(t')dt'/\varepsilon} \\ &= \sum_{j=1}^{m} \overline{c_j^{+}(t)}\varphi_j^{-}(t)\mathrm{e}^{i\int_0^t k_j(t')dt'/\varepsilon} + \sum_{j=1}^{m} \overline{c_j^{-}(t)}\varphi_j^{+}(t)\mathrm{e}^{-i\int_0^t k_j(t')dt'/\varepsilon}, \end{aligned} \tag{B.11}$$

i.e.,

$$\begin{aligned} d_j^+(t) &= \overline{c_j^-(t)}, \\ d_j^-(t) &= \overline{c_j^+(t)}, \quad \forall j = 1, \dots, m, \quad \forall t \in \mathbf{R}. \end{aligned} \tag{B.12}$$

Finally, using the definition (7.23) and the above property for $t = \pm\infty$, we get for any $\mathbf{d}^\pm(-\infty) \in \mathbf{C}^m$ that

(B.13)

$$\begin{pmatrix} \mathbf{d}^+(+\infty) \\ \mathbf{d}^-(+\infty) \end{pmatrix} = \begin{pmatrix} S_{++} & S_{+-} \\ S_{-+} & S_{--} \end{pmatrix} \begin{pmatrix} \mathbf{d}^+(-\infty) \\ \mathbf{d}^-(-\infty) \end{pmatrix} = \begin{pmatrix} \overline{S_{--}} & \overline{S_{-+}} \\ \overline{S_{+-}} & \overline{S_{++}} \end{pmatrix} \begin{pmatrix} \mathbf{d}^+(-\infty) \\ \mathbf{d}^-(-\infty) \end{pmatrix},$$

from which the result follows. □

A CLASSICAL THEOREM ON THE SINGULARITIES OF LEGENDRE SERIES IN C^3 AND ASSOCIATED SYSTEM OF HYPERBOLIC PARTIAL DIFFERENTIAL EQUATIONS*

PETER A. McCOY[†]

Abstract. A classical theorem of Nehari relates the singularities of Legendre series expansions in C_z with those of associated Taylor's series in C_t. The generalization of Nehari's theorem is known for Legendre series in $C_{z_1 \times z_2}$. In this paper, function theoretic methods develop the analogous relationships between the singularities of series expanded as triple products of Legendre polynomials in $C_{z_1 \times z_2 \times z_3}$ and those of associated analytic functions in C_t. The singularities of these generalized Legendre series are determined by certain elliptic curves. Moreover, these series satisfy a system of hyperbolic partial differential equations (PDEs) in C^3 that are connected to Bochner's study of Poisson processes in R^2.

Key words. Legendre series, singularities, function-theoretic methods

1. Introduction.

There is a classical theorem of Szego [15] that relates the singularities of a real zonal harmonic series with the singularities of an analytic function of a single complex variable. Szego's theorem was extended to Legendre series in the complex plane by Nehari [14]. Both theorems relied on the argument used by Hadamard [10] in his multiplication of singularities theorem. Subsequently, Gilbert [7, 8] generalized the Hadamard argument by developing the "envelope method" and used this procedure to study the singularities of harmonic functions in R^3 as well as the singularities of solutions of many classes of elliptic partial differential equations (PDEs). One of the distinct features of the theory is its utility in transforming information about the properties of singularities of analytic functions into the corresponding theorems on the structure of singularities of the solutions. Notable theorems concerning the location and type of the singularities of analytic functions are found in the work of Taylor, Mandelbrojt, and Fabry (see [6, 10]). Examples of their function theoretic extensions are found in the references (see Bergman [4], Begehr and Gilbert [2, 3] and Kracht and Kreyszig [11]).

The Nehari theorem was framed in the setting of hyperbolic PDEs by McCoy [12, 13], who considered analytic functions $F(z_1, z_2)$ that are expanded in series of products of ultraspherical polynomials in the complex space $C^2 := C_{z_1} \times C_{z_2}$. The singularities of these series were shown to lie on a certain quadratic curve embedded in C^2. This curve is defined in relation to the singularities of $F(z_1, z_2)$ and a unique analytic function $f(t)$ of one complex variable known as the "associate." The hyperbolic equation under discussion was used by Bochner [5] to characterize symmetric Poisson

[†]Mathematics Department, United States Naval Academy, Annapolis, MD 21402-5002 (pam@sma.usna.navy.mil).

processes on the square. We find a generalization of Nehari's theorem to C^3 that can be interpreted as an extension of Bochner's Poisson process equation.

The aim of this study is to extend Nehari's theorem to analytic functions

$$f(z_1, z_2, z_3) = \sum_{n=0}^{\infty} \omega_n a_n P_n(z_1) P_n(z_2) P_n(z_3) \tag{1.1a}$$

of three complex variables $(z_1, z_2, z_3) \in C^3 := C_{z_1} \times C_{z_2} \times C_{z_3}$, where $\omega_n = (n + 1/2)$ and the $P_n(z)$ are the Legendre polynomials of degree "n." Our focus is on the relationship between the singularities of $F(z_1, z_2, z_3)$ and those of the associated analytic function

$$f(t) = \sum_{n=0}^{\infty} a_n t^n \tag{1.1b}$$

of the complex variable $t \in C_t$.

We establish that the singularities of F are located on certain elliptic curves in C^3. These curves are determined by means of function theoretic relationships between the singularities of the function pair $\{F, f\}$. The method is to construct reciprocal integral transforms linking the generalized Legendre series with its associate. Application of the Hadamard, end pinch, and envelope methods provides the appropriate relationships between the singularities of the associated functions.

2. Preliminaries.

We begin by establishing that $F(x_1, x_2, x_3)$ and the associate $f(t)$ are locally analytic. The transforms defining the association will be constructed in due course. Let $f(t)$ be analytic at the origin. Elementary function theory confirms that the radius of convergence of the expansion in (1b), and thus the distance to the first singularity, is $r_o = \lim\sup_{n\to\infty} |a_n|^{-1/n}$. We exclude entire functions and require that $r_0 < \infty$. Similarly, consider the expansion in (1a) for the Legendre series $F(x_1, x_2, x_3)$. The estimate $|P_n(x)| \sim O(1/n^{1/2})$ (see [9, p. 68]) verifies that this series converges in a sphere of radius r_0.

The point is to consider the Legendre series $F(x_1, x_2, x_3)$ in the complex domain. The series is analytically continued to an open set about the origin in $C_{z_1 \times z_2 \times z_3}$. Local analyticity follows by observing that from Darboux's extension of the Laplace–Heine formula [16] one finds the asymptotic estimate $|P_n(z_1)P_n(z_2)P_n(z_3)| \sim \delta^n(z_1)\delta^n(z_2)\delta^n(z_3)$ on the domain $E_{\delta(z_1)} \times E_{\delta(z_2)} \times E_{\delta(z_3)}$. This domain is formed by the tensor product of the ellipses $E_{\delta(z_j)} = \{z_j \in C_{z_j} : |z_j - 1| + |z_j + 1| < \delta(z_j)\}$ for $1 \le j \le 3$ under the assumption that the $\max_{1 \le j \le 3} \delta(z_j)$ is sufficiently small.

The first step is to show that the functions $F(z_1, z_2, z_3)$ and $f(t)$ are associated by integral operators. The kernel for the ascending operator is defined as

$$K(t; z_1, z_2, z_3) = \sum_{n=0}^{\infty} \omega_n t^n P_n(z_1) P_n(z_2) P_n(z_3). \tag{2.1}$$

Following previous arguments, it is easy to check that the kernel is analytic in a neighborhood of the origin in C^4. It follows from Cauchy's theorem that

$$F(z_1, z_2, z_3) = (1/2\pi i) \int_{L_t} f(t) K(t^{-1}; z_1, z_2, z_3) dt/t. \tag{2.2}$$

The contour L_t is a simple closed curve that is homologous to the circle $\gamma : |t| = (\sigma + \epsilon)^{-1}$ modulo the singularities of the integrand, and $\epsilon > 0$ is sufficiently small.

The function element $F(z_1, z_2, z_3)$ defined in (3) by contour deformation is analytic on its domain of association (see Gilbert [8, p. 24]).

The inverse operator is based on the kernel

$$K_*(t; z_1, z_2, z_3) = \sum_{n=0}^{\infty} \omega_n^2 t^n P_n(z_1) P_n(z_2) P_n(z_3), \tag{2.3}$$

which is also analytic in a neighborhood of the origin in C^4. It follows from the orthogonality of the Legendre polynomials $\int_{-1}^{+1} P_n(s) P_m(s) ds = \omega_n^{-1} \delta_{nm}$ that the inversion of (3) is carried out by the transform

$$f(t) = \int_{L_{z_1}} \int_{L_{z_2}} \int_{L_{z_3}} K_*(t; z_1, z_2, z_3) F(z_1, z_2, z_3) dz_1 dz_2 dz_3, \tag{2.4}$$

which is formulated here as a function element on its domain of association. The contours L_{z_1}, L_{z_2}, and L_{z_3} are simple open curves that are homologous to the segment $[-1, +1]$ modulo the singularities of the integrand. The contours have their end points fixed at $\{-1, +1\}$. The function element $f(t)$ associated with $F(z_1, z_2, z_3)$ by (5) is analytic on its domain of association. The kernels in (2) and (4) are related in a simple way as $K_*(t; z_1, z_2, z_3) = [t\partial_t + 1/2] K(t; z_1, z_2, z_3)$ or, more compactly, as

$$K_*(t; z_1, z_2, z_3) = t^{1/2} \partial_t [t^{1/2} K(t; z_1, z_2, z_3)]. \tag{2.5}$$

3. The integral transforms.

The reciprocal integral transforms in (3) and (5) are now reformulated to suit our analysis. We expand the kernel of the ascending operator as a symmetric function of the variables z_1, z_2, and z_3. This symmetric expansion is distinguished by the notation $K(t; z_1, z_2, z_3) := \Gamma(t; z_1, z_2, z_3)$, where

$$\Gamma(t; z_1, z_2, z_3) = \left\{ (1/3) \sum_{j=1}^{3} K_j(t; z_1, z_2, z_3) \right\}. \tag{3.1}$$

The terms in the expansion are

$$K_j(t; z_1, z_2, z_3) = \int_{L_\zeta} K(t; 1, z_j, \zeta) [K(1; z_1, z_2, z_3)]_{z_j = \zeta} d\zeta \tag{3.2}$$

for $1 \leq j \leq 3$. The contour L_t is a simple open curve that is homologous to the segment $[-1, +1]$ modulo the singularities of the integrand and has its end points fixed at $\{-1, +1\}$. Any one of the kernels K_j taken individually would suffice in the role of K but taken alone complicates the analysis later on.

The symmetric expansions of the kernels are now converted to closed-form expressions. Let us examine the first function appearing in the product in the integrand of (8). This function is put into closed form by appealing to Watson's integral [17] as follows:

$$\begin{aligned} K(t; 1, z_j, \zeta) &= (1/4\pi i) \int_{L_\tau} J(t; \Omega(\tau; z_j, \zeta)) d\tau/\tau, \\ J(t; \Omega) &= (1 - t^2)/(1 - 2t\Omega + t^2)^{3/2}, \\ \Omega(\tau; z_j, \zeta) &= z_j \zeta + (1 - z_j^2)^{1/2} (1 - \zeta^2)^{1/2} (\tau + \tau^{-1})/2 \end{aligned} \tag{3.3}$$

for $1 \leq j \leq 3$. The contour L_τ is homologous to the unit circle modulo the singularities of the integrand.

Turning to the second factor in the integrand in (8), we find that the closed-form expressions of these functions are determined by Grosjean [9, p. 68] as $K(1; x_1, x_2, x_3) = \pi^{-1}(1 - x_1^2 - x_2^2 - x_3^2 + 2x_1x_2x_3)^{-1/2}$ for points in the primary domain. The primary domain is defined by the points inside and on the cubic surface $\mathbf{S} : \{(x_1, x_2, x_3) : x_1^2 + x_2^2 + x_3^2 - 2x_1x_2x_3 = 1\}$ that are interior to the cube $[-1, +1]^3$. For points in the cube that are located outside the surface $\mathbf{S}$, the kernel $K(1; x_1, x_2, x_3) = 0$. When the kernel is analytically continued to C^3, the resulting function element

$$K(1; z_1, z_2, z_3) = \pi^{-1}(1 - z_1^2 - z_2^2 - z_3^2 + 2z_1z_2z_3)^{-1/2} \tag{3.4}$$

is understood to originate from the primary domain and the transforms in (8) are referenced to this element. We remark about the behavior of the series $K(1; x_1, x_2, x_3)$ along the sides of the cube. The series converges to a well-defined function off the diagonals $x_2 = \pm x_1$ and exhibits delta function behavior on the diagonals in the plane $x_3 = 1$. These points are not contained in the domain of association.

The kernels in (8) are written in closed form by applying (9) as

$$\begin{aligned} &K_j(t; z_1, z_2, z_3) \\ &= (1/4\pi i) \int_{L_\tau} \int_{L_\zeta} \{(1 - t^2)/(1 - 2t\Omega(\tau; z_j, \zeta) + t^2)^{3/2}\} \\ &\quad \times [K(1; z_1, z_2, z_3)]_{z_j = \zeta} d\zeta\, d\tau/\tau \end{aligned} \tag{3.5}$$

for $1 \leq j \leq 3$. This step converts the kernel in (7) into the closed symmetric expression

$$\begin{aligned} &\Gamma(t; z_1, z_2, z_3) \\ &= (1/12\pi i) \sum_{j=1}^{3} \left\{ \int_{L_\tau} \int_{L_\zeta} J(t; \Omega(\tau; z_j, \zeta))[K(1; z_1, z_2, z_3)]_{z_j = \zeta} \right\} d\zeta\, d\tau/\tau. \end{aligned} \tag{3.6}$$

The kernel of the inverse operator is reformulated by a similar procedure. Define

$$\Gamma_*(t; z_1, z_2, z_3) = \left\{ (1/3) \sum_{j=1}^{3} K_{j,*}(t; z_1, z_2, z_3) \right\}, \tag{3.7}$$

where the $K_{j,*}(t; z_1, z_2, z_3) = \int_{L_\zeta} K_*(t; 1, z_j, \zeta)[K(1; z_1, z_2, z_3)]_{z_j = \zeta} d\zeta$, and rely on (6) to write

$$K_*(t; 1, z_j, \zeta) = (1/4\pi i) \int_{L_\tau} t^{1/2} \partial_t [t^{1/2} J(t; \Omega(\tau; z_j, \zeta))]\, d\tau/\tau \tag{3.8}$$

for $1 \leq j \leq 3$. The kernel of the inverse operator is now put into closed symmetric form as

$$\Gamma_*(t; z_1, z_2, z_3) = t^{1/2} \partial_t [t^{1/2} \Gamma(t; z_1, z_2, z_3)]. \tag{3.9}$$

The principal branches of the function elements are taken. We note that $\Gamma(t^{-1}; z_1, z_2, z_3) = -t\Gamma(t; z_1, z_2, z_3)$. This observation brings us to the integral transform pair whose kernels are both in closed form and invariant under cyclic permutations of the variables z_1, z_2, and z_3.

Theorem 3.1. *The T-transforms linking the function elements F and f on their domains of association are*

$$F(z_1, z_2, z_3) = T[f] := (-1/2\pi i) \int_{L_t} f(t)\Gamma(t; z_1, z_2, z_3)dt, \tag{16a}$$

$$f(t) = T^{-1}[F] := \int_{L_{z_1}} \int_{L_{z_2}} \int_{L_{z_3}} \Gamma_*(t; z_1, z_2, z_3)F(z_1, z_2, z_3)dz_1dz_2dz_3. \tag{16b}$$

4. The singular manifolds. The function elements in (16) are analytically continued from their initial domains of definition to larger domains of association by contour deformation. During the continuation, the singularities in the integrands move, and the contours are deformed to avoid singularities that approach them along intersecting trajectories. There may be circumstances under which no further deformation is possible without contact occurring between the contour and the singularity at a particular point. Such a point is a singularity of the integrand but is not necessarily a singularity of the transformed function element. The object is to extract the actual singularities of a function element from the set of possible singularities. An authentic singularity is identified if it corresponds to a singularity of the associated element under the inverse transform. There are three types of circumstances in which this event could occur. The corresponding singularities are referred to as the Hadamard, end pinch, and envelope singularities.

Let us begin the discussion by considering a function element $F(z_1, z_2, z_3)$ whose associate $f(t)$ has an isolated singularity at the point $t = \alpha$. The set of possible singularities of $F(z_1, z_2, z_3)$ is expressed as $PS[F] = [SH(f; \alpha)] \cup [EP(f; \alpha)] \cup [SE(f; \alpha)]$, where the constituent sets are the respective (possible) Hadamard, end pinch, and envelope singularities. The set of possible singularities $PS[F] := PM(f; \alpha)$ is determined from the integrand of the transform in (16a) as having the parametric form

$$PM(f; \alpha) = \cup_{1\leq j\leq 3}\{PM_j(f; \alpha) \cap B_j(Z)\}, \tag{4.17}$$

where the sets

$$PM_j(f; \alpha) = \{Z : \sigma - \Omega(\tau; z_j, \zeta) = 0; (\tau, \zeta) \in L_\tau \times L_\zeta, \varpi(\alpha, \sigma) = \varpi(\tau, \eta) = 0\}$$

and

$$B_j(Z) = \{Z : \varphi(Z) = 0; z_j = \zeta, \zeta \in L_\zeta\}, \quad 1 \leq j \leq 3.$$

For convenience, we designate $Z := (z_1, z_2, z_3)$ or $(Z) := (z_1, z_2, z_3)$, where the interpretation is clear in context. The auxiliary functions are defined as $\varphi(x, y, z) := 1 - x^2 - y^2 - z^2 + 2xyz = (1 - y^2)(1 - z^2) - (x - yz)^2$ and $\varpi(x, y) := x^2 - 2xy + 1$. The function φ is invariant under cyclic permutations of its argument; i.e., $\varphi(x, y, z) = \varphi(y, z, x) = \varphi(z, x, y)$. The analysis will be facilitated by rewriting the sets

$$PM_j(f; \alpha) = \{Z : \psi(\sigma, z_j, \zeta, \eta) = 0, (\tau, \zeta) \in L_\tau \times L_\zeta; \varpi(\alpha, \sigma) = \varpi(\tau, \eta) = 0\},$$
$$1 \leq j \leq 3,$$

where the function $\psi(\sigma, z, \zeta, \eta) := (\sigma - z\zeta)^2 - (1 - z^2)(1 - \zeta^2)\eta^2$.

The set of Hadamard singularities $SH(f; \alpha) = \cup_{1\leq j\leq 3}SH_j(f; \alpha)$ corresponding to the Hadamard singularities $SH_j(f; \alpha)$ contained in the sets $PM_j(f; \alpha) \cap B_j(Z)$ is obtained by eliminating the parameter "ζ" from the principal branches of the manifolds. Working with the set $B_j(Z)$ defined in (17) produces roots $\zeta = \xi_\pm(z_2, z_3) := z_2 z_3 \pm (1 - z_2^2)^{1/2}(1 - z_3^2)^{1/2}$ for the case $j = 1$. The eliminants of the remaining sets $B_2(Z)$ and $B_3(Z)$ are also computed. The end result is that the Hadamard singularities for the ascending operator in (16a) are defined parametrically by the surfaces

$$PH(f; \alpha) = M((z_1, z_2, z_3); \alpha) \cup M((z_2, z_3, z_1); \alpha) \cup M((z_3, z_1, z_2); \alpha), \tag{4.18}$$

where

$$M((x, y, z); \alpha) = \{(x, y, z) \in C^3 : \psi(\sigma, x, \zeta, \eta) = 0, \zeta = \xi_\pm(y, z); \varpi(\alpha, \sigma) = \varpi(\tau, \eta) = 0\}.$$

The next step is to consider the set of possible singularities for the function element $f(t)$ defined by the descending operator in (16b). Designate this set as $PS[f] = [SH(F; Z_o)] \cup [EP(F; Z_o)] \cup [SE(F; Z_0)]$, where $SH(F; Z_o)$, $EP(F; Z_o)$, and $SE(F; Z_o)$ are the respective Hadamard, end pinch, and envelope singularities. Let the associate $F(z_1, z_2, z_3)$ be singular at $Z_o = (z_{1,o}, z_{2,o}, z_{3,o}) \in B(Z)$, where $B(Z) = \{Z : \varphi(Z) = 0\}$. By examining the T-transforms and taking advantage of the role played by the kernel $\Gamma(t; Z)$ in the integrands, the relevant sets are determined to be

$$PM(F; Z_o) = \cup_{1 \le j \le 3} PM_j(F; Z_o), \tag{4.19}$$

where the sets

$$\begin{aligned} PM_j(F; Z_o) = \{t \in C : \sigma - \Omega(\tau; z_j; \zeta) = 0; (\tau, \zeta, Z) \in L_\tau \times L_\zeta \times L_{z_1} \times L_{z_2} \times L_{z_3}; \\ Z_0 = (z_{1,o}, z_{2,o}, z_{3,o}) \in B_j(Z); \varpi(t, \sigma) = \varpi(\tau, \eta) = 0\} \end{aligned}$$

are defined parametrically for $1 \le j \le 3$.

The set of Hadamard singularities of the function element $f(t)$ is $SH(F; Z_o) = \cup_{1 \le j \le 3} SH_j(F; Z_o)$. The singularities contained in this set are embedded in the set $PM(F; Z_o)$. By eliminating the parameters, one determines that the singularities of the descending operator defined in (16b) are

$$SH(F; Z_o) = M_*(t; (z_{1,o}, z_{2,o}, z_{3,o})) \cup M_*(t; (z_{2,o}, z_{3,o}, z_{1,o})) \cup M_*(t; (z_{3,o}, z_{1,o}, z_{2,o})), \tag{4.20}$$

where

$$M_*(t; (x, y, z)) = \{t \in C : \varpi(t, \sigma) = \varpi(\tau, \eta) = 0; \psi(\sigma, x, \zeta, \eta) = 0, \zeta = \xi_\pm(y, z)\}.$$

We observe that the preceding arguments are symmetric. Bearing in mind that the actual singularities determined in the analysis are, in general, subsets of the sets of Hadamard singularities of the associated function pair $\{F, f\}$, we summarize the results in the following statement.

THEOREM 4.1. *Let $\{F, f\}$ be a T-transform associated function element pair. Then the points Z_o and t_o are the respective Hadamard singularities if and only if $Z_o \in SH(f; t_o)$ and $t_o \in SH(F; Z_o)$.*

It is an easy matter at this point to dispose of the end pinch singularities. These singularities are distinguished by the fixed points $\{-1, +1\}$ at the ends of open contours of integration. As end points, they remain fixed during the contour deformation and, thus, must be considered in terms of singularities that approach them. The end pinch singularities of the ascending operator are expressed in parametric form as

$$EP(f;\alpha) = \cup_{1\le j\le 3}\{EP_j(f;\alpha) \cap EB_j(f;\alpha)\}.$$

The sets of singularities

$$\begin{aligned} EP_j(f;\alpha) = \{Z; \sigma - \Omega(\tau; z_j, \pm 1) = 0,\\ \partial_\tau[\sigma - \Omega(\tau; z_j, \pm 1)] = 0, \tau \in L_\tau; \varpi(\alpha,\sigma) = \varpi(\tau,\eta) = 0\}\end{aligned}$$

are of a "mixed" type since L_τ is a closed contour. The reasoning requires a combination of end pinch and envelope arguments which leads to the eliminant

$$EP_j(f;\alpha) = \{Z : \varphi(Z) = 0, z_j = \pm\sigma;\ \varpi(z,\sigma) = 0\}.$$

The sets $EB_j(Z) = \{Z : \varphi(Z) = 0,\ z_j = \zeta = \pm\sigma\}$ for $1 \le j \le 3$. Combining these sets yields the following for $1 \le j \le 3$:

$$EP_j(f;\alpha) \cap EB_j(f;\alpha) = \{Z : \varphi(Z) = 0, z_j = \pm\sigma;\ \varpi(\alpha,\sigma) = 0\}. \tag{4.21a}$$

Similarly, the end pinch singularities of the descending operator are

$$EP(F; Z_o) = \cup_{1\le j\le 3} EP_j(F; Z_o),$$

where

$$\begin{aligned} EP_j(F;Z_o) = \{t \in C : \sigma - \Omega(\tau; z_j, \pm 1) = \partial_\tau[\sigma - \Omega(\tau; z_j, \pm 1)] = 0;\\ \tau \in L_\tau, z_j = \pm 1; Z \in EB_j(F; Z_o), \varpi(t,\sigma) = \varpi(\tau,\eta) = 0\}\end{aligned}$$

for $1 \le j \le 3$. In the sets $EB_j(F;Z_o) = \{Z : (Z) = (Z_o) = (\pm 1, \pm 1, \pm 1);\ \varphi(Z) = 0\}$ the minus signs are selected pairwise. The eliminant in this case is

$$EP_j(F;Z_o) = \{t \in C_t : \varphi(Z) = 0, z_j = \pm\sigma \text{ and } z_k = \pm 1 \text{ for } z_k \ne z_j; \varpi(t,\sigma) = 0\}. \tag{4.21b}$$

We state the following result to summarize the analysis leading to (21).

THEOREM 4.2. *Let $\{F, f\}$ be a T-transform associated function pair. If $f(t)$ is singular at the point t_o, then $EP(f;t_o)$ is the set of end pinch singularities of $F = T[f]$. In addition, if $F(Z)$ is singular at $Z_o : \varphi(Z_o) = 0$, the set of end pinch singularities of the element function $f = T^{-1}[F]$ is $EP(F;Z_o)$.*

We now turn to the envelope singularities of the transform pair. The envelope singularities of the ascending operator are

$$SE(f;\alpha) = \cup_{1\le j\le 3}\{SE_j(f;\alpha) \cap SE_j^*(f;\alpha)\},$$

where the sets are defined in terms of the auxiliary functions

$$\Phi_j(\sigma,\tau,Z,\zeta) = [\sigma - \Omega(\tau; z_j, \zeta)][\varphi(z_1,z_2,z_3)|_{z_j=\zeta}],$$

since

$$SE(f;\alpha) = \{Z : \Phi_j(\sigma,\tau,Z,\zeta) = 0, (\tau,\zeta) \in L_\tau \times L_\zeta;\ \varpi(\alpha,\sigma) = \varpi(\tau,\eta) = 0\}$$

and

$$\begin{aligned} SE_j^*(f;\alpha) = \ &\{Z : \partial_\tau\Phi_j(\sigma,\tau,Z,\zeta) = \partial_\zeta\Phi_j(\sigma,\tau,Z,\zeta) = 0,\\ &(\tau,\zeta) \in L_\tau \times L_\zeta;\ \varpi(\alpha,\sigma) = \varpi(\tau,\eta) = 0\}, \quad 1 \le j \le 3.\end{aligned}$$

We will eliminate the variables from the three systems

$$\Phi_j(\sigma,\tau,Z,\zeta)=0, \tag{4.22a}$$

$$\partial_\tau\Phi_j(\sigma,\tau,Z,\zeta)=0, \tag{4.22b}$$

$$\partial_\zeta\Phi_j(\sigma,\tau,Z,\zeta)=0, \tag{4.22c}$$

$1\le j\le 3$. Working with (22a,b) and eliminating "τ" give the equations $\sigma-\Omega(\tau;z_j;\zeta)|_{\tau=\pm1}=0$, which lead to the parametric form

$$SE_{1,1}(f;\alpha)=\bigcup_{1\le j\le 3}\{Z:\varphi(\sigma,z_j,\zeta)=0,\varphi(Z)|_{z_j=\zeta}=0;\ \varpi(\alpha,\sigma)=0\} \tag{4.23a}$$

when $\tau=1$. Solving the equation $\varphi(z_1,z_2,z_3)=0$ for the variable "z_1" yields $z_1=\xi_\pm(z_2,z_3)$ with $z_1=\zeta$ as expected. We do not place this into (23a) but leave (23a) in its parametric form. The other cases are analogous. The choice $\tau=-1$ results in $\sigma=z_j\zeta$ and $\varphi(z_1,z_2,z_3)|_{z_j=\zeta}=0$ for $1\le j\le 3$. The remaining cases are similar, and one eliminates "ζ" in each pair of equations to find that

$$SE_{1,2}(f;\alpha)=\bigcup_{1\le j\le 3}\{Z:\varphi(Z)|_{z_j\to\sigma/z_j}=0,z_j\ne 0;\ \varpi(\alpha,\sigma)=0\}. \tag{4.23b}$$

The arrow symbol ($\to$) is read as "replace by." We combine these results as

$$SE_1^*(f;\alpha)=SE_{1,1}(f;\alpha)\cup SE_{1,2}(f;\alpha).$$

Turning our attention to (22a,c), we find that

$$\partial_\zeta\Phi_j(\sigma,\tau,Z,\zeta)=[\sigma-\Omega(\tau;z_j;\zeta)]\partial_\zeta\varphi(Z)|_{z_j=\zeta}+\partial_\zeta[\sigma-\Omega(\tau;z_j;\zeta)]\varphi(Z)|_{z_j=\zeta}=0$$

for $1\le j\le 3$. Evaluating the equation $\partial_\zeta\Phi_j=0$ under the presumption that $\varphi(Z)|_{z_j=\zeta}=0$ gives $[\sigma-\Omega(\tau;z_j;\zeta)](-2\zeta+2z_kz_l)=0$, where $\{k,l\}\in\{1,2,3\}\backslash\{j\}$, $k\ne l$. The eliminants produce

$$\begin{aligned}SE_{2,1}(f;\alpha)=\bigcup_{1\le j\le 3}\{Z:&\ \psi(\sigma,z_j,\zeta,\eta)|_{\zeta\to z_kz_l}=0;\\ &\varphi(z_j,z_k,z_l)|_{z_j\to z_kz_l}=0;\ \varpi(\alpha,\sigma)=\varpi(\tau,\eta)=0\},\end{aligned} \tag{4.23c}$$

where the indices $\{j,k,l\}$ are distinct. On the other hand, proceeding from $\partial_\zeta\Phi_j=0$ (under the assumption that $\sigma-\Omega(\tau;z_j;\zeta)=0$) yields $z_j^2(1-\zeta^2)=(1-z_j^2)\zeta^2\eta^2$ and $\zeta^2=\kappa(z_j,\eta)$, where $\kappa(x,\eta):=x^2/(\eta^2+(1-\eta^2)x^2)$. The resulting sets are stated parametrically as

$$SE_{2,2}(f;\alpha)=\bigcup_{1\le j\le 3}\{Z:\sigma-\Omega(\tau;z_j;\zeta)=0,\zeta^2=\kappa(z_j,\eta);\ \varpi(\alpha,\sigma)=\varpi(\tau,\eta)=0\}. \tag{4.23d}$$

The other cases involving $\partial_\zeta\Phi_j=0$ are part of previous discussions. We define

$$SE_2^*(f;\alpha)=SE_{2,1}(f;\alpha)\cup SE_{2,2}(f;\alpha).$$

In summary, the envelope singularities of $F=T[f]$ that do not reduce to Hadamard or end pinch singularities are given by

$$SE(f;\alpha)=SE_1^*(f;\alpha)\cup SE_2^*(f;\alpha).$$

We consider the singularities for the descending operator $f = T^{-1}[F]$, focusing on singularities that were not previously identified as of the Hadamard or end pinch type. We define the sets

$$SE(F; Z_o) = \cup_{1\leq j\leq 3}\{SE_j(F; Z_o) \cap SE_j^*(F; Z_o)\},$$

where

$$SE_j(F; Z_o) = \{t \in C_t : \Phi_j(\sigma, \tau, Z, \zeta) = 0, (\tau, \zeta, Z) \in L_\tau \times L_\zeta \times L_{z_1} \times L_{z_2} \times L_{z_3}; \\ \varpi(t, \sigma) = \varpi(\tau, \eta) = 0\}$$

and

$$SE_j^*(F; Z_o) = \{t \in C_t : \partial_\tau\Phi_j(\sigma, \tau, Z, \zeta) = \partial_\zeta\Phi_j(\sigma, \tau, Z, \zeta) = \partial_{z_k}\Phi_j(\sigma, \tau, Z, \zeta) = 0, \\ 1 \leq k \leq 3; \\ (\tau, \zeta, Z) \in L_\tau \times L_\zeta \times L_{z_1} \times L_{z_2} \times L_{z_3}; \varpi(t, \sigma) = \varpi(\tau, \eta) = 0\}$$

for $1 \leq j \leq 3$. The relevant systems of equations are

$$\Phi_j(\sigma, \tau, Z, \zeta) = 0, \tag{4.24a}$$

$$\partial_\tau\Phi_j(\sigma, \tau, Z, \zeta) = \partial_\zeta\Phi_j(\sigma, \tau, Z, \zeta) = 0, \tag{4.24b}$$

$$\partial_{z_k}\Phi_j(\sigma, \tau, Z, \zeta) = 0 \tag{4.24c}$$

for $1 \leq j, k \leq 3$. The eliminants for (24a,b) are analogous with those for (22), (23). The results are

$$SE_1^*[F; Z_o] = SE_{1,1}[F; Z_o] \cup SE_{1,2}[F; Z_o],$$

where

$$SE_{1,1}[F; Z_o] = \bigcup_{1\leq j\leq 3}\{t \in C_t : \varpi(t, \sigma) = 0; \varphi(Z_o)|_{z_{o,j}=\zeta} = 0, \varphi(\sigma, z_{o,j}, \zeta) = 0, \varphi(Z_o) = 0\}$$

and

$$SE_{1,2}[F; Z_o] = \bigcup_{1\leq j\leq 3}\{t \in C_t : \varpi(t, \sigma) = 0; \varphi(Z_o)|_{z_{o,j}\to\sigma/z_{o,j}} = 0, \varphi(Z_o) = 0\}.$$

In similar fashion, we find the sets

$$SE_2^*[F; Z_o] = SE_{2,1}[F; Z_o] \cup SE_{2,2}[F; Z_o],$$

where

$$SE_{2,1}[F; Z_o] = \bigcup_{1\leq j\leq 3}\{t \in C_t : \varpi(t, \sigma) = 0; \psi(\sigma, z_{o,j}, \zeta, \eta)|_{\zeta=z_{o,k}z_{o,l}} = 0, \\ \varphi(Z_o) = 0, \varpi(\tau, \eta) = 0\}$$

and

$$SE_{2,2}[F; Z_o] = \bigcup_{1\leq j\leq 3}\{t \in C_t : \varpi(t, \sigma) = 0; \sigma - \Omega(\tau, z_{o,j}, \zeta) = 0, \\ \zeta^2 = \kappa(z_{o,j}, \eta), \varphi(Z_o) = 0,\ \varpi(\tau, \eta) = 0\}.$$

By symmetry, the eliminants of (24a,c) are identical with those of (22a,c) in the case $j = k$. Let us consider the remaining eliminants in (24c) for $j \neq k$. One computes here that $\partial_{z_k}\Phi_j(\sigma, \tau, Z, \zeta) = 0$ and finds that

$$SE_3^*[F; Z_o] = \bigcup_{1\le j\le 3} \{t \in C_t : \varpi(t, \sigma) = 0; \psi(\sigma, z_j, \zeta, \eta) = 0,$$
$$\partial_{z_k}\varphi|_{z_j=\zeta} = 0, \partial_{z_l}\varphi|_{z_j=\zeta} = 0, \varphi(Z_o) = 0, \varpi(\tau, \eta) = 0\},$$

where the indices are taken as distinct. This set has been specified in parametric form with "ζ" defined implicitly for brevity. By combining the three cases, the envelope set of the descending operator is thus

$$SE[F; Z_o] = \bigcup_{1\le j\le 3} SE_j^*[F; Z_o].$$

We summarize our findings as follows.

THEOREM 4.3. *The set of envelope singularities of the function element $F(Z)$ represented by the transform $F = T[f]$ is $SE(f; t_o)$, where the associate $f(t)$ is singular at the point t_o. The set of envelope singularities of the function element $f(t)$ represented by the transform $f = T^{-1}[F]$ is $SE(F; Z_o)$, where the associate $F(Z)$ is singular at $Z_o : \varphi(Z_o) = 0$. Moreover, the point $Z_o \in SE(f; t_o)$ is a true envelope singularity of $F(Z)$ if and only if $t_o \in SE(F; Z_o)$ is the corresponding singularity of the function element $f(t)$ determined by $f = T^{-1}[F]$.*

5. Hyperbolic PDEs and Poisson processes. Function theory typically studies singularities of elliptic PDEs in terms of analytic functions. An interesting property of the generalized Legendre series F is that they are solutions of a system of hyperbolic PDEs in C^3 that form an extension of a problem studied by Bochner [5] in connection with Poisson processes in R^2. Bochner views the hyperbolic equation $\{\partial_{x_1}[\sigma_{\alpha,\beta}(x_1, x_2)\partial_{x_1}] - \partial_{x_2}[\sigma_{\alpha,\beta}(x_2, x_1)\partial_{x_2}]\}F(x_1, x_2) = 0, \sigma_{\alpha,\beta}(x_1, x_2) = (1 - x_1)^{\alpha+1}(1 + x_1)^{\beta+1}(1 - x_2)^{\alpha}(1 + x_2)^{\beta}$ on the square $[-1, +1]^2$ for parameters α, $\beta \ge -1/2$, $\alpha + \beta \ge -1/2$. The boundary condition $F(x_1, 1) = g(x_1)$ is imposed along a side $-1 \le x_1 \le +1$.

Consider the system of hyperbolic PDEs

$$\{\partial_{z_1}[\rho(z_1)\partial_{z_1}] - \partial_{z_2}[\rho(z_2)\partial_{z_2}]\}F(z_1, z_2, z_3) = 0,$$
$$\{\partial_{z_2}[\rho(z_2)\partial_{z_2}] - \partial_{z_3}[\rho(z_3)\partial_{z_3}]\}F(z_1, z_2, z_3) = 0,$$
$$\{\partial_{z_3}[\rho(z_3)\partial_{z_3}] - \partial_{z_1}[\rho(z_1)\partial_{z_1}]\}F(z_1, z_2, z_3) = 0$$

for $(z_1, z_2, z_3) \in C^3$ with $\rho(z) = \sigma_{0,0}(z, z)$. In R^3 it is easy to use Legendre's equation to verify that the series $F(x_1, x_2, x_3)$ is a solution of the system in a neighborhood of the origin and that it satisfies the boundary conditions of the type $F(x_1, 1, 1) = g(x_1)$, $-1 \le x_1 \le +1$ on the faces of the cube $[-1, +1]^3$. The series $F(z_1, z_2, z_3)$ admits an analytic continuation to C^3 which may be considered in the context of Bochner's problem as a process that has been extended to several complex variables. The curves and surfaces containing the singularities of the solutions may be interpreted as locating a distribution that creates the process.
